For the set of even invariants, the fact that Γ is Hermitian means that it transforms as $\Gamma \to S\Gamma\bar{S}^{-1}$ and this complicates the invariants and their relationships quite considerably. In II, it was claimed that the set, $\mathcal{J}$, given in Table I, is a complete set for these invariants. This table gives the invariants in terms of the symmetric matrices $C=\Gamma\Psi\bar{\Gamma}$ and $D=\Gamma\Psi^2\bar{\Gamma}$. Also, the invariants $\det A$ and $\det B$ have been used instead of $[A^3]$ and $[B^3]$. While it was not proved that every element of $\mathcal{J}$ is irreducible, it seemed unlikely that there would be any identity to express any of them in term of even invariants of lower degree. In fact, this is confirmed in Sec. VI.

Also in II, a large number of syzygies were found by making use of the fact that skew-symmetrizing over $n+1$ indices will give an expression which is zero. For example, for any 3×3 matrices, X, Y, and Z,

$$X^{[A}{}_A Y^B{}_B Z^C{}_C \delta^{D]}{}_E=0. \tag{2}$$

When expanded, this equation gives a matrix identity satisfied by 3×3 matrices. Several syzygies of even invariants were obtained by multiplying such matrix identities by C, D or CD and then taking the trace. These syzygies are linear in the invariants

$$\mathbf{u}=([AC],[ABC],[AB^2C])^T,$$

$$\mathbf{v}=([A^2C],[A^2BC],[A^2B^2C])^T,$$

$$\mathbf{w}=([A^2D],[A^2BD],[A^2B^2D])^T.$$

Other syzygies were found that were quadratic in these invariants.

III. SOME PRELIMINARY RESULTS

Any invariant of Ψ and Γ can be expressed in terms of fully contracted products of $\Psi^A{}_B$, $\Gamma^A{}_{\dot{B}}$, ϵ^{ABC} and their conjugates. Since dotted and undotted indices must both occur in pairs, each term in an invariant of odd degree in Γ must have an odd number of factors of ϵ^{ABC} and an odd number of factors of $\epsilon^{\dot{A}\dot{B}\dot{C}}$. Furthermore, since any two factors of ϵ^{ABC} (and any two of $\epsilon^{\dot{A}\dot{B}\dot{C}}$) can be written in terms of Kronecker delta functions, it will be sufficient to consider odd invariants that have one factor of ϵ^{ABC} and one factor of $\epsilon^{\dot{A}\dot{B}\dot{C}}$. Note that each of these factors will change sign under an orthogonal transformation whose determinant is -1, but the product, $\epsilon^{ABC}\epsilon^{\dot{A}\dot{B}\dot{C}}$, will transform as a tensor under any orthogonal transformation. The simplest odd invariant is $\det(\Gamma^A{}_{\dot{B}})=\frac{1}{6}\epsilon^{\dot{A}\dot{B}\dot{C}}\epsilon_{ABC}\Gamma^A{}_{\dot{A}}\Gamma^B{}_{\dot{B}}\Gamma^C{}_{\dot{C}}$. However, this quantity is complex unless α, the determinant of the metric of the space of bivectors, is real. For this reason, it is preferable to express the odd invariants in terms of $e_{ABC}=\sqrt{\alpha}\epsilon_{ABC}$. Then,

$$\Delta=\frac{1}{6}e^{\dot{A}\dot{B}\dot{C}}e_{ABC}\Gamma^A{}_{\dot{A}}\Gamma^B{}_{\dot{B}}\Gamma^C{}_{\dot{C}}=\sqrt{\frac{\alpha}{\bar{\alpha}}}\det(\Gamma^A{}_{\dot{B}}) \tag{3}$$

is real. This is the same quantity, Δ, that was introduced in I and it is proportional to the invariant, r_2, of Carminati and McLenaghan.

Any odd invariant will be a sum of terms, each of which is an even invariant (or a constant) multiplied by an invariant of the form

$$(L,M,N)=e^{\dot{A}\dot{B}\dot{C}}e_{ABC}L^A{}_{\dot{A}}M^B{}_{\dot{B}}N^C{}_{\dot{C}}, \tag{4}$$

where L, M, and N are each products of the matrices Ψ, $\bar{\Psi}$, Γ, and $\bar{\Gamma}$. Therefore, the elements of $\mathcal{K}_0$ can be assumed to have this form. The following theorem further restricts the possible form of the elements of $\mathcal{K}_0$. In the statement of the theorem, Ψ and Ψ^2 are treated as distinct quantities.

Theorem: *The elements of* $\mathcal{K}_0$ *can be chosen to have the form of either* (Γ,Γ,N), *where N has at most one factor of each of* Ψ, Ψ^2, $\bar{\Psi}$ *and* $\bar{\Psi}^2$, *or* (Γ,M,N), *where M and N between them have exactly one factor of each of* Ψ, Ψ^2, $\bar{\Psi}$, *and* $\bar{\Psi}^2$.

In order to prove this theorem, some intermediate results are needed.

Lemma 1: Any invariant of the form (L,M,N) is equivalent to an expression where the odd invariants all have the form (Γ,M,N).

Proof: It follows from the identity, $e^{\dot{A}\dot{B}\dot{C}}e_{[ABC}P^A{}_{D]}Q^D{}_{\dot{A}}M^B{}_{\dot{B}}N^C{}_{\dot{C}}=0$, that, if $L^A{}_{\dot{A}}=P^A{}_DQ^D{}_{\dot{A}}$,

$$\begin{aligned}(PQ,M,N)&=[P](Q,M,N)-(Q,PM,N)-(Q,M,PN)\\&\approx-(Q,PM,N)-(Q,M,PN).\end{aligned} \tag{5}$$

Similarly, if $L^A{}_{\dot{A}}=P^A{}_{\dot{D}}Q^{\dot{D}}{}_{\dot{A}}$, then $(PQ,M,N)\approx-(P,MQ,N)-(P,M,NQ)$. Therefore, if $L=P\Gamma Q$,

$$(P\Gamma Q,M,N)\approx(\Gamma,PMQ,N)+(\Gamma,PM,NQ)+(\Gamma,MQ,PN)+(\Gamma,M,PNQ),$$

and hence the result. □

Lemma 2: Any invariant of the type $(\Gamma,\Gamma M,\Gamma N)$ *can be factorized and so is reducible.*

Proof: In the expression, $e^{\dot{A}\dot{B}\dot{C}}e_{ABC}\Gamma^A{}_{\dot{A}}\Gamma^B{}_{\dot{D}}M^{\dot{D}}{}_{\dot{B}}\Gamma^C{}_{\dot{E}}N^{\dot{E}}{}_{\dot{C}}$, the factors $e_{ABC}\Gamma^A{}_{\dot{A}}\Gamma^B{}_{\dot{D}}\Gamma^C{}_{\dot{E}}$ can be replaced by $\Delta e_{\dot{A}\dot{D}\dot{E}}$ and it follows that $(\Gamma,\Gamma M,\Gamma N)=\Delta([M][N]-[MN])$. This result is a generalization of the factorization of the invariant D^-D^-S (of Géhéniau and Debever[5]) first noted by Carminati and McLenaghan and also discussed in I.

In I it is shown that, if any matrix product has two separate factors of Ψ, Eq. (2) can be used to combine these two factors into a single factor of Ψ^2. A similar result holds for (Γ,M,N).

Lemma 3: Any invariant, (Γ,M,N), *for which M* and *N* between them contain two separate factors of Ψ can be expressed in terms of invariants with the factors of Ψ combined into a single factor of Ψ^2.

Proof: If both factors of Ψ were in either *M* or *N*, Eq. (2) could be used to combine them into Ψ^2. Therefore, Ψ would need to be a factor of both *M* and *N*. If Ψ was not the first factor of either *M* or *N* then, by Lemma 2, (Γ,M,N) could be factorized.

If Ψ was the first factor of *M* but not of *N*, $(\Gamma,M,N)=(\Gamma,\Psi P,\Gamma Q)$ where *Q* has a factor of Ψ. Making use of the result following Eq. (5), $(\Gamma,\Psi P,\Gamma Q)\approx-(\Gamma Q,\Psi P,\Gamma)-(\Gamma,\Psi PQ,\Gamma)$, so $(\Gamma,\Psi P,\Gamma Q)\approx-\frac{1}{2}(\Gamma,\Psi PQ,\Gamma)$. Then ΨPQ can be written in terms of matrix products where the two factors of Ψ have been combined.

If Ψ was the first factor of both *M* and *N* then, making use of Eq. (5),

$$\begin{aligned}(\Gamma,M,N)&=(\Gamma,\Psi P,\Psi Q)\\&\approx-(\Gamma,\Psi^2P,Q)-(\Psi\Gamma,\Psi P,Q)\\&\approx-(\Gamma,\Psi^2P,Q)+(\Psi^2\Gamma,P,Q)+(\Psi\Gamma,P,\Psi Q)\\&\approx-(\Gamma,\Psi^2P,Q)+(\Psi^2\Gamma,P,Q)-(\Gamma,P,\Psi^2Q)-(\Gamma,\Psi P,\Psi Q),\end{aligned}$$

and, once again, (Γ,M,N) can be expressed in terms of invariants where the two factors of Ψ have been combined.

This result can be extended to factors of Ψ^2, $\overline{\Psi}$, and $\overline{\Psi}^2$. Therefore, the elements of $\mathcal{K}_0$ can be chosen so that *M* and *N* between them have at most one factor of Ψ, Ψ^2, $\overline{\Psi}$, and $\overline{\Psi}^2$.

Proof of Theorem: In order to obtain the main theorem it remains to show that, if *M* and *N* do not have exactly one factor of each of Ψ, Ψ^2, $\overline{\Psi}$, and $\overline{\Psi}^2$, then (Γ,M,N) can be reduced to (Γ,Γ,P).

If neither *M* or *N* contains a factor of $\overline{\Psi}$, for example, one of them (*M* say) must have Γ as its last factor. Then $(\Gamma,Q\Gamma,N)\approx-(Q\Gamma,\Gamma,N)-(\Gamma,\Gamma,QN)$. Therefore, $(\Gamma,Q\Gamma,N)\approx-\frac{1}{2}\times(\Gamma,\Gamma,QN)$. The result for Ψ, Ψ^2, and $\overline{\Psi}^2$ can be obtained similarly. □

IV. THE ODD INVARIANTS

It turns out that any invariants with a given degree in Γ, Ψ, and $\overline{\Psi}$ will be equivalent to each other to within a constant multiple. Thus it is sufficient to take one representative of each case. The odd invariants of degree three in Γ will be considered first. The invariant, Δ, with no factors of Ψ, etc. has already been defined in Eq. (3). Θ_{mn} will denote an invariant of degree three in Γ and degrees *m* and *n* in Ψ and $\overline{\Psi}$, respectively. It follows from Lemma 2 that these invariants must contain at least one factor of Ψ or Ψ^2 and one of $\overline{\Psi}$ or $\overline{\Psi}^2$. Thus the next simplest odd invariant after Δ is

$$\Theta_{11}=\tfrac{1}{2}(\Gamma,\Gamma,\Psi\Gamma\overline{\Psi}).$$

Θ_{11} is real and is proportional to the invariant m_4 defined by Carminati and McLenaghan.[9] By multiplying out the expressions for Δ and Θ_{11}, it is straightforward to show that

$$\Delta\Theta_{11}=[AB^2C]-[B][ABC]-\tfrac{1}{2}([B^2]-[B]^2)[AC]. \tag{6}$$

This is actually a modified version of the equation for m_4 given in I. It also shows that, when the odd invariants are included, $[AB^2C]$ is reducible.

Other invariants of this type are

$$\Theta_{21}=\overline{\Theta}_{12}=\tfrac{1}{2}(\Gamma,\Gamma,\Psi^2\Gamma\overline{\Psi}),$$

$$\Theta_{22}=\tfrac{1}{2}(\Gamma,\Gamma,\Psi^2\Gamma\overline{\Psi}^2),$$

$$\Theta_{33}=\tfrac{1}{2}(\Gamma,\Psi\Gamma\overline{\Psi},\Psi^2\Gamma\overline{\Psi}^2).$$

Note that there are no invariants with degree three in Γ that have degree three in either Ψ or $\overline{\Psi}$, but not both. Equations similar to Eq. (6) for $\Delta\Theta_{mn}$ can also be found using straightforward index manipulations, except for the equation for $\Delta\Theta_{33}$. This equation is longer than the others and the manipulations needed would be quite complicated. It was actually obtained by the method of undetermined coefficients developed by Ouchterlony[15] and described in the next section. The equation is given in the Appendix. The equations for $\Delta\Theta_{mn}$ show that $[AB^2C],[A^2B^2C]$, $[A^2B^2D]$, and $[A^2BACD]$ are reducible and so would no longer be in the complete set. They would be replaced by Θ_{11}, Θ_{12}, Θ_{22}, and Θ_{33}. Similarly, $\det B$ would be replaced by Δ. Since the product of any two odd invariants must be of degree six in Γ, it is clear that these are the only elements of $\mathcal{J}$ that are reducible in this way. The invariants, Θ_{mn}, are irreducible and so must be in the set $\mathcal{K}_0$. They would also be contained in a complete set of invariants of the Riemann tensor.

The idea that some elements of $\mathcal{J}$ can simply be replaced by an element of $\mathcal{K}_0$ to form a complete set for all invariants is rather appealing. Unfortunately, there are several other odd invariants that are irreducible that also need to be included in a complete set. These are invariants of degree five in Γ and can be defined as follows:

$$\Lambda_{11}=\tfrac{1}{2}(\Gamma,\Gamma,\Psi K\Gamma\overline{\Psi}),$$

$$\Lambda_{21}=\overline{\Lambda}_{12}=\tfrac{1}{2}(\Gamma,\Gamma,\Psi^2K\Gamma\overline{\Psi}),$$

$$\Lambda_{22}=\tfrac{1}{2}(\Gamma,\Gamma,\Psi^2K\Gamma\overline{\Psi}^2),$$

$$\Lambda_{31}=\overline{\Lambda}_{13}=\tfrac{1}{2}(\Gamma,\Gamma,\Psi^2K\Psi\Gamma\overline{\Psi}),$$

$$\Lambda_{32}=\overline{\Lambda}_{23}=\tfrac{1}{2}(\Gamma,\Gamma,\Psi^2K\Psi\Gamma\overline{\Psi}),$$

$$\Lambda_{33}=\tfrac{1}{2}(\Gamma,\Gamma,\Psi\Gamma\overline{\Psi}^2\overline{\Gamma}\Psi^2\Gamma\overline{\Psi}).$$

Note that there are several possible forms for the invariant of degree three in Ψ and $\overline{\Psi}$. For example, $(\Gamma,K\Psi\Gamma\overline{\Psi},\Psi^2\Gamma\overline{\Psi}^2)$ and $(\Gamma,\Psi K\Gamma\overline{\Psi},\Psi^2\Gamma\overline{\Psi}^2)$ are two possibilities. The first is equivalent to $-\tfrac{1}{2}(\Gamma,\Gamma,\Psi^2\Gamma\overline{\Psi}^2\overline{\Gamma\Psi}\Gamma\overline{\Psi})$. The second is equivalent to $(\Psi\Gamma\overline{\Psi},K\Gamma,\Psi^2\Gamma\overline{\Psi}^2)$ which, in turn, is equivalent to invariants like the first. In all cases, the invariant can be put into the form (Γ,Γ,N). Different orderings of the factors in N result in invariants that are equivalent to Λ_{33} above.

It can be shown that none of these invariants is reducible. One way to see this is as follows. If Λ_{11} is reducible, it must be a linear combination of odd invariants of lower degree. The only possibility would be $\Lambda_{11}=E_1\Theta_{11}+E_2\Delta$, where E_1 and E_2 are even invariants of the appropriate degree. If this equation is multiplied by Δ, it should be possible to identify E_1 and E_2 so that either the equation is identically satisfied, or the result is syzygy of even invariants. Neither of these situations is the case, so Λ_{11} is irreducible. This method can be extended to the other invariants, Λ_{mn}.

Invariants of degree greater than five in Γ can be shown to be reducible. For example, for the invariant, $(\Gamma,\Gamma,\Psi K^2\Gamma\overline{\Psi})$, $\Psi K^2\Gamma\overline{\Psi}\approx -K\Psi K\Gamma\overline{\Psi}-K^2\Psi K\Gamma\overline{\Psi}$. Therefore $(\Gamma,\Gamma,\Psi K^2\Gamma\overline{\Psi})$ can be reduced to invariants for which the first factor of each matrix is Γ. These can be factorized, so the invariant is reducible. Similar arguments can be applied to most other invariants of degree greater than 5 in Γ. The exception is those invariants of degree three in both Ψ and $\bar{\Psi}$ and degree 7 in Γ. It is not too difficult to show that each such invariant can be expressed in terms of invariants of the type (Γ,Γ,N). These invariants can then be reduced to one of the following:

$$\begin{gathered}(\Gamma,\Gamma,\Psi K\Gamma\bar{\Psi}^2\bar{\Gamma}\Psi^2\Gamma\bar{\Psi}),\\(\Gamma,\Gamma,\Psi\Gamma\bar{\Psi}^2\bar{\Gamma}K\Psi^2\Gamma\bar{\Psi}),\\(\Gamma,\Gamma,\Psi\Gamma\bar{\Psi}^2\bar{\Gamma}\Psi^2K\Gamma\bar{\Psi}),\\(\Gamma,\Gamma,\Psi K\Psi^2\Gamma\bar{\Psi}^2\bar{K}\bar{\Psi}).\end{gathered}$$

To show that the first three are equivalent, use the expanded form of Eq. (2) and Lemma 2. Thus, the first few factors of N in the first invariant can be written as $(\Psi)(K)(\Gamma\bar{\Psi}^2\bar{\Gamma})$ which is equivalent to $-(\Psi)(\Gamma\bar{\Psi}^2\bar{\Gamma})(K)$ + ''terms whose first factor is Γ.'' Therefore, the first invariant is equivalent to a multiple of the second. Similarly, it is also equivalent to a multiple of the third. The equivalence to the final invariant follows from $\Psi(K)(\Gamma\bar{\Psi}^2\bar{\Gamma})(\Psi^2)\approx-\Psi(K)(\Psi^2)(\Gamma\bar{\Psi}^2\bar{\Gamma})-\Psi(\Gamma\bar{\Psi}^2\bar{\Gamma})(\Psi^2)(K)-\Psi(\Gamma\bar{\Psi}^2\bar{\Gamma})(K)(\Psi^2)$. There is a slight advantage in choosing

$$\tilde{\Lambda}_{33}=\tfrac{1}{2}(\Gamma,\Gamma,\Psi^2K\Psi\Gamma\bar{\Psi}\bar{K}\bar{\Psi}^2)$$

as the representative of these invariants. We should now investigate whether or not $\tilde{\Lambda}_{33}$ is reducible. In fact it is quite difficult (though presumably not impossible) to show this one way or the other by using the current techniques. However, the fact that it is reducible can be demonstrated by once again using the method of undetermined coefficients. This method, and the result for $\tilde{\Lambda}_{33}$, will be discussed in the next section.

Taking this work into account, it is clear that the elements of the set $\mathcal{K}_0$, are

$$\begin{array}{llll}\Delta & & & \\ & \Theta_{11},\Lambda_{11}, & \Theta_{12},\Lambda_{12}, & \Lambda_{13}\\ & \Theta_{21},\Lambda_{21}, & \Theta_{22},\Lambda_{22}, & \Lambda_{23}\\ & \Lambda_{31}, & \Lambda_{32}, & \Theta_{33},\Lambda_{33}.\end{array}\tag{7}$$

There are 15 real invariants and they would all need to be included in a complete set of the invariants of the Riemann tensor. On the other hand, some of the elements of $\mathcal{J}$ will not appear in the complete set. These are the six invariants

$$\begin{array}{llll}\det B & & & \\ & [AB^2C], & [AB^2D], & \\ & [A^2B^2C], & [A^2B^2D], & \\ & & & [A^2BACD].\end{array}\tag{8}$$

Therefore, including the odd invariants will increase the size of the complete set by 9. The complete set, $\mathcal{K}$, is given in Table II. If the Ricci scalar, R, is included, the set will be a complete set of Riemann invariants.

TABLE II. This is the set $\mathcal{K}$. Any invariant of Ψ and Γ can be written as a polynomial function of these invariants.

Real invariants	Complex invariants
$[B]=[K]$	
$[B^2]=[K^2]$	$[A^2]=[\Psi^2]$
$\Delta=\det\Gamma$	$\det A=\det\Psi$
	$[AB]=[\Psi K]=\overline{[C]}$
	$[AB^2]=[\Psi K^2]=\overline{[BC]}$
	$[A^2B]=[\Psi^2 K]=\overline{[D]}$
	$[A^2B^2]=[\Psi^2 K^2]=\overline{[BD]}$
$[AC]=[\Psi\Gamma\overline{\Psi\Gamma}]$	$[AD]=[\Psi\Gamma\bar{\Psi}^2\bar{\Gamma}]$
$[ABC]=[\Psi K\Gamma\bar{\Psi}\bar{\Gamma}]$	$=\overline{[A^2C]}$
$\Theta_{11}=\frac{1}{2}(\Gamma,\Gamma,\Psi\Gamma\bar{\Psi})$	$[ABD]=[\Psi K\Gamma\bar{\Psi}^2\bar{\Gamma}]$
$[A^2D]=[\Psi^2\Gamma\bar{\Psi}^2\bar{\Gamma}]$	$=\overline{[A^2BC]}$
$[A^2BD]=[\Psi^2 K\Gamma\bar{\Psi}^2\bar{\Gamma}]$	$\Theta_{21}=\frac{1}{2}(\Gamma,\Gamma,\Psi^2\Gamma\bar{\Psi})$
$\Theta_{22}=\frac{1}{2}(\Gamma,\Gamma,\Psi^2\Gamma\bar{\Psi}^2)$	$=\bar{\Theta}_{12}$
$\Theta_{33}=\frac{1}{2}(\Gamma,\Psi\Gamma\bar{\Psi},\Psi^2\Gamma\bar{\Psi}^2)$	
	$\Lambda_{21}=\frac{1}{2}(\Gamma,\Gamma,\Psi^2 K\Gamma\bar{\Psi})$
$\Lambda_{11}=\frac{1}{2}(\Gamma,\Gamma,\Psi K\Gamma\bar{\Psi})$	$=\bar{\Lambda}_{12}$
$\Lambda_{22}=\frac{1}{2}(\Gamma,\Gamma,\Psi^2 K\Gamma\bar{\Psi}^2)$	$\Lambda_{31}=\frac{1}{2}(\Gamma,\Gamma,\Psi^2 K\Psi\Gamma\bar{\Psi})$
$\Lambda_{33}=\frac{1}{2}(\Gamma,\Gamma,\Psi\Gamma\bar{\Psi}^2\bar{\Gamma}\Psi^2\Gamma\bar{\Psi})$	$=\bar{\Lambda}_{13}$
	$\Lambda_{32}=\frac{1}{2}(\Gamma,\Gamma,\Psi^2 K\Psi\Gamma\bar{\Psi}^2)$
	$=\bar{\Lambda}_{23}$

V. SYZYGIES OF THE ODD INVARIANTS

One identity that remains to be found for the work in Sec. IV is the one that gives an expression for $\tilde{\Lambda}_{33}$ in terms of the other invariants. The Second Fundamental Theorem states that it must be possible to obtain any such identity from the property that skew-symmetrizing over four indices must annihilate any tensor in three dimensions. Unfortunately, the details of how this might be achieved in this case remain unclear. Therefore, we resort to other means. The identity must have the form,

$$a_1\tilde{\Lambda}_{33}=\sum_{i=1}^{15} E_i O_i\,, \tag{9}$$

where the O_i are the elements of $\mathcal{K}_0$ and each of the E_i is an even invariant of the appropriate degree. For example, the coefficient of Θ_{22} in Eq. (9) will be of first degree in Ψ and $\bar{\Psi}$ and fourth degree in Γ (or second degree in K). It must have the form

$$a[B][AC]+b[ABC]+c[AB][C],$$

where a, b, and c are undetermined coefficients. Altogether there are 65 undetermined coefficients, a_i, (including a_1) in Eq. (9).

Ouchterlony[15] has shown that if the form of the syzygy is known as in this case, the coefficients can often be determined by a numerical procedure. Using the procedure, he independently found the syzygy for nonsymmetric 3×3 matrices [Eq. (6) of II] as well as several syzygies for sets of 2×2 matrices. The coefficients, a_i, have the property that they will satisfy Eq. (9) for any choice of the components of Ψ and Γ. Hence, each numerical choice for these components will give a homogeneous equation for the a_i. A set of 65 or more numerical values of Ψ and Γ chosen at random should give a complete set of equations for the a_i. If the coefficient matrix of this set of homogeneous equations is M, the null space of M will contain the possible solutions for a_i. If the values of the components and the subsequent calculations have finite precision, these solutions and the resulting syzygies will only be approximate. The exact, rational coefficients can be found by taking linear combinations so that the first nonzero component of each vector is 1 and, if this is the ith component, $a_i = 0$ for each of the other vectors. Once this is done, the remaining components will be close to rational numbers, and it should be possible to identify the correct values. Finally, the syzygies can often be simplified further by taking appropriate linear combinations. This method is used here to obtain some of the syzygies of odd invariants, and is used in Sec. VI to find some more syzygies of even invariants.

The application of the method to find the syzygies (9) is straightforward and it turns out that there are six syzygies of this type. One of these [Eq. (B1)] is an equation for $\tilde{\Lambda}_{33}$ so this invariant is reducible. The other five express homogeneous linear relations between the elements of $\mathcal{K}_0$, where the coefficients are even invariants. One linear combination of these syzygies does not contain any of the Λ_{mn}. This is also given in the Appendix. The same method was used to search for any identities of lower degree that were linear in the odd invariants, but none were found. This confirms that the invariants Θ_{mn} and Λ_{mn} are irreducible. It is possible there will be syzygies of higher degree, but no attempt has been made to find these.

There are also syzygies that are quadratic in the odd invariants. The equations for $\Delta\Theta_{mn}$ mentioned in the previous section are examples of these. However, these identities can be solved for $[AB^2C]$, etc. and so are best seen as ''reducing equations'' for these invariants rather than as syzygies of invariants of a complete set. Expressions can also be found for $\Delta\Lambda_{mn}$. The expression for $\Delta\Lambda_{11}$ is given in Appendix B. There will be similar equations to express the product of any two odd invariants in terms of even invariants. These equations can be found by writing the product of the two odd invariants in index notation and then expressing $e^{ABC}e_{DEF}$ and $e^{\dot{A}\dot{B}\dot{C}}e_{\dot{D}\dot{E}\dot{F}}$ in terms of Kronecker delta functions. They can also be found by using the numerical procedure described above. The equation for Θ_{11}^2 is in Appendix B.

VI. SYZYGIES OF THE EVEN INVARIANTS

Now the syzygies of odd invariants in Sec. V can be used to obtain some new syzygies of even invariants. As in II, each identity will be characterized by its degree in Ψ, K, and $\bar{\Psi}$, even though some identities may have a fractional degree in K. A syzygy whose degrees in Ψ, K, and $\bar{\Psi}$ are l, m, and n, respectively will be said to have degree (l,m,n). If the five syzygies that are linear in the odd invariants are multiplied by Δ, and the expressions for $\Delta\Theta_{mn}$ and $\Delta\Lambda_{mn}$ are used, the result is some syzygies of even invariants that have degree (3,5,3). A check with the degrees of the identities found in II shows that these must be new identities. The appearance of these new identities suggests that there may be more. These could be found by an exhaustive use of the property that skew-symmetrizing over $n+1$ indices gives an expression that is zero. However, once again, it is simplest to use the method of undetermined coefficients to obtain the required relations. The idea is, for any given degree, construct all products, E_i, of invariants in $\mathcal{J}$ that have that degree and use the method to find all sets of coefficients a_i such that

$$\sum a_i E_i = 0$$

for any numerical choice of Ψ and Γ.

The method of construction of the identities in II indicates that all syzygies of first degree in $\bar{\Psi}$ have already have been found. Consequently, all syzygies of first degree in Ψ will also be known. The next group to look at is those with degree $(2,m,2)$. The first one to be found had degree (2,4,2). Of all the syzygies of invariants of even degree, this one has the lowest degree. As the degree of Ψ, K, or $\bar{\Psi}$ is increased, the number of syzygies also increases. Incidently, this procedure also showed that there were no syzygies of degree (3,3,3). This fact rules out the possibility that the invariant, $[A^2BACD]$, can be expressed as a polynomial function of even invariants of lower degree. In fact, all the elements of $\mathcal{J}$ can similarly be shown to be irreducible (in terms of even invariants), thereby justifying the claim that $\mathcal{J}$ is a complete set for the even invariants Ψ and Γ.

The degrees of the syzygies found, and the number of new independent syzygies of each degree are

$$\begin{array}{ccc} (2,4,2) & (3,4,2) & (3,4,3) \\ 1 \text{ syzygy} & 1 \text{ syzygy} & 2 \text{ syzygies} \\ (2,5,2) & (3,5,2) & (3,5,3) \\ 1 \text{ syzygy} & 2 \text{ syzygies} & 5 \text{ syzygies} \\ (2,6,2) & (3,6,2) & (3,6,3) \\ 2 \text{ syzygies} & 3 \text{ syzygies} & 3 \text{ syzygies} \end{array}.$$

The complex conjugates of syzygies of degree $(3,m,2)$ are syzygies of degree $(2,m,3)$. The rest are real or, in some cases, purely imaginary. Also, the five syzygies of degree (3,5,3) are simply independent linear combinations of those obtained from the syzygies that are linear in the odd invariants. While this list is exhaustive for the given degrees, there may be syzygies of still higher degree. Of course, syzygies of a given degree can include multiples of syzygies of lower degree. There were 28 syzygies of degree (3,6,3). However, 21 of these could be obtained as multiples of other syzygies, leaving 7 new syzygies.

Since there is only one syzygy of degree (2,4,2), it can be labeled by T^{242}. The terms that are quadratic in **u**, **v**, and **w** are given by

$$T^{242}=\mathbf{u}^T F_1 \mathbf{u}+\cdots, \tag{10}$$

where

$$F_1=\begin{pmatrix} -\frac{1}{2}[B]^2+\frac{1}{2}[B^2], & [B], & -1 \\ [B], & -1, & 0 \\ -1, & 0, & 0 \end{pmatrix}.$$

The syzygy of degree (3,4,2) has the form

$$T^{342}=\mathbf{v}^T F_1 \mathbf{u}+\cdots. \tag{11}$$

There are two syzygies of degree (3,4,3). These can be arbitrarily labeled T^{343a} and T^{343b}. They are given by

$$T^{343a}=\overline{\mathbf{v}}^T F_1 \mathbf{v}+\mathbf{w}^T F_1 \mathbf{u}+\cdots,$$

$$T^{343b}=\overline{\mathbf{v}}^T F_2 \mathbf{v}-\mathbf{w}^T F_2 \mathbf{u}-4[B][A^2BACD]+\cdots, \tag{12}$$

where

$$F_2=\begin{pmatrix} [B]^2-5[B^2], & 2[B], & 6 \\ 2[B], & -18, & 0 \\ 6, & 0, & 0 \end{pmatrix},$$

and the term involving $[A^2BACD]$ has been included. By taking the appropriate linear combinations of all these syzygies, there does appear to be some common elements in some of them. This can be seen in those terms of the syzygies that are quadratic in **u**, **v**, and **w**. These terms are given in Appendix C. The full equation for T^{242} is also given in the Appendix. The complete set of equations is available from the web site, http://www.jcu.edu.au/˜mages/ in a form suitable for input into most computer algebra packages. Alternatively, they may be obtained directly from the author.

VII. CONCLUSION

This work substantially completes the program, begun in Ref. 1, of finding a complete set of invariants of the Riemann tensor. The complete set consists of the elements of $\mathcal{K}$ together with the Ricci scalar, R, a total of 38 real invariants. Incorporating the odd invariants has made the complete set more cumbersome, rather than enabling some simplification. Clearly, such a large complete set will be unwieldy in most situations. However, there are now a large number of syzygies available that can be used to express the elements of this set in terms of some smaller set. The possibilities seem to separate into two cases, depending on whether Δ is zero or nonzero. In either case, the syzygies contain sufficient information to calculate all elements of the complete set from a relatively small number of them.

If Δ is known and $\Delta \neq 0$, the odd invariants (which have been the focus of this paper) can readily be obtained from the set of even invariants, $\mathcal{J}$. In this case, apart from Δ itself, the odd invariants may assume less importance. On the other hand, it was noted in II that the set $\mathcal{I}$, together with **u**, will be sufficient to determine all elements of $\mathcal{J}$ by the solution of linear equations only. (Indeed, it may be possible to achieve this starting with just $\mathcal{I}$ and $[AC]$.) Therefore, for most purposes, if $\Delta \neq 0$, it will be sufficient to have a knowledge of the set $\mathcal{I}$ (with $\det B$ replaced by Δ) and the invariants **u** and R.

There are several Segre-types of the Ricci tensor for which $\Delta = 0$ and so this case should not be overlooked. It might be expected that the odd invariants are more important in this case. If Δ is equal to zero, the equations for $\Delta\Theta_{mn}$ and $\Delta\Lambda_{mn}$ show that there will be many more relationships between the elements of $\mathcal{J}$, and it may be possible to use these to determine $\mathcal{J}$ from a knowledge of $\mathcal{I}$ only. At the same time, it should also be possible to start with one of the odd invariants, Θ_{11} say, and use the equations for their products to calculate the remaining odd invariants. For the specific case of metrics generated by Maxwell fields this task is even easier. For these metrics, $\Gamma_{A\dot{B}} \propto \Phi_A \bar{\Phi}_{\dot{B}}$ and, of all the odd invariants defined, the only one that is nonzero is Θ_{33}.

There remains the task of relating algebraic properties of elements of the complete set to geometric and physical properties of space–time. It is expected that the syzygies found in this paper and the preceding two papers will play an important role in that work.

ACKNOWLEDGMENTS

I would like to thank Brian Edgar and Erik Ouchterlony for informing me of their work on using numerical methods to find syzygies, and for responding to my many queries on their method. I would also like to thank S. Bonanos for bringing the error in the cubic equation for $[A^2B^2]$ to my attention. I am grateful to Ian Whittingham who has, once again, made a number of helpful suggestions on the final manuscript.

APPENDIX A: SYZYGY FOR SYMMETRIC MATRICES

This is the corrected version of the syzygy connecting the elements of a complete set for two symmetric 3×3 matrices. If both matrices are trace-free,

$$c_3[A^2B^2]^3 + c_2[A^2B^2]^2 + c_1[A^2B^2] + c_0 = 0,$$

where

$$c_3=-4,$$

$$c_2=[AB]^2+5[A^2][B^2],$$

$$c_1=2[B^2][A^2B]^2+2[A^2][AB^2]^2-2[AB][AB^2][A^2B]-2[A^2][B^3][A^2B]$$
$$-2[A^3][B^2][AB^2]-[A^2][B^2][AB]^2+2[A^3][B^3][AB]-2[A^2]^2[B^2]^2,$$

$$c_0=-\tfrac{4}{3}([B^3][A^2B]^3+[A^3][AB^2]^3)+[A^2B]^2[AB^2]^2-\tfrac{1}{2}[A^2][B^2]([B^2][A^2B]^2+[A^2][AB^2]^2)$$
$$+2[A^3][B^3][A^2B][AB^2]-\tfrac{4}{9}[A^3][B^3][AB]^3+\tfrac{2}{3}[AB]^2([A^3][B^2][AB^2]+[A^2][B^3][A^2B])$$
$$+\tfrac{1}{4}[A^2]^2[B^2]^2[AB]^2-\tfrac{1}{3}[AB]([A^2]^2[B^3][AB^2]+[A^3][B^2]^2[A^2B])+\tfrac{2}{3}[A^2][B^2]([A^3][B^2]$$
$$\times[AB^2]+[A^2][B^3][A^2B])-\tfrac{2}{3}[A^2][A^3][B^2][B^3][AB]+\tfrac{1}{4}[A^2]^3[B^2]^3+\tfrac{1}{18}([A^3]^2[B^2]^3$$
$$+[A^2]^3[B^3]^2)-\tfrac{1}{3}[A^3]^2[B^3]^2.$$

APPENDIX B: SYZYGIES OF ODD INVARIANTS

This Appendix contains some of the syzygies of odd invariants. The first is the equation for $\tilde{\Lambda}_{33}$ in terms of the other invariants,

$$8\tilde{\Lambda}_{33}=\Delta(2[\overline{A^2}][A^2C][AB]-2\det\bar{A}[A^2][AB^2]-4[A^2][\overline{A^2}][ABC]-2[A^2B][\overline{A^2}][AC]$$
$$+2\det\bar{A}[A^2][AB][B]+4[A^2][\overline{A^2}][AC][B]+4\det A\det\bar{A}[B]^2-4\det A\det\bar{A}[B^2]$$
$$-2\det A[\overline{A^2}][BC]+2[A^2][AD][C]+2\det A[\overline{A^2}][B][C]-2[A^2][AC][D])$$
$$+(4[A^2B^2][\overline{A^2}]-16[A^2BD]-4[A^2B][\overline{A^2}][B]+8[A^2D][B]+[A^2][\overline{A^2}][B]^2$$
$$-[A^2][\overline{A^2}][B^2]+4[A^2][BD]+8[A^2B][D]-4[A^2][B][D])\Theta_{11}+(8[ABC]$$
$$-8[AC][B])\Theta_{22}+8[AC]\Lambda_{22}. \tag{B1}$$

There are five other syzygies of the same degree that are linear in the odd invariants. One of these is real, and does not involve any of the Λ_{mn},

$$0=\Delta(2[\overline{A^2}][A^2C][AB]-4[A^2][\overline{A^2}][ABC]-2[A^2B][\overline{A^2}][AC]+6[A^2D][AC]-6[A^2C][AD]$$
$$+2[A^2][\overline{A^2}][AC][B]+3\det A\det\bar{A}[B]^2-3\det A\det\bar{A}[B^2]+2[A^2][\overline{A^2}][AB][C]$$
$$+2[A^2][AD][C]-2[A^2][AC][D])+(-4[B]^2+4[B^2])\Theta_{33}+(-4[A^2B^2][\overline{A^2}]$$
$$+12[A^2BD]+4[A^2B][\overline{A^2}][B]-4[A^2D][B]-[A^2][\overline{A^2}][B]^2+[A^2][\overline{A^2}][B^2]$$
$$-4[A^2][BD]-8[A^2B][D]+4[A^2][B][D])\Theta_{11}+(4[\overline{A^2}][AB^2]-12[ABD]$$
$$-4[\overline{A^2}][AB][B]+4[AD][B]+8[AB][D])\Theta_{21}+(-12[A^2BC]+4[A^2C][B]$$
$$+4[A^2][BC]+8[A^2B][C]-4[A^2][B][C])\Theta_{12}+(12[ABC]-4[AC][B]$$
$$-8[AB][C])\Theta_{22}. \tag{B2}$$

The following is the equation for $\Delta\Theta_{33}$. This equation shows that $[A^2BACD]$ is reducible. Also given is the equation for $\Delta\Lambda_{11}$. Other expressions for $\Delta\Lambda_{mn}$ are a bit longer, with the equation for $\Delta\Lambda_{33}$ having 61 terms,

$$\begin{aligned}8\Delta\Theta_{33}=&-8[A^2BACD]+12\det A\det\bar{A}\det B-2\det\bar{A}[A^2B^2][AB]-2\det\bar{A}[A^2B][AB^2]\\&+2[A^2][\overline{A^2}][AB^2C]+4[A^2D][ABC]-4[A^2C][ABD]+4[A^2BD][AC]\\&-4[A^2BC][AD]+4\det\bar{A}[A^2B][AB][B]-2[A^2][\overline{A^2}][ABC][B]-2[A^2D][AC][B]\\&+2[A^2C][AD][B]+[A^2][\overline{A^2}][AC][B]^2+\det A\det\bar{A}[B]^3-[A^2][\overline{A^2}][AC][B^2]\\&-\det A\det\bar{A}[B][B^2]+4[A^2B][AD][C]-2\det A[BD][C]+4[A^2C][AB][D]\\&-2\det A[BC][D]+4\det A[B][C][D].\end{aligned}\tag{B3}$$

$$\begin{aligned}4\Delta\Lambda_{11}=&-2\det B[AC]+4[AB^2C][B]-2[ABC][B]^2+[AC][B]^3-2[ABC][B^2]\\&-[AC][B][B^2]+2[AB^2][BC]-2[AB][B][BC]-2[AB^2][B][C]+[AB][B]^2[C]\\&+[AB][B^2][C].\end{aligned}\tag{B4}$$

The following is the equation for Θ_{11}^2:

$$\begin{aligned}8\Theta_{11}{}^2=&14\Delta^2[A^2][\overline{A^2}]+4[\overline{A^2}][AB][AB^2]-16[AB][ABD]-16[ABC][AC]+8[AB^2][AD]\\&+4[A^2B^2][\overline{A^2}][B]-16[A^2BD][B]-4[\overline{A^2}][AB]^2[B]+8[AC]^2[B]-2[A^2B][\overline{A^2}][B]^2\\&+12[A^2D][B]^2+[A^2][\overline{A^2}][B]^3-2[A^2B][\overline{A^2}][B^2]-4[A^2D][B^2]-[A^2][\overline{A^2}][B][B^2]\\&+8[A^2C][BC]+8[A^2B][BD]+4[A^2][B][BD]-16[A^2BC][C]+8[AB][AC][C]\\&+4[A^2][BC][C]+8[A^2B][C]^2-4[A^2][B][C]^2+8[A^2B^2][D]+8[AB]^2[D]\\&-8[A^2B][B][D]-2[A^2][B]^2[D]-2[A^2][B^2][D]-48\Delta\Theta_{22}.\end{aligned}\tag{B5}$$

APPENDIX C: SYZYGIES OF EVEN INVARIANTS

The quadratic terms (as well as the coefficient of $[A^2BACD]$) of the remaining syzygies of even invariants are given below,

$$\begin{aligned}T^{252}&=\mathbf{u}^TG_1\mathbf{u}+\cdots,\\T^{352a}&=\mathbf{u}^TG_1\mathbf{v}+\cdots,\\T^{352b}&=\mathbf{u}^TG_2\mathbf{v}+\cdots,\\T^{353a}&=\bar{\mathbf{v}}^TG_1\mathbf{v}+\mathbf{w}^TG_1\mathbf{u}+\cdots,\\T^{353b}&=\mathbf{w}^TG_2\mathbf{u}+\cdots,\\T^{353c}&=\bar{\mathbf{v}}^TG_2\mathbf{v}+\cdots,\\T^{353d}&=\bar{\mathbf{v}}^TG_3\mathbf{v}-\mathbf{w}^TG_3\mathbf{u}-2([B]^2+[B^2])[A^2BACD]+\cdots,\\T^{353e}&=\bar{\mathbf{v}}^TG_4\mathbf{v}-\mathbf{w}^TG_4\mathbf{u}-(2[B]^2-8[B^2])[A^2BACD]+\cdots,\end{aligned}\tag{C1}$$

where

$$G_1=\begin{pmatrix}\det B, & 0, & 0\\ 0, & -[B], & 1\\ 0, & 1, & 0\end{pmatrix},\quad G_2=\begin{pmatrix}0, & [B^2], & -[B]\\ -[B^2], & 0, & 3\\ [B], & -3, & 0\end{pmatrix},$$

$$G_3=\begin{pmatrix} -2[B][B^2], & 3[B]^2-2[B^2], & 3[B] \\ 3[B]^2-2[B^2], & -16[B], & 3 \\ 3[B], & 3, & 0 \end{pmatrix},$$

$$G_4=\begin{pmatrix} 3\det B, & 4[B^2]-2[B]^2, & -2[B] \\ 4[B^2]-2[B]^2, & 9[B], & -3 \\ -2[B], & -3, & 0 \end{pmatrix},$$

$$T^{262a}=\mathbf{u}^T H_1 \mathbf{u}+\cdots,$$

$$T^{262b}=\mathbf{u}^T H_2 \mathbf{u}+\cdots,$$

$$T^{362a}=\mathbf{u}^T H_1 \mathbf{v}+\cdots,$$

$$T^{362b}=\mathbf{u}^T H_2 \mathbf{v}+\cdots,$$

$$T^{362c}=\mathbf{u}^T H_3 \mathbf{v}+\cdots,$$

$$T^{363a}=-\overline{\mathbf{v}}^T(H_1+H_2)\mathbf{v}+(-32\det B+4[B]^3-8[B][B^2])[A^2BACD]+\cdots,$$

$$T^{363b}=\mathbf{w}^T(H_1+H_2)\mathbf{u}+(-32\det B+4[B]^3-8[B][B^2])[A^2BACD]+\cdots, \tag{C2}$$

$$T^{363c}=\overline{\mathbf{v}}^T H_1 \mathbf{v}+\mathbf{w}^T H_1 \mathbf{u}+\cdots,$$

$$T^{363d}=\overline{\mathbf{v}}^T H_3 \mathbf{v}+\cdots,$$

$$T^{363e}=\mathbf{w}^T H_3 \mathbf{u}+\cdots,$$

$$T^{363f}=\overline{\mathbf{v}}^T H_4 \mathbf{v}-\mathbf{w}^T H_4 \mathbf{u}+(-24\det B+4[B]^3-8[B][B^2])[A^2BACD]+\cdots,$$

$$T^{363g}=\overline{\mathbf{v}}^T H_5 \mathbf{v}-\mathbf{w}^T H_5 \mathbf{u}+(42\det B-5[B]^3+9[B][B^2])[A^2BACD]+\cdots,$$

where

$$H_1=\begin{pmatrix} 0, & 2\det B, & 0 \\ 2\det B, & -[B]^2+[B^2], & 0 \\ 0, & 0, & 2 \end{pmatrix},$$

$$H_2=\begin{pmatrix} 0, & -[B]^3+[B][B^2], & 2[B]^2-2[B^2] \\ -[B]^3+[B][B^2], & 7[B]^2+[B^2], & -12[B] \\ 2[B]^2-2[B^2], & -12[B], & 18 \end{pmatrix},$$

$$H_3=\begin{pmatrix} 0, & 6\det B-[B]^3-[B][B^2], & 4[B]^2-2[B^2] \\ -6\det B+[B]^3+[B][B^2], & 0, & -10[B] \\ -4[B]^2+2[B^2], & 10[B], & 0 \end{pmatrix},$$

$$H_4=\begin{pmatrix} 0, & -[B]^3+3[B][B]^2, & -2[B^2] \\ -[B]^3+3[B][B]^2, & 5[B]^2-9[B^2], & -2[B] \\ -2[B^2], & -2[B], & 6 \end{pmatrix},$$

$$H_5=\begin{pmatrix} 0, & -[B][B]^2, & 2[B]^2-[B^2] \\ -[B][B]^2, & [B]^2+3[B^2], & -7[B] \\ 2[B]^2-[B^2], & -7[B], & 12 \end{pmatrix}.$$

$T^{242}=0$ is the syzygy of lowest degree. It is given by

$$\begin{aligned} 8T^{242}=&-4\det B[A^2B][\overline{A^2}]+24\det B[A^2D]+4[\overline{A^2}][AB^2]^2-16[AB][AB^2D]-8[ABC]^2\\ &-16[AB^2][ABD]-16[AB^2C][AC]-16[A^2B^2D][B]+6\det B[A^2][\overline{A^2}][B]\\ &-4[\overline{A^2}][AB][AB^2][B]+16[AB][ABD][B]+16[ABC][AC][B]+8[AB^2][AD][B]\\ &-4[A^2B^2][\overline{A^2}][B]^2+16[A^2BD][B]^2+2[\overline{A^2}][AB]^2[B]^2-4[AC]^2[B]^2\\ &-8[AB][AD][B]^2+4[A^2B][\overline{A^2}][B]^3-8[A^2D][B]^3-[A^2][\overline{A^2}][B]^4\\ &+8[A^2B^2][\overline{A^2}][B^2]-16[A^2BD][B^2]-2[\overline{A^2}][AB]^2[B^2]+4[AC]^2[B^2]\\ &+8[AB][AD][B^2]-8[A^2B][\overline{A^2}][B][B^2]+16[A^2D][B][B^2]+3[A^2][\overline{A^2}][B]^2[B^2]\\ &-2[A^2][\overline{A^2}][B^2]^2-16[A^2BC][BC]+8[AB][AC][BC]+8[A^2C][B][BC]\\ &+4[A^2][BC]^2-16[A^2B^2][BD]+8[AB]^2[BD]+16[A^2B][B][BD]-4[A^2][B]^2[BD]\\ &+8[A^2][B^2][BD]-16[A^2B^2C][C]+8[AB^2][AC][C]+16[A^2BC][B][C]\\ &-8[AB][AC][B][C]-8[A^2C][B]^2[C]+8[A^2C][B^2][C]+8[A^2B][BC][C]\\ &-4[A^2][B][BC][C]+8[A^2B^2][C]^2-8[A^2B][B][C]^2+2[A^2][B]^2[C]^2\\ &-2[A^2][B^2][C]^2-4\det B[A^2][D]+8[AB][AB^2][D]+16[A^2B^2][B][D]\\ &-8[AB]^2[B][D]-16[A^2B][B]^2[D]+4[A^2][B]^3[D]+8[A^2B][B^2][D]\\ &-8[A^2][B][B^2][D]. \end{aligned} \tag{C3}$$

APPENDIX D: NOTATION

TABLE III. This is a list of the main symbols used in this paper.

Ψ, Γ	3×3 complex matrices that represent the Weyl tensor and the trace-free Ricci tensor
A	Ψ
$B=K$	$\Gamma\bar{\Gamma}$
C	$\Gamma\bar{\Psi}\bar{\Gamma}$
D	$\Gamma\bar{\Psi}^2\bar{\Gamma}$
$[A]$	Square brackets are used to denote the trace of a matrix
$\mathbf{u}$	$([AC],[ABC],[AB^2C])^T$
$\mathbf{v}$	$([A^2C],[A^2BC],[A^2B^2C])^T$
$\mathbf{w}$	$([A^2D],[A^2BD],[A^2B^2D])^T$
Δ	$\frac{1}{6}e^{\dot{A}\dot{B}\dot{C}}e_{ABC}\Gamma^{A}{}_{\dot{A}}\Gamma^{B}{}_{\dot{B}}\Gamma^{C}{}_{\dot{C}}$ $=\sqrt{\alpha/\bar{\alpha}}\,\det(\Gamma^{A}{}_{\dot{B}})$
(L,M,N)	$e^{\dot{A}\dot{B}\dot{C}}e_{ABC}L^{A}{}_{\dot{A}}M^{B}{}_{\dot{B}}N^{C}{}_{\dot{C}}$
$\mathcal{I}$	A complete set for invariants of Ψ and K
$\mathcal{J}$	A complete set for even invariants of Ψ and Γ
$\mathcal{K}_0$	A set of irreducible odd invariants
$\mathcal{K}$	A complete set for invariants of Ψ and Γ

Symplecton for $\mathcal{U}_h(sl(2))$ and representations of $SL_h(2)$

N. Aizawa
Department of Applied Mathematics, Osaka Women's University, Sakai, Osaka 590-0035, Japan

(Received 22 March 1999; accepted for publication 14 June 1999)

Polynomials of boson creation and annihilation operators which form irreducible tensor operators for Jordanian quantum algebra $\mathcal{U}_h(sl(2))$, called h-symplecton, are introduced and their properties are investigated. It is shown that many properties of symplecton for Lie algebra $sl(2)$ are extended to h-symplecton. The h-symplecton is also a basis of irreducible representation of $SL_h(2)$ dual to $\mathcal{U}_h(sl(2))$. As an application of the procedure used to construct h-symplecton, we construct the representation bases of $SL_h(2)$ on the quantum h-plane. © *1999 American Institute of Physics.* [S0022-2488(99)01211-6]

I. INTRODUCTION

It is no doubt that well-developed representation theories are necessary when we apply algebraic objects to physics. The simplest examples in quantum physics are angular momentum algebra $su(2)$ and rotation matrices in three-dimensional space SO(3). Their algebraic structure is simple but contents of representation theories are quite rich.[1] To investigate these algebraic objects or their complexification could be a foundation for further investigation of higher dimensional objects.

As for deformation of Lie groups and Lie algebras, q-deformation of Lie algebra $sl(2)$ and Lie group $SL(2)$ (and their real form) is studied quite well. Their representation theories have attracted much interest in both physics and mathematics and give a way to higher dimensional cases.[2] There exists, however, some other deformation of Lie groups and algebras and these are generally called nonstandard deformation. The most studied one may be the so-called Jordanian deformation obtained by Drinfeld twist from a Lie algebra or a known quantum algebra. The simplest examples are, of course, the Jordanian deformation of Lie algebra $sl(2)$ and its dual. The Jordanian deformation of Lie group $SL(2)$, denoted by $SL_h(2)$, is studied in Refs. 3, 4, 5 and then Ohn introduced its dual algebra, namely, Jordanian deformation of $sl(2)$ denoted by $\mathcal{U}_h(sl(2))$.[6] The Jordanian quantum algebra $\mathcal{U}_h(sl(2))$ is more natural than the q-deformed $sl(2)$ in the sense that it is regarded as the angular momentum algebra with nonstandard coproduct (Sec. III) and we can use ordinary boson operators to represent $\mathcal{U}_h(sl(2))$, while it is hard to regard the q-deformed $sl(2)$ as angular momentum and q-deformed boson algebras are used for representations.[7] However, the representation theories of $\mathcal{U}_h(sl(2))$ and $SL_h(2)$ have not been developed yet. We do not know, for example, the Racha coefficients and matrix elements of the universal R-matrix for $\mathcal{U}_h(sl(2))$. As for $SL_h(2)$, even its representation matrices are not obtained.

In this article, in order to develop representation theories for Jordanian deformed algebras, we study symplecton for $\mathcal{U}_h(sl(2))$ and apply it to investigate representation matrices of $SL_h(2)$. The use of symplecton could be legitimated by recalling the properties of symplecton and q-deformed case. The symplecton, introduced by Biedenharn and Louck,[8,9] is a polynomial of boson creation and annihilation operators which form an irreducible tensor operator of $sl(2)$, that is, symplecton is a basis of irreducible representation (irrep.) for both $sl(2)$ and $SL(2)$. It is known that the symplecton is written in terms of Gauss hypergeometric function and product of two symplecton is reduced to a series of symplecton with Racha coefficients. In Ref. 8, application of symplecton to the Elliot model for nuclei is discussed, then it is found that Weyl-ordered polynomials for position and momentum operators are equivalent to symplecton.[10] Many properties of symplecton are inherited from $sl(2)$ to the q-deformed case.[2,11,12] The q-deformed symplecton, called

q-symplecton, is a irreducible tensor operator so that it is a irrep. basis for q-deformed $sl(2)$ and $SL(2)$. The q-symplecton is written in terms of q-hypergeometric function and product of two q-symplecton is reduced to a series of q-symplecton with q-Racha coefficients. q-Deformation of the Weyl-ordered polynomial[13] is formulated with q-symplecton. These facts show that symplecton is a powerful tool to investigate representation.

The plan of this article is as follows. Next three sections are mainly preparation for symplecton of $\mathcal{U}_h(sl(2))$. We often call the symplecton for $\mathcal{U}_h(sl(2))$ h-symplecton. The next section is a review of symplecton for $sl(2)$. Some of the properties of symplecton listed in Sec. II will be extended to h-symplecton. Section III is devoted to the Jordanian quantum algebra $\mathcal{U}_h(sl(2))$ and Jordanian quantum group $SL_h(2)$. We give new results on the twist element and Racha coefficients for $\mathcal{U}_h(sl(2))$. In Sec. IV, tensor operators for a Hopf algebra is introduced according to Ref. 14 and the relation between tensor operators for a Lie algebra and a Hopf algebra obtained by Drinfeld twist is discussed. Applying the result in Sec. IV, the h-symplecton is constructed from the $sl(2)$ symplecton in Sec. V. The properties of h-symplecton are studied in Secs. V and VI. We shall consider another irreducible tensor operators obtained from the quantum h-plane for $\mathcal{U}_h(sl(2))$ in Sec. VII and using these tensor operators, as well as h-symplecton, irreps. of $SL_h(2)$ are considered. Section VIII is concluding remarks.

II. SYMPLECTON FOR $sl(2)$

The symplecton realization of $sl(2)$ is said to be ''minimal,'' since only one kind of boson operator is used. It is in marked contrast to the well-known Jordan–Schwinger realization where two kinds of bosons are necessary. Let us first review the definition and important properties of the $sl(2)$ symplecton.[8,9]

Let $\bar{a},a$ be boson operators satisfying $[\bar{a},a]=1$, and define

$$J_+=-\tfrac{1}{2}a^2,\quad J_-=\tfrac{1}{2}\bar{a}^2,\quad J_0=\tfrac{1}{2}(a\bar{a}+\bar{a}a). \tag{II.1}$$

It is easy to verify that (II.1) satisfies the $sl(2)$ commutation relations

$$[J_0,J_\pm]=\pm 2J_\pm,\quad [J_+,J_-]=J_0. \tag{II.2}$$

The symplecton is a polynomial in $\bar{a}$ and a and form a irreducible tensor operator of $sl(2)$ belonging to the spin j representation $(j=\tfrac{1}{2},1,\tfrac{3}{2},\ldots)$. Namely the symplecton, denoted by $P_j^m(a,\bar{a})$, is defined by

$$\begin{aligned}[][J_\pm,P_j^m]&=\sqrt{(j\mp m)(j\pm m+1)}P_j^{m\pm 1},\\ [J_0,P_j^m]&=2mP_j^m.\end{aligned} \tag{II.3}$$

The basic idea of symplecton is to treat $\bar{a}$ and a in a symmetric way. To this end, the usual ''boson calculus'' is replaced with the so-called ''symplecton calculus,'' that is, instead of the boson vacuum $|0\rangle$ satisfying $\bar{a}|0\rangle=0$, the formal ket $|\,\rangle$ which is not annihilated by both $\bar{a}$ and a is introduced. The representation bases in the realization (II.1) are formed by letting P_j^m act on $|\,\rangle$, and the action of generators on the bases is defined by $J_\alpha|jm\rangle=[J_\alpha,P_j^m]|\,\rangle$. There exists an appropriate definition of an inner product for these $|jm\rangle$, so that we obtain the usual unitary representations of $sl(2)$ with spin j.

The explicit form of the polynomials $P_j^m(a,\bar{a})$ is found by solving $[J_+,P_j^j]=0$ to obtain $P_j^j=a^{2j}$, and then using the action of J_- to calculate P_j^m,

$$P_j^m(a,\bar{a})=\frac{1}{2^{j-m}}\left[\frac{(2j)!(j-m)!}{(j+m)!}\right]^{1/2}\sum_{s=0}^{j-m}\frac{\bar{a}^{j-m-s}a^{j+m}\bar{a}^s}{s!(j-m-s)!}. \tag{II.4}$$

An alternative form for P_j^m is obtained by starting with $P_j^{-j}=\bar{a}^{2j}$ and then using the action of J_+,

$$P_j^m(a,\overline{a})=\frac{1}{2^{j+m}}\left[\frac{(2j!)!(j+m)!}{(j-m)!}\right]^{1/2}\sum_{s=0}^{j+m}\frac{a^s\overline{a}^{j-m}a^{j+m-s}}{s!(j+m-s)!}. \tag{II.5}$$

We would like to list some properties of $sl(2)$ symplecton. For their proof or detail, we refer the reader to Refs. 8 and 9.

(1) A set of polynomials $\{P_j^m(a,\overline{a})|m=-j,-j+1,...,j\}$ forms representation bases for the Lie group $SL(2)$ as well as the Lie algebra $sl(2)$. The boson commutation relation is covariant under the action of $SL(2)$ defined by

$$(a',\overline{a}')=(a,\overline{a})\begin{pmatrix}x & u\\ v & y\end{pmatrix}, \tag{II.6}$$

where the 2×2 matrix is an element of $SL(2)$. The transformed polynomial $P_j^m(a',\overline{a}')$ is decomposed into $P_j^m(a,\overline{a})$ multiplied by polynomials in the entries of $SL(2)$ matrix,

$$P_j^m(a',\overline{a}')=\sum_n P_j^n(a,\overline{a})d_{nm}^j(g)\quad g\in SL(2). \tag{II.7}$$

The $(2j+1)\times(2j+1)$ matrix $d_{nm}^j(g)$ gives an irrep. of $SL(2)$ and is called Wigner's *d*-function in physics terminology.

(2) The polynomials $P_j^m(a,\overline{a})$ have a generating function. Let ξ, η be ordinary *c*-numbers commuting with $a,\overline{a}$. Then

$$(\xi a+\eta\overline{a})^{2j}=\sqrt{(2j)!}\sum_{m=-j}^{j}\Phi_{jm}(\xi,\eta)P_j^m(a,\overline{a}), \tag{II.8}$$

where Φ_{jm} are well-known representation bases of both $sl(2)$ and $SL(2)$,

$$\Phi_{jm}(\xi,\eta)=\frac{\xi^{j+m}\eta^{j-m}}{\sqrt{(j+m)!(j-m)!}}. \tag{II.9}$$

Irreps. of $sl(2)$ are constructed on (II.9) by the realization

$$J_+=\xi\frac{d}{d\eta},\ J_-=\eta\frac{d}{d\xi},\ J_0=\xi\frac{d}{d\xi}-\eta\frac{d}{d\eta}, \tag{II.10}$$

while irreps. of $SL(2)$ are obtained by the following transformation:

$$(\xi',\eta')=(\xi,\eta)\begin{pmatrix}x & u\\ v & y\end{pmatrix}, \tag{II.11}$$

it follows that

$$\Phi_j^m(\xi',\eta')=\sum_n \Phi_j^n(\xi,\eta)\,d_{nm}^{\,j}(g), \tag{II.12}$$

where we have obtained the same *d*-function as (II.7).

(3) The symplecton polynomials can be expressed in terms of Gauss hypergeometric function ${}_2F_1(a,b;c;z)$. The polynomial ${}_2F_1(a,b;c;z)$ is defined by

$${}_2F_1(a,b;c;z)=\sum_{n=0}^{\infty}\frac{(a)_n(b)_n}{n!(c)_n}z^n, \tag{II.13}$$

where $(a)_n$ stands for the sifted factorial

$$(a)_n=\begin{cases}1 & n=0\\ a(a+1)\cdots(a+n-1) & n=1,2,...\end{cases}. \tag{II.14}$$

Now define the operator $N=a\overline{a}$, then the symplecton $P_j^m(a,\overline{a})$ is written in terms of ${}_2F_1(a,b;c;z)$ with $z=-1$ and the parameters *a*, *c* become functions of operator *N*. The expression (II.4) becomes

$$P_j^m=\frac{1}{2^{j+m}}\left[\frac{(2j)!}{(j+m)!(j-m)!}\right]^{1/2}\frac{(N+j-m)!}{(N-2m)!}\,{}_2F_1(-N+2m,-j+m;-N-j+m;-1)(\overline{a})^{-2m}. \tag{II.15}$$

In this way, properties of P_j^m are reduced to properties of the hypergeometric function. Especially, the equivalence of two form (II.4) and (II.5) is explained by the formula

$$ {}_2F_1(a,b;c;z)=(1-z)^{c-a-b}\,{}_2F_1(c-a,c-b;c;z). \tag{II.16}$$

(4) The polynomials $P_j^m(a,\overline{a})$ are transformed under the action $a\to\overline{a},\ \overline{a}\to -a$,

$$P_j^m(\overline{a},-a)=(-1)^{j-m}P_j^{-m}(a,\overline{a}). \tag{II.17}$$

To define an inner product for the bases $|jm\rangle = P_j^m|\ \rangle$, the property (II.17) and the product formula discussed below play a crucial role.

(5) Let P_j^m and $P_{j'}^{m'}$ be the symplecton polynomials, then they obey the product law

$$P_j^m P_{j'}^{m'}=\sum_{k=|j-j'|}^{j+j'} \langle k|j|j'\rangle C_{m',m,m+m'}^{j',j,k} P_k^{m+m'}, \tag{II.18}$$

where

$$\langle k|j|j'\rangle = 2^{k-j-j'}(2k+1)^{-1/2}\nabla(kjj'),$$

$$\nabla(abc)=\left[\frac{(a+b+c+1)!}{(a+b-c)(a-b+c)!(-a+b+c)!}\right]^{1/2}, \tag{II.19}$$

and $C_{m',m,m+m'}^{j',j,k}$ is the Clebsch–Gordan coefficient (CGC) for $sl(2)$. The associativity of the products $(P_a^\alpha P_b^\beta)P_c^\gamma = P_a^\alpha(P_b^\beta P_c^\gamma)$ gives a relation between ‘‘triangle functions,’’

$$\nabla(acf)\nabla(bdf)=(2f+1)\sum_e W(abcd;ef)\nabla(abe)\nabla(cde), \tag{II.20}$$

where $W(abcd;ef)$ is the Racha coefficient.

The inner product for $|jm\rangle$ is defined by

$$\langle jm|j'm'\rangle = \langle|(-1)^{j-m}P_j^{-m}\cdot P_{j'}^{m'}|\rangle, \tag{II.21}$$

and the operation $\langle|(\cdots)|\rangle$ means to take only the $j=0$ part of the expression $(\cdots)$. Applying the product law (II.18) to the RHS of (II.21), we see that that the $j=0$ part is given by the CGC $C_{m,m',0}^{j,j',0}$, so that the bases $|jm\rangle$ are orthonormal.

III. JORDANIAN DEFORMATION OF $sl(2)$ AND $SL(2)$

The Jordanian quantum algebras $\mathcal{U}_h(\mathbf{g})$ are obtained from the (universal enveloping algebra $\mathcal{U}(\mathbf{g})$ of) Lie algebras $\mathbf{g}$ from Drinfeld twist.[15] We denote the coproduct, conuit and antipode for $\mathcal{U}(\mathbf{g})$, when it is regarded as a Hopf algebra, by Δ, ϵ, S, respectively. With the invertible element $\mathcal{F}\in\mathcal{U}(\mathbf{g})\otimes\mathcal{U}(\mathbf{g})$ satisfying

$$(\epsilon\otimes id)(\mathcal{F})=(id\otimes\epsilon)(\mathcal{F})=1, \tag{III.1}$$

$$\mathcal{F}_{12}(\Delta\otimes id)(\mathcal{F})=\mathcal{F}_{23}(id\Delta)(\mathcal{F}), \tag{III.2}$$

the algebra $\mathcal{U}_h(\mathbf{g})$ is defined by the same commutation relations as $\mathbf{g}$ and the following Hopf algebra mappings:

$$\tilde{\Delta}=\mathcal{F}\Delta\mathcal{F}^{-1},\quad \tilde{\epsilon}=\epsilon,\quad \tilde{S}=uSu^{-1}, \tag{III.3}$$

where $u=m(id\otimes S)(\mathcal{F})$, $u^{-1}=m(S\otimes id)(\mathcal{F}^{-1})$, m denotes the usual product in $\mathbf{g}$. This is a triangular Hopf algebra whose universal R-matrix is given by $\mathcal{R}=\mathcal{F}_{21}\mathcal{F}^{-1}$.

For the case of $\mathbf{g}=sl(2)$, $\mathcal{F}$ is given by[16]

$$\mathcal{F}=\exp(-\tfrac{1}{2}J_0\otimes\sigma),\quad \sigma=-\ln(1-2hJ_+). \tag{III.4}$$

The twist element $\mathcal{F}$ used here gives different form of $\mathcal{U}_h(sl(2))$ from the one in Ref. 6. The relationship between these two forms is given in Appendix A. The explicit form of Hopf algebra mappings for $\mathcal{U}_h(sl(2))$ is summarized in Appendix B (some of them will be used in the later computation). An application of the $\mathcal{U}_h(sl(2))$ to the Heisenberg spin chain is found in Ref. 16. The finite dimensional highest weight irreps. for $\mathcal{U}_h(sl(2))$ are same as $sl(2)$, because of the same commutation relations. We shall use the following lemmas on tensor product representations in subsequent sections.

Lemma III.1 (Ref. 16): *Let V^{j_1}, V^{j_2} be the representation space with the highest weight j_1, j_2. Then the tensor product of them is completely reducible, i.e.,*

$$V^{j_1}\otimes V^{j_2}=\bigoplus_{j=|j_1-j_2|}^{j_1+j_2} V^j,$$

and the bases of V^j are given by

$$e_m^{(j_1j_2)j}=\sum C^{j_1,j_2,j}_{m_1,m_2,m}F^{j_1,j_2}_{k_1,k_2,m_1m_2}e^{j_1}_{k_1}\otimes e^{j_2}_{k_2}, \tag{III.5}$$

where $C^{j_1,j_2,j}_{m_1,m_2,m}$ is the CGC of $sl(2)$ and $F^{j_1,j_2}_{k_1,k_2,m_1,m_2}$ is the matrix element of $\mathcal{F}$ on $V^{j_1}\otimes V^{j_2}$. The explicit form of matrix elements $F^{j_1,j_2}_{k_1,k_2,m_1,m_2}$ is given in Appendix C. (It seems to be the first time to show the explicit form of $F^{j_1,j_2}_{k_1,k_2,m_1,m_2}$ in the literature, and this also gives the explicit form of the R-matrix for $\mathcal{U}_h(sl(2))$.)

Lemma III.2: The Racha coefficients for $sl(2)$ and $\mathcal{U}_h(sl(2))$ coincide.
Lemma III.2 is proved in Appendix D.

The matrix quantum group dual to $\mathcal{U}_h(sl(2))$ is called the Jordanian quantum group $SL_h(2)$. It is generated by four elements x, y, u and v subject to the relations[3,4,5]

$$[v,x]=hv^2,\quad [u,x]=h(1-x^2),$$
$$[v,y]=hv^2,\quad [u,y]=h(1-y^2), \tag{III.6}$$
$$[x,y]=h(xv-yv),\quad [v,u]=h(xv+vy).$$

It follows that the central element of $SL_h(2)$ which gives the determinant of the quantum matrix

$$T=\begin{pmatrix} x & u \\ v & y \end{pmatrix} \tag{III.7}$$

is defined by

$$\det T=xy-uv-hxv=1. \tag{III.8}$$

The $SL_h(2)$ has a Hopf algebra structure. The relations (III.6) and Hopf algebra mappings are summarized in the FRT-formalism[17] with the R-matrix

$$R=\begin{pmatrix} 1 & h & -h & h^2 \\ 0 & 1 & 0 & h \\ 0 & 0 & 1 & -h \\ 0 & 0 & 0 & 1 \end{pmatrix}. \tag{III.9}$$

The coproduct, the counit, and the antipode are given by

$$\Delta(T)=T\otimes T,$$

$$\epsilon(T)=\begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix},$$

$$S(T)=T^{-1}=\begin{pmatrix}y-hv & -u-h(y-x)+h^2v\\ -v & x+hv\end{pmatrix}.$$

Let us define the d-function for $SL_h(2)$ using the notion of comodule. A vector space M is called right $SL_h(2)$ comodule if there is a map $\rho: M\to M\otimes SL_h(2)$ such that the following relations are satisfied

$$(\rho\otimes id)\circ\rho=(id_M\otimes\Delta)\circ\rho, \quad (id_M\otimes\epsilon)\circ\rho=id_M, \tag{III.10}$$

where id_M stands for the identity map in M. Using bases e_i of M, the map ρ is written as

$$\rho(e_i)=\sum_j e_j\otimes\tilde{d}_{ji}, \tag{III.11}$$

it follows that the relations (III.10) are rewritten as

$$\Delta(\tilde{d}_{ij})=\sum_k \tilde{d}_{ik}\otimes\tilde{d}_{kj}, \quad \epsilon(\tilde{d}_{ij})=\delta_{ij}. \tag{III.12}$$

We call the $\tilde{d}_{ij}$ satisfying (III.11) and (III.12) the d-function for $SL_h(2)$. In the following sections, we deal with the case in which the vector space M has an algebraic structure. It is natural, in this case, to require that the map ρ should respect the extra structure on M.

IV. TENSOR OPERATORS AND TWIST

To define the symplecton for $\mathcal{U}_h(sl(2))$, it is necessary to extend the notion of tensor operators to Hopf algebra. This has been carried out by Rittenberg and Scheunert.[14] Tensor operators are defined for each realization of the Hopf algebra $\mathcal{H}$ under consideration. Assuming that we have a realization of $\mathcal{H}$, we first define the adjoint action.

Definition IV.1: Let W,W' be a representation space of $\mathcal{H}$, and let t be an operator which carries W into W'. Then the adjoint action of $X\in\mathcal{H}$ on t is defined by

$$\mathrm{ad}\,X(t)=m(id\otimes S)(\Delta(X)(t\otimes 1)). \tag{IV.1}$$

The adjoint action has two important properties

$$\mathrm{ad}\,XX'(t)=\mathrm{ad}\,X\circ\mathrm{ad}\,X'(t), \quad \mathrm{ad}\,X(t\otimes s)=\sum_i \mathrm{ad}\,X_i(t)\otimes\mathrm{ad}\,X_i'(s), \tag{IV.2}$$

where the coproduct for X is written as $\Delta(X)=\Sigma_i X_i\otimes X_i'$. From these properties, we see that the adjoint action gives a representation of $\mathcal{H}$,

$$\mathrm{ad}[X,X'](t)=[\mathrm{ad}\,X,\mathrm{ad}\,X'](t). \tag{IV.3}$$

Tensor operators for $\mathcal{H}$ are defined as operators which form representation bases of $\mathcal{H}$ under the adjoint action.

Definition IV.2: Let $D(X)$ be a representation matrix of $X\in\mathcal{H}$. The operators t_α are called the tensor operator, if they satisfy the relation

$$\mathrm{ad}\, X(t_\alpha)=\sum_\beta D(X)_{\beta\alpha}t_\beta. \tag{IV.4}$$

If the representation is irreducible, the tensor operators are called irreducible tensor operators.

The explicit form of the adjoint action for $\mathcal{U}_h(sl(2))$ reads

$$\begin{aligned}\mathrm{ad}\, J_0(t)&=[J_0,t]e^{-\sigma},\\ \mathrm{ad}\, J_+(t)&=e^{-\sigma}[J_+e^{\sigma},t],\\ \mathrm{ad}\, J_-(t)&=\left[J_-+hJ_0+\frac{h}{2}J_0^2,t\right]e^{-\sigma}-h[J_0,t]e^{-2\sigma}-\frac{h}{2}[J_0,[J_0,t]]e^{-2\sigma}.\end{aligned} \tag{IV.5}$$

Some examples of the $\mathcal{U}_h(sl(2))$ tensor operators are considered in Ref. 18 and they are applied to construct boson algebra which is covariant under the action of Jordanian matrix quantum groups.[19]

Since the coproduct for the Lie algebra and Jordanian quantum algebra is related via the twist element (III.3), tensor operators for these algebras are also related by twisting via $\mathcal{F}$.[20]

Lemma IV.1: Let t_α be tensor operators for the Lie algebra $\mathbf{g}$ *and $\tilde{t}_\alpha$ be corresponding ones for Jordanian quantum algebra $\mathcal{U}_h(\mathbf{g})$. Then these tensor operators are related via the twist element $\mathcal{F}$,*

$$\tilde{t}_\alpha=m(id\otimes\tilde{S})(\mathcal{F}(t_\alpha\otimes 1)\mathcal{F}^{-1}), \tag{IV.6}$$

$$t_\alpha=m(id\otimes S)(\mathcal{F}^{-1}(\tilde{t}_\alpha\otimes 1)\mathcal{F}). \tag{IV.7}$$

Proof: The first relation (IV.6) is derived in Ref. 20 (Proposition 3). The second one (IV.7) is its inverse. The expression used in Lemma IV.1 is different from Ref. 20, it may be good to show the second relation as an example of the proof. It is proved by showing the substitution of (IV.7) into (IV.6) gives the identity map.

Let us write the twist element and its inverse as

$$\mathcal{F}=\sum f^a\otimes f_a,\quad \mathcal{F}^{-1}=\sum g^a\otimes g_a,$$

then

$$u=\sum f^aS(f_a),\quad u^{-1}=\sum S(g^a)g_a,$$

and the relation (IV.6) becomes

$$\tilde{t}_\alpha=\sum f^at_\alpha g^b\tilde{S}(f_ag_b)=\sum f^at_\alpha g^buS(f_ag_b)u^{-1}=\sum f^at_\alpha S(f_a)u^{-1}, \tag{IV.8}$$

where we used

$$\sum g^buS(g_b)=\sum g^bf^aS(g_bf_a)=m(id\otimes S)(\mathcal{F}^{-1}\mathcal{F})=1.$$

On the other hand, the relation (IV.7) is rewritten

$$t_\alpha=\sum g^a\tilde{t}_\alpha f^bS(g_af_b)=\sum g^a\tilde{t}_\alpha uS(g_a). \tag{IV.9}$$

Substituting (IV.9) into (IV.8),

$$\tilde{t}_\alpha = \sum f^a g^b \tilde{t}_\alpha u S(f_a g_b) u^{-1} = \sum f^a g^b \tilde{t}_\alpha \tilde{S}(f_a g_b) = m(id \otimes \tilde{S})(\mathcal{F}\mathcal{F}^{-1}(\tilde{t}_\alpha \otimes 1)) = \tilde{t}_\alpha .$$

This proves the second relation in Lemma IV.1. □

V. SYMPLECTON POLYNOMIALS FOR $\mathcal{U}_h(sl(2))$

In this section, we derive the explicit form of the symplecton for $\mathcal{U}_h(sl(2))$ and investigate its properties. Since $\mathcal{U}_h(sl(2))$ has the same commutation relations as $sl(2)$, $\mathcal{U}_h(sl(2))$ and $sl(2)$ have the same realizations. Therefore the symplecton realization for $\mathcal{U}_h(sl(2))$, which is identical to the one for $sl(2)$, is the realization in terms of the usual boson operators. This is a contrast to the q-symplecton where the q-deformed boson operators are used.

Let $\bar{a}$ and a be boson operators satisfying $[\bar{a},a]=1$, then the generators of $\mathcal{U}_h(sl(2))$ are realized by

$$J_+ = -\tfrac{1}{2}a^2, \quad J_- = \tfrac{1}{2}\bar{a}^2, \quad J_0 = \tfrac{1}{2}(a\bar{a} + \bar{a}a). \tag{V.1}$$

The h-symplecton, denoted by $\tilde{P}_j^m(a,\bar{a})$, is defined as a polynomial in $\bar{a},a$ satisfying

$$\begin{aligned} \mathrm{ad}\, J_\pm(\tilde{P}_j^m) &= \sqrt{(j \mp m)(j \pm m + 1)}\,\tilde{P}_j^{m\pm 1}, \\ \mathrm{ad}\, J_0(\tilde{P}_j^m) &= 2m\tilde{P}_j^m , \end{aligned} \tag{V.2}$$

where the adjoint action on the LHS is given by (IV.5). Using Lemma IV.1, the explicit form of h-symplecton is obtained from the corresponding one for $sl(2)$.

Proposition V.1: The explicit form of the h-symplecton defined by (V.2) is given by

$$\tilde{P}_j^m(a,\bar{a}) = P_j^m(a,\bar{a}) e^{m\sigma}, \tag{V.3}$$

where σ is given in (III.4) and $P_j^m(a,\bar{a})$ denotes $sl(2)$ symplecton.

Proof: By definition of $sl(2)$ symplecton, it holds that

$$(J_0 - 2m)P_j^m = P_j^m J_0 .$$

Using this and the RHS of (IV.8),

$$\tilde{P}_j^m = \sum_{n=0}^{\infty} \frac{1}{n!}\left(-\frac{1}{2}\right)^n P_j^m (J_0 + 2m)^n S(\sigma)^n u^{-1} = P_j^m \sum_{n=0}^{\infty}\sum_{s=0}^{n} \frac{(-1)^n (2m)^s}{2^n (n-s)!\, s!} J_0^{n-s} (\sigma)^n u^{-1}.$$

Changing the order of sum, then replacing $n-s$ with n, we obtain

$$\tilde{P}_j^m = P_j^m \sum_{s,n=0}^{\infty} \frac{(-1)^{n+s}(2m)^s}{2^{n+s} n!\, s!} J_0^n S(\sigma)^{n+s} u^{-1}. \tag{V.4}$$

Note that

$$u = \sum_{n=0}^{\infty}\left(-\frac{1}{2}\right)^n \frac{1}{n!} J_0^n S(\sigma)^n,$$

and (III.3), it follows that (V.4) is rewritten as

$$\tilde{P}_j^m = P_j^m \sum_{s=0}^{\infty} \left(-\frac{1}{2}\right)^s \frac{(2m)^s}{s!} \tilde{S}(\sigma)^s = P_j^m e^{m\sigma},$$

where (B4) is used in the last equality. □

We would like to show some explicit form of h-symplecton. For $j=1/2$,

$$\tilde{P}_{1/2}^{-1/2} = \bar{a} e^{-\sigma/2} \equiv \bar{a}_h, \quad \tilde{P}_{1/2}^{1/2} = \bar{a} e^{\sigma/2} \equiv a_h, \tag{V.5}$$

and for $j=1$,

$$\tilde{P}_1^{-1} = \bar{a}^2 e^{-\sigma} = \bar{a}_h^2 + h \bar{a}_h a_h,$$

$$\tilde{P}_1^0 = (\bar{a} a + a \bar{a})/\sqrt{2} = (\bar{a}_h a_h + a_h \bar{a}_h - h a_h^2)/\sqrt{2}, \tag{V.6}$$

$$\tilde{P}_1^1 = a^2 e^{\sigma} = a_h^2.$$

The $j=1/2$ h-symplecton forms covariant h-deformed oscillator algebra

$$[\bar{a}_h, a_h] = 1 - h a_h^2, \tag{V.7}$$

i.e., the commutation relation (V.7) is preserved under the action of $SL_h(2)$,

$$(a_h', \bar{a}_h') = (a_h, \bar{a}_h) \begin{pmatrix} x & u \\ v & y \end{pmatrix}. \tag{V.8}$$

This shows that it is possible to construct representations of $\mathrm{SL}_h(2)$ on h-symplecton. We shall discuss it later. It may be worth noting that the action (V.8) is different from the ones in Refs. 19 and 20, where a and $\bar{a}$ are *not* mixed by the action of quantum groups.

The $j=1$ h-symplecton forms an algebra isomorphic to $sl(2)$. Its commutation relations are

$$[P_0^1, P_1^1] = 2\sqrt{2} P_1^1 (1 - h P_1^1),$$

$$[P_1^0, P_1^{-1}] = -2\sqrt{2} P_1^{-1} (1 - h P_1^1), \tag{V.9}$$

$$[P_1^1 P_1^{-1}] = -2\sqrt{2} (1 - h P_1^1) P_1^0.$$

The generators of $sl(2)$ are written in terms of P_1^m,

$$J_+ = -\tfrac{1}{2} P_1^1 (1 - h P_1^1), \quad J_0 = \frac{1}{\sqrt{2}} P_1^0, \quad J_- = \tfrac{1}{2} P_1^{-1} (1 - h P_1^1). \tag{V.10}$$

We see, from the explicit form of h-symplecton (V3), that the h dependence of polynomial $\tilde{P}_j^m(a,\bar{a})$ is absorbed in σ which is an infinite polynomial in a^2. Recall that the relationship between $sl(2)$ symplecton and Gauss hypergeometric function ${}_2F_1$ is given in terms of the operator $N = a\bar{a}$, then we see that the factor $e^{m\sigma}$ in (V.3) does not affect this relationship. Therefore the specific hypergeometric function for h-symplecton may be again ${}_2F_1$.

The fact that the $j=1/2$ h-symplecton forms covariant h-oscillator algebra may suggest that it is useful to write h-symplecton in terms of covariant h-oscillators (V.5).

Proposition V.2: The h-symplecton is written in terms of covariant h-oscillators as follows. The corresponding expression for (II.4) is

$$\tilde{P}_j^m(a_h,\overline{a_h})=\frac{1}{2^{j-m}}\left[\frac{(2j)!(j-m)!}{(j+m)!}\right]^{1/2}\sum_{s=0}^{j-m}\frac{1}{s!(j-m-s)!}$$
$$\times\overline{a_h}(\overline{a_h}+ha_h)\cdots\{\overline{a_h}+(j-m-s-1)ha_h\}a_h^{j+m}$$
$$\times\{\overline{a_h}-(2m+s)ha_h\}\{\overline{a_h}-(2m+s-1)ha_h\}\cdots\{\overline{a_h}-(2m+1)ha_h\}, \quad \text{(V.11)}$$

and for (II.5) is

$$\tilde{P}_j^m(a_h,\overline{a_h})=\frac{1}{2^{j+m}}\left[\frac{(2j)!(j+m)!}{(j-m)!}\right]^{1/2}\sum_{s=0}^{j+m}\frac{1}{s!(j+m-s)!}$$
$$\times a_h^s(\overline{a_h}-hsa_h)\{\overline{a_h}+h(1-s)a_h\}\cdots\{\overline{a_h}+h(j-m-1-s)a_h\}a_h^{j+m-s}. \quad \text{(V.12)}$$

Proof: From (V.5),

$$\overline{a}=\overline{a_h}e^{\sigma/2}, \quad a=a_he^{-\sigma/2}.$$

Substituting these into (II.4) and (II.5), straightforward calculation proves the proposition. □

In order to discuss generating functions for *h*-symplecton, it is possible to apply Lemma IV.1 to the generating function (II.8) for $sl(2)$ symplecton, since the RHS of (II.8) is a sum of tensor operators of $sl(2)$. It follows that the RHS of (II.8) becomes the sum of *h*-symplecton; $\sqrt{(2j)!}\sum_{m=-j}^{j}\Phi_{jm}\tilde{P}_j^m$. However the LHS may be quite complicated and may not be in closed form. Another way to obtain generating functions for *h*-symplecton is to substitute (V.3) and (V.5) into (II.8),

$$(\xi a_he^{-\sigma/2}+\eta\overline{a_h}e^{\sigma/2})^{2j}=\sqrt{(2j)!}\sum_{m=-j}^{j}\Phi_{jm}(\xi,\eta)\tilde{P}_j^m(a_h,\overline{a_h})e^{-m\sigma}. \quad \text{(V.13)}$$

It is possible to remove σ from (V.13) by using the relation $e^{\sigma}+ha_h^2=1$, however, the obtained relation is quite complicated. Therefore the simplest generating function for *h*-symplecton may be (V.13), where the σ is regarded as a independent quantity subject to the relations

$$[\sigma,a_h]=0, \ [\sigma,\overline{a_h}]=2ha_h, \quad \text{(V.14)}$$

and $\lim_{h\to 0}\sigma=0$.

VI. PRODUCT LAW FOR *h*-SYMPLECTON

It is possible to extend the product law (II.18) for $sl(2)$ symplecton to *h*-symplecton. The product law plays a crucial role when the symplecton calculus is considered. In this section, we first prove the product law for *h*-symplecton by using the one for $sl(2)$ symplecton, then consider the symplecton calculus for $\mathcal{U}_h(sl(2))$.

Theorem VI.1: *Let* $\tilde{P}_j^m$ *and* $\tilde{P}_{j'}^{m'}$ *be h-symplecton, then these obey the product law,*

$$\tilde{P}_j^m\tilde{P}_{j'}^{m'}=\sum_{k=|j-j'|}^{j+j'}\sum_{n,n'}\langle k|j|j'\rangle(F^{-1})_{n,n'm,m'}^{j,j'}C_{n',m,n'+m}^{j',j,k}\tilde{P}_k^{n'+m}, \quad \text{(VI.1)}$$

where $C_{m_1,m_2,m}^{j_1,j_2,j}$ *is the CGC for* $sl(2)$ *and*

$$\langle k|j|j'\rangle=2^{k-j-j'}(2k+1)^{-1/2}\nabla(kjj'),$$

$$\nabla(abc)=\left[\frac{(a+b+c+1)!}{(a+b-c)!(a-b+c)!(-a+b+c)!}\right]^{1/2}. \tag{VI.2}$$

Proof: From Proposition V.1,

$$\tilde{P}_j^m\tilde{P}_{j'}^{m'}=P_j^m e^{m\sigma}\tilde{P}_{j'}^{m'}e^{-m\sigma}e^{m\sigma}.$$

Using the Hopf algebra mappings for σ given in (B4), we see that the adjoint action of $e^{m\sigma}$ is given by

$$\mathrm{ad}e^{m\sigma}(t)=e^{m\sigma}te^{-m\sigma}. \tag{VI.3}$$

h-Symplecton is an irreducible tensor operator of $\mathcal{U}_h(sl(2))$, and it follows that

$$e^{m\sigma}\tilde{P}_{j'}^{m'}e^{-m\sigma}=\mathrm{ad}e^{m\sigma}(\tilde{P}_{j'}^{m'})=\sum_{n'}(e^{m\sigma})_{n',m'}^{j'}\tilde{P}_{j'}^{n'}$$
$$=\sum_{n,n'}\delta_{n,m}(e^{m\sigma})_{n',m'}^{j'}\tilde{P}_{j'}^{n'}=\sum_{n,n'}(F^{-1})_{n,n'm,m'}^{j,j'}\tilde{P}_{j'}^{n'}, \tag{VI.4}$$

where the matrix elements of $\mathcal{F}$ (C4) is used in the last equality. Therefore, we have

$$\tilde{P}_j^m\tilde{P}_{j'}^{m'}=\sum_{n,n'}(F^{-1})_{n,n'm,m'}^{j,j'}P_j^m\tilde{P}_{j'}^{n'}e^{m\sigma}=\sum_{n,n'}(F^{-1})_{n,n'm,m'}^{j,j'}P_j^mP_{j'}^{n'}e^{(n'+m)\sigma}.$$

Applying the product law (II.18) for $sl(2)$ symplecton, Theorem VI.1 is proved. □

Corollary VI.1: The associativity of the products $(\tilde{P}_a^\alpha\tilde{P}_b^\beta)\tilde{P}_c^\gamma=\tilde{P}_a^\alpha(\tilde{P}_b^\beta\tilde{P}_c^\gamma)$ *gives the same relation as (II.20) for the triangle function* $\nabla(abc)$ *that appeared in Theorem VI.1.*

Proof: The associativity gives the same relation as (II.20), but the Racha coefficients are replaced with the ones for $\mathcal{U}_h(sl(2))$. From Lemma III.2, these two kinds of Racha coefficients coincide. □

Let us now consider the h-symplecton calculus. We assume the formal ket$|\,\rangle$ and that both $\bar{a}|\,\rangle$ and $a|\,\rangle$ are nonvanishing vectors. Then the vectors defined by $|jm\rangle=\tilde{P}_j^m|\,\rangle$ are irrep. bases of $\mathcal{U}_h(sl(2))$ provided that the action of $X\in\mathcal{U}_h(sl(2))$ is defined by $X|jm\rangle=\mathrm{ad}X(\tilde{P}_j^m)|\,\rangle$. The dual bases are defined by $\langle jm|=\langle\,|\tilde{P}_j^{-m}(-1)^{j-m}$ in order to keep the correspondence with the $h=0$ case. The action of $X\in\mathcal{U}_h(sl(2))$ is, of course, given by $\langle jm|=\langle\,|\mathrm{ad}X(\tilde{P}_j^{-m})(-1)^{j-m}$. The inner product is defined in the same manner as $h=0$ case, namely,

$$\langle jm|j'm'\rangle=\langle\,|(-1)^{j-m}\tilde{P}_j^{-m}\cdot\tilde{P}_{j'}^{m'}|\,\rangle,$$

the operation $\langle|(\cdots)|\rangle$ means to take only the $j=0$ part of the expression $(\cdots)$. Applying the product law (VI.1) for h-symplecton, we obtain

$$\langle jm|j'm'\rangle=\delta_{j,j'}2^{-2j}F_{-m,m\ -m,m'}^{j,j}. \tag{VI.5}$$

Therefore the vectors $|jm\rangle$ and $|j'm'\rangle$ are orthonormal if they belong to different irreps. but *not* orthonormal if they belong to a same irrep. The nonvanishing part on the RHS of (VI.5) depends on only the twist element $\mathcal{F}$.

From the product law, we can show the following relations for h-symplecton:

Proposition VI.1: The following relations hold for h-symplecton:

$$\sum_{m,m'}\tilde{P}_j^m\tilde{P}_{j'}^{m'}F_{m,m'l,l'}^{j,j'}=\sum_k\langle k|j|j'\rangle C_{l',l,l'+k}^{j',j,k}\tilde{P}_k^{l+l'}, \tag{VI.6}$$

$$\tilde{P}^{m'}_{j'}(a_h,\overline{a_h}+2hma_h)=\sum_{l=0}(F^{-1})^{j,j'}_{n,n'm,m'}\tilde{P}^{m'+l}_{j'}(a_h,\overline{a_h}). \tag{VI.7}$$

Proof: The relation (VI.6) is easily proved by multiplying the product law (VI.1) by $F^{j,j'}_{n,n'm,m'}$ and summing over m,m'. The relation (VI.7) is derived by moving $e^{m\sigma}$ to the right of $P^{m'}_{j'}$ in (VI.4). One can do that by using the relations

$$e^{m\sigma}a_h=a_he^{m\sigma},\quad e^{m\sigma}\overline{a_h}=(\overline{a_h}+2hma_h)e^{m\sigma}.$$

□

VII. QUANTUM *h*-PLANE AND REPRESENTATIONS OF $SL_h(2)$

The Jordanian quantum algebra $\mathcal{U}_h(sl(2))$ and Jordanian quantum group $SL_h(2)$ are dual each other. It follows that any representation basis of $\mathcal{U}_h(sl(2))$ is also representation basis for $SL_h(2)$ belonging to the same representation. Since *h*-symplecton is an irrep. basis of $\mathcal{U}_h(sl(2))$, it is also an irrep. basis of $SL_h(2)$. We have seen this for $j=1/2$ in Sec. V. The relation (V.8) can be generalized to arbitrary *j*,

$$\tilde{P}^m_j(a'_h,\overline{a'_h})=\sum_n \tilde{P}^n_j(a_h,\overline{a_h})\tilde{d}^j_{nm}(g)\qquad g\in SL_h(2). \tag{VII.1}$$

We can obtain *d*-functions for $\mathcal{U}_h(sl(2))$ by substituting (V.8) into the explicit form of *h*-symplecton given in Proposition V.2. However, as is seen from the explicit form, the actual computation seems to be complicated.

The use of quantum *h*-plane[21] provides us a procedure which is a little bit simpler in computation. In this section, we shall find irrep. bases for $SL_h(2)$ in terms of the quantum *h*-plane which give the same irreps. as *h*-symplecton by using the tensor operator approach. Recall that the functions $\Phi_{jm}(\xi,\eta)$ defined by (II.9) are irrep. bases of $sl(2)$ in the realization (II.10) and irrep. bases of SL(2) under (II.11) as well. We can regard $\Phi_{jm}(\xi,\eta)$ as an irreducible tensor operator of $sl(2)$, since it is easy to verify that

$$\begin{aligned}[J_\pm,\Phi_{jm}]&=\sqrt{(j\mp m)(j\pm m+1)}\Phi_{jm\pm1},\\ [J_0,\Phi_{jm}]&=2m\Phi_{jm}.\end{aligned} \tag{VII.2}$$

From Lemma IV.1, it is easy to find the corresponding irreducible tensor operators for $\mathcal{U}_h(sl(2))$.

Proposition VII.1: Let ξ, η be commutative numbers, then the following are irreducible tensor operators for $\mathcal{U}_h(sl(2))$:

$$\tilde{\Phi}_{jm}(\xi,\eta)=\Phi_{jm}(\xi,\eta)e^{m\sigma}, \tag{VII.3}$$

where

$$\sigma=-\ln\left(1-2h\xi\frac{d}{g\eta}\right).$$

For $j=1/2$, we have

$$\tilde{\Phi}_{(1/2)(1/2)}=\xi e^{\sigma/2}\equiv\xi_h,\quad \tilde{\Phi}_{(1/2)(-1/2)}=\eta e^{-\sigma/2}\equiv\eta_h, \tag{VII.4}$$

and they satisfy the commutation relation

$$[\xi_h,\eta_h]=h\xi_h^2, \tag{VII.5}$$

this corresponds to the commutation relation of quantum h-plane in Ref. 21. It is easily verified that the commutation relation (VII.5) is preserved under the action of $SL_h(2)$,

$$(\xi_h', \eta_h') = (\xi_h, \eta_h)\begin{pmatrix} x & u \\ v & y \end{pmatrix}. \tag{VII.6}$$

It is an easy exercise to write $\tilde{\Phi}_{jm}$ in terms of ξ_h and η_h. Then $\tilde{\Phi}_{jm}(\xi_h, \eta_h)$ forms irrep. bases of $SL(2)$, that is, the d-functions for $SL_h(2)$ are obtained by substituting (VII.6) into $\tilde{\Phi}_{jm}(\xi_h, \eta_h)$.

Proposition VII.2: Irreps. of $SL_h(2)$ on the quantum h-plane are obtained by

$$\tilde{\Phi}_{jm}(\xi_h', \eta_h') = \sum_k \tilde{\Phi}_{jk}(\xi_h, \eta_h)\tilde{d}^j_{km}, \tag{VII.7}$$

where the irrep. bases are given by

$$\begin{aligned}\tilde{\Phi}_{jm} &= c_{jm}\xi_h^{j+m}(\eta_h - h(j+m)\xi_h)(\eta_h - h(j+m-1)\xi_h)\cdots(\eta_h - h(2m+1)\xi_h),\\ &= c_{jm}\eta_h(\eta_h + h\xi_h)\cdots(\eta_h + (j-m-1)h\xi_h)\xi_h^{j+m},\end{aligned} \tag{VII.8}$$

with

$$c_{jm} = \frac{1}{\sqrt{(j+m)!(j-m)!}}.$$

Since $\tilde{P}_{jm}$ and $\tilde{\Phi}_{jm}$ give the same irreps. of $\mathcal{U}_h(sl(2))$, they also give the same d-functions of $SL_h(2)$. Indeed, the explicit computation shows that we obtain the same d-functions for $j=1/2$ and $j=1$. The $j=1/2$ case gives the 2×2 quantum matrix T (III.7) itself, while $j=1$ d-function reads

$$d^1 = \begin{pmatrix} x^2 + hxv & \sqrt{2}(ux + huv) & u^2 + hu(x+y+hv) \\ \sqrt{2}xv & 1 + 2uv & \sqrt{2}(uy + huv) \\ v^2 & \sqrt{2}yv & y^2 + hyv \end{pmatrix}. \tag{VII.9}$$

The d-functions for $SL_h(2)$ are also discussed in Ref. 22, where the authors assert that the d-functions can be obtained from the q-deformed ones via a contraction method and show some explicit examples. Another way to obtain the d-functions is to use the recurrence relations for d-functions. This will be discussed in a separate publication.

VIII. CONCLUDING REMARKS

We have constructed h-symplecton in this article and investigated some of its properties. It has been seen that many properties of $sl(2)$ symplecton are inherited to h-symplecton. Unfortunately, h-dependence of h-symplecton is absorbed in σ, namely, twist element $\mathcal{F}$, so that we cannot see specific hypergeometric function for h-deformation. It will become clear what kind of hypergeometric functions are specific to h-deformed quantities if we obtain explicit form of d-function for $SL_h(2)$ as in the case of q-deformed $SU(2)$.[23] The $sl(2)$ symplecton has a simple generating function. We presented (V.13) as a generating function for h-symplecton. However, this may be one of possible choices, we might find simpler generating function. The use of quantum h-plane ξ_h, η_h instead of ξ, η is one of the possibilities. We have done some calculation to find simpler form of generating function in terms of ξ_h and η_h, however, all what we obtained have more complicated form.

We would like to emphasize the usefulness of Lemma IV.1. This provides us with a much simpler procedure to obtain h-symplecton than starting with the definition (V.2) and using the lemma, we could easily find another irrep. bases (VII.8) for $SL_h(2)$. This lemma is, of course, applicable to any Jordanian quantum algebra, since we usually know the explicit form of twist element. Furthermore, the lemma is extended to quasitriangular Hopf algebras.[24] For quasitriangular Hopf algebras, the twist elements are usually not known, they are known up to certain order of the deformation parameters. It is expected that many properties of tensor operators for quasitriangular Hopf algebras are studied based on the present knowledge of the tensor operators for Lie algebras via Lemma IV.1, even if the explicit form of tensor operators is not obtained. It may also be possible to apply Lemma IV.1 to the investigation of q-symplecton.

APPENDIX A: RELATION TO OHN's $\mathcal{U}_h(sl(2))$

Ohn defined in Ref. 6 $\mathcal{U}_h(sl(2))$ as an algebra generated by H, X, and Y subject to

$$\begin{aligned} &[X,Y]=H, \quad [H,X]=2\,\frac{\sinh hX}{h}, \\ &[H,Y]=-Y(\cosh hX)-(\cosh hX)Y. \end{aligned} \tag{A1}$$

Meanwhile, the commutation relations of $J_\pm$, J_0, which are generators of $\mathcal{U}_h(sl(2))$ in this article, are same as $sl(2)$. These two kinds of generators are related by

$$\begin{aligned} &H=e^{-\sigma/2}J_0, \quad X=\frac{\sigma}{2h}, \\ &Y=e^{-\sigma/2}\left(J_-+\frac{h}{2}J_0^2\right)-\frac{h}{8}e^{\sigma/2}(e^{-\sigma}-1). \end{aligned} \tag{A2}$$

By this relation, not only the commutation relations but also the Hopf algebra mappings are transformed each other. The relation (A2) corresponds to the one parameter case discussed in Ref. 25, where the two parameter Jordanian deformation of $gl(2)$ is considered.

APPENDIX B: HOPF ALGEBRA STRUCTURE OF $\mathcal{U}_h(sl(2))$

We here give explicit formulas for the coproduct, counit, and antipode of $\mathcal{U}_h(sl(2))$ calculated from (III.3).

(i) Coproduct,

$$\begin{aligned} &\tilde{\Delta}(J_0)=J_0\otimes e^{\sigma}+1\otimes J_0, \\ &\tilde{\Delta}(J_+)=J_+\otimes 1+e^{-\sigma}\otimes J_+, \\ &\tilde{\Delta}(J_-)=J_-\otimes e^{\sigma}+1\otimes J_- -hJ_0\otimes e^{\sigma}J_0-\frac{h}{2}J_0(J_0+2)\otimes e^{\sigma}(e^{\sigma}-1). \end{aligned} \tag{B1}$$

(ii) Counit,

$$\tilde{\epsilon}(X)=0, \quad X=J_\pm, J_0. \tag{B2}$$

(iii) Antipode,

$$\begin{aligned} &\tilde{S}(J_0)=-J_0e^{-\sigma}, \quad \tilde{S}(J_+)=-J_+e^{\sigma}, \\ &\tilde{S}(J_-)=-J_-e^{-\sigma}-\frac{h}{2}J_0^2(e^{-\sigma}+1)e^{-\sigma}+hJ_0(e^{-\sigma}-1)e^{-\sigma}. \end{aligned} \tag{B3}$$

All of these are reduced to the ones for $sl(2)$ in the limit of $h=0$. The Hopf algebra mappings for σ have simple form

$$\tilde{\Delta}(\sigma)=\sigma\otimes 1+1\otimes\sigma,\quad \tilde{\epsilon}(\sigma)=0,\quad \tilde{S}(\sigma)=-\sigma. \tag{B4}$$

APPENDIX C: MATRIX ELEMENTS OF $\mathcal{F}$

In this Appendix, we show the explicit formula of matrix elements of the twist element $\mathcal{F}$ (III.4) and some of their properties. We denote an irrep. basis of $\mathcal{U}_h(sl(2))$ by the bracket notation $|jm\rangle$ for the sake of simplicity.

It is easily verified the following relations from (III.3):

$$\begin{aligned}\tilde{\Delta}(J_\pm)\mathcal{F}|j_1m_1\rangle\otimes|j_2m_2\rangle&=\sqrt{(j_1\mp m_1)(j_1\pm m_1+1)}\mathcal{F}|j_1m_1\pm 1\rangle\otimes|j_2m_2\rangle\\&\quad+\sqrt{(j_2\mp m_2)(j_2\pm m_2+1)}\mathcal{F}|j_1m_1\rangle\otimes|j_2m_2\pm 1\rangle,\\ \tilde{\Delta}(J_0)\mathcal{F}|j_1m_1\rangle\otimes j_2m_2\rangle&=2(m_1+m_2)\mathcal{F}|j_1m_1\rangle\otimes|j_2m_2\rangle.\end{aligned} \tag{C1}$$

It shows that the vectors $\mathcal{F}|j_1m_1\rangle\otimes|j_2m_2\rangle$ for $\mathcal{U}_h(sl(2))$ play the same role as $|j_1m_1\rangle\otimes|j_2m_2\rangle$ for $sl(2)$. Equation (III.5) is readily obtained from this. Another proof of Lemma III.1 with the bases of $\mathcal{U}_h(sl(2))$ in Ref. 6 is found in Refs. 26 and 27.

In the bracket notation, matrix elements of $\mathcal{F}$ are defined by

$$F^{j_1,j_2}_{k_1,k_2\ \ m_1,m_2}=\langle j_1k_1|\otimes\langle j_2k_2|\mathcal{F}|j_1m_1\rangle\otimes|j_2m_2\rangle.$$

We first show a relationship between the matrix elements of $\mathcal{F}$ and its inverse

$$F^{j_1,j_2}_{-n_1,-n_2\ \ -m_1,-m_2}=(F^{-1})^{j_1,j_2}_{m_1,m_2\ \ n_1,n_2}. \tag{C2}$$

The LHS of (C2) is calculated as

$$\begin{aligned}\text{LHS}&=\langle j_1-n_1|\otimes\langle j_2-n_2|\sum_{l=0}^{\infty}\frac{(-J_0)^l\otimes\sigma^l}{2^l l!}|j_1-m_1\rangle\otimes|j_2-m_2\rangle\\&=\delta_{n_1,m_1}\langle j_2-n_2|\exp(n_1\sigma)|j_2-m_2\rangle,\end{aligned} \tag{C3}$$

where $\langle j_1-n_1|J_0=-2n_1\langle j_1-n_1|$ is used. While the RHS is

$$\text{RHS}=\langle j_1m_1|\otimes\langle j_2m_2|\sum_{l=0}^{\infty}\frac{J_0^l\otimes\sigma^l}{2^l l!}|j_1n_1\rangle\otimes|j_2n_2\rangle=\delta_{m_1,n_1}\langle j_2m_2|\exp(n_1\sigma)|j_2n_2\rangle. \tag{C4}$$

Note that

$$J_+|jm\rangle=\sqrt{(j-m)(j+m+1)}|jm+1\rangle,$$

$$\langle j-m|J_+=\sqrt{(j-m)(j+m+1)}\langle j-m-1|.$$

It follows that any polynomials in J_+, denoted by $f(J_+)$, satisfies

$$\langle jm|f(J_+)|jn\rangle=\langle j-n|f(J_+)|j-m\rangle. \tag{C5}$$

Since σ is a polynomial in J_+, we see that (C3) is equal to (C4). Thus (C2) has been proved.

We next show that the matrix elements of $\mathcal{F}$ are given by

$$F^{j_1,j_2}_{k_1,k_2\ m_1,m_2}=\delta_{k_1,m_1}\theta(m_2\leqslant k_2\leqslant j_2)$$
$$\times S^{j_2}_{k_2,m_2}\begin{cases}\dfrac{(2k_2-2m_1-2m_2-2)!!}{(k_2-m_2)!(-2m_1-2)!!}h^{k_2-m_2}, & \text{for } m_1\leqslant 0,\\ (-2h)^{k_2-m_2}\displaystyle\sum_{l=0}^{j_2-m_2}(-1)^l\binom{2m_1}{k_2-m_2-l}\dfrac{(2l+2m_1-2)!!}{2^l l!(2m_1-2)!!}, & \text{for } m_1>0,\end{cases} \tag{C6}$$

where $n!!=1$ for $n\leqslant 0$ and $\theta(m_2\leqslant k_2\leqslant j_2)=1$ if and only if the inequality in the parentheses holds, otherwise θ vanishes. $S^{j_2}_{k_2,m_2}$ is defined by

$$S^{j_2}_{k_2,m_2}=\left\{\frac{(j_2-m_2)!(j_2+k_2)!}{(j_2+m_2)!(j_2-k_2)!}\right\}^{1/2}.$$

To prove (C6), note that similar to (C4), we have

$$F^{j_1,j_2}_{k_1,k_2\ m_1,m_2}=\delta_{k_1,m_1}\langle j_2k_2|e^{-m_1\sigma}|j_2m_2\rangle. \tag{C7}$$

One can use the power series expansion in order to compute the RHS of (C7),

$$(1-X)^{-l/2}=\sum_{n=0}^{\infty}\frac{(2n+l-2)!!}{2^n n!(l-2)!!}X^n,\quad l\in\mathbf{Z}_+. \tag{C8}$$

(i) For $m_1\leqslant 0$.
Let $m_1=-l/2$ ($l\in\mathbf{Z}_+$) and using (C8),

$$e^{-m_1\sigma}|j_2m_2\rangle=(1-2hJ_+)^{-l/2}|j_2m_2\rangle$$
$$=\sum_{n=0}^{j_2-m_2}\frac{(2n+l-2)!!}{2^n n!(l-2)!!}(2h)^n\left\{\frac{(j_2-m_2)!(j_2+m_2+n)!}{(j_2+m_2)!(j_2-m_2-n)!}\right\}^{1/2}|j_2m_2+n\rangle.$$

Therefore $\langle j_2k_2|e^{-m_1\sigma}|j_2m_2\rangle$ takes values if and only if $k_2=m_2+n$. This proves the first part of (C6).

(ii) For $m_1>0$.
Let $m_1=l/2\,(l\in\mathbf{Z}_+)$. Since

$$e^{-m_1\sigma}|j_2m_2\rangle=e^{-l\sigma}e^{l\sigma/2}|j_2m_2\rangle,$$

we can apply the previous result to compute $e^{l\sigma/2}|j_2m_2\rangle$ and then applying the binomial expansion to $e^{-l\sigma}=(1-2hJ_+)^l_-$,

$$e^{-m_1\sigma}|j_2m_2\rangle=\sum_{t=0}^{j_2-m_2}\frac{(2t+l-2)!!}{2^t t!(l-2)!!}(2h)^t\left\{\frac{(j_2-m_2)!(j_2+m_2+t)!}{(j_2+m_2)!(j_2-m_2-t)!}\right\}^{1/2}e^{-l\sigma}|j_2m_2+t\rangle$$
$$=\sum_{n=0}^{l}\sum_{t=0}^{j_2-m_2}\binom{l}{n}\frac{(2t+l-2)!!}{2^t t!(l-2)!!}(-1)^n(2h)^{t+n}\left\{\frac{(j_2-m_2)!(j_2+m_2+t+n)!}{(j_2+m_2)!(j_2-m_2-t-n)!}\right\}^{1/2}$$
$$\times|j_2m_2+t+n\rangle.$$

Replacing $t+n$ with n, we obtain

$$e^{-m_1\sigma}|j_2m_2\rangle=\sum_{t,n}(-1)^t(-2h)^n\binom{l}{n-t}\times\frac{(2t+l-2)!!}{2^t t!(l-2)!!}\left\{\frac{(j_2-m_2)!(j_2+m_2+n)!}{(j_2+m_2)!(j_2-m_2-n)!}\right\}^{1/2}\quad |j_2m_2+n\rangle.$$

Again $\langle j_2k_2|e^{-m_1\sigma}|j_2m_2\rangle$ takes values if and only if $k_2=m_2+n$. This completes the proof of (C6).

We can obtain the explicit formula for the universal *R*-matrix in the irreps. with highest weight j_1 and j_2 by combining (C6) and relation (C2), since the universal *R*-matrix for $\mathcal{U}_h(sl(2))$ is given by $\mathcal{R}=\mathcal{F}_{21}\mathcal{F}^{-1}$.

APPENDIX D: PROOF OF LEMMA III.2

Let V^a, and V^b, and V^c be representation spaces of $\mathcal{U}_h(sl(2))$ with highest weight *a*, *b*, and *c*, respectively. Bases of each space are denoted as e^a_α, $-a\leqslant\alpha\leqslant a$. We would like to construct irrep. bases in the space $V^a\otimes V^b\otimes V^c$ in two ways, namely, $(V^a\otimes V^b)\otimes V^c$ and $V^a\otimes(V^b\otimes V^c)$. According to the discussion in Appendix B, irrep. bases in the space $V^a\otimes V^b$ are given by

$$e^{(ab)d}_\delta=\sum C^{a,b,d}_{\alpha,\beta,\delta}\,\mathcal{F}\,e^a_\alpha\otimes e^b_\beta.$$

Then we couple these with the bases in V^c to obtain

$$\psi^e_\epsilon=\sum C^{d,c,e}_{\delta,\gamma,\epsilon}(\tilde{\Delta}\otimes id)(\mathcal{F})e^{(ab)d}_\delta\otimes c^c_\gamma=\sum C^{d,c,e}_{\delta,\gamma,\epsilon}C^{a,b,d}_{\alpha,\beta,\delta}(\tilde{\Delta}\otimes id)(\mathcal{F})\mathcal{F}_{12}e^a_\alpha\otimes e^b_\beta\otimes e^c_\gamma.$$

Similarly we obtain the following bases when we couple V^b and V^c first:

$$\psi'^e_\epsilon=\sum C^{a,f,e}_{\alpha,\rho,\epsilon}C^{b,c,f}_{\beta,\gamma,\rho}(id\otimes\tilde{\Delta})(\mathcal{F})\mathcal{F}_{23}e^a_\alpha\otimes e^b_\beta\otimes e^c_\gamma.$$

From (B4),

$$(id\otimes\tilde{\Delta})(\mathcal{F})=\exp(-\tfrac{1}{2}J_0\otimes\tilde{\Delta}(\sigma))=\mathcal{F}_{12}\mathcal{F}_{13}.$$

Using the relations (III.3), (III.2) and above

$$(\tilde{\Delta}\otimes id)(\mathcal{F})=\mathcal{F}_{12}(\Delta\otimes id)(\mathcal{F})\mathcal{F}_{12}^{-1}=\mathcal{F}_{23}(id\otimes\Delta)(\mathcal{F})\mathcal{F}_{12}^{-1}=(id\otimes\tilde{\Delta})(\mathcal{F})\mathcal{F}_{23}\mathcal{F}_{12}^{-1}=\mathcal{F}_{12}\mathcal{F}_{13}\mathcal{F}_{23}\mathcal{F}_{12}^{-1}.$$

It follows that ψ^e_ϵ and ψ'^e_ϵ are rewritten as

$$\psi^e_\epsilon=\sum C^{d,c,e}_{\delta,\gamma,\epsilon}C^{a,b,d}_{\alpha,\beta,\delta}\mathcal{F}_{12}\mathcal{F}_{13}\mathcal{F}_{23}e^a_\alpha\otimes e^b_\beta\otimes e^c_\gamma,$$

$$\psi'^e_\epsilon=\sum C^{a,f,e}_{\alpha,\rho,\epsilon}C^{b,c,f}_{\beta,\gamma,\rho}\mathcal{F}_{12}\mathcal{F}_{13}\mathcal{F}_{23}e^a_\alpha\otimes e^b_\beta\otimes e^c_\gamma.$$

The Racha coefficients $W_h(abce;df)$ for $\mathcal{U}_h(sl(2))$ is defined by

$$\psi_{\epsilon}^{e}=\sum_{f} \sqrt{(2d+1)(2f+1)}W_h(abce;df)\psi_{\epsilon}'^{e}. \tag{D1}$$

It is now obvious that the Racha coefficients for $\mathcal{U}_h(sl(2))$ satisfy the relation

$$\sum_{\delta} C_{\delta,\gamma,\epsilon}^{d,c,e}C_{\alpha,\beta,\delta}^{a,b,d}=\sum_{f,\rho} C_{\alpha,\rho,\epsilon}^{a,f,e}C_{\beta,\gamma,\rho}^{b,c,f}\sqrt{(2d+1)(2f+1)}W_h(abce;df). \tag{D2}$$

This is the same relation for the Racha coefficients for $sl(2)$. This proves Lemma III.2.

Towards the canonical tensor operators of $u_q(3)$. II. The denominator function problem

Sigitas Drobažis Ališauskas[a)]
Institute of Theoretical Physics and Astronomy, A. Goštauto 12, Vilnius 2600, Lithuania

(Received 17 May 1999; accepted for publication 21 July 1999)

The explicit denominator (normalization) function of the canonical tensor operators of the quantum algebra $u_q(3)$, corresponding to the maximal null space case is derived *ab initio* in terms of double basic hypergeometric series, which cannot be obtained as any q-extension of the SU(3) denominator polynomial $G^1_{b''}(\Delta,x)$ in terms of multiple (double or triple) balanced hypergeometric series, introduced by Biedenharn, Louck, and their collaborators (although their $q=1$ versions are shown being equivalent). The corresponding orthonormal seed isoscalar factors of the coupling (Wigner–Clebsch–Gordan) coefficients of $u_q(3)$ and SU(3) with multiple irreducible representations are presented. Conjectured expression of the q-polynomials [which ratios appear in the $u_q(3)$ and (new) SU(3) denominator functions for an arbitrary value of the canonical multiplicity label t of the repeating irreducible representations] in terms of multiple partition dependent q-series (extension of the maximal and minimal null space versions) is presented and considered. © *1999 American Institute of Physics.* [S0022-2488(99)01311-0]

I. INTRODUCTION AND PRELIMINARIES

The matrix elements of unit SU(3) canonical tensor operators,[1–4] which are characterized by the null space inclusion property, together with their Hermitian and conjugation properties and vanishing conditions of certain SU(3):U(2) maximal shift isoscalar factors (isofactors or matrix elements of projective[3] canonical tensor operators), reveal themselves as the most universal complete algebraic system for the orthonormal coupling (Wigner or Clebsch–Gordan) coefficients of the SU(3) group with the repeating irreducible representations (irreps) in the direct product decomposition. (For their numerical applications, see Ref. 5.) It is noticeable that the normalization problem of the coupling coefficients in the canonical splitting of the multiplicity for SU(3) (emphasized in many papers by Biedenharn, Louck and their collaborators) has been solved explicitly.[4,6] with the normalization coefficients or denominator functions $D^2(\Gamma_t,x)$ expressed in terms of the ratio of the preliminary guessed remarkable polynomials $G^t_{b''}(\Delta;x)$, which for the fixed multiplicity label t are completely determined by their null space (the weight space distribution of zeros), polynomial, and symmetry properties.[3] (We are using here and throughout an integer b'' for the irrep parameter instead of q in order to escape mixing with a deformation parameter.) Particularly, the investigation of the new class of special functions was started from the polynomials $G^1_{b''}(\Delta;x)$ of the maximal null space case;[7,8] their multiple well-poised series version of Holman *et al.*[9] has been extended to SU(n) by Milne.[10] However, the role of q-extension[11] of this multiple well-poised series for the quantum algebra $u_q(n)$ is not clear and the rather complicated generating and denominator function technique of Refs. 3, 4 hardly may be extended from SU(3) to the quantum algebra $u_q(3)$ with generic $q\neq 1$.

In a previous paper,[12] some important constructive elements of the explicit matrix elements of the $u_q(3)$ canonical tensor operators were derived using the generalized projection operator technique [extended from SU(3) canonical tensor operators as presented in Ref. 13] and some distinc-

[a)]Electronic mail: sigal@itpa.lt

tive and symmetry properties of the SU(3) and $u_q(3)$ canonical isofactors were considered. Particularly, explicit normalized isofactors of $u_q(3)$ characterized by the maximal null space were presented. However, the expressions of normalization coefficients (3.7b) and (3.14b) of Ref. 12 in terms of double sums are not universal (in some regions they are indefinite), although Eq. (3.14b), together with the symmetry relations (3.7a) and (3.14a), always can be helpful. Both Eqs. (3.7b) and (3.14b) turn into finite series only for the definite couples of fixed integers, related to restriction of the multiplicity of repeating irreps, in contrast with the SU(3) case,[4,7] when a single of such fixed integer parameters is sufficient.

In our paper,[14] mainly devoted to the overlaps of biorthogonal coupling coefficients of SU(3) and $u_q(3)$ (expressed in terms of classic and basic hypergeometric series), some matrix elements of the self-adjoint unit canonical tensor operators with the minimal null space are also derived (including their explicit normalization) and some boundary (seed) isofactors with the maximal null space[12] are specified as single sums (related to basic hypergeometric series, in contrast with multiple series,[15,16] cf. Ref. 17). In our last paper,[18] the expansion of the matrix elements of SU(3) and $u_q(3)$ canonical tensor operators in terms of the biorthogonal (dual) coupling coefficients[19,20] is considered. The composition of these dual expansions gives the explicit overlap coefficients for the Draayer–Akiyama construction[5,13] and, particularly, the normalization of explicit canonical seed isofactors, specified for the minimal null space cases (more general as the self-adjoint ones) and also presented as single sums (again related to the classic or basic hypergeometric series, respectively). In this minimal null space case, the normalization coefficients or denominator functions are expressed in terms of double sums and turn into finite series for a fixed integer, related to the multiplicity of repeating irreps. In this aspect they are similar to the denominator functions in the SU(3) case,[4,7,21] although they are rather different in their structure.

In the present paper, the solution of problems of Ref. 12 is under continuation; the normalization coefficients (denominator functions) of the canonical tensor operators are considered for the quantum algebra $u_q(3)$ and reconsidered for the SU(3) group. Some previously derived results are reviewed below in this section. In Sec. II, new expressions of the normalization coefficients (denominator functions) for the matrix elements of the SU(3) and $u_q(3)$ unit canonical tensor operators with the maximal null space are derived *ab initio*, using the dual expansion technique.[14,18] The extreme canonical seed isofactors and their normalization coefficients are expressed in terms of the finite series (single and double, respectively) for fixed multiplicity of repeating irreps. The symmetry properties [which were essential for the proof[3,8] of the uniqueness of solutions[4,7] for the denominator functions in the SU(3) case] are also demonstrated for the new denominator functions. In Sec. III, a conjecture about a q-generalization of the polynomial $G^t_{b''}(\Delta;x)$ in terms of partition dependent multiple q-factorial series for an arbitrary value of the multiplicity label t (valid also for the maximal t) is presented and discussed. Some symmetries and other properties of these new multiple q-factorial series are compared with the SU(3) case.[4]

Here and in what follows we use the same notations for irreps and basis states of SU(3) and $u_q(3)$ as were used in Refs. 12–14, 18, 19, with $(a\,b)$ for the mixed tensor irreps and $a=m_{13}-m_{23}$, $b=m_{23}-m_{33}$ where $[m_{13},m_{23},m_{33}]$ is a partition and m_{ij} are the Gelfand–Tsetlin parameters. The basis states are labeled by the hypercharge $y=m_{12}+m_{22}-\frac{2}{3}(m_{13}+m_{23}+m_{33})$ [or $z=\frac{1}{3}(b-a)-\frac{1}{2}y=m_{23}-\frac{1}{2}(m_{12}+m_{22})$], the isospin $i=\frac{1}{2}(m_{12}-m_{22})$ and its projection $i_z=m_{11}-\frac{1}{2}(m_{12}+m_{22})$. The parameter z usually is more convenient in explicit expressions than y, because linear combinations $i\pm z\geqslant 0$, $a+z-i\geqslant 0$, $b-z-i\geqslant 0$ are integers. For the state of irrep $(a\,b)$ in the coproduct $(a'b')\otimes(a''b'')$ decomposition, $z=z'+z''+v$, where again $v=\frac{1}{3}(a'-b'+a''-b''-a+b)$ is an integer. The parameters of the highest weight state take on the values $y_0=\frac{1}{3}(a+2b)$, $i_0=\frac{1}{2}a=-z_0$, while for the lowest weight state $\overline{y_0}=-\frac{1}{3}(2a+b)$, $\overline{i}_0=\frac{1}{2}b=\overline{z_0}$ and for the maximal isospin state $y_m=\frac{1}{3}(a-b)$, $i_m=\frac{1}{2}(a+b)$, $z_m=\frac{1}{2}(b-a)$.

The multiplicity r of irrep (ab) in the coproduct $(a'b')\otimes(a''b'')$ decomposition (intertwining number) is equal to $r=\min r_{\alpha\beta\gamma}+1$ $(\alpha=1,2,3;\beta=1,2,3,;\gamma=1,2)$ where integers $r_{\alpha\beta\gamma}$ form the $3\times 3\times 2$ array (1.3b) of Ref. 12 with equidistant parameters in the layers, rows, and columns. The multiplicity $\mathcal{M}$ of the canonical tensor operators $T^{(a''b'')t}_{y''_0 i''_0 i''_z}$ with fixed shifts $a-a'$ and $b-b'$ may exceed the external multiplicity r (see Refs. 12–14) and in this case the lowest values of the canonical multiplicity label $t=1,2,...,\mathcal{M}$ may be eliminated by the null space inclusion property.[3]

We use the Cartan–Weyl generators $E_{ik}(i,j,k=1,2,3)$ of the unitary quantum algebra $u_q(3)=U_q(u(3))$, with generic q and composite generators expressed in terms of q-deformed commutators, which satisfy the commutation relations[12,22,23] and the corresponding coproduct expansion rules. Here and in what follows $[x]$ and $[x]!$ are, respectively, the q-numbers and q-factorials,

$$[x]=(q^x-q^{-x})/(q-q^{-1}),\quad [x]!=[x][x-1]\ldots[2][1],$$

$$(\alpha|q)_n=\prod_{k=0}^{n-1}[a+k],\quad [a|q]_n=\prod_{k=0}^{n-1}[a-k], \tag{1.1}$$

$$[1]!=[0]!=(\alpha|q)_0=[\alpha|q]_0=1,$$

which are invariant under substitution $q\leftrightarrow q^{-1}$.

Solution of the equation system (2.14) of Ref. 12 for the bilinear combinations of canonical isofactors under conditions $t\leqslant\hat{I}'-i_m+i''_m+1$ is not always possible, in contrast with the results of our last papers,[14,18] where using the recursive constructions [a recoupling technique analogous with (2.13) and (5.1) of Ref. 13] the following superpositions of the canonical boundary (asymmetric seed) isofactors were derived:

$$(\tilde{T}^k|\eta_{-,+,\tilde{I}})_q=\sum_{t\geqslant k+1}U_3\left\{\begin{matrix}(a'b') & (a''-k,\overset{1}{b''}-k) & (a\,b)\\ \\ \overset{k+1}{(k\,k)} & (a\,b) & \overset{t}{(a''b'')}\end{matrix}\right\}_q\left[\begin{matrix}(a'b') & \overset{t}{(a''b'')} & (ab)\\ \\ y_0'i_0' & \overline{y_0''i_0''} & \tilde{y}\tilde{I}\end{matrix}\right]_q^{(3)} \tag{1.2a}$$

$$=\frac{([a+1][b+1][a+b+2][b']![a'+b'+1]!)^{1/2}\Gamma[ab\tilde{I}\tilde{z}]\nabla[\overline{i_0''}i_0'\tilde{I}]}{([b'']!)^{1/2}\mathcal{N}\binom{q,k}{a''b''}[a'b';ab]}$$

$$\times\sum_{j,j'}\frac{(-1)^{(b''-a''-k)/2-\tilde{I}+j}q^{Q_6+j(j+1)-j'(j'+1)+3\tilde{I}/(\tilde{I}+1)/2}}{\nabla^2[\frac{1}{2}(a''-k),\frac{1}{2}a',j]\nabla^2[\frac{1}{2}(a'+a''-a-k)-v,\frac{1}{2}a,j]}$$

$$\times\frac{[2j+1][2j'+1]}{[b-v+\frac{1}{2}(a'+a''-k)-j+1]![b-v+\frac{1}{2}(a'+a''-k)+j+2]!}$$

$$\times\frac{\nabla^2[\frac{1}{2}(a''+b'')-k,k',j]}{\nabla^2[\frac{1}{2}(b''-k),\frac{1}{2}a',j']\nabla^2[\frac{1}{2}k,j',\tilde{I}]\Gamma^2[abj',\tilde{z}-\frac{1}{2}k]}, \tag{1.2b}$$

(which can be also used for expansion of more universal coupling coefficients in terms of biorthogonal isofactors with superscript $-$, $+$, $\tilde{I}$). Here and in what follows $\tilde{z}=\frac{1}{2}(b''-a')+v)$, $\nabla[abc]$ and $\Gamma[abiz]$ denote, respectively, the functions

$$\nabla[abc]=\left(\frac{[a+b-c]![a-b+c]![a+b+c+1]!}{[b+c-a]!}\right)^{1/2}, \tag{1.3}$$

and

$$\Gamma[abiz]=\left(\frac{[i+z]![a+z-i]![a+z+i+1]!}{[i-z]![b-z-i]![b-z+i+1]!}\right)^{1/2}. \tag{1.4}$$

The renormalization factor

$$\mathcal{N}\begin{pmatrix} q,k \\ a''b'' \end{pmatrix}[a'b';ab]=\frac{\mathcal{D}\begin{pmatrix} q,t=1 \\ a''-k,b''-k \end{pmatrix}[a'b';ab]\mathcal{D}\begin{pmatrix} q,t=k+1 \\ k\,k \end{pmatrix}[a\,b;a\,b]}{[a''-k]![b''-k]!([k]!)^{1/2}} \tag{1.5}$$

is expressed in terms of the denominator functions[12,14] $\mathcal{D}\binom{q,t}{\cdots}[\cdots]$ of the $u_q(3)$ canonical tensor operators with maximal and minimal null space, respectively, and the corresponding q-phase Q_6 is expressed as follows:

$$\begin{aligned} Q_6=&(b'-v+1)(b'+b''-b+v-k)-\tfrac{1}{8}(a'+b''-k)(a'+b''-k+2)\\ &-\tfrac{1}{2}(a''-k)(a+b'-a''+k+v)+\tfrac{1}{2}(b''-k)(b''-b+v-k)\\ &-\tfrac{1}{4}(a+b-b'-b''-v+k)(a+b-b'-b''-v+k+2)-\tfrac{1}{8}k^2+\tfrac{3}{4}k+\tfrac{1}{2}k\tilde{z}. \end{aligned} \tag{1.6}$$

Particular canonical boundary (seed) isofactors may be derived from (1.2b) by means of a Gram–Schmidt procedure, beginning from $k=\mathcal{M}-1$, and using the overlaps $(\tilde{T}^k|\tilde{T}^{k'})_q$ equivalent to bilinear combination of special recoupling coefficients (3.16) of Ref. 18,

$$\sum_{t>\max(k,k')} U_3\begin{Bmatrix} (a'b') & \overset{1}{(a''-k,b''-k)} & (ab) \\ \overset{k+1}{(kk)} & (ab) & (a''b'') \end{Bmatrix}_q \times U_3\begin{Bmatrix} (a'b') & \overset{1}{(a''-k',b''-k')} & (ab) \\ \overset{k'+1}{(k'k')} & (ab) & \overset{t}{(a''b'')} \end{Bmatrix}_q \tag{1.7a}$$

$$=(\tilde{T}^k|\tilde{T}^{k'})_q=\sum_{\tilde{j}',\tilde{I}}(\tilde{T}^k|\eta^{+,\tilde{j}'',+})_q(\eta_{+,\tilde{j}'',+}|\eta^{-,+,\tilde{I}})_q(\eta_{-,+,\tilde{I}}|\tilde{T}^{k'})_q. \tag{1.7b}$$

Here the expansion coefficients of the twisted tensor operators $\tilde{T}^{(a''b'')t=k+1,q}_{y''i''i''_z}$ in terms of nonorthonormal tensor operators, which correspond to the dual coupled states $|\eta_{+,\tilde{j}'',+})_q$, is expressed [see (3.13b) of Ref. 18] as follows:

$$(\tilde{T}^k|\eta^{+,\tilde{j}'',+})_q=\frac{(-1)^{\tilde{j}'',\tilde{z}''}[a+b'-a''+v+k+1]!}{\mathcal{N}\begin{pmatrix}q,k\\a''b''\end{pmatrix}[a'b';ab]\nabla[\tfrac{1}{2}b',\tfrac{1}{2}b,\tilde{j}'']([\tilde{j}''+\tilde{z}'']!)^{1/2}}$$

$$\times\frac{H[a''b''\tilde{j}''\tilde{z}'']([2\tilde{j}''+1][\tilde{j}'-\tilde{z}']!)^{1/2}}{([a+1]![a+b+2]![a']![a'+b'+1]![a'']![b'']![a''+b''+1]!)^{1/2}}$$

$$\times\sum_{n,s',s''}\frac{(-1)^{n+s'}q^{R+(s''-s')(b'+b''+a+v+3)+k(s'-b')+n(a+b'-a''+v+k+2)}}{[n]![b''+v-k-n]![a'+a''-a-v-k-n]![a-a'+v+n]!}$$

$$\times\times\frac{[a'-n]![b-b''-v+k+n]![\tilde{j}''+\tilde{z}''+s']![s'']![b-b'-v+s'']!}{[s']![\tilde{j}''-\tilde{z}''-s']![b-b'-v+s']![s''-s']![k+s'-s'']!}$$

$$\times\frac{[a-a'+b''+v-k+s''+n+1]![a+b''+v+s'+2]!}{[a-a'+b''+v-k+s''+1]![b'+v-s'']![b''-k+s''+1]!}$$

$$\times\frac{[b'+v-s']!}{[a-a'-a''+v+ks''+n]![s+b''+v-k+s''+2]!},\tag{1.8}$$

where $\tilde{z}''=\frac{1}{2}(b-b')-v$, $\tilde{z}'=\frac{1}{2}(a''-a)-v$ and $H[abiz]$ denotes the function

$$H[abiz]=([a+z-i]![a+z+i+1]![b-z-i]![b-z+i+1]!)^{1/2}.\tag{1.9}$$

In Eq. (1.8) the same renormalization factor (1.5) and the q-phase,

$$\begin{aligned}R=&-Q_1(b'a'aba''b'';\tilde{j}''\tilde{z}'')-\tfrac{1}{2}\tilde{z}'(3\tilde{z}'+2a'-2b')\\&-\tfrac{1}{8}(a^2-a''^2)+\tfrac{1}{2}a'b'+b'-\tfrac{1}{2}(a+b-3a'-a''-b'')\\&+a''(b''+v-k)+\tfrac{1}{2}(b''-k)(a'-b'-b''+b-v+k)+\tfrac{1}{2}(a''-k)\\&\times(-a-2b-a''+v+k-4)+(a-a'+v)(a+b'+v+2)\\&+\tfrac{1}{2}k(k-2a''+v-3)-\tfrac{1}{4}(a-a''+2v)(a''+2b''),\end{aligned}\tag{1.10}$$

with

$$\begin{aligned}Q_1(a'b'a''b''a\,b;\tilde{J}\tilde{z})&=Q_1(b''a''b'a'b\,a;\tilde{J},-\tilde{z})\\&=\tfrac{1}{2}\{\tilde{J}(\tilde{J}+1)+\tilde{z}(3\tilde{z}+2a-2b)-ab+\tfrac{1}{2}(a'+b'')+a''+b'-a-b\}\end{aligned}\tag{1.11}$$

are used.

The auxiliary triangle overlap matrix in Eq. (1.7b) is expressed as follows:

$$(\eta_{+,\tilde{j}'',+}|\eta^{-,+,\tilde{I}})_q=q^{Q_1(baa'b'b''a'';\tilde{j}'',-\tilde{z}''}-Q_1(b''a''b'a'ba;\tilde{I},-\tilde{z})-b'/2-a'$$

$$\times(-1)^{\tilde{j}''-\tilde{z}''}\frac{[2\tilde{I}+1]\nabla[\tfrac{1}{2}b',\tfrac{1}{2}b,\tilde{j}'']H[a''b''\tilde{j}''\tilde{z}'']}{\nabla[\tfrac{1}{2}a',\tfrac{1}{2}b'',\tilde{I}]H[ab\tilde{I}\tilde{z}]}$$

$$\times\left(\frac{[a]![a+b+1]![a']![\tilde{j}''-\tilde{z}'']![\tilde{I}+\tilde{z}]![2\tilde{j}''+1]}{[a'']![a''+b''+1]![b']![\tilde{j}''+\tilde{z}'']![\tilde{I}-\tilde{z}]![b+1]}\right)^{1/2}$$

$$\frac{[\tilde{I}+\tilde{j}''+\frac{1}{2}(a-a''+v)]!(a-a''+v|q)_{\tilde{I}-\tilde{j}''+(a''-a-v)/2}}{[\tilde{I}-\tilde{j}''+\frac{1}{2}(a''-a-v)]![\tilde{I}+\tilde{j}''+\frac{1}{2}(a''-a-v)+1]!}$$

(see corrected Eq. (3.17) of Ref. 18).

II. DENOMINATOR FUNCTIONS OF CANONICAL TENSOR OPERATORS WITH THE MAXIMAL NULL SPACE

Using (3.1) of Ref. 12 (as a double sum, with fixed summation parameters $j'=\frac{1}{2}b'$ and m') and q-version of Minton's summation formula we derived (cf. Ref. 14) the boundary (seed) canonical isofactors with the multiplicity label, which corresponds to the maximal null space,

$$\begin{bmatrix} (a'b') & \overset{t=1}{(a''b'')} & (ab) \\ \\ \overline{y_0'}\,\overline{i_0'} & \tilde{y}''\tilde{j}'' & \overline{y_0}\,\overline{i_0} \end{bmatrix}^{(3)}_q$$

$$=(-1)^{a'+a''-a-v}\frac{([a+1]![a+b+2]![a']![a'+b'+1]!)^{1/2}}{\mathcal{D}\begin{pmatrix} q,t=1 \\ a''b''\end{pmatrix}[a'b';ab]\nabla[\frac{1}{2}b,\frac{1}{2}b',\tilde{j}'']}$$
$$\times\frac{([a'']![b'']![a''+b''+1]![2\tilde{j}''+1][\tilde{j}''-\tilde{z}'']!)^{1/2}}{([\tilde{j}''+\tilde{z}'']!)^{1/2}H[a''b''\tilde{j}''\tilde{z}''][a'+a''-v+1]!}$$
$$\times\sum_s\frac{(-1)^s q^{Q_5-s(a'+a''-v+1)}[\tilde{j}''+\tilde{z}''+s]![b'+v-s]!}{[s]![\tilde{j}''-\tilde{z}''-s]![-v+s]![a'+a''+b-v-s+2]!}, \tag{2.1a}$$

$$=(-1)^{b''-\tilde{z}''-\tilde{j}''}\frac{\Delta[\frac{1}{2}b,\frac{1}{2}b',\tilde{j}'']([a+1]![a+b+2]![a']![a'+b'+1]!)^{1/2}}{\mathcal{D}\begin{pmatrix} q,t=1 \\ a''b''\end{pmatrix}[a'b';a\,b]H[a''b''\tilde{j}''\tilde{z}'']}$$
$$\times\frac{([a'']![b'']![a''+b''+1]![2\tilde{j}''+1][\tilde{j}''-\tilde{z}'']![\tilde{j}''+\tilde{z}'']!)^{1/2}}{[a'+a''+b-v+2]![b'+b''+a+v+2]!}$$
$$\times\sum_s\frac{q^{Q_5-(\tilde{j}''-\tilde{z}'')(a+b'+b''+v-\tilde{j}''-\tilde{z}''+2)+s\{(b'+b)/2-\tilde{j}''+1\}}}{[s]![\tilde{j}''-\tilde{z}''-s]![\tilde{j}''+\frac{1}{2}(b-b')-s]![-v+s]!}$$
$$\times\frac{[b'+b''+a+v+s+2]!}{[a'+a''+v+\tilde{z}''-\tilde{j}''+s+1]!}, \tag{2.1b}$$

where $\Delta[a,b,c]$ denotes the triangle coefficient

$$\Delta[a,b,c]=\left(\frac{[a+b-c]![a-b+c]![-a+b+c]!}{[a+b+c+1]!}\right)^{1/2}, \tag{2.2}$$

and Q_5 denotes the q-phase,

$$Q_5=(a'+a''-a-v)^2+\tfrac{1}{2}\{(b'+b''-b+v)(a+b-2b''-2v)+av+\tilde{i}''(\tilde{i}''+1)\}-\tfrac{1}{8}(b-b')(b-b'+2). \tag{2.3}$$

The sums that appeared in (2.1a) and (2.1b) can be expressed in terms of the basic hypergeometric series ${}_3\phi_2$ related to the Clebsch–Gordan coefficient of the quantum algebra $u_q(1,1)$. Second version (2.1b) is more convenient for numerical calculations[24] (because it includes a minimal number of terms in the sum, and all its terms are of the same sign) and is derived using the following rearrangements of series:

$$\sum_s \frac{q^{-s\{(b'+b)/2+\tilde{j}''+1\}}}{[s]![\tilde{j}''-\tilde{z}''-s]![\tilde{j}''+\frac{1}{2}(b'-b)-s]![b-b'-v+s]!} \times\frac{[a+b''+v+s+1]!}{[\frac{1}{2}(b'+b)-\tilde{j}''+b''+a+v+s+2]!}$$
$$=\sum_{s,s',u'}\frac{q^{-s(\tilde{j}''+\tilde{z}''+u')-s'(b'+v-u')+u'-\tilde{j}''+\tilde{z}''}}{[s-\tilde{j}''+\tilde{z}''+u']![\tilde{j}''-\tilde{z}''-s]![\tilde{j}''+\frac{1}{2}(b'-b)-s]![b-b'-v+s]!}\times\frac{(-1)^{\tilde{j}''-\tilde{z}''-s'-u'}[a+b''+v+s'+1]!}{[s']![\tilde{j}''-\tilde{z}''-s'-u']![\frac{1}{2}(b'+b)-\tilde{j}''+b''+a+v+s'+2]!} \tag{2.4a}$$

$$=\sum_{s,s',u}\frac{q^{-s(b'+b''+a+v+u+2)+s'(a+b''-\tilde{z}''-\tilde{j}''+u+2)}}{[s-\tilde{j}''+\tilde{z}''+u]![\tilde{j}''-\tilde{z}''-s]![\tilde{j}''+\frac{1}{2}(b'-b)-s]![b-b'-v+s']!}\times\frac{(-1)^{\tilde{j}''-\tilde{z}''-s'-u}[a+b''+v+s'+1]!}{[s']![\tilde{j}''-\tilde{z}''-s'-u]![\frac{1}{2}(b'+b)-\tilde{j}''+b''+a+v+s+2]!} \tag{2.4b}$$

in analogy with Refs. 25, 26. Summation over u' or u in (2.4a) or (2.4b) is related to $\delta_{s,s'}$ and gives the l.h.s., when the Chu–Vandermonde summation formulas (cf. Refs. 25–27) lead either to the sum in (2.1a) or to the sum in (2.1b).

Denominator function $\mathcal{D}\binom{q,t=1}{a''b''}[a'b';ab]$ may be derived from overlap

$$(\tilde{T}^0|\tilde{T}^{k'})_q=\delta_{0,k'}=\sum_{\tilde{j}'',\tilde{I}}(\tilde{T}^0|\eta^{+,\tilde{j}'',+})_q(\eta_{+,\tilde{j}'',+}|\eta^{-,+,\tilde{I}})_q(\eta_{-,+\tilde{I}}|\tilde{T}^0)_q$$
$$=\sum_{\tilde{j}''}(\tilde{T}^0|\eta^{+,\tilde{j}'',+})_q\left[\begin{array}{ccc}(a'b') & \overset{t=1}{(a''b'')} & (a\,b)\\ & & \\ \overline{y_0'}\,\overline{i_0'} & \tilde{y}''\tilde{j}'' & \overline{y_0}\,\overline{i_0}\end{array}\right]^{(3)}_q, \tag{2.5}$$

with the boundary (seed) canonical isofactors expressed by means of (2.1a) and overlaps (expansion coefficients)

$$(\widetilde{T}^0|\eta^{+,\overline{\tilde{j}''},+})_q=(-1)^{b''-\tilde{z}''-\tilde{j}''}\frac{q^{R+(a'+a''-a-v)(a+b'-a''+v+2)}[a+b'-a''+v+1]!}{\mathcal{D}\begin{pmatrix} q,t=1 \\ a''b'' \end{pmatrix}[a'b';a\,b]H[a''b''\tilde{j}''\tilde{z}'']\nabla[\tfrac{1}{2}b',\tfrac{1}{2}b,\tilde{j}'']}$$

$$\times\left(\frac{[a'']![b'']![a''+b''+1]![2\tilde{j}''+1][\tilde{j}''-\tilde{z}'']!}{[a+1]![a+b+2]![a']![a'+b'+1]![\tilde{j}''+\tilde{z}'']!}\right)^{1/2}$$

$$\times\sum_n \frac{q^{-n(a+b'-a''+v+2)}[\tilde{j}''+\tilde{z}''+n]![b'+v-n]![a-a''+v+n]!}{[n]![\tilde{j}''-\tilde{z}''-n]![b-b'-v+n]!} \quad (2.6)$$

derived as a special case of (1.8) after summation over $s=s'$ of the balanced basic hypergeometric series[27] ${}_3\phi_2$, which appeared for $k=0$. Hence we write

$$\mathcal{D}^2\begin{pmatrix} q,t=1 \\ a''b'' \end{pmatrix}[a'b';a\,b]$$

$$=q^{Q_5+R}\frac{[a'']![b'']![a''+b''+1]![a+b'-a''+v+1]!}{[a'+a''-v+1]!}$$

$$\times\sum_{\tilde{j}'',n,s'}\frac{(-1)^{\tilde{j}''-\tilde{z}''+s'}[2\tilde{j}''+1][\tilde{j}''-\tilde{z}'']![\tilde{j}''+\tilde{z}''+n]!}{[\tilde{j}''+\tilde{z}'']![\tfrac{1}{2}(b'+b)-\tilde{j}'']![\tfrac{1}{2}(b'+b)+\tilde{j}''+1]!}$$

$$\times\frac{q^{(a'+a''-a-v-n)(a+b'-a''+v+2)}[b'+v-n]![a-a''+v+n]!}{H^2[a''b''\tilde{j}''\tilde{z}''][n]![\tilde{j}''-\tilde{z}''-n]![b-b'-v+n]!}$$

$$\times\frac{q^{-s(a'+a''+v+1)}[j''+\tilde{z}''+s']![b'+v-s']!}{[s']![\tilde{j}''-\tilde{z}''-s']![-v+s']![a'+a''+b-v-s'+2]!} \quad (2.7a)$$

$$=\frac{q^{Q_5+R}[a'']![b'']![a+b'-a''+v+1]!}{[a'+a''-v+1]![b'+b''+v+1]![a''+b-v+1]!}$$

$$\times\sum_{s,s',n}\frac{(-1)^{b-b'-s+s'}[b'+v-s']![a-a''+v+n]![b'+v-n]!}{[-v+s']![a'+a''+b-v-s'+2]![a-a'+b''+v-s]!}$$

$$\times\frac{q^{(a'+a''-a-v-n)(a+b'-a''+v+2)-s(a'+a''-v+1)}}{[s]![b''-s]![b-v-s]![b-b'-2v+s'+n-s]!}$$

$$\times\frac{[a''+b''+b-v-s+1]![b-b'-2v+s'+n]!}{[b-b'-v+n]![b'-b+2v-s'+s]![b'-b+2v-n+s]!}. \quad (2.7b)$$

We rearranged the sum over $\tilde{j}''$ as a very well-poised ${}_8\phi_7$ series of (2.7a) into the balanced ${}_4\phi_3$ series which corresponds to the sum over s in (2.7b) (related to the most symmetric expression for $q-6j$ coefficient) in analogy with (4.8) of Ref. 18 using Watson's formula (2.5.1) of Ref. 27 as presented by (6.10) of Ref. 28 with parameters

$$a\to b'-b+2v+1,\ \ b\to s'+1,\ \ c\to -b+v+2,$$

$$d\to n+1,\ \ e\to a'-b''-a-v,\ \ N\to b'',\ \ s\to\tilde{j}''+\tilde{z}''.$$

Further we replace some factors in (2.7b) as follows:

$$\frac{[b-b'-2v+s'+n]!}{[-v+s']![b-b'-v+n]![s]![b-b'-2v+s'+n-s]!}$$
$$=\sum_{s''}\frac{q^{s''(b-b'-2v+s'+n)-s(s'-v)}}{[s'']![s'-v-s'']![s-s'']![b-b'-v+n-s+s'']!}$$

and use the Chu–Vandermonde formulas[25–27] for summation over s,s'.

Finally after change of summation parameters we obtain the new expression for the denominator function

$$\mathcal{D}^2\binom{q,t=1}{a''b''}[a'b';a\,b]$$
$$=q^{-(a'+b-2v+2)(a'+a''-a-v)-v(b'+v+1)+(b''+v)(b'+b+2)}$$
$$\times\frac{[a'']![b'']![a+b'-a''+v+1]![a'-b''+b-v+1]!}{[a'+a''-v+1]![b'+b''+v+1]![a+b''+v+1]![a''+b-v+1]!}$$
$$\times\sum_{n,n'}\frac{q^{n(a'+a+2)-n'(b'+b+2)}[b-b''-v+n]![b+a''-v+n+1]!}{[n]![a-a'+v+n]![n']![b'-b+v+n']![b''-n-n']![b''+v-n-n']!}$$
$$\times\frac{[a'-b''-v+n']![a'+a''-v+n'+1]!}{[a+b'-a''-b''+v+n+n'+1]![a+b'+v+n+n'+2]!},\tag{2.8}$$

which is indefinite only if both

$$b-b''-v<0\quad\text{and}\quad b'-a''+v<0,$$

or

$$a'-b''-v<0\quad\text{and}\quad a-a''+v<0,$$

i.e., in the null space situation, when isofactors (2.1b) are vanishing.

We see that the expression for denominator function (2.8) satisfies the symmetry relations

$$\mathcal{D}^2\binom{q,t=1}{a''b''}[a'b';a\,b]=\mathcal{D}^2\binom{q^{-1},t=1}{b''a''}[b'a';b\,a]\tag{2.9a}$$

$$=q^{b'(a'-b''+b-v+2)-a''(b'-a''+a+v+2)}\mathcal{D}^2\binom{q^{-1},t=1}{a''b''}[ba;b'a']\tag{2.9b}$$

$$=\frac{q^{v(3v-a'-b')}[a'']![b'']!}{[a''-v]![b''+v]!}\mathcal{D}^2\binom{q,t=1}{a''-v,b''+v}[a'-v,b'+v;a+v,b-v]\tag{2.9c}$$

$$=\frac{q^{(a'-a-v)(a+b'-a''-b''+2)}[a'']![b'']!}{[a'+a''-a-v]![a-a'+b''+v]!}$$
$$\times\mathcal{D}^2\binom{q^{-1},t=1}{a'+a''-a-v,a-a'+b''+v}[a+v,b';a'-v,b]\tag{2.9d}$$

$$=\frac{q^{(b-b'-v)(a+b'-a''+v+2)}[a'']![b'']!}{[a''-b'+b-v]![b'+b''-b+v]!}$$
$$\times\mathcal{D}^2\left(\begin{matrix}q^{-1},t=1\\ a''-b'+b-v,b'+b''-b+v\end{matrix}\right)[a',b-v;a,b'+v]. \tag{2.9e}$$

Relations (2.9a) and (2.9b) coincide with (3.7a) and (3.14a) of Ref. 12, when the Regge-type symmetry relations (2.9c), (2.9d), and (2.9e) correspond to transposition of layers, rows, and columns, respectively, in subarray (1.5b) of Ref. 12, characterizing the multiplicity of the canonical tensor operators. Substitution $q\to q^{-1}$ in (2.9a) and (2.9b) is correlated with transposition of the whole array (1.3b) (interchange of its rows and columns). Hence, the symmetry group of denominator function (2.8) includes 16 elements. In analogy with Refs. 4 and 21 for fixed integer b'' we may re-express the denominator function,

$$\mathcal{D}^2\left(\begin{matrix}q,t=1\\ a''b''\end{matrix}\right)[a'b';a\,b]=\frac{q^{-(a'+b-2v+2)(a'+a''-a-v)-v(b'+v+1)+(b''+v)(b'+b+2)}}{[b'+b''+v+1]![a+b''+v+1]![b''+v]!}$$
$$\times\frac{[a'']![a'-b''+b-v+1]![b-b''-v]![a'-b''-v]!}{[a-a'+b''+v]![b'+b''-b+v]![a+b'+b''+v+2]!}\mathbf{G}^1_{b''}(\Delta;x)_q \tag{2.10}$$

in terms of q-polynomials,

$$\mathbf{G}^1_{b''}(\Delta_1,\Delta_2,\Delta_3;x_1,x_2,x_3)_q$$
$$=\sum_{n,n'}\frac{q^{n(a'+a+2)-n'(b'+b+2)}}{[n]![n']![b''-n-n']!}$$
$$\times[a-a'+b''+v|q]_{b''-n}(b-b''-v+1|q)_n(b+a''-v+2|q)_n$$
$$\times[b''+v|q]_{n+n'}[a+b'+b''+v+2|q]_{b''-n-n'}$$
$$\times[a+b'-a''+v+1|q]_{b''-n-n'}$$
$$\times[b'+b''-b+v|q]_{b''-n'}(a'-b''-v+1|q)_{n'}(a'+a''-v+2|q)_{n'} \tag{2.11a}$$

$$=[a-a'+b''+v|q]_{b''}[b''+v|q]_{b''}[b'+b''-b+v|q]_{b''}$$
$$\times\sum_{n,n'}q^{n(a'+a+2)-n'(b'+b+2)}\frac{(b-b''-v+1|q)_n(b+a''-v+2|q)_n}{[n]!(a-a'+v+1|q)_n}$$
$$\times\frac{(-a-b'-b''-v-2|q)_{b''-n-n'}(-a-b'+a''-v-1|q)_{b''-n-n'}}{[b''-n-n']!(v+1|q)_{b''-n-n'}}$$
$$\times\frac{(a'-b''-v+1|q)_{n'}(a'+a''-v+2|q)_{n'}}{[n']!(b'-b+v+1|q)_{n'}}, \tag{2.11b}$$

where

$$x_1=b'+1,\;\; x_2=-a'-b'-2,\;\; x_3=a'+1,$$
$$\Delta_1=a-a'+b''+v,\;\; \Delta_2=b''+v,\;\; \Delta_3=b'+b''-b+v. \tag{2.12}$$

The symmetry properties of the polynomials $G^{t}_{b''}(\Delta_1,\Delta_2,\Delta_3;x_1,x_2,x_3)$ were quite important for the proof of the uniqueness of solution in Ref. 4. Let us consider the symmetries of $\mathbf{G}^{1}_{b''}(\Delta_1,\Delta_2,\Delta_3;x_1,x_2,x_3)_q$. The evident symmetry properties

$$\mathbf{G}^{1}_{b''}(\Delta_1,\Delta_2,\Delta_3;x_1,x_2,x_3)_q=\mathbf{G}^{1}_{b''}(\Delta_3,\Delta_2,\Delta_1;x_3,x_2,x_1)_{q^{-1}} \tag{2.13a}$$

$$=q^{b''(b'+b+2)}\mathbf{G}^{1}_{b''}(\Delta_1,\Delta_3,\Delta_2;x_1,x_3,x_2)_{q^{-1}} \tag{2.13b}$$

$$=q^{-b''(a'+a+2)}\mathbf{G}^{1}_{b''}(\Delta_2,\Delta_1,\Delta_3;x_2,x_1,x_3)_{q^{-1}} \tag{2.13c}$$

$$=q^{-b''(b'+b+2)}\mathbf{G}^{1}_{b''}(\Delta_2,\Delta_3,\Delta_1;x_2,x_3,x_1)_{q} \tag{2.13d}$$

$$=q^{b''(a'+a+2)}\mathbf{G}^{1}_{b''}(\Delta_3,\Delta_1,\Delta_2;x_3,x_1,x_2)_{q} \tag{2.13e}$$

(with a'',b'' fixed) correspond to substitutions

$$a'\leftrightarrow b,\ \ b'\leftrightarrow a;$$

$$a'\to -a-b-3,\ \ b'\leftrightarrow b,\ \ a\to -a'-b'-3,\ \ v\to b'-b+v;$$

$$a'\leftrightarrow a,\ \ b'\to -a-b-3,\ \ b\to -a'-b'-3,\ \ v\to a-a'+v;$$

$$a'\to b'\to -a'-b'-3,\ \ a\to b\to -a-b-3,\ \ v\to b'-b+v;$$

$$b'\to a'\to -a'-b'-3,\ \ b\to a\to -a-b-3,\ \ v\to a-a'+v;$$

respectively, or to the row permutations in array A_1,

$$A_1(\Delta;x)=\begin{bmatrix}\Delta_1 & \Delta_2+x_1 & \Delta_3-x_1\\ \Delta_2 & \Delta_3+x_2 & \Delta_1-x_2\\ \Delta_3 & \Delta_1+x_3 & \Delta_2-x_3\end{bmatrix} \tag{2.14a}$$

$$=\begin{bmatrix}a-a'+b''+v & b'+b''+v+1 & b''-b+v-1\\ b''+v & b''-a'-b+v-2 & b'+b''+a+v+2\\ b'+b''-b+v & a+b''+v+1 & b''-a'+v-1\end{bmatrix} \tag{2.14b}$$

[see Eq. (1.6) of Ref. 4]. Relation (2.13a) follows directly from (2.9b), but we failed to find such definition of q-polynomial which allowed to escape additional q-phases in other symmetry relations.

In order to check the symmetry of q-polynomial (2.11a) with respect to the column permutations and transpositions of array A_1, (and to find the corresponding q-phases), we use in (2.7b) the rearranged sums over s,

$$\sum_s \frac{[a''+b''+b-v-s+1]!}{[s]![b''-s]![a-a'+b''+v-s]![b-b'-2v+s'+n-s]!}$$
$$\times\frac{(-1)^{b-b'+s}}{[b-v-s]![b'-b+2v-s'+s]![b'-b+2v-n+s]!}$$
$$=\frac{[a''+b''+b'+v-s'-n+1]!}{[b'+v-s']![b'+v-n]![a'+a''-a-v-s']!}$$

$$\times\frac{[b'+b''+v+1]!}{[a'+a''-a-v-n]![a-a'+b''+v]![b-b'-2v+s'+n]!}$$

$$\times\sum_{s}(-1)^{s'+n+s}\frac{[a'+a''-a-v-s]![b'+v-s]![a-a'+b''+v+s]!}{[s]![n-s]![s'-s]![a''-s'-n+s]![b'+b''+v-s+1]!} \tag{2.15a}$$

$$=\frac{[b'+b''+v+1]![a''+b-v+1]!}{[b-b'-2v+s'+n]![b-v]![n]![b'+v-s']![a''-n]![a'+a''-a-v-n]!}$$

$$\times\sum_{s}(-1)^{a''-s}\frac{[a''+b-v-s'-s]![b-b'+a''-2v+n-s]!}{[s]![a''-s'-s]![a-a'+b''+v-s]!}$$

$$\times\frac{[a'+a''-a-v-n+s]!}{[a'-a-v+s]![a''+b-v-s+1]!}, \tag{2.15b}$$

in accordance with alternative expressions and the Regge symmetry of $q-6j$ coefficients.[25,26] Hence instead of (2.8) we obtain

$$\mathcal{D}^2\begin{pmatrix} q,t=1 \\ a''b'' \end{pmatrix}[a'b';a\,b]$$

$$=\frac{q^{(a+b'+2v+2)(a'+a''-a-v)-v(b'+v+1)-a''(a+b+2)}[a'']![b'']!}{[b''+v]![b'+b''-b+v]![a-a'+b''+v]![a'+a''-v+1]![a''+b-v+1]!}$$

$$\times\sum_{s,s''}(-1)^{a''-s''}\frac{q^{s''(a+b-a'+1)-s(a+b'+2)}[b'+v-s]![a-a'+b''+v+s]!}{[s]![a'+a''-a-v-s]![s''-s]![a''-b'+b-v+s-s'']!}$$

$$\times\frac{[a+v+s-s'']![b'+b''-b+v+s''-s']![a''+b''+v-s'']!}{[-v+s'']![a''-s'']![a'+a''+b-v-s''+2]!} \tag{2.16a}$$

$$=q^{(a+b'+v+2)(a'+a''-a-v)+vb''-a''(b'+b''+a+v+2)}$$

$$\times\frac{[a'']![b'']![a+b'-a''+v+1]!}{[b'+b''+a+v+2]!}$$

$$\times\sum_{s,n}\frac{q^{s(b+b''+a+v+2)-n(a+b'-a''+v+2)}[b'+v-n]![a-a''+v+n]!}{[n]![a''-n]![a'+a''-a-v-n]![b-b'-v+n]![s]![a''-v-s]!}$$

$$\times\frac{[a-a'+b''+v+n-s]![a'+a''-a-v-n+s]!}{[a-a'+b''+v-s]![a'-a-v+s]![a'+s+1]![a''+b-v-s+1]!}, \tag{2.16b}$$

in the first case replacing some factors in (2.7b) with inserted (2.15a) by

$$\sum_{s''}(-1)^{a''-n+s-s''}\frac{q^{(s''-s')(b'+a''+b''+v-s'-n+1)-(a''-s'-n+s)(a'+a''+b-v-s'+2)}[a+v+s-s'']!}{[s''-s']![a''-n+s-s'']![a'+a''+b-v-s''+2]!}$$

and using the Chu–Vandermonde formulas[25–27] for summation over s,s', and in the second case, using the Chu–Vandermonde formula, after inserting (2.15b), for summation over s'. Expression (2.16a) [with factor $q^{b''(a-b')}$] may be also derived from (2.8), applying (2.9a) and using interchange of the first and third column of array (2.14b), together with transition $q\to q^{-1}$.

Otherwise, expression (2.16b) is an analog of (3.14b) or (3.7b) of Ref. 12, but in contrast with these two formulas, all its terms are positive and (in all non-null-space situations) definite. Besides it is invariant (up to an elementary factor) with respect to transposition of array A (2.14b). In the SU(3) $(q=1)$ case (2.16b) may be rearranged replacing some ratios of factorials by the Chu–Vandermonde formulas in analogy with (3.17) of Ref. 13. This way the SU(3) denominator function may be written as follows:

$$\mathcal{D}^2\begin{pmatrix} t=1 \\ a''b'' \end{pmatrix}(a'b';a\,b)$$
$$=\frac{a''!b''!(a+b'-a''+v+1)!(a'-b''+b-v+1)!}{(a'+a''+b-v+2)!(b'+b''+a+v+2)!}\sum_{n,n'}\frac{(b-b''-v+n)!}{n!(a-a'+v+n)!}$$
$$\times\frac{(a'-b''-v+n')!}{(b'+b''+v-n+1)!n'!(b'-b+v+n')!(b''-n-n')!(b''+v-n-n')!}$$
$$\times\frac{(a'+a''+b''+b-v-n-n'+2]!}{(a+b''+v-n'+1)!(a+b'-a''-b''+v+n+n'+1)!} \tag{2.17}$$

accepting the form related to less symmetric form (5.6) of $\mathcal{G}^1_{b''}(A)$ function.[4] Although expression (2.17) resembles Eq. (2.8) (the majority of factorial arguments, dependent on summation parameters, coinciding in the both versions), the separate sums in (2.17) are related to the balanced hypergeometric functions, which q-extension cannot include q-phases dependent on summation parameters, in contrast with (2.8).

We may apply also the q-Saalschütz identity,

$$\sum_r \frac{(a|q)_r(b|q)_r}{[r]!(c|q)_r}\frac{(c-a-b|q)_{s-r}}{[s-r]!}=\frac{(c-a|q)_s(c-b|q)_s}{(c|q)_s[s]!}, \tag{2.18}$$

as presented in Refs. 29, 30, separately to each row of the q-polynomial (2.11b) depending on n, $b''-n-n'$, and n', respectively, and perform the summation over n,n', using the Chu–Vandermonde formulas. This way we obtain a new expression

$$\mathbf{G}^1_{b''}(\Delta_1,\Delta_2,\Delta_3;x_1,x_2,x_3)_q$$
$$=[a-a'+b''+v|q]_{b''}[b''+v|q]_{b''}[b'+b''-b+v|q]_{b''}$$
$$\times\sum_{s,s'} q^{s(a'+a+2)-s'(b'+b+2)}\frac{(-b'-b''-v-1|q)_s(a''-b'-v|q)_s}{[s]!(a-a'+v+1|q)_s}$$
$$\times\frac{(a'-b''+b-v+2|q)_{b''-s-s'}(a'+a''+b-v+3|q)_{b''-s-s'}}{[b''-s-s']!(v+1|q)_{b''-s-s'}}$$
$$\times\frac{(-a-b''-v-1|q)_{s'}(a''-a-v|q)_{s'}}{[s']!(b'-b+v+1|q)_{s'}}, \tag{2.19}$$

which corresponds to permutation of the second and third column of array A_1 (2.14b), together with transition $q\to q^{-1}$. Thus, the determinantal symmetry of the q-polynomial $\mathbf{G}^1_{b''}(\Delta;x)_q$ with 72 elements (in terms of the transpositions of the elements of array A_1) is demonstrated.

Otherwise, the symmetry relations (2.9c), (2.9d), and (2.9e) with 8 elements [in terms of the transpositions of the elements of subarray (1.5b) of Ref. 12] correspond to the reduction formulas of G functions.[3,4]

III. CONJECTURE ABOUT GENERIC DENOMINATOR FUNCTIONS

In Refs. 3 and 4, it was demonstrated, that the ratio $G^{t-1}_{b''}(\Delta;x)/G^t_{b''}(\Delta;x)$ of subsequent polynomials (4.2) or (5.6) of Ref. 4 (with $G^0_{b''}=G^{b''+1}_{b''}=1$) appears, together with the definite linear factors, under the square root sign in the denominator (normalization) function $D(\Gamma_t;x)$ of the SU(3) canonical tensor operators. For the denominator function of the $u_q(3)$ canonical tensor operators, the corresponding linear factors turn into the definite q-numbers, together with the definite q-phase factors, but q-extension of expression (4.2) or (5.6) of Ref. 4 is meaningless. We introduce here the following q-analog of the denominator polynomial,

$$
\begin{aligned}
&\mathbf{G}^t_{b''}(\Delta_1,\Delta_2,\Delta_3;x_1,x_2,x_3)_q\\
&=\prod_{s=1}^{t}\frac{[b''-s+1]!}{[s-1]!}\sum_{\lambda,\mu,\nu}\frac{g(\lambda,\mu,\nu;[b''-t+1]^t)}{M[\lambda]M[\mu]M[\nu]}q^{(a'+a+2)\Sigma_s\lambda_s-(b'+b+2)\Sigma_s\mu_s}\\
&\quad\times\prod_{s=1}^{t}(x_1-\Delta_3+t-s|q)_{\lambda_s}(x_1-\Delta_3+a''+b''+2-s|q)_{\lambda_s}[\Delta_1+1-s|q]_{b''-t+1-\lambda_s}\\
&\quad\times[\Delta_1-x_2-t+s|q]_{\nu_s}[\Delta_1-x_2-a''-b''-2+s|q]_{\nu_s}[\Delta_2+1-s|q]_{b''-t+1-\nu_s}\\
&\quad\times(x_3-\Delta_2+t-s|q)_{\mu_s}(x_3-\Delta_2+a''+b''+2-s|q)_{\mu_s}[\Delta_3+1-s|q]_{b'-t+1-\mu_s}
\end{aligned}\tag{3.1a}
$$

$$
\begin{aligned}
&=\prod_{s=1}^{t}\frac{[b''-s+1]!}{[s-1]!}\prod_{i=1}^{3}\prod_{s=1}^{t}[\Delta_i+1-s|q]_{b''-t+1}\\
&\quad\times\sum_{\lambda,\mu,\nu}g(\lambda,\mu,\nu;[b''-t+1])q^{(a'+a+2)\Sigma_s\lambda_s-(b'+b+2)\Sigma_s\mu_s}\\
&\quad\times\langle{}_2\mathcal{F}_1[b-b''-v+t,a''+b-v+2;a-a'+v+t]|\lambda\rangle_q\\
&\quad\times\langle{}_2\mathcal{F}_1[-a-b'-b''-v+t-3,-a-b'+a''-v-1;v+t]|\nu\rangle_q\\
&\quad\times\langle{}_2\mathcal{F}_1[a'-b''-v+t,a'+a''-v+2;b'-b+v+t]|\mu\rangle_q
\end{aligned}\tag{3.1b}
$$

in terms of variables (2.12), where $\lambda=[\lambda_1,\lambda_2,\ldots,\lambda_t]$, μ, ν are the partitions which may denote irreps of $\mathrm{U}(t)$. Coefficients $g(\lambda,\mu,\nu;[b''-t+1]^t)$ are the Littlewood–Richardson numbers, i.e., they are equal to the multiplicity of the irrep $[b''-t+1,...,b''-t+1]$ ($b''-t+1$ repeated t times) in the direct product $\lambda\times\mu\times\nu$ decomposition. Factor $M[\lambda]$ corresponds to a q-analog of the measure of the Young frame λ,

$$
\begin{aligned}
M[\lambda]&=\frac{\Pi_{s=1}^t[\lambda_s+t-s]!}{\Pi_{r<s}[\lambda_r-\lambda_s+s-r]}=(\dim[\lambda])^{-1}\prod_{s=1}^{t}(t-s+1|q)_{\lambda_s},\\
\dim[\lambda]&=\frac{\Pi_{r<s}[\lambda_r-\lambda_s+s-r]}{[1]![2]!\cdots[t-1]!}.
\end{aligned}\tag{3.2}
$$

Generalized q-hypergeometric coefficients in (3.1b) are defined by

$$
\langle{}_2\mathcal{F}_1[a,b;c]|\lambda\rangle_q=M^{-1}[\lambda]\prod_{s=1}^{t}\frac{(a-s+1|q)_{\lambda_s}(b-s+1|q)_{\lambda_s}}{(c-s+1|q)_{\lambda_s}}\tag{3.3}
$$

(cf. Refs. 4, 29–31) and appear as expansion coefficients of generalized q-hypergeometric (Gauss) series

$$
{}_2\mathcal{F}_1[a,b;c;q;z]_{\pm}=\sum_{\lambda}\langle{}_2\mathcal{F}_1[a,b;c]|\lambda\rangle_q q^{\pm(a+b-c-t)\Sigma\lambda_s}e_\lambda(z)\tag{3.4}
$$

in terms of symmetric (Schur) functions $e_\lambda(z)$ with $z=(z_1,z_2,\dots,z_t)$.

Expression (3.1a) turn into (2.11a) for $t=1$ with $g(\lambda,\mu,\nu;[b''-t+1])=\delta_{\lambda_1+\mu_1+\nu_1,b''}$. Otherwise, for $t=b''$ we obtain

$$\begin{aligned}\mathbf{G}_{b''}^{b''}&(\Delta_1,\Delta_2,\Delta_3;x_1,x_2,x_3)_q\\&=\sum_{n,n'}\frac{q^{n(a'+a+2)-n'(b'+b+2)}}{[n]![n']![b''-n-n']!}\\&\quad\times(a-a'+v+1|q)_{b''-n}[b-v|q]_n[b+a''-v+2|q]_n\\&\quad\times(v+1|q)_{n+n'}(a+b'+v+3|q)_{b''-n-n'}(b'-a''+a+v+1|q)_{b''-n-n'}\\&\quad\times(b'-b+v+1|q)_{b''-n'}[a'-v|q]_{n'}[a'+a''-v+2|q]_{n'},\end{aligned}\tag{3.5}$$

since $g(\lambda,\mu,\nu;[1^{b''}])=1$ only if $\lambda=[1^n]$, $\mu=[1^{n'}]$, $\nu=[1^{b''-n-n'}]$ and vanishes otherwise. Function $\mathbf{G}_{b''}^{b''}$ is equivalent to the q-polynomial factor of the denominator function $\mathbf{D}^2\left({q,t=b''+1 \atop a''b''}\right)[a'b';ab]$, which may be derived from (4.8c) of Ref. 18 after interchange of layers of array (1.3b) of Ref. 12, i.e., applying to $\mathbf{D}^2\left({q,t=b''+v+1 \atop a''b''}\right)[a'b';ab]$ the substitution

$$\begin{aligned}&a'\leftrightarrow a'-v,\quad b'\leftrightarrow b'+v,\quad a''\leftrightarrow a''-v,\\&b''\leftrightarrow b''+v,\quad a\leftrightarrow a+v,\quad b\leftrightarrow b-v.\end{aligned}\tag{3.6}$$

In a similar manner as in Sec. IV of Ref. 4 we may derive for (3.1a) the reduction formulas and find the weight space $\mathbf{W}_{b''}^t(\Delta)$ of zeros. For example, when $v<0$ the separate factors

$$\begin{aligned}\prod_{s=1}^{t}&[a-a'+b''+v+1-s|q]_{-v}[b'+b''-b+v+1-s|q]_{-v}\\&\times[a+b'+s+2|q]_{-v}[a+b'-a''+v+s|q]_{-v}\end{aligned}\tag{3.7}$$

may be extracted from (3.1a), since the factor $[b''+v+1-s|q]_{b''-t+1-\nu_s}$ vanish unless $\nu_t\geqslant -v$. In this case the separate blocks of (3.1a) may be rearranged into a close form as (4.9) and (4.10) of Ref. 4, with new parameters, using the new summation partition $\nu_t'=[\nu_1+v,\nu_2+v,\dots,\nu_t+v]$, and taking into account the identity

$$\begin{aligned}&\frac{g(\lambda,\mu,\nu;[b''-t+1]^t)}{M[\nu]}\prod_{s=1}^{t}[b''-s+1]![b''+v+1-s|q]_{b''-t+1-\nu_s}\\&\quad=\frac{g(\lambda,\mu,\nu';[b''+v-t+1]^t)}{M[\nu']}\prod_{s=1}^{t}[b''+v-s+1]![b''+1-s|q]_{b''-t+1-\nu_s'}.\end{aligned}\tag{3.8}$$

Hence, for $t=b''+v$, $v<0$ the q-polynomial factor of (3.1a) accepts after rearrangement the form related to the corresponding q-polynomial factor of $\mathbf{D}^2\left({q,t=b''+v+1 \atop a''b''}\right)[a'b';ab]$, as presented by (4.8c) of Ref. 18. Analogical rearrangement of (3.1a) is also possible when $a-a'+v<0$ or $b'-b+v<0$.

We are still unable to prove the general expression (3.1a) for $1<t<\mathcal{M}$ in the generic $u_q(3)$, $q\neq 1$, case. As it is shown by Theorem 3.2 of Ref. 4 the polynomial $G_{b''}^t(\Delta;x)$ is the unique polynomial that possesses the following properties: (i) total degree $2t(b''-t+1)$ in x_1,x_2,x_3, (ii) determinantal symmetry, and (iii) the weight space $\mathbb{W}_{b''}^t(\Delta)$ of zeros. The properties (i) and (iii) for $\mathbf{G}_{b''}^t(\Delta_1,\Delta_2,\Delta_3;x_1,x_2,x_3)_{q=1}$ may be checked in a similar manner as it was done in Sec. IV of Ref. 4. Evidently, this polynomial is invariant under row interchange in array

$$A_t(\Delta;x)=\begin{bmatrix}\Delta_1-t+1 & \Delta_2+x_1-t+1 & \Delta_3-x_1-t+1\\ \Delta_2-t+1 & \Delta_3+x_2-t+1 & \Delta_1-x_2-t+1\\ \Delta_3-t+1 & \Delta_1+x_3-t+1 & \Delta_2-x_3-t+1\end{bmatrix}. \tag{3.9}$$

Otherwise, the generalized hypergeometric coefficients $\langle {}_2\mathcal{F}_1(a,b;c)|\lambda\rangle$, $\langle {}_2\mathcal{F}_1(a',b';c')|\mu\rangle$, and $\langle {}_2\mathcal{F}_1(a'',b'';c'')|\nu\rangle$ in (3.1b) for $q=1$ either may be expanded using the generalization of Saalschütz identity[29–31] separately, or their product may be rearranged using the following generalized version of (2.2) of Ref. 30,

$$\sum_{\lambda,\mu,\nu} g(\lambda\mu\nu;\Lambda)\langle {}_2\mathcal{F}_1(c-a,c-b;c)|\lambda\rangle\langle {}_2\mathcal{F}_1(c'-a',c'-b';c')|\mu\rangle$$
$$\times\langle {}_2\mathcal{F}_1(c''-a'',c''-b'';c'')|\nu\rangle$$
$$=\sum_{\lambda,\mu,\nu,\kappa} g(\lambda\mu\nu\kappa;\Lambda)\langle {}_2\mathcal{F}_1(a,b;c)|\lambda\rangle\langle {}_2\mathcal{F}_1(a',b';c')|\mu\rangle\langle {}_2\mathcal{F}_1(a'',b'';c'')|\nu\rangle$$
$$\times\langle {}_1\mathcal{F}_0(c-a-b+c'-a'-b'+c''-a''-b'')|\kappa\rangle, \tag{3.10}$$

where

$$\langle {}_1\mathcal{F}_0[d]\kappa\rangle_q=M^{-1}[\kappa]\prod_{s=1}^{t}(d-s+1|q)_{\kappa_s} \tag{3.11}$$

[taking the three factor version of generalized Euler identity (2.1) of Ref. 30 as generating function for relation (3.10)]. Since in the (3.1b) case $d=c-a-b+c'-a'-b'+c''-a''-b''=0$, factor $\langle {}_1\mathcal{F}_0(0)|\kappa\rangle=0$, unless κ is a trivial partition of 0. Hence Eq. (3.10) corresponds to the column 2–column 3 interchange of the array A_t. In the generic $q\neq 1$ case for this purpose it would be reasonable to use the q-generalized partition dependent Saalschütz identity,

$$\sum_{\mu,\nu} g(\mu\nu;\lambda)\langle {}_2\mathcal{F}_1[a,b;c]|\mu\rangle_q\langle {}_1\mathcal{F}_0[c-a-b]|\nu\rangle_q=\langle {}_2\mathcal{F}_1[c-a,c-b;c]|\lambda\rangle_q, \tag{3.12}$$

and the q-generalized partition dependent binomial identity (a multiple q-analog of the Chu–Vandermonde formula),

$$\sum_{\mu,\nu} g(\mu\nu;\lambda)q^{y\Sigma\mu_s-x\Sigma\nu_s}\langle {}_1\mathcal{F}_0[x]|\mu\rangle_q\langle {}_1\mathcal{F}_0[y]|\nu\rangle_q=\langle {}_1\mathcal{F}_0[x+y]|\lambda\rangle_q, \tag{3.13}$$

(cf. Refs. 29–31). Although we did not prove Eqs. (3.12) and (3.13) for generic λ and $q\neq 1$, it was demonstrated that coefficients $g(\mu\nu;\lambda)$ appear here and in the multiple series (3.1a)–(3.1b) as usual Littlewood–Richardson numbers rather than special q-dependent analogs of Littlewood–Richardson coefficients.[32–35]

Unfortunately, we had not proved the symmetry of polynomial

$$\mathbf{G}^{t}_{b''}(\Delta_1,\Delta_2,\Delta_3;x_1,x_2,x_3)_{q=1}$$

with respect of the transposition of array A. The attempts to perform the transformations which lead from (2.8) to (2.16b) in the generic $t>1$ case were unsuccessful.

IV. CONCLUDING REMARKS

We obtained completed and universal solutions for the normalized canonical seed isofactors of SU(3) and $u_q(3)$ with extreme values of multiplicity label, which may replace the conjectured algorithm (20) and other initial steps of computation algorithm[5] of the normalized SU(3) coupling coefficients. New expressions for the denominator function of the maximal null space case of the $u_q(3)$ canonical tensor operators, which cannot be derived in frames of the traditional SU(3) technique,[7–10] give also the new expressions and relations for the denominator function of the SU(3) canonical tensor operators as special function accepting the different forms. Nevertheless, similarly as algorithm (20) of Ref. 5 and extended for more than 20 years (beginning in 1972–1975[7,8,21,36]) resolution of the SU(3) denominator function problem before the final result[4,31] was derived, the present study of the normalization coefficients for the $u_q(3)$ canonical tensor operators in the generic multiplicity label case is inconclusive and search for generating functions related to multiple q-version of Euler identity and other techniques for investigation of multiple partition dependent q-factorial series need to be developed.

Institut de Physique Théorique, Université Catholique de Louvain, B-1348 Louvain-la-Neuve, Belgium, and CTSPS, Clark Atlanta University, Atlanta, Georgia 30314

(Received 21 April 1999; accepted for publication 20 July 1999)

We derive Galilean wavelets, by which we mean coherent states of the affine Galilei group, that is, the Galilei group extended by independent space and time dilations. The construction follows a general method based on square integrable group representations, possibly modulo a subgroup, i.e., on a homogeneous space of the underlying group. We also examine the restriction to the Schrödinger subgroup, which contains only dilations that leave invariant the Schrödinger and the heat equations. © *1999 American Institute of Physics.* [S0022-2488(99)01111-1]

I. INTRODUCTION: SPACE–TIME WAVELETS

Wavelet analysis has become by now a widely used technique in signal and image processing. It is a particular time-frequency, or rather time-scale, method, which is specially efficient at detecting and analyzing nonstationary effects in signals, such as discontinuities, transients, etc. Mathematically speaking, wavelets are simply coherent states associated to affine groups of various dimensions.

However, for analyzing a signal with such a technique, which privileges prior knowledge, it is advisable to choose a wavelet that matches the characteristics of the signal as well as possible. For instance, analyzing a static signal requires only a static wavelet, that is, a coherent state associated to some symmetry group of space, containing dilations of some kind. On the contrary, in the case of a time-dependent signal (such as a movie or video sequence), one needs a *time-dependent* wavelet, in other words, a coherent state associated to a symmetry group of space–time.

Then the question arises, how does one construct wavelets adapted to a given setup? A possible answer is given by the general theory of coherent states developed in Refs. 1 and 2 and thoroughly described in Refs. 3 and 4. The construction proceeds in two steps. First, one chooses an appropriate group G of transformations applicable to the signal under consideration. Next one selects a square integrable representation U of G, possibly modulo a subgroup, if any. Then the corresponding coherent states (CS) are simply the elements of the orbit under U of a fixed vector η in the representation space.

In this paper, we will apply this approach to the construction of time-dependent wavelets. However, there are several possibilities for the group G, depending on the kinematics (i.e., relativity group) one chooses.

(i) *Kinematical or Euclidean wavelets:* This is the simplest case. G consists of space–time translations, space–time dilations (denoted a, a_0, respectively), space rotations (which reduce to reflections in one space dimension), and time reflection.

(ii) *Galilean wavelets:* G is the *affine Galilei group*, which combines the (extended) Galilei group with independent space and time dilations (a,a_0).

[a)]Electronic mail: antoine@fyma.ucl.ac.be
[b)]Present address: Faculté des Sciences, Université du Burundi, Bujumbura, Burundi.

(iii) *Schrödinger wavelets:* Here G consists of the Galilei group plus Schrödinger dilations, i.e., with the constraint $a_0 = a^2$ (that is, dilations that leave invariant the Schrödinger and the heat equations).[5,6]

(iv) *Relativistic wavelets: G* is the *Weyl–Poincaré group*, combining the Poincaré group with relativistic space–time dilations, characterized by the relation $a_0 = a$.

Kinematical wavelets have been introduced by Duval-Destin and Murenzi[7] for the analysis of simple motion, and later applied by Murenzi *et al.*[8] to various practical problems of motion tracking. Relativistic (Poincaré) wavelets have been constructed by Bohnké,[9] using mathematical work of Unterberger,[10] and also (in 1+1 dimensions), by Bertrand and Bertrand.[11] But the Galilean case has been largely undocumented up to now, maybe because of the complicated structure of the Galilei group.[12,13] Some results were obtained in Ref. 14, but a comprehensive study is still missing, except for the brief overview given in Ref. 15. This paper aims at filling this gap.

The general affine Galilei group and the Schrödinger subgroup are treated in Secs. II and III, respectively. For the convenience of the reader, we have briefly summarized in Appendices A and B the general construction method of coherent states associated to square integrable group representations, following Refs. 1–4, and the Mackey method of induced representations.

II. THE EXTENDED AFFINE GALILEI GROUP AND ITS UNITARY REPRESENTATIONS

A. The affine Galilei group

The kinematics of a free nonrelativistic physical particle is governed by its invariance under the action of the Galilei group,[12] which is a ten parameter group $\mathcal{G}_0$ of transformations of Newtonian space–time (we work in 3 space dimensions, although the whole discussion extends to n dimensions, for any $n \geqslant 3$). An element $g \in \mathcal{G}_0$ is of the form

$$g = (b, \mathbf{a}, \mathbf{v}, R), \quad b \in \mathbb{R}, \quad \mathbf{a}, \mathbf{v} \in \mathbb{R}^3, \quad R \in \mathrm{SO}(3), \tag{2.1}$$

where b is a time translation and $\mathbf{a}$ a spatial translation, $\mathbf{v}$ a velocity boost, and R a spatial rotation. The action of g on a space–time point $(\mathbf{x}, t)$ is given by $g(\mathbf{x}, t) = (\mathbf{x}', t')$, where

$$\mathbf{x}' = R\mathbf{x} + \mathbf{v}t + \mathbf{a}, \quad t' = t + b. \tag{2.2}$$

The group law of $\mathcal{G}_0$ is

$$(b, \mathbf{a}, \mathbf{v}, R)(b', \mathbf{a}', \mathbf{v}', R') = (b + b', \mathbf{a} + b'\mathbf{v} + R\mathbf{a}', \mathbf{v} + R\mathbf{v}', RR'). \tag{2.3}$$

The next step is to construct projective representations of $\mathcal{G}_0$ by the standard method of central extensions.[12]

In order to get Galilean wavelets, we have to replace $\mathcal{G}_0$ by the affine group obtained by combining $\mathcal{G}_0$ with independent space and time dilations. Thus our program should be, first, to define the semidirect product $\mathcal{G}_0 \rtimes \mathcal{D}_2$ of the pure Galilei group $\mathcal{G}_0$ with a two-dimensional dilation group $\mathcal{D}_2 \equiv (\mathbb{R}_*^+)^2 \simeq \mathbb{R}^2$, and then to construct projective representations of the resulting group as usual. However, a straightforward computation, given in Appendix C, shows that the only central extensions of $\mathcal{G}_0 \rtimes \mathcal{D}_2$ by $\mathbb{R}$ are of the form $\mathcal{G}_0 \rtimes G_{\mathrm{WH}}$, where G_{WH} is the Weyl–Heisenberg group, itself a central extension of $\mathcal{D}_2$. In particular, the central extension procedure fails to generate mass, as it does in the usual situation, where no dilations are considered.

The only alternative is to reverse the order of the two constructions:

(1) Take first a central extension of $\mathcal{G}_0$ by $\mathbb{R}$, which yields the extended Galilei group $\mathcal{G}^M$ corresponding to the extension parameter $M > 0$.

(2) Construct the semidirect product $\mathcal{G}_{\mathrm{aff}}^M = \mathcal{G}^M \rtimes \mathcal{D}_2$, the extended affine Galilei group.

However, as we shall see below, M should *not* be interpreted as mass, but rather as a mass unit or mass scale (the physical mass varies under dilations, whereas M is fixed).

As for the first step, the group $\mathcal{G}_0$ admits a one-parameter family of central extensions $\mathcal{G}^M$, indexed by $M>0$.[12,13] Writing a generic element of $\mathcal{G}^M$ as $g=(\theta,b,\mathbf{a};\mathbf{v};R)$, with $\theta\in\mathbb{R}$, the structure of $\mathcal{G}^M$ is defined by the multiplication law

$$
\begin{aligned}
gg' &= (\theta,b,\mathbf{a};\mathbf{v};R)(\theta',b',\mathbf{a}';\mathbf{v}';R') \\
&= (\theta+\theta'+\xi(g,g'),b+b',\mathbf{a}+b'\mathbf{v}+R\mathbf{a}';\mathbf{v}+R\mathbf{v}';RR'). \qquad (2.4)
\end{aligned}
$$

The quantity ξ: $\mathcal{G}_0\times\mathcal{G}_0\to\mathbb{R}$ is a *multiplier*, which up to equivalence (in the sense of cocycles), can be taken as

$$\xi(g,g')=M[\mathbf{v}\cdot R\mathbf{a}'+\tfrac{1}{2}b'\mathbf{v}^2],\quad M=\text{const}>0. \qquad (2.5)$$

Next we introduce separate space ($a\equiv e^{\sigma}$) and time ($a_0\equiv e^{\tau}$) dilations, corresponding to the following action on space–time, which replaces (2.2),

$$\mathbf{x}'=e^{\sigma}R\mathbf{x}+e^{\tau}\mathbf{v}t+\mathbf{a},\quad t'=e^{\tau}t+b,\quad \sigma,\tau\in\mathbb{R}. \qquad (2.6)$$

Then the multiplication law of $\mathcal{G}^M_{\text{aff}}$ reads, with $g\equiv(\theta,b,\mathbf{a};\mathbf{v};R,\sigma,\tau)$,

$$
\begin{aligned}
gg' &= (\theta+e^{2\sigma-\tau}\theta'+M[e^{\sigma}\mathbf{v}\cdot R\mathbf{a}'+\tfrac{1}{2}e^{\tau}\mathbf{v}^2b'],b+e^{\tau}b',\mathbf{a}+e^{\tau}b'\mathbf{v}+e^{\sigma}R\mathbf{a}'; \\
&\times \mathbf{v}+e^{\sigma-\tau}R\mathbf{v}';RR',\sigma+\sigma',\tau+\tau'). \qquad (2.7)
\end{aligned}
$$

The inverse of an element $g\in\mathcal{G}^M_{\text{aff}}$ is given by

$$
\begin{aligned}
(\theta,b,\mathbf{a};\mathbf{v};R;\sigma,\tau)^{-1} &= (-e^{\tau-2\sigma}\theta+Me^{\tau-2\sigma}[\mathbf{v}\cdot\mathbf{a}-\tfrac{1}{2}b\mathbf{v}^2],-e^{-\tau}b,e^{-\sigma}R^{-1}(b\mathbf{v}-\mathbf{a}); \\
&-e^{\tau-\sigma}R^{-1}\mathbf{v};R^{-1},-\sigma,-\tau). \qquad (2.8)
\end{aligned}
$$

From this law, we note that $\mathcal{G}^M_{\text{aff}}$ is a semidirect product,

$$\mathcal{G}^M_{\text{aff}}=\mathcal{T}\rtimes(\mathcal{V}\rtimes(\mathrm{SO}(3)\times\mathbb{R}^2)), \qquad (2.9)$$

where $\mathcal{T}=\{(\theta,b,\mathbf{a};\mathbf{0};I,0,0)\}\sim\mathbb{R}^5$ and $\mathcal{V}=\{(0,0,\mathbf{0};\mathbf{v};I,0,0)\}\sim\mathbb{R}^3$ are two Abelian subgroups of $\mathcal{G}^M_{\text{aff}}$.

In addition, the center of $\mathcal{G}^M_{\text{aff}}$ is trivial, which shows indeed that the latter cannot be a central extension. However, it is in fact an extension of $\mathcal{G}_0\rtimes\mathcal{D}_2$, but a noncentral one.

B. Orbits under $\mathcal{V}\rtimes(\mathrm{SO}(3)\times\mathbb{R}^2)$ in $\mathcal{T}^*$

Since $\mathcal{G}^M_{\text{aff}}$ is a semidirect product of the form $G=\mathcal{T}\rtimes H$, with $\mathcal{T}$ Abelian and $H=\mathcal{V}\rtimes(\mathrm{SO}(3)\times\mathbb{R}^2)$, its unitary irreducible representations (UIR) may be constructed by the Mackey method of induced representations. As described in Appendix B, the first step of the scheme is to compute the orbits under H in $\mathcal{T}^*$, the dual of $\mathcal{T}$.

According to (2.7), the action of $(\mathbf{v};R,\sigma,\tau)\in\mathcal{V}\rtimes(\mathrm{SO}(3)\times\mathbb{R}^2)$ on the element $(\theta,b,\mathbf{a})\in\mathcal{T}$ is given by

$$(\mathbf{v};R,\sigma,\tau)(\theta,b,\mathbf{a})=(e^{2\sigma-\tau}\theta+M[e^{\sigma}\mathbf{v}\cdot R\mathbf{a}+\tfrac{1}{2}e^{\tau}b\mathbf{v}^2],e^{\tau}b,e^{\tau}b\mathbf{v}+e^{\sigma}R\mathbf{a}). \qquad (2.10)$$

Let us denote by $(q,E,\mathbf{p})$ the generic element of $\mathcal{T}^*$. The action of $(q,E,\mathbf{p})$ on $(\theta,b,\mathbf{a})$ is defined by

$$\langle q,E,\mathbf{p}|\theta,b,\mathbf{a}\rangle=q\theta+Eb-\mathbf{p}\cdot\mathbf{a}, \qquad (2.11)$$

where $\mathbf{p}\cdot\mathbf{a}$ denotes the Euclidean scalar product in $\mathbb{R}^3$. According to (B1) and (2.10), the action of $(\mathbf{v};R,\sigma,\tau)\in H$ on $(q,E,\mathbf{p})$ is defined by

$$\langle(\mathbf{v};R,\sigma,\tau)(\theta,b,\mathbf{a})|(q,E,\mathbf{p})\rangle=\langle(\theta,b,\mathbf{a})|(\mathbf{v};R,\sigma,\tau)^{-1}(q,E,\mathbf{p})\rangle. \tag{2.12}$$

A straightforward calculation then gives

$$(\mathbf{v};R,\sigma,\tau)(q,E,\mathbf{p})=(e^{\tau-2\sigma}q,e^{-\tau}E+e^{-\sigma}R\mathbf{p}\cdot\mathbf{v}+\tfrac{1}{2}qMe^{\tau-2\sigma}\mathbf{v}^2,e^{-\sigma}R\mathbf{p}+e^{\tau-2\sigma}qM\mathbf{v}). \tag{2.13}$$

These relations, which are a part of the coadjoint action of $\mathcal{G}_{\rm aff}^M$,[15] show that the real mass parameter is not M, but rather the combination qM, and it varies under dilations, as it should.

The determination of the orbits under $H=\mathcal{V}\rtimes(\mathrm{SO}(3)\times\mathbb{R}^2)$ in $\mathcal{T}^*$ is equivalent to solving the following problem. Given two elements $(q,E,\mathbf{p})$, $(q',E',\mathbf{p}')$ in $\mathcal{T}^*$, does there exist an element $(\mathbf{v};R,\sigma,\tau)$ in $\mathcal{V}\rtimes(\mathrm{SO}(3)\times\mathbb{R}^2)$ such that $(\mathbf{v};R,\sigma,\tau)(q,E,\mathbf{p})=(q',E',\mathbf{p}')$? From (2.13), answering this question amounts to solving the system

$$\begin{aligned} q'&=e^{\tau-2\sigma}q,\\ E'&=e^{-\tau}E+e^{-\sigma}\mathbf{v}\cdot R\mathbf{p}+\tfrac{1}{2}e^{\tau-2\sigma}qM\mathbf{v}^2,\\ \mathbf{p}'&=e^{-\sigma}R\mathbf{p}+e^{\tau-2\sigma}qM\mathbf{v}, \end{aligned} \tag{2.14}$$

in the unknown $(\mathbf{v};R,\sigma,\tau)$. From (2.14) it is clear that the sign of q is invariant on each orbit. Then a straightforward calculation yields

$$e^{\tau}=\frac{q'}{q}e^{2\sigma},\quad q\left(E-\frac{\mathbf{p}^2}{2qM}\right)=e^{2\sigma}q'\left(E'-\frac{\mathbf{p}'^2}{2q'M}\right),\quad \mathbf{v}=\frac{1}{q'M}(\mathbf{p}'-e^{-\sigma}R\mathbf{p}). \tag{2.15}$$

Therefore, the sign of $E-(\mathbf{p}^2/2qM)$ is also invariant on each orbit. All the elements $(q,E,\mathbf{p})$ such that $E-(\mathbf{p}^2/2qM)>0$ (resp. $E-(\mathbf{p}^2/2qM)<0$) are on the same orbit, which has the same dimension as $\mathcal{T}$, namely 5. Similarly, the elements $(q,E,\mathbf{p})$ such that $E-(\mathbf{p}^2/2qM)=0$ are on the same orbit, of dimension 4.

C. The UIR associated with the orbit $q>0$, $E-(\mathbf{p}^2/2qM)>0$

Let us consider in $\mathcal{T}^*$ the point $p_0\equiv(q_0,E_0,\mathbf{p}_0)=(1,1,\mathbf{0})$. The isotropy group of p_0 is SO(3). Thus the inducing subgroup is $\mathcal{K}=\mathcal{T}\rtimes\mathrm{SO}(3)$ and there is a one-to-one correspondence between $X\equiv\mathcal{G}_{\rm aff}^M/\mathcal{K}$ and the set $\{(e^{\tau-2\sigma},e^{-\tau}+\tfrac{1}{2}e^{\tau-2\sigma}M\mathbf{v}^2,e^{\tau-2\sigma}M\mathbf{v})\}$ with $(\mathbf{v};I,\sigma,\tau)\in\mathcal{V}\rtimes(\mathrm{SO}(3)\times\mathbb{R}^2)$.

Since the isotropy group of p_0 is SO(3), the element Λ_p defined in (B3), that is,

$$\Lambda_p p_0=p,\ \text{ with }\ p\equiv(q,E,\mathbf{p}), \tag{2.16}$$

may be taken in the form $\Lambda_p=(\mathbf{v};I,\sigma,\tau)$. Thus we obtain the system

$$q=e^{\tau-2\sigma},\ \ E=e^{-\tau}+\tfrac{1}{2}e^{\tau-2\sigma}M\mathbf{v}^2,\ \ \mathbf{p}=e^{\tau-2\sigma}M\mathbf{v}, \tag{2.17}$$

whose solution reads

$$\mathbf{v}=\frac{\mathbf{p}}{qM},\ \ \tau=-\ln\left(E-\frac{\mathbf{p}^2}{2qM}\right),\ \ \sigma=-\tfrac{1}{2}\ln q\left(E-\frac{\mathbf{p}^2}{2qM}\right). \tag{2.18}$$

In this way, we have defined a section s: $X\to\mathcal{G}_{\rm aff}^M$ as required in (B3). Let us consider the element $(a,\Lambda)^{-1}(0,\Lambda_p)$ and denote by $(0,\Lambda_{p'})$ the representative of its class (here we have put $a\equiv(\theta,b,\mathbf{a})\in\mathcal{T}$ and $\Lambda\equiv(\mathbf{v};R,\sigma,\tau)\in H$). A straightforward calculation then yields

$$(a,\Lambda)^{-1}(0,\Lambda_p)=(0,\Lambda_{p'})\cdot k, \tag{2.19}$$

with

$$k^{-1}=(\Lambda_p^{-1}a,I)(0,R), \tag{2.20}$$

and

$$\begin{aligned} p'\equiv(q',E',\mathbf{p}')=\Lambda^{-1}p=(\mathbf{v};R,\sigma,\tau)^{-1}p \\ =(e^{2\sigma-\tau}q,e^{\tau}[E-\mathbf{p}\cdot\mathbf{v}+\tfrac{1}{2}qM\mathbf{v}^2],e^{\sigma}R^{-1}[\mathbf{p}-qM\mathbf{v}]). \end{aligned} \tag{2.21}$$

We may define a UIR of $\mathcal{K}$ by

$$L(k^{-1})=e^{i\langle p_0|\Lambda_p^{-1}a\rangle}D_j(R)=e^{i\langle p|a\rangle}D_j(R) \tag{2.22}$$

with D_j a UIR of SO(3). From (2.21) it is easy to check that

$$dq'dE'd^3\mathbf{p}'=e^{5\sigma}dqdEd^3\mathbf{p}. \tag{2.23}$$

The representation (2.22) of $\mathcal{K}$ then induces a UIR of $\mathcal{G}_{\text{aff}}^M$ defined according to (B6) by the following formula:

$$\begin{aligned} (U_{++}(g)\psi)(\Lambda_p)\equiv(U_{++}(\theta,b,\mathbf{a};\mathbf{v};R,\sigma,\tau)\psi)(\Lambda_p) \\ =e^{i(q\theta+Eb-\mathbf{p}\cdot\mathbf{a})}e^{5\sigma/2}D_j(R)\psi(\Lambda_{p'}), \end{aligned} \tag{2.24}$$

with p' given by (2.21). The representation space of U_{++} is $\mathfrak{H}_L\simeq L^2(X_{++},dqdEd^3\mathbf{p};\mathfrak{H}_j)$, where $X_{++}=\{(q,E,\mathbf{p}):q>0,E-\mathbf{p}^2/2qM>0\}$ and $\mathfrak{H}_j$ is the representation space of D_j.

D. Square integrability of the representation U_{++}

The left invariant measure on $\mathcal{G}_{\text{aff}}^M$ is given by the formula

$$d\mu_l(g)=e^{3\tau-8\sigma}d\theta\ db\ d^3\mathbf{a}\ d^3\mathbf{v}\ dm(R)d\sigma d\tau,\quad g\equiv(\theta,b,\mathbf{a};\mathbf{v};R,\sigma,\tau), \tag{2.25}$$

with $dm(R)$ the usual invariant measure on SO(3). The square integrability condition (A2) is satisfied if there exists a nonzero $\psi\in\mathfrak{H}_L$ such that

$$d(\psi)\equiv\int_{\mathcal{G}_{\text{aff}}^M}|\langle U_{++}(g)\psi|\psi\rangle|^2d\mu_l(g)<\infty. \tag{2.26}$$

In the sequel we consider for SO(3) only the trivial, spin 0, representation $D_j=I$, the generalization to others being straightforward. The square integrability condition (2.28) then reads

$$\begin{aligned} 0<\int_{\mathcal{G}_{\text{aff}}^M}\left\{\int_{X_{++}}e^{5\sigma/2}e^{-i(q\theta+Eb-\mathbf{p}\cdot\mathbf{a})}\overline{\psi((\mathbf{v};R,\sigma,\tau)^{-1}(q,E,\mathbf{p}))}\psi(q,E,\mathbf{p})dqdEd^3\mathbf{p}\right\} \\ \times\left\{\int_{X_{++}}e^{5\sigma/2}e^{i(\hat{q}\theta+\hat{E}b-\hat{\mathbf{p}}\cdot\mathbf{a})}\psi((\mathbf{v};R,\sigma,\tau)^{-1}(\hat{q},\hat{E},\hat{\mathbf{p}}))\overline{\psi(\hat{q},\hat{E},\hat{\mathbf{p}})}d\hat{q}d\hat{E}d^3\hat{\mathbf{p}}\right\} \\ \times e^{3\tau-8\sigma}d\theta\ db\ d^3\mathbf{a}\ d^3\ \mathbf{v}dm(R)d\sigma d\tau<\infty. \end{aligned} \tag{2.27}$$

After integration over θ, b, $\mathbf{a}$, condition (2.27) reduces to

$$0<\int e^{3(\tau-\sigma)}|\psi(q,E,\mathbf{p})|^2|\psi((\mathbf{v};R,\sigma,\tau)^{-1}(q,E,\mathbf{p}))|^2dqdEd^3\mathbf{p}\ d^3\mathbf{v}\ d\sigma d\tau dm(R)<\infty, \tag{2.28}$$

and, since SO(3) is compact, (2.28) holds if

$$\int e^{3(\tau-\sigma)}|\psi(q,E,\mathbf{p})|^2|\psi((\mathbf{v};R,\sigma,\tau)^{-1}(q,E,\mathbf{p}))|^2 dq dE d^3\mathbf{p}\ d^3\mathbf{v}\ d\sigma d\tau<\infty. \tag{2.29}$$

For the analysis of (2.29), let us perform the coordinate transformation $(q,E,\mathbf{p})\mapsto(\boldsymbol{\xi},I,\eta,\zeta)\in\mathcal{V}\rtimes(\mathrm{SO}(3)\times\mathbb{R}^2$ defined by

$$(q,E,\mathbf{p})=(\boldsymbol{\xi};I,\eta,\zeta)(1,1,\mathbf{0})=(e^{\zeta-2\eta},e^{-\zeta}+\tfrac{1}{2}Me^{\zeta-2\eta}\boldsymbol{\xi}^2,e^{\zeta-2\eta}M\boldsymbol{\xi}). \tag{2.30}$$

Since $(\mathbf{v};R,\sigma,\tau)^{-1}(\boldsymbol{\xi};I,\eta,\zeta)=(e^{\zeta-\eta}R^{-1}(\mathbf{v}-\boldsymbol{\xi});I,\sigma-\eta,\tau-\zeta)^{-1}(\mathbf{0};R^{-1},0,0)$, we may also define new coordinates $\mathbf{v}'$, σ', τ' by the formula

$$(e^{\zeta-\eta}R^{-1}(\mathbf{v}-\boldsymbol{\xi});I,\sigma-\eta,\tau-\zeta)^{-1}(\mathbf{0};R,0,0)^{-1}=(\mathbf{v}';I,\sigma',\tau')(\mathbf{0};R^{-1},0,0). \tag{2.31}$$

Taking inverses, we can write (2.31) in the form

$$e^{\zeta-\eta}(\mathbf{v}-\boldsymbol{\xi})=-e^{\tau'-\sigma'}\mathbf{v}',\quad \sigma=-\sigma'+\eta,\quad \tau=-\tau'+\zeta. \tag{2.32}$$

From the coordinate transformations defined by (2.30) and (2.32), we deduce directly

$$dq dE d^3\mathbf{p}=2M^3e^{3\zeta-8\eta}d\eta\ d\zeta\ d^3\boldsymbol{\xi}, \tag{2.33}$$

$$e^{3(\tau-\sigma)}d^3\mathbf{v}d\sigma d\tau=d^3\mathbf{v}'d\sigma'd\tau'. \tag{2.34}$$

The square integrability condition (2.29) then reads

$$\int e^{3\tau-8\eta}|\tilde{\psi}(\boldsymbol{\xi},\eta,\zeta)|^2 d^3\boldsymbol{\xi}\ d\eta\ d\zeta\int|\tilde{\psi}(\mathbf{v},\sigma,\tau)|^2 d^3\mathbf{v}\ d\sigma d\tau<\infty, \tag{2.35}$$

where we have written $\tilde{\psi}(\boldsymbol{\xi},\eta,\zeta)\equiv\psi(q,E,\mathbf{p})=\psi((\boldsymbol{\xi};I,\eta,\zeta)(1,1,\mathbf{0}))$. More generally, the square integrability condition

$$d(\psi,\phi)\equiv\int_{\mathcal{G}_{\mathrm{aff}}^M}|\langle U_{++}(g)\psi|\phi\rangle|^2 d\mu_l(g)<\infty,\quad \forall\phi\in\mathfrak{H}_L \tag{2.36}$$

is easily shown, using (2.33) and (2.18) again, to be equivalent to

$$d(\psi,\phi)\sim\|\phi\|^2\int|\tilde{\psi}(\mathbf{v};\sigma,\tau)|^2 d^3\mathbf{v}d\sigma d\tau=\|\phi\|^2\int_{X_{++}}\frac{|\psi(q,E,\mathbf{p})|^2}{q^4\left(E-\dfrac{\mathbf{p}^2}{2qM}\right)}dq dE d^3\mathbf{p}<\infty,\quad\forall\phi\in\mathfrak{H}_L. \tag{2.37}$$

There is obviously a dense set of functions ψ satisfying this condition, so that we obtain the following:

Proposition 1: The representation U_{++} defined by (2.26) is square integrable over the group $\mathcal{G}_{\mathrm{aff}}^M$, a vector $\psi\in\mathfrak{h}_L$ being admissible iff the last integral in (2.37) converges.

Of course, the same property holds for the irreducible representations associated to the other five-dimensional orbits, corresponding to $(E-(\mathbf{p}^2/2qM))<0$ and/or $q<0$. Since these are all the orbits which have nonzero Lebesgue measure in $\mathcal{T}^*$, we could have inferred the result from the general study of square integrability made by Aniello *et al.*[16] We refer the reader to the forthcoming monograph, Ref. 4, for a systematic analysis.

E. Galilean wavelets

According to Proposition 1, any admissible vector $\eta \in \mathfrak{H}_L$ generates a tight frame of Galilean wavelets, indexed by $\mathcal{G}_{\rm aff}^M$ itself and defined, as usual (see Appendix A) by $\eta_g = U_{++}(g)\eta$, $g \in \mathcal{G}_{\rm aff}^M$, with the expression (2.24) for the representation. These are of course CS of the Gilmore–Perelomov-type.

In addition, it is possible to construct sets of wavelets indexed by fewer parameters by taking quotients $Y=\mathcal{G}_{\rm aff}^M/K$ by various closed subgroups K and appropriate sections $s:Y\to\mathcal{G}_{\rm aff}^M$. The simplest example is obtained if we take for K the subgroup $\mathcal{T}_0 \simeq \mathbb{R}$ of time dilations $e^{-\tau}$. The corresponding coset space $Y=\mathcal{G}_{\rm aff}^M/\mathcal{T}_0$ is parametrized by points $y=(\theta,b,\mathbf{a};\mathbf{v};R,\sigma)$. We consider first the basic or Galilean section $s_0:Y\to\mathcal{G}_{\rm aff}^M$,

$$s_0(y)=(\theta,b,\mathbf{a};\mathbf{v};R,\sigma,0). \tag{2.38}$$

A straightforward calculation shows that the admissibility condition (A11) reduces to setting $E-(\mathbf{p}^2/2qM)=1$ (or a constant different from 0) in the integral (2.37), that is, a vector $\eta\in\mathfrak{H}_L$ is admissible mod$(\mathcal{T}_0,s_0)$ iff the following integral converges:

$$\int\int_{q>0} q^{-4}\left|\eta\left(q,1+\frac{\mathbf{p}^2}{2qM},\mathbf{p}\right)\right|^2 dq\,d^3\mathbf{p}<\infty. \tag{2.39}$$

We consider now a general section,

$$s_\beta(y)=s_0(y)(0,0,\mathbf{0};\mathbf{0};I;0,\beta(y))=(\theta,b,\mathbf{a};\mathbf{v};R,\sigma,\beta(y)), \tag{2.40}$$

where $\beta:Y\to\mathcal{T}_0\equiv\mathbb{R}$ is a Borel function and $\beta(y)\in\mathcal{T}_0$ represents a time dilation. Again this corresponds to a relation between the variables $(q,E,\mathbf{p})$, which may conveniently be written as $f_\beta(q,E,\mathbf{p})=0$. Thus the admissibility condition mod$(\mathcal{T}_0,s_\beta)$ reads

$$\int_{X_{++}} \frac{|\eta(q,E,\mathbf{p})|^2}{q^4\left(E-\dfrac{\mathbf{p}^2}{2qM}\right)}\,\delta(f_\beta(q,E,\mathbf{p}))\,dq\,dE\,d^3\mathbf{p}<\infty. \tag{2.41}$$

For any such admissible vector η, one obtains a dense set of CS, indexed by $Y=\mathcal{G}_{\rm aff}^M/\mathcal{T}_0$ and given by $\eta_{s_\beta(y)}=U_{++}(s_\beta(y))\eta$, where $U_{++}(s_\beta(y))$ is the representation (2.24) with τ replaced by $\beta(y)$ in (2.21). Of course, for $\beta(y)\equiv 0$, one recovers the Galilean section s_0.

An interesting example is given by $\beta(y)=2\sigma$, i.e., the Schrödinger case. The corresponding constraint relation is simply $q=1$, so that we get the admissibility condition,

$$\int\int_{E-\mathbf{p}^2/2M>0} \frac{|\eta(1,E,\mathbf{p})|^2}{E-\dfrac{\mathbf{p}^2}{2M}}\,dE\,d^3\mathbf{p}<\infty. \tag{2.42}$$

Notice that the q-integration has disappeared in (2.42), because inserting the factor $\delta(q-1)$ in (2.41) is equivalent to quotienting out the subgroup Θ of phase factors, in addition to $\mathcal{T}_0$. We will study this example in detail in the next section.

III. PROJECTIVE REPRESENTATIONS OF THE SCHRÖDINGER GROUP

Another possibility is to impose from the beginning the relation $\tau=2\sigma$, that is, to start from the Galilei–Schrödinger group $\mathcal{G}_S=\mathcal{G}_0\rtimes\mathcal{D}_S$, where $\mathcal{D}_S$ is the corresponding one-dimensional subgroup of $\mathcal{D}_2$, and then to construct projective representations of it, that is, to determine central extensions $\mathcal{G}_S^M$ of $\mathcal{G}_S$ by $\mathbb{R}$. The motivation for this restriction is that $\mathcal{G}_S$ is a natural invariance group of both the Schrödinger and the heat equations[5,6] (the full invariance group, called the

Schrödinger group, contains in addition the so-called *expansions*, the nonrelativistic analogs of pure conformal transformations). This restriction leads to several drastic modifications with respect to the case of $\mathcal{G}_{\text{aff}}^M$.

The group law of $\mathcal{G}_S^M$ reads

$$(\theta,b,\mathbf{a};\mathbf{v};R,\sigma)(\theta',b',\mathbf{a}';\mathbf{v}';R',\sigma') = (\theta+\theta'+M[e^{\sigma}\mathbf{v}\cdot R\mathbf{a}'+\tfrac{1}{2}e^{2\sigma}\mathbf{v}^2],b+e^{2\sigma}b', \mathbf{a}+e^{2\sigma}b'\mathbf{v}+e^{\sigma}R\mathbf{a}';\mathbf{v}+e^{\sigma}R\mathbf{v}';RR',\sigma+\sigma'). \tag{3.1}$$

As a consequence, $\mathcal{G}_S^M$ has a nontrivial center, namely the one-dimensional subgroup Θ of phase factors, isomorphic to $\mathbb{R}$. The group $\mathcal{G}_S^M$ is a semidirect product, with structure $\mathcal{G}_S^M = \mathcal{T}\rtimes(\mathcal{V}\rtimes \mathrm{SO}(3)\times\mathbb{R})$.

As shown in Appendix C, the extended Galilei–Schrödinger group $\mathcal{G}_S^M$ coincides with the subgroup of $\mathcal{G}_{\text{aff}}^M$ defined by the equation $\tau=2\sigma$. Therefore, $\mathcal{G}_S^M$ is also a semidirect product of $\mathcal{G}^M$ by $\mathcal{D}_S$, and we have, with $\lhd_M$ denoting a central extension with parameter M,

$$\mathcal{G}_S^M = \mathbb{R}\lhd_M\mathcal{G}_S \equiv \mathbb{R}\lhd_M(\mathcal{G}_0\rtimes\mathcal{D}_S) = \mathcal{G}^M\rtimes\mathcal{D}_S \equiv (\mathbb{R}\lhd_M\mathcal{G}_0)\rtimes\mathcal{D}_S\,.$$

Thus, in the Schrödinger case, the two operations $\lhd_M$ and $\rtimes$ commute.

Next we proceed with the construction of the induced UIRs of $\mathcal{G}_S^M$, exactly as in the previous sections. According to (2.15), the automorphisms induced in $\mathcal{T}^*$ by $\mathcal{V}\rtimes(\mathrm{SO}(3)\times\mathbb{R})$ are given by

$$(\mathbf{v};R,\sigma)(q,E,\mathbf{p}) = (q,e^{-2\sigma}E+e^{-\sigma}\mathbf{v}\cdot R\mathbf{p}+\tfrac{1}{2}qM\mathbf{v}^2,e^{-\sigma}R\mathbf{p}+qM\mathbf{v}). \tag{3.2}$$

Thus q is a constant on each orbit. Let us fix $q=q_0>0$. Then we have three cases to analyze,

$$E-\frac{\mathbf{p}^2}{2q_0M}<0,\quad E-\frac{\mathbf{p}^2}{2q_0M}=0,\quad E-\frac{\mathbf{p}^2}{2q_0M}>0, \tag{3.3}$$

the first and the last ones corresponding to generic orbits, the second one to a degenerate, lower dimensional orbit. As before, we consider only the last case.

It is easy to check that all the points $(E,\mathbf{p})$ such that $E-(\mathbf{p}^2/2q_0M)>0$ are equivalent to the point $(1,\mathbf{0})$, whose isotropy group is SO(3). The inducing group is then $K=\mathcal{T}\rtimes SO(3)$. The section $s:X=\mathcal{G}_S^M/K\to\mathcal{G}_S^M$ is defined as for $\mathcal{G}_{\text{aff}}^M$ and we obtain the following UIR of $\mathcal{G}_S^M$:

$$(U_+^{(q_0)}(\theta,b,\mathbf{a};\mathbf{v};R,\sigma)\psi)(E,\mathbf{p}) = e^{5\sigma/2}e^{i(q_0\theta+Eb-\mathbf{p}\cdot\mathbf{a})}D_j(R)\,\psi((\mathbf{v};R,\sigma)^{-1}(E,\mathbf{p})), \tag{3.4}$$

with D_j a UIR of SO(3) and

$$(\mathbf{v};R,\sigma)^{-1}(E,\mathbf{p}) = (e^{2\sigma}[E-\mathbf{p}\cdot\mathbf{v}+\tfrac{1}{2}q_0M\mathbf{v}^2],e^{\sigma}R^{-1}[\mathbf{p}-q_0M\mathbf{v}]). \tag{3.5}$$

The representation space of $U_+^{(q_0)}$ is $\mathfrak{H}_L^{(q_0)}\simeq L^2(X_+^{(q_0)},dE\,d^3\mathbf{p};\mathfrak{H}_j)$, where $X_+^{(q_0)}=\{(E,\mathbf{p}): E-\mathbf{p}^2/2q_0M>0\}$ and $\mathfrak{H}_j$ is the representation space of D_j.

For the purpose of the analysis of the square integrability of the representation (3.3), we consider again the trivial, spin zero, representation D_0 of SO(3). From (2.25), the left invariant measure on $\mathcal{G}_S^M$ is

$$d\mu_l(g) = e^{-2\sigma}d\theta\;\;db\;\;d^3\mathbf{a}\;\;d^3\mathbf{v}\;\;dm(R)\,d\sigma,\quad g\equiv(\theta,b,\mathbf{a};\mathbf{v};R,\sigma), \tag{3.6}$$

with $dm(R)$ the usual invariant measure on SO(3). Of course, the representation $U_+^{(q_0)}$ cannot be square integrable on the whole group $\mathcal{G}_S^M$, since the center $\Theta\simeq\mathbb{R}$ of the latter is noncompact. Thus we consider the square integrability on the quotient $Y=\mathcal{G}_S^M/\Theta$. We define a section $s:Y\to\mathcal{G}_S^M$ as follows:

$$s(b,\mathbf{a};\mathbf{v};R,\sigma)=(0,b,\mathbf{a};\mathbf{v};R,\sigma). \tag{3.7}$$

The square integrability mod(Θ,s) amounts to

$$\int |\psi(E,\mathbf{p})|^2 |\psi((\mathbf{v};R,\sigma)^{-1}(E,\mathbf{p}))|^2 e^{3\sigma} dE d^3\mathbf{p} \ \ d^3\mathbf{v} \ \ d\sigma<\infty. \tag{3.8}$$

In order to verify the validity of this relation, we proceed exactly as in Sec. D above. First, we perform the following coordinate transformation $(E,\mathbf{p})\mapsto(\boldsymbol{\xi},I,\eta)$ defined by

$$(E,\mathbf{p})=(\boldsymbol{\xi},I,\eta)(1,\mathbf{0})=(e^{-2\eta}+\tfrac{1}{2}q_0M\boldsymbol{\xi}^2,q_0M\boldsymbol{\xi}). \tag{3.9}$$

Since $(\mathbf{v};R,\sigma)^{-1}(\boldsymbol{\xi},I,\eta)=(e^{\eta}R^{-1}[\mathbf{v}-\boldsymbol{\xi}],I,\sigma-\eta)^{-1}(\mathbf{0},R,0)^{-1}$, we may also define new coordinates by the formula

$$(e^{\eta}R^{-1}[\mathbf{v}-\boldsymbol{\xi}],I,\sigma-\eta)^{-1}(\mathbf{0},R,0)^{-1}=(\mathbf{v}',I,\sigma')(\mathbf{0},R,0)^{-1}, \tag{3.10}$$

or, equivalently,

$$e^{\eta}(\mathbf{v}-\boldsymbol{\xi})=-e^{\sigma'}R\mathbf{v}', \quad \sigma'=-\sigma+\eta. \tag{3.11}$$

From the coordinate transformations (3.9) and (3.11), we deduce

$$dE d^3\mathbf{p}=2M^3e^{-2\eta}d\eta d^3\boldsymbol{\xi}, \ \ e^{3\sigma}d^3\mathbf{v} \ \ d\sigma=d^3\mathbf{v}'d\sigma'. \tag{3.12}$$

The square integrability condition (3.8) then reads

$$\|\psi\|^2\int |\tilde{\psi}(\mathbf{v};\sigma)|^2 d^3\mathbf{v} \ \ d\sigma=\frac{\|\psi\|^2}{q_0^4}\int_{X_+^{(q_0)}} \frac{|\psi(E,\mathbf{p})|^2}{E-\dfrac{\mathbf{p}^2}{2q_0M}} dE d^3\mathbf{p}<\infty. \tag{3.13}$$

In conclusion, we may state

Proposition 2: The representation $U_+^{(q_0)}$ defined by (3.4) is square integrable over the group $\mathcal{G}_S^M$ modulo its center Θ, the phase subgroup, and the section s given in (3.7), a vector $\psi \in \mathfrak{H}_L^{(q_0)}$ being admissible iff the integral in (3.13) converges.

A similar result may be obtained for the $(n+1)$-dimensional Schrödinger group, for any $n \geqslant 1$.

Clearly there is a dense set of admissible vectors ψ, and each of them generates a tight frame of CS, of the Gilmore–Perelomov-type. Typical wavelets of this kind are, for instance, in space–time:

(a) the Schrödinger–Marr wavelet,

$$\check{\psi}_{\mathrm{SM}}(\mathbf{x},t)=\left(i\partial_t+\frac{\Delta}{2m}\right)e^{-(\mathbf{x}^2+t^2)/2};$$

(b) the Schrödinger–Cauchy wavelet,

$$\check{\psi}_{\mathrm{SC}}(\mathbf{x},t)=\left(i\partial_t+\frac{\Delta}{2m}\right)\frac{1}{(t+i)\Pi_{j=1}^3(x_j+i)}.$$

Here we have put $m=q_0M$, so that m is the true mass, as it appears in the Schrödinger equation, as observed in Ref. 13. Preliminary numerical analysis of these functions reveal a rather complicated structure. Yet the wavelet transform they generate is, by construction, well adapted to quantum situations governed by the Schrödinger equation, and one may hope that they will prove useful in problems such as the description of Rydberg states in atomic physics, or in the description of laser–atom interactions.

Our last remark is to make the connection between the analysis of the extended Galilei–Schrödinger group $\mathcal{G}_S^M$ and the special subgroup discussed at the end of Sec. E. Mathematically, imposing the constraint $q=1$ in (2.41), inserting a factor $\delta(q-1)$, is equivalent to quotienting out the subgroup Θ. In technical terms, the original representation space $\mathfrak{H}_L \simeq L^2(X_{++}, dq\,dE\,d^3\mathbf{p};\mathfrak{H}_j)$ is a direct integral over q,

$$\mathfrak{H}_L = \int_{q>0}^{\oplus} \mathfrak{H}_L^{(q)} dq, \tag{3.14}$$

and we are taking the restriction to a single component, corresponding to $q=1$, or, more generally, $q=q_0$. As a result, the phase factor in $U_+^{(q_0)}$ is trivial, and may be factored out, exactly as for the Weyl–Heisenberg group.

We also note, in conclusion, that the same analysis may be done for the other nondegenerate orbit, corresponding to $E-(\mathbf{p}^2/2q_0M)<0$. One gets another UIR of $\mathcal{G}_S^M$, called $U_-^{(q_0)}$, and acting in the Hilbert space $\mathfrak{H}_{L-}^{(q_0)} \equiv L^2(X_-^{(q_0)}, dE\,d^3\mathbf{p};\mathfrak{H}_j)$. The two spaces $\mathfrak{H}_{L\pm}^{(q_0)} \equiv L^2(X_\pm^{(q_0)}, dE\,d^3\mathbf{p};\mathfrak{H}_j)$ deserve to be called Schrödinger–Hardy spaces, because they are the genuine analogs of the usual Hardy spaces on $\mathbb{R}$, i.e., the subspaces of progressive, resp. antiprogressive, wavelets.

ACKNOWLEDGMENTS

During the early stages of this work, we enjoyed the collaboration of C. Kalisa and M. N. Hounkonnou. In addition we benefited from interesting discussions with S. T. Ali and R. Murenzi, and some of the calculations have been checked and corrected by St. Liénart. It is a pleasure to thank them all.

APPENDIX A: GROUP RELATED COHERENT STATES: A GENERAL FORMALISM

In this section, we present a quick survey of the main results of the coherent state formalism. Besides the standard texts such as Ref. 17 or Ref. 18, a systematic discussion may be found in the review paper, Ref. 3, or the original papers.[1,2]

1. Coherent states on a locally compact group

Let G be a locally compact group, dg the left invariant Haar measure on G and $g \mapsto U(g)$ a continuous, unitary irreducible representation of G in a Hilbert space $\mathfrak{H}$.

A vector $\eta \in \mathfrak{H}$ is said to be *admissible* if

$$d(\eta) = \int_G |\langle U(g)\eta|\eta\rangle|^2 dg < \infty, \tag{A1}$$

or, equivalently, if

$$0 < \int_G |\langle U(g)\eta|\phi\rangle|^2 dg < \infty, \quad \forall \phi \in \mathfrak{H}. \tag{A2}$$

Let $\mathcal{A}$ be the set of all admissible vectors in $\mathfrak{H}$. If $\mathcal{A} \neq \{0\}$, then it is dense in $\mathfrak{H}$. In particular, $\mathcal{A} = \mathfrak{H}$ if and only if G is unimodular, i.e., it has a Haar measure which is both left and right invariant. If $\mathcal{A} \neq \{0\}$, the representation U of G in $\mathfrak{H}$ is said to be *square integrable*. The positive constant $d(\eta)$ is often called the formal dimension of U.

Let $\eta \in \mathcal{A}$ be fixed. Then the map $W_\eta : \mathfrak{H} \to L^2(G, dg)$, defined by

$$(W_\eta \phi)(g) = d(\eta)^{1/2} \langle U(g)\eta|\phi\rangle, \quad \phi \in \mathfrak{H}, \tag{A3}$$

is isometric. Equivalently, the vectors $\eta_g \equiv U(g)\eta$ generate a a resolution of the identity

$$d(\eta)^{-1}\int_G |\eta_g\rangle\langle\eta_g| dg = I_{\mathfrak{H}}, \tag{A4}$$

where $I_{\mathfrak{H}}$ is the identity operator in $\mathfrak{H}$. Then the orbit $\mathcal{S}(\eta)=\{\eta_g\equiv U(g)\eta, g\in G\}$ of η under the action of G is an overcomplete family of vectors in $\mathfrak{H}$, indexed by the points of G. These vectors are called *coherent states* (CS) associated with the representation U and the map W_η the *coherent state map*, or the *wavelet transform*.[3]

In addition, the map W_η intertwines U with the left regular representation U_L of G,

$$W_\eta U(g)=U_L(g)W_\eta, \quad \forall g\in G. \tag{A5}$$

This means that every square integrable representation is unitarily equivalent to a subrepresentation of the left regular representation of G. The set of UIR's with this property is called the *discrete series* of representations of G, since they correspond to the discrete (or atomic) part of the Plancherel measure that governs the decomposition of the left regular representation into irreducible components. However, the square integrability property itself is sometimes taken as a definition of the discrete series representations. For further information, see, for instance, Ref. 19.

The isometry property of W_η has interesting consequences.

(1) The range $\mathfrak{H}_\eta$ of W_η is a closed subspace of $L^2(G,dg)$. Denote by P_η the corresponding projection operator, $\mathfrak{H}_\eta = W_\eta\mathfrak{H} = P_\eta L^2(G,dg)$, with

$$W_\eta W_\eta^* = P_\eta, \quad W_\eta^* W_\eta = I_{\mathfrak{H}}. \tag{A6}$$

Then the projection operator P_η is an integral operator, with kernel $K_\eta : G\times G\to\mathbb{C}$ given by $K_\eta(g,g')=d(\eta)^{-1}\langle\eta_g|\eta_{g'}\rangle$, that is,

$$(P_\eta\phi)(g)=\int_G K(g,g')\phi(g')dg', \quad \forall\phi\in L^2(G,dg). \tag{A7}$$

(2) Since $P_\eta = P_\eta^2$, the kernel satisfies the relation

$$K_\eta(g,g')=\int_G K_\eta(g,g'')K_\eta(g'',g')dg''. \tag{A8}$$

In particular, Eq. (A8) gives the reproducing property of the kernel K_η,

$$\phi_\eta(g)=\int_G K_\eta(g,g')\phi_\eta(g')dg', \quad \forall g\in G, \quad \forall\phi_\eta\in\mathfrak{H}_\eta. \tag{A9}$$

Thus K_η is called a *reproducing kernel* and the space $\mathfrak{H}_\eta$ is called a reproducing kernel Hilbert space.

(3) Finally, again by the isometry property (A6), the map W_η may be inverted on its range by the adjoint operator, and one obtains a *reconstruction formula*,

$$W_\eta^{-1}\Phi = \int_G \Phi(g)\,\eta_g dg, \quad \Phi\in\mathfrak{H}_\eta. \tag{A10}$$

Typical examples of square integrable representations are the natural representations of the (connected) affine groups of the line or the plane, namely, the ''$ax+b$'' group (translations and dilations of $\mathbb{R}$) and the similitude group of the plane, $\mathrm{SIM}(2)=\mathbb{R}^2\rtimes(\mathbb{R}_*^+\times\mathrm{SO}(2))$ (translations, dilations, and rotations of $\mathbb{R}^2$). The corresponding coherent states are the familiar *wavelets*, in one and two dimensions, respectively.

2. Generalization: CS on homogeneous spaces

However, most continuous UIRs of G are not square integrable. For instance, there is none if the center of G is noncompact or, more generally, if G has no discrete series, like the Poincaré group. Moreover, it might be desirable to have a family of coherent states which are not indexed by the points of G itself, but rather by the points of some homogeneous space $X=G/H$, where H is a closed subgroup of G. A typical example is $H=H_\eta$, the isotropy subgroup (up to a phase) of η: this is the familiar case of the Gilmore–Perelomov coherent states.[18,20,21]

In all such cases, one may recover most of the previous theory under additional conditions, as follows. Let U be a UIR of G on a Hilbert space $\mathfrak{H}$, ν be a (quasi-)invariant measure on $X=G/H$ and $\sigma:X\to G$ a Borel section. The representation U is then said to be *square integrable mod* (H,σ) if there exists a nonzero $\eta\in\mathfrak{H}$ such that

$$0<\int_X |\langle U(\sigma(x))\eta|\phi\rangle|^2 d\nu(x)=\langle\phi|A_\sigma\phi\rangle<\infty,\quad \forall\phi\in\mathfrak{H}, \tag{A11}$$

where A_σ is a bounded invertible operator. For such a vector η, which is said to be admissible mod(H,σ), one defines as *(covariant) coherent states* the vectors $\eta_{\sigma(x)}=U(\sigma(x))\eta$, $x\in X$. In this way one obtains a total set $\mathcal{S}_\sigma=\mathcal{S}_\sigma(\eta)$ of vectors in $\mathfrak{H}$, indexed by the points of X.

If the inverse operator A_σ^{-1} is also bounded, the set $\mathcal{S}_\sigma$ is called a *frame*, and a *tight frame* if A_σ is a multiple of the identity, $A_\sigma=\lambda I_{\mathfrak{H}}$. This terminology is borrowed from the theory of nonorthogonal expansions,[22,23] to which the present construction reduces in the where X is a purely discrete space, with ν a counting measure.

The covariant coherent states have essentially the same properties as the ordinary ones. Assume for simplicity that we have a frame and that the measure ν is invariant. Then one has successively

(1) *A coherent state map* W_η: $\mathfrak{H}\to L^2(X,d\nu)$, given by

$$\phi\mapsto(W_\eta\phi)(x)=\langle\eta_{\sigma(x)}|\phi\rangle. \tag{A12}$$

Then $\mathfrak{H}_\eta=\mathrm{Ran}\,W_\eta$ is complete with respect to the scalar product $\langle\Phi|\Psi\rangle_\eta\equiv\langle\Phi|W_\eta A_\sigma^{-1}W_\eta^{-1}\Psi\rangle$, and W_η: $\mathfrak{H}\to\mathfrak{H}_\eta$ is an isometry.

(2) *A resolution of the frame operator* A_σ:

$$\int_X |\eta_{\sigma(x)}\rangle\langle\eta_{\sigma(x)}|d\nu(x)=A_\sigma. \tag{A13}$$

(3) *A reproducing kernel:* The orthogonal projector $P_\eta:L^2(X,d\nu)\to\mathfrak{H}_\eta$ is an integral operator K_σ with reproducing kernel $K_\sigma(x,y)=\langle\eta_{\sigma(x)}|A_\sigma^{-1}\eta_{\sigma(y)}\rangle$.

(4) *A reconstruction formula:* W_η is invertible on its range and

$$W_\eta^{-1}\Phi=\int_X \Phi(x)A_\sigma^{-1}\eta_{\sigma(x)}d\nu(x),\quad \Phi\in\mathfrak{H}_\eta. \tag{A14}$$

This general construction encompasses, of course, the standard Gilmore–Perelomov CS, such as[18,20,21]

(a) CS of semisimple groups, such as SU(2), which yields spin CS, SU(1,1), used for defining path integrals, or SO(3,2) and Sp(4,$\mathbb{R}$), familiar in nuclear physics.

(b) The Weyl–Heisenberg group G_{WH}, which yields the canonical (oscillator) CS (here H is the center of G_{WH}); the map W_η is called the Windowed Fourier Transform or Gabor Transform.

(c) The similitude group SIM(n) of $\mathbb{R}^n(n\geqslant 3)$: for $H=\mathrm{SO}(n-1)$, one gets the axisymmetric n-dimensional wavelets.

In addition, it yields CS for many groups which have no square integrable representations, and are thus inaccessible to the Gilmore–Perelomov method. A notable example is that of the relativity groups, such as the Euclidean, the Galilei or the Poincaré groups, or more generally, the semidirect product $G=V\rtimes S$ of a vector space V by a semisimple group S of automorphisms of V. In that case, one usually takes for $X=G/H$ a coadjoint orbit of G, i.e., a natural phase space for the system at hand. It follows that $H\neq H_\eta$, for any η, since H contains translations. Thus it is imperative to use the general construction in order to get CS.[2,3]

The interesting point is that, when one combines these groups with dilations, thus getting the corresponding affine groups, square integrability is often regained. This is true in the Poincaré case, as shown by Unterberger[10] and Bohnké.[9] It is also true for the (extended) Galilei group, as shown in this paper. But it is *not* true in the Weyl–Heisenberg case; the affine Weyl–Heisenberg group has no square integrable representations, and one has to go to appropriate homogeneous spaces.[24]

APPENDIX B: THE MACKEY METHOD OF INDUCED REPRESENTATIONS

For the convenience of the reader, we recall briefly in this Appendix the essential points of the Mackey method of induced representations. Let G be a Lie group of the form $G=\mathcal{T}\rtimes H$, a semidirect product of the Abelian group $\mathcal{T}\sim\mathbb{R}^n$ $(n>0)$ with the semisimple group H. We denote by $\mathcal{T}^*$ the dual of $\mathcal{T}$ and by $\langle x|a\rangle$ the action of the element $x\in\mathcal{T}^*$ on the element $a\in\mathcal{T}$. Every element $h\in H$ induces an automorphism in $\mathcal{T}$, and thus by duality induces the automorphism in $\mathcal{T}^*$ defined as follows:

$$\langle hx|a\rangle=\langle x|h^{-1}a\rangle,\quad \forall(a,x)\in\mathcal{T}\times\mathcal{T}^*. \tag{B1}$$

The unitary irreducible representations of $\mathcal{T}$ are one-dimensional, that is, characters, and are given by

$$\chi_{x_0}(a)=\exp\, i\langle x_0|a\rangle,\quad \forall a\in\mathcal{T}, \tag{B2}$$

with x_0 a fixed element of $\mathcal{T}^*$. Given $x_0\in\mathcal{T}^*$, let $H_0\subset H$ be its isotropy subgroup, $K=\mathcal{T}\rtimes H_0$ and $X=G/K\simeq H/H_0$. Then there is a one-to-one correspondence between X and the set Hx_0, and we may define a section

$$s:X\to G:s(x)=(0,\Lambda_x),\quad \text{where}\ \ \Lambda_x x_0=x. \tag{B3}$$

Let L be the UIR of K which coincides with χ_{x_0} on $\mathcal{T}$ and with the UIR D of H_0 on H_0. Then the Hilbert space $\mathfrak{H}_L$ of the UIR of G induced by L is defined as follows.

We consider functions f defined on G with values in $\mathfrak{K}_L$, the Hilbert space of the representation L, and satisfying the following covariance property:

$$f(gk)=L(k^{-1})f(g),\quad g\in G,\quad k\in K. \tag{B4}$$

Therefore, f is completely determined if we define its value for an arbitrary element of every left coset modulo K. Since left cosets are labeled by elements of Hx_0 according to (B3), we may choose a quasi-invariant measure $d\mu(x)$ on $X=G/K$ and then consider elements $f:G\to\mathfrak{K}_L$, whose restriction $f(\Lambda_x)\equiv f(0,\Lambda_x)$ to the representatives $(0,\Lambda_x)$ form a Hilbert space $\mathfrak{H}_L\simeq L^2(X,d\mu;\mathfrak{K}_L)$ with respect to the scalar product

$$\langle f'|f\rangle=\int_X\langle f'(\Lambda_x)|f(\Lambda_x)\rangle_L\, d\mu(x), \tag{B5}$$

where $\langle\cdot|\cdot\rangle_L$ denotes the scalar product in $\mathfrak{K}_L$. The representation U of G in $\mathfrak{H}_L$ induced by the representation L of K is then defined as follows:

$$(U(a,\Lambda)f)(\Lambda_x)=\left|\frac{d\mu(x')}{d\mu(x)}\right|^{1/2} e^{i\langle x|a\rangle}D(\Lambda_x^{-1}\Lambda\Lambda_{x'})f(\Lambda_{x'}), \tag{B6}$$

with $(0,\Lambda_{x'})$ the representative of the class of the element $(a,\Lambda)^{-1}(0,\Lambda_x)$. It is easy to check that $\Lambda_x^{-1}\Lambda\Lambda_{x'}\in H_0$.

Remark: If $x_0'\in Hx_0$, its isotropy group H_0' is conjugate to H_0. The point is that the inducing procedure applied to x_0' gives the same representation U (up to equivalence), provided the equivalence class of D does not change. Therefore the Mackey method implies the determination of all the orbits under H in $\mathcal{T}^*$ and their respective isotropy groups (up to conjugation).

APPENDIX C: CENTRAL EXTENSIONS OF $\mathcal{G}_0 \rtimes D_2$ BY $\mathbb{R}$

1. The structure of $\mathcal{G}_0 \rtimes \mathcal{D}_2$

The generic element $g\in\mathcal{G}_0\rtimes\mathcal{D}_2$ is parametrized as $g=(b,\mathbf{a};\mathbf{v};R,\sigma,\tau)$ and the multiplication law is defined by

$$\begin{aligned}&(b,\mathbf{a};\mathbf{v};R,\sigma,\tau)(b',\mathbf{a}';\mathbf{v}';R',\sigma',\tau')\\&\quad=(b+e^{\tau}b',\mathbf{a}+e^{\sigma}[b'\mathbf{v}+R\mathbf{a}'];\mathbf{v}+e^{\sigma-\tau}R\mathbf{v}';RR',\sigma+\sigma',\tau+\tau'),\end{aligned} \tag{C1}$$

with $b,\mathbf{a},\mathbf{v},R,\sigma,\tau$ representing, respectively, time translations, space translations, pure Galilei transformations, rotations, space dilations, and time dilations. Their respective infinitesimal generators are given by H for the subgroup of time translations, P_i $(i=1,2,3)$ for translations along the coordinate axis i, K_i $(i=1,2,3)$ for pure Galilei transformations along the axis i, J_i $(i=1,2,3)$ for rotations around the coordinate axis i, D_S for space dilations, D_T for time dilations. The only nonvanishing commutators between these generators are the following, where ϵ_{ijk} is the totally antisymmetric tensor of order three:

$$\begin{aligned}&[J_i,J_j]=\epsilon_{ijk}J_k,\ \ [H,D_T]=-H,\\&[J_i,P_j]=\epsilon_{ijk}P_k,\ \ [P_i,D_S]=-P_i,\\&[J_i,K_j]=\epsilon_{ijk}K_k,\ \ [K_i,D_S]=-K_i,\\&[H,K_i]=-P_i,\ \ [K_i,D_T]=K_i.\end{aligned} \tag{C2}$$

In particular, one has

$$[D_S,D_T]=0. \tag{C3}$$

2. Central extensions of $\mathcal{G}_0 \rtimes \mathcal{D}_2$

In order to construct central extensions of Lie groups, it is easier to deal with the Lie algebra of the group than with the group itself. Therefore, instead of searching for the central extensions of the group $\mathcal{G}_0\rtimes\mathcal{D}_2$, we will determine the equivalence classes of central extensions of its Lie algebra.

Let $\mathfrak{g}$ be a real Lie algebra. Then every central extension of $\mathfrak{g}$ is determined by a skew-symmetric bilinear form $B:\mathfrak{g}\to\mathbb{R}$ such that

$$B([X,Y],Z)+B([Y,Z],X)+B([Z,X],Y)=0,\quad \forall X,Y,Z\in\mathfrak{g}, \tag{C4}$$

with $[\cdot,\cdot]$ denoting the Lie bracket in $\mathfrak{g}$. The extension associated to B is trivial if there exists a linear form $f:\mathfrak{g}\to\mathbb{R}$ such that

$$B(X,Y)=f([X,Y]),\quad \forall X,Y\in\mathfrak{g}, \tag{C5}$$

and two extensions are equivalent if their bilinear forms differ by a trivial one.

For the Lie algebra of $\mathcal{G}_0$ the existence of a one-parameter family of nontrivial extensions is due to the fact that $B(K_i, P_j) = \gamma\delta_{ij}$, with $\gamma \in \mathbb{R}$ an arbitrary number, which is related to the usual physical concept of mass.[12] In the case of $\mathcal{G}_0 \rtimes \mathcal{D}_2$, however, this is impossible. Indeed, we have

$$B([D_S, K_i], P_i) + B([K_i, P_i], D_S) + B([P_i, D_S], K_i) = 0, \tag{C6}$$

which implies, using (C2), that

$$B(K_i, P_i) = 0. \tag{C7}$$

The relation (C7) can also be obtained using D_T,

$$B([D_T, K_i], P_i) + B([K_i, P_i], D_T) + B([P_i, D_T], K_i) = 0. \tag{C8}$$

On the other hand, we may write

$$B(D_S, D_T) = \gamma, \tag{C9}$$

with $\gamma \in \mathbb{R}$ an arbitrary number. It is then easy to check that the commutation relations of the central extensions of the Lie algebra (C2) coincide with the latter, except for (C3), which now reads

$$[D_S, D_T] = \gamma I, \tag{C10}$$

where I is the generator of the center of the extension. Since (C10) means that $\{D_S, D_T, I\}$ is a Lie algebra isomorphic to the Weyl–Heisenberg algebra, the central extensions so obtained will be semidirect products of $\mathcal{G}_0$ with the Weyl–Heisenberg group, and none of them yields a mass observable.

Alternatively, one may ask whether the Lie algebra (C2) contain a subalgebra, whose central extensions generate the mass in the usual sense. Since (C7) can be derived from (C6) as well as from (C8), such a subalgebra, if it exists, must contain an element of the form

$$D_{ST} = D_S + \lambda D_T \tag{C11}$$

with $\lambda \neq 0$. Replacing D_S by D_{ST} in (C6) gives

$$(2 - \lambda) B(K_i, P_i) = 0. \tag{C12}$$

Thus the only solution generating a mass operator is given by $\lambda = 2$, namely,

$$B(K_i, P_i) = \gamma, \quad [K_i, P_i] = \gamma I, \tag{C13}$$

with $\gamma \in \mathbb{R}$ and I the generator of the center of the extension. Hence we obtain precisely the commutation relations of the central extensions of the Schrödinger group. It is then easy to check that these extensions coincide with the subgroup of $\mathcal{G}_{\text{aff}}^M$ defined by the equation

$$\tau = 2\sigma. \tag{C14}$$

In other words, in the Schrödinger case, the two operations of central extension and of taking a semidirect product with the dilation group commute.

On the braided Fourier transform on the *n*-dimensional quantum space

Giovanna Carnovale[a)]
Mathematisch Instituut, P.O. Box 80.010, 3508 TA, Utrecht, The Netherlands

(Received 19 November 1998; accepted for publication 27 March 1999)

We work out in detail a theory of integrability on the braided covector Hopf algebra and the braided vector Hopf algebra of type A_n introduced by Majid. Using a braided Fourier transform very similar to the one defined by Kempf and Majid we obtain n-dimensional analogs of results by Koornwinder expressing the correspondence between products of the q^2-Gaussian $g_{q^2}(\underline{x})$ times monomials, and products of the q^2-Gaussian $G_{q^2}(\underline{\partial})$ times q^2-Hermite polynomials under the transform. We invert the correspondence by finding a suitable inversion, different from the one of Kempf and Majid. We show that with this transforms, whenever $n\geqslant 2$, the Plancherel measure will depend on the parity of the power series that we are transforming. [S0022-2488(99)00410-7]

I. INTRODUCTION

Recently Majid (see Ref. 1 and references therein) has defined a generalization of the concept of Hopf algebra, namely braided groups. Hopf superalgebras and genuine Hopf algebras are examples of these objects, but there are more examples, associated to quantum groups, since the category of representations of a quasitriangular Hopf algebra is braided. These objects appear also in Ref. 2 with different terminology.

Kempf and Majid introduced[3] an integration theory for a class of braided groups arising from matrix solutions of the quantum Yang–Baxter equation as ‘‘braided covector algebras’’ (see also Ref. 1). They used this theory to define a formal braided Fourier transform and its inverse on these algebras. In their paper they also present the case of the braided line as an example, and the n-dimensional case in less detail.

The main problem in their theory is that it is very difficult to find an explicit integral that behaves well enough. They provide powerful general results in a theoretical way, but the description in specific cases is often hard to handle. Besides, they do not provide a definition of convergence of an integral nor do they treat in their article the case when a generalized function may be called integrable.

The purpose of this paper is to work out as far as we can the example of the n-dimensional quantum space of type A_n viewed as a braided group. We will provide different definitions of integrability, with examples and counterexamples, with respect to an integral similar to that in Ref. 3. Our definitions are based on extensions of representations of the braided covector and vector algebras. Using these facts, one can show in a more rigorous way the translation invariance of the integral proved in Ref. 3. We define different types of Fourier transforms, all based on but different from Ref. 3. One of them looks more like that in Ref. 4 since the integral does not have trivial braiding with elements in the braided group, and because the braided antipode appears in the definition. We also took inspiration from Ref. 5, where an analog of the Fourier transform for the case of the braided line is also studied, although the transform in Ref. 5 goes from an algebra to itself, while we are looking for a transform going from an algebra to its braided dual, as in Refs. 3, 4, and 6.

We find an n-dimensional analog of the correspondence between products of q^2-Gaussians

[a)]Electronic mail address: carnoval@math.u-cergy.fr

times monomials and other q^2-Gaussians times q^2-Hermite polynomials, similar to the classical case and to the results for the braided line in Ref. 5. We give also inverses for our transforms that invert the correspondence mentioned above, similarly to what appears in Ref. 5. The main tool for this inversion formula is the symmetry between the braided vector algebra and the braided covector algebra. Kempf and Majid had already defined an inversion formula in their article, but they used properties that our integral does not have. Other inversion formulas for the braided line are to be found in Ref. 6 where the case of distributions is also treated.

One of the most interesting results is that whenever $n \geqslant 2$, there is a loss of symmetry, so that the Plancherel measure will no longer be the same in the whole space. Indeed there is a action of $\mathbf{Z}_2^n$ associated to the parity of the power series we are working with, and the Plancherel measure will be constant only on the subspaces of power series with constant parity. Therefore, the transforms we define can also be seen as sine and cosine transform. A phenomenon of break of symmetry for q-integrals was also noted in Ref. 7, where the authors were defining a calculus associated to a q-deformed Heisenberg algebra.

Other definitions of analogs of the Fourier transform on genuine Hopf algebras, quantum spaces, or commutative algebras appeared before Ref. 5 in Refs. 8–10.

II. NOTATION AND PRELIMINARIES

In this paper a complex algebra has, unless otherwise stated, always a unit and q is a real number in (0,1). For a positive integer m, and for any $q \neq 1$ we write $[m]_q = (q^m - 1)/(q-1)$ and $[m]_q! = \Pi_{j=1}^m [j]_q$.

For any $a \in \mathbf{R}$ and for any $k \in \mathbf{Z}_{\geqslant 0}$, we will put $(a;q)_k = \Pi_{l=0}^{k-1}(1-aq^l)$. We will also write $(a;q)_\infty = \lim_{k\to\infty}(a;q)_k$ and for r real numbers $a_1,\ldots,a_r$ we will put $(a_1,\ldots,a_r;q)_\infty = \Pi_{j=1}^r (a_j;q)_\infty$. Finally, for $a \geqslant b$ with a and b both in $\mathbf{Z}_{\geqslant 0}$ in we will use the q-binomial coefficient $\left[{a \atop b}\right]_q = [a]_q!/[b]_q![a-b]_q! = (q;q)_a/(q;q)_b(q;q)_{a-b}$.

Whenever for any capital character E we have a multi-index $E = (e_1,\ldots,e_n)$ we will put $E_i = \Sigma_{j=1}^{i-1} e_j$ and $E^i = \Sigma_{j=i+1}^n e_j$. Hence $|E| = e_i + E_i + E^i$ for every $i.$

We identify the set $\{+,-\}$ with $\mathbf{Z}_2$, letting $+$ correspond to $\bar{0}$ and $-$ correspond to $\bar{1}$, so that n-tuples in $\{+,-\}^n$ can be identified with n-tuples in $\mathbf{Z}_2^n$. By means of this identification we define the map $A:\mathbf{Z}^n \to \mathbf{Z}_2^n \to \{+,-\}^n$ by reducing modulo 2 first, i.e., $A(b) = +$ if b is even and $-$ otherwise. We will also denote by $B:\{+,-\}^n \to \{0,1\}^n \subset \mathbf{Z}^n$ the map sending each ''even'' entry to 0 and each ''odd'' entry to 1.

Given an operator on the twofold tensor product of an n-dimensional vector space V, we identify this operator with the $n^2 \times n^2$ matrix R and we denote its entries by R^{ab}_{cd} where a, b are the row entries and c, d are the column entries. For such an R, the operator acting on the p-fold tensor product of V (for $p \geqslant 2$) as R on the ith and jth components and as the identity elsewhere will be denoted by R_{ij}. For summation we will use Einstein convention.

We recall that a braided group over a field K is an associative algebra A with multiplication m and a coassociative coalgebra with comultiplication Δ and counit ε together with an invertible linear map $\Psi: A\otimes A \to A \otimes A$ called braiding, and a linear map $S:A\to A$ called braided antipode such that the following properties hold: $\Psi(m\otimes \mathrm{id}) = (\mathrm{id}\otimes m)(\Psi\otimes\mathrm{id})(\mathrm{id}\otimes\Psi)$; $\Psi(\mathrm{id}\otimes m) = (m\otimes\mathrm{id})(\mathrm{id}\otimes\Psi)(\Psi\otimes\mathrm{id})$; $(\mathrm{id}\otimes\Delta)\circ\Psi = (\Psi\otimes\mathrm{id})(\mathrm{id}\otimes\Psi)(\Delta\otimes\mathrm{id})$; $(\Delta\otimes\mathrm{id})\circ\Psi = (\mathrm{id}\otimes\Psi)(\Psi\otimes\mathrm{id})(\mathrm{id}\otimes\Delta)$; $1\varepsilon = m(\mathrm{id}\otimes S)\Delta = m(S\otimes\mathrm{id})\Delta$; $\Delta m = (m\otimes m)(\mathrm{id}\otimes\Psi\otimes\mathrm{id})(\Delta\otimes\Delta)$; $\varepsilon\circ m = \varepsilon\otimes\varepsilon$; and $\Delta(1) = 1\otimes 1$. If there is no braided antipode, A is called a ''braided bialgebra.''

We will work with two particular braided groups, namely the braided covector Hopf algebra $\hat{V}(R)$ and the braided vector algebra $V(R)$ associated to the standard matrix solution R of the quantum Yang–Baxter equation of type A_n [i.e., defining the quantum group $\mathrm{SL}_q(n)$]. For a general definition of braided covector and vector algebra, see Ref. 1, Chap. 10. One sees there that these algebras are comodule algebras for $\mathrm{SL}_q(n)$, and that all possible vector spaces obtained by tensoring $\hat{V}(R)$ and $V(R)$ can be provided by an algebra structure such that they are again comodule algebras for $\mathrm{SL}_q(n)$. The product is then defined by means of the braidings and the product in $\hat{V}(R)$ and $V(R)$.

In this particular case $\hat{V}(R)$ is the unital associative algebra generated by $x_1,\ldots,x_n$, with relations given by $x_ix_j=qx_jx_i$ if $i>j$, i.e., $\hat{V}(R)$ is the n-dimensional quantum space. The counit is given by $\varepsilon(x_j)=0$ for every j. We know that this algebra has a basis given by (increasing) ordered monomials $x_1^{e_1}\ldots x_n^{e_n}$. The general formulas for the braiding Ψ, the comultiplication Δ, and the antipode S in Ref. 1 reduce as follows:

$$\Psi(x_i\otimes x_j)=\begin{cases} qx_j\otimes x_i, & \text{if } i<j,\\ q^2x_i\otimes x_i, & \text{if } i=j,\\ (q^2-1)x_i\otimes x_j+qx_j\otimes x_i, & \text{if } i>j,\end{cases}$$

so that, for $i<j$, $\Psi(x_i^a\otimes x_j^b)=q^{ab}x_j^b\otimes x_i^a$,

$$\Delta(x_1^{e_1}\cdots x_n^{e_n})=\sum_{j_1=0}^{e_1}\cdots\sum_{j_n=0}^{e_n}\left(\prod_{i=1}^{n}\begin{bmatrix} e_i\\ j_i\end{bmatrix}_{q^2}\right)q^{\Sigma_v J_v(e_v-j_v)}x_1^{e_1-j_1}\cdots x_n^{e_n-j_n}\otimes x_1^{j_1}\cdots x_n^{j_n},$$

and $S(x_1^{e_1}\cdots x_n^{e_n})=(-1)^{|E|}q^{|E|^2-|E|}x_1^{e_1}\cdots x_n^{e_n}$.

Here $V(R)$ is the associative unital algebra generated by $\partial_1,\ldots,\partial_n$, with relations given by $\partial_i\partial_j=q\partial_j\partial_i$ if $i<j$. The ordered monomials provide a basis for $V(R)$. In this case we fix the basis given by ordered monomials with decreasing order. The braiding, counit, comultiplication, and antipode are given by

$$\Psi(\partial_i\otimes\partial_j)=\begin{cases} q\partial_j\otimes\partial_i, & \text{if } i>j,\\ q^2\partial_i\otimes\partial_i, & \text{if } i=j,\\ (q^2-1)\partial_i\otimes\partial_j+q\partial_j\otimes\partial_i, & \text{if } i<j,\end{cases}$$

$\varepsilon(\partial_j)=0$ for every j, $S(\partial_n^{e_n}\cdots\partial_1^{e_1})=(-1)^{|E|}q^{|E|^2-|E|}\partial_n^{e_n}\cdots\partial_1^{e_1}$, and

$$\Delta(\partial_n^{e_n}\cdots\partial_1^{e_1})=\sum_{j_n=0}^{e_n}\cdots\sum_{j_1=0}^{e_1}\left(\prod_{i=1}^{n}\begin{bmatrix} e_i\\ j_i\end{bmatrix}_{q^2}\right)q^{\Sigma_u J^u(e_u-j_u)}\partial_n^{e_n-j_n}\cdots\partial_1^{e_1-j_1}\otimes\partial_n^{j_n}\cdots\partial_1^{j_1}.$$

By Majid's theory (see Corollary 9.2.14 and Proposition 10.3.6 in Ref. 1) we recover the braiding between $\hat{V}(R)$ and $V(R)$ and between $V(R)$ and $\hat{V}(R)$. They are given by

$$\Psi_{V(R),\hat{V}(R)}(\partial_i\otimes x_j)=\begin{cases} q^{-1}x_j\otimes\partial_i, & \text{if } i\neq j,\\ q^{-2}x_j\otimes\partial_j+\sum_{r>j}(q^{-2}-1)x_r\otimes\partial_r, & \text{if } i=j,\end{cases}$$

$$\Psi_{\hat{V}(R),V(R)}(x_i\otimes\partial_j)=\begin{cases} q^{-1}\partial_j\otimes x_i, & \text{if } i\neq j,\\ \sum_{r<j}(q^{-2}-1)q^{-2(j-r)}\partial_r\otimes x_r+q^{-2}\partial_j\otimes x_j, & \text{if } i=j.\end{cases}$$

For every choice of nonzero constants c_j, for $j=1,\ldots,n$, there is an algebra isomorphism ψ between $\hat{V}(R)$ and $V(R)$ mapping x_j to $c_j\partial_{n+1-j}$, such that $\Delta_{V(R)}\circ\psi=(\psi\otimes\psi)\circ\Delta_{\hat{V}(R)}$ and $S_{V(R)}\circ\psi=S_{\hat{V}(R)}$. In particular, for $c_j=q^{-j+(1/2)(n-1)}$ for every j, then we also have $\Psi_{V(R),V(R)}(\psi\otimes\psi)=\Psi_{\hat{V}(R),\hat{V}(R)}$.

For this choice of the c_j's we have

$$(\psi^{-1}\otimes\psi)\circ\Psi_{\hat{V}(R),V(R)}=\Psi_{V(R),V(R)}\circ(\psi\otimes\psi^{-1}),$$

$$(\psi\otimes\psi^{-1})\circ\Psi_{V(R),\hat{V}(R)}=\Psi_{\hat{V}(R),V(R)}\circ(\psi^{-1}\otimes\psi),$$

however, ψ is not a morphism in the braided category since it is *not* true that $(\psi\otimes\mathrm{id})\circ\Psi_{\hat{V}(R),V(R)}=\Psi_{\hat{V}(R),\hat{V}(R)}\circ(\mathrm{id}\otimes\psi)$, as one can easily see by computing the actions of the left-hand side and of the right-hand side on $(\partial_2\otimes x_1)$ for $n=2$. This has to do with the fact that $\hat{V}(R)$ and $V(R)$ are not dual as braided groups in the sense that there is no invariant quantum metric (see Ref. 1 and references therein).

It is also well known that there is a left action of $V(R)$ on $\hat{V}(R)$ where each ∂_j acts by means of braided partial differentiation with respect to x_j. In the A_n case, this turns out to be, for $f(\underline{x})\in\hat{V}(R)$,

$$\partial_j f(\underline{x})=x_j^{-1}\left[\frac{f(q^2x_1,\ldots,q^2x_j,x_{j+1},\ldots,x_n)-f(q^2x_1,\ldots,q^2x_{j-1},x_j,\ldots x_n)}{(q^2-1)}\right],$$

where the inverse of x_j is only formal, and ''apparent.'' In particular, one has

$$\partial_j(x_1^{e_1}\cdots x_n^{e_n})=[e_j]_{q^2}q^{E_j}x_1^{e_1}\cdots x_{j-1}^{e_{j-1}}x_j^{e_j-1}x_{j+1}^{e_{j+1}}\cdots x_n^{e_n}.$$

Formally we can repeat the same constructions with $\hat{V}(R)^{\mathrm{ext}}$ [resp. $V(R)^{\mathrm{ext}}$], the algebra of formal power series in the x_j's (resp. ∂_j's) with the given defining relations. In this case everything that we have described above is defined as in $\hat{V}(R)$ and $V(R)$.

Specializing the results about the braided exponential map in Ref. 1 and references therein, one has

$$\exp(x|\partial):=\sum_{e_1,\ldots,e_n\geq 0} x_1^{e_1}\cdots x_n^{e_n}\otimes\frac{\partial_n^{e_n}}{[e_n]_{q^2}!}\cdots\frac{\partial_1^{e_1}}{[e_1]_{q^2}!}.$$

By Example 10.4.16 in Ref. 1 this is equal to $e_{q^{-2}}((1-q^{-2})\Sigma_{i=1}^n x_i\otimes\partial_i)$, where $e_q(z)=\Sigma_{k=0}^\infty z^k/(q;q)_k$ (see Ref. 5 for further details). It follows by straightforward computation that $\exp(x|\partial)$ is also equal to $E_{q^2}((1-q^2)\Sigma_{i=1}^n x_i\otimes\partial_i)$, where $E_{q^2}(z)=\Sigma_{k=0}^\infty q^{(1/2)k(k-1)}z^k/(q;q)_k$. Corollary 10.4.17 in Ref. 1, which appeared first in Ref. 11, gives us also a braided version of the Taylor formula. This is given by

$$\begin{aligned}f(\Delta(x_1),\ldots,\Delta(x_n))&=f(x_1+y_1,\ldots,x_n+y_n)\\&=\sum_{e_1,\ldots,e_n\geq 0} y_1^{e_1}\cdots y_n^{e_n}\left(\frac{\partial_n^{e_n}}{[e_n]_{q^2}!}\cdots\frac{\partial_1^{e_1}}{[e_1]_{q^2}!}f(x_1,\ldots,x_n)\right)\\&=\exp(y|\partial)f(\underline{x})\end{aligned}$$

where $y_j=x_j\otimes 1$ and x_i stands for $1\otimes x_i$ after the second equality sign.

III. INTEGRATION ON $\hat{V}(R)^{\mathrm{ext}}$

We start with the ''indefinite'' integral with respect to x_i. We repeat shortly the definition in Ref. 3, where the integral is viewed as an operator on $\hat{V}(R)^{\mathrm{ext}}$.

Definition 3.1: The braided partial integral with respect to x_i acting on $f(\underline{x})\in\hat{V}(R)^{\mathrm{ext}}$ is given by

$$\int_0^{x_i} f:=(1-q^2)\sum_{k=0}^{\infty} q^{2k}x_i f(q^{-2}x_1,\ldots,q^{-2}x_{i-1},q^{2k}x_i,x_{i+1},\ldots,x_n).$$

It is easy to see that the operator defined above acts as a pseudo inverse for the partial differential operator ∂_i. It is indeed only a right inverse, since it acts as a left inverse for ∂_i only on series containing x_i in every monomial of its expansion (see remark in Ref. 3, p. 6815). Each

$\int_0^{x_i}$ is a well-defined operator from $\hat{V}(R)^{\mathrm{ext}}$ to $\hat{V}(R)^{\mathrm{ext}}$ since for every basis monomial $x_1^{e_1}\cdots x_n^{e_n}$ we can write $\int_0^{x_i}x_1^{e_1}\cdots x_n^{e_n}$ as a monomial in the x_j's with a coefficient that is a *convergent* series of complex numbers. Since one can read $\int_0^{x_i}f$ as a ''function'' of the x_j's, it makes sense to consider $\int_0^{ax_i}$ for a nonzero constant a. In particular we can define $\int_0^{(-1)^r q^1 x_i} f$ for every integer r and l as $(-1)^r(1-q^2)\Sigma_{k=0}^{\infty}q^{2k+l}x_i f(q^{-2}x_1,\ldots q^{-2}x_{i-1},(-1)^r q^{2k+l}x_i,x_{i+1},\ldots x_n)$.

Then, for every $f\in\hat{V}(R)^{\mathrm{ext}}$

$$\int_{-x_i}^{x_i} f := \int_0^{x_i} f - \int_0^{-x_i} f \quad \text{and} \quad \int_{-x_i\cdot\infty}^{x_i\cdot\infty} f := \lim_{r\to\infty}\int_{-q^{-2r}x_i}^{q^{-2r}x_i} f$$

are defined. The last definition is only formal so far, because the image of a power series is no longer a power series (coefficients might be infinite sums themselves), and we have no notion of convergence. One cannot find a convergence set because one cannot give nonzero values to noncommuting variables. This issue can be solved in different ways, so that we can give a meaning to equalities as well. The ideas here are based on the approaches of Kempf and Majid in Ref. 3 and of Koornwinder in Ref. 5 who treated the one-dimensional case. His approach was by means of extension of a suitable representation of $\hat{V}(R)^{\mathrm{ext}}$ and the search of a family of eigenvectors for which the integral would have a convergent eigenvalue. We approach the problem not for a single infinite integral, but for the n-dimensional integral $I(f) := \int_{-x_n\cdot\infty}^{x_n\cdot\infty}\cdots\int_{-x_i\cdot\infty}^{x_1\cdot\infty} f$ which is formally

$$(1-q^2)^n\sum_{k_n=-\infty}^{\infty}\cdots\sum_{k_1=-\infty}^{\infty}\sum_{\varepsilon\in\{\pm1\}^n} q^{2|K|+\binom{n}{2}}x_1\cdots x_n f(\varepsilon_1 q^{2k_1}x_1,\ldots,\varepsilon_n q^{2k_n}x_n).$$

As we said, $I(f)$ is not an element of $\hat{V}(R)^{\mathrm{ext}}$, in general, since the coefficients with respect to the elements of the basis are not always definite. In order to define integrability, we fix an action of $\hat{V}(R)$ on the space of power series in the n commuting variables $z_1,\ldots,z_n$ with complex coefficients. This representation corresponds with the choice of a normal form for the monomials in $\hat{V}(R)$. The representation, denoted by $\triangleright$, for monomials in the x_i's acting on monomials in the z_j's, is given by

$$x_1^{e_1}\cdots x_n^{e_n}\triangleright z_1^{h_1}\cdots z_n^{h_n} = q^{\Sigma_{i=1}^n e_j H_i} z_1^{h_1+e_1}\cdots z_n^{h_n+e_n},$$

and can be extended linearly to an action of $\hat{V}(R)$ on formal power series in the z_j's. We can restrict the space on which we act by taking the space V of power series which are absolutely convergent in a neighborhood of zero. This makes sense because the z_i's commute with each other. We see that this space is invariant under the action of $\hat{V}(R)$. Moreover, we see that we can extend the representation of $\hat{V}(R)$ on V to a representation of the class C given by the power series f in the x_i's such that $f\triangleright 1\in V$. Indeed one can see that

(A) $\forall f=f(\underline{x})\in C$ and $\forall g=g(\underline{z})\in V$ it holds that $(f\triangleright g)(\underline{z})$ belongs to V because the associated series of absolute values is majorized by the product in V of series of absolute values associated to $f\triangleright 1$ and g.

(B) $\forall f$ and $g\in C$, their product $fg\in C$ because $(fg)\triangleright 1 = f\triangleright(g\triangleright 1)\in V$ by property (A). Moreover,

(C) $\forall f\in C$, $f\triangleright 1=0 \Leftrightarrow f\equiv 0$.

From now on we write $f_{.1}$ for $f\triangleright 1$, for any expression $f(\underline{x})$ for which the action on 1 makes sense. We would like to extend the representation now to the formal expressions of type $I(f)$ for $f\in C$. This does not always make sense, hence we have to add further conditions. Let us take the subclass C' of C given by the series in C such that

(a) $f_{.1}$ can be continued analytically on $\mathbf{R}^n+iU$ for some open neighborhood U of 0 in $\mathbf{R}^n$;

(b) $f_{.1}$ is absolutely q^2-integrable for every $\underline{z}\in\mathbf{R}^n$ for which every $z_j\neq 0$, i.e.,

$$\sum_{k_1=-\infty}^{\infty}\cdots\sum_{k_n=-\infty}^{\infty}\sum_{\varepsilon\in\{\pm1\}^n} q^{2|K|}|z_1|\cdots|z_n||f_{\cdot 1}(\varepsilon_1 q^{2k_1}z_1,\ldots,\varepsilon_n q^{2k_n}z_n)|<\infty$$

for $\underline{z}$ outside the standard hyperplanes.

The class C' will be the class of integrable power series. For those series we can compute $I(f)_{\cdot 1}$, and this turns out to be

$$(I(f))_{\cdot 1}=(1-q^2)^n\left[\sum_{k_n=-\infty}^{\infty}\cdots\sum_{k_1=-\infty}^{\infty}\sum_{\varepsilon} q^{2|K|+\binom{n}{2}}x_1\cdots x_n f(\varepsilon_1 q^{2k_1}x_1,\ldots,\varepsilon_n q^{2k_n}x_n)\right]\triangleright 1$$
$$=\int_{-q^{n-1}z_1\cdot\infty}^{q^{n-1}z_1\cdot\infty}\cdots\int_{-q^{n-i}z_i\cdot\infty}^{q^{n-i}z_i\cdot\infty}\cdots\int_{-z_n\cdot\infty}^{z_n\cdot\infty} f_{\cdot 1}(t_1,\ldots,t_n)\,d_{q^2}t_n\cdots d_{q^2}t_1,$$

where the q^2-integral in the last line is the q^2-Jackson integral in n variables obtained by iterating (8.11) in Ref. 5. It is clear that if $f\in C'$, then $(I(f))_{\cdot 1}$ converges whenever $z_j\neq 0$ for every j.

Because of (C), two objects in C are equal if and only if they act in the same way on 1. Following this philosophy, we say that two q^2-integrals of objects in C' are equal if and only if they act in the same way on 1. This will be our tool to show equalities then.

The first purpose is to show translation invariance of the operator I in a less formal way than in Ref. 3 where this appeared first. For this we need an extra assumption on the elements in C', since we have to use Taylor's series, hence partial derivatives. We consider $f\in C'$ satisfying the following.

(c) For some $\eta>0$ there exists for each $J\in(\mathbf{Z}_{\geq 0})^n$ some constant C_J such that

$$|(D_{1,q^2}^{j_1}\cdots D_{n,q^2}^{j_n}f_{\cdot 1})(z_1,\ldots,z_n)|\leq C_J\prod_{k=1}^{n}(1+|z_k|^2)^{-(1+\eta)}$$

if $\underline{z}\in\mathbf{R}^n$, where D_{j,q^2} denotes the standard q^2-Jackson partial derivative with respect to z_j.

For an f in C', condition (c) implies that all the Jackson derivatives of $f_{\cdot 1}$ are absolutely q^2-integrable for all $\underline{z}$ in a neighborhood of 0 minus the intersection with the standard hyperplanes.

One sees immediately that $(\partial_i f)_{\cdot 1}=(D_{i,q^2}f_{\cdot 1})(qz_1,\ldots,qz_{i-1},z_i\ldots,z_n)$. We show now that it makes sense to compute $I(\partial_n^{j_n}\cdots\partial_1^{j_1}f)\triangleright 1$, and that this is equal to zero whenever $(j_1,\ldots,j_n)\neq(0,\ldots,0)$. We write

$$F_{\cdot 1}^{J}(z_1,\ldots,z_n):=(\partial_n^{j_n}\cdots\partial_1^{j_1}f)\triangleright 1=(D_{1,q^2}^{j_1}\cdots D_{n,q^2}^{j_n}(f_{\cdot 1}))(q^{J^1}z_1,\ldots,q^{J^n}z_n).$$

Hence $F_{\cdot 1}^{J}(\underline{z})\in V$ if f satisfies condition (c). Moreover, $F_{\cdot 1}^{J}$ is absolutely q^2-Jackson integrable if and only if for every choice of $(h_1,\ldots,h_n)\in\{\pm 1\}^n$

$$\sum_{\underline{\varepsilon}\in\{\pm1\}^n}\sum_{k_i=0}^{\infty}\cdots\sum_{k_n=0}^{\infty} q^{2K\cdot H}|z_1\cdots z_n||F_{\cdot 1}^{J}(q^{2k_1h_1}\varepsilon_1 z_1,\ldots,q^{2k_nh_n}\varepsilon_n z_n)|$$

has a positive radius of convergence. Hence, if condition (c) holds for $f(\underline{x})$, and since the above sums are of the form

$$\sum_{\underline{\varepsilon}}\sum_{k_1=0}^{\infty}\cdots\sum_{k_n=0}^{\infty} q^{2K\cdot H}|z_1\cdots z_n(D_{1,q^2}^{j_1}\cdots D_{n,q^2}^{j_n}f_{\cdot 1})(q^{2k_1h_1+J^1}\varepsilon_1 z_1,\ldots,q^{2k_nh_n+J^n}\varepsilon_n z_n)|$$
$$\leq C_J|z_1\cdots z_n|\sum_{\underline{\varepsilon}}\sum_{k_1=0}^{\infty}\cdots\sum_{k_n=0}^{\infty} q^{2K\cdot H}\prod_{r=1}^{n}(1+|q^{2k_rh_r}z_r|^2)^{-(1+\eta)}$$

that converges since $q\in(0,1)$, one sees that the $F^{J}_{\cdot 1}$ are q^2-integrable.

Moreover, for every $\gamma=(\gamma_1,\dots,\gamma_n)$ with γ_j in $\mathbf{R}-\{0\}$ we have

$$q^{\Sigma_{k=1}^n J^k}\int_{-\gamma_1\cdot\infty}^{\gamma_1\cdot\infty}\cdots\int_{-\gamma_n\cdot\infty}^{\gamma_n\cdot\infty}F^{J}_{\cdot 1}(t_1,\dots,t_n)d_{q^2}t_n\cdots d_{q^2}t_1$$

$$=\int_{-q^{J^1}\gamma_1\cdot\infty}^{q^{J^1}\gamma_1\cdot\infty}\cdots\int_{-q^{J^n}\gamma_n\cdot\infty}^{q^{J^n}\gamma_n\cdot\infty}D^{j_1}_{1,q^2}\cdots D^{j_n}_{n,q^2}f_{\cdot 1}(t_1,\dots,t_n)d_{q^2}t_n\cdots d_{q^2}t_1=0.$$

The proof is as in the one-dimensional case (see Ref. 5). Hence we can state the following.

Lemma 3.2: Let $f\in C'$ *satisfy condition* (c). *Then for every* $J\neq\underline{0}$ *there holds* $(I(\partial_n^{j_n}\cdots\partial_1^{j_1}f))\triangleright 1\equiv 0$, *so that we can conclude that* $I(\partial_n^{j_n}\cdots\partial_1^{j_1}f)=0$.

Proof: One has

$$(I(\partial_n^{j_n}\cdots\partial_1^{j_1}f))_{\cdot 1}=\int_{-q^{n-1}z_1\cdot\infty}^{q^{n-1}z_1\cdot\infty}\cdots\int_{-q^{n-i}z_i\cdot\infty}^{q^{n-i}z_i\cdot\infty}\cdots\int_{-z_n\cdot\infty}^{z_n\cdot\infty}F^{J}_{\cdot 1}(t_1,\dots,t_n)d_{q^2}t_n\cdots d_{q^2}t_1=0.$$

□

Proposition 3.3: Let $f\in C'$ *satisfy* (c). *Then* $(\mathrm{id}\otimes I)\Delta(f)=1\otimes(If)$.

Proof: By the braided Taylor formula we have

$$(\mathrm{id}\otimes I)(\Delta f)=\sum_{j_1,\dots,j_n\geqslant 0}\frac{y_1^{j_1}\cdots y_n^{j_n}}{[j_1]_{q^2}!\cdots[j_n]_{q^2}!}I(\partial_n^{j_n}\cdots\partial_1^{j_1}f),$$

but this is by Lemma 3.2 equal to the term with all j_k's equal to 0. □

Proposition 3.4: Let $f(\underline{x})\in C$ *such that* (c) *holds for every* $\eta>0$. Then the statement of Proposition 3.3 holds for every polynomial $p(\underline{x})$ times $f(\underline{x})$.

Proof: It is not restrictive to assume that $p(\underline{x})$ is a monomial. By property (A) there follows that also $p(\underline{x})f(\underline{x})\in C$. We have to check that condition. (c) holds for every element of the form $x_1^{e_1}\cdots x_n^{e_n}f(\underline{x})$. One sees immediately that

$$(x_1^{e_1}\cdots x_n^{e_n}f(\underline{x}))\triangleright 1=f_{\cdot 1}(q^{E^1}z_1,\dots,q^{E^n}z_n)z_1^{e_1}\cdots z_n^{e_n}\in V$$

if $f(\underline{x})\in C$, so that $(x_1^{e_1}\cdots x_n^{e_n}f(\underline{x}))_{\cdot 1}$ makes sense.

Condition (c) is on the q^2-Jackson partial derivatives on commuting variables, and it holds for $x_1^{e_1}\cdots x_n^{e_n}f(\underline{x})$ as a consequence of the fact that for two functions $a(\underline{z})$ and $b(\underline{z})$ and for any $j=1,\dots,n$,

$$D_{j,q^2}(a(\underline{z})b(\underline{z}))=(D_{j,q^2}a(\underline{z}))(b(z_1,\dots,z_{j-1},q^2z_j,z_{j+1},\dots,z_n))+a(\underline{z})D_{j,q^2}(b(\underline{z})).$$

Then, by Proposition 3.3 we have the statement. □

We have a description of a class of power series in the x_i's for which integration makes sense, although we are not able so far to make a complete classification of integrable functions. The same problem is treated in Ref. 6 for the one-dimensional case. Still, what we have is enough to allow computations in the following case.

Example 1: The q^2-Gaussian $g_{q^2}(\underline{x})$ is

$$g_{q^2}(\underline{x}):=e_{q^4}(-\underline{x}\cdot\underline{x})=e_{q^4}\left(-\sum_{j=1}^n x_j^2\right)=\prod_{j=1}^n e_{q^4}(-x_j^2),$$

where the last equality holds because of Proposition 3.1 in Ref. 5 (this result was already in Ref. 12) and the product in the above formula is taken with increasing order on the variables. It satisfies conditions (a), (b), and (c) for every $\eta>0$. This is a consequence of the one-dimensional case (see Ref. 5) and the fact that

$$(g_{q^2}(\underline{x}))_{.1}(\underline{z})=\prod_{j=1}^{n} e_{q^4}(-z_j^2), \quad \partial_j(g_{q^2}(\underline{x}))=-\frac{x_j}{(1-q^2)}g_{q^2}(\underline{x})$$

and that

$$D^{j_1}_{q^2,1}\cdots D^{j_n}_{q^2,n}\left(e_{q^4}\left(-\sum_{k=1}^{n} z_k^2\right)\right)=p(\underline{z})e_{q^4}\left(-\sum_{k=1}^{n} z_k^2\right),$$

where $p(\underline{z})$ is a polynomial in the z_j's.

It follows then that also elements of the form

$$x_1^{a_1}g_{q^2}(x_1)\cdots x_n^{a_n}g_{q^2}(x_n)=x_1^{a_1}\cdots x_n^{a_n}e_{q^4}\left(-\sum_j (q^{-A^j}x_j)^2\right)$$

satisfy condition (c), so that for every $p_j(x_j)\in\hat{V}(R)$ we can integrate every element of the form $p_1(x_1)g_{q^2}(x_1)\cdots p_n(x_n)g_{q^2}(x_n)$.

In particular, for $f(\underline{x})=g_{q^2}(x_1)x_1^{a_1}\cdots g_{q^2}(x_n)x_n^{a_n}$ one can compute

$$\begin{aligned}(I(f))_{.1}|_{z=\gamma}&=\int_{-q^{n-1}\gamma_1\cdot\infty}^{q^{n-1}\gamma_1\cdot\infty}\cdots\int_{-q^{n-i}\gamma_i\cdot\infty}^{q^{n-i}\gamma_i\cdot\infty}\cdots\int_{-\gamma_n\cdot\infty}^{\gamma_n\cdot\infty} f_{.1}(t_1,\ldots.t_n)d_{q^2}t_n\cdots d_{q^2}t_1\\
&=\prod_{j=1}^{n}\left(\int_{-q^{n-j}\gamma_j\cdot\infty}^{q^{n-j}\gamma_j\cdot\infty} e_{q^4}(-t_j^2)t_j^{a_j}d_{q^2}t_j\right)\\
&=\begin{cases}\prod_{j=1}^{n}(c_{q^2}(\gamma_j q^{n-j})q^{-a_j^2/2}(q^2;q^4)_{a_j/2}), & \text{if } a_j \text{ even } \forall_j,\\ 0, & \text{otherwise,}\end{cases}\end{aligned}$$

where

$$c_{q^2}(\gamma)=\frac{2(1-q^2)(q^4,-q^2\gamma^2,-q^2\gamma^{-2};q^4)_\infty}{(-\gamma^2,-q^4\gamma^{-2},q^2;q^4)_\infty}$$

as in formula (8.15) in Ref. 5. In particular,

$$(I(f))_{.1}|_{z=\gamma}=q^{-\Sigma_j a_j^2/2}\prod_j (q^2;q^4)_{a_j/2}(I(g_{q^2}(\underline{x})))|_{z=\gamma}$$

if all a_j's are even, and 0 otherwise, hence we can conclude that

$$I(f)=\begin{cases}q^{-\Sigma_j a_j^2/2}\prod_j (q^2;q^4)_{a_j/2}(I(g_{q^2}(\underline{x}))), & \text{if } a_j \text{ is even } \forall_j,\\ 0, & \text{otherwise.}\end{cases}$$

The observation that the integral of the Gaussian times a monomial is equal to a constant times the integral of the Gaussian appeared in Refs. 1 and 3 first. In our case we have to deal with the shift and this depends on the choice of our global integral. ♠

Remark: The reader may wonder whether we could have chosen another realization of $\hat{V}(R)^{\mathrm{ext}}$ and of the integrals of elements of $\hat{V}(R)^{\mathrm{ext}}$ other than $f \triangleright 1$. Of course one might consider a different representation, or a different choice of the normal form. The advantages of a representation associated to the choice of a normal form is the fact that it is enough to test operators on 1 to state an equivalence in $\hat{V}(R)$. The advantage of the particular normal form that we have chosen is based on the fact that C is closed under product, hence we have a map from formal expressions in $x_1 \ldots, x_n$ to formal expressions in the $z_1, \ldots, z_n$ such that on rather big subspaces it comes exactly from an algebra homomorphism. If we had chosen another normal form, we could no longer extend the representation π of $\hat{V}(R)$ on V to a representation of the subset S of $\hat{V}(R)^{\mathrm{ext}}$ such that $\pi(S)(1) \subset V$. Take, for instance, $n=2$, and the representation of $\hat{V}(R)$ on $\mathbf{R}[[z,w]]$ given by $\pi(x_1)(f(z,w)) = zf(z,q^{-1}w)$ and $\pi(x_2)(f(z,w)w) = f(z,w)$. This is the representation associated to the choice of the normal form with x_2 preceding x_1. ♠

Then $a = \Sigma_{k=0}^{\infty} x_1^k$ and $b = \Sigma_{l=0}^{\infty} x_2^l$ belong to S, but ab does not belong to S since $\pi(\Sigma_{k=0}^{\infty} x_1^k)(\pi(\Sigma_{l=0}^{\infty} x_2^l)(1)) = \Sigma_{k,l=0}^{\infty} q^{-kl} z^k \omega^l \notin V$.

IV. LATTICE INTEGRABILITY

In the previous section we saw a definition of integrable series in $\hat{V}(R)^{\mathrm{ext}}$. Unfortunately, the above method fails for another analog of the Gaussian we would like to q^2-integrate, namely the q^2-Gaussian

$$G_{q^2}(\underline{x}) := E_{q^4}(-\underline{x} \cdot \underline{x}) = E_{q^4}\left(-\sum_{j=1}^{n} x_j^2\right) = E_{q^4}(-x_n^2) \cdots E_{q^4}(-x_1^2).$$

In Ref. 5, Sec. 9, it is also shown that $G_{q^2}(\underline{x})$ does not satisfy condition (c), nor condition (b) for $n=1$. On the other hand, it is also shown there that for a given choice of a q^2-lattice of the form $\{\pm q^{2k}\gamma | k \in \mathbf{Z}\}$, namely for $\gamma=1$, $(I(G_{q^2}(x_1)))_{\cdot 1}|_{z_1=1}$ is absolutely convergent. Hence one can introduce a weaker version of integrability in $\hat{V}(R)^{\mathrm{ext}}$, which we will call *''lattice integrability,''* requiring for an $f(\underline{x})$ such that $f_{\cdot 1}$ is entire that there is a q^2-lattice $L(\gamma) = \{(\pm \gamma_1 q^{2k_1}, \ldots, \pm \gamma_n q^{2k_n}) | K \in \mathbf{Z}^n\}$ in $\mathbf{R}^n_{\neq 0}$ such that the expression $(I(f))_{\cdot 1}|_{z \in L(\gamma)}$ is absolutely convergent. Of course if a generalized function is q^2-integrable, then it is lattice integrable for every choice of a lattice. One can easily see that the power series $E_{q^4}(-x_1^2) \cdots E_{q^4}(-x_n^2)$ is lattice integrable for $\gamma = (q^{n-1}, \ldots, q^{n-j}, \ldots, 1)$. Unfortunately, this power series is not the q^2-Gaussian $G_{q^2}(\underline{x})$ that we wanted to integrate, for $n \geqslant 2$. Besides, we can show that already for $n=2$, $G_{q^2}(\underline{x})$ is not lattice integrable although it is entire.

(Counter)example 1: Let us consider $G_{q^2}(\underline{x})$ for $n=2$. We write for simplicity $x_1 = x$ and $x_2 = y$, and $z_1 = z$, $z_2 = w$. Then

$$G_{q^2}(\underline{x}) = \sum_{k,l=0}^{\infty} \frac{(-1)^{k+l} q^{2k^2+2l^2-2k-2l} y^{2l} x^{2k}}{(q^4;q^4)_l (q^4;q^4)_k} = \sum_{l=0}^{\infty} \frac{(-1)^l q^{2l^2-2l} E_{q^4}(-(q^{2l}x)^2) y^{2l}}{(q^4;q^4)_l},$$

hence

$$\begin{aligned} G_{q^2}(\underline{x})_{\cdot 1} &= \sum_{k,l=0}^{\infty} \frac{(-1)^{k+l} q^{2k^2+2l^2-2k-2l} q^{4kl} z^{2k} w^{2l}}{(q^4;q^4)_l (q^4;q^4)_k} \\ &= \sum_{l=0}^{\infty} \frac{(-1)^l q^{2l^2-2l} E_{q^4}(-(q^{2l}z)^2) w^{2l}}{(q^4;q^4)_l} \\ &= \sum_{k=0}^{\infty} \frac{(-1)^k q^{2k^2-2k} E_{q^4}(-(q^{2k}w)^2) z^{2l}}{(q^4;q^4)_k}, \end{aligned}$$

which is entire since it is majorized by $E_{q^4}(|w|^2)E_{q^4}(|z|^2)$. Now we wonder whether this expression is lattice integrable or not. In order to have that, we would need that for some $\gamma=(\gamma_1,\gamma_2)$,

$$\int_{-q\gamma_1\cdot\infty}^{q\gamma_1\cdot\infty}\int_{-\gamma_2\cdot\infty}^{\gamma_2\cdot\infty}|(G_{q^2})_{.1}(t_1,t_2)|\,d_{q^2}\underline{t}<\infty.$$

For this we would need that

$$\sum_{h_1=-\infty}^{\infty}\sum_{h_2=-\infty}^{\infty}q^{2|H|}\left|\sum_{l=0}^{\infty}\frac{(-1)^l q^{2l^2-2l}E_{q^4}(-(q^{2l+2h_1}q\gamma_1)^2)(q^{2h_2}\gamma_2)^{2l}}{(q^4;q^4)_l}\right|<\infty,$$

therefore we have to look at the limit for $h_j\to-\infty$ of the summands. Clearly by the discussion in Sec. 9 of Ref. 5, we see that we would need to have $\gamma_1=q$. With a similar reasoning we see that γ_2 must be equal to 1. Now, for general z and w we have

$$\begin{aligned}(G_{q^2}(\underline{x})_{.1})(z,w)&=\sum_{l=0}^{\infty}\frac{(-1)^l q^{2l^2-2l}w^{2l}(q^{4l}z^2;q^4)_\infty}{(q^4;q^4)_l}\\&=(z^2;q^4)_\infty\sum_{l=0}^{\infty}\frac{(-1)^l q^{2l^2-2l}w^{2l}}{(q^4;q^4)_l(z^2;q^4)_l}\\&=(z^2;q^4)_\infty{}_1\phi_1(0;z^2;q^4,w^2),\end{aligned}$$

which is the q^4 version of the q-Bessel function described in Ref. 9. For $(z,w)=(q^{2-2r},q^{2s})$ with $r\geqslant 0$ and s any integer, we have, by the estimates (2.6) and the following extimates in Ref. 9, that

$$|(G_{q^2}(\underline{x})_{.1})(q^{2-2r},q^{2s})|=q^{2r(r-1)}q^{4rs}(q^{4r+4};q^4)_\infty|{}_1\phi_1(0;q^{4r+4};q^4,q^{4r+4s})|.$$

For $r\to\infty$ and $s=-r$ this behaves like $q^{2r(r-1)-4r^2}\to\infty$. Hence $G_{q^2}(\underline{x})$ is not lattice integrable. ♠

Remarks: An analog of the symmetry (2.2) for q-Bessel functions in Ref. 9 holds in our case, namely,

$$E_{q^4}(-x_1^2)\,{}_1\phi_1(0;x_1^2;q^4,x_2^2)=G_{q^2}(\underline{x})={}_1\phi_1(0;x_2^2;q^4,x_1^2)E_{q^4}(-x_2^2),$$

once we agree that in ${}_1\phi_1$ every time we have a product of type $x_2^1/(x_1^2;q^4)_l$, the terms in x_1 have to be taken *before* the terms in x_2. Hence, in general, one has

$$E_q(-x_1-x_2)=E_q(-x_1)\,{}_1\phi_1(0;x_1;q,x_2)={}_1\phi_1(0;x_2;q,x_1)E_q(-x_2)$$

with the above meaning for ${}_1\phi_1$ in noncommuting variables.

Another equality involving a ${}_1\phi_1$ and exponentials in q-commuting variables is obtained by writing $E_q(-x_1)E_q(-x_2)$ as

$$(x_2;q)_\infty\sum_{l=0}^{\infty}\frac{(-1)^l q^{(1/2)(l^2-l)}(q^{-1}x_2;q)_l x_1^l}{(q;q)_l}$$

and using (3.12) in Ref. 5 with $x_1=-y$ and $x_2=-x$. Then one obtains

$$\sum_{l=0}^{\infty}\frac{(-1)^l q^{(1/2)(l^2-l)}x_1^l(x_2;q)_l}{(q;q)_l}=E_q(x_1x_2)E_q(-x_1),$$

where the sum on the left-hand side can be considered as a ${}_1\phi_1$ in noncommuting variables once assumed that x_1 always precedes x_2 in products. These facts were pointed out to me by T. Koornwinder. ♠

On the other hand, one can easily check that for every $A=(a_1,\ldots,a_n)$ in $\mathbf{R}^n_{>0}$ and every $E=(e_1,\ldots,e_n)$, then $x_1^{e_1}\cdots x_n^{e_n}E_{q^4}(-(a_1x_1)^2)\cdots E_{q^4}(-(a_nx_n)^2)$ is lattice integrable in the q^2-lattice generated by γ where $\gamma_j=a_j^{-1}q^{n-j+E^j}$. Unfortunately, lattice integrability carries a lot of technical work with it whenever one wants to prove anything like translation invariance, for instance. This is a consequence of the fact that, in order to state that the integral of $\partial_n^{e_n}\cdots\partial_1^{e_1}f(\underline{x})$ is zero, one needs to keep track of the lattice in which this series is integrable, which in general is not the same as the lattice in which $f(\underline{x})$ is integrable, unless e_j is even for every j. Indeed, consider $n=2$ and $f(\underline{x})=E_{q^4}(-x_1^2)E_{q^4}(-x_2^2)$. Then, $f(\underline{x})$ is integrable for $(\gamma_1,\gamma_2)=(q,1)$ while $\partial_2(f(\underline{x}))=-E_{q^4}(-q^2x_1^2)[x_2/(1-q^2)]E_{q^4}(-q^4x_2^2)$ is integrable for $(\gamma_1,\gamma_2)=(1,1)$. However, since ''morally'' the integral of a function which is odd in a variable is zero, we might as well *define* the integral of every odd function to be zero by changing the definition of the integral. Namely, we define the new integral I' to be the integral of the even part of the series $f(\underline{x})$. We formalize this definition.

Let $f(\underline{x})$ be any formal power series in the x_j's. We want to decompose it in 2^n series depending on the parity with respect to each variable. Let

$$\Pi_j^{\pm}:\hat{V}(R)^{\text{ext}}\to\hat{V}(R)^{\text{ext}}f(\underline{x})\mapsto\tfrac{1}{2}(f(\underline{x})\pm f(x_1,\ldots,x_{j-1},-x_j,x_{j+1},\ldots,x_n))$$

for every j and for any choice of $\pm$. This makes sense formally, and makes sense even concretely for the series in C. Clearly those operators commute; they are projections on the space of power series that are even (resp. odd) in the jth variable, so that $\Pi_j^+\Pi_j^-=0$ for every j. We define then for every choice of β in $\{\pm\}^n$ the operators $\Pi_\beta:\hat{V}(R)\to\hat{V}(R)$ as $(\Pi_1^{\beta_1})\circ\cdots\circ(\Pi_n^{\beta_n})$. They are all projections on their image E_β, and clearly the decomposition of the space of power series in the x_i's descends to a decomposition of the space C in 2^n spaces that we will call C_β. We also write $V^\beta:=C_\beta\triangleright 1$. We will denote $\Pi_{(+,\ldots,+)}$ by Π_0 for simplicity.

In particular, $\Pi_0 f(\underline{x})=2^{-n}\Sigma_{\varepsilon\in\{\pm1\}^n}f(\varepsilon_1x_1,\ldots,\varepsilon_nx_n)$ is even in every variable, and we define the integral I' to be the composition $I\circ\Pi_0$.

Remarks: Since we work in characteristic zero, $I'f$ is also formally equal to

$$\int_0^{x_n\cdot\infty}\cdots\int_0^{x_1\cdot\infty}\sum_{\varepsilon\in\{\pm\}^n}f(\varepsilon_1x_1,\ldots,\varepsilon_nx_n).$$

Clearly the class of I' integrable series is bigger than the class of I integrable series, since all odd series are integrable and their integral is zero. Since I' integrability of a series $f(\underline{x})$ coincides with I integrability of $\Pi_0 f(\underline{x})$, if $f(\underline{x})$ is a series which is even in all the variables, then $f(\underline{x})$ is I integrable $\Leftrightarrow f(\underline{x})$ is I' integrable since $f(\underline{x})=\Pi_0 f(\underline{x})$. ♠

One can also introduce lattice I' integrability. Again, for series in $C_{(+,\ldots,+)}$, lattice integrability and lattice I' integrability trivially coincide, and for a generic $f(\underline{x})$, lattice I' integrability trivially coincides with lattice I integrability of $\Pi_0 f(\underline{x})$ in the same lattice.

We can provide generalizations of Lemma 3.2, and Propositions 3.3 and 3.4 by introducing condition (c′) for an f such that $\Pi_0 f\in C'$:

(c′) For some $\eta>0$, there exists for each $J=(j_1,\ldots,j_n)\in\mathbf{Z}^n_{\geqslant 0}$ and $\beta\in\{\pm\}^n$ such that j_k is even (resp. odd) if $\beta_k=+$ (resp. $-$), some constant K_J such that

$$|(D_{1,q^2}^{j_1}\cdots D_{n,q^2}^{j_n}(\Pi_\beta f)_{\cdot 1})(z_1,\ldots,z_n)|\leqslant K_J\prod_{k=1}^{n}(1+|z_k|^2)^{-(1+\eta)}$$

if $\underline{z}\in\mathbf{R}^n$.

Then we have the following Lemma

Lemma 4.1: Let $f\in C'$ *satisfy condition* (c′). *Then for every* $J\neq \underline{0}$ *there holds* $(I'(\partial_n^{j_n}\cdots\partial_1^{j_1}f))\triangleright 1\equiv 0$, *so that we can conclude that* $I'(\partial_n^{j_n}\cdots\partial_1^{j_1}f)=0$.

Proof: $I'(\partial_n^{j_n}\cdots\partial_1^{j_1}f)=I(\partial_n^{j_n}\cdots\partial_1^{j_1}\Pi_\beta f)$ for β related to J as in condition (c′). □

Proposition 4.2: Let $f\in C'$ *satisfy* (c′). *Then* $(\mathrm{id}\otimes I')\Delta(f)=1\otimes(I'f)$. □

Proposition 4.3: Let $f(\underline{x})\in C$ *such that* (c′) *holds for every* $\eta>0$. *Then the statement of Proposition 3.2 holds for every polynomial* $p(\underline{x})$ *times* $f(\underline{x})$. □

We also have another invariance property that is analogous to the classical property (for $n=1$):

$$\int_{-\infty}^{\infty}\frac{1}{2}(f(x)+f(-x))\,dx=\int_{-\infty}^{\infty}\frac{1}{2}(f(x+y)+f(x-y))\,dx.$$

Proposition 4.4: Let $f(\underline{x})\in C'$ *satisfy* (c′). *Then* $(\mathrm{id}\otimes I)(\Pi_0\otimes\mathrm{id})\Delta(f)=1\otimes(I'f)$. *If* $f(\underline{x})$ *satisfies condition* (c′) *for every* $\eta>0$, *then the statement is true for every series of the form* $x_1^{e_1}\cdots x_n^{e_n}f(\underline{x})$.

Proof: The proof uses Taylor's formula with summation only on even j_k's. □

Observe that for even j_k's

$$\begin{aligned}(I(\partial_n^{j_n}\cdots\partial_1^{j_1}f))_{\cdot 1}&=(I'(\partial_n^{j_n}\cdots\partial_1^{j_1}f))_{\cdot 1}\\ &=q^{-\Sigma_k J^k}\int_{-q^{n-1}z_1\cdot\infty}^{q^{n-1}z_1\cdot\infty}\cdots\int_{-z_n\cdot\infty}^{z_n\cdot\infty}D_{1,q^2}^{j_1}\cdots D_{n,q^2}^{j_n}f_{\cdot 1}(t_1,\ldots,t_n)\,d_{q^2}t_n\cdots d_{q^2}t_1,\end{aligned}$$

hence the proposition above is interesting also because it can be proved for lattice integrability with simple changes in the hypothesis and in the proof. This reads as follows. Let $\gamma=(\gamma_1,\ldots,\gamma_n)\in\mathbf{R}^n$. We define the following spaces,

$$C(\gamma)=\{f(\underline{x})\in\hat{V}(R)^{\mathrm{ext}}|f_{\cdot 1}|_{z=\gamma}\ \text{is absolutely convergent}\}$$

and $C(q^{2K},\gamma)$ as the space of $f(\underline{x})\in C(\gamma)$ such that $f_{\cdot 1}$ can be continued analytically on a domain containing the q^2-lattice $L(\gamma)$ generated by γ. Clearly $C(\gamma)$ is closed with respect to the multiplication, hence it acts on the space V_γ of power series in commuting variables $z_1,\ldots,z_n$ that are absolutely convergent for $z=\gamma$, hence on a polydisc with polyradius $(|\gamma_1|,\ldots,|\gamma_n|)$. Let $f(\underline{x})$ be a series in $C(q^{2K}\gamma)$ for a given γ. Then it makes sense to investigate $I'(f(\underline{x}))_{\cdot 1}$ at $z_j=q^{n-j}\gamma_j$ and if this expression is absolutely convergent, then we say that $f(\underline{x})$ is lattice integrable. Actually, we would only need $\Pi_0(f)\in C(q^{2K},\gamma)$, but, since we want to compute integrals of products, we keep the restriction on $f(\underline{x})$.

Consider now the lattice version of condition (c):

(c″) Let $f(\underline{x})\in C(q^{2K},\gamma)$ be such that for every J with even entries $j_1,\ldots,j_n$, the Jackson partial derivatives $D_{1,q^2}^{j_1}\cdots D_{n,q^2}^{j_n}f_{\cdot 1}$ exist on the lattice $L(\gamma)$, and are such that

$$|(D_{1,q^2}^{j_1}\cdots D_{n,q^2}^{j_n}(f_{\cdot 1}))(q^{\pm 2k_1}\gamma_1,\ldots,q^{\pm 2k_n}\gamma_n)|=O(q^{2(1+\eta)K_-})$$

for $k_i\to\infty$, for some $\eta>0$, where K_- is the sum of the k_j's appearing with the minus sign.

We introduce the equivalence relation $\sim_\gamma$ between two expressions $f(\underline{x})$ and $g(\underline{x})$ belonging to $C(q^{2K},\gamma)$ as follows:

$$f(\underline{x})\sim_\gamma g(\underline{x})\Leftrightarrow f_{\cdot 1}(\underline{z})=g_{\cdot 1}(\underline{z}),\forall \underline{z}\in L(\gamma).$$

Proposition 4.5: Let $f(\underline{x})$ *satisfy condition* (c′) *for a given* γ, *and let* γ' *denote the n-tuple* $(q^{n-1}\gamma_1,\ldots,q^{n-j}\gamma_j,\ldots,\gamma_n)$. *Then we have the following.*

(i) *For every* J *such that every* j_k *is even,* $I'(\partial_n^{j_n}\cdots\partial_1^{j_1}f)\sim_{\gamma'}=0$.

(ii) $(\mathrm{id}\otimes I)(\Pi_0\otimes\mathrm{id})\Delta(f)\sim_{\gamma'}1\otimes(I'f)$.

Moreover, if f(x̲) satisfies condition (c″) *for every* η *and for every* $J\in\mathbf{Z}_{\geqslant 0}^n$, *then for every monomial* $x_1^{e_1}\cdots x_n^{e_n}$ we have the following.

(iii) $I'(\partial_n^{2j_n}\cdots\partial_1^{2j_1}(x_1^{e_1}\cdots x_n^{e_n}f(\underline{x})))\sim_{\gamma''}0$ *for every J, where* $\gamma''_j=q^{n-j+E^j}\gamma_j$.
(iv) $(\mathrm{id}\otimes I)(\Pi_0\otimes\mathrm{id})\Delta(x_1^{e_1}\cdots x_n^{e_n}f(\underline{x}))\sim_{\gamma''}1\otimes I'(x_1^{e_1}\cdots x_n^{e_n}f(\underline{x}))$ *where* γ'' *is as above.*

Proof: Statements (i) and (ii) are clear by the remark after the proof of Proposition 4.4. In order to prove (iii) we recall that

$$q^{4\Sigma_k J^k}I'(\partial_n^{2j_n}\cdots\partial_1^{2j_1}(x_1^{e_1}\cdots x_n^{e_n}f(\underline{x})))_{\cdot 1}$$
$$=\int_{-q^{n-1}z_1\cdot\infty}^{q^{n-1}z_1\cdot\infty}\cdots\int_{-z_n\cdot\infty}^{z_n\cdot\infty}D_{1,q^2}^{2j_1}\cdots D_{n,q^2}^{2j_n}(t_1^{e_1}\cdots t_n^{e_n}f_{\cdot 1}(q^{E^1}t_1,\ldots,q^{E^n}t_n))\,d_{q^2}t,$$

hence for $\underline{z}=\gamma''$ this expression converges, and it converges to zero. By invariance under q^2-shifts of the Jackson integral we get the statement. Statement (iv) follows from statement (iii). □

Remark: Observe that in the proof of (iii) in Proposition 4.5 the lattice in which we compute the equality depends only on the parity of the e_j's and that it is enough to be able to keep under control the partial Jackson derivatives of $(P_\beta f)_{\cdot 1}$ with $\beta_j=+(\mathrm{resp.}-)$ if e_j is even (resp. odd).♠

One may check that $E_{q^4}(-x_1^2)\cdots E_{q^4}(-x_n^2)$ satisfies all conditions of Proposition 4.5. Computations are left to the reader.

V. LATTICE ORDER INTEGRABILITY

We are still left with the problem that the q^2-Gaussian $G_{q^2}(\underline{x})$ is not lattice integrable, even with respect to I'. We have to weaken again our condition and introduce the concept of *lattice order integrability*. To simplify notation, we use analogs of I' instead of I. What we do is repeatedly apply a one-dimensional integral with respect to a noncommutative variable, say x_j. If this expression ''has a meaning'' (i.e., this expression applied to 1 converges after evaluation at $z_j=\gamma_j$), then we will identify it with a power series in noncommuting variables, in one variable less, and we are allowed to go further and repeat the procedure. Namely:

Definition 5.1: A formal power series $f(\underline{x})\in C$ *is said to be lattice order integrable (l.o. integrable) if there is an ordering of 1,...,n, denoted by the corresponding permutation* $\sigma\in S_n$, *and an n-tuple* $\gamma\in\mathbf{R}^n_{>0}$ *such that for every* $j\in\{1,...,n\}$ *the expression* $\int_{\sigma(j)}(I_{\sigma(j-1)}\cdots I_{\sigma(1)}f)$ *is entire, where* $\int_{\sigma(k)}g$ *and* $I_{\sigma(k)}g$ *are defined inductively as follows. For a formal power series f in* $\{x_1,\ldots,x_n\}-\{x_{\sigma(1)},\ldots,x_{\sigma(k-1)}\}$, $\int_{\sigma(k)}f$ *is the formal expression in the commuting variables* $\{z_1,\ldots,z_n\}-\{z_{\sigma(1)},\ldots,z_{\sigma(k)}\}$ *defined as*

$$\left(\int_{\sigma(k)}f\right)(\underline{z}):=\left(\int_{-x_{\sigma(k)}\cdot\infty}^{x_{\sigma(k)}\cdot\infty}\prod_0 f\right)_{\cdot 1}\Bigg|_{z_{\sigma(k)}=\gamma_{\sigma(k)}}.$$

If $\int_{\sigma(k)}f$ *is entire,* $I_{\sigma(k)}f$ *will denote the unique power series in the noncommuting indeterminates* $\{x_1,\ldots,x_n\}-\{x_{\sigma(1)},\ldots,x_{\sigma(k)}\}$ *such that* $(\int_{\sigma(1)}f)=(I_{\sigma(1)}f)_{\cdot 1}$. *If* $f(\underline{x})$ *is l.o. integrable, we define the constant* $I''_{(\sigma,\gamma)}f:=\int_{\sigma(n)}(I_{\sigma(n-1)}\cdots I_{\sigma(1)}f)$ *to be the lattice order integral of* $f(\underline{x})$ *associated to the order* σ *and the lattice L(γ).*

Clearly there is quite a difference between I and $I''_{(\sigma,\gamma)}$ since I maps formal power series to formal expressions in $x_1,\ldots,x_n$ while $I''_{(\sigma,\gamma)}$ maps l.o. integrable power series to constants. We will see later what the relation is between the two maps, on the space where they are both defined. We will also see in the examples that even if a power series is l.o. integrable for every order, it could still not be lattice integrable.

Observe that by definition of $\int_l$, power series that are odd in some variables are automatically defined to be l.o. integrable and that the integral will be zero for every choice of σ. For this reason, we will only investigate lattice order integrability for even power series. We can state a few results about lattice order integrability.

Proposition 5.2: Let $f(\underline{x})$ *be an even element of* $\hat{V}(R)^{\mathrm{ext}}$ *such that, for some* $\tau\in S_n$, *and for some power series in one indeterminate* $f_1,\ldots,f_n$, *we can write* $f(\underline{x})=f_{\rho(1)}(x_{\rho(1)})\cdots$

$f\rho(n)(x\rho(n))$ where $\rho=\tau^{-1}$. If $f(\underline{x})$ is l.o. integrable and every $\int_l f\neq 0$, then each f_j (viewed as a power series in one variable) is entire and lattice integrable. Conversely, if each f_j (viewed as a power series in one variable) is entire and lattice integrable, then $f(\underline{x})$ is l.o. integrable. In this case, $f(\underline{x})$ is lattice order integrable for every order σ and a suitable lattice depending on σ. Moreover, one has

$$I''_{(\sigma,\gamma)}(f(\underline{x}))=q^{\mathrm{l}(\sigma)+\mathrm{l}(\tau)}\prod_{j=1}^{n}\int_{-\gamma_j\cdot\infty}^{\gamma_j\cdot\infty}(f_j)_{\cdot 1}(t_j)\,d_{q^2}t_j\,,$$

where l *denotes the usual length of a permutation.*

Proof: ($\Rightarrow$) Suppose that $f(\underline{x})$ is as in the hypothesis, and that each f_j is entire and lattice integrable for a given $\tilde{\gamma}_j$. We write $f_j(x_j)=\Sigma_k c_{jk}x_j^k$ for every j. For an n-tuple K and for $p\in\{1,...,n\}$, we will also write

$$K_{\tau,p}:=\sum_{\substack{j>p\\ \tau(j)<\tau(p)}}k_j\quad\text{and}\quad K^{\tau,p}:=\sum_{\substack{j<p\\ \tau(j)>\tau(p)}}k_j\,.$$

We fix a σ. Then for $\sigma(1)=l$ and $\gamma_l=\tilde{\gamma}_l$ one has

$$\begin{aligned}\left(\int_l f\right)&(z_1,\ldots,z_{l-1},z_{l+1},\ldots,z_n)\\ &=2(1-q^2)\sum_{h=-\infty}^{\infty}q^{2h}\gamma_l\sum_{K'}c_{1k_1}\cdots\hat{c}_{lk_n}\cdots c_{nk_n}(q^{-1}z_1)^{k_1}\cdots(q^{-1}z_{l-1})^{k_{l-1}}\\ &\quad\times z_{l+1}^{k_{l+1}}\cdots z_n^{k_n}q^{\Sigma_{j\neq l}k_jK'_{\tau,j}}f_l(q^{2h+K'_{\tau,p}+K'^{\tau,p}}\gamma_l),\end{aligned}$$

where K' is the $(n-1)$-tuple obtained by K by deleting $\sigma(1)=l$, and

$$K'_{\tau,p}:=\sum_{\substack{l\neq j>p\\ \tau(j)<\tau(p)}}k_j\quad\text{and}\quad K^{\tau,p}:=\sum_{\substack{l\neq j<p\\ \tau(j)>\tau(p)}}k_j\,.$$

The last equality holds because

$$\begin{aligned}\sum_p k_pK_{\tau,p}&=k_lK_{\tau,l}+\sum_{p>l}k_pK_{\tau,p}+\sum_{p<l}k_pK_{\tau,p}\\ &=k_lK_{\tau,l}+\sum_{p>l}k_pK'_{\tau,p}+\sum_{p<l}k_pK'_{\tau,p}+\sum_{\substack{p<l\\ \tau(l)<\tau(p)}}k_pk_l\\ &=k_l(K_{\tau,l}+K^{\tau,l})+\sum_{p\neq l}k_pK'_{\tau,p}\,.\end{aligned}$$

By convergence of the q^2-Jackson integral of $f_{l\cdot 1}$, together with the fact that the other f_k's are entire and the fact that $K'_{\tau,p}+K'^{\tau,p}$ is an even number because the f_j's are even, one can invert the order of summation in the above sum, using dominated convergence. One gets

$$\left(\int_l f\right)(z_1,\dots,z_{l-1},z_{l+1},\dots,z_n)$$
$$=\sum_{K'} q^{\Sigma_{j\neq l}k_jK'_{\tau,j}}c_{1k_1}\cdots c_{nk_n}(q^{-1}z_1)^{k_1}\cdots(q^{-1}z_{l-1})^{k_{l-1}}z_{l+1}^{k_{l+1}}\cdots z_n^{k_n}$$
$$\times q^{-K'_{\tau,p}-K'^{\tau,p}}\int_{-q^{K'_{\tau,p}+K'^{\tau,p}}\gamma_l\cdot\infty}^{q^{K'_{\tau,p}+K'^{\tau,p}}\gamma_l\cdot\infty}(f_l)_{\cdot 1}(t_l)\,d_{q^2}t_l\,.$$

The above power series is entire since all the f_j's are, and one finds that

$$I_{\sigma(1)}f=\left(\int_{-\gamma_l\cdot\infty}^{\gamma_l\cdot\infty}(f_l)_{\cdot 1}(t_l)\,d_{q^2}t_l\right)\prod_{\substack{j\\ \rho(j)\neq l}} f_{\rho(j)}(q^{\eta_{\rho(j)}+\theta_{\rho(j)}}x_{\rho(j)})$$

with

$$\eta_k=\begin{cases}-1, & \text{if } k<\sigma(1),\\ 0, & \text{if } k>\sigma(1),\end{cases}\qquad \theta_k=\begin{cases}-1, & \text{if } k<l \text{ and } \tau(k)>\tau(l),\\ 1, & \text{if } k>l \text{ and } \tau(k)<\tau(l),\\ 0, & \text{otherwise.}\end{cases}$$

Therefore, we are again in the hypothesis of the proposition, but in the case $(n-1)$. Since the statement in one dimension is obvious, lattice order integrability is proved, considering a shifted lattice. For every new step we make, the argument of the f_j that still has to be integrated will be shifted by powers of q. If one goes through computations, one finds that the exponential of q in the shift of the argument of f_r with $r=\sigma(s)$ is

$$-\Sigma_s(\sigma,\tau)=-[\#\{j<s|\sigma(s)<\sigma(j)\}+\#\{j<s|(\sigma(j)-\sigma(s))(\tau\sigma(j)-\tau\sigma(s))<0\}],$$

hence the right lattice to integrate is the one defined by $\gamma_{\sigma(s)}=\tilde{\gamma}_{\sigma(s)}q^{\Sigma_s(\sigma,\tau)}$. In this setting, the integral will be the product of the q^2-Jackson integrals of the $f_{j\cdot 1}$'s multiplied by a power of q with exponent

$$\sum_{s=1}^n \Sigma_s(\sigma,\tau)=l(\sigma)+\sum_{s=1}^n \#\{j<s|(\sigma(j)-\sigma(s))(\tau\sigma(j)-\tau\sigma(s))<0\}=\mathrm{l}(\sigma)+\mathrm{l}(\tau),$$

since the second term in the sum is equal to the cardinality of

$$\{j,s|j<s\}\cap(\{j,s|\sigma(j)<\sigma(s),\tau\sigma(j)>\tau\sigma(s)\}\cup\{j,s|\sigma(s)<\sigma(j),\tau\sigma(s)>\tau\sigma(j)\}).$$

For the converse of the statement, one sees that if $f(\underline{x})$ can be written as a product of one-dimensional power series, those series have to be entire, and if there is a σ such that $f(\underline{x})$ is lattice order integrable, this means that $f_{\sigma(1)}$ is lattice integrable on $q^{2k_1}\gamma_{\sigma(1)}$, and so on, for the following f_j's, with shifted argument. By the $\Rightarrow$ part, we see that lattice order integrability has to hold for every σ'. □

Example 1: By the above proposition, for every $a_j\neq 0$ and for every $e_j\in\mathbf{Z}_{\geqslant 0}$ the formal power series

$$f(\underline{x})=x_n^{e_n}E_{q^4}(-a_n^2x_n^2)\cdots x_1^{e_1}E_{q^4}(-a_1^2x_1^2)$$

is l.o. integrable for every σ and $\gamma_{\sigma(k)}=a_{\sigma(k)}^{-1}q^{(k-1)+\#\{j<k|\sigma(k)<\sigma(j)\}}$, since in this case $\tau(k)=n-k+1$. In particular, $G_{q^2}(q^2\underline{x})$ and all products of type $G_{q^2}(q^2\underline{x})x_1^{e_1}\cdots x_n^{e_n}$ are l.o. integrable for every choice of the order σ. One has

$$I''_{(\sigma,\gamma)}f=\begin{cases} b_{q^2}^n\left[\prod_j (q^2;q^4)_{f_j}\right]q^{2n+2|E|}q^{\binom{n}{2}}q^{l(\sigma)}\prod_{j=1}^n a_j^{-1-e_j} & \text{if } e_j=2f_j \text{ for every } j,\\ 0, \quad \text{otherwise}, \end{cases}$$

where $b_{q^2}=(1-q^2)(q^2,-q^2,-1;q^2)_\infty$ and the result follows by Ref. 5. In particular we observe that the result depends on the choice of σ only in a straightforward way and that $L(\gamma)$ does not depend on E, but only on σ and the a_j's. Therefore one may consider the relation between $I''_{(\sigma,\gamma)}f$ and $I''_{(\sigma,\gamma)}(E_{q^4}(-\Sigma_k a_k^2x_k^2))$. One immediately sees that if all the e_j's are even,

$$I''_{(\sigma,\gamma)}(f)=\frac{(\Pi_j(q^2;q^4)_{f_j})q^{2|E|}}{(\Pi_j a_j^{e_j})}I''_{(\sigma,\gamma)}\left(E_{q^4}\left(-\sum_k a_k^2x_k^2\right)\right).$$

We say in this case (and whenever an equivalence of integrals $I''_{(\sigma,\gamma)}$ holds, with the same σ and γ on both sides) that $I(x_n^{e_n}E_{q^4}(-a_n^2x_n^2)\cdots x_1^{e_1}E_{q^4}(-a_1^2x_1^2))$ is ''*weakly equivalent*'' to $I(E_{q^4x}(-\Sigma_k a_k^2x_k^2))$. In particular, one has weak equivalence of the expression $I(x_n^{e_n}\times E_{q^4}(-q^2x_n^2)\cdots x_1^{e_1}E_{q^4}(-q^2x_1^2))$ and the expression $\Pi_j(q^2;q^4)_{f_j}I(G_{q^2}(q^2\underline{x}))$. We also want to point out that the above $f(\underline{x})$ is an example of the fact that one can have l.o. integrability for every order and still not have lattice integrability. ♠

Properties and Remarks:

(a) It is easy to check that if $f(\underline{x})$ is l.o. integrable for the order σ and the lattice $L(\gamma)$. Then, for every n-tuple of nonzero real numbers $(a_1,\ldots,a_n)$, the power series $f_A(\underline{x})=f(a_1x_1,\ldots,a_nx_n)$ is also l.o. integrable for the same order σ and for γ replaced by $\tilde{\gamma}$ where $\tilde{\gamma}_j=a_j^{-1}\gamma_j$ for every j. Then one has equivalence of the numbers $I''_{(\sigma,\gamma)}(f)=(a_1\cdots a_n)I''_{(\sigma,\tilde{\gamma})}(f_A)$.

(b) It is also obvious that if $f(\underline{x})$ is l.o. integrable for σ and γ. Then the resulting $I''_{(\sigma,\gamma)}(f)$ is invariant under shifts of each γ_j by even powers of q.

(c) In the definition of lattice order integrability the requirement on the $\int_{\sigma(k)}f$'s to be entire for every k can be weakened to analyticity. The weaker version of the definition is left to the reader. ♠

□

By the discussion above, one can conclude that for well-behaved series [by this we mean series satisfying condition (c), (c′), etc.] also the integral $I''_{(\sigma,\gamma)}$ is invariant under translation.

Remarks: The whole construction of lattice order integrability may look artificial, and it may seem to be a definition that is useful only in a noncommutative setting. However, this is not the case. One can define a similar concept of integrability also for power series in commutative variables.

VI. THE BRAIDED FOURIER TRANSFORM

Now we have all ingredients for the introduction of braided Fourier transforms on a subspace of $\hat{V}(R)^{\text{ext}}$. We introduce two transforms, related to each other by a shift in the arguments and the application of the antipode to one of them. As we already said, the first time that a Fourier transform for this kind of algebra appeared was in Ref. 3, from which we took inspiration. One of the goals of this section is to provide n-dimensional analogs to formulas (8.19)–(8.21), hence to Theorem 8.1 in Ref. 5. The difference with Ref. 5 is that in our version, the algebra $\hat{V}(R)^{\text{ext}}\otimes V(R)^{\text{ext}}$ has the braided product $(m\otimes m)(\text{id}\otimes\Psi\otimes\text{id})$ instead of the ordinary one, although in normal form his formulas and ours for $n=1$ coincide. The difference with Ref. 3 lies mainly in the fact that our integral is not bosonic [i.e., it does not have trivial braiding with elements of the algebras $\hat{V}(R)^{\text{ext}}$ and $V(R)^{\text{ext}}$]. The use of the antipode appears also in Ref. 4 where the case of finite-dimensional braided groups is treated. The following transforms behave nicely with respect to a convolution product and with respect to the action of $V(R)$ on $\hat{V}(R)^{\mathrm{ext}}$. They also respect various classical properties of the Fourier transform. These facts are developed in Refs. 3 and 13.

We say that an element $f(\underline{x})$ of $\hat{V}(R)^{\mathrm{ext}}$ is of class $\mathcal{I}$ if $f(\underline{x})x_1^{e_1}\cdots x_n^{e_n}$ is I' integrable for every monomial $x_1^{e_1}\cdots x_n^{e_n}$. We say that it is of class $\mathcal{I}_{(\sigma,\gamma)}$ if for every monomial $x_1^{e_1}\cdots x_n^{e_n}$, the power series $f(\underline{x})x_1^{e_1}\cdots x_n^{e_n}$ is lattice order integrable for σ and γ.

Again, we do not provide a complete classification of $\mathcal{I}$, but we give a class for which this makes sense, which is big enough to reach our goal. Indeed, power series satisfying condition (c) of Sec. III belong to $\mathcal{I}$, hence products of $e_{q^2}(-x_j^2)$ and polynomials belong to $\mathcal{I}$ provided that for every $j\in\{1,...,n\}$, the one-dimensional q^2-Gaussian $e_{q^2}(-x_j^2)$ appears in the product.

Definition 6.1: The braided Fourier transforms F and F_S are defined on the class $\mathcal{I}$ and they have images in $\hat{V}(R)^{\mathrm{ext}}\otimes V(R)^{\mathrm{ext}}$. They are given by

$$F:=(I'\otimes\mathrm{id})(m\otimes\mathrm{id})\left(\mathrm{id}\otimes\exp\left(x\left|\frac{i}{(1-q^2)}(\partial_1,\dots,q^{-j+1}\partial_j,\dots,q^{-n+1}\partial_n)\right)\right.\right),$$

$$F_S:=(I'\otimes S)(m\otimes\mathrm{id})\left(\mathrm{id}\otimes\exp\left(x\left|\frac{iq^2}{(1-q^2)}(q^{n-1}\partial_1,\dots,q^{n-j}\partial_j,\dots,\partial_n)\right)\right.\right).$$

For an $f(\underline{x})\in\mathcal{I}\cap C_\beta$ one has that

$$F(f(\underline{x})):=(I'\otimes\mathrm{id})\left(f(\underline{x})E_{q^2}\left(i\sum_{j=1}^{n}x_j\otimes q^{-(j-1)}\partial_j\right)\right)$$

$$=\sum_{\substack{e_1,\dots,e_n\\A(e_j)=\beta_j}}I(f(\underline{x})x_1^{e_1}\cdots x_n^{e_n})\otimes\frac{i^{|E|}q^{-\Sigma_jE^j}}{\Pi_{j=1}^n(q^2;q^2)_{e_j}}\partial_n^{e_n}\cdots\partial_1^{e_1}$$

and

$$F_S(f(\underline{x})):=(I'\otimes S)\left(f(\underline{x})E_{q^2}\left(iq^2\sum_{j=1}^{n}x_j\otimes q^{(n-j)}\partial_j\right)\right)$$

$$=\sum_{\substack{e_1,\dots,e_n\\A(e_j)=\beta_j}}I(f(\underline{x})x_1^{e_1}\cdots x_n^{e_n})\otimes\frac{(-i)^{|E|}q^{|E|^2-\Sigma_je_jE_j+|E|+\Sigma_jE_j}}{\Pi_{j=1}^n(q^2;q^2)_{e_j}}\partial_1^{e_1}\cdots\partial_n^{e_n},$$

where $A(e_j)=+(\mathrm{resp.}-)$ if e_j is even (resp. odd). Here we used that $S(\partial_n^{e_n}\cdots\partial_1^{e_1})=(-1)^{|E|}q^{|E|^2-|E|-\Sigma_je_jE_j}\partial_1^{e_1}\cdots\partial_n^{e_n}$. It is clear that the second components in the tensor product of $F(f(\underline{x}))$ and of $F_S(f(\underline{x}))$ will also have parity β. In order to provide formulas analogous to (8.21) and (8.19) in Ref. 5, we need to compute F_S for

$$M(\underline{x},A)=e_{q^4}(-x_1^2)x_1^{a_1}\cdots e_{q^4}(-x_n^2)x_n^{a_n}=x_1^{a_1}\cdots x_n^{a_n}e_{q^4}\left(-\sum_j(q^{-A_j}x_j)^2\right)$$

and for $H(\underline{x},A)=e_{q^4}(-x_1^2)\tilde{h}_{a_1}(x_1;q^2)\cdots e_{q^4}(-x_n^2)\tilde{h}_{a_n}(x_n;q^2)$ where the $\tilde{h}_{a_j}$'s are the *discrete q-Hermite II polynomials* (see Ref. 14 and references therein) that are defined by

$$\tilde{h}_l(z;q):=z^l{}_2\phi_1(q^{-n},q^{-n+1};0;q^2,-q^2z^{-2})=(q;q)_l\sum_{k=0}^{[1/2]}\frac{(-1)^kq^{-2kl+k(2k+1)}{}_zl-2k}{(q^2;q^2)_k(q;q)_{l-2k}}.$$

Both $M(\underline{x},A)$ and $H(\underline{x},A)$ satisfy condition (c) of Sec. III, so that the transform in defined on both series. We first compute the transform F_S on a generic $f(\underline{x})$. In order to give a meaning to the transform we apply the realization map π_γ sending a power series $g(\underline{x})$ to $g_{\cdot 1}(\underline{z})$, followed by evaluation at $\underline{z}=\gamma$, to the first component of $F_S(f(\underline{x}))$. By the assumption that $f(\underline{x})\in\mathcal{I}$ we know that this is well defined so that $(\pi_\gamma\otimes\mathrm{id})F_S(f(\underline{x}))$ is a genuine power series in the noncommuting ∂_j's. By the computations in the previous section, one obtains, for an $f(\underline{x})\in C_\beta\cap\mathcal{I}$,

$$(\pi_\gamma\otimes\mathrm{id})(F_S(f(\underline{x})))=\sum_{\substack{e_1,\ldots,e_n\\ A(e_j)=\beta_j}}\frac{(-i)^{|E|}q^{\Sigma_j(e_j^2+e_j)}}{\Pi_{k=1}^n(q^2;q^2)_{e_k}}\times\left(\int_{-\gamma_1 q^{n-1+E_1}\cdot\infty}^{\gamma_1 q^{n-1+E_1}\cdot\infty}\cdots\int_{-\gamma_n q^{E_n}\cdot\infty}^{\gamma_n q^{E_n}\cdot\infty}f_{\cdot 1}(\underline{t})t_1^{e_1}\cdots t_n^{e_n}d_{q^2}\underline{t}\right)\partial_1^{e_1}\cdots\partial_n^{e_n}.$$

By invariance of the q^2-integral we see that the integration bounds do not depend on E, but only on the parity of its components, hence they only depend on β. In particular, for $f(\underline{x})=f_1(x_1)\cdots f_n(x_n)\in\mathcal{I}\cap C_\beta$ one has that

$$(\pi_\gamma\otimes\mathrm{id})F_S(f(\underline{x}))=\prod_{k=1}^n\left[\sum_{A(e_k)=\beta_k}\frac{(-i)^{e_k}q^{e_k^2+e_k}\partial_k^{e_k}}{(q^2;q^2)_{e_k}}\left(\int_{-q^{B(\beta)_k+n-k}\gamma_k\cdot\infty}^{q^{B(\beta)_k+n-k}\gamma_k\cdot\infty}[(f_k)_{\cdot 1}(t_k)]t_k^{e_k}d_{q^2}t_k\right)\right],$$

where the product is taken in *increasing* order and $B(\beta)=(b(\beta)_1,\ldots,b(\beta)_n)$ is the n-tuple $\{0,1\}^n$ such that the kth entry is 0 (resp. 1) if β_k is even (resp. odd) and $B(\beta)_k=\Sigma_{j=1}^{k-1}b(\beta)_j$ as usual.

Hence we come to an n-dimensional version of formula (8.21) in Ref. 5. Let $M(\underline{x},A)$ as above. We remind the reader that in this case $\beta_j=+(\text{resp.}-)$ if a_j is even (resp. odd). Then we use the one-dimensional case to obtain our result. Indeed, expanding in power series the left-hand side of (8.21) and using q^2 instead of q one has

$$c_{q^2}(\gamma)q^{-a^2-a}i^a h_a(t;q^2)E_{q^4}(-q^4t^2)=\sum_{\substack{k\geqslant 0\\ k+a\ \text{even}}}\frac{i^k q^{k^2+k}}{(q^2;q^2)_k}\left(\int_{-\gamma\cdot\infty}^{\gamma\cdot\infty}x^{a+k}e_{q^4}(-x^2)\,d_{q^2}x\right)t^k$$
$$=\sum_{\substack{k\geqslant 0\\ k+a\ \text{even}}}\frac{i^k q^{k^2+k}}{(q^2;q^2)_k}c_{q^2}(\gamma)q^{-(a+k)^2/2}(q^2;q^4)_{(a+k)/2}t^k.$$

Using the above formula we obtain

$$(\pi_\gamma\otimes\mathrm{id})F_S(M(\underline{x},A))=\prod_{j=1}^n\left[c_{q^2}(q^{n-j+B(\beta)_j}\gamma_j)\times\sum_{\substack{e_j\geqslant 0\\ e_j+a_j\ \text{even}}}\left(\frac{(-i)^{e_j}q^{e_j^2+e_j}}{(q^2;q^2)_{e_j}}q^{-(e_j+a_j)^2/2}(q^2;q^4)_{e_j+a_j/2}\right)\partial_j^{e_j}\right]$$
$$=(-i)^{|A|}\left[\prod_{j=1}^n c_{q^2}(q^{n-j+B(\beta)_j}\gamma_j)\right]q^{\Sigma_j a_j(1-a_j)}\times\prod_{k=1}^n[E_{q^4}(-q^4\partial_k^2)h_{a_k}(\partial_k;q^2)],\tag{1}$$

where

(i) the product is taken in *increasing* order, and

(ii) $h_l(z;q^2)$ is the discrete q^2-*Hermite I* polynomial of degree l (see Ref. 14 and references therein) and is defined as

$$h_l(z;q^2):=z^l{}_2\phi_0(q^{-2l},q^{2-2l};;q^4,q^{4l-2}z^{-2})=(q^2;q^2)_l\sum_{k=0}^{[l/2]}\frac{(-1)^k q^{2k(k-1)}z^{l-2k}}{(q^4;q^4)_k(q^2;q^2)_{l-2k}}.$$

We observe that the only part of $(\pi_\gamma\otimes\mathrm{id})F_S(M(\underline{x},A))$ involving the γ_j's is the coefficient, equal to $[\int_{-q^{B(\beta)_n x_n}\cdot\infty}^{q^{B(\beta)_n x_n}\cdot\infty}\cdots\int_{-q^{B(\beta)_1 x_1}\cdot\infty}^{q^{B(\beta)_1 x_1}\cdot\infty}g_{q^2}]_{\cdot 1}|_{\underline{z}=\gamma}$, i.e., it is a shifted integral of the Gaussian $g_{q^2}(\underline{x})$ where the shift only depends on the parity of the function $M(\underline{x},A)$, i.e., only on the parity of the a_j's. So, we conclude that

$$F_S(e_{q^4}(-x_1^2)x_1^{a_1}\cdots e_{q^4}(-x_n^2)x_n^{a_n})=\left[\int_{-q^{B(\beta)_n x_n}\cdot\infty}^{q^{B(\beta)_n x_n}\cdot\infty}\cdots\int_{-q^{B(\beta)_1 x_1}\cdot\infty}^{q^{B(\beta)_1 x_1}\cdot\infty}g_{q^2}\right]$$
$$\otimes(-i)^{|A|}q^{\Sigma_j a_j(1-a_j)}\prod_{k=1}^{n}\,[E_{q^4}(-q^4\partial_k^2)h_{a_k}(\partial_k;q^2)]. \qquad (2)$$

The above result gives the analog of the classical reciprocity between Gaussians times a monomial and rescaled Gaussians times a Hermite polynomial under the Fourier transform in $\mathbf{R}^n$. From the above result we derive an analog of formula (8.19) in Ref. 5, for $H(\underline{x},A)$ defined above. $H(\underline{x},A)$ is also contained in one of the subspaces C_β since each $\tilde{h}_a(x_j;q^2)$ has constant parity. We obtain

$$F_S(e_{q^4}(-x_1^2)\tilde{h}_{a_1}(x_1;q^2)\cdots e_{q^4}(-x_n^2)\tilde{h}_{a_n}(x_n;q^2))$$
$$=\left[\int_{-q^{B(\beta)_n x_n}\cdot\infty}^{q^{B(\beta)_n x_n}\cdot\infty}\cdots\int_{-q^{B(\beta)_1 x_1}\cdot\infty}^{q^{B(\beta)_1 x_1}\cdot\infty}g_{q^2}\right]$$
$$\otimes\prod_{k=1}^{n}\left[(q^2;q^2)_{a_k}\sum_{S_k=0}^{[1/2a_k]}\frac{(-i)^{a_k}q^{-a_k^2+a_k}}{(q^4;q^4)_{s_k}(q^2;q^2)_{a_k-2s_k}}h_{a_k-2s_k}(\partial_k;q^2)E_{q^4}(-q^4\partial_k^2)\right]$$
$$=\left[\int_{-q^{B(\beta)_n x_n}\cdot\infty}^{q^{B(\beta)_n x_n}\cdot\infty}\cdots\int_{-q^{B(\beta)_1 x_1}\cdot\infty}^{q^{B(\beta)_1 x_1}\cdot\infty}g_{q^2}\right](-i)^{|A|}q^{\Sigma_k(a_k-a_k^2)}\otimes\prod_{j=1}^{n}\,(\partial_j^{a_j}E_{q^4}(-q^4\partial_j^2)), \qquad (3)$$

where the last equality follows from (10) in Ref. 5 and the product is taken in increasing order.

Observe that for well-behaved functions, and for an n-tuple $A=(a_1,\ldots,a_n)$ of nonzero real numbers, the braided Fourier transform of $f(a_1x_1,\ldots,a_nx_n)$ can be obtained by the braided Fourier transform of $f(\underline{x})$. More precisely, $(\pi_\gamma\otimes\mathrm{id})F_S(f(a_1x_1,\ldots,a_nx_n))=(\Pi_j a_j)^{-1}(\pi_{\tilde{\gamma}}\otimes\mathrm{id})\times(F_S(f(\underline{x})))(a_1^{-1}\partial_1,\ldots,a_n^{-1}\partial_n)$, where $\tilde{\gamma}$ denotes the n-tuple obtained by γ multiplying each component γ_j by a_j. Clearly, similar results holds for $(\pi_\gamma\otimes\mathrm{id})F$, hence they hold for F_S and for F.

Now we want to compute the braided Fourier transform for monomials or polynomials times a q^2-Gaussian of type $G_{q^2}(\underline{x})$. We cannot use the same definition since $G_{q^2}(\underline{x})$ is not even lattice integrable. Therefore, we introduce a weaker notion of braided Fourier transform.

Definition 6.2: The ''weak'' braided Fourier transforms $F''(\sigma,\gamma)$ and $F''_S(\sigma,\gamma)$ are defined on the class $\mathcal{I}_{(\sigma,\gamma)}$. They map this class to $V(R)^{\mathrm{ext}}$ and they are defined as

$$F''(\sigma,\gamma):=(I''_{(\sigma,\gamma)}\otimes\mathrm{id})(m\otimes\mathrm{id})\left(\mathrm{id}\otimes\exp\left(x\left|\frac{i}{(1-q^2)}(\partial_1,\ldots,q^{1-j}\partial_j,\ldots,q^{1-n}\partial_n)\right)\right)\right),$$

$$F''_S(\sigma,\gamma):=(I''_{(\sigma,\gamma)}\otimes S)(m\otimes\mathrm{id})\left(\mathrm{id}\otimes\exp\left(x\left|\frac{iq^2}{(1-q^2)}(q^{n-1}\partial_1,\ldots,q^{n-j}\partial_j,\ldots,\partial_n)\right)\right)\right).$$

We will use this new notion in order to derive an n-dimensional version of (8.20) in Ref. 5. Namely, we will derive the transform $F''(\sigma,\gamma)$ of the formal power series $N(\underline{x},A) = E_{q^4}(-q^4x_n^2)x_n^{a_n}\cdots E_{q^4}(-q^4x_1^2)x_1^{a_1}$ for given positive integers $a_1,\ldots,a_n$. One has to compute $I''_{(\sigma,\gamma)}(N(\underline{x},A)x_1^{e_1}\cdots x_n^{e_n})$ for every E with each $e_j\equiv a_j \pmod 2$, for some fixed σ and γ. This makes sense by the computations in Sec. V because $N(\underline{x},A)x_1^{e_1}\cdots x_n^{e_n}$ is equal to

$$q^{-\Sigma_j E^j(e_j+a_j)}E_{q^4}(-q^{4-2E^n}x_n^2)x_n^{e_j+a_j}\cdots E_{q^4}(-q^{4-2E^1}x_1^2)x_1^{e_1+a_1},$$

which is l.o. integrable for every σ, with $\gamma_{\sigma(k)} = q^{(k-1)+A^{\sigma(k)}+\#\{j<k|\sigma(j)>\sigma(k)\}}$. In particular, since we showed that the resulting integrals differ only by a factor $q^{l(\sigma)}$, we compute it only for $\sigma=\mathrm{id}$ and $\gamma_k = q^{k-1+A^k}$. Then, denoting by $N'(\underline{x},A)$ the power series obtained by $N(\underline{x},A)$ by multiplying the argument of the $E_{q^4}(-x_j^2)$ by q^{-E^j} for every j, one has

$$F''(\sigma,\gamma)(N(\underline{x},A)) = \sum_{\substack{e_1,\ldots,e_n\\ e_j+a_j=2h_j}} \frac{i^{|E|}q^{-\Sigma_j E_j - \Sigma_j E^j(e_j+a_j)}}{\Pi_j(q^2;q^2)_{e_j}}(I''_{(\mathrm{id},\gamma)}(N'(\underline{x},A+E)))\partial_n^{e_n}\cdots\partial_1^{e_1}.$$

Hence

$$\begin{aligned}F''(\sigma,\gamma)(N(\underline{x},A)) &= (-1)^{|A|}I''_{(\mathrm{id},\tilde{\gamma})}\left(E_{q^4}\left(-\sum_j q^4x_j^2\right)\right)\prod_{j=n}^{1}\left[\sum_{e_j+a_j=2h_j}\frac{(-i)^{e_j}(q^2;q^4)_{h_j}}{\Pi_j(q^2;q^2)_{e_j}}\partial_j^{e_j}\right]\\ &= q^{\Sigma_j(a_j^2-a_j)}i^{|A|}b_{q^2}^n q^{\binom{n}{2}}\left(\prod_{j=n}^{1}\tilde{h}_{a_j}(\partial_j;q^2)e_{q^4}(-\partial_j^2)\right).\end{aligned} \tag{4}$$

Here $\tilde{\gamma}$ denotes the n-tuple such that $\tilde{\gamma}_k = q^{A^k}\gamma_k$ and the product is taken in decreasing order. For the last equality we used (9.15) and (8.20) in Ref. 5.

Using the definition of the h_{a_j}'s, formula (4) above, and formula (8.17) in Ref. 5 one also gets the following result:

$$\begin{aligned}&F''(\sigma,\gamma)(E_{q^4}(-q^4x_n^2)h_{a_n}(x_n;q^2)\cdots E_{q^4}(-q^4x_1^2)h_{a_1}(x_1;q^2))\\ &\quad= i^{|A|}q^{\Sigma_j(a_j^2-a_j)}I''_{(\sigma,\tilde{\gamma})}\left(E_{q^4}\left(-q^4\sum_j x_j^2\right)\right)\prod_{j=n}^{1}\partial_j^{a_j}e_{q^4}(-\partial_j^2),\end{aligned} \tag{5}$$

where the product is taken in *decreasing* order and $\tilde{\gamma}$ is given by $\tilde{\gamma}_k = q^{A^k}\gamma_k$ for every k as before.

VII. INTEGRAL ON $V(R)^{\mathrm{ext}}$ AND INVERSE TRANSFORM

We provide now an inverse for the braided Fourier transforms, at least on the subspaces of the image of $\mathcal{I}$ and $\mathcal{I}_{(\sigma,\chi)}$. In order to do this we need also the integral on $V(R)^{\mathrm{ext}}$. Since there is a symmetry between $\hat{V}(R)^{\mathrm{ext}}$ and $V(R)^{\mathrm{ext}}$, one can simply repeat the definitions and computations keeping in mind that whenever we had a left action involving $\hat{V}(R)^{\mathrm{ext}}$, we will need a right action in the case of $V(R)^{\mathrm{ext}}$. We will only provide the necessary formulas, while the properties and the proofs of similar statements as those of Secs. III–V are left to the reader. We observe that all the results in this Section can be achieved both by direct computation or by using the symmetry $\psi:\hat{V}(R)^{\mathrm{ext}}\to V(R)^{\mathrm{ext}}$ defined in Sec. II.

Similarly as for $\hat{V}(R)^{\mathrm{ext}}$, $\hat{V}(R)^{\mathrm{ext}}$ acts on the right on $V(R)^{\mathrm{ext}}$ by braided partial differentiation. For a monomial $\partial_n^{e_n}\cdots\partial_1^{e_1}$, and for $j\in\{1,\ldots,n\}$ we have

$$(\partial_n^{e_n}\cdots\partial_1^{e_1})\leftharpoonup x_j = [e_j]_{q^2}\partial_n^{e_n}\cdots\partial_{j+1}^{e_{j+1}}\partial_j^{e_j-1}(q\partial_{j-1})^{e_{j-1}}\cdots(q\partial_1)^{e_1}.$$

There holds a right version of Taylor's formula, namely,

$$\Delta(g(\underline{\partial}))=g(\Delta(\underline{\partial}))=g(\underline{\partial})\leftharpoondown\left(\sum_{e_1,\ldots,e_n\geqslant 0}\frac{x_1^{e_1}\cdots x_n^{e_n}\otimes\partial_n^{e_n}\cdots\partial_1^{e_1}}{[e_1]_{q^2}!\cdots[e_n]_{q^2}!}\right).$$

The (indefinite) q^2-integral acting from the right is

$$g(\underline{\partial})\leftharpoondown\int_0^{\partial_i}:=(1-q^2)\sum_{k=0}^{\infty}g(\partial_n,\ldots,q^{2k}\partial_i,q^{-2}\partial_{i-1},\ldots,q^{-2}\partial_1)q^{2k}\partial_i,$$

and again as in the case of $\hat{V}(R)^{\text{ext}}$, one can define $\int_0^{a\partial_i}$ for a nonzero constant a. The global integral is formally obtained as the limit for all $r_j\to\infty$ of

$$g(\underline{\partial})\leftharpoondown\int_{-q^{-2r_1}\partial_1}^{q^{-2r_1}\partial_1}\cdots\int_{-q^{-2r_n}\partial_n}^{q^{-2r_n}\partial_n},$$

where

$$g(\underline{\partial})\leftharpoondown\int_{-a\partial_j}^{a\partial_j}:=\left(g(\underline{\partial})\leftharpoondown\int_0^{a\partial_j}\right)-\left(g(\underline{\partial})\leftharpoondown\int_0^{-a\partial_j}\right)$$

for every a. Hence we have formally

$$g(\underline{\partial})\leftharpoondown\int^{\underline{\partial}}:=g(\underline{\partial})\leftharpoondown\int_{-\partial_1\cdot\infty}^{\partial_1\cdot\infty}\cdots\int_{-\partial_n\cdot\infty}^{\partial_n\cdot\infty}$$

$$=(1-q^2)^n\sum_{\underline{\varepsilon}\in\{\pm1\}^n}\sum_{k_n=-\infty}^{\infty}\cdots\sum_{k_1=-\infty}^{\infty}g(\varepsilon_n q^{2k_n}\partial_n,\ldots,\varepsilon_1 q^{2k_1}\partial_1)q^{2|K|}\partial_1\cdots\partial_n.$$

As in Sec. III, one can define an action of $V(R)$ on the power series in the n commuting indeterminates $z_1,\ldots,z_n$, in order to give a meaning to the integral. One can use this action to define integrability, lattice integrability, and lattice order integrability as in Secs. IV and V, and we leave this to the reader. The action will be the right regular action after the choice of a normal form. It is denoted by $\triangleleft$ and it is defined on monomials as

$$(z_1^{k_1}\cdots z_n^{k_n})\triangleleft\partial_n^{e_n}\cdots\partial_1^{e_1}:=q^{\Sigma_j K_j e_j}z^{e_1+k_1}\cdots z_n^{e_n+k_n}=z_1^{k_1}(q^{K_1}z_1)^{e_1}\cdots z_n^{k_n}(q^{K_n}z_n)^{e_n}.$$

For simplicity we will denote $1\triangleleft g(\underline{\partial}):={}_{1.}g(\underline{z})$ for every expression $g(\underline{\partial})$ for which the action on 1 makes sense.

As in Sec. IV we construct projections $P_j^{\pm}$ defined on $V(R)$ and $V(R)^{\text{ext}}$ for every $j=1,\ldots,n$ and every choice of $+$ or $-$ as follows:

$$P_j^{\pm}:V(R)^{\text{ext}}\to V(R)^{\text{ext}}g(\underline{\partial})\mapsto\tfrac{1}{2}[g(\underline{\partial})\pm g(\ldots,-\partial_j,\ldots)].$$

Again, the $P_j^{\pm}$'s commute with each other, they are projections on the subspaces of $V(R)^{\text{ext}}$ consisting of even (resp. odd) elements with respect to the jth variable, and $P_j^{+}P_j^{-}=0$ for every j. Then, for every $\beta\in\{-,+\}^n$ we define P_β as the composite $P_1^{\beta_1}\circ\cdots\circ P_n^{\beta_n}$. The P_β's are all projections on their image G_β and clearly the decomposition $V(R)^{\text{ext}}=\oplus_\beta G_\beta$ corresponds to the decomposition of $\mathbf{C}[[\underline{z}]]$ in series that are either odd or even in each variable after applying the action on 1. We write P_0 for $P_{(+,\ldots,+)}$. We can define again the integral J' defined by $J'g:=(P_0 g)\leftharpoondown\int^{\underline{\partial}}$.

In particular one can check that for a $g(\underline{\partial})$ for which this makes sense one has

$$_{1\cdot}\left((P_0(g(\underline{\partial})))\leftharpoonup\int^{\underline{\partial}}\right)=\int_{-z_1q^{n-1}\cdot\infty}^{z_1q^{n-1}\cdot\infty}\cdots\int_{-z_nq^{n-n}\cdot\infty}^{z_nq^{n-n}\cdot\infty}{}_{1\cdot}(P_0(g))(\underline{t})\,d_{q^2}\underline{t}$$

and

$$_{1\cdot}(g\leftharpoonup D_1^{j_1}\cdots D_n^{j_n})=(D_{q^2}^{J}(1\cdot g))(q^{J^1}z_1,\ldots,q^{J^n}z_n),$$

We also observe that under the ''symmetry'' $\psi:\hat{V}(R)^{\mathrm{ext}}\to V(R)^{\mathrm{ext}}$ mapping x_j to $q^{-j+(1/2)(n-1)}\partial_{n-j+1}$ one has

$$\psi(If(x_1,\ldots,x_n))=q^{-n}\left[(\psi(f(\underline{x}))(\underline{\partial}))\leftharpoonup\int_{-q^{-n+1}\partial_1\cdot\infty}^{q^{-n+1}\partial_1\cdot\infty}\cdots\int_{-q^{-n+2j-1}\partial_j\cdot\infty}^{q^{-n+2j-1}\partial_j\cdot\infty}\cdots\int_{-q^{n-1}\partial_n\cdot\infty}^{q^{n-1}\partial_n\cdot\infty}\right].\qquad(6)$$

One defines the integral $J''_{(\sigma,\gamma)}$ for l.o. integrable power series as the right-handed version of $\hat{I}''_{(\sigma,\gamma)}$. We will need $J''_{(\sigma,\gamma)}(E_{q^4}(-q^4\partial_1^2)\partial_1^{a_1},\ldots,E_{q^4}(-q^4\partial_n^2)\partial_n^{a_n})$. One checks as for the case of $\hat{V}(R)^{\mathrm{ext}}$ that the integrand is actually is l.o. integrable for every σ for a suitable choice of γ, and that the results differ only by a factor $q^{\mathrm{l}(\sigma)}$. In particular, for $\sigma=\mathrm{id}$ one needs $\gamma_k=q^{(k-1)+A^k}$ and one gets

$$J''_{(\sigma,\gamma)}(E_{q^4}(-q^4\partial_1^2)\partial_1^{a_1},\ldots,E_{q^4}(-q^4\partial_n^2)\partial_n^{a_n})=\begin{cases}q^{\binom{n}{2}}b_{q^2}^{n}\prod_j(q^2;q^4)_{b_j}, & \text{if } a_j=2b_j\,\forall j,\\ 0, & \text{otherwise.}\end{cases}$$

Hence,

$$J''_{(\sigma,\gamma)}(E_{q^4}(-q^4\partial_1^2)\partial_1^{a_1}\ldots,E_{q^4}(-q^4\partial_n^2)\partial_n^{a_n})=\left(J''_{(\sigma,\gamma)}\left(E_{q^4}\left(-q^4\sum_j\partial_j^2\right)\right)\right)\prod_j(q^2;q^2)_{b_j}$$

if $a_j=2b_j$ for every j.

Properties like right invariance of the integral, nullity of the integral of the partial derivative of a power series, etc., can be proved as in Sec. III–V.

We introduce now an inversion formula for F_S and F and their weak analogs. We will use the symmetry between $\hat{V}(R)^{\mathrm{ext}}$ and $V(R)^{\mathrm{ext}}$ and the results at the end of the previous section in order to provide an analog of Theorem 8.1 in Ref. 5. An inversion formula for the braided Fourier transform is to be found in Ref. 3, but the authors had the hypothesis that the integral is ''bosonic,'' i.e., it has a trivial braiding with $\hat{V}(R)$, or $V(R)$ for $n\geqslant 2$, which is not our case as the reader can easily check (see also Ref. 15 for a few remarks about this property of the integral). Moreover, the element *vol* in Ref. 3 is not necessarily convergent.

We say that a power series $g(\underline{\partial})$ in $V(R)^{\mathrm{ext}}$ is *of class* $\mathcal{J}$ if every monomial times $g(\underline{\partial})$ is J' integrable. This is possible, for instance, if $g(\underline{\partial})$ satisfies conditions similar to condition (c) of Sec. III. We say that $g(\underline{\partial})$ is *of class* $\mathcal{J}_{(\sigma,\gamma)}$ if there is an order σ and a lattice $L(\gamma)$ such that every monomial times $g(\underline{\partial})$ is lattice order integrable for σ and γ.

Definition 7.1: We define the linear maps G, $G_S:\mathcal{J}\to\hat{V}(R)^{\mathrm{ext}}\otimes V(R)^{\mathrm{ext}}$ *by*

$$G:=\left[(\mathrm{id}\otimes m)\left(\exp\left(x\left|\frac{i}{(1-q^2)}(\partial_1,\ldots,q^{-j+1}\partial_j,\ldots,q^{-n+1}\partial_n)\right.\right)\otimes\mathrm{id}\right)\right]\leftharpoonup(\mathrm{id}\otimes J'),$$

$$G_S:=\left[(S\otimes m)\left(\exp\left(x\left|\frac{iq^2}{(1-q^2)}(q^{n-1}\partial_1,\ldots,q^{n-j}\partial_j,\ldots,\partial_n)\right.\right)\otimes\mathrm{id}\right)\right]\leftharpoonup(\mathrm{id}\otimes J').$$

For instance, for G_S, the transform of a given $g(\underline{\partial})\in\mathcal{J}$ of fixed parity β will be

$$G_S(g(\underline{\partial}))=\left((S\otimes\mathrm{id})\left(E_{q^2}\left(iq^2\sum_j q^{(n-j)}x_j\otimes\partial_j\right)\right)g(\underline{\partial})\right)\leftharpoondown(\mathrm{id}\otimes J')$$

$$=\sum_{\substack{e_1,\dots,e_n\\ A(e_j)=\beta_j}}\frac{(-i)^{|E|}q^{|E|^2+|E|}q^{\Sigma_j(n-j)e_j}}{\Pi_j(q^2;q^2)_{e_j}}x_1^{e_1}\cdots x_n^{e_n}\otimes(\partial_n^{e_n}\cdots\partial_1^{e_1}g(\underline{\partial})\leftharpoondown(\mathrm{id}\otimes J')).$$

If $\tau: V(R)^{\mathrm{ext}}\otimes\hat{V}(R)^{\mathrm{ext}}\to\hat{V}(R)^{\mathrm{ext}}\otimes V(R)^{\mathrm{ext}}$ denotes the usual flip operator, putting $c_j=q^{-j+(1/2)(n-1)}$ for every $j=1,...,n$ we observe after some computations that, for $f(\underline{x})=f_1(x_1)\cdots f_n(x_n)$ with f_j of parity β_j, there holds

$$\tau(\psi\otimes\psi^{-1})F_S(f(\underline{x}))=\sum_{\substack{e_1,\dots,e_n\\ A(e_j)=\beta_j}}\frac{(-i)^{|E|}q^{|E|^2+|E|+\Sigma_jE^j}}{\Pi_j(q^2;q^2)_{e_j}}(c_1^{-1}x_1)^{e_n}\cdots(c_j^{-1}x_j)^{e_{n-j+1}}\cdots(c_n^{-1}x_n)^{e_1}$$

$$\otimes[\partial_n^{e_1}\cdots\partial_1^{e_n}f_1(\partial_n)\cdots f_n(\partial_1)]\leftharpoondown\int_{-q^{-n+1+E_n-E_1}c_n\partial_1\cdot\infty}^{q^{-n+1+E_n-E^1}c_n\partial_1\cdot\infty}\cdots\int_{-c_1q^{n-1+E_1-E^n}\partial_n\cdot\infty}^{c_1q^{n-1+E_1-E^n}\partial_n\cdot\infty}.$$

Hence, we see that the formal expression of $\tau(\psi\otimes\psi^{-1})F_S(f(\underline{x}))$ coincides with the formal expression of

$$G_S(f_1(\partial_n)\cdots f_n(\partial_1))((c_1^{-1}x_1,\dots,c_n^{-1}x_n)\otimes(q^{n-1+E_1-E^1}c_1\partial_n,\dots,q^{E_n-E^n+1-n}c_n\partial_1)).$$

In the same way one shows that the formal expression of $\tau(\psi\otimes\psi^{-1})F(f(\underline{x}))$ coincides with

$$G(f_1(\partial_n)\cdots f_n(\partial_1))((c_1^{-1}x_1,\dots,c_n^{-1}x_n)\otimes(q^{n-1+E_1-E^1}c_1\partial_n,\dots,q^{E_n-E^n+1-n}c_n\partial_1)).$$

We can use the symmetry between F_S and G_S, together with formula (2), in order to compute $G_S(\partial_n^{a_n}e_{q^4}(-\partial_n^2)\cdots\partial_1^{a_1}e_{q^4}(-\partial_1^2))$ for given positive integers $a_1,\dots,a_n$ of parity, respectively, $\beta_1,\dots,\beta_n$. This symmetry tells us that

$$G_S(e_{q^4}(-\partial_n^2)\partial_n^{a_n}\cdots e_{q^4}(-\partial_1^2)\partial_1^{a_1})=(L_\psi\otimes L'_{\psi,\beta})[\tau(\psi\otimes\psi^{-1})\tau F_S(e_{q^4}(-x_1^2)x_1^{a_n}\cdots e_{q^4}(-x_n^2)x_n^{a_1})],$$

where L_ψ is the shift operator mapping x_j to c_jx_j and $L'_{\psi,\beta}$ is the shift operator mapping ∂_j to $q^{n-2j+1+B(\beta)^j-B(\beta)_j}c_{n-j+1}^{-1}\partial_j$. Then the above expression is equal to

$$(-i)^{|A|}q^{\Sigma_j(a_j-a_j^2)}\prod_{j=n}^{1}[E_{q^4}(-q^4x_j^2)h_{a_j}(x_j;q^2)]\otimes L'_{\psi,\beta}\psi\int_{-q^{B(\beta)^1}x_n\cdot\infty}^{q^{B(\beta)^1}x_n\cdot\infty}\cdots\int_{-q^{B(\beta)^n}x_1\cdot\infty}^{q^{B(\beta)^n}x_1\cdot\infty}g_{q^2}$$

$$=(-i)^{|A|}q^{\Sigma_j(a_j-a_j^2)}\prod_{j=n}^{1}[E_{q^4}(-q^4x_j^2)h_{a_j}(x_j;q^2)]$$

$$\otimes q^{-n}L'_{\psi,\beta}\left(g_{q^2}(c_1\partial_n,\dots,c_n\partial_1)\leftharpoondown\int_{-q^{B(\beta)^1-n+1}\partial_1\cdot\infty}^{q^{B(\beta)^1-n+1}\partial_1\cdot\infty}\cdots\int_{-q^{B(\beta)^n+n-1}\partial_n\cdot\infty}^{q^{B(\beta)^n+n-1}\partial_n\cdot\infty}\right).$$

Hence we can conclude that

$$G_S(e_{q^4}(-\partial_n^2)\partial_n^{a_n}\cdots e_{q^4}(-\partial_1^2)\partial_1^{a_1})=(-i)^{|A|}q^{\Sigma_j(a_j-a_j^2)}\prod_{j=n}^{1}[E_{q^4}(-q^4x_j^2)h_{a_j}(x_j;q^2)]$$

$$\otimes\left(g_{q^2}\leftharpoondown\int_{-q^{B(\beta)_1}\partial_1\cdot\infty}^{q^{B(\beta)_1}\partial_1\cdot\infty}\cdots\int_{-q^{B(\beta)_n}\partial_n\cdot\infty}^{q^{B(\beta)_n}\partial_n\cdot\infty}\right), \tag{7}$$

where the second component of the tensor product clearly depends only on the parity of the a_j's. Formula (7) can also be obtained by direct computation. Using the definition of the $\tilde{h}_m(z;q^2)$, with the same relation as before between the a_j's and the β_j's, one obtains

$$G_S(\tilde{h}_{a_n}(\partial_n;q^2)e_{q^4}(-\partial_n^2)\cdots\tilde{h}_{a_1}(\partial_1;q^2)e_{q^4}(-\partial_1^2))$$
$$=(-i)^{|A|}q^{\Sigma_j(a_j-a_j^2)}\prod_{j=n}^{1}[E_{q^4}(-q^4x_j^2)x_j^{a_j}]\otimes\left(g_{q^2}\leftharpoonup\int_{-q^{B(\beta)_1}\partial_1\cdot\infty}^{q^{B(\beta)_1}\partial_1\cdot\infty}\cdots\int_{-q^{B(\beta)_n}\partial_n\cdot\infty}^{q^{B(\beta)_n}\partial_n\cdot\infty}\right),\quad(8)$$

which is the $V(R)^{\mathrm{ext}}$ version of (3). By these results we can conclude the following:

Proposition 7.2: Let $\beta=(\beta_1,\dots,\beta_n)\in\{\pm 1\}^n$, σ *be any order, and* γ *be the n-tuple with components given by* $\gamma_{\sigma(k)}=q^{B(\beta)^{\sigma(k)}+k-1+\#\{j<k|\sigma(j)>\sigma(k)\}}$. *Then on power series in* $\hat{V}(R)^{\mathrm{ext}}$ *of type* $E_{q^4}(-q^4x_n^2)p_n(x_n)\cdots E_{q^4}(-q^4x_1^2)p_1(x_1)$, *where the* p_i*'s are polynomials of fixed parity* $\beta_1,\dots,\beta_n$, *there holds*

$$G_S\circ F''(\sigma,\gamma)=\mathrm{id}\otimes(I''_{(\sigma,\tilde{\gamma})}G_{q^2}(q^2\underline{x}))\left(g_{q^2}\leftharpoonup\int_{-q^{B(\beta)_1}\partial_1\cdot\infty}^{q^{B(\beta)_1}\partial_1\cdot\infty}\cdots\int_{-q^{B(\beta)_n}\partial_n\cdot\infty}^{q^{B(\beta)_n}\partial_n\cdot\infty}\right),$$

where $\tilde{\gamma}$ *is such that* $\tilde{\gamma}_k=\gamma_k q^{B(\beta)_k}$ *for every k. Therefore for power series in* $V(R)^{\mathrm{ext}}$ *of the form* $w_n(\partial_n)e_{q^4}(-\partial_n^2)\cdots w_1(\partial_1)e_{q^4}(-\partial_1^2)$, *where the* w_j*'s are polynomials of fixed parity* $\beta_1,\dots,\beta_n$, *one has*

$$(F''(\sigma,\gamma)\otimes\mathrm{id})G_S=\mathrm{id}\otimes(I''_{(\sigma,\tilde{\gamma})}G_{q^2}(q^2\underline{x}))\left(g_{q^2}\leftharpoonup\int_{-q^{B(\beta)_1}\partial_1\cdot\infty}^{q^{B(\beta)_1}\partial_1\cdot\infty}\cdots\int_{-q^{B(\beta)_n}\partial_n\cdot\infty}^{q^{B(\beta)_n}\partial_n\cdot\infty}\right)$$

with $\tilde{\gamma}$ *as before.*

Proof: It follows by (5) and (7). □

A slightly more general version of this proposition holds by considering a proper γ and q^2-Gaussians where the argument is multiplied by a nonzero constant.

We also want to consider another inverse transform, the weak transform inverting (2) and (3).

Definition 7.3: The ''weak'' transforms $G''(\sigma,\gamma)$ *and* $G''_S(\sigma,\gamma)$ *map* $\mathcal{J}_{(\sigma,\gamma)}$ to $\hat{V}(R)^{\mathrm{ext}}$ *and are defined as*

$$G''(\sigma,\gamma)\coloneqq\left[(\mathrm{id}\otimes m)\left(\exp\left(x\left|\frac{i}{(1-q^2)}(\partial_1,\dots,q^{-j+1}\partial_j,\dots,q^{-n+1}\partial_n)\right)\otimes\mathrm{id}\right)\right]\leftharpoonup(\mathrm{id}\otimes J''_{(\sigma,\gamma)}),$$

$$G''_S(\sigma,\gamma)\coloneqq\left[(S\otimes m)\left(\exp\left(x\left|\frac{iq^2}{(1-q^2)}(q^{n-1}\partial_1,\dots,q^{n-j}\partial_j,\dots,\partial_n)\right)\otimes\mathrm{id}\right)\right]\leftharpoonup(\mathrm{id}\otimes J''_{(\sigma,\gamma)}).$$

As in formulas (4) and (5), one finds, for $\sigma=\mathrm{id}$ and $\gamma_k=q^{A^k+k-1}$ (and similarly for different σ's),

$$G''_{(\mathrm{id},\gamma)}(E_{q^4}(-q^4\partial_1^2)\partial_1^{a_1}\cdots E_{q^4}(-q^4\partial_n^2)\partial_n^{a_n})=q^{\Sigma_j(a_j^2-a_j)}i^{|A|}\left(\prod_{j=1}^{n}\tilde{h}_{a_j}(x_j;q^2)e_{q^4}(-x_j^2)\right)$$
$$\times[J''_{(\mathrm{id},\tilde{\gamma})}(G_{q^2}(q^2\underline{\partial}))]\quad(9)$$

and

$$G''_{(\mathrm{id},\gamma)}(E_{q^4}(-q^4\partial_1^2)h_{a_1}(\partial_1)\cdots E_{q^4}(-q^4\partial_n^2)h_{a_n}(\partial_n))$$
$$=q^{\Sigma_j(a_j^2-a_j)}i^{|A|}\left(\prod_{j=1}^{n}x_j^{a_j}e_{q^4}(-x_j^2)\right)[J''_{(id,\tilde{\gamma})}(G_{q^2}(q^2\underline{\partial}))],\quad(10)$$

where in both formulas $\tilde{\gamma}_k = q^{k-1}$ for every k and the product is taken in increasing order. These formulas can be obtained by using the symmetry or by direct computation. One has the second inversion property.

Proposition 7.4: Let $\beta = (\beta_1, \ldots, \beta_n) \in \{\pm 1\}^n$, σ *be any order, and* γ *be the n-tuple with components given by* $\gamma_{\sigma(k)} = q^{B(\beta)^{\sigma(k)} + k - 1 + \#\{j<k | \sigma(j) > \sigma(k)\}}$. *Then on power series in* $V(R)^{\mathrm{ext}}$ *of type* $E_{q^4}(-q^4 \partial_1^2) p_1(\partial_1) \cdots E_{q^4}(-q^4 \partial_n^2) p_n(\partial_n)$, *where the* p_j*'s are polynomials of fixed parity* $\beta_1, \ldots, \beta_n$, *there holds*

$$F_S \circ G''(\sigma,\gamma) = \left[\int_{-q^{B(\beta)_n} x_n \cdot \infty}^{q^{B(\beta)_n} x_n \cdot \infty} \cdots \int_{-q^{B(\beta)_1} x_1 \cdot \infty}^{q^{B(\beta)_1} x_1 \cdot \infty} g_{q^2} \right] (J''_{(\sigma,\tilde{\gamma})}(G_{q^2}(q^2 \underline{\partial}))) \otimes \mathrm{id},$$

where $\tilde{\gamma}_{\sigma(k)} = \gamma_{\sigma(k)} q^{B(\beta)^{\sigma(k)}}$. *Therefore for power series in* $\hat{V}(R)^{\mathrm{ext}}$ *having the form* $w_1(x_1) \times e_{q^4}(-x_1^2) \cdots w_n(x_n) e_{q^4}(-x_n^2)$ *where the* w_j*'s are polynomials of fixed parity* $\beta_1, \ldots, \beta_n$, *one has*

$$(\mathrm{id} \otimes G''(\sigma,\gamma)) F_S = \left[\int_{-q^{B(\beta)_n} x_n \cdot \infty}^{q^{B(\beta)_n} x_n \cdot \infty} \cdots \int_{-q^{B(\beta)_1} x_1 \cdot \infty}^{q^{B(\beta)_1} x_1 \cdot \infty} g_{q^2} \right] (J''_{(\sigma,\tilde{\gamma})}(G_{q^2}(q^2 \underline{\partial}))) \otimes \mathrm{id}$$

with $\tilde{\gamma}$ *as before.*

Proof: It follows by (2), (3), (9), and (10). □

One observes that in this case the Plancherel measure is always a product of integrals of q^2-Gaussians, but the integration bounds depend on the parity of the power series. So these transforms could also be seen as sine and cosine transforms (see for this also Ref. 9 where the q-sine and q-cosine transforms in commuting variables are defined).

Remark: The break in symmetry appearing in q^2-integration is a phenomenon that has recently been observed in Ref. 7. Sometimes this lack of symmetry can be avoided, for instance if the generalized function $f(\underline{x})$ that we want to integrate (and transform) is lattice integrable in $L(\gamma)$ and $L(q\gamma)$. In this case we could replace q^2-integration by q-integration since $\int_{-\gamma\cdot\infty}^{\gamma\cdot\infty} f_{\cdot 1}(t)\, d_q t = \int_{-\gamma\cdot\infty}^{\gamma\cdot\infty} f_{\cdot 1}(t)\, d_{q^2} t + \int_{-q\gamma\cdot\infty}^{q\gamma\cdot\infty} f_{\cdot 1}(t)\, d_{q^2} t$. The new defined integral will be again invariant under translation. The q-integral of a q^2-Gaussians $g_{q^2}(\underline{x})$ times a monomial will be similar to the q^2-integral of the same expression. Using the q-integral in the definition of $(\pi_\gamma \otimes \mathrm{id}) F_S$ will provide results similar to formula (1) but with $\Pi_j c_{q^2}(q^{n-j+B(\beta)_j} \gamma_j)$ replaced by $\Pi_j (c_{q^2}(\gamma_j) + c_{q^2}(q\gamma_j))$. The result will be therefore independent of the parity of the a_j's. However, this approach cannot be used for $G_{q^2}(\underline{x})$, since we have seen that there is only one q^2-lattice for which $G_{q^2}(\underline{x})$ is lattice order integrable. ♠

(Received 16 April 1999; accepted for publication 3 June 1999)

We introduce a noncommutative differential calculus on the two-parameter *h*-superplane via a contraction of the (p,q)-superplane. We manifestly show that the differential calculus is covariant under $GL_{h_1,h_2}(1|1)$ transformations. We also give a two-parameter deformation of the $(1+1)$-dimensional phase space algebra. [S0022-2488(99)04010-4]

I. INTRODUCTION

Quantum groups are a generalization of the concept of classical groups. The theory of quantum groups has become an important branch of mathematical physics and a new branch of mathematics. An approach to obtain the quantum groups is to identify the elements of a quantum group with the linear transformations of a space with noncommuting coordinates. It is known, from the work of Woronowicz,[1] that one can define a consistent differential calculus on the noncommutative space of a quantum group. Thus quantum group is a concrete example of noncommutative differential geometry.[2]

During the past few years, Wess–Zumino[3] have developed a differential calculus on the quantum (hyper)plane which is covariant under the action of the quantum group $GL_q(n)$. The natural extension of their scheme to superspace[4] was given by Soni[5] and the two-parameter differential calculus on the superplane has been worked out by Chung.[6] A differential calculus on the *h*-plane was given by Karimipour[7] and the two-parameter analog was introduced by Aghamohammadi.[8]

In this paper we construct a two-parameter differential calculus on the quantum *h*-superplane using the methods of Ref. 9. The paper is organized as follows: in Sec. II we obtain the (h_1,h_2)-superplanes via a contraction from the (p,q)-superplanes. We define derivatives and differentials on the (h_1,h_2)-superplane of noncommuting coordinates and give their commutation rules. In Sec. III we manifestly show that the differential calculus is covariant under the action of the quantum supergroup $GL_{h_1,h_2}(1|1)$ of Ref. 10. We give a two-parameter deformation of the $(1+1)$-dimensional phase space algebra in Sec. IV, and in the following section we show that the (p,q)-deformed superoscillator algebra satisfies the undeformed super-oscillator algebra when objects are transformed into new objects such that they are singular for certain values of the deformation parameters.

II. DIFFERENTIAL CALCULUS ON THE *h*-SUPERPLANE

In this work we denote (p,q)-deformed objects by primed quantities. Unprimed quantities represent transformed coordinates. As usual, we shall always assume that even (bosonic) objects commute with everything and odd (Grassmann) objects anticommute among themselves. Before discussing the two-parameter differential calculus on the *h*-superplane we give some notations and useful formulas in the following section. This first section closely follows the approach of Ref. 10.

[a)]Electronic mail: scelik@fened.msu.edu.tr

A. Quantum *h*-superplane

Quantum superplane is an associative coordinate algebra $\mathcal{A}_q$ equipped with a set $\{x', \theta'\}$ of generators x', θ'. The commutation relations of the generators is defined by[4]

$$x'\theta' - q\theta' x' = 0. \tag{1a}$$

$$\theta'^2 = 0, \tag{1b}$$

where q is a nonzero complex deformation parameter. The coordinates neither commute nor anticommute unless $q \to \pm 1$, respectively. In this work we shall use the limits $p \to 1, q \to 1$ to make a contraction.

We now introduce new coordinates x and θ, in terms of x' and θ', by[10]

$$\begin{aligned} x &= x' - \frac{h_1}{p-1}\theta', \\ \theta &= -\frac{h_2}{q-1}x' + \left(1 - \frac{h_1 h_2}{(p-1)(q-1)}\right)\theta'. \end{aligned} \tag{2}$$

Using relation (1), it is easy to verify that

$$x\theta = q\theta x + h_2 x^2, \tag{3a}$$

where the new deformation parameter h_2 commutes with the coordinate x and anticommutes with the coordinate θ. Similarly, from (1a) one obtains

$$\theta^2 = -h_2 \theta x. \tag{3b}$$

where

$$h_1 h_2 = -h_2 h_1, \quad h_1^2 = 0 = h_2^2. \tag{4}$$

That is, the new deformation parameters h_1 and h_2 are odd (Grassmann) numbers which anticommute. Note that although in the $p \to 1$, $q \to 1$ limits the transformation (2) is ill behaved, the resulting commutation relations are well defined.

The relations (3) define a new deformation,[11] which we called the h_2-deformation of the algebra of coordinate functions on the Manin superplane generated by x and θ in the limit $q \to 1$, and will be denoted by $\mathcal{A}_{h_2}$.

Differential calculus on the quantum superplane $\mathcal{A}_{h_2}$ requires the introduction of differentials $\mathrm{d}x, \mathrm{d}\theta$. The complete framework also includes the commutation relations of these differentials with the coordinates and derivatives.

B. Relations between coordinates and differentials

To establish a noncommutative differential calculus on the quantum superplane $\mathcal{A}_{h_2}$, we assume that the commutation relations between the coordinates and their differentials have the following form:

$$\begin{aligned} x'\mathrm{d}x' &= A\,\mathrm{d}x' x', \\ x'\mathrm{d}\theta' &= C_{11}\mathrm{d}\theta' x' + C_{12}\mathrm{d}x'\theta', \\ \theta'\mathrm{d}x' &= C_{21}\mathrm{d}x'\theta' + C_{22}\mathrm{d}\theta' x', \\ \theta'\mathrm{d}\theta' &= B\,\mathrm{d}\theta'\theta'. \end{aligned} \tag{5}$$

Now we would like to transform these relations to unprimed quantities to determine the coefficients *A*, *B*, and C_{ij}. We first introduce the exterior differential d.

The exterior differential d is an operator which gives the mapping from the coordinates to the differentials

$$\mathsf{d}: Z^i \rightarrow \mathsf{d}Z^i, \tag{6}$$

where $Z^1=x$, $Z^2=\theta$, $\mathsf{d}Z^1=\mathsf{d}x$, and $\mathsf{d}Z^2=\mathsf{d}\theta$. We demand that the exterior differential d has to satisfy two properties; the nilpotency

$$\mathsf{d}^2=0, \tag{7}$$

and the graded Leibniz rule

$$\mathsf{d}(FG)=(\mathsf{d}F)G+(-1)^{\hat{F}}F(\mathsf{d}G), \tag{8}$$

where $\hat{F}$ is the Grassmann degree of *F*, that is, $\hat{F}=0$ for even variables and $\hat{F}=1$ for odd variables. We wish to substitute into (5) the differentials $\mathsf{d}x'$ and $\mathsf{d}\theta'$ together with the coordinates x' and θ'. The deformation parameters h_1 and h_2 are both odd numbers and the exterior differential d is also odd. Therefore the action of the exterior differential d on αu is defined by

$$\mathsf{d}(\alpha u)=(-1)^{\hat{\alpha}}\alpha \mathsf{d}u, \tag{9}$$

where α is a number (even or odd) and *u* is a coordinate of superplane. So we can write from (2)

$$\begin{aligned} \mathsf{d}x &= \mathsf{d}x' + \frac{h_1}{p-1}\mathsf{d}\theta', \\ \mathsf{d}\theta &= \frac{h_2}{q-1}\mathsf{d}x' + \left(1-\frac{h_1h_2}{(p-1)(q-1)}\right)\mathsf{d}\theta'. \end{aligned} \tag{10}$$

Note that if we consider *x* and θ as functions of two variables (say x' and θ') and differentiate (2), as usual, then we do not obtain the expressions in (10). To obtain (10) one must take the differential from the left in Eq. (2). In the Appendix, we explain this in detail.

We now substitute (2) and (10) into (5) which are not explicitly written here. It will be calculate the coefficients *A*, *B* and C_{ij}. We first assume that

$$\mathsf{d}x'\mathsf{d}\theta' = p^{-1}\mathsf{d}\theta'\mathsf{d}x', \quad (\mathsf{d}x')^2=0. \tag{11}$$

Then we have

$$\mathsf{d}\theta\mathsf{d}x = p\mathsf{d}x\mathsf{d}\theta - h_1(\mathsf{d}\theta)^2, \tag{12a}$$

and

$$(\mathsf{d}x)^2 = h_1\mathsf{d}x\mathsf{d}\theta. \tag{12b}$$

Consequently, the coefficients are determined as follows:

$$\begin{aligned} &A \ \text{ undetermined}, \quad B=1, \\ &C_{11}=q, \quad C_{12}=pq-1, \quad C_{21}=0, \quad C_{22}=-p. \end{aligned} \tag{13}$$

Here we shall choose *A* equal to *pq* since the relations are then well defined.

C. Relations of derivatives and coordinates

In this section we shall define the derivatives and find the commutation relations of derivatives with coordinates and the commutation relations between derivatives. We first introduce the matrix[10]

$$g=\begin{pmatrix} 1+h_1h_2/(p-1)(q-1) & h_1/(p-1) \\ h_2/(q-1) & 1 \end{pmatrix}. \tag{14}$$

It is easy to verify that the matrix g is a supermatrix. Thus we can write the transformation in (2) of the form

$$Z'=gZ, \quad Z'=\begin{pmatrix} x' \\ \theta' \end{pmatrix}. \tag{15}$$

Let us denote the partial derivatives with respect to x' and θ' by

$$\partial_{x'}=\frac{\partial}{\partial x'}, \quad \partial_{\theta'}=\frac{\partial}{\partial \theta'},$$

respectively. The transformation law of the partial derivatives is then defined by

$$\partial'=(g^{\mathrm{st}})^{-1}\partial, \quad \partial=\begin{pmatrix} \partial_x \\ \partial_\theta \end{pmatrix}, \tag{16}$$

where g^{st} denotes the supertranspose of g. Explicitly

$$\partial_{x'}=\partial_x-\frac{h_2}{q-1}\partial_\theta, \quad \partial_{\theta'}=\frac{h_1}{p-1}\partial_x+\left(1-\frac{h_1h_2}{(p-1)(q-1)}\right)\partial_\theta. \tag{17}$$

Note that, when one demands the validity of the chain rule, to obtain the expressions in (17) it must be assumed that the derivatives act from the left on the transformed variables. This case will also be explained in detail in the Appendix.

We know that the exterior differential d is defined by

$$\mathsf{d}=\mathsf{d}x'\,\partial_{x'}+\mathsf{d}\theta'\,\partial_{\theta'}. \tag{18a}$$

Substituting (10) and (17) into (18a) one obtains

$$\mathsf{d}=\mathsf{d}x\,\partial_x+\mathsf{d}\theta\,\partial_\theta, \tag{18b}$$

that is, d preserves its form. So, since

$$\mathsf{d}F(x,\theta)=\mathsf{d}x\,\partial_xF+\mathsf{d}\theta\,\partial_\theta F, \tag{19}$$

for any function F, replacing F with xF and θF we get the following relations:

$$\begin{aligned}
\partial_x x&=1+pqx\partial_x+h_1\theta\partial_x+h_2x\partial_\theta+h_1h_2(x\partial_x+\theta\partial_\theta)+(pq-1)\theta\partial_\theta,\\
\partial_x\theta&=p\theta\partial_x-ph_2(x\partial_x+\theta\partial_\theta),\\
\partial_\theta x&=qx\partial_\theta-qh_1(x\partial_x+\theta\partial_\theta),\\
\partial_\theta\theta&=1-\theta\partial_\theta+h_1\theta\partial_x+h_2x\partial_\theta+h_1h_2(x\partial_x+\theta\partial_\theta).
\end{aligned} \tag{20}$$

We now find the commutation rules between derivatives. These rules can be easily obtained by using the nilpotency of the exterior differential. Thus we write

$$0=\mathrm{d}^2=\mathrm{d}x\,\mathrm{d}\theta(p\partial_x\partial_\theta-\partial_\theta\partial_x+h_1\partial_x^2)+(\mathrm{d}\theta)^2(\partial_\theta^2-h_1\partial_x\partial_\theta),$$

which says that

$$\partial_\theta\partial_x=p\partial_x\partial_\theta+h_1\partial_x^2,\quad \partial_\theta^2=h_1\partial_x\partial_\theta. \tag{21}$$

The complete framework of the differential calculus requires commutation relations of the differentials with derivatives.

D. Relations of differentials with derivatives

Finally we shall find the commutation relations between differentials and derivatives. We assume that they have the following form in terms of primed quantities:

$$\begin{aligned}
\partial_{x'}\mathrm{d}x'&=A_{11}\mathrm{d}x'\partial_{x'}+A_{12}\mathrm{d}\theta'\partial_{\theta'},\\
\partial_{x'}\mathrm{d}\theta'&=A_{21}\mathrm{d}\theta'\partial_{x'}+A_{22}\mathrm{d}x'\partial_{\theta'},\\
\partial_{\theta'}\mathrm{d}x'&=B_{11}\mathrm{d}x'\partial_{\theta'}+B_{12}\mathrm{d}\theta'\partial_{x'},\\
\partial_{\theta'}\mathrm{d}\theta'&=B_{21}\mathrm{d}\theta'\partial_{\theta'}+B_{22}\mathrm{d}x'\partial_{x'}.
\end{aligned}\tag{22}$$

Substituting (10) and (17) into (22) and using

$$\mathrm{d}(\mathrm{d}x)=-(\mathrm{d}x)\mathrm{d},\quad \mathrm{d}(\mathrm{d}\theta)=(\mathrm{d}\theta)\mathrm{d}, \tag{23a}$$

and the relation

$$\partial_i(X^j\mathrm{d}X^k)=\delta^i{}_j\delta^k{}_l\mathrm{d}X^k, \tag{23b}$$

where $\partial_1=\partial_x$ and $\partial_2=\partial_\theta$, we determine the coefficients A_{ij} and B_{ij}. So one has

$$\begin{aligned}
\partial_x\mathrm{d}x&=pq\,\mathrm{d}x\partial_x+h_1\mathrm{d}\theta\partial_x-h_2\mathrm{d}x\partial_\theta+h_1h_2(\mathrm{d}x\partial_x+\mathrm{d}\theta\partial_\theta)+(pq-1)\mathrm{d}\theta\partial_\theta,\\
\partial_x\mathrm{d}\theta&=p\,\mathrm{d}\theta\partial_x+ph_2(\mathrm{d}x\partial_x+\mathrm{d}\theta\partial_\theta),\\
\partial_\theta\mathrm{d}x&=-q\,\mathrm{d}x\partial_\theta-qh_1(\mathrm{d}x\partial_x+\mathrm{d}\theta\partial_\theta),\\
\partial_\theta\mathrm{d}\theta&=\mathrm{d}\theta\partial_\theta-h_1\mathrm{d}\theta\partial_x+h_2\mathrm{d}x\partial_\theta+h_1h_2(\mathrm{d}x\partial_x+\mathrm{d}\theta\partial_\theta).
\end{aligned}\tag{24}$$

E. Algebra of one-forms

In this section we shall define two one-forms using the generators of $\mathcal{A}$ and find the commutation relations of one-forms.

If we call them w and u then one can define them as follows:

$$w=\mathrm{d}x\,x^{-1},\quad u=\mathrm{d}\theta\,x^{-1}-\mathrm{d}x\,x^{-1}\theta x^{-1}. \tag{25}$$

We denote the algebra of one-forms generated by two elements w and u by Ω. The generators of the algebra Ω with the generators of $\mathcal{A}$ satisfy the following relations:

$$\begin{aligned}
xw&=wx-h_1ux,\quad \theta w=-w\theta+h_1u\theta,\\
xu&=ux,\quad \theta u=u\theta-h_2(w\theta+ux).
\end{aligned}\tag{26}$$

The commutation rules of the generators of Ω are

$$w^2=0, \quad wu=uw. \tag{27}$$

Using (18b) and (25), if we define the operators T and ∇ as

$$T=x\partial_x+\theta\partial_\theta, \quad \nabla=x\partial_\theta, \tag{28}$$

then we have

$$T\nabla=\nabla T, \quad \nabla^2=0, \tag{29}$$

as a subalgebra of gl(1|1).

The action of T and ∇ on the generators x and θ is

$$\begin{aligned} Tx&=x+xT, \quad \nabla x=x\nabla-h_1xT,\\ T\theta&=\theta+\theta T, \quad \nabla\theta=x-\theta\nabla+h_1\theta T. \end{aligned} \tag{30}$$

III. THE SUPERGROUP $GL_{h_1,h_2}(1|1)$ AND COVARIANCE

It is well known that the quantum supergroup $GL_{p,q}(1|1)$ acts as a linear transformation on the quantum superplane, preserves (1) and the dual relations

$$\varphi'^2=0, \quad \varphi'y'-p^{-1}y'\varphi'=0. \tag{31}$$

In extending this property of covariance under the coaction of $GL_{p,q}(1|1)$, from the superplane to its calculus, it will be assumed that the deformed group structure implies and is implied by invariance of the intermediary relations (5) under linear transformations of the quantum superplane. In the present work, this will be applied to the (h_1,h_2)-deformed superplane.

In this section we would like to discuss the meaning of covariance in a graded version of noncommutative differential calculus of Wess–Zumino[3] for the two-parameter case. Before proceeding, we define the dual quantum h-superplane.

To define the dual quantum superplane, we interpret the differentials $\mathsf{d}x$ and $\mathsf{d}\theta$, as the coordinates of the dual superplane, as follows:

$$\mathsf{d}x=\varphi, \quad \mathsf{d}\theta=y. \tag{32}$$

Now the quantum dual h-superplane generated by y, φ with the relations (12) in the limit $p\rightarrow 1$ will be denoted by $\mathsf{d}\mathcal{A}_{h_1}$. If we assume that $\mathcal{A}_{h_2}$ and $\mathsf{d}\mathcal{A}_{h_1}$ have to be covariant under the coaction,

$$\delta(x)=a\otimes x+\beta\otimes\theta, \quad \delta(\theta)=\gamma\otimes x+d\otimes\theta, \tag{33a}$$

$$\delta(\mathsf{d}Z)=(\tau\otimes\mathsf{d})\,\delta(Z), \quad \tau(u)=(-1)^{\hat{u}}u, \tag{33b}$$

and that β, γ anticommute with θ, φ, h_1, and h_2 we get the corresponding (h_1,h_2)-deformation of the supergroup $GL(1|1)$ as a quantum matrix supergroup $GL_{h_1,h_2}(1|1)$ generated by a, β, γ, d with the relations[10]

$$a\beta=\beta a-h_1(a^2-\beta\gamma-ad),\quad d\beta=\beta d+h_1(d^2+\beta\gamma-da),$$
$$a\gamma=\gamma a+h_2(a^2+\gamma\beta-ad),\quad d\gamma=\gamma d-h_2(d^2-\gamma\beta-da),$$
$$\beta^2=h_1\beta(a-d),\quad \gamma^2=h_2\gamma(d-a), \tag{34}$$
$$\beta\gamma=-\gamma\beta+(h_1\gamma-h_2\beta)(a-d),$$
$$ad=da+h_1(a-d)\gamma+h_2\beta(a-d),$$

where

$$\mathcal{D}=ad^{-1}-\beta d^{-1}\gamma d^{-1}=d^{-1}a-d^{-1}\beta d^{-1}\gamma.$$

The two-parameter differential calculus on the quantum superplane is explicitly as follows: The commutation relations of variables and their differentials are

$$x\theta=\theta x+h_2x^2,\quad \theta^2=-h_2\theta x,$$
$$\varphi y=y\varphi+h_1y^2,\quad \varphi^2=h_1\varphi y. \tag{35}$$

Note that the last two relations of (35) are obtained from (14) and (15). However they can also be obtained from (31) with the limits $p\to 1, q\to 1$.

The commutation relations between variables and derivatives are

$$\partial_x x=1+x\partial_x-h_1\theta\partial_x+h_2x\partial_\theta+h_1h_2(x\partial_x+\theta\partial_\theta),$$
$$\partial_x\theta=\theta\partial_x-h_2(x\partial_x+\theta\partial_\theta),$$
$$\partial_\theta x=x\partial_\theta-h_1(x\partial_x+\theta\partial_\theta), \tag{36}$$
$$\partial_\theta\theta=1-\theta\partial_\theta-h_1\theta\partial_x+h_2x\partial_\theta+h_1h_2(x\partial_x+\theta\partial_\theta),$$

and those among the derivatives are

$$\partial_x\partial_\theta=\partial_\theta\partial_x-h_1\partial_x^2,\quad \partial_\theta^2=h_1\partial_\theta\partial_x. \tag{37}$$

The commutation relations of variables with their differentials are

$$x\varphi=\varphi x+h_1(\varphi\theta-yx)+h_1h_2\varphi x,$$
$$xy=yx-h_1y\theta-h_2\varphi x+h_1h_2\varphi\theta,$$
$$\theta\varphi=-\varphi\theta+h_1y\theta-h_2\varphi x-h_1h_2yx, \tag{38}$$
$$\theta y=y\theta-h_2(\varphi\theta+yx)-h_1h_2y\theta.$$

The commutation relations between derivatives and differentials are

$$\partial_x\varphi=\varphi\partial_x+h_1y\partial_x-h_2\varphi\partial_\theta+h_1h_2(\varphi\partial_x+y\partial_\theta),$$
$$\partial_x y=y\partial_x+h_2(\varphi\partial_x+y\partial_\theta),$$
$$\partial_\theta\varphi=-\varphi\partial_\theta-h_1(\varphi\partial_x+y\partial_\theta), \tag{39}$$
$$\partial_\theta y=y\partial_\theta-h_1y\partial_x+h_2\varphi\partial_\theta+h_1h_2(\varphi\partial_x+y\partial_\theta).$$

Note that this calculus goes back to those of Ref. 9 when $h_1=0$ and $h_2=h$. This calculus is slightly different from Ref. 10. The reason for this difference is the use of commutation relations of the dual *exterior* superplane in Ref. 10 instead of the dual superplane in this work.

We now discuss the covariance of the differential calculus. The covariance here means that all the relations between coordinates x,θ, differentials $\mathrm{d}x,\mathrm{d}\theta$ and derivatives ∂_x, ∂_θ, etc. must preserve their form when one changes the coordinates by

$$x\to ax+\beta\theta, \quad \theta\to\gamma x+d\theta, \tag{40}$$

where the matrix $T=\begin{pmatrix} a & \beta \\ \gamma & d \end{pmatrix}$ is an element of the quantum supergroup $GL_{h_1,h_2}(1|1)$ acting on the quantum superplane. We must change the differentials by

$$\mathrm{d}x\to a\mathrm{d}x-\beta\mathrm{d}\theta, \quad \mathrm{d}\theta\to-\gamma\mathrm{d}x+d\mathrm{d}\theta, \tag{41}$$

since the odd objects anticommute among themselves. Covariance can be maintained if one defines the transformation law of the partial derivatives as follows:

$$\begin{aligned} \partial_x &\to (a^{-1}-a^{-1}\gamma d^{-1}\beta a^{-1})\partial_x - a^{-1}\gamma d^{-1}\partial_\theta, \\ \partial_\theta &\to (d^{-1}-d^{-1}\beta a^{-1}\gamma d^{-1})\partial_\theta + d^{-1}\beta a^{-1}\partial_x. \end{aligned} \tag{42}$$

IV. A TWO-PARAMETER DEFORMATION OF CLASSICAL PHASE SPACE

We shall now give a two-parameter deformation of the $(1+1)$-dimensional classical phase space. We denote the algebra (35)–(37) generated by coordinates x,θ and the derivatives ∂_x and ∂_θ by $\mathcal{B}_{h_1,h_2}$. It is interesting to note that simply identifying ∂_x and ∂_θ with ip_x and p_θ is not compatible with the hermiticity of coordinates and momenta. To identify ∂_x and ∂_θ with the momenta ip_x and p_θ, one must take care of the Hermiticity of the coordinates and momenta. To this end, we first define the Hermitian conjugation of the coordinates x and θ, respectively, as

$$x^+=(1+2h_1h_2)x+2h_1\theta, \quad \theta^+=(1-2h_1h_2)\theta+2h_2x. \tag{43}$$

It is then easy to see that the Hermiticity of x^+ and θ^+ impose some condition on the deformation parameters, i.e., h_1 is a real parameter and h_2 is a pure imaginary parameter,

$$\overline{h_1}=h_1, \quad \overline{h_2}=-h_2, \tag{44}$$

where the bar denotes complex conjugation. In this case, the Hermitian conjugation of the derivatives ∂_x and ∂_θ are

$$\partial_x^+=-(1+2h_1h_2)\partial_x+2h_2\partial_\theta, \quad \partial_\theta^+=(1-2h_1h_2)\partial_\theta+2h_1\partial_x. \tag{45}$$

In the $h_1\to0, h_2\to0$ limits the definitions (43) and (45) go back to those of the classical case.

The relations (35)–(37) are now invariant under the transformations (43) and (45). The above involution allows us to define the Hermitian operators,

$$\hat{x}=(1+h_1h_2)x+h_1\theta, \quad \hat{\theta}=(1-h_1h_2)\theta+h_2x, \tag{46}$$

and, as bosonic and fermionic momenta,

$$\hat{p}_x=i[(1+h_1h_2)\partial_x-h_2\partial_\theta], \quad \hat{p}_\theta=(1-h_1h_2)\partial_\theta+h_1\partial_x. \tag{47}$$

The final form of the (h_1,h_2)-deformed phase space algebra is

$$
\begin{gathered}
\hat{x}\hat{\theta}=\hat{\theta}\hat{x}+h_2\hat{x}^2, \quad \hat{\theta}^2=-h_2\hat{\theta}\hat{x},\\
\hat{p}_x\hat{p}_\theta=\hat{p}_\theta\hat{p}_x+ih_1\hat{p}_x^2, \quad \hat{p}_\theta^2=-ih_1\hat{p}_x\hat{p}_\theta,\\
\hat{p}_x\hat{x}=i+\hat{x}\hat{p}_x+ih_2\hat{x}\hat{p}_\theta-h_1\hat{\theta}\hat{p}_x+h_1h_2(1+\hat{x}\hat{p}_x+i\hat{\theta}\hat{p}_\theta),\\
\hat{p}_x\hat{\theta}=\hat{\theta}\hat{p}_x-h_2(\hat{x}\hat{p}_x+i\hat{\theta}\hat{p}_\theta),\\
\hat{p}_\theta\hat{x}=\hat{x}\hat{p}_\theta+h_1(i\hat{x}\hat{p}_x-\hat{\theta}\hat{p}_\theta),\\
\hat{p}_\theta\hat{\theta}=1-\hat{\theta}\hat{p}_\theta+h_2\hat{x}\hat{p}_\theta+ih_1\hat{\theta}\hat{p}_x-h_1h_2(1+i\hat{x}\hat{p}_x-\hat{\theta}\hat{p}_\theta).
\end{gathered}
\tag{48}
$$

This gives a (h_1,h_2)-deformed phase space algebra which may be used to study the $(1+1)$-dimensional quantum phase space.

Note that we can derive a deformed super-Clifford algebra from the phase space algebra as follows: suppose that we define gamma matrices

$$
\gamma^1\equiv\hat{p}_\theta, \quad \gamma^2\equiv\hat{\theta}, \quad c^1\equiv\hat{p}_x, \quad c^2\equiv\hat{x}. \tag{49}
$$

Then, they satisfy the super-Clifford algebra,

$$
\begin{gathered}
c^1c^2=c^2c^1-h_1\gamma^2c^1+i(1+h_2c^2\gamma^1)+h_1h_2(1+\gamma^2\gamma^1+c^2c^1),\\
c^1\gamma^2=\gamma^2c^1-h_2(c^2c^1+i\gamma^2\gamma^1),\\
\gamma^1c^1=c^1\gamma^1-ih_1(c^1)^2, \quad \gamma^1c^2=c^2\gamma^1-h_1(\gamma^2\gamma^1-ic^2c^1),\\
\gamma^1\gamma^2=1-\gamma^2\gamma^1+ih_1\gamma^2c^1+h_2c^2\gamma^1-h_1h_2(1+c^2c^1-\gamma^2\gamma^1),\\
(\gamma^1)^2=-ih_1c^1\gamma^1, \quad (\gamma^2)^2=-h_2\gamma^2c^2,\\
\gamma^2c^2=c^2\gamma^2-h_2(c^2)^2.
\end{gathered}
\tag{50}
$$

V. A COMMENT ON SUPEROSCILLATORS

We know that introducing one ''bosonic'' and one ''fermionic'' oscillator, A and B, respectively, and making the usual identification

$$
x'\leftrightarrow A^+, \quad \theta'\leftrightarrow B^+, \quad \partial_{x'}\leftrightarrow A, \quad \partial_{\theta'}\leftrightarrow B. \tag{51}
$$

one constructs the quantum superoscillator algebra which is covariant under the quantum supergroup $GL_{p,q}(1|1)$. Under identification (2) and (17) one has

$$
\begin{gathered}
x\leftrightarrow A^+-\frac{h_1}{p-1}B^+, \quad \partial_x\leftrightarrow\left(1+\frac{h_1h_2}{(p-1)(q-1)}\right)A+\frac{h_2}{q-1}B,\\
\theta\leftrightarrow\left(1-\frac{h_1h_2}{(p-1)(q-1)}\right)B^+-\frac{h_2}{q-1}A^+, \quad \partial_\theta\leftrightarrow B-\frac{h_1}{p-1}A,
\end{gathered}
\tag{52}
$$

where

$$
\overline{p}=q. \tag{53}
$$

Substituting (52) into (20) and (3), surprisingly all (h_1,h_2)-dependence cancels and one obtains the usual (p,q)-deformed superoscillator algebra[12]

$$AA^{+}=1+pqA^{+}A+(pq-1)B^{+}B,$$
$$BB^{+}=1-B^{+}B, \quad B^{2}=0=B^{+2},$$
$$AB^{+}=pB^{+}A, \quad AB=p^{-1}BA, \tag{54}$$
$$A^{+}B=q^{-1}BA^{+}, \quad A^{+}B^{+}=qB^{+}A^{+}.$$

In the $p\to 1, q\to 1$ limits, we get an undeformed superoscillator algebra.

APPENDIX: NONVALIDITY OF THE ACT FROM THE RIGHT

In this appendix, we show that a two-parameter covariant differential calculus on the quantum h-superplane can be constructed only if the derivatives and differentials act from the left.

Consider the change of coordinates which is given by (2)

$$x'=\left(1+\frac{h_1h_2}{(p-1)(q-1)}\right)x+\frac{h_1}{p-1}\,\theta, \quad \theta'=\theta+\frac{h_2}{q-1}\,x. \tag{A1}$$

If we interpret the symbols $\mathsf{d}x$ and $\mathsf{d}\theta$ as differentials acting from the right and demanding the validity of the chain rule, we have

$$\mathsf{d}x=\mathsf{d}x'\frac{\partial x}{\partial x'}+\mathsf{d}\theta'\frac{\partial x}{\partial \theta'}=\mathsf{d}x'+\mathsf{d}\theta'\left(-\frac{h_1}{p-1}\right)=\mathsf{d}x'-\frac{h_1}{p-1}\,\mathsf{d}\theta' \tag{A2}$$

and

$$\mathsf{d}\theta=\frac{h_2}{q-1}\,\mathsf{d}x'+\left(1+\frac{h_1h_2}{(p-1)(q-1)}\right)\mathsf{d}\theta'. \tag{A3}$$

Therefore, for example,

$$\mathsf{d}x'=\left(1+\frac{h_1h_2}{(p-1)(q-1)}\right)\mathsf{d}x+\frac{h_1}{p-1}\,\mathsf{d}\theta, \tag{A4}$$

so that

$$\text{RHS of (A4)}=\left(1+\frac{h_1h_2}{(p-1)(q-1)}\right)\mathsf{d}x'-\frac{h_1}{p-1}\,\mathsf{d}\theta'+\frac{h_1}{p-1}\,\mathsf{d}\theta'+\frac{h_1h_2}{(p-1)(q-1)}\,\mathsf{d}x'\neq \mathsf{d}x'.$$

Similarly, if we write, from the chain rule,

$$\partial_x=\left(1+\frac{h_1h_2}{(p-1)(q-1)}\right)\partial_{x'}+\frac{h_2}{q-1}\,\partial_{\theta'}\,, \tag{A5}$$

and

$$\partial_\theta=\frac{h_1}{p-1}\,\partial_{x'}+\partial_{\theta'}\,, \tag{A6}$$

then

$$\partial_{x'}=\partial_x-\frac{h_2}{q-1}\,\partial_\theta, \quad \partial_{\theta'}=-\frac{h_1}{p-1}\,\partial_x+\left(1-\frac{h_1h_2}{(p-1)(q-1)}\right)\partial_\theta, \tag{A7}$$

so that, for example

$$\text{RHS of (A6)}=\left(1-2\,\frac{h_1h_2}{(p-1)(q-1)}\right)\partial_\theta\neq\partial_\theta .$$

This asymmetry between right and left derivative and differential for transformed variables stems from the matrix g in (14) which off-diagonal elements are odd. That is, g is a supermatrix and so the supertranspose must be used.

(Received 29 January 1999; accepted for publication 16 April 1999)

After defining cohomologically higher-order BRST and anti-BRST operators for a compact simple algebra $\mathcal{G}$, the associated higher-order Laplacians are introduced and the corresponding supersymmetry algebra Σ is analyzed. These operators act on the states generated by a set of fermionic ghost fields transforming under the adjoint representation. In contrast with the standard case, for which the Laplacian is given by the quadratic Casimir, the higher-order Laplacians W are not, in general, given completely in terms of the Casimir–Racah operators, and may involve the ghost number operator. The higher-order version of the Hodge decomposition is exhibited. The example of $su(3)$ is worked out in detail, including the expression of its higher-order Laplacian W.

I. INTRODUCTION

BRST symmetry,[1,2] or ''quantum gauge invariance,'' has played an important role in the quantization of non-Abelian gauge theories. The nilpotency of the operator $\mathcal{Q}$ generating the global BRST symmetry implies that the renormalization of gauge theories involves cohomological aspects: the physical content of the theory belongs to the kernel of $\mathcal{Q}$, the physical (BRST-invariant) states being defined by BRST-cocycles modulo BRST-trivial ones (coboundaries). The inclusion of the BRST symmetry in the Batalin–Vilkovisky antibracket–antifield formalism (see Refs. 3, 4 for further references), itself of a rich geometrical structure,[3–9] and where the antifields are the sources of the BRST transformations, has made of BRST quantization the most powerful method for quantizing systems possessing gauge symmetries. In particular, it is indispensable for understanding the general structure of string amplitudes. It is thus interesting to explore its possible generalizations and their cohomological structure.

An essential ingredient of $\mathcal{Q}$ is what we shall denote here the BRST *operator*,

$$s=-\frac{1}{2}C_{ij}{}^{k}c^{i}c^{j}\frac{\partial}{\partial c^{k}} \quad i,j,k=1,...,r=\dim\mathcal{G}, \tag{1.1}$$

where the c^i are anticommuting Grassmann (or *ghost*) variables transforming under the adjoint representation of the (compact semisimple) Lie group G of Lie algebra $\mathcal{G}$. In Yang Mills theories

the c's correspond to the ghost fields, and (1.1) above is just part of the generator of the BRST transformations for the gauge group G. This paper is devoted to the generalizations of (1.1) and its associated *anti*-BRST *operator* $\bar{s}$.[10–16]

Using a Euclidean metric to raise and lower indices,[17] $\bar{s}$ is given by

$$\bar{s}=\frac{1}{2}C_{ij}{}^{k}c_{k}\frac{\partial}{\partial c_i}\frac{\partial}{\partial c_j}. \tag{1.2}$$

The $s(\bar{s})$ operator increases (decreases) the ghost number by one. The BRST and anti-BRST operators may be used to construct a Laplacian,[18,12,13,19,14,16] $\Delta=\bar{s}s+s\bar{s}$; clearly, Δ does not change the ghost number. It turns out (see Refs. 12–14) that this operator is given by the (second-order) Casimir operator of $\mathcal{G}$.

A few years ago, van Holten[14] discussed the BRST complex, generated by the s_ρ and $\bar{s}_\rho$ operators,

$$s_\rho=c^i\rho(X_i)-\frac{1}{2}C_{ij}{}^{k}c^ic^j\frac{\partial}{\partial c^k},\quad \bar{s}_\rho=-\rho(X_i)\frac{\partial}{\partial c_i}+\frac{1}{2}C_{ij}{}^{k}c_k\frac{\partial}{\partial c_i}\frac{\partial}{\partial c_j}, \tag{1.3}$$

in connection with the cohomology of compact semisimple Lie algebras. They act on generic states of ghost number q of the form

$$\psi=\frac{1}{q!}\psi^A_{i_1\cdots i_q}c^{i_1}\cdots c^{i_q}\otimes e_A. \tag{1.4}$$

The operators in (1.3) differ from those in (1.1), (1.2) by the inclusion of the ρ term, where $\rho^A{}_B$ is a representation of the Lie algebra $\mathcal{G}$ on a vector space V with basis $\{e_A\}$, $A=1,\ldots,\dim V$. However (see the *Remark* in Sec. II), only the trivial representation case is interesting. For $\rho=0$ the generic states have the form

$$\psi=\frac{1}{q!}\psi_{i_1\cdots i_q}c^{i_1}\cdots c^{i_q}, \tag{1.5}$$

and we shall consider mostly this case. The operators s, $\bar{s}$ and the Laplacian Δ may be used to define s-closed, $\bar{s}$-closed (coclosed), and harmonic states. A state ψ [Eq. (1.5)] is called s-closed, $\bar{s}$-closed, or harmonic if $s\psi=0$, $\bar{s}\psi=0$, or $\Delta\psi=0$, respectively. In this way, and using the nilpotency of s and $\bar{s}$, one may introduce a Hodge decomposition for (1.5) as a sum of an s-closed, an $\bar{s}$-closed, and a harmonic state. The interesting fact is that, using the above Euclidean metric on $\mathcal{G}$, one may introduce a positive scalar product among states ψ', ψ, of ghost numbers q', q by

$$\langle\psi',\psi\rangle:=\frac{1}{q!}\psi'_{j_1\cdots j_q}\psi^{j_1\cdots j_q}\delta_{q'q}. \tag{1.6}$$

Using the Hodge $*$ operator for δ_{ij}, it follows that $s=(-1)^{r(q+1)}*\bar{s}*$ (on states of ghost number q), and that s and $\bar{s}$ are also adjoint to each other with respect to the scalar product (1.6). As a result, there is a complete analogy between the harmonic analysis of forms, in which d and $\delta=(-1)^{r(q+1)+1}*d*$ are adjoint to each other, and the Hodge-like decomposition of states ψ for the operators s, $\bar{s}$[14] (see also Sec. II). This follows from the fact that, due to their anticommuting character, the ghost variables c may be identified[20] with (say) the left-invariant one-forms on the group manifold G, so that the action of s on c determines the Maurer–Cartan (MC) equations.

The nilpotency of the BRST operators (1.1) or (1.3) results from the Jacobi identity satisfied by the structure constants $C_{ij}{}^{k}$ of $\mathcal{G}$. This identity can also be viewed as a three-cocycle condition on the fully antisymmetric C_{ijk}, which define a nontrivial three-cocycle for any semisimple $\mathcal{G}$. This observation indicates the existence of a generalization by using the higher-order cocycles for $\mathcal{G}$. The cohomology ring of all compact simple Lie algebras of rank l (for simplicity, we shall assume G simple henceforth) is generated by l (classes of) nontrivial primitive cocycles, associated with the l invariant, symmetric primitive polynomials of order m_s ($s=1,...,l$) which, in turn, define the l Casimir–Racah operators (Refs. 21–23; also see Ref. 24 and references therein). The different integers m_s depend (for $s\neq 1$) on the specific simple algebra considered. It has been shown in Ref. 25 that, associated to each cocycle of order $2m_s-1$ there exists a higher-order BRST operator s_{2m_s-2} carrying ghost number $2m_s-3$, defined by the coordinates $\Omega^j_{i_1\ldots i_{2m_s-2}}$ of the $(2m_s-1)$-cocycle on $\mathcal{G}$ [we shall also give in (3.17) the corresponding operator $s_{\rho(2m_s-2)}$ for the $\rho\neq 0$ case]. The $\Omega^j_{i_1\ldots i_{2m_s-2}}$ may also be understood as being the (fully antisymmetric) higher-order structure constants of a higher $(2m_s-2)$-order algebra,[25] for which the multibrackets have $(2m_s-2)$ entries. The standard (lowest, $s=1$) case corresponds to $m_1=2$, $\forall\ \mathcal{G}$ (the invariant is Cartan–Killing metric), to the three-cocycle C_{ijk} and to the ordinary Lie algebra bracket. The $(2m_s-2)$-brackets of these higher-order algebras satisfy a generalized Jacobi identity, which again follows from the fact that the higher-order structure constants define $(2m_s-1)$-cocycles for the Lie algebra cohomology. These $(2m_s-2)$-algebras constitute a particular example (in which only one coderivation survives) of the strongly homotopy algebras,[26] which have recently appeared in different physical theories that share common cohomological aspects, as in closed string field theory,[27,28] the higher order generalizations of the antibracket[29,30] and the Batalin–Vilkovisky complex (see Ref. 31 and references therein). Higher-order structure constants satisfying generalized Jacobi identities of the types considered in Ref. 25 [see (3.11) below] and Ref. 32 have also appeared in a natural way in the extended master equation in the presence of higher-order conservation laws.[9]

In Sec. III of this paper we introduce, together with the l general BRST operators for a simple Lie algebra, the corresponding l anti-BRST operators $\overline{s}_{2m_s-2}$ and their associated higher-order Laplacians. We show there that harmonic analysis may be carried out in general (the standard case in Ref. 14 corresponds to $m_s=m_1=2$), although the Laplacians do not, in general, correspond to the Casimir–Racah operators. Nevertheless, we shall show that s_{2m_s-2} and $\overline{s}_{2m_s-2}$ are related to each other by means of the Hodge $*$ operator, and that they are also adjoints of each other. After showing that the different higher-order BRST, anti-BRST, and Laplacian operators generate, for each value $s=1,...,l$, a supersymmetry algebra Σ_{m_s}, we discuss its representations. The example of $\mathcal{G}=su(3)$ is studied in full in Sec. IV, where we construct the general $su(3)$ states and show the $su(3)$ representations contained in the $\Sigma_{m_s}=\Sigma_2,\Sigma_4$ irreducible multiplets.

II. THE STANDARD BRST COMPLEX AND HARMONIC STATES

Let $\mathcal{G}$ be defined by

$$[X_i,X_j]=C_{ij}{}^kX_k,\quad i,j,k=1,..., r\equiv\dim\mathcal{G}, \tag{2.1}$$

where $\{X_i\}_{i=1}^r$ is a basis of $\mathcal{G}$. For instance, we may think of $\{X_i\}$ as a basis for the left-invariant (LI) vector fields $X_i^L(g)\equiv X_i(g)$ on the group manifold $G(X_i(g)\in\mathfrak{X}^L(G))$.

Let V be a vector space. In the Chevalley–Eilenberg formulation (CE)[33] of the Lie algebra cohomology, the space of q-dimensional cochains $C^q(\mathcal{G},V)$ is spanned by the V-valued skew-symmetric mappings,

$$\psi:\mathcal{G}\wedge\stackrel{q}{\cdots}\wedge\mathcal{G}\rightarrow V,\quad \psi(g)=\frac{1}{q!}\psi^A_{i_1\cdots i_q}\omega^{i_1}(g)\wedge\cdots\wedge\omega^{i_q}(g)\otimes e_A, \tag{2.2}$$

where the $\{\omega^i(g)\}$ form a basis of $\mathcal{G}^*$ (LI one-forms on G), dual to the basis $\{X_i\}$ of LI vector fields on G, and the index $A=1,...,\dim V$ labels the components in V. Let ρ be a representation of $\mathcal{G}$ on V ($\rho:\mathcal{G}\rightarrow\mathrm{End}(V)$). The action of the Lie algebra coboundary operator s_ρ, $s_\rho{}^2=0$, on the q-cochains ψ^A (1.4) is given by the following.

Definition 2.1: (Coboundary operator) The coboundary operator s_ρ: $C^q(\mathcal{G},V)\rightarrow C^{q+1}(\mathcal{G},V)$ is defined by

$$(s_\rho\psi)^A(X_1,\ldots,X_{q+1}) := \sum_{i=1}^{q+1} (-1)^{i+1}\rho(X_i)^A_{.B}(\psi^B(X_1,\ldots,\hat{X}_i,\ldots,X_{q+1})) + \sum_{\substack{j,k=1\\ j<k}}^{q+1} (-1)^{j+k}\psi^A([X_j,X_k], \quad X_1,\ldots,\hat{X}_j,\ldots,\hat{X}_k,\ldots,X_{q+1}). \quad (2.3)$$

The space of q-cocycles $Z^q_\rho(\mathcal{G},V)$ (i.e., Ker s) modulo the q-coboundaries $B^q_\rho(\mathcal{G},V)$ (i.e., Im s) defines the qth Lie algebra cohomology group $H^q_\rho(\mathcal{G},V)$.

Since we are assuming $\mathcal{G}$ semisimple, Whitehead's lemma states that, for ρ nontrivial,

$$H^q_\rho(\mathcal{G},V)=0, \quad \forall q \geqslant 0, \quad (2.4)$$

and we can restrict ourselves to $\rho=0$ cohomology for which the action of s_ρ reduces to the second term on the rhs of Eq. (2.3).

For the trivial representation, s acts on ψ (1.5) in the same manner as the exterior derivative d acts on LI forms. It is then clear that we may replace the $\{\omega^i(g)\}$ by the ghost variables $\{c^i\}$,

$$c^ic^j=-c^jc^i \quad \left(\{c^i,c^j\}=0, \quad \left\{c^i,\frac{\partial}{\partial c^j}\right\}=\delta^i_j\right), \quad i,j=1,\ldots,r, \quad (2.5)$$

and the space of q-cochains by polynomials of (ghost) number $q \leqslant r$. The BRST operator (1.1) $s=s_2$ (the subindex 2 is added for convenience; its meaning will become clear in Sec. III) may be taken as the coboundary operator for the $(\rho=0)$ Lie algebra cohomology.[20] Indeed, the relations,

$$s_2c^k=-\tfrac{1}{2}C_{ij}{}^kc^ic^j \quad [\text{or} \;\; s_2c=-\tfrac{1}{2}[c,c], \quad c=c^i\rho(X_i)], \quad (2.6)$$

reproduce the MC equations. As a result, the Lie algebra cohomology may be equivalently formulated in terms of skew-symmetric tensors on $\mathcal{G}$, LI forms on G, or polynomials in ghost space (see, e.g., Ref. 34).

In the sequel we shall introduce the Grassmann variables π_i to refer to the "partial derivative" $\partial/\partial c^i$, appropriate for using the "ghost representation" for the cochains/states. These two sets of variables (c^i,π_j) generate a Clifford-like algebra,[35] defined by

$$\{c_i,\pi_j\}=\delta_{ij}, \quad \{c_i,c_j\}=0=\{\pi_i,\pi_j\}. \quad (2.7)$$

The algebra (2.7) admits the (order reversing) involution $\overline{\cdot}: c_i \mapsto \overline{c_i}=\pi_i$, $\pi_i \mapsto \overline{\pi_i}=c_i$. The *anti*-BRST *operator* $\overline{s_2}$ is given by

$$\overline{\cdot}: s_2 \mapsto \overline{s_2}, \quad \overline{s_2}=\frac{1}{2}C_{ij}{}^kc_k\pi^i\pi^j \quad \left(=\frac{1}{2}C_{ij}{}^kc_k\frac{\partial}{\partial c_i}\frac{\partial}{\partial c_j}\right), \quad (2.8)$$

and it is also nilpotent. Denoting the space of the BRST q-cochains (1.5) by $C^q(\mathcal{G})$, it follows that

$$s_2: C^q(\mathcal{G})\rightarrow C^{q+1}(\mathcal{G}), \quad \overline{s_2}: C^q(\mathcal{G})\rightarrow C^{q-1}(\mathcal{G}). \quad (2.9)$$

The presence of a metric (δ_{ij}) on $\mathcal{G}$ allows us to introduce the $*$ operator $[*: C^q(\mathcal{G}) \rightarrow C^{r-q}(\mathcal{G})]$ in the standard way. On q-forms on G,

$$(*\psi)=\frac{1}{q!}\frac{1}{(r-q)!}\epsilon_{i_1\cdots i_r}\psi^{i_1\cdots i_q}\omega^{i_{q+1}}\wedge\cdots\wedge\omega^{i_r}. \quad (2.10)$$

and

$$*^2=(-1)^{q(r-q)}=(-1)^{q(r-1)}. \tag{2.11}$$

The scalar product of two LI q-forms on G, $\langle\cdot,\cdot\rangle : C^q(\mathcal{G})\otimes C^q(\mathcal{G})\to\mathbb{R}$ is then given by

$$\begin{aligned}\langle\psi',\psi\rangle:=\int_G \psi'\wedge*\psi &= \int_G \frac{1}{q!^2}\frac{1}{(r-q)!}\psi'_{j_1\cdots j_q}\epsilon_{i_1\cdots i_q j_{q+1}\cdots j_r}\psi^{i_1\cdots i_q}\epsilon^{j_1\cdots j_r}\omega^1\wedge\cdots\wedge\omega^r\\ &=\int_G\frac{1}{q!^2}\epsilon^{j_1\cdots j_q}_{i_1\cdots i_q}\psi'_{j_1\cdots j_q}\psi^{i_1\cdots i_q}\omega^1\wedge\cdots\wedge\omega^r\\ &=\frac{1}{q!}\psi'_{j_1\cdots j_q}\psi^{j_1\cdots j_q}\int_G\omega^1\wedge\cdots\wedge\omega^r,\end{aligned} \tag{2.12}$$

and, normalizing the (compact) group volume $\int_G\omega^1\wedge\cdots\wedge\omega^r$ to 1, reduces to (1.6). Clearly,[36]

$$\langle\psi',\psi\rangle=\langle\psi,\psi'\rangle,\quad \langle\psi,\psi\rangle>0\quad \forall\psi\neq 0. \tag{2.13}$$

The codifferential δ is introduced, as usual, as the adjoint of the exterior derivative d, i.e., for a $(q-1)$-form ψ',

$$\begin{aligned}\langle d\psi',\psi\rangle=\int_G d\psi'\wedge*\psi=(-1)^q\int_G\psi'\wedge d*\psi\\ =(-1)^{q+(q-1)(r-q+1)}\int_G\psi'\wedge*(*d*\psi)\\ \equiv\int_G\psi'\wedge*\delta\psi=\langle\psi',\delta\psi\rangle,\end{aligned} \tag{2.14}$$

so that

$$\delta=(-1)^{r(q+1)+1}*d*,\quad (d=(-1)^{r(q+1)}*\delta*),\quad \delta^2=0. \tag{2.15}$$

The correspondence $\omega^i(g)\leftrightarrow c^i$, $d\leftrightarrow s_2$ above allows us to translate all this into the BRST language. First one checks, on any BRST q-cochain (1.5), that the basic operators c^i and π^i are transformed by $*$, according to

$$\pi^i=(-1)^{r(q+1)}*c^i*,\quad c^i=(-1)^{r(q+1)+1}*\pi^i*, \tag{2.16}$$

so that

$$\begin{aligned}&*(c^{i_1}\cdots c^{i_{2k}})*=(-1)^{(r+1)q+k}\pi^{i_1}\cdots\pi^{i_{2k}},\quad *(c^{i_1}\cdots c^{i_{2k+1}})*=(-1)^{r(q+1)+k}\pi^{i_1}\cdots\pi^{i_{2k+1}},\\ &*(\pi^{i_1}\cdots\pi^{i_{2k}})*=(-1)^{(r+1)q+k}c^{i_1}\cdots c^{i_{2k}},\quad *(\pi^{i_1}\cdots\pi^{i_{2k+1}})*=(-1)^{r(q+1)+k+1}c^{i_1}\cdots c^{i_{2k+1}}.\end{aligned} \tag{2.17}$$

As a consequence of (2.16), one finds for $\psi'\in C^{q+1}(\mathcal{G})$, $\psi\in C^q(\mathcal{G})$,

$$\begin{aligned}\langle\psi',c^i\psi\rangle=\int_G\psi'\wedge*c^i\psi=(-1)^{q(r-q)}\int_G\psi'\wedge*c^i**\psi\\ =(-1)^q\int_G\psi'\wedge\pi^i*\psi\\ =\int_G\pi^i\psi'\wedge*\psi=\langle\pi^i\psi',\psi\rangle,\end{aligned} \tag{2.18}$$

using the fact that π^i is a graded derivative and that $\psi' \wedge * \psi \equiv 0$. Thus, c^i and π^i are adjoints to each other with respect to the inner product $\langle , \rangle$ or, in other words, the involution $\overline{\cdot}$ defines the adjoint with respect to $\langle , \rangle$. Thus, $s_2 \sim d$ and (2.15) lead to

$$\overline{s_2} = (-1)^{r(q+1)+1} * s_2 *, \tag{2.19}$$

since

$$\begin{aligned}\delta = (-1)^{r(q+1)+1} * d * \sim (-1)^{r(q+1)+1} * s_2 * \\ &= -(-1)^{r(q+1)+1} \tfrac{1}{2} C_{ij}{}^k * c^i c^j \pi_k * \\ &= -(-1)^{r(q+1)+1+(q-1)(r-q+1)+q(r-q)} \tfrac{1}{2} C_{ij}{}^k * c^i ** c^j ** \pi_k * \\ &= \tfrac{1}{2} C_{ij}{}^k \pi^i \pi^j c_k = \overline{s_2}.\end{aligned} \tag{2.20}$$

The anticommutator of the nilpotent operators s_2 and $\overline{s_2}$ defines the Laplacian $\Delta \equiv W_2$, $W_2 : C^q(\mathcal{G}) \to C^q(\mathcal{G})$,

$$W_2 := \{ s_2 , \overline{s_2} \} = (s_2 + \overline{s_2})^2. \tag{2.21}$$

The operators W_2, s_2, $\overline{s_2}$ generate the supersymmetry algebra Σ_2,

$$[s_2, W_2] = 0, \quad [\overline{s_2}, W_2] = 0, \quad \{ s_2, \overline{s_2} \} = W_2. \tag{2.22}$$

Σ_2 has the structure of a central extension of $(s_2, \overline{s_2})$ by W_2, the Laplacian being the central generator. The operator W_2 is invariant under the involution $\overline{\cdot}(W_2 = \overline{W_2})$ and commutes with $*$, since

$$\begin{aligned} * W_2 * = * (s_2 \overline{s_2} + \overline{s_2} s_2) * = (-1)^{(q-1)(r-q+1)} * (s_2 ** \overline{s_2} + \overline{s_2} ** s_2) * \\ &= (-1)^{(q-1)(r-q+1) + r(q-1) + 1 + rq} (\overline{s_2} s_2 + s_2 \overline{s_2}) \\ &= (-1)^{q(r-q)} W_2, \end{aligned} \tag{2.23}$$

which, with the help of (2.11), implies $[W_2, *] = 0$. Then, as in the standard Hodge theory on compact Riemannian manifolds, we have the following.

Lemma 2.1: A BRST cochain ψ is W_2 harmonic, $W_2 \psi = 0$, iff it is s_2 and $\overline{s_2}$ closed.

Proof: It is clear that if $s_2 \psi = 0 = \overline{s_2} \psi$, then $W_2 \psi = 0$. Now, if $W_2 \psi = 0$,

$$0 = \langle \psi, W_2 \psi \rangle = \langle \psi, (s_2 \overline{s_2} + \overline{s_2} s_2) \psi \rangle = \langle \overline{s_2} \psi, \overline{s_2} \psi \rangle + \langle s_2 \psi, s_2 \psi \rangle; \tag{2.24}$$

from (2.13) easily follows that both terms have to be zero, and hence $s_2 \psi = 0 = \overline{s_2} \psi$.

Theorem 2.1: Each BRST cochain ψ admits the Hodge decomposition,

$$\psi = s_2 \alpha + \overline{s_2} \beta + \gamma, \tag{2.25}$$

where γ is W_2 harmonic (the proof of Theorem 3.1 below includes this case).

To find the algebraic meaning of W_2, let us write the generators X_i on ghost space as

$$X_i \equiv - C_{ij}{}^k c^j \pi_k. \tag{2.26}$$

They act on BRST cochains in the same way as the Lie derivatives with respect to the LI vector fields on G act on LI forms on G:

$$X_i c^k = - C_{ij}{}^k c^j \tag{2.27}$$

[cf. $L_{X_i}\omega^k = -C_{ij}{}^k\omega^j$, in which $X_i \in \mathfrak{X}^L(G)$ and $\omega \in \mathfrak{X}^{*L}(G)$]. The X_i in (2.26) are in the adjoint representation of $\mathcal{G}$ and satisfy $\overline{X_i} = -X_i$ and $*X_i = X_i*$. *Invariant states* are those for which $X_i\psi = 0$, $i = 1,...,r$.

In terms of X_i, the operators s_2 and $\overline{s_2}$ may be written as

$$s_2 = \tfrac{1}{2}c^i X_i, \quad \overline{s_2} = -\tfrac{1}{2}\pi^j X_j, \tag{2.28}$$

Using the fact that c^i and π^j transform in the adjoint representation,

$$X_k c^i = -C_{kr}{}^i c^r, \quad X_k \pi^i = -C_{kr}{}^i \pi^r, \tag{2.29}$$

it is easy to see that[38]

$$W_2 = -\tfrac{1}{2}\mathcal{C}^{(2)} = -\tfrac{1}{2}\delta^{ij}X_i X_j, \tag{2.30}$$

i.e., the Laplace-type operator is proportional to the second-order Casimir operator of the algebra.

Remark: The expression for W_2 in Refs. 12–14 contains more terms due to the fact that these authors consider $\rho \neq 0$, in general. But, as noticed in Ref. 14, $\rho = 0$ is the only possibility if we restrict ourselves to *nontrivial* harmonic states. In fact, we prove here that this is a direct consequence of Whitehead's lemma (2.4). Let τ be the operator defined by its action on (V-valued) q-cochains ψ through

$$(\tau\psi)^A_{i_1 \cdots i_{q-1}} = k^{ij}\rho(X_i)^A_B \psi^B_{j i_1 \cdots i_{q-1}}. \tag{2.31}$$

It may be verified that

$$[(s_\rho\tau + \tau s_\rho)\psi]^A_{i_1 \cdots i_q} = \psi^B_{i_1 \cdots i_q}\mathcal{C}^{(2)}(\rho)^A_B, \tag{2.32}$$

where $\mathcal{C}^{(2)}(\rho)^A_B \equiv k^{ij}\rho(X_i)^A_C\rho(X_j)^C_B$ is the Casimir operator for the representation ρ, and hence proportional to δ^A_B. It then follows that for any $\rho \neq 0$ q-cocycle ψ $(s_\rho\psi = 0)$,

$$s_\rho(\tau\psi\mathcal{C}^{(2)}(\rho)^{-1}) \propto \psi, \tag{2.33}$$

i.e., ψ is a (trivially harmonic state) coboundary generated by a $(q-1)$-cochain proportional to $\tau\psi\mathcal{C}^{(2)}(\rho)^{-1}$, q.e.d. Hence, any nontrivial BRST-invariant state ψ $(s_2\psi = 0,\ \psi \neq s_2\varphi)$ is a $\mathcal{G}$ singlet and, as a consequence of Theorem 2.1, its class contains a unique W_2 harmonic representative.

From (2.30) we also deduce the following.

Lemma 2.2: A state ψ is W_2 harmonic iff it is invariant,[39] $X_i\psi = 0$.

Proof: If ψ is invariant, $W_2\psi = -\tfrac{1}{2}\delta^{ij}X_i X_j\psi = 0$. If ψ is W_2 harmonic,

$$0 = \langle\psi, W_2\psi\rangle = -\tfrac{1}{2}\langle\psi, \delta^{ij}X_i X_j\psi\rangle = \tfrac{1}{2}\delta^{ij}\langle X_i\psi, X_j\psi\rangle, \tag{2.34}$$

and $X_j\psi = 0$, since $\langle\,,\,\rangle$ is nondegenerate, q.e.d. In fact, if ψ is invariant, ψ is both s_2 and $\overline{s_2}$ closed by (2.28).

Corollary 2.1: Each nontrivial element in the cohomology ring $H^*(\mathcal{G})$ may be represented by an invariant state.

Proof: Let $\psi \in Z(\mathcal{G})$ be nontrivial. Hence, its decomposition has the form

$$\psi = s_2\alpha + \gamma. \tag{2.35}$$

Therefore $\psi - s_2\alpha$ is in the cohomology class of ψ and is harmonic (and hence invariant).

III. HIGHER-ORDER BRST AND ANTI-BRST OPERATORS

A. Invariant tensors

The considerations of the previous section rely on the nilpotent operator s_2 and its adjoint, both constructed out of the structure constants C_{ijk}. The latter determine a skew-symmetric tensor of order three, which can be seen as a third-order cocycle $C=C_{ijk}c^ic^jc^k$ and, additionally, is invariant under the action of the Lie algebra generators X_k. Indeed, acting on C with the X's, one gets a sum of three terms, in each of which one of the indices of C is transformed in the adjoint representation and the statement of invariance is equivalent to the Jacobi identity. Notice that we need not saturate every index of C_{ijk} with the same type of variable in order to get an invariant quantity—it suffices that each type of variable transforms in the adjoint representation [for example, s_2 in (1.1), which is also invariant, involves saturating two c's and one π].

The cohomology of simple Lie algebras contains, besides the three cocycle C above, other, higher-order skew-symmetric tensors with similar properties. As mentioned in the Introduction, any compact simple Lie algebra $\mathcal{G}$ of rank l has l primitive cocycles given by skew-symmetric tensors $\Omega^{(2m_s-1)}_{i_1 i_2 \cdots i_{2m_s-1}}$ $(s=1,...,l)$, associated to the l Casimir–Racah primitive invariants of rank m_s.[21–23,25] Their invariance is expressed by the equation

$$\sum_{j=1}^{2m_s-1} C_{bi_j}{}^{a}\Omega^{(2m_s-1)}_{i_1 i_2 \cdots \hat{i}_j a i_{j+1} \cdots i_{2m_s-1}}=0. \tag{3.1}$$

Due to the MC equations, the above relation implies that $\Omega^{(2m_s-1)}_{i_1 \cdots i_{2m_s-1}}\omega^{i_1}\cdots\omega^{i_{2m_s-1}}$ is a cocycle for the Lie algebra coboundary operator (2.3) for $\rho=0$ (in the language of forms, this is equivalent to saying that any bi-invariant form is closed, and hence a CE cocycle). The existence of these cocycles is related to the topology of the corresponding group manifold, in particular, to the odd-sphere product structure that the simple compact group manifolds have from the point of view of real homology (see, e.g., Refs. 33, 40–42, 34). We may use the correspondence $c^i \leftrightarrow \omega^i$ and the discussion after Theorem 2.1 to move freely from the CE approach to the BRST one here.

Let us consider for definiteness the case of $su(n)$, for which $m_1=2$, $m_2=3$,..., $m_l=n$, and there exist $l=(n-1)$ different primitive skew-symmetric tensors of rank 3,5,...,$2n-1$. Consider, for a given m, the $(2m-1)$-form,

$$\Omega^{(2m-1)}=\frac{1}{(2m-1)!}\mathrm{Tr}(\theta\wedge \overset{2m-1}{\cdots} \wedge\theta), \tag{3.2}$$

where $\theta\equiv\omega^iT_i$ and $T_i\in\mathcal{G}$ is in the defining representation of $su(n)$. Since $d\Omega^{(2m-1)}=0$, the coordinates of $\Omega^{(2m-1)}$ provide a $(2m-1)$-cocycle on $su(n)$. One can show (see, e.g., Ref. 24) that

$$\Omega^{(2m-1)}_{\rho i_2 \cdots i_{2m-2}\sigma}=\frac{1}{(2m-3)!}k_{\rho l_1 \cdots l_{m-1}}C_{j_2 j_3}{}^{l_1}\cdots C_{j_{2m-2}\sigma}{}^{l_{m-1}}\epsilon^{j_2\cdots j_{2m-2}}_{i_2\cdots i_{2m-2}}, \tag{3.3}$$

is a skew-symmetric tensor, where

$$k_{\rho l_1 \cdots l_{m-1}}=s\,\mathrm{Tr}(T_\rho T_{l_1}\cdots T_{l_{m-1}}) \tag{3.4}$$

is a symmetric invariant tensor given by the symmetrized trace of a product of m generators [its invariance can be expressed by an equation similar to (3.1)]. Symmetric invariant tensors $k_{i_1\cdots i_m}$ give rise to Casimir–Racah operators,

$$\mathcal{C}^{(m)} = k^{i_1 \cdots i_m} X_{i_1} \cdots X_{i_m}, \tag{3.5}$$

which commute with the generators; $\mathcal{C}^{(2)}$ is the standard quadratic Casimir operator.

B. Higher-order operators

The above family of cocycles Ω can be used to construct *higher-order* BRST *operators*.[25,32] To each invariant tensor of rank m_s corresponds a BRST operator s_{2m_s-2}, which in terms of the coordinates $\Omega_{i_1 \cdots i_{2m_s-2}}{}^{\sigma}$ of the $(2m_s-1)$-cocycle (3.3), is given by

$$s_{2m_s-2} = -\frac{1}{(2m_s-2)!} \Omega^{(2m_s-1)}_{i_1 \cdots i_{2m_s-2}}{}^{\sigma} c^{i_1} c^{i_2} \cdots c^{i_{2m_s-2}} \pi_\sigma . \tag{3.6}$$

These operators are particularly interesting in view of the property

$$\{s_{2m_s-2}, s_{2m_{s'}-2}\} = 0, \quad s, s' = 1,...,l; \tag{3.7}$$

i.e., they are nilpotent and anticommute (see Ref. 25 for a proof).

For each m_s, $s > 1$, we may look at s_{2m-2} (we shall often write m for m_s henceforth) as a *higher-order coboundary* operator, s_{2m-2}: $C^q(\mathcal{G}) \to C^{q+(2m-3)}(\mathcal{G})$. The analog of the MC equation (2.6) for s_{2m-2} is given by

$$s_{2m-2} c^a = -\frac{1}{(2m-2)!} \Omega^{(2m-1)}_{i_1 \cdots i_{2m-2}}{}^{a} c^{i_1} c^{i_2} \cdots c^{i_{2m-2}}, \tag{3.8}$$

which may also be written as

$$s_{2m-2} c = -\frac{1}{(2m-2)!} [c, \overset{2m-2}{\cdots}, c], \tag{3.9}$$

where $[c, \overset{2m-2}{\cdots}, c] := c^{i_1} \cdots c^{i_{2m_2}} [T_{i_1}, \ldots, T_{i_{2m-2}}]$ and the higher-order structure constants of the $(2m-2)$ bracket[25] are given by the $(2m-1)$ cocycle, i.e.,

$$[T_{i_1}, \ldots, T_{i_{2m-2}}] = \Omega^{(2m-1)}_{i_1 \cdots i_{2m-2}}{}^{a} T_a . \tag{3.10}$$

Using (3.9), the nilpotency of s_{2m-2} follows from the higher-order Jacobi identity,

$$s^2_{2m_2} c = -\frac{1}{(2m-2)!} \frac{1}{(2m-3)!} [c, \overset{2m-3}{\cdots}, c, [c, \overset{2m-2}{\cdots}, c]] = 0, \tag{3.11}$$

which the rhs of (3.11) satisfies as a consequence of $\Omega^{(2m-1)}_{i_1 \cdots i_{2m-2}}{}^{a}$ being a cocycle.

Moreover, for each $\mathcal{G}$ we may introduce the *complete BRST operator* **s**,[25]

$$\begin{aligned} \mathbf{s} = & -\frac{1}{2} C_{j_1 j_2}{}^{\sigma} c^{j_1} c^{j_2} \pi_\sigma - \cdots - \frac{1}{(2m_s-2)!} \Omega^{(2m_s-1)}_{j_1 \cdots j_{2m_s-2}}{}^{\sigma} c^{j_1} \cdots c^{j_{2m_s-2}} \pi_\sigma - \cdots \\ & - \frac{1}{(2m_l-2)!} \Omega^{(2m_l-1)}_{j_1 \cdots j_{2m_l-2}}{}^{\sigma} c^{j_1} \cdots c^{j_{2m_l-2}} \pi_\sigma \\ \equiv & \, s_2 + \cdots + s_{2m_s-2} + \cdots + s_{2m_l-2} . \end{aligned} \tag{3.12}$$

This operator is nilpotent, and its terms have (except for some additional ones that break the generalized Jacobi identities, which are at the core of the nilpotency of s_{2m_s-2}), the same structure as those that appear in closed string theory[27] and lead to a strongly homotopy algebra.[26] In fact, the higher-order structure constants (which here have definite values and a geometrical meaning as higher-order cocycles of $\mathcal{G}$) correspond to the string correlation functions giving the string couplings. Since the expression for **s** in the homotopy Lie algebra that underlies closed string theory already includes a term of the form $f^{\sigma}_{j_1} c^{j_1} \pi_\sigma$, f nilpotent, $\mathbf{s}^2=0$ is not satisfied [as it is for (3.12)] by means of a sum of independently satisfied Jacobi identities, and, in particular, the $C_{ij}{}^k$ do not satisfy the Jacobi identity and hence do not define a Lie algebra.

For each s_{2m-2} we now introduce its adjoint *anti*-BRST *operator* $\overline{s}_{2m-2}$,

$$\overline{s}_{2m-2} = -\frac{1}{(2m-2)!} \Omega^{(2m-1)}_{i_1 \cdots i_{2m-2}}{}^{\sigma} c_\sigma \pi^{i_{2m-2}} \cdots \pi^{i_1}$$
$$= -\frac{(-1)^{m-1}}{(2m-2)!} \Omega^{(2m-1)}_{i_1 \cdots i_{2m-2}}{}^{\sigma} c_\sigma \pi^{i_1} \cdots \pi^{i_{2m-2}}. \tag{3.13}$$

Each pair $(s_{2m-2}, \overline{s}_{2m-2})$ allows us to construct a *higher-order* Laplacian W_{2m-2},

$$W_{2m-2} = (s_{2m-2} + \overline{s}_{2m-2})^2 = s_{2m-2}\overline{s}_{2m-2} + \overline{s}_{2m-2} s_{2m-2}. \tag{3.14}$$

Clearly, s_{2m-2}, $\overline{s}_{2m-2}$, and W_{2m-2} all commute with the generators X_i, and we have the following.

Lemma 3.1: For each $s=1,...,l$, the higher-order BRST and anti-BRST operators s_{2m_s-2} and $\overline{s}_{2m_s-2}$, together with their associated Laplacian W_{2m_s-2} define the superalgebra Σ_{m_s},

$$[s_{2m_s-2}, W_{2m_s-2}] = 0, \quad [\overline{s}_{2m_s-2}, W_{2m_s-2}] = 0, \quad \{s_{2m_s-2}, \overline{s}_{2m_s-2}\} = W_{2m_s-2}, \tag{3.15}$$

which has a central extension structure.

For $s=1$, $m_1=2$, $W_2=\Delta$, and the above expressions reproduce (1.1), (2.6), (2.8), and (2.22).

The BRST (anti-BRST) operator s_{2m-2} ($\overline{s}_{2m-2}$), acting on a monomial in the c's, raises (lowers) its ghost number by $2m-3$ while W_{2m-2} leaves the ghost number invariant and is self-adjoint. We notice that all terms in s_{2m-2} ($\overline{s}_{2m-2}$) contain one $(2m-2)\pi$, and that the term with the maximum number of π's in W_{2m-2} contains (at most) $2m-2$ of them. This is so because the two terms with $2m-1$ π's (from $s_{2m-2}\overline{s}_{2m-2}$, $\overline{s}_{2m-2}s_{2m-2}$) cancel, as one can verify. The BRST operator s_{2m-2} annihilates all states of ghost number $q > r-2m+2$, as well as zeroth-order states. Similarly, $\overline{s}_{2m-2}$ annihilates states of ghost number $q < 2m-2$ and the top state $c_1 \cdots c_r$. It follows that zero- and r-ghost number states are both W_{2m-2} harmonic.

Let us establish now the relation between the $\overline{\cdot}$ operation [the adjoint with respect to the inner product in (2.12)] and the conjugation by the Hodge $*$ operator, as these apply to s_{2m-2}.

Lemma 3.2: The following equalities hold on any state (BRST cochain) of ghost number q,

$$\overline{s}_{2m-2} = (-1)^{r(q+1)+1} * s_{2m-2} *, \quad s_{2m-2} = (-1)^{r(q+1)} * \overline{s}_{2m-2} *, \quad s_{2m-2} * = (-1)^q * \overline{s}_{2m-2}; \tag{3.16}$$

notice that the sign factors do not depend on m and hence they coincide with those of (2.15). The proof is straightforward, using (2.11), (2.17), where care should be taken to substitute the ghost numbers actually ''seen'' by the operators.

Although we shall not use them here we also introduce, for the sake of completeness, the V-valued higher-order coboundary operators $s_{\rho_{(2m_s-2)}}$ for a nontrivial representation $\rho \in \mathrm{End}\, V$ of the $(2m_s-2)$-algebra. They are given by

$$s_{\rho(2m_s-2)} = c^{i_1} \cdots c^{i_{2m_s-3}} \rho(X_{i_1}) \cdots \rho(X_{i_{2m_s-3}}) - \frac{1}{(2m_s-2)!} \Omega^{(2m_s-1)}_{i_1 \cdots i_{2m_s-2}}{}^{\sigma} c^{i_1} c^{i_2} \cdots c^{i_{2m_s-2}} \pi_\sigma. \tag{3.17}$$

It may be seen that the nilpotency of $s_{\rho_{(2m_s-2)}}$ is guaranteed by the fact that the skew-symmetric product of $(2m_s-2)$ ρ's, which defines the multibracket $(2m_s-2)$-algebra for an appropriate ρ [Eq. (3.10) with $T\rightarrow\rho$], satisfies the corresponding generalized Jacobi identity as before.

C. Higher-order Hodge decomposition and representations of Σ_{m_s}

Let us now look at the irreducible representations of (3.15), which have the same structure as the supersymmetry algebra. Since W_{2m-2} commutes with $s_{2m-2}, \overline{s}_{2m-2}$, each multiplet of states will have a fixed W_{2m-2} eigenvalue. Let us call γ a W_{2m-2}-*harmonic state* iff $W_{2m-2}\gamma=0$. Then Lemma 2.1 transcribes trivially to the present higher-order case so that γ is harmonic iff it is s_{2m-2} and $\overline{s}_{2m-2}$-closed. Hence, a harmonic state γ is a singlet of Σ_m. We may also extend Theorem 2.1 and prove the following.

Theorem 3.1: (*Higher-order Hodge decomposition*) Each BRST cochain ψ admits a unique decomposition,

$$\psi=s_{2m-2}\alpha+\overline{s}_{2m-2}\beta+\gamma, \tag{3.18}$$

where γ is W_{2m-2}-harmonic.

Proof: We denote by $\mathcal{S}$ the space of all states (i.e., skew-symmetric polynomials in the c's), $\mathcal{K}_{2m-2}$ the kernel of W_{2m-2} (W_{2m-2}-harmonic space) and $\mathcal{K}^{\perp}_{2m-2}$ the complement of $\mathcal{K}_{2m-2}$ in $\mathcal{S}$. Let $P_W^{(0)}$ be the projector from $\mathcal{S}$ to $\mathcal{K}_{2m-2}$. Let $\psi\in\mathcal{S}$; then, $(1-P_W^{(0)})\psi$ lies in $\mathcal{K}^{\perp}_{2m-2}$. However, since the restriction of W_{2m-2} to $\mathcal{K}^{\perp}_{2m-2}$ is invertible, there exists a unique ϕ in $\mathcal{K}^{\perp}_{2m-2}$ such that $(1-P_W^{(0)})\psi=W_{2m-2}\phi$, from which we get

$$\psi=W_{2m-2}\phi+P_W^{(0)}\psi=s_{2m-2}(\overline{s}_{2m-2}\phi)+\overline{s}_{2m-2}(s_{2m-2}\phi)+P_W^{(0)}\psi, \tag{3.19}$$

which provides the desired decomposition of ψ with $\alpha=\overline{s}_{2m-2}\phi$, $\beta=s_{2m-2}\phi$, and $\gamma=P_W^{(0)}\psi$, q.e.d.

To complete the analysis of the irreducible representations of Σ, consider now an eigenstate χ of W_{2m-2} for nonzero (and hence positive) eigenvalue w, $W_{2m-2}\chi=w\chi$, $w>0$. This gives rise to the states

$$\phi\equiv s_{2m-2}\chi,\quad \psi\equiv\overline{s}_{2m-2}\chi,\quad \sigma\equiv s_{2m-2}\overline{s}_{2m-2}\chi. \tag{3.20}$$

Further applications of s_{2m-2} or $\overline{s}_{2m-2}$ produce linear combinations of the above states, for example, $\overline{s}_{2m-2}s_{2m-2}\chi=W_{2m-2}\chi-s_{2m-2}\overline{s}_{2m-2}\chi=w\chi-\sigma$, etc. The quartet $\{\chi,\phi,\psi,\sigma\}$ collapses to a doublet if either $s_{2m-2}\chi=0$ or $\overline{s}_{2m-2}\chi=0$. In this case, χ is the Clifford vacuum and s_{2m-2}, or $\overline{s}_{2m-2}$, respectively, plays the role of the annihilation operator. Let χ be neither s_{2m-2} nor $\overline{s}_{2m-2}$-closed. The state σ of (3.20) is, by construction, s_{2m-2}-closed. Then, we can always choose a linear combination of χ and σ that is $\overline{s}_{2m-2}$ closed. Indeed, for the $\{\chi,\phi,\psi,\sigma\}$ of (3.20), we easily compute

$$\|\phi\|^2+\|\psi\|^2=\langle s_{2m-2}\chi,s_{2m-2}\chi\rangle+\langle\overline{s}_{2m-2}\chi,\overline{s}_{2m-2}\chi\rangle=\langle\chi,W_{2m-2}\chi\rangle=w, \tag{3.21}$$

where we have taken $\|\chi\|^2\equiv\langle\chi,\chi\rangle=1$. Setting

$$q=\sqrt{w},\quad \|\phi\|=q\sin\theta,\quad \|\psi\|=q\cos\theta, \tag{3.22}$$

we find that the following linear combinations:

$$\chi'=\frac{1}{q\sin\theta}(q\chi-q^{-1}\sigma),\quad \sigma'=\frac{1}{q^2\cos\theta}\sigma,\quad \phi'=\frac{1}{q\sin\theta}\phi,\quad \psi'=\frac{1}{q\cos\theta}\psi, \tag{3.23}$$

form an orthonormal set, with the doublet $\{\chi',\phi'\}$ satisfying

$$\overline{s}_{2m-2}\chi'=0, \quad s_{2m-2}\chi'=q\phi'; \quad s_{2m-2}\phi'=0, \quad \overline{s}_{2m-2}\phi'=q\chi', \tag{3.24}$$

and similarly for $\{\psi',\sigma'\}$, i.e., the two doublets decouple. Notice that θ in (3.22), $0<\theta<\pi/2$, is the angle between χ and σ in the $\chi-\sigma$ plane:

$$\langle\chi,\sigma\rangle=q^2\cos^2\theta=\|\chi\|\cdot\|\sigma\|\cos\theta. \tag{3.25}$$

Once in the primed basis of (3.23), $s_{2m-2}\overline{s}_{2m-2}\xi$ (where ξ stands for any of the four primed states above) is equal to either $w\xi$ or 0, and hence, $s_{2m-2}\overline{s}_{2m-2}$ commutes with all operators that commute with W_{2m-2} (similarly for $\overline{s}_{2m-2}s_{2m-2}$). Thus, the representation of the different superalgebras Σ_m fall, in all cases, into singlets (harmonic states) and pairs of doublets. Singlets and doublets here are the trivial analogs of the ''short'' (massless) and ''long'' (massive) multiplets of the standard supersymmetry algebra.

Owing to the particular importance of harmonicity, we investigate the relation between the kernel of a higher-order Laplacian and that of $W_2\propto\mathcal{C}^{(2)}$. To this end, we rewrite s_{2m-2} as (Greek indices below also range in $1,...,r\equiv\dim\mathcal{G}$),

$$\begin{aligned}
s_{2m-2}&=-\frac{1}{(2m-2)!}\Omega^{(2m-1)}_{i_1\cdots i_{2m-2}}{}^{\sigma}c^{i_1}\cdots c^{i_{2m-2}}\pi_\sigma\\
&=-\frac{1}{(2m-2)!}k_{j_1\cdots j_{m-1}}{}^{\sigma}C_{\rho i_2}{}^{j_1}\cdots C_{i_{2m-3}i_{2m-2}}{}^{j_{m-1}}c^{\rho}c^{i_2}\cdots c^{i_{2m-2}}\pi_\sigma\\
&=\frac{1}{(2m-2)!}\left(\sum_{r=2}^{m-1}k_{i_2j_2\cdots\hat{j}_r\alpha\cdots j_{m-1}}{}^{\sigma}C_{\rho j_r}{}^{\alpha}C_{i_3i_4}{}^{j_2}\cdots C_{i_{2r-1}i_{2r}}{}^{j_r}\cdots C_{i_{2m-3}i_{2m-2}}{}^{j_{m-1}}\right.\\
&\qquad\left.+k_{i_2j_2\cdots j_{m-1}}{}^{\alpha}C_{\alpha\rho}{}^{\sigma}C_{i_3i_4}{}^{j_2}\cdots C_{i_{2m-3}i_{2m-2}}{}^{j_{m-1}}\right)c^{\rho}c^{i_2}\cdots c^{i_{2m-2}}\pi_\sigma\\
&=\frac{1}{(2m-2)!}k_{\beta j_1\cdots j_{m-2}}{}^{\alpha}C_{i_1i_2}{}^{j_1}\cdots C_{i_{2m-5}i_{2m-4}}{}^{j_{m-2}}c^{\beta}c^{i_1}\cdots c^{i_{2m-4}}X_\alpha,
\end{aligned}\tag{3.26}$$

where the invariance of $k_{j_1\cdots j_{m-1}}{}^{\sigma}$ has been used in the third line and the Jacobi identity in the last equality. Similarly, $\overline{s}_{2m-2}$ may be written as

$$\overline{s}_{2m-2}=-(-1)^m\frac{1}{(2m-2)!}k_{\beta j_1\cdots j_{m-2}}{}^{\alpha}C_{i_1i_2}{}^{j_1}\cdots C_{i_{2m-5}i_{2m-4}}{}^{j_{m-2}}\pi^{\beta}\pi^{i_1}\cdots\pi^{i_{2m-4}}X_\alpha. \tag{3.27}$$

This proves the following.

Lemma 3.3: The higher-order BRST and anti-BRST operators s_{2m-2}, $\overline{s}_{2m-2}$ may be written as

$$s_{2m-2}=\Omega^{\alpha}X_\alpha, \quad \overline{s}_{2m-2}=-\overline{\Omega}^{\alpha}X_\alpha, \tag{3.28}$$

where

$$\Omega^{\alpha}\equiv\frac{1}{(2m-2)!}k_{\beta j_1\cdots j_{m-2}}{}^{\alpha}C_{i_1i_2}{}^{j_1}\cdots C_{i_{2m-5}i_{2m-4}}{}^{j_{m-2}}c^{\beta}c^{i_1}\cdots c^{i_{2m-4}}, \tag{3.29}$$

$$\overline{\Omega}^{\alpha}\equiv(-1)^m\frac{1}{(2m-2)!}k_{\beta j_1\cdots j_{m-2}}{}^{\alpha}C_{i_1i_2}{}^{j_1}\cdots C_{i_{2m-5}i_{2m-4}}{}^{j_{m-2}}\pi^{\beta}\pi^{i_1}\cdots\pi^{i_{2m-4}}. \tag{3.30}$$

For $m=2$ one gets $\Omega^{\alpha}=\frac{1}{2}c^{\alpha},\overline{\Omega}^{\alpha}=\frac{1}{2}\pi^{\alpha}$ and the expression (2.28) for s_2, $\overline{s_2}$ is recovered. As a W_2-harmonic state is invariant, the above relation shows that the kernel of W_2 is contained in the kernel of W_{2m_s-2} for all m_s, $s=2,...,l$. It follows from (3.28) that an invariant state is s_{2m-2} and $\overline{s}_{2m-2}$-closed, and hence the following lemma.

Lemma 3.4: Every invariant state is W_{2m-2} harmonic.

In the particular realization of the Σ_{m_s} algebra (3.15) in terms of ghosts and antighosts given in (3.6), (3.13), W_{2m_s-2} is ghost number preserving and commutes with the Lie algebra generators X_i. There exists therefore a basis of the c's in which W_{2m_s-2}, $s=1,...,l$ is diagonal. For a fixed ghost number q, the $\binom{r}{q}$ independent monomials $c_{i_1}\cdots c_{i_q}$ transform as the fully antisymmetric part of the qth tensor power of the adjoint representation of $\mathcal{G}$. This antisymmetric part is $\mathcal{G}$-reducible and W_{2m_s-2} will have a fixed eigenvalue in each of its irreducible components (which will change, in general, when going from one irreducible representation to another of the same or different ghost number). s_{2m_s-2} and $\overline{s}_{2m_s-2}$ connect states belonging to the same $\mathcal{G}$-irreducible representation and with the same W_{2m_s-2}-eigenvalue (but of different ghost number), and such states will fall into one of the Σ_{m_s} multiplets (singlets or doublets) discussed above. As the generators X_i commute with $*$, the $\mathcal{G}$-irreducible representation decomposition pattern will be symmetrical under $q\rightarrow r-q$.

The l Casimir–Racah operators $\mathcal{C}^{(m_s)}$, take fixed eigenvalues within each $\mathcal{G}$-irreducible component, which is uniquely labeled by them. The same irreducible representation may appear more than once, with equal or with different ghost numbers; the Casimirs will not distinguish among these different copies of the same irreducible representation. As mentioned, $W_2\equiv\Delta=-\frac{1}{2}\mathcal{C}^{(2)}$ [Eq. (2.30)]. An important question that naturally arises is whether W_{2m_s-2} also reduces, for $s>2$, to some higher-order Casimir–Racah operator or, more generally, to a sum of products of them. Since W_{2m_s-2} commutes with the X's [realized in ghost space via (2.26)] an equivalent question is whether it belongs to the universal enveloping algebra $\mathcal{U}(\mathcal{G})$ of $\mathcal{G}$. The answer is negative and we address this point in the next section, working out in full the $su(3)$ case.

IV. THE CASE OF $su(3)$

We opt here for mild departures from our previous conventions: the generators will now be chosen Hermitian so as to work with real eigenvalues and the normalization of all operators is such that fractional eigenvalues are avoided.

A. Invariant tensors and operators

The $su(3)$ algebra $[T_i,T_j]=if_{ij}{}^kT_k$, $i=1,...,8$, is determined by the nonzero structure constants $f_{ij}{}^k$ that are reproduced for convenience (Table I). These are also the coordinates of the $su(3)$ three-cocycle. The well-known third-order symmetric tensor d_{ijk} (Table II) gives the third-order Casimir–Racah operator. From d_{ijk} and (3.3) one finds the $su(3)$ five-cocycle coordinates[24] (Table III).

The Casimirs C_2 and C_3,

$$C_2=T^iT_i,\quad C_3=d^{ijk}T_iT_jT_k, \tag{4.1}$$

are related to the operators (3.5) simply by

$$C_2=-\mathcal{C}^{(2)},\quad C_3=-i\mathcal{C}^{(3)}. \tag{4.2}$$

TABLE I. Nonzero structure constants for $su(3)$.

$f_{123}=1$	$f_{147}=1/2$	$f_{156}=-1/2$
$f_{246}=1/2$	$f_{257}=1/2$	$f_{345}=1/2$
$f_{367}=-1/2$	$f_{458}=\sqrt{3}/2$	$f_{678}=\sqrt{3}/2$

TABLE II. Nonzero-components of the symmetric invariant d_{ijk} for $su(3)$.

$d_{118}=1/\sqrt{3}$	$d_{228}=1/\sqrt{3}$	$d_{338}=1/\sqrt{3}$	$d_{888}=-1/\sqrt{3}$
$d_{448}=-1/(2\sqrt{3})$	$d_{558}=-1/(2\sqrt{3})$	$d_{668}=-1/(2\sqrt{3})$	$d_{778}=-1/(2\sqrt{3})$
$d_{146}=1/2$	$d_{157}=1/2$	$d_{247}=-1/2$	$d_{256}=1/2$
$d_{344}=1/2$	$d_{355}=1/2$	$d_{366}=-1/2$	$d_{377}=-1/2$

The antisymmetric cocycles, on the other hand, give rise to the BRST and anti-BRST operators s_2, $\overline{s_2}$, s_4, $\overline{s_4}$ [see also (3.13)],

$$s_2=-\frac{1}{2}f_{ij}{}^{k}c^ic^j\pi_k, \quad s_4=-\frac{1}{4!}\Omega_{i_1i_2i_3i_4}{}^{\sigma}c^{i_1}c^{i_2}c^{i_3}c^{i_4}\pi_\sigma; \tag{4.3}$$

$$s_2{}^2=s_4{}^2=0=\overline{s_2}^2=\overline{s_4}^2, \quad s_2s_4+s_4s_2=0=\overline{s_2}\,\overline{s_4}+\overline{s_4}\,\overline{s_2}. \tag{4.4}$$

The corresponding Laplacians are

$$W_2=(s_2+\overline{s_2})^2=s_2\overline{s_2}+\overline{s_2}s_2, \quad W_4=(s_4+\overline{s_4})^2=s_4\overline{s_4}+\overline{s_4}s_4, \tag{4.5}$$

and satisfy, in addition to (2.22),

$$[W_2,(s_4,\overline{s_4},W_4)]=0, \quad [W_4,s_4]=0=[W_4,\overline{s_4}]. \tag{4.6}$$

Notice that W_4 does not commute with s_2 or $\overline{s_2}$ (but, being invariant, it does commute with W_2). As W_2 is proportional to C_2, we only refer to the latter in the sequel. Also, to avoid fractional eigenvalues, we define $W\equiv 4!W_4$.

B. Decomposition into irreducible representations

In general, a monomial in the c's of ghost number q transforms in $\mathbf{8}^{\wedge q}$, the part of the qth tensor power of $su(3)$ adjoint representation that is totally antisymmetric in the q factors. The reduction of $\mathbf{8}^{\wedge q}$ into irreducible representations of $su(3)$ can be achieved by a variety of methods. One way, which gives results useful in our analysis below, employs conventional tensor methods. We first quote the results:

$$\begin{aligned}
\mathbf{8}^{\wedge 0}&=\mathbf{1}=\mathbf{8}^{\wedge 8}\\
\mathbf{8}^{\wedge 1}&=\mathbf{8}=\mathbf{8}^{\wedge 7}\\
\mathbf{8}^{\wedge 2}&=\mathbf{8}+\mathbf{10}+\overline{\mathbf{10}}=\mathbf{8}^{\wedge 6}\\
\mathbf{8}^{\wedge 3}&=\mathbf{1}+\mathbf{8}+\mathbf{10}+\overline{\mathbf{10}}+\mathbf{27}=\mathbf{8}^{\wedge 5}\\
\mathbf{8}^{\wedge 4}&=2\times\mathbf{8}+2\times\mathbf{27},
\end{aligned} \tag{4.7}$$

noting the symmetry $\mathbf{8}^{\wedge q}=\mathbf{8}^{\wedge(r-q)}$, and then describe the tensorial method of developing the results in a fully explicit form.

We may refer to $su(3)$ irreducible representations either by dimension, or else in highest weight $\{\lambda_1,\lambda_2\}$ notation. In the latter notation $\{1,0\}$ and $\{0,1\}$ denote the "quark" and "anti-quark" representations $\mathbf{3}$ and $\overline{\mathbf{3}}$ each of dimension 3, and $\{\lambda_1,\lambda_2\}$ denotes the representation whose highest weight is $\mathbf{w}(\lambda_1,\lambda_2)=\lambda_1\mathbf{w}(1,0)+\lambda_2\mathbf{w}(0,1)$, where $\mathbf{w}(1,0)$, $\mathbf{w}(0,1)$ are the weights of $\mathbf{3}$, $\overline{\mathbf{3}}$, respectively. The representation $\{\lambda_1,\lambda_2\}$ has dimension

TABLE III. Nonzero coordinates of the $su(3)$ five-cocycle.

$\Omega_{12345}=1/4$	$\Omega_{12367}=1/4$	$\Omega_{12458}=\sqrt{3}/12$
$\Omega_{12678}=-\sqrt{3}/12$	$\Omega_{13468}=-\sqrt{3}/12$	$\Omega_{13578}=-\sqrt{3}/12$
$\Omega_{23478}=\sqrt{3}/12$	$\Omega_{23568}=-\sqrt{3}/12$	$\Omega_{45678}=-\sqrt{3}/6$

$$d(\lambda_1,\lambda_2)=\tfrac{1}{2}(\lambda_1+1)(\lambda_2+1)(\lambda_1+\lambda_2+2), \tag{4.8}$$

and Casimir operators (4.1) whose eigenvalues are[43]

$$C_2(\lambda_1,\lambda_2)=\tfrac{1}{3}(\lambda_1^2+\lambda_1\lambda_2+\lambda_2^2)+\lambda_1+\lambda_2, \tag{4.9}$$

$$C_3(\lambda_1,\lambda_2)=\tfrac{1}{18}(\lambda_1-\lambda_2)(\lambda_1+2\lambda_2+3)(2\lambda_1+\lambda_2+3)=-C_3(\lambda_2,\lambda_1). \tag{4.10}$$

Since $C_3(\lambda_1,\lambda_2)=-C_3(\lambda_2,\lambda_1)$, C_3 vanishes for all self-conjugate $(\lambda_1=\lambda_2)$ irreducible representations. The results for the representations ρ that occur in (4.7) are given in the table,

$$\begin{array}{ccc} \dim\rho & \{\lambda_1,\lambda_2\} & (C_2,C_3) \\ \mathbf{1} & \{0,0\} & (0,0) \\ \mathbf{8} & \{1,1\} & (3,0) \\ \mathbf{10} & \{3,0\} & (6,9) \\ \overline{\mathbf{10}} & \{0,3\} & (6,-9) \\ \mathbf{27} & \{2,2\} & (8,0) \end{array}\;. \tag{4.11}$$

Turning to the tensor analysis of tensors spanned, for $0\leqslant q\leqslant 8$, by the monomials $c_{i_1}\cdots c_{i_q}$, we start with the case $q=1$, where c_i describes the basis of the $su(3)$ adjoint representation, i.e., an octet. In the case $q=2$,

$$d_i=f_{ijk}c_jc_k \tag{4.12}$$

describes an independent octet, the only one available since $d_{ijk}c_jc_k\equiv 0$. The remaining tensor, irreducible over the field $\mathbb{R}$ is

$$c_ic_j-\tfrac{1}{3}f_{ijk}d_k=(\mathbf{20}_2)_{ij}, \tag{4.13}$$

for which $f_{ijk}(\mathbf{20}_2)_{ij}=0$ by construction. The notation implies that it has 20 components, agreeing with the simple count $\binom{8}{2}-8$. To reduce it into separate $\mathbf{10}$ and $\overline{\mathbf{10}}$ pieces can be done only over the field of complex numbers, but this is not needed here.[44] We may also write

$$c_ic_j=(c_ic_j-\tfrac{1}{3}f_{ijk}d_k)+\tfrac{1}{3}f_{ijk}d_k=(P_{20})_{ij,pq}c_pc_q+(P_8)_{ij,pq}c_pc_q, \tag{4.14}$$

where the projectors are given by

$$\begin{aligned}(P_{20})_{ij,pq}&=\tfrac{1}{2}(\delta_{ip}\delta_{jq}-\delta_{iq}\delta_{jp})-\tfrac{1}{3}f_{ijl}f_{lpq},\\ (P_8)_{ij,pq}&=\tfrac{1}{3}f_{ijl}f_{lpq}.\end{aligned} \tag{4.15}$$

The projection properties and orthogonality can be checked using well-known properties of $su(3)$ f tensors,[24,45] etc. Also, we have trivially,

$$P_{20}+P_8=U,\quad U_{ij,pq}=\tfrac{1}{2}(\delta_{ip}\delta_{jq}-\delta_{iq}\delta_{jp}), \tag{4.16}$$

where U is the relevant form of the unit operator in the ghost number $q=2$ space spanned by the antisymmetric tensors $c_i c_j$. Direct calculations on the explicit form for d_k given by (4.12) and for $(\mathbf{20}_2)_{ij}$ by (4.13) show that these have the C_2 eigenvalues 3 and 6 in (4.11).

The space spanned at $q=3$ by the tensor components $c_i c_j c_k$ gives rise easily to the singlet (0,0),

$$Y=f_{ijk}c_i c_j c_k = c_i d_i, \tag{4.17}$$

and the $su(3)$ octet,

$$e_i = d_{ijk} c_j d_k. \tag{4.18}$$

This is the only $q=3$ octet, since

$$\xi_i = f_{ijk} c_j d_k = 0 \tag{4.19}$$

follows from the definition (4.12) of d_k and the Jacobi identity for the f tensor. We note, however, that $\xi_i=0$ is a set of eight nonempty verifiable identities among various trilinears $c_i c_j c_k$. To build other irreducible tensors, it is natural to look at the tensors

$$c_i d_j - c_j d_i, \tag{4.20}$$

$$c_i d_j + c_j d_i, \tag{4.21}$$

with *a priori* 28 and 36 components. The former (4.20) is irreducible and defines $(\mathbf{20}_3)_{ij}$ as it stands, because $\xi_i=0$ yield eight identities automatically satisfied by its components. It is also not hard to check that the C_2 eigenvalue is 6. The latter (4.21) is not irreducible, but by extracting the scalar (4.17) and the octet (4.18), we find the irreducible tensor of $27=36-1-8$ components,

$$(\mathbf{27}_3)_{ij} = c_i d_j + c_j d_i - \tfrac{1}{4}\delta_{ij} Y - \tfrac{6}{5} d_{ijk} e_k. \tag{4.22}$$

It is easy to see that contracting with δ_{ij} and d_{ijk} gives zero as irreducibility requires. It is hard, needing a good selection of $su(3)$ such f- and d-tensor identities, as found in Ref. 24, to prove that C_2 indeed has eigenvalue 8 for $(\mathbf{27}_3)_{ij}$. We could turn results (4.17), (4.18), (4.20), and (4.22) into the form

$$c_i c_j c_k = \sum_R P^R_{ijk,pqr} c_p c_q c_r, \tag{4.23}$$

involving a complete set of orthogonal projectors for $R=1$, 8, 20, and 27.

Since the case at $q=4$ involves repetitions, it is best at this point to review the situation regarding octets. At $q=1$, 2, 3, we have

$$c_i, \quad d_i, \quad e_i, \tag{4.24}$$

and no others. At $q=4$, we find

$$f_i = d_{ijk} d_j d_k = \Omega_{i i_1 i_2 i_3 i_4} c_{i_1} c_{i_2} c_{i_3} c_{i_4}, \tag{4.25}$$

but $f_{ijk} d_j d_k \equiv 0$. A second octet that can be checked easily to be linearly independent of f_i is $Y c_i$. We may build other $q=4$ octets, but these will not give anything new, since, e.g., we can prove the results

$$d_{ijk} c_j e_k = -\tfrac{2}{3} c_i Y, \quad f_{ijk} c_j e_k = f_i. \tag{4.26}$$

It is thus now obvious that the complete family of octets can be presented as

$$\begin{array}{ccccccc} q=1 & 2 & 3 & 4 & 5 & 6 & 7 \\ c_i & d_i & e_i & f_i & & & \\ & & & Yc_i & Yd_i & Ye_i & Yf_i. \end{array} \tag{4.27}$$

As a check, we find that Yf_i (for example) is as expected,

$$Yf_1 \sim c_2c_3c_4c_5c_6c_7c_8 \sim *c_1. \tag{4.28}$$

An alternative but equivalent treatment would employ certain duals of f_i, e_i, d_i, c_i in place of Yc_i, Yd_i, Ye_i, Yf_i in (4.27). Of course, for the last case, we have just proved the easy bit of the equivalence. In fact, the use of duals in explicit work is much less convenient than the choice used in (4.27). To indicate this, and to do something instructive in its own right, we make explicit the dual relation of f_i and Yc_i (see also Ref. 24, Sec. 8).

To make contact with a dual to the octet f_i of (4.25) replace $c_{i_1}c_{i_2}c_{i_3}c_{i_4}$ there by $\epsilon_{i_1i_2i_3i_4j_1j_2j_3j_4}c_{j_1}c_{j_2}c_{j_3}c_{j_4}$ to reach

$$p_i = \Omega_{ii_1i_2i_3i_4}\epsilon_{i_1i_2i_3i_4j_1j_2j_3j_4}c_{j_1}c_{j_2}c_{j_3}c_{j_4}, \tag{4.29}$$

which clearly belongs to $\mathbf{8}^{\wedge 4}$. To relate p_i to Yc_i, we need the identity

$$\frac{1}{4!}\Omega_{ii_1i_2i_3i_4}\epsilon_{i_1i_2i_3i_4j_1j_2j_3j_4} = \frac{2}{\sqrt{3}}\delta_{i[j_1}f_{j_2j_3j_4]}, \tag{4.30}$$

in which the divisor 4! on the left is actually matched by one implicit in our definition of square antisymmetrization brackets on the right. Identity (4.30) allows us to prove

$$p_i = \frac{4!\cdot 2}{\sqrt{2}}c_iY = -\frac{4!\cdot 2}{\sqrt{3}}Yc_i, \tag{4.31}$$

as expected.

The contraction $i=j_1$ of (4.30) gives

$$\frac{1}{4!}\Omega_{i_1i_2i_3i_4i_5}\epsilon_{i_1i_2i_3i_4i_5j_1j_2j_3} = \frac{5}{2\sqrt{3}}f_{j_1j_2j_3}, \tag{4.32}$$

which is an evident and easily checked analog of the result,

$$\frac{1}{3!}f_{j_1j_2j_3}\epsilon_{j_1j_2j_3i_1i_2i_3i_4i_5} = -2\sqrt{3}\Omega_{i_1i_2i_3i_4i_5}, \tag{4.33}$$

given in Ref. 24, Eq. (8.14). The latter is a contraction of the more useful identity,

$$\frac{1}{3!}f_{ij_1j_2}\epsilon_{j_1j_2i_1i_2i_3i_4i_5i_6} = -4\sqrt{3}\delta_{i[i_1}\Omega_{i_2i_3i_4i_5i_6]}. \tag{4.34}$$

This may be used, as we used (4.30), to reach, e.g., eventually the dual relationship of d_i to Ye_i.

While the above tensorial analysis provides an explicit construction from first principles of all the entries of (4.7), the use of s_2 and s_4 expedites explicit work. For example, since $[s_2,X_i]=0=[s_4,X_i]$, s_2 and s_4 also commute with C_2 and C_3. Thus, s_2 (for example) either raises the ghost number of a tensor by one, leaving its $su(3)$ nature unaltered or else annihilates it. Thus $s_2c_i \sim d_i$, $s_2d_i=0$. Similarly, $s_4c_i \sim f_i$ and $\overline{s_2}s_4f_i \sim e_i$. Likewise,

$$s_2(\mathbf{20}_2)_{ij}=s_2(c_ic_j-\tfrac{1}{3}f_{ijk}d_k)\sim d_ic_j-c_id_j=-(\mathbf{20}_3)_{ij}\,, \tag{4.35}$$

since $s_2d_i=0$, which confirms what has been seen to hold above.

Further, we might expect $s_2(\mathbf{27}_3)_{ij}$ to yield one of the required $(\mathbf{27}_4)_{ij}$. Indeed $s_2d_i=0$, $s_2Y=0$, and $s_2e_k=f_k$ allow us to write

$$s_2(\mathbf{27}_3)_{ij}=d_id_j-\tfrac{3}{5}d_{ijk}f_k\equiv(\mathbf{27}_4)_{ij}\,. \tag{4.36}$$

A second 27-tensor in $\mathbf{8}^{\wedge 4}$ that is linearly independent of $(\mathbf{27}_4)_{ij}$ of (4.36) is suggested immediately by duality arguments. One replaces $c_{i_1}c_{i_2}c_{i_3}c_{i_4}$ in $d_id_j=f_{ii_1i_2}f_{ji_3i_4}c_{i_1}c_{i_2}c_{i_3}c_{i_4}$, etc. by $\epsilon_{i_1i_2i_3i_4j_1j_2j_3j_4}c_{j_1}c_{j_2}c_{j_3}c_{j_4}$. We thereby reach a tensor $(\mathbf{27}'_4)_{ij}$ that is plainly linearly independent of $(\mathbf{27}_4)_{ij}$. It turns out to be proportional to

$$(\mathbf{27}'_4)_{ij}=c_ie_j+c_je_i-\tfrac{4}{5}d_{ijk}Yc_k\,, \tag{4.37}$$

which can be seen to satisfy $d_{ijl}(27'_4)_{ij}=0$, using (4.26), as well as $(27'_4)_{ii}=0$, so that it is irreducible, with 27 components. Further, $(27_5)_{ij}$ can now be written down explicitly by the action of s_2 on $(27'_4)_{ij}$. No systematic work on projectors for $q=4$ has been done.

C. The Laplacian *W*

From the analysis of Sec. IV B of the $su(3)$ representations contained in $\mathbf{8}^{\wedge q}$, $0\leqslant q\leqslant 8$, where q is the ghost number, it can be seen that the states φ of the system are labeled by the eigenvalues of the ghost number operator $Q=c^i\pi_i$, $Q\varphi=q\varphi$, and of the $su(3)$ Casimirs C_2 and C_3 that label states within each $su(3)$ representation. Since W commutes with Q, C_2, C_3, we expect it to have well-defined eigenvalues on all the states of the system, and we might further expect it to be defined as a specific function of Q, C_2, C_3.

Some progress can be made analytically to compute W eigenvalues. For example, for c_i and d_i given by (4.12), which describe $q=1$, $q=2$ octets, we may compute directly from (4.5) the results

$$Wc_i=5c_i\,,\quad Wd_i=0. \tag{4.38}$$

These calculations, the latter already nontrivial, depend, among other things, on the identities

$$\begin{aligned}\Omega_{i_1i_2i_3i_4p}\Omega_{i_1i_2i_3i_4q}&=5\,\delta_{pq}\,,\\ \Omega_{i_1i_2i_3ab}\Omega_{i_1i_2i_3pq}&=\tfrac{1}{2}(\delta_{ap}\delta_{bq}-\delta_{aq}\delta_{bp}+f_{abi}f_{pqi}),\end{aligned} \tag{4.39}$$

of which only the first follows from the definition of Ω easily. Note also that since W distinguishes between different octets, Eq. (4.38), it cannot be a pure function of the Casimirs: it depends also on Q, which does not belong to the $\mathcal{U}(su(3))$ enveloping algebra.

The results of Sec. IV A also allow the minimal polynomials for C_2 and C_3 to be deduced. These are

$$C_2(C_2-3)(C_2-6)(C_2-8)=0, \tag{4.40}$$

$$C_3(C_3+9)(C_3-9)=0, \tag{4.41}$$

and the orthogonal projectors on the various eigenspaces for C_2 and C_3 are

$$P_0^{(2)} = -\tfrac{1}{144}(C_2-3)(C_2-6)(C_2-8), \quad P_0^{(3)} = -\tfrac{1}{81}(C_3+9)(C_3-9),$$
$$P_3^{(2)} = \tfrac{1}{45}C_2(C_2-6)(C_2-8), \quad P_{-9}^{(3)} = \tfrac{1}{162}C_3(C_3-9),$$
$$P_6^{(2)} = -\tfrac{1}{36}C_2(C_2-3)(C_2-8), \quad P_9^{(3)} = \tfrac{1}{162}C_3(C_3+9), \tag{4.42}$$
$$P_8^{(2)} = \tfrac{1}{80}C_2(C_2-3)(C_2-6).$$

Further progress by analytic methods soon becomes difficult, and we have made use of FORM.[46] This enables us first to compute all W eigenvalues, discussed below, and to find the following identities:

$$C_2C_3 = 6C_3,$$
$$C_3{}^2 = -\tfrac{9}{4}C_2(C_2-3)(C_2-8),$$
$$C_2W = 3W - \tfrac{1}{2}C_2(C_2-3)(C_2-8), \tag{4.43}$$
$$W^2 = 5W + \tfrac{2}{27}C_3{}^2.$$

These results allow the recovery of (4.40), (4.41) as a mild check on our procedures, and the deduction of the minimal polynomial of W,

$$W(W-5)(W-6) = 0, \tag{4.44}$$

which comprises, as it should, all the eigenvalues of W found in practice. Also, the orthogonal projectors onto the eigenspaces of W are

$$P_0^{(W)} = \tfrac{1}{30}(W-5)(W-6), \quad P_5^{(W)} = -\tfrac{1}{5}W(W-6), \quad P_6^{(W)} = \tfrac{1}{6}W(W-5). \tag{4.45}$$

Various useful inferences can be made regarding eigenspaces. For example, alongside the previous result $\ker C_2 \subseteq \ker W$, we have $\ker W \subseteq \ker C_3$. Also,

$$P_9^{(3)} + P_{-9}^{(3)} = P_6^{(2)} = P_6^{(W)},$$
$$P_0^{(2)}P_0^{(W)} = P_0^{(2)},$$
$$P_8^{(2)}P_0^{(W)} = P_8^{(2)}, \tag{4.46}$$
$$P_0^{(W)} + P_5^{(W)} = P_0^{(3)}.$$

So far no explicit expression for W in terms of Q, C_2, C_3 is at hand. The major complication in the pattern of the W-eigenvalues of the $su(3)$ representations in $\mathbf{8}^{\wedge q}$ concerns the octets. For these, the ghost number $q=1$, 4, 4, 7 octets have eigenvalue $W=5$ and the $q=2$, 3, 5, 6 octets $W=0$. This suggests the use of Lagrangian interpolation to define a function,

$$f(q) = \tfrac{1}{360}[(q-4)^2 - 10(q-7)(q-1)](q-2)(q-3)(q-5)(q-6), \tag{4.47}$$

which equals 1 at $q=1$, 4, 4, 7 and 0 at $q=2$, 3, 5, 6, so that for these values, $f(q)^2 = f(q)$. It is then immediate to see that the formula

$$W = \tfrac{1}{9}C_2(C_2-6)(C_2-8)f(Q) - \tfrac{1}{6}C_2(C_2-3)(C_2-8) = 5P_3^{(2)}f(Q) + 6P_6^{(2)}, \tag{4.48}$$

correctly predicts the W-eigenvalues of all states. The last two equations of (4.43) also follow directly, using projector properties, $f(Q)^2 = f(Q)$, and the second equation of (4.43). We should

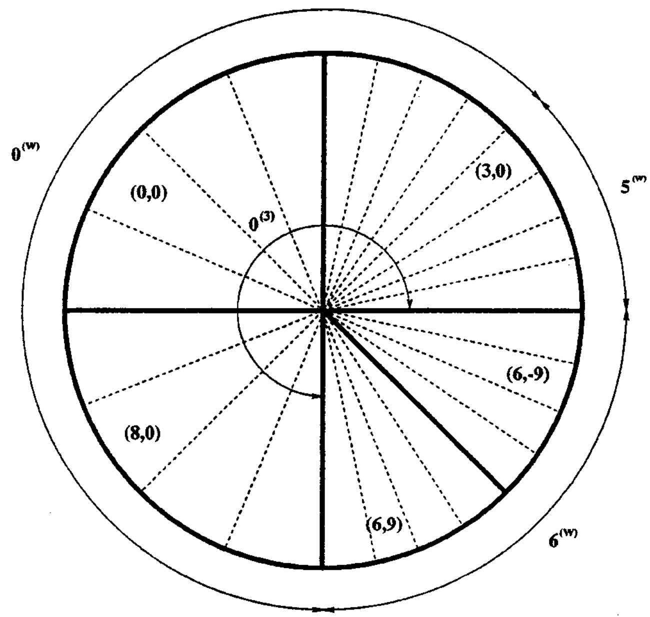

FIG. 1. The spectrum of the Casimirs (C_2,C_3) and of $W_4 \propto W$.

stress here that $f(Q)^2=f(Q)$ holds only for $q\in\{1,2,...,7\}$, whereas the allowed range of values of q is {0, 1,..., 8}. But this does not matter for (4.48), because although $f(Q)$ is finite $(=-27)$ at $q=0$ and $q=8$, $C_2=0$ for the $q=0$ and $q=8$ states. Finally, FORM confirms that W defined by (4.48), and $W=4!W_4$ given by (4.5) are equal as operators.

A final remark about the form of (4.47), (4.48) is in order here. Observing that $f(Q)=f(8-Q)$, one is led to write (4.47) in terms of $u:=Q(8-Q)$, finding

$$f(Q)=F(u):=\tfrac{1}{40}(u-6)(u-12)(u-15) \tag{4.49}$$

(a form that can also be directly derived by Lagrangian interpolation). A different approach is to start from the minimal polynomial for u,

$$u(u-7)(u-12)(u-15)(u-16)=0, \tag{4.50}$$

and write down directly a function $\tilde{F}(u)$, with $\tilde{F}(u)=0$ at $u=0$, 12, 15 and $\tilde{F}(u)=1$ at $u=7$, 16,

$$\tilde{F}(u)=P_7^{(u)}+P_{16}^{(u)}, \tag{4.51}$$

the projectors $P_\lambda^{(u)}$ being defined in the standard way from (4.50). Using this $\tilde{F}(u)$ in place of $F(u)=f(Q)$ in (4.48) also gives correctly W—the difference $\tilde{F}-F$ is annihilated by $P_3^{(2)}$. We note incidentally that the operators $M_{ij}:=c_i\pi_j-c_j\pi_i$, $i<j$, generate the algebra spin(8), the quadratic Casimir of which is proportional to u (since $M_{ij}M_{ij}=-2u$), i.e., (4.48) gives W in terms of the quadratic Casimirs of $su(3)$ and spin(8).

The results of the previous analysis may be summarized in the diagram of Fig. 1 representing the spectra of C_2, C_3, and W. The solid circular disk represents all the $2^8=256$ states available in $\oplus_{i=0}^{8}\mathbf{8}^{\wedge i}$. The four quadrants represent the four eigenspaces (0, 3, 6, 8) of C_2 while the numbers in parentheses are the eigenvalues of C_2, C_3 valid in each disk segment (bordered by solid black lines). Dashed lines within each disk segment separate multiple copies of the same irreducible representation, corresponding, in general, to states of a different ghost number. The arcs outside the disk specify the three (0,5,6) W-eigenspaces. We summarize its key features.

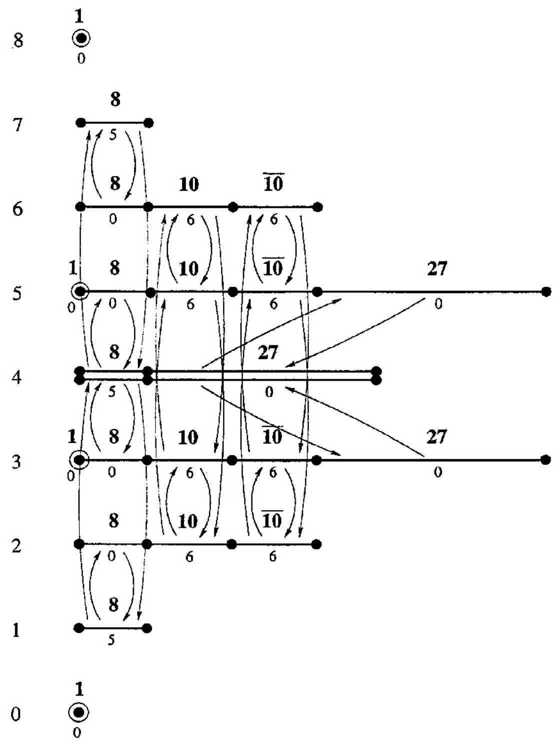

FIG. 2. Decomposition of $\oplus_{i=0}^{8}\mathbf{8}^{\wedge i}$ into irreps of $su(3)$ and the action of $s_2(\overline{s_2})$ and $s_4(\overline{s_4})$ on them (notice that $[s_2(\overline{s_2}),W]\neq 0$). The eigenvalue of W appears under each irrep.

(i) The eigenspace $\mathrm{Im}\,P_6^{(2)}$, equal to $\mathrm{Im}\,P_6^{(W)}$, is split into two parts with the same number of states, labeled by the C_3 eigenvalues 9 and -9. With the help of (4.11) we recognize these, respectively, as the **10** and $\overline{\mathbf{10}}$ $su(3)$ representations, each of which appears four times, with ghost numbers 2, 3, 5, and 6.

(ii) The (0, 0) subspace (i.e., $\ker C_2 = \mathcal{K}_2$), contains four invariant states [the $su(3)$ singlets **1**], with ghost numbers 0, 3, 5, and 8. All of them are W harmonic as well, i.e., Σ_4 singlets.

(iii) (8, 0) (=**27**) appears four times, with ghost numbers 3, 5, and 4 (twice) and is also W harmonic.

(iv) (3, 0) (=**8**) appears eight times, with ghost numbers 1 to 7 (twice for 4).

The diagram shows that $\mathcal{K}_2 + \mathrm{Im}\,P_8^{(2)} \subset \mathcal{K}_4 \subset \ker C_3$. $\mathcal{K}_4$ contains half of the copies of the adjoint representation, the rest belonging to the W eigenvalue 5.

To look now at the representations of Σ_2 and Σ_4 in (2.22) and (3.15), it is convenient to depict the $su(3)$ representations as in the diagram of Fig. 2 and to analyze there the role played by s_2, s_4 and their adjoints $\overline{s_2}$, $\overline{s_4}$ in interconnecting them. Each *straight line* segment in this diagram represents an irreducible representation. All segments in the same line correspond to the same ghost number, while singlets are represented by circles. The arrows between segments depict the action of the s's [solid (black) lines for s_2, $\overline{s_2}$, dotted (gray) lines for s_4, $\overline{s_4}$]; the number below each segment is the W eigenvalue of the irreducible representation. In the following we denote, e.g., by $\mathbf{10}_3$ the irreducible representation **10** with ghost number 3, while a further superscript $u(l)$ [for upper (lower)] distinguishes between the two ghost number 4 representations $\mathbf{8}_4$'s and $\mathbf{27}_4$'s. We point out the following.

(i) Referring to multiplets of the superalgebra (3.15) quartets-turned-into-pairs-of-doublets, according to the remark of Sec. III C, appear three times. For Σ_2, the quartet $\{\mathbf{8}_4^u, \mathbf{8}_5, \mathbf{8}_3, \mathbf{8}_4^l\}$ actually consists of the pair of doublets $\{\mathbf{8}_5, \mathbf{8}_4^u\}$, $\{\mathbf{8}_4^l, \mathbf{8}_3\}$—a similar pattern is exhibited by the **27**'s in the same orders as well as by the Σ_4 quartet $\{\mathbf{8}_4^u, \mathbf{8}_7, \mathbf{8}_1, \mathbf{8}_4^l\}$. The degeneracy seen in the

$q=4$ line is then resolved by noting that s_2 annihilates one octet and $\overline{s_2}$ the other (and similarly for the **27**).

(ii) Besides the above ''split quartets,'' we also have the Σ_2 doublets $\{\mathbf{8}_2,\mathbf{8}_1\}$, $\{\mathbf{10}_3,\mathbf{10}_2\}$, $\{\overline{\mathbf{10}}_3,\overline{\mathbf{10}}_2\}$, the Σ_4 doublets $\{\mathbf{10}_5,\mathbf{10}_2\}$, $\{\overline{\mathbf{10}}_5,\overline{\mathbf{10}}_2\}$, and their $*$ images $\{\mathbf{8}_7,\mathbf{8}_6\}$, $\{\mathbf{10}_6,\mathbf{10}_5\}$, $\{\overline{\mathbf{10}}_6,\overline{\mathbf{10}}_5\}$ and $\{\mathbf{10}_6,\mathbf{10}_3\}$, $\{\overline{\mathbf{10}}_6,\overline{\mathbf{10}}_3\}$, respectively. Notice that W changes eigenvalue within all Σ_2 doublets involving **8**'s, reflecting its failure to commute with s_2.

(iii) The $su(3)$ (and hence Σ_2, Σ_4) singlet $\mathbf{1}_0$ is simply the constant monomial 1, while $\mathbf{1}_3$ is the three-cocycle $f_{ijk}c^ic^jc^k=Y$. The other two singlets are the ''top form'' $c_1\cdots c_8$ and the five-cocycle $\Omega_{i_1\cdots i_5}c^{i_1}\cdots c^{i_5}$, $*$ images of the first two, respectively.

(iv) $\mathbf{8}_1$ consists of the eight c^k's. This is ''lifted'' by s_2 to give $\mathbf{8}_2\sim\{f_{ij}{}^kc^ic^j\}$ and by s_4, giving $\mathbf{8}_4^l\sim\{\Omega_{i_1i_2i_3i_4}{}^kc^{i_1}c^{i_2}c^{i_3}c^{i_4}\}$. $\mathbf{8}_3$ is the image of $\mathbf{8}_1$ under $\overline{s_2}s_4$, i.e., $\mathbf{8}_3 \sim\{f_{i_1ab}\Omega_{i_2i_3}{}^{abk}c^{i_1}c^{i_2}c^{i_3}\}$. The $q\to r-q$ symmetry accounts for the rest of the **8**'s. Notice that $\mathbf{8}_2$, $\mathbf{8}_3$ cannot be lifted by s_4 since they are W-harmonic.

V. CONCLUDING REMARKS

We have introduced and studied in this paper the supersymmetry algebra generated by the higher-order BRST operators. The central term in the algebra is given, in the standard (lowest-order) case, by the (quadratic) Casimir. As shown explicitly by the expression of W_4 for the algebra $\mathcal{G}=su(3)$, the higher-order Laplacians may involve the ghost number operator, which, unlike the Casimir–Racah operators, lies outside the enveloping algebra $\mathcal{U}(\mathcal{G})$. Thus, the fact that $\Delta\in\mathcal{U}(\mathcal{G})$ in the standard case is rather exceptional.

We wish to conclude with a purely mathematical remark. Using the correspondence $c_i\leftrightarrow$LI forms on the group manifold, the standard BRST operator s_2 may be identified with the exterior derivative d acting on forms. The basic properties of d, $d:\wedge^q\to\wedge^{q+1}$, $d^2=0$ (and of the codifferential δ) may be extended by introducing generalized operators $\tilde{d}$ in two different ways. One is by replacing the exterior differential by a higher-order nilpotent endomorphism $\tilde{d}'$ satisfying $(\tilde{d}')^k=0$, to study the associated generalized homology, etc.[47,48] This approach is reminiscent of the one used to generalize ordinary supersymmetry to fractional supersymmetry (for a review with earlier references see Ref. 49). The second one replaces d by a pth-order differential, $\tilde{d}$, p odd, satisfying $\tilde{d}_p:\wedge^q\to\wedge^{q+p}$, $\tilde{d}_p^2=0$, and it is this second point of view that corresponds to the analysis presented in this paper. In fact, the higher BRST operator s_{2m-3} may be considered as an explicit construction of this differential for $p=(2m-3)$, which acts *on LI* forms on the group manifold by translating (3.8) using the above correspondence. $\tilde{d}_p$ is an odd operator satisfying

$$\tilde{d}_p(\alpha\wedge\beta)=(\tilde{d}_p\alpha)\wedge\beta+(-1)^n\alpha\wedge(\tilde{d}_p\beta), \tag{5.1}$$

where n is the order of the LI form α. We recall that, using the (standard) product between manifolds and forms (given by $\langle\mathcal{M},\alpha\rangle=\int_{\mathcal{M}}\alpha$) one can define the adjoint ∂ of the exterior derivative d. Acting on manifolds, ∂ reduces their dimension by one, is nilpotent, and admits the interpretation as a boundary operator. Using an analogous procedure, one might think of defining the adjoint $\tilde{\partial}_p$ of $\tilde{d}_p$ as an operator. Acting on manifolds, it would reduce their dimension by p, being also nilpotent, and the question would arise whether it, too, admits a simple topological interpretation. One might also ask further, whether an analog of Stokes' theorem could be formulated along these lines or whether the spectrum of the higher-order Laplacians studied here provides topological information about the underlying manifold. We do not know whether these mathematical constructions involving $\tilde{d}_p$ can be carried through, in general.

To conclude we would like to stress that the cohomological properties used in this paper are also relevant in other related fields, although it may not be directly apparent. They determine and classify, for instance, the local conserved charges, in principal, chiral models (see Refs. 50 and references therein), and are also important in W algebras (see, for instance, Refs. 51–54), where BRST-type techniques, and hence Lie algebra cohomology, are relevant.

[35] The algebra (2.7) can be represented by a Clifford algebra (see, e.g., Ref. 14). Namely, if we define $c_i = \frac{1}{2}(\gamma_i$

$-i\gamma_{i+r})$, $\pi_i=\frac{1}{2}(\gamma_i+i\gamma_{i+r})$, $i=1,...,r$, where the γ's are the generators of a $2r$-dimensional Clifford algebra, then c_i and π_i verify the relations (2.7).

[36] Using the c's to write ψ [Eq. (1.5)], rather than the ω's of (2.12), one might introduce a Berezin[37] integral measure to define $\langle\psi',\psi\rangle$ above as $\int dc^1\cdots dc^r\psi'^\dagger\psi$[14] for states ψ' and ψ of ghost numbers q and $r-q$, respectively. However, this leads to a product that is not positive definite[14] and, moreover, does not have the natural geometrical interpretation above.

[37] F. A. Berezin, ''Differential forms on supermanifolds,'' Sov. J. Nucl. Phys. **30**, 605–609 (1979); *Introduction to Superanalysis* (Reidel, Dordrecht, 1987).

[38] Taking advantage of the Cartan formalism by means of the equivalences $s_2\sim d$, $\overline{s_2}\sim(-1/2)L_j i_j$ (where i_j indicates the inner product) and $X_j\sim L_j$, we may rapidly find $W_2\sim(-1/2)[dL_j i_j+L_j i_j d]=(-1/2)L_j[d i_j+i_j d]=(-1/2)L_j L_j$.

[39] The CE analog to the BRST q-cochains, the LI q-forms on G, automatically satisfy $L_{X^R}\psi=0$, since the RI vector fields X^R on G generate the left transformations. The invariance under the right transformations ($L_X\psi=0$, where X is a LI vector field, or $X\psi=0$ in the BRST formulation) is an additional condition. Thus, invariance above really means bi-invariance (under the left and right group translations) in the CE formulation of Lie algebra cohomology.

We make use of the properties of product integrals to obtain a surface product integral representation for the Wilson loop operator. The result can be interpreted as the non-Abelian version of Stokes' theorem. © *1999 American Institute of Physics.*[S0022-2488(99)04610-1]

I. INTRODUCTION

Our main purpose of this work is to make use of product integrals to give two unambiguous proofs of the non-Abelian version of Stokes' theorem. The product integral formalism has been used extensively in the theory of differential equations and of matrix-valued functions.[1] In the latter context, it has a built-in feature for keeping track of the *order* of the matrix-valued functions involved. As a result, product integrals are ideally suited for the description of *path ordered* quantities such as holonomies. Moreover, since the theory is well developed independently of particular applications, we can be confident that the properties of such path ordered quantities that we establish using this method are correct and unambiguous.

Among the important advantages of the product integral representation of the path-dependent exponential of a matrix-valued function is that in such a framework the Banach space structure of the corresponding matrix-valued functions is already built into the formalism. In particular, for a closed path enclosing an orientable two-surface, this will permit a surface representation of such operators. Based on the central role of Stokes' theorem in physics and in mathematics, it is not surprising that the non-Abelian version of this theorem has attracted a good deal of attention in the physics literature.[2–12] The central features of the earlier attempts[2–8] have been reviewed and improved upon in a recent work.[9] Other recent works on the non-Abelian Stokes theorem[10–12] focus on specific problems such as confinement,[11] zigzag symmetry[12] suggested by Polyakov,[13] etc. With one exception,[9] the authors of these works seem to have been unaware of a 1927 work in the mathematical literature by Schlessinger[14] that bear strongly on the content of this theorem. Schlesinger's work dealt with integrals of matrix-valued functions and their ordering problems. This amounts to establishing the non-Abelian Stokes theorem in two (target space) dimensions. By an appropriate extension and reinterpretation of his results, we show using the product integral approach that this theorem is valid in any target space dimension.

This work is organized as follows: To make this manuscript self-contained, we review in Sec. II the main features of product integration[1] and state without proof a number of theorems that will be used in the proof of the non-Abelian Stokes theorem. In Sec. III, we deal with path ordered exponentials of matrix-valued functions that can be expressed as product integrals and turn to the proof of the non-Abelian Stokes theorem for orientable surfaces. In Sec. IV, we give a variant of this proof. In Sec. V, we explicitly demonstrate the gauge covariance of the results obtained in Secs. III and IV. Finally, Sec. V is devoted to some additional remarks.

II. SOME PROPERTIES OF PRODUCT INTEGRALS

One of the initial motivations for the introduction of product integrals was[1] to solve differential equations of the type

$$Y'(s)=A(s)Y(s). \tag{1}$$

In this expression, $Y(s)$ is an n-dimensional vector, $A(s)$ is a matrix-valued function, and a prime indicates differentiation. So, for two real numbers a and b, the problem is to obtain $Y(b)$ given $Y(a)$. To deal with this problem, we make a partition $P=\{s_0,s_1,\ldots,s_n\}$ of the interval $[a,b]$. Let $\Delta s_k=s_k-s_{k-1}$ for $k=1,\ldots,n$, and set $a=s_0$, $b=s_n$. Then, solving the differential equation in each subinterval, we can write approximately[1]

$$Y(b)\approx\prod_{k=1}^{n} e^{A(s_k)\Delta s_k}Y(a)\equiv\Pi_P(A)Y(a). \tag{2}$$

Since $A(s)$ is matrix valued, the order in this product is important. Let $\mu(P)$ be the length of the longest Δs_k in the partition P. Then, as $\mu(P)\to 0$, we get

$$Y(b)=\lim_{\mu(P)\to 0}\Pi_P(A)Y(a). \tag{3}$$

The limit is clearly valid for all $Y(a)$.

The limit of the ordered product on the right-hand side of Eq. (3) is the fundamental expression in the definition of a product integral.[1] It is formally defined, in an obvious notation, as

$$\prod_{a}^{x} e^{A(s)ds}=\lim_{\mu(P)\to 0}\Pi_P(A)\equiv F(x,a). \tag{4}$$

It is easy to see that $F(x,a)$ satisfies the differential equation

$$\frac{d}{dx}F(x,a)=A(x)F(x,a), \tag{5}$$

with $F(a,a)=1$. The corresponding integral equation is

$$F(x,a)=1+\int_a^x ds\, A(s)F(s,a). \tag{6}$$

Clearly, $F(a,a)=1$, and $F(x,a)$ is unique.

Consider now some of the properties of the product integral matrices. For each $x\in[a,b]$ the product integral is nonsingular, and its determinant is given by

$$\det\left(\prod_{a}^{x} e^{A(s)ds}\right)=e^{\int_a^x \mathrm{tr}\,A(s)ds}. \tag{7}$$

In analogy with the additive property of ordinary integrals, product integrals have the multiplicative property, or the composition rule,

$$\prod_{z}^{x} e^{A(s)ds}=\prod_{y}^{x} e^{A(s)ds}\prod_{z}^{y} e^{A(s)ds}, \tag{8}$$

where $x,y,z\epsilon[a,b]$ and $z\leqslant y\leqslant x$. The result is independent of the choice of y and any further decomposition of the products on the right-hand side.

Derivatives with respect to the end points are given by

$$\frac{\partial}{\partial x}\prod_{y}^{x} e^{A(s)ds}=A(x)\prod_{y}^{x} e^{A(s)ds}, \tag{9}$$

and

$$\frac{\partial}{\partial y}\prod_{y}^{x} e^{A(s)ds}=-\prod_{y}^{x} e^{A(s)ds}A(y). \tag{10}$$

One of the fundamental features associated with a connection is the notion of parallel transport. To see how it can be formulated in product integral formalism, consider a map $P:[a,b]\rightarrow \mathbf{C}_{n\times n}$, which is continuously differentiable. Then $P(x)$ is an indefinite product integral if for a given $A(s)$,

$$P(x)=\prod_{a}^{x} e^{A(s)ds}P(a). \tag{11}$$

Next, we define an operation known as L operation that is like the logarithmic derivative operation on non-singular functions. Let

$$LP(x)=P'(x)P^{-1}(x), \tag{12}$$

where the prime indicates differentiation. Then, from Eq. (11) it follows that

$$(LP)(x)=A(x).$$

One of the byproducts of this operation is that

$$L(PQ)(x)=LP(x)+P(x)(LQ(x))P^{-1}(x). \tag{13}$$

The L operation is a crucial ingredient in establishing the analog of the fundamental theorem of calculus for product integrals. With the map P as defined above, this theorem states that

$$\prod_{a}^{x} e^{(LP)(s)ds}=P(x)P^{-1}(a). \tag{14}$$

From the results given above, it follows that P is a solution of the initial value problem,

$$P'(x)=(LP(x))P(x). \tag{15}$$

With the unique solution given by Eq. (11), this establishes the fundamental theorem of product integration. Just as in ordinary integration, the knowledge of simple product integrals can be used to evaluate more complicated product integrals. For example, one can prove the *sum rule* for product integrals:

$$\prod_{a}^{x} e^{[A(s)+B(s)]ds}=P(x)\prod_{a}^{x} e^{P^{-1}(s)B(s)P(s)ds}. \tag{16}$$

Finally, we state two other important properties of product integrals that will be used in the sequel. One is the *similarity theorem,* which states that

$$P(x)\prod_{a}^{x} e^{B(s)ds}P^{-1}(a)=\prod_{a}^{x} e^{[LP(s)+P(s)B(s)P^{-1}(s)]ds}. \tag{17}$$

The other property is differentiation with respect to a parameter. Let

$$P(x,y;\lambda)=\prod_{y}^{x} e^{A(s;\lambda)ds}, \tag{18}$$

where λ is a parameter. Then the differentiation rule with respect to this parameter is given by

$$\frac{\partial}{\partial\lambda}P(x,y;\lambda)=\int_{y}^{x} ds\, P(x,s;\lambda)\left(\frac{\partial}{\partial\lambda}A(s;\lambda)\right)P(s,y;\lambda). \tag{19}$$

III. THE NON-ABELIAN STOKES THEOREM

To provide the background for using the product integral formalism of Sec. II to prove the non-Abelian Stokes theorem, we begin with a statement of the problem as it arises in a physical context. Let M be an n-dimensional manifold representing the space–time (target space). Let A be a (connection) one-form on M. When M is a differentiable manifold, we can choose a local basis dx^{μ}, $\mu=1,...,n$, and express A in terms of its components:

$$A(x)=A_{\mu}(x)dx^{\mu}.$$

We take A to have values in the Lie algebra, or a representation thereof, of a Lie group. Then, with T_k, $k=1,...,m$, representing the generators of the Lie group, the components of A can be written as

$$A_{\mu}(x)=A_{\mu}^{k}(x)T_k.$$

With these preliminaries, we can express the path ordered phase factor of the non-Abelian gauge theories[15–18] in the form

$$W_{ab}(C)=\mathcal{P}e^{\int_e^b A},$$

where $\mathcal{P}$ indicates path ordering, and C is a path in M. When the path C is closed, the corresponding holonomy operator becomes

$$W(C)=\mathcal{P}e^{\oint A}. \tag{20}$$

The path C in M can be described in terms of an intrinsic parameter σ, so that for points x^{μ} of M, which lie on the path C, we have $x^{\mu}=x^{\mu}(\sigma)$. One can then write

$$A_{\mu}(x(\sigma))dx^{\mu}=A(\sigma)d\sigma,$$

where

$$A(\sigma)\equiv A^{\mu}(x(\sigma))\frac{dx^{\mu}(\sigma)}{d\sigma}.$$

It is the quantity $A(\sigma)$, and the variations thereof, which we will identify with the matrix-valued functions of the product integral formalism.

Let us next consider the loop operator. For simplicity, we assume that M has trivial first homology group with integer coefficients, i.e., $H_1(M,\mathbf{Z})=0$. This ensures that the loop may be taken to be the boundary of a two-dimensional surface Σ in M. More explicitly, we take the two-surface to be an orientable submanifold of M. It will be convenient to describe the properties of the two-surface in terms of its intrinsic parameters σ and τ or σ^a, $a=0,1$. So, for the points of the manifold M, which lie on Σ, we have $x=x(\sigma,\tau)$. The components of the one-form A on Σ can be obtained by means of the vielbeins (by the standard pullback construction):

$$v_a^{\mu}=\partial_a x^{\mu}(\sigma).$$

Thus, we get

$$A_a = v_a^\mu A_\mu .$$

The curvature two-form F of the connection A is given by

$$F = dA + A\wedge A = \tfrac{1}{2} F_{\mu\nu}\, dx^\mu \wedge dx^\nu .$$

The components of F on Σ can again be obtained by means of the vielbeins:

$$F_{ab} = v_a^\mu v_b^\nu F_{\mu\nu} .$$

We want to express the loop operator in terms of the product integral definition in a specific way. To achieve this, we begin with the definition of the path ordered phase factor in terms of a product integral. Consider the continuous map $A:[s_0,s_1]\rightarrow \mathbf{C}_{n\times n}$, where $[s_0,s_1]$ is a real interval. Then, we define the non-Abelian phase factor given above in terms of a product integral as follows:

$$\mathcal{P} e^{\int_{s_0}^{s_1} A(s)ds} \equiv \prod_{s_0}^{s_1} e^{A(s)ds}.$$

In particular, anticipating that we will identify the closed path C over which the Wilson loop is defined with the boundary of a two-surface, it is convenient to work from the beginning with the matrix-valued functions $A(\sigma,\tau)$. This means that our expression for the path ordered phase factor will depend on a parameter. That is, let

$$A:[\sigma_0,\sigma_1]\times[\tau_0,\tau_1]\rightarrow \mathbf{C}_{n\times n}, \tag{21}$$

where $[\sigma_0,\sigma_1]$ and $[\tau_0,\tau_1]$ are real intervals on the two surface Σ and hence in M. Then, we define the path ordered phase factor,

$$P(\sigma,\sigma_0;\tau) = \prod_{\sigma_0}^{\sigma} e^{A_1(\sigma';\tau)d\sigma'} \equiv \mathcal{P} e^{\int_{\sigma_0}^{\sigma} A_1(\sigma';\tau)d\sigma'}. \tag{22}$$

In this expression, $\mathcal{P}$ indicates path ordering with respect to σ as defined by the product integral, while τ is a parameter. To be able to describe such an operator for a closed path, we similarly define the path-dependent operator,

$$Q(\sigma;\tau,\tau_0) = \prod_{\tau_0}^{\tau} e^{A_0(\sigma;\tau')d\tau'} \equiv \mathcal{P} e^{\int_{\tau_0}^{\tau} A_0(\sigma;\tau')d\tau'}. \tag{23}$$

In this case, the path ordering is with respect to τ, and σ is a parameter.

To prove the non-Abelian version of the Stokes theorem, we want to make use of product integration techniques to express the holonomy loop operator as an integral over a two-dimensional surface bounded by the corresponding loop. In terms of the intrinsic coordinates of such a surface, we can write this loop operator in the form

$$W(C) = \mathcal{P} e^{\oint A_\alpha\, d\sigma^\alpha}, \tag{24}$$

where, as mentioned above,

$$\sigma^a = (\tau,\sigma); \quad a = (0,1). \tag{25}$$

The expression for the loop operator depends only on the homotopy class of paths in M to which the closed path C belongs. We can, therefore, parametrize the path C in any convenient manner consistent with its homotopy class. In particular, we can break up the path into piecewise continuous segments along which either σ or τ remains constant. The composition rule for product integrals given by Eq. (8) ensures that this breakup of the closed loop into a number of segments does not depend on the intermediate points on the closed path, which are used for this purpose. So, we write the closed loop operator as

$$W = W_4 W_3 W_2 W_1 . \tag{26}$$

In this expression, W_k, $k=1,...,4$, are Wilson lines such that $\tau=$const along W_1 and W_3, and $\sigma=$const along W_2 and W_4. We emphasize that the expressions $\sigma=$const and $\tau=$const represent arbitrary curves.

To see the advantage of parametrizing the closed path in this manner, consider the exponent of Eq. (24):

$$A_a \, d\sigma^a = A_0 \, d\tau + A_1 \, d\sigma. \tag{27}$$

Along each segment, one or the other of the terms on the right-hand side vanishes. For example, along the segment $[\sigma_0, \sigma]$, we have $\tau' = \tau_0 =$const. Recalling Eqs. (22) and (23), we get for the segments W_1 and W_2, respectively,

$$W_1 = \prod_{\sigma_0}^{\sigma} e^{A_1(\sigma';\tau_0)d\sigma'} \equiv \mathcal{P} e^{\int_{\sigma_0}^{\sigma} A_1(\sigma';\tau_0)d\sigma'} = P(\sigma,\sigma_0;\tau_0), \tag{28}$$

and

$$W_2 = \prod_{\tau_0}^{\tau} e^{A_0(\sigma;\tau')d\tau'} \equiv \mathcal{P} e^{\int_{\tau_0}^{\tau} A_0(\sigma;\tau')d\tau'} = Q(\sigma;\tau,\tau_0). \tag{29}$$

When the two-surface Σ requires more than one coordinate patch to cover it, the connections in different coordinate patches must be related to each other in their overlap region by transition functions.[16] Then, the decomposition given in Eq. (26) must be suitably augmented to take this complication into account. The product integral representation of the path ordered phase factor and the composition rule for product integrals given by Eq. (8) will still make it possible to describe the corresponding loop operator as a composite product integral. For definiteness, we will confine ourselves to the representation given by Eq. (26).

It is convenient for later purposes to define two composite Wilson line operators U and T according to

$$U(\sigma,\tau) = Q(\sigma;\tau,\tau_0) P(\sigma,\sigma_0;\tau), \tag{30}$$

$$T(\sigma;\tau) = P(\sigma,\sigma_0;\tau) Q(\sigma_0;\tau,\tau_0). \tag{31}$$

Using the first of these, we have

$$W_2 W_1 = U(\sigma,\tau). \tag{32}$$

Similarly, we have, for W_3 and W_4,

$$W_3 = P^{-1}(\sigma,\sigma_0;\tau), \tag{33}$$

and

$$W_4 = Q^{-1}(\sigma_0;\tau,\tau_0). \tag{34}$$

From Eq. (31), it follows that

$$W_4 W_3 = T^{-1}(\sigma,\tau). \tag{35}$$

Appealing again to Eq. (8) for the composition of product integrals, it is clear that this expression for the Wilson loop operator is independent of the choice of the point (σ,τ). In terms of the quantities T and U, the closed loop operator will take the compact form

$$W=T^{-1}(\sigma;\tau)U(\sigma;\tau). \tag{36}$$

As a first step in the proof of the non-Abelian Stokes theorem, we obtain the action of the L-derivative operator on W:

$$L_\tau W=L_\tau[T^{-1}(\sigma,\tau)Q(\sigma;\tau,\tau_0)P(\sigma,\sigma_0;\tau_0)]. \tag{37}$$

Using the definition of the L operation given by Eq. (12), noting that $P(\sigma,\sigma_0;\tau_0)$ is independent of τ, and carrying out the L operations on the right-hand side (rhs), we get

$$\begin{aligned}L_\tau W=L_\tau T^{-1}(\sigma,\tau)+T^{-1}(\sigma,\tau)[L_\tau Q(\sigma;\tau,\tau_0)\\ +Q(\sigma;\tau,\tau_0)(L_\tau P(\sigma,\sigma_0;\tau_0))Q^{-1}(\sigma;\tau,\tau_0)]T(\sigma,\tau).\end{aligned} \tag{38}$$

Simplifying this expression by means of Eqs. (12) and (13), we end up with

$$L_\tau W=T^{-1}(\sigma,\tau)[A_0(\sigma,\tau)-L_\tau T(\sigma,\tau)]T(\sigma,\tau). \tag{39}$$

Next, we prove the analog of Eq. (14), which applies to an elementary product integral, for the composite loop operator defined by Eqs. (26) and (36).

Theorem 1: *The loop operator given by Eq. (36) can be expressed in the form*

$$W=\prod_{\tau_0}^{\tau} e^{T^{-1}(\sigma,\tau')[A_0(\sigma,\tau')-L_\tau T(\sigma,\tau')]T(\sigma,\tau')d\tau'}. \tag{40}$$

To prove this theorem, first we note from the definition of the L operation that the right-hand side (rhs) of this equation can be written as

$$\text{rhs}=\prod_{\tau_0}^{\tau} e^{[T^{-1}(\sigma;\tau')A_0(\sigma;\tau')T(\sigma;\tau')-T^{-1}(\sigma;\tau')(\partial/\partial\tau')T(\sigma;\tau')]d\tau'}. \tag{41}$$

Noting that $-T^{-1}\,\partial_\tau T=L_\tau T$, we can use the similarity theorem given by Eq. (17) to obtain

$$\text{rhs}=T^{-1}(\sigma;\tau)\prod_{\tau_0}^{\tau} e^{A_0(\sigma;\tau')d\tau'}T(\sigma;\tau_0). \tag{42}$$

Moreover, making use of the defining Eq. (23), we get

$$\text{rhs}=T^{-1}(\sigma;\tau)Q(\sigma;\tau,\tau_0)P(\sigma,\sigma_0;\tau_0)Q(\sigma;\tau_0,\tau_0)=T^{-1}(\sigma;\tau)U(\sigma;\tau). \tag{43}$$

The last line is clearly the expression for W given by Eq. (36).

Finally, we want to express the quantity W in yet another form, which we state as the following.

Theorem 2: *The loop operator defined in Eq. (36) can be expressed as a surface integral of the field strength:*

$$W=\prod_{\tau_0}^{\tau} e^{\int_{\sigma_0}^{\sigma}T^{-1}(\sigma';\tau')F_{01}(\sigma';\tau')T(\sigma';\tau')d\sigma'\,d\tau'}, \tag{44}$$

where F_{01} is the 0–1 component of the non-Abelian field strength.

To prove this theorem, we note that

$$\frac{\partial}{\partial\sigma}[T^{-1}(\sigma,\tau)A_0(\sigma,\tau)T(\sigma,\tau)]=T^{-1}(\sigma,\tau)[\partial_\sigma A_0(\sigma,\tau)+[A_0(\sigma,\tau),A_1(\sigma,\tau)]]T(\sigma,\tau). \tag{45}$$

Moreover,

$$\frac{\partial}{\partial\sigma}\{T^{-1}(\sigma,\tau)(L_\tau T(\sigma,\tau))T(\sigma,\tau)\}=T^{-1}(\sigma,\tau)\partial_\tau A_1(\sigma,\tau)T(\sigma,\tau). \tag{46}$$

It then follows that

$$\begin{aligned}\frac{\partial}{\partial\sigma}(\{T^{-1}(\sigma,\tau)[A_0(\sigma,\tau)-L_\tau T(\sigma,\tau)]\}T(\sigma,\tau))\\ &=T^{-1}(\sigma,\tau)\left[\frac{\partial}{\partial\sigma}A_0(\sigma,\tau)-\frac{\partial}{\partial\tau}A_1(\sigma,\tau)+[A_0(\sigma,\tau),A_1(\sigma,\tau)]\right]T(\sigma,\tau)\\ &=T^{-1}(\sigma,\tau)F_{01}(\sigma,\tau)T(\sigma,\tau).\end{aligned} \tag{47}$$

The last step follows from the definition of the field strength in terms of the connection given above:

$$F_{01}=\frac{\partial}{\partial\sigma}A_0(\sigma,\tau)-\frac{\partial}{\partial\tau}A_1(\sigma,\tau)+[A_0(\sigma,\tau),A_1(\sigma,\tau)]. \tag{48}$$

Integrating Eq. (47) with respect to σ, we get

$$T^{-1}(\sigma,\tau)[A_0(\sigma,\tau)-L_\tau T(\sigma,\tau)]T(\sigma,\tau)=\int_{\sigma_0}^{\sigma}T^{-1}(\sigma';\tau')F_{01}(\sigma';\tau')T(\sigma';\tau')d\sigma'\,d\tau'. \tag{49}$$

We thus arrive at the surface integral representation of the loop operator:[19]

$$W=\prod_{\tau_0}^{\tau}e^{\int_{\sigma_0}^{\sigma}T^{-1}(\sigma';\tau')F_{01}(\sigma';\tau')T(\sigma';\tau')d\sigma'\,d\tau'}. \tag{50}$$

We note that in this expression the ordering of the operators is defined with respect to τ, whereas σ is a parameter. Recalling the antisymmetry of the components of the field strength, we can rewrite this expression in terms of path ordered exponentials familiar from the physics literature:

$$W=\mathcal{P}_\tau e^{(1/2)\int_\Sigma d\sigma^{ab}\,T^{-1}(\sigma;\tau)F_{ab}(\sigma;\tau)T(\sigma;\tau)}, \tag{51}$$

where $d\sigma^{ab}$ is the area element of the two-surface. Despite appearances, it must be remembered that σ and τ play very different roles in this expression.

IV. A SECOND PROOF

To illustrate the power and the flexibility of the product integral formalism, we give here a variant of the previous proof for the non-Abelian Stokes theorem. This time the proof makes essential use of the nontrivial relation (19) for product integrals. We start with the form of W given in Eq. (36) and take its derivatives with respect to τ:

$$\frac{\partial W}{\partial \tau} = \partial_\tau Q^{-1}(\sigma_0;\tau,\tau_0)P^{-1}(\sigma,\sigma_0;\tau)Q(\sigma;\tau,\tau_0)P(\sigma,\sigma_0;\tau_0)$$
$$+Q^{-1}(\sigma_0;\tau,\tau_0)\partial_\tau P^{-1}(\sigma,\sigma_0;\tau)Q(\sigma;\tau,\tau_0)P(\sigma,\sigma_0;\tau_0)$$
$$+Q^{-1}(\sigma_0;\tau,\tau_0)P^{-1}(\sigma,\sigma_0;\tau)\partial_\tau Q(\sigma;\tau,\tau_0)P(\sigma,\sigma_0;\tau_0). \tag{52}$$

Here, we have made use of the fact that $P(\sigma,\sigma_0;\tau_0)$ is independent of τ. Applying Eq. (12) to W and using Eq. (31), we get

$$L_\tau W = \frac{\partial W}{\partial \tau} W^{-1} = T^{-1}(\sigma;\tau)[A_0(\sigma;\tau) - P(\sigma,\sigma_0;\tau)A_0(\sigma_0;\tau)P^{-1}(\sigma,\sigma_0;\tau)$$
$$-\partial_\tau P(\sigma,\sigma_0;\tau)P^{-1}(\sigma,\sigma_0;\tau)]T(\sigma;\tau). \tag{53}$$

Now we can use Eq. (19) to evaluate the derivative of the product integral with respect to the parameter τ:

$$\partial_\tau P(\sigma,\sigma_0;\tau) = \int_{\sigma_0}^{\sigma} d\sigma'\, P(\sigma,\sigma';\tau)\partial_\tau A_1(\sigma';\tau)P(\sigma',\sigma_0;\tau). \tag{54}$$

Then, after some simple manipulations using the defining equations for the various terms in Eq. (53), we get, setting $P(\sigma,\sigma_0;\tau) = P(\tau)$,

$$T^{-1}(\sigma;\tau)\partial_\tau P(\tau)P^{-1}(\tau)T(\sigma;\tau) = \int_{\sigma_0}^{\sigma} d\sigma'\, T^{-1}(\sigma';\tau)\partial_\tau A_1(\sigma';\tau)T(\sigma';\tau). \tag{55}$$

Using Eq. (9) and the fact that $P(\sigma_0,\sigma_0;\tau) = 1$, we can write the rest of Eq. (53) as an integral too:

$$T^{-1}(\sigma;\tau)[A_0(\sigma;\tau) - P(\sigma,\sigma_0;\tau)A_0(\sigma_0;\tau)P^{-1}(\sigma,\sigma_0;\tau)]T(\sigma;\tau)$$
$$= Q^{-1}(\sigma_0;\tau,\tau_0)[P^{-1}(\sigma,\sigma_0;\tau)A_0(\sigma;\tau)P(\sigma,\sigma_0;\tau) - A_0(\sigma_0)]Q(\sigma_0;\tau,\tau_0)$$
$$= \int_{\sigma_0}^{\sigma} d\sigma'\, P^{-1}(\sigma',\sigma_0;\tau)(\partial_\tau A_0(\sigma',\tau) + [A_0(\sigma',\tau), A1(\sigma',\tau)])P(\sigma',\sigma_0;\tau). \tag{56}$$

Combining Eqs. (53), (55), and (56), we obtain

$$L_\tau W = \frac{\partial W}{\partial \tau} W^{-1} = \int_{\sigma_0}^{\sigma} d\sigma'\, T^{-1}(\sigma',\tau)F_{01}(\sigma',\tau)T(\sigma',\tau). \tag{57}$$

Finally, recalling Eq. (14), we are immediately led to Eq. (50), which was obtained by the previous method of proof.

There are two reasons for the relative simplicity of this proof over the one that was given in the previous section. One is due to the use of differentiation with respect to a parameter according to Eq. (19). The other is due to the use of Eq. (14) for the composite operator W. In the first proof, the use of this theorem for W was not assumed. Its justification for using it in the second proof lies in the composition law for product integrals given by Eq. (8).

V. GAUGE COVARIANCE OF THE RESULT

As a consistency check, we must show that the surface representation given by Eq. (50) is gauge covariant. To this end, it will be recalled that under a gauge transformation, the components of the connection, i.e., the gauge potentials, transform according to[20]

$$A_\mu(x)\rightarrow g(x)A_\mu(x)g^{-1}(x)-g(x)\partial_\mu g(x)^{-1}. \tag{58}$$

The components of the field strength (curvature) transform covariantly:

$$F_{\mu\nu}(x)\rightarrow g(x)F_{\mu\nu}(x)g^{-1}(x). \tag{59}$$

From these, it follows that[20]

$$\mathcal{P}e^{\int_a^b A_\mu(x)dx^\mu}\rightarrow g(b)(\mathcal{P}e^{\int_a^b A_\mu(x)dx^\mu})g^{-1}(a). \tag{60}$$

Equivalently, from its definition (22) in terms of product integrals, it is easy to show that the gauge transform of the quantity $P(\sigma,\sigma_0;\tau)$ has the form

$$g(\sigma;\tau)g^{-1}(\sigma_0;\tau)\prod_{\sigma_0}^{\sigma} e^{g(\sigma_0;\tau)A_1(\sigma';\tau)g^{-1}(\sigma_0;\tau)}. \tag{61}$$

To show the gauge covariance of the surface representation, we need to know how the operator $T(\sigma,\tau)$ transforms under gauge transformations. To this end, we note that the Wilson line $Q(\sigma;\tau,\tau_0)$ given by Eq. (23) transforms as

$$Q(\sigma;\tau,\tau_0)=\prod_{\tau_0}^{\tau} e^{A_0(\sigma;\tau')d\tau'}\rightarrow g(\sigma;\tau)Q(\sigma;\tau,\tau_0)g^{-1}(\sigma;\tau_0). \tag{62}$$

Then, the gauge transform of the composite operator $T(\sigma,\tau)$ given by Eq. (31) follows immediately:

$$T(\sigma;\tau)=P(\sigma,\sigma_0;\tau)Q(\sigma_0;\tau,\tau_0)\rightarrow g(\sigma;\tau)T(\sigma;\tau)g^{-1}(\sigma_0;\tau_0). \tag{63}$$

From the above results, it is straightforward to show that the surface integral representation of Wilson loop transforms as

$$W\rightarrow\prod_{\tau_0}^{\tau} e^{g(\sigma_0;\tau_0)(\int_{\sigma_0}^{\sigma}T^{-1}(\sigma';\tau')F_{01}(\sigma';\tau')T(\sigma';\tau')dt')g^{-1}(\sigma_0;\tau_0)}. \tag{64}$$

It follows from the composition rule (8) that the constant factors in the exponent factorize, so that under gauge transformations the surface representation of transforms covariantly, i.e.,

$$W\rightarrow g(\sigma_0;\tau_0)\prod_{\tau_0}^{\tau} e^{\int_{\sigma_0}^{\sigma}T^{-1}(\sigma';\tau')F_{01}(\sigma';\tau')T(\sigma';\tau')dt'}g^{-1}(\sigma_0;\tau_0). \tag{65}$$

We view this result as a nontrivial confirmation of our proofs.

VI. CONCLUDING REMARKS

We have provided two proofs of the non-Abelian Stokes theorem using the product integral method. An immediate question that comes to mind is whether there is a supersymmetric generalization of this theorem. Given the important developments in supersymmetric gauge theories in recent years, this question is not merely of academic interest. To explore this possibility using the product integral method, it is necessary to generalize this method to encompass Grassmann-valued operators. It turns out that such a generalization is indeed possible.[21] Further developments of this subject will be reported in a forthcoming work.

Functional determinants from Wronski Green functions

H. Kleinert[a] and A. Chervyakov[b]
Freie Universität Berlin, Institut für Theoretische Physik, Arnimallee14, D-14195 Berlin, Germany

(Received 24 March 1998; accepted for publication 17 June 1998)

A general technique is developed for calculating functional determinants of second-order differential operators with Dirichlet, periodic, and antiperiodic boundary conditions, without the knowledge of spectral properties. As an example, we give explicit formulas for a harmonic oscillator with an arbitrary time-dependent frequency, where our result is a generalization of the Gel'fand–Yaglom famous formula for Dirichlet boundary conditions. Our technique is based on the Wronski's construction of Green functions, which does not require spectral knowledge. Our final formula expresses the ratios of functional determinants in terms of an ordinary 2×2 determinant of a constant matrix constructed from two linearly independent solutions of the homogeneous differential equations associated with second-order differential operators. For ratios of determinants encountered in semiclassical fluctuations around a classical solution, the result can further be expressed in terms of the classical solution. Special properties of operators with a zero mode are exhibited. © *1999 American Institute of Physics.* [S0022-2488(99)02609-2]

I. INTRODUCTION

Gaussian path integrals appear in many physical problems, for instance, in all semiclassical approximations of fluctuating systems. They typically require the evaluation of a functional determinant of a second-order differential operator.[1] For Dirichlet boundary conditions, a first general solution of this problem was given by Gel'fand and Yaglom,[2] based on the lattice approximation to path integrals in the continuum limit. Their result was expressed in terms of a simple differential equation for the functional determinant. Unfortunately, the Gel'fand–Yaglom method becomes rather complicated for periodic and antiperiodic boundary condition relevant in quantum statistics (see Sec. 2.12 in Ref. 1). In recent work,[3,4] functional determinants of second-order differential operators were calculated via a reduction to the simpler first-order formalism. Divergences were removed by zeta-function regularization,[5] which has the disadvantage of a physical quantity depending unnecessarily on the analytic properties of generalized zeta functions. Moreover, the first-order formalism makes the treatment of zero modes of the second-order differential operator quite cumbersome.[6]

In this paper we present a systematic method for finding *ratio* functional determinants of second-order differential operators with Dirichlet, periodic, and antiperiodic boundary conditions. By focusing our attention upon ratios instead of the determinants themselves, we avoid the need of regularization. The main virtue of our method is that it takes advantage of Wronski's elegant construction method for Green functions. This permits us to reduce the functional determinant of a second-order differential operator to an ordinary determinant of a constant 2×2 matrix formed from solutions of the homogeneous differential equation associated with the differential operator.

For semiclassical fluctuations around a classical solution, our final result can be expressed entirely in terms of a classical trajectory. Furthermore, for fluctuation operators with a zero mode, a case encountered in many semiclassical calculations, we find a universal expression for the ratio of determinants without the zero mode.

II. BASIC RELATIONS

The typical fluctuation action arising in semiclassical approximations has a quadratic Lagrangian of the form

$$L_{\rm fl}=\frac{M}{2}[\dot{x}^2-\Omega^2(t)x^2]. \tag{1}$$

Physically, this Lagrangian describes a harmonic oscillator with a time-dependent frequency $\Omega(t)$. The path integral for such a system was studied in several papers.[7,8] For such an oscillator, both the quantum mechanical propagator and the thermal partition function contain a phase factor $\exp[i\mathcal{A}_{\rm cl}(x)]$ and are multiplied by a pre-exponential fluctuation factor proportional to

$$F(t_b,t_a)\sim\left(\frac{\operatorname{Det}K_1}{\operatorname{Det}\tilde{K}}\right)^{-1/2}, \tag{2}$$

where $K_1=-\partial_t^2-\Omega^2(t)\equiv K_0-\Omega^2(t)$ is the kernel of the second variation of action $\mathcal{A}[x])$ along the classical path $x_{\rm cl}(t)$. The linear operator K_1 acts on the space of twice differentiable functions $y(t)=\delta x(t)$ on an interval $t\in[t_a,t_b]$ with appropriate boundary conditions. These are Dirichlet boundary conditions $y(t_a)=y(t_b)=0$ in the quantum-mechanical case, and periodic (antiperiodic) $y(t_b)=\pm y(t_a),\dot{y}(t_b)=\pm\dot{y}(t_a)$ in the quantum statistical case. In these two cases the operator $\tilde{K}$ may be chosen as K_0 or $K_0-\omega_0^2$, respectively, where ω_0 is a time-independent oscillator frequency. The ratio of determinants (2) arises naturally from the normalization of the path integral and is well defined.[1] Furthermore, this ratio has the Fredholm property

$$\frac{\operatorname{Det}K_1}{\operatorname{Det}\tilde{K}}=\operatorname{Det}\tilde{K}^{-1}K_1, \tag{3}$$

with a multiplicative anomaly being equal to unity.[9] Since the operator $\tilde{K}^{-1}K_1$ is of the form $I+B$, with B an operator of the trace class, it has a well-defined determinant, even without any regularization.

To calculate $F(t_b,t_a)$, we introduce a one-parameter family of operators K_g depending linearly on the parameter g:$K_g=K_0-g\Omega^2(t)$, $0\leqslant g\leqslant 1$. The above property (3) allows us to make use of the well-known formula $\log\operatorname{Det}\tilde{K}^{-1}K_g=\operatorname{Tr}\log\tilde{K}^{-1}K_g$ to relate the g derivative of the logarithm of the ratio (2) to the trace of the Green function of the operator K_g as follows:

$$\partial_g\log\operatorname{Det}\tilde{K}^{-1}K_g=-\operatorname{Tr}\Omega^2(t)G_g(t,t'), \tag{4}$$

the Green function being defined by

$$G_g(t,t')=[-\partial_t^2-g\Omega^2(t)]^{-1}\delta(t-t'). \tag{5}$$

Another proof of Eq. (4) can be found in Ref. 3. Note that formula (4) holds for the operator K_g by itself rather than the ratio $K^{-1}K_g$, provided we regularize the divergent trace on the right-hand side with the help of a generalized zeta functions $\zeta_{K_g}(s)=\Sigma_i\lambda^{-s}$, where the sum runs over all eigenvalues of the operator K_g. The sum converges for sufficinetly large s and may be defined for smaller s by analytic continuation (see Ref. 5). The zeta function yields the functional determinant itself via the formula $\operatorname{Det}K_g=\exp[-\zeta'_{K_g}(0)]$.

By integrating (4), we obtain for the ratio of functional determinants (3):

$$\operatorname{Det}\tilde{K}^{-1}K_g=C\exp\left\{-\int_0^g dg'\int_{t_a}^{t_b}dt\,\Omega^2(t)G_{g'}(t,t)\right\}, \tag{6}$$

where $C = \mathrm{Det}\,\tilde{K}^{-1}K_0$ is a g-independent constant. This is our basic formula to be supplemented by an appropriate boundary condition to Eq. (5) for the Green function, as we shall now discuss in detail.

III. DIRICHLET BOUNDARY CONDITIONS

A general solution of Eq. (5) may be expressed in terms of advanced or retarded Green functions as follows:

$$G_g^-(t,t') = G_g^+(t',t) = \Theta_{tt'} \cdot f_g(t,t'), \tag{7}$$

where $\Theta_{tt'} = \Theta(t-t')$ is Heaviside's function and $f_g(t,t')$ is a combination,

$$f_g(t,t') = \frac{1}{W_g}[\eta_g(t)\xi_g(t') - \xi_g(t)\eta_g(t')], \tag{8}$$

of two linearly independent solutions $\eta_g(t)$ and $\xi_g(t)$ of the homogeneous equation,

$$[-\partial_t^2 - g\Omega^2(t)]h_g(t) = 0. \tag{9}$$

The constant W_g is the time-independent Wronski determinant $W_g = \eta_g\dot{\xi}_g - \dot{\eta}_g\xi_g$. The solution (7) is not unique since it leaves room for an additional general solution of the homogeneous equation (9) with an arbitrary coefficient. This freedom is removed by appropriate boundary conditions. Consider first the quantum mechanical case, which requires Dirichlet boundary conditions $y(t_b) = y(t_a) = 0$ for the eigenfunctions $y(t)$ of K_1, implying for the Green function the boundary conditions

$$\begin{aligned} G_g(t_a,t') &= 0, \quad t \leqslant t', \\ G_g(t',t_b) &= 0, \quad t' \leqslant t. \end{aligned} \tag{10}$$

The operator $\tilde{K}$ in the ratio (2) is equal to K_0, and the constant C in Eq. (6) is unity. After imposing (10), the Green function is uniquely given by Wronski's formula:

$$G_g(t,t') = \frac{\Theta_{tt'} f_g(t',t_a) f_g(t_b,t) + \Theta_{t't} f_g(t,t_a) f_g(t_b,t')}{f_g(t_a,t_b)}, \tag{11}$$

where

$$f_g(t_a,t_b) = \frac{\mathrm{Det}\,\Lambda_g}{W_g} \neq 0, \tag{12}$$

with Λ being a constant (2×2)-matrix,

$$\Lambda = \begin{pmatrix} \eta_a & \xi_a \\ \eta_b & \xi_b \end{pmatrix}, \tag{13}$$

formed from the solutions $\eta_g(t)$ and $\xi_g(t)$ at arbitrary $g \neq 1$. Note that these solutions are restricted only to the condition (12). The result is unique and well defined, assuming the absence of a zero mode $\xi(t)$ of the operator K_1 with Dirichlet boundary conditions $\xi_a = \xi_b = 0$. Such a mode would cause problems, since according to (10), the Wronski determinant W would vanish at the initial point, and thus for all t.

Excluding zero modes, we obtain from (8):

$$\mathrm{Tr}\,\Omega^2(t)G_g(t,t')=\frac{1}{f_g(t_a,t_b)}\int_{t_a}^{t_b}dt\,\Omega^2(t)f_g(t,t_a)f_g(t_b,t). \tag{14}$$

To perform the time integral on the right-hand side, we make use of the identity

$$\Omega^2(t)\xi(t)\eta(t)=\partial_t[\dot{\eta}_g(t)\partial_g\xi_g(t)-\eta_g(t)\partial_g\dot{\xi}_g(t)]. \tag{15}$$

This follows from Eq. (9) for $\eta_g(t)$, and an analogous equation for $\xi_{\tilde{g}}(t)$, after multiplying the first by $\xi_{\tilde{g}}(t)$ and the second by $\eta_g(t)$, and taking their difference. In the limit $\tilde{g}\to g$, we obtain (15) from the linear term in $\tilde{g}-g$. Inserting (15) into (14), we see that

$$\mathrm{Tr}\,\Omega^2(t)G_g(t,t')=-\partial_g\log\left(\frac{\mathrm{Det}\,\Lambda_g}{W_g}\right). \tag{16}$$

Substituting (16) into (6), we find

$$\mathrm{Det}\,K_0^{-1}K_1=\frac{\mathrm{Det}\,\Lambda_1}{W_1}\Big/\frac{\mathrm{Det}\,\Lambda_0}{W_0}, \tag{17}$$

where $\mathrm{Det}\,\Lambda_0/W_0=t_b-t_a$. In a time-sliced quantum mechanical path integral, where the time slices have the width ϵ, the determinant of $K_0=-\partial_t^2$ is finite and has the value[1]

$$\mathrm{Det}\,K_0=(t_b-t_a)/\epsilon, \tag{18}$$

so that we obtain

$$\mathrm{Det}\,K_1=D(t_b)/\epsilon, \tag{19}$$

where $D(t)=[\eta_1(t_a)\xi_1(t)-\eta_1(t)\xi_1(t_a)]/W_1$ is a solution of the Gel'fand–Yaglom initial value problem (see Sec. 2.7 in Ref. 1):

$$K_1D(t)=0;\quad D(t_a)=0,\quad \dot{D}(t_a)=1. \tag{20}$$

For a harmonic oscillator with a time-dependent frequency $\Omega(t)$, it is convenient to relate the set of two independent solutions $\eta_1(t)$ and $\xi_1(t)$ to the classical path $x_{\mathrm{cl}}(t)=x_a\xi(t)+x_b\eta(t)$ satisfying the end point conditions $x_{\mathrm{cl}}(t_a)=x_a$ and $x_{\mathrm{cl}}(t_b)=x_b$. Since this construction satisfies $\eta_a=\xi_b=0$, $\eta_b=\xi_a=1$, and $W=\dot{\xi}_b=-\dot{\eta}_a$, the explicit solution being

$$\xi(t)=\frac{\partial x_{\mathrm{cl}}(t)}{\partial x_a}=\frac{q(t)q_b\sin\omega_0(\tau_b-\tau)}{q_aq_b\sin\omega_0(\tau_b-\tau_a)},$$
$$\eta(t)=\frac{\partial x_{\mathrm{cl}}(t)}{\partial x_b}=\frac{q(t)q_a\sin\omega_0(\tau-\tau_a)}{q_aq_b\sin\omega_0(\tau_b-\tau_a)}. \tag{21}$$

They are parametrized by two functions $\tau(t)$ and $q(t)$ satisfying the constraint

$$\omega_0\dot{\tau}q^2=1, \tag{22}$$

where ω_0 is an arbitrary constant frequency. The function $q(t)$ satisfies the Ermakov–Pinney equation,[10]

$$\ddot{q}+\Omega^2(t)q-q^{-3}=0. \tag{23}$$

Inserting (21) into (17), we obtain for the harmonic oscillator with a time-dependent frequency $\Omega(t)$ the ratio of functional determinants,

$$\mathrm{Det}\, K_0^{-1} K_1 = \frac{q_a q_b \sin \omega_0(\tau_b - \tau_a)}{(t_b - t_a)}, \tag{24}$$

where subscripts a and b indicate evaluation at $t = t_a$ and $t = t_b$, respectively. We check this representation by expressing the right-hand side in terms of the classical action $\mathcal{A}_{\mathrm{cl}}(x)$. With the same normalization as in (18), this yields the well-known one-dimensional Van-Vleck formula,

$$\mathrm{Det}\, K_1 = -M[\partial^2 \mathcal{A}_{\mathrm{cl}}(x_a, x_b; t_b - t_a)/\partial x_a\, \partial x_b]^{-1}. \tag{25}$$

To conclude this section we note that the ratio (17) can easily be extended to the stochastic case, where the final position of the trajectory $x(t)$ remains unspecified. To this end we consider Eqs. (14) and (15) with a variable upper time $t' \geqslant t \geqslant t_a$. Then the eigenvalues of the operator $K_0^{-1} K_1$ become functions of t' with a phase factor produced by each passage through a focal point.

IV. PERIODIC AND ANTIPERIODIC BOUNDARY CONDITIONS

Consider now periodic (antiperiodic) boundary conditions $y(t_b) = \pm y(t_a)$, $\dot{y}(t_b) = \pm \dot{y}(t_a)$ for the eigenfunctions $y(t)$ of the operator K_1 and for the Green function $G^{p}_{a}(t,t')$:

$$\begin{aligned} G^{p}_{a}(t_b, t') &= \pm G^{p}_{a}(t_a, t'), \\ \dot{G}^{p}_{a}(t_b, t') &= \pm \dot{G}^{p}_{a}(t_a, t'), \end{aligned} \tag{26}$$

where $T = t_b - t_a$ is the period. In both cases, the frequency $\Omega(t)$ and Dirac's δ function in Eq. (5) are also assumed to be periodic (antiperiodic) with the same period. The general solution of Eq. (5) satisfying the boundary conditions (26) is constructed by adding to (7) an expression of the same type as before, using the same homogeneous solutions $\eta_g(t)$ and $\xi_g(t)$. The result has the form

$$G^{p}_{a\,g}(t,t') = G_g(t,t') \mp \frac{[f_g(t,t_a) \pm f_g(t_b,t)][f_g(t',t_a) \pm f_g(t_b,t')]}{\Delta^{p}_{a} \cdot f_g(t_a,t_b)}, \tag{27}$$

with the condition

$$\Delta^{p}_{a} = \frac{\mathrm{Det}\, \bar{\Lambda}^{p}_{a\,g}}{W_g} \neq 0, \tag{28}$$

where $\bar{\Lambda}^{p}_{a}$ are now the (2×2)-constant matrices,

$$\bar{\Lambda}^{p}_{a} = \begin{pmatrix} (\eta_b \mp \eta_a) & (\xi_b \mp \xi_a) \\ (\dot{\eta}_b \mp \dot{\eta}_a) & (\dot{\xi}_b \mp \dot{\xi}_a), \end{pmatrix}, \tag{29}$$

evaluated at $g \neq 1$. In analogy to Eq. (16) we now find the formula

$$\mathrm{Tr}\, \Omega^2(t) G^{p}_{a\,g}(t,t') = -\partial_g \log\left(\frac{\mathrm{Det}\, \bar{\Lambda}^{p}_{a\,g}}{W_g} \right). \tag{30}$$

Substituting this into (6) and setting $g=1$, we obtain the ratio of the functional determinants for periodic boundary conditions,

$$\mathrm{Det}\,\tilde{K}^{-1}K_1=\frac{\mathrm{Det}\,\Lambda_1^p}{W_1}\Bigg/ 4\sin^2\frac{\omega_0(t_b-t_a)}{2}. \tag{31}$$

Here $\mathrm{Det}\,\tilde{K}=\mathrm{Det}(-\partial_t^2-\omega_0^2)$ is the fluctuation determinant of the harmonic oscillator, which in the same normalization as in (18) is equal to

$$\mathrm{Det}\,\tilde{K}=4\sin^2\frac{\omega_0(t_b-t_a)}{2}, \tag{32}$$

and thus the formula

$$\mathrm{Det}\,K_1=\frac{(\eta_b-\eta_a)(\dot{\xi}_b-\dot{\xi}_a)-(\xi_b-\xi_a)(\dot{\eta}_b-\dot{\eta}_a)}{W}, \tag{33}$$

the right-hand side being evaluated at $g=1$. For antiperiodic boundary conditions, the analogous expressions are

$$\mathrm{Det}\,\tilde{K}_1^{-1}=\frac{\mathrm{Det}\,\Lambda_1^a}{W_1}\Bigg/ 4\cos^2\frac{\omega_0(t_b-t_a)}{2}, \tag{34}$$

$$\mathrm{Det}\,K_1=\frac{(\eta_b+\eta_a)(\dot{\xi}_b+\dot{\xi}_a)-(\xi_b+\xi_a)(\dot{\eta}_b+\dot{\eta}_a)}{W}. \tag{35}$$

For a harmonic oscillator with a time-dependent frequency $\Omega(t)$, we use again the representation (21) for $\xi(t)$ and $\eta(t)$ in terms of the functions $p(t)$ and $q(t)$, which, in addition to (22) and (23), have the following properties: the function $p(t)$ is periodic and even,

$$p(t+T)=p(t),\quad p(-t)=p(t), \tag{36}$$

so that $p_b=p_a$, whereas the function $q(t)$ satisfies

$$q(t+T)=q(t)+q_b,\quad q_a=0, \tag{37}$$

where $T\equiv(t_b-t_a)$. Inserting now the solutions (21) into (31) and (34), we find the ratio of functional determinants for a harmonic oscillator with a time-dependent frequency $\Omega(t)$ with periodic boundary conditions,

$$\mathrm{Det}\,\tilde{K}^{-1}K_1=4\sin^2\frac{\omega_0 q_b}{2}\Bigg/ 4\sin^2\frac{\omega_0 t}{2}, \tag{38}$$

and with antiperiodic boundary conditions,

$$\mathrm{Det}\,\tilde{K}^{-1}K_1=4\cos^2\frac{\omega_0 q_b}{2}\Bigg/ 4\cos^2\frac{\omega_0 t}{2}. \tag{39}$$

Only formula (24) for the Dirichlet boundary condition has been known in the literature (see Refs. 7 and 8). The periodic and antiperiodic formulas (38) and (39) are new, although they have had predecssors on the lattice.[11] Moreover, our new derivation has the advantage of employing only Wronski's simple construction method for Green functions. The general expressions for the functional determinants (19), (33), and (35) are form invariant under an arbitrary changes $(\eta,\xi)\to(\tilde{\eta},\tilde{\xi})$ of the basic set $\eta(t)$ and $\xi(t)$ of two independent solutions of the homogeneous equation (9).

V. TREATMENT OF ZERO MODE

Contrary to the case of a harmonic oscillator with a time-dependent frequency $\Omega(t)$, in which the operator K_1 has no zero mode, consider now the situation where such a zero mode is present. It is typically encountered for fluctuations around localized classical solutions $x_{\rm cl}(t)$ such as solitons or instantons,[1] where the frequency $\Omega(t)$ in the operator K_1 has the special form $\Omega^2(t) = V''(x_{\rm cl}(t))/M$. The fluctuation Lagrangian (1) arises from the second-order variation around $x(t)=x_{\rm cl}(t)$ of a Lagrangian $L=\dot{x}^2/2-V(x)$, which has no explicit time dependence, so that $x_{\rm cl}(t)$ and $x_{\rm cl}(t+t_0)$ are equally good solutions of $\ddot{x}=-V'(x)$, which makes $\dot{x}_{\rm cl}(t)$ a zero mode of K_1, caused by translation invariance along the time axis.[12]

For simplicity, we shall assume the presence of only a single zero mode, which we choose as one of two independent solutions of the homogeneous differential equation, say $\eta(t)$. For Dirichlet boundary conditions, we call this a Dirichlet zero mode with the properties

$$\eta_b=0, \quad \eta_a=0. \tag{40}$$

For periodic and antiperiodic boundary conditions, the zero mode satisfies

$$\eta_b\mp\eta_a=0, \quad \dot{\eta}_b\mp\dot{\eta}_a=0, \tag{41}$$

respectively. As pointed out earlier, the Wronski construction for evaluating ratios of functional determinants is not applicable here since the conditions (12) and (28) are violated as a consequence of (40) and (41). In order to enforce (12) and (28), we modify the boundary conditions (40) and (41) by a small regulator parameter $\epsilon>0$, and determine new independent solutions $\eta^\epsilon(t)$ and $\xi^\epsilon(t)$ with $\eta^\epsilon(t)\to\eta(t)$ and $\xi^\epsilon(t)\to\xi(t)$ for $\epsilon\to 0$. The specific form of regularized boundary conditions will be irrelevant, requiring only the condition for the regularized Wronskian,

$$W^\epsilon=\eta^\epsilon\dot{\xi}^\epsilon-\dot{\eta}^\epsilon\xi^\epsilon=W, \tag{42}$$

being independent of ϵ. One may imagine such a regularization as a simple shifting of limiting end points of the time interval (t_a,t_b), provided that the operator K_1 remains nonsingular. Since the conditions (12) and (28) are now satisfied, the Wronski construction and our modification for periodic and antiperiodic boundary conditions provides us directly with the regularized determinants $\mathrm{Det}\,K_1^\epsilon$, which tend to small values in the limit $\epsilon\to 0$. In terms of $\eta^\epsilon(t)$ and $\xi^\epsilon(t)$, these determinants are given explicitly by the expressions (19), (33), and (35) for Dirichlet, periodic, and antiperiodic boundary conditions, respectively. We now remove the zero mode from the determinant using the standard methods.[13] The determinant without such a zero mode is defined by

$$\mathrm{Det}'\,K_1=\lim_{\varepsilon\to 0}\frac{\mathrm{Det}\,K_1^\varepsilon}{\delta\lambda^\varepsilon}, \tag{43}$$

where $\delta\lambda^\varepsilon$ is a small eigenvalue associated with the eigenfunction $\eta^\varepsilon(t)+\delta\eta^\varepsilon(t)$,

$$K_1\,\delta\eta^\varepsilon=\delta\lambda^\varepsilon\,\eta^\varepsilon, \tag{44}$$

with the limit $\delta\lambda^\varepsilon\to 0$ for $\varepsilon\to 0$. To first order in ε, it follows from (44) that

$$(\delta\eta^\varepsilon\,\dot{\eta}^\varepsilon-\delta\dot{\eta}^\varepsilon\,\eta^\varepsilon)\big|_{t_a}^{t_b}\approx\delta\lambda^\varepsilon\int_{t_a}^{t_b}dt\,\eta^2(t)\equiv\delta\lambda^\varepsilon\langle\eta|\eta\rangle. \tag{45}$$

Substituting (19) and (45) into (43), we obtain the functional determinant without a zero mode for the operator K_1 with Dirichlet boundary conditions,

$$\mathrm{Det}'\, K_1 = -\lim_{\varepsilon\to 0} \frac{\xi_a^\varepsilon \xi_b^\varepsilon}{W^2} \langle \eta | \eta \rangle = -\frac{\langle \eta | \eta \rangle}{\dot{\eta}_b \dot{\eta}_a}. \tag{46}$$

For the operator K_1 with periodic and antiperiodic boundary conditions, the analogous calculation extracting the zero mode from the functional determinant gives

$$\mathrm{Det}'\, K_1 = \pm \lim_{\varepsilon\to 0} \frac{(\xi_a^\varepsilon \dot{\xi}_b^\varepsilon - \xi_b^\varepsilon \dot{\xi}_a^\varepsilon)}{W^2} \langle \eta | \eta \rangle = -\frac{(\xi_b \mp \xi_a)\langle \eta | \eta \rangle}{\eta_b W}. \tag{47}$$

These formulas are useful for semiclassical calculations of path integrals processing nontrivial classical solutions such as solitons or instantons.[1] Note that our expressions (46) and (47) for the functional determinants are independent of the specific choice of regularization.

Note added. Further useful formulas, in particular an extremely efficient one for the fluctuation determinant of a solution of the equation of motion, can be found in recent detailed paper by H. Kleinert and A. Chervyakov, ''Simple explicit formulas for Gaussian path integrals with time-dependent frequencies,'' quantph/9803016, Phys. Lett. **A245**, 345 (1998).

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 40, NUMBER 11 NOVEMBER 1999

The inhomogeneous quantum groups from differential calculi with classical dimension

M. Lagraa and N. Touhami
Laboratoire de Physique Théorique, Université d'Oran Es-Sénia, 31100 Algérie, France

(Received 19 November 1997; accepted for publication 12 March 1999)

From the bicovariant first-order differential calculus on inhomogeneous Hopf algebra $\mathcal{B}$ we construct the set of right-invariant Maurer–Cartan one-forms considered as a right-invariant basis of a bicovariant $\mathcal{B}$-bimodule over which we develop the Woronowicz general theory of differential calculus on quantum groups. In this formalism, we introduce suitable functionals on $\mathcal{B}$ which control the inhomogeneous commutation rules. In particular, we find that the homogeneous part of commutation rules between the translations and those between the generators of the homogeneous part of $\mathcal{B}$ and translations are controlled by different R-matrices satisfying characteristic equations.
[S0022-2488(99)00110-3]

I. INTRODUCTION

The Poincaré group plays a fundamental role in physics. It is intrinsically connected to the geometry of the space-time on which the physical systems are described and could be invariant under its action. Then, it is especially interesting to study the noncommutative version of the Poincaré group from which one can hope to obtain new insight on the underlying space–time geometry as, for example, an improved ultraviolet in quantum field theories or a description of symmetries in a future quantum Einstein–Cartan gravity.

The construction of quantum Poincaré group and quantum space–times has already been considered by several authors.[1–8] These constructions start either from the existence of an R-matrix and the consistency of the commutation rules between the different elements of the generators of the Poincaré group and those of the quantum space–times or from the projection of homogeneous quantum groups. In certain works this consistency is only obtained by introducing an extra generator.[4,6]

Recently, in the work Podles and Woronowicz[9] inhomogeneous commutation rules for an inhomogeneous Hopf algebra without dilatation have been constructed. This construction is based on the existence of a bicovariant submodule of the inhomogeneous algebra regarded as a left module (over the homogeneous part) generated by translations and leads to the same R-matrix, subject to the condition $R^2 = I^{\otimes 2}$, which controls the homogeneous parts of the different commutation rules.

It is well known that the usual way of constructing differential calculus on quantum groups consists first of constructing the quantum group, and then defining the bicovariant calculi, using right ad-invariant ideals. In such a case, for some deformations the basic one-forms span the space with dimension exceeding the group dimension or the number of its Lie algebra generators. In this paper, we present a quite different way based on the inverse order of construction: we introduce first the right-invariant differential calculus by assuming Cartan–Maurer types of formulas, and then show which classes of deformations of inhomogeneous symmetries are required for bicovariance of an assumed differential calculus. Using the fact that the homogeneous part of the inhomogeneous quantum group is a Hopf subalgebra, we obtain inhomogeneous commutation rules between elements of the inhomogeneous Hopf algebra $\mathcal{B}$. In particular, the homogeneous parts of the commutation rules are controlled by different R-matrices satisfying characteristic equations. This formalism eliminates from the beginning the mismatch of the space of the basic one-forms and the group dimensions and gives an extension of the results presented in Ref. 9 and the condition of the existence of differential calculus, with the classical dimension of Ref. 10.

The present paper is organized as follows: In Sec. II, we recall some basic notions about the inhomogeneous Hopf algebra and construct a right-invariant basis of the bimodule over this algebra. This right-invariant basis allows us to generalize, in Sec. III, the Woronowicz proposal[11] to the inhomogeneous Hopf algebra by introducing suitable functionals over $\mathcal{B}$. The study of these functionals leads us to construct inhomogeneous commutation rules between the elements of $\mathcal{B}$ whose homogeneous parts are controlled by different R-matrices satisfying characteristic equations. Finally, we investigate in Sec. IV the consistency conditions between these functionals and the different commutation rules of the inhomogeneous quantum group. Throughout this paper we use Einstein's convention (sum over repeated indices) and for the simplicity of calculations we define $v\top w\in M_{NN}(\mathcal{B})$ by $(v\top w)^{nm}_{kl}=v^n_k w^m_l$, $n,m,k,l\in 1,...,N$, for any v and $w\in M_N(\mathcal{B})$.

II. DIFFERENTIAL CALCULUS ON INHOMOGENEOUS QUANTUM GROUPS

In this section, we start by recalling some basic background about inhomogeneous Hopf algebra $\mathcal{B}$ and the covariant first-order differential calculus to construct a bicovariant bimodule Γ of one-forms over $\mathcal{B}$ and a basis of the vector space $\Gamma_{\rm inv}\subset\Gamma$ of all right-invariant elements of Γ.

An inhomogeneous quantum group $\mathcal{G}$ is built from a quantum group $\mathcal{H}$ and translations described by elements p^n, $n=1,...,N$ corresponding to an irreducible representation Λ^n_m of $\mathcal{H}$. The corresponding Hopf algebras are treated as algebras of functions on quantum groups, Poly$(\mathcal{G})=\mathcal{B}$ and Poly$(\mathcal{H})=\mathcal{A}$. More precisely, following Ref. 9, one defines $\mathcal{B}$ as follows.

(1) An abstract unital Hopf algebra generated by $\mathcal{A}$ and elements p^n such that $I_{\mathcal{B}}=I_{\mathcal{A}}=I$.
(2) $\mathcal{A}$ is a Hopf subalgebra of $\mathcal{B}$.
(3) $\mathcal{P}=\left(\begin{smallmatrix}\Lambda & p\\ 0 & I\end{smallmatrix}\right)$ is a representation of $\mathcal{G}$.
(4) There exists $n\in 1,...,N$ such that $p^n\notin\mathcal{A}$.
(5) $\Gamma_p\mathcal{A}\subset\Gamma_p$, where $\Gamma_p=\mathcal{A}X+\mathcal{A}$, $X=\text{span}\,(p^n,n=1,...,N)$.

By virtue of (2) and (3) above, $\mathcal{B}$ is endowed with the following linear maps:

(i) The coaction (algebra homomorphism) $\Delta:\mathcal{B}\to\mathcal{B}\otimes\mathcal{B}$,

$$\Delta(a)=a_{(1)}\otimes a_{(2)},\quad a\in\mathcal{B},$$

satisfyies the coassociativity condition

$$(\Delta\otimes\text{id})\Delta(a)=(\text{id}\otimes\Delta)\Delta(a)=a_{(1)}\otimes a_{(2)}\otimes a_{(3)}.$$

Due to the representation $\mathcal{P}$ of $\mathcal{G}$ the coaction acts on the generators as

$$\Delta(\Lambda^n_m)=\Lambda^n_k\otimes\Lambda^k_m,$$

$$\Delta(p^n)=\Lambda^n_k\otimes p^k+p^n\otimes I.$$

(ii) The counit (character) $\varepsilon:\mathcal{B}\to\mathcal{C}$ satisfies

$$(\varepsilon\otimes\text{id})\Delta(a)=(\text{id}\otimes\varepsilon)\Delta(a)=a,\quad a\in\mathcal{B},$$

acts on the generators as

$$\varepsilon(\Lambda^n_m)=\delta^n_m\quad\text{and}\quad\varepsilon(p^n)=0.$$

(iii) The antipode (algebra antihomomorphism) $S:\mathcal{B}\to\mathcal{B}$ satisfies

$$m\circ(S\otimes\text{id})\Delta(a)=m\circ(\text{id}\otimes S)\Delta(a)=I_{\mathcal{B}}\varepsilon(a),\quad a\in\mathcal{B},$$

where $m:\mathcal{B}\otimes\mathcal{B}\rightarrow\mathcal{B}$ is the multiplication map. It acts on the generators as

$$S(\Lambda^n_k)\Lambda^k_m=\varepsilon(\Lambda^n_m)=\delta^n_m=\Lambda^n_k S(\Lambda^k_m),$$

$$S(\Lambda^n_k)p^k+S(p^n)=\varepsilon(p^n)=0=\Lambda^n_k S(p^k)+p^n.$$

One says[11] that (Γ,d) is a first-order differential calculus on the inhomogeneous Hopf algebra $(\mathcal{B},\Delta,S,\varepsilon)$ if $d:\mathcal{B}\rightarrow\Gamma$ is a linear map obeying the Leibniz rule, $d(ab)=(da)b+a(db)$ for any $a,b\in\mathcal{B}$. Γ is a bimodule over $\mathcal{B}$ and every element of Γ is of the form $\Sigma_k a_k db_k$, where a_k, $b_k\in\mathcal{B}$. We say that (Γ,d) is left covariant if for any a_k, $b_k\in\mathcal{B}$

$$\sum_k a_k db_k=0\Leftrightarrow\sum_k \Delta(a_k)(\mathrm{id}\otimes d)\Delta(b_k)=0$$

and is right covariant if

$$\sum_k a_k db_k=0\Leftrightarrow\sum_k \Delta(a_k)(d\otimes\mathrm{id})\Delta(b_k)=0.$$

(Γ,d) is bicovariant if it is left and right covariant. This notion of covariant differential calculus leads to the left-coaction Δ_L and right-coaction Δ_R which are bimodule homomorphisms

$$\Delta_{L(R)}(a\rho b)=\Delta(a)\Delta_{L(R)}(\rho)\Delta(b),\quad a,b\in\mathcal{B},\rho\in\Gamma, \tag{1}$$

and satisfy

$$\Delta_L d=(\mathrm{id}\otimes d)\Delta,\quad \Delta_R d=(d\otimes\mathrm{id})\Delta,$$
$$(\varepsilon\otimes\mathrm{id})\Delta_L=\mathrm{id}\quad\text{and}\quad(\mathrm{id}\otimes\varepsilon)\Delta_R=\mathrm{id}. \tag{2}$$

For a bicovariant bimodule, the following condition is satisfied:

$$(\Delta_L\otimes\mathrm{id})\Delta_R=(\mathrm{id}\otimes\Delta_R)\Delta_L\,.$$

Since, $\mathcal{B}=\mathrm{Poly}(\mathcal{G})=\mathrm{Poly}(\Lambda,p)$, $d\Lambda^n_m$ and dp^n generate Γ as a bimodule of one-forms over $\mathcal{B}$. We therefore have the following.

Lemma (2.1):

$$\Theta^n_{Rm}=d\Lambda^n_k S(\Lambda^k_m)\quad\text{and}\quad\Pi^n_R=dp^n-\Theta^n_k p^k \tag{3}$$

form a basis of the vector space $\Gamma_{\mathrm{inv}}\subset\Gamma$ of all right-invariant elements of Γ.

Proof: Since p^n correspond to an irreducible representation Λ of $\mathcal{H}$, they are linearly independent, and so are $S(p^n)=-S(\Lambda^n_m)p^m$. Then $d\Lambda^n_m$ and dp^n or $d\Lambda^n_m$ and $dS(p^n)$ form a basis of the one-form vector space which generates Γ as a $\mathcal{B}$-bimodule from which we can choose an another basis $d(\Lambda^n_k)S(\Lambda^k_m)=\Theta^n_{Rm}$ and $\Lambda^n_k dS(p^k)=p^n-\Theta^n_{Rm}p^m=\Pi^n_R$. To show the right invariance, it suffices to apply (1), (2), and the properties of the Hopf algebra structure of $\mathcal{B}$ to get

$$\Delta_R(\Theta^n_{Rm})=d\Lambda^n_l S(\Lambda^p_m)\otimes\Lambda^l_k S(\Lambda^k_p)=\Theta^n_{Rm}\otimes I, \tag{4}$$

$$\begin{aligned}\Delta_R(\Pi^n_R)&=d\Lambda^n_k\otimes p^k+dp^n\otimes I-\Theta^n_{Rm}\Lambda^m_k\otimes p^k-\Theta^n_{Rm}p^m\otimes I\\&=\Theta^n_{Rm}\Lambda^m_k\otimes p^k+(dp^n-\Theta^n_{Rm}p^m)\otimes I-\Theta^n_{Rm}\Lambda^m_k\otimes p^k=\Pi^n_R\otimes I,\end{aligned} \tag{5}$$

$$\Delta_L(\Theta^n_{Rm})=\Lambda^n_l S(\Lambda^k_m)\otimes\Theta^l_{Rk}, \tag{6}$$

$$\Delta_L(\Pi^n_R)=\Lambda^n_k\otimes dp^k-\Lambda^n_k S(\Lambda^l_m)\Lambda^m_p\otimes\Theta^k_{Rl}p^p-\Lambda^n_k S(\Lambda^l_m)p^m\otimes\Theta^k_{Rl}$$
$$=\Lambda^n_k\otimes(dp^k-\Theta^k_{Rl}p^l)+\Lambda^n_k S(p^l)\otimes\Theta^k_{Rl}=\Lambda^n_k\otimes\Pi^k_R+\Lambda^n_k S(p^l)\otimes\Theta^k_{Rl}. \tag{7}$$

Q.E.D.

Remark (2.1): Note that we can construct from Π^n_R and Θ^n_{Rm} a left-invariant basis as

$$\Theta^n_{Lm}=S(\Lambda^n_k S(\Lambda^l_m))\Theta^k_{Rl}, \tag{8}$$

$$\Pi^n_L=S(\Lambda^n_m)\Pi^m_R+S(\Lambda^n_m S(p^k))\Theta^m_{Rk}, \tag{9}$$

satisfying

$$\Delta_L(\Theta^n_{Lm})=I\otimes\Theta^n_{Lm} \quad \text{and} \quad \Delta_L(\Pi^n_L)=I\otimes\Pi^n_L,$$

$$\Delta_R(\Theta^n_{Lm})=\Theta^k_{Ll}\otimes S(\Lambda^n_k S(\Lambda^l_m)),$$

$$\Delta_R(\Pi^n_L)=\Pi^k_L\otimes S(\Lambda^n_k)+\Theta^k_{Ll}\otimes S(\Lambda^n_k S(p^l)).$$

The bicovariance condition of these bases can be checked by direct computation. In the following, we consider the bases $\Theta^n_{Rm}=\Theta^n_m$ and $\Pi^n_R=\Pi^n$.

III. COMMUTATION RULES FOR INHOMOGENEOUS HOPF ALGEBRAS

Now, we are ready to study the commutation rules for inhomogeneous Hopf algebras by generalizing the formalism of the bicovariant bimodule theory of Ref. 11 to our bimodule presented in the previous section. Since Π^n and Θ^n_m form a right-invariant basis, we are in the case where we can apply the different stages of Theorem (2.3) of Ref. 11 to state that there exist linear functionals f^n_m, f^{nk}_m, f^n_{km}, and $f^{nl}_{mk}\in\mathcal{B}'$ such that

$$\Pi^n a=(a\star f^n_k)\Pi^k+(a\star f^{nl}_k)\Theta^k_l, \tag{10}$$

$$\Theta^n_m a=(a\star f^n_{mk})\Pi^k+(a\star f^{nl}_{mk})\Theta^k_l, \tag{11}$$

and

$$b\Pi^n=\Pi^k(b\star f^n_k\circ S)+\Theta^k_l(b\star f^{nl}_k\circ S),$$

$$b\Theta^n_m=\Pi^k(b\star f^n_{mk}\circ S)+\Theta^k_l(b\star f^{nl}_{mk}\circ S)$$

where the convolution product of a functional $f\in\mathcal{B}'$ and an element a of $\mathcal{B}$ is defined as $a\star f=(f\otimes\mathrm{id})\Delta(a)$. From (10) and (11), one deduces

$$f^n_k(I)=\delta^n_k, \quad f^{nl}_{mk}(I)=\delta^n_k\delta^l_m, \quad f^n_{mk}(I)=0, \quad f^{nl}_k(I)=0 \tag{12}$$

by setting $a=I$, and

$$\Pi^n ab=(ab\star f^n_k)\Pi^k+(ab\star f^{nl}_k)\Theta^k_l$$
$$=((a\star f^n_l)(b\star f^l_k)+(a\star f^{np}_q)(b\star f^q_{pk}))\Pi^k+((a\star f^n_q)(b\star f^{ql}_k)+(a\star f^{np}_q)(b\star f^{ql}_{pk}))\Theta^k_l,$$

$$\Theta^n_m ab=(ab\star f^n_{mk})\Pi^k+(ab\star f^{nl}_{mk})\Theta^k_l$$
$$=((a\star f^n_{mq})(b\star f^q_k)+(a\star f^{nq}_{mp})(b\star f^p_{qk}))\Pi^k+((a\star f^n_{mq})(b\star f^{ql}_k)+(a\star f^{np}_{mq})(b\star f^{ql}_{pk}))\Theta^k_l,$$

for any $a,b\in\mathcal{B}$. Comparing the coefficients multiplying Π and Θ and then applying ε, we get

$$f^n_m(ab)=f^n_k(a)f^k_m(b)+f^{nk}_l(a)f^l_{km}(b), \tag{13}$$

$$f^{nk}_{ml}(ab)=f^{np}_{mq}(a)f^{qk}_{pl}(b)+f^n_{mq}(a)f^{qk}_l(b), \tag{14}$$

$$f^n_{ml}(ab)=f^{np}_{mq}(a)f^q_{pl}(b)+f^n_{mk}(a)f^k_l(b), \tag{15}$$

$$f^{nk}_l(ab)=f^n_q(a)f^{qk}_l(b)+f^{np}_q(a)f^{qk}_{pl}(b). \tag{16}$$

Applying now Δ_L on both sides of (10) and (11), we obtain, respectively,

$$\begin{aligned}\Lambda^n_p a_{(1)}\otimes\Pi^p a_{(2)}+\Lambda^n_p S(p^q)a_{(1)}\otimes\Theta^p_q a_{(2)}\\ =f^n_p(a_{(1)})a_{(2)}\Lambda^p_k\otimes a_{(3)}\Pi^k+(f^{nq}_p(a_{(1)})a_{(2)}\Lambda^p_k S(\Lambda^l_q)+f^n_p(a_{(1)})a_{(2)}\Lambda^p_k S(p^l))\otimes a_{(3)}\Theta^k_l\end{aligned} \tag{17}$$

and

$$\begin{aligned}\Lambda^n_q S(\Lambda^p_m)a_{(1)}\otimes\Theta^q_p a_{(2)}=f^n_{mp}(a_{(1)})a_{(2)}\Lambda^p_k\otimes a_{(3)}\Pi^k+(f^n_{mp}(a_{(1)})a_{(2)}\Lambda^p_k S(p^l)\\ +f^{nq}_{mp}(a_{(1)})a_{(2)}\Lambda^p_k S(\Lambda^l_q))\otimes a_{(3)}\Theta^k_l.\end{aligned} \tag{18}$$

By virtue of (10) and (11), the left-hand sides of previous equations can be rewritten respectively as

$$\begin{aligned}(\Lambda^n_p a_{(1)}f^p_k(a_{(2)})+\Lambda^n_p S(p^q)f^p_{qk}(a_{(2)}))\otimes a_{(3)}\Pi^k\\ +(\Lambda^n_p a_{(1)}f^{pl}_k(a_{(2)})+\Lambda^n_p S(p^q)a_{(1)}f^{pl}_{qk}(a_{(2)}))\otimes a_{(3)}\Theta^k_l\end{aligned}$$

and

$$\Lambda^n_q S(\Lambda^p_m)a_{(1)}f^q_{pk}(a_{(2)})\otimes a_{(3)}\Pi^k+\Lambda^n_q S(\Lambda^p_m)a_{(1)}f^{ql}_{pk}(a_{(2)})\otimes a_{(3)}\Theta^k_l.$$

Substituting the first expression into the left-hand side of (17) and the second into the left-hand side of (18), comparing the coefficients multiplying $I\otimes\Pi$ and $I\otimes\Theta$, and then applying $I\otimes\varepsilon$, we obtain

$$\Lambda^n_k(f^k_m\star a)+\Lambda^n_k S(p^l)(f^k_{lm}\star a)=(a\star f^n_k)\Lambda^k_m, \tag{19}$$

$$\Lambda^n_k(f^{kl}_m\star a)+\Lambda^n_k S(p^q)(f^{kl}_{qm}\star a)=(a\star f^n_k)\Lambda^k_m S(p^l)+(a\star f^{nk}_q)\Lambda^q_m S(\Lambda^l_k), \tag{20}$$

$$\Lambda^n_k S(\Lambda^q_m)(f^k_{ql}\star a)=(a\star f^n_{mk})\Lambda^k_l, \tag{21}$$

$$\Lambda^n_k S(\Lambda^q_m)(f^{kp}_{ql}\star a)=(a\star f^n_{mk})\Lambda^k_l S(p^p)+(a\star f^{nq}_{mk})\Lambda^k_l S(\Lambda^p_q), \tag{22}$$

for any $a\in\mathcal{B}$. In the following, we assume that

$$f^{nk}_{ml}=\tilde{f}^k_m\star f^n_l,\quad f^{nk}_m=\tilde{\eta}^k\star f^n_m,\quad \text{and}\ f^n_{km}=\tilde{\eta}_k\star f^n_m \tag{23}$$

where $\tilde{\eta}^n$, $\tilde{\eta}_n$ and $\tilde{f}^n_m\in\mathcal{B}'$ and the convolution product of two functionals $\in\mathcal{B}'$ is defined as $(f_1\star f_2)(a)=(f_1\otimes f_2)\Delta(a)$ for any $a\in\mathcal{B}$. The substitution of (23) into (12) gives

$$\tilde{\eta}^n(I)=0,\quad \tilde{\eta}_n(I)=0,\quad \text{and}\ \tilde{f}^n_m(I)=\delta^n_m, \tag{24}$$

and the substitution of (23) into (13)–(16) and (19) gives, respectively,

$$f^n_m(ab)=(\varepsilon(a_{(1)})\varepsilon(b_{(1)})+\tilde{\eta}^k(a_{(1)})\tilde{\eta}_k(b_{(1)}))f^n_l(a_{(2)})f^l_m(b_{(2)}), \tag{25}$$

$$f^{nk}_{ml}(ab)=\tilde{f}^{k}_{m}(a_{(1)}b_{(1)})f^{n}_{l}(a_{(2)}b_{(2)})=(\tilde{f}^{p}_{m}(a_{(1)})\tilde{f}^{k}_{p}(b_{(1)})+\tilde{\eta}_{m}(a_{(1)})\tilde{\eta}^{k}(b_{(1)}))f^{n}_{q}(a_{(2)})f^{q}_{l}(b_{(2)}), \tag{26}$$

$$f^{n}_{km}(ab)=\tilde{\eta}_{k}(a_{(1)}b_{(1)})f^{n}_{m}(a_{(2)})b_{(2)})=(\tilde{f}^{p}_{k}(a_{(1)})\tilde{\eta}_{p}(b_{(1)})+\tilde{\eta}_{k}(a_{(1)})\varepsilon(b_{(1)}))f^{n}_{q}(a_{(2)})f^{q}_{m}(b_{(2)}), \tag{27}$$

$$f^{nk}_{m}(ab)=\tilde{\eta}^{k}(a_{(1)}b_{(1)})f^{n}_{m}(a_{(2)}b_{(2)})=(\varepsilon(a_{(1)})\tilde{\eta}^{k}(b_{(1)})+\tilde{\eta}^{p}(a_{(1)})\tilde{f}^{k}_{p}(b_{(1)}))f^{n}_{q}(a_{(2)})f^{q}_{m}(b_{(2)}), \tag{28}$$

and

$$\Lambda^{n}_{k}(f^{k}_{m}\star a)+\Lambda^{n}_{k}S(p^{l})(\tilde{\eta}_{l}\star f^{k}_{m}\star a)=(a\star f^{n}_{k})\Lambda^{k}_{m}. \tag{29}$$

Using now the associativity of the convolution product and making the substitution of (29) into the right-hand side of (20)–(22), we get

$$\tilde{\eta}^{i}\star f^{k}_{j}\star a+S(p^{l})(\tilde{f}^{i}_{l}\star f^{k}_{j}\star a)=(f^{k}_{j}\star a)S(p^{i})+(f^{k}_{j}\star a\star\tilde{\eta}^{l})S(\Lambda^{i}_{l})+S(p^{l})(\tilde{\eta}_{l}\star f^{k}_{j}\star a)S(p^{i})+S(p^{p})\times(\tilde{\eta}_{p}\star f^{k}_{j}\star a\star\tilde{\eta}^{l})S(\Lambda^{i}_{l}), \tag{30}$$

$$S(\Lambda^{k}_{m})(\tilde{\eta}_{k}\star f^{n}_{l}\star a)=(f^{n}_{l}\star a\star\tilde{\eta}_{m})+S(p^{k})(\tilde{\eta}_{k}\star f^{n}_{l}\star a\star\tilde{\eta}_{m}), \tag{31}$$

and

$$S(\Lambda^{l}_{m})(\tilde{f}^{i}_{l}\star f^{k}_{j}\star a)=S(\Lambda^{l}_{m})(\tilde{\eta}_{l}\star f^{k}_{j}\star a)S(p^{i})+(f^{k}_{j}\star a\star\tilde{f}^{l}_{m})S(\Lambda^{i}_{l})+S(p^{q})(\tilde{\eta}_{q}\star f^{k}_{j}\star a\star\tilde{f}^{l}_{m})S(\Lambda^{i}_{l}), \tag{32}$$

where we have multiplied from the left by $S(\Lambda^{p}_{n})$ and we have used (21) before (29) to obtain (32). We see from these relations that for any $a\in\mathcal{A}$, (30) is a commutation rule between elements of $\mathcal{A}$ and p^n and (29), (31), and (32) involve p^n in the commutation rules between elements of $\mathcal{A}$. Demanding $\mathcal{A}$ to be a Hopf subalgebra of $\mathcal{B}$ [condition (2)] leads to the following.

Proposition (3.1): $\mathcal{A}$ is a Hopf subalgebra of $\mathcal{B}$ iff

$$\tilde{\eta}_{n}(a)=0, \quad a\in\mathcal{A}. \tag{33}$$

Proof: For $\mathcal{A}$ to be a Hopf subalgebra of $\mathcal{B}$, (29) and (32) must involve commutation rules between elements of $\mathcal{A}$ only. This is satisfied if the term $\Lambda^{n}_{k}S(p^{l})(\tilde{\eta}_{l}\star f^{k}_{m}\star a)$ of (29) vanishes. Multiplying it from the left by $S(\Lambda^{i}_{n})$ and using the fact that $S(p^{l})$ are linearly independent and generate with the unity the bimodule Γ_p [see condition (5)], one obtains $\tilde{\eta}_{l}\star f^{i}_{m}\star a=0$ which permits us to write, for any a and $b\in\mathcal{A}$, (25) under the form

$$f^{n}_{m}(ab)=f^{n}_{k}(a)f^{k}_{m}(b)\Rightarrow f^{n}_{k}\star f^{k}_{m}\circ S=f^{n}_{k}\circ S\star f^{k}_{m}=\delta^{n}_{m}\varepsilon. \tag{34}$$

Replacing a by $f^{m}_{k}\circ S\star a$ into $\tilde{\eta}_{l}\star f^{i}_{m}\star a=0$ and then acting ε, we get $\tilde{\eta}_{l}(a)=0$ for any $a\in\mathcal{A}$ which implies also that Eq. (31) is trivial and the term of (32) which involves p^n in the commutation rules between elements of $\mathcal{A}$ vanishes. Conversely, it is easy to see that if $\tilde{\eta}_{l}(a)=0$ for any $a\in\mathcal{A}$, the relations (29) and (32) involve commutation rules between elements of $\mathcal{A}$ only and, therefore, $\mathcal{A}$ is a Hopf subalgebra of $\mathcal{B}$. Q.E.D.

By virtue of this proposition, one deduces certain results which will be used in the following.

(1) Equation (11) can be written as

$$\Theta^{n}_{m}a=(a\star f^{nl}_{mk})\Theta^{k}_{l}, \quad a\in\mathcal{A},$$

which shows that the set of the right-invariant one-forms Θ^n_m generates a subimodule, $\Gamma_{\mathcal{A}}\subset\Gamma$, over $\mathcal{A}$ and for $\tilde{\eta}_n(p^k)=0$ it generates a $\mathcal{B}$-subimodule of Γ. Since it transforms according to an adjoint representation Λ of $\mathcal{H}$ (6), the assumption $f^{nl}_{mk}=\tilde{f}^l_m\star f^n_k$ is justified.[12]

(2) For any $a\in\mathcal{A}$, (26) can be written as

$$\tilde{f}^k_m(a_{(1)}b_{(1)})f^n_l(a_{(2)}b_{(2)})=\tilde{f}^p_m(a_{(1)})\tilde{f}^k_p(b_{(1)})f^n_q(a_{(2)})f^q_l(b_{(2)})=\tilde{f}^p_m(a_{(1)})\tilde{f}^k_p(b_{(1)})f^n_l(a_{(2)}b_{(2)}),$$

where we have used (34) to get the right-hand side. Multiplying both sides from the right by $f^l_r(S(a_{(3)}b_{(3)}))$ and using again (34), we get

$$\tilde{f}^n_m(ab)=\tilde{f}^k_m(a)\tilde{f}^n_k(b),\quad a,b\in\mathcal{A}. \tag{35}$$

Following similar considerations, one obtains from (28)

$$\tilde{\eta}^n(ab)=\varepsilon(a)\tilde{\eta}^n(b)+\tilde{\eta}^m(a)\tilde{f}^n_m(b),\quad a,b\in\mathcal{A}, \tag{36}$$

which leads to

$$\begin{aligned}\tilde{\eta}^l(\Lambda^n_kS(\Lambda^k_m)=\tilde{\eta}^l(\delta^n_m)=0=\tilde{\eta}^l(S(\Lambda^n_m))+\tilde{\eta}^q(\Lambda^n_k)\tilde{f}^l_q(S(\Lambda^k_m)),\\ \tilde{\eta}^l(S(\Lambda^n_k)\Lambda^k_m)=\tilde{\eta}^l(\delta^n_m)=0=\tilde{\eta}^l(\Lambda^n_m)=\tilde{\eta}^q(S(\Lambda^n_k))\tilde{f}^l_q(\Lambda^k_m).\end{aligned} \tag{37}$$

Now replacing ab by $-S(\Lambda^a_b)p^b=S(p^a)$ into (28) and using (37), one obtains

$$\tilde{\eta}^n(S(p^a))=-\tilde{\eta}^n(p^a)-\tilde{\eta}^k(S(\Lambda^a_b))\tilde{f}^n_k(p^b). \tag{38}$$

On the other hand, by using (33), (27) gives

$$(\tilde{\eta}_k\star f^n_m)(S(p^a))=\tilde{\eta}_k(S(p^c))f^n_m(S(\Lambda^a_c))=-(\tilde{\eta}_k\star f^n_m)(S(\Lambda^a_b)p^b)=-\tilde{f}^p_k(S(\Lambda^c_b))\tilde{\eta}_p(p^b)f^n_m(S(\Lambda^a_c)),$$

which can be multiplied from the right by $f^m_l(\Lambda^c_d)$ to give

$$\tilde{\eta}_n(S(p^a))=-\tilde{f}^k_n(S(\Lambda^a_b))\tilde{\eta}_k(p^b). \tag{39}$$

A similar computation gives respectively from (25) and (26)

$$f^n_m(p^a)=-f^n_m(\Lambda^a_bS(p^b))=-f^n_k(\Lambda^a_b)f^k_m(S(p^b))-\tilde{\eta}^k(\Lambda^a_b)\tilde{\eta}_k(S(p^b))\delta^n_m \tag{40}$$

and

$$\tilde{f}^n_m(p^a)=-\tilde{f}^k_m(\Lambda^a_b)\tilde{f}^n_k(S(p^b))+\tilde{\eta}^k(\Lambda^c_b)\tilde{\eta}_k(S(p^b))\tilde{f}^n_m(\Lambda^a_c). \tag{41}$$

We are now ready to investigate the different commutation rules of the inhomogeneous Hopf algebra $\mathcal{B}$.

First, due to Proposition (3.1), (29) reduces to

$$\Lambda^n_k(f^k_m\star a)=(a\star f^n_k)\Lambda^k_m \tag{42}$$

for any $a\in\mathcal{A}$ and gives

$$\Lambda^n_mp^a=f^n_k(\Lambda^a_b)p^b\Lambda^k_m+f^n_k(p^a)\Lambda^k_m-\Lambda^n_k\Lambda^a_bf^k_m(p^b)-\Lambda^n_mS(p^l)\Lambda^a_b\tilde{\eta}_l(p^b) \tag{43}$$

for $a=p^a$.

Second, replacing $a\in\mathcal{B}$ by $S(a)$ into (30)–(32) and then acting on both sides S^{-1}, we get, respectively,

$$(a\star f^k_m\circ S\star \tilde{\eta}^l\circ S)+(a\star f^k_m\circ S\star \tilde{f}^l_q\circ S)p^q$$
$$=p^l(a\star f^k_m\circ S)+p^l(a\star f^k_m\circ S\star \tilde{\eta}_q\circ S)p^q+\Lambda^l_p(\tilde{\eta}^p\circ S\star a\star f^k_m\circ S)$$
$$+\Lambda^l_p(\tilde{\eta}^p\circ S\star a\star f^k_m\circ S\star \tilde{\eta}_q\circ S)p^q, \tag{44}$$

$$(a\star f^n_l\circ S\star \tilde{\eta}_k\circ S)\Lambda^k_m=\tilde{\eta}_m\circ S\star a\star f^n_l\circ S+(\tilde{\eta}_m\circ S\star a\star f^n_l\circ S\star \tilde{\eta}_q\circ S)p^q, \tag{45}$$

and

$$(a\star f^k_j\circ S\star \tilde{f}^i_l\circ S)\Lambda^l_m=p^i(a\star f^k_j\circ S\star \tilde{\eta}_l\circ S)\Lambda^l_m+\Lambda^i_l(\tilde{f}^l_m\circ S\star a\star f^k_j\circ S)+\Lambda^i_l(\tilde{f}^l_m\circ S\star a\star f^k_j\circ S\star \tilde{\eta}_q\circ S)p^q. \tag{46}$$

Due to Proposition (3.1), (45) is trivial for $a\in\mathcal{A}$ and, by replacing a by $(a\star f^n_k)\in\mathcal{A}$, the equations (46) and (44) give, respectively,

$$\Lambda^n_k(\tilde{f}^k_m\circ S\star a)=(a\star \tilde{f}^n_k\circ S)\Lambda^k_m \tag{47}$$

and

$$p^n a=(a\star \tilde{f}^n_k\circ S)p^k+a\star \tilde{\eta}^n\circ S-\Lambda^n_k(\tilde{\eta}^k\circ S\star a). \tag{48}$$

For $a=p^a$, the equations (45) and (46) give, respectively,

$$\Lambda^k_m\tilde{\eta}_k(S(p^a))=\tilde{\eta}_m(S(p^b))\Lambda^a_b \tag{49}$$

and

$$\Lambda^n_m p^b(\delta^a_b+\tilde{\eta}_b(S(p^a)))=(\tilde{f}^n_k(S(\Lambda^a_b))-\delta^n_b\tilde{\eta}_k(S(p^a)))p^b\Lambda^k_m+\tilde{f}^n_k(S(p^a))\Lambda^k_m-\Lambda^n_k\Lambda^a_b\tilde{f}^k_m(S(p^b)). \tag{50}$$

To compare (50) with (43), we have to compute the fourth term of the right-hand side of (43), which can be written as

$$-\Lambda^n_m S(p^l)\Lambda^a_c\tilde{\eta}_l(p^c)=\Lambda^n_m S(\Lambda^l_k)p^k\Lambda^a_c\tilde{\eta}_l(p^c)$$
$$=-\Lambda^n_m p^l\tilde{\eta}_l(p^a)+\Lambda^n_m\tilde{\eta}^k(S(\Lambda^a_b))\tilde{\eta}_k(p^b)-\Lambda^n_m\Lambda^a_b\tilde{\eta}^k(S(\Lambda^b_c))\tilde{\eta}_k(p^c), \tag{51}$$

where we have used (39),

$$p^k\Lambda^a_c=\tilde{f}^k_l(S(\Lambda^a_b))\Lambda^b_c p^l+\tilde{\eta}^k(S(\Lambda^a_b))\Lambda^b_c-\Lambda^k_l\Lambda^a_b\tilde{\eta}^l(S(\Lambda^b_c)), \tag{52}$$

obtained from (48) by setting $a=\Lambda^a_c$, and

$$S(\Lambda^k_m)\Lambda^a_c\tilde{\eta}_k(p^c)=\tilde{\eta}_m(p^a), \tag{53}$$

obtained from (21) by setting $a=p^a$ and by using (23) and Proposition (3.1).

Replacing the fourth term of the right-hand side of (43) by (51), we get

$$\Lambda^n_m p^b(\delta^a_b+\tilde{\eta}_b(S(p^a)))=f^n_k(\Lambda^a_b)p^b\Lambda^k_m+(f^n_k(p^a)+\delta^n_k\tilde{\eta}^p(S(\Lambda^a_b))\tilde{\eta}_p(p^b))\Lambda^k_m$$
$$-\Lambda^n_k\Lambda^a_b(f^k_m(p^b)+\delta^k_m\tilde{\eta}^p(S(\Lambda^b_c))\tilde{\eta}_p(p^c)), \tag{54}$$

which can be written, after the make of use of (37), (39), and (40), under the form

$$\Lambda^n_m p^b(\delta^a_b+\tilde{\eta}_b(S(p^a)))=f^n_k(\Lambda^a_c)p^c\Lambda^k_m-f^n_l(\Lambda^a_b)f^l_k(S(p^b))\Lambda^k_m+\Lambda^n_k\Lambda^a_b f^k_l(\Lambda^b_c)f^l_m(S(p^c)). \tag{55}$$

Therefore, by virtue of the condition (5) of the inhomogeneous Hopf algebra definition, we can deduce from (55) and (50) that

$$\tilde{f}^n_k(S(\Lambda^a_b))=f^n_k(\Lambda^a_b)+\delta^n_b\tilde{\eta}_k(S(p^a)) \tag{56}$$

and

$$\tilde{f}^n_k(S(p^a))=-f^n_l(\Lambda^a_b)f^l_k(S(p^b))=f^n_k(p^a)+\delta^n_k\tilde{\eta}^l(S(\Lambda^a_b))\tilde{\eta}_l(p^b), \tag{57}$$

where we have used (40) to get the second relation. Let us note that, for $a=\Lambda^a_b$, the equations (47) and (42) are consistent in virtue of (56) and (49).

Now, multiplying both sides of (55) from the left by $f(S(\Lambda))$, we get

$$p^n\Lambda^k_m=f^k_q(S(\Lambda^n_p))(\delta^p_l+\tilde{\eta}_l(S(p^p)))\Lambda^q_m p^l+f^k_q(S(p^n))\Lambda^q_m-\Lambda^n_q\Lambda^k_p f^p_m(S(p^q)), \tag{58}$$

where we have used (42). Comparing the latter equation with (52), we obtain

$$\tilde{f}^n_l(S(\Lambda^k_q))=f^k_q(S(\Lambda^n_p))(\delta^p_l+\tilde{\eta}_l(S(p^p))) \tag{59}$$

and

$$\tilde{\eta}^n(S(\Lambda^k_q))=f^k_q(S(p^n)). \tag{60}$$

Substituting (56) into (59), we get

$$f^n_l(\Lambda^k_q)+\delta^n_q\tilde{\eta}_l(S(p^k))=f^k_q(S(\Lambda^n_p))(\delta^p_l+\tilde{\eta}^l(S(p^p))), \tag{61}$$

which can be written, after multiplying both sides by $f^m_k(\Lambda^t_n)$, as

$$(f^m_k(\Lambda^t_n)-\delta^m_n\delta^t_k)(f^n_l(\Lambda^k_q)+\delta^n_q\delta^k_l+\delta^n_q\tilde{\eta}_l(S(p^k)))=0 \tag{62}$$

or, using again (56),

$$(\tilde{f}^m_k(S(\Lambda^t_n))-\delta^m_n\delta^t_k-\delta^m_n\tilde{\eta}_k(S(p^t)))(\tilde{f}^n_l(S(\Lambda^k_q))+\delta^n_q\delta^k_l)=0, \tag{63}$$

which are the characteristic equations for the matrices $R^{mt}_{nk}=f^m_k(\Lambda^t_n)$ and $\tilde{R}^{mt}_{nk}=\tilde{f}^m_k(S(\Lambda^t_n))$. To have the commutation rules between the translations, it suffices to replace a by p^a into (44) to get after some straightforward computation

$$\begin{aligned}p^n p^m=&(\tilde{f}^n_k(S(\Lambda^m_l))-\delta^n_l\tilde{\eta}_k(S(p^m)))p^l p^k+\tilde{\eta}^n(S(\Lambda^m_k))p^k+\tilde{f}^n_k(S(p^m))p^k\\&+\tilde{\eta}^n(S(p^m))-\Lambda^n_k\Lambda^m_l\tilde{\eta}^k(S(p^l))\\=&f^n_k(\Lambda^m_l)p^l p^k-(f^n_k(\Lambda^m_l)-\delta^n_l\delta^m_k)\tilde{\eta}^l(S(\Lambda^k_p))p^p\\&+\tilde{\eta}^n(S(p^m))-\Lambda^n_k\Lambda^m_l\tilde{\eta}^k(S(p^l)),\end{aligned} \tag{64}$$

where we have used (56), (57), and (60). With the assumption (23), we have the following from the previous considerations.

Theorem (3.1): Let $\mathcal{B}$ an inhomogeneous Hopf algebra satisfying conditions (1)–(5) on which there exists a bicovariant differential calculus. Then there exist functionals f^n_m, $\tilde{f}^n_m$, $\tilde{\eta}^n$, and $\tilde{\eta}_m\in\mathcal{B}'$ satisfying (24), (25)–(28), (33), (56), (57), (59), and (60) such that the relations (42), (48), and (64) are satisfied.

IV. CONSISTENCY CONDITIONS

Here we shall continue the study of the consistency conditions between the different functionals and the commutation rules of the generators of $\mathcal{G}$. In the following we set $R^{kn}_{ml}=f^k_l(\Lambda^n_m)$, $\widetilde{R}^{kn}_{ml}=\widetilde{f}^k_l(S(\Lambda^n_m))$, $Q^n_k=\widetilde{\eta}_k(S(p^n))$, $Z^{nm}_k=\widetilde{\eta}^n(S(\Lambda^m_k)=f^m_k(S(p^n))$ [see (60)], $\widetilde{Z}^{nm}_k=\widetilde{f}^n_k(S(p^m))=-R^{nm}_{pq}Z^{pq}_k$ [see (57)], and $T^{nm}=\widetilde{\eta}^n(S(p^m))$. We start this study as follows.

Lemma (4.1):

$$Q^n_m=\lambda\,\delta^n_m,\quad \lambda\in\mathcal{C},\quad \lambda\neq-1. \tag{65}$$

Proof: Applying f^a_b and $\widetilde{f}^a_b\circ S$ on both sides of (49), we obtain respectively $(I\otimes Q)R=R(Q\otimes I)$ and $(I\otimes Q)\widetilde{R}=\widetilde{R}(Q\otimes I)$, implying, due to (56) $(\widetilde{R}=R+I\otimes Q)$, $I\otimes Q^2=Q\otimes Q$ which solution is of the form (65). For $\lambda=-1$, we see from (62) that the R-matrix is not invertible. Q.E.D.

Applying f^a_b on both sides of (42) and $\widetilde{f}^a_b\circ S$ on both sides of (47) for $a=\Lambda^p_q$ and using (34) and (35), we get the Yang–Baxter equations for the matrices R,

$$(I\otimes R)(R\otimes I)(I\otimes R)=(R\otimes I)(I\otimes R)(R\otimes I), \tag{66}$$

and $\widetilde{R}$,

$$(I\otimes\widetilde{R})(\widetilde{R}\otimes I)(I\otimes\widetilde{R})=(\widetilde{R}\otimes I)(I\otimes\widetilde{R})(\widetilde{R}\otimes I). \tag{67}$$

Since the $\widetilde{R}$-matrix is tied to the R-matrix by (56), it is necessary to check the consistency between both Yang–Baxter equations. Applying f^a_b on both sides of (47) and $\widetilde{f}^a_b\circ S$ on both sides of (42) for $a=\Lambda^p_q$, we obtain

$$(R\otimes I)(I\otimes R)(\widetilde{R}\otimes I)=(I\otimes\widetilde{R})(R\otimes I)(I\otimes R) \tag{68}$$

and

$$(\widetilde{R}\otimes I)(I\otimes\widetilde{R})(R\otimes I)=(I\otimes R)(\widetilde{R}\otimes I)(I\otimes\widetilde{R}). \tag{69}$$

Replacing (56) on both sides of (68) and (69) and using (66), we obtain, respectively,

$$(R\otimes I)(I\otimes R)(I\otimes Q\otimes I)=(I\otimes I\otimes Q)(R\otimes I)(I\otimes R),$$

and

$$\begin{aligned}&(R\otimes I)(I\otimes I\otimes Q)(R\otimes I)+(I\otimes Q\otimes I)(I\otimes R)(R\otimes I)+(I\otimes Q\otimes I)(I\otimes I\otimes Q)(R\otimes I)\\&\quad=(I\otimes R)(R\otimes I)(I\otimes I\otimes Q)+(I\otimes R)(I\otimes Q\otimes I)(I\otimes R)+(I\otimes R)(I\otimes Q\otimes I)(I\otimes I\otimes Q).\end{aligned}$$

By virtue of (65) the first equation is satisfied and, using (62) $[R^2=-R(I\otimes Q)+I\otimes I+I\otimes Q]$, we can see that the second equation is also satisfied. Now, replacing the third factor of the left-hand side and the first factor of the right-hand side of (67) by (56) and using (69), we get

$$(\widetilde{R}\otimes I)(I\otimes\widetilde{R})(I\otimes Q\otimes I)=(I\otimes I\otimes Q)(\widetilde{R}\otimes I)(I\otimes\widetilde{R}),$$

which is satisfied in virtue of (65). Therefore (66)–(69) are equivalent. The action of $\widetilde{\eta}^a\circ S$ on both sides of (49) gives

$$ZQ=(I\otimes Q)Z, \tag{70}$$

and on (42) and (47) gives, for $a=\Lambda^p_q$,

$$(Z\otimes I)R+(\widetilde{R}\otimes I)(I\otimes Z)R=(I\otimes R)(Z\otimes I)+(I\otimes R)(\widetilde{R}\otimes I)(I\otimes Z) \tag{71}$$

and

$$(Z\otimes I)\tilde{R}+(\tilde{R}\otimes I)(I\otimes Z)\tilde{R}=(I\otimes\tilde{R})(Z\otimes I)+(I\otimes\tilde{R})(\tilde{R}\otimes I)(I\otimes Z), \qquad (72)$$

where we have used (36). Due to (65), the equation (70) is satisfied and if we use (56) in (72) and compare with (71), we obtain

$$(Z\otimes I)(I\otimes Q)+(\tilde{R}\otimes I)(I\otimes Z)(I\otimes Q)=(I\otimes I\otimes Q)(Z\otimes I)+(I\otimes I\otimes Q)(\tilde{R}\otimes I)(I\otimes Z),$$

which is satisfied by virtue of (65) or (70). Therefore, the relation (71) implies (72).

We pass now to the action of the different functionals on the commutation rules between the generators of $\mathcal{A}$ and the translations. Applying $\tilde{\eta}_a\circ S$ on both sides of (52) and using the relations

$$\tilde{\eta}_a(aS(p^n))=\tilde{f}_a^b(a)\,\tilde{\eta}_b(S(p^n))$$

and

$$\tilde{\eta}_a(S(p^n)a)=\tilde{\eta}_a(S(p^n))\varepsilon(a)$$

obtained from (27) for any $a\in\mathcal{A}$, we get $(Q\otimes I)\tilde{R}=\tilde{R}(I\otimes Q)$, which is satisfied due to (65). Applying $f_b^a\circ S$ and $\tilde{f}_b^a\circ S$ on both sides of (52), we get, respectively,

$$\begin{aligned}&(I\otimes R^{-1})(Z\otimes I)+(I\otimes R^{-1})(R^{-1}\otimes I)(I\otimes Q\otimes I)(I\otimes Z)\\&\quad=(\tilde{R}\otimes I)(I\otimes Z)R^{-1}+(Z\otimes I)R^{-1}-(I\otimes R^{-1})(R^{-1}\otimes I)(I\otimes Z)\end{aligned} \qquad (73)$$

and

$$\begin{aligned}&(\tilde{Z}\otimes I)\tilde{R}-(I\otimes Z)\tilde{R}-(I\otimes Q\otimes I)(I\otimes Z)\tilde{R}\\&\quad=(I\otimes\tilde{R})(\tilde{R}\otimes I)(I\otimes\tilde{Z})+(I\otimes\tilde{R})(I\otimes I\otimes Q)(Z\otimes I)-(\tilde{R}\otimes I)(I\otimes\tilde{R})(Z\otimes I),\end{aligned} \qquad (74)$$

where we have used (25) to have the first equation and

$$\tilde{f}_b^a(S(p^n)a)=\tilde{f}_b^c(S(p^n))\tilde{f}_c^a(a)+\tilde{\eta}_b(S(p^n))\,\tilde{\eta}^a(a)$$

and

$$\tilde{f}_b^a(aS(p^n))=\tilde{f}_b^c(a)\tilde{f}_c^a(S(p^n))-\tilde{f}_b^a(a_{(1)})\,\tilde{\eta}^d(a_{(2)})\,\tilde{\eta}_d(S(p^n)),$$

obtained from (26) for any $a\in\mathcal{A}$, to have the second equation. Multiplying both sides of (71) from the left by $I\otimes R^{-1}$ and from the right by R^{-1} and using (59) $[\tilde{R}=R^{-1}+R^{-1}(I\otimes Q)]$, we retrieve the equation (73). To investigate the equation (74), we have to multiply both sides of (72) from the left by $-(R\otimes I)$ to get

$$(\tilde{Z}\otimes I)\tilde{R}-(I\otimes Z)\tilde{R}-(I\otimes Q\otimes I)(I\otimes Z)\tilde{R}=-(R\otimes I)(I\otimes\tilde{R})(Z\otimes I)-(R\otimes I)(I\otimes\tilde{R})(\tilde{R}\otimes I)(I\otimes Z),$$

where we have used $\tilde{Z}=-RZ$ and $R\tilde{R}=I\otimes I+I\otimes Q$. Replacing R by $\tilde{R}-I\otimes Q$ on the right-hand side and using (67) and again $\tilde{Z}=-RZ$, we retrieve (74). Therefore, (71) implies (73) and (74).

Finally the action of $\tilde{\eta}^a\circ S$ on both sides of (52) gives

$$(R\otimes I-I\otimes I\otimes I)((I\otimes Z)Z-(Z\otimes I)Z)+T\otimes I-(I\otimes\tilde{R})(\tilde{R}\otimes I)(I\otimes T)=0, \qquad (75)$$

where we have used the relations

$$\tilde{\eta}^a(S(ap^n))=\tilde{\eta}^b(S(p^n))\tilde{f}_b^a(S(a))$$

and

$$\tilde{\eta}^a(S(p^n a))=\varepsilon(S(a))\tilde{\eta}^a(S(p^n))+\tilde{\eta}^b(S(a))\tilde{f}^a_b(S(p^n))-\tilde{\eta}^a(S(a_{(2)}))\tilde{\eta}^b(S(a_{(1)}))\tilde{\eta}_b(S(p^n))$$

obtained from (28) for any $a\in\mathcal{A}$.

We consider now the commutation rules between the translations. From

$$\tilde{\eta}_a(S(p^m)S(p^n))=\tilde{f}^b_a(S(p^m))\tilde{\eta}_b(S(p^n))-\tilde{\eta}_a(S(p^k))\tilde{\eta}^b(S(\Lambda^m_k))\tilde{\eta}_b(S(p^n)),$$

obtained from (27), we can see that the action of $\tilde{\eta}_a\circ S$ on both sides of (64) gives

$$(R-I\otimes I)((Q\otimes I)\tilde{Z}-(Q\otimes I)ZQ-ZQ)=0.$$

From (65) and $\tilde{Z}=-RZ$ we can rewrite the left-hand side of this equation as $-(R-I\otimes I)(R+I\otimes I+I\otimes Q)ZQ$, which vanishes by virtue of (62). Applying $f^a_b\circ S$, $\tilde{f}^a_b\circ S$, and $\tilde{\eta}^a\circ S$ on both sides of (64), we get, respectively,

$$\begin{aligned}(R\otimes I-I\otimes I\otimes I)((I\otimes Z)Z-(Z\otimes I)Z+(I\otimes R^{-1})(R^{-1}\otimes I)(I\otimes Q\otimes I)(I\otimes T))\\ +(T\otimes I)-(I\otimes R^{-1})(R^{-1}\otimes I)(I\otimes T)=0,\end{aligned}\tag{76}$$

$$\begin{aligned}(I\otimes R-I\otimes I\otimes I)((\tilde{Z}\otimes I)\tilde{Z}+(T\otimes I)Q-(I\otimes Q\otimes I)(I\otimes Z)\tilde{Z}-(I\otimes Q\otimes I)(I\otimes T)\\ -(I\otimes Z)\tilde{Z})+(I\otimes T)-(\tilde{R}\otimes I)(I\otimes\tilde{R})(T\otimes I)=0,\end{aligned}\tag{77}$$

and

$$(I\otimes R-I\otimes I\otimes I)((\tilde{Z}\otimes I)T-(I\otimes\tilde{Z})T)-(Z\otimes I)T-(\tilde{R}\otimes I)(I\otimes Z)T=0,\tag{78}$$

where we have used (25) to have (76),

$$\begin{aligned}\tilde{f}^a_b(S(p^m)S(p^n))=\tilde{f}^c_b(S(p^m))\tilde{f}^a_c(S(p^n))+\tilde{\eta}_b(S(p^m))\tilde{\eta}^a(S(p^n))\\ -\tilde{f}^a_b(S(p^k))\tilde{\eta}^c(S(\Lambda^m_k))\tilde{\eta}_c(S(p^n))-\delta^a_b\tilde{\eta}^c(S(p^m))\tilde{\eta}_c(S(p^n))\end{aligned}$$

obtained from (26) to have (77), and

$$\tilde{\eta}^a(S(p^m)S(p^n))=\tilde{\eta}^b(S(p^m))\tilde{f}^a_b(S(p^n))-\tilde{\eta}^a(S(p^k))\tilde{\eta}^b(S(\Lambda^m_k))\tilde{\eta}_b(S(p^n))$$

obtained from (28) to have (78). The consistency of (75)–(78) requires the following.

Lemma (4.2): The relations (75)–(78) are consistent if

$$T=-\tilde{R}T,\quad \lambda\neq 0,\quad -2.\tag{79}$$

Proof: Multiplying both sides of (75) and (76) from the left by $(\tilde{R}\otimes I+I\otimes I\otimes I)$ and both sides of (77) and (78) from the left by $(I\otimes\tilde{R}+I\otimes I\otimes I)$ and using the relation $(\tilde{R}+I\otimes I)(R-I\otimes I)=0$, we obtain the following consistency conditions:

$$(\tilde{R}\otimes I+I\otimes I\otimes I)(T\otimes I-(I\otimes\tilde{R})(\tilde{R}\otimes I)(I\otimes T))=0,\tag{80}$$

$$(\tilde{R}\otimes I+I\otimes I\otimes I)(T\otimes I-(I\otimes R^{-1})(R^{-1}\otimes I)(I\otimes T))=0,\tag{81}$$

$$(I\otimes\tilde{R}+I\otimes I\otimes I)(I\otimes T-(\tilde{R}\otimes I)(I\otimes\tilde{R})(T\otimes I))=0,\tag{82}$$

and

$$(I\otimes\tilde{R}+I\otimes I\otimes I)((Z\otimes I)T+(\tilde{R}\otimes I)(I\otimes Z)T)=0. \tag{83}$$

From (80) and (81), it follows

$$(\tilde{R}\otimes I+I\otimes I\otimes I)((I\otimes\tilde{R})(\tilde{R}\otimes I)(I\otimes T))-(I\otimes R^{-1})(R^{-1}\otimes I)(I\otimes T))=0, \tag{84}$$

and from (67) and $(I\otimes R^{-1})(R^{-1}\otimes I)(I\otimes\tilde{R})=(\tilde{R}\otimes I)(I\otimes R^{-1})(R^{-1}\otimes I)$ obtained by multiplying both sides of (68) from the left and from the right by $(I\otimes R^{-1})(R^{-1}\otimes I)$, we can rewrite (84) as

$$((I\otimes\tilde{R})(\tilde{R}\otimes I)-(I\otimes R^{-1})(R^{-1}\otimes I))(I\otimes(\tilde{R}T+T))=0.$$

Multiplying it by $(R\otimes I)(I\otimes R)$ and using $R\tilde{R}=I\otimes I+I\otimes Q$, we obtain $(I\otimes I\otimes Q(2+Q))(I\otimes(\tilde{R}T+T))=0$, which is equivalent, by virtue of (65), to $\lambda(2+\lambda)(\tilde{R}+I\otimes I)T=0$ leading to (79) for $\lambda\neq 0$ or -2. From (79) and (67) we may see that the equation (82) is satisfied and it is also easy to see that the equation (83) is obtained by multiplying both sides of (72) from the right by T and by using (79). Q.E.D.

Remark (4.1): Note that for $\lambda=-2$ the characteristic equation (62) reduces to $(R-I\otimes I)^2=0$ showing that R does not possess negative eigenvalues and, therefore, in this case, we cannot construct from it antisymmetric products. [In the following we shall assume the relation (79) for $\lambda=-2$.]

Remark (4.2): For the case $\lambda=0$ we have $\tilde{R}=R=R^{-1}$ from which we see that the relations (80) and (81) are identical and cannot imply (79). However, by multiplying both sides of (64) by $\tilde{R}+I\otimes I$ and by using (62) we can deduce in this case the following consistency condition,

$$C^{nm}-\Lambda^n_k\Lambda^m_l C^{kl}=0, \tag{85}$$

where we have used (47) for $a=\Lambda$ and $C^{nm}=(\tilde{R}^{nm}_{kl}+\delta^n_k\delta^m_l)$. In fact, by applying $f^a_b\circ S$ and $\tilde{f}^a_b$ on both sides of (85), we get, respectively,

$$(\tilde{R}\otimes I+I\otimes I\otimes I)(T\otimes I)-(I\otimes R^{-1})(R^{-1}\otimes I)(I\otimes\tilde{R}+I\otimes I\otimes I)(I\otimes T)=0$$

and

$$(I\otimes\tilde{R}+I\otimes I\otimes I)(I\otimes T)-(\tilde{R}\otimes I)(I\otimes\tilde{R})(\tilde{R}\otimes I+I\otimes I\otimes I)(T\otimes I)=0,$$

which are identical to the relations (81) and (82) by virtue of (67). To get the relation (83), we apply $\tilde{\eta}^a\circ S$ on both sides of (85) to have

$$(Z\otimes I)(\tilde{R}+I\otimes I)T+(\tilde{R}\otimes I)(I\otimes Z)(\tilde{R}+I\otimes I)T=0,$$

where we have used (24) and (36). By virtue of (72) we can see that this relation is equivalent to (83). Therefore, for $\lambda=0$ the consistency condition is not $RT=-T$ as assumed in remark (3.11) of Ref. 9 but (85).

Comparing now (75) with (76), we obtain

$$(R\otimes I-I\otimes I\otimes I)(I\otimes R^{-1})(R^{-1}\otimes I)(I\otimes Q\otimes I)(I\otimes T)-(I\otimes R^{-1})(R^{-1}\otimes I)(I\otimes T)$$
$$=-(I\otimes\tilde{R})(\tilde{R}\otimes I)(I\otimes T). \tag{86}$$

Replacing R by $\tilde{R}-I\otimes Q$ and using $(\tilde{R}\otimes I)(I\otimes R^{-1})(R^{-1}\otimes I)=(I\otimes R^{-1})(R^{-1}\otimes I)(I\otimes\tilde{R})$, (65) and (79), we can write the left-hand side as

$$-(I\otimes R^{-1})(R^{-1}\otimes I)(I\otimes I\otimes I+I\otimes I\otimes Q+I\otimes Q\otimes I+I\otimes I\otimes Q^2)(I\otimes T),$$

which can be identified as the right-hand side of (86) by using (59) and (65). Therefore, (75) is equivalent to (76).

Remark (4.3): For $\lambda=0$ the relations (75) and (76) are identical, but for $\lambda=-2$ we must assume the relation (79) to have the equivalency between (75) and (76).

To investigate the equation (77), we multiply both sides of (71) from the left by $(R\otimes I)$ and from the right by Z to obtain

$$(\tilde{Z}\otimes I)\tilde{Z}+(I\otimes\tilde{R})(I\otimes\tilde{Z})\tilde{Z}=(R\otimes I)(I\otimes R)(Z\otimes I)Z+(R\otimes I)(I\otimes R)(\tilde{R}\otimes I)(I\otimes Z)Z,$$

where we have used $\tilde{Z}=-RZ$ and $R\tilde{R}=I\otimes I+I\otimes Q=\tilde{R}R=I\otimes I+Q\otimes I$ [due to (62) and (65)]. Now, multiplying both sides from the left by $I\otimes R-I\otimes I\otimes I$, we obtain

$$\begin{aligned}&(I\otimes R-I\otimes I\otimes I)((\tilde{Z}\otimes I)\tilde{Z}-(I\otimes\tilde{Z})\tilde{Z})\\&\quad=(I\otimes R-I\otimes I\otimes I)(R\otimes I)(I\otimes R)((Z\otimes I)Z+(\tilde{R}\otimes I)(I\otimes Z)Z),\end{aligned}$$

where we have used (68) and $(R-I\otimes I)\tilde{R}=-(R-I\otimes I)$. Taking into account this equation, (77) can be written as

$$\begin{aligned}&(I\otimes R-I\otimes I\otimes I)((R\otimes I)(I\otimes R)((Z\otimes I)Z+(\tilde{R}\otimes I)(I\otimes Z)Z)+(I\otimes I\otimes Q)(T\otimes I)\\&\quad-(I\otimes Q\otimes I)(I\otimes T))+I\otimes T-(\tilde{R}\otimes I)(I\otimes\tilde{R})(T\otimes I)=0.\end{aligned}$$

Multiplying both sides from the left by $-(I\otimes R^{-1})(R^{-1}\otimes I)$ and using $(I\otimes R^{-1})(R^{-1}\otimes I)(I\otimes R)=(R\otimes I)(I\otimes R^{-1})(R^{-1}\otimes I)$, we obtain

$$\begin{aligned}&(R\otimes I-I\otimes I\otimes I)((I\otimes Z)Z-(Z\otimes I)Z-(I\otimes R^{-1})(R^{-1}\otimes I)(I\otimes I\otimes Q)(T\otimes I)+(I\otimes R^{-1})(R^{-1}\otimes I)\\&\quad\times(I\otimes Q\otimes I)(I\otimes T))-(I\otimes R^{-1})(R^{-1}\otimes I)(I\otimes T)+(I\otimes R^{-1})(R^{-1}\otimes I)(\tilde{R}\otimes I)(I\otimes\tilde{R})(T\otimes I)\\&\quad=0=-(R\otimes I-I\otimes I\otimes I)(I\otimes R^{-1})(R^{-1}\otimes I)(I\otimes I\otimes Q)(T\otimes I)-T\otimes I\\&\qquad+(I\otimes R^{-1})(R^{-1}\otimes I)(\tilde{R}\otimes I)(I\otimes\tilde{R})(T\otimes I),\end{aligned}$$

where we have used (76) to have the right-hand side which gives, by using (56) into the third factor of the last term,

$$\begin{aligned}&-(R\otimes I-I\otimes I\otimes I)(I\otimes R^{-1})(R^{-1}\otimes I)(I\otimes I\otimes Q)(T\otimes I)+(I\otimes R^{-1})(I\otimes I\otimes Q)(T\otimes I)\\&\quad+(I\otimes R^{-1})(R^{-1}\otimes I)(I\otimes\tilde{R})(I\otimes I\otimes Q)(T\otimes I)=0.\end{aligned}$$

For $\lambda=0$ this relation is trivial, and for $\lambda\neq 0$ we use (79) and (59) into the second term and (56) into the third term to obtain

$$\begin{aligned}&-(R\otimes I-I\otimes I\otimes I)(I\otimes R^{-1})(R^{-1}\otimes I)(I\otimes I\otimes Q)(T\otimes I)-(I\otimes R^{-1})(R^{-1}\otimes I)(I\otimes I\otimes Q)(T\otimes I)\\&\quad+(I\otimes R^{-1})(R^{-1}\otimes I)(I\otimes R)(I\otimes I\otimes Q)(T\otimes I)=0,\end{aligned}$$

which is satisfied by virtue of $(I\otimes R^{-1})(R^{-1}\otimes I)(I\otimes R)=(R\otimes I)(I\otimes R^{-1})(R^{-1}\otimes I)$. Therefore, (77) is also equivalent to (75) and (76).

Now, we consider the consistency of the commutation rules (64) and the braiding properties of the product of three generators of $\mathcal{B}$. After the insertion of (64) into the first term of the right-hand side of (64) itself, we get

$$\begin{aligned}p\mathsf{T}p&=R^2(p\mathsf{T}p)-(R+I\otimes I)(R-I\otimes I)Zp+(R+I\otimes I)T-(\Lambda\mathsf{T}\Lambda)(R+I\otimes I)T\\&=p\mathsf{T}p-(I\otimes Q)((R-I\otimes I)((p\mathsf{T}p)-Zp)+T-(\Lambda\mathsf{T}\Lambda)T),\end{aligned}$$

where we have used into the first right-hand side (42) for $a=\Lambda$ to have the last term and (62), (56), and (79) to have the second right-hand side. We observe from (64) that the second term of the second right-hand side vanishes, implying the consistency of these commutation rules. For the product of three translations, we have

$$\begin{aligned} p\mathsf{T}p\mathsf{T}p &= (p\mathsf{T}p)\mathsf{T}p \\ &= (R\otimes I)(p\mathsf{T}(p\mathsf{T}p)) + r\mathsf{T}p \\ &= (R\otimes I)((I\otimes R)((p\mathsf{T}p)\mathsf{T}p) + p\mathsf{T}r) + r\mathsf{T}p \\ &= (R\otimes I)(I\otimes R)(R\otimes I)(p\mathsf{T}p\mathsf{T}p) + (R\otimes I)(I\otimes R)(r\mathsf{T}p) + (R\otimes I)(p\mathsf{T}r) + r\mathsf{T}p, \end{aligned}$$

where $r=-(R-I\otimes I)Zp+T-(\Lambda\mathsf{T}\Lambda)T$. On the other hand,

$$\begin{aligned} p\mathsf{T}p\mathsf{T}p = p\mathsf{T}(p\mathsf{T}p) &= (I\otimes R)((p\mathsf{T}p)\mathsf{T}p) + p\mathsf{T}r \\ &= (I\otimes R)((R\otimes I)(p\mathsf{T}(p\mathsf{T}p)) + r\mathsf{T}p) + p\mathsf{T}r \\ &= (I\otimes R)(R\otimes I)(I\otimes R)(p\mathsf{T}p\mathsf{T}p) + (I\otimes R)(R\otimes I)(p\mathsf{T}r) \\ &\quad + (I\otimes R)(r\mathsf{T}p) + p\mathsf{T}r. \end{aligned}$$

The Yang–Baxter equation (66) implies

$$A(r\mathsf{T}p) = B(p\mathsf{T}r), \tag{87}$$

where

$$A = (R\otimes I)(I\otimes R) - I\otimes R + I\otimes I\otimes I,$$

$$B = (I\otimes R)(R\otimes I) - R\otimes I + I\otimes I\otimes I.$$

Replacing on both sides of (87) r by $-(R-I\otimes I)Zp+T-(\Lambda\mathsf{T}\Lambda)T$, we obtain

$$\begin{aligned} &-A(R\otimes I - I\otimes I\otimes I)(Z\otimes I)(p\mathsf{T}p) + A(T\otimes I)p - A(\Lambda\mathsf{T}\Lambda\mathsf{T}p)T \\ &\quad = -B(I\otimes R - I\otimes I\otimes I)(I\otimes Z)(p\mathsf{T}p) + B(I\otimes T)p - B(p\mathsf{T}\Lambda\mathsf{T}\Lambda)T. \end{aligned} \tag{88}$$

Using (52) $[p\mathsf{T}\Lambda = \tilde{R}(\Lambda\mathsf{T}p) + Z\Lambda - (\Lambda\mathsf{T}\Lambda)Z]$, we can rewrite the third term of the right-hand side of (88) as

$$\begin{aligned} B(p\mathsf{T}\Lambda\mathsf{T}\Lambda)T &= B(\tilde{R}\otimes I)(\Lambda\mathsf{T}p\mathsf{T}\Lambda)T + B(Z\otimes I)(\Lambda\mathsf{T}\Lambda)T - B(\Lambda\mathsf{T}\Lambda\mathsf{T}\Lambda)T \\ &= B(\tilde{R}\otimes I)(I\otimes\tilde{R})(\Lambda\mathsf{T}\Lambda\mathsf{T}p)T + B(\tilde{R}\otimes I)(I\otimes Z)(\Lambda\mathsf{T}\Lambda)T \\ &\quad - B(\tilde{R}\otimes I)(\Lambda\mathsf{T}\Lambda\mathsf{T}\Lambda)(I\otimes Z)T + B(Z\otimes I)(\Lambda\mathsf{T}\Lambda)T - B(\Lambda\mathsf{T}\Lambda\mathsf{T}\Lambda)(Z\otimes I)T. \end{aligned} \tag{89}$$

A straightforward computation shows that

$$B(\tilde{R}\otimes I)(I\otimes\tilde{R}) = A + (I\otimes I\otimes Q)(\tilde{R}\otimes I + I\otimes I\otimes I), \tag{90}$$

where we have used $R\tilde{R} = I\otimes I + I\otimes Q$ and (56). Multiplying both sides of (90) from the right by $(\Lambda\mathsf{T}\Lambda\mathsf{T}p)T$ and using (47) for $a=\Lambda$ and (79), we get

$$A(\Lambda\mathsf{T}\Lambda\mathsf{T}p)T = B(\tilde{R}\otimes I)(I\otimes\tilde{R})(\Lambda\mathsf{T}\Lambda\mathsf{T}p)T.$$

We see from (90) that for $\lambda=0$ this relation is satisfied without using (79). On the other hand, by using (42) and (47) for $a=\Lambda$, we can rewrite the third and the fifth terms of the right-hand side of (89) as

$$(\Lambda\top\Lambda\top\Lambda)B(Z\otimes I+(\tilde{R}\otimes I)(I\otimes Z))T.$$

Using $\tilde{Z}=-RZ$, $R\tilde{R}=\tilde{R}R=I\otimes I+I\otimes Q$, and (56) we get

$$B(Z\otimes I+(\tilde{R}\otimes I)(I\otimes Z)T=-(I\otimes R-I\otimes I\otimes I)(\tilde{Z}\otimes I-I\otimes\tilde{Z})T+(Z\otimes I)T+(\tilde{R}\otimes I)(I\otimes Z)T, \tag{91}$$

which vanishes by virtue of (78). Therefore (88) reduces to

$$\begin{aligned}&-A(R\otimes I-I\otimes I\otimes I)(Z\otimes I)(p\top p)+A(T\otimes I)p\\&\quad=-B(I\otimes R-I\otimes I\otimes I)(I\otimes Z)(p\top p)+B(I\otimes T)p-B(Z\otimes I+(\tilde{R}\otimes I)(I\otimes Z))(\Lambda\top\Lambda)T.\end{aligned} \tag{92}$$

Using now

$$A(R\otimes I-I\otimes I\otimes I)=B(I\otimes R-I\otimes I\otimes I)=\Lambda_3,$$

we may rewrite (92) as

$$\Lambda_3(Z\otimes I-I\otimes Z)(p\top p)-A(T\otimes I)p+B(I\otimes T)p-B(Z\otimes I+(\tilde{R}\otimes I)(I\otimes Z))(\Lambda\top\Lambda)T=0. \tag{93}$$

From the properties of Λ_3 and $(R-I\otimes I)\tilde{R}=-(R-I\otimes I)$, we have

$$\begin{aligned}\Lambda_3(Z\otimes I-I\otimes Z)(p\top p)&=\Lambda_3(Z\otimes I+(\tilde{R}\otimes I)(I\otimes Z))(p\top p)\\&=B(I\otimes R)(Z\otimes I+(\tilde{R}\otimes I)(I\otimes Z))(p\top p)-B(Z\otimes I+(\tilde{R}\otimes I)(I\otimes Z))(p\top p).\end{aligned}$$

Using (64) in the second term of the right-hand side, we obtain

$$\begin{aligned}&B(I\otimes R)(Z\otimes I+(\tilde{R}\otimes I)(I\otimes Z))(p\top p)-B(Z\otimes I+(\tilde{R}\otimes I)(I\otimes Z))R(p\top p)\\&\quad+B(Z\otimes I+(\tilde{R}\otimes I)(I\otimes Z))(R-I\otimes I)Zp-B(Z\otimes I+(\tilde{R}\otimes I)(I\otimes Z))T\\&\quad+B(Z\otimes I+(\tilde{R}\otimes I)(I\otimes Z))(\Lambda\top\Lambda)T.\end{aligned}$$

The first and the second terms vanish by virtue of (71) and the fourth term vanishes by virtue of (91). Therefore, (93) reduces to

$$+B(Z\otimes I+(\tilde{R}\otimes I)(I\otimes Z))(R-I\otimes I)Zp-A(T\otimes I)p+B(I\otimes T)p,$$

which can be written, after making of use of (71), as

$$\begin{aligned}&+B(I\otimes R-I\otimes I\otimes I)(Z\otimes I+(\tilde{R}\otimes I)(I\otimes Z))Zp-A(T\otimes I)p+B(I\otimes T)p\\&\quad=\Lambda_3(Z\otimes I+(\tilde{R}\otimes I)(I\otimes Z))Zp-A(T\otimes I)p+B(I\otimes T)p\\&\quad=A(R\otimes I-I\otimes I\otimes I)((Z\otimes I)Z-(I\otimes Z)Z)p-A(T\otimes I)p+B(I\otimes T)p,\end{aligned}$$

which reduces, due to (75), to

$$-A(I\otimes\tilde{R})(\tilde{R}\otimes I)(I\otimes T)p+B(I\otimes T)p,$$

which vanishes according to the same calculation of (90).

The same procedure is applied to $p\mathsf{T}p\mathsf{T}\Lambda$ to have

$$
\begin{aligned}
p\mathsf{T}p\mathsf{T}\Lambda = p\mathsf{T}(p\mathsf{T}\Lambda) = {} & (I\otimes\tilde{R})((p\mathsf{T}\Lambda)\mathsf{T}p) + (I\otimes Z)(p\mathsf{T}\Lambda) - ((p\mathsf{T}\Lambda)\mathsf{T}\Lambda)Z \\
= {} & (I\otimes\tilde{R})(\tilde{R}\otimes I)(\Lambda\mathsf{T}(p\mathsf{T}p)) + (I\otimes\tilde{R})(Z\otimes I)(\Lambda\mathsf{T}p) - (I\otimes\tilde{R})(\Lambda\mathsf{T}\Lambda\mathsf{T}p)Z \\
& + (I\otimes Z)\tilde{R}(\Lambda\mathsf{T}p) + (I\otimes Z)Z\Lambda - (I\otimes Z)(\Lambda\mathsf{T}\Lambda)Z - (\tilde{R}\otimes I)(\Lambda\mathsf{T}(p\mathsf{T}\Lambda))Z \\
& - (Z\otimes I)(\Lambda\mathsf{T}\Lambda)Z + (\Lambda\mathsf{T}\Lambda\mathsf{T}\Lambda)(Z\otimes I)Z \\
= {} & (I\otimes\tilde{R})(\tilde{R}\otimes I)(I\otimes R)(\Lambda\mathsf{T}p\mathsf{T}p) - (I\otimes\tilde{R})(\tilde{R}\otimes I)(I\otimes R - I\otimes I\otimes I)(I\otimes Z) \\
& \times(\Lambda\mathsf{T}p) + (I\otimes\tilde{R})(\tilde{R}\otimes I)(I\otimes T)\Lambda - (I\otimes\tilde{R})(\tilde{R}\otimes I)(\Lambda\mathsf{T}\Lambda\mathsf{T}\Lambda)(I\otimes T) \\
& + (I\otimes\tilde{R})(Z\otimes I)(\Lambda\mathsf{T}p) - (I\otimes\tilde{R})(\Lambda\mathsf{T}\Lambda\mathsf{T}p)Z + (I\otimes Z)\tilde{R}(\Lambda\mathsf{T}p) \\
& + (I\otimes Z)Z\Lambda - (I\otimes Z)(\Lambda\mathsf{T}\Lambda)Z - (\tilde{R}\otimes I)(I\otimes\tilde{R})(\Lambda\mathsf{T}\Lambda\mathsf{T}p)Z - (\tilde{R}\otimes I) \\
& \times(I\otimes Z)(\Lambda\mathsf{T}\Lambda)Z + (\tilde{R}\otimes I)(\Lambda\mathsf{T}\Lambda\mathsf{T}\Lambda)(I\otimes Z)Z - (Z\otimes I)(\Lambda\mathsf{T}\Lambda)Z \\
& + (\Lambda\mathsf{T}\Lambda\mathsf{T}\Lambda)(Z\otimes I)Z.
\end{aligned}
$$

On the other hand,

$$
\begin{aligned}
p\mathsf{T}p\mathsf{T}\Lambda = (p\mathsf{T}p)\mathsf{T}\Lambda = {} & (R\otimes I)(p\mathsf{T}(p\mathsf{T}\Lambda)) - (R\otimes I - I\otimes I\otimes I)(Z\otimes I)(p\mathsf{T}\Lambda) \\
& + (T\otimes I)\Lambda - (\Lambda\mathsf{T}\Lambda\mathsf{T}\Lambda)(T\otimes I) \\
= {} & (R\otimes I)(I\otimes\tilde{R})((p\mathsf{T}\Lambda)\mathsf{T}p) + (R\otimes I)(I\otimes Z)(P\mathsf{T}\Lambda) - (R\otimes I) \\
& \times((p\mathsf{T}\Lambda)\mathsf{T}\Lambda)Z - (R\otimes I - I\otimes I\otimes I)(Z\otimes I)\tilde{R}(\Lambda\mathsf{T}p) - (R\otimes I - I \\
& \otimes I\otimes I)(Z\otimes I)Z\Lambda + (R\otimes I - I\otimes I\otimes I)(Z\otimes I)(\Lambda\mathsf{T}\Lambda)Z + (T\otimes I)\Lambda \\
& - (\Lambda\mathsf{T}\Lambda\mathsf{T}\Lambda)(T\otimes I) \\
= {} & (R\otimes I)(I\otimes\tilde{R})(\tilde{R}\otimes I)(\Lambda\mathsf{T}p\mathsf{T}p) + (R\otimes I)(I\otimes\tilde{R})(Z\otimes I)(\Lambda\mathsf{T}p) \\
& - (R\otimes I)(I\otimes\tilde{R})(\Lambda\mathsf{T}\Lambda\mathsf{T}p)Z + (R\otimes I) \\
& \times(I\otimes Z)\tilde{R}(\Lambda\mathsf{T}p) + (R\otimes I)(I\otimes Z)Z\Lambda - (R\otimes I)(I\otimes Z)(\Lambda\mathsf{T}\Lambda)Z \\
& - (R\otimes I)(\tilde{R}\otimes I)(\Lambda\mathsf{T}p\mathsf{T}\Lambda)Z - (R\otimes I)(Z\otimes I)(\Lambda\mathsf{T}\Lambda)Z + (R\otimes I) \\
& \times(\Lambda\mathsf{T}\Lambda\mathsf{T}\Lambda)(Z\otimes I)Z - (R\otimes I - I\otimes I\otimes I)(Z\otimes I)\tilde{R}(\Lambda\mathsf{T}p) \\
& - (R\otimes I - I\otimes I\otimes I)(Z\otimes I)Z\Lambda + (R\otimes I - I\otimes I\otimes I)(Z\otimes I) \\
& \times(\Lambda\mathsf{T}\Lambda)Z + (T\otimes I)\Lambda - (\Lambda\mathsf{T}\Lambda\mathsf{T}\Lambda)(T\otimes I).
\end{aligned}
$$

Using again (52), we can replace $(R\otimes I)(\tilde{R}\otimes I)(\Lambda\mathsf{T}p\mathsf{T}\Lambda)Z$ by

$$
\begin{aligned}
& (R\otimes I)(\tilde{R}\otimes I)(I\otimes\tilde{R})(\Lambda\mathsf{T}\Lambda\mathsf{T}p)Z + (R\otimes I)(\tilde{R}\otimes I)(I\otimes Z)(\Lambda\mathsf{T}\Lambda)Z \\
& - (R\otimes I)(\tilde{R}\otimes I)(\Lambda\mathsf{T}\Lambda\mathsf{T}\Lambda)(I\otimes Z)Z.
\end{aligned}
$$

We remark that (69) implies the equality between the coefficients multiplying $\Lambda\mathsf{T}p\mathsf{T}p$.

For the coefficient multiplying $\Lambda\mathsf{T}p$, we must have the following relation,

$$(R\otimes I)(I\otimes\tilde{R})(Z\otimes I)+(R\otimes I)(I\otimes Z)\tilde{R}-(R\otimes I-I\otimes I\otimes I)(Z\otimes I)\tilde{R}$$
$$=-(I\otimes\tilde{R})(\tilde{R}\otimes I)(I\otimes R-I\otimes I\otimes I)(I\otimes Z)+(I\otimes\tilde{R})(Z\otimes I)+(I\otimes Z)\tilde{R},$$

which can be written under the form

$$(R\otimes I-I\otimes I\otimes I)((I\otimes\tilde{R})(Z\otimes I)-(Z\otimes I)\tilde{R}+(I\otimes Z)\tilde{R}+(I\otimes\tilde{R})(\tilde{R}\otimes I)(I\otimes Z))=0$$

where we have used (69). By using $(R-I\otimes I)\tilde{R}=-(R-I\otimes I)$ we can replace the third term of the second factor by $-(\tilde{R}\otimes I)(I\otimes Z)\tilde{R}$ to see that this relation is satisfied by virtue of (72). It is also easy to see that the coefficients multiplying Λ are precisely the relation (75) and those multiplying $(\Lambda\top\Lambda)Z$ and $(\Lambda\top\Lambda\top p)Z$ are equal in virtue of $R\tilde{R}=I\otimes I+I\otimes Q$ and (56). Using (42) and (47) for $a=\Lambda$, we obtain for the coefficients multiplying $\Lambda\top\Lambda\top\Lambda$ the same relation as (75) yielding the consistency of the braiding of $p\top p\top\Lambda$.

Finally by using $\Lambda\top\Lambda=R(\Lambda\top\Lambda)R^{-1}$, obtained from (42) for $a=\Lambda$, and (71) we can show by a similar way the consistency of the braiding of $p\top\Lambda\top\Lambda$.

Then from the results of this section, we have the following.

Theorem (4.1): Let $\mathcal{G}$ be an inhomogeneous quantum group, as defined in Sec. II, with the following commutation rules

$$R(\Lambda\top\Lambda)=(\Lambda\top\Lambda)R,$$

$$p\top\Lambda=\tilde{R}(\Lambda\top p)+Z\Lambda-(\Lambda\top\Lambda)Z,$$

$$p\top p=R(p\top p)-(R-I\otimes I)Zp+T-(\Lambda\top\Lambda)T.$$

Then,

$$\tilde{R}=R+I\otimes Q=R^{-1}+R^{-1}(I\otimes Q),$$

$$Q=\lambda I,\quad \lambda\in C,\quad \lambda\neq-1,$$

$$T=-\tilde{R}T\quad\text{for }\lambda\neq0\quad\text{or}\quad(\tilde{R}+I\otimes I)T-(\Lambda\top\Lambda)(\tilde{R}+I\otimes I)T=0\quad\text{for }\lambda=0,$$

$$(R\otimes I)(I\otimes R)(R\otimes I)=(I\otimes R)(R\otimes I)(I\otimes R),$$

$$(Z\otimes I)R+(\tilde{R}\otimes I)(I\otimes Z)R=(I\otimes R)(Z\otimes I)+(I\otimes R)(\tilde{R}\otimes I)(I\otimes Z),$$

$$(R\otimes I-I\otimes I\otimes I)\quad((I\otimes Z)Z-(Z\otimes I)Z)+T\otimes I-(I\otimes\tilde{R})(\tilde{R}\otimes I)(I\otimes T)=0$$

and

$$(I\otimes R)-I\otimes I\otimes I)((\tilde{Z}\otimes I)T-(I\otimes\tilde{Z})T)-(Z\otimes I)T-(\tilde{R}\otimes I)(I\otimes Z)T=0$$

with

$$\tilde{Z}=-RZ.$$

V. DISCUSSIONS AND CONCLUSIONS

We end this paper by noticing the following.

(1) Let us recall that (10) and (11) imply that f_l^n, f_{kl}^{nm}, f_l^{nm}, and f_{kl}^n are linear functionals on $\mathcal{B}$, but not $\tilde{f}_k^m$, $\tilde{\eta}^m$, and $\tilde{\eta}_k$. Then their action on both sides of inhomogeneous commutation relations (48) and (64) is not justified, but a tedious and straightforward computation shows that they give the same results that those obtained directly by using f_{kl}^{nm}, f_l^{nm}, and f_{kl}^n.

(2) From (35), (36), and (24), we see that $\mathcal{A}\ni a\rightarrow\tilde{\rho}(a)=\left(\begin{smallmatrix}\tilde{f}(a) & \tilde{\eta}(a)\\ 0 & \varepsilon(a)\end{smallmatrix}\right)\in M_N(C)$ is a unital anti-homomorphism.

(3) Replacing a and $b\in\mathcal{A}$, respectively, by $S(a)$ and $S(b)$ into (36) and by setting $\eta^k=\tilde{\eta}^k\circ S$, we get

$$\eta^n(ab)=\eta^n(a)\varepsilon(b)+\tilde{f}^n_m(S(a))\eta^m(b),\quad a,b\in\mathcal{A}. \tag{94}$$

Then, although the formalism presented above is quite different from those of Ref. 9, we arrive at similar results for the commutation rules between the elements of $\mathcal{A}$ and the translations (48) and (94). These formulas become identical with those of Ref. 9 if $\tilde{f}^n_m(S(a))=f^n_m(a)$ for any $a\in\mathcal{A}$. The latter condition is satisfied for $\tilde{\eta}_n(p^a)=0$ and it is true, as a consequence of (56) and (57), for any $a\in\mathcal{B}$. In this case, (34), (35), and (94) are also true for any a and $b\in\mathcal{B}$ and (94) can be combined with (34) to see that $\mathcal{A}\ni a\rightarrow\rho(a)=\left(\begin{smallmatrix}f(a) & \eta(a)\\ 0 & \varepsilon(a)\end{smallmatrix}\right)\in M_N(C)$ is a unital homomorphism. In this case the R-matrix is subject to a strong constraint $R^2=I^{\otimes 2}$ as in Ref. 9.

(4) Using (85) and setting $T=-2T'$ we can rewrite, for $\lambda=0$, the commutation rules between the translations as

$$(R^{nm}_{kl}-\delta^n_k\delta^m_l)(p^kp^l-Z^{kl}_qp^q+T'^{kl}-\Lambda^k_q\Lambda^l_pT'^{qp})=0,$$

which are identical to those of Ref. 9. In this case one can also see that (75) reduces to the condition of the existence of covariant differential calculus on a quantum Minkowski space found in Ref. 10.

(Received 2 December 1998; accepted for publication 2 June 1999)

A four-field lattice furnished by Blaszak and Marciniak is transformed into bilinear form upon introducing two auxiliary independent variables. A Bäcklund transformation in bilinear form is found for the lattice and the corresponding nonlinear superposition formula is rigorously established. As a consequence, soliton solutions to the lattice are derived. © *1999 American Institute of Physics.* [S0022-2488(99)02811-X]

I. INTRODUCTION

Recently, Blaszak and Marciniak have derived several three-field and four-field lattices[1] as an application of r-matrix formalism to the algebra of shift operators. Two examples are

$$a_t(n)=c(n+1)-c(n-1), \tag{1}$$

$$b_t(n)=a(n-1)c(n-1)-a(n)c(n), \tag{2}$$

$$c_t(n)=c(n)(b(n)-b(n+1)), \tag{3}$$

and

$$u_t(n)=u(n)(v(n)-v(n-1)), \tag{4}$$

$$v_t(n)=w(n)u(n+1)-u(n)w(n-1), \tag{5}$$

$$w_t(n)=q(n)u(n+2)-u(n)q(n-1), \tag{6}$$

$$q_t(n)=u(n+3)-u(n), \tag{7}$$

both of which have Abelian symmetry algebras of infinite dimensions. Recently, an integrable symplectic map connected with (1)–(3) and its hierarchy was obtained by Wu and Geng[2] and

[a)]Electronic mail: hxb@lsec.cc.ac.cn

master symmetries were presented by the discrete zero curvature equation by one of the authors (Ma) and Fuchssteiner.[3] Moreover, (1)–(3) were transformed into bilinear equations by introducing an auxiliary independent variable, and thus a Bäcklund transformation and its nonlinear superposition formula were established by one of the authors (X.-B.H.) and Zhu.[4] As a result, soliton solutions to Eqs. (1)–(3) were found.

However, to the best of our knowledge, so far there have not been any results on solutions of the lattice (4)–(7) in the literature. In this paper, we would like to present a way to construct solutions to the Eqs. (4)–(7) by establishing a Bäcklund transformation and its nonlinear superposition formula for the lattice (4)–(7). As an application of the obtained results, soliton solutions of (4)–(7) are derived. The basic tool used in this paper is Hirota's bilinear formalism. As usual, the crucial step of using Hirota's method is to transform the system of equations under consideration into bilinear form, which is far from algorithmic and often highly technical. In Sec. II, through a long computation, we will show a way of deriving a bilinear form for the lattice (4)–(7). Then a Bäcklund transformation in bilinear form will be presented in Sec. III and the corresponding nonlinear superposition formula will be established in Sec. IV. Finally in Sec. V, a conclusion will be given. Some bilinear operator identities, which are fundamental and necessary for our discussion, are listed in Appendix A.

II. BILINEAR FORM

In this section, we want to derive a bilinear form for the lattice (4)–(7). To that end, let us make

$$u(n)=\frac{f(n+1)f(n-1)}{f^2(n)},\qquad v(n)=\left(\ln\frac{f(n+1)}{f(n)}\right)_t. \tag{8}$$

Our choice of the above-mentioned transformation comes from an observation that the first Eq. (4) of the lattice can be transformed into the following form:

$$(\ln u(n))_t=v(n)-v(n-1).$$

Furthermore let us introduce an auxiliary independent variable z such that

$$(D_tD_z-2e^{D_n}+2)f(n)\cdot f(n)=0, \tag{9}$$

where Hirota's bilinear differential operator $D_x^mD_t^k$, bilinear difference operator $\exp(\delta D_n)$ and bilinear differential-difference operator $D_x^mD_t^k\exp(\delta D_n)$ are defined as follows:[5–9]

$$D_x^mD_t^k a\cdot b\equiv\left(\frac{\partial}{\partial x}-\frac{\partial}{\partial x'}\right)^m\left(\frac{\partial}{\partial t}-\frac{\partial}{\partial t'}\right)^k a(x,t)b(x',t')|_{x'=x,t'=t},$$

$$\exp(\delta D_n)a(n)\cdot b(n)\equiv\exp\left[\delta\left(\frac{\partial}{\partial n}-\frac{\partial}{\partial n'}\right)\right]a(n)b(n')|_{n'=n}=a(n+\delta)b(n-\delta),$$

$$D_x^mD_t^k\exp(\delta D_n)a(n)\cdot b(n)\equiv\left(\frac{\partial}{\partial x}-\frac{\partial}{\partial x'}\right)^m\left(\frac{\partial}{\partial t}-\frac{\partial}{\partial t'}\right)^k a(n+\delta,x,t)b(n-\delta,x',t')|_{x'=x,t'=t}.$$

Then from (7) to (9), we know that

$$q_t(n)=\frac{f(n+4)f(n+2)}{f^2(n+3)}-\frac{f(n+1)f(n-1)}{f^2(n)}=\frac{\partial^2}{\partial t\partial z}\ln\frac{f(n+3)}{f(n)},$$

which implies that we can choose

$$q(n)=\frac{\partial}{\partial z}\ln\frac{f(n+3)}{f(n)}. \tag{10}$$

From here it is clear that the introduction of auxiliary variable z makes it easy to solve $q(n)$ in terms of f without containing any explicit integral. That is also our motivation for introducing the auxiliary variable z. Substituting (8) and (10) into Eq. (5) allows us to take

$$(\ln f(n+1))_{tt}=w(n)u(n+1),$$

from which it follows that

$$w(n)=\frac{1}{2}\,\frac{D_t^2 f(n+1)\cdot f(n+1)}{f(n+2)f(n)}. \tag{11}$$

Furthermore from (6) we have

$$\frac{1}{2}\,\frac{D_t(D_t^2 f(n+1)\cdot f(n+1))\cdot f(n+2)f(n)}{f^2(n+2)f^2(n)}=\frac{f(n+1)D_z f(n+3)\cdot f(n)}{f^2(n+2)f(n)} - \frac{f(n+1)D_z f(n+2)\cdot f(n-1)}{f^2(n)f(n+2)}$$

or

$$\begin{aligned}&\tfrac{1}{2}D_t(D_t^2 f(n)\cdot f(n))\cdot(e^{D_n}f(n)\cdot f(n))\\&\quad=2\sinh(\tfrac{1}{2}D_n)(D_z e^{(3/2)D_n}f(n)\cdot f(n))\cdot(e^{(1/2)D_n}f(n)\cdot f(n)).\end{aligned} \tag{12}$$

By use of (9) and (A1)–(A3), we can compute that

$$\begin{aligned}D_t(D_t^2 f(n)\cdot f(n))\cdot(e^{D_n}f(n)\cdot f(n))&=D_t(D_t^2 f(n)\cdot f(n))\cdot f^2(n)+\tfrac{1}{6}D_t(D_t^3 D_z f(n)\cdot f(n))\cdot f^2(n)\\&\quad-\tfrac{2}{3}\sinh(\tfrac{1}{2}D_n)[(D_t^3 e^{(1/2)D_n}f(n)\cdot f(n))\cdot(e^{(1/2)D_n}f(n)\cdot f(n))\\&\quad+3(D_t e^{(1/2)D_n}f(n)\cdot f(n))\cdot(D_t^2 e^{(1/2)D_n}f(n)\cdot f(n))].\end{aligned} \tag{13}$$

Now from (12) and by use of (13), (A4), and (A5) we can have the following relation:

$$\begin{aligned}&2\sinh(\tfrac{1}{2}D_n)(D_z e^{(3/2)D_n}f(n)\cdot f(n))\cdot(e^{(1/2)D_n}f(n)\cdot f(n))\\&\quad=\tfrac{3}{8}D_t(D_t^2 f(n)\cdot f(n))\cdot f^2(n)+\tfrac{1}{16}D_t(D_t^3 D_z f(n)\cdot f(n))\cdot f^2(n)\\&\qquad+\tfrac{1}{8}D_t(D_t^2 e^{D_n}f(n)\cdot f(n))\cdot f^2(n)-\tfrac{1}{2}\sinh(\tfrac{1}{2}D_n)(D_t^3 e^{(1/2)D_n}f(n)\cdot f(n))\\&\qquad\cdot(e^{(1/2)D_n}f(n)\cdot f(n))+\tfrac{1}{2}\{\sinh(\tfrac{1}{2}D_n)(D_t D_y e^{(1/2)D_n}f(n)\cdot f(n))\\&\qquad\cdot(e^{(1/2)D_n}f(n)\cdot f(n))-\tfrac{1}{2}D_t(D_y e^{D_n}f(n)\cdot f(n))\cdot f^2(n)\},\end{aligned} \tag{14}$$

where we have introduced another auxiliary independent variable y such that

$$D_t^2 e^{(1/2)D_n}f(n)\cdot f(n)=D_y e^{(1/2)D_n}f(n)\cdot f(n).$$

Finally, (14) can be decoupled into the following two bilinear equations:

$$(D_t^2 e^{D_n}+3D_t^2+\tfrac{1}{2}D_t^3 D_z-2D_y e^{D_n})f(n)\cdot f(n)=0,$$

$$(D_t^3 e^{(1/2)D_n} + 4D_z e^{(3/2)D_n} - D_y D_t e^{(1/2)D_n}) f(n)\cdot f(n) = 0.$$

To sum up, we obtain the following bilinear form for the lattice (4)–(7):

$$(D_t D_z - 2e^{D_n} + 2) f(n)\cdot f(n) = 0, \tag{15}$$

$$D_t^2 e^{(1/2)D_n} f(n)\cdot f(n) = D_y e^{(1/2)D_n} f(n)\cdot f(n), \tag{16}$$

$$(D_t^2 e^{D_n} + 3D_t^2 + \tfrac{1}{2} D_t^3 D_z - 2D_y e^{D_n}) f(n)\cdot f(n) = 0, \tag{17}$$

$$(D_t^3 e^{(1/2)D_n} + 4D_z e^{(3/2)D_n} - D_y D_t e^{(1/2)D_n}) f(n)\cdot f(n) = 0. \tag{18}$$

III. BÄCKLUND TRANSFORMATION

In this section, we derive a bilinear Bäcklund transformation (BT) for the system of the bilinear Eqs. (15)–(18). The concrete form of BT is presented as follows:

Theorem 1: The bilinear system of Eqs. (15)–(18) has the following Bäcklund transformation:

$$(D_z + \lambda^{-1} e^{-D_n} + \mu) f(n)\cdot g(n) = 0, \tag{19}$$

$$(D_t e^{-(1/2)D_n} - \lambda e^{(1/2)D_n} + \gamma e^{-(1/2)D_n}) f(n)\cdot g(n) = 0, \tag{20}$$

$$(D_y e^{-(1/2)D_n} - \lambda D_t e^{(1/2)D_n} - \lambda\gamma e^{(1/2)D_n} + \omega e^{-(1/2)D_n}) f(n)\cdot g(n) = 0, \tag{21}$$

$$\begin{aligned}(\lambda^{-1} D_t^3 e^{-(1/2)D_n} &+ D_t^2 e^{(1/2)D_n} + 2\gamma D_t e^{(1/2)D_n} + 4\gamma^2 e^{(1/2)D_n} + 3\lambda^{-1}\gamma D_t^2 e^{-(1/2)D_n} - 2D_y e^{(1/2)D_n} \\ &- 2\omega e^{(1/2)D_n} + \nu e^{-(1/2)D_n}) f(n)\cdot g(n) = 0,\end{aligned} \tag{22}$$

$$\begin{aligned}(2D_t^3 e^{-D_n} &+ 2D_t D_y e^{-D_n} + 6\gamma D_t^2 e^{-D_n} + \tfrac{1}{2}\lambda\nu e^{-D_n} + 8\lambda^{-1} e^{-2D_n} + 2\omega D_t e^{-D_n} + 2\gamma D_y e^{-D_n} \\ &+ 4\lambda^2 D_t e^{D_n} + 6\gamma^2 D_t e^{-D_n} + 2\omega\gamma e^{-D_n} + 3\gamma^3 e^{-D_n} + \theta e^{D_n}) f(n)\cdot g(n) = 0,\end{aligned} \tag{23}$$

where $\lambda,\ \mu,\ \gamma,\ \omega,\ \nu$, and θ are arbitrary constants.

Proof: Let $f(n)$ be a solution of Eqs. (15)–(18). What we need to prove is that the function $g(n)$ satisfying (19)–(23) is another solution of Eqs. (15)–(18), i.e.,

$$P_1 \equiv (D_z D_t - 2e^{D_n} + 2) g(n)\cdot g(n) = 0,$$

$$P_2 \equiv (D_t^2 e^{(1/2)D_n} - D_y e^{(1/2)D_n}) g(n)\cdot g(n) = 0,$$

$$P_3 \equiv (D_t^2 e^{D_n} + 3D_t^2 + \tfrac{1}{2} D_t^3 D_z - 2D_y e^{D_n}) g(n)\cdot g(n) = 0,$$

$$P_4 \equiv (D_t^3 e^{(1/2)D_n} + 4D_z e^{(3/2)D_n} - D_y D_t e^{(1/2)D_n}) g(n)\cdot g(n) = 0.$$

In fact, a similar deduction to that in Refs. 10 and 11 can give rise to $P_1=0$, $P_2=0$. Thus we focus on showing that $P_3=0$ and $P_4=0$. Let us first prove that $P_3=0$. Making use of (A6) and (A7) can give

$$\begin{aligned}-2P_3 f^2(n) = 2[&(D_t^2 e^{D_n} + 3D_t^2 + \tfrac{1}{2} D_t^3 D_z - 2D_y e^{D_n}) f\cdot f] g^2 \\ &- 2[(D_t^2 e^{D_n} + 3D_t^2 + \tfrac{1}{2} D_t^3 D_z - 2D_y e^{D_n}) g\cdot g] f^2 + 3[(D_z D_t - 2e^{D_n} + 2) f\cdot f] \\ &\times (D_t^2 g\cdot g) - 3(D_t^2 f\cdot f)[(D_z D_t - 2e^{D_n} + 2) g\cdot g]\end{aligned}$$

$$
\begin{aligned}
&= I_1 - 8\sinh(\tfrac{1}{2}D_n)[(D_y e^{(1/2)D_n} f\cdot g)\cdot(e^{-(1/2)D_n} f\cdot g) - (e^{(1/2)D_n} f\cdot g)\\
&\quad \cdot(D_y e^{-(1/2)D_n} f\cdot g)] - 4D_t\cosh(\tfrac{1}{2}D_n)[(D_t e^{(1/2)D_n} f\cdot g)\cdot(e^{-(1/2)D_n} f\cdot g)\\
&\quad -(e^{(1/2)D_n} f\cdot g)\cdot(D_t e^{-(1/2)D_n} f\cdot g)] - 4\sinh(\tfrac{1}{2}D_n)[(D_t^2 e^{(1/2)D_n} f\cdot g)\\
&\quad \cdot(e^{-(1/2)D_n} f\cdot g) - 2(D_t e^{(1/2)D_n} f\cdot g)\cdot(D_t e^{-(1/2)D_n} f\cdot g)\\
&\quad +(e^{(1/2)D_n} f\cdot g)\cdot(D_t^2 e^{-(1/2)D_n} f\cdot g)],
\end{aligned}
\tag{24}
$$

where the function I_1 is defined by

$$
\begin{aligned}
I_1 &\equiv [(D_t^3 D_z + 6D_t^2 + 6D_t^2 e^{D_n}) f\cdot f] g^2 - f^2 (D_t^3 D_z + 6D_t^2 + 6D_t^2 e^{D_n}) g\cdot g\\
&\quad + 3[(D_z D_t - 2e^{D_n} + 2) f\cdot f](D_t^2 g\cdot g) - 3(D_t^2 f\cdot f)[(D_z D_t - 2e^{D_n} + 2) g\cdot g].
\end{aligned}
$$

Using a similar deduction to that in Ref. 12, we have

$$
\begin{aligned}
I_1 &= 4\lambda^{-1}\sinh(\tfrac{1}{2}D_n)(D_t^3 e^{-(1/2)D_n} f\cdot g)\cdot(e^{-(1/2)D_n} f\cdot g) + 12\sinh(\tfrac{1}{2}D_n)(D_t^2 e^{(1/2)D_n} f\cdot g)\\
&\quad \cdot(e^{-(1/2)D_n} f\cdot g) + 24\gamma\sinh(\tfrac{1}{2}D_n)(D_t e^{(1/2)D_n} f\cdot g)\cdot(e^{-(1/2)D_n} f\cdot g) + 24\gamma^2\sinh(\tfrac{1}{2}D_n)\\
&\quad \times(e^{(1/2)D_n} f\cdot g)\cdot(e^{-(1/2)D_n} f\cdot g) + 12\lambda^{-1}\gamma\sinh(\tfrac{1}{2}D_n)(D_t^2 e^{-(1/2)D_n} f\cdot g)\cdot(e^{-(1/2)D_n} f\cdot g).
\end{aligned}
$$

Thus by using (A8)–(A11), (20), and (21) equality (24) can be further reduced to the following:

$$
\begin{aligned}
-2P_3 f^2(n) &= 4\lambda^{-1}\sinh(\tfrac{1}{2}D_n)(D_t^3 e^{-(1/2)D_n} f\cdot g)\cdot(e^{-(1/2)D_n} f\cdot g) + 4\sinh(\tfrac{1}{2}D_n)(D_t^2 e^{(1/2)D_n} f\cdot g)\\
&\quad \cdot(e^{-(1/2)D_n} f\cdot g) + 8\gamma\sinh(\tfrac{1}{2}D_n)(D_t e^{(1/2)D_n} f\cdot g)\cdot(e^{-(1/2)D_n} f\cdot g) + 16\gamma^2\sinh(\tfrac{1}{2}D_n)\\
&\quad \times(e^{(1/2D_n} f\cdot g)\cdot(e^{-(1/2)D_n} f\cdot g) + 12\lambda^{-1}\gamma\sinh(\tfrac{1}{2}D_n)(D_t^2 e^{-(1/2)D_n} f\cdot g)\\
&\quad \cdot(e^{-(1/2)D_n} f\cdot g) - 8\sinh(\tfrac{1}{2}D_n)(D_y e^{(1/2)D_n} f\cdot g)\cdot(e^{-(1/2)D_n} f\cdot g)\\
&\quad - 8\omega\sinh(\tfrac{1}{2}D_n)(e^{(1/2)D_n} f\cdot g)\cdot(e^{-(1/2)D_n} f\cdot g) = 0,
\end{aligned}
$$

which implies that $P_3 = 0$.

Second, let us prove that $P_4 = 0$. By using (A12)–(A25) and (19)–(22), we can deduce the following relation

$$
\begin{aligned}
-P_4 e^{(3/2)D_n} f\cdot f &= [(D_t^3 e^{(1/2)D_n} + 4D_z e^{(3/2)D_n} - D_y D_t e^{(1/2)D_n}) f\cdot f][e^{(3/2)D_n} g\cdot g] - [e^{(3/2)D_n} f\cdot f]\\
&\quad \times[(D_t^3 e^{(1/2)D_n} + 4D_z e^{(3/2)D_n} - D_y D_t e^{(1/2)D_n}) g\cdot g]\\
&= \sinh(\tfrac{1}{2}D_n)(e^{D_n} f\cdot g)\cdot[(2D_t^3 e^{-D_n} + 2D_t D_y e^{-D_n} + 6\gamma D_t^2 e^{-D_n} + \tfrac{1}{2}\lambda\nu e^{-D_n}\\
&\quad + 8\lambda^{-1} e^{-2D_n} + 2\omega D_t e^{-D_n} + 2\gamma D_y e^{-D_n} + 4\lambda^2 D_t e^{D_n} + 6\gamma^2 D_t e^{-D_n}\\
&\quad + 2\omega\gamma e^{-D_n}) f\cdot g] - 3\gamma^2\sinh(D_n)(e^{(1/2)D_n} f\cdot g)\cdot(-\gamma e^{-(1/2)D_n} f\cdot g)\\
&= \sinh(\tfrac{1}{2}D_n)(e^{D_n} f\cdot g)\cdot[(2D_t^3 e^{-D_n} + 2D_t D_y e^{-D_n} + 6\gamma D_t^2 e^{-D_n} + \tfrac{1}{2}\lambda\nu e^{-D_n}\\
&\quad + 8\lambda^{-1} e^{-2D_n} + 2\omega D_t e^{-D_n} + 2\gamma D_y e^{-D_n} + 4\lambda^2 D_t e^{D_n} + 6\gamma^2 D_t e^{-D_n} + 2\omega\gamma e^{-D_n}\\
&\quad + 3\gamma^3 e^{-D_n}) f\cdot g] = 0.
\end{aligned}
$$

Thus the proof of Theorem 1 is completed.

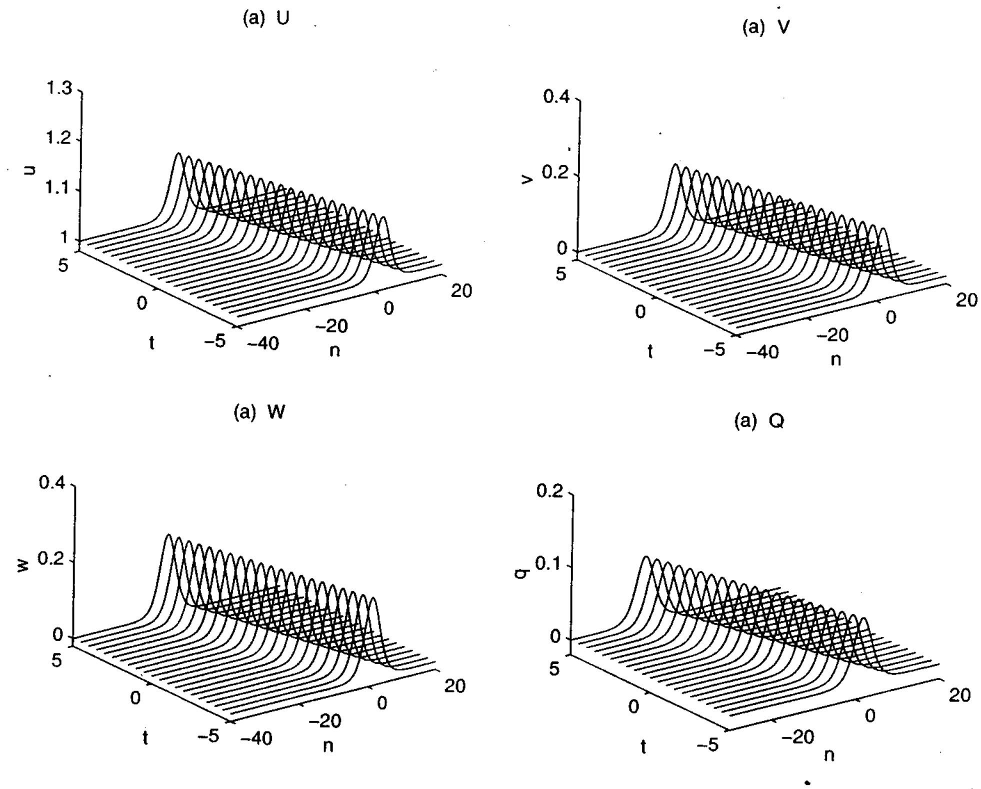

FIG. 1. 1-soliton solution of the lattice (4)–(7).

By using the BT given by (19)–(23), we can easily obtain the following solution from the trivial solution $f(n)=1$:

$$g(n)=1+\exp(\eta), \quad \eta=pn+qt+rz+sy+\eta^0 \tag{25}$$

with

$$\lambda^4=e^p(1+e^p+e^{2p}), \quad \mu=-\lambda^{-1}, \quad \gamma=\lambda, \quad \omega=\lambda^2, \quad \nu=-2\lambda^2, \quad \theta=-4\lambda^3-8\lambda^{-1},$$

where p is an arbitrary constant, $q=\lambda(1-e^{-p})$, $r=\lambda^{-1}(e^p-1)$, $s=\lambda^2(1-e^{-2p})$ and η^0 is an arbitrary constant. Therefore the corresponding one-soliton solution of the lattice (4)–(7) is

$$\begin{aligned} u(n)&=\frac{g(n+1)g(n-1)}{g^2(n)}, \quad v(n)=\left(\ln\frac{g(n+1)}{g(n)}\right)_t, \\ q(n)&=\left(\ln\frac{g(n+3)}{g(n)}\right)_z, \quad w(n)=\frac{1}{2}\,\frac{D_t^2 g(n+1)\cdot g(n+1)}{g(n+2)g(n)}, \end{aligned} \tag{26}$$

with $g(n)$ being given by (25). The plot of the solution (26) is shown in Fig. 1, where we choose $p=0.7$, $\lambda\approx 1.94$, $\eta^0=0$, $z=1$, $y=1$.

IV. NONLINEAR SUPERPOSITION FORMULA

In the following, we shall simply denote, without confusion, $f(n,t)$ by $f(n)$ or f. The corresponding nonlinear superposition formula is shown in the following theorem.

Theorem 2: Let f_0 be a solution of Eqs. (15)–(18). Suppose that f_i $(i=1,2)$ are two other solutions of (15)–(18) which are related to f_0 under the BT(19)–(23) with parameters $(\lambda_i,\mu_i,\gamma_i,\omega_i,\nu_i,\theta_i)$, i.e., $f_0 \rightarrow^{(\lambda_i,\mu_i,\gamma_i,\omega_i,\nu_i.\theta_i)} f_i$ $(i=1,2)$, where $\lambda_1\lambda_2 \neq 0$, $f_j \neq 0$ $(j=0,1,2)$. Then f_{12} defined by

$$\exp(-\tfrac{1}{2}D_n) f_0 \cdot f_{12} = k[\lambda_1 \exp(-\tfrac{1}{2}D_n) - \lambda_2 \exp(\tfrac{1}{2}D_n)] f_1 \cdot f_2, \tag{27}$$

where k is a nonzero constant, is a new solution which is related to f_1 and f_2 under the BT(19)-(23) with parameters $(\lambda_2,\mu_2,\gamma_2,\omega_2,\nu_2,\theta_2)$ and $(\lambda_1,\mu_1,\gamma_1,\omega_1,\nu_1,\theta_1)$, respectively.

In order to prove Theorem 2, we first establish some basic lemmas. In what follows, we always assume that the hypotheses of Theorem 2 are satisfied and f_{12} is determined by (27). Besides we set

$$J_i(n) \equiv (D_t e^{-(1/2)D_n} - \lambda_i e^{(1/2)D_n} + \gamma_i e^{-(1/2)D_n}) f_0(n) \cdot f_i(n), \quad i=1,2$$

$$K_i(n) \equiv (D_y e^{-(1/2)D_n} - \lambda_i D_t e^{(1/2)D_n} - \lambda_i \gamma_i e^{(1/2)D_n} + \omega_i e^{-(1/2)D_n}) f_0(n) \cdot f_i(n), \quad i=1,2$$

$$L_i(n) \equiv (\lambda_i^{-1} D_t^3 e^{-(1/2)D_n} + D_t^2 e^{(1/2)D_n} + 2\gamma_i D_t e^{(1/2)D_n} + 4\gamma_i^2 e^{(1/2)D_n} + 3\lambda_i^{-1}\gamma_i D_t^2 e^{-(1/2)D_n}$$
$$- 2D_y e^{(1/2)D_n} - 2\omega_i e^{(1/2)D_n} + \nu_i e^{-(1/2)D_n}) f_0(n) \cdot f_i(n), \quad i=1,2.$$

Lemma 1: The bilinear relations hold:

$$(D_z + \lambda_2^{-1} e^{-D_n} + \mu_2) f_1 \cdot f_{12} = 0, \tag{28}$$

$$(D_z + \lambda_1^{-1} e^{-D_n} + \mu_1) f_2 \cdot f_{12} = 0, \tag{29}$$

$$(D_t e^{-(1/2)D_n} - \lambda_2 e^{(1/2)D_n} + \gamma_2 e^{-(1/2)D_n}) f_1 \cdot f_{12} = 0, \tag{30}$$

$$(D_t e^{-(1/2)D_n} - \lambda_1 e^{(1/2)D_n} + \gamma_1 e^{-(1/2)D_n}) f_2 \cdot f_{12} = 0, \tag{31}$$

$$-D_z f_1 \cdot f_2 + (\mu_1 - \mu_2) f_1 f_2 - \frac{1}{k\lambda_1\lambda_2} e^{-D_n} f_0 \cdot f_{12} = 0, \tag{32}$$

$$(\lambda_2 D_t e^{(1/2)D_n} + \lambda_1 D_t e^{-(1/2)D_n} - 2\lambda_2\gamma_1 e^{(1/2)D_n} + 2\lambda_1\gamma_2 e^{-(1/2)D_n}) f_1 \cdot f_2 + \frac{1}{k} D_t e^{-(1/2)D_n} f_0 \cdot f_{12} = 0. \tag{33}$$

Proof: (28)–(33) can be proved similarly as in Refs. 10 and 11.

Lemma 2: The bilinear relations hold:

$$-D_t f_1 \cdot f_2 + (\gamma_1 - \gamma_2) f_1 f_2 - \frac{1}{k} f_0 f_{12} = 0, \tag{34}$$

$$D_y e^{-(1/2)D_n} f_1 \cdot f_{12} = (\lambda_2 D_t e^{(1/2)D_n} + \lambda_2\gamma_2 e^{(1/2)D_n} - \omega_2 e^{-(1/2)D_n}) f_1 \cdot f_{12}, \tag{35}$$

$$D_y e^{-(1/2)D_n} f_2 \cdot f_{12} = (\lambda_1 D_t e^{(1/2)D_n} + \lambda_1\gamma_1 e^{(1/2)D_n} - \omega_1 e^{-(1/2)D_n}) f_2 \cdot f_{12}. \tag{36}$$

Proof: First, according to the hypotheses of Theorem 2, we have

$$J_1(n) f_2(n+\tfrac{1}{2}) - J_2(n) f_1(n+\tfrac{1}{2}) = 0,$$

from which, by use of (A26) and (27), it follows that (34) holds. Next, since f_1 and f_2 are two solutions of (15)–(18), we have

$$[(D_t^2e^{(1/2)D_n}-D_ye^{(1/2)D_n})f_1\cdot f_1](e^{(1/2)D_n}f_2\cdot f_2) \\ -(e^{(1/2)D_n}f_1\cdot f_1)[(D_t^2e^{(1/2)D_n}-D_ye^{(1/2)D_n})f_2\cdot f_2]=0,$$

which can be rewritten as

$$-\frac{1}{k\lambda_2}(e^{-(1/2)D_n}f_0\cdot f_2)[(D_ye^{-(1/2)D_n}-\lambda_2D_te^{(1/2)D_n}-\lambda_2\gamma_2e^{(1/2)D_n}+\omega_2e^{-(1/2)D_n})f_1\cdot f_{12}]=0$$

by use of (A2), (A27)–(A30), (27), (30), and (34). Therefore (35) holds. Similarly we can prove that (36) also holds.

Lemma 3: The bilinear relations hold:

$$(\lambda_2^{-1}D_t^3e^{-(1/2)D_n}+D_t^2e^{(1/2)D_n}+2\gamma_2D_te^{(1/2)D_n}+4\gamma_2^2e^{(1/2)D_n}+3\lambda_2^{-1}\gamma_2D_t^2e^{-(1/2)D_n} \\ -2D_ye^{(1/2)D_n}-2\omega_2e^{(1/2)D_n}+\nu_2e^{-(1/2)D_n})f_1\cdot f_{12}=0, \tag{37}$$

$$(\lambda_1^{-1}D_t^3e^{-(1/2)D_n}+D_t^2e^{(1/2)D_n}+2\gamma_1D_te^{(1/2)D_n}+4\gamma_1^2e^{(1/2)D_n}+3\lambda_1^{-1}\gamma_1D_t^2e^{-(1/2)D_n} \\ -2D_ye^{(1/2)D_n}-2\omega_1e^{(1/2)D_n}+\nu_1e^{-(1/2)D_n})f_2\cdot f_{12}=0. \tag{38}$$

Proof: Since f_1 and f_2 are two solutions of Eqs. (15)–(18), we have

$$[(D_t^3D_z+6D_t^2+2D_t^2e^{D_n}-4D_ye^{D_n})f_1\cdot f_1]f_2^2-[(D_t^3D_z+6D_t^2+2D_t^2e^{D_n}-4D_ye^{D_n})f_2\cdot f_2]f_1^2 \\ +3[(D_zD_t-2e^{D_n}+2)f_1\cdot f_1](D_t^2f_2\cdot f_2)-3(D_t^2f_1\cdot f_1)[(D_zD_t-2e^{D_n}+2)f_2\cdot f_2]=0.$$

On the other hand, using a similar deduction as in Ref. 12, we obtain that

$$[(D_t^3D_z+6D_t^2+6D_t^2e^{D_n})f_1\cdot f_1]f_2^2-[(D_t^3D_z+6D_t^2+6D_t^2e^{D_n})f_2\cdot f_2]f_1^2 \\ +3[(D_zD_t-2e^{D_n}+2)f_1\cdot f_1](D_t^2f_2\cdot f_2)-3(D_t^2f_1\cdot f_1)[(D_zD_t-2e^{D_n}+2)f_2\cdot f_2] \\ =-\frac{2}{k\lambda_1\lambda_2}e^{-(1/2)D_n}\{[(D_t^3e^{-(1/2)D_n}+3\lambda_2D_t^2e^{(1/2)D_n}+3\gamma_2D_t^2e^{-(1/2)D_n}+6\lambda_2\gamma_2^2e^{(1/2)D_n} \\ +6\lambda_2\gamma_2D_te^{-(1/2)D_n})f_0\cdot f_2]\cdot(e^{-(1/2)D_n}f_1\cdot f_{12})-(e^{-(1/2)D_n}f_0\cdot f_2)\cdot[(D_t^3e^{-(1/2)D_n} \\ +3\lambda_2D_t^2e^{(1/2)D_n}+3\gamma_2D_t^2e^{(1/2)D_n}+6\lambda_2\gamma_2^2e^{(1/2)D_n}+6\lambda_2\gamma_2D_te^{-(1/2)D_n})f_1\cdot f_{12}]\}.$$

Thus by using (A6), (A7), (A31)–(A33), (27), and (34), we have

$$\frac{2}{k\lambda_1}e^{-(1/2)D_n}(e^{-(1/2)D_n}f_0\cdot f_2)\cdot[(\lambda_2^{-1}D_t^3e^{-(1/2)D_n}+D_t^2e^{(1/2)D_n}+2\gamma_2D_te^{(1/2)D_n}+4\gamma_2^2e^{(1/2)D_n} \\ +3\lambda_2^{-1}\gamma_2D_t^2e^{-(1/2)D_n}-2D_ye^{(1/2)D_n}-2\omega_2e^{(1/2)D_n}+\nu_2e^{-(1/2)D_n})f_1\cdot f_{12}]=0,$$

which implies that (37) holds. Similarly we can show that (38) holds.

Lemma 4: The bilinear relation holds:

$$(\lambda_1D_t^2e^{-(1/2)D_n}-\lambda_2D_t^2e^{(1/2)D_n}+4\lambda_2\gamma_1D_te^{(1/2)D_n}+4\lambda_1\gamma_2D_te^{-(1/2)D_n}-4\lambda_2\gamma_1^2e^{(1/2)D_n} \\ +4\lambda_1\gamma_2^2e^{-(1/2)D_n})f_1\cdot f_2-\frac{1}{k}D_t^2e^{-(1/2)D_n}f_0\cdot f_{12}+\frac{4}{k}\lambda_1\lambda_2e^{(1/2)D_n}f_0\cdot f_{12}=0. \tag{39}$$

Proof: According to the hypotheses of Theorem 2, we have

$$\frac{1}{\lambda_1}[J_1(n)]_t f_2\left(n-\frac{1}{2}\right)-\frac{1}{\lambda_2}[J_2(n)]_t f_1\left(n-\frac{1}{2}\right)-\frac{\gamma_1}{\lambda_1}J_1(n)f_2\left(n-\frac{1}{2}\right)+\frac{\gamma_2}{\lambda_2}J_2(n)f_1\left(n-\frac{1}{2}\right)=0,$$

which implies that (39) holds by use of (27), (33), and (34).

Lemma 5: The bilinear relation holds:

$$\begin{aligned}&(\lambda_1 D_y e^{-(1/2)D_n}+\lambda_2 D_y e^{(1/2)D_n}+2\lambda_1\omega_2 e^{-(1/2)D_n}-2\lambda_2\omega_1 e^{(1/2)D_n})f_1\cdot f_2\\&\quad+\left(\frac{1}{k}D_y e^{-(1/2)D_n}+\frac{2}{k}\lambda_1\lambda_2 e^{(1/2)D_n}\right)f_0\cdot f_{12}=0.\end{aligned} \tag{40}$$

Proof: Based on the hypotheses of Theorem 2, we have

$$\lambda_2 K_1(n)f_2(n-\tfrac{1}{2})-\lambda_1 K_2(n)f_1(n-\tfrac{1}{2})=0,$$

which implies that (40) holds upon using (27) and (33).

Lemma 6: The bilinear relation holds:

$$D_y f_1\cdot f_2+(\omega_2-\omega_1)f_1 f_2+\frac{1}{k}D_t f_0\cdot f_{12}+\frac{1}{k}(\gamma_1+\gamma_2)f_0 f_{12}=0. \tag{41}$$

Proof: According to the hypotheses of Theorem 2, we obtain

$$K_1(n)f_2(n+\tfrac{1}{2})-K_2(n)f_1(n+\tfrac{1}{2})=0,$$

which lead to (41) upon taking into account (27) and (33).

Lemma 7: The bilinear relation holds:

$$\begin{aligned}&-\frac{1}{k}D_t^3 e^{-(1/2)D_n}f_0\cdot f_{12}+\frac{4\lambda_1\lambda_2}{k}D_t e^{(1/2)D_n}f_0\cdot f_{12}-\frac{8\lambda_1\lambda_2}{k}(\gamma_1+\gamma_2)e^{(1/2)D_n}f_0\cdot f_{12}\\&\quad+6\lambda_2\gamma_1 D_t^2 e^{(1/2)D_n}f_1\cdot f_2-6\lambda_1\gamma_2 D_t^2 e^{-(1/2)D_n}f_1\cdot f_2+2\lambda_1\lambda_2\nu_1 e^{(1/2)D_n}f_1\cdot f_2\\&\quad-2\lambda_1\lambda_2\nu_2 e^{-(1/2)D_n}f_1\cdot f_2-12\lambda_1\gamma_2^2 D_t e^{-(1/2)D_n}f_1\cdot f_2-12\lambda_2\gamma_1^2 D_t e^{(1/2)D_n}f_1\cdot f_2\\&\quad+12\lambda_2\gamma_1^3 e^{(1/2)D_n}f_1\cdot f_2-12\lambda_1\gamma_2^3 e^{-(1/2)D_n}f_1\cdot f_2\\&\quad-\lambda_1 D_t^3 e^{-(1/2)D_n}f_1\cdot f_2-\lambda_2 D_t^3 e^{(1/2)D_n}f_1\cdot f_2=0.\end{aligned} \tag{42}$$

Proof: It follows from the hypotheses of Theorem 2 that

$$\begin{aligned}&\frac{1}{4}L_1(n)f_2\left(n-\frac{1}{2}\right)-\frac{1}{4}L_2(n)f_1\left(n-\frac{1}{2}\right)+\frac{3}{2}\frac{\gamma_1^2}{\lambda_1}J_1(n)f_2\left(n-\frac{1}{2}\right)-\frac{3}{2}\frac{\gamma_2^2}{\lambda_2}J_2(n)f_1\left(n-\frac{1}{2}\right)\\&\quad-\frac{3}{2}\frac{\gamma_1}{\lambda_1}[J_1(n)]_t f_2\left(n-\frac{1}{2}\right)+\frac{3}{2}\frac{\gamma_2}{\lambda_2}[J_2(n)]_t f_1\left(n-\frac{1}{2}\right)+\frac{3}{4}\lambda_1^{-1}[J_1(n)]_{tt}f_2\left(n-\frac{1}{2}\right)\\&\quad-\tfrac{3}{4}\lambda_2^{-1}[J_2(n)]_{tt}f_1(n-\tfrac{1}{2})=0.\end{aligned}$$

This tells that (42) holds by using (27), (33), (A34), and (A35).

Lemma 8: The bilinear relation holds:

$$\begin{aligned}&[-D_y D_t e^{-(1/2)D_n}+2\lambda_1\lambda_2 D_t e^{(1/2)D_n}+4\lambda_1\lambda_2(\gamma_1+\gamma_2)e^{(1/2)D_n}]f_0\cdot f_{12}+k(2\lambda_2\omega_1 D_t e^{(1/2)D_n}\\&\quad+2\lambda_1\omega_2 D_t e^{-(1/2)D_n}+2\lambda_2\gamma_1 D_y e^{(1/2)D_n}+2\lambda_1\gamma_2 D_y e^{-(1/2)D_n}-\lambda_2 D_y D_t e^{(1/2)D_n}\\&\quad+\lambda_1 D_y D_t e^{-(1/2)D_n}-4\lambda_2\gamma_1\omega_1 e^{(1/2)D_n}+4\lambda_1\gamma_2\omega_2 e^{-(1/2)D_n})f_1\cdot f_2=0.\end{aligned} \tag{43}$$

Proof: According to the hypotheses of Theorem 2, we have

$$\lambda_1^{-1}[K_1(n)]_t f_2\left(n-\frac{1}{2}\right)-\lambda_2^{-1}[K_2(n)]_t f_1\left(n-\frac{1}{2}\right)-\frac{\gamma_1}{\lambda_1}K_1(n)f_2\left(n-\frac{1}{2}\right)$$
$$+\frac{\gamma_2}{\lambda_2}K_2(n)f_1\left(n-\frac{1}{2}\right)=0,$$

which shows that (43) holds by using (27), (33), (A36), and (A37).

Lemma 9: The bilinear relation holds:

$$2\gamma_2\sinh(D_n)(e^{(1/2)D_n}f_0\cdot f_{12})\cdot(e^{(1/2)D_n}f_1\cdot f_2)-D_t\cosh(D_n)(e^{(1/2)D_n}f_0\cdot f_{12})\cdot(e^{(1/2)D_n}f_1\cdot f_2)$$
$$+\sinh(D_n)[(D_te^{(1/2)D_n}f_0\cdot f_{12})\cdot(e^{(1/2)D_n}f_1\cdot f_2)+(e^{(1/2)D_n}f_0\cdot f_{12})\cdot(D_te^{(1/2)D_n}f_1\cdot f_2)]$$
$$=-\frac{\lambda_2}{\lambda_1}e^{-(1/2)D_n}[(e^{D_n}f_0\cdot f_2)\cdot(D_te^{D_n}f_1\cdot f_{12})-(D_te^{D_n}f_0\cdot f_2)\cdot(e^{D_n}f_1\cdot f_{12})]. \tag{44}$$

Proof. On the one hand, by use of (A38), (A39), and (30), we can have

$$2\gamma_2\sinh(D_n)(e^{(1/2)D_n}f_0\cdot f_{12})\cdot(e^{(1/2)D_n}f_1\cdot f_2)-D_t\cosh(D_n)(e^{(1/2)D_n}f_0\cdot f_{12})\cdot(e^{(1/2)D_n}f_1\cdot f_2)$$
$$+\sinh(D_n)[(D_te^{(1/2)D_n}f_0\cdot f_{12})\cdot(e^{(1/2)D_n}f_1\cdot f_2)+(e^{(1/2)D_n}f_0\cdot f_{12})\cdot(D_te^{(1/2)D_n}f_1\cdot f_2)]$$
$$=\lambda_2[(e^{(3/2)D_n}f_0\cdot f_2)(e^{(1/2)D_n}f_1\cdot f_{12})-(e^{(1/2)D_n}f_0\cdot f_2)(e^{(3/2)D_n}f_1\cdot f_{12}).$$

On the other hand, by use of (A40) and (30), we can have

$$e^{-(1/2)D_n}[(e^{D_n}f_0\cdot f_2)\cdot(D_te^{D_n}f_1\cdot f_{12})-(D_te^{D_n}f_0\cdot f_2)\cdot(e^{D_n}f_1\cdot f_{12}]$$
$$=-\lambda_1[(e^{(3/2)D_n}f_0\cdot f_2)(e^{(1/2)D_n}f_1\cdot f_{12})-(e^{(1/2)D_n}f_0\cdot f_2)(e^{(3/2)D_n}f_1\cdot f_{12})].$$

Therefore combining these two equalities leads to the required equality (44).

We now turn to the proof of Theorem 2. Based on Lemma 1, Lemma 2, and Lemma 3, it suffices to show that

$$(2D_t^3e^{-D_n}+2D_tD_ye^{-D_n}+6\gamma_2D_t^2e^{-D_n}+\tfrac{1}{2}\lambda_2\nu_2e^{-D_n}+8\lambda_2^{-1}e^{-2D_n}+2\omega_2D_te^{-D_n}+2\gamma_2D_ye^{-D_n}$$
$$+4\lambda_2^2D_te^{D_n}+6\gamma_2^2D_te^{-D_n}+2\omega_2\gamma_2e^{-D_n}+3\gamma_2^3e^{-D_n}+\theta_2e^{D_n})f_1\cdot f_{12}=0, \tag{45}$$

$$(2D_t^3e^{-D_n}+2D_tD_ye^{-D_n}+6\gamma_1D_t^2e^{-D_n}+\tfrac{1}{2}\lambda_1\nu_1e^{-D_n}+8\lambda_1^{-1}e^{-2D_n}+2\omega_1D_te^{-D_n}+2\gamma_1D_ye^{-D_n}$$
$$+4\lambda_1^2D_te^{D_n}+6\gamma_1^2D_te^{-D_n}+2\omega_1\gamma_1e^{-D_n}+3\gamma_1^3e^{-D_n}+\theta_1e^{D_n})f_2\cdot f_{12}=0. \tag{46}$$

Since f_1 and f_2 are two solutions of Eqs. (15)–(18), we have

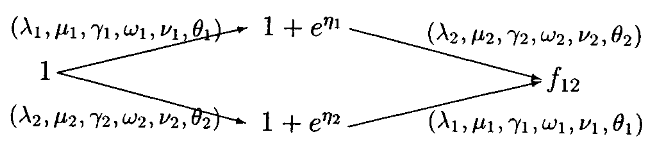
$$[(D_t^3e^{(1/2)D_n}+4D_ze^{(3/2)D_n}-D_yD_te^{(1/2)D_n})f_1\cdot f_1][e^{(3/2)D_n}f_2\cdot f_2]$$
$$-[(D_t^3e^{(1/2)D_n}+4D_ze^{(3/2)D_n}-D_yD_te^{(1/2)D_n})f_2\cdot f_2][e^{(3/2)D_n}f_1\cdot f_1]=0. \tag{47}$$

Taking advantage of (A12)–(A14), (A41)–(A43), (27), (32)–(34), and (39)–(44), we can rewrite (47) as

$$-\frac{1}{k\lambda_1}e^{-(1/2)D_n}(e^{D_n}f_0\cdot f_2)\cdot\left[\left(D_t^3e^{-D_n}+D_yD_te^{-D_n}+3\gamma_2D_t^2e^{-D_n}+\frac{1}{4}\lambda_2\nu_2e^{-D_n}\right.\right.$$
$$+4\lambda_2^{-1}e^{-2D_n}+\omega_2D_te^{-D_n}+\gamma_2D_ye^{-D_n}+2\lambda_2^2D_te^{D_n}+3\gamma_2^2D_te^{-D_n}+\omega_2\gamma_2e^{-D_n}$$
$$\left.\left.+\frac{3}{2}\gamma_2^3e^{-D_n}+\frac{1}{2}\;\theta_2e^{D_n}\right)f_1\cdot f_{12}\right]=0, \tag{48}$$

which implies that (45) holds. Similarly we can prove that (46) also holds. Therefore we have completed the proof of theorem 2.

As an application of the nonlinear superposition formula (27), we can construct soliton solutions of the Blaszak–Marciniak lattice of the Eqs. (15)–(18). Choose for example $f_0=1,k=1/\lambda_1-\lambda_2$. It is easily verified that



where f_{12} is given by

$$f_{12}=1+\frac{\lambda_1e^{-p_1}-\lambda_2}{\lambda_1-\lambda_2}e^{\eta_1}+\frac{\lambda_1-\lambda_2e^{-p_2}}{\lambda_1-\lambda_2}e^{\eta_2}+\frac{\lambda_1e^{-p_1}-\lambda_2e^{-p_2}}{\lambda_1-\lambda_2}e^{\eta_1+\eta_2} \tag{49}$$

with

$$\eta_i=p_in+q_it+r_iz+s_iy+\eta_i^0,\quad q_i=\lambda_i(1-e^{-p_i}),\quad r_i=\lambda_i^{-1}(e^{p_i}-1),\quad s_i=\lambda_i^2(1-e^{-2p_i})$$

and

$$\lambda_i^4=e^{p_i}(1+e^{p_i}+e^{2p_i}),\quad \mu_i=-\lambda_i^{-1},\quad \gamma_i=\lambda_i,\quad \omega_i=\lambda_i^2,\quad \nu_i=-2\lambda_i^2,\quad \theta_i=-4\lambda_i^3-8\lambda_i^{-1}$$

in which the p_i $(i=1,2)$ are arbitrary constants. Thus the corresponding 2-soliton solution of (4)–(7) is

$$u(n)=\frac{f_{12}(n+1)f_{12}(n-1)}{f_{12}^2(n)},\quad v(n)=\left(\ln\frac{f_{12}(n+1)}{f_{12}(n)}\right)_t$$
$$q(n)=\left(\ln\frac{f_{12}(n+3)}{f_{12}(n)}\right)_z,\quad w(n)=\frac{1}{2}\,\frac{D_t^2f_{12}(n+1)\cdot f_{12}(n+1)}{f_{12}(n+2)f_{12}(n)} \tag{50}$$

with $f_{12}(n)$ being given by (49). The plot of (50) is shown in Fig. 2 where we chose $p_1=1.2$, $p_2=1.42$, $\lambda_1\approx-2.67$, $\lambda_2\approx3.10$, $\eta_1^0=\eta_2^0=0$, $z=1$, $y=1$.

In general, along this line, we can generate multisoliton solutions for the Blaszak–Marciniak lattice (4)–(7) successively.

V. CONCLUSION

By introducing two auxiliary variables, a four-field lattice introduced by Blaszak and Marciniak[1] is transformed into Hirota's bilinear form. The transformation of the dependent variables are given by (8), (10), and (11). A bilinear Bäcklund transformation (Theorem 1) is found and its corresponding nonlinear superposition formula (Theorem 2) is rigorously proved. As a

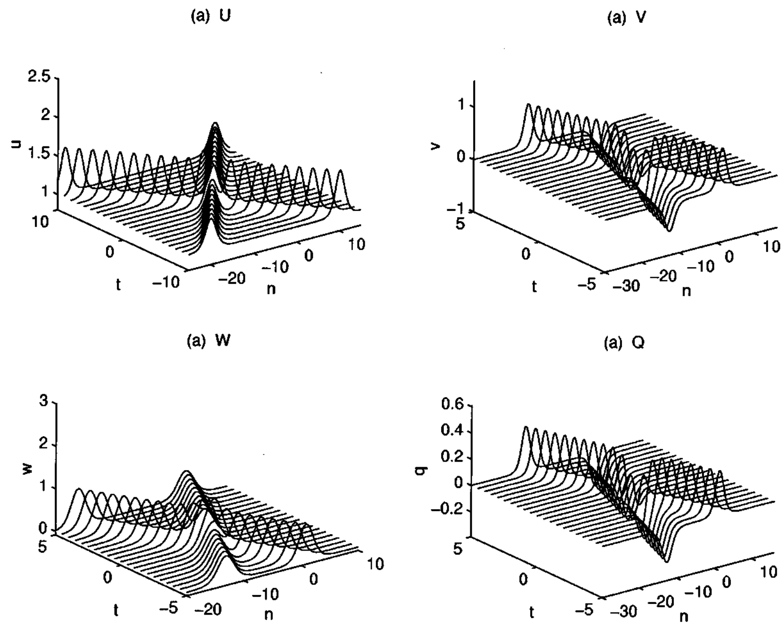


FIG. 2. 2-soliton solution of the lattice (4)–(7).

consequence, one-soliton and two-soliton solutions to the lattice are constructed. In principle, the resulted nonlinear superposition formula guarantees the existence of multisoliton solutions and tells us how to construct them explicitly.

APPENDIX: HIROTA BILINEAR OPERATOR IDENTITIES

The following bilinear operator identities hold for arbitrary functions a,b,c and d:

$$D_t^3(D_zD_ta\cdot a)\cdot a^2=D_t[(D_t^3D_za\cdot a)\cdot a^2+3(D_tD_za\cdot a)\cdot(D_t^2a\cdot a)], \tag{A1}$$

$$D_t^{2n+1}a\cdot a=0,\quad n=0,1,2,\ldots, \tag{A2}$$

$$\begin{aligned}D_t^3(e^{D_n}a\cdot a)\cdot a^2=2\sinh(\tfrac{1}{2}D_n)[(D_t^3e^{(1/2)D_n}a\cdot a)\cdot(e^{(1/2)D_n}a\cdot a)\\+3(D_te^{(1/2)D_n}a\cdot a)\cdot(D_t^2e^{(1/2)D_n}a\cdot a)],\end{aligned} \tag{A3}$$

$$\begin{aligned}&D_t[(D_t^2e^{D_n}a\cdot a)\cdot a^2+(e^{D_n}a\cdot a)\cdot(D_t^2a\cdot a)]\\&\quad=2\sinh(\tfrac{1}{2}D_n)[(D_t^3e^{(1/2)D_n}a\cdot a)\cdot(e^{(1/2)D_n}a\cdot a)+(D_t^2e^{(1/2)D_n}a\cdot a)\cdot(D_te^{(1/2)D_n}a\cdot a)],\end{aligned} \tag{A4}$$

$$\begin{aligned}&2\sinh(\tfrac{1}{2}D_n)[(D_yD_te^{(1/2)D_n}a\cdot a)\cdot(e^{(1/2)D_n}a\cdot a)+(D_te^{(1/2)D_n}a\cdot a)\cdot(D_ye^{(1/2)D_n}a\cdot a)]\\&\quad=D_t(D_ye^{D_n}a\cdot a)\cdot a^2,\end{aligned} \tag{A5}$$

We describe the construction of some finite dimensional nonunitary representations of $E(2)$, the Lie group of Euclidean transformations in the plane. Some properties of these representations are also discussed, with emphasis on indecomposable representations. © *1999 American Institute of Physics.* [S0022-2488(99)02711-5]

I. INTRODUCTION

The group $E(2)$ of Euclidean transformations in two dimensions is the noncompact semidirect product group $[\mathbb{R}^2]\mathrm{SO}(2)$, which consists of Abelian translations in the plane together with rotations. Its unitary irreducible representations (unirreps) are either one-dimensional representations or infinite dimensional representations which can be constructed in the standard way by induction.[1] Much less is known about the finite dimensional, nonunitary representations of $E(2)$, the prototype of which is the ''natural'' representation

$$\pi:(R(\theta),x,y)\mapsto\begin{pmatrix}\cos\theta & -\sin\theta & x\\ \sin\theta & \cos\theta & y\\ 0 & 0 & 1\end{pmatrix} \tag{1}$$

in terms of 3×3 matrices, where $R(\theta)$ is the SO(2) rotation parametrized by the angle θ, and (x,y) is a vector describing the translation part of the transformation.

The representation of Eq. (1) was obtained in the familiar way from a 2×2 representation of SO(2), which is extended to a 3×3 matrix by addition of an extra line and an extra column with appropriate entries to account for the translation part of $E(2)$. This representation is not irreducible, but it is indecomposable.

It is the objective of this paper to present an explicit method of obtaining some finite-dimensional indecomposable representations of $E(2)$.

One can verify, using Eq. (1), the composition rule for $E(2)$ elements,

$$(R(\theta_1),x_1,y_1)\cdot(R(\theta_2),x_2,y_2)=(R(\theta_1+\theta_2),x_1+x_2\cos\theta_1-y_2\sin\theta_1,y_1+x_2\sin\theta_1+y_2\cos\theta_1). \tag{2}$$

From this composition rule, we can write a general element $(R(\theta),x,y)$ as the product $(1,x,y)\cdot(R(\theta),0,0)$, where $(1,0,0)=(R(\theta=0),0,0)$ is the unit element.

Throughout this paper, we will use complex coordinates, with $z=x+iy$. We can then obtain the 2×2 representations

$$\pi:(R(\theta),x,y)\equiv(R(\theta),z)\mapsto\begin{pmatrix}e^{i\theta} & z\\ 0 & 1\end{pmatrix},\quad \tilde{\pi}:(R(\theta),z)\mapsto\begin{pmatrix}1 & 0\\ \bar{z} & e^{-i\theta}\end{pmatrix}, \tag{3}$$

where $(R(\theta),z)$ now denotes an element of $E(2)$, and where the bar denotes complex conjugation. The composition rule now reads

$$(R(\theta_1),z_1)\cdot(R(\theta_2),z_2)=(R(\theta_1+\theta_2),z_1+z_2e^{i\theta_1}). \tag{4}$$

The full transformation in real space can be obtained from the real and imaginary parts of the complex transformation.

A motivation for our work is that $E(2)\sim[\mathbb{R}^2]\mathrm{SO}(2)$ represents the simplest nontrivial example of a semidirect product group, a family very useful in physics as it contains, amongst others, the rigid rotor group $[\mathbb{R}^5]\mathrm{SO}(3)$ of nuclear and molecular physics and the Poincaré group $[\mathbb{R}^4]\mathrm{SO}(3,1)$ of spacetime translations and boosts.

The starting point of our method is the Lie algebra $e(2)$ of the group $E(2)$. (We will jump freely between the algebra $e(2)$ and the group $E(2)$; all representations of $e(2)$ discussed here can be integrated to representations of $E(2)$.) Thus, suppose that $\pi(R(\theta),z)$ is a representation of $E(2)$ on a finite-dimensional space V. (It is a slight abuse of notation to write $\pi(R(\theta),z)$ because the representations will, in general, depend on both z and $\bar{z}$. However, this shorthand notation causes no problem. Technically speaking, we are thinking of z as an element of the complex plane, regarded as a *real* Lie group, not a complex Lie group.) Then, V decomposes into weight subspaces according to the action of SO(2),

$$V=\oplus W_k,$$

where

$$W_k=\{v\in V:\pi(R(\theta),0)v=e^{ik\theta}v\}, \tag{5}$$

where $k\in\mathbb{Z}$ so that $\pi(R(\theta+2\pi),z)=\pi(R(\theta),z)$ for representations of $E(2)$. We denote by

$$l_0=-i\frac{\partial}{\partial\theta}\pi(R(\theta),z)|_{\theta=z=0},\quad p_+=\frac{\partial}{\partial z}\pi(R(\theta),z)|_{\theta=z=0},\quad p_-=\frac{\partial}{\partial\bar{z}}\pi(R(\theta),z)|_{\theta=z=0}, \tag{6}$$

a basis for the $e(2)$ algebra, with nonzero commutation relations given by

$$[p_+,p_-]=0,\quad [l_0,p_\pm]=\pm p_\pm. \tag{7}$$

The elements p_+ and p_- are, respectively, ''raising'' and ''lowering'' operators, in the sense that

$$p_+W_k\subseteq W_{k+1},\quad p_-W_k\subseteq W_{k-1}. \tag{8}$$

In particular, for finite dimensional representations, they are nilpotent.

We have found that a useful and compact way of describing a representation of the $e(2)$ algebra is to display the result of Eqs. (7) and (8) in a graphical or diagrammatic form. We derive in Sec. II the rules for constructing representations of $e(2)$ that have no weight multiplicity. The tensor product of two such representations is simply obtained by combining their respective graphs in an appropriate way, as shown in Sec. II C. The resulting graph describes a representation of $e(2)$ which may or may not be decomposable; the problem of decomposing a tensor product turns out to be highly nontrivial, and we present in Sec. VIII some results on this issue.

A feature of tensor product representations and of certain other representations that we will present is that they typically contain indecomposable submodules with nontrivial weight multiplicities. One should recall that, thus far, the bulk of the results for $E(2)$ have dealt with unitary infinite dimensional representations, obtained either by induction or by the method of contraction,[2,3] where one considers representations of $E(2)$ as appropriate limits of representations of SU(2); in both cases, the weight multiplicity is never greater than 1. For the finite dimensional case, some of our representations can be thought of as smooth deformations of SU(2) representations. More generally, representations with trivial weight multiplicities are best accommodated inside the formalism of graded contractions[4] of SU(2), where the grading subgroup is the continuous subgroup $SO(2)\subset E(2)$. However, it is clear that the contraction of an SU(2) irrep cannot possibly yield a representation of $E(2)$ with nontrivial weight multiplicities. The possibility of constructing indecomposable modules containing arbitrarily high weight multiplicities is therefore, to our knowledge, completely new.

The representations of $E(2)$ that we construct belong to an identifiable family which, we think, is likely to contain many representations useful in physics. To illustrate this point, we give, in Sec. V, some explicit realizations of our representations. Moreover, the graphical method behind our results can certainly be adapted to more complicated semidirect product groups.[5]

II. STRING REPRESENTATIONS

In this section we discuss representations with weight multiplicities equal to 1, i.e., representations V for which, in the notation of (5), $\dim(W_k)\leqslant 1$, for all k. For such a representation, we let M and N be, respectively, the maximum and minimum nontrivial weights.

A. Some lemmas

Lemma 0: Every one-dimensional representation of $E(2)$ is of the form

$$\chi_k:(R(\theta),z)\mapsto e^{ik\theta}, \tag{9}$$

for some $k\in\mathbb{Z}$.

Proof: The translation subgroup T, i.e., the subgroup consisting of all elements of the form $(R(0),z)$, is the commutator subgroup of $E(2)$. So any one-dimensional representation of $E(2)$ must factor through the quotient $E(2)/T$, which is isomorphic to SO(2); the one-dimensional representations of SO(2) are of the specified form. □

Lemma 1: Let $0\neq|\varphi_k\rangle$ be an arbitrary vector in the one-dimensional subspace $W_k\subset V$. Then, at least one of $p_+|\varphi_k\rangle$ and $p_-(p_+|\varphi_k\rangle)$ must be zero for $[p_+,p_-]=0$ to be satisfied.

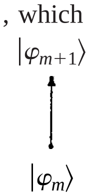
Proof: The raising and lowering operators p_+ and p_- are nilpotent and, since they commute, so is their product, the so(2)-invariant operator p_+p_-. The restriction of p_+p_- to any W_k subspace is therefore nilpotent. The only nilpotent operator on a one-dimensional space is the zero operator. If the W_k subspaces are all one-dimensional, this shows that $p_+p_-=0$ on V.

For an alternate, more explicit, proof, let $p_+p_-|\varphi_k\rangle=\alpha_k|\varphi_k\rangle$, where α_k is a proportionality constant. This holds since the subspace W_k is one-dimensional and p_+p_- is a weight-preserving operator. Since the representation is finite dimensional, there exists n such that $(p_+p_-)^n|\varphi_k\rangle=(p_+)^n(p_-)^n|\varphi_k\rangle=\alpha_k^n|\varphi_k\rangle=0$, from which it follows that $\alpha_k=0$. □

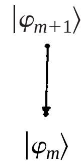
Proposition 1: If we specify on which subspaces W_m the raising and lowering operators are zero and on which they are nonzero, subject to the condition in lemma 1, this determines a unique representation of $e(2)$. The resulting representation is indecomposable if and only if p_+W_m and p_-W_{m+1} are not both zero for any m with $N\leqslant m<M$.

Proof: Because of the condition, we can choose a basis $\{|\varphi_m\rangle$ s.t. $l_0|\varphi_m\rangle=m|\varphi_m\rangle\}$ of eigenstates of l_0, with $|\varphi_m\rangle\in W_m$, for each m, and such that for each $m\in\{N,\ldots,M-1\}$, precisely one of the following holds:

(i) $p_+|\varphi_m\rangle=|\varphi_{m+1}\rangle$ and $p_-|\varphi_{m+1}\rangle=0$, which we represent by



(ii) $p_+|\varphi_m\rangle=0$ and $p_-|\varphi_{m+1}\rangle=|\varphi_m\rangle$, with graph,



or

(iii) $p_+|\varphi_m\rangle=0$ and $p_-|\varphi_{m+1}\rangle=0$, i.e., there is no arrow between $|\varphi_{m+1}\rangle$ and $|\varphi_m\rangle$,

$$\begin{array}{c}|\varphi_m\rangle\\ \vdots\\ |\varphi_{m+1}\rangle\end{array}.$$

Relative to the basis $\{|\varphi_M\rangle,|\varphi_{M-1}\rangle,\ldots,|\varphi_{N+1}\rangle,|\varphi_N\rangle\}$, so(2) acts diagonally, p_+ is represented by a matrix which is zero except for a 1 immediately above the diagonal corresponding to each m for which possibility (i) above holds, and p_- is represented by a matrix which is zero except for a 1 immediately below the diagonal corresponding to each $m+1$ for which possibility (ii) above holds.

Clearly the matrices for p_+ and p_- commute. The remaining commutators $[l_0,p_\pm]=\pm p_\pm$ are satisfied since, for instance, $(l_0p_+-p_+l_0)|\varphi_m\rangle=l_0|\varphi_{m+1}\rangle-mp_+|\varphi_m\rangle=|\varphi_{m+1}\rangle=p_+|\varphi_m\rangle$ by construction.

If $p_+W_k=0=p_-W_{k+1}$, then

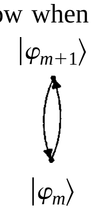
$$V=(\oplus_{m\leq k}W_m)\oplus(\oplus_{m>k}W_m) \tag{10}$$

is an $e(2)$-decomposition. Conversely, suppose $V=U\oplus U'$ is an $e(2)$-decomposition but that condition (iii) above does not hold for any $k\in\{N,N+1,...,M-1\}$. We can assume there exists $m\in\{N,N+1,...,M-1\}$ such that $W_m\subseteq U$, $W_{m+1}\subseteq U'$. Then either $p_+(W_m)$ or $p_-(W_{m+1})$ is nonzero. Since U and U' are both $e(2)$-spaces, this shows $U\cap U'\neq\{0\}$, a contradiction. □

Representations with weight multiplicities all equal to 1 will be called string representations.

B. String representations in graphical form

To a representation thus constructed, we can associate a graph as a mnemonic device to remember which of the conditions (i), (ii) or (iii) hold between two neighboring weight subspaces W_m and W_{m+1} by drawing an up arrow from W_m to W_{m+1} when (i) applies, a down arrow from W_{m+1} to W_m when (ii) applies, and no arrow when (iii) occurs; subgraphs of the type



for which $p_+|\varphi_m\rangle\neq0$ and $p_-|\varphi_{m+1}\rangle\neq0$, cannot occur.

To obtain a representation of $E(2)$ relative to the chosen basis, we start by exponentiating separately the diagonal matrix of l_0 to obtain the image of $(R(\theta),0)\in$ SO(2), and the off-diagonal matrix elements of the generators of translations p_+ and p_- to obtain $(1,z)$. The element $(R(\theta),z)$ is then constructed from the matrix multiplication of $(1,z)\cdot(R(\theta),0)$.

For instance, the ''raising string'' representation of $e(2)$, with a graph consisting only of up arrows, exponentiates to the $E(2)$ representation,

$$\Rightarrow \pi_1:(R(\theta),z)\mapsto \begin{pmatrix} e^{iM\theta} & e^{i(M-1)\theta}z & e^{i(M-2)\theta}\frac{1}{2}z^2 & \dots & \frac{e^{i(N+1)\theta}}{(M-N+1)!}z^{M-N+1} & \frac{e^{iN\theta}}{(M-N)!}z^{M-N} \\ 0 & e^{i(M-1)\theta} & e^{i(M-2)\theta}z & \dots & \frac{e^{i(N+1)\theta}}{(M-N+2)!}z^{M-N+2} & \frac{e^{iN\theta}}{(M-N+1)!}z^{M-N+1} \\ \vdots & \vdots & \vdots & & \vdots & \vdots \\ 0 & 0 & 0 & \dots & e^{i(N+1)\theta} & e^{iN\theta}z \\ 0 & 0 & 0 & \dots & 0 & e^{iN\theta} \end{pmatrix}, \tag{11}$$

containing the SO(2) unirreps $M,M-1,\dots,N$ each with multiplicity 1. It is indecomposable.

The ''lowering string'' representation

$$\Rightarrow \pi_2:(R(\theta),z)\mapsto \begin{pmatrix} e^{iM\theta} & 0 & 0 & \dots & 0 & 0 \\ e^{iM\theta}\bar{z} & e^{i(M-1)\theta} & 0 & \dots & 0 & 0 \\ e^{iM\theta}\frac{1}{2}\bar{z}^2 & e^{i(M-1)\theta}\bar{z} & e^{i(M-2)\theta} & \dots & 0 & 0 \\ \vdots & \vdots & \vdots & & \vdots & \vdots \\ \frac{e^{iM\theta}}{(M-N-1)!}\bar{z}^{M-N-1} & \frac{e^{i(M-1)\theta}}{(M-N-2)!}\bar{z}^{M-N-2} & \dots & \dots & e^{i(N+1)\theta} & 0 \\ \frac{e^{iM\theta}}{(M-N)!}\bar{z}^{M-N} & \frac{e^{i(M-1)\theta}}{(M-N-1)!}\bar{z}^{M-N-1} & \dots & \dots & e^{i(N+1)\theta}\bar{z} & e^{iN\theta} \end{pmatrix} \tag{12}$$

contains the SO(2) unirreps $M,M-1,\dots,N$ each with multiplicity 1, and nontrivial lowering operators between each pair of adjacent SO(2) subspaces. It is also indecomposable.

The five-dimensional representation with graph

$$\Rightarrow \pi_3:(R(\theta),z)\mapsto \begin{pmatrix} e^{2i\theta} & 0 & 0 & 0 & 0 \\ e^{2i\theta}\bar{z} & e^{i\theta} & z & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & e^{-i\theta} & e^{-2i\theta}z \\ 0 & 0 & 0 & 0 & e^{-2i\theta} \end{pmatrix} \tag{13}$$

is decomposable into two subspaces $V_1\oplus V_2$, containing respectively the SO(2) irreps 2,1,0 and $-1,-2$.

The three-dimensional representation

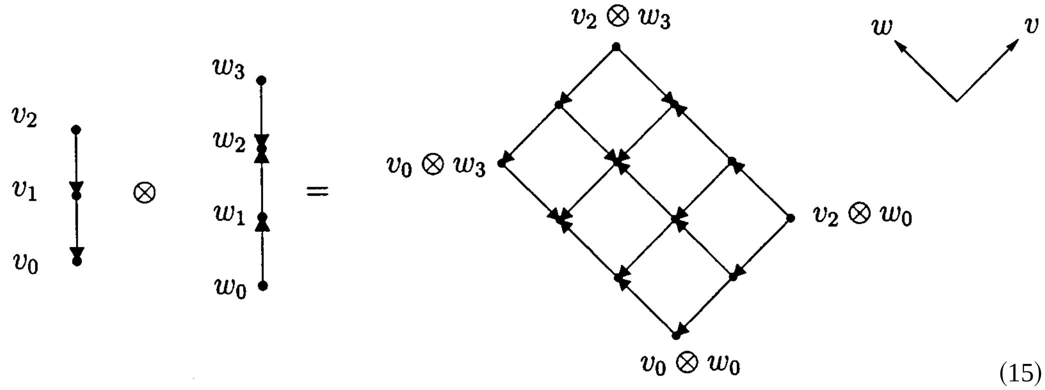
$$\Rightarrow \pi_4:(R(\theta),z)\mapsto \begin{pmatrix} e^{i\theta} & z & 0 \\ 0 & 1 & 0 \\ 0 & \bar{z} & e^{-i\theta} \end{pmatrix} \tag{14}$$

is indecomposable and equivalent to the ''natural'' representation of Eq. (1).

Note that, if π is an $E(2)$ representation containing the SO(2) irreps $M,M-1,\dots,N$, then $\chi_k\cdot\pi$ is another (inequivalent) representation containing the SO(2) irreps $M+k,M-1+k,\dots,N+k$.

C. Tensor product of two strings

Finally, it is also easy to represent the tensor product of two string representations in a graphical way. Thus, if V_1 and V_2 are two representations of $E(2)$ spanned, respectively, by $\{v_i, i=m_1, m_1-1, \ldots n_1\}$ and $\{w_j, j=m_2, m_2-1, \ldots, n_2\}$, then a basis for the tensor product representation $V_1 \otimes V_2$ is given by the points $v_i \otimes w_j$ having coordinates (i,j) on a two-dimensional grid. The arrows between point $v_i \otimes w_j$ and $v_k \otimes w_l$ are determined from the action of the $e(2)$ elements on v_i or w_j. Thus, for instance, consider the following tensor product:



(15)

where the final two-dimensional graph has been tilted so that states with the same weight occur at the same horizontal height. (The ''corner'' states on the graph have been explicitly indicated.)

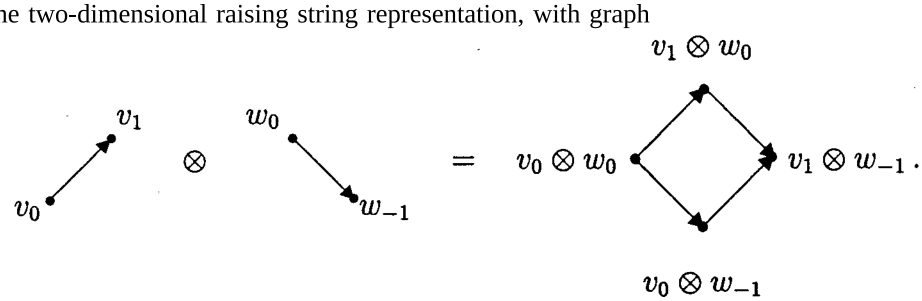
III. PARALLELOGRAM REPRESENTATIONS

A. The parallelogram representation as tensor product

Consider the representation

$$\pi_5 : (R(\theta), z) \mapsto \begin{pmatrix} 1 & 0 \\ \bar{z} & e^{-i\theta} \end{pmatrix} \otimes \begin{pmatrix} e^{i\theta} & z \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} e^{i\theta} & z & 0 & 0 \\ 0 & 1 & 0 & 0 \\ e^{i\theta}\bar{z} & z\bar{z} & 1 & e^{-i\theta} z \\ 0 & \bar{z} & 0 & e^{-i\theta} \end{pmatrix}, \tag{16}$$

which is obtained from the tensor product of the two-dimensional lowering string representation and the two-dimensional raising string representation, with graph



(17)

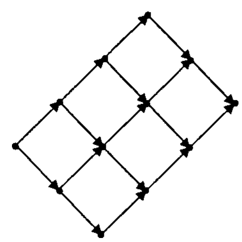
Claim: The representation π_5 is indecomposable.

Proof: Otherwise suppose $V = U \oplus U'$ is a nontrivial decomposition, and that one of the two subspaces, say U, contains a vector v in the two-dimensional subspace W_0 of weight 0 of the form $v = \alpha_1(v_0 \otimes w_0) + \alpha_2(v_1 \otimes w_{-1})$, with $\alpha_1 \neq 0$. By acting with $p_+ p_-$, we find $p_+ p_- v = \alpha_1(v_1 \otimes w_{-1})$ must also be in U. Thus, $v_1 \otimes w_{-1} \in W_0$ is also in U (since $\alpha_1 \neq 0$) and so $v - \alpha_2(v_1 \otimes w_{-1}) = \alpha_1(v_0 \otimes w_0) \in U$. Since $p_+(v_0 \otimes w_0) = v_1 \otimes w_0 \in U$ and $p_-(v_0 \otimes w_0) = v_0 \otimes w_{-1} \in U$ as well, we find that $U = V, U' = \{0\}$, a contradiction. □

This generalizes to larger representations. For $M \geqslant 0$, let V_M be the ''raising-string'' representation with lowest weight 0 and highest weight M. It has a weight basis consisting of the lowest weight vector v_0 of weight 0, and nonzero weight vectors $v_k = (p_+)^k v_0$, for $k = 1,...,M$, with $p_+(v_M) = 0$; the dimension is $M+1$. Similarly, for $N \geqslant 0$, let V_{-N} be the ''lowering-string'' representation with lowest weight $-N$ and highest weight 0. It has a weight basis consisting of the highest weight vector w_0 of weight 0, and nonzero weight vectors $w_{-k} = (p_-)^k w_0$, for $k = 1,...,N$, with $p_-(w_{-N}) = 0$; the dimension is $N+1$. The action of p_- on V_M and the action of p_+ on V_{-N} are both trivial.

The ''parallelogram'' representation $V_{M,-N}$ is the tensor product $V_{M,-N} = V_M \otimes V_{-N}$; it has lowest weight $-N$, highest weight M, and dimension $(M+1)(N+1)$. Since $v_k \otimes w_{-l} = (p_+)^k (p_-)^l v_0 \otimes w_0 = (p_-)^l (p_+)^k v_0 \otimes w_0$, we see that $V_{M,-N}$ is generated by the weight vector $v_0 \otimes w_0$, which we call the ''initial vector.'' Twisting by the character $\chi_r : (R(\theta), z) \mapsto e^{ir\theta}$, $r \in \mathbb{Z}$, gives a parallelogram representation $V_{M,-N;r} = \chi_r \otimes V_{M,-N}$ with lowest weight $r-N$, highest weight $r+M$, and dimension $(M+1)(N+1)$; it is generated by the ''initial vector'' $\chi_r \otimes v_0 \otimes w_0$.

For instance, the graph



(18)

is associated with the $V_{3,-2;r}$ parallelogram representation.

Lemma 2: The parallelogram representation $V_{M,-N;r}$ is indecomposable.

Proof: Let $V_{M,-N;r} = U \oplus U'$ be a decomposition. Choose a basis T whose first vector is $\phi_0 = \chi_r \otimes v_0 \otimes w_0$ and whose first d_r vectors $\phi_0, p_+p_-\phi_0, (p_+p_-)^2\phi_0, \ldots, (p_+p_-)^{d_r-1}\phi_0$ span the weight subspace W_r (of dimension d_r). Writing vectors in terms of this basis, we have that the initial vector is $\phi_0 = \chi_r \otimes v_0 \otimes w_0 = (1,0,0,\ldots)^T$. Let $v = (\alpha_1, \alpha_2, \ldots, \alpha_{d_r}, 0, \ldots)^T, \alpha_1 \neq 0$, be an otherwise arbitrary vector in W_r. Assume that $v \in U$, and consider

$$
\begin{aligned}
p_+p_- v &= (0, \alpha_1, \alpha_2, \ldots, \alpha_{d_r-1}, 0, \ldots)^T \in U, \\
(p_+p_-)^2 v &= (0,0,\alpha_1, \alpha_2, \ldots, \alpha_{d_r-2}, 0, \ldots)^T \in U, \\
&\vdots \\
(p_+p_-)^{d_r-3} v &= (0, \ldots, \alpha_1, \alpha_2, \alpha_3, 0, \ldots)^T \in U, \\
(p_+p_-)^{d_r-2} v &= (0, \ldots, \alpha_1, \alpha_2, 0, \ldots)^T \in U, \\
(p_+p_-)^{d_r-1} v &= (0, \ldots, 0, \alpha_1, 0, \ldots)^T \in U.
\end{aligned} \tag{19}
$$

Thus, the d_rth basis vector

$$
v_{d_r} = \frac{1}{\alpha_1}(p_+p_-)^{d_r-1}(\chi_r \otimes v_0 \otimes w_0) = (0, \ldots, 1, 0, \ldots)^T \in U \tag{20}
$$

(since $\alpha_1 \neq 0$ by assumption). If this vector is in U, then the vector

$$v_{d_r-1}=\frac{1}{\alpha_1}((p_+p_-)^{d_r-2}v-\alpha_2 v_{d_r})=(0,\ldots,1,0,0,\ldots)^T\in U \tag{21}$$

as well, and so is

$$v_{d_r-2}=\frac{1}{\alpha_1}((p_+p_-)^{d_r-3}v-\alpha_2 v_{d_r-1}-\alpha_3 v_{d_r})=(0,\ldots,1,0,0,0,\ldots)^T\in U, \tag{22}$$

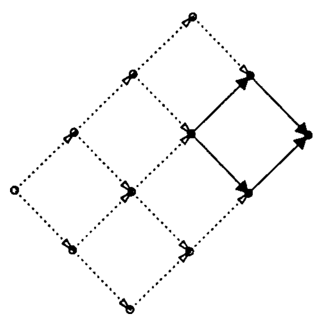
and so forth until one shows that all basis vectors in W_r are in U. In effect, this argument is based on the observation that the matrix of the restriction to each weight space of the operator p_+p_- is a triangular matrix.

In particular, the initial vector $\chi_r\otimes v_0\otimes w_0$ is in U and, since an arbitrary basis state $\chi_r\otimes v_s\otimes w_{-q}\in V$ can be obtained as $(p_+)^s(p_-)^q(\chi_r\otimes v_0\otimes w_0)$, it follows that $U=V$ and $U'=\{0\}$, which shows that V is indecomposable. □

In this way, we can construct indecomposable representations with arbitrarily high weight multiplicities.

B. Subrepresentations of the parallelogram

Observation: A vector $X_{k,-l,r}=\chi_r\otimes v_k\otimes w_{-l}=(p_+)^k(p_-)^l(\chi_r\otimes v_0\otimes w_0)$ generates a subrepresentation of $V_{M,-N;r}$ that is isomorphic to $V_{M-k,l-N;r+k-l}$. An example of this is given in Eq. (23), where, in $V_{3,-2;0}$, a 2×2 parallelogram subrepresentation $V_{1,-1;1}$ is generated by $X_{2,1,0}=(p_+)^2p_-(v_0\otimes w_0)$,



(23)

Proposition 2: Every subrepresentation of a parallelogram representation $V_{M,-N;r}$ can be expressed as the subrepresentation generated by finitely many ''initial vectors'' of the form $(p_+)^k(p_-)^l(\chi_r\otimes v_0\otimes w_0)$, for suitable k, l. The subrepresentations of $V_{M,-N;r}$ are all indecomposable.

Proof: First, note that the weight subspace $W_s\subset V_{M,-N;r}$ is spanned by vectors of the form $\{(p_+)^k(p_-)^l(\chi_r\otimes v_0\otimes w_0)|k-l=s-r\}$. The action of p_+p_- on this basis is to map

$$p_+p_-:(p_+)^k(p_-)^l(\chi_r\otimes v_0\otimes w_0)\mapsto(p_+)^{k+1}(p_-)^{l+1}(\chi_r\otimes v_0\otimes w_0). \tag{24}$$

Now, suppose $U\subset V_{M,-N;r}$ is an indecomposable subrepresentation with nontrivial intersection with the weight space W_s. Choose the minimal k such that U contains a nonzero vector $v\in W_s$ of the form

$$v=\sum_{i\geq 0}\alpha_i(p_+)^{\tilde{k}+i}(p_-)^{\tilde{l}+i}(\chi_r\otimes v_0\otimes w_0),\ \alpha_0\neq 0,\ \tilde{k}-\tilde{l}=s-r. \tag{25}$$

Then, by the p_+p_- argument of Lemma 2, all vectors of the form

$$(p_+)^{\tilde{k}+i}(p_-)^{\tilde{l}+i}(\chi_r\otimes v_0\otimes w_0),\ i\geqslant 0, \tag{26}$$

must be in U, and $(p_+)^{\tilde{k}}(p_-)^{\tilde{l}}(\chi_r\otimes v_0\otimes w_0)$ is an initial vector for the subspace of weight s in U.

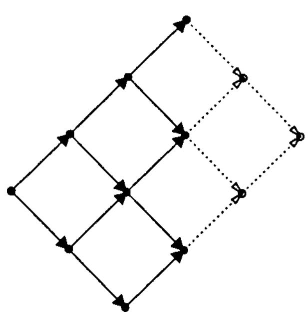
Do this for each weight s of U and discard redundant choices (vectors as above that are contained in the subspace generated by another such vector). The remaining finitely many ''initial vectors'' generate the whole space U. Note that the initial vectors have distinct weights.

Now suppose $U=U_1\oplus U_2$ is a decomposition. Fix one of the initial vectors described above. Then one of U_1, U_2, say U_1, contains a weight vector with nonzero overlap with this chosen initial vector. But then U_1 actually contains that initial vector, because of the triangularity of the operator p_+p_-, as above. If there is only one initial vector, then we are done, by Lemma 2 and the previous Observation. Otherwise, notice that once U_1 contains $(p_+)^k(p_-)^l(\chi_r\otimes v_0\otimes v_0)$, it must also contain the ''final vector'' $(p_+)^m(p_-)^n(\chi_r\otimes v_0\otimes v_0)=(p_+)^{m-k}\times(p_-)^{n-l}((p_+)^k(p_-)^l(\chi_r\otimes v_0\otimes v_0))$. But then U_1 must contain all the initial vectors, and hence all of U, so U is indecomposable. □

Corollary: A basis for any subrepresentation of the parallelogram representation $V_{m,-n;r}$ *is given by vectors of the form* $(p_+)^k(p_-)^l(\chi_r\otimes v_0\otimes v_0)$ *contained in this subrepresentation.*

C. Quotient representations

Consider the representation associated with the graph



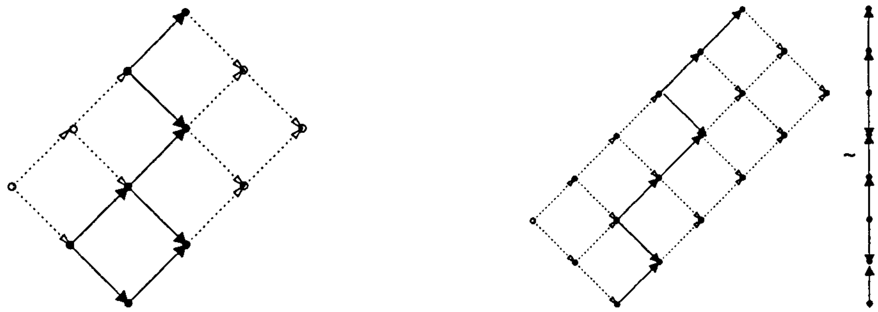
$$\Rightarrow \pi_6:(R(\theta),z)\mapsto \begin{pmatrix} e^{4i\theta} & ze^{3i\theta} & \frac{1}{2}z^2e^{2i\theta} & 0 & \frac{1}{6}z^3e^{i\theta} & 0 & 0 & 0 & 0 \\ 0 & e^{3i\theta} & ze^{2i\theta} & 0 & \frac{1}{2}z^2e^{i\theta} & 0 & 0 & 0 & 0 \\ 0 & 0 & e^{2i\theta} & 0 & ze^{i\theta} & 0 & 0 & 0 & 0 \\ 0 & \bar{z}e^{3i\theta} & 0 & e^{2i\theta} & 0 & ze^{i\theta} & \frac{1}{2}z^2 & 0 & 0 \\ 0 & 0 & 0 & 0 & e^{i\theta} & 0 & 0 & 0 & 0 \\ 0 & 0 & \bar{z}e^{2i\theta} & 0 & 0 & e^{i\theta} & z & 0 & 0 \\ 0 & 0 & 0 & 0 & \bar{z}e^{i\theta} & 0 & 1 & 0 & 0 \\ 0 & 0 & \frac{1}{2}z^2e^{2i\theta} & 0 & 0 & ze^{i\theta} & 0 & 1 & ze^{-i\theta} \\ 0 & 0 & 0 & 0 & \frac{1}{2}\bar{z}^2e^{i\theta} & 0 & \bar{z} & 0 & e^{-i\theta} \end{pmatrix}. \tag{27}$$

This representation can be constructed by starting from the parallelogram $V_{3,-2;0}$, and by removing (or, equivalently, setting to 0) each line and column corresponding to a node in the subrepresentation with initial vectors $v_3\otimes w_{-1}$ and $v_2\otimes w_{-2}$. It is therefore a quotient of the parallelogram $V_{3,-2;r}$.

Lemma 3: Quotient representations of a parallelogram are indecomposable.

Proof: Such a quotient representation has a single initial vector, $v=v_0\otimes w_0$. Let $V=V_1\oplus V_2$ be a decomposition. By the p_+p_- triangularity argument, the whole weight space containing v must be in either V_1 or V_2; without loss of generality, we assume that it is in V_1, and thus v itself is in V_1. Since everything in V can be obtained from $v=v_0\otimes w_0$ by acting with $e(2)$ generators, it follows that $V_1=V, V_2=\{0\}$, i.e., V is indecomposable. □

It is also possible to take quotients of subrepresentations of a parallelogram, as shown on the left-hand side of Eq. (28), or even to make a string representation out of a quotient of a subparallelogram, as shown on the right-hand side of that figure.



(28)

Thus, we can claim that

Proposition 3: A subquotient of a subrepresentation of the parallelogram $V_{m,-n;r}$ (i.e., the quotient of two subrepresentations of the parallelogram $V_{m,-n;r}$) is indecomposable, provided that its graph is connected.

Proof: Let i,j uniquely label a minimal set of initial vectors $X_{i,j,r}=(p_+)^i(p_-)^j(\chi_r)\otimes v_0 \otimes w_0)$ of weight $r+i-j$ in such a representation V. Because initial vectors cannot have the same weight, the elements in the set $\{X_{i,j,k}\}$ can be ordered by increasing weight. These initial vectors are also those of a subrepresentation of the parallelogram $V_{m,-n;r}$. Let $V=V_1\oplus V_2$. Using the p_+p_- triangularity argument, the vectors generated from an initial vector all belong to the same subspace, either V_1 or V_2, depending on whether the initial vector is in V_1 or V_2. However, the subspaces generated by two consecutive initial vectors must have a nontrivial intersection, for otherwise the graph would be disconnected (into the vectors in or above the higher subspace and the vectors in or below the lower subspace).

By the p_+p_- triangularity argument, each weight space in this intersection must belong to only one of V_1 or V_2. Thus, the subspaces generated by two consecutive initial vectors must belong to the same subspace, and, continuing this way, all subspaces must belong to the same subspace, say V_1. This means that V_2 is empty and we are done. □

The last noteworthy result on quotients of subparallelograms is as follows:

Proposition 4: Given a (connected) string representation, there exists a subquotient of a parallelogram which is isomorphic to this string.

Proof: In the string representation, let m be the number of up arrows, n the number of down arrows, and construct $V_{m,-n;r}$, with r adjusted so that the highest weight of $V_{m,-n;r}$ is equal to the highest weight of the string, i.e., $m+r$. If the topmost arrow of the string is a down arrow then the highest weight state of the representation, $\chi_r\otimes v_m\otimes w_0$ is the heaviest initial vector of the subrepresentation. Otherwise, the initial vectors are ''sources'' of the type

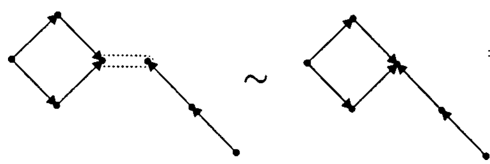
unless the bottom-most arrow of the string is an up arrow, in which case the lightest initial vector is the lowest weight vector of the representation, $\chi_r\otimes v_0\otimes w_{-N}$. The heaviest initial vector, for instance, is always of the form $\chi_r\otimes v_l\otimes w_0$. Next, we note that terminal vectors are either highest or lowest weight vectors or ''sinks'' of the type

If the topmost arrow in the string is a down arrow, then $\chi_r\otimes v_n\otimes w_0$ is an initial vector; if the bottommost arrow is an up arrow, then $\chi_r \otimes v_0 \otimes w_{-m}$ is an initial vector. For each ''source,'' as described above, V has an initial vector $\chi_r \otimes v_k \otimes w_{-l}$, where $m-k$ is the number of up arrows above the source and $n-l$ is the number of down arrows below it.

Having identified the initial vectors, one then constructs the corresponding subrepresentation V of $V_{m,-n;r}$. Consider now the subrepresentation $V' \subset V$ obtained by applying the operator $p_+ p_-$ to V, i.e., $V' = p_+ p_-(V)$. The original string is the subquotient V/V'. □

IV. GLUING

Not all representations need be quotients or subquotients of parallelograms. For instance, consider the representation



$$\Rightarrow \pi_7 : (R(\theta), z) \mapsto \begin{pmatrix} e^{i\theta} & z & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ e^{i\theta}\overline{z} & z\overline{z} & 1 & e^{-i\theta}z & e^{-i\theta}z & e^{-2i\theta}\frac{1}{2}z^2 \\ 0 & \overline{z} & 0 & e^{-i\theta} & 0 & 0 \\ 0 & 0 & 0 & 0 & e^{-i\theta} & e^{-2i\theta}z \\ 0 & 0 & 0 & 0 & 0 & e^{-2i\theta} \end{pmatrix} \tag{29}$$

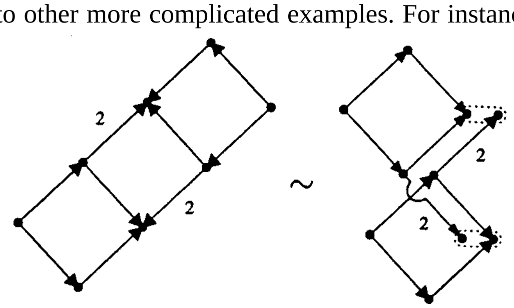
with $\dim(W_1)=1$, $\dim(W_0)=\dim(W_{-1})=2$, $\dim(W_{-2})=1$. It is constructed by identifying the terminal vector of the 2×2 parallelogram representation of Eq. (17) with the terminal node of an extra two-element raising string ending at the terminal node, i.e., by ''gluing'' the parallelogram and the raising string at one node in the manner indicated by the graph.

Claim: The representation π_7 is indecomposable.

Proof: Otherwise suppose $V = U \oplus U'$ is a nontrivial decomposition. We can assume U contains the weight space W_{-2}. In this case, it also contains the standard basis vectors $\hat{e}_5 = (0,0,0,0,1,0)^T$ and $\hat{e}_4 = (0,0,0,1,0,0)^T$. But this last vector is the ''terminal node'' of the subspace which is isomorphic to π_5, and the argument given in connection to this representation shows that either U or U' must contain all of this subspace. Since we have already seen that U must contain e_4, it must contain all of the π_5 subspace, and therefore must be all of V. □

This can be generalized to other more complicated examples. For instance, the representation

π_8 :



(30)

can be realized as shown as a two-point gluing. Note that the factors of 2 in the graph indicate that the corresponding matrix element is of strength 2 rather than 1, as has been thus far assumed throughout this paper. The representation π_8 can also be shown to be indecomposable.

Not all gluings are indecomposable. The representation of Fig. (53), which is obtained by gluing together two strings, is decomposable, as will be seen in Sec. VII.

V. EXPLICIT REALIZATIONS

In this section, we would like to exhibit some of the more interesting amongst the many explicit realizations of the $e(2)$ algebra, along with examples of the kind of representations that we have so far described.

Nonunitary representations occur in physics mostly as representations carried by tensor operators. Thus, if $\hat{T}_i^\lambda$ is the ith component of a tensor operator $\hat{T}^\lambda$ transforming by the representation λ, and if $\mathcal{O}$ is a representation of an element of $e(2)$ by linear operators, then the action of $\mathcal{O}$ on $\hat{T}^\lambda$ is given by

$$\mathcal{O}:\hat{T}_i^\lambda \mapsto [\mathcal{O},\hat{T}_i^\lambda] = \sum_j \alpha_{ij}\hat{T}_j^\lambda, \tag{31}$$

where α_{ij} are, in general, complex coefficients.

A. The adjoint representation

Let,

$$p_+ \mapsto \tfrac{1}{2}e^{-i\theta}\left(\frac{\partial}{\partial r} - \frac{i}{r}\frac{\partial}{\partial\theta}\right),\ p_- \mapsto \tfrac{1}{2}e^{i\theta}\left(\frac{\partial}{\partial r} + \frac{i}{r}\frac{\partial}{\partial\theta}\right),\ l_0 \mapsto i\frac{\partial}{\partial\theta}. \tag{32}$$

If we let these operators act on one another, we obtain the adjoint representation of $e(2)$, with the graph given in Eq. (14).

B. Raising string or lowering string representations

Let

$$p_+ \mapsto e^{i\theta}\frac{\partial}{\partial r},\ p_- \mapsto 0,\ l_0 \mapsto -i\frac{\partial}{\partial\theta}, \tag{33}$$

and consider the set of polynomials $\{e^{ik\theta}r^q, e^{i(k+1)\theta}r^{q-1}, e^{i(k+2)\theta}r^{q-2}, \ldots, e^{i(k+q)\theta}\}$, with $k \in \mathbb{Z}, q \in \mathbb{Z}^+$.

Using Eq. (31) and the realization of Eq. (33), one sees that these polynomials carry a representation equivalent to a raising string representation of dimension $q+1$ with lowest weight k.

Similarly, the realization

$$p_+ \mapsto 0,\ p_- \mapsto e^{-i\theta}\frac{\partial}{\partial r},\ l_0 \mapsto -i\frac{\partial}{\partial\theta}, \tag{34}$$

action on the polynomials $\{e^{in\theta}r^q, e^{i(n-1)\theta}r^{q-1}, \ldots, e^{i(n-q)\theta}\}$, with $n \in \mathbb{Z}, q \in \mathbb{Z}^+$, is a lowering string representation of dimension $q+1$ with lowest weight $n-q$.

We obtain a less trivial example if we let the operators of Eq. (32) act on the polynomials $\{r^t e^{it\theta}, r^{t-1}e^{i(t-1)\theta}, \ldots, 1\}$, which yields a raising string representation with highest weight vector $r^t e^{it\theta}$ of weight t.

In a similar way, the polynomials $\{r^t e^{-it\theta}, r^{t-1}e^{-i(t-1)\theta}, \ldots, 1\}$ span a lowering string representation of $E(2)$ under the action of the operators of Eq. (32).

C. Parallelograms

Consider the three operators

$$p_+ = \frac{\partial^2}{\partial x^2} + 2i\frac{\partial^2}{\partial x\partial y} - \frac{\partial^2}{\partial y^2} = \frac{\partial^2}{\partial \overline{w}^2},$$

$$p_-=\frac{\partial^2}{\partial x^2}-2i\frac{\partial^2}{\partial x\partial y}-\frac{\partial^2}{\partial y^2}=\frac{\partial^2}{\partial w^2}, \tag{35}$$

$$l_0=-\frac{i}{2}\left(x\frac{\partial}{\partial y}-y\frac{\partial}{\partial x}\right)=w\frac{\partial}{\partial w}-\bar{w}\frac{\partial}{\partial \bar{w}}. \tag{36}$$

With the identification $p_\pm \leftrightarrow \hat{Q}_{\pm 2}, l_0 \leftrightarrow \frac{1}{2}\hat{l}_z$, these are easily recognized as forming an $e(2)$ subalgebra of $[\mathbb{R}]^5$so(3), the algebra of the rigid rotor.

We now consider the operators

$$\hat{X}_{LM}=\sqrt{\frac{2^{L+M}(L+M)!(L-M)!L!}{(2L)!}}\sum_t \frac{\omega^t\tilde{\omega}^{t-M}z^{L+M-2t}}{2^t t!(t-M)!(L+M-2t)!}, \tag{37}$$

which can be recognized as proportional to the spherical harmonics

$$Y_{LM}(\theta,\varphi)=\sqrt{\frac{(2L+1)!}{4\pi 2^L L!}}\hat{X}_{LM} \tag{38}$$

if we make the identifications

$$\omega=\frac{-e^{i\varphi}\sin\theta}{\sqrt{2}},\quad z=\cos\theta,\quad \tilde{\omega}=\frac{e^{-i\varphi}\sin\theta}{\sqrt{2}}. \tag{39}$$

In general, we have

$$[p_\pm,\hat{X}_{LM}]=\alpha_{LM}\hat{X}_{L-2,M\pm 2}, \tag{40}$$

with

$$\alpha_{LM}=\langle \hat{X}_{L-2,M\pm 2}|p_\pm|\hat{X}_{LM}\rangle, \tag{41}$$

with the upper and lower sign valid for $p_\pm$, respectively, and where the number $\langle \hat{X}_{L-2,M\pm 2}|p_\pm|\hat{X}_{LM}\rangle$ is computed using the standard boson inner product. With these we can build a variety of parallelograms. (Note that the $e(2)$ weight is $\frac{1}{2}M$.)

Thus, for instance, the set of nine operators $\{\hat{X}_{80},\hat{X}_{6,\pm 2},\hat{X}_{4,\pm 4},\hat{X}_{40},\hat{X}_{2,\pm 2},\hat{X}_{00}\}$ are the components of a tensor which carries the parallelogram representation $V_{2,-2,0}$ with

$$\langle \hat{X}_{L-2,M\pm 2}|p_\pm|\hat{X}_{LM}\rangle=\sqrt{\frac{(2L+1)L(L-1)}{2L-3}}(L,M;2,\pm 2|L-2,M\pm 2), \tag{42}$$

where $(L,M;2,\pm 2|L-2,M\pm 2)$ is an SO(3) Clebsch–Gordan coefficient.

Similarly, the set $\{\hat{X}_{71},\hat{X}_{51},\hat{X}_{5,-3},\hat{X}_{33},\hat{X}_{3,-1},X_{11}\}$ are the six components of a tensor which carries the parallelogram representation $V_{2,-1;1}$.

Subparallelograms of these or of any parallelogram are obtained by simply removing from the original parallelogram all the basis polynomials not contained in the subrepresentations.

It is also possible to obtain parallelograms from the realization of Eq. (32). Repeated action of these operators on the initial vector $r^p e^{in\theta}$ produce the parallelogram representation $V_{(1/2)(p+n),-(1/2)(p-n);n}$. Note that, since $\frac{1}{2}(p+n)$ and $\frac{1}{2}(p-n)$ must be integers, $p+n$ must be even for the representation to remain finite dimensional.

The realization of Eq. (32) is a special case of the more general realization

$$p_+ \mapsto r^x e^{i(x-1)\theta}\left(\frac{\partial}{\partial r} - \frac{i}{r}\frac{\partial}{\partial \theta}\right), p_- \mapsto r^{-y} e^{i(y+1)\theta}\left(\frac{\partial}{\partial r} + \frac{i}{r}\frac{\partial}{\partial \theta}\right),$$

$$l_0 \mapsto i\frac{(x-y-2)}{2(x-1)(y+1)}\frac{\partial}{\partial \theta} + \frac{(x+y)}{2(x-1)(y+1)} r \frac{\partial}{\partial r}, \tag{43}$$

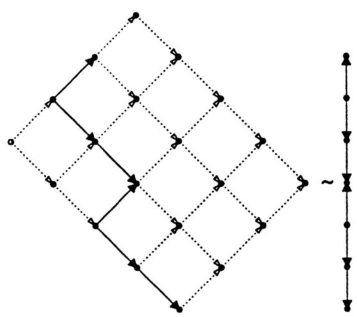
from which we can extract various parallelograms. (The exponents m,n of the initial vector $r^m e^{in\theta}$ must satisfy some conditions if the representation is to remain finite dimensional.)

D. Quotients and strings

Consider now the realization

$$p_+ \mapsto e^{i\theta}\frac{\partial^2}{\partial r^2},\ p_- \mapsto e^{-i\theta}\frac{\partial}{\partial r},\ l_0 = -i\frac{\partial}{\partial \theta}. \tag{44}$$

Acting on the initial vector r^4 to generate a parallelogram, and removing from this parallelogram the basis states r^4 and $r^3 e^{-i\theta}$, we obtain the string representation



$$\Rightarrow \pi_9:(R(\theta),w) \mapsto \begin{pmatrix} e^{-4i\theta} & \bar{w}e^{-3i\theta} & \frac{1}{2}\bar{w}^2 e^{-2i\theta} & 0 & 0 & 0 & 0 \\ 0 & e^{-3i\theta} & \bar{w}e^{-2i\theta} & 0 & 0 & 0 & 0 \\ 0 & 0 & e^{-2i\theta} & 0 & 0 & 0 & 0 \\ 0 & 0 & we^{-2i\theta} & e^{-i\theta} & \bar{w} & \frac{1}{2}\bar{w}^2 e^{i\theta} & 0 \\ 0 & 0 & 0 & 0 & 1 & \bar{w}e^{i\theta} & 0 \\ 0 & 0 & 0 & 0 & 0 & e^{i\theta} & 0 \\ 0 & 0 & 0 & 0 & 0 & we^{i\theta} & e^{2i\theta} \end{pmatrix}, \tag{45}$$

spanned by the basis states $\{e^{2i\theta}, e^{i\theta}r^2, r, e^{-i\theta}, e^{-2i\theta}r^2, e^{-3i\theta}r, e^{-4i\theta}\}$.

A nice feature of this string is that it represents an example of a $\mathbb{Z}_3$ graded-contraction of su(2) into $e(2)$, as discussed in Ref. 4. The grading is generated by the SO(2) subgroup $e^{(2\pi/3)l_0}$. The carrier space V decomposes into $V = V_0 \oplus V_1 \oplus V_2$, which contain the basis states

$$V_0 = \{r, e^{-3i\theta}r\},\ V_1 = \{e^{i\theta}r^2, e^{-2i\theta}r^2\},\ V_2 = \{e^{2i\theta}, e^{-i\theta}, e^{-4i\theta}\}, \tag{46}$$

while the basis elements of Eq. (44) have grades 1, 2, and 0, respectively.

VI. TENSORING TWO RAISING OR TWO LOWERING STRINGS

In Sec. III A, we considered the tensoring of a raising and a lowering string representation. The resulting parallelogram, as well as all its subrepresentations and ''connected'' subquotients, were shown to be indecomposable.

The next simplest example of tensor product is the product of two raising or two lowering string representations. This yields a tensor product representation that is always decomposable into a sum of raising or lowering string representations. The decomposition is closely related to the decomposition of SU(2) tensor products.

In this section, we discuss only the tensor product of two raising string representations since the case of two lowering strings is handled in the exact same way.

A. Raising strings as contractions of su(2) irreps

Consider the su(2) algebra spanned by the operators $\{L_+, L_-, L_0\}$, with the usual nonzero commutation relations

$$[L_0, L_\pm] = \pm L_\pm, \quad [L_+, L_-] = 2L_0. \tag{47}$$

If we now rescale the su(2) generators to

$$L_- \rightarrow \mathcal{L}_- = \epsilon L_-, \quad L_+ \rightarrow \mathcal{L}_+ = L_+, \quad L_0 \rightarrow \mathcal{L}_0 = L_0, \tag{48}$$

express the su(2) commutation relations in terms of the $\mathcal{L}$ generators, and take the limit as $\epsilon \rightarrow 0$, we see that

$$\begin{aligned} [\mathcal{L}_+, \mathcal{L}_-] &= \lim_{\epsilon\rightarrow 0} \epsilon [L_+, L_-] = \lim_{\epsilon\rightarrow 0} \epsilon 2 L_0 = \lim_{\epsilon\rightarrow 0} 2\epsilon \mathcal{L}_0 = 0, \\ [\mathcal{L}_0, \mathcal{L}_-] &= \lim_{\epsilon\rightarrow 0} \epsilon [L_0, L_-] = \lim_{\epsilon\rightarrow 0} -\epsilon L_- = -\mathcal{L}_-, \end{aligned} \tag{49}$$

with the commutator $[\mathcal{L}_+, \mathcal{L}_0]$ remaining unchanged from the su(2) commutator. We recover the algebra $e(2)$ by the identification $\mathcal{L}_\pm = p_\pm, \mathcal{L}_0 = l_0$, but, because the generators L_- and L_+ have been treated asymmetrically, the resulting representation cannot be unitary.

This is an example of a contraction.[2] The more familiar example of rescaling, where L_- and L_+ are treated on the same footing and both multiplied by the scale factor ε, leads to unitary infinite dimensional representations. Coming back to Eq. (49), suppose that we are given a standard unitary representation Γ_j of the su(2) algebra, of dimension, say, $2j+1$. The effect of taking the $\epsilon \rightarrow 0$ limit of the asymmetric scaling is to leave matrix elements of $\mathcal{L}_+ = L_+$ and $\mathcal{L}_0 = L_0$ unchanged, while setting to 0 the matrix elements of $\mathcal{L}_- = \epsilon L_-$. The resulting representation, where $p_- = \mathcal{L}_- = 0$ everywhere but where $p_+ = \mathcal{L}_+$ acts by raising the weight of the su(2) states, is clearly equivalent to a $(2j+1)$-dimensional raising string representation γ_j. The equivalence relation just rescales the nonzero su(2) matrix elements of L_+ to the standard $e(2)$ matrix elements of p_+, which are 1. Thus, we can write, for a raising string representation

$$\gamma_j = \lim_{\epsilon\rightarrow 0} \Gamma_j. \tag{50}$$

The lowest weight of γ_j is $-j$. A general raising string representation $\gamma_{j;k}$ of dimension $2j+1$ with lowest weight $-j+k$ can be obtained by twisting γ_j by a character χ_k.

(Note that one can obtain a lowering string representation from an su(2) representation by scaling $L_+ \rightarrow \mathcal{L}_+ = \epsilon L_+$ and leaving the other two generators unchanged.)

The advantage of introducing limits in such a fashion is that one can then think of raising string representations as smooth deformations of su(2) representations.

B. Decomposing tensor products of two raising strings

First, recall that the tensor product $j_1 \otimes j_2$ of two su(2) representations j_1 and j_2 of dimensions $2j_1+1$ and $2j_2+1$, respectively, decomposes into a sum of su(2) representations of dimension $2j+1$, with possible values of j given by $|j_1-j_2|, |j_1-j_2|+1, |j_1-j_2|+2, \ldots, j_1+j_2$, and where each value of j allowed by the inequality occurs exactly once.

Proposition 5: The tensor product of two raising string representations $\gamma_{j_1;r_1} \otimes \gamma_{j_2;r_2}$ *of dimensions* $2j_1+1$ *and* $2j_2+1$, *respectively, decomposes into a sum of raising string representations. The representations occuring in this tensor product have the dimensions* $2j+1$, *where* j *takes the possible values* $|j_1-j_2|, |j_1-j_2|+1, |j_1-j_2|+2, \ldots, j_1+j_2$, *and where each value of* j *allowed by the inequality occurs exactly once.*

Proof: Write

$$\begin{aligned}\gamma_{j_1;r_1}\otimes\gamma_{j_2;r_2}&=\chi_{r_1}\otimes(\lim_{\epsilon\to 0}\Gamma_{j_1})\otimes\chi_{r_2}\otimes(\lim_{\epsilon\to 0}\Gamma_{j_2})\\&=\chi_{r_1+r_2}\otimes(\lim_{\epsilon\to 0}\Gamma_{j_1}\otimes\Gamma_{j_2})\\&=\chi_{r_1+r_2}\otimes\left(\lim_{\epsilon\to 0}\sum_j\ \Gamma_j\right),\quad |j_1-j_2|\le j\le j_1+j_2,\\&=\chi_{r_1+r_2}\otimes\left(\sum_j\ \gamma_j\right),\\&=\sum_j\ \gamma_{j;r_1+r_2}.\end{aligned}\tag{51}$$

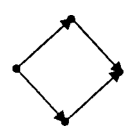
□

Note that, because the limiting process by which we transform the su(2) irrep into an $e(2)$ representation is smooth, i.e., because it is possible to define a sequence of su(2) representations parametrized by ϵ such that the limit when $\epsilon\to 0$ of this sequence corresponds to a raising string representation, it is possible to interchange the process of taking the limit with the process of taking the tensor product.

One may further remark that this limiting process cannot be used to analyze parallelogram representations, since those correspond to tensor products of a raising and a lowering string representations, i.e., a tensor product of ''different'' contractions.

VII. ACYCLIC REPRESENTATIONS AS SUMS OF STRINGS

The decomposition of the tensor product of two raising or two lowering representations is a special case of a more general theorem regarding ''acyclic'' representations, i.e., representations containing no ''cycles'' of the form



An algebraic characterization of such acyclic representations is that the operator p_+p_- is 0 everywhere. The main result of this section is that acyclic representations are always decomposable into sums of string representations.

Definition: A finite-dimensional representation V of $E(2)$ is said to be *acyclic* if $p_+p_-=0$ on V.

Clearly a string is acyclic, by Proposition 1. For that matter, a direct sum of strings must be acyclic. The goal of this section is to prove the converse: that any acyclic representation must be a direct sum of strings. We begin by establishing some machinery.

We need first a concept which is not restricted to acyclic representations, that of a ''chain.'' We define a ''chain'' to be a finite sequence of strictly increasing weight vectors $v_r, v_{r+1},\dots,v_s$ in V, where each v_j has weight j, and such that for each $r\le j<s$, either $p_+(v_j)=v_{j+1}$ or $p_-(v_{j+1})=v_j$.

Thus, for instance, in the 2×2 parallelogram representation of Eq. (17), which is not acyclic, there are infinitely many chains, each containing $v_1\otimes w_0$ and $v_0\otimes w_{-1}$ but each containing as middle element an otherwise arbitrary nonzero linear combination of $v_0\otimes w_0$ and $v_1\otimes w_{-1}$.

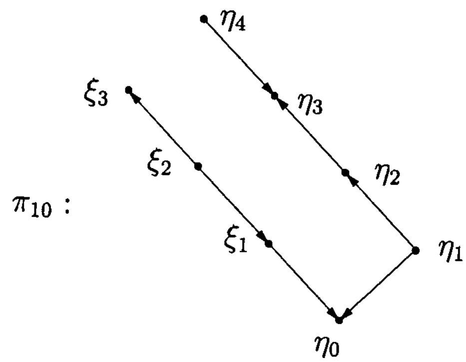
Specializing now to acyclic representations, we see that the condition $p_+p_-=0$ implies that it is not possible to have both $p_+(v_j)\neq 0$ *and* $p_-(v_{j+1})\neq 0$. A chain is ''maximal'' if it cannot be extended by including additional vectors (necessarily at the top or the bottom). The space spanned by the vectors in a maximal chain is a subrepresentation of V, necessarily a string.

Begin by observing that any weight vector can always be embedded in a maximal chain, i.e., it is always possible to find a maximal chain which contains a specified weight vector. Suppose that we have already defined N maximal chains,

$$
\begin{aligned}
&v^1_{r_1}, v^1_{r_1+1}, \ldots, v^1_{s_1};\\
&v^2_{r_2}, v^2_{r_2+1}, \ldots, v^2_{s_2};\\
&\ldots\\
&\ldots\\
&v^N_{r_N}, v^N_{r_N+1}, \ldots, v^N_{s_N}.
\end{aligned}
\tag{52}
$$

Note that we have displayed the chains horizontally rather than vertically for convenience. The chains need not all start nor end at the same weight nor all have the same length. Suppose that they are ''fully independent,'' in the sense that the vectors $\{v^m_i\}$ form a linearly independent set. Note that if v is any vector in the ''span'' of the N chains, i.e., the space spanned by the vectors $\{v^m_i\}$, then $p_+(v)$ and $p_-(v)$ are also in the span of these chains, again because of the assumption that $p_+p_-=0$.

As an inductive step, we have to show how to find $N+1$ fully independent maximal chains in V. It will be fruitful to illustrate the various steps of the induction with the following example.



(53)

This representation is found by gluing the string representations containing $\{\eta_4,\eta_3,\eta_2,\eta_1,\eta_0\}$ and $\{\xi_3,\xi_2,\xi_1,\eta_0\}$ at the common node η_0. In the example, we assume that $N=1$ and that the first maximal chain in π_{10} contains $\{v^1_4=\eta_4, v^1_3=\eta_3, v^1_2=\eta_2, v^1_1=\eta_1, v^1_0=\eta_0\}$.

Let k be the highest weight for which the kth weight space is not spanned by the vectors $\{v^m_k : m=1,...,N\}$ that lie in the kth weight space of the first N chains. (In π_{10}, we have $k=3$.)

If there is a vector v in the kth weight space which satisfies $p_+(v)=0$ but which is not in the span of the $\{v^m_k\}$, we will choose it as the top vector in a new chain. Because the $(k+1)$th weight space is by construction contained in the span of the N chains, the action of p_- on vectors in the $(k+1)$th weight space must also take them into the span of these N chains, so that v cannot be in the image of p_-.

The other possibility is that every v in the kth weight space which is not in the span of the $\{v^m_k\}$ satisfies $p_+(v)\neq 0$. Choose such a v. But the intersection of the $(k+1)$th weight space with the image of p_+ is spanned by the vectors $\{p_+(v^m_k)\}$. It is therefore possible to find a (nonzero) vector of the form $v'=v-\Sigma c_m v^m_k$ satisfying $p_+(v')=0$; since v' is not in the span of the $\{v^m_k\}$, this is a contradiction.

In the example, this first step could yield $v^2_3=\xi_3$ as the top state of the second chain in π_{10}.

Having found the top vector for a new chain, $v^{N+1}_{s_{N+1}}$, with $s_{N+1}=k$, we can attempt to construct the rest of the chain inductively by extending it from below.

Suppose we have constructed a chain $v^{N+1}_{s_{N+1}}, \ldots, v^{N+1}_{l+1}, v^{N+1}_l$ so that it and the original N maximal chains form a fully independent set, in the sense defined above.

If $p_-(v^{N+1}_l)=0$, and if v^{N+1}_l is not in the image of p_+, then we have constructed a maximal chain, with $r_{N+1}=l$, completing the inductive step. In all other cases, it necessary to perform an induction to extend the chain.

In general, the situation is that the induction leaves us with the possibility of constructing $N+1$ fully independent chains, none of which can be extended at the ''top,'' meaning that for each $m=1,...,N+1$, $p_+(v^m_{s_m})=0$ and $v^m_{s_m}$ is not in the image of p_-. At least one of the chains is nonmaximal; we will assume that the $(N+1)$th chain is nonmaximal, with lowest weight l, and that l is the maximum of the lowest weights of the nonmaximal chains. (Note that, although the $(N+1)$th chain has so far only been extended as low as weight l, it is, by assumption, not maximal and can therefore certainly be extended below l.) Let L be the number of nonmaximal chains with lowest weight l.

We will produce $N+1$ chains, none of which can be extended at the top, so that the number of nonmaximal chains with lowest weight l is strictly less than L, and so that none of the chains are nonmaximal with lowest weight greater than l. Induction on L will then allow us to construct $N+1$ chains so that any nonmaximal chains among them have lowest weight below l, and, continuing in this way, we can produce $N+1$ maximal chains.

If $p_-(v^{N+1}_l)=0$ and $v^{N+1}_l=p_+(v'')$, for some weight vector v'' of weight $l-1$, then choose such a v'' and let $v^{N+1}_{l-1}=v''$. Note that the resulting chain and the chains labeled 1 to N still form a fully independent set, because v^{N+1}_{l-1} cannot possibly be in the span of the chains labeled 1 to N, since $p_+(v^{N+1}_{l-1})=v^{N+1}_l$ is not in those N chains. Extending the $(N+1)$th chain by adding v^{N+1}_{l-1} gives a chain which has lowest weight $l-1$, which reduces the number of nonmaximal chains with lowest weight l and completes the inductive step in this case.

If $p_-(v^{N+1}_l)$ is nonzero but linearly independent of $\{v^1_{l-1}, v^2_{l-1}, \ldots, v^N_{l-1}\}$, then let $v^{N+1}_{l-1}=p_-(v^{N+1}_l)$. The resulting $(N+1)$th chain and the original N maximal chains still form a fully independent set, and the $(N+1)$th chain has lowest weight $l-1$, which completes the inductive step in this case.

In the example of π_{10}, these two situations occur. Starting with the top vector ξ_3, we see that $p_-\xi_3=0$ but that $p_+\xi_2=\xi_3$, so that the chain containing ξ_3 can be extended to include ξ_2. Since $p_-\xi_2=\xi_1$, which is linearly independent of η_1, the vector of weight 1 which is in the first maximal chain, we can again extend the chain containing $\{\xi_3,\xi_2\}$ to include ξ_1. However, $p_-\xi_1=\eta_0$, which is already in the first maximal chain. We therefore have $l=1$. The second chain contains $\{\xi_3,\xi_2,\xi_1\}$, and it is not maximal.

It could be, (as in the case with ξ_1 in π_1), that $p_-(v^{N+1}_l)$ is in the span of $\{v^1_{l-1}, v^2_{l-1}, \ldots, v^N_{l-1}\}$. Suppose

$$p_-(v^{N+1}_l)=\sum_{m=1}^{N} a_m v^m_{l-1}=\sum_{m=1}^{N} a_m p_-(v^m_l). \tag{54}$$

(The last equality holds because a linear combination of vectors from the N chains that is in the image of p_- must be the image under p_- of a linear combination of vectors from the N chains, because of our assumption that $p_+p_-=0$.) Then let $a_{N+1}=-1$ and consider the vector

$$u_l=-v^{N+1}_l+\sum_{m=1}^{N} a_m v^m_l=\sum_{m=1}^{N+1} a_m v^m_l. \tag{55}$$

It satisfies $p_-(u_l)=0$. Note that, although v^{N+1}_l is not in the image of p_+, this is not necessarily true of u_l. Reordering if necessary, we can assume that $u_l=\Sigma_{m=1}^{N_0} a_m v_l^m$, with $1\leqslant N_0\leqslant N+1$ and $a_m\neq 0$, $p_-(v_l^m)\neq 0$, for $1\leqslant m\leqslant N_0$ (i.e., we reorder so that the first m coefficients in u_l are nonzero.)

In the example of π_{10}, Eq. (55) produces the vector $u_1=-\xi_1+\eta_1$, which is not in the first (maximal) nor in the second (nonmaximal) chain. There is no reordering necessary as u_1 is a linear combination of the two vectors in the first and second chains, i.e., $a_1,a_2\neq 0$, so that $N_0=2=N$.

The situation is as follows. We have $N+1$ ''bottom'' vectors; u_l and the bottom vectors of the original N maximal chains. We have $N+1$ top vectors and the subspace spanned by the vectors in the $N+1$ chains, but no chains containing u_l. It is then a matter of reorganizing the states in the subspace so as to replace one of the existing $N+1$ chains with one that contains u_l. First we construct a chain containing u_l. There is a unique integer $\mu_1\geqslant l$ so that $(p_+)^{\mu_1-l}(u_l)\neq 0$ and $(p_+)^{\mu_1-l+1}(u_l)=0$; let $u_i=(p_+)^{i-l}(u_l)$, for $l\leqslant i\leqslant\mu_1$.

In the example of π_{10}, this integer is $\mu_1=3$ since it is possible to act $\mu_1-l=3-1=2$ times on $u_1=-\xi_1+\eta_1$ before getting $(p_+)^3(-\xi_1+\eta_1)=0$. Thus we have $u_1=-\xi_1+\eta_1, u_2=\eta_2, u_3=\eta_3$.

Reordering the chains if necessary, we can assume that $u_{\mu_1}=\Sigma_{m=1}^{N_1} a_m v_{\mu_1}^m$, with $a_m\neq 0$ whenever $1\leqslant m\leqslant N_1$, for some $N_1\leqslant N_0$. (In π_1, we have $N_1=1$ since u_3 can be expressed as a linear combination of a single vector.)

If u_{μ_1} is not in the image of p_-, then the chain $u_l,\ldots,u_{\mu_1}$ cannot be extended further at the top; it is a ''raising chain.'' If u_{μ_1} is in the image of p_-, then it is possible to add a ''lowering chain'' above it. Indeed, in this case there is some $\nu_1\geqslant 1$ so that

$$(p_-)^{i-\mu_1}\left(\sum_{m=1}^{N_1} a_m v_i^m\right)=u_{\mu_1}, \tag{56}$$

for all i with $\mu_1\leqslant i\leqslant\nu_1$, and so that $\Sigma_{m=1}^{N_1} a_m v_{\nu_1}^m$ is not in the image of p_-. For all i with $\mu_1\leqslant i\leqslant\nu_1$, let $u_i=\Sigma_{m=1}^{N_1} a_m v_i^m$. These vectors form a lowering chain.

In the example of π_{10}, we have $\nu_1=4$ since $p_-\eta_4=\eta_3=u_3$. The chain now contains $u_1=-\xi_1+\eta_1$, $u_2=\eta_2$, $u_3=\eta_3$, $u_4=\eta_4$.

We continue in the same way, finding positive integers $N_0\geqslant N_1\geqslant N_2\geqslant\cdots\geqslant N_t$ and integers $l=\mu_0=\nu_0\leqslant\mu_1<\nu_1<\mu_2<\nu_2<\cdots<\mu_t\leqslant\nu_t$; making a suitable rearrangement of the $N+1$ chains; and for each $1\leqslant j\leqslant t$, and for each i with $\nu_{j-1}\leqslant i\leqslant\mu_j$, letting

$$u_i=(p_+)^{i-\nu_{j-1}}(u_{\nu_{j-1}}), \tag{57}$$

and for each i with $\mu_j\leqslant i\leqslant\nu_j$, letting

$$u_i=\sum_{m=1}^{N_j} a_m v_i^m, \tag{58}$$

so that for each i with $\mu_j<i\leqslant\nu_j$,

$$p_-(u_i)=u_{i-1}. \tag{59}$$

In this way we have constructed a lowering chain between each μ_j and ν_j. Because

$$p_+(u_i)=u_{i+1}, \tag{60}$$

for each i with $\nu_{j-1}\leqslant i<\mu_j$, $j=1,\ldots,t$, there is a raising chain between each ν_{j-1} and μ_j.

In the example of π_{10}, we have $t=1$, as there is only one raising and one lowering chain to be glued to the vector $u_1=-\xi_1+\eta_1$. Our process therefore stops at $\nu_1=4$.

We can continue the construction until we reach a point where $p_+(u_{\nu_t})=0$, so the chain cannot continue up to higher weights. Note that for

$$u_{\nu_t}=\sum_{m=1}^{N_t} a_m v_{\nu_t}^m \tag{61}$$

to be in the kernel of p_+, it must be true that $p_+(v_{\nu_t}^m)=0$, for each $1\leqslant m\leqslant N_t$. And if u_{ν_t} is not in the image of p_-, then at least one of the vectors $v_{\nu_t}^m$, for $1\leqslant m\leqslant N_t$, must not be in the image of p_-. Renumbering yet again, if necessary, we can assume that this is true for $m=1$, which means that ν_t is the highest weight of the chain $\{v_i^1\}$.

In the example of π_{10}, we have $u_4=\eta_4$ as the top vector; η_4 is in the kernel of p_+ and not in the image of p_-. Thus, with the renumbering, the chain $\{u_4,u_3,u_2,u_1\}$ becomes the first chain.

The vectors $u_l,u_{l+1},\ldots,u_{\nu_t}$ form a chain. They all lie in the span of the linearly independent vectors making up the $N+1$ chains $\{v_i^m\}$, for $m=1,...,N+1$. Since $p_-(u_l)=0$, either u_l is not in the image of p_+, in which case the chain $\{u_l,u_{l+1},\ldots,u_{\nu_t}\}$ is maximal, or $u_l=p_+(u_{l-1})$, for some weight vector u_{l-1} of weight $l-1$. It can be added to produce a longer chain $\{u_{l-1},u_l,u_{l+1},\ldots,u_{\nu_t}\}$. Observe that u_{l-1} cannot be in the space spanned by the chains $\{v_i^1\},\ldots,\{v_i^{N+1}\}$. We have constructed a chain $\{u_i\}$; in one case it is maximal, and in the other it has lowest weight $l-1$.

In the example of π_{10}, the chain is maximal since $u_1=-\xi_1+\eta_1$ is not in the image of p_+.

Since every one of the vectors u_i, for $i\geqslant l$, contains a nonzero component in what is now labeled as the first chain $\{v_i^1\}$, we can replace the chain $\{v_i^1\}$ with the chain $\{u_i\}$ and the resulting $N+1$ chains will still be fully independent.

At this point there are different possibilities. One is that the chain labeled $\{v_i^1\}$ that was removed was the original nonmaximal chain $\{v_i^{N+1}\}$, and it has just been replaced by the chain $\{u_i\}$. This does not apply to π_{10}; the original second chain is not identical to the newly constructed maximal chain.

Otherwise, the original nonmaximal chain $\{v_i^{N+1}\}$ with lowest weight l is still present. In this case we can change its label back to $v_l^{N+1},\ldots,v_{s_{N+1}}^{N+1}$. But now $p_-(v_l^{N+1})$ is not in the span of the vectors in the other N chains, since $p_-(v_l^1)$ is no longer present in the other N chains. This means that the $(N+1)$th chain can be extended to include $p_-(v_l^{N+1})$ as its ''bottom'' vector.

In the example of π_{10}, this is what happens. The original second chain contained $\{\xi_3,\xi_2,\xi_1\}$. Since $p_-\xi_1=\eta_0$, which is no longer in the span of the newly constructed first maximal chain, we can extend this second chain to include η_0.

In either case, the number of nonmaximal chains with lowest weight l has been reduced.

In the example of π_{10}, we now restart the induction with $\{\eta_4,\eta_3,\eta_2,-\xi_1+\eta_1\}$ as the first maximal chain and $\{\xi_3,\xi_2,\xi_1,\eta_0\}$ as the second chain, we find that now $k=3$, $N=1$ but $l=0$. However, $p_-\eta_0=0$ and η_0 is not in the image of p_+. Thus, the second chain is maximal as it is. This concludes the inductions: we have found the decomposition of π_{10} as the sum of two strings.

Theorem 1: A finite-dimensional representation V of $E(2)$ is acyclic if and only if V is a direct sum of indecomposable representations, in each of which the weight spaces are all of dimension 1.

Proof: ($\Leftarrow$) Trivial.

($\Rightarrow$) The above argument shows that, given N fully independent maximal chains that do not span all of V, it is possible to construct $N+1$ fully independent maximal chains.

In attempting this construction, we may reach a situation where there are $N+1$ fully independent chains, but not all of them are maximal. We let l be the maximum of the lowest weights of the nonmaximal strings. The inductive step described above reduces the number of nonmaximal strings with lowest weight l. Repeated application of this procedure will eventually reduce l, the maximum of the lowest weights of the nonmaximal strings.

Continuing with an induction on l, we can eventually eliminate all the nonmaximal chains, producing $N+1$ fully independent maximal chains, as required.

Then, since the number of fully independent chains is certainly bounded by the dimension of the whole space V, we will eventually be able to construct enough chains that they span the whole space. □

VIII. DISCUSSION AND CONCLUSION

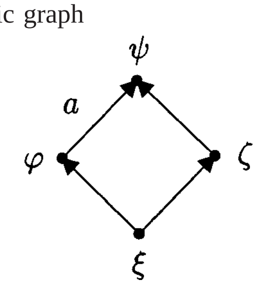
In this paper, we have described numerous finite dimensional indecomposable representations of $E(2)$ by means of a method which encapsulates in graphical form all the necessary information to explicitly construct, up to a character, a representation.

The basic type representation is the string, in which all the weight subspaces are of dimension one. Using lemma 1 and proposition 1, we can associate to a string representation a graph, from which it is easy to determine if the representation is decomposable or not. In an indecomposable string representation, the ‘‘strength’’ of the $e(2)$ matrix element connecting two states is irrelevant; all indecomposable strings representations are equivalent to representations for which this matrix element is 1.

We have been successful in showing the indecomposability of another very important class of representations, the parallelograms and all their subrepresentations and quotients. Parallelograms and their subrepresentations may contain nontrivial weight multiplicities, an unusual feature for representations of $E(2)$. We have also shown how acyclic representations can be decomposed into sums of string representations.

The problem of decomposing a general graph containing nontrivial weight multiplicities arising either per se or as from the tensor product of two general string representations is difficult.

Consider for instance the acyclic graph



(62)

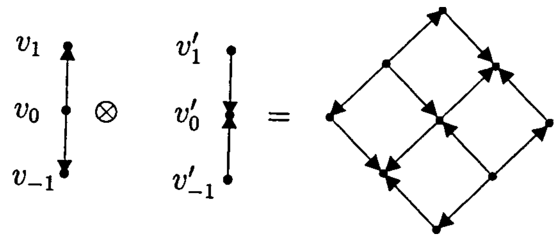
with basis states $\{\xi,\varphi,\zeta,\psi\}$, in which $p_+\varphi=a\psi$, with all other nonzero matrix elements being 1. When $a=-1$, the representation decomposes into a sum containing two (inequivalent) two-dimensional subrepresentations.

When $a\neq-1$, however, this can be decomposed into a sum of a three-dimensional and a one-dimensional string. The special case where $a=1$ corresponds to a tensor product of the two-dimensional raising string with itself.

The decomposability of some graphs can be understood in terms of representations of S_n, the permutation group of n objects. Unfortunately, arguments based on the permutation group are of limited use because (i) the S_n-invariant subspaces may themselves decompose further (for instance, in the tensor product of a three-dimensional raising string with itself, the six-dimensional subspace that carries the fully symmetric representation of S_2 can be divided into a five-dimensional and a one-dimensional indecomposable raising string), (ii) experience has shown that the problem of deciding if a given graph (string or otherwise) can be obtained by tensoring n copies of a given string is nontrivial.

There is, however, one case which we would like to mention. Consider the tensor product of an indecomposable string V, with a basis of weight vectors $v_l,\ldots,v_m$ with $l\leqslant m$, with another indecomposable string V' With weight vectors $v'_{-m},\ldots,v'_{-l}$ such that $p_+v'_{-k-1}=v'_{-k}$ if and only if $p_+v_k=v_{k+1}$ and $p_-v'_{-k}=v_{-k-1}$ if and only if $p_-v_{k+1}=v_k$. The tensor product $V\otimes V'$ is decomposable into two parts, one of which is the one-dimensional indecomposable representation with basis vector $v=\Sigma_{k=l}{}^m(-1)^k v_k\otimes v'_{-k}$, because V' occurs when we tensor together $(l-m-1)$ copies of V.

The simplest example of this is found in (63).



(63)

In this example, $V\otimes V'$ decomposes into an eight-dimensional representation isomorphic to (30) and a one-dimensional subspace $v=v_0\otimes v'_0-v_1\otimes v'_{-1}+v_2\otimes v'_{-2}$. Note that, obviously, the weights of V' could be shifted up or down and the tensor product would still be decomposable. What is important is the relative positions of the arrows, not the actual weights.

This family of decomposable tensor products can be related to the symmetric group as follows. It can be shown that, if the dimension of V is d, then the $(d-1)$-fold tensor product of V with itself contains, up to a character, V' in the S_{d-1}-invariant subspace labeled by a Young tableau containing a single column of $d-1$ boxes.

In the example of (63), V is of dimension $d=3$, and a basis for the three-dimensional representation of $V\otimes V$ which carries the S_2 representation labeled by 1 column of 2 boxes is given by

$$v'_{-2}=\chi_{-3}\otimes\det\begin{vmatrix} w_1 & x_1 \\ w_0 & x_0\end{vmatrix},\quad v'_{-1}=\chi_{-3}\otimes\det\begin{vmatrix} w_2 & x_2 \\ w_0 & x_0\end{vmatrix},\quad v'_0=\chi_{-3}\otimes\det\begin{vmatrix} w_2 & x_2 \\ w_1 & x_1\end{vmatrix}, \tag{64}$$

where $w_i, x_j, i,j=0,1,2$ are basis states for the first and second copy of V in the tensor product $V\otimes V$, respectively. The representation V' can be reconstructed if we observe that the nonzero matrix elements of $p_\pm$ are given by

$$\begin{aligned} p_+v'_{-2}&=\chi_{-3}\otimes\det\begin{vmatrix} p_+w_1 & p_+x_1 \\ w_0 & x_0\end{vmatrix}+\det\begin{vmatrix} w_1 & x_1 \\ p_+w_0 & p_+x_0\end{vmatrix}=\chi_{-3}\otimes\det\begin{vmatrix} w_2 & x_2 \\ w_0 & x_0\end{vmatrix}=v'_{-1},\\ p_-v'_0&=\chi_{-3}\otimes\det\begin{vmatrix} p_-w_2 & p_-x_2 \\ w_1 & x_1\end{vmatrix}+\chi_{-3}\otimes\det\begin{vmatrix} w_2 & x_2 \\ p_-w_1 & p_-x_1\end{vmatrix}=\chi_{-3}\otimes\det\begin{vmatrix} w_2 & x_2 \\ w_0 & x_0\end{vmatrix}=v'_0. \end{aligned} \tag{65}$$

From this, it can be seen how the decomposition of $V\otimes V'$ is related to the action of symmetric group on $(V)^d$, and why the scalar v is alternating in nature.

Finally, even if all the examples of decomposable tensor products discussed in this paper can ultimately be related to the symmetric group, we believe that there very likely exist decomposable graphs with nontrivial weight multiplicities which are unrelated to S_n. We have, unfortunately, been unable to isolate a provable conjecture on this matter. The low-dimensional examples of this section are sufficiently complex to illustrate the difficulty of the general problem.

In a subsequent publication, we will investigate the role of gluings of the type found in (30) in the construction of finite dimensional representations.

There is no doubt that results similar to Lemma 1 and Proposition 1 can be extended to other groups,[5] in particular within the context of graded contractions.[4] It is also reasonable to expect that the method can be generalized to the construction of finite dimensional representations of other semidirect product groups. In that regard, one should observe that the operator p_+p_- is in fact, the $e(2)$ Casimir operator, so that one way of generalizing the concept of string representations to other groups is to require that the appropriate Casimir be 0. It remains to see how other concepts, such as parallelograms, can be generalized to other examples.

Level-one representations of the quantum affine superalgebra $U_q[gl(\hat{N}|N)]$ associated with the appropriate nonstandard system of simple roots and q-vertex operators (intertwining operators) associated with the level-one modules are constructed explicitly in terms of free bosonic fields. © *1999 American Institute of Physics.* [S0022-2488(99)02111-8]

I. INTRODUCTION

The algebraic analysis approach[1,2] based on quantum affine algebra symmetries enables one not only to solve massive or off-critical integrable models directly in the thermodynamic limit but also to compute their correlation functions[3] and form factors[4] in the form of integrals by applying the techniques similar to those used so successfully in the critical cases (see, for example, Ref. 5). The key components behind this method are infinite dimensional highest weight representations of the quantum affine algebras and the corresponding q-vertex operators[6] which are intertwiners of these representations. As in the critical cases, this procedure requires the explicit construction of the highest weight representations and vertex operators in terms of free bosonic fields.

By now, the level-one representations and vertex operators have been constructed in terms of free bosons for most quantum affine bosonic algebras (see, e.g., Refs. 7–12). In contrast, much less has been known for the case of quantum affine superalgebras. For the type I quantum affine superalgebra $U_q[gl(\hat{M}|N)]$, $M\neq N$, the level-one representations and vertex operators have been investigated in Ref. 13 (see Ref. 14 for a level-k free boson realization of $U_q[sl(\hat{2}|1)]$). In particular, the level-one irreducible highest weight representations of $U_q[gl(\hat{2}|1)]$ were studied in some details and the corresponding characters were derived.[13] These representations have been re-examined and used to compute the correlation functions of the q-deformed supersymmetric $t-J$ model in Ref. 15.

So far in the literature, the very interesting case of $M=N$ has been largely ignored. The only exception is[16] where the special case of $M=N=2$ was treated and the type I vertex operators involving infinite dimensional evaluation (or level-zero) representations were also constructed for this special case. By contrast, we shall consider the general $M=N$ case and investigate both type I and type II vertex operators with respect to finite dimensional evaluation modules. The $M=N$ case is interesting since it seems to us that $U_q[gl(\hat{N}|N)]$ is the only untwisted superalgebra which has a nonstandard system where all simple roots are odd or fermionic. It also seems to be the only superalgebra where a vertex type quasi-Hopf twistor can be constructed[17] and thus the corresponding elliptic quantum supergroup $\mathcal{A}_{q,p}[gl(\hat{N}|N)]$ can be introduced.

In this paper, we construct a level-one representation of $U_q[gl(\hat{N}|N)]$ by bosonizing the Drinfeld generators. We also construct the vertex operators associated with the level-one representations in terms of the free bosonic fields.

It should be pointed out that the $M=N$ case, treated in this paper, is more complicated than the $M\neq N$ case considered in Ref. 13. For the $M=N$ case, the Cartan matrix is degenerate, i.e., not invertible. As is well known, the invertibility of Cartan matrix is essential in the construction of vertex operators. We overcome this problem by enlarging the Cartan subalgebra in an appropriate way. Moreover, we shall work in a nonstandard system of simple roots, in contrast to Ref. 13 in which a standard system was used. Then our method is a generalization and modification of that used in Ref. 13. We also remark that the ideas in the present paper is applicable to the study of higher level vertex operator representations of quantum affine superalgebras.

The layout of this paper is the following. In Sec. II, we describe the Drinfeld realization[18] of $U_q[gl(\hat{N}|N)]$ in the nonstandard system of simple roots and determine the ''main terms'' [19] in the coproduct formulas of the Drinfeld generators. In Sec. III, we derive the $2N$-dimensional evaluation (or level-zero) representations of $U_q[gl(\hat{N}|N)]$. In Sec. IV, we investigate the bosonization of $U_q[gl(\hat{N}|N)]$ and construct an explicit level-one representation in terms of free bosonic fields. Section V is devoted to the study of the bosonization of the level-one vertex operators.

II. QUANTUM AFFINE SUPERALGEBRA $U_q[gl(\hat{N}|N)]$

As is well-known, a given Kac–Moody superalgebra[20] allows many inequivalent systems of simple roots. A system of simple roots is called distinguished if it has minimal odd roots. Let $\{\alpha_i, i=0,1,...,2N-1\}$ denote a chosen set of simple roots of the affine superalgebra $gl(\hat{N}|N)$. Let (,) be a fixed invariant bilinear form on the root space. Let $\mathcal{H}$ be the Cartan subalgebra and throughout we identify the dual $\mathcal{H}^*$ with $\mathcal{H}$ via (,). As is shown in Ref. 17, $gl(\hat{N}|N)$ has a simple root system in which all simple roots are odd (or fermionic). This system can be constructed from the distinguished simple root system by using the ''extended'' Weyl operation[21] repeatedly. We have the following simple roots, all of which are odd (or fermionic)

$$\alpha_0=\delta-\epsilon_1+\epsilon_{2N},$$
$$\alpha_l=\epsilon_l-\epsilon_{l+1},\quad l=1,2,...,2N-1 \tag{II.1}$$

with δ, $\{\epsilon_k\}_{k=1}^{2N}$ satisfying

$$(\delta,\delta)=(\delta,\epsilon_k)=0,\quad (\epsilon_k,\epsilon_{k'})=(-1)^{k+1}\delta_{kk'}. \tag{II.2}$$

Such a simple root system is usually called non-standard. The generalized symmetric Cartan matrix $(a_{ii'})$ takes the form

$$a_{01}\equiv(\alpha_0,\alpha_1)=-1,\quad a_{0,2N-1}\equiv(\alpha_0,\alpha_{2N-1})=1,$$
$$a_{ll'}\equiv(\alpha_l,\alpha_{l'})=(-1)^{l+1}(\delta_{l,l'-1}-\delta_{l,l'+1}),\quad l,l'=1,2,...,2N-1. \tag{II.3}$$

This Cartan matrix is degenerate. To obtain a nondegenerate Cartan matrix, we extend Ref. 22 $\mathcal{H}$ by adding to it the element

$$\alpha_{2N}=\sum_{k=1}^{2N}\epsilon_k. \tag{II.4}$$

In the following, we denote by $\tilde{\mathcal{H}}$ the extended Cartan subalgebra and by $\tilde{\mathcal{H}}^*$ the dual of $\tilde{\mathcal{H}}$. The enlarged Cartan matrix has the following extra matrix elements:

$$a_{2N,2N}\equiv(\alpha_{2N},\alpha_{2N})=0,\quad a_{i,2N}\equiv(\alpha_i,\alpha_{2N})=2\cdot(-1)^{i+1}. \tag{II.5}$$

Let $\{h_0,h_1,\ldots,h_{2N},d\}$ be a basis of $\tilde{\mathcal{H}}$, where h_{2N} is the element in $\tilde{\mathcal{H}}$ corresponding to α_{2N} and d is the usual derivation operator. We shall write $h_i=\alpha_i$ $(i=0,1,...,2N)$ with α_i given by (II.1), (II.4). Let $\{\Lambda_0,\Lambda_1,\ldots,\Lambda_{2N},c\}$ be the dual basis with Λ_j being fundamental weights and c the canonical central element. We have[17]

$$\Lambda_{2N}=\frac{1}{2N}\sum_{k=1}^{2N}(-1)^{k+1}\epsilon_k,$$

$$\Lambda_i=d+\sum_{k=1}^{i}(-k)^{k+1}\epsilon_k-\frac{i}{2N}\sum_{k=1}^{2N}(-1)^{k+1}\epsilon_k, \tag{II.6}$$

where $i=0,1,...,2N-1$.

The quantum affine superalgebra $U_q[gl(\hat{N}|N)]$ is a quantum (or q-) deformation of the universal enveloping algebra of $gl(\hat{N}|N)$ and is generated by the Chevalley generators $\{e_i, f_i\ q^{h_j}, d|i=0,1,...,2N-1, j=0,1,...,2N\}$. The $\mathbf{Z}_2$-grading of the Chevalley generators is $[e_i]=[f_i]=1$, $i=0,1,...,2N-1$ and zero otherwise. The defining relations are

$$hh'=h'h, \quad \forall h\in\tilde{H},$$

$$q^{h_j}e_iq^{-h_j}=q^{a_{ij}}e_i, \quad [d,e_i]=\delta_{i0}e_i,$$

$$q^{h_j}f_iq^{-h_j}=q^{-a_{ij}}f_i, \quad [d,f_i]=-\delta_{i0}f_i,$$

$$[e_i,f_{i'}]=\delta_{ii'}\frac{q^{h_i}-q^{-h_i}}{q-q^{-1}},$$

$$[e_i,e_{i'}]=[f_i,f_{i'}]=0, \text{ for } a_{ii'}=0,$$

$$[[e_0,e_1]_{q^{-1}},[e_0,e_{2N-1}]_q]=0,$$

$$[[e_l,e_{l-1}]_{q^{(-1)^l}},[e_l,e_{l+1}]_{q^{(-1)^{l+1}}}]=0,$$

$$[[e_{2N-1},e_{2N-2}]_{q^{-1}},[e_{2N-1},e_0]_q]=0,$$

$$[[f_0,f_1]_{q^{-1}},[f_0,f_{2N-1}]_q]=0,$$

$$[[f_l,f_{l-1}]_{q^{(-1)^l}},[f_l,f_{l+1}]_{q^{(-1)^{l+1}}}]=0,$$

$$[[f_{2N-1},f_{2N-2}]_{q^{-1}},[f_{2N-1},f_0]_q]=0, \quad l=1,2,...,2N-2. \tag{II.7}$$

Here and throughout, $[a,b]_x\equiv ab-(-1)^{[a][b]}xba$ and $[a,b]\equiv[a,b]_1$. The fourth order q-Serre relations are obtained by using Yamane's Dynkin diagram procedure.[23]

$U_q[gl(\hat{N}|N)]$ is a $\mathbf{Z}_2$-graded quasitriangular Hopf algebra endowed with the following coproduct Δ, counit ϵ and antipode S:

$$\Delta(h)=h\otimes 1+1\otimes h,$$

$$\Delta(e_i)=e_i\otimes 1+q^{h_i}\otimes e_i, \quad \Delta(f_i)=f_i\otimes q^{-h_i}+1\otimes f_i,$$

$$\epsilon(e_i)=\epsilon(f_i)=\epsilon(h)=0,$$

$$S(e_i)=-q^{-h_i}e_i, \quad S(f_i)=-f_iq^{h_i}, \quad S(h)=-h, \tag{II.8}$$

where $i=0,1,...,2N-1$ and $h\in\tilde{\mathcal{H}}$. Notice that the antipode S is a $\mathbf{Z}_2$-graded algebra antihomomorphism. Namely, for any homogeneous elements $a,b\in U_q[gl(\hat{N}|N)]$ $S(ab)=(-1)^{[a][b]}S(b)S(a)$, which extends to inhomogeneous elements through linearity. Moreover,

$$S^2(a)=q^{-2\rho}aq^{2\rho}, \quad \forall a\in U_q[gl(\hat{N}|N)], \tag{II.9}$$

where ρ is an element in $\tilde{\mathcal{H}}$ such that $(\rho,\alpha_i)=(\alpha_i,\alpha_i)/2$ for any simple root α_i, $i=0,1,2,...,2N-1$. Explicitly,

$$\rho=\frac{1}{2}\sum_{k=1}^{2N}(-1)^k\epsilon_k, \tag{II.10}$$

which coincides with $\overline{\rho}$, the half-sum of positive roots of $gl(N|N)$ in the present simple root system. The multiplication rule on the tensor products is $\mathbf{Z}_2$-graded: $(a\otimes b)(a'\otimes b')=(-1)^{[b][a']}(aa'\otimes bb')$ for any homogeneous elements $a,b,a',b'\in U_q[gl(\hat{N}|N)]$. We can also introduce the element in $\tilde{\mathcal{H}}$,

$$\tilde{\rho}=\sum_{i=0}^{2N-1}\Lambda_i+\xi N\Lambda_{2N}, \tag{II.11}$$

which gives the principal gradation

$$[\tilde{\rho},e_i]=e_i,\quad [\tilde{\rho},f_i]=-f_i,\quad i=0,1,...,2N-1. \tag{II.12}$$

In (II.11), ξ is an arbitrary constant.

$U_q[gl(\hat{N}|N)]$ can also be realized in terms of the Drinfeld generators[18] $\{X_m^{\pm,i},\ H_n^j,\ q^{\pm H_0^j},\ c\ d|m\in\mathbf{Z},\ n\in\mathbf{Z}-\{0\},\ i=1,2,...,2N-1,\ j=1,2,...,2N\}$. The $\mathbf{Z}_2$-grading of the Drinfeld generators is given by $[X_m^{\pm,i}]=1$ for all $i=1,...2N-1$, $m\in\mathbf{Z}$ and $[H_n^j]=[H_0^j]=[c]=[d]=0$ for all $j=1,...,2N$, $n\in\mathbf{Z}-\{0\}$. The relations satisfied by the Drinfeld generators reads (see Refs. 23, 24 for the Drinfeld realization of $U_q[gl(\hat{N}|N)]$ in the distinguished system of simple roots)

$$\begin{gathered}
[c,a]=[d,H_0^j]=[H_0^j,H_n^{j'}]=0,\quad \forall a\in U_q[gl(\hat{N}|N)],\\
q^{H_0^j}X_n^{\pm,i}q^{-H_0^j}=q^{\pm a_{ij}}X_n^{\pm,i},\quad [d,X_n^{\pm,i}]=nX_n^{\pm,i},\ [d,H_n^j]=nH_n^j,\\
[H_n^j,H_m^{j'}]=\delta_{n+m,0}\frac{[a_{jj'}n]_q[nc]_q}{n},\quad [H_n^j,X_m^{\pm,i}]=\pm\frac{[a_{ij}n]_q}{n}X_{n+m}^{\pm,i}q^{\mp|n|c/2},\\
[X_n^{+,i},X_m^{-,i'}]=\frac{\delta_{ii'}}{q-q^{-1}}(q^{(c/2)(n-m)}\psi_{n+m}^{+,i}-q^{-(c/2)(n-m)}\psi_{n+m}^{-,i}),\\
[X_n^{\pm,i},X_m^{\pm,i'}]=0\ \text{ for }\ a_{ii'}=0,\quad [X_{n+1}^{\pm,i},X_m^{\pm,i'}]_{q^{\pm a_{ii'}}}-[X_{m+1}^{\pm,i'},X_n^{\pm,i}]_{q^{\pm a_{ii'}}}=0,\\
[[X_m^{\pm,l},X_{m'}^{\pm,l-1}]_{q^{(-1)^l}},[X_n^{\pm,l},X_{n'}^{\pm,l+1}]_{q^{(-1)^{l+1}}}]\\
+[[X_n^{\pm,l},X_m^{\pm,l-1}]_{q^{(-1)^l}},[X_m^{\pm,l},X_{n'}^{\pm,l+1}]_{q^{(-1)^{l+1}}}]=0,\quad l=2,...,2N-2,
\end{gathered} \tag{II.13}$$

where $[x]_q=(q^x-q^{-x})/(q-q^{-1})$ and $\psi_n^{\pm,j}$ are related to $H_{\pm n}^j$ by relations

$$\sum_{n\in\mathbf{Z}}\psi_n^{\pm,j}z^{-n}=q^{\pm H_0^j}\exp\left(\pm(q-q^{-1})\sum_{n>0}H_{\pm n}^jz^{\mp n}\right). \tag{II.14}$$

The following relations can be proved by induction:

$$H_n^j=\frac{1}{q-q^{-1}}\sum_{p_1+2p_2+\cdots+\cup_n=n}\frac{(-1)^{\Sigma p_i-1}(\Sigma p_i-1)!}{p_1!\cdots p_n!}(q^{-H_0^j}\psi_1^{+,j})^{p_1}\cdots(q^{-H_0^j}\psi_n^{+,j})^{p_n},$$

$$H^j_{-n}=\frac{1}{q^{-1}-q}\sum_{p_1+2p_2+\cdots+np_n=n}\frac{(-1)^{\Sigma p_i-1}(\Sigma p_i-1)!}{p_1!\cdots p_n!}(q^{H^j_0}\psi^{-,j}_{-1})^{p_1}\cdots(q^{H^j_0}\psi^{-,j}_{-n})^{p_n}. \tag{II.15}$$

The Chevalley generators are related to the Drinfeld generators by the formulas,

$$h_i=H^i_0,\quad e_i=X^{+,i}_0,\quad f_i=X^{-,i}_0,\quad i=1,2,...,2N-1,$$

$$h_{2N}=H^{2N}_0,\quad h_0=c-\sum_{k=1}^{2N-1}H^k_0,$$

$$e_0=[X^{-,2N-1}_0,[X^{-,2N-2}_0,\ldots,[X^{-,3}_0,[X^{-,2}_0,X^{-,1}_1]_q]_{q^{-1}}\cdots]_q]_{q^{-1}}q^{-\Sigma_{k=1}^{2N-1}H^k_0},$$

$$f_0=(-1)^N q^{\Sigma_{k=1}^{2N-1}H^k_0}[[\cdots[[X^{+,1}_{-1},X^{+,2}_0]_{q^{-1}},X^{+,3}_0]_q,\ldots,X^{+,2N-2}_0]_{q^{-1}},X^{+,2N-1}_0]_q. \tag{II.16}$$

The coproduct of the Drinfeld generators is not known in full. However, for our purpose it suffices to derive the ''main terms''[19] in the coproduct formulas. We have

Proposition 1: For $m\in\mathbf{Z}_{\geqslant 0}$, $n\in\mathbf{Z}_{>0}$ *and* $i=1,2,...,2N-1$,

$$\Delta(X^{+,i}_m)=X^{+,i}_m\otimes q^{mc}+q^{H^i_0+2mc}\otimes X^{+,i}_m+\sum_{k=0}^{m-1}q^{(1/2)(m+3k)c}\psi^{+,i}_{m-k}\otimes q^{(m-k)c}X^{+,i}_k \bmod N_-\otimes N^2_+,$$

$$\Delta(X^{+,i}_{-n})=X^{+,i}_{-n}\otimes q^{-nc}+q^{-H^i_0}\otimes X^{+,i}_{-n}+\sum_{k=1}^{n-1}q^{(1/2)(n-k)c}\psi^{-,i}_{k-n}\otimes q^{(k-n)c}X^{+,i}_{-n} \bmod N_-\otimes N^2_+,$$

$$\Delta(X^{-,i}_n)=X^{-,i}_n\otimes q^{H^i_0}+q^{nc}\otimes X^{-,i}_n+\sum_{k=1}^{n-1}q^{(n-k)c}X^{-,i}_k\otimes q^{(1/2)(k-n)c}\psi^{+,i}_{n-k} \bmod N^2_-\otimes N_+,$$

$$\Delta(X^{-,i}_{-m})=X^{-,i}_{-m}\otimes q^{-H^i_0-2mc}+q^{-mc}\otimes X^{-,i}_{-m}$$
$$+\sum_{k=0}^{m-1}q^{(k-m)c}X^{-,i}_{-k}\otimes q^{-(1/2)(m+3k)c}\psi^{-,i}_{k-m} \bmod N^2_-\otimes N_+,$$

$$\Delta(H^i_n)=H^i_n\otimes q^{(1/2)nc}+q^{(3/2)nc}\otimes H^i_n \bmod N_-\otimes N_+,$$

$$\Delta(H^i_{-n})=H^i_{-n}\otimes q^{-(3/2)nc}+q^{-(1/2)nc}\otimes H^i_{-n} \bmod N_-\otimes N_+, \tag{II.17}$$

where $N_\pm$ *and* $N^2_\pm$ *are the left ideals generated by* $X^{\pm,k}_l$ *and* $X^{\pm,k}_l X^{\pm,k'}_{l'}$, k, $k'=1,...,2N-1$; l, $l'\in\mathbf{Z}$, *respectively.*

Remark: (i) We do not write down the formulas for $\Delta(H^{2N}_{\pm n})$ because they are not needed in this paper. $\Delta(H^{2N}_{\pm n})$ can be determined by requiring that Δ preserves the commutation relations (II.13). (ii) Modulo $N_+\otimes N_-+N_-\otimes N_+$, the elements $\psi^{\pm,i}_{\pm n}$ $(n\geqslant 0)$ are grouplike,

$$\Delta(\psi^{+,i}_n)=\sum_{k=0}^{n}q^{(3/2)kc}\psi^{+,i}_{n-k}\otimes q^{(1/2)(n-k)c}\psi^{+,i}_k,$$

$$\Delta(\psi^{-,i}_{-n})=\sum_{k=0}^{n}q^{-(1/2)kc}\psi^{-,i}_{k-n}\otimes q^{(3/2)(k-n)c}\psi^{-,i}_{-k}. \tag{II.18}$$

Define the Drinfeld currents or generating functions,

$$X^{\pm,i}(z)=\sum_{n\in\mathbf{Z}} X_n^{\pm,i} z^{-n-1},\quad \psi^{\pm,j}(z)=\sum_{n\in\mathbf{Z}} \psi_n^{\pm,j} z^{-n}. \tag{II.19}$$

In terms of these currents, (II.13) read

$$\psi^{\pm,j}(z)\psi^{\pm,j'}(w)=\psi^{\pm,j'}(w)\psi^{\pm,j}(z),$$

$$\psi^{+,j}(z)\psi^{-,j'}(w)=\frac{(z-wq^{c+a_{jj'}})(z-wq^{-c-a_{jj'}})}{(z-wq^{c-a_{jj'}})(z-wq^{-c+a_{jj'}})}\psi^{-j'}(w)\psi^{+,j}(z),$$

$$\psi^{+,j}(z)X^{\pm,i}(w)=q^{\pm a_{ij}}\frac{z-wq^{\mp(c/2)\mp a_{ij}}}{z-wq^{\mp(c/2)\pm a_{ij}}}X^{\pm,i}(w)\psi^{+,j}(z),$$

$$\psi^{-,j}(z)X^{\pm,i}(w)=q^{\pm a_{ij}}\frac{z-wq^{\pm(c/2)\mp a_{ij}}}{z-wq^{\pm(c/2)\pm a_{ij}}}X^{\pm,i}(w)\psi^{-,j}(z),$$

$$[X^{+,i}(z),X^{-,i'}(w)]=\frac{\delta_{ii'}}{(q-q^{-1})zw}\left(\delta\left(\frac{w}{z}q^{c}\right)\psi^{+,i}(wq^{(c/2)})-\delta\left(\frac{w}{z}q^{-c}\right)\psi^{-,i}(wq^{-(c/2)})\right),$$

$$X^{\pm,i}(z)X^{\pm,i'}(w)+X^{\pm,i'}(w)X^{\pm,i}(z)=0,\ \text{ for }\ a_{ii'}=0,$$

$$(z-wq^{\pm a_{ii'}})X^{\pm,i}(z)X^{\pm,i'}(w)+(zq^{\pm a_{ii'}}-w)X^{\pm,i'}(w)X^{\pm,i}(z)=0,$$

$$\{[[X^{\pm,l}(z_1),X^{\pm,l-1}(z)]_{q^{(-1)^l}},[X^{\pm,l}(z_2),X^{\pm,l+1}(w)]_{q^{(-1)^{l+1}}}]\}+\{z_1\leftrightarrow z_2\}=0,\ \ l=2,3,...,2N-2. \tag{II.20}$$

These current commutation relations can be derived from the super version[24,25] of the RS algebra[26] by means of the Gauss decomposition technique of Ding and Frenkel.[27]

III. LEVEL-ZERO REPRESENTATION

We consider the evaluation representation V_z of $U_q[gl(\widehat{N|N})]$, where V is an $2N$-dimensional graded vector space with basis vectors $\{v_1,v_2,\ldots,v_{2N}\}$. The $\mathbf{Z}_2$-grading of the basis vectors is chosen to be $[v_j]=[(-1)^j+1]/2$. Let $e_{j,j'}$ be the $2N\times 2N$ matrices satisfying $(e_{j,j'})_{kk'}=\delta_{jk}\delta_{j'k'}$ or equivalently $e_{i,j}v_k=\delta_{jk}v_i$, (which implies that for any operator A its matrix elements $A_{j,i}$ are defined by $Av_i=A_{j,i}v_j$). In the homogeneous gradation, the Chevalley generators on V_z are represented by

$$e_i=e_{i,i+1},\quad f_i=(-1)^{i+1}e_{i+1,i},\quad i=1,2,...,2N-1,$$

$$h_i=(-1)^{i+1}(e_{i,i}+e_{i+1,i+1}),\quad h_{2N}=\sum_{k=1}^{2N}(-1)^{k+1}e_{k,k},$$

$$e_0=ze_{2N,1},\quad f_0=-z^{-1}e_{1,2N},\quad h_0=-e_{1,1}-e_{2N,2N}. \tag{III.1}$$

Let V^{*S} be the left dual module of V, defined by

$$(a\cdot v^*)(v)=(-1)^{[a][v^*]}v^*(S(a)v),\quad \forall a\in U_q[gl(\widehat{N|N})],\quad v\in V, v^*\in V^*. \tag{III.2}$$

Namely, the representations on V^{*S} are given by

$$\pi_{V^{*S}}(a)=\pi_V(S(a))^{\mathrm{st}},\quad \forall a\in U_q[gl(\widehat{N|N})], \tag{III.3}$$

where st denotes the supertransposition defined by $(A_{i,j})^{\rm st}=(-1)^{[j]([i]+[j])}A_{j,i}$. Note that in general $((A_{i,j})^{\rm st})^{\rm st}=(-1)^{[A]}A_{i,j}\neq A_{i,j}$. Let V_z^{*S} be the $2N$-dimensional evaluation module corresponding to V^{*S}. On V_z^{*S}, the Chevalley generators are represented by

$$e_i=-(-1)^i q^{(-1)^i} e_{i+1,i},\quad f_i=-q^{(-1)^{i+1}} e_{i,i+1},\quad i=1,2,...,2N-1,$$

$$h_i=(-1)^i(e_{i,i}+e_{i+1,i+1}),\quad h_{2N}=\sum_{k=1}^{2N}(-1)^k e_{k,k},$$

$$e_0=zqe_{1,2N},\quad f_0=z^{-1}q^{-1}e_{2N,1},\quad h_0=e_{1,1}+e_{2N,2N}. \qquad \text{(III.4)}$$

Proposition 2: The Drinfeld generators are represented on V_z by

$$H_m^i=(-1)^{i+1}\frac{[m]_q}{m}q^{(-1)^i m}(q^{x_i}z)^m(e_{i,i}+e_{i+1,i+1}),$$

$$H_m^{2N}=z^m\frac{[2m]_q}{m}\left[-q^m\sum_{l=1}^N e_{2l,2l}+\sum_{l=1}^N (y+(l-1)(1-q^m))(e_{2l-1,2l-1}+e_{2l,2l})\right],$$

$$H_0^i=(-1)^{i+1}(e_{i,i}+e_{i+1,i+1}),\quad H_0^{2N}=\sum_{k=1}^{2N}(-1)^{k+1}e_{k,k},$$

$$X_m^{+,i}=(q^{x_i}z)^m e_{i,i+1},\quad X_m^{-,i}=(-1)^{i+1}(q^{x_i}z)^m e_{i+1,i}, \qquad \text{(III.5)}$$

and on V_z^{*S} by

$$H_m^i=(-1)^i\frac{[m]_q}{m}q^{(-1)^{i+1}m}(q^{-x_i z})^m(e_{i,i}+e_{i+1,i+1}),$$

$$H_m^{2N}=-z^m\frac{[2m]_q}{m}\left[-q^{-m}\sum_{l=1}^N e_{2l,2l}+\sum_{l=1}^N (-y^*+(l-1)(1-q^{-m}))(e_{2l-1,2l-1}+e_{2l,2l})\right],$$

$$H_0^i=(-1)^i(e_{i,i}+e_{i+1,i+1}),\quad H_0^{2N}=\sum_{k=1}^{2N}(-1)^k e_{k,k},$$

$$X_m^{+,i}=-(-1)^i q^{(-1)^i}(q^{-x_{i_z}})^m e_{i+1,i},\quad X_m^{-,i}=-q^{(-1)^{i+1}}(q^{-x_{i_z}})^m e_{i,i+1}, \qquad \text{(III.6)}$$

where $i=1,...,2N-1$, $x_i=\Sigma_{l=1}^i(-1)^{l+1}=[(-1)^{i+1}+1]/2$ and y, y^* are arbitrary constants.

IV. FREE BOSON REALIZATION AT LEVEL ONE

We use the notations similar to those in Refs. 9 and 13. Let us introduce bosonic oscillators $\{A_n^j,\ c_n^l,\ Q_{A^j},\ Q_{c^l}|n\in\mathbf{Z},\ j=1,2,...,2N,\ l=1,2,...,N\}$ which satisfy the commutation relations

$$[A_n^j,A_m^{j'}]=\delta_{n+m,0}\frac{[a_{jj'}n]_q[n]_q}{n},\quad [A_0^j,Q_{A^{j'}}]=a_{jj'},$$

$$[c_n^l,c_m^{l'}]=\delta_{ll'}\delta_{n+m,0}\frac{[n]_q^2}{n},\quad [c_0^l,Q_{c^{l'}}]=\delta_{ll'}. \qquad \text{(IV.1)}$$

The remaining commutation relations are zero. Introduce the currents

$$H^j(z;\kappa)=Q_{A^j}+A_0^j\ln z-\sum_{n\neq 0}\frac{A_n^j}{[n]_q}q^{\kappa|n|}z^{-n},$$

$$c^l(z)=Q_{c^l}+c_0^l\ln z-\sum_{n\neq 0}\frac{c_n^l}{[n]_q}z^{-n} \tag{IV.2}$$

and set

$$H_\pm^j(z)=H^j(q^{+(1/2)}z;-\tfrac{1}{2})-H^j(q^{\mp(1/2)}z;\tfrac{1}{2})=\pm(q-q^{-1})\sum_{n>0}A_{\pm n}^j z^{\mp n}\pm A_0^i\ln q. \tag{IV.3}$$

We make a basis transformation and express A_n^j and Q_{A^j} in terms of a new set of bosonic oscillators $\{a_n^j,\ Q_{a^j}|j=1,2,...,2N\}$ as

$$A_n^i=(-1)^{i+1}(a_n^i+a_n^{i+1}),\ \ A_n^{2N}=\frac{q^n+q^{-n}}{2}\sum_{l=1}^{2N}(-1)^{l+1}a_n^l,$$

$$Q_{A^i}=(-1)^{i+1}(Q_{a^i}+Q_{a^{i+1}}),\ \ Q_{A^{2N}}=\sum_{l=1}^{2N}(-1)^{l+1}Q_{a^l}, \tag{IV.4}$$

where $i=1,...,2N-1$ and $\{a_n^j,Q_{a^j}\}$ satisfy the commutation relations

$$[a_n^j,a_m^{j'}]=(-1)^{j+1}\delta_{jj'}\delta_{n+m,0}\frac{[n]_q^2}{n},\quad [a_0^j,Q_{a^{j'}}]=(-1)^{j+1}\delta_{jj'}. \tag{IV.5}$$

Now we state our main result in this section on the free boson realization of $U_q[gl(\widehat{N|N})]$ at level one.

Theorem 1: *The Drinfeld generators of $U_q[gl(\widehat{N|N})]$ at level one are realized by the free boson fields as*

$$c=1,\quad \psi^{\pm,j}(z)=e^{H_\pm^j(z)},\quad j=1,2,...,2N,$$

$$X^{\pm,i}(z)=:e^{\pm H^i(z;\mp 1/2)}Y^{\pm,i}(z):F^{\pm,i},\quad i=1,2,...,2N-1, \tag{IV.6}$$

where

$$F^{\pm,2k-1}=\prod_{l=1}^{k-1}e^{\pm\sqrt{-1}\pi a_0^{2l-1}},\quad F^{\pm,2k}=\prod_{l=1}^{k}e^{\mp\sqrt{-1}\pi a_0^{2l-1}},$$

$$Y^{+,2k-1}(z)=e^{c^k(z)},$$

$$Y^{-,2k-1}(z)=\frac{1}{z(q-q^{-1})}(e^{-c^k(qz)}-e^{-c^k(q^{-1}z)}),$$

$$Y^{+,2k}(z)=Y^{-,2k-1}(z)=\frac{1}{z(q-q^{-1})}(e^{-c^k(qz)}-e^{-c^k(q^{-1}z)}),$$

$$Y^{-,2k}(z)=-Y^{+,2k-1}(z)=-e^{c^k(z)},\quad k=1,2,...,N. \tag{IV.7}$$

Proof: We prove this theorem by checking that they satisfy the defining relations (II.20) of $U_q[gl(\widehat{N|N})]$ with $c=1$. It is easily seen that the first two relations in (II.20) are true by construction. The third and fourth ones follow from the definition of $X^{\pm,i}(z)$ and the commutativity between a_n^j and c_n^l. So we only need to check the last three relations in (II.20).

We write

$$Z^{\pm,i}(z) = :e^{\pm H^i(z;\mp 1/2)}:F^{\pm,i}. \tag{IV.8}$$

It is easily shown that

$$Z^{+,i}(z)Z^{+,i'}(w) = \begin{cases} :Z^{+,i}(z)Z^{+,i'}(w): & \text{for } a_{ii'}=0 \text{ and } i \leqslant i', \\ -:Z^{+,i}(z)Z^{+,i'}(w): & \text{for } a_{ii'}=0 \text{ and } i > i', \\ (z-q^{-1}w):Z^{+,i}(z)Z^{+,i'}(w): & \text{for } a_{ii'}=1 \text{ and } i < i', \\ -(z-q^{-1}w):Z^{+,i}(z)Z^{+,i'}(w): & \text{for } a_{ii'}=1 \text{ and } i > i', \\ (z-q^{-1}w)^{-1}:Z^{+,i}(z)Z^{+,i'}(w): & \text{for } a_{ii'}=-1, \end{cases} \tag{IV.9}$$

$$Z^{-,i}(z)Z^{-,i'}(w) = \begin{cases} :Z^{-,i}(z)Z^{-,i'}(w): & \text{for } a_{ii'}=0 \text{ and } i \leqslant i', \\ -:Z^{-,i}(z)Z^{-,i'}(w): & \text{for } a_{ii'}=0 \text{ and } i > i' \\ (z-qw):Z^{-,i}(z)Z^{-,i'}(w): & \text{for } a_{ii'}=1 \text{ and } i < i', \\ -(z-qw):Z^{-,i}(z)Z^{-,i'}(w): & \text{for } a_{ii'}=1 \text{ and } i > i', \\ (z-qw)^{-1}:Z^{-,i}(z)Z^{-,i'}(w): & \text{for } a_{ii'}=-1, \end{cases} \tag{IV.10}$$

$$Z^{+,i}(z)Z^{-,i'}(w) = \begin{cases} :Z^{+,i}(z)Z^{-,i'}(w): & \text{for } a_{ii'}=0 \text{ and } i \leqslant i', \\ -:Z^{+,i}(z)Z^{-,i'}(w): & \text{for } a_{ii'}=0 \text{ and } i > i', \\ (z-w)^{-1}:Z^{+,i}(z)Z^{-,i'}(w): & \text{for } a_{ii'}=1 \text{ and } i < i', \\ -(z-w)^{-1}:Z^{+,i}(z)Z^{-,i'}(w): & \text{for } a_{ii'}=1 \text{ and } i > i', \\ (z-w):Z^{+,i}(z)Z^{-,i'}(w): & \text{for } a_{ii'}=-1. \end{cases} \tag{IV.11}$$

We have similar formulas for $Z^{+,i'}(w)Z^{+,i}(z)$, $Z^{-,i'}(w)Z^{-,i}(z)$, and $Z^{-,i'}(w)Z^{+,i}(z)$.

We now compute operator products $Y^{+,i}(z)Y^{+,i'}(w)$ and $Y^{+,i}(z)Y^{-,i'}(w)$. It is easily seen from the definition of $Y^{\pm,i}(z)$ that the nontrivial products are those corresponding to $i=i'$ and $a_{ii'}=1$. Note that $a_{ii'}=1$ whenever $i=2k-1$, $i'=2k$ (or $i=2k$, $i'=2k-1$) where $k=1,2,...,N-1$. The corresponding operator products are

$$Y^{+,2k-1}(z)Y^{+,2k}(w) = \frac{1}{w(q-q^{-1})}\left(\frac{:e^{c^k(z)}e^{-c^k(qw)}:}{z-qw} - \frac{:e^{c^k(z)}e^{-c^k(q^{-1}w)}:}{z-q^{-1}w}\right),$$

$$Y^{-,2k-1}(z)Y^{-,2k}(w) = -\frac{1}{z(q-q^{-1})}\left(\frac{:e^{-c^k(qz)}e^{c^k(w)}:}{qz-w} - \frac{:e^{-c^k(q^{-1}z)}e^{c^k(w)}:}{q^{-1}z-w}\right),$$

$$Y^{+,2k-1}(z)Y^{-,2k}(w) = -(z-w):Y^{+,2k-1}(z)Y^{-,2k}(w):$$

$$\begin{aligned} Y^{+,2k}(z)Y^{-,2k-1}(w) = \frac{1}{zw(q-q^{-1})}\big(&q(z-w):e^{-c^k(qz)}e^{-c^k(qw)}: \\ &-q^{-1}(z-w):e^{-c^k(q^{-1}z)}e^{-c^k(q^{-1}w)}: \\ &-(qz-q^{-1}w):e^{-c^k(qz)}e^{-c^k(q^{-1}w)}: \\ &-(q^{-1}z-qw):e^{-c^k(q^{-1}z)}e^{-c^k(qw)}:\big). \end{aligned} \tag{IV.12}$$

Since $Y^{+,2k}(z)=Y^{-,2k-1}(z)$ and $Y^{-,2k}(z)=-Y^{+,2k-1}(z)$, the products $Y^{+,i}(z)Y^{+,i}(w)$ and $Y^{\pm,i}(z)Y^{\mp,i}(w)$ can be deduced from (IV.12). For example,

$$Y^{+,2k}(z)Y^{-,2k}(w)=-Y^{+,2k}(z)Y^{+,2k-1}(w)=\frac{1}{z(q-q^{-1})}\left(\frac{:e^{-c^k(q^{-1}z)}e^{c^k(w)}:}{q^{-1}z-w}-\frac{:e^{-c^k(qz)}e^{c^k(w)}:}{qz-w}\right). \tag{IV.13}$$

By means of (IV.9), (IV.11), (IV.10), and (IV.12) we can show that the last three relations in (II.20) are satisfied by (IV.7). For instance,

$$\begin{aligned}[X^{+,2k}(z),Z^{-,2k-1}(w)]&=-\frac{1}{zw(q-q^{-1})^2}:Z^{+,2k}(z)Z^{-2,k-1}(w):\left(\frac{1}{z-w}+\frac{1}{w-z}\right)\\&\quad\times((qz-q^{-1}w):e^{-c^k(qz)}e^{-c^k(q^{-1}w)}:+(q^{-1}z-qw):e^{-c^k(q^{-1}z)}e^{-c^k(qw)}:)\\&=-\frac{1}{z^2w(q-q^{-1})^2}:Z^{+,2k}(z)Z^{-,2k-1}(w):\delta\left(\frac{w}{z}\right)\\&\quad\times((qz-q^{-1}w):e^{-c^k(qz)}e^{-c^k(q^{-1}w)}:+(q^{-1}z-qw):e^{-c^k(q^{-1}z)}e^{-c^k(qw)}:)\\&=0.\end{aligned} \tag{IV.14}$$

V. BOSONIZATION OF LEVEL-ONE VERTEX OPERATORS

In this section, we study the level-one vertex operators[6] of $U_q[gl(\widehat{N|N})]$. Let $V(\lambda)$ be the highest weight $U_q[gl(\widehat{N|N})]$-module with the highest weight λ. Consider the following intertwiners of $U_q[gl(\widehat{N|N})]$-modules:[2]

$$\Phi_\lambda^{\mu V}(z):\quad V(\lambda)\to V(\mu)\otimes V_z, \tag{V.1}$$

$$\Phi_\lambda^{\mu V^*}(z):\quad V(\lambda)\to V(\mu)\otimes V_z^{*S}, \tag{V.2}$$

$$\Psi_\lambda^{V\mu}(z):\quad V(\lambda)\to V_z\otimes V(\mu), \tag{V.3}$$

$$\Psi_\lambda^{V^*\mu}(z):\quad V(\lambda)\to V_z^{*S}\otimes V(\mu). \tag{V.4}$$

They are intertwiners in the sense that for any $x\in U_q[gl(\widehat{N|N})]$,

$$\Xi(z)\cdot x=\Delta(x)\cdot\Xi(z),\quad \Xi(z)=\Phi_\lambda^{\mu V}(z),\ \Phi_\lambda^{\mu V^*}(z),\ \Psi_\lambda^{V\mu}(z),\ \Psi_\lambda^{V^*\mu}(z). \tag{V.5}$$

These intertwiners are even operators, that is their gradings are $[\Phi_\lambda^{\mu V}(z)]=[\Phi_\lambda^{\mu V^*}(z)]=[\Psi_\lambda^{V\mu}(z)]=[\Psi_\lambda^{V^*\mu}(z)]=0$. According to Ref. 2, $\Phi_\lambda^{\mu V}(z)$ ($\Phi_\lambda^{\mu V^*}(z)$) is called type I (dual) vertex operator and $\Psi_\lambda^{V\mu}(z)$ ($\Psi_\lambda^{V^*\mu}(z)$) type II (dual) vertex operator.

We expand the vertex operators as[2]

$$\Phi_\lambda^{\mu V}(z)=\sum_{j=1}^{2N}\Phi_{\lambda,j}^{\mu V}(z)\otimes v_j,\quad \Phi_\lambda^{\mu V^*}(z)=\sum_{j=1}^{2N}\Phi_{\lambda,j}^{\mu V^*}(z)\otimes v_j^*,$$

$$\Psi_\lambda^{V\mu}(z)=\sum_{j=1}^{2N}v_j\otimes\Psi_{\lambda,j}^{V\mu}(z),\quad \Psi_\lambda^{V^*\mu}(z)=\sum_{j=1}^{2N}v_j^*\otimes\Psi_{\lambda,j}^{V^*\mu}(z). \tag{V.6}$$

Then the intertwining property (V.5) reads in terms of components,

$$\sum \Phi^{\mu V}_{\lambda,j}(z)x\otimes v_j(-1)^{[v_j][x]}=\sum x_{(1)}\Phi^{\mu V}_{\lambda,j}(z)\otimes x_{(2)}v_j(-1)^{[v_j][x_{(2)}]},$$

$$\sum \Phi^{\mu V^*}_{\lambda,j}(z)x\otimes v^*_j(-1)^{[v^*_j][x]}=\sum x_{(1)}\Phi^{\mu V^*}_{\lambda,j}(z)\otimes x_{(2)}v^*_j(-1)^{[v^*_j][x_{(2)}]},$$

$$\sum v_j\otimes\Psi^{V\mu}_{\lambda,j}(z)x=\sum x_{(1)}v_j\otimes x_{(2)}\Psi^{V\mu}_{\lambda,j}(z)(-1)^{[v_j][x_{(2)}]},$$

$$\sum v^*_j\otimes\Psi^{V^*\mu}_{\lambda,j}(z)x=\sum x_{(1)}v^*_j\otimes x_{(2)}\Psi^{V^*\mu}_{\lambda,j}(z)(-1)^{[v^*_j][x_{(2)}]}, \tag{V.7}$$

where we have used the notation $\Delta(x)=\Sigma_x x_{(1)}\otimes x_{(2)}$ and the fact that the vertex operators are even which implies $[\Phi^{\mu V}_{\lambda,j}(z)]=[\Phi^{\mu V^*}_{\lambda,j}(z)]=[\Psi^{V\mu}_{\lambda,j}(z)]=[\Psi^{V^*\mu}_{\lambda,j}(z)]=[v_j]=[(-1)^j+1]/2$.

Introduce the even operators $\phi(z)$, $\phi^*(z)$, $\psi(z)$, and $\psi^*(z)$,

$$\phi(z)=\sum_{j=1}^{2N}\phi_j(z)\otimes v_j,\quad \phi^*(z)=\sum_{j=1}^{2N}\phi^*_j(z)\otimes v^*_j,$$

$$\psi(z)=\sum_{j=1}^{2N}v_j\otimes\psi_j(z),\quad \psi^*(z)=\sum_{j=1}^{2N}v^*_j\otimes\psi^*_j(z). \tag{V.8}$$

The grading of the components is given by $[\phi_j(z)]=[\phi^*_j(z)]=[\psi_j(z)]=[\psi^*_j(z)]=[(-1)^j+1]/2$. Now we state

Proposition 3: Assume that the operators $\phi(z)$, $\phi^*(z)$, $\psi(z)$, $\psi^*(z)$ satisfy the intertwining relations (V.7). Then the operators $\phi(z)$ and $\psi(z)$ with respect to V_z are determined by the components $\phi_{2N}(z)$ and $\psi_1(z)$, respectively. With respect to V^{*S}_z, the operators $\phi^*(z)$ and $\psi^*(z)$ are determined by $\phi^*_1(z)$ and $\psi^*_{2N}(z)$, respectively. More explicitly, we have for $l=1,2,...,2N-1$,

$$(-1)^l\phi_l(z)=[\phi_{l+1}(z),f_l]_{q^{(-1)^l}},$$

$$[\phi_l(z),f_l]_{q^{(-1)^l}}=0,$$

$$[\phi_k(z),f_l]=0,\quad k\neq l,l+1, \tag{V.9}$$

$$q^{(-1)^{l+1}}\phi^*_{l+1}(z)=[\phi^*_l(z),f_l]_{q^{(-1)^{l+1}}},$$

$$[\phi^*_{l+1}(z),f_l]_{q^{(-1)^{l+1}}}=0,$$

$$[\phi^*_k(z),f_l]=0,\quad k\neq l,l+1, \tag{V.10}$$

$$\psi_{l+1}(z)=[\psi_l(z),e_l]_{q^{(-1)^{l+1}}},$$

$$[\psi_{l+1}(z),e_l]_{q^{(-1)^{l+1}}}=0,$$

$$[\psi_k(z),e_l]=0,\quad k\neq l,l+1, \tag{V.11}$$

$$(-1)^{l+1}q^{(-1)^l}\psi^*_l(z)=[\psi^*_{l+1}(z),e_l]_{q^{(-1)^l}},$$

$$[\psi^*_l(z),e_l]_{q^{(-1)^l}}=0,$$

$$[\psi_k^*(z),e_l]=0,\quad k\neq l,l+1. \tag{V.12}$$

Next we determine the relations of the components $\phi_{2N}(z)$, $\phi_1^*(z)$, $\psi_1(z)$, $\psi_{2N}^*(z)$ and the Drinfeld generators. By means of proposition 1 and the intertwining relations, we have

Proposition 4: For $\phi(z)$ *associated with* V_z,

$$\begin{aligned}
&[\phi_{2N}(z),X^{+,i}(w)]=0,\\
&q^{h_i}\phi_{2N}(z)q^{-h_i}=q^{-\delta_{i,2N-1}}\phi_{2N}(z),\\
&[H_n^i,\phi_{2N}(z)]=-\delta_{i,2N-1}q^{(3/2)n}\frac{[n]_q}{n}z^n\phi_{2N}(z),\\
&[H_{-n}^i,\phi_{2N}(z)]=-\delta_{i,2N-1}q^{-(1/2)n}\frac{[n]_q}{n}z^{-n}\phi_{2N}(z);
\end{aligned} \tag{V.13}$$

for $\phi^*(z)$ *associated with* V_z^*,

$$\begin{aligned}
&[\phi_1^*(z),X^{+,i}(w)]=0,\\
&q^{h_i}\phi_1^*(z)q^{-h_i}=q^{\delta_{i,1}}\phi_1^*(z),\\
&[H_n^i,\phi_1^*(z)]=\delta_{i,1}q^{(3/2)n}\frac{[n]_q}{n}z^n\phi_1^*(z),\\
&[H_{-n}^i,\phi_1^*(z)]=\delta_{i,1}q^{-(1/2)n}\frac{[n]_q}{n}z^{-n}\phi_1^*(z);
\end{aligned} \tag{V.14}$$

for $\psi(z)$ *associated with* V_z,

$$\begin{aligned}
&[\psi_1(z),X^{-,i}(w)]=0,\\
&q^{h_i}\psi_1(z)q^{-h_i}=q^{-\delta_{i,1}}\psi_1(z),\\
&[H_n^i,\psi_1(z)]=-\delta_{i,1}q^{(1/2)n}\frac{[n]_q}{n}z^n\psi_1(z),\\
&[H_{-n}^i,\psi_1(z)]=-\delta_{i,1}q^{-(3/2)n}\frac{[n]_q}{n}z^{-n}\psi_1(z);
\end{aligned} \tag{V.15}$$

and for $\psi^*(z)$ *associated with* V_z^*,

$$\begin{aligned}
&[\psi_{2N}^*(z),X^{-,i}(w)]=0,\\
&q^{h_i}\psi_{2N}^*(z)q^{-h_i}=q^{\delta_{i,2N-1}}\psi_{2N}^*(z),\\
&[H_n^i,\psi_{2N}^*(z)]=\delta_{i,2N-1}q^{(1/2)n}\frac{[n]_q}{n}z^n\psi_{2N}^*(z),\\
&[H_{-n}^i,\psi_{2N}^*(z)]=\delta_{i,2N-1}q^{-(3/2)n}\frac{[n]_q}{n}z^{-n}\psi_{2N}^*(z).
\end{aligned} \tag{V.16}$$

In order to obtain bosonized expressions of the vertex operators, we introduce the following combinations of the bosonic oscillators

$$A_n^{*i}=\sum_{l=1}^{2N-1} a_{il}^{-1}A_n^l+\frac{2}{q^n+q^{-n}}a_{i,2N}^{-1}A_n^{2N},$$

$$A_0^{*i}=\sum_{l=1}^{2N} a_{il}^{-1}A_0^l,\quad Q_{A^i}^{*}=\sum_{l=1}^{2N} a_{il}^{-1}Q_{A^l},\quad i=1,2,\ldots,2N-1, \tag{V.17}$$

which satisfy the relations

$$[A_n^{*i},A_m^{i'}]=\delta_{ii'}\delta_{n+m,0}\frac{[n]_q^2}{n},$$

$$[A_n^{*i},A_m^{*i'}]=a_{ii'}^{-1}\delta_{n+m,0}\frac{[n]_q^2}{n},$$

$$[A_0^{*i},Q_{A^{i'}}]=\delta_{ii'},\quad [A_0',Q_{A^{i'}}^{*}]=\delta_{ii'},$$

$$[A_0^{*i},Q_{A^{i'}}^{*}]=a_{ii'}^{-1},\quad i,i'=1,2,\ldots,2N-1. \tag{V.18}$$

Introduce the currents,

$$H^{*,j}(z;\kappa)=Q_{A^j}^{*}+A_0^{*j}\ln z-\sum_{n\neq 0}\frac{A_n^{*j}}{[n]_q}q^{k|n|}z^{-n}. \tag{V.19}$$

Now we state our main theorem in this section on the bosonic realization of the operators $\phi(z)$, $\phi^{*}(z)$, $\psi(z)$, and $\psi^{*}(z)$ at level one. Thanks to the previous propositions, we only need to determine one component for each operator and the other components are represented by the integral of the currents.

Theorem 2: *The components* $\phi_{2N}(z)$, $\phi_1^{*}(z)$, $\psi_1(z)$, *and* $\psi_{2N}^{*}(z)$ *can be realized explicitly as follows:*

$$\phi_{2N}(z)=:e^{-H^{*,2N-1}(qz;(1/2))}e^{c^N(qz)}:e^{-\sqrt{-1}\pi a_0^1}\prod_{l=1}^{N-1}e^{-\sqrt{-1}\pi[(2N+l)/2N]a_0^{2l+1}},$$

$$\phi_1^{*}(z)=:e^{H^{*,1}(qz;(1/2))}:\prod_{l=1}^{N-1}e^{\sqrt{-1}\pi[(2N-l)/2N]a_0^{2l+1}},$$

$$\psi_1(z)=:e^{-H^{*,1}(qz;-(1/2))}:\prod_{l=1}^{N-1}e^{\sqrt{-1}\pi[(2N-l)/2N]a_0^{2l+1}},$$

$$\psi_{2N}^{*}(z)=\frac{1}{z(q-q^{-1})}:e^{H^{*,2N-1}(qz;-(1/2))}(e^{-c^N(q^2z)}-e^{-c^N(z)}):$$
$$\times e^{-\sqrt{-1}\pi a_0^1}\prod_{l=1}^{N-1}e^{-\sqrt{-1}\pi[(2N+1)/2N]a_0^{2l+1}}. \tag{V.20}$$

Proof: This theorem is proved by checking that the construction satisfies all the intertwining relations.

Remark: The following inverse elements of the extended Cartan matrix are needed to determine the cocycle factors appearing in above theorem:

$$a^{-1}_{2N-1,2l}=a^{-1}_{2N-1,2l+1}=-\frac{l}{N},\quad l=1,2,...,N-1,$$

$$a^{-1}_{2N-1,1}=0,\quad a^{-1}_{2N-1,2N}=\frac{1}{2N},$$

$$a^{-1}_{1,2l-1}=a^{-1}_{1,2l}=\frac{N-l}{N},\quad l=1,2,...,N-1,$$

$$a^{-1}_{1,2N-1}=0,\quad a^{-1}_{1,2N}=\frac{1}{2N}. \tag{V.21}$$

We are now in a position to state the following result:

Proposition 5: The vertex operators $\Phi_\lambda^{\mu V}(z)$, $\Phi_\lambda^{\mu V^*}(z)$, $\Psi_\lambda^{V\mu}(z)$, *and* $\Psi_\lambda^{V^*\mu}(z)$, *if they exist, have the same bosonized expressions as the operators* $\phi(z)$, $\phi^*(z)$, $\psi(z)$, *and* $\psi^*(z)$, *respectively*.

This proposition follows immediately from the fact that the formers and the latters obey the same intertwining properties. Identifying $\Phi_\lambda^{\mu V}(z)$, $\Phi_\lambda^{\mu V^*}(z)$, $\Psi_\lambda^{V\mu}(z)$, and $\Psi_\lambda^{V^*\mu}(z)$ with $\phi(z)$, $\phi^*(z)$, $\psi(z)$, and $\psi^*(z)$, respectively, then the bosonic realization of the vertex operators is easily seen to be given by propositions 3, 4 and theorem 2.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 40, NUMBER 11 NOVEMBER 1999

Erratum: "Analytical solution of the relativistic Coulomb problem with a hard core interaction for a one-dimensional spinless Salpeter equation" [J. Math. Phys. 40, 1119 (1999)]

F. Brau
Université de Mons-Hainaut, Place du Parc 20, B-7000 Mons, Belgium

(Received 15 June 1999; accepted for publication 7 July 1999)

[S0022-2488(99)01911-8]

The supposedly exact formula for the bound-state spectrum of the one-dimensional relativistic Coulomb problem with a hard core interaction, given in Eq. (33) of this paper, is incorrect. The first part of this paper (Sec. II) which contains the evaluation of the action of the operator $\sqrt{-d_x^2+m^2}$ on the functions $x^n e^{-\beta x}$ (using the integral representation of this operator obtained in this paper), is correct if we consider the whole x axis. Application to the Coulomb problem must involve normalizable wave functions. That is why we have only considered the positive part of the x axis leading to wave functions of the form: $P_n(x)e^{-\beta x}\theta(x)$, where $\theta(x)$ is the Heaviside function. Unfortunately, as a consequence of the nonlocality of the square root operator, the action of this operator on these functions leads to rather different expressions than the action on the functions $P_n(x)e^{-\beta x}$, as calculated in Sec. II, even if we consider the results of these actions only on the positive x axis. We have not obtained the correct spectrum and the correct wave functions. We regret that we did not point out this problem earlier.

Erratum: ''Rest frame system for asymptotically flat space–times'' [J. Math. Phys. 39, 6631 (1998)]

Osvaldo M. Moreschi[a)] and Sergio Dain[b)]
FaMAF, Universidad Nacional de Córdoba, Ciudad Universitaria, 5000 Córdoba, Argentina

(Received 11 June 1999; accepted for publication 12 July 1999)

There is an error in the original presentation of the theorem 6.1. The corrected Sec. VI is:

VI. GLOBAL EXISTENCE OF NICE SECTIONS NEAR THE STATIONARY CASE

The results appearing in the previous sections deal only with local properties of nice sections; in this section the issue of global existence will be tackled. In Ref. 2 it was proved that there exists a four-parameter family of nice sections in a stationary space–time. This suggests that when radiation is ''small'' one could probably find an analogous result. In what follows we will apply once more the implicit function theorem to prove this assertion.

Let $C^0(\mathcal{I}^+)$ represent the vector space of all bounded continuous functions on scri plus, with the norm $\|F\|_{C^0(\mathcal{I}^+)}=\sup|F(u,\zeta,\zeta)|$. The vector space $C^0(\mathcal{I}^+)$ defines a Banach space.

Let X, Y and Z represent the spaces defined in Sec. III, and let us denote with Ξ the space whose elements are of the form $\xi=(x,F)$, with $x\in X$, $F\in C^0(\mathcal{I}^+)$ and with norm $\|\xi\|=\|x\|_X+\|F\|_{C^0(\mathcal{I}^+)}$. The space Ξ is a Banach space. Consider now the map from (Ξ,Y) into Z defined by

$$\Phi(\xi,y)=Dy-\left(\int_{u_0}^{x+y}F(u,\zeta,\overline{\zeta})du+\Psi(u_0,\zeta,\overline{\zeta})+K(x+y,F;\zeta,\overline{\zeta})^3M(x+y,F)\right), \tag{71}$$

which coincide with the map $f(x,y)$ defined in Sec. III, but where now it is taken into account explicitly the dependence on the flux F. The Fréchet derivative of this map with respect to the variable y is

$$\Phi_y(\xi,y)\,\delta y=D\,\delta y-\left[F(u=\gamma=x+y,\zeta,\overline{\zeta})\,\delta y+K^3\left(\frac{4P_{\underline{a}}}{M}-3K\ l_{\underline{a}}(\zeta,\overline{\zeta})\right)\delta P^{\underline{a}}\right], \tag{72}$$

where $P_{\underline{a}}$, M, and K are evaluated at $u=\gamma=x+y$; in particular one has

$$P^{\underline{a}}(\gamma)=-\frac{1}{4\pi}\int l^{\underline{a}}(\zeta,\overline{\zeta})\int_{u_0}^{\gamma}F(u,\zeta,\overline{\zeta})du\ dS^2+P^{\underline{a}}(u=u_0) \tag{73}$$

and $\delta P^{\underline{a}}$ is given by

$$\delta P^{\underline{a}}=-\frac{1}{4\pi}\int l^{\underline{a}}(\zeta,\overline{\zeta})F(u=\gamma=x+y,\zeta,\overline{\zeta})\,\delta y\ dS^2. \tag{74}$$

Let us denote with ξ_0 the nonradiation case, that is, $\xi_0=(x_0,F=0)$; we have shown in Ref. 2 that there exists a relation $y_0(x_0)$ such that $\Phi(\xi_0,y_0)=0$, for any translation x_0; in other words,

in the absence of radiation $(F=0)$, the map $\gamma_0(x_0)=x_0+y_0(x_0)$ defines a four-parameter family of nice sections globally on scri. It is observed that $\delta P^{\underline{a}}(F=0)=0$; therefore

$$\Phi_y(\xi(x,F=0),y)\,\delta y=D\,\delta y, \tag{75}$$

and it is clear that the map $\delta z=\Phi_y(\xi(x,F=0),y)\,\delta y$ from Y onto Z is invertible; that is, it is an homeomorphism of Y onto Z.

The implicit function theorem implies that there exists a unique continuous mapping G defined in a neighborhood $U_0\subset C^0(\mathcal{I}^+)$ of $F=0$, $G:U_0\rightarrow Y$, parametrized by x_0, such that $G(\xi(x_0,F=0))=y_0$ and $\Phi(\xi(x_0,F),y)=0$ for $F\in U_0$.

Let us call *small radiation data* the one that satisfies $\dot{\sigma}\dot{\bar{\sigma}}=F\in U_0$ in the last result. Then, the continuity properties contained in the implicit function theorem and the fact that x lives in a four-dimensional vector space, imply the following result:

Theorem 6.1:

For small radiation data there exists a global four-parameter family of nice sections at scri.

A general formalism for the quantum description of many-body systems is developed, using the principal-axis hyperspherical parametrization of coordinates. This formalism is applied to four-particle systems for which the exact kinetic energy operator is derived using a model constraints and dynamical constraints. Then, using the supersymmetry and shape invariance approach, we obtained in a closed form the eigenvalues and eigenfunctions of a wide class of noncentral potentials for the adiabatically constrained four-particle systems. © *1999 American Institute of Physics.* [S0022-2488(99)00112-7]

I. INTRODUCTION

In the field of molecular and chemical physics, the parametrization (for the purpose of dynamical studies) of the configuration of N-atom system which is likely to undergo very large amplitude deformations is, in most cases, looked for in terms of coordinates among which the distances are as few as possible and, on the contrary, the angles as many as possible. This is so in the context of quantum mechanics and in view of variational calculations requiring the evaluation of matrix elements, because of a practical intrinsic weakness of the radial function basis which have to span the domain $[0,\infty[$ and are often of a delicate use for computing Hamiltonian matrix elements, whereas (owing to the cyclic character of the angular coordinates) there exist a variety of practicable analytical angular function basis sets, for instance the spherical harmonics basis for any pair of angles that are mathematically spherical.

Moreover, the configuration of the molecular system is usually thought of in terms of $3N-6$ internal coordinates. This is consistent with the description of the rotation of a very deformable system as that of a body-fixed (BF) frame of reference, i.e., a frame with its origin at the center of mass and its axes rotating in a prescribed manner when the atoms (or only a few of them) move. With respect to the space-fixed (SF) frame of reference (with origin at the center of mass and axes parallel to those of the laboratory-fixed (LF) frame), the BF frame is oriented by means of three Euler angles. Finally, the translation of the center of mass in the LF frame is generally eliminated.

It has been established[1–5] that an useful expression of the exact nonrelativistic quantum-mechanical Hamiltonian operator of a molecular system made up of N atoms viewed in a BF frame of reference (O,x,y,z) and described in size and shape by a complete set of internal coordinates $\{q^i;\ i=1,2,\ldots,3N-6\}$ is very complex and contains at least seven terms plus the potential energy term.

The $3N-6$ internal coordinates q^i are invariant under rotations; this means that the expressions $q^i=q^i(x^1,x^2,\ldots,x^\alpha,\ldots,x^{3N})$, where the x^α are the Cartesian BF-coordinates of the particles, are unchanged whatever orientation of the BF-frame. In most cases, such coordinates turn out to be either distances between two points, or planar angles between three points, or still dihedral atoms or centers of mass of groups of atoms as well. Next, the orientation of the BF-frame is supposed to be uniquely defined by means of the three so-called ''axial constraints.''[4,6]

[a)]Electronic mail: hounkon@syfed.bj.refer.org

Last of all, the Hamiltonian of the system expressed with respect to the particle coordinates in the BF-frame, is designed to operate on a wave function that is normalized according to the usual (i.e., Euclidean) normalization convention, i.e., the volume element $d\tau_1 = [g(\mathbf{q})]^{-1/2} dq^1 dq^2 \cdots dq^{3N-6} d\psi d\beta d\gamma$ (the parameters will be defined later) is to be used when calculating matrix elements.

The hyperspherical parametrizations constitute the most appropriate answer to the requirement of few distances and many angles among the internal coordinates describing molecular systems with possible very deformed configurations. Their main feature is that the length-type internal coordinates are reduced to a single one (the so-called hyperradius ρ), all the others being angles (with various possible definitions, see below) so that, the overall rotation being also considered, the system configuration and orientation are described by one distance (ρ) and $3N-4$ angles. Whatever the actual parametrization, the hyperradius definition is unique and invariant,[7]

$$\rho^2 = \sum_{\lambda=1}^{N-1} \mu_\lambda \rho_\lambda^2 = \sum_{\alpha=1}^{N} \sum_{g} |r_{\alpha g}|^2,$$

where, any set of $n=N-1$ Jacobi vectors $\{\rho_\lambda^2\}$ being associated with the N-atom system, μ_λ and ρ_λ are, respectively, the reduced mass and the length of one vector, μ is the totally symmetric characteristic mass, and $r_{\alpha g}$ denotes the component $(g=x,y,z)$ of the mass-weighted position vector $\mathbf{r}_\alpha$ of the αth particle viewed in the body-fixed frame (BF).

The analytical treatment of this system has been the subject of many investigations these last years.[3,4] Among the most remarkable works, we can quote the papers by Parker,[8] Kosloff *et al.*,[9] and other remarkable contributions.[10–18]

To treat four-particle systems, we subject the system to model constraints, e.g., either in rigidifying a few bonds or entire atomic groups or in adjusting the variations of some internal coordinates (called inactive) to those of a few coordinates considered the most important ones for the dynamics. Indeed imposing model constraints alters the dimensions of the configuration space, so each differential operator must be modified accordingly.[19] Moreover, when only internal deformations are considered, the molecule is studied for zero total angular momentum $\mathbf{J}$, a condition that is physically realistic since $\mathbf{J}$ is a constant of motion. One of the purposes of this paper is, for the adiabatically constrained four-particle systems, to show that noncentral potentials that are separable in their coordinates and may have up to nine parameters can be solved by the operator method by using the well known results for the various shape invariance potentials (SIP). More precisely, we show that the energy eigenvalues and eigenfunctions of noncentral but separable potentials in PAH coordinates can be simply written down by applying supersymmetry and shape invariance to $\theta_3, \phi, \theta,$ and ρ dependent potentials.

The paper is organized as follows: In Sec. II, we recall a general formalism of quantization of many-body systems. In Sec. III, we construct the quantum-mechanical Hamiltonian for four-particle systems in terms of the quasimomenta using principal axis hyperspherical (PAH) coordinates. In Sec. IV, we subject the four-particle to model constraints and derive the exact kinetic energy operator derived. In Sec. V, using the results for the known SIP, we obtain in a closed form the eigenvalues and the eigenfunctions for noncentral but separable potentials.

II. GENERAL FORMALISM OF THE MANY BODY SYSTEM QUANTIZATION

Let $\mathbf{q}=(q^1,q^2,\ldots,q^{3n})$, $n=N-1$ be a set of curvilinear coordinates well suited for the description of a dynamical system, and let $\mathbf{p}=(p_1,p_2,\ldots,p_{3n})$ be the corresponding conjugate momenta in classical mechanics. The kinetic energy T can always be expressed as a quadratic form of momenta,

$$T = \frac{1}{2} \sum_{i,j=1}^{3n} p_i g^{ij}(\mathbf{q}) p_j, \tag{2.1}$$

where

$$[g^{ij}]=\begin{bmatrix} \underline{S}(\mathbf{q}) & \underline{C}^{\dagger}(\mathbf{q}) \\ \underline{C}(\mathbf{q}) & \underline{I}(\mathbf{q}) \end{bmatrix}^{-1}=\begin{bmatrix} \underline{\Sigma} & \underline{\Gamma}^{\dagger} \\ \underline{\Gamma} & \underline{\mu} \end{bmatrix} \tag{2.2}$$

with $\underline{S}(\mathbf{q})$ the $(3N-6)$-dimensional symmetric matrix of elements,

$$S_{ij}=\sum_{\alpha=1}^{N}[\partial_{q_i}r_{\alpha x}\partial_{q_j}r_{\alpha x}+\partial_{q_i}r_{\alpha y}\partial_{q_j}r_{\alpha y}+\partial_{q_i}r_{\alpha z}\partial_{q_j}r_{\alpha z}]\quad (i,j=1,2,\ldots,3N-6); \tag{2.3}$$

$\underline{C}(\mathbf{q})$ the $3\times(3N-6)$ Coriolis matrix of elements,

$$C_{gj}=\sum_{\alpha=1}^{N}[r_{\alpha g'}\partial_{q_j}r_{\alpha g''}-r_{\alpha g''}\partial_{q_j}r_{\alpha g'}] \tag{2.4}$$

$$(j=1,2,\ldots,3N-6;g,g',g''\ \text{is an even permutation of}\ x,y,z),$$

and $\underline{I}(\mathbf{q})$ being the usual inertia tensor represented by the three-dimensional symmetric matrix of elements,

$$I_{gg'}=\sum_{\alpha=1}^{N}\left[\sum_{g''}r_{\alpha g''}^{2}\delta_{gg'}-r_{\alpha g}r_{\alpha g'}\right]\quad (g,g'=x,y,z). \tag{2.5}$$

Now, one is always at liberty to use a *nonsingular* $3n$-dimensional matrix $\underline{B}(\mathbf{q})$, depending only on the coordinates, to transform the momenta into quasimomenta, namely,

$$p_K=\sum_{i=1}^{3n}[\underline{B}(\mathbf{q})]_K^i p_i\qquad (K=1,2,\ldots,3n). \tag{2.6}$$

The determinant of $\underline{B}(\mathbf{q})$ is denoted by

$$t^{-1}=\mathrm{Det}(\underline{B}(\mathbf{q})). \tag{2.7}$$

T can be rewritten as

$$T=\frac{1}{2}\sum_{K,L=1}^{3n}p_K g^{KL}(\mathbf{q})p_L \tag{2.8}$$

with

$$g^{KL}(\mathbf{q})=\sum_{i,j=1}^{3n}[\underline{B}^{-1}(\mathbf{q})]_i^K g^{ij}(\mathbf{q})[\underline{B}^{-1}(\mathbf{q})]_j^L\qquad (K,L=1,2,\ldots,3n) \tag{2.9}$$

so that, if $g(\mathbf{q})=\mathrm{Det}([g^{ij}(\mathbf{q})])$ and $\tilde{g}(\mathbf{q})=\mathrm{Det}([g^{KL}(\mathbf{q})])$, then

$$g(\mathbf{q})=\tilde{g}(\mathbf{q})t^{-2}(\mathbf{q}). \tag{2.10}$$

In quantum mechanics, let p_i be replaced by the Hermitian operator $\hat{p}_i$. Operators $\hat{q}$ and $\hat{p}$ act in the standard Hilbert space $\mathcal{H}$ and must satisfy the Heisenberg commutation relations

$$[\hat{q}^i,\hat{p}_j]=i\hbar\,\delta_j^i,\quad [\hat{q},\hat{I}_d]=[\hat{p},\hat{I}_d]=0.$$

Here $\hat{I}_d$ is the identity operator, $\hbar$ is Planck's constant, and the bracket means the commutator $[\hat{A},\hat{B}]=\hat{A}\hat{B}-\hat{B}\hat{A}$.

$$\hat{p}_i=-i\hbar\frac{1}{g^{-1/4}}\partial_{q_i}g^{-1/4}\quad (i=1,2,\ldots,3n). \tag{2.11}$$

In keeping, for the quasimomentum operators, with the same definition as above

$$\hat{p}_K=\sum_{i=1}^{3n}[\underline{B}(\mathbf{q})]^i_K\hat{p}_i\quad (K=1,2,\ldots,3n). \tag{2.12}$$

As long as the Euclidean volume element of the configuration space

$$d\tau_1=dx^1dx^2dx^3\cdots dx^{3N}=[g(\mathbf{q})]^{-1/2}dq^1dq^2\cdots dq^{3N-6}d\psi\,d\beta\,d\gamma$$

is used for the calculation of the matrix elements as integrals, the differential kinetic energy operator must be written as

$$\hat{T}=\frac{1}{2}\sum_{K,L=1}^{3n}\hat{p}_K g^{KL}(\mathbf{q})\hat{p}_L+V_D(\mathbf{q}) \tag{2.13}$$

$$=-\frac{\hbar^2}{2}\sum_{K,L=1}^{3n}\left[\frac{1}{g^{-1/4}}\partial_{q^K}g^{KL}\partial_{q^L}g^{-1/4}-\left(\frac{1}{g^{-1/4}}\partial_{q^K}g^{KL}\partial_{q^L}g^{-1/4}\right)\right] \tag{2.14}$$

$$=-\frac{\hbar^2}{2}\sum_{K,L=1}^{3n}\left[\frac{1}{g^{-1/2}}\partial_{q^K}g^{KL}g^{-1/2}\partial_{q^L}\right] \tag{2.15}$$

$$=-\frac{\hbar^2}{2}\sum_{K,L=1}^{3n}\left[g^{KL}\partial_{q^K}\partial_{q^L}+\left(\frac{1}{g^{-1/2}}\partial_{q^K}g^{KL}g^{-1/2}\right)\partial_{q^L}\right] \tag{2.16}$$

$$=-\frac{\hbar}{2}\sum_{K,L=1}^{3n}[g^{KL}\partial_{q^K}\partial_{q^L}+\Gamma^L_1\partial_{q^L}]. \tag{2.17}$$

The four expressions (2.13)–(2.16) call for several definitions and a few comments.

(i) Since the kinetic energy operator must be purely differential (in Euclidean normalization), whereas

$$\sum_{K,L=1}^{3n}\left[\frac{1}{g^{-1/4}}\partial_{q^K}g^{KL}\partial_{q^L}g^{-1/4}\right]$$

only is not; $V_D(\mathbf{q})$ the so-called ''extra potential'' (term discussed in Ref. 14, Appendix 2), which is a pure multiplicative operator, appears to make up the T differential.

(ii) When an operator appears in an expression in parentheses, it is always assumed not to operate beyond these parentheses.

If the classical Hamiltonian is known in the form

$$H=T(\mathbf{q,p})+V(\mathbf{q}), \tag{2.18}$$

where $T(\mathbf{q,p})$ is written as in Eq. (2.8), its quantization simply amounts to rewriting it as in Eq. (2.13) by means of the quantities in Eqs. (2.11) that are to be explicitly calculated.

III. QUANTUM-MECHANICAL PAH HAMILTONIAN FOR THE UNCONSTRAINED FOUR-PARTICLE SYSTEM IN TERMS OF THE QUASIMOMENTA

In this case, the set of the PAH coordinates is $(\rho,\theta,\phi,\theta_1,\theta_2,\theta_3,\psi,\beta,\gamma)$, where ρ is the hyperradius; θ and ϕ the spherical coordinates to parametrize the mass-weighted gyration radii; ψ,β, and γ the three usual Eulerian angles to orient the (BF) with respect to the (SF); θ_1,θ_2, and θ_3 are the so-called hyperangles.[10,11,15] We deal with $n=N-1=3$ in all the above expressions (2.1)–(2.18). So we have

$$[g^{KL}]=\begin{pmatrix} \underline{s}(\mathbf{q}) & \underline{0} & \underline{0} \\ \underline{0} & \frac{1}{\rho^2}\underline{b}(\mathbf{q}) & \frac{1}{\rho^2}\underline{d}(\mathbf{q}) \\ \underline{0} & \frac{1}{\rho^2}\underline{d}(\mathbf{q}) & \frac{1}{\rho^2}\underline{b}(\mathbf{q}) \end{pmatrix}, \tag{3.19}$$

where each element in the matrix above denotes a 3×3 diagonal matrix, respectively,

$$\underline{s}(\mathbf{q})=\begin{pmatrix} 1 & 0 & 0 \\ 0 & \frac{1}{\rho^2} & 0 \\ 0 & 0 & \frac{1}{\rho^2\sin^2\theta} \end{pmatrix}, \tag{3.20}$$

$$\underline{b}(\mathbf{q})=\begin{pmatrix} \frac{\cos^2\theta+\sin^2\theta\sin^2\phi}{(\cos^2\theta-\sin^2\theta\sin^2\phi)^2} & 0 & 0 \\ 0 & \frac{\cos^2\theta+\sin^2\theta\cos^2\phi}{(\cos^2\theta-\sin^2\theta\cos^2\phi)^2} & 0 \\ 0 & 0 & \frac{1}{\sin^2\theta\cos^2 2\phi} \end{pmatrix}, \tag{3.21}$$

and

$$\underline{d}(\mathbf{q})=\begin{pmatrix} \frac{\sin 2\theta\sin\phi}{(\cos^2\theta-\sin^2\theta\sin^2\phi)^2} & 0 & 0 \\ 0 & \frac{\sin 2\theta\cos\phi}{(\cos^2\theta-\sin^2\theta\sin^2\phi)^2} & 0 \\ 0 & 0 & \frac{\sin 2\phi}{\sin^2\theta\cos^2 2\phi} \end{pmatrix}. \tag{3.22}$$

ρ,θ, and ϕ are the three spherical coordinates which allow the parametrization of the three mass-weighted gyration radii of the system. The following result is obtained:

$$\tilde{g}(\mathbf{q})=\frac{16}{[\rho^8\sin^3\theta\cos 2\phi(4\cos^2\theta\cos 2\theta+\sin^4\theta\sin^2 2\phi)]^2}. \tag{3.23}$$

Here, the number of the Jacobi vectors describing the internal conformation of the system is $n=3$.

In addition, we have

$$\begin{pmatrix} \hat{K}_x \\ \hat{K}_y \\ \hat{K}_z \end{pmatrix} = -i\hbar \underline{\tilde{B}}(\theta_1,\theta_2) \begin{pmatrix} \partial_{\theta_1} \\ \dfrac{1}{\sqrt{\sin\theta_2}} \partial_{\theta_3} \sqrt{\sin\theta_2} \\ \partial_{\theta_3} \end{pmatrix}, \tag{3.24}$$

where the 3×3-dimensional matrix $\underline{\tilde{B}}(\theta_1,\theta_2)$, according to relation (2.6), is defined by

$$\underline{\tilde{B}} = \underline{\omega}^{*-1},$$

where $\underline{\omega}^{*-1}$ is still the 3×3 matrix, appears in the expression of $\underline{B}(\mathbf{q})$, the overall matrix transforming the momenta into quasimomenta, as follows:

$$\underline{B}(\mathbf{q})_{9\times9} = \begin{pmatrix} \underline{1}_{3\times3} & \underline{0}_{3\times3} & \underline{0}_{3\times3} \\ \underline{0}_{3\times3} & \underline{\tilde{B}}(\theta_1,\theta_2)_{3\times3} & \underline{0}_{3\times3} \\ \underline{0}_{3\times3} & \underline{0}_{3\times3} & \underline{\omega}^{*-1}(\gamma,\beta)_{3\times3} \end{pmatrix}. \tag{3.25}$$

This corresponds to the fact that

(i) The operators in the left hand column vector of Eq. (3.24) are actually the quasimomentum operators to be used;

(ii) The 3×3 unit matrix in the upper of $\underline{B}(\mathbf{q})$ in Eq. (3.25) is for

$$\hat{p}_\rho = -i\hbar\,(1/\rho^4)\,\partial_\rho \rho^4, \quad \hat{p}_\theta = -i\hbar\,(1/\sqrt{g_\theta})\,\partial_\theta \sqrt{g_\theta}, \quad \hat{p}_\phi = -i\hbar\,\partial_\phi,$$

with

$$g_\theta = \sin^3\theta(4\cos^2\theta\cos 2\theta + \sin^4\theta\sin^2 2\phi),$$

which are unaffected by the transformation, and

(iii) $\underline{\omega}^{*-1}(\gamma,\beta)$ in the lower right corner is for the overall-rotation angular-momentum vector operator definition,

$$\underline{\omega}^{*-1}(\theta_1,\theta_2) = \begin{pmatrix} -\sin\theta_1\cot\theta_2 & \cos\theta_1 & \sin\theta_1/\sin\theta_2 \\ -\cos\theta_1\cot\theta_2 & -\sin\theta_1 & \cos\theta_1/\sin\theta_2 \\ 1 & 0 & 0 \end{pmatrix}. \tag{3.26}$$

This matrix stands for the transformation of angular (quasi) velocities into angular (quasi) momenta, namely,

$$\begin{pmatrix} \hat{K}_x \\ \hat{K}_y \\ \hat{K}_z \end{pmatrix} = -i\hbar \underline{\omega}^{*-1}(\theta_1,\theta_2) \begin{pmatrix} \partial_{\theta_1} \\ \dfrac{1}{\sqrt{\sin\theta_2}} \partial_{\theta_2} \sqrt{\sin\theta_2} \\ \partial_{\theta_3} \end{pmatrix} \tag{3.27}$$

as well as

$$\begin{pmatrix} \hat{J}_x \\ \hat{J}_y \\ \hat{J}_z \end{pmatrix} = -i\hbar \underline{\omega}^{*-1}(\gamma,\beta) \begin{pmatrix} \partial\gamma \\ \frac{1}{\sqrt{\sin\beta}}\partial_\beta\sqrt{\sin\beta} \\ \partial_\psi \end{pmatrix}. \tag{3.28}$$

$\hat{\mathbf{K}}$ is the so-called pseudo-angular momentum vector operator,[10,12] which concerns the internal motion of the system (the hyperangles θ_1, θ_2, and θ_3 are actually internal coordinates), whereas $\hat{\mathbf{J}}$ is the usual total angular momentum operator for the overall rotation of the system (Eulerian angles ψ,β,γ). This results in

$$\begin{gathered} \hat{J}_z = -i\hbar\partial_\gamma \\ \hat{\mathbf{J}}^2 = -\hbar^2\left[\frac{1}{\sin^2\beta}(\partial_\gamma^2+\partial_\psi^2-2\cos\beta\partial_\psi\partial_\gamma)+\partial_\beta^2+\cot\beta\partial_\beta\right] \end{gathered} \tag{3.29}$$

and similar expressions for $\hat{\mathbf{K}}$, by substituting θ_1, θ_2, and θ_3 for γ,β, and ψ.

Let us come back to the quantization problem. Since $\underline{B}$ is block triangular, we have

$$t^{-1} = \mathrm{Det}(\underline{\omega}^{*-1}(\theta_1,\theta_2))\mathrm{Det}(\underline{\omega}^{*-1}(\gamma,\beta)) \tag{3.30}$$

so that

$$|t^{-1}| = \frac{1}{\sin\beta\sin\theta_2} \tag{3.31}$$

and Eqs. (2.10) and (3.23) yield

$$[g(\mathbf{q})]^{-1/2} = \rho^8\sin^3\theta\cos 2\phi(4\cos^2\theta\cos 2\theta+\sin^4\theta\sin^2 2\phi)\sin\theta_2\sin\beta. \tag{3.32}$$

g clearly does not depend on $\theta_1, \theta_3, \gamma$, and ψ.

Now, for Euclidean volume element of the configuration space,

$$d\tau_1 = [g(\mathbf{q})]^{-1/2} d\rho\, d\theta\, d\phi\, d\theta_1\, d\theta_2\, d\theta_3\, d\psi\, d\beta\, d\gamma.$$

The PAH Hamiltonian is written as

$$\hat{H}_1 = \hat{T}_1 + V(\rho,\theta,\phi,\theta_1,\theta_2,\theta_3). \tag{3.33}$$

Equations (2.16) and (3.32) yield

$$\hat{T}_1 = -\frac{\hbar^2}{2}\left[\partial_\rho^2+\frac{8}{2\rho}\partial_\rho\right]+\frac{[\hat{\Lambda}_8^2]_1}{2\rho^2} \tag{3.34}$$

$$= -\frac{\hbar^2}{2}\hat{\Lambda}_9, \tag{3.35}$$

$\hat{\Lambda}_9$ being the Laplacian. $[\hat{\Lambda}_8^2]_1$ is the so-called ''grand-angular-momentum'' operator, for the eight-dimensional hypersphere embedded into the nine-dimensional configuration space of the 3 mass-weighted Jacobi vectors describing the system, after separation of the center of mass. In applying the quantization rules given in section above, $[\hat{\Lambda}_8^2]_1$ is written as

$$[\hat{\Lambda}_8^2]_1 = -\hbar^2\left[\partial_\theta^2 + \Lambda_\theta^*\partial_\theta + \frac{1}{\sin^2\theta}[\partial_\phi^2 + \Lambda_\phi^*\partial_\phi]\right] + \sum_{g=x,y,z}[b_{gg}(\hat{J}_g^2 + \hat{K}_g^2) + 2d_{gg}\hat{J}_g\hat{K}_g], \tag{3.36}$$

where the b_{gg} and d_{gg}'s depend on θ and ϕ only [they are given in Eqs. (3.21) and (3.22), respectively] and Λ_θ^* and Λ_ϕ^* are given by

$$\Lambda_\theta^* = 3\cot\theta - 2\sin 2\theta \frac{4\cos^2\theta + 2\cos 2\theta - \sin^2\theta\sin^2 2\phi}{4\cos^2\theta\cos 2\theta + \sin^4\theta\sin^2 2\phi};$$

$$\Lambda_\phi^* = 2\left[-\tan 2\phi + \frac{\sin^4\theta\sin 4\phi}{4\cos^2\theta\cos 2\theta + \sin^4\theta\sin^2 2\phi}\right]. \tag{3.37}$$

Obviously, the part of $\hat{T}_1$ that is linear in $\partial\theta_1, \partial\theta_2, \partial\theta_3$ as it comes out of Eq. (2.16), i.e., the $\Gamma^L(\mathbf{q})$ coefficients in Eq. (2.18), has been entirely re-expressed in terms of the quasimomentum operators $\hat{\mathbf{K}}_g$ $(g=x,y,z)$.

IV. RIGIDLY OR ADIABATICALLY CONSTRAINED FOR THE FOUR-PARTICLE SYSTEM

In order to avoid untractable calculations, we decide to freeze m of $3N-6$ internal coordinates, in other words if we decide to subject the system to m model constraints, it is convenient to split up the set of the $3N-6$ coordinates $\mathbf{q}$ as follows: $\mathbf{q}=(\mathbf{q}',\mathbf{q}'')$ where $\mathbf{q}'=(q^1,q^2,\ldots,q^n)$ is the set of $n=3N-6-m$ coordinates that remain free and $\mathbf{q}''=(q^{n+1},q^{n+2},\ldots,q^{3N-6})$ is the set of the m coordinates that are frozen, so that imposing the m model constraints comes down to putting $\mathbf{q}''=\mathbf{q}''_0$ (and hence $\dot{\mathbf{q}}''=0$) with $\mathbf{q}''_0$ a set of m constants. The partition of $\underline{\Sigma}$ into $\underline{\Sigma}'$, $\underline{\Sigma}''$, and $\underline{\sigma}$, and that of $\underline{\Gamma}$ into $\underline{\Gamma}'$ and $\underline{\Gamma}''$, result from the splitting of $\mathbf{q}$ into $\mathbf{q}'$ and $\mathbf{q}''$. The constraint-free Hamiltonian expression of T [Eq. (2.1)] can be written also as Eq. (4.38),[19,20]

$$T = \frac{1}{2}[\mathbf{p}'|\mathbf{p}''|\mathbf{J}]\begin{bmatrix}\underline{\Sigma}' & \underline{\sigma}^\dagger & \underline{\Gamma}'^\dagger \\ \underline{\sigma} & \underline{\Sigma}'' & \underline{\Gamma}''^\dagger \\ \underline{\Gamma}' & \underline{\Gamma}'' & \underline{\mu}\end{bmatrix}\begin{bmatrix}\mathbf{p}'^\dagger \\ \mathbf{p}'^\dagger \\ \mathbf{J}^\dagger\end{bmatrix}, \tag{4.38}$$

where $\mathbf{p}'$ and $\mathbf{p}''$ denote the quasimomenta conjugate to the internal coordinates $\mathbf{q}'$, $\mathbf{q}''$, and $\mathbf{J}$ the total angular momentum.

(a) Distinguishing carefully the independent dynamic variables $\mathbf{p}$ and $\mathbf{J}$ in the Hamiltonian approach, cf. Eq. (2.1), from their expressions as linear combinations of $\dot{\mathbf{q}}'$ and ω, the latter being the independent dynamic variables in the Lagrangian frame work, will turn out to be an important point.

(b) Imposing model constraints amounts to cancelling components of $\dot{\mathbf{q}}$ (other than ω), which equally means suppressing the corresponding lines and columns of matrix $[g_{ij}]$ (inverse of $[g^{ij}]$ in relation (2.2)); whereas forcing the dynamical constraint $\mathbf{J}=0$ amounts to suppressing the last three lines and columns in matrix $[g^{ij}]$.

Let us apply the dynamic constraint $\mathbf{J}=0$ and the model constraints $\{\dot{\theta}_1=\dot{\theta}_2=0\}$ to our four-particle system, putting $\mathbf{q}'=(\rho,\theta,\ \phi,\ \theta_3)$. The square matrix in relation (4.38) yields [see also (3.19)],

$$\underline{\Sigma}' = [g^{KL}] = [g^{KL}]_{\text{constraint}}, \tag{4.39}$$

where $\underline{\Sigma}'$ is the diagonal matrix obtained by suppressing the 4th, 5th, and the three last columns and rows of the matrix in relation (3.19). So the elementary volume of the constrained space configuration is $d\tau_1 = d\tau_1|_{\text{constraint}} = \rho^3\sin^2\theta\cos 2\phi d\rho\, d\theta\, d\phi\, d\theta_3$.

The constrained Hamiltonian writes

$$\hat{H}=\hat{H}|_{\text{constraint}}=-\frac{\hbar^2}{2}\left[\left(\partial_\rho^2+\frac{3}{\rho}\partial_\rho\right)+\frac{1}{\rho^2\sin^2\theta}\partial_\theta\sin^2\theta\partial_\theta\right.$$
$$\left.+\frac{1}{\rho^2\sin^2\theta}(\partial_\phi^2-2\tan 2\phi\partial_\phi)+\frac{1}{\rho^2\sin^2\theta\cos^2 2\phi}\partial_{\theta_3}^2\right]. \tag{4.40}$$

V. SUPERSYMMETRY CONSTRAINED FOUR-PARTICLE SYSTEM

In this section, we first explain how supersymmetric shape-invariant potentials may be used to solve a problem of constrained four-particle system. The potential of this problem in PAH coordinates is denoted by $V(\rho,\theta,\phi,\theta_3)$, and the problem is formally equivalent to that of one particle in a four-dimensional hyperspherical coordinate.[21] It is well known that further separation of the variables $\rho,\theta,\phi,$ and θ_3 in classical (or quantum) equations of motion takes place[22] for the form

$$V(\rho,\theta,\phi,\theta_3)=V(\rho)+\frac{V(\theta)}{\rho^2}+\frac{V(\phi)}{\rho^2\sin^2\theta}+\frac{V(\theta_3)}{\rho^2\sin^2\theta\cos^2 2\phi}, \tag{5.41}$$

where $V(\rho),V(\theta),V(\phi)$, and $V(\theta_3)$ are arbitrary functions of their argument. For such a form, the problem is immediately integrable and the four constants of motion are easily obtained. The Schrödinger equation for the eigenvalue problem is ($\hbar=1,\rho^2\rightarrow 2\rho^2$),

$$[\hat{H}|_{\text{con}}+V(\rho,\theta,\phi,\theta_3)]\Psi_{nn_1n_2n_3}=E_{nn_1n_2n_3}\Psi_{nn_1n_2n_3}. \tag{5.42}$$

Writing the eigenfunction $\Psi(\rho,\theta,\phi,\theta_3)$ as

$$\Psi(\rho,\theta,\phi,\theta_3)=\frac{U(\rho)}{\rho^{3/2}}\times\frac{H(\theta)}{\sin\theta}\times\frac{Q(\phi)}{\cos^{1/2}2\phi}\times K(\theta_3), \tag{5.43}$$

after some algebra, we obtain

$$-\frac{d^2}{d\theta_3^2}K(\theta_3)+V(\theta_3)K(\theta_3)=k^2K(\theta_3), \tag{5.44}$$

$$-\frac{d^2}{d\phi^2}Q(\phi)+[V(\phi)+(k^2-1)\sec^2 2\phi]Q(\phi)=m^2Q(\phi), \tag{5.45}$$

$$-\frac{d^2}{d\theta^2}H(\theta)+[V(\theta)+(m^2-1)\csc^2\theta]H(\theta)=l^2H(\theta), \tag{5.46}$$

$$-\frac{d^2}{d\rho^2}U(\rho)+\left[V(\rho)+\frac{(l^2-\frac{1}{4})}{\rho^2}\right]U(\rho)=E_{nn_1n_2n_3}U(\rho). \tag{5.47}$$

The four constants of motion are the eigenvalues $E_{nn_1n_2n_3},l^2,m^2$, and k^2.

At this stage, we use the well known result of supersymmetry that for shape-invariant potentials, the solutions may be obtained algebraically.[23–25] To appreciate what is meant by shape-invariance, consider a ''super potential'' $W(u)$, where the variable u may stand for ρ,θ,ϕ, or θ_3. The supersymmetric partners $V_-(u)$ and $V_+(u)$ are (W^2-W') and (W^2+W'), respectively, the prime denoting a differentiation with respect to u. If the pair $V_\pm$ are of the same shape, but differ only in the parameters which appear in them, they are said to be shape invariant. More precisely, if the partner potentials $V_\pm(u,a_1)$ satisfy the condition[26,27]

$$V_+(u,a_1)=V_-(u,a_2)+\Re(a_1), \tag{5.48}$$

where a_1 is a set of parameters, a_2 is a function of a_1 (say $a_2=f(a_1)$) and the remainder $\Re(a_1)$ is independent of u, $V_\pm$ are said to be shape invariant. In such a case, the energy spectrum of the Hamiltonian with the potential V_- is given by

$$E_n^{(-)}(a_1)=\sum_{j=1}^{n}\Re(a_j), \quad E_0^{(-)}(a_1)=0 \tag{5.49}$$

with $a_j=f^{j-1}(a_1)$, i.e., the function f applies $(j-1)$-times. Subsequently, it has been shown that the corresponding eigenfunction can be obtained algebraically.[25,28,29]

Take

$$V(\rho,\theta,\phi,\theta_3)=\frac{\Omega^2}{4}\rho^2+\frac{\delta}{\rho^2}+\frac{C}{\rho^2\sin^2\theta}+\frac{D}{\rho^2\cos^2\theta}+\frac{F}{\rho^2\sin^2\theta\sin^2 2\phi}+\frac{G}{\rho^2\sin^2\theta\cos^2 2\phi}$$
$$+\frac{I}{\rho^2\sin^2\theta\cos^2 2\phi\sin^2\mu\theta_3}+\frac{J}{\rho^2\sin^2\theta\cos^2 2\phi\cos^2\mu\theta_3}, \tag{5.50}$$

with nine parameters $\Omega,\delta,C,D,F,G,I,J,$ and μ. Comparing Eqs. (5.41) and Eqs. (5.50), we obtain

$$V(\theta_3)=I\csc^2\mu\theta_3+J\sec^2\mu\theta_3 \tag{5.51}$$

and if the superpotential W is chosen as

$$W=A\tan\mu\theta_3-B\cot\mu\theta_3, \quad A,B>0, \tag{5.52}$$

then, the corresponding (shape invariant) potentials $V_\mp$ are

$$V_\mp=-(A+B)^2+A(A\mp\mu)\sec^2\mu\theta_3+B(B\mp\mu)\csc^2\mu\theta_3. \tag{5.53}$$

Hence,

$$V_+(\theta_3,A,B,\mu)=V_-(\theta_3,A+\mu,B+\mu,\mu)+(A+B+2\mu)^2-(A+B)^2. \tag{5.54}$$

On comparing Eqs. (5.51) and (5.53), we see that, discounting the overall constant $-(A+B)^2$, $V(\theta_3)$ and V_- are identical if $I=B(B-\mu)$ and $J=A(A-\mu)$.

Thus, the energy eigenvalues k^2 of Eq. (5.44) with $V(\theta_3)=V_-(\theta_3)$ follow from Eqs. (5.44), (5.48), and (5.54),

$$k^2=(A+B+2n\mu)^2 \quad n=0,1,2,\dots . \tag{5.55}$$

The corresponding eigenfunctions are given by[27,28]

$$K(\theta_3)=(\sin\mu\theta_3)^{B/\mu}(\cos\mu\theta_3)^{A/\mu}P_n^{(B/\mu)-(1/2),(A/\mu)-(1/2)}(\cos 2\mu\theta_3), \tag{5.56}$$

where $P_n^{\alpha,\beta}$ is the Jacobi polynomial.

Using the same algebra procedure as before, the eigenvalues m^2 and l^2 with their eigenfunctions are found to be, respectively,

$$m^2=(A_1+B_1+4n_1+1)^2, \tag{5.57}$$

$$Q(\phi)=(\sin 2\phi)^{B/2}(\cos 2\phi)^{(A_1/2)+(1/2)}P_{n_1}^{(B/_1/2)-(1/2),(A_1/2)}(\cos 4\phi), \tag{5.58}$$

where $G+k^2=A_1^2,\ F=B_1(B_1-2),\ n_1=0,1,2,\ldots,$ and

$$l^2=(A_2+B_2+2n_2+1)^2, \tag{5.59}$$

$$H(\theta)=(\sin\theta)^{B_2+1}(\cos\theta)^{A_2}P_{n_1}^{B_2+(1/2),A_2-(1/2)}(\cos 2\theta), \tag{5.60}$$

where $C+m^2=B_2^2, D=A_2(A_2-1), n_2=0,1,2,\ldots.$

Choosing the superpotential

$$W=A_3\rho-\frac{(B_3+1)}{\rho}, \tag{5.61}$$

the corresponding shape invariant potential V_- is given by

$$V_-(\rho)=A_3^2\rho^2+\frac{B_3(B_3+1)}{\rho^2}-A_3(2B_3+3). \tag{5.62}$$

Some algebra shows that

$$V_+(\rho,A_3,B_3)=V_-(\rho,A_3,B_3+1)-A_3(2B_3+3)+A_3(2B_3+1). \tag{5.63}$$

The energy eigenvalues of the potential in Eq. (5.50) is $((\omega^2/4)=A_2^2,\ \delta+l^2=(B_3+1/2)^2)$,

$$E_{n,n_1,n_2,n_3}=(2n_3+B_3+\tfrac{3}{2})\omega, \tag{5.64}$$

while the corresponding hyperradial part of the eigenfunction is[30]

$$U(\rho)=\rho^{B_3+1}\exp\left[-\frac{\omega\rho^2}{4}\right]L_{n_3}^{B_3+(1/2)}\left(\frac{1}{2}\omega\rho^2\right). \tag{5.65}$$

L_α^β is the Laguerre polynomials.

Thus the total eigenfunction for the noncentral potential Eq. (5.50) is given by the form (5.43), with $U(\rho),H(\theta),Q(\phi),$ and $K(\theta_3)$ given by Eqs. (5.65), (5.60), (5.58), and (5.56), respectively.

The energy eigenvalues are expressed in terms of the nine parameters,

$$E_{n,n_1,n_2,n_3}=[(2n_3+1)+(\delta+l^2)^{1/2}]\omega, \tag{5.66}$$

$$l^2=\left|\left(2n_2+\frac{3}{2}\right)+\sqrt{D+\frac{1}{4}}+\left\{C+\left[2(2n_1+1)+\sqrt{1+F}+\left(G+\left(\sqrt{I+\frac{\mu^2}{4}}+\sqrt{J+\frac{\mu^2}{4}}+(2n+1)\mu\right)^2\right)^{1/2}\right]^2\right\}^{1/2}\right|^2. \tag{5.67}$$

To conclude, let us point out that the four-body constrained systems involved here lead to a solvable potential with nine parameters. This is remarkable. Recall that the most general solvable central potentials of Natanzon-type[25,31] are built with six parameters while the noncentral solvable potential reconstruction needs seven parameters in three dimensions.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 40, NUMBER 12 DECEMBER 1999

Coulomb wave functions with complex values of the variable and the parameters

Aleksander Dzieciol, Staffan Yngve, and Per Olof Fröman
Department of Theoretical Physics, University of Uppsala, Box 803, S-751 08 Uppsala, Sweden

(Received 8 June 1998; accepted for publication 22 June 1999)

The motivation for the present paper lies in the fact that the literature concerning the Coulomb wave functions $F_L(\eta,\rho)$ and $G_L(\eta,\rho)$ is a jungle in which it may be hard to find a safe way when one needs general formulas for the Coulomb wave functions with complex values of the variable ρ and the parameters L and η. For the Coulomb wave functions and certain linear combinations of these functions we discuss the connection with the Whittaker function, the Coulomb phase shift, Wronskians, reflection formulas $(L\to -L-1)$, integral representations, series expansions, circuital relations $(\rho\to\rho e^{\pm i\pi})$ and asymptotic formulas on a Riemann surface for the variable ρ. The parameters L and η are allowed to assume complex values. © *1999 American Institute of Physics.* [S0022-2488(99)01710-7]

I. INTRODUCTION

The literature on Coulomb wave functions is very extensive and difficult to survey. The presentation of Yost, Breit, and Wheeler,[1] which contains the first general treatment, was later followed by the review article by Hull and Breit.[2] For particular purposes one has found it convenient to introduce a large number of functions that are solutions of the Coulomb differential equation.[3–9] For the standard Coulomb wave functions $F_L(\eta,\rho)$ and $G_L(\eta,\rho)$ in Abramowitz and Stegun,[10] one, in general, assumes the variable ρ to be real, the angular momentum quantum number L to be a non-negative integer, and the parameter η to be real. However, in theoretical physics there appear problems in which one needs Coulomb wave functions with complex values of the variable ρ and the parameters L and η. This is the case, for instance, in Regge pole theory, where the angular momentum is complex, in scattering theory, when the energy is complex, and in quantum defect theory for closed channels. In the existing literature it is, however, hard or impossible to find general formulas for the standard Coulomb wave functions $F_L(\eta,\rho)$ and $G_L(\eta,\rho)$ with complex values of the variable ρ and the parameters L and η. For such values of the parameters the analytic properties of the Coulomb phase shift $\sigma_L(\eta)$ make the discussion of these Coulomb wave functions much more complicated than the discussion of the related Whittaker function, and it is therefore desirable to present the result of such a discussion in a surveyable way.

Our purpose in the present paper is to present and collect general formulas for the standard Coulomb wave functions $F_L(\eta,\rho)$ and $G_L(\eta,\rho)$, which are solutions of the differential equation

$$\frac{d^2\psi}{d\rho^2}+\left(1-\frac{2\eta}{\rho}-\frac{L(L+1)}{\rho^2}\right)\psi=0, \tag{1.1}$$

and certain linear combinations of these functions, viz.,

$$\psi_\pm(L,\eta,\rho)=G_L(\eta,\rho)\pm iF_L(\eta,\rho), \tag{1.2}$$

when the variable ρ and the parameters L and η are allowed to assume complex values without unnecessary restrictions. In Sec. II we express the functions $\psi_+(L,\eta,\rho)$ and $\psi_-(L,\eta,\rho)$ in terms of the Whittaker function. For the Coulomb phase shift $\sigma_L(\eta)$, which appears in these formulas, we investigate the rather complicated limiting properties when L and η are complex and $\eta\to 0$, and we also present the behavior of $\sigma_L(\eta)$ when the quantities $L+1\pm i\eta$ are both large. Wronskian relations for the functions in (1.2) are also presented. In Sec. III we express $\psi_\pm(-L-1,\eta,\rho)$ in terms of $\psi_\pm(L,\eta,\rho)$, and we also express $F_{-L-1}(\eta,\rho)$ and $G_{-L-1}(\eta,\rho)$ in terms of $F_L(\eta,\rho)$ and $G_L(\eta,\rho)$. In these formulas there appears a quantity $x(L,\eta)$, the rather complicated limiting properties of which as $\eta\to 0$ we investigate. From the definition of $x(L,\eta)$ we first derive an alternative formula for $x(L,\eta)$ and then formulas for $\partial x(L,\eta)/\partial L$ and $\partial x(L,\eta)/\partial\eta$. When $2L$ is an integer and $\eta\neq 0$, we obtain a simple formula for $x(L,\eta)$, with the aid of which we can simplify the previously mentioned formulas that express $\psi_\pm(-L-1,\eta,\rho)$ in terms of $\psi_\pm(L,\eta,\rho)$, as well as the formulas that express $F_{-L-1}(\eta,\rho)$ and $G_{-L-1}(\eta,\rho)$ in terms of $F_L(\eta,\rho)$ and $G_L(\eta,\rho)$. In Sec. IV we present integral representations for $\psi_\pm(L,\eta,\rho)$ and $F_L(\eta,\rho)$. In Sec. V, $F_L(\eta,\rho)$ is expanded in powers of ρ, and from this formula we obtain a formula for $\partial \ln F_L(\eta,\rho)/\partial L$ when $2L+1$ is *not* a negative integer. Simplified formulas obtained when $L=-\frac{1}{2}$ are also given. Formulas for $G_L(\eta,\rho)$ are presented in Sec. VI. The cases when $2L$ is not an integer and when $2L$ is an integer (in particular, when $L=-\frac{1}{2}$) are discussed separately. In Sec. VII, $\psi_+(L,\eta,\rho)$ and $\psi_-(L,\eta,\rho)$ are expressed in terms of $\psi_+(L,-\eta,\rho e^{+i\pi})$ and $\psi_-(L,-\eta,\rho e^{+i\pi})$, as well as in terms of $\psi_+(L,-\eta,\rho e^{-i\pi})$ and $\psi_-(L,-\eta,\rho e^{-i\pi})$, and $F_L(\eta,\rho)$ and $G_L(\eta,\rho)$ are expressed in terms of $F_L(-\eta,\rho e^{+i\pi})$ and $G_L(-\eta,\rho e^{+i\pi})$, as well as in terms of $F_L(-\eta,\rho e^{-i\pi})$ and $G_L(-\eta,\rho e^{-i\pi})$. General asymptotic formulas for $\psi_\pm(L,\eta,\rho)$, $F_L(\eta,\rho)$, and $G_L(\eta,\rho)$, valid for fixed complex values of L and η, when ρ tends to infinity, while $\arg\rho$ has an arbitrary fixed value, are given in Sec. VIII.

II. COULOMB WAVE FUNCTIONS EXPRESSED IN TERMS OF THE WHITTAKER FUNCTION, COULOMB PHASE SHIFT, AND WRONSKIANS

One can express $\psi_+(L,\eta,\rho)$ and $\psi_-(L,\eta,\rho)$ in terms of the Whittaker function as follows:

$$\psi_+(L,\eta,\rho)=\exp\{i[\sigma_L(\eta)-(L+i\eta)\pi/2]\}W_{-i\eta,L+1/2}(2\rho e^{-i\pi/2}), \tag{2.1a}$$

$$\psi_-(L,\eta,\rho)=\exp\{-i[\sigma_L(\eta)-(L-i\eta)\pi/2]\}W_{i\eta,L+1/2}(2\rho e^{+i\pi/2}), \tag{2.1b}$$

where $\sigma_L(\eta)$ is the Coulomb phase shift, defined as

$$\sigma_L(\eta)=\frac{1}{2i}[\ln\Gamma(L+1+i\eta)-\ln\Gamma(L+1-i\eta)], \tag{2.2}$$

and the logarithms $\ln\Gamma(L+1\pm i\eta)=\ln|\Gamma(L+1\pm i\eta)|+i\arg\Gamma(L+1\pm i\eta)$ are uniquely determined by the requirements that

$$L+1\pm i\eta\neq 0,\quad -\pi<\arg(L+1\pm i\eta)<\pi, \tag{2.3a}$$

$$\ln\Gamma(L+1\pm i\eta)\quad \text{is real when } L+1\pm i\eta \text{ is positive.} \tag{2.3b}$$

When L is *not* a negative number $\leqslant -1$, we obtain from (2.2),

$$\sigma_L(0)=0,\quad \text{except when } L \text{ is real and } \leqslant -1. \tag{2.4a}$$

When L is a real number <-1 but *not* an integer, we realize that

$$\lim_{\eta\to 0}\ln\Gamma(L+1\pm i\eta)-\ln|\Gamma(L+1)|=\mp[-L]\pi i,\quad \text{when } \operatorname{Re}\eta>0, \tag{2.5a}$$

$$\lim_{\eta\to 0}\ln\Gamma(L+1\pm i\eta)-\ln|\Gamma(L+1)|=\pm[-L]\pi i,\quad \text{when } \operatorname{Re}\eta<0, \tag{2.5b}$$

where $[-L]$ denotes the integer part of $-L$, and hence we obtain from (2.2),

$$\lim_{\eta\to 0}\sigma_L(\eta)=\begin{cases}-[-L]\pi, & \text{when Re }\eta>0,\\ +[-L]\pi, & \text{when Re }\eta<0.\end{cases}$$

$$\text{when } L \text{ is a negative number } <-1 \text{ but } \textit{not} \text{ an integer.} \tag{2.4b}$$

When L is a negative integer, and η is sufficiently small, we have the approximate formula

$$\Gamma(L+1\pm i\eta)=\frac{(-1)^{-L-1}+O(\eta)}{(-L-1)!(\pm i\eta)}, \tag{2.6}$$

with the aid of which we obtain

$$\lim_{\eta\to 0}\{\ln\Gamma(L+1\pm i\eta)+\ln[(-L-1)!|\eta|]\}$$
$$=i[\pm(L+\tfrac{1}{2})\pi+\pi/2-\arg(i\eta)],\quad \text{when } 0<\arg(i\eta)<\pi, \tag{2.7a}$$

$$\lim_{\eta\to 0}\{\ln\Gamma(L+1\pm i\eta)+\ln[(-L-1)!|\eta|]\}$$
$$=i[\mp(L+\tfrac{1}{2})\pi-\pi/2-\arg(i\eta)],\quad \text{when } -\pi<\arg(i\eta)<0, \tag{2.7b}$$

and hence we obtain from (2.2),

$$\lim_{\eta\to 0}\sigma_L(\eta)=\begin{cases}+(L+\tfrac{1}{2})\pi, & \text{when Re }\eta>0,\\ -(L+\tfrac{1}{2})\pi, & \text{when Re }\eta<0,\end{cases}\quad L=\text{negative integer.} \tag{2.4c}$$

Since the functions $\ln\Gamma(L+1\pm i\eta)$ are uniquely defined when the conditions (2.3a) and (2.3b) are fulfilled, one obtains from (2.2) the formula

$$\sigma_L(-\eta)=-\sigma_L(\eta), \tag{2.8}$$

which is consistent with (2.4a)–(2.4c). From (2.2), it also follows that

$$\exp[\pm i\sigma_L(\eta)]=\left(\frac{\exp[\frac{1}{2}\ln\Gamma(L+1+i\eta)]}{\exp[\frac{1}{2}\ln\Gamma(L+1-i\eta)]}\right)^{\pm 1}=\left(\frac{\Gamma(L+1+i\eta)}{\Gamma(L+1-i\eta)}\right)^{\pm 1/2}, \tag{2.9}$$

$$\frac{\exp[+i\sigma_L(\eta)]}{\Gamma(L+1+i\eta)}=\frac{\exp[-i\sigma_L(\eta)]}{\Gamma(L+1-i\eta)}=\exp[-\tfrac{1}{2}\ln\Gamma(L+1+i\eta)]\exp[-\tfrac{1}{2}\ln\Gamma(L+1-i\eta)]$$
$$=[\Gamma(L+1+i\eta)\Gamma(L+1-i\eta)]^{-1/2}, \tag{2.10}$$

the expressions in the last members of (2.9) and (2.10) being only shorthand notations for the precise expressions in the penultimate members.

We shall now investigate the behavior of $\sigma_L(\eta)$ when the quantities $L+1\pm i\eta$ are both large. Replacing (2.3a) by the more restrictive requirements that

$$|L+1\pm i\eta|\gg 1,\quad -\pi+\epsilon\leqslant\arg(L+1\pm i\eta)\leqslant\pi-\epsilon, \tag{2.3a$'$}$$

where ϵ is a fixed, arbitrarily small, positive number, we have the asymptotic expansion given by Eq. (5) on p. 32 in Ref. 11, i.e., with our notation,

$$\ln\Gamma(L+1\pm i\eta)\sim(L+\tfrac{1}{2}\pm i\eta)\ln(L+\tfrac{1}{2}\pm i\eta)-(L+\tfrac{1}{2}\pm i\eta)+\ln(2\pi)^{1/2}$$
$$-\frac{1}{24(L+\frac{1}{2}\pm i\eta)}+\cdots,\quad |L+\tfrac{1}{2}\pm i\eta|\gg 1, \tag{2.11}$$

where, for defining the appropriate branch of $\ln(L+\frac{1}{2}\pm i\eta)$, one has to choose $\ln(L+\frac{1}{2}\pm i\eta)$ to be close to $\ln(L+1\pm i\eta)$ when $L+\frac{1}{2}\pm i\eta$ is large. Using (2.11), we obtain from (2.2) the formula

$$\sigma_L(\eta)\sim\frac{1}{2i}[(L+\tfrac{1}{2}+i\eta)\ln(L+\tfrac{1}{2}+i\eta)-(L+\tfrac{1}{2}-i\eta)\ln(L+\tfrac{1}{2}-i\eta)]-\eta,$$
$$|L+\tfrac{1}{2}\pm i\eta|\gg 1. \tag{2.12}$$

In the particular situation when L and η are real, we can write (2.12) as

$$\sigma_L(\eta)\sim(L+\tfrac{1}{2})\arctan\frac{\eta}{L+\frac{1}{2}}+\eta\ln[(L+\tfrac{1}{2})^2+\eta^2]^{1/2}-\eta,$$
$$L \text{ and } \eta \text{ are real, } L+\tfrac{1}{2}\pm i\eta|\gg 1. \tag{2.13}$$

Using Eq. (34b) in Sec. 2 of Ref. 12 and (2.1a) and (2.1b) in the present paper, one finds that

$$\psi_+(L,\eta,\rho)\frac{d}{d\rho}\psi_-(L,\eta,\rho)-\psi_-(L,\eta,\rho)\frac{d}{d\rho}\psi_+(L,\eta,\rho)=-2i. \tag{2.14}$$

From (1.2) and (2.14) we get

$$G_L(\eta,\rho)\frac{d}{d\rho}F_L(\eta,\rho)-F_L(\eta,\rho)\frac{d}{d\rho}G_L(\eta,\rho)=1, \tag{2.15}$$

and hence

$$\frac{d}{d\rho}\frac{G_L(\eta,\rho)}{F_L(\eta,\rho)}=-\frac{1}{[F_L(\eta,\rho)]^2}. \tag{2.16}$$

From this formula, it follows that

$$\frac{G_L(\eta,\rho)}{F_L(\eta,\rho)}=-\int_{\rho_0}^{\rho}\frac{d\rho}{[F_L(\eta,\rho)]^2}, \tag{2.17}$$

where, however, the constant lower limit of integration ρ_0 is unknown.

In the next section we shall relate the Coulomb wave functions with the parameters $-L-1$ and η to the Coulomb wave functions with the parameters L and η. To that purpose we also need the phase shift $\sigma_{-L-1}(\eta)$ for the unique definition of which we, in analogy to (2.3a) and (2.3b), require that

$$-L\pm i\eta\neq 0,\quad -\pi<\arg(-L\pm i\eta)<\pi, \tag{2.18a}$$

$$\ln\Gamma(-L\pm i\eta)\quad \text{is real when} -L\pm i\eta \text{ is positive.} \tag{2.18b}$$

Throughout the next section we shall thus assume that the conditions (2.3a), (2.3b) and (2.18a), (2.18b) are fulfilled simultaneously. As we shall now show, the requirements (2.3a) and (2.18a) can be reformulated in a more concrete way.

Since $|(L+1+i\eta)-(-L-i\eta)|=2|L+\frac{1}{2}+i\eta|$ and $[(L+1+i\eta)+(-L-i\eta)]/2=\frac{1}{2}$, the distance in a complex plane between the points $L+1+i\eta$ and $-L-i\eta$ is $2|L+\frac{1}{2}+i\eta|$, and the middle point of the straight line segment joining these two points is the point $\frac{1}{2}$. When $|L+\frac{1}{2}+i\eta|<\frac{1}{2}$, the conditions (2.3a) with the upper signs, as well as the conditions (2.18a) with the lower signs, are thus automatically fulfilled. When $|L+\frac{1}{2}+i\eta|\geqslant\frac{1}{2}$ these conditions are fulfilled if either $-\pi<\arg(L+1+i\eta)<0$ or $0<\arg(L+1+i\eta)<\pi$. By replacing η by $-\eta$ we obtain similar conditions under which (2.3a) with the lower signs and (2.18a) with the upper signs are fulfilled.

III. REFLECTION FORMULAS ($L\to-L-1$)

Throughout this section we shall assume that the conditions stated at the end of the previous section, implying the simultaneous validity of (2.3a), (2.3b) and (2.18a), (2.18b), are fulfilled. Then the Coulomb phase shifts $\sigma_L(\eta)$ and $\sigma_{-L-1}(\eta)$ are both defined.

Replacing in (2.1a) and (2.1b) L by $-L-1$, we obtain

$$\psi_+(-L-1,\eta,\rho)=\exp\{i[\sigma_{-L-1}(\eta)+(L+1-i\eta)\pi/2]\}W_{-i\eta,-L-1/2}(2\rho e^{-i\pi/2}), \quad (3.1a)$$

$$\psi_-(-L-1,\eta,\rho)=\exp\{-i[\sigma_{-L-1}(\eta)+(L+1+i\eta)\pi/2]\}W_{i\eta,-L-1/2}(2\rho e^{+i\pi/2}). \quad (3.1b)$$

Since, according to Eq. (18a) in Sec. 2 of Ref. 12, the Whittaker function $W_{\kappa,\mu/2}(z)$ is an even function of the parameter μ, we obtain from (2.1a) and (3.1a),

$$\psi_+(-L-1,\eta,\rho)=\exp[ix(L,\eta)]\psi_+(L,\eta,\rho), \quad (3.2a)$$

and from (2.1b) and (3.1b),

$$\psi_-(-L-1,\eta,\rho)=\exp[-ix(L,\eta)]\psi_-(L,\eta,\rho), \quad (3.2b)$$

where the phase $x(L,\eta)$ is defined as

$$x(L,\eta)=(L+\tfrac{1}{2})\pi+\sigma_{-L-1}(\eta)-\sigma_L(\eta), \quad (3.3)$$

and thus has the property that

$$x(-L-1,\eta)=-x(L,\eta). \quad (3.4)$$

From (1.2) (3.2a), and (3.2b), we obtain

$$F_{-L-1}(\eta,\rho)=\cos x(L,\eta)F_L(\eta,\rho)+\sin x(L,\eta)G_L(\eta,\rho), \quad (3.5a)$$

$$G_{-L-1}(\eta,\rho)=-\sin x(L,\eta)F_L(\eta,\rho)+\cos x(L,\eta)G_L(\eta,\rho). \quad (3.5b)$$

Next, we shall derive formulas for $x(L,\eta)$ in the limit when $\eta\to0$. We remark in advance that the resulting formulas (3.6a)–(3.6d) fulfill (3.4).

When L is *not* a real number $\leqslant-1$ or $\geqslant0$, we obtain from (3.3) with the aid of (2.4a) and the corresponding formula with L replaced by $-L-1$,

$$x(L,0)=(L+\tfrac{1}{2})\pi, \quad \text{except when } L \text{ is real and } \leqslant-1 \text{ or } \geqslant0. \quad (3.6a)$$

When L is a real number <-1 but *not* an integer, we have $\sigma_{-L-1}(0)=0$ according to (2.4a) with L replaced by $-L-1$, and we obtain $\lim_{\eta\to0}\sigma_L(\eta)$ from (2.4b). From (3.3), we then obtain

$$\lim_{\eta\to0}x(L,\eta)=\begin{cases}(L+\frac{1}{2}+[-L])\pi, & \text{when Re }\eta>0,\\ (L+\frac{1}{2}-[-L])\pi, & \text{when Re }\eta<0,\end{cases}$$
$$\text{when } L \text{ is a real number } <-1 \text{ but } \textit{not} \text{ an integer}. \quad (3.6b)$$

When L is a real number >0 but *not* an integer, we have $\sigma_L(0)=0$ according to (2.4a), and we obtain $\lim_{\eta\to0}\sigma_{-L-1}(\eta)$ from (2.4b) with L replaced by $-L-1$. From (3.3) we then obtain

$$\lim_{\eta\to 0} x(L,\eta)=\begin{cases}(L+\frac{1}{2}-[L+1])\pi, & \text{when Re }\eta>0,\\ (L+\frac{1}{2}+[L+1])\pi, & \text{when Re }\eta<0,\end{cases}$$

$$\text{when } L \text{ is a real number } >0 \text{ but } \textit{not} \text{ an integer.} \tag{3.6c}$$

When L is an integer (positive, negative, or zero), we use (2.4a), (2.4c), and also these formulas with L replaced by $-L-1$, to obtain from (3.3),

$$\lim_{\eta\to 0} x(L,\eta)=\begin{cases}0, & \text{when Re }\eta>0,\\ (2L+1)\pi, & \text{when Re }\eta<0,\end{cases}\quad L=\text{integer.} \tag{3.6d}$$

Replacing in (2.2) L by $-L-1$, we get

$$\sigma_{-L-1}(\eta)=\frac{1}{2i}[\ln\Gamma(-L+i\eta)-\ln\Gamma(-L-i\eta)], \tag{3.7}$$

where the branches of the logarithms are to be chosen such that $\ln\Gamma(-L+i\eta)$ is a real number when $-L+i\eta$ is a positive number, and $\ln\Gamma(-L-i\eta)$ is a real number when $-L-i\eta$ is a positive number. With the aid of (2.2) and (3.7), we obtain

$$\exp\{2i[\sigma_{-L-1}(\eta)-\sigma_L(\eta)]\}=\frac{\Gamma(-L+i\eta)\Gamma(L+1-i\eta)}{\Gamma(-L-i\eta)\Gamma(L+1+i\eta)}, \tag{3.8}$$

and hence with the use of the reflection formula for the gamma function,

$$\exp\{2i[\sigma_{-L-1}(\eta)-\sigma_L(\eta)]\}=\frac{\sin[\pi(L+1+i\eta)]}{\sin[\pi(L+1-i\eta)]}. \tag{3.9}$$

Using (3.9), we obtain from (3.3),

$$\exp[2ix(L,\eta)]=\exp[(2L+1)\pi i]\frac{\sin[\pi(L+1+i\eta)]}{\sin[\pi(L+1-i\eta)]}, \tag{3.10}$$

and thus

$$x(L,\eta)=(L+\tfrac{1}{2})\pi+\frac{1}{2i}\ln\frac{\sin[\pi(L+1+i\eta)]}{\sin[\pi(L+1-i\eta)]}, \tag{3.11}$$

where according to (3.6a) the branch of the logarithm is to be chosen such that the logarithm is equal to zero when $\eta=0$ and L is a real number between -1 and 0. We can also write (3.10) as

$$\exp[2ix(L,\eta)]=\frac{1-\exp[+2\pi i(L+i\eta)]}{1-\exp[-2\pi i(L-i\eta)]}. \tag{3.12}$$

By partial logarithmic differentiation of (3.12) with respect to L, we obtain the formula

$$\begin{aligned}\frac{\partial x(L,\eta)}{\partial L}&=\frac{2\pi[1-\cos(2\pi L)\exp(2\pi\eta)]}{1-2\cos(2\pi L)\exp(2\pi\eta)+\exp(4\pi\eta)}\\ &=\frac{2\pi[1-\cos(2\pi L)\exp(2\pi\eta)]}{[1-\cos(2\pi L)\exp(2\pi\eta)]^2+\sin^2(2\pi L)\exp(4\pi\eta)},\end{aligned} \tag{3.13a}$$

and by partial logarithmic differentiation of (3.12) with respect to η, we obtain the formula

$$\frac{\partial x(L,\eta)}{\partial \eta}=\frac{2\pi \sin(2\pi L)\exp(2\pi\eta)}{1-2\cos(2\pi L)\exp(2\pi\eta)+\exp(4\pi\eta)}$$
$$=\frac{2\pi \sin(2\pi L)\exp(2\pi\eta)}{[1-\cos(2\pi L)\exp(2\pi\eta)]^2+\sin^2(2\pi L)\exp(4\pi\eta)}. \tag{3.13b}$$

When $2L$ is an integer and Re $\eta\neq 0$, we obtain from (3.13a),

$$\frac{\partial x(L,\eta)}{\partial L}=\frac{2\pi}{1-(-1)^{2L}\exp(2\pi\eta)},\quad \text{Re }\eta\neq 0,\ 2L=\text{integer}, \tag{3.14}$$

and from (3.13b), $\partial x(L,\eta)/\partial\eta=0$, and hence, when arg η is kept constant,

$$x(L,\eta)=\lim_{\eta\to 0} x(L,\eta),\quad \text{Re }\eta\neq 0,\ 2L=\text{integer}. \tag{3.15}$$

From this formula it follows, with the use of (3.6a)–(3.6d), that

$$x(L,\eta)=\begin{cases}0 & \text{when Re }\eta>0,\\ (2L+1)\pi, & \text{when Re }\eta<0,\end{cases}\quad 2L=\text{integer}. \tag{3.16}$$

Using (3.16), we obtain from (3.2a) and (3.2b),

$$\psi_{\pm}(-L-1,\eta,\rho)=\begin{cases}\psi_{\pm}(L,\eta,\rho), & \text{when Re }\eta>0,\\ (-1)^{2L+1}\psi_{\pm}(L,\eta,\rho), & \text{when Re }\eta<0,\end{cases}\quad 2L=\text{integer}, \tag{3.17}$$

and from (3.5a) and (3.5b),

$$F_{-L-1}(\eta,\rho)=\begin{cases}F_L(\eta,\rho), & \text{when Re }\eta>0,\\ (-1)^{2L+1}F_L(\eta,\rho), & \text{when Re }\eta<0,\end{cases}\quad 2L=\text{integer}, \tag{3.18a}$$

$$G_{-L-1}(\eta,\rho)=\begin{cases}G_L(\eta,\rho), & \text{when Re }\eta>0,\\ (-1)^{2L+1}G_L(\eta,\rho), & \text{when Re }\eta<0,\end{cases}\quad 2L=\text{integer}. \tag{3.18b}$$

From (3.18a) and (3.18b) one obtains the formula

$$\frac{G_{-L-1}(\eta,\rho)}{F_{-L-1}(\eta,\rho)}=\frac{G_L(\eta,\rho)}{F_L(\eta,\rho)},\quad \text{when Re }\eta\neq 0,\quad 2L=\text{integer}, \tag{3.19}$$

which can also be obtained from (3.5a), (3.5b) and (3.16).

IV. INTEGRAL REPRESENTATIONS

According to Eq. (5) in Sec. 5 of Ref. 12, we have for the Whittaker function the integral representation

$$W_{\kappa,\mu/2}(z)=\frac{z^{\kappa}e^{-z/2}}{\Gamma((\mu+1)/2-\kappa)}\int_0^{\infty}\exp(-w)w^{(\mu-1)/2-\kappa}\left(1+\frac{w}{z}\right)^{(\mu-1)/2+\kappa}dw,$$
$$z\neq 0,\quad -\pi<\arg z<\pi, \tag{4.1}$$

which is valid when $\text{Re}[(\mu+1)/2-\kappa]>0$; otherwise the integral does not converge at $w=0$. The integration in (4.1) is to be performed along the positive part of the real w axis with $\arg w=0$ and $\arg(1+w/z)\to -\arg z$ as $w\to\infty$.

With the aid of (4.1) we obtain from (2.1a),

$$\psi_+(L,\eta,\rho)=\frac{\exp\{+i[\rho-\eta\ln(2\rho)-L\pi/2+\sigma_L(\eta)]\}}{\Gamma(L+1+i\eta)}$$
$$\times\int_0^\infty \exp(-w)w^{L+i\eta}\left(1+\frac{we^{+i\pi/2}}{2\rho}\right)^{L-i\eta}dw,$$
$$\rho\neq 0,\quad -\pi/2<\arg\rho<3\pi/2,\quad \mathrm{Re}(L+1+i\eta)>0, \tag{4.2a}$$

and from (2.1b),

$$\psi_-(L,\eta,\rho)=\frac{\exp\{-i[\rho-\eta\ln(2\rho)-L\pi/2+\sigma_L(\eta)]\}}{\Gamma(L+1-i\eta)}$$
$$\times\int_0^\infty \exp(-w)w^{L-i\eta}\left(1+\frac{we^{-i\pi/2}}{2\rho}\right)^{L+i\eta}dw,$$
$$\rho\neq 0,\quad -3\pi/2<\arg\rho<\pi/2,\quad \mathrm{Re}(L+1-i\eta)>0. \tag{4.2b}$$

The integrations in (4.2a) and (4.2b) are to be performed along the positive part of the real w axis with $\arg w=0$ and $\arg[1+we^{i\pi/2}/(2\rho)]\to\pi/2-\arg\rho$ as $w\to\infty$ in (4.2a), but $\arg[1+we^{-i\pi/2}/(2\rho)]\to-\pi/2-\arg\rho$ as $w\to\infty$ in (4.2b). For the sake of clarity, we remark that $\mathrm{Re}(L+1\pm i\eta)>0$ implies that the conditions (2.3a) are fulfilled. Referring to (2.2), we emphasize that always when the Coulomb phase shift $\sigma_L(\eta)$ or a Coulomb wave function (including ψ_+ and ψ_-) with the parameters L and η appears, it is tacitly assumed that the conditions (2.3a) and (2.3b) are fulfilled. Therefore we have, in general, not found it necessary to repeat these conditions, and also, in the following, we shall assume that these conditions (even if they are not stated explicitly) are fulfilled for formulas involving $\sigma_L(\eta)$ or Coulomb wave functions with the parameters L and η.

When $L+i\eta$ and $L-i\eta$, respectively, is not an integer, the integrand in (4.2a) and (4.2b), respectively, has a branch point at $w=0$, and we can rewrite the integral by using a contour that encircles the point $w=0$. Thus, if we introduce a contour of integration Γ, which will be defined below, and use the reflection formula for the gamma function, we can rewrite (4.2a) as

$$\psi_+(L,\eta,\rho)=-\frac{1}{2\pi i}\exp\{+i[\rho-\eta\ln(2\rho)-3L\pi/2-i\eta\pi+\sigma_L(\eta)]\}\Gamma(-L-i\eta)$$
$$\times\int_\Gamma \exp(-w)w^{L+i\eta}\left(1+\frac{we^{+i\pi/2}}{2\rho}\right)^{L-i\eta}dw,$$
$$\rho\neq 0,\quad -\pi/2<\arg\rho<3\pi/2,\quad L+i\eta\neq \text{integer}, \tag{4.3a}$$

and (4.2b) as

$$\psi_-(L,\eta,\rho)=-\frac{1}{2\pi i}\exp\{-i[\rho-\eta\ln(2\rho)+L\pi/2-i\eta\pi+\sigma_L(\eta)]\}\Gamma(-L+i\eta)$$
$$\times\int_\Gamma \exp(-w)w^{L-i\eta}\left(1+\frac{we^{-i\pi/2}}{2\rho}\right)^{L+i\eta}dw,$$
$$\rho\neq 0,\quad -3\pi/2<\arg\rho<\pi/2,\quad L-i\eta\neq \text{integer}, \tag{4.3b}$$

where Γ is a contour of integration that begins at infinity with $\arg w=0$, encircles the origin in the positive sense without encircling the point $2i\rho$ for (4.3a) and point $-2i\rho$ for (4.3b), and ends at infinity with $\arg w=2\pi$; see Fig. 1. The conditions $\mathrm{Re}(L+1\pm i\eta)>0$ in (4.2a) and (4.2b) do not apply to (4.3a) and (4.3b). With the aid of the reflection formula for the gamma function and (2.10), the formulas (4.2a), (4.2b) and (4.3a), (4.3b) can be rewritten in alternative ways.

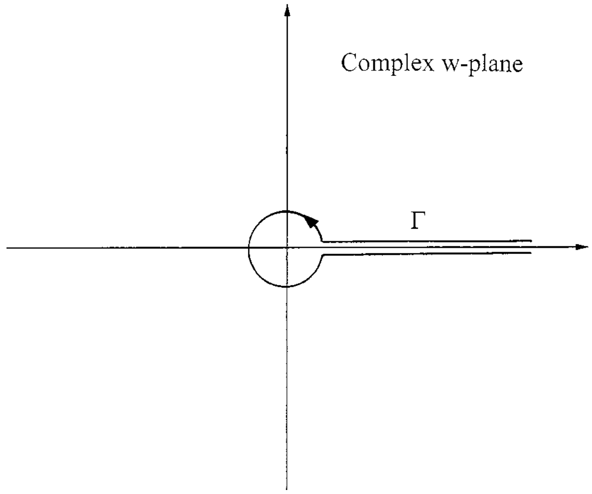

FIG. 1. The contour Γ, which must not encircle the points $+2i\rho$ and $-2i\rho$.

Introducing instead of w a new integration variable s by putting in (4.2a),

$$w=e^{i\pi/2}\rho(1+s),\quad \rho\neq 0,\quad \arg(1+s)=-\pi/2-\arg\rho$$

$$1+we^{i\pi/2}/(2\rho)=(1-s)/2,\quad \arg(1-s)\rightarrow\pi/2-\arg\rho\quad \text{as}\ \ s\rightarrow\infty, \tag{4.4a}$$

and in (4.2b),

$$w=e^{-i\pi/2}\rho(1-s),\quad \rho\neq 0,\quad \arg(1-s)=\pi/2-\arg\rho,$$

$$1+we^{-i\pi/2}/(2\rho)=(1+s)/2,\quad \arg(1+s)\rightarrow-\pi/2-\arg\rho\quad \text{as}\ \ s\rightarrow\infty, \tag{4.4b}$$

we get

$$\psi_{+}(L,\eta,\rho)=\frac{2i\exp[i\sigma_L(\eta)-\eta\pi/2]}{\Gamma(L+1+i\eta)}(\rho/2)^{L+i}$$
$$\times\int_{-1}^{+\infty e^{-i\pi/2}/\rho}\exp(-i\rho s)(1+s)^{L+i\eta}(1-s)^{L-i\eta}\,ds,$$
$$\rho\neq 0,\quad -\pi/2<\arg\rho<3\pi/2,\quad \mathrm{Re}(L+1+i\eta)>0, \tag{4.5a}$$

and, when (2.10) is also used,

$$\psi_{-}(L,\eta,\rho)=\frac{2i\exp[i\sigma_L(\eta)-\eta\pi/2]}{\Gamma(L+1+i\eta)}(\rho/2)^{L+1}$$
$$\times\int_{1}^{+\infty e^{-i\pi/2}/\rho}\exp(-i\rho s)(1+s)^{L+i\eta}(1-s)^{L-i\eta}\,ds,$$
$$\rho\neq 0,\quad -3\pi/2<\arg\rho<\pi/2,\quad \mathrm{Re}(L+1-i\eta)>0. \tag{4.5b}$$

Using (1.2), (4.5a), and (4.5b), we obtain

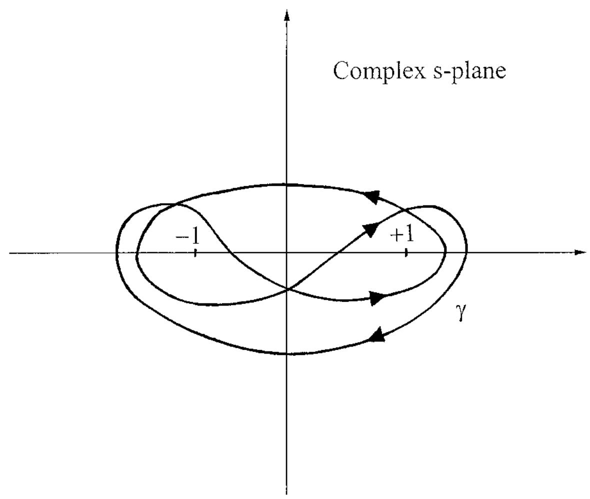

FIG. 2. The contour γ.

$$F_L(\eta,\rho)=\frac{\exp[i\sigma_L(\eta)-\eta\pi/2]}{\Gamma(L+1+i\eta)}(\rho/2)^{L+1}\int_{-1}^{+1}\exp(-i\rho s)(1+s)^{L+i\eta}(1-s)^{L-i\eta}\,ds,$$

$$\operatorname{Re}(L+1+i\eta)>0,\quad \operatorname{Re}(L+1-i\eta)>0. \tag{4.6}$$

Although (4.6) has been obtained from (4.5a) and (4.5b), which are simultaneously valid only when $\rho\neq0$ and $-\pi/2<\arg\rho<\pi/2$, one realizes by means of analytic continuation that (4.6) is valid for any value of $\arg\rho$ (when $\rho\neq0$) and also for $\rho=0$. With the aid of (2.10), the formula (4.6) can be written in alternative ways.

Assuming that $L+i\eta\neq$ integer and $L-i\eta\neq$ integer, so that the integrand in (4.6) has branch points at $s=-1$ and $s=+1$, we let γ be a contour of integration that starts at a point on the real s axis between $s=-1$ and $s=+1$, where $\arg(1+s)=\arg(1-s)=0$, encircles successively, on a Riemann surface, $s=+1$ in the positive sense, $s=-1$ in the positive sense, $s=+1$ in the negative sense, $s=-1$ in the negative sense, and returns to the starting point; see Fig. 2. When we make this contour as small as possible, it coincides with the real s axis between $s=-1$ and $s=+1$, except for infinitesimally small circles around $s=-1$ and $s=+1$, and then we find that

$$\begin{aligned}
&\int_\gamma \exp(-i\rho s)(1+s)^{L+i\eta}(1-s)^{L-i\eta}\,ds\\
&=\int_{-1}^{+1}\exp(-i\rho s)(1+s)^{L+i\eta}(1-s)^{L-i\eta}\,ds\\
&+\exp[2\pi i(L-i\eta)]\int_{+1}^{-1}\exp(-i\rho s)(1+s)^{L+i\eta}(1-s)^{L-i\eta}\,ds\\
&+\exp[2\pi i(L+i\eta)+2\pi i(L-i\eta)]\int_{-1}^{+1}\exp(-i\rho s)(1+s)^{L+i\eta}(1-s)^{L-i\eta}\,ds\\
&+\exp[2\pi i(L+i\eta)]\int_{+1}^{-1}\exp(-i\rho s)(1+s)^{L+i\eta}(1-s)^{L-i\eta}\,ds\\
&=\{1-\exp[2\pi i(L+i\eta)]\}\{1-\exp[2\pi i(L-i\eta)]\}\\
&\quad\times\int_{-1}^{+1}\exp(-i\rho s)(1+s)^{L+i\eta}(1-s)^{L-i\eta}\,ds,
\end{aligned}$$

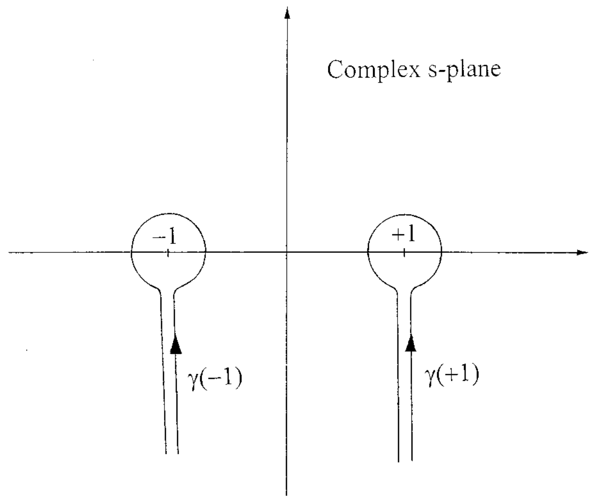

FIG. 3. The contours $\gamma(-1)$ and $\gamma(+1)$, drawn for the special case when arg $\rho=0$.

where $\arg(1+s)=\arg(1-s)=0$ in each integral with the limits of integration -1 and $+1$. Using this formula, we can write (4.6) as

$$F_L(\eta,\rho)=\frac{\exp[i\sigma_L(\eta)-\eta\pi/2]}{\Gamma(L+1+i\eta)\{1-\exp[2\pi i(L+i\eta)]\}\{1-\exp[2\pi i(L-i\eta)]\}}\times(\rho/2)^{L+1}\int_\gamma \exp(-i\rho s)(1+s)^{L+i\eta}(1-s)^{L-i\eta}\,ds,$$

$$L+i\eta\neq\text{integer},\quad L-i\eta\neq\text{integer}. \tag{4.7}$$

Note that although the derivation of (4.7) was made under the conditions $\mathrm{Re}(L+1+i\eta)>0$, $\mathrm{Re}(L+1-i\eta)>0$ and $L+i\eta\neq$ integer, $L-i\eta\neq$ integer (the last two conditions ensure that the contour of integration γ cannot be shrunk to a point), we can now disregard the first two conditions. The formula (4.7) is still valid on account of analytic continuation.

Introducing in (4.3a) instead of w a new integration variable s by putting in analogy to (4.4a),

$$w=e^{i\pi/2}\rho(1+s),\quad \rho\neq 0,\quad \arg(1+s)=-\pi/2-\arg\rho+\arg w,$$

$$1+we^{i\pi/2}/(2\rho)=(1-s)/2,$$

$$\arg(1-s)\to\pi/2-\arg\rho \text{ at infinity, where the integration starts and stops,} \tag{4.8a}$$

we get

$$\psi_+(L,\eta,\rho)=-\frac{1}{\pi}\exp[i\sigma_L(\eta)-\eta\pi/2-i(L+i\eta)\pi]\Gamma(-L-i\eta)(\rho/2)^{L+1}\times\int_{\gamma(-1)}\exp(-i\rho s)(1+s)^{L+i\eta}(1-s)^{L-i\eta}\,ds,$$

$$\rho\neq 0,\quad -\pi/2<\arg\rho<3\pi/2,\quad L+i\eta\neq\text{integer}, \tag{4.9a}$$

where $\gamma(-1)$ is a contour of integration that starts at infinity with $\arg(1+s)=-\pi/2-\arg\rho$ and $\arg(1-s)=\pi/2-\arg\rho$, encircles the point $s=-1$ in the positive sense without encircling the point $s=+1$, and returns to infinity with $\arg(1+s)=3\pi/2-\arg\rho$ and $\arg(1-s)=\pi/2-\arg\rho$; see Fig. 3. Recalling (4.8a) and the restrictions on $\arg\rho$ in (4.9a), we see that $-2\pi<\arg(1+s)<0$ and $-\pi<\arg(1-s)<\pi$ at the point at infinity where the integration starts, and $0<\arg(1+s)<2\pi$ and $-\pi<\arg(1-s)<\pi$ at the point at infinity where the integration stops.

Introducing in (4.3b) instead of w a new integration variable s by putting in analogy to (4.4b),

$$w=e^{-i\pi/2}\rho(1-s),\quad \rho\neq 0,\quad \arg(1-s)=\pi/2-\arg\rho+\arg w,$$

$$1+we^{-i\pi/2}/(2\rho)=(1+s)/2,$$

$$\arg(1+s)\rightarrow-\pi/2-\arg\rho \text{ at infinity, where the integration starts and stops,} \tag{4.8b}$$

we get

$$\psi_-(L,\eta,\rho)=-\frac{1}{\pi}\exp[-i\sigma_L(\eta)-\eta\pi/2-i(L-i\eta)\pi]\Gamma(-L+i\eta)(\rho/2)^{L+1}$$
$$\times\int_{\gamma(+1)}\exp(-i\rho s)(1+s)^{L+i\eta}(1-s)^{L-i\eta}\,ds,$$
$$\rho\neq 0,\quad -3\pi/2<\arg\rho<\pi/2,\quad L-i\eta\neq\text{integer}, \tag{4.9b}$$

where $\gamma(+1)$ is a contour of integration that starts at infinity with $\arg(1-s)=\pi/2-\arg\rho$ and $\arg(1+s)=-\pi/2-\arg\rho$, encircles the point $s=+1$ in the positive sense without encircling the point $s=-1$, and returns to infinity with $\arg(1-s)=5\pi/2-\arg\rho$ and $\arg(1+s)=-\pi/2-\arg\rho$; see Fig. 3. Recalling (4.8b) and the restrictions on $\arg\rho$ in (4.9b), we see that $0<\arg(1-s)<2\pi$ and $-\pi<\arg(1+s)<\pi$ at the point at infinity where the integration starts, and $2\pi<\arg(1-s)<4\pi$ and $-\pi<\arg(1+s)<\pi$ at the point at infinity where the integration stops.

The formula (4.7) can also be derived from (4.9a) and (4.9b), but that derivation is much more complicated than the derivation given previously in the present paper.

V. POWER SERIES FOR $F_L(\eta,\rho)$

Expanding in (4.6) the exponential $\exp(-i\rho s)$ in a power series and substituting $s=\pm(2u-1)$, where either the upper or the lower sign can be used, we obtain

$$F_L(\eta,\rho)=\frac{\exp[i\sigma_L(\eta)-\eta\pi/2]}{2\Gamma(L+1+i\eta)}$$
$$\times(2\rho)^{L+1}\sum_{k=0}^{\infty}\frac{(\pm i\rho)^k}{k!}\sum_{m=0}^{k}\binom{k}{m}(-2)^m\int_0^1 u^{m+L\pm i\eta}(1-u)^{L\mp i\eta}\,du,$$
$$\text{Re}(L+1+i\eta)>0,\quad \text{Re}(L+1-i\eta)>0, \tag{5.1}$$

where the integration is performed along the real u axis with $\arg u=\arg(1-u)=0$. In a similar way, as (4.7) was obtained from (4.6) we obtain from (5.1),

$$F_L(\eta,\rho)=\frac{\exp[i\sigma_L(\eta)-\eta\pi/2]}{2\Gamma(L+1+i\eta)\{1-\exp[2\pi i(L+i\eta)]\}\{1-\exp[2\pi i(L-i\eta)]\}}$$
$$\times(2\rho)^{L+1}\sum_{k=0}^{\infty}\frac{(\pm i\rho)^k}{k!}\sum_{m=0}^{k}\binom{k}{m}(-2)^m\int u^{m+L\pm i\eta}(1-u)^{L\mp i\eta}\,du,$$

$$L+i\eta\neq\text{integer},\quad L-i\eta\neq\text{integer},\tag{5.2}$$

where the integration is performed along a contour that starts at a point on the real u axis between $u=0$ and $u=+1$, where $\arg u=\arg(1-u)=0$, encircles successively, on a Riemann surface, $u=+1$ in the positive sense, $u=0$ in the positive sense, $u=+1$ in the negative sense, $u=0$ in the negative sense, and returns to the starting point. This contour of integration is thus analogous to the contour of integration γ in Fig. 2. Recalling the definition of the beta function and the expression for the beta function in terms of gamma functions, we have

$$\int_0^1 u^{m+L\pm i\eta}(1-u)^{L\mp i\eta}\,du=B(m+L+1\pm i\eta,L+1\mp i\eta)$$
$$=\frac{\Gamma(m+L+1\pm i\eta)\Gamma(L+1\mp i\eta)}{\Gamma(m+2L+2)},$$
$$\mathrm{Re}(L+1+i\eta)>0,\quad \mathrm{Re}(L+1-i\eta)>0,\tag{5.3}$$

where the integration is performed along the real u axis, and

$$\frac{\int u^{m+L\pm i\eta}(1-u)^{L\mp i\eta}\,du}{\{1-\exp[2\pi i(L+i\eta)]\}\{1-\exp[2\pi i(L-i\eta)]\}}$$
$$=B(m+L+1\pm i\eta,L+1\mp i\eta)=\frac{\Gamma(m+L+1\pm i\eta)\Gamma(L+1\mp i\eta)}{\Gamma(m+2L+2)},$$
$$L+i\eta\neq\text{integer},\quad L-i\eta\neq\text{integer},\tag{5.4}$$

where the contour of integration is the same as in (5.2). From (5.1), (5.3), and (2.2), or from (5.2), (5.3), and (2.2), we obtain

$$F_L(\eta,\rho)=\exp[\mp i\sigma_L(\eta)-\eta\pi/2](2\rho)^{L+1}\sum_{k=0}^{\infty}\frac{(\pm i\rho)^k}{k!}\sum_{m=0}^{k}\binom{k}{m}(-2)^m\frac{\Gamma(m+L+1\pm i\eta)}{2\Gamma(m+2L+2)},\tag{5.5}$$

where one can use either the upper or the lower signs. Since it follows from (2.3a) that $L\pm i\eta$ must not be a negative integer, the gamma functions $\Gamma(m+L+1\pm i\eta)$ cannot have poles for allowed values of the parameters L and η. The conditions in (5.1), (5.3) and (5.2), (5.4), which are associated with the integral representations used, do not apply anymore. With the use of (2.9) or (2.10), we can write (5.5) as

$$F_L(\eta,\rho)=\frac{[\Gamma(L+1+i\eta)\Gamma(L+1-i\eta)]^{1/2}}{2\exp(\eta\pi/2)}(2\rho)^{L+1}\bar{\Phi}_L(\eta,\rho),\tag{5.6}$$

with

$$\bar{\Phi}_L(\eta,\rho)=\frac{1}{\Gamma(L+1\pm i\eta)}\sum_{k=0}^{\infty}\frac{(\pm i\rho)^k}{k!}\sum_{m=0}^{k}\binom{k}{m}(-2)^m\frac{\Gamma(m+L+1\pm i\eta)}{\Gamma(m+2L+2)}.\tag{5.7}$$

For the precise definition of the square root in (5.6) we refer to the explanation below (2.10). As regards (5.7), we note that $\Gamma(L+1\pm i\eta)$ cannot be equal to zero and is finite because of (2.3a). When L, η, and ρ are real, the function $\bar{\Phi}_L(\eta,\rho)$ is according to (5.7) given by either of two complex conjugate expressions, and hence $\bar{\Phi}_L(\eta,\rho)$ must in that case be real. Our formulas (5.6) and (5.7) are to be compared with formulas in subsections 14.1.4–14.1.7 in Ref. 10, which apply when L is a nonnegative integer and η is real.

When $2L+1$ is *not* a negative integer, the terms in (5.7) corresponding to $k\leqslant -2L-2 = 2|L|-2$ vanish. The first nonvanishing term in the series (5.7) is then proportional to $\rho^{2|L|-1}$.

When $2L+1$ is *not* a negative integer, $\Gamma(2L+2)$ is finite and different from zero, and the term corresponding to $k=0$ in (5.7) is finite and does not vanish. In this case it is convenient to rewrite (5.6) along with (5.7) as follows:

$$F_L(\eta,\rho)=\frac{[\Gamma(L+1+i\eta)\Gamma(L+1-i\eta)]^{1/2}}{2\exp(\eta\pi/2)\Gamma(2L+2)}(2\rho)^{L+1}\sum_{k=0}^{\infty} c_{L,k}(\eta)\rho^k,\quad c_{L,0}(\eta)=1,$$

$$2L+1\neq \text{negative integer}, \tag{5.8}$$

where

$$c_{L,k}(\eta)=\frac{(\pm i)^k}{k!}\sum_{m=0}^{k}\binom{k}{m}(-2)^m\frac{\Gamma(2L+2)\Gamma(m+L+1\pm i\eta)}{\Gamma(m+2L+2)\Gamma(L+1\pm i\eta)},\quad 2L+1\neq \text{negative integer}. \tag{5.9}$$

In (5.9) one can use either the upper or the lower signs, and thus it is seen that

$$c_{L,k}(\eta)=(-1)^k c_{L,k}(-\eta). \tag{5.10}$$

Inserting $\psi=F_L(\eta,\rho)$ with the expression (5.8) for $F_L(\eta,\rho)$ into (1.1), and recalling that $c_{L,0}(\eta)=1$, we obtain the formulas

$$c_{L,0}(\eta)=1, \tag{5.11a}$$

$$c_{L,1}(\eta)=\eta/(L+1), \tag{5.11b}$$

$$k(k+2L+1)c_{L,k}(\eta)=2\eta c_{L,k-1}(\eta)-c_{L,k-2}(\eta),\quad k\geqslant 2, \tag{5.11c}$$

which one can use instead of (5.9) to calculate the coefficients $c_{L,k}(\eta)$. When L and η are real, the coefficients $c_{L,k}(\eta)$ are according to (5.9) given by either of two complex conjugate expressions, and hence $c_{L,k}(\eta)$ must in that case be real. This also follows from (5.11a)–(5.11c). In the still more particular case when L is a non-negative integer and η is real, (5.8) along with (5.11a)–(5.11c) agrees with the power series for $F_L(\eta,\rho)$ given in subsections 14.1.4–14.1.7 in Ref. 10, our $c_{L,k}(\eta)$ being the same as their $A^L_{L+1+k}(\eta)$.

From (5.8), it follows that

$$\frac{\partial}{\partial L}\ln F_L(\eta,\rho)=\ln(2\rho)-\frac{2\Gamma'(2L+2)}{\Gamma(2L+2)}+\frac{\Gamma'(L+1+i\eta)}{2\Gamma(L+1+i\eta)}+\frac{\Gamma'(L+1-i\eta)}{2\Gamma(L+1-i\eta)}$$
$$+\frac{\Sigma_{k=0}^{\infty}(\partial c_{L,k}/\partial L)\rho^k}{\Sigma_{k=0}^{\infty}c_{L,k}\rho^k},\quad 2L+1\neq \text{negative integer}. \tag{5.12}$$

To obtain the coefficients $\partial c_{L,k}/\partial L$ in (5.12) we differentiate (5.11a)–(5.11c) partially with respect to L, getting

$$\frac{\partial c_{L,0}}{\partial L}=0, \tag{5.13a}$$

$$\frac{\partial c_{L,1}}{\partial L}=-\frac{\eta}{(L+1)^2}, \tag{5.13b}$$

$$k(k+2L+1)\frac{\partial c_{L,k}}{\partial L}=2\eta\frac{\partial c_{L,k-1}}{\partial L}-\frac{\partial c_{L,k-2}}{\partial L}-2kc_{L,k}, \quad k\geqslant 2. \tag{5.13c}$$

Of special interest, when $2L+1$ is not a negative integer, is the particular case $L=-\frac{1}{2}$. For $L=-\frac{1}{2}$ we obtain from (5.8), with the aid of the reflection formula for the gamma function,

$$F_{-1/2}(\eta,\rho)=\left(\frac{\pi}{\exp(2\pi\eta)+1}\right)^{1/2}\rho^{1/2}\sum_{k=0}^{\infty}c_{-1/2,k}\rho^k, \quad c_{-1/2,0}=1, \tag{5.14}$$

where the square root is positive for real values of η, and from (5.12),

$$\left(\frac{\partial}{\partial L}\ln F_L(\eta,\rho)\right)_{L=-1/2}=\ln(2\rho)+2\gamma+\frac{\Gamma'(\frac{1}{2}+i\eta)}{2\Gamma(\frac{1}{2}+i\eta)}+\frac{\Gamma'(\frac{1}{2}-i\eta)}{2\Gamma(\frac{1}{2}-i\eta)}+\frac{\Sigma_{k=0}^{\infty}(\partial c_{L,k}/\partial L)_{L=-1/2}\rho^k}{\Sigma_{k=0}^{\infty}c_{-1/2,k}\rho^k}, \tag{5.15}$$

where $\gamma=-\Gamma'(1)/\Gamma(1)=-\Gamma'(1)=0.5772...$ is Euler's constant. Defining

$$d_0=-\left(\ln 2+2\gamma+\frac{\Gamma'(\frac{1}{2}+i\eta)}{2\Gamma(\frac{1}{2}+i\eta)}+\frac{\Gamma'(\frac{1}{2}-i\eta)}{2\Gamma(\frac{1}{2}-i\eta)}\right), \tag{5.16}$$

and expanding [cf. (5.11a), (5.13a), and (5.13b)]

$$\frac{\Sigma_{k=0}^{\infty}(\partial c_{L,k}/\partial L)_{L=-1/2}\rho^k}{\Sigma_{k=0}^{\infty}c_{-1/2,k}\rho^k}=-\sum_{k=1}^{\infty}d_k\rho^k=-(4\eta\rho+\cdots), \tag{5.17}$$

we can write (5.15) as

$$\left(\frac{\partial}{\partial L}\ln F_L(\eta,\rho)\right)_{L=-1/2}=-\left(\ln(1/\rho)+\sum_{k=0}^{\infty}d_k\rho^k\right)=[\ln(1/\rho)+4\eta\rho+\cdots]. \tag{5.18}$$

VI. FORMULAS FOR $G_L(\eta,\rho)$

Solving the reflection formula (3.5a) with respect to $G_L(\eta,\rho)$, we obtain

$$G_L(\eta,\rho)=\frac{F_{-L-1}(\eta,\rho)-\cos x(L,\eta)F_L(\eta,\rho)}{\sin x(L,\eta)}. \tag{6.1}$$

This formula can be directly used only when $\sin x(L,\eta)\neq 0$, and from (3.12) it follows that $\sin x(L,\eta)\neq 0$ when and only when $2L$ is not an integer (positive, negative, or zero), while η is unspecified. When $2L$ is not an integer, one can thus use (6.1) directly, and by inserting into this formula (5.8) and the formula that one obtains from (5.8) by replacing L by $-L-1$, one obtains $G_L(\eta,\rho)$ as the sum of two series in which there is no term containing $\ln\rho$. Since the series (5.8) for $F_L(\eta,\rho)$ contains the factor $(2\rho)^{L+1}$, and the corresponding series for $F_{-L-1}(\eta,\rho)$ contains the factor $(2\rho)^{-L}$, and since $2L$ is *not* an integer, one obtains $G_L(\eta,\rho)$ as the sum of two series that cannot be combined into one series.

When $2L$ is an integer, the denominator of (6.1) is equal to zero according to (3.16), and the numerator of (6.1) is equal to zero according to (3.16) and (3.18a). To use (6.1) in such a particular case, one applies l'Hospital's rule, getting, since according to (3.16) the phase $x(L,\eta)$ is an integer multiple of π,

$$G_L(\eta,\rho)=\frac{\dfrac{\partial F_{-L-1}(\eta,\rho)}{\partial L}-\cos x(L,\eta)\,\dfrac{\partial F_L(\eta,\rho)}{\partial L}}{\cos x(L,\eta)\,\dfrac{\partial x(L,\eta)}{\partial L}},\quad 2L=\text{integer}. \tag{6.2}$$

With the use of (3.14) and (3.16) we obtain from (6.2),

$$G_L(\eta,\rho)=\frac{(-1)^{2L}\exp(2\pi\eta)-1}{2\pi}\times\begin{cases}\left(\dfrac{\partial F_L(\eta,\rho)}{\partial L}+\dfrac{\partial F_{-L-1}(\eta,\rho)}{\partial(-L-1)}\right), & \text{when Re }\eta>0,\\ \left(\dfrac{\partial F_L(\eta,\rho)}{\partial L}+(-1)^{2L+1}\dfrac{\partial F_{-L-1}(\eta,\rho)}{\partial(-L-1)}\right), & \text{when Re }\eta<0,\end{cases}\quad 2L=\text{integer}. \tag{6.3}$$

From (6.3) we obtain with the use of (3.18a) the formula

$$\frac{G_L(\eta,\rho)}{F_L(\eta,\rho)}=\frac{(-1)^{2L}\exp(2\pi\eta)-1}{2\pi}\left(\frac{\partial\ln F_L(\eta,\rho)}{\partial L}+\frac{\partial\ln F_{-L-1}(\eta,\rho)}{\partial(-L-1)}\right),$$

$$\text{Re }\eta\neq 0,\quad 2L=\text{integer}, \tag{6.4}$$

from which one easily obtains (3.19) in an alternative way.

When $2L=-1$ we obtain from (6.4),

$$\frac{G_{-1/2}(\eta,\rho)}{F_{-1/2}(\eta,\rho)}=-\frac{\exp(2\pi\eta)+1}{\pi}\left(\frac{\partial\ln F_L(\eta,\rho)}{\partial L}\right)_{L=-1/2}. \tag{6.5}$$

Inserting (5.18) into (6.5), we obtain

$$\frac{G_{-1/2}(\eta,\rho)}{F_{-1/2}(\eta,\rho)}=\frac{\exp(2\pi\eta)+1}{\pi}\left(\ln(1/\rho)+\sum_{k=0}^{\infty}d_k\rho^k\right)=\frac{\exp(2\pi\eta)+1}{\pi}[\ln(1/\rho)+4\eta\rho+\cdots]. \tag{6.6}$$

When $2L$ is an integer $\neq -1$ we first note that because of (3.19) it is sufficient to consider the case when $L\geqslant 0$. Then we write (6.4) as

$$\frac{G_L(\eta,\rho)}{F_L(\eta,\rho)}=\frac{(-1)^{2L}\exp(2\pi\eta)-1}{2\pi}\left\{2\ln\rho+\frac{\partial\ln[\rho^{-L-1}F_L(\eta,\rho)]}{\partial L}+\rho^{-(2L+1)}\left[\rho^{(2L+1)}\frac{\partial\ln[\rho^L F_{-L-1}(\eta,\rho)]}{\partial(-L-1)}\right]\right\}, \tag{6.7}$$

and point out that from (5.6) and (5.7) it follows that $\partial\ln[\rho^{-L-1}F_L(\eta,\rho)]/\partial L$ as well as $\rho^{(2L+1)}\partial\ln[\rho^L F_{-L-1}(\eta,\rho)]/\partial(-L-1)$ can be expanded in a power series of ρ with the constant term $\neq 0$. The formula thus obtained from (6.7) is related to formulas in subsections 14.1.14–14.1.20 in Ref. 10.

VII. CIRCUITAL RELATIONS

To obtain formulas for the Coulomb wave functions for arbitrary values of arg ρ, it is convenient to use circuital relations. For the Coulomb wave function $F_L(\eta,\rho)$ with complex values of ρ, and allowed complex values of L and η, one obtains from (5.8) and (5.10) the circuital relation

$$F_L(\eta,\rho) = -\exp[+i\pi(L+i\eta)]F_L(-\eta,\rho e^{-i\pi}), \tag{7.1a}$$

which remains valid if i is replaced by $-i$. For the linear combinations (1.2) of the Coulomb wave functions with arbitrary complex values of ρ, and allowed complex values of L and η, one obtains from (2.1a), (2.1b), and (2.8) the circuital relation

$$\psi_+(L,\eta,\rho) = \exp[-i\pi(L+i\eta)]\psi_-(L,-\eta,\rho e^{-i\pi}). \tag{7.2a}$$

Using (1.2), (7.1a), and (7.2a), we obtain

$$\begin{aligned}\psi_-(L,\eta,\rho) &= \exp[+i\pi(L+i\eta)]\psi_+(L,-\eta,\rho e^{-i\pi})\\ &\quad -\{\exp[+i\pi(L+i\eta)]-\exp[-i\pi(L+i\eta)]\}\psi_-(L,-\eta,\rho e^{-i\pi}).\end{aligned} \tag{7.2b}$$

Using (1.2), (7.1a), and (7.2a), we then obtain

$$\begin{aligned}G_L(\eta,\rho) &= \exp[-i\pi(L+i\eta)]G_L(-\eta,\rho e^{-i\pi})\\ &\quad +i\{\exp[+i\pi(L+i\eta)]-\exp[-i\pi(L+i\eta)]\}F_L(-\eta,\rho e^{-i\pi}).\end{aligned} \tag{7.1b}$$

Now we obtain from (7.1a),

$$F_L(\eta,\rho) = -\exp[-i\pi(L-i\eta)]F_L(-\eta,\rho e^{+i\pi}), \tag{7.3a}$$

which like (7.1a) remains valid when i is replaced by $-i$, from (7.1a) and (7.1b),

$$\begin{aligned}G_L(\eta,\rho) &= \exp[+i\pi(L-i\eta)]G_L(-\eta,\rho e^{+i\pi})\\ &\quad +i\{\exp[+i\pi(L-i\eta)]-\exp[-i\pi(L-i\eta)]\}F_L(-\eta,\rho e^{+i\pi}),\end{aligned} \tag{7.3b}$$

from (7.2a) and (7.2b),

$$\begin{aligned}\psi_+(L,\eta,\rho) &= \{\exp[+i\pi(L-i\eta)]-\exp[-i\pi(L-i\eta)]\}\psi_+(L,-\eta,\rho e^{+i\pi})\\ &\quad +\exp[-i\pi(L-i\eta)]\psi_-(L,-\eta,\rho e^{+i\pi}),\end{aligned} \tag{7.4a}$$

and from (7.2a),

$$\psi_-(L,\eta,\rho) = \exp[+i\pi(L-i\eta)]\psi_+(L,-\eta,\rho e^{+i\pi}). \tag{7.4b}$$

For the Weber functions, which are related to Coulomb wave functions with $L=-\frac{1}{4}$, circuital relations were obtained by P. O. Fröman, Karlsson, and Yngve (unpublished report included in Yngve's thesis 1972) who noticed that the circuital relations for these functions given in Ref. 10, subsections 19.18.4 and 19.18.5, and in Ref. 13, Eqs. (281) and (282), have to be corrected by the replacement of ϕ_2 by $ia\pi/2$ and of $[\Gamma(1/2-ia)/\Gamma(1/2+ia)]^{1/2}$ by $\exp(a\pi/2)$.

VIII. ASYMPTOTIC FORMULAS

We recall that when considering a Coulomb wave function with the parameters L and η, or a linear combination $\psi_\pm$ of two such Coulomb wave functions, we always assume that the conditions (2.3a) and (2.3b) are fulfilled.

In Sec. IV we have, for the sake of simplicity, used fixed contours of integration in the formulas (4.1), (4.2a), (4.2b), (4.3a), and (4.3b). We can, however, rotate these contours of integration as long as the integrals remain convergent, and thus extend the region of validity for arg ρ. After the contours in (4.2a), (4.2b) and (4.3a), (4.3b) have been rotated, we introduce the expansions

$$\left(1+\frac{we^{\pm i\pi/2}}{2\rho}\right)^{L\mp i\eta}=\sum_{k=0}^{\infty}\binom{L\mp i\eta}{k}\left(\frac{we^{\pm i\pi/2}}{2\rho}\right)^{k}, \tag{8.1}$$

and change the order of summation and integration to get the asymptotic expansions

$$\psi_{+}(L,\eta,\rho)\sim\frac{\exp\{+i[\rho-\eta\ln(2\rho)-L\pi/2+\sigma_L(\eta)]\}}{\Gamma(L+1+i\eta)}\times\sum_{k=0}^{\infty}\binom{L-i\eta}{k}\left(\frac{-1}{2i\rho}\right)^{k}\int_0^{\infty}\exp(-w)w^{L+i\eta+k}\,dw,$$

$$-\pi<\arg\rho<2\pi,\quad \mathrm{Re}(L+1+i\eta)>0, \tag{8.2a}$$

$$\psi_{-}(L,\eta,\rho)\sim\frac{\exp\{-i[\rho-\eta\ln(2\rho)-L\pi/2+\sigma_L(\eta)]\}}{\Gamma(L+1-i\eta)}\times\sum_{k=0}^{\infty}\binom{L+i\eta}{k}\left(\frac{1}{2i\rho}\right)^{k}\int_0^{\infty}\exp(-w)w^{L-i\eta+k}\,dw,$$

$$-2\pi<\arg\rho<\pi,\quad \mathrm{Re}(L+1-i\eta)>0, \tag{8.2b}$$

and

$$\psi_{+}(L,\eta,\rho)\sim-\frac{1}{2\pi i}\exp\{+i[\rho-\eta\ln(2\rho)-3L\pi/2-i\eta\pi+\sigma_L(\eta)]\}\Gamma(-L-i\eta)\times\sum_{k=0}^{\infty}\binom{L-i\eta}{k}\left(\frac{-1}{2i\rho}\right)^{k}\int_{\Gamma}\exp(-w)w^{L+i\eta+k}\,dw,$$

$$-\pi<\arg\rho<2\pi,\quad L+i\eta\neq\text{integer}, \tag{8.3a}$$

$$\psi_{-}(L,\eta,\rho)\sim-\frac{1}{2\pi i}\exp\{-i[\rho-\eta\ln(2\rho)+L\pi/2-i\eta\pi+\sigma_L(\eta)]\}\Gamma(-L+i\eta)\times\sum_{k=0}^{\infty}\binom{L+i\eta}{k}\left(\frac{1}{2i\rho}\right)^{k}\int_{\Gamma}\exp(-w)w^{L-i\eta+k}\,dw,$$

$$-2\pi<\arg\rho<\pi,\quad L-i\eta\neq\text{integer}. \tag{8.3b}$$

Note that we started with the rotated contours, but in (8.2a), (8.2b) and (8.3a), (8.3b), where the regions of arg ρ for the validity of the formulas are extended, we could, according to Cauchy's integral theorem, use the fixed contours again. This is possible only *after* we have made the expansions (8.1). Since

$$\int_0^{\infty}\exp(-w)w^{L\pm i\eta+k}\,dw=\Gamma(L+1\pm i\eta+k), \tag{8.4}$$

we obtain from (8.2a) and (8.2b),

$$\psi_+(L,\eta,\rho)\sim\frac{\exp\{+i[\rho-\eta\ln(2\rho)-L\pi/2+\sigma_L(\eta)]\}}{\Gamma(L+1+i\eta)}\sum_{k=0}^{\infty}\binom{L-i\eta}{k}\left(\frac{-1}{2i\rho}\right)^k\Gamma(L+1+i\eta+k),$$

$$-\pi<\arg\rho<2\pi, \tag{8.5a}$$

$$\psi_-(L,\eta,\rho)\sim\frac{\exp\{-i[\rho-\eta\ln(2\rho)-L\pi/2+\sigma_L(\eta)]\}}{\Gamma(L+1-i\eta)}\sum_{k=0}^{\infty}\binom{L+i\eta}{k}\left(\frac{1}{2i\rho}\right)^k\Gamma(L+1-i\eta+k),$$

$$-2\pi<\arg\rho<\pi, \tag{8.5b}$$

and since, as a consequence of (8.4),

$$\int_\Gamma \exp(-w)w^{L\pm i\eta+k}\,dw=(-1)^{k+1}\frac{2\pi i\exp[(L\pm i\eta)\pi i]}{\Gamma(-L\mp i\eta-k)}, \tag{8.6}$$

we obtain from (8.3a) and (8.3b),

$$\psi_+(L,\eta,\rho)\sim\exp\{+i[\rho-\eta\ln(2\rho)-L\pi/2+\sigma_L(\eta)]\}$$
$$\times\sum_{k=0}^{\infty}\binom{L-i\eta}{k}\left(\frac{1}{2i\rho}\right)^k\frac{\Gamma(-L-i\eta)}{\Gamma(-L-i\eta-k)},$$

$$-\pi<\arg\rho<2\pi, \tag{8.7a}$$

$$\psi_-(L,\eta,\rho)\sim\exp\{-i[\rho-\eta\ln(2\rho)-L\pi/2+\sigma_L(\eta)]\}$$
$$\times\sum_{k=0}^{\infty}\binom{L+i\eta}{k}\left(\frac{-1}{2i\rho}\right)^k\frac{\Gamma(-L+i\eta)}{\Gamma(-L+i\eta-k)},$$

$$-2\pi<\arg\rho<\pi. \tag{8.7b}$$

With the aid of the reflection formula for the gamma function, one can easily show that (8.5a) and (8.5b) are the same as (8.7a) and (8.7b), respectively. The conditions (2.3a) are, of course, assumed to be fulfilled, but the limitations on the parameters L and η associated with the integral representations used in Sec. IV do not appear in (8.5a), (8.5b) and (8.7a), (8.7b).

Keeping in (8.5a), (8.5b) or (8.7a), (8.7b) only the term corresponding to $k=0$, we obtain the asymptotic formulas (8.8b), (8.8b′) corresponding to $\nu=0$ (to be given below), and from these formulas we obtain with the aid of the circuital relations (7.2a), (7.2b) and (7.4a), (7.4b) the asymptotic formulas (8.8a), (8.8a′), (8.8b), (8.8b′), and (8.8c), (8.8c′) for an arbitrary integer ν. From the asymptotic formulas (8.8a)–(8.8c′), where ν is an arbitrary integer, and ε is a fixed, arbitrarily small, positive number, one obtains with the aid of (1.2) the asymptotic formulas (8.9a)–(8.9c′), the consistency of which can be checked with the aid of the circuital relations (7.1a), (7.1b) and (7.3a), (7.3b). The consistency of the asymptotic formulas given below can also be checked with the aid of the reflection formulas (3.2a), (3.2b) and (3.5a), (3.5b). The asymptotic formulas below, in which, for the sake of simplicity, we have written σ_L instead of $\sigma_L(\eta)$, are valid when the parameters L and η are kept fixed, while ρ is sufficiently large. We also remark that one can replace $\exp[\pm i\sigma_L(\eta)]$ by the last member of (2.9) with the branch of the square root chosen as described below (2.9) and (2.10).

The asymptotic formulas (8.8a)–(8.8c′) and (8.9a)–(8.9c′) are, in general, valid in intervals for $\arg\rho$ of the extension $2\pi-2\varepsilon$. However, for $\nu=0$ (8.8b) and (8.8c) give the same asymptotic formula for ψ_+, which is thus valid for $-\pi+\varepsilon<\arg\rho<2\pi-\varepsilon$, and for $\nu=0$ (8.8a′) and (8.8b′) give the same asymptotic formula for ψ_-, which is thus valid for $-2\pi+\varepsilon<\arg\rho<\pi-\varepsilon$. For the particular value $\nu=0$ the asymptotic formulas (8.8b), (8.8c) and (8.8a′), (8.8b′) are thus valid in intervals for $\arg\rho$ of the extension $3\pi-2\varepsilon$, as is also seen from (8.5a), (8.5b) and (8.7a), (8.7b).

When $(2\nu-2)\pi+\epsilon<\arg\rho<2\nu\pi-\epsilon$ *we have*

$$\psi_+\sim\frac{\exp[-2(\nu-1)\pi\eta]}{\sin(2\pi L)}\{\sin(2\nu\pi L)-\sin[2(\nu-1)\pi L]\exp(-2\pi\eta)\}$$
$$\times\exp\{+i[\rho-\eta\ln(2\rho)-L\pi/2+\sigma_L]\}$$
$$-\frac{\exp(+2\nu\pi\eta)}{\sin(2\pi L)}\sin[2(\nu-1)\pi L]\{1-\exp[-2\pi i(L-i\eta)]\}$$
$$\times\exp\{-i[\rho-\eta\ln(2\rho)-L\pi/2+\sigma_L]\} \tag{8.8a}$$

and

$$\psi_-\sim\frac{\exp[-2(\nu-1)\pi\eta]}{\sin(2\pi L)}\sin(2\nu\pi L)\{1-\exp[2\pi i(L+i\eta)]\}\exp\{+i[\rho-\eta\ln(2\rho)-L\pi/2+\sigma_L]\}$$
$$-\frac{\exp[+2(\nu-1)\pi\eta]}{\sin(2\pi L)}\{\sin[2(\nu-1)\pi L]\exp(2\pi\eta)-\sin(2\nu\pi L)\}$$
$$\times\exp\{-i[\rho-\eta\ln(2\rho)-L\pi/2+\sigma_L]\}, \tag{8.8a$'$}$$

and hence

$$F_L(\eta,\rho)\sim\frac{\exp[+2\nu\pi i(L+i\eta)]}{2i}\exp\{+i[\rho-\eta\ln(2\rho)-L\pi/2+\sigma_L]\}$$
$$-\frac{\exp[+2(\nu-1)\pi i(L-i\eta)]}{2i}\exp\{-i[\rho-\eta\ln(2\rho)-L\pi/2+\sigma_L]\}, \tag{8.9a}$$

and

$$G_L(\eta,\rho)\sim\frac{\exp[-2(\nu-1)\pi\eta]}{2\sin(2\pi L)}(\sin(2\nu\pi L)\{2-\exp[2\pi i(L+i\eta)]\}$$
$$-\sin[2(\nu-1)\pi L]\exp(-2\pi\eta))\exp\{+i[\rho-\eta\ln(2\rho)-L\pi/2+\sigma_L]\}$$
$$-\frac{\exp(+2\nu\pi\eta)}{2\sin(2\pi L)}(\sin[2(\nu-1)\pi L]\{2-\exp[-2\pi i(L-i\eta)]\}$$
$$-\sin(2\nu\pi L)\exp(-2\pi\eta))\exp\{-i[\rho-\eta\ln(2\rho)-L\pi/2+\sigma_L]\}. \tag{8.9a$'$}$$

When $(2\nu-1)\pi+\epsilon<\arg\rho<(2\nu+1)\pi-\epsilon$, *we have*

$$\psi_+\sim\frac{\exp[-2(\nu-1)\pi\eta]}{\sin(2\pi L)}\{\sin(2\nu\pi L)-\sin[2(\nu-1)\pi L]\exp(-2\pi\eta)\}$$
$$\times\exp\{+i[\rho-\eta\ln(2\rho)-L\pi/2+\sigma_L]\}$$
$$-\frac{\exp[+2(\nu+1)\pi\eta]}{\sin(2\pi L)}\sin(2\nu\pi L)\{1-\exp[-2\pi i(L-i\eta)]\}$$
$$\times\exp\{-i[\rho-\eta\ln(2\rho)-L\pi/2+\sigma_L]\} \tag{8.8b}$$

and

$$\psi_- \sim \frac{\exp[-2(\nu-1)\pi\eta]}{\sin(2\pi L)}\sin(2\nu\pi L)\{1-\exp[2\pi i(L+i\eta)]\}$$
$$\times\exp\{+i[\rho-\eta\ln(2\rho)-L\pi/2+\sigma_L]\}$$
$$-\frac{\exp(+2\nu\pi\eta)}{\sin(2\pi L)}\{\sin(2\nu\pi L)\exp(2\pi\eta)-\sin[2(\nu+1)\pi L]\}$$
$$\times\exp\{-i[\rho-\eta\ln(2\rho)-L\pi/2+\sigma_L]\}, \tag{8.8b$'$}$$

and hence

$$F_L(\eta,\rho)\sim\frac{\exp[2\nu\pi i(L+i\eta)]}{2i}\exp\{+i[\rho-\eta\ln(2\rho)-L\pi/2+\sigma_L]\}$$
$$-\frac{\exp[2\nu\pi i(L-i\eta)]}{2i}\exp\{-i[\rho-\eta\ln(2\pi)-L\pi/2+\sigma_L]\} \tag{8.9b}$$

and

$$G_L(\eta,\rho)\sim\frac{\exp[-2(\nu-1)\pi\eta]}{2\sin(2\pi L)}(\sin(2\nu\pi L)\{2-\exp[2\pi i(L+i\eta)]\}$$
$$-\sin[2(\nu-1)\pi L]\exp(-2\pi\eta))\exp\{+i[\rho-\eta\ln(2\rho)-L\pi/2+\sigma_L]\}$$
$$-\frac{\exp[2(\nu+1)\pi\eta]}{2\sin(2\pi L)}(\sin(2\nu\pi L)\{2-\exp[-2\pi i(L-i\eta)]\}$$
$$-\sin[2(\nu+1)\pi L]\exp(-2\pi\eta))\exp\{-i[\rho-\eta\ln(2\rho)-L\pi/2+\sigma_L]\}. \tag{8.9b$'$}$$

When $2\nu\pi+\epsilon<\arg\rho<(2\nu+2)\pi-\epsilon$, *we have*

$$\psi_+\sim\frac{\exp(-2\nu\pi\eta)}{\sin(2\pi L)}\{\sin[2(\nu+1)\pi L]-\sin(2\nu\pi L)\exp(-2\pi\eta)\}$$
$$\times\exp\{+i[\rho-\eta\ln(2\rho)-L\pi/2+\sigma_L]\}$$
$$-\frac{\exp[+2(\nu+1)\pi\eta]}{\sin(2\pi L)}\sin(2\nu\pi L)\{1-\exp[-2\pi i(L-i\eta)]\}$$
$$\times\exp\{-i[\rho-\eta\ln(2\rho)-L\pi/2+\sigma_L]\} \tag{8.8c}$$

and

$$\psi_-\sim\frac{\exp(-2\nu\pi\eta)}{\sin(2\pi L)}\sin[2(\nu+1)\pi L]\{1-\exp[+2\pi i(L+i\eta)]\}$$
$$\times\exp\{+i[\rho-\eta\ln(2\rho)-L\pi/2+\sigma_L]\}$$
$$-\frac{\exp(+2\nu\pi\eta)}{\sin(2\pi L)}\{\sin(2\nu\pi L)\exp(2\pi\eta)-\sin[2(\nu+1)\pi L]\}$$
$$\times\exp\{-i[\rho-\eta\ln(2\rho)-L\pi/2+\sigma_L]\}, \tag{8.8c$'$}$$

and hence

$$F_L(\eta,\rho)\sim\frac{\exp[2(\nu+1)\pi i(L+i\eta)]}{2i}\exp\{+i[\rho-\eta\ln(2\rho)-L\pi/2+\sigma_L]\}$$
$$-\frac{\exp[2\nu\pi i(L-i\eta)]}{2i}\exp\{-i[\rho-\eta\ln(2\rho)-L\pi/2+\sigma_L]\} \tag{8.9c}$$

and

$$G_L(\eta,\rho)\sim\frac{\exp(-2\nu\pi\eta)}{2\sin(2\pi L)}(\sin[2(\nu+1)\pi L]\{2-\exp[2\pi i(L+i\eta)]\}$$
$$-\sin(2\nu\pi L)\exp(-2\pi\eta))\exp\{+i[\rho-\eta\ln(2\rho)-L\pi/2+\sigma_L]\}$$
$$-\frac{\exp[2(\nu+1)\pi\eta]}{2\sin(2\pi L)}(\sin(2\nu\pi L)\{2-\exp[-2\pi i(L-i\eta)]\}$$
$$-\sin[2(\nu+1)\pi L]\exp(-2\pi\eta))\exp\{-i[\rho-\eta\ln(2\rho)-L\pi/2+\sigma_L]\}. \tag{8.9c$'$}$$

ACKNOWLEDGMENTS

In the spring of 1995 two of the authors (Fröman and Yngve) were invited to participate in the program *Exponential Asymptotics* at the Isaac Newton Institute for Mathematical Sciences in Cambridge, England. These authors wish to express their gratitude to the Isaac Newton Institute for a most fruitful time in an extremely stimulating scientific atmosphere. They are also much indebted to Professor Frank Olver and other participants for fruitful discussions.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 40, NUMBER 12 DECEMBER 1999

Phase-integral formulas for Coulomb wave functions with complex values of the variable and the parameters

Aleksander Dzieciol, Staffan Yngve, and Per Olof Fröman
Department of Theoretical Physics, University of Uppsala, Box 803, S-751 08 Uppsala, Sweden

(Received 8 June 1998; accepted for publication 22 June 1999)

Phase-integral formulas for the Coulomb wave functions $F_L(\eta,\rho)$ and $G_L(\eta,\rho)$ and certain linear combinations of these functions, with complex values of the variable ρ and the parameters L and η, are obtained explicitly up to the fifth order of the phase-integral approximation for two different choices of the base function.

I. INTRODUCTION

The central role played by Coulomb wave functions in different fields of theoretical physics made the need for easily tractable analytic approximate formulas apparent already in the early days of quantum mechanics. The WKB method was a powerful tool, which, however, soon revealed certain deficiencies that have remained unremedied in the literature on Coulomb wave functions. Already, Kramers[1] had found that to obtain correct results for a quantal particle in an attractive Coulomb field by means of the ordinary WKB method in first-order approximation it is necessary to replace $L(L+1)$ by $(L+1/2)^2$, where L is the angular momentum quantum number. When applying that method to hydrogenic atoms, Young and Uhlenbeck[2] also found that the same replacement is necessary to obtain the correct wave function close to the origin and the correct Balmer formula. In their well-known and frequently quoted article Yost, Wheeler, and Breit[3] pointed out that the WKB method gives only a crude approximation of the Coulomb wave functions, frequently with errors of an unknown amount, and that the replacement of $L(L+1)$ by $(L+1/2)^2$ does not always improve formulas obtained by means of the ordinary WKB method. Langer[4] gave a new argument for the replacement in question. Bartlett, Rice, and Good, Jr.,[5] confirmed that the applicability of the ordinary WKB method to the differential equation for the Coulomb wave functions is uncertain in the neighborhood of the origin, and that it would be desirable to have a more definite method, which did not require an adjustment of the approximate solution. In their comprehensive review article on Coulomb wave functions, M. H. Hull, Jr., and Breit[6] state that Langer's above-mentioned argument cannot be regarded as more than an indication of likelihood regarding the applicability of the approximation.

The literature on Coulomb wave functions is to a large extent restricted to the consideration of real values of the variable ρ and the parameters L and η. Thus, one does not find general formulas that apply to complex values of the variable ρ and the parameters L and η in standard handbooks; see, for instance, Abramowitz and Stegun.[7] However, in theoretical physics there often appear problems in which one uses Coulomb wave functions with complex values of the variable and the parameters. This is the case, for instance, in Regge pole theory, where the angular momentum is complex, in scattering theory, when the energy is complex, and in quantum defect theory for closed channels.

Accurate approximations for special functions of mathematical physics can be obtained by means of the phase-integral method in which one uses a phase-integral approximation of arbitrary order generated from an unspecified base function. This method has its origin in the WKB method, but further development has yielded the just mentioned phase-integral method, which in essential respects differs from the WKB method; see Chap. 1 in a book by Fröman and Fröman[8] and a paper by Dammert and P. O. Fröman.[9] The phase-integral method is freed from the previously mentioned deficiencies of the WKB method, and, when a conveniently high order of the phase-integral approximation is used, it yields formulas of very high accuracy within their regions of validity. An application of the phase-integral method to special functions has been made in a paper by P. O. Fröman, Karlsson, and Yngve,[10] in which phase-integral formulas for Bessel functions were obtained.

Our purpose in the present paper is to use the phase-integral method to derive phase-integral formulas up to the fifth-order approximation for the Coulomb wave functions $F_L(\eta,\rho)$ and $G_L(\eta,\rho)$, and certain linear combinations of these functions, which are solutions of the differential equation,

$$d^2\psi/d\rho^2+[1-2\eta/\rho-L(L+1)/\rho^2]\psi=0. \tag{1.1}$$

The phase-integral formulas obtained are very general, since we allow the variable ρ and the parameters L and η to assume complex values without unnecessary restrictions. To make the formulas valid for a large range of parameter values, we consider two essentially different choices of the base function, which are appropriate when L is sufficiently large, and when L is sufficiently small while η is sufficiently large, respectively. The phase-integral formulas are valid close to $\rho=0$ only for the one of the choices of the base-function, which is appropriate when L is sufficiently large.

II. PHASE-INTEGRAL APPROXIMATION GENERATED FROM AN UNSPECIFIED BASE FUNCTION

In this section we consider the Schrödinger-like differential equation,

$$d^2\psi/d\rho^2+R(\rho)\psi=0, \tag{2.1}$$

where for the moment we let $R(\rho)$ be an unspecified analytic function of the complex variable ρ. As described in more detail by Fröman and Fröman,[8] Chap. 1, Sec. 1.3.1, we introduce into (2.1) a ''small'' book-keeping parameter λ that is finally put equal to unity. Thus we get the auxiliary differential equation,

$$d^2\psi/d\rho^2+[Q^2(\rho)/\lambda^2+R(\rho)-Q^2(\rho)]\psi=0, \tag{2.2}$$

which goes over into (2.1) when $\lambda=1$. The function $Q(\rho)$ is the unspecified base function from which the phase-integral approximation is generated. The auxiliary differential equation (2.2) has two linearly independent solutions of the form

$$f_1(\rho)=q^{-1/2}(\rho)\exp[+iw(\rho)], \tag{2.3a}$$

$$f_2(\rho)=q^{-1/2}(\rho)\exp[-iw(\rho)], \tag{2.3b}$$

where

$$w(\rho)=\int^{\rho}q(\rho)d\rho. \tag{2.4}$$

Inserting (2.3a) or (2.3b) for ψ into (2.2), we obtain

$$q^{+1/2}d^2q^{-1/2}/d\rho^2-q^2+Q^2(\rho)/\lambda^2+R(\rho)-Q^2(\rho)=0. \tag{2.5}$$

Introducing instead of ρ the variable

$$\zeta=\int^{\rho}Q(\rho)d\rho, \tag{2.6}$$

we can write (2.5) in the form

$$1-\left(\frac{q\lambda}{Q(\rho)}\right)^2+\epsilon_0\lambda^2+\left(\frac{q\lambda}{Q(\rho)}\right)^{+1/2}\frac{d^2}{d\zeta^2}\left(\frac{q\lambda}{Q(\rho)}\right)^{-1/2}\lambda^2=0, \tag{2.7}$$

where

$$\epsilon_0=Q^{-3/2}(\rho)d^2Q^{-1/2}(\rho)/d\rho^2+R(\rho)/Q^2(\rho)-1. \tag{2.8}$$

To obtain a formal solution of (2.7), we put

$$q\lambda/Q(\rho)=\sum_{n=0}^{\infty} Y_{2n}\lambda^{2n}, \tag{2.9}$$

where Y_0 is assumed to be different from zero, and Y_{2n} $(n=0,1,2,...)$ are independent of λ. Inserting the expansion (2.9) into (2.7), expanding the left-hand member in powers of λ, and putting the coefficient of each power of λ equal to zero, we get $Y_0=\pm 1$ and a recurrence formula, from which one can successively obtain the functions $Y_2, Y_4, Y_6,\ldots,$ each one of which can be expressed in terms of ϵ_0, defined by (2.8), and derivatives of ϵ_0 with respect to ζ. Since we have both $+$ and $-$ in the exponents of (2.3a) and (2.3b), it is no restriction to choose $Y_0=1$. The first few functions Y_{2n} are then

$$Y_0=1, \tag{2.10a}$$

$$Y_2=\frac{1}{2}\epsilon_0, \tag{2.10b}$$

$$Y_4=-\frac{1}{8}\left(\epsilon_0^2+\frac{d^2\epsilon_0}{d\zeta^2}\right). \tag{2.10c}$$

The choice of the unspecified base function $Q(\rho)$ shows itself only in the expressions (2.6) and (2.8) for ζ and ϵ_0, respectively, which depend explicitly on $R(\rho)$ and $Q(\rho)$, while the expressions for the functions Y_{2n}, which are given in terms of ϵ_0 and derivatives of ϵ_0 with respect to ζ, do not depend explicitly on $R(\rho)$ and the choice of the base function $Q(\rho)$. The expressions for the functions Y_{2n} can therefore be determined once and for all. We also remark that at the zeros and poles of $Q^2(\rho)$ the functions $Q(\rho)$ and $Q^{-1/2}(\rho)$ may have branch points, whereas the functions ϵ_0, Y_{2n} and $q(\rho)/Q(\rho)$ are all single valued.

Truncating the infinite series in (2.9) at $n=N$, we obtain

$$q(\rho)=Q(\rho)\sum_{n=1}^{N} Y_{2n}\lambda^{2n-1}. \tag{2.11}$$

Inserting (2.11) into (2.3a), (2.3b), and (2.4), and putting $\lambda=1$, we get the phase-integral approximation of the order $2N+1$, generated from the base function $Q(\rho)$, which is an approximate solution of the original differential equation (2.1). For $N>0$ the function $q(\rho)$ has poles at the transition zeros and simple zeros in the neighborhood of each transition zero.[11] In the first order the phase-integral approximation is the same as the usual JWKB approximation if $Q(\rho)=R^{1/2}(\rho)$, but in higher orders it differs in essential respects from the JWKB approximation of corresponding order; see Chap. 1 in Refs. 8 and 9.

In the present paper we would prefer to choose as the fixed lower limit of integration in (2.4) and (2.6) either a first-order zero or a first-order pole of $Q^2(\rho)$. Unfortunately, this can be done in (2.4) only for the first order of the phase-integral approximation, since for the higher-order approximations the integral would be divergent. In this situation we replace (2.4) and (2.6) by

$$w(\rho)=\int_{(t)}^{\rho} q(\rho)d\rho=\frac{1}{2}\int_{\Gamma_t(\rho)} q(\rho)d\rho, \tag{2.12a}$$

$$\zeta(\rho)=\int_t^{\rho} Q(\rho)d\rho, \tag{2.12b}$$

where t is the first-order zero or first-order pole in question. The integral in the second member of (2.12a) is a shorthand notation, introduced by Fröman *et al.*,[12] pp. 158–161, for the contour integral in the last member of (2.12a), where $\Gamma_t(\rho)$ is a path of integration that starts at the point corresponding to ρ on a Riemann sheet adjacent to the complex ρ plane under consideration, encircles t in the positive or in the negative sense, and ends at ρ. It is immaterial for the value of the contour integral whether the path of integration encircles t in the positive or in the negative sense, but the terminal point must be the point ρ in the complex ρ plane under consideration. In the first order of the phase-integral approximation, the contour integral can be replaced by an ordinary integral from t to ρ, i.e.,

$$\int_{(t)}^{\rho} q(\rho)d\rho=\int_t^{\rho} Q(\rho)d\rho=\zeta(\rho), \quad \text{first-order approximation.} \tag{2.13}$$

In the present paper we shall consider the differential equation for the Coulomb wave functions, which one obtains by putting in (2.1), with well-known notations,

$$R(\rho)=1-2\eta/\rho-L(L+1)/\rho^2, \tag{2.14}$$

and we shall choose the base function to be

$$Q(\rho)=(1-2\eta/\rho-\Lambda^2/\rho^2)^{1/2}, \tag{2.15}$$

where Λ is a conveniently chosen complex constant. From experience with the phase-integral method it is known that when L is sufficiently large, it is convenient to choose $\Lambda=L+\frac{1}{2}$, whereas when L is sufficiently small and η is sufficiently large, it is convenient to choose $\Lambda=0$. We restrict ourselves to cases when $\rho^2Q^2(\rho)$ has simple zeros by assuming that $\eta^2+\Lambda^2\neq 0$. We introduce in the complex ρ plane a cut that joins the roots $\eta\pm(\eta^2+\Lambda^2)^{1/2}$ of the equation $\rho^2Q^2(\rho)=0$. When $\Lambda\neq 0$, we extend this cut by a cut from one of these roots to the origin. As a result $Q^{-1/2}(\rho)$, and hence $q^{-1/2}(\rho)$ is a single valued function of ρ, whether Λ is equal to zero or different from zero. The phase of $Q^{-1/2}(\rho)$ is chosen such that $Q^{-1/2}(\rho)\to 1$ as $\rho\to\infty$. To make the integrals in (2.12a) and (2.12b) single valued, we replace the complex ρ plane by a Riemann surface with the above-mentioned cut on each Riemann sheet. Since the point t is assumed to be a simple zero of $\rho^2Q^2(\rho)$, it is either a first-order zero or a first-order pole of $Q^2(\rho)$.

We now define

$$\delta=\lim_{\rho\to\infty}\left(\int_{(t)}^{\rho} q(\rho)d\rho-[\rho-\eta\ln(2\rho)]\right), \tag{2.16}$$

where the path of integration is the same as in (2.12a). The branch of $\ln(2\rho)$ is determined by the value of $\ln(2t)$, which will be prescribed later. The value of δ depends on L, η, Λ, and the order $2N+1$ of the phase-integral approximation. It also depends on the choice of the transition point t. Inserting (2.11) with $\lambda=1$ into (2.16), we obtain

$$\delta=\sum_{n=0}^{N}\delta^{(2n+1)}, \tag{2.17}$$

with

$$\delta^{(1)} = \lim_{\rho\to\infty}\left(\int_t^{\rho} Q(\rho)d\rho - [\rho - \eta\ln(2\rho)]\right), \tag{2.18a}$$

$$\delta^{(2n+1)} = \int_{(t)}^{\infty} Y_{2n}Q(\rho)d\rho, \quad n>0. \tag{2.18b}$$

As already mentioned, the phase of $Q^{-1/2}(\rho)$ is chosen such that $Q^{-1/2}(\rho)$ tends to unity as ρ tends to infinity, and the case $\Lambda = \pm i\eta$ is excluded, since we assume $\rho^2 Q^2(\rho)$ to have two *simple* zeros; see (2.15). We thus assume that $\eta^2+\Lambda^2\neq 0$.

The essential problem in the present paper is the calculation of $\delta^{(2n+1)}$. This is problematical for $n=0$, since the expression for the integral in (2.18a) contains a logarithm, the appropriate branch of which must be clearly specified when ρ moves away from t. For $n>0$ there are no real difficulties but only the question of evaluating rather complicated integrals.

III. CALCULATION OF $\delta^{(2n+1)}$

The integral in (2.18a) can be evaluated in explicit analytical form. For the corresponding indefinite integral one obtains with the aid of (2.15) the formula

$$\int^{\rho} Q(\rho)d\rho = \rho Q(\rho) - \eta\ln\{\rho[1+Q(\rho)]-\eta\} + \frac{\Lambda}{2i}\ln\frac{\Lambda Q(\rho)+i(\eta+\Lambda^2/\rho)}{\Lambda Q(\rho)-i(\eta+\Lambda^2/\rho)}. \tag{3.1}$$

With the aid of (2.15) one also obtains the identities

$$\{\rho[1+Q(\rho)]-\eta\}\{\rho[1-Q(\rho)]-\eta\} = \eta^2+\Lambda^2, \tag{3.2a}$$

$$[\Lambda Q(\rho)+i(\eta+\Lambda^2/\rho)][\Lambda Q(\rho)-i(\eta+\Lambda^2/\rho)] = (\eta^2+\Lambda^2). \tag{3.2b}$$

Since $\eta^2+\Lambda^2\neq 0$ it follows from (3.2a) and (3.2b) that no one of the logarithms in (3.1) has a branch point off the cuts of the Riemann surface for the complex variable ρ. The logarithms in (3.1) are thus single-valued when ρ does not encircle the cut, but the first logarithm in (3.1) changes when ρ moves from one Riemann sheet to another. To obtain the definite integral in (2.18a), we choose the constant lower limit of integration in (3.1) to be one of the two roots of the equation $\rho^2 Q^2(\rho)=0$, i.e., from (2.15),

$$t = \eta \pm (\eta^2+\Lambda^2)^{1/2}, \tag{3.3}$$

where we choose $(\eta^2+\Lambda^2)^{1/2}=\eta$ when $\Lambda=0$ and $(\eta^2+\Lambda^2)^{1/2}=\Lambda$ when $\eta=0$. From (3.1) we now obtain the formula

$$\int_t^{\rho} Q(\rho)d\rho = \rho Q(\rho) - \eta\ln\frac{\rho[1+Q(\rho)]-\eta}{t-\eta} + \Lambda\left(\frac{1}{2i}\ln\frac{\Lambda Q(\rho)+i(\eta+\Lambda^2/\rho)}{\Lambda Q(\rho)-i(\eta+\Lambda^2/\rho)} - \frac{\pi}{2}\right), \tag{3.4}$$

where for $\rho=t$ the first logarithm is equal to zero and the second logarithm (when $\Lambda\neq 0$) is equal to πi; note that $t\neq 0$ and $Q(t)=0$ when $\Lambda\neq 0$. Since the logarithms in (3.4) have no branch points off the cuts of the Riemann surface, they are uniquely determined on that surface.

To treat the first logarithm in (3.4), we want to find a curve on which that logarithm is real and increases from 0 to $+\infty$ as ρ moves from t to ∞. To this purpose we put

$$\frac{\rho[1+Q(\rho)]-\eta}{t-\eta} = r, \tag{3.5}$$

where it is required that r is real and $\geqslant 1$. From (3.5) we obtain

$$Q(\rho)=\frac{r(t-\eta)+\eta}{\rho}-1. \tag{3.6}$$

Inserting (2.15) into (3.6) and squaring the resulting equation, and noting that $\eta^2+\Lambda^2=(t-\eta)^2$ according to (3.3), we obtain after some calculations,

$$\rho=\tfrac{1}{2}(r+1/r)(t-\eta)+\eta. \tag{3.7}$$

From (3.7) it is seen that as r increases from 1 to $+\infty$, ρ moves from t to ∞ along the straight line that emerges from t in the direction opposite to the direction from t to η. By means of (3.7) and (3.3) one finds that the point $\rho=0$ may lie on this straight line when Λ/η is purely imaginary and to its absolute value smaller than unity. When $\Lambda=0$ the straight line may emerge from but not pass through the point $\rho=0$. When $\Lambda\neq 0$ and ρ is sufficiently small, the left-hand member of (3.5) is a single valued function of ρ that does not change sign when ρ changes sign, and there appear therefore no difficulties if the straight line passes through $\rho=0$. Since $Q(\rho)\to 1$ as $\rho\to\infty$, and because of (3.7), we obtain from (3.5),

$$\ln\frac{\rho[1+Q(\rho)]-\eta}{t-\eta}\sim\ln(2\rho)-\ln(t-\eta),\quad \rho\to\infty, \tag{3.8}$$

where $\mathrm{Im}\ln(2\rho)=\mathrm{Im}\ln(t-\eta)=\arg(t-\eta)$ when $\arg\rho=\arg(t-\eta)$.

To discuss the second logarithm in (3.4), we consider first the particular case when $\Lambda\neq 0$ and $\eta=0$, and we choose the sign of Λ such that $t=\Lambda$; see (3.3). With $\eta=0$ we obtain from (2.15),

$$\rho=\frac{\Lambda}{(1-Q^2)^{1/2}},\quad \eta=0, \tag{3.9}$$

where we choose the sign of the square root such that $\rho=\Lambda=t$ when $Q(\rho)=0$. With the aid of (3.9) we can write the second logarithm in (3.4) with $\eta=0$ as

$$\ln\frac{Q(\rho)+i[1-Q^2(\rho)]^{1/2}}{Q(\rho)-i[1-Q^2(\rho)]^{1/2}},\quad \eta=0. \tag{3.10}$$

This logarithm is equal to πi when $\rho=t$, i.e., when $Q(\rho)=0$, since the second logarithm in (3.4) is equal to πi when $\Lambda\neq 0$ and $\rho=t$. Letting ρ move from t to ∞ in such a way that $Q(\rho)$ is real and increases monotonically from 0 to 1, which according to (3.9) means that $\arg\rho=\arg\Lambda$, we find from (3.10) that the value of the logarithm at $\rho=+\infty\exp(i\arg\Lambda)$ is equal to 0. When $\rho\to+\infty\exp(i\arg\Lambda)$ we therefore have for the second logarithm in (3.4) the expression

$$\ln\frac{\Lambda+i\eta}{\Lambda-i\eta}\to 0,\quad \text{as}\quad \eta\to 0. \tag{3.11}$$

This must be true for any value of $\arg\rho$, since in the limit $\rho\to\infty$ the logarithm is independent of ρ.

In the limit $\rho\to\infty$ we obtain from (3.4) with the aid of (2.15), (3.8), and (3.11) the formula

$$\int_t^\rho Q(\rho)d\rho\sim\rho-\eta\ln(2\rho)+\eta[\ln(t-\eta)-1]+\Lambda\left(\frac{1}{2i}\ln\frac{\Lambda+i\eta}{\Lambda-i\eta}-\frac{\pi}{2}\right), \tag{3.12}$$

where $\mathrm{Im}\ln(2\rho)=\mathrm{Im}\ln(t-\eta)=\arg(t-\eta)$ when $\arg\rho=\arg(t-\eta)$, and the last logarithm in (3.12) tends to 0 as $\eta\to 0$.

Inserting (3.12) into (2.18a), we obtain the formula

$$\delta^{(1)}=\eta[\ln(t-\eta)-1]+\Lambda\left(\frac{1}{2i}\ln\frac{\Lambda+i\eta}{\Lambda-i\eta}-\frac{\pi}{2}\right),\quad \Lambda=0 \quad\text{or}\quad \Lambda\neq 0. \tag{3.13}$$

It is seen that $\delta^{(1)}$ depends on the choice of the transition point t. In the particular situation when Λ and η are real, and we use the upper sign in (3.3), we can write (3.13) as

$$\begin{aligned}\delta^{(1)}&=\eta[\ln(t-\eta)-1]+\Lambda[\arctan(\eta/\Lambda)-\pi/2]\\ &=\eta[\ln(\eta^2+\Lambda^2)^{1/2}-1]+\Lambda[\arctan(\eta/\Lambda)-\pi/2],\quad \Lambda=0\quad\text{or}\quad\Lambda\neq 0.\end{aligned} \tag{3.13$'$}$$

As regards the higher-order contributions $\delta^{(2n+1)}$ $(n>0)$, which one obtains from (2.18b), we shall not present the derivation, but only give the expressions for $\delta^{(3)}$ and $\delta^{(5)}$.

When $\Lambda=0$, one obtains

$$\delta^{(3)}=-\frac{1+6L(L+1)}{12\eta}=\frac{1-3(2L+1)^2}{24\eta},\quad \Lambda=0, \tag{3.14a}$$

$$\delta^{(5)}=\frac{1-30[L(L+1)]^2}{360\eta^3}=\frac{7-30(2L+1)^2+15(2L+1)^4}{2880\eta^3},\quad \Lambda=0. \tag{3.15a}$$

It is seen that these quantities are independent of the choice of the transition point t.

If in Eqs. (6.3.44a)–(6.3.44c) in Ref. 13 we replace l by L and η_0 by η and put $\eta_2=\eta_4=0$, we obtain from Eq. (6.3.44a) in Ref. 13 our formula (3.13′), and we obtain from Eqs. (6.3.44b) and (6.3.44c) in Ref. 13 our formulas (3.14a) and (3.15a).

When $\Lambda\neq 0$, one obtains

$$\delta^{(3)}=\frac{(L+\frac{1}{2})^2-\Lambda^2}{2\Lambda}\left(\frac{1}{2i}\ln\frac{\Lambda+i\eta}{\Lambda-i\eta}-\pi/2\right)+\frac{\eta}{24(\Lambda^2+\eta^2)},\quad \Lambda\neq 0, \tag{3.14b}$$

$$\begin{aligned}\delta^{(5)}=&-\frac{[(L+\frac{1}{2})^2-\Lambda^2]^2}{8\Lambda^3}\left(\frac{1}{2i}\ln\frac{\Lambda+i\eta}{\Lambda-i\eta}-\pi/2\right)-\frac{\eta}{2(\Lambda^2+\eta^2)}\left(\frac{(L+\frac{1}{2})^2-\Lambda^2}{2\Lambda}\right)^2\\ &-\frac{\eta[(L+\frac{1}{2})^2-\Lambda^2]}{24(\Lambda^2+\eta^2)^2}-\frac{7\eta}{960(\Lambda^2+\eta^2)^2}+\frac{7\eta^3}{720(\Lambda^2+\eta^2)^3},\quad \Lambda\neq 0.\end{aligned} \tag{3.15b}$$

It is seen that $\delta^{(3)}$ and $\delta^{(5)}$ do not depend on the choice of the transition point t. In the particular situation when Λ and η are real, we can write (3.14b) and (3.15b) as

$$\delta^{(3)}=\frac{(L+\frac{1}{2})^2-\Lambda^2}{2\Lambda}[\arctan(\eta/\Lambda)-\pi/2]+\frac{\eta}{24(\Lambda^2+\eta^2)},\quad \Lambda\neq 0, \tag{3.14b$'$}$$

$$\begin{aligned}\delta^{(5)}=&-\frac{[(L+\frac{1}{2})^2-\Lambda^2]^2}{8\Lambda^3}[\arctan(\eta/\Lambda)-\pi/2]-\frac{\eta}{2(\Lambda^2+\eta^2)}\left(\frac{(L+\frac{1}{2})^2-\Lambda^2}{2\Lambda}\right)^2\\ &-\frac{\eta[(L+\frac{1}{2})^2-\Lambda^2]}{24(\Lambda^2+\eta^2)^2}-\frac{7\eta}{960(\Lambda^2+\eta^2)^2}+\frac{7\eta^3}{720(\Lambda^2+\eta^2)^3},\quad \Lambda\neq 0.\end{aligned} \tag{3.15b$'$}$$

If in Eqs. (6.3.35a)–(6.3.35c) in Ref. 13, we replace ξ_0 by Λ and η_0 by η, and use for ξ_2 and ξ_4 Eqs. (6.3.34a) and (6.3.34b) in Ref. 13 with l replaced by L, and put $\eta_2=\eta_4=0$, we obtain (3.13′), (3.14a′), and (3.15b′).

When $L \neq -\frac{1}{2}$ and one wants the phase-integral functions to be approximate solutions of the differential equation for the Coulomb wave functions also close to $\rho=0$, one chooses $\Lambda = L+\frac{1}{2}$. When Λ is chosen in this way, the formulas (3.14b), (3.14b′) and (3.15b), (3.15b′) are simplified considerably.

IV. PHASE-INTEGRAL FORMULAS FOR COULOMB WAVE FUNCTIONS

According to (2.3a), (2.3b), (2.12a), (2.15), and (2.16), we have, when $\rho \to \infty$ for fixed L, η and Λ,

$$f_1(\rho) \sim \exp\{+i[\rho - \eta \ln(2\rho) - L\pi/2 + \sigma_L(\eta) - \Delta]\}, \quad \rho \to \infty, \tag{4.1a}$$

$$f_2(\rho) \sim \exp\{-i[\rho - \eta \ln(2\rho) - L\pi/2 + \sigma_L(\eta) - \Delta]\}, \quad \rho \to \infty, \tag{4.1b}$$

where [cf. Eq. (6.3.26) in Ref. 13]

$$\Delta = \sigma_L(\eta) - L\pi/2 - \delta. \tag{4.2}$$

According to Eqs. (8.8a–c′) and (8.9a–c′) in Ref. 14, the Coulomb wave functions $F_L(\eta,\rho)$ and $G_L(\eta,\rho)$, as well as the functions $\psi_\pm(L,\eta,\rho)$ defined by Eq. (1.2) in Ref. 14, are asymptotically, for fixed values of L and η and large values of ρ, linear combinations of $\exp\{\pm i[\rho - \eta \ln(2\rho) - L\pi/2 + \sigma_L(\eta)]\}$. For sufficiently large values of ρ and fixed values of L, η, and Λ, one can, according to (4.1a) and (4.1b), replace $\exp\{+i[\rho - \eta \ln(2\rho) - L\pi/2 + \sigma_L(\eta)]\}$ by $\exp(+i\Delta) f_1(\rho)$ and $\exp\{-i[\rho - \eta \ln(2\rho) - L\pi/2 + \sigma_L(\eta)]\}$ by $\exp(-i\Delta) f_2(\rho)$. Equations (8.8a–c′) and (8.9a–c′) in Ref. 14, which give asymptotic expressions for $\psi_\pm(L,\eta,\rho)$, $F_L(\eta,\rho)$, and $G_L(\eta,\rho)$ when $\rho \to \infty$ for fixed L and η, can therefore be written as follows.

When $(2\nu-2)\pi + \epsilon < \arg \rho < 2\nu\pi - \epsilon$, *we get*

$$\psi_+ \sim \frac{\exp[-2(\nu-1)\pi\eta + i\Delta]}{\sin(2\pi L)} \{\sin(2\nu\pi L) - \sin[2(\nu-1)\pi L]\exp(-2\pi\eta)\} f_1(\rho) - \frac{\exp(+2\nu\pi\eta - i\Delta)}{\sin(2\pi L)} \sin[2(\nu-1)\pi L]\{1 - \exp[-2\pi i(L - i\eta)]\} f_2(\rho), \tag{4.3a}$$

$$\psi_- \sim \frac{\exp[-2(\nu-1)\pi\eta + i\Delta]}{\sin(2\pi L)} \sin(2\nu\pi L)\{1 - \exp[2\pi i(L + i\eta)]\} f_1(\rho) - \frac{\exp[+2(\nu-1)\pi\eta - i\Delta]}{\sin(2\pi L)} \{\sin[2(\nu-1)\pi L]\exp(2\pi\eta) - \sin(2\nu\pi L)\} f_2(\rho), \tag{4.3a′}$$

$$F_L(\eta,\rho) \sim \frac{\exp[+2\nu\pi i(L + i\eta) + i\Delta]}{2i} f_1(\rho) - \frac{\exp[+2(\nu-1)\pi i(L - i\eta) - i\Delta]}{2i} f_2(\rho), \tag{4.4a}$$

$$G_L(\eta,\rho) \sim \frac{\exp[-2(\nu-1)\pi\eta + i\Delta]}{2\sin(2\pi L)} (\sin(2\nu\pi L)\{2 - \exp[2\pi i(L + i\eta)]\} - \sin[2(\nu-1)\pi L]\exp(-2\pi\eta)) f_1(\rho) - \frac{\exp(+2\nu\pi\eta - i\Delta)}{2\sin(2\pi L)} (\sin[2(\nu-1)\pi L]\{2 - \exp[-2\pi i(L - i\eta)]\} - \sin(2\nu\pi L)\exp(-2\pi\eta)) f_2(\rho). \tag{4.4a′}$$

When $(2\nu-1)\pi+\epsilon<\arg\rho<(2\nu+1)\pi-\epsilon$, *we get*

$$\psi_{+}\sim\frac{\exp[-2(\nu-1)\pi\eta+i\Delta]}{\sin(2\pi L)}\{\sin(2\nu\pi L)-\sin[2(\nu-1)\pi L]\exp(-2\pi\eta)\}f_1(\rho)$$
$$-\frac{\exp[+2(\nu+1)\pi\eta-i\Delta]}{\sin(2\pi L)}\sin(2\nu\pi L)\{1-\exp[-2\pi i(L-i\eta)]\}f_2(\rho), \tag{4.3b}$$

$$\psi_{-}\sim\frac{\exp[-2(\nu-1)\pi\eta+i\Delta]}{\sin(2\pi L)}\sin(2\nu\pi L)\{1-\exp[2\pi i(L+i\eta)]\}f_1(\rho)$$
$$-\frac{\exp(+2\nu\pi\eta-i\Delta)}{\sin(2\pi L)}\{\sin(2\nu\pi L)\exp(2\pi\eta)-\sin[2(\nu+1)\pi L]\}f_2(\rho), \tag{4.3b$'$}$$

$$F_L(\eta,\rho)\sim\frac{\exp[2\nu\pi i(L+i\eta)+i\Delta]}{2i}f_1(\rho)-\frac{\exp[2\nu\pi i(L-i\eta)-i\Delta]}{2i}f_2(\rho), \tag{4.4b}$$

$$G_L(\eta,\rho)\sim\frac{\exp[-2(\nu-1)\pi\eta+i\Delta]}{2\sin(2\pi L)}(\sin(2\nu\pi L)\{2-\exp[2\pi i(L+i\eta)]\}$$
$$-\sin[2(\nu-1)\pi L]\exp(-2\pi\eta))f_1(\rho)$$
$$-\frac{\exp[2(\nu+1)\pi\eta-i\Delta]}{2\sin(2\pi L)}(\sin(2\nu\pi L)\{2-\exp[-2\pi i(L-i\eta)]\}$$
$$-\sin[2(\nu+1)\pi L]\exp(-2\pi\eta))f_2(\rho). \tag{4.4b$'$}$$

When $2\nu\pi+\epsilon<\arg\rho<(2\nu+2)\pi-\epsilon$, *we get*

$$\psi_{+}\sim\frac{\exp(-2\nu\pi\eta+i\Delta)}{\sin(2\pi L)}\{\sin[2(\nu+1)\pi L]-\sin(2\nu\pi L)\exp(-2\pi\eta)\}f_1(\rho)$$
$$-\frac{\exp[+2(\nu+1)\pi\eta-i\Delta]}{\sin(2\pi L)}\sin(2\nu\pi L)\{1-\exp[-2\pi i(L-i\eta)]\}f_2(\rho), \tag{4.3c}$$

$$\psi_{-}\sim\frac{\exp(-2\nu\pi\eta+i\Delta)}{\sin(2\pi L)}\sin[2(\nu+1)\pi L]\{1-\exp[+2\pi i(L+i\eta)]\}f_1(\rho)$$
$$-\frac{\exp(+2\nu\pi\eta-i\Delta)}{\sin(2\pi L)}\{\sin(2\nu\pi L)\exp(2\pi\eta)-\sin[2(\nu+1)\pi L]\}f_2(\rho), \tag{4.3c$'$}$$

$$F_L(\eta,\rho)\sim\frac{\exp[2(\nu+1)\pi i(L+i\eta)+i\Delta]}{2i}f_1(\rho)-\frac{\exp[2\nu\pi i(L-i\eta)-i\Delta]}{2i}f_2(\rho), \tag{4.4c}$$

$$G_L(\eta,\rho)\sim\frac{\exp(-2\nu\pi\eta+i\Delta)}{2\sin(2\pi L)}(\sin[2(\nu+1)\pi L]\{2-\exp[2\pi i(L+i\eta)]\}$$
$$-\sin(2\nu\pi L)\exp(-2\pi\eta))f_1(\rho)$$
$$-\frac{\exp[2(\nu+1)\pi\eta-i\Delta]}{2\sin(2\pi L)}(\sin(2\nu\pi L)\{2-\exp[-2\pi i(L-i\eta)]\}$$
$$-\sin[2(\nu+1)\pi L]\exp(-2\pi\eta))f_2(\rho). \tag{4.4c$'$}$$

The asymptotic formulas (8.8a–c′) and (8.9a–c′) in Ref. 14, from which the phase-integral formulas (4.3a–c′) and (4.4a–c′) in the present paper have been derived, are valid only when, for fixed values of L and η, ρ tends to infinity. The phase-integral formulas (4.3a–c′) and (4.4a–c′) in the present paper, however, may remain valid when, still for fixed values of L and η, the variable ρ moves from infinity along convenient paths of monotonicity, provided that ρ does not come too close to a transition point. These formulas have thus a considerably larger region of validity on the Riemann surface for the complex variable ρ than the formulas (8.8a-c′) and (8.9a–c′) in Ref. 14. To determine in detail the regions of validity for (4.3a–c′) and (4.4a–c′) and the significance of each one of the two terms in these formulas, one uses the basic estimates (4.3a)–(4.3d) in Ref. 15, which apply to a path on which the absolute value of $\exp[iw(\rho)]$ increases monotonically (in the nonstrict sense) from the initial point to the final point, and the corresponding basic estimates for a path on which the absolute value of $\exp[-iw(\rho)]$ increases monotonically (in the nonstrict sense) from the initial point to the final point.

For large values of ρ the phase-integral formulas (4.3a–c′) and (4.4a–c′), like the asymptotic formulas (8.8a–c′) and (8.9a–c′) in Ref. 14, are, in general, valid in intervals for $\arg\rho$ of the extension $2\pi-2\epsilon$, but for the reasons mentioned in Sec. VIII of Ref. 14, the phase-integral formula (4.3b,c) with $\nu=0$ for ψ_+ is valid for $-\pi+\epsilon<\arg\rho<2\pi-\epsilon$, and the phase-integral formula (4.3a′,b′) with $\nu=0$ for ψ_- is valid for $-2\pi+\epsilon<\arg\rho<\pi-\epsilon$. For the particular value $\nu=0$, the phase-integral formulas (4.3b,c) and (4.3a′,b′) for ψ_+ and ψ_-, respectively, are thus valid in intervals for $\arg\rho$ of the extension $3\pi-2\epsilon$, when ρ is large.

We recall that on the Riemann surface for the complex variable ρ we have introduced the cut described below (2.15) in Sec. II. We also remark that because of (4.2) the quantities exp $(\pm i\sigma_L)$, which depend on both L and η, appear in (4.3a–c′) and (4.4a–c′), and that these quantities can be replaced by the expressions given in Eq. (2.9) in Ref. 14.

V. CONCLUSIONS

Up to the fifth-order approximation phase-integral formulas are given, in (4.4a–c′) for the Coulomb wave functions $F_L(\eta,\rho)$ and $G_L(\eta,\rho)$, and in (4.3a–c′) for the linear combinations $\psi_\pm(L,\eta,\rho)=G_L(\eta,\rho)\pm iF_L(\eta,\rho)$. The quantity Δ in these phase-integral formulas, which is given by (4.2), (2.17), (2.18a), and (2.18b), depends on the choice of the base function $Q(\rho)$ and the order $2N+1$ of the phase-integral approximation. The base function $Q(\rho)$ is given by (2.15), where Λ may be either equal zero (which is appropriate when L is sufficiently small, while η is sufficiently large) or different from zero (which is appropriate when L is sufficiently large). The phase of $Q^{-1/2}(\rho)$ is chosen such that $Q^{-1/2}(\rho)\rightarrow 1$ as $\rho\rightarrow\infty$, the restriction $\eta^2+\Lambda^2\neq 0$ is introduced on the parameters L and η, and certain cuts are introduced, as explained between (2.15) and (2.16). The phase-integral approximation is valid close to $\rho=0$ only when $\Lambda=L+\frac{1}{2}\neq 0$. The quantities $\delta^{(2n+1)}$ in (2.17) are for $2n+1=1$, 3, and 5 given by (3.13), (3.13′), (3.14a), and (3.15a) when $\Lambda=0$, and by (3.13), (3.13′), (3.14b), (3.14b′), (3.15b), and (3.15b′) when $\Lambda\neq 0$. For the choice $\Lambda=L+\frac{1}{2}$ the formulas (3.14b), (3.14b′) and (3.15b), (3.15b′) become considerably simplified.

ACKNOWLEDGMENTS

In the spring of 1995 two of the authors (Fröman and Yngve) were invited to participate in the program Exponential Asymptotics at the Isaac Newton Institute for Mathematical Sciences in Cambridge, England. These authors wish to express their gratitude to the Isaac Newton Institute for a most fruitful time in an extremely stimulating scientific atmosphere. They are also much indebted to Professor Frank Olver and other participants for fruitful discussions.

The collective dynamics of solitons with a coset space G/H as moduli space is studied. It is shown that the collective band for a vibrational state is given by the inequivalent coset space quantization corresponding to the representation of H carried by the vibration. To leading order the collective dynamics is free motion in G/H coupled to background gauge fields determined by the vibrational state. © *1999 American Institute of Physics.* [S0022-2488(99)01412-7]

I. INTRODUCTION

Solitons arise as static finite energy solutions to the equations of motion of nonlinear field theories. In general, a given soliton depends upon a set of parameters or moduli, and is a point in the manifold of solutions of equal energy, or moduli space. In many cases this manifold is simply an homogeneous or coset space G/H, where G is the group of symmetries of the action and $H \subset G$ is the symmetry of the solitonic solution.

Around a soliton there are two kinds of quantum excitations. The first corresponds to collective motion in the moduli space. The second are vibrational (intrinsic) excitations out of it. If the energy for the collective excitations is much lower than that for the vibrational ones the low energy spectrum can be approximately described by collective bands associated with each vibrational state. These bands can be described by an effective quantum mechanical problem given by the motion of a particle in the moduli space. However, as is well known from molecular and nuclear rotational bands, different vibrational states may have different collective bands. It is the purpose of this paper to show that in the case when the moduli space of the soliton is a coset space G/H a simple description of the collective bands of vibrational states can be given in terms of inequivalent coset space quantizations introduced by Mackey,[1] and more recently studied by Landsman and Linden[2] and McMullan and Tsutsui,[3] among others.

Since the soliton is invariant under the subgroup H, vibrational excitations fit into irreducible representations (irreps) of H. Below we show that the collective band corresponding to a vibrational state in a representation χ of H realizes a representation of G induced by χ. This representation of G is reducible, and when it is broken into irreducible representations the whole collective band is obtained. This is equivalent to saying that the collective band for a vibrational state is given by the inequivalent quantization of G/H corresponding to the irrep χ of H carried by the vibration. In this way we find that collective motion is a physical example of the inequivalent coset space quantizations.

The lowest energy collective band of the soliton is that of the ground state of the vibrations. If the ground state is in the trivial representation of H, our results provide nothing new for

determining this band, which is obtained from the usual (trivial) quantization of free motion in G/H. However, although the soliton is invariant under H, the quantum ground state need not be in the trivial representation because of topological factors which may arise when adiabatically performing the operations of H. For example, in the SU (3) Skyrmion the Wess–Zumino–Witten term[4] contributes with an extra phase. The same happens with the SU (2) Skyrmion[5] when it is quantized as a fermion. For the $B=1$ Skyrmion the result is the well-known fact that the ground state has spin an isospin 1/2.

The outline of this paper is as follows: In Sec. II we introduce a model[6] which generically describes a soliton model. The action is invariant under a group G of transformation of the fields but the soliton only under a subgroup H, so that the moduli space is a coset space G/H. In Sec. III we summarize Mackey's[1] approach to the quantization on a coset space, and the more recent results by Landsman and Linden[2] and McMullan and Tsutsui.[3] Section IV is the main section of this paper. There we demonstrate the relation between the wave functions and energies of the collective bands of vibrational states and the corresponding ones of the inequivalent coset space quantizations. Finally, in Sec. V we give our conclusions. We also discuss an example of a possible application of our results.

II. THE MODEL

Let us consider a general bosonic field theory in $d+1$ dimensions. The fields $\phi^s(\mathbf{x},t)$ are real and take their values in an internal space $\mathcal{T}$. The variables $\mathbf{x}$ and t are space and time coordinates, and $s=1...\dim(\mathcal{T})$ is an internal index. At any given time the fields $\phi^s(\mathbf{x},t)$ determine a configuration of the system, given by a map from R^d (or a compactification of it) into $\mathcal{T}$. The set of these maps corresponds to the configuration space $\mathcal{C}$ of the theory. The action is taken to be quadratic in the time derivatives of the fields, namely,

$$S=\int dt d^d x\left(\frac{1}{2}G_{st}\dot{\phi}^s(\mathbf{x},t)\dot{\phi}^t(\mathbf{x},t)-V\right), \tag{1}$$

where sums over repeated indices are implicit and,

$$G_{st}=G_{st}[\phi(\mathbf{x})]=G_{st}(\phi^{s_1},\partial_{i_1}\phi^{s_2},\ldots,\partial_{i_1\cdots i_n}\phi^{s_n}),$$

$$V=V[\phi(\mathbf{x})]=V(\phi^{s_1},\partial_{i_1}\phi^{s_2},\ldots,\partial_{i_1\cdots i_n}\phi^{s_n}),$$

are functions of the fields and a finite number of its spatial derivatives. For example if the action corresponds to a nonlinear σ-model,

$$S=\int dt d^d x\left(\frac{1}{2}g_{st}(\phi)\partial^\mu\phi^s(\mathbf{x},t)\partial_\mu\phi^t(\mathbf{x},t)-v(\phi)\right), \tag{2}$$

the functionals G_{st} and V are given by,

$$G_{st}=g_{st}(\phi),\quad V=g_{st}(\phi)\boldsymbol{\partial}\phi^s\boldsymbol{\partial}\phi^t+v(\phi), \tag{3}$$

that is, the spatial derivatives are included in V. In other cases, for example the Skyrme model,[5] the function G_{st} depend also on the spatial derivatives of the field. A useful way of thinking about the system is to consider it as a particle moving in the infinite dimensional space of configurations $\mathcal{C}$ (i.e., of maps from R^d into $\mathcal{T}$) with a potential V and a metric given by $g_{st}(\mathbf{x},\mathbf{y})=G_{st}\delta^d(\mathbf{x}-\mathbf{y})$.

The equations of motion following from the action (1) have static solutions which satisfy

$$\frac{\delta}{\delta\phi^s(\mathbf{x})}\int d^d y V[\phi(\mathbf{y})]=\frac{\partial V}{\partial\phi^s(\mathbf{x})}-\partial_{i_1}\frac{\partial V}{\partial(\partial_{i_1}\phi^s(\mathbf{x}))}+\cdots+(-)^n\partial_{i_1\cdots i_n}\frac{\partial V}{\partial(\partial_{i_1\cdots i_n}\phi^s(\mathbf{x}))}=0. \tag{4}$$

For our present purpose we assume that Eqs. (4) have soliton solutions. We consider the case in which the action S is invariant under an unbroken finite-dimensional compact group G of transformations of the fields,

$$\phi^s(\mathbf{x}) \mapsto R_g^s[\phi(\mathbf{x})], \quad g \in G. \tag{5}$$

This group usually includes spatial rotations and internal transformations of the fields. The invariance of the action under these transformations is expressed as,

$$G_{st}[\phi(\mathbf{x})]\delta^3(x-y) = \int d^dz \frac{\delta R_g^u[\phi(\mathbf{z})]}{\delta\phi^s(\mathbf{x})} \frac{\partial R_g^v[\phi(\mathbf{z})]}{\delta\phi^t(\mathbf{y})} G_{uv}[\phi(\mathbf{z})], \tag{6}$$

$$\int d^dx V[\phi(x)] = \int d^dx V[R_g[\phi(x)]]. \tag{7}$$

The first condition can be rephrased saying that the transformations are isometries of the space $\mathcal{C}$.

Let us consider a soliton solution $\tilde{\phi}(\mathbf{x})$ of (4), i.e., a minimum of the potential $\int V[\phi]d^dx$. In general, $\tilde{\phi}(\mathbf{x})$ is only invariant under a subgroup H of the symmetry group G of the action. Due to the invariance of the potential under G, any configuration $R_g[\tilde{\phi}(\mathbf{x})]$ obtained by acting with G on $\tilde{\phi}(\mathbf{x})$ is also a solution. The whole family of solutions, known as the moduli space of the soliton, is thus given by the orbit of $\tilde{\phi}(\mathbf{x})$ under G, and is therefore an homogeneous or coset space,

$$\mathcal{M} = O_G(\tilde{\phi}) = G/H. \tag{8}$$

It is possible that there exist other zero modes not related to symmetries of the action, but we shall ignore that possibility here. Consider now fluctuations around the soliton, $\tilde{\phi}(\mathbf{x}) \to \tilde{\phi}(\mathbf{x}) + \varphi(\mathbf{x},t)$. The linearized equations for the fluctuations read,

$$\tilde{G}_{st}\ddot{\varphi}^t(\mathbf{x},t) + \int d^dy K_{st}(\mathbf{x},\mathbf{y})\varphi^t(\mathbf{y},t) = 0, \tag{9}$$

where $\tilde{G}_{st}$ is evaluated on the solution, $\tilde{G}_{st} = G_{st}[\tilde{\phi}(\mathbf{x})]$ and,

$$K_{st}(\mathbf{x},\mathbf{y}) = \left.\frac{\delta^2 V}{\delta\phi^s(\mathbf{x})\delta\phi^t(\mathbf{y})}\right|_{\phi=\tilde{\phi}}. \tag{10}$$

The fluctuations can be understood as infinitesimal vectors in the tangent space to $\mathcal{C}$ at the point $\tilde{\phi}(\mathbf{x})$. The (infinite) set of those normal to the moduli space $\mathcal{M}$ are massive excitations, since $\mathcal{M}$ is the ''valley'' of minima of the static energy. They satisfy,

$$\int d^dy K_{st}(\mathbf{x},\mathbf{y})\varphi^t(\mathbf{y},t) - \omega_n^2 \tilde{G}_{st}\psi_n^t(\mathbf{x}) = 0, \tag{11}$$

where n labels the modes, $\omega_n \neq 0$, and $\psi_n^s(\mathbf{x})$ are the corresponding normalized eigenfunctions, $\int d^dx \tilde{G}_{st}\psi_n^s(\mathbf{x})\psi_m^t(\mathbf{x}) = \delta_{nm}$. The fluctuations tangent to $\mathcal{M}$ are massless, and are usually known as zero modes. They satisfy,

$$\int d^dy K_{st}(\mathbf{x},\mathbf{y})\varphi^t(\mathbf{y},t)\psi_\alpha^t(\mathbf{y}) = 0, \tag{12}$$

where $\alpha=1,...,\dim(G/H)$ label the zero modes, which are given by the nonvanishing infinitesimal transformations (5) of the soliton, $\psi_\alpha^s(\mathbf{x})=\delta_\alpha\tilde{\phi}^s(\mathbf{x})$. The norm of the zero modes corresponds to the inertia tensor of the soliton,

$$\mathcal{I}_{\alpha\beta}=\int d^d x\,\tilde{G}_{st}\psi^s_\alpha(\mathbf{x})\psi^t_\beta(\mathbf{x}). \tag{13}$$

The massive and zero modes satisfy the completeness relation,

$$\tilde{G}_{st}[\delta^{nm}\psi^s_n(\mathbf{x})\psi^t_m(\mathbf{y})+\mathcal{I}^{\alpha\beta}\psi^s_\alpha(\mathbf{x})\psi^s_\beta(\mathbf{y})]=\delta^d(x-y), \tag{14}$$

where $\mathcal{I}^{\alpha\beta}$ is the inverse of the inertia tensor.

Quantum-mechanically, the massive modes correspond to vibrations of the soliton, while the zero modes to collective motion in $\mathcal{M}$. We are interested in the case in which the collective energy is much smaller than the vibrational one. Schematically, this is given by

$$\frac{\hbar^2}{\mathcal{I}}\ll\hbar\omega\Rightarrow\frac{\hbar}{\mathcal{I}\omega}\ll 1, \tag{15}$$

where $\mathcal{I}$ is the inertia for the collective motion and ω the frequency for the intrinsic excitations. In this regime it is natural to treat the collective motion exactly and the vibrations in perturbation theory. The relation (15) implies that the small parameter is proportional to $\hbar$, and therefore the perturbative expansion is an expansion in loops (in powers of $\hbar$). In the following $\hbar=1$, so that the expansion parameter is $1/\mathcal{I}\omega$.

In order to proceed with the quantization around the soliton $\tilde{\phi}(\mathbf{x})$ it is necessary to treat differently the massive vibrations from the zero modes. One possible approach, which will prove useful to our purposes, is to introduce collective coordinates by performing a transformation of the fields $\phi^s(\mathbf{x},t)$ with time dependent parameters,[7–10,6]

$$\phi^s(\mathbf{x},t)\mapsto R^s_{g(\alpha)}[\phi(\mathbf{x},t)], \tag{16}$$

where $\alpha^a(t)$ $(a=1,...,\dim(G))$ parameterize G. The action (1) is not symmetric under this time dependent transformations, and it changes to,

$$S\mapsto\int dt\,d^d x\left(\frac{1}{2}G_{st}D_0\phi^s(\mathbf{x},t)D_0\phi^t(\mathbf{x},t)-V\right). \tag{17}$$

The covariant time derivatives are given by,

$$D_0\phi^s(\mathbf{x},t)=\dot{\phi}^s(\mathbf{x},t)+\dot{\alpha}^a(t)\zeta^b_a(\alpha(t))\delta_b\phi^s(\mathbf{x},t), \tag{18}$$

where $\zeta^b_a(\alpha)$ are components of the left-invariant Cartan–Maurer one-form $g^{-1}dg=d\alpha^a\zeta^b_a(\alpha)T_b$, with T_a being the infinitesimal group generators, and $\delta_a\phi^s(\mathbf{x},t)$ correspond to the infinitesimal transformations (5). The transformed action (17) is invariant under gauge transformations, i.e., time dependent transformations of the fields and the collective coordinates,

$$\delta_\varepsilon\phi^s(\mathbf{x},t)=\varepsilon^a(t)\delta_a\phi^s(\mathbf{x},t),\quad \delta_\varepsilon\alpha^a(t)=-\varepsilon^b(t)\Theta^a_b(\alpha(t)),\quad (\Theta=\zeta^{-1}). \tag{19}$$

The transformed action (17) can be understood as describing the problem from an arbitrary moving frame of reference, its motion given by the collective coordinates.

The classical Hamiltonian corresponding to the action (17) is given by

$$\mathcal{H}=\int d^d x\left(\frac{1}{2}G^{st}[\phi(\mathbf{x},t)]\pi_s(\mathbf{x},t)\pi_t(\mathbf{x},t)+V[\phi(\mathbf{x},t)]\right)-\lambda_a(t)\Phi_a(t), \tag{20}$$

where $\pi_s(\mathbf{x},t)$ are the canonical momenta conjugate to $\phi^s(\mathbf{x},t)$, i.e., $\{\pi_s(\mathbf{x},t),\phi^t(\mathbf{y},t)\} = -\delta_s^t\delta^d(x-y)$, and $\lambda_a(t)$ are Lagrange multipliers which impose the first class constraints $\Phi_a = J_a - I_a$, which generate the gauge transformations (19).[11] We display also the explicit dependence of G_{st} and V on the fields. The operators J_a are the generators for the infinitesimal transformations of the fields,

$$J_a = \int d^d x \, \pi_s(\mathbf{x}) \, \delta_a \phi^s(\mathbf{x}), \tag{21}$$

and I_a are the right generators for the collective coordinates, $I_a = \Theta_a^b \mathcal{P}_b$, where $\mathcal{P}_a$ are the conjugate momenta to the collective coordinates, $\{\alpha^a, \mathcal{P}_b\} = \delta_b^a$. While the gauge symmetry (19) acts from the right on the collective coordinates, the original symmetry G acts from the left. The operators that generate the left infinitesimal transformations of the collective coordinates are correspondingly given by $L_a = \hat{\Theta}_a^b \mathcal{P}_b$, where $\hat{\zeta}_a^b(\alpha)$ are components of the right-invariant Cartan–Maurer one-form $dgg^{-1} = d\alpha^a \hat{\zeta}_a^b(\alpha) T_b$, and $\hat{\Theta} = \hat{\zeta}^{-1}$.

The gauge algebra $\mathbf{g}$, generated by the constraints $\Phi_a = J_a - I_a$, can be decomposed into $\mathbf{g} = \mathbf{h} + \mathbf{p}$, where the subalgebra $\mathbf{h}$ is generated by $\Phi_i = J_i - I_i$ $(i = 1,...,\dim(H))$, while the complement $\mathbf{p}$ is generated by $\Phi_\alpha = J_\alpha - I_\alpha$ $(\alpha = \dim(H)+1,...,\dim(G))$. The operators J_i generate the subgroup of transformations of the fields that leave the soliton $\tilde{\phi}(\mathbf{x})$ invariant, while J_α generate the transformations which change it. Since H is a subgroup, the operators J_i close under commutation, $[J_i, J_j] = iC_{ij}^k J_k$, where C_{ab}^c are the structure constants of G. Furthermore, as G is compact the generators J_α can be chosen in such a way that

$$[J_i, J_\alpha] = iC_{i\alpha}^\beta J_\beta, \tag{22}$$

which shows that J_α transform in a representation (possibly reducible) of H.

As is usual in this kind of problems, the idea is to replace the zero mode excitations of the fields $\phi(\mathbf{x},t)$ by the collective coordinates $\alpha(t)$, by means of a suitable gauge fixing of action (17). It is important to note that the number of zero modes is equal to the dimension of G/H, while the number of collective variables is $\dim(G)$. By gauge fixing the constraints Φ_α we will eliminate the zero modes in favor of the collective coordinates α^α on G/H. We will make use of the remaining H-gauge symmetry to prove that the effective collective dynamics of the soliton can be understood in terms of inequivalent coset space quantizations.

III. INEQUIVALENT COSET SPACE QUANTIZATIONS

In this section we review briefly the approach developed by Mackey to the quantization of a system whose configuration space is a coset space G/H.[1] This must be distinguished from the quantization of G/H as a phase space, which is discussed for example in Ref. 12 (and references therein). It was shown by Mackey that when the configuration space is a coset space G/H there are many different quantizations not equivalent to each other by unitary transformations, which are labeled by the unitary irreps χ of the subgroup H. The wave functions in a given inequivalent quantization are vector valued, taking values in the representation space V_χ. They can be obtained from vector valued functions in G which satisfy (χ-equivariant condition),

$$f_\mu(gh) = \pi_{\nu\mu}^\chi(h) f_\nu(g), \tag{23}$$

where $g \in G$, $h \in H$, and $\pi^\chi(h)$ are the matrices of the representation χ of H. The left regular representation of G is defined on functions of G acting as,

$$f(g) \overset{g_1}{\rightarrow} f(g_1^{-1} g). \tag{24}$$

Equation (23) is invariant under this action. Therefore, the set of functions $f_\mu(g)$ satisfying condition (23) transforms under the left action of G in a representation called the representation of G induced by χ. See Refs. 1 and 13 for the definition and properties of induced representations.

Given a local section σ:$G/H\rightarrow G$ every element $g\in G$ can be uniquely written as,

$$g=\sigma(\xi(g))h_\sigma(g), \tag{25}$$

where $\xi\in G/H$ and $h\in H$. This allows to define a one-to-one correspondence between the set of functions $f_\mu(g)$ and functions $F_\mu:G/H\rightarrow V_\chi$ such that,

$$f_\mu(g)=\pi^\chi_{\nu\mu}(h(g))F_\nu(\xi(g)). \tag{26}$$

The functions $F_\mu(\xi)$ transform under G in the induced representation as,

$$F_\mu(\xi)\overset{g}{\rightarrow}\pi^\chi_{\nu\mu}(h_\sigma(g^{-1}\sigma(\xi)))F_\nu(g^{-1}\xi), \tag{27}$$

where $g^{-1}\xi=\xi(g^{-1}\sigma(\xi))$ defines the action of G on G/H.

Landsman and Linden[2] studied the dynamical consequences of the inequivalent quantizations for the motion of a particle in G/H. They discovered that in the nontrivial quantum sectors the particle couples to a background gauge field A_α, known as the H-connection, which takes values in the representation of the sub-algebra $\pi^\chi(\mathbf{h})$. The Hamiltonian is given by,

$$\mathcal{H}=-\tfrac{1}{2}g^{\alpha\beta}(\nabla_\alpha+A_\alpha)(\partial_\beta+A_\beta), \tag{28}$$

where ∇_α is the covariant derivative constructed out of the metric $g_{\alpha\beta}$ on G/H. Due to the H-connection the Hamiltonian is matrix valued (in the trivial representation of H it reduces to minus one-half the Laplacian $-\frac{1}{2}\Delta_{G/H}=-\frac{1}{2}g^{\alpha\beta}\nabla_\alpha\partial_\beta$).

McMullan and Tsutsui[3] developed a different approach to the inequivalent quantizations. Using the fact that in Eq. (25) $h\in H$ can be further decomposed as $h=r(h)s(h)$, where s belongs to the Cartan subgroup of H, they showed that instead of Mackey's functions $f_\mu(g)$ one can use its highest weight component f_χ evaluated at $g=\sigma r$ (i.e., $s=1$). The condition (23) implies that these functions are annihilated by the raising operators $E_{\varphi>0}$ in the Chevalley basis $\{H_\alpha,E_\varphi\}$ of $\mathbf{h}$. In this case the wave functions are scalars, which allows for a simpler definition of the corresponding path integral.

IV. COLLECTIVE DYNAMICS

In this section we will prove that the collective band associated with an intrinsic vibrational state can be obtained from the inequivalent quantization corresponding to the representation of the subgroup H carried by the vibration. To see this we consider the canonical quantization of the action (17) introduced in Sec. II. This action has a G-gauge invariance due to the introduction of the collective coordinates as additional variables. Gauge fixing the G/H part of the gauge symmetry allows to eliminate the zero modes in favor of the collective coordinates. The remaining H-gauge invariance can be treated with the Dirac method of imposing the constraints on the wave functions.[11] In our case this becomes Mackey's condition (23) for the collective wave functions associated to a given vibrational state. Alternatively, the collective coordinates which parameterize H can be eliminated, fixing the H-gauge symmetry. In this case the wave functions become $F_\mu(x)$ of Eq. (27) and the Hamiltonian that of Landsman and Linden.

A. Elimination of the zero modes

We start by eliminating the zero modes in favor of collective coordinates on G/H.

Let us expand the fields in terms of fluctuations around the soliton. The fluctuations can be written as linear combinations of the normal modes (11) and (12),

$$\phi^s(\mathbf{x},t)=\tilde{\phi}^s(\mathbf{x})+\psi_n^s(\mathbf{x})q_n(t)+\psi_\alpha^s(\mathbf{x})q_\alpha(t), \tag{29}$$

where the time dependent coefficients $q_A(t)$ (A stands both for n and α) are now the dynamical degrees of freedom. The conjugate momenta to the fields read,

$$\pi_s(\mathbf{x},t)=\tilde{G}_{st}[\psi_n^t(\mathbf{x})p_n(t)+\mathcal{I}^{\alpha\beta}\psi_\alpha^t(\mathbf{x})p_\beta(t)], \tag{30}$$

where p_A are conjugate to q_A. Inserting these expressions into the Hamiltonian (20), and making use of the equations for the normal modes (11), (12) and their orthogonality relations, we obtain up to quadratic order in the fluctuations,

$$\mathcal{H}=E_{\text{clas}}+\tfrac{1}{2}(p_n^2+\omega_n^2q_n^2)+\tfrac{1}{2}\mathcal{I}^{\alpha\beta}p_\alpha p_\beta-\lambda_a\Phi_a+O(q^3,pq^2). \tag{31}$$

The first term is the classical soliton energy $E_{\text{clas}}=\int d^dxV[\tilde{\phi}(\mathbf{x})]$. The second are the (infinite) harmonic oscillators corresponding to the vibrations of the soliton. The third term are the zero modes, and is purely kinetic. Anharmonic terms have been omitted.

Expanding similarly the constraints we get,

$$\Phi_\alpha=p_\alpha+(D_\alpha)_{AB}p_Aq_B-I_\alpha+O(pq^2), \tag{32}$$

$$\Phi_i=(D_i)_{AB}p_Aq_B-I_i+O(pq^2), \tag{33}$$

where we have kept up to quadratic terms in the fluctuations but the collective operators are treated exactly. The matrices $(D_a)_{AB}$ are defined as,

$$(D_a)_{AB}=\int d^dx\tilde{G}_{st}\psi_A^s(\mathbf{x})\delta_a\psi_B^t(\mathbf{x}), \tag{34}$$

where $\delta_a\psi_A^t(\mathbf{x})$ are the infinitesimal transformations (5) of the eigenfunctions, and correspond to the representation of G under which the fluctuations transform.

We want to eliminate the degrees of freedom associated with the zero energy fluctuations (q_α,p_α). We achieve this by choosing to fix the gauge invariance generated by Φ_α the following gauge fixing conditions,

$$q_\alpha=0, \quad (\alpha=1,...,\dim(G/H)), \tag{35}$$

which satisfy, $\{q_\alpha,\Phi_\beta\}\approx\delta_{\alpha\beta}+(D_\beta)_{\alpha n}q_n+O(q^2)$, where $\approx$ indicates evaluated where (35) holds. This gauge condition *does not* fix the H-gauge invariance generated by Φ_i since, $\{q_\alpha,\Phi_i\}\approx 0$, where we have used the fact that massive and zero fluctuations do not mix under H and therefore $(D_i)_{\alpha n}=0$.

We now replace the Poisson brackets by Dirac brackets,[11]

$$\{A,B\}_D=\{A,B\}-\{A,q_\alpha\}(\delta_{\alpha\beta}-D_{\beta\alpha n}q_n)\{\Phi_\beta,B\}, \tag{36}$$

in order to treat the gauge conditions and constraints as operator identities. We are then able to solve p_α from the equations $\Phi_\alpha=0$,

$$p_\alpha=I_\alpha-(D_\alpha)_{nm}P_nq_m+O(pq^2,Iq). \tag{37}$$

Replacing (q_α,p_α) by Eqs. (35), (37) in the Hamiltonian (31) we obtain,

$$\mathcal{H}=E_{\text{clas}}+\tfrac{1}{2}(p_n^2+\omega_n^2q_n^2)+\tfrac{1}{2}\mathcal{I}^{\alpha\beta}I_\alpha I_\beta-\mathcal{I}^{\alpha\beta}I_\alpha(D_\beta)_{nm}p_nq_m-\lambda_i(t)\Phi_i(t)+O(q^3,pq^2,Ipq^2). \tag{38}$$

The zero modes have been completely eliminated. Instead we have a kinetic term for the collective coordinates and a coupling between the collective coordinates and the vibrations. Anharmonic terms in the vibrations and higher order vibration-collective couplings have been omitted.

B. Collective energy eigenfunctions

The Hamiltonian (38) describes the dynamics of the system in the 1-loop approximation for the vibrations, while the collective motion is treated exactly. To this order, the spectrum corresponds to vibrational states and on top of each state a collective band. There is still the *H*-gauge symmetry.

Since the soliton is invariant under the subgroup *H*, the vibrations split into irreducible representations (irreps) of *H*. Consider now a given vibrational state classified by the irrep χ of *H*, and lets derive the *effective* collective dynamics for this state from the Hamiltonian (38). In other words, we restrict to energies which can only excite collective modes, but not any other vibrational ones. Taking into account this restriction, the wave functions for a state in the collective band has the general form,

$$\psi(q,\alpha)=\varphi_\mu(q)f_\mu(\alpha). \tag{39}$$

The functions $\varphi_\mu(q)$ $(\mu=1,...,\dim(\chi))$ form a basis for the irrep χ of the vibration, while the collective functions $f_\mu(\alpha)$ are arbitrary and have to be determined. We still have to take into account the *H*-gauge invariance. As mentioned above, to deal with it we apply Dirac's method of imposing the constraints on the wave functions.[11] This restricts the wave functions (39) to satisfy $\Phi_i\psi(q,\alpha)=0\forall_i$, which imposes on the collective functions the conditions,

$$I_i f_\mu(\alpha)=i(T_i)^\chi_{\nu\mu}f_\nu(\alpha)\quad \forall_i . \tag{40}$$

Here $(T_i)^\chi_{\mu\nu}$ are the infinitesimal generators of *H* in the χ representation. This is the infinitesimal version of Eq. (23). This condition also holds for the discrete transformations $h\in H$, which together with (40) imply for all $h\in H$,

$$R_h f_\mu(\alpha)=\pi^\chi_{\nu\mu}(h)f_\nu(\alpha), \tag{41}$$

where R_h stands for the right action of h on the group element parameterized by α, $g(\alpha)\to g(\alpha)h$. Therefore, the collective functions $f_\mu(\alpha)$ satisfy Mackey's condition (23), i.e., they transform under the left action of *G* in the representation of *G* induced by the representation χ of *H*.[13] In other words, the states in the collective band are those of the inequivalent quantization of G/H given by the representation χ of *H* carried by the intrinsic state.

In order to diagonalize the Hamiltonian (38) we can make use of the original symmetry *G*. The induced representation of *G* under which the collective functions in (39) transform is reducible. It can be broken into irreducible components. In fact, by the Peter–Weyl theorem[13] the collective functions $f_\mu(\alpha)$ can be rewritten as,

$$f_\mu(\alpha)=C^{IMN}_\mu D^I_{MN}(\alpha), \tag{42}$$

where the sum is over all irreps *I* of *G* defined by the matrices $D^I_{MN}(\alpha)$. Under the left action of *G* each term of the sum transforms in the corresponding representation *I* of *G*. Under the right action of *H* each term in (42) transforms in the representation *I* of *G* considered as a representation of *H*. This representation of *H* is in general reducible and can be broken in irreducible pieces, $I|_H=\chi_1+\cdots+\chi_n$, where χ_i are irreps of *H*. In this decomposition, the representation χ carried by the vibrations appears a number of times we denote by $d_{I\chi}$, that is, $I|_H=d_{I\chi}\chi+$other irreps. Condition (41) implies that the linear combination (42) must be restricted to

$$f_\mu(\alpha)=C^{IMN}_k D^I_{M\mu_k}(\alpha), \tag{43}$$

where k runs over the $d_{I\chi}$ representations $\chi_k=\chi$, and μ_k indicates the μth component of irrep χ_k. This means that each representation I of G appears in the collective band a number of times equal to $d_{I\chi}$.

The collective band of the vibration is given by the restriction of the Hamiltonian (38) to the subspace of functions (39), which satisfy the condition (41). The first two terms in (38) are constant throughout the band, and the last one vanishes on physical states. The collective Hamiltonian reads,

$$\mathcal{H}_{\text{coll}}=\text{const}+\tfrac{1}{2}\mathcal{I}^{\alpha\beta}I_\alpha I_\beta-\mathcal{I}^{\alpha\beta}I_\alpha M_\beta, \tag{44}$$

where M_α stand for the restriction of the operators $(D_\alpha)_{nm}p_n q_m$ to the subspace span by the vibrational functions $\varphi_\mu(q)$, that is, $M_\alpha=\langle\varphi_\mu|(D_\alpha)_{nm}p_n q_m|\varphi_\nu\rangle$. The collective Hamiltonian is invariant under the action of G by the left, and so does not mix different representations I. Therefore, it can be diagonalized in subspaces of dimension $d_{I\chi}$. It is easy to check that it also commutes with the simultaneous action of H on the intrinsic states (J_i) and on the collective coordinates from the right (I_i). This ensures that it preserves the physical condition $\Phi_i=0$ which the states ψ of Eq. (39) satisfy.

The diagonalization of $\mathcal{H}_{\text{coll}}$ in each subspace of dimension $d_{I\chi}>1$ must be performed case by case. However, some more information can be obtained using the H-invariance. The restricted matrices M_α no longer satisfy the G algebra, but they still satisfy,

$$[J_i,M_\alpha]=iC_{i\alpha}^{\beta}M_\beta, \tag{45}$$

which means that they transform under H in the same representation as J_α. By the Wigner–Eckart theorem in the group H, they are determined by Clebsch–Gordan coefficients up to as many independent constants as irreps of H are contained in this representation. The number of irreps also gives the number of independent inertia moments in $\mathcal{I}_{\alpha\beta}$. This is as far as we can go using symmetry arguments in the general case.

If G/H is a symmetric space a considerable simplification arises. In this case, there is an involutive automorphism $\tau:\mathbf{g}\to\mathbf{g}$ $(\tau^2=id_{\mathbf{g}})$ under which the generators satisfy,[13]

$$\tau J_i\tau=J_i, \tag{46}$$

$$\tau J_\alpha\tau=-J_\alpha. \tag{47}$$

We assume that τ acts on the fields $\phi^s(\mathbf{x},t)$ as $\tau:\phi^s(\mathbf{x},t)\mapsto\tau^s[\phi(\mathbf{x},t)]$ with $\tau^s[\tilde{\phi}(\mathbf{x})]=\tilde{\phi}(\mathbf{x})$. Equation (46) states that τ commutes with J_i, so a representation of H has a definite eigenvalue of $\tau(\pm1)$, and therefore by (47) we have $M_\alpha=0$. Another simplification is that the representation of H under which J_α transform is irreducible, so there is only one moment of inertia $\mathcal{I}$. The collective Hamiltonian becomes,

$$\mathcal{H}_{\text{coll}}=\frac{1}{2\mathcal{I}}I_\alpha^2=\frac{1}{2\mathcal{I}}(I_a^2-I_i^2), \tag{48}$$

and the $d_{I\chi}$ states,

$$\psi_{IM\chi}(q,\alpha)=\varphi_\mu(q)D^I_{M\mu_k}(\alpha)\quad(k=1,...,d_{I\chi}), \tag{49}$$

are degenerate eigenstates, since I_a^2 and I_i^2 are Casimirs of G and H, respectively.

C. Landsman and Linden Hamiltonian

In the previous section we found the collective wavefunctions by treating the H-gauge invariance by means of the Dirac method of imposing the constraints on the states. However, the dynamical consequences of the Mackey condition (41) on the collective functions are best understood by fixing the H-gauge symmetry.

Let us make the natural gauge choice of setting the collective coordinates related to motion on the subgroup $\alpha^i=0$. This fixes the H-gauge symmetry generated by Φ_i, i.e., $\{\alpha^i,\Phi_j\}\approx\delta^i_j$. Proceeding as before, we eliminate the pairs $(\alpha^i,\mathcal{P}_i)$ by solving $\mathcal{P}_i$ from the equations $\Phi_i=0$. This gives

$$\mathcal{P}_i=(D_i)_{nm}p_nq_m, \tag{50}$$

where we have used that $\Theta^j_i(0)=\delta^i_j$. Since the vibrations fall into irreps of H, if we restrict to a given vibrational state classified by χ, the above equation reduces to,

$$\mathcal{P}_i=\langle\varphi_\mu|(D_i)_{nm}p_nq_m|\varphi_\nu\rangle=-i(T_i)^\chi_{\mu\nu}, \tag{51}$$

where $(T_i)^\chi_{\mu\nu}$ are the generators of H in the irrep χ. Replacing in the collective operators I_α we get,

$$I_\alpha=\Theta^\beta_\alpha(\xi)\mathcal{P}_\beta+i\Theta^\beta_\alpha(\xi)\zeta^i_\beta(\xi)(T_i)^\chi_{\mu\nu}, \tag{52}$$

where $\xi\in G/H_0$ (i.e., the coordinates $\alpha^{a=1,\ldots,\dim(G/H)}$), being H_0 the identity component of H. In this gauge the collective functions f_μ become the functions $F_\mu(\xi)$ of Sec. III, and the collective Hamiltonian (44) becomes,

$$\mathcal{H}_{\text{coll}}=\text{const}-\tfrac{1}{2}g^{\alpha\beta}(\nabla_\alpha+A_\alpha)(\partial_\beta+A_\beta)-\tfrac{1}{2}g^{\alpha\beta}[(\nabla_\alpha+A_\alpha)B_\beta+B_\alpha(\partial_\beta+A_\beta)]. \tag{53}$$

The second term corresponds to Landsman–Linden Hamiltonian (28), with the metric on G/H_0 given by $g_{\alpha\beta}(\xi)=\mathcal{I}_{\gamma\delta}\zeta^\gamma_\alpha(\xi)\zeta^\delta_\beta(\xi)$, and the H_0-connection by,

$$(A_\alpha)_{\mu\nu}=-i\zeta^i_\alpha(T_i)^\chi_{\mu\nu}. \tag{54}$$

The third term in (53) gives the coupling to an extra background field,

$$(B_\alpha)_{\mu\nu}=-i\zeta^\beta_\alpha(M_\beta)_{\mu\nu}, \tag{55}$$

which comes from the ''Coriolis'' terms in (44). In general, for real representations, this is an SO(dimχ) connection, and is similar to the induced connections studied in Ref. 14.

The H_0-connection ensures that Hamiltonian (53) applied to functions independent of α^i gives the same result as Hamiltonian (44) acting on functions over G which satisfy Mackey condition (40). When $H_0\neq H$ the functions $F_\mu(\xi)$ are still restricted by condition (41) for the discrete elements of H. This restriction can be lifted including a pure gauge connection which associates a discrete element of H with each nontrivial path in $\Pi_1(G/H)$ (holonomy factors). The relation between inequivalent quantizations and holonomy factors in the path integral is discussed in Ref. 15.

V. CONCLUSIONS

We have discussed the collective bands of intrinsic states found when quantizing around a soliton solution with moduli space isomorphic to G/H. The result is that the collective band of an intrinsic vibrational state realizes an inequivalent coset space quantization given by the representation of H under which the intrinsic state transforms. The collective Hamiltonian is that of Landsman and Linden,[2] which describes free motion on G/H coupled to a background H-gauge field. Besides, there may be other background gauge fields coming from the Coriolis terms. The extra degrees of freedom associated with the nontrivial quantizations are given by the intrinsic coordinates. In this way, we have given a physical example of the inequivalent quantizations studied in Refs. 1–3.

Some of the consequences for the collective quantization of a soliton with moduli space G/H are the following. The states in the collective band of a vibration carrying the representation χ of H are classified by the irreducible representations I of the symmetry group G. Each irrep I appears in the band as many times as χ is contained in its decomposition into irreps of H. This also gives to lowest order the dimension of the collective Hamiltonian matrix within this subspace, from which the energies of the states are obtained. Determining the collective bands is analogous to calculating the rotational spectra of polyatomic molecules,[16] and our results can be understood as a generalization of this problem to a general symmetry group.

This work may be of interest for obtaining the spins and isospins bands of the ground state of multiskyrmions[17,18] and their excited states, which have been found for topological charges $B=2$ and $B=4$ by Barnes *et al.*[19,20] The symmetry group of the Skyrme model is the direct product of the spatial and isospatial rotations and the combined parity (without considering spatial translations) $G=\mathrm{SO}(3)_S\times\mathrm{SO}(3)_I\times P$. As described in Ref. 21, the symmetry group of a Skyrmion $H\subset G$ is given by pairs $(h,D(h))$, where h is an element of the spatial group $\mathrm{O}(3)_S$, and $D(h)$ an element of the isospin group $\mathrm{O}(3)_I$. The mapping $D:h\mapsto D(h)$ is a three-dimensional real representation of H, and $\det h=\det D(h)$. For example, for the $B=2$ case $H=D_\infty$ (not considering parity). The ground state is in the non trivial one-dimensional representation Σ^- if the Skyrmion is quantized as a fermion. Therefore, the lowest allowed state of the band are $(I=1,\ S=0)$ or $(I=0,\ S=1)$, since they are the lowest irreps of G containing Σ^- in its decomposition. Similarly, the other states of the band can be obtained. The $B=2$ case has already been considered in Ref. 22, but we expect the more systematic treatment presented here will be useful in more complicated situations, as for $B>2$, where the subgroup H is discrete.[23]

Ground states of a model in nonrelativistic quantum electrodynamics. I

Fumio Hiroshima[a)]
TU-München, Zentrum Mathematik, Arcis Strasse 21, D-80290 München, Germany

(Received 29 March 1999; accepted for publication 6 July 1999)

The system of a one charged nonrelativistic particle with external potentials minimally coupled to a massless quantized radiation field is considered. An ultraviolet cutoff is imposed on the quantized radiation field and the charged particle has spin 1/2. The class of external potentials considered in this paper contains *Coulomb potentials*. It is shown that the ground states of the system exist provided that a coupling constant is in a region. © *1999 American Institute of Physics.* [S0022-2488(99)03111-4]

I. INTRODUCTION

In this paper and Ref. 1 we are concerned with the ground states of a model in nonrelativistic quantum electrodynamics. In the present paper we prove the existence of the ground states of the model which describes the system of a nonrelativistic spin 1/2 particle minimally coupled to a massless quantized radiation field with external potentials (the Pauli–Fierz model[2]). The class of the external potentials considered in this paper includes Coulomb potentials. The quantized radiation field is quantized in the Coulomb gauge and has an ultraviolet cutoff. The Pauli–Fierz model interprets the physical phenomenon "Lamb shift."[3–7]

In the past few decades, several articles have been devoted to the study of the Pauli–Fierz model and has provoked a great deal of controversy.[8–14] A great deal of effect has been made on showing the existence of ground states of related models.[11,14–19]

In the previous paper[14] we have proved the existence of the ground states of the Pauli–Fierz model with external potentials V such as $V=x^2+V_0$, where V_0 is infinitesimally small with respect to the Laplacian. Hence this derives us to a question whether the ground states of the system with Coulomb potentials exist or not.[13] The goal of this paper is to prove the existence of the ground states of the Pauli–Fierz model with a general class of external potentials containing Coulomb potentials.

We shall show the strategy of this paper. A good place to start is to survey Ref. 14. Let H be the Hamiltonian of the system, which is a self-adjoint operator acting in a Hilbert space $\mathcal{H}$. One first introduces artificial mass $m>0$ of photon and define H_m. Second, we define H_m^a by lattice approximation of H_m with lattice length $2\pi/a$.[11,14,16,17,20] We call the bottom of the spectrum of self-adjoint operator T by the ground state energy of T. It is established that the spectrum of H_m^a is purely discrete in the neighborhood of its ground state energy. Then the ground states of H have been constructed in Ref. 14 through (1) a norm resolvent convergence of H_m^a to H_m as $a\to\infty$ (thus one knows that the ground states of H_m exist); (2) nonzero weak limit of a ground state of H_m as $m\to 0$ (the limit is just a ground state of H). To show (1) in Ref. 14 it plays an important role that particles are confined by external potentials such as $V=x^2+V_0$. Then in our case it seems, however, to be difficult to show (1). In order to avoid such sufferings we shall find a family of unitary transformations U_a. That goes to the very heart of solving our problem. We shall show that, instead of H_m^a, the operator $U_aH_m^aU_a^{-1}$ converges to an operator which is unitarily equivalent to H_m as $a\to\infty$ in the norm resolvent sense. Then we see that H_m has a ground state. Finally in the similar way as that of Ref. 14 we prove the existence of the ground states of H.

[a)]Electronic mail: hiro@mathematik.tu-muenchen.de

This paper is organized as follows: In Sec. II, we define the Pauli–Fierz model and we give Hypotheses 1, 2, and 3. Section III A is devoted to defining the lattice approximated Hamiltonians, gives Hypothesis 4 and considers the spectrum in the neighborhood of their ground state energy. In Sec. III B, we introduce a family of unitary transformations. Section III C offers the key to proving existence of ground states; we shall show convergence of operators in a norm resolvent sense. In Sec. III D we give Hypothesis 5 and some binding. In Sec. III E we give Hypothesis 6 and state the main theorem (Theorem 3.14). In Sec. III F we show a weak convergence of ground states.

II. DEFINITION OF A HAMILTONIAN

In this section we give a quick sketch of definition of the Pauli–Fierz model and carefully show some inequalities.

A. Quantized radiation fields

The Boson Fock space $\mathcal{F}$ over $W:=L^2(\mathbb{R}^3)\oplus L^2(\mathbb{R}^3)$ is defined by $\mathcal{F}:=\oplus_{N=0}^{\infty}[\otimes_s^N W]$, where $\otimes_s^N W$, $N\geqslant 1$, denotes the N-fold symmetric tensor product of W and $\otimes_s^0 W:=\mathbb{C}$. We denote by $\mathcal{F}_{\rm fin}$ the finite particle subspace (Ref. 21, X.7). The bare vacuum vector $\Omega\in\mathcal{F}$ is defined by $\Omega:=\{1,0,0,...\}$. We denote by $(\cdot,\cdot)_{\mathcal{K}}$ the scalar product on Hilbert space $\mathcal{K}$ and by $\|\cdot\|_{\mathcal{K}}$ the associated norm. Scalar product $(f,g)_{\mathcal{K}}$ is linear in g and antilinear in f. Unless confusion arising we omit $\mathcal{K}$ in $\|\cdot\|_{\mathcal{K}}$ and $(\cdot,\cdot)_{\mathcal{K}}$, respectively. We denote by $a^\dagger(F)$ and $a(F)$, $F\in W$, the smeared creation operator and the smeared annihilation operator defined on $\mathcal{F}_{\rm fin}$, respectively. In particular, for notational convenience, we define $a^{\dagger r}$ and a^r, $r=1,2$, by $a^{\dagger 1}(f):=a^\dagger(f\oplus 0)$, $a^{\dagger 2}(f):=a^\dagger(0\oplus f)$ and $a^1(f):=a(f\oplus 0)$, $a^2(f):=a(0\oplus f)$, $f\in L^2(\mathbb{R}^3)$, respectively. They satisfy canonical commutation relations on $\mathcal{F}_{\rm fin}$,

$$[a^r(f),a^{\dagger s}(g)]=\delta_{rs}(\overline{f},g), \tag{2.1}$$

$$[a^r(f),a^s(g)]=[a^{\dagger r}(f),a^{\dagger s}(g)]=0,\quad r,s=1,2, \tag{2.2}$$

$$(a^r(f)\Psi,\Phi)=(\Psi,a^{\dagger r}(\overline{f})\Phi),\quad \Phi,\Psi\in\mathcal{F}_{\rm fin}, \tag{2.3}$$

where $\overline{f}$ is the complex conjugate of f. We formally write $a^{\sharp r}(f)=\int a^{\sharp r}(k)f(k)dk$, $r=1,2$, where $a^{\sharp r}$ denotes a^r or $a^{\dagger r}$. For a contraction operator T on W, the second quantization of T is denoted by $\Gamma(T)$ (Ref. 21, X.7). In particular, for a nonnegative self-adjoint operator h in W, $\Gamma(e^{-th}),t\geqslant 0$, is a strongly continuous symmetric one-parameter semigroup on $\mathcal{F}$. Hence we can define a nonnegative self-adjoint operator $d\Gamma(h)$ in $\mathcal{F}$ by $\Gamma(e^{-th})=e^{-td\Gamma(h)},t\geqslant 0$. Note that $d\Gamma(h)\Omega=0$. The free Hamiltonian H_f in $\mathcal{F}$ is defined by $H_f:=d\Gamma(\omega\oplus\omega)$, where ω is the multiplication operator by $\omega(k):=|k|$ ($|k|$ is the three-dimensional Euclidean norm of k). Besides the number operator N is defined by $N:=d\Gamma(I\oplus I)$. We set

$$\mathcal{M}:=\{f:\text{Borel measureable}\,|\,\|f\|_n:=\|\omega^{n/2}f\|_{L^2(R^3)}<\infty\}.$$

The following relative bounds are well known:

$$\|a^{\dagger r}(f)\Psi\|\leqslant\|f\|_{-1}\|H_f^{1/2}\Psi\|+\|f\|_0\|\Psi\|,\quad f\in\mathcal{M}_{-1}\cap\mathcal{M}_0, \tag{2.4}$$

$$\|a^r(f)\Psi\|\leqslant\|f\|_{-1}\|H_f^{1/2}\Psi\|,\quad f\in\mathcal{M}_{-1}\cap\mathcal{M}_0, \tag{2.5}$$

$$\|a^{\dagger r}(f)\Phi\|\leqslant\|f\|_0\|(N+I)^{1/2}\Phi\|,\quad f\in\mathcal{M}_0, \tag{2.6}$$

$$\|a^r(f)\Phi\|\leqslant\|f\|_0\|N^{1/2}\Phi\|,\quad f\in\mathcal{M}_0, \tag{2.7}$$

where $\Psi\in D(H_f^{1/2})$ and $\Phi\in D(N^{1/2})$. With an ultraviolet cutoff ρ, we define a quantized radiation field $A_\mu(x)$ and a quantized magnetic field $B_\mu(x),\mu=1,2,3$, by

$$A_\mu(x) := A_\mu(\rho,x) := \sum_{r=1}^{2} \int \frac{dk}{\sqrt{2\omega(k)}} \{\rho(k) e_\mu^r(k) e^{-ikx} a^{\dagger r}(k) + \rho(-k) e_\mu^r(k) e^{ikx} a^r(k)\},$$

$$B_\mu(x) := B_\mu(\rho,x)$$
$$:= -i \sum_{r=1}^{2} \int \frac{dk}{\sqrt{2\omega(k)}} \{\rho(k)(k\times e^r(k))_\mu e^{-ikx} a^{\dagger r}(k) + \rho(-k)(-k\times e^r(k))_\mu e^{ikx} a^r(k)\},$$

where $e^r = (e_1^r, e_2^r, e_3^r)$, $r = 1, 2$, are polarization vectors which satisfy $e^r(k) e^s(k) = \delta_{rs}$, $ke^r(k) = 0$, $a.e. k \in \mathbb{R}^3$. We set $A_\mu := A_\mu(\rho) := A_\mu(\rho,0)$ and $B_\mu := B_\mu(\rho) = B_\mu(\rho,0)$, $\mu = 1,...,d$.

B. Definition of a Hamiltonian

The Hilbert space $\mathcal{H}$ of the system is given by

$$\mathcal{H} := L^2(\mathbb{R}^3;\mathbb{C}^2) \otimes \mathcal{F} := \mathcal{H}_p \otimes \mathcal{F}.$$

We work in units which is $c = \hbar = 1$ and put the mass of the particle one. Then the Hamiltonian H of the system is defined by

$$H = (1/2)\{\boldsymbol{\sigma}\cdot(\mathbf{P}\otimes I - e\mathbf{A}(x))\}^2 + V\otimes I + I \otimes H_f,$$

where $\mathbf{A}(x) := (A_1(x), A_2(x), A_3(x))$, $\mathbf{P} := (P_1, P_2, P_3) := (-i\nabla_{x_1}, -i\nabla_{x_2}, -i\nabla_{x_3})$, V is an external potential, and $\boldsymbol{\sigma} := (\sigma_1, \sigma_2, \sigma_3)$ defined by

$$\sigma_1 := \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \sigma_2 := \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \sigma_3 := \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}.$$

We immediately see that on $\mathcal{E} := C_0^\infty(\mathbb{R}^3)\hat{\otimes}\mathcal{F}_{\rm fin}$,

$$H = H_p \otimes I + I \otimes H_f + eH_I + e^2 H_{II} + eH_{III},$$

where $H_p := -(1/2)\Delta + V$, $H_I := -(\mathbf{P}\otimes I)\cdot\mathbf{A}(x)$, $H_{II} := (1/2)\mathbf{A}(x)\cdot\mathbf{A}(x)$, $H_{III} := (1/2)\boldsymbol{\sigma}\cdot\mathbf{B}(x)$. Unless confusion arising we abbreviate both $X\otimes I$ and $I\otimes X$ as X in what follows. We introduce Hypotheses 1 and 2.

Hypothesis 1: The ultraviolet cutoff ρ is such that $\rho \in \mathcal{M}_{-2}\cap\mathcal{M}_{-1}\cap\mathcal{M}_0\cap\mathcal{M}_1$ and that $\overline{\rho(k)} = \rho(-k)$.

Hypothesis 2: The external potential V is such that H_p is essentially self-adjoint on $C_0^\infty(\mathbb{R}^3)$ and that there exist constants a and b such that

$$\|-(1/2)\Delta f\| \leq a\|H_p f\| + b\|f\|^2, \quad f \in C_0^\infty(\mathbb{R}^3). \tag{2.8}$$

Moreover there exists $\Sigma \leq \infty$ such that $(-\infty, \Sigma] \cap \sigma(H_p) \subset \sigma_d(H_p)$, where $\sigma(T)$ and $\sigma_d(T)$ denote the spectrum and the discrete spectrum of T, respectively.

Note that (2.8) implies that, with the same a as in (2.8),

$$(f, -(1/2)\Delta f) \leq a(f, H_p f) + b'\|f\|, \quad f \in C_0^\infty(\mathbb{R}^3),$$

where b' is a positive constant. We fix a, b, b' and Σ throughout this paper. We have two standard examples in mind. One choice is (1) $V \in L^2(\mathbb{R}^3) + L^\infty(\mathbb{R}^3)$ with isolated ground state energy, e.g., $V(x) = -1/|x|$. The other is (2) $V(x)\to\infty$ as $|x|\to\infty$, e.g., $V(x) = |x|^2$. For the first case (1), the essential spectrum of H_p has continuum edge, i.e., $\Sigma < \infty$. For the latter case (2), H_p has purely discrete spectrum, i.e., one can take $\Sigma = \infty$. Let

$$r_n := \|\rho\|_n.$$

We have, by (2.4) and (2.5), for $\Psi \in \mathcal{E}$,

$$\|H_I\Psi\| \leq A\|H_f\Psi\| + B\|H_p\Psi\| + C\|\Psi\|, \tag{2.9}$$

$$\|H_{II}\Psi\| \leq D\|H_f\Psi\| + E\|\Psi\|, \tag{2.10}$$

$$\|H_{III}\Psi\| \leq F\|H_f\Psi\| + G\|\Psi\|, \tag{2.11}$$

where

$$\begin{gathered} A := 6r_{-2}, \quad B := 6a(2r_{-2}+r_{-1}), \quad C := 6b(2r_{-2}+r_{-1}) + 3r_{-1}, \\ D = E := 6(r_{-2}+r_{-1})^2 + 3k(r_{-2}+r_{-1})(r_0+r_1), \\ F := 6r_0/\sqrt{2}, \;\; G := 3r_1/\sqrt{2}, \quad k := (2\pi)^{-5/2}\int_0^\infty \sqrt{\lambda}/(\lambda+1)\,d\lambda. \end{gathered} \tag{2.12}$$

We define

$$e_0 := \frac{-(A+B+F) + \sqrt{(A+B+F)^2 + 4D}}{2D}.$$

We set $g[T] := \inf \sigma(T)$. In particular we set $\Sigma_0 := g[H_p]$. Hypothesis 3 is as follows:

Hypothesis 3: The coupling constant e is such that $0 \leq e < e_0$.

Proposition 2.1 (Ref. 22): We assume that Hypotheses 1, 2, and 3 hold. Then H is self-adjoint on $D(H_p)\cap D(H_f)$, bounded below and essentially self-adjoint on any core of $H_0 := H_p + H_f$.

Proof: Note that $\|H_f\Psi\| \leq \|H_0\Psi\| + |\Sigma_0|\|\Psi\|$ and $\|H_p\Psi\| \leq \|H_0\Psi\| + 2|\Sigma_0|\|\Psi\|$. Then, by (2.9), (2.10), and (2.11), we see that for $\Psi \in \mathcal{E}$,

$$\|H_I\Psi\| \leq (A+B)\|H_0\Psi\| + C\|\Psi\| + (A+2B)|\Sigma_0|\|\Psi\|, \tag{2.13}$$

$$\|H_{II}\Psi\| \leq D\|H_0\Psi\| + E\|\Psi\| + D|\Sigma_0|\|\Psi\|, \tag{2.14}$$

$$\|H_{III}\Psi\| \leq F\|H_0\Psi\| + G\|\Psi\| + F|\Sigma_0|\|\Psi\|. \tag{2.15}$$

Hence Kato–Rellich Theorem (Ref. 21, Theorem X.12) yields the desired results. □

Remark 2.2: Essential self-adjointness of H for arbitrary coupling constant $e \in \mathbb{R}$ is studied in Ref. 23.

We shall estimate the ground state energy of H. Let $\Psi \in \mathcal{E}$. We have

$$\begin{aligned} |(\Psi, H_I\Psi)| &\leq A'(\Psi, H_f\Psi) + B'(\Psi, H_p\Psi) + C'\|\Psi\|^2 \\ &\leq (A'+B')(\Psi, H_0\Psi) + (C' - A'\Sigma_0)\|\Psi\|^2, \end{aligned} \tag{2.16}$$

$$|(\Psi, H_{II}\Psi)| \leq D'(\Psi, H_f\Psi) + E'\|\Psi\|^2 \leq D'(\Psi, H_0\Psi) + (E' - D'\Sigma_0)\|\Psi\|^2, \tag{2.17}$$

$$|(\Psi, H_{III}\Psi)| \leq F'(\Psi, H_f\Psi) + G'\|\Psi\|^2 \leq F'(\Psi, H_0\Psi) + (G' - F'\Sigma_0)\|\Psi\|^2, \tag{2.18}$$

where

$$\begin{gathered} A' := 6r_{-2}/\sqrt{2}, \quad B' := 6a\sqrt{2}r_{-2}, \quad C' := 6b\sqrt{2}r_{-2}, \quad D' := 3(r_{-2}+r_{-1})r_{-2}, \\ E' := (3/2)(r_{-2}+r_{-1})r_{-1}, \quad F' = G' = 6r_0/(2\sqrt{2}). \end{gathered} \tag{2.19}$$

Hence we see that

$$(1-eA'-eB'-e^2D'-eF')(\Psi,H_0\Psi)+(eA'+e^2D'+eF')\Sigma_0\|\Psi\|^2 \\ -(eC'+e^2E'+eG')\|\Psi\|^2\leqslant(\Psi,H\Psi). \tag{2.20}$$

Moreover we have

$$(\Psi,H\Psi)\leqslant(1+eA'+eB'+e^2D'+eF')(\Psi,H_0\Psi) \\ +(eC'+e^2E'+eG')\|\Psi\|^2-(eA'+e^2D'+eF')\Sigma_0\|\Psi\|^2. \tag{2.21}$$

Since H is essentially self-adjoint on any core of H_0 for coupling constant $0\leqslant e<e_0$, in view of (2.20) and (2.21), we get, for $0\leqslant e<e_0$,

$$|g[H]-\Sigma_0|\leqslant\Delta(\rho), \tag{2.22}$$

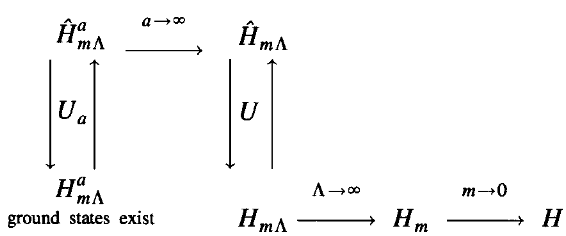
where

$$\Delta(\rho):=e(B'\Sigma_0+C')+e^2E'+eG' \\ =e6\sqrt{2}r_{-2}(a\Sigma_0+b')+e^23(2r_{-2}+r_{-1})r_{-1}/2+e3r_0/\sqrt{2}.$$

Note that $a\Sigma_0+b'\geqslant 0$.

III. EXISTENCE OF GROUND STATES

Before we come on to a closer analysis of the existence of the ground states of H, let us pause here to look briefly at our strategy. We shall introduce three parameters m, a, Λ, and define self-adjoint operators $H^a_{m\Lambda}$, $H_{m\Lambda}$, and H_m, respectively. In addition to this we construct unitary operators U and U_a in $\mathcal{H}$, and define $\hat{H}_{m\Lambda}:=UH_{m\Lambda}U^{-1}$ and $\hat{H}^a_{m\Lambda}:=U_aH^a_{m\Lambda}U_a^{-1}$, respectively.



First, we shall show that $H^a_{m\Lambda}$ has purely discrete spectrum in the neighborhood of $g[H^a_{m\Lambda}]$. Second, we shall show the norm resolvent convergence of $\hat{H}^a_{m\Lambda}$ to $\hat{H}_{m\Lambda}$ as $a\to\infty$. Then by unitary equivalences between $H^a_{m\Lambda}$, and $\hat{H}^a_{m\Lambda}$, and between $H_{m\Lambda}$ and $\hat{H}_{m\Lambda}$, we can see that $H_{m\Lambda}$ has also purely discrete spectrum in the neighborhood of $g[H_{m\Lambda}]$. (See diagram 1, where $a\to\infty$ and $\Lambda\to\infty$ are in the sense of norm resolvent and $m\to 0$ in the sense of strong resolvent.) Finally the similar arguments on $\Lambda\to\infty$ and $m\to 0$ as those in Ref. 16 lead us to the final goal; we show the existence of the ground states of H. Remark that it is *difficult* to show the norm resolvent convergence of $H^a_{m\Lambda}\to H_{m\Lambda}$ as $a\to\infty$ directly with potentials V in Hypothesis 2.

A. Lattice approximation

Lattice approximation is essentially contained in Ref. 20; to make this paper as self-contained as possible we include a version of the proof here for the convenience of the reader. Define the set of lattice points by $\Gamma_a:=\{k=(k_1,k_2,k_3)|k_\mu=2\pi n_\mu/a,n_\mu\in\mathbb{Z},\mu=1,2,3\}$. Let $l_2(\Gamma_a)$ be the set of l_2 sequences over Γ_a. We define $\mathcal{F}_a$ as $\mathcal{F}_a:=\oplus_{n=0}^\infty\otimes_s^n[l_2(\Gamma_a)\oplus l_2(\Gamma_a)]$. By the map $l_2(\Gamma_a)\ni\{a_l\}_{l\in\Gamma_a}\mapsto(a/2\pi)\Sigma_{l\in\Gamma_a}a_l\chi_{\Gamma(l,a)}(\cdot)\in L^2(\mathbb{R}^3)$, we identify $l_2(\Gamma_a)$ with a subspace in $L^2(\mathbb{R}^3)$, where $\chi_{\Gamma(l,a)}(\cdot),l\in\Gamma_a$, is the characteristic function of

$$\Gamma(l,a):=[l_1,l_1+2\pi/a)\times[l_2,l_2+2\pi/a)\times[l_3,l_3+2\pi/a)\subset\mathbb{R}^3.$$

Then we identify $l_2(\Gamma_a)\oplus l_2(\Gamma_a)$ with the subspace of W and regard $\mathcal{F}_a$ as the closed subspace of $\mathcal{F}$. For $0<m$ and $0<a$, we define nonnegative self-adjoint operators by

$$H_{fm}^a := d\Gamma((\omega_a+m)\oplus(\omega_a+m)),$$

$$H_{fm} := d\Gamma((\omega+m)\oplus(\omega+m)),$$

where $\omega_a(k):=\omega(k_a)$ and $k_a:=(k_{1,a},k_{2,a},k_{3,a})$ is a step function, i.e., $k_{\mu,a}=2\pi n/a$, if $k_\mu \in[2\pi n/a,2\pi n/a+2\pi/a), n\in\mathbb{Z}$. The operator H_{fm}^a is reduced by $\mathcal{F}_a$ and $H_{fm}^a\lceil_{F_a}$ has purely discrete spectrum. We define

$$A_\mu^a(x):=\sum_{r=1}^2 \int dk \sum_{l\in\Gamma_a} X_{\Gamma(l,a)}(k)\left\{\frac{\rho(l)e^{-ilx}e_\mu^r(l)}{\sqrt{2\omega(l)}}a^{\dagger r}(k)+\frac{\rho(-l)e^{ilx}e_\mu^r(l)}{\sqrt{2\omega(l)}}a^r(k)\right\},$$

$$B_\mu^a(x):=-i\sum_{r=1}^2 \int dk \sum_{l\in\Gamma_a} X_{\Gamma(l,a)}(k) \times\left\{\frac{\rho(l)e^{-ilx}(l\times e^r(l))_\mu}{\sqrt{2\omega(l)}}a^{\dagger r}(k)+\frac{\rho(-l)e^{ilx}(-l\times e^r(l))_\mu}{\sqrt{2\omega(l)}}a^r(k)\right\}.$$

Thus H_m^a and H_m are given by

$$H_m^a := H_p+H_{fm}^a+eH_I^a+e^2H_{II}^a+eH_{III}^a,$$

$$H_m := H_p+H_{fm}+eH_I+e^2H_{II}+eH_{III},$$

where H_I^a, H_{II}^a, and H_{III}^a are defined with $A_\mu(x)$ and $B_\mu(x)$ in H_I, H_{II}, and H_{III} replaced by $A_\mu^a(x)$ and $B_\mu^a(x)$, respectively. Let X_Λ be the characteristic function of $\{k\in\mathbb{R}^3 \| k|<\Lambda\}$. We set $\rho_\Lambda:=X_\Lambda\rho$. We define $H_{m\Lambda}^a$ by H_m^a with ρ replaced by ρ_Λ. We set $A_\mu^a:=A_\mu^a(\rho,0)$, $B_\mu^a:=B_\mu^a(\rho,0)$, $A_{\Lambda\mu}^a:=A_\mu^a(\rho_\Lambda,0)$, $B_{\Lambda\mu}^a:=B_\mu^a(\rho_\Lambda,0)$, $A_{\Lambda\mu}:=A_\mu(\rho_\Lambda,0)$ and $B_{\Lambda\mu}:=B_\mu(\rho_\Lambda,0)$.

Lemma 3.1: We assume that Hypotheses 1, 2, and 3 hold. Then (1) H_m is self-adjoint on $\mathcal{D}_m:=D(H_p)\cap D(H_{fm})$, bounded below and essentially self-adjoint on any core of

$$H_{0,m}:=H_p+H_{fm};$$

(2) for sufficiently large a, $H_{m\Lambda}^a$ is self-adjoint on $\mathcal{D}_m$, bounded below and essentially self-adjoint on any core of

$$H_{0,m}^a:=H_p+H_{fm}^a.$$

Proof: Proof is the same as that of Proposition 2.1. We omit it. □

Let A', B', C', D', E', F', and G' be in (2.19), and $A'_{a\Lambda}$, $B'_{a\Lambda}$, $C'_{a\Lambda}$, $D'_{a\Lambda}$, $E'_{a\Lambda}$, $F'_{a\Lambda}$, and $G'_{a\Lambda}$, are defined by A', B', C', D', E', F', G' with ρ replaced by $\rho_{a\Lambda}:=\Sigma_{l\in\Gamma_l}X_{\Gamma(l,a)}(\cdot)\rho_\Lambda(l)$, respectively.

Lemma 3.2: Assume that Hypotheses 1, 2, and 3 hold. Let $\Psi\in\mathcal{E}$. Then the following inequalities hold:

$$(1)\quad (1-eA'-eB'-e^2D'-eF')(\Psi,H_{0,m}\Psi)+(eA'+e^2D'+eF')\Sigma_0\|\Psi\|^2 -(eC'+e^2E'+eG')\|\Psi\|^2\leqslant(\Psi,H_m\Psi); \tag{3.1}$$

$$(2)\quad (\Psi,H_m\Psi)\leqslant(1+eA'+eB'+e^2D'+eF')(\Psi,H_{0,m}\Psi) +(eC'+e^2E'+eG')\|\Psi\|^2-(eA'+e^2D'+eF')\Sigma_0\|\Psi\|^2; \tag{3.2}$$

(3) $(1-eA'_{a\Lambda}-eB'_{a\Lambda}-e^2D'_{a\Lambda}-eF'_{a\Lambda})(\Psi,H^a_{0,m}\Psi)+(eA'_{a\Lambda}+e^2D'_{a\Lambda}+eF'_{a\Lambda})\Sigma_0\|\Psi\|^2$

$$-(eC'_{a\Lambda}+e^2E'_{a\Lambda}+eG'_{a\Lambda})\|\Psi\|^2\leqslant(\Psi,H^a_{m\Lambda}\Psi); \tag{3.3}$$

(4) $(\Psi,H^a_{m\Lambda}\Psi)\leqslant(1+eA_{a\Lambda}+eB_{a\Lambda}+e^2D_{a\Lambda}+eF_{a\Lambda})(\Psi,H^a_{0,m}\Psi)$

$$+(eC_{a\Lambda}+e^2E_{a\Lambda}+eG_{a\Lambda})\|\Psi\|^2-(eA_{a\Lambda}+e^2D_{a\Lambda}+eF_{a\Lambda})\Sigma_0\|\Psi\|^2. \tag{3.4}$$

In particular,

$$|\Sigma_0-g[H_m]|\leqslant\Delta(\rho), \tag{3.5}$$

$$|\Sigma_0-g[H^a_{m\Lambda}]|\leqslant\Delta(\rho_{a\Lambda}). \tag{3.6}$$

Proof: Note that for sufficient large a, $(\Psi,H_0\Psi)\leqslant(\Psi,H^a_{0,m}\Psi)$. Then by (2.16), (2.17), and (2.18), one sees (3.3) and (3.4). (3.1) and (3.2) are proved quite similarly. □

We introduce Hypothesis 4:

Hypothesis 4: The coupling constant e is such that $2\Delta(\rho)/(1-eB')<\Sigma-\Sigma_0$.

Lemma 3.3: We assume that Hypotheses 1, 2, 3, and 4 hold. Let a be sufficiently large and m be such that

$$0<m\leqslant(1-eB')(\Sigma-\Sigma_0)-2\Delta(\rho). \tag{3.7}$$

Then $[g[H^a_{m\Lambda}],g[H^a_{m\Lambda}]+m)\subset\sigma_d(H^a_{m\Lambda})$.

Remark 3.4: By (3.6) and a limiting argument, for sufficiently large a, (3.7) implies that

$$0<(1-eB'_{a\Lambda})(\Sigma-\Sigma_0)+(\Sigma_0-g[H^a_{m\Lambda}])-\Delta(\rho_{a\Lambda})-m. \tag{3.8}$$

Proof: For notational brevity, we put $H_a:=H^a_{m\Lambda}$ and $g_a:=g[H^a_{m\Lambda}]$. Moreover set $\overline{H_p}:=H_p-\Sigma_0$. Let $E_T(\mathcal{B})$ be the spectral projection of operator T on Borel set $\mathcal{B}\subset\mathbb{R}$ and $\dim E_T(\mathcal{B})$ the dimension of the range of $E_T(\mathcal{B})$. Put

$$\mathcal{H}=\mathcal{H}_p\otimes[\mathcal{F}_a\oplus\mathcal{F}_a^\perp]=[\mathcal{H}_p\otimes\mathcal{F}_a]\oplus[\mathcal{H}_p\otimes\mathcal{F}_a^\perp]:=\mathcal{H}_1\oplus\mathcal{H}_2.$$

We see that H_a is reduced by $\mathcal{H}_1$ (Ref. 14, Lemma 3.7). By (2.16), (2.17), and (2.18), we have

$$(\Psi,H_a\Psi)\geqslant(\Psi,(\beta H_f+\overline{\alpha H_p}-\Delta(\rho_{a\Lambda})+\Sigma_0)\Psi), \tag{3.9}$$

where $\alpha:=1-eB'_{a\Lambda}$, $\beta:=1-(eA'_{a\Lambda}+e^2D'_{a\Lambda}+eF'_{a\Lambda})$. Note that by Hypothesis 3, $\alpha>0$ and $\beta>0$. We have, for $\Psi_1\in\mathcal{H}_1\cap D(H_a)$, by (3.9),

$$(\Psi_1,(H_a-m-g_a)\Psi_1)$$

$$\geqslant(\Psi_1,E_{\overline{H_p}}([0,\Sigma-\Sigma_0))\otimes(\beta H^a_{fm}-(m+g_a-\Sigma_0+\Delta(\rho_{a\Lambda})))\Psi_1)$$

$$+\{\alpha(\Sigma-\Sigma_0)-(m+g_a-\Sigma_0+\Delta(\rho_{a\Lambda}))\}(\Psi_1,E_{\overline{H_p}}([\Sigma-\Sigma_0,\infty))\Psi_1) \tag{3.10}$$

$$+(\Psi_1,E_{\overline{H_p}}([\Sigma-\Sigma_0,\infty))\otimes\beta H^a_{fm}\Psi_1). \tag{3.11}$$

By virtue of (3.8), (3.10) is non-negative, and (3.11) is also non-negative. Therefore we have

$$\mathrm{Ran}\,E_{H_a}([g_a,g_a+m))\lceil_{\mathcal{H}_1}\subset\mathrm{Ran}\,E_{\overline{H_p}}([0,\Sigma-\Sigma_0))\otimes E_{H^a_{fm}}([0,(m+g_a-\Sigma_0+\Delta(\rho_{a\Lambda}))/\beta))\lceil_{\mathcal{H}_1}.$$

Note that $g_a+\Delta(\rho_{a\Lambda})\geqslant\Sigma_0$. Thus it follows that

$$\dim E_{H_a}([g_a,g_a+m))\lceil_{\mathcal{H}_1}\leqslant \dim E_{\overline{H_p}}([0,\Sigma-\Sigma_0))\cdot \dim E_{H^a_{fm}}([0,(m+g_a-\Sigma_0+\Delta(\rho_{a\Lambda}))/\beta)).$$

On the other hand, we have $(\Psi_2,H_a\Psi_2)\geqslant(g_a+m)\|\Psi_2\|^2$ (Ref. 6, Lemma 3.7). Thus we obtain $\mathrm{Ran}\,E_{H_a}([g_a,g_a+m))=\mathrm{Ran}\,E_{H_a}([g_a,g_a+m))\lceil_{\mathcal{H}_1}$. Hence it follows that

$$\dim E_{H_a}([g_a,g_a+m))\leqslant \dim E_{H_a}([g_a,g_a+m))\lceil_{\mathcal{H}_1}<\infty.$$

Thus proof is complete. □

B. Unitary transformations

We define unitary transformations U and U_a by

$$U:=\exp\left(i\sum_{\mu=1}^{3} x_\mu\otimes d\Gamma(k_\mu)\right),\quad U_a:=\exp\left(i\sum_{\mu=1}^{3} x_\mu\otimes d\Gamma(k_{\mu,a})\right),\quad a>0.$$

Define

$$\mathcal{O}:=\mathcal{L}\{F(x)a^{\dagger r1}(e^{-i\theta_1(k)x}f_1)\cdots a^{\dagger r_n}(e^{-i\theta_n(k)x}f_n)\Omega,\Omega\,|\,F\in C_0^\infty(\mathbb{R}^3),f_j\in L_c^2(\mathbb{R}^3),$$
$$\theta_j(k)\in\mathcal{L}\{k,k_a\},r_j=1,2,\quad j=1,2,...,n,n\in N\},$$

where $\mathcal{L}\{\cdots\}$ denotes the finite linear hull of the vectors in $\{\cdots\}$ and $L_c^2(\mathbb{R}^3)$ is the set of functions in $L^2(\mathbb{R}^3)$ with compact support. Since $\mathcal{O}$ is a core for both $H_{0,m}$ and $H^a_{0,m}$, by Lemma 3.1, $\mathcal{O}$ is a core for both $H_{m\Lambda}$ and $H^a_{m\Lambda}$. Note that operators $U,U_a,d\Gamma(k_\mu)$, $d\Gamma(k_{\mu,a})$, H_{fm}, H^a_{fm}, and $a^{\sharp r}(e^{-i\theta(k)x}f)$, $\theta(k)\in\mathcal{L}\{k,k_a\}$, leave $\mathcal{O}$ invariant.

Lemma 3.5: The unitary operators U and U_a satisfy that, on $\mathcal{O}$,

$$UH_{m\Lambda}U^{-1}=(1/2)\{\boldsymbol{\sigma}\cdot(\mathbf{P}_T-e\mathbf{A}_\Lambda)\}^2+H_{fm}+V, \tag{3.12}$$

$$U_aH^a_{m\Lambda}U_a^{-1}=(1/2)\{\boldsymbol{\sigma}\cdot(\mathbf{P}^a_T-e\mathbf{A}^a_\Lambda)\}^2+H^a_{fm}+V, \tag{3.13}$$

where $\mathbf{P}_T:=(P_{T1},P_{T2},P_{T3})$ *and* $\mathbf{P}^a_T:=(P^a_{T1},P^a_{T2},P^a_{T3})$ *with* $P_{T\mu}:=P_\mu-d\Gamma(k_\mu)$ *and* $P^a_{T\mu}:=P_\mu-d\Gamma(k_{\mu,a})$, $\mu=1,2,3$. *Moreover* U_a *leaves* $\mathcal{H}_1$ *invariant*.

Proof: It is easily seen that, on $\mathcal{O}$, $U\mathbf{P}U^{-1}=\mathbf{P}_T$, $U_a\mathbf{P}U_a^{-1}=\mathbf{P}^a_T$, $Ua^r(e^{ikx}f)U^{-1}=a^r(f)$, $Ua^{\dagger r}(e^{-ikx}f)U^{-1}=a^{\dagger r}(f)$, $U_aa^r(e^{ik_ax}f)U_a^{-1}=a^r(f)$, $U_aa^{\dagger r}(e^{-ik_ax}f)U_a^{-1}=a^{\dagger r}(f)$, $UH_{fm}U^{-1}=H_{fm}$, $U_aH^a_{fm}U_a^{-1}=H^a_{fm}$. Thus (3.12) and (3.13) follow. Let $\Psi=F\otimes a^{\dagger r_1}(f_1)\cdots a^{\dagger r_n}(f_n)\Omega$, $F\in C_0^\infty(\mathbb{R}^3)$, $f_j\in l_2(\Gamma_a)$, $j=1,...,n$. The finite linear hull of the form of Ψ's is dense in $\mathcal{H}_1$. Since $e^{-ik_ax}f_j\in l_2(\Gamma_a)$, $j=1,...,n$, for each $x\in\mathbb{R}^3$, we have

$$UF\otimes a^{\dagger r_1}(f_1)\cdots a^{\dagger r_n}(f_n)\Omega=Fa^{\dagger r_1}(e^{-ik_ax}f_1)\cdots a^{\dagger r_n}(e^{-ik_ax}f_n)\Omega\in\mathcal{H}_1.$$

Thus U leaves $\mathcal{H}_1$ invariant. □

We write the right-hand sides of (3.12) and (3.13) as $\hat{H}_{m\Lambda}$ and $\hat{H}^a_{m\Lambda}$, respectively.

Lemma 3.6: The operators $\hat{H}_{m\Lambda}$ *and* $\hat{H}^a_{m\Lambda}$ *are essentially self-adjoint on* $\mathcal{O}$. *The unitary operator U maps* $D(\hat{H}_{m\Lambda})$ *onto* $D(H_{m\Lambda})$ *with* (3.12) *and* U_a *maps* $D(\hat{H}^a_{m\Lambda})$ *onto* $D(H^a_{m\Lambda})$ *with* (3.13).

Proof: Since $\mathcal{O}$ is a core for $H_{m\Lambda}$ and U maps $\mathcal{O}$ onto itself, $UH_{m\Lambda}U^{-1}\lceil_{\mathcal{O}}$ is essentially self-adjoint, which implies that $\hat{H}_{m\Lambda}\lceil_{\mathcal{O}}$ is essentially self-adjoint. Thus U maps $D(\hat{H}_{m\Lambda})$ onto $D(H_{m\Lambda})$ with (3.12). For the case of $\hat{H}^a_{m\Lambda}$, $H^a_{m\Lambda}$, and U_a, it is similarly proved. □

We define $H_T:=\mathbf{P}_T\cdot\mathbf{P}_T+V+H_{fm}$ and $H^a_T:=\mathbf{P}^a_T\cdot\mathbf{P}^a_T+V+H^a_{fm}$. Then $\hat{H}^a_{m\Lambda}=H^a_T+\mathbf{Q}_a$ and $\hat{H}_{m\Lambda}=H_T+\mathbf{Q}$, where $\mathbf{Q}_a:=-e\mathbf{P}^a_T\cdot\mathbf{A}^a_\Lambda+(e^2/2)\mathbf{A}^a_\Lambda\cdot\mathbf{A}^a_\Lambda+(e/2)\boldsymbol{\sigma}\cdot\mathbf{B}^a_\Lambda$ and $\mathbf{Q}:=-e\mathbf{P}^a_T\cdot\mathbf{A}_\Lambda+(e^2/2)\mathbf{A}_\Lambda\cdot\mathbf{A}_\Lambda+(e/2)\boldsymbol{\sigma}\cdot\mathbf{B}_\Lambda$.

Lemma 3.7: Assume that Hypotheses 1, 2, and 3 hold. Then, for sufficiently large a, there exist positive constant γ which is independent of sufficiently large a so that, for $\Psi\in\mathcal{O}$,

$$\|H_T\Psi\|\le\gamma(\|\hat{H}_{m\Lambda}\Psi\|+\|\Psi\|), \tag{3.14}$$

$$\|H_T^a\Psi\|\le\gamma(\|\hat{H}_{m\Lambda}^a\Psi\|+\|\Psi\|). \tag{3.15}$$

Proof: One sees that there exists constants $\alpha<1$ and $\beta\ge 0$ which are independent of large a so that $\|(eH_I^a+e^2H_{II}^a+eH_{III}^a)\Psi\|\le\alpha\|H_{0,m}^a\Psi\|+\beta\|\Psi\|$ for $\Psi\in\mathcal{O}$. Since U_a leaves $\mathcal{O}$ invariant, $\|\mathbf{Q}_a\Psi\|\le\alpha\|H_T^a\Psi\|+\beta\|\Psi\|$ for $\Psi\in\mathcal{O}$. Thus it follows that $\|H_T^a\Psi\|\le(1-\alpha)^{-1}\|\hat{H}_{m\Lambda}^a\Psi\|+\beta(1-\alpha)^{-1}\|\Psi\|$, which implies (3.15). (3.14) is proved similarly. □

C. Existence of ground states with artificial mass

The purpose of this subsection is to obtain the following lemma:

Lemma 3.8: We assume that Hypotheses 1, 2, and 3 hold. Then, for $z\in\mathbb{C}\setminus\mathbb{R}$,

$$\lim_{a\to\infty}(\hat{H}_{m\Lambda}^a-z)^{-1}=(\hat{H}_{m\Lambda}-z)^{-1} \tag{3.16}$$

in the uniform norm.

Before proving Lemma 3.8, we prepare a lemma. We have $0\le k_\mu-k_{\mu,a}\le 2\pi/a$, $\mu=1,2,3$. Then it follows that for $\Psi\in D(H_{fm})$,

$$\|(d\Gamma(k_\mu)-d\Gamma(k_{\mu,a}))\Psi\|\le\frac{2\pi}{ma}\|H_{fm}\Psi\|,\quad \mu=1,2,3. \tag{3.17}$$

Lemma 3.9: Let $\Psi\in\mathcal{O}$. Then there exists a positive constant α so that

$$\|P_{T\mu}^a\Psi\|\le\alpha(\|H_T^a\Psi\|+\|\Psi\|),\quad \mu=1,2,3,$$

$$\|H_f^{1/2}\Psi\|\le\alpha(\|H_T\Psi\|+\|\Psi\|),\quad \|H_f^{1/2}\Psi\|\le\alpha(|vH_T^a\Psi\|+\|\Psi\|),$$

$$\|H_{fm}\Psi\|\le\alpha(\|H_T\Psi\|+\|\Psi\|),\quad \|H_{fm}\Psi\|\le\alpha(\|H_T^a\Psi\|+\|\Psi\|).$$

Proof: One sees that $\|P_\mu\Psi\|\le\alpha(\|H_{0,m}^a\Psi\|+\|\Psi\|)$. Since U_a leaves $\mathcal{O}$ invariant, the first inequality holds. The other inequalities are handled similarly.

Proof of Lemma 3.8:

We set $\mathbf{R}:=(\hat{H}_{m\Lambda}-z)^{-1}$ and $\mathbf{R}_a:=(\hat{H}_{m\Lambda}^a-z)^{-1}$. We have

$$\mathbf{R}-\mathbf{R}_a=\sum_{\mu=1}^{3}(I_\mu^a+eII_\mu^a+e^2III_\mu^a+eIV_\mu^a)+R^a,$$

where

$$I_\mu^a:=\mathbf{R}_a((P_{T\mu}^a)^2-(P_{T\mu})^2)\mathbf{R},\quad II_\mu^a:=\mathbf{R}_a(P_{T\mu}^aA_{\Lambda\mu}^a-P_{T\mu}A_{\Lambda\mu})\mathbf{R},$$

$$III_\mu^a:=\mathbf{R}_a((A_{\Lambda\mu}^a)^2-(A_{\Lambda\mu})^2)\mathbf{R},\quad IV_\mu^a:=\mathbf{R}_a(\sigma_\mu B_{\Lambda\mu}^a-\sigma_\mu B_{\Lambda\mu})\mathbf{R},$$

$$R^a:=\mathbf{R}_a(H_{fm}^a-H_{fm})\mathbf{R}.$$

We shall check that I_μ^a, II_μ^a, III_μ^a, IV_μ^a, and R^a go to zero as $a\to\infty$, respectively. We also denote the norm of operators in $\mathcal{H}$ by $\|\cdot\|$. For $f\in\mathcal{M}_n$, we define $R_n(f):=\|f-\sum_{l\in\Gamma_a}f(l)X_{\Gamma(l,a)}\|_n$. Note that, if f has a compact support, then $R_n(f)$ goes to zero as $a\to\infty$. We put

$$X_n := \max_{\mu=1,2,3,r=1,2} R_n\left(\frac{\rho_\Lambda e^r_\mu}{\sqrt{2\omega}}\right), \quad Y_n := \max_{\mu=1,2,3,r=1,2} R_n\left(\frac{\rho_\Lambda (k\times e^r)_\mu}{\sqrt{2\omega}}\right), \quad Z_n := \max_{\mu=1,2,3,r=1,2} \left\|\frac{\rho_\Lambda e^r_\mu}{\sqrt{2\omega}}\right\|_n .$$

Define

$$\alpha := \max\left\{\begin{array}{ll} \|H_{fm}(H_T^a - z^*)^{-1}\|, & \|H_{fm}(H_T - z^*)^{-1}\| \\ \|H_f^{1/2}(H_T^a - z^*)^{-1}\|, & \|H_f^{1/2}(H_T - z^*)^{-1}\| \\ \|P^a_{T\mu}(H_T^a - z^*)^{-1}\| & \end{array}\right\}, \quad \beta := \max\{\|H_T^a \mathbf{R}_a^\sharp\|, \|H_T \mathbf{R}^\sharp\|\},$$

where $\mathbf{R}^\sharp$ (resp. $\mathbf{R}_a^\sharp$) denotes $\mathbf{R}$ or $\mathbf{R}^*$ (resp. $\mathbf{R}_a$ or $\mathbf{R}_a^*$) and z^*, z or $\overline{z}.$ The existence of α and β is ensured by Lemmas 3.7 and 3.9. Note that $\|(H_{fm} - H_{fm}^a)\Psi\| \leqslant 2C_a(1-C_a)^{-1}\|H_{fm}\Psi\|$ for $\Psi \in D(H_{fm})$, where $C_a := \sqrt{3}(\pi/a)(1/(2m)+1)$ (Ref. 16, Lemmas 3.1 and 3.6). Thus

$$\|\mathbf{R}^a\| \leqslant \frac{1}{|\mathfrak{F}z|}\,\frac{2C_a}{1-C_a}\,\alpha\beta. \tag{3.18}$$

We see that, by (3.17),

$$\begin{aligned} |(\Psi, I_\mu^a \Phi)| &\leqslant |(P^a_{T\mu}\mathbf{R}_a^*\Psi, (P^a_{T\mu} - P_{T\mu})\mathbf{R}\Phi)| + |((P^a_{T\mu} - P_{T\mu})\mathbf{R}_a^*\Psi, P_{T\mu}\mathbf{R}\Phi)| \\ &\leqslant \frac{2\pi}{ma}\{\|P^a_{T\mu}(H_T^a - \overline{z})^{-1}(H_T^a - \overline{z})\mathbf{R}_a^*\Psi\|\|H_{fm}(H_T - z)^{-1}(H_T - z)\mathbf{R}\Phi\| \\ &\quad + \|H_{fm}(H_T^a - \overline{z})^{-1}(H_T^a - \overline{z})\mathbf{R}_a^*\Psi\|\|P_{T\mu}(H_T - z)^{-1}(H_T - z)\mathbf{R}\Phi\|\} \\ &\leqslant \frac{2\cdot 2\pi}{ma}(\alpha\beta)^2\|\Psi\|\|\Phi\|. \end{aligned} \tag{3.19}$$

We see that by Lemma 4.10,

$$\begin{aligned} |(\Psi, II_\mu^a \Phi)| &\leqslant \|P^a_{T\mu}\mathbf{R}_a^*\Psi\|\|(A^a_{A_{\Lambda\mu}} - A_{\Lambda\mu})\mathbf{R}\Phi\| + \|(P^a_{T\mu} - P_{T\mu})\mathbf{R}_a^*\Psi\|\|A_{\Lambda\mu}\mathbf{R}\Phi\| \\ &\leqslant 2\|P^a_{T\mu}(H_T^a - \overline{z})^{-1}(H_T^a - \overline{z})\mathbf{R}_a^*\Psi\| \\ &\quad \times\{2X_{-1}\|H_f^{1/2}(H_T - z)^{-1}(H_T - z)\mathbf{R}\Phi\| + X_0\|\mathbf{R}\Phi\|\} \\ &\quad + \left(\frac{2\cdot 2\pi}{ma}\right)\|H_{fm}(H_T^a - \overline{z})^{-1}(H_T^a - \overline{z})\mathbf{R}_a^*\Psi\| \\ &\quad \times\{2Z_{-1}\|H_f^{1/2}(H_T - z)^{-1}(H_T - z)\mathbf{R}\Phi\| + Z_0\|\mathbf{R}\Phi\|\} \\ &\leqslant 2\left\{\alpha\beta\left(2\alpha\beta X_{-1} + \frac{X_0}{|\mathfrak{F}z|}\right) + \frac{2\pi}{ma}\alpha\beta\left(2\alpha\beta Z_{-1} + \frac{Z_0}{|\mathfrak{F}z|}\right)\right\}\|\Psi\|\|\Phi\|. \end{aligned} \tag{3.20}$$

We have

$$III_\mu^a = (1/2)\mathbf{R}_a\{(A^a_{\Lambda\mu} - A_{\Lambda\mu})A_{\Lambda\mu} + A^a_{\Lambda\mu}(A^a_{\Lambda\mu} - A_{\Lambda\mu})\}\mathbf{R}.$$

The first term in III_μ^a can be estimated as follows:

$$\begin{aligned} &|((A^a_{\Lambda\mu} - A_{\Lambda\mu})\mathbf{R}_a^*\Psi, A_{\Lambda\mu}\mathbf{R}\Phi)| \\ &\quad \leqslant 2\{X_{-1}\|H_f^{1/2}(H_T^a - \overline{z})^{-1}(H_T^a - \overline{z})\mathbf{R}_a^*\Psi\| + X_0\|\mathbf{R}_a^*\Psi\|\} \\ &\qquad \times\{2Z_{-1}\|H_f^{1/2}(H_T - z)^{-1}(H_T - z)\mathbf{R}\Phi\| + Z_0\|\mathbf{R}\Phi\|\} \end{aligned}$$

$$\leqslant 2\left(2\alpha A X_{-1}+\frac{X_0}{|\Im z|}\right)\left(2\alpha\beta Z_{-1}+\frac{Z_0}{|\Im z|}\right)\|\Psi\|\|\Psi\|. \tag{3.21}$$

The second term in III_μ^a are similarly handled. We see that

$$|(\Psi, IV_\mu^a\Phi)|\leqslant 2\|\mathbf{R}_a^*\Psi\|\{2Y_{-1}\|H_f^{1/2}(H_T-z)^{-1}(H_T-z)\mathbf{R}\Phi\|+Y_0\|\mathbf{R}\Phi\|\}$$
$$\leqslant \frac{2}{|\Im z|}\left(2\alpha\beta Y_{-1}+\frac{Y_0}{|\Im z|}\right)\|\Psi\|\|\Phi\|. \tag{3.22}$$

Thus, by (3.18), (3.19), (3.20), (3.21), and (3.22), R^a, I_μ^a, II_μ^a, III_μ^a, and IV_μ^a, $\mu=1,2,3$, go to zero, as $a\to\infty$, respectively. Hence (3.16) follows.

Lemma 3.10: We assume that Hypotheses 1, 2, 3, and 4 hold and that m satisfies (3.7). *Then* $[g[H_m],g[H_m]+m)\subset\sigma_d(H_m)$. *In particular, the ground states of* H_m *exist.*

Proof: By Lemma 3.3 and (3.13), $[g[\hat{H}_{m\Lambda}^a],g[\hat{H}_{m\Lambda}^a]+m)\subset\sigma_d(\hat{H}_{m\Lambda}^a)$. Lemma 3.9 and (Ref. 24, Lemma 4.6) yield that $[g[\hat{H}_{m\Lambda}],g[\hat{H}_{m\Lambda}]+m)\subset\sigma_d(\hat{H}_{m\Lambda})$, which implies that, by (3.12), $[g[H_{m\Lambda}],g[H_{m\Lambda}]+m)\subset\sigma_d(H_{m\Lambda})$. Since $\|\rho_\Lambda-\rho\|_n\to 0$ as $\Lambda\to\infty$ for $n=-2,-1$, $\lim_{L\to\infty}(H_{m\Lambda}-z)^{-1}=(H_m-z)^{-1}$ in the uniform norm. Then $[g[H_m],g[H_m]+m)\subset\sigma_d(H_m)$. □

D. Binding

Let Ω_m be a ground state of H_m. Define $T:=K\otimes E_{H_f}(\{0\})$, where K is a projection on $L^2(\mathbb{R}^3)$. In this subsection, we estimate both $\|N^{1/2}\Omega_m\|$ and $|(T\Omega_m,(eH_I+e^2H_{II}+eH_{III})\Omega_m)|$. Notation A,B,C,D,E,F,G are in (2.12). Define

$$A'':=A/2, B'':=6ar_{-2}, C'':=6br_{-2}, C'':=6br_{-2}, D'':=E'':=D/2=E/2, F'':=G'':=F/2=G/2.$$

Let

$$P:=e(A+B+F)+e^2D,\quad Q_1:=e(C+G)+e^2E,\quad Q_2:=e(A+2B+F)+e^2D,$$

$$P'':=e(A''+B''+F'')+e^2D'',\quad Q_1'':=e(C''+G'')+e^2E'',\quad Q_2'':=e(A''+2B''+F'')+e^2D''.$$

We define $\mathcal{B}:=\max\{|\Sigma_0-\Delta(\rho)|,|\Sigma_0+\Delta(\rho)|\}$. By (3.5), $|g[H_m]|\leqslant\mathcal{B}$. We have

$$\|P_\mu^2\Omega_m\|\leqslant\|P_\mu^2(H_0-i)^{-1}\|\|(H_0-i)(H_m-i)^{-1}\|\|(H_m-i)\Omega_m\|$$
$$\leqslant\|P_\mu^2(H_0-i)^{-1}\|\|(H_0-i)(H_m-i)^{-1}\|(\mathcal{B}+1)\|\Omega_m\|.$$

Since $\|P_\mu^2\Psi\|\leqslant 2a\|H_p\Psi\|+2b\|\Psi\|\leqslant 2a\|H_0\Psi\|+(4a|\Sigma_0|+2b)\|\Psi\|$ for $\Psi\in\mathcal{E}$,

$$\|P_\mu^2(H_0-i)^{-1}\|\leqslant 2a+2b+4a|\Sigma_0|. \tag{3.23}$$

Moreover since $\|H_0\Psi\|\leqslant\|H_m\Psi\|+e\|H_I\Psi\|+e^2\|H_{II}\Psi\|+e\|H_{III}\Psi\|+2|\Sigma_0|\|\Psi\|$ for $\Psi\in\mathcal{E}$,

$$\|H_0\Psi\|\leqslant\frac{1}{1-P}\{\|H_m\Psi\|+(Q_1+(Q_2+2)|\Sigma_0|)\|\Psi\|\}. \tag{3.24}$$

Hence it follows that

$$\|(H_0-i)(H_m-i)^{-1}\|\leqslant\frac{1}{1-P}+\frac{Q_1+(Q_2+2)|\Sigma_0|}{1-P}+1. \tag{3.25}$$

We define $\mathcal{A}:=(2-P+Q_1+(Q_2+2)|\Sigma_0|)(2a+2b+4a|\Sigma_0|)(1-P)^{-1}$. Thus, by (3.23) and (3.25), $\|P_\mu^2\Omega_m\|\leqslant\mathcal{A}(\mathcal{B}+1)\|\Omega_m\|$. In particular,

$$\|P_\mu\Omega_m\|\leq\sqrt{\mathcal{A}(\mathcal{B}+1)}\|\Omega_m\|. \tag{3.26}$$

We introduce Hypothesis 5:

Hypothesis 5: The ultraviolet cutoff ρ holds that $r_{-3}<\infty$ and the coupling constant e satisfies that

$$r_{-3}\leq\frac{1-3er_{-1}/\sqrt{2}}{6e(\sqrt{\mathcal{A}(\mathcal{B}+1)/2}+3er_{-1}/2)}.$$

Lemma 3.11: We assume that Hypotheses 1, 2, 3, 4, and 5 hold. Then $\|N^{1/2}\Omega_m\|\leq\delta(e)<1$, *where* $\delta(e)$ *is a positive constant.*

Proof: By (2.6), (2.7), and (3.26), we have

$$\|N^{1/2}\Omega_m\|^2\leq\frac{3\cdot 2e}{\sqrt{2}}r_{-3}\|N^{1/2}\Omega_m\|\sqrt{\mathcal{A}(\mathcal{B}+1)}\|\Omega_m\|$$

$$+\frac{3\cdot 2e^2}{2}r_{-3}r_{-1}\|N^{1/2}\Omega_m\|(\|N^{1/2}\Omega_m\|+\|(N+I)^{1/2}\Omega_m\|)+\frac{3\cdot 2e}{2\sqrt{2}}r_{-1}\|N^{1/2}\Omega_m\|\|Q_m\|.$$

Hence from Hypothesis 5 it follows that

$$\frac{\|N^{1/2}\Omega_m\|}{\|\Omega_m\|}\leq\frac{6er_{-3}(\sqrt{\mathcal{A}(\mathcal{B}+1)/2}+er_{-1}/2)+3e/\sqrt{2}r_{-1}}{1-6e^2r_{-3}r_{-1}}:=\delta(e)<1.$$

Thus lemma follows. □

Next we shall estimate $|(T\Omega_m,(eH_I+e^2H_{II}+eH_{III})\Omega_m)|$. Note that $a^r(f)Q\Psi=0$ for $f\in L^2(\mathbb{R}^3)$. We have

$$\frac{|(T\Omega_m,H_I\Omega_m)|}{\|T\Omega_m\|}\leq(A''+B'')\|H_0\Omega_m\|+C'\|\Omega_m\|+(A''+2B'')|\Sigma_0|\|\Omega_m\|,$$

$$\frac{|(T\Omega_m,H_{II}\Omega_m)|}{\|T\Omega_m\|}\leq D''\|H_0\Omega_m\|+E''\|\Omega_m\|+D''|\Sigma_0|\|\Omega_m\|,$$

$$\frac{|(T\Omega_m,H_{III}\Omega_m)|}{\|T\Omega_m\|}\leq F''\|H_0\Omega_m\|+G''\|\Omega_m\|+F''|\Sigma_0|\|\Omega_m\|.$$

From (3.24) it follows that

$$\frac{|(T\Omega_m,(eH_I+e^2H_{II}+eH_{III})\Omega_m)|}{\|T\Omega_m\|}\leq\frac{P''}{1-P}\{\mathcal{B}+Q_1+(Q_2+2)|\Sigma_0|)\}+Q_1''+Q_2''|\Sigma_0|. \tag{3.27}$$

We put the right-hand side of (3.27) by $\mathcal{C}$.

E. Overlap and existence of ground states

Without loss of generality, we can assume that $\|\Omega_m\|=1$. Then we can find a subsequence $\{m_j\}_{j=1}^\infty$ so that $\Omega_0:=w-\lim_{j\to\infty}\Omega_{m_j}$ exists.

Lemma 3.12: We assume that Hypotheses 1, 2, and 3 hold. Then $\lim_{m\to 0}g[H_m]=g[H]$.

Proof: See Ref. 14, Lemma 3.13: □

We introduce Hypothesis 6:

Hypothesis 6: The coupling constant e is such that $\Sigma-\Sigma_0>\Delta(\rho)+\mathcal{C}/\sqrt{1-\delta(e)^2}$. Note that Hypothesis 6 implies that $\Sigma-g[H_m]>0$.

Lemma 3.13: We assume that Hypotheses 1, 2, 3, 4, 5, and 6 hold. Then $\Omega_0 \neq 0$.

Proof: Put $P := E_{H_p}([\Sigma_0, \Sigma)) \otimes E_{H_f}(\{0\})$, $Q := E_{H_p}([\Sigma, \infty)) \otimes E_{H_f}(\{0\})$. Then we have $(\Omega_m, P\Omega_m) \geqslant 1 - \|N^{1/2}\Omega_m\|^2 - (\Omega_m, Q\Omega_m)$. Since $(\Omega_m, Q(H_p - g[H_m])\Omega_m) = -(\Omega_m, Q(eH_I + e^2 H_{II} + eH_{III})\Omega_m)$, (3.27) implies that $(\Sigma - g[H_m])(\Omega_m, Q\Omega_m) \leqslant \mathcal{C}\|Q\Omega_m\|$. Hence,

$$(\Omega_m, P\Omega_m) \geqslant 1 - \delta(e)^2 - (\mathcal{C}/\Sigma - g[H_m]))^2. \tag{3.28}$$

Taking the subsequence $\{m_j\}_{j=1}^{\infty}$, we see that both sides of (3.28) converge with

$$(\Omega_0, P\Omega_0) \geqslant 1 - \delta(e)^2 - (\mathcal{C}(\Sigma - g[H]))^2. \tag{3.29}$$

The right-hand side of (3.29) is positive by Hypotheses 5 and 6. Thus lemma follows. □

We state the main theorem.

Theorem 3.14: *We assume that Hypotheses 1, 2, 3, 4, 5, and 6 hold. Then* Ω_0 *is a ground state of H. In addition to this, we assume that* H_p *has a unique ground state* ϕ. *Then,*

$$\lim_{e \to 0} \|\phi \otimes \Omega - \Omega_0\| = 0.$$

Proof: By Lemmas 3.12 and 3.13, the theorem follows. □

F. Convergence of ground states

Define the Hamiltonian with ''g-factor'' as follows:

$$H_g := (1/2)(\mathbf{P} - e\mathbf{A}(x))^2 + V + H_f + (g/2)\boldsymbol{\sigma} \cdot \mathbf{B}(x).$$

Since $0 \leqslant g \leqslant 1$, under Hypotheses 1, 2, 3, 4, 5, and 6, their ground states exist. We denote a normalized ground state of H_g by $\Omega(g); \|\Omega(g)\| = 1$. Then there exists a subsequence $\{g_j\}_{j=1}^{\infty}$ so that $\tilde{\Omega} := w - \lim_{j \to \infty} \Omega(g_j)$ exists.

Theorem 3.15: *We assume that Hypotheses 1, 2, 3, 4, 5, and 6 hold, and the ground state* $\Omega(0)$ *is a unique ground state of* $H_{g=0}$. *Then* $\tilde{\Omega} = \theta\Omega(0)$, *where* $0 < |\theta| \leqslant 1$.

Proof: It is easily seen that H_g converges to $H_{g=0}$ as $g \to 0$ in the sense of the norm resolvent. Thus $g[H_g] \to g[H_{g=0}]$ as $g \to 0$. We define $\tilde{\mathcal{A}}$, $\tilde{\mathcal{B}}$, and $\tilde{\mathcal{C}}$ by $\mathcal{A}$, $\mathcal{B}$, and $\mathcal{C}$ with F, G, F', G', F'', and G'' replaced by zero, respectively. Let $P = E_{H_p}([\Sigma_0, \Sigma)) \otimes E_{H_f}(\{0\})$. From (3.29) it follows that

$$(\tilde{\Omega}, P\tilde{\Omega}) \geqslant 1 - \left\{ \frac{6er_{-3}(\sqrt{\tilde{\mathcal{A}}(\tilde{\mathcal{B}}+1)/2} + er_{-1}/2)}{1 - 6e^2 r_{-3} r_{-1}} \right\}^2 - \left(\frac{\tilde{\mathcal{C}}}{\Sigma - g[H_{g=0}]} \right)^2 > 0.$$

Hence $\tilde{\Omega} \neq 0$. Then $\tilde{\Omega}$ is a ground state of $H_{g=0}$. Thus, the theorem follows. □

Remark 3.16: In the case of $g > 1$, *taking the coupling constant e sufficiently small, we can see that ground states of* H_g *exists and Theorem 3.15 holds.*

Remark 3.17: In the case of $\Sigma = \infty$, *we do not need Hypotheses 4 and 6 in Theorems 3.14 and 3.15.*

Note added in proof: After the completion of this paper, by V. Bach we have learned that Hypothesis 5 (infrared cutoff) is not needed[25] (cf. Ref. 26).

(Received 4 May 1999; accepted for publication 19 July 1999)

Recently we have presented an ansatz which allows us to construct skyrmion fields from the harmonic maps of S^2 to CP^{N-1}. In this paper we examine this construction in detail and use it to construct, in an explicit form, new static spherically symmetric solutions of the SU(N) Skyrme models. We also discuss some properties of these solutions.
[S0022-2488(99)02612-2]

I. INTRODUCTION

The Skyrme model presents an opportunity to understand nuclear physics as a low energy limit of quantum chromodynamics (QCD). The model was initially proposed as a theory of strong interactions of hadrons,[1] but recently, it was shown to be the low energy limit of QCD in the large N_c limit.[2] Since then further work has suggested that topologically nontrivial solutions of this model, known as skyrmions, can be identified with classical ground states of light nuclei. However, a thorough understanding of the structure and dynamics of multiskyrmion configurations is required before a more qualitative assessment of the validity of this application of the model can be made.

The SU(N) Skyrme model involves fields which take values in SU(N); i.e., are described by SU(N) valued functions of $\vec{x}$ and t. Its static solutions correspond to field configurations describing multiskyrmions. In this paper we construct new solutions for fields whose energy density is spherically symmetric.

Multiskyrmions are stationary points (maxima or saddle points) of the static energy functional, which is given in topological charge units by

$$E=\frac{1}{12\pi^2}\int_{R^3}\left\{-\frac{1}{2}\mathrm{tr}(\partial_i UU^-)^2-\frac{1}{16}\mathrm{tr}[\partial_i UU^{-1},\partial_j UU^{-1}]^2\right\}d^3\vec{x}, \tag{1}$$

where $U(\vec{x})\in \mathrm{SU}(N)$.

In this case multiskyrmions are solutions of the equation

$$\partial_i(\partial_i UU^{-1}-\tfrac{1}{4}[\partial_j UU^{-1},[\partial_j UU^{-1},\partial_i UU^{-1}]])=0. \tag{2}$$

We have, for simplicity, set the mass terms to zero. This has been done for convenience, since the conventional mass terms introduce only small changes and, as we will see later, affect only profile functions. Therefore, all our discussion can be easily generalized to include such mass terms.

a)Electronic mail: T.Ioannidou@ukc.ac.uk
b)Electronic mail: B.M.A.G.Piette@durham.ac.uk
c)Electronic mail: W.J.Zakrzewski@durham.ac.uk

Finiteness of the energy functional requires that $U(\vec{x})$ approaches a constant matrix at spatial infinity, which can be chosen to be the identity matrix by a global SU(N) transformation. So, without any loss of generality, we can impose the following boundary condition on U: $U \to I$ as $|\vec{x}| \to \infty$.

Since $U \to I$ as $|\vec{x}| \to \infty$ is a mapping from $S^3 \to \mathrm{SU}(N)$, it can be classified by the third homotopy group $\pi_3(\mathrm{SU}(N)) \equiv Z$ or, equivalently, by the integer valued winding number

$$B = \frac{1}{24\pi^2} \int_{R^3} \epsilon_{ijk} \operatorname{tr}(\partial_i U U^{-1} \partial_j U U^{-1} \partial_k U U^{-1}) d^3\vec{x}, \tag{3}$$

which is a topological invariant. This winding number classifies the solitonic sectors in the model, and as Skyrme has argued,[1] $B(U)$ may be identified with the baryon number of the field configuration.

Up to now most of the studies involving the Skyrme model have concentrated on the SU(2) version of the model and its embeddings into SU(N). The simplest nontrivial classical *solution* involves a single skyrmion ($B=1$) and has already been discussed by Skyrme.[1] The energy density of this solution is radially symmetric and, as a result, using the so-called hedgehog ansatz one can reduce (2) to an ordinary differential equation, which then has to be solved numerically. Many solutions with $B>1$ of the SU(2) model have also been computed numerically and, in all cases, the solutions are very symmetrical (cf. Battye, and Sutcliffe,[3] and references therein). However, since the model is not integrable, with few exceptions, explicit solutions (even) for spherical symmetric SU(N) skyrmions are not known.

The first example of a *nonembedded* solution for a higher group was the SO(3) soliton, corresponding to a bound system of two skyrmions, which was found by Balachandran *et al.*,[4] Another solution, with a large SU(3) strangeness content, was found by Kopeliovich, Schwesinger, and Stern.[5] However, all other known multiskyrmion configurations seem to be the embeddings of the solutions of the SU(2) model.

Recently, we have shown[6] how to construct low energy states of the SU(N) model by using CP^{N-1} harmonic maps. Our discussion involved only one projector. In this paper, we extend our method to more projectors. We show that, for the SU(N) model, when we take $N-1$ projectors which lead to spherically symmetric energy densities, the full equations of the model separate and the problem of finding exact solutions is reduced to having to solve $N-1$ coupled nonlinear ordinary differential equations for $N-1$ profile functions. This way we obtain a whole family of new spherical symmetric multibaryon solutions of the SU(N) models. Our solutions include the SU(3) dibaryon configuration of Balachandran *et al.*[4] and the nontopological SU(3) four baryon configuration of Ref. 6. Our solutions do not correspond to the global minima of the energy density as the SU(2) embedded solutions with the same baryon number have energies smaller than the energy of the solutions we present here.

II. HARMONIC MAPS

In Ref. 6 we generalized the SU(2) ansatz of Houghton, Manton, and Sutcliffe[7] to SU(N). This generalization involved rewriting the expression of Houghton and co-workers as a projector from S^2 to CP^{N-1}. It gave us a new way of interpreting old results and of deriving expressions for the low energy SU(N) field configurations which are *not* simple embeddings of SU(2) fields. In particular, the energy distributions exhibit very different symmetries from those of the embeddings. The method also gave us a new solution of the SU(3) model, which lies in the topologically trivial sector of the model (i.e., it has zero baryon number) and so, obviously, is not stable.

The method of Ref. 6 can be generalized further, to involve more projectors. In fact, we can exploit here some ideas taken from the theory of harmonic maps of $S^2 \to CP^{N-1}$,[8,9] since they play an important role in our construction.

Recall (cf. Ref. 9) that in N-dimensional space there is a ''natural'' set of projectors: $S^2 \to CP^{N-1}$ maps, which are constructed as follows.

Write each projector P as

$$P(V)=\frac{V\otimes V^{\dagger}}{|V|^{2}}, \tag{4}$$

where V is a N-component complex vector of two variables ξ and $\bar{\xi}$ which locally parameterize S^2. In terms of the more familiar θ and φ, they are given by $\xi=\tan(\theta/2)e^{i\varphi}$. The first projector is obtained by taking $V=f(\xi)$, i.e., an analytic vector of ξ; while the other projectors are obtained from the original V by differentiation and Gramm–Schmidt orthogonalization. If we define an operator P_+ by its action on any vector $v\in C^{N9}$ as

$$P_{+}v=\partial_{\xi}v-v\,\frac{v^{\dagger}\partial_{\xi}v}{|v|^{2}}, \tag{5}$$

then the further vectors $P_+^k v$ can be defined by induction: $P_+^k v=P_+(P_+^{k-1}v)$.

Therefore, in general, we can consider projectors P_k of the form (4) corresponding to the family of vectors $V\equiv V_k=P_+^k f$ [for $f=f(\xi)$] as

$$P_k=P(P_+^k f),\quad k=0,...,N-1, \tag{6}$$

where, due to the orthogonality of the projectors, we have $\Sigma_{k=0}^{N-1}P_k=1$.

The orthogonality properties of our projectors follow from the following properties of vectors $P_+^k f$ which hold when f is holomorphic:

$$(P_+^k f)^{\dagger}P_+^l f=0,\quad k\neq l, \tag{7}$$

$$\partial_{\bar{\xi}}(P_+^k f)=-P_+^{k-1}f\,\frac{|P_+^k f|^2}{|P_+^{k-1}f|^2},\quad \partial_{\xi}\left(\frac{P_+^{k-1}f}{|P_+^{k-1}f|^2}\right)=\frac{P_+^k f}{|P_+^{k-1}f|^2}. \tag{8}$$

Note that, for SU(N), the last projector P_{N-1} in the sequence corresponds to an antianalytic vector; (i.e., the components of $V_{N-1}=P_+^{N-1}f$, up to an irrelevant overall factor which cancels in the projector, are functions of only $\bar{\xi}$).

Our new SU(N) generalisation of Ref. 6 involves the introduction of $N-1$ projectors, i.e.,

$$\begin{aligned}U&=\exp\left\{ig_0\left(P_0-\frac{I}{N}\right)+ig_1\left(P_1-\frac{I}{N}\right)+\cdots+ig_{N-2}\left(P_{N-2}-\frac{I}{N}\right)\right\}\\&=e^{-ig_0/N}(I+A_0P_0)e^{-ig_1/N}(I+A_1P_1)\cdots e^{-ig_{N-2}/N}(I+A_{N-1}P_{N-2}),\end{aligned} \tag{9}$$

where $g_k=g_k(r)$, for $k=0,...,N-2$, are the profile functions and $A_k=e^{ig_k}-1$. Note that the projector P_{N-1} is not included in Eq. (9) since it is the linear combination of the others. (Our previous ansatz given in Ref. 6 corresponds to putting all the profile functions, but the first one, equal to zero.)

The spherically symmetric maps into CP^{N-1} are given by

$$f=(f_0,f_1,\ldots,f_{N-1})^t,$$

where

$$f_k=\xi^k\sqrt{C_{k+1}^{N-1}}, \tag{10}$$

where C_{k+1}^{N-1} denote the binomial coefficients. Furthermore, as we prove in the Appendix, the modulus of the corresponding vector $P_+^k f$ for f of the above-mentioned form is

$$|P_+^k f|^2=\alpha(1+|\xi|^2)^{N-2k-1}, \tag{11}$$

where α depends on N and k.

III. CONSTRUCTING THE SKYRMION SOLUTIONS

In this section we construct a family of exact spherical symmetric solutions of the SU(N) Skyrme models. In fact, we show that for each SU(N) model the Skyrme field involving $N-1$ projectors leads to an exact solution involving $N-1$ profile functions.

A. Skyrme equations

The Skyrme equations (2), when rewritten in spherical coordinates, take the form:

$$\partial_r\left[r^2R_r+\frac{1}{4}\left(A_{\theta r\theta}+\frac{1}{\sin^2\theta}A_{\varphi r\varphi}\right)\right]+\frac{1}{\sin\theta}\partial_\theta\left[\sin\theta\left\{R_\theta+\frac{1}{4}\left(A_{r\theta r}+\frac{1}{r^2\sin^2\theta}A_{\varphi\theta\varphi}\right)\right\}\right]$$
$$+\frac{1}{\sin^2\theta}\partial_\varphi\left[R_\varphi+\frac{1}{4}\left(A_{r\varphi r}+\frac{1}{r^2}A_{\theta\varphi\theta}\right)\right]=0, \tag{12}$$

where $R_i=U^{-1}U_i$ and $A_{\alpha\beta\gamma}\equiv[R_\alpha,[R_\beta,R_\gamma]]$.

It is easy to see, using (9), that

$$R_r=i\sum_{j=0}^{N-2}\dot{g}_j\left(P_j-\frac{I}{N}\right), \tag{13}$$

where $\dot{g}_j(r)$ denotes the derivative of $g_j(r)$ with respect to its argument; and that, in terms of the holomorphic variables ξ and $\bar{\xi}$,

$$\begin{aligned}R_\xi&=\exp\left[\left(-i\sum_{k=0}^{N-2}g_kP_k\right)\right]\partial_\xi\left[\exp\left(i\sum_{i=0}^{N-2}g_iP_i\right)\right]\\&=\left[1+\sum_{k=0}^{N-2}(e^{-ig_k}-1)P_k\right]\left[\sum_{l=0}^{N-2}(e^{ig_l}-1)P_{l\xi}\right]\\&=\sum_{i=1}^{N-1}[e^{i(g_i-g_{i-1})}-1]\frac{V_iV_{i-1}^\dagger}{|V_{i-1}|^2},\end{aligned} \tag{14}$$

where the last line follows from the identity $\exp[(-i\Sigma_{k=0}^{N-2}g_kP_k)]=1+\Sigma_{k=0}^{N-2}(e^{-ig_k}-1)P_k$. Here, $g_{N-1}=0$ and $R_{\bar{\xi}}=-(R_\xi)^\dagger$.

Next we note that

$$\partial_\theta=\frac{1+|\xi|^2}{2\sqrt{|\xi|^2}}(\xi\partial_\xi+\bar{\xi}\partial_{\bar{\xi}}),\quad \partial_\varphi=i(\xi\partial_\xi-\bar{\xi}\partial_{\bar{\xi}}), \tag{15}$$

and rewrite all the terms in (12) in terms of R_ξ, $R_{\bar{\xi}}$, and R_τ and their commutators, i.e.,

$$\partial_\theta(\sin\theta R_\theta)+\frac{1}{\sin\theta}\partial_\phi R_\phi=(1+|\xi|^2)\sqrt{|\xi|^2}((R_\xi)_{\bar{\xi}}+(R_{\bar{\xi}})_\xi), \tag{16}$$

$$A_{\theta r\theta}+\frac{1}{\sin^2\theta}A_{\varphi r\varphi}=\frac{(1+|\xi|^2)^2}{2}\{[R_{\bar{\xi}},[R_r,R_\xi]]+[R_\xi,[R_r,R_{\bar{\xi}}]]\}, \tag{17}$$

$$\sin\theta\partial_\theta(\sin\theta A_{r\theta r})+\partial_\phi(A_{r\varphi r})=2|\xi|^2([R_r,[R_\xi,R_r]]_{\bar{\xi}}+[R_r,[R_{\bar{\xi}},R_r]]_\xi), \tag{18}$$

$$\begin{aligned}\partial_\theta\left(\frac{A_{\varphi\theta\varphi}}{\sin\theta}\right)+\frac{1}{\sin\theta}\partial_\phi(A_{\theta\varphi\theta})=\frac{(1+|\xi|^2)\sqrt{|\xi|^2}}{2}&[\partial_{\bar{\xi}}((1+|\xi|^2)^2[R_\xi,[R_\xi,R_{\bar{\xi}}]])\\&-\partial_\xi((1+|\xi|^2)^2[R_{\bar{\xi}},[R_\xi,R_{\bar{\xi}}]])].\end{aligned} \tag{19}$$

Thus Eq. (12), when rewritten in the holomorphic variables, becomes

$$\partial_r\left[r^2R_r+\frac{(1+|\xi|^2)^2}{8}([R_{\bar\xi},[R_r,R_\xi]]+[R_\xi,[R_r,R_{\bar\xi}]])\right]+\frac{(1+|\xi|^2)^2}{2}((R_{\bar\xi})_\xi+(R_\xi)_{\bar\xi})$$
$$+\frac{(1+|\xi|^2)^3}{8r^2}(\xi[R_\xi,[R_\xi,R_{\bar\xi}]]-\bar\xi[R_{\bar\xi},[R_\xi,R_{\bar\xi}]])+\frac{(1+|\xi|^2)^4}{16r^2}([R_\xi,[R_\xi,R_{\bar\xi}]]_{\bar\xi}$$
$$-[R_{\bar\xi},[R_\xi,R_{\bar\xi}]]_\xi)+\frac{(1+|\xi|^2)^2}{8}([R_r,[R_{\bar\xi},R_r]]_\xi+[R_r,[R_\xi,R_r]]_{\bar\xi})=0. \tag{20}$$

Using (9) we observe that

$$[R_\xi,R_{\bar\xi}]=2P_0\frac{|V_1|^2}{|V_0|^2}(1-\cos(g_1-g_0))-2P_{N-1}\frac{|V_{N-1}|^2}{|V_{N-2}|^2}(1-\cos(g_{N-2}))$$
$$+2\sum_{i=1}^{N-2}P_i\left[\frac{|V_{i+1}|^2}{|V_i|^2}(1-\cos(g_{i+1}-g_i))-\frac{|V_i|^2}{|V_{i-1}|^2}(1-\cos(g_i-g_{i-1}))\right], \tag{21}$$

$$[R_\xi,[R_\xi,R_{\bar\xi}]]=\sum_{i=1}^{N-1}\left(\mu_i\frac{|V_{i+2}|^2}{|V_{i+1}|^2}+\nu_i\frac{|V_{i+1}|^2}{|V_i|^2}+\rho_i\frac{|V_i|^2}{|V_{i-1}|^2}\right)\frac{V_iV_{i-1}^\dagger}{|V_{i-1}|^2}, \tag{22}$$

$$[R_r,[R_{\bar\xi},R_r]]=\sum_{i=1}^{N-1}s_i\frac{V_{i-1}V_i^\dagger}{|V_{i-1}|^2}, \tag{23}$$

where μ, ν, and ρ are functions of $g_k(r)$, only; while s_i are functions of $g_k(r)$ and their derivatives.

Since $V_k=P_+^kf$, one can show that $|V_i|^2/|V_{i-1}|^2\propto(1+|\xi|^2)^{-2}$; while $\partial_\xi(1+|\xi|^2)^{-2}=-2\bar\xi(1+|\xi|^2)^{-3}$ and thus, the derivative terms involving $[R_\xi,[R_\xi,R_{\bar\xi}]]$ in (20) cancel leaving us with derivatives of $V_iV_{i-1}^\dagger/|V_{i-1}|^2$—which are proportional to $\Sigma_{i=1}^{N-1}(1+|\xi|^2)^{-2}(P_i-P_{i-1})h_i$, where h_i involve functions of $g_k(r)$ [due to (8)], multiplied by terms of the form $|V_i|^2/|V_{i-1}|^2$. So the factors $(1+|\xi|^2)^{-4}$ in (20) cancel—leaving us with a sum of differences of two successive projectors multiplied by functions dependent only on r.

Following the above argument and using the properties of R_r, etc., one can show that the terms $[R_r,[R_\xi,R_r]]_{\bar\xi}$ in (20) are proportional to $\Sigma_{i=1}^{N-1}S_i(1+|\xi|^2)^{-2}(P_i-P_{i-1})$, where S_i are functions of $g_k(r)$ and their derivatives—leaving us, once again, with a sum of differences of two successive projectors multiplied by functions dependent only on r.

Finally, the contribution of the terms $(1+|\xi|^2)R_{\xi\bar\xi}$ is given by $\Sigma_{i=1}^{N-1}(P_i-P_{i-1})H_i$, where H_i are only functions of g_k; while the commutators in (17) are equal to a sum of projectors multiplied by $(1+|\xi|^2)^{-2}$, which cancel out in (20). In addition, $\partial_r(r^2R_r)=i\Sigma_{i=0}^{N-2}(P_i-I/N)(2r\dot g_i+r^2\ddot g_i)$.

We note that, for our choice of the vectors V_k, all the dependence on ξ and $\bar\xi$ in (20) resides only in the projectors (the rest of it cancels out). The terms involving $\partial_r(r^2R_r)$ give us expressions involving $I/N-P_i$ while all the other terms give us expressions involving P_i-P_{i-1}. Although N projectors arise in (20), the projector P_{N-1} can be re-expressed in terms of the previous ones—giving $N-1$ factors involving the harmonic maps P_i-I/N (for $i=0,...,N-2$). To satisfy (20) the coefficients of such factors have to vanish leaving us with $N-1$ equations for the $N-1$ profile functions g_i. Hence, if these equations have solutions then they correspond to exact solutions of the SU(N) Skyrme models.

Notice that (10) implies that these solutions have a covariant spherical symmetry. A general rotation of the sphere realized by the Möbius transformation $z\rightarrow\tilde z=(az+b)/(\bar a-\bar bz)$ where $|a|^2+|b|^2=1$. It is easy to show that $\tilde f(z)=[1/(\bar a-\bar bz)^{N-1}]Af$ where A is a matrix depending only on a and b and their complex conjugates. Moreover $|Af(z)|^2=|\tilde{f}(\bar{a}-\bar{b}z)^{N-1}|^2=(|z|^2+1)^{N-1}=|f(z)|^2$ proving that A is an SU(N) matrix and that a rotation of the sphere in R^3 is equivalent to a global gauge transformation on f.

We must now show that $P_+^k f \to A P_+^k f$ under the Möbius transformation. To do this we use the fact that $P_+^k f=(1-P_0-P_1-\cdots-P_{k-1})\partial_z^k f$. As $\tilde{\partial}_z=(\bar{a}-\bar{b}z)^2\partial_z$ we can write

$$\tilde{\partial}_z^k \tilde{f}=(\bar{a}-\bar{b}z)^2\partial_z\left(\frac{Af}{(\bar{a}-\bar{b}z)^k}\right), \tag{24}$$

implying that

$$P_+^k \tilde{f}=(1-\tilde{P}_0-\tilde{P}_1-\cdots-\tilde{P}_{k-1})\frac{1}{(\bar{a}-\bar{b}z)^{N-2k}}A\partial z^k f. \tag{25}$$

By induction, this shows that the P_k all transform under the same unitary conjugation and that the Möbius transformation is equivalent to a global SU (N) gauge transformation on (9).

The $N-1$ equations for the profile functions can be obtained either from (20)—which is a hard task; or from the variation of the energy (1)—using (9) and integrating out ξ and $\bar{\xi}$ variables. Clearly, the two methods give the same equations.

Let us stress that our procedure hinges on having $N-1$ profile functions and on the very special form of our vectors V_k. Had we taken other vectors V_k, we would have obtained some ξ and $\bar{\xi}$ dependence outside the projectors; while had we taken less than $N-1$ profile functions and projectors we would have obtained too many equations for our functions. It is only in the case of $N-1$ projectors that we get the right number of equations.

B. Energy dependence on profile functions

The energy (1), when written in the holomorphic variables, becomes

$$E=-\frac{i}{12\pi^2}\int r^2\,dr\,d\xi\,d\bar{\xi}\,tr\left(\frac{1}{(1+|\xi|^2)^2}R_r^2+\frac{1}{r^2}|R_\xi|^2+\frac{1}{4r^2}[R_r,R_\xi][R_r,R_{\bar{\xi}}]-\frac{(1+|\xi|^2)^2}{16r^4}[R_{\bar{\xi}},R_\xi]^2\right). \tag{26}$$

Using (13) and (14) we find that

$$\mathrm{tr}\,R_r^2=\frac{1}{N}\left(\sum_{i=0}^{N-2}\dot{g}_i\right)^2-\sum_{i=0}^{N-2}\dot{g}_i^2, \tag{27}$$

$$\mathrm{tr}|R_\xi|^2=-2\sum_{i=1}^{N-1}B_i, \tag{28}$$

$$\mathrm{tr}([R_r,R_\xi][R_r,R_{\bar{\xi}}])=-2\sum_{k=1}^{N-1}B_k(\dot{g}_k-\dot{g}_{k-1})^2, \tag{29}$$

$$\mathrm{tr}[R_{\bar{\xi}},R_\xi]^2=4\left(B_1^2+\sum_{i=1}^{N-2}(B_i-B_{i+1})^2+B_{N-1}^2\right), \tag{30}$$

where $B_i=|V_i|^2/|V_{i-1}|^2(1-\cos(g_i-g_{i-1}))$ and $[R_{\bar{\xi}},R_\xi]=2\Sigma_{l=1}^{N-1}(P_{l-1}-P_l)B_l$.

Since $|V_k|^2/|V_{k-1}|^2=k(N-k)(1+|\xi|^2)^{-2}$ (see the Appendix) all terms in (26) have a factor $(1+|\xi|^2)^{-2}$ and the integration over ξ and $\bar{\xi}$ is a topological constant, i.e., $i\int d\xi\, d\bar{\xi}(1+|\xi|^2)^{-2}=2\pi$. Thus we get

$$E=\frac{1}{6\pi}\int r^2\,dr\Bigg\{-\frac{1}{N}\left(\sum_{i=0}^{N-2}\dot{g}_i\right)^2+\sum_{i=0}^{N-2}\dot{g}_i^2+\frac{1}{2r^2}\sum_{k=1}^{N-1}(\dot{g}_k-\dot{g}_{k-1})^2D_k$$
$$+\frac{2}{r^2}\sum_{k=1}^{N-1}D_k+\frac{1}{4r^4}\left(D_1^2+\sum_{k=1}^{N-2}(D_k-D_{k+1})^2+D_{N-1}^2\right)\Bigg\}, \tag{31}$$

where $D_k=k(N-k)(1-\cos(g_k-g_{k-1}))$.

Let us, for simplicity, take $F_k=g_k-g_{k+1},(k=0,...,N-2)$ with $F_{N-2}=g_{N-2}$. Then, the variation of the integrand of the energy $\tilde{E}$ with respect to the functions $\dot{F}_l$ (for $l=0,...,N-2$) is

$$\frac{\partial\tilde{E}}{\partial\dot{F}_l}=\left[-\frac{2(l+1)}{N}\sum_{i=0}^{N-2}(i+1)\dot{F}_i+2\sum_{k=0}^{l}\left(\sum_{i=k}^{N-2}\dot{F}_i\right)+\frac{1}{r^2}\dot{F}_lD_{l+1}\right]r^2, \tag{32}$$

where $D_k=k(N-k)(1-\cos F_{k-1})$.

Therefore, the equations of motion for the functions F_i, and thus for the profile functions, are

$$-\frac{2(l+1)}{N}\sum_{i=0}^{N-2}(i+1)\ddot{F}_i+2\sum_{k=0}^{l}\sum_{i=k}^{N-2}\ddot{F}_i+\frac{1}{r^2}\ddot{F}_l(l+1)(N-l-1)(1-\cos F_l)$$
$$+\frac{1}{2r^2}\dot{F}_l^2(l+1)(N-l-1)\sin F_l+\frac{2}{r}\left(-\frac{2(l+1)}{N}\sum_{i=0}^{N-2}(i+1)\dot{F}_i+2\sum_{k=0}^{l}\left(\sum_{i=k}^{N-2}\dot{F}_i\right)\right)$$
$$-\frac{2}{r^2}(l+1)(N-l-1)\sin F_l-\frac{1}{r^4}(l+1)^2(N-l-1)^2(1-\cos F_l)\sin F_l$$
$$+\frac{1}{2r^4}(l+1)(N-l-1)\sin F_l[l(N-l)(1-\cos F_{l-1})$$
$$+(l+2)(N-l-2)(1-\cos F_{l+1})]=0. \tag{33}$$

Equation (33) can be solved numerically by imposing the appropriate boundary conditions on the profile functions. To do this we have to specialize to a particular model, i.e., for specific N and diagonalize the terms involving the second derivatives. The simplest cases: $N=2$, $N=3$, and $N=4$ involve 1, 2, or 3 functions and will be discussed in the next sections.

IV. TOPOLOGICAL PROPERTIES AND SYMMETRIES

Before we discuss special cases, let us first investigate the general topological properties of our fields.

The topological charge (3), which in many applications of the Skyrme model is identified with the baryon number, is given by

$$B=\frac{1}{8\pi^2}\int dr\,d\xi\,d\bar{\xi}\,\mathrm{tr}(R_r[R_{\bar{\xi}},R_\xi]), \tag{34}$$

when written in the complex coordinates.

Due to (21) and (13) the terms involving $\dot{g}_i/N$ in R_r after taking the trace cancel and the expression for the baryon number simplifies to

$$B=-\frac{i}{4\pi^2}\int dr\,d\xi\,d\bar{\xi}\sum_{i=0}^{N-2}\dot{F}_i(1-\cos F_i)\frac{|V_{i+1}|^2}{|V_i|^2}$$
$$=\frac{1}{2\pi}\int dr\sum_{i=0}^{N-2}\dot{F}_i(1-\cos F_i)(i+1)(N-i-1)$$
$$=\frac{1}{2\pi}\sum_{i=0}^{N-2}(i+1)(N-i-1)(F_i-\sin F_i)_{r=0}^{r=\infty}. \tag{35}$$

As $g_i(\infty)=0$ (required for the finiteness of the energy) the only contributions to the topological charge come from $F_i(0)$.

The $N-1$ equations for the profile functions and their differences given in (33) have many symmetries. These symmetries can be used to derive special skyrmion solutions which involve a smaller number of profile functions and projectors.

The main symmetry of our expressions, are the independent interchanges

$$F_k\leftrightarrow F_{N-k-2} \quad \text{for } k=0,...,N-2. \tag{36}$$

This symmetry follows from the fact the terms $D_k=k(N-k)(1-\cos F_{k-1})$ which appear in the energy are symmetric under the interchange: $D_k\leftrightarrow D_{N-k}$ when $F_{k-1}\leftrightarrow F_{N-k-1}$. In addition, all the other terms in the energy also exhibit this symmetry since they are combinations of F_i and their derivatives.

V. SPHERICAL SKYRMIONS

The simplest case corresponds to the SU (2) spherically symmetric skyrmion. This is the solution which was found 30 years ago by Skyrme and is usually presented in terms of the well-known hedgehog ansatz.

A. SU (3) Skyrme model

In this case $N=3$ and we have two functions: F_0 and F_1. The energy density $\mathcal{E}$, such that $E=(6\pi)^{-1}\int\mathcal{E}r^2\,dr$, is given by

$$\mathcal{E}=\frac{2}{3}(\dot{F}_0^2+\dot{F}_1^2+\dot{F}_0\dot{F}_1)+\frac{1}{r^2}[(\dot{F}_0^2+4)(1-\cos F_0)+(\dot{F}_1^2+4)(1-\cos F_1)]$$
$$+\frac{2}{r^4}[(1-\cos F_0)^2-(1-\cos F_0)(1-\cos F_1)+(1-\cos F_1)^2], \tag{37}$$

and the equations for the profile functions are

$$\ddot{F}_0\left(1+\frac{3}{2r^2}(1-\cos F_0)\right)+\frac{\ddot{F}_1}{2}+\frac{2\dot{F}_0+\dot{F}_1}{r}+\frac{3\sin F_0}{4r^2}\left[\dot{F}_0^2-4-\frac{4(1-\cos F_0)}{r^2}+\frac{2(1-\cos F_1)}{r^2}\right]=0,$$
$$\ddot{F}_1\left(1+\frac{3}{2r^2}(1-\cos F_1)\right)+\frac{\ddot{F}_0}{2}+\frac{2\dot{F}_1+\dot{F}_0}{r}+\frac{3\sin F_1}{4r^2}\left[\dot{F}_1^2-4-\frac{4(1-\cos F_1)}{r^2}+\frac{2(1-\cos F_0)}{r^2}\right]=0. \tag{38}$$

These equations can be solved numerically when the right boundary conditions have been imposed.

However, by letting $F_0=F_1=F$ (i.e., using the symmetry) they reduce to

$$\ddot{F}\left(1+\frac{1-\cos F}{r^2}\right)+\frac{2\dot{F}}{r}+\frac{\sin F}{2r^2}\left[\dot{F}^2-4-\frac{2(1-\cos F)}{r^2}\right]=0. \tag{39}$$

Equation (39) coincides with the equation for the profile function of a single SU (2) skyrmion. Here we note that as $F_0(0)=F_1(0)=2\pi$ the topological charge of our solution is four. Thus the energy of this configuration, which corresponds to four skyrmions is $E_{B=4}=4\times 1.232$, i.e., is exactly four times the energy of one skyrmion. We see that we have a static solution corresponding to four noninteracting skyrmions, placed on top of each other in such a way that their energy density is spherically symmetric.

In addition, there is a further symmetry which allows us to set $F_0=-F_1=G$. In this case the equations reduce to

$$\ddot{G}\left(\frac{1}{2}+\frac{3}{2r^2}(1-\cos G)\right)+\frac{\dot{G}}{r}+\frac{3\sin G}{4r^2}\left[\dot{G}^2-4-\frac{2(1\text{-}\cos G)}{r^2}\right]=0. \tag{40}$$

Let us note that, since $F_0=g_0-g_1$ and $F_1=g_1$, this case corresponds to $g_0=0$ and thus, the field (9) involves only one projector, namely P_1. This solution is the topologically trivial solution discussed in Ref. 6 and its energy is 3.861.

Finally, the Balachandran *et al.* skyrmion solution can be obtained from (38) by imposing the following boundary conditions: $g_0(0)=2\pi$, $g_1(0)=0$, and $g_0(\infty)=0$, $g_1(\infty)=0$; its energy is $E_{B=2}=2.3764$.

B. SU (4) Skyrme model

In this case the energy density becomes

$$\begin{aligned}\mathcal{E}=&\frac{1}{4}(3\dot{F}_0^2+4\dot{F}_1^2+3\dot{F}_2^2+4\dot{F}_0\dot{F}_1+4\dot{F}_1\dot{F}_2+2\dot{F}_0\dot{F}_2)+\frac{1}{2r^2}[3(\dot{F}_0^2+4)(1-\cos F_0)\\&+4(\dot{F}_1^2+4)(1-\cos F_1)+3(\dot{F}_2^2+4)(1-\cos F_2)]+\frac{1}{2r^4}\{9(1-\cos F_0)^2+16(1-\cos F_1)^2\\&+9(1-\cos F_2)^2-12(1-\cos F_0)(1-\cos F_1)-12(1-\cos F_1)(1-\cos F_2)\},\end{aligned} \tag{41}$$

while the equations for F_0, F_1, and F_2 are more complicated:

$$\begin{aligned}&\ddot{F}_0\left(1+\frac{2(1-\cos F_0)}{r^2}\right)+\frac{2\ddot{F}_1+\ddot{F}_2}{3}+\frac{3\dot{F}_0+4\dot{F}_1+2\dot{F}_2}{3r}\\&\quad+\frac{\sin F_0}{r^2}\left[\dot{F}_0^2-4-\frac{6(1-\cos F_0)}{r^2}+\frac{4(1-\cos F_1)}{r^2}\right]=0,\\&\ddot{F}_1\left(1+\frac{2(1-\cos F_1)}{r^2}\right)+\frac{\ddot{F}_0+\ddot{F}_2}{2}+\frac{2\dot{F}_1+\dot{F}_0+\dot{F}_2}{r}\\&\quad+\frac{\sin F_1}{r^2}\left[\dot{F}_1^2-4-\frac{8(1-\cos F_1)}{r^2}+\frac{3(1-\cos F_0)}{r^2}+\frac{3(1-\cos F_2)}{r^2}\right]=0,\\&\ddot{F}_2\left(1+\frac{2(1-\cos F_2)}{r^2}\right)+\frac{\ddot{F}_0+2\ddot{F}_1}{3}+\frac{6\dot{F}_2+2\dot{F}_0+4\dot{F}_1}{3r}\\&\quad+\frac{\sin F_2}{r^2}\left[\dot{F}_2^2-4-\frac{6(1-\cos F_2)}{r^2}+\frac{4(1-\cos F_1)}{r^2}\right]=0.\end{aligned} \tag{42}$$

These equations have the previously mentioned symmetry $F_k \leftrightarrow F_{N-k-2}$, which allows us to set $F_0 = F_2$ by keeping F_1 arbitrary.

In addition, letting $F_0 = F_1 = F_2 = F$ the above-mentioned system reduces to Eq. (39) and therefore, the configuration which consists of ten skyrmions (as $B = [3F_0(0) + 4F_1(0) + 3F_2(0)]/2\pi = 10$) is $E_{B=10} = 10 \times 1.232$, i.e., is exactly ten times the energy of one skyrmion. Once again we have a solution describing many skyrmions, which are noninteracting and whose energy density is spherically symmetric.

In addition, letting $F_0 = -F_2 = G$ we spot that when $F_1 = 0$, we have a solution of the form

$$\ddot{G}\left(1 + \frac{3(1-\cos G)}{r^2}\right) + \frac{2\dot{G}}{r} + \frac{3\sin G}{2r^2}\left[\dot{G}^2 - 4 - \frac{6(1-\cos G)}{r^2}\right] = 0, \tag{43}$$

which corresponds to a nontopological solution, i.e., its baryon number is zero; however, the corresponding configuration consists of three skyrmions and three antiskyrmions. [Recall that the profile functions are $g_0 = 0$ and $g_1 = g_2$, i.e., the field (9) involves only one projector of rank two—namely $P_1 + P_2$.]

In general, however, the solutions depend on more functions. We can always assume that the functions F_i go to zero at infinity, so the topological charge of a solution is determined, using (35), by the boundary value of each F_i at the origin. When each of these values is positive the solution is a mixture of skyrmions. When some F_i's take positive and some F_i's take negative values at the origin the solution corresponds to a mixture of skyrmions and antiskyrmions. This is very similar to what happens in the two-dimensional Grasmannian sigma model.[8]

We have solved numerically Eq. (42) taking all combinations, modulo the exchange of F_0 and F_2, of 0, 2π, and -2π for the value of F_i at the origin. The results are summarized as follows.

$F_0(0)$	$F_1(0)$	$F_2(0)$	B	Energy	E/baryon	SU(2) En
2π	0	0	3	3.518	1.173	3.429
0	2π	0	4	4.788	1.197	4.464
2π	0	2π	6	7.225 53	1.204	6.654
2π	2π	0	7	8.452 19	1.207	7.7693
2π	2π	2π	10	12.32	1.232	⋯
2π	-2π	2π	6-4	8.852	0.8852	⋯
2π	2π	-2π	7-3	9.896	0.9896	⋯
2π	0	-2π	3-3	6.634 22	1.106	⋯
-2π	2π	0	4-3	6.614 78	0.945	⋯

The first five solutions are bound states of skyrmions with energies larger than the energies of the corresponding SU (2) solutions.[3] Moreover, the excitation energy of the first two solutions is very small. As previously mentioned, the energy of the $B = 10$ solution is exactly ten times the energy of a single skyrmion solution. These solutions are all spherically symmetric and thus they are all more symmetrical than the corresponding SU (2) solutions.

The last four solutions are bound states of skyrmions and antiskyrmions. Although their energies are very small, we know that these solutions must be unstable.

VI. CONCLUSIONS

In this paper we have shown how to construct radially symmetric solutions of the SU (N) Skyrme models. In the general case these solutions depend on $N-1$ profile functions which have to be determined numerically. In some cases we can exploit symmetries of our expressions and reduce the number of functions. Thus in the case of SU (3) we can recover the topologically trivial solution discussed in Ref. 6.

We have not discussed the derived solutions in much detail. Their properties and their relation to physics deserve further study and these topics are currently under investigation.

ACKNOWLEDGMENT

We thank C. Houghton, V. Kopeliovich, and P. Sutcliffe for their interest.

APPENDIX: MODULUS OF $|P^k{}_+ f|^2$

Here we prove Eq. (11) for f given by (10). This result can be proved by induction. Note that, the modulus of the N-dimensional vector f is $|f|^2=(1+|\xi|^2)^{N-1}$ and therefore, $|P_+f|^2|f|^2=|f|^2|\partial_+ f|^2-|f^\dagger\partial_+ f|^2=(N-1)(1+|\xi|^2)^{N-3}|f|^2$, therefore, $|P_+f|^2=(N-1)(1+|\xi|^2)^{N-3}$.

As

$$P_+^{k+1}f=\partial_\xi P_+^k f-P_+^k f\,\frac{(P_+^k f)^\dagger\partial_\xi P_+^k f}{|P_+^k f|^2}, \tag{A1}$$

using (8) we get

$$|P_+^{k+1}f|^2|P_+^k f|^2=|\partial_\xi P_+^k f|^2|P_+^k f|^2-|\partial_\xi|P_+^k f|^2|^2, \tag{A2}$$

$$\partial_\xi\partial_{\bar\xi}|P_+^k f|^2=|\partial_\xi P_+^k f|^2+(P_+^k f)^\dagger\partial_{\bar\xi}\partial_\xi P_+^k f, \tag{A3}$$

$$(P_+^k f)^\dagger\partial_\xi\partial_{\bar\xi}(P_+^k f)=-(P_+^k f)^\dagger\partial_\xi(P_+^{k-1}f)\,\frac{|P_+^k f|^2}{|P_+^{k-1}f|^2}=-\frac{|P_+^k f|^4}{|P_+^{k-1}f|^2}, \tag{A4}$$

which finally, leads to

$$|P_+^{k+1}f|^2=\partial_\xi\partial_{\bar\xi}|P_+^k f|^2+\frac{|P_+^k f|^4}{|P_+^{k-1}f|^2}-\frac{|\partial_\xi|P_+^k f|^2|^2}{|P_+^k f|^2}. \tag{A5}$$

Therefore if $|P_+^k f|^2=\alpha(1+|\xi|^2)^{N-2k-1}$ and $|P_+^{k-1}f|^2=\beta(1+|\xi|^2)^{N-2k\pm1}$ then

$$|P_+^{k+1}f|^2=\gamma(1+|\xi|^2)^{N-2k-3}, \tag{A6}$$

where $\gamma=\alpha(N-2k-1)+\alpha^2/\beta$. To find γ we again use induction, recalling that the coefficients of the two lowest terms in the sequence are 1 and $N-1$, respectively. Then it is easily seen that

$$|P_+^k f|^2=k!(N-1)(N-2)\cdots(N-k)(1+|\xi|^2)^{N-2k-1}, \tag{A7}$$

in which the last term in the sequence corresponds to $k=N-1$.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 40, NUMBER 12 DECEMBER 1999

Two algebraic properties of thermal quantum field theories

Christian D. Jäkel[a)]
Dipartimento di Matematica, Via della Ricerca Scientifica, Università di Roma ''Tor Vergata,'' I-00133 Roma, Italy

(Received 26 April 1999; accepted for publication 23 August 1999)

We establish the Schlieder and the Borchers property for thermal field theories. In addition, we provide some information on the commutation and localization properties of projection operators.
[S0022-2488(99)00312-6]

I. INTRODUCTION

Recently, the author has explored the general structure of thermal field theories in some detail. Here we would like to fill in a gap which concerns two basic results, namely, the Borchers and the Schlieder property. Both results will look familiar to the experts and even the proofs which we will present here are more or less standard (see, e.g., Ref. 1 for a convenient collection of the corresponding results in the vacuum sector). However, a close inspection shows that the fundamental differences between thermal and vacuum QFT are clearly reflected in slightly different assumptions and consequences. For completeness we add a list of properties (due to Florig and Summers[2]) which are all equivalent to the Schlieder property.

In the algebraic formulation (as described in the monograph by Haag)[3] a QFT is cast into an inclusion preserving map

$$\mathcal{O} \rightarrow \mathcal{A}(\mathcal{O}) \tag{1}$$

which assigns to any open bounded region $\mathcal{O}$ in Minkowski space $\mathbb{R}^4$ a unital C^*-algebra $\mathcal{A}(\mathcal{O})$. The Hermitian elements of the *abstract* C^*-algebra $\mathcal{A}(\mathcal{O})$ are interpreted as the observables which can be measured at times and locations in $\mathcal{O}$. The physical states are described by positive, linear, and normalized functionals. By the GNS-construction, any state ω on $\mathcal{A}$ gives rise to a Hilbert space $\mathcal{H}_\omega$ and a representation π_ω together with a cyclic vector Ω_ω, such that

$$\omega(a) = (\Omega_\omega, \pi_\omega(a)\Omega_\omega) \quad \forall a \in \mathcal{A} = \overline{\bigcup_{\mathcal{O}\subset \mathbb{R}^4} \mathcal{A}(\mathcal{O})}^{C^*}. \tag{2}$$

The representation π_ω automatically determines the values of certain macroscopic observables in all states, which are normal (A linear functional on $\mathcal{A}$ is said to be normal relative to π_ω, if it is continuous with respect to the ultraweak topology determined by π_ω. Since normal states differ only locally from ω, various global physical situations will manifest themselves in unitarily inequivalent GNS-representations.) w.r.t. π_ω (these are exactly those states which can be specified by density matrices $\rho \in \mathcal{B}(\mathcal{H}_\omega)$, $\rho > 0$, $\mathrm{Tr}\rho = 1$). Thus a state is specified macroscopically by a representation and microscopically by a density matrix.

The relevant states describing thermal equilibrium, the so-called KMS-states, will soon be distinguished within the set of all time-invariant normalized, positive linear functionals of $\mathcal{A}$ by their stability properties with respect to timelike translations. Since the associated GNS-representations will allow a unitary implementation of the time-evolution, we will take advantage

of it and formulate our problems in the better developed Hilbert space setting. But before we do so, we should mention that the net $\mathcal{O}\to\mathcal{A}(\mathcal{O})$ satisfies a number of properties which do not depend on the representation:

(i) The net $\mathcal{O}\to\mathcal{A}(\mathcal{O})$ is isotonous, i.e., there exists a unital embedding

$$\mathcal{A}(\mathcal{O}_1)\hookrightarrow\mathcal{A}(\mathcal{O}_2) \qquad \text{if} \quad \mathcal{O}_1\subset\mathcal{O}_2. \tag{3}$$

This property, called isotony, allows us to consider the quasilocal algebra $\mathcal{A}$ which is defined in (2) as the C^*-inductive limit of the local algebras. The elements of $\mathcal{A}$ are called quasilocal observables; they can be approximated in norm topology by strictly local elements; the total energy, total charge, etc., are considered as unobservable; these quantities refer to infinitely extended regions and cannot be controlled by local measurements.

(ii) Observables localized in spacelike separated space–time regions commute,

$$\mathcal{A}(\mathcal{O}_1)\subset\mathcal{A}^c(\mathcal{O}_2) \qquad \text{if} \quad \mathcal{O}_1\subset\mathcal{O}_2'. \tag{4}$$

Here $\mathcal{O}'$ denotes the spacelike complement of $\mathcal{O}$ and $\mathcal{A}^c(\mathcal{O})$ denotes the set of operators in $\mathcal{A}$ which commute with all operators in $\mathcal{A}(\mathcal{O})$.

(iii) The space–time symmetry of Minkowski space manifests itself in the existence of a representation

$$\alpha:(\Lambda,x)\mapsto\alpha_{\Lambda,x}\in\mathrm{Aut}(\mathcal{A}), \quad (\Lambda,x)\in\mathcal{P}_+^\uparrow, \tag{5}$$

of the (orthochronous) Poincaré group $\mathcal{P}_+^\uparrow$. Lorentz-transformations Λ and space–time translations x act geometrically,

$$\alpha_{\Lambda,x}(\mathcal{A}(\mathcal{O}))=\mathcal{A}(\Lambda\mathcal{O}+x) \quad \forall(\Lambda,x)\in\mathcal{P}_+^\uparrow. \tag{6}$$

For the present letter we may restrict our list of assumptions to include only the (strongly continuous) one-parameter subgroup of time-translations $\tau:\mathbb{R}\to\mathrm{Aut}(\mathcal{A})$. Of course, it acts geometrically, i.e.,

$$\tau_t(\mathcal{A}(\mathcal{O}))=\mathcal{A}(\mathcal{O}+te) \quad \forall t\in\mathbb{R}. \tag{7}$$

Here e is a unit vector denoting the time direction with respect to a given Lorentz-frame.

Remark: Let $h\in L^1(\mathbb{R},dt)$ such that the Fourier-transform $\tilde{h}$ of h has compact support. If the group of automorphisms $\tau:\mathbb{R}\to\mathrm{Aut}(\mathcal{A})$ is strongly continuous, then the Bochner integral

$$a_h=\int dt\,h(x)\,\tau_t(a), \quad a\in\mathcal{A}, \tag{8}$$

exists in $\mathcal{A}$ and defines an entire analytic element for the time-translations. Recall that $b\in\mathcal{A}$ is called an analytic element for the group τ, if there exists some $\lambda>0$, a strip $S(-\lambda,\lambda):=\{z\in\mathbb{C}:|\mathfrak{J}z|<\lambda\}$ and a function $g:S(-\lambda,\lambda)\to\mathcal{A}$ such that

(a) $g(t)=\tau_t(b)$ for all $t\in\mathbb{R}$;

(b) $z\mapsto\omega(g(z))$ is analytic for all states ω over $\mathcal{A}$.

An analytic element is called entire analytic, if $\lambda=\infty$; i.e., $S(-\lambda,\lambda)=\mathbb{C}$. $\mathcal{A}_\tau$ will denote the set of entire analytic elements for the group τ.

We now turn to thermal equilibrium states. Kubo[4] and subsequently Martin and Schwinger[5] found out that the Green's functions of finite-volume Gibbs-states satisfy an auxiliary boundary condition in the complex plane with respect to the time-evolution. The crucial step was to recognize that the so-called KMS-condition not only characterizes the finite-volume Gibbs-states but remains valid in the thermodynamic limit.[6] Nowadays, the KMS-condition is commonly accepted as the appropriate criterion for equilibrium of finite and infinite systems. However, only recently Buchholz and Junglas have shown that a large class of relativistic models admits KMS-states.[7]

Definition: A state ω_β over $\mathcal{A}$ is called a (τ, β)-KMS-state for some $\beta\in\mathbb{R}\cup\{\pm\infty\}$, if

$$\omega_\beta(a\,\tau_{i\beta}(b))=\omega_\beta(ba) \tag{9}$$

for all a, b in a norm dense, τ-invariant*-subalgebra of $\mathcal{A}_\tau$.

The GNS-representation $(\pi_\beta, \mathcal{H}_\beta, \Omega_\beta)$ of the net $\mathcal{O} \to \mathcal{A}(\mathcal{O})$ associated with a KMS-state ω_β assigns to any $\mathcal{O} \subset \mathbb{R}^4$ a von Neumann algebra

$$\mathcal{R}_\beta(\mathcal{O}) = \pi_\beta(\mathcal{A}(\mathcal{O}))''. \tag{10}$$

$\mathcal{R}_\beta := \pi_\beta(\mathcal{A})''$ possesses a cyclic (due to the GNS-construction) and separating (due to the KMS-condition) vector, namely, Ω_β.

The general analysis of KMS-states (see, e.g., Ref. 8) extends a number of results well known in classical ergodic theory to the noncommutative case. For instance, the set of KMS-states for any fixed $\beta > 0$ is a weak-* compact, convex set. In fact, an arbitrary KMS-state can be represented in a unique manner as a convex superposition of extremal KMS-states. (A KMS-state is called extremal, if it cannot be decomposed into other KMS-states.) Moreover, KMS-states can be distinguished within the set of all (physical) states from first principles. In a number of pioneering articles it has been demonstrated that the extremal KMS-states of an infinitely extended medium change continuously as the Hamiltonian is perturbed slightly. This condition characterizes the extremal KMS-states; they are precisely those states which are distinguished among (possible other) stationary states by the fact that they turn continuously into the unperturbed states as a certain family of perturbations tends to zero.[9,10] The same condition may also be interpreted as an adiabatic invariance.[11] Extremal KMS-states return to their original form at the end of a procedure in which the dynamical law is changed by a local perturbation which is slowly switched on and, as $t \to \infty$ slowly switched off again. A further important characteristic of KMS-states is their passivity,[12] which is the requirement that the energy of the system at time t can only have increased if the Hamiltonian depends on the time and has returned to its initial form at time t. This condition is just the second law of thermodynamics; it fixes the sign of β and means that no energy can be removed from a KMS-state having $\beta > 0$, just as a periodic process can extract no energy from the ground state.

Although the representation independent aspects of the map $\mathcal{O} \to \mathcal{A}(\mathcal{O})$ clearly deserve attention [it seems that the abstract operator algebraic formulation is inevitable for the description of nonequilibrium situations in which also the macroscopic observables (e.g., the specific heat, the mean magnetization, etc.) will change in the course of time], we will now specify our results and assumptions in the more restrictive Hilbert space framework. To be precise, in the remainder of this letter we will consider a thermal field theory (TFT), specified by a von Neumann algebra $\mathcal{R}_\beta$ with a cyclic and separating vector Ω_β and a net of subalgebras

$$\mathcal{O} \to \mathcal{R}_\beta(\mathcal{O}) \tag{11}$$

subject to the following conditions:

(i) The subalgebras associated with spacelike separated space–time regions commute, i.e.,
$$\mathcal{R}_\beta(\mathcal{O}_1) \subset \mathcal{R}_\beta(\mathcal{O}_2)' \qquad \text{if} \quad \mathcal{O}_1 \subset \mathcal{O}_2'. \tag{12}$$
Note that $\mathcal{R}_\beta(\mathcal{O})'$ denotes the commutant of $\mathcal{R}_\beta(\mathcal{O})$ in $\mathcal{B}(\mathcal{H}_\beta)$; i.e., $\mathcal{R}_\beta(\mathcal{O})'$ includes both $\mathcal{R}_\beta'$ and $\mathcal{R}_\beta(\mathcal{O}')$ as subalgebras.

(ii) The time-evolution is unitarily implemented by the modular group $t \mapsto \Delta^{it}$ (see, e.g., Ref. 8) associated with the pair $(\mathcal{R}_\beta, \Omega_\beta)$, i.e.,
$$\Delta = e^{-\beta H_\beta} \quad \text{and} \quad \Delta^{-it/\beta} \mathcal{R}_\beta(\mathcal{O}) \Delta^{it/\beta} = \mathcal{R}_\beta(\mathcal{O} + te) \quad \forall t \in \mathbb{R}. \tag{13}$$
Here H_β denotes the generator of the time-evolution and e is the unit vector denoting the time direction w.r.t. the distinguished rest frame.

(iii) $\mathcal{H}_\beta$ is separable and Ω_β is the unique—up to a phase—time-invariant vector in $\mathcal{H}_\beta$.

(iv) Ω_β is cyclic for $\mathcal{R}_\beta(\mathcal{O})$, where $\mathcal{O}$ is any open subset of $\mathbb{R}^4$, i.e.,
$$\overline{\mathcal{R}_\beta(\mathcal{O}) \Omega_\beta} = \mathcal{H}_\beta. \tag{14}$$
Ω_β shares the "Reeh–Schlieder property" (14) with the following dense set of vectors,
$$\mathcal{D}_\tau = \{ \Psi = \pi_\beta(a) \Omega_\beta \in \mathcal{H}_\beta : a, a^{-1} \in \mathcal{A}_\tau \} \subset \mathcal{R}_\beta \Omega_\beta. \tag{15}$$

We will show that under these assumptions the following statements are valid:

(i) (Schlieder property). Given two open space–time regions $\mathcal{O}$, $\hat{\mathcal{O}}$ and some $\delta > 0$ such that

$$\mathcal{O} + te \subset \mathcal{O} \qquad \text{for} \quad |t| < \delta, \tag{16}$$

the Schlieder property holds for the algebras $\mathcal{R}_\beta(\mathcal{O})$ and $\mathcal{R}_\beta(\hat{\mathcal{O}})'$. (Recall that a pair of von Neumann algebras $\mathcal{M}$ and $\mathcal{N}$ satisfies the Schlieder property iff $0 \neq M \in \mathcal{M}$ and $0 \neq N \in \mathcal{N}$ implies that $MN \neq 0$.)

(ii) (Borchers property; also called Property B). Given a nonzero projection operator $E \in \mathcal{R}_\beta(\mathcal{O})$, where $\mathcal{O} \subset \mathbb{R}^4$ is bounded, there exists a partial isometry V in the von Neumann algebra $\mathcal{R}_\beta(\hat{\mathcal{O}})$, associated with a slightly larger region $\hat{\mathcal{O}}$, such that $V^*V = \mathbb{1}$ and $VV^* = E$. One writes

$$E \sim \mathbb{1}_{\mathrm{mod}\, \mathcal{R}_\beta(\mathcal{O})}. \tag{17}$$

Recall that a factor $\mathcal{M}$ is called type III, if $E \sim \mathbb{1}_{\mathrm{mod}\mathcal{M}}$ for all self-adjoint projections $E \in \mathcal{M}$. Thus $\mathcal{R}_\beta(\mathcal{O})$ is ''almost'' a factor of type III.

Remark: If the pair $(\mathcal{A}, \tau)$ is asymptotically Abelian in time, i.e.,

$$\lim_{t \to \infty} \| [a, \tau_t(b)] \| = 0 \quad \forall a, b \in \mathcal{A} \tag{18}$$

and ω_β is an extremal KMS state, then Ω_β is the unique—up to a phase—time-invariant vector in $\mathcal{H}_\beta$. The Reeh–Schlieder property (iv) can be derived from the relativistic KMS-condition[13] provided the net $\mathcal{O} \to \mathcal{R}_\beta(\mathcal{O})$ satisfies additivity.[14] [The net $\mathcal{O} \to \mathcal{R}_\beta(\mathcal{O})$ is called additive if $\cup_i \mathcal{O}_i = \mathcal{O} \Rightarrow \vee_i \mathcal{R}_\beta(\mathcal{O}_i) = \mathcal{R}_\beta(\mathcal{O})$. Here $\mathcal{R}_1 \vee \mathcal{R}_2$ denotes the von Neumann algebra generated by the algebras $\mathcal{R}_1$ and $\mathcal{R}_2$.] Junglas[15] has shown that the Reeh–Schlieder property of Ω_β also follows from the standard KMS-condition, if ω_β is locally normal w.r.t. the vacuum representation. Note that we do *not* require that there exists a group of unitary operators in $\mathcal{B}(\mathcal{H}_\beta)$ which implements spacelike translations, since spatial translation invariance may be spontaneously broken in a KMS-state.

II. TWO BASIC PROPERTIES OF TFTs

We start with the analogon of a result of Borchers (see Ref. 16).

Lemma II.1: Let $E \in \mathcal{R}_\beta$, $\|E\| = 1$ *and let* $F = F^* = F^2 \in \mathcal{B}(\mathcal{H}_\beta)$ *be a projection operator such that*

$$[e^{-itH_\beta} F e^{itH_\beta}, E] = 0 \quad \forall |t| < \delta. \tag{19}$$

Then $FE = 0$ *implies* $F e^{itH_\beta} E = 0$ *for all* $t \in \mathbb{R}$.

Proof: It is sufficient to show that

$$(\Phi, e^{-itH_\beta} F e^{itH_\beta} E \Psi) = 0 \quad \forall t \in \mathbb{R} \tag{20}$$

for the dense set of vectors $\Phi, \Psi \in \mathcal{D}_\tau$ introduced in (15). By construction, the vectors in $\mathcal{D}_\tau$ are entire analytic for the energy, i.e., $\mathcal{D}_\tau \subset \mathcal{D}(e^{-zH_\beta})$ for all $z \in \mathbb{C}$. Due to the KMS-relation,

$$\mathcal{R}_\beta \Omega_\beta \subset \mathcal{D}(e^{-\lambda H_\beta}) \quad \forall 0 \leq \lambda \leq \beta/2. \tag{21}$$

Thus the function

$$z \mapsto (e^{i\bar{z}H_\beta}\Phi, F e^{izH_\beta} E \Psi) \tag{22}$$

is analytic in the strip $0 < \Im z < \beta/2$, while the function

$$z \mapsto (e^{i\bar{z}H_\beta} E^* \Phi, F e^{izH_\beta} \Psi) \tag{23}$$

is analytic in the strip $-\beta/2<\mathfrak{J}z<0$. Both functions are bounded and analytic and have continuous boundary values for $\mathfrak{J}z\searrow 0$ and $\mathfrak{J}z\nearrow 0$, respectively. Now (19) implies

$$\lim_{\mathfrak{J}z\searrow 0}(e^{i\bar{z}H_\beta}\Phi,Fe^{izH_\beta}E\Psi)=\lim_{\mathfrak{J}z\nearrow 0}(e^{i\bar{z}H_\beta}E^*\Phi,Fe^{izH_\beta}\Psi)\quad\forall|t|<\delta. \tag{24}$$

Using the Edge-of-the-Wedge Theorem[17] one concludes that there exists a function

$$f_{E,F}:G_\delta\to\mathbb{C} \tag{25}$$

which is analytic on the doubly cut strip

$$G_\delta=\{z\in\mathbb{C}:-\beta/2<\mathfrak{J}z<\beta/2\}\setminus\{z\in\mathbb{C}:\mathfrak{J}z=0,|\mathfrak{R}z|\geqslant\delta\} \tag{26}$$

and satisfies

$$f_{E,F}(z)=\left\{\begin{matrix}(e^{i\bar{z}H_\beta}\Phi,Fe^{izH_\beta}E\Psi)\\(e^{i\bar{z}H_\beta}E^*\Phi,Fe^{izH_\beta}\Psi)\end{matrix}\right\}\quad\text{for}\quad\left\{\begin{matrix}0<\mathfrak{J}z<\beta/2\\-\beta/2<\mathfrak{J}z<0\end{matrix}\right\}. \tag{27}$$

Continuity and $FE=0$ imply $f_{E,F}(0)=0$. According to Lagrange's theorem $f_{E,F}(z)$ vanishes identically if 0 is a zero of infinite order. This follows from the original arguments of Borchers; put

$$t_j^{(i)}:=\frac{\delta j}{2in},\quad i\in\mathbb{N},\quad j=1,...,n. \tag{28}$$

Now set

$$f^+_{t_1^{(i)},\dots,t_n^{(i)}}(z):=(e^{i\bar{z}H_\beta}\Phi,F(t_1^{(i)})\cdots F(t_n^{(i)})e^{izH_\beta}E\Psi)\qquad\text{for}\quad 0\leqslant\mathfrak{J}z\leqslant\beta/2 \tag{29}$$

and

$$f^-_{t_1^{(i)},\dots,t_n^{(i)}}(z):=(e^{i\bar{z}H_\beta}E^*\Phi,F(t_1^{(i)})\cdots F(t_n^{(i)})e^{izH_\beta}\Psi)\qquad\text{for}\quad -\beta/2\leqslant\mathfrak{J}z\leqslant 0, \tag{30}$$

where

$$F(t_j^{(i)}):=e^{-it_j^{(i)}H_\beta}Fe^{it_j^{(i)}H_\beta}. \tag{31}$$

Both functions are analytic in the interior of their domains and bounded and continuous at the boundary. Since $|t_j^{(i)}|\leqslant\delta/2$ for all $i\in\mathbb{N}$ and $j\in\{1,...,n\}$ implies that

$$[E,e^{-itH_\beta}F(t_1^{(i)})\cdots F(t_n^{(i)})e^{itH_\beta}]=0\quad\forall|\mathfrak{R}z|<\delta/2, \tag{32}$$

the boundary values for $\mathfrak{J}z\searrow 0$ resp. $\mathfrak{J}z\nearrow 0$ coincide for $|\mathfrak{R}z|<\delta/2$. Applying the Edge-of-the-Wedge Theorem[17] one concludes that f^+ and f^- are the restrictions to the upper (resp. lower) half of the doubly cut strip $\mathcal{G}_{\delta/2}$ of a function

$$f_{t_1^{(i)},\dots,t_n^{(i)}}(z):=\left\{\begin{matrix}f^+_{t_1^{(i)},\dots,t_n^{(i)}}(z)\\f^-_{t_1^{(i)},\dots,t_n^{(i)}}(z)\end{matrix}\right\}\quad\text{for}\quad\left\{\begin{matrix}0<\mathfrak{J}z<\beta/2\\-\beta/2<\mathfrak{J}z<0\end{matrix}\right\}, \tag{33}$$

which is defined and analytic for $z\in\mathcal{G}_{\delta/2}$. The function $f_{t_1^{(i)},\dots,t_n^{(i)}}(z)$ has continuous boundary values for $z\to\partial\mathcal{G}_{\delta/2}$. Since Φ and Ψ are elements of $\mathcal{D}_\tau$ (see (15)), there exist two operators A, $B\in\pi_\beta(\mathcal{A}_\tau)$ such that $\Phi=A\Omega_\beta$ and $\Psi=B\Omega_\beta$. Applying the maximum modulus principle we obtain the following estimate:

$$\begin{aligned}|f_{t_1^{(i)},\dots,t_n^{(i)}}(z)| &\leq \sup_{w\in\partial\mathcal{G}_\epsilon} |f_{t_1^{(i)},\dots,t_n^{(i)}}(w)| \\ &\leq \max\{\|e^{(\beta/2)H_\beta}A\Omega_\beta\|\|B\|,\|A\|\|e^{(\beta/2)H_\beta}B\Omega_\beta\|\} \\ &\leq \|A\|\|B\| =: M_{\Phi,\Psi} \quad \forall z\in\mathcal{G}_{\delta/2}. \end{aligned} \tag{34}$$

For example,

$$\begin{aligned}\sup_{\{w\in\mathbb{C}:\ \mathrm{Im}\, w=\beta/2\}} f_{t_1^{(i)},\dots,t_n^{(i)}}(w) &= \sup_{s\in\mathbb{R}}(e^{(is+(\beta/2))H_\beta}A\Omega_\beta, F(t_1^{(i)})\cdots F(t_n^{(i)})e^{isH_\beta}J^2e^{-(\beta/2)H_\beta}EB\Omega_\beta) \\ &= \sup_{s\in\mathbb{R}}(e^{(\beta/2)H_\beta}A\Omega_\beta, e^{-isH_\beta}F(t_1^{(i)})\cdots F(t_n^{(i)})e^{isH_\beta}JB^*E^*\Omega_\beta) \\ &\leq \|e^{(\beta/2)H_\beta}A\Omega_\beta\|\|B\| \leq \|J\|\|A^*\Omega_\beta\|\|B\| \leq \|A\|\|B\|. \end{aligned} \tag{35}$$

Here we used $\|\Omega_\beta\|=1$, $\|E\|=1$, $\|F\|=1$ and $\|e^{-isH_\beta}\|=1$ for all $s\in\mathbb{R}$. We emphasize that at this point also the specific properties of a KMS state are used; in the last line of (35) we made use of the modular conjugation J associated with the pair $(\mathcal{R}_\beta,\Omega_\beta)$ (see, e.g., Ref. 8 for a general account on modular theory). By assumption $FE=0$, hence

$$f_{t_1^{(i)},\dots,t_n^{(i)}}(-t_j^{(i)})=0. \tag{36}$$

We conclude that inside the circle $|z|<\delta/2$ each of the functions $f_{t_1^{(i)},\dots,t_n^{(i)}}(z)$ possesses n zeros for pairwise different values of $t_j^{(i)}$. Thus all of the functions

$$\frac{f_{t_1^{(i)},\dots,t_n^{(i)}}(z)}{\Pi_{j=1}^n(z+t_j^{(i)})}, \quad i\in\mathbb{N}, \tag{37}$$

are analytic in the open disk $D_{\delta/2}$ of radius $\delta/2$ centered at the origin. Note that by definition $D_{\delta/2}\subset\mathcal{G}_{\delta/2}$. Yet the number of zeros does not change in the limit $i\to\infty$ and consequently, for $i>1$,

$$\left|\frac{f_{t_1^{(i)},\dots,t_n^{(i)}}(z)}{\Pi_{j=1}^n(z+t_j^{(i)})}\right| \leq \sup_{w\in\partial D_{\delta/2}} \frac{|f_{t_1^{(i)},\dots,t_n^{(i)}}(w)|}{\Pi_{j=1}^n|w+t_j^{(i)}|} \leq M_{\Phi,\Psi}\cdot\left(\frac{4}{\delta}\right)^n \quad \forall z\in D_{\delta/2}. \tag{38}$$

In the last inequality we used $|w+t_j^{(i)}|\geq\big||w|-|t_j^{(i)}|\big|$ and $|w|=\delta/2$ together with $|t_j^{(i)}|<\delta/4$ for $i>1$ and $j\in\{1,\dots,n\}$. Hence,

$$|f_{t_1^{(i)},\dots,t_n^{(i)}}(z)| \leq M_{\Phi,\Psi}\cdot\left(\frac{4}{\delta}\right)^n\prod_{j=1}^n |z+t_j^{(i)}| \leq \mathrm{const}\cdot|z|^n \quad \text{as } i\to\infty \quad \forall z\in D_{\delta/2}. \tag{39}$$

Because of $F^2=F$, it is obvious that $f_{0,\dots,0}(z)=f_{E,F}(z)$. The map $t\mapsto e^{itH_\beta}$ is strongly continuous, thus

$$|f_{t_1^{(i)},\dots,t_n^{(i)}}(z)-f_{0,\dots,0}(z)|\to 0 \quad \text{as } i\to\infty, \tag{40}$$

uniformly in $z\in G_{\delta/2}$. Thus

$$|f_{E,F}(z)|\leq \mathrm{const}\cdot|z|^n \quad \forall z\in D_{\delta/2}. \tag{41}$$

Hence 0 is a zero of nth order. Since $n\in\mathbb{N}$ was arbitrary, we conclude that $f_{E,F}(z)$ vanishes identically for all choices of Φ, $\Psi\in\mathcal{D}_\tau$. □

As a consequence of assumption (iii) ω_β is mixing and therefore the next lemma is more or less obvious.

Lemma II.2: Let $E, F \in \mathcal{B}(\mathcal{H}_\beta)$ *be two projection operators and assume that*

$$F e^{itH_\beta} E = 0 \quad \forall t \in \mathbb{R}. \tag{42}$$

It follows that $E\Omega_\beta \neq 0$ *implies* $F\Omega_\beta = 0$.

Proof: By assumption, Ω_β is the unique—up to a phase—normalized eigenvector for the discrete eigenvalue {0}, thus (Ref. 8)

$$0 = \lim_{T\to\infty} \frac{1}{2T} \int_{-T}^{T} dt (\Omega_\beta, E e^{itH_\beta} F \Omega_\beta) = (\Omega_\beta, E\Omega_\beta)(\Omega_\beta, F\Omega_\beta) = \|E\Omega_\beta\|^2 \cdot \|F\Omega_\beta\|^2. \tag{43}$$

Hence, if $E\Omega_\beta \neq 0$, then $F\Omega_\beta = 0$. □

We add a result whose analogon in the vacuum sector is due to Schlieder (see Ref. 18, p. 220).

Corollary II.3: Let $E \in \mathcal{R}_\beta$ *be a nonzero projection and* $\xi \in \mathcal{H}_\beta$ *an arbitrary nonzero vector. It follows that the set of points*

$$\{t \in \mathbb{R} : E e^{itH_\beta} \xi \neq 0\} \tag{44}$$

is dense in $\mathbb{R}$.

Proof: For $t \in \mathbb{R}$ fixed, the set of vectors

$$\mathcal{H}_t := \{\Psi \in \mathcal{H}_\beta : E e^{iH_\beta t} \Psi = 0\} \tag{45}$$

is a closed subspace of $\mathcal{H}_\beta$. We set

$$\mathcal{H}_{]-\infty,\infty[} := \bigcap_{-\infty<t<\infty} \mathcal{H}_t . \tag{46}$$

By construction, $\mathcal{H}_{]-\infty,\infty[}$ is the intersection of closed subspaces and therefore $\mathcal{H}_{]-\infty,\infty[}$ itself is a closed subspace of $\mathcal{H}_\beta$. Let P denote the projection onto $\mathcal{H}_{]-\infty,\infty[}$. Clearly,

$$E e^{itH_\beta} P = 0 \quad \forall t \in \mathbb{R}. \tag{47}$$

Now $0 \neq E \in \mathcal{R}_\beta$ implies $E\Omega_\beta \neq 0$. Therefore Lemma II.2 implies $P\Omega_\beta = 0$. Since $e^{-iH_\beta{}^t} E e^{iH_\beta{}^t} \in \mathcal{R}_\beta$ for all $t \in \mathbb{R}$, we conclude that

$$e^{-iH_\beta t} E e^{itH_\beta} D P = 0 \quad \forall D \in \mathcal{R}_\beta', \quad \forall t \in \mathbb{R}. \tag{48}$$

Let $\hat{P}$ denote the projection onto the closed linear subspace $\overline{\mathcal{R}_\beta' \mathcal{H}_{]-\infty,\infty[}}$. Clearly,

$$E e^{itH_\beta} \hat{P} = 0 \quad \forall t \in \mathbb{R}. \tag{49}$$

But by definition P is the maximal projection such that $E e^{iH_\beta{}^t} P = 0$ holds for all $t \in \mathbb{R}$. It follows that $\hat{P} \leq P$. On the other hand

$$\mathcal{H}_{]-\infty,\infty[} \subset \overline{\mathcal{R}_\beta' \mathcal{H}_{-\infty,\infty[}} \tag{50}$$

implies $P \leq \hat{P}$, thus $P = \hat{P}$. We conclude that $P \in \mathcal{R}_\beta$. Since Ω_β is separable for $\mathcal{R}_\beta$, $P\Omega_\beta = 0$ implies $P = 0$. It follows that for any vector $\xi \in \mathcal{H}_\beta$ there exists some $t \in \mathbb{R}$ such that

$$E e^{itH_\beta} \xi \neq 0. \tag{51}$$

Now consider the projection P_ξ onto the one-dimensional subspace $\mathbb{C} \cdot \xi$ and assume there exists some $\delta > 0$ such that

$$Ee^{itH_\beta}P_\xi=0 \quad \forall|t-s|<\delta \tag{52}$$

with $s\in\mathbb{R}$ fixed. Set $P_\xi(s)=e^{isH_\beta}P_\xi e^{-isH_\beta}$. Then $P_\xi(s)=P_\xi(s)^2=P_\xi(s)^*$ is a projection and

$$Ee^{itH_\beta}P_\xi(s)=0 \quad \forall|t|<\delta. \tag{53}$$

Lemma II.1 implies that

$$Ee^{itH_\beta}P_\xi=0 \quad \forall t\in\mathbb{R}, \tag{54}$$

in contradiction to (51). Thus the set $\{t\in\mathbb{R}:Ee^{itH_\beta}\xi\neq 0\}$ does not contain any open intervall. Consequently, it is dense in $\mathbb{R}$. □

Theorem II.4: *(Schlieder property). Let $\mathcal{O}$ and $\hat{\mathcal{O}}$ denote two open (not necessarily bounded) space–time regions such that*

$$\mathcal{O}+te\subset\hat{\mathcal{O}} \quad \forall|t|<\delta, \quad \delta>0. \tag{55}$$

It follows that $0\neq A\in\mathcal{R}_\beta(\mathcal{O})$ and $0\neq B\in\mathcal{R}_\beta(\hat{\mathcal{O}})'$ implies $AB\neq 0$.

Proof: Let $A\in\mathcal{R}_\beta(\mathcal{O})$ and $B\in\mathcal{R}_\beta(\hat{\mathcal{O}})'$. We have to show that $AB=0$ implies $A=0$ or $B=0$. If either A or B is unitary, then $AB=0$ implies $B=0$ or $A=0$. Thus only the case when both A and B are not unitary has to be considered in detail. In this case one of the expressions A^*A or AA^* is unequal to $\mathbb{1}$. The same is true for B^*B or BB^*. Without loss of generality we assume that $A^*A\neq\mathbb{1}$ and $BB^*\neq\mathbb{1}$. With A^*A also the spectral projections of A^*A belong to $\mathcal{R}_\beta(\mathcal{O})$ and with BB^* also the spectral projections of BB^* belong to $\mathcal{R}_\beta(\hat{\mathcal{O}})'$. Thus

$$A^*ABB^*=0 \tag{56}$$

implies $FE=0$ for all spectral projections $E\in\mathcal{R}_\beta(\mathcal{O})$, $F\in\mathcal{R}_\beta(\hat{\mathcal{O}})'$ from the spectral resolution of A^*A and BB^*, respectively. Since $E\in\mathcal{R}_\beta(\mathcal{O})$ and $F\in\mathcal{R}_\beta(\hat{\mathcal{O}})'$ we find

$$[e^{-itH_\beta}Fe^{itH_\beta},E]=0 \quad \forall|t|<\delta. \tag{57}$$

Consequently, Lemma II.1 implies

$$Fe^{itH_\beta}E=0 \quad \forall t\in\mathbb{R} \tag{58}$$

and from Lemma II.2 it follows that $E\Omega_\beta=0$ or $F\Omega_\beta=0$. Finally, Ω_β is separating for both $\mathcal{R}_\beta(\mathcal{O})$ and $\mathcal{R}_\beta(\hat{\mathcal{O}})'$. Thus $E=0$ or $F=0$.

Remark: The Schlieder property implies that $\mathcal{R}_\beta(\mathcal{O})$ is almost a factor, namely,

$$\mathcal{R}_\beta(\mathcal{O})\cap\mathcal{R}_\beta(\hat{\mathcal{O}})'=\mathbb{C}\cdot\mathbb{1}. \tag{59}$$

This can be seen as follows: assume

$$\mathcal{R}_\beta(\mathcal{O})\cap\mathcal{R}_\beta(\hat{\mathcal{O}})'\neq\mathbb{C}\cdot\mathbb{1}. \tag{60}$$

It follows that there exists a nontrivial projection P such that both

$$P\in\mathcal{R}_\beta(\mathcal{O})\cap\mathcal{R}_\beta(\hat{\mathcal{O}})' \quad \text{and} \quad (\mathbb{1}-P)\in\mathcal{R}_\beta(\mathcal{O})\cap\mathcal{R}_\beta(\hat{\mathcal{O}})'. \tag{61}$$

Set $A=P$ and $B=(\mathbb{1}-P)$. The Schlieder property implies $P=0$ or $\mathbb{1}-P=0$, in contradiction to the assumption that P is a nontrivial projection.

The Schlieder property is a first step towards the ‘‘statistical independence’’ of $\mathcal{R}_\beta(\mathcal{O})$ and $\mathcal{R}_\beta(\hat{\mathcal{O}})'$. In fact, several precise conditions for ‘‘statistical independence’’ have been proposed; an overview can be found in Ref. 19. Florig and Summers have collected a list of properties which are equivalent to the Schlieder property.[2]

Corollary II.5 (Florig and Summers): Assume that $\mathcal{H}_\beta$ is separable. Let $\mathcal{O}$, $\hat{\mathcal{O}}$ denote a pair of space–time regions such that the closure of the open region $\mathcal{O}$ is contained in the interior of $\hat{\mathcal{O}}$. It follows that

(i) $\mathcal{R}_\beta(\mathcal{O})$ and $\mathcal{R}_\beta(\hat{\mathcal{O}})'$ are C^*-independent, i.e., for every state ω_1 on $\mathcal{R}_\beta(\mathcal{O})$ and every state ω_2 on $\mathcal{R}_\beta(\hat{\mathcal{O}})'$ there exists a state ω on $\mathcal{R}_\beta$ such that $\omega_{|\mathcal{R}_{\beta(\mathcal{O})}}=\omega_1$ and $\omega_{|\mathcal{R}_{\beta(\hat{\mathcal{O}})'}}=\omega_2$.

(ii) $\mathcal{R}_\beta(\mathcal{O})$ and $\mathcal{R}_\beta(\hat{\mathcal{O}})'$ are W^*-independent, i.e., for every normal state ω_1 on $\mathcal{R}_\beta(\mathcal{O})$ and every normal state ω_2 on $\mathcal{R}_\beta(\hat{\mathcal{O}})'$ there exists a normal state ω on $\mathcal{R}_\beta$ such that $\omega_{|\mathcal{R}_{\beta(\mathcal{O})}}=\omega_1$ and $\omega_{|\mathcal{R}_{\beta(\hat{\mathcal{O}})'}}=\omega_2$.

(iii) For any nonzero vectors $\Phi,\Psi\in\mathcal{H}_\beta$ there exists $A'\in\mathcal{R}_\beta(\mathcal{O})'$ and $B'\in\mathcal{R}_\beta(\hat{\mathcal{O}})$ such that $A'\Phi=B'\Psi\neq 0$.

(iv) The ordered pair $(\mathcal{R}_\beta(\mathcal{O}),\mathcal{R}_\beta(\hat{\mathcal{O}})')$ is strictly local; i.e., for any nonzero projection $E\in\mathcal{R}_\beta(\mathcal{O})$ and any state $\omega\in\mathcal{R}_\beta(\hat{\mathcal{O}})'_*$ there exists a state $\phi\in(\mathcal{R}_\beta(\mathcal{O})\vee\mathcal{R}_\beta(\hat{\mathcal{O}})')_*$ such that $\phi(E)=1$ and $\phi_{|\mathcal{R}_{\beta(\hat{\mathcal{O}})'}}=\omega$.

(v) For any nontrivial projections $E\in\mathcal{R}_\beta(\mathcal{O})$, $F\in\mathcal{R}_\beta(\hat{\mathcal{O}})'$ and $\lambda,\mu\in[0,1]$ there exists a state ϕ on $\mathcal{B}(\mathcal{H}_\beta)$ such that $\phi(E)=\lambda$ and $\phi(F)=\mu$.

(vi) $\mathcal{R}_\beta(\mathcal{O})$ and $\mathcal{R}_\beta(\hat{\mathcal{O}})'$ are statistically independent in the sense of Haag and Kastler; i.e., for every state ω_1 on $\mathcal{R}_\beta(\mathcal{O})$ and every state ω_2 on $\mathcal{R}_\beta(\hat{\mathcal{O}})'$ there exists a state ω on $\mathcal{R}$ such that

$$\omega(AB)=\omega_1(A)\omega_2(B) \tag{62}$$

for all $A\in\mathcal{R}_\beta(\mathcal{O})$ and all $B\in\mathcal{R}_\beta(\hat{\mathcal{O}})'$.

(vii) $\|AB\|=\|A\|\|B\|$ for all $A\in\mathcal{R}_\beta(\mathcal{O})$ and all $B\in\mathcal{R}_\beta(\hat{\mathcal{O}})'$.

(viii) The von Neumann algebras $\mathcal{R}_\beta(\mathcal{O})$ and $\mathcal{R}_\beta(\hat{\mathcal{O}})'$ are algebraically independent; i.e., given two arbitrary sets $\{A_i:\ i=1,...,m\}$ and $\{B_j:j=1,...,n\}$ of linear independent elements of $\mathcal{R}_\beta(\mathcal{O})$ and $\mathcal{R}_\beta(\hat{\mathcal{O}})'$, respectively, the collection $\{A_iB_j:i=1,...,m;\ j=1,...,n\}$ is linearly independent in $\mathcal{R}_\beta(\mathcal{O})\odot\mathcal{R}_\beta(\hat{\mathcal{O}})'$.

(ix) The map $\eta:(\mathcal{R}_\beta(\mathcal{O}),\mathcal{R}_\beta(\hat{\mathcal{O}})')\to\mathcal{R}_\beta(\mathcal{O})\odot\mathcal{R}_\beta(\hat{\mathcal{O}})'$ defined by

$$\eta(A,B)=A\otimes B,\quad A\in\mathcal{R}_\beta(\mathcal{O}),\quad B\in\mathcal{R}_\beta(\hat{\mathcal{O}})', \tag{63}$$

is an isomorphism continuous in the minimal C^*-cross norm on the algebraic tensor product $\mathcal{R}_\beta(\mathcal{O})\odot\mathcal{R}_\beta(\hat{\mathcal{O}})'$ and can therefore be continuously extended to a surjective homomorphism $\overline{\eta}:\mathcal{R}_\beta(\mathcal{O})\vee\mathcal{R}_\beta(\hat{\mathcal{O}})'\to\mathcal{R}_\beta(\mathcal{O})\otimes\mathcal{R}_\beta(\hat{\mathcal{O}})'$.

Remark: If $\mathcal{R}_\beta(\mathcal{O})$ is a factor of type III acting on a separable Hilbert space, then Corollary II.5 remains valid, if we replace $\mathcal{R}_\beta(\hat{\mathcal{O}})'$ by $\mathcal{R}_\beta(\mathcal{O})'$. It is remarkable that for such a pair all normal partial states have normal extensions, none of which is allowed to be a product state, and also all partial states have extensions to product states, none of which can be normal.

Theorem II.6: *(Borchers property). Let $\mathcal{O}$ and $\hat{\mathcal{O}}$ denote two open and bounded space–time regions such that*

$$\mathcal{O}+te\subset\hat{\mathcal{O}}\quad\forall|t|<\delta,\quad\delta>0. \tag{64}$$

Given a nonzero projection $E\in\mathcal{R}_\beta(\mathcal{O})$, there exists a partial isometry $V\in\mathcal{R}_\beta(\hat{\mathcal{O}})$ such that $V^*V=\mathbb{1}$ and $VV^*=E$.

Proof: Once the Schlieder property is proven for $\mathcal{R}_\beta(\mathcal{O})$ and $\mathcal{R}_\beta(\hat{\mathcal{O}})'$, the Borchers property follows by standard arguments (see Refs. 16, 1 for the corresponding result in the vacuum sector). We present them here for the sake of completeness only. By assumption the spacelike complement $\hat{\mathcal{O}}'$ of $\hat{\mathcal{O}}$ is not empty. Thus any vector $\Phi \in \mathcal{D}_\tau$ is cyclic for $\mathcal{R}_\beta(\hat{\mathcal{O}})' \supset \mathcal{R}_\beta(\hat{\mathcal{O}}')$. We show that $E\Phi$ is separating for $\mathcal{R}_\beta(\hat{\mathcal{O}})'$; choose a region $\mathcal{O}_0$ such that

$$\mathcal{O}_0 \subset \mathcal{O}' \cap \hat{\mathcal{O}} \tag{65}$$

and consider some $B \in \mathcal{R}_\beta(\hat{\mathcal{O}})'$ such that $BE\Phi = 0$. Locality implies that $BEC\Phi = 0$ for any $C \in \mathcal{R}_\beta(\mathcal{O}_0)$. By the Reeh–Schlieder property the set $\{C\Phi : C \in \mathcal{R}_\beta(\mathcal{O}_0)\}$ is dense in $\mathcal{H}_\beta$ and therefore $BE = 0$. Now the Schlieder property for $\mathcal{R}_\beta(\mathcal{O})$ and $\mathcal{R}_\beta(\hat{\mathcal{O}})'$ implies $B = 0$, since by assumption $E \neq 0$. We conclude that $E\Phi$ is separating for $\mathcal{R}_\beta(\hat{\mathcal{O}})'$. Hence, the normal state

$$B \mapsto (E\Phi, BE\Phi) \tag{66}$$

is faithful on $\mathcal{R}_\beta(\hat{\mathcal{O}})'$ and there exists a vector $\Psi \in \mathcal{H}_\beta$ cyclic for $\mathcal{R}_\beta(\hat{\mathcal{O}})'$ such that

$$(E\Phi, B^*BE\Phi) = (\Psi, B^*B\Psi) \quad \forall B \in \mathcal{R}_\beta(\hat{\mathcal{O}})'. \tag{67}$$

It follows that $V : \mathcal{H}_\beta \to \mathcal{H}_\beta$, given by

$$VB\Psi = BE\Phi \quad \forall B \in \mathcal{R}_\beta(\hat{\mathcal{O}})', \tag{68}$$

defines an isometry. Both Φ and Ψ are cyclic for $\mathcal{R}_\beta(\hat{\mathcal{O}})'$, thus V is densely defined and its range spans $E\mathcal{H}_\beta$. Moreover,

$$CVB\Psi = CBE\Phi = VCB\Psi \quad \forall C \in \mathcal{R}_\beta(\hat{\mathcal{O}})'. \tag{69}$$

Thus V commutes with all $C \in \mathcal{R}_\beta(\hat{\mathcal{O}})'$ on the dense set $\{B\Psi : B \in \mathcal{R}_\beta(\hat{\mathcal{O}})'\} \subset \mathcal{H}_\beta$ and therefore $V \in \mathcal{R}_\beta(\hat{\mathcal{O}})$. □

Remark: The Borchers property has interesting consequences for the actual preparation of states: Given an arbitrary state ω on $\mathcal{R}_\beta(\mathcal{O}) \vee \mathcal{R}_\beta(\hat{\mathcal{O}})'$, we set

$$\omega_V(C) := \omega(V^*CV) \quad \forall C \in \mathcal{R}_\beta(\mathcal{O}) V \mathcal{R}(\hat{\mathcal{O}})'. \tag{70}$$

It follows that

$$\omega_V(E) = \omega(V^*VV^*V) = \mathbb{1} \quad \text{and} \quad \omega_V(\mathbb{1} - E) = 0. \tag{71}$$

Moreover,

$$\omega_V(B) = \omega(V^*BV) = \omega(B) \quad \forall B \in \mathcal{R}(\hat{\mathcal{O}})'. \tag{72}$$

This demonstrates that the Borchers property allows us to prepare a state ω_V which satisfies the properties (71) and (72) by a strictly local operation. We emphasize that the state given remains completely unchanged in the spatial complement of $\hat{\mathcal{O}}$. This is a remarkable difference to the usual collapse of the wave-function type of preparation.

Nonrelativistic quantum Hamiltonian for Lorentz violation

V. Alan Kostelecký and Charles D. Lane
Physics Department, Indiana University, Bloomington, Indiana 47405

(Received 18 May 1999; accepted for publication 30 August 1999)

A method is presented for deriving the nonrelativistic quantum Hamiltonian of a free massive fermion from the relativistic Lagrangian of the Lorentz-violating standard-model extension. It permits the extraction of terms at arbitrary order in a Foldy–Wouthuysen expansion in inverse powers of the mass. The quantum particle Hamiltonian is obtained and its nonrelativistic limit is given explicitly to third order. © *1999 American Institute of Physics.* [S0022-2488(99)01712-0]

I. INTRODUCTION

Establishing the physical relevance of a Lagrangian in relativistic quantum field theory often requires a determination of its nonrelativistic content. The Foldy–Wouthuysen (FW) transformation[1] provides a systematic approach to understanding the low-energy effects of certain theories. Given the relativistic quantum Hamiltonian for a theory of massive four-component fermions, the nonrelativistic quantum Hamiltonian for the corresponding two-component particle can be derived in an expansion in inverse powers of the fermion mass.

In this work, we use generalized FW methods to investigate the quantum particle Hamiltonian that describes the physics of a free massive two-component fermion emerging from the relativistic Lagrangian of the Lorentz-violating standard-model extension.[2] This standard-model extension is based on the idea of spontaneous Lorentz breaking in an underlying theory[3] and has been used for various investigations placing constraints on possible violations of Lorentz symmetry,[2,4–15] several of which depend crucially on the nonrelativistic physics of free massive fermions. In these investigations, specific terms in the nonrelativistic Hamiltonian have been derived as needed, but a full treatment has been lacking. Here, we provide a systematic approach that permits extraction of the relevant terms in the nonrelativistic Hamiltonian at arbitrary order in the FW approximation. We obtain the quantum particle Hamiltonian and provide explicitly the form of the nonrelativistic Hamiltonian to third order. Our results are directly relevant to recent analyses of muon and clock-comparison experiments[14,15] and are expected to have substantial impact on further studies of the physical implications of the standard-model extension.

The general form of the relativistic Lagrangian for a free spin-$\frac{1}{2}$ Dirac fermion ψ of mass m in the standard-model extension is[2]

$$\mathcal{L}=\tfrac{1}{2}i\overline{\psi}(\gamma_\nu+c_{\mu\nu}\gamma^\mu+d_{\mu\nu}\gamma_5\gamma^\mu+e_\nu+if_\nu\gamma_5+\tfrac{1}{2}g_{\lambda\mu\nu}\sigma^{\lambda\mu})\overleftrightarrow{\partial}^\nu\psi$$
$$-\overline{\psi}(m+a_\mu\gamma^\mu+b_\mu\gamma_5\gamma^\mu+\tfrac{1}{2}H_{\mu\nu}\sigma^{\mu\nu})\psi. \tag{1}$$

This is a generalization of the usual relativistic Lagrangian for a free massive Dirac fermion. The Dirac matrices $\{1,\gamma_5,\gamma^\mu,\gamma_5\gamma^\mu,\sigma^{\mu\nu}\}$ have conventional properties, and the Minkowski metric $\eta_{\mu\nu}$ has signature -2. The parameters a_μ, b_μ, $c_{\mu\nu}$, $d_{\mu\nu}$, e_μ, f_μ, $g_{\lambda\mu\nu}$, and $H_{\mu\nu}$ control the extent of Lorentz violation in the theory. In a given observer inertial frame, they can be regarded as fixed real Lorentz vectors or tensors. Note that $H_{\mu\nu}$ can be taken as antisymmetric, $c_{\mu\nu}$ and $d_{\mu\nu}$ as traceless, and $g_{\lambda\mu\nu}$ as antisymmetric in the first two indices. Since Lorentz symmetry is known to be valid to high precision, any nonzero parameters in nature would need to be minuscule. We therefore restrict our attention in this work to terms linear in these parameters.

In Sec. II, the relativistic particle–antiparticle Hamiltonian H corresponding to the Lagrangian (1) is obtained. Some basic information about our procedure for extracting its FW form is discussed in Sec. III, together with our definition of the relevant FW sequence. Features of this sequence are derived in Sec. IV, and the quantum particle Hamiltonian and its nonrelativistic limit to third order are explicitly presented in Sec. V.

II. RELATIVISTIC QUANTUM HAMILTONIAN

The first step in deriving low-energy effects of the Lorentz-violating terms is to obtain the relativistic Hamiltonian H associated with the Lagrangian (1). However, methods for direct construction of H are inadequate because Eq. (1) contains couplings involving time derivatives. For example, applying the Euler–Lagrange equations to $\mathcal{L}$ and solving for H from the equation $i\partial_0\psi=H\psi$ results in a non-Hermitian Hamiltonian and a corresponding nonunitary time evolution.

One method of bypassing this technical difficulty is to perform a field redefinition $\psi=A\chi$ in the Langrangian,[5] with A chosen such that the dependence of the Lagrangian on $\partial_0\chi$ is just that of the usual Dirac Lagrangian. Then, the wave function associated with χ evolves conventionally in time. The field redefinition leaves unchanged the physics, while it causes the time-derivative couplings to be replaced by extra terms in the Lagrangian.

To implement this idea, we write the Lagrangian (1) in the forms

$$\mathcal{L}\equiv\tfrac{1}{2}i\overline{\psi}\Gamma_\nu\overleftrightarrow{\partial}^\nu\psi-\overline{\psi}M\psi=\tfrac{1}{2}i\overline{\chi}\gamma_0\overleftrightarrow{\partial}^0\chi+\tfrac{1}{2}i\overline{\chi}(\overline{A}\Gamma_jA)\overleftrightarrow{\partial}^j\chi-\overline{\chi}(\overline{A}MA)\chi, \tag{2}$$

where Γ_ν and M are defined according to the correspondence with Eq. (1), and $\overline{\psi}=\overline{\chi}\overline{A}$ with $\overline{A}:=\gamma^0A^\dagger\gamma^0$. In the second expression the Lorentz indices are separated into timelike and spacelike Cartesian components, $\mu\equiv 0$ and $j=1, 2, 3$, with summation on repeated indices understood.

The choice

$$A=1-\tfrac{1}{2}\gamma^0(\Gamma_0-\gamma_0), \quad \overline{A}=1-\tfrac{1}{2}(\Gamma_0-\gamma_0)\gamma^0 \tag{3}$$

implements the equality (2) to linear order in the parameters for Lorentz violation. Derivation of the relativistic Hamiltonian H can then proceed through the Euler–Lagrange equations, which take the form of a modified Dirac equation:

$$(i\overline{A}\Gamma_\mu A\partial^\mu-\overline{A}MA)\chi=0. \tag{4}$$

We find

$$H=-\gamma^0\overline{A}\Gamma_jAp^j+\gamma^0\overline{A}MA, \tag{5}$$

where the three-momentum of the particle is denoted p_j, and H obeys the equation $i\partial_0\chi=H\chi$.

Explicitly, the relativistic Hamiltonian can be written

$$H=m(\gamma^0+\mathcal{P}_0+\mathcal{O}_0+\mathcal{E}_0), \tag{6}$$

where

$$\begin{aligned}
m\mathcal{P}_0&:=-p_j\gamma^0\gamma^j,\\
m\mathcal{O}_0&:=[-b_0+(d_{0j}+d_{j0})p^j]\gamma_5+[a_j-(c_{jk}-c_{00}\eta_{jk})p^k]\gamma^0\gamma^j+if_jp^j\gamma_5\gamma^0\\
&\quad+i[H_{0j}+(g_{j0k}+g_{jk0})p^k]\gamma^j,\\
m\mathcal{E}_0&:=[a_0-(c_{0j}+c_{j0})p^j-me_0]+[-b_j+(d_{jk}-d_{00}\eta_{jk})p^k-\tfrac{1}{2}m\epsilon^{klm}\eta_{jm}g_{kl0}]\gamma_5\gamma^0\gamma^j\\
&\quad-[mc_{00}+e_jp^j]\gamma^0-[\tfrac{1}{2}\epsilon^{klm}\eta_{jm}H_{kl}+md_{j0}-\epsilon^{lmn}\eta_{jn}(\tfrac{1}{2}g_{lmk}-\eta_{km}g_{l00})p^k]\gamma_5\gamma^j.
\end{aligned} \tag{7}$$

In these expressions, the totally antisymmetric rotation tensor ϵ^{jkl} satisfies $\epsilon_{123}=+1$ and $\epsilon^{jkl}=-\epsilon_{jkl}$. The particular decomposition of H into the four terms in (6) is chosen for later convenience.

As an aside, we remark that the relativistic Hamiltonian is also readily found if the theory (1) is extended to include a minimal coupling to a U(1) gauge field A_μ. It suffices to replace the partial derivative $i\partial_\mu$ in Eq. (1) with the covariant derivative $iD_\mu := i\partial_\mu - qA_\mu$, where q is the particle charge. The relativistic Hamiltonian then has the same form as in Eqs. (6) and (7), except that all occurrences of p_j must be replaced with $\pi_j := p_j - qA_j$ and the term qA_0 must be added to Eq. (6). The resulting Hamiltonian is relevant, for example, for studies of Lorentz-violating effects in quantum electrodynamics.

III. DEFINITION OF THE FW SEQUENCE

In the strict nonrelativistic limit, the lower two components of the relativistic wave function χ are negligible, so the upper two components of χ suffice to determine the nonrelativistic particle behavior. However, more generally the Dirac equation couples the upper and lower components of χ. The object of the Foldy–Wouthuysen procedure is to find a (momentum-dependent) unitary transformation

$$H \mapsto \tilde{H} := e^{iS} H e^{-iS} = \exp[\mathrm{ad}(iS)]H, \tag{8}$$

where $\mathrm{ad}(X)Y := [X,Y]$, such that $\tilde{H}$ is 2×2 block diagonal. This therefore decouples the upper and lower components of the FW-transformed wave function $\phi := e^{iS}\chi$. Requiring hermiticity of S ensures that e^{iS} is unitary. It follows that $\tilde{H}$ is Hermitian and that both Hamiltonians H and $\tilde{H}$ describe the same physics. The FW transformation amounts to a unitary rotation in the Hilbert space of the free-particle states that preserves the dominance of the upper two components of the wave function. The quantum particle Hamiltonian h_{rel} and the nonrelativistic limit h we seek are given by the leading 2×2 block of $\tilde{H}$.

Solving directly for $\tilde{H}$ would be of interest but is challenging in the general case. Instead, we present a method that allows approximation of $\tilde{H}$ to arbitrary accuracy in an expansion in powers of $|\vec{p}|/m$. The basic idea is to apply a succession of transformations of the type (8), chosen so that each iteration of the transformed Hamiltonian has a smaller block off-diagonal part than the previous one. The exact FW transformation is the limit of this sequence. Although more direct approaches can yield a low-order approximation to h without the use of our method, the results derived here permit straightforward calculation of h_{rel} and of h to any desired order.

For definiteness in what follows, we work within the Dirac-Pauli representation of the Dirac matrices, for which

$$\gamma^0 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad \gamma^j = \begin{pmatrix} 0 & \sigma^j \\ -\sigma^j & 0 \end{pmatrix},$$

where σ^j are the usual Pauli matrices. We define a matrix to be *even* if it is block diagonal and *odd* if it is block off-diagonal. Any 4×4 matrix X can be uniquely written as the sum of an even part and an odd part, $X = \mathrm{even}(X) + \mathrm{odd}(X)$, where $\mathrm{odd}(X) = \frac{1}{2}\gamma^0[\gamma^0, X]$ and $\mathrm{even}(X) = \frac{1}{2}\gamma^0\{\gamma^0, X\}$.

We seek a sequence of FW transformations such that the odd part of the Hamiltonian progressively decreases in some suitable matrix norm, such as $\|A\| := \max_{a,b}\{|A_{ab}|\}$ for $a,b=1,2,3,4$. In the remainder of this section, an appropriate sequence $\{H_n\}$ of Hamiltonians is introduced. For each n, we also introduce a parameter t_n that turns out to provide a measure of the size of $\mathrm{odd}(H_n)$. We show in Sec. IV that with our definition for the FW sequence roughly N iterations are needed to arrive at a nonrelativistic Hamiltonian that is even to order $(|\vec{p}|/m)^{(3^N-1)}$.

To start the FW sequence, choose

$$H_0 = m_0(\gamma^0 + \mathcal{P}_0 + \mathcal{O}_0 + \mathcal{E}_0), \tag{9}$$

where $m_0 := m$ and the terms $\mathcal{P}_0$, $\mathcal{O}_0$, and $\mathcal{E}_0$ are defined in Eq. (7). This decomposition of H_0 into four parts has the following useful properties: (i) $\mathcal{P}_0$ and $\mathcal{O}_0$ are odd; (ii) $\mathcal{E}_0$ is even; (iii) $\mathcal{O}_0$ and $\mathcal{E}_0$ are first order in parameters for Lorentz violation, so products of these quantities can be neglected; and (iv) $\mathcal{P}_0^2$ is proportional to the 4×4 Dirac identity matrix, with proportionality coefficient $t_0^2 = |\vec{p}|^2/m^2$. We choose for the initial FW transformation the Hermitian matrix S_0 defined by

$$iS_0 := \frac{1}{2m_0}\gamma^0[\mathrm{odd}(H_0)] = \tfrac{1}{2}\gamma^0(\mathcal{P}_0 + \mathcal{O}_0). \tag{10}$$

This choice ensures that the odd part of $\exp[\mathrm{ad}(iS_0)]H_0$ is smaller than the odd part of H_0.

Our FW sequence is then defined iteratively by

$$H_{n+1} := e^{iS_n} H_n e^{-iS_n} = \sum_{k=0}^{\infty} \frac{1}{k!} \underbrace{[iS_n,[iS_n,\cdots[iS_n}_{k \text{ commutations with } iS_n},H_0]\cdots]] = \exp[\mathrm{ad}(iS_n)]H_n \tag{11}$$

and

$$iS_{n+1} := \frac{1}{2m_{n+1}}\gamma^0[\mathrm{odd}(H_{n+1})]. \tag{12}$$

Note that

$$H_{n+1} = \left\{ \prod_{k=0}^{n} \exp[\mathrm{ad}(iS_k)] \right\} H_0, \tag{13}$$

where the product represents map composition.

In Sec. IV, we find that each H_{n+1} can be written in the form

$$H_{n+1} = m_{n+1}(\gamma^0 + \mathcal{P}_{n+1} + \mathcal{O}_{n+1} + \mathcal{E}_{n+1}), \tag{14}$$

where the decomposition has the following useful properties: (i) $\mathcal{P}_{n+1}$ and $\mathcal{O}_{n+1}$ are odd; (ii) $\mathcal{E}_{n+1}$ is even; (iii) $\mathcal{O}_{n+1}$ and $\mathcal{E}_{n+1}$ are first order in parameters for Lorentz violation; and (iv) $\mathcal{P}_{n+1}^2$ is proportional to the identity matrix, with proportionality coefficient t_{n+1}^2 determined by t_n^2. The existence of a decomposition of the form (14) for arbitrary n, as well as the case (9) above, is a key feature making it feasible to calculate the quantum particle Hamiltonian.

IV. CALCULATION OF THE FW SEQUENCE

To calculate the FW sequence defined in Sec. III, the explicit form is needed of the operator $\exp[\mathrm{ad}(iS_n)]$ connecting H_n to H_{n+1} according to Eq. (11). Although $\mathrm{ad}(iS_n)H_n$ can be obtained directly using the properties of the Dirac matrices, calculation of $\exp[\mathrm{ad}(iS_j)]H_n$ is more challenging because it is defined by an infinite series. To address this issue, we adopt the following approach: regard $\mathrm{ad}(iS_n)$ as a linear map on a suitable vector space $\mathcal{V}_n$ containing both H_n and H_{n+1}, and find a matrix expression of this map that can be exponentiated.

The first step in implementing this approach is to define $\mathcal{V}_n$ for each n. It is convenient to introduce $\mathcal{V}_n$ as the span of a set of basis vectors $\mathcal{B}_n$, defined in terms of the operators $\gamma^0, \mathcal{P}_n, \mathcal{O}_n, \mathcal{E}_n$ determining H_n together with the particular combinations of these four operators that determine $\mathrm{ad}(iS_n)H_n$ and thus also H_{n+1}. For each n, we define the ordered set

$$\mathcal{B}_n := \{\gamma^0, \mathcal{P}_n, \mathcal{O}_n, \mathcal{P}_n\{\mathcal{P}_n,\mathcal{O}_n\}, \gamma^0[\mathcal{P}_n,\mathcal{E}_n], \mathcal{E}_n, \gamma^0\{\mathcal{P}_n,\mathcal{O}_n\}, \mathcal{P}_n[\mathcal{P}_n,\mathcal{E}_n]\}. \tag{15}$$

The eight-dimensional vector space $\mathcal{V}_n$ is formally defined as the real span of this set, so the elements of $\mathcal{B}_n$ by definition form a (linearly independent) basis. One advantage of this vector space is its relatively small dimensionality, which makes it susceptible to practical calculation. We can thus specify a vector $V \in \mathcal{V}_n$ by eight components $V_1, \ldots, V_8$:

$$V := V_1 \gamma^0 + V_2 \mathcal{P}_n + V_3 \mathcal{O}_n + V_4 \mathcal{P}_n \{\mathcal{P}_n, \mathcal{O}_n\} + V_5 \gamma^0 [\mathcal{P}_n, \mathcal{E}_n] + V_6 \mathcal{E}_n + V_7 \gamma^0 \{\mathcal{P}_n, \mathcal{O}_n\} + V_8 \mathcal{P}_n [\mathcal{P}_n, \mathcal{E}_n] \leftrightarrow (V_1, \ldots, V_8). \tag{16}$$

For example, $H_n \leftrightarrow m_n(1,1,1,0,0,1,0,0)$.

The reader is warned to avoid confusing the properties of the elements (15) as a basis for the vector space $\mathcal{V}_n$ with their possible relationships when viewed as operators on the Hilbert space of wave functions. For example, the calculations below hold even if certain basis elements vanish as operators. Note also that for different n the corresponding vector spaces $\mathcal{V}_n$ differ *a priori*. However, since both $H_n \in \mathcal{V}_n$ and $H_{n+1} \in \mathcal{V}_n$, the vector space $\mathcal{V}_n$ is invariant under the action of $\exp[\mathrm{ad}(iS_n)]$, which means $\mathcal{V}_n \supseteq \mathcal{V}_{n+1}$ for all n.

With the above notation, we can present the results of a direct calculation of $\mathrm{ad}(iS_n)V$ for $V \in \mathcal{V}_n$ performed using the properties of the Dirac matrices:

$$\mathrm{ad}(iS_n)V \leftrightarrow (t_n^2 V_2, -V_1, -V_1, -V_7, \tfrac{1}{2}V_6 + t_n^2 V^8, 0, \tfrac{1}{2}V_2 + \tfrac{1}{2}V_3 + t_n^2 V_4, -V_5). \tag{17}$$

In this expression, t_n^2 is determined iteratively from t_{n-1}^2 through the relation

$$t_{n+1}^2 = \left(\frac{\cos t_n - \dfrac{\sin t_n}{t_n}}{\cos t_n + t_n \sin t_n} \right)^2 t_n^2. \tag{18}$$

Here and in what follows, we define functions of t_n through their power-series expressions. All relevant functions of t_n implicitly involve only powers of t_n^2 (and hence powers of $t_0^2 = |\vec{p}|^2/m^2$), so it suffices to define t_n^2. Note that $t_{n+1} \sim t_n^3$ to leading order in t_n, so $t_n \sim t_0^{(3^n)}$. This means that t_n rapidly approaches zero if $t_0 \ll 1$, which ultimately is the reason for the rapid convergence of our FW sequence.

With respect to the basis $\mathcal{B}_n$, the matrix map of $\mathrm{ad}(iS_n)$ can be extracted from Eq. (17) and is given by

$$\mathrm{ad}(iS_n) \leftrightarrow \begin{pmatrix} 0 & t_n^2 & 0 & 0 & 0 & 0 & 0 & 0 \\ -1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ -1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & 0 & 0 & \tfrac{1}{2} & 0 & t_n^2 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & \tfrac{1}{2} & \tfrac{1}{2} & t_n^2 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & -1 & 0 & 0 & 0 \end{pmatrix}. \tag{19}$$

The exponential of this matrix can be found in closed form, but its detailed expression is unimportant. It can be used to calculate $\exp[\mathrm{ad}(iS_n)]H_n$, which allows us to express H_{n+1} in terms of H_n according to Eq. (14) with

$$m_{n+1}=(\cos t_n+t_n\sin t_n)m_n\,,\quad m_{n+1}\mathcal{P}_{n+1}=\left(\cos t_n-\frac{\sin t_n}{t_n}\right)m_n\mathcal{P}_n\,,$$

$$m_{n+1}\mathcal{O}_{n+1}=\left(\cos t_n-\frac{\sin t_n}{t_n}\right)m_n\mathcal{O}_n+\frac{1}{2t_n^2}\left(\frac{\sin t_n}{t_n}-t_n\sin t_n-\cos t_n\right)m_n\mathcal{P}_n\{\mathcal{P}_n\,,\mathcal{O}_n\}$$
$$+\frac{\sin t_n}{2t_n}m_n\gamma^0[\mathcal{P}_n\,,\mathcal{E}_n], \tag{20}$$

$$m_{n+1}\mathcal{E}_{n+1}=m_n\mathcal{E}_n+(\tfrac{1}{2}\cos t_n)m_n\gamma^0\{\mathcal{P}_n\,,\mathcal{O}_n\}+\left(\frac{\cos t_n-1}{2t_n^2}\right)m_n\mathcal{P}_n[\mathcal{P}_n\,,\mathcal{E}_n].$$

A measure of the convergence of the FW sequence can be introduced using $t_n\sim t_0^{(3^n)}$. In terms of a suitable matrix norm, $\|\mathrm{odd}(H_{n+1})\|\sim t_n^2\|\mathrm{odd}(H_n)\|+t_n\|\mathcal{E}_0\|\sim t_0^{2(3^n)}\|\mathrm{odd}(H_n)\|+t_0^{(3^n)}\|\mathcal{E}_0\|$. Thus, as n grows $\|\mathrm{odd}(H_n)\|$ rapidly approaches zero as $(|\vec{p}|/m)^{3^n}$. Even a relatively small value of n can therefore produce a good approximation to the quantum particle Hamiltonian.

V. NONRELATIVISTIC QUANTUM HAMILTONIAN

The quantum particle Hamiltonian h_{rel} and its nonrelativistic quantum limit h are generated in the limit of the FW sequence studied in the last section. Next, we demonstrate how to obtain these using simple matrix multiplication, and we explicitly present h_{rel} and h to order t_0^3.

The calculation at the kth-iteration level in the FW sequence requires obtaining the composite map $\Pi_{n=0}^k\exp[\mathrm{ad}(iS_n)]$. For each n in the FW sequence, the matrix $\mathrm{ad}(iS_n)$ and the action of $\exp[\mathrm{ad}(iS_n)]$ are given with respect to the basis $\mathcal{B}_n$. Since in general the vector space $\mathcal{V}_n$ varies with n, immediate calculation of $\Pi_{n=0}^k\exp[\mathrm{ad}(iS_n)]$ by matrix multiplication is inappropriate. Instead, we first obtain the components of each matrix with respect to the special basis $\mathcal{B}_0$. Ordinary matrix multiplication can then be used to derive $\Pi_{n=0}^k\exp[\mathrm{ad}(iS_n)]$.

The matrix for each map $\exp[\mathrm{ad}(iS_n)]$ can be expressed in terms of t_n. Explicitly, the nonzero entries for $\exp[\mathrm{ad}(iS_n)]$ with respect to the basis $\mathcal{B}_0$ are:

$$\exp[\mathrm{ad}(iS_n)]\leftrightarrow\begin{pmatrix} c_n+t_n^2s_n & 0 & 0 & 0 & 0 & 0 & 0 & 0\\ 0 & c_n-s_n & 0 & 0 & 0 & 0 & 0 & 0\\ 0 & 0 & c_n-s_n & 0 & 0 & 0 & 0 & 0\\ 0 & 0 & (s_n-t_n^2s_n-c_n)/2t_0^2 & -t_n^2s_n & 0 & 0 & -t_ns_n/t_0 & 0\\ 0 & 0 & 0 & 0 & -t_n^2s_n & t_ns_n/2t_0 & 0 & t_0t_ns_n\\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0\\ 0 & 0 & t_nc_n/2t_0 & t_0t_nc_n & 0 & 0 & c_n & 0\\ 0 & 0 & 0 & 0 & -t_nc_n/t_0 & (c_n-1)/2t_0^2 & 0 & c_n \end{pmatrix}, \tag{21}$$

where we have defined $c_n:=\cos t_n\approx 1-\frac{1}{2}t_n^2$, and $s_n:=\sin t_n/t_n\approx 1-\frac{1}{6}t_n^2$.

Since $t_n\to 0$ as $n\to\infty$, it follows that $\exp[\mathrm{ad}(iS_n)]$ becomes a diagonal matrix with entries (1, 0, 0, 0, 0, 1, 1, 1) in this limit. The product $\Pi_{n=0}^k\exp[\mathrm{ad}(iS_n)]$ therefore converges as $k\to\infty$, so the limiting FW sequence giving the quantum particle Hamiltonian indeed exists. It can be shown that

$$\prod_{j=0}^{\infty}\exp[\mathrm{ad}(iS_j)]\leftrightarrow\begin{pmatrix} \gamma & 0 & 0 & 0 & 0 & 0 & 0 & 0\\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0\\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0\\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0\\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0\\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0\\ 0 & 0 & \frac{1}{2\gamma} & [t_0^2] & 0 & 0 & [1-\frac{1}{2}t_0^2] & 0\\ 0 & 0 & 0 & 0 & \left[-1+\frac{1}{2}t_0^2\right] & -\frac{1}{2\gamma(\gamma+1)} & 0 & \left[1-\frac{1}{2}t_0^2\right] \end{pmatrix}, \tag{22}$$

where $\gamma := \sqrt{1+t_0^2}$ is the usual relativistic gamma factor. Since the limiting FW Hamiltonian is obtained by applying this matrix to $H_0\leftrightarrow(1,1,1,0,0,1,0,0)$, the entries in brackets are irrelevant and so we have evaluated them only to order t_0^2. Thus, we find the limiting FW Hamiltonian to be

$$\tilde{H}=\gamma m_0\gamma^0+m_0\mathcal{E}_0+\frac{m_0}{2\gamma}\gamma^0\{\mathcal{P}_0,\mathcal{O}_0\}-\frac{m_0}{2\gamma(\gamma+1)}\mathcal{P}_0[\mathcal{P}_0,\mathcal{E}_0], \tag{23}$$

an expression that is accurate to all orders in t_0. Substitution from Eq. (7) yields the explicit form

$$\begin{aligned}\tilde{H}=\gamma m\gamma^0&+\left\{a_0-me_0-m(c_{0j}+c_{j0})\frac{p^j}{m}\right\}+\left\{-\frac{mc_{00}}{\gamma}+(a_j-me_j)\frac{p^j}{\gamma m}-m(c_{jk}-\eta_{jk}c_{00})\frac{p^jp^k}{\gamma m^2}\right\}\gamma^0\\ &+\Bigg\{-(md_{j0}+\tfrac{1}{2}\epsilon^{kl}{}_jH_{kl})+\left[-\frac{b_0\eta_{jk}}{\gamma}+m\epsilon^{lm}{}_j(\tfrac{1}{2}g_{lmk}-\eta_{km}g_{l00})\right]\frac{p^k}{m}\\ &\quad+\left[m(d_{0l}+d_{l0})-\frac{(\gamma-1)m^2}{p^2}(md_{l0}+\tfrac{1}{2}\epsilon^{mn}{}_lH_{mn})\right]\eta_{jk}\frac{p^lp^k}{\gamma m^2}\\ &\quad+\left[\frac{(\gamma-1)m^2}{2p^2}m\epsilon^{nq}{}_lg_{nqk}\right]\eta_{jm}\frac{p^kp^lp^m}{\gamma m^3}\Bigg\}\gamma_5\gamma^j\\ &+\Bigg\{\left[-b_j-\frac{1}{2}m\epsilon^{kl}{}_jg_{kl0}\right]\frac{1}{\gamma}+[\epsilon^l{}_{kj}H_{0l}+m(d_{jk}-\eta_{jk}d_{00})]\frac{p^k}{\gamma m}\\ &\quad+\left[m\epsilon^m{}_{lj}(g_{m0k}+g_{mk0})+\frac{(\gamma-1)m^2}{p^2}\eta_{jl}\left(b_k+\frac{1}{2}m\epsilon^{mn}{}_kg_{mn0}\right)\right]\frac{p^kp^l}{\gamma m^2}\\ &\quad+\left[-\frac{(\gamma-1)m^2}{p^2}m(d_{kl}-\eta_{kl}d_{00})\right]\eta_{jm}\frac{p^kp^lp^m}{\gamma m^3}\Bigg\}\gamma_5\gamma^0\gamma^j.\end{aligned} \tag{24}$$

This equation gives the FW form of the relativistic quantum Hamiltonian for a four-component fermion.

Certain limiting forms of Eq. (24) are directly relevant to experiment. For applications involving relativistic two-component particles, such as the analysis of muon storage-ring experiments,[14] it suffices to retain only the upper left block $h_{\rm rel}$ of $\tilde{H}$:

$$
\begin{aligned}
h_{\mathrm{rel}}=\gamma m&+\left(a_0-\frac{mc_{00}}{\gamma}-me_0\right)+[a_j-\gamma m(c_{0j}+c_{j0})-me_j]\frac{p^j}{\gamma m}\\
&-m(c_{jk}-\eta_{jk}c_{00})\frac{p^jp^k}{\gamma m^2}+\left\{\left[-\frac{1}{\gamma}b_j+md_{j0}+\frac{1}{2}\epsilon^{kl}{}_jH_{kl}-\frac{1}{2\gamma}m\epsilon^{kl}{}_jg_{kl0}\right]\right.\\
&+\left[\eta_{jk}b_0+m(d_{jk}-\eta_{jk}d_{00})+\epsilon^l{}_{kj}H_{0l}-\gamma m\epsilon^{lm}{}_j\left(\frac{1}{2}g_{lmk}-\eta_{km}g_{l00}\right)\right]\frac{p^k}{\gamma m}\\
&+\left[\frac{(\gamma-1)m^2}{p^2}\left(b_k+md_{k0}+\frac{1}{2}\epsilon^{mn}{}_kH_{mn}+\frac{1}{2}m\epsilon^{mn}{}_kg_{mn0}\right)\eta_{jl}\right.\\
&\qquad\left.-m(d_{0k}+d_{k0})\eta_{jl}+m\epsilon^m{}_{lj}(g_{m0k}+g_{mk0})\right]\frac{p^kp^l}{\gamma m^2}\\
&\qquad\left.+\frac{(\gamma-1)m^2}{p^2}\left[-m(d_{kl}-\eta_{kl}d_{00})-\frac{1}{2}m\epsilon^{nq}{}_lg_{nqk}\right]\eta_{jm}\frac{p^kp^lp^m}{\gamma m^3}\right\}\sigma^j.
\end{aligned}
\tag{25}
$$

This is the quantum particle Hamiltonian associated with the original Lorentz-violating theory.

For many low-energy applications, including analyses of high-precision atomic experiments,[5–8,15] only nonrelativistic and subleading relativistic terms in the quantum particle Hamiltonian are needed. To third order in $|\vec{p}|/m$, the nonrelativistic quantum Hamiltonian h for the two-component fermion is

$$
\begin{aligned}
h=m&+\frac{p^2}{2m}+(a_0-mc_{00}-me_0)+\left(-b_j+md_{j0}-\frac{1}{2}m\epsilon_{jkl}g_{kl0}+\frac{1}{2}\epsilon_{jkl}H_{kl}\right)\sigma^j\\
&+[-a_j+m(c_{0j}+c_{j0})+me_j]\frac{p_j}{m}\\
&+\left[b_0\delta_{jk}-m(d_{kj}+d_{00}\delta_{jk})-m\epsilon_{klm}\left(\frac{1}{2}g_{mlj}+g_{m00}\delta_{jl}\right)-\epsilon_{jkl}H_{l0}\right]\frac{p_j}{m}\sigma^k\\
&+\left[m\left(-c_{jk}-\frac{1}{2}c_{00}\delta_{jk}\right)\right]\frac{p_jp_k}{m^2}\\
&+\left\{\left[m(d_{0j}+d_{j0})-\frac{1}{2}\left(b_j+md_{j0}+\frac{1}{2}m\epsilon_{jmn}g_{mn0}+\frac{1}{2}\epsilon_{jmn}H_{mn}\right)\right]\delta_{kl}\right.\\
&\qquad\left.+\frac{1}{2}\left(b_l+\frac{1}{2}m\epsilon_{lmn}g_{mn0}\right)\delta_{jk}-m\epsilon_{jlm}(g_{m0k}+g_{mk0})\right\}\frac{p_jp_k}{m^2}\sigma^l+\frac{1}{2}(a_j\delta_{kl}-me_j\delta_{kl})\frac{p_jp_kp_l}{m^3}\\
&\qquad+\frac{1}{2}\left[(-b_0\delta_{jm}+md_{mj}+\epsilon_{jmn}H_{n0})\delta_{kl}+\left(-md_{jk}-\frac{1}{2}m\epsilon_{knp}g_{npj}\right)\delta_{lm}\right]\frac{p_jp_kp_l\sigma^m}{m^3}.
\end{aligned}
\tag{26}
$$

Note that the form of Eq. (23) includes all even elements of the basis set $\mathcal{B}_0$. This means that all possible combinations of the parameters for Lorentz violation are already contained in Eq. (26). Higher-order corrections to the nonrelativistic Hamiltonian involve only products of these combinations with powers of $|\vec{p}|^2/m^2$. One interesting implication of this result is that nonrelativistic experiments with single free fermions (or fermions in weak external fields) can at most be sensitive to the particular linear combinations of parameters for Lorentz violation appearing in Eq. (26). Disentangling individual parameters requires a different class of experiment.

As a final remark, note that our methods can also be used to obtain the nonrelativistic quantum Hamiltonian $\overline{h}$ for the antifermion. The result for $\overline{h}$ can be expressed in the same form as Eq. (26), with the substitutions $a_\mu \to \overline{a}_\mu = -a_\mu$, $b_\mu \to \overline{b}_\mu = +b_\mu$, $c_{\mu\nu} \to \overline{c}_{\mu\nu} = +c_{\mu\nu}$, $d_{\mu\nu} \to \overline{d}_{\mu\nu} = -d_{\mu\nu}$, $e_\mu \to \overline{e}_\mu = -e_\mu$, $f_\mu \to \overline{f}_\mu = -f_\mu$, $g_{\lambda\mu\nu} \to \overline{g}_{\lambda\mu\nu} = +g_{\lambda\mu\nu}$, $H_{\mu\nu} \to \overline{H}_{\mu\nu} = -H_{\mu\nu}$. This result is useful for experiments testing Lorentz symmetry with antimatter.

(Received 22 December 1998; accepted for publication 10 March 1999)

A simple method is proposed to construct the spectral zeta functions required for calculating the electromagnetic vacuum energy with boundary conditions given on a sphere or on an infinite cylinder. When calculating the Casimir energy in this approach no exact divergencies appear and no renormalization is needed. The starting point of the consideration is the representation of the zeta functions in terms of contour integral, further the uniform asymptotic expansion of the Bessel function is essentially used. After the analytic continuation, needed for calculating the Casimir energy, the zeta functions are presented as infinite series containing the Riemann zeta function with rapidly falling down terms. The spectral zeta functions are constructed exactly for a material ball and infinite cylinder placed in a uniform endless medium under the condition that the velocity of light does not change when crossing the interface. As a special case, perfectly conducting spherical and cylindrical shells are also considered in the same line. In this approach one succeeds, specifically, in justifying, in mathematically rigorous way, the appearance of the contribution to the Casimir energy for cylinder which is proportional to $\ln(2\pi)$. © *1999 American Institute of Physics.* [S0022-2488(99)04507-7]

I. INTRODUCTION

A considerable achievement in theoretical investigations of the Casimir effect[1,2] was its calculation for massive fields (scalar and spinor) with boundary conditions on a sphere.[3,4] The various divergent contributions had been discussed in detail from the point of view of the general theory of adiabatic expansions (resp. heat kernel expansion). In a subsequent paper[5] it was clarified in which cases the calculation of the Casimir energy, after the proper renormalization, yields a meaningful (unique) result and in which not independently of the regularization used. For a massive field a well defined result can be obtained in any case using the normalization condition proposed there. Instead, for a massless field the heat kernel coefficient a_2 must vanish in order to allow for a meaningful calculation of the Casimir energy. For instance, this is the case for a material body characterized by a polarizability and a permittivity when the speeds of light inside and outside are the same or their difference is small. The vanishing of a_2 for the Dirichlet and Robin boundary conditions (and as a consequence for the conductor and bag boundary conditions) when taking inside and outside contributions together made Boyer's[6] and all subsequent calcula-

[c)]Electronic mail: Michael.Bordag@itp.uni-leipzig.de

tions possible and meaningful. When using a clever regularization (like the zeta functional one[7,8]) it is even possible to avoid the appearance of divergencies other than that in the Minkowski space contribution at all.

Practically every problem on calculation of the Casimir energy (or force) has been considered multiply with employment of more and more effective and elaborated mathematical methods. For example, the first calculation of the Casimir energy of a perfectly conducting spherical shell[6] carried out by Boyer in 1968 has required computer calculations during 3 years.[9] Later this problem was considered in many papers.[10–12] By making use of the modern methods[13] it can be solved practically without numerical calculations (with a precision of a few percent). It requires only the application of the uniform asymptotic expansion for the Bessel functions.

In recent papers[14,15] the Casimir energy of a compact ball[16] and infinite cylinder has been calculated by making use of the mode-by-mode summation technique. In these problems two sums appear, over the roots of radial frequency equation at fixed value of angular momentum and then over angular momentum. The either of these sums is divergent. In papers[14,15] for each of these summation a separate regularization has been used. The first summation was carried out by applying the contour integration with subsequent subtraction of the contribution of an infinite homogeneous space. The second sum was evaluated by making use of the Riemann ζ function technique. However the procedure of analytic continuation, required by rigorous approach, has not been considered there.

The present paper pursues the aim to eliminate the minor points of preceding considerations, i.e., the Casimir energy for two configurations mentioned above will be calculated by the rigorous ζ function techniques, and the analytic continuation of the relevant spectral ζ functions will be carried out exactly. An essential advantage of this regularization procedure is that no manifestly divergent expressions arise in its framework, and it gives a final finite result without any subtractions (renormalizations).

The layout of this paper is as follows. In Sec. II, the spectral zeta function is constructed for a compact ball placed in uniform endless medium when the light velocity is the same inside and outside the ball. As a special case the zeta function for perfectly conducting spherical shell is also considered. In Sec. III the spectral functions for infinite cylinder are constructed under the same conditions. These results provide a firm footing for the previous calculations of the Casimir energy for given boundary conditions by making use of a ''naive'' zeta function method. In Sec. IV the obtained results are shortly discussed.

II. CASIMIR ENERGY OF A COMPACT BALL UNDER THE CONDITION $\epsilon\mu=1$

In the ζ function method[7,8] the Casimir energy E_C is defined in the following way. Let ω_p's be the eigenfrequencies of the quantum field system under the influence of the boundary conditions, and let $\overline{\omega_p}$'s be the same frequencies when the boundaries are removed. By making use of this spectrum one defines the ζ function for the problem in hand,

$$\zeta(s)=\sum_{\{p\}}(\omega_p^{-s}-\overline{\omega_p}^{-s}). \tag{2.1}$$

Here the summation (or integration) should be done over all the quantum numbers $\{p\}$ specifying the spectrum. The parameter s is considered at first to belong to region of the complex plane s where the sum (2.1) exists. Further the analytic continuation of (2.1) to the point $s=-1$ should be constructed. After that one puts

$$E_C=\tfrac{1}{2}\zeta(s=-1). \tag{2.2}$$

Let us consider a solid ball of radius a, consisting of a material which is characterized by permittivity ϵ_1 and permeability μ_1. The ball is assumed to be placed in an infinite medium with permittivity ϵ_2 and permeability μ_2. The eigenfrequencies of electromagnetic field for this configuration are determined by the frequency equation for the TE modes,[17]

$$\Delta_l^{\mathrm{TE}}(a\omega)\equiv\sqrt{\epsilon_1\mu_2}\,\tilde{s}_l'(k_1a)\tilde{e}_l(k_2a)-\sqrt{\epsilon_2\mu_1}\,\tilde{s}_l(k_1a)\tilde{e}_l'(k_2a)=0, \tag{2.3}$$

and the analogous equation for the TM modes

$$\Delta_l^{\mathrm{TM}}(a\omega)\equiv\sqrt{\epsilon_2\mu_1}\,\tilde{s}_l'(k_1a)\tilde{e}_l(k_2a)-\sqrt{\epsilon_1\mu_2}\,\tilde{s}_l(k_1a)\tilde{e}_l'(k_2a)=0, \tag{2.4}$$

where $k_i=\sqrt{\epsilon_i\mu_i}\omega,\ i=1,2$ are the wave numbers inside and outside the ball, respectively. Here $\tilde{s}_l(x)$ and $\tilde{e}_l(x)$ are the Riccati–Bessel functions,

$$\tilde{s}_l(x)=\sqrt{\frac{\pi}{2x}}J_{l+1/2}(x), \quad \tilde{e}_l(x)=\sqrt{\frac{\pi}{2x}}H^{(1)}_{l+1/2}(x), \tag{2.5}$$

and prime stands for the differentiation with respect to their arguments, k_1a or k_2a. The orbital momentum l in Eqs. (2.3) and (2.4) assumes the values 1,2,... .

As usual when one is dealing with an analytic continuation, it is convenient to represent the sum (2.1) in terms of the contour integral

$$\zeta_C(s)=\sum_{l=1}^{\infty}\frac{2l+1}{2\pi i}\lim_{\mu\to 0}\oint_C dz(z^2+\mu^2)^{-s/2}\frac{d}{dz}\ln\frac{\Delta_l^{\mathrm{TE}}(az)\Delta_l^{\mathrm{TM}}(az)}{\Delta_l^{\mathrm{TE}}(\infty)\Delta_l^{\mathrm{TM}}(\infty)}, \tag{2.6}$$

where the contour C surrounds, counterclockwise, the roots of the frequency equations in the right half-plane. For brevity we write in (2.6) simply $\Delta_l(\infty)$ instead of $\lim_{a\to\infty}\Delta_l(az)$. Transition to the complex frequencies z in Eq. (2.6) is accomplished by introducing the unphysical photon mass μ,

$$\omega\to(z^2+\mu^2)^{s/2}|_{\mu\to 0}. \tag{2.7}$$

Extension to the complex z-plane of the frequency equations $\Delta_l^{\mathrm{TE}}(az)$ and $\Delta_l^{\mathrm{TM}}(az)$ should be done in the following way. In the upper (lower) half-plane the Hankel functions of the first (second) kind $H_\nu^{(2)}(az)(H_\nu^{(1)}(az))$ must be used.[18] Location of the roots of Eqs. (2.3) and (2.4) enables one to deform the contour C into a segment of the imaginary axis $(-i\Lambda,i\Lambda)$ and a semicircle of radius Λ in the right half-plane. When Λ tends to infinity the contribution along the semicircle into $\zeta_{\mathrm{ball}}(s)$ vanishes because the argument of the logarithmic function in the integrand tends in this case to 1. As a result we obtain

$$\zeta_{\mathrm{ball}}(s)=-a^s\sum_{l=1}^{\infty}\frac{(2l+1)}{2\pi i}\lim_{\mu\to 0}\int_{-i\infty}^{+i\infty}dz(z^2+\mu^2)^{-s/2}\frac{d}{dz}\ln\frac{\Delta_l^{\mathrm{TE}}(z)\Delta_l^{\mathrm{TM}}(z)}{\Delta_l^{\mathrm{TE}}(\infty)\Delta_l^{\mathrm{TM}}(\infty)}. \tag{2.8}$$

Now we impose the condition that the velocity of light inside and outside the ball is the same

$$\epsilon_1\mu_1=\epsilon_2\mu_2=c^{-2}. \tag{2.9}$$

Under this assumption the argument of the logarithm in (2.8) can be simplified considerably[14] with the result

$$\zeta_{\mathrm{ball}}(s)=\left(\frac{c}{a}\right)^{-s}\sum_{l=1}^{\infty}(2l+1)\frac{\sin(\pi s/2)}{\pi}\int_0^{\infty}dy\,y^{-s}\frac{d}{dy}\ln[1-\xi^2\sigma_l^2(y)], \tag{2.10}$$

where

$$\xi=\frac{\epsilon_1-\epsilon_2}{\epsilon_1+\epsilon_2}, \quad \sigma_l(y)=\frac{d}{dy}[s_l(y)e_l(y)]. \tag{2.11}$$

Here $s_l(y)$ and $e_l(y)$ are the modified Riccati–Bessel functions,

$$s_l(x)=\sqrt{\frac{\pi x}{2}}I_\nu(x),\quad e_l(x)=\sqrt{\frac{2x}{\pi}}K_\nu(x),\quad \nu=l+1/2. \tag{2.12}$$

More details concerning the contour integral representation of the spectral ζ functions can be found in Refs. 3, 19–21.

Further the analytic continuation of Eq. (2.10) is accomplished by expressing the sum over l in terms of the Riemann ζ function. This cannot be done in a closed form. Making use of the uniform asymptotic expansion (UAE) for the Bessel functions in increase powers of $1/\nu$ enables one to construct the analytic continuation looked for in the form of the series, the terms of which are expressed through the Riemann ζ function. The problem of the convergence of this series does not arise because its terms go down very fast.

We demonstrate this keeping only two terms in the UAE for the product of the Bessel functions $I_\nu(\nu z)K_\nu(\nu z)$,[22]

$$I_\nu(\nu z)K_\nu(\nu z)\simeq\frac{t}{2\nu}\left[1+\frac{t^2(1-6t^2+t^4)}{8\nu^2}+\cdots\right],\quad t=\frac{1}{\sqrt{1+z^2}}. \tag{2.13}$$

After changing the integration variable $y=\nu z$ in Eq. (2.10) we substitute (2.13) into this formula and expand the logarithm function up to the order ν^{-3} keeping at the same time only the terms linear in ξ^2. The last assumption is not principal. It is introduced for simplicity and in order to have possibility of a direct comparison with the results of Ref. 14. Thus we have

$$\frac{d}{dz}\ln\left\{1-\xi^2\left[\frac{d}{dz}(zI_\nu(\nu z)K_\nu(\nu z))\right]^2\right\}$$
$$=\frac{3}{2}\frac{\xi^2}{\nu^2}zt^8+\frac{\xi^2}{16\nu^4}zt^8(-12+216t^2-600t^4+420t^6)+O(\nu^{-6}). \tag{2.14}$$

Integration over z can be done by making use of the formula

$$\int_0^\infty z^{-\alpha-1}t^\beta dz=\frac{1}{2}\frac{\Gamma\left(\frac{\alpha+\beta}{2}\right)\Gamma\left(-\frac{\alpha}{2}\right)}{\Gamma\left(\frac{\beta}{2}\right)}. \tag{2.15}$$

Also the properties of the Γ function,

$$\Gamma(z)\Gamma(1-z)=\frac{\pi}{\sin\pi z},\quad \Gamma(1+z)=z\Gamma(z) \tag{2.16}$$

prove to be useful. After simple calculations we arrive at the result

$$\zeta_{\text{ball}}(s)\simeq\frac{\xi^2}{32}\left(\frac{c}{a}\right)^{-s}s(2+s)(4+s)\left(\sum_{l=1}^\infty \nu^{-1-s}+p(s)\sum_{l=1}^\infty \nu^{-3-s}+\cdots\right),\quad \nu=l+1/2, \tag{2.17}$$

where

$$p(s)=-\frac{1}{2}\left[1-\frac{9}{4}(6+s)+\frac{5}{8}(6+s)(8+s)-\frac{7}{192}(6+s)(8+s)(10+s)\right]. \tag{2.18}$$

The zeta function $\zeta_{\text{ball}}(s)$ represented in the form (2.17) is defined for $\text{Re}\,s>0$ due to the first sum over l. This term corresponds to the order $1/\nu$ in the uniform asymptotic expansion (2.13). The second sum in (2.17), defined at $\text{Re}\,s>-2$, has been generated by the term $\sim 1/\nu^3$ in Eq. (2.13).

It is clear that the terms of order $1/\nu^{2k+1}$ in (2.13) will give rise to the singularity of $\zeta_{\mathrm{ball}}(s)$ at the points $s=-2k,\ k=0,1,2,\ldots$. Due to the multipliers in front of the square brackets in (2.17) the first three singularities are really the indefinitenesses like $0\cdot\infty$.

The analytic continuation of Eqs. (2.17), (2.18) into the region $\mathrm{Re}\, s\leqslant 0$ can be accomplished by expressing the sums over angular momentum l through the Riemann ζ function according to the formula,[23]

$$\sum_{l=1}^{\infty}\nu^{-s}=(2^s-1)\zeta(s)-2^s,\quad \nu=l+1/2. \tag{2.19}$$

As a result one gets

$$\zeta_{\mathrm{ball}}(s)\simeq\frac{\xi^2}{32}\left(\frac{c}{a}\right)^{-s}s(2+s)(4+s)\{(2^{1+s}-1)\zeta(1+s) -2^{1+s}+p(s)[(2^{3+s}-1)\zeta(1+s)-2^{3+s}]+\cdots\}. \tag{2.20}$$

The singularities in Eq. (2.17) are transformed in (2.20) into the poles of the Riemann ζ functions at the points $s=2k,\ k=0,1,2,\ldots$,

$$\begin{aligned}\zeta(1+s)&\simeq\frac{1}{s}+\gamma+\cdots,\quad s\to 0,\\ \zeta(3+s)&\simeq\frac{1}{s+2}+\gamma+\cdots,\quad s\to -2,\\ \zeta(5+s)&\simeq\frac{1}{s+4}+\gamma+\cdots,\quad s\to -4,\end{aligned} \tag{2.21}$$

where γ is the Euler constant. The first three poles are annihilated by the multipliers in front of the curly brackets in Eq. (2.20). The first surviving singularity (simple pole) appears only at the point $s=-6$. Thus the formula (2.20) affords the required analytic continuation of the function $\zeta_{\mathrm{ball}}(s)$ into the region $\mathrm{Re}\, s<0$. In view of Eq. (2.2) we are interested in the point $s=-1$, where $\zeta_{\mathrm{ball}}(s)$ given by (2.20) is regular,

$$\zeta_{\mathrm{ball}}(-1)=\frac{3\xi^2c}{32a}\left[1+\frac{9}{128}\left(\frac{\pi^2}{2}-4\right)+\cdots\right]. \tag{2.22}$$

It is exactly the first two terms in Eq. (3.10) of Ref. 14. The procedure of analytic continuation presented above can be extended in a straightforward way to the arbitrary order of the uniform asymptotic expansion (2.13). Certainly in this case analytical calculations should be done by making use of MATHEMATICA or MAPLE.

The problem under consideration with $\xi=1$ is of a special interest because in this case it gives the Casimir energy of a perfectly conducting spherical shell. As it was noted above, this configuration has been considered by many authors. We present here the basic formulas which afford the analytical continuation of the corresponding spectral ζ function. We again content ourselves with two terms in the UAE (2.13). It is impossible to put simply $\xi=1$ in the next formula (2.14). One has to do the expansion here anew keeping all the terms $\sim 1/\nu^4$. This gives

$$\frac{d}{dz}\ln\left\{1-\left[\frac{d}{dz}(zI_\nu(\nu z)K_\nu(\nu z))\right]^2\right\}=\left[\frac{3}{2\nu^2}zt^8+\frac{3}{4\nu^4}zt^8(-1+18t^2-50t^4+35t^6)+O(\nu^{-6})\right]. \tag{2.23}$$

After integration and elementary simplifications we arrive at the following result for the spectral zeta function in hand,

$$\zeta_{\text{shell}}(s) \simeq \frac{1}{32a^{-s}} s(2+s)(4+s)\left[\sum_{l=1}^{\infty} \nu^{-1-s} + q(s)\sum_{l=1}^{\infty} \nu^{-3-s} + \cdots\right], \tag{2.24}$$

where

$$q(s) = \frac{1}{3840}(480+868s+504s^2+71s^3). \tag{2.25}$$

Obviously formula (2.23) has the same singularities as Eq. (2.17), i.e., it is defined for $\mathrm{Re}\, s>0$. The analytic continuation is accomplished by making use of Eq. (2.19),

$$\zeta_{\text{shell}}(s) \simeq \frac{1}{32a^{-s}} s(2+s)(4+s)\{(2^{1+s}-1)\zeta(1+s) - 2^{1+s} + q(s)[(2^{3+s}-1)\zeta(3+s) - 2^{3+s}] + \cdots\}. \tag{2.26}$$

The nearest singularity in this formula is simple pole at $s=-6$. As above it is originated in the term $\sim 1/\nu^7$ in the UAE (2.13). At the point $s=-1$ the spectral zeta function $\zeta_{\text{shell}}(s)$ is regular and gives the following value for the Casimir energy of a perfectly conducting spherical shell,

$$E_{\text{shell}}(-1) = \frac{1}{2}\zeta_{\text{shell}}(-1) = \frac{3}{64a}\left[1 - \frac{3}{256}\left(\frac{\pi^2}{2}-4\right) + \cdots\right] = \frac{1}{a}0.046361\ldots. \tag{2.27}$$

Without considering the analytic continuation and by not carrying out the analysis of the singularities in the complex s plane this result has been obtained in Ref. 13.

Undoubtedly, the calculation of the Casimir energy of a nonmagnetic dielectric ball ($\epsilon_1\mu_1 \neq \epsilon_2\mu_2$) by a rigorous ζ function method is also of a special interest. However, in this case the very definition of the spectral zeta function should probably be changed in order to incorporate the contact terms which seem to be essential in this problem.[24–26]

III. VACUUM ENERGY OF ELECTROMAGNETIC FIELD WITH BOUNDARY CONDITIONS GIVEN ON AN INFINITE CYLINDER

Calculation of the Casimir energy of an infinite cylinder[27,15] proves to be a more involved problem in comparison with that for a sphere. In this section the spectral zeta function $\zeta_{\text{cyl}}(s)$, for this configuration will be constructed, its analytical continuation into the left half-plane of the complex variable s will be carried out, and relevant singularities will be analyzed.

Thus we are considering an infinite cylinder of radius a which is placed in a uniform unbounded medium. The permittivity and the permeability of the material making up the cylinder are ϵ_1 and μ_1, respectively, and those for the surrounding medium are ϵ_2 and μ_2. We assume again that the condition (2.9) is fulfilled. In this case the electromagnetic oscillations can again be divided into the transverse-electric (TE) modes and transverse-magnetic (TM) modes. In terms of the cylindrical coordinates (r,θ,z) the eigenfunctions of the given boundary value problem contain the multiplier

$$\exp(\pm i\omega t + ik_z z + in\theta) \tag{3.1}$$

and their dependence on r is described by the Bassel functions J_n for $r<a$ and by the Hankel functions $H_n^{(1)}$ or $H_n^{(2)}$ for $r>a$. The frequencies of TE- and TM-modes are determined, respectively, by the equations[17]

$$\Delta_n^{\text{TE}}(\lambda,a) \equiv \lambda a[\mu_1 J_n'(\lambda a)H_n(\lambda a) - \mu_1 J_n(\lambda a)H_n(\lambda a)'] = 0, \tag{3.2}$$

$$\Delta_n^{\mathrm{TM}}(\lambda,a)\equiv\lambda a[\epsilon_1 J_n'(\lambda a)H_n(\lambda a)-\epsilon_1 J_n(\lambda a)H_n(\lambda a)']=0, \tag{3.3}$$

where $n=0,\pm1,\pm2,\ldots$. Here λ is the eigenvalue of the corresponding transverse (membranelike) boundary value problem

$$\lambda^2=\frac{\omega^2}{c^2}-k_z^2. \tag{3.4}$$

In a complete analogy with the preceding section we define the Casimir energy per unit length of the cylinder through the spectral zeta function

$$E_{\mathrm{cyl}}=\tfrac{1}{2}\zeta_{\mathrm{cyl}}(-1). \tag{3.5}$$

Let λ_{nr} be the roots of the frequency Eqs. (3.2) and (3.3), then the function $\zeta_{\mathrm{cyl}}(s)$ is introduced in the following way:

$$\zeta_{\mathrm{cyl}}(s)=c^{-s}\int_{-\infty}^{+\infty}\frac{dk_z}{2\pi}\sum_{n,r}[(\lambda_{nr}(a)+k_z^2)^{-s/2}-(\lambda_{nr}(\infty)+k_z^2)^{-s/2}]. \tag{3.6}$$

In terms of the contour integral it can be represented in the form

$$\zeta_{\mathrm{cyl}}(s)=\frac{c^{-s}}{2\pi i}\int_{-\infty}^{+\infty}\frac{dk_z}{2\pi}\sum_{n=-\infty}^{+\infty}\oint_C(\lambda^2+k_z^2)^{-s/2}d_\lambda\ln\frac{\Delta_n^{\mathrm{TE}}(\lambda a)\Delta_n^{\mathrm{TM}}(\lambda a)}{\Delta_n^{\mathrm{TE}}(\infty)\Delta_n^{\mathrm{TM}}(\infty)}. \tag{3.7}$$

Again we can take the contour C to consist of the imaginary axis $(+i\infty,-i\infty)$ closed by a semicircle of an infinitely large radius in the right half-plane. Continuation of the expressions $\Delta_n^{\mathrm{TE}}(\lambda a)$ and $\Delta_n^{\mathrm{TM}}(\lambda a)$ into the complex plane λ should be done in the same way as in the preceding section, i.e., by using $H_n^{(1)}(\lambda)$ for $\mathrm{Im}\,\lambda<0$ and $H_n^{(2)}(\lambda)$ for $\mathrm{Im}\,\lambda>0$. On the semicircle the argument of the logarithm in Eq. (3.7) tends to 1. As a result this part of the contour C does not give any contribution into the zeta function $\zeta_{\mathrm{cyl}}(s)$. When integrating along the imaginary axis we choose the branch line of the function $\phi(\lambda)=(\lambda^2+k_z^2)^{-s/2}$ to run between $-ik_z$ and $+ik_z$, where $k_z=+\sqrt{k_z^2}>0$ and use further that branch of this function which assumes real values when $|y|<k_z$, where $y=\mathrm{Im}\,\lambda$. More precisely we have

$$\phi(iy)=\begin{cases} e^{-i\pi s/2}(y^2-k_z^2)^{-s/2}, & y>k_z, \\ (k_z^2-y^2)^{-s/2}, & |y|<k_z, \\ e^{i\pi s/2}(y^2-k_z^2)^{-s/2}, & y<-k_z. \end{cases} \tag{3.8}$$

Employment of the Hankel functions $H_n^{(1)}(\lambda)$ and $H_n^{(2)}(\lambda)$ by extending the expressions $\Delta_n^{\mathrm{TE}}(\lambda)$ and $\Delta_n^{\mathrm{TM}}(\lambda)$ into the complex plane λ, as it was noted above, gives rise to the argument of the logarithm function depending only on y^2 on the imaginary axis. It means that the derivative of the logarithm is an odd function of y. As a result the segment of the imaginary axis $(-ik_z,+ik_z)$ gives zero, and Eq. (3.7) acquires the form

$$\zeta_{\mathrm{cyl}}(s)=\frac{c^{-s}}{\pi^2}\sin\frac{\pi s}{2}\sum_{n=-\infty}^{+\infty}\int_0^\infty dk_z\int_{k_z}^\infty(y^2-k_z^2)^{-s/2}d_y\ln\frac{\Delta^{\mathrm{TE}}(iay)_n\Delta_n^{\mathrm{TM}}(iay)}{\Delta_n^{\mathrm{TE}}(i\infty)\Delta_n^{\mathrm{TM}}(i\infty)}. \tag{3.9}$$

Changing the order of integration of k_z and y and taking into account the value of the integral,

$$\int_0^y dk_z(y^2-k_z^2)^{-s/2}=\frac{\sqrt{\pi}}{2}y^{1-s}\frac{\Gamma\left(1-\frac{s}{2}\right)}{\Gamma\left(\frac{3-s}{2}\right)},\quad \mathrm{Re}\,s<2, \tag{3.10}$$

we obtain after the substitution $ay \to y$,

$$\zeta_{\rm cyl}(s)=\frac{1}{2\sqrt{\pi}a\Gamma\left(\frac{s}{2}\right)\Gamma\left(\frac{3-s}{2}\right)}\left(\frac{c}{a}\right)^{-s}\sum_{n=-\infty}^{+\infty}\int_0^\infty dy y^{1-s}\frac{d}{dy}\ln[1-\xi^2\mu_n^2(y)], \tag{3.11}$$

where

$$\mu_n(y)=y(I_n(y)K_n(y))', \quad \xi=\frac{\epsilon_1-\epsilon_2}{\epsilon_1+\epsilon_2}. \tag{3.12}$$

We shall again content ourselves with the first two terms in the uniform asymptotic expansion (2.13) and take into account only the terms linear in ξ^2. In this approximation, upon changing the integration variable $y=nz$, $n=\pm 1,\pm 2,...$, we have

$$\ln\left\{1-\xi^2\left[z\frac{d}{dz}(I_n(nz)K_n(nz))\right]^2\right\}=-\xi^2\frac{z^4t^6}{4n^2}\left[1+\frac{t^2}{4n^2}(3-30t^2+35t^4)+O(n^{-4})\right]. \tag{3.13}$$

Now we substitute (3.13) into all the terms in (3.11) with $n\neq 0$. The term with $n=0$ in this sum will be treated by subtracting and adding to the logarithmic function the quantity

$$-\frac{\xi^2}{4}\frac{y^4}{(1+y^2)^3}. \tag{3.14}$$

As a result the zeta function $\zeta_{\rm cyl}(s)$ can be presented now as the sum of three terms,

$$\xi_{\rm cyl}(s)=Z_1(s)+Z_2(s)+Z_3(s), \tag{3.15}$$

where

$$Z_1(s)=\frac{\left(\frac{c}{a}\right)^{-s}}{2\sqrt{\pi}a\Gamma\left(\frac{s}{2}\right)\Gamma\left(\frac{3-s}{2}\right)}\int_0^\infty dy y^{1-s}\frac{d}{dy}\left\{\ln[1-\xi^2\mu_0^2(y)]+\frac{\xi^2}{4}y^4t^6\right\}, \tag{3.16}$$

$$Z_2(s)=-\xi^2\left(\frac{c}{a}\right)^{-s}\frac{2\Sigma_{n=1}^{+\infty}n^{-s-1}+1}{8\sqrt{\pi}a\Gamma\left(\frac{s}{2}\right)\Gamma\left(\frac{3-s}{2}\right)}\int_0^\infty dz z^{1-s}\frac{d}{dz}(z^4t^6), \tag{3.17}$$

$$Z_3(s)=-\xi^2\frac{2\left(\frac{c}{a}\right)^{-s}\Sigma_{n=1}^{+\infty}n^{-3-s}}{32\sqrt{\pi}a\Gamma\left(\frac{s}{2}\right)\Gamma\left(\frac{3-s}{2}\right)}\int_0^\infty dz z^{1-s}\frac{d}{dz}[z^4t^8(3-30t^2+35t^4)]. \tag{3.18}$$

In these equations $Z_1(s)$ has accumulated the term with $n=0$ from Eq. (3.11) subtracted by (3.14); $Z_2(s)$ involves the contribution of the term of order $1/n^2$ in expansion (3.13) and the added expression (3.14); $Z_3(s)$ is generated by the terms of order $1/n^4$ in the expansion (3.13).

Taking into account that

$$\mu_0^2(y)|_{y\to 0}\to 1 \quad \text{and} \quad \mu_0^2(y)|_{y\to\infty}\to\frac{1}{4y^2}+\frac{3}{16y^4}, \tag{3.19}$$

the integration by parts in Eq. (3.16) can be done for $-3<\mathrm{Re}\, s<1$ with the result

$$Z_1(s)=\frac{s-1}{2\sqrt{\pi}a\Gamma\left(\frac{s}{2}\right)\Gamma\left(\frac{3-s}{2}\right)}\left(\frac{c}{a}\right)^{-s}\int_0^\infty dy\, y^{-s}\left\{\ln[1-\xi^2\mu_0^2(y)]+\frac{\xi^2}{4}y^4t^6(y)\right\}. \tag{3.20}$$

With allowance for (3.19) one infers easily that the function $Z_1(s)$ is an analytic function of the complex variable s in the region $-3<\mathrm{Re}\,s<1$. In the linear order of ξ^2 it reduces to

$$Z_1^{\mathrm{lin}}(s)=\xi^2\frac{s-1}{2\sqrt{\pi}a\Gamma\left(\frac{s}{2}\right)\Gamma\left(\frac{3-s}{2}\right)}\left(\frac{c}{a}\right)^{-s}\int_0^\infty dy\, y^{-s}\left[\frac{y^2}{4(1+y^2)^3}-\mu_0^2(y)\right]. \tag{3.21}$$

This function is also analytic in the region $-3<\mathrm{Re}\,s<1$. Integration in Eq. (3.17) can be accomplished exactly by making use of the formula

$$\int_0^\infty dz\, z^{1-s}\frac{d}{dz}(z^4t^6)=\frac{s-1}{4}\Gamma\left(\frac{1+s}{2}\right)\Gamma\left(\frac{5-s}{2}\right), \quad -1<\mathrm{Re}\,s<5. \tag{3.22}$$

This gives for $Z_2(s)$ in (3.17),

$$Z_2(s)=\xi^2\left(\frac{c}{a}\right)^{-s}\frac{(1-s)(3-s)}{64\sqrt{\pi}a}\left(2\sum_{n=1}^\infty n^{-s-1}+1\right)\frac{\Gamma\left(\frac{1+s}{2}\right)}{\Gamma\left(\frac{s}{2}\right)}. \tag{3.23}$$

In view of the sum over n in (3.23) the function $Z_2(s)$ is defined only for $\mathrm{Re}\,s>0$.

For simplicity we apply in Eq. (3.18) the integration by parts which is correct for $-3<\mathrm{Re}\,s<2$ and leads to the result,

$$Z_3(s)=\xi^2\left(\frac{c}{a}\right)^{-s}\frac{(1-s)(3-s)(7s^2-4s-27)}{6144\sqrt{\pi}a}\frac{\Gamma\left(\frac{3+s}{2}\right)}{\Gamma\left(\frac{s}{2}\right)}\sum_{n=1}^\infty n^{-s-3}. \tag{3.24}$$

Again the sum over n in (3.24) gives the restriction $\mathrm{Re}\,s>-2$ for definition of the function $Z_3(s)$.

Thus the spectral zeta function $\zeta_{\mathrm{cyl}}(s)$ in the linear approximation with respect to ξ^2 and with allowance for the first two terms in the UAE (3.13) is given by

$$\zeta_{\mathrm{cyl}}(s)=Z_1^{\mathrm{lin}}(s)+Z_2(s)+Z_3(s), \tag{3.25}$$

where the Z's are presented in Eqs. (3.21), (3.23), and (3.24), respectively. Summing up all the restrictions on the complex variable s which have been imposed when deriving Eqs. (3.21), (3.23), and (3.24), we infer that $\zeta_{\mathrm{cyl}}(s)$ is defined in the strip $0<\mathrm{Re}\,s<1$. In order to continue these equations into the surroundings of the point $s=-1$, it is sufficient to express the sum in Eq. (3.23) in terms of the Riemann ζ function and consider the right-hand side of Eq. (3.22) as an analytic continuation of its left-hand side to this region,

$$Z_2(s)=\xi^2\left(\frac{c}{a}\right)^{-s}\frac{(1-s)(3-s)}{64\sqrt{\pi}a}[2\zeta(s+1)+1]\frac{\Gamma\left(\frac{1+s}{2}\right)}{\Gamma\left(\frac{s}{2}\right)}. \tag{3.26}$$

It is left now to take the limit $s\to -1$ in Eqs. (3.21), (3.23), and (3.26). A special care should be paid when calculating this limit in (3.26) in view of the poles of the function $\Gamma((1+s)/2)$ at this point. Using the values

$$\zeta(0)=-\tfrac{1}{2},\quad \zeta'(0)=-\tfrac{1}{2}\ln 2\pi,\quad \Gamma'(1)=-\gamma, \tag{3.27}$$

one derives

$$\lim_{s\to -1}[2\zeta(1+s)+1]\Gamma\left(\frac{1+s}{2}\right)=\lim_{s\to -1}[2\zeta(0)+2\zeta'(0)(1+s)+O((1+s)^2)+1]$$
$$\times\left[\frac{2}{1+s}-\gamma+O(1+s)\right]=-2\ln(2\pi). \tag{3.28}$$

With allowance for this we obtain from (3.26)

$$Z_2(-1)=\frac{c\xi^2}{2\pi a^2}\frac{1}{4}\ln(2\pi). \tag{3.29}$$

The appearance of the finite term proportional to $\ln(2\pi)$ is remarkable for the problem under consideration. It is derived here in a consistent way by making use of an analytic continuation of the relevant spectral zeta function. In Ref. 15 it was obtained in a more transparent though not rigorous way.

Gathering together Eqs. (3.21), (3.24) with $s=-1$ and Eq. (3.29) we have

$$\xi_{\text{cyl}}(-1)=\frac{c\xi^2}{2\pi a^2}\left\{\int_0^\infty y d_y\left[\frac{y^4}{4(1+y^2)^3}-\mu_0^2(y)\right]+\frac{1}{48}\sum_{n=1}^{+\infty}\frac{1}{n^2}+\frac{1}{4}\ln(2\pi)\right\}$$
$$=\frac{c\xi^2}{2\pi a^2}(-0.490878+0.34269+0.459469)=\frac{c\xi^2}{2\pi a^2}0.002860. \tag{3.30}$$

This result is not the final answer in the problem in hand. The point is that in view of severe cancellations in (3.30) the contribution of the next term in the UAE (3.13) proves to be essential. Its account gives[15]

$$\zeta_{\text{cyl}}(-1)=0. \tag{3.31}$$

Thus the Casimir energy of a compact cylinder possessing the same speed of light inside and outside proves to be zero. The consideration presented in this section can be extended to the next term of order $\sim 1/n^6$ in the UAE (3.13) in a straightforward way. Therefore we shall not present here these rather cumbersome expressions.[28]

Now we address the consideration of a special case when $\xi=1$. It corresponds to a perfectly conducting cylindrical shell.[15] Instead of the expansion (3.13) we have

$$\ln\left\{1-\left[z\frac{d}{dz}(I_n(nz)K_n(nz))\right]^2\right\}=-\frac{z^4t^6}{4n^2}\left[1+\frac{t^2}{4n^2}\left(3-30t^2+35t^4+\frac{1}{2}z^4t^4\right)+O(n^{-4})\right]. \tag{3.32}$$

Proceeding in the same way as above we obtain for the spectral zeta function concerned

$$\zeta_{\text{cyl}}^{\text{shell}}(s)=Z_1(s)+Z_2(s)+Z_3(s), \tag{3.33}$$

where $Z_1(s)$ is given by Eq. (3.20) with $c=1$, $\xi=1$, $Z_2(s)$ is the same as in Eq. (3.26) with $c=1$, and $Z_3(s)$ now is

$$Z_3(s)=\frac{(1-s)(3-s)(71s^2-52s-235)}{61440\sqrt{\pi}a^{1-s}}\frac{\Gamma\left(\frac{3+s}{2}\right)}{\Gamma\left(\frac{s}{2}\right)}\sum_{n=1}^{+\infty} n^{-3-s}. \tag{3.34}$$

At the point $s=-1$ it has the value

$$\zeta_{\rm cyl}^{\rm shell}(-1)=\frac{1}{2\pi a^2}(-0.6517)+\frac{1}{2\pi a^2}\frac{7}{480}\sum_{n=1}^{+\infty}\frac{1}{n^2}+\frac{1}{8\pi a^2}\ln(2\pi)$$
$$=\frac{1}{2\pi a^2}(-0.6517+0.0240+0.4595)=-\frac{1}{a^2}0.0268. \tag{3.35}$$

This exactly reproduces the contribution of the first two terms in calculations of the Casimir energy for cylindrical shell in Ref. 15. With higher accuracy this energy is given by[27]

$$E_{\rm cyl}^{\rm shell}=-\frac{1}{a^2}0.01356. \tag{3.36}$$

In a recent paper[29] the vacuum energy of a perfectly conducting cylindrical surface has been calculated to much higher accuracy by making use of another version of the zeta function technique. By integrating over dk_z directly in Eq. (3.6) the authors reduced this problem to investigation of the zeta function for circle, which has been considered earlier by introducing the partial wave zeta functions for interior and exterior region separately. In this respect our approach dealing only with one spectral zeta function for given boundary conditions proves to be more simple and straightforward.

IV. CONCLUSION

The method for constructing the spectral zeta functions developed here proceeds from the contour integral representation with a subsequent employment of the uniform asymptotic expansions for the Bessel functions. Upon an analytic continuation the zeta functions prove to be presented as (infinite) series over the Riemann ζ functions with rapidly decreasing terms [see, for example, Eqs. (2.20) and (2.26)].

We did not pursue here the goal of obtaining high accuracy when calculating the Casimir energy. In fact we seek to present the consideration in such a form that no manifest divergencies appear. An obvious advantage of the regularization method in hand does not need any renormalization.

By treating the boundary condition given on an infinite cylinder, we have clearly demonstrated the importance of a consistent analytic continuation of the relevant spectral zeta function, in contrast to identifying simply the sum of the type $\Sigma_{n=1}^{\infty}n^{-s}$ with the Riemann ζ function, in order to involve correctly the contributions to the Casimir energy proportional to $\ln(2\pi)$.

Consideration in this framework of the same configuration of vacuum electromagnetic field but with different velocities of light inside and outside the boundaries probably will demand the modification of the definition of the spectral zeta functions for incorporating in a proper way the contact terms important in this case.[24–26]

ACKNOWLEDGMENTS

This work has been completed during the stay of one of the authors (V.V.N.) at Salerno University. It is a pleasant duty for him to thank Professor G. Scarpetta, Dr. G. Lambiase, and Dr. A. Feoli for kind hospitality. The work was accomplished by partial financial support of the Heisenberg–Landau Program and by the fund MURST ex 60% and ex 40% DPR 382/80.

[18] If we are considering only outgoing waves it is natural to use the solutions of the Maxwell equations which are finite (or at least do not grow infinitely) in the future. Such solutions should be proportional to $\exp(-i\omega t)H_\nu^{(1)}(\omega r)$ when ω lies in the lower half-plane. For the upper half-plane ω, the solutions describing outgoing waves and finite in the future should contain the factor $\exp(i\omega t)H_\nu^{(2)}(\omega r)$.

[28] More precisely, in Ref. 15 not only the next term in the UAE (3.13) has been taken into account but also the first 5 terms in the sum in (3.18) were taken exactly instead of using their asymptotics n^{-3-s}. This turns out to be essential for reaching the required precision. However this point is not critical for our consideration because $Z_3(s)$ does not need analytic continuation.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 40, NUMBER 12 DECEMBER 1999

Quasilinearization method and its verification on exactly solvable models in quantum mechanics

V. B. Mandelzweig[a)]
Physics Department, Hebrew University, Jerusalem 91904, Israel

(Received 10 June 1999; accepted for publication 7 September 1999)

The proof of the convergence of the quasilinearization method of Bellman and Kalaba, whose origin lies in the theory of linear programming, is extended to large and infinite domains and to singular functionals in order to enable the application of the method to physical problems. This powerful method approximates solution of nonlinear differential equations by treating the nonlinear terms as a perturbation about the linear ones, and is not based, unlike perturbation theories, on existence of some kind of small parameter. The general properties of the method, particularly its uniform and quadratic convergence, which often also is monotonic, are analyzed and verified on exactly solvable models in quantum mechanics. Namely, application of the method to scattering length calculations in the variable phase method shows that each approximation of the method sums many orders of the perturbation theory and that the method reproduces properly the singular structure of the exact solutions. The method provides final and reasonable answers for infinite values of the coupling constant and is able to handle even super singular potentials for which each term of the perturbation theory is infinite and the perturbation expansion does not exist. [S0022-2488(99)01812-5]

I. INTRODUCTION

Most problems of physics are not solvable exactly and therefore should be tackled with the help of analytical or numerical approximation methods. In quantum mechanics and quantum field theory over the years many such methods were developed, from perturbation theories, Wentzel–Kramers–Brillouin (WKB) approach and Monte Carlo simulations to lattice computations, strong coupling approximation, 1/N expansion, and so on. The purpose of this paper is to apply to quantum mechanical problems an additional very powerful approximation technique called the quasilinearization method (QLM), whose origin lies in the theory of linear programming. The method, whose iterations are carefully constructed to yield rapid quadratic convergence and often monotonicity, was developed around 30 years ago by Bellman and Kalaba to solve a wide variety of nonlinear ordinary and partial differential equations or their systems arising in such different physics, engineering, and biology problems as orbit determination, detection of periodicities, radiative transfer, and cardiology.[1,2] The modern developments and applications of the method to different fields are given in Ref. 3. QLM, however, was never systematically studied or extensively applied in quantum physics though references to it could be found in well-known monographs[4,5] dealing with the variable phase approach to potential scattering as well as in a few scattered research papers.[6–9] This could be explained by the fact that convergence of the method has been proved only under rather restrictive conditions[1,2] which generally are not fulfilled in physical applications, such as, for example, a rather small domain of variables or forces which are finite everywhere in the domain (see the following). A goal of this work is to reformulate the proof of the convergence for more realistic physical conditions of infinite domains and forces which

[a)]Electronic-mail: victor@vms.huji.ac.il

could be singular at certain points of the domains. We also show how to deal with solutions which themselves could be infinite at certain values of variable such as, for example, scattering amplitudes at values corresponding to bound state energies, etc.

Since this is our first paper on the subject, in order to make presentation as simple and short as possible, we limit ourselves to the case of the first-order nonlinear ordinary differential equation in one variable. Physically this covers the quantum mechanics of one particle in a central field since in this case the Schrödinger equation for a wave function could be rewritten as the Ricatti equation for its logarithmic derivative.

Our proof of the convergence of the quasilinearization method for a general nonlinear ordinary or partial nth order differential equation in N-dimensional space could be formulated along the same lines and will be given in a subsequent article.

The paper is arranged as follows. In Sec. II we present the main ideas and conditions of convergence of the quasilinearization approach, formulated by Bellman and Kalaba[1,2] for the case of the first-order nonlinear ordinary differential equation in one variable, and modify their proof in order to meet the physical reality of infinite interval of the variable or the possibility of singular potentials. In order to highlight the power of the method in Sec. III we consider examples of different singular and nonsingular, attractive and repulsive potentials $V(r)$ for which the nonlinear first-order ordinary differential equation

$$\frac{da(r)}{dr} = -V(r)(r+a(r))^2, \quad a(0)=0, \tag{1.1}$$

for an S-wave scattering length $a_0 = a(\infty)$, obtained in variable phase approach,[4,5] can be solved exactly and compare the iterations obtained by the Bellman–Kalaba linearization method with exact solutions and with the usual perturbation theory. Our results, advantages of the method, and its possible future applications are discussed in Sec. IV.

II. THE QUASILINEARIZATION METHOD (QLM)

The aim of QLM is to obtain the solution $v(z)$ of a nonlinear first-order differential equation

$$\frac{dv(z)}{dz} = g(v(z),z) \tag{2.1}$$

with the boundary condition $v(a)=c$ as a limit of a sequence of linear differential equations. This goal is easily understandable in view of the fact that there is no useful technique of presenting the general solution of Eq. (2.1) in terms of a finite set of particular solutions as in a linear case where, as a result of the superposition property, the equation could be solved analytically or numerically in a convenient fashion. In addition, the sequence should be constructed in such a way as to obtain quadratic convergence and, if possible, monotonicity.

The shift of the coordinate $z=x+a$ and of the solution itself $u(x)=v(x+a)-c$ reduces Eq. (1) to the canonical form[10]

$$\frac{du(x)}{dx} = f(u(x),x), \quad u(0)=0, \tag{2.2}$$

where $f(u(x),x) \equiv g(u(x)+c,x+a)$.

The QLM prescription[1,2] determines the $n+1$ iterative approximation $u_{n+1}(x)$ to the solution of Eq. (2.2) as a solution of

$$u'_{n+1}(x) = f(u_n,x) + (u_{n+1}(x)-u_n(x)) f_u(u_n,x), \quad u_{n+1}(0)=0, \tag{2.3}$$

where the function $f_u(u,x)=\partial f(u,x)/\partial u$ is a functional derivative of a functional $f(u(x),x)$. If one defines m as an upper limit of a maximum of absolute values of the functional and its first and second functional derivatives

$$\max(|f(u(x),x)|,|f_u(u,x)|,|\tfrac{1}{2}f_{uu}(u,x)|)\leqslant m<\infty, \tag{2.4}$$

one can prove that the sequence of iterations $u_n(x)$, $n=1,2,\ldots$ converges *uniformly and quadratically* on the interval $[0,b]$ to solution $u(x)$ of Eq. (2.2) for bm sufficiently small. Indeed, introducing the metric $\|g\|$ of the function $g(x)$ as a maximum of the function on the interval $[0,b]$,

$$\|g\|=\max|g(x)|,0\leqslant x\leqslant b, \tag{2.5}$$

and introducing notations $\Delta u_{n+1}(x)=u(x)-u_n(x)$, $\delta u_{n+1}(x)=u_{n+1}(x)-u_n(x)$ one proves[1,2] the following inequalities:

$$\|\Delta u_{n+1}\|\leqslant k\|\Delta u_n\|^2, \tag{2.6}$$

$$\|\delta u_{n+1}\|\leqslant k\|\delta u_n\|^2, \tag{2.7}$$

$$k=\frac{bm}{1-bm}, \tag{2.8}$$

which establish the uniform quadratic convergence of sequence $u_n(x)$ on $[0,b]$ for sufficiently small bm. A simple induction of Eq. (2.7) shows[2] that $\delta u_{n+1}(x)$ for an arbitrary $l<n$ satisfies the inequality

$$\|\delta u_{n+1}\|\leqslant(k\|\delta u_{l+1}\|)^{2^{n-l}}/k, \tag{2.9}$$

or for $l=0$,

$$\|\delta u_{n+1}\|\leqslant(k\|\delta u_1\|)^{2^n}/k. \tag{2.10}$$

The convergence depends therefore upon the quantity $q_1=k\|u_1-u_0\|$, where zero iteration $u_0(x)$ satisfies the condition $u_0(0)=0$ and is chosen from physical and mathematical considerations. In view of Eq. (2.8) the convergence is reached if bm is sufficiently small. However, from Eq. (2.9) it follows that for the convergence it is sufficient that just one of the quantities $q_m=k\|\delta u_{m+1}\|$ will be small enough. Consequently, one can always hope[2] that even if the first convergent coefficient q_1 is large a well chosen initial approximation u_0 results in a smallness of at least one of the convergence coefficients q_m, $m>1$, which enables a rapid convergence of the iteration series for $n>m$.

One can prove in addition[1,2] that the convergence is monotonic from below (above), if functional $f(u(x),x)$ is strictly convex (concave), that is if the second functional derivative $f_{uu}(u,x)$ in interval $[0,b]$ exists and is strictly positive (negative).

The QLM treats the nonlinear terms as a perturbation about the linear ones[1,2] and is not based, unlike perturbation theories, on the existence of some kind of small parameter. In the proof of Bellman and Kalaba, a small parameter, bm, however, does appear sort of through the back door. The requirement of small bm is unfortunately too restrictive in most physical problems where m and b are often large or infinite, since x normally changes in an infinite domain and many potentials are infinite at some points in the domain. For example, in the case of the variable phase equation—Eq. (1.1), since most of the realistic forces, like Yukawa, Coulomb, van der Waals, or hard core potentials, are infinite at origin, a function

$$f(a(x),x)=-V(x)(x+a(x))^2 \tag{2.11}$$

or its first

$$f_a(a(x),x) = -2V(x)(x + a(x)) \tag{2.12}$$

or second

$$f_{aa}(a(x),x) = -2V(x) \tag{2.13}$$

functional derivatives, are infinite at the origin. This means $m = \infty$, which is a zero convergence interval. However it has been well known for a long time[4,5,11] that a first approximation of QLM gives finite and reasonable results even for super singular $1/r^n$, $n \geq 4$ potentials for which all the terms of the usual perturbation theory are strongly divergent. It indicates that the condition bm being small may be too restrictive and should be relaxed.

Our goal now is to modernize the proof of uniform quadratic convergence of QLM so the requirement of smallness of an interval for large m as well as the requirement of m being finite is removed. Let us subtract from both sides of Eq. (2.2) a term $h(w(x),x)u(x)$, where $w(x)$ and $h(w(x),x)$ are some arbitrary function and functional, respectively, which we chose later. We obtain

$$\frac{du(x)}{dx} - h(w(x),x)u(x) = f(u(x),x) - h(w(x),x)u(x), \quad u(0) = 0. \tag{2.14}$$

The integral form of Eq. (2.14) is

$$u(x) = \int_0^x ds(f(u(s),s) - h(w(s),s)u(s)) \exp \int_s^x dt h(w(t),t), \tag{2.15}$$

or, in case of nonzero boundary condition $u(0) = c$,

$$u(x) = c \exp \int_0^x dt h(w(t),t) + \int_0^x ds(f(u(s),s) - h(w(s),s)u(s)) \exp \int_s^x dt h(w(t),t), \tag{2.16}$$

which can be checked easily by a simple differentiation.

We consider three different forms of function $w(x)$ and its functional $h(w(x),x)$:

$$h(w(x),x)) \equiv 0, \tag{2.17}$$

$$h(w(x),x) = f_w(w(x),x), \quad w(x) \equiv 0, \tag{2.18}$$

$$h(w(x),x) = f_w(w(x),x), \quad w(x) \equiv u(x). \tag{2.19}$$

We can now define the iteration scheme by setting the function $u(x)$ on the right equal to its nth approximation $u_n(x)$ and obtaining the $(n+1)$th approximation on the left-hand side. The zero approximation $u_0(x)$ is chosen from some mathematical or physical considerations and satisfies the boundary condition $u_0(0) = 0$. We get three different iteration schemes, corresponding to Eqs. (2.17)–(2.19), respectively:

$$u_{n+1}(x) = \int_0^x ds(f(u_n(s),s), \tag{2.20}$$

$$u_{n+1}(x) = \int_0^x ds(f(u_n(s),s) - f_u(0,s)u_n(s)) \exp \int_s^x dt f_u(0,t), \tag{2.21}$$

and

$$u_{n+1}(x)=\int_0^x ds(f(u_n(s),s)-f_u(u_n(s),s)u_n(s))\exp\int_s^x dt f_u(u_n(t),t). \tag{2.22}$$

In case of nonzero boundary condition $u(0)=c$ the iteration sequence should be slightly modified. For example, in this case, according to Eq. (2.16), Eq. (2.22) has a somewhat different form, namely

$$u_{n+1}(x)=c\exp\int_0^x dt\, f_u(u_n(t),t)+\int_0^x ds(f(u_n(s),s)-f_u(u_n(s),s)u_n(s))\exp\int_s^x dt\, f_u(u_n(t),t). \tag{2.23}$$

Let us concentrate in the beginning on Eq. (2.22), which, being the solution of Eq. (2.3), displays the iteration sequence of the QLM. The subtraction of Eq. (2.3) for n and $n-1$ gives a similar differential equation for the difference $\delta u_{n+1}(x)=u_{n+1}(x)-u_n(x)$:

$$\delta u'_{n+1}(x)=f(u_n(x),x)-f(u_{n-1}(x),x)+\delta u_{n+1}(x)f_u(u_n(x),x)-\delta u_n(x)f_u(u_{n-1}(x),x),$$

$$\delta u_{n+1}(0)=0. \tag{2.24}$$

By use of the mean value theorem[12] one can write

$$f(u_n(x),x)=f(u_{n-1}(x),x)+\delta u_n(x)f_u(u_{n-1}(x),x)+\tfrac{1}{2}f_{uu}(\overline{u_n}(x),x)\,\delta u_n^2(x), \tag{2.25}$$

where $\overline{u_n}(x)$ lies between $u_n(x)$ and $u_{n-1}(x)$. As a result Eq. (2.24) could be written as

$$\delta u'_{n+1}(x)-\delta u_{n+1}(x)f_u(u_n(x),x)=\tfrac{1}{2}f_{uu}(\overline{u_n}(x))\,\delta u_n^2(x), \tag{2.26}$$

whose solution has a form

$$\delta u_{n+1}(x)=\frac{1}{2}\int_0^x ds\, f_{uu}(\overline{u_n}(s),s)\,\delta u_n^2(s)\exp\int_s^x dt\, f_u(u_n(t),t). \tag{2.27}$$

Obviously,

$$|\delta u_{n+1}(x)|\leqslant\frac{1}{2}\int_0^x ds|f_{uu}(\overline{u_n}(s),s)||\delta u_n(s)|^2\exp\int_s^x dt\, f_u(u_n(t),t)$$

$$\leqslant k_n(x)\cdot|\delta u_n(\bar{x})|^2\leqslant k_n(b)\cdot\|\delta u_n\|^2. \tag{2.28}$$

Here $\bar{x}$ is the point on the interval $[0,x]$ where $|\delta u_n(x)|$ is maximal,

$$k_n(x)=\frac{1}{2}\int_0^x ds|f_{uu}(\overline{u_n}(s),s)|\exp\int_s^x dt\, f_u(u_n(t),t), \tag{2.29}$$

and positiveness of the integrand in Eq. (2.29) as well as definition (2.5) are used. Since Eq. (2.28) is correct for any x in the interval $[0,b]$, it is correct also for a value of $x\in[0,b]$ for which $|\delta u_{n+1}(x)|$ reaches its maximal value. This gives

$$\|\delta u_{n+1}\|\leqslant k_n(b)\cdot\|\delta u_n\|^2. \tag{2.30}$$

Let us assume the boundness of the first two functional derivatives of $f(u(x),x)$, that is the existence of bounding functions $F(x)$ and $G(x)$ which for any u and x satisfy

$$f_u(u(x),x))\leqslant F(x), \quad |f_{uu}(u(x),x)|\leqslant G(x). \tag{2.31}$$

In this case $k_n(b) \leqslant k(b)$, where

$$k(b)=\frac{1}{2}\int_0^b ds\, G(s)\exp\int_s^b dt\, F(t), \tag{2.32}$$

and Eq. (2.30) could be written in the form

$$\|\delta u_{n+1}\| \leqslant k(b)\cdot\|\delta u_n\|^2, \tag{2.33}$$

which is identical to Eq. (2.7) but with $k=k(b)$ instead of k given by Eq. (2.8). We can reproduce the results of Bellman and Kalaba[1,2] by following their bounding restriction Eq. (2.4) and setting $F(x)=m$, $G(x)=2m$. In this case the integrals in Eq. (2.32) could be easily calculated and give $k(b)=(1-e^{-mb})/e^{-mb}$, which for small mb reduces to the expression for k given by Eq. (2.8). However, as we will see in different examples in Sec. III, $k(b)$ given by Eq. (2.32), unlike k given by Eq. (2.8), could be sufficiently small also for an infinite interval length b and for singular functions $G(x)$ and $F(x)$. This means that the quantity $q_1(b)$,

$$q_1(b)=k(b)\|u_1-u_0\|, \tag{2.34}$$

which is responsible for the convergence [see the discussion after Eq. (2.10)] could be less than unity and thus assure the convergence even in this case. As was pointed out there, the rapid convergence is actually enough that an initial guess for zero iteration is sufficiently good to ensure the smallness of just one of the convergence coefficients $q_m(b)=k(b)\|u_{m+1}-u_m\|$.

With the uniform quadratic convergence of the sequence $u_n(x)$ for the intervals $[0,b]$ in which at least one of the convergence coefficients $q_m(b)<1$ now proven, one can conclude from Eq. (2.27), that in addition for strictly convex (concave) functionals $f(u(x),x)$ the difference $u_{n+1}(x)-u_n(x)$ is strictly positive (negative), which establishes the monotonicity of the convergence from below (above), respectively, on this interval.

If $F(x)$ is a sign-definite function and $G(x)=|F(x)|$, the integral in Eq. (2.32) could be taken explicitly and produces a simple expression for $k(b)$,

$$k(b)=\frac{1}{2}\left|\exp\int_0^b dt\, F(t)-1\right|. \tag{2.35}$$

The subtraction of Eq. (2.3) from Eq. (2.2) gives

$$\Delta u'_{n+1}(x)=f(u,x)-f(u_n(x),x)+\Delta u_{n+1}(x) f_u(u_n(x),x)-\Delta u_n(x) f_u(u_n(x),x),$$

$$\Delta u_{n+1}(0)=0, \tag{2.36}$$

which is similar to Eq. (2.24)—the starting point for our derivation of Eq. (2.33). The derivation along the same lines, starting from Eq. (2.36), gives the analog of Eq. (2.6) with k changed to $k(b)$:

$$\|\Delta u_{n+1}\| \leqslant k(b)\cdot\|\Delta u_n\|^2. \tag{2.37}$$

Equation (2.31) again confirms the uniform quadratic convergence of the sequence u_n to a solution $u(x)$ of Eq. (2.2). One can show in exactly the same fashion as before that for strictly convex (concave) functionals $f(u(x),x)$ difference Δu_{n+1} is strictly positive (negative), proving in this case the monotonic convergence to a limiting function u from below (above), respectively.

In case the solution $u(x)$ and, respectively, its iterations $u_n(x)$ are going to infinity at some points on interval $[0,b]$, Eq. (2.22) could become meaningless. To deal with it, it is necessary to regularize Eq. (2.2), that is reformulate it in terms of a new function $v(x)$ which is finite, as, for example, to change to function $v(x)=1/u(x)$ for $|u(x)|>1$, the prescription which is used in the present work, or to set $u(x)=\tan v(x)$ as it was suggested in Refs. 13 and 14. The corresponding nonlinear equations for $v(x)$ have the form

$$\frac{dv(x)}{dx}=-v(x)^2 f\left(\frac{1}{v(x)},x\right),\quad v(0)=u(c),\quad |u(c)|=1, \tag{2.38}$$

and

$$\frac{dv(x)}{dx}=\cos^2 v(x) f(\tan v(x),x),\quad v(0)=0, \tag{2.39}$$

respectively.

Let us now turn our attention to the iteration sequences given by Eqs. (2.20) and (2.21). These successive approximation schemes were considered by Picard[15] and Calogero, Babikov, and Fluegge (CBF),[4,5,11] respectively. The quadratic convergence, reached in QLM, is based on a specific choice of function $w(x)$ and its functional $h(w(x),x)$ given by Eq. (2.19) which, in view of the mean value theorem of Eq. (2.25), assures cancellation of the first power of $\delta u_n(x)$ and $\Delta u_n(x)$ in recurrence relations of Eqs. (2.24) and (2.36), respectively. Such cancellation will not happen for the Picard and CBF choices of $w(x)$ and $h(w(x),x)$, given by Eqs. (2.17) and (2.18). One obtains, therefore, for these approximation schemes the usual inequality characteristic of the first-order convergence

$$\|\delta u_{n+1}\|<p\|\delta u_n\|, \tag{2.40}$$

where p is a correspondent convergence coefficient. This leads, instead of the very rapid 2^n-power type of convergence, displayed in Eqs. (2.33) and (2.37), to the much slower geometric convergence

$$\|\delta u_{n+1}\|<p^n\|\delta u_1\|. \tag{2.41}$$

III. QLM SCATTERING LENGTH CALCULATIONS AND THEIR COMPARISON WITH THE PERTURBATION THEORY AND EXACT SOLUTIONS

In Sec. II we proved that the QLM successive approximations to the exact solution $u(x)$ of Eq. (2.22) given by Eq. (2.2) converge quadratically and uniformly on interval $[0,b]$, where b is found from the requirement that one of the convergent coefficients $q_m(b)$ defined in a paragraph following Eq. (2.34) is less than unity. In addition for strictly convex (concave) functionals $f(u(x),x)$ the convergence to a limiting function u is monotonic from below (above), respectively.

In order to highlight the power of the method in this section we consider examples of different singular and nonsingular, attractive and repulsive potentials for which the nonlinear first-order ordinary differential equation for an S-wave scattering length, Eq. (1.1), obtained in variable phase approach[4,5] could be solved exactly. We will compare the iterations obtained by the Bellman–Kalaba quasilinearization method (QLM) with exact solutions and with the usual perturbation theory.

A. Square well potential

1. Repulsive square well

Let us start from the repulsive square well potential

$$V(r)=\frac{\lambda}{R^2}\Theta(R-r), \tag{3.1}$$

where $\Theta(R-r)$ is the Heavyside function and λ is a potential strength, which for now is assumed to be positive. The change of variables to the dimensionless variable $x=\sqrt{\lambda}(r/R)$ and dimensionless function $A(x)=\sqrt{\lambda}[a(xR/\sqrt{\lambda})]/R$ allows one to express Eq. (1.1) for $x\leqslant x_0$, $x_0=\sqrt{\lambda}$ in a form

$$\frac{dA(x)}{dx}=-(x+A(x))^2, \quad A(0)=0. \tag{3.2}$$

For $x>x_0$ $A(x)$ is a constant equal to the dimensionless scattering length $A_0=\sqrt{\lambda}(a_0/R)$, the scattering length itself being $a_0\equiv a(R)$. A further change of the function to $u(x)=x+A(x)$ gives a familiar equation for the hyperbolic tangent,

$$\frac{du(x)}{dx}=1-u^2(x), \quad u(0)=0. \tag{3.3}$$

The exact variable scattering length $a(r)$ for the repulsive square well potential is therefore

$$a(r)=\frac{R}{\sqrt{\lambda}}\tanh\left(\sqrt{\lambda}\frac{r}{R}\right)-r, \tag{3.4}$$

while the scattering length is given by

$$a_0=R\left(\frac{\tanh\sqrt{\lambda}}{\sqrt{\lambda}}-1\right)\equiv R\left(\frac{\tanh x_0}{x_0}-1\right). \tag{3.5}$$

Here we use the Calogero definition of the scattering length[4]

$$a_0=\lim_{k\to 0}\frac{\tan\delta(k)}{k}, \tag{3.6}$$

δ is a scattering phase, which is different in sign from the definition used in most publications.

Before considering the QLM, let us turn to the usual perturbation theory. Displaying explicitly the dependence of the potential on the coupling constant $V(r)=\lambda v(r)$ and expanding $a(r)$ in powers of λ, one obtains from Eq. (1.1):

$$\sum_{k=1}^{\infty}\lambda^k a_k'(r)=-\lambda v(r)\left(r+\sum_{n=1}^{\infty}\lambda^n a_n(r)\right)^2. \tag{3.7}$$

Comparisons of coefficients before the powers of λ gives the recurrence relation

$$a_k'(r)=-v(r)\left(r^2\delta_{k1}+2ra_{k-1}(r)+\sum_{n=1}^{k-2}a_{k-n-1}(r)\cdot a_n(r)\right), \quad k=1,2,3\ldots \tag{3.8}$$

The successive integrations of Eq. (3.8) produce the expansion $a(r)$ in the powers of the coupling constant. The first three terms of the perturbation expansion of the variable scattering length, for example, are

$$a_1(r)=-\int_0^r ds\, s^2 v(s),$$

$$a_2(r)=-\int_0^r ds\, 2s v(s) a_1(s), \tag{3.9}$$

$$a_3(r) = -\int_0^r ds\, v(s)(2sa_2(s) + a_1^2(s)),$$

and so on. For $u(x)$ this expansion gives

$$u(x) = x - \frac{1}{3}x^3 + \frac{2}{15}x^5 - \frac{17}{315}x^7 + \frac{62}{2835}x^9 - \frac{1382}{155\,925}x^{11} + \frac{21\,844}{6\,081\,075}x^{13} - \frac{929\,569}{638\,512\,875}x^{15} + \frac{6\,404\,582}{10\,854\,718\,875}x^{17} + O(x^{19}). \tag{3.10}$$

These series, of course, could also be obtained by using the power series expansion of tanh(x). The power expansion of scattering length is given by Eqs. (3.10) and (3.5), the latter can be written in the form $a_0 = R([u(x_0)/x_0] - 1)$.

Let us consider now the approximate QLM solutions of Eq. (3.3), choosing as a zero approximation a solution of this equation for a very small x: $u_0(x) = x$. The recurrence relation (2.22) now has the form

$$u_{n+1}(x) = \int_0^x ds(1 + u_n^2(s))\exp\left(-2\int_s^x dt\, u_n(t)\right), \tag{3.11}$$

while the nth approximation to the scattering length is given by

$$a_{0,n} = R\left(\frac{u_n(x_0)}{x_0} - 1\right). \tag{3.12}$$

The substitution of the zero iteration in Eq. (3.11) leads to a first-order approximation,

$$u_1(x) = -i\frac{\sqrt{\pi}}{4}\mathrm{erf}(ix)e^{-x^2} + \frac{x}{2}, \tag{3.13}$$

where erf(x) is the error function.[16] Expansion of (3.13) in power series enables a comparison with perturbation series (3.10),

$$u_1(x) = x - \frac{1}{3}x^3 + \frac{2}{15}x^5 - \frac{4}{105}x^7 + \frac{8}{945}x^9 + O(x^{11}), \tag{3.14}$$

which shows that the first approximation reproduces exactly three terms of the perturbation series, that is two more terms than was given correctly by the zero QLM approximation $u_0(x) = x$. This improvement of the representation of the perturbation series not by one, but by two powers of λ is, of course, precisely what one should expect from the quadratic convergence. In addition, the fourth term is also mostly correct being $-\frac{12}{315}$ vis-a-vis exact $-\frac{17}{315}$. The second iteration $u_2(x)$ could not be calculated analytically, but could be computed numerically or expressed by power series expansion with the help of symbolic computation program.[17] The latter gives

$$u_2(x) = x - \frac{1}{3}x^3 + \frac{2}{15}x^5 - \frac{17}{315}x^7 + \frac{62}{2835}x^9 - \frac{1382}{155\,925}x^{11} + \frac{21\,844}{6\,081\,075}x^{13} - \frac{918\,844}{638\,512\,875}x^{15} + \frac{39\,944}{70\,945\,875}x^{17} + O(x^{19}). \tag{3.15}$$

One can see that the second iteration of QLM reproduces correctly the first seven terms of the perturbation series, an improvement by 4 powers of λ compare with previous QLM approximation

$u_1(x)$. In addition, the eighth and ninth terms of the power series expansion of $u_2(x)$ are very close to their precise values in perturbation theory, being $-\frac{918\,844}{638\,512\,875}$ and, 5.63×10^{-4} vis-a-vis exact values $-\frac{929\,569}{638\,512\,875}$ and 5.90×10^{-4}, respectively.

Aside from the fact that already first QLM approximations sum many orders of the usual perturbation theory, the QLM iterations, unlike the perturbation series, have meaning also for a large or even infinite values of coupling constant. Indeed, for $\lambda\to\infty$ any term of the perturbation series is infinite. Even for a finite moderately large potential strength $\lambda\geqslant2.5$ perturbation expansion (3.10) diverges since the power series expansion of the hyperbolic tangent of x_0 converges[16] only for $x_0<\pi/2$, that is for $\lambda<\pi^2/4$. On the other side, the QLM approximations to the scattering length are finite. The first QLM approximation to scattering length (3.13) in view of an asymptotic expression

$$\mathrm{erf}(z)\simeq\left(1-\frac{e^{-z^2}}{\sqrt{\pi}z}\right) \tag{3.16}$$

for $|z|\to\infty$[16] shows that the scattering length in this approximation equals $-R/2$, a reasonable approximation to exact value $a_0=-R$. The computation of the scattering length in the second QLM approximation gives again a finite and improved result $a_0=-\frac{3}{4}R$.

To tackle more rigorously the question of convergence of the iteration series for dimensionless scattering length $A_{0,n}=a_{0,n}/R$ given by Eqs. (3.11) and (3.12) to exact result $A_0=a_0/R$ let us turn to the convergence condition demanding the smallness of convergence coefficient (2.34), which in this case is given by

$$q_1(b)=k(b)\|a_{0,1}-a_{0,0}\|=k(b)\left\|\frac{u_1(x)-u_0(x)}{x}\right\|=k(b)\cdot\max_{0\leqslant x\leqslant b}\left|\frac{u_1(x)}{x}-1\right|. \tag{3.17}$$

To calculate $q_1(b)$ one first has to estimate $k(b)$ using, for example, Eq. (2.35). From Eq. (3.3) and the boundary condition there follows $u(-x)=-u(x)$. We can consider therefore only positive branch of the solution whose extremum is reached when $u'(x)=1-u^2(x)=0$, that is when $u(x)=1$. This means that $0\leqslant u(x)\leqslant1$. Since the first and second functional derivatives of $f(u(x),x)=1-u^2(x)$ equal $-2u(x)$ and -2, respectively, one can set $F(x)=-2$ and $G(x)=|F(x)|=2$, which gives

$$k(b)=\tfrac{1}{2}|e^{-2b}-1|\leqslant\tfrac{1}{2}. \tag{3.18}$$

In view of the fact that, due to the properties[16] of the error function $|u_1(x)/x-1|\leqslant\frac{1}{2}$ for all positive x, one obtains that $q_1(b)\leqslant\frac{1}{4}$ for all values of b. Thus the convergence of QLM approximations Eq. (3.11), and therefore $a_{0,n}$, given by Eq. (3.12), to the exact scattering length a_0 in case of the repulsive square well is uniform and quadratic for all values of x_0, that is for all values of coupling constant λ.

2. Attractive square well

The same conclusions are correct also for the attractive square well potential the equations for which are obtained by changing λ to $-\lambda$. The equation for $u(x)$ now has a form

$$\frac{du(x)}{dx}=1+u^2(x),\quad u(0)=0. \tag{3.19}$$

Its solution is

$$u(x)=\tan x \tag{3.20}$$

and the scattering length is given by

$$a_0=R\left(\frac{\tan\sqrt{\lambda}}{\sqrt{\lambda}}-1\right)\equiv R\left(\frac{u(x_0)}{x_0}-1\right). \tag{3.21}$$

The QLM subsequent approximations are obtained with the help of recursion equations

$$u_{n+1}(x)=\int_0^x ds(1-u_n^2(s))\exp\left(2\int_s^x dt\, u_n(t)\right). \tag{3.22}$$

Choosing the zero QLM approximation as before in form $u_0(x)=x$ leads to first QLM approximation,

$$u_1(x)=\frac{\sqrt{\pi}}{4}\operatorname{erf}(x)e^{x^2}+\frac{x}{2}. \tag{3.23}$$

Now there is, however, an additional difficulty, since exact scattering length $a_0(x_0)$ is a singular function of $x_0=\sqrt{\lambda}$ and becomes infinite at values of the coupling constant corresponding to zero bound state energies $\lambda=((2n+1)\,\pi/2)^2$. This finds reflection in the fact that $u_1(x_0)$ is increasing very fast for x_0 around $\pi/2$. To deal with it let us, in accordance with the discussion in Sec. II, regularize Eq. (3.19), that is to rewrite it for $|u(x)|>1$ in terms of a new function

$$v(x)=\frac{1}{u(x)}. \tag{3.24}$$

Defining c as a singular point where $u(c)=\infty$ one obtains, according to Eq. (2.38), the following nonlinear equation for $v(x)$:

$$\frac{dv(x)}{dx}=-(1+v(x)^2), \quad v(c)=\frac{1}{u(c)}=0. \tag{3.25}$$

In view of Eq. (3.19) a solution of Eq. (3.25) is $v(x)=u(c-x)$. Equation (3.24) then gives

$$u(x)=\frac{1}{u(c-x)}. \tag{3.26}$$

Setting $x=c/2$ allows us to write

$$u^2\left(\frac{c}{2}\right)=1 \tag{3.27}$$

for constant c. Since the solution of Eq. (3.19) should be an odd function of x,

$$u(-x)=-u(x), \tag{3.28}$$

it is enough to choose only a positive branch of Eq. (3.27), that is

$$u\left(\frac{c}{2}\right)=1. \tag{3.29}$$

From Eqs. (3.26) and (3.28) follows the $2c$ periodicity of solution $u(x)$: $u(x+2c)=1/u(c-(x+2c))=-1/u(x+c)=-u(c-(c+x))=u(x)$. Thus it is enough to find a solution only on the interval $(0,2c)$. We can now formulate the following result.

The nth QLM approximation $U_n(x)$ to the solution of Eq. (3.19) on the interval $[0,2c_n]$, which is able to properly describe a singularity, is given by

$$U_n(x)=u_n(x)\Theta\left(\frac{c_n}{2}-x\right)\Theta(x)+\frac{1}{u_n(c_n-x)}\Theta\left(x-\frac{c_n}{2}\right)\Theta\left(\frac{3c_n}{2}-x\right)$$
$$+u_n(x-2c_n)\Theta\left(x-\frac{3c_n}{2}\right)\Theta(2c_n-x), \tag{3.30}$$

where the nth QLM approximation $u_n(x)$ on interval $(0,c_n/2)$ is found with the help of recurrence relations Eq. (3.22) and the nth approximate value c_n of c is given by

$$u_n\left(\frac{c_n}{2}\right)=1. \tag{3.31}$$

Computation of $c_n/2$ shows that the differences between the exact value $c=\pi/2$ and approximate values c_n are very small already for the first and second QLM iterations, namely $(c_1-\pi/2)$ and $(c_2-\pi/2)$ are 0.005 29 and 0.000 001 32, the errors of 0.5% and 10^{-4}%, respectively. Since the nth QLM approximation, Eq. (3.30), has a pole at $x_0=c_n$, $\lambda=c_n^2$ gives a value of potential strength corresponding to a zero energy bound state. One sees that the QLM description of such state is extremely accurate already in the first and especially in the second approximations.

To prove the uniform quadratic convergence of the QLM iterations it is enough, in view of Eqs. (3.28) and (3.30) to consider $u_n(x)$ only on intervals $(0,c_n/2)$ which are very close to interval $(0,\pi/4)$. Since the first and second functional derivatives of the left-hand side of Eq. (3.19) are $2u(x)$ and 2, respectively, and $|u(x)|\leqslant 1$, one can chose $F(x)=G(x)=2$ and use Eq. (2.35), which produces a simple expression for $k(b)$,

$$k(b)=\tfrac{1}{2}(e^{2b}-1). \tag{3.32}$$

This leads to the following result for $q_1(b)$:

$$q_1(b)=\frac{1}{2}(e^{2b}-1)\left(\frac{\sqrt{\pi}}{4}\operatorname{erf}(b)e^{b^2}-\frac{b}{2}\right). \tag{3.33}$$

A simple computation shows that $0<q_1(b)<1$ for $0<b<0.92$, which proves the uniform quadratic convergence of the QLM iterations on even larger interval (0,0.92) than interval $(0,\pi/4)$ and thus the convergence of the sequence $U_n(x_0)$ to the exact solution $\tan x_0$ on the interval $(0,2c_n)$ $\approx(0,\pi)$. In view of its $2c_n\approx\pi$ periodicity the nth QLM approximation $U_n(x_0)$ converges therefore to the exact solution for all x_0, that is for all values of the coupling constant λ.

The extremely fast convergence of QLM approximations given by Eq. (3.30) is evident from the ratios of the first [Eq. (3.23)] and second [Eq. (3.22) for n=1] QLM iterations to the exact solution (3.20), which are shown in Figs. 1 and 2, respectively.

B. δ-function potential

In case of the δ-function potential

$$V(r)=\frac{\lambda}{R}\delta(r-R), \tag{3.34}$$

Eq. (1.1) for the scattering length has the form

$$A'(x)=\lambda(x-A(x))^2\delta(x-1)\equiv\lambda(1-A(x))^2\delta(x-1),\quad A(0)=0, \tag{3.35}$$

where $x=r/R$ and $A(x)=-a(r)/R$ are dimensionless variable and variable scattering length, respectively; note, that in Eq. (3.35) $A(x)$ could not be set equal $A(1)$, since $A(x)$ is discontinu-

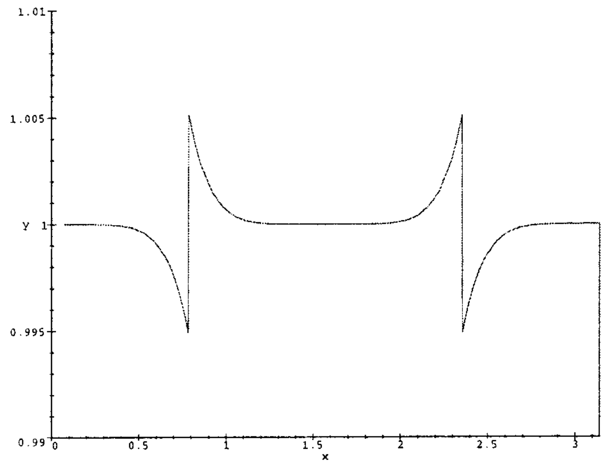

FIG. 1. The ratio of the first QLM iteration to the exact solution for the attractive square well as a function of the potential strength λ (axis x).

ous at $x=1$, its derivative being proportional to the δ-function. Introduction of a new function $y(x)=\lambda\Theta(x-1)$, $y(0)=0$, $y(\infty)=\lambda$ with a derivative $dy(x)=\lambda\,\delta(x-1)dx$ reduces Eq. (3.35) to the form

$$\frac{dA(y)}{dy}=(1-A(y))^2, \quad A(y)_{y=0}=0. \tag{3.36}$$

A solution of Eq. (3.36) is

$$A(y)=\frac{y}{1+y}. \tag{3.37}$$

An exact solution of Eq. (1.1) for the δ-potential thus is given by $a(r)=-RA(y)\equiv-R[\lambda\Theta(r-R)]/[1+\lambda\Theta(r-R)]$. The scattering length a_0 equals $a(r)_{r=\infty}\equiv-R\lambda/(1+\lambda)$. It is is singular at $\lambda=-1$, reflecting the existence of the zero energy bound state for the unit potential strength.

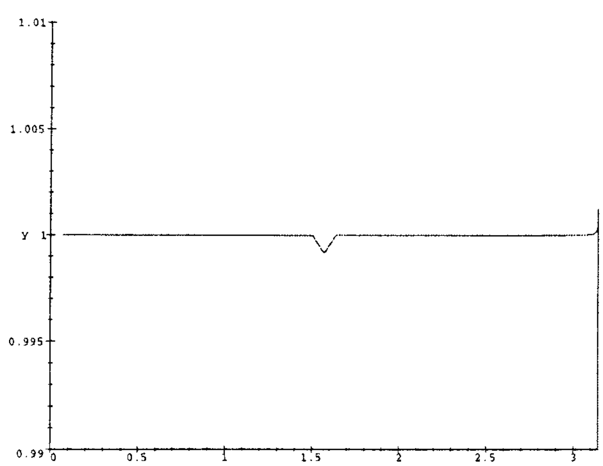

FIG. 2. Same as in Fig. 1, but for the second QLM approximation.

1. Repulsive δ-function potential

Let us now consider QLM approximations to the exact solution (3.37) in the case of the repulsive δ-function potential, $\lambda>0$. According to Eq. (2.22) they are given by the following iteration sequence:

$$A_{n+1}(y)=\int_0^y ds(1-A_n^2(s))\exp\left(-2\int_s^y dt(1-A_n(t)\right), \tag{3.38}$$

since the functional derivative of the right-hand part of Eq. (3.36) equals $-2(1-A(y))$. The introduction of the nth approximation $u_n(y)=1-A_n(y)$ to a function $u(y)=1-A(y)=1/(1+y)$ helps to write recurrence relationship (3.38) in a simpler form:

$$u_{n+1}(y)=\exp\left(-2\int_0^y dt\, u_n(t)\right)+\int_0^y ds\, u_n^2(s))\exp\left(-2\int_s^y dt\, u_n(t)\right), \tag{3.39}$$

which coincides with the QLM iteration scheme (2.23) for Eq. (3.36), rewritten with the help of the function $u(x)=1-A(x)$ as

$$u'(x)=-u(x)^2, \quad u(0)=1, \tag{3.40}$$

Since for $x=\infty$ $y=\lambda$, $u_n(\lambda)$ gives the nth approximation to $u(\lambda)=1-A_0(\lambda)=1/(1+\lambda)$ where $A_0(\lambda)$ is the exact dimensionless scattering length.

Let us chose as a zero approximation $u_0(y)\equiv u(0)=1$. The substitution in Eq. (3.39) for $n=0$ gives

$$u_1(y)=\tfrac{1}{2}(1+e^{-2y}). \tag{3.41}$$

One can see that already the first approximation $u_1(\lambda)$ for $\lambda\to\infty$ is finite and equals $\frac{1}{2}$, which gives a value of $\frac{1}{2}$ for the approximate dimensionless scattering length vis-a-vis the exact value $A_0=1$. Each term in the perturbation series for $u(\lambda)$,

$$u(\lambda)=\sum_{m=0}^{\infty}(-\lambda)^m, \tag{3.42}$$

in this case is infinite while the perturbation expansion itself is divergent already for $|\lambda|\geqslant 1$. The comparison of perturbation expansion (3.42) with the perturbative expansion of the first QLM approximation (3.41),

$$u_1(\lambda)=\tfrac{1}{2}(1+e^{-2\lambda})=1-\lambda+\lambda^2-\tfrac{2}{3}\lambda^3+\tfrac{1}{3}\lambda^4-\tfrac{2}{15}\lambda^5+O(\lambda^6), \tag{3.43}$$

shows that in this approximation the perturbation series is correct up to the fourth term. The next, second approximation also could be calculated analytically with the help of symbolic computation program[17] and gives the rather cumbersome expression

$$u_2(\lambda)=-1/4\,\frac{-2\sqrt{e^{e^{-2\lambda}}}-e^{1/2-\lambda}+\sqrt{2\pi}\,\mathrm{erf}\left(\dfrac{e^{-\lambda}}{\sqrt{2}}\right)\sqrt{e^{e^{-2\lambda}}}e^{1/2}-e^{1/2+\lambda}-\sqrt{2\pi}\,\mathrm{erf}\left(\dfrac{1}{\sqrt{2}}\right)e^{1/2}\sqrt{e^{e^{-2\lambda}}}}{\sqrt{e^{e^{-2\lambda}}}e^{1/2(-e^{-2\lambda}+2\lambda+1)}}. \tag{3.44}$$

For $\lambda\to\infty$ the largest term both in the numerator and denominator is $e^{1/2+\lambda}$. Therefore $u_2(\infty)=\frac{1}{4}$, which corresponds to the second QLM approximation to A_0 being $\frac{3}{4}$, a significant improvement compared with the result, obtained in this limit in the first QLM approximation (3.41). The computation of the power series expansion yields

$$u_2(\lambda)=1-\lambda+\lambda^2-\lambda^3+\lambda^4-\lambda^5+\lambda^6-\frac{62}{63}\lambda^7+\frac{79}{84}\lambda^8-\frac{4931}{5670}\lambda^9+O(\lambda^{10}). \tag{3.45}$$

The perturbation series in the second QLM approximation is given correctly up to the seventh term, while the coefficients of the eighth and ninth terms are different only by $\frac{1}{63}$ and $\frac{5}{84}$, that is by 1.6% and 6%, respectively.

Analytic calculation of the third QLM approximation seems impossible but the power series expansion could be evaluated with the help of the same program,[17] which yields

$$\begin{aligned}u_3(\lambda)=&1-\lambda+\lambda^2-\lambda^3+\lambda^4-\lambda^5+\lambda^6-\lambda^7+\lambda^8-\lambda^9+\lambda^{10}-\lambda^{11}+\lambda^{12}-\lambda^{13}+\lambda^{14}\\&-\frac{59\,534}{59\,535}\lambda^{15}+\frac{1\,904\,891}{1\,905\,120}\lambda^{16}-\frac{12\,139\,457}{12\,145\,140}\lambda^{17}\\&+\frac{161\,721\,779}{161\,935\,200}\lambda^{18}-\frac{113\,880\,892\,943}{114\,225\,041\,700}\lambda^{19}+O(\lambda^{20}).\end{aligned} \tag{3.46}$$

In the third QLM approximation the first 15 terms of the perturbation series are given exactly while the next 5 terms have coefficients extremely close to being exact.

Summing up, the number of the terms given precisely in the zero, first, second, and third QLM approximations equals 1, 3, 7, and 15, increasing by 2, 2^2 and 2^3, respectively, that is according to geometric progression with $q=2$, exactly as one should expect from the quadratic law of the convergence. The number N_n of perturbation series terms reproduced exactly in the nth QLM approximation is therefore

$$N_n=\sum_{k=0}^{n} q^k=\frac{q^{n+1}-1}{q-1}=2^{n+1}-1 \tag{3.47}$$

and for larger n approximately doubles with n increasing by each unit. For example, the sixth QLM approximation reproduces exactly $2^7-1=127$ terms of the perturbation expansion, while the twelfth approximation reproduces already $2^{13}-1=8191$ terms, and so on.

The numerical computation of $u_3(\infty)$ gives 0.125, corresponding to $A_0=0.875$, a finite and gratifying result.

Comparison of the first three QLM approximations $u_n(\lambda)$, $n=1,2,3$ with exact solution $u(\lambda)=1/(1+\lambda)$ and its perturbation expansion (3.42) containing 15 terms (up to λ^{14}, inclusively) for the δ-function potential with the potential strength λ changing in the interval (0,10) is shown graphically in Fig. 3. One can see that each subsequent QLM approximation reproduces the exact solution better than the previous one up to infinite values of the coupling constant, while even the 15th-order perturbation theory is not able to describe the exact solution adequately beyond $\lambda=1$.

To prove the uniform quadratic convergence of QLM iterations let us note that the first and second functional derivatives of the left hand side of Eq. (3.40) are $-2u(x)$ and -2, respectively, exactly as in the case of the repulsive square well which was discussed earlier. The extremal value of $u(x)$, reached when $u'(x)=-u^2(x)=0$, is, obviously, zero, which, in view of boundary condition $u(0)=1$, means $0\leqslant u(x)\leqslant 1$. This allows one to choose the same functions $F(x)=-2$, $G(x)=2$ as for the repulsive square well, and consequently results in the same expression 3.18 for $k(b)$. Since it follows from Fig. 3 that the maximal difference between zero and first QLM approximations $\|u_1(x)-u_1(x)\|$ equals $\frac{1}{2}$, one obtains as before $q_1(b)\leqslant\frac{1}{4}$, which proves the uniform quadratic convergence of the QLM iterations for all values of b. This means that the

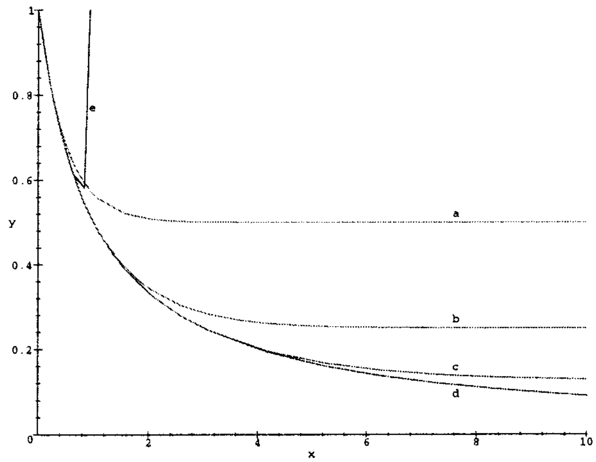

FIG. 3. Comparison of first three QLM approximations $u_n(\lambda), n=1,2,3$, curves a, b, and c, respectively, with exact solution $u(\lambda)=1/(1+\lambda)$, curve d, and its perturbation expansion (3.42), curve e, containing 15 terms (up to λ^{14}, inclusively), for the δ-function potential with the potential strength λ (axis x) changing in the interval (0,10).

convergence of subsequent QLM approximations to the exact scattering length for the repulsive δ-function potential is uniform and quadratic for all values of coupling constant λ, including very large and infinite ones.

2. Attractive δ-function potential

For negative λ the subsequent approximations $u_n(\lambda)$ start to increase very rapidly with $|\lambda|$ as one can see, for example, from analytic expressions (3.41) and (3.44). According to discussion before Eq. (2.38) we have to switch in this case in Eq. (3.40) to a new function $v(x)=1/u(x)$, which thus satisfies the trivial equation $v'(x)=1$ with a boundary condition $v(0)=1$. The QLM solution of this equation in the nth approximation, calculated from Eq. (2.23), is $v_n(x)=1+x$ or $u_n(x)=1/(1+x)$ for any n, which means that this form of the equation for the attractive δ-function potential generates an exact solution in any QLM approximation and there is no need for further investigation.

C. Inverse square potential

Let us consider now the inverse square potential

$$V(r)=\frac{\lambda}{r^2}\Theta(R-r), \tag{3.48}$$

where λ is the dimensionless coupling constant. As is well known,[18] this potential produces a fall to the center in case of $\lambda<-\frac{1}{4}$. For $r\leqslant R$, Eq. (1.1) for the scattering length could be written in the form

$$A'(x)=-\lambda\left(1+\frac{A(x)}{x}\right)^2, \quad A(0)=0, \tag{3.49}$$

where $x=r/R$ and $A(x)=a(r)/R$ are the dimensionless variable and variable scattering length, respectively; for $x>1$, $A(x)\equiv A(1)$ is a constant and represents the dimensionless scattering length A_0. Looking for a solution in the form $A(x)=x\alpha(x)$, we obtain for $\alpha(x)$,

$$\alpha'(x)=-\frac{1}{x}[\alpha(x)+\lambda(1+\alpha(x))^2. \tag{3.50}$$

Note, that in this equation boundary condition $\alpha(0)=0$ is not necessary: $\alpha(x)$ could be any function regular at $x=0$ so that condition $A(0)=0$ is satisfied. Setting $\alpha(x)=\text{constant}\equiv A_0$ gives an algebraic equation $A_0=-\lambda(1+A_0)^2$ whose solution is given by $A_0=-1-1/2\lambda(1\pm\sqrt{1+4\lambda})$. Since for $\lambda\to 0$ there should be no scattering only solution with the minus sign before the square root should be chosen, since only for this solution $A_0\to 0$ when $\lambda\to 0$. Setting for convenience $g=4\lambda$ we finally obtain

$$A_0=-1-\frac{2}{g}(1-\sqrt{1+g}). \tag{3.51}$$

The solution has a singularity, namely a branch point, at $g=-1$, that is at $\lambda=-\frac{1}{4}$. The singularity marks the beginning of interval $-\infty<\lambda<-\frac{1}{4}$ where a fall to the center takes place[18] and the expression for the scattering length becomes complex, its real and imaginary parts for $g<-1$ are given by

$$\operatorname{Re}A_0=-1-\frac{2}{g},\quad \operatorname{Im}A_0=\frac{2}{g}\sqrt{-1-g}. \tag{3.52}$$

Note that in view of our definition (3.6) of the scattering length one has to chose $\operatorname{Im}A_0\geqslant 0$.[18] The perturbation series for the scattering length could be obtained by expansion of the square root in Eq. (3.51) in the power series which gives

$$\begin{aligned}
A_0=&-\frac{1}{4}g+\frac{1}{8}g^2-\frac{5}{64}g^3+\frac{7}{128}g^4-\frac{21}{512}g^5+\frac{33}{1024}g^6-\frac{429}{16\,384}g^7\\
&+\frac{715}{32\,768}g^8\frac{2431}{131\,072}g^9+\frac{4199}{262\,144}g^{10}-\frac{29\,393}{2\,097\,152}g^{11}+\frac{52\,003}{4\,194\,304}g^{12}\\
&-\frac{185\,725}{16\,777\,216}g^{13}+\frac{334\,305}{33\,554\,432}g^{14}-\frac{9\,694\,845}{1\,073\,741\,824}g^{15}+\frac{17\,678\,835}{2\,147\,483\,648}g^{16}\\
&-\frac{64\,822\,395}{8\,859\,934\,592}g^{17}+\frac{119\,409\,675}{17\,179\,869\,184}g^{18}-\frac{883\,631\,595}{137\,438\,953\,472}g^{19}\\
&+\frac{1\,641\,030\,105}{274\,877\,906\,944}g^{20}-\frac{6\,116\,566\,755}{1\,099\,511\,627\,776}g^{21}+\frac{11\,435\,320\,455}{2\,199\,023\,255\,552}g^{22}\\
&-\frac{171\,529\,806\,825}{35\,184\,372\,088\,832}g^{23}+\frac{322\,476\,036\,831}{70\,368\,744\,177\,664}g^{24}-\frac{1\,215\,486\,600\,363}{281\,474\,976\,710\,656}g^{25}\\
&+\frac{2\,295\,919\,134\,019}{562\,949\,953\,421\,312}g^{26}-\frac{17\,383\,387\,729\,001}{4\,503\,599\,627\,370\,496}g^{27}\\
&+\frac{32\,968\,493\,968\,795}{9\,007\,199\,254\,740\,992}g^{28}-\frac{125\,280\,277\,081\,421}{36\,028\,797\,018\,963\,968}g^{29}\\
&+\frac{238\,436\,656\,380\,769}{72\,057\,594\,037\,927\,936}g^{30}-\frac{14\,544\,636\,039\,226\,909}{4\,611\,686\,018\,427\,387\,904}g^{31}\\
&+\frac{27\,767\,032\,438\,524\,099}{9\,223\,372\,036\,854\,775\,808}g^{32}+O(g^{33}).
\end{aligned} \tag{3.53}$$

The expansion is convergent[16] for $|g|<1$, that is for $|\lambda|<\frac{1}{4}$.

Let us now turn our attention to QLM approximations and their convergence. The QLM iterations sequences are easiest to find by considering differential form 2.3 of Eq. (2.22) which could be written as

$$\alpha'_{n+1}(x) = -\frac{1}{x}\left[\frac{g}{4}(1-\alpha_n^2(x)) + \alpha_{n+1}(x)\left(1+\frac{g}{2}(1+\alpha_n(x))\right)\right]. \tag{3.54}$$

The assumption that $\alpha_n(x)$ are constant functions, $\alpha_n(x)\equiv c_n$, immediately establish the QLM recurrence relationship

$$c_{n+1} = -g\frac{1-c_n^2}{4+2g(1+c_n)}. \tag{3.55}$$

Note that since $c_{n+1}\to 0$ when $g\to 0$ each approximation to the scattering amplitude vanishes for $g=0$ as it should be since in the absence of the potential there is no scattering. The convergence of the QLM iteration sequence to the exact solution (3.51) is obvious. Indeed, for $n\to\infty$, Eq. (3.55) is

$$c_\infty = -g\frac{1-c_\infty^2}{4+2g(1+c_\infty)}, \tag{3.56}$$

whose solution vanishing for $g\to 0$ is given by the expression for A_0 in Eq. (3.51). The QLM approximation c_n to the dimensionless scattering length for an infinite n therefore indeed is $c_\infty \equiv A_0$ as we wanted to show.

The explicit calculation of the first few QLM approximations, starting from the usual initial guess $c_0=0$ gives

$$c_1 = -\frac{g}{4+2g}, \tag{3.57}$$

$$c_2 = -1/4\frac{(16+16g+3g^2)g}{(8+8g+g^2)(2+g)}, \tag{3.58}$$

$$c_3 = -1/8\frac{(4096+12\,288g+14\,080g^2+7680g^3+2016g^4+224g^5+7g^6)g}{(128+256g+160g^2+32g^3+g^4)(2+g)(8+8g+g^2)}. \tag{3.59}$$

These expressions, unlike that of the perturbation theory, give finite values also for $g>1$ or even for $g=\infty$, where the first, second, and third QLM approximations give $-\frac{1}{2}$, $-\frac{3}{4}$, $-\frac{7}{8}$ vis-a-vis the exact value $A_0=-1$; the fourth approximation, not given here because of its cumbersome form, results in $-\frac{15}{16}$, and so on. The convergence of these values is from above in agreement with the law of convergence for the concave functions proved in Sec. II, since the second functional derivative $-\lambda/x^2$ of the right-hand side of Eq. (3.49) is negative for the repulsive potential.

The expansion of the QLM approximations in the power series in the coupling constant shows as in previous examples that each QLM iteration sums exactly many perturbation series terms, whose number is given by Eq. (3.47). One obtains:

$$c_0 = 0, \tag{3.60}$$

$$c_1 = -\frac{1}{4}g + \frac{1}{8}g^2 - \frac{1}{16}g^3 + \frac{1}{32}g^4 - \frac{1}{64}g^5 + O(g^6), \tag{3.61}$$

$$c_2 = -\frac{1}{4}g + \frac{1}{8}g^2 - \frac{5}{64}g^3 + \frac{7}{128}g^4 - \frac{21}{512}g^5 + \frac{33}{1024}g^6 - \frac{107}{4096}g^7 + \frac{177}{8192}g^8 - \frac{593}{32\,768}g^9 + O(g^{10}), \tag{3.62}$$

$$c_3 = -\frac{1}{4}g + \frac{1}{8}g^2 - \frac{5}{64}g^3 + \frac{7}{128}g^4 - \frac{21}{512}g^5 + \frac{33}{1024}g^6 - \frac{429}{16\,384}g^7 + \frac{715}{32\,768}g^8 - \frac{2431}{131\,072}g^9 + \frac{4199}{262\,144}g^{10} - \frac{29\,393}{2\,097\,152}g^{11} + \frac{52\,003}{4\,194\,304}g^{12} - \frac{185\,725}{16\,777\,216}g^{13} + \frac{334\,305}{33\,554\,432}g^{14} - \frac{2\,423\,711}{268\,435\,456}g^{15} + \frac{4\,419\,705}{536\,870\,912}g^{16} - \frac{16\,205\,537}{2\,147\,483\,648}g^{17} + \frac{29\,852\,049}{4\,294\,967\,296}g^{18} - \frac{220\,900\,693}{34\,359\,738\,368}g^{19} + O(g^{20}), \tag{3.63}$$

$$c_4 = -\frac{1}{4}g + \frac{1}{8}g^2 - \frac{5}{64}g^3 + \frac{7}{128}g^4 - \frac{21}{512}g^5 + \frac{33}{1024}g^6 - \frac{429}{16\,384}g^7 + \frac{715}{32\,768}g^8 - \frac{2431}{131\,072}g^9 + \frac{4199}{262\,144}g^{10} - \frac{29\,393}{2\,097\,152}g^{11} + \frac{52\,003}{4\,194\,304}g^{12}\frac{185\,725}{16\,777\,216}g^{13} + \frac{334\,305}{33\,554\,432}g^{14} - \frac{9\,694\,845}{1\,073\,741\,824}g^{15} + \frac{17\,678\,835}{2\,147\,483\,648}g^{16} - \frac{64\,822\,395}{8\,589\,934\,592}g^{17} + \frac{119\,409\,675}{17\,179\,869\,184}g^{18} - \frac{883\,631\,595}{137\,438\,953\,472}g^{19} + \frac{1\,641\,030\,105}{274\,877\,906\,944}g^{20} - \frac{6\,116\,566\,755}{1\,099\,511\,627\,776}g^{21} + \frac{11\,435\,320\,455}{2\,199\,023\,255\,552}g^{22} - \frac{171\,529\,806\,825}{35\,184\,372\,088\,832}g^{23} + \frac{322\,476\,036\,831}{70\,368\,744\,177\,664}g^{24} - \frac{1\,215\,486\,600\,363}{281\,474\,976\,710\,656}g^{25} + \frac{2\,295\,919\,134\,019}{562\,949\,953\,421\,312}g^{26} - \frac{17\,383\,387\,729\,001}{4\,503\,599\,627\,370\,496}g^{27} + \frac{32\,968\,493\,968\,795}{9\,007\,199\,254\,740\,992}g^{28} - \frac{125\,280\,277\,081\,421}{36\,028\,797\,018\,963\,968}g^{29} + \frac{238\,436\,656\,380\,769}{72\,057\,594\,037\,927\,936}g^{30} - \frac{3\,636\,159\,009\,806\,727}{1\,152\,921\,504\,606\,846\,976}g^{31} + \frac{6\,941\,758\,109\,631\,017}{2\,305\,843\,009\,213\,693\,952}g^{32} + O(g^{33}). \tag{3.64}$$

Comparison of Eqs. (3.60)–(3.64) with Eq. (3.53) shows that the QLM iterations with $n = 0,1,2,3,4$ reproduce exactly 1,3,7,15,31 terms of the perturbation series, respectively, in exact agreement with Eq. (3.47), while the next few terms have coefficients extremely close to being exact. The number of terms given precisely by the zero, first, second, third and fourth QLM approximations is increasing by 2, 2^2, 2^3 and 2^4, exactly as we saw earlier in the case of the δ-function potential and in precise agreement with the quadratic law of the convergence, proved in Sec. II. Due to simplicity of the algebraic recurrence relations (3.55) Eq. (3.47) for number N_n of the perturbation series terms given precisely by the nth QLM approximation could be checked for higher QLM approximations. For example, in Sec. III B on the example of the repulsive δ-potential we concluded that $N_6=127$. The simple calculation using a symbolic manipulation program[17] shows immediately that it is precisely the same for the inverse square potential. Indeed, the first seven nonzero terms of the expansion in powers of g of difference A_0-c_6 between exact scattering length Eq. (3.51) and its sixth QLM approximation are

$$-\frac{1}{28\,948\,022\,309\,329\,048\,855\,892\,746\,252\,171\,976\,963\,317\,496\,166\,410\,141\,009\,864\,396\,001\,978\,282\,409\,984}g^{127}$$

$$+\frac{127}{57\,896\,044\,618\,658\,097\,711\,785\,492\,504\,343\,953\,926\,634\,992\,332\,820\,282\,019\,728\,792\,003\,956\,564\,819\,968}g^{128},$$

$$-\frac{16319}{231\,584\,178\,474\,632\,390\,847\,141\,970\,017\,375\,815\,706\,539\,969\,331\,281\,128\,078\,915\,168\,015\,826\,259\,279\,872}g^{129},$$

$$+\frac{707\,135}{463\,168\,356\,949\,264\,781\,694\,283\,940\,034\,751\,631\,413\,079\,938\,662\,562\,256\,157\,830\,336\,031\,652\,518\,559\,744}g^{130},$$

$$-\frac{92\,988\,123}{3\,705\,346\,855\,594\,118\,253\,554\,271\,520\,278\,013\,051\,304\,639\,509\,300\,498\,049\,262\,642\,688\,253\,220\,148\,477\,952}g^{131},$$

$$+\frac{2\,473\,622\,041}{7\,410\,693\,711\,188\,236\,507\,108\,543\,040\,556\,026\,102\,609\,279\,018\,600\,996\,098\,525\,285\,376\,506\,440\,296\,955\,904}g^{132},$$

$$-\frac{110\,916\,205\,323}{29\,642\,774\,844\,752\,946\,028\,434\,172\,162\,224\,104\,410\,437\,116\,074\,403\,984\,394\,101\,141\,506\,025\,761\,187\,823\,616}g^{133}, \tag{3.65}$$

exactly as one expects from Eq. (3.47). In addition, one can see that the next terms of the perturbation series are also reproduced extremely well, their difference with the precise terms being infinitesimally small. Namely, the coefficient of 127th power of g is about 3.45×10^{-76}, the coefficient of 128th power is about 2.19×10^{-74}, and so on.

For the attractive potential expressions (3.57)–(3.59) become singular, with the number of zeros of denominators increasing with each iteration. This, of course, is a reflection of the fact that the exact scattering length A_0 has a branch point at $g=-1$ and a cut line along the real axis between $g=-1$ and $g=-\infty$. When n is increasing, the poles are getting closer and closer to each other and fuse together at $n=\infty$, where, as we saw earlier, the exact amplitude and its singularity are reproduced.

To handle the singularities one can try, as we have discussed earlier, to consider instead of the function $\alpha(x)$ a new function $\beta(x)$ such that $\alpha(x)=1/\beta(x)$. Substitution of Eq. (3.65) into Eq. (3.50) leads to

$$\beta'(x)=\frac{1}{x}[\beta(x)+\lambda(1+\beta(x))^2, \tag{3.66}$$

which is different from Eq. (3.50) only by the sign of the right-hand side. The QLM iterations sequence is found as before by considering differential form (2.3) of Eq. (2.22):

$$\beta'_{n+1}(x)=\frac{1}{x}\left[\frac{g}{4}(1-\beta_n^2(x))+\beta_{n+1}(x)\left(1+\frac{g}{2}(1+\beta_n(x))\right)\right], \tag{3.67}$$

which leads under a previous assumption of β_n being a constant function, $\beta_n\equiv c_n$, to exactly the same QLM recurrence relations (3.55). Again, the convergence of the QLM series follows from the fact that at $n\to\infty$ we have the same Eq. (3.56), as before, with only distinction—since now the scattering amplitude in the limit $n=\infty$ is given by $1/\beta_\infty$, one should take a solution of this equation which is going to infinity at $g\to0$ rather than to zero. Such solution is given by

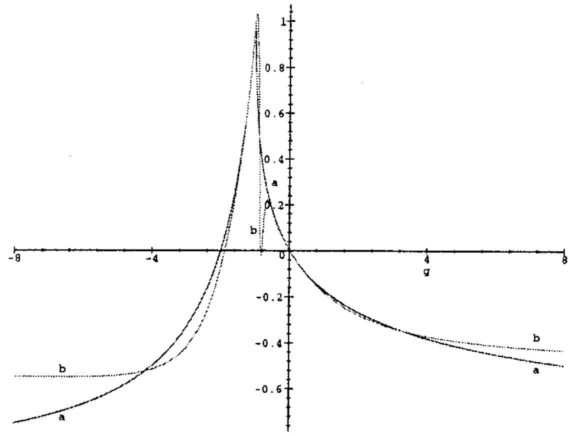

FIG. 4. Comparison of real parts of the exact scattering length (curve a) and of the second QLM approximation to it (curve b) for inverse square potential, $|g|\leqslant 8$.

$$\beta_\infty=-1-\frac{2}{g}(1+\sqrt{1+g}). \tag{3.68}$$

The $n=\infty$ QLM approximation to the scattering length A_0 thus equals to

$$\frac{1}{\beta_\infty}=\frac{1}{-1-\frac{2}{g}(1+\sqrt{1+g})}$$

$$\equiv-1-\frac{2}{g}(1-\sqrt{1+g}), \tag{3.69}$$

which indeed coincides exactly with expression (3.51) for A_0.

Since the change to $\beta_n(x)=1/\alpha_n(x)$ does not give anything new, the only way to avoid the singularities in the case of attractive potential seems therefore to use the fact that the zero approximation could be an arbitrary, not necessarily real, number, and to choose c_0 as a complex number with a positive imaginary part of the same order as a real part. The necessity of choosing c_0 complex in the case of the attractive potential follows also from the fact that in this case the fall to the center happens. The inelastic cross section for zero energies, determined by the imaginary part of the S-wave scattering length,[18] could not therefore be zero; however, from recurrence relations (3.55) it is obvious that unless the initial guess c_0 is a complex number, all subsequent QLM approximations are real.

Comparison of real and imaginary parts of the scattering length with those calculated in the second and third QLM approximations for an arbitrary initial guess $\alpha_0=1+i$ and for coupling constant values $|\lambda|\leqslant 2$ ($|g|\leqslant 8$) is shown in Figs. 4–7. One can see that already for the second QLM iteration the agreement between the exact scattering length and the QLM approximation to it is quite good. It improves visibly for the next QLM iteration. For the fourth and next iterations the distinction between exact and approximate scattering length is difficult to see and therefore the correspondent graphs are not shown.

D. Inverse quartic potential

Our next and last example is the inverse quartic potential of radius ρ,

$$V(r)=\lambda\frac{R^2}{r^4}\Theta(\rho-r), \tag{3.70}$$

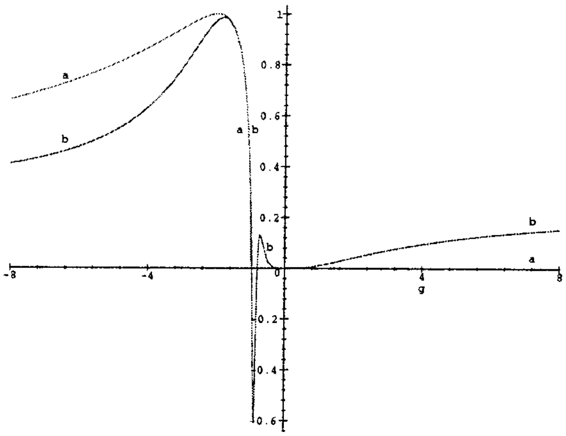

FIG. 5. Comparison of imaginary parts of the exact scattering length (curve a) and of the second QLM approximation to it (curve b) for inverse square potential, $|g|\leqslant 8$.

where λ is a dimensionless coupling constant. For $r\leqslant\rho$ the equation for a variable scattering length $a(r)$ is given by

$$\frac{da(r)}{dr}=-\lambda\frac{R^2}{r^4}(r+a(r))^2,\quad a(0)=0, \tag{3.71}$$

while the scattering length a_0 equals $a(\rho)$. Introduction of the dimensionless function $\alpha(x)=a(r)/R\sqrt{\lambda}$ and of the dimensionless variable $x=r/R\sqrt{\lambda}$ reduces Eq. (3.71) to

$$\frac{d\alpha(x)}{dx}=-\frac{1}{x^4}(x+\alpha(x))^2,\quad \alpha(0)=0, \tag{3.72}$$

whose solution is obviously given by

$$\alpha(x)=-\frac{x}{1+x}. \tag{3.73}$$

Since for $r=\rho$ $x=x_0=\rho/R\sqrt{\lambda}$, and $\alpha(\rho/R\sqrt{\lambda})=-\rho/(\rho+R\sqrt{\lambda})$, the dimensionless scattering length $A_0=a_0/R$ is given by

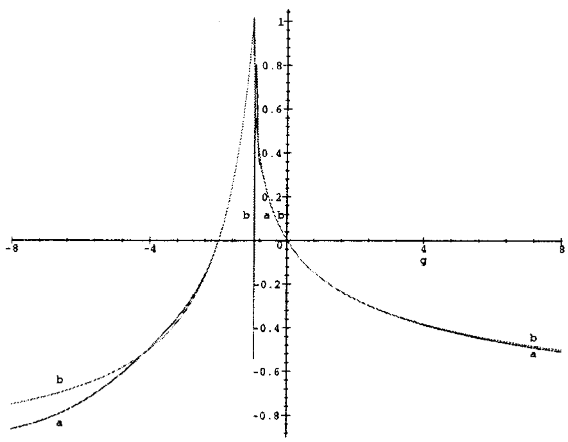

FIG. 6. Same as in Fig. 4, but in the third QLM approximation.

$$A_0=\sqrt{\lambda}\,\alpha\left(\frac{\rho}{R\sqrt{\lambda}}\right)=-\frac{\rho\sqrt{\lambda}}{\rho+R\sqrt{\lambda}}\equiv-\frac{\rho}{R}\,\frac{y_0}{1+y_0},\quad y_0=\frac{1}{x_0}=\frac{R}{\rho}\sqrt{\lambda}, \tag{3.74}$$

which coincides with that found in Ref. 19 and also in Refs. 4, 11, and 14, where ρ is set to ∞. The solution has a singularity, namely a branch point, at $\lambda=0$. The singularity marks the beginning of interval $-\infty<\lambda<0$, where potential is attractive and a fall to the center takes place[18,20] and where the expression for the scattering length A_0 becomes complex. We consider therefore only repulsive potentials.

As always, let us start from the perturbation expansion (3.7), whose coefficients $a_n(r)$ are calculated from recurrence relations (3.8). In view of a strong singularity of the potential at the origin from Eq. (3.9) it follows, however, that first coefficient $a_1(r)$, and therefore all the others, are infinite. The perturbation expansion does not exist, which, of course, is a consequence of the branch point singularity of the scattering length directly at $\lambda=0$.

There is, however, no problems with the QLM approximations to solution (3.73), whose iteration sequence in this case is given by

$$\alpha_{n+1}(x)=-\int_0^x\frac{ds}{s^4}[s^2-\alpha_n^2(s)]\exp\left(-2\int_s^x\frac{dt}{t^4}(t+\alpha_n(t))\right). \tag{3.75}$$

Starting from the usual initial guess $\alpha_0(x)=0$ one easily computes[4,11] the first iteration $\alpha_1(x)=-\exp(1/x^2\int_0^x ds/s^2\,e^{-1/s^2})$, which substitution $s=1/\sqrt{t}$ reduces to a form $\alpha_1(x)=-\frac{1}{2}\exp(1/x^2\int_{1/x^2}^\infty dt/t^{1/2}\,e^{-t})\equiv-\sqrt{\pi}/2\,e^{1/x^2}\,\mathrm{erfc}(1/x)$. The dimensionless scattering length in the first QLM approximation therefore is

$$A_{0,1}=\sqrt{\lambda}\,\alpha_1(x_0)=-\frac{\sqrt{\pi}}{2}\,\frac{\rho}{R}\,y_0e^{y_0^2}\,\mathrm{erfc}(y_0), \tag{3.76}$$

where $\mathrm{erfc}(x)=1-\mathrm{erf}(x)$ is the complementary error function.[16] One can see that $A_{0,1}$, like A_0, is a function of y_0 and therefore has the same branch point singularity at $\lambda=0$ as the exact scattering length.

To obtain a higher QLM approximation it is convenient to remove a fourth power of variable in the denominators of the integrals in Eq. (3.75). To do this, let us introduce a new variable $y=1/x$ and a new function $\beta(x)=\alpha(1/x)$ with a boundary condition $\beta(\infty)=\alpha(0)=0$. Equation (3.72) then has the form

$$\frac{d\beta(y)}{dy}=(1+y\beta(y))^2,\quad \beta(\infty)=0, \tag{3.77}$$

whose exact solution is given by

$$\beta(y)=-\frac{1}{(1+y)}, \tag{3.78}$$

while Eq. (3.75) is written as

$$\beta_{n+1}(y)=-\int_y^\infty ds[1-s^2\beta_n^2(s)]\exp\left(2\int_s^y dt\,t(1+\beta_n(t))\right). \tag{3.79}$$

The nth QLM approximation to $\alpha(x)$ is $\alpha_n(x)=\beta_n(1/x)\equiv\beta_n(y)$ so that $\alpha(x_0)\equiv\beta(y_0)$ and the initial guess could be chosen $\beta_0(x)\equiv\beta(\infty)=0$. In the long ranged case $\rho=\infty$, $y_0=0$, and, since $\mathrm{erfc}(0)=1$, $A_{0,1}=-\sqrt{\pi}/2\sqrt{\lambda}=-0.886\sqrt{\lambda}$, a very good approximation[11] to exact value $A_0=-\sqrt{\lambda}$. The next QLM approximation, which can be computed numerically, results in $A_{0,2}=-0.988\sqrt{\lambda}$, a precision of 1.2%. For comparison, calculation of A_0 in the second CBF approxi-

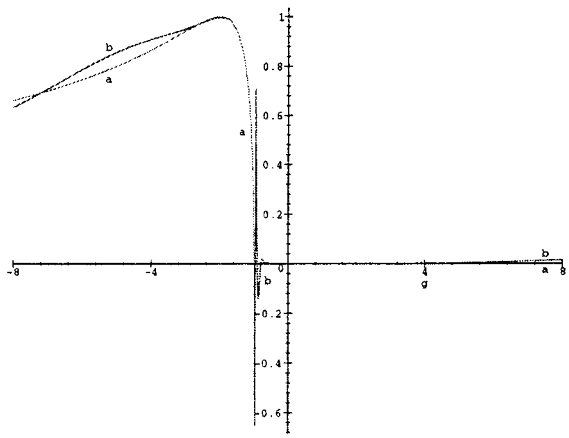

FIG. 7. Same as in Fig. 5, but in the third QLM approximation.

mation, Eq. (2.21), which in this case reduces to a simple minded linearization approach,[11] based on neglecting a nonlinear term, gives $A_{0,2}=-0.954\sqrt{\lambda}$, precision of only 4.6%. In the infinite coupling finite range case y_0 is very large and one can use asymptotic expression (3.16), which gives $A_{0,1}=-\frac{1}{2}\rho/R$, a reasonable first approximation to exact value $A_0=-\rho/R$. In the next, second QLM approximation, the numerical computation yelds $A_{0,2}=-\frac{3}{4}\rho/R$, a significant improvement.

The uniform quadratic convergence of QLM sequence (3.75) is proved, according to Eq. (2.34), by showing that the first convergence coefficient $q_1(b)$ is less than unity. In our case, we have chosen $\alpha_0(x)\equiv 0$ and therefore $q_1(b)=k(b)\|\alpha_1(x)\|\leqslant k(b)$, since in view of the properties of the complimentary error function[16] $|\alpha_1(x)|\leqslant 1$ for all x.

To estimate $k(b)$ we have to know $G(x)$ and $F(x)$, which have to satisfy inequalities (2.31). Since the first and the second derivatives of the right-hand side of Eq. (3.72) are $-2/x^4(x+\alpha(x))$ and $-2/x^4$, respectively, and since the scattering length for the repulsive potential has no poles and should be finite, $\alpha(x)\leqslant M$ where M is some positive constant, and therefore one can choose $G(x)=F(x)\equiv F_1(x)=2M/x^4$. For small $(x\leqslant\epsilon)$, where $\epsilon\ll 1$ is some small but finite number, looking for $\alpha(x)$ in the form $\alpha(x)\sim ax+bx^2$ and substituting in Eq. (3.72) gives $a=-1$, $b=1$. The first functional derivative for small x therefore equals $-2/x^2$ and one can choose in this case negative boundary function $F(x)\equiv F_2(x)=-2/x^2$ and $G(x)=|F_2(x)|$.

Separating in Eq. (2.35) for $k(b)$ smaller and larger values of x gives

$$k(b)=\frac{1}{2}\left|C\exp\int_0^{\epsilon}dt\,F_2(t)-1\right|, \tag{3.80}$$

where $C=\exp\int_{\epsilon}^{b}dt\,F_1(t)$ is a finite constant even for infinite interval $b=\infty$. Since $\exp(\int_0^{\epsilon}dtF_2(t))=\exp(-2\int_0^{b}dt\,1/t^2)=\exp(2/t\,|_{+0}^{\epsilon})=0$, Eq. (3.80) gives $k(b)\equiv\frac{1}{2}$ und thus $q_1(b)\leqslant\frac{1}{2}$, which proves uniform quadratic convergence of QLM iteration sequence $\alpha_n(x_0)$, Eq. (3.75), on the whole interval $(0,\infty)$, that is for all values of coupling constant λ, including large and infinite ones.

IV. CONCLUSION

Summing up, we have reformulated the proof of the convergence of the quasilinearization method (QLM) of Bellman and Kalaba[1,2] by removing unnecessary restrictive conditions generally not fulfilled in physical applications, and have generalized the proof for large or infinite domains of variables and for functionals which are singular at some points in the domain. We also have shown how to deal with solutions which are infinite at certain values of variable such as, for example, scattering amplitudes at values corresponding to bound state energies, etc.

In order to make presentation as simple and short as possible, we have limited ourselves here to the case of the first-order nonlinear ordinary differential equation in one variable, which physically covers the quantum mechanics of one particle in a central field (in this case the Schrödinger equation for a wave function could be rewritten as the nonlinear Ricatti equation for its logarithmic derivative) though the same modernization of the Bellman and Kalaba proof[1,2] could be provided also for a general nonlinear ordinary or partial nth order differential equations in the N-dimensional space.

In order to highlight the power of the method in Sec. III we have considered examples of different singular and nonsingular, attractive and repulsive potentials $V(r)$ for which the nonlinear first-order ordinary differential equation (1.1) for the S-wave scattering length $a_0=a(\infty)$ obtained in variable phase approach[4,5] could be solved exactly and have compared the iterations obtained by the Bellman–Kalaba linearization method with exact solutions and with the usual perturbation theory. The results could be summed up as follows.

(i) The sequence $u_n(x),\ n=1,2,\ldots$ of QLM iterations, Eq. (2.22), converges *uniformly and quadratically* to solution $u(x)$ of Eq. (2.2). For the convergence on the interval $[0,b]$ is enough that an initial guess for zero iteration is sufficiently good to ensure the smallness of just one of convergence coefficients $q_m(b)=k(b)\|u_{m+1}-u_m\|$, where $k(b)$ is given by Eq. (2.32) or Eq. (2.35). In addition, for strictly convex (concave) functionals $f(u(x),x)$ difference $u_{n+1}(x)-u_n(x)$ is strictly positive (negative), which establishes *the monotonicity* of the convergence from below (above), respectively, on this interval.

(ii) The QLM treats the nonlinear terms as a perturbation about the linear ones[1,2] and is not based, unlike perturbation theories, on the existence of some kind of small parameter. As a result, it is able to handle, unlike the perturbation theory, large or even infinite values of the coupling constant.

(iii) Comparison of QLM with the perturbation theory shows that each QLM iteration reproduces and sums many orders of perturbation theory exactly and in addition many more orders approximately. Namely, in agreement with the quadratic pattern of the convergence, the number N_n of the terms of the perturbation series, reproduced exactly in the nth QLM approximations, equals $2^{n+1}-1$, and approximately the same number of terms is reproduced approximately. The number of the exactly reproduced terms thus doubles with each subsequent QLM approximation, and reaches, for example, 127 terms in the sixth QLM approximation, 8191 terms in the twelfth QLM approximation and so on.

(iv) QLM handles without any problems not only singular potentials, like the inverse squared potential, for which the perturbation theory is divergent outside a narrow interval of the values of the coupling constant, but even super singular potentials, like reverse quartic potential, for which perturbation series are not existent at all, since their calculation leads to infinities in each order of the perturbation expansion.

(v) As we saw in all of our examples, QLM easily handles different singularities, like poles or branch point singularities, reproducing correct type of the singularity already in first iterations.

(vi) Although the analytic calculations of third and higher approximation in QLM, like in the usual perturbation theory, in most cases (excluding inverse square potential) seem impossible, the simplicity of the QLM iterational sequence Eq. (2.22) (which, unlike perturbation theory, containes no sums on intermediate energy states) assures nonproblematic numerical calculation of higher order iterations, while the extremely fast convergence of the method allows accurate estimate of the solution after relatively small number of iterations.

In view of all this, since most equations of physics, from classical mechanics to quantum field theory, are either not linear or could be transformed to a nonlinear form, the quasilinear method may turn out to be extremely useful and in many cases more advantageous than the perturbation theory or its different modifications, like expansion in inverse powers of the coupling constant, $1/N$ expansion, etc.

Picard–Fuchs equations and Whitham hierarchy in $N=2$ supersymmetric SU$(r+1)$ Yang–Mills theory

Yűji Ohta

(Received 6 July 1999; accepted for publication 4 August 1999)

In general, Whitham dynamics involves infinitely many parameters called Whitham times, but in the context of $N=2$ supersymmetric Yang–Mills theory it can be regarded as a finite system by restricting the number of Whitham times appropriately. For example, in the case of SU$(r+1)$ gauge theory without hypermultiplets, there are r Whitham times and they play an essential role in the theory. In this situation, the generating meromorphic one-form of the Whitham hierarchy on the Seiberg–Witten curve is represented by a finite linear combination of meromorphic one-forms associated with these Whitham times, but it turns out that there are various differential relations among these differentials. Since these relations can be written only in terms of the Seiberg–Witten one-form, their consistency conditions are found to give the Picard–Fuchs equations for the Seiberg–Witten periods.

I. INTRODUCTION

Thanks to the study of electromagnetic duality initiated by Seiberg and Witten,[1] the prepotential of the low energy effective action of $N=2$ supersymmetric Yang–Mills theory was turned out to be viewed as a function on a complex projective space having singularities when the masses of charged particles vanish. This complex projective space can be identified with the moduli space of a Riemann surface determined by several physical requirements, thus the effective theory can be considered to be controlled by the geometry of moduli space of a Riemann surface.[2–16] According to this observation, since the effective coupling constants of the theory are interpreted as the period matrix of a Riemann surface, determining the period matrix from the calculation of periods becomes equivalent to evaluating effective coupling constants. It is interesting that the instanton contributions to prepotential[17] can be obtained from the evaluation of periods and the prepotentials obtained in this way[18–26] are known to be consistent with the instanton calculus.[26–33] In these studies, the method based on Picard–Fuchs equations[18–25,34–38] played a crucial role.

However, on the one hand, the theory of prepotential often shows unexpected aspects behind the effective theory. For example, it is known that the Seiberg–Witten solutions can be understood in the framework of Whitham theory.[39,40] Gorsky *et al.*[41] noticed that the Whitham dynamics in $N=2$ Yang–Mills theory could be written essentially by only a finite number of Whitham times and found that the second-order derivatives of prepotential over the Whitham times could be represented by an elliptic function associated with the Seiberg–Witten curve.

However, we can further learn more aspects of the Whitham hierarchy in gauge theory from the basic idea of Gorsky *et al.*[41] For instance, note that since the number of time variables of the hierarchy is restricted to be finite the generating meromorphic one-form of the Whitham hierarchy is represented by a finite linear combination of meromorphic one-forms associated with these Whitham times. Then we can expect that there must be closed differential relations among these meromorphic differentials associated with Whitham times. In fact, a detailed study supports this observation and the aim of the paper is to show the consequence of these relations, especially, a connection to Picard–Fuchs equations for the Seiberg–Witten periods.

The paper is organized as follows. In Sec. II, we briefly summarize the Whitham dynamics in SU$(r+1)$ gauge theory. In addition, following Gorsky *et al.*,[41] we consider the situation where the number of Whitham times is finite. Since the meromorphic one-forms on a Seiberg–Witten curve consisting of the Whitham hierarchy must always be represented by simply a linear combination of Abelian differentials, we can expect the existence of differential relations among these meromorphic one-forms. In Sec. III, it is shown that such relations can in fact be found and as a result Picard–Fuchs equations for the Seiberg–Witten periods are available from this view point. It should be noted that the generating meromorphic differential of the Whitham hierarchy can be written in terms of the Seiberg–Witten one-form. This indicates that it is sufficient to consider only the Seiberg–Witten periods in order to calculate the periods of the Whitham hierarchy. In Sec. IV, it is shown that the SU(3) Picard–Fuchs equations for the Seiberg–Witten periods can be obtained from the Picard–Fuchs equations with Whitham times for the periods of the Whitham hierarchy by considering the specialization condition to the Seiberg–Witten model. Section V is a brief summary.

II. WHITHAM HIERARCHY IN GAUGE THEORY

In this section, we briefly sketch the relation between the Seiberg–Witten solution and Whitham dynamics in the context of $N=2$ supersymmetric Yang–Mills theory.[39–41]

A. Seiberg–Witten solution

To begin with, let us recall that the Seiberg–Witten curve in SU$(r+1)$ gauge theory without matter hypermultiplets[2–4] is given by the characteristic equation

$$\det[x-L(\omega)]=0 \tag{2.1}$$

of the Lax operator $L(\omega)$ for Toda chain with $r+1$ sites,[39] where x is the eigenvalue of $L(\omega)$ and ω is the spectral parameter. (2.1) can be rewritten in the form of spectral curve

$$P(x)=\Lambda_{\mathrm{SU}(r+1)}^{r+1}\left(\omega+\frac{1}{\omega}\right), \tag{2.2}$$

where $\Lambda_{\mathrm{SU}(r+1)}$ is the dynamical mass parameter and

$$P(x):=x^{r+1}-\sum_{i=2}^{r+1} u_i x^{r+1-i} \tag{2.3}$$

represents the simple singularity of type A_r with moduli u_i. This spectral curve (2.2) can be further rewritten in the familiar hyperelliptic form[2–4]

$$y^2=P^2-4\Lambda^2, \tag{2.4}$$

where $\Lambda:=\Lambda_{\mathrm{SU}(r+1)}^{r+1}$ and we have introduced

$$y:=\Lambda_{\mathrm{SU}(r+1)}^{r+1}\left(\omega-\frac{1}{\omega}\right). \tag{2.5}$$

Note that the hyperelliptic curve (2.4) is a Riemann surface of genus r.

For a study of Riemann surface, it is often useful to consider the periods of Abelian differentials over the one-cycles on the surface. In the case at hand, we can take $2r$ one-cycles (A_i,B_i) $(i=1,\ldots,r)$ on (2.4) as a canonical basis (B_i are symplectic duals of A_i), which can be expressed by using the branching points of (2.4).

On the other hand, in order to interpret the components of a period matrix constructed from periods of Abelian differentials as the effective coupling constants, the combination of Abelian differentials must be fixed uniquely up to total derivatives. In addition, in general, there are three kinds of Abelian differentials on a Riemann surface, but that of the third kind is not required here because we are considering a pure gauge theory. Therefore, the expected meromorphic differential one-form is expressed by the Abelian differentials of the first and second kinds, and the one satisfying these requirements is called the Seiberg–Witten differential $dS_{\rm SW}$, given by

$$dS_{\rm SW} := x\frac{d\omega}{\omega} = x\frac{\partial_x P}{y}dx, \tag{2.6}$$

where we have ignored the numerical normalization for simplicity, and then the Seiberg–Witten periods are given by the loop integrals over the canonical cycles

$$a_i := \oint_{A_i} dS_{\rm SW}, \quad a_{D_i} := \oint_{B_i} dS_{\rm SW}. \tag{2.7}$$

Note that $dS_{\rm SW}$ can be viewed as the canonical one-form of the integrable system. In this way, we can see the relation between the Seiberg–Witten solution and integrable system.

B. Whitham hierarchy

We have seen that the Seiberg–Witten solution has a connection to the integrable system, but it can also be viewed as part of the Whitham theory of solitons on a Riemann surface.

To see this, let us recall that in general Whitham theory consists of the following three ingredients:[42]

(1) Riemann surface of genus g.
(2) Punctures on the surface.
(3) Existence of local coordinates near the punctures.

Gorsky *et al.*[41] noticed that the meromorphic differentials of the second kind $d\Omega_n$ of $(n+1)$th order punctures $(n>0)$ on a Riemann surface were defined up to a linear combination of g holomorphic differentials $d\omega_i$ and considered how to fix this combination by taking two basic requirements. The first one was to require

$$\oint_{A_i} d\Omega_n = 0 \tag{2.8}$$

and the second one was to introduce new meromorphic differentials $d\hat{\Omega}_n$, which enjoy the property that their differentiations over the moduli coincide with holomorphic differentials.

According to their result,[41] the differential

$$dS := \sum_{n=1}^{\infty} T_n d\hat{\Omega}_n = \sum_{i=1}^{g} \alpha_i d\omega_i + \sum_{n=1}^{\infty} T_n d\Omega_n \tag{2.9}$$

with infinitely many parameters T_n called Whitham times is found to be the expected solution which is suitable for applications to gauge theory. For this new meromorphic differential dS, the periods

$$\alpha_i := \oint_{A_i} dS, \quad \alpha_{D_i} := \oint_{B_i} dS \tag{2.10}$$

can be defined in a natural way.

Next, in order to make contact with the Seiberg–Witten solution, Gorsky *et al.*[41] regarded the Riemann surface used here as the Seiberg–Witten hyperelliptic curve (2.4).

In such a situation, they found that the Whitham hierarchy could actually be written only by first r time variables and gave an explicit expression of dS. In particular, in the case of SU$(r+1)$ gauge theory, n is restricted to $n<r+1$. Namely, in this situation, the periods (2.10) reduce to

$$\alpha_i=\sum_{n=1}^{r} T_n \oint_{A_i} d\hat{\Omega}_n, \quad \alpha_{D_i}=\sum_{n=1}^{r} T_n \oint_{B_i} d\hat{\Omega}_n \tag{2.11}$$

and $d\hat{\Omega}_n$ are given by

$$d\hat{\Omega}_n=R_n\frac{d\omega}{\omega}, \quad R_n:=P_+^{n/(r+1)}. \tag{2.12}$$

In this expression, $P_+^{n/(r+1)}$ means the non-negative terms in the expansion of $P^{n/(r+1)}$ for a large x, and in general, $P^{n/(r+1)}$ in SU$(r+1)$ gauge theory is easily found to give

$$P^{n/(r+1)}=x^n-\frac{n}{r+1}u_2x^{n-2}-\frac{n}{r+1}u_3x^{n-3}-\frac{n}{r+1}\left[u_4+\frac{u_2^2}{2}\left(1-\frac{n}{r+1}\right)\right]x^{n-4}-\cdots. \tag{2.13}$$

Note that the periods are now represented by a finite linear combination of $d\hat{\Omega}_n$ because we are only considering for the $n<r+1$ case. In addition, from (2.12), it is immediately seen that the Seiberg–Witten solution is recovered at the point

$$(T_1,T_2,T_3,\ldots,T_r)=(1,0,0,\ldots,0). \tag{2.14}$$

In fact, we find $d\hat{\Omega}_1=dS_{\mathrm{SW}}$. Of course, in this case, we have $dS=dS_{\mathrm{SW}}$.

III. PICARD–FUCHS STRUCTURE BEHIND WHITHAM HIERARCHY

A. Relations among meromorphic differentials

We have seen that dS is represented by a linear combination of $d\hat{\Omega}_n$ and also that $d\hat{\Omega}_1=dS_{\mathrm{SW}}$. Then, are $d\hat{\Omega}_n$ for $n\neq 1$ related to dS_{SW}? If we can find any relation among them, the role of the Seiberg–Witten solution in Whitham dynamics will be clarified.

To find an answer to this question, let us notice that any meromorphic differential on a Riemann surface must always be written in terms of the basis of Abelian differentials on the surface. Of course, this must be true also for $d\hat{\Omega}_n$ for all n. Therefore, if we consider a differentiation of $d\hat{\Omega}_n$ over moduli, it will ultimately be represented by a linear combination of various $d\hat{\Omega}_n$ and their derivatives. However, actually, in the case of the Seiberg–Witten Riemann surface, we can show that the derivatives of $d\hat{\Omega}_n$ for $n>1$ are obtained from the Seiberg–Witten differential $d\hat{\Omega}_1$. Thus as a result, we can conclude that dS is generated from $d\hat{\Omega}_1$ and accordingly the periods of dS can be directly determined through the Seiberg–Witten periods themselves.

To see this more concretely, let us consider the case of $d\hat{\Omega}_2$ as an example. Since the differentiations of $d\hat{\Omega}_2$ over moduli are

$$\frac{\partial d\hat{\Omega}_2}{\partial u_i}=\frac{dx}{y}\left[-2\,\delta_{2,i}\,x^r+\frac{\delta_{2,i}}{r+1}\sum_{j=2}^{r+1}(r+1-j)u_jx^{r-j}+2x^{r+2-i}\right], \tag{3.1}$$

where $\delta_{i,j}$ are Kronecker's delta symbols, and those for $d\hat{\Omega}_1$ are

$$\frac{\partial d\hat{\Omega}_1}{\partial u_i}=\frac{x^{r+1-i}}{y}dx, \tag{3.2}$$

it is easy to see that

$$\frac{\partial d\hat{\Omega}_2}{\partial u_2}=\frac{2}{r+1}\sum_{i=2}^{r+1}(r+1-i)u_i\frac{\partial d\hat{\Omega}_1}{\partial u_{i+1}},\quad \frac{\partial d\hat{\Omega}_2}{\partial u_i}=2\frac{\partial d\hat{\Omega}_1}{\partial u_{i-1}}\quad (i\neq 2). \tag{3.3}$$

Note that in the derivation of (3.1) and (3.2) we have used the general formulas

$$\frac{\partial d\hat{\Omega}_n}{\partial u_i}=\frac{dx}{y}[\partial_{u_i}R_n\cdot\partial_x P-\partial_x R_n\cdot\partial_{u_i}P]+d\left(\frac{R_n\partial_{u_i}P}{y}\right). \tag{3.4}$$

In a similar way, we can obtain differential relations between $d\hat{\Omega}_n$ for $n>1$ and $d\hat{\Omega}_1$, but we omit the derivations for them and show only the result for $n=3$ and 4 cases here.

For $d\hat{\Omega}_3$:

$$\begin{aligned}
\frac{\partial d\hat{\Omega}_3}{\partial u_2}&=-\frac{3}{r+1}\left[u_2\frac{\partial d\hat{\Omega}_1}{\partial u_2}-\sum_{i=2}^{r+1}(r+1-i)u_i\frac{\partial d\hat{\Omega}_1}{\partial u_i}\right],\\
\frac{\partial d\hat{\Omega}_3}{\partial u_3}&=-\frac{3}{r+1}\left[u_2\frac{\partial d\hat{\Omega}_1}{\partial u_3}-\sum_{i=2}^{r+1}(r+1-i)u_i\frac{\partial d\hat{\Omega}_1}{\partial u_{i+1}}\right],\\
\frac{\partial d\hat{\Omega}_3}{\partial u_i}&=3\left[\frac{\partial d\hat{\Omega}_1}{\partial u_{i-2}}-\frac{u_2}{r+1}\frac{\partial d\hat{\Omega}_1}{\partial u_i}\right]\quad (i\neq 2,3).
\end{aligned} \tag{3.5}$$

For $d\hat{\Omega}_4$:

$$\begin{aligned}
\frac{\partial d\hat{\Omega}_4}{\partial u_2}&=-\frac{4}{r+1}\left[u_3\frac{\partial d\hat{\Omega}_1}{\partial u_2}-\sum_{i=3}^{r+1}(r+1-i)u_i\frac{\partial d\hat{\Omega}_1}{\partial u_{i-1}}-\frac{r-3}{r+1}u_2\sum_{i=2}^{r+1}(r+1-i)u_i\frac{\partial d\hat{\Omega}_1}{\partial u_{i+1}}\right],\\
\frac{\partial d\hat{\Omega}_4}{\partial u_3}&=-\frac{4}{r+1}\left[2u_2\frac{\partial d\hat{\Omega}_1}{\partial u_2}+u_3\frac{\partial d\hat{\Omega}_1}{\partial u_3}-\sum_{i=2}^{r+1}(r+1-i)u_i\frac{\partial d\hat{\Omega}_1}{\partial u_i}\right],\\
\frac{\partial d\hat{\Omega}_4}{\partial u_4}&=-\frac{4}{r+1}\left[2u_2\frac{\partial d\hat{\Omega}_1}{\partial u_3}+u_3\frac{\partial d\hat{\Omega}_1}{\partial u_4}-\sum_{i=2}^{r+1}(r+1-i)u_i\frac{\partial d\hat{\Omega}_1}{\partial u_{i+1}}\right],\\
\frac{\partial d\hat{\Omega}_4}{\partial u_i}&=4\left[\frac{\partial d\hat{\Omega}_1}{\partial u_{i-3}}-\frac{2u_2}{r+1}\frac{\partial d\hat{\Omega}_1}{\partial u_{i-1}}-\frac{u_3}{r+1}\frac{\partial d\hat{\Omega}_1}{\partial u_i}\right]\quad (i\neq 2,3,4).
\end{aligned} \tag{3.6}$$

B. Picard–Fuchs equations from Whitham hierarchy

If the derivatives of $d\hat{\Omega}_n$ over moduli for $n>1$ are eliminated from relations (3.3), (3.5), and (3.6) by using differentiations, the equations satisfied by $d\hat{\Omega}_1$ will be obtained. Furthermore, since $d\hat{\Omega}_1=dS_{\mathrm{SW}}$, we can identify such equations as Picard–Fuchs equations for Seiberg–Witten periods.

To see this, it is enough to consider the cross derivatives of $d\hat{\Omega}_n$. For example, for $d\hat{\Omega}_2$, from $[\partial_2\partial_i-\partial_i\partial_2]d\hat{\Omega}_2=0$, where $\partial_i:=\partial/\partial u_i$, we get

$$\left[(r+1)\partial_2\partial_{i-1}-(r+1-i)\partial_{i+1}-\sum_{j=2}^{r+1}(r+1-j)u_j\partial_i\partial_{j+1}\right]d\hat{\Omega}_1=0 \quad (i\neq 2), \tag{3.7}$$

which are the Picard–Fuchs equations obtained by several authors.[26,37] For other $d\hat{\Omega}_n$, we can construct similar equations and, in fact, we can obtain the ''hierarchy'' of Picard–Fuchs equations as follows:

$$\left[\sum_{i=2}^{r+1}(r+1-i)u_i(\partial_3\partial_i-\partial_2\partial_{i+1})\right]d\hat{\Omega}_1=0,$$

$$\left[(r+1-i)\partial_{i+1}-(r+1)\partial_3\partial_{i-2}+\sum_{j=2}^{r+1}(r+1-j)u_j\partial_i\partial_{j+1}\right]d\hat{\Omega}_1=0 \quad (i\neq 2,3),$$

$$\left[(r+1)\partial_2\partial_{i-2}-(r+2-i)\partial_i-\sum_{j=2}^{r+1}(r+1-j)u_j\partial_i\partial_j\right]d\hat{\Omega}_1=0 \quad (i\neq 2,3),$$

$$\Bigg[2(r+1)u_2\partial_2^2+(r-3)(r-2)u_2\partial_4+(r+1)\sum_{i=3}^{r+1}(r+1-i)u_i\partial_{i-1}\partial_3+(r-3)u_2 \times\sum_{i=2}^{r+1}(r+1-i)u_i\partial_{i+1}\partial_3-(r+1)\sum_{i=2}^{r+1}(r+1-i)u_i\partial_i\partial_2\Bigg]d\hat{\Omega}_1=0,$$

$$\Bigg[2(r+1)u_2\partial_2\partial_3+(r-3)^2u_2\partial_5+(r+1)\sum_{i=3}^{r+1}(r+1-i)u_i\partial_{i-1}\partial_4-(r+1) \times\sum_{i=2}^{r+1}(r+1-i)u_i\partial_{i+1}\partial_2+(r-3)u_2\sum_{i=2}^{r+1}(r+1-i)u_i\partial_{i+1}\partial_4\Bigg]d\hat{\Omega}_1=0, \tag{3.8}$$

$$\Bigg[(r+1)^2\partial_2\partial_{i-3}-2(r+1)u_2\partial_{i-1}\partial_2-(r+1)(r+3-i)\partial_{i-1}-(r-3)(r+1-i)u_2\partial_{i+1} -(r+1)\sum_{j=3}^{r+1}(r+1-j)u_j\partial_i\partial_{j-1}-(r-3)u_2\sum_{j=2}^{r+1}(r+1-j)u_j\partial_i\partial_{j+1}\Bigg]d\hat{\Omega}_1=0 \quad (i\neq 2,3,4),$$

$$\left[2u_2(\partial_2\partial_4-\partial_3^2)-\sum_{i=2}^{r+1}(r+1-i)u_i(\partial_4\partial_i-\partial_3\partial_{i+1})\right]d\hat{\Omega}_1=0,$$

$$\left[2u_2(\partial_3\partial_i-\partial_4\partial_{i-1})+(r+1)\partial_4\partial_{i-3}-(r+1-i)\partial_{i+1}-\sum_{j=2}^{r+1}(r+1-j)u_j\partial_i\partial_{j+1}\right]d\hat{\Omega}_1=0 \quad (i\neq 2,3,4),$$

$$\left[2u_2(\partial_i\partial_2-\partial_3\partial_{i-1})+(r+1)\partial_3\partial_{i-3}-(r+2-i)\partial_i-\sum_{j=2}^{r+1}(r+1-j)u_j\partial_i\partial_j\right]d\hat{\Omega}_1=0 \quad (i\neq 2,3,4).$$

Note that the equations in (3.8) are all second-order equations and in some cases we can simplify them by using $(\partial_i\partial_j-\partial_p\partial_q)d\hat{\Omega}_1=0$, where $i+j=p+q$.[26,37]

C. Picard–Fuchs equations as a complete system

Of course, as a complete Picard–Fuchs system, it is not necessary to consider all equations in (3.7) and (3.8). In general, since there are r moduli parameters in the $SU(r+1)$ gauge theory, it is sufficient to extract at least r independent equations from them.

To see this, let us notice the equations in (3.7). Since the number of the equations is $r-1$, one more equation is necessary. However, we cannot obtain the expected equation from (3.8) because the equations presented there do not have the instanton corrections. If the instanton correction terms are not included in any one of Picard–Fuchs equations, the prepotential obtained from them will not show the instanton corrections precisely. Therefore, we require that the remaining one must include instanton terms.

Actually, such an equation was recognized by Ito and Yang[43] as the scaling relation. There, the Picard–Fuchs system was realized by two kinds of equations, one of which is the Gauss–Manin system and the other is the scaling relation. Since the Gauss–Manin system does not involve instanton corrections, the situation looks like ours. Therefore, also for our case, the scaling relation may be used as the remaining Picard–Fuchs equation.

For this, let us consider the Eulerian operator

$$\mathcal{E}:=\sum_{i=2}^{r+1} iu_i\partial_i+(r+1)\Lambda\partial_\Lambda, \tag{3.9}$$

which acts as

$$\mathcal{E}d\hat{\Omega}_n=nd\hat{\Omega}_n \tag{3.10}$$

for all $n>0$. (3.10) indicates that the degree of $d\hat{\Omega}_n$ is n. Realizing (3.10) as an equation only in terms of moduli derivatives can be easily accomplished by considering the squaring equation $(\mathcal{E}-n)^2d\hat{\Omega}_n=0$.[37,43]

In this way, we can associate r independent Picard–Fuchs equations for $d\hat{\Omega}_1$.

IV. PICARD–FUCHS EQUATIONS WITH WHITHAM TIMES

A. The SU(3) Picard–Fuchs equations

Next, let us consider Picard–Fuchs equations for the periods (α_i,α_{D_i}) of the Whitham hierarchy. In the case of $r=1$, the resulting Picard–Fuchs equation takes the same form with the usual one[18] up to rescaling of T_1. For this reason, we do not discuss this case, and instead, let us consider the $r=2$ case in order to find a nontrivial example of Picard–Fuchs equations with Whitham times.

In this case, the Picard–Fuchs equations with the Whitham times are found to be in the form

$$\mathcal{L}_j(\alpha_i,\alpha_{D_i})=0, \tag{4.1}$$

where

$$
\begin{aligned}
\mathcal{L}_1=&\frac{54u^2vT_1T_2-(108\Lambda^2-4u^3-27v^2)(uT_2^2-3T_1^2)}{u(-3T_1^2+4uT_2^2)}\partial_u^2\\
&-\frac{3[(-108\Lambda^2+4u^3+27v^2)T_1T_2+8uv(uT_2^2-3T_1^2)]}{2(3T_1^2-4uT_2^2)}\partial_u\partial_v\\
&+\frac{T_2[8(108\Lambda^2-4u^3-27v^2)(-3T_1^2+uT_2^2)T_2-9uvT_1(15T_1^2+28uT_2^2)]}{2u(3T_1^2-4uT_2^2)^2}\partial_u\\
&+\frac{2(108\Lambda^2-4u^3-27v^2)(3T_1^2-uT_2^2)T_1T_2+3uv(9T_1^4+27uT_1^2T_2^2-4u^2T_2^4)}{u(3T_1^2-4uT_2^2)^2}\partial_v+1,
\end{aligned}
\tag{4.2}
$$

$$
\begin{aligned}
\mathcal{L}_2=&\frac{-54u^2vT_1T_2+(108\Lambda^2-4u^3-27v^2)(uT_2^2-3T_1^2)}{3(3T_1^2-4uT_2^2)}\partial_v^2\\
&-\frac{3[8uv(uT_2^2-3T_1^2)+(-108\Lambda^2+4u^3+27v^2)T_1T_2]}{2(3T_1^2-4uT_2^2)}\partial_u\partial_v\\
&-\frac{45vT_1T_2}{2(3T_1^2-4uT_2^2)}\partial_u+\frac{3v(3T_1^2+uT_2^2)}{3T_1^2-4uT_2^2}\partial_v+1.
\end{aligned}
$$

Though the derivation of Picard–Fuchs equations for other higher r is straightforward, the result turns out to be too lengthy and complicated, so we do not consider these cases in this paper.

B. Specializations of SU(3) Picard–Fuchs equations

It may be instructive to see specializations of (4.2). With the help of (2.14), it is straightforward to make sure that the equations in (4.2) yield the usual SU(3) Picard–Fuchs equations[18] $\mathcal{L}_j(a_i,a_{D_i})=0$ for the Seiberg–Witten periods, which can be identified with Appell's F_4 system,[44–47]

$$
\begin{aligned}
&\mathcal{L}_1\to L_1:=(4u^3+27v^2-108\Lambda^2)\partial_u^2+12u^2v\,\partial_u\partial_v+3uv\,\partial_v+u,\\
&\mathcal{L}_2\to L_2:=(4u^3+27v^2-108\Lambda^2)\partial_v^2+36uv\,\partial_u\partial_v+9v\,\partial_v+3.
\end{aligned}
\tag{4.3}
$$

Note that the consistency condition of (4.3) leads to $[u\partial_v^2-3\partial_u^2](a_i,a_{D_i})=0$, which coincides with (3.7) for $r=2$.

On the other hand, from (4.2) with $(T_1,T_2)=(0,1)$, we can also consider Picard–Fuchs equations $\hat{L}_j(\oint_{A_i}d\hat{\Omega}_2,\oint_{B_i}d\hat{\Omega}_2)=0$ for the periods of $d\hat{\Omega}_2$, where

$$
\begin{aligned}
&\mathcal{L}_1\to\hat{L}_1:=u(4u^3+27v^2-108\Lambda^2)\partial_u^2+12u^3v\,\partial_u\partial_v-(4u^3+27v^2-108\Lambda^2)\partial_u-3u^2v\,\partial_v+4u^2,\\
&\mathcal{L}_2\to\hat{L}_2:=(4u^3+27v^2-108\Lambda^2)\partial_v^2+36uv\,\partial_u\partial_v-9v\,\partial_v+12.
\end{aligned}
\tag{4.4}
$$

From (4.4), we can obtain a relation like that from (4.3), but the same equation is also available from (3.3), provided $\partial d\hat{\Omega}_1/\partial u_i$ are eliminated from (3.3).

Finally, note that we have

$$\hat{L}_j(\alpha_i,\alpha_{D_i})=T_1\hat{L}_j\left(\oint_{A_i}d\hat{\Omega}_1,\ \oint_{B_i}d\hat{\Omega}_1\right),\quad L_j(\alpha_i,\alpha_{D_i})=T_2L_j\left(\oint_{A_i}d\hat{\Omega}_2,\ \oint_{B_i}d\hat{\Omega}_2\right)\qquad(4.5)$$

from (2.9), (4.3), and (4.4).

V. SUMMARY

In this paper, we have discussed the SU$(r+1)$ gauge theory in the standpoint of Whitham dynamics and realized $r-1$ Picard–Fuchs equations for Seiberg–Witten periods as consistency equations among meromorphic differentials associated with Whitham times. In addition, we have used the scaling relation as the remaining independent equation in order to include the instanton corrections. Though the generalization to other cases except SU$(r+1)$ group is straightforward, the case of exceptional gauge groups would be interesting because there are two types of Seiberg–Witten curves in these gauge theories.[7,11–16] In particular, it may be interesting to know how the differences of physics expected from these two curves[12,16,24,25] are reflected in the Whitham theory and the Picard–Fuchs structure behind it.

Of course, our construction of Picard–Fuchs equations may provide helpful information not only for these cases but also when we consider the relation among flat coordinates,[48,49] Witten–Dijkgraaf–Verlinde–Verlinde equations,[50–55] and the Whitham hierarchy.[39–41] We are now planning a discussion with respect to this point.

Wigner–Weyl correspondence and semiclassical quantization in spherical coordinates

Bill Poirier[a)]
The James Franck Institute, The University of Chicago, Chicago, Illinois 60637

(Received 20 January 1999; accepted for publication 7 September 1999)

The Wigner–Weyl quantum-to-classical correspondence rule is nonunique with respect to coordinate choice. This ambiguity can be exploited to improve the accuracy of semiclassical approximations. For instance, the well-known Langer modification was recently derived by applying a coordinate transformation to the radial Schrödinger equation prior to using the Wigner–Weyl rule—albeit only by presuming exact quantum solutions for all nonradial degrees of freedom [J. J. Morehead, J. Math. Phys. **36**, 5431 (1995)]. In this paper, the full classical Hamiltonian is derived in all degrees of freedom, using a (hyper)spherical coordinate Wigner–Weyl correspondence with a Langer-like modification of polar angles. For central force Hamiltonians, the new result is radially equivalent to that of Langer, and to the standard Cartesian form. The new correspondence is superior with respect to all angular momentum operators however, in that the resultant semiclassical eigenvalues are exact—a desirable goal, evidently achieved here for the first time. © *1999 American Institute of Physics.* [S0022-2488(99)01912-X]

I. INTRODUCTION

When viewed as mathematical structures, classical and quantum mechanics are in many respects very similar. In both cases, physical observables may be regarded as elements of a unital Lie $*$-algebra.[1] Moreover, in each case there is an important class of algebra automorphisms—the canonical (unitary) transformations—which induces an equivalence relation on the algebraic elements. Physically, this reflects the fact that canonically (unitarily) equivalent observables are indistinguishable from one another—these observables can even be regarded as characterizing ''the same'' physical system, if the transformation is interpreted as a passive change of coordinates.

Despite similarities, though, the classical and quantum algebras are *not* isomorphic. Thus, although a one-to-one correspondence can be established between the two, it is impossible to preserve the equivalence relation described above. The upshot is that a given quantum operator $\hat{A}$ can be mapped to physically distinct classical observables $A,A',A'',\ldots,$ depending on the choice of coordinates. This is a basic theoretical fact, which has thus far received surprisingly little attention; the issue is addressed in some detail in Sec. II. Indeed, even the correspondence rule itself[2–7]—discovered independently by Weyl[2] and Wigner[3] in the early days of the quantum theory—is usually omitted from the standard texts.

In any event, this paper concerns itself with semiclassical approximations, and how they are affected by the choice of correspondence coordinates. All semiclassical methods are canonically invariant in the following sense: Once the classical observable has been established, quantities such as Wentzel–Kramers–Brillouin (WKB) eigenvalues are the same in all canonical coordinate systems. However, because the Wigner–Weyl (WW) rule itself is *non*invariant, these quantities do vary with the coordinates used to obtain the correspondence. It follows that in this sense, some coordinate systems are better than others, vis-à-vis the accuracy of the resultant WKB approximations. It is the author's contention that a basic understanding of these preferred coordinate

a)Electronic mail: billp@rainbow.uchicago.edu

systems is a worthwhile pursuit—with respect to improving semiclassical calculations, and perhaps also in terms of providing physical insight.

The central force Hamiltonians $H = T + V(r)$ (Sec. III) and their generalizations with respect to dimensionality and form (respectively, Secs. IV and V) constitute the particular focus of the present work. These systems have always occupied a special role in physics, in part because of their prevalence in nature, but also because they lend themselves readily to analytical solution. It is well-known that the three-dimensional central force problem decouples, if spherical—rather than Cartesian—coordinates are used. The former are closely related to the action-angle variables, and are therefore more fundamentally associated with the Hamiltonian than the latter—despite the simplicity of the Cartesian expressions.

If the theories of mechanics admit any favoritism at all with respect to coordinates, then surely the action-angle variables are the preferred choice. It is therefore natural to ask whether proximity to action-angle coordinates is related to the efficacy of the resultant WW correspondence. This paper attempts to provide at least a partial answer to this question. More specifically, we determine whether the WKB approximation, as applied to the classical central force Hamiltonians obtained from a correspondence in spherical coordinates, is better or worse than that obtained from the standard correspondence in Cartesian coordinates.

The question of choosing correspondence coordinates appropriate for central force Hamiltonians has been addressed previously, albeit in a context of reduced dimensionality. If the quantum Hamiltonian is expressed in spherical coordinates, and the angular momentum operator $\hat{L}^2$ replaced with its exact quantum eigenvalues, then the one-dimensional radial Schrödinger equation results. This equation is often tackled semiclassically; in this context, it is well known that the results are improved dramatically under the ''Langer modification''[8–11]—which amounts to adding an extra $+1/(8mr^2)$ term to the classical Hamiltonian (in units where $\hbar = 1$, as will be used throughout this paper).

Over the years, many justifications for the introduction of Langer's extra term have been provided—beginning with that of Langer himself,[8] who believed it necessary to retain a differential equation with a Schrödinger-like form. In more recent years, the intrinsic Gaussian curvature of the constrained configuration space[12–16] has come to be regarded as the essential rationale. These treatments do not focus on the issue of correspondence coordinates; implicitly however, they presume a WW correspondence in the radial coordinate r. On the other hand, if the WW correspondence is obtained in the coordinate $x = \ln r$ rather than in r itself, then the ''extra'' term is present right from the start.

Evidently, this line of reasoning was first proposed in a paper by Morehead,[17] which shall be referred to extensively in this work. It should be noted that Langer himself made use of the same logarithmic coordinate transformation as Morehead, but not in any canonically meaningful way. Langer's procedure is related to the Podolsky transformation,[18] which can be regarded as a special case of the WW correspondence rule—though it is doubtful that Langer was aware of this. Unlike the WW rule however, the Podolsky procedure is inherently limited to observables that are quadratic in the momenta. Consequently, Langer's original derivation applies only to $T + V(r)$ Hamiltonians, whereas Morehead's approach allows the modification to be generalized for arbitrary radial operators.

The approach of this paper, in turn, can be considered a generalization of Morehead's work. The notion of the coordinate dependence of the WW correspondence rule is used throughout, as is Langer's modification—whose appropriate extension to polar angles is investigated herein. The present method is a fully WKB treatment however—i.e., one in which all of the degrees of freedom are treated semiclassically. In contrast, Morehead uses a mixed method, for which all but the radial degree of freedom are treated quantum mechanically. The mixed method is therefore only applicable to radial Hamiltonians, for which the two approaches will be shown to be essentially identical. However, the present method can also be applied to quantities that depend on the spherical angles, such as angular momenta. Indeed, WKB results for $\hat{L}^2$ and its N-dimensional generalizations shall be presented, which reproduce the quantum eigenvalues and degeneracies *exactly*. To the author's best knowledge, there is no other semiclassical treatment in the current literature that also does so.

II. THEORETICAL BACKGROUND

In this section, we review the Wigner–Weyl (WW) correspondence rule, the Podolsky kinetic energy transformation, Morehead's derivation of the Langer modification, and other theoretical aspects pertinent to the subsequent discussion. We begin with the basic task of specifying the exact correspondence between quantum operators and classical observables, for one-dimensional systems.

This fundamental problem has been with us since the inception of quantum mechanics. The conventional wisdom states that (1) there is no difficulty for kinetic-plus-potential ($T+V$) Hamiltonians, and (2) the more general case with position-momentum cross terms is an inherently many-to-one correspondence—presumably because multiplicative ordering matters in quantum mechanics, but not in classical mechanics. This seemingly innocuous description is intuitively sensible, and can even be found in standard texts.[19] Nevertheless, such a viewpoint is essentially *incorrect on both points*.

The cross terms dilemma was effectively resolved with the advent of the correspondence rules of Weyl and Wigner. Weyl's approach is to allow just one possible ordering of $\hat{q}$ and $\hat{p}$ operators to correspond to each classical monomial $q^m p^n$,[20] where q and p are canonically conjugate position and momentum variables. Quantum operators which are properly ''Weyl-ordered'' thus correspond to classical observables—the ''Weyl symbols''—in a manifestly unique manner.[2,6] Wigner's method, on the other hand, converts the position matrix representation of the operator to a mixed position-momentum representation, using a Fourier-like transformation.[3,5] That the end result of the Wigner prescription is identical to the Weyl symbol—if (q,p) are true canonical coordinates, and for legitimate polynomial expansions—was shown by Moyal.[4]

The WW rule certainly provides a one-to-one correspondence between quantum operators and classical Weyl symbols, and would appear to remove all arbitrariness from the correspondence procedure. As mentioned in Sec. I, however, a more subtle ambiguity still remains with respect to the property of canonical (unitary) invariance. It is in this sense that the WW correspondence fails to be unique; for one could always choose to express the initial Hamiltonian in a different coordinate system, thereby obtaining a canonically inequivalent correspondence. Moreover, *no* Hamiltonians are safe from this kind of ambiguity—not even those of the standard $T+V$ form. The only class of observables whose WW correspondence is always canonically invariant are the canonical coordinates themselves.

It is helpful to express these ideas in more precise mathematical language. Let $\hat{A}=A(\hat{q},\hat{p})$ be a Hermitian operator, expressed in terms of $\hat{q}$ and $\hat{p}$, the generators of the quantum algebra. These generators are presumed to be a conjugate pair of position and momentum operators, satisfying the canonical commutation relation

$$\hat{q}\hat{p}-\hat{p}\hat{q}=i\hat{I}. \tag{2.1}$$

Because the algebraic relation of Eq. (2.1) holds, there can be many different algebraic expressions $A(\hat{q},\hat{p})$ that result in the same operator $\hat{A}$. For convenience, we choose $A(\hat{q},\hat{p})$ to be Weyl-ordered. Thus, if ''$W[\ ]$'' denotes the WW mapping from quantum operators to classical Weyl symbols, then $W[\hat{A}]=A(q,p)$. The real-valued classical function $A(q,p)$ is the Weyl symbol corresponding to $\hat{A}$, *as obtained in the coordinates* $(\hat{q},\hat{p})$.

Let us consider a unitary transformation $\hat{U}$ that has the following effect on the generators:

$$\hat{U}^\dagger\hat{q}\hat{U}=\hat{Q}=Q(\hat{q},\hat{p}), \tag{2.2}$$

$$\hat{U}^\dagger\hat{p}\hat{U}=\hat{P}=P(\hat{q},\hat{p}), \tag{2.3}$$

where the algebraic expressions $Q(\hat{q},\hat{p})$, etc., are once again presumed to be Weyl-ordered. The new operators $\hat{Q}$ and $\hat{P}$ satisfy Eq. (2.1), and are therefore canonically conjugate in the quantum sense. In addition, it can be shown that the corresponding Weyl symbols $Q(q,p)$ and $P(q,p)$ satisfy the classical Poisson bracket—thereby comprising a canonically conjugate pair in the classical sense as well. We can therefore establish a one-to-one correspondence between quantum unitary transformations $\hat{U}$, and classical canonical transformations—designated $\mathcal{C}_U$. It can be shown, moreover, that this correspondence preserves the group properties of the transformations, so that $\hat{U}^{-1}$ corresponds to $\mathcal{C}_U^{-1}$, etc.

Under the passive unitary transformation $\hat{U}^{-1}$, the algebraic expression for $\hat{A}$ becomes

$$\hat{A}=A(q(\hat{Q},\hat{P}),p(\hat{Q},\hat{P})). \tag{2.4}$$

Under the corresponding canonical transformation $\mathcal{C}_U^{-1}$, the Weyl symbol $A(q,p)$ becomes $A(q(Q,P),p(Q,P))$. However, the right-hand side of Eq. (2.4) is *not*, in general, Weyl-ordered in $\hat{Q}$ and $\hat{P}$. Therefore,

$$A(q(Q,P),p(Q,P))\neq A'(Q,P), \tag{2.5}$$

where $A'(Q,P)$ is the Weyl symbol for $\hat{A}$ that actually is obtained in the coordinates $(\hat{Q},\hat{P})$. Therefore, the Weyl symbols $A(q,p)$ and $A'(Q,P)$ are not in general canonically equivalent.

In the preceding analysis, and throughout this paper, we rely on the notion of ''true canonical coordinates,'' which can be defined algebraically as the set of Hermitian elements $\hat{q}$ for which there exists a (conjugate) Hermitian element $\hat{p}$ such that Eq. (2.1) is satisfied. Not all Hermitian operators fit the bill—implying that the simple practice of assigning $\hat{p}\rightarrow -i\partial/\partial q$ is not always valid. For example, the spectrum of a true canonical coordinate must be Cartesian—i.e., nondegenerate, real, and ranging continuously from $-\infty$ to $+\infty$. This follows from Eq. (2.1), and from the fact that the translation operator $\exp(iq_0\hat{p})$ is unitary for all real q_0. In this strict sense, therefore, all bounded coordinates such as radii and angles, are not considered truly canonical.

A similar situation also holds in the classical realm. Consider the action-angle transformation

$$\phi=-\arctan(p/q), \quad J=(q^2+p^2)/2. \tag{2.6}$$

The coordinates (ϕ,J) are *almost* truly canonical, but not quite—because Eq. (2.6) is ill-defined at the origin (although the classical Poisson bracket is satisfied everywhere else in phase space). This disqualifies ϕ and J from being true canonical coordinates, although they are obviously still useful; we shall refer to such coordinates as being ''canonical-like.''

This distinction is relevant for the Hamiltonians of this paper, for which ''hyperspherical coordinates''—the N-dimensional generalization of (r,θ,ϕ)—shall be employed. These coordinates—also called ''ultraspherical''[21–23]—are significant, because the Hamiltonian and other constants of the motion become weakly separable when expressed in hyperspherical form (Appendix). Weakly separable basis representations have previously been investigated for other quantum applications.[24–26] Among other advantages, such representations necessarily involve product—though not necessarily direct product—basis sets.

Hyperspherical coordinates are not true canonical coordinates, because the transformation from the original Cartesian system is ill-defined at the origin. The standard WW rule does not apply in such cases; therefore there is some question as to how to establish a correspondence. Our provisional resolution shall be to retain Weyl ordering in the canonical-like conjugate pairs such as $(\hat{\phi},\hat{p}_\phi)$, with the usual conjugate momenta assignments, i.e., $(N=3)$,

$$\hat{p}_r\rightarrow -i\frac{\partial}{\partial r}, \quad \hat{p}_\theta\rightarrow -i\frac{\partial}{\partial \theta}, \quad \hat{p}_\phi\rightarrow -i\frac{\partial}{\partial \phi}. \tag{2.7}$$

There is empirical evidence suggesting that this rule is appropriate, at least for localized operators, i.e., those that depend polynomially on the hyperspherical momenta (Sec. V).[17,27] We presume this to be the case for the Hamiltonians considered in this paper.

There is another, less fundamental context in which Eq. (2.7) may not hold—even for true canonical coordinates. In general, differential quantum operator assignments are meaningless, unless the associated Jacobian weight factor that appears in the orthonormality relations is also specified. In particular, Eq. (2.7) applies only if the Jacobian weight factor is unity.[18] We shall refer to differential operator expressions as being in ''canonical(-like) form'' if the associated weight factor is unity over all of configuration space (except for subspaces of measure zero). Although the standard Cartesian differential expressions are almost always in canonical form, nontrivial weight factors can accrue, for instance, when the chain rule is used to effect a coordinate transformation.

The chain rule is usually invoked in the context of point transformations, i.e., canonical transformations for which the new positions are functions of the old positions only. Although the chain rule is perfectly valid for this, the Podolsky transformation—where applicable—is usually preferred, because it automatically preserves the canonical-like form of the differential expressions. It is for this reason that the Podolsky transformation is closely related to the WW correspondence in the new coordinates. In fact, by Weyl-ordering the Podolsky-transformed kinetic energy, and then transforming classically back to the original coordinates, one obtains the original Weyl symbol plus an additional ''quantum correction'' term. Quantum corrections are mass- and $\hbar$-dependent functions of position, that appear in the classical expressions when cross terms are introduced by the coordinate transformation.[28,29] They can be interpreted as a measure of the lack of canonical invariance associated with the WW correspondence for a particular observable.

It is as a quantum correction term, for instance, that the Langer modification arises in the point transformation of the one-dimensional radial Schrödinger equation, from the coordinate r to the coordinate $x=\ln r$. This is, at any rate, the essence of Morehead's argument.[17] His analysis does not tell us, however, why this *particular* coordinate should be singled out for the correspondence. Given that any other choice would result in a different classical Hamiltonian, it remains a mystery as to why x happens to be so beneficial for the subsequent semiclassical analysis (designated ''method I''). Most likely, this question cannot be properly addressed unless a fully WKB treatment is used. The method of this paper does in fact constitute such a treatment; accordingly, some tentative arguments are presented in Sec. V—but the question is still very much an open one.

As it happens, Langer's classical Hamiltonian has also been obtained using an alternate, fully WKB method. In this second approach—which does *not* employ any modification—the WW correspondence is obtained in the original Cartesian coordinates, and then solved semiclassically using Einstein–Brillouin–Keller (EBK) quantization. This second approach shall be referred to as ''method II,'' in contradistinction to the mixed, spherical coordinate method I of the preceding paragraph. Evidently, there is no improvement to be gained from a Langer-like modification, if Cartesian coordinates are used to begin with. This suggests that method I's success may be related to the fact that $x=\ln r$ is more Cartesian-like than r (Sec. V)—an idea that will motivate a similar transformation of the polar angle coordinates in Sec. III and IV.

Given that the Cartesian correspondence (method II) already yields Langer's result for the $N=3$ central force Hamiltonians, and also that the Cartesian forms are the simplest because they do not involve quantum corrections, one may well ask whether there is any point to considering other coordinates. There are, however, several important reasons for doing so. The Cartesian correspondence does not, for instance, yield very good WKB results for the angular momentum operators such as $\hat{L}^2$. For radial operators, moreover, the advantages of method II do not extend to more general Hamiltonian forms, as Morehead discovered. He found in fact, that method I is generally preferable to method II. The comparison is a bit unfair though, because the mixed method I assumes exact eigenvalues for the angular momentum operators, whereas the fully WKB method II does not. We can, however, legitimately compare method II to the fully WKB method III introduced in this paper, which is closely related to method I.

III. THREE-DIMENSIONAL $T+V(r)$ HAMILTONIANS

The nonrelativistic quantum central force Hamiltonian of arbitrary dimensionality is given in Cartesian coordinates as

$$\hat{H}=\frac{\hat{p}_1^2+\cdots+\hat{p}_N^2}{2m}+V(\hat{r}), \tag{3.1}$$

where $\hat{r}^2=\hat{x}_1^2+\cdots+\hat{x}_N^2$, and $N=3$ for the standard three-dimensional case. For our purposes, the quantum Hamiltonian is *always* equivalent to Eq. (3.1), regardless of the particular coordinate system in which it might be expressed.

In contrast, the Weyl symbol of $\hat{H}$, and all associated canonically invariant quantities (e.g., WKB eigenvalues) depend on the correspondence coordinates; but once the classical symbol H is obtained, any canonical transformation can be applied without affecting those quantities. We shall often find it convenient to use one set of coordinates to obtain the correspondence, and another to express the Hamiltonian. To avoid confusion, *all explicit references and equation labels henceforth refer to the correspondence coordinates*; the expression coordinates are generally self-evident from the context. Thus, the ''Cartesian Weyl symbol'' that corresponds to the $N=3$ Hamiltonian of Eq. (3.1) can be given as follows:

$$H=\frac{p_r^2}{2m}+\left(\frac{1}{2mr^2}\right)\left(p_\theta^2+\frac{p_\phi^2}{\sin^2\theta}\right)+V(r) \qquad \text{(Cartesian)}. \tag{3.2}$$

Although we have chosen to express this symbol in spherical coordinates, the label ''(Cartesian)'' denotes the coordinates that were actually used for the correspondence.

In dealing with multidimensional Hamiltonians, it is useful both classically and quantally to obtain the other independent constants of the motion. In the present case, these are of course found in the angular momentum operators $\hat{L}^2$ and $\hat{L}_z$. The Cartesian Weyl symbols for these operators are as follows:

$$L^2=p_\theta^2+\frac{p_\phi^2}{\sin^2\theta}, \quad L_z=p_\phi \qquad \text{(Cartesian)}. \tag{3.3}$$

The Cartesian symbols for $\hat{H}$, $\hat{L}^2$, and $\hat{L}_z$ are very straightforward, even when expressed in spherical coordinates, because they do not involve quantum correction terms.

On the other hand, when the WW correspondence is obtained directly in spherical coordinates, potential-like quantum correction terms arise (Sec. II). The L_z symbol is unaffected, but L^2 becomes

$$L^2=p_\theta^2+\frac{p_\phi^2}{\sin^2\theta}-\frac{1}{2}-\frac{1}{4}\cot^2\theta \qquad \text{(spherical)}, \tag{3.4}$$

with a corresponding change in the symbol for H. In principle, the p_r^2 term in Eq. (3.2) might have also gained a quantum correction, but this turns out to be zero when $N=3$.

Thus far, we have not improved matters much by switching the correspondence from Cartesian to spherical coordinates. The new, negatively singular contribution to L^2 is clearly unphysical, and the corresponding WKB eigenvalues are less accurate than the Cartesian ones. In fact, they are not even properly degenerate, as is easy to demonstrate. First, solve the L_z problem semiclassically; then, substitute the resultant eigenvalues $L_z\to m\in\mathbb{Z}$ into the classical L^2 expression, and solve the resultant θ problem semiclassically. Labeling the resultant eigenstates via the index $n_\theta\in\{0,1,...\}$, the WKB eigenvalues of L^2 are obtained as a function of m and n_θ. If this function depends only on $\ell=n_\theta+|m|$, then the degeneracy pattern is correct; this is true for Eq. (3.3), but not for Eq. (3.4).

The situation can be improved somewhat by using $\mu = \cos\theta$ rather than θ for the polar correspondence, as was explored by the author in a recent paper.[30] This yields the much simpler quantum correction of $-1/2$. Moreover, the WKB eigenvalues are now properly degenerate, and—in comparison with the true quantum results—are seen to be too *small* by $-1/4$ (in contrast with the Cartesian values, which are well known to be too large by this amount).

Before proceeding, it is worth examining the ''μ-spherical'' L^2 symbol as expressed in the μ-spherical coordinates themselves.[30]

$$L^2 = (1-\mu^2)p_\mu^2 + \frac{p_\phi^2}{(1-\mu^2)} - \frac{1}{2} \quad (\mu\text{-spherical}). \tag{3.5}$$

Because of the altered form of the kinetic energy, Eq. (3.5) is no longer Schrödinger-like. Nevertheless, Eq. (3.5) bears a strong resemblance to the (free-particle) radial Hamiltonian as considered by Langer, in that there is a positive centrifugal barrier in μ, which diverges in an inverse-squared fashion as either end point is approached. This similarity shall soon be exploited to develop a Langer-like modification for polar angles.

In the present state of affairs, the WKB eigenvalues for $\hat{L}^2$ are still too low; our task is thus to determine whether it is expedient to improve the situation via yet another coordinate transformation. In doing so, let us reiterate the primary motivation for considering spherical coordinates—that they separate the full Hamiltonian problem into three one-dimensional problems, and are therefore closely related to the action-angle coordinates. Because H is only weakly separable in (r,θ,ϕ) however, the one-dimensional problems must be solved in a specific order, as discussed in the Appendix.

If separability is in fact the principal criterion for distinguishing the most successful correspondence coordinates, then the spherical coordinates are by no means the only choice that fits the bill. It has been shown[25] that any arbitrary canonical transformation acting on each of the spherical coordinates *independently*, will yield a new coordinate system that preserves the weak separability property (Appendix). Any *modified* spherical coordinates obtained in this fashion should therefore also be under consideration. For the present application let us restrict ourselves to point transformations, but otherwise allow the mapping $(r,\theta,\phi) \to (x,\beta,\alpha)$ given by

$$x = X(r), \quad \beta = B(\theta), \quad \alpha = A(\phi) \tag{3.6}$$

to be completely arbitrary.

As for specifying the ''best'' transformations $X(r)$, $B(\theta)$, and $A(\phi)$, this is somewhat difficult to justify *a priori*. Motivated by past successes however, we shall remain as close to Langer as possible. The choice for $X(r)$ should evidently be that of Langer and Morehead, i.e., $x = \ln r$. With this choice, the current approach (method III) becomes closely related to method I; the only difference between the two is that method I requires the exact solution of the $\hat{L}^2$ problem, whereas this is dealt with semiclassically in method III.

Without explaining precisely *why* the Langer/Morehead transformation works as well as it does for the radial coordinate, let us consider something similar for the angular coordinates θ and ϕ. In the case of ϕ, L_z is the conjugate momentum itself, implying that the WW correspondence is canonically invariant in this case (Sec. II). However, it is L_z^2 rather than L_z that appears in Eq. (3.4); given that the WKB eigenvalues of $\hat{L}_z^2$ are already exact in the ϕ correspondence, this coordinate is left alone. No modification is required here—perhaps because the azimuthal coordinate, though finite, is unbounded (Sec. V).

On the other hand, the spherical L^2 symbol is an ideal candidate for a Langer-like modification in θ. In the Langer modification proper, the singular bound at $r=0$ is extended to $x=-\infty$. In the case of θ, there are two singular bounds instead of one; nevertheless, a logarithmic transformation that extends β to $\pm\infty$ can still be defined—one simply deals with $\beta \leqslant 0$ and $\beta \geqslant 0$ separately. The question arises as to whether θ or μ should be used in the exponential relation. We

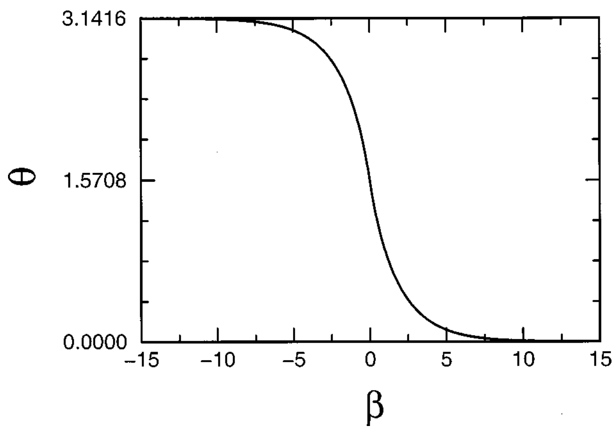

FIG. 1. Langer-like transformation from the unbounded, Cartesian-like coordinate β to the doubly bounded, polar angle coordinate θ. There is a discontinuity in the second derivative at $\beta=0$.

choose μ, because the centrifugal singularity is more like that of the radial problem, and also because the WKB eigenvalues of Eq. (3.5) exhibit the physically correct degeneracies. The piecewise transformations are as follows:

$$\begin{aligned} \mu &= e^{\beta}-1 \quad (\mu,\beta\leqslant 0), \\ \mu &= 1-e^{-\beta} \quad (\mu,\beta\geqslant 0). \end{aligned} \tag{3.7}$$

The above-mentioned transformation relations are a primary result of this paper, and are believed to comprise the correct generalization of Langer's modification for polar angle coordinates. A composite graph is given in Fig. 1. Despite the awkward discontinuity in the second derivative at $\beta=0$, it is unlikely that any other point transformation is as effective as Eq. (3.7), insofar as semiclassical accuracy is concerned. This issue is examined more closely in Sec. V.

Having specified the transformations $A(\phi)$, $B(\theta)$, and $X(r)$, it remains to determine the modifications to the L^2 and H Weyl symbols that result when the WW correspondence is obtained in the new, modified spherical coordinates. Using the standard Podolsky expression with Weyl ordering (Sec. II), it can be shown that the quantum correction to the spherical p_θ^2 symbol of Eq. (3.4) is

$$\tfrac{1}{4}(g'(\beta))^2,$$

where

$$g(\beta)=1/\theta'(\beta), \quad \theta=\theta(\beta)=B^{-1}(\beta). \tag{3.8}$$

In the $\beta\geqslant 0$ region for instance, where $\theta=\arccos(1-e^{-\beta})$, the correction is found to be

$$\mathrm{QC}(\theta\to\beta)=\tfrac{1}{4}\csc^2\theta. \tag{3.9}$$

It is easy to verify that Eq. (3.9) is also correct for $\beta\leqslant 0$. In any event, when the above result is combined with Eq. (3.4), the total quantum correction for L^2 [as compared to the Cartesian symbol of Eq. (3.3)] becomes simply $-1/4$. The WKB eigenvalues of L^2 under the new correspondence are therefore *exact*. Moreover, the degeneracy pattern is also correct, in that

$$L^2_{m,n_\theta}=\ell(\ell+1), \quad \ell=n_\theta+|m|. \tag{3.10}$$

Moving on to H, it is immediately clear from the exactness of the L^2 eigenvalues that the new radial Hamiltonian must be identical to the standard Langer-modified form of method I. More explicitly, the $-1/(8mr^2)$ correction from the L^2 contribution is exactly cancelled by the $+1/(8mr^2)$ Langer modification term from $\hat{p}_r^2$, thus resulting in a classical H symbol that is equivalent to the Cartesian symbol of method II. The coordinates (x,β,ϕ) shall be referred to as ''modified'' or ''logarithmic'' spherical coordinates; the associated WW correspondence and subsequent WKB quantization comprise the new method III.

The accuracy of all three methods, with respect to semiclassical approximations for three-dimensional central force Hamiltonians, is therefore identical. In method III however, we now have a fully WKB approach—incorporating the standard Langer modification explicitly—against which direct comparisons with method II can be legitimately made. Despite the elegance of the Cartesian symbols of method II, method III is evidently superior, for the WKB eigenvalues of L^2 as determined by method II are only approximate.

IV. *N*-DIMENSIONAL $T+V(r)$ HAMILTONIANS

For $N>3$, the generalization of the spherical coordinates are the hyperspherical coordinates, discussed in Sec. II. These are appropriate for our purposes, because they render the N-dimensional $T+V(r)$ Hamiltonians of Eq. (3.1) weakly separable, regardless of the dimensionality (Appendix). We shall continue to refer to these as ''central force Hamiltonians,'' though not in the sense of a many-body system with central force pair potentials. In any event, one still has an azimuthal angle ϕ and a radial coordinate r; but arranged in between these two are now $(N-2)$ polar angles θ_k, with $1\leq k\leq(N-2)$.

Associated with each polar angle coordinate θ_k is a constant of the motion $\hat{I}^{(k)}$, where our use of the index k is slightly different from that of Morehead,[17] and very different from that of Alcarás.[23] For convenience, let us define a zeroth constant $\hat{I}^{(0)}=\hat{p}_\phi^2$. The collection of $(N-1)$ constants $\hat{I}^{(k)}$ are in involution (commute) with the Hamiltonian $\hat{H}$, and with each other. They are conveniently expressed in terms of certain angular momentum quantities, with $\hat{I}^{(N-2)}$ being equivalent to $\hat{L}^2$.

Being weakly separable, the N-dimensional Hamiltonian problem is equivalent to a collection of N one-dimensional problems, one for each of the hyperspherical coordinates—but these one-dimensional problems must be solved in the proper order, starting with the $\hat{I}^{(0)}$ problem in ϕ, and working up to the generalized radial Schrödinger equation in r. Using hyperspherical coordinates, Morehead found that methods I and II can be generalized in a straightforward manner for arbitrary dimensionality N; moreover, he found the two to be equivalent with respect to N-dimensional central force Hamiltonians. Our task in this section is therefore to generalize method III in analogous fashion.

We must first work out the explicit Weyl symbols for the $\hat{I}^{(k)}$ operators in the various coordinate systems. The operators themselves are conveniently expressed in the Cartesian coordinates $(\hat{x}_i,\hat{p}_i)$ as sums of the squared generalized angular momentum operators[23,31]

$$\hat{L}_{ij}^2=(\hat{x}_i\hat{p}_j-\hat{x}_j\hat{p}_i)^2. \tag{4.1}$$

Despite the quadraticity in the momenta, the Cartesian Weyl symbols of the $\hat{L}_{ij}^2$'s do not have quantum corrections. In other words, the operator ordering in Eq. (4.1) is equivalent to Weyl ordering, so that the corresponding symbols are obtained by simply removing the carets from Eq. (4.1).

In any event, when the above-mentioned Cartesian Weyl symbols are expressed in hyperspherical coordinates, the following recursive relations are obtained:[17,23]

$$I^{(0)}=p_\phi^2,$$

$$I^{(1)} = p_{\theta_1}^2 + I^{(0)} \csc^2 \theta_1,$$
$$\vdots$$
$$I^{(k)} = p_{\theta_k}^2 + I^{(k-1)} \csc^2 \theta_k,$$
$$\vdots$$
$$I^{(N-2)} = p_{\theta_{N-2}}^2 + I^{(N-3)} \csc^2 \theta_{N-2} \qquad \text{(Cartesian)}. \tag{4.2}$$

The above-mentioned Cartesian relations are undeniably elegant, in that every $I^{(k)}$ is recursively equivalent to every other. Moreover, a successive WKB analysis of each of the $I^{(k)}$ in turn, yields the correct degeneracy structure to the pattern of eigenvalues. This pattern is extremely degenerate; for each $I^{(k)}$, the allowed quantum numbers ℓ_k are given by $\ell_k = n_1 + \cdots + n_k + |m|$, where each of the n_i is a non-negative integral index, as in Eq. (3.10).

Despite the correct degeneracy, however, the WKB eigenvalues themselves are quantitatively far from exact in the Cartesian correspondence. Moreover, the errors become *quadratically* worse with increasing k, and are least accurate for the most physically relevant of the constants, $\hat{I}^{(N-2)} = \hat{L}^2$. More specifically, the Cartesian WKB eigenvalues are given as

$$I_{\ell_k}^{(k)} = \left(\ell_k + \frac{k}{2} \right)^2 = \ell_k^2 + k\ell_k + \frac{k^2}{4} \qquad \text{(Cartesian)}, \tag{4.3}$$

whereas the exact quantum results are

$$I_{\ell_k}^{(k)} = \ell_k(\ell_k + k) = \ell_k^2 + k\ell_k \qquad \text{(exact quantum)}. \tag{4.4}$$

The Cartesian WKB eigenvalues are therefore too large, by $k^2/4$.

Now on to the hyperspherical correspondence. It is natural to deal with the recursive relations of Eq. (4.2) by induction. Assuming, therefore, that the hyperspherical $I^{(k-1)}$ symbol is known, then the Eq. (4.2) relation must also hold for the hyperspherical $I^{(k)}$ symbol, apart from a potential-like quantum correction term in θ_k. In other words,

$$I^{(k)} = p_{\theta_k}^2 + \frac{I^{(k-1)}}{\sin^2 \theta_k} + \mathrm{QC}_k(\theta_k) \qquad \text{(hyperspherical)}. \tag{4.5}$$

It is necessary to derive an explicit expression for the $\mathrm{QC}_k(\theta_k)$. The most straightforward way to obtain these is to apply the Podolsky procedure with Weyl ordering to the Cartesian $\hat{L}_{ij}^2$'s of Eq. (4.1). However, it is more convenient simply to use the known differential forms of these operators in hyperspherical coordinates. This will involve another kind of transformation however, from standard to canonical-like form (Sec. II).

The standard differential forms of the $\hat{I}^{(k)}$ operators are usually expressed in the ''μ-hyperspherical'' coordinates $(r, \mu_{1 \leqslant k \leqslant (N-2)}, \phi)$, where $\mu_k = \cos \theta_k$. From the standard ultraspherical equation[32] we find

$$\hat{I}_0^{(k)} = -(1-\mu_k^2) \frac{d^2}{d\mu_k^2} + (k+1)\mu_k \frac{d}{d\mu_k} \qquad \text{(standard form)}, \tag{4.6}$$

where $\hat{I}_0^{(k)} = \hat{I}^{(k)} - \hat{I}^{(k-1)} \csc^2 \hat{\theta}_k$. The standard form of Eq. (4.6) is associated with a nontrivial Jacobian weight factor that depends on the μ-hyperspherical coordinates. The Eq. (4.6) differential expression is therefore not in canonical-like form, in that $\hat{p}_{\mu_k}$ is not equivalent to $-i d/d\mu_k$ (Sec. II).

In addition to converting Eq. (4.6) into canonical-like form, we also transform from μ-hyperspherical to hyperspherical coordinates. Note that all of these manipulations are strictly quantum mechanical, and as yet have nothing to do with the WW correspondence. The final step will be to properly Weyl order the new expression for $\hat{I}_0^{(k)}$ in $\hat{\theta}_k$ and $\hat{p}_{\theta_k}$, so that the WW correspondence in these coordinates becomes manifest.

Using the chain rule to transform Eq. (4.6) to the coordinate θ_k yields

$$\hat{I}_0^{(k)} = -\frac{d^2}{d\theta_k^2} - k\cot\theta_k \frac{d}{d\theta_k} \qquad \text{(standard form)}, \tag{4.7}$$

where we have not yet taken the Jacobian weight factor into account. The original weight factor[21] was $(\sin\theta_k)^{k-1}$; however, the transformation from μ_k to θ_k introduces an extra $\sin\theta_k$ factor, resulting in the new weight factor

$$w_k(\theta_k) = \sin^k \theta_k . \tag{4.8}$$

A canonical-like form for the differential $\hat{I}_0^{(k)}$ expression of Eq. (4.7) is easily obtained by substituting the differentials with the correct expressions for the $\hat{p}_{\theta_k}$. These are as follows:[33]

$$\hat{p}_{\theta_k} = -i w_k^{-1/2} \frac{d}{d\theta_k} w_k^{1/2} = -i\frac{d}{d\theta_k} - i\frac{k}{2}\cot\theta_k \qquad \text{(standard form)}. \tag{4.9}$$

Substituting Eq. (4.9) into Eq. (4.7) yields

$$\hat{I}_0^{(k)} = \hat{p}_{\theta_k}^2 + \frac{k^2}{4}\cot^2\hat{\theta}_k - i\frac{k}{2}(\cot\hat{\theta}_k \hat{p}_{\theta_k} - \hat{p}_{\theta_k}\cot\hat{\theta}_k). \tag{4.10}$$

Although $\hat{\theta}_k$ and $\hat{p}_{\theta_k}$ are not true canonical coordinates, we nevertheless proceed using Eq. (2.1) to evaluate the last term in Eq. (4.10)—which in any case is a localized operator (Sec. II). The last term thereby becomes $-k/(2\sin^2\hat{\theta}_k)$.

Thus far we have been working with $\hat{I}_0^{(k)}$, for which $\hat{I}^{(k-1)}$ is in effect taken to be zero. By induction, however, we can restore the full $\hat{I}^{(k)}$ expression for any k, resulting at last in the following recursive, canonical-like relation:

$$\hat{I}^{(k)} = \hat{p}_{\theta_k}^2 + \frac{\hat{I}^{(k-1)}}{\sin^2\hat{\theta}_k} + \frac{k^2}{4}\cot^2\hat{\theta}_k - \frac{k/2}{\sin^2\hat{\theta}_k} \qquad \text{(canonical-like form)}. \tag{4.11}$$

Since Eq. (4.11) is already manifestly Weyl ordered in the $\{\hat{\theta}_{i\le k}, \hat{p}_{\theta_{i\le k}}\}$, the hyperspherical Weyl symbols are once again obtained by simply removing the carets. Note that the $(k+2=N=3)$ result is consistent with Eq. (3.4).

The quantum correction terms in the caretless version of Eq. (4.11) are k dependent, so that the various θ_k problems are no longer recursively equivalent to each other. Nevertheless, in the generalization of method III, let us employ the same exponential transformation for each of the $(N-2)$ polar coordinates. In other words, the modified hyperspherical (MHS) coordinates become $(x, \beta_{N-2}, \ldots, \beta_1, \phi)$, where β_k is given in terms of μ_k via Eq. (3.7).

In switching the WW correspondence from the hyperspherical to the modified hyperspherical coordinates, it is only the $\hat{p}_{\theta_k}^2$ term in Eq. (4.11) that contributes to the modification. This is because the coordinate change is a point transformation of the positions only. Moreover, since all of the $\hat{p}_{\theta_k}^2$ terms look alike, the modification must take the same form for each value of k, i.e., that of Eq. (3.9).

Incorporating the above modification, the total quantum correction for the MHS Weyl symbol for $\hat{I}^{(k)}$ (again, as compared to the Cartesian symbols) can be written as follows:

$$\mathrm{QC}_k(\text{Cartesian}\rightarrow\text{MHS}) = \frac{(k-1)^2/4}{\sin^2\theta_k} - \frac{k^2}{4}. \tag{4.12}$$

We shall prove by induction that the WKB eigenvalues for the $I^{(k)}$, obtained using the above-mentioned corrections, are exact for all k.

Let us assume that the WKB eigenvalues for $\hat{I}^{(k-1)}$ are exact in the MHS correspondence. If so, then we can replace the MHS symbol $I^{(k-1)}$ with one of its exact eigenvalues, in the MHS expression for $I^{(k)}$. In other words, we make the substitution

$$I^{(k-1)} \rightarrow I^{(k-1)}_{\ell_{k-1}} = \ell^2_{k-1} + (k-1)\ell_{k-1}. \tag{4.13}$$

By combining like terms in the MHS expression for $I^{(k)}$, we obtain an expression that defines the one-dimensional classical problem in θ_k:

$$I^{(k)}(\theta_k, p_{\theta_k}) = p^2_{\theta_k} + \frac{(\ell_{k-1} + (k-1)/2)^2}{\sin^2\theta_k} - \frac{k^2}{4} \qquad (\text{MHS}). \tag{4.14}$$

Now in view of Eqs. (4.3) and (4.4), it is clear that WKB quantization of Eq. (4.14) yields exact eigenvalues for the corresponding $\hat{I}^{(k)}$ operators. This is, of course, provided that the WKB eigenvalues are exact for the MHS symbol for $\hat{I}^{(k-1)}$. The WKB eigenvalues of the MHS symbol $I^{(0)}$ are the same as in Sec. III, and are therefore known to be exact. By induction then, the fully WKB eigenvalues of the $I^{(k)}$ observables in the MHS correspondence are also exact, for all values of k.

The degeneracy pattern of the WKB eigenvalues is also correct. This is due to the perfect square form of the numerator in the second term on the right-hand side of Eq. (4.14). Such a form is required to ensure that the eigenvalues of $I^{(k)}$ are degenerate in $l_k = n_k + l_{k-1}$. Of course, the true quantum eigenvalues are *not* perfect (half-)integral squares, but quantities which are smaller by a k-dependent constant. Thus, the quantum correction terms of Eq. (4.12) perform a delicate ''balancing act,'' wherein the first correction term compensates for the deviation from squareness of the $I^{(k-1)}$ contribution, and the second term introduces the correct deviation for the overall $I^{(k)}$ expression.

It should be emphasized that such a situation would be impossible under the standard Cartesian correspondence. Using a Cartesian approach, one would have to substitute *either* the fully WKB values *or* the exact quantum values for $I^{(k-1)}$ in Eq. (4.2). The former choice (method II) would yield the right degeneracy pattern, but highly inaccurate eigenvalues. More accurate results would be obtained with the latter choice (similar to method I), but these would no longer be properly degenerate. Obtaining both accuracy and degeneracy is evidently nontrivial.

It remains only to examine the radial coordinate WKB problem, as specified by the central force Hamiltonian $\hat{H}$ itself [Eq. (3.1)] under the MHS correspondence. Comparing this to the other two methods is trivial; since the MHS WKB eigenvalues for $\hat{I}^{(N-2)} = \hat{L}^2$ are exact, then method III must once again be equivalent to method I, and also to method II. It follows, for instance,[17] that the WKB wave functions for the radial states will have the correct asymptotic behavior as $r \rightarrow 0$.

To summarize the results thus far, we find that for all $T + V(r)$ Hamiltonians of arbitrary dimensionality, all three semiclassical methods yield identical results. However, only methods II and III are fully WKB treatments, admitting of a legitimate comparison. Although the radial coordinate WKB problems are the same for all three methods, method III is the only one that yields exact eigenvalues for the physically relevant Casimir-invariant quantities $\hat{I}^{(k)}$, associated with the angular hyperspherical coordinates.

V. ARBITRARY SPHERICALLY SYMMETRIC OBSERVABLES

In this section, we extend the analysis to arbitrary spherically symmetric observables, not necessarily of the Eq. (3.1) form. As noted by Morehead, the ability to generalize the Langer procedure to incorporate non-Schrödinger-like operators is a direct consequence of the WW correspondence interpretation, and would certainly not be possible using Langer's original theory. Put another way, Weyl ordering is more general than the Podolsky method, because it is not limited to polynomial forms in the momenta of order two or less.

Regardless of the total dimensionality N, a spherically symmetric operator $\hat{A}$ can be written as

$$\hat{A}=A(\hat{r},\hat{p}_r;\hat{I}^{(N-2)}) \quad \text{with} \quad \hat{I}^{(N-2)}=\hat{L}^2. \tag{5.1}$$

Thus, $\hat{A}$ depends only on $\hat{r}$, $\hat{p}_r$, and $\hat{L}^2$. Once again, the $\hat{I}^{(k)}$ are all constants of the motion, so that $\hat{A}$ is weakly separable in the hyperspherical coordinates. For such operators, Morehead found that methods I and II are *not* equivalent to each other.[17] It is therefore natural to ask which of the two should perform better, with respect to the accuracy of WKB results. Without offering a general proof, he suggested that method I is better, a claim which he supported with several specific results.

For example, Morehead showed that for all $\hat{A}$'s that are localized operators (differential operators in his language), method I yields exact asymptotic behavior for the radial WKB wave functions in the limit $r\rightarrow 0$. He also showed by constructing an explicit counterexample that this is false for method II. As for the accuracy of the WKB eigenvalues, this is very difficult to characterize in general. However, for the following simple non-Schrödinger-like test case

$$\hat{A}=\frac{1}{2}(\hat{r}\hat{p}^2+\hat{p}^2\hat{r})+\hat{r}, \quad \hat{p}^2=\hat{p}_r^2+\frac{\hat{L}^2}{\hat{r}^2}, \tag{5.2}$$

Morehead showed that method I yields exact eigenvalues, whereas the eigenvalues of method II are inexact.

Insofar as method III is concerned, it is a trivial matter to show that III is equivalent to I if $\hat{A}$ is linear in $\hat{L}^2$—again, because the MHS WW correspondence yields exact WKB eigenvalues for $\hat{L}^2$. The $\hat{A}$ of Eq. (5.2) is a linear $\hat{L}^2$ operator, for example. For such operators, method III should perhaps be considered a derivation of method I—it is in any event probably the best justification that one can provide for comparing the radial Langer-modified WKB method (I) to the Cartesian approach (method II).

On the other hand, it is impossible for *any* fully semiclassical method to be equivalent to method I in the more general case where $\hat{A}$ may depend *non*linearly on $\hat{L}^2$. This is due to the fact that the WW correspondence fails to preserve algebraic relationships, regardless of the coordinate system. Consequently, $W[f(\hat{L}^2)]\neq f(W[\hat{L}^2])$ generally, so that the WKB eigenvalues of $f(\hat{L}^2)$ are not necessarily exact. Nevertheless, the situation characterizing the present method III is probably the best that can be expected of a fully WKB approach.

There is a sense in which we can meaningfully extend the correspondence between methods I and III still further, however. Mathematically, an arbitrary weakly separable operator in hyperspherical coordinates (Appendix) is given by

$$\hat{A}=A(\hat{r},\hat{p}_r;\hat{I}^{(N-2)},\ldots,\hat{I}^{(0)}). \tag{5.3}$$

If we restrict ourselves to weakly separable operators which depend no more than linearly on each of the $\hat{I}^{(k)}$'s individually, then methods I and III are once again equivalent.

Equation (5.3) is not necessarily spherically symmetric. Nevertheless, we can still solve the radial problem independently of the other coordinates, for it is weak separability that is mathematically required in this regard, not rotational invariance. Even in just three dimensions, the expanded class of Eq. (5.3) contains some physically relevant operators that would not otherwise be included, such as

$$\hat{A}=B(\hat{L}_x^2+\hat{L}_y^2)+C\hat{L}_z^2, \tag{5.4}$$

reminiscent of the symmetric top free rotor.

In all cases such as Eq. (5.4) (or even $\hat{A}=\hat{L}^2+\hat{I}^{(0)}\hat{I}^{(1)}\hat{I}^{(2)}$) where $\hat{A}$ is independent of the radial coordinate, the WKB eigenvalues of method III are exact. In the more general case involving $\hat{r}$ and $\hat{p}_r$, the advantages of method I/III over method II, as discussed in Sec. IV, still apply. In particular, the eigenvalue spectra of the former are expected to be more accurate, and the asymptotic behavior of the radial wave functions is exact.

Having presented some of the advantages that the MHS correspondence provides, as well as a fairly broad class of observables which evidently benefit from such a treatment, some possible explanations shall now be offered as to why this approach seems to work so well. As Morehead put it however,[17] ''there still appears to be no general proof.'' The arguments sketched in the remainder of this section should therefore be considered somewhat speculative.

Putting off consideration of the Langer-like modifications for the moment, it seems likely that the success of a correspondence obtained in some kind of hyperspherical-*like* coordinate system is probably *due* to the fact that the Hamiltonians considered are separable when expressed in such coordinates. Presumably, the closer one can get to action-angle coordinates, the better—provided, of course, that the system is integrable.

One indication that a rationale such as this might be correct is that the WW correspondence in action-angle coordinates actually does preserve the algebraic structure, due to the mutual commutativity of the action operators $\hat{J}_k$ (Appendix). In other words,

$$W[H(\hat{J}_1,\ldots,\hat{J}_N)]=H(J_1,\ldots,J_N), \tag{5.5}$$

presuming of course that the Weyl ordering rule still holds, at least for a reasonable class of such $H(\hat{J}_1,\ldots,\hat{J}_N)$'s. In any case, this is significant because it implies that if the $\hat{J}_i$ are quantized exactly, then so would be all Hamiltonians obtained from them.

On the other hand, it is not entirely clear whether one can define a general WW correspondence rule in action-angle coordinates, and if so, for which observables conventional Weyl ordering would still apply. After all, the action-angle coordinates are not truly canonical, only canonical-like, as discussed in Sec. II. Even in hyperspherical coordinates, the validity of using the Weyl ordering rules for nonlocalized operators has been called into question. The author shares Morehead's view that a generalized new correspondence rule, for use with canonical-like coordinates such as radii and angles, is probably in order.

At present however, we have only the WW correspondence rule at our disposal; its use with canonical-like coordinates should be regarded as increasingly suspect, the further removed one is from a Cartesian system. The present application (i.e., weakly separable Hamiltonians in hyperspherical-like coordinates) should perhaps be viewed as a happy medium between Cartesian and action-angle coordinates. Because of the centrifugal potentials, the nonazimuthal coordinates are effectively somewhat Cartesian; and we can evidently get away with using Weyl ordering, at least for localized Hamiltonians.

As for the advantages of the Langer and related modifications, the improvement is likely related to the fact that the new coordinates are more like true canonical coordinates—ranging from $-\infty$ to $+\infty$, etc. Qualitative supporting evidence is provided by the following fact: Any Eq. (3.6) transformation which extends the coordinate bounds to $\pm\infty$ gives rise to a positive quantum correction term. This results in corrections to the WKB eigenvalues which are also positive, i.e., in the direction of the true eigenvalues.

There are, however, many such transformations available; and we have yet to account for why the specific exponential transforms of Langer and Eq. (3.7)—which yield exact results for the kinetic energies $\{\hat{I}^{(0)},\ldots,\hat{I}^{(N-2)},\hat{T}_r\}$ in the WKB approximation—work as well as they do. Most likely this is related to the specific form of these observables, rather than to some intrinsically special property of the exponential function. It is nevertheless worth investigating how ''special'' these transformations really are.

There is one obvious generalization of the Langer and Eq. (3.7) transformations that does not affect the semiclassical results at all. The scale transformation $\beta \to a\beta$ with a a real constant, results in the same quantum correction to p_θ^2 as for $a=1$. Thus, we can alter the length scale arbitrarily in Eq. (3.7), by replacing β with $a\beta$. Apart from this small generalization however, there appears to be little room for modification. As discussed in Sec. IV, there is a very delicate balance required of the quantum corrections in the polar angle problems.

Even for the simplest case of $N=3$, the author has been unable to find any transformation other than Eq. (3.7) that yields exact results for $\hat{L}^2$—including the seemingly more ''natural'' choices $\theta = \arccos(-\tanh\beta)$ and $\theta = \arctan(\beta) + \pi/2$. It is extremely unlikely that there are *any* other transformations that yield the right quantum correction potentials for *all* values of k; although a rigorous proof would involve a careful analysis of the appropriate nonlinear differential equation implied by Eqs. (3.8) and (4.12).

VI. CONCLUSIONS

This paper builds upon the earlier work of Langer[8] and Morehead.[17] In particular, the lack of canonical symmetry of the Wigner–Weyl correspondence rule has been exploited to improve the accuracy of semiclassical quantization, via a change of coordinates involving all N degrees of freedom. This has led to the somewhat surprising result that the Cartesian correspondence is *not* ideal from a semiclassical perspective, despite the elegance of the Cartesian expressions.

In its stead, a modified (hyper)spherical correspondence is proposed, which has been shown to be better than the Cartesian correspondence in several respects, for both Hamiltonian and angular momentum observables. The WKB eigenvalue spectra of the angular momentum-related quantities $\hat{I}^{(k)}$ was shown to be exact, for instance. Although a complete explanation for this success is still lacking, the weak separability of the observables in a hyperspherical-like coordinate system is almost certainly a key factor, as is the transformation from polar to Cartesian-like coordinates induced by Eq. (3.7).

Being a fully WKB method that treats all degrees of freedom semiclassically, the modified hyperspherical method III presented in this paper can be legitimately compared with the standard Cartesian method II. This situation is unlike that of previous spherical coordinate approaches, such as Morehead's method I, which have tended to be mixed methods. Some of the latter rely on geometric curvature or theory-of-constraints arguments to justify the introduction of the Langer modification.[12–16] It should perhaps be noted that the present work seems to question the essential significance of such arguments, in that the entire, unconstrained configuration space is employed here. Moreover, it is not clear that these other approaches would generalize as successfully beyond the three-dimensional case—though this has yet to be investigated, to the author's best knowledge. In contrast, the success of the modified hyperspherical method has been verified for arbitrary dimensionality, and for an extended class of Hamiltonians.

It was also demonstrated in a fully WKB manner, that for this extended class, the radial WKB wave functions exhibit the correct asymptotic behavior as $r \to 0$. In the future, the author would like to apply a similar analysis (i.e., the method of comparison equations[10,17]) to the WKB wave functions associated with the various polar angles for $N>3$, the so-called ''hyperspherical harmonics.''[21,23] It is also hoped that some progress will be made toward an improved correspondence rule for canonical-like coordinates. Such a rule would presumably extend the benefits of the modified (hyper)spherical correspondence to *non*localized observables, and might also enable a correspondence directly in the action-angle coordinates.

The author wishes to thank Professor John C. Light for his support, and also Dr. X. Sun for bringing the work of J. J. Morehead to his attention. This work was supported, in part, by NSF Grant. No. CHE-9634440

APPENDIX: WEAKLY SEPARABLE HAMILTONIANS

The notion of weak separability in quantum mechanics has been examined in a series of earlier papers.[24–26] This appendix investigates a form of weak separability for which each degree of freedom comprises its own coordinate tier.[25] The present analysis is presented from a classical perspective, although all results could apply equally well to quantum mechanics.

A Hamiltonian H is said to be ''weakly separable'' in the N coordinates ξ_i (with $1 \leqslant i \leqslant N$), provided there exist N constants of the motion F_i such that

$$H = H(F_1, \ldots, F_N), \quad F_i = F_i(\xi_i, p_i, F_1, \ldots, F_{i-1}), \tag{A1}$$

with p_i canonically conjugate to ξ_i. The F_i comprise a cascading, ordered sequence of constants of the motion, in involution with the Hamiltonian and with each other. They cannot in general be considered action coordinates, although their existence implies that H is integrable.

In fact, the solution of each F_i problem—treated as a one-dimensional observable in (ξ_i, p_i) parametrized by the $F_{j<i}$—gives rise to the transformation to the true action-angle coordinates (ϕ_i, J_i). The explicit transformation is given by

$$\begin{aligned} \phi_i(\xi_1, p_1 \ldots, \xi_i, p_i) &= \phi_i^{(F_1, \ldots, F_{i-1})}(\xi_i, p_i), \\ J_i(\xi_1, p_1 \ldots, \xi_i, p_i) &= J_i^{(F_1, \ldots, F_{i-1})}(\xi_i, p_i), \end{aligned} \tag{A2}$$

Where $J_i^{(F_1, \ldots, F_{i-1})}(\xi_i, p_i)$ is the parametrized action associated with the one-dimensional F_i problem, etc.

In contrast to the weakly separable situation, H is said to be ''strongly separable'' in the ξ_i coordinates if

$$H = H(F_1, \ldots, F_N), \quad F_i = F_i(\xi_i, p_i). \tag{A3}$$

The Eq. (A3) definition of strong separability is slightly more general than what has been used in the past.[25]

As in the weakly separable case, a strongly separable system can be solved completely by treating each of the F_i's as independent, one-dimensional systems. The indexing of the various F_i problems is arbitrary however, unlike that of the weakly separable case. As a result, the strongly separable F_i problems can be solved in any order, whereas in the weakly separable case, we must proceed in sequence from F_1 to F_N, due to the fact that the $F_{j<i}$ appear as parameters in the F_i problem.

The ordering requirement on weakly separable systems is not, in practice, a serious limitation; for all intents and purposes, a weakly separable representation is as convenient as a strongly separable one. As a constraint upon possible coordinate systems in which to express a particular H however, the weakly separable form is much preferred over the strongly separable form, because it is *far* less restrictive than the latter. There is, in general, an enormous variety of coordinate systems in which the expression of a given Hamiltonian is weakly separable. For the strongly-separable case, however, one is in effect constrained to using action-angle coordinates only.

More accurately, each of the action-angle coordinate pairs (ϕ_i, J_i), when viewed as functions of the strongly separable coordinates, must depend only on the single pair (ξ_i, p_i). In the weakly separable case however, the corresponding limitation is much less severe: (ϕ_i, J_i) may depend arbitrarily on the entire set of coordinates $\{\xi_1, p_1, \ldots, \xi_i, p_i\}$, for each value of i. Incidentally, these restrictions imply that both strong separability and weak separability are preserved by canonical transformations that affect each (ξ_i, p_i) pair independently.

A weakly separable treatment is particularly useful for the Hamiltonians considered in this paper, because only a point transformation of the original Cartesian positions is required to obtain a weakly separable expression for H. In contrast, any strongly separable expression would require a more general canonical transformation involving both positions and momenta. The subsequent modification via Eq. (3.6), in addition to preserving weak separability, also preserves the point transformation property.

On separable Schrödinger equations

Renat Zhdanov[a] and Alexander Zhalij[b]
Institute of Mathematics of the Academy of Sciences of Ukraine, Tereshchenkivska Street 3, 252004 Kyiv, Ukraine

(Received 18 November 1998; accepted for publication 2 August 1999)

We classify $(1+3)$-dimensional Schrödinger equations for a particle interacting with the electromagnetic field that are solvable by the method of separation of variables. As a result, we get 11 classes of the vector potentials of the electromagnetic field $A(t,\vec{x})=(A_0(t,\vec{x}),\vec{A}(t,\vec{x}))$ providing separability of the corresponding Schrödinger equations. It is established, in particular, that the necessary condition for the Schrödinger equation to be separable is that the magnetic field must be independent of the spatial variables. Next, we prove that any Schrödinger equation admitting variable separation into second-order ordinary differential equations can be reduced to one of the 11 separable Schrödinger equations mentioned above and carry out variable separation in the latter. Furthermore, we apply the results obtained for separating variables in the Hamilton–Jacobi equation. © *1999 American Institute of Physics.* [S0022-2488(99)02211-2]

I. INTRODUCTION

Being invented by Fourier and Euler long ago, the method of separation of variables is still the most powerful and efficient one for integrating linear partial differential equations (PDEs). This is especially the case for PDEs having variable coefficients, where the standard Fourier transform is no longer applicable. Moreover, this method proves to be a useful tool for constructing particular solutions of some nonlinear partial differential equations such as the nonlinear Laplace,[1] wave,[2,3] and heat conductivity equations[4–6] in $(1+1)$ dimensions.

The principal object of study in the present paper is a problem of the separation of variables in the Schrödinger equation (SE) for a particle interacting with the electromagnetic field,

$$(p_0-p_ap_a)\,\psi(t,\vec{x})=0. \tag{1}$$

Here we use the notations

$$p_0=i\,\frac{\partial}{\partial t}-eA_0(t,\vec{x}),\quad p_a=i\,\frac{\partial}{\partial x_a}-eA_a(t,\vec{x}),\quad a=1,2,3,$$

where $A=(A_0,A_1,A_2,A_3)$ is the vector potential of the electromagnetic field, $e=$const. Hereafter the summation over the repeated indices from 1 to 3 is understood.

Böcher is believed to be the first to obtain in Ref. 7 a systematic classification of coordinate systems enabling separability of the three-dimensional stationary SE,

$$(-\Delta+E)\,\psi(\vec{x})=0, \tag{2}$$

where Δ is the Laplacian in three dimensions.

He has shown that Eq. (2) is separable via the separation *Ansatz*,

$$\psi(\vec{x})=\varphi_1(\omega_1(\vec{x}))\varphi_2(\omega_2(\vec{x}))\varphi_3(\omega_3(\vec{x})), \tag{3}$$

[b]Electronic-mail: zhaliy@imath.kiev.ua

in 11 inequivalent coordinate systems $\omega_1(\vec{x}),\omega_2(\vec{x}),\omega_3(\vec{x})$. We list these following the famous paper by Eisenhart,[8] where a rigorous geometric derivation of the corresponding results is given. Note that the coordinate systems are given in the implicit form $x_a=z_a(\omega_1,\omega_2,\omega_3)$, $a=1,2,3$.

(1) Cartesian coordinate system,

$$z_1=\omega_1,\quad z_2=\omega_2,\quad z_3=\omega_3,\qquad \omega_1,\omega_2,\omega_3\in\mathbf{R}.$$

(2) Cylindrical coordinate system,

$$z_1=e^{\omega_1}\cos\omega_2,\quad z_2=e^{\omega_1}\sin\omega_2,\quad z_3=\omega_3,\qquad 0\leqslant\omega_2<2\pi,\quad \omega_1,\omega_3\in\mathbf{R}.$$

(3) Parabolic cylindrical coordinate system,

$$z_1=(\omega_1^2-\omega_2^2)/2,\quad z_2=\omega_1\omega_2,\quad z_3=\omega_3,\qquad \omega_1>0,\quad \omega_2,\omega_3\in\mathbf{R}.$$

(4) Elliptic cylindrical coordinate system,

$$z_1=a\cosh\omega_1\cos\omega_2,\quad z_2=a\sinh\omega_1\sin\omega_2,\quad z_3=\omega_3,\qquad \omega_1>0,\quad -\pi<\omega_2\leqslant\pi,\quad \omega_3\in\mathbf{R},\quad a>0.$$

(5) Spherical coordinate system,

$$z_1=\omega_1^{-1}\operatorname{sech}\omega_2\cos\omega_3,\quad z_2=\omega_1^{-1}\operatorname{sech}\omega_2\sin\omega_3,\quad z_3=\omega_1^{-1}\tanh\omega_2,\qquad \omega_1>0,\quad \omega_2\in\mathbf{R},\quad 0\leqslant\omega_3<2\pi.$$

(6) Prolate spheroidal coordinate system,

$$z_1=a\operatorname{cosech}\omega_1\operatorname{sech}\omega_2\cos\omega_3,\quad a>0,\quad z_2=a\operatorname{cosech}\omega_1\operatorname{sech}\omega_2\sin\omega_3,\quad z_3=a\coth\omega_1\tanh\omega_2,\qquad \omega_1>0,\quad \omega_2\in\mathbf{R},\quad 0\leqslant\omega_3<2\pi. \tag{4}$$

(7) Oblate spheroidal coordinate system,

$$z_1=a\operatorname{cosec}\omega_1\operatorname{sech}\omega_2\cos\omega_3,\quad a>0,\quad z_2=a\operatorname{cosec}\omega_1\operatorname{sech}\omega_2\sin\omega_3,\quad z_3=a\cot\omega_1\tanh\omega_2,\qquad 0<\omega_1<\pi/2,\quad \omega_2\in\mathbf{R},\quad 0\leqslant\omega_3<2\pi.$$

(8) Parabolic coordinate system,

$$z_1=e^{\omega_1+\omega_2}\cos\omega_3,\quad z_2=e^{\omega_1+\omega_2}\sin\omega_3,\quad z_3=(e^{2\omega_1}-e^{2\omega_2})/2,\qquad \omega_1,\omega_2\in\mathbf{R},\quad 0\leqslant\omega_3\leqslant 2\pi.$$

(9) Paraboloidal coordinate system,

$$z_1=2a\cosh\omega_1\cos\omega_2\sinh\omega_3,\quad a>0,\quad z_2=2a\sinh\omega_1\sin\omega_2\cosh\omega_3,\quad z_3=a(\cosh 2\omega_1+\cos 2\omega_2-\cosh 2\omega_3)/2,\qquad \omega_1,\omega_3\in\mathbf{R},\quad 0\leqslant\omega_2<\pi.$$

(10) Ellipsoidal coordinate system,

$$z_1=a\frac{1}{\operatorname{sn}(\omega_1,k)}\operatorname{dn}(\omega_2,k')\operatorname{sn}(\omega_3,k),\quad a>0,$$

$$z_2=a\frac{\operatorname{dn}(\omega_1,k)}{\operatorname{sn}(\omega_1,k)}\operatorname{cn}(\omega_2,k')\operatorname{cn}(\omega_3,k),$$

$$z_3 = a\frac{\mathrm{cn}(\omega_1,k)}{\mathrm{sn}(\omega_1,k)}\mathrm{sn}(\omega_2,k')\mathrm{dn}(\omega_3,k),$$
$$0<\omega_1<K,\quad -K'\leqslant\omega_2\leqslant K',\quad 0\leqslant\omega_3\leqslant 4K.$$

(11) Conical coordinate system,

$$z_1=\omega_1^{-1}\mathrm{dn}(\omega_2,k')\mathrm{sn}(\omega_3,k),$$
$$z_2=\omega_1^{-1}\mathrm{cn}(\omega_2,k')\mathrm{cn}(\omega_3,k),$$
$$z_3=\omega_1^{-1}\mathrm{sn}(\omega_2,k')\mathrm{dn}(\omega_3,k),$$
$$\omega_1>0,\quad -K'\leqslant\omega_2\leqslant K',\quad 0\leqslant\omega_3\leqslant 4K.$$

Here we use the usual notations for the trigonometric, hyperbolic and Jacobi elliptic functions, $k(0<k<1)$ being the modulus of the latter and $k'=(1-k^2)^{1/2}$.

By the evident reasons, the coordinate systems 1, 2–4, and 5–11 from the above list are called completely split, partially split, and nonsplit, correspondingly.

Note that the above list differs slightly from the one presented in Ref. 8, since we have rearranged the coordinate systems $\omega_1,\omega_2,\omega_3$ in such a way that the relations

$$\Delta\omega_a=0,\quad a=1,2,3 \tag{5}$$

hold for all the cases 1–11.

Next, for each of the coordinate systems, Eisenhart[9] determined the form of the potential $V(\vec{x})$ that permits the separation of variables.

The Eisenhart's technique has been applied by Olevskii[10] for separating variables in the Laplace–Beltrami operator in the spaces of constant curvature (see, also Ref. 11).

Smorodinsky and Winternitz with co-workers[12,13] started a systematic study of potentials for which the stationary SE in two and three dimensions admits the separation of variables in two or more coordinate systems (so-called superintegrable potentials). The classification of these potentials has been completed by Evans.[14]

In the mid 1970s a series of papers by Miller and Kalnins appears, where a symmetry approach to variable separation has been developed. This approach is based on the well-known fact that a solution with separated variables is a common eigenfunction of first- or second-order differential operators, which commute each with another and with the operator of an equation under consideration. Further details and an extensive list of references can be found in the monograph[15] (also see, the review by Koornwinder[16]). Boyer, Kalnins, and Miller have obtained a systematic solution of the variable separation in the time-dependent $(1+2)$-dimensional free SE within the framework of the symmetry approach.[17] Later on, Boyer has described all coordinate systems providing separability of the $(1+2)$-dimensional SE having the potential $V(x_1,x_2)=\alpha/x_1^2+\beta/x_2^2$.[18] Reid has completely solved the problem of variable separation in the three-dimensional time-dependent SE for a free particle.[19]

Independently, the symmetry approach to the separation of variables in the equations of quantum mechanics and quantum field theory was developed by Shapovalov, who was the first to give a systematic treatment of the problem of variable separation in the Dirac equation using its non-Lie symmetry[20] and by Bagrov with collaborators (see, Ref. 21 and references therein). Shapovalov and Sukhomlin[22] have obtained some separable SEs of the form (1), however, their results are not complete. Let us also mention the papers[23,24] where the physical aspects of the problem of the separation of variables in some $(1+3)$- and $(1+1)$-dimensional SE with time-dependent potentials are studied.

In the present paper we are mainly devoted to the inverse problem of variable separation in SE (1), namely, to one of the classifying PDEs of the form (1) that can be solved by the method of separation of variables. Clearly, to be able to handle this problem efficiently, we need a precise algorithmic definition of what the separation of variables is. We have suggested a possible definition of the separation of variables applicable both to linear[25,26] and nonlinear[27] PDEs, which enables developing an efficient approach to solving classification problems for

$(1+2)$-dimensional time-dependent Schrödinger equations having time-independent[26,27] and time-dependent scalar potentials.[28] Recently, we have obtained an exhaustive classification of separable Schrödinger equations (1) in $(1+2)$ dimensions with $A_3=0$.[29]

In the present paper we solve completely the problem of variable separation in SE (1) into second-order ordinary differential equations in a sense that we obtain all possible forms of the vector potential $A(t,\vec{x})=(A_0(t,\vec{x}),A_1(t,\vec{x}),A_2(t,\vec{x}),A_3(t,\vec{x}))$ providing separability of (1). Furthermore, we construct inequivalent coordinate systems enabling us to separate variables in the corresponding SEs and carry out variable separation.

The paper has the following structure. In the second section we solve the classification problem for SE (1) and obtain all vector functions $A(t,\vec{x})$ such that (1) is separable. What is more, we consider briefly the problem of the separation of variables in SE having the generalized Coulomb potential and construct all the possible coordinate systems providing its separability. The third section is devoted to the application of the results of Sec. II to separate variables in the $(1+3)$-dimensional Hamilton–Jacobi equation. In a concluding section we indicate some further applications of the results obtained in the paper.

II. SEPARATION OF VARIABLES IN THE SCHRÖDINGER EQUATION

With all the variety of approaches to a separation of variables in PDEs, one can notice the three generic principles respected by all of them, namely, the following.

(1) Representation of a solution to be found in a separated (factorized) form via several functions of one variable.
(2) Requirement that the above mentioned functions of one variable should satisfy some ordinary differential equations.
(3) Dependence of the so found solution on several arbitrary (continuous or discrete) parameters, called spectral parameters or separation constants.

By a proper formalizing the above features we have formulated in Ref. 27 an algorithm for variable separation in linear PDEs. Below we apply this algorithm in order to classify separable SEs of the form (1).

We say that SE (1) is separable in a coordinate system t, $\omega_a=\omega_a(t,\vec{x})$, $a=1,2,3$ if the separation Ansatz,

$$\psi(t,\vec{x})=Q(t,\vec{x})\varphi_0(t)\prod_{a=1}^{3}\varphi_a(\omega_a(t,\vec{x}),\vec{\lambda}), \tag{6}$$

reduces PDE (1) to four ordinary differential equations for the functions φ_μ, $(\mu=0,1,2,3)$,

$$\varphi_0'=U_0(t,\varphi_0;\vec{\lambda}),\qquad \varphi_a''=U_a(\omega_a,\varphi_a,\varphi_a';\vec{\lambda}). \tag{7}$$

Here $U_0,\dots,U_3$ are some smooth functions of the indicated variables, $\vec{\lambda}=(\lambda_1,\lambda_2,\lambda_3)\in\Lambda=\{\text{an open domain in } \mathbf{R}^3\}$ are separation constants and, what is more,

$$\operatorname{rank}\left\|\begin{matrix}\frac{\partial U_0}{\partial\lambda_1} & \frac{\partial U_0}{\partial\lambda_2} & \frac{\partial U_0}{\partial\lambda_3}\\ \frac{\partial U_1}{\partial\lambda_1} & \frac{\partial U_1}{\partial\lambda_2} & \frac{\partial U_1}{\partial\lambda_3}\\ \frac{\partial U_2}{\partial\lambda_1} & \frac{\partial U_2}{\partial\lambda_2} & \frac{\partial U_2}{\partial\lambda_3}\\ \frac{\partial U_3}{\partial\lambda_1} & \frac{\partial U_3}{\partial\lambda_2} & \frac{\partial U_3}{\partial\lambda_3}\end{matrix}\right\|=3. \tag{8}$$

The above condition secures the essential dependence of a solution with separated variables on the separation constants $\vec{\lambda}$.

Formulas (6)–(8) form the input data of the method. The principal steps of the procedure of variable separation in SE (1) are as follows.

(1) We insert the *Ansatz* (6) into SE and express the derivatives $\varphi_0', \varphi_1'', \varphi_2'', \varphi_3''$ in terms of functions $\varphi_0, \varphi_1, \varphi_2, \varphi_3, \varphi_1', \varphi_2', \varphi_3'$ using Eqs. (7).
(2) We regard $\varphi_0, \varphi_1, \varphi_2, \varphi_3, \varphi_1', \varphi_2', \varphi_3', \lambda_1, \lambda_2, \lambda_3$ as the new independent variables $y_1, \ldots, y_{10}$. As the functions $Q, \omega_1, \omega_2, \omega_3$ are independent of the variables $y_1, \ldots, y_{10}$ we can split by these and get an overdetermined system of nonlinear partial differential equations for unknown functions $Q, \omega_1, \omega_2, \omega_3$.
(3) After solving the above system we get an exhaustive description of coordinate systems providing separability of SE.

Having performed the first two steps of the above algorithm, we arrive at the conclusion that the separation equations (7) are linear both in $\varphi_0, \ldots, \varphi_3$ and $\lambda_1, \lambda_2, \lambda_3$ [the principal reason for this is the fact that SE (1) is linear].

Next, we introduce an equivalence relation $\mathcal{E}$ on the set of all coordinate systems providing the separability of SE. We say that two coordinate systems $t, \omega_1, \omega_2, \omega_3$ and $\tilde{t}, \tilde{\omega}_1, \tilde{\omega}_2, \tilde{\omega}_3$ are equivalent if the corresponding *Ansätze* (6) are transformed one into another by the group transformations from the Lie transformation group admitted by SE (1) with $A=0$; the invertible transformations of the form

$$t \to \tilde{t} = f_0(t), \quad \omega_i \to \tilde{\omega}_i = f_i(\omega_i), \tag{9}$$

$$Q \to \tilde{Q} = Q l_0(t) l_1(\omega_1) l_2(\omega_2) l_3(\omega_3), \tag{10}$$

where $f_0, \ldots, f_3, l_0, \ldots, l_3$ are some smooth functions and $i=1,2,3$.

This equivalence relation reflects the freedom in the choice of the functions $Q, \omega_1, \omega_2, \omega_3$ and separation constants $\lambda_1, \lambda_2, \lambda_3$ preserving the form of the separation *Ansatz* (6). It splits the set of all possible coordinate systems into equivalence classes. In a sequel, when presenting the lists of coordinate systems enabling us to separate variables in SE we will give only one representative for each equivalence class.

Within the equivalence relation $\mathcal{E}$ we can always choose the reduced equations (7) to be

$$i\varphi_0' = (T_0(t) - T_i(t)\lambda_i)\varphi_0, \quad \varphi_a'' = (F_{a0}(\omega_a) + F_{ai}(\omega_a)\lambda_i)\varphi_a, \tag{11}$$

where T_0, T_i, F_{a0}, F_{ai} are some smooth functions of the indicated variables, $a=1,2,3$. With this remark the system of nonlinear PDEs for unknown functions $Q, \omega_1, \omega_2, \omega_3$ takes the form

$$\frac{\partial \omega_i}{\partial x_a} \frac{\partial \omega_j}{\partial x_a} = 0, \quad i \neq j, \quad i,j=1,2,3; \tag{12}$$

$$\sum_{i=1}^{3} F_{ia}(\omega_i) \frac{\partial \omega_i}{\partial x_j} \frac{\partial \omega_i}{\partial x_j} = T_a(t), \quad a=1,2,3; \tag{13}$$

$$2\left(\frac{\partial Q}{\partial x_j} + ieQA_j\right)\frac{\partial \omega_a}{\partial x_j} + Q\left(i\frac{\partial \omega_a}{\partial t} + \Delta\omega_a\right) = 0, \quad a=1,2,3; \tag{14}$$

$$Q\sum_{i=1}^{3} F_{i0}(\omega_i) \frac{\partial \omega_i}{\partial x_j} \frac{\partial \omega_i}{\partial x_j} + i\frac{\partial Q}{\partial t} + \Delta Q + 2ieA_a\frac{\partial Q}{\partial x_a} + Q\left(T_0(t) + ie\frac{\partial A_a}{\partial x_a} - eA_0 - e^2 A_a A_a\right) = 0. \tag{15}$$

Thus, the problem of variable separation in SE reduces to integrating the system of ten nonlinear PDEs for four functions. What is more, some coefficients are arbitrary functions that should be determined while integrating Eqs. (12)–(15). We have succeeded in constructing the general solution of the later, which yields, in particular, all possible vector-potentials $A(t,\vec{x}) = (A_0(t,\vec{x}),\dots,A_3(t,\vec{x}))$ such that SE (1) is solvable by the method of separation of variables.

The integration procedure relies heavily upon the results on the separation of variables in the stationary SE (2). That is why we will briefly consider the principal steps of application of our approach for separating variables in Eq. (2) with $E=1$,

$$\Delta_3\psi-\psi=0. \tag{16}$$

Inserting the separation *Ansatz*,

$$\psi(\vec{x})=Q(\vec{x})\varphi_1(\omega_1(\vec{x}))\phi_2(\omega_2(\vec{x}))\varphi_3(\omega_3(\vec{x})),$$

into (16) and taking into account the relations

$$\varphi_a''=(F_{a1}(\omega_a)+F_{a2}(\omega_a)\lambda_1+F_{a3}(\omega_a)\lambda_2)\varphi_a, \quad a=1,2,3,$$

we get the system of nonlinear partial differential equations for the functions $Q,\omega_1,\omega_2,\omega_3$,

$$\begin{aligned}
&\text{(i)} \quad \frac{\partial\omega_i}{\partial x_a}\frac{\partial\omega_j}{\partial x_a}=0, \quad i\neq j, \quad i,j=1,2,3;\\
&\text{(ii)} \quad \sum_{i=1}^{3} F_{ia}(\omega_i)\frac{\partial\omega_i}{\partial x_j}\frac{\partial\omega_i}{\partial x_j}=0, \quad a=2,3;\\
&\text{(iii)} \quad 2\frac{\partial Q}{\partial x_j}\frac{\partial\omega_a}{\partial x_j}+Q\Delta\omega_a=0, \quad a=1,2,3;\\
&\text{(iv)} \quad Q\sum_{i=1}^{3} F_{i1}(\omega_i)\frac{\partial\omega_i}{\partial x_j}\frac{\partial\omega_i}{\partial x_j}+\Delta Q-Q=0.
\end{aligned} \tag{17}$$

Now we can utilize the classical results on variable separation in the stationary SE (16). According to Ref. 8 the general solution $\vec{\omega}=\vec{\omega}(\vec{x})$ of system (17) splits into 11 inequivalent classes whose representatives are given in (4).

As $\omega_1,\omega_2,\omega_3$ are functionally independent, the inequality

$$\det\left\|\frac{\partial\omega_i}{\partial x_a}\right\|_{i,a=1}^{3}\neq 0, \tag{18}$$

holds. Taking into account this fact and relations (5), we get from (iii) that $Q(\vec{x})=\text{const}$, whence it follows that without losing generality we may choose $Q(\vec{x})=1$. In view of this we rewrite system (17) in the following way:

$$\begin{aligned}
&\frac{\partial\omega_i}{\partial x_a}\frac{\partial\omega_j}{\partial x_a}=0, \quad i\neq j, \quad i,j=1,2,3;\\
&\sum_{i=1}^{3} F_{ij}(\omega_i)\omega_{ix_a}\omega_{ix_a}=\delta_{1j}, \quad j=1,2,3,
\end{aligned} \tag{19}$$

where δ_{1j} is the Kronecker symbol.

System (19) coincides with the system of Eqs. (12) and (13) under $T_1=1$, $T_2=T_3=0$. Next, in view of arbitrariness of the choice of the separation constants $\lambda_1,\lambda_2,\lambda_3$ we can always suppose that $T_1(t_0)=1$, $T_1(t_0)=T_2(t_0)=0$ for some $t_0\in\mathbf{R}$. Consequently, system (12), (13) with $t=t_0$ takes the form (19). This is a key point enabling us to use the results of Ref. 8 for integrating system (12), (13).

Lemma 1: The general solution $\vec{\omega}=\vec{\omega}(t,\vec{x})$ of the system of partial differential equations (12), (13) is given implicitly by the following formulas:

$$\vec{x}=\mathcal{T}(t)H(t)\vec{z}(\vec{\omega})+\vec{w}(t). \tag{20}$$

Here $\mathcal{T}(t)$ is the time-dependent 3×3 *orthogonal matrix*:

$$\mathcal{T}(t)=\begin{pmatrix} \cos\alpha\cos\beta-\sin\alpha\sin\beta\cos\gamma & -\cos\alpha\sin\beta-\sin\alpha\cos\beta\cos\gamma & \sin\alpha\sin\gamma \\ \sin\alpha\cos\beta+\cos\alpha\sin\beta\cos\gamma & -\sin\alpha\sin\beta+\cos\alpha\cos\beta\cos\gamma & -\cos\alpha\sin\gamma \\ \sin\beta\sin\gamma & \cos\beta\sin\gamma & \cos\gamma \end{pmatrix} \tag{21}$$

α,β,γ being arbitrary smooth functions of t;$\vec{z}=\vec{z}(\vec{\omega})$ is given by one of the 11 formulas from (4); *$H(t)$ is the* 3×3 *diagonal matrix,*

$$H(t)=\begin{pmatrix} h_1(t) & 0 & 0 \\ 0 & h_2(t) & 0 \\ 0 & 0 & h_3(t) \end{pmatrix}, \tag{22}$$

where (a) $h_1(t),h_2(t),h_3(t)$ are arbitrary smooth functions for the completely split coordinate system [case 1 from (4)], (b) $h_1(t)=h_2(t)$, $h_1(t)$, $h_3(t)$ being arbitrary smooth functions, for the partially split coordinate systems [cases 2–4 from (4)], (c) $h_1(t)=h_2(t)=h_3(t),h_1(t)$ being an arbitrary smooth function, for nonsplit coordinate systems [cases 5–11 from (4)], and $\vec{\omega}(t)$ stands for the vector column whose entries $\omega_1(t),\omega_2(t),\omega_3(t)$ are arbitrary smooth functions of t.

Proof: First we perform the hodograph transformation in the system of PDEs (12), (13),

$$t=t,\quad x_a=u_a(t,\omega_1,\omega_2,\omega_3),\quad a=1,2,3. \tag{23}$$

Direct computation shows that the following identities hold:

$$\begin{gathered}(1)\quad \omega_{ix_a}\omega_{jx_a}\equiv\frac{1}{\delta^2}(\Omega_{ik}\Omega_{jk}-\Omega_{ij}\Omega_{kk}),\quad (i,j,k)=\text{cycle}(1,2,3),\\ (2)\quad \omega_{ix_a}\omega_{ix_a}\equiv\frac{1}{\delta^2}(\Omega_{jj}\Omega_{kk}-\Omega_{jk}^2),\quad (i,j,k)=\text{cycle}(1,2,3),\end{gathered} \tag{24}$$

where

$$\Omega_{ij}=\frac{\partial u_a}{\partial\omega_i}\frac{\partial u_a}{\partial\omega_j},\qquad \delta=\det\left\|\frac{\partial u_a}{\partial\omega_b}\right\|_{a,b=1}^{3}\neq0.$$

Consequently, the initial system (12), (13), after being rewritten in the new variables, reads as

$$\begin{gathered}\frac{\partial u_a}{\partial\omega_i}\frac{\partial u_a}{\partial\omega_j}=0,\quad i\neq j,\quad i,j=1,2,3;\\ \sum_{(i,j,k)=\text{cycle}(1,2,3)}F_{ia}(\omega_i)\frac{\partial u_b}{\partial\omega_j}\frac{\partial u_b}{\partial\omega_j}\frac{\partial u_c}{\partial\omega_k}\frac{\partial u_c}{\partial\omega_k}=\delta^2T_a(t),\quad a=1,2,3.\end{gathered} \tag{25}$$

If we introduce three vectors,

$$\vec{v}_1=\frac{\partial\vec{u}}{\partial\omega_1},\quad \vec{v}_2=\frac{\partial\vec{u}}{\partial\omega_2},\quad \vec{v}_3=\frac{\partial\vec{u}}{\partial\omega_3},$$

then the first three equations of system (25) read as $\vec{v}_a\vec{v}_b=0$, $(a,b=1,2,3,\ a\neq b)$. Consequently $\vec{v}_1,\vec{v}_2,\vec{v}_3$ form an orthogonal system of vectors in the space $\mathbf{R}^3$. It is well known from the analytical geometry that the most general form of these vectors can be expressed via the Euler angles,

$$\frac{\partial\vec{u}}{\partial\omega_1}=R_1\begin{Bmatrix}\cos f_1\cos f_2-\sin f_1\sin f_2\cos f_3\\ \sin f_1\cos f_2+\cos f_1\sin f_2\cos f_3\\ \sin f_2\sin f_3\end{Bmatrix},$$

$$\frac{\partial\vec{u}}{\partial\omega_2}=R_2\begin{Bmatrix}-\cos f_1\sin f_2-\sin f_1\cos f_2\cos f_3\\ -\sin f_1\sin f_2+\cos f_1\cos f_2\cos f_3\\ \cos f_2\sin f_3\end{Bmatrix},\tag{26}$$

$$\frac{\partial\vec{u}}{\partial\omega_3}=R_3\begin{Bmatrix}\sin f_1\sin f_3\\ -\cos f_1\sin f_3\\ \cos f_3\end{Bmatrix},$$

where $f_1,\ldots,\ R_3$ are arbitrary smooth functions of $t,\ \omega_1,\omega_2,\omega_3$. The above formulas give the most general form of functions $\partial u_a/\partial\omega_b,\ a,b=1,2,3$ that satisfy the first three equations from (25). Next, inserting (26) into the remaining equations from (25) yields

$$\sum_{i=1}^{3}F_{ij}(\omega_i)R_i^{-2}=T_j(t),\quad j=1,2,3.\tag{27}$$

Thus, we have transformed system (25) to equivalent form (26), (27), where one should take into account the compatibility conditions for the system of PDEs (26),

$$\frac{\partial}{\partial\omega_k}\left(\frac{\partial u_i}{\partial\omega_j}\right)=\frac{\partial}{\partial\omega_j}\left(\frac{\partial u_i}{\partial\omega_k}\right),\quad j\neq k,\quad i,j,k=1,2,3.$$

Hence, we get the overdetermined system of nonlinear PDEs for the functions f_1,f_2,f_3,

$$\cos f_3\frac{\partial f_1}{\partial\omega_1}+\frac{\partial f_2}{\partial\omega_1}=-R_2^{-1}\frac{\partial R_1}{\partial\omega_2},$$

$$\cos f_3\frac{\partial f_1}{\partial\omega_2}+\frac{\partial f_2}{\partial\omega_2}=R_1^{-1}\frac{\partial R_2}{\partial\omega_1},$$

$$\cos f_3\frac{\partial f_1}{\partial\omega_3}+\frac{\partial f_2}{\partial\omega_3}=0,$$

$$\cos f_2\frac{\partial f_3}{\partial\omega_1}+\sin f_2\sin f_3\frac{\partial f_1}{\partial\omega_1}=0,$$

$$\cos f_2\frac{\partial f_3}{\partial\omega_2}+\sin f_2\sin f_3\frac{\partial f_1}{\partial\omega_2}=-R_3^{-1}\frac{\partial R_2}{\partial\omega_3},$$

$$\cos f_2 \frac{\partial f_3}{\partial \omega_3} + \sin f_2 \sin f_3 \frac{\partial f_1}{\partial \omega_3} = R_2^{-1} \frac{\partial R_3}{\partial \omega_2},$$

$$\sin f_2 \frac{\partial f_3}{\partial \omega_1} - \cos f_2 \sin f_3 \frac{\partial f_1}{\partial \omega_1} = -R_3^{-1} \frac{\partial R_1}{\partial \omega_3},$$

$$\sin f_2 \frac{\partial f_3}{\partial \omega_2} - \cos f_2 \sin f_3 \frac{\partial f_1}{\partial \omega_2} = 0,$$

$$\sin f_2 \frac{\partial f_3}{\partial \omega_3} - \cos f_2 \sin f_3 \frac{\partial f_1}{\partial \omega_3} = R_1^{-1} \frac{\partial R_3}{\partial \omega_1}.$$

While integrating the above system we have to differentiate between the two cases: (1) $\sin f_3 \neq 0$ and (2) $\sin f_3 = 0$.

Case 1. Suppose the condition $\sin f_3 \neq 0$ holds. Then we can solve the above system with respect to $\partial f_a / \partial \omega_b$, $(a,b=1,2,3)$ and get

$$\begin{aligned}
\frac{\partial f_1}{\partial \omega_1} &= R_3^{-1} \frac{\partial R_1}{\partial \omega_3} \cos f_2 \operatorname{cosec} f_3, \\
\frac{\partial f_1}{\partial \omega_2} &= -R_3^{-1} \frac{\partial R_2}{\partial \omega_3} \sin f_2 \operatorname{cosec} f_3, \\
\frac{\partial f_1}{\partial \omega_3} &= R_2^{-1} \frac{\partial R_3}{\partial \omega_2} \sin f_2 \operatorname{cosec} f_3 - R_1^{-1} \frac{\partial R_3}{\partial \omega_1} \cos f_2 \operatorname{cosec} f_3, \\
\frac{\partial f_2}{\partial \omega_1} &= -R_2^{-1} \frac{\partial R_1}{\partial \omega_2} - R_3^{-1} \frac{\partial R_1}{\partial \omega_3} \cos f_2 \cot f_3, \\
\frac{\partial f_2}{\partial \omega_2} &= R_1^{-1} \frac{\partial R_2}{\partial \omega_1} + R_3^{-1} \frac{\partial R_2}{\partial \omega_3} \sin f_2 \cot f_3, \\
\frac{\partial f_2}{\partial \omega_3} &= -R_2^{-1} \frac{\partial R_3}{\partial \omega_2} \sin f_2 \cot f_3 + R_1^{-1} \frac{\partial R_3}{\partial \omega_1} \cos f_2 \cot f_3, \\
\frac{\partial f_3}{\partial \omega_1} &= -R_3^{-1} \frac{\partial R_1}{\partial \omega_3} \sin f_2, \\
\frac{\partial f_3}{\partial \omega_2} &= -R_3^{-1} \frac{\partial R_2}{\partial \omega_3} \cos f_2, \\
\frac{\partial f_3}{\partial \omega_3} &= R_2^{-1} \frac{\partial R_3}{\partial \omega_2} \cos f_2 + R_1^{-1} \frac{\partial R_3}{\partial \omega_1} \sin f_2.
\end{aligned} \tag{28}$$

From the compatibility conditions of the above system of PDEs we get the system of nonlinear differential equations for R_1, R_2, R_3:

$$(1) \quad R_1 R_2 \frac{\partial^2 R_3}{\partial \omega_1 \partial \omega_2} - R_1 \frac{\partial R_2}{\partial \omega_1} \frac{\partial R_3}{\partial \omega_2} - R_2 \frac{\partial R_1}{\partial \omega_2} \frac{\partial R_3}{\partial \omega_1} = 0,$$

$$(2)\quad R_2R_3\frac{\partial^2 R_1}{\partial\omega_2\partial\omega_3}-R_2\frac{\partial R_1}{\partial\omega_3}\frac{\partial R_3}{\partial\omega_2}-R_3\frac{\partial R_1}{\partial\omega_2}\frac{\partial R_2}{\partial\omega_3}=0,$$

$$(3)\quad R_1R_3\frac{\partial^2 R_2}{\partial\omega_1\partial\omega_3}-R_3\frac{\partial R_1}{\partial\omega_3}\frac{\partial R_2}{\partial\omega_1}-R_1\frac{\partial R_2}{\partial\omega_3}\frac{\partial R_3}{\partial\omega_1}=0,$$

$$(4)\quad R_1^2R_2^2\frac{\partial R_2}{\partial\omega_3}\frac{\partial R_3}{\partial\omega_3}+R_1^2R_3^2\frac{\partial R_2}{\partial\omega_2}\frac{\partial R_3}{\partial\omega_2}-R_2^2R_3^2\frac{\partial R_2}{\partial\omega_1}\frac{\partial R_3}{\partial\omega_1}-R_1^2R_2^2R_3\frac{\partial^2 R_2}{\partial\omega_3\,\partial\omega_3}-R_1^2R_2R_3^2\frac{\partial^2 R_3}{\partial\omega_2\,\partial\omega_2}=0, \tag{29}$$

$$(5)\quad R_1^2R_2^2\frac{\partial R_1}{\partial\omega_3}\frac{\partial R_3}{\partial\omega_3}-R_1^2R_3^2\frac{\partial R_1}{\partial\omega_2}\frac{\partial R_3}{\partial\omega_2}+R_2^2R_3^2\frac{\partial R_1}{\partial\omega_1}\frac{\partial R_3}{\partial\omega_1}-R_1^2R_2^2R_3\frac{\partial^2 R_1}{\partial\omega_3\,\partial\omega_3}-R_1R_2^2R_3^2\frac{\partial^2 R_3}{\partial\omega_1\,\partial\omega_1}=0,$$

$$(6)\quad -R_1^2R_2^2\frac{\partial R_1}{\partial\omega_3}\frac{\partial R_2}{\partial\omega_3}+R_1^2R_3^2\frac{\partial R_1}{\partial\omega_2}\frac{\partial R_2}{\partial\omega_2}+R_2^2R_3^2\frac{\partial R_1}{\partial\omega_1}\frac{\partial R_2}{\partial\omega_1}-R_1^2R_2R_3^2\frac{\partial^2 R_1}{\partial\omega_2\,\partial\omega_2}$$

$$-R_1R_2^2R_3^2\frac{\partial^2 R_2}{\partial\omega_1\,\partial\omega_1}=0.$$

Remarkably, there is no need for a direct integrating of the system of nonlinear PDEs (29), since it has been solved by Eisenhart[8] under the assumption that R_1, R_2, R_3 are independent of t. The only thing to be done is to find out in which way the temporal variable t enters into the general solution of system (26)–(29) in the case under study.

As shown above, the problem of variable separations in SE (16) reduces to integrating system (19) and, what is more, the general solution of the latter is given within the equivalence relation (9) by one of the formulas from (4). Consequently, if we fix the temporal variable t to be equal to $t_0\in\mathbf{R}$, then after integrating equations (26)–(29) we get within the equivalence relation (9) formulas (4).

In view of this fact we can solve relations (25) under $t=t_0$ with respect to $F_{ij}(\omega_i)$ [note that F_{ij} are independent of t] for each class of functions $\vec{x}=\vec{z}(\vec{\omega})$ given in (4). The results of these calculations are presented below in the form of 3×3 Stäckel matrices $\mathcal{F}_1,\dots,\mathcal{F}_{11}$, whose (i,j)th entry is the corresponding function $F_{ij}(\omega_i)$. We give the canonical forms of the matrices $\mathcal{F}_1,\dots,\mathcal{F}_{11}$ up to the choice of separation constants λ_i, $i=1,2,3$ in (11):

$$\mathcal{F}_1=\begin{pmatrix}1&0&0\\0&1&0\\0&0&1\end{pmatrix},\quad \mathcal{F}_2=\begin{pmatrix}e^{2\omega_1}&-1&0\\0&1&0\\0&0&1\end{pmatrix},$$

$$\mathcal{F}_3=\begin{pmatrix}\omega_1^2&-1&0\\\omega_2^2&1&0\\0&0&1\end{pmatrix},\quad \mathcal{F}_4=\begin{pmatrix}a^2\cosh^2\omega_1&1&0\\-a^2\cos^2\omega_2&-1&0\\0&0&1\end{pmatrix},$$

$$\mathcal{F}_5=\begin{pmatrix}\omega_1^{-4}&-\omega_1^{-2}&0\\0&\cosh^{-2}\omega_2&-1\\0&0&1\end{pmatrix},$$

$$\mathcal{F}_6=\begin{pmatrix}a^2\sinh^{-4}\omega_1&-\sinh^{-2}\omega_1&-1\\a^2\cosh^{-4}\omega_2&\cosh^{-2}\omega_2&-1\\0&0&1\end{pmatrix},$$

$$\mathcal{F}_7=\begin{pmatrix} a^2\sin^{-4}\omega_1 & -\sin^{-2}\omega_1 & 1\\ -a^2\cosh^{-4}\omega_2 & \cosh^{-2}\omega_2 & -1\\ 0 & 0 & 1\end{pmatrix},$$

$$\mathcal{F}_8=\begin{pmatrix} e^{4\omega_1} & -e^{2\omega_1} & -1\\ e^{4\omega_2} & e^{2\omega_2} & -1\\ 0 & 0 & 1\end{pmatrix}, \tag{30}$$

$$\mathcal{F}_9=\begin{pmatrix} a^2\cosh^2 2\omega_1 & -a\cosh 2\omega_1 & -1\\ -a^2\cos^2 2\omega_2 & a\cos 2\omega_2 & 1\\ a^2\cosh^2 2\omega_3 & a\cosh 2\omega_3 & -1\end{pmatrix},$$

$$\mathcal{F}_{10}=\begin{pmatrix} \dfrac{\mathrm{dn}^4(\omega_1,k)}{\mathrm{sn}^4(\omega_1,k)} & -\dfrac{\mathrm{dn}^2(\omega_1,k)}{\mathrm{sn}^2(\omega_1,k)} & 1\\ -k'^4\,\mathrm{cn}^4(\omega_2,k') & k'^2\,\mathrm{cn}^2(\omega_2,k') & -1\\ k^4\,\mathrm{cn}^4(\omega_3,k) & k^2\,\mathrm{cn}^2(\omega_3,k) & 1\end{pmatrix},$$

$$\mathcal{F}_{11}=\begin{pmatrix} \omega_1^{-4} & -\omega_1^{-2} & 0\\ 0 & k'^2\,\mathrm{cn}^2(\omega_2,k') & -1\\ 0 & k^2\,\mathrm{cn}^2(\omega_3,k) & 1\end{pmatrix}.$$

With the explicit forms of the functions F_{ij}, $(i,j=1,2,3)$ in hand, we can solve (27) with respect to R_1,R_2,R_3. Inserting the result obtained into (29) and splitting by $\omega_1,\omega_2,\omega_3$ yield the final forms of the functions R_1,R_2,R_3:

(1) $R_i^2=T_i^{-1},\ \ i=1,2,3;$

(2) $R_1^2=R_2^2=T_1^{-1}e^{2\omega_1},\quad R_3^2=T_3^{-1};$

(3) $R_1^2=R_2^2=T_1^{-1}(\omega_1^2+\omega_2^2),\quad R_3^2=T_3^{-1};$

(4) $R_1^2=R_2^2=T_1^{-1}a^2(\cosh 2\omega_1-\cos 2\omega_2),\quad R_3^2=T_3^{-1};$

(5) $R_1^2=T_1^{-1}\omega_1^{-4},\quad R_2^2=R_3^2=T_1^{-1}\omega_1^{-2}\cosh^{-2}\omega_2;$

(6) $R_1^2=T_1^{-1}a^2\sinh^{-2}\omega_1(\sinh^{-2}\omega_1+\cosh^{-2}\omega_2),$

$R_2^2=T_1^{-1}a^2\cosh^{-2}\omega_2(\sinh^{-2}\omega_1+\cosh^{-2}\omega_2),$

$R_3^2=T_1^{-1}a^2\sinh^{-2}\omega_1\cosh^{-2}\omega_2;$

(7) $R_1^2=T_1^{-1}a^2\sin^{-2}\omega_1(\sin^{-2}\omega_1-\cosh^{-2}\omega_2),$

$R_2^2=T_1^{-1}a^2\cosh^{-2}\omega_2(\sin^{-2}\omega_1-\cosh^{-2}\omega_2),$

$R_3^2=T_1^{-1}a^2\sin^{-2}\omega_1\cosh^{-2}\omega_2;$

(8) $R_1^2=T_1^{-1}e^{2\omega_1}(e^{2\omega_1}+e^{2\omega_2}),\quad R_2^2=T_1^{-1}e^{2\omega_2}(e^{2\omega_1}+e^{2\omega_2}),$

$R_3^2=T_1^{-1}e^{2(\omega_1+\omega_2)};$

$$(9)\quad R_1^2=T_1^{-1}a^2(\cosh 2\omega_1-\cos 2\omega_2)(\cosh 2\omega_1+\cosh 2\omega_3),$$

$$R_2^2=T_1^{-1}a^2(\cosh 2\omega_1-\cos 2\omega_2)(\cos 2\omega_2+\cosh 2\omega_3),$$

$$R_3^2=T_1^{-1}a^2(\cosh 2\omega_1+\cosh 2\omega_3)(\cos 2\omega_2+\cosh 2\omega_3);$$

$$(10)\quad R_1^2=T_1^{-1}\left(\frac{\mathrm{dn}^2(\omega_1,k)}{\mathrm{sn}^2(\omega_1,k)}-k'^2\,\mathrm{cn}^2(\omega_2,k')\right)\left(\frac{\mathrm{dn}^2(\omega_1,k)}{\mathrm{sn}^2(\omega_1,k)}+k^2\,\mathrm{cn}^2(\omega_3,k)\right),$$

$$R_2^2=T_1^{-1}\left(\frac{\mathrm{dn}^2(\omega_1,k)}{\mathrm{sn}^2(\omega_1,k)}-k'^2\,\mathrm{cn}^2(\omega_2,k')\right)(k'^2\,\mathrm{cn}^2(\omega_2,k')+k^2\,\mathrm{cn}^2(\omega_3,k)),$$

$$R_3^2=T_1^{-1}\left(\frac{\mathrm{dn}^2(\omega_1,k)}{\mathrm{sn}^2(\omega_1,k)}+k^2\,\mathrm{cn}^2(\omega_3,k)\right)(k'^2\,\mathrm{cn}^2(\omega_2,k')+k^2\,\mathrm{cn}^2(\omega_3,k));$$

$$(11)\quad R_1^2=T_1^{-1}\omega_1^{-4},\quad R_2^2=R_3^2=T_1^{-1}\omega_1^{-2}(k'^2\,\mathrm{cn}^2(\omega_2,k')+k^2\,\mathrm{cn}^2(\omega_3,k)). \tag{31}$$

Inserting the above expressions into (28), we see that the system obtained (we denote it temporarily as $\mathcal{S}$) does not depend explicitly on t. It is in involution and hence its general solution depends on three arbitrary functions of t. As a direct check shows the functions

$$f_1=\mathrm{arccot}(\cos\gamma\cot(\tilde f_1+\beta)+\sin\gamma\cot\tilde f_3\,\mathrm{cosec}(\tilde f_1+\beta))+\alpha,$$

$$f_2=\mathrm{arccot}(\cos\tilde f_3\cot(\tilde f_1+\beta)+\sin\tilde f_3\cot\gamma\,\mathrm{cosec}(\tilde f_1+\beta))+\tilde f_2,$$

$$f_3=\arccos(\cos\gamma\cos\tilde f_3-\sin\gamma\sin\tilde f_3\cos(\tilde f_1+\beta)), \tag{32}$$

where α, β, γ are arbitrary functions of t and $\tilde f_1,\tilde f_2,\tilde f_3$ are (time-independent) solutions of the system $\mathcal{S}$ under $t=t_0$, satisfy the system $\mathcal{S}$ identically. Since formulas (32) contain three arbitrary functions of t, they give the general solution of the system $\mathcal{S}$. Substituting (32) into (26) yields

$$\frac{\partial\vec u}{\partial\omega_1}=R_1\mathcal{T}(t)\left\{\begin{matrix}\cos\tilde f_1\cos\tilde f_2-\sin\tilde f_1\sin\tilde f_2\cos\tilde f_3\\ \sin\tilde f_1\cos\tilde f_2+\cos\tilde f_1\sin\tilde f_2\cos\tilde f_3\\ \sin\tilde f_2\sin f_3\end{matrix}\right\},$$

$$\frac{\partial\vec u}{\partial\omega_2}=R_2\mathcal{T}(t)\left\{\begin{matrix}-\cos\tilde f_1\sin\tilde f_2-\sin\tilde f_1\cos\tilde f_2\cos\tilde f_3\\ -\sin\tilde f_1\sin\tilde f_2+\cos\tilde f_1\cos\tilde f_2\cos\tilde f_3\\ \cos\tilde f_2\sin f_3\end{matrix}\right\}, \tag{33}$$

$$\frac{\partial\vec u}{\partial\omega_3}=R_3\mathcal{T}(t)\left\{\begin{matrix}\sin\tilde f_1\sin\tilde f_3\\ -\cos\tilde f_1\sin\tilde f_3\\ \cos\tilde f_3\end{matrix}\right\},$$

where the matrix $\mathcal{T}(t)$ is given by formula (21).

If we choose in the system obtained $t=t_0$, then its general solution is given within the equivalence relation $\mathcal{E}$ (9) by one of the formulas from (4). In view of this fact it is not difficult to integrate system (33) and thus get formulas (20), where $h_1(t),h_2(t),h_3(t)$ are expressed via $T_1(t),T_2(t),T_3(t)$,

$$
\begin{array}{ll}
(1) & T_i = h_i^{-2}, \quad i=1,2,3; \\
(2)-(4) & T_1 = h_1^{-2}, \quad T_2 = 0, \quad T_3 = h_3^{-2}; \\
(5)-(11) & T_1 = h_1^{-2}, \quad T_2 = T_3 = 0.
\end{array} \tag{34}
$$

Case 2. Let the relation $\sin f_3 = 0$ be valid. In this case we have an analog of system (28),

$$
\begin{gathered}
\frac{\partial g}{\partial \omega_1} = -R_2^{-1} \frac{\partial R_1}{\partial \omega_2}, \quad \frac{\partial g}{\partial \omega_2} = R_1^{-1} \frac{\partial R_2}{\partial \omega_1}, \\
\frac{\partial g}{\partial \omega_3} = 0, \quad \frac{\partial R_1}{\partial \omega_3} = 0, \quad \frac{\partial R_2}{\partial \omega_3} = 0, \quad \frac{\partial R_3}{\partial \omega_1} = 0, \quad \frac{\partial R_3}{\partial \omega_2} = 0,
\end{gathered} \tag{35}
$$

with $g = \pm f_1 + f_2$ and an analog of system (29),

$$
\begin{gathered}
R_1^2 R_3^2 \frac{\partial R_1}{\partial \omega_2} \frac{\partial R_2}{\partial \omega_2} + R_2^2 R_3^2 \frac{\partial R_1}{\partial \omega_1} \frac{\partial R_2}{\partial \omega_1} - R_1^2 R_2 R_3^2 \frac{\partial^2 R_1}{\partial \omega_2 \, \partial \omega_2} - R_1 R_2^2 R_3^2 \frac{\partial^2 R_2}{\partial \omega_1 \partial \omega_1} = 0, \\
\frac{\partial R_1}{\partial \omega_3} = 0, \quad \frac{\partial R_2}{\partial \omega_3} = 0, \quad \frac{\partial R_3}{\partial \omega_1} = 0, \quad \frac{\partial R_3}{\partial \omega_2} = 0.
\end{gathered} \tag{36}
$$

A system of PDEs (35), (36) is fairly simple and is easily integrated. As a result we get a particular case of (20) with $\sin \gamma = 0$. The lemma is proved. $\triangleright$

With this result in hand it is not difficult to integrate the remaining equations from the system under study. Indeed, Eqs. (14) and (15) may be treated as algebraic equations for the functions $A_j(t,\vec{x})$, $j=1,2,3$ and $A_0(t,\vec{x})$, correspondingly.

There are two different configurations of the electromagnetic field that should be considered separately. The first one is the case of a vanishing magnetic field $\vec{H} = \mathrm{rot}\, \vec{A}$, namely, the case when

$$
A_{ix_j} = A_{jx_i}, \quad i \neq j, \quad i,j = 1,2,3. \tag{37}
$$

Provided the above equality does not hold we have a nonvanishing magnetic field $\vec{H}$.

A. The case of nonvanishing magnetic field

Let us represent the complex-valued function Q in (6) as $Q = \exp(S_1 + iS_2)$, where S_1, S_2 are real-valued functions. Now, if we take into account that the components of the vector potential $A(t,\vec{x})$ and functions $\omega_1, \omega_2, \omega_3$ are real-valued functions, then after inserting Q into (14) with the use of (5) we can split the obtained equations into real and imaginary parts:

$$
\frac{\partial S_1}{\partial x_j} \frac{\partial \omega_a}{\partial x_j} = 0, \quad a = 1,2,3; \tag{38}
$$

$$
2\left(\frac{\partial S_2}{\partial x_j} + eA_j \right) \frac{\partial \omega_a}{\partial x_j} + \frac{\partial \omega_a}{\partial t} = 0, \quad a = 1,2,3. \tag{39}
$$

In view of (18) we get from (38) the relations $S_{1x_j} = 0$, $j = 1,2,3$. Hence, $S_1 = S_1(t)$ and within the equivalence relation $\mathcal{E}$ (10) we may choose S_1 to be equal to 0. Next, making use of the gauge invariance of SE (1) we get from (39) that within the equivalence relation $\mathcal{E}$ the equalities $S_{2x_i} = 0$, $i = 1,2,3$ hold, whence $S_2 = S_2(t)$. Again, in view of (10) we may put $S_2 = 0$, which means that the factor Q may be chosen as 1. With this result system (39) reduces to the system of three linear algebraic equations for the functions A_1, A_2, A_3,

$$\omega_{at} = -2e\,\omega_{ax_i} A_i\,, \quad a = 1,2,3.$$

The determinant of this system is not equal to zero due to (18). Consequently, it has a unique solution. Making in this solution the hodograph transformation (23), we get the following expressions for A_1, A_2, A_3:

$$\vec{A} = \frac{1}{2e}\,\frac{\partial \vec{u}(t,\vec{\omega})}{\partial t}.$$

Inserting into the above formula $\vec{x} = \vec{u}(t,\vec{\omega})$ from (20) yields the explicit forms of the spacelike components of the vector potential of the electromagnetic field $A(t,\vec{x})$,

$$\vec{A}(t,\vec{x}) = \frac{1}{2e}\left(\mathcal{M}(t)(\vec{x} - \vec{w}) + \dot{\vec{w}}\right). \tag{40}$$

Here we use the designation

$$\mathcal{M}(t) = \dot{\mathcal{T}}(t)\mathcal{T}^{-1}(t) + \mathcal{T}(t)\dot{H}(t)H^{-1}(t)\mathcal{T}^{-1}(t), \tag{41}$$

where $\mathcal{T}(t)$, $H(t)$ are variable 3×3 matrices defined by formulas (21) and (22), correspondingly, $\vec{w} = (w_1(t), w_2(t), w_3(t))^T$ and the dot over a symbol means differentiation with respect to t.

Given the form (40) of the spacelike components of the vector potential $A(t,\vec{x})$, the condition for the magnetic field $\vec{H}$ not to vanish means that at least one of the expressions,

$$\dot{\alpha} + \dot{\beta}\cos\gamma, \quad \dot{\beta}\cos\alpha\sin\gamma - \dot{\gamma}\sin\alpha, \quad \dot{\beta}\sin\alpha\sin\gamma + \dot{\gamma}\cos\alpha, \tag{42}$$

does not turn into zero. Hence, in view of the identity

$$\dot{\mathcal{T}}\mathcal{T}^{-1} = \begin{pmatrix} 0 & -(\dot{\alpha} + \dot{\beta}\cos\gamma) & -(\dot{\beta}\cos\alpha\sin\gamma - \dot{\gamma}\sin\alpha) \\ \dot{\alpha} + \dot{\beta}\cos\gamma & 0 & -(\dot{\beta}\sin\alpha\sin\gamma + \dot{\gamma}\cos\alpha) \\ \dot{\beta}\cos\alpha\sin\gamma - \dot{\gamma}\sin\alpha & \dot{\beta}\sin\alpha\sin\gamma + \dot{\gamma}\cos\alpha & 0 \end{pmatrix},$$

whose validity is checked by straightforward computation, we conclude that $\mathcal{T} \neq \mathrm{const}$. At last, solving (15) yields the explicit form of A_0,

$$A_0(t,\vec{x}) = \frac{1}{e}\left(\sum_{i=1}^{3} F_{i0}(\omega_i)\,\frac{\partial \omega_i}{\partial x_j}\,\frac{\partial \omega_i}{\partial x_j} + T_0(t)\right) + iA_{ax_a} - eA_aA_a\,.$$

As the function A_0 is real valued, we have to find the real part of the right-hand side of the above equality. Making use of (40) yields

$$2eA_{ax_a} = \sum_{i=1}^{3} \frac{\dot{h}_i}{h_i}.$$

This, in its turn, gives the imaginary part of $T_0 = T_0(t)$,

$$T_0 = \tilde{T}_0 - \frac{i}{2}\sum_{i=1}^{3}\frac{\dot{h}_i}{h_i}, \quad \mathrm{Im}\,\tilde{T}_0 = 0. \tag{43}$$

Finally, we get

$$A_0(t,\vec{x}) = \frac{1}{e}\left(\sum_{i=1}^{3} F_{i0}(\omega_i)\frac{\partial\omega_i}{\partial x_j}\frac{\partial\omega_i}{\partial x_j} + \tilde{T}_0(t)\right) - eA_aA_a, \tag{44}$$

where $F_{10}(\omega_1), F_{20}(\omega_2), F_{30}(\omega_3)$ are arbitrary smooth functions, A_1, A_2, A_3 are given by (40), and the functions $\omega_a = \omega_a(t,\vec{x})$, $a=1,2,3$ are defined implicitly by formulas (20)–(22) and (4). In order to keep an exposition of the results compact, we do not present here $A_0(t,\vec{x})$ in full detail, since the corresponding expressions are too cumbersome.

Thus we have proved the following assertion.

Theorem 1: *SE (1) for the case of nonvanishing magnetic field admits separation of variables if and only if the spacelike components A_1, A_2, A_3 of the vector potential of the electromagnetic field are linear in the spatial variables and given by (40) and, furthermore, the timelike component A_0 is given by (44).*

Summing up, we conclude that conditions (40) and (44) provide separability of SE for the case of a nonvanishing magnetic field. And what is more, the solutions with separated variables are of the form (6) with $Q=1$, where the functions $\omega_1(t,\vec{x}), \omega_2(t,\vec{x}), \omega_3(t,\vec{x})$ are given implicitly by formulas (20)–(22) and (4). In fact, we have the 11 classes of vector potentials $A(t,\vec{x})$ corresponding to the 11 classes of coordinate systems $\omega_a = \omega_a(t,\vec{x})$, $a=1,2,3$. SE (1) for each class of the functions $A_0(t,\vec{x}), \vec{A}(t,\vec{x})$ defined by (40) and (44) under arbitrary $\tilde{T}_0(t), F_{a0}(\omega_a)$, and fixed arbitrary functions $\alpha(t), \beta(t), \gamma(t), w_a(t), h_a(t)$, $a=1,2,3$ separates in exactly one coordinate system. The separation equations read as (11), where the coefficients F_{ai}, $a,i=1,2,3$ are the entries of the corresponding Stäckel matrices (30), functions T_a, $a=1,2,3$ are listed in (34), and the functions T_0, F_{a0}, $a=1,2,3$ are arbitrary smooth functions defining the form of the timelike component of the vector potential $A(t,\vec{x})$ [see (44)].

Note that proper specifying the functions $F_{a0}(\omega_a)$, $a=1,2,3$, may yield additional possibilities for variable separation in the corresponding SE. What we mean is that for some particular forms of the vector potential $A(t,\vec{x})$ (40), (44) there might exist several coordinate systems (20)–(22) enabling us to separate the corresponding SE. However, the detailed study of this problem goes beyond the scope of the present paper.

As an illustration the previous section, we consider the problem of separation of variables in SE (1), where the vector potential of the electromagnetic field is of the form

$$2e\vec{A} = \begin{pmatrix} 0 & -s_1(t) & -s_2(t) \\ s_1(t) & 0 & -s_3(t) \\ s_2(t) & s_3(t) & 0 \end{pmatrix}\vec{x}, \tag{45}$$

$$eA_0 = \frac{q}{|\vec{x}|} - \frac{1}{4}\left((s_1(t)x_2 + s_2(t)x_3)^2 + (s_1(t)x_1 - s_3(t)x_3)^2 + (s_2(t)x_1 + s_3(t)x_2)^2\right).$$

Here $q=\text{const}$ and

$$s_1(t) = \dot{\alpha}(t) + \dot{\beta}(t)\cos\gamma(t),$$

$$s_2(t) = \dot{\beta}(t)\cos\alpha(t)\sin\gamma(t) - \dot{\gamma}(t)\sin\alpha(t),$$

$$s_3(t) = \dot{\beta}(t)\sin\alpha(t)\sin\gamma(t) + \dot{\gamma}(t)\cos\alpha(t),$$

where $\alpha(t), \beta(t), \gamma(t)$ are arbitrary smooth functions. Evidently, choosing $\alpha(t)=\text{const}$, $\beta(t)=\text{const}$, and $\gamma(t)=\text{const}$ yields the standard Coulomb potential.

Making use of the results of Theorem 1, we conclude that SE with potential of the form (45) separates in four coordinate systems,

$$\vec{x} = \mathcal{T}(t)\vec{z},$$

where $\mathcal{T}$ is the time-dependent 3×3 orthogonal matrix (21), and $\vec{z}$ is one of the following coordinate systems:

(1) spherical [formula 5 from (4)],

(2) prolate spheroidal II [formula 6 from (4)], where one should replace z_3 with $z_3=a(\coth\omega_1\tanh\omega_2\pm1)$,

(3) parabolic [formula 8 from (4)],

(4) conical [formula 11 from (4)].

The separation equations (11) for these cases take the form

(1)

$$
\begin{aligned}
&i\varphi_0'=-\lambda_1\varphi_0,\\
&\varphi_1''=(\lambda_1\omega_1^{-4}-\lambda_2\omega_1^{-2}+q\omega_1^{-3})\varphi_1,\\
&\varphi_2''=(\lambda_2\operatorname{sech}^2\omega_2-\lambda_3)\varphi_2,\\
&\varphi_3''=\lambda_3\varphi_3.
\end{aligned}
$$

Integrating these equations yields a family of exact solutions of SE (1) with potential (45) that are products of the exponential, confluent hypergeometric,[30] and Legendre[30] functions:

(2)

$$
\begin{aligned}
&i\varphi_0'=-\lambda_1\varphi_0,\\
&\varphi_1''=(\lambda_1a^2\sinh^{-4}\omega_1-\lambda_2\sinh^{-2}\omega_1-\lambda_3+qa\cosh\omega_1\sinh^{-3}\omega_1)\varphi_1,\\
&\varphi_2''=(\lambda_1a^2\cosh^{-4}\omega_2+\lambda_2\cosh^{-2}\omega_2-\lambda_3\mp qa\sinh\omega_2\cosh^{-3}\omega_2)\varphi_2,\\
&\varphi_3''=\lambda_3\varphi_3.
\end{aligned}
$$

Integrating these equations yields a family of exact solutions of SE (1) with potential (45) in separated form that are products of the exponential and Coulomb spheroidal functions.[31]

(3)

$$
\begin{aligned}
&i\varphi_0'=-\lambda_1\varphi_0,\\
&\varphi_1''=(\lambda_1e^{4\omega_1}-\lambda_2e^{2\omega_1}-\lambda_3+2qe^{2\omega_1})\varphi_1,\\
&\varphi_2''=(\lambda_1e^{4\omega_2}+\lambda_2e^{2\omega_2}-\lambda_3)\varphi_1,\\
&\varphi_3''=\lambda_3\varphi_3.
\end{aligned}
$$

Integrating these equations yields a family of exact solutions of SE (1) with potential (45) that are products of the exponential and confluent hypergeometric functions.

(4)

$$
\begin{aligned}
&i\varphi_0'=-\lambda_1\varphi_0,\\
&\varphi_1''=(\lambda_1\omega_1^{-4}-\lambda_2\omega_1^{-2}+q\omega_1^{-3})\varphi_1,\\
&\varphi_2''=(\lambda_2k'^2\operatorname{cn}^2(\omega_2,k')-\lambda_3)\varphi_2,\\
&\varphi_3''=(\lambda_2k^2\operatorname{cn}^2(\omega_3,k)+\lambda_3)\varphi_3.
\end{aligned}
$$

Integrating these equations yields a family of exact solutions of SE (1) with potential (45) that are products of the exponential, confluent hypergeometric, and Lamé[30] functions.

Note that these families are parametrized both by integration constants and by the three continuous spectral parameters $\lambda_i, i=1,2,3$. Under appropriate initial and boundary conditions the latter become discrete, i.e., $\lambda_i=\lambda_{in}, n=1,2,3,...$, and we get a basis for expanding arbitrary smooth solutions of SE (1) with potential (45) in a properly chosen Hilbert space (for more details, see Ref. 15).

B. The case of vanishing magnetic field

Provided condition (37) holds true, we can, without loss of generality, put $\vec{A}=0$ at the expense of the gauge invariance of SE. Representing the complex-valued function Q in (6) as $Q=\exp(S_1+iS)$, inserting into (14) and splitting the obtained equations into real and imaginary parts analogously to what has been done for the case of a nonvanishing magnetic field we arrive at the conclusion that S_1 may be chosen to be equal to zero. Furthermore, the function $S=S(t,\vec{x})$ satisfy the over-determined system of linear partial differential equations

$$2\frac{\partial S}{\partial x_j}\frac{\partial \omega_a}{\partial x_j}+\frac{\partial \omega_a}{\partial t}=0, \quad a=1,2,3. \tag{46}$$

Solving it with respect to the derivatives $\partial S/\partial x_j$, $j=1,2,3$ [which is always possible due to (18)] and making in the relations obtained the hodograph transformation (23), yields

$$2\vec{\nabla}S=\mathcal{M}(t)(\vec{x}-\vec{w})+\dot{\vec{w}}, \tag{47}$$

where $\mathcal{M}(t)$ is the 3×3 matrix (41) and $\vec{w}=(w_1(t),w_2(t),w_3(t))^T$. The direct check shows that system (47) is compatible if and only if all the expressions given in (42) vanish identically. Hence, we conclude that the matrix $\mathcal{T}$ is constant. Utilizing the invariance of SE (1) with respect to the rotation group we can choose $\mathcal{T}=I$, where I is the unit 3×3 matrix. Given this condition, (20) takes the form

$$\vec{x}=H(t)\vec{z}(\vec{\omega})+\vec{w}(t), \tag{48}$$

and, furthermore,

$$\mathcal{M}(t)=\dot{H}(t)H^{-1}(t).$$

Next, integrating (47) and taking into account the equivalence relation (10) we get

$$S=\frac{1}{2}\sum_{i=1}^{3}\left(\frac{\dot{h}_i}{h_i}\left(\frac{x_i^2}{2}-w_ix_i\right)+\dot{w}_ix_i\right). \tag{49}$$

Substituting (49) into (15) yields the form of $A_0(t,\vec{x})$,

$$eA_0(t,\vec{x})=\sum_{i=1}^{3}F_{i0}(\omega_i)\frac{\partial\omega_i}{\partial x_j}\frac{\partial\omega_i}{\partial x_j}+\tilde{T}_0(t)-\frac{1}{4}\sum_{i=1}^{3}\left(\frac{\ddot{h}_i}{h_i}x_i^2+2\left(\ddot{w}_i-\frac{\ddot{h}_i}{h_i}w_i\right)x_i+\left(\dot{w}_i-\frac{\dot{h}_i}{h_i}w_i\right)^2\right), \tag{50}$$

the function $T_0(t)$ being given by (43).

Thus, we have proved the following assertion.

Theorem 2: *Given the restriction (37), SE (1) admits a separation of variables if and only if it is gauge equivalent to SE with* $\vec{A}=\vec{0}$ *and* A_0 *being given by (50).*

Consequently, the conditions $\vec{A}=\vec{0}$ and (50) provide separability of SE for the case of a vanishing magnetic field. Furthermore, the solutions with separated variables are of the form (6) with $Q=\exp(iS)$, where $S=S(t,\vec{x})$ is given by (49), the functions $\omega_1(t,\vec{x}),\omega_2(t,\vec{x}),\omega_3(t,\vec{x})$ are given implicitly by formulas (48), (22), and (4). Again, we have the 11 classes of vector potentials $A(t,\vec{x})$ corresponding to the 11 classes of coordinate systems $\omega_a=\omega_a(t,\vec{x})$, $a=1,2,3$. SE (1) for each class of the functions $A_0(t,\vec{x}),\vec{A}(t,\vec{x})=\vec{0}$ defined by (50) under arbitrary $\tilde{T}_0(t),F_{a0}(\omega_a)$, and fixed arbitrary functions $w_a(t),h_a(t)$, $a=1,2,3$ separates in exactly one coordinate system. The separation equations read as (11), where the coefficients F_{ai}, $a,i=1,2,3$ are the entries of the corresponding Stäckel matrices (30), functions T_a, $a=1,2,3$ are listed in (34) and the functions $T_0,F_{a0},a=1,2,3$ are arbitrary smooth functions defining the form of the timelike component of the vector potential $A(t,\vec{x})$ [see (50)].

If we fix the temporal variable t to be equal to $t_0\in\mathbf{R}$ in the above obtained results, then it is not difficult to classify separable stationary Schrödinger equations for a particle interacting with the electromagnetic field $A(\vec{x})=(A_0(\vec{x}),\vec{A}(\vec{x}))$,

$$(p_ap_a+eA_0+E)\psi(\vec{x})=0, \tag{51}$$

where $p_a=i\partial/\partial x_a-eA_a$, $a=1,2,3$, $e=\text{const}$, and E is a spectral parameter, and thus recover the classical result by Eisenhart.[9]

III. SEPARATION OF VARIABLES IN THE HAMILTON–JACOBI EQUATION

It is well known that there exists a deep connection between the separation of variables in the Schrödinger and Hamilton–Jacobi equations (see, e.g., Ref. 16). The Hamilton–Jacobi equation,

$$u_t+eA_0+(u_{x_a}+eA_a)(u_{x_a}+eA_a)=0, \tag{52}$$

separates in any coordinate system providing separability of the Schrödinger equations (1) and, what is more, the inverse assertion is not true. We will make use of this connection for the sake of classifying separable Hamilton–Jacobi equations.

First we fix the usual form of the separation *Ansatz* for the Hamilton–Jacobi equation,

$$u(t,\vec{x})=S(t,\vec{x})+\varphi_0(t)+\sum_{i=1}^{3}\varphi_i(\omega_i(t,\vec{x})), \tag{53}$$

and, furthermore, fix the form of the ordinary differential equations for $\varphi_0,\varphi_1,\varphi_2,\varphi_3$,

$$\varphi_0'=-T_0(t)-T_i(t)\lambda_i,\quad \varphi_a'=(-F_{a0}(\omega_a)+F_{ai}(\omega_a)\lambda_i)^{1/2}. \tag{54}$$

Now, inserting the *Ansatz* (53) into Eq. (52), eliminating the first derivatives of the functions $\varphi_0,\varphi_1,\varphi_2,\varphi_3$ with the use of the above equations and splitting by the variables $\varphi_0,\varphi_1,\varphi_2,\varphi_3,\lambda_1,\lambda_2,\lambda_3$, we arrive at the following system of nonlinear partial differential equations for the functions $S,\omega_1,\omega_2,\omega_3$:

$$\frac{\partial\omega_i}{\partial x_a}\frac{\partial\omega_j}{\partial x_a}=0,\quad i\neq j,\quad i,j=1,2,3;$$

$$\sum_{i=1}^{3}F_{ia}(\omega_i)\frac{\partial\omega_i}{\partial x_j}\frac{\partial\omega_i}{\partial x_j}=T_a(t),\quad a=1,2,3;$$

$$2\left(\frac{\partial S}{\partial x_j}+eA_j\right)\frac{\partial\omega_a}{\partial x_j}+\frac{\partial\omega_a}{\partial t}=0,\quad a=1,2,3;$$

$$-\sum_{i=1}^{3}F_{i0}(\omega_i)\frac{\partial\omega_i}{\partial x_j}\frac{\partial\omega_i}{\partial x_j}+\frac{\partial S}{\partial t}+2eA_a\frac{\partial S}{\partial x_a}+\frac{\partial S}{\partial x_a}\frac{\partial S}{\partial x_a}-T_0(t)+eA_0+e^2A_aA_a=0. \tag{55}$$

The general solution $\vec{\omega}=\vec{\omega}(t,\vec{x})$ of the first six equations of the above system [which coincide with Eqs. (12) and (13)] can be reduced with the help of an appropriate equivalence transformation $\mathcal{E}$ to such a form that it satisfies the Laplace equation (5).

It is not difficult to become convinced of the fact that making the change of variables,

$$Q(t,\vec{x})=\exp(iS(t,\vec{x})), \tag{56}$$

in (12)–(15) yields the system that coincides with (55) with an exception of the last equation, where an additional term $-i(\Delta S+eA_{ax_a})$ appears. As shown in the previous section, this term is a function of t only and is absorbed by T_0. Consequently, all the results on variable separation for SE apply to the case of the Hamilton–Jacobi equation (52) as well.

IV. CONCLUDING REMARKS

Theorems 1–2 give a complete solution of the problem of classification of SE's (1) and (51) that are solvable within the framework of the method of separation of variables. By appropriate reductions of these results we can get the results on the separation of variables in SE's for a particle interacting with the electromagnetic field in one[24] and two[26,27] spatial dimensions. For example, in order to recover the results of Ref. 27 one has to choose $\partial\psi/\partial x_3=0$ and consider the completely and partially split coordinate systems from the list (4).

It follows from Theorem 1 that the choice of magnetic fields $\vec{H}$ allowing for variable separation in the corresponding SE is very restricted. Namely, the magnetic field should be independent of spatial variables x_1,x_2,x_3 in order to provide the separability of SE (1) into three second-order ordinary differential equations. However, if we allow for separation equations to be of lower order, then additional possibilities for variable separation in SE arise. As an example we give the vector-potential,

$$A(t,\vec{x})=(A_0(\sqrt{x_1^2+x_2^2}),0,0A_3(\sqrt{x_1^2+x_2^2})),$$

where A_0,A_3 are arbitrary smooth functions. SE (1) with this vector potential separates in the cylindrical coordinate system $t,\omega_1=\ln(\sqrt{x_1^2+x_2^2})$, $\omega_2=\arctan(x_1/x_2)$, $\omega_3=x_3$ into two first-order and one second-order ordinary differential equations. The corresponding magnetic field $\vec{H}=\operatorname{rot}\vec{A}$ is evidently x dependent.

As mentioned in the Introduction, a possibility of variable separation in SE is intimately connected to its symmetry properties. Namely, solutions with separated variables are common eigenfunctions of three mutually commuting symmetry operators of SE. For all the cases of variable separation in SE (1) these operators can be constructed in explicit form, in analogy to what has been done in Ref. 26 for the $(1+2)$-dimensional case. They are expressed in terms of the coefficients of the separation equations (11). This fact enables application of the methods of the representation theory of Lie algebras for a further analysis of special functions arising as solutions of separation equations in the spirit of the famous Bateman's project [15].

The last remark is that the technique developed in the present paper can be directly applied in order to separate variables in the Pauli equation for a particle with spin $\frac{1}{2}$ moving in the electromagnetic field and in the Fokker–Planck equation with a constant diagonal diffusion matrix.

A study of the above-mentioned problems is in progress now and will be reported in our future publications.

(Received 25 May 1999; accepted for publication 14 June 1999)

Let $q_1, q_2, \ldots, q_N$ be the coordinates of N particles on the circle, interacting with the integrable potential $\Sigma_{j<k}^{N} \wp(q_j - q_k)$, where $\wp$ is the Weierstrass elliptic function. We show that every symmetric elliptic function in $q_1, q_2, \ldots, q_N$ is a meromorphic function in time. We give explicit formulas for these functions in terms of genus $N-1$ theta functions.
[S0022-2488(99)01512-1]

I. INTRODUCTION

The elliptic Calogero system,[1]

$$\frac{d^2}{dt^2} q_i = -\sum_{j \neq i} \wp'(q_i - q_j), \quad i = 1,2,\ldots,N \tag{1.1}$$

is a canonical Hamiltonian system, describing the motion of N particles on the circle $S^1 = \mathbb{R}/\omega\mathbf{Z}$, $\omega \in \mathbb{R}$, with Hamiltonian (energy)

$$H = \frac{1}{2} \sum_{j=1}^{N} p_j^2 + \sum_{j<k}^{N} \wp(q_j - q_k), \tag{1.2}$$

where $\wp(q) = \wp(q|\omega, \omega')$ is the Weierstrass elliptic function

$$\wp(q|\omega,\omega') = \sum_{m,n \in \mathbf{Z}} (q + m\omega + n\omega')^{-2}, \quad \omega'/\omega \notin \mathbb{R}. \tag{1.3}$$

Denote by Γ_1 the elliptic curve $\mathbb{C}/\{2\omega\mathbf{Z} + 2\omega'\mathbf{Z}\}$ with period lattice generated by 2ω and $2\omega'$. The Hamiltonian H is invariant under the obvious action of the permutation group $\mathcal{S}_n$, so the phase space of the compexified system is the cotangent bundle $T^*(S^N\Gamma_1)$ of the Nth symmetric product $S^N\Gamma_1$.

It is known that this system has two Lax representations (Refs. 1, 2, also see Ref. 3 for details). The Lax operator L defines N integrals of motion $I_k(p,q) = k^{-1}\mathrm{tr}(L^k), k = 1,\ldots,N$. It was proved in Ref. 4 that these integrals are in involution and hence this system is completely integrable in the Jacobi–Liouville sense.[5,6]

The Krichever Lax pair has a spectral parameter. This means that the equations of motion of the system under consideration are equivalent to the matrix equation

$$i\dot{L}(\lambda) = [L(\lambda), M(\lambda)], \tag{1.4}$$

a)Electronic mail: gavrilov@picard.ups-tlse.fr.
b)On leave of absence from Institute for Theoretical and Experimental Physics, 117259 Moscow, Russia. Current electronic mail: perelomo@posta.unizar.es.

where $L(\lambda)=L(p,q;\lambda)$ and $M(\lambda)=M(p,q;\lambda)$ are two matrices of order N,

$$\{L(\lambda)\}_{jk}=p_j\,\delta_{jk}+i\,(1-\delta_{jk})\,\Phi(q_j-q_k,\lambda); \tag{1.5}$$

$$\{M(\lambda)\}_{jk}=\delta_{jk}\left(\sum_{l\neq j}\wp(q_j-q_l)-\wp(\lambda)\right)+(1-\delta_{jk})\,\Phi'(q_j-q_k,\lambda); \tag{1.6}$$

$$\Phi(q,\lambda)=\frac{\sigma(q-\lambda)}{\sigma(q)\,\sigma(\lambda)}\exp(\zeta(\lambda)\,q); \tag{1.7}$$

$$\sigma(q)=q\prod_{m,n}{}'\left(1-\frac{q}{\omega_{mn}}\right)\exp\left[\frac{q}{\omega_{mn}}+\frac{1}{2}\left(\frac{q}{\omega_{mn}}\right)^2\right], \tag{1.8}$$

$$\zeta(q)=\frac{\sigma'(q)}{\sigma(q)},\quad \omega_{mn}=m\omega+n\omega'.$$

As it was shown by Krichever,[2] the equations of motion may be ''linearized'' on the Jacobian of the spectral curve

$$\Gamma^N=\{(\lambda,\mu): f(\lambda,\mu)\equiv\det(L(\lambda)-\mu I)=0\}. \tag{1.9}$$

Namely, let

$$\theta(\mathbf{z}|B)=\sum_{\mathbf{N}\in\mathbf{Z}^N}e^{\pi i\langle\mathbf{N},B\mathbf{N}\rangle+2\pi i\langle\mathbf{N},\mathbf{z}\rangle},\quad \mathbf{z}\in\mathbb{C}^N \tag{1.10}$$

be the Riemann theta function with period matrix B, where

$$B=(B_{ij}),\quad B=B^t,\quad \operatorname{Im}B>0,\quad \langle x,y\rangle=\sum_j x_jy_j,\quad i,j=1,\ldots,N.$$

It has been shown by Krichever[2] that, if B is the period matrix of the curve Γ^N, then for suitable constant vectors $U,V,W\in\mathbb{C}^N$ and for a fixed parameter $t\in\mathbb{C}$, the equation

$$\theta(Uq+Vt+W)=0,\quad q\in\mathbb{C} \tag{1.11}$$

has exactly N solutions $q=q_j(t)$ on the Jacobian Jac (Γ^N) of the curve Γ^N. The functions $q_j(t)$ provide solutions of the elliptic Calogero system (1.1). The equation (1.11) for these solutions is, however, not explicit and seems to be not well understood.

The aim of the present paper is to give ''the effectivization'' of these formulas based on the projection method by Olshanetsky and Perelomov[7,8] of explicit integration of the equations of motion in the rational and the trigonometric cases, as well as on the algebro-geometric approach of Krichever.[9,2]

II. EXPLICIT SOLUTIONS

Let Γ_N be a genus N Riemann surface which is an N-sheeted covering of an elliptic curve Γ_1,

$$\Gamma_N\xrightarrow{\pi}\Gamma_1. \tag{2.1}$$

It follows from a theorem of Weierstrass (see, for example, Refs. 10, 11, 12, and 13, Theorem 7.4) that the period matrix of the curve Γ_N in a suitable basis has the form (I,B), where $I=\operatorname{diag}(1,1,\ldots,1)$, and

$$B=\begin{pmatrix} \frac{\tau}{N} & \frac{k}{N} & 0 & \dots & 0 \\ \frac{k}{N} & b_{22} & b_{23} & \dots & b_{2N} \\ 0 & b_{32} & b_{33} & \dots & b_{3N} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & b_{N2} & b_{N3} & \dots & b_{NN} \end{pmatrix} \tag{2.2}$$

for a suitable positive integer k. Consider the Riemann theta function $\theta(x,\mathbf{t})=\theta(x,\mathbf{t}|B)$, where $\mathbf{t}=(t_1,t_2,\dots,t_{N-1})$, $(x,\mathbf{t})\in\mathbb{C}^N$. We have

$$\theta(x+1,\mathbf{t})=\theta(x,\mathbf{t}),\theta(x+\tau,\mathbf{t})=e^{-2\pi iNx-\pi iN\tau}\theta(x,\mathbf{t}),i=\sqrt{-1} \tag{2.3}$$

and therefore for any fixed $\mathbf{t}$ the function $\theta(x,\mathbf{t})$ is an elliptic theta function of order N.[14] In particular it has exactly N zeros on $\Gamma_1=\mathbb{C}/\{\mathbf{Z}+\tau\mathbf{Z}\}$ which we denote by $x_i(\mathbf{t})$, $i=1,2,\dots,N$.

Lemma 2.1: *The following identity holds:*

$$\frac{\partial^2}{\partial x^2}\log\ \theta(x,\mathbf{t}|B)=\sum_{i=1}^{N}\wp(x-x_i(\mathbf{t})|\tau)+N\frac{\theta_1'''(0)}{3\theta_1'(0)},$$

where[15]

$$\theta_1(x|\tau)=\theta\begin{bmatrix}1/2\\1/2\end{bmatrix}(x|\tau).$$

Proof: The relations

$$\theta_1(x+1)=-\theta_1(x),\theta_1(x+\tau)=-e^{-2\pi ix-\pi i\tau}\theta_1(x) \tag{2.4}$$

compared to (2.3) imply that

$$\left(\frac{\theta(x,\mathbf{t})}{\prod_{i=1}^{N}\theta_1(x-x_i(\mathbf{t}))}\right)^2 \tag{2.5}$$

is a meromorphic function in x on Γ_1 which has no poles, and hence it is a constant (in x). It follows that

$$\frac{\partial^2}{\partial x^2}\log\frac{\theta(x,\mathbf{t})}{\prod_{i=1}^{N}\theta_1(x-x_i(\mathbf{t}))}\equiv 0.$$

Finally we use that

$$\wp(x)=-\frac{\partial^2}{\partial x^2}\log\sigma(x),\qquad \theta_1(x)=c\ \exp(\eta x^2)\ \sigma(x), \tag{2.6}$$

where

$$\eta=-\frac{\theta_1'''(0)}{6\theta_1'(0)}$$

and c is a suitable constant.[15] □

Theorem 2.2: *The Krichever curve Γ^N is an N-sheeted covering of an elliptic curve $\Gamma_1 = \mathbb{C}/\{\mathbf{Z}+\tau\mathbf{Z}\}$. There exists a canonical homology basis and a normalized basis of holomorphic one-forms on Γ^N, such that the corresponding period matrix of Γ_N takes the form (I,B), where $I=\mathrm{diag}(1,1,\ldots,1)$, and*

$$B=\begin{pmatrix} \frac{\tau}{N} & \frac{1}{N} & 0 & \ldots & 0 \\ \frac{1}{N} & b_{22} & b_{23} & \ldots & b_{2N} \\ 0 & b_{32} & b_{33} & \ldots & b_{3N} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & b_{N2} & b_{N3} & \ldots & b_{NN} \end{pmatrix}. \tag{2.7}$$

In the same basis the vectors U and V in (1.11) *read*

$$U=(1,0,\ldots,0), V=(0,V_2,\ldots,V_N). \tag{2.8}$$

A direct proof (without using the Weierstrass theorem) of the above Theorem will be given in the last section. From now on we make the convention that $2\omega=1$ so the period lattice of Γ_1 is

$$\mathbf{Z}+\tau\mathbf{Z}, \quad \tau=2\omega'/2\omega=2\omega'.$$

Corollary 2.3: The symmetric functions

$$f_k(t)=\sum_{i=1}^{N} \wp^{(k)}(q_i(t))$$

are meromorphic in t. Explicit formulas for them are obtained from Lemma 2.1,

$$f_0(t)=\frac{\partial^2}{\partial x^2}\log\,\theta(x,\mathbf{t})\big|_{x=0}-N\frac{\theta_1'''(0)}{3\theta_1'(0)},$$

$$f_k(t)=(-1)^k\frac{\partial^{k+2}}{\partial x^{k+2}}\log\,\theta(x,\mathbf{t})\big|_{x=0}, \quad k>0,$$

where

$$\mathbf{t}=(V_2t+W_2,V_3t+W_3,\ldots,V_Nt+W_N).$$

Our next construction is motivated by Refs. 7, 8, and 2. Let us define the function

$$F(x,t)=\prod_{j=1}^{N}\frac{\sigma(x-q_j(t))}{\sigma(x)\sigma(q_j(t))}=[\theta_1'(0)]^{-N}]\prod_{j=1}^{N}\frac{\theta_1(x-q_j(t))}{\theta_1(x)\theta_1(q_j(t))}, \quad \sum_{j=1}^{N} q_j(t)=0, \tag{2.9}$$

where

$$q_j(t), \quad t\in\mathbb{C}, \quad j=1,2,\ldots,N,$$

is a solution of the elliptic Calogero system.

Lemma 2.4: $F(x,t)$ is a meromorphic function in x on Γ_1 and meromorphic function in t on $\mathbb{C}$, explicitly given by

$$F(x,t)=[-\theta_1'(0)]^{-N}]\frac{\theta(Ux+Vt+W)}{\theta_1(x)^N\theta(Vt+W)}. \tag{2.10}$$

Proof: We already noted that the function (2.5) is a constant in *x*, and hence

$$\frac{\theta(x,\mathbf{t})}{\Pi_{i=1}^N\theta_1(x-x_i(\mathbf{t}))}\equiv\frac{\theta(0,\mathbf{t})}{\Pi_{i=1}^N\theta_1(-x_i(\mathbf{t}))}.$$

This combined with (2.8) gives

$$\frac{\Pi_{i=1}^N\theta_1(x-q_i(t))}{\Pi_{i=1}^N\theta_1(q_i(t))}=(-1)^N\frac{\theta(Ux+Vt+W)}{\theta(Vt+W)}.$$

□

The expansion of $F(x,t)$ on the basis of first order theta functions in x defines $(N-1)$ meromorphic functions in the variables $q_1,\ldots,q_N$ which are also meromorphic functions in t with only simple poles. Hence we can take them as new ''good'' variables. The expansion of $F(x,t)$ can be obtained by making use of the addition formulas for elliptic functions. In the case $N=2$, we have the following ''addition formula''[15]

$$F(x,t)=-\frac{\sigma(x-q)\,\sigma(x+q)}{\sigma^2(x)\sigma^2(q)}=\wp(x)-\wp(q), \tag{2.11}$$

which generalizes for arbitrary N in the following way

Lemma 2.5: For any $\mathbf{q}=(q_1,q_2,\ldots,q_N),x$, *such that* $\Sigma q_j=0$ *define*

$$F(x,\mathbf{q})=\prod_{j=1}^N\frac{\sigma(x-q_j)}{\sigma(x)\sigma(q_j)}, \tag{2.12}$$

$$\Delta(\mathbf{q})=(N-1)!\det\begin{vmatrix}1 & \wp(q_1) & \wp'(q_1) & \ldots & \wp^{(N-3)}(q_1)\\ 1 & \wp(q_2) & \wp'(q_2) & \ldots & \wp^{(N-3)}(q_2)\\ \ldots & \ldots & \ldots & \ldots & \ldots\\ 1 & \wp(q_{N-1}) & \wp'(q_{N-1}) & \ldots & \wp^{(N-3)}(q_{N-1})\end{vmatrix}. \tag{2.13}$$

The following identity holds:

$$F(x,\mathbf{q})\Delta(\mathbf{q})\equiv\det\begin{vmatrix}1 & \wp(x) & \wp'(x) & \ldots & \wp^{(N-2)}(x)\\ 1 & \wp(q_1) & \wp'(q_1) & \ldots & \wp^{(N-2)}(q_1)\\ \ldots & \ldots & \ldots & \ldots & \ldots\\ 1 & \wp(q_{N-1}) & \wp'(q_{N-1}) & \ldots & \wp^{(N-2)}(q_{N-1})\end{vmatrix}. \tag{2.14}$$

Remark: The substitution $x=q_N$ in (2.14) gives the following addition formula for the Weierstrass $\wp$-function:

$$\det\begin{vmatrix}1 & \wp(q_1) & \wp'(q_1) & \ldots & \wp^{(N-2)}(q_1)\\ 1 & \wp(q_2) & \wp'(q_2) & \ldots & \wp^{(N-2)}(q_2)\\ \ldots & \ldots & \ldots & \ldots & \ldots\\ 1 & \wp(q_N) & \wp'(q_N) & \ldots & \wp^{(N-2)}(q_N)\end{vmatrix}\equiv 0. \tag{2.15}$$

Proof: For fixed $\mathbf{q}=(q_1,q_2,\ldots,q_N)$ the functions in the left and right-hand side of the identity (2.14) are meromorphic in x on the elliptic curve Γ_1. Both of them have a pole of order N at $x=0$ and simple zeros at $x=q_1,\ldots,q_{N-1}$. It follows that their ratio is a first order elliptic function, and hence a constant in x. To compute this constant we use that $\sigma(x)=x+\ldots$, $\wp(x)=1/x^2+\ldots$, and then compare the Laurent series of the two functions in a neighborhood of $x=0$. □

Note finally that if for fixed $\mathbf{q}$ and $\tilde{\mathbf{q}}$ holds $F(x,\mathbf{q})\equiv F(x,\tilde{\mathbf{q}})$, then up to a permutation $\mathbf{q}=\tilde{\mathbf{q}}$. Therefore there is a one-to-one correspondence between the coefficients of $\wp^k(x)$ in the expansion of $F(x,\mathbf{q})$, and the points of the $(N-1)$th symmetric power of the elliptic curve $\Gamma_1\setminus\{0\}$. In particular every meromorphic function on this symmetric power is a rational function in the above coefficients. This implies the following:

Corollary 2.6: Let $f(x)$ be a meromorphic function on the elliptic curve Γ_1, and let S be a symmetric rational function in $N-1$ variables. If $q_1(t),q_2(t),\ldots,q_N(t)$, $\Sigma q_i\equiv 0$ is a solution of the elliptic Calogero system, then $S(f(q_1(t),f(q_2(t)),\ldots,f_{N-1}(q_{N-1}(t)))$ is a meromorphic function in t.

The further analysis of the explicit formulas for the solutions of the elliptic Calogero system can be based on Lemma 2.4, Lemma 2.5, and the identity

$$F(x,t)\equiv F(x,\mathbf{q}(t)).$$

Consider the seemingly trivial case of two particles $(N=2)$. Let us give first an explanation of the Krichever formula (1.11) for the solutions $q_1(t)=-q_2(t)$. Put $q_1-q_2=q$ and $p_1=-p_2=p$. The Hamiltonian H becomes $H(p,q)=p^2+\wp(q)$, and the reduced Hamiltonian system is

$$\frac{d}{dt}q=2p,\ \ \frac{d}{dt}p=-\wp'(q),\ \ (q,p)\in T^*\Gamma_1. \tag{2.16}$$

The Lax matrix L is

$$L(\lambda)=\begin{pmatrix} p & i\Phi(q,\lambda) \\ i\Phi(-q,\lambda) & -p \end{pmatrix}$$

and the corresponding spectral polynomial

$$\det(L(\lambda)-\mu I)=\mu^2-p^2+\Phi(q,\lambda)\Phi(-q,\lambda)=\mu^2-p^2+\wp(\lambda)-\wp(q)=\mu^2+\wp(\lambda)-H(p,q)$$

defines a spectral curve

$$\Gamma_2=\{(\mu,\lambda):\mu^2+\wp(\lambda)=h\}.$$

Suppose that $h=H(p,q)$ is fixed in such a way, that the meromorphic function $\wp(\lambda)-h$ has two distinct zeros on Γ_1. The spectral curve Γ_2 is a double ramified covering over the elliptic curve Γ_1 with projection map $\pi:\Gamma_2\to\Gamma_1:(\mu,\lambda)\to\lambda$. It follows that Γ_2 is a genus two curve with holomorphic differentials

$$\omega_1=d\lambda,\quad \omega_2=\frac{d\lambda}{\mu}.$$

On the other hand Γ_2 is identified to the orbit

$$\{(p,q)\in T^*\Gamma_1=:H(p,q)=h\}$$

under the map

$$(p,q)\to(\mu,\lambda).$$

Consider further the embedding of the orbit Γ_2 into its Jacobian variety Jac(Γ_2)

$$\Gamma_2 \to \mathrm{Jac}(\Gamma_2): P \to \left(\int_{P_0}^{P} d\lambda, \int_{P_0}^{P} \frac{d\lambda}{\mu} \right). \tag{2.17}$$

By the Riemann theorem,[16] the curve $\Gamma_2 \subset \mathrm{Jac}(\Gamma_2)$ defines a divisor which coincides, up to addition of a constant, with the Riemann theta divisor $\Theta \subset \mathrm{Jac}(\Gamma_2)$ on the Jacobian variety $\mathrm{Jac}(\Gamma_2)$.

Let $(p(t),q(t))$ be a solution of the elliptic Calogero system, with initial condition $(p(t_0),q(t_0)) = P_0$. Taking into consideration that

$$\frac{d\lambda}{\mu} = 2\,dt, \quad d\lambda = dq, \quad (\lambda,\mu) \in \Gamma_2,$$

formula (2.17) takes the form

$$T^*\Gamma_1 = \mathbb{C} \times \Gamma_1 \ni (p(t),q(t)) \to (2t - 2t_0, q(t) - q(t_0)) \in \mathrm{Jac}(\Gamma_2). \tag{2.18}$$

It follows that there exist constant vectors $\mathbf{a},\mathbf{b},\mathbf{c} \in \mathbb{C}^2$ such that

$$\theta(\mathbf{a}q(t) + \mathbf{b}t + \mathbf{c}) \equiv 0. \tag{2.19}$$

Of course these constants depend on the choice of symplectic homology basis and the choice of normalized basis of holomorphic one-forms. Namely, let a,b be two loops on Γ_1, such that $\pi^{-1}(a) = \{a_1,a_2\}$, $\pi^{-1}(b) = \{b_1,b_2\}$, where a_i,b_j represent an integer symplectic homology basis on Γ_2: $a_i \circ b_j = \delta_{ij}$, $a_i \circ a_j = 0$, $b_i \circ b_j = 0$. Then,

$$\int_{a_1} d\lambda = \int_{a_2} d\lambda, \quad \int_{b_1} d\lambda = \int_{b_2} d\lambda,$$

$$\int_{a_1} \frac{d\lambda}{\mu} = -\int_{a_2} \frac{d\lambda}{\mu}, \quad \int_{b_1} \frac{d\lambda}{\mu} = -\int_{b_2} \frac{d\lambda}{\mu}.$$

If we define a new symplectic basis

$$\tilde{a}_1 = a_1 + a_2, \tilde{a}_2 = b_1 - b_2, \tilde{b}_1 = b_1, \tilde{b}_2 = a_2$$

and normalize the two holomorphic one-forms as

$$d\lambda \to \frac{d\lambda}{\int_{\tilde{a}} \pi^* d\lambda} = \frac{d\lambda}{2\int_a d\lambda}, \quad \frac{d\lambda}{\mu} \to \frac{d\lambda/\mu}{\int_{\tilde{a}_2} d\lambda/\mu},$$

then the period matrix of Γ_2 takes the form

$$\begin{pmatrix} 1 & 0 & \tau_1/2 & 1/2 \\ 0 & 1 & 1/2 & \tau_2/2 \end{pmatrix},$$

where

$$\tau_1 = \frac{\int_b d\lambda}{\int_a d\lambda}, \tau_2 = \frac{\int_{a_2} d\lambda/\mu}{\int_{b_1} d\lambda/\mu}.$$

This, together with (2.18) implies that

$$\mathbf{a}=\left(\frac{1}{\int_{\tilde{a}_1} d\lambda},0\right)=\left(\frac{1}{2\int_a d\lambda},0\right),\mathbf{b}=\left(0,\frac{1}{\int_{b_1} d\lambda/\mu}\right).$$

Finally the vector $\mathbf{c}$ is arbitrary and plays the role of initial condition. The function $F(x,t)$ defined in (2.9) takes the form

$$F(x,t)=-\frac{\sigma(x-q(t))\,\sigma(x+q(t))}{\sigma^2(x)\sigma^2(q(t))} \tag{2.20}$$

and hence[15,17]

$$F(x,t)=\wp(x)-\wp(t). \tag{2.21}$$

So the elliptic function $\wp(q|\omega,\omega')$, and also

$$\mathrm{sn}^2(q,k)\sim\frac{\theta_1^2(q|k)}{\theta_4^2(q|k)},\quad \mathrm{cn}^2(q,k)\sim\frac{\theta_2^2(q|k)}{\theta_4^2(q|k)},\quad \mathrm{dn}^2(q,k)\sim\frac{\theta_3^2(q|k)}{\theta_4^2(q|k)} \tag{2.22}$$

are ''good'' variables (in the sense that they are meromorphic in t). The equation of motion for them takes a very simple form. We get

$$\mathrm{sn}^2(q,k)=1-a^2+a^2\,\mathrm{sn}^2(\gamma t,\tilde{k}), \tag{2.23}$$

where

$$a^2=\frac{h-1}{h},\quad \gamma=2(h-k^2),\quad \tilde{k}^2=\frac{h-1}{h-k^2}\,k^2. \tag{2.24}$$

One can easily show that the even functions $\mathrm{cn}\,(q,k)$ and $\mathrm{dn}\,(q,k)$ (but not $\mathrm{sn}\,(q,k)$) are ''good'' variables and we get as in[3]

$$\mathrm{cn}\,(q,k)=\alpha\,\mathrm{cn}\,(\gamma t,\tilde{k}), \tag{2.25}$$

$$\mathrm{dn}\,(q,k)=\beta\,\mathrm{dn}\,(\gamma t,\tilde{k}),\ b=(k/\tilde{k})a. \tag{2.26}$$

III. REDUCTION OF THETA FUNCTIONS

The reduction theory was elaborated by Weierstrass (see, for example, Ref. 10) and Poincaré.[11,12] Consider first the case $N=2$. The Riemann theta function associated with the Riemann matrix (2.7) has the form,

$$\theta(z_1,z_2)=\sum_{n_i,n_j}\exp\{i\pi[B_{ij}n_in_j+2n_jz_j]\},\quad i,j=1,2, \tag{3.1}$$

where

$$B_{11}=\tau_1/2,\quad B_{22}=\tau_2/2,\quad B_{12}=B_{21}=1/2.$$

A straightforward computation gives

$$\theta(z_1,z_2)=\sum_{n_1,n_2}\exp\left\{i\pi\left[\tau_1\frac{n_1^2}{2}+n_1n_2+\tau_2\frac{n_2^2}{2}+2n_1z_1+2n_2z_2\right]\right\}$$
$$=\sum_{k_1,n_2\in\mathbf{Z}}\exp\{i\pi[2\tau_1k_1^2+4k_1z_1]\}\exp\left\{i\pi\left[\tau_2\frac{n_2^2}{2}+2n_2z_2\right]\right\}$$
$$+\sum_{k_1,n_2\in\mathbf{Z}}\exp\left\{i\pi\left[2\tau_1\left(k_1+\frac{1}{2}\right)^2+4\left(k_1+\frac{1}{2}\right)z_1\right]\right\}\exp\left\{i\pi\left[\tau_2\frac{n_2^2}{2}+2\left(n_2+\frac{1}{2}\right)z_2\right]\right\}$$
$$=\theta_3(2z_1|2\tau_1)\ \theta_3\left(z_2\left|\ \frac{\tau_2}{2}\right.\right)+\theta_2(2z_1|2\tau_1)\ \theta_4\left(z_2\left|\ \frac{\tau_2}{2}\right.\right),$$

where $\theta_1,\theta_2,\theta_3$, and θ_4 are defined by formulas,

$$\theta_1(z|\tau)=\theta\begin{bmatrix}1/2\\1/2\end{bmatrix}(z|\tau)=2q^{1/4}\sum_{n=1}^{\infty}(-1)^nq^{n(n+1)}\sin[(2n+1)\pi z];\tag{3.2}$$

$$\theta_2(z|\tau)=\theta\begin{bmatrix}1/2\\0\end{bmatrix}(z|\tau)=2q^{1/4}\sum_{n=1}^{\infty}q^{n(n+1)}\cos[(2n+1)\pi z];\tag{3.3}$$

$$\theta_3(z|\tau)=\theta\begin{bmatrix}0\\0\end{bmatrix}(z|\tau)=1+2\sum_{n=1}^{\infty}q^{n^2}\cos(2\pi nz);\ q=\exp(i\pi\tau);\tag{3.4}$$

$$\theta_4(z|\tau)=\theta\begin{bmatrix}0\\1/2\end{bmatrix}(z,\tau)=1+2\sum_{n=1}^{\infty}(-1)^nq^{n^2}\cos(2\pi nz).\tag{3.5}$$

So in this case, the equation $\theta(z_1,z_2)=0$ is equivalent either to

$$A\ \mathrm{dn}(2z_1|4\tau_1)\ \mathrm{dn}(z_2|\tau_2)+\mathrm{cn}(2z_1|4\tau_1)=0,\tag{3.6}$$

or to

$$A\ \mathrm{dn}(2z_2|4\tau_2)\ \mathrm{dn}(z_1|\tau_1)+\mathrm{cn}(2z_2|4\tau_2)=0,\tag{3.7}$$

where

$$A=\frac{\theta_3(0|4\tau_1)\ \theta_3(0|\tau_2)}{\theta_2(0|4\tau_1)\ \theta_4(0|\tau_2)}\tag{3.8}$$

or

$$\mathrm{dn}(z_1|\tau_1)=B\ \mathrm{dn}(2iz_2+K|\tilde{\tau}_2).\tag{3.9}$$

Let us give also a more symmetric form of the theta divisor for this case,

$$\mathrm{dn}(2z_1,k_1)\ \mathrm{dn}(2z_2,k_2)+\mathrm{dn}(2z_1,k_1)\ \mathrm{cn}(2z_2,k_2)+\mathrm{cn}(2z_1,k_1)\ \mathrm{dn}(2z_2,k_2)$$
$$-\mathrm{cn}(2z_1,k_1)\ \mathrm{cn}(2z_2,k_2)=0.\tag{3.10}$$

Using the constraint $\theta(\mathbf{a}x+\mathbf{b}t+\mathbf{c})=0$ and taking $z_1=q$, $z_2=(1/2)K+i\gamma t$, we get once again (2.25) and (2.26).

Consider now the case of arbitrary N. Let $\theta(z_1,z_2,\ldots,z_N|B)$ be the Riemann theta function with period matrix as in Theorem 2.2. In a quite similar way we get

$$\theta(z_1,z_2,\ldots,z_N)=\sum_{j=0}^{N-1}\theta_j(z_1)\,\Theta_j(z_2,\ldots,z_N),\tag{3.11}$$

where

$$\theta_j(z_1)=\theta\begin{bmatrix} j/N \\ 0 \end{bmatrix}(Nz_1|N^2\tau_1),\tag{3.12}$$

$$\Theta_j(z_2,\ldots,z_N)=\Theta\begin{bmatrix} 0 & 0 & \cdots & 0 \\ j/N & 0 & \cdots & 0 \end{bmatrix}(z_2,\ldots,z_N|\hat{B}).\tag{3.13}$$

In the above formula $\hat{B}$ is the right lower $(N-1)\times(N-1)$ minor of B (2.7), and the theta functions with fractional characteristics are defined, for example, in Refs. 19,18,14,13. A reduction formula similar to (3.11), but containing N^2 terms, can be found in Ref. 13, Corollary 7.3.

IV. GEOMETRY OF THE SPECTRAL CURVE

In this section we prove Theorem 2.2.

Let Γ_N be a genus N Riemann surface which is an N-sheeted covering of an elliptic curve Γ_1

$$\Gamma_N\xrightarrow{\pi}\Gamma_1.\tag{4.1}$$

Choose two loops a,b which generate the fundamental group $\pi_1(\Gamma_1,P)$, $P\in\Gamma_1$, and denote $\check{\Gamma}_1=\Gamma_1\setminus\{a\cup b\}$. Let us suppose for simplicity that the ramification points of the projection map π are distinct. Connect further these ramification points by non-intersecting arcs $\gamma_i\subset\check{\Gamma}_1$. The set $\pi^{-1}(\check{\Gamma}_1\setminus\cup_i\gamma_i)$ is a disjoint union of N "sheets." To reconstruct the topological covering (4.1) we have to indicate how the opposite borders of the cuts γ_i are glued, as well how the opposite borders of the (preimages of the) cuts a and b respectively are glued together. Thus there is only a finite number of topologically different coverings (4.1). It may be shown that the Krichever curve (1.9) is of genus at most N, and for generic (p_i,q_i) its genus is exactly N. The projection map π (4.1) is defined then by $\pi(\mu,\lambda)=\lambda$. From now on we shall always assume that (p_i,q_i) are generic. In the case when Γ_N is the genus N Krichever spectral curve (1.9), and Γ_1 is the elliptic curve with half periods ω,ω', the covering (4.1) has a number of special properties.

To prove (2.7) we shall need the following:

Proposition 4.1: Let Γ_N *be the Krichever curve* (1.9). *There exist loops* $a,b\in\pi_1(\Gamma_1,P)$ *such that, if* $\check{\Gamma}_1=\Gamma_1\setminus\{a\cup b\}$, $\partial\check{\Gamma}_1=a\circ b\circ a^{-1}\circ b^{-1}$, *then (i)* $\pi^{-1}(\check{\Gamma}_1)$ *is connected; (ii)* $\pi^{-1}(\partial\check{\Gamma}_1)$ *has exactly N connected components.*

On its hand the above proposition implies the following:

Proposition 4.2: There exists loops $a,b\in\pi_1(\Gamma_1,P)$, $P\in\Gamma_1$, *such that*

$$\pi^{-1}(a)=\{a_1,a_2,\ldots,a_N\},\pi^{-1}(b)=\{b_1,b_2,\ldots,b_N\},$$

where a_i,b_i *represent a symplectic homology basis of* $H_1(\Gamma_N,\mathbf{Z})$, $a_i\circ b_j=\delta_{ij}$.

Proof of (2.7) assuming Proposition 4.2: Let $d\lambda$ be the holomorphic one-form on Γ_1. Then the pullback $\pi^*d\lambda$ of $d\lambda$ is a holomorphic one-form on Γ_N and we have

$$\int_{a_i}\pi^*d\lambda=\int_a d\lambda,\int_{b_i}\pi^*d\lambda=\int_b d\lambda.$$

Choose the following new integer homology basis of Γ_N:

$$\tilde{a}_1=a_1+a_2+\ldots a_N,\quad \tilde{b}_1=b_1,$$

$$\tilde{a}_2 = Nb_1 - b_1 - b_2 - \ldots - b_N, \quad \tilde{b}_2 = a_2,$$

and

$$\tilde{a}_i = b_i - b_1, \quad \tilde{b}_i = a_2 - a_i, \quad i = 3, \ldots, N.$$

This is also a symplectic basis of $H_1(\Gamma_N, \mathbf{Z})$, as

$$\sum_{i=1}^{N} \tilde{a}_i \wedge \tilde{b}_i = \sum_{i=1}^{N} a_i \wedge b_i.$$

Let $\omega_1, \omega_2, \ldots, \omega_N$ be a basis of holomorphic one-forms on Γ_N, such that

$$\omega_1 = \frac{d\lambda}{\int_{\tilde{a}_1} d\lambda}, \int_{\tilde{a}_i} \omega_j = \delta_{ij}.$$

Then $B = (\int_{\tilde{b}_j} \omega_i)_{i,j}^{N,N}$ is a symmetric matrix with positive definite imaginary part, such that

$$\int_{\tilde{b}_1} \omega_1 = \frac{\tau}{N}, \int_{\tilde{b}_2} \omega_1 = \frac{1}{N}, \int_{\tilde{b}_i} \omega_1 = 0, \ i \geqslant 3$$

which completes the proof of 2.7.

Proof of Proposition 4.1: First of all let us note that if the claim holds for some Krichever curve, then it holds for any Krichever curve. Indeed, the space of all such curves is parameterized by $\mathbb{C}^{N-1}$ (the first integrals of the integrable Hamiltonian system (1.4)) and hence it is connected. Let us fix a generic point (p_i, q_i), $i = 1, 2, \ldots, N$. It is enough to prove now our proposition for at least one pair of half-periods ω, ω', for example for $|\omega|, |\omega'| \sim \infty$.

Let us represent $\check{\Gamma}_1 \subset \mathbb{C} = \mathbb{P}^1 \setminus \infty$ as the interior of the period parallelogram formed by 2ω and $2\omega'$. When $|\omega| \to \infty$, $|\omega'| \to \infty$, the boundary. $\partial \check{\Gamma}_1 = a \circ b \circ a^{-1} \circ b^{-1}$ tends to $\infty \in \mathbb{P}^1$, and $\check{\Gamma}_1$ tends to $\check{\Gamma}_1^{\infty} = \mathbb{C}$. In a similar way we define the ''limit'' curve $\check{\Gamma}_N^{\infty}$ which is explicitly described in the following way. When $|\omega| \to \infty$, $|\omega'| \to \infty$, then on any compact set the Weierstrass functions $\sigma(q), \zeta(q), \wp(q)$ tend to $q, 1/q, 1/q^2$ respectively, and hence the function $\Phi(q,\lambda)$ tends to

$$\frac{q - \lambda}{q\lambda} \exp(q/\lambda).$$

Denote the corresponding ''limit'' Lax matrix (1.5) by $L^{\infty}(\lambda)$. The curve $\check{\Gamma}_N^{\infty}$ is the affine curve

$$\{(\lambda, \mu) : \det(L^{\infty}(\lambda) - \mu I_N) = 0\}$$

completed with N distinct points corresponding to $\lambda = 0$. The last holds true if and only if the ramification points of the projection map π (4.1) tend to some values different from $\lambda = 0$ (it is easy to check that this is a generic condition on (p_i, q_i)). We shall also suppose that these values are different from $\lambda = \infty$ (another generic condition). Under these restrictions one may prove (as in Ref. 2) that $\check{\Gamma}_N^{\infty}$ is a Riemann sphere, with N punctures (the preimages of $\lambda = \infty$). We obtain thus a map $\pi: \mathbb{P}^1 \to \mathbb{P}^1$ with $2N-2$ ramification points different from $\lambda = 0, \infty$. The fact that $\pi^{-1}(\mathbb{C})$ is connected implies the part (i) of the proposition, and the fact that $\pi^{-1}(\infty)$ is a disjoint union of N points implies (ii).

Proof of Proposition 4.2: Let us represent $\check{\Gamma}_N$ by a graph with N vertices. A vertex corresponds to a sheet (see the beginning of this section), an edge connects two vertices if and only if the corresponding sheets have a common ramification point. Proposition 4.1 (i) implies that the graph is connected, and (ii) that each sheet contains an even number of ramification points. As the total number of ramification points is $2N-2$ and each point belongs to exactly two sheets, then in addition the graph of $\check{\Gamma}_N$ is simply connected.

Consider now the punctured curve

$$\tilde{\Gamma}_1=\check{\Gamma}_1\setminus\cup_i R_i,$$

where $R_i, i=1,\ldots,2N-2$ are the ramification points of π. The fundamental group $\pi_1(\tilde{\Gamma}_1,P)$ has a natural representation in the permutation group S_n. Namely, when a point $Q\in\Gamma_1$ makes one turn along a loop $a\in\pi_1(\tilde{\Gamma}_1,P)$, the set $\pi^{-1}(P)=\cup_{i=1}^N P_i$ is transformed to itself. If the loops a and b induce the identity permutation, then $\pi^{-1}(a)$, $\pi^{-1}(b)$ are disjoint unions of N loops with obvious intersections, which implies Proposition 4.2. If not, we shall modify a and b.

Let $c\in\pi_1(\tilde{\Gamma}_1,P)$ be a loop which makes one turn around some ramification point of π. Then c induces a permutation which exchanges the two sheets containing the ramification point. As the graph of $\check{\Gamma}_N$ is connected then all such transpositions generate the permutation group S_n. Thus for suitable c the loop $a\circ c$ induces the identity permutation. It remains to substitute $a\to a\circ c$ and to note that $a=a\circ c$ in $\pi_1(\Gamma_1,P)$.

Proof of (2.8) (compare to Ref. 13, Theorem 7.14): Let $0\in\Gamma_1$ be the pole of $\wp(z)$. We denote

$$\pi^{-1}(0)=\{\infty_1,\infty_2,\ldots,\infty_N\},\quad \infty_i\in\Gamma_N.$$

In a neighborhood of each point ∞_i on the Krichever curve $\{(\lambda,\mu):f(\lambda,\mu)=0\}$ the meromorphic function μ has the following Laurent expansion:[9]

$$\mu=-\frac{1}{\lambda}+O(1),\quad i=1,2,\ldots,N-1,$$

$$\mu=\frac{N-1}{\lambda}+O(1).$$

It follows that if

$$\omega_j=f_j(P)d\lambda,\quad P=(\lambda,\mu)\in\Gamma_N$$

is a differential of first kind (i.e., holomorphic) on Γ_N, then $\mu\omega_j$ is a differential of third kind with simple poles at ∞_i. The sum of the residues of $\mu\omega_j$ is equal to

$$\sum_{i=1}^{N-1} f_j(\infty_i)-(N-1)f_j(\infty_N)=0. \tag{4.2}$$

Let Ω be a differential of second kind on Γ_N with a single pole at ∞_N. Such is for example the differential

$$\frac{\mu^2-\wp(\lambda)}{\dfrac{\partial f}{\partial\mu}(\lambda,\mu)}d\lambda.$$

If moreover Ω is normalized as

$$\int_{\tilde{a}_i}\Omega=0,$$

then it is well known that the vector V is collinear to

$$\left(\int_{\tilde{b}_1} \Omega, \int_{\tilde{b}_2} \Omega, \dots, \int_{\tilde{b}_N} \Omega \right)$$

(see, for example, Ref. 13). Equivalently, if we apply the reciprocity law to the differentials of second and first kind Ω, ω_i, we get that V is colinear to

$$(f_1(\infty_N), f_2(\infty_N), \dots, f_N(\infty_N)).$$

On the other hand

$$\tilde{a}_1 = a_1 + a_2 + \dots + a_N = \pi^{-1}(a)$$

and hence

$$\int_{\tilde{a}_1} \omega_i = \sum_{k=1}^{N} \int_a f_i(\lambda, \mu_k) d\lambda,$$

where $(\lambda, \mu_k) \in \Gamma_N$ are the N preimages of $\lambda \in \Gamma_1$. It is clear that $\Sigma_{k=1}^N f_i(\lambda, \mu_k)$ is a single-valued function on Γ_1. As ω_i is a holomorphic differential on Γ_N and $d\lambda$ is the holomorphic differential on Γ_1, then $\Sigma_{k=1}^N f_i(\lambda, \mu_k)$ is a holomorphic function on Γ_1 and hence a constant. As ω_i is a normalized basis of holomorphic forms, then $\int_{\tilde{a}_1} \omega_i = 0$ for $i \geqslant 2$, and hence

$$\sum_{k=1}^{N} \int_a f_i(\lambda, \mu_k) d\lambda = \sum_{k=1}^{N} f_i(\lambda, \mu_k) \int_a d\lambda \equiv 0, \quad (\lambda, \mu) \in \Gamma_N, \quad i \geqslant 2.$$

Therefore,

$$\sum_{k=1}^{N} f_i(\lambda, \mu_k) \equiv 0, \quad i \geqslant 2,$$

which combined with (4.2) implies that

$$f_i(\infty_N) = 0, \quad i \geqslant 2$$

and hence the vector V is colinear to (1,0, . . . ,0). In fact V is equal to this vector, because $q_i(t) \in \Gamma_1 = \mathbb{C}/\{\mathbf{Z} + \tau \mathbf{Z}\}$. Finally, we may always suppose that $U = (0, U_2, \dots, U_N)$. Indeed the Calogero system (1.1) is invariant under the translation

$$q_i \rightarrow q_i - V_1 t.$$

SU(N) skyrmions and harmonic maps

T. Ioannidou[a]
Institute of Mathematics, University of Kent at Canterbury, Canterbury CT2 7NF, United Kingdom

B. Piette[b] and W. J. Zakrzewski[c]
Department of Mathematical Sciences, University of Durham, Durham DH1 3LE, United Kingdom

(Received 6 July 1999; accepted for publication 14 September 1999)

Harmonic maps from S^2 to CP^{N-1} are introduced to construct low-energy configurations of the SU(N) Skyrme model. We show that one of such maps gives an exact, topologically trivial, solution of the SU(3) model. We study various properties of these maps and show that, in general, their energies are only a little higher than the energies of the corresponding SU(2) embeddings. Moreover, we show that the baryon and energy densities of the SU(3) configurations with baryon number $B=3-6$ are more symmetrical than their SU(2) analogs, thus suggesting that there exist solutions of the model with these symmetries. We also show that any SU(2) solution embedded into the SU(4) Skyrme model becomes a topologically trivial solution of this model.
[S0022-2488(99)02712-7]

I. INTRODUCTION

The Skyrme model is now well established as an effective classical theory used to describe nuclei[1,2] for which the field, which describes pions and other pseudoscalar mesons, is valued in SU(N). To have finite-energy configurations, one must require that the field $U(\vec{x},t)$ goes to a constant matrix, say I, at spatial infinity: $U\to I$ as $|\vec{x}|\to\infty$. This effectively compactifies the three-dimensional Euclidean space into S^3 and hence implies that the field configurations of the Skyrme model can be considered as maps from S^3 into SU(N).

In the static limit, the energy of the Skyrme model with a mass term is

$$E=\frac{1}{12\pi^2}\int_{R^3}\left\{-\frac{1}{2}\,\mathrm{tr}(\partial_i U\,U^{-1})^2-\frac{1}{16}\,\mathrm{tr}[\partial_i U\,U^{-1},\partial_j U\,U^{-1}]^2-\frac{m_\pi^2}{2}\,\mathrm{tr}(U^{-1}+U-2I)\right\}d^3\vec{x}, \tag{1}$$

when the energy is expressed in the same units as the baryon number. In this case, the static fields U obey the equation

$$\partial_i\left(\partial_i U\,U^{-1}-\frac{1}{4}[\partial_j U\,U^{-1},[\partial_j U\,U^{-1},\partial_i U\,U^{-1}]]\right)-\frac{m_\pi^2}{4}(U-U^{-1})=0. \tag{2}$$

As the third homotopy class of SU(N) is Z, every field configuration is characterized by an integer:

$$B=\frac{1}{24\pi^2}\int_{R^3}\epsilon_{ijk}\,\mathrm{tr}(\partial_i U\,U^{-1}\,\partial_j U\,U^{-1}\,\partial_k U\,U^{-1})d^3\vec{x}, \tag{3}$$

[b]Electronic mail: B.M.A.G.Piette@durham.ac.uk
[c]Electronic mail: W.J.Zakrzewski@durham.ac.uk

which is interpreted as the baryon number;[2,3] therefore, the lowest-energy state in the $B=1$ sector can be identified with the (classical) nucleon. From the mathematical point of view these field configurations represent three-dimensional topological solitons.

Up to now most of the studies involving the Skyrme model have concentrated on its SU(2) version and its embeddings into SU(N). The simplest nontrivial classical solution involves a single skyrmion ($B=1$) and has already been discussed by Skyrme.[1] The energy density of this solution is radially symmetric and, as a result, using the so-called hedgehog ansatz one can reduce (2) to an ordinary differential equation that can then be solved numerically. Many solutions with $B>1$ have also been computed numerically and in all cases the energy densities of these solutions are very symmetrical and exhibit interesting patterns (cf. Battye *et al.*[4] and references therein).

Last year, Houghton *et al.*[5] showed that using rational maps from S^2 to S^2 one can easily construct field configurations for the SU(2) model that are close to being solutions of the model: they have energies slightly higher than the energies of the exact solutions found numerically, but the symmetries of the baryon and energy densities are the same. When these configurations are used as initial conditions in a relaxation program, the fields do not change much as they evolve toward the exact solutions.

However, so far, very little has been done for the SU(N) model when $N>2$—except the obvious SU(2) embeddings. The first example of a *nonembedding* configuration for a higher group was the $SO(3)$ soliton, which corresponds to a bound system of two skyrmions, and that was found using the chiral field ansatz by Balachandran *et al.*[6] Another configuration, with a large SU(3) strangeness content, was found by Kopeliovich *et al.*[7] However, all other known skyrmion configurations seem to have been the embeddings of the solutions of the SU(2) model.

In the following sections, we construct baryon configurations for the SU(N)($N>2$) Skyrme model, with energies slightly higher than the corresponding SU(2) embbedings—using harmonic maps from S^2 to CP^{N-1}. However, the difference between the two energies, in most cases, is less than the energy of a pion. In most cases, the configurations are more symmetrical than their SU(2) embeddings, implying that the SU(N) Skyrme model has solutions with a larger symmetry than those of the SU(2) one. These solutions might have energies higher than the SU(2) embeddings and might be unstable, but our construction provides an upper bound on their energies. As these solutions have an excitation energy smaller than the pion mass, they will have to be considered in any attempt to quantize the low-energy modes of the Skyrme model.

II. SU(2) EMBEDDINGS

Any solution of the SU(N') model is automatically a solution of any SU(N) model when $N'<N$—as a simple embedding. The energy, the baryon number, and all other properties are unchanged by this operation, and so such embeddings have the same properties as the original fields. However, less obvious embeddings exist in which new fields have different properties from the original ones. In particular, it can be can shown that any solution of the SU(2) model generates a solution of the SU(4) one.

A special feature of the SU(2) field is that it can be written as

$$U=\vec{\phi}\cdot\vec{\tau}, \tag{4}$$

where $\vec{\tau}=(1,i\sigma_1,i\sigma_2,i\sigma_3)$ and the σ's stand for the Pauli matrices. The unitarity of U requires that $\vec{\phi}\cdot\vec{\phi}=1$. Introducing the notation that $\vec{\phi}_i=\partial_i\vec{\phi}$ and $\vec{\phi}_{ij}=\partial_i\,\partial_j\vec{\phi}$, it is easy to see that the energy density of this SU(2) field is

$$\mathcal{E}_2=(\vec{\phi}_i\cdot\vec{\phi}_i)+\tfrac{1}{2}[(\vec{\phi}_i\cdot\vec{\phi}_i)^2-(\vec{\phi}_i\cdot\vec{\phi}_j)^2], \tag{5}$$

and the equations of motion that follow from (2) are

$$\vec{\phi}_{ii}+\vec{\phi}_{ii}(\vec{\phi}_j\cdot\vec{\phi}_j)+\vec{\phi}_i(\vec{\phi}_{ij}\cdot\vec{\phi}_j)-\vec{\phi}_{ij}(\vec{\phi}_i\cdot\vec{\phi}_j)-\vec{\phi}_j(\vec{\phi}_{ii}\cdot\vec{\phi}_j)-\vec{\phi}(\vec{\phi}\cdot\vec{\phi}_{ii})$$
$$-\vec{\phi}[(\vec{\phi}\cdot\vec{\phi}_{ii})(\vec{\phi}_j\cdot\vec{\phi}_j)-(\vec{\phi}\cdot\vec{\phi}_{ij})(\vec{\phi}_i\cdot\vec{\phi}_j)]=0. \tag{6}$$

A SU(4) field can be constructed out of any S^3 field $\vec{\phi}$ as

$$U=U_0(I-2\vec{\phi}\otimes\vec{\phi}^\dagger), \tag{7}$$

where U_0 is a constant matrix. Note that, as can easily be seen by direct expansion of (7), $\det U=-\det U_0$ and so by choosing U_0 to be a constant matrix of determinant -1 we see that U is unitary. In this case, $U^{-1}=(I-2\vec{\phi}\otimes\vec{\phi}^\dagger)U_0^{-1}$ and the U_0's cancel in (2).

To derive the equation that the field $\vec{\phi}$ must satisfy so that (7) is a solution of (2), with $m_\pi=0$, we note that $\vec{\phi}\cdot\vec{\phi}=1$ gives

$$\partial_j U\, U^{-1}=2\vec{\phi}_j\otimes\vec{\phi}^\dagger-2\vec{\phi}\otimes\vec{\phi}_j^\dagger, \tag{8}$$

and so (2) becomes

$$2\partial_i[\vec{\phi}\otimes\vec{\phi}_j^\dagger(\vec{\phi}_j\cdot\vec{\phi}_i)-\vec{\phi}\otimes\vec{\phi}_i^\dagger(\vec{\phi}_j\cdot\vec{\phi}_j)+\vec{\phi}_i\otimes\vec{\phi}^\dagger(\vec{\phi}_j\cdot\vec{\phi}_j)-\vec{\phi}_j\otimes\vec{\phi}^\dagger(\vec{\phi}_i\cdot\vec{\phi}_j)]+\partial_i(\vec{\phi}_i\otimes\vec{\phi}^\dagger-\vec{\phi}\otimes\vec{\phi}_i^\dagger)$$
$$=0. \tag{9}$$

It can easily be shown that Eqs. (9) and (6) are equivalent, implying that $\vec{\phi}$ satisfies the equation of the SU(2) Skyrme model (9). Thus, any solution of the SU(2) model can be transformed into a solution of the SU(4) model by the embedding (7).

The solutions obtained this way are topologically trivial since their baryon density vanishes identically. Moreover, their energy density is four times larger than the corresponding energy of the original SU(2) field (5), i.e., $\mathcal{E}_4=4\mathcal{E}_2$.

This suggests that these particular SU(4) solutions may be interpreted as states corresponding to $2B$ skyrmions and $2B$ antiskyrmions, where B is the baryon number of the original SU(2) solution. Incidentally, a similar situation arises in two-dimensions, where any B solitonic solution of the CP^1 model gives a topologically trivial solution of the CP^2 model, which can be interpreted as a bound state of $2B$ solitons and $2B$ antisolitons.[8]

III. HARMONIC MAPS

The idea of the Houghton *et al.* construction[5] is to separate the radial and the angular dependence of the fields by using an appropriate ansatz. Using the polar coordinates (r,θ,ϕ) in $\mathbf{R}^3$, our SU(N) generalization of the SU(2) Houghton *et al.*'s rational map ansatz is

$$U(r,\theta,\phi)=e^{2ig(r)(P-I/N)}=e^{-2ig(r)/N}(I+(e^{2ig}-1)P), \tag{10}$$

where P is a $N\times N$ Hermitian projector that depends only on the angular variables (θ, ϕ) and $g(r)$ is the radial profile function. Note that the matrix P is a harmonic map from S^2 into CP^{N-1}. Hence it is convenient, rather than using the polar coordinates, to map the sphere onto the complex plane via a stereographic projection and, instead of θ and ϕ, use the complex coordinate ξ and its conjugate. Thus, P can be written as

$$P(V)=\frac{V\otimes V^\dagger}{|V|^2}, \tag{11}$$

where V is an N-component complex vector (dependent on ξ and $\bar{\xi}$).

For (10) to be well defined at the origin, the radial profile function $g(r)$ has to satisfy $g(0)=\pi$ while the boundary value $U\rightarrow I$ at $r=\infty$ requires that $g(\infty)=0$. An attractive feature of the ansatz (10) is that it leads to a simple expression for the energy density that can be successively minimized with respect to the parameters of the projector P and then with respect to the shape of the profile function $g(r)$. This procedure is then expected to give good approximations to multi-skyrmion field configurations.

Moreover, we will show that this method not only allows us to find such field configurations but also gives us an exact *nontopological* solution of the SU(3) Skyrme model. We will also present some upper bounds on the energy of some multiskyrmion field configurations in the SU(N) model (with radially symmetric energy density distribution). In what follows, we restrict our attention to the case $m_\pi = 0$.

To find an exact solution of the SU(3) model, we put (10) into (2) and obtain

$$\begin{aligned}
&-\frac{2i}{r^2}\partial_r(g_r r^2)\left(\frac{1}{N}-P\right)-\frac{i}{2r^2}\partial_r(g_r|A|^2)(1+|\xi|^2)^2([P_{\bar\xi},PP_\xi]+[P_\xi,PP_{\bar\xi}])\\
&+\frac{\bar{A}|A|^2}{16r^4}(1+|\xi|^2)^2\{\partial_{\bar\xi}((1+|\xi|^2)^2[P_\xi,[P_{\bar\xi}P_\xi]])-\partial_\xi((1+|\xi|^2)^2[P_{\bar\xi},[P_{\bar\xi},P_\xi]])\}\\
&+\frac{|A|^4}{16r^4}(1+|\xi|^2)^2\{\partial_{\bar\xi}((1+|\xi|^2)^2[P_\xi P,[P_{\bar\xi},P_\xi]])-\partial_\xi((1+|\xi|^2)^2[P_{\bar\xi}P,[P_{\bar\xi},P_\xi]])\}\\
&+\frac{1}{r^2}(1+g_r^2)(1+|\xi|^2)^2\left[\bar{A}P_{\xi\bar\xi}+\frac{|A|^2}{2}(\partial_\xi(P_{\bar\xi}P)+\partial_{\bar\xi}(P_\xi P))\right]=0,
\end{aligned}\tag{12}$$

where $A=e^{-2ig}-1$.

Moreover, the energy (1) simplifies to

$$E=\frac{1}{3\pi}\int dr\left(A_N g_r^2 r^2+2\mathcal{N}\sin^2 g(1+g_r^2)+\mathcal{I}\frac{\sin^4 g}{r^2}\right),\tag{13}$$

where

$$A_N=\frac{2}{N}(N-1),\tag{14}$$

$$\mathcal{N}=\frac{i}{2\pi}\int d\xi\, d\bar\xi\, \mathrm{tr}(|\partial_\xi P|^2),\tag{15}$$

$$\mathcal{I}=\frac{i}{4\pi}\int d\xi\, d\bar\xi(1+|\xi|^2)^2\,\mathrm{tr}([\partial_\xi P,\partial_{\bar\xi}P]^2).\tag{16}$$

As the integrals $\mathcal{N}$ and $\mathcal{I}$ in (13) are independent of r, we can minimize (13) by first minimizing $\mathcal{N}$ and $\mathcal{I}$ as functions of P and then with respect to the profile function g.

However, since $\mathcal{N}$ is the expression for the energy of the two-dimensional Euclidean CP^2 sigma model, all classical solutions contain the so-called self-dual solutions, instantons or holomorphic maps from S^2 into CP^{N-1}—introduced in Ref. 9 and are given by the projector P of the form (11) with $V=f(\xi)$. In this case, the energy $\mathcal{N}$ is the degree of f, i.e., the degree of the highest-order polynomial in ξ among the components of f after all their common factors have been canceled out.

By a Bogomolny-type argument it can be shown that

$$\begin{aligned}
E&=\frac{1}{3\pi}\int dr\left[\left(g_r r\sqrt{A_N}+\sqrt{\mathcal{I}}\frac{\sin^2 g}{r}\right)^2+2N\sin^2 g(1+g_r)^2-2g_r\sin^2 g(2N+\sqrt{A_N\mathcal{I}})\right]\\
&\geqslant\frac{1}{3}(2N+\sqrt{A_N\mathcal{I}}).
\end{aligned}\tag{17}$$

Finally, the baryon number for this ansatz is

$$B=\frac{i}{\pi^2}\int d\xi\, d\bar{\xi}\,\mathrm{tr}(P[\partial_\xi P,\partial_{\bar{\xi}}P])\int_0^\infty dr\,\sin^2 g\, g_r=\frac{i}{2\pi}\int d\xi\, d\bar{\xi}\,\mathrm{tr}(P[\partial_{\bar{\xi}}P,\partial_\xi P]), \tag{18}$$

which is the topological charge of the two-dimensional CP^{N-1} sigma model. In this calculation we have used the boundary conditions on the profile function g.

In the next two sections, we will show that this ansatz gives us interesting low-energy field configurations of the SU(N) Skyrme model, which are not the SU(2) embeddings. To minimize E we will, first of all, fix the baryon number $\mathcal{N}=B$ of the configurations in which we are interested. We will then minimize $\mathcal{I}$ over all maps of degree B and then derive a second-order differential equation for g by minimizing the energy (13), treating $\mathcal{N}$ and $\mathcal{I}$ as parameters.

IV. SU(3) EXACT SOLUTION

When the projector P is analytic, i.e., is of the form

$$P_0=P(f)=\frac{ff^\dagger}{|f|^2}, \tag{19}$$

where f is a holomorphic vector (i.e., whose entries are functions only of ξ) then P_0 satisfies the equation

$$P_0\,\partial_\xi P_0=0,\quad \partial_\xi P_0\,P_0=\partial_\xi P_0, \tag{20}$$

i.e., the self-dual equations of the two-dimensional CP^{N-1} sigma models.[8]

Following Ref. 10, we define a new operator P_+, by its action on any vector $v\in C^N$, as

$$P_+v=\partial_\xi v-\frac{v(v^\dagger\,\partial_\xi v)}{|v|^2}, \tag{21}$$

and then define further vectors $P_+^k v$ by induction: $P_+^k v=P_+(P_+^{k-1}v)$.

Next, we note the following useful properties of $P_+^k f$ when f is holomorphic:

$$(P_+^k f)^\dagger P_+^l f=0,\quad k\neq l, \tag{22}$$

$$\partial_{\bar{\xi}}(P_+^k f)=-P_+^{k-1}f\,\frac{|P_+^k f|^2}{|P_+^{k-1}f|^2},\quad \partial_\xi\left(\frac{P_+^{k-1}f}{|P_+^{k-1}f|^2}\right)=\frac{P_+^k f}{|P_+^{k-1}f|^2}. \tag{23}$$

These properties either follow directly from the definition of the P_+ operator or are very easy to prove.[8]

It is also convenient to define projectors corresponding to the family of $P_+^k f$ vectors:

$$P_k=P(P_+^k f),\quad k=0,\ldots,N-1, \tag{24}$$

which always satisfy the relation $\Sigma_{k=0}^{N-1}P_k=I$.

Taking $P=P_k$, for a given k, and using the above properties we observe that all the terms in (12), except the first one, can be gathered into one term if and only if

$$\frac{|P_+f|^2}{|f|^2}\equiv\frac{\mathcal{K}}{(1+|\xi|^2)^2}, \tag{25}$$

where $\mathcal{K}$ is a constant. Moreover, in the SU(2) case, the projectors P_0 and P_1 satisfy the relation $P_0+P_1=I$, and for $f=(1,\xi)^t$ all the terms in (12) are proportional to one common matrix—thus giving a second-order differential equation for the profile function g. This means that the Skyrme field (10), in the case when g satisfies its equation, is an *exact* solution of Eq. (12). A little thought shows that this is the well-known hedgehog solution.

Unfortunately, this discussion does not generalize to higher SU(N) groups—with one exception. Note that in the SU(3) model, if we take $P(V)=P_1$ and use the fact that $P_0+P_1+P_2=I$, all the matrix terms in Eq. (12) become proportional to each other, leading to a second order differential equation for the profile function, if and only if

$$\frac{|P_+^2 f|^2}{|P_+ f|^2}+\frac{|P_+ f|^2}{|f|^2}\equiv\frac{\tilde{\mathcal{K}}}{(1+|\xi^2|)^2}, \tag{26}$$

where $\tilde{\mathcal{K}}$ is a constant. This last condition is satisfied if

$$f=(1,\sqrt{2}\xi,\xi^2)^t. \tag{27}$$

Thus, by taking $P=P_1$ for f of the form (27), and requiring g to satisfy the equation

$$g_{rr}\left(\frac{1}{3}+2\,\frac{\sin^2 g}{r^2}\right)+\frac{2}{3}\,\frac{g_r}{r}+\frac{\sin 2g}{r^2}\left(g_r^2-1-\frac{\sin^2 g}{r^2}\right)=0, \tag{28}$$

we see that (10) is an *exact* solution of the SU(3) model.

For this solution, the parameters in the energy density can be evaluated analytically; we have $A_N=\frac{4}{3}$, $\mathcal{N}=4$, $\mathcal{I}=4$, and the total energy is found to be $E=3.861$.

To understand what this solution corresponds to, we calculate the topological charge of this configuration and get

$$B=\frac{i}{\pi}\int d\xi\, d\bar{\xi}\left(\frac{|P_+^2 f|^2}{|P_+ f|^2}-\frac{|P_+ f|^2}{|f|^2}\right), \tag{29}$$

which due to the conditions (22), (23), and (26) is identically zero.

Although the baryon density is identically zero, the solution itself is nontrivial. This follows from the fact that the CP^2 sigma model harmonic map P_1 corresponds to a mixture of two solitons and two antisolitons. Thus, it seems reasonable to interpret this solution as describing a bound state of two skyrmions and two antiskyrmions and as such to be unstable, i.e., correspond to a saddle point of the energy. However, let us emphasize once again; this field configuration is a genuine (although topologically trivial) solution of the SU(3) Skyrme model.

It is easy to see that this new field configuration has an energy density distribution shaped like a shell (i.e., is radially symmetric). To see this, note that for this solution, $\mathrm{tr}(|\partial_\xi P|^2)$ and $\mathrm{tr}([\partial_\xi P,\partial_{\bar{\xi}} P]^2)$ that appear in (15) and (16), are proportional to $(1+|\xi|^2)^{-2}$ and $(1+|\xi|^2)^{-4}$, respectively; demonstrating this symmetry. The radial energy density of this solution is given in Fig. 1, and one sees that, indeed, it corresponds to a shell.

V. SU(N) RADIALLY SYMMETRIC SKYRME FIELDS

In general, our method does not give us further solutions, but it is a matter of simple algebra to show that the condition (25) is true for any $N\geqslant 2$ when the modulus of the vector f is some power of $(1+|\xi|^2)$; i.e., for

$$f=(f_0,\ldots,f_i,\ldots,f_{N-1})^t:\quad f_i=\xi^i\sqrt{C_{i+1}^{N-1}}, \tag{30}$$

where C_{i+1}^{N-1} denotes the binomial coefficients. Note that in this case, the constant $\mathcal{K}$ in (25) is equal to the degree of the vector f: i.e., $\mathcal{K}=n$.

Using the condition (25) the integrals involving $P=P_0$ in the energy (13) can be evaluated analytically,

$$\mathcal{N}=n,\quad \mathcal{I}=(N-1)^2=n^2. \tag{31}$$

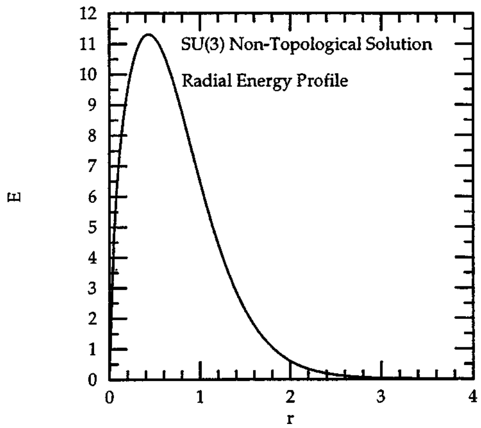

FIG. 1. Energy profile of the nontopological solution.

Due to the analyticity of the projector P_0, the baryon number of this field is $B=n$, i.e., the degree of f.

When $m_\pi \neq 0$ the energy (13) for the ansatz (10) becomes

$$E=\frac{1}{3\pi}\int dr\left\{A_N g_r^2 r^2+2\mathcal{N}\sin^2 g(1+g_r^2)+\mathcal{I}\frac{\sin^4 g}{r^2}\right.$$
$$\left.+m_\pi^2 r^2\left[(N-1)\left(1-\cos\left(\frac{2g}{N}\right)\right)+1-\cos\left(\frac{(N-1)2g}{N}\right)\right]\right\}. \tag{32}$$

Minimizing (32) given (31) leads to the following equation for the profile function:

$$g_{rr}\left(A_N+2n\frac{\sin^2 g}{r^2}\right)+2A_N\frac{g_r}{r}+\frac{\sin 2g}{r^2}\left(n(g_r^2-1)-n^2\frac{\sin^2 g}{r^2}\right)$$
$$-m_\pi^2\left(\frac{N-1}{N}\right)\left[\sin\left(\frac{2g}{N}\right)+\sin\left(\frac{(N-1)2g}{N}\right)\right]=0, \tag{33}$$

where A_N is given by (14).

Solving (33) to determine g and then calculating the energy of the configuration we find that, for small m_π, the energy for these configurations is a little higher than the energy of the SU(2) embedded ansatz with the same baryon number B when the mass is zero. However, when the mass increases, the picture changes.

We have looked at field configurations corresponding to $B=2-4$ for the SU(2) embeddings and for the SU(N) spherical symmetric fields (30) where $N=B+1$, and studied the dependence of their energies on m_π. In all cases at low values of the mass the embeddings have lower energies while as the mass increases the energies increase. However, as the embedding energies increase faster for all low B there is a value of m_π above which the embedding energy is higher. This value of m_π is quite large and it increases with the increase of B.

The results are summarized in Table I, which gives values of the energy for different values of the mass; while in Fig. 2, we present the plots of the dependence on m_π of the energies for the embeddings and for the radially symmetric fields (30). Note that for low values of m_π the energy per skyrmion of the harmonic ansatz configuration is lower than the energy of a single skyrmion—demonstrating the existence of bound states. For larger values of m_π our new field configurations become less massive than the embeddings and for even larger values of m_π either the bound states do not exist or the approximation through harmonic maps becomes unreliable.

TABLE I. Mass dependence of the energy for the radially symmetric configurations in the SU(2)–SU(5) models.

m_π	SU(2) $E_{B=1}$	SU(2) $E_{B=2}$	SU(3) $E_{B=2}$	SU(2) $E_{B=3}$	SU(4) $E_{B=3}$	SU(2) $E_{B=4}$	SU(5) $E_{B=4}$
0	1.232	2.416	2.444	3.553	3.644	4.546	4.838
0.2	1.247	2.444	2.472	3.594	3.683	4.597	4.886
1	1.416	2.795	2.808	4.125	4.172	5.270	5.520
2.23	1.693	3.381	3.370	5.021	5.006	6.419	6.615
7	2.510	5.101	5.030	7.634	7.478	9.776	9.880
30	4.783	9.836	9.633	14.793	14.339	18.971	18.948

Note that, although the Skyrme field ansatz (30) is axially symmetric the energy density is radially symmetric. In fact, a rotation by an angle α in the xy plane is equivalent to a unitary transformation $U \rightarrow A^{-1}UA$, where $A = e^{-iN(N-1)\alpha/2}\,\mathrm{diag}(1,e^{i\alpha},e^{2i\alpha},\ldots,e^{(N-1)i\alpha})$. Since the $B>2$ SU(2) skyrmion solutions have only discrete symmetries, the SU(N) skyrmion solutions for $N \geqslant 4$ are more symmetrical than the corresponding SU(2) embeddings. However, the $B=2$ SU(2) solution is already axially symmetric and so the symmetry arguments do not help us in comparing the SU(3) and SU(2) solutions.

The energy of the exact $B=3$ SU(2) skyrmion solution (for $m_\pi=0.2$) is $E=3.470$. From Table I, we see that the energy difference between this SU(2) solution and our $B=3$ SU(4) configuration is, approximately, equal to the pion mass. However, the energy of the actual axially symmetric $B=3$ SU(4) solution is clearly lower than that of our configuration, leading to an even smaller energy difference. Also, the energy of the exact $B=4$ SU(2) skyrmion (for the same value of the pion mass) is $E=4.522$. In this case, the energy gap with our $B=4$ SU(5) configuration is nearly twice as large as the pion mass; i.e., it is less clear whether the energy gap between the exact axially symmetric solution and the SU(2) embedding remains lower than the pion mass.

VI. SU(3) CASE

In this section, we restrict our attention to the SU(3) model with $m_\pi=0$ and construct low-energy states with a baryon number from one up to six. From now on, $N=3$ and so A_N, given by (14), becomes $A_N=\frac{4}{3}$.

A. General discussion

As in the previous section, we minimize (13) by first minimizing the integrals $\mathcal{N}$ and $\mathcal{I}$ as functions of P and then minimizing (13) with respect to the profile function g. Once again, $\mathcal{N}$ is

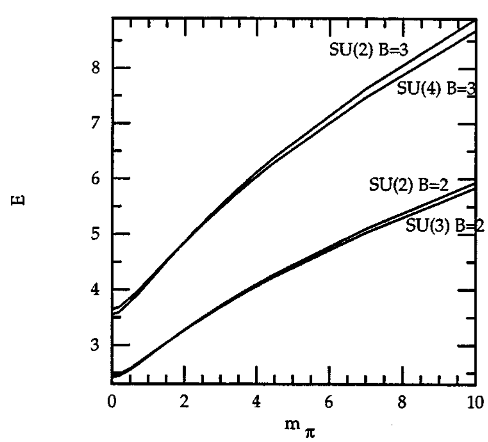

FIG. 2. Mass dependence of the SU(2) and SU($B+1$) harmonic map configurations for $B=2-3$.

minimized by the so-called self-dual solutions of the Euclidean CP^2 sigma model. They are given by (20), where f is any polynomial holomorphic vector $f(\xi)$ and their energy $\mathcal{N}$ is given by the degree of f.

Next, we note that the angular part of the baryon charge (18) coincides with the expression for the topological charge of the CP^2 sigma model, and so simplifies to

$$B=\frac{1}{8\pi}\int dS(1+|\xi|^2)^2\frac{|P_+f|^2}{|f|^2}, \tag{34}$$

where $dS\equiv\sin\theta\,d\theta\,d\phi=2i(1+|\xi|^2)^{-2}\,d\xi\,d\bar{\xi}$.

To minimize (13) for a configuration with a given baryon number B, we take $f(\xi)$ to be a holomorphic vector of degree B, which, by construction, minimizes $\mathcal{N}$. First we use the global SU(3) invariance of the model to reduce the number of parameters to the moduli space of the two-dimensional sigma model to

$$f=\begin{pmatrix}\xi^B+a_{B-1}\xi^{B-1}+\cdots+a_1\xi\\ b_{B-1}\xi^{B-1}+b_{B-2}\xi^{B-2}+\cdots b_1\xi+b_0\\ c_{B-2}\xi^{B-2}+c_{B-3}\xi^{B-3}+\cdots+c_1\xi+c_0\end{pmatrix}, \tag{35}$$

where all the coefficients are complex except b_{B-1}, which can be taken to be real. Then we substitute (19) for f of the form (35) into $\mathcal{I}$ and minimize numerically the integral with respect to all the coefficients. Finally, treating $\mathcal{N}=n$ and $\mathcal{I}$ as two fixed parameters, we minimize (13) by solving the resultant equation for g:

$$g_{rr}\left(1+2\mathcal{N}\frac{3\sin^2 g}{4r^2}\right)+2\frac{g_r}{r}+\frac{3\sin 2g}{4r^2}\left[\mathcal{N}(g_r^2-1)-\mathcal{I}\frac{\sin^2 g}{r^2}\right]=0. \tag{36}$$

An interesting feature of the SU(2) multiskyrmion solutions is the shape of surfaces of constant energy or baryon density. In fact, the energy and the baryon densities of the skyrmion solutions look very similar. For the baryon density these surfaces look like hollow shell-like structures with holes in it, while for the energy densities the holes are partly filled in and so are represented by local minima.[4]

In order to investigate the situation for our SU(3) field configurations, we have to look at the components of f given in (35) and study their effects on the density (34). Writing $f=(K,L,M)^t$, where K, L, and M are polynomials of degree B, $B-1$, and $B-2$, respectively, the integrand of (18) takes the form

$$\mathcal{B}=g_r\sin^2 g(1+|\xi|^2)^2\frac{|K_\xi L-L_\xi K|^2+|K_\xi M-M_\xi K|^2+|M_\xi L-L_\xi M|^2}{(|K|^2+|L|^2+|M|^2)^2}. \tag{37}$$

Note that the integrand of (37) is a scalar with respect to U(3) transformations applied to the vector f. Hence, any modifications of f that can be interpreted as such U(3) transformations are symmetries of (37).

The radial factor $g_r\sin^2 g$ in (37) indicates that if the angular part of the density vanishes, the baryon density will have radial holes going from the origin to infinity. For the density to vanish at some point we must require that the three factors in the numerator of (37) must vanish together, i.e., must have a common root. This is true when the three polynomials, $R_1=K_\xi L-L_\xi K$, $R_2=K_\xi M-M_\xi K$, and $R_3=M_\xi L-L_\xi K$, have a common factor. However, these polynomials have $2(B-1)$, $2B-3$, and $2(B-2)$ roots, respectively; with, in addition, a possible root at infinity (i.e., the south pole of the sphere). By counting powers we see that the density does not vanish at $\xi=\infty$ unless L is a polynomial of degree less than $B-1$.

From this we conclude that the baryon density can have, at most, $2B-3$ holes but, in general, it is likely to have fewer holes if any. Of course, when some terms in (37) vanish, the expression may (but does not have to) have a local minimum. Note that this is in contrast with the SU(2)

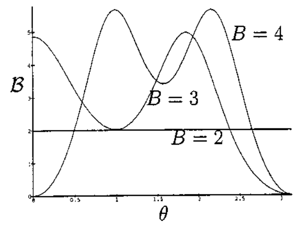

FIG. 3. The θ angular dependence of the baryon density (34).

configurations of Houghton *et al.*,[5] which always have $2(B-1)$ holes. In the SU(2) case, the vector f has only two components and so there is only one factor in the numerator of the baryon density, which thus has $2(B-1)$ zeros.

B. Specific fields

In this section we present the detailed form of harmonic maps that are used in the construction of the SU(3) skyrmion field ansatze.

First of all, the $B=1$ case, as discussed in Sec. V, is the SU(2) embedded skyrmion (i.e., the hedgehog ansatz). Next, we discuss field configurations for $B=2-6$. In each case, having found the map that minimizes $\mathcal{I}$, we solve numerically (36) and determine the corresponding profile function g. In Fig. 3 we present the θ angular dependence of the baryon densities for $B=2-4$ (no ϕ dependence). In Fig. 4, we present plots of surfaces of constant baryon density for $B=3-6$. The values we have chosen are, respectively, 0.3 times the maximum value of the topological density. (In all the graphs that follow, we always express the constant value for the curve as a fraction of the maximum density value.) The energy and baryon density for all the fields has the same symmetry and a virtually indistinguishable shape.

For $B=2$, using the ansatz (35), we have minimized $\mathcal{I}$ numerically and have found f to agree with the ansatz presented in Sec. V, i.e., to be given by

$$f=(\xi^2,\sqrt{2}\xi,1)^t. \tag{38}$$

For this field configuration $|P_+f|^2/|f|^2=2/(1+|\xi|^2)^2$ and, hence, as shown in Fig. 3, the baryon and energy density are independent of the polar angles on the sphere. Thus, the energy density of the $B=2$ field represents a shell.

The field (38) is axially symmetric, i.e., a rotation of an angle α in the xy plane is equivalent to the isorotation $U\rightarrow A^{-1}UA$, where $A=\mathrm{diag}(e^{-i\alpha},1,e^{i\alpha})$. This symmetry is identical to the symmetry of the $B=2$ SU(2) solutions.

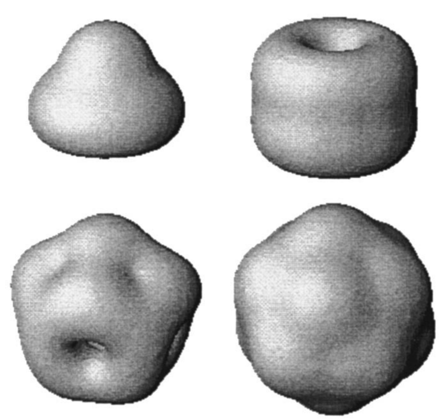

FIG. 4. Surfaces of constant baryon density for $B=3-6$.

For $B=3$, the numerical minimisation of $\mathcal{I}$ leads to the following expression for *f*:

$$f=(\xi^3,1.576\xi,\sqrt{2}^{-1})^t. \tag{39}$$

The baryon density of this configuration is axially symmetric and has the shape of a *torus with a sphere on top of it*. Since all the components of *f* are monomials, a transformation $\xi\to\xi'=\xi e^{i\alpha}$ for any α (i.e., a rotation around the *z*-axis), can be interpreted as the SU(3) transformation $U\to A^{-1}UA$, where $A=e^{-4/3i\alpha}\,\mathrm{diag}(e^{3i\alpha},e^{i\alpha},1)$. Hence, the configuration is axially symmetric—which proves the existence of an axially symmetric SU(3) solution with lower energy than the energy of this configuration (cf. Table III).

The baryon density for (39) does not vanish except when $|\xi|^2$ is infinite. This comes from the fact that the three terms in the numerator of (37) do not have common factors; however, as the second term of (39) is a polynomial of degree one, the baryon density vanishes for $\xi=\infty$. Indeed, we see in Fig. 4(a) that the density vanishes on the negative part of the *z*-axis ($\theta=\pi$).

For $B=4$ we find

$$f=(\xi^4,2.7191\xi^2,1)^t. \tag{40}$$

This configuration also leads to energy and baryon densities that are axially symmetric and have the shape of *two tori on top of each other close to the equator of the sphere* [see Fig. 4(b)]. These densities are invariant under a rotation around the *z*-axis, which is equivalent to the SU(3) transformation: $U\to A^{-1}UA$ where $A=\mathrm{diag}(e^{-2i\alpha},1,e^{-2i\alpha})$.

Note that the baryon density for (39) does vanish when ξ is zero or when its modulus $|\xi^2|$ is infinite. This happens as the three terms in the numerator of (37) have a single common factor at $\xi=0$, and the second term of *f* is a polynomial of degree two—implying once again that the baryon density vanishes when $\xi=\infty$. Indeed, this can be seen in Fig. 4(b); clearly the density vanishes along the *z*-axis ($\theta=0$ and $\theta=\pi$).

Let us mention that the energy densities of our configuration for $B=3-4$ are remarkably similar to the density of a SU(2) configuration corresponding to the scattering of three (four) skyrmions in an attractive channel,[11] and of three (four) monopoles.[12]

The holomorphic vector for $B=5$ is given by

$$f=(\xi^5-2.7\xi,2\xi^4+1,9/2\,\xi^3)^t, \tag{41}$$

and the baryon density resembles a structure consisting of *two deformed tori*, close to the equator, with an *additional ball* at the north pole of the angular sphere [see Fig. 4(c)]. Let us stress that the energy densities of the SU(2) embeddings have very different shapes and symmetries.

It is easy to check that the baryon density corresponding to the field in (41) does not have any holes. Note that by taking *f* in the form close to (41), i.e.,

$$f=\left(\xi^5+\frac{3C}{D}\xi,D\xi^4+C,E\xi^3\right)^t, \tag{42}$$

all the three terms in the numerator of (37) have zeros when

$$\xi^4=\frac{3C}{D}, \tag{43}$$

which would give four holes in the baryon density. So, since our field (41) is not very different from (42), our densities have minima; corresponding to the holes (43) partially filled in, by going from (42) to (41).

The holomorphic vector for $B=6$ is given by

$$f=(\xi^6+3\xi,1-3\xi^5,k\xi^3)^t, \tag{44}$$

TABLE II. Energy of SU(3) harmonic ansatz compared to the energy of the SU(2) harmonic ansatz and the energy of the SU(2) solutions obtained numerically.

B	$\mathcal{I}$(SU(3))	SU(3) En/Sk (Ans.)	SU(2) En/Sk (Ans.)	SU(2) En/Sk (Sol.)
1	1	1.232	1.232	1.232
2	4	1.222	1.208	1.171
3	10.65356	1.215	1.184	1.143
4	18.04501	1.184	1.137	1.116
5	27.26	1.164	1.147	1.116
6	37.33	1.1458	1.137	1.109

where k was found, numerically, to be 7.06. Once again, the baryon density of the field (44) does not have any holes but has regions where it is small but nonzero [see Fig. 4(d)]. This figure shows that this configuration has an *icosahedral symmetry* and this leads us to the conclusion that, modulo a SU(3) global transformation, (44) must be invariant under the following transformation:[13] $\xi \to \xi' = \xi e^{i2\pi/5}$ (i.e., a rotation by 72° around the z-axis); $\xi \to \xi' = -\xi^{-1}$ (which corresponds to $\theta \to \pi - \theta$ and $\phi \to \pi - \phi$) and $\xi \to \xi' = (\xi + b)(b\xi + 1)^{-1}$, where $b = 2\cos(2\pi/5) = (\sqrt{5}-1)/2$. This last transformation imposes a condition on k in (44): it is easy to see that the SU(3) transformation on f must be of the form $U = R/\det(R)^{1/3}$, with

$$R = \begin{pmatrix} 25+15a & 10+5a & (150+100a)k^{-1} \\ 10+5a & 25+15a & -(150+100a)k^{-1} \\ -k(3+2a) & k(3+2a) & 15+10a \end{pmatrix}, \tag{45}$$

where $a = -(1+\sqrt{5})/2$. Imposing the condition that the rows and columns of R are orthogonal to each other implies that $k = \sqrt{50} \approx 7.071$, which is within the precision of our numerical minimization program.

In Table II we present the energy values of the resulting Skyrme fields. All the numerical values of the energies are given in units of B and hence are close to unity. These values are then compared with the SU(2) skyrmion embeddings obtained using rational maps in Ref. 5. We see that both field configurations have similar values of energy, although the energies of the embeddings are marginally lower.

The symmetries of our $B=3-4$ and $B=6$ configurations are larger than the symmetry of the corresponding SU(2) embeddings. Therefore, solutions with the same symmetry as our configurations must exist and they will have lower energies than our fields. (Table II gives the upper bound on the energy of these solutions.) From Table III, it can be observed that in all three cases, the energy differences between our configurations and the corresponding SU(2) embeddings are lower or comparable to the pion mass.

This does not mean that the embeddings are closer (in shape of their energy densities) to the lowest-energy solutions of the SU(3) model. Our harmonic map fields and the embedded fields have very different symmetries, and as their energies are very close to each other it is pure

TABLE III. Energy of SU(2) multiskyrmion solutions for pion masses $m_\pi = 0$ and $m_\pi = 0.2$.

B	$E_{m_\pi=0}$	$E_{m_\pi=0.2}$

speculation to argue which are nearer (in their shapes) to the lowest-energy solutions. The true solutions may be close to either or neither of them, or it may be that the model has many different solutions, almost degenerate in energy. When the symmetries are different we do expect different solutions to exist, although some of them may not correspond to the local minima of the energy. This issue will be resolved only when detailed and reliable numerical studies of the SU(3) model have been performed.

VII. CONCLUSIONS

In this paper, we have discussed various static field configurations of the SU(N) Skyrme model. We have shown that, in addition to the obvious embeddings, any solution of the SU(2) model generates a solution of the SU(4) model. This solution is topologically trivial (i.e., zero baryon density) and its energy is equal to four times the energy of the original SU(2) solution.

Next, we have generalized the rational map ansatz of Houghton *et al.*[5] using harmonic maps and found another SU(3) exact spherically symmetric skyrmion solution. The baryon number of this solution is also zero and its energy is less than four (in topological units). We have argued that it represents a bound state of two skyrmions and two antiskyrmions.

Then we have presented topologically nontrivial field configurations of the SU(N) Skyrme model with radially symmetric energy densities—using harmonic maps. They correspond to $B=N-1$ skyrmions in SU(N) models. Although in the massless case their energies have turned out also to be above those of the SU(2) embeddings; when mass is added to the model, for sufficiently large masses, their energies can be lower than the energies of the embeddings.

We have also looked at various field configurations of the SU(3) model. The energy and baryon densities of these SU(3) fields exhibit shell-like structures; in all cases, except for $B=1$, they are different from the corresponding structures seen in the SU(2) model and are more symmetrical. Their energies are slightly higher but comparable to those of the embeddings. However, their different symmetry properties imply that there exist true solutions with these symmetries and with energies lower than our configurations. Thus, the model has at least two types of low-energy solutions. To know more about them, one will have to perform three-dimensional numerical simulations—this so far has not been done.

ACKNOWLEDGMENTS

The authors would like to thank V. Kopeliovich and J. Garraham for their help in finding a numerical mistake in the earlier report of this work (in the form of two papers). We also thank C. J. Houghton for his interest and correspondence about the symmetries of our field configurations.

Quasi-Lagrangian systems of Newton equations

(Received 19 October 1998; accepted for publication 21 July 1999)

Systems of Newton equations of the form $\ddot{q}=-\frac{1}{2}A^{-1}(q)\nabla k$ with an integral of motion quadratic in velocities are studied. These equations generalize the potential case (when $A=I$, the identity matrix) and they admit a curious quasi-Lagrangian formulation which differs from the standard Lagrange equations by the plus sign between terms. A theory of such quasi-Lagrangian Newton (qLN) systems having two functionally independent integrals of motion is developed with focus on two-dimensional systems. Such systems admit a bi-Hamiltonian formulation and are proved to be completely integrable by embedding into five-dimensional integrable systems. They are characterized by a linear, second-order partial differential equation PDE which we call the fundamental equation. Fundamental equations are classified through linear pencils of matrices associated with qLN systems. The theory is illustrated by two classes of systems: separable potential systems and driven systems. New separation variables for driven systems are found. These variables are based on sets of nonconfocal conics. An effective criterion for existence of a qLN formulation of a given system is formulated and applied to dynamical systems of the Hénon–Heiles type. © *1999 American Institute of Physics.* [S0022-2488(99)00912-3]

I. INTRODUCTION

In this paper we introduce and study such systems of Newton equations $\ddot{q}=M(q)$ that can be generated as equations of the form

$$0=\frac{d}{dx}\frac{\partial E}{\partial \dot{q}}+\frac{\partial E}{\partial q}\equiv\delta^{+}E \tag{1.1}$$

by an energylike function quadratic in $\dot{q}$,

$$E(q,\dot{q})=\sum_{i,j=1}^{n}A_{ij}(q)\dot{q}_i\dot{q}_j+k(q)\equiv\dot{q}^tA\dot{q}+k(q), \tag{1.2}$$

where $A(q)$ is an $n\times n$ symmetric matrix with real entries $A_{ij}(q)$. Here and in what follows we use the standard mechanical notation $q=(q_1,\ldots,q_n)^t$, $\dot{q}=(\dot{q}_1,\ldots,\dot{q}_n)^t$, for position and velocity vectors (the superscript t denotes the transpose of a matrix), where $\dot{q}_k=(\partial/\partial x)q_k$, $k=1,...,n$, with $x\in\mathbf{R}$ being the independent (time) variable. By Newton equations we mean second-order ordinary differential equations (ODEs) of the form: acceleration $\ddot{q}$ is equal to the velocity independent force $M(q)$. The force M may be potential or not.

b)On leave of absence from Department of Physics, A. Mickiewicz University, Poznań, Poland. Electronic mail: krmar@mai.liu.se
c)Electronic mail: halun@mai.liu.se

The equations in (1.1) are called here *quasi-Lagrangian* (qL) equations since they differ from the Lagrange equations for $E(q,\dot{q})$ by sign between terms only. These equations are shortly denoted $0=\delta^+E=(\delta_1^+E,\ldots,\delta_n^+E)^t$ where

$$\delta_k^+E=\frac{d}{dx}\frac{\partial E}{\partial \dot{q}_k}+\frac{\partial E}{\partial q_k}.$$

The qL equations are not invariant with respect to arbitrary point transformation, but it can be easily shown that they remain invariant with respect to the affine change of variables $q=SQ+h$ where $Q=(Q_1,\ldots,Q_n)^t$ are the new variables and $S\in \mathrm{GL}(n),h\in \mathbf{R}^n$.

In the present article we shall mainly discuss quasi-Lagrangian sets of Newton equations (qLN) generated by a function E of the form (1.2) in the two-dimensional space of variables $q=(q_1,q_2)=(r,w)$. This class of equations (which seems to be completely new) is a very interesting class because of its rich differential-algebraic structure and also because it contains (as special cases) the well understood class of point-separable potential Newton equations $\ddot{q}=-\partial V(q)/\partial q$ and the class of nonpotential Newton equations of the triangular form $\ddot{r}=M_1(r,w)$, $\ddot{w}=M_2(w)$ which we shall call *driven* systems. The qLN systems are not necessarily Lagrangian and thus they do not have any straightforward Hamiltonian formulation.

In this paper we develop a theory of completely integrable sets of qLN equations characterized by the existence of two functionally independent integrals of motion quadratic in velocities: E as above and $F=\dot{q}^tB(q)\dot{q}+l(q)$. The existence of a second integral of motion has far-reaching consequences; it eventually leads to wide classes of completely integrable qLN systems.

Example 1.1: The function $E=r\dot{r}\dot{w}-w\dot{r}^2-\alpha wr^2+\frac{1}{2}dr^2+(w^2/2r^4)$ when inserted into (1.1) gives rise to

$$0=\begin{bmatrix}\frac{d}{dx}\frac{\partial E}{\partial \dot{r}}+\frac{\partial E}{\partial r}\\ \frac{d}{dx}\frac{\partial E}{\partial \dot{w}}+\frac{\partial E}{\partial w}\end{bmatrix}=\begin{bmatrix}-2w\left(\ddot{r}-\alpha r+\frac{w}{r^5}\right)+r(\ddot{w}-4\alpha w+d)\\ r\left(\ddot{r}-\alpha r+\frac{w}{r^5}\right)\end{bmatrix}$$
$$=\begin{bmatrix}-2w & r\\ r & 0\end{bmatrix}\begin{bmatrix}\ddot{r}-M_1(r,w)\\ \ddot{w}-M_2(w)\end{bmatrix}, \tag{1.3}$$

which is equivalent to a set of two Newton equations

$$\ddot{r}=\alpha r-\frac{w}{r^5}\equiv M_1(r,w),$$
$$\ddot{w}=4\alpha w-d\equiv M_2(w), \tag{1.4}$$

since the matrix

$$\begin{bmatrix}-2w & r\\ r & 0\end{bmatrix}$$

is nonsingular. We see that the operation $0=\delta^+E$ generates *linear combinations* of the Newton equations (1.4).

Equations (1.4) were discovered accidentally as a Newton parametrization of the second stationary flow of the Harry Dym hierarchy:[1]

$$0=(\tfrac{1}{4}\partial^3-\alpha\partial)(\alpha u^{-3/2}-\tfrac{5}{16}\dot{u}^2u^{-7/2}+\tfrac{1}{4}\ddot{u}u^{-5/2})=(\tfrac{1}{4}\partial^3-\alpha\partial)(-r^5\ddot{r}-\alpha r^6)$$

(here $\partial=\partial/\partial x$), where we substituted $u=r^{-4}$. The substitution $w=-r^5\ddot{r}+\alpha r^6$ gives the system (1.4). The particular feature of (1.4) is that it is a driven system: the equation for w can be solved independently and then the solution $w(x)$ drives the equation for r.

II. GENERAL PROPERTIES OF QUASI-LAGRANGIAN NEWTON SYSTEMS

Let us consider an n-dimensional qL system $0=\delta^+E$ with (quadratic in velocities) energylike function

$$E(q,\dot{q})=\sum_{i,j=1}^{n} A_{ij}(q)\dot{q}_i\dot{q}_j+k(q) \tag{2.1}$$

with a symmetric (which can be assumed without loss of generality) matrix $A(q)=A^t(q)$. We shall formulate the necessary and sufficient condition for the matrix $A(q)$ to make the equations $0=\delta^+E$ equivalent to the set of equations

$$0=\ddot{q}-M(q) \tag{2.2}$$

with a velocity independent force $M(q)=(M_1(q),\ldots,M_n(q))^t$.

Theorem 2.1: *For the function E given by (2.1) with a nonsingular matrix $A(q)$ the following conditions are equivalent:*

(1) *The equations $0=\delta^+E$ are equivalent to the set of Newton equations $\ddot{q}=M(q)$ with velocity independent forces $M=-\frac{1}{2}A^{-1}(q)\nabla k(q)$.*
(2) *The function E is an integral of motion for the qL system $0=\delta^+E$.*
(3) *The matrix elements $A_{ij}(q)$ satisfy the following set of ''cyclic'' differential equations:*

$$0=\partial_iA_{jk}(q)+\partial_jA_{ki}(q)+\partial_kA_{ij}(q) \quad \text{for all} \quad i,j,k=1,...,n. \tag{2.3}$$

Throughout the whole article the symbol ∇ denotes the gradient operator and $\partial_i=\partial/\partial q_i$. Later on we will also use the notation $\partial_{ij}=\partial^2/\partial q_i\partial q_j$.

Statement (2) of the above theorem explains the name ''energylike'' for the function E.

Proof: Let us calculate the ith equation in $0=\delta^+E$:

$$\begin{aligned}0=\delta_i^+E=\frac{d}{dx}\frac{\partial E}{\partial\dot{q}_i}+\frac{\partial E}{\partial q_i}&=\frac{d}{dx}\left(2\sum_j A_{ij}(q)\dot{q}_j\right)+\sum_{j,k}\partial_iA_{jk}(q)\dot{q}_j\dot{q}_k+\partial_ik\\&=2\sum_j A_{ij}(q)\ddot{q}_j+\partial_ik+\sum_{j,k}(\partial_iA_{jk}(q)+\partial_jA_{ki}(q)+\partial_kA_{ij}(q))\dot{q}_j\dot{q}_k.\end{aligned} \tag{2.4}$$

The last equality in (2.4) is due to the symmetry of $A(q)$. Thus, clearly, $2A\ddot{q}+\nabla k=0$ if and only if the equations (2.3) are satisfied and the equivalence of (1) and (3) is established.

Let us now calculate the total derivative of E with respect to *x:*

$$\begin{aligned}\dot{E}&=\sum_i\left(2\sum_j A_{ij}\ddot{q}_j+\partial_ik\right)\dot{q}_i+\sum_{i,j,k}\partial_kA_{ij}\dot{q}_i\dot{q}_j\dot{q}_k\\&=\sum_i\left(2\sum_j A_{ij}\ddot{q}_j+\partial_ik\right)\dot{q}_i+\frac{1}{3}\sum_{i,j,k}(\partial_iA_{jk}+\partial_jA_{ki}+\partial_kA_{ij})\dot{q}_i\dot{q}_j\dot{q}_k.\end{aligned} \tag{2.5}$$

The second term on the right-hand side of the above equation has been rewritten by renaming indices. It contains precisely the cyclic conditions (2.3). So, if one (and thus both) of the statements (1) and (3) are satisfied, then both terms in (2.5) vanish. On the other hand, if $\dot{E}=0$, then terms at different powers of $\dot{q}_i$ in (2.5) must be equal to zero, which implies both 1 and 3.

Remark 2.2: For $n=2$ the general solution of equations (2.3) can easily be found. It is

$$A_{11}(w)=aw^2+bw+\alpha,$$
$$2A_{12}(r,w)=-2arw-br-cw+\beta, \tag{2.6}$$
$$A_{22}(r)=ar^2+cr+\gamma,$$

with some real constants $a,b,c,\alpha,\beta,\gamma$. The corresponding qLN equations read explicitly as

$$0=\begin{bmatrix} \dfrac{d}{dx}\dfrac{\partial E}{\partial \dot r}+\dfrac{\partial E}{\partial r} \\ \dfrac{d}{dx}\dfrac{\partial E}{\partial \dot w}+\dfrac{\partial E}{\partial w}\end{bmatrix}=2\begin{bmatrix} A_{11} & A_{12} \\ A_{12} & A_{22}\end{bmatrix}\begin{bmatrix}\ddot r - M_1(r,w) \\ \ddot w - M_2(r,w)\end{bmatrix},$$

where

$$M_1(r,w)=\frac{1}{2\det(A)}\left(A_{12}\frac{\partial k}{\partial w}-A_{22}\frac{\partial k}{\partial r}\right),$$

$$M_2(r,w)=\frac{1}{2\det(A)}\left(A_{12}\frac{\partial k}{\partial r}-A_{11}\frac{\partial k}{\partial w}\right).$$

The remaining part of this work is mostly devoted to the case when qLN equations $\ddot q=-\frac{1}{2}A^{-1}\nabla k$ generated by E admit a *second* (quadratic in velocities) integral of motion $F(q,\dot q)=\Sigma_{i,j=1}^n B_{ij}(q)\dot q_i\dot q_j+l(q)\equiv\dot q^tB(q)\dot q+l(q)$ which is linearly, and therefore functionally, independent of E.

Theorem 2.3 (qLN systems with two integrals): *Let the qLN system of Newton equations,*

$$0=\delta^+E=2A(\ddot q+\tfrac{1}{2}A^{-1}\nabla k), \tag{2.7}$$

generated by the function $E(q,\dot q)=\dot q^tA(q)\dot q+k(q)$, admit a second, functionally independent quadratic integral of motion $F(q,\dot q)=\dot q^tB(q)\dot q+l(q)$. Then we have the following.

(1) The matrix $B(q)$ has the same structure as the matrix $A(q)$ in the sense that the coefficients $B_{ij}(q)$ of $B(q)$ satisfy the set of cyclic differential equations (2.3).

(2) *If* $\det(B)\neq 0$, *then*

$$A^{-1}\nabla k=B^{-1}\nabla l, \tag{2.8}$$

and so the qLN system $0=\delta^+F=2B(\ddot q+\frac{1}{2}B^{-1}\nabla l)$ generates the same Newton equations as E.

(3) *Any differentiable function $f(E,F)$ generates the same system of Newton equations [by $0=\delta^+f(E,F)$] as E does. In particular, any linear combination, $\lambda E+\mu F$ generates the same system of Newton equations.*

The statement (2) shows one of the peculiar features of qLN systems: all quadratic (in velocities) integrals of motion of a qLN system generate the same system (see also Sec. 151 in Ref. 2).

Proof: The requirement $\dot B=0$ yields [cf. (2.5)]

$$0=\sum_i\left(2\sum_j B_{ij}(q)\ddot q_j+\partial_i l\right)\dot q_i+\sum_{i,j,k}\partial_kB_{ij}\dot q_i\dot q_j\dot q_k$$
$$=\sum_i \dot q_i\left(2B\left(-\frac{1}{2}A^{-1}\nabla k\right)+\nabla l\right)_i+\sum_{i,j,k}\partial_kB_{ij}\dot q_i\dot q_j\dot q_k, \tag{2.9}$$

where the index i at the vector expression containing matrices B and A^{-1} denotes its ith component. The equality is satisfied identically with respect to $\dot{q}$ and so both sums must be separately equal to zero. It follows that B_{ij} satisfy the cyclic conditions $\partial_i B_{jk} + \text{cycl} = 0$ and that $2B(-\frac{1}{2}A^{-1}\nabla k) + \nabla l = 0$. The latter yields precisely the equation (2.8) since we assumed det(B) $\neq 0$. So the statements (1) and (2) are proved.

The operator δ^+ acts as differentiation on the algebra of constants of motion, so that

$$0 = \delta^+ f(E,F) = \frac{\partial f}{\partial E}\delta^+ E + \frac{\partial f}{\partial F}\delta^+ F = 2\left(\frac{\partial f}{\partial E}A + \frac{\partial f}{\partial F}B\right)(\ddot{q} - M)$$

(where $M = -\frac{1}{2}A^{-1}\nabla k = -\frac{1}{2}B^{-1}\nabla l$), which proves the statement (3) of the theorem. Q.E.D.

It is important to stress that the equation (2.8) is the necessary and sufficient condition for the equivalence of the qLN system (2.7) and the qLN system generated by $F = \dot{q}^t B(q)\dot{q} + l(q)$. This condition will be used later.

III. qLN EQUATIONS IN TWO DIMENSIONS

We shall from now on restrict our considerations to the case $n = 2$. We will use the notation $q = (q_1, q_2)^t = (r, w)^t$. The case of arbitrary n is studied in a separate paper.[3]

For $n = 2$ Theorem 2.3 contains two special cases which explain the connection of our theory with classical results[2] about separable potential Newton equations and with the class of driven systems where one of the Newton equations depends only on a single variable r or w and can be solved on its own.

Corollary 3.1: Assume that the Newton equations

$$\ddot{r} = M_1(r,w), \quad \ddot{w} = M_2(r,w) \tag{3.1}$$

generated by the integral $E = \dot{q}^t A(q)\dot{q} + k(q)$ *[with the matrix A given by (2.6)] as* $0 = \delta^+ E$ *have a potential force:* $M_1 = -\partial V/\partial r$, $M_2 = -\partial V/\partial w$. *Then the potential* $V(r,w)$ *satisfies the Bertrand–Darboux equation*[2]

$$\begin{aligned} 0 = {} & (V_{ww} - V_{rr})(-2arw - br - cw + \beta) + 2V_{rw}(aw^2 - ar^2 + bw - cr + \alpha - \gamma) \\ & + 3V_r(2aw + b) - 3V_w(2ar + c) \end{aligned} \tag{3.2}$$

(where the indices at V denote partial derivatives with respect to r and w) with the coefficients $a,b,c,\alpha,\beta,\gamma$ *being exactly the coefficients of the polynomials in entries of the matrix A as given by (2.6). This means that the Newton system (3.1) can be solved by separating variables in the related Hamilton–Jacobi equation (see Ref. 2).*

Proof: If M is potential, then, according to Theorem 2.3, $M = -\frac{1}{2}A^{-1}\nabla k = -\nabla V$ and so $\nabla k = 2A\nabla V$. The potential V exists provided that $\partial^2 k/\partial r \partial w = \partial^2 k/\partial w \partial r$. This yields exactly the Bertrand–Darboux equation (3.2) for V. Q.E.D.

Remark 3.2: The quantity $k(r,w)/\det(A)$ satisfies the same Bertrand–Darboux equation as the potential V. This result can be verified directly but it also follows from Theorem 4.1 in the next section.

Remark 3.3: Let us emphasize that the Hamiltonian system

$$\dot{r} = s, \quad \dot{w} = z, \quad \dot{s} = -\frac{\partial V}{\partial r}, \quad \dot{z} = -\frac{\partial V}{\partial w}$$

generated by a separable natural Hamiltonian $\mathrm{H} = \frac{1}{2}(s^2 + z^2) + V(r,w)$ can be reconstructed as the qLN system $0 = \delta^+ E = 2A(\ddot{q} + \frac{1}{2}A^{-1}\nabla k)$ from its second integral of motion E. This is easy to see, since the above Hamilton equations are equivalent to $\ddot{r} = -\partial V/\partial r, \ddot{w} = -\partial V/\partial w$.

The second class of equations satisfying the assumptions of Theorem 2.3 is the class of qLN systems of the form

$$\ddot{r} = M_1(r,w), \quad \ddot{w} = M_2(w), \tag{3.3}$$

which naturally generalizes the system in Example 1.1. Such systems are called *driven* since the equation for w can be solved independently and then $w(x)$ can be substituted into the equation for r. Observe that the second equation (and thus the whole system) admits an extra integral of motion of the form $F(w,\dot{w}) = \dot{w}^2/2 - \int M_2(w)\, dw$. The qLN system $0 = \delta^+ E$ attains the form (3.3) if and only if the second component M_2 of the force $-\frac{1}{2}A^{-1}\nabla k$ does not depend on *r:*

$$\frac{\partial}{\partial r}(A^{-1}\nabla k)_2 = 0. \tag{3.4}$$

Example 3.4: The qLN equations generated by the function

$$E = r\dot{r}\dot{w} - w\dot{r}^2 + k(r,w)$$

are driven [i.e., have the form (3.3)] provided that $k(r,w)$ satisfies the following second-order PDE:

$$0 = \frac{\partial}{\partial r}\left(\frac{1}{r}k_r + \frac{2w}{r^2}k_w\right),$$

which is a specialization of (3.4). The general solution of the above equation is

$$k(r,w) = f\left(\frac{r^2}{w}\right) + r^2 g(w)$$

with arbitrary twice differentiable functions f and g. The corresponding qLN system attains the form

$$\ddot{r} = -rg'(w) + \frac{r}{w^2}f'\left(\frac{r^2}{w}\right), \quad \ddot{w} = -2\frac{d}{dw}(wg(w))$$

and can be solved by quadratures (see Sec. VII). The second integral of motion of our system, $F = \dot{w}^2/2 - \int M_2(w)\, dw = \dot{w}^2/2 + 2wg(w)$, yields the matrix B

$$B = \begin{bmatrix} 0 & 0 \\ 0 & \frac{1}{2} \end{bmatrix},$$

which is singular so F does not generate our system. However, any linear combination $\lambda E + \mu F$ of E and F (with both λ and $\mu \neq 0$) is another integral of motion with a nonsingular matrix $B' = \lambda A + \mu B$ and thus it generates the same driven system as E.

Existence of two functionally independent constants of motion does not automatically imply Liouville integrability since we also need a Hamiltonian formulation for our equations of motion. Our systems usually do not have a Lagrangian formulation and so they do not have the standard Hamiltonian formulation. On the other hand, the special system discussed in Example 1.1, being a stationary flow of the Harry Dym hierarchy, is expected to be integrable. The question thus arises if/when our qLN systems possess a nonstandard Hamiltonian formulation. In Sec. VI we shall demonstrate the existence of new Poisson structures for qLN systems and their close relationship with Poisson pencils for separable potentials. We shall also explain there when and in what sense our qLN systems are integrable.

IV. FUNDAMENTAL EQUATION

We shall now characterize those two-dimensional qLN systems which admit two (quadratic in velocities) functionally independent integrals of motion E and F, with the force $M=-\frac{1}{2}A^{-1}\nabla k=-\frac{1}{2}B^{-1}\nabla l$. We remind the reader that for $n=2$ we use the notation $q=(q_1,q_2)^t=(r,w)^t$.

Let us consider two symmetric 2×2 matrices $A(r,w)$ and $B(r,w)$ both satisfying the cyclic conditions (2.3). According to Remark 2.2 they must have the following structure,

$$A=\begin{bmatrix} A_{11} & A_{12} \\ A_{12} & A_{22} \end{bmatrix}, \quad B=\begin{bmatrix} B_{11} & B_{12} \\ B_{12} & B_{22} \end{bmatrix} \tag{4.1}$$

with the polynomial entries given by [cf. (2.6)]

$$\begin{aligned} A_{11}(w)&=a_1w^2+b_1w+\alpha_1, \\ 2A_{12}(r,w)&=-2a_1rw-b_1r-c_1w+\beta_1, \\ A_{22}(r)&=a_1r^2+c_1r+\gamma_1, \end{aligned} \tag{4.2}$$

and

$$\begin{aligned} B_{11}(w)&=a_2w^2+b_2w+\alpha_2, \\ 2B_{12}(r,w)&=-2a_2rw-b_2r-c_2w+\beta_2, \\ B_{22}(r)&=a_2r^2+c_2r+\gamma_2, \end{aligned} \tag{4.3}$$

with some arbitrary real constants $a_1,\ldots,\gamma_2$.

Theorem 4.1 (fundamental equation): *Let*

$$\begin{bmatrix} \ddot r \\ \ddot w \end{bmatrix}=-\frac{1}{2}A^{-1}\nabla k=-\frac{1}{2}B^{-1}\nabla l, \tag{4.4}$$

with nonsingular 2×2 *matrices A, B given by (4.1), (4.2), and (4.3), be a set of qLN equations. Then the functions* $K_1=k/\det(A)$ *and* $K_2=l/\det(B)$ *both satisfy the same linear, second-order, partial differential equation*

$$\begin{aligned} 0=&2(A_{12}B_{22}-A_{22}B_{12})K_{rr}-2(A_{11}B_{22}-A_{22}B_{11})K_{rw}+2(A_{11}B_{12}-A_{12}B_{11})K_{ww} \\ &+3(A_{12}\partial_rB_{22}-B_{12}\partial_rA_{22}+A_{22}\partial_wB_{11}-B_{22}\partial_wA_{11})K_r-3(A_{11}\partial_rB_{22}-B_{11}\partial_rA_{22} \\ &+A_{12}\partial_wB_{11}-B_{12}\partial_wA_{11})K_w+3(\partial_rA_{22}\partial_wB_{11}-\partial_rB_{22}\partial_wA_{11})K, \end{aligned} \tag{4.5}$$

which explicitly reads

$$\begin{aligned} 0=&2K_{rr}[\gamma_2\beta_1-\gamma_1\beta_2+(b_2\gamma_1-\gamma_2b_1+\beta_1c_2-c_1\beta_2)r+(\gamma_1c_2-\gamma_2c_1)w+(b_2c_1-c_2b_1+a_2\beta_1 \\ &-a_1\beta_2)r^2+2(\gamma_1a_2-\gamma_2a_1)wr+(a_1b_2-a_2b_1)r^3+(a_2c_1-c_2a_1)wr^2]+4K_{rw}[\alpha_2\gamma_1-\alpha_1\gamma_2 \\ &+(\alpha_2c_1-\alpha_1c_2)r+(b_2\gamma_1-\gamma_2b_1)w+(\alpha_2a_1-\alpha_1a_2)r^2+(\gamma_1a_2-\gamma_2a_1)w^2+(b_2c_1-c_2b_1)rw \\ &+(a_1b_2-a_2b_1)wr^2+(a_2c_1-c_2a_1)rw^2]+2K_{ww}[\alpha_1\beta_2-\alpha_2\beta_1+(\alpha_2b_1-\alpha_1b_2)r \\ &+(\alpha_2c_1-\alpha_1c_2+b_1\beta_2-b_2\beta_1)w+(a_1\beta_2-a_2\beta_1+b_2c_1-c_2b_1)w^2+2(\alpha_2a_1-\alpha_1a_2)wr \\ &+(a_2c_1-c_2a_1)w^3+(a_1b_2-a_2b_1)rw^2]+3K_r[2b_2\gamma_1-2\gamma_2b_1+\beta_1c_2-c_1\beta_2 \\ &+(3b_2c_1-3c_2b_1+2a_2\beta_1-2a_1\beta_2)r+4(\gamma_1a_2-\gamma_2a_1)w+4(a_1b_2-a_2b_1)r^2 \end{aligned}$$

$$+4(a_2c_1-c_2a_1)rw]+3K_w[2\alpha_2c_1-2\alpha_1c_2+b_1\beta_2-b_2\beta_1+(2a_1\beta_2-2a_2\beta_1$$
$$+3b_2c_1-3c_2b_1)w+4(\alpha_2a_1-\alpha_1a_2)r+4(a_2c_1-c_2a_1)w^2+4(a_1b_2-a_2b_1)rw]$$
$$+6K[b_2c_1-c_2b_1+2(a_1b_2-a_2b_1)r+2(a_2c_1-c_2a_1)w] \tag{4.6}$$

with K denoting either K_1 *or* K_2 *and* $K_r=\partial K/\partial r$, $K_{rr}=\partial^2K/\partial r^2$ *and so on.*

Conversely, any solution $K_2(q)$ *of the equation (4.5) generates two different systems of qLN equations* $\ddot{q}=-\frac{1}{2}A^{-1}\nabla k_1=-\frac{1}{2}B^{-1}\nabla l_1$ *and* $\ddot{q}=-\frac{1}{2}A^{-1}\nabla k_2=-\frac{1}{2}B^{-1}\nabla l_2$*, where the functions* k_1,k_2,l_1,l_2 *are determined by the equations*

$$l_1=K_2\det(B),\quad \nabla k_1=AB^{-1}\nabla(K_2\det(B)),$$
$$k_2=K_2\det(A),\quad \nabla l_2=BA^{-1}\nabla(K_2\det(A)). \tag{4.7}$$

We will call the equation (4.5) the *fundamental equation* associated with the matrices A and B.

The fundamental equation plays a crucial role in our theory of qLN systems. Observe that it is invariant with respect to the transformation $A\mapsto\lambda A+\mu B$, $B\mapsto\lambda' A+\mu' B$, $(\lambda,\lambda',\mu,\mu'\in\mathbf{R})$ since the coefficients at every monomial in this equation are skew-symmetric in A and B. This is consistent with statement (3) of Theorem 2.3, which asserts that if any pair E,F of functions generates a qLN system, then the linear combinations $\lambda E+\mu F$ and $\lambda' E+\mu' F$ also generate the same system. This explains that the assumption of nonsingularity for both A and B is nonessential since if $\det(A)\neq 0$, a singular matrix B can always be substituted by an invertible matrix $B'=\lambda A+\mu B$. We shall investigate further properties of the fundamental equation in the next theorem.

Notice that in the second part of Theorem 4.1 one has to reconstruct l_2 and k_1 by integrating the expressions for ∇l_2 and for ∇k_1. This can always be done, as the above theorem implicitly states. Also, notice that in the fundamental equation (4.6) all terms of degree 4 and higher cancel so that the polynomial degree of coefficients in this equation is less than or equal to 3.

Proof (of Theorem 4.1): Our qLN system (4.4) is generated by either of the two functions $E(q,\dot{q})=\dot{q}^tA\dot{q}+k$ and $F(q,\dot{q})=\dot{q}^tB\dot{q}+l$ and so the condition (2.8), i.e., $A^{-1}\nabla k=B^{-1}\nabla l$, must be satisfied. This implies that $\nabla l=BA^{-1}\nabla k$. This equation for the function l has solutions if and only if its compatibility condition $l_{rw}=l_{wr}$ is satisfied. This yields a PDE for the function k which, after the substitution $k=K_1\det(A)$ and with use of the cyclic conditions (2.3), yields that K_1 satisfies equation (4.5). By inserting into this equation the explicit form of the polynomials $A_{11},\ldots,B_{22}$ we obtain (4.6). On the other hand, the condition (2.8) implies also $\nabla k=AB^{-1}\nabla l$, and its compatibility condition $k_{rw}=k_{wr}$ gives a PDE which in terms of $K_2=l/\det(B)$ must attain the form (4.5) with interchanged entries of A and B (since the equation $\nabla k=AB^{-1}\nabla l$ becomes $\nabla l=BA^{-1}\nabla k$ when one exchanges A,k and B,l). Due to the skew-symmetry of coefficients of the equation for K_1 with respect to the entries of matrices A,B [clearly seen from the form of (4.5)], the obtained equation for K_2 differs from the equation for K_1 by a minus sign on the right-hand side only. This proves that K_1 and K_2 both satisfy (4.5) (notice, however, that this does *not* imply $K_1=K_2$).

The existence of k_1 [i.e., the possibility of integrating the equations (4.7) in order to obtain k_1] follows from the fact that the condition $\partial^2k_1/\partial r\partial w=\partial^2k_1/\partial w\partial l$ together with $\nabla k_1=AB^{-1}\nabla(K_2\det(B))$ yields precisely the fundamental equation for K_2 which is satisfied due to assumptions. One can similarly prove the existence of l_2. The second statement of the theorem can now be proved by checking that both pairs k_1,l_1 and k_2,l_2 given by (4.7) satisfy the condition (2.8) and thus give rise to two systems of qLN equations. Q.E.D.

Remark 4.2: For $B(q)=\frac{1}{2}I$ (a 2×2 identity matrix) the equation (4.5) becomes the Bertrand–Darboux equation (3.2) characterizing all separable potentials since in this case $\ddot{q}=-\frac{1}{2}B^{-1}\nabla l=-\nabla l$ is a potential equation.

The next theorem shows that there exists a recursive relation between two different qLN systems constructed from a given solution $K_2(q)$ of the fundamental equation (4.5). This makes it possible to construct a doubly infinite sequence of qLN systems corresponding to a given fundamental equation.

Theorem 4.3 (recursion theorem): *Let k_1, l_1 and k_2, l_2 be two pairs of functions determined by a given solution K_2 of the fundamental equation (4.5) as in (4.7). Then these functions are related by the following linear algebraic equations:*

$$k_2 = l_1 \det(AB^{-1}), \quad l_2 = l_1 \operatorname{Tr}(AB^{-1}) - k_1 \tag{4.8}$$

(where Tr *denotes trace of matrix). Moreover, in the infinite sequence*

$$\begin{array}{ccccccccccc} & k_0 & & & & k_1 & & & & k_2 & & \\ & & & & \nearrow & & & & \nearrow & & & \nearrow \\ \cdots & \downarrow & & K_1 & & \downarrow & & K_2 & & \downarrow & & K_3 & & \cdots \\ & & \nearrow & & & & \nearrow & & & & \nearrow & \\ & l_0 & & & & l_1 & & & & l_2 & & \end{array} \tag{4.9}$$

of triples $(K_m, k_m, l_m), m \in \mathbf{Z}$, defined recursively by

$$k_m = l_{m-1} \det(AB^{-1}), \quad l_m = l_{m-1} \operatorname{Tr}(AB^{-1}) - k_{m-1} \tag{4.10}$$

and by

$$K_m = k_m / \det(A) = l_{m-1} / \det(B),$$

the functions k_m and l_m satisfy $A^{-1}\nabla k_m = B^{-1}\nabla l_m$ and thus they both determine the same (for a given m) qLN system $\ddot{q} = -\frac{1}{2}A^{-1}\nabla k_m = -\frac{1}{2}B^{-1}\nabla l_m$. All functions K_m satisfy the fundamental equation (4.5) and are related through the following two-step recursion:

$$K_{m+1} = K_m \operatorname{Tr}(AB^{-1}) - K_{m-1} \det(AB^{-1}). \tag{4.11}$$

The above recursion is reversible. The solution K_m placed between l_{m-1} and k_m determines both l_{m-1} and k_m. The recursion (4.11) is soluble. Namely, if we denote the eigenvalues of the matrix AB^{-1} by λ_1 and λ_2, then it can be proved that for the case $\lambda_1 \neq \lambda_2$ the solution of (4.11) is

$$K_m = \frac{1}{\lambda_1 - \lambda_2}(K_1 - \lambda_2 K_0)\lambda_1^m + \frac{1}{\lambda_1 - \lambda_2}(K_0\lambda_1 - K_1)\lambda_2^m,$$

while in the case $\lambda_1 = \lambda_2$ the solution of (4.11) becomes

$$K_m = K_0 \lambda_1^m + \left(\frac{K_1}{\lambda_1} - K_0\right) m \lambda_1^m.$$

In both cases K_0 and K_1 are two subsequent solutions of the fundamental equation in the sequence (4.9) which are related by

$$\nabla(K_1 \det(B)) = BA^{-1}\nabla(K_0 \det(A)).$$

In order to prove the recursion theorem we need the following lemma.

Lemma 4.4: Let $X = AB^{-1}$ with matrices A,B as above. Then

$$X^{-1}\nabla(\det(X)) = \nabla(\operatorname{Tr}(X)).$$

This lemma follows from the cyclic properties (2.3) of matrices A and B by a lengthy but straightforward calculation.

Proof (of the recursion theorem): Consider a solution K_2 of the fundamental equation and the functions $k_1, l_1; k_2, l_2$ defined by (4.7). Then obviously $k_2/\det(A)=l_1/\det(B)$, which immediately implies $k_2=l_1\det(AB^{-1})$. Let $X=AB^{-1}$. Then

$$\begin{aligned}\nabla l_2-\nabla(l_1\,\mathrm{Tr}\,(X)-k_1)&=X^{-1}\nabla(K_2\det(A))-\nabla(K_2\det(B)\,\mathrm{Tr}\,(X))+X\nabla(K_2\det(B))\\&=X^{-1}\nabla(K_2\det(A))-(\mathrm{Tr}\,(X)I-X)\nabla(K_2\det(B))-K_2\det(B)\nabla(\mathrm{Tr}\,(X))\\&=X^{-1}\nabla(K_2\det(A))-X^{-1}\det(X)\nabla(K_2\det(B))-K_2\det(B)\nabla(\mathrm{Tr}\,(X))\\&=K_2\det(B)(X^{-1}\nabla(\det(X))-\nabla(\mathrm{Tr}\,(X)))=0,\end{aligned}$$

where we used that $X^2-\mathrm{Tr}\,(X)X+\det(X)I=0$ as follows from the Cayley–Hamilton theorem. The last equality is due to Lemma 4.4 above. Thus $l_2=l_1\,\mathrm{Tr}\,(X)-k_1$ up to a nonessential additive constant. This proves the first assertion of the theorem.

If we now define the sequence $\{(k_m, l_m)\}$ via the recursive procedure (4.10), then a simple induction argument shows that each pair (k_m, l_m) satisfies the condition (2.8) and thus both k_m and l_m determine the same qLN system. Moreover, each $K_m=k_m/\det(A)=l_{m-1}/\det(B)$ is a solution of the fundamental equation as theorem (4.1) states. Finally, to obtain (4.11) it is enough to insert the formula $K_m=k_m/\det(A)=l_{m-1}/\det(B)$ into the second equation in (4.10). Q.E.D.

Example 4.5 (cf. Remark 4.2): For $B=\frac{1}{2}I$ (the potential case) the recursion (4.8) takes the form

$$k_2=4V_1\det(A),\quad V_2=2\,\mathrm{Tr}\,(A)V_1-k_1$$

with $V_1=l_1$. This is the separable case when (4.5) reduces to the Bertrand–Darboux equation. In the generic case, i.e., when $a\neq 0$ in (2.6), the matrix $A(q)$ can be reduced [with the use of affine transformations $q=SQ+h$ with $S\in \mathrm{GL}\,(2,\mathbf{R}), h\in\mathbf{R}^2$, see also Sec. V] to the form

$$A(q)=\begin{bmatrix}-q_2^2+\lambda_2 & q_1q_2\\ q_1q_2 & -q_1^2+\lambda_1\end{bmatrix}.$$

If we now start with the harmonic oscillator potential $V_1=\frac{1}{2}(q_1^2+q_2^2)$, then the condition $\nabla V_1=\frac{1}{2}A^{-1}\nabla k_1$ gives $k_1=\lambda_2q_1^2+\lambda_1q_2^2$ and the recursion formulas specify to

$$k_2=2(q_1^2+q_2^2)(\lambda_1\lambda_2-\lambda_2q_1^2-\lambda_1q_2^2),$$

$$V_2=\lambda_1q_1^2+\lambda_2q_2^2-(q_1^2+q_2^2)^2,$$

thus reproducing the potential of the Garnier system.[4] It can be shown that the above formulas prolongate to the $n=2$ case of the recursion for the Jacobi family of elliptic separable potentials.[5]

In order to explain the character of the recursion (4.9) more completely, let us consider instead of the pair (A,B) of cyclic matrices another pair $(A+\mu B,B)$ with $\mu\in\mathbf{R}$. As it can be shown (see below), this pair determines the same fundamental equation as the pair (A,B) does. By choosing a solution K_2 of the fundamental equation and the pair $(A+\mu B,B)$ we arrive at a different qLN system $\ddot{q}=M_\mu(q)=-\frac{1}{2}(A+\mu B)^{-1}\nabla(K_2\det(A+\mu B))$. It turns out that the force $M_\mu(q)$ is a linear combination of two neighboring forces in the sequence (4.9) generated by K_2.

Lemma 4.6: Let A and B be two 2×2 matrices satisfying the cyclic conditions (2.3) and let K be a solution of the fundamental equation associated with A and B. Let also $\mu\in\mathbf{R}$. Then

$$(A+\mu B)^{-1}\nabla(K\det(A+\mu B))=A^{-1}\nabla(K\det(A))+\mu B^{-1}\nabla(K\det(B)).$$

This lemma is a consequence of Lemma 4.4. It says that a solution of a given fundamental equation determines the force M (and so the system of qLN equations) up to *linear combinations* of two consecutive systems in the recursion (4.9).

As we have mentioned, the matrices A and B uniquely determine the fundamental equation. The choice of A,B which generate a given fundamental equation is, however, not unique since the pair $A' = \alpha A + \beta B,\ B' = \gamma A + \delta B$ determines the same equation. One can also ask to what extent a given fundamental equation determines the pair (A,B). The precise relationship between pairs (A,B) and the fundamental equation is explained in the following theorem.

Theorem 4.7: *Let (A,B) be a pair of linearly independent matrices A, B satisfying the cyclic conditions (2.3). Then there is a 1–1 relationship between the linear span $\{\lambda A + \mu B : \lambda, \mu \in \mathbf{R}\}$ of A and B and the fundamental equation (4.5), i.e.,*

(1) *any two linearly independent matrices $A' = \alpha A + \beta B,\ B' = \gamma A + \delta B$ determine the same fundamental equation as (A, B) does.*
(2) *If the pair (A',B') determines the same fundamental equation as (A,B) does, then the matrices A' and B' belong to the linear span $\{\lambda A + \mu B\}$ of A* and *B.*

Proof: An easy calculation shows that the fundamental equation associated with the matrices $A' = \alpha A + \beta B$ and $B' = \gamma A + \delta B$ differs from the fundamental equation associated with the matrices A and B by the multiplicative factor $\alpha\delta - \beta\gamma$ on the right-hand side, i.e., by the nonzero determinant of the transformation between (A,B) and (A',B'), and so it is, in fact, the same equation. This shows assertion (1) of the theorem.

Assume now that the equation (4.5) is associated with a pair (A,B). Consider the vector $\vec{X} = (X_1, X_2, X_3)^t \in \mathbf{R}^3$ of the coefficients of (4.5) at the highest derivatives K_{rr}, K_{rw}, K_{ww}, respectively. Then

$$X_1 = A_{12}B_{22} - A_{22}B_{12},$$
$$X_2 = A_{22}B_{11} - A_{11}B_{22},$$
$$X_3 = A_{11}B_{12} - A_{12}B_{11}, \tag{4.12}$$

or

$$\vec{X} = \vec{A} \times \vec{B}, \tag{4.13}$$

where $\vec{A} = (A_{11}, A_{12}, A_{22})^t$ and $\vec{B} = (B_{11}, B_{12}, B_{22})^t$ are three-dimensional vectors depending on r and w. Hence, for a fixed (r,w) both vectors $\vec{A}$ and $\vec{B}$ are orthogonal to $\vec{X}$. The coefficients at K_r, K_w, and K yield equations which are differential consequences of (4.12) and so they do not impose any additional restrictions on (A,B). Suppose now that there exist matrices A' and B' satisfying the cyclic condition (2.3) and associated with the same fundamental equation. This means that the equation (4.13) has another solution, i.e., that $\vec{X} = \vec{A}' \times \vec{B}'$, so that the vectors $\vec{A}'$ and $\vec{B}'$ are orthogonal to $\vec{X}$ and, in consequence, they are linear combinations of $\vec{A}$ and $\vec{B}$: $\vec{A}' = \alpha\vec{A} + \beta\vec{B},\ \vec{B}' = \gamma\vec{A} + \delta\vec{B}$ with some coefficients that may depend on r and w. For the corresponding matrices it immediately follows that

$$A' = \alpha A + \beta B, \quad B' = \gamma A + \delta B.$$

It remains to show that the coefficients α, β, γ, δ in fact do not depend on r nor w. This can be shown by inserting the explicit form (4.2) and (4.3) of entries of matrices A,B, A' and B' into (4.12). This shows assertion (2) of the theorem. Q.E.D.

V. AFFINE INEQUIVALENT FORMS OF FUNDAMENTAL EQUATION

In this section we are interested in characterizing all different types of two-dimensional qLN systems admitting two functionally independent integrals of motion E and F which are quadratic in velocities, i.e., systems of the form

$$\ddot{q}=M=-\tfrac{1}{2}A^{-1}\nabla k=-\tfrac{1}{2}B^{-1}\nabla l, \tag{5.1}$$

where M is the force of the system. Every such system is described by a pair of matrices $A(q),B(q)$ satisfying the cyclic conditions (2.3) and by a pair of functions $k(q)$, $l(q)$ satisfying $A^{-1}\nabla k=B^{-1}\nabla l$. We remind the reader that the functions $k/\det(A)$ and $l/\det(B)$ satisfy the same fundamental equation with the coefficients completely determined by the matrix elements of A and B.

Let us first consider how the qLN system $0=\delta^{+}E=2A(\ddot{q}+\tfrac{1}{2}A^{-1}\nabla k)$ transforms under the affine transformation of coordinates

$$q=SQ+h,\quad S\in \mathrm{GL}(2,\mathbf{R}),\quad h\epsilon\mathbf{R}^2, \tag{5.2}$$

where $Q=(Q_1,\dots,Q_n)^t$. It is easy to see that, under the affine transformation (5.2), the generating function E transforms as

$$E(q(Q),\dot{q}(\dot{Q}))=\dot{Q}^tS^tA(q(Q))SQ+k(q(Q)), \tag{5.3}$$

where $q(Q)=SQ+h$ and so $\dot{q}(\dot{Q})=S\dot{Q}$. It can be shown by a direct verification that the transformed matrix

$$A_Q(Q)=S^tA(q(Q))S \tag{5.4}$$

in (5.3) also satisfies the cyclic conditions (2.3) and therefore (5.3) generates a qLN system. This means that the qLN system $0=2A(\ddot{q}+\tfrac{1}{2}A^{-1}\nabla k)$ is indeed *invariant* with respect to the affine change of coordinates (5.2).

Let us now consider the system (5.1). Using (5.4) one can prove that the fundamental equation associated with the pair (A,B) of matrices is also invariant with respect to the affine transformations (5.2). This means that we can simplify this fundamental equation by performing an appropriate affine change of coordinates. However, Theorem 4.7 makes it possible to classify fundamental equations, and therefore the corresponding qLN systems, by classifying *pairs* of matrices (A,B). Instead of working with the coefficients of the fundamental equation we can thus work with linear spans $\{\lambda A+\mu B\}$ of A and B. Since the affine transformations do not change the polynomial degree of matrices A,B, the set of all linear spans of A and B can be divided into affine inequivalent classes corresponding to different polynomial degree of A and B. Each equivalence class will be represented by the algebraically simplest pair of matrices obtained by the use of affine transformations and linear combining of matrices (since the latter leave the fundamental equation unchanged, see above).

In order to be more precise we shall introduce some notation. By $A^{(i)}$ $(i=0,1,2)$ we will denote all matrices A which satisfy the cyclic conditions (2.3) and have the highest degree of polynomial entries equal to i. So, for example, the general form of matrices in the class $A^{(1)}$ is

$$\begin{bmatrix} bq_1+\alpha & -\tfrac{1}{2}bq_1-\tfrac{1}{2}cq_2+\tfrac{1}{2}\beta \\ * & cq_1+\gamma \end{bmatrix}$$

with arbitrary constants (parameters) b,c,α,β,γ. We will use the symbol $*$ to denote matrix elements determined by the symmetry of a given matrix. Moreover, by $[A^{(i)},B^{(j)}]$ $(i,j=0,1,2)$ we will denote the class of (nonordered) pairs (A,B) of linearly independent matrices A,B such that one of the matrices belongs to $A^{(i)}$ and the other to $B^{(j)}$. We have, of course, $[A^{(i)},B^{(j)}]=[A^{(j)},B^{(i)}]$ and so we have precisely six such classes. Obviously, all classes $[A^{(i)},B^{(j)}]$ are invariant with respect to the affine transformations (5.2). Notice that if $(A,B)\in[A^{(2)},B^{(2)}]$, we can kill the coefficient a_2 at the second degree monomials in B by subtraction $B\mapsto B-(a_2/a_1)A$ so every element of this class can be reduced to an element in $[A^{(2)},B^{(1)}]$. Thus we have to consider only five classes. It is easy to realize that the five classes $[A^{(i)},B^{(j)}]$ with $i\geqslant j,j<2$ are invariant with respect to the affine transformations (5.2) and with respect to taking linear combinations of pairs (A,B). These two operations can now be used to find for every class a simple representing pair (A,B) which has a minimal number of free parameters (a simple representative). Consider, for example, the class $[A^{(2)}, B^{(0)}]$. The general form of matrices belonging to this class is

$$A=\begin{bmatrix} a_1q_2^2+b_1b_2+\alpha_1 & -a_1q_1q_2-\frac{1}{2}b_1q_1-\frac{1}{2}c_1q_2+\beta_1/2 \\ * & a_1q_1^2+c_1q_1+\gamma_1 \end{bmatrix},$$
$$B=\begin{bmatrix} \alpha_2 & \frac{\beta_2}{2} \\ \frac{\beta_2}{2} & \gamma_2 \end{bmatrix}. \tag{5.5}$$

Translation by the vector $h=-(1/2a_1)(c_1,b_1)^t$ kills b_1 and c_1 in the matrix A. Since translations obviously preserve the form of B the above pair of matrices attains the form

$$A=\begin{bmatrix} a_1q_2^2+\alpha_1 & -a_1q_1q_2+\frac{\beta_1}{2} \\ * & a_1q_1^2+\gamma_1 \end{bmatrix}, \quad B=\begin{bmatrix} \alpha_2 & \frac{\beta_2}{2} \\ \frac{\beta_2}{2} & \gamma_2 \end{bmatrix}$$

with some new constants denoted by the same letters as in (5.5). Further, the transformation $A\mapsto A-(\beta_1/\beta_2)B$ kills the coefficient β_1 in A. In the case when $\beta_2=0$ we can still kill β_1 in A by the linear transformation $q=SQ$ with

$$S=\begin{bmatrix} \frac{-t\gamma_1-\beta_1/2}{\alpha_1+t\beta_1/2} & 1 \\ 1 & t \end{bmatrix},$$

where $t\in\mathbf{R}$ must be chosen so that $\alpha_1+t\beta_1/2\neq 0$ and $\det(S)\neq 0$, which can be always done. Finally, we can divide both matrices by a_1 and $2\alpha_2$, respectively. So, a simple representative of the class $[A^{(2)}, B^{(0)}]$ has the form

$$A=\begin{bmatrix} q_2^2+\alpha_1 & -q_1q_2 \\ * & q_1^2+\gamma_1 \end{bmatrix}, \quad B=\begin{bmatrix} \frac{1}{2} & \frac{\beta_2}{2} \\ \frac{\beta_2}{2} & \gamma_2 \end{bmatrix} \tag{5.6}$$

with four essential parameters. Both separable and driven systems belong to this class since $B=\frac{1}{2}I$ for separable systems and $B=\operatorname{diag}(\frac{1}{2},0)$ for driven systems.

We perform a similar reduction for each class $[A^{(i)}, B^{(j)}], i\geq j, j<2$. The results are presented below.

It is also easy to see that one can pass from one invariant class $[A^{(i)}, B^{(j)}]$ to another by specifying values of free parameters. For example, by setting $a_1=0$ we obtain $[A^{(1)}, B^{(1)}]$ from $[A^{(2)}, B^{(1)}]$; by setting $b_2=c_2=0$ we get $[A^{(1)}, B^{(0)}]$ and so on as shown in Fig. 1. This figure presents—for all classes $[A^{(i)}, B^{(j)}]$—complete results of simplification of a generic pair (A,B) belonging to each class with the use of linear combinations and affine transformations.

Below we list the form of the fundamental equation (4.6) corresponding to the simple representative pair (A,B) of each class as given in Fig. 1. We use the notation $K_i=\partial K/\partial q_i$, $K_{ij}=\partial^2K/\partial q_j\partial q_i$.

(a) For $[A^{(2)}, B^{(1)}]$,

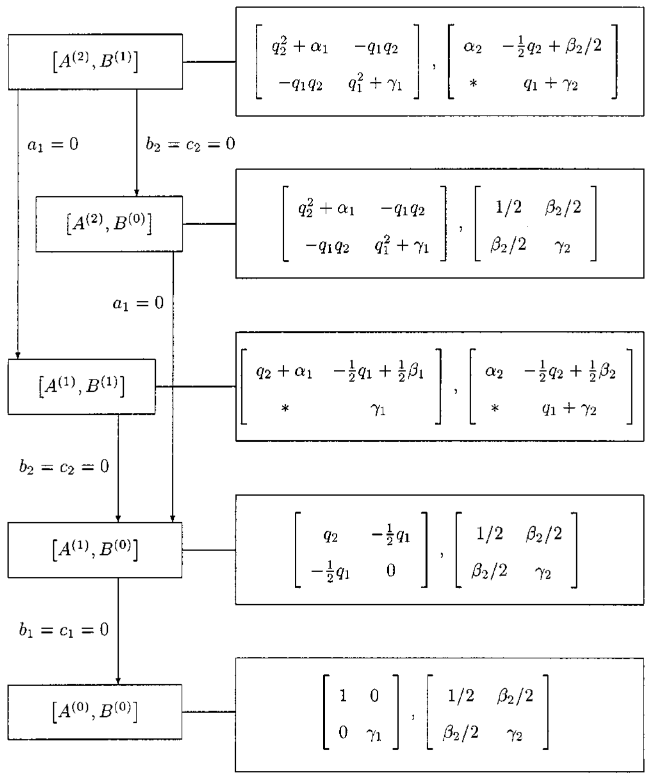

FIG. 1. Classification diagram.

$$0=K_{11}(-\gamma_1\beta_2+\gamma_1q_2-2\gamma_2q_1q_2-\beta_2q_1^2-q_1^2q_2)+2K_{12}(\alpha_2\gamma_1-\alpha_1\gamma_2-\alpha_1q_1-\gamma_2q_2^2+\alpha_2q_1^2$$
$$-q_1q_2^2)+K_{22}(\alpha_1\beta_2-\alpha_1q_2+2\alpha_2q_1q_2+\beta_2q_2^2-q_2^3)+3K_1(-\beta_2q_1-2\gamma_2q_2-2q_1q_2)$$
$$+3K_2(-\alpha_1+2\alpha_2q_1+\beta_2q_2-2q_2^2)-6q_2K.$$

(b) For $[A^{(2)},B^{(0)}]$,

$$0=K_{11}(-\gamma_1\beta_2-2\gamma_2q_1q_2-\beta_2q_1^2)+2K_{12}(\gamma_1-\alpha_1\gamma_2-\gamma_2q_2^2+q_1^2)$$
$$+K_{22}(\alpha_1\beta_2+2q_1q_2+\beta_2q_2^2)+3K_1(-\beta_2q_1-2\gamma_2q_2)+3K_2(2q_1+\beta_2w). \tag{5.7}$$

(c) For $[A^{(1)},B^{(1)}]$,

$$0=2K_{11}(\gamma_2\beta_1-\gamma_1\beta_2+(-\gamma_2+\beta_1)q_1+q_2-q_1^2)$$
$$+4K_{12}(\alpha_2\gamma_1-\alpha_1\gamma_2-\alpha_1q_1-\gamma_2q_2-q_1q_2)$$
$$+2K_{22}(\alpha_1\beta_2-\alpha_2\beta_1+\alpha_2q_1+(\beta_2-\alpha_1)q_2-q_2^2)$$
$$+3K_1(-2\gamma_2+\beta_1-3q_1)+3K_2(-2\alpha_1+\beta_2-3q_2)-6K.$$

(d) For $[A^{(1)},B^{(0)}]$,

$$0=2\gamma_2q_1K_{11}+4\gamma_2q_2K_{12}-2(q_1/2+\beta_2q_2)K_{22}+6\gamma_2K_1-3\beta_2K_2. \tag{5.8}$$

(e) For $[A^{(0)},B^{(0)}]$,

$$0=\gamma_1\beta_2K_{11}+2(\alpha_1\gamma_2-\alpha_2\gamma_1)K_{12}-\alpha_1\beta_2K_{22}. \tag{5.9}$$

What we present here is an illustrative characterization of different types of fundamental equations in terms of matrix pairs (A,B). This provides a good intuitive description of the world of qLN equations and helps to specify where two particular classes—separable potentials and driven systems—belong. An alternative way of classifying qLN equations with two quadratic integrals of motion is to simplify the fundamental equation (4.5) with the use of affine transformations as has been done for the Bertrand–Darboux equation[2] (see Example 5.1 below). This may amount to a similar picture as we have presented above, but the principles of simplification of the third-order polynomials at K_{rr}, K_{rw}, and K_{ww} are more difficult to discern. This is yet to be done.

Example 5.1: The classification of types of the Bertrand–Darboux equation with respect to Euclidean transformations leads to three forms of this equation which are separable in either elliptic, parabolic, or Cartesian coordinates. According to Corollary 3.1, if a potential two-dimensional Newton system

$$\ddot{q}_1 = -\frac{\partial V}{\partial q_1}, \quad \ddot{q}_2 = -\frac{\partial V}{\partial q_2}$$

with $V = V(q_1, q_2)$ possesses a second integral of motion of the form $E = \dot{q}^t A \dot{q} + k(q)$ with $A \in A^{(2)}$, then it has the qLN form $\ddot{q} = -\frac{1}{2}A^{-1}\nabla k = -\frac{1}{2}B^{-1}\nabla V$ with $B = \frac{1}{2}I$ where I is 2×2 identity matrix. Moreover, the potential V must satisfy the Bertrand–Darboux equation (3.2). This system belongs to the class $[A^{(2)}, B^{(0)}]$ with $\beta_2 = 0$ and with $\alpha_2 = \gamma_2 = \frac{1}{2}$. The corresponding fundamental equation is exactly the Bertrand–Darboux equation since in this case $K = V/\det(B) = 4V$. The simplification procedure described above does not alter the form of the matrix $B = \frac{1}{2}I$ and so the corresponding fundamental equation (5.7) attains the form

$$0 = (V_{22} - V_{11})q_1 q_2 + V_{12}(q_1^2 - q_2^2 + \gamma_1 - \alpha_1) - 6q_2 V_1 + 6q_1 V_2, \tag{5.10}$$

which has only one essential parameter $\gamma_1 - \alpha_1$. This form of the Bertrand–Darboux equation separates in the elliptic coordinates.[2] The specification $a_1 = 0$ reduces the class $[A^{(2)}, B^{(0)}]$ to $[A^{(1)}, B^{(0)}]$. The corresponding fundamental equation after the simplification procedure attains the form (5.8). In the case when $B = \frac{1}{2}I$, the final form of B (after simplification) will be exactly the same (i.e., with $\beta_2 = 0$, $\alpha_2 = \gamma_2 = \frac{1}{2}$), and so the fundamental equation (5.8) reads

$$0 = q_1(V_{11} - V_{22}) + 2q_2 V_{12} + 3V_1.$$

It does not contain any parameters now. This equation separates in the parabolic coordinates.[2] Further specification $b_1 = c_1 = 0$ leads to the class $[A^{(0)}, B^{(0)}]$ of constant symmetric matrices. The corresponding fundamental equation in the course of simplification attains the form (5.9) which in the case $B = \frac{1}{2}I$ (again, this form of B survives the simplification procedure—in this case just the diagonalization of A by a rotation) yields $V_{\xi\eta} = 0$, where ξ, η are coordinates which originate by a rotation of the Cartesian coordinates x,y. This is the case of the Bertrand–Darboux equation separable in (rotated) Cartesian coordinates.

The above example indicates that the fundamental equation plays the same role in the theory of qLN equations as the Bertrand–Darboux equation does in the theory of separable potential forces $M = -\partial V/\partial q$. For separable potentials the characteristic coordinates of the Bertrand–Darboux equation determine the coordinates of separation which makes it possible to solve the corresponding Newton equations by quadratures. In Sec. VII we prove a similar result for the class of two-dimensional driven systems by showing that the characteristic coordinates of the fundamental equation associated with a given driven system separate this system, i.e., that in these coordinates it is possible to integrate the system by quadratures. The question whether the characteristic coordinates of the fundamental equation separate general qLN systems admitting two integrals of motion remains to be investigated. We have here to do with a much broader theory depending on five essential parameters while the Bertrand–Darboux equation depends on one parameter only.

VI. HAMILTONIAN STRUCTURES AND COMPLETE INTEGRABILITY

In this section we will establish a Hamiltonian formulation of two-dimensional qLN systems and discuss their complete integrability. Let us consider first the qLN system $0=\delta^+ E = 2A(\ddot{q} + \frac{1}{2}A^{-1}\nabla k(q))$ generated by the function $E=\dot{q}^t A(q)\dot{q}+k(q)$, $q=(q_1,q_2)^t$ with the 2×2 matrix $A(q)$ satisfying the cyclic conditions (2.3). This system usually does not have any Lagrangian formulation and thus it does not have the standard Hamiltonian formulation. However, we can always embed this system in a Hamiltonian qLN system in the five-dimensional phase space of variables (q_1,q_2,p_1,p_2,d) as the following theorem states.

Theorem 6.1 (Hamiltonian form of qLN systems): *Let*

$$0=\ddot{q}+\tfrac{1}{2}A^{-1}(q)\nabla(k(q)+d\lambda\,\det(A(q))) \tag{6.1}$$

with $q=(q_1,q_2)^t$ *be the qLN system generated by*

$$\hat{E}=\dot{q}^t A(q)\dot{q}+k(q)+d\lambda\,\det(A(q))\equiv E+d\lambda\,\det(A)$$

with some constant λ *and with* $d\in\mathbf{R}$. *Let also* $\mathcal{M}$ *be the extended five-dimensional phase space of variables* (q_1,q_2,p_1,p_2,d) *with* $p_i=\dot{q}_i$, $i=1,2$. *Then the system* (6.1) *is equivalent to*

$$\begin{bmatrix}\dot{q}\\ \dot{p}\\ \dot{d}\end{bmatrix}=\left[\begin{array}{cc|c} 0 & -(\lambda/2)G(q) & p\\ (\lambda/2)G^t(q) & -(\lambda/2)F(q,p) & \hat{M}(q,d)\\ \hline -p^t & -\hat{M}^t(q,d) & 0\end{array}\right]\nabla_{\mathcal{M}}d\equiv\Pi_A\nabla_{\mathcal{M}}d, \tag{6.2}$$

where $\nabla_{\mathcal{M}}=(\partial/\partial q_1,\partial/\partial q_2,\partial/\partial p_1,\partial/\partial p_2,\partial/\partial d)^t$ *is the gradient operator in* $\mathcal{M}$ *and where the* 2×2 *matrices G and F and the vector* $\hat{M}$ *are given by*

$$G(q)=\det(A)A^{-1}=\begin{bmatrix} A_{22} & -A_{12}\\ -A_{12} & A_{11}\end{bmatrix},$$

$$F_{12}(q,p)=\frac{1}{2}\left(\frac{\partial A_{22}}{\partial q_1}p_2-\frac{\partial A_{11}}{\partial q_2}p_1\right),\quad F=-F^t,$$

$$\hat{M}(q,d)=M(q)-\tfrac{1}{2}d\lambda A^{-1}\nabla(\det(A))$$

with $M(q)=-\frac{1}{2}A^{-1}\nabla k$ *being the force of the qLN system* $0=\delta^+E$. *Moreover, the antisymmetric matrix* Π_A *is Poisson and so* (6.2) *is the Hamiltonian formulation of (6.1).*

Notice that the matrix G obtained above is symmetric due to the symmetry of A.

Proof: Since $\nabla_{\mathcal{M}}d=(0,0,0,0,1)^t$, the equation (6.2) yields $\dot{q}=p$, $\dot{p}=\hat{M}=-\frac{1}{2}A^{-1}\nabla(k+d\lambda\,\det(A))$, $\dot{d}=0$, i.e., it reproduces (6.1). The matrix Π_A is antisymmetric and it is straightforward to verify that it satisfies the Jacobi identity in the phase space $\mathcal{M}$. Q.E.D.

We remind the reader that the operator $\Pi: T^*\mathcal{M}\to T\mathcal{M}$ mapping fiberwise the cotangent bundle $T^*\mathcal{M}$ of $\mathcal{M}$ into the tangent bundle $T\mathcal{M}$ is Poisson if the bilinear mapping $\{\cdot,\cdot\}_\Pi: C^\infty(\mathcal{M})\times C^\infty(\mathcal{M})\to C^\infty(\mathcal{M})$ defined for any pair of functions $f,g:\mathcal{M}\to\mathbf{R}$ by

$$\{f,g\}_\Pi=\langle\nabla_{\mathcal{M}}f,\Pi\nabla_{\mathcal{M}}g\rangle$$

(where $\langle\cdot,\cdot\rangle$ is the dual map between cotangent and tangent spaces of $\mathcal{M}$) is a Poisson bracket.

Remark 6.2: In the hyperplane $d=0$ the solutions of (6.2) coincide with the solutions of $\ddot{q}=-\frac{1}{2}A^{-1}\nabla k$. Thus our original qLN system $\ddot{q}=-\frac{1}{2}A^{-1}\nabla k$ is in a natural way embedded in the Hamiltonian system (6.2).

Proposition 6.3: The function

$$\hat{E}=p^tA(q)p+k(q)+d\lambda\ \det(A(q))$$

is a Casimir function for the Poisson operator Π_A *in* (6.2), *that is,* $\Pi_A\nabla_{\mathcal{M}}\hat{E}=0$.

One can check this proposition by a direct verification.

A statement converse to the second statement of Theorem 6.1 also holds.

Theorem 6.4: *Let the antisymmetric matrix*

$$\Pi=\left[\begin{array}{cc|c} 0 & -(\lambda/2)G(q) & p \\ (\lambda/2)G^t(q) & -(\lambda/2)F(q,p) & \hat{M}(q,d) \\ \hline -p^t & -\hat{M}^t(q,d) & 0 \end{array}\right] \tag{6.3}$$

be a Poisson operator in the space of variables (q,p,d). *Then*

(1) $G(q)$ *must have the form*

$$G(q)=\begin{bmatrix} aq_1^2+cq_1+\gamma & aq_1q_2+\frac{b}{2}q_1+\frac{c}{2}q_2-\frac{\beta}{2} \\ * & aq_2^2+bq_2+\alpha \end{bmatrix} \tag{6.4}$$

(thus it is symmetric) with some constants $a,b,c,\alpha,\beta,\gamma$ *and so*

$$G=\begin{bmatrix} A_{22} & -A_{12} \\ -A_{21} & A_{11} \end{bmatrix} \tag{6.5}$$

for some symmetric matrix $A(q)$ *satisfying the cyclic conditions (2.3). In other words,* $\Pi=\Pi_A$ *with* Π_A *defined in (6.2) and with*

$$A=\begin{bmatrix} G_{22} & -G_{12} \\ -G_{21} & G_{11} \end{bmatrix}.$$

(2) $F(q,p)$ *must have the form*

$$F_{12}(q,p)=\frac{1}{2}\left(\frac{\partial A_{22}}{\partial q_1}p_2-\frac{\partial A_{11}}{\partial q_2}p_1\right),\quad F=-F^t. \tag{6.6}$$

(3) $\hat{M}(q,d)$ *must have the form*

$$\hat{M}(q,d)=M(q)+d\lambda N(q),$$

where $-2AM(q)=\nabla k$ *for some function* $k(q)$, *so if* $\det(G)\neq 0$, *then* $M(q)=-\frac{1}{2}A^{-1}\nabla k$, *and where* $N(q)=-\frac{1}{2}A^{-1}\nabla(\det(A))$.

Proof: The conditions $\{\{q_i,q_j\}_\Pi,q_k\}_\Pi+\text{cycl}=0$ and $\{\{q_i,q_j\}_\Pi,p_k\}_\Pi+\text{cycl}=0$ (where ''cycl'' means the cyclic permutation of expressions) hold identically due to the block structure of Π. The condition $\{\{q_i,q_j\}_\Pi,d\}_\Pi+\text{cycl}=0$ yields the symmetry of G: $G=G^t$. Further,

$$0=\{\{q_i,p_j\}_\Pi,d\}_\Pi+\text{cycl}=-\frac{\lambda}{2}\left(p_1\frac{\partial G_{ij}}{\partial q_1}+p_2\frac{\partial G_{ij}}{\partial q_2}\right)+\frac{\lambda}{2}F_{ij}-p_i\frac{\partial \hat{M}_j}{\partial d}.$$

Let us denote the right-hand side of the above equality by $-(\lambda/2)R_{ij}$. Notice that $\partial\hat{M}_j/\partial d$ cannot depend on d, and so we have $\partial\hat{M}_j/\partial d=\lambda N_j(q)$ for some vector $N(q)=(N_1(q),N_2(q))^t$ which yields $\hat{M}(q,d)=M(q)+d\lambda N(q)$ for some vector $M(q)$. By taking linear combinations of the conditions $R_{ij}=0$ and using the symmetry of G and the antisymmetry of F we get the following sets of equations:

$$\frac{\partial G_{11}}{\partial q_2}=\frac{\partial G_{22}}{\partial q_1}=0, \quad \frac{\partial G_{11}}{\partial q_1}=2N_1, \quad \frac{\partial G_{22}}{\partial q_2}=2N_2, \tag{6.7}$$

$$\frac{\partial G_{12}}{\partial q_1}=N_2, \quad \frac{\partial G_{12}}{\partial q_2}=N_1, \tag{6.8}$$

$$F_{12}=p_2N_1-p_1N_2. \tag{6.9}$$

The equations (6.7) show that G_{11} and N_1 depend only on q_1 and that G_{22} and N_2 depend only on q_2. The equations (6.8) give $\partial N_1/\partial q_1=\partial^2 G_{12}/\partial q_1\partial q_2=\partial N_2/\partial q_2$ and so all terms in this expression must be equal to a constant a. Integration yields

$$N_1=aq_1+c/2, \quad N_2=aq_2+b/2, \tag{6.10}$$

where b and c are integration constants. Substituting (6.10) into (6.7) and (6.8) and integrating we get (6.4). If we now introduce the symmetric matrix A by the equality (6.5) and use (6.7) then (6.9) will attain the form (6.6).

It is straightforward to check that with the above forms of F and G the conditions $\{\{p_i,p_j\}_\Pi,p_k\}_\Pi+\mathrm{cycl}=0$ and $\{\{q_i,p_j\}_\Pi,p_k\}_\Pi+\mathrm{cycl}=0$ are satisfied identically.

Further, the condition $\{\{p_1,p_2\}_\Pi,d\}_\Pi+\mathrm{cycl}=0$ after some calculations attains the form

$$0=\frac{\partial}{\partial q_1}(G_{11}M_2-G_{21}M_1)-\frac{\partial}{\partial q_2}(G_{22}M_1-G_{12}M_2),$$

which means that in the vector

$$\begin{bmatrix} G_{22}M_1-G_{12}M_2 \\ -G_{21}M_1+G_{11}M_2 \end{bmatrix}=\begin{bmatrix} G_{22} & -G_{12} \\ -G_{21} & G_{11} \end{bmatrix}\begin{bmatrix} M_1 \\ M_2 \end{bmatrix}=AM,$$

the mixed derivatives of its components are equal and so this vector is equal to the gradient of some function $-\frac{1}{2}k(q)$, that is, $AM=-\frac{1}{2}\nabla k$ or $M=-\frac{1}{2}A^{-1}\nabla k$.

Finally, by direct calculation we verify that $N=-\frac{1}{2}A^{-1}\nabla(\det(A))$ and so statement (3) of the theorem is proved. Q.E.D.

Remark 6.5: This theorem generalizes the result of Ref. 6. In particular, if we assume $M=-\nabla V(q)$, then we recover the known second Poisson operator for separable potential systems.[7]

Notice that $\hat{M}$ is the force of the two-dimensional qLN system (6.1). This means that every Poisson operator of the form (6.3) is a Poisson operator for some qLN system of the form (6.1).

We are now in position to investigate complete integrability of qLN systems admitting two quadratic, functionally independent integrals of motion. Notice first that Theorem 6.4 provides us with an alternative way of characterizing qLN systems generated by a quadratic integral of motion *E:* by starting with a Poisson operator of the form (6.3) we arrive at qLN systems generated by the Hamiltonian $\mathrm{H}(q,p,d)=d$ which admit a quadratic integral E. In a similar way the following theorem characterizes all qLN systems admitting two independent quadratic integrals E,F.

Theorem 6.6 (Poisson pencil): *Consider the antisymmetric operator*

$$\Pi_\mu=\left[\begin{array}{cc|c} 0 & -(\lambda/2)G_\mu(q) & p \\ (\lambda/2)G_\mu^t(q) & -(\lambda/2)F_\mu(q,p) & M(q)+d\lambda N_\mu(q) \\ \hline -p^t & -M^t(q)-d\lambda N_\mu^t(q) & 0 \end{array}\right], \tag{6.11}$$

where

$$G_\mu=\begin{bmatrix} A_{22} & -A_{12} \\ -A_{21} & A_{11}\end{bmatrix}-\mu\begin{bmatrix} B_{22} & -B_{12} \\ -B_{21} & B_{11}\end{bmatrix}\equiv G_A-\mu G_B,$$

with both matrices A and B satisfying the cyclic conditions (2.3),

$$[F_\mu]_{12}=\frac{1}{2}\left(\frac{\partial(A_{22}-\mu B_{22})}{\partial q_1}p_2-\frac{\partial(A_{11}-\mu B_{11})}{\partial q_2}p_1\right)\equiv[F_A]_{12}-\mu[F_B]_{12}$$

(*with* $F=-F^t$, $F_A=-F_A^t$, $F_B=-F_B^t$) *and*

$$N_\mu=-\tfrac{1}{2}A^{-1}\nabla(\det(A))+\tfrac{1}{2}\mu B^{-1}\nabla(\det(B))\equiv N_A-\mu N_B.$$

Then Π_μ *is Poisson if and only if*

$$M(q)=-\tfrac{1}{2}A^{-1}\nabla k=-\tfrac{1}{2}B^{-1}\nabla l \tag{6.12}$$

for some functions $k(q)$ *and* $l(q)$. *Moreover, if we let*

$$\Pi_\mu=\Pi_1-\mu\Pi_2\equiv\left[\begin{array}{cc|c} 0 & -(\lambda/2)G_A & p \\ (\lambda/2)G_A^t & -(\lambda/2)F_A & M+d\lambda N_A \\ \hline -p^t & -M^t-d\lambda N_A^t & 0\end{array}\right]-\mu\left[\begin{array}{cc|c} 0 & -(\lambda/2)G_B & 0 \\ (\lambda/2)G_B^t & -(\lambda/2)F_B & d\lambda N_B \\ \hline 0 & -d\lambda N_B^t & 0\end{array}\right],$$

then both operators Π_1 *and* Π_2 *are Poisson and so* $\Pi_\mu=\Pi_1-\mu\Pi_2$ *is a Poisson pencil.*

Proof: According to the proof of Theorem 6.4 the matrix Π_μ satisfies all the Jacobi identities except possibly for $\{\{p_1,p_2\}_{\Pi_\mu},d\}_{\Pi_\mu}+\text{cycl}=0$, since Π_μ differs from $\Pi_{A-\mu B}=\Pi_A-\mu\Pi_B$ by the form of $M(q)$ only. Like in the proof of Theorem 6.4 we find that $\{\{p_1,p_2\}_{\Pi_\mu},d\}_{\Pi_\mu}+\text{cycl}=0$ yields that the mixed derivatives of the components of the vector $-2(A-\mu B)M$ are equal and so $-2(A-\mu B)M=\nabla(k-\mu l)$ for some functions $k(q)$ and $l(q)$. By comparing coefficients at different powers of μ we get $-2AM=\nabla k$ and $-2BM=\nabla l$ and thus $M=-\frac{1}{2}A^{-1}\nabla k=-\frac{1}{2}B^{-1}\nabla l$.

Further, $\Pi_1=\Pi_A$ in the notation of Theorem 6.4 so it is Poisson. Easy calculation shows that Π_2 is Poisson, too. Q.E.D.

The above theorem states that if $M(q)$ is the force of a qLN system admitting two functionally independent integrals of motion, then the matrix Π_μ is a Poisson pencil. We will establish its Casimir function, which will be a polynomial in μ. This will lead to a bi-Hamiltonian chain containing the qLN system (6.1). We will prove that this chain is completely integrable. In this way we will show that our original qLN system $\ddot{q}=-\frac{1}{2}A^{-1}\nabla k=-\frac{1}{2}B^{-1}\nabla l$ can be naturally embedded in a completely integrable bi-Hamiltonian system.

Proposition 6.7: Suppose that Π_μ *is Poisson, i.e., that (6.12) is satisfied. Then the function*

$$H_\mu=p^t(A-\mu B)p+k-\mu l+d\lambda\ \det(A-\mu B) \tag{6.13}$$

is a Casimir function for Π_μ, i.e., $\Pi_\mu\nabla H_\mu=0$.

Proof: This proposition is a consequence of Proposition 6.3. If we modify the matrix Π_A by substituting the matrix A by $A-\mu B$ and substituting k with $k-\mu l$ we obtain the matrix

$$\left[\begin{array}{cc|c} 0 & -\frac{\lambda}{2}G_\mu & p \\ \frac{\lambda}{2}G_\mu^t & -\frac{\lambda}{2}F_\mu & \widetilde{M}_\mu \\ \hline -p^t & -\widetilde{M}_\mu^t & 0 \end{array}\right], \tag{6.14}$$

where

$$\widetilde{M}_\mu=-\tfrac{1}{2}(A-\mu B)^{-1}\nabla(k-\mu l)-\tfrac{1}{2}d\lambda(A-\mu B)^{-1}\nabla(\det(A-\mu B)).$$

Due to Proposition 6.3 the function (6.13) is the Casimir of (6.14). However, (6.14) is, in fact, equal to Π_μ since it can be verified that $-\frac{1}{2}(A-\mu B)^{-1}\nabla(k-\mu l)=-\frac{1}{2}A^{-1}\nabla k=-\frac{1}{2}B^{-1}\nabla l$ and that $(A-\mu B)^{-1}\nabla(\det(A-\mu B))=A^{-1}\nabla(\det(A))-\mu B^{-1}\nabla(\det(B))$. Q.E.D.

Let us collect terms in H_μ at different powers of μ:

$$H_\mu=p^tAp+k+d\lambda\det(A)+\mu(-p^tBp-l-d\lambda Y)+\mu^2(d\lambda\det(B))\equiv\hat{E}+\mu\hat{F}+\mu^2\hat{H}$$

with $Y=B_{11}A_{22}+B_{22}A_{11}-2B_{12}A_{12}$. Then the above proposition gives

$$\begin{aligned} 0=\Pi_\mu\nabla H_\mu&=(\Pi_1-\mu\Pi_2)\nabla(\hat{E}+\mu\hat{F}+\mu^2\hat{H}) \\ &=\Pi_1\nabla\hat{E}+\mu(\Pi_1\nabla\hat{F}-\Pi_2\nabla\hat{E})+\mu^2(\Pi_1\nabla\hat{H}-\Pi_2\nabla\hat{F})-\mu^3\Pi_2\nabla\hat{H}. \end{aligned}$$

By equating to zero the coefficients at different powers of μ we obtain the following bi-Hamiltonian chain:

$$\begin{aligned} \Pi_1\nabla\hat{E}&=0, \\ \Pi_1\nabla\hat{F}&=\Pi_2\nabla\hat{E}, \\ \Pi_1\nabla\hat{H}&=\Pi_2\nabla\hat{F}, \\ 0&=\Pi_2\nabla\hat{H}. \end{aligned} \tag{6.15}$$

Theorem 6.8: *The bi-Hamiltonian chain (6.15) is completely integrable, i.e., both nontrivial bi-Hamiltonian vector fields,*

$$V_1=\Pi_1\nabla\hat{F}=\Pi_2\nabla\hat{E},\quad V_2=\Pi_1\nabla\hat{H}=\Pi_2\nabla\hat{F},$$

in (6.15) are completely integrable.

Proof (modification of the proof of Liouville–Arnold theorem[8]): Consider the two-dimensional manifold $\mathcal{N}=\{x\in\mathcal{M}:\hat{E}(x)=E_0,\hat{F}(x)=F_0,\hat{H}(x)=H_0\}$ in $\mathcal{M}$. Poisson brackets of all pairs of $\hat{E},\hat{F},\hat{H}$ induced by both structures Π_0 and Π_1 are equal to zero, since the functions $\hat{E},\hat{F},\hat{H}$ all belong to the same bi-Hamiltonian chain. For instance, $\{\hat{F},\hat{H}\}_{\Pi_1}=\langle\nabla\hat{F},\Pi_1\nabla\hat{H}\rangle=\langle\nabla\hat{F},\Pi_2\nabla\hat{F}\rangle=\{\hat{F},\hat{F}\}_{\Pi_2}=0$ with the second equality being a consequence of the bi-Hamiltonian structure of V_2. It follows that the Lie bracket $[V_1,V_2]$ of both vector fields V_1 and V_2 is equal to zero, $[V_1,V_2]=[\Pi_1\nabla\hat{F},\Pi_1\nabla\hat{H}]=0$, since the mappings $\Pi_i\nabla$ $(i=1,2)$ are Lie algebra homomorphisms between the Lie algebra of vector fields on $\mathcal{M}$ and the Lie algebra of all smooth functions on $\mathcal{M}$ with the Lie bracket defined by $[f_1,f_2]=\{f_1,f_2\}_{\Pi_i}$. Moreover, $\langle\nabla\hat{E},V_1\rangle=\langle\nabla\hat{E},\Pi_2\nabla\hat{E}\rangle$

$=\{\hat{E},\hat{E}\}_{\Pi_2}=0$ and similarly $\langle\nabla\hat{F},V_1\rangle=\langle\nabla\hat{H},V_2\rangle=0$, which proves that V_1 is tangent to $\mathcal{N}$. In the same way one can show that V_2 is also tangent to $\mathcal{N}$. Direct verification shows that V_1 and V_2 are linearly independent. We thus have a two-dimensional submanifold $\mathcal{N}$ in $\mathcal{M}$ equipped with a pair of linearly independent, commuting vector fields V_1 and V_2. We can now apply the construction of Liouville-Arnold[8] and conclude that both V_1 and V_2 are completely integrable. Q.E.D.

Corollary 6.9: The qLN system $\ddot{q}=M=-\frac{1}{2}A^{-1}\nabla k=-\frac{1}{2}B^{-1}\nabla l$ *with two linearly independent matrices A and B satisfying the cyclic conditions (2.3) is completely integrable in the sense that the trajectories of the system*

$$\begin{bmatrix}\dot{q}\\ \dot{p}\end{bmatrix}=\begin{bmatrix}p\\ M\end{bmatrix} \tag{6.16}$$

coincide on the hyperplane $d=0$ *with the trajectories of the completely integrable five-dimensional system*

$$\begin{bmatrix}\dot{q}\\ \dot{p}\\ \dot{d}\end{bmatrix}=V_2=\Pi_1\nabla\hat{H}=\Pi_2\nabla\hat{F}. \tag{6.17}$$

Proof: Consider the vector field V_2 from (6.15). Obviously

$$V_2=\Pi_1\nabla\hat{H}=\lambda\,\det(B)\Pi_1\nabla d+\lambda d\Pi_1\nabla(\det(B))$$

and so in the hyperplane $d=0$ we have

$$V_2|_{d=0}=\lambda\,\det(B)\begin{bmatrix}p\\ M\\ 0\end{bmatrix}, \tag{6.18}$$

which means that the hyperplane $d=0$ is invariant with respect to the action of the vector field V_2. The formula (6.18) also shows that in the hyperplane $d=0$ the vector field of the system (6.17) is parallel to the vector field of the system (6.16) and so their trajectories must coincide. Q.E.D.

Thus we have shown that the system (6.16) is embedded in the completely integrable bi-Hamiltonian system (6.17). The trajectories of (6.16) stay on the intersection of invariant manifolds for (6.17) with the hyperplane $d=0$. Also, since we can now solve the system (6.17) by quadratures the time evolution of the coefficient $\lambda\,\det(B)$ in (6.18) can be calculated which makes it possible to solve the system (6.16) by quadratures too.

VII. NEW TYPES OF SEPARATION VARIABLES FOR DRIVEN qLN SYSTEMS

In this section we study an important class of two-dimensional qLN equations called driven systems. We find for all such systems their separation variables and prove their integrability by quadratures. The variables of separation are of a completely new type: they consist of families of conics which are non-confocal in contrast with the classical separability theory for potential systems.

We remind the reader that we call a two-dimensional Newton system *driven* if one of the two differential equations depends on one variable only. By renaming the variables if necessary, we can always arrange for such a system to take the form

$$\begin{aligned}\ddot{q}_1&=M_1(q_1,q_2),\\ \ddot{q}_2&=M_2(q_2).\end{aligned} \tag{7.1}$$

The second equation can be solved on its own and its solution $q_2(x)$ then determines the equation for q_1, which explains the name ''driven.'' A driven system always has one integral of motion $F=\dot{q}_2^2/2-\int M_2\,dq_2$, obtained by integrating the second equation once, but, in general, there need not exist any others.

Here we shall consider driven systems that admit a quasi-Lagrangian formulation $\ddot{q}=-\frac{1}{2}A^{-1}\nabla k(q)$. Here, as usual, $A(q)$ is a nondegenerate 2×2 matrix satisfying the cyclic conditions (2.3), i.e., a matrix of the form

$$A=\begin{bmatrix} aq_2^2+bq_2+\alpha & -aq_1q_2-\frac{b}{2}q_1-\frac{c}{2}q_2+\frac{\beta}{2} \\ -aq_1q_2-\frac{b}{2}q_1-\frac{c}{2}q_2+\frac{\beta}{2} & aq_1^2+cq_1+\gamma \end{bmatrix}. \tag{7.2}$$

Such a system always has *two* functionally independent integrals of motion $E=\dot{q}^tA\dot{q}+k(q)$ and $F=\dot{q}_2^2/2-\int M_2\,dq_2$.

By examining the second component of the equation $\ddot{q}=-\frac{1}{2}A^{-1}\nabla k(q)$, we immediately see that a qLN system is driven iff

$$A_{12}\partial_1 k-A_{11}\partial_2 k=2\,\det(A)M_2(q_2), \tag{7.3}$$

for some function $M_2(q_2)$ depending on q_2 only. We can produce driven qLN systems with any given $M_2(q_2)$ and $A(q)$ by solving for $k(q)$ in this equation. The case $A_{11}=0$ is degenerate and will be treated separately later (see Remark 7.6), so we assume from now on that $A_{11}\neq 0$.

We start by introducing separation variables for (7.1) as characteristic coordinates for (7.3).

Definition 7.1: Define curvilinear coordinates $(u,v)=(u(q),v(q))$ as follows. Let u be a parameter indexing the family of characteristic curves of (7.3) given by

$$\dot{q}(x)=\begin{bmatrix} A_{12}(q(x)) \\ -A_{11}(q(x)) \end{bmatrix}, \tag{7.4}$$

and let $v=q_2$.

In other words, the curves given by (7.4) are the coordinate curves of constant u. For a given matrix A these curves can be explicitly calculated. In Theorem 7.7 we will describe these curves more explicitly. Let us just note for the moment that they are not parallel to the curves of constant v, because of the assumption $A_{11}\neq 0$. Thus the above description really defines a coordinate system (at least locally). There is some freedom in the choice of u, but this will not affect our results. By abuse of notation we will write $f(q_1,q_2)$ and $f(u,v)$ for the same function f expressed in different coordinate systems.

Lemma 7.2: The general solution of (7.3) is

$$k(u,v)=f(u)+D(u,v)g(v), \tag{7.5}$$

where f is an arbitrary function, $D=\det(A)$, and

$$g(q_2)=\frac{-2}{A_{11}(q_2)}\int M_2(q_2)\,dq_2.$$

Proof: Along each characteristic curve $q(x)$ given by (7.4) we can consider (7.3) as an ODE

$$\frac{d}{dx}k(q(x))=2D(q(x))M_2(q_2(x)),$$

with general solution

$$k(q(x))=D(q(x))g(q_2(x))+f,$$

where f is a constant of integration. This can be verified by direct differentiation; the cyclic conditions imply that

$$\frac{d}{dx}D(q(x))=\partial_1 D\dot{q}_1+\partial_2 D\dot{q}_2=\partial_1 DA_{12}+\partial_2 D(-A_{11})=-D\partial_2 A_{11},$$

and thus

$$\begin{aligned}\frac{d}{dx}k(q)=\frac{d}{dx}(D(q)g(q_2)+f)=\frac{dD}{dx}g+D\partial_2 g\dot{q}_2\\ =-D\partial_2 A_{11}g+D\partial_2 g(-A_{11})\\ =-D\partial_2(A_{11}g)=2DM_2.\end{aligned}$$

The constant of integration f can be different for different characteristic curves, so when we express the result in terms of u and v, f will depend on u (but not on v). Q.E.D.

Lemma 7.3: Equation (7.3) is equivalent, under the substitution $k=K\det(A)$, to the equation

$$A_{12}\partial_{11}K-A_{11}\partial_{12}K-\tfrac{3}{2}\partial_2 A_{11}\partial_1 K=0, \tag{7.6}$$

which is the fundamental equation (4.5) associated with the matrices A and

$$B=\begin{bmatrix}0 & 0\\ 0 & \tfrac{1}{2}\end{bmatrix}.$$

Proof: Equation (7.3) implies

$$\partial_1\left(\frac{-A_{12}\partial_1 k+A_{11}\partial_2 k}{\det(A)}\right)=0.$$

Conversely, this expression can be integrated to give (7.3), where $M_2(q_2)$ is an arbitrary function of integration. By substituting $k=K\det(A)$ and simplifying the resulting expression using the cyclic conditions one obtains (7.6). Comparison with the general expression for the fundamental equation in Theorem 4.1 proves the second statement of the lemma. Q.E.D.

Remarks 7.4: The fundamental equation (7.6) is hyperbolic. Its characteristic coordinates are precisely the coordinates (u,v) of Definition (7.1). The general solution is $K(u,v)=f(u)/D(u,v)+g(v)$, as can be seen by combining the above lemmas.

Let us turn to the question of how to integrate a driven qLN system. The solution $q_2(x)$ of the second equation can be found by quadrature from $F=\dot{q}_2^2/2-\int M_2\,dq_2$:

$$\int\frac{dq_2}{\sqrt{2F+2\int M_2 dq_2}}=\pm\int dx. \tag{7.7}$$

Inserting $q_2(x)$ and $\dot{q}_2(x)$ into

$$E=A_{11}(q_2)\dot{q}_1^2+2A_{12}(q_1,q_2)\dot{q}_1\dot{q}_2+A_{22}(q_1)\dot{q}_2^2+k(q_1,q_2)$$

would give a first-order ODE for $q_1(x)$, but there is no obvious way to solve this equation since the variables q_1 and x do not separate. We will now show how to proceed instead.

Theorem 7.5: *Every driven qLN system can be integrated by quadratures using the characteristic coordinates (u,v) of the fundamental equation (7.6) as separation variables.*

Proof: We use the notation of Lemma 7.2. Let the system be generated by $E=\dot{q}^tA\dot{q}+k(q)$ with $k(u,v)=f(u)+D(u,v)g(v)$. Since $v=q_2$, we can express F as $F=\frac{1}{2}(\dot{v}^2+A_{11}(v)g(v))$ and calculate $v(x)$ by quadrature, as above. Now note that since the curves of constant u by definition have tangent $\dot{q}=(A_{12},-A_{11})^t$, we must have $\nabla u=\rho(q)(A_{11},A_{12})^t$ for some function $\rho(q)$, whose exact form depends on the choice of u. This gives $\dot{u}=\partial_1 u\dot{q}_1+\partial_2 u\dot{q}_2=\rho(q)(A_{11}\dot{q}_1+A_{12}\dot{q}_2)$, and thus

$$\begin{aligned}\dot{u}^2=\rho^2A_{11}\left(A_{11}\dot{q}_1^2+2A_{12}\dot{q}_1\dot{q}_2+\frac{A_{12}^2}{A_{11}}\dot{q}_2^2\right)&=\rho^2A_{11}\left(E-A_{22}\dot{q}_2^2-k(q)+\frac{A_{12}^2}{A_{11}}\dot{q}_2^2\right)\\&=\rho^2A_{11}\left(E-\left(A_{22}-\frac{A_{12}^2}{A_{11}}\right)\dot{v}^2-f(u)-Dg(v)\right)\\&=\rho^2A_{11}\left(E-\frac{D}{A_{11}}(2F-A_{11}g(v))-f(u)-Dg(v)\right)\\&=\rho^2A_{11}\left(E-\frac{2D}{A_{11}}F-f(u)\right).\end{aligned}$$

In order to complete the proof, we will show that $\rho(u,v)=\phi(u)|A_{11}(v)|^{-3/2}$ and $D(u,v)/A_{11}(v)=\psi(u)$ for some functions ϕ and ψ, since this implies that the variables u and x separate. Explicitly, we can then find $u(x)$ from the quadrature

$$\int\frac{du}{\phi(u)\sqrt{E-2\psi(u)F-f(u)}}=\pm\int\frac{dx}{A_{11}(v(x))},\tag{7.8}$$

after which the inverse coordinate transformation gives us $q_1(x)$. Notice that for a given matrix A, the characteristic coordinates (u,v) can be calculated explicitly so that the function ρ and thus ϕ and ψ can be easily calculated and used in the quadrature (7.8) above. The theorem covers, however, all the cases at once without any need of calculating ρ explicitly.

To see that $\rho(u,v)=\phi(u)|A_{11}(v)|^{-3/2}$, note that $\partial_{12}u=\partial_{21}u$ implies that $\rho(q)$ satisfies the PDE

$$0=\partial_1(\rho A_{12})-\partial_2(\rho A_{11})=A_{12}\partial_1\rho-A_{11}\partial_2\rho-\tfrac{3}{2}\partial_2A_{11}\rho,$$

which has the same characteristic curves (7.4) as Eq. (7.3). Along such a curve we determine ρ by integrating

$$\frac{d}{dx}\rho(q(x))=\frac{3}{2}\partial_2A_{11}(q_2(x))\rho(q(x)),$$

which, taking into account $\dot{q}_2(x)=-A_{11}(q_2(x))$, gives

$$\rho(q(x))=\phi|A_{11}(q_2(x))|^{-3/2}.$$

The integration constant ϕ can be different on different characteristic curves, so changing to (u,v) coordinates we obtain

$$\rho(u,v)=\phi(u)|A_{11}(v)|^{-3/2},$$

as desired.

Finally, we calculate the total derivative of the function $\psi(q)=D(q)/A_{11}(q_2)$ along a characteristic curve:

$$\frac{d}{dx}\psi(q(x))=\partial_1\left(A_{22}-\frac{A_{12}^2}{A_{11}}\right)A_{12}-\partial_2\left(A_{22}-\frac{A_{12}^2}{A_{11}}\right)A_{11}.$$

Using the cyclic conditions, we find that this expression is identically zero. This implies that ψ is constant along the coordinate curves of constant u, i.e., $\psi=\psi(u)$. This completes the proof.

Q.E.D.

Remark 7.6: The degenerate case $A_{11}=0$ can be treated as follows. Since $a=b=\alpha=0$, the expression (7.2) for A reduces to

$$A=\begin{bmatrix} 0 & -\frac{c}{2}q_2+\frac{\beta}{2} \\ -\frac{c}{2}q_2+\frac{\beta}{2} & cq_1+\gamma \end{bmatrix} \tag{7.9}$$

and Eq. (7.3) reduces to

$$A_{12}\partial_1 k=2(-A_{12}^2)M_2(q_2),$$

with the general solution

$$k(q)=-2A_{12}(q_2)M_2(q_2)q_1+k_2(q_2).$$

We calculate $q_2(x)$ by quadrature as before. Inserting $q_2(x)$ and $\dot{q}_2(x)$ into $E=2A_{12}\dot{q}_1\dot{q}_2+A_{22}\dot{q}_2^2+k(q_1,q_2)$ yields in this case an equation of the form $\dot{q}_1(x)+\xi(x)q_1(x)=\eta(x)$, from which we can find $q_1(x)$ by quadrature.

Theorem 7.7: *The separation coordinates for driven qLN systems, i.e., the characteristic coordinates (u,v) of the fundamental equation (7.6), are of one of the following types, determined by the coefficients in the matrix A:*

(1) *fanlike hyperbolic, if $a\neq 0$ and $b^2/4-a\alpha=0$;*
(2) *axial hyperbolic, if $a\neq 0$ and $b^2/4-a\alpha<0$;*
(3) *two-point elliptic-hyperbolic, if $a\neq 0$ and $b^2/4-a\alpha>0$;*
(4) *one-point parabolic, if $a=0$ and $b\neq 0$; and*
(5) *parallel parabolic, if $a=0$ and $b=0$.*

Proof: We will compute explicitly the curves given by (7.4), which constitute the curves of constant u. (The curves of constant v are just horizontal lines, since $v=q_2$.) Inserting the explicit expression (7.2) for the matrix A into (7.4), we obtain

$$\begin{bmatrix}\dot{q}_1\\ \dot{q}_2\end{bmatrix}=-\begin{bmatrix} aq_1q_2+\frac{b}{2}q_1+\frac{c}{2}q_2-\frac{\beta}{2} \\ aq_2^2+bq_2+\alpha \end{bmatrix}. \tag{7.10}$$

When solving these equations, we distinguish four different cases, depending on the values of the parameters in A.

The case $a\neq 0$. By setting $r_1=aq_1+c/2$ and $r_2=aq_2+b/2$, which is just rescaling of the axes and translation of the origin, we transform (7.10) into

$$\begin{bmatrix}\dot r_1\\ \dot r_2\end{bmatrix}=\begin{bmatrix}-r_1r_2+C_1\\ -r_2^2+C_2\end{bmatrix},\quad \text{where}\begin{cases}C_1=bc/4+a\beta/2,\\ C_2=b^2/4-a\alpha.\end{cases} \tag{7.11}$$

Subcase $C_2=0$ *(type 1).* Either $r_2=0$, or $r_2=(x+D_1)^{-1}$ and $r_1=C_1(x+D_1)/2+D_2(x+D_1)^{-1}$, where D_1 and D_2 are constants of integration. Eliminating x and writing u instead of D_2, we obtain

$$r_1=\frac{C_1}{2r_2}+ur_2, \tag{7.12}$$

which represents a family of hyperbolas, each with asymptotes $r_2=0$ and $r_2=r_1/u$. The solution $r_2=0$ found above corresponds to the limiting cases $u\to\pm\infty$ (see Fig. 2).

Subcase $C_2\neq 0$ *(type 2 and 3).* The substitution $s_1=r_1-C_1r_2/C_2$, $s_2=r_2$ yields

$$\begin{bmatrix}\dot s_1\\ \dot s_2\end{bmatrix}=\begin{bmatrix}-s_1s_2\\ -s_2^2+C_2\end{bmatrix}, \tag{7.13}$$

and thus

$$\frac{ds_1}{ds_2}=\frac{\dot s_1}{\dot s_2}=\frac{s_2}{s_2^2-C_2}s_1,$$

resulting in

$$s_1^2=u^2|s_2^2-C_2|. \tag{7.14}$$

If $C_2<0$ (type 2), this represents in the s plane a family of hyperbolas centered around the s_1 axis, with asymptotes $s_2=\pm s_1/u$ and vertices $(\pm u\sqrt{-C_2},0)$ [Fig. 3(a)].

If $C_2>0$ (type 3), we obtain in the region $|s_2|>\sqrt{C_2}$ a family of hyperbolas with asymptotes $s_2=\pm s_1/u$ and vertices $(0,\pm\sqrt{C_2})$, and in the region $|s_2|<\sqrt{C_2}$ a family of ellipses with vertices

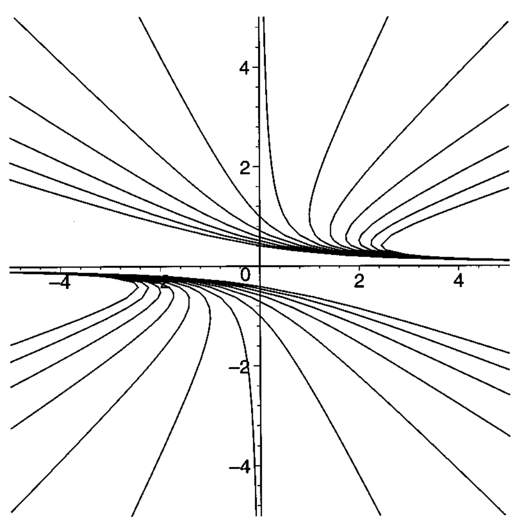

FIG. 2. Fan-like hyperbolic.

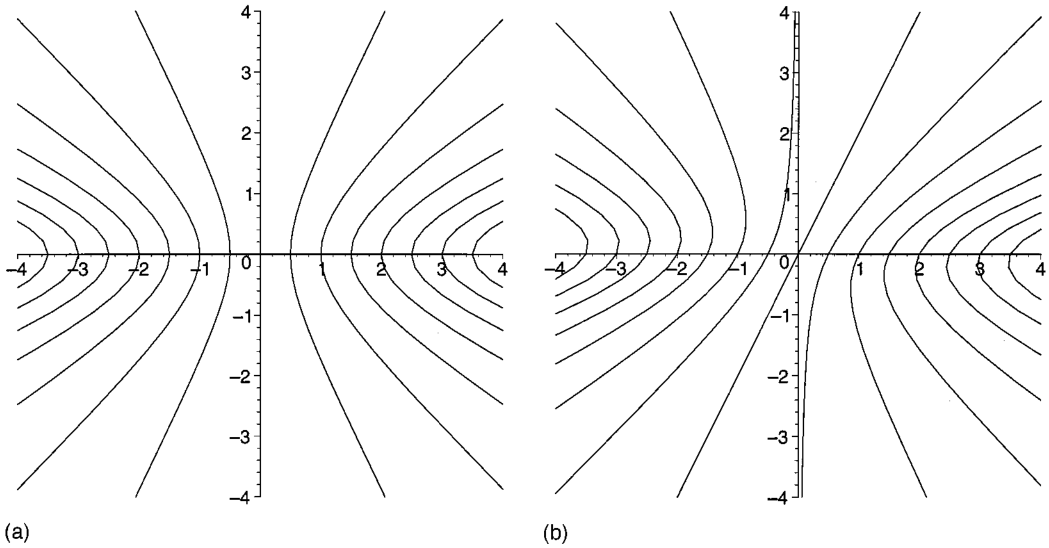

FIG. 3. (a) Axial-hyperbolic in the *s*-plane. (b) Axial-hyperbolic in the *r*-plane.

$(0,\pm\sqrt{C_2})$ and $(0,\pm u\sqrt{C_2})$. The corresponding curves in the r plane are obtained by a shear in the s_1 direction with factor C_1/C_2 [Figs. 3(b) and 4(b)]. They are still hyperbolas and ellipses, but not aligned parallel with the r axes.

The case $a=0$. *Subcase* $b\neq 0$ *(type 4)*. Translating the origin by $r_1=q_1-(\alpha c/b^2+\beta/b)$ and $r_2=q_2+\alpha/b$, we obtain

$$\begin{bmatrix}\dot r_1\\ \dot r_2\end{bmatrix}=\begin{bmatrix}-\dfrac{b}{2}r_1-\dfrac{c}{2}r_2\\ -br_2\end{bmatrix}, \tag{7.15}$$

which yields

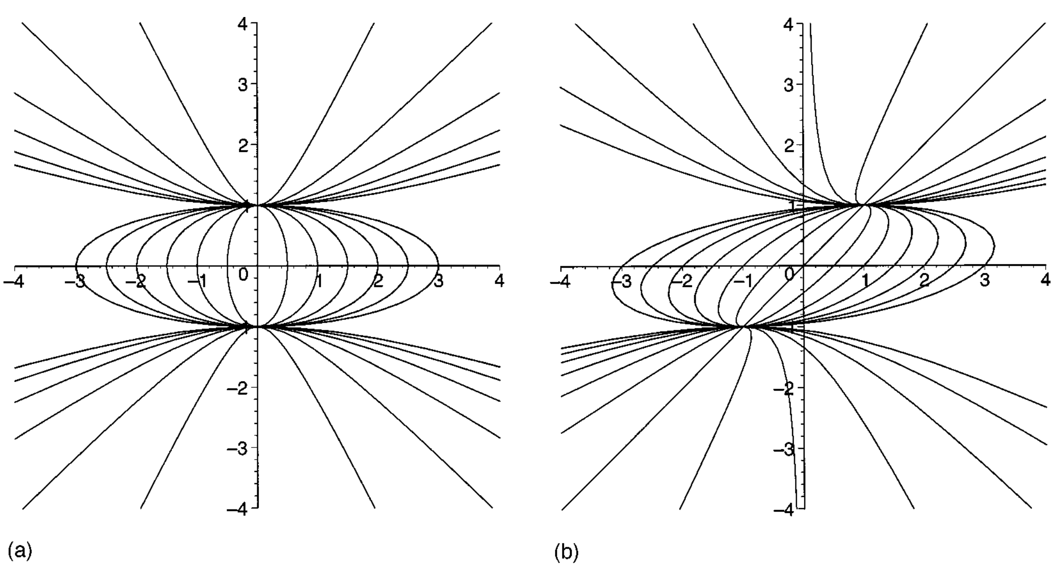

FIG. 4. (a) Two-point elliptic-hyperbolic in the *s*-plane. (b) Two-point elliptic-hyperbolic in the *r*-plane.

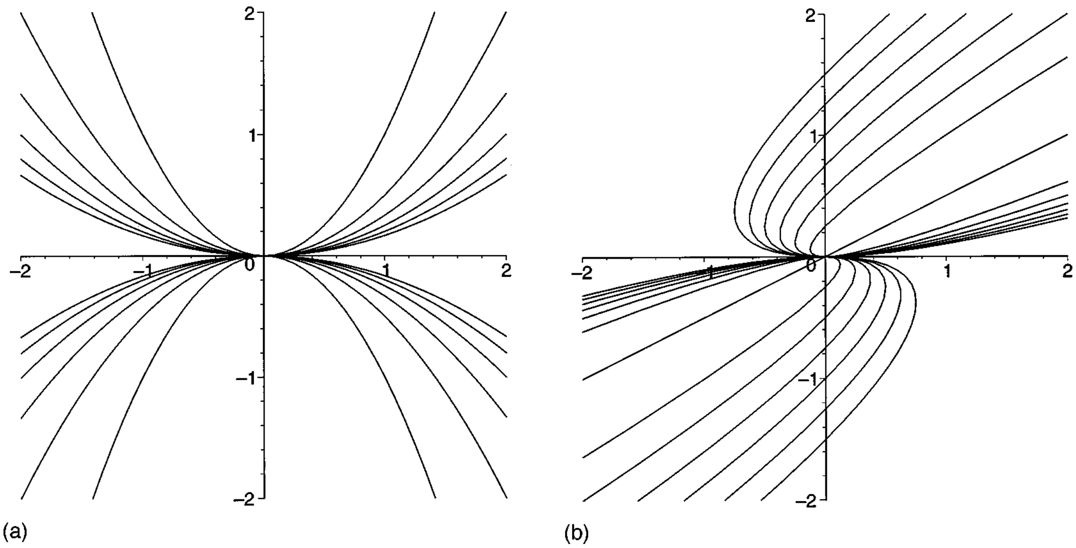

FIG. 5. (a) One-point parabolic in the s-plane. (b) One-point parabolic in the r plane.

$$\left(r_1-\frac{c}{b}r_2\right)^2=ur_2. \tag{7.16}$$

With $s_1=r_1-cr_2/b$, $s_2=r_2$, we obtain in the s plane a family of parabolas $s_2=s_1^2/u$ [Fig. 5(a)]. The corresponding curves in the r plane are parabolas obtained by a shear in the s_1 direction with factor c/b [Fig. 5(b)].

Subcase $b=0$ *(type 5)*. Here we can assume that $\alpha\neq 0$, or else we get the degenerate case $A_{11}=0$. A simple calculation shows that

$$q_1=-\frac{c}{4\alpha}q_2^2+\frac{\beta}{2\alpha}q_2+u, \tag{7.17}$$

which is a family of translated parabolas seen in Fig. 6 (or straight lines, if $c=0$). Q.E.D.

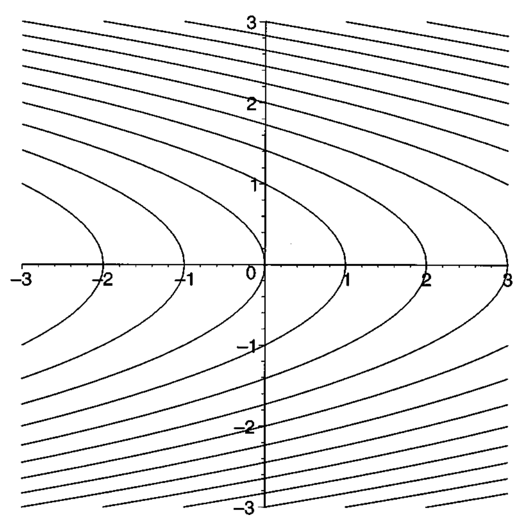

FIG. 6. Parallel-parabolic.

VIII. EXAMPLES AND APPLICATIONS

The notion of a qLN force $M(q)=-\frac{1}{2}A^{-1}(q)\nabla k(q)$ naturally generalizes the concept of a potential force $M(q)=-\nabla k(q)$, which is a special case. The qLN forces admit an integral of motion quadratic in velocities, which in the potential case becomes the energy integral. The function $k(q)$ may be called a ''quasi-potential'' of the force $M(q)$.

A given force is easy to test for the existence of a qLN formulation, provided that one knows the general form of the matrix $A(q)$ solving the cyclic condition (2.3). In two dimensions $A(q)$, given by

$$A(r,w)=\begin{bmatrix} aw^2+bw+\alpha & -arw-\frac{b}{2}r-\frac{c}{2}w+\frac{\beta}{2} \\ -arw-\frac{b}{2}r-\frac{c}{2}w+\frac{\beta}{2} & ar^2+cr+\gamma \end{bmatrix},$$

depends on six arbitrary parameters, and a qLN formulation exists provided that the mixed derivatives of $\nabla k(r,w)=-2A(r,w)M(r,w)$ are equal for some nonzero values of the parameters $a,b,c,\alpha,\beta,\gamma$. We thus have the following lemma:

Lemma 8.1: A given force $M(r,w)=(M_1(r,w),M_2(r,w))^t$ *admits a qLN formulation* $M(r,w)=-\frac{1}{2}A^{-1}(r,w)\nabla k(r,w)$ *if and only if there is a nontrivial solution A, with* det(*A*)≠0, *of the equation*

$$0=\frac{\partial}{\partial w}\left((aw^2+bw+\alpha)M_1+\left(-arw-\frac{b}{2}r-\frac{c}{2}w+\frac{\beta}{2}\right)M_2\right)$$
$$-\frac{\partial}{\partial r}\left(\left(-arw-\frac{b}{2}r-\frac{c}{2}w+\frac{\beta}{2}\right)M_1+(ar^2+cr+\gamma)M_2\right). \tag{8.1}$$

Lemma 8.2 (Criterion of integrability, $n=2$*): Equation (8.1) has a two-parameter family of solutions for* $A(r,w)$ *if and only if* $\ddot{q}=M(q)$ *admits two functionally independent integrals of motion E and F quadratic in velocities.*

Proof: If such $E=\dot{q}^tA\dot{q}+k$ and $F=\dot{q}^tB\dot{q}+l$ exist, then $\lambda E+\mu F=\dot{q}^t(\lambda A+\mu B)\dot{q}+(\lambda k+\mu l)$ is an integral of motion for all λ and μ, and thus $\lambda A+\mu B$ is a two-parameter solution of (8.1).

Conversely, if there is a two-parameter solution $D(\lambda,\mu)$ of (8.1), then there are linearly independent integrals E and F with $A=D(1,0)$ and $B=D(0,1)$. Q.E.D.

These two lemmas make it simple to test a given two-dimensional force for the existence of a qLN formulation, and to show integrability if a two-parameter family of solutions for A exists.

Example 8.3 (gH-H system): The generalized Hénon–Heiles (gH-H) system[9] is defined by the potential

$$V(q_1,q_2)=c_1q_1q_2^2-\frac{c_2q_1^3}{3}+\frac{c_0}{2q_2^2},\quad c_1,c_2\neq 0.$$

It is known to be integrable in three cases: the Korteweg–de Vries (KdV) case $6c_1+c_2=0$, the Sawada–Kotera (S-K) case $c_1+c_2=0$, and the Kaup–Kupershmidt (K-K) case $16c_1+c_2=0$. In the KdV case, and also in the S-K case, if $c_0=0$, the second integral of motion is quadratic in velocities, in the other cases it is quartic. The system appears naturally when integrating the equation $0=(\frac{1}{4}\partial^3+2c_1u\partial+c_1u_x)(\frac{1}{4}u_{xx}-\frac{1}{4}c_2u^2)$, which for the above cases corresponds to the stationary flow of the fifth-order KdV, S-K, and K-K soliton equations. This observation explained[10] the remarkable connection of the integrable cases of the gH-H system with soliton hierarchies.

We shall apply our criterion for existence of a qLN formulation to two Newton representations of the gH-H system; the original system in q variables

$$\ddot{q}_1 = -\frac{\partial V}{\partial q_1} = -c_1 q_2^2 + c_2 q_1^2, \qquad \ddot{q}_2 = -\frac{\partial V}{\partial q_2} = -2c_1 q_1 q_2 + \frac{c_0}{q_2^3}, \tag{8.2}$$

and another system in r variables

$$\ddot{r}_1 = r_2 + (c_1 + c_2) r_1^2, \qquad \ddot{r}_2 = c_3 - 10c_1 r_1 r_2 - 10c_1\left(c_1 + \frac{c_2}{3}\right) r_1^3, \tag{8.3}$$

which is equivalent[11] to the q system under the map $r_1 = q_1,\ r_2 = -c_1(q_1^2 + q_2^2),\ c = -4c_1[\frac{1}{2}(\dot{q}_1^2 + \dot{q}_2^2) + V(q_1, q_2)]$. The r system does not have any natural Lagrangian or Hamiltonian formulation and its integrability has previously been studied only through its equivalence with the original gH-H system. We will show here a more direct approach based on the qLN theory.

Beginning with the q system, we insert the right-hand side M from (8.2) into (8.1), identifying (q_1, q_2) with (r,w) as usual. Since the powers $r^i w^j$ are linearly independent, the coefficients at different powers must be individually zero. This gives, after some simplification, that $a = b = 0$, $\alpha = \gamma$ arbitrary, $(6c_1 + c_2)c = 0$, $(c_1 + c_2)\beta = 0$ and $c_0\beta = 0$. This means that we always have a solution $A = tI$ (of course, corresponding to the energy integral, since the system has a potential). Moreover, in two cases there exists a two-parameter solution; when $6c_1 + c_2 = 0$,

$$A = t\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} + s\begin{bmatrix} 0 & -q_2 \\ -q_2 & 2q_1 \end{bmatrix},$$

and, when $c_1 + c_2 = c_0 = 0$,

$$A = t\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} + s\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}.$$

So in this way we have recovered the KdV and S-K $(c_0 = 0)$ cases, while the K-K and S-K $(c_0 \neq 0)$ cases, with a quartic extra integral, fall outside of the qLN theory.

Performing the same procedure for the r system (8.3), we find that $a = 0$, $4c_1\gamma + b = 0$, $(31c_1 + c_2)c = (3c_1^2 + c_1 c_2)c = 0$, $2\alpha - 3c_3 c = 0$, and $(6c_1 + c_2)\beta = 0$. Since we have excluded the trivial case $c_1 = 0$, it follows that $c = \alpha = 0$, so that the solution is

$$A = t\begin{bmatrix} -2r_2 & r_1 \\ r_1 & 1/2c_1 \end{bmatrix}$$

except for the KdV case $6c_1 + c_2 = 0$ which admits a two-parameter solution

$$A = t\begin{bmatrix} -2r_2 & r_1 \\ r_1 & \dfrac{1}{c_1} \end{bmatrix} + s\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}.$$

This agrees with the known fact[11] that for the r system the second integral is quartic in velocities in the S-K and K-K cases and thus cannot be found by this method.

Suppose, however, that we had found the second integral in these cases by some other method. Then we would still have use for the qLN theory in proving the system's integrability, since the r parametrization admits the nonstandard Hamiltonian formulation (6.2) with $\lambda=1$ and c_3 playing the role of the fifth variable d. (This coincides with the Hamiltonian formulation that was found in Ref. 11 by transferring the standard Hamiltonian formulation from the q parametrization, except for naming the momenta in reverse order; here $p_i=\dot{r}_i$, while in that paper $s_1=\dot{r}_2$, $s_2=\dot{r}_1$.)

For example, in the S-K case ($c_1=-c_2=\frac{1}{2}$) we have

$$\begin{bmatrix} \dot{r}_1 \\ \dot{r}_2 \\ \dot{p}_1 \\ \dot{p}_2 \\ \dot{c}_3 \end{bmatrix} = \left[\begin{array}{cccc|c} 0 & 0 & -1/2 & -r_1/2 & p_1 \\ & 0 & -r_1/2 & r_2 & p_2 \\ & * & 0 & -p_1/2 & r_2 \\ & * & * & 0 & c_3-5r_1r_2-(5/3)r_1^3 \\ \hline * & * & * & * & 0 \end{array}\right] \nabla_{\mathcal{M}} c_3,$$

with the commuting integrals of motion $E=-2r_2p_1^2+2r_1p_1p_2+p_2^2+4r_1r_2^2+\frac{2}{3}r_1^3(r_1^2+5r_2)+c_3(-r_1^2-2r_2)$, which is a Casimir, the Hamiltonian c_3, and $F=\frac{3}{2}p_1^4-6r_1r_2p_1^2+(3r_1^2-r_2)p_1p_2+r_1p_2^2+\frac{7}{2}r_1^2r_2^2+\frac{10}{3}r_1^4r_2+\frac{5}{6}r_1^6+\frac{1}{3}r_2^3+(-2r_1r_2-r_1^3+\frac{3}{2}p_1^2)c_3$, which is quartic in momenta.

In order to give an impression of the wealth of different types of nonpotential Newton forces belonging to our theory, we will now examine solutions of the fundamental equation (4.5) for some specified pairs of matrices A and B. Any such solution corresponds to an integrable qLN system, and once one solution has been found, a whole family of solutions can be constructed using the recursion theorem 4.3.

Example 8.4 (One-dimensional complex motion): If we take A and B as

$$A=\begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}, \quad B=\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix},$$

then the fundamental equation reduces to the Laplace equation $K_{rr}+K_{ww}=0$. Given a solution $K(r,w)$, i.e., a harmonic function, we have $k=K\det(A)=-K$, so k is also harmonic. We find the corresponding l from the relation

$$\nabla l = BA^{-1}\nabla k = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix} \nabla k,$$

which is nothing but the Cauchy–Riemann equations for k and l, so l is the harmonic conjugate of k. The corresponding qLN system $\ddot{r}=-k_r/2$, $\ddot{w}=k_w/2$ can be integrated by introducing the complex variable $z=r+iw$ and the complex integral of motion $\mathcal{E}=E+iF=(\dot{r}^2-\dot{w}^2+k)+i(2\dot{r}\dot{w}+l)=(\dot{r}+i\dot{w})^2+(k+il)=\dot{z}^2+f(z)$, where $f(z)=k(z)+il(z)$ is analytic. We can now determine z, and thus r and w, from $\dot{z}=\pm\sqrt{\mathcal{E}-f(z)}$ by one complex quadrature.

Repeated application of the recursion formula (4.10) yields in this case the standard cycle of conjugate harmonic pairs $(k,l)\to(l,-k)\to(-k,-l)\to(-l,k)\to(k,l)$.

Example 8.5 (Fundamental equation separable in polar coordinates): Let

$$A=\begin{bmatrix} -2w & r \\ r & 0 \end{bmatrix}, \quad B=\begin{bmatrix} 0 & w \\ w & -2r \end{bmatrix}.$$

Then the fundamental equation becomes $0=2(r^2K_{rr}+2rwK_{rw}+w^2K_{ww})+9(rK_r+wK_w)+6K$, which in polar coordinates ($r=R\cos\phi$, $w=R\sin\phi$) transforms into $0=2R^2K_{RR}+9RK_R+6K$.

The general solution of this equation is $K(R,\phi)=f_0(\phi)R^{-2}+g_0(\phi)R^{-3/2}$, for some arbitrary functions f_0 and g_0. Changing back to r and w, we find that the general solution of the fundamental equation in this case is

$$K(r,w)=f_0\left(\arctan\frac{w}{r}\right)\frac{r^{-2}}{1+(w/r)^2}+g_0\left(\arctan\frac{w}{r}\right)\frac{r^{-3}}{(1+(w/r)^2)^{3/2}}=f\left(\frac{w}{r}\right)r^{-2}+g\left(\frac{w}{r}\right)r^{-3},$$

where f and g are arbitrary functions.

Finally, let us conclude with an example of a three-dimensional qLN system. A detailed treatment of higher-dimensional qLN systems is presented in a separate article.[3]

Example 8.6: The Newton system

$$\ddot{r}_1=-10r_1^2+4r_2,$$

$$\ddot{r}_2=-16r_1r_2+10r_1^3+4r_3,$$

$$\ddot{r}_3=-20r_1r_3-8r_2^2+30r_1^2r_2-15r_1^4+d$$

was found in Ref. 12 as a parametrization of the seventh-order stationary KdV flow. It has three integrals of motion

$$E_1=\dot{r}_1\dot{r}_3+\frac{\dot{r}_2^2}{2}+10r_1^2r_3-4r_2r_3+8r_1r_2^2-10r_1^3r_2+3r_1^5-dr_1,$$

$$E_2=r_3\dot{r}_1^2-r_1\dot{r}_2^2+r_2\dot{r}_1\dot{r}_2-\dot{r}_2\dot{r}_3-r_1\dot{r}_1\dot{r}_3+4r_1^2r_2^2+5r_1^4r_2-\frac{5}{2}r_1^6$$
$$-4r_2^3+2r_3^2-12r_1r_2r_3+\frac{dr_1^2}{2}+dr_2,$$

$$E_3=\frac{1}{8}(r_2^2\dot{r}_1^2+r_1^2\dot{r}_2^2+\dot{r}_3^2-(2r_1r_2+4r_3)\dot{r}_1\dot{r}_2+2r_1\dot{r}_2\dot{r}_3+2r_2\dot{r}_1\dot{r}_3)+r_1r_2^3-3r_1^3r_2^2$$
$$+\frac{5}{4}r_1^5r_2+2r_1r_3^2+\frac{5}{4}r_1^4r_3-r_1^2r_2r_3+r_2^2r_3-\frac{d}{4}(r_1r_2-r_3),$$

which all are quadratic in velocities. This means that the system is generated by any of them through the quasi-Lagrangian equations. From the velocity-dependent parts we find

$$\begin{bmatrix}0&0&1\\0&1&0\\1&0&0\end{bmatrix},\quad \begin{bmatrix}2r_3&r_2&-r_1\\r_2&-2r_1&-1\\-r_1&-1&0\end{bmatrix},\quad \begin{bmatrix}r_2^2&-r_1r_2-2r_3&r_2\\-r_1r_2-2r_3&r_1^2&r_1\\r_2&r_1&1\end{bmatrix}$$

as examples of 3×3-matrices satisfying the cyclic conditions (2.3).

IX. CONCLUSIONS

In this article we have developed a new theory—the theory of quasi-Lagrangian Newton equations. It was originally inspired by interesting properties of the second stationary flow of the Harry Dym hierarchy, which led us to a broad theory which encompasses the classical separability theory but goes far beyond the classical results—the classical Bertrand–Darboux theory of separability for two-dimensional potential forces depends on one essential free parameter while our theory depends on five parameters.

The main part of this work has been focused on two-dimensional qLN systems which admit two integrals of motion E and F quadratic in velocities. These systems have only a nonstandard Hamiltonian formulation and are completely integrable by embedding into five-dimensional Liouville integrable systems. All such qLN systems are characterized by a single PDE called here the fundamental equation. We have shown that there is a one-to-one correspondence between fundamental equations and linear pencils $\lambda A + \mu B$ of matrices A and B. These linear pencils have been classified in Sec. V. In Sec. VII the class of driven systems has been studied in detail and new types of separation variables (non-confocal conics) have been found. We have also shown that any given force can be effectively tested for the existence of qLN formulation, which can further be used for unveiling its complete integrability and for solving the corresponding Newton equation. We have illustrated this by several examples including the generalized Hénon-Heiles system (Sec. VIII).

There are several natural directions of development of the theory of qLN systems. The n-dimensional versions of our main theorems on fundamental equation and on complete integrability have already been formulated and proved in Ref. 3.

The great wealth of different types of integrable Newton equations contained in the fundamental equation remains to be studied. Here we have only discussed two special cases: separable systems and driven systems. However, one of the most challenging questions yet to be answered is the existence of separation variables for the fundamental equation in its most general form. It can lead to new and interesting connections with the classical theory of separability of the Hamilton–Jacobi equation and of linear PDEs.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 40, NUMBER 12 DECEMBER 1999

Relativistic gas: Moment equations and maximum wave velocity

Guy Boillat[a] and Tommaso Ruggeri[b]
Department of Mathematics and Research Center of Applied Mathematics-(C.I.R.A.M.), University of Bologna, Via Saragozza 8, 40123 Bologna, Italy

(Received 16 August 1999; accepted for publication 7 September 1999)

For a rarefied relativistic gas we consider the N-moment equations associated with the relativistic Boltzmann–Chernikov equation and we require the compatibility with the entropy principle thus obtaining a closed symmetric hyperbolic system. This interesting form permits one to deduce a lower and an upper bound for the maximum velocity of a wave propagating in a monoatomic or a degenerate gas of fermions or bosons and to prove that when this number N increases this velocity tends to the speed of light. © *1999 American Institute of Physics.* [S0022-2488(99)02012-5]

I. INTRODUCTION

The thermo-mechanical evolution of a gas must be described in the relativistic context if the function $\gamma = mc^2/kT$ of the absolute temperature T is sufficiently small: $\gamma \ll 1$ (m, c, and k are, respectively, the atomic mass, the light velocity, and the Boltzmann constant). Relativistic fluid dynamics have possible applications in stellar physics and are appropriate for very hot gas, e.g., the white dwarfs, or for some degenerate gas in which the particle mass is very small, such as in the photon gas or in the neutrino gas.

As is well known in the case of rarefied gas we have two possible approaches; one in the context of phenomenological theory (continuum models), the second one using the relativistic kinetic theory. Ordinary relativistic thermodynamics was first developed by Eckart[1] and suffers from the paradox of infinite velocity due to the fact that the partial differential system is of parabolic type. Relativistists have shown a keen interest in the development of *extended thermodynamics*[2] that solves the paradox starting from the pioneering paper of Cattaneo.[3] The first approach of relativistic extended thermodynamics was given by Müller[4] and Israel[5] and was presented in a systematic manner by Liu, Müller, and Ruggeri.[6] This hyperbolic theory not only solves the paradox but also is in perfect agreement with the 14 moment equations deduced by Marle[7] from the Chernikov–Boltzmann kinetic equation.[8]

In Ref. 9 the closure procedure of extended thermodynamics[2] was applied to the N-moment system associated with both the classical and relativistic Boltzmann equation.

In particular it was proved that the compatibility with an entropy principle implies that the (truncated) distribution function f depends on a single variable χ that is a polynomial in the four-momentum with coefficients (*main field*) that are solutions of a symmetric hyperbolic system: the macroscopic field equations for the gas in nonequilibrium.

In wave problems the maximum wave speed plays a particular role (e.g., phase velocity in high frequencies, light scattering, shock waves, etc., see Ref. 2). Taking into account the special form of the symmetric hyperbolic system it was possible to deduce a lower bound estimate for the maximum velocity $\lambda_{\max}$ of a wave propagating in an equilibrium state. In the classical context this velocity increases without limit with N while in the relativistic case it was verified that the light speed c is an upper bound.[9] In Ref. 10 a lower bound was calculated also in the relativistic case

[a]Permanent address: Department of Applied Mathematics, University of Clermont, France; electronic mail: boillat@riemann.ing.unibo.it
[b]Electronic mail: ruggeri@lagrange.ing.unibo.it

for nondegenerate gas and it was proved that when the number of moments increases the maximum velocity does indeed tend to c. A review article on these subjects may be found in the recent survey of Müller.[11]

The aim of this paper is to extend this last result to a generic gas including also the interesting cases of degenerate Fermi–Dirac and Bose–Einstein gases.

The paper is organized in the following manner. In Sec. II we introduce the moment equations associated with the Chernikov–Boltzmann kinetic equation. In Sec. III we consider a finite number of moments and we close the system through the procedure of extended thermodynamics that is equivalent to the one obtained by the *maximum entropy principle*. In Sec. IV we deduce for all kinds of gases a lower and upper bound for the maximum wave speed, proving that when the number of moments tends to infinity this velocity tends to the light velocity.

II. BOLTZMANN–CHERNIKOV EQUATION AND MOMENTS

In the relativistic kinetic theory of a rarefied gas the phase density $f(x^\alpha,p^\alpha)$ $(\alpha=0,1,2,3)$ satisfies the Boltzmann–Chernikov equation[8,12]

$$p^\alpha\partial_\alpha f=Q,\quad \partial_\alpha=\partial/\partial x^\alpha, \tag{1}$$

in which x^α and p^α are the space–time coordinates and the four-momentum of an atom, respectively. We have $p_\alpha p^\alpha=(p^0)^2-\mathbf{p}^2=m^2c^2$, $\mathbf{p}^2=(p^1)^2+(p^2)^2+(p^3)^2$. The right-hand side of (1) is due to collision between the atoms.

Upon multiplication by $p^A(A=0,1,2,...)$ and integration the Boltzmann–Chernikov equation provides an infinite system of balance equations

$$\partial_\alpha F^{\alpha A}=g^A,\quad A=0,1,2,..., \tag{2}$$

for the moments $F^{\alpha A}$ and productions g^A given by

$$F^{\alpha A}(x^\beta)=\int p^\alpha p^A f\,dP,\quad g^A(x^\beta)=\int Qp^A f\,dP, \tag{3}$$

where A is a multi-index

$$p^A=\begin{cases}1\\ p^{\alpha_1}p^{\alpha_2}\cdots p^{\alpha_A},\end{cases}\quad F^{\alpha A}=\begin{cases}F^\alpha\\ F^{\alpha\alpha_1\ldots\alpha_A},\end{cases}\quad g^A=\begin{cases}0 & \text{for } A=0\\ g^{\alpha_1\cdots\alpha_A} & \text{for } A\geqslant 1\end{cases}$$

and $0\leqslant\alpha_1\leqslant\alpha_2\leqslant\ldots\leqslant\alpha_A\leqslant 3$.

The first five equations of (2) are the conservation laws of the number of particles and energy–momentum. According by the first five productions vanish: $g^A=0$ for $A=0,1$. The volume element of momentum space is given by $dP=d^3p/p^0=dp^1dp^2dp^3/p^0$ and the integrals—supposed convergent—are taken over the whole of $\mathbf{p}$ space.

On the other hand if we consider as momentum

$$h^\alpha=k\int p^\alpha\{(s^2-1+\ln f)f+s(1-sf)\ln(1-sf)\}dP, \tag{4}$$

where $s=0,+1,-1$ corresponds, respectively, to the nondegenerate gas, the Fermi gas, and the Bose gas, we obtain from (1) the supplementary inequality (H-Theorem)

$$\partial_\alpha h^\alpha=\Sigma\leqslant 0. \tag{5}$$

The previous expression represents the balance of entropy when we identify $-h^\alpha$ and $-\Sigma$ with the entropy four-vector and the entropy production, respectively.

III. FINITE SYSTEM OF MOMENT EQUATIONS AND CLOSURE

We consider now a finite number of moment equations (2) with the tensorial index $A=0,...,n$. In this case the main problem is the so-called *closure problem*. In fact the number of moments is larger than the number of moment equations and therefore constitutive equations are needed to determine the system. In Ref. 9 we proposed the closure procedure of extended thermodynamics[2] requiring the compatibility with an entropy principle that plays an important role in selecting the physical class of constitutive equation in thermomechanics. This consists in assuming that any differentiable solution of the finite moment equations (2) with $A=0,...,n$ is also a solution of the supplementary entropy law (5) which appears now as a constraint.

We recall that for a general quasilinear system of balance laws of type (2) the compatibility with the entropy law (5) implies the existence of a privileged field (*main field*) $u'_A(x^\alpha)$ and a four-vector $h'^\alpha(u'_A)$ (*generators*) such that[13,14]

$$F^{\alpha A}=\frac{\partial h'^\alpha}{\partial u'_A},\quad h^\alpha=\sum_{A=0}^{n} u'_A\frac{\partial h'^\alpha}{\partial u'_A}-h'^\alpha,\quad \Sigma=\sum_{A=0}^{n} u'_A g^A,\quad A=0,1,...,n. \tag{6}$$

In the present case from $(3)_1$ and $(6)_1$ we obtain

$$dh'^\alpha=\sum_{A=0}^{n} F^{\alpha A}du'_A=\sum_{A=0}^{n}\int p^\alpha p^A\, du'_A\, f\, dP. \tag{7}$$

It follows that f must be a function of the single variable

$$\chi=\sum_{A=0}^{n} u'_A p^A, \tag{8}$$

while

$$h'^\alpha=\int F(\chi)p^\alpha\, dP,\quad \frac{dF(\chi)}{d\chi}=f(\chi). \tag{9}$$

From $(6)_2$ we obtain the admissible entropy four-vector

$$h^\alpha=\int (\chi f(\chi)-F(\chi))p^\alpha\, dP. \tag{10}$$

The remaining condition is the so-called residual inequality that requires that the admissible productions $g^A(u'_B)$ are such that

$$\Sigma=\sum_{A=0}^{n} u'_A g^A(u'_B)\leqslant 0. \tag{11}$$

Therefore we have verified the following: *The compatibility of the truncated moment system with the entropy principle requires that the truncated distribution function f depend on a single variable χ given by (8), while the entropy four-vector and the productions satisfy (10) and the residual inequality (11).*

In Ref. 9 (see also Ref. 2, p. 218 sqq) it was shown that this closure procedure is equivalent to the one obtained by the so-called *maximum entropy principle* by which the truncated distribution function is chosen such that the entropy density thought of as a generic functional of $f: h^0=\int\Psi(f)d^3p$ is a maximum under the constraint that the moments $\int f p^A d^3p$ are assigned functions F^{0A}. In fact it is easy to verify that $\Psi(f)$ must be equal to $\chi f-F$ and the Lagrange multipliers in the maximization procedure are nothing but the main field variables u'_A. The first author that applied the idea of maximization of entropy in nonequilibrium thermodynamics was

Dreyer,[15] who started from the observation of Kogan[16] that the Grad's 13-moment density maximizes the entropy. The procedure of maximizing entropy was introduced in information theory and physics by Jaynes.[17,18]

By (6) the finite system of moments (2) becomes

$$\sum_{B=0}^{n} H^{\alpha AB}(u'_C)\partial_\alpha u'_B = g^A(u'_C), \quad A=0,1,...,n \tag{12}$$

with the symmetric matrices

$$H^{\alpha AB} = \int \frac{df}{d\chi} p^\alpha p^A p^B \, dP, \tag{13}$$

and $H^{\alpha AB}\xi_\alpha$ is positive definite for any timelike vector $(\xi_\alpha \xi^\alpha > 0)$ if $df/d\chi > 0$. This implies that the system of truncated moments (12) is [in the main field variables $u'_A(x^\alpha)$] a symmetric hyperbolic system (in the sense of Friedrichs) for which the Cauchy problem is well posed.[19]

The wave surface $\phi(x^\alpha)=0$ is solution of the characteristic equation

$$\det(H^{\alpha AB}\partial_\alpha \phi) = 0. \tag{14}$$

As a consequence, the four-gradient $\partial_\alpha \phi$ cannot be timelike and therefore the velocities of wave propagation cannot exceed the velocity of light, i.e., $\lambda_{\max} \leqslant c$. When the number of equations increases it has already been shown that the maximum wave velocity cannot decrease.[20] The question is now: does this velocity tends to c when n tends to infinity? This is the subject of the next paragraph.

We observe that since all of the indices in the main field $u'_{\alpha_1 \cdots \alpha_k}$ may assume the values 0, 1, 2, 3 and therefore,—following Refs. 9 and 10—the components $u'_{\alpha_1 \cdots \alpha_k}$ may be mapped into the variables u'_{pqrs} with $p+q+r+s=k(k=1,...,n)$, where p,q,r,s are the numbers of indices among $\alpha_1 \ldots \alpha_k$ which are equal to 0, 1, 2 or 3 respectively. Because p^0 is equal to $\sqrt{m^2c^2+\mathbf{p}^2}$, the first index p can take only two values: 0 and 1. Now, since the number of elements with the sum of three integers $q+r+s=k$ with $k=0,...,m$ is $(m+1)(m+2)(m+3)/6$, the number $N(n)$ of independent components of u'_{pqrs}-''and equations,''-up to order n is $N(n)=(n+1)(n+2)(n+3)/6 + n(n+1)(n+2)/6$. Therefore the maximum tensorial index n that appears in the moment system is related to the number N of independent moments and field equations through[10]

$$N(n) = \tfrac{1}{6}(n+1)(n+2)(2n+3), \quad N(n+1) = N(n) + (n+2)^2.$$

Assuming that (10) is of the form (4) follows

$$k\{f(s^2-1+\ln f) + s(1-sf)\ln(1-sf)\} = \chi f - F \tag{15}$$

from which (by differentiation)

$$f(\chi) = \frac{1}{e^{-\chi/k}+s}. \tag{16}$$

Summarizing we have: *The admissible truncated distribution function $f(\chi)$ such that the finite moment system (2) is compatible with the entropy principle (5) with entropy four-vector given by (4) is of the form (16) with χ given by (8) and u'_A solution of the symmetric hyperbolic system (12).*

IV. PROPAGATION IN AN EQUILIBRIUM STATE AND MAXIMUM WAVE VELOCITY

A thermodynamic equilibrium state is defined as the state for which the productions g^A vanish and the entropy production $-\Sigma$ reaches its minimum value, i.e., zero. The main field variables are privileged also in this context because it is possible to prove that all are zero[2,21] with exception of the first five:[14]

$$u' = \frac{G}{T}, \quad u'_\alpha = -\frac{u_\alpha}{T}, \tag{17}$$

where G and u_α are, respectively, the chemical potential and the four velocity. Therefore for any truncation index n the χ given by (8) reduces in the equilibrium state to $\chi/k = (G - u_\alpha p^\alpha)/(kT)$ and in the rest frame in which $u^i = 0$, $u^0 = c$, we have

$$\frac{\chi}{k} = -a - \gamma\sqrt{1 + \frac{\mathbf{p}^2}{m^2c^2}}, \tag{18}$$

with $a = -G/KT$, $\gamma = mc^2/kT$. In this case the distribution function (16) becomes the well-known Jüttner equilibrium distribution.[22] We recall that for a fermi gas a can assume all real values while for bosons $a + \gamma > 0$.

According to (14) the wave velocity λ in the direction of the normal $\mathbf{n}$ to the wave front is an eigenvalue of

$$\det(H^{iAB}n_i - \lambda H^{0AB}) = 0. \tag{19}$$

The matrix in (19) is negative semidefinite for the maximum eigenvalue, that is if we take $\mathbf{n} \equiv (1,0,0)$ the components of the matrix

$$H^{1AB} - \lambda_{\max} H^{0AB} = \int \frac{df}{d\chi} p^A p^B (p^1 - \lambda p^0)\, dP,$$

satisfy the inequalities $a_{ii}a_{jj} - a_{ij}^2 \geqslant 0$ so that choosing $p^A = (p^1)^n$, $p^B = (p^1)^{n-1}$, we have

$$\frac{\lambda_{\max}^2}{c^2} \int \frac{df}{d\chi} (p^1)^{2n} d^3p \int \frac{df}{d\chi} (p^1)^{2(n-1)} d^3p \geqslant \left(\int \frac{df}{d\chi} (p^1)^{2n} \frac{d^3p}{p^0} \right)^2 \tag{20}$$

since the integrals of odd functions vanish.

Introducing as in Ref. 10 the spherical coordinates $p^1 = mcr \sin\theta \cos\varphi$, $p^2 = mcr \sin\theta \sin\varphi$, $p^3 = mcr \cos\theta$ the previous inequality with (16) and (18) yields after some straightforward calculations

$$\frac{\lambda_{\max}^2}{c^2} \geqslant \frac{2n-1}{2n+1} \frac{J_{n+1}^2}{I_n I_{n+1}}, \tag{21}$$

where

$$I_n = \int_0^\infty \phi(r) r^{2n}\, dr, \quad J_n = \int_0^\infty \frac{\phi(r) r^{2n}}{\sqrt{1+r^2}}\, dr,$$

$$\phi(r) = \frac{e^{\psi(r)}}{(1 + s e^{\psi(r)})^2}, \quad \psi(r) = \frac{\chi}{k} = -a - \gamma\sqrt{1+r^2}.$$

Therefore we have: *For any type of gas including the degenerate gas of fermions and bosons the largest wave velocity satisfies the lower and upper bounds*:

$$\frac{2n-1}{2n+1}\frac{J_{n+1}^2}{I_n I_{n+1}} \leqslant \frac{\lambda_{\max}^2}{c^2} \leqslant 1. \tag{22}$$

Now our aim is to prove that when $n\to\infty$, $\lambda_{\max}\to c$. Integrating by parts

$$I_n = \int_0^\infty \phi(r)\frac{d(r^{2n+1})}{2n+1} = \frac{\gamma}{2n+1}\int_0^\infty \phi(r)\frac{1-se^{\psi}}{1+se^{\psi}}\frac{r^{2n+2}}{\sqrt{1+r^2}}dr,$$

and taking into account that

$$\frac{1-se^{\psi}}{1+se^{\psi}} \leqslant C, \quad C = \begin{cases} 1 & \text{for } s=0,1 \\ (1+e^{-(a+\gamma)})/(1-e^{-(a+\gamma)}) & \text{for } s=-1, \end{cases}$$

it follows

$$I_n \leqslant \frac{\gamma C}{2n+1}\int_0^\infty \frac{\phi r^{2n+2}}{\sqrt{1+r^2}}dr \Rightarrow J_{n+1} \geqslant \frac{2n+1}{\gamma C} I_n \tag{23}$$

and (21) becomes

$$\frac{\lambda_{\max}^2}{c^2} \geqslant \frac{2n-1}{2n+1}\left(\frac{2n+1}{\gamma C}\right)^2 \frac{I_n}{I_{n+1}}. \tag{24}$$

On the other hand for any constant μ,

$$0 \leqslant \int_0^\infty \phi\left(r^n\mu + \frac{r^{n+2}}{\sqrt{1+r^2}}\right)^2 dr \leqslant \mu^2 I_n + 2\mu J_{n+1} + I_{n+1},$$

which shows that

$$J_{n+1}^2 \leqslant I_n I_{n+1}$$

and by (23)

$$\left(\frac{2n+1}{\gamma C}\right)^2 \frac{I_n}{I_{n+1}} \leqslant 1. \tag{25}$$

Let M_s be the maximum of $\phi(r)$:

$$M_0 = e^{-(a+\gamma)}, \quad M_1 = \frac{1}{4}, \quad M_{-1} = \frac{e^{-(a+\gamma)}}{(1-e^{-(a+\gamma)})^2}$$

and consider now the series of functions

$$u_n(r) = \frac{1}{(n!)^2}\left(\frac{r\gamma C}{2}\right)^{2n}\phi(r) \leqslant \frac{M_s}{(n!)^2}\left(\frac{R\gamma C}{2}\right)^{2n},$$

which converges uniformly for all finite values of $r\leqslant R$ to the function $\phi(r)I_0(\gamma C r)$ where $I_0(x)$ is the Bessel function.

The integral

$$U_n(R) = \int_0^R u_n\, dr = \frac{1}{(n!)^2}\left(\frac{\gamma C}{2}\right)^{2n}\mathcal{I}_n(R), \quad \mathcal{I}_n(R) = \int_0^R \phi(r) r^{2n} dr, \quad I_n = \mathcal{I}_n(\infty)$$

exists and this series is convergent. We can choose R and n large enough so that the ratio

$$\frac{U_n(R)}{U_{n+1}(R)}=\left(\frac{2n+2}{2n+1}\right)^2\left(\frac{2n+1}{\gamma C}\right)^2\frac{\mathcal{I}_n(R)}{\mathcal{I}_{n+1}(R)}$$

is as close as we like to the left member of (25). Because of the convergence of the series it always exists an n as large as we wish such that this ratio is larger than or equal to 1. Therefore it is close to 1 and so, by (24), is $\lambda_{\max}/c$ which, on the other hand, is a nondecreasing function of n[20] and cannot exceed 1 and then must tend to 1 as n tends to infinity.

In conclusion *when the number of moments tends to infinity the maximum wave velocity tends for all kind of gases to the light velocity*.

These results are in perfect agreement with a recent numerical simulation given in Ref. 23 in which the maximum velocity was evaluated for increasing values of the truncation index n for different values of γ and a.

Integral representations of thermodynamic 1PI Green's functions in the world-line formalism

Haru-Tada Sato[a)]
Institut für Theoretische Physik, Universität Heidelberg, Philosophenweg 16, D-69120 Heidelberg, Germany

(Received 5 March 1999; accepted for publication 18 March 1999)

The issue discussed is a thermodynamic version of the Bern–Kosower master amplitude formula, which contains all necessary one-loop Feynman diagrams. It is demonstrated how the master amplitude at finite values of temperature and chemical potential can be formulated within the framework of the world-line formalism. In particular we present an elegant method of how to introduce a chemical potential for a loop in the master formula. Various useful integral formulas for the master amplitude are then obtained. The nonanalytic property of the master formula is also derived in the zero temperature limit with the value of chemical potential kept finite. © *1999 American Institute of Physics.* [S0022-2488(99)00812-9]

I. INTRODUCTION

Based on the field theory limit of string theory (with infinite string tension limit), a very elegant method was invented several years ago: the Bern–Kosower (BK) rules to obtain one-loop gluon scattering amplitudes in a compact form[1] (see also Ref. 2). For example, five gluon scatterings are efficiently calculated by using these rules,[3] and various field theory limits have been studied along the line of the BK formalism: perturbative gravity,[4] super Yang–Mills theory,[5] bosonic string theory approach,[6] and multi-loop generalizations.[7–9]

The most important and conspicuous point in the BK formalism is that all Feynman diagrams are included in a single master integrand. In this formalism, we hence do not compute the loop integrals and the Dirac traces of respective Feynman diagrams. These facts can also be achieved by another approach, called the world-line formalism, which reformulates Feynman (field theory) amplitudes similar to string theory amplitudes; i.e., the field theory amplitudes can generally be obtained as a path integral average of vertex operators.[10–17]

In fact, there have been established many examples: ϕ^3 theory,[10,11] QED,[12,13] axial vector and pseudo-scalar couplings,[14,15] Yang–Mills theory[16,17] (see also Refs. 18 and 19), and more references can be found in Ref. 20. Both world-line and string theory methods help each other, and are useful to get an insight for solving mutually related problems each in its own way; for example, this viewpoint has been very useful for specifying pinching limits and corners of string moduli in the multi-loop analysis.[8] It is very interesting that these two methods, which differ entirely from the conventional Feynman diagram technique, improve the computational efficiency for obtaining Feynman amplitudes.

However, compared to these developments, their thermodynamic versions have not been studied very much[21–25] from the viewpoint of general formulation for constructing a master amplitude formula. In particular, there has been no general and convenient method of how to introduce a chemical potential for a loop in the world-line formalism. Before stepping in an unexplored calculation by using the formalism, it is important to establish a definite and universal foundation in the first place. In this paper, therefore, as a basic step on the thermodynamic generalization of world-line field theory, we present a universal and fundamental prescription of one-loop N-point amplitudes at finite values of temperature and chemical potential without help of

[a)]Electronic mail: sato@thphys.uni-heidelberg.de

any standard calculation. We shall study the amplitude of a particular form (the master formula), where the loop integration and the Matsubara summation are *a priori* finished and Feynman's parameter integrals are only left—laying emphasis on the point that we never mean the Feynman integrals as a single Feynman diagram, but as a sum of *all diagrams*. It is certainly nontrivial to introduce a chemical potential (as well as a temperature) with keeping this advantageous point pertaining to the master formula intact.

We address the following points in the matter of the thermodynamic generalization (at finite values of the temperature β^{-1} and the chemical potential μ for a loop). First, we present a formulation of the thermodynamic amplitudes along the same line as the nonthermodynamic world-line formalism. In particular, the way of introducing the chemical potential is a nontrivial problem. Since we do not introduce any idea of the continuous or discrete momentum integration/summation, we have to find an alternative to the shift of internal discrete momenta:

$$\omega_n \to \omega_n + i\mu. \tag{1.1}$$

This situation may be understood in the following way: In the standard method, the inverse temperature β is introduced by summing up all topological different S^1 paths along the zeroth component (imaginary time) direction. On the other hand, in the world-line formalism, this procedure modifies the path integral of a corresponding periodic world-line field $x^0(\sigma)$, $0\leqslant\sigma\leqslant 1$, into a summation of the path integrals with $x^0(\sigma)$ shifted by

$$x^0(\sigma) \to x^0(\sigma) + n\beta\sigma. \tag{1.2}$$

Although the radius β of S^1 and the world-line circumference (the unity) have nothing to do with each other, the shift (1.2) involves the world-line coordinate σ as well. In this sense, the way of prescribing the temperature and hence the chemical potential becomes different from the standard Matsubara formalism. To introduce the chemical potential, one may of course transform a world-line amplitude formula to the Feynman–Matsubara form, and then resume the world-line form after some efforts to apply the shift (1.1). However, such a calculation does not utilize the merits of the master formula at all, and there should be a more direct and transparent method to introduce μ within the world-line formalism (without tracing back and referring any internal loop calculation).

To this end, we propose a new rule, instead of (1.1), to introduce the internal chemical potential. It is simply done by applying the new shift procedure

$$\overline{\omega} \to \overline{\omega} + i\mu, \tag{1.3}$$

where $\overline{\omega}$ is an average of the zeroth components of external continuous/discrete momenta k_j^0, $j=1,2,...N$, with the summation weights σ_j (the local coordinates of the external legs on the closed loop). The prescription (1.3) is neither conceivable nor explicable from the standard method (1.1), because ω_n is the internal momentum while $\overline{\omega}$ concerns the external one. The parameter $\overline{\omega}$ will easily be identified in due course, if we adopt a statistical parameter to discern between boson and fermion loops when summing up the S^1 paths: This parameter dependence should vanish at the $\beta\to\infty$ limit as expected in the nonthermodynamic world-line formalism.

Another nontriviality in this formalism is how to derive a nonanalytic property at $\beta=\infty$ with finite μ from the master amplitude formula. Since the nonanalytic property can be derived from the $\beta=\infty$ limits of pure thermodynamic parts, we first have to separate a pure thermodynamic part $\tilde{\Gamma}_N^{\beta\mu}$ from a full thermodynamic amplitude $\Gamma_N^{\beta\mu}$. If the master integrand of $\Gamma_N^{\beta\mu}$ is composed only of the Jacobi Θ-function, the story is simple as expected. However, in a more complicated case like a photon scattering, the master integrand is not such a simple form but a product of a β- and μ-dependent operator $\mathcal{V}_{\beta\mu}$ and the Jacobi Θ-function part $\mathcal{K}_{\beta\mu}$. The pure thermodynamic parts of these quantities, $\tilde{\mathcal{V}}_{\beta\mu}$ and $\tilde{\mathcal{K}}_{\beta\mu}$, can easily be separated from their original full quantities, but we show that the pure thermodynamic part $\tilde{\Gamma}_N^{\beta\mu}$ is nontrivially given by $\mathcal{V}_{\beta\mu}\times\tilde{\mathcal{K}}_{\beta\mu}$ against naive expectation. (The simple arithmetical splittings indicate one more contribution, however, we shall show that it vanishes.) Separating the $\tilde{\Gamma}_N^{\beta\mu}$ in this way, we then analyze the nonanalytic property of the master amplitude at zero temperature.

This paper is organized as follows. In Sec. II, we explain our notations, definitions, and the general structure of master amplitudes at zero temperature. In Sec. III, we derive a set of general formulas for a master amplitude at finite β and μ parts by parts: path integral normalization and (scalar) kinematical factor in Sec. III A, and reduced kinematical factor in Sec. III b. In Sec. III c, we show a general master formula for the purely thermodynamic part of the full amplitude $\Gamma_N^{\beta\mu}$, and also prove the above statement, i.e., $\tilde{\Gamma}_N^{\beta\mu} \sim \mathcal{V}_{\beta\mu} \times \tilde{K}_{\beta\mu}$. The replacement rule (1.3) is verified in Appendices A–C from the viewpoints of both Feynman rule's calculation and the world-line formalism. In Secs. IV and V, for arbitrary N, we derive various integral formulas by analyzing two kinds of Θ-function representations, and check their consistency. Several explicit results are also presented up to $N=5$. In Sec. VI, we derive the nonanalytic property of the master formula in the zero temperature limit with the chemical potential kept finite. Section VII contains summary and conclusions.

II. NOTATIONS AND DEFINITIONS

First, we summarize the general structure of the one-loop N-point master amplitudes in the nonthermodynamic world-line formalism. (We assume that a particle change does not occur while circulating along the loop.) We refer the reader to Refs. 12, 16, and 20 for more details. The master amplitude of general form (for N external momenta k_j^μ, $j=1,2,...,N$, $\mu=0,1,...,D-1$) is written in terms of the closed path integrals of bosonic $x^\mu(\sigma)$ and fermionic $\psi^\mu(\sigma)$ world-line fields as follows:

$$\Gamma_N = \frac{1}{2}\int_0^\infty \frac{ds}{s} \oint \mathcal{D}x^\mu(\sigma)\mathcal{D}\psi^\mu(\sigma)\exp\left[-\int_0^1 \mathcal{L}(\sigma)\, d\sigma\right]\prod_{j=1}^N V_j \tag{2.1}$$

with the world-line Lagrangian and the vertex operators

$$\mathcal{L}(\sigma) = \frac{1}{4s}\left(\frac{\partial x^\mu(\sigma)}{\partial\sigma}\right)^2 + \frac{1}{2}\,\psi^\mu(\sigma)\frac{\partial}{\partial\sigma}\,\psi_\mu(\sigma) + sm^2, \tag{2.2}$$

$$V_j = s\int_0^1 d\sigma\, v_j[x(\sigma),\psi(\sigma)]e^{ik_j\cdot x(\sigma)}, \quad j=1,2,...,N, \tag{2.3}$$

where $k_j\cdot x$ stands for the Lorentz contraction, and we often omit the Lorentz indices as long as obvious. The zero mode integral of the bosonic path integral should be excluded.[18] The explicit form of v_j depends on what particle is inserted in the loop as an external leg; for example, $v_j=1$ for ϕ^3 theory, and is in Eq. (C2) for the photon vertex case. Note that our world-line coordinate σ is dimensionless, and is related to the standard notation[20] by scaling $\tau=s\sigma$. For the path integral average of a general quantity F,

$$\langle F(x,\psi)\rangle \equiv \mathcal{N}^{-1}\oint \mathcal{D}x\mathcal{D}\psi\exp\left[-\int_0^1 \mathcal{L}(\sigma)\, d\sigma\right]F(x,\psi), \tag{2.4}$$

one may use the Wick contractions with (the Euclidean metric is given by $g^{\mu\nu}=-\delta^{\mu\nu}$)

$$\langle x^\mu(\sigma_1)x^\nu(\sigma_2)\rangle = -sg^{\mu\nu}G(\sigma_1,\sigma_2), \tag{2.5}$$

$$\langle \psi^\mu(\sigma_1)\psi^\nu(\sigma_2)\rangle = \tfrac{1}{2}g^{\mu\nu}\,\mathrm{sign}\,(\sigma_1-\sigma_2), \tag{2.6}$$

where $\mathcal{N}$ is the path integral normalization

$$\mathcal{N}=\oint \mathcal{D}x\mathcal{D}\psi \exp\left[-\int_0^1 \mathcal{L}(\sigma)\, d\sigma\right]=e^{-sm^2}(4\pi s)^{-D/2}, \tag{2.7}$$

and G is the bosonic world-line correlator

$$G(\sigma_i,\sigma_j)=|\sigma_i-\sigma_j|-(\sigma_i-\sigma_j)^2\equiv G_{ij}. \tag{2.8}$$

Performing the path integrals (or Wick contractions), we arrive at the following master amplitude formula:

$$\Gamma_N=c\int_0^1 d\sigma_1\int_0^1 d\sigma_2\cdots\int_0^1 d\sigma_N\int_0^\infty ds\, s^{N-1}\mathcal{V}\times\mathcal{K}, \tag{2.9}$$

where the constant c depends on the particle circulating in a loop. (It is also related to an over-counting factor of σ-integration regions.[26]) For example,

$$c=\begin{cases}\frac{1}{2} & \text{for a (neutral) scalar loop}\\ -\frac{1}{2}\,\mathrm{tr}[1] & \text{for a fermion loop}\end{cases}, \tag{2.10}$$

where the $\mathrm{tr}[1]$ expresses the trace of a unit matrix in the D-dimensional gamma matrix space. For a gluon loop, c is no longer a simple constant.[16,17] The quantity $\mathcal{K}$, which we shall call the *kinematical factor* (multiplied by the normalization $\mathcal{N}$), is defined by the world-line path integral average of N scalar vertex operators[10,16]

$$\mathcal{K}\equiv\mathcal{N}\left\langle\prod_{j=1}^N e^{ik_jx(\sigma_j)}\right\rangle=\oint \mathcal{D}x^\mu\mathcal{D}\psi^\mu\left(\prod_{j=1}^N e^{ik_jx(\sigma_j)}\right)\exp\left[-\int_0^1\mathcal{L}(\sigma)\,d\sigma\right]. \tag{2.11}$$

The $\mathcal{V}$ stands for an effective vertex function, which is obtained by

$$\mathcal{V}=\frac{\langle\Pi_{j=1}^N v_j \exp[ik_j\cdot x(\sigma_j)]\rangle}{\langle\Pi_{j=1}^N \exp[ik_j\cdot x(\sigma_j)]\rangle}. \tag{2.12}$$

We shall refer to this quantity as the *vertex structure function/operator*, which corresponds to the quantities called the *reduced kinematical factor*[1] or the generating kinematical factor.[16] At this stage, the $\mathcal{V}$ is still a function of s and σ_j $(j=1,2,...,N)$, however, it will be generalized to an operator in the thermodynamic case.

If the vertex structure function can be expanded in the form

$$\mathcal{V}=\sum_{l\in\mathbb{Z}} a_l s^{l-N}\exp[-sb_l], \tag{2.13}$$

where the coefficients a_l and b_l may not depend on s, but on σ_j, and the amplitude (2.9) is obtained as the sum of the ''partial'' amplitudes

$$\mathcal{A}_l\overset{\text{def.}}{=}\int_0^\infty ds\, s^{l-1}\mathcal{K}=\int_0^\infty ds\, s^{l-1}\mathcal{N}\left\langle\prod_{j=1}^N e^{ik_j\cdot x(\sigma_j)}\right\rangle, \tag{2.14}$$

with shifting m^2 to m^2+b_l.

In the case of finite β, we assume the zeroth components of the external momenta k_j^μ to be the bosonic Matsubara frequencies

$$k_j^0=\omega_{k_j}=\frac{2\pi}{\beta}n_j, \tag{2.15}$$

as well as

$$k_j \cdot x \equiv \omega_{k_j} x^0 - \mathbf{k}_j \cdot \mathbf{x}. \tag{2.16}$$

In this paper, we shall not consider the fermionic external states, since the bosonic external states are only well formulated in the world-line formalism—however, one may formally generalize to the fermionic states. We use the notations for the counterparts of Eqs. (2.9), (2.11), (2.7), (2.12), and (2.14):

$$\Gamma_N^\beta, \quad \mathcal{K}_\beta, \quad \mathcal{N}_\beta, \quad \mathcal{V}_\beta, \quad \mathcal{A}_l^\beta. \tag{2.17}$$

In the case of finite μ and β, we denote

$$\Gamma_N^{\beta\mu}, \quad \mathcal{K}_{\beta\mu}, \quad \mathcal{N}_{\beta\mu}, \quad \mathcal{V}_{\beta\mu}, \quad \mathcal{A}_l^{\beta\mu}. \tag{2.18}$$

We explain how to define these quantities in the next section.

III. THE THERMODYNAMIC GENERALIZATION

A. The kinematical factor $\mathcal{K}_{\beta\mu}$ and the normalization $\mathcal{N}_{\beta\mu}$

We take a two-step procedure to introduce the temperature and the chemical potential. As the first step, we consider the $\mu=0$ case. Basically we follow the same method as discussed in Refs. 22–25, and we start with the following slightly general definition:

$$\Gamma_N^\beta \overset{\text{def.}}{=} \sum_{n=-\infty}^{\infty} e^{2n\pi i/\epsilon} \Gamma_N \big|_{x^0(\sigma)\to x^0(\sigma)+n\beta\sigma}, \tag{3.1}$$

where ϵ is a constant related to the statistics of the loop. For example, the $\epsilon=2$ case corresponds to a fermion loop, and the $\epsilon=\infty$ case to a bosonic loop. Without specifying the value of ϵ, we deal with both cases simultaneously (formally fractional statistics as well). The Γ_N on the right-hand side (rhs) of the above formula denotes the path integral representation (2.1), and the replacement (1.2) should be applied to the x^0 fields for all variables σ_j. In a nutshell, we have only to replace the bosonic path integral in the following way:

$$\oint \mathcal{D}x^\mu \to \oint_\beta \mathcal{D}x^\mu \equiv \sum_{n=-\infty}^{\infty} e^{2n\pi i/\epsilon} \oint_{x^0(\sigma)\to x^0(\sigma)+n\beta\sigma} \mathcal{D}x^\mu. \tag{3.2}$$

For simplicity, let us consider the $\mathcal{V}=1$ case, or the ''partial'' amplitude $\mathcal{A}_N$ [the $l=N$ term in (2.13)]. In this case, we have only to generalize the kinematical factor $\mathcal{K}$ to the finite temperature version $\mathcal{K}_\beta$;

$$\mathcal{K}_\beta \overset{\text{def.}}{=} \sum_{n=-\infty}^{\infty} e^{2n\pi i/\epsilon} \mathcal{N} \left\langle \prod_{j=1}^{N} e^{ik_j\cdot x(\sigma_j)} \right\rangle \Bigg|_{x^0(\sigma)\to x^0(\sigma)+n\beta\sigma} \tag{3.3}$$

$$= (4\pi s)^{-D/2} e^{-sM^2} \Theta_3\left(\frac{1}{\epsilon} + \frac{\beta\overline{\omega}}{2\pi}, i\frac{\beta^2}{4\pi s} \right), \tag{3.4}$$

where the definition of $\Theta_3(v,\tau)$ is

$$\Theta_3(v,r) = \sum_{n=-\infty}^{\infty} e^{n^2\tau\pi i} e^{2nv\pi i}, \tag{3.5}$$

and we have introduced the following two s-independent quantities:

$$M^2 = m^2 - \sum_{i<j,=1}^{N} k_i \cdot k_j G_{ij}, \tag{3.6}$$

$$\overline{\omega} = \sum_{j=1}^{N} \sigma_j \omega_{k_j}. \tag{3.7}$$

Here the two-point correlator (world-line Green's function) G_{ij}, given by Eq. (2.8), looks different from the one used in Ref. 22; however, the value of M^2 does not differ under the condition of momentum conservation regarding the external legs. The sign of M^2 seems not always to be positive in spite that $0 \leqslant G_{ij} \leqslant \frac{1}{2}$. We then assume $M^2 \geqslant 0$ in the following discussion, choosing the off-shell symmetric point (satisfying the momentum conservation constraint)

$$k_i k_j = \delta_{ij} k^2 + (\delta_{ij} - 1) \frac{1}{N-1} k^2. \tag{3.8}$$

For the $\mathcal{V} \neq 1$ case, we have to apply Eq. (3.2) to the $\mathcal{V}$ and $\mathcal{K}$ parts at the same time; however, the things are rather straightforward. We refer the reader to Appendix C for an example.

The second step is to introduce the chemical potential for the internal loop. One may do it with applying the Jacobi transformation to the quantity $\mathcal{K}_\beta$; i.e., rewriting Eq. (3.4) in such a way to revive the discrete summation over internal Matsubara frequencies ω_n, one may perform the replacement (1.1) (see Ref. 24 for more details). However, this is a roundabout way, since one has to make the Matsubara summation reappear in spite of dealing with the world-line formulation, where the integration and summation of the loop are already performed. Instead, we propose a much simpler and direct alternative method to steer clear of this problem. It can be promptly done by the replacement (1.3),

$$\overline{\omega} \to \Omega \equiv \overline{\omega} + i\mu. \tag{3.9}$$

This shift looks similar to (1.1); however, we stress that our shifting parameter is not the internal frequency but an average of external ones [cf. Eq. (3.7)]. In this sense, this prescription is nontrivial. For a rigorous reader, we put a justification of this replacement in Appendix A (the case of $\mathcal{V}=1$), and also refer to Appendix B for a more complicated case (the $\mathcal{V} \neq 1$ case). After all, the general path integral average for finite μ can be obtained in a couple of simple replacements:

$$\oint \mathcal{D}x^\mu \to \oint_\beta \mathcal{D}x^\mu \to \oint_{\beta\mu} \mathcal{D}x^\mu \equiv \oint_\beta \mathcal{D}x^\mu \big|_{\overline{\omega}\to\Omega}. \tag{3.10}$$

Note that the fermion path integral does not change by any means.

Let us write down the thermodynamic kinematical factor $\mathcal{K}_{\beta\mu}$ and the normalization factor $\mathcal{N}_{\beta\mu}$. Applying the above replacement to Eq. (3.4), we thereby yield the desired thermodynamic kinematical factor for finite β and μ:

$$\mathcal{K}_{\beta\mu} \overset{\text{def.}}{=} \text{Eq. (3.4)}\big|_{\overline{\omega}\to\Omega} \tag{3.11}$$

$$= (4\pi s)^{-D/2} e^{-sM^2} \Theta_3\left(i\frac{\beta\overline{\mu}}{2\pi}, i\frac{\beta^2}{4\pi s} \right), \tag{3.12}$$

where we have introduced the shorthand notation $\overline{\mu}$ by reason of analogy to the vacuum amplitude of a scalar loop

$$\overline{\mu} \equiv \mu - i\overline{\omega} - \frac{2\pi i}{\epsilon\beta} = -i\left(\Omega + \frac{2\pi}{\epsilon\beta} \right). \tag{3.13}$$

We refer to the representation (3.12) as the *first representation*. This representation with $\overline{\mu}=0$ ($\mu=\overline{\omega}=0$, $\epsilon=\infty$) is studied in Ref. 22. We also obtain another expression (which we shall call the *second representation*) through the Jacobi transformation,

$$\mathcal{K}_{\beta\mu}=\frac{1}{\beta}(4\pi s)^{(1-D)/2}e^{-s(M^2-\overline{\mu}^2)}\Theta_3\left(\frac{2s\overline{\mu}}{\beta},i\frac{4\pi s}{\beta^2}\right). \tag{3.14}$$

Note that for a fermion loop ($\epsilon=2$), the above first and the second Θ_3 representations become the Θ_4 and Θ_2 representations, respectively.

We can extract the thermodynamic quantity $\mathcal{N}_{\beta\mu}$ corresponding to the path integral normalization (2.7) from the kinematical factor $\mathcal{K}_{\beta\mu}$. If we rewrite Eq. (3.12) as

$$\mathcal{K}_{\beta\mu}=e^{-sm^2}(4\pi s)^{-D/2}\Theta_3\left(i\frac{\beta\overline{\mu}}{2\pi},i\frac{\beta^2}{4\pi s}\right)\exp\left[s\sum_{i<j}^{N}k_i\cdot k_jG_{ij}\right]$$
$$=\frac{1}{\beta}(4\pi s)^{(1-D)/2}e^{-s(m^2-\overline{\mu}^2)}\Theta_3\left(\frac{2s\overline{\mu}}{\beta},\frac{4\pi is}{\beta^2}\right)\left\langle\prod_{j=1}^{N}e^{ik_j\cdot x(\sigma_j)}\right\rangle, \tag{3.15}$$

the noncorrelator part can be regarded as an overall normalization to the N-point correlator of zero temperature type (the zeroth components k_j^0 are formally regarded as continuous variables here). Paraphrasing this fact in analogy to Eq. (2.11),

$$\mathcal{K}_{\beta\mu}\equiv\mathcal{N}_{\beta\mu}\left\langle\prod_{j=1}^{N}e^{ik_j\cdot x(\sigma_j)}\right\rangle=\oint_{\beta\mu}\mathcal{D}x\mathcal{D}\psi\exp\left[-\int_0^1\mathcal{L}(\sigma)d\sigma\right]\prod_{j=1}^{N}e^{ikj\cdot x(\sigma_j)}, \tag{3.16}$$

the thermodynamic version of the path integral normalization (for finite β and μ) is found to be

$$\mathcal{N}_{\beta\mu}=\frac{1}{\beta}(4\pi s)^{(1-D)/2}e^{-s(m^2-\overline{\mu}^2)}\Theta_3\left(\frac{2s\overline{\mu}}{\beta},\frac{4\pi is}{\beta^2}\right). \tag{3.17}$$

This is exactly the same normalization as assumed in Ref. 21 (taking a mass term inclusion into account).

B. The vertex structure operator $\mathcal{V}_{\beta\mu}$

In this subsection, we discuss the part of vertex structure ($\mathcal{V}\neq 1$). Because of the diversities of explicit forms of $\mathcal{V}$, there is no concrete formula such as Eq. (3.12). However, we can derive a general property of the pure thermodynamic part $\tilde{\mathcal{V}}_{\beta\mu}$. To explain this, we classify $\mathcal{V}$ into two categories by the criterion whether or not $\mathcal{V}$ contains local world-line variables σ_j.

First, let us start with the first category, the σ-independent $\mathcal{V}$ case. Apparently, $\mathcal{V}=1$ is the case. A nontrivial example of this category is the $\pi^0\to 2\gamma$ decay ($\epsilon=2$, $D=4$) without background field:[24]

$$c\mathcal{V}=-\mathrm{tr}[1]m\lambda e^2\epsilon_{\mu\nu\rho\sigma}\epsilon_1^\mu\epsilon_2^\nu k_1^\rho k_2^\sigma, \tag{3.18}$$

where λ is the pseudo-scalar coupling, m and e the (space–time) fermion mass and the quantum electrodynamics (QED) coupling constant. Another nontrivial example is the effective potential of a fermion loop ($\epsilon=2$, $N=0$) in a constant magnetic field in D dimensions.[21] In this case, $\mathcal{V}$ depends on the integration variable s,

$$c\mathcal{V}=-\tfrac{1}{2}\mathrm{tr}[1]sB\coth(sB), \tag{3.19}$$

and this is the case of the expansion (2.13), if we use

$$\coth(sB)=1+2\sum_{n=1}^{\infty} e^{-2nsB}. \tag{3.20}$$

With the shift $M^2\to M^2+2lB$, this case is essentially described by the ''partial'' amplitude $\mathcal{A}_1$ defined by Eq. (2.14). Now, at finite values of β and μ, we can, in principle, express any thermodynamic vertex structure function $\mathcal{V}_{\beta\mu}$ as

$$\mathcal{V}_{\beta\mu}=\mathcal{V}+\tilde{\mathcal{V}}_{\beta\mu}, \tag{3.21}$$

where $\tilde{\mathcal{V}}_{\beta\mu}$ denotes the purely thermodynamic part. However, in this category, as can be seen from the above examples, we simply have

$$\mathcal{V}_{\beta\mu}=\mathcal{V}, \quad \tilde{\mathcal{V}}_{\beta\mu}=0 \quad (\text{for } \sigma\text{-independent } \mathcal{V}), \tag{3.22}$$

because the $\mathcal{V}$'s of this category do not contain the local world-line variables σ_j, strictly speaking the G_{ij} which are generated by the bosonic field correlation from v_j. Recall that the β dependence only appears through the shift $x^0\to x^0+n\beta\sigma$ in the formula (3.1). The β dependence cannot be created from the quantity which does not contain an x-field correlation.

Second, let us consider the other category, the σ-dependent $\mathcal{V}$ case. In this category, we obtain a nonzero structure function $\tilde{\mathcal{V}}_{\beta\mu}$. We here consider the photon polarization case by way of example. In this case, the $\mathcal{V}$ is given by Eq. (C5) at zero temperature:[16]

$$\mathcal{V}=\epsilon_1\cdot\epsilon_2\frac{1}{s}\ddot{G}_{12}+\epsilon_1\cdot k_2\epsilon_2\cdot k_1(\dot{G}_{12})^2+\epsilon_1\cdot\epsilon_2 k_1\cdot k_2-\epsilon_1\cdot k_2\epsilon_2\cdot k_1, \tag{3.23}$$

where dots on G_{12} means the first and the second derivatives wrt the first argument of G_{12}. The thermodynamic generalization can be done by applying the formulas (3.1) and (3.9). For ease of presentation, we put the computational details in Appendix C, and a comparison with the Feynman diagram technique is also in Appendix B. For finite β, we derive Eq. (C17):

$$\mathcal{V}_\beta=\mathcal{V}-\epsilon_0^1\epsilon_0^2\left(\frac{1}{s}\frac{\partial}{\partial\bar{\omega}}\right)^2-\frac{1}{s}\frac{\partial}{\partial\bar{\omega}}(\epsilon_0^1\epsilon_2\cdot k_1-\epsilon_0^2\epsilon_1\cdot k_2)\dot{G}_{12}, \tag{3.24}$$

and then, shifting $\bar{\omega}\to\Omega$, we acquire the operator part given by Eq. (C19):

$$\tilde{\mathcal{V}}_{\beta\mu}=-\epsilon_0^1\epsilon_0^2\left(\frac{1}{s}\frac{\partial}{\partial\Omega}\right)^2-\frac{1}{s}\frac{\partial}{\partial\Omega}(\epsilon_0^1\epsilon_2\cdot k_1-\epsilon_0^2\epsilon_1\cdot k_2)\dot{G}_{12}. \tag{3.25}$$

Note that the origin of $\partial/\partial\Omega$ is the Wick contractions of the bosonic world-line fields furnished in the v_j parts of photon vertex operators [see Eqs. (C2) and (C10)], and it always happens if a vertex operator comprises a bosonic field in such a way.

We therefore conclude that if $\mathcal{V}$ includes G_{ij} or its derivatives, $\tilde{\mathcal{V}}_{\beta\mu}$ gives rise to a differential polynomial in $\partial/\partial\Omega$, and otherwise $\tilde{\mathcal{V}}_{\beta\mu}=0$. An important result following from this fact is

$$\tilde{\mathcal{V}}_{\beta\mu}\times\mathcal{K}=0 \quad (\text{for all } \mathcal{V}). \tag{3.26}$$

This is a model-independent result, and we shall make use of this relation in order to decouple the pure thermodynamic part $\tilde{\Gamma}_N^{\beta\mu}$ from the total N-point amplitude $\Gamma_N^{\beta\mu}$.

C. The master formulas $\tilde{\Gamma}_N^{\beta\mu}$ and $\tilde{\mathcal{A}}_l^{\beta\mu}$

Gathering the formulas obtained in the above sections, we compose the purely thermodynamic master amplitude $\tilde{\Gamma}_N^{\beta\mu}$, and define the thermodynamic ''partial'' amplitudes $\mathcal{A}_l^{\beta\mu}$. Applying the following formula to the first representation (3.12),

$$\Theta_3(v,\tau)=1+2\sum_{n=1}^{\infty} e^{n^2\tau\pi i}\cos(2n\pi v), \tag{3.27}$$

we separate the pure thermodynamic part $\tilde{\mathcal{K}}_{\beta\mu}$ from $\mathcal{K}_{\beta\mu}$ as

$$\mathcal{K}_{\beta\mu}=\mathcal{K}+\tilde{\mathcal{K}}_{\beta\mu}, \tag{3.28}$$

where

$$\tilde{\mathcal{K}}_{\beta\mu}=2(4\pi s)^{-D/2}e^{-sM^2}\sum_{n=1}^{\infty} e^{-n^2\beta^2/4s}\cosh(n\beta\overline{\mu}), \tag{3.29}$$

or, for the second representation (3.14),

$$\tilde{\mathcal{K}}_{\beta\mu}=\frac{2}{\beta}(4\pi s)^{(1-D)/2}e^{-s(M^2-\overline{\mu}^2)}\sum_{n=1}^{\infty} e^{-s(2n\pi/\beta)^2}\cos\left(\frac{4n\pi s\overline{\mu}}{\beta}\right). \tag{3.30}$$

For a given $\mathcal{V}_{\beta\mu}$, the thermodynamic master amplitude $\Gamma_N^{\beta\mu}$ is calculated as

$$\Gamma_N^{\beta\mu}\overset{\text{def.}}{=}c\int_0^1 d\sigma_1\int_0^1 d\sigma_2\cdots\int_0^1 d\sigma_N\int_0^{\infty} ds\, s^{N-1}\mathcal{V}_{\beta\mu}\times\mathcal{K}_{\beta\mu}. \tag{3.31}$$

Using the decompositions (3.21) and (3.28) with the general formula (3.26), we find

$$\Gamma_N^{\beta\mu}=\Gamma_N+\tilde{\Gamma}_N^{\beta\mu}, \tag{3.32}$$

where

$$\tilde{\Gamma}_N^{\beta\mu}\overset{\text{def.}}{=}c\int_0^1 d\sigma_1\int_0^1 d\sigma_2\cdots\int_0^1 d\sigma_N\int_0^{\infty} ds\, s^{N-1}\mathcal{V}_{\beta\mu}\times\tilde{\mathcal{K}}_{\beta\mu}. \tag{3.33}$$

Therefore we have only to separate the pure thermodynamic part of $\mathcal{K}_{\beta\mu}$ in order to obtain the purely thermodynamic part $\tilde{\Gamma}_N^{\beta\mu}$: no separation in the $\mathcal{V}_{\beta\mu}$ part at all. [Note the difference between Eqs. (3.31) and (3.33).]

As can be inferred from the examples in Sec. III B, a general expansion form of $\mathcal{V}_{\beta\mu}$ is

$$\mathcal{V}_{\beta\mu}=\sum_{l,n\in Z} a_{ln}s^{l-N}\frac{\partial^n}{\partial\Omega^n}\exp[-sb_l]. \tag{3.34}$$

where the coefficients a_{ln} and b_l may not depend on s, but on $\sigma_j(j=1,2,...,N)$. In analogy to Eq. (2.14), the relevant ''partial'' amplitudes for Eqs. (3.31) and (3.33) are defined as

$$\mathcal{A}_l^{\beta\mu}\overset{\text{def.}}{=}\int_0^{\infty} ds\, s^{l-1}\mathcal{K}_{\beta\mu}|_{m^2\to m^2+b_l}, \tag{3.35}$$

$$\tilde{\mathcal{A}}_l^{\beta\mu} \overset{\text{def.}}{=} \int_0^\infty ds\, s^{l-1} \tilde{\mathcal{K}}_{\beta\mu}|_{m^2 \to m^2 + b_l}, \tag{3.36}$$

and of course the following relation holds:

$$\mathcal{A}_l^{\beta\mu} = \mathcal{A}_l + \tilde{\mathcal{A}}_l^{\beta\mu}. \tag{3.37}$$

In the following sections, we present various integral representations for the pure thermodynamic parts $\tilde{\mathcal{A}}_l^{\beta\mu}$ of the N-point ''partial'' amplitudes without specifying any values of N, D, and ϵ. These parts are the essential quantities to analyze the zero temperature limits with revealing the nonanalyticity on μ.

IV. THE INTEGRAL FORMULAS FROM THE FIRST REPRESENTATION

In this section, we derive various integral formulas for $\tilde{\mathcal{A}}_l^{\beta\mu}$ based on the first representation (3.12). This representation is examined in the special case $l=1$ (with $N=0$ and $\epsilon=2$), and actually $(4\pi)^{D/2}\tilde{\mathcal{A}}_1^{\beta\mu}$ is the function $\mathcal{O}_\beta$ analyzed in Ref. 21:

$$\mathcal{O}_\beta(m) = 4\sum_{n=1}^{\infty} (-1)^n \cosh(n\beta\mu)\left(\frac{n\beta}{2m}\right)^{1-D/2} K_{D/2-1}(n\beta m). \tag{4.1}$$

We want to generalize this function to more generic l and ϵ cases, and it is convenient to mimic the computational technique of Ref. 21, introducing the parallel notation

$$\mathcal{O}_\beta^{(k)}(M) \overset{\text{def.}}{=} (4\pi)^{D/2}\tilde{\mathcal{A}}_l^{\beta\mu}; \quad k \equiv 2l+1-D. \tag{4.2}$$

Hereafter, for simplicity we set

$$b_l = 0, \tag{4.3}$$

and, for later convenience, we also define

$$d \equiv 3-k = D+2-2l. \tag{4.4}$$

From Eqs. (3.29) and (3.36), the pure thermodynamic part $\tilde{\mathcal{A}}_l^{\beta\mu}$ is now given by

$$\mathcal{O}_\beta^{(k)}(M) = 2(4\pi)^{D/2}\int_0^\infty ds\, s^{l-1}(4\pi s)^{-D/2} e^{-sM^2}\sum_{n=1}^{\infty} e^{-n^2\beta^2/4s}\cosh(n\beta\overline{\mu}). \tag{4.5}$$

Performing the s integration, we obtain

$$\mathcal{O}_\beta^{(k)}(M) = 4\sum_{n=1}^{\infty} \cosh(n\beta\overline{\mu})\left(\frac{n\beta}{2M}\right)^{1-d/2} K_{d/2-1}(n\beta M), \tag{4.6}$$

where $K_\nu(z)$ is the modified Bessel function of second kind. This is a generalized version (for arbitrary ϵ and l) of the above function $\mathcal{O}_\beta$. The aim is to obtain integral representations with performing the summation in Eq. (4.6) (for generic k or d). To this end, we first apply the following formula to Eq. (4.6):

$$K_\nu(z) = \frac{\sqrt{\pi}(z/2)^\nu}{\Gamma(\nu+\frac{1}{2})}\int_1^\infty e^{-zt}(t^2-1)^{\nu-1/2}\,dt; \quad \mathrm{Re}\,\nu > -\frac{1}{2}, \mathrm{Re}\,z > 0, \tag{4.7}$$

and note that the $k<2(d>1)$ and $k\geqslant 2(d\leqslant 1)$ cases involve different calculations. Here we put a few remarks. For the convergence of the summation over n, we have to assume

$$\mu<M \tag{4.8}$$

in order to satisfy the condition

$$|e^{-\beta(Mt\pm\overline{\mu})}|=e^{-\beta(Mt\pm\mu)}<1;\quad t>1. \tag{4.9}$$

The $k=1,0,-1(d=2,3,4)$ cases are calculated in Ref. 21, and the $k=3(d=0)$ case corresponds to Ref. 24, although they did not discuss this representation. (Note that their argument belongs to our second representation.)

(i) In the first case, $k<2(d>1)$, the condition on ν in the formula (4.7) is satisfied as it is; i.e., $\nu=d/2-1>-\frac{1}{2}$, and the calculation is almost parallel to Ref. 21. We then just write down the result

$$\mathcal{O}_\beta^{(k)}(M)=\frac{-2\sqrt{\pi}}{\Gamma((d-1)/2)}\left[\int_0^\infty \frac{(u^2+2Mu)^{(d-3)/2}}{1-e^{\beta(u+M+\overline{\mu})}}\,du+(\overline{\mu}\to-\overline{\mu})\right], \tag{4.10}$$

where we note that the minus sign of the denominator differs from the previous formula [Eq. (3.13) in Ref. 21]. For later convenience, let us derive another formula from this result. Performing the change of variable $u=M(\sqrt{p^2+1}-1)$, and applying the formula $\Gamma(z)\Gamma(1-z)=\pi/\sin \pi z$ with $z=(d-1)/2$, we derive

$$\mathcal{O}_\beta^{(k)}(M)=\frac{2}{\sqrt{\pi}}\,\Gamma\left(\frac{k}{2}\right)M^{1-k}\sin\left(\frac{2-k}{2}\,\pi\right)\int_0^\infty \frac{p^{1-k}(p^2+1)^{-1/2}}{e^{\beta X_+(p)}-1}\,dp+(\overline{\mu}\to-\overline{\mu}), \tag{4.11}$$

where we have introduced the compact notation

$$X_\pm(p)=M\sqrt{p^2+1}\pm\overline{\mu}. \tag{4.12}$$

(ii) In the second case, $2\leqslant k(d\leqslant 1)$, the calculation is similar to the case (i), excepting the point that we apply the formula (4.7) for $\nu=1-d/2$ instead of $\nu=d/2-1$ owing to the relation $K_\nu(z)=K_{-\nu}(z)$. Then the summation over n in Eq. (4.6) leads to the Lerch transcendental function:

$$\begin{aligned}\mathcal{O}_\beta^{(k)}(M)&=\alpha\int_1^\infty dt\,(t^2-1)^{(1-d)/2}e^{-\beta(Mt+\overline{\mu})}\Phi(e^{-\beta(Mt+\overline{\mu})},d-2,1)+(\overline{\mu}\to-\overline{\mu})\\&=\frac{\alpha\Gamma(3-d)}{2\pi i}\int_1^\infty dt\,(t^2-1)^{(1-d)/2}\int_\infty^{(0+)}\frac{(-z)^{d-3}dz}{1-e^{z+\beta(Mt+\mu)}}+(\overline{\mu}\to-\overline{\mu}),\end{aligned} \tag{4.13}$$

where just for conciseness we have defined the coefficient

$$\alpha=\frac{\sqrt{4\pi}}{\Gamma((3-d)/2)}\left(\frac{\beta}{2}\right)^{2-d}=\frac{\sqrt{4\pi}}{\Gamma(k/2)}\left(\frac{\beta}{2}\right)^{k-1}. \tag{4.14}$$

The z-integrand (4.13) possesses poles at $z=0$ and $z=-\beta Mt\pm\beta\overline{\mu}+2n\pi i$ $(n\in Z)$. Since $-\beta(Mt\pm\mu)$ is a negative value, there is no pole in the positive region on the real axis other than $z=0$ as long as $\beta\overline{\omega}+2\pi/\epsilon$ is not an integer. With the change of variable $t=\sqrt{p^2+1}$, and a replacement of one derivative $\partial/\partial z$ by $\partial/\partial p$, we have

$$\mathcal{O}(M)=\alpha\,\frac{(-1)^{-k}\Gamma(k)}{M\beta(k-1)!}\,\frac{\partial^{k-2}}{\partial z^{k-2}}\int_0^\infty p^{k-2}\frac{\partial}{\partial p}\left(\frac{1}{1-e^{z+\beta X_+}}\right)dp\big|_{z=0}+(\overline{\mu}\to-\overline{\mu}). \tag{4.15}$$

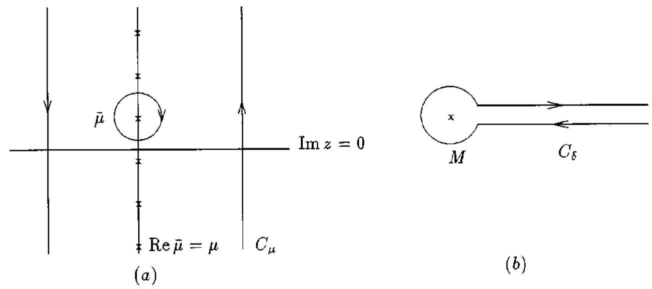

FIG. 1. The contours C_μ and C_δ. (a) The C_μ impounds an infinite number of poles at $z=\overline{\mu}+2n\pi i$, where n denotes nonzero integers. (b) Coming from $z=\infty+i\epsilon$ and going to $z=\infty-i\epsilon$, the C_δ impounds the pole at $z=M$.

Because of $k\geqslant 2$, the surface terms from a partial integral vanish in Eq. (4.15), and finally we find

$$\mathcal{O}_\beta^{(k)}(M)=2\Gamma\left(\frac{k+1}{2}\right)\frac{(-1)^{1-k}\beta^{k-2}(k-2)}{M(k-1)!}\frac{\partial^{k-2}}{\partial z^{k-2}}\int_0^\infty \frac{p^{k-3}}{1-e^{z+\beta X_+}}\,dp\Big|_{z=0}+(\overline{\mu}\to-\overline{\mu}). \tag{4.16}$$

More explicitly, we present the results for $k=2,3,4$ as follows:

$$\mathcal{O}_\beta^{(2)}(M)=-\frac{\sqrt{\pi}}{M}\left[\frac{1}{1-e^{\beta(M+\overline{\mu})}}+(\overline{\mu}\to-\overline{\mu})\right], \tag{4.17}$$

$$\mathcal{O}_\beta^{(3)}(M)=\frac{\beta}{M}\int_0^\infty \frac{e^{\beta X_+}}{(1-e^{\beta X_+})^2}\,dp+(\overline{\mu}\to-\overline{\mu}), \tag{4.18}$$

$$\mathcal{O}_\beta^{(4)}(M)=-\frac{\sqrt{\pi}}{2M^3}\left[\frac{1}{1-e^{\beta(M+\overline{\mu})}}-\frac{\beta M e^{\beta(M+\overline{\mu})}}{(1-e^{\beta(M+\overline{\mu})})^2}+(\overline{\mu}\to-\overline{\mu})\right]. \tag{4.19}$$

For even values of k, one may directly perform the summation (4.6) without using the integral representation (4.7), e.g., using $K_{1/2}(z)=\sqrt{\pi/2z}e^{-z}$ and $K_{3/2}(z)=\sqrt{\pi/2z}(1+z^{-1})e^{-z}$ for $k=2$ and 4. We will see in the next section that the results (4.11) and (4.17)–(4.19) can be reproduced from the second representation as well.

V. THE INTEGRAL FORMULAS FROM THE SECOND REPRESENTATION

In this section, based on the second representation (3.14) case, we derive some more formulas on $\mathcal{O}_\beta^{(k)}(M)$, with rederiving the results of the previous section. From Eqs. (3.30), (3.36), and (4.2), we have the following form of the pure thermodynamic part to start with:

$$\mathcal{O}_\beta^{(k)}(M)=\frac{(4\pi)^{1/2}}{\beta}\int_0^\infty ds\, s^{(k-2)/2}e^{-s(M^2-\overline{\mu}^2)}\sum_{n\in Z,\neq 0}e^{-s(2n\pi/\beta)^2}\cos(4n\pi s\overline{\mu}/\beta). \tag{5.1}$$

The summation can be converted to the integrals on the contour C_μ [see Fig. 1(a)]:

$$\mathcal{O}_\beta^{(k)}(M)=\frac{1}{2}(4\pi)^{1/2}\int_0^\infty ds\, s^{(k-2)/2}e^{-sM^2}\frac{1}{2\pi i}\int_{C_\mu}\frac{e^{sz^2}}{e^{\beta(z-\mu)}-1}\,dz+(\overline{\mu}\to-\overline{\mu}). \tag{5.2}$$

After performing the s integration, one may deform the contour C_μ into another one C_δ [Fig. 1(b)] in the same way as Ref. 24, thus obtaining

$$\mathcal{O}_\beta^{(k)}(M)=\sqrt{\pi}\Gamma\left(\frac{k}{2}\right)\frac{1}{2\pi i}\int_\infty^{(M+)}\frac{(M^2-z^2)^{-k/2}}{e^{\beta(z-\bar{\mu})}-1}\,dz+(\bar{\mu}\to-\bar{\mu}). \tag{5.3}$$

Parametrizing the circular part of C_δ (centered at M) by $z=M(1-\delta e^{i\phi})$, and using $p^2=z^2-1$ for the remaining parts of the contour, we arrive at

$$\mathcal{O}_\beta^{(k)}(M)=\frac{2}{\sqrt{\pi}}\Gamma\left(\frac{k}{2}\right)M^{1-k}\sin\left(\frac{2-k}{2}\pi\right)\times\left[\int_{\sqrt{2\delta}}^\infty\frac{p^{1-k}(p^2+1)^{-1/2}}{e^{\beta X_+}-1}\,dp+\frac{[1/(2-k)](2\delta)^{1-k/2}}{e^{\beta(M-\bar{\mu})}-1}+(\bar{\mu}\to-\bar{\mu})\right]. \tag{5.4}$$

Substituting $k=3$ and $\epsilon=2$, Eq. (5.4) reproduces the result (without background field) of Ref. 24.

Here are a few remarks on the computational difference between Ref. 24 and ours. We have extracted the pure thermodynamic part (5.1) from the beginning, and this fact is expressed by the circle at $\bar{\mu}$ in C_μ. On the other hand, in the method of Ref. 24, one needs an algebra to separate the nonthermodynamic part by using

$$\frac{-1}{e^{\beta(z-\mu)}-1}=1+\frac{1}{e^{-\beta(z-\mu)}-1}. \tag{5.5}$$

The first term on the rhs of Eq. (5.5) corresponds to the nonthermodynamic part, and the second term to the following expression instead of Eq. (5.2):

$$\mathcal{O}_{\beta\mu}^{(k)}(M)=(4\pi)^{1/2}\int_0^\infty ds\,s^{(k-2)/2}e^{-sM^2}\frac{1}{2\pi i}\times\left\{\int_{C_+}\frac{e^{s(z-i\bar{\omega})^2}}{e^{\beta(z-\bar{\mu}-i\bar{\omega})}-1}+\int_{C_-}\frac{e^{s(z-i\bar{\omega})^2}}{e^{-\beta(z-\bar{\mu}-i\bar{\omega})}-1}\right\}dz, \tag{5.6}$$

where the contours $C_\pm$ run from $\mu\pm o-i\infty$ to $\mu\pm o+i\infty$ for a small value of o. Although one can of course obtain the same result (5.4) from Eq. (5.6), it is not obvious at first glance that the C_- integral term corresponds to the $\bar{\mu}\to-\bar{\mu}$ term of Eq. (5.3).

Now, further results depend on the cases (i) and (ii). In the case (i), $k<2$, the second term in the square brackets on the rhs of Eq. (5.4) is proportional to $\delta^{1-k/2}$, and vanishes as $\delta\to 0$. Therefore Eq. (5.4) reproduces the first representation result (4.11).

In the case (ii), $k\geqslant 2$, the $\delta^{1-k/2}$ term diverges as $\delta\to 0$. We expect that it can be canceled with the lower surface term from the first integral in the square brackets on the rhs of Eq. (5.4). This can be seen by a partial integral with applying the formula

$$\frac{d}{dp}\left(\frac{\sqrt{p^2+1}}{p}\right)=\frac{1}{p^2\sqrt{p^2+1}} \tag{5.7}$$

to the p integration in Eq. (5.4) as follows:

$$\int_{\sqrt{2\delta}}^\infty\frac{p^{1-k}(p^2+1)^{-1/2}}{e^{\beta X_+}-1}\,dp=\frac{[1/(k-2)](2\delta)^{1-k/2}}{e^{\beta(M-\bar{\mu})}-1}+\frac{1}{2-k}\times\int_0^\infty p^{3-k}\left\{\frac{(p^2+1)^{-3/2}}{e^{\beta X_+}-1}+\frac{M\beta(p^2+1)^{-1}e^{\beta X_+}}{(e^{\beta X_+}-1)^2}\right\}dp. \tag{5.8}$$

The first term on the rhs of Eq. (5.8) cancels the divergence as expected, and we derive

$$\mathcal{O}_\beta^{(k)}(M)=\sqrt{4\pi}\Gamma\left(\frac{k}{2}\right)M^{1-k}\frac{\sin([(2-k)/2]\pi)}{(2-k)\pi}\times\left[\int_0^\infty p^{3-k}\left\{\frac{(p^2+1)^{-3/2}}{e^{\beta X_+}-1}+\frac{M\beta(p^2+1)^{-1}e^{\beta X_+}}{(e^{\beta X_+}-1)^2}\right\}dp+(\bar{\mu}\to-\bar{\mu})\right]. \tag{5.9}$$

Putting $t^2=p^2+1$ in Eq. (5.9), we finally obtain the following concise expression:

$$\mathcal{O}_\beta^{(k)}(M)=\sqrt{4\pi}\Gamma\left(\frac{k}{2}\right)M^{1-k}\frac{\sin([(2-k)/2]\pi)}{(2-k)\pi}\int_1^\infty\sqrt{t^2-1}^{2-k}\frac{\partial}{\partial t}\left[\frac{t^{-1}}{1-e^{\beta(Mt+\bar{\mu})}}\right]dt+(\bar{\mu}\to-\bar{\mu}), \tag{5.10}$$

which is an alternative representation of Eq. (4.16). As a result, we have derived two expressions in each case: Eqs. (4.10) and (4.11) in the case (i), and Eqs. (4.16) and (5.10) in the case (ii). In Eq. (4.16) we have to perform $k-2$ derivatives (after one integration), while just one integration in Eq. (5.10), whose integrand thus contains a common Boltzmann factor for all $k(\geqslant 2)$.

Let us check the consistency of Eq. (5.10) with the previous result (4.16) for $k=2,3,4$. The $k=2$ case (4.17) is immediate from the representation (5.10), however, let us handle these three cases simultaneously. Using $(p^2+1)^{-1}=1-p^2(p^2+1)^{-1}$, we first divide the second term in the curly brackets in Eq. (5.9), and then perform a partial integral on the rhs in the following quantity:

$$-\int_0^\infty p^{3-k}\frac{M\beta p^2(p^2+1)^{-1}e^{\beta X_+}}{(e^{\beta X_+}-1)^2}\,dp=\int_0^\infty p^{3-k}\frac{p}{\sqrt{p^2+1}}\frac{\partial}{\partial p}\left(\frac{1}{e^{\beta X_+}-1}\right)dp. \tag{5.11}$$

Changing the integration variable by $t^2=p^2+1$, we arrive at

$$\mathcal{O}_\beta^{(k)}(M)=\sqrt{4\pi}\Gamma\left(\frac{k}{2}\right)M^{1-k}\frac{\sin([(2-k)/2]\pi)}{(2-k)\pi}[I_k+(\bar{\mu}\to-\bar{\mu})], \tag{5.12}$$

where

$$I_k=\int_1^\infty\sqrt{t^2-1}^{2-k}t\left[\frac{k-3}{t}N(t)-N'(t)\right]dt \tag{5.13}$$

and $N'(t)\equiv\partial_t N(t)$ means the derivative of the function

$$N(t)=\frac{1}{e^{\beta(Mt-\bar{\mu})}-1}. \tag{5.14}$$

For the $k=2$ and 3 cases, this expression is sufficient to see the consistency in each. However, for the $k=4$ case, notice that we have to extract a singularity, which cancels a zero from the sine function in Eq. (5.10), and we hence perform a partial integral once more:

$$I_k=-\int_1^\infty\frac{1}{4-k}\sqrt{t^2-1}^{4-k}\frac{\partial}{\partial t}\left[(k-3)\frac{N(t)}{t}-N'(t)\right]dt,\quad 2\leqslant k<4, \tag{5.15}$$

where the surface terms can be dropped only when $k<4$ [also in Eq. (5.11)], and this is the reason why this formula is valid for $2\leqslant k<4(-1<d\leqslant 1)$. Substituting $k=2,3,4-\epsilon$ (with $\epsilon\to 0$), we verify that these expressions for I_k reproduce Eqs. (4.17)–(4.19). In this sense, Eq. (5.10) is equivalent to Eq. (4.16).

For further values of k, one should repeat the similar calculation for each interval between zero points of the sine function. For example, for $k=6$ and 8, we obtain

$$\mathcal{O}_\beta^{(6)}(M)=\frac{\pi}{16M^5}\,[3N(1)-3N'(1)+N''(1)], \tag{5.16}$$

$$\mathcal{O}_\beta^{(8)}(M)=\frac{\sqrt{\pi}}{8M^7}\,[15N(1)-15N'(1)+6N''(1)-N'''(1)]. \tag{5.17}$$

These pure thermodynamic ''partial'' amplitudes exactly correspond to the $N=4$ and 5 pure thermodynamic amplitudes in $D=3$ when $\mathcal{V}_{\beta\mu}=\mathcal{V}$ (the first category). In $D=4$, odd k integers are the similar cases. For the second category, for example, the N-photon amplitude in $D=4$, we need to combine the quantities from $k=-1$ to $2N-5$. These cases cannot get rid of nonintegrated quantities such as Eq. (4.18). After all, Eqs. (4.16) and (5.10) describe the general amplitude formulas which contain all Feynman diagrams.

VI. THE $\beta\to\infty$ LIMIT

In the above arguments, we have assumed $\mu<M$, and all $\beta\to\infty$ limits vanish because of it:

$$\mathcal{O}_\beta^{(k)}\xrightarrow{\beta\to\infty}0. \tag{6.1}$$

To obtain a nontrivial (nonzero) limit, we should remove this condition after all. In this sense, the μ dependence of the master amplitudes is nonanalytic. To see this, we need to transform the function $\mathcal{O}_\beta^{(k)}$ in a form indicating a Bose (or a Fermi) distribution, and we already derived this kind of representations in Secs. IV and V.

Let us begin with the case (i) $k<2$, in particular, the case of $k=0$ (which is also an odd dimensional case $D=2l+1$ by the way). From Eq. (4.10) with changing the variable $E=u+M$, we have

$$\mathcal{O}_\beta^{(0)}(M)=-2\sqrt{\pi}\int_M^\infty\frac{dE}{1\pm e^{\beta(E-\mu')}}+(\mu'\to-\mu'), \tag{6.2}$$

where the plus/minus signs correspond to the Fermi/Bose statistics, and we put

$$\mu'=\mu-i\overline{\omega}. \tag{6.3}$$

Equation (6.2) can be interpreted an effective action or total energy density with the chemical potential μ' and the mass $M(<\mu',E)$. Now, we understand in Eq. (6.2) that the $\mathcal{O}_\beta^{(0)}$ becomes zero as $\beta\to\infty$ if $\mu'<E$, while the $\mathcal{O}_\beta^{(0)}$ takes a nonzero value if $E<\mu'$. The similar arguments apply to the case of generic k value in the following way. Since we observe

$$e^{\beta(M-\overline{\mu}+u)}=e^{\beta(u+M-\mu)}e^{i\beta(\overline{\omega}+2\pi/\epsilon\beta)}\xrightarrow{\beta\to\infty}0\quad\text{for }u<\mu-M, \tag{6.4}$$

we have the finite upper boundary on the integral (4.10) at $u=\mu-M$, thus obtaining

$$\begin{aligned}\mathcal{O}_\infty^{(k)}(M)\equiv\lim_{\beta\to\infty}\mathcal{O}_\beta^{(k)}(M)&=\frac{-2\sqrt{\pi}}{\Gamma((2-k)/2)}\int_0^{\mu-M}(u^2+2Mu)^{-k/2}du\,\theta(\mu-M)\\&=\frac{-2\sqrt{\pi}}{\Gamma((4-k)/2)}(2M)^{-k/2}(\mu-M)^{(2-k)/2}F\left(\frac{k}{2},\frac{2-k}{2},\frac{4-k}{2};\frac{M-\mu}{2M}\right)\\&\quad\times\theta(\mu-M).\end{aligned} \tag{6.5}$$

The explicit results for $k=-1,0,1$ are

$$\mathcal{O}_\infty^{(1)}(M) = -2 \operatorname{arccosh}(\mu/M)\,\theta(\mu - M), \tag{6.6}$$

$$\mathcal{O}_\infty^{(0)}(M) = -2\sqrt{\pi}(\mu - M)\,\theta(\mu - M), \tag{6.7}$$

$$\mathcal{O}_\infty^{(-1)}(M) = [-2\mu\sqrt{\mu^2 - M^2} + 2M^2 \operatorname{arccosh}(\mu/M)]\,\theta(\mu - M). \tag{6.8}$$

In one of the $k=0$ cases ($D=3$, $N=0$, $l=1$, $\epsilon=2$),[21] Eq. (6.7) coincides with an exact result in Ref. 27.

The case (ii) $k \geqslant 2$ can also be estimated in the same way. Applying the similar treatment as above to the Boltzmann factor in Eq. (5.10), we then obtain the nonzero limit given by

$$\mathcal{O}_\infty^{(k)}(M) = -\sqrt{4\pi}\,\Gamma\left(\frac{k}{2}\right) M^{1-k} \frac{\sin([(2-k)/2]\pi)}{(2-k)\pi} \int_1^{\mu/M} (t^2 - 1)^{(2-k)/2} \frac{dt}{t^2}\,\theta(\mu - M). \tag{6.9}$$

Performing the t integration, some of the explicit results (the $k=2,3,4$ cases) can be shown as follows:

$$\mathcal{O}_\infty^{(2)}(M) = \frac{\sqrt{\pi}}{M}\left(\frac{M}{\mu} - 1\right)\theta(\mu - M), \tag{6.10}$$

$$\mathcal{O}_\infty^{(3)}(M) = -\frac{1}{\mu M}\sqrt{\left(\frac{\mu}{M}\right)^2 - 1}\,\theta(\mu - M), \tag{6.11}$$

$$\mathcal{O}_\infty^{(4)}(M) = -\frac{\sqrt{\pi}}{2M^3}\,\theta(\mu - M). \tag{6.12}$$

The calculations are rather straightforward for further k values, and the general formula (6.9) suffices. The ϵ dependence is gone away from the $\mathcal{O}_\infty^{(k)}$. This is natural because there is no difference in the kinematical factors (hence in ''partial'' amplitudes) between boson and fermion loops at zero temperature.

VII. CONCLUSIONS

In this paper, we studied the thermodynamic generalization of the one-loop amplitudes which can be cast into the BK master formula (2.9) at zero temperature (with zero chemical potential). We followed the two-step procedure: first, calculating the path integral S^1 summation (3.1) to introduce the temperature, and then performing the shift manipulation (1.3) to insert the chemical potential in a loop. This procedure has been applied parts by parts to the kinematical factor $\mathcal{K}$, the normalization factor $\mathcal{N}$, and the vertex structure function (reduced kinematical factor) $\mathcal{V}$, and we have derived the general formulas for these parts. From Eqs. (3.31), (3.34), and (3.35), the thermodynamic N-point amplitude of general form is thus summarized as

$$\Gamma_N^{\beta\mu} = c \sum_{l,n \in Z} a_{ln} \frac{\partial^n}{\partial \Omega^n} \int_0^1 d\sigma_1 \int_0^1 d\sigma_2 \cdots \int_0^1 d\sigma_N\, \mathcal{A}_l^{\beta\mu}. \tag{7.1}$$

One can check the validity of this master formula in various cases; the free effective potentials and the photon polarization in Appendix B, the effective potential in a constant magnetic field in Ref. 21, and the $\pi^0 \to 2\gamma$ decay in Ref. 24, etc.

The detail analyses on the building blocks $\mathcal{V}_{\beta\mu}$ and $\mathcal{K}_{\beta\mu}$ have given us useful information. We have realized that the total thermodynamic kinematical factor $\mathcal{K}_{\beta\mu}$ behaves as the thermodynamically generalized normalization to the zero-temperature-type correlator shown in Eq. (3.17). This is certainly a useful result and makes calculations for large N much simpler than ever; namely, we have only to attach the new normalization $\mathcal{N}_{\beta\mu}$ to the N-point scalar correlator (with switching

$k_j^0 \to \omega_{k_j}$). Another interesting point is that the pure thermodynamic part of a vertex structure function can be expressed in terms of either vanishing or Ω-differential operators, and this fact makes it possible to decouple the master formula (3.31) into $\Gamma_N^{\beta\mu} = \Gamma_N + \tilde{\Gamma}_N^{\beta\mu}$ in a nontrivial way [cf. Eqs. (3.31) and (3.33)]. It is worth noticing that we do not decouple the vertex structure function but the kinematical factor only. From Eqs. (3.33), (3.34), and (3.36), we then conclude that the pure thermodynamic master amplitude is simply given by

$$\tilde{\Gamma}_N^{\beta\mu} = c \sum_{l,n\in Z} a_{ln} \frac{\partial^n}{\partial\Omega^n} \int_0^1 d\sigma_1 \int_0^1 d\sigma_2 \cdots \int_0^1 d\sigma_N \, \tilde{\mathcal{A}}_l^{\beta\mu}. \tag{7.2}$$

Apart from Γ_N, the pure thermodynamic part is renormalization free, and hence Eq. (7.2) is the final form to apply our integral formulas derived in Secs. IV–VI. More explicitly, we have [from Eqs. (3.13) and (4.2)]

$$\tilde{\Gamma}_N^{\beta\mu} = c(4\pi)^{-D/2} \sum_{l,n\in Z} a_{ln}(-i)^n \frac{\partial^n}{\partial\bar{\mu}^n} \int_0^1 d\sigma_1 \int_0^1 d\sigma_2 \cdots \int_0^1 d\sigma_N \, \mathcal{O}_\beta^{(2l+1-D)}(M)\big|_{m^2\to m^2+b_l}, \tag{7.3}$$

and, in particular, for the $\beta\to\infty$ limit with $\mu\neq 0$

$$\lim_{\beta\to\infty} \tilde{\Gamma}_N^{\beta\mu} = c(4\pi)^{-D/2} \sum_{l\in Z} a_{l0} \int_0^1 d\sigma_1 \int_0^1 d\sigma_2 \cdots \int_0^1 d\sigma_N \, \mathcal{O}_\infty^{(2l+1-D)}(M)\big|_{m^2\to m^2+b_l}. \tag{7.4}$$

The thermodynamic master amplitudes (7.3) and (7.4) are provided with Eqs. (4.16), (5.10), and (6.9), and several explicit ''partial amplitudes'' $\mathcal{O}_\beta^{(k)}$ are also given up to $k=8$.

In the master formulas (7.2) and (7.3), the ''partial'' amplitudes $\tilde{\mathcal{A}}_l^{\beta\mu}$ or $\mathcal{O}_\beta^{(k)}$ (*s* integrals of the pure thermodynamic kinematical factor) are the fundamental computational blocks in our formalism, and in Secs. IV and V, we focused on some mathematical aspects and techniques how to calculate these integrals. We derived various representations and formulas on these integrals for arbitrary values of *N, D*, and ϵ. It is obvious that a variety of equivalent formulas makes it easy to find some relation and consistency with the results obtained by different methods. These should generally be related by analytic continuation, and a different analytic expression is certainly useful by definition; i.e., another formula can cover the region which cannot be reached in an original representation, and it also overcomes some defect of an inconvenient representation. For example, in Ref. 21, a dual rotation is used to obtain an electric gap equation from a magnetic one in a four-fermion model. We expect such a kind of utility when our formulas are applied in more explicit stages.

Although we could have possibly simplified our results furthermore through a certain technique,[22] our formulas were sufficiently convenient to extract the nonzero values of zero temperature limit with μ kept finite. For this purpose, it is necessary to have the integral representation, such as Eqs. (4.10) and (5.10), which clearly indicates a nonanalytic cut in its integrand at $\beta=\infty$. We also had to go beyond the condition $\mu<M$ in these representations; however, this might be justified by analytic continuation, and at least we know that the $k=0$ case coincides with the exact result.

We have examined the model-independent structure of the thermodynamic BK master formula with consulting several simple examples. The model dependence appears in the vertex structure functions, and hence one has to evaluate the vertex structure in the first place for explicit calculations in each model. This task is case by case and will become more lengthy as *N* increases for the cases involving more bosonic *x* fields in the vertex operator v_j parts such as photon, gluon, and pseudo-scalar particle. However, our systematic prescription is certainly promising to obtain the (pure) thermodynamic *N*-point amplitudes in a straightforward way as long as the $\mathcal{V}_{\beta\mu}$ belongs to the general form (3.34). Finally, we should not forget the advantage that the world-line formula encapsulates all necessary Feynman diagrams in a single integrand.

APPENDIX A: INSERTION OF CHEMICAL POTENTIAL

In this appendix, we give a brief explanation of the shift procedure (3.9). First consider the vacuum case $\overline{\omega}=0$. In this case, $M^2=m^2$ and

$$-\mathrm{Tr}\ln(\partial^2+m^2)=\frac{1}{\beta}\sum_n \int \frac{d^Dp}{(2\pi)^{D-1}}\int_0^\infty \frac{ds}{s}\, e^{-s(p^2+m^2)}. \tag{A1}$$

We usually perform the insertion of chemical potential in terms of the shift

$$p^2=p_0^2+\vec{p}^{\,2}\rightarrow(\omega_n+i\mu)^2+\vec{p}^{\,2} \tag{A2}$$

with the internal Matsubara frequencies

$$\omega_n=\frac{2\pi}{\beta}\left(n+\frac{1}{\epsilon}\right), \tag{A3}$$

and we have

$$\sum_n e^{-s(\omega_n+i\mu)^2}=e^{s\overline{\mu}_0^2}\Theta_3\left(\frac{2s\overline{\mu}_0}{\beta},is\frac{4\pi}{\beta^2}\right), \tag{A4}$$

where we have defined

$$\overline{\mu}_0=\mu-\frac{2\pi i}{\epsilon\beta}. \tag{A5}$$

Thus, we prove Eq. (3.14) for $N=0$:

$$\text{Eq. (A1)}=\frac{1}{\beta}\int_0^\infty\frac{ds}{s}\,(4\pi s)^{(1-D)/2}e^{s(\overline{\mu}_0^2-m^2)}\Theta_3\left(\frac{2s\overline{\mu}_0}{\beta},is\frac{4\pi}{\beta^2}\right). \tag{A6}$$

For further nonzero values of N, the proofs are straightforward, and we shall not explain the details anymore. For example, one can find the $N=2$ case in Appendix B.

Instead, we add a supplemental interpretation. Applying the transformation

$$\frac{\sqrt{4\pi s}}{\beta}\,e^{s\overline{\mu}_0^2}\Theta_3\left(\frac{2s\overline{\mu}_0}{\beta},is\frac{4\pi}{\beta^2}\right)=\Theta_3\left(\frac{i\beta\overline{\mu}_0}{2\pi},i\frac{\beta^2}{4\pi s}\right), \tag{A7}$$

we rewrite Eq. (A6) as

$$\text{Eq. (A6)}=\mathcal{A}_0^{\beta\mu}=\int_0^\infty\frac{ds}{s}\,(4\pi s)^{-D/2}e^{-sm^2}\Theta_3\left(i\frac{\beta\overline{\mu}_0}{2\pi},i\frac{\beta^2}{4\pi s}\right). \tag{A8}$$

Here $\overline{\mu}_0$ now appears only in the first argument of the Θ_3, and remember that $\overline{\omega}$ also appears in the same place as $\overline{\mu}_0$ does for $N\neq 0$. Taking account of exponent's additivity in the first argument of Θ_3 [*q.v.* Eq. (3.5)], one can imagine that the final result is given by the replacement of $\overline{\mu}_0$ with $\overline{\mu}_0-i\overline{\omega}(=\overline{\mu})$. This result coincides with the $\mathcal{K}_{\beta\mu}$ obtained by the shift manipulation (3.9) in $\mathcal{K}_\beta$.

APPENDIX B: PHOTON SELF-ENERGY PART FROM FEYNMAN RULE

In this appendix, we rearrange the $N=2$ Feynman amplitude of photon scattering into the world-line formula at finite β and μ. The photon self-energy part (in $D=4$) by the Feynman diagram technique is written in the form

$$\Pi_\beta = -\frac{1}{\beta}\sum_n \int \frac{d^3p}{(2\pi)^3}\frac{\mathrm{Tr}[\not\epsilon_1(\not p - \not k_1)\not\epsilon_2 \not p]}{p^2(p-k)^2}, \tag{B1}$$

where $p^\mu = (\omega_n, \vec{p})$, $k_i^\mu = (\omega_{k_i}, \vec{k}_i)$, and $\epsilon_i \equiv \epsilon_\mu^i$, $i=1,2$. We also make use of $k^\mu = k_1^\mu = -k_2^\mu$. The QED coupling e is set to be the unity for simplicity. For convenience, we decompose the Π_β into the following three parts:

$$\Pi_i = \frac{1}{\beta}\sum_n \int \frac{d^3p}{(2\pi)^3} W_i, \tag{B2}$$

in terms of

$$-\mathrm{Tr}\,[\not\epsilon_1(\not p - \not k)\not\epsilon_2 \not p] = W_1 + W_2 + W_3, \tag{B3}$$

where

$$W_1 = 2\epsilon_1\cdot\epsilon_2(p^2 + (p-k)^2), \tag{B4}$$

$$W_2 = 2(\epsilon_1\cdot\epsilon_2 k_1\cdot k_2 - \epsilon_1\cdot k_2 \epsilon_2\cdot k_1), \tag{B5}$$

$$W_3 = -2\epsilon_1\cdot(2p - k_1)\epsilon_2\cdot(2p-k_1). \tag{B6}$$

Applying the Feynman integral formula

$$\frac{1}{p^2(p-k)^2} = \int_0^\infty ds s \int_0^1 du e^{-sk^2(u-u^2)} e^{-s(p-(1-u)k)^2}, \tag{B7}$$

we easily rewrite Π_1 and Π_2 in the following forms:

$$\Pi_1 = \frac{4\epsilon_1\cdot\epsilon_2}{\beta}\sum_n \int_0^\infty \frac{ds s}{(4\pi s)^{3/2}}\int_0^1 du e^{-sk^2(u-u^2)} e^{-s(\omega_n + a)^2}\frac{1}{s}\,\delta(1-u), \tag{B8}$$

$$\Pi_2 = (\epsilon_1\cdot\epsilon_2 k_1\cdot k_2 - \epsilon_1\cdot k_2\epsilon_2\cdot k_1)\frac{2}{\beta}\sum_n \int_0^\infty \frac{ds s}{(4\pi s)^{3/2}}\int_0^1 du e^{-sk^2(u-u^2)} e^{-s(\omega_n+a)^2}, \tag{B9}$$

where

$$a = (1-u)\omega_k. \tag{B10}$$

The Π_3 can be rewritten in the similar way by using Eq. (B7) and shifting $\vec{p} \to \vec{p} + (1-u)\vec{k}$ in the p-integral. After some algebra, we have

$$\Pi_3 = \frac{2}{\beta}\sum \int_0^\infty \frac{ds}{(4\pi s)^{3/2}}\, s\int_0^1 du e^{-sk^2(u-u^2)} e^{-s(\omega_n+a)^2}$$
$$\times\left[\frac{2}{s}\,(\epsilon_0^1\epsilon_0^2 - \epsilon_1\cdot\epsilon_2) - \{2\epsilon_0^1(\omega_n + a) - (1-2u)\epsilon_1\cdot k\}\{2\epsilon_0^2(\omega_n+a) - (1-2u)\epsilon_2\cdot k\}\right]. \tag{B11}$$

Gathering Eqs. (B8), (B9), and (B11), we obtain

$$\Pi_\beta=\frac{2}{\beta}\sum_n \int_0^\infty \frac{dss}{(4\pi s)^{3/2}}\int_0^1 due^{-sk^2(u-u^2)}e^{-s(\omega_n+a)^2}\Bigg[\frac{2}{s}\,\epsilon_1\cdot\epsilon_2\{\delta(1-u)-1\}$$
$$+(\epsilon_1\cdot\epsilon_2 k_1\cdot k_2-\epsilon_1\cdot k_2\epsilon_2\cdot k_1)-(1-2u)^2\epsilon_1\cdot k\epsilon_2\cdot k-4\epsilon_0^1\epsilon_0^2\left\{(\omega_n+a)^2-\frac{1}{2s}\right\}$$
$$+2(1-2u)(\epsilon_0^1\epsilon_2\cdot k+\epsilon_0^2\epsilon_1\cdot k)(\omega_n+a)\Bigg]. \tag{B12}$$

Now, we can eliminate the forms $(\omega_n+a)^m, m=1,2$, in the summand of Eq. (B12) due to the following operations:

$$-\frac{1}{2s}\,\partial_a\sum_n e^{-s(\omega_n+a)^2}=\sum_n (\omega_n+a)e^{-s(\omega_n+a)^2}, \tag{B13}$$

$$\left(\frac{1}{2s}\,\partial_a\right)^2\sum_n e^{-s(\omega_n+a)^2}=\sum_n \left[(\omega_n+a)^2-\frac{1}{2s}\right]e^{-s(\omega_n+a)^2}. \tag{B14}$$

The a dependence of the summand exponential can be transformed into a linear exponent form by using the Jacobi transformation:

$$\sum_n e^{-s(\omega_n+a)^2}=e^{-sa^2}\Theta_2\left(\frac{2sia}{\beta},\frac{is4\pi}{\beta^2}\right)$$
$$=\frac{\beta}{\sqrt{4\pi s}}\,\Theta_4\left(\frac{\beta a}{2\pi},\frac{i\beta^2}{4\pi s}\right)=\frac{\beta}{\sqrt{4\pi s}}\sum_n (-1)^n e^{-n^2\beta^2/4s}e^{in\beta a}. \tag{B15}$$

Then we are allowed to perform the following replacement in the transformed summands,

$$\frac{\partial}{\partial a}\to in\beta, \tag{B16}$$

and we finally derive the formula

$$\Pi_\beta=2\int_0^\infty\frac{dss}{(4\pi s)^{4/2}}\int_0^1 due^{-sk^2(u-u^2)}\sum_n (-1)^n e^{-n^2\beta^2/4s}e^{in\beta a}\Bigg[\epsilon_0^1\epsilon_0^2\frac{n^2\beta^2}{s^2}+\frac{in\beta}{s}(2u-1)$$
$$\times(\epsilon_0^1\epsilon_2\cdot k_1-\epsilon_0^2\epsilon_1\cdot k_2)+\frac{2}{s}\,\epsilon_1\cdot\epsilon_2\{\delta(1-u)-1\}+(\epsilon_1\cdot\epsilon_2 k_1\cdot k_2-\epsilon_1\cdot k_2\epsilon_2\cdot k_1)$$
$$+(1-2u)^2\epsilon_1\cdot k_2\epsilon_2\cdot k_1\Bigg]. \tag{B17}$$

For $\mu\neq 0$, we have only to make the standard shift (1.1), and this causes the following change of the a defined in Eq. (B10):

$$a\to(1-u)\omega_k+i\mu. \tag{B18}$$

This modification exactly corresponds to the shift (3.9). Note that the a coincides with $\overline{\omega}$ with fixing $\sigma_1=1$.

APPENDIX C: WORLD-LINE METHOD FOR PHOTON SELF-ENERGY PART

In this appendix, we illustrate how we obtain the thermodynamic version of the vertex structure function in the case of $N=2$ photon scattering. In the world-line formalism, the photon self-energy part at zero temperature can be obtained from the formula

$$\Gamma_2=-\frac{1}{2}\,2^{D/2}\int_0^\infty \frac{ds}{s}\,e^{-sm^2}\oint \mathcal{D}x\mathcal{D}\psi\,\exp\left[-\int_0^s\left(\frac{1}{4}\,\dot{x}(\tau)+\frac{1}{2}\,\psi\dot{\psi}\right)d\tau\right]V_1V_2, \tag{C1}$$

where $V_j\,,j=1,2$, are the photon vertex operators

$$V_j=-ie\int_0^s d\tau_j\,(\epsilon_j\cdot\dot{x}+2i\psi\cdot\epsilon_j\psi\cdot k_j)(\tau_j)e^{ik_jx(\tau_j)}, \tag{C2}$$

and $\dot{x}=\partial_\tau x$, etc. In the following, we set the QED coupling $e=1$ as assumed in Appendix B. Here we follow the standard world-line notation τ, which is related to the main text notation σ by

$$\tau_j=s\sigma_j\,. \tag{C3}$$

Equation (C1) is known to become

$$\Gamma_2=-\frac{1}{2}\,2^{D/2}\int_0^\infty \frac{ds}{s}\int_0^s d\tau_1\int_0^s d\tau_2\mathcal{V}\times\mathcal{K} \tag{C4}$$

with the vertex structure function

$$\mathcal{V}=\epsilon_1\cdot\epsilon_2\ddot{G}_B^{12}+\epsilon_1\cdot k_2\epsilon_2\cdot k_1(\dot{G}_B^{12})^2+(\epsilon_1\cdot\epsilon_2k_1\cdot k_2-\epsilon_1\cdot k_2\epsilon_2\cdot k_1)(G_F^{12})^2, \tag{C5}$$

and the kinematical factor

$$\mathcal{K}=\mathcal{N}\langle e^{ik_1\cdot x(\tau_1)}e^{ik_2\cdot x(\tau_2)}\rangle=e^{-sm^2}\oint\oint\mathcal{D}x\exp\left[-\int_0^s\frac{1}{4}\,\dot{x}^2d\tau\right]\prod_{j=1}^{2}\,e^{ik_j\cdot x(\tau_j)}$$
$$=(4\pi s)^{-D/2}e^{-sm^2}e^{k_1\cdot k_2G_B^{12}}, \tag{C6}$$

where

$$G_B^{12}=|\tau_1-\tau_2|-\frac{(\tau_1-\tau_2)^2}{s},\quad G_F^{12}=\mathrm{sign}\,(\tau_1-\tau_2). \tag{C7}$$

The path integral normalizations are chosen to be

$$\oint\mathcal{D}x\exp\left[-\int_0^s\frac{1}{4}\,\dot{x}^2\,d\tau\right]=(4\pi s)^{-D/2},\quad \oint\mathcal{D}\psi\exp\left[-\int_0^s\psi\cdot\dot{\psi}\,dr\right]=1. \tag{C8}$$

It can be said that the kinematical factor is defined by the insertions of the ϕ^3 scalar vertex operators

$$V_j=\int_0^s d\tau_j\exp[ik_j\cdot x(\tau_j)],\quad j=1,2. \tag{C9}$$

According to the program presented in Sec. III, we are led to calculate the following path integral at finite temperature:

$$\Gamma_2^\beta = -\frac{1}{2}\,2^{D/2}(ie)^2\int_0^\infty \frac{ds}{s}\,e^{-sm^2}\oint \mathcal{D}x\mathcal{D}\psi \exp\left[-\int_0^s\left(\frac{1}{4}\,\dot{x}^2+\frac{1}{2}\,\psi\cdot\dot{\psi}\right)d\tau\right]$$
$$\times\left(\prod_{i=1}^2\int_0^s d\tau_i e^{ik_i x(\tau_i)}\right)\sum_n (-1)^n e^{-n^2\beta^2/4s}e^{in(\beta/s)(\tau_1-\tau_2)\omega_k}$$
$$\times\left(\epsilon_0^1\frac{n\beta}{s}+\epsilon^1\cdot\dot{x}+2i\psi\cdot\epsilon_1\psi\cdot k_1\right)(\tau_1)\left(\epsilon_0^2\frac{n\beta}{s}+\epsilon^2\cdot\dot{x}+2i\psi\cdot\epsilon_2\psi\cdot k_2\right)(\tau_2). \tag{C10}$$

Using the Wick contraction method with the correlators

$$\langle x^\mu(\tau_1)x^\nu(\tau_2)\rangle = -g^{\mu\nu}G_B^{12}, \quad \langle \psi^\mu(\tau_1)\psi^\nu(\tau_2)\rangle = \tfrac{1}{2}g^{\mu\nu}G_F^{12}, \tag{C11}$$

one can verify the coincidence of the Γ_2^β with the Π_β derived in Appendix B; we have arrived at the form

$$\Pi_\beta = \frac{1}{2}\,2^{D/2}\int_0^\infty \frac{ds}{s}\,e^{-sm^2}\left(\prod_{j=1}^2\int_0^s d\tau_j\right)\sum_n (-1)^n\mathcal{K}_\beta^{(n)}(\mathcal{V}+\tilde{\mathcal{V}}), \tag{C12}$$

where

$$\tilde{\mathcal{V}} = \epsilon_0^1\epsilon_0^2\frac{n^2\beta^2}{S^2}+\frac{in\beta}{s}\,(\epsilon_0^1\epsilon_2\cdot k_1-\epsilon_0^2\epsilon_1\cdot k_2)\dot{G}_B^{12}, \tag{C13}$$

and the $\mathcal{K}_\beta^{(n)}$ is the nth mode of the bosonic two point function at finite β defined by

$$\mathcal{K}_\beta^{(n)} = \oint \mathcal{D}x \exp\left[-\int_0^s (1/4)\dot{x}^2\right]\prod_{j=1}^2 e^{ik_j\cdot x(\tau_j)}\big|_{x^0\to x^0+n\beta\tau/s}$$
$$= e^{-n^2\beta^2/4s}e^{in\beta(\tau_1-\tau_2)\omega_k/s}(4\pi s)^{-D/2}e^{-k^2G_B^{12}}. \tag{C14}$$

Here Eq. (C12) with (C13) and (C14) reproduces the Feynman rule result (B17) with rescaling $\tau_i = s\sigma_i$ and fixing $\sigma_1 = 1$ with $\sigma_2 = u$. Note that $\dot{G}_B^{12}$ behaves as $2u-1$ in this respect.

Let us further rewrite the above $\tilde{\mathcal{V}}$ in an operator form suitable to Eq. (3.31). In the following, we shall not employ the fixing $\sigma_1 = 1$. As shown in Appendix B, we can replace $in\beta$ with $\partial/\partial\bar{\omega}$, where

$$\bar{\omega} = (\sigma_1-\sigma_2)\omega_k, \tag{C15}$$

and we therefore find

$$\Gamma_2^\beta = \frac{1}{2}\,2^{D/2}\int_0^\infty ds s\left(\prod_{i=1}^2\int_0^1 d\sigma_i\right)\mathcal{V}_\beta\times\mathcal{K}_\beta \tag{C16}$$

with having

$$\mathcal{V}_\beta = \mathcal{V}-\epsilon_0^1\epsilon_0^2\left(\frac{1}{s}\,\frac{\partial}{\partial\bar{\omega}}\right)^2-\frac{1}{s}\,\frac{\partial}{\partial\bar{\omega}}(\epsilon_0^1\epsilon_2\cdot k_1-\epsilon_0^2\epsilon_1\cdot k_2)\dot{G}_B^{12} \tag{C17}$$

and

$$\mathcal{K}_\beta = \sum_n (-1)^n\mathcal{K}_\beta^{(n)}e^{-sm^2}, \tag{C18}$$

where the change of variables $\tau_i = s\sigma_i$ in G_B^{12} should be understood. Since we already justified the shift (3.9) in the end of Appendix B, we can use the following parts for the finite μ case:

$$\mathcal{V}_{\beta_\mu} = \mathcal{V}_\beta\left[\frac{\partial}{\partial\overline{\omega}} \to \frac{\partial}{\partial\Omega}\right], \quad \mathcal{K}_{\beta_\mu} = \mathcal{K}_\beta[\,\overline{\omega} \to \Omega\,]. \tag{C19}$$

Substituting these in Eq. (C16), we obtain the two-point function $\Gamma_2^{\beta\mu}$, which therefore coincides with the corresponding Feynman rule result suggested at the end of Appendix B.

(Received 25 March 1999; accepted for publication 8 April 1999)

Interacting systems consisting of two rotators and a pendulum are considered, in a case in which the uncoupled systems have three very different characteristic time scales. The abundance of unstable quasiperiodic motions in phase space is studied via the Lindstedt series regarded as a sum of Feynman graphs and studied with renormalization group techniques based on Eliasson's work on KAM tori. The result is a strong improvement, compared to our previous results, on the domain of validity of bounds that imply existence of invariant tori, large homoclinic angles, long heteroclinic chains, and drift-diffusion in phase space. © *1999 American Institute of Physics.* [S0022-2488(99)03310-1]

I. THE HAMILTONIAN SYSTEM

1.1. Let $(\varphi,\alpha_1,\alpha_2)=(\varphi,\boldsymbol{\alpha})\in\mathbb{T}^3$ be three angles (i.e., positions on circles); let $(I,A_1,A_2)=(I,\mathbf{A})\in\mathbb{R}^3$ be their conjugate momenta (or ''actions''). We consider the Hamiltonian function, depending on two parameters $\varepsilon,\eta>0$, defined by

$$\mathcal{H}=\eta^{1/2}\Omega_1A_1+\eta\frac{A_1^2}{2J}+\eta^{-1/2}\Omega_2A_2+\frac{I^2}{2J_0}+J_0g_0^2(\cos\varphi-1)+\varepsilon f(\varphi,\alpha_1,\alpha_2), \tag{1.1}$$

with f an *even* trigonometric polynomial of degree N, N_0 in $\boldsymbol{\alpha}$, φ, respectively; $\Omega_1,\Omega_2,J,J_0,g_0$ are positive constants.

This system describes two rotators (one anisochronous, labeled #1, and one isochronous, labeled #2) interacting with a pendulum which has its free (i.e., with $\varepsilon=0$) unstable equilibrium position at $I=0$, $\varphi=0$ and the stable one at $I=0$, $\varphi=\pi$. The scale of frequency of the pendulum is $O(1)$ in η; at the same time the two rotators rotate at constant speed $O(\eta^{1/2})$ and $O(\eta^{-1/2})$, respectively. Hence the system has three time scales; we assume $\eta<1$ so that the *slow* rotator is the #1 rotator.

The free motion admits invariant tori of dimension 2 (namely parameterized by $\mathbf{A}$, a constant vector, by $\boldsymbol{\alpha}$ arbitrary, and with $I=0$, $\varphi=0$) which are unstable and possess stable (labeled $+$) and unstable (labeled $-$) three-dimensional manifolds (parameterized by $\mathbf{A}$, the same constant vector, by $\boldsymbol{\alpha}$, φ arbitrary, and with $I=\pm J_0g_0\sqrt{2(1-\cos\varphi)}$).

We shall study properties that eventually hold when $\eta\to0$. It is well known (see Refs. 1 and 2, for instance) that if ε is small most of the unperturbed tori and their manifolds still exist, just a little deformed. This means that (under the condition stated below) there exist functions $\mathbf{U}^{\pm}_{\mathbf{A}'}(\varphi,\boldsymbol{\alpha})$

[a)]Electronic mail: giovanni@ipparco.roma1.infn.it
[b)]Electronic mail: gentile@ipparco.roma1.infn.it
[c)]Electronic mail: vieri@ipparco.roma1.infn.it

and $V^{\pm}_{\mathbf{A}'}(\varphi,\boldsymbol{\alpha})$ which are divisible by ε and analytic in $\boldsymbol{\alpha}$, φ, ε, for $\boldsymbol{\alpha}\in\mathbb{T}^2$, $|\varphi|<2\pi$, $|\varepsilon|<\varepsilon_0$, with ε_0 small enough, such that an initial datum starting on the (three-dimensional) surfaces W^{σ}_{ε}, $\sigma=\pm$, defined as

$$\mathbf{A}^{\sigma}(\varphi,\boldsymbol{\alpha})=\mathbf{A}'+\mathbf{U}^{\sigma}_{\mathbf{A}'}(\varphi,\boldsymbol{\alpha}),\quad I^{\sigma}(\varphi,\boldsymbol{\alpha})=\pm J_0 g_0\sqrt{2(1-\cos\varphi)}+V^{\sigma}_{\mathbf{A}'}(\varphi,\boldsymbol{\alpha}),\tag{1.2}$$

evolves, when the time $t\to\pm\infty$, tending to be confused with a quasiperiodic motion on a invariant torus $\mathcal{T}(\mathbf{A}')$, with rotation vector

$$\boldsymbol{\omega}'=(\omega_1',\omega_2'),\quad \omega_1'\overset{\text{def}}{=}\eta^{1/2}\Omega_1+\eta J^{-1}A_1',\quad \omega_2'\overset{\text{def}}{=}\eta^{-1/2}\Omega_2,\tag{1.3}$$

and furthermore such asymptotic motion takes place with $\mathbf{A}$ moving quasiperiodically *with average* $\mathbf{A}'$.

All this holds if $\boldsymbol{\omega}'$ *verifies the Diophantine condition*,

$$|\boldsymbol{\omega}'\cdot\boldsymbol{\nu}|>C|\boldsymbol{\nu}|^{-\tau},\quad \forall\boldsymbol{\nu}\in\mathbb{Z}^2\backslash\{\mathbf{0}\},\tag{1.4}$$

for $C,\tau>0$ (which may depend also on η). The values of ε for which we shall be able to prove the above will be so small that the part of the stable and unstable manifolds with $|\varphi|<\frac{3}{2}\pi$ *can be represented as a graph of* $\mathbf{A}$, I *over* $\boldsymbol{\alpha}$, φ. (Note that if $\varepsilon=0$ they are graphs over $\boldsymbol{\alpha}$, φ for $|\varphi|$ smaller than *any* prefixed quantity $<2\pi$.) Hence we look, since the beginning, for invariant tori which have the latter property.

The approach to the invariant tori, of the points that lie on their stable manifolds, will be exponential in the sense that their distances $d(t)$ to the tori will be such that

$$\lim_{t\to+\infty} t^{-1}\log d(t)^{-1}=\overline{g_0},\quad \overline{g_0}\equiv\overline{g_0}(\varepsilon)\overset{\text{def}}{=}(1+\Gamma(\varepsilon,g_0))g_0,\tag{1.5}$$

for a suitable analytic function $\Gamma(\varepsilon,g_0)$, divisible by ε. We shall call $\overline{g_0}$ the *Lyapunov exponent* of the torus (it will depend on ε as well as on the considered torus, i.e., on $\boldsymbol{\omega}'$ and on η). The exponent relative to the approach to the same torus along its unstable manifold (as $t\to-\infty$) will be the same, by time reversal symmetry defined below.

We fix throughout the paper τ ($\tau\geq 1$) and *we shall mainly study the dependence of* ε_0, *i.e., our estimate for the analyticity radius, as a function of* η: $\varepsilon_0=\varepsilon_0(C,\eta)$.

1.2. *Remark:* The relation (1.3) between the value of the average action and the rotation vector is nontrivial and it has been named in Refs. 3 and 4 (where it was pointed out) by saying that the tori of (1.1) are ''torsion free'' or ''twistless.'' It is a remarkable symmetry property of (1.1), see Refs. 3, 5, 6.

1.3. If $\varepsilon=0$ the stable and unstable manifolds coincide (because the pendulum separatrix is degenerate); it is a degeneracy that is lost when $\varepsilon\neq 0$ and generically the manifolds will have only pairwise isolated trajectories in common, called *homoclinic trajectories*.

Nevertheless time reversal symmetry and parity symmetry (the latter symmetry is due to the assumption of evenness of f) hold for (1.1). If S^t denotes the time evolution and the involution map i (composition of parity and time reversal) is defined by $i(\varphi,\boldsymbol{\alpha},I,\mathbf{A})=(2\pi-\varphi,-\boldsymbol{\alpha},I,\mathbf{A})$, then $iS^t=S^{-t}i$ and there are relations between the stable and unstable manifolds that are preserved even for $\varepsilon\neq 0$. Namely,

$$\begin{aligned}\mathbf{U}^{+}_{\mathbf{A}'}(\varphi,\boldsymbol{\alpha})&=\mathbf{U}^{-}_{\mathbf{A}'}(2\pi-\varphi,-\boldsymbol{\alpha}),\\ V^{+}_{\mathbf{A}'}(\varphi,\boldsymbol{\alpha})&=V^{-}_{\mathbf{A}'}(2\pi-\varphi,-\boldsymbol{\alpha}),\end{aligned}\tag{1.6}$$

where care must be exercised because the manifolds contain *two* points over each $\boldsymbol{\alpha}$, φ. (This is in fact already so for $\varepsilon=0$.) Hence if $\varphi\simeq\pi$ the relations in (1.6) concern points that lie on different connected manifolds; to understand what happens one should try a drawing taking into account that the above representations are considered only for $|\varphi|<\frac{3}{2}\pi$.

Looking at the manifolds at $\varphi=\pi$, *assuming their existence and that they are graphs above* $\boldsymbol{\alpha}$, φ for $|\varphi|<\frac{3}{2}\pi$, Eqs. (1.6) imply that, fixed $\mathbf{A}'$,

$$\mathbf{Q}(\alpha)\stackrel{\text{def}}{=}\mathbf{U}^{+}_{\mathbf{A}'}(\pi,\boldsymbol{\alpha})-\mathbf{U}^{-}_{\mathbf{A}'}(\pi,\boldsymbol{\alpha})=-\mathbf{Q}(-\boldsymbol{\alpha}),\tag{1.7}$$

so that $\mathbf{Q}(\mathbf{0})=\mathbf{0}$; but, in general, $\mathbf{Q}(\boldsymbol{\alpha})\neq\mathbf{0}$ for $\boldsymbol{\alpha}\neq\mathbf{0}$.

The function $\mathbf{Q}(\boldsymbol{\alpha})$ is called the *homoclinic splitting* (or simply *splitting*) *vector* at $\varphi=\pi$, and the determinant of the matrix with entries $\partial_{\alpha_i}Q_j(\mathbf{0})$ (splitting matrix) is called the *splitting*. One can more generally consider $\underline{Z}\equiv\underline{Z}(\varphi,\boldsymbol{\alpha})=(\mathbf{U}^{+}_{\mathbf{A}'}(\varphi,\boldsymbol{\alpha})-\mathbf{U}^{-}_{\mathbf{A}'}(\varphi,\boldsymbol{\alpha}),V^{+}_{\mathbf{A}'}(\varphi,\boldsymbol{\alpha})-V^{-}_{\mathbf{A}'}(\varphi,\boldsymbol{\alpha}))$ which would be the splitting vector at φ. Here and henceforth the vectors in $\mathbb{R}^l$ will be denoted with an underlined letter (while the boldface is used for vectors in $\mathbb{R}^{l-1}$); so far $l=3$, but shortly we shall consider $l\geqslant 3$. The function $\underline{Z}$ can be written as the gradient of a generating function Φ, i.e., $\underline{Z}=(\partial_\varphi\Phi,\partial_\alpha\Phi)$. This is a result due to Eliasson who points out that it follows immediately from the Lagrangian nature of the stable and unstable manifolds. It is a further symmetry property. (It can alternatively be easily seen from the explicit expressions for the stable and unstable manifolds equations derived in Ref. 3, which also provide a general algorithm for constructing the function Φ as a convergent series in ε for ε small; see Ref. 7.)

The symmetry of (1.1) (hence the consequent oddness of $\mathbf{Q}(\boldsymbol{\alpha})$) implies that there is one trajectory which swings through $\varphi=\pi$ when $\boldsymbol{\alpha}$ is exactly $\mathbf{0}$: it tends to the same invariant torus as $t\to\pm\infty$, provided the torus exists and its stable and unstable manifolds are graphs over $\boldsymbol{\alpha}$, φ over an interval of φ greater than $|\varphi|<\pi$.

In this paper we prove the following results:

1.4. **Theorem:** *Given the Hamiltonian (1.1), given constants s,* $\Omega>0$ *and given* $\eta>0$ *small enough, the following assertions hold:*

(1) *There are invariant tori with rotation vectors* $\boldsymbol{\omega}'$ *for all* $\boldsymbol{\omega}'$ *verifying the Diophantine condition (1.4) with constant* $C=C(\eta)=\Omega e^{-s\eta^{-1/2}}$ *and* $|\omega_1'|\in[\frac{1}{2}\Omega_1\eta^{1/2},2\Omega_1\eta^{1/2}]$.
(2) *Such tori exist for* $|\varepsilon|<\varepsilon_0=O(\eta^2)$ *and for* η *small enough.*
(3) *They can be parameterized by their average actions* $\mathbf{A}'$; *the angular velocity is then given by the rotation vector* $\boldsymbol{\omega}'\equiv(\Omega_1\eta^{1/2}+\eta J_1^{-1}A_1',\Omega_2\eta^{-1/2})$ *(i.e., they are "twistless") and the Lyapunov exponents have the form* $\overline{g_0}=(1+\Gamma(\varepsilon,g_0))g_0$, *with* $\Gamma(\varepsilon,g_0)$ *analytic in* ε *and divisible by* ε.
(4) *The parametric equations for such tori and for their stable and unstable manifolds ("whiskers") can be computed by a convergent perturbation series in powers of* ε *around the unperturbed tori with the same rotation vector and their corresponding stable and unstable manifolds*.
(5) *At the homoclinic intersection with* $\varphi=\pi$ *(existing by symmetry), between the stable manifold and the unstable manifold of each torus, the splitting is generically given by the Mel'nikov integral which is of order* $O(\varepsilon^2\eta^{-\beta}e^{-(\pi/2)g_0^{-1}\eta^{-(1/2)}})$, *for* ε *small enough, with* β *depending on the degree* N_0 *in* φ *of the perturbation f; one can take* $\beta=2N_0-1$ *and the asymptotic formula holds if* $|\varepsilon|<\eta^\zeta$, $\zeta=2(N_0+3)$ *and* η *is small enough*.

1.5. *Remark:* The novelty of the theorem is the "sharp" bound $\varepsilon_0=O(\eta^2)$. If we "only" require $\varepsilon_0=O(\eta^{(9/2)+})$ where $\frac{9}{2}+$ is any prefixed positive number $>\frac{9}{2}$ the result is proved in Ref. 6 (see also Refs. 2 or 5). The improvement is made possible by the *totally different technique* used (with respect to Ref. 6); a technique that has interest in its own right and, we think, beyond the result itself. In fact the proof of the last assertion of the theorem is the content of Ref. 8, and the values of the constants β and ζ are taken from Appendix A2 of Ref. 8.

1.6. Theorem 1.4 will be proved by a further extension of Eliasson's method,[9,4,10,5] for the KAM theorem. The following discussion will show the correctness of the intuition that ''new'' small divisors appear in the perturbation expansion *at orders spaced by* $O(\eta^{-1})$. So that the coupling constant is effectively $O(\varepsilon^{\eta^{-1}})$ and the analyticity condition is expected to be $\varepsilon^{\eta^{-1}}C(\eta)^{-q}$ small (for some $q>0$, determined as in the discussion in Remark 5.16, item (4), below). Hence the analyticity condition will be $\varepsilon C(\eta)^{-q\eta}$ small rather than the far worse $\varepsilon C(\eta)^{-q}$ small, that is implied directly from lemma 1 in Ref. 2 (where $q=6$ is an estimate).

In the one degree of freedom case the corresponding problem is studied in Ref. 11. It is a problem that arises naturally in the context of Nekhoroshev theory. In our case the rotation vector is not one-dimensional, so that the cancellations between resonances typical of small divisors problems,[9,3,10,5] have to be exploited in order to prove convergence of the perturbative series. The fact that the two components of the rotation vector (1.3) are so different in scale has the consequence that small divisors can appear only at high orders, so that the dependence of the radius convergence on the Diophantine constant $C(\eta)$ is highly improvable with respect the ''naïve'' one, as explained above; the proof of such an assertion is the subject of the present paper (as, in the weaker form, already of Ref. 6).

1.7. The paper is organized as follows. In Secs. II, III, IV the formalism is concisely illustrated and the graphic representations of the whiskers in terms of tree graphs is exhibited (for systems more general than (1.1); see (2.1) below). The analysis is brief but self-contained, with references to Refs. 3, 5 only given for further insight and details. The basic formalism is in Sec. III, then we work out in Sec. III two specific examples to explain the origin of the graphical interpretation, and in Sec. IV we set up the general Feynman rules for evaluating the equations of the whiskers (and the splitting vector as a particular case) as a sum of quantities that can be elementarily evaluated. In Sec. V bounds are derived, assuring the convergence of the perturbative series defining the whiskers in the more general system in (2.1) below and leading to Theorem 1.4, when restricted to the Hamiltonian (1.1).

The bounds are derived along the lines of Refs. 3, 5; the main part is the derivation of the bounds for the part of the expansion corresponding to what we call the contributions due to ''trees without leaves;'' this is done fully and self consistently in Sec. V and in the related appendices. Once the bounds on the contributions from trees without leaves are established, *which is the real difficulty*, the same analysis can be applied to bound the other contributions. Since this is simply reduced, without any further technical problems, to the case of contributions from the simpler trees with no leaves we do not repeat this part of the discussion which is done in Ref. 5 following the corresponding analysis done in Refs. 3, 10.

In Appendix A we relegate some technical details, while Appendix C concerns the cancellation analysis of Ref. 5, needed in order to treat the small divisors problems, with more details, with respect to the quoted paper. An original technical part is also in Appendix B and deals with the improvement of the dependence of the convergence radius on the Diophantine constant $C(\eta)$.

We do not comment here on the obvious relevance of the above results for the theory of Arnold diffusion, see Refs. 6 and 12.

II. LINDSTEDT SERIES FOR WHISKERED TORI

We use the formalism of Ref. 5. It would be pointless to repeat here the technical work required to motivate the necessity or usefulness of the notations, and we cannot imagine that any reader may have interest in the matter that follows unless he has some experience with Eliasson's method, as exposed in Ref. 9 and complemented in Refs. 3, 4, 10, 5. The references to Refs. 3, 5 are given only to point at places where further details on the motivations of the assertions can be found.

The following analysis innovates Ref. 5 in Sec. V because of the extension of Siegel–Bryuno's bound described in Appendix B below; this section and the next two provide a *self-contained* description of the graphical algorithm exploited in Sec. V and Appendix B.

2.1. In the following we shall consider a Hamiltonian (''Thirring model'') more general than the one in (1.1), i.e., a Hamiltonian which couples a pendulum with $l-1$ rotators via a perturbation f_1 which is always an *even trigonometric polynomial,*

$$\mathcal{H}=\boldsymbol{\omega}\cdot\mathbf{A}+\frac{1}{2J}\mathbf{A}\cdot\mathbf{A}+\frac{I^2}{2J_0}+J_0g_0^2f_0(\varphi)+\varepsilon J_0g_0^2f_1(\varphi,\boldsymbol{\alpha})+J_0g_0^2\gamma(\varepsilon,g_0)f_0(\varphi), \tag{2.1}$$

where $(\boldsymbol{\alpha},\mathbf{A})\in\mathbb{T}^{l-1}\times\mathbb{R}^{l-1}$, $(\varphi,I)\in\mathbb{T}^1\times\mathbb{R}^1$, $J_0>0$, J is a diagonal matrix, with $0<\det J\leqslant+\infty$, and

$$f_1(\varphi,\boldsymbol{\alpha})=\sum_{\substack{n\in\mathbb{Z}\\|n|\leqslant N_0}}\sum_{\substack{\nu\in\mathbb{Z}^{l-1}\\|\nu|\leqslant N}}f^1_{\underline{\nu}}e^{i(\nu\cdot\alpha+n\varphi)},\quad f^1_{\underline{\nu}}=f^1_{-\underline{\nu}},$$
$$f_0(\varphi)=(\cos\varphi-1)=\sum_{\substack{|n|=1\\\nu=0}}f^0_{\underline{\nu}}e^{i(\nu\cdot\alpha+n\varphi)}, \tag{2.2}$$

with $\underline{\nu}=(\nu_0,\boldsymbol{\nu})\equiv(n,\boldsymbol{\nu})\in\mathbb{Z}\times\mathbb{Z}^{l-1}$ and $|\boldsymbol{\nu}|=\sum_{j=1}^{l-1}|\nu_j|$; we prefer to consider the Hamiltonian (2.1) with l arbitrary because the Lindstedt series analysis holds for any $l\geqslant1$. So that the value $l=3$ and the existence of three time scales will be used only to obtain the second bound in (5.13) below.

The last term in (2.1) could be put together with the free pendulum potential $J_0g_0^2(\cos\varphi-1)$ thus modifying the ''gravity acceleration'' g_0^2 into $(1+\gamma(\varepsilon,g_0))g_0^2$; the term with $\gamma(\varepsilon,g_0)=\sum_{k=1}^{\infty}\gamma_k(g_0)\varepsilon^k$ is added because we follow here the approach in Ref. 5. We show that, given $s,\Omega,\eta,\boldsymbol{\omega}'$, with η small enough and $\boldsymbol{\omega}'$ verifying the Diophantine condition in Theorem 1.4, then one can fix $\gamma(\varepsilon,g_0)$ so that, for $|\varepsilon|<O(\eta^2)$, there is an invariant torus with average (over time) action $\mathbf{A}'$, with the properties in Theorem 1.4 and with Lyapunov exponent g_0 and rotation $\boldsymbol{\omega}'\equiv\boldsymbol{\omega}+J^{-1}\mathbf{A}'$. In other words by adding a *counterterm* to the Hamiltonian (1.1) one gets a new Hamiltonian system, (2.1), with an invariant torus with rotation $\boldsymbol{\omega}'$ *and Lyapunov exponent exactly equal to the prefixed* g_0 (see also Sec. II, 2.7 below).

We further show that, fixed $\boldsymbol{\omega}'$, $\gamma(\varepsilon,g_0)$ is jointly analytic in ε,g_0, if g_0 varies near a prefixed $\overline{g_0}>0$. Going back to the original Hamiltonian (1.1) we *therefore* set $g_0^2=\overline{g}_0^2(1+\gamma(\varepsilon,\overline{g}_0))$ and we can invert the latter relation as $\overline{g}_0^2=(1+\Gamma(\varepsilon,g_0))g_0^2$ for ε small enough (this will mean, for $|\varepsilon|<O(\eta^2)$). Hence by interpreting g_0^2 in (1.1) as $\overline{g}_0^2(1+\gamma(\varepsilon,\overline{g}_0))$, so that (1.5) holds, we obtain Theorem 1.4 as a corollary of the above statements.

Of course a similar proof could be done without first fixing the Lyapunov exponent $\overline{g_0}$ and then inverting the relation between the ''dressed exponent'' $\overline{g_0}$ and the ''bare'' one g_0. But it is well known, from the analogous problem in renormalization theory, that it is wiser technically and conceptually to work, in perturbation theory, with prefixed physical quantities (i.e., dressed ones). The idea that perturbation theory would be simpler, in the technical estimates, is the key idea beyond[3,10] that is introduced in Ref. 5.

2.2. From now on let us denote by $\boldsymbol{\alpha}$ the initial value of the rotators angles (i.e., at time $t=0$). We define by $X_j^\sigma(t;\boldsymbol{\alpha})$, $j=0,...,2l-1$, the values of the variables at time t that are reached from initial data $X^\sigma(0;\boldsymbol{\alpha})=(\pi,\boldsymbol{\alpha},I^\sigma(0;\mathbf{0}),\mathbf{A}^\sigma(0;\mathbf{0}))$, with the given $\boldsymbol{\alpha}$, with $\varphi=\pi$ and with I, $\mathbf{A}$ such that $X^\sigma(0;\boldsymbol{\alpha})$ is on the stable $(\sigma=+)$ or unstable $(\sigma=-)$ manifolds of the invariant torus that we are searching for; the convention on the labels of X is that

$$X_0^\sigma=\varphi^\sigma;\quad X_j^\sigma=\alpha_j^\sigma,\quad\text{for } 1<j<l;$$
$$X_l^\sigma=I^\sigma;\quad X_j^\sigma=A_j^\sigma,\quad\text{for } l<j<2l. \tag{2.3}$$

All functions in (2.3) depend on t and $\boldsymbol{\alpha}$ (the symbols $I^\sigma(t;\boldsymbol{\alpha})$ and $\mathbf{A}^\sigma(t;\boldsymbol{\alpha})$ should not be confused with $I^\sigma(\varphi,\boldsymbol{\alpha})$ and $\mathbf{A}^\sigma(\varphi,\boldsymbol{\alpha})$ defined in (1.2); in the following no ambiguity can arise as the quantities I^σ and $\mathbf{A}^\sigma$ *will be used always with the meaning in (2.3)* and as functions of t, $\boldsymbol{\alpha}$).

This is a parameterization of the stable and unstable manifolds in terms of $\boldsymbol{\alpha}$, t where $\boldsymbol{\alpha}$ is the value of the angular coordinates at the moment in which $\varphi=\pi$, and t is the time elapsed since. The parameterization is different from the one in terms of $\boldsymbol{\alpha}$, φ in (1.2) unless, of course, it is $\varphi=\pi$ and correspondingly $t=0$. Hence the splitting vector (1.7) at $\varphi=\pi$ can also be written $Q_j(\boldsymbol{\alpha}) = X_j^+(0;\boldsymbol{\alpha}) - X_j^-(0,\boldsymbol{\alpha})$, $j=l+1,...,2l-1$. Note that we do not need to consider explicitly the splitting in the I-coordinates because, by energy conservation, they are functions of $\varphi, \boldsymbol{\alpha}, \mathbf{A}^{\pm}$.

Let $\mathbf{A}'$ be given and let $\boldsymbol{\omega}'$ in (1.3) be Diophantine with constants $C=C(\eta)$, $\tau>0$; see (1.4). We look for an invariant torus and for its stable and unstable manifolds with the property that the quasiperiodic rotation on the torus takes place at velocity $\boldsymbol{\omega}'$ and, *at the same time*, the action variables oscillate with an average position $\mathbf{A}'$.

Before proceeding we remark that the above *two* requirements may seem contradictory as there may seem to be no reason for being able to prescribe simultaneously the ''spectrum'' $\boldsymbol{\omega}'$ and the ''average action'' $\mathbf{A}'$ of the invariant tori. In fact this property of ''*twistless*'' motion on the tori or of ''*absence of torsion*'' is very remarkable (see Remark 1.2 and Ref. 3); it will appear as due to the special symmetries of the system (2.1) and to the separation of the energy into a quadratic part involving actions only and an angular part involving only the angles.

Note also that we could confine ourselves to study the torus with average position $\mathbf{A}'=\mathbf{0}$, as in Refs. 3, 5 because any torus can be reduced to that one through a trivial canonical transformation (a translation in the action variables). This explains why in the quoted papers only the torus covered with rotation vector $\boldsymbol{\omega}$ is explicitly considered; however in the following we consider also $\mathbf{A}'\neq\mathbf{0}$, as we are interested in showing the abundance of such tori in phase space (see the Remark 1.5).

The quantity $X_j^{\sigma}(t;\boldsymbol{\alpha})$ can be graphically represented as sum of *values* which can be associated with tree graphs, that we shall call ''Feynman graphs'' or ''trees'' *tout court*, see Fig. 1. The trees are partially ordered sets of points, called *nodes*, connected by unit lines, called *branches*, and they are ''oriented'' towards a point called *root*, which is reached by a single branch of the tree. Given two nodes v and w of a tree, we say that w precedes v ($w\leq v$) if there is a path connecting w to v, oriented from w to v. With an abuse of notations we shall sometimes consider a tree as the collection of its nodes, sometimes as the collection of its branches and sometimes as the collection of both nodes and branches. The root *will not* be considered a node.

A typical tree considered below can be drawn as in Fig. 1; the labels meaning and the caption of such a drawing (which has to be interpreted as a mathematical formula) will be elucidated in the coming sections.

The branch starting at the node v and linking it to the uniquely determined next node (or to the root), which we call v', will be denoted by λ_v: there is a unique correspondence between nodes and branches starting at them. We shall say that λ_v exits from v and enters v'; given a node v we shall say that a branch λ *pertains* to v if either λ enters v or λ exits from v; e.g., in Fig. 1 the line $v_1v_0\equiv\lambda_{v_1}$ ''exits'' v_1 and ''enters'' v_0, hence it pertains to both.

In Ref. 3 two expansions are considered for the functions $X_j^{\sigma}(t;\boldsymbol{\alpha})$ representing the stable and unstable manifolds; one of them is used to exhibit cancellations taking place at all orders in the sums that express the coefficients of the power series in ε of the splitting vector;[3,13,8] it is somewhat more involved than the other one that is convenient to just discuss convergence of the perturbation series for the splitting vector and that we shall use here. This is the reason why (as in Ref. 5) we shall not have trees whose lowest nodes carry a graphical decoration called *form factor*, or *fruit* in Refs. 3, 8. Nevertheless some of the nodes will still have a particular structure; to characterize them we introduce, below as in Ref. 5, the notion of ''*leaf*,'' which is related to the notion of fruit in Ref. 3, from which it differs (and it, even, differs slightly from the similar notion of leaf in Ref. 5), see below for the motivation of the name.

2.3. As mentioned, Fig. 1 has to be regarded as a mathematical formula expressing a function of the labels and of the topological structure of the trees. We now prepare the notation for the definition of ''value'' of a tree (following Ref. 5) (see Ref. 3 for a simpler case); the derivation is not difficult but somewhat long and unusual for the subject (the breakthrough work[9] still does not seem to be well known in its technical aspects!). We discuss it in detail not only for completeness

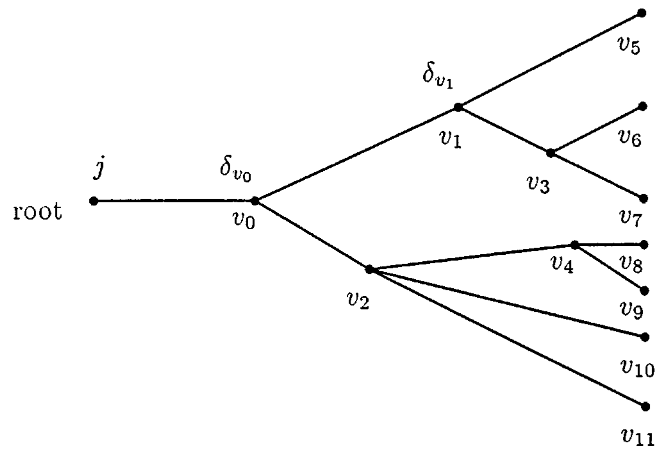

FIG. 1. A tree ϑ with $m=12$, and some labels. The line numbers, distinguishing the lines, and their orientation pointing at the root, are not shown. The lines length should be the same but it is drawn of arbitrary size. The nodes labels δ_v are indicated only for two nodes.

but in the attempt to clarify a construction that has generated quite a few new results starting from the work of Ref. 9, see Refs. 3, 8, 14.

Let us consider the unperturbed motion $X^0(t)\equiv(\varphi^0(t),\boldsymbol{\alpha}+\boldsymbol{\omega}'t,I^0(t),\mathbf{A}')$, where $(\varphi^0(t),I^0(t))$ is the separatrix motion, generated by the pendulum in (2.1) starting at $t=0$ in $\varphi=\pi$, $\mathbf{A}=\mathbf{A}'$, $I=-2J_0g_0$, so that $\varphi^0(t)=4\arctan e^{-g_0t}$. Let $X^\sigma(t;\alpha)$, $\sigma=\text{sign } t=\pm$, be the evolution, under the flow generated by (1.1), of the point on W^σ_ε which at time $t=0$ is $(\pi,\boldsymbol{\alpha},I^\sigma(\boldsymbol{\alpha},\pi),\mathbf{A}^\sigma(\boldsymbol{\alpha},\pi))$, see (1.2); let

$$X^\sigma(t)\equiv X^\sigma(t;\boldsymbol{\alpha})\equiv\sum_{h\geqslant0}X^{h\sigma}(t;\boldsymbol{\alpha})\varepsilon^h=\sum_{h\geqslant0}X^{h\sigma}(t)\varepsilon^h,\quad \sigma=\pm, \tag{2.4}$$

be the power series in ε of X^σ (which we want to show to be convergent for ε small); note that $X^{0\sigma}\equiv X^0$ is the unperturbed whisker. We shall often omit writing explicitly the $\boldsymbol{\alpha}$ variable among the arguments of various $\boldsymbol{\alpha}$-dependent functions, to simplify the notations, and we shall regard the two functions $X^{h\sigma}(t)$, as forming a single function $X^h(t)$, which is $X^{h+}(t)$ if $\sigma=+$, $t>0$, and $X^{h-}(t)$ if $\sigma=-$, $t<0$.

Components of X will be labeled j, $j=0,\ldots,2l-1$, consistently with (2.3), with the convention that $X_0\overset{\text{def}}{=}X_-$ describes the coordinate φ, $(X_j)_{j=1,\ldots,l-1}\overset{\text{def}}{=}\mathbf{X}_\downarrow$ describes the $\boldsymbol{\alpha}$ coordinates, $X_l\overset{\text{def}}{=}X_+$ describes the I coordinate and $(X_j)_{j=l+1,\ldots,2l-1}\overset{\text{def}}{=}\mathbf{X}_\uparrow$ describes the $\mathbf{A}$ coordinates,

$$X\overset{\text{def}}{=}(X_j)_{j=0,\ldots,2l-1}\overset{\text{def}}{=}(X_-,\mathbf{X}_\downarrow,X_+,\mathbf{X}_\uparrow), \tag{2.5}$$

i.e., we write first the angle and then the action components, first the pendulum and then the rotators. The $\uparrow$ (''up'') and $\downarrow$ (''down'') labels recall that the components with labels $\downarrow$ $(0<j<l)$ have ''lower'' index than the variables with labels $\uparrow$ $(l<j)$, which have a ''higher'' index (a mnemonically useful fact, on first reading at least).

Inserting (2.4) into the Hamilton equation associated with (2.1) we get that the coefficients $X^{h\sigma}(t)$, $h\geqslant1$, satisfy the hierarchy of linear equations

$$\frac{d}{dt}X^{h\sigma}(t)=L(t)X^{h\sigma}(t)+F^{h\sigma}(t), \tag{2.6}$$

with $F^{h\sigma}(t)$ a $2l$-vector and the $2l\times2l$-matrix $L(t)$ is

$$L(t)=\begin{pmatrix} 0 & \mathbf{0} & J_0^{-1} & \mathbf{0} \\ \mathbf{0} & 0 & \mathbf{0} & J^{-1} \\ g_0^2 J_0 \cos\varphi^0(t) & \mathbf{0} & 0 & \mathbf{0} \\ \mathbf{0} & 0 & \mathbf{0} & 0 \end{pmatrix}. \tag{2.7}$$

For instance, $F^{1\sigma}(t)$ is a $2l$-vector with the first $0,...,l-1$ components vanishing (a consequence of the assumption that the perturbation only depends on the angular variables), with the lth component equal to $-J_0 g_0^2 \partial_\varphi f_1(\varphi^0(t),\boldsymbol{\alpha}+\boldsymbol{\omega}' t)+J_0 g_0^2 \gamma_1(g_0)\sin(\varphi^0(t))$ and with the remaining components equal to $-J_0 g_0^2 \partial_\alpha f_1(\varphi^0(t),\boldsymbol{\alpha}+\boldsymbol{\omega}' t)$.

In general $F^{h\sigma}$ depends upon $X^0,\dots,X^{h-1\sigma}$ *but not on* $X^{h\sigma}$. The entries of the $(2l\times 2l)$ matrix L have different meaning according to their position; the $\mathbf{0}$'s in the first and third row are $(l-1)$-(row)-vectors, the $\mathbf{0}$'s in the first and third column are $(l-1)$-(column)-vectors, and the 0's and J^{-1} in the second and fourth column are $(l-1)\times(l-1)$-matrices, while the 0's in the first and third columns are scalars (as J_0^{-1} is). The perturbed motions will be described by *dimensionless* quantities Ξ, Φ,

$$X_j^{h\sigma}=\Xi_j^{h\sigma},\quad 0\leqslant j\leqslant l-1,\quad X_j^{h\sigma}=J_0 g_0 \Xi_j^{h\sigma},\quad l\leqslant j\leqslant 2l-1,$$
$$\mathbf{F}_\uparrow^{h\sigma}=J_0 g_0^2 \boldsymbol{\Phi}_\uparrow^{h\sigma},\quad F_+^{h\sigma}=J_0 g_0^2 \Phi_+^{h\sigma}. \tag{2.8}$$

The simple form of the Hamiltonian equations for φ, $\boldsymbol{\alpha}$, namely $\dot\varphi=J_0^{-1}I$, $\dot{\boldsymbol{\alpha}}=\boldsymbol{\omega}+J^{-1}\mathbf{A}$ implies that $\boldsymbol{\Phi}_j^{h\sigma}=F_j^{h\sigma}\equiv 0$, for $j=0,...,l-1$. For instance,

$$\Phi^{1\sigma}=(0,\mathbf{0},-\partial_\varphi f_1(\varphi^0(t),\boldsymbol{\alpha}+\boldsymbol{\omega}' t)+\gamma_1(g_0)\sin(\varphi_0(t)),--\partial_\alpha f_1(\varphi^0(t),\boldsymbol{\alpha}+\boldsymbol{\omega}' t)). \tag{2.9}$$

Given the form of $L(t)$ and the vanishing of the first l components $F_-^{h\sigma}$, $\mathbf{F}_\downarrow^{h\sigma}$ of $F^{h\sigma}$, for $h\geqslant 1$, the above hierarchy of equations (determining the stable and unstable manifolds) takes the form

$$\frac{1}{g_0}\frac{d}{dt}\Xi_+^{h\sigma}=\cos\varphi^0\Xi_-^{h\sigma}+\Phi_+^{h\sigma},\quad \frac{1}{g_0}\frac{d}{dt}\boldsymbol{\Xi}_\uparrow^{h\sigma}=\boldsymbol{\Phi}_\uparrow^{h\sigma},$$
$$\frac{1}{g_0}\frac{d}{dt}\Xi_-^{h\sigma}=\Xi_+^{h\sigma},\quad \frac{1}{g_0}\frac{d}{dt}\boldsymbol{\Xi}_\downarrow^{h\sigma}=J_0 J^{-1}\boldsymbol{\Xi}_\uparrow^{h\sigma}. \tag{2.10}$$

And, for all $h\geqslant 1$, we can easily write (via Taylor expansion and order matching) the following formula for $\Phi^{h\sigma}$ in terms of the coefficients $\Xi^0,\dots,\Xi^{h-1\sigma}$ and of the derivatives of f_0 and $f_1\equiv f$, see (2.2). The first l components of $\boldsymbol{\Phi}^{h\sigma}$ vanish, as said above, $\Phi_-^{h\sigma}\equiv 0$, $\boldsymbol{\Phi}_\downarrow^{h\sigma}\equiv\mathbf{0}$, and

$$\boldsymbol{\Phi}_\uparrow^{h\sigma}=-\sum_{|\underline{m}|\geqslant 0}(\partial_\alpha f_1)_{\underline{m}}(\varphi^0,\boldsymbol{\alpha}+\boldsymbol{\omega}' t)\sum_{(h_j^i)_{\underline{m},h-1}}\prod_{i=0}^{l-1}\prod_{j=1}^{m_i}\Xi_i^{h_j^i\sigma},$$
$$\Phi_+^{h\sigma}\equiv-\sum_{|\underline{m}|\geqslant 2}(\partial_\varphi f_0(\varphi))_{\underline{m}}(\varphi^0)\sum_{(h_j^0)_{\underline{m},h}}\prod_{j=1}^{m_0}\Xi_-^{h_j^0\sigma}-\sum_{p=1}^{h}\sum_{|\underline{m}|\geqslant 0}\gamma_p(g_0)$$
$$\times(\partial_\varphi f_0(\varphi))_{\underline{m}}(\varphi^0)\sum_{(h_j^0)_{\underline{m},h-p}}\prod_{j=1}^{m_0}\Xi_-^{h_j^0\sigma}-\sum_{|\underline{m}|\geqslant 0}(\partial_\varphi f_1)_{\underline{m}}(\varphi^0,\boldsymbol{\alpha}$$
$$+\boldsymbol{\omega}' t)\sum_{(h_j^i)_{\underline{m},h-1}}\prod_{i=0}^{l-1}\prod_{j=1}^{m_i}\Xi_i^{h_j^i\sigma}, \tag{2.11}$$

where $(G)_{\underline{m}}(\cdot)$, with $G\in\{\partial_\varphi f_0,\partial_\alpha f_1,\partial_\varphi f_1\}$, and $(h_j^i)_{\underline{m},q}$, with $h_j^i\geqslant 1$, are defined as

$$
\begin{aligned}
&(G)_{\underline{m}}(\cdot)\equiv\left(\frac{\partial_{\varphi}^{m_0}\partial_{\alpha_1}^{m_1}\cdots\partial_{\alpha_{l-1}}^{m_{l-1}}G}{m_0!m_1!\cdots m_{l-1}!}\right)(\cdot),\\
&(h_j^i)_{\underline{m},q}\equiv(h_1^0,\ldots,h_{m_0}^0,h_1^1,\ldots,h_{m_1}^1,\ldots,h_1^{l-1},\ldots,h_{m_{l-1}}^{l-1}),\\
&\text{with}\quad\sum_{i=0}^{l-1}\sum_{j=1}^{m_i}h_j^i=q,
\end{aligned}
\tag{2.12}
$$

and $m_i\geqslant 0$, $m=(m_0,\ldots,m_{l-1})$, $|\underline{m}|=\Sigma_{i=0}^{l}m_i$. Note that the first two sums in the expression for $\Phi_+^{h\sigma}$ can only involve vectors $\underline{m}$ with $m_j=0$ if $j\geqslant 1$ (so that $|\underline{m}|=m_0$), because the function f_0, see (2.2), depends only on φ and not on $\boldsymbol{\alpha}$. The evolution of Ξ^h is determined by integrating (2.7), if the initial data are known. The $h=1$ case requires a suitable interpretation of the symbols, given explicitly by (2.9).

Elementary quadrability of the free pendulum equations on the separatrix leads to the following expression for the ''*Wronskian matrix*'' $W(t)$ of the separatrix motion for the pendulum appearing in (2.1), with initial data at $t=0$ given by $\varphi=\pi$, $I=-2g_0J_0$, i.e., $\Xi_+^0=-2$. The matrix

$$
W(t)=\begin{pmatrix} w_{00}(t) & w_{0l}(t)\\ w_{l0}(t) & w_{ll}(t)\end{pmatrix}
\tag{2.13}
$$

is defined to be the solution of the linearization of the free pendulum equation around the separatrix solution, with data $W(0)=1$ and with $J_0=1$ (*because we use dimensionless solutions* Ξ, see (2.10)),

$$
\begin{aligned}
&W(t)=\begin{pmatrix} \dfrac{1}{\cosh g_0t} & \dfrac{\bar{w}(t)}{4}\\ -\dfrac{\sinh g_0t}{\cosh^2 g_0t} & \left(1-\dfrac{\bar{w}(t)}{4}\dfrac{\sinh g_0t}{\cosh^2 g_0t}\right)\cosh g_0t\end{pmatrix},\\
&\bar{w}(t)\equiv\frac{2g_0t+\sinh 2g_0t}{\cosh g_0t}.
\end{aligned}
\tag{2.14}
$$

The evolution of the I,φ components, i.e., $\Xi_j^{h\sigma}$ with $j=0,l$ (also identified with the components with subscripts $\pm$, see (2.5)) can be determined from $W(t)$, by integrating (2.6) for the 0 and l components, to be

$$
\begin{pmatrix}\Xi_-^{h\sigma}\\ \Xi_+^{h\sigma}\end{pmatrix}=W(t)\begin{pmatrix}0\\ \Xi_+^{h\sigma}(0)\end{pmatrix}+W(t)\int_0^{g_0t}W^{-1}(\tau)\begin{pmatrix}0\\ \Phi_+^{h\sigma}(\tau)\end{pmatrix}dg_0\tau.
\tag{2.15}
$$

Thus, denoting by w_{ij} $(i,j=0,l)$ the entries of $W(t)$, (2.15) becomes, for $h\geqslant 1$,

$$
\begin{aligned}
&\Xi_-^{h\sigma}(t)=w_{0l}(t)\left(\Xi_+^{h\sigma}(0)+\int_0^{g_0t}w_{00}(\tau)\Phi_+^{h\sigma}(\tau)dg_0\tau\right)-w_{00}(t)\int_0^{g_0t}w_{0l}(\tau)\Phi_+^{h\sigma}(\tau)dg_0\tau,\\
&\Xi_+^{h\sigma}(t)=w_{ll}(t)\left(\Xi_+^{h\sigma}(0)+\int_0^{g_0t}w_{00}(\tau)\Phi_+^{h\sigma}(\tau)dg_0\tau\right)-w_{l0}(t)\int_0^{g_0t}w_{0l}(\tau)\Phi_+^{h\sigma}(\tau)dg_0\tau,
\end{aligned}
\tag{2.16}
$$

having used that $\Xi_-^{h,\sigma}(0)=0$ because the initial datum for φ is fixed and ε-independent. Likewise integration of Eqs. (2.11) for the $\uparrow,\downarrow$ components yields, for $h\geqslant 1$,

$$\Xi_{\downarrow}^{h\sigma}(t)=J^{-1}J_0\left[g_0t\left(\Xi_{\uparrow}^{h\sigma}(0)+\int_0^{g_0t}\Phi_{\uparrow}^{h\sigma}(\tau)dg_0\tau\right)-\int_0^{g_0t}g_0\tau\Phi_{\uparrow}^{h\sigma}(\tau)dg_0\tau\right],$$
$$\Xi_{\uparrow}^{h\sigma}(t)=\left(\Xi_{\uparrow}^{h\sigma}(0)+\int_0^{g_0t}\Phi_{\uparrow}^{h\sigma}(\tau)dg_0\tau\right), \tag{2.17}$$

having used that the $\Xi_{\downarrow}^{h\sigma}(0)\equiv\mathbf{0}$ because the initial datum for $\boldsymbol{\alpha}$ is fixed and ε-independent. Equations (2.16) and (2.17) can be used to find a reasonably simple algorithm to represent the whiskers equations to all orders $h\geqslant 1$ of the perturbation expansion.

2.4. The initial data in (2.16) and (2.17) have to be *determined by imposing that the solutions (to all orders) become quasiperiodic* as $t\rightarrow\sigma\infty$. This is quite easy and (as to be expected) this condition is simply that $\Xi_{+}^{h\sigma}(0)$, $\Xi_{\uparrow}^{h\sigma}(0)$ are determined by imposing that the integrals in parentheses become integrals between $\sigma\infty$ and t, i.e., $\Xi_{+}^{h\sigma}(0)=\int_{\sigma\infty}^{0}\cdots$ and $\Xi_{\uparrow}^{h\sigma}(0)=\int_{\sigma\infty}^{0}\cdots$; see below.

However the latter integrals are no longer necessarily convergent properly (a few examples suffice to see this); hence one has to go carefully through the process of imposing the correct asymptotic behavior in order to see what is the meaning to be given to such integrals $\int_{\sigma\infty}^{t}$. The analysis can be found in Refs. 3 and 5. The result is that all expressions under integral sign can be written as sums of functions that are rather special, namely,

$$M(t)=\sigma^{\chi}\frac{(\sigma g_0t)^j}{j!}e^{i\boldsymbol{\omega}'\cdot\boldsymbol{\nu}t-pg_0\sigma t}, \tag{2.18}$$

with $\chi,j,\boldsymbol{\nu},p$ integers and $p\geqslant -1$ (see below), so that one has

$$\Xi^{h\sigma}(t)=\sum_{\nu\in\mathbb{Z}^{l-1}}\sum_{p=-1}^{\infty}\tilde{\Xi}^{h\sigma}(\boldsymbol{\nu},p)e^{i\boldsymbol{\omega}'\cdot\boldsymbol{\nu}t-pg_0\sigma t},$$
$$\Phi^{h\sigma}(t)=\sum_{\nu\in\mathbb{Z}^{l-1}}\sum_{p=-1}^{\infty}\tilde{\Phi}^{h\sigma}(\boldsymbol{\nu},p)e^{i\boldsymbol{\omega}'\cdot\boldsymbol{\nu}t-pg_0\sigma t}, \tag{2.19}$$

where we explicitly write down only the dependence on $\boldsymbol{\nu}$ and p (clearly also the fixed constants like $J,J_0,g_0,\ldots$ enter).

The series turn out to be convergent for $\sigma t>0$; however their sums have *no singularity* at $t=0$ and can be analytically continued for $\sigma t<0$ (i.e., $x\geqslant 1$). More precisely the functions that one has to integrate are contained in an *algebra* $\hat{\mathcal{M}}$ on which the integration operations that we need can be given a meaning.

Definition (Ref. 3): Let $\hat{\mathcal{M}}$ *be the space of the functions of t which can be represented, for some* $k\geqslant 0$, *as*

$$M(t)=\sum_{j=0}^{k}\frac{(\sigma tg_0)^j}{j!}M_j^{\sigma}(x,\boldsymbol{\omega}t),\quad x\equiv e^{-\sigma g_0t},\quad \sigma=\operatorname{sign}t, \tag{2.20}$$

with $M_j^{\sigma}(x,\psi)$ *a trigonometric polynomial in* ψ *with coefficients holomorphic in the x-plane in the annulus* $0<|x|<1$, *with possible singularities, outside the open unit disk, in a closed cone centered at the origin, with axis of symmetry on the imaginary axis and half opening* $<\pi/2$, *and possible polar singularities at* $x=0$. *The smallest cone containing the singularities will be called the singularity cone of M.*

The proper interpretation of the improper integrals $\int_{\sigma\infty}^{g_0t}M(\tau)dg_0\tau$, which henceforth will be denoted by $⨍_{\sigma\infty}^{g_0t}M(\tau)dg_0\tau$, is simply the *residuum* at $R=0$ of the analytic function

$$\mathcal{I}_R M \stackrel{\text{def}}{=} \int_{\sigma\infty+i\theta}^{g_0 t} e^{-Rg_0\sigma z} M(z)\, dg_0 z, \tag{2.21}$$

(where θ is arbitrarily prefixed) which is defined and holomorphic for Re $R>0$ and large enough, i.e.,

$$\mathcal{I}M(t) \equiv \int_{\sigma\infty}^{g_0 t} dg_0\tau M(\tau) \stackrel{\text{def}}{=} \oint \frac{dR}{2\pi i R} \mathcal{I}_R M(t). \tag{2.22}$$

By linear extension this defines the integration of function in $\hat{\mathcal{M}}$ for $|x|<1$. The analyticity in x around $x=\pm 1$ and the remarks that $(d/dg_0 t)\mathcal{I}M(t) \equiv M(t)$, i.e., $\mathcal{I}M(t) \equiv \mathcal{I}M(t') + \int_{g_0 t'}^{g_0 t} dg_0 \tau M(\tau)$, so that $\mathcal{I}M(t)$ is a special primitive of $M(t)$ (at fixed σ), allow us to analytically continue the result of the integration to a function in $\hat{\mathcal{M}}$. The operator $\mathcal{I}$ maps the algebra $\hat{\mathcal{M}}$ into itself because one checks that on the monomial (2.18) one has

$$\mathcal{I}M(t) = \begin{cases} -g_0^{-1}\sigma^{\chi+1} e^{i\boldsymbol{\omega}'\cdot\boldsymbol{\nu}t - pg_0\sigma t} \displaystyle\sum_{h=0}^{j} \frac{(g_0\sigma t)^{j-h}}{(j-h)!} \frac{1}{(p - i\sigma g_0^{-1}\boldsymbol{\omega}'\cdot\boldsymbol{\nu})^{h+1}}, & \text{if } |p|+|\boldsymbol{\nu}|>0, \\ g_0^{-1}\sigma^{\chi+1} \dfrac{(\sigma g_0 t)^{j+1}}{(j+1)!}, & \text{otherwise}, \end{cases} \tag{2.23}$$

showing, in particular, that the radius of convergence in x of $\mathcal{I}M$, for a general M, is the same as that of M. But in general the singularities will not be polar, even when those of the M_j^σ's were such.

We shall see that the cases $|p|+|\boldsymbol{\nu}|=0$ do not enter in the discussion (a feature of the method of Ref. 5). The complete expression of $X^{h\sigma}(t)$ becomes

$$\begin{aligned} \Xi_-^{h\sigma}(t) &= w_{0l}(t)\mathcal{I}(w_{00}\Phi_+^{h\sigma})(t) - w_{00}(t)(\mathcal{I}(w_{0l}\Phi_+^{h\sigma})(t) - \mathcal{I}(w_{0l}\Phi_+^{h\sigma})(0^\sigma)) \stackrel{\text{def}}{=} \mathcal{O}(\Phi_+^{h\sigma})(t), \\ \boldsymbol{\Xi}_\downarrow^{h\sigma}(t) &= J^{-1}J_0(\mathcal{I}^2(\boldsymbol{\Phi}_\uparrow^{h\sigma})(t) - \mathcal{I}^2(\boldsymbol{\Phi}_\uparrow^{h\sigma})(0^\sigma)) \stackrel{\text{def}}{=} \overline{\mathcal{I}^2}(\boldsymbol{\Phi}_\uparrow^{h\sigma}(t)), \\ \Xi_+^{h\sigma}(t) &= w_{ll}(t)\mathcal{I}(w_{00}\Phi_+^{h\sigma})(t) - w_{l0}(t)(\mathcal{I}(w_{0l}\Phi_+^{h\sigma})(t) - \mathcal{I}(w_{0l}\Phi_+^{h\sigma})(0^\sigma)) \stackrel{\text{def}}{=} \mathcal{O}_+(\Phi_+^{h\sigma})(t), \\ \boldsymbol{\Xi}_\uparrow^{h\sigma}(t) &= \mathcal{I}(\boldsymbol{\Phi}_\uparrow^{h\sigma})(t), \end{aligned} \tag{2.24}$$

where $\mathcal{O},\mathcal{O}_+,\overline{\mathcal{I}^2}$ are implicitly defined here (and $\mathcal{I}^2$ is $\mathcal{I}$ applied twice); and $\Xi^{h\sigma}$, $\Phi^{h\sigma} \equiv (0,\mathbf{0},\Phi_+^{h\sigma},\boldsymbol{\Phi}_\uparrow^{h\sigma})$ are introduced in (2.9). While $\Xi^{h\sigma}$ has nonzero components over both the *angle* $(j=0,...,l-1)$ and over the *action* $(j=l,\ldots,2l-1)$ components, the $\Phi^{h\sigma}$ has, as already noted, only the action directions nonzero; the notation 0^σ means the limit as $t\to 0$ from the left $(\sigma=-)$ or from the right $(\sigma=+)$, but below we shall drop the superscript on 0 (always clear from he context because it is the same as the superscript σ of the functions $\Xi^{h\sigma}$). Furthermore, with the definitions (2.19) of $\tilde{\boldsymbol{\Phi}}_\uparrow^{h\sigma}(\boldsymbol{\nu},p)$ one finds also the property (with the notations in (2.1)),

$$\tilde{\boldsymbol{\Phi}}_\uparrow^{h\sigma}(\mathbf{0},0) = \mathbf{0}, \tag{2.25}$$

for all $h\geqslant 1$.

We shall repeatedly use that in order to compute $\Xi_j^{h\sigma}$ we only need $\Xi_{j'}^{h'\sigma}$ with $0 \leqslant j' < l$ (i.e., only $\Xi_+^{h'\sigma}$, $\Xi_\uparrow^{h'\sigma}$) and $h' < h$. This follows from (2.24) and (2.11); whether we want to compute an ''*action component*'' ($\Xi_j^{h\sigma}$, $j \geqslant l$) or an ''*angle component*'' ($\Xi_j^{h\sigma}$, $j < l$) of $\Xi^{h\sigma}$, we only need the angle components of lower orders, i.e., $\Xi_{j'}^{h'\sigma}$ with $h' < h$ and $j' < l$.

2.5. The linearity of the last of (2.24), together with (2.25) and the *t*-dependence of $\mathbf{\Phi}^{h\sigma}(t)$ in (2.19), implies that the prefixed value $\mathbf{A}'$ *has the interpretation of average action* of the quasiperiodic motion on the invariant torus to which the trajectories that we study asymptote; see the third statement in Theorem 1.4. This corresponds to the identity of Ref. 2 (see, in the latter reference, the first of (6.34) and its proof in Appendix (A12)) that follows from the symplectic structure of the equations of motion, according to a well known argument going back to Poincaré,[15] discussed also in Refs. 9,16. It is a property that generated the qualification of ''*twistless tori*'' given in Ref. 3 to such tori; the ''dispersion relation'' linking the frequencies to the average actions *does not change* or *is not twisted* when the perturbation is switched on. This is a property, established in the present context in (33) of Ref. 5, that can be ultimately traced back to the fact that in the above models the twist condition is not needed for establishing a KAM theorem.

2.6. By combining (2.24) and (2.11), (2.12) (and recalling (2.8)) the representation in terms of trees is immediate; the integrals in (2.24) and the lower order X^h in (2.11) become *recursively* multiple (improper) integrals over dummy ''time'' variables.

In this operation each function $(-\partial_\alpha f_1(\varphi^0(t), \boldsymbol{\alpha} + \boldsymbol{\omega}' t))_{\underline{m}}$ and $(-\partial_\varphi f_0(\varphi^0(t)))_{\underline{m}}$ is expanded as a linear combination of monomials $M(t)$ having the form $\sigma^\chi(\sigma g_0 t)^j (j!)^{-1} x^n e^{i\omega' \cdot \nu t}$ with $x = e^{-g_0 \sigma t}$; see (2.18).

The form of (2.11) shows that the integrations occur in a hierarchical order; *hence one can describe them by a tree*. The integrands can be identified by attaching to each node of the tree suitably many labels. We shall first illustrate the construction of the trees via two examples (in Sec. III, below); this can be useful in order to understand the general case (see also Refs. 3 and 5).

2.7. We shall establish, also recursively, that $\Xi^{h\sigma}$ will be expanded in monomial like (2.18) with $j=0$ and $p \geqslant 0$, so that at $t \to \pm\infty$ the quantities $\Xi^{h\sigma}$ will approach exponentially fast quasiperiodic functions describing the motion on the invariant torus. The approach will be proportional to $e^{-g_0|t|}$ or to a higher power of this quantity. This, together with the remark that at order 0 (i.e., on the unperturbed motion) the approach is precisely proportional to $e^{-g_0|t|}$ (in the I, φ coordinates), will imply that at least for $j = 0, l$ (and ''generically'' also for the other coordinates)

$$\lim_{t\to\infty} \frac{1}{\sigma t} \log|\Xi_j^\sigma(t)|^{-1} = g_0, \tag{2.26}$$

i.e., that the Lyapunov exponents of the torus are $\pm g_0$.

Before stating the general graphical rules to represent (2.24) in terms of explicitly performed integrals, we discuss in detail two examples; understanding them facilitates enormously, we think, the understanding of the general cases which will be exposed referring to the examples to make it more concrete.

III. TWO EXAMPLES OF THE TREES CONSTRUCTION

3.1. We discuss how to make more explicit (2.24) by performing two ''third order'' examples. The first order reduces trivially to the first order formulas (Mel'nikov integral); the second order is also a bit too simple and is left to the reader; the first two orders will be, of course, implicitly done below, because to compute the third order one needs the first and second, too.

To third order the last line in (2.24) gives $\mathbf{\Xi}_\uparrow^{3\sigma}(t) = \mathcal{I}(\mathbf{\Phi}_\uparrow^{3\sigma})(t)$, where $\mathbf{\Phi}_\uparrow^{3\sigma}$ can be expressed through the first equation in (2.11), so that, for $j = l+1, \ldots, 2l-1$, one has

$$\Phi_j^{3\sigma} = -\frac{1}{2}\partial_{\alpha_j}\partial_\varphi^2 f_1 \Xi_-^{1\sigma}\Xi_-^{1\sigma} - \partial_{\alpha_j}\partial_\varphi f_1 \Xi_-^{2\sigma} - \sum_{p=1}^{l-1}\partial_{\alpha_j}\partial_{\alpha_p}\partial_\varphi f_1 \Xi_p^{1\sigma}\Xi_-^{1\sigma}$$

$$-\frac{1}{2}\sum_{p,q=1}^{l-1}\partial_{\alpha_j}\partial_{\alpha_p}\partial_{\alpha_q} f_1 \Xi_p^{1\sigma}\Xi_q^{1\sigma} - \sum_{p=1}^{l-1}\partial_{\alpha_j}\partial_{\alpha_p} f_1 \Xi_p^{2\sigma}, \tag{3.1}$$

where $\Xi^{1\sigma}$ and $\Xi^{2\sigma}$ can be written by using once more (2.24) (the first two lines only as per the general remark in the last paragraph of Sec. II, 2.4).

We consider explicitly two contributions to $\boldsymbol{\Xi}_\uparrow^{3\sigma}(t)$. Recalling that $\sigma=+$ corresponds to the stable manifold and $\sigma=-$ to the unstable one, the first will be

$$\frac{1}{2}\int_{\sigma\infty}^{g_0 t} dg_0 \tau_{v_0}(-\partial_{\alpha_j\alpha_p\alpha_q} f_1(\varphi^0(\tau_{v_0}), \boldsymbol{\alpha}+\boldsymbol{\omega}'\tau_{v_0})\Xi_p^{1\sigma}(\tau_{v_0})\Xi_q^{1\sigma}(\tau_{v_0}), \tag{3.2}$$

arising from the fourth contribution in the r.h.s. of (3.1). The contribution (3.2) can be written more explicitly, by using again the expression for $\boldsymbol{\Xi}_\downarrow^{1\sigma}$ in (2.25), as

$$\frac{1}{2}\int_{\sigma\infty}^{g_0 t} dg_0 \tau_{v_0}(-\partial_{\alpha_j\alpha_p\alpha_q} f_1)(\tau_{v_0})\overline{\mathcal{I}^2}(-\partial_{\alpha_p} f_1(\tau_{v_1}))(\tau_{v_0})\overline{\mathcal{I}^2}(-\partial_{\alpha_p} f_1(\tau_{v_2}))(\tau_{v_0}), \tag{3.3}$$

where the $\overline{\mathcal{I}^2}$ operations involve, see (2.24), integrations over variables that we can call τ_{v_1}, τ_{v_2} and the derivatives of f_1 are evaluated at $(\varphi^0(\tau_{v_n}), \boldsymbol{\alpha}+\boldsymbol{\omega}'\tau_{v_n})$, $n=0,1,2$. Such variables have been indicated explicitly using the abbreviated notation (τ_{v_n}) and with a obvious abuses of notation (they should not appear at all, except τ_{v_0}, being dummy).

The second example is obtained by considering the contribution with $h_2^0=2$ from the first line of (2.11), i.e., the second contribution in the r.h.s. of (3.1),

$$\int_{\sigma\infty}^{g_0 t}(-\partial_{\alpha_j\varphi} f_1)(\tau_{v_0})\Xi_-^{2\sigma}(\tau_{v_0})d\tau_{v_0}, \tag{3.4}$$

still imagining the derivatives of f_1 evaluated at $(\varphi^0(\tau_{v_0}), \boldsymbol{\alpha}+\boldsymbol{\omega}'\tau_{v_0})$. This contribution will be the sum of several terms, because $\Xi_-^{2\sigma}(\tau_{v_0})$ has to be expressed by using (2.24) and (2.11). One of the (many) contributions will be

$$\frac{1}{2}\int_{\sigma\infty}^{g_0 t} dg_0 \tau_{v_0}(-\partial_{\alpha_j\varphi} f_1)(\tau_{v_0})\mathcal{O}(-\partial_\varphi^3 f_0(\tau_{v_1})\mathcal{O}(-\partial_\varphi f_1(\tau_{v_2}))(\tau_{v_1})$$
$$\times\mathcal{O}(-\partial_\varphi f_1(\tau_{v_3}))(\tau_{v_1}))(\tau_{v_0}), \tag{3.5}$$

where the $\mathcal{O}$ operations involve, see (2.24), integrations over variables that we can call τ_{v_1}, τ_{v_2}, τ_{v_3} and the derivatives of f_0, f_1 are evaluated at $(\varphi^0(\tau_{v_n}), \boldsymbol{\alpha}+\boldsymbol{\omega}'\tau_{v_n})$, $n=0,1,2,3$. Such variables have been indicated explicitly with the same abuse of notation as above; and the dependence on τ of the derivatives of f_0, f_1 has again been simply denoted by adding the symbol (τ_{v_n}) instead of the full argument $(\varphi^0(\tau_{v_n}), \boldsymbol{\alpha}+\boldsymbol{\omega}'\tau_{v_n})$.

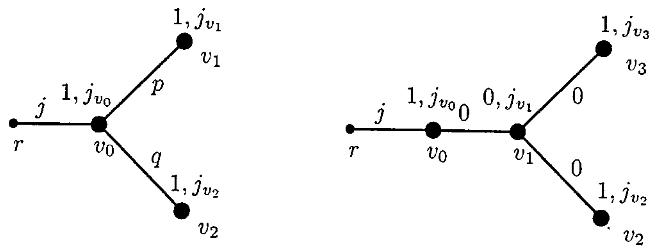

FIG. 2. Graphic representation of the contributions (3.3) and (3.5).

A complete representation of the above two contributions to $\Xi_j^{3\sigma}(t)$ is given, *with enormous notational simplification*, by the trees in Fig. 2, where the labels on the nodes v are denoted δ_v, j_v and those on the lines λ_v are denoted j_{λ_v}.

The label $\delta_v=0,1$ on the node v indicates selection of f_{δ_v}, i.e., of f_0 or f_1, the label j_v denotes a derivative with respect to φ if $j_v=l$ or with respect to α_{j_v} if $j_v=l+1,...,2l-1$. For the label j_{λ_v} associated with the branch λ_v following v, one has $j_{\lambda_v}=j_v-l$ for all v except for the highest node v_0, for which one has $j_{\lambda_{v_0}}=j_{v_0}$. In the examples above, (3.3) and (3.5) correspond, respectively, to the first figure in Fig. 2 with $j_{v_0}=j$, $j_{v_1}=p+l$, $j_{v_2}=q+l$ and to the second with $j_{v_1}=j_{v_2}=j_{v_3}=l$, $j_{v_0}=j$, (hence $j_{\lambda_{v_1}}=j_{\lambda_{v_2}}=j_{\lambda_{v_3}}=0$, $j_{v_0}=j$). In the examples the labels p,q correspond to $\partial_{\alpha_p},\partial_{\alpha_q}$ in (3.3).

3.2. *Remark:* The exception for the meaning of $j_{\lambda_{v_0}}$ is convenient, in the above cases, as the integration over τ_{v_0} differs from the others: the inner ones evaluate $\Xi_j^{h\sigma}$ for $j=0,...,l-1$, because the functions f_0,f_1 only depend on the angle variables (see the last paragraph in Sec. II); the last integral, however, evaluates in the examples a component of $\boldsymbol{\Xi}_{\uparrow}^{h\sigma}$ (which is labeled $j=l+1,...,2l-1$), but, in general, j can be any value $j=0,...,2l-1$. Note that this is not so for the inner labels j_λ which must be angle labels $j_\lambda=0,...,l-1$. So, in general, we shall have that the value of a tree with $j_{\lambda_{v_0}}=j$ contributes to $\Xi_j^{h\sigma}$.

IV. TREES AND FEYNMAN GRAPHS APPROACH TO WHISKERS CONSTRUCTION: THE GENERAL CASE

We now proceed to describe the general case.

4.1. To compute the splitting vector we only need to consider the variable t equal to 0. However we shall be also interested in $\Xi^{h\sigma}(\boldsymbol{\alpha},t)$ for $\sigma t>0$, for instance in order to study how fast the invariant torus is approached by the motions on its stable and unstable manifolds (to obtain its Lyapunov exponent). Hence it will be natural to attribute the label t to the root: this will also remind that the integral over τ_{v_0} has to be performed between $\sigma\infty$ and t, (the value $\sigma=-$ corresponds to the unstable manifold and the value $\sigma=+$ corresponds to the stable one). Since we shall *never* consider the stable manifold for $t>0$ or the unstable for $t<0$ the value of σ will be the same as that of the sign of t.

We shall be interested in computing not only $\mathbf{X}_{\uparrow}^{\sigma}(0;\boldsymbol{\alpha})-\mathbf{A}'$ (or $\mathbf{X}_{\uparrow}^{\sigma}(t;\boldsymbol{\alpha})-\mathbf{A}'$), as in Ref. 8, but, more generally, $X^{\sigma}(t;\boldsymbol{\alpha})-X^0(t;\boldsymbol{\alpha})$, with $\sigma=\text{sign}\,t$, (here X^0 denotes the unperturbed motion).

In general the rules to express $X^{\sigma}(t;\boldsymbol{\alpha})-X^0(t;\boldsymbol{\alpha})$ as sum of ''values'' associated with trees will be described now, assuming that the reader follows us by applying and checking them to the special cases (3.3), (3.5), illustrated in Fig. 2.

The reader might be helped in following the construction of the algorithm to express the stable and unstable manifolds below, by keeping in mind that we simply decompose the (quite involved and recursively defined by (2.24), (2.11)) expressions for the whiskers, so far obtained, *further*.

The purpose being of reducing their evaluation to *very elementary algebraic operations*; ultimately just products of simple factors associated with the nodes (and their labels) of a tree, that we shall call ''coupling constants,'' and of factors associated with the branches (and their labels), that we shall call ''propagators,'' each of which can be trivially evaluated and trivially bounded.

To each node we attach an *order label* $\delta_v = 0,1$, see Fig. 2, and a corresponding function f_{δ_v}; if a node v bears a label $\delta_v = 1$ the associated functions is f_1 and if it bears a label $\delta_v = 0$ it is f_0.

To each node v of a tree ϑ, see Fig. 1, we associate an integration *time variable* τ_v and an *integration operation*, which corresponds to $\overline{\mathcal{I}}^2$ or $\mathcal{O}$ if the node *is not the highest node* v_0 and to $\overline{\mathcal{I}}^2$ or $\mathcal{O}$ or $\mathcal{I}$ or $\mathcal{O}_+$ if the node v *is the highest*, i.e., $v = v_0$. This is so because in the first case (a ''lower node'') one must use the first two equations in (2.24) because in (2.11) only angle components of $X^{h\sigma}$ appear, while in the second case (that of the highest node) one can use all of (2.24) since we can evaluate either an angle coordinate $\Xi_j^{h\sigma}(\boldsymbol{\alpha},t)$, $j<l$, or an action coordinate, $j \geqslant l$.

When $v < v_0$ the choice between the two possibilities will be marked by an *action label* j_v associated with each node; if $j_v = l$, $v < v_0$, then we choose $\mathcal{O}$, if $j_v = l+1,...,2l-1$, $v < v_0$, we choose $\overline{\mathcal{I}}^2$.

When v is the highest node v_0, there are therefore more possibilities; to distinguish between them we use the *action label* j_{v_0} and the *branch label* $j_{\lambda_{v_0}}$, which can be equal either to j_{v_0} or to $j_{v_0} - l$. So when $v = v_0$ and $j_{v_0} = l$, we choose $\mathcal{O}$ if $j_{\lambda_{v_0}} = j_{v_0} - l = 0$ and $\mathcal{O}_+$ if $j_{\lambda_{v_0}} = j_{v_0} = l$, see (2.24), while when $v = v_0$ and $j_{v_0} > l$, we choose $\overline{\mathcal{I}}^2$ if $j_{\lambda_{v_0}} = j_{v_0} - l$ and $\mathcal{I}$ if $j_{\lambda_{v_0}} = j_{v_0}$, see (2.24).

As said in Remark 3.2, the meaning of the branch label is that a tree with $j_{\lambda_{v_0}} = j$ is a graphic representation of a ''contribution'' to $\Xi_j^{h\sigma}$. Therefore if $j_{\lambda_{v_0}} \geqslant l$ we call the branch an *action branch* and if $j_{\lambda_{v_0}} < l$ we call it an *angle branch*.

In the first of the figures in Fig. 2 integrals with respect to the nodes v_1, v_2 are of the type $\overline{\mathcal{I}}^2$. In the second the integrals over the τ_{v_n}, $n = 1,2,3$, are all of the type $\mathcal{O}$. In both cases the integrals over τ_{v_0} are of the form $\mathcal{I}$ because we fixed $j_{\lambda_{v_0}} = j > l$ to be an action label. We can associate a branch label j_{λ_v} also to the inner branches with $v < v_0$; however, in this case one has necessarily $j_{\lambda_v} = j_v - l$ because the inner branches necessarily represent angle components $\Xi_j^{h\sigma}$ with $j<l$, see (2.11). Hence no information is carried by such labels that we define only for uniformity of notation. The latter labels appear in Fig. 2 as *j*,*p*,*q* in the first tree and as *j*, 0, 0, 0 in the second one. The labels j_λ corresponding to the lines pertaining to a node v determine, as in the examples of Sec. III, which derivatives have to be taken of the function f_{δ_v} which is associated with v; each line λ_v with label j_{λ_v} corresponds to a derivative of f_{δ_v} with respect to φ if $j_{\lambda_v} = 0$ or to $\alpha_{j_{\lambda_v}}$ if $0 < j_{\lambda_v} < l$.

The integrations over the node times τ_v must be thought of as improper integrals, in the above sense, from $\sigma\infty$ to either $\tau_{v'}$ or 0 because (2.24) contains various integrals between such extremes. *It will be convenient to distinguish between such terms*.

This can be easily done by adding, on each node, a new label ρ_v also equal to 0, 1; if $\rho_v = 1$ this means, naturally, that in the evaluation of the integration operations relative to the node v we select the terms that correspond to integrations between $\sigma\infty$ and $\tau_{v'}$ while if $\rho_v = 0$ we select the integrations between $\sigma\infty$ and 0. We shall imagine that also the highest node carries a label ρ_{v_0} which is 1 necessarily if we consider only $\Xi_\uparrow(t)$ (because this implies that the function associated with the highest node must appear differentiated with respect to a α-component, see above and (2.11)), but which could be 0 for the other components of $\Xi(t)$. Recall also that in this case $\tau_{v'} \equiv t$, see (2.24).

We remark that the hierarchical structure of the integrations implies that if $\rho_v = 1$ and if v' is the node immediately following (in the direction of the root) v along the tree then one has $\tau_v > \tau_{v'}$ if $\sigma = +$ and $\tau_v < \tau_{v'}$ if $\sigma = -$, while τ_v, $\tau_{v'}$ have the same sign but are otherwise unrelated if $\rho_v = 0$; see (2.24) and check this in the examples.

Besides the labels already introduced also the labels $\rho_v=0,1$, just described but not shown in Fig. 2, should be imagined carried by each node.

Given a tree labeled as above we pick up the nodes v with $\rho_v=0$ which are closest to the root, and consider the subtrees having such nodes as highest nodes. We call each such subtree, i.e., each such node *together with the subtrees ending in it* (and its labels), a *leaf*. [This definition is slightly different from the one given in Ref. 5, where the leaf represents a collection of trees and, as explained below, is related to a resummation operation (see also comments in Sec. IV, 4.3 item (v), below, and (4.27)), that we do not consider here.] The name is natural if one imagines to enclose the part of the tree including the node v itself and half of the line λ_v into a circle (or, more pictorially, into a leaf shaped contour): hence, to whom tries the drawing, it will look like the *venations* of a leaf and the half line outside it will look like its *stalk*.

All nodes which do not belong to any leaves will be called *free nodes*; they carry, by construction, a label $\rho_v=1$, so that the corresponding time variables are hierarchically ordered from the lowest nodes up to the root; i.e., if $w<v$ then $\tau_w<\tau_v$ if $\sigma=+$ and $\tau_w>\tau_v$ if $\sigma=-$. Given a tree ϑ let us call ϑ_f the set of free nodes in ϑ, and call Θ_L the set of highest nodes of the leaves.

Each f_{δ_v} function, associated with the node v with order label δ_v, can be decomposed into its Fourier harmonics. This can be done graphically by adding to each node v a *mode* label $\underline{\nu}_v=(\nu_{0v},\boldsymbol{\nu}_v)\equiv(n_v,\boldsymbol{\nu}_v)\in\mathbb{Z}^l$, with $|\boldsymbol{\nu}_v|\leq N$ and $|n_v|\leq N_0$, that denotes the particular harmonic selected for the node v. If $(j_v,\delta_v,\rho_v,\underline{\nu}_v)$ are the labels of v we will associate with v the quantity $f^{\delta_v}_{\boldsymbol{\nu}_v}e^{i(\omega\cdot\nu_v\tau_v+n_v\varphi^0(\tau_v))}$ multiplied by appropriate products of factors in_v (one per φ-derivative) and $i\nu_{vj}$ (one per α_j-derivative, $j=j_{\lambda_v}$). If the mode labels $\underline{\nu}_v$ are specified for each v we shall define the *momentum* $\boldsymbol{\nu}(v)$ ''flowing'' on a branch λ_v as the sum of all the angle mode components $\boldsymbol{\nu}_w$ of the nodes w *preceding* the branch, with v included,

$$\boldsymbol{\nu}(v)\overset{\text{def}}{=}\sum_{w\in\vartheta,w\leq v}\boldsymbol{\nu}_w; \tag{4.1}$$

the momentum $\boldsymbol{\nu}(v_0)$ flowing through the root branch will be called the *total momentum* (of the tree).

We shall define also the *total free momentum* of the tree as the sum of the mode labels of the free nodes; more generally, for any free node v we can define the *free momentum* flowing through the branch λ_v as

$$\boldsymbol{\nu}_0(v)=\sum_{w\in\vartheta_f,w\leq v}\boldsymbol{\nu}_w. \tag{4.2}$$

For instance, in the above examples the two contributions (3.3), (3.5) (represented by Fig. 2) are decomposed into sums of several distinct contributions once the ρ_v and the mode labels ν_v are specified.

Likewise we can look at a leaf as a tree; the momentum $\boldsymbol{\nu}'$ flowing through its stalk will then be called the internal *leaf momentum*. Note that its value gives *no contribution* to the total free momentum of the tree to which the leaf belongs.

The free momenta will turn out to describe the harmonics of the time dependent quasiperiodic motion around the invariant tori, while the Fourier expansion modes of $X^{h\sigma}(t;\boldsymbol{\alpha})$ as a function of $\boldsymbol{\alpha}$ are related to the sum of the free momenta *and* of all the internal leaf momenta. This is an important difference: it is a property stressed in Ref. 3 where it is referred as ''quasiflatness,'' source of the main difficulties and interest in the theory of homoclinic splitting, see Refs. 3, 8, 6, 7.

4.2. The trees contributions of the examples of Sec. III will be sums over the various labels of ''values'' of trees decorated by more labels,

$$\frac{1}{2}\int_{\sigma\infty}^{g_0 t} dg_0 \tau_{v_0}(-i\nu_{v_0 j})(i\nu_{v_0 p})(i\nu_{v_0 q}) f^1_{\underline{\nu}_{v_0}} e^{i(\boldsymbol{\nu}_{v_0}\cdot\boldsymbol{\omega}'\tau_{v_0}+n_{v_0}\varphi^0(\tau_{v_0}))} \cdot \overline{\mathcal{I}}^2((-i\nu_{v_1 p}) f^1_{\underline{\nu}_{v_1}} e^{i(\boldsymbol{\nu}_{v_1}\cdot\boldsymbol{\omega}'\tau_{v_1}+n_{v_1}\varphi^0(\tau_{v_1}))})(\rho_{v_1}\tau_{v_0}) \cdot \overline{\mathcal{I}}^2((-i\nu_{v_2 q}) f^1_{\underline{\nu}_{v_2}} e^{i(\boldsymbol{\nu}_{v_2}\cdot\boldsymbol{\omega}'\tau_{v_2}+n_{v_2}\varphi^0(\tau_{v_2}))})(\rho_{v_2}\tau_{v_0}), \tag{4.3}$$

for (3.3) and

$$\frac{1}{2}\int_{\sigma\infty}^{g_0 t} dg_0 \tau_{v_0}(-i\nu_{v_0 j})(in_{v_0}) f^1_{\underline{\nu}_{v_0}} e^{i(\boldsymbol{\nu}_{v_0}\cdot\boldsymbol{\omega}'\tau_{v_0}+n_{v_0}\varphi^0(\tau_{v_0}))} \mathcal{O}((-in_{v_1}) f^0_{\underline{\nu}_{v_1}} e^{in_{v_1}\varphi^0(\tau_{v_1})} \cdot \mathcal{O}((-in_{v_2}) f^1_{\underline{\nu}_{v_2}} e^{i(\boldsymbol{\nu}_{v_2}\cdot\boldsymbol{\omega}'\tau_{v_2}+n_{v_2}\varphi^0(\tau_{v_2}))})(\rho_{v_2}\tau_{v_1}) \cdot \mathcal{O}((-in_{v_3}) f^1_{\underline{\nu}_{v_3}} e^{i(\boldsymbol{\nu}_{v_3}\cdot\boldsymbol{\omega}'\tau_{v_3}+n_{v_3}\varphi^0(\tau_{v_3}))})(\rho_{v_3}\tau_{v_1})), \tag{4.4}$$

for (3.5), with the conventions following (3.3) about the dummy integration variables.

The integration operations are still fairly involved, as it can be seen from (2.24) and from the expressions for $\overline{\mathcal{I}}^2$ and $\mathcal{O}$. With the above conventions for the dummy variables and noting that, for any function F in $\hat{\mathcal{M}}$,

$$\overline{\mathcal{I}}^2(F(\tau))(t) = J^{-1}J_0(\mathcal{I}(g_0(t-\tau)F(\tau))(t) - \mathcal{I}(g_0(t-\tau)F(\tau))(0)), \tag{4.5}$$

we see that the integration over the τ_v has (by (2.24)) one of the two forms, when $\rho_v=1$ and v' is not the root (so that $j_{\lambda_v}=j_v-l$),

$$(1)\quad \mathcal{I}((w_{0l}(\tau_{v'})w_{00}(\tau_v) - w_{00}(\tau_{v'})w_{0l}(\tau_v))\cdot e^{i(\boldsymbol{\omega}'\cdot\boldsymbol{\nu}_v\tau_v+n_v\varphi^0(\tau_v))}G_v(\tau_v))(\tau_{v'}),\quad j_{\lambda_v}=0,$$

$$(2)\quad \mathcal{I}(g_0(\tau_{v'}-\tau_v)\cdot e^{i(\boldsymbol{\omega}'\cdot\boldsymbol{\nu}_v\tau_v+n_v\varphi^0(\tau_v))}G_v(\tau_v))(\tau_{v'}),\quad 0<j_{\lambda_v}<l, \tag{4.6}$$

where $G_v(\tau_v)$ is a function that depends on the structure of the tree formed by the nodes preceding v and by the labels attached to the nodes. If $\rho_v=0$ it has one of the two forms

$$(1)\quad w_{00}(\tau_{v'})\mathcal{I}(w_{0l}(\tau_v)e^{i(\boldsymbol{\omega}'\cdot\boldsymbol{\nu}_v\tau_v+n_v\varphi^0(\tau_v))}G_v(\tau_v))(0),\quad j_{\lambda_v}=0,$$

$$(2)\quad \mathcal{I}(g_0\tau_v e^{i(\boldsymbol{\omega}'\cdot\boldsymbol{\nu}_v\tau_v+n_v\varphi^0(\tau_v))}G_v(\tau_v))(0),\quad 0<j_{\lambda_v}<l. \tag{4.7}$$

When v' is the root the operations involved in the evaluation of the τ_v-integral are slightly different *if* $j_{\lambda_{v_0}}=j_{v_0}$, i.e., if we are considering contributions to the action coordinates (if $j_{\lambda_{v_0}}=j_{v_0}-l$ we still have integrations of the form (4.6) or (4.7)). If $j_{\lambda_{v_0}}=j_{v_0}$ the integrations are particularly simple if we are interested in the evaluation of the splitting vector (1.7), that is $j_{v_0}>l$ and $t=0$; in such a case the last two of (2.24) are relevant and setting $v=v_0$ the integration over τ_{v_0} is the value for $\tau_{v'}$ of

$$(1)\quad \mathcal{I}(w_{00}(\tau_v)e^{i(\boldsymbol{\omega}'\cdot\boldsymbol{\nu}_v\tau_v+n_v\varphi^0(\tau_v))}G_v(\tau_v))(0),\quad j_{\lambda_v}=l,$$

$$(2)\quad \mathcal{I}(e^{i(\boldsymbol{\omega}'\cdot\boldsymbol{\nu}_v\tau_v+n_v\varphi^0(\tau_v))}G_v(\tau_v))(0),\quad j_{\lambda_v}>l, \tag{4.8}$$

because, if $\tau_{v'}=0$, one has $w_{ll}(0)=1$ and $w_{l0}(0)=0$; see (2.14) and the last two of (2.24).

More generally, if $\tau_{v_0'}=t\neq 0$, setting $v=v_0$ and $r=v_0'$, one defines for $\rho_{v_0}=1$,

$$
\begin{aligned}
&(1)\quad \mathcal{I}((w_{0l}(\tau_{v'})w_{00}(\tau_v)-w_{00}(\tau_{v'})w_{0l}(\tau_v))\cdot e^{i(\boldsymbol{\omega}'\cdot\boldsymbol{\nu}_v\tau_v+n_v\varphi^0(\tau_v))}G_v(\tau_v))(\tau_{v'}),\quad j_{\lambda_v}=0,\\
&(2)\quad \mathcal{I}(g_0(\tau_{v'}-\tau_v)\cdot e^{i(\boldsymbol{\omega}'\cdot\boldsymbol{\nu}_v\tau_v+n_v\varphi^0(\tau_v))}G_v(\tau_v))(\tau_{v'}),\quad 0<j_{\lambda_v}<l,\\
&(3)\quad \mathcal{I}((w_{ll}(\tau_{v'})w_{00}(\tau_v)-w_{l0}(\tau_{v'})w_{0l}(\tau_v))\cdot e^{i(\boldsymbol{\omega}'\cdot\boldsymbol{\nu}_v\tau_v+n_v\varphi^0(\tau_v))}G_v(\tau_v))(\tau_{v'}),\quad j_{\lambda_v}=l,\\
&(4)\quad \mathcal{I}(e^{i(\boldsymbol{\omega}'\cdot\boldsymbol{\nu}_v\tau_v+n_v\varphi^0(\tau_v))}G_v(\tau_v))(\tau_{v'}),\quad j_{\lambda_v}>l,
\end{aligned}
\tag{4.9}
$$

(see the last two relations in (2.24)) and for $\rho_{v_0}=0$

$$
\begin{aligned}
&(1)\quad w_{00}(\tau_{v'})\mathcal{I}(w_{0l}(\tau_v)e^{i(\boldsymbol{\omega}'\cdot\boldsymbol{\nu}_v\tau_v+n_v\varphi^0(\tau_v))}G_v(\tau_v))(0),\quad j_{\lambda_v}=0,\\
&(2)\quad \mathcal{I}(g_0\tau_v e^{i(\boldsymbol{\omega}'\cdot\boldsymbol{\nu}_v\tau_v+n_v\varphi^0(\tau_v))}G_v(\tau_v))(0),\quad 0<j_{\lambda_v}<l.\\
&(3)\quad w_{l0}(\tau_{v'})\mathcal{I}(w_{0l}(\tau_v)e^{i(\boldsymbol{\omega}'\cdot\boldsymbol{\nu}_v\tau_v+n_v\varphi^0(\tau_v))}G_v(\tau_v))(0),\quad j_{\lambda_v}=l,\\
&(4)\quad 0,\quad j_{\lambda_v}>l;
\end{aligned}
\tag{4.10}
$$

note that, for $\tau_{v'}=t=0$ and $j_{\lambda_{v_0}}\geqslant l$, (4.9) and (4.10), summed together, give (4.8).

Hence each node still describes a rather complicated set of operations: it is, therefore, convenient to consider separately the terms that appear in (4.6)–(4.10). This can be done by simply adding further labels at each node. To this end, looking at the integrals in (4.7) and (4.10), at $\rho_v=0$, and in (4.6) and (4.9), at $\rho_v=1$, we see that the following kernels are involved in the integrals:

$$
\begin{aligned}
&w^0_{j_{\lambda_v}}(\tau_{v'},\tau_v)=\begin{cases} w_{00}(\tau_{v'})w_{0l}(\tau_v), & v>v_0,\ j_v=l\rightarrow j_{\lambda_v}=0,\\ g_0\tau_v, & v>v_0,\ j_v>l\rightarrow 0<j_{\lambda_v}<l,\end{cases}\\
&w^0_{j_{\lambda_{v_0}}}(t,\tau_{v_0})=\begin{cases} w_{00}(t)w_{0l}(\tau_{v_0}), & j_{v_0}=l,\quad j_{\lambda_{v_0}}=0,\\ g_0\tau_{v_0}, & j_{v_0}>l,\quad 0<j_{\lambda_{v_0}}<l,\\ w_{l0}(t)w_{0l}(\tau_{v_0}), & j_{v_0}=l,\quad j_{\lambda_{v_0}}=l\\ 0, & j_{v_0}>l,\quad j_{\lambda_{v_0}}>l,\end{cases}\\
&w^1_{j_{\lambda_v}}(\tau_{v'},\tau_v)=\begin{cases} w_{0l}(\tau_{v'})w_{00}(\tau_v)-w_{00}(\tau_{v'})w_{0l}(\tau_v), & v>v_0,\ j_v=l\rightarrow j_{\lambda_v}=0,\\ g_0(\tau_{v'}-\tau_v), & v>v_0,\ j_v>l\rightarrow 0<j_{\lambda_v}<l,\end{cases}\\
&w^1_{j_{\lambda_{v_0}}}(t,\tau_{v_0})=\begin{cases} w_{0l}(t)w_{00}(\tau_{v_0})-w_{00}(t)w_{0l}(\tau_{v_0}), & j_{v_0}=l,\quad j_{\lambda_{v_0}}=0,\\ g_0(t-\tau_{v_0}), & j_{v_0}>l,\quad 0<j_{\lambda_{v_0}}<l,\\ w_{ll}(t)w_{00}(\tau_{v_0})-w_{l0}(t)w_{0l}(\tau_{v_0}), & j_{v_0}=l,\ j_{\lambda_{v_0}}=l,\\ 1, & j_{v_0}>l,\quad j_{\lambda_{v_0}}>l,\end{cases}
\end{aligned}
\tag{4.11}
$$

respectively appearing in (4.7) and (4.10), at $\rho_v=0$, and in (4.6) and (4.9), at $\rho_v=1$.

The function in (4.11) involving the Wronskian matrix elements can be computed from (2.14) and one finds, for instance, that the function in the seventh row on the r.h.s. is

$$w_{0l}(\tau_{v'})w_{00}(\tau_v)-w_{00}(\tau_{v'})w_{0l}(\tau_v)=\frac{1}{2}\left\{\frac{g_0(\tau_{v'}-\tau_v)}{\cosh g_0\tau_{v'}\cosh g_0\tau_v}+\frac{\sinh g_0\tau_{v'}}{\cosh g_0\tau_v}-\frac{\sinh g_0\tau_v}{\cosh g_0\tau_{v'}}\right\};\tag{4.12}$$

hence if we consider (4.6)–(4.10) we note that the integrals over τ_v involve functions that can be written, for $\rho=\rho_v$, $\tau=\tau_v$, $\tau'=\tau_{v'}$ and for suitable coefficients $c_j(\rho,\alpha,v)$, ($\rho=1$ if we consider (4.6), (4.9) and $\rho=0$ if we consider (4.7), (4.10)),

$$\sum_{\alpha=-1}^{2}T_\rho^{(\alpha)}(\rho\tau',\tau)Y^{(\alpha)}(\tau',\tau)c_j(\rho,\alpha,v),\tag{4.13}$$

where $Y^{(\alpha)}(\tau',\tau)$ are given, if $x=e^{-\sigma g_0\tau}$ and $x'=e^{-\sigma g_0\tau'}$, by

$$\begin{aligned}
Y^{(-1)}(\tau',\tau)&=\frac{1}{2}\frac{\sinh g_0\tau}{\cosh g_0\tau'}\exp[in\varphi^0(\tau)]=\sum_{k'=1}^{\infty}\sum_{k=-1}^{\infty}y_n^{(-1)}(k',k)x'^{k'}x^k,\\
Y^{(0)}(\tau',\tau)&=\frac{1}{2}\frac{\exp[in\varphi^0(\tau)]}{\cosh g_0\tau'\cosh g_0\tau}=\sum_{k'=1}^{\infty}\sum_{k=1}^{\infty}y_n^{(0)}(k',k)x'^{k'}x^k,\\
Y^{(1)}(\tau',\tau)&=\frac{1}{2}\frac{\sinh g_0\tau'}{\cosh g_0\tau}\exp[in\varphi^0(\tau)]=\sum_{k'=-1}^{\infty}\sum_{k=1}^{\infty}y_n^{(1)}(k',k)x'^{k'}x^k,\\
Y^{(2)}(\tau',\tau)&=\exp[in\varphi^0(\tau)]=\sum_{k=0}^{\infty}\tilde{y}_n^{(2)}(0,k)x^k,\quad k'\equiv 0;
\end{aligned}\tag{4.14}$$

(with k' odd in the first three functions), which define the coefficients $y_n^{(\alpha)}(k',k)$ for $\alpha=-1,0,1,2$ (it is easily checked that k' is *odd* in the first three relations) and we set, for $\alpha=-1,0,1,2,$

$$T_\rho^{(\alpha)}(\rho\tau',\tau)=\begin{cases}g_0(\tau'-\tau) & \text{if } \alpha \text{ is either 0 or 2 and } \rho=1,\\ g_0\tau & \text{if } \alpha \text{ is either 0 or 2 and } \rho=0,\\ 1 & \text{if } \alpha \text{ is either } -1 \text{ or } 1.\end{cases}\tag{4.15}$$

Likewise we shall set, defining the coefficients $\tilde{y}_n^{(\alpha)}(k',k)$, for $\alpha=-1,0,1$, and $\overline{y}_n^{(-1)}(k',k)$,

$$\begin{aligned}
\tilde{Y}^{(\alpha)}(\tau',\tau)&=-\tanh g_0\tau' Y^{(\alpha)}(\tau',\tau)\stackrel{\text{def}}{=}\sum_{k'=-\alpha}^{\infty}\sum_{k=\alpha}^{\infty}\tilde{y}_n^{(\alpha)}(k',k)x'^{k'}x^k,\quad \alpha=\pm 1,\\
\tilde{Y}^{(0)}(\tau',\tau)&=-\tanh g_0\tau' Y^{(0)}(\tau',\tau)\stackrel{\text{def}}{=}\sum_{k'=1}^{\infty}\sum_{k=1}^{\infty}\tilde{y}_n^{(0)}(k',k)x'^{k'}x^k,\\
\tilde{Y}^{(2)}(\tau',\tau)&=Y^{(2}(\tau',\tau)\stackrel{\text{def}}{=}\sum_{k=1}^{\infty}\tilde{y}_n^{(2)}(0,k)x^k,\\
\overline{Y}^{(1)}(\tau',\tau)&=\frac{\cosh g_0\tau'}{\cosh g_0\tau}\exp[in\varphi^0(\tau)]\stackrel{\text{def}}{=}\sum_{k'=-1}^{\infty}\sum_{k=1}^{\infty}\overline{y}_n^{(1)}(k',k)x'^{k'}x^k,\\
\tilde{T}_1^{(0)}(\tau',\tau)&=g_0(\tau'-\tau),\quad \tilde{T}_1^{(2)}(\tau',\tau)\equiv 1,\quad \tilde{T}_0^{(0)}(0,\tau)=T_0^{(0)},
\end{aligned}\tag{4.16}$$

where k' is odd except that for $\tilde{Y}^{(2)}(\tau',\tau)$; in all other cases the $T,\tilde{T},\overline{T}$-functions will be defined 1 (no matter which is the value of the labels that we attribute to them); this is done to uniformize the notation.

The label k will be called the *incoming hyperbolic mode* and k' the *outgoing hyperbolic mode* for reasons that become clear by contemplating (4.19) below.

In terms of (4.14)–(4.16) the functions (4.11) multiplied by $\exp[in_v\varphi^0(\tau_v)]$ can be expressed as in (4.13), thus defining implicitly the coefficients $c_j(\rho,\alpha,v)$ in (4.13),

$$
\begin{aligned}
& w^0_{j_{\lambda_v}}(\tau_{v'},\tau_v)\exp[in_v\varphi^0(\tau_v)] \\
&\quad = \begin{cases} T_0^{(0)}(0,\tau_v)Y^{(0)}(\tau_{v'},\tau_v)+Y^{(-1)}(\tau_{v'},\tau_v), & j_{\lambda_v}=j_v-l=0, \\ T_0^{(2)}(0,\tau_v)Y^{(2)}(\tau_{v'},\tau_v), & 0<j_{\lambda_v}=j_v-l<l, \end{cases} \\
& w^0_{j_{\lambda_{v_0}}}(t,\tau_{v_0})\exp[in_{v_0}\varphi^0(\tau_{v_0})] \\
&\quad = \begin{cases} T_0^{(0)}(0,\tau_{v_0})Y^{(0)}(t,\tau_{v_0})+Y^{(-1)}(t,\tau_{v_0}), & j_{\lambda_{v_0}}=j_{v_0}-l=0, \\ T_0^{(2)}(0,\tau_{v_0})Y^{(2)}(t,\tau_{v_0}), & 0<j_{\lambda_{v_0}}=j_{v_0}-l<l, \\ \tilde{T}_0^{(0)}(0,\tau_{v_0})\tilde{Y}^{(0)}(t,\tau_{v_0})+\tilde{Y}^{(-1)}(t,\tau_{v_0}), & j_{v_0}=j_{\lambda_{v_0}}=l, \\ 0, & j_{v_0}=j_{\lambda_{v_0}}>l, \end{cases} \\
& w^1_{j_{\lambda_v}}(\tau_{v'},\tau_v)\exp[in_v\varphi^0(\tau_v)] \\

\end{aligned}
\tag{4.17}
$$

One could avoid introducing the $\tilde{T}$ functions as they are simply related to the T functions or are just identically 1: however it is convenient to introduce them to make the above formulas more symmetric and therefore easier to keep in mind while working with.

Finally, we define the coefficients $\xi_j(k',0)$ by the power series expansion,

$$\frac{1}{\cosh g_0\tau'}=\sum_{k'=1}^{\infty}\xi_l(k',0)x'^{k'},\quad k'\geqslant 1,\ \text{odd},$$
$$1=\xi_j(0,0),\quad j>l, \tag{4.18}$$

where $x'=e^{-\sigma g_0\tau'}$ and k' is odd, which occurs as coefficient $w_{00}(\tau')$ in (4.7) (when $\rho_v=0$, i.e., $v\in\Theta_L$).

The above definitions (taken from (42) and (45) in Ref. 5) suffice to discuss the whiskers (and therefore the splitting in the action variables).

The (4.13) allow us to introduce a ''relatively simple notation;'' we can add to each node a *badge* label $\alpha_v=(-1,0,1,2)$ that will distinguish which choice we make between the possibilities in (4.14) and (4.16) and two *hyperbolic mode* labels k'_v, k_v which select which particular term we choose in the sums in (4.14) and (4.16); they are integer numbers $\geqslant -1$. We shall not have to introduce labels to distinguish terms coming from the expansions of $Y^{(\alpha)}$, $\tilde{Y}^{(\alpha)}$, $\overline{Y^{(\alpha)}}$ bearing the same badge α because one can check that the labels α_v together with j_v and v itself uniquely determine which choice has to be made.

In terms of the latter labels we can define a *hyperbolic momentum* of a line λ_v as a label $p(v)\in\mathbb{Z}$ which will be the sum of all the hyperbolic modes of the nodes that precede v *plus* the incoming hyperbolic mode of the node v itself: this is the sum of the labels k_w associated with all free nodes $w\leqslant v$, with v included, and of the labels k'_w associated with all the *free* nodes $w<v$ or *highest* nodes of the leaves $w<v$, with v *not* included,

$$p(v)=k_v+\sum_{\substack{w\in\vartheta_f\\ w<v}}(k_w+k'_w)+\sum_{\substack{w\in\Theta_L\\ w<v}}k'_w. \tag{4.19}$$

A *very important property* is that $k_w+k'_w\geqslant 0$, by (4.14) and (4.16), and $k'_w\geqslant 0$ if $w\in\Theta_L$, by (4.18), so that $p(v)\geqslant -1$. Furthermore if $p(v)=0$ then *either* $k_v=-1$ and $k_w+k'_w=0$ for all $w<v$ except one single node $\tilde{w}<v$ (which is either in ϑ_f or Θ_L) for which $k_{\tilde{w}}+k'_{\tilde{w}}=1$, *or* $k_v=0$ and $k_w+k'_w=0$ for all $w<v$. If $p(v)=-1$ then $k_v=-1$ and $k_w+k'_w=0$ for all $w<v$.

In the above analysis we have not taken explicitly into account the possibility of contributions to $\Phi_+^{h\sigma}$ coming from the third line in (2.11), i.e., counterterm contributions. They are, of course, possible and they can be taken immediately into account in the graphical representation by considering the nodes with a label $\delta_v=0$ and adding to them a *counterterm label* κ_v, a non-negative integer. If $\kappa_v=0$ this will mean that the node represents a contribution from the first line of the definition of $\Phi_+^{h\sigma}$, i.e., a contribution that is unrelated to the counterterms, while if $\kappa_v\geqslant 1$ the node represents a contribution from the term with $p=\kappa_v$ in the second line contribution to $\Phi_+^{h\sigma}$ in (2.11).

4.3. The trees carry, at this point, quite a few decorating labels and each tree together with all its labels will represent a ''very simple'' contribution to the value of the hth order coefficient in the Taylor expansion in ε (at fixed η of course) of the $\Xi_{h\sigma}$ vector. Very simple means that the improper integrals that correspond to each term are very easy to evaluate explicitly and lead to a result that can be expressed as a product of factors determined by the labels of the tree and associated with the nodes and with the lines, see (4.30), below. We list here the set of labels that have been introduced,

j_v	action labels,
j_{λ_v}	branch labels,
δ_v	order labels,
ρ_v	leaf labels,
ν_v	mode labels,
$\boldsymbol{\nu}(v)$	momentum in the branch λ_v following v,

$\boldsymbol{\nu}_0(v)$	free momentum in the branch λ_v following v,
α_v	badge labels,
(k'_v,k_v)	hyperbolic mode labels,
$p(v)$	hyperbolic momentum in the branch λ_v following v,
κ_v	counterterm labels.

There are some constraints between the labels, which follow from the rules stated in Secs. IV, 4.1 and IV, 4.2 and from the choice of the counterterms (the latter will be discussed in Sec. IV, 4.5 below),

(1) one has $j_{\lambda_v}=j_v-l$ if $v<v_0$ and $j_{\lambda_v}=j_v$ or $j_{\lambda_v}=j_v-l$ if $v=v_0$ (see Sec. IV, 4.1);
(2) if $\rho_v=0$ then $\alpha_v\neq 1$, (see (4.17));
(3) if $j_{\lambda_v}\neq 0$, l, then $\alpha_v=2$, otherwise if $j_{\lambda_v}=0,l$, then α_v can be -1, 0, 1, (see (4.17));
(4) $\delta_v=0$ implies $j_v=l$ (by the $\boldsymbol{\alpha}$-independence of f_0);
(5) k_v, k'_v, $p(v)\geqslant -1$, (see (4.14), (4.16) and comment following (4.19));
(6) $(p(v),\boldsymbol{\nu}_0(v))\neq(0,\mathbf{0})$, see Remark 4.6 below.

In terms of such labels, given a decorated tree ϑ_0 with m_0 nodes and with highest node v_0, we can define the *value* of a *subtree* ϑ with m free nodes, highest node w (preceding the highest node v_0 of ϑ_0: $w\leqslant v_0$) and label $j_{\lambda_w}=0,...,l-1$, $\rho_w=0,1$. It will be given by the expression

$$\mathrm{Val}(\vartheta)=\left[\prod_{\substack{v\in\vartheta_f\\ v\leqslant w}}\int_{\sigma\infty}^{\rho_v g_0\tau_{v'}}dg_0\tau_v\mathcal{V}_v(\vartheta)\right]\left[\prod_{v\in\Theta_L}\mathcal{L}_v(\vartheta)\right]\left[\prod_{\substack{v\in\vartheta_f\\ \delta_v=0}}\gamma_{\kappa_v}(g_0)\right], \tag{4.20}$$

where the integration is the improper integration $\mathcal{I}$ (in the sense of Sec. II, 2.4), the tree ϑ consists of a ''free'' m-nodes tree ϑ_f with leaves attached to a (possibly empty) subset of the nodes of ϑ_f, and the following notation has been used:

(i) The coefficients $\mathcal{V}_v(\vartheta)$ and $\mathcal{L}_v(\vartheta)$ are described by the collection of labels enumerated above. They can be written, respectively, as

$$\mathcal{V}_v(\vartheta)=\overline{F}_{\underline{\nu}_v}\hat{T}^{(\alpha_v)}_{\rho_v}(\rho_v\tau_{v'},\tau_v)e^{i\boldsymbol{\omega}'\cdot\boldsymbol{\nu}_v\tau_v}x_v^{k_v}\prod_{\substack{w\in\vartheta\\ w'=v}}x_v^{k'_w}(-1)^{\delta_{\alpha_v,-1}}\hat{y}^{(\alpha_v)}_{n_v}(k'_v,k_v), \tag{4.21}$$

and

$$\mathcal{L}_v(\vartheta)=\xi_{j_v}(k'_v,0)L^{h_v\sigma}_{j_v\boldsymbol{\nu}(v)}(\vartheta), \tag{4.22}$$

where $x_v=\exp[-\sigma g_0\tau_v]$ and $\hat{y}^{(\alpha_v)}_{n_v}$, $\hat{T}^{(\alpha_v)}_{\rho_v}$ are (see (4.17)) either

(a) $y^{(\alpha_v)}_{n_v}$, $T^{(\alpha_v)}_{\rho_v}$, if either $v<v_0$ or $v=v_0$ and $j_{\lambda_{v_0}}=j_{v_0}-l$, or
(b) $\tilde{y}^{(\alpha_v)}_{n_v}$ or $\overline{y}^{(1)}_{n_v}$ and $\tilde{T}^{(\alpha_v)}_{\rho_v}$ or $\overline{T}^{(\alpha_v)}_{\rho_v}$, if $v=v_0$ and $j_{\lambda_{v_0}}=j_{v_0}$.

Furthermore $\rho_v=1$ if $v<w$, while ρ_w can be either 0 or 1; j_{λ_w} can have any value $0,...,2l-1$ if $w=v_0$, in any other case $j_{\lambda_v}=0,...,l-1$ (see above). In (4.21)

$$\overline{F}_{\underline{\nu}_v}=\left(\frac{J_0}{J}\right)^{(1-\delta_{j_v,l})(1-\delta_{j_v,j_{\lambda_v}})}f^{\delta_v}_{\underline{\nu}_v}\left[(-i\nu_v)_{j_v-l}\prod_{\substack{w\in\vartheta\\ w'=v}}(i\nu_v)_{j_w-l}\right] \tag{4.23}$$

depends on the labels $(\delta,\underline{\nu},j)$ of the node v and of its predecessors w's (recall that by (2.2) $\underline{\nu}_v=(n_v,\boldsymbol{\nu}_v)$); in (4.22) the quantity $L^{h_v\sigma}_{j_v\boldsymbol{\nu}(v)}(\vartheta)$ is called the ''*value of the leaf*'' v of order h_v (see item (v) below for its definition). The matrix J is not, in general, a multiple of the identity and J_0J^{-1} will be interpreted as acting on the rotator components of $\underline{\nu}_v$ (and it will be 1 when raised to the power 0).

(i) For the purposes of the cancellations analysis performed in Appendix C, the exact form of a few coefficients among the $y_{n_v}^{(\alpha_v)}(k_v',k_v)$'s turns out to be essential, so that we list them here,

$$\begin{gathered} y_{n_v}^{(-1)}(2,-1)=0,\quad y_{n_v}^{(-1)}(1,-1)=\sigma/2,\quad y_{n_v}^{(-1)}(1,0)=2in_v,\\ y_{n_v}^{(1)}(0,1)=0,\quad y_{n_v}^{(1)}(-1,1)=\sigma/2,\quad y_{n_v}^{(1)}(-1,2)=2in_v,\\ y_{n_v}^{(2)}(1,0)=0,\quad y_{n_v}^{(2)}(0,0)=1,\quad y_{n_v}^{(2)}(0,1)=4in_v\sigma. \end{gathered}\tag{4.24}$$

The coefficients $\tilde{y}^{(-1)}(1,-1)$, $\tilde{y}^{(-1)}(1,0)$, $\tilde{y}^{(1)}(-1,1)$ and $\overline{y}^{(1)}(-1,2)$ are equal to the corresponding (i.e., with the same values of the labels k',k) $y^{(\alpha)}(k',k)$ coefficients.

(ii) The value of a leaf with highest node v in (4.22) is *not* the same as the value $L_{j_v\boldsymbol{\nu}(v)}^{h_v\sigma}$ in Ref. 5; this is because of the above mentioned change in notation (see the sixth item in Sec. IV 1). In Ref. 5 leaf values are defined as sums of the values of all leaves (in the sense we use now) with fixed order, action label and total momentum. Then the leaf value considered here, $L_{j_v\boldsymbol{\nu}(v)}^{h_v\sigma}(\vartheta)$, is a single contribution to the $L_{j_v\boldsymbol{\nu}(v)}^{h_v\sigma}$ of Ref. 5, and depends *only* on the part of the tree ϑ consisting of the nodes $w\leqslant v$; if we call ϑ_v such a subtree, we can write (*temporarily, just for the purposes of comparison*) the present definition of leaf value as $L_{j_v\boldsymbol{\nu}(v)}^{h_v\sigma}(\vartheta)\equiv\overline{L}_{j_v\boldsymbol{\nu}(v)}^{h_v\sigma}(\vartheta_v)$ (as it depends only on the labels of the subtree ϑ_v). In order to make a link between the different notations note that $L_{j\boldsymbol{\nu}}^{h\sigma}$ in Ref. 5 would be, with our present notations, just the sum

$$L_{j\boldsymbol{\nu}}^{h\sigma}\overset{\text{def}}{=}\sum_{\substack{\vartheta_{v_0}\in\mathcal{T}_{\boldsymbol{\nu},h}\\ j_{v_0}=j}}\overline{L}_{j\boldsymbol{\nu}}^{h\sigma}(\vartheta_{v_0}),\tag{4.25}$$

where ϑ_{v_0} is the part of the tree ϑ on which the leaf value really depends and $\mathcal{T}_{\boldsymbol{\nu},h}$ is defined after (4.27) below.

Coming back to our notations we define the *leaf value* $L_{j\boldsymbol{\nu}}^{h\sigma}(\vartheta)$, with $j=j_{v_0}$, (where the the first and third of (4.11) should be used), to be the value of a tree ϑ with $j_{\lambda_{v_0}}=j_{v_0}-l$ and $\rho_{v_0}=0$.

(iii) By construction (see (2.11) and corresponding comments), and if Θ_L is the set of highest nodes in the leaves, the total perturbation order k of ϑ is

$$k=\sum_{\substack{v\in\vartheta_f\\ \delta_v=0}}\kappa_v+\sum_{v\in\vartheta_f}\delta_v+\sum_{v\in\Theta_L}h_v=\sum_{\substack{v\in\vartheta\\ \delta_v=0}}\kappa_v+\sum_{v\in\vartheta}\delta_v,\quad m<2k.\tag{4.26}$$

(iv) Both the counterterms and the leaf values of a given perturbation order are recursively defined in terms of the same quantities with lower orders. In fact $\gamma_\kappa(g_0)$ admits a graphical representation as sum of tree values defined as in (4.20) with the difference that the integration operation corresponding to the highest node of the tree has to be suitably modified (see (4.32) below).

If Val(ϑ) is defined as in (4.20) (and in item (iv) above) then, by construction, one has

$$\Xi_j^{h\sigma}(t;\boldsymbol{\alpha})=\sum_{\boldsymbol{\nu}\in\mathbb{Z}^{l-1}}\Xi_{j\boldsymbol{\nu}}^{h\sigma}(t)e^{i\boldsymbol{\nu}\cdot\alpha},\quad \Xi_{j\boldsymbol{\nu}}^{h\sigma}(t)=\frac{1}{m_0!}\sum_{\substack{\vartheta_0\in\mathcal{T}_{\boldsymbol{\nu},h}\\ j_{\lambda_{v_0}}=j}}\text{Val}(\vartheta_0),\tag{4.27}$$

where $\mathcal{T}_{\boldsymbol{\nu},h}$ is the collection of all trees with total momentum $\boldsymbol{\nu}$ and order h. In (4.27) $m_0!^{-1}$ is a combinatorial factor, which depends on the way we count trees: the simplest is to think that the tree branches of ϑ are pairwise distinct and are distinguished by a label $1,2,\dots,m_0$, if m_0 is the number of nodes in the tree ϑ. In the latter case, which corresponds to our choice, the factor is simply $m_0!^{-1}$, see Refs. 3, 5, provided we regard as identical two trees that can be overlapped by pivoting the branches entering a node (rigidly, together with the subtree attached to them) around any node; as in Ref. 3 we shall call *numbered trees* the trees so counted.

4.4 *Remark:* Since the value of any leaf with highest node v depends only on the labels of the nodes $w \leqslant v$, Eq. (4.20) factorizes into a product of leaf values times a product of counterterms (whose value, so far arbitrary, has still to be specified and it will be, in the analysis between (4.31) and (4.32) when intervening compatibility requirements will dictate its value) times a factor

$$\left[\prod_{\substack{v\in\vartheta_f\\ v\leqslant w}} \int_{\sigma\mu}^{\rho_v g_0 \tau_{v'}} dg_0 \tau_v \mathcal{V}_v(\vartheta)\right]\left[\prod_{v\in\Theta_L} \xi_v(k'_v,0)\right], \tag{4.28}$$

which does not depend on the leaves.

4.5. The extra effort with respect to the approach without counterterms developed in Refs. 3 and 10, gives here (as in Ref. 5) a reward; few combinations of powers of the ‘‘times’’ τ_v appear in the integrand in (4.21). The time variables, by (4.21) and (4.14)–(4.17), appear only via exponentials like

$$e^{-\sigma(\tau_v-\tau_{v'})a} \quad \text{or} \quad (\tau_{v'}-\tau_v)e^{-\sigma(\tau_v-\tau_{v'})a}, \tag{4.29}$$

for some complex $a=(g_0 p(v)-i\sigma\boldsymbol{\omega}'\cdot\boldsymbol{\nu}_0(v))$, yielding, respectively, upon integration, a^{-1} or a^{-2}. Note also that by the hierarchical structure of the trees one has $\sigma(\tau_{v'}-\tau_v)\geqslant 0$.

This greatly simplifies the actual performance of the integration operations which, once one gets familiarity with the formalism, are trivial. One can say that the absence of high powers of the τ_v's is due to having *a priori* fixed the Lyapunov exponent g_0 by means of the counterterms (by contrast in Refs. 3, 10 arbitrary powers of τ_v appeared because g_0 is *not* fixed *a priori*).

Of course the triviality of the integrations is entirely due to the above *very fine* decomposition, into terms identified by labeled trees, of the more compact (but ‘‘difficult’’ to integrate) integrands appearing in (4.6)–(4.12) and in the middle terms in (4.14).

Once all the integration operations will have been performed, the tree value in (4.20) will become a product of ‘‘*factors*,’’ in complete analogy with what one is accustomed to find when defining *Feynman graphs* in Field Theory. The factors are associated with the nodes v and with the branches λ_v. The value of a tree ϑ will then be *defined* as

$$\begin{aligned}\mathrm{Val}(\vartheta)=e^{i\boldsymbol{\omega}'\cdot\boldsymbol{\nu}_0(v_0)t-\sigma g_0[k'_{v_0}+p(v_0)]t}&\left[\prod_{\substack{\lambda_v\in\vartheta\\ v\in\vartheta_f}}\left(-\frac{\sigma g_0}{g_0 p(v)-i\sigma\boldsymbol{\omega}'-\boldsymbol{\nu}_0(v)}\right)^{r_v}\right]\\ &\cdot\left[\prod_{v\in\vartheta_f}\overline{F}_{\underline{\nu}_v}(-1)^{\delta_{\alpha_v,-1}}y_{n_v}^{(\alpha_v)}(k'_v,k_v)\right]\\ &\cdot\left[\prod_{v\in\Theta_L}\xi_{j_v}(k'_v,0)L_{j_v\nu}^{h_v\sigma}(\vartheta)\right]\left[\prod_{\substack{v\in\vartheta_f\\ \delta_v=0}}\gamma_{\kappa_v}(g_0)\right],\end{aligned} \tag{4.30}$$

where r_v is either 1 or 2, and the case $(\boldsymbol{\nu}_0(v),p(v))=(\mathbf{0},0)$ has to be *excluded* for any node $v \in \vartheta_f$. This is not to claim that no trees with $\boldsymbol{\nu}_0(v)=\mathbf{0}$, $p(v)=0$ can be drawn by following the above rules; this is a *further rule* to impose on the labels in order that the analysis does not become contradictory requires fixing the function $\gamma(\varepsilon,g_0)$ conveniently; the consistence criterion determines $\gamma(\varepsilon,g_0)$ uniquely. This rule is a natural extension of the corresponding rule holding in perturbation theory of KAM tori, which was discussed by Lindstedt and Newcomb for the lowest orders of the perturbation expansions and which was proved to hold at all orders by Poincaré;[15] see the last paragraph in Sec. II, 2.4 above and the Remark 4.6, (c), below.

The values of the numbers r_v arise from the time variables integrals via the mechanism just illustrated above (whereby one either gets a^{-1} or a^{-2} from the integration of the functions (4.29)).

The factors $-(\sigma g_0)^{r_v}[g_0 p(v)-i\boldsymbol{\omega}'\cdot\boldsymbol{\nu}_0(v)]^{-r_v}$, associated with the branches, will be called *propagators* or *small divisors*. The first name arises from the possible interpretation of the trees as Feynman graphs of a suitable field theory, see Ref. 17; the second name corresponds to the usual name given in Mechanics to such expressions generated by perturbation expansions.

It can be useful to write, if v_0 is the highest node of ϑ and $j_{\lambda_{v_0}}=0$,

$$\mathrm{Val}(\vartheta)=e^{i\boldsymbol{\omega}'\cdot\boldsymbol{\nu}_0(v_0)t-\sigma g_0[k'_{v_0}+p(v_0)]t}\left(-\frac{\sigma g_0}{g_0 p(v_0)-i\sigma\boldsymbol{\omega}'\cdot\boldsymbol{\nu}_0(v_0)}\right)^{r_{v_0}}\overline{\mathrm{Val}}(\vartheta), \tag{4.31}$$

so defining the quantity $\overline{\mathrm{Val}}(\vartheta)$ (this is a well known kind of operation on Feynman graphs, which associates with a graph another value gruesomely called the value of the *amputated* graph, amputated tree in our case). Moreover we can define $\overline{\mathrm{Val}}(\vartheta)$ also for $(\boldsymbol{\nu}_0(v_0),p(v_0))=(\mathbf{0},0)$ as no vanishing denominator appears in its expression. It is however clear that nodes with $(\boldsymbol{\nu}_0(v),p(v_0))=(\mathbf{0},0)$ must not appear at all in the trees that we consider, for (4.30) to make sense as it is written. This implies, not surprisingly, a consistence problem, namely, one has to check that the sum of all the $\overline{\mathrm{Val}}(\vartheta)$ over trees of a given order and with $(\boldsymbol{\nu}_0(v_0),p(v_0))=(\mathbf{0},0)$ cancel so that lines λ_v with $(\boldsymbol{\nu}_0(v),p(v_0))=(\mathbf{0},0)$ never appear, neither for $v=v_0$ nor for $v<v_0$.

The cancellation is made possible because we still have freedom to fix the counterterms and *their choice is in fact uniquely determined by the conditions that they be such that the needed cancellation takes place*. The quantities $\overline{\mathrm{Val}}(\vartheta)$ are convenient in order to find and to express the counterterms and also the ''resonance values'' introduced later (see Appendix C). One checks, see Appendix A, that the counterterms can be explicitly written, if $\mathcal{T}_{\boldsymbol{\nu},h}$ is the collection of all trees with total momentum $\boldsymbol{\nu}$ and order h, as

$$\gamma_k(g_0)=-\tfrac{1}{2}\sum^{*}_{\substack{\vartheta\in\mathcal{T}_{0,\kappa},\alpha_{v_0}=-1\\ p(v_0)=0,\nu_0(v_0)=0,k'_{v_0}=1}}\overline{\mathrm{Val}}(\vartheta), \tag{4.32}$$

and the $*$ means that the sum is further restricted so that the tree contains no leaves. This choice being simply imposed by the requirement that no contribution with $(\boldsymbol{\nu}_0(v_0),p(v_0))=(\mathbf{0},0)$ can arise for $\Xi_{-}^{h\sigma}(t)$; see Appendix A.

4.6 *Remarks:* (a) The presence of the counterterms will manifest itself not only through the elimination of the trees whose value would be meaningless if evaluated via (4.30) but also, and mainly, in the fact that the elements of the algebra $\hat{\mathcal{M}}$ met in the successive integrations have a special form (namely always like one of the (4.29)) which implies that the result of the improper integrals is *not* as complicated as one could fear from (2.24). This leads to the simple expression (4.32) (see Appendix A1 of Ref. 3 for what would otherwise happen without counterterms).

(b) From (4.31) one sees that if $j_{\lambda_{v_0}}>l$ it is natural to collect together the terms with $p(v_0)=0$: for them, since $j_{\lambda_{v_0}}>l$, in (4.30) one must have $k'_{v_0}+p(v_0)=0$ by the last of (4.14). Note also that by (2.26) the case $(\boldsymbol{\nu}_0(v),p(v_0))=(\mathbf{0},0)$ is excluded. If $j_{\lambda_{v_0}}\leqslant l$ we, likewise, collect the terms with $k'_{v_0}+p(v_0)=0$ and, for similar reasons the term with $k'_{v_0}+p(v_0)=-1$ cannot be present (see again (4.14) and (4.16), and use $p(v_0)\geqslant -1$ supplemented by the relations between the labels $p(v_0)$ and k'_{v_0} which will be exhibited in Sec. V 1).

Hence the cases with $p(v_0)+k'_{v_0}=-1$ are excluded by construction [the initial data $\Xi^{h\sigma}(0,\boldsymbol{\alpha})$ were determined precisely by imposing boundedness at $\sigma t=+\infty$, i.e., by imposing the absence of divergent terms in the expansion in powers of $x=e^{-g_0\sigma t}$ which would correspond to the terms with $p(v_0)=-1$] and we see that the sum of the values of the trees with $p(v_0)+k_{v'_0}=0$ give us the equations for the actions and the angles of the invariant torus to which the

TABLE I. Possible cases when $p(v)=0,-1$.

$p(v)$	k_v	k'_v	α_v	j_v
-1	-1	odd≥ 1	-1	l
0	-1	odd≥ 1	-1	l
0	0	≥ 1	-1	l
0	0	≥ 0	2	$>l$

whiskers considered are asymptotic; the terms with $p(v_0)+k_{v'_0}=0$ asymptote to quasiperiodic functions of $\boldsymbol{\omega}t$ so that replacing $\boldsymbol{\omega}t$ by $\boldsymbol{\psi}\in T^{l-1}$ one gets a parameterization of the points on the tori in terms of a point $\boldsymbol{\psi}\in T^{l-1}$ on a ''standard torus.''

And the terms with $k'_{v_0}+p(v_0)=1$ provide the leading corrections. Since such terms are present already to order 0 (as one sees from the expression of the pendulum separatrix) the distance between a point moving on the stable manifold of the torus and the torus itself will be proportional to $x=e^{-g_0\sigma t}$ as $\sigma t\to\infty$ so that g_0 has the interpretation of Lyapunov exponent of the invariant torus; see (2.26) in Sec. II, 2.6.

(c) Summarizing, *the case* $(\boldsymbol{\nu}_0(v),p(v))=(\mathbf{0},0)$ *has to be ruled out as a consequence of* (2.25) *and of* (4.32), *respectively, for the contributions to* $\Xi^{h\sigma}_{\uparrow}$ *and to* $\Xi^{h\sigma}_{+}$ *(see the last constraint listed at the beginning of Sec. IV, 4.3). All cases with* $k'_{v_0}+p(v_0)=-1$ *are also excluded.*

V. BOUNDS

We now discuss how to bound the value of a tree or of a sum of a small number of trees which we take for simplicity without leaves and without counterterms. The more general case will be eventually reduced, see below, to the one we consider here.

We shall discuss first how to bound values of trees without leaves and counterterms such that $p(v_0)=0$ if v_0 is the highest node; hence we shall consider trees, always without leaves and counterterms, with $p(v_0)=0$. At the end we shall see how the presence of leaves and counterterms modifies the analysis.

The following discussion is ''locally'' simple, but ''globally'' delicate and repeats that in Ref. 5, Sec. IV, the conclusions are also summarized in the Tables I–IV.

From (4.19) it follows that the hyperbolic momentum $p(v)$ is $p(v)\geq -1$ and, as remarked after (4.19), $p(v)=0$ can occur only in special cases; more precisely if $p(v)=0$, then k_v is either -1 or 0, and

(1) if $k_v=0$, all free nodes w preceding v (whether immediately or not) have $k'_w+k_w=0$, while
(2) if $k_v=-1$, all free nodes w preceding v have $k'_w+k_w=0$, *except* for a single node $\tilde{w}<v$ such that $k'_{\tilde{w}}+k_{\tilde{w}}=1$.

In the latter case we call $\mathcal{P}$ the path of nodes (i.e., the totally ordered set of nodes) which connect v to $\tilde{w}$, both extremes included (see also Ref. 5, Sec. IV).

Supposing $p(v)=-1,0$ and recalling that $\alpha_v<2$ implies k'_v odd, the expansions (4.14) impose that there are *very few possible choices* of the values of the hyperbolic modes at $w\leq v$;

TABLE II. Cases $p(v)=0$, $w\notin\mathcal{P}$.

α_w	-1	0	1	2
(k'_w,k_w)	$(1,-1)$	impossible	$(-1,1)$	(0,0)
p(w)	-1	impossible	1	0
j_w	l	impossible	l	$>l$

TABLE III. Cases $p(v)=0$, $w\in\mathcal{P}$, $w>\tilde{w}$.

α_w	-1	0	1	2
(k'_w,k_w)	$(1,-1)$	impossible	$(-1,1)$	$(0,0)$
$p(w)$	0	impossible	2	1
j_w	l	impossible	l	$>l$

(1) if there is no path or there is a path linking v to $\tilde{w}$ but $w\neq\tilde{w}$ and $w\notin\mathcal{P}$, then $k_w+k_{w'}=0$ and the cases $\alpha_w=1$, $\alpha_w=-1$ and $\alpha_w=2$ require, respectively, $(k'_w,k_w)=(-1,1)$, $(k'_w,k_w)=(1,-1)$ and $(k'_w,k_w)=(0,0)$: correspondingly $p(w)=1$, $p(w)=-1$ and $p(w)=0$. While, for $w\in\mathcal{P}$, the value of $p(w)$ ''increases by one unit,'' i.e., $p(w)=2$, $p(w)=0$ and $p(w)=1$ for $w\in\mathcal{P}$;
(2) if $w=\tilde{w}$ then $k_w+k_{w'}=1$ and the cases $\alpha_{\tilde{w}}=1$, $\alpha_{\tilde{w}}=-1$ and $\alpha_{\tilde{w}}=2$ require, respectively, $(k'_{\tilde{w}},k_{\tilde{w}})=(-1,2)$, $(k'_{\tilde{w}},k_{\tilde{w}})=(1,0)$ and $(k'_{\tilde{w}},k_{\tilde{w}})=(0,1)$ (correspondingly $p(\tilde{w})=2$, $p(\tilde{w})=0$ and $p(\tilde{w})=1$).

Note that in both cases $\alpha_w=0$ is not possible.

The above analysis covers both cases $v<v_0$ and $v=v_0$, as the functions in (4.14) and in (4.16) have the same dependence on τ (hence on k).

The latter properties have to be considered as a further restriction to impose on the tree labels, and play an essential role for the discussion of the cancellations.[5]

Moreover if $p(v)=0$, then

(1) if $k_v=0$ then v can be preceded only by leaves with the highest nodes w having $j_w>l$, because k'_w must be 0 in such a case, so that the second of (4.18) applies;
(2) if $k_v=-1$, then all the leaves again must have the highest node w with $j_w>l$, except at most one leaf with highest node $\tilde{w}$ with $j_{\tilde{w}}=l$ and $k'_{\tilde{w}}=1$.

We extend the definition of path also to the case $p(v)=0$, $k_v=0$, by setting $\mathcal{P}\overset{\text{def}}{=}\emptyset$ if $j_v=l$ and $\mathcal{P}\overset{\text{def}}{=}v$ if $j_v=l$, only for purposes of notational convenience (see below). This is consistent with the above tables and does not change them.

5.2. *Remark:* Note that, if a tree (or subtree) ϑ_0 with the highest node v_0 has a total hyperbolic momentum $p(v_0)=0$, then there is one and only one path $\mathcal{P}$, and, if $\mathcal{P}\neq\emptyset$, then $\mathcal{P}$ connects the node v_0 to some node $\tilde{w}<v_0$. In fact, if there is a path $\mathcal{P}\neq\emptyset$, the node $\tilde{w}$ is so defined that $k_{\tilde{w}}+k'_{\tilde{w}}=1$; then if $k_{v_0}=0$ there cannot be any of such nodes (and $\mathcal{P}=v_0$ in such a case), while if $k_{v_0}=-1$ there must be one and only one such node. This simply follows from the analysis in Sec. V, 5.1 by noting that all nodes $w<v_0$ except $\tilde{w}$ must have $k_w+k'_w=0$.

5.3. The small divisors can be really ''small'' only when $p(v)=0$: if $p(v)\neq 0$, they are bounded by $g_0^{-r_v}$, i.e., by a quantity of order $O(1)$. So one can consider all free nodes in the trees, among the ones having $p(v)=0$, which are closest to the root. All free nodes v between them and the root have propagators which are not small because $|p(v)|\geqslant 1$ (see also Ref. 5, p. 298).

Given a tree ϑ_0 with m free nodes, from each subtree ϑ ending in a node v_0 with $p(v_0)=0$ (here v_0 is some node of ϑ_0: it becomes the highest node of ϑ), one obtains contributions which can be naturally collected together (recall Remark 4.4) into a contribution to the tree value (see (4.30)) consisting of a factor

$$\prod_{v\leqslant v_0}\overline{F}_{\underline{\nu}_v}G_v[\boldsymbol{\omega}'\cdot\boldsymbol{\nu}_0(v)]y'_v, \tag{5.1}$$

(here the product is over all free nodes preceding v_0) times a product of counterterms $\gamma_{\kappa_v}(g_0)$ for

TABLE IV. Cases $p(v)=0$, $w=\tilde{w}$.

α_w	-1	0	1	2
(k'_w,k_w)	(1,0)	impossible	$(-1,2)$	(0,1)
$p(w)$	0	impossible	2	1
j_w	l	impossible	l	$>l$

$v\in\vartheta_f$ with $\delta_v=0$, times a products of factors $\xi_{j_v}(k'_v,0)L^{h_v\sigma}_{j_v\nu(v)}$, for each $v\in\Theta_L$; see (4.30). The vector $\boldsymbol{\nu}_0(v)$ is the free momentum (defined above; see (4.2)) flowing through the branch λ_v, the coefficients y'_v are related to the expansions (4.14) via

$$y'_v=\begin{cases}\frac{1}{2}[y^{(1)}_{n_v}(-1,1)+y^{(-1)}_{n_v}(1,-1)]=\sigma/2 & \text{if } v\in\mathcal{P},\alpha_v\in\{-1,1\},\\ (-1)^{\delta_{\alpha_v,-1}}y^{(\alpha_v)}_{n_v}(k_{v'},k_v) & \text{otherwise}\end{cases} \tag{5.2}$$

where $\mathcal{P}$ denotes the path in ϑ (there is always one such path, possibly the empty set, because we suppose $p(v_0)=0$); and $G_v[\boldsymbol{\omega}'\cdot\boldsymbol{\nu}_0(v)]$ is related to the propagator of the branch λ_v, and it will have the form

$$G_v[\boldsymbol{\omega}'\cdot\boldsymbol{\nu}_0(v)]=\begin{cases} g_0^2[i\boldsymbol{\omega}'\cdot\boldsymbol{\nu}_0(v)]^{-2} & \text{if } v\notin\mathcal{P},\ j_v>l,\\ -\sigma g_0^2[g_0^2+(\boldsymbol{\omega}'\cdot\boldsymbol{\nu}_0(v))^2]^{-1} & \text{if } v\notin\mathcal{P},\ j_v=l,\\ g_0^{2-\delta_{j_v,l}}[-\sigma(g_0p(v)-i\sigma\boldsymbol{\omega}'\cdot\boldsymbol{\nu}_0(v))]^{-(2-\delta_{j_v,l})} & \text{if } v\in\mathcal{P},\ \alpha_v\neq-1,\\ g_0[i\boldsymbol{\omega}'\cdot\boldsymbol{\nu}_0(v)]^{-1} & \text{if } v\in\mathcal{P},\ \alpha_v=-1,\end{cases} \tag{5.3}$$

where $p(v)\neq0$ in the third line, because

(a) The first line is such because if $j_v>l$ one has necessarily $\alpha_v=2$, see Tables I–IV, and we have to integrate a function $g_0(\tau_{v'}-\tau_v)e^{in_v\varphi^0(\tau_v)}$ so that $k_v\geq0$; hence $k_v=p(v)=0$ and we have the second function in (4.29) to integrate.

(b) The second line is such because if $v\notin\mathcal{P}$, $j_v=l$ we have $w^1_l(\tau_{v'},\tau_v)e^{in_v\varphi^0(\tau_v)}$ which is a sum of three terms (see the third of (4.17)); the first has $k_v+k_{v'}\geq2$ so is excluded (recall that $p(v_0)=0$ and $v\leq v_0$); while the second only sees the contribution to $Y^{(1)}$ with $k'_v=-1$, $k_v=1$, see (4.14), and the third only contributes by the term with $k'_v=1$, $k_v=-1$ in $Y^{(-1)}$. In the two cases one has $p(v)=1$ or $p(v)=-1$, respectively; adding up together the latter two contributions and using the first of (5.2) to compute the sum of the coefficients we get

$$\frac{-\sigma g_0y^{(1)}_{n_v}(-1,1)}{g_0-i\sigma\boldsymbol{\omega}'\cdot\boldsymbol{\nu}_0(v)}-\frac{-\sigma g_0y^{(-1)}_{n_v}(1,-1)}{-g_0-i\sigma\boldsymbol{\omega}'\cdot\boldsymbol{\nu}_0(v)}=\frac{\sigma}{2}\,\frac{-2\sigma g_0^2}{g_0^2+(\boldsymbol{\omega}'\cdot\boldsymbol{\nu}_0(v))^2}, \tag{5.4}$$

as it can be read from the coefficients in the intermediate column of (4.24) and from $p(v)=\alpha_v=\pm1$.

(c) The third line of (5.3) is obtained by noting that, if $v\in\mathcal{P}$, $v>\tilde{w}$ one has $p(v)=1+k_v$, so that, if $j_v=l$ and $\alpha_v\neq-1$, then $p(v)>0$, see Table III; if $v=\tilde{w}$ and $\alpha_v\neq-1$, one has $p(v)\neq0$, see Table IV (note that $\alpha_v\neq2,0$ so that we have to consider the first integrand in (4.29)).

If $j_v>l$, then $\alpha_v=2$, and, by the Tables III and IV one has $k_{v'}=0$, $k_v\geq0$ and $k_v+k_{v'}=1$, so that $k_v=1$ and $p(v)=2$; while, if $v=w$, then $k_{v'}=0$, $k_v\geq0$ and $k'_v+k_v=1$ imply $k_v=1$, so that $p(v)=1$. So in both cases $p(v)\geq1$.

(d) The fourth line is found by looking at the Tables III and IV as follows: if $\alpha_v=-1$, $v\in\mathcal{P}$, $v>\tilde{w}$, one has $k_v+k'_v=0$, hence $k_v=-1$, $k_{v'}=1$ and $p(v)=0$; this happens only if $j_v=l$ so that we have to consider the first integral in (4.29) and we get the fourth relation.

This shows that the only trees that do not have a value tending to 0 as $t\to\sigma\infty$, i.e., are those with $p(v_0)+k'_{v_0}=0$ (all the others tend to 0 as a power of $x=e^{-g_0\sigma t}$), have propagators that are even functions of the momenta flowing in them. In fact the observation on the absence of paths preceding v_0 implies that only the first two propagators in (5.3) appear in such trees. Since, as already remarked, the trees with $p(v_0)+k'_{v_0}=0$ give the equations of the tori this is an interesting check that the tori equations so obtained at $t=+\infty$ and $t=-\infty$ do *coincide*. A similar analysis, and check, holds for the cases $j_{\lambda_{v_0}}\leq l$.

5.4. *Remark:* Collecting together the contributions from $\alpha_v=-1$ and $\alpha_v=1$, for $v\notin\mathcal{P}$, is a convenient operation and has nothing to do with the deeper resummations that imply the cancellations necessary for convergence estimates: the systematic use of this operation should be described by adding a label to the trees on the nodes $v\notin\mathcal{P}$ and replacing on the branches which give rise to one of the two propagators in (5.4) the α_v label by the new label (e.g., a $*$ label which indicates that we consider the sum of the values of a tree with $\alpha_v=1$ and one with $\alpha_v=-1$). We shall do this without explicitly mentioning the new label, to simplify the notation. Moreover we can no more associate a label $p(v)$ to a node of this kind, as two factors with different $p(v)$ label ($p(v)=\pm 1$ for $\alpha_v=\pm 1$) have been considered together; nevertheless we shall modify slightly the definition of $p(v)$ by setting $p(v)\overset{\text{def}}{=}$ in such a case (and letting it unchanged in all the other cases).

We shall continue to call $G_v[\boldsymbol{\omega}'\cdot\boldsymbol{\nu}_0(v)]$ a *propagator* as, for the purposes of the following analysis, only such modified version of the original propagators appearing in (4.30) plays a role.

5.5. Furthermore we define the *degree D* of a propagator to be $D=2$ if either $v\notin\mathcal{P}$ or $v\in\mathcal{P}$, $j_v>l$ (hence $\alpha_v\neq-1$), and $D=1$ otherwise (the constraint, see (4.3), $1\leq r_v\leq 2$ implies that the power to which the divisors appear raised is either 1 or 2); by extension we shall say that a branch λ has degree $D_\lambda=D$ if the corresponding propagator has degree D.

The coefficients $\overline{F}_{\underline{\nu}_v}$ and y'_v in (5.1) satisfy the bounds

$$|y'_v|\leq 4N,\quad \prod_{v\leq v_0}|\overline{F}_{\underline{\nu}_v}|\leq(\mathcal{C}N^2)^m, \tag{5.5}$$

for some constant $\mathcal{C}$ depending on the perturbation f_1 in (2.1); see (2.6), (2.13), and (2.18). For instance, one can take

$$\mathcal{C}=\max\{|J^{-1}|J_0,1\}\max_{|n|\leq N_0,|\nu|\leq N}|f_{\underline{\nu}}|; \tag{5.6}$$

see (4.23), where $|J^{-1}|$ is the maximum of the matrix elements of the (diagonal) matrix J^{-1}.

To bound the product in (5.1), we shall consider simultaneously the cases $k_{v_0}=0,-1$; if $k_{v_0}=0$ the path $\mathcal{P}$ is supposed to be reduced to a single node, v_0, or to the empty set, $\emptyset$, depending on the value of j_{v_0} (respectively, $j_{v_0}=l$, and $j_{v_0}>l$, see above).

What follows below and in Appendix B really goes beyond Ref. 5, although it constitutes a natural extension of it. From now now let us consider the case $l=3$ and the Hamiltonian (1.1).

We shall assume first a condition on the rotation vectors stronger than the Diophantine one, as done in Refs. 3, 18, 5, i.e., we suppose that they satisfy a *strong Diophantine condition*,

$$\begin{aligned}&(1)\quad C_0|\boldsymbol{\omega}_0\cdot\boldsymbol{\nu}|\geq|\boldsymbol{\nu}|^{-\tau},\quad \mathbf{0}\neq\boldsymbol{\nu}\in\mathbb{Z}^2,\quad C_0^{-1}=\eta^{-1/2}C(\eta),\\ &(2)\quad \min_{0\geq p\geq n}|C_0|\boldsymbol{\omega}_0\cdot\boldsymbol{\nu}|-2^p|\geq 2^{n+1},\ \text{ if }\ n\leq 0,\quad 0<|\boldsymbol{\nu}|\leq(2^{n+3})^{-1/\tau},\end{aligned} \tag{5.7}$$

where n, $p\in\mathbb{Z}$, $n\leq 0$, and

$$\boldsymbol{\omega}_0\equiv\eta^{-1/2}(\Omega_1+\eta^{1/2}J^{-1}A_1)^{-1}\boldsymbol{\omega}'=(1,\eta^{-1}(\Omega_1+\eta^{1/2}J^{-1}A_1)^{-1}\Omega_2), \tag{5.8}$$

so that $\boldsymbol{\omega}' \cdot \boldsymbol{\nu} = \eta^{1/2}(\Omega_1 + \eta^{1/2} J^{-1} A_1)\boldsymbol{\omega}_0 \cdot \boldsymbol{\nu}$. We suppose also that $A_1 \in [-\eta^{-1/2}R, \eta^{-1/2}R]$, with $R \leqslant J\Omega_1/2$, so that $\eta^{1/2}(\Omega_1 + \eta^{1/2}J^{-1}A_1) \geqslant \eta^{1/2}\Omega_1/2$.

If we write $\boldsymbol{\omega}' = (\eta^{1/2}\Omega_1 + \eta J^{-1}A_1', \eta^{-1/2}\Omega_2)$ then the measure of the set of A_1''s such that $\boldsymbol{\omega}_0$ verifies the strong Diophantine condition (5.7) has measure of size $O(C_0^{-1}\eta^{-3/2})$.

By reasoning as in Ref. 18, once the case of strong Diophantine vectors has been understood, it can be extended to cover also the case of the usual (weaker) Diophantine condition (expressed by (1) in (5.7) above). Alternatively one could follow the approach in Ref. 19 avoiding completely considering condition (2) in (5.7) and assuming only the ''usual'' condition (1) in (5.7). We shall not perform such an analysis (which can be easily adapted from the quoted papers), and we shall confine ourselves to the case of strongly Diophantine vectors. [Basically the argument is the following: The analysis that we present does not change if $2^p, 2^n$ are replaced by exponentials in another base q (larger than 1) or even if they are replaced by $\gamma(p), \gamma(n)$, where $\gamma(p)/q \xrightarrow[p\to-\infty]{}$, and if in the second of (5.7) we substitute $2^p, 2^{n+1}, 2^{n+3}$ by, respectively, $\gamma(p), \gamma(n+1), \gamma(n+3)$. One then proves a simple arithmetic lemma (see Ref. 18), whereby it follows that, if the first of (5.7) is verified and if $\gamma(p)$ is suitably chosen, then the second holds with $\gamma(p), \gamma(n+1), \gamma(n+3)$ replacing $2^p, 2^{n+1}, 2^{n+3}$.]

Keeping in mind that $C_0 = \eta^{-1/2} e^{+s\eta^{-1/2}}$ is enormous we shall say that

$$
\begin{aligned}
&(1) \quad G_v[\boldsymbol{\omega}' \cdot \boldsymbol{\nu}_0(v)] \quad \text{is on scale 1, if } C_0|\boldsymbol{\omega}_0 \cdot \boldsymbol{\nu}_0(v)| > C_0/4, \text{ or if } p(v) \neq 0;\\
&(2) \quad G_v[\boldsymbol{\omega}' \cdot \boldsymbol{\nu}_0(v)] \quad \text{is on scale 0, if } 1/2 < C_0|\boldsymbol{\omega}_0 \cdot \boldsymbol{\nu}_0(v)| \leqslant C_0/4;\\
&(3) \quad G_v[\boldsymbol{\omega}' \cdot \boldsymbol{\nu}_0(v)] \quad \text{is on scale } n \leqslant -1, \text{ if } 2^{n-1} < C_0|\boldsymbol{\omega}_0 \cdot \boldsymbol{\nu}_0(v)| \leqslant 2^n.
\end{aligned}
\tag{5.9}
$$

5.6. *Remark:* Note that in the above definition of scale the second and third cases can arise only if $p(v)=0$. The propagators on scale 1 can be bounded by 4^2 if $p(v)=0$ and by 1 if $p(v)\neq 0$. Note also that the definition of the scales $n=0$ and $n=1$ is different from Refs. 3 and 5: *this is an important modification*, exploited in Appendix B, useful in order to take advantage from the existence of different scale times.

5.7. As it is well known, (5.1) cannot usefully be bounded by just taking the absolute value of each factor and bounding the denominators by using the Diophantine condition. This is true not only if one wants to get the improved bounds that we are studying, but also if one, more modestly, wants to show convergence for ε small enough; this is a problem usually referred to as a ''*small divisors problem*.''

Useful bounds are nevertheless possible, as shown first in similar cases in Ref. 9, because one can collect the contributions from the various trees into pairwise disjoint (''*nonoverlapping*'') classes whose values add up to a quantity that verifies much better bounds than the individual elements of the same class. Each class $\mathcal{F}(\vartheta)$ will be determined by one of its elements ϑ called a *representative*. This means that there are important cancellations within each class.

The classes can be constructed by collecting trees which have the same *resonance structures*. The key notion of resonance is recalled below and the description of the classes will follow it.

Definition: A ''cluster'' T of scale n_T *will be a maximal connected set of branches with scales* $n > n_T$ *and with at least one branch of scale* n_T.

A free node v will be defined to be internal to T, $v \in T$, if at least one of the branches leading to it or coming from it, i.e., *pertaining to* v (as defined in Sec. IV), belongs to T; a leaf with highest node v' will be defined to be internal to the cluster T if $v' \in T$.

A branch λ_v is called *external* to T if it does not belong to T but it pertains to a node v internal to T, and it said to be entering T if the node v' following it is in T, exiting from T if $v \in T$ (note that an external branch of T is not any branch outside T). We define the *degree* D_T of a cluster T to be the degree of its exiting branch, and the *order* k_T of T to be given by the same formula as (4.26), with the extra constraint that the nodes are internal to T.

Definition: A ''resonance'' V will be a cluster with only two external branches λ_{v_0} *and* λ_{v_1} *carrying the same free momentum,* $\boldsymbol{\nu}_0(v_0) = \boldsymbol{\nu}_0(v_1)$ *and with order ''not too high,'' i.e.,*

$$k_V < \max\{N^{-1}2^{-(n_{\lambda_{v_0}}+3)/\tau},(\gamma N\eta)^{-1}\}, \quad \gamma \stackrel{\text{def}}{=} \frac{4\Omega_1}{\Omega_2}. \tag{5.10}$$

The branch exiting from a resonance will be called a resonant branch, and the scale $n_{\lambda_{v_0}}$ *of the two branches entering and exiting the resonance will be called the resonance-scale. The degree of the propagator of the exiting branch will be called the degree* D_V *of the resonance.*

Even though a node v either with $\delta_v=0$, $\kappa_v\geq 1$ or with $\delta_v=1$, $\boldsymbol{\nu}_v=\mathbf{0}$ is not a cluster in the above sense (because it does not consist of branches) we shall nevertheless regard it as a cluster when there are only one incoming branch and one exiting branch of equal scale. *Therefore, we shall also regard it as a resonance*, if

$$\kappa_v < \max\{N^{-1}2^{-(n_{\lambda_{v_0}}+3)/\tau},(\gamma N\eta)^{-1}\}, \quad \text{when} \quad \delta_v=0, \ k_v\geq 1,$$

$$1 < \max\{N^{-1}2^{-(n_{\lambda_{v_0}}+3)/\tau},(\gamma N\eta)^{-1}\}, \quad \text{when} \quad \delta_v=1, \ \boldsymbol{\nu}_v=\mathbf{0};$$

note that the restriction that if $\delta_v=0=\kappa_v$ there are at least two branches entering v implies that no node with $\delta_v=0=\kappa_v$ can be a resonance.

Definition: A resonance will be called ''strong'' if $p(v_0)=p(v_1)=0$.

All resonances on scale ≤ 0 are strong (see Remark 5.6).

5.8. It is important to note that a strong resonance of degree 2 is necessarily such that also the degree of the entering branch *must* be 2. No branch inside it can be of order 1 and no path can precede v_0. This is so because $D_{\lambda_{v_0}}=2$ implies $j_{v_0}>l$ (see the first of (5.3)) and $p(v_0)=0$ implies that $\alpha_{v_0}=2$, $k_{v_0}=0$, $k'_{v_0}=0$ so any path preceding v_0 would necessarily imply the contradiction $p(v_0)=1$. Also if $D_{\lambda_{v_1}}=1$, $D_{\lambda_{v_0}}=2$ one must have $j_{v_1}=l$ hence $k_{v_1}=0$ (otherwise $p(v_0)>0$) so that $k'_{v_1}=0$: but $\alpha_{v_1}<2$ and k'_{v_1} must be odd. The cases $D_{\lambda_{v_0}}=1$, $D_{\lambda_{v_1}}=1,2$ are both allowed.

5.9. Given a tree ϑ, let V be a resonance (if there are any) with entering branch λ_{v_1} of degree $D_{\lambda_{v_1}}=2$. Then consider the family of all trees which can be obtained from ϑ by detaching the part of the tree having λ_{v_1} as root branch and reattaching it to all the remaining nodes *internal to V but external to the resonances contained inside the cluster* V (if any); to the just defined set of trees we add all the trees obtained by reversing simultaneously the signs of the latter modes of the nodes (this can be done as the sum of the mode vectors $\boldsymbol{\nu}_w$ of such nodes, $w\in V$, vanishes). The set of all the so obtained trees will be denoted $\mathcal{F}_V(\vartheta)$.

The definition of resonance and the strong Diophantine condition insures that all the trees so constructed have a well defined value (*i.e.* no division by zero occurs in evaluating it with the above rules); see the Remark 5.10, (1), below.

If the entering branch λ_{v_1} of the resonance has degree $D_{\lambda_{v_1}}=1$ then also the exiting branch λ_{v_0} has degree $D_{\lambda_{v_0}}=1$, and we collect together with the considered tree also the tree which is obtained from ϑ through the following operation. Replace the resonance V with *a single node v* carrying labels $\delta_v=0$ and $\kappa_v=k_V$, if k_V is the order of the resonance. The set of all the so obtained trees will be denoted by $\mathcal{F}_V(\vartheta)$: the definition of the class $\mathcal{F}_V(\vartheta)$ will therefore depend on the degree of the branch entering V.

Then repeat the above operations for all resonances in ϑ. Thus a class $\mathcal{F}(\vartheta)$ has been constructed and the number of elements of $\mathcal{F}(\vartheta)$ is bounded by the product $\Pi_V 2\mathcal{N}_V$ of the numbers $\mathcal{N}_V$ of branches in each resonance V *which are not* contained inside inner resonances. The latter product is bounded by $\exp \Sigma_V 2\mathcal{N}_V \leq \exp 2m$; the $\mathcal{F}(\vartheta)$ can be obtained starting from any of its elements (which therefore we shall call *representatives* of the class): this is again a *consequence of the strong Diophantine condition*, see Ref. 5.

5.10. *Remarks:* (1) The strong Diophantine condition plays a role here that should be stressed. In fact one checks that because of it the scale of a branch inside a resonance *cannot* change too much, as one considers the different members of a given family. Not enough to change the sets of branches that belong to a given resonance and insures that the different families of trees *do not* *overlap*; for this reason the strong Diophantine condition leads to a simplification of the analysis (the simplification in the simpler case of the KAM theory). A simplification that is however not major (as explained informally in Ref. 3 and as shown in Ref. 18).

(2) To see how the above difficulty is bypassed by using the alternative approach of Refs. 20, 19, we refer to the conclusive comments in Ref. 20, Sec. III.

5.11. Consider trees with $p(v_0)=0$, if v_0 is the highest node of the tree; then the expression of each tree value contains a product like (5.1). As mentioned in the Introduction *we consider only trees without leaves*.

Since the leaf values factorize with respect the product (5.1), they can be dealt with separately, and no overlap arises with the cancellation mechanisms acting on the product (5.1), so that leaves can be easily taken into account; see Appendix C 3 (see also Refs. 3, 10, 5).

The counterterms can also be explicitly expanded in terms of tree values, according to (3.2), which again we can imagine to have no leaves (see however, the comments in Appendix C, 3 below).

The cancellation mechanisms described in Refs. 10, 5 (and recalled in Appendix C) lead to the bound (on a given family $\mathcal{F}(\vartheta)$) described above, in Sec. V, 5.9, see (5.1), (4.30), (4.23),

$$\left(\frac{1}{\eta^{1/2}}\right)^{2m}\left[(4N^3\mathcal{C}')^m 2^{4m}e^{2m}\prod_{n\leqslant 0}(C_0^{2N_n^2}2^{-2nN_n^2})(C_0^{N_n^1}2^{-nN_n^1})\right]\cdot$$

$$\cdot\left[\prod_{n\leqslant 0}\prod_{T,n_T=n}\prod_{i=1}^{m_T^1(n)}2^{(n-n_i+3)}\prod_{i=1}^{m_T^2(n)}2^{2(n-n_i+3)}\right], \tag{5.11}$$

where $\mathcal{C}'=\max\{(2g_0/\Omega_1)^2,4^2\}\mathcal{C}$, with $\mathcal{C}$ the dimensionless constant defined in (5.6); m is the number of nodes $v\geqslant v_0$; N_n^j is the number of propagators on scale n and of degree j in ϑ, which can be written as

$$N_n^j=\overline{N_n^j}+\sum_{\substack{T\\ n_T=n,D_T=j}}(-1)+\sum_{\substack{T\\ n_T=n}}m_T^j(n), \tag{5.12}$$

where $m_T^j(n)$ is the number of resonances on scale n and degree j (i.e., with entering branch having a propagator of degree j) contained inside the cluster T. The terms $\widetilde{N}_n^j$, $j=1,2$, which count the number of propagators *which do not correspond to resonant branches* plus the number of clusters on scale n and of degree j in ϑ, satisfy the bounds

$$\sum_{j=1}^{2}\overline{N_n^j}\leqslant 4mN2^{(n+3)/\tau},\qquad \sum_{n=-\infty}^{0}\sum_{j=1}^{2}\overline{N_n^j}\leqslant 4m\gamma N\eta, \tag{5.13}$$

(with $\gamma=4\Omega_1/\Omega_2$) which are proven in Appendix B. The first square bracket in (5.11) is the bound on the product of individual elements in the family $\mathcal{F}(\vartheta)$ times the bound on their number $\Pi_V 2\mathcal{N}_V<e^{2m}$, see above. The second square bracket term is the part coming from the maximum principle (in the form of Schwarz's lemma), applied to bound the sums of the tree values (''*resummations*'') over the classes $\mathcal{F}(\vartheta)$ introduced above; this is a *nontrivial product of small factors* that arise from the cancellations associated with the resummations, see Appendix C. In (5.11) n_i is the scale of the cluster V_i which is the ith resonance inside T, as in Ref. 5. The $\eta^{-m/2}$ arises as a lower bound on the small divisors of the form $\boldsymbol{\omega}'\cdot\boldsymbol{\nu}$ on scale $n=1$ (for $n=1$ we use the better bound $|\boldsymbol{\omega}_0\cdot\boldsymbol{\nu}|\geqslant 2^2\eta^{1/2}$).

5.12. *Remark:* The first bound (5.13) holds for all n and for all Hamiltonians of the form (2.1). On the contrary the second bound in (5.13) will follow from the fact that the rotation vector $\boldsymbol{\omega}_0$ has the form (5.8), with η small, and will be used to control the (huge) factors C_0 in (5.11).

5.13. Hence by substituting (5.12) and the first of (5.13) into (5.11) we see that, for $j=1,2$, the $m_T^j(n)$ is taken away by the first factor in $2^{jn}2^{-jn_i}$, while the remaining 2^{-jn_i} are compensated by the -1 before the $+m_T^j(n)$ in (5.11) taken from the factors with $T=V_i$ (note that there are always enough -1's), and therefore (5.11) is bounded by

$$\left(\frac{2}{\eta^{1/2}}\right)^{2m}(4N^3\mathcal{C}')^m e^m 2^{4m}2^{8m}C_0^{8m\gamma N\eta}\prod_{n=-\infty}^{0}2^{-8mNn2^{(n+3)/\tau}}, \tag{5.14}$$

because the product of the factors C_0 in (5.11) can be bounded by using the second of (5.13), since the product does not contain the $n=1$ factor. The last product in (5.14) is bounded by

$$\prod_{n=-\infty}^{0}2^{-8mNn2^{(n+3)/\tau}}\leqslant\exp\left[8mN2^{3/\tau}\log 2\sum_{p=1}^{\infty}p2^{-p/\tau}\right], \tag{5.15}$$

hence, by adding the remark that the perturbation degree k and the number of tree nodes m are related by $m<2k$, a bound on the sum over all the subtrees of order k with $p(v_0)=0$, $\boldsymbol{\nu}(v_0)=\boldsymbol{\nu}$ (recalling that the number of trees with m nodes is $<4^m m!$) is

$$\Delta_k\overset{\text{def}}{=}\left|\frac{1}{|\mathcal{F}(\vartheta)|}\sum_{\vartheta'\in\mathcal{F}(\vartheta)}\prod_{v\in\vartheta'}\overline{F}_{\underline{\nu}_v}G_v[\boldsymbol{\omega}'\cdot\boldsymbol{\nu}_0(v)]\tilde{y}_v\right|\leqslant B_0^{2k}\eta^{-2k}, \tag{5.16}$$

for some positive constant B_0. The normalization constant $|\mathcal{F}(\vartheta)|$ is introduced in order to avoid overcountings; in fact if $\vartheta'\in\mathcal{F}(\vartheta)$ then $\vartheta\in\mathcal{F}(\vartheta')$, so that, without dividing by $|\mathcal{F}(\vartheta)|$ in (5.16), each tree would be counted $|\mathcal{F}(\vartheta)|$ times.

If $C_0^{-1}=\eta^{-1/2}C(\eta)$ is chosen as in the statement of Theorem 1.4, an explicit calculation gives the bound on (5.11) of the form $(\eta^{-1/2})^{4k}B_0^k$, $k\geqslant 1$, and

$$B_0=2^{18}(4N^3\mathcal{C}')\exp\left[2+4\gamma N\eta\log\eta+8s\gamma N\eta^{1/2}+8N2^{3/\tau}\log 2\sum_{p=1}^{\infty}p2^{-p/\tau}\right], \tag{5.17}$$

which is bounded uniformly in η (for $\eta\leqslant 1$).

5.14. In the previous section trees with $p(v_0)=0$ have been considered; in particular only the contributions (5.1) arising from the value (4.30), once the corresponding tree has been deprived of leaves and counterterms, have been bounded and the bound (5.16) has been obtained through a suitable resummation operation. In such a case the sum over the labels (k_v',k_v) is trivial because the condition $p(v_0)=0$ imposes that only a few values (up to three per node) can be assumed by the hyperbolic mode labels; also the sum over the mode labels $\underline{\nu}_v$ cannot create any problems. In fact for any node v one has $|\underline{\nu}_v|\leqslant N$ and $|n_v|\leqslant N_0$ (see the eighth item in Sec. IV 1).

The cases $p(v_0)\neq 0$ as well as those involving graphs containing leaves or counterterms can be treated in the same manner as already done in Refs. 3, 5. We provide, in Appendix D, a quick description of the construction of the analyticity bound $\varepsilon_0=D^{-1}$ with

$$\varepsilon_0^{-1}=D=[B2^6l(2N+1)^{2l-1}(2N_0+1)]^2,\quad B=\max(B_0\eta^{-1},B_1), \tag{5.18}$$

and B_1 is a suitable numerical constant.

The part of Theorem 1.4 not concerning the connection between the average action $\mathbf{A}'$ and the rotation vector $\boldsymbol{\omega}'$ nor the splitting size follows.

5.15. Determining the exact splitting size (i.e., the leading behavior asymptotically as $\eta\to 0$ with $\varepsilon<B\eta^2$) is *not* trivial because of the existence of major cancellations in the evaluation of the determinant of the splitting matrix; however the analysis in Ref. 8 dealt with this question in detail; in the latter paper remarkable cancellations are exhibited and an exact formula for the splitting angles is derived (see (7.19) of Ref. 8).

One gets the results in the last item of Theorem 1.4 simply if Ref. 8 and the first part of Theorem 1.4 (to estimate the remainders) are used; then the claimed bounds on the splitting follow immediately (see Remark 1.5). In Ref. 6 an improvement of lemma 1 and lemma 1′ of Ref. 2 was used instead to control the density of tori in phase space (the lemmata in Ref. 2 were, as such, useless already in the case in Ref. 8 because they would require that ε be far smaller than the ε_0 of Theorem 1.4); see Ref. 6, where this is discussed in detail and differs from our case only because it relied on a theorem weaker than Theorem 1.4 above (as the radius of convergence estimate there is proportional to η to the power $\frac{9}{2}+$ rather than our 2).

5.16. *Remarks:*

(1) The bound (5.16) and the discussion in Sec. V 14 imply the convergence of the perturbative expansions for the parametric equations of the invariant tori (for the Hamiltonian (1.1)), if $|\varepsilon|<\varepsilon_0=O(\eta^2)$. This bound on the convergence radius should be compared with the value given by Ref. 6, which, for $\mathcal{N}=O(\eta^{-1/2})$, gives $\varepsilon_0=O(\eta^{9/2}/\log^2\eta^{-1})$. *As usual the Lindstedt series gives a much better estimate than the classical method* (i.e., an exponent 2 vs ~4.5). We do not see immediately how to improve substantially the classical estimate without important changes in the architecture of the proof of Ref. 6, although this should be possible; on the other hand, from the above analysis, $\varepsilon_0=O(\eta^2)$ might be close to an optimal result. If so it should be no surprise that our analysis is so delicate.

(2) In the Hamiltonian (1.1), (2.1) the polynomial dependence of the interaction on the rotators angles has very likely a purely technical motivation (as it simplifies the analysis) and could probably be relaxed into a more general analytical dependence, as in Ref. 13. On the contrary the hypothesis that the perturbation is a trigonometric polynomial of degree N_0 in φ is fundamental to get the correct asymptotic behavior, in order to apply the results in Ref. 8, where the dominance of Mel'nikov integral is proven *provided the perturbation is polynomially small in a power of* η^{N_0} (so that the results of Ref. 8 become meaningless for $N_0\to\infty$).

(3) A bound of the form (5.16) holds under the weaker condition that $C(\eta)\leqslant e^{-s\eta^{-a}}$, with $a\leqslant 1$ (see (5.17)).

(4) If q is defined as in Sec. I, 1.6 so that $|\varepsilon|C(\eta)^{q\eta}<1$ implies analyticity in ε, the above analysis gives that q can be taken $q=8\gamma N$. In general all the bounds found so far are not uniform in N; in order to deal with the analytical case in the frame of the exploited formalism one should bound the small divisors by using the results of Ref. 19 or Eliasson-Siegel's bound (see, for instance, Ref. 14), and use explicitly as in Ref. 13 the exponential decay in $\boldsymbol{\nu}$ of the Fourier coefficients $f^1_{\boldsymbol{\nu}}$.

(5) Note that we have convergence for $|\varepsilon|<O(\eta^2)$, while the asymptoticity of the splitting estimate follows only for $|\varepsilon|<O(\eta^\zeta)$ (with $\zeta=2(N_0+3)$), which is *much smaller* for $\eta\to 0$. Then the question is: What will be the asymptotics for ε small enough to be in the convergence domain but too large to be in the domain of the asymptotic result? There is some evidence that there is a critical value T_c such that, if $\varepsilon=\eta^T$, then for $T>T_c$ the asymptotic formula that we can prove only for $T>\zeta$ holds, but for $T=T_c$ it is modified remaining qualitatively of the same size $O(e^{-(1/2)\eta^{-(1/2)}})$ and for $T<T_c$ it becomes qualitatively different. The analogy with the critical point scaling phenomena seems to be substantial and, keeping in mind that the above theory can be interpreted as a field theory, see Ref. 17, one would say that the region $T>T_c$ is described by a trivial fixed point; a nontrivial fixed point describes the case $T=T_c$ and another ''low temperature'' fixed point describes the cases $T<T_c$. Evidence in this direction comes also from the theory of the standard map and its developments.[21,22,23]

APPENDIX A: COUNTERTERMS

1. To order h one can write, by using (2.11), (2.24), and (4.11),

$$\Xi_-^{h\sigma}(t)=\int_{\sigma\infty}^{t} d\tau w_0^1(t,\tau)(\Phi_+^{h\sigma}(\tau;\gamma_1(g_0),\ldots,\gamma_{h-1}(g_0))+\gamma_h(g_0)\sin\varphi^0(\tau))+\int_{\sigma\infty}^{0} d\tau w_0^0(t,\tau)$$
$$\times(\Phi_+^{h\sigma}(\tau;\gamma_1(g_0),\ldots,\gamma_{h-1}(g_0))+\gamma_h(g_0)\sin\varphi^0(\tau)), \tag{A1}$$

where $\Phi_+^{h\sigma}(t;\gamma_1(g_0),\ldots,\gamma_{h-1}(g_0))$ takes into account all the contributions to $\Phi_+^{h\sigma}=(J_0g_0^2)^{-1}F_+^{h\sigma}$ except the only one explicitly depending on $\gamma_h(g_0)$, which is given by $\gamma_h(g_0)\sin\varphi^0(\tau)$.

We shall impose, recursively, that the contributions to the integrands in (A1) arising from amputated trees (see comments after (4.31)) with $(\boldsymbol{\nu}_0(v_0),p(v_0))=(\mathbf{0},0)$, *without leaves and without end nodes bearing a counterterm label* (see Remark A, 2 below), compensate exactly the contributions due to the trees with a single node representing a counterterm of order h (i.e., the terms with $\gamma_h(g_0)$ in (A1)). The first described type of contributions can be written

$$\mathcal{W}_1=w_l^1(t,\tau)\Phi_+^{h\sigma}(\tau;\gamma_1(g_0),\ldots,\gamma_{h-1}(g_0))\equiv\sum_{\nu\in\mathbb{Z}^{l-1}}\sum_{p=-1}^{\infty}\tilde{\mathcal{W}}_1(\boldsymbol{\nu},p)e^{i\boldsymbol{\omega}'\cdot\boldsymbol{\nu}t-pg_0\sigma t} \tag{A2}$$

in the first integral in (A1) and

$$\mathcal{W}_0=w_l^0(t,\tau)\Phi_+^{h\sigma}(\tau;\gamma_1(g_0),\ldots,\gamma_{h-1}(g_0))\equiv\sum_{p=-1}^{\infty}\sum_{\nu\in\mathbb{Z}^{l-1}}\tilde{\mathcal{W}}_0(\boldsymbol{\nu},p)e^{i\boldsymbol{\omega}'\cdot\boldsymbol{\nu}t-pg_0\sigma t} \tag{A3}$$

in the second one. Imposing that such contributions are canceled by the contributions with $p=0$ arising from $w_l^1(t,\tau)\gamma_h(g_0)\sin\varphi^0(\tau)$ and $w_l^0(t,\tau)\gamma_h(g_0)\sin\varphi^0(\tau)$ gives our prescription on how to fix $\gamma_h(g_0)$.

Since two integrals are involved (one for $\rho_{v_0}=1$ and one for $\rho_{v_0}=0$), the first time dependent and the second time independent, two conditions may seem to be required; however, note that $\sin\varphi^0(t)=2\sinh g_0t/\cosh^2 g_0t$ is expanded in odd powers of $x=e^{-\sigma g_0 t}$, hence the only terms appearing in (A2) and (A3) which can contribute to $p=0$ are, in both cases, those involving $y^{(-1)}(k'_{v_0},k_{v_0})$, with $k_{v_0}=-1$. This means that the contributions with $p=0$ arising from (A2) and (A3) are equal, so that no compatibility problem arises.

Note that an expression analogous to (A1) is obtained also for $\Xi_+^{h\sigma}(t)$; however the terms with $p=0$ have the same form as in (A1) (see (4.17) for $j_{\lambda_{v_0}}=l$ and for $j_{\lambda_{v_0}}=0$), so that if no term with $(\boldsymbol{\nu}_0(v_0),p(v_0)=(\mathbf{0},0))$ contributes to $\Xi_-^{h\sigma}(t)$, then also no term with $(\boldsymbol{\nu}_0(v_0),p(v_0))=(\mathbf{0},0)$ contributes to $\Xi_+^{h\sigma}(t)$.

2. Remark: It may seem strange that we exclude from the definition of the counterterms trees with leaves; in fact one can imagine to realize trees with $(\boldsymbol{\nu}(v_0),p(v_0))=(\mathbf{0},0)$ also by trees which contain leaves with a stalk bearing a label $j_w>l$ or $j_w=l$ and internal momenta $(\boldsymbol{\nu}',p')$. Such terms would give rise to $\boldsymbol{\alpha}$-dependent counterterms which of course are not allowed; however, it turns out that the sum over all contributions to tree values of trees with $(\boldsymbol{\nu}(v_0),p(v_0))=(\mathbf{0},0)$ from such trees cancel *exactly*; this is explained together with the other cancellations built in our algorithm, in Appendix C (see Appendix C, 5 in particular).

3. Let us consider the first integral in (A1). Corresponding to the node v_0 of each tree whose value contributes to $\Xi_-^{h\sigma}(t)$ there is a coefficient $\tilde{y}_{n_{v_0}}(k'_{v_0},k_{v_0})$, see (4.14), (4.17). Then from (A1) and the just formulated condition to impose we obtain

$$\sum_{\substack{\vartheta\in\mathcal{T}_{0,h},\alpha_{v_0}=-1\\ p(v_0)=0,k'_{v_0}=1}} \overline{\mathrm{Val}}(\vartheta)+\gamma_h(g_0)w_l^1(t,\tau)\sin\varphi_0(\tau)\Big|_{k'=1,p=0}=0, \tag{A4}$$

where the sum is over the set $\mathcal{T}_{0,h}$ of all trees of order h and momentum $\boldsymbol{\nu}(v_0)=\mathbf{0}$, with $\boldsymbol{\nu}_0(v_0)=\mathbf{0}$ (see Remark A, 2), $p(v_0)=0$, $j_{v_0}=l$ and $k'_{v_0}=1$; hence if $p(v_0)=0$, $j_{v_0}=l$, one must have $k_{v_0}=-1$, hence $\alpha_{v_0}=-1$ and $k'_{v_0}=1$ which is a possible case indeed.

A trivial calculation (just take into account that $y_{n_v}^{(-1)}(1,-1)=\sigma/2$ and $\sin\varphi^0(\tau)=4\sigma x+O(x^3)$) gives

$$w_l^1(t,\tau)\sin\varphi_0(\tau)|_{k'=1,p=0}=2, \tag{A5}$$

so that (4.32) follows; the above follows Ref. 5, p. 287.

APPENDIX B: (IMPROVED) RESONANT SIEGEL–BRYUNO'S BOUND

1. We follow the idea of Pöschel[24] (see also Refs. 3, 18, 5). In the discussion, we focus on the scale labels, so that it is quite irrelevant which value the $p(v)$'s, $v\in\vartheta$, assume, and therefore which resonances are strong and which are not.

Calling $N_n^*(\vartheta)$ the number of nonresonant branches carrying a scale label $\leqslant n$, in a tree ϑ with m nodes, we shall prove first that

$$N_n^*(\vartheta)\leqslant 2mE_n-1,\quad E_n\overset{\text{def}}{=}N2^{(3+n)/\tau},\quad n\leqslant 1, \tag{B1}$$

provided that $N_n^*(\vartheta)>0$, and

$$N_0^*(\vartheta)\leqslant 2m\gamma N\eta-1,\quad \gamma\overset{\text{def}}{=}4\Omega_1/\Omega_2, \tag{B2}$$

if $N_0^*(\vartheta)>0$.

Define, as in Sec. V, 5.7, $\boldsymbol{\omega}_0=(1,\eta^{-1}(\Omega_1+\eta^{1/2}J^{-1}A_1)^{-1}\Omega_2)$. Then $C_0|\boldsymbol{\omega}_0\cdot\boldsymbol{\nu}|>|\boldsymbol{\nu}|^{-\tau}$ for all $\mathbf{0}\neq\boldsymbol{\nu}\in\mathbb{Z}^{l-1}$; see (5.7). Assume also η so small that $C_0\geqslant 2$ (this is not restrictive as we are interested in $\eta\to 0$).

Set $E_n\equiv N2^{(n+3)/\tau}$ as in (B1). Note that if $m\leqslant E_n^{-1}$ one has $N_n^*(\vartheta)=0$. In fact $m\leqslant E_n^{-1}$ implies that, for all $v\in\vartheta$, $|\boldsymbol{\nu}_0(v)|\leqslant NE_n^{-1}$, i.e., $C_0|\boldsymbol{\omega}_0\cdot\boldsymbol{\nu}_0(v)|\geqslant(N^{-1}E_n)^\tau=2^{n+3}$, so that there are no clusters T with $n_T=n$. Note also that if $m\leqslant(\gamma N\eta)^{-1}$, with $\gamma=4\Omega_1/\Omega_2$, then $N_0^*(\vartheta)=0$, as $|\boldsymbol{\omega}_0\cdot\boldsymbol{\nu}_0(v)|\geqslant 1$ for all $v\in\vartheta$ in such a case.

2. Let us prove first the inequality (B1). If ϑ has the root branch either with scale $>n$, or with scale $\leqslant n$ and resonant, then calling $\vartheta_1,\vartheta_2,\ldots,\vartheta_k$ the subtrees of ϑ ending into the highest node v_0 of ϑ and with $m_j>E_n^{-1}$ nodes, $j=1,...,k$, one has $N_n^*(\vartheta)=N_n^*(\vartheta_1)+\cdots+N_n^*(\vartheta_k)$ and the statement is inductively implied from its validity for $m'<m$ and from the just proved fact that $N_n^*(\vartheta)=0$ if $m\leqslant E_n^{-1}$.

If the root branch is on scale $\leqslant n$ and nonresonant, one has $N_n^*(\vartheta)\leqslant 1+\Sigma_{i=1}^k N_n^*(\vartheta_i)$: if $k=0$ the statement is trivial, if $k\geqslant 2$ the statement is again inductively implied by its validity for $m'<m$. If $k=1$ one has $N_n^*(\vartheta)\leqslant 1+2m_1E_n-1$, hence we once more have a trivial case unless the order m_1 of ϑ_1 is $m_1>m-(2E_n)^{-1}$: but in the latter case we shall show that the root branch of ϑ_1 has scale $>n$.

Accepting the last statement (which will be proved below), one will obtain $N_n^*(\vartheta)=1+N_n^*(\vartheta_1)=1+N_n^*(\vartheta'_1)+\cdots+N_n^*(\vartheta'_{k'})$, where ϑ'_j's are the k' subtrees ending into the highest node of ϑ'_1 with orders $m'_j>E_n^{-1}$, $j=1,...,k'$. Going once more through the analysis the only nontrivial case is if $k'=1$ with the root branch of ϑ'_1 nonresonant; and in such case $N_n^*(\vartheta'_1)=N_n^*(\vartheta''_1)+\cdots+N_n(\vartheta''_{k''})$, etc., until we reach a trivial case or a tree of order $\leqslant m-(2E_n)^{-1}$.

It remains to check that if $m-m_1<(2E_n)^{-1}$ then the root branch of ϑ_1 has a scale $>n$. Let us proceed by *reductio ad absurdum*. Suppose that the root branch of ϑ_1 is on scale $\leqslant n$. Then $C_0|\boldsymbol{\omega}_0\cdot\boldsymbol{\nu}_0(v_0)|\leqslant 2^n$ and $C_0|\boldsymbol{\omega}_0\cdot\boldsymbol{\nu}_0(v_1)|\leqslant 2^n$, if v_1 is the highest node of ϑ_1. Hence $C_0|\boldsymbol{\omega}_0\cdot(\boldsymbol{\nu}_0(v)-\boldsymbol{\nu}_0(v_1))|<2^{n+1}$ (equality would imply violation of the strong Diophantine property, (5.7)), and the Diophantine condition implies that

$$|\boldsymbol{\nu}_0(v_0)-\boldsymbol{\nu}_0(v_1)|>2^{-(n+1)/\tau}\equiv\delta, \tag{B3}$$

because $\boldsymbol{\nu}_0(v_0)\neq\boldsymbol{\nu}_0(v_1)$ (the root branch of ϑ being supposed nonresonant). But $m-m_1<(2E_n)^{-1}$, so that $|\boldsymbol{\nu}_0(v_0)-\boldsymbol{\nu}_0(v_1)|<(2E_n)^{-1}N<2^{-1}2^{-(n+3)/\tau}=2^{-(1+2/\tau)}\delta<\delta$, which contradicts the inequality (B3).

3. Let us prove now (B2). If ϑ has the root branch either with scale 1, or with scale $\leqslant 0$ and resonant, then calling $\vartheta_1,\vartheta_2,\ldots,\vartheta_k$ the subtrees of ϑ ending into the highest node v_0 of ϑ and with $m_j>(\gamma N\eta)^{-1}$ nodes, $j=1,\ldots,k$, one has $N_0^*(\vartheta)=N_0^*(\vartheta_1)+\cdots+N_0^*(\vartheta_k)$ and the statement is inductively implied from its validity for $m'<m$ and from the fact that $N_0^*(\vartheta)=0$ if $m\leqslant(\gamma N\eta)^{-1}$.

If the root branch is on scale $\leqslant 0$ and nonresonant, one has $N_0^*(\vartheta)\leqslant 1+\Sigma_{i=1}^k N_0^*(\vartheta_i)$; if $k=0$ the statement is trivial, if $k\geqslant 2$ the statement is again inductively implied by its validity for any $m'<m$. If $k=1$ we once more have a trivial case unless the order m_1 of ϑ_1 is $m_1>m-(2\gamma N\eta)^{-1}$, but in the latter case the root branch of ϑ_1 has scale 1.

Accepting the last statement (which will be proved below), one will obtain $N_0^*(\vartheta)=1+N_0^*(\vartheta_1)=1+N_0^*(\vartheta_1')+\cdots+N_0^*(\vartheta_{k'}')$, where ϑ_j''s are the k' subtrees ending into the highest node of ϑ_1' with orders $m_j'>(2\gamma N\eta)^{-1}$. Going once more through the analysis the only nontrivial case is if $k'=1$ and in that case $N_0^*(\vartheta_1')=N_0^*(\vartheta_1'')+\cdots+N_0(\vartheta_{k''}'')$, etc., until we reach a trivial case or a tree of order $\leqslant m-(2\gamma N\eta)^{-1}$.

It remains to check that, if $m-m_1<(2\gamma N\eta)^{-1}$, then the root branch of ϑ_1 has scale 1. Suppose that the root branch of ϑ_1 is on scale $\leqslant 0$. Then $p(v_1)\neq 0$ and $|\boldsymbol{\omega}_0\cdot\boldsymbol{\nu}_0(v_0)|\leqslant 1/4$, $|\boldsymbol{\omega}_0\cdot\boldsymbol{\nu}_0(v_1)|\leqslant 1/4$, if v_1 is the highest node of ϑ_1, i.e.,

$$|\boldsymbol{\omega}_0\cdot(\boldsymbol{\nu}_0(v_0)-\boldsymbol{\nu}_0(v_1))|\leqslant 1/2. \tag{B4}$$

As the root branch of ϑ is supposed nonresonant, then $m-m_1<(2\gamma N\eta)^{-1}$ implies that $0<|\boldsymbol{\nu}_0(v_0)-\boldsymbol{\nu}_0(v_1)|<(2\gamma N\eta)^{-1}N=(2\gamma\eta)^{-1}$, so that one would have $|\boldsymbol{\omega}_0\cdot(\boldsymbol{\nu}(v_0)-\boldsymbol{\nu}(v_1))|\geqslant 1$, which is contradictory with the inequality (B4).

4. A similar induction can be used to prove that if the number of branches on scale n is $N_n(\vartheta)>0$ then the number $p_n(\vartheta)$ of clusters of scale n verifies the bound

$$p_n(\vartheta)\leqslant 2mN2^{(n+3)/\tau}-1. \tag{B5}$$

In fact this is true for $m\leqslant E_n^{-1}$, if E_n is defined as in Appendix B1. Otherwise, if the highest tree node v_0 is not in a cluster on scale n, one calls $\vartheta_1,\ldots,\vartheta_k$ the subtrees ending into v_0, and one has $p_n(\vartheta)=p_n(\vartheta_1)+\cdots+p_n(\vartheta_k)$, so that the statement follows by induction. If v_0 is in a cluster V of scale n, and $\vartheta_1,\ldots,\vartheta_k$ are the subtrees entering the cluster containing v_0 and with orders $m_j>E_n^{-1}$, one will find $p_n(\vartheta)=1+p_n(\vartheta_1)+\cdots+p_n(\vartheta_k)$. Again we can assume that $k=1$, the other cases being trivial. But in such case there will be only one branch entering the cluster V and it will have a propagator of scale $\leqslant n-1$. Therefore the cluster V must contain at least E_n^{-1} nodes. This means that $m_1\leqslant m-(2E_n)^{-1}$.

Finally, the bound

$$\sum_{n=-\infty}^{0} p_n(\vartheta)\leqslant 2m\gamma N\eta-1 \tag{B6}$$

is a trivial consequence of (B2).

5. Let $\overline{N}_n^* \leqslant N_n^*$ be the number of nonresonant branches on scale n. Then if $\overline{N}_n$ is the number of nonresonant branches *plus* the number of clusters on scale n, $\overline{N}_n^*$ verifies the bounds

$$\overline{N}_n^* = (\overline{N}_n^* + p_n) - p_n \equiv \overline{N}_n - p_n \leqslant 4mN2^{(n+3)/\tau} - 2 - \sum_{\substack{T \\ n_T = n}} (1) \leqslant 4mN2^{(n+3)/\tau} + \sum_{\substack{T \\ n_T = n}} (-1). \tag{B7}$$

This proves that (B1) and (B5) imply an inequality analogous to the first of (5.13); likewise one derives an inequality similar to the second of (5.13) by combining (B2) and (B6).

APPENDIX C: CANCELLATIONS BETWEEN RESONANCES

In this Appendix we recall briefly the cancellation mechanisms of Ref. 5. We provide this as a guide to the reader and as a tune up of a fine points of the analysis of Ref. 5 (the analysis in Appendix C 2 is given here in full details while in Ref. 5 it was left out).

1. Consider a tree ϑ with a strong resonance V of order k_V. Let λ_{v_0} and λ_{v_1} be, respectively, the exiting and entering branches of V. There are two possibilities; either the degree of the propagator corresponding to the branch exiting from V is $D_{\lambda_{v_0}} = 2$ or it is $D_{\lambda_{v_0}} = 1$ (equivalently the degree of the resonance is either $D_V = 2$ or $D_V = 1$).

Let us discuss first the case in which the degree D_V of the resonance is $D_V = 2$. Then $j_{v_0} > l$ (see (5.3) and the comments after the definition of strong resonance in Sec. V, 5.9) and, by following the notations of Sec. V, 5.1, we shall say that $\mathcal{P} = \emptyset$, i.e., there is no path $\mathcal{P}$ ending into v_0. It follows, from the properties of $\mathcal{P}$ discussed at the beginning of Sec. V, 5.1 above, that $p(v_1) = 0$ implies $j \equiv j_{v_1} > l$ and $D_{\lambda_{v_1}} = 2$ (see again (5.3)).

Consider all the trees belonging to the class $\mathcal{F}(\vartheta)$ which are obtained from ϑ by detaching the subtree having as branch root the entering branch λ_{v_1} of the resonance and attaching it to all the remaining nodes of V (see the definition of the class $\mathcal{F}_V(\vartheta)$ in Sec. 5 I). As a consequence of such an operation some of the branches internal to the resonance have changed the free momentum by an amount $\boldsymbol{\nu}_0(v_1)$, and if w is the node inside V to which the branch λ_{v_1} is attached and $j_{v_1} - l > 0$, then $\overline{F}_{\underline{\nu}_w}$ (see (4.23)), has the form of an even function of $\underline{\nu}_w$ times a factor $(i\nu_{wj})$.

We shall call the *resonance value* $\mathcal{R}_V$ the product of factors appearing in the definition of the tree value and relative only to the nodes and branches internal to the resonance V,

$$\mathcal{R}_V = \overline{F}_{\underline{\nu}_{v_0}} y'_{v_0} \prod_{\substack{v \in V \\ v < v_0}} \overline{F}_{\underline{\nu}_v} y'_v G_v[\boldsymbol{\omega}' \cdot \boldsymbol{\nu}_0(v)], \tag{C1}$$

and shall consider the resonance value as a function of the quantity $\mu \equiv \boldsymbol{\omega}_0 \cdot \boldsymbol{\nu}_0(v_1)$.

Then for $\mu = 0$ a quantity proportional to $\Sigma_{w \in V} \boldsymbol{\nu}_{wj}$ is constructed, but such a quantity is vanishing by definition of resonance, as $j = j_{v_1} - l > 0$.

If we sum also on an overall change of signs of the mode labels of the nodes internal to the resonance (by following the definition of the class $\mathcal{F}(\vartheta)$ given in Sec. V, 5.9), we obtain a zero contribution also to first order in μ (here the even parity of the perturbation f is essential, see Refs. 3 and 5).

This can be seen by using the explicit form of the functions in (4.21), i.e., the coefficients listed in (4.24). Noting that in the present case *there cannot be any* $\mathcal{P}$ *inside* V the only propagators we can associate with the branches internal to V have the form of the two first terms of (5.3), so that, for $\mu = 0$, *they are even functions of the mode labels*. Moreover in such a case the analysis in Sec. V, 5.1 shows that $\alpha_v = -1$, $\alpha_v = 1$ and $\alpha_v = 2$ imply, respectively, $k'_v = -k_v = 1$, $k'_v = -k_v = -1$ and $k'_v = -k_v = 0$ (the case $\alpha_v = 0$ is not possible here), then no n_v labels appear in the coefficients $y_{n_v}^{(\alpha_v)}(k'_v, k_v)$ corresponding to the nodes $v \leqslant v_0$ (see the list of coefficients in (4.24)).

Therefore all the dependence on the n_v labels is through the factors $\overline{F}_{\underline{\nu}_v}$ in (4.23). This yields that there is an even number of the n_v (if there are any) corresponding to the nodes $v \in V$: two for each branch λ_v with $j_v = l$, by taking into account that $j_{v_0}, j_{v_1} > l$, so that no change is produced by the sign reversal (since, by the parity properties of the Hamiltonians (1.1) and (2.1), one has also $f^{\delta_v}_{\underline{\nu}_v} = f^{\delta_v}_{-\underline{\nu}_v}$). This means that the resonance value is an even function of μ.

2. Let us now consider the case in which the strong resonance is of degree $D_V = 1$ and the tree ϑ has no leaves inside V. In such a case $\alpha_{v_0} = -1$ and $j_{v_0} = l$, hence $D_{\lambda_{v_0}} = 1$ (see (5.3)), then a first order zero in μ will be enough. Moreover there is a $\mathcal{P}$ inside the resonance, we shall distinguish between the cases $v_1 \notin \mathcal{P}$ and $v_1 \in \mathcal{P}$.

Let us consider first the case $v_1 \notin \mathcal{P}$ (in particular this is the case when $\mathcal{P} = v_0$, $k_{v_0} = 0$, provided $k_V \geqslant 2$). In such a case $j_{v_1} > l$ and we can reason as above to obtain a first order zero. Note that in such a case there would be no cancellations between tree values of trees obtained by the sign reversal operation.

On the contrary, if $v_1 \in \mathcal{P}$, then $k_{v_0} = -1$, and one has also $\alpha_{v_1} = -1$ and $j_{v_1} = l$. In this case consider together with the tree ϑ also the tree ϑ' obtained from ϑ by performing the following operation (recall the definition of $\mathcal{F}_V(\vartheta)$): replace the resonance V with a single node v carrying labels $\delta_v = 0$ and $\kappa_v = k_V$ (if k_V is the order of the resonance V), then express the counterterm $\gamma_{\kappa_v}(g_0)$ associated with the node v in terms of trees. If ϑ_1 is the subtree having λ_{v_1} as a root branch, then the values of the two considered trees ϑ and ϑ' can be written, respectively, as $\mathrm{Val}(\vartheta) = A(\vartheta)\mathcal{R}_V \mathrm{Val}(\vartheta_1)$ and $\mathrm{Val}(\vartheta') = A(\vartheta)[\gamma_{k_V}(g_0)\sigma/2]\mathrm{Val}(\vartheta_1)$, where $\sigma/2 = y_v^{(-1)}(1, -1)$ and $A(\vartheta)$ takes into account the factors corresponding to all nodes *not* preceding v_0, and has the same value for both ϑ and ϑ'.

The resonance value $\mathcal{R}_V$, for $\mu = 0$, can be written as

$$\mathcal{R}_V = \overline{\mathrm{Val}}(\vartheta_0) i n_{v_1'}, \quad \text{for some} \quad \vartheta_0 \in \mathcal{T}_{0,k} \quad \text{with} \quad p(v_0) = 0, \quad k_{v_0} = -1, \tag{C2}$$

see the definitions (4.30) and (4.31) of tree value and the definition (C1) of resonance value; remember that we are considering resonances V with degree $D_V = 1$, so that $k_{v_0} = -1$ and, as a consequence, $k'_{v_0} \geqslant 1$; see (4.14). The counterterm $\gamma_\kappa(g_0)$ can be represented in terms of trees as in (4.32); note that, if the tree contributing to $\gamma_\kappa(g_0)$ has $k_{v_0} = -1$, the condition $\alpha_{v_0} = -1$ implies that such a tree has a node $w > v_0$ with $k_w + k'_w = 1$, while all the other nodes $v \neq w$ have $k_v + k'_v = 0$.

Among the contributions in (4.32) to $\gamma_{k_V}(g_0)$ there will be a quantity $\overline{\mathrm{Val}}(\vartheta_2)$, where ϑ_2 will have the same topological form of ϑ_0 in (C2) with the node w such that $k_w + k'_w = 1$ corresponding to the node $v'_1 \in V$; then we denote both nodes by w.

Then $\overline{\mathrm{Val}}(\vartheta_0)$ will be related to $\overline{\mathrm{Val}}(\vartheta_2)$ by

$$\overline{\mathrm{Val}}(\vartheta_2) = -\left[\frac{y^{(\alpha_v)}_{n_v}(k'_w, k_w)|_{k'_w + k_w = 1}}{y^{(\alpha_v)}_{n_v}(k'_w, k_w)|_{k'_w + k_w = 0}} \right] \overline{\mathrm{Val}}(\vartheta_0), \tag{C3}$$

so that a look at the coefficients listed in and after (4.24) shows that the factor in square brackets in (C3) (when it is not vanishing) is equal to $4 i n_w \sigma$. The quantity $\overline{\mathrm{Val}}(\vartheta_2)$, in order to contribute to $\gamma_{k_V}(g_0)\sigma/2$, has to be multiplied by a factor -4σ extra with respect to $\overline{\mathrm{Val}}(\vartheta_0)$, which, on the other hand, has to be multiplied by $i n_w$ in order to contribute to the resonance value $\mathcal{R}_V$ (see (4.32)).

Then, for $\mu = 0$, by summing the values of the two considered contributions one obtains

$$A(\vartheta)\left[\overline{\mathrm{Val}}(\vartheta_0) i n_w - \frac{1}{4\sigma} \overline{\mathrm{Val}}(\vartheta_2) \right] \mathrm{Val}(\vartheta_1), \tag{C4}$$

which is zero by (C3), so that a first order zero is obtained.

3. If there are leaves, nothing changes in the discussion of Appendix C 1, as $k_{v_0}=0$ implies that only leaves w with $j_w > l$ are possible, and $\xi_w(k'_w,0)\equiv 1$ in such a case (see (4.18)).

In Appendix C 2 when discussing the case $v_1 \in \mathcal{P}$, one has to take care of the case in which there is a leaf with highest node $\tilde{w}$ with $k'_w=1$ (such a leaf will be at the end of the path $\mathcal{P}$). In fact the resonances having as entering branch a branch of the path $\mathcal{P}$ cannot have any leaves with $k'_w=1$, while when considering the graphical representation for $\gamma_\kappa(g_0)$, there will be also contributions arising from trees containing a leaf; such contributions will be either of the form (4.32) with $\overline{\mathrm{Val}}(\vartheta_2)=\overline{\mathrm{Val}}(\vartheta_2) in_{v'_1}\xi_{v_1}(1,0)L^{h_1\sigma}_{l\nu(v_1)}(\vartheta_2)$, or of the form $\gamma_\kappa(g_0)=\gamma_{\kappa-h_1}(g_0) in_{v'_1}\xi_{v_1}$ $(1,0)L^{h_1\sigma}_{l\nu(v_1)}(\vartheta_2)$, where $h_1 \geqslant 1$, and ϑ'_2 is a suitable tree of order $k-h_1$. Then one realizes that the two contributions cancel exactly, so that no new case has to be discussed with respect to the analysis of Appendix C, 2.

4. The above discussion completes the proof of approximate cancellations of resonance values (i.e., of cancellations to first and second order, according to the degree of the resonant branch). The existence of cancellations, approximate to the first or second order, is all is needed to obtain the bound (5.16); the analysis continues exactly as in Ref. 5 and is based on simple analyticity arguments that allow us to exploit, via the maximum principle, the fact that in a resonance with momentum $\boldsymbol{\nu}$ the functions of $\mu=\boldsymbol{\omega}_0\cdot\boldsymbol{\nu}$ that have been considered above have a zero in μ of order 1 or 2.

A complete analysis showing that the higher orders contributions (i.e., the part which does not cancel) can be performed as in Ref. 5, Appendix B, and the final result is given by the bound (5.16) in Sec. V, 5.13.

5. We shall show now that all contributions with $(\boldsymbol{\nu}_0(v_0),p(v_0))=(\mathbf{0},0)$ involved in the definition of the counterterms (see Appendix A) must have automatically also $\boldsymbol{\nu}(v_0)=\mathbf{0}$. The analysis performed in Sec. V, 5.1 shows that in order to have $p(v_0)=0$ (for $j_{v_0}=l$), there can be any number of leaves with highest nodes w such that $j_w > l$ and only one leaf w with $j_w=l$ (contributing, respectively, $k'_w=0$ and $k'_w=1$ to $p(v_0)$).

Each time a leaf with $j_w > l$ appears, if we sum together the values of all trees obtained by detaching the leaf with its stalk, then reattaching it to all the other nodes of ϑ_f, we obtain a vanishing contribution: simply by the cancellation mechanism described in Appendix C 1 (assuring there the first order zero), *which, now, is an exact cancellation as the leaf does not contribute to the free momenta of the branches of* ϑ_f, *so that it does not modify the propagators*. So we can suppose that no leaf with $j_w > l$ is possible in trees involved in the determination of the counterterms.

In the same way, if we have a tree ϑ having a leaf with $j_w=l$ and $h_w=h-h_1$ (for some h_1), we can reason as in Appendix C, 2 and consider, together with ϑ, also the tree formed by only one free node, carrying a counterterm label h_1 and bearing the same leaf as ϑ. The same cancellation mechanism described in Appendix C, 2 apply now; again the only difference is that now the cancellation is exact (by the same reason as before).

This shows that no tree with leaves can contribute to $(\boldsymbol{\nu}_0(v_0),p(v_0))=(\mathbf{0},0)$, so that for such trees one has $\boldsymbol{\nu}(v_0)=\boldsymbol{\nu}_0(v_0)=\mathbf{0}$. This, together with the analysis in Appendix A, 1 proves (A4).

APPENDIX D: GRAPHS WITH NONZERO TOTAL HYPERBOLIC MOMENTUM, WITH LEAVES OR WITH COUNTERTERMS

1. Consider first the cases $p(v_0)\neq 0$. In this case we consider the nodes $w < v_0$ with $p(w) =0$ and which are the nearest to v_0; by construction all nodes z between v_0 and the just singled out nodes have $p(z)\neq 0$. Let us denote by $\tilde{\vartheta}$ the set of such nodes z and k_1 the sum of their order labels. The subtrees having as root branches the branches exiting from the nodes w can be considered as trees of the kind of the previous sections (i.e., with $p(w)=0$), so that the integrations corresponding to their nodes can be performed and discussed as before and a bound

$B_0^{2k_0}\eta^{-2k_0}$ follows, if $k_0=k-k_1$. All the other nodes (in $\tilde{\vartheta}$) have $p(z)\neq 0$, so that no real small divisor appears (i.e., the propagators are trivially bounded by (1). The *only delicate point to discuss* concerns the sum over the hyperbolic mode labels, but this can be done as in Ref. 5, p. 292, (or in Ref. 3, item 7 in Appendix A), to which we refer for details beyond the summary that follows.

By noting that the Laurent expansion of each function (of x and x') appearing in (4.14) and (4.16) starts from $k\geqslant -1$ and $k'\geqslant =1$, we can denote by M_1 the maximum of all such functions (multiplied by $1/x$ and $1/x'$, respectively, when $k=-1$ and $k'=-1$) in a disk of radius $\lambda=1/2$. If M_2 is the coefficient of the term with $k_v=-1$ or $k_v'=-1$, set $M=\max\{M_1,M_2\}$.

Consider the tree value (4.20). If $\sigma t<1$, the first integral (corresponding to the highest node v_0) can be split into the sum of two integral, the first one from $\sigma\infty$ to $\sigma 1$ (here the value 1 is an arbitrarily chosen positive number) and the second one from $\sigma 1$ to t. Let us denote by $I_m(\vartheta)$ the first integral and $J_m(\vartheta)$ the second one, if m is the number of nodes in ϑ.

For the nodes $v\in\tilde{\vartheta}$, one has

(1) for each node the associated propagator is bounded by 1 (as $p(v)\neq 0$),
(2) $\Pi_{v\in\tilde{\vartheta}}|\overline{F}_{\nu_v}|\leqslant (CN^2)^{2k_1}$,
(3) for each node v one has $|y_{n_v}^{(\alpha_v)}(k_v,k_v')|\leqslant M2^{k_v+k_v'}$,
(4) the last integration (on τ_{v_0}) produces a factor $\exp[-k_{v_0}'+p(v_0)]=\exp[-\Sigma_{v\in\tilde{\vartheta}}(k_v+k_v')]$.

Then the sum over the hyperbolic mode labels can be performed and gives, for each node $v\in\tilde{\vartheta}$, a factor A^2, where

$$A=\sum_{k=-1}^{\infty}\left(\frac{2}{e}\right)^k=\frac{e^2}{2(e-2)}. \tag{D1}$$

The contribution to $I_m(\vartheta)$ arising from $\tilde{\vartheta}$ a bound $B_1^{2k_1}$ is obtained, $B_1=A^2\mathcal{C}N^2M$, so that, for $I_m(\vartheta)$ a bound

$$B^{2k},\quad B\geqslant\max\{B_0\eta^{-1},B_1\} \tag{D2}$$

is obtained (see (5.6) for the meaning of $\mathcal{C}$).

By taking into account the integral $J_m(\vartheta)$, one can perform a splitting of the integration domain for the integrals corresponding to the nodes immediately preceding v_0 (now for each such nodes the second integral is from $\sigma 1$ to τ_{v_0}), and, iterating such a splitting, one finds that $\mathrm{Val}(\vartheta)$ can be written as sum of at most 2^m terms each of which has the form (for some integer p),

$$\left[\prod_{v\in\vartheta^*}\int_{\sigma 1}^{\tau_{v'}}d\tau_v(\cdots)\right]I_{m_1}(\vartheta_1)\cdots I_{m_p}(\vartheta_p), \tag{D3}$$

where $\vartheta_1,\ldots,\vartheta_p$ are disjoint subtress of ϑ and ϑ^* is the set of the m_0 nodes in ϑ not belonging to any such subtrees and $m_1+\cdots+m_p+m_0=m$. The dots between the parentheses denote the product of the functions in

$$\prod_{w\in\vartheta}Y^{(\alpha_w)}(\tau_w',\tau_w) \tag{D4}$$

which depend on τ_v, for a given $v\in\vartheta^*$, and therefore is a quantity bounded by 1 (see (4.14) and (4.16)). Note that the functions Y have *no singularity* as functions of their arguments $x=e^{\sigma g\tau}$, $x'=e^{\sigma g\tau'}$, when $x,x'=1$ (or $\tau,\tau'=0$), even though the values $x,x'=1$ lie on the convergence circle (the singularities being at $x,x'=\pm i$). Furthermore each integration from $\sigma 1$ to $\tau_{v'}$, once the integrand has been bounded, gives 1, while the integrals $I_{m_j}(\vartheta_j)$, $j=1,...,p$ can be bounded as before.

Of course, if $\sigma t>1$, the discussion is easier as no splitting of the integration domains is needed.

So we can conclude that a final bound $(2B)^{2k}$ is obtained for Val(ϑ); so far neither leaves nor counterterms have been considered.

2. Introducing the leaves and the counterterms, one sees (recall Remark 4.4) that the value of any tree ϑ can be always be written as the product of a factor like (4.28) times the product of the counterterms and of the leaf values; each counterterm can be decomposed in turn as sum of values of amputated trees (see (4.32)). As each leaf and each amputated tree can contain other leaves and counterterms we can iterate such a decomposition procedure, until, at the end, the value of the tree ϑ, with highest node v_0, turns out to be given by the product of factorizing terms which (1) either are of the form (4.28), with $\rho_w=0$ for any subtree with highest node $w<v_0$ and with $\rho_w=0,1$ if $w=v_0$, (2) or differ from (4.28) simply because no integration is performed corresponding to the highest node.

The terms as in item (1) correspond to subtrees contributing to leaf values (for $w<v_0$) and to Val(ϑ) itself (for $w=v_0$), while the terms as in item (2) correspond to amputated trees contributing to counterterms. Then a natural decomposition of the tree ϑ into subtrees $\tilde{\vartheta}$ (amputated or not) follows: each of such subtree contains neither counterterms nor leaves (by construction). Furthermore the subtrees contributing to leaves are linked to nodes of some other subtrees through their stalks, while the amputated subtrees are not linked to any node (as there is no branch exiting from the highest node). To keep memory of the node to which the counterterm label is attached we can draw a hatched line connecting the amputated subtree to such a node.

So for each subtree $\tilde{\vartheta}$ (amputated or not) one can reason as above and a bound B^{m_0} is obtained, if B is the same constant as before and if $m_0\leqslant 2k_0$ is the number of free nodes of the subtree. For all of them the resummation described in Sec. V, 5.9 has to be performed, to bound the values of the subtrees ϑ_v, with $p(v)=0$, $v\in\tilde{\vartheta}$: such a resummation is taken into account by the constant B. By collecting together all bounds one obtains, for the (normalized) sum of the values of the all trees ϑ' generated by the resummations corresponding to the families $\mathcal{F}(\vartheta_v)$, a bound B^{2k}, if k is the order of ϑ.

Therefore we are left with the sum of all possible ways to arrange leaves and counterterms. The choice of the leaves is uniquely determined by the assignments of the labels ρ_v, $v\in\vartheta$, so that it gives a factor 2^m (recall that the number of nodes m is such that $m<2k$).

In the same way one can deal with the counterterms; simply one has to distinguish between solid and hatched lines, so that another factor 2^m is produced.

3. Then the sum over all the other labels can be performed, in the same way as for the contributions without leaves and without counterterms (see the beginning of this subsection). The sum over the hyperbolic modes has been taken into account by the constant B (see (D2)); moreover

(1) the sum over the mode labels is bounded by $(2N+1)^{m(l-1)}(2N_0+1)^m$,
(2) the sum over the angle labels is bounded by l^m,
(3) the sum over the order labels is bounded by 2^m,
(4) the sum over the badge labels is bounded by 2^m.

Therefore, by taking into account that the momenta and the hyperbolic momenta are uniquely determined by the mode labels and, respectively, the hyperbolic mode labels and that the sums over the leaf labels and counterterms labels have been already considered, we are left with the sum of (unlabeled) numbered trees (see comments after (4.27)): but these are no more than $2^{2m}m!$, so that, both for $X^{k\sigma}_{j\nu}(t)$ and $\gamma_k(g_0)$, a final bound D^k is obtained, for some constant D: in terms of B the constant D is given by $D=B2^6l(2N+1)^{(l-1)}(2N_0+1)$, i.e., (5.18). In particular one has that D is proportional to η^{-2}, as B is so.

Note that, as a matter of fact, we have bounded $\Xi_{j\nu}^{h\sigma}(t)$ in (4.27) by neglecting the constraint on j and $\boldsymbol{\nu}$. Therefore, by making use of the fact that the Fourier coefficients with $|\boldsymbol{\nu}|>h(N+N_0)$ vanish at order h as a consequence of the trigonometric assumption on the perturbation f_1, see (2.2), the bound $(2B)^{2k}$ is a bound both for the Fourier coefficients of $X^\sigma(t;\boldsymbol{\alpha})$ and for the function $X^\sigma(t;\boldsymbol{\alpha})$ itself.

(Received 28 June 1999; accepted for publication 16 August 1999)

In this work we develop a general procedure for constructing the recursion operators for nonlinear integrable equations admitting Lax representation. Several new examples are given. In particular, we find the recursion operators for some KdV-type systems of integrable equations. © *1999 American Institute of Physics.* [S0022-2488(99)03212-0]

I. INTRODUCTION

It is well known that most of the integrable nonlinear partial differential equations,

$$u_t = F(t,x,u,u_x,\ldots,u_{nx}), \tag{1}$$

admit a Lax representation,

$$L_t = [A,L], \tag{2}$$

so that the inverse scattering method is applicable. The generalized symmetries[1] of (1) have also Lax representations with the same L operator,

$$L_{t_n} = [A_n, L], \quad n \geqslant 1. \tag{3}$$

The recursion operator $\mathcal{R}$, satisfying the equation (see Ref. 2)

$$\mathcal{R}_t + [D_{\mathrm{F}}, \mathcal{R}] = 0, \tag{4}$$

where D_{F} is the Frechét derivative of the function F, generates symmetries of (1) starting from the simplest ones. In general, $\mathcal{R}$ is a nonlocal operator (a pseudodifferential operator).

The construction of the recursion operator of a given integrable system (1) is not an easy task. Several works are devoted to this subject. Among these works, most of the authors use (4) for the construction of the recursion operator.[3–8] There are several difficulties in this direct approach. The main problems are the choices of the order of $\mathcal{R}$ and the structure of the nonlocal terms. This is an approach having no relation with the Lax representation (2).

On the other hand, some of the authors used Lax representation for this purpose. Most of these works are related to the squared eigenfunctions of the Lax operator[9–13] and are based on finding an eigenvalue equation for the squared eigenfunctions of the Lax operator. The operator corresponding to this eigenvalue equation turns out to be the adjoint of the recursion operator.

[a]Electronic mail: gurses@fen.bilkent.edu.tr

There is an alternative use of the Lax representation to construct recursion operators. This approach is based on the explicit construction of the A_n operators (3). It was first used by Symes,[14] Adler[15] (see also Dorfman–Fokas,[16] Fokas–Gel'fand[17]) and Antonowicz–Fordy.[18,19] Although these authors use the Lax representation in different ways, their approach is basically the same. Symes and Adler use the Gel'fand–Dikii[20] construction of the A_n operators. On the other hand, Antonowicz–Fordy determines these operators from integrability condition (3) and by using an ansatz for A_n. Their basic aim is to determine the Hamiltonian operators θ_1 and θ_2[21] of the equations under consideration. The recursion operator is simply given by $\mathcal{R}=\theta_2\theta_1^{-1}$. Their approach is based on some explicit formulas for coefficients of the A_n operator. This is necessary to find the Hamiltonian operators θ_1 and θ_2, and it seems that this approach is quite effective to determine the bi-Hamiltonian structure for the simple cases but it becomes more complicated when the L-operator has a sophisticated structure.

If one is interested only in the determination of the recursion operator $\mathcal{R}$, we shall show in this work that it is possible to succeed this without any concrete information of the coefficients of A_n operators. We use only an ansatz $\tilde{A}=\mathcal{P}A+R$ that relates A_n operators for different n. Here $\mathcal{P}$ is some operator that commutes with the L operator and R is the remainder.

We follow this basic idea, partially used by Symes,[14] Adler.[15] Shabat and Sokolov,[22] and establish an extremely simple, effective, and algorithmic method for the construction of recursion operators when the Lax representation (2) is given.[23]

In the next section we consider the case where L is a scalar operator. We first consider the case where L is a differential operator and then the case where it is a pseudodifferential operator. In each case we present our method, discuss the reductions, and give examples for illustrations. In Sec. III we consider Lax operator taking values in a Lie algebra. We give our method both for the general case and also for the reductions. We give one example for each case in the text. Several additional examples are given in the Appendices A, B, and C corresponding to all different cases.

II. SCALAR LAX REPRESENTATIONS

First we consider equations with the scalar Lax representations of the form

$$L_t=[A,L], \tag{5}$$

where L is, in general, a pseudodifferential operator of order m and A is a differential operator whose coefficients are functions of x and t.

The different choice of operators A for a given L leads to a hierarchy of nonlinear systems (3). It is well known that one can define operators A_n by the following formula:[20]

$$A_n=(L^{n/m})_+, \tag{6}$$

where $L^{n/m}$ is a pseudodifferential series of the form $L^{n/m}=\Sigma_{-\infty}^{n} v_i D^i$ and $(L^{n/m})_+=\Sigma_{i=0}^{n} v_i D^i$. Here v_i are some concrete functions depending on the coefficients of L and D is the total derivative with respect to x.

In Refs. 25 and 26 the relationships between the Kac–Moody algebras and special types of scalar differential and pseudodifferential operators L were established. All corresponding integrable systems are Hamiltonian ones. For most of them a second Hamiltonian structure is not known up to now.

In this section and Appendices A, B, and C we consider the simplest systems from Refs. 25 and 26 as examples and find their recursion operators. In the sequel these examples will be referred to as Drinfeld–Sokolov (DS) systems. It is interesting to note that in all these examples the order of the recursion operator is equal to the Coexter number of the corresponding Kac–Moody algebra.

A. Gel'fand–Dikii systems

In this section we shall consider the case where L is a differential operator,

$$L = D^m + u_{m-2}D^{m-2} + \cdots + u_0, \tag{7}$$

where u_i, $i=0,1,...,m-2$ are functions of x, t. In the framework of Ref. 25, this corresponds to the Kac–Moody algebras of the type $A^{(1)}_{m-1}$.

To show that (3) is equivalent to a system of $(m-1)$ evolution equations with respect to u_i one can use the following standard reasoning. Set

$$L^{n/m} = (L^{n/m})_+ + (L^{n/m})_-, \tag{8}$$

where $(L^{n/m})_+$ is the differential part of the series $L^{n/m}$ and $(L^{n/m})_-$ is a series of order$\leqslant -1$. Since $[L, L^{n/m}] = 0$ we have

$$[(L^{n/m})_+, L] = [L, (L^{n/m})_-]. \tag{9}$$

The left-hand side of (9) is a differential operator, but the right side is a series of order$\leqslant n-2$. Thus, both sides of (3) are differential operators of order$\leqslant n-2$ and it is equivalent to a system of evolution equations for the dependent variables u_i, $i=0,1,...,m-2$. This system can be obtained by comparing the coefficients of D^i, where $0,...,m-2$ in (3).

Since $L^{(n+m)/m} = LL^{n/m}$, then we have

$$A_{m+n} = (LL^{n/m})_+ = L(L^{n/m})_+ + (L(L^{n/m})_-)_+, \tag{10}$$

which leads directly to

$$L_{t_{n+m}} = [A_{n+m}, L] = LL_{t_n} + [(L(L^{n/m})_-)_+, L]. \tag{11}$$

The above equation (11) has been given also by Symes[14] (see also Adler's paper[15]). In his work Symes expressed the coefficients of the both parts of (11), in a rather complicated way, in terms of some finite set of coefficients of the resolvent for an L operator. That allows him to express $L_{t_{n+m}}$ in terms of L_{t_n}. This relation gives directly the recursion operator. He gave explicit formulas for the cases $m=2$ and $m=3$.

In this section we shall show that in order to construct the recursion operator it suffices to know only that

$$L_{t_{n+m}} = LL_{t_n} + [R_n, L]. \tag{12}$$

Obviously, it follows from the following.

Proposition 1: For any n,

$$A_{n+m} = LA_n + R_n, \tag{13}$$

where R_n is a differential operator of order $\leqslant m-1$.

Proof: The relation (13) coincides with (10) if we put

$$R_n = (L(L^{n/m})_-)_+. \tag{14}$$

Since $(L^{n/m})_-$ is a series of order $\leqslant -1$, then $\mathrm{ord}(R_n) \leqslant m-1$.

Remark 1: It follows from the formula

$$A_{n+m} = (L^{n/m}L)_+ = (L^{n/m})_+L + ((L^{n/m})_-L)_+, \tag{15}$$

that

$$A_{n+m}=A_nL+\overline{R_n}\,, \tag{16}$$

and

$$L_{t_{n+m}}=L_{t_n}L+[L,\overline{R_n}], \tag{17}$$

where $\overline{R_n}$ is a differential operator of order $\leqslant m-1$.

To find the recursion operator we can simply equate the coefficients of different powers of D in (12). It is easy to see that in this comparison of the coefficients of D^i, $i=2m-2,...,m-1$ we determine R_n in terms of the coefficients of operators L and L_{t_n}. It is important that the resulting formulas turn out to be linear in the coefficients of L_{t_n}. The remaining coefficients of D^i, $i=m-2,...,0$ in (12) give us the relation

$$\begin{pmatrix} u_0 \\ \cdot \\ \cdot \\ \cdot \\ u_{m-2} \end{pmatrix}_{t_{n+m}} =\mathcal{R}\begin{pmatrix} u_0 \\ \cdot \\ \cdot \\ \cdot \\ u_{m-2} \end{pmatrix}_{t_n}, \tag{18}$$

where $\mathcal{R}$ is a recursion operator. Instead of (12) one can use (17). The corresponding recursion operators coincide.

Example 1. KdV equation: The KdV equation,

$$u_t=\tfrac{1}{4}(u_{3x}+6uu_x), \tag{19}$$

has a Lax representation with

$$L=D^2+u, \quad A=(L^{3/2})_+\,. \tag{20}$$

Since in this case $L_{t_{n+2}}=u_{t_{n+2}}\equiv u_{n+2}$ and $L_{t_n}=u_{t_n}\equiv u_n$, the main relation (12) takes the form

$$u_{n+2}=(D^2+u)\cdot u_n+[R_n,L], \tag{21}$$

with $R_n=a_nD+b_n$.

Now if we equate successively to zero the coefficients of D^2, D, and D^0 in the above equation, we obtain

$$a_n=\tfrac{1}{2}D^{-1}(u_n), \quad b_n=\tfrac{3}{4}u_n\,,$$

and

$$u_{n+2}=(\tfrac{1}{4}D^2+u+\tfrac{1}{2}u_xD^{-1})u_n\,,$$

that gives the standard recursion operator for the KdV equation,

$$\mathcal{R}=\tfrac{1}{4}D^2+u+\tfrac{1}{2}u_xD^{-1}. \tag{22}$$

In the same way one can find a recursion operator for the Boussinesq equation (see Appendix A).

B. Symmetric and skew-symmetric reductions of a differential Lax operator

The standard reductions of the Gel'fand–Dikii systems are given by the conditions $L^*=L$ or $L^*=-L$. Here $*$ denotes the adjoint operation defined as follows. Let L be a differential operator,

$L=\Sigma a_i D^i$. Its adjoint L^* is given by $L^*=\Sigma(-D)^i \cdot a_i$. It is easy to see that if $L^*=L$ then $m=\mathrm{ord}(L)$ must be an even integer. For the case $L^*=-L$, it must be an odd integer.

It is well known that for both reductions all possible A_n are defined by (6), where n takes odd integer values. This condition provides that $(A_n)^*=-A_n$ that is necessary for (3) to be compatible.

If $L^*=L$, the formula $A_{n+m}=(LL^{n/m})_+=(L^{(n+m)/m})_+$ gives a correct A_n operator since $n+m$ is an odd integer. Thus, in this case Proposition 1 remains valid and the recursion operator can be found from (12) or (17).

On the other hand, if $L^*=-L$ then both integers m and n are odd and hence their sum $m+n$ is an even integer. This means that $(L^{(n+m)/m})_+$ cannot be taken as an A_n operator. In this (skew adjoint) case we must take

$$A_{n+2m}=(L^{(n+2m)/m})_+=(L^2L^{n/m})_+ ,$$

to find the recursion operator. Following the proof of Proposition 1 we obtain Proposition 2.

Proposition 2: If $L^*=-L$ then

$$A_{n+2m}=L^2A_n+R_n , \tag{23}$$

where $\mathrm{ord}(R_n)<2\,\mathrm{ord}(L)$. It follows from (23) that

$$L_{t_{n+2m}}=L^2L_{t_n}+[R_n ,L]. \tag{24}$$

Remark 2: Instead of (23) we can use the ansatz

$$A_{n+2m}=LA_nL+\tilde{R}_n , \tag{25}$$

or

$$A_{n+2m}=A_nL^2+\tilde{\tilde{R}}_n . \tag{26}$$

The recursion operators obtained by the utility of (23), (25), and (26) all coincide.

In the works,[25,26] more general reductions $L^\dagger=\pm L$ were also considered. Here $L^\dagger=KL^*K^{-1}$, where K is a given differential operator, such that LK^{-1} is a differential operator. In this general reductions, as well, possible A_n operators are given by (6), with n being an odd integer. Propositions 1 and 2 are valid for this general symmetric and skew-symmetric cases and hence one can use Eqs. (12), (24) accordingly to obtain the recursion operators.

Example 2. Kupershmidt equation: This equation,

$$u_t=u_{5x}+10uu_{3x}+25u_xu_{2x}+20u^2u_x , \tag{27}$$

has the Lax pair

$$L=D^3+2uD+u_x , \quad A=(L^{5/3})_+ . \tag{28}$$

In this case $L^*=-L$; therefore we use Eq. (24) with

$$\tilde{R}_n=a_nD^5+b_nD^4+c_nD^3+d_nD^2+e_nD+f_n . \tag{29}$$

By equating the coefficients of powers of D in (24), we obtain

$$a_n=\tfrac{2}{3}D^{-1}(u_n), \quad b_n=\tfrac{11}{3}u_n , \quad c_n=\tfrac{1}{9}(20uD^{-1}(u_n)+73u_{n,x}),$$

$$d_n=\tfrac{1}{3}(10u_xD^{-1}(u_n)+22uu_n+27u_{n,2x}),$$

$$e_n=\tfrac{1}{27}(70u_{2x}D^{-1}(u_n)-2D^{-1}(u_{2x}u_n)+40u^2D^{-1}(u_n)-8D^{-1}(u^2u_n)$$
$$+134u_{n,3x}+212uu_{n,x}+184u_xu_n),$$

$$f_{n,x}=\tfrac{1}{27}(20u_{4x}D^{-1}(u_n)+74u_{3x}u_n+126u_{2x}u_{n,x}+40uu_{2x}D^{-1}(u_n)+40u_x^2D^{-1}(u_n)$$
$$+136u_xu_{n,2x}+27uu_xu_n+28u_{n,5x}+64uu_{n,3x}+16u^2u_{n,x}),$$

and the recursion operator for the Kupershmidt equation:

$$\mathcal{R}=D^6+12uD^4+36u_xD^3+(49u_{2x}+36u^2)D^2+5(7u_{3x}+24uu_x)D+13u_{4x}+82uu_{2x}+69u_x^2$$
$$+32u^3+2u_xD^{-1}(u_{2x}+4u^2)+2(u_{5x}+10uu_{3x}+25u_xu_{2x}+20u^2u_x)D^{-1}. \tag{30}$$

C. Pseudodifferential Lax operator

In this section we generalize our scheme to the case of pseudodifferential Lax operators. The only difference is that in formulas like (13) and (23) the R_n operator also becomes a pseudodifferential operator.

It follows from these formulas that the structure of the nonlocal terms in R_n is, in general, similar to the nonlocal terms in L since A_{n+m} and A_n are differential operators.

For skew-symmetric case, A_n may be defined by either (23) or (25), or (26). In the pseudo-differential case they are not equivalent, in the sense that the nonlocal part of R_n depends on which ansatz we choose. For illustration, let us consider the case $L=MD^{-1}$, where M is a differential operator. The following lemma shows that if $L^\dagger=L$ or $L^\dagger=-L$, where

$$L^\dagger=DL^*D^{-1}, \tag{31}$$

then the formulas (13) and (25) are much suitable then (16), (23), and (26).

Lemma: Let $L^\dagger=\epsilon L$, where $\epsilon=\pm1$. Then

$$R_n=D^{m-1}+\cdots+a_0,\quad \text{for}\ \ \epsilon=1, \tag{32}$$

where R_n is defined by (13), and

$$\tilde{R}_n=D^{2m-1}+\cdots+a_{-1}D^{-1},\quad \text{for}\ \ \epsilon=-1, \tag{33}$$

where $\tilde{R}_n$ is defined by (25).

Proof: If $L=MD^{-1}$ then $L^\dagger=\epsilon L$ implies $M^*=-\epsilon M$. It is easy to show that $(L^{1/m})^\dagger=-L^{1/m}$. Hence $(L^{n/m})^\dagger=-L^{n/m}$ for an odd integer n. Define now a series K_n by

$$L^{n/m}=DK_n.$$

It is easy to prove that $K_n^*=K_n$. Since $K_n=(K_n)_++(K_n)_-$ and $(K_n)^*=K_n$, we have

$$(K_n)_+^*=(K_n)_+,\quad (K_n)_-^*=(K_n)_-.$$

From the last formula it follows that $\mathrm{ord}(K_n)_-\leqslant-2$, which leads to an important result,

$$A_n=(L^{n/m})_+=D(K_n)_+.$$

This implies that

$$LA_n=M(K_n)_+ \tag{34}$$

is a differential operator. Now using (34) in (13) and (25) for the cases $\epsilon=1$ and $\epsilon=-1$, respectively, we find the ansatz for A_n given by (32) and (33).

Example 3 ($\epsilon=-1$)*:* It is known that the KdV equation has, besides the standard Lax representation, the following Lax pair:

$$L=(D^2+u)D^{-1}, \quad A=(L^3)_+ . \tag{35}$$

The L operator satisfies the reduction $L^\dagger=-L$. According to the formula (33) we have

$$\tilde{R}_n=a_nD+b_n+c_nD^{-1}.$$

It follows from (25) that

$$a_n=D^{-1}(u_n), \quad b_n=u_n , \quad c_n=-u_{n,x}-uD^{-1}(u_n).$$

The remaining equation in (25) gives the recursion operator

$$\mathcal{R}=D^2+4u+2u_xD^{-1}. \tag{36}$$

Example 4 ($\epsilon=1$). *DSIII system:* The DSIII system[25,26] is given by

$$\begin{aligned} u_t&=-u_{3x}+6uu_x+6v_x , \\ v_t&=2v_{3x}-6uv_x . \end{aligned} \tag{37}$$

The nonlocal Lax representation for this system is

$$\begin{aligned} L&=(D^5-2uD^3-2D^3u-2Dw-2wD)D^{-1}, \\ A&=(L^{3/4})_+ , \end{aligned} \tag{38}$$

where $w=v-u_{2x}$. Since $L^\dagger=L$ we can use (32), which gives us

$$R_n=a_nD^3+b_nD^2+c_nD+d_n . \tag{39}$$

By equating the coefficients of the powers of D in (25), we obtain

$$a_n=D^{-1}(u_n), \quad b_n=4u_n ,$$

$$c_n=\tfrac{1}{2}(-6uD^{-1}(u_n)+11u_{n,x}+2D^{-1}(uu_n)+2D^{-1}(v_n)),$$

$$d_{n,x}=-\tfrac{1}{2}(6u_{2x}D^{-1}(u_n)+10u_xu_n-5u_{n,3x}+4uu_{n,x}-6v_{n,x}).$$

The recursion operator of the DSIII is found as

$$\mathcal{R}=\begin{pmatrix} \mathcal{R}_0^0 & \mathcal{R}_1^0 \\ \mathcal{R}_0^1 & \mathcal{R}_1^1 \end{pmatrix}, \tag{40}$$

with

$$\begin{aligned} \mathcal{R}_0^0&=D^4-8uD^2-12u_xD-8u_{2x}+16u^2+16v+(-2u_{3x}+12uu_x+12v_x)D^{-1}+4u_xD^{-1}u, \\ \mathcal{R}_1^0&=-10D^2+8u+4u_xD^{-1}, \\ \mathcal{R}_0^1&=10v_xD+12v_{2x}+(4v_{3x}-12uv_x)D^{-1}+4v_xD^{-1}u, \\ \mathcal{R}_1^1&=-4D^4+16uD^2+8u_xD+16v+4v_xD^{-1}. \end{aligned} \tag{41}$$

This recursion operator has recently been given in Ref. 6.

III. MATRIX *L* OPERATOR OF THE FIRST ORDER

In this section we demonstrate how our approach, given in the previous sections, can be generalized to the case where L is a matrix operator of the form

$$L=D_x+\lambda a+q(x,t). \tag{42}$$

A. General case

Let us consider the Lax operator (42), where q and a belong to a Lie algebra g and λ is the spectral parameter. The constant element a is supposed to be such that

$$g=\mathrm{Ker}(\mathrm{ad}_a)\oplus \mathrm{Im}(\mathrm{ad}_a). \tag{43}$$

First, let us recall the procedure[25] of constructing the A operators for the Lax operator (42).

Proposition 3: There exist unique series,

$$u=u_{-1}\lambda^{-1}+u_{-2}\lambda^{-2}+\cdots, \quad u_i\in \mathrm{Im}(\mathrm{ad}_a), \tag{44}$$

$$h=h_0+h_{-1}\lambda^{-1}+h_{-2}\lambda^{-2}+\cdots, \quad h_i\in \mathrm{Ker}(\mathrm{ad}_a), \tag{45}$$

such that

$$e^{\mathrm{ad}_u}(L)=L+[u,L]+\tfrac{1}{2}[u,[u,L]]+\cdots=D_x+a\lambda+h. \tag{46}$$

Let b be a constant element of g such that $[b,\mathrm{Ker}(\mathrm{ad}_a)]=\{0\}$. It follows from (45) that $[b\lambda^n,D_x+a\lambda+h]=0$. Hence $[\Phi_{b,n},L]=0$, where

$$\Phi_{b,n}=e^{-\mathrm{ad}_u}(b\lambda^n). \tag{47}$$

Then the corresponding A operator of the form

$$A_{b,n}=b\lambda^n+a_{n-1}\lambda^{n-1}+\cdots+a_0, \tag{48}$$

is defined by the formula

$$A_{b,n}=(\Phi_{b,n})_+, \tag{49}$$

where

$$\left(\Sigma_{-\infty}^{n}\alpha_i\lambda^i\right)_+=\Sigma_0^n\alpha_i\lambda^i. \tag{50}$$

According to (47),

$$\Phi_{b,n+1}=\lambda\Phi_{b,n}. \tag{51}$$

Hence

$$A_{b,n+1}=(\lambda\Phi_{b,n})_+=\lambda(\Phi_{b,n})_++(\lambda(\Phi_{b,n})_-)_+. \tag{52}$$

The last formula shows that

$$A_{b,n+1}=\lambda A_{b,n}+R_n, \quad R_n\in g, \tag{53}$$

where R_n does not depend on λ. Substituting (53) into the Lax equation $L_{t_{n+1}}=[A_{b,n+1},L]$, we get

$$L_{t_{n+1}}=\lambda L_{t_n}+[R_n,L]. \tag{54}$$

Using the ansatz (54), one can easily find the corresponding recursion operator.

Example 5: The system

$$u_t=-\tfrac{1}{2}u_{xx}+u^2v,$$
$$v_t=\tfrac{1}{2}v_{xx}-v^2u, \tag{55}$$

is equivalent to the nonlinear Schrödinger equation, has a Lax operator

$$L=D+\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}\lambda+\begin{pmatrix}0 & u\\ v & 0\end{pmatrix}. \tag{56}$$

The Lie algebra g in this example coincides with $sl(2)$.

Using (54) with

$$R_n=\begin{pmatrix}a_n & b_n\\ c_n & -a_n\end{pmatrix},$$

we find that

$$a_n=\tfrac{1}{2}D^{-1}(vu_n+uv_n),$$
$$b_n=\tfrac{1}{2}u_n,\quad c_n=-\tfrac{1}{2}v_n,$$

and the recursion operator of the system (55) is given by

$$\mathcal{R}=\begin{pmatrix}-\tfrac{1}{2}D+uD^{-1}v & uD^{-1}u\\ -vD^{-1}v & \tfrac{1}{2}D-vD^{-1}u\end{pmatrix}. \tag{57}$$

B. Reductions in matrix case

In the general case considered in the previous section the A_n operators belong to the Lie algebra,

$$\mathfrak{a}_+=\{\Sigma_{i=0}^{\kappa}a_i\lambda^i,\ \ a_i\in g,\ \ \kappa\in Z_+\}, \tag{58}$$

that is a subalgebra of the Lie algebra,

$$\mathfrak{a}=\{\Sigma_{-\infty}^{\kappa}a_i\lambda^i,\ \ \alpha_i\in g,\ \ \kappa\in Z\}. \tag{59}$$

A standard σ reduction is defined by any automorphism σ of the Lie algebra g of finite order κ. Because $\sigma^\kappa=\mathrm{Id}$, the eigenvalues of σ are $\epsilon^i, i=0,...,\kappa-1$, where ϵ is a primitive κ root of unity.

Let g_i be an eigenspace corresponding to eigenvalue ϵ^i. Then the following reduction $a_j\in g_i$, where $i=j(\mathrm{mod}\ \kappa)$ in (58) and (59) is compatible with Eqs. (3). Note that according to this definition $a\in g_1$, and the potential $q(x,t)$ in (42) belongs to g_0 or, the same, satisfies $\sigma(q)=q$.

It is easy to see that, to satisfy such a reduction, we must use the ansatz

$$A_{b,n+\kappa}=\lambda^\kappa A_{b,n}+R_n, \tag{60}$$

where

$$R_n=r_{\kappa-1}\lambda^{\kappa-1}+\cdots+r_0,\quad r_i\in g_i. \tag{61}$$

Further generalizations are associated with modifications of sign ‘‘+’’ in (50), which corresponds to the simplest decomposition of algebra $\mathfrak{a}$ into the direct sum of two subalgebras,

$$\mathfrak{a}=\mathfrak{a}_+\oplus\mathfrak{a}_-\,, \tag{62}$$

where $\mathfrak{a}_+$ is given by (58) and

$$\mathfrak{a}_-=\{\Sigma_{-\infty}^{-1}a_i\lambda^i,\ \ a_i\in g\}. \tag{63}$$

The sign ''+'' in (50) is the projection of onto $\mathfrak{a}_+$ parallel to $\mathfrak{a}_-$. If we have a different decomposition (62), then the construction from Proposition 3 is also valid, but we have the following condition:

$$R_n\in\mathfrak{a}_+\cap\lambda\,\mathfrak{a}_-\,, \tag{64}$$

instead of $R_n\in g$. If we also have the σ reduction, we must use the most general ansatz (60), where

$$R_n\in\mathfrak{a}_+\cap\lambda^{\kappa}\mathfrak{a}_-\,. \tag{65}$$

Example 6: Let us consider the following equation:

$$u_t=\tfrac{1}{4}u_{xxx}-\tfrac{3}{8}u_{xx}u+\tfrac{3}{8}uu_{xx}-\tfrac{3}{8}uu_xu, \tag{66}$$

where u is a square matrix of arbitrary size, or more generally, u belongs to an arbitrary associative algebra $\mathcal{K}$. This equation has a Lax representation with

$$L=D+\begin{pmatrix}0&\mathbf{1}\\ \mathbf{1}&0\end{pmatrix}\lambda+\begin{pmatrix}u&0\\0&0\end{pmatrix}. \tag{67}$$

Here $\mathbf{1}$ is the unity of $\mathcal{K}$. The reduction (67) can be described as follows (see Ref. 27). The Lie algebra g is the algebra of all 2×2 matrices with entries belonging to $\mathcal{K}$. The automorphism σ is defined by

$$\sigma(X)=TXT^{-1}, \tag{68}$$

where

$$T=\begin{pmatrix}\mathbf{1}&0\\0&-\mathbf{1}\end{pmatrix}.$$

Obviously $\sigma^2=\mathrm{Id}$ and eigenvalues of σ are 1 and -1. The corresponding eigenspaces are

$$g_0=\begin{Bmatrix}*&0\\0&*\end{Bmatrix},\quad g_1=\begin{Bmatrix}0&*\\ *&0\end{Bmatrix}, \tag{69}$$

and therefore the coefficients a_i in (59) have the following structure:

$$a_{2j}=\begin{pmatrix}*&0\\0&*\end{pmatrix},\quad a_{2j+1}=\begin{pmatrix}0&*\\ *&0\end{pmatrix}. \tag{70}$$

The subalgebra $\mathfrak{a}_+$ is given by (58), where the coefficients have the structure (70) and, additionally,

$$a_0=\begin{pmatrix}*&0\\0&0\end{pmatrix}.$$

The subalgebra $\mathfrak{a}_-$ has the following form:

$$\mathfrak{a}_- = \Sigma_{-\infty}^{0} a_i \lambda^i, \tag{71}$$

where a_0 is of the form

$$a_0 = \begin{pmatrix} \alpha & 0 \\ 0 & \alpha \end{pmatrix}, \quad \alpha \in \mathcal{K}.$$

The A operator for (66) is given by formula $A = (\Phi_{a,3})_+$ [see (49)], where

$$a = \begin{pmatrix} 0 & \mathbf{1} \\ \mathbf{1} & 0 \end{pmatrix},$$

and ''+'' means the projection onto $\mathfrak{a}_+$ parallel to $\mathfrak{a}_-$.

According to (65), R_n is of the form

$$R_n = \begin{pmatrix} a_n & 0 \\ 0 & a_n \end{pmatrix} \lambda^2 + \begin{pmatrix} 0 & b_n \\ c_n & 0 \end{pmatrix} \lambda + \begin{pmatrix} d_n & 0 \\ 0 & 0 \end{pmatrix}. \tag{72}$$

It follows from

$$L_{t_{n+2}} = \lambda^2 L_{t_n} + [R_n, L], \tag{73}$$

that

$$u_n - a_{n,x} + [a_n, u] + b_n - c_n = 0 \quad c_n - b_n - a_{n,x} = 0,$$

$$d_n - b_{n,x} - u b_n = 0, \quad d_n + c_{n,x} - c_n u = 0,$$

$$u_{n+2} = -d_{n,x} + [d_x, u].$$

Finding a_n, b_n, c_n, and d_n from this system, we obtain the following recursion operator:

$$\mathcal{R} = -(D + \mathrm{ad}_u)(-D + R_u)(2D + \mathrm{ad}_u)^{-1}(D + L_u)D(2D + \mathrm{ad}_u)^{-1}, \tag{74}$$

where R_u and L_u are the operators of right and left multiplications by u, respectively.

Note that in the commutative case (66) coincides with the modified KdV equation. It is easy to verify that (74) becomes the standard recursion operator of a modified KdV equation. All factors in (74) have to be regarded as operators acting on a (noncommutative) polynomial depending on $u, u_x, u_{xx}, \ldots$.

IV. CONCLUSION

In this work we devoted ourselves in the construction of recursion operators when the Lax representation is given. We have shown that our approach can be easily generalized to all cases where the L operator is a polynomial of λ. It would be interesting to generalize it for the cases of more complicated λ dependence of L as well as for the cases of $2+1$-dimensional equations, Toda-type lattices, and ordinary differential equations.

APPENDIX A: EXAMPLE TO SEC. II A

The Boussinesq equation,

$$u_{tt} = -\tfrac{1}{3}(u_{4x} + 2(u^2)_{2x}), \tag{A1}$$

can be expressed in the form of a pair of first-order evolution equations,

$$u_t = v_x,$$
$$v_t = -\tfrac{1}{3}(u_{3x} + 8uu_x). \tag{A2}$$

This system has a Lax pair,

$$L = D^3 + 2uD + u_x + v, \quad A = (L^{2/3})_+. \tag{A3}$$

To construct the recursion operator for this system, we use Eq. (12) with the differential operator,

$$R_n = a_n D^2 + b_n D + c_n.$$

By equating the coefficients of the powers of D in (12), we find

$$a_n = \tfrac{2}{3}D^{-1}(u_n), \quad b_n = \tfrac{1}{3}(5u_n + D^{-1}(v_n)),$$
$$c_n = \tfrac{1}{9}(6v_n + 8uD^{-1}(u_n) + 10u_{n,x}),$$

and after that we obtain the recursion operator of the form (40) for (A2) with

$$\begin{aligned} \mathcal{R}_0^0 &= 3v + 2v_x D^{-1}, \\ \mathcal{R}_1^0 &= D^2 + 2u + u_x D^{-1}, \\ \mathcal{R}_0^1 &= -(\tfrac{1}{3}D^4 + \tfrac{10}{3}uD^2 + 5u_x D + 3u_{2x} + \tfrac{16}{3}u^2 + (\tfrac{2}{3}u_{3x} + \tfrac{16}{3}uu_x)D^{-1}), \\ \mathcal{R}_1^1 &= 3v + v_x D^{-1}. \end{aligned} \tag{A4}$$

APPENDIX B: EXAMPLES TO SEC. II B

1. Sawada–Kotera equation

The Lax pair for the Sawada–Kotera equation,[28]

$$u_t = u_{5x} + 5uu_{3x} + 5u_x u_{2x} + 5u^2 u_x, \tag{B1}$$

is given by

$$L = D^3 + uD, \quad A = (L^{5/3})_+. \tag{B2}$$

In this example, $L^\dagger = -L$, where $L^\dagger = D^{-1}L^* D$ and L is skew-symmetric, then we use (24). The operator $\tilde{R}_n$ has the same form as (29), with the coefficients given by

$$a_n = \tfrac{1}{3}D^{-1}(u_n), \quad b_n = \tfrac{5}{3}u_n, \quad c_n = \tfrac{1}{9}(5uD^{-1}(u_n) + 29u_{n,x}),$$
$$d_n = \tfrac{1}{9}(5u_x D^{-1}(u_n) + 14uu_n + 26u_{n,2x}),$$

$$e_n=\tfrac{1}{27}(10u_{2x}D^{-1}(u_n)-2D^{-1}(u_{2x}u_n)-D^{-1}(u^2u_n)+5u^2D^{-1}(u_n)$$
$$+28u_{n,3x}+32uu_{n,x}+32u_xu_n),$$
$$f_n=0.$$

The recursion operator is given as

$$\mathcal{R}=D^6+6uD^4+9u_xD^3+(9u^2+11u_{2x})D^2+(10u_{3x}+21uu_x)D+5u_{4x}+16uu_{2x}+6u_x^2+4u^3$$
$$+(u_{5x}+5uu_{3x}+5u_xu_{2x}+5u^2u_x)D^{-1}+u_xD^{-1}(u^2+2u_{2x}). \tag{B3}$$

2. DSI system

The DSI system,[25,26]

$$u_t=3vv_x,$$
$$v_t=2v_{3x}+2uv_x+vu_x, \tag{B4}$$

has a Lax representation with

$$L=[D^3+(u+v)D+\tfrac{1}{2}(u+v)_x][D^3+(u-v)D+\tfrac{1}{2}(u-v)_x],$$
$$A=(L^{1/2})_+. \tag{B5}$$

Here R_n is a differential operator of order 5, and since L is symmetric we again use Eq. (12). The expressions for the coefficients of the operator R_n are very long and complicated. Hence we do not display them here. We find that the recursion operator $\mathcal{R}$ of this system is of the form (40), where

$$\mathcal{R}_0^0=-4D^6-24uD^4-27u_xD^3+2(-49u_{2x}-18u^2+42v^2)D^2+10(-7u_{3x}-12uu_x+30vv_x)D$$
$$-26u_{4x}-82uu_{2x}-69u_x^2+222vv_x+141v_x^2-16u^3+48v^2u$$
$$+2(-2u_{5x}-10uu_{3x}-25u_xu_{2x}-10u^2u_x+15v^2u_x+30vv_{3x}+45v_xv_{2x}+30uvv_x)D^{-1}$$
$$+2u_xD^{-1}(3v^2-2u^2-u_{2x}),$$

$$\mathcal{R}_1^0=168vD^4+204vD^3+6(21v_{2x}+32uv)D^2+6(40vu_x+7v_{3x}+22uv_x)D$$
$$+6(13vu_{2x}+10u_xv_x+v_{4x}+5uv_{2x}+4vu^2+12v^3)+108vv_xD^{-1}v+2u_xD^{-1}(6uv+9v_{2x}), \tag{B6}$$
$$\mathcal{R}_0^1=56vD^4+268v_xD^3+2(243v_{2x}+32uv)D^2+2(36vu_x+219v_{3x}+106uv_x)D$$
$$+2(27vu_{2x}+92u_xv_x+99v_{ax}+99uv_{2x}+4vu^2+12v^3)+2(10vu_{3x}+35u_{2x}v_x+45u_xv_{2x}$$
$$+10uvu_x+18v_{5x}+30uv_{3x}+10u^2v_x+15v^2v_x)D^{-1}+2v_xD^{-1}(3v^2-2u^2-u_{2x}),$$

$$\mathcal{R}_1^1=108D^6+216uD^4+432u_xD^3+6(81u_{2x}+18u^2+22v^2)D^2+6(45u_{3x}+36uu_x+70vv_x)D$$
$$+3(18u_{4x}+18uu_{2x}+9u_x^2+98vv_{2x}+67v_x^2+32uv^2)+36(2v_{3x}+2v_xu+vu_x)D^{-1}v$$
$$+2v_xD^{-1}(6uv+9v_{2x}).$$

3. DSII system

The DSII system,[25,26]

$$u_t = 3v_x,$$
$$v_t = -2(v_{3x} + uv_x + vu_x), \tag{B7}$$

has a Lax representation with

$$L = (D^5 + uD^3 + D^3u + (v + \tfrac{1}{2}u^2)D + D(v + \tfrac{1}{2}u^2))D,$$
$$A = (L^{1/2})_+ . \tag{B8}$$

Since L is symmetric we again use Eq. (12). In this case the operator R_n is given as follows:

$$R_n = a_n D^5 + b_n D^4 + c_n D^3 + d_n D^2 + e_n D, \tag{B9}$$

where

$$a_n = \tfrac{1}{3}D^{-1}(u_n), \quad b_n = \tfrac{5}{3}u_n,$$
$$c_n = \tfrac{1}{9}[5uD^{-1}(u_n) + 3D^{-1}(v_n) + 29u_{n,x}],$$
$$d_n = \tfrac{1}{9}[5u_xD^{-1}(u_n) + 26u_{n,2x} + 14uu_n + 12v_n],$$
$$e_n = \tfrac{1}{27}[5(2u_{2x} + u^2 + 3v)D^{-1}(u_n) - 3D^{-1}(vu_n + uv_n) + 9uD^{-1}(v_n)$$
$$-2D^{-1}(u_{2x}u_n + \tfrac{1}{2}u^2u_n) + 54u_xu_n + 28u_{n,3x} + 32(uu_{n,x} - u_nu_x) + 42v_{n,x}].$$

The recursion operator (40) for the system can be found as[29]

$$\mathcal{R}_0^0 = -D^6 - 6uD^4 - 9u_xD^3 - (11u_{2x} + 9u^2 + 42v)D^2 + (-10u_{3x} - 21uu_x - 30v_x)D$$
$$-5u_{4x} - 16uu_{2x} - 6u_x^2 - 60v_{2x} - 4u^3 - 24vu + (-u_{5x} - 5uu_{3x} - 5u_xu_{2x}$$
$$-5u^2u_x - 15vu_x - 15v_{3x} - 15uv_x)D^{-1} - u_xD^{-1}(2u_{2x} + u^2 + 3v),$$
$$\mathcal{R}_1^0 = -42D^4 - 48uD^2 - 87u_xD - 6(7u_{2x} + u^2 - 6v) + 27v_xD^{-1} - 3u_xD^{-1}u,$$
$$\mathcal{R}_0^1 = 28vD^4 + 106v_xD^3 + (165v_{2x} + 32uv)D^2 + (54vu_x + 132v_{3x} + 74v_xu)D + 30vu_{2x} + 79u_xv_x$$
$$+54v_{4x} + 57uv_{2x} + 4u^2v - 24v^2 + (10vu_{3x} + 25v_xu_{2x} + 30u_xv_{2x} + 10uvu_x + 9v_{5x} + 15uv_{3x}$$
$$+5u^2v_x - 15vv_x)D^{-1} - v_xD^{-1}(3v + u^2 + 2u_{2x}),$$
$$\mathcal{R}_1^1 = 27D^6 + 54uD^4 + 135u_xD^3 + 3(54u_{2x} + 9u^2 - 22v)D^2 + 3(36u_{3x} + 27uu_x - 28v_x)D$$
$$+3(9u_{4x} + 9uu_{2x} + 9u_x^2 - 21v_{2x} - 16vu) - 18(v_{3x} + u_xv + v_xu)D^{-1} - 3v_xD^{-1}u. \tag{B10}$$

4. DSIV system

The DSIV system,[25,26] which is also known as the Hirota–Satsuma system,[30,31]

$$u_t = \tfrac{1}{2}u_{3x} + 3uu_x - 6vv_x,$$
$$v_t = -v_{3x} - 3uv_x, \tag{B11}$$

has Lax representation with

$$L = (D^2 + u + v)(D^2 + u - v), \quad A = (L^{3/4})_+ . \tag{B12}$$

Since the operator L is symmetric we use Eq. (12). In this case the operator R_n has the same form as (39), with coefficients given by

$$a_n=\tfrac{1}{2}D^{-1}(u_n), \quad b_n=\tfrac{7}{4}u_n-\tfrac{1}{2}v_n,$$

$$c_n=\tfrac{1}{8}[6uD^{-1}(u_n)+2D^{-1}(uu_n)-4D^{-1}(vv_n)+17u_{n,x}-12v_{n,x}],$$

$$d_{n,x}=\tfrac{1}{16}[6u_{2x}D^{-1}(u_n)-12v_{2x}D^{-1}(u_n)+30u_xu_n-8u_xv_n+24uu_{n,x}$$
$$+15u_{n,3x}-12v_xv_n-8uv_{n,x}-20vv_{n,x}-28v_{n,3x}].$$

The recursion operator (40) for the given system is

$$\begin{aligned}
\mathcal{R}_0^0&=\tfrac{1}{4}D^4+2uD^2+3u_xD+2u_{2x}+4(u^2-v^2)+(3uu_x-6vv_x+\tfrac{1}{2}u_{3x})D^{-1}+u_xD^{-1}u,\\
\mathcal{R}_1^0&=-5vD^2-4v_xD-v_{2x}-4uv-2u_xD^{-1}v,\\
\mathcal{R}_0^1&=-\tfrac{5}{2}v_xD-3v_{2x}-(v_{3x}+3uv_x)D^{-1}+v_xD^{-1}u,\\
\mathcal{R}_1^1&=-D^4-4uD^2-2u_xD-4v^2-2v_xD^{-1}v.
\end{aligned} \tag{B13}$$

5. $N=3$ Hirota–Satsuma system

This system is given by[29]

$$\begin{aligned}
u_t&=\tfrac{1}{4}u_{3x}+3uu_x+3(-v^2+w)_x,\\
v_t&=-\tfrac{1}{2}v_{3x}-3uv_x,\\
w_t&=-\tfrac{1}{2}w_{3x}-3uw_x.
\end{aligned} \tag{B14}$$

This is an example for the $N=3$ system that covers some other $N=2$ systems as special cases. For instance, letting $w=0$, we get DSIV and letting $v=0$ we get DSIII systems.

The corresponding Lax pair is

$$L=(D^2+2u-2v)(D^2+2u+2v)+4w, \quad A=(L^{3/4})_+. \tag{B15}$$

In this case the operator L is symmetric and hence R_n has the same form as (39), with the coefficients

$$a_n=D^{-1}(u_n), \quad b_n=\tfrac{7}{2}u_n+v_n,$$

$$c_n=\tfrac{1}{4}[12uD^{-1}(u_n)+4D^{-1}(uu_n+w_n-2vv_n)+17u_{n,x}+12v_{n,x}],$$

$$d_{n,x}=\tfrac{1}{8}[12u_{2x}D^{-1}(u_n)+24v_{2x}D^{-1}(u_n)+60u_xu_n+16u_xv_n+15u_{n,3x}+48uu_{n,x}+24v_xu_n$$
$$-40v_xv_n+20v_{n,3x}+16vv_{n,x}+20w_{n,x}].$$

The recursion operator is given by

$$\mathcal{R}=\begin{pmatrix} \mathcal{R}_0^0 & \mathcal{R}_1^0 & \mathcal{R}_2^0 \\ \mathcal{R}_0^1 & \mathcal{R}_1^1 & \mathcal{R}_2^1 \\ \mathcal{R}_0^2 & \mathcal{R}_1^2 & \mathcal{R}_2^2 \end{pmatrix}, \tag{B16}$$

where

$$\mathcal{R}_0^0 = \tfrac{1}{4}D^4 + 4uD^2 + 6u_xD + 4(u_{2x} + 4u^2 - 4v^2 + 4w) + 4(\tfrac{1}{4}u_{3x} + 3uu_x - 6vv_x + 3w_x)D^{-1} + 4u_xD^{-1}u,$$

$$\mathcal{R}_1^0 = -2(5vD^2 + 4v_xD + v_{2x} + 8uv + 4u_xD^{-1}v),$$

$$\mathcal{R}_2^0 = 5D^2 + 8u + 4u_xD^{-1},$$

$$\mathcal{R}_0^1 = -5u_xD - 6v_{2x} - 2(v_{3x} + 6v_xu)D^{-1} + 4v_xD^{-1}u,$$

$$\mathcal{R}_1^1 = -D^4 - 8uD^2 - 4u_xD + 8(8w - 2v^2) - 8v_xD^{-1}v - 8D^{-1}w_x,$$

$$\mathcal{R}_2^1 = 4(v_xD^{-1} + 2D^{-1}v_x),$$

$$\mathcal{R}_0^2 = -5w_xD - 6w_{2x} - 2(v_{3x} + 6w_xu)D^{-1} + 4w_xD^{-1}u.$$

$$\mathcal{R}_1^2 = -16vD^{-1}w_x - 8w_xD^{-1}v,$$

$$\mathcal{R}_2^2 = -D^4 - 8uD^2 - 4u_xD + 16(w - v^2) + 4w_xD^{-1} + 16vD^{-1}v_x. \tag{B17}$$

APPENDIX C: EXAMPLES TO SEC. III

1. Non-Abelian Schrödinger equation

This is the system given by

$$u_t = -\tfrac{1}{2}u_{xx} + uvu, \qquad v_t = \tfrac{1}{2}v_{xx} + vuv, \tag{C1}$$

where u and v belong to $\mathcal{K}$ (see Example 6 for the notations). The Lax operator of (C1) is given by

$$L = D + \begin{pmatrix} \mathbf{1} & 0 \\ 0 & -\mathbf{1} \end{pmatrix}\lambda + \begin{pmatrix} 0 & u \\ v & 0 \end{pmatrix}. \tag{C2}$$

The corresponding formula (54) reduces to

$$\begin{pmatrix} 0 & u_{n+1} \\ v_{n+1} & 0 \end{pmatrix} = \lambda \begin{pmatrix} 0 & u_n \\ v_n & 0 \end{pmatrix} + [R_n, L], \tag{C3}$$

where

$$R_n = \begin{pmatrix} a_n & b_n \\ c_n & -a_n \end{pmatrix}. \tag{C4}$$

The formula (C3) gives us both a_n, b_n, c_n and the recursion operator $\mathcal{R}$. They are given by

$$a_n = \tfrac{1}{2}D^{-1}(u_nv + uv_n), \quad b_n = \tfrac{1}{2}u_n, \quad c_n = -\tfrac{1}{2}u_n, \tag{C5}$$

$$\mathcal{R} = \frac{1}{2}\begin{pmatrix} -D + R_uD^{-1}R_v + L_uD^{-1}L_v & R_uD^{-1}L_u + L_uD^{-1}R_u \\ -L_vD^{-1}R_v - R_vD^{-1}L_v & D - R_vD^{-1}R_u - L_vD^{-1}L_u \end{pmatrix}. \tag{C6}$$

2. Non-Abelian modified KdV equation

The standard non-Abelian modified KdV equation is given by

$$u_t=\tfrac{1}{4}u_{xxx}-\tfrac{3}{4}u_xu^2-\tfrac{3}{4}u^2u_x. \tag{C7}$$

The Lax representation of this equation is given

$$L=D+\begin{pmatrix}0 & \mathbf{1}\\ \mathbf{1} & 0\end{pmatrix}\lambda+\begin{pmatrix}u & 0\\ 0 & -u\end{pmatrix}. \tag{C8}$$

The recursion operator $\mathcal{R}$ can be found from (60) and (61). In our case the automorphism σ is the same as in Example 6, and formulas (60) and (61) give us

$$\begin{pmatrix}0 & u_{n+1}\\ v_{n+1} & 0\end{pmatrix}=\lambda^2\begin{pmatrix}0 & u_n\\ v_n & 0\end{pmatrix}+[R_n,L], \tag{C9}$$

where

$$R_n=\begin{pmatrix}0 & a_n\\ b_n & 0\end{pmatrix}\lambda+\begin{pmatrix}c_n & 0\\ 0 & d_n\end{pmatrix}. \tag{C10}$$

Using (C9) we find a_n,b_n,c_n,d_n from the following:

$$b_n-a_n=u_n,\quad -a_{n,x}-a_nu-ua_n+c_n-d_n=0,$$

$$-b_{n,x}+b_nu+ub_n+d_n-c_n=0,\quad d_{n,x}+c_{n,x}=[c_n-d_n,u],$$

$$u_{n+1}=d_{n,x}+[d_n,u].$$

The resulting recursion operator is given by

$$\mathcal{R}=\tfrac{1}{4}(D-\mathrm{ad}_u\cdot D^{-1}\cdot \mathrm{ad}_u)(D-(L_u+R_u)D^{-1}(L_u+R_u)). \tag{C11}$$

(Received 20 January 1999; accepted for publication 14 June 1999)

Using a formal variable separation approach, a nonlinear partial differential equation can be solved by solving ordinary different equations or even algebraic equations. Taking the KdV–Burgers and modified KdV–Burgers equations with background interaction as simple examples, some explicit solitary wave solutions which are induced by background source and nonlinearity or dispersion are obtained.
 [S0022-2488(99)00411-9]

I. INTRODUCTION

As the linear physics has been developed quite well and the real natural phenomena are nonlinear, the main interest of many scientists has been focused on the nonlinear science. To solve some types of special nonlinear problems, the so-called completely integrable models, many powerful methods like the inverse scattering transformation (IST),[1] Bäcklund and Dabourx transformations,[2] symmetry reduction,[3] bilinear approach,[4] standard[5] and extended[6] Painlevé analysis, etc. have been developed by various authors. In comparison with the linear case, it is known that IST is an extension of the Fourier transformation in the nonlinear case. In addition to the Fourier transformation, there is another powerful tool called the variable separation method in the linear case. However, there is little progress on obtaining some special solutions by means of a corresponding variable separation method in the nonlinear case. In Ref. 7, one of the present authors (Lou) and Lu have obtained some special solutions for the Davey–Stewartson equation by using a special variable separation procedure. A more systematic ''variable separation'' approach has been established by means of the symmetry constraints.[8–10] In that approach, although the independent variables of a reduced field have not totally been separated the field satisfies some lower-dimensional equations. However this type of procedure is used only for integrable models which possess Lax pairs. In this paper we try to extended the method to any models no matter they possess Lax pairs or not.

In the next section, we review the symmetry constraint approach of the KdV equation simply. The extended method is proposed to solve any nonlinear equation in Sec. III. Section IV is used to apply the method to a special nonintegrable model, KdV–Burgers (KdVB) and modified KdV–Burgers (MKdVB) equation. The last section is a short summary and discussion.

II. SYMMETRY CONSTRAINT APPROACH OF THE KDV EQUATION

It is known that the KdV equation

$$u_t-6uu_x-u_{xxx}=0 \tag{1}$$

possesses a Lax pair

$$\psi_{xx}+u\psi=\lambda\psi, \tag{2}$$

$$\psi_t = 2(u-\lambda)\psi_x - u_x\psi. \tag{3}$$

Equivalently, setting $\psi_x = \phi$, (2) and (3) can be written as

$$\begin{pmatrix} \psi \\ \phi \end{pmatrix}_x = \begin{pmatrix} 0 & 1 \\ \lambda - u & 0 \end{pmatrix} \begin{pmatrix} \psi \\ \phi \end{pmatrix}, \tag{4}$$

$$\begin{pmatrix} \psi \\ \phi \end{pmatrix}_t = \begin{pmatrix} -u_x & 2(u-\lambda) \\ -u_{xx} - 2(u-\lambda)^2 & u_x \end{pmatrix} \begin{pmatrix} \psi \\ \phi \end{pmatrix}. \tag{5}$$

A symmetry of the KdV equation (1) is defined as a solution of its linearized equation

$$\sigma_t - 6\sigma u_x - 6u\sigma_x - \sigma_{xxx} = 0, \tag{6}$$

that means (1) is form invariant under the transformation

$$u \to u + \epsilon\sigma, \tag{7}$$

where ϵ being a infinitesimal parameter.

It is known that $(\psi^2)_x$ and u_x are two typical symmetries of the KdV equation.[11] If we substitute the symmetry constraint condition

$$u_x - (\psi^2)_x = 0, \quad \text{i.e.,} \quad u = \psi^2 \tag{8}$$

into the Lax pair (4) and (5), we have

$$\begin{pmatrix} \psi \\ \phi \end{pmatrix}_x = \begin{pmatrix} \phi \\ \lambda\psi - \psi^3 \end{pmatrix} \equiv K_1, \tag{9}$$

$$\begin{pmatrix} \psi \\ \phi \end{pmatrix}_t = \begin{pmatrix} -2\lambda\phi \\ -2\lambda(\lambda\psi - \psi^3) \end{pmatrix} \equiv K_2. \tag{10}$$

Now, if we can get a solution of the lower dimensional Eqs. (9) and (10) then we can get a corresponding solution of the KdV equation at the same time from the symmetry constraint relation (8). It is clear that only one independent variable appears explicitly in Eqs. (9) and (10) though the dependent variables ψ and ϕ are the functions of the both independent variables x and t. Because ψ and ϕ are functions of two variables and only one independent variable appears in Eqs. (9) and (10), we may call this type of symmetry constraints as the ''formal variable separation approach.''

III. GENERAL FORMAL VARIABLE SEPARATION APPROACH

It is known that the procedure shown in the last section dependent on the existence of the Lax pair. In other words, the method is valid for completely integrable models. However, most of real physical models are not completely integrable. Can we get a hint to established a more general variable separation method to solve general nonlinear problems? Fortunately, the answer is positive!

In order to get some special solutions of a general $(n+1)$-dimensional N order PDE,

$$F(t, x_1, x_2, \ldots, x_n, u, u_{x_i}, u_{x_i x_j}, \ldots, u_{x_{i_1} x_{i_j} \cdots x_{i_N}}) \equiv F(u) = 0, \tag{11}$$

we may introduce a set of formally variable separated equations at first

$$\Psi_{x_i} = K_i, \quad i = 0,1,2,\ldots, \quad n, \quad x_0 \equiv t, \tag{12}$$

where $\Psi\equiv(\psi_1,\psi_2,\ldots,\psi_M)^T$ and $K_i\equiv K_i(\Psi)$ are M component matrix functions. The matrix functions K_i should be commuted to each other

$$[K_i,K_j]\equiv K_i'K_j-K_j'K_i\equiv\frac{\partial}{\partial\epsilon}(K_i(\Psi+\epsilon K_j)-K_j(\Psi+\epsilon K_i))\bigg|_{\epsilon=0} \tag{13}$$

because the compatibility conditions $\Psi_{x_ix_j}=\Psi_{x_jx_i}$. Finally one can suppose that the solution of (11) is related to Ψ by

$$u=U(\Psi) \tag{14}$$

and determine the functions U and K_i by substituting (12) and (14) into (11).

In the simple example given in the last section, $M=2$, $\Psi=(\psi,\phi)^T$, the compatibility condition is satisfied naturally because $K_2\sim K_1$ and the function U is given by the symmetry constraint condition (8) simply. The simplicity in the KdV equation is because of its integrability. In general case, it is insignificant to find some suitable K_i and U to give out some special exact solutions especially in nonintegrable case. For concreteness, we turn to treat a concrete example.

IV. EXPLICIT SOLUTIONS OF THE KdVB AND MKdVB EQUATION WITH BACKGROUND SOURCE

Usually, one treats the nonlinear equations describing nonlinear problems without background interactions for simplicity. Some authors have considered the case in which the background interaction is periodic[12] and nonperiodical.[13] The general KdVB and MKdVB with source have the form

$$u_t+\sum_{p=1}^{P}a_pu^pu_x+cu_{xxx}+\gamma u_{xx}=\sum_{q=0}^{Q}b_qu^q, \tag{15}$$

where the right-hand side of (15) is the source term and the summation term in the left-hand side is the usual nonlinear interaction of the MKdVB $(P>1)$ and the KdVB $(P=1)$ equations. The solitary wave solutions of three special cases, $\{\gamma=0,a_1=0,P=2,Q=3\}$, $\{P=1,Q=0\}$ and $\{c=0,P=1,Q=3\}$ have been given by Lan and Wang.[13]

Now, we treat the general MKdVB equation (15) by using the formal variable separation approach proposed in the last section. In this paper, we take only $M=1$ in (12), i.e., the formally variable separation equations have the forms

$$\Psi_x=K_1(\Psi),\quad \Psi_t=K_2(\Psi), \tag{16}$$

where $\Psi=\Psi(x,t)$ is a scalar function of $\{x,t\}$ and $K_i(\Psi)=K_i$, $i=1,2$ are functions of Ψ with the compatibility condition

$$[K_1,K_2]=0. \tag{17}$$

In the single component case, $K_2=\omega K_1$ with constant ω is an only possible solution of (17). Substituting (14) and (16) into (15) we know that (14) solves Eq. (15) if two functions K_1 and U satisfy the following ordinary differential equation:

$$\omega K_1U'+K_1U'\sum_{p=1}^{P}a_pU^p+cK_1(U'''K_1^2+3K_1K_1'U''$$
$$+K_1K_1''U'+K_1'^2U')+\gamma K_1(K_1U''+K_1'U')=\sum_{q=0}^{Q}b_qU^q. \tag{18}$$

In real application, for any fixed K_1, we can get a corresponding solution of (15) by solving (18). For instance, we can take K_1 as a polynomial function of Ψ,

$$K_1=\sum_{j=0}^{J} A_j\Psi^j \tag{19}$$

to get solitary wave solutions of (15). Equation (18) with (19) can always be solved by means of power series approach by setting

$$U=\sum_{j=0}^{\infty} U_j\Psi^j \tag{20}$$

and fixing the expansion coefficients from (18) recursively. If we take $J=1$ and $J=2$ in (19), (20) is equivalent to the usual exponential and tanh expansions used by many authors. In some special selections of a_p and b_q in (15), (20) may be truncated, then some closed explicit solitary wave solutions

$$U=\sum_{r=0}^{R} U_r\Psi^r \tag{21}$$

can be obtained. In the usual KdV and MKdV systems, the solitons are caused by the balance between the effects of the dispersion and the nonlinear interactions. Once the background interactions exist, the solitary waves may be caused in four ways, (i) by the balance between the effects of the dispersion $(c\neq 0)$ and the nonlinear interactions $(a_p\neq 0)$, (ii) by the balance between the effects of the dispersion and background interaction $(b_q\neq 0)$, (iii) by the balance between the effects of the background interactions and the nonlinear interactions, and (iv) by the balance of all three effects. Now we discuss the truncation conditions caused by balance among the linear dispersion, nonlinear interactions and background interactions.

Substituting (21) and (16) with (19) into (18) we know that the highest order terms of Ψ in the background, dispersion, and the nonlinear interactions read $b_QU_Q^R\Psi^{QR}$, $cA_J^3U_RR((R-1)(R-2)+3J(R-1)+J(2J-1))\Psi^{R+3J-3}$, and $RA_Ja_PU_R^{P+1}\Psi^{(P+1)R+J-1}$, respectively. From the above leading order terms, we know that (i) if a solitary wave is caused by the effects of the dispersion and the nonlinear interactions, the balance conditions are

$$\begin{gathered}(P+1)R+J-1=R+3J-3>QR,\\ RA_Ja_PU_R^{P+1}=-cA_J^3U_RR(((R-2)+3J)(R-1)+J(2J-1));\end{gathered} \tag{22}$$

(ii) if a solitary wave is caused by the effects of the dispersion and the background interactions, the balance conditions read

$$(P+1)R+J-1<R+3J-3=QR,\quad b_QU_Q^R=cA_J^3U_RR((R-1)((R-2)+3J)+J(2J-1)); \tag{23}$$

(iii) if a solitary wave is caused by the effects of the nonlinear interactions and the background interactions, the balance conditions become

$$(P+1)R+J-1=QR>R+3J-3,\quad b_QU_Q^R=RA_Ja_PU_R^{P+1} \tag{24}$$

and (iv) if a solitary wave is caused by all three effects, the balance conditions have the forms

$$\begin{gathered}(P+1)R+J-1=R+3J-3=QR,\\ b_QU_Q^R=cA_J^3U_RR((R-1)(R-2)+3J(R-1)+J(2J-1))+RA_Ja_PU_R^{P+1}.\end{gathered} \tag{25}$$

Finally, we list some special types of solitary wave solutions of (15) for $J=2$ in cases (22)–(25). The general solution of (16) with (19) and $J=2$ reads

$$\Psi=\frac{\psi_1\exp((\psi_2-\psi_1)A_2(x+\omega t+x_0))+\psi_2}{1+\exp((\psi_2-\psi_1)A_2(x+\omega t+x_0))}, \tag{26}$$

where x_0 is an arbitrary constant and

$$\psi_1=\frac{1}{2A_2}(\sqrt{A_1^2-4A_0A_2}-A_1),\quad \psi_2=\frac{1}{2A_2}(-\sqrt{A_1^2-4A_0A_2}-A_1). \tag{27}$$

A. Solitary waves caused by the balance between the dispersion and the nonlinear interactions

Substituting $J=2$ into (22), we know that the solitary wave solution with the form (21) and (26) exist for $(P+1)R+1=R+3>QR$. The simplest two cases read

$$\{R=1,P=2,Q\leqslant 3\},\ \text{and}\ \{R=2,P=1,Q\leqslant 2\}. \tag{28}$$

For the first subcase of (28), the solitary wave solution can be obtained by substituting (19) and (21) into (18). The final result shows us that if the model parameters satisfy a condition

$$\begin{aligned}&54b_3^5c^3-54c^2(a_2\gamma-3ca_1V)b_3^4+(18a_2^2c\gamma^2-27c^2(a_1^2+4\gamma a_1V+4Vcb_2)a_2)b_3^3\\&+((-9c^2b_1-2\gamma^3)a_2^3+9c(2\gamma V+a_1)(a_1\gamma+4cb_2)a_2^2-9a_2c^2a_1^3V)b_3^2\\&+((3cb_1\gamma-9c^2Vb_0)a_2^4-3c(3cVb_1a_1+4Vb_2\gamma^2+3cb_2^2+4b_2\gamma a_1)a_2^3\\&+18a_2^2c^2Vb_2a_1^2)b_3+3cb_2(b_2\gamma+3b_1cV)a_2^4-9c^2a_2^3Vb_2^2a_1=0,\end{aligned} \tag{29}$$

then (15) possesses a kink type solitary wave solution

$$u=u_0+\Psi,\quad u_0=-\frac{3b_3c-3A_1a_2c-\gamma a_2+3a_1Vc}{6ca_1V} \tag{30}$$

with

$$\omega=\frac{1}{A_2}\left(\frac{1}{3}A_0a_2^2+2a_2u_0A_1-a_1A_1-3b_3u_0+b_2-(a_1u_0+7cA_1^2+3\gamma A_1+a_2u_0^2)A_2\right), \tag{31}$$

$$A_0=\frac{V(b_0+b_3u_0^3+b_1u_0+b_2u_0^2)}{a_1A_1+2a_2u_0A_1+2\gamma VA_1+3b_3u_0+b_2+6cVA_1^2},\quad A_2=\pm\sqrt{\frac{-a_2}{6c}}\equiv V, \tag{32}$$

and A_1 being an arbitrary constant.

In the second case, the solitary waves have the form

$$u=u_0+u_1\Psi+u_2\Psi^2 \tag{33}$$

with Ψ being given by (26) while the parameters can be taken in four different ways:
(A)

$$\gamma=12b_2ca_1^{-1}, \tag{34}$$

$$u_0=\frac{b_1^2-4b_0b_2}{192b_2^4c}a_1^3-\frac{b_1}{2b_2}-\frac{3A_1c}{a_1^2}(a_1A_1+4b_2), \tag{35}$$

$$A_2=-\frac{1}{100a_1^2c^2A_0(\gamma a_1+18b_2c)}((25(5b_1-\gamma A_1^2+10b_2u_0)c^2+\gamma^3)a_1^3$$
$$+4b_2c(75cA_1(A_1c+\gamma)-4\gamma^2)a_1^2-4c^2b_2^2(-13\gamma+150A_1c)a_1-48b_2^3c^3), \quad (36)$$

$$\omega=-\left(u_0a_1+\left((8A_2A_0+A_1^2)c+\frac{6}{5}A_1\gamma-\frac{\gamma^2}{25c}\right)-\frac{2b_2}{25a_1}(30A_1c+23\gamma)+\frac{96}{25a_1^2}b_2^2c\right), \quad (37)$$

$$u_2=-\frac{12cA_2^2}{a_1},\ \ u_1=-\frac{12A_2}{5a_1^2}(-2b_2c+5cA_1a_1+\gamma a_1), \quad (38)$$

where A_1 is an arbitrary constant;

(B) In the second subcase, all the parameters can still expressed by (35)–(38) while (34) should be changed as

$$\gamma=2b_2ca_1^{-1}; \quad (39)$$

(C) If conditions (34) and (35) are replaced by

$$625c^2(-b_1^2+4b_0b_2)a_1^6+144b_2^2(\gamma a_1-2b_2c)^4=0 \quad (40)$$

and

$$u_0=-\frac{1}{50b_2ca_1^3}(6b_2(-(\gamma a_1-2b_2c)^2+10a_1c(\gamma a_1-2b_2c)A_1+25c^2A_1^2a_1^2)+25b_1ca_1^3), \quad (41)$$

we get the third type of solitary wave solution of (15) with the form (33);

(D) In the first three subcases, A_1 is a free parameter and there is a restriction condition on the model parameters. For the forth type of solitary wave solution of the form (33), there is no constraint on the model parameters if A_1 is fixed by

$$15625c^4(-b_1^2+4b_0b_2)a_1^6+(-25a_1^2c^2(\gamma a_1-12b_2c)A_1^2$$
$$+300a_1b_2c^2(\gamma a_1-2b_2c)A_1+(\gamma a_1-12b_2c)(\gamma a_1-2b_2c)^2)^2=0 \quad (42)$$

and u_0 is given by

$$u_0=-\frac{1}{250b_2c^2a_1^3}(-25a_1^2c^2(\gamma a_1-12b_2c)A_1^2+300a_1b_2c^2(\gamma a_1-2b_2c)A_1$$
$$+125b_1c^2a_1^3-48b_2^3c^3+\gamma^3a_1^3+52b_2^2c^2\gamma a_1-16b_2\gamma^2a_1^2c), \quad (43)$$

while the forms of (36)–(38) are remained to have the same forms though the parameters u_0 and A_1 in (36)–(38) should be replaced by (42) and (43).

B. Solitary wave solution caused by the balance between the dispersion and the background interactions

When $J=2$, the first condition of (23) becomes $(P+1)R+1<R+3=QR$. The simplest case is

$$R=1, \quad P=1, \quad Q=4. \quad (44)$$

In this case, if the model parameters are restricted by

$$2cVV_0^2+(\omega_0+cV_1^2+\gamma V_1)V_0+b_0=0, \quad (45)$$

where

$$V\equiv-\left(\frac{b_4}{6c}\right)^{1/3},\quad V_1\equiv-\frac{1}{12cV^2}(b_3+a_1V+2\gamma V^2), \tag{46}$$

$$V_0\equiv\frac{-b_1V+2\gamma V_1^2V+6cV_1^3V+a_1V_1^2+V_1b_2}{V(a_1+2\gamma V)}, \tag{47}$$

and

$$\omega_0\equiv-\frac{1}{V}(a_1V_1+3\gamma V_1V+8cV^2V_0+b_2+7cVV_1^2), \tag{48}$$

the form of the solitary wave solution is given by

$$u=u_0+u_1\Psi \tag{49}$$

with (26) and u_0 and u_1 being arbitrary while

$$A_2=Vu_1,\quad A_1=-\frac{1}{12cV^2}(b_3+a_1V+2\gamma V^2+4u_0b_4), \tag{50}$$

$$A_0=\frac{1}{u_1V(a_1+2\gamma V)}(-b_1V+2\gamma V_1^2V+6cV_1^3V+a_1V_1^2+V_1b_2-4b_4u_0^3V+(6a_1b_4-3b_3V)u_0^2+(3a_1b_3-2b_2V)u_0), \tag{51}$$

$$\omega=-\frac{1}{V}(a_1V_1+3\gamma V_1V+8cV^2V_0+b_2+7cVV_1^2+6b_4u_0^2+(3b_3+a_1V)u_0). \tag{52}$$

C. Solitary wave solution caused by the balance between the nonlinear interactions and the background interactions

The first condition of (24) reduces to $(P+1)R+1=QR>R+3$, for $J=2$. The simplest one case is

$$R=1,\quad P=3,\quad Q=5. \tag{53}$$

The corresponding solitary wave solution has the form of (49) also. Substituting (49) and (53) into (18), one can find that solitary wave of the form (49) with (26) exist for the following two restrictions among the model parameters that are satisfied:

$$b_0a_3-2cb_5C_0^2+\omega_0C_0a_3+cC_1^2C_0a_3+\gamma C_1C_0a_3=0, \tag{54}$$

$$-2\gamma b_5C_0+A_1C_0a_3+b_1a_3+\omega_0C_1a_3+\gamma C_1^2a_3-8cb_5C_0C_1+cC_1^3a_3=0, \tag{55}$$

where

$$C_1=\frac{1}{a_3^4}(6cb_5^3-b_4a_3^3+a_2b_5a_3^2), \tag{56}$$

$$C_0=\frac{1}{a^3}(-a_2C_1a_3^2-2\gamma b_5^2-b_3a_3^2+a_1b_5a_3-12cb_5^2C_1), \tag{57}$$

$$\omega_0=\frac{1}{a_3b_5}(a_1C_1a_3^2-3\gamma C_1b_5a_3-7cb_5C_1^2a_3+a_2C_0a_3^2+b_2a_3^2+8cb_5^2C_0). \tag{58}$$

The constants u_0 and u_1 are remains free again when A_2, A_1, A_0 and ω in (26) is given by

$$A_2=-b_5u_1/a_3, \tag{59}$$

$$A_1=(6cb_5^3-2u_0b_5a_3^3-b_4a_3^3+a_2b_5a_3^2)/a_3^4, \tag{60}$$

$$A_0=\frac{1}{a_3^3u_1}(b_5(a_1+2a_2u_0)a_3-3a_3^3u_0A_1-(a_2A_1+b_3+4b_4u_0+7b_5u_0^2)a_3^2-b_5^2(2\gamma+12cA_1)), \tag{61}$$

$$\omega=\frac{1}{a_2b_5}(3u_0(u_0A_1+u_1A_0)a_3^3+(6b_4u_0^2+3b_3u_0+2a_2u_0A_1+b_2+9b_5u_0^3+a_2u_1A_0+a_1A_1)a_3^2$$
$$+(-a_1u_0-3\gamma A_1-a_2u_0^2-7cA_1^2)b_5a_3+8cu_1b_5^2A_0). \tag{62}$$

D. Solitary wave caused by the effects of the nonlinear interactions, dispersion, and the background interactions

In $J=2$ case, the first condition of (25) is simplified to $(P+1)R+1=QR=R+3$ with the only positive integer solution

$$R=1,\quad P=2,\quad Q=4. \tag{63}$$

If the restriction condition

$$2cVC_0^2+(cC_1^2+\omega_0+\gamma C_1)C_0+b_0=0, \tag{64}$$

with

$$C_1=-\frac{b_3+2\gamma V^2+a_1V}{a_2+12cV^2}, \tag{65}$$

$$C_0=\frac{2\gamma C_1^2V-b_1V+6cC_1^3V+C_1b_2+a_1C_1^2}{2\gamma V^2+a_1V-a_2C_1}, \tag{66}$$

$$\omega_0=-\frac{1}{V}(a_1C_1+7cVC_1^2+b_2+3\gamma C_1V+a_2u_1C_0+8cu_1V^2C_0), \tag{67}$$

where V is a root of

$$6cV^3+a_2V+b_4=0, \tag{68}$$

we can obtain the solitary wave solution which are caused by all three effects in the form with two arbitrary constants u_0 and u_1 while A_2, A_1, A_0 and ω in (26) is expressed as

$$A_2=Vu_1, \tag{69}$$

$$A_1=-\frac{4b_4u_0+2a_2u_0V+b_3+2\gamma V^2+a_1V}{a_2+12cV^2}, \tag{70}$$

$$A_0=\frac{1}{u_1(2\gamma V^2+2a_2u_0V+a_1V-a_2A_1)}(6cA_1^3V+(2\gamma V+2A_2u_0+a_1)A_1^2$$
$$+(b_2+6b_4u_0^2+3b_3u_0)A_1-4b_4u_0^3V-b_1V-2b_2u_0V-3b_3u_0^2V), \tag{71}$$

$$\omega=-((a_2V+6b_4)u_0^2+(3b_3+a_1V+2a_2A_1)u_0$$
$$+(a_2+8cV^2)u_1A_0+7cVA_1^2+(a_1+3\gamma V)A_1+b_2)/V. \tag{72}$$

V. SUMMARY AND DISCUSSION

In linear physics, both the Fourier transformation approach and the variable separation method play a very important role. However, in nonlinear physics, both the traditional Fourier transformation approach and the variable separation method are not valid again. For some special types of nonlinear equations, the so-called completely integrable models, the inverse scattering transformation approach is considered as the extension of the Fourier transformation and the symmetry constraint approach or the nonlinearization of the Lax pair can be considered as a type of extension of the variable separation approach. Nevertheless, most of the problems in nonlinear physics are not completely integrable. Many mathematicians and physicists have been trying to find some powerful methods to solve the nonlinear partial differential equations which are not completely integrable models, but there is little progress in this direction except for the symmetry reduction and the perturbation theory basing on the inverse scattering transformation.

In this paper, we have extended the formal variable separation approach to a general form such that the method can be used to solve both the integrable and nonintegrable models. Using the method to a general modified KdV equation with background interactions, we know that once a solution of a formally variable separated system is obtained, a corresponding solution of the modified KdVB equation can be obtained by solving an ordinary differential equation. When we restrict the functions that appeared in the variable formally separated system as polynomial functions, the ordinary differential equation can be solved using the series method. In some special cases where some restricted conditions on the model parameters are satisfied, the series solution becomes a closed truncated form.

Once the background interactions exist for the KdVB and modified KdVB system, the solitary wave may be formed in some different ways. Usually, the soliton solution is caused by the balance between nonlinear interactions and dispersion. From our calculations, we know that the solitary wave solutions can be formed by the balance of any two of three effects: dispersion, nonlinear interactions, and background interactions. Some special explicit solitary wave solutions in four possible cases are listed in Sec. IV.

In this paper, we treat only the formally variable separation system (16) as one component for the KdVB MKdVB equation. In one component case for (16), the only allowed solution has the traveling wave form. To get nontraveling wave solutions, one has to treat the method with more components. More about the formally variable separation approach is worthy of further study.

(Received 22 February 1999; accepted for publication 30 June 1999)

The (m-vector) k-constrained Kadomtsev–Petviashvili (KP) hierarchy is shown to be a ''pseudo''-reduction of the $(m+1)$-component KP hierarchy. To facilitate the implementation of this reduction on the level of the solutions, the typical multi-component KP solutions are mapped onto solutions of a Toda molecule-type equation from which (Wronskian and Grammian) solutions for the constrained KP hierarchy follow. The reduction of the associated linear systems is discussed and its importance for the choice of bilinear representation of the reduced systems is explained. © *1999 American Institute of Physics.* [S0022-2488(99)01310-9]

I. INTRODUCTION

Judging by the considerable body of work which has appeared on the topic of constrained KP systems, one would expect their properties to be quite well understood by now. Among the most important facts discovered (apart from the original formulation of the ''constrained hierarchies,'' see Refs. 1–3 for a full account of these) there are the bilinear representation of the reduced systems,[4,5] the interpretation of the constraint procedure in terms of the basic KP construction (be it on a pseudo-differential, Grassmanian,[6] or purely bilinear level,[4,7]), and, of course, the description of various classes of solutions.[8–12] The motivation for this paper however, stems from our belief that many (if not most) of these features are best appreciated in the framework of multi-component KP hierarchies. As it will turn out, the problem of constructing solutions plays a central role therein.

At this early point, in order to render the main object we wish to study slightly more tangible—the m-vector, k-constrained KP hierarchy—we shall characterize it in terms of the familiar KP tau functions: a necessary condition for a KP tau function $\tau(\mathbf{x})$ [depending on a set of coordinates $\mathbf{x}=(x_1,x_2,x_3,\dots)$] to be a tau function for the m-vector, k-constrained KP hierarchy is that its x_k-derivative τ_{x_k} is a superposition of m (quite particular) KP tau functions: $\tau_{x_k}=\sum_{i=1}^m\hat{\tau}_i$, the actual description of such a ''constrained'' tau function $\tau(\mathbf{x})$ and the corresponding $\hat{\tau}_i$'s being the main problem to be solved. Note that as one may always consider all $\hat{\tau}_i\equiv 0$, the standard k-reductions of the KP hierarchy are included here as well.

In the past a variety of solution methods for the constrained KP evolutions have been proposed but, undoubtedly, the most important and fruitful method which has been employed is that of so-called Darboux–Bäcklund transformations.[13] Actually, it was recognized early on that this construction—which works so well in the KP case—should also be adaptable to the specific problem of constructing ''constrained'' solutions. Several applications of Darboux–Bäcklund transformations have been reported in the mean-time: ordinary Darboux transformations have been used to construct Wronskian-type determinant solutions whereas binary-type Darboux transformations have been shown to yield Grammian solutions for the reduced hierarchies.[14,10] Going through the literature on this topic one feature of these methods immediately ''jumps'' out at the reader: in some cases[10,11] authors are discussing solutions generated through Darboux–Bäcklund transformations which appear to be more general than those treated in other accounts. The difference almost always resides in the particular choice of the *vacuum* solution for the constrained equations which is used as a *seed* in the recursive application of the transformations. However, the problem which invariably arises is how to construct an appropriate vacuum. Any recursion formula or solution expressed in terms of a postulated vacuum remains rather ''empty'' without an actual construction of at least one example of such a ''general'' vacuum. In other words, the problem of obtaining solutions ultimately boils down to constructing vacuum solutions, or, put another way, to proving the existence or nonexistence of nontrivial vacuum solutions. Along the course of the present discussion we shall comment on this problem.

An interesting property of the solutions of the constrained hierarchies obtainable through consecutive Darboux–Bäcklund transformations is that (at least in the simplest case of the scalar constraints, i.e., for $m=1$) the transformation chain can be viewed as a Toda-like system.[11] In this paper we wish to invert and at the same time strengthen this relation by presenting a discussion of the m-vector k-constrained KP hierarchy as a reduction of the multi (2, 3,...)-component KP hierarchy,[15] in which multi-dimensional generalizations of the (molecule-type) Toda chains take up a prominent place.

First of all, we believe this to be a natural description of the constrained systems as for example their bilinear representations or the interpretation of the constrained tau functions arise quite effortlessly from reductions of the multi-component KP hierarchies. As we shall try to advocate, another advantage of the present point of view is the relative ease with which Wronskian and Grammian solutions for the reduced hierarchies can be obtained. As mentioned above, although such solutions have been discussed by a number of authors (including the present ones),[8–11,14,16] we have the feeling that their origins have never been quite clear altogether. All these solutions exhibit a remarkable ''bi-directional'' structure which, at least for ordinary vacuum, appears to bear no trace of the constraints imposed on the original KP solutions; a situation quite opposed to that of the standard k-reductions of the KP hierarchy. We will show that this structure is inherited from the solutions of (what is essentially) the Toda molecule system. Furthermore, we shall make a case for the importance of the constructability of appropriate vacuum solutions by showing that the present reduction procedure does not give rise to solutions which genuinely refer to nontrivial vacuum. Although the procedure allows for the description of what would be general Darboux–Bäcklund orbits, it becomes immediately apparent that there is no hope whatsoever of obtaining anything (apart from minor adjustments of previously stated results) more general than the solutions already presented in Ref. 14.

In the next paragraph we introduce the construction of the multi-component KP hierarchy itself. The language in which the hierarchy is formulated is that of free charged fermion operators, essentially following the treatment given in Refs. 17 and 18. In Sec. II, we discuss the reductions we shall impose on the multi-component KP hierarchies in order to obtain constrained KP evolutions. These reductions are of a ''nonstandard'' type and we would like to refer to them as ''pseudo-reductions'' to set them apart from regular dimensional reductions. Here we use the qualification ''pseudo'' in the original sense of Hirota,[19] meaning that in the set of coordinates introduced for the original hierarchy the reduction is not quite a dimensional one, as (generically) only the dependence on a single variable will be eliminated by it. The effect of these reductions then proves to be such that they impose a constraint on that part of the original hierarchy which consists of the KP evolutions. The present paper is, however, not intended to give a full account of the effect of such reductions on the multi-component KP hierarchies themselves (as that would lead us too far from our immediate goal), but rather to study their effect on the KP evolutions. In an earlier paper[20] we discussed the origin (similar to the above) of a particular generalized k-constraint for the KP hierarchy, lying within the 2-D Toda lattice hierarchy. There, obtaining solutions proved to be rather effortless as they arose immediately from those for the Toda lattice itself. Here we shall see that the structure of the solutions of the multi-component KP hierarchy differs considerably from that of the solutions we shall find eventually for the reduced systems. In order to establish a clear link we shall first have to recast them into a form which is particularly well suited for imposing the reduction. All this will be explained in the fourth part of this paper. Finally, for the scalar constraints several comments on the available bilinear descriptions for the constrained KP hierarchies can be made. Starting from the reduced multi-component linear system it will become obvious that every reduced hierarchy essentially allows for three different bilinear descriptions. Each description has its own underlying linear formulation, well adapted to that particular case, all of them being related by rather trivial gauge transformations.

II. MULTI-COMPONENT KP HIERARCHIES

We begin by describing the *n*-component KP hierarchy (by and large following notations introduced by the Kyoto school[17,21,22] rather than those found in Ref. 15) in terms of charged (free) fermion creation-annihilation operators $\psi_i^{(\alpha)},\psi_j^{*(\beta)}(i,j\in\mathbf{Z}+\frac{1}{2};\ \alpha,\beta=1,...,n)$ carrying ''charges'' $+1$ and -1, respectively. The operators satisfy the anticommutation relations:

$$[\psi_i^{(\alpha)},\psi_j^{*(\beta)}]_+=\delta_{\alpha,\beta}\delta_{i+j,0};\quad [\psi_i^{(\alpha)},\psi_j^{(\beta)}]_+=[\psi_i^{*(\alpha)},\psi_j^{*(\beta)}]_+=0. \tag{2.1}$$

For the (usual) Fock representation of this algebra (and for its dual representation), one introduces cyclic vectors $|\mathrm{vac}\rangle$ (and $\langle\mathrm{vac}|$):

$$\begin{aligned}\psi_i^{(\alpha)}|\mathrm{vac}\rangle=\psi_i^{*(\alpha)}|\mathrm{vac}\rangle=0 \quad \text{for } i>0,\\ \langle\mathrm{vac}|\psi_i^{(\alpha)}=\langle\mathrm{vac}|\psi_i^{*(\alpha)}=0 \quad \text{for } i<0.\end{aligned} \tag{2.2}$$

For our purposes it will prove worthwhile to use the (invertible) *shift* operators S_α,

$$\begin{aligned}S_\alpha\psi_i^{(\alpha)}=\psi_{i-1}^{(\alpha)}S_\alpha,\quad S_\alpha\psi_i^{*(\alpha)}=\psi_{i+1}^{*(\alpha)}S_\alpha,\\ S_\alpha\psi_i^{(\beta)}=-\psi_i^{(\beta)}S_\alpha,\quad S_\alpha\psi_i^{*(\beta)}=-\psi_i^{*(\beta)}S_\alpha,\qquad \text{for } \alpha\neq\beta,\end{aligned} \tag{2.3}$$

to represent the (dual) Fock states

$$\begin{aligned}|m_1,m_2,\ldots,m_n\rangle\equiv S_1^{m_1}S_2^{m_2}\cdots S_n^{m_n}|\mathrm{vac}\rangle,\\ \langle m_1,m_2,\ldots,m_n|\equiv\langle\mathrm{vac}|S_n^{-m_n}\cdots S_2^{-m_2}S_1^{-m_1}\end{aligned} \tag{2.4}$$

of total charge $\Sigma_{i=1}^n m_i$ but referring to particular ''colors'' m_i (the m_i being integers). These states are orthonormal with respect to the usual pairing $\langle\mathrm{vac}|1|\mathrm{vac}\rangle=1$:

$$\langle m_1,m_2,\ldots,m_n|m_1',m_2',\ldots,m_n'\rangle=\delta_{m_1,m_1'}\delta_{m_2,m_2'}\cdots\delta_{m_n,m_n'}. \tag{2.5}$$

We also introduce formal operators $\psi^{(\alpha)}(p)$ and $\psi^{*(\alpha)}(q)$ depending on some parameters p and q:

$$\psi^{(\alpha)}(p)\equiv\sum_{j\in\mathbf{Z}+1/2}\psi_j^{(\alpha)}p^{-j-1/2},\quad \psi^{*(\alpha)}(q)\equiv\sum_{j\in\mathbf{Z}+1/2}\psi_j^{*(\alpha)}q^{-j-1/2}, \tag{2.6}$$

for which ''time'' evolutions with respect to n different sets of infinitely many variables $\mathbf{x}^{(\alpha)}\equiv(x_1^{(\alpha)},x_2^{(\alpha)},\ldots,x_l^{(\alpha)},\ldots)$ $(\alpha=1,...n)$ can be defined in terms of the Hamiltonian:

$$H(\mathbf{x})\equiv\sum_{\alpha=1}^{n}\sum_{l=1}^{\infty}x_l^{(\alpha)}H_l^{(\alpha)}\quad\text{with}\quad H_l^{(\alpha)}\equiv\sum_{j\in Z+1/2}:\psi_{-j}^{(\alpha)}\psi_{j+l}^{*(\alpha)}: \tag{2.7}$$

($::$ denotes the usual normal ordering $:\psi_i^{(\alpha)}\psi_j^{*(\alpha)}:=\psi_i^{(\alpha)}\psi_j^{*(\alpha)}-\langle\mathrm{vac}|\psi_i^{(\alpha)}\psi_j^{*(\alpha)}|\mathrm{vac}\rangle$). Note also that $H_l^{(\alpha)}|\mathrm{vac}\rangle=0$, $\forall l\geq 1$ and accordingly that $\exp(H(\mathbf{x}))|\mathrm{vac}\rangle=1$. The evolutions for $\psi^{(\alpha)}(p)$ and $\psi^{*(\alpha)}(q)$wrt the coordinates $\mathbf{x}$ are then given by

$$e^{H(\mathbf{x})}\psi^{(\alpha)}(p)e^{-H(\mathbf{x})}=\psi^{(\alpha)}(p)e^{\xi_\alpha(x,p)},\quad e^{H(\mathbf{x})}\psi^{*(\alpha)}(q)e^{-H(\mathbf{x})}=\psi^{*(\alpha)}(q)e^{-\xi_\alpha(\mathbf{x},q)}, \tag{2.8}$$

where $\xi_\alpha(\mathbf{x},k)=\Sigma_{l=1}^{\infty}x_l^{(\alpha)}k^l$. Making use of the time evolutions $g(\mathbf{x})=e^{H(\mathbf{x})}ge^{-H(\mathbf{x})}$ of an element g of (a suitable completion of the $\mathrm{GL}(\infty)$ group—generated by elements

$$\sum_{\alpha,\beta}\sum_{i,j} c_{ij}^{\alpha\beta}\psi^{(\alpha)}(p_i)\psi^{*(\beta)}(q_j)+c \tag{2.9}$$

of (a completion of) the $\mathrm{gl}(\infty)$ algebra[15]—the n-component tau functions $\tau^{\mathbf{m}}(\mathbf{x})$ are defined as expectation values:

$$\tau^{\mathbf{m}}(\mathbf{x})\equiv\langle\mathbf{m}|g(\mathbf{x})|vac\rangle \tag{2.10}$$

for zero-charge states with color $\mathbf{m}=(m_1,m_2,\ldots,m_n)$:

$$\langle\mathbf{m}|=\langle\mathrm{vac}|S_n^{-m_n}\cdots S_2^{-m_2}S_1^{-m_1},\quad \sum_{i=1}^{n} m_i=0. \tag{2.11}$$

These tau functions satisfy the well-known bilinear identity,[15,17] $\forall\mathbf{x},\mathbf{x}'$:

$$\sum_{\alpha=1}^{n}\mathrm{Res}_\lambda[(-1)^{\Sigma_{i=1}^{\alpha-1}(k_i+k_2')}\lambda^{k_\alpha-k_\alpha'-2}e^{\xi_\alpha(x-x',\lambda)}\tau^{\mathbf{k}-\boldsymbol{\delta}_\alpha}(\mathbf{x}-\boldsymbol{\epsilon}_\alpha(\lambda))\tau^{\mathbf{k}'+\boldsymbol{\delta}_\alpha}(\mathbf{x}'+\boldsymbol{\epsilon}_\alpha(\lambda))]=0 \tag{2.12}$$

for $\mathbf{k}$, $\mathbf{k}'$ subject to $\Sigma_{\alpha=1}^{n}k_\alpha-1=\Sigma_{\alpha=1}^{n}k_\alpha'+1=0$. The shifts $\boldsymbol{\delta}_\alpha$ and $\boldsymbol{\epsilon}_\alpha(\lambda)$ only affect the αth component:

$$\begin{gathered}\mathbf{k}\pm\boldsymbol{\delta}_\alpha=(k_1,\ldots,k_\alpha\pm1,\ldots,k_n),\\ \mathbf{x}\pm\boldsymbol{\epsilon}_\alpha(\lambda):\ \mathbf{x}^{(\alpha)}\rightarrow\left(x_1^{(\alpha)}\pm\frac{1}{\lambda},x_2^{(\alpha)}\pm\frac{1}{2\lambda^2},x_3^{(\alpha)}\pm\frac{1}{3\lambda^3},\cdots\right).\end{gathered} \tag{2.13}$$

At lowest order, we find that the bilinear identity (2.12) contains a system of coupled second-order equations[15] made up of $n(n-1)$ copies of Toda molecule equations[23,24] (expressed using the Hirota D-operators[25]),

$$D_{x_1^{(\beta)}}D_{x_1^{(\alpha)}}\tau^{\mathbf{k}}\cdot\tau^{\mathbf{k}}=2\tau^{\mathbf{k}+\boldsymbol{\delta}_\beta-\boldsymbol{\delta}_\alpha}\tau^{\mathbf{k}-\boldsymbol{\delta}_\beta+\boldsymbol{\delta}_\alpha}\quad\forall\beta\neq\alpha, \tag{2.14}$$

and a higher-order system involving $x_2^{(\beta)}$-derivatives

$$D_{x_2^{(\beta)}}D_{x_1^{(\alpha)}}\tau^{\mathbf{k}}\cdot\tau^{\mathbf{k}}=2D_{x_1^{(\beta)}}\tau^{\mathbf{k}+\boldsymbol{\delta}_\beta-\boldsymbol{\delta}_\alpha}\cdot\tau^{\mathbf{k}-\boldsymbol{\delta}_\beta+\boldsymbol{\delta}_\alpha}\quad\forall\beta\neq\alpha \tag{2.15}$$

[as will be explained later on, opposed to the ordinary A_∞ Toda lattice,[17,26] the lattices described by the equations (2.14) correspond to finite or at most semi-infinite chains of tau functions, hence the name ''molecule'']. An intrinsic property of the n-component KP hierarchy (which is crucial to our further purposes) is that a tau function $\tau^{\mathbf{n}}$ always satisfies the (one-component) KP hierarchy expressed in terms of some variable $\mathbf{x}^{(\beta)}$. This can be readily seen as the bilinear identity (2.12) collapses to the regular KP bilinear identity when $\mathbf{k}=\mathbf{n}+\boldsymbol{\delta}_\beta$ and $\mathbf{k}'=\mathbf{n}-\boldsymbol{\delta}_\beta$ (for some specific βth variable) with $\mathbf{x}^{(\alpha)}=\mathbf{x}^{(\alpha)\prime}\,\forall\alpha\neq\beta$.

Introducing the functions

$$V_{\mathbf{k}}^{(\beta)}(\mathbf{x};p)=\langle\mathbf{k}+\boldsymbol{\delta}_\beta|e^{H(\mathbf{x})}\psi^{(\beta)}(p)g|\mathrm{vac}\rangle=(-1)^{\Sigma_{i=1}^{\beta-1}k_i}\tau^{\mathbf{k}}(\mathbf{x}-\boldsymbol{\epsilon}_\beta(p))p^{k_\beta}e^{\xi_\beta(\mathbf{x},p)}, \tag{2.16}$$

we can write down a bilinear identity describing the linear problem which underlies the n-component KP evolutions ($\forall\mathbf{x},\mathbf{x}'$):

$$\sum_{\alpha=1}^{n} \mathrm{Res}_\lambda [\epsilon_{\alpha\beta} (-1)^{\delta_{\alpha,\beta}+\Sigma_{i=1}^{\alpha-1}(k_i+k_i')} \lambda^{k_\alpha - k_\alpha' - 2 - \delta_{\alpha,\beta}} e^{\xi_\alpha(\mathbf{x}-\mathbf{x}',\lambda)}$$
$$\times \tau^{\mathbf{k}-\boldsymbol{\delta}_\alpha}(\mathbf{x}-\boldsymbol{\epsilon}_\alpha(\lambda)) V^{(\beta)}_{\mathbf{k}'+\boldsymbol{\delta}_\alpha}(\mathbf{x}'+\boldsymbol{\epsilon}_\alpha(\lambda);p)] = -V^{(\beta)}_{\mathbf{k}-\boldsymbol{\delta}_\beta}(\mathbf{x};p)\, \tau^{\mathbf{k}'+\boldsymbol{\delta}_\beta}(\mathbf{x}'), \tag{2.17}$$

with

$$\epsilon_{\alpha\beta} = \begin{cases} -1, & \text{if } \alpha < \beta. \\ 1, & \text{if } \alpha \geqslant \beta. \end{cases} \tag{2.18}$$

The linear problem itself can then be expressed in terms of the *wavefunctions*

$$\Psi^{(\beta)}_{\mathbf{k}}(\mathbf{x};p) = \frac{V^{(\beta)}_{\mathbf{k}}(\mathbf{x};p)}{\tau^{\mathbf{k}}(\mathbf{x})} \quad \forall \beta = 1,...,n, \tag{2.19}$$

the lowest-order equations being ($\forall \alpha \neq \beta$)

$$[\Psi^{(\beta)}_{\mathbf{k}}(\mathbf{x};p)]_{x_1^{(\beta)}} = v^{(\beta,\alpha)}_{\mathbf{k}} \Psi^{(\beta)}_{\mathbf{k}}(\mathbf{x};p) + \epsilon_{\alpha\beta} \Psi^{(\beta)}_{\mathbf{k}+\boldsymbol{\delta}_\beta-\boldsymbol{\delta}_\alpha}(\mathbf{x};p)$$
$$[\Psi^{(\beta)}_{\mathbf{k}}(\mathbf{x};p)]_{x_1^{(\alpha)}} = \epsilon_{\beta\alpha}\, e^{-\theta^{(\beta,\alpha)}_{\mathbf{k}}} \Psi^{(\beta)}_{\mathbf{k}-\boldsymbol{\delta}_\beta+\boldsymbol{\delta}_\alpha}(\mathbf{x};p) \tag{2.20}$$

(remark that, when considering, e.g., the $x^{(\beta)}$-variables, the functions $\Psi^{(\beta)}_{\mathbf{k}}(\mathbf{x};p)$ are nothing but standard wavefunctions for the KP hierarchy expressed in those coordinates).

In the above linear equations we made use of the variables

$$\theta^{(\beta,\alpha)}_{\mathbf{k}} = \log \frac{(\tau^{\mathbf{k}})^2}{\tau^{\mathbf{k}+\boldsymbol{\delta}_\beta-\boldsymbol{\delta}_\alpha} \tau^{\mathbf{k}-\boldsymbol{\delta}_\beta+\boldsymbol{\delta}_\alpha}}, \tag{2.21}$$

$$v^{(\beta,\alpha)}_{\mathbf{k}} = \left[\log \frac{\tau^{\mathbf{k}+\boldsymbol{\delta}_\beta-\boldsymbol{\delta}_\alpha}}{\tau^{\mathbf{k}}} \right]_{x_1^{(\beta)}}. \tag{2.22}$$

Obviously, the following relationship exists between these variables,

$$[\theta^{(\beta,\alpha)}_{\mathbf{k}}]_{x_1^{(\beta)}} = v^{(\beta,\alpha)}_{\mathbf{k}-\boldsymbol{\delta}_\beta+\boldsymbol{\delta}_\alpha} - v^{(\beta,\alpha)}_{\mathbf{k}}, \tag{2.23}$$

as a result of which we find the 2-D Toda-lattice-like nonlinear equations[26]

$$[\theta^{(\beta,\alpha)}_{\mathbf{k}}]_{x_1^{(\beta)},x_1^{(\alpha)}} = 2\exp(-\theta^{(\beta,\alpha)}_{\mathbf{k}}) - \exp(-\theta^{(\beta,\alpha)}_{\mathbf{k}+\boldsymbol{\delta}_\beta-\boldsymbol{\delta}_\alpha}) - \exp(-\theta^{(\beta,\alpha)}_{\mathbf{k}-\boldsymbol{\delta}_\beta+\boldsymbol{\delta}_\alpha}) \tag{2.24}$$

as compatibility conditions of the linear system (2.20) [note that the ‘‘compatibility’’ conditions which the first equations in the system (2.20) obviously impose are rather involved and of higher order]. Formula (2.21) acts as the dependent variable transformation connecting the above nonlinear equations to the bilinear equations (2.14). A bilinear identity similar to (2.17), describing the adjoint linear problem in terms of adjoint wavefunctions

$$\Psi^{*(\beta)}_{\mathbf{k}}(\mathbf{x};q) = \frac{\langle \mathbf{k}-\boldsymbol{\delta}_\beta | e^{H(\mathbf{x})} \psi^{*(\beta)}(q) g | \mathrm{vac} \rangle}{\tau^{\mathbf{k}}(\mathbf{x})} \quad \forall \beta = 1,...,n, \tag{2.25}$$

will not be given here as its explicit form is of no real importance in what follows. Remark, however, that a ratio $\tau^{\mathbf{n}+\boldsymbol{\delta}_\beta-\boldsymbol{\delta}_\gamma}/\tau^{\mathbf{n}} (\gamma \neq \beta)$ satisfies the (one-component) KP linear problem expressed in terms of the $\mathbf{x}^{(\beta)}$-variables and the $\tau^{\mathbf{n}}$ tau function and that similarly the ratio $\tau^{\mathbf{n}-\boldsymbol{\delta}_\beta+\boldsymbol{\delta}_\gamma}/\tau^{\mathbf{n}}$ satisfies the adjoint linear problem for the KP hierarchy in the $\mathbf{x}^{(\beta)}$-variables. The former property can easily be proven by choosing $\mathbf{k}=\mathbf{n}+2\boldsymbol{\delta}_\beta-\boldsymbol{\delta}_\gamma$, $\mathbf{k}'=\mathbf{n}-\boldsymbol{\delta}_\beta$, and $\mathbf{x}^{(\alpha)}=\mathbf{x}^{(\alpha)'}$ for all $\alpha\neq\beta$ and some specific $\gamma\neq\beta$ in the bilinear identity (2.12), reducing it to a modified KP bilinear identity in the $\mathbf{x}^{(\beta)}$ variables.

Finally, let us turn to some important examples of multi-component tau functions. In general, these are constructed through (auto-) Bäcklund transformations performed on the group elements $g\in\mathrm{GL}(\infty)$:

$$g\to(c+\phi\phi^*)g, \tag{2.26}$$

with constant c and where ϕ and ϕ^* are generalized fermion operators

$$\phi=\sum_{\alpha=1}^{n}\mathrm{Res}_{p_\alpha}[h_\alpha(p_\alpha)\psi^{(\alpha)}(p_\alpha)],\quad \phi^*=\sum_{\alpha=1}^{n}\mathrm{Res}_{q_\alpha}[h_\alpha^*(q_\alpha)\psi^{*(\alpha)}(q_\alpha)], \tag{2.27}$$

defined in terms of certain ''densities'' h_α and h_α^*.

The corresponding tau functions then transform as[27]

$$\tau(\mathbf{x})=\langle\mathrm{vac}|g(\mathbf{x})|\mathrm{vac}\rangle\to\hat{\tau}(\mathbf{x})=\langle\mathrm{vac}|e^{H(\mathbf{x})}(c+\phi\phi^*)g|\mathrm{vac}\rangle\equiv\tau(\mathbf{x})\times\Omega(\mathbf{x}), \tag{2.28}$$

the resulting tau function being ''factorizable'' in terms of a so-called (multi-component) *eigenfunction potential* $\Omega(\mathbf{x})$:

$$\Omega(\mathbf{x})\equiv\sum_{\alpha,\beta}^{n}\mathrm{Res}_{p_\alpha,q_\beta}[h_\alpha(p_\alpha)h_\beta^*(q_\beta)\Omega^{(\alpha,\beta)}(\mathbf{x})], \tag{2.29}$$

$$\Omega^{(\alpha,\beta)}(\mathbf{x})=\langle\mathrm{vac}|e^{H(\mathbf{x})}\psi^{(\alpha)}(p_\alpha)\psi^{*(\beta)}(q_\beta)g|\mathrm{vac}\rangle/\tau(\mathbf{x}). \tag{2.30}$$

A basic explicit solution arises from repeated Bäcklund transformations (2.26) applied to the *vacuum* element $g^{\mathrm{vac}}=1$,

$$g_G=\prod_{i=1}^{N}(c_i+\phi_i\phi_i^*), \tag{2.31}$$

in terms of generalized operators as in (2.27),

$$\phi_i=\sum_{\alpha=1}^{n}\mathrm{Res}_{p_{\alpha,i}}[h_{\alpha,i}(p_{\alpha,i})\psi^{(\alpha)}(p_{\alpha,i})],\quad \phi_i^*=\sum_{\alpha=1}^{n}\mathrm{Res}_{q_{\alpha,i}}[h_{\alpha,i}^*(q_{\alpha,i})\psi^{*(\alpha)}(q_{\alpha,i})], \tag{2.32}$$

and by using Wick's theorem to calculate the corresponding tau function for the color $\mathbf{k}\equiv\mathbf{0}$:

$$\tau_G^0=\det[(m_{ij})_{N\times N}]. \tag{2.33}$$

The entries of this Grammian determinant are well-defined potentials m_{ij}:[7,27,28]

$$(m_{ij})_{x_1^{(\alpha)}}=\varphi_i^{(\alpha)}\varphi_j^{*(\alpha)}\quad\forall\alpha=1,\ldots,n, \tag{2.34}$$

$$(m_{ij})_{x_k^{(\alpha)}}=A_k^{(\alpha)}[\varphi_i^{(\alpha)},\varphi_j^{*(\alpha)}]\equiv\sum_{s=0}^{k-1}(-1)^s(\varphi_i^{(\alpha)})_{(k-1-s)x_i^{(\alpha)}}(\varphi_j^{*(\alpha)})_{sx_i^{(\alpha)}}, \tag{2.35}$$

$$(A_k^{(\alpha)}[\varphi_i^{(\alpha)},\varphi_j^{*(\alpha)}])_{x_l^{(\alpha)}}=(A_l^{(\alpha)}[\varphi_i^{(\alpha)},\varphi_j^{*(\alpha)}])_{x_k^{(\alpha)}}\quad\forall k,l. \tag{2.36}$$

The functions $\varphi_i^{(\alpha)}$ and $\varphi_j^{*(\alpha)}$ appearing in the determinant (2.33)

$$\varphi_i^{(\alpha)}=\mathrm{Res}_{p_{\alpha,i}}[h_{\alpha,i}(p_{\alpha,i})\epsilon^{\xi_\alpha(\mathbf{x},p_{\alpha,i})}],\quad \varphi_j^{*(\alpha)}=\mathrm{Res}_{q_{\alpha,j}}[h^*_{\alpha,j}(q_{\alpha,j})\epsilon^{-\xi_\alpha(\mathbf{x},q_{\alpha,j})}],\tag{2.37}$$

only depend on the $\mathbf{x}^{(\alpha)}$-coordinates and satisfy the dispersion relations ($\forall l=1,2,...$)

$$(\varphi_i^{(\alpha)})_{x_l^{(\alpha)}}=(\varphi_i^{(\alpha)})_{lx_1^{(\alpha)}},\quad (\varphi_j^{*(\alpha)})_{x_l^{(\alpha)}}=(-1)^{l+1}(\varphi_j^{*(\alpha)})_{lx_l^{(\alpha)}}.\tag{2.38}$$

The tau functions $\tau^{\boldsymbol{\delta}_\beta-\boldsymbol{\delta}_\alpha}$ and $\tau^{\boldsymbol{\delta}_\alpha-\boldsymbol{\delta}_\beta}$ linked to the tau function (2.33) by the lattice equations (2.14) can be easily calculated from the above group element g_G by what amounts to a Schlesinger transformation, e.g.,[29]

$$\mathcal{S}_{\beta\alpha}:\ g\to\epsilon_{\beta\alpha}S_\beta^{-1}S_\alpha g\ \Rightarrow\ \tau^{\boldsymbol{\delta}_\beta-\boldsymbol{\delta}_\alpha}=\epsilon_{\beta\alpha}\langle\mathrm{vac}|S_\beta^{-1}S_\alpha g_G(\mathbf{x})|\mathrm{vac}\rangle.\tag{2.39}$$

In fact, all tau functions of different color in the zero-charge section of the Fock space can be obtained by application of such transformations. Use of Wick's theorem then shows that, in general, these tau functions are representable as determinants of combined Wronskian/Grammian type:

$$H_{(\beta_1,\dots,\beta_l)}^{(\alpha_1\dots,\alpha_k)}=\begin{vmatrix}\mathbf{O}_{N_W\times N_W} & W^*_{(\alpha_1,\dots,\alpha_k)}\\ W_{(\beta_1,\dots,\beta_l)} & (m_{ij})_{N\times N}\end{vmatrix},\tag{2.40}$$

the indices $\{\alpha_1,\dots,\alpha_k,\beta_1,\dots,\beta_l\}$ forming a subset of the set $\{1,...,n\}$ (i.e., $k+l\leqslant n$) and where $N_W=\Sigma_{s=1}^k N_{\alpha_s}=\Sigma_{s=1}^l N_{\beta_s}\leqslant N$. The matrices $W_{(\beta_1,\dots,\beta_l)}$ and $W^*_{(\alpha_1,\dots,\alpha_k)}$ themselves exhibit a block structure,

$$W_{(\beta_1,\dots,\beta_l)}\equiv(\mathcal{W}_{N_{\beta_1}}(\varphi^{(\beta_1)})\cdots\mathcal{W}_{N_{\beta_l}}(\varphi^{(\beta_1)})),\quad W^*_{(\alpha_1,\dots,\alpha_k)}\equiv\begin{pmatrix}\mathcal{W}^*_{N_{\alpha_1}}(\varphi^{*(\alpha_1)})\\ \vdots\\ \mathcal{W}^*_{N_{\alpha_k}}(\varphi^{*(\alpha_k)})\end{pmatrix},\tag{2.41}$$

defined in terms of Wronskian-like matrices

$$\mathcal{W}_{N_\beta}(\varphi^{(\beta)})=\begin{pmatrix}\varphi_1^{(\beta)} & (\varphi_1^{(\beta)})_{x_1^{(\beta)}} & \cdots & (\varphi_1^{(\beta)})_{(N_\beta-1)x_1^{(\beta)}}\\ \vdots & \vdots & \ddots & \vdots\\ \varphi_N^{(\beta)} & (\varphi_N^{(\beta)})_{x_1^{(\beta)}} & \cdots & (\varphi_N^{(\beta)})_{(N_\beta-1)x_1^{(\beta)}}\end{pmatrix},\tag{2.42}$$

$$\mathcal{W}^*_{N_\alpha}(\varphi^{*(\alpha)})=\begin{pmatrix}\varphi_1^{*(\alpha)} & \cdots & \varphi_N^{*(\alpha)}\\ (\varphi_1^{*(\alpha)})_{x_1^{(\alpha)}} & \cdots & (\varphi_N^{*(\alpha)})_{x_1^{(\alpha)}}\\ \vdots & \ddots & \vdots\\ (\varphi_1^{*(\alpha)})_{(N_\alpha-1)x_1^{(\alpha)}} & \cdots & (\varphi_N^{*(\alpha)})_{(N_\alpha-1)x_1^{(\alpha)}}\end{pmatrix}.\tag{2.43}$$

The ''effect'' of the Schlesinger transformation $\mathcal{S}_{\beta\alpha}$ (2.39) on such a general determinant (2.40) then is to add a column (containing N_β^{th} $x_1^{(\beta)}$-derivatives) to the β-component block in W, while deleting the last row of the α-component block in W^*. A Schlesinger $\mathcal{S}_{\beta_i\beta_j}$ ($\mathcal{S}_{\alpha_i\alpha_j}$) acts by adding and deleting columns (rows) in the β_i and β_j (α_j and α_i!) blocks, respectively. Moreover, the determinant of the matrix $W_{(1,\dots,n)}$ itself is a Wronskian tau function for the multi-component KP hierarchy, constructed from a trivial element $g^{\mathrm{vac}}=1$ by means of the repeated action of so-called Darboux transformations:

$$gW=S_1^{-N_1}S_2^{-N_2}\cdots S_n^{-N_n}\prod_{i=1}^{N}\phi_i\ \Rightarrow\ |W_{(1,\dots,n)}|=\langle\mathrm{vac}|gW(\mathbf{x})|\mathrm{vac}\rangle\tag{2.44}$$

with $N=\Sigma_{i=1}^{n}N_i$, some N_i's possibly being zero. The Schlesinger transformation (2.39) acts on $W_{(1,\ldots,n)}$ as described above for $\mathcal{S}_{\beta_i\beta_j}$. Similarly, the determinant of $W^*_{(1,\ldots,n)}$ is a Wronskian tau function as well, this time obtained through repeated action of adjoint Darboux transformations:[27] $g\rightarrow S\phi^* g$. The Schlesinger action is as explained above for $\mathcal{S}_{\alpha_i\alpha_j}$.

III. PSEUDO-REDUCTIONS

In this section we shall consider a reduction procedure which describes the constrained KP hierarchies as part of an m-component KP hierarchy, for which m denotes the number of components ($m\geqslant 2$). As mentioned in the Introduction, this reduction procedure will turn out to be of a rather nonstandard type as it generically does not act as a dimensional reduction for the entire multi-component hierarchy, but only eliminates certain (lowest order) time evolutions in favor of other time variables. Because of this fact and because of the considerable notational complexity already apparent in the previous section, we shall first rewrite some of the relevant formulas in a more telling way.

In our discussion of reductions, we shall be primarily interested in their effect on the molecule Toda evolutions for tau functions (2.14) and their derivative nonlinear fields (2.24). Furthermore, as the ultimate goal is to describe a reduction of the KP hierarchy which only involves a single set of variables, we shall privilege the $\mathbf{x}^{(1)}$-variables by taking them to be the (final) KP variables whereby dropping the superscript altogether: $\mathbf{x}^{(1)}\rightarrow\mathbf{x}$. The other sets of $\mathbf{x}^{(\alpha)}$-variables in the multi-component hierarchy will be renamed as $\mathbf{y}^{(\alpha)}$ $(\alpha=2,\ldots,m)$. In this new notation, the $\mathbf{x}$-evolutions of a (multi-component) tau function $\tau(\mathbf{x},\mathbf{y}^{(\alpha)})$ are governed by the ''standard'' KP evolution equations, with respect to which one is permitted to think of the $\mathbf{y}^{(\alpha)}$-evolutions as being purely parametric. Also, as we only consider tau functions defined in the zero-charge section of the Fock space(s), we shall drop the explicit reference to the (basic) color $\mathbf{k}$ in the description of the tau functions, e.g., $\tau^{\mathbf{k}+\boldsymbol{\delta}_\gamma}\rightarrow\tau^{\boldsymbol{\delta}_\gamma}$.

In the following our chief interest will be the subset of bilinear equations among (2.14) describing the x_1-evolutions of the multi-component tau functions:

$$D_{x_1}D_{y_1^{(\alpha)}}\tau\cdot\tau=2\,\tau^{\boldsymbol{\delta}_1-\boldsymbol{\delta}_\alpha}\tau^{\boldsymbol{\delta}_\alpha-\boldsymbol{\delta}_1}\quad\forall\,\alpha=2,\ldots,m, \tag{3.1}$$

the relevant linear problem being

$$\begin{aligned}&[\Psi(\lambda)]_{x_1}=v^{(1,\alpha)}\Psi(\lambda)+\Psi_{\boldsymbol{\delta}_1-\boldsymbol{\delta}_\alpha}(\lambda),\\&[\Psi(\lambda)]_{y_1^{(\alpha)}}=-e^{-\theta^{(1,\alpha)}}\Psi_{\boldsymbol{\delta}_\alpha-\boldsymbol{\delta}_1}(\lambda),\end{aligned} \tag{3.2}$$

where we have dropped the reference to the first component in $\Psi^{(1)}\rightarrow\Psi$, as well as the explicit dependence on the $\mathbf{x}$ and $\mathbf{y}^{(\alpha)}$ variables or on the $\mathbf{k}$-state in $\Psi(p),v^{(1,\alpha)}$ and $\theta^{(1,\alpha)}$. As for the functions $\Psi(\mathbf{x},\mathbf{y}^{(\alpha)};\lambda)$, it should be clear (cf. Sec. II) that they solve the standard KP linear problem expressed in the $\mathbf{x}$-coordinates.

Let us now, for some fixed integer k, impose the following reduction on the m-component tau functions:

$$\sum_{\alpha=2}^{m}\tau_{y_1^{(\alpha)}}=\tau_{x_k}. \tag{3.3}$$

In the excellent account of the multi-component KP hierarchy given in Ref. 15 it is shown that the case $k=1$ is a standard reduction for m-component hierarchies[30] as it results in subsequent identifications of the sort $\Sigma_{\alpha=2}^{m}\tau_{y_l^{(\alpha)}}=\tau_{x_l}$, $\forall\, l=1,2,\ldots$. The generic case, however, does not produce such subsequent identities for the $\mathbf{x}$- and $\mathbf{y}$- variables considered here (suitable coordinate transformations might alter this picture considerably, but these are a different topic altogether). Hence, we shall refer to the reduction (3.3) as a pseudo reduction. However, the effect of this reduction on the **x** dependence of the tau functions is dramatic, as it allows us to eliminate the $\mathbf{y}^{(\alpha)}$ dependence from the equations (3.1):

$$D_{x_1}D_{x_k}\tau\cdot\tau=2\sum_{\alpha=2}^{m}\tau^{\boldsymbol{\delta}_1-\boldsymbol{\delta}_\alpha}\tau^{\boldsymbol{\delta}_\alpha-\boldsymbol{\delta}_1}, \tag{3.4}$$

thereby providing a constraint on the **x**-evolutions of the tau functions. If, after this reduction, we choose to regard the $\mathbf{y}^{(\alpha)}$-variables as mere parameters—the **x**-evolution being the only relevant one—we obtain a constraint on ordinary KP tau functions. Equation (3.4) can be rewritten as

$$(\log\tau)_{x_1x_k}=\tau^{-2}\sum_{\alpha=2}^{m}\tau^{\boldsymbol{\delta}_1-\boldsymbol{\delta}_\alpha}\tau^{\boldsymbol{\delta}_\alpha-\boldsymbol{\delta}_1}=\sum_{\alpha=2}^{m}q_\alpha r_\alpha, \tag{3.5}$$

where the functions q_α and r_α are defined as the ratios

$$q_\alpha=\frac{\tau^{\boldsymbol{\delta}_1-\boldsymbol{\delta}_\alpha}}{\tau},\qquad r_\alpha=\frac{\tau^{\boldsymbol{\delta}_\alpha-\boldsymbol{\delta}_1}}{\tau}, \tag{3.6}$$

for which it was pointed out in the previous section that they correspond to solutions of the KP linear problem (q_α) and adjoint linear problem (r_α). If we now consider the one-component case of the eigenfunction potential (2.30) introduced in Sec. III,

$$\Omega(\mathbf{x})=\mathrm{Res}_{p,q}[\langle\mathrm{vac}|e^{H(\mathbf{x})}h(p)\psi(p)h^*(q)\psi^*(q)g|\mathrm{vac}\rangle]/\tau(\mathbf{x}), \tag{3.7}$$

we recover the standard KP eigenfunction potential. We shall not go into too much detail here (the interested reader is referred to Refs. 7, 31, 27 and 28 for a full account on eigenfunction potentials), but we do need to mention two basic properties which are of importance to our discussion. First, as $\Omega(\mathbf{x})$ is a well-defined potential wrt gradients in **x** [generalizing the one-component case of the potential in (2.34)], it can, for example, be defined (up to an arbitrary constant) in terms of its x_1 derivative,

$$[\Omega(\Phi,\Phi^*)]_{x_1}=\Phi(\mathbf{x})\Phi^*(\mathbf{x}), \tag{3.8}$$

where the functions $\Phi(\mathbf{x})$ and $\Phi^*(\mathbf{x})$ are general solutions to the KP linear and adjoint linear problems, respectively:

$$\Phi(\mathbf{x})=\mathrm{Res}_p[h(p)\langle 1|e^{H(\mathbf{x})}\psi(p)g|\mathrm{vac}\rangle]/\tau(\mathbf{x}), \tag{3.9}$$

$$\Phi^*(\mathbf{x})=\mathrm{Res}_q[h^*(q)\langle -1|e^{H(x)}\psi^*(q)g|\mathrm{vac}\rangle]/\tau(\mathbf{x}). \tag{3.10}$$

Second and most importantly, a shift (2.13) on the **x**-variables in $\Omega(\Phi,\Phi^*)$ is also completely defined in terms of its ''constituent'' functions $\Phi(\mathbf{x})$ and $\Phi^*(\mathbf{x})$:

$$\Omega(\mathbf{x}-\boldsymbol{\epsilon}(\lambda))-\Omega(\mathbf{x})\equiv-\frac{1}{\lambda}\Phi(\mathbf{x})\Phi^*(\mathbf{x}-\boldsymbol{\epsilon}(\lambda)). \tag{3.11}$$

In other words, to each pair of functions (q_α, r_α) in (3.5) we can associate a KP eigenfunction potential $\Omega_\alpha(\mathbf{x})$

$$[\Omega_\alpha(\mathbf{x})]_{x_1}=q_\alpha r_\alpha\quad\forall\alpha=2,\ldots,m, \tag{3.12}$$

and hence the constraint (3.5) is equivalent to

$$(\log \tau)_{x_k} = \sum_{\alpha=2}^{m} \Omega_\alpha(q_\alpha, r_\alpha) + C(\mathbf{x}), \quad C_{x_1}=0. \tag{3.13}$$

Next we shall proceed to show that the function $C(\mathbf{x})$ is not only independent of x_1, but that it actually is a constant that can be absorbed into the definitions of the potentials Ω_α. The result, however, is that the pseudo-reduction (3.3) turns the Toda molecule equations (3.1) into a relation which, when imposed on KP tau functions, reduces the KP hierarchy to an $(m-1)$-vector k-constrained hierarchy (see Ref. 7 for a full discussion of the implications of this particular relation and the way it corresponds to other definitions of constrained hierarchies):

$$\tau_{x_k} = \sum_{\alpha=2}^{m} \tau \times \Omega_\alpha(q_\alpha, r_\alpha) = \sum_{\alpha=2}^{m} \hat{\tau}_\alpha \tag{3.14}$$

[that a product $\tau\Omega_\alpha(q_\alpha, r_\alpha)$ actually defines a new KP tau function $\hat{\tau}_\alpha$ should be clear from the defining property (2.28) of an eigenfunction potential].

Proving that $C_{x_l}=0(\forall l=1,2,...)$ is quite straightforward if one expresses the second equation in the linear system (3.2) in terms of tau functions,

$$\begin{aligned}
[\Psi(\lambda)]_{y_1^{(\alpha)}} &= -\frac{\tau^{\boldsymbol{\delta}_1-\boldsymbol{\delta}_\alpha}\tau^{\boldsymbol{\delta}_\alpha-\boldsymbol{\delta}_1}}{\tau^2} \times \frac{V^{(1)}_{\boldsymbol{\delta}_\alpha-\boldsymbol{\delta}_1}(\lambda)}{\tau^{\boldsymbol{\delta}_\alpha-\boldsymbol{\delta}_1}} \\
&= -\frac{1}{\lambda}\frac{\tau^{\boldsymbol{\delta}_1-\boldsymbol{\delta}_\alpha}}{\tau} \times \frac{\tau^{\boldsymbol{\delta}_\alpha-\boldsymbol{\delta}_1}(\mathbf{x}-\boldsymbol{\epsilon}(\lambda))}{\tau} e^{\xi(\mathbf{x},\lambda)},
\end{aligned} \tag{3.15}$$

making use of the definitions (2.21), (2.19), and (2.16) (for the color $\mathbf{k}=\boldsymbol{\delta}_\alpha-\boldsymbol{\delta}_1$), also allowing one to write

$$\begin{aligned}
[\log \Psi(\lambda)]_{y_1^\alpha} &= -\frac{1}{\lambda}\frac{\tau^{\boldsymbol{\delta}_1-\boldsymbol{\delta}_\alpha}}{\tau} \times \frac{\tau^{\boldsymbol{\delta}_\alpha-\boldsymbol{\delta}_1}(\mathbf{x}-\boldsymbol{\epsilon}(\lambda))}{\tau(\mathbf{x}-\boldsymbol{\epsilon}(\lambda))} \\
\Leftrightarrow \left[\log \frac{\tau(\mathbf{x}-\boldsymbol{\epsilon}(\lambda))}{\tau}\right]_{y_1^{(\alpha)}} &= -\frac{1}{\lambda} q_\alpha r_\alpha(\mathbf{x}-\boldsymbol{\epsilon}(\lambda))
\end{aligned} \tag{3.16}$$

[remark that the exponential appearing in $\Psi(\lambda)$ only depends on $\mathbf{x}$]. If one now imposes the pseudo reduction (3.3) on this last equation, one obtains

$$\begin{aligned}
\left[\log \frac{\tau(\mathbf{x}-\boldsymbol{\epsilon}(\lambda))}{\tau}\right]_{x_k} &= -\frac{1}{\lambda}\sum_{\alpha=2}^{m} q_\alpha r_\alpha(\mathbf{x}-\boldsymbol{\epsilon}(\lambda)) \\
&= \sum_{\alpha=2}^{m} [\Omega_\alpha(\mathbf{x}-\boldsymbol{\epsilon}(\lambda)) - \Omega_\alpha(\mathbf{x})].
\end{aligned} \tag{3.17}$$

due to property (3.11) of the eigenfunction potentials. Comparison with relation (3.13) (and a shifted version thereof) immediately shows that $C(\mathbf{x}-\boldsymbol{\epsilon}(\lambda))=C(\mathbf{x})$ and hence that C is actually a constant.

The effect of the pseudo-reduction on the linear problem for the KP hierarchy is also easily calculated. We immediately have that

$$[\Psi(\lambda)]_{x_k} = \sum_{\alpha=2}^{m} [\Psi(\lambda)]_{y_1^{(\alpha)}} + \lambda^k \Psi(\lambda), \tag{3.18}$$

which, due the linear equations (3.2), can be made independent of the $\mathbf{y}^{(\alpha)}$-variables:

$$[\Psi(\lambda)]_{x_k}-\lambda^k\Psi(\lambda)+\sum_{\alpha=2}^{m} e^{-\theta^{(1,\alpha)}}\Psi_{\boldsymbol{\delta}_\alpha-\boldsymbol{\delta}_1}(\lambda)=0, \tag{3.19}$$

after which these can be regarded as mere parameters appearing in the functions $\Psi(\mathbf{x};\lambda)$. Finally, the above equation can be turned into a relation which contains no reference whatsoever to the multi-component nature of the functions involved and which can then be imposed as a constraint on the KP linear problem. It suffices to notice that because of the obvious identifications,

$$v^{(1,\alpha)}=[\log q_\alpha]_{x_1}, \quad v^{(1,\alpha)}_{\boldsymbol{\delta}_\alpha-\boldsymbol{\delta}_1}=-[\log r_\alpha]_{x_1}, \quad \theta^{(1,\alpha)}=-\log q_\alpha r_\alpha, \tag{3.20}$$

the first set of linear equations in (3.2) contains two very special equations,

$$(q_\alpha\partial_{x_1}q_\alpha^{-1})[\Psi(\lambda)]=\Psi_{\boldsymbol{\delta}_1-\boldsymbol{\delta}_\alpha}(\lambda), \tag{3.21}$$

$$(r_\alpha^{-1}\partial_{x_1}r_\alpha)[\Psi_{\boldsymbol{\delta}_\alpha-\boldsymbol{\delta}_1}(\lambda)]=\Psi(\lambda), \tag{3.22}$$

on account of which we have the property that

$$(q_\alpha\partial_{x_1}q_\alpha^{-1})[e^{-\theta^{(1,\alpha)}}\Psi_{\boldsymbol{\delta}_\alpha-\boldsymbol{\delta}_1}(\lambda)]=q_\alpha r_\alpha\Psi(\lambda). \tag{3.23}$$

Hence, in an appropriate pseudo-differential context where the ''inverse'' of relation (3.23) is meaningful, formula (3.19) can be cast into a pseudo-differential constraint on the KP wavefunctions:

$$[\Psi(\lambda)]_{x_k}+\sum_{\alpha=2}^{m} q_\alpha\partial^{-1}r_\alpha\Psi(\lambda)=\lambda^k\Psi(\lambda), \tag{3.24}$$

which is nothing but the spectral problem for the $(m-1)$-vector k-constrained KP hierarchy discussed in much detail in Refs. 3, 11 and 1 where it is used to define the constrained KP hierarchies. In the last section of this paper we shall discuss different ways of turning the constraint (3.19) into a purely differential spectral problem and connections of these to different bilinear forms for the reduced hierarchies.

IV. SOLUTIONS OF THE CONSTRAINED KP HIERARCHIES

We now come to the problem of constructing solutions for the $(m-1)$-vector k-constrained KP hierarchy, in light of the reduction procedure which was described in the previous chapter. However, taking the constraint (3.3) at face value, it is not at all clear how to implement it on explicit examples of multi-component tau functions in order to obtain a reduced tau function. The key to solving this problem lies with the Toda molecule equation (3.1). As is described in the literature for Wronskian solutions,[24] there exist two different types of Wronskian determinants solving the Toda molecule equation: those of multi-component type [as in (2.44)] and those of so-called *bidirectional* type.[32] Between these two types of solutions there exists a peculiar correspondence which is, so to speak, tailored to the pseudo-reduction we wish to impose. Similarly, for the hybrid Wronskian/Grammian determinants described in Sec. II, there also exists a transition from multi-component ones to ''bidirectional'' ones, with a slight abuse of language as will be seen shortly (no written account of this correspondence is known to the authors). Before starting, let us introduce a rather explicit notation for the multi-component tau functions we shall be discussing. Instead of referring to different colors in the labels of the tau functions as we did up to now, we shall refer to the explicit form of, e.g., the Wronskian determinant (2.44) by labeling tau functions with the number of columns in the determinant alotted to each component:

$$\tau_{\mathbf{N}} \equiv \tau_{(N_1, N_2, \ldots, N_m)} = |W_{(1,\ldots,m)}|, \tag{4.1}$$

or slightly more involved for hybrid determinants (2.40) of size N,

$$\tau_{\mathbf{N}} \equiv \tau_{(N_1, N_2, \ldots, N_m)} = \sigma\, H^{(\alpha_1, \ldots, \alpha_k)}_{(\beta_1, \ldots, \beta_l)}, \tag{4.2}$$

where the l-tuple $(\beta_1, \ldots, \beta_l)$ corresponds to positive indices N_i for the tau function, whereas the k-tuple $(\alpha_1, \ldots, \alpha_k)$ for the adjoint Wronskian part corresponds to *negative* indices N_i, the number of rows in each component block then being $|N_i|$ [the factor $\sigma = -\mathrm{sgn}(N_1)$ is included in (4.2) to take care of the change in sign induced by the Schlesinger transformation (2.39) when the index N_1 becomes strictly greater than 0]. At this point it should also be remarked that the above tau functions always give rise to *finite* Toda chains (as opposed to semi-infinite ones). Clearly, the Toda molecule equations (3.1) link tau functions related through the Schlesinger actions described at the end of Sec. II, i.e., $\tau_{(N_1 N_2, \ldots, N_m)}$ is connected to two other tau functions $\tau_{(N_1 \pm 1, \ldots, N_\alpha \mp 1, \ldots)}$ in a chain. This means that tau functions (4.1) in the Wronskian chains become trivially zero whenever one of the components is ''exhausted'' (i.e., after some N_α or $N_1 = 0$), the number of nonzero tau functions (the ''chain length'') being equal to $L_\alpha = N_1 + N_\alpha + 1$. The hybrid tau functions (4.2) become trivial whenever the size of the Wronskian blocks (N_W) reaches that of the Grammian part (N), $N_W = N$, as the determinant then factorizes into the product of two determinants, one of which is independent of x_1 while the other does not depend on x_α. The length of such a chain can also be expressed in terms of the tau function labels (which can be negative in this case) as $L_\alpha = (2N+1) - |N_1 + N_\alpha|$.

A. Bidirectional Wronskian determinants

We start by discussing the case of Wronskian solutions, which is by far the simpler one. In a paper by Hirota *et al.*[24] on the 2-D molecule Toda equation, it is explained how two-component solutions $\tau_{(N_1, N_2)}$ for the molecule equation can give rise to determinant solutions with a striking bidirectional structure (which were originally obtained by Leznov and Saveliev[32]),

$$\overleftrightarrow{\tau}_n = \begin{vmatrix} f & f_{x_1} & \cdots & f_{(n-1)x_1} \\ f_{y_1} & f_{x_1, y_1} & \cdots & f_{(n-1)x_1, y_1} \\ \vdots & \vdots & \ddots & \vdots \\ f_{(n-1)y_1} & \cdots & \cdots & f_{(n-1)x_1, (n-1)y_1} \end{vmatrix}, \tag{4.3}$$

the function $f(\mathbf{x}, \mathbf{y})$ depending on both sets of coordinates $\mathbf{x}$ and $\mathbf{y}$; subscripts denote (multiple) derivatives. That $\overleftrightarrow{\tau}_n$ satisfies the two-component case of (3.1) is easily verified since the Toda molecule equation

$$D_{x_1} D_{y_1} \overleftrightarrow{\tau}_n \cdot \overleftrightarrow{\tau}_n = 2\, \overleftrightarrow{\tau}_{n+1} \overleftrightarrow{\tau}_{n-1} \tag{4.4}$$

immediately reduces to a simple Jacobi identity (alternatively, see Ref. 24 for a proof based on Lapace expansions of determinants).

As it is very instructive to describe the correspondence with the two-component tau functions $\tau_{(N_1, N_2)}$ in detail and as notations in the multi-component case are quite involved, we shall at first limit ourselves to this example; afterwards the two-component case can readily be extended to the general m-component one. Our starting point is the observation that the Toda equations (3.1) are invariant under gauge transformations $\tau \to \tau \times X(\mathbf{x}) Y(\mathbf{y}^{(\alpha)})$, combined with the obvious fact that two tau functions suffice to completely determine a particular Toda chain (τ_n and $\tau_{n\pm1}$ always unambiguously define $\tau_{n\mp1}$). Hence, setting the tau function $\overleftrightarrow{\tau}_0 = 1$ [which can be identified with $\tau_{(0,N)} = |\mathcal{W}_N(\varphi^{(2)})|$ up to a gauge transformation in $\mathbf{y}$], we can ''mimic'' the Toda chain 1, f, $f f_{x_1, y_1} - f_{x_1} f_{y_1}, \ldots$ using two-component Wronskians:

$$\overleftrightarrow{\tau}_0 \equiv 1, \quad \overleftrightarrow{\tau}_1 = f(\mathbf{x},\mathbf{y}) \equiv \frac{\tau_{(1,N-1)}}{\tau_{(0,N)}} \Rightarrow \overleftrightarrow{\tau}_2 = \frac{\tau_{(2,N-2)}}{\tau_{(0,N)}}, \quad \ldots . \tag{4.5}$$

As pointed out above, this identification is unambiguous and thus the above sequence of bidirectional Wronskians will have finite length as well. Actually, from the explicit form of the function f as defined above in terms of matrices (2.42),

$$f(\mathbf{x},\mathbf{y}) = \sum_{i=1}^{N} (-1)^{1+i} \varphi_i^{(1)} \frac{M_{iN}[\mathcal{W}_N(\varphi^{(2)})]}{|\mathcal{W}_N(\varphi^{(2)})|} \tag{4.6}$$

(the symbol $M_{ij}[A]$ stands for the minor of the ijth element in the matrix A), it can easily be calculated that $\overleftrightarrow{\tau}_N$ factorizes and therefore becomes trivial in that it only depends on the $\mathbf{x}$-coordinates: $\overleftrightarrow{\tau}_N = |\mathcal{W}_N(\varphi^{(1)})|$.

Now that we have expressed bidirectional tau functions for the Toda molecule equations in terms of two-component tau functions, we can immediately find solutions of the form (4.3) to the reduced Toda molecule equations (3.4). It suffices to notice that although it is not a two-component tau function itself, because of the reduction (3.3) the following identity still holds for $f(\mathbf{x},\mathbf{y})$:

$$f_{y_1} = \left(\frac{\tau_{(1,N-1)}}{\tau_{(0,N)}} \right)_{y_1} \overset{Eq.(3.3)}{=} \left(\frac{\tau_{(1,N-1)}}{\tau_{(0,N)}} \right)_{x_k} = f_{x_k}. \tag{4.7}$$

However, whereas the gauge transformation we applied in the sequence (4.5) alters the $\mathbf{y}$-dependence of $\tau_{(1,N)}$, it does not alter its $\mathbf{x}$-evolutions and thus we have that the function $f(\mathbf{x},\mathbf{y})$ as defined in (4.5) is still a KP tau function for the $\mathbf{x}$-coordinates. Moreover, being defined as the ratio of two two-component tau functions related by a Schlesinger transformation, $f(\mathbf{x},\mathbf{y})$ also solves the KP linear problem in $\mathbf{x}$ with respect to the tau function $\tau_{(0,N)}$ (which for these evolutions is a mere constant). Hence it follows that $f(\mathbf{x},\mathbf{y})$ is an arbitrary function of $\mathbf{x}$ apart from the requirement that it satisfies the (standard) dispersion relations which also appear in Wronskian solutions of the KP hierarchy:

$$f_{x_l} = f_{lx_1} 0 \quad \forall l = 1,2,\ldots . \tag{4.8}$$

Consequently, we have that the bidirectional Wronskian determinants,

$$\overleftrightarrow{\tau}_n = \begin{vmatrix} f & f_{x_1} & \cdots & f_{(n-1)x_1} \\ f_{x_k} & f_{x_1 x_k} & \cdots & f_{(n-1)x_1, x_k} \\ \vdots & \vdots & \ddots & \vdots \\ f_{(n-1)x_k} & \cdots & \cdots & f_{(n-1)x_1,(n-1)x_k} \end{vmatrix}, \tag{4.9}$$

are KP tau functions which also satisfy the constraint (3.14). In other words, this means that we have constructed a Wronskian solution for the scalar $(m=1)$ k-constrained KP hierarchy. These solutions appear in several papers.[4,8,11,33] Obviously, the functions q and r associated to these tau functions in the formulation (3.14) of the scalar k-constraint are given by the ratios [cf. formula (3.6)]

$$q = \frac{\overleftrightarrow{\tau}_{n+1}}{\overleftrightarrow{\tau}_n}, \quad r = \frac{\overleftrightarrow{\tau}_{n-1}}{\overleftrightarrow{\tau}_n}. \tag{4.10}$$

In the general case of the m-component KP hierarchy, the construction of bidirectional Wronskians goes through in pretty much the same way. First, we have to remark that the Toda molecule equations (3.1) allow for more general Wronskian solutions of type (4.3). Assigning the symbol $\mathcal{B}_{n,N}(f)$ to the matrix appearing in (4.3) as

$$\mathcal{B}_{n_i,n}(f_i)\equiv\begin{pmatrix} (f_i) & (f_i)_{x_1} & \cdots & (f_i)_{(n-1)x_1} \\ (f_i)_{y_1^{(i+1)}} & (f_i)_{x1,y_1^{(i+1)}} & \cdots & (f_i)_{(n-1)x_1,y_1^{(i+1)}} \\ \vdots & \vdots & \ddots & \vdots \\ (f_i)_{(n_i-1)y_1^{(i+1)}} & \cdots & \cdots & (f_i)_{(n-1)x_1,(n_i-1)y_1^{(i+1)}} \end{pmatrix}, \tag{4.11}$$

we have that determinants ($n=\Sigma_{i=1}^{m-1}n_i$)

$$\overleftrightarrow{\tau}_{n_1,\ldots n_{m-1}}=\begin{vmatrix} \mathcal{B}_{n_1,n}(f_1) \\ \vdots \\ \mathcal{B}_{n_{m-1},n}(f_{m-1}) \end{vmatrix}, \tag{4.12}$$

with functions $f_i(\mathbf{x},\mathbf{y}^{(i+1)})$ $(i=1,...,m-1)$ only depending on $\mathbf{x}$ and $\mathbf{y}^{(i+1)}$ each, still satisfy the Toda molecule equations (3.1) [or (4.4) with $\mathbf{y}=\mathbf{y}^{(i+1)}$ if one prefers]. This can be seen by direct calculation, a verification which is very much the same as in case of equation (4.4) because the different blocks in the determinants only depend on a single set of $\mathbf{y}^{(l)}$ coordinates and each Toda equation therefore only involves a single one of those blocks. Actually, this rather trivial intertwining (or should one say ''lack of'') of the different components $\mathbf{y}^{(l)}$ in the determinants (4.12) is at the same time a disappointment as well as a blessing. What is disappointing is that it makes it clear straightaway that there is no chance whatsoever for a general m-component Wronskian tau function to be mapped onto the above determinants, for such a mapping would entangle the components in a nontrivial way. One rather has to look at it as follows: the ''lattice'' of Toda chains one can obtain by Schlesinger transformations starting from a generic (N-sized) m-component Wronskian (2.44) contains exactly $m-1$ suitable starting pairs $(\alpha=1,...,m-1)$,

$$\overleftrightarrow{\tau}_{0,...,0}=1 \qquad \overleftrightarrow{\tau}_{\ldots,0,n_\alpha=1,0,\ldots}=f_\alpha(\mathbf{x},\mathbf{y}^{(\alpha+1)})\equiv\frac{\tau_{(1,...,0,N_{\alpha+1}=N-1,0,...)}}{\tau_{(\ldots,0,N_{\alpha+1}=N,0,\ldots)}}, \tag{4.13}$$

suitable for constructing strains of determinants $\overleftrightarrow{\tau}_{\ldots,0,n_\alpha,0,\ldots}$ in exactly the same way as was done for the two-component case. As these involve $m-1$ different gauge transformations (and as these destroy the tau function nature of the resulting determinants), the different strains are not related to each other as real (m-component) Toda chains would be. They can, however, be assembled into a single determinant expression like (4.12), as is explained above. The upside of this lack of nontrivial intertwining is that the pseudo-reduction (3.3) still implies that $(f_\alpha)_{y_1^{(\alpha+1)}}=(f_\alpha)_{x_k}$, making the construction of solutions to the constraint equation (3.14) a matter of replacing $y_1^{(l)}$-derivatives in (4.12) by x_k-derivatives. Thus one obtains the Wronskian solutions to the $(m-1)$ vector k-constrained KP hierarchy which were also described in Refs. 8, 10 and 11. The functions q_α and r_α associated to the tau functions in the constraint (3.14) are of course given by the obvious generalizations of the two-component ones (4.10).

B. Grammian determinants

Let us now move on to the hybrid-type solutions (4.2) and the solutions these give rise to for the constrained KP hierarchies. Again, initially we shall limit ourselves to the two-component case after which the generalization to the m-component case will be straightforward. Consider a Grammian tau function made up of potentials $\omega_{ij}(\mathbf{x},\mathbf{y})$ defined by their x_1-derivatives

$$\overleftrightarrow{\tau}_{N,N}=|(\omega_{ij})_{N\times N}|, \quad (\omega_{ij})_{x_1}=f_{(i-1)y_1}f_j^*, \tag{4.14}$$

in terms of a function $f(\mathbf{x},\mathbf{y})$ and N functions $f_j^*(\mathbf{x},\mathbf{y})$ obeying the dispersion relations

$$f_{x_n}=f_{nx_1} \quad (f_j^*)_{x_n}=(-1)^{n+1}(f_j^*)_{nx_1}, \tag{4.15}$$

$$(f_j^*)_{y_1}=-\mu_j f_j^*. \tag{4.16}$$

As should be clear from the discussion in Sec. II, the $\omega_{ij}(\mathbf{x},\mathbf{y})$ are well-defined potentials in the $\mathbf{x}$-coordinates, determined up to some functions $F_{ij}(\mathbf{y})$ which we require here to be related to only N arbitrary functions $F_{1j}(\mathbf{y})$ by means of the recursion relations:

$$F_{i+1,j}(\mathbf{y})\equiv(F_{ij})_{y_1}+\mu_j F_{ij} \quad \forall_i=1,\ldots,N. \tag{4.17}$$

Remark that the above requirement is equivalent to imposing the following recurrence relation on the $\omega_{ij}(\mathbf{x},\mathbf{y})$:

$$(\omega_{ij})_{y_1}=\omega_{i+1,j}-\mu_j\omega_{ij}, \tag{4.18}$$

for N ''original'' potentials ω_{1i}, the functions F_{ij} being (unambiguously) defined by $\omega_{ij}[f \equiv 0; f_j^*\equiv 0]=F_{ij}$. Furthermore, in analogy to the matrices (2.42) and (2.43), we also define matrices

$$\overleftrightarrow{\mathcal{W}}_{N,n}(f)=\begin{pmatrix} f & f_{x_1} & \cdots & f_{(n-1)x_1} \\ f_{y_1} & f_{y_1,x_1} & \cdots & f_{y_1,(n-1)x_1} \\ \vdots & \vdots & \ddots & \vdots \\ f_{(N-1)y_1} & f_{(N-1)y_1,x_1} & \cdots & f_{(N-1)y_1,(n-1)x_1} \end{pmatrix}, \tag{4.19}$$

$$\overleftrightarrow{\mathcal{W}}^*_{n,N}(f_j^*)=\begin{pmatrix} f_1^* & \cdots & f_N^* \\ (f_1^*)_{x_1} & \cdots & (f_N^*)_{x_1} \\ \vdots & \ddots & \vdots \\ (f_1^*)_{(n-1)x_1} & \cdots & (f_N^*)_{(n-1)x_1} \end{pmatrix}. \tag{4.20}$$

Because of relations (4.16) and (4.18), the following derivatives of $\overleftrightarrow{\tau}_N$ can be easily expressed in terms of these matrices ($\mu=\Sigma_{j=1}^N \mu_N$):

$$(\overleftrightarrow{\tau}_{N,N})_{x_1}=-\begin{vmatrix} (\omega_{ij})_{N\times N} & \overleftrightarrow{\mathcal{W}}_{N,1} \\ \overleftrightarrow{\mathcal{W}}^*_{1,N} & 0 \end{vmatrix} \quad (\overleftrightarrow{\tau}_{N,N})_{y_1}=-\mu\overleftrightarrow{\tau}_N+\begin{vmatrix} (\omega_{ij})_{(N-1)\times N} \\ (\omega_{N+1,1}\cdots\omega_{N+1,N}) \end{vmatrix}, \tag{4.21}$$

$$(\overleftrightarrow{\tau}_{N,N})_{x_1,y_1}=-\mu(\overleftrightarrow{\tau}_N)_{x_1}-\begin{vmatrix} (\omega_{ij})_{(N-1)\times N} & \overleftrightarrow{\mathcal{W}}_{N-1,1} \\ (\omega_{N+1,1}\cdots\omega_{N+1,N}) & f_{Ny_1} \\ \overleftrightarrow{\mathcal{W}}^*_{1,N} & 0 \end{vmatrix} \tag{4.22}$$

with the convention that the symbol $(\omega_{ij})_{M\times N}$ denotes the $M\times N$ matrix obtained from $(\omega_{ij})_{N\times N}$ by the obvious addition or deletion of rows of ω_{ij} [the entries in additional rows being of course defined in terms of the previous ones using (4.18)]. Then, it is straightforward to show (using a simple Jacobi determinant identity) that $\overleftrightarrow{\tau}_N$ satisfies the Toda molecule equation

$$\tfrac{1}{2}D_{x_1}D_{y_1}\overleftrightarrow{\tau}_{N,N}\cdot\overleftrightarrow{\tau}_{N,N}\equiv\overleftrightarrow{\tau}_{N,N}(\overleftrightarrow{\tau}_{N,N})_{x_1,y_1}-(\overleftrightarrow{\tau}_{N,N})_{x_1}(\overleftrightarrow{\tau}_{N,N})_{y_1}=\overleftrightarrow{\tau}_{N,N+1}\overleftrightarrow{\tau}_{N,N-1}, \tag{4.23}$$

with $\overleftrightarrow{\tau}_{N,M}$ (for $M\neq N$) defined as

$$\overleftrightarrow{\tau}_{N,M<N}=\begin{vmatrix}(\omega_{ij})_{M\times N}\\ \overleftrightarrow{\mathcal{W}}^{*}_{N-M,N}\end{vmatrix},\quad \overleftrightarrow{\tau}_{N,M>N}=|(\omega_{ij})_{M\times N}\quad \overleftrightarrow{\mathcal{W}}_{M,M-N}|. \tag{4.24}$$

In general, it can be shown that these determinants $\overleftrightarrow{\tau}_{N,M}$ also satisfy the above Toda molecule equation, the proof being a straightforward generalization of the preceding one. It should also be noted that these solutions again exhibit a certain ''bidirectionality'' which is crucial in these proofs.

We can now proceed to discuss the construction of such determinant solutions using two-component tau functions. Due to the dispersion relation (4.16) we have that $(\overleftrightarrow{\tau}_{N,0})_{y_1}=-\mu\overleftrightarrow{\tau}_{N,0}$ and hence that $\overleftrightarrow{\tau}_{N,0}$ can actually be used as the starting point of the chain of $\overleftrightarrow{\tau}_{N,M}$ we wish to describe. We therefore first have to find a suitable two-component partner for this determinant. This can be done by considering the tau function $\tau_{(-N,N)}\,(N\geqslant 0)$, as defined in (4.2), together with a gauge $Y(\mathbf{y})=|\mathcal{W}_N(\varphi^{(2)})|^{-1}\times|\mathcal{W}^*_N(\varphi^{*(2)})|\times V(-\mu_j)^{-1}$ where we have chosen the $\mathbf{y}$-component adjoint functions to be

$$\varphi^{*(2)}_j\equiv\exp(-\xi(\mathbf{y},\mu_j)); \tag{4.25}$$

$V(-\mu_j)$ is the Vandermonde determinant in $-\mu_1,\dots,-\mu_j$. Hence we obtain a solution $\tau_{(-N,N)}$ to the (two-component) Toda molecule equations (3.1):

$$\begin{vmatrix}\mathbf{O}_{N\times N} & \mathcal{W}^*_N(\varphi^{*(1)})\\ \mathcal{W}_N(\varphi^{(2)}) & (m_{ij})_{N\times N}\end{vmatrix}\times|\mathcal{W}_N(\varphi^{(2)})|^{-1}\prod_{j=1}^{N}e^{-\xi(y,\mu_j)}=\mathcal{W}^*_N(-\varphi^{*(1)})\prod_{j=1}^{N}e^{-\xi(y,\mu_j)}, \tag{4.26}$$

which matches a determinant of the form $\overleftrightarrow{\tau}_{N,0}$ by choosing

$$f^*_j(\mathbf{x},\mathbf{y})\equiv-\varphi^{*(1)}_j e^{-\xi(\mathbf{y},\mu_j)}\quad \forall_j=1,\dots,N. \tag{4.27}$$

It can readily be verified that these $f^*_j(\mathbf{x},\mathbf{y})$ indeed satisfy the dispersion relations (4.15) and (4.16).

The second determinant in the Toda chain (4.23) can be written as

$$\overleftrightarrow{\tau}_{N,1}=\sum_{j=1}^{N}(-1)^{1+j}\omega_{1j}M_{Nj}[\overleftrightarrow{\mathcal{W}}^*_{N,N}]. \tag{4.28}$$

On the other hand, a Laplace expansion of the determinant $\tau_{(1-N,N-1)}$ given by (4.2) yields the following expression [after gauge transformation $Y(\mathbf{y})$]:

$$\tau_{(1-N,N-1)}\times|\mathcal{W}_N(\varphi^{(2)})|^{-1}\prod_{j=1}^{N}e^{-\xi(\mathbf{y},\mu_j)}=|\mathcal{W}_N(\varphi^{(2)})|^{-1}\sum_{i=1}^{N}M_{Ni}[\overleftrightarrow{\mathcal{W}}^*_{N,N}]e^{-\xi(\mathbf{y},\mu_i)}\times\left(\sum_{j=1}^{N}m_{ji}M_{jN}[\mathcal{W}_N(\varphi^{(2)})]\right), \tag{4.29}$$

which suggests the identification $(\forall_i=1,\dots,N)$

$$\omega_{1i}=e^{-\xi(\mathbf{y},\mu_i)}|\mathcal{W}_N(\varphi^{(2)})|^{-1}\left(\sum_{j=1}^{N}m_{ji}M_{jN}[\mathcal{W}_N(\varphi^{(2)})]\right). \tag{4.30}$$

Then, the x_1-derivative of ω_{1i} allows for an easy determination of the function $f(\mathbf{x},\mathbf{y})$ (the potential m_{ji} is the only part in this expression which depends on the $\mathbf{x}$-variables):

$$(\omega_{1i})_{x_1}=ff_i^*=e^{-\xi(\mathbf{y},\mu_i)}|\mathcal{W}_N(\varphi^{(2)})|^{-1}\left(\sum_{j=1}^N \varphi_j^{(1)}\varphi_i^{*(1)}M_{jN}[\mathcal{W}_N(\varphi^{(2)})]\right)$$

$$\overset{Eq.(4.27)}{\Leftrightarrow} f(\mathbf{x},\mathbf{y})=-\sum_{j=1}^N \varphi_j^{(1)}\frac{M_{jN}[\mathcal{W}_N(\varphi^{(2)})]}{|\mathcal{W}_N(\varphi^{(2)})|}, \tag{4.31}$$

which is essentially the same solution to the KP linear problem as in case of the Wronskian determinants (4.6). Hence, we have succeeded in expressing the functions f, f_j^* and the potentials ω_{1j} in terms of two-component tau functions. Moreover, the nontrivial $\mathbf{y}$-contribution in the two-component potentials m_{ij} is responsible for the fact that the ω_{1j} are only defined up to some arbitrary functions $F_{1j}(\mathbf{y})$. The other determinant solutions $\overleftrightarrow{\tau}_{N,M}$ in the Toda chain can now be calculated explicitly from the two determinants $\overleftrightarrow{\tau}_{N,0}$ and $\overleftrightarrow{\tau}_{N,1}$ we just constructed. The fact that this chain is finite follows from the exact identification with the two-component Toda chain $\tau_{M-N,N-M}$, but is not entirely trivial if one attempts a proof directly on the determinants themselves.

Of course, since the function $f(\mathbf{x},\mathbf{y})$ is the same as before, we know that it behaves as $f_{y_1}=f_{x_k}$ under the pseudo-reduction (3.3) and that it solves the KP linear problem in $\mathbf{x}$. Similarly, because the functions $f_j^*(\mathbf{x},\mathbf{y})$ defined in (4.27) can be expressed as the product of two two-component (adjoint) Wronskian tau functions $|W^*|$, we have that the pseudo-reduction not only implies that $(f_j^*)_{y_1}=(f_j^*)_{x_k}$, but [due to (4.27)] also that

$$(f_j^*)_{x_k}=-\mu_j f_j^*. \tag{4.32}$$

Discarding now the $\mathbf{y}$ dependence as merely parametric, we can define the potentials ω_{ij} as pure (one-component) KP eigenfunction potentials by replacing the recurrence relation (4.18) by

$$(\omega_{ij})_{x_k}=\omega_{i+1,j}-\mu_j\omega_{ij}. \tag{4.33}$$

This implies that the ''arbitrary'' constants c_{ij} in the potentials ω_{ij} [defined by $(\omega_{ij})_{x_1}=f_{(i-1)x_k}f_j^*$] are not all arbitrary, but are recursively defined in terms of N initial ones; in particular $c_{i+1,j}=\mu_j c_{ij}$. Hence, with $\overleftrightarrow{\tau}_{N,N}=|(\omega_{ij})|$ we have constructed a particular example of a KP Grammian solution which also satisfies the constraint (3.4) and thus $\overleftrightarrow{\tau}_{N,N}$ is a Grammian solution to the scalar k-constrained KP hierarchy. Similar solutions have been discussed previously in Refs. 7, 14, and 10. The functions q and r appearing in the constraint (3.14) are given by

$$q=\frac{\overleftrightarrow{\tau}_{N,N+1}}{\overleftrightarrow{\tau}_{N,N}}, \quad r=\frac{\overleftrightarrow{\tau}_{N,N-1}}{\overleftrightarrow{\tau}_{N}}. \tag{4.34}$$

We shall only briefly sketch the extension to the m-component case. It suffices to note that there also exist solutions ($N=\Sigma_{i=1}^{m-1}N_i$) to the Toda molecule equations in the form

$$\overleftrightarrow{\tau}_{N,N_1,\ldots,N_{m-1}}=\begin{vmatrix} (\omega_{ij}^{(1)})_{N_1\times N} \\ \vdots \\ (\omega_{ij}^{(m-1)})_{N_{m-1}\times N}\end{vmatrix}, \tag{4.35}$$

$$(\omega_{ij}^{(l)})_{x_1}=[f_l(\mathbf{x},\mathbf{y}^{(l+1)})]_{(i-1)y_1^{(l+1)}}f_j^*(\mathbf{x},\mathbf{y}), \tag{4.36}$$

where [in contrast to the $m-1$ functions $f_l(\mathbf{x},\mathbf{y}^{(l+1)})$] the N functions $f_j^*(\mathbf{x},\mathbf{y})$ depend on $\mathbf{x}$ and on all of the $\mathbf{y}^\alpha$ coordinates, such that

$$(f_l)_{x_n}=(f_l)_{nx_1}, \quad (f_j^*)_{x_n}=(-1)^{n+1}(f_j^*)_{nx_1}, \tag{4.37}$$

$$(f_j^*)_{y_1^{(\alpha)}} = -\mu_j^{(\alpha)} f_j^* \quad \forall \alpha = 2,...,m \tag{4.38}$$

(the proof being identical to the two-component case). The determinants (4.24) associated to these solutions are the obvious extensions of the above ones; in case of $M<N$, the ''adding or deleting'' of rows of potentials are restricted to a particular block (i.e., a particular coordinate set). Again, the different blocks in these determinants lead, so to speak, separate lives, and can therefore only be linked (by different gauges) to sequences of m-component tau functions which refer to different starting points. Thus, repeating the above construction step-by-step for each starting point $\tau_{(-N,\ldots,0,N_\alpha=N,0,\ldots)}$ of chains of m-component tau functions (4.2), for particular gauges $|\mathcal{W}_N(\varphi^{(\alpha)})|^{-1}\times\prod_{\beta=2}^m|\mathcal{W}_N^*(\varphi^{*(\beta)})|V(-\mu_j^{(\beta)})^{-1}$ and for the choice of $\varphi^{*(\beta)} = \exp[-\xi(\mathbf{y}^{(\beta)},\mu_j^{(\beta)})]$ $(\beta=2,...,m)$, we find that the

$$f_j^*(x,y) = -\varphi_j^{*(1)} \prod_{\beta=2}^m e^{-\xi(\mathbf{y}^{(\beta)},\mu_j^{(\beta)})} \quad \forall j=1,...,N. \tag{4.39}$$

One then proceeds to $\tau_{(1-N,\ldots,0,N_\alpha=N-1,0,\ldots)}$, which yields $m-1$ different functions f_l and consequently the $m-1$ series of potentials $\omega_{1j}^{(l)}$ needed to define the determinants (4.35). Since the functions f_l only depend on a single set of $\mathbf{y}$-variables and as the functions f_j^* obey

$$(f_j^*)_{x_k} = -\mu_j f_j^* \quad \text{with} \quad \mu_j = \sum_{\alpha=2}^m \mu_j^{(\alpha)}, \tag{4.40}$$

the pseudo-reduction is performed in exactly the same way as in the two-component case: i.e., the $(m-1)$-vector k-constrained KP hierarchy possesses Grammian solutions of type (4.35) where, at each occurrence, $y_1^{(l)}$ is replaced by x_k.

C. Alternative dispersion relations

In all the above solutions, Wronskians and Grammians alike, the functions appearing in the determinants (or in the potentials) satisfy trivial versions of the KP linear problem like the dispersion relations (4.15). This is because the tau functions themselves always refer to a trivial (i.e., constant) ''vacuum'' when one thinks of them as resulting from Bäcklund–Darboux transformations (as was explained in Sec. II). Some authors,[11,10] however, present determinant solutions referring to nontrivial vacuum, i.e., defined in terms of functions which satisfy nontrivial KP linear problems. The bidirectional nature of these solutions then manifests itself through a (highly) nonlinear operator, taking over the role of the ∂_{x_k}-operator. We shall briefly describe such solutions for the case of Wronskian solutions and scalar k-constrained hierarchies. However, it will turn out that these particular solutions can always be reformulated such that they again refer to trivial vacuum.

We shall use a Toda chain of two-component *adjoint* Wronskian solutions:

$$\tau_{(N_1,N_2)} = |W_{(1,2)}^*|, \quad N=N_1+N_2. \tag{4.41}$$

Starting the Toda chain with the tau function $\tau_{(N,0)}$, we take this to be our ''vacuum:''

$$\tau^V \equiv \tau_{(N,0)} = |\mathcal{W}_N^*(\varphi^{*(1)})|. \tag{4.42}$$

Now, performing exactly the same construction as in case of the Wronskian solutions, the second tau function in the chain allows us to define a function

$$g(\mathbf{x},\mathbf{y}) \equiv \frac{\tau_{(N-1,1)}}{\tau^V} = \sum_{i=1}^N (-1)^{i+N} \frac{M_{Ni}[\mathcal{W}_N^*(\varphi^{*(1)})]}{|\mathcal{W}_N^*(\varphi^{*(1)})|} \varphi_i^{*(2)}, \tag{4.43}$$

eventually giving rise to a chain of bidirectional Wronskian solutions,

$$\tau^V \times \begin{vmatrix} g & g_{x_1} & \cdots & g_{(n-1)x_1} \\ g_{y_1} & g_{x_1,y_1} & \cdots & g_{(n-1)x_1,y_1} \\ \vdots & \vdots & \ddots & \vdots \\ g_{(n-1)y_1} & \cdots & \cdots & g_{(n-1)x_1,(n-1)y_1} \end{vmatrix} \quad n=1,2...,N, \tag{4.44}$$

to the Toda molecule equation. Remark that we did not perform any gauge transformations on the original two-component chain, so the initial tau function τ^V appears as a multiplicative factor in these solutions. The ratio which defines $g(\mathbf{x},\mathbf{y})$ is actually the ratio of two tau functions $\tau^{\boldsymbol{\delta}_1-\boldsymbol{\delta}_2}$ and $\tau(=\tau^V)$ related by a Schlesinger transformation S_{12} (see Sec. II) and hence $g(\mathbf{x},\mathbf{y})$ is a solution of the KP linear problem[34,35,27,31] expressed in terms of the tau function τ^V:

$$p_n(-\tilde{\partial}_{\mathbf{x}})\Psi = \Psi \times p_{n-1}(-\tilde{\partial}_{\mathbf{x}})(\log \tau^V)_{x_1} \quad \forall n \geqslant 2 \tag{4.45}$$

{the operators $p_n(\tilde{\theta})$ are defined in terms of the Schur polynomials: $\Sigma_{n=1}^{\infty} p_n(\tilde{\theta})\lambda^n = \exp[\Sigma_{l=1}^{\infty}\theta_l / l\, \lambda^l]$}. In addition to these equations, the function $g(\mathbf{x},\mathbf{y})$ satisfies an additional identity stemming from the fact that we require the vacuum tau function τ^V itself to satisfy the constraint (3.14); the product $\tau^V g$ being a two-component tau function, the pseudo-reduction then yields

$$(\tau^V g)_{y_1} = \tau^V g_{y_1} = \tau^V_{x_k} g + \tau^V g_{x_k} \Leftrightarrow g_{y_1} = g_{x_k} + g\Omega(q^V, r^V). \tag{4.46}$$

As for the functions q^V and r^V, since the vacuum tau function τ^V is a Wronskian determinant [expressed in terms of solutions $\varphi^{*(1)}(\mathbf{x})$ of a trivial, i.e., vacuum $=1$, KP linear problem] which also has to solve the constrained hierarchy, one is forced to put

$$\varphi_j^{*(1)} = f^*_{(j-1)x_k}, \quad q^V = \frac{M_{NN}[\mathcal{W}_N^*(\varphi_j^{*(1)})]}{\tau^V(\varphi_j^{*(1)})}, \quad r^V = \frac{|\mathcal{W}_{N+1}^*(\varphi_j^{*(1)})|}{\tau^V(\varphi_j^{*(1)})} \tag{4.47}$$

for some function $f^*: f^*_{x_n} = (-1)^{n+1} f^*_{nx_1}$. Furthermore, it is easily seen that the function $g(\mathbf{x},\mathbf{y})$ can only satisfy the constraint (4.46) in all generality if the summation in its definition (4.43) is restricted to a single term such that $g(\mathbf{x},\mathbf{y}) = F(\mathbf{y}) \times q^V$. Equation (4.46) can then be written as

$$\partial_{y_1}(g) = \partial_{x_k}(g) + q^V \Omega(g, r^V), \tag{4.48}$$

allowing us to implement the pseudo-reduction on the determinants (4.44). It suffices to replace all occurrences of y_1-derivatives by the operator $\mathcal{L}_k \cdot = \partial_{x_k} \cdot + q^V \Omega(\cdot, r^V)$— note that as q^V nor r^V depend on the $\mathbf{y}$-variables, we can identify $\partial^n_{y_1}$ with $\mathcal{L}_k^n$—and at the same time guaranteeing that the resultant determinant is of (one-component) KP type. This last statement follows from comparison of the operator $\mathcal{L}_k$ with the constraint on the KP linear problem (3.24), as is explained in Ref. 14 and also in Refs. 10 and 11, where solutions of this type are presented and to which we also refer the reader for the relevant details on the operator $\mathcal{L}_k$.

At face value it might seem that we truly have constructed solutions which refer to a nontrivial vacuum. It is, however, not difficult to see that all these solutions can be rearranged such that they take the form of mere Wronskian solutions in the functions f^*. The following reasoning proves this fact: for all practical matters considered, we can look upon the above solutions as being linked in a Toda-like manner (if not directly, then at least through the construction in terms of real Toda chains), one ''end'' of which is given by the determinants

$$T_0 \equiv \tau^V = |\mathcal{W}_N^*(f^*_{(j-1)x_k})|, \tag{4.49}$$

$$T_1 \equiv \tau^V g = M_{NN}[\mathcal{W}_N^*(f^*_{(j-1)x_k})] = |\mathcal{W}_{N-1}^*(f^*_{(j-1)x_k})|. \tag{4.50}$$

However, this sequence could just as easily have been obtained by starting from the ''opposite'' end of the same two-component Toda chain, i.e., at some $\tau_{(0,M\geqslant N)}$ rather than $\tau_{(N,0)}$. The resulting sequence is then a chain of bidirectional Wronskian determinants in terms of the function $f^*: T_M = 1, T_{M-1} = f^*, f^* f^*_{x_1,x_k} - f^*_{x_1} f^*_{x_k}, \ldots,$ eventually reaching T_1 and T_0 and beyond. Thus, although the solutions (4.44) appear to be referring to nontrivial vacuum, in practice they do not. Unfortunately, it seems that in all explicitly ''constructable'' cases a similar thing will happen, i.e., the determinants will always be such that they can be reexpressed in terms of functions solving trivial dispersion relations, rather than full-fledged linear problems. This fact is intimately related with the restriction to finite Toda molecule chains if one regards them as being constructed as part of m-component hierarchies. This, in the fermionic picture, is an immediate result of being restricted to constant elements as starting points for sequences of Bäcklund transformations for the elements of GL(∞) generating the tau functions.

V. THE SCALAR CONSTRAINTS: BILINEAR DESCRIPTIONS

In this last section we discuss some peculiar properties of the scalar k-constrained KP hierarchies, with regard to their natural bilinear description. When imposing the pseudo-reduction on the linear problem for the two-component hierarchy (see Sec. III) it becomes clear that in this particular case the reduced linear equation (3.19) can be freed of all reference to the different components in essentially three different ways. All three resulting linear constraints lead to a natural (and very different) bilinear representation of the reduced nonlinear systems, for which the linear constraints then act as spectral problems.

A first way to turn the (two-component case of) equation (3.19),

$$(\Psi)_{x_k} - \lambda^k \Psi + qr\Psi_{\boldsymbol{\delta}_2 - \boldsymbol{\delta}_1} = 0, \tag{5.1}$$

into a (purely) differential spectral problem for the constrained KP hierarchies is by rather trivially introducing the auxiliary field $\Phi = r\Psi_{\boldsymbol{\delta}_2 - \boldsymbol{\delta}_1}$, for which we have [due to (3.22)] that

$$\Phi_x = r\Psi. \tag{5.2}$$

Note that because of (the $m=2$ case of) the constraint (3.14), the product qr is defined in terms of a single tau function,

$$qr = (\log \tau)_{x,x_k}, \tag{5.3}$$

where we from now on denote x_1 by x for simplicity. Now, from the KP linear problem as given by formula (4.45), it can be seen that any x_k-derivative $(k \geqslant 2)$ of a solution Ψ can be expressed (recursively) in terms of its x-derivatives $\Psi_{nx} (n \leqslant k)$ and derivatives of the $k-1$ functions contained in the set $\mathcal{T} = \{(\log \tau)_{x_1 x_l} | l \leqslant k-1\}$. Hence we can always rewrite the scalar constraint (5.1)

$$(\Psi)_{x_k} + q\Phi = \lambda^k \Psi \tag{5.4}$$

as a first-order spectral problem (in x) for the $(k+1)$-vector $(\psi_1 = \Psi, \psi_2 = \Psi_x, \ldots, \psi_k = \Psi_{(k-1)x}, \psi_{k+1} = \Phi)^t$, with coefficients defined in terms of the $k+1$ functions in $\mathcal{T} \cup \{q,r\}$. The higher-order $(x_{n\neq k})$ evolutions of this vector are calculated from (5.2) and the KP linear problem (4.45) and all of them will have coefficients defined in terms of these same functions $\mathcal{T} \cup \{q,r\}$. The first example (at $k=1$) is of course the well-known Ablowitz-Kaup-Newell-Segur (AKNS) spectral problem (see, e.g., Ref. 36 for a list of interesting systems obtainable at various values of k):

$$\begin{pmatrix} \psi_1 \\ \psi_2 \end{pmatrix}_x = \begin{pmatrix} \lambda & -q \\ r & 0 \end{pmatrix} \begin{pmatrix} \psi_1 \\ \psi_2 \end{pmatrix} \tag{5.5}$$

with lowest-order evolution

$$\begin{pmatrix} \psi_1 \\ \psi_2 \end{pmatrix}_{x_2} = \begin{pmatrix} \lambda^2 + 2qr & -q_x - \lambda q \\ r_x - \lambda r & qr \end{pmatrix} \begin{pmatrix} \psi_1 \\ \psi_2 \end{pmatrix}. \tag{5.6}$$

The nonlinear fields q and r are representable as ratios of KP tau functions (denoted here as $q = \tau^*/\tau$ and $r = \tau_*/\tau$) for which it was mentioned in Sec. II that the pairs (τ^*, τ) and (τ_*, τ) satisfy the modified KP bilinear equations. Hence, as the constraint (3.14) also has a bilinear representation in these three tau functions,

$$D_x D_{x_k} \tau \cdot \tau = 2 \tau^* \tau_*, \tag{5.7}$$

we can give a bilinear description of the nonlinear evolution equations governed by the above linear problems by imposing the bilinear constraint (5.7) on the modified KP bilinear hierarchies for (τ^*, τ) and (τ_*, τ) (see, e.g., Ref. 17 for a list of bilinear equations for the modified KP hiearchy). In this way we describe the scalar k-constrained KP hierarchies in terms of only three tau functions τ, τ^*, and τ_*. For example, from the above example we recover the well-known bilinear form of the AKNS equations:

$$\begin{aligned} q_{x_2} &= q_{2x} + 2q^2 r, \\ r_{x_2} &= -r_{2x} - 2qr^2, \end{aligned} \quad \leftrightarrow \begin{cases} D_x^2 \tau \cdot \tau = 2 \tau^* \tau_*, \\ (D_{x_2} - D_x^2) \tau^* \cdot \tau = 0, \\ (D_{x_2} + D_x^2) \tau_* \cdot \tau = 0. \end{cases} \tag{5.8}$$

A second example (omitting the relevant linear problem) is that of $k=2$ which—up to a gauge and coordinate transformation—can be identified as the Yajima–Oikawa system[37] $[w = (\log \tau)_{2x}]$:

$$\begin{aligned} q_{x_2} &= q_{2x} + 2wq, \\ r_{x_2} &= -(r_{2x} + 2wr) \\ w_{x_2} &= (qr)_x, \end{aligned} \quad \leftrightarrow \begin{cases} D_x D_{x_2} \tau \cdot \tau = 2 \tau^* \tau_*, \\ (D_{x_2} - D_x^2) \tau^* \cdot \tau = 0, \\ (D_{x_2} + D_x^2) \tau_* \cdot \tau = 0. \end{cases} \tag{5.9}$$

Another way of obtaining differential spectral problems from (5.1) is by introducing a slightly different auxiliary field $\Phi = qr \Psi_{\boldsymbol{\delta}_2 - \boldsymbol{\delta}_1}$, since in this case formula (3.22) tells us that

$$\Phi_x - (\log q)_x \Phi = qr \Psi. \tag{5.10}$$

This again allows us to rewrite the linear constraint (5.1) as a first-order spectral problem (in x) for the $(k+1)$-vector $(\psi_1 = \Psi, \psi_2 = \Psi_x, \ldots, \psi_k = \Psi_{(k-1)x}, \psi_{k+1} = \Phi)^t$, but this time with coefficients defined in terms of the $k+1$ functions in $\mathcal{T} \cup \{h \equiv \log q, (\log \tau)_{x, x_k} = qr\}$. As we now eliminated the explicit dependence on the r field (and hence on the τ_* tau function), we should look for a bilinear description of the resulting nonlinear systems in terms of only two tau functions: τ^* and τ. The answer lies with the x_k derivative of τ. In Sec. III it is explained that the constraint (3.14) actually tells us that the x_k derivative of τ is not only again a tau function (say, $\hat{\tau}$), but a very special one indeed, as it can be expressed using an eigenfunction potential. The element of $\mathrm{GL}(\infty)$ describing $\hat{\tau}$ is obtained from that for τ (let's call this one g) by a mere Bäcklund transformation on g:

$$\tau_{x_k} = \langle \mathrm{vac} | \hat{g}(x) | \mathrm{vac} \rangle \quad \text{with} \quad \hat{g} = (c + \phi \phi^*) g. \tag{5.11}$$

The tau function τ^* in its turn is linked to τ (and therefore to g) by the Darboux transformation,

$$\tilde{g} = S^{-1} \phi g \Rightarrow \tau^* \equiv \langle 1 | \Phi(\mathbf{x}) g(\mathbf{x}) | \mathrm{vac} \rangle = q \times \tau, \tag{5.12}$$

which is only a different way of saying that the pair (τ^*,τ) satisfies the modified KP bilinear equations (i.e., that q is a solution to the KP linear equations). However, since the (generalized) fermion operators are nilpotent, we immedately have that

$$S^{-1}\phi\hat{g}=S^{-1}\phi(c+\phi\phi^*)g=cS^{-1}\phi g\sim\tilde{g}, \tag{5.13}$$

and thus we see that the pair (τ^*,τ_{x_k}) also satisfies the modified KP bilinear equations. In other words, one can also give a bilinear description of the scalar k-constrained KP hierarchy by replacing the bilinear constraint (5.7) by an expression which states that both pairs (τ^*,τ) and (τ^*,τ_{x_k}) satisfy the modified KP bilinear hierarchies, i.e., using only two tau functions. The corresponding nonlinear equations are then expressible in the $k+1$ fields $\mathcal{T}\cup\{h,u\}$ with $h=\log\tau^*/\tau$ and $u\equiv(\log\tau)_{x,x_k}=qr$. These are, of course, related to the previous ones by simple dependent variable transformations, their linear problems being related by gauge transformations (as is clear from the construction). The most famous occurrence of this fact is that for the Broer–Kaup system,[38] which is obtained for the basic case $k=1$. As was described above, its spectral problem is

$$\begin{pmatrix}\psi_1\\ \psi_2\end{pmatrix}_x=\begin{pmatrix}\lambda & -1\\ u & h_x\end{pmatrix}\begin{pmatrix}\psi_1\\ \psi_2\end{pmatrix}, \tag{5.14}$$

with lowest-order evolution

$$\begin{pmatrix}\psi_1\\ \psi_2\end{pmatrix}_{x_2}=\begin{pmatrix}\lambda^2+u & -h_x-\lambda\\ \lambda u+h_xu-u_x & -h_{2x}-h_x^2-u\end{pmatrix}\begin{pmatrix}\psi_1\\ \psi_2\end{pmatrix}. \tag{5.15}$$

The compatibility condition of this system (Broer–Kaup) can be bilinearized as

$$\begin{array}{l} h_{x_2}=h_{2x}+h_x^2+2u,\\ u_{x_2}=(2h_xu-u_x)_x,\end{array}\leftrightarrow\begin{cases}(D_{x_2}-D_x^2)\tau^*\cdot\tau=0,\\ (D_{x_2}-D_x^2)\tau^*\cdot\tau_x=0.\end{cases} \tag{5.16}$$

Remark that for KP tau functions τ this last bilinear equation can be rewritten as $(D_{x_2}-D_x^2)\tau^*\cdot\tau_x=0\Leftrightarrow D_x(D_{x_2}-D_x^2)\tau^*\cdot\tau=0$, a property which extends to all the bilinear equations in the modified KP hierarchy. The correspondence between the AKNS hierarchy and the Broer–Kaup hierarchy has been discussed by a number of authors in the past;[19,39,35] the present construction has the nice feature of allowing one to dispense altogether with gauge transformations for ''energy dependent'' eigenvalue problems[40] or constraints for modified KP hierarchies[36] in order to appreciate the fact that both hierarchies describe exactly the same systems. It should be clear from the construction that such gauge transformations are a general feature of the (scalar) k-constrained KP hierarchies. In particular, for the Yajima–Oikawa system, one finds the following ''partner'' system,

$$\begin{array}{l} h_{x_2}=h_{2x}+h_x^2+2w,\\ w_{x_2}=u_x,\\ u_{x_2}=(2h_xu-u_x)_x,\end{array}\leftrightarrow\begin{cases}(D_{x_2}-D_x^2)\tau^*\cdot\tau=0,\\ D_{x_2}(D_{x_2}-D_x^2)\tau^*\cdot\tau=0'\end{cases} \tag{5.17}$$

providing an alternative bilinearization of the Yajima–Oikawa equations using only two tau functions [$h=\log\tau^*/\tau$, $w=(\log\tau)_{2x}$ and $u=(\log\tau)_{x,x_2}$].

Finally, there exists a third bilinear description of the k-constrained KP hierarchy, one in which only a single tau function plays a role. Using property (3.23), we immediately have the spectral equation

$$\left(\partial_x-\frac{q_x}{q}\right)[\Psi_{x_k}-\lambda^k\Psi]+qr\Psi=0. \tag{5.18}$$

Performing now the pseudo-reduction (3.3) on the (two-component version of the) higher-order evolution (2.15), we obtain

$$(\log\tau)_{x_2,x_k}=\tau^{-2}(\tau_x^*\tau_*-\tau^*\tau_{*x})=q_xr-qr_x, \tag{5.19}$$

which, together with (5.3), yields the following expression for h:

$$h\equiv\frac{q_x}{q}=\frac{(\log\tau)_{x_2,x_k}+(\log\tau)_{2x,x_k}}{2(\log\tau)_{x,x_k}}. \tag{5.20}$$

Accordingly, we can reexpress the spectral problem as

$$(\partial_x-h)[\Psi_{x_k}-\lambda^k\Psi]+u\Psi=0, \tag{5.21}$$

but where $u=(\log\tau)_{x,x_k}$ and h are defined in terms of only one tau function τ. The KP linear problem (4.45) allows us to rewrite this spectral problem in terms of a (scalar) $(k+1)$st-order differential operator in x, with coefficients defined in terms of the $k+1$ functions $\{(\log\tau)_{x_1,x_l}|l\leqslant k\}\cup\{(\log\tau)_{x_2,x_k}\}$. The compatibility conditions of this operator and the usual evolution operators for the KP linear problem yield nonlinear equations which can be bilinearized using a single tau function. The corresponding bilinear forms are readily obtained by realizing that the k-constraint imposes the requirement that x_k-derivatives of tau functions should again be KP tau functions, in other words, that not only τ should satisfy the KP bilinear equations but τ_{x_k} as well. Of course all these systems (at every value of k) are gauge equivalent with the ones we described earlier. For example, in the case $k=1$ the condition discussed above yields (at lowest order) the system of bilinear equations,

$$\begin{gathered}(4D_xD_{x_3}-D_x^4-3D_{x_2}^2)\tau\cdot\tau=0,\\ (4D_xD_{x_3}-D_x^4-3D_{x_2}^2)\tau_x\cdot\tau_x=0,\end{gathered} \tag{5.22}$$

the last of which can be recombined with the first one so as to give

$$D_x^2(4D_xD_{x_3}-D_x^4-3D_{x_2}^2)\tau\cdot\tau=0 \tag{5.23}$$

provided τ is a KP tau function. When expressed in the fields $(\log\tau)_{2x}$ and $(\log\tau)_{x,x_2}$, this bilinear system yields the first two members of what was identified as a *nonlocal Boussinesq* hierarchy,[41–43] which first appeared as an equation governing the amplitude (squared) of the nonlinear Schrödinger waves.[44] Obviously, this hierarchy is gauge equivalent to the AKNS system given earlier. The ''one-field'' bilinearization of the k-constrained KP hierarchies was originally proposed in Ref. 4 and was actually first discovered for the example of the nonlocal-Boussinesq system.[42]

As a final example we give (at $k=2$) the following single field bilinearization of the Yajima–Oikawa system:

$$\begin{gathered}(4D_xD_{x_3}-D_x^4-3D_{x_2}^2)\tau\cdot\tau=0,\\ D_{x_2}^2(4D_xD_{x_3}-D_x^4-3D_{x_2}^2)\tau\cdot\tau=0,\end{gathered} \tag{5.24}$$

VI. CONCLUSIONS

We feel the description of constrained KP hiearchies offers a number of appealing features, notably the ease with which the tau function interpretation of the constraints can be obtained. As an important consequence of this interpretation we explained how the scalar *k*-constrained KP hierarchy possesses three different bilinear representations, each corresponding in a natural way to different nonlinearizations whose mutual connections were always regarded as somewhat ''special.'' Here we showed these are an intrinsic feature of constrained hierarchies.

We also paid a lot of attention to the explicit construction of solutions. In particular, two types of solutions, Wronskians and hybrid Wronskian/Grammians, were constructed. We would like to point out that previous accounts on Grammian-type solutions somehow disregarded the nature of the ''arbitrary'' constants which appear in the entries of the Grammian determinants. As we showed in Sec. IV, these constants are not quite arbitrary, but exhibit a structure similar to that of the actual Grammian entries. As for the Wronskian solutions (4.12), it should be clear that these allow for a slight generalization in that one can add a number (say M) of ''*k*-reduced''-like Wronskian blocks. These would contain rows expressed using *k*-reduced solutions to the KP linear problem, meaning functions $f_i(\mathbf{x})$ $(i=1,...,M)$ which—besides the dispersion relations (4.8)—have to satisfy $(f_i)_{x_k}=c_i f_i$ for some constants c_i. Such extended Wronskians clearly solve the constraint (3.14) as they can be viewed as part of an $(m-1+M)$-vector *k*-constrained hierarchy, but one for which the functions q_j corresponding to these extra blocks are always identically zero (Wronskian determinants, solely expressed in terms of such functions, will solve the *k*-reduced KP hierarchy). It is interesting to note that very similar solutions arise when one adopts a vertex operator approach to constrained KP evolutions, as described in Ref. 12. It seems worthwhile to try and understand why exactly these particular solutions should appear in the vertex operator formalism.

Finally, there remains the (general) problem of whether or not one can construct examples of determinant solutions whose entries genuinely satisfy nontrivial KP linear problems (as opposed to solutions as those discussed in the latter part of Sec. IV). As we explained, this problem can be traced back to the choice of starting point in GL(∞) if one thinks of the determinants as being constructed through Bäcklund transformations applied to such a vacuum element (cf. Sec. II).

(Received 2 June 1999; accepted for publication 7 September 1999)

Binary constrained flows of soliton equations admitting 2×2 Lax matrices have $2N$ degrees of freedom, which is twice as many degrees of freedom than in the case of monoconstrained flows. By using the normal method, their Lax matrices directly give rise to first N pairs of canonical separated variables for their separation of variables. We propose a new method to introduce the other N pairs of canonical separated variables and additional separated equations. The Jacobi inversion problems for binary constrained flows are established. Finally, the factorization of soliton equations by two commuting binary constrained flows and the separability of binary constrained flows enable us to construct the Jacobi inversion problems for some soliton hierarchies.

I. INTRODUCTION

The separation of variables is one of the most universal methods for solving completely integrable (classical and quantum) models. It has been applied successfully to the study of a large number of finite-dimensional integrable Hamiltonian systems (FDIHSs) (see, e.g., Refs. 1–12), as well as infinite-dimensional integrable Hamiltonian systems in the determination of finite-dimensional quasiperiodic solutions (see, e.g., Refs. 13–18). In many cases the separation of variables of integrable classical systems prepares the passage to the corresponding quantum systems. For the classical integrable systems subject to the inverse scattering method, the standard construction of the action-angle variables using the poles of the Baker–Akhiezer function is in fact equivalent to the separation of variables.[4]

For a FDIHS, let m denote the number of degrees of freedom, and P_i, $i=1,...,m$, be functionally independent integrals of motion in involution, the separation of variables means to construct m pairs of canonical separated variables v_k, u_k, $k=1,...,m$,[2–4]

$$\{u_k,u_l\}=\{v_k,v_l\}=0, \quad \{v_k,u_l\}=\delta_{kl}, \quad k,l=1,...,m, \tag{1.1}$$

and m functions f_k such that

$$f_k(u_k,v_k,P_1,\dots,P_m)=0, \quad k=1,...,m. \tag{1.2}$$

Equation (1.2) is called the separated equation, which gives rise to an explicit factorization of the Liouville tori.

For the FDIHSs with the Lax matrices admitting the r-matrices of the *XXX*, *XXZ* and *XYZ* type, there is a general approach to introduce canonical separated variables.[2–4,8] The correspond-

b)Electronic mail: mawx@cityu.edu.hk

ing separated equations enable us to express the generating function of canonical transformation in completely separated form as an Abelian integral on the associated invariant spectral curve. The resulted linearizing map is essentially the Abel map to the Jacobi variety of the spectral curve, thus providing a link, through purely Hamiltonian methods, with the algebro-geometric linearization methods given by Refs. 19–22.

An important feature of the separation of variables for a FDIHS is that the number of canonical separated variables u_k should be equal to the number m of degrees of freedom. In some cases, the number of u_k resulting from the normal method may be less than m and so some additional canonical separated variables should be introduced. So far very few models in these cases have been studied. These cases remain a challenging problem.[4] In recent years binary constrained flows of soliton hierarchies have attracted attention (see, e.g., Refs. 23–29), whose basic idea was described in Ref. 30. The degree of freedom for binary constrained flows admitting 2×2 Lax matrices is an even natural number usually denoted by $2N$. By using the method,[2–4,8] the Lax matrices allow one to directly introduce first N pairs of canonical separated variables $u_1,\ldots,u_N$ and $v_1,\ldots,v_N$. The other N pairs of canonical separated variables $u_{N+1},\ldots,u_{2N}$ and $v_{N+1},\ldots,v_{2N}$ may be constructed by the method in Ref. 3. In this paper we propose a new method for determining additional N pairs of canonical separated variables and separated equations for binary constrained flows. The main idea is to construct two functions $\tilde{B}(\lambda)$ and $\tilde{A}(\lambda)$ defining $u_{N+1},\ldots,u_{2N}$ by the set of zeros of $\tilde{B}(\lambda)$ and $v_{N+k}=\tilde{A}(u_{N+k})$. To keep the canonical conditions (1.1) and the requirement for the separated equation (1.2), it is found that certain commutator relations should be imposed on $\tilde{B}(\lambda)$, $\tilde{A}(\lambda)$ and $\tilde{A}(\lambda)$ has some link with the generating function of integrals of motion of binary constrained flows, which provides a way to construct the $\tilde{B}(\lambda)$ and $\tilde{A}(\lambda)$. In fact, we have to modify the original approach for introducing $u_1,\ldots,u_N$ and $v_1,\ldots,v_N$ so that $u_1,\ldots,u_{2N}$ and $v_1,\ldots,v_{2N}$ are canonical conjugated. Having produced the separation of variables, we further construct the Jacobi inversion problems for binary constrained flows. This method is somewhat different from that for introducing canonical variables presented in Ref. 31 and can be applied to more binary constrained flows.

Briefly, separation of variables can be characterized as a reduction of a multidimensional problem to a set of one-dimensional ones. The separation of variables of soliton equations in this paper contains two steps of separation of variables. The first step is to factorize $(1+1)$-dimensional soliton equations into two commuting x- and t-FDIHSs via binary constrained flows, namely the x and t dependencies of the soliton equations are separated by the x- and t-FDIHSs obtained from the x- and t-binary constrained flows. The second step is to produce separation of variables for the x- and t-FDIHDs by our method to be proposed later on. Finally, combining the factorization of soliton equations with the Jacobi inversion problems for x- and t-FDIHSs enables us to establish the Jacobi inversion problems for soliton equations. We will present the separation of variables for the Korteweg–de Vries (KdV) hierarchy, the AKNS hierarchy, and the Kaup–Newell hierarchy via their binary constrained flows. In fact, we employ our method in a little different way for those three cases.

In Sec. II, we recall the binary constrained flows of KdV hierarchy and present factorization of the KdV equations into the x- and t-binary constrained flows. By means of the Lax matrix $M=\begin{pmatrix} A(\lambda) & B(\lambda) \\ C(\lambda) & -A(\lambda) \end{pmatrix}$ for the binary constrained flows, the method in Refs. 2–4 and 8 introduce the first N pairs of canonical variables $u_1,\ldots,u_N$ by the set of zeros of $B(\lambda)$ and $v_k=2A(u_k)$. We propose a new method to construct two new functions $\tilde{B}(\lambda)$ and $\tilde{A}(\lambda)$ for introducing $u_{N+1},\ldots,u_{2N}$ by the set of zeros of $\tilde{B}(\lambda)$ and $v_{N+k}=\tilde{A}(u_{N+k})$. The construction of $\tilde{B}(\lambda)$ and $\tilde{A}(\lambda)$ is based on an observation that the canonical conditions (1.1) need certain commutator relations between $\tilde{A}(\lambda)$, $\tilde{B}(\lambda)$, and the requirement for the separated equation (1.2) links $\tilde{A}(\lambda)$ with another generating function of integrals of motion. To guarantee that $v_1,\ldots,v_{2N}$ and $u_1,\ldots,u_{2N}$ are canonical conjugated, we also have to modify the original way for introducing $u_1,\ldots,u_N$ and $v_1,\ldots,v_N$. Then we establish the Jacobi inversion problems for the x- and t-binary constrained flows. Finally, these Jacobi inversion problems together with the factorization of the KdV equations give rise to the

Jacobi inversion problems for the KdV equations. In Sec. III, the factorization of the Ablowitz-Kaup-Newell-Segur (AKNS) equations is given. Since $B(\lambda)$ for the binary constrained AKNS flows, unlike the $B(\lambda)$ for the binary constrained KdV flows, has only $N-1$ zeros, we have to modify the method proposed in Sec. II in order to find $2N$ pairs of canonical variables for the binary constrained AKNS flows. In Sec. IV, we present the factorization of the Kaup–Newell equations. Since the commutator relations of $A(\lambda)$, $B(\lambda)$, and $C(\lambda)$ for the binary constrained Kaup–Newell flows are quite different from those for both the binary constrained KdV flows and the binary constrained AKNS flows, we need to further modify the method in Secs. II and III in order to find the separation of variables for the Kaup–Newell equations. Finally some remarks are made in Sec. V.

II. SEPARATION OF VARIABLES FOR THE KdV EQUATIONS

In this section, we use the binary constrained flows of KdV hierarchy to illustrate our method of introducing canonical separated variables. Then we show how to produce the separation of variables for the KdV equations. To make the paper self-contained, we first briefly describe the binary constrained flows of the KdV hierarchy.[26]

A. Binary constrained flows of the KdV hierarchy

Let us start from the Schrödinger equation[32]

$$\phi_{xx}+(\lambda+u)\phi=0,$$

which can be rewritten as the following spectral problem:

$$\phi_x=U(u,\lambda)\phi, \quad U(u,\lambda)=\begin{pmatrix} 0 & 1 \\ -\lambda-u & 0 \end{pmatrix}, \quad \phi=\begin{pmatrix} \phi_1 \\ \phi_2 \end{pmatrix}. \tag{2.1}$$

Its adjoint representation reads

$$V_x=[U,V]\equiv UV-VU. \tag{2.2}$$

Set

$$V=\sum_{i=0}^{\infty}\begin{pmatrix} a_i & b_i \\ c_i & -a_i \end{pmatrix}\lambda^{-i}. \tag{2.3}$$

Equation (2.2) yields

$$a_0=b_0=0, \quad c_0=-1, \quad a_1=0, \quad b_1=1, \quad c_1=-\tfrac{1}{2}u,$$

$$a_2=\tfrac{1}{4}u_x, \quad b_2=-\tfrac{1}{2}u, \quad c_2=\tfrac{1}{8}(u_{xx}+u^2),\ldots,$$

and in general

$$b_{k+1}=Lb_k=-\tfrac{1}{2}L^{k-1}u, \quad a_k=-\tfrac{1}{2}b_{k,x}, \tag{2.4a}$$

$$c_k=-\tfrac{1}{2}b_{k,xx}-b_{k+1}-b_k u, \quad k=1,2,..., \tag{2.4b}$$

where

$$L=-\tfrac{1}{4}\partial^2-u+\tfrac{1}{2}\partial^{-1}u_x, \quad \partial=\partial_x, \quad \partial^{-1}\partial=\partial\partial^{-1}=1.$$

Set

$$V^{(n)}(u,\lambda)=\sum_{i=0}^{n+1}\begin{pmatrix} a_i & b_i \\ c_i & -a_i \end{pmatrix}\lambda^{n+1-i}+\begin{pmatrix} 0 & 0 \\ b_{n+2} & 0 \end{pmatrix}, \tag{2.5}$$

and take the time evolution law of ϕ as

$$\phi_{t_n}=V^{(n)}(u,\lambda)\phi. \tag{2.6}$$

Then the compatibility condition of Eqs. (2.1) and (2.6) gives rise to the nth KdV equation which can be written as the infinite-dimensional Hamiltonian system

$$u_{t_n}=-2b_{n+2,x}=\partial L^n u=\partial\frac{\delta H_n}{\delta u}, \tag{2.7}$$

where the Hamiltonian H_n is given by

$$H_n=\frac{4b_{n+3}}{2n+3},\quad \frac{\delta H_n}{\delta u}=-2b_{n+2}.$$

The matrix V determined by (2.2) and (2.3) also satisfies the adjoint representation of (2.6),

$$V_{t_n}=[V^{(n)},V], \tag{2.8}$$

when u satisfies (2.7).

For $n=1$ we have

$$\phi_{t_1}=V^{(1)}(u,\lambda)\phi,\quad V^{(1)}=\begin{pmatrix}\frac{1}{4}u_x & \lambda-\frac{1}{2}u\\ -\lambda^2-\frac{1}{2}u\lambda+\frac{1}{4}u_{xx}+\frac{1}{2}u^2 & -\frac{1}{4}u_x\end{pmatrix}, \tag{2.9}$$

and Eq. (2.7) for $n=1$ is the well-known KdV equation

$$u_{t_1}=-\tfrac{1}{4}(u_{xxx}+6uu_x). \tag{2.10}$$

The adjoint spectral problem reads

$$\psi_x=-U^T(u,\lambda)\psi,\quad \psi\begin{pmatrix}\psi_1\\ \psi_2\end{pmatrix}. \tag{2.11}$$

We have[26]

$$\frac{\delta\lambda}{\delta u}=\beta\,\mathrm{Tr}\left[\begin{pmatrix}\phi_1\psi_1 & \phi_1\psi_2\\ \phi_2\psi_1 & \phi_2\psi_2\end{pmatrix}\frac{\partial U(u,\lambda)}{\partial u}\right]=-\beta\psi_2\phi_1, \tag{2.12}$$

where β is some constant.

The binary x-constrained flows of the KdV hierarchy (2.7) consist of the equations obtained from the spectral problem (2.1) and the adjoint spectral problem (2.11) for N distinct real numbers λ_j and the restriction of the variational derivatives for the conserved quantities H_{k_0} (for any fixed k_0) and λ_j:

$$\Phi_{1,x}=\Phi_2,\quad \Phi_{2,x}=-\Lambda\Phi_1-u\Phi_1, \tag{2.13a}$$

$$\Psi_{1,x}=\Lambda\Psi_2+u\Psi_2,\quad \Psi_{2,x}=-\Psi_1, \tag{2.13b}$$

$$\frac{\delta H_{k_0}}{\delta u}-\beta^{-1}\sum_{j=1}^{N}\frac{\delta\lambda_j}{\delta u}=-2b_{k_0+2}+\langle\Psi_2,\Phi_1\rangle=0. \tag{2.13c}$$

Such a constraint (2.13c) has been recognized as a symmetry constraint.[25,26,30] Hereafter we denote the inner product in $\mathbf{R}^N$ by $\langle .,.\rangle$ and

$$\Phi_i=(\phi_{i1},\ldots,\phi_{iN})^T,\quad \Psi_i=(\psi_{i1},\ldots,\psi_{iN})^T,\quad i=1,2,\quad \Lambda=\mathrm{diag}(\lambda_1,\ldots,\lambda_N).$$

For $k_0=0$, we have

$$b_2=-\tfrac{1}{2}u=\tfrac{1}{2}\langle\Psi_2,\Phi_1\rangle,$$

i.e.,

$$u=-\langle\Psi_2,\Phi_1\rangle. \tag{2.14}$$

By substituting (2.14) into (2.13a) and (2.13b), the first binary x-constrained flow becomes a finite-dimensional Hamiltonian system (FDHS)[26]

$$\Phi_{1x}=\frac{\partial F_1}{\partial\Psi_1},\quad \Phi_{2x}=\frac{\partial F_1}{\partial\Psi_2},\quad \Psi_{1x}=-\frac{\partial F_1}{\partial\Phi_1},\quad \Psi_{2x}=-\frac{\partial F_1}{\partial\Phi_2}, \tag{2.15}$$

with the Hamiltonian

$$F_1=\langle\Psi_1,\Phi_2\rangle-\langle\Lambda\Psi_2,\Phi_1\rangle+\tfrac{1}{2}\langle\Psi_2,\Phi_1\rangle^2.$$

The binary t_n-constrained flows of the KdV hierarchy (2.7) are defined by the replicas of (2.6) and its adjoint system for N distinct real number λ_j,

$$\begin{pmatrix}\phi_{1j}\\ \phi_{2j}\end{pmatrix}_{t_n}=V^{(n)}(u,\lambda_j)\begin{pmatrix}\phi_{1j}\\ \phi_{2j}\end{pmatrix},\quad \begin{pmatrix}\psi_{1j}\\ \psi_{2j}\end{pmatrix}_{t_n}=-(V^{(n)}(u,\lambda_j))^T\begin{pmatrix}\psi_{1j}\\ \psi_{2j}\end{pmatrix},\quad j=1,\ldots,N, \tag{2.16}$$

as well as the nth KdV equation itself (2.7) in the case of the higher-order constraint for $k_0\geqslant 1$. Under the constraint (2.14) and the x-FDHS (2.15), the binary t_1-constrained flow obtained from (2.16) with $V^{(1)}$ given by (2.9) can also be written as a t_1-FDHS,

$$\Phi_{1,t_1}=\frac{\partial F_2}{\partial\Psi_1},\quad \Phi_{2,t_1}=-\frac{\partial F_2}{\partial\Psi_2},\quad \Psi_{1,t_1}=-\frac{\partial F_2}{\partial\Phi_1},\quad \Psi_{2,t_1}=-\frac{\partial F_2}{\partial\Psi_2}, \tag{2.17}$$

with the Hamiltonian

$$F_2=-\langle\Lambda^2\Psi_2,\Phi_1\rangle+\langle\Lambda\Psi_1,\Phi_2\rangle+\tfrac{1}{2}\langle\Psi_2,\Phi_1\rangle\langle\Lambda\Psi_2,\Phi_1\rangle+\tfrac{1}{2}\langle\Psi_2,\Phi_1\rangle\langle\Psi_1,\Phi_2\rangle+\tfrac{1}{8}(\langle\Psi_2,\Phi_2\rangle$$
$$-\langle\Psi_1,\Phi_1\rangle)^2.$$

The Lax representation for the x-FDHS (2.15) and the t_1-FDHS (2.17) can be deduced from the adjoint representation (2.2) and (2.8) by using the method in[33,34]

$$M_x=[\widetilde{U},M],\quad M_{t_n}=[\widetilde{V}^{(n)},M], \tag{2.18}$$

where $\widetilde{U}$ and $\widetilde{V}^{(n)}$ are obtained from U and $V^{(n)}$ by a substitution of (2.14), and the Lax matrix M is given by

$$M=\begin{pmatrix}A(\lambda) & B(\lambda)\\ C(\lambda) & -A(\lambda)\end{pmatrix},$$

$$A(\lambda)=\frac{1}{4}\sum_{j=1}^{N}\frac{\psi_{1j}\phi_{1j}-\psi_{2j}\phi_{2j}}{\lambda-\lambda_j},\quad B(\lambda)=1+\frac{1}{2}\sum_{j=1}^{N}\frac{\psi_{2j}\phi_{1j}}{\lambda-\lambda_j}, \tag{2.19}$$

$$C(\lambda)=-\lambda+\frac{1}{2}\langle\Psi_2,\Phi_1\rangle+\frac{1}{2}\sum_{j=1}^{N}\frac{\psi_{1j}\phi_{2j}}{\lambda-\lambda_j}.$$

Equation (2.18) implies that $\frac{1}{2}\mathrm{Tr}\,M^2(\lambda)=A^2(\lambda)+B(\lambda)C(\lambda)$ is the generating function of integrals of motion for (2.15) and (2.17). A straightforward calculation yields

$$A^2(\lambda)+B(\lambda)C(\lambda)\equiv P(\lambda)=-\lambda+\sum_{j=1}^{N}\left[\frac{P_j}{\lambda-\lambda_j}+\frac{P_{N+j}^2}{(\lambda-\lambda_j)^2}\right], \tag{2.20}$$

where P_j, $j=1,...,2N$, are $2N$ independent integrals of motion for the FDHSs (2.15) and (2.17),

$$P_j=\frac{1}{2}\psi_{1j}\phi_{2j}+\left(-\frac{1}{2}\lambda_j+\frac{1}{4}\langle\Psi_2,\Phi_1\rangle\right)\psi_{2j}\phi_{1j}$$
$$+\frac{1}{8}\sum_{k\neq j}\frac{1}{\lambda_j-\lambda_k}[(\psi_{1j}\phi_{1j}-\psi_{2j}\phi_{2j})(\psi_{1k}\phi_{1k}-\psi_{2k}\phi_{2k})+4\psi_{1j}\phi_{2j}\psi_{2k}\phi_{1k}],$$
$$j=1,...,N \tag{2.21a}$$

$$P_{N+j}=\tfrac{1}{4}(\psi_{1j}\phi_{1j}+\psi_{2j}\phi_{2j}),\quad j=1,...,N. \tag{2.21b}$$

It is easy to verify that

$$F_1=2\sum_{j=1}^{N}P_j,\quad F_2=2\sum_{j=1}^{N}(\lambda_jP_j+P_{N+j}^2). \tag{2.22}$$

With respect to the standard Poisson bracket it is found that

$$\{A(\lambda),A(\mu)\}=\{B(\lambda),B(\mu)\}=0,\quad \{C(\lambda),C(\mu)\}=A(\mu)-A(\lambda), \tag{2.23a}$$

$$\{A(\lambda),B(\mu)\}=\frac{1}{2(\lambda-\mu)}[B(\mu)-B(\lambda)], \tag{2.23b}$$

$$\{A(\lambda),C(\mu)\}=\frac{1}{2(\lambda-\mu)}[C(\lambda)-C(\mu)], \tag{2.23c}$$

$$\{B(\lambda),C(\mu)\}=\frac{1}{\lambda-\mu}[A(\mu)-A(\lambda)]. \tag{2.23d}$$

It follows from (2.23) that

$$\{A^2(\lambda)+B(\lambda)C(\lambda),A^2(\mu)+B(\mu)C(\mu)\}=0,$$

which implies that P_j, $j=1,...,2N$, are in involution:

$$\{P_k,P_l\}=0,\quad k,l=1,...,2N.$$

Therefore the FDHSs (2.15) and (2.17) are integrable and commute with each other. The construction of (2.15) and (2.17) ensures that if $(\Psi_1,\Psi_2,\Phi_1,\Phi_2)$ satisfies the finite-dimensional integrable Hamiltonian systems (FDIHSs) (2.15) and (2.17) simultaneously, then u defined by (2.14) solves the KdV equation (2.10).

In general, by substituting (2.14) and using (2.15), the t_n-constrained flow (2.16) becomes a t_n-FDIHS and the nth KdV equation (2.7) is factorized by the x-FDIHS (2.15) and the t_n-FDIHS. Set

$$A^2(\lambda)+B(\lambda)C(\lambda)=\lambda\sum_{k=0}^{\infty}\tilde{F}_k\lambda^{-k}, \tag{2.24a}$$

where $\tilde{F}_k$, $k=1,2,...$, are also integrals of motion for both the x-FDIHSs (2.15) and the t_n-binary constrained flows (2.16). Comparing (2.24a) with (2.20), one gets

$$\tilde{F}_0=-1,\quad \tilde{F}_1=0,\quad \tilde{F}_k=\sum_{j=1}^{N}[\lambda_j^{k-2}P_j+(k-2)\lambda_j^{k-3}P_{N+j}^2],\quad k=2,3,\ldots. \tag{2.24b}$$

By employing the method in Refs. 34 and 35, the t_n-FDIHS obtained from the t_n-constrained flow (2.16) is found to be of the form

$$\Phi_{1,t_n}=\frac{\partial F_{n+1}}{\partial\Psi_1},\quad \Phi_{2,t_n}=\frac{\partial F_{n+1}}{\partial\Psi_2},\quad \Psi_{1,t_n}=-\frac{\partial F_{n+1}}{\partial\Phi_1},\quad \Psi_{2,t_n}=-\frac{\partial F_{n+1}}{\partial\Phi_2}, \tag{2.25a}$$

with the Hamiltonian

$$F_{n+1}=\sum_{m=0}^{n}\left(\frac{1}{2}\right)^{m-1}\frac{\alpha_m}{m+1}\sum_{l_1+\cdots+l_{m+1}=n+2}\tilde{F}_{l_1}\cdots\tilde{F}_{l_{m+1}}, \tag{2.25b}$$

where $l_1\geqslant 1,\ldots, l_{m+1}\geqslant 1$, $\alpha_0=1$, $\alpha_1=\frac{1}{2}$, $\alpha_2=\frac{3}{2}$, and[34,35]

$$\alpha_m=2\alpha_{m-1}+\sum_{l=1}^{m-2}\alpha_l\alpha_{m-l-1}-\frac{1}{2}\sum_{l=1}^{m-1}\alpha_l\alpha_{m-l},\quad m\geqslant 3. \tag{2.25c}$$

The nth KdV equation (2.7) is factorized by the x-FDIHS (2.15) and the t_n-FDIHS (2.25).

For example, for the second equation in the KdV hierarchy (2.7) with $n=2$,

$$u_{t_2}=\tfrac{1}{16}(u_{xxxx}+10uu_{xx}+5u_x^2+10u^3)_x, \tag{2.26}$$

the Hamiltonian F_3 for the t_2-FDIHS reads

$$F_3=2\tilde{F}_4+\frac{1}{2}\tilde{F}_2^2=2\sum_{j=1}^{N}(\lambda_j^2P_j+2\lambda_jP_{N+j}^2)+\frac{1}{2}\left(\sum_{j=1}^{N}P_j\right)^2. \tag{2.27}$$

Then the second KdV equation (2.26) is factorized by the x-FDIHS (2.15) and the t_2-FDIHS with the Hamiltonian F_3.

B. The separation of variables for the KdV equations

An effective way to introduce the separated variables v_k, u_k and to obtain the separated equations is to use the Lax matrix M and the generating function of integrals of motion. For the FDIHSs (2.15) and (2.17), we can define the first N pairs of the canonical variables u_k, v_k, $k=1,...,N$, by the method.[2,3,4,8] The commutator relations (2.23) and the generating function of integrals of motion (2.20) enable us to define $u_1,\ldots,u_N$ by the set of zeros of $B(\lambda)$,

$$B(\lambda)=1+\frac{1}{2}\sum_{j=1}^{N}\frac{\psi_{2j}\phi_{1j}}{\lambda-\lambda_j}=\frac{R(\lambda)}{K(\lambda)}, \tag{2.28a}$$

where

$$R(\lambda)=\prod_{k=1}^{N}(\lambda-u_k),\quad K(\lambda)=\prod_{k=1}^{N}(\lambda-\lambda_k),$$

and $v_1,\ldots,v_N$ by

$$v_k=A_1(u_k), \quad k=1,...,N, \tag{2.28b}$$

where

$$A_1(\lambda)=2A(\lambda)=\frac{1}{2}\sum_{j=1}^{N}\frac{\psi_{1j}\phi_{1j}-\psi_{2j}\phi_{2j}}{\lambda-\lambda_j}.$$

As we will see later, the commutator relations (2.23) guarantee that $u_1,\ldots,u_N$ and $v_1,\ldots,v_N$ satisfy the canonical conditions (1.1). Then substituting u_k into (2.20) gives rise to the separated equations

$$v_k=A_1(u_k)=2\sqrt{P(u_k)}=2\sqrt{-u_k+\sum_{j=1}^{N}\left[\frac{P_j}{u_k-\lambda_j}+\frac{P_{N+j}^2}{(u_k-\lambda_j)^2}\right]}, \quad k=1,...,N.$$

Now the reason for taking our choice of $B(\lambda)$ and $A_1(\lambda)$ becomes apparent.

The FDIHSs (2.15) and (2.17) have $2N$ degrees of freedom, therefore we need to introduce the other N pairs of canonical variables v_k,u_k, $k=N+1,...,2N$. The main idea is to construct two suitable functions $\tilde{B}(\lambda),\tilde{A}(\lambda)$ in order to define $u_{N+1},\ldots,u_{2N}$ by the set of zeros of $\tilde{B}(\lambda)$ and $v_{N+1},\ldots,v_{2N}$ by $v_{N+k}=\tilde{A}(u_{N+k})$. The above mentioned way for introducing u_k,v_k, $k=1,...,N$ stimulates us to impose two requirements on $\tilde{B}(\lambda)$ and $\tilde{A}(\lambda)$ in order to construct them. First, the canonical conditions (1.1) require that $\tilde{B}(\lambda)$ and $\tilde{A}(\lambda)$ satisfy

$$\{\tilde{B}(\lambda),\tilde{B}(\mu)\}=\{\tilde{B}(\lambda),B(\mu)\}=\{\tilde{A}(\lambda),\tilde{A}(\mu)\}=\{\tilde{A}(\lambda),B(\mu)\}=\{\tilde{A}(\lambda),A_1(\mu)\}=0, \tag{2.29a}$$

$$\{\tilde{A}(\lambda),\tilde{B}(\mu)\}=\frac{1}{\lambda-\mu}[\tilde{B}(\mu)-\tilde{B}(\lambda)], \tag{2.29b}$$

$$\{A_1(\lambda),\tilde{B}(\mu)\}=0. \tag{2.29c}$$

The second requirement is that the equation $v_{N+k}=\tilde{A}(u_{N+k})$ should give rise to the separated equations. Notice that P_{N+j} given by (2.21b) are integrals of motion for the FDIHSs (2.15) and (2.17), we can construct another generating function $\tilde{A}(\lambda)$ of integrals of motion by

$$\tilde{A}(\lambda)=\frac{1}{2}\sum_{j=1}^{N}\frac{\psi_{1j}\phi_{1j}+\psi_{2j}\phi_{2j}}{\lambda-\lambda_j}=2\sum_{j=1}^{N}\frac{P_{N+j}}{\lambda-\lambda_j}. \tag{2.30a}$$

We may use $\tilde{A}(\lambda)$ to define $v_{N+1},\ldots,v_{2N}$ since substituting u_{N+k} into Eq. (2.30a) immediately leads to the separated equations for v_{N+k} and u_{N+k}. It is easy to see that $\{\tilde{A}(\lambda),B(\mu)\}=\{\tilde{A}(\lambda),\tilde{A}(\mu)\}=\{\tilde{A}(\lambda),A_1(\mu)\}=0$. We look for $\tilde{B}(\lambda)$ in the form

$$\tilde{B}(\lambda)=1+\frac{1}{2}\sum_{j=1}^{N}\frac{1}{\lambda-\lambda_j}(\delta_1\phi_{1j}^2+\delta_2\phi_{1j}\phi_{2j}+\delta_3\phi_{2j}^2).$$

By requiring $\tilde{B}(\lambda)$ to satisfy (2.29a) and (2.29b), one gets $\delta_1=1$, $\delta_2=\delta_3=0$, i.e.,

$$\tilde{B}(\lambda)=1+\frac{1}{2}\sum_{j=1}^{N}\frac{\phi_{1j}^2}{\lambda-\lambda_j}. \tag{2.30b}$$

But $\tilde{B}(\lambda)$ does not fit (2.29c). In fact, we have

$$\{A_1(\lambda),\tilde{B}(\mu)\}=\frac{1}{\lambda-\mu}[\tilde{B}(\mu)-\tilde{B}(\lambda)]. \tag{2.31}$$

However, (2.29a), (2.29b), and (2.31) enable us to replace $A_1(\lambda)$ by $\overline{A}(\lambda)$,

$$\overline{A}(\lambda)\equiv A_1(\lambda)-\tilde{A}(\lambda)=-\sum_{j=1}^{N}\frac{\psi_{2j}\phi_{2j}}{\lambda-\lambda_j}, \tag{2.32}$$

and we will redefine v_k by $v_k=\overline{A}(u_k)$.

Then a straightforward calculation shows that $\overline{B}(\lambda)=B(\lambda),\overline{A}(\lambda),\tilde{B}(\lambda),\tilde{A}(\lambda)$ satisfy the following required commutator relations:

$$\{\overline{B}(\lambda),\overline{B}(\mu)\}=\{\tilde{B}(\lambda),\tilde{B}(\mu)\}=\{\overline{A}(\lambda),\overline{A}(\mu)\}=\{\tilde{A}(\lambda),\tilde{A}(\mu)\}=0, \tag{2.33a}$$

$$\{\overline{B}(\lambda),\tilde{B}(\mu)\}=\{\overline{B}(\lambda),\tilde{A}(\mu)\}=\{\tilde{B}(\lambda),\overline{A}(\mu)\}=\{\overline{A}(\lambda),\tilde{A}(\mu)\}=0, \tag{2.33b}$$

$$\{\overline{A}(\lambda),\overline{B}(\mu)\}=\frac{1}{\lambda-\mu}[\overline{B}(\mu)-\overline{B}(\lambda)],\quad \{\tilde{A}(\lambda),\tilde{B}(\mu)\}=\frac{1}{\lambda-\mu}[\tilde{B}(\mu)-\tilde{B}(\lambda)]. \tag{2.33c}$$

We have the following proposition.

Proposition 1: Assume that $\lambda_j,\phi_{ij},\psi_{ij}\in\mathbf{R}$, $i=1,2$, $j=1,...,N$. *Introduce the separated variables* $u_1,\dots,u_{2N}$ *by the set of zeros of* $\overline{B}(\lambda)$ *and* $\tilde{B}(\lambda)$:

$$\overline{B}(\lambda)=1+\frac{1}{2}\sum_{j=1}^{N}\frac{\psi_{2j}\phi_{1j}}{\lambda-\lambda_j}=\frac{R(\lambda)}{K(\lambda)}, \tag{2.34a}$$

$$\tilde{B}(\lambda)=1+\frac{1}{2}\sum_{j=1}^{N}\frac{\phi_{1j}^2}{\lambda-\lambda_j}=\frac{\overline{R}(\lambda)}{K(\lambda)}, \tag{2.34b}$$

with

$$R(\lambda)=\prod_{k=1}^{N}(\lambda-u_k),\quad \overline{R}(\lambda)=\prod_{k=1}^{N}(\lambda-u_{N+k}),$$

and $v_1,\dots,v_{2N}$ *by*

$$v_k=\overline{A}(u_k)=A_1(u_k)-\tilde{A}(u_k)=-\sum_{j=1}^{N}\frac{\psi_{2j}\phi_{2j}}{u_k-\lambda_j},\quad k=1,...,N, \tag{2.34c}$$

$$v_{N+k}=\tilde{A}(u_{N+k})=\frac{1}{2}\sum_{j=1}^{N}\frac{\psi_{1j}\phi_{1j}+\psi_{2j}\phi_{2j}}{u_{N+k}-\lambda_j},\quad k=1,...,N. \tag{2.34d}$$

If $u_1,\dots,u_N$, *are single zeros of* $\overline{B}(\lambda)$, *then* $v_1,\dots,v_{2N}$ *and* $u_1,\dots,u_{2N}$ *are canonically conjugated, i.e., they satisfy* (1.1).

Proof: Notice that

$$\lim_{\lambda\to\lambda_j-0}\tilde{B}(\lambda)=-\infty,\qquad \lim_{\lambda\to\lambda_j+0}\tilde{B}(\lambda)=\infty,$$

it is easy to see that

$$u_{N+1}<\lambda_1<u_{N+2}<\lambda_2<\cdots<u_{2N}<\lambda_N. \tag{2.35}$$

We have $\overline{B}'(u_k)\neq 0$, $\widetilde{B}'(u_{N+k})\neq 0$. Hereafter the prime denotes the differentiation with respect to λ. In what follows, we take k, $l=1,...,N$. It follows from (2.33b) that

$$0=\{u_k,\widetilde{B}(u_{N+l})\}=\widetilde{B}'(u_{N+l})\{u_k,u_{N+l}\}+\{u_k,\widetilde{B}(\mu)\}|_{\mu=u_{N+l}},$$

$$0=\{\overline{B}(u_k),u_{N+l}\}=\overline{B'}(u_k)\{u_k,u_{N+l}\}+\{\overline{B}(\lambda),u_{N+l}\}|_{\lambda=u_k},$$

$$\begin{aligned}0&=\{\overline{B}(u_k),\widetilde{B}(u_{N+l})\}\\&=\overline{B}'(u_k)\widetilde{B}'(u_{N+l})\{u_k,u_{N+l}\}+\overline{B}'(u_k)\{u_k,\widetilde{B}(\mu)\}|_{\mu=u_{N+l}}\\&\quad+\widetilde{B}'(u_{N+l})\{\overline{B}(\lambda),u_{N+l}\}|_{\lambda=u_k}+\{\overline{B}(\lambda),\widetilde{B}(\mu)\}|_{\lambda=u_k,\mu=u_{N+l}}\\&=\overline{B'}(u_k)\widetilde{B}'(u_{N+l})\{u_k,u_{N+l}\}+\overline{B'}(u_k)\{u_k,\widetilde{B}(\mu)\}|_{\mu=u_{N+1}}+\widetilde{B}'(u_{N+l})\{\overline{B}(\lambda),u_{N+l}\}|_{\lambda=u_k},\end{aligned}$$

which together lead to $\{u_k,u_{N+l}\}=0$. Similarly, $\{u_k,u_l\}=0$, $\{u_{N+k},u_{N+l}\}=0$.

Using (2.33b), (2.33c), and the above-mentioned results, one gets

$$\begin{aligned}\{v_k,\overline{B}(\mu)\}|_{\mu=u_l}&=\{\overline{A}(u_k),\overline{B}(\mu)\}|_{\mu=u_l}\\&=\overline{A'}(u_k)\{u_k,\overline{B}(\mu)\}|_{\mu=u_l}+[\{\overline{A}(\lambda),\overline{B}(\mu)\}|_{\lambda=u_k}]|_{\mu=u_l},\\&=\overline{A'}(u_k)[\{u_k,\overline{B}(u_l)\}-\overline{B'}(u_l)\{u_k,u_l\}]+[\{\overline{A}(\lambda),\overline{B}(\mu)\}|_{\lambda=u_k}]|_{\mu=u_l}\\&=[\{\overline{A}(\lambda),\overline{B}(\mu)\}|_{\lambda=u_k}]|_{\mu=u_l}\\&=\frac{\overline{B}(\mu)-\overline{B}(u_k)}{u_k-\mu}|_{\mu=u_l}\\&=-\delta_{kl}\overline{B'}(u_k),\end{aligned}$$

and

$$0=\{v_k,\overline{B}(u_l)\}=\overline{B}(u_l)\{v_k,u_l\}+\{v_k,\overline{B}(\mu)\}|_{\mu=u_l},$$

then

$$\begin{aligned}\{v_k,u_l\}&=-\frac{1}{\overline{B'}(u_l)}\{v_k,\overline{B}(\mu)\}|_{\mu=u_l}\\&=\delta_{kl}\frac{\overline{B'}(u_k)}{\overline{B'}(u_l)}=\delta_{kl}.\end{aligned}$$

In the same way, one gets $\{v_{N+k},u_{N+l}\}=\delta_{kl}$. The following equalities;

$$\{v_k,u_{N+l}\}=\{\overline{A}(u_k),u_{N+l}\}=\{\overline{A}(\lambda),u_{N+l}\}|_{\lambda=u_k},$$

$$0=\{\overline{A}(\lambda),\widetilde{B}(u_{N+l})\}=\widetilde{B}'(u_{N+l})\{\overline{A}(\lambda),u_{N+l}\},$$

yield $\{v_k,u_{N+l}\}=0$ and similarly $\{v_{N+k},u_l\}=0$.

Finally,

$$
\begin{aligned}
\{v_k, v_{N+l}\} &= \{\overline{A}(u_k), \widetilde{A}(u_{N+l})\} \\
&= \overline{A}'(u_k)\{u_k, \widetilde{A}(\mu)\}|_{\mu=u_{N+l}} + \overline{A}'(u_{N+l})\{\overline{A}(\lambda), u_{N+l}\}|_{\lambda=u_k} \\
&= \overline{A}'(u_k)[\{u_k, v_{N+l}\} - \widetilde{A}'(u_{N+l})\{u_k, u_{N+l}\}] \\
&\quad + \widetilde{A}'(u_{N+l})[\{v_k, u_{N+l}\} - \overline{A}'(u_k)\{u_k, u_{N+l}\}] = 0,
\end{aligned}
$$

similarly

$$\{v_k, v_l\} = \overline{A}'(u_k)\{u_k, v_l\} + \widetilde{A}'(u_l)\{v_k, u_l\} = -\overline{A}'(u_k)\delta_{kl} + \overline{A}'(u_l)\delta_{kl} = 0,$$

and $\{v_{N+k}, v_{N+l}\} = 0$. This completes the proof.

It follows from (2.34a) and (2.34b) that

$$\psi_{2j}\phi_{1j} = 2\frac{R(\lambda_j)}{K'(\lambda_j)}, \quad \phi_{1j}^2 = 2\frac{\overline{R}(\lambda_j)}{K'(\lambda_j)}, \quad j = 1,\ldots,N,$$

or

$$\phi_{1j} = \sqrt{\frac{2\overline{R}(\lambda_j)}{K'(\lambda_j)}}, \quad \psi_{2j} = \frac{\sqrt{2}R(\lambda_j)}{\sqrt{\overline{R}(\lambda_j)K'(\lambda_j)}}, \quad j = 1,\ldots,N. \tag{2.36}$$

Also (2.34a) results

$$u = -\langle \Psi_2, \Phi_1 \rangle = 2\sum_{j=1}^{N} (u_j - \lambda_j). \tag{2.37}$$

We now present the separated equations. By substituting u_k into (2.20), u_{N+k} into (2.30a), and using (2.34), one gets the separated equations

$$
\begin{aligned}
v_k = A_1(u_k) - \widetilde{A}(u_k) &= 2\sqrt{P(u_k)} - \widetilde{A}(u_k) \\
&= 2\sqrt{-u_k + \sum_{j=1}^{N}\left[\frac{P_j}{u_k - \lambda_j} + \frac{P_{N+j}^2}{(u_k - \lambda_j)^2}\right]} - 2\sum_{j=1}^{N}\frac{P_{N+j}}{u_k - \lambda_j}, \\
&\quad k = 1,\ldots,N,
\end{aligned} \tag{2.38a}
$$

$$v_{N+k} = \widetilde{A}(u_{N+k}) = 2\sum_{j=1}^{N}\frac{P_{N+j}}{u_{N+k} - \lambda_j}, \quad k = 1,\ldots,N. \tag{2.38b}$$

Replacing v_k by the partial derivative $\partial S/\partial u_k$ of the generating function S of the canonical transformation and interpreting the P_i as integration constants, Eqs. (2.38a) and (2.38b) give rise to the Hamilton–Jacobi equations which are completely separable and may be integrated to give the completely separated solution

$$
\begin{aligned}
S(u_1,\ldots,u_{2N}) &= \sum_{k=1}^{N}\left[\int^{u_k}(2\sqrt{P(\lambda)} - \widetilde{A}(\lambda))d\lambda + \int^{u_{N+k}}\widetilde{A}(\lambda)d\lambda\right] \\
&= 2\sum_{k=1}^{N}\left[\int^{u_k}\sqrt{P(\lambda)}d\lambda - \sum_{i=1}^{N} P_{N+i}\ln\left|\frac{u_k - \lambda_i}{u_{N+k} - \lambda_i}\right|\right].
\end{aligned} \tag{2.39}
$$

The linearizing coordinates are then

$$Q_i=\frac{\partial S}{\partial P_i}=\sum_{k=1}^{N}\int^{u_k}\frac{1}{(\lambda-\lambda_i)\sqrt{P(\lambda)}}d\lambda,\quad i=1,...,N, \tag{2.40a}$$

$$Q_{N+i}=\frac{\partial S}{\partial P_{N+i}}=2\sum_{k=1}^{N}\left[\int^{u_k}\frac{P_{N+i}}{(\lambda-\lambda_i)^2\sqrt{P(\lambda)}}d\lambda-\ln\left|\frac{u_k-\lambda_i}{u_{N+k}-\lambda_i}\right|\right],\quad i=1,...,N. \tag{2.40b}$$

By using (2.22), the linear flow induced by (2.15) is then given by

$$Q_i=\gamma_i+x\frac{\partial F_1}{\partial P_i}=\gamma_i+2x,\quad Q_{N+i}=2\gamma_{N+i}+x\frac{\partial F_1}{\partial P_{N+i}}=2\gamma_{N+i},\quad i=1,...,N. \tag{2.41}$$

Hereafter γ_i, $i=1,...,2N$, are arbitrary constants. Combining Eqs. (2.40a) and (2.40b) with Eq. (2.41) leads to the Jacobi inversion problem for the FDIHS (2.15),

$$\sum_{k=1}^{N}\int^{u_k}\frac{1}{(\lambda-\lambda_i)\sqrt{P(\lambda)}}d\lambda=\gamma_i+2x,\quad i=1,...,N, \tag{2.42a}$$

$$\sum_{k=1}^{N}\left[\int^{u_k}\frac{P_{N+i}}{(\lambda-\lambda_i)^2\sqrt{P(\lambda)}}d\lambda-\ln\left|\frac{u_k-\lambda_i}{u_{N+k}-\lambda_i}\right|\right]=\gamma_{N+i},\quad i=1,...,N. \tag{2.42b}$$

The ϕ_{1j}, ψ_{2j} and $\langle\Psi_2,\Phi_1\rangle$ defined by (2.36) and (2.37) are the symmetric functions of u_k, $k=1,...,2N$. If, by using the Jacobi inversion technique,[19] ϕ_{1j}, ψ_{2j}, and $\langle\Psi_2,\Phi_1\rangle$ can be obtained from (2.42), then ϕ_{2j},ψ_{1j} can be found from the first and the last equation in (2.15) by an algebraic calculation, respectively. The $(\phi_{1j},\phi_{2j},\psi_{1j},\psi_{2j})$ provides the solution to the FDIHS (2.15).

By using (2.22), the linear flow induced by (2.17) is then given by

$$Q_i=\overline{\gamma_i}+\frac{\partial F_2}{\partial P_i}t_1=\overline{\gamma_i}+2\lambda_i t_1,$$
$$Q_{N+i}=2\overline{\gamma}_{N+i}+\frac{\partial F_2}{\partial P_{N+i}}t_1=2\overline{\gamma}_{N+i}+4P_{N+i}t_1,\quad i=1,...,N, \tag{2.43}$$

where $\overline{\gamma_i}$ are arbitrary constants. Combining Eqs. (2.40a) and (2.40b) with Eq. (2.43) leads to the Jacobi inversion problem for the FDIHS (2.17),

$$\sum_{k=1}^{N}\int^{u_k}\frac{1}{(\lambda-\lambda_i)\sqrt{P(\lambda)}}d\lambda=\overline{\gamma_i}+2\lambda_i t_1,\quad i=1,...,N, \tag{2.44a}$$

$$\sum_{k=1}^{N}\left[\int^{u_k}\frac{P_{N+i}}{(\lambda-\lambda_i)^2\sqrt{P(\lambda)}}d\lambda-\ln\left|\frac{u_k-\lambda_i}{u_{N+k}-\lambda_i}\right|\right]=\overline{\gamma}_{N+i}+2P_{N+i}t_1,\quad i=1,...,N. \tag{2.44b}$$

Finally, since the KdV equation (2.10) is factorized by the FDIHSs (2.15) and (2.17), combining Eqs. (2.42a) and (2.42b) with Eqs. (2.44a) and (2.44b) and using (2.37) give rise to the Jacobi inversion problem for the KdV equation (2.10),

$$\sum_{k=1}^{N}\int^{u_k}\frac{1}{(\lambda-\lambda_i)\sqrt{P(\lambda)}}d\lambda=\gamma_i+2x+2\lambda_i t_1,\quad i=1,...,N, \tag{2.45a}$$

$$\sum_{k=1}^{N}\left[\int^{u_k}\frac{P_{N+i}}{(\lambda-\lambda_i)^2\sqrt{P(\lambda)}}d\lambda-\ln\left|\frac{u_k-\lambda_i}{u_{N+k}-\lambda_i}\right|\right]=\gamma_{N+i}+2P_{N+i}t_1,\quad i=1,...,N. \tag{2.45b}$$

Notice that u defined by (2.37) is the symmetric function of u_k, $k=1,...,N$. If, by using the Jacobi inversion technique,[19] u can be found in terms of Riemann theta functions by solving (2.45), then u provides the solution of the KdV equation (2.10).

In general, since the nth KdV equation (2.7) is factorized by the x-FDIHS (2.15) and the t_n-FDIHS (2.25), the above-mentioned procedure can be applied to find the Jacobi inversion problem for the nth KdV equation (2.7). We have the following proposition.

Proposition 2: The Jacobi inversion problem for the nth KdV equation (2.7) is given by

$$\sum_{k=1}^{N}\int^{u_k}\frac{1}{(\lambda-\lambda_i)\sqrt{P(\lambda)}}d\lambda=\gamma_i+2x+t_n\sum_{m=0}^{n}\left(\frac{1}{2}\right)^{m-1}\alpha_m\sum_{l_1+\cdots+l_{m+1}=n+2}\lambda_i^{l_{m+1}-2}\tilde{F}_{l_1}\cdots\tilde{F}_{l_m},$$
$$i=1,...,N, \tag{2.46a}$$

$$\sum_{k=1}^{N}\left[\int^{u_k}\frac{P_{N+i}}{(\lambda-\lambda_i)^2\sqrt{P(\lambda)}}d\lambda-\ln\left|\frac{u_k-\lambda_i}{u_{N+k}-\lambda_i}\right|\right]$$
$$=\gamma_{N+i}+t_n\sum_{m=0}^{n}\left(\frac{1}{2}\right)^{m-2}\alpha_m\sum_{l_1+\cdots+l_{m+1}=n+2}(l_{m+1}-2)\lambda_i^{l_{m+1}-3}P_{N+i}\tilde{F}_{l_1}\cdots\tilde{F}_{l_m},$$
$$i=1,...,N, \tag{2.46b}$$

where $l_1\geqslant 1,..., l_{m+1}\geqslant 1$ *and* $\tilde{F}_{l_1},\ldots,\tilde{F}_{l_m}$, *are given by* (2.24b).

For example, by using (2.27), the Jacobi inversion problem for the second KdV equation (2.26) is given by

$$\sum_{k=1}^{N}\int^{u_k}\frac{1}{(\lambda-\lambda_i)\sqrt{P(\lambda)}}d\lambda=\gamma_i+2x+\left(2\lambda_i^2+\sum_{j=1}^{N}P_j\right)t_2,\quad i=1,...,N, \tag{2.47a}$$

$$\sum_{k=1}^{N}\left[\int^{u_k}\frac{P_{N+i}}{(\lambda-\lambda_i)^2\sqrt{P(\lambda)}}d\lambda-\ln\frac{u_k-\lambda_i}{u_{N+k}-\lambda_i}\right]=\gamma_{N+i}+4\lambda_iP_{N+i}t_2,\quad i=1,...,N. \tag{2.47b}$$

The u solved from the Jacobi inversion problem (2.47) provides the solution for the second KdV equation (2.26).

The Jacobi inversion problem for the KdV hierarchy in our case is somewhat different from that derived by means of the stationary equations of the KdV hierarchy,[36] since there is an additional term $-\ln|u_k-\lambda_i|+\ln|u_{N+k}-\lambda_i|$ in (2.46b).

III. THE SEPARATION OF VARIABLES FOR THE AKNS EQUATIONS

A. Binary constrained flows of the AKNS hierarchy

For the AKNS spectral problem[37]

$$\phi_x=U(u,\lambda)\phi,\quad U(u,\lambda)=\begin{pmatrix}-\lambda & q\\ r & \lambda\end{pmatrix},\quad \phi=\begin{pmatrix}\phi_1\\ \phi_2\end{pmatrix},\quad u=\begin{pmatrix}q\\ r\end{pmatrix}, \tag{3.1}$$

its adjoint representation (2.2) and (2.3) yield

$$a_0=-1,\quad b_0=c_0=0,\quad a_1=0,\quad b_1=q,\quad c_1=r,\quad a_2=\tfrac{1}{2}qr,\ldots,$$

and in general

$$\begin{pmatrix} c_{k+1} \\ b_{k+1} \end{pmatrix} = L \begin{pmatrix} c_k \\ b_k \end{pmatrix}, \quad a_k = \partial^{-1}(qc_k - rb_k), \quad k=1,2,..., \tag{3.2}$$

$$L = \frac{1}{2} \begin{pmatrix} \partial - 2r\partial^{-1}q & 2r\partial^{-1}r \\ -2q\partial^{-1}q & -\partial + 2q\partial^{-1}r \end{pmatrix}.$$

Take

$$\phi_{t_n} = V^{(n)}(u,\lambda)\phi, \quad V^{(n)}(u,\lambda) = \sum_{i=0}^{n} \begin{pmatrix} a_i & b_i \\ c_i & -a_i \end{pmatrix} \lambda^{n-i}. \tag{3.3}$$

Then the compatibility condition of Eqs. (3.1) and (3.3) gives rise to the AKNS hierarchy

$$u_{t_n} = \begin{pmatrix} q \\ r \end{pmatrix}_{t_n} = JL^n \begin{pmatrix} r \\ q \end{pmatrix} = J \frac{\delta H_{n+1}}{\delta u}, \quad n=1,2,..., \tag{3.4}$$

where the Hamiltonian H_n and the Hamiltonian operator J are given by

$$J = \begin{pmatrix} 0 & -2 \\ 2 & 0 \end{pmatrix}, \quad H_n = \frac{2a_{n+1}}{n+1}, \quad \begin{pmatrix} c_n \\ b_n \end{pmatrix} = \frac{\delta H_n}{\delta u}, \quad n=1,2,... .$$

For $n=2$ we have

$$\phi_{t_2} = V^{(2)}(u,\lambda)\phi, \quad V^{(2)} = \begin{pmatrix} -\lambda^2 + \frac{1}{2}qr & q\lambda - \frac{1}{2}q_x \\ r\lambda + \frac{1}{2}r_x & \lambda^2 - \frac{1}{2}qr \end{pmatrix}, \tag{3.5}$$

and the AKNS equation (3.4) for $n=2$ reads

$$q_{t_2} = -\tfrac{1}{2}q_{xx} + q^2 r, \quad r_{t_2} = \tfrac{1}{2}r_{xx} - r^2 q. \tag{3.6}$$

The adjoint AKNS spectral problem is Eq. (2.11) with U given by (3.1). We have[25]

$$\frac{\delta\lambda}{\delta u} = \begin{pmatrix} \dfrac{\delta\lambda}{\delta q} \\[2mm] \dfrac{\delta\lambda}{\delta r} \end{pmatrix} = \beta \,\mathrm{Tr}\left[\begin{pmatrix} \phi_1\psi_1 & \phi_1\psi_2 \\ \phi_2\psi_1 & \phi_2\psi_2 \end{pmatrix} \frac{\partial U(u,\lambda)}{\partial u} \right] = \beta \begin{pmatrix} \psi_1\phi_2 \\ \psi_2\phi_1 \end{pmatrix}. \tag{3.7}$$

The binary x-constrained flows of the AKNS hierarchy (3.4) are defined by[25,29]

$$\Phi_{1,x} = -\Lambda\Phi_1 + q\Phi_2, \quad \Phi_{2,x} = r\Phi_1 + \Lambda\Phi_2, \tag{3.8a}$$

$$\Psi_{1,x} = \Lambda\Psi_1 - r\Psi_2, \quad \Psi_{2,x} = -q\Psi_1 - \Lambda\Psi_2, \tag{3.8b}$$

$$\frac{\delta H_{k_0}}{\delta u} - \beta^{-1}\sum_{j=1}^{N} \frac{\delta\lambda_j}{\delta u} = \begin{pmatrix} c_{k_0} \\ b_{k_0} \end{pmatrix} - \begin{pmatrix} \langle\Psi_1,\Phi_2\rangle \\ \langle\Psi_2,\Phi_1\rangle \end{pmatrix} = 0. \tag{3.8c}$$

For $k_0 = 1$, we have

$$\begin{pmatrix} c_1 \\ b_1 \end{pmatrix} = \begin{pmatrix} r \\ q \end{pmatrix} = \begin{pmatrix} \langle\Psi_1,\Phi_2\rangle \\ \langle\Psi_2,\Phi_1\rangle \end{pmatrix} = 0. \tag{3.9}$$

By substituting (3.9) into (3.8a) and (3.8b), the first binary x-constrained flow becomes a x-FDHS,[25]

$$\Phi_{1x}=\frac{\partial F_1}{\partial \Psi_1},\quad \Phi_{2x}=\frac{\partial F_1}{\partial \Psi_2},\quad \Psi_{1x}=-\frac{\partial F_1}{\partial \Phi_1},\quad \Psi_{2x}=-\frac{\partial F_1}{\partial \Phi_2},\tag{3.10}$$

with the Hamiltonian

$$F_1=\langle \Lambda\Psi_2,\Phi_2\rangle-\langle \Lambda\Psi_1,\Phi_1\rangle+\langle \Psi_2,\Phi_1\rangle\langle \Psi_1,\Phi_2\rangle.$$

Under the constraint (3.9) and the FDHS (3.10), the binary t_2-constrained flow obtained from (3.3) with $V^{(2)}$ given by (3.5) and its adjoint equation for N distinct real number λ_j can also be written as a t_2-FDHS,

$$\Phi_{1,t_2}=\frac{\partial F_2}{\partial \Psi_1},\quad \Phi_{2,t_2}=\frac{\partial F_2}{\partial \Psi_2},\quad \Psi_{1,t_2}=-\frac{\partial F_2}{\partial \Phi_1},\quad \Psi_{2,t_2}=-\frac{\partial F_2}{\partial \Phi_2},\tag{3.11}$$

with the Hamiltonian

$$\begin{aligned}F_2=&\langle \Lambda^2\Psi_2,\Phi_2\rangle-\langle \Lambda^2\Psi_1,\Phi_1\rangle+\langle \Psi_2,\Phi_1\rangle\langle \Lambda\Psi_1,\Phi_2\rangle+\langle \Lambda\Psi_2,\Phi_1\rangle\langle \Psi_1,\Phi_2\rangle\\&-\tfrac{1}{2}(\langle \Psi_2,\Phi_2\rangle-\langle \Psi_1,\Phi_1\rangle)\langle \Psi_2,\Phi_1\rangle\langle \Psi_1,\Phi_2\rangle.\end{aligned}$$

The Lax representation for the FDHSs (3.10) and (3.11) which can also be deduced from the adjoint representation (2.2) and (2.8) are presented by (2.18) with the entries of the Lax matrix M given by[29]

$$A(\lambda)=-1+\frac{1}{2}\sum_{j=1}^{N}\frac{\psi_{1j}\phi_{1j}-\psi_{2j}\phi_{2j}}{\lambda-\lambda_j},\tag{3.12a}$$

$$B(\lambda)=\sum_{j=1}^{N}\frac{\psi_{2j}\phi_{1j}}{\lambda-\lambda_j},\quad C(\lambda)=\sum_{j=1}^{N}\frac{\psi_{1j}\phi_{2j}}{\lambda-\lambda_j}.\tag{3.12b}$$

A straightforward calculation yields

$$A^2(\lambda)+B(\lambda)C(\lambda)\equiv P(\lambda)=1+\sum_{j=1}^{N}\left[\frac{P_j}{\lambda-\lambda_j}+\frac{P_{N+j}^2}{(\lambda-\lambda_j)^2}\right],\tag{3.13}$$

where P_j, $j=1,\ldots,2N$, are $2N$ independent integrals of motion for the FDHSs (3.10) and (3.11),

$$P_j=\psi_{2j}\phi_{2j}-\psi_{1j}\phi_{1j}+\frac{1}{2}\sum_{k\neq j}\frac{1}{\lambda_j-\lambda_k}[(\psi_{1j}\phi_{1j}-\psi_{2j}\phi_{2j})(\psi_{1k}\phi_{1k}-\psi_{2k}\phi_{2k})+4\psi_{1j}\phi_{2j}\psi_{2k}\phi_{1k}],$$
$$j=1,\ldots,N,\tag{3.14a}$$

$$P_{N+j}=\tfrac{1}{2}(\psi_{1j}\phi_{1j}+\psi_{2j}\phi_{2j}),\quad j=1,\ldots,N.\tag{3.14b}$$

It is easy to verify that

$$F_1=\sum_{j=1}^{N}(\lambda_jP_j+P_{N+j}^2)-\frac{1}{4}\left(\sum_{j=1}^{N}P_j\right)^2,\tag{3.15a}$$

$$F_2=\sum_{j=1}^{N}(\lambda_j^2P_j+2\lambda_jP_{N+j}^2)-\frac{1}{2}\left(\sum_{j=1}^{N}P_j\right)\sum_{j=1}^{N}(\lambda_jP_j+P_{N+j}^2)+\frac{1}{8}\left(\sum_{j=1}^{N}P_j\right)^3.\tag{3.15b}$$

With respect to the standard Poisson bracket it is found that

$$\{A(\lambda),A(\mu)\}=\{B(\lambda),B(\mu)\}=\{C(\lambda),C(\mu)\}=0, \tag{3.16a}$$

$$\{A(\lambda),B(\mu)\}=\frac{1}{\lambda-\mu}[B(\mu)-B(\lambda)], \tag{3.16b}$$

$$\{A(\lambda),C(\mu)\}=\frac{1}{\lambda-\mu}[C(\lambda)-C(\mu)], \tag{3.16c}$$

$$\{B(\lambda),C(\mu)\}=\frac{2}{\lambda-\mu}[A(\mu)-A(\lambda)]. \tag{3.16d}$$

Then $\{A^2(\lambda)+B(\lambda)C(\lambda),A^2(\mu)+B(\mu)C(\mu)\}=0$ implies that P_j, $j=1,...,2N$, are in involution. The AKNS equation (3.6) is factorized by the x-FDIHS (3.10) and the t_2-FDIHS (3.11), namely, if $(\Psi_1,\Psi_2,\Phi_1,\Phi_2)$ satisfies the FDIHSs (3.10) and (3.11) simultaneously, then (q, r) given by (3.9) solves the AKNS equation (3.6). In general, the factorization of the nth AKNS equations (3.4) will be presented at the end of Sec. III B.

B. The separation of variables for the AKNS equations

In contrast with the $B(\lambda)$ in the Lax matrix M for the constrained KdV flows, the $B(\lambda)$ given by (3.12b) has only $N-1$ zeros, one has to define the canonical variables u_k, v_k, $k=1,...,2N$, in a little different way. The commutator relations (3.16) and the generating function of integrals of motion (3.13) enable us to introduce $u_1,\ldots,u_N$ by means of $B(\lambda)$ in the following way:

$$B(\lambda)=\sum_{j=1}^{N}\frac{\psi_{2j}\phi_{1j}}{\lambda-\lambda_j}=e^{u_N}\frac{R(\lambda)}{K(\lambda)}, \tag{3.17a}$$

where

$$R(\lambda)=\prod_{k=1}^{N-1}(\lambda-u_k),\quad K(\lambda)=\prod_{k=1}^{N}(\lambda-\lambda_k),$$

and $v_1,\ldots,v_N$ by

$$v_k=A(u_k),\quad k=1,...,N-1,\quad v_N=\tfrac{1}{2}(\langle\Psi_1,\Phi_1\rangle-\langle\Psi_2,\Phi_2\rangle). \tag{3.17b}$$

Equation (3.17a) yields

$$u_N=\ln\langle\Psi_2,\Phi_1\rangle. \tag{3.17c}$$

Then it is easy to verify that

$$\{u_N,B(\mu)\}=\{v_N,A(\mu)\}=0,\quad \{v_N,u_N\}=1, \tag{3.18a}$$

$$\{u_N,A(\mu)\}=-\frac{B(\mu)}{\langle\Psi_2,\Phi_1\rangle},\quad \{v_N,B(\mu)\}=B(\mu). \tag{3.18b}$$

As we will show later, the commutator relations (3.16) and (3.18) guarantee that $u_1,\ldots,u_N$, $v_1,\ldots,v_N$ satisfy the canonical conditions (1.1).

We now need to construct two functions $\tilde{B}(\lambda)$, $\tilde{A}(\lambda)$ to define $u_{N+1},\ldots,u_{2N}$ by means of $\tilde{B}(\lambda)$ and $v_{N+1},\ldots,v_{2N}$ by $v_{N+k}=\tilde{A}(u_{N+k})$. By the exactly same argument as in Sec. II B, we construct $\tilde{A}(\lambda)$ by

$$\tilde{A}(\lambda)=\frac{1}{2}\sum_{j=1}^{N}\frac{\psi_{1j}\phi_{1j}+\psi_{2j}\phi_{2j}}{\lambda-\lambda_j}=\sum_{j=1}^{N}\frac{P_{N+j}}{\lambda-\lambda_j}, \tag{3.19a}$$

since Eq. (3.19a) enables us to obtain immediately the separated equation (1.2) for v_{N+k} and u_{N+k}, and $\tilde{B}(\lambda)$ by

$$\tilde{B}(\lambda)=\sum_{j=1}^{N}\frac{\phi_{1j}^2}{\lambda-\lambda_j}. \tag{3.19b}$$

Then it is easy to verify that $A(\lambda),B(\lambda),\tilde{A}(\lambda),\tilde{B}(\mu)$ satisfy the commutator relations

$$\{\tilde{B}(\lambda),\tilde{B}(\mu)\}=\{\tilde{B}(\lambda),B(\mu)\}=\{\tilde{A}(\lambda),\tilde{A}(\mu)\}=\{\tilde{A}(\lambda),B(\mu)\}=\{\tilde{A}(\lambda),A(\mu)\}=0, \tag{3.20a}$$

$$\{\tilde{A}(\lambda),\tilde{B}(\mu)\}=\frac{1}{\lambda-\mu}[\tilde{B}(\mu)-\tilde{B}(\lambda)], \tag{3.20b}$$

$$\{A(\lambda),\tilde{B}(\mu)\}=\frac{1}{\lambda-\mu}[\tilde{B}(\mu)-\tilde{B}(\lambda)]. \tag{3.20c}$$

Relation (3.20c) does not fit the requirement for the canonical conditions (1.1). According to (3.20) and (3.16) we can replace $A(\lambda)$ by $\overline{A}(\lambda)$,

$$\overline{A}(\lambda)\equiv A(\lambda)-\tilde{A}(\lambda)=-1-\sum_{j=1}^{N}\frac{\psi_{2j}\phi_{2j}}{\lambda-\lambda_j}, \tag{3.21}$$

namely, we redefine $v_1,\ldots,v_N$ by

$$v_k=\overline{A}(u_k)=A(u_k)-\tilde{A}(u_k)=-1-\sum_{j=1}^{N}\frac{\psi_{2j}\phi_{2j}}{u_k-\lambda_j},\quad k=1,\ldots,N-1, \tag{3.22a}$$

$$v_N=-\langle\Psi_2,\Phi_2\rangle. \tag{3.22b}$$

We now define $u_{N+1},\ldots,u_{2N}$ by $\tilde{B}(\lambda)$ as follows:

$$\tilde{B}(\lambda)=\sum_{j=1}^{N}\frac{\phi_{1j}^2}{\lambda-\lambda_j}=e^{u_{2N}}\frac{\overline{R}(\lambda)}{K(\lambda)},\quad \overline{R}(\lambda)=\prod_{k=1}^{N-1}(\lambda-u_{N+k}), \tag{3.23a}$$

and $v_{N+1},\ldots,v_{2N}$ by

$$v_{N+k}=\tilde{A}(u_{N+k})=\frac{1}{2}\sum_{j=1}^{N}\frac{\psi_{1j}\phi_{1j}+\psi_{2j}\phi_{2j}}{u_{N+k}-\lambda_j},\quad k=1,\ldots,N-1, \tag{3.23b}$$

$$v_{2N}=\tfrac{1}{2}(\langle\Psi_1,\Phi_1\rangle+\langle\Psi_2,\Phi_2\rangle). \tag{3.23c}$$

Equation (3.23a) leads to

$$u_{2N}=\ln\langle\Phi_1,\Phi_1\rangle. \tag{3.23d}$$

Then a straightforward calculation shows that $\overline{B}(\lambda)=B(\lambda)$, $\overline{A}(\lambda),\tilde{B}(\lambda),\tilde{A}(\lambda)$ satisfy the commutator relations (2.33) and

$$\{u_N,\overline{B}(\mu)\}=\{u_N,\tilde{B}(\mu)\}=\{u_N,\tilde{A}(\mu)\}=0,\quad \{u_N,\overline{A}(\mu)\}=-\frac{\overline{B}(\mu)}{\langle\Psi_2,\Phi_1\rangle},\tag{3.24a}$$

$$\{v_N,\overline{A}(\mu)\}=\{v_N,\tilde{B}(\mu)\}=\{v_N,\tilde{A}(\mu)\}=0,\quad \{v_N,\overline{B}(\mu)\}=\overline{B}(\mu),\tag{3.24b}$$

$$\{u_{2N},\overline{B}(\mu)\}=\{u_{2N},\overline{A}(\mu)\}=\{u_{2N},\tilde{B}(\mu)\}=0,\quad \{u_{2N},\tilde{A}(\mu)\}=-\frac{\tilde{B}(\mu)}{\langle\Psi_1,\Phi_1\rangle},\tag{3.24c}$$

$$\{v_{2N},\overline{B}(\mu)\}=\{v_{2N},\overline{A}(\mu)\}=\{v_{2N},\tilde{A}(\mu)\}=0,\quad \{v_{2N},\tilde{B}(\mu)\}=\tilde{B}(\mu),\tag{3.24d}$$

$$\{v_N,u_N\}=1,\quad \{v_{2N},u_{2N}\}=1,\tag{3.24e}$$

$$\{u_{2N},u_N\}=\{u_{2N},v_N\}=\{v_{2N},u_N\}=\{v_{2N},v_N\}=0.\tag{3.24f}$$

We have the following proposition.

Proposition 3: Assume that $\lambda_j,\ \phi_{ij},\ \psi_{ij}\in\mathbf{R},\ i=1,2,\ j=1,...,N$. *Introduce the separated variables* $u_1,\ldots,u_{2N}$ *by the* $\overline{B}(\lambda)$ *and* $\tilde{B}(\lambda)$:

$$\overline{B}(\lambda)=B(\lambda)=\sum_{j=1}^{N}\frac{\psi_{2j}\phi_{1j}}{\lambda-\lambda_j}=e^{u_N}\frac{R(\lambda)}{K(\lambda)},\tag{3.25a}$$

$$\tilde{B}(\lambda)=\sum_{j=1}^{N}\frac{\phi_{1j}^2}{\lambda-\lambda_j}=e^{u_{2N}}\frac{\overline{R}(\lambda)}{K(\lambda)},\tag{3.25b}$$

with

$$R(\lambda)=\prod_{k=1}^{N-1}(\lambda-u_k),\quad \overline{R}(\lambda)=\prod_{k=1}^{N-1}(\lambda-u_{N+k}),$$

and $v_1,\ldots,v_{2N}$ *by*

$$v_k=\overline{A}(u_k)=A(u_k)=-\tilde{A}(u_k)=-1-\sum_{j=1}^{N}\frac{\psi_{2j}\phi_{2j}}{u_k-\lambda_j},\quad k=1,...,N-1,\tag{3.25c}$$

$$v_N=-\langle\Psi_2,\Phi_2\rangle,\tag{3.25d}$$

$$v_{N+k}=\tilde{A}(u_{N+k})=\frac{1}{2}\sum_{j=1}^{N}\frac{\psi_{1j}\phi_{1j}+\psi_{2j}\phi_{2j}}{u_{N+k}-\lambda_j},\quad k=1,...,N-1,\tag{3.25e}$$

$$v_{2N}=\tfrac{1}{2}(\langle\Psi_1,\Phi_1\rangle+\langle\Psi_2,\Phi_2\rangle).\tag{3.25f}$$

If $u_1,\ldots,u_N$, *are single zeros of* $\overline{B}(\lambda)$, *then* $v_1,\ldots,v_{2N}$ *and* $u_1,\ldots,u_{2N}$ *are canonically conjugated, i.e., they satisfy* (1.1).

Proof: By using the exactly same method as in the proof of proposition 1, the commutator relations (2.33) guarantee that $u_1,\ldots,u_{N-1},\ v_1,\ldots,v_{N-1}$ satisfy the canonical conditions (1.1). By using the similar method, for example, it is found from (3.24) that for $k=1,...,N-1$, we have

$$0=\{u_N,\overline{B}(u_k)\}=\overline{B}'(u_k)\{u_N,u_k\}+\{u_N,\overline{B}(\mu)\}|_{\mu=u_k}=\overline{B}'(u_k)\{u_N,u_k\},$$

$$\{u_N,v_k\}=\{u_N,\overline{A}(u_k)\}=\overline{A}'(u_k)\{u_N,u_k\}-\frac{\overline{B}(\mu)}{\langle\Psi_2,\Phi_1\rangle}\bigg|_{\mu=u_k}=0,$$

which gives rise to $\{u_N,u_k\}=\{u_N,v_k\}=0$ and so on. In this way we complete the proof.

It follows from (3.25a) and (3.25b) that

$$\psi_{2j}\phi_{1j}=e^{u_N}\frac{R(\lambda_j)}{K'(\lambda_j)},\quad \phi_{1j}^2=e^{u_{2N}}\frac{\overline{R}(\lambda_j)}{K'(\lambda_j)},\quad j=1,...,N,$$

or

$$\phi_{1j}=\sqrt{\frac{e^{u_{2N}}\overline{R}(\lambda_j)}{K'(\lambda_j)}},\quad \psi_{2j}=\frac{e^{u_N}R(\lambda_j)}{\sqrt{e^{u_{2N}}\overline{R}(\lambda_j)K'(\lambda_j)}},\quad j=1,..,N. \tag{3.26}$$

Equations (3.9) and (3.17c) result in

$$q=e^{u_N}. \tag{3.27}$$

We now present the separated equations. By substituting u_k into (3.13), u_{N+k} into (3.19a) and using (3.25c) and (3.25e), one gets the separated equations

$$\begin{aligned}v_k=A(u_k)-\tilde{A}(u_k)&=\sqrt{P(u_k)}-\tilde{A}(u_k)\\ &=\sqrt{1+\sum_{j=1}^{N}\left[\frac{P_j}{u_k-\lambda_j}+\frac{P_{N+j}}{(u_k-\lambda_j)^2}\right]}-\sum_{j=1}^{N}\frac{P_{N+j}}{u_k-\lambda_j},\quad k=1,...,N-1,\end{aligned} \tag{3.28a}$$

$$v_{N+k}=\tilde{A}(u_{N+k})=\sum_{j=1}^{N}\frac{P_{N+j}}{u_{N+k}-\lambda_j},\quad k=1,...,N-1. \tag{3.28b}$$

It is easy to see from (3.14) that

$$\langle\Psi_2,\Phi_2\rangle-\langle\Psi_1,\Phi_1\rangle=\sum_{i=1}^{N}P_i,\quad \langle\Psi_1,\Phi_1\rangle+\langle\Psi_2,\Phi_2\rangle=2\sum_{i=1}^{N}P_{N+i},$$

which together with (3.25d) and (3.25f) leads to

$$v_N=-\frac{1}{2}\sum_{i=1}^{N}(P_i+2P_{N+i}),\quad v_{2N}=\sum_{i=1}^{N}P_{N+i}. \tag{3.28c}$$

Replacing v_k by the partial derivative $\partial S/\partial u_k$ of the generating function S of the canonical transformation and interpreting the P_i as integration constants, Eqs. (3.28a)–(3.28c) may be integrated to give the generating function of the canonical transformation

$$S(u_1,\ldots,u_{2N})=\sum_{k=1}^{N-1}\left[\int^{u_k}(\sqrt{P(\lambda)}-\tilde{A}(\lambda))d\lambda+\int^{u_{N+k}}\tilde{A}(\lambda)d\lambda\right]$$

$$-\frac{1}{2}\sum_{i=1}^{N}(P_i+2P_{N+i})u_N+\sum_{i=1}^{N}P_{N+i}u_{2N}$$

$$=\sum_{k=1}^{N-1}\left[\int^{u_k}\sqrt{P(\lambda)}d\lambda-\sum_{i=1}^{N}P_{N+i}\ln\left|\frac{u_k-\lambda_i}{u_{N+k}-\lambda_i}\right|\right]$$

$$-\frac{1}{2}\sum_{i=1}^{N}(P_i+2P_{N+i})u_N+\sum_{i=1}^{N}P_{N+i}u_{2N}. \tag{3.29}$$

The linearizing coordinates are then

$$Q_i=\frac{\partial S}{\partial P_i}=\frac{1}{2}\sum_{k=1}^{N-1}\int^{u_k}\frac{1}{(\lambda-\lambda_i)\sqrt{P(\lambda)}}d\lambda-\frac{1}{2}u_N,\quad i=1,\ldots,N, \tag{3.30a}$$

$$Q_{N+i}=\frac{\partial S}{\partial P_{N+i}}=\sum_{k=1}^{N-1}\left[\int^{u_k}\frac{P_{N+i}}{(\lambda-\lambda_i)^2\sqrt{P(\lambda)}}d\lambda-\ln\left|\frac{u_k-\lambda_i}{u_{N+k}-\lambda_i}\right|\right]-u_N+u_{2N},$$

$$i=1,\ldots,N. \tag{3.30b}$$

By using (3.15a), the linear flow induced by the FDIHS (3.10) together with Eqs. (3.30a) and (3.30b) leads to the Jacobi inversion problem for the FDIHS (3.10),

$$\sum_{k=1}^{N-1}\int^{u_k}\frac{1}{(\lambda-\lambda_i)\sqrt{P(\lambda)}}d\lambda-u_N=\gamma_i+\left(2\lambda_i-\sum_{k=1}^{N}P_k\right)x,\quad i=1,\ldots,N, \tag{3.31a}$$

$$\sum_{k=1}^{N-1}\left[\int^{u_k}\frac{P_{N+i}}{(\lambda-\lambda_i)^2\sqrt{P(\lambda)}}d\lambda-\ln\left|\frac{u_k-\lambda_i}{u_{N+k}-\lambda_i}\right|\right]-u_N+u_{2N}=\gamma_{N+i}+2P_{N+i}x,\quad i=1,\ldots,N. \tag{3.31b}$$

By using (3.15b), the linear flow induced by the FDIHS (3.11) and Eqs. (3.30a) and (3.30b) result in the Jacobi inversion problem for the FDIHS (3.11),

$$\sum_{k=1}^{N-1}\int^{u_k}\frac{1}{(\lambda-\lambda_i)\sqrt{P(\lambda)}}d\lambda-u_N=\overline{\gamma}_i+\left[2\lambda_i^2-\sum_{k=1}^{N}(\lambda_kP_k+\lambda_iP_k+P_{N+k}^2)+\frac{3}{4}\left(\sum_{k=1}^{N}P_k\right)^2\right]t_2,$$

$$i=1,\ldots,N, \tag{3.32a}$$

$$\sum_{k=1}^{N-1}\left[\int^{u_k}\frac{P_{N+i}}{(\lambda-\lambda_i)^2\sqrt{P(\lambda)}}d\lambda-\ln\left|\frac{u_k-\lambda_i}{u_{N+k}-\lambda_i}\right|\right]-u_N+u_{2N}$$

$$=\overline{\gamma}_{N+i}+P_{N+i}\left(4\lambda_i-\sum_{k=1}^{N}P_k\right)t_2,$$

$$i=1,\ldots,N. \tag{3.32b}$$

Then, since the AKNS equations (3.6) are factorized by the FDIHSs (3.10) and (3.11), combining Eqs. (3.31a) and (3.31b) with Eqs. (3.32a) and (3.32b) gives rise to the Jacobi inversion problem for the AKNS equations (3.6),

$$\sum_{k=1}^{N-1}\int^{u_k}\frac{1}{(\lambda-\lambda_i)\sqrt{P(\lambda)}}d\lambda-u_N$$
$$=\gamma_i+\left(2\lambda_i-\sum_{k=1}^{N}P_k\right)x+\left[2\lambda_i^2-\sum_{k=1}^{N}(\lambda_kP_k+\lambda_iP_k+P_{N+k}^2)+\frac{3}{4}\left(\sum_{k=1}^{N}P_k\right)^2\right]t_2,$$
$$i=1,...,N, \tag{3.33a}$$

$$\sum_{k=1}^{N}\left[\int^{u_k}\frac{P_{N+i}}{(\lambda-\lambda_i)^2\sqrt{P(\lambda)}}d\lambda-\ln\left|\frac{u_k-\lambda_i}{u_{N+k}-\lambda_i}\right|\right]-u_N+u_{2N}$$
$$=\gamma_{N+i}+2P_{N+i}x+P_{N+i}\left(4\lambda_i-\sum_{k=1}^{N}P_k\right)t_2,$$
$$i=1,...,N. \tag{3.33b}$$

If ϕ_{1j}, ψ_{2j}, q defined by (3.26) and (3.27) can be solved from (3.33) by using the Jacobi inversion technique, then ϕ_{2j}, ψ_{1j} can be obtained from the first equation and the last equation in (3.10) by an algebraic calculation, respectively. Finally q and $r=\langle\Psi_1,\Phi_2\rangle$ provides the solution to the AKNS equations (3.6).

In general, in order to obtain the Jacobi inversion problem for the nth AKNS equations (3.4), we set

$$A^2(\lambda)+B(\lambda)C(\lambda)=\sum_{k=0}^{\infty}\tilde{F}_k\lambda^{-k}, \tag{3.34}$$

where $\tilde{F}_k$, $k=1,2,...$, are also integrals of motion for both the FDHS (3.10) and the t_n-binary constrained flow. Comparing (3.34) with (3.13), one gets

$$\tilde{F}_0=1,\quad \tilde{F}_k=\sum_{j=1}^{N}[\lambda_j^{k-1}P_j+(k-1)\lambda_j^{k-2}P_{N+j}^2],\quad k=1,2,... . \tag{3.35}$$

The nth AKNS equations (3.4) are factorized by the x-FDIHS (3.10) and the t_n-FDIHS with the Hamiltonian F_n given by[25]

$$F_n=2\sum_{m=0}^{n}\left(-\frac{1}{2}\right)^m\frac{\alpha_m}{m+1}\sum_{l_1+\cdots+l_{m+1}=n+1}\tilde{F}_{l_1}\cdots\tilde{F}_{l_{m+1}}, \tag{3.36}$$

where $l_1\geqslant 1,...,\ l_{m+1}\geqslant 1$, and α_m are given by (2.25c). In the same way, we have the following proposition.

Proposition 4: The Jacobi inversion problem for the nth AKNS equations (3.4) is of the form

$$\sum_{k=1}^{N-1}\int^{u_k}\frac{1}{(\lambda-\lambda_i)\sqrt{P(\lambda)}}d\lambda-u_N=\gamma_i+\left(2\lambda_i-\sum_{k=1}^{N}P_k\right)x$$
$$+2t_n\sum_{m=0}^{n}\left(-\frac{1}{2}\right)^m\alpha_m\sum_{l_1+\cdots+l_{m+1}=n+1}\lambda_i^{l_{m+1}-1}\tilde{F}_{l_1}\cdots\tilde{F}_{l_m},$$
$$i=1,...,N, \tag{3.37a}$$

$$\sum_{k=1}^{N}\left[\int^{u_k}\frac{P_{N+i}}{(\lambda-\lambda_i)^2\sqrt{P(\lambda)}}d\lambda-\ln\left|\frac{u_k-\lambda_i}{u_{N+k}-\lambda_i}\right|\right]-u_N+u_{2N}$$
$$=\gamma_{N+i}+2P_{N+i}x+4t_n\sum_{m=0}^{n}\left(-\frac{1}{2}\right)^m\alpha_m\sum_{l_1+\cdots+l_{m+1}=n+1}(l_{m+1}-1)\lambda_i^{l_{m+1}-2}P_{N+i}\tilde{F}_{l_1}\cdots\tilde{F}_{l_m},$$
$$i=1,...,N, \tag{3.37b}$$

where $l_1\geqslant 1,..., l_{m+1}\geqslant 1$, *and* $\tilde{F}_{l_1},\ldots\tilde{F}_{l_m}$, *are given by* (3.35).

IV. THE SEPARATION OF VARIABLES FOR THE KAUP–NEWELL EQUATIONS

A. Binary constrained flows of the Kaup–Newell hierarchy

For the Kaup–Newell spectral problem[38]

$$\phi_x=U(u,\lambda)\phi,\quad U(u,\lambda)=\begin{pmatrix}-\lambda^2 & q\lambda\\ r\lambda & \lambda^2\end{pmatrix},\quad \phi=\begin{pmatrix}\phi_1\\ \phi_2\end{pmatrix},\quad u=\begin{pmatrix}q\\ r\end{pmatrix}, \tag{4.1}$$

its adjoint representation (2.2) and (2.3) yields

$$a_0=1,\quad a_2=-\tfrac{1}{2}qr,\quad b_1=-q,\quad c_1=-r,\quad b_3=\tfrac{1}{2}(q^2r+q_x),\quad c_3=\tfrac{1}{2}(qr^2-r_x),\ldots,$$

and in general $a_{2k+1}=b_{2k}=c_{2k}=0$,

$$\begin{pmatrix}c_{2k+1}\\ b_{2k+1}\end{pmatrix}=L\begin{pmatrix}c_{2k-1}\\ b_{2k-1}\end{pmatrix},\quad a_{2k}=\frac{1}{2}\,\partial^{-1}(qc_{2k-1,x}+rb_{2k-1,x}),\quad k=1,2,..., \tag{4.2}$$

$$L=\tfrac{1}{2}\begin{pmatrix}\partial-r\partial^{-1}q\partial & -r\partial^{-1}r\partial\\ -q\partial^{-1}q\partial & -\partial-q\partial^{-1}r\partial\end{pmatrix}.$$

Take

$$\phi_{t_n}=V^{(n)}(u,\lambda)\phi,\quad V^{(n)}(u,\lambda)=\sum_{i=0}^{n-1}\begin{pmatrix}a_{2i}\lambda^{2n-2i} & b_{2i+1}\lambda^{2n-2i-1}\\ c_{2i+1}\lambda^{2n-2i-1} & -a_{2i}\lambda^{2n-2i}\end{pmatrix}. \tag{4.3}$$

Then the compatibility condition of Eqs. (4.1) and (4.3) gives rise to the Kaup–Newell hierarchy

$$u_{t_n}=\begin{pmatrix}q\\ r\end{pmatrix}_{t_n}=J\begin{pmatrix}c_{2n-1}\\ b_{2n-1}\end{pmatrix}=J\,\frac{\delta H_{2n-2}}{\delta u},\quad n=1,2,..., \tag{4.4}$$

where the Hamiltonian H_n and the Hamiltonian operator J are given by

$$J=\begin{pmatrix}0 & \partial\\ \partial & 0\end{pmatrix},\quad H_{2n}=\frac{4a_{2n+2}-rc_{2n+1}-qb_{2n+1}}{2n},\quad \begin{pmatrix}c_{2n+1}\\ b_{2n+1}\end{pmatrix}=\frac{\delta H_{2n}}{\delta u}.$$

For $n=2$ we have

$$\phi_{t_2}=V^{(2)}(u,\lambda)\phi,\quad V^{(2)}=\begin{pmatrix}\lambda^4-\tfrac{1}{2}qr\lambda^2 & -q\lambda^3+\tfrac{1}{2}(q^2r+q_x)\lambda\\ -r\lambda^3+\tfrac{1}{2}(qr^2-r_x)\lambda & -\lambda^4+\tfrac{1}{2}qr\lambda^2\end{pmatrix}, \tag{4.5}$$

and the coupled derivative nonlinear Schrödinger (CDNS) equations obtained from Eq. (4.4) for $n=2$ read

$$q_{t_2}=\tfrac{1}{2}q_{xx}+\tfrac{1}{2}(q^2r)_x\,,\quad r_{t_2}=-\tfrac{1}{2}r_{xx}+\tfrac{1}{2}(r^2q)_x\,. \tag{4.6}$$

The adjoint Kaup–Newell spectral problem is Eq. (2.11) with U given by (4.1). We have[25]

$$\frac{\delta\lambda}{\delta u}=\begin{pmatrix}\dfrac{\delta\lambda}{\delta q}\\ \dfrac{\delta\lambda}{\delta r}\end{pmatrix}=\beta\,\mathrm{Tr}\left[\begin{pmatrix}\phi_1\psi_1 & \phi_1\psi_2\\ \phi_2\psi_1 & \phi_2\psi_2\end{pmatrix}\frac{\partial U(u,\lambda)}{\partial u}\right]=\beta\begin{pmatrix}\lambda\,\psi_1\phi_2\\ \lambda\,\psi_2\phi_1\end{pmatrix}. \tag{4.7}$$

The binary x-constrained flows of the Kaup–Newell hierarchy (4.4) are defined by

$$\Phi_{1,x}=-\Lambda^2\Phi_1+q\Lambda\Phi_2,\quad \Phi_{2,x}=r\Lambda\Phi_1+\Lambda^2\Phi_2, \tag{4.8a}$$

$$\Psi_{1,x}=\Lambda^2\Psi_1-r\Lambda\Psi_2,\quad \Psi_{2,x}=-q\Lambda\Psi_1-\Lambda^2\Psi_2, \tag{4.8b}$$

$$\frac{\delta H_{k_0}}{\delta u}-\beta^{-1}\sum_{j=1}^{N}\frac{\delta\lambda_j}{\delta u}=\begin{pmatrix}c_{2k_0+1}\\ b_{2k_0+1}\end{pmatrix}-\frac{1}{2}\begin{pmatrix}\langle\Lambda\Psi_1,\Phi_2\rangle\\ \langle\Lambda\Psi_2,\Phi_1\rangle\end{pmatrix}=0. \tag{4.8c}$$

For $k_0=1$, we have

$$\begin{pmatrix}c_1\\ b_1\end{pmatrix}=-\begin{pmatrix}r\\ q\end{pmatrix}=\frac{1}{2}\begin{pmatrix}\langle\Lambda\Psi_1,\Phi_2\rangle\\ \langle\Lambda\Psi_2,\Phi_1\rangle\end{pmatrix}=0. \tag{4.9}$$

By substituting (4.9) into (4.8a) and (4.8b), the first binary x-constrained flow becomes a FDHS

$$\Phi_{1x}=\frac{\partial F_1}{\partial\Psi_1},\quad \Phi_{2x}=\frac{\partial F_1}{\partial\Psi_2},\quad \Psi_{1x}=-\frac{\partial F_1}{\partial\Phi_1},\quad \Psi_{2x}=-\frac{\partial F_1}{\partial\Phi_2}, \tag{4.10}$$

with the Hamiltonian

$$F_1=\langle\Lambda^2\Psi_2,\Phi_2\rangle-\langle\Lambda^2\Psi_1,\Phi_1\rangle-\tfrac{1}{2}\langle\Lambda\Psi_2,\Phi_1\rangle\langle\Lambda\Psi_1,\Phi_2\rangle.$$

Under the constraint (4.9) and the FDHS (4.10), the binary t_2-constrained flow obtained from (4.3) with $V^{(2)}$ given by (4.5) and its adjoint equation for N distinct real numbers λ_j can also be written as a FDHS,

$$\Phi_{1,t_2}=\frac{\partial F_2}{\partial\Psi_1},\quad \Phi_{2,t_2}=\frac{\partial F_2}{\partial\Psi_2},\quad \Psi_{1,t_2}=-\frac{\partial F_2}{\partial\Phi_1},\quad \Psi_{2,t_2}=-\frac{\partial F_2}{\partial\Phi_2}, \tag{4.11}$$

with the Hamiltonian

$$\begin{aligned}F_2=&-\langle\Lambda^4\Psi_2,\Phi_2\rangle+\langle\Lambda^4\Psi_1,\Phi_1\rangle+\tfrac{1}{2}\langle\Lambda\Psi_2,\Phi_1\rangle\langle\Lambda^3\Psi_1,\Phi_2\rangle+\tfrac{1}{2}\langle\Lambda^3\Psi_2,\Phi_1\rangle\langle\Lambda\Psi_1,\Phi_2\rangle\\ &-\tfrac{1}{32}\langle\Lambda\Psi_2,\Phi_1\rangle^2\langle\Lambda\Psi_1,\Phi_2\rangle^2+\tfrac{1}{8}(\langle\Lambda^2\Psi_2,\Phi_2\rangle-\langle\Lambda^2\Psi_1,\Phi_1\rangle)\langle\Lambda\Psi_2,\Phi_1\rangle\langle\Lambda\Psi_1,\Phi_2\rangle.\end{aligned}$$

The Lax representation for the FDHSs (4.10) and (4.11) are presented by (2.18) with the entries of the Lax matrix M given by

$$A(\lambda)=1+\frac{1}{4}\sum_{j=1}^{N}\frac{\lambda_j^2(\psi_{1j}\phi_{1j}-\psi_{2j}\phi_{2j})}{\lambda^2-\lambda_j^2}, \tag{4.12a}$$

$$B(\lambda)=\frac{1}{2}\lambda\sum_{j=1}^{N}\frac{\lambda_j\psi_{2j}\phi_{1j}}{\lambda^2-\lambda_j^2},\quad C(\lambda)=\frac{1}{2}\lambda\sum_{j=1}^{N}\frac{\lambda_j\psi_{1j}\phi_{2j}}{\lambda^2-\lambda_j^2}. \tag{4.12b}$$

A straightforward calculation yields

$$A^2(\lambda)+B(\lambda)C(\lambda)\equiv P(\lambda)=1+\sum_{j=1}^{N}\left[\frac{P_j}{\lambda^2-\lambda_j^2}+\frac{\lambda_j^4P_{N+j}^2}{(\lambda^2-\lambda_j^2)^2}\right], \tag{4.13}$$

where P_j, $j=1,...,2N$, are $2N$ independent integrals of motion for the FDIHSs (4.10) and (4.11),

$$P_j=-\frac{1}{2}\lambda_j^2(\psi_{2j}\phi_{2j}-\psi_{1j}\phi_{1j})+\frac{1}{8}\langle\Lambda\Psi_2,\Phi_1\rangle\lambda_j\psi_{1j}\phi_{2j}+\frac{1}{8}\langle\Lambda\Psi_1,\Phi_2\rangle\lambda_j\psi_{2j}\phi_{1j}+\frac{1}{8}$$
$$\times\sum_{k\neq j}\frac{1}{\lambda_j^2-\lambda_k^2}[\lambda_j^2\lambda_k^2(\psi_{1j}\phi_{1j}-\psi_{2j}\phi_{2j})(\psi_{1k}\phi_{1k}-\psi_{2k}\phi_{2k})+2\lambda_j\lambda_k(\lambda_j^2+\lambda_k^2)\psi_{1j}\phi_{2j}\psi_{2k}\phi_{1k}],$$
$$j=1,...,N, \tag{4.14a}$$

$$P_{N+j}=\tfrac{1}{4}(\psi_{1j}\phi_{1j}+\psi_{2j}\phi_{2j}),\quad j=1,...,N. \tag{4.14b}$$

It is easy to verify that

$$F_1=-2\sum_{j=1}^{N}P_j,\quad F_2=2\sum_{j=1}^{N}(\lambda_j^2P_j+\lambda_j^4P_{N+j}^2)-\frac{1}{2}\left(\sum_{j=1}^{N}P_j\right)^2, \tag{4.15a}$$

$$\langle\Psi_2,\Phi_2\rangle+\langle\Psi_1,\Phi_1\rangle=4\sum_{j=1}^{N}P_{N+j}. \tag{4.15b}$$

By inserting $\lambda=0$, (4.13) leads to

$$1+\frac{1}{4}(\langle\Psi_2,\Phi_2\rangle-\langle\Psi_1,\Phi_1\rangle)=\sqrt{P(0)}=\sqrt{1+\sum_{j=1}^{N}[-P_j\lambda_j^{-2}+P_{N+j}^2]}. \tag{4.16}$$

With respect to the standard Poisson bracket it is found that

$$\{A(\lambda),A(\mu)\}=\{B(\lambda),B(\mu)\}=\{C(\lambda),C(\mu)\}=0, \tag{4.17a}$$

$$\{A(\lambda),B(\mu)\}=\frac{\mu}{2(\lambda^2-\mu^2)}[\mu B(\mu)-\lambda B(\lambda)], \tag{4.17b}$$

$$\{A(\lambda),C(\mu)\}=\frac{\mu}{2(\lambda^2-\mu^2)}[\lambda C(\lambda)-\mu C(\mu)], \tag{4.17c}$$

$$\{B(\lambda),C(\mu)\}=\frac{\lambda\mu}{\lambda^2-\mu^2}[A(\mu)-A(\lambda)]. \tag{4.17d}$$

Then $\{A^2(\lambda)+B(\lambda)C(\lambda),\ A^2(\mu)+B(\mu)C(\mu)\}=0$ implies that P_j, $j=1,...,2N$, are in involution. The CDNS equations (4.6) are factorized by the x-FDIHS (4.10) and the t_2-FDIHS (4.11), namely, if $(\Psi_1,\Psi_2,\Phi_1,\Phi_2)$ satisfies the FDIHSs (4.10) and (4.11) simultaneously, then $(q,\ r)$ given by (4.9) solves the CDNS equations (4.6). The factorization of the nth Kaup–Newell equations (4.4) will be presented at the end of Sec. IV B.

B. The separation of variables for the Kaup–Newell equations

Since the commutator relations (4.17) are quite different from (2.23) and (3.16), we have to modify a little bit of the method presented in Secs. II and III. Let us denote $\tilde{\lambda}=\lambda^2$, $\tilde{\lambda}_j=\lambda_j^2$. The entries of the Lax matrix M given by (4.12) can be rewritten as

$$A(\tilde{\lambda})=1+\tfrac{1}{4}(\langle\Psi_2,\Phi_2\rangle-\langle\Psi_1,\Phi_1\rangle)+\tfrac{1}{2}\tilde{\lambda}A_1(\tilde{\lambda}),\quad B(\tilde{\lambda})=\tfrac{1}{2}\sqrt{\tilde{\lambda}}\overline{B}(\tilde{\lambda}), \tag{4.18a}$$

where

$$A_1(\overline{\lambda})=\frac{1}{2}\sum_{j=1}^{N}\frac{\psi_{1j}\phi_{1j}-\psi_{2j}\phi_{2j}}{\tilde{\lambda}-\tilde{\lambda}_j},\quad \overline{B}(\tilde{\lambda})=\sum_{j=1}^{N}\frac{\sqrt{\tilde{\lambda}_j}\psi_{2j}\phi_{1j}}{\tilde{\lambda}-\tilde{\lambda}_j}. \tag{4.18b}$$

It is easy to see that

$$\{A_1(\tilde{\lambda}),A_1(\tilde{\mu})\}=\{\overline{B}(\tilde{\lambda}),\overline{B}(\tilde{\mu})\}=0, \tag{4.19a}$$

$$\{A_1(\tilde{\lambda}),\overline{B}(\tilde{\mu})\}=\frac{1}{\tilde{\lambda}-\tilde{\mu}}[\overline{B}(\tilde{\mu})-\overline{B}(\tilde{\lambda})]. \tag{4.19b}$$

It follows from (4.16) and (4.18a) that

$$A(\tilde{\lambda})=\sqrt{1+\sum_{j=1}^{N}[-P_j\tilde{\lambda}_j^{-1}+P_{N+j}^2]}+\tfrac{1}{2}\tilde{\lambda}A_1(\tilde{\lambda}). \tag{4.19c}$$

The commutator relations (4.19) and the generating function of integrals of motion (4.13) enable us to introduce $u_1,\dots,u_N$ in the following way:

$$\overline{B}(\tilde{\lambda})=\sum_{j=1}^{N}\frac{\sqrt{\tilde{\lambda}_j}\psi_{2j}\phi_{1j}}{\tilde{\lambda}-\tilde{\lambda}_j}=e^{u_N}\frac{R(\tilde{\lambda})}{K(\tilde{\lambda})}, \tag{4.20}$$

where

$$R(\tilde{\lambda})=\prod_{k=1}^{N-1}(\tilde{\lambda}-u_k),\quad K(\tilde{\lambda})=\prod_{k=1}^{N}(\tilde{\lambda}-\tilde{\lambda}_k),$$

and $v_1,\dots,v_N$ by $A_1(\tilde{\lambda})$.

By the exactly same argument as in Secs. II and III, we construct $\tilde{A}(\tilde{\lambda})$ and $\tilde{B}(\tilde{\lambda})$ by

$$\tilde{A}(\tilde{\lambda})=\frac{1}{2}\sum_{j=1}^{N}\frac{\psi_{1j}\phi_{1j}+\psi_{2j}\phi_{2j}}{\tilde{\lambda}-\tilde{\lambda}_j}=2\sum_{j=1}^{N}\frac{P_{N+j}}{\tilde{\lambda}-\tilde{\lambda}_j}, \tag{4.21}$$

$$\tilde{B}(\tilde{\lambda})=\sum_{j=1}^{N}\frac{\phi_{1j}^2}{\tilde{\lambda}-\tilde{\lambda}_j}, \tag{4.22}$$

and, for the same reason, we have to replace $A_1(\tilde{\lambda})$ by $\overline{A}(\tilde{\lambda})$,

$$\overline{A}(\tilde{\lambda})\equiv A_1(\tilde{\lambda})-\tilde{A}(\tilde{\lambda})=-\sum_{j=1}^{N}\frac{\psi_{2j}\phi_{2j}}{\tilde{\lambda}-\tilde{\lambda}_j}. \tag{4.23}$$

Then we have the following proposition.

Proposition 5: Assume that $\lambda_j, \phi_{ij}, \psi_{ij} \in \mathbf{R}$, $i=1,2$, $j=1,...,N$. *Introduce the separated variables* $u_1,\ldots,u_{2N}$ *by the* $\overline{B}(\tilde{\lambda})$ *and* $\tilde{B}(\tilde{\lambda})$:

$$\overline{B}(\tilde{\lambda})=\sum_{j=1}^{N}\frac{\sqrt{\tilde{\lambda}_j}\psi_{2j}\phi_{1j}}{\tilde{\lambda}-\tilde{\lambda}_j}=e^{u_N}\frac{R(\tilde{\lambda})}{K(\tilde{\lambda})}, \tag{4.24a}$$

$$\tilde{B}(\tilde{\lambda})=\sum_{j=1}^{N}\frac{\phi_{1j}^2}{\tilde{\lambda}-\tilde{\lambda}_j}=e^{u_{2N}}\frac{\overline{R}(\tilde{\lambda})}{K(\tilde{\lambda})}, \tag{4.24b}$$

with

$$R(\tilde{\lambda})=\prod_{k=1}^{N-1}(\tilde{\lambda}-u_k), \quad \overline{R}(\tilde{\lambda})=\prod_{k=1}^{N-1}(\tilde{\lambda}-u_{N+k}),$$

and $v_1,\ldots,v_{2N}$ *by*

$$v_k=\overline{A}(u_k)=A_1(u_k)-\tilde{A}(u_k)=-\sum_{j=1}^{N}\frac{\psi_{2j}\phi_{2j}}{u_k-\tilde{\lambda}_j}, \quad k=1,...,N-1, \tag{4.24c}$$

$$v_N=-\langle\Psi_2,\Phi_2\rangle, \tag{4.24d}$$

$$v_{N+k}=\overline{A}(u_{N+k})=\frac{1}{2}\sum_{j=1}^{N}\frac{\psi_{1j}\phi_{1j}+\psi_{2j}\phi_{2j}}{u_{N+k}-\tilde{\lambda}_j}, \quad k=1,...,N-1, \tag{4.24e}$$

$$v_{2N}=\tfrac{1}{2}(\langle\Psi_1,\Phi_1\rangle+\langle\Psi_2,\Phi_2\rangle). \tag{4.24f}$$

If $u_1,\ldots,u_N$, *are single zeros of* $\overline{B}(\lambda)$, *then* $v_1,\ldots,v_{2N}$ *and* $u_1,\ldots,u_{2N}$ *are canonically conjugated, i.e., they satisfy* (1.1).

Proof: It follows from (4.24a) and (4.24b) that

$$u_N=\ln\langle\Lambda\Psi_2,\Phi_1\rangle, \tag{4.25}$$

$$u_{2N}=\ln\langle\Psi_1,\Phi_1\rangle. \tag{4.26}$$

By a straightforward calculation, it is found that $\overline{B}(\tilde{\lambda})$, $\overline{A}(\tilde{\lambda})$, $\tilde{B}(\tilde{\lambda})$, $\tilde{A}(\tilde{\lambda})$ satisfy the commutator relations (2.33) with λ, μ replaced by $\tilde{\lambda}$, $\tilde{\mu}$, as well as the following commutator relations:

$$\{u_N,\overline{B}(\mu)\}=\{u_N,\tilde{B}(\mu)\}=\{u_N,\tilde{A}(\mu)\}=0, \quad \{u_N,\overline{A}(\mu)\}=-\frac{\overline{B}(\mu)}{\langle\Lambda\Psi_2,\Phi_1\rangle}, \tag{4.27a}$$

$$\{v_N,\overline{A}(\mu)\}=\{v_N,\tilde{B}(\mu)\}=\{v_N,\tilde{A}(\mu)\}=0, \quad \{v_N,\overline{B}(\mu)\}=\overline{B}(\mu), \tag{4.27b}$$

$$\{u_{2N},\overline{B}(\mu)\}=\{u_{2N},\overline{A}(\mu)\}=\{u_{2N},\tilde{B}(\mu)\}=0, \quad \{u_{2N},\tilde{A}(\mu)\}=-\frac{\tilde{B}(\mu)}{\langle\Psi_1,\Phi_1\rangle}, \tag{4.27c}$$

$$\{v_{2N},\overline{B}(\mu)\}=\{v_{2N},\overline{A}(\mu)\}=\{v_{2N},\tilde{A}(\mu)\}=0, \quad \{v_{2N},\tilde{B}(\mu)\}=\tilde{B}(\mu), \tag{4.27d}$$

$$\{v_N,u_N\}=1, \quad \{v_{2N},u_{2N}\}=1, \tag{4.27e}$$

$$\{u_{2N},u_N\}=\{u_{2N},v_N\}=\{v_{2N},u_N\}=\{v_{2N},v_N\}=0. \tag{4.27f}$$

Then in the exactly same way as for propositions 1 and 3, we can complete the proof.
It follows from (4.24a) and (4.24b) that

$$\lambda_j\psi_{2j}\phi_{1j}=e^{u_N}\frac{R(\lambda_j^2)}{K'(\lambda_j^2)},\quad \phi_{1j}^2=e^{u_{2N}}\frac{\overline{R}(\lambda_j^2)}{K'(\lambda_j^2)},\quad j=1,...,N, \tag{4.28}$$

or

$$\phi_{1j}=\sqrt{\frac{e^{u_{2N}}\overline{R}(\lambda_j^2)}{K'(\lambda_j^2)}},\quad \psi_{2j}=\frac{e^{u_N}R(\lambda_j^2)}{\lambda_j\sqrt{e^{u_{2N}}\overline{R}(\lambda_j^2)K'(\lambda_j^2)}},\quad j=1,...,N. \tag{4.29}$$

Equations (4.9) and (4.25) result in

$$q=-\tfrac{1}{2}e^{u_N}. \tag{4.30}$$

We now present the separated equations. By substituting u_k into (4.13), u_{N+k} into (4.21), and using (4.19c), (4.24c), and (4.24e), one gets the separated equations

$$v_k=A_1(u_k)-\widetilde{A}(u_k)=\frac{2}{u_k}[\sqrt{\widetilde{P}(u_k)}-\sqrt{P(0)}]-2\sum_{j=1}^{N}\frac{P_{N+j}}{u_k-\lambda_j^2},\quad k=1,...,N-1, \tag{4.31a}$$

$$v_{N+k}=\widetilde{A}(u_{N+k})=2\sum_{j=1}^{N}\frac{P_{N+j}}{u_{N+k}-\lambda_j^2},\quad k=1,...,N-1, \tag{4.31b}$$

where $P(0)$ are given by (4.16) and

$$\widetilde{P}(\tilde{\lambda})=1+\sum_{j=1}^{N}\left[\frac{P_j}{\tilde{\lambda}-\lambda_j^2}+\frac{\lambda_j^4P_{N+j}^2}{(\tilde{\lambda}-\lambda_j^2)^2}\right].$$

It follows from (4.15b), (4.16), (4.24d), and (4.24f) that

$$v_N=2-2\sqrt{P(0)}-2\sum_{i=1}^{N}P_{N+i},\quad v_{2N}=2\sum_{i=1}^{N}P_{N+i}. \tag{4.31c}$$

Replacing v_k by the partial derivative $\partial S/\partial u_k$ of the generating function S of the canonical transformation and interpreting the P_i as integration constants, Eqs. (4.31a)–(4.31c) may be integrated to give the generating function of the canonical transformation

$$\begin{aligned}S(u_1,\dots,u_{2N})=&\sum_{k=1}^{N-1}\left[\int^{u_k}\left(\frac{2}{\tilde{\lambda}}\sqrt{\widetilde{P}(\tilde{\lambda})}-\frac{2}{\tilde{\lambda}}\sqrt{P(0)}-\widetilde{A}(\tilde{\lambda})\right)d\tilde{\lambda}+\int^{u_{N+k}}\widetilde{A}(\tilde{\lambda})d\tilde{\lambda}\right]\\&+\left(2-2\sqrt{P(0)}-2\sum_{i=1}^{N}P_{N+i}\right)u_N+2\sum_{i=1}^{N}P_{N+i}u_{2N}\\=&\sum_{k=1}^{N-1}\left[\int^{u_k}\frac{2}{\tilde{\lambda}}\sqrt{\widetilde{P}(\tilde{\lambda})}d\tilde{\lambda}-2\sqrt{P(0)}\ln|u_k|-2\sum_{i=1}^{N}P_{N+i}\ln\left|\frac{u_k-\lambda_i^2}{u_{N+k}-\lambda_i^2}\right|\right]\end{aligned}$$

$$+\left(2-2\sqrt{P(0)}-2\sum_{i=1}^{N} P_{N+i}\right)u_N+2\sum_{i=1}^{N} P_{N+i}u_{2N}.$$

The linearizing coordinates are then

$$Q_i=\frac{\partial S}{\partial P_i}=\sum_{k=1}^{N-1}\left[\int^{u_k}\frac{1}{\tilde{\lambda}(\tilde{\lambda}-\lambda_i^2)\sqrt{\tilde{P}(\tilde{\lambda})}}d\tilde{\lambda}+\frac{1}{\lambda_i^2\sqrt{P(0)}}\ln|u_k|\right]+\frac{1}{\lambda_i^2\sqrt{P(0)}}u_N,\quad i=1,\ldots,N, \tag{4.33a}$$

$$Q_{N+i}=\frac{\partial S}{\partial P_{N+i}}=\sum_{k=1}^{N-1}\left[\int^{u_k}\frac{2\lambda_i^4P_{N+i}}{\tilde{\lambda}(\tilde{\lambda}-\lambda_i^2)^2\sqrt{\tilde{P}(\tilde{\lambda})}}d\tilde{\lambda}-\frac{2P_{N+i}}{\sqrt{P(0)}}\ln|u_k|\right.$$
$$\left.-2\ln\left|\frac{u_k-\lambda_i^2}{u_{N+k}-\lambda_i^2}\right|\right]-2\left(\frac{P_{N+i}}{\sqrt{P(0)}}+1\right)u_N+2u_{2N},\quad i=1,\ldots,N. \tag{4.33b}$$

By using (4.15a), the linear flow induced by (4.10) together with Eqs. (4.33a) and (4.33b) leads to the Jacobi inversion problem for the FDIHS (4.10),

$$\sum_{k=1}^{N-1}\left[\int^{u_k}\frac{1}{\tilde{\lambda}(\tilde{\lambda}-\lambda_i^2)\sqrt{\tilde{P}(\tilde{\lambda})}}d\tilde{\lambda}+\frac{1}{\lambda_i^2\sqrt{P(0)}}\ln|u_k|\right]+\frac{1}{\lambda_i^2\sqrt{P(0)}}u_N=\gamma_i-2x,$$
$$i=1,\ldots,N, \tag{4.34a}$$

$$\sum_{k=1}^{N-1}\left[\int^{u_k}\frac{2\lambda_i^4P_{N+i}}{\tilde{\lambda}(\tilde{\lambda}-\lambda_i^2)^2\sqrt{\tilde{P}(\tilde{\lambda})}}d\tilde{\lambda}-\frac{2P_{N+i}}{\sqrt{P(0)}}\ln|u_k|\right]-2\ln\left|\frac{u_k-\lambda_i^2}{u_{N+k}-\lambda_i^2}\right|\Bigg]-2\left(\frac{P_{N+i}}{\sqrt{P(0)}}+1\right)u_N+2u_{2N}$$
$$=\gamma_{N+i},\quad i=1,\ldots,N. \tag{4.34b}$$

By using (4.15a), the linear flow induced by (4.11) and Eqs. (4.34a) and (4.34b) yield the Jacobi inversion problem for the FDIHS (4.11),

$$\sum_{k=1}^{N-1}\left[\int^{u_k}\frac{1}{\tilde{\lambda}(\tilde{\lambda}-\lambda_i^2)\sqrt{\tilde{P}(\tilde{\lambda})}}d\tilde{\lambda}+\frac{1}{\lambda_i^2\sqrt{P(0)}}\ln|u_k|\right]+\frac{1}{\lambda_i^2\sqrt{P(0)}}u_N$$
$$=\overline{\gamma_i}+\left(2\lambda_i^2-\sum_{k=1}^{N}P_k\right)t_2,\quad i=1,\ldots,N, \tag{4.35a}$$

$$\sum_{k=1}^{N-1}\left[\int^{u_k}\frac{2\lambda_i^4P_{N+i}}{\tilde{\lambda}(\tilde{\lambda}-\lambda_i^2)^2\sqrt{\tilde{P}(\tilde{\lambda})}}d\tilde{\lambda}-\frac{2P_{N+i}}{\sqrt{P(0)}}\ln|u_k|\right]-2\ln\left|\frac{u_k-\lambda_i^2}{u_{N+k}-\lambda_i^2}\right|\Bigg]-2\left(\frac{P_{N+i}}{\sqrt{P(0)}}+1\right)u_N+2u_{2N}$$
$$=\overline{\gamma}_{N+i}+4\lambda_i^4P_{N+i}t_2,\quad i=1,\ldots,N. \tag{4.35b}$$

Finally, since the CDNS equations (4.6) are factorized by the FDIHS (4.10) and (4.11), combining Eqs. (4.34) and (4.35) gives rise to the Jacobi inversion problem for the CDNS equations (4.6),

$$\sum_{k=1}^{N-1}\left[\int^{u_k}\frac{1}{\tilde\lambda(\tilde\lambda-\lambda_i^2)\sqrt{\tilde P(\tilde\lambda)}}d\tilde\lambda+\frac{1}{\lambda_i^2\sqrt{P(0)}}\ln|u_k|\right]+\frac{1}{\lambda_i^2\sqrt{P(0)}}u_N$$

$$=\gamma_i-2x+\left(2\lambda_i^2-\sum_{k=1}^{N}P_k\right)t_2,\quad i=1,\dots,N, \tag{4.36a}$$

$$\sum_{k=1}^{N-1}\left[\int^{u_k}\frac{2\lambda_i^4P_{N+i}}{\tilde\lambda(\tilde\lambda-\lambda_i^2)^2\sqrt{\tilde P(\tilde\lambda)}}d\tilde\lambda-\frac{2P_{N+i}}{\sqrt{P(0)}}\ln|u_k|\right]-2\ln\left|\frac{u_k-\lambda_i^2}{u_{N+k}-\lambda_i^2}\right|\Bigg]-2\left(\frac{P_{N+i}}{\sqrt{P(0)}}+1\right)u_N+2u_{2N}$$

$$=\gamma_{N+i}+4\lambda_i^4P_{N+i}t_2,\quad i=1,\dots,N. \tag{4.36b}$$

If ϕ_{1j}, ψ_{2j}, q defined by (4.29) and (4.30) can be solved from (4.36) by using the Jacobi inversion technique, then ϕ_{2j}, ψ_{1j} can be obtained from the first equation and the last equation in (4.10), respectively. Finally q and $r=-\langle\Lambda\Psi_1,\Phi_2\rangle$ provides the solution to the CDNS equations (4.6).

In general, the above mentioned procedure can be applied to the whole Kaup–Newell hierarchy (4.4). Set

$$A^2(\lambda)+B(\lambda)C(\lambda)=\sum_{k=0}^{\infty}\tilde F_k\lambda^{-2k}, \tag{4.37a}$$

where $\tilde F_k$, $k=1,2,\dots$, are also integrals of motion for both the x-FDHSs (4.10) and the t_n-binary constrained flows (2.16). Comparing (4.37a) with (4.13), one gets

$$\tilde F_0=1,\quad \tilde F_k=\sum_{j=1}^{N}[\lambda_j^{2k-2}P_j+(k-1)\lambda_j^{2k}P_{N+j}^2],\quad k=1,2,\dots . \tag{4.37b}$$

By employing the method in Refs. 34 and 35, the t_n-FDIHS obtained from the t_n-constrained flow is of the form

$$\Phi_{1,t_n}=\frac{\partial F_n}{\partial\Psi_1},\quad \Phi_{2,t_n}=\frac{\partial F_n}{\partial\Psi_2},\quad \Psi_{1,t_n}=-\frac{\partial F_n}{\partial\Phi_1},\quad \Psi_{2,t_n}=-\frac{\partial F_n}{\partial\Phi_2}, \tag{4.38a}$$

with the Hamiltonian

$$F_n=2\sum_{m=0}^{n-1}\left(-\frac{1}{2}\right)^m\frac{\alpha_m}{m+1}\sum_{l_1+\cdots+l_{m+1}=n}\tilde F_{l_1}\cdots\tilde F_{l_{m+1}}, \tag{4.38b}$$

where $l_1\geqslant1,\dots,l_{m+1}\geqslant1$, and α_m are given by (2.25c). Since the nth Kaup–Newell equations (4.4) is factorized by the x-FDIHS (4.10) and the t_n-FDIHS (4.38). We have the following proposition.

Proposition 6: The Jacobi inversion problem for the nth Kaup–Newell equations (4.4) is given by

$$\sum_{k=1}^{N-1}\left[\int^{u_k}\frac{1}{\tilde\lambda(\tilde\lambda-\lambda_i^2)\sqrt{\tilde P(\tilde\lambda)}}d\tilde\lambda+\frac{1}{\lambda_i^2\sqrt{P(0)}}\ln|u_k|\right]+\frac{1}{\lambda_i^2\sqrt{P(0)}}u_N$$

$$=\gamma_i-2x+2t_n\sum_{m=0}^{n-1}(-\tfrac{1}{2})^m\alpha_m\sum_{l_1+\cdots l_{m+1}=n}\lambda_i^{2l_{m+1}-2}\tilde F_{l_1}\cdots\tilde F_{l_m},\quad i=1,\dots,N, \tag{4.39a}$$

$$\sum_{k=1}^{N-1}\left[\int^{u_k}\frac{2\lambda_i^4 P_{N+i}}{\tilde{\lambda}(\tilde{\lambda}-\lambda_i^2)^2\sqrt{\tilde{P}(\tilde{\lambda})}}d\tilde{\lambda}-\frac{2P_{N+i}}{\sqrt{P(0)}}\ln|u_k|\right]-2\ln\left|\frac{u_k-\lambda_i^2}{u_{N+k}-\lambda_i^2}\right|\Bigg]-2\left(\frac{P_{N+i}}{\sqrt{P(0)}}+1\right)u_N+2u_{2N}$$
$$=\gamma_{N+i}+4t_n\sum_{m=0}^{n-1}\left(-\frac{1}{2}\right)^m\alpha_m\sum_{l_1+\cdots l_{m+1}=n}(l_{m+1}-1)\lambda_i^{2l_{m+1}}P_{N+i}\tilde{F}_{l_1}\cdots\tilde{F}_{l_m},\quad i=1,\ldots,N, \tag{4.39b}$$

where $l_1\geqslant 1,\ldots,\ l_{m+1}\geqslant 1$, *and* $\tilde{F}_{l_1},\ldots\tilde{F}_{l_m}$, *are given by* (4.37b).

For example, the third equations in the Kaup–Newell hierarchy with $n=3$ are of the form

$$q_{t_3}=-\tfrac{1}{4}q_{xxx}-\tfrac{3}{8}(q^3r^2+2qrq_x)_x,\quad r_{t_3}=-\tfrac{1}{4}r_{xxx}-\tfrac{3}{8}(r^3q^2-2qrr_x)_x. \tag{4.40}$$

The Kaup–Newell equations (4.40) can be factorized by the x-FDIHS (4.10) and t_3-FDIHS with the Hamiltonian F_3 defined by

$$F_3=\sum_{j=1}^{N}(2\lambda_j^4P_j+4\lambda_j^6P_{N+j}^2)-\left[\sum_{j=1}^{N}(\lambda_j^2P_j+\lambda_j^4P_{N+j}^2)\right]\sum_{j=1}^{N}P_j+\frac{1}{4}\left(\sum_{j=1}^{N}P_j\right)^3. \tag{4.41}$$

The Jacobi inversion problem for Eq. (4.40) is given by

$$\sum_{k=1}^{N-1}\left[\int^{u_k}\frac{1}{\tilde{\lambda}(\tilde{\lambda}-\lambda_i^2)\sqrt{\tilde{P}(\tilde{\lambda})}}d\tilde{\lambda}+\frac{1}{\lambda_i^2\sqrt{P(0)}}\ln|u_k|\right]+\frac{1}{\lambda_i^2\sqrt{P(0)}}u_N$$
$$=\gamma_i-2x+\left[2\lambda_i^4-\sum_{j=1}^{N}(\lambda_j^2P_j+\lambda_i^2P_j+\lambda_j^4P_{N+j}^2)+\frac{3}{4}\left(\sum_{j=1}^{N}P_j\right)^2\right]t_3,\quad i=1,\ldots,N.$$

$$\sum_{k=1}^{N-1}\left[\left[\int^{u_k}\frac{2\lambda_i^4P_{N+i}}{\tilde{\lambda}(\tilde{\lambda}-\lambda_i^2)^2\sqrt{\tilde{P}(\tilde{\lambda})}}d\tilde{\lambda}-\frac{2P_{N+i}}{\sqrt{P(0)}}\ln|u_k|\right]-2\ln\left|\frac{u_k-\lambda_i^2}{u_{N+k}-\lambda_i^2}\right|\right]$$
$$-2\left(\frac{P_{N+i}}{\sqrt{P(0)}}+1\right)u_N+2u_{2N}$$
$$=\gamma_{N+i}+\left[8\lambda_i^6P_{N+i}-2\lambda_i^4P_{N+j}\sum_{j=1}^{N}P_j\right]t_3,\quad i=1,\ldots,N.$$

V. CONCLUDING REMARKS

This paper proposed a new method to find the additional N pairs canonical separated variables for the separation of variables for binary constrained flows of soliton hierarchies. For a certain kind of integrable models, a general approach to the separation of variables was proposed in Refs. 2–4 by taking the poles of the properly normalized Baker–Akhiezer function and the corresponding eigenvalues of the Lax operator as separated variables. As pointed out in Ref. 4, there is no guarantee that the separated variables so constructed satisfy the canonical conditions (1.1). The method proposed in this paper is to start directly from the canonical conditions (1.1) and the requirement for the separated equations (1.2). We introduced $2N$ pairs of separated variables by means of four functions $\bar{B}(\lambda)$, $\bar{A}(\lambda)$, $\tilde{B}(\lambda)$, and $\tilde{A}(\lambda)$, which are constructed in such way that they satisfy certain commutator relations required by the canonical conditions (1.1) and $\bar{A}(\lambda)$ and $\tilde{A}(\lambda)$ are linked to the generating functions of the integrals of motion for the models. This method ensures that the separated variables are canonically conjugated. We produced two sets of separated equations directly from two generating functions of integrals of motion. It seems that the separated equations are intimately connected with the generating functions of integrals of motion.

The finite gap solutions or finite-dimensional quasiperiodic solutions for the KdV equation was studied in Ref. 36 by means of the stationary equation of the KdV hierarchy called the Lax–Novikov equation. By the standard Jacobi inversion technique,[19] the finite-dimensional quasiperiodic solution can be given in an explicit form in terms of the Riemann theta functions associated with the invariant spectral curve. The Jacobi inversion problem (2.45) for the KdV equation is somewhat different from that in Ref. 36 due to some additional terms. The Jacobi inversion problems for some binary constrained flows require the development of the standard Jacobi inversion technique in order to solve them explicitly.

Cosmological and spherically symmetric solutions with intersecting p-branes

V. D. Ivashchuk[a)] and V. N. Melnikov
Center for Gravitation and Fundamental Metrology, VNIIMS, 3-1 M. Ulyanovoy Str., Moscow, 117313, Russia

(Received 20 January 1999; accepted for publication 12 May 1999)

Multidimensional model describing the cosmological evolution and/or spherically symmetric configuration with $n+1$ Einstein spaces in the theory with several scalar fields and forms is considered. When electro-magnetic composite p-brane ansatz is adopted, n ''internal'' spaces are Ricci-flat, one space M_0 has a nonzero curvature, and all p-branes do not ''live'' in M_0, a class of exact solutions is obtained if certain block-orthogonality relations on p-brane vectors are imposed. A subclass of spherically symmetric solutions (containing nonextremal p-brane black holes) is considered. Post-Newtonian parameters are calculated. © *1999 American Institute of Physics.* [S0022-2488(99)00510-1]

I. INTRODUCTION

At present there exists a special interest to the so-called M- and F theories, etc.[1–4] These theories are ''supermembrane'' analogues of superstring models[5] in $D=11,12$, etc. The low-energy limit of these theories leads to models governed by the action

$$S=\int_M d^Dz\sqrt{|g|}\left\{R[g]-h_{\alpha\beta}g^{MN}\partial_M\varphi^\alpha\partial_N\varphi^\beta-\sum_{a\in\Delta}\frac{\theta_a}{n_a!}\exp[2\lambda_a(\varphi)](F^a)^2_g\right\}, \tag{1.1}$$

where $g=g_{MN}\,dz^M\otimes dz^N$ is the metric $(M,N=1,\dots,D)$, $\varphi=(\varphi^\alpha)\in\mathbb{R}^l$ is a vector from dilatonic scalar fields, $(h_{\alpha\beta})$ is a nondegenerate symmetric $l\times l$ matrix $(l\in\mathbb{N})$, $\theta_a=\pm 1$,

$$F^a=dA^a=\frac{1}{n_a!}F^a_{M_1\cdots M_{n_a}}dz^{M_1}\wedge\cdots\wedge dz^{M_{n_a}} \tag{1.2}$$

is a n_a-form $(n_a\geq 1)$ on a D-dimensional manifold M, Λ is cosmological constant and λ_a is a 1-form on $\mathbb{R}^l$: $\lambda_a(\varphi)=\lambda_{a\alpha}\varphi^\alpha$, $a\in\Delta$, $\alpha=1,\dots,l$. In (1.1) we denote $|g|=|\det(g_{MN})|$,

$$(F^a)^2_g=F^a_{M_1\cdots M_{n_a}}F^a_{N_1\cdots N_{n_a}}g^{M_1N_1}\cdots g^{M_{n_a}N_{n_a}}, \tag{1.3}$$

$a\in\Delta$, where Δ is some finite set. In the models with one time all $\theta_a=1$ when the signature of the metric is $(-1,+1,\dots,+1)$.

In Ref. 6 it was shown that after dimensional reduction on the manifold $M_*\times M_1\times\cdots\times M_n$ and when the composite p-brane ansatz is considered (for review see, for example, Refs. 6, 7, and 8) the problem is reduced to the gravitating self-interacting σ-model with certain constraints imposed. For electric p-branes see also Refs. 9, 10, and 11 (in Ref. 11 the composite electric case was considered). (For pure gravitational sector see Refs. 12 and 13) This representation may be considered as a powerful tool for obtaining different solutions with intersecting p-branes (analogs of membranes). In Refs. 6 and 14 the Majumdar–Papapetrou-type solutions were obtained (for the noncomposite electric case see Refs. 9 and 10 and for composite electric

[a)]Electronic mail: ivas@rgs.phys.msu.su

case see Ref. 11). These solutions correspond to Ricci-flat (M_i, g^i), $i=1,\ldots,n$, and were generalized also to the case of Einstein internal spaces.[6] Earlier some special classes of these solutions were also considered in Refs. 15–22. The obtained solutions take place, when certain orthogonality relations (on couplings parameters, dimensions of ''branes,'' total dimension) are imposed.

In cosmological (or spherically symmetric) case $M_* = \mathbb{R}$ and the problem is effectively reduced to Toda-like system with the Lagrangian[23]

$$L = \frac{1}{2}\bar{G}_{AB}\dot{x}^A\dot{x}^B - \sum_{s\in S_*} A_s \exp(2U_A^s x^A), \tag{1.4}$$

with the zero-energy constraint $E=0$, where $(\bar{G}_{AB})$ is a nondegenerate symmetric $N\times N$ matrix $(N=n+l)$, $A_s \neq 0$, $x=(x^A)\in\mathbb{R}^N$, $U^s=(U_A^s)\in\mathbb{R}^N$, $s\in S_*$. The considered cosmological model contains some stringy cosmological models (see, for example, Ref. 24). It may be obtained (at classical level) from multidimensional cosmological model with perfect fluid[25,26] as a special case.

The integrability of the Lagrange equations corresponding to (1.4) crucially depends upon the scalar products $(U^{s_1}, U^{s_2})=0$, $s_1, s_2 \in S_*$, where

$$(U,U') = \bar{G}^{AB} U_A U'_B, \tag{1.5}$$

$U,U' \in \mathbb{R}^N$, where $(\bar{G}^{AB}) = (\bar{G}_{AB})^{-1}$.

In the ''orthogonal'' case

$$(U^s, U^{s'}) = 0 \tag{1.6}$$

$s,s' \in S_*$, a class of cosmological and spherically symmetric solutions was obtained.[23] Special cases were also considered in Refs. 27–30. The solutions with the horizon were considered in details in Refs. 23, 31–35. We note that the ''orthogonality'' relation (1.6) is known in literature as a ''no-force'' condition.

In this paper we consider a more general ''block-orthogonal'' case:

$$S_* = S_1 \cup \ldots \cup S_k, \quad S_i \cap S_j = \emptyset, \quad i \neq j, \tag{1.7}$$

$S_i \neq \emptyset$, i.e., the set S is a union of k nonintersecting (nonempty) subsets $S_1, \ldots, S_k$, and

$$(U^s, U^{s'}) = 0 \tag{1.8}$$

for all $s\in S_i$, $s'\in S_j$, $i\neq j$; $i,j=1,\ldots,k$. According to (1.8) the set of vectors $(U^s, s\in S)$ has a block-orthogonal structure with respect to the scalar product (1.5): it splits into k mutually orthogonal blocks $(U^s, s\in S_i)$, $i=1,\ldots,k$. Here we find a class of special solutions to Lagrange equations corresponding to the Lagrangian (1.1) (see Appendix B). Using this result we find a family of cosmological and/or spherically symmetric solutions with composite electromagnetic p-branes (see Sec. IV) in the case when n ''internal'' spaces are Ricci-flat, one space M_0 has a nonzero curvature, and all p-branes do not ''live'' in M_0, if block-orthogonality relations (on p-brane vectors U^s) (1.7) and (1.8) are imposed. These solutions generalize the solutions from Ref. 23 with orthogonal set of vectors U^s. A special class of ''block-orthogonal'' solutions (with coinciding parameters ν_s inside blocks) was considered earlier in Ref. 36.

Recently a class of Majumdar–Papapetrou type solutions with p-branes was obtained in Ref. 14 (see also Ref. 37) for block-orthogonal case. For the solutions from Ref. 14 U^s vectors may be related to finite-dimensional Lie algebras or hyperbolic (Kac–Moody) algebras but not to affine (Kac–Moody) algebras.

We also note that there exists a large variety of p-brane Toda solutions (open or closed) when certain intersection rules are satisfied.[23] The scalar products $(U^s, U^{s'})$, $s,s' \in S_*$, in this case are governed by Cartan matrices of finite-dimensional or affine Lie algebras. For concrete exact solutions see also Refs. 27, 38, and 39.

In Sec. V we consider a subclass of spherically symmetric solutions. This subclass contains nonextremal p-brane black holes for special values of ''Kasner-like'' parameters. In Sec. VI we calculate post-Newtonian parameters β and γ (Eddington parameters) for the spherically symmetric solutions. These parameters may be useful for possible physical applications.

II. THE MODEL

The equations of motion corresponding to (1.1) have the following form:

$$R_{MN}-\tfrac{1}{2}g_{MN}R=T_{MN}, \tag{2.1}$$

$$\Delta[g]\varphi^{\alpha}-\sum_{a\in\Delta}\theta_a\frac{\lambda_a^{\alpha}}{n_a!}e^{2\lambda_a(\varphi)}(F^a)_g^2=0, \tag{2.2}$$

$$\nabla_{M_1}[g](e^{2\lambda_a(\varphi)}F^{a,M_1\cdots M_{n_a}})=0, \tag{2.3}$$

$a\in\Delta$; $\alpha=1,\ldots,l$. In (2.2) $\lambda_a^{\alpha}=h^{\alpha\beta}\lambda_{a\beta}$, where $(h^{\alpha\beta})$ is matrix inverse to $(h_{\alpha\beta})$. In (2.1)

$$T_{MN}=T_{MN}[\varphi,g]+\sum_{a\in\Delta}\theta_a e^{2\lambda_a(\varphi)}T_{MN}[F^a,g], \tag{2.4}$$

where

$$T_{MN}[\varphi,g]=h_{\alpha\beta}(\partial_M\varphi^{\alpha}\partial_N\varphi^{\beta}-\tfrac{1}{2}g_{MN}\partial_P\varphi^{\alpha}\partial^P\varphi^{\beta}), \tag{2.5}$$

$$T_{MN}[F^a,g]=\frac{1}{n_a!}\left[-\frac{1}{2}g_{MN}(F^a)_g^2+n_aF^a_{MM_2\ldots M_{n_a}}F_N^{a,M_2\ldots M_{n_a}}\right]. \tag{2.6}$$

In (2.2) and (2.3) $\Delta[g]$ and $\nabla[g]$ are Laplace–Beltrami and covariant derivative operators, respectively, corresponding to g.

Let us consider the manifold

$$M=\mathbb{R}\times M_0\times\cdots\times M_n \tag{2.7}$$

with the metric

$$g=w\mathrm{e}^{2\gamma(u)}du\otimes du+\sum_{i=0}^{n}\mathrm{e}^{2\phi^i(u)}g^i, \tag{2.8}$$

where $w=\pm1$, u is a distinguished coordinate which, by convention, will be called ''time;'' $g^i=g^i_{m_in_i}(y_i)dy_i^{m_i}\otimes dy_i^{n_i}$ is a metric on M_i satisfying the equation

$$R_{m_in_i}[g^i]=\xi_ig^i_{m_in_i}, \tag{2.9}$$

$m_i,n_i=1,\ldots,d_i$; $d_i=\dim M_i$, $\xi_i=\text{const}$, $i=0,\ldots,n$; $n\in\mathbb{N}$. Thus, (M_i,g^i) are Einstein spaces. The functions γ,ϕ^i: $(u_-,u_+)\to\mathbb{R}$ are smooth.

Remark: It is more correct to write in (2.8) $\hat{g}^i$ instead of g^i, where $\hat{g}^i=p_i^*g^i$ is the pullback of the metric g^i to the manifold M by the canonical projection: p_i: $M\to M_i$, $i=0,\ldots,n$. In what follows we omit ''hats'' for simplicity.

Each manifold M_i is assumed to be oriented and connected, $i=0,\ldots,n$. Then the volume d_i-form

$$\tau_i=\sqrt{|g^i(y_i)|}dy_i^1\wedge\cdots\wedge dy_i^{d_i}, \tag{2.10}$$

and the signature parameter

$$\varepsilon(i)=\text{sign}\,\det(g^i_{m_i n_i})=\pm 1 \tag{2.11}$$

are correctly defined for all $i=0,\ldots,n$.

Let

$$\Omega_0=\{\emptyset,\{0\},\{1\},\ldots,\{n\},\{0,1\},\ldots,\{0,1,\ldots,n\}\} \tag{2.12}$$

be a set of all subsets of

$$I_0\equiv\{0,\ldots,n\}. \tag{2.13}$$

Let $I=\{i_1,\ldots,i_k\}\in\Omega_0$, $i_1<\ldots<i_k$. We define a form

$$\tau(I)\equiv\tau_{i_1}\wedge\cdots\wedge\tau_{i_k}, \tag{2.14}$$

of rank

$$d(I)\equiv\sum_{i\in I} d_i, \tag{2.15}$$

and a corresponding p-brane submanifold

$$M_I\equiv M_{i_1}\times\cdots\times M_{i_k}, \tag{2.16}$$

where $p=d(I)-1$ $(\dim M_I=d(I))$. We also define ε-symbol

$$\varepsilon(I)\equiv\varepsilon(i_1)\cdots\varepsilon(i_k). \tag{2.17}$$

For $I=\emptyset$ we put $\tau(\emptyset)=\varepsilon(\emptyset)=1$, $d(\emptyset)=0$.

For fields of forms we adopt the following ‘‘composite electro-magnetic’’ ansatz

$$F^a=\sum_{I\in\Omega_{a,e}}\mathcal{F}^{(a,e,I)}+\sum_{J\in\Omega_{a,m}}\mathcal{F}^{(a,m,J)}, \tag{2.18}$$

where

$$\mathcal{F}^{(a,e,I)}=d\Phi^{(a,e,I)}\wedge\tau(I), \tag{2.19}$$

$$\mathcal{F}^{(a,m,J)}=\mathrm{e}^{-2\lambda_a(\varphi)}*(d\Phi^{(a,m,J)}\wedge\tau(J)), \tag{2.20}$$

$a\in\Delta$, $I\in\Omega_{a,e}$, $J\in\Omega_{a,m}$ and

$$\Omega_{a,e},\Omega_{a,m}\subset\Omega_0. \tag{2.21}$$

[For empty $\Omega_{a,v}=\emptyset$, $v=e,m$, we put $\Sigma_{\emptyset}=0$ in (2.18)]. In (2.20) $*=*[g]$ is the Hodge operator on (M,g).

For the potentials in (2.19) and (2.20) we put

$$\Phi^s=\Phi^s(u), \tag{2.22}$$

$s\in S$, where

$$S=S_e\sqcup S_m, \quad S_v\equiv\sqcup_{a\in\Delta}\{a\}\times\{v\}\times\Omega_{a,v}, \tag{2.23}$$

$v=e,m$. Here $\sqcup$ means the union of nonintersecting sets. The set S consists of elements $s=(a_s,v_s,I_s)$, where $a_s\in\Delta$, $v_s=e,m$, and $I_s\in\Omega_{a,v_s}$ are ''color,'' ''electro-magnetic,'' and ''brane'' indices, respectively.

For dilatonic scalar fields we put

$$\varphi^\alpha=\varphi^\alpha(u), \tag{2.24}$$

$\alpha=1,\ldots,l$.

From (2.19) and (2.20) we obtain the relations between dimensions of p-brane worldsheets and ranks of forms

$$d(I)=n_a-1, \quad I\in\Omega_{a,e}, \tag{2.25}$$

$$d(J)=D-n_a-1, \quad J\in\Omega_{a,m}, \tag{2.26}$$

in electric and magnetic cases, respectively.

III. LAGRANGE REPRESENTATION

Here, like in Ref. 23, we impose a restriction on p-brane configurations, or, equivalently, on $\Omega_{a,v}$. We assume that the energy momentum tensor (T_{MN}) has a block-diagonal structure [as it takes place for (g_{MN})]. Sufficient restrictions on $\Omega_{a,v}$ that guarantee a block-diagonality of (T_{MN}) are presented in Appendix A.

It follows from Ref. 6 (see Proposition 2 in Ref. 6) that the equations of motion (2.1)–(2.3) and the Bianchi identities

$$d\mathcal{F}^s=0, \quad s\in S \tag{3.1}$$

for the field configuration (2.8), (2.18)–(2.20), (2.22), (2.24) with the restrictions (A2), (A3) (from Appendix A) imposed are equivalent to equations of motion for Lagrange system with the Lagrangian

$$L=\frac{1}{2}\mathcal{N}\left\{G_{ij}\dot{\phi}^i\dot{\phi}^j+h_{\alpha\beta}\dot{\varphi}^\alpha\dot{\varphi}^\beta+\sum_{s\in S}\varepsilon_s\exp[-2U^s(\phi,\varphi)](\dot{\Phi}^s)^2-2\mathcal{N}^{-2}V(\phi)\right\}, \tag{3.2}$$

where $\dot{x}\equiv dx/du$,

$$V=V(\phi)=\frac{w}{2}\sum_{i=0}^{n}\xi_i d_i e^{-2\phi^i+2\gamma_0(\phi)} \tag{3.3}$$

is the potential with

$$\gamma_0(\phi)\equiv\sum_{i=0}^{n}d_i\phi^i, \tag{3.4}$$

and

$$\mathcal{N}=\exp(\gamma_0-\gamma)>0 \tag{3.5}$$

is the lapse function,

$$U^s=U^s(\phi,\varphi)=-\chi_s\lambda_{a_s}(\varphi)+\sum_{i\in I_s}d_i\phi^i, \tag{3.6}$$

$$\varepsilon_s = (-\varepsilon[g])^{(1-\chi_s)/2}\varepsilon(I_s)\theta_{a_s} \tag{3.7}$$

for $s=(a_s, v_s, I_s)\in S$, $\varepsilon[g]=\mathrm{sign}\det(g_{MN})$, [more explicitly (3.7) reads $\varepsilon_s=\varepsilon(I_s)\theta_{a_s}$ for $v_s=e$ and $\varepsilon_s=-\varepsilon[g]\varepsilon(I_s)\theta_{a_s}$, for $v_s=m$]

$$\chi_s=+1, \quad v_s=e, \tag{3.8}$$

$$\chi_s=-1, \quad v_s=m, \tag{3.9}$$

and

$$G_{ij}=d_i\delta_{ij}-d_id_j \tag{3.10}$$

are components of the ''pure cosmological'' minisupermetric; $i,j=0,\ldots,n$.[40]

Let $x=(x^A)=(\phi^i,\varphi^\alpha)$,

$$\bar{G}=\bar{G}_{AB}\,dx^A\otimes dx^B=G_{ij}\,d\phi^i\otimes d\phi^j+h_{\alpha\beta}\,d\varphi^\alpha\otimes d\varphi^\beta, \tag{3.11}$$

$$(\bar{G}_{AB})=\begin{pmatrix} G_{ij} & 0 \\ 0 & h_{\alpha\beta}\end{pmatrix}, \tag{3.12}$$

$U^s(x)=U^s_Ax^A$ is defined in (3.6) and

$$(U^s_A)=(d_i\delta_{iI_s},-\chi_s\lambda_{a_s\alpha}). \tag{3.13}$$

Here

$$\delta_{iI}\equiv\sum_{j\in I}\delta_{ij}=\begin{matrix}1, & i\in I\\ 0, & i\notin I\end{matrix} \tag{3.14}$$

is an indicator of i belonging to I. The potential (3.3) reads

$$V=\sum_{j=0}^{n}\frac{w}{2}\xi_j\,d_j\mathrm{e}^{2U^j(x)}, \tag{3.15}$$

where

$$U^j(x)=U^j_Ax^A=-\phi^j+\gamma_0(\phi), \tag{3.16}$$

$$(U^j_A)=(-\delta^j_i+d_i,0). \tag{3.17}$$

The integrability of the Lagrange system (3.2) depends upon the scalar products of co$-$vectors U^j, U^s corresponding to $\bar{G}$:

$$(U,U')=\bar{G}^{AB}U_AU'_B, \tag{3.18}$$

where

$$(\bar{G}^{AB})=\begin{pmatrix} G^{ij} & 0 \\ 0 & h^{\alpha\beta}\end{pmatrix} \tag{3.19}$$

is matrix inverse to (3.12). Here (as in Ref. 40)

$$G^{ij}=\frac{\delta^{ij}}{d_i}+\frac{1}{2-D}, \tag{3.20}$$

$i,j=0,\ldots,n$. These products have the following form[26,6]

$$(U^i,U^j)=\frac{\delta_{ij}}{d_j}-1, \tag{3.21}$$

$$(U^s,U^{s'})=d(I_s\cap I_{s'})+\frac{d(I_s)d(I_{s'})}{2-D}+\chi_s\chi_{s'}\lambda_{a\alpha}\lambda_{b\beta}h^{\alpha\beta}, \tag{3.22}$$

$$(U^s,U^i)=-\delta_{iI_s}, \tag{3.23}$$

where $s=(a_s,v_s,I_s)$, $s'=(a_{s'},v_{s'},I_{s'})\in S$.

IV. COSMOLOGICAL AND SPHERICALLY SYMMETRIC SOLUTIONS

Here we put the following restrictions on the parameters of the model

$$\textbf{(i)}\quad \xi_0\neq 0,\quad \xi_1=\cdots=\xi_n=0, \tag{4.1}$$

i.e., one space is curved and others are Ricci-flat,

$$\textbf{(ii)}\quad 0\notin I_s,\quad \forall s=(a_s,v_s,I_s)\in S, \tag{4.2}$$

i.e., all ''brane'' manifolds M_{I_s} [see (2.16)] do not contain M_0.

We also impose a block-orthogonality restriction on the set of vectors $(U^s, s\in S)$. Let

$$S=S_1\sqcup\cdots\sqcup S_k, \tag{4.3}$$

$S_i\neq\emptyset$, $i=1,\ldots,k$, and

$$\textbf{(iii)}\quad (U^s,U^{s'})=d(I_s\cap I_{s'})+\frac{d(I_s)d(I_{s'})}{2-D}+\chi_s\chi_{s'}\lambda_{a_s\alpha}\lambda_{a_{s'}\beta}h^{\alpha\beta}=0, \tag{4.4}$$

for all $s=(a_s,v_s,I_s)\in S_i$, $s'=(a_{s'},v_{s'},I_{s'})\in S_j$, $i\neq j$; $i,j=1,\ldots,k$. Relation (4.3) means that the set S is a union of k nonintersecting (nonempty) subsets $S_1,\ldots,S_k$. According to (4.4) the set of vectors $(U^s, s\in S)$ has a block-orthogonal structure with respect to the scalar product (3.18), i.e., it splits into k mutually orthogonal blocks $(U^s, s\in S_i)$, $i=1,\ldots,k$.

From **(i)** we get for the potential (3.15)

$$V=\tfrac{1}{2}w\xi_0 d_0 e^{2U^0(x)}, \tag{4.5}$$

where

$$(U^0,U^0)=\frac{1}{d_0}-1<0 \tag{4.6}$$

[see (3.21)].

From **(ii)** and (3.23) we get

$$(U^0,U^s)=0 \tag{4.7}$$

for all $s\in S$. Thus, the set of co-vectors U^0, $U^s, s\in S$ [belonging to dual space $(\mathbb{R}^{n+1+l})^*\simeq\mathbb{R}^{n+1+l}$] has also a block-orthogonal structure with respect to the scalar product (3.18).

Here we will integrate the Lagrange equations corresponding to the Lagrangian (3.2) and hence we will find classical exact solutions when the restrictions (A2) and (A3) from Appendix A are imposed.

First we integrate the ''Maxwell equations'' (for $s \in S_e$) and Bianchi identities (for $s \in S_m$):

$$\frac{d}{du}(\exp(-2U^s)\dot{\Phi}^s)=0 \Leftrightarrow \dot{\Phi}^s = Q_s \exp(2U^s), \tag{4.8}$$

where Q_s are constants, $s \in S$. We put

$$Q_s \neq 0, \tag{4.9}$$

for all $s \in S$.

Let us fix the time gauge as follows:

$$\gamma = \gamma_0, \quad \mathcal{N}=1, \tag{4.10}$$

i.e., the harmonic time gauge is used.

For fixed $Q=(Q_s, s \in S)$ the Lagrange equations for the Lagrangian (3.2) corresponding to $(x^A)=(\phi^i,\varphi^\alpha)$, when relations (4.10) and (4.8) are substituted, are equivalent to the Lagrange equations for the Lagrangian[23]

$$L_Q = \tfrac{1}{2}\bar{G}_{AB}\dot{x}^A\dot{x}^B - V_Q, \tag{4.11}$$

with the zero-energy constraint

$$E_Q = \tfrac{1}{2}\bar{G}_{AB}\dot{x}^A\dot{x}^B + V_Q = 0, \tag{4.12}$$

where

$$V_Q = V + \frac{1}{2}\sum_{s \in S} \varepsilon_s Q_s^2 \exp[2U^s(x)], \tag{4.13}$$

$(\bar{G}_{AB})$ and V are defined in (3.12) and (4.5), respectively.

When the conditions **(i)**–**(iii)** are satisfied exact solutions to Lagrange equations corresponding to (4.11) with the potential (4.13) and V from (4.5) could be readily obtained using the relations from Appendix B.

The solutions read

$$x^A(u) = -\frac{U^{0A}}{(U^0,U^0)}\ln|f_0(u)| - \sum_{s \in S}\eta_s \nu_s^2 U^{sA}\ln|f_s(u)| + c^A u + \bar{c}^A. \tag{4.14}$$

Functions f_0 and f_s in (4.14) are the following:

$$f_0(u) = |\xi_0(d_0-1)|^{1/2} s(u-u_0, w\xi_0, C_0) \tag{4.15}$$

$$= \left|\frac{\xi_0(d_0-1)}{C_0}\right|^{1/2} \mathrm{sh}(\sqrt{C_0}(u-u_0)), C_0>0, \xi_0 w>0; \tag{4.16}$$

$$= \left|\frac{\xi_0(d_0-1)}{C_0}\right|^{1/2} \sin(\sqrt{|C_0|}(u-u_0)), C_0<0, \xi_0 w>0; \tag{4.17}$$

$$= \left| \frac{\xi_0(d_0-1)}{C_0} \right|^{1/2} \mathrm{ch}(\sqrt{C_0}(u-u_0)), C_0>0, \xi_0 w<0; \tag{4.18}$$

$$= |\xi_0(d_0-1)|^{1/2}(u-u_0), C_0=0, \xi_0 w>0; \tag{4.19}$$

and

$$f_s(u) = \frac{|Q_s|}{|\nu_s|} s(u-u_s, -\eta_s\varepsilon_s, C_s) \tag{4.20}$$

$$= \frac{|Q_s|}{|\nu_s||C_s|^{1/2}} \mathrm{sh}(\sqrt{C_s}(u-u_s)), \quad C_s>0, \quad \eta_s\varepsilon_s<0; \tag{4.21}$$

$$= \frac{|Q_s|}{|\nu_s||C_s|^{1/2}} \sin(\sqrt{|C_s|}(u-u_s)), \quad C_s<0, \quad \eta_s\varepsilon_s<0; \tag{4.22}$$

$$= \frac{|Q_s|}{|\nu_s||C_s|^{1/2}} \mathrm{ch}(\sqrt{C_s}(u-u_s)), \quad C_s>0, \quad \eta_s\varepsilon_s>0; \tag{4.23}$$

$$\frac{|Q_s|}{|\nu_s|}(u-u_s), \quad C_s=0, \quad \eta_s\varepsilon_s<0; \tag{4.24}$$

where C_0, C_s, u_0, u_s are constants, $s \in S$. The function $s(u,\xi,C)$ is defined in Appendix B.

The parameters $\eta_s = \pm 1$, $\nu_s \neq 0$, $s \in S$, satisfy the relations

$$\sum_{s' \in S} (U^s, U^{s'}) \eta_{s'} \nu_{s'}^2 = 1, \tag{4.25}$$

for all $s \in S$, with scalar products $(U^s, U^{s'})$ defined in (3.22).

The constants C_s, u_s are coinciding inside blocks:

$$u_s = u_{s'}, \quad C_s = C_{s'}, \tag{4.26}$$

$s, s' \in S_i$, $i = 1, \ldots, k$ [see relation (B13) from Appendix B]. The ratios $\varepsilon_s Q_s^2/(\eta_s \nu_s^2)$ are also coinciding inside blocks, or, equivalently,

$$\varepsilon_s \eta_s = \varepsilon_{s'} \eta_{s'}, \tag{4.27}$$

$$\frac{Q_s^2}{\nu_s^2} = \frac{Q_{s'}^2}{\nu_{s'}^2}, \tag{4.28}$$

$s, s' \in S_i$, $i = 1, \ldots, k$. Here we used the relations (4.6) and (4.7).

The contravariant components $U^{rA} = \bar{G}^{AB} U_B^r$ are[23]

$$U^{0i} = -\frac{\delta_0^i}{d_0}, \quad U^{0\alpha} = 0, \tag{4.29}$$

$$U^{si} = G^{ij} U_j^s = \delta_{iI_s} - \frac{d(I_s)}{D-2}, \quad U^{s\alpha} = -\chi_s \lambda_{a_s}^{\alpha}. \tag{4.30}$$

Using (4.14), (4.6), (4.30), and (4.29) we obtain

$$\phi^i = \frac{\delta_0^i}{1-d_0} \ln|f_0| - \sum_{s \in S} \eta_s \nu_s^2 \left(\delta_{iI_s} - \frac{d(I_s)}{D-2} \right) \ln|f_s| + c^i u + \bar{c}^i \tag{4.31}$$

and

$$\varphi^\alpha = \sum_{s \in S} \eta_s \nu_s^2 \chi_s \lambda_{a_s}^\alpha \ln|f_s| + c^\alpha u + \bar{c}^\alpha, \tag{4.32}$$

$\alpha = 1, \dots, l$.

Vectors $c = (c^A)$ and $\bar{c} = (\bar{c}^A)$ satisfy the linear constraint relations [see (B20) in Appendix B]

$$U^0(c) = U_A^0 c^A = -c^0 + \sum_{j=0}^n d_j c^j = 0, \tag{4.33}$$

$$U^0(\bar{c}) = U_A^0 \bar{c}^A = -\bar{c}^0 + \sum_{j=0}^n d_j \bar{c}^j = 0, \tag{4.34}$$

$$U^s(c) = U_A^s c^A = \sum_{i \in I_s} d_i c^i - \chi_s \lambda_{a_s \alpha} c^\alpha = 0, \tag{4.35}$$

$$U^s(\bar{c}) = U_A^s \bar{c}^A = \sum_{i \in I_s} d_i \bar{c}^i - \chi_s \lambda_{a_s \alpha} \bar{c}^\alpha = 0, \tag{4.36}$$

$s \in S$. The (3.4) reads

$$\gamma_0(\phi) = \frac{d_0}{1-d_0} \ln|f_0| + \sum_{s \in S} \frac{d(I_s)}{D-2} \eta_s \nu_s^2 \ln|f_s| + c^0 u + \bar{c}^0. \tag{4.37}$$

The zero-energy constraint reads (see Appendix B)

$$E = E_0 + \sum_{s \in S} E_s + \frac{1}{2} \bar{G}_{AB} c^A c^B = 0, \tag{4.38}$$

where $E_0 = C_0 (U^0, U^0)^{-1}/2$, $E_s = C_s (\eta_s \nu_s^2)/2$. Using relations (3.10), (3.12), (4.6), and (4.33) we rewrite (4.38) as

$$C_0 \frac{d_0}{d_0 - 1} = \sum_{s \in S} C_s \nu_s^2 \eta_s + h_{\alpha\beta} c^\alpha c^\beta + \sum_{i=1}^n d_i (c^i)^2 + \frac{1}{d_0 - 1} \left(\sum_{i=1}^n d_i c^i \right)^2. \tag{4.39}$$

From relation

$$\exp(2U^s) = f_s^{-2}, \tag{4.40}$$

following from (4.4), (4.7), (4.14), (4.35), and (4.36) we get for electric-type forms (2.19)

$$\mathcal{F}^s = Q_s f_s^{-2} du \wedge \tau(I_s), \tag{4.41}$$

$s \in S_e$, and for magnetic-type forms (2.20)

$$\mathcal{F}^s = e^{-2\lambda_a(\varphi)} * [Q_s f_s^{-2} du \wedge \tau(I_s)] = \bar{Q}_s \tau(\bar{I}_s), \tag{4.42}$$

$s \in S_m$, where $\overline{Q_s} = Q_s \varepsilon(I_s)\mu(I_s)w$ and $\mu(I) = \pm 1$ is defined by the relation $\mu(I) du \wedge \tau(I_0) = \tau(\overline{I}) \wedge du \wedge \tau(I)$. The relation (4.42) follows from the formula (5.26) from Ref. 6 (for $\gamma = \gamma_0$).

Relations for the metric follows from (4.31) and (4.37)

$$g = \left(\prod_{s \in S} [f_s^2(u)]^{\eta_s d(I_s)\nu_s^2/(D-2)} \right) \Bigg\{ [f_0^2(u)]^{d_0/(1-d_0)} e^{2c^0 u + 2\overline{c^0}} [w\, du \otimes du + f_0^2(u) g^0] + \sum_{i=1}^{n} \left(\prod_{s \in S} [f_s^2(u)]^{-\eta_s \nu_s^2 \delta_{iI_s}} \right) e^{2c^i u + 2\overline{c^i}} g^i \Bigg\}. \tag{4.43}$$

Thus, here we obtained the ''block-orthogonal'' generalization of the solution from Ref. 23. This solution describes the evolution of $n+1$ spaces $(M_0, g_0), \ldots, (M_n, g_n)$, where (M_0, g_0) is an Einstein space of nonzero curvature, and (M_i, g^i) are ''internal'' Ricci-flat spaces, $i = 1, \ldots, n$; in the presence of several scalar fields and forms. The solution is presented by relations (4.32), (4.41)–(4.43) with the functions f_0, f_s defined in (4.15)–(4.24) and the relations on the parameters of solutions c^A, $\overline{c^A}$ $(A = i, \alpha)$, C_0, C_s, u_s, Q_s, η_s, ν_s $(s \in S)$ imposed in (4.25)–(4.28), (4.33)–(4.36), (4.39), respectively.

This solution describes a set of charged (by forms) overlapping p-branes $[p_s = d(I_s) - 1$, $s \in S]$ ''living'' on submanifolds (isomorphic to) M_{I_s} (2.16), where the sets I_s do not contain 0, i.e., all p-branes live in ''internal'' Ricci-flat spaces.

The solution is valid if the dimensions of p-branes and dilatonic coupling vector satisfy the relations (4.4). In ''orthogonal'' noncomposite case these solutions were considered in Refs. 29 and 28 (electric case) and Ref. 35 (electro-magnetic case). For $n = 1$ see also Refs. 24 and 27. In block-orthogonal (noncomposite) case a special class of solutions with ν_s^2 coinciding inside blocks was considered earlier in Ref. 36.

V. SPHERICALLY SYMMETRIC SOLUTIONS

Here we consider the spherically symmetric case

$$w = 1, \quad M_0 = S^{d_0}, \quad g^0 = d\Omega_{d_0}^2, \tag{5.1}$$

where $d\Omega_{d_0}^2$ is the canonical metric on a unit sphere S^{d_0}, $d \geqslant 2$. We also assume that

$$M_1 = \mathbb{R}, \quad g^1 = -dt \otimes dt \tag{5.2}$$

(here M_1 is a time manifold) and

$$1 \in I_s, \quad \forall s \in S, \tag{5.3}$$

i.e., all p-branes have a common time direction t.

For integration constants we put $\overline{c^A} = 0$,

$$c^A = \overline{\mu}(\overline{b^A} - b^A), \tag{5.4}$$

$$\overline{b^A} = \overline{\mu} \sum_{r \in S} \eta_r \nu_r^2 U^{rA} - \overline{\mu} \delta_1^A, \tag{5.5}$$

$$C_0 = \overline{\mu}^2, \tag{5.6}$$

$$C_s = \overline{\mu}^2 b_s^2, \quad b_s > 0, \tag{5.7}$$

where $\bar{\mu}>0$, $\bar{S}=\{0\}\cup S$ and $\eta_0\nu_0^2=(U^0,U^0)^{-1}$.

The only essential restrictions imposed are the inequalities $C_0,C_s>0$ that cut a subclass in the class of solutions from Sec. IV. This subclass contains nonextremal black hole solutions and its ''Kasner-like'' (non-black-hole) deformations. For extremal black hole solutions one should consider the special case $C_0=C_s=0$. (For extremal black hole solutions and its multicenter generalizations see Ref. 14.)

Due to (4.26) the parameters b_s, $s\in S$, are coinciding inside blocks:

$$b_s=b_{s'}, \tag{5.8}$$

$s,s'\in S_i$, $i=1,\dots,k$.

It may be verified that the restrictions (4.33) and (4.35) are satisfied identically if and only if

$$U^0(b)=U_A^0 b^A=-b^0+\sum_{j=0}^{n} d_j b^j=1, \tag{5.9}$$

$$U^s(b)=U_A^s b^A=\sum_{i\in I_s} d_i b^i-\chi_s\lambda_{a_s\alpha}b^\alpha=1, \tag{5.10}$$

$s\in S$. This follows from identities $U^0(\bar{b})=1$ and $U^s(\bar{b})=1$, $s\in S$.

Relation (4.39) reads

$$\sum_{s\in S}\eta_s\nu_s^2(b_s^2-1)+h_{\alpha\beta}b^\alpha b^\beta+\sum_{i=1}^{n} d_i(b^i)^2+\frac{1}{d_0-1}\left(\sum_{i=1}^{n} d_i b^i\right)^2=\frac{d_0}{d_0-1}, \tag{5.11}$$

where the relation [equivalent to (5.9)]

$$b^0=\frac{1}{1-d_0}\left[\sum_{j=1}^{n} d_j b^j-1\right], \tag{5.12}$$

is used.

Now we rewrite a solution (under restrictions imposed) in a so-called ''Kasner-type'' form that is more suitable for analyzing the behavior at large distances and for singling out the black hole solutions. For this reason we introduce a new radial variable $R=R(u)$ by relations

$$\exp(-2\bar{\mu}u)=1-\frac{2\mu}{R^{\bar{d}}},\quad \mu=\bar{\mu}/\bar{d}>0,\quad \bar{d}=d_0-1, \tag{5.13}$$

$u>0$, $R^{\bar{d}}>2\mu$. For the function

$$f_s(u)=\frac{|Q_s|}{2\bar{\mu}b_s|\nu_s|}[\exp(\bar{\mu}b_s(u-u_s))+\eta_s\varepsilon_s\exp(-\bar{\mu}b_s(u-u_s))] \tag{5.14}$$

we put the restriction $f_s(0)=1$, or, equivalently,

$$\exp(-\bar{\mu}b_s u_s)+\eta_s\varepsilon_s\exp(\bar{\mu}b_s u_s)=\frac{2\bar{\mu}b_s|\nu_s|}{|Q_s|}. \tag{5.15}$$

This restriction guarantees the asymptotical flatness of the $(2+d_0)$-dimensional section of the metric in the limit $R\to+\infty$ (or, when, $u\to+0$). It follows from (5.15) that $u_s<0$ for $\eta_s\varepsilon_s=-1$. In any case $f_s(u)>0$ for $u\geq 0$.

Then, solutions for the metric and scalar fields [see (4.32) and (4.43)] may be written as follows:

$$g=\left(\prod_{s\in S}\bar{H}_s^{2\eta_s d(I_s)\nu_s^2/(D-2)}\right)\left\{F^{b^0-1}dR\otimes dR+R^2F^{b^0}d\Omega^2_{d_0}\right.$$
$$\left.-\left(\prod_{s\in S}\bar{H}_s^{-2\eta_s\nu_s^2}\right)F^{b^1}dt\otimes dt+\sum_{i=2}^{n}\left(\prod_{s\in S}\bar{H}_s^{-2\eta_s\nu_s^2\delta_{iI_s}}\right)F^{b^i}g^i\right\}, \tag{5.16}$$

$$\varphi^\alpha=\sum_{s\in S}\eta_s\nu_s^2\chi_s\lambda_{a_s}^\alpha\ln\bar{H}_s+\frac{1}{2}b^\alpha\ln F, \tag{5.17}$$

where

$$F=1-\frac{2\mu}{R^{\bar{d}}}, \tag{5.18}$$

$$\bar{H}_s=\hat{H}_sF^{(1-b_s)/2}, \tag{5.19}$$

$$\hat{H}_s=1+\hat{P}_s\frac{(1-F^{b_s})}{2\mu b_s}, \tag{5.20}$$

$$\hat{P}_s=-\varepsilon_s\eta_sP_s, \tag{5.21}$$

$$P_s=\frac{|Q_s|}{\bar{d}|\nu_s|}\exp(\mu u_s)>0, \tag{5.22}$$

$s\in S$. Due to (4.26)–(4.28) parameters P_s and $\hat{P}_s$ are coinciding inside blocks:

$$P_s=P_{s'},\quad \hat{P}_s=\hat{P}_{s'}, \tag{5.23}$$

$s,s'\in S_i$, $i=1,\dots,k$. Parameters b_s are also coinciding inside blocks, see (5.8). Parameters b_s, b^i, b^α obey the relations (5.10)–(5.12).

The fields of forms are given by (2.19) and (2.20) with

$$\Phi^s=\frac{\nu_s}{H_s'}, \tag{5.24}$$

$$H_s'=\left[1-P_s'\hat{H}_s^{-1}\frac{(1-F^{b_s})}{2\mu b_s}\right]^{-1}, \tag{5.25}$$

$$P_s'=-\frac{Q_s}{\nu_s\bar{d}}, \tag{5.26}$$

$s\in S$. It follows from (5.15), (5.20), (5.21), and (5.26) that

$$(P_s')^2=P_s(\hat{P}_s+2b_s\mu)=-\varepsilon_s\eta_s\hat{P}_s(\hat{P}_s+2b_s\mu), \tag{5.27}$$

$s\in S$. This relation is self-consistent, i.e., its left- and right-hand sides have the same sign, since due to (5.15) and (5.22):

$$P_s < 2\mu b_s \tag{5.28}$$

for $\varepsilon_s \eta_s = +1$ and hence

$$\hat{P}_s > -2 b_s \mu, \tag{5.29}$$

for all $s \in S$.

Remark: The black hole solution from Ref. 14 may be obtained from our spherically-symmetric solutions (5.16)–(5.27) when

$$b^1 = b_s = 1, \quad b^i = b^\alpha = 0, \tag{5.30}$$

$s \in S$, $i = 0,2, \ldots ,n$; $\alpha = 1, \ldots ,l$. For details see Ref. 41.

We note that the obtained solution generalizes the solutions from Ref. 42 (in the pure gravitational case) and Ref. 43 (in the case of gravity with one scalar field).

VI. POST-NEWTONIAN APPROXIMATION

Let $d_0 = 2$. Here we consider the four-dimensional section of the metric (5.16)

$$g^{(4)} = U\{F^{b^0 - 1} dR \otimes dR + F^{b^0} R^2 d\Omega_2^2 - U_1 F^{b^1} dt \otimes dt\}, \tag{6.1}$$

where $F = 1 - (2\mu/R)$, and

$$U = \prod_{s \in S} \bar{H}_s^{2\eta_s d(I_s) \nu_s^2/(D-2)}, \tag{6.2}$$

$$U_1 = \prod_{s \in S} \bar{H}_s^{-2\eta_s \nu_s^2}, \tag{6.3}$$

$$U_i = \prod_{s \in S} \bar{H}_s^{-2\eta_s \nu_s^2 \delta_{iI_s}}, \quad i > 1, \tag{6.4}$$

$R > 2\mu$.

We may suppose that some real astrophysical objects (e.g., stars) are described by the four-dimensional ''physical'' metric (6.1), i.e., they are ''traces'' of extended multidimensional objects (charged *p*-branes).

Introducing a new radial variable ρ by the relation

$$R = \rho \left(1 + \frac{\mu}{2\rho} \right)^2, \tag{6.5}$$

$(\rho > \mu/2)$, we rewrite the metric (6.1) in a three-dimensional conformally flat form

$$g^{(4)} = U\left\{ -U_1 F^{b^1} dt \otimes dt + F^{b^0} \left(1 + \frac{\mu}{2\rho} \right)^4 \delta_{ij} dx^i \otimes dx^j \right\}, \tag{6.6}$$

$$F = \left(1 - \frac{\mu}{2\rho} \right)^2 \left(1 + \frac{\mu}{2\rho} \right)^{-2}, \tag{6.7}$$

where $\rho^2 = |x|^2 = \delta_{ij} x^i x^j$ $(i,j = 1,2,3)$.

For possible physical applications we should calculate the post-Newtonian parameters β and γ (Eddington parameters) using the following relations (see, for example, Ref. 44 and references therein)

$$g_{00}^{(4)} = -(1-2V+2\beta V^2) + O(V^3), \tag{6.8}$$

$$g_{ij}^{(4)} = \delta_{ij}(1+2\gamma V) + O(V^2), \tag{6.9}$$

$i,j=1,2,3$, where

$$V = \frac{GM}{\rho} \tag{6.10}$$

is the Newton's potential, G is the gravitational constant, M is the gravitational mass. From (6.6)–(6.10) we get

$$GM = \mu b^1 + \sum_{s\in S} \eta_s \nu_s^2 [\hat{P}_s + (b_s - 1)\mu]\left(1 - \frac{d(I_s)}{D-2}\right) \tag{6.11}$$

and for $GM \neq 0$

$$\beta - 1 = \frac{1}{2(GM)^2} \sum_{s\in S} \eta_s \nu_s^2 \hat{P}_s (\hat{P}_s + 2 b_s \mu)\left(1 - \frac{d(I_s)}{D-2}\right), \tag{6.12}$$

$$\gamma - 1 = -\frac{1}{GM}\left[\mu(b^0 + b^1 - 1) + \sum_{s\in S} \eta_s \nu_s^2 [\hat{P}_s + (b_s - 1)\mu]\left(1 - 2\frac{d(I_s)}{D-2}\right)\right]. \tag{6.13}$$

It follows from (5.27) and (6.12) and the inequalities $d(I_s) < D-2$ (for all $s \in S$) that the following inequalities take place:

$$\beta > 1, \text{ if all } \varepsilon_s = -1, \tag{6.14}$$

$$\beta < 1, \text{ if all } \varepsilon_s = +1. \tag{6.15}$$

There exists a large variety of configurations with $\beta = 1$ when the relation $\varepsilon_s = \text{const}$ is broken.

There exist also nontrivial p-brane configurations with $\gamma = 1$.

Proposition: Let the set of p-branes consist of several pairs of electric and magnetic branes. Let any such pair $(s, \bar{s} \in S)$ correspond to the same color index, i.e., $a_s = a_{\bar{s}}$, and $\hat{P}_s = \hat{P}_{\bar{s}}$, $b_s = b_{\bar{s}}$, $\eta_s \nu_s^2 = \eta_{\bar{s}} \nu_{\bar{s}}^2$. Then for $b^0 + b^1 = 1$ we get

$$\gamma = 1. \tag{6.16}$$

The proposition can be readily proved using the relation $d(I_s) + d(I_{\bar{s}}) = D-2$, following from (2.25) and (2.26).

Observational restrictions: The observations in the solar system give the tight constraints on the Eddington parameters[44]

$$\gamma = 1.000 \pm 0.002, \tag{6.17}$$

$$\beta = 0.9998 \pm 0.0006. \tag{6.18}$$

The first restriction is a result of the Viking time-delay experiment.[45] The second restriction follows from (6.17) and the analysis of the laser ranging data to the Moon. In this case a high precision test based on the calculation of the combination $(4\beta - \gamma - 3)$ appearing in the Nordtvedt effect[46] is used.[47] We note, that as it was pointed in Ref. 44 the ''classic'' tests of general relativity, i.e., the Mercury-perihelion and light deflection tests, are somewhat outdated.

For small enough $\hat{p}_s = \hat{P}_s / GM$, $b_s - 1$, $b^1 - 1$, b^i $(i > 1)$ of the same order we get $GM \sim \mu$ and hence

$$\beta-1\sim\sum_{s\in S}\eta_s\nu_s^2\hat{p}_s\left(1-\frac{d(I_s)}{D-2}\right), \tag{6.19}$$

$$\gamma-1\sim-b^0-b^1+1-\sum_{s\in S}\eta_s\nu_s^2[\hat{p}_s+b_s-1]\left(1-2\frac{d(I_s)}{D-2}\right), \tag{6.20}$$

i.e., $\beta-1$ and $\gamma-1$ are of the same order. Thus for small enough $\hat{p}_s$, b_s-1, b^1-1, b^i $(i>1)$ it is possible to fit the ''solar system'' restrictions (6.17) and (6.18).

There exists also another possibility to satisfy these restrictions.

One brane case: Let us consider a special case of one p-brane. In this case we have

$$\eta_s\nu_s^{-2}=d(I_s)\left(1-\frac{d(I_s)}{D-2}\right)+\lambda^2. \tag{6.21}$$

Relations (6.12), (6.13), and (6.21) imply that for large enough values of (dilatonic coupling constant squared) λ^2 and $b^0+b^1=1$ it is possible to perform the ''fine tuning'' the parameters (β,γ) near the point (1, 1) even if the parameters $\hat{P}_s$ are big.

VII. CONCLUSIONS

In this paper we obtained exact solutions to Einstein equations for the multidimensional cosmological model describing the evolution of n Ricci-flat spaces and one Einstein space M_0 of nonzero curvature in the presence of composite electro-magnetic p-branes. The solutions were obtained in the block-orthogonal case (4.4), when p-branes do not ''live'' in M_0. We also considered the spherically symmetric solutions containing nonextremal p-brane black holes.[36,14] The relations for post-Newtonian parameters β and γ are obtained.

APPENDIX A: RESTRICTIONS ON *p*-BRANE CONFIGURATIONS

Restrictions on $\Omega_{a,v}$*:*[23] Let

$$w_1\equiv\{i|i\in\{0,\ldots,n\},d_i=1\}. \tag{A1}$$

The set w_1 describes all one-dimensional manifolds among M_i $(i\geqslant 0)$. We impose the following restrictions on the sets $\Omega_{a,v}$ (2.21):

$$W_{ij}(\Omega_{a,v})=\varnothing, \tag{A2}$$

$a\in\Delta;\ v=e,m;\ i,j\in w_1,\ i<j$ and

$$W_j^{(1)}(\Omega_{a,m},\Omega_{a,e})=\varnothing, \tag{A3}$$

$a\in\Delta;\ j\in w_1$. Here

$$W_{ij}(\Omega_*)\equiv\{(I,J)|I,J\in\Omega_*,\ \ I=\{i\}\sqcup(I\cap J),\quad J=\{j\}\sqcup(I\cap J)\}, \tag{A4}$$

$i,j\in w_1,\ i\neq j,\ \Omega_*\subset\Omega_0$ and

$$W_j^{(1)}(\Omega_{a,m},\Omega_{a,e}) \equiv \{(I,J) \in \Omega_{a,m} \times \Omega_{a,e} | \bar{I} = \{j\} \sqcup J\}, \tag{A5}$$

$j \in w_1$. In (A5)

$$\bar{I} \equiv I_0 \setminus I \tag{A6}$$

is ''dual'' set, ($I_0 = \{0,1,\ldots,n\}$).

The restrictions (A2) and (A3) are trivially satisfied when $n_1 \leqslant 1$ and $n_1 = 0$, respectively, where $n_1 = |w_1|$ is the number of one-dimensional manifolds among M_i. They are also satisfied in the noncomposite case when all $|\Omega_{a,v}| = 1$. For $n_1 \geqslant 2$ and $n_1 \geqslant 1$, respectively, these restrictions forbid certain pairs of two p-branes, corresponding to the same form $F^a, a \in \Delta$:

APPENDIX B: SOLUTIONS WITH BLOCK-ORTHOGONAL SET OF VECTORS

Let

$$L = \frac{1}{2}\langle \dot{x}, \dot{x} \rangle - \sum_{s \in S} A_s \exp(2\langle b_s, x \rangle) \tag{B1}$$

be a Lagrangian, defined on $V \times V$, where V is a n-dimensional vector space over $\mathbb{R}$, $A_s \neq 0$, $s \in S$; $S \neq \emptyset$, and $\langle \cdot, \cdot \rangle$ is a nondegenerate real-valued quadratic form on V. Let

$$S = S_1 \sqcup \cdots \sqcup S_k, \tag{B2}$$

all $S_i \neq \emptyset$, and

$$\langle b_s, b_{s'} \rangle = 0, \tag{B3}$$

for all $s \in S_i$, $s' \in S_j$, $i \neq j$; $i,j = 1,\ldots,k$.

Let us suppose that there exists a set $h_s \in \mathbb{R}$, $h_s \neq 0$, $s \in S$, such that

$$\sum_{s \in S} \langle b_s, b_{s'} \rangle h_{s'} = -1, \tag{B4}$$

for all $s \in S$, and

$$\frac{A_s}{h_s} = \frac{A_{s'}}{h_{s'}}, \tag{B5}$$

$s,s' \in S_i$, $i = 1,\ldots,k$, (the ratio A_s/h_s is constant inside S_i).

Then, the Euler–Lagrange equations for the Lagrangian (B1)

$$\ddot{x} + \sum_{s \in S} 2A_s b_s \exp(2\langle b_s, x \rangle) = 0, \tag{B6}$$

have the following special solutions

$$x(t) = \frac{1}{2} \sum_{s \in S} h_s b_s \ln\left[y_s^2(t) \left| \frac{2A_s}{h_s} \right| \right] + \alpha t + \beta, \tag{B7}$$

where $\alpha, \beta \in V$,

$$\langle \alpha, b_s \rangle = \langle \beta, b_s \rangle = 0, \tag{B8}$$

$s \in S$, and functions $y_s(t) \neq 0$ satisfy the equations

$$\frac{d}{dt}\left(y_s^{-1}\frac{dy_s}{dt}\right)=-\xi_s y_s^{-2}, \tag{B9}$$

with

$$\xi_s=\mathrm{sign}\left(\frac{A_s}{h_s}\right), \tag{B10}$$

$s\in S$, and coincide inside blocks:

$$y_s(t)=y_{s'}(t), \tag{B11}$$

$s,s'\in S_i$, $i=1,\ldots,k$. More explicitly

$$y_s(t)=s(t-t_s,\xi_s,C_s), \tag{B12}$$

where constants $t_s,C_s\in\mathbb{R}$ coincide inside blocks

$$t_s=t_{s'},\quad C_s=C_{s'}, \tag{B13}$$

$s,s'\in S_i$, $i=1,\ldots,k$, and

$$s(t,\xi,C)\equiv\frac{1}{\sqrt{C}}\mathrm{sh}(t\sqrt{C}),\xi=+1,\quad C>0; \tag{B14}$$

$$\frac{1}{\sqrt{-C}}\sin(t\sqrt{-C}),\xi=+1,\quad C<0; \tag{B15}$$

$$t,\xi=+1,\quad C=0; \tag{B16}$$

$$\frac{1}{\sqrt{C}}\mathrm{ch}(t\sqrt{C}),\xi=-1,\quad C>0. \tag{B17}$$

For the energy

$$E=\frac{1}{2}\langle\dot{x},\dot{x}\rangle+\sum_{s\in S}A_s\exp(2\langle b_s,x\rangle) \tag{B18}$$

corresponding to the solution (B7) we have

$$E=\frac{1}{2}\sum_{s\in S}C_s(-h_s)+\frac{1}{2}\langle\alpha,\alpha\rangle. \tag{B19}$$

For dual vectors $u^s\in V^*$ defined as $u^s(x)=\langle b_s,x\rangle$, $\forall x\in V$, we have $\langle u^s,u^l\rangle_*=\langle b_s,b_l\rangle$, where $\langle\cdot,\cdot\rangle_*$ is dual form on V^*. The orthogonality conditions (B8) read

$$u^s(\alpha)=u^s(\beta)=0, \tag{B20}$$

$s\in S$.

Kostant's cubic Dirac operator of Lie superalgebras

Teparksorn Pengpan[a)]
Institute for Fundamental Theory, Department of Physics, University of Florida, Gainesville, Florida 32611

(Received 7 September 1999; accepted for publication 15 September 1999)

We extend equal rank embedding of reductive Lie algebras to that of basic Lie superalgebras. The Kac character formulas for equal rank embedding are derived in terms of subalgebras and Kostant's cubic Dirac operator for equal rank embedding of Lie superalgebras is constructed from both even and odd generators and their related structure constants.
[S0022-2488(99)03012-1]

I. INTRODUCTION

The study of some patterns,[1] connected with $N=1$ supergravity theory in 11 dimensions, has led to a recent understanding in terms of a Weyl character formula by GKRS,[2] based on equal rank embedding of reductive Lie algebras. By using the construction of equal rank embedding of reductive Lie algebras, all possible equal rank embeddings were catalogued, and nearly all supersymmetric multiplets of massless and massive particles that are already known in supersymmetric gauge field theories emerge as the lowest lines of the infinite tower multiplet spectra, some of them shown in detail in Ref. 1. Immediately after the appearance of the Weyl character formula for equal rank embedding as an index formula for the Dirac operator, Kostant moved the subject forward and related the multiplet spectrum to the kernel of a cubic Dirac operator, which he introduced around 30 years ago.[3]

In this paper, we extend the Gross–Kostant–Ramond–Sternberg (GKRS) Weyl character formula and Kostant's cubic Dirac operator for equal rank embedding of reductive Lie algebras to those of basic Lie superalgebras. In Sec. II, we give a brief review in GKRS's paper. A derivation of the Weyl character formula for an equal rank embedding is shown. In Sec. III, we extend the equal rank embedding construction of reductive Lie algebras shown in Sec. II to that of basic Lie superalgebras. The Kac character formulas are written in terms of equal rank subalgebras. In Sec. IV, we give a simple and explicit formulation for a typical representation of type I Lie superalgebras. In Sec. V, we build a multiplet of type I Lie superalgebras from that of reductive Lie algebras. In Sec. VI, Kostant's cubic Dirac operator is constructed for full Lie superalgebras and then for equal rank embeddings.

II. WEYL CHARACTER FORMULA AND EQUAL RANK EMBEDDINGS OF REDUCTIVE LIE ALGEBRAS

Let r be an equal rank subalgebra of reductive Lie algebras, g, and let **C** be of the order of C, the ratio of the Weyl group of g to that of r. The restricted conditions for this kind of equal rank embedding, $g\supset r$, are that (1) positive roots of g must contain those of r, i.e., $\Phi^+(g)\supset\Phi^+(r)$, and (2) the simple roots of g and r must be chosen consistently so that the positive Weyl chamber of r contains that of g. In the Cartan–Weyl basis, the c elements of the Weyl group in C acting on the sum of highest weight, λ, and the Weyl vector of g, ρ_g, and then after subtracting by the Weyl vector of r, ρ_r, generate **C** irreducible representations of r, called a **C** multiplet,

$$c\cdot\lambda := c(\lambda+\rho)_g-\rho_r\,.$$

[a)]Electronic mail: tpengpan@phys.ufl.edu

The Weyl character formula of the irreducible representation of g, V_λ, can be rewritten in terms of the irreducible representation of r, $U_{c\cdot\lambda}$, as follows:

$$\begin{aligned}\mathrm{ch}\,V_\lambda &= \frac{\Sigma_{w\in W(g)}\,\mathrm{sgn}(w)e^{w(\lambda+\rho_g)}}{\Sigma_{w\in W(g)}\,\mathrm{sgn}(w)e^{w\rho_g}}\\ &= \frac{\Sigma_{c\in C}\,\mathrm{sgn}(c)(\Sigma_{w_r\in W(r)}\,\mathrm{sgn}(w_r)e^{w_r(c\cdot\lambda+\rho_r)})}{(\Pi_{\phi\in\Phi^+(g/r)}(e^{\phi/2}-e^{-\phi/2}))(\Pi_{\phi\in\Phi+(r)}(e^{\phi/2}-e^{-\phi/2}))},\\ &= \frac{1}{\Delta}\sum_{c\in C}\,\mathrm{sgn}(c)\,\mathrm{ch}\,U_{c\cdot\lambda}, \end{aligned} \tag{1}$$

where Δ is the character difference of two spinor modules, S^+ and S^-, of $SO(p=g/r)$, i.e.,

$$\Delta := \prod_{\phi\in\Phi^+(g/r)} (e^{\phi/2}-e^{-\phi/2}) = \mathrm{ch}\,S^+ - \mathrm{ch}\,S^-.$$

The beauty of Eq. (1) is that it gives us

$$V_\lambda\otimes S^+ - V_\lambda\otimes S^- = \sum_{c\in C}\,\mathrm{sgn}(c)U_{c\cdot\lambda}. \tag{2}$$

Equation (2) should be viewed as an equation in the Grothendieck ring of r. The lhs is the character of the difference between two representations of the same dimension as the representation of g with highest weight λ, this representation restricted to r tensored with each of the half-spin representations of $\mathrm{SO}(p)$, where $p=\dim g-\dim r$, restricted to r. In the other words, the lhs is the algebraic index of the Dirac operator associated to λ and the two half-spin representations. The alternating sum on the rhs is just the dimension difference between the kernel and cokernel of the Dirac operator. All the representations on the rhs are inequivalent, and so the rhs is the end result of a lot of cancellation on the lhs, in short an index formula for the Dirac operator. One of the remarkable consequences of Eq. (2) is that, on the lhs, the order of difference of $V_\lambda\otimes S^+$ and $V_\lambda\otimes S^-$ is always equal to **C**, independent of λ, and, on the rhs, the multiplicity of each $U_{c\cdot\lambda}$ representation is exactly one.

Notice that **C** is equal to the Euler number, which is a topological invariant of the coset manifold, G/R, corresponding to exponentiation of g/r. From our catalog of equal rank embedding of reductive Lie algebras, we would like to give some examples of the coset manifolds, where supersymmetric multiplets appear to be in their lowest lines of the infinite tower multiplet spectra. $N=2$ hypermultiplet, $N=4$ vector multiplet, and $N=8$ supergravity multiplet, which undoubtedly emerge in the lowest lines of $\mathrm{SU}(N+1)\supset\mathrm{SU}(N)\times\mathrm{U}(1)$ and $\mathrm{SO}(N+2)\supset\mathrm{SO}(N)\times\mathrm{SO}(2)$ series live on the N-dimensional complex projective space and $(N+2)$-dimensional complex Grassmannian manifolds, respectively. If SO(2) or U(1) is viewed as the light-cone little group, these lowest line spectra are massless supermultiplets in four-dimensional space–time. Whereas $N=1$, $N=2$, $N=3$, and $N=4$ massive (massless) multiplets in four-dimensional (six-dimensional) space–time that emerge in the lowest lines of the $\mathrm{Sp}(2N+2)\supset\mathrm{Sp}(2N)\times\mathrm{Sp}(2)$ series live on N-dimensional quaternionic projective space. The last multiplet that we would like to mention is the $N=1$ massless (massive) supergravity triplet in 11-dimensional (10-dimensional) space–time. The triplet emerges from $F_4\supset\mathrm{SO}(9)$ and lives on a (16-dimensional) Cayley plane. All infinite tower multiplet spectra are a kernel of Kostant's cubic Dirac operator, $\not{\mathcal{K}}$,

$$\mathrm{Ker}(\not{\mathcal{K}}_\lambda^2) = \mathrm{Ker}(\not{\mathcal{K}}_\lambda) = \sum_{c\in C}\,\mathrm{sgn}(c)U_{c\cdot\lambda}.$$

For more analytical details on Kostant's operator, see Ref. 4.

III. KAC CHARACTER FORMULAS AND EQUAL RANK EMBEDDING OF BASIC LIE SUPERALGEBRAS

Now, we extend the results of reductive Lie algebras to Lie superalgebras with nondegenerate Killing form. According to Kac's classification,[5] there are two types of basic Lie superalgebras type I, which is $su(m|n)$ and $osp(2|2n)$ and type II, which is $osp(2m+1|2n)$, $osp(1|2n)$, $osp(2m|2n)$, $osp(4|2;\alpha)$, $F(4)$, and $G(3)$.

Let $g=g_{\mathrm{even}}\oplus g_{\mathrm{odd}}$ be the Lie superalgebras with the root system $\Phi=\Phi_{\mathrm{even}}\cup\Phi_{\mathrm{odd}}$. For type I, g_{even} is simple, i.e., $g_{\mathrm{even}}=g_0$, and, for type II, g_{even} can be graded into $g_2\oplus g_0\oplus g_{-2}$. While, for the odd part of both type I and II, odd generators can be graded into fermionic creation and annihilation ones, i.e. $g_{\mathrm{odd}}=g_1\oplus g_{-1}$. The Poincaré–Birkhoff–Witt theorem for Lie algebras can be applied to the case of Lie superalgebras with some extension.[6] This grading gives us a universal enveloping algebra, $\mathcal{U}(g)$, e.g., for type I,

$$\mathcal{U}(g)=\mathcal{U}(g_1)\otimes\mathcal{U}(g_0)\otimes\mathcal{U}(g_{-1}).$$

Define root subsystems, $\bar{\Phi}_{\mathrm{even}}$ and $\bar{\Phi}_{\mathrm{odd}}$, such that $\bar{\Phi}_{\mathrm{even}}=\{\alpha|\alpha/2\notin\Phi_{\mathrm{odd}}\}$ and $\bar{\Phi}_{\mathrm{odd}}=\{\beta|2\beta\notin\Phi_{\mathrm{even}}\}$. Since Φ_{even}, Φ_{odd}, $\bar{\Phi}_{\mathrm{even}}$, and $\bar{\Phi}_{\mathrm{odd}}$ are invariant under the action of the Weyl group of g_{even}. Hence, the Weyl group of g is equal to that of g_{even}, i.e., $W(g)=W(g_{\mathrm{even}})$. Define the Weyl vector of g to be one-half the sum of positive even roots minus one-half the sum of positive odd roots, i.e., $\rho=\rho_{\mathrm{even}}-\rho_{\mathrm{odd}}$. Let $V(\Lambda)$ be a representation of g with Λ as a highest weight in dual Cartan subalgebra. The highest weight representations of g are classified into typical and atypical. The representation is typical if, for $\forall\beta\in\bar{\Phi}^{+}_{\mathrm{odd}}(\Lambda+\rho,\beta)\neq 0$; otherwise, it is atypical. The typical Kac character and supercharacter formulas of $V(\Lambda)$ are defined, respectively, as

$$\mathrm{ch}\,V(\Lambda)=\frac{N_1}{N_0}\sum_{w\in W(g)}\mathrm{sgn}(w)e^{w(\Lambda+\rho)},\tag{3}$$

$$\mathrm{sch}\,V(\Lambda)=\frac{N_1'}{N_0}\sum_{w\in W(g)}\mathrm{sgn}(\bar{w})e^{w(\Lambda+\rho)},\tag{4}$$

where

$$N_0=\prod_{\alpha\in\Phi^{+}_{\mathrm{even}}}(e^{\alpha/2}-e^{-\alpha/2}),$$

$$N_1=\prod_{\beta_{+}\in\Phi^{+}_{\mathrm{odd}}}(e^{\beta/2}+e^{-\beta/2}),$$

and

$$N_1'=\prod_{\beta_{+}\in\Phi^{+}_{\mathrm{odd}}}(e^{\beta/2}-e^{-\beta/2}).$$

The sgn(w) and ($\bar{w}$) are sign change due to number of reflections with respect to Φ^{+}_{even} and $\bar{\Phi}^{+}_{\mathrm{even}}$.

In general, in an equal rank embedding of Lie superalgebras r in g with $\Phi^{+}(r)\subset\Phi^{+}(g)$ and **C** as an index of the Weyl group of r in the Weyl group of g, a **C** multiplet of r is obtained by

$$c\cdot\Lambda:=c(\Lambda+\rho)_g-\rho_r,$$

where $c\in C$. Under the condition that $\Phi^{+}_{\mathrm{even,odd}}(r)$ is invariant under the action of c, i.e., $c\cdot\Phi^{+}_{\mathrm{even,odd}}(r)=\Phi^{+}_{\mathrm{even,odd}}(r)$, the typical Kac character formula of g module $V(\Lambda)$ can be written in terms of the r module $U(c\cdot\Lambda)$ as follows:

$$\mathrm{ch}\,V(\Lambda)=\frac{\Pi_{\beta\in\Phi^{+}_{\mathrm{odd}}(g)}(e^{\beta/2}+e^{-\beta/2})}{\Pi_{\alpha\in\Phi^{+}_{\mathrm{even}}(g)}(e^{\alpha/2}+e^{-\alpha/2})}\sum_{w\in W(g)}\mathrm{sgn}(w)e^{w(\Lambda+\rho_g)}$$

$$=\left(\frac{\Pi_{\beta\in\Phi^{+}_{\mathrm{odd}}(g/r)}(e^{\beta/2}+e^{-\beta/2})}{\Pi_{\alpha\in\Phi^{+}_{\mathrm{even}}(g/r)}(e^{\alpha/2}-e^{-\alpha/2})}\right)\sum_{c\in C}\mathrm{sgn}\,(c)\mathrm{ch}\,U(c\cdot\Lambda). \tag{5}$$

Similarly done, the typical Kac supercharacter becomes

$$\mathrm{sch}\,V(\Lambda)=\left(\frac{\Pi_{\beta\in\Phi^{+}_{\mathrm{odd}}(g/r)}(e^{\beta/2}-e^{-\beta/2})}{\Pi_{\alpha\in\Phi^{+}_{\mathrm{even}}(g/r)}(e^{\alpha/2}-e^{-\alpha/2})}\right)\sum_{c\in C}\mathrm{sgn}(c)\mathrm{sch}\,U(c\cdot\Lambda). \tag{6}$$

For type I Lie superalgebras, there are both typical and atypical representations. For the typical representation, superdimension, $\mathrm{sdim}V(\Lambda)=\dim V_{\mathrm{even}}(\Lambda)-\dim V_{\mathrm{odd}}(\Lambda)$, is equal to zero. Whereas, $\mathrm{sdim}V(\Lambda)$ of the atypical representation is not. Every type I odd root is zero length and $\Phi^{+}_{\mathrm{even}}=\overline{\Phi}^{+}_{\mathrm{even}}$. Since ρ_{odd} is invariant under the action of the Weyl group, i.e., $w\rho_{\mathrm{odd}}=\rho_{\mathrm{odd}}$. The type I typical Kac character formula (3) can be written as

$$\mathrm{ch}\,V(\Lambda)=\prod_{\beta_+\in\Phi_1^+}(1+e^{-\beta})\mathrm{ch}\,V_0(\Lambda)=\prod_{\beta_-\in\Phi_1^-}(1+e^{\beta_-})\mathrm{ch}\,V_0(\Lambda). \tag{7}$$

Multiplying out the product factor on the rhs of Eq. (7), we obtain a Chern character of an exterior algebra over g_{-1},

$$\prod_{\beta-\in\Phi_1^-}(1+e^{\beta_-})=\sum_{n=0}^{n=\dim(\Phi^-_{-1})}\mathrm{ch}(\wedge^n g_{-1})=\mathrm{ch}(\wedge g_{-1}).$$

So, Eq. (7) simply becomes

$$\mathrm{ch}\,V(\Lambda)=\mathrm{ch}(\wedge g_{-1})\mathrm{ch}\,V_0(\Lambda). \tag{8}$$

Similarly, the type I typical Kac supercharacter can be shown to be

$$\mathrm{sch}\,V(\Lambda)=\prod_{\beta_-\in\Phi_1^-}(1-e^{\beta_-})\mathrm{ch}\,V_0(\Lambda)=\mathrm{sch}(\wedge g_{-1})\mathrm{ch}\,V_0(\Lambda). \tag{9}$$

On the other hand, since $\{g_{-1},g_{-1}\}=0$, the universal enveloping algebra over g_{-1}, $\mathcal{U}(g_{-1})$, is isomorphic to the exterior algebra over $g_{-1},\wedge(g_{-1})$. The g module $V(\Lambda)$ can be induced by applying the antisymmetric combinations of the g_{-1} generators on $V_0(\Lambda)$, i.e.,

$$V(\Lambda)=\wedge(g_{-1})\otimes V_0(\Lambda)\simeq\mathcal{U}(g_{-1})\otimes V_0(\Lambda). \tag{10}$$

The character and supercharacter of Eq. (10) are exactly Eq. (8) and Eq. (9).

In an equal rank embedding, $g\supset r$, of type I, which has **C** as an index of $W(r)$ in $W(g)$ and is restricted to the condition that $\Phi^{+}(g)\supset\Phi^{+}(r)$, Eq. (7) becomes

$$\mathrm{ch}\,V(\Lambda)=\frac{1}{\Delta}\prod_{\beta_-\in\Phi_1^-(g/r)}(1+e^{\beta_-})\sum_{c\in C}\mathrm{sgn}(c)\left(\prod_{\beta_-\in\Phi_1^-(r)}(1+e^{\beta_-})\mathrm{ch}\,U_0(c\cdot\Lambda)\right),$$

i.e.,

$$\mathrm{ch}\, V(\Lambda)(\mathrm{ch}\, S^{+}-\mathrm{ch}\, S^{-})=\mathrm{ch}(\wedge(g_{-1}/r_{-1}))\sum_{c\in C}\ \mathrm{sgn}(c)\mathrm{ch}\, U(c\cdot\Lambda). \tag{11}$$

Similarly done for the supercharacter, we obtain

$$\mathrm{sch}\, V(\Lambda)(\mathrm{ch}\, S^{+}-\mathrm{ch}\, S^{-})=\mathrm{sch}(\wedge(g_{-1}/r_{-1}))\sum_{c\in C}\ \mathrm{sgn}(c)\mathrm{sch}\, U(c\cdot\Lambda). \tag{12}$$

Equation (11) and Eq. (12) correspond to

$$V(\Lambda)\otimes S^{+}-V(\Lambda)\otimes S^{-}=\wedge(g_{-1}/r_{-1})\otimes\sum_{c\in C}\ \mathrm{sgn}(c)U(c\cdot\Lambda). \tag{13}$$

Now, Eq. (13) can also be derived explicitly from Eq. (10). By decomposing the g_{-1} basis such that $g_{-1}=(g_{-1}/r_{-1})\oplus r_{-1}$, there exists a map $(g_{-1}/r_{-1})\oplus r_{-1}\mapsto(g_{-1}/r_{-1})\otimes 1+1\otimes r_{-1}$ from $(g_{-1}/r_{-1})\oplus r_{-1}$ to $(g_{-1}/r_{-1})\otimes r_{-1}$, which extends uniquely to an isomorphism of exterior algebra,

$$\wedge(g_{-1}/r_{-1}\oplus r_{-1})\simeq\wedge(g_{-1}/r_{-1})\otimes\wedge(r_{-1}).$$

By substituting the above equation into Eq. (10) and tensoring on both sides by $(S^{+}-S^{-})$, we obtain

$$\begin{aligned}V(\Lambda)\otimes S^{+}-V(\Lambda)\otimes S^{-}&=\wedge(g_{-1}/r_{-1})\otimes\sum_{c\in C}\ \mathrm{sgn}(c)(\wedge(r_{-1})\otimes U_0(c\cdot\Lambda))\\&=\wedge(g_{-1}/r_{-1})\otimes\sum_{c\in C}\ \mathrm{sgn}(c)U(c\cdot\Lambda),\end{aligned}$$

which is exactly Eq. (13).

For $\mathrm{osp}(1|2n)$ of type II Lie superalgebras, every $\mathrm{osp}(1|2n)$ odd root has length equal to one-half the short positive one and

$$\rho_{\mathrm{osp}(1|2n)}=\rho_{\mathrm{even}}-\rho_{\mathrm{odd}}=(n-\tfrac{1}{2},n-\tfrac{3}{2},\ldots,\tfrac{1}{2}).$$

Furthermore, every $\mathrm{osp}(1|2n)$ representation is typical, but $\dim V_{\mathrm{even}}(\Lambda)\neq\dim V_{\mathrm{odd}}(\Lambda)$. Nevertheless, the Kac character and supercharacter formulas of an $\mathrm{osp}(1|2n)$ representation can be shown to be similar to that of Lie algebra, i.e.,

$$\mathrm{ch}\, V(\Lambda)=\frac{\Sigma_{w\in W}\,\mathrm{sgn}(w)e^{w(\Lambda+\rho)}}{\Sigma_{w\in W}\,\mathrm{sgn}(w)e^{w(\rho)}}, \tag{14}$$

$$\mathrm{sch}\, V(\Lambda)=\frac{\Sigma_{w\in W}\,\mathrm{sgn}(\overline{w})e^{w(\Lambda+\rho)}}{\Sigma_{w\in W}\,\mathrm{sgn}(\overline{w})e^{w(\rho)}}. \tag{15}$$

The equal rank embedding of $\mathrm{osp}(1|2m)\times\mathrm{osp}(1|2n-2m)$ in $\mathrm{osp}(1|2n)$ is the only possible type with the full subsuperalgebra. In this case, all odd generators of g are completely eaten by the r. Whereas, the even generators of g that are left form the orthogonal complement basis to the even basis of r under the Killing form of g. Under the restriction to an r module, Eq. (14) and Eq. (15) simply become

$$\mathrm{ch}\, V(\Lambda) = \frac{1}{\Delta} \sum_{c \in C} \mathrm{sgn}(c) \mathrm{ch}\, U(c \cdot \Lambda), \tag{16}$$

and

$$\mathrm{sch}\, V(\Lambda) = \frac{1}{\Delta} \sum_{c \in C} \mathrm{sgn}(c) \mathrm{sch}\, U(c \cdot \Lambda). \tag{17}$$

Both Eq. (16) and Eq. (17) correspond to

$$V(\Lambda) \otimes S^{+} - V(\Lambda) \otimes S^{-} = \sum_{c \in C} \mathrm{sgn}(c) U(c \cdot \Lambda). \tag{18}$$

For the rest of type II, we use Kac character and the supercharacter formulas of equal rank embedding, Eq. (5) and Eq. (6). If g_1 and g_{-1} are vector spaces of odd generators, there is a canonical linear map from $\wedge^a g_1 \otimes \wedge^b g_{-1}$ to $\wedge^{a+b}(g_1 \oplus g_{-1})$, which takes $((g_1)_1 \wedge \cdots \wedge (g_1)_a) \otimes ((g_{-1})_1 \wedge \cdots \wedge (g_{-1})_b)$ to $((g_1)_1 \wedge \cdots \wedge (g_1)_a \wedge (g_{-1})_1 \wedge \cdots \wedge (g_{-1})_b)$. This determines a linear isomorphism,

$$\begin{aligned} \wedge(g_1 \oplus g_{-1}) &\simeq \bigoplus_{a=0}^{N} (\wedge^{N-a} g_1 \otimes \wedge^a g_{-1}) \\ &\simeq \wedge g_1 \otimes \wedge g_{-1}. \end{aligned}$$

The prefactor N_1 of the Kac character formula is generally the character of the exterior algebra over the direct sum of g_1 and g_{-1} vector spaces,

$$\begin{aligned} \prod_{\beta \in \Phi_1^{+}} (e^{\beta/2} + e^{-\beta/2}) &= \prod_{\beta_{\pm} \in \Phi_1^{\pm}} (e^{\beta_{+}/2} + e^{\beta_{-}/2}) \\ &= \mathrm{ch} \wedge (g_1 \oplus g_{-1}). \end{aligned}$$

Finally, the type II typical Kac character and supercharacter can be written as

$$\mathrm{ch}\, V(\Lambda)(\mathrm{ch}\, S^{+} - \mathrm{ch}\, S^{-}) = \mathrm{ch} \wedge (g_1/r_1 \oplus g_{-1}/r_{-1}) \sum_{c \in C} \mathrm{sgn}(c) \mathrm{ch}\, U(c \cdot \Lambda), \tag{19}$$

and

$$\mathrm{sch}\, V(\Lambda)(\mathrm{ch}\, S^{+} - \mathrm{ch}\, S^{-}) = \mathrm{sch} \wedge (g_1/r_1 \oplus g_{-1}/r_{-1}) \sum_{c \in C} \mathrm{sgn}(c) \mathrm{sch}\, U(c \cdot \Lambda), \tag{20}$$

which correspond to

$$V(\Lambda) \otimes S^{+} - V(\Lambda) \otimes S^{-} = \wedge (g_1/r_1 \oplus g_{-1}/r_{-1}) \otimes \sum_{c \in C} \mathrm{sgn}(c) U(c \cdot \Lambda). \tag{21}$$

IV. REPRESENTATIONS OF $\wedge g_{-1}$ OF TYPE I LIE SUPERALGEBRAS

For type I Lie superalgebras with a nondegenerate Killing form, the typical representation is induced by applying g_{-1} generators on a g_0 module. Therefore, we need to know an explicit representation of $\wedge g_{-1}$ in terms of a g_0 module. Let N be a dimension of Φ_1^{-}. The exterior algebra over g_{-1} is

$$\wedge g_{-1}=\bigoplus_{k=0}^{N}\wedge^{k}g_{-1},$$

with dimension

$$\dim(\wedge g_{-1})=\bigoplus_{k=0}^{N}\dim(\wedge^{k}g_{-1})=\sum_{k=0}^{N}\binom{N}{k}=2^{N},$$

and superdimension

$$\mathrm{sdim}(\wedge g_{-1})=\bigoplus_{k=0}^{N}\mathrm{sdim}(\wedge^{k}g_{-1})=\sum_{k=0}^{N}(-1)^{k}\binom{N}{k}=0.$$

Let $Q^{\dagger}_{i=1,2,\ldots,N}$ be N completely antisymmetric fermionic generators that transform in the fundamental representation of g_0. The fermionic generators generate even and odd modules that are isomorphic to a direct sum of two spinor representations of $\mathrm{so}(2N)$. One of the spinor representations of $\mathrm{so}(2N)$ is the even module of $\wedge g_{-1}$, called the bosonic module, and the other is the odd module of $\wedge g_{-1}$, called the fermionic module. Let T^{+} be the bosonic module and T^{-} be the fermionic module of $\mathrm{so}(2N)$, such that

$$\begin{aligned}T^{+}&=\wedge^{0}g_{-1}\oplus\wedge^{2}g_{-1}\oplus\wedge^{4}g_{-1}\oplus\cdots\\&=\big((Q_i^{\dagger})^{0}\oplus(Q_i^{\dagger})^{2}\oplus(Q_i^{\dagger})^{4}\oplus\cdots\big)|1\rangle_0\\&\equiv\text{bosonic module},\end{aligned}$$

and

$$\begin{aligned}T^{-}&=\wedge^{1}g_{-1}\oplus\wedge^{3}g_{-1}\oplus\wedge^{5}g_{-1}\oplus\cdots\\&=\big((Q_i^{\dagger})^{1}\oplus(Q_i^{\dagger})^{3}\oplus(Q_i^{\dagger})^{5}\oplus\cdots\big)|1\rangle_0\\&\equiv\text{fermionic module}.\end{aligned}$$

With a restriction to the g_0 module, the type I typical representation is

$$\begin{aligned}V(\Lambda)&=\wedge g_{-1}\otimes V_0(\Lambda)\\&=(T^{+}\oplus T^{-})\otimes V_0(\Lambda).\end{aligned}$$

For $\mathrm{su}(m|n)$, the $\wedge g_{-1}$ representation is isomorphic to a direct sum of two spinor representations of $\mathrm{so}(2mn)$. With a restriction to $\mathrm{su}(m)\times\mathrm{su}(n)\times\mathrm{u}(1)$, $Q_i^{\dagger}$ transforms as $(m,n)_{-1}$, where -1 is a $u(1)$ charge.

Ex. 1 $\mathrm{su}(2|1)$*:*

$$\dim(g_{-1})=2^{2}=1+2+1;$$

$Q_i^{\dagger}\sim 2_{-1}$,

$$T^{+}=1_0\oplus 1_{-2},$$

$$T^{-}=2_{-1},$$

$$V_{\mathrm{su}(2|1)}(\Lambda)=(T^{+}\oplus T^{-})\otimes V_{\mathrm{su}(2)\times\mathrm{u}(1)}(\Lambda).$$

Ex. 2 $\mathrm{su}(3|1)$*:*

$$\dim(g_{-1})=2^3=1+3+3+1;$$

$Q_i^\dagger \sim 3_{-1}$

$$T^+=1_0\oplus\bar{3}_{-2},$$

$$T^-=3_{-1}\oplus 1_{-3},$$

$$V_{\mathrm{su}(3|1)}(\Lambda)=(T^+\oplus T^-)\otimes V_{\mathrm{su}(3)\times \mathrm{u}(1)}(\Lambda).$$

Ex. 3 su(3|2):

$$\dim(g_{-1})=2^6=1+6+15+20+15+6+1;$$

$Q_i^\dagger \sim (3,2)_{-1}$,

$$T^+=(1,1)_0\oplus(\bar{3},3)_{-2}\oplus(6,1)_{-2}\oplus(6,1)_{-4}\oplus(3,3)_{-4}\oplus(1,1)_{-6},$$

$$T^-=(3,2)_{-1}\oplus(8,2)_{-3}\oplus(4,1)_{-3}\oplus(\bar{3},2)_{-5},$$

$$V_{su(3|2)}(\Lambda)=(T^+\oplus T^-)\otimes V_{\mathrm{su}(3)\times \mathrm{su}(2)\times \mathrm{u}(1)}(\Lambda).$$

Ex. 4 su(4|2):

$$\dim(g_{-1})=2^8=1+8+28+56+70+56+28+8+1,$$

$Q_i^\dagger \sim (4,2)_{-1}$,

$$T^+=(1,1)_0\oplus(10,1)_{-2}\oplus(6,3)_{-2}\oplus(20',1)_{-4}\oplus(15,3)_{-4}\oplus(5,1)_{-4}\oplus\overline{(10,1)}_{-6}\oplus(6,3)_{-6}\oplus(1,1)_{-8},$$

$$T^-=(4,2)_{-1}\oplus(20,1)_{-3}\oplus(\bar{4},4)_{-3}\oplus\overline{(20,1)}_{-5}\oplus(4,4)_{-5}\oplus(\bar{4},2)_{-7},$$

$$V_{\mathrm{su}(4|2)}(\Lambda)=(T^+\oplus T^-)\otimes V_{\mathrm{su}(4)\times \mathrm{su}(2)\times \mathrm{u}(1)}(\Lambda).$$

For osp$(2|2n)$, $\wedge g_{-1}$ representation is a direct sum of two spinor representations of so$(4n)$. With restriction to sp$(2n)\times u(1)$, $Q_i^\dagger$ transforms as $(2n)_{-1}$ with -1 as a $u(1)$ charge.

Ex. 5 osp(2|4):

$$\dim(g_{-1})=2^4=1+4+6+4+1;$$

$Q_i^\dagger \sim 4_{-1}$,

$$T^+=1_0\oplus 5_{-2}\oplus 1_{-2}\oplus 1_{-4},$$

$$T^-=4_{-1}\oplus 4_{-3},$$

$$V_{\mathrm{osp}(2|4)}(\Lambda)=(T^+\oplus T^-)\otimes V_{\mathrm{sp}(4)\times u(1)}(\Lambda).$$

Ex. 6 osp(2|6):

$$\dim(g_{-1})=2^6=1+6+15+20+15+6+1;$$

$Q_i^\dagger \sim 6_{-1}$,

$$T^+=1_0\oplus 14_{-2}\oplus 1_{-2}\oplus 14_{-4}\oplus 1_{-4}\oplus 1_{-6},$$

$$T^- = 6_{-1} \oplus 14'_{-3} \oplus 6_{-3} \oplus 6_{-5},$$

$$V_{\mathrm{osp}(2|6)}(\Lambda) = (T^+ \oplus T^-) \otimes V_{\mathrm{sp}(6)\times \mathrm{u}(1)}(\Lambda).$$

V. BUILDING TYPE I C MULTIPLETS AND KOSTANT'S CUBIC DIRAC OPERATOR

For type I Lie superalgebras, there is a remarkable point we would like to mention. From the multiplet spectrum of equal rank embedding of reductive Lie algebras, $r_0 \subset g_0$, we can build the spectrum of the type I Lie superalgebras on top of them by simply tensoring them with a module generated by r_{-1} generators. The r_{-1} generators transform in the fundamental representation of r_0.

Define $\wedge(r_{-1}) = R^+ \oplus R^-$ such that

$$U(\Lambda) = \wedge(r_{-1}) \otimes U_0(\Lambda) = (R^+ \oplus R^-) \otimes U_0(\Lambda).$$

Tensoring on both side of Eq. (2) with $\wedge(r_{-1})$, we obtain

$$\wedge(r_{-1}) \otimes (V_0(\Lambda)\otimes S^+ - V_0(\Lambda)\otimes S^-) = \sum_{c\in C} \mathrm{sgn}(c)(\wedge(r_{-1})\otimes U_0(c\cdot\Lambda))$$

$$= \sum_{c\in C} \mathrm{sgn}(c) U(c\cdot \Lambda). \tag{22}$$

Under restriction to an r_0 module, whenever $V_0(\Lambda)$ on the lhs of Eq. (22) is $\mathrm{su}(n)\times \mathrm{u}(1)$, or $\mathrm{sp}(2n)\times \mathrm{u}(1)$, there is an emergence of a type I typical **C** multiplet on the rhs. Notice in the case that $U(c\cdot\Lambda)$ is $\mathrm{su}(m|n)$, the representations of $R^\pm$ are similar to those of $S^\pm$ except $u(1)$ values.

Let $g = r \oplus p$ be Lie superalgebras where p is the orthogonal complement to r under the nondegenerate Killing form of g. Let $p = p_{\mathrm{even}} \oplus p_{\mathrm{odd}} = p_0 \oplus p_1 \oplus p_{-1}$. Tensoring on both sides of Eq. (22) by $\wedge p_{-1}$, we get

$$V(\Lambda)\otimes S^+ - V(\Lambda)\otimes S^- = \wedge p_{-1} \otimes \sum_{c\in C} \mathrm{sgn}(c) U(c\cdot\Lambda), \tag{23}$$

which is exactly Eq. (13). Now, we need to get rid of $\wedge p_{-1}$ on the rhs of Eq. (23) by mapping it into identity. To do so, we do a tensor product on both sides of Eq. (23) by the following contraction, sometimes called an internal product, on exterior powers between vector space and its dual:

$$\wedge^N(p_{\mathrm{odd}}) = \wedge^N p_1 \otimes \wedge^N p_{-1} = \mathbf{1}.$$

Equation (23) becomes

$$(\wedge^N p_{\mathrm{odd}}) \otimes V(\Lambda) \otimes (S^+ - S^-) = \mathbf{1} \otimes \sum_{c\in C} \mathrm{sgn}(c) U(c\cdot\Lambda). \tag{24}$$

As already known, the character form of a Dirac operator, $\partial\!\!\!/ \in C(p)$, with a map $\partial\!\!\!/ : S^\pm \to S^\mp$, is

$$\mathrm{ch}(\partial\!\!\!/) = \mathrm{ch}(S^+) - \mathrm{ch}(S^-).$$

The character of Eq. (1) implies that there exists a Kostant's Dirac operator, $\mathcal{K}\!\!\!/ \in \mathcal{U}(g_{\mathrm{even}}) \otimes C(p_{\mathrm{even}})$, with a map

$$\mathcal{K}\!\!\!/_\lambda : V_\lambda \otimes S^\pm \to V_\lambda \otimes S^\mp. \tag{25}$$

Similarly, the character of Eq. (24) suggests that there exists the operator for Lie superalgebras, $\not{\mathcal{K}}_\Lambda \in \mathcal{U}(p_{\rm odd}) \otimes \mathcal{U}(g_{\rm even} \oplus g_{\rm odd}) \otimes C(p_{\rm even})$, with a map

$$\not{\mathcal{K}}_\Lambda : V(\Lambda) \otimes S^{\pm} \rightarrow V(\Lambda) \otimes S^{\mp}. \tag{26}$$

VI. KOSTANT's CUBIC DIRAC OPERATOR FOR AN EQUAL RANK EMBEDDING OF LIE SUPERALGEBRAS

Let L_i and F_a be even and odd generators, respectively, for Z_2-graded Lie superalgebras such that

$$[L_i, L_j] = f_{[ijk]} L_k,$$

$$\{F_a, F_b\} = f_{i(ab)} L_i,$$

and

$$[L_i, F_a] = f_{[ia]b} F_b,$$

where $i,j,k = 1,2,...,\dim(g_0)$ and $a,b = 1,2,...,\dim(g_1)$. The Kostant's cubic Dirac operator of Lie superalgebras is extended from that of Lie algebras by adding just two terms; a linear term in odd operators and a structure constant term, i.e.,

$$\not{\mathcal{K}}_\Lambda = \not{\mathcal{K}}_\Lambda^0 + \not{\mathcal{K}}_\Lambda^1, \tag{27}$$

where

$$\not{\mathcal{K}}_\Lambda^0 = \gamma_i L_i - \tfrac{1}{2} \gamma_{[ijk]} f_{[ijk]} \tag{28}$$

and

$$\not{\mathcal{K}}_\Lambda^1 = \alpha_a F_a - \tfrac{1}{2} \gamma_i \alpha_{(ab)} f_{i(ab)}. \tag{29}$$

The sum over all indices is assumed in the above equations, where $[\cdots]$ in the subscript is for the antisymmetric sum and $(\cdots)$ for the symmetric sum. Equation (28) is the Kostant' cubic Dirac operator for reductive Lie algebras. The γ matrices associated to even generators are normalized so that

$$\{\gamma_i, \gamma_j\} = \delta_{ij},$$

which gives

$$\{\gamma_{i'}, \gamma_{[ijk]}\} = \delta_{i'k} \gamma_{[ij]}.$$

The α matrices associated to odd generators are subjected to the following conditions.

(I) $\{\gamma_i, \alpha_a\} = 0$. This relation is consistent with the antisymmetric property of the product of even and odd generators.

(II) $\{\alpha_a, [\alpha_b, \alpha_c]\} + \{[\alpha_a, \alpha_c], \alpha_b\} = [\alpha_{(ab)}, \alpha_c] = 0$. This property is due to invariance of odd generators under the Killing form.

Squaring Eq. (28), we get

$$\begin{aligned}(\not{\mathcal{K}}_\Lambda^0)^2 &= \tfrac{1}{2} \gamma_{(ij)} \{L_i, L_j\} + \tfrac{1}{2} \gamma_{[ij]} [L_i, L_j] - \tfrac{1}{2} \{\gamma_{i'}, \gamma_{[ijk]}\} f_{[ijk]} L_{i'} + (\tfrac{1}{2} \gamma_{[ijk]} f_{[ijk]})^2 \\ &= \tfrac{1}{2} \gamma_{(ij)} \{L_i, L_j\} + (\tfrac{1}{2} \gamma_{[ijk]} f_{[ijk]})^2. \end{aligned} \tag{30}$$

Notice that the linear terms in even generators cancel each other. Thus, Eq. (30) is explicitly invariant under the action of even and odd generators. The first term of Eq. (30) is the quadratic Casimir operator of reductive Lie algebras,

$$C_2^0(\Lambda)=\tfrac{1}{2}\gamma_{(ij)}\{L_i,L_j\}. \tag{31}$$

Since ρ_0, one-half the sum of positive even roots can be identified as

$$\rho_0=\tfrac{1}{2}\gamma_{[ijk]}f_{[ijk]}. \tag{32}$$

The second term of Eq. (30) is the Freudenthal–de Vries' strange formula,

$$\begin{aligned}(\rho,\rho)_0&=(\tfrac{1}{2}\gamma_{[ijk]}f_{[ijk]})^2=\tfrac{1}{24}\ \dim(g_0)h_0^\vee(\theta,\theta)_0\\&=\tfrac{1}{24}\ \dim(g_0)C_2^{0\mathrm{ad}}.\end{aligned} \tag{33}$$

Where, in the above equation, $h^\vee$ is the dual Coxeter number, θ is the highest root, and C_2^{ad} is the quadratic Casimir value in the adjoint representation.

Squaring Eq. (29), we get

$$\begin{aligned}(\not{\mathcal{K}}_\Lambda^1)^2&=\tfrac{1}{2}\alpha_{[ab]}[F_a,F_b]+\tfrac{1}{2}\alpha_{(ab)}\{F_a,F_b\}-\tfrac{1}{2}\gamma_i[\alpha_{(ab)},\alpha_{a'}]f_{i[ab]}F_{a'}+(\tfrac{1}{2}\gamma_i\alpha_{(ab)}f_{i(ab)})^2\\&=\tfrac{1}{2}\alpha_{[ab]}[F_a,F_b]+\tfrac{1}{2}\alpha_{(ab)}f_{i(ab)}L_i+(\tfrac{1}{2}\gamma_i\alpha_{(ab)}f_{i(ab)})^2.\end{aligned} \tag{34}$$

In contrary to the even part, Eq. (34) by itself is not invariant due to the presence of a linear term in even generators. The linear term in L_i will be cancelled out by one of the the cross terms of the square of the combined even and odd Kostant's cubic Dirac operator,

$$\begin{aligned}(\not{\mathcal{K}}_\Lambda)^2=&(\not{\mathcal{K}}_\Lambda^0)^2+(\not{\mathcal{K}}_\Lambda^1)^2+\{\gamma_i,\alpha_a\}L_iF_a-\tfrac{1}{2}\{\gamma_{[ijk]},\alpha_a\}f_{[ijk]}F_a-\tfrac{1}{2}\{\gamma_i,\gamma_{i'}\}\alpha_{(ab)}f_{i'(ab)}L_i\\&-\tfrac{1}{2}\gamma_i[\alpha_{(ab)},\alpha_{a'}]f_{i(ab)}F_{a'}+\tfrac{1}{2}\{\gamma_{[ijk]},\gamma_{i'}\}\alpha_{(ab)}f_{[ijk]}f_{i'(ab)}\\&=\gamma_{(ij)}L_{(i}L_{j)}+\alpha_{[ab]}F_{[a}F_{b]}+(\tfrac{1}{2}\gamma_{[ijk]}f_{[ijk]})^2+(\tfrac{1}{2}\gamma_i\alpha_{(ab)}f_{i(ab)})^2+\tfrac{1}{2}\gamma_{[ij]}\alpha_{(ab)}f_{[ijk]}f_{k(ab)}.\end{aligned} \tag{35}$$

Since ρ_1, one-half the sum of positive odd roots, can be identified as

$$\rho_1=-\tfrac{1}{2}\gamma_i\alpha_{(ab)}f_{i(ab)}. \tag{36}$$

Recall that, for Lie superalgebras, $\rho=\rho_0-\rho_1$. Equation (35) can be simply written as

$$(\not{\mathcal{K}}_\Lambda)^2=C_2(\Lambda)+(\rho,\rho), \tag{37}$$

where

$$C_2(\Lambda)=\gamma_{(ij)}L_{(i}L_{j)}+\alpha_{[ab]}F_{[a}F_{b]}.$$

The Laplacian operator turns out to be invariant under the action of even and odd generators of g again. For Lie superalgebras, the generalization of the Freudenthal–de Vries strange formula still holds,[7]

$$(\rho,\rho)=\frac{h^\vee}{24}(\dim g_0-\dim g_1), \tag{38}$$

where $h^\vee$'s, the dual Coxeter numbers of g, are given in Table I.

In an equal rank embedding of Lie superalgebras, $g\supset r$, with $\Phi_g\supset\Phi_r$, let the even and odd generators, L_i and F_a, span the basis of g. According to the $g=r\oplus p$ decomposition, $L_{\hat{i}}$ and $F_{\hat{a}}$ span the basis of r and L_I and F_A span the basis of p, the orthogonal complement of r under the Killing form of g. The Kostant's cubic Dirac operator on $p=g/r$ is

$$\not{\mathcal{K}}_p=\not{\mathcal{K}}_g-\not{\mathcal{K}}_r=\gamma_IL_I+\alpha_AF_A-\tfrac{1}{2}\gamma_{[IJK]}f_{[IJK]}-\tfrac{1}{2}\gamma_I\alpha_{(AB)}f_{I(AB)}, \tag{39}$$

TABLE I. Dual Coxeter numbers of basic Lie superalgebras.

g	$h^\vee$
$\mathrm{su}(m\|n)$	$\|m-n\|$
$\mathrm{osp}(2\|2n)$	n
$\mathrm{osp}(2m+1\|n)$	$2(m-n)-1$ if $m>n, n-m+\frac{1}{2}$ if $m\leqslant n$
$\mathrm{osp}(2m\|n)$	$2(m-n-1)$ if $m\geqslant n, n-m+1$ if $m<n+1$
$\mathrm{osp}(4\|2;\alpha)$	0
$F(4)$	3
$G(3)$	2

where $f_{[IJK]}$ and $f_{I(AB)}$ are the structure constants of g that are not in r. Since, under the Killing form of g, r and p bases are orthogonal to each other,

$$\{\gamma_{\hat{i}},\gamma_I\}=\{\gamma_{\hat{i}},\alpha_A\}=\{\alpha_{\hat{a}},\gamma_I\}=\{\alpha_{\hat{a}},\alpha_A\}=0.$$

As a result, we have

$$\{\not{\mathcal{K}}_r,\not{\mathcal{K}}_p\}=0.$$

The square of Kostant's coset cubic Dirac operator simply is

$$(\not{\mathcal{K}}_p)^2=(\not{\mathcal{K}}_g)^2-(\not{\mathcal{K}}_r)^2=(C_2+(\rho,\rho))_g-(C_2+(\rho,\rho))_r\,. \tag{40}$$

Notice that both $(\not{\mathcal{K}}_g)^2$ and $(\not{\mathcal{K}}_r)^2$ commute with the generators of r. Hence, $(\not{\mathcal{K}}_p)^2$ is also invariant under the action of r.

In conclusion, we have derived the Kac character formulas and have constructed Kostant's cubic Dirac operator for equal rank embeddings of Lie superalgebras. In case of reductive Lie algebras, the coset space method of equal rank embeddings led to a Kazama–Suzuki model construction of a new class of unitary $N=2$ superconformal theories[8] and a subclass of the construction could be represented by Landau–Ginzburg models.[9] In case of Lie superalgebras, it deserves to be pursued whether there will be any relevance of the coset superspace method to a construction of any physical model.

Cones and causal structures on topological and differentiable manifolds

(Received 4 June 1999; accepted for publication 14 July 1999)

General definitions for causal structures on manifolds of dimension $d+1>2$ are presented for the topological category and for any differentiable one. Locally, these are given as cone structures via local (pointwise) homeomorphic or diffeomorphic abstraction from the standard null cone variety in $\mathbb{R}^{d+1}$. Weak ($\mathscr{C}$) and strong ($\mathscr{C}^m$) local cone (LC) structures refer to the cone itself or a manifold thickening of the cone, respectively. After introducing cone (C-)causality, a causal complement with reasonable duality properties can be defined. The most common causal concepts of space–times are generalized to the present topological setting. A new notion of precausality precludes inner boundaries within future/past cones. LC-structures, C-causality, a topological causal complement, and precausality may be useful tools in conformal and background independent formulations of (algebraic) quantum field theory and quantum gravity. © *1999 American Institute of Physics.* [S0022-2488(99)00712-4]

I. INTRODUCTION

While classical general relativity usually employs a Lorentzian space–time metric, all genuine approaches to quantum gravity are free of such a metric background. This poses the question of whether there still exists a notion of structure which captures some essential features of light cones and their mutual relations in manifolds in a purely topological manner without a priori recursion to a Lorentzian metric or a conformal class of such metrics. Below we will see that the answer is positive.

It is a well known folk theorem that the causal structure on a Lorentzian manifold determines its metric up to conformal transformations. In Refs. 1 and 2 a path topology for strongly causal space–times was defined which then determined their differential, causal, and conformal structure. In Ref. 3 it was shown that the conformal class of a Lorentzian metric can be reconstructed from the characteristic surfaces of the manifold. Similarly, Ref. 4 gives a nice proof that the null cones determine the Lorentzian metric (modulo global sign) up to a conformal factor. All these previous results already indicate that the notion of a causal structure could exist indeed in a different and possibly more general setting than that of Lorentzian space–times. However, all the previously mentioned investigations in the literature assume a priori the existence of some undetermined Lorentzian metric and then show that it can be determined modulo conformal transformation uniquely by some other structure.

Motivated by the requirements on suitable structures for a theory of quantum gravity, in this paper new notions of causal structure are developed which do not assume a priori the existence of any (Lorentzian) metric or conformal metric but rather work on arbitrary topological and differential manifolds.

In Sec. II weak ($\mathscr{C}$) and strong ($\mathscr{C}^m$) local cone (LC) structures are defined on any topological (or differentiable) manifold M. These structures are given by continuous (or differentiable) fami-

[a)]Electronic mail: mrainer@rz.uni-potsdam.de

lies of pointwise homeomorphisms from the standard null cone variety in $\mathbb{R}^{d+1}$ or a manifold thickening thereof, respectively, into M. In the differentiable case it turns out that a strong LC structure implies the existence of a conformal Lorentzian metric, while a weak LC structure already implies its uniqueness should one exist. However, the metric resulting from a strong LC structure contains only pointwise information about the asymptotic structure of the cone at the vertex. Within a given manifold thickening of the cone at a given point of M, the cone in any neighborhood of the vertex need a priori not at all be related to the null structure spanned by the null geodesics of this metric. However, if such a relationship holds in some region, then all the cones in that region are consistent with each other and this way yield a notion of causality.

In Sec. III we provide precisely those definitions of causality which allow us to formulate the consistency of different strength for cones at different points, in some or any open region in M. Cone (C-) causality allows first of all the definition of a causal complement with reasonable properties. It enables us also to define in a topological (differentiable) manner spacelike, null, and timelike curves. We discuss C-causality also in the particular context of a fibration. Generalizations of the most common causality notions for space–times in purely topological terms are provided. In the case of Lorentzian manifolds these notions agree with the usual ones and they assume their usual hierarchy. Finally, precausality is defined as a notion which makes the future and the past of any cone homeomorphic to the future and the past of the standard cone $\mathcal{C}$ in $\mathbb{R}^{d+1}$, respectively.

The discussion points out some of the major open issues which require further investigation. It addresses also the issues of causal diffeomorphisms, foliations, and possible restrictions of the cone structure and causality from the manifold to an embedded graph therein, giving also a perspective for possible applications in conformal and background independent quantum field theories and quantum gravity.

Here and below a CAT manifold refers to a Hausdorff (T_2) space with a CAT structure, where CAT$=\mathcal{C}^0$ (the topological category) or CAT$\subset\mathcal{C}^1$ (any differentiable category). If CAT$\subset\mathcal{C}^1$, a CAT homeomorphism is a diffeomorphism and a CAT continuous map is a differentiable map. For differentiable categories we also define $\mathrm{CAT}_{-1}:=\mathcal{C}^r$ if CAT$=\mathcal{C}^{r+1}$, $\mathrm{CAT}_{-1}:=\mathcal{C}^\infty$ if CAT $=\mathcal{C}^\infty$, and $\mathrm{CAT}_{-1}:=\mathcal{C}^\omega$ if CAT$=\mathcal{C}^\omega$.

II. LOCAL CONE (LC) STRUCTURES OF MANIFOLDS

In this section we derive local notions of a cone structure on a topological $d+1$-dimensional manifold M (CAT$\subset\mathcal{C}^0$). Let

$$\mathscr{C}:=\{x\in\mathbb{R}^{d+1}:x_0^2=(x-x_0e_0)^2\},\mathscr{C}^+:=\{x\in\mathscr{C}:x_0\geqslant 0\},\mathscr{C}^-:=\{x\in\mathscr{C}:x_0\leqslant 0\} \tag{2.1}$$

be the standard (unbounded double) light cone, and the forward and backward subcones in $\mathbb{R}^{d+1}$, respectively.

The standard open interior and exterior of $\mathscr{C}$ is defined as

$$\mathcal{I}:=\{x\in\mathbb{R}^{d+1}:x_0^2>(x-x_0e_0)^2\},\mathcal{E}:=\{x\in\mathbb{R}^{d+1}:x_0^2<(x-x_0e_0)^2\}. \tag{2.2}$$

A *manifold thickening* with thickness $m>0$ is given as

$$\mathscr{C}^m=\{x\in\mathbb{R}^{d+1}:|x_0^2-(x-x_0e_0)^2|<m^2\}. \tag{2.3}$$

The characteristic topological data of the standard cone is encoded in the topological relations of all its manifold subspaces (which includes in particular also the singular vertex O) and among each other.

Typical (CAT) manifold subspaces of $\mathscr{C}$ are the standard future and past cones $\mathscr{C}^\pm$, and the standard light rays,

$$l(n):=\{x\in\mathcal{C}:x_0=(x,n)\}, \tag{2.4}$$

where $n \in S^{d-1} \subset p$ is a normal direction in the d-dimensional hyperplane $p := \{x \in \mathbb{R}^{d+1} : (x,y) = 0, \forall y \in a\}$ perpendicular to the cone axis $a := \{x \in \mathbb{R}^{d+1} : x = \lambda e_0, \lambda \in \mathbb{R}\}$.

The topological relations between all the CAT manifold subspaces of the cone are the natural data which will be required to be conserved under a homeomorphism of the cone as a topological space into the manifold M at any point p.

Let τ denote the closed sets of the manifold topology of $\mathscr{C} - O$. The set $\mathscr{C}$ can either inherit the induced topology τ_1 from $\mathbb{R}^{d+1}$ which is T_1 but not T_2 (Hausdorff) or it can be equipped with a more coarse subtopology defined in terms of closed sets as $\tau_2 := \{\{0\} \cup V : V \in \tau\} \cup \{V \in \tau\}$ which is Hausdorff. However, τ_2 places geometrically unnatural restrictions on possible submanifolds of $\mathscr{C}$. Hence, unless specified otherwise, $\mathscr{C}$ will be equipped with τ_1.

Definition 1: Let M be a CAT manifold. A (CAT) *(null) cone* at $p \in \operatorname{int} M$ is the homeomorphic image $\mathscr{C}_p := \phi_p \mathscr{C}$ of a homeomorphism of topological spaces $\phi_p : \mathscr{C} \to \mathscr{C}_p \subset M$ with $\phi_p(0) = p$, such that we have the following.

(i) Every (CAT) submanifold $N \subset \mathscr{C}$ is mapped (CAT) homeomorphically on a submanifold $\phi_p(N) \subset M$.

(ii) For any two submanifolds $N_1, N_2 \subset \mathscr{C}$ there exist homeomorphisms $\phi_p(N_1) \cap \phi_p(N_2) \cong N_1 \cap N_2$ and $\phi_p(N_1) \cup \phi_p(N_2) \cong N_1 \cup N_2$ of (CAT) manifolds if these are (CAT) manifolds and as topological spaces otherwise

(iii) If CAT $\subset \mathcal{C}^1$ then for any two CAT curves $c_1, c_2 :]-\epsilon, \epsilon[\to \mathscr{C}$ with $c_1(0) = c_2(0) = p$ it holds that $T_0 c_1 = T_0 c_2 \Rightarrow T_p(\phi_p \circ c_1)|_{]-\epsilon,\epsilon[} = T_p(\phi_p \circ c_2)|_{]-\epsilon,\epsilon[}$.

Condition (iii) says that in the differentiable case the well defined notion of transversality of intersections at the vertex is preserved by ϕ_p.

On each homeomorphic cone $\mathscr{C}_p$ at any $p \in \operatorname{int} M$, the topology τ_1 or τ_2 of $\mathscr{C}$ yields under ϕ_p likewise a non-Hausdorff T_1 topology $\phi_p(\tau_1)$ or a T_2 one $\phi_p(\tau_2)$. However, $\phi_p \circ \tau_2$ would unnaturally restrict the possible submanifolds of $\mathscr{C}$, while $\phi_p \circ \tau_1$ is consistent with the topology induced from M.

Definition 2: An *(ultraweak) cone structure* on M is an assignment $\operatorname{int} M \ni p \to \mathscr{C}_p$ of a cone at every $p \in \operatorname{int} M$.

A cone structure on M can, in general, be rather wild with cones at different points totally unrelated unless we impose a topological connection between the cones at different points. Most naturally the connection is provided by continuity of the family $\{\mathscr{C}_p\}$. This allows us to define local cone (LC) structures.

Definition 3: Let M be a CAT manifold. A *weak ($\mathscr{C}$) local cone (LC)-structure* on M is a cone structure which is (CAT) continuous, i.e., $\{p \to \mathscr{C}_p\}$ is a (CAT) continuous family.

Given a cone structure one wants to know first of all under which conditions, for given $p \in \operatorname{int} M$, an exterior and interior of the cone can be distinguished locally, i.e., for any open neighborhood $U \ni p$ within $(M - \mathscr{C}_p) \cap U$.

Proposition 1: Let $\forall p \in \operatorname{int} M$ exist open (CAT) submanifolds $\mathcal{I}_p$ and $\mathcal{E}_p$ such that the interior of M decomposes in the disjoint union $\operatorname{int} M = \mathscr{C}_p \mathring{\cup} \mathcal{I}_p \mathring{\cup} \mathcal{E}_p$.

(i) Then $\mathcal{I}_p$ and $\mathcal{E}_p$ can be topologically distinguished locally in any neighborhood of the vertex p if and only if for any neighborhood $U \ni p$ it holds $(\mathcal{I}_p|_U) \not\cong (\mathcal{E}_p|_U)$.

(ii) Given any neighborhood $U \ni p$ assume $\exists k \in \mathbb{N}_0 : \Pi_k(\mathcal{I}_p|_U) \neq \Pi_k(\mathcal{E}_p|_U)$. Then $\mathcal{I}_p$ and $\mathcal{E}_p$ can be topologically distinguished locally in any neighborhood of the vertex p.

Proof: (i) follows from $U - \mathscr{C}_p|_U = \mathcal{I}_p|_U \mathring{\cup} \mathcal{E}_p|_U$. (ii) holds because homotopy groups are topological invariants. □

Note that, although $\mathscr{C}_p = \phi_p(\mathscr{C})$, $\mathcal{I}$ and $\mathcal{E}$ here need not be homeomorphic to $\phi_p(\mathcal{I})$ and $\phi_p(\mathcal{E})$, respectively. The notion of precausality (see below in Sec. III) is set up to ensure $\mathcal{E}_p \cong \phi_p(\mathcal{E})$.

A weak LC structure at each point $p \in \operatorname{int} M$ defines a characteristic topological space $\mathscr{C}_p$ of codimension 1 which is Hausdorff everywhere but at p. In particular $\mathscr{C}_p$ does not contain any open $U \ni p$ from the manifold topology of M. However, stronger structures can be defined as follows.

Definition 4: Let M be a CAT manifold. A (CAT) *(manifold) thickened cone* of thickness

$m > 0$ at $p \in \text{int}\, M$ is the (CAT) homeomorphic image $\mathscr{C}_p^m := \phi_p \mathscr{C}^m$ of a (CAT) homeomorphism of manifolds $\phi_p : \mathscr{C} \to \mathscr{C}_p \subset M$ with $\phi_p(0) = p$.

Note that due to the manifold property the notion of a thickened cone is much more simple than that of a cone itself. It also clear that now the only consistent topology on $\mathscr{C} \subset \mathscr{C}_p$ is τ_1 and correspondingly $\phi_p(\tau_1)$ on $\mathscr{C}_p \subset \mathscr{C}_p^m$.

Definition 5: A *thickened cone structure* on M is an assignment $\text{int}M \ni p \mapsto \mathscr{C}_p^{m(p)}$ of a thickened cone at every $p \in \text{int}\, M$.

Note that in general the thickness m can vary from point to point in M. Here $m : M \to \mathbb{R}_+$ is an a priori not necessarily continuous function. However, an important case even more special than the continuous one is that of constant m.

Definition 6: A *homogeneously thickened cone structure* on M is a thickened cone structure $\text{int}M \ni p \to \mathscr{C}_p$ with constant thickness m.

Although homogeneity might be too restrictive, at least continuity of structures on M is a natural assumption in the topological category.

Definition 7: Let M be a CAT manifold. A *strong* ($\mathscr{C}^m$) *LC structure* on M is a (CAT) continuous family of (CAT) homeomorphisms $\phi_p : \mathscr{C}^m \to \mathscr{C}_p^{m(p)} \subset M$ with $\phi_p(0) = p$ and such that the thickness m is a CAT function on M.

In particular the conditions of (ii) in Proposition 1 apply for all manifolds of dimension $d + 1 > 2$ with a strong LC-structure, while a weak LC-structure at $p \in \text{int}\, M$ may not be able to distinguish $\mathcal{I}_p|_U$ and $\mathcal{E}_p|_U$ within any $U \ni p$.

Theorem 1: Let M carry a strong LC structure. At any $p \in \text{int}\, M$ there exists an open $U \ni p$ such that for $d := \dim M - 1 > 0$ it is $|\Pi_0(\mathcal{I}_p|_U)| = 2$ and $\Pi_{d-1}(\mathcal{E}_p|_U) = \Pi_{d-1}(S^{d-1})$; for $d > 1$ it is $\Pi_{d-1}(\mathcal{I}_p|_U) = 0$ and $|\Pi_0(\mathcal{E}_p|_U)| = 1$; for $d = 1$ it is $\Pi_{d-1}(\mathcal{I}_p|_U) = \Pi_{d-1}(\mathcal{E}_p|_U) = \Pi_0(S^0)$, i.e., $|\Pi_0(\mathcal{I}_p|_U)| = |\Pi_0(\mathcal{E}_p|_U)| = 2$, and in dimension $d = 0$ it is $\mathcal{I}_p = \mathcal{E}_p = \emptyset$.

Proof: For all $p \in \text{int}\, M$ the strong LC structure provides a thickened cone $\mathscr{C}_p^{m(p)}$. Since $m(p) > 0$, $\mathscr{C}_p^{m(p)}$ contains always a neighborhood $U \ni p$ homeomorphic to a neighborhood $\phi_p^{-1}(U) \ni 0$ of the standard cone which in any dimension has the desired properties. □

At any interior point $p \in \text{int}\, M$ the open exterior $\mathcal{E}_p$ and the open interior $\mathcal{I}_p$ of the cone $\mathscr{C}_p$ are locally topologically distinguishable for $d > 1$, indistinguishable for $d = 1$, and empty for $d = 0$. With a strong LC structure $\mathcal{I}_p|_U \neq \mathcal{E}_p|_U \forall U \ni p \Leftrightarrow d + 1 > 2$, whence locally in any neighborhood $U \ni p$ the interior and exterior of $\mathscr{C}_p \cap U$ at p in U has an intrinsic invariant meaning. $\mathscr{C}_p|_U$ divides $U - \mathcal{C}_p|_U$ in three open submanifolds: a noncontractable exterior $\mathcal{E}_p|_U$ plus two contractable connected components of $\mathcal{I} =: \mathcal{F}|_U \cup \mathcal{P}|_U$, the *local future* $\mathcal{F}_p|_U$ and the *local past* $\mathcal{P}_p|_U$ with $\partial \mathcal{F}_p|_U = \mathscr{C}_p^+|_U$ where $\mathscr{C}_p^+ := (\phi_p \mathscr{C}^+)$, and $\partial \mathcal{P}_p|_U = \mathscr{C}_p^-|_U$ where $\mathscr{C}_p^- := \phi_p \mathscr{C}^-$, respectively. This also raises the question of if and how $\mathcal{F}_p$ and $\mathcal{P}_p$ or their local restriction to $U \ni p$ can be distinguished. This problem is solved by a topological $\mathbb{Z}_2$ connection (see also Sec. III below).

Given a strong LC structure, a local (conformal) metric can always be proven to exist on any differentiable manifold M with CAT$\subset \mathscr{C}^1$. Within such CAT, any metric η on $\mathbb{R}^{d+1}$ can be restricted to $\mathscr{C}^m$ and pulled back pointwise along $(\phi_p)^{-1}$ to a metric g on $\mathscr{C}_p^{m(p)}$. The CAT continuity of the family $\{p \to \mathscr{C}_p^{m(p)}\}$ implies CAT$_{-1}$ continuity of the family $\{p \to g|_{\mathscr{C}_p^{m(p)}}\}$. So we can extract a CAT$_{-1}$ continuous metric $\{p \mapsto g_p\}$.

Here we are interested in particular only in Lorentzian metrics which are *locally compatible* with a (weak or strong) LC structure in the sense that $\eta_0(v,v) = 0 \Leftrightarrow v \in T_x N, \ \forall (x,v) \in TN$, with arbitrary submanifold $N \subset \mathscr{C} \subset \mathbb{R}^{d+1}$, and correspondingly with $\mathscr{C}_p \supset \phi_p(N) \cong N$, it holds that

$$g_p(V(p), V(p)) = 0 \Leftrightarrow V(p) \in T_p \phi_p(N), \forall p \in \text{int}\, M, \tag{2.5}$$

i.e., locally at any vertex the cone determines the characteristic null directions in the tangent space.

On the other hand, the cone structure poses an equivalence relation on Lorentzian metrics which are compatible with the LC structure. Given any such metric g, the corresponding equivalence class $[g]$ is the conformal class of g. We summarize the existence and uniqueness result as follows.

Proposition 2: Given a strong LC structure on a (CAT) manifold, (i) there always exist a (CAT_{-1}) Lorentzian metric g on M compatible with the LC structure.

(ii) the conformal class $[g]$ of LC compatible metrics is uniquely determined by the LC structure.

The existence of a conformal Lorentzian metric is guaranteed by a *strong* LC structure, but not by a weak one. However, since conditions 3.2 needs only the existence of the tangent bundle of $\mathscr{C}_p$, uniqueness is assured already by a differentiable *weak* LC structure.

Although at each $p \in \operatorname{int} M$ a CAT strong LC structure on M admits a conformal class $[g]$ of CAT_{-1} Lorentzian metrics g with characteristic directions in T_pM tangential to $\mathscr{C}_p$, away from the vertex p the cones of the LC structure need not at all be compatible with the null structure of any conformal metric $[g]$. This reflect the fact that, apart from its local vertex structure, a strong LC structure is still much more flexible than a conformal structure. For any $q \neq p$ the tangent directions given by $T_q\mathscr{C}_p$ need a priori not be related to tangent directions of null curves of g, since the cone (or its thickening) at p is in general unrelated to that at q. The need for compatibility conditions between cones at different points motivates the introduction of some of the causality structures in open regions of M introduced later in the following section.

III. CAUSALITY STRUCTURES ON MANIFOLDS

Given a (weak or strong) LC structure one wants to know first of all under which conditions, for given $p \in \operatorname{int} M$ an exterior and interior of the cone can be distinguished within the complement $M - \mathscr{C}_p$. This problem is the global analog of the local one which was answered by Proposition 1 and Theorem 1 above.

Proposition 3: Assume that at $p \in \operatorname{int} M$ there are open (CAT) submanifolds $\mathcal{I}_p$ and $\mathcal{E}_p$ such that the interior of M decomposes into the disjoint union $\operatorname{int} M = \mathscr{C}_p \mathring{\cup} \mathcal{I}_p \mathring{\cup} \mathcal{E}_p$. Assume $\exists k \in \mathbb{N}_0 : \Pi_k(\mathcal{I}_p) \neq \Pi_k(\mathcal{E}_p)$. Then $\mathcal{I}_p$ and $\mathcal{E}_p$ can be topologically distinguished.

Proof: $\operatorname{int} M - \mathscr{C}_p = \mathcal{I}_p \mathring{\cup} \mathcal{E}_p$, and homotopy groups are topological invariants. □

In particular the conditions of Proposition 3 apply for $d+1>2$ in particular to all manifolds with the following topological structure.

Example 1: Let in any dimension $d := \dim M - 1 > 0$ at any $p \in \operatorname{int} M$ be $|\Pi_0(\mathcal{I}_p)| = 2$ and $\Pi_{d-1}(\mathcal{E}_p) = \Pi_{d-1}(S^{d-1})$, for $d>1$ be $\Pi_{d-1}(\mathcal{I}_p) = 0$ and $|\Pi_0(\mathcal{E}_p)| = 1$, for $d=1$ be $\Pi_{d-1}(\mathcal{I}_p) = \Pi_{d-1}(\mathcal{E}_p) = \Pi_0(S^0)$, i.e., $|\Pi_0(\mathcal{I}_p)| = |\Pi_0(\mathcal{E}_p)| = 2$, and in dimension $d=0$ be $\mathcal{I}_p = \mathcal{E}_p = \emptyset$ at any $p \in \operatorname{int} M$. Then in particular $\mathcal{I}_p \not\cong \mathcal{E}_p \Leftrightarrow d+1>2$. The open exterior $\mathcal{E}_p$ and the open interior $\mathcal{I}_p$ of the cone $\mathscr{C}_p$ at any interior point $p \in \operatorname{int} M$ are topologically distinct for $d>1$, indistinguishable for $d=1$, and empty for $d=0$.

In the case of Example 1, $\mathscr{C}_p$ divides $M - \mathscr{C}_p$ in three open submanifolds, a noncontractible exterior $\mathcal{E}_p$, plus two contractible connected components of $\mathcal{I}_p =: \mathcal{F}_p \cup \mathcal{P}_p$, the future $\mathcal{F}_p$ and the past $\mathcal{P}_p$ with $\partial \mathcal{F}_p = \mathscr{C}_p^+ := \phi_p \mathscr{C}^+$ and $\partial \mathcal{P}_p = \mathscr{C}_p^- := \phi_p \mathscr{C}^-$, respectively. This raises also the question of if and how $\mathcal{F}_p$ and $\mathcal{P}_p$ can be distinguished.

Let M be differentiable and τ be any vector field $M \to TM$ such that at any $p \in \operatorname{int} M$ its orientation agrees with that of $\phi_p(a)$. Such a orientation vector field comes naturally along with a (CAT_{-1}) $\mathbb{Z}_2$-connection on M which allows us to compare the orientation $\tau(p)$ at different $p \in \operatorname{int} M$. Given a strong LC structure on M, the $\mathbb{Z}_2$-connection is in fact provided via continuity of $p \mapsto T_p \phi_p(a)$. Then τ is tangent to an integral curve segment through p from $\mathcal{P}_p$ to $\mathcal{F}_p$. In particular, $\mathcal{F}_p$ and $\mathcal{P}_p$ are distinguished from each other by a consistent τ-orientation on M.

If M is not differentiable, in order to distinguish continuously $\mathcal{P}_p$ from $\mathcal{F}_p$ on $\operatorname{int} M$ it remains just to impose a topological $\mathbb{Z}_2$-connection on $\operatorname{int} M$ a fortiori.

In order to obtain a more specific causal structure it remains to identify natural consistency conditions for the intersections of cones of different points. In order to define topologically timelike, lightlike, and spacelike relations, and a reasonable causal complement, we introduce the following causal consistency conditions on cones.

Definition 8: M is (locally) cone causal or C-causal in an open region U, if it carries a (weak or strong) LC structure and in U the following relations between different cones in $\operatorname{int} M$ hold.

(1) For $p \neq q$ one and only one of the following is true:

(i) q and p are causally timelike related, $q \ll p :\Leftrightarrow q \in \mathcal{F}_p \wedge p \in \mathcal{P}_q$ (or $p \ll q$);

(ii) q and p are causally lightlike related, $q \lhd p :\Leftrightarrow q \in \mathscr{C}_p^+ - \{p\} \wedge p \in \mathscr{C}_q^- - \{q\}$ (or $p \lhd q$);

(iii) q and p are causally unrelated, i.e., relatively spacelike to each other, $q \bowtie p :\Leftrightarrow q \in \mathcal{E}_p \wedge p \in \mathcal{E}_q$.

(2) Other cases (in particular nonsymmetric ones) do not occur. M is *locally C-causal*, if it is C-causal in any region $U \subset M$. M is *C-causal* if conditions (1) and (2) hold $\forall p \in \mathscr{C}$.

Let M be C-causal in U. Then, $q \ll p \Leftrightarrow \exists r : q \in \mathcal{P}_r \wedge p \in \mathcal{F}_r$, and $q \lhd p \Leftrightarrow \exists r : q \in \mathscr{C}_r^+ \wedge p \in \mathscr{C}_r^-$.

If an open curve $\mathbb{R} \ni s \mapsto c(s)$ or a closed curve $S^1 \ni s \mapsto c(s)$ is embedded in M, then in particular its image is $\mathrm{im}(c) \equiv c(\mathbb{R}) \cong \mathbb{R}$ or $\mathrm{im}(c) \equiv c(S^1) \cong S^1$, respectively, whence it is free of self-intersections. Such a curve is called *spacelike*: $\Leftrightarrow \forall p \equiv c(s) \in \mathrm{im}(c) \exists \epsilon : c|_{]s-\epsilon, s+\epsilon[\setminus \{s\}} \in \mathcal{E}_{c(s)}$, and *timelike*: $\Leftrightarrow \forall p \equiv c(s) \in \mathrm{im}(c) \exists \epsilon : c|_{]s-\epsilon, s+\epsilon[\setminus \{s\}} \in \mathcal{I}_{c(s)}$.

Note that C-causality of M forbids a multiple refolding intersection topology for any two cones. In particular along any timelike curve the future/past cones do not intersect, because otherwise there would exist points which are simultaneously timelike and lightlike related. Continuity then implies that future/past cones in fact foliate the part of M which they cover. Hence, if there exists a fibration $\mathbb{R} \hookrightarrow \mathrm{int}\, M \twoheadrightarrow \Sigma$, then C-causality implies that the future/past cones foliate in particular on any fiber. In fact, given a fibration, one could define also a weaker form of causality just by the foliating property of all future/past cones on each fiber. (Physically this situation corresponds to ultralocal classical clocks. Quantum uncertainty of the fiber would require us to take appropriate ensemble averages over some bundle of neighboring fibers which then contains in particular spacelike related vertices on the fibers of the bundle. Then the corresponding future or past cones intersect for sure, and even timelike related ones of different fibers *may* intersect!) C-causality, however, requires more, namely the future/past cones of *all* timelike related vertices should be nonintersecting, not only those in a particular fiber.

Therefore C-causality allows also a reasonable definition of a *causal complement*.

Definition 9: For any open set S in a C-causal manifold M the causal complement is defined as

$$S^{\perp} := \bigcap_{p \in \mathrm{cl} S} \mathcal{E}_p, \tag{3.1}$$

where $\mathrm{cl}S$ denotes the closure in the topology induced from the manifold. Although the causal complement is always open, it will in general not be a contractable region even if S itself is so.

Assume p and q are timelike related, $p \in \mathcal{P}_q$ and $q \in \mathcal{F}_p$. $\mathcal{K}_p^q := \mathcal{F}_p \cap \mathcal{P}_q$ is the bounded open double cone between p and q. Given any bounded open $\mathcal{K}$ such that $\exists p, q \in M : \mathcal{K} = \mathcal{F}_p \cap \mathcal{P}_q$, we set $i^+(\mathcal{K}) := \{q\}$, $i^-(\mathcal{K}) := \{p\}$, and $i^0(\mathcal{K}) := \mathscr{C}_p^+ \cap \mathscr{C}_q^-$. For any $\mathcal{K}_p^q \subset M$ let $\mathrm{cl_c}(\mathcal{K}_p^q)$ be its causal closure.

Since C-causality prohibits relative refolding of cones, it also ensures that $(\mathcal{K}_p^q)^{\perp\perp} = \mathcal{K}_p^q$, i.e. the causal complement is a duality operation on double cones.

The open double cones of a C-causal manifold M generate a topology, called the *double cone topology* which is a genuine generalization of the usual Alexandrov topology for strongly causal space–times. For strongly causal space–times the Alexandrov topology is equivalent to the manifold topology.[5,6] When M fails to be locally causal the double cone topology may be coarser than the manifold topology.

Let us discuss now possible natural relations that can appear between two double cones $\mathcal{K}_1$ and $\mathcal{K}_2$ of a C-causal manifold. First there is the case $\mathcal{K}_1 \cap \mathcal{K}_2 = \emptyset$ which corresponds to causally unrelated sets. For $\mathcal{K}_1 \cap \mathcal{K}_2 \neq \emptyset$, the intersection is such that $\mathcal{K}_1 \cup \mathcal{K}_2 - \mathcal{K}_1 \cap \mathcal{K}_2$ is either given by two disconnected pieces or it is connected. In the latter case we distinguish whether $\partial\mathcal{K}_1 \cap \partial\mathcal{K}_2$ is empty or not. It is in the former case that one of $\mathcal{K}_1$ and $\mathcal{K}_2$ will be contained in the other.

Local C-causality does a priori not preclude other more pathological possibilities. However, it is possible to define in a purely topological manner more refined causality notions.

Definition 10: Let M be a C-causal manifold.

(i) M is globally hyperbolic: $\Leftrightarrow \mathrm{cl_c}\mathcal{K}_p^q$ compact $\forall p, q \in M$

(ii) M is *causally simple*: $\Leftrightarrow \mathrm{cl}_c \mathcal{K}_p^q$ closed $\forall p,q \in M$

(iii) M is *causally continuous*: $\Leftrightarrow$ M is distinguishing and both $\mathcal{F}: p \mapsto \mathcal{F}_p$ and $\mathcal{P}: q \mapsto \mathcal{P}_q$ are continuous

(iv) M is *stably causal*: $\Leftrightarrow$ M admits $\mathcal{C}^0$ function $f: M \to \mathbb{R}$ strictly monotonously increasing along each future directed nonspacelike curve (global time function)

(v) M is *strongly causal*: $\Leftrightarrow$ the topology generated by $\{\mathcal{K}_p^q\}_{p,q \in M}$ is equivalent to the manifold topology of M

(vi) M is *distinguishing*: $\Leftrightarrow \mathcal{F}_p = \mathcal{F}_q \Rightarrow p = q \wedge \mathcal{P}_p = \mathcal{P}_q \Rightarrow p = q$

(vii) M is *causal*: $\Leftrightarrow$ every closed curve in M is not nonspacelike

(viii) M is *chronological*: $\Leftrightarrow$ every closed curve in M is not timelike

If a manifold carries a Lorentzian metric we saw in Sec. II above that this is locally compatible with a strong LC structure. Beyond that it is an interesting question under which conditions a Lorentzian metric is *compatible* with some LC structure in the sense that $\eta_x(v,v) = 0 \Leftrightarrow [x \in \mathscr{C} \Rightarrow v \in T\mathscr{C} := \cup_{y \in N \subset \mathcal{C}} T_y N]$ where $N \subset \mathcal{C}$ is a submanifold of $\mathscr{C}$ with codimension 0 when x is not the vertex of $\mathscr{C}$ and codimension 1 when it is the vertex, and, correspondingly,

$$g_q(V(q),V(q)) = 0 \Leftrightarrow \left[\forall p \in M : q \in \mathscr{C}_p \Rightarrow V(q) \in T\mathscr{C}_p := \bigcap_{r \in \mathcal{C}} T_r \phi_p(N) \right], \tag{3.2}$$

i.e., the cones are the characteristic surfaces of the Lorentzian metric. As pointed out above, this does not hold in general. However, one might search for sufficient and necessary causality conditions such that this compatibility holds. A systematic investigation of this point is beyond our present investigations. Let us rather assure the correspondence of the causality notions of Def. 10 to the usual ones in the case of a Lorentzian space–time.

Theorem 2: Let M carry a smooth Lorentzian metric g. Then the Lorentzian metric determines a C-causal structure. If a C-causal structure of M is related to a Lorentz metric, then the definitions (i)–(viii) agree with the standard definitions and the following chain of implications of properties of M holds: globally hyperbolic $\Rightarrow$ causally simple $\Rightarrow$ causally continuous $\Rightarrow$ stably causal $\Rightarrow$ strongly causal $\Rightarrow$ distinguishing $\Rightarrow$ causal $\Rightarrow$ chronological.

Proof: Given a smooth Lorentzian metric g the cones determined by the null structure $[g]$ respect the relations of Def. 8, because otherwise there would exist some singularities. For (v) in the case of Lorentzian manifolds see Ref. 6; for the other notions and for the chain of implications see Ref. 7. □

Finally let us define a condition which excludes the existence of singularities or internal boundaries within the future and past cones.

Definition 11: Let M carry a (weak or strong) LC structure.

(i) M is precausal in an open region $U \subset M$, if the $d+1$-parameter CAT family $\{\phi_p\}_{p \in U}$ of CAT homeomorphisms $\phi_p : \mathbb{R}^{d+1} \supset V \to U$ is such that at any $p \in U$ it is $\mathscr{C}_p|_U = \phi_p \mathscr{C}|_V$, and any CAT submanifold of $\mathscr{C}_p$ or $(M - \mathscr{C}_p) \cap U$ is a CAT homeomorphic image of $\mathscr{C}$ or $(\mathbb{R}^{d+1} - \mathscr{C}) \cap V$, respectively. M is *locally precausal* iff it is precausal in any open region $U \subset M$.

(ii) M is *precausal* if it is locally precausal such that in the CAT $d+1$-parameter family $\{\phi_p\}_{p \in U}$ any CAT homeomorphism extends also to a homeomorphism of the interior $\phi_p : \mathcal{E} \to \mathcal{E}_p$.

IV. DISCUSSION AND PERSPECTIVE

Above we presented topological definitions of local (i.e., pointwise) cone (LC) structures for a general topological or differentiable manifold M of dimension $d+1 > 2$ and notions of causality on M in a purely topological manner. It is remarkable that such definitions are possible, whence the usual recursion to a Lorentzian metric becomes redundant.

Proposition 1 gives criteria which locally distinguish the exterior and the interior of the cone at any point from each other. Proposition 3 and Example 1 provide concrete global topological conditions for M in order to allow the relative distinction of interior and exterior of all its cones.

Minkowski space is obviously a manifold which satisfies the conditions for topologically distinguished interior and exterior according to Example 1. It is, however, a priori not clear what for each given category CAT of manifolds is the largest class of manifolds with the topological structure described in Example 1.

We saw that a global consistent distinction between future and past cones requires just a topological $\mathbb{Z}_2$-connection. Note that, as an important possible application, the canonical approach to quantum gravity comes always along with such a connection. In fact the canonical configuration variables for oriented manifolds maybe there be chosen as $\mathrm{SO}(d+1)$-connections.

The presented LC structures, C-causality, and other our purely topological causality notions provide some alternative to the poset approach [8–11] for defining causality in quantum theories of quantum gravity. While that approach is based on a much weaker local notion of causality on sets, which essentially involves only a partial ordering, the present definition gives us the possibility of working with the local definition of causality on differentiable manifolds which still captures the essential notions for curves in a C-causal manifold to be lightlike, timelike or spacelike without the need of an underlying Lorentzian structure. For any set S in a C-causal manifold a topological notion of a causal complement $S^{\perp}$ is given by (3.1). Any double cone $\mathcal{K}$ in a C-causal manifold then has the duality property $\mathcal{K}^{\perp\perp}=\mathcal{K}$.

Some advantages of conformal invariance in the quantization in minisuperspace models of higher-dimensional Einstein gravity have been pointed out in Refs. 12, 13. In particular, factor ordering problems can be resolved uniquely this way. For a more general background independent quantum theory the restriction of local diffeomorphisms to those consistent with a causal structure, say, e.g., a LC structure, on the whole manifold might appear too restrictive. After all a strong LC structure implies already the existence of a conformal metric, whence diffeomorphisms may be restricted locally to conformal ones. Nevertheless note that even a strong LC structure is much more flexible than a conformal metric structure. The local cones of different vertices might refold away from their vertices with rather complicated intersection topologies while a CAT continuous conformal metric within its (regular!) domain does not admit refolding singularities of the characteristic surfaces, each of the which is spanned out by all the null geodesics passing through a given vertex. Of course refolding and the associated singularities should be a topic of further more systematic investigations elsewhere.

The canonical approach to field quantization usually employs a foliation $\Sigma\hookrightarrow \mathrm{int}\, M \twoheadrightarrow \mathbb{R}$. This raises the question of when this is consistent with a (C-)causal structure. This may roughly be answered as follows: A CAT foliation of M may be said to be consistent with a C-causal structure, if for any open set O in a CAT slice $\Sigma\subset M$ there exists a double cone $\mathcal{K}\subset \mathrm{int}\, M$ such that $i^0(\mathcal{K})\subset\partial(\mathcal{K}\cap\Sigma)$ (compare also Sec. III, below Def. 9).

Consider now such a double cone $\mathcal{K}$ in M with $O:=\mathcal{K}\cap\Sigma$ and $\partial O=i^0(\mathcal{K})$ and a diffeomorphism ϕ in M with pullbacks $\phi^{\Sigma}\in\mathrm{Diff}(\Sigma)$ to Σ and $\phi^{\mathcal{K}}\in\mathrm{Diff}(\Sigma)$ to $\mathcal{K}$. If $\phi(\mathcal{K})=\mathcal{K}$, it can be naturally identified with an element of $\mathrm{Diff}(\mathcal{K})$. ($\phi|_{M-K}=\mathrm{id}_{M-\mathcal{K}}$ is a sufficient but not necessary condition for that to be true.) If in addition $\phi(\Sigma)=\Sigma$ then also $\phi(O)=O$, and $\phi|_O$ is a diffeomorphism of O.

When M is homeomorphic to $\Sigma\times\mathbb{R}$ it is straightforward to extend the above from a single hypersurface $\Sigma\subset M$ to a foliation of M via a 1-parameter set of embeddings $\Sigma\hookrightarrow M$.

For a canonical approach to quantum gravity, one might want to work with a restriction of the causal structure to cones with their vertices on a given graph Γ within a slice Σ of a foliation. A given topological (differentiable) causal structure, selects particular causal homeomorphisms (diffeomorphisms) which preserve it. A strong LC structure on all of M already implies the existence of a conformal metric structure and a requirement of compatibility with that metric would reduce the local covariance group to local conformal diffeomorphisms. One might, however, also weaken the LC and causal structure of the manifold by considering in any leaf Σ of a given foliation only cones with vertices on $\Gamma\subset\Sigma$ instead on all of Σ. A natural choice for Γ is the dual graph of a triangulation. Then the cones have to CAT vary along the edges, but at least for $\mathrm{CAT}\supset C^{\infty}$ the cones at the vertices of the graph can be freely ascribed. Consequently, a geometry constructed on that basis will be invariant under diffeomorphisms much more general than conformal ones.

Let us, however, also emphasize that, although the existence of a local conformal metric is guaranteed by a strong LC structure, it is a priori not obvious that this metric should play any significant rôle. Then, however, also the need to restrict diffeomorphisms to those compatible with the conformal metric may be questioned. One might eventually expect that within some approach to quantum geometry a cone at a vertex $p \in O \subset \Sigma$ should be replaced by an appropriate average over cones with vertices within some region O of minimal Heisenberg uncertainty. Then the flexibility of the weak and strong LC structures makes them interesting concepts and potential ingredients for a possible definition of quantum causality too. Presently, however, this is still a matter of many speculations.

Classically, the existence of a local metric requires only the differentiable structure in an arbitrary small neighborhood of the vertex, and the defined LC structures fix the preferred null directions only locally at each vertex. With sufficiently strong notions of causality (e.g., C-causality above) the null structures of this metric may become consistent with the global structure of cones of the LC structure. Note that in the case of a given Lorentz metric null geodesics lie on cones, and with sufficiently strong causality, e.g. global hyperbolicity, these cones have to be consistent with respect to each other and under variation of the vertex without refolding into each other (i.e., in particular without conjugate points).

For Lorentzian manifolds there is a hierarchy of common notions of causality which have been generalized above. Provided our definitions of causality are sufficiently natural it should be possible to prove (at least parts) of this hierarchy in the more general topological setting. However, a complete investigation of the mutual relations between different topological causality concepts is beyond the scope and goal of the present paper.

It should be emphasized that the above was just brief demonstration of the possibility to introduce notions of cones and causality on CAT topological manifolds without a metric. In particular, weak and strong LC structures, C-causality, precausality, and some generalizations of the most common notions of causality have been obtained. However, the investigation is far from complete. It remains for future work to develop the topological approach to causal structures on manifolds further, to investigate better some of its implications, and last not least to demonstrate its applicability in background independent formulations of algebraic quantum field theory and quantum gravity.

We estimate from above the set of knots, $\Omega(n,\mu)$, generated by closure of the n-string 1+1- and 2+1-dimensional braids of irreducible length $\mu(\mu \gg 1)$ in the limit $n \gg 1$. © *1999 American Institute of Physics.* [S0022-2488(99)04307-8]

I. INTRODUCTION

Besides the traditional fundamental topological issues concerning the construction of new topological invariants, investigation of homotopic classes and fibre bundles we mark a set of ajoint but much less studied problems. First of all, we mean the problem of so-called ''knot entropy'' calculation. Most generally it can be formulated as follows. Take the lattice $\mathbb{Z}^3$ embedded in the space $\mathbb{R}^3$. Let Ω be the ensemble of all possible closed non-self-intersecting N-step paths with one common fixed point on $\mathbb{Z}^3$; by ω_N we denote the particular configuration of the trajectory. The main question is: what is the fraction P_N of the trajectories $\omega_N \in \Omega$ belonging to some specific homotopic class characterized by the topological invariant Inv (we do not specify the way of defining the topological invariant). The distribution function $P\{\text{Inv}\}$ satisfies the obvious normalization condition $\Sigma_{\text{all } \omega_N \in \Omega} P_N\{\text{Inv}\} = 1$.

In the present paper we pay attention to the statistical problem concerning the estimation of the set $\Omega = \{\Omega^{(1)}, \Omega^{(2)}\}$ of knots generated by closure of braids embedded in 1+1- and 2+1-dimensions (see the definitions below).

The paper is organized as follows. Below we give the basic definitions of the standard 1+1-dimensional and 2+1-dimensional braid groups as well as formulate the basic results; Sec. II is devoted to the estimations of the sets $\Omega^{(1)}$ and $\Omega^{(2)}$ using the concept of 1+1- and 2+1-locally-free groups; while in the Conclusion we discuss in more details the corollaries following our consideration.

A. The basic definitions

(1) The 1+1-dimensional (''standard'') braid group $B^{(1)}_{n+1}$ of $n+1$ strings has n generators $\{\sigma_1, \sigma_2, \ldots, \sigma_n$ and their inverses$\}$ [see Fig. 1(a)] with the following relations:

$$\begin{aligned} \sigma_i\sigma_{i+1}\sigma_i &= \sigma_{i+1}\sigma_i\sigma_{i+1} \quad (1 \le i < n) \\ \sigma_i\sigma_j &= \sigma_j\sigma_i \quad (|i-j| \ge 2) \\ \sigma_i\sigma_i^{-1} &= \sigma_i^{-1}\sigma_i = e. \end{aligned} \tag{1}$$

(2) The 2+1-dimensional (''surface'') braid group $B^{(2)}_{n+1}$ can be defined in the following way (see, for instance Refs. 1, 2). Consider the two-dimensional lattice $\mathbb{Z}^2$ and take distinct points $P_1, P_2, \ldots, P_{n+1} \in \mathbb{Z}^2$. A 2+1-braid of $n+1$ strings on $\mathbb{Z}^2$ based at $\{P_1, P_2, \ldots, P_{n+1}\}$ is an $n+1$-tuple $b = (b_1, \ldots, b_{n+1})$ of paths, $b_i : [1,N] \to \mathbb{Z}^2$, such that

(i) $b_i(1) = P_i$ and $b_1(1) \in \{P_1, P_2, \ldots, P_{n+1}\} \forall i \in \{1, ... n+1\}$;

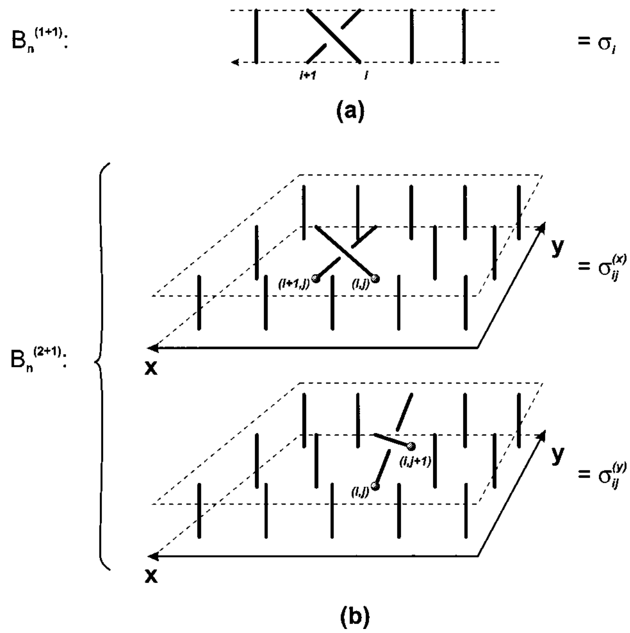

FIG. 1. Representation of (a) $1+1$-braid group generator, σ_i; (b) $2+1$-braid group generators $\sigma^x_{i,j}$ and $\sigma^y_{i,j}$.

(ii) $b_i(t) \neq b_j(t) \forall \{i,j\} \in \{1,...,n+1\},\ i \neq j;\ t \in [1,N]$.

The braid group $B^{(2)}_{n+1}$ on $\mathbb{Z}^2$ based at $\{P_1, P_2, \ldots, P_{n+1}\}$ is the group of homotopy classes of braids based at $\{P_1, P_2, \ldots, P_{n+1}\}$. The group $B^{(2)}_{n+1}$ has $2(n \times n)$ generators $\{(\sigma^{(x)}_{11}, \sigma^{(y)}_{11}), \ldots, (\sigma^{(x)}_{1n}, \sigma^{(y)}_{1n}); \ldots; (\sigma^{(x)}_{n1}, \sigma^{(y)}_{n1}), \ldots, (\sigma^{(x)}_{nn}, \sigma^{(y)}_{nn})$ and their inverses$\}$ [see Fig. 1(b)] with the following relations:

$$
\begin{gathered}
\sigma^{(x)}_{i,j}\sigma^{(x)}_{i+1,j}\sigma^{(x)}_{i,j} = \sigma^{(x)}_{i+1,j}\sigma^{(x)}_{i,j}\sigma^{(x)}_{i+1,j} \quad (1 \leqslant \{i,j\} \leqslant n) \\
\sigma^{(y)}_{i,j}\sigma^{(y)}_{i,j+1}\sigma^{(y)}_{i,j} = \sigma^{(y)}_{i,j+1}\sigma^{(y)}_{i,j}\sigma^{(y)}_{i,j+1} \quad (1 \leqslant \{i,j\} \leqslant n) \\
\sigma^{(x)}_{i,j}\sigma^{(y)}_{i,j}\sigma^{(x)}_{i,j} = \sigma^{(y)}_{i,j}\sigma^{(x)}_{i,j}\sigma^{(y)}_{i,j} \quad (1 \leqslant \{i,j\} \leqslant n) \\
\sigma^{(x)}_{i_1,j_1}\sigma^{(x)}_{i_2,j_2} = gj^{(x)}_{i_2,j_2}\sigma^{(x)}_{i_1,j_1} \quad (|i_1 - i_2| > 1 \ \text{ or } \ |j_1 - j_2| > 0) \\
\sigma^{(x)}_{i_1,j_1}\sigma^{(y)}_{i_2,j_2} = \sigma^{(y)}_{i_2,j_2}\sigma^{(x)}_{i_1,j_1} \quad (i_2 - i_1 \neq \{0,1\} \ \text{ or } \ j_1 - j_2 \neq \{0,1\}) \\
\sigma^{(x)}_{i,j}(\sigma^{(x)}_{i,j}))^{-1} = \sigma^{(y)}_{i,j}(\sigma^{(y)}_{i,j}))^{-1} = e.
\end{gathered} \tag{2}
$$

The braid groups $B^{(1)}_n$ and $B^{(2)}_n$ have the following general properties:

(a) Any arbitrary word written in terms of ''letters''—generators of the groups $B^{(1)}_n$ or $B^{(2)}_n$—gives a particular braid.

(b) The *length*, *N*, of the braid is the total number of used letters, while the *minimal irreducible length*, μ, hereafter referred to as the ''primitive length'' is the shortest noncontractible length of a particular braid which remains after applying of all possible group relations. Diagrammatically the braid can be represented as a set of crossed strings going from the top to the bottom appeared after subsequent gluing the braid generators.

(c) The closed braid appears after gluing the ''upper'' and the ''lower'' free ends of the braid on the cylinder.

B. The main results

Our basic results might be formulated in a geometrically clear way. Consider two sets of braids $\{B_n^{(1)}\}$ and $\{B_n^{(2)}\}$, embedded in $1+1$- and $2+1$-dimensions correspondingly. Let each particular braid has the primitive length μ and is represented by n strings.

Then

(1) The set $\Omega^{(1)}(n,\mu)$ of knots which can be generated by the standard braids of given irreducible length $\mu(\mu\geqslant 1)$ from the set $\{B_n^{(1)}\}$ ($n=\text{const}\geqslant 1$) is restricted from above by the value

$$\Omega^{(1)}(n,\mu)<\frac{32\pi^2}{\log^4 2}\frac{2^n}{n^3}7^{\mu-1}. \tag{3}$$

(2) The set $\Omega^{(2)}(n,\mu)$ of knots which can be generated by the surface braids of given irreducible length $\mu(\mu\geqslant 1)$ from the set $\{B_n^{(2)}\}$ ($n=\text{const}\geqslant 1$) is restricted from above by the value

$$\Omega^{(2)}(n,\mu)<\frac{32n^2}{\pi^2}\left(\frac{2n}{\log n}\right)^{\mu-1}. \tag{4}$$

(See the Conclusion for more detailed discussion of the results (3) and (4).)

II. COMBINATORICS OF WORDS

Any braid corresponds to some knot or link. The correspondence between braids and knots is not mutually single valued and each knot or link can be represented by infinite series of different braids. However, we can estimate from above the partition functions $\Omega^{(1)}(n,\mu)$ and $\Omega^{(2)}(n,\mu)$ of all possible knots generated by the ensemble of all $1+1$- and $2+1$-braids of primitive length μ using the following obvious fact. *The sets $\Omega^{(1)}(n,\mu)$ and $\Omega^{(2)}(n,\mu)$ are bounded from above by the number of all distinct words of the primitive length μ in $1+1$- and $2+1$-braid groups correspondingly.* Thus in what follows we are aimed in the estimation of the number of non-equivalent words in the standard and surface braid groups.

A. Definitions of 1+1- (''standard'') and 2+1- (''surface'') locally free groups

(1) Following the ideas of Vershik concerning the notion of the ''local groups''[3] and the papers,[4] where the concept of a ''locally free'' group was proposed at first in the topological context, let us define the group, $\mathcal{LF}_{n+1}^{(1)}$, which has n generators $\{f_1,\dots,f_n$ and their inverses$\}$ with the relations,

$$\begin{cases} f_j f_k = f_k f_j \ \text{ for } \ |j-k|\geqslant 2 \\ f_i f_i^{-1} = e. \end{cases} \tag{5}$$

We call the group with relations (5) the $1+1$-dimensional ''locally free group,'' because each pair of generators $(f_j, f_{j\pm 1})$ produces a free subgroup of the group $\mathcal{LF}_{n+1}^{(1)}$.

The group $\mathcal{LF}_{n+1}^{(1)}$ can be obtained from the braid group $B_{n+1}^{(1)}$ if we replace the braiding (''Yang–Baxter-type'') relations by the free ones. The geometrical interpretation of the generators of a group $\mathcal{LF}_{n+1}^{(1)}$ is shown in Fig. 2(a).

Apparently, in mathematical literature the notion similar to our ''locally free group'' appeared first in the paper[5] devoted to the investigation of the combinatorial properties of rearrangements of

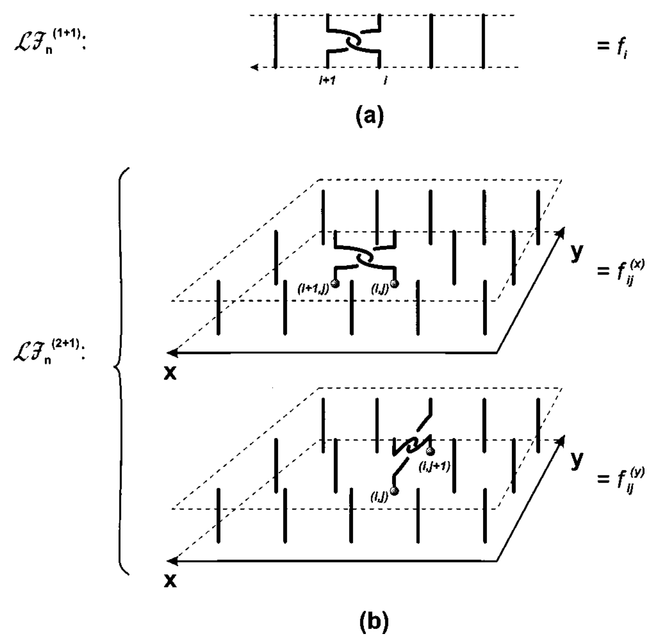

FIG. 2. Representation of (a) $1+1$-locally free group generator, f_i; (b) $2+1$-locally free group generators $f^x_{i,j}$ and $f^y_{i,j}$.

sequences, known also as ''partially commutative monoids'' (see Ref. 6, and references therein).

(2) The $2+1$-dimensional (''surface'') locally free group $\mathcal{LF}^{(2)}_{n+1}$ has $2(n\times n)$ generators $\{(f^{(x)}_{11},f^{(y)}_{11}),\dots,(f^{(x)}_{1n},f^{(y)}_{1n});\dots;(f^{(x)}_{n1},f^{(y)}_{n1}),\dots,(f^{(x)}_{nn},f^{(y)}_{nn})$ and their inverses$\}$ with the following relations:

$$f^{(x)}_{i_1,j_1}f^{(x)}_{i_2,j_2}=f^{(x)}_{i_2,j_2}f^{(x)}_{i_1,j_1}\quad(|j_1-j_2|>0\ \text{ or }\ |i_1-i_2|>1)$$

$$f^{(x)}_{i_1,j_1}f^{(y)}_{i_2,j_2}=f^{(y)}_{i_2,j_2}f^{(x)}_{i_1,j_1}\quad(i_2-i_1\neq\{0,1\}\ \text{ or }\ j_1-j_2\neq\{0,1\})\tag{6}$$

$$f^{(x)}_{i,j}(f^{(x)}_{i,j})^{-1}=f^{(y)}_{i,j}(f^{(y)}_{i,j})^{-1}=e.$$

Thus, we can construct the $2+1$-locally free group $\mathcal{LF}^{(2)}_{n+1}$ from the surface braid group $B^{(2)}_{n+1}$ if we replace the braiding relations of the neighboring generators by the ''full monodromy,'' i.e., by the free group relations [see Fig. 2(b)].

The following important properties of $1+1$- and $2+1$-locally free groups should be mentioned.

(i) By definition the locally free groups $\mathcal{LF}^{(1)}_{n+1}$ and $\mathcal{LF}^{(2)}_{n+1}$ have less relations than the braid groups $B^{(1)}_{n+1}$ and $B^{(2)}_{n+1}$ correspondingly. *Thus, the number of distinct words of the primitive length* μ *in the* $1+1$- *and* $2+1$-*braid groups is bounded from above by the number of distinct words of the primitive length* μ *in the* $1+1$- *and* $2+1$-*locally free groups.*

(ii) By construction (compare Figs. 1 and 2) the monodromy generators f_i ($i\in[1,n]$) of the group $\mathcal{LF}^{(1)}_{n+1}$ and $f^{(x,y)}_{i,j}$ ($\{i,j\}\in[1,n]$) of the group $\mathcal{LF}^{(2)}_{n+1}$ can be written as $f_i=(\sigma_i)^2$ ($i\in[1,n]$) and $f^{(x,y)}_{i,j}=(\sigma^{(x,y)}_{i,j})^2$ ($\{i,j\}\in[1,n]$), where σ_i and $\sigma^{(x,y)}_{i,j}$ are the generators of the groups $B^{(1)}_{n+1}$ and $B^{(2)}_{n+1}$ correspondingly. *Thus, the number of distinct words of the primitive length* 2μ *in the* $1+1$- *and* $2+1$-*braid groups is bounded from below by the* *number of distinct words of the primitive length μ in the $1+1$- and $2+1$-locally free groups.*

B. Computation of number of nonequivalent words in 1+1- and 2+1-locally free groups

We derive explicitly the expressions of the numbers $V^{(1)}(n,\mu)$ and $V^{(2)}(n,\mu)$ of all nonequivalent primitive words of length μ in the groups $\mathcal{LF}_{n+1}^{(1)}$ and $\mathcal{LF}_{n+1}^{(2)}$, respectively. Our computations are based on the so-called "normal order" representation of words proposed by Vershik in Ref. 7 (see also Ref. 4).

1. The group $\mathcal{LF}_{n+1}^{(1)}$

Let us represent each word W_p of irreducible length μ in the group $\mathcal{LF}_{n+1}^{(1)}$ in the "standard" form

$$W_p=(f_{\alpha_1})^{m_1}(f_{\alpha_2})^{m_2}\cdots(f_{\alpha_s})^{m_s}, \tag{7}$$

where $\Sigma_{i=1}^{s}|m_i|=\mu$ $(m_i\neq 0\,\forall i;\ 1\leqslant s\leqslant\mu)$ and the sequence of generators f_{α_i} in Eq. (7) *for all distinct* f_{α_i}, satisfies the following local rules[4] ("normal order" representation),

(i) If $f_{\alpha_i}=f_1$, then $f_{\alpha_{i+1}}=f_2$;

(ii) If $f_{\alpha_i}=f_k$ $(2\leqslant k\leqslant n-1)$, then $f_{\alpha_{i+1}}\in\{f_1,\ldots,f_{k-1},f_{k+1},\}$;

(iii) If $f_{\alpha_i}=f_n$, then $f_{\alpha_{i+1}}\in\{f_1,\ldots,f_{n-1}\}$.

The rules (i)–(iii) give the prescription how to encode and enumerate all distinct primitive words in the group $\mathcal{LF}_{n+1}^{(1)}$. If the sequence of generators in the primitive word W_p does not satisfy the rules (i)–(iii), we commute the generators in the word W_p until the normal order is restored. Hence, the normal order representation enables one to give the unique coding of all nonequivalent primitive words in our group.

Let $\theta_n(m)$ be the number of all distinct sequences of $m+1$ generators, $0\leqslant m\leqslant\mu-1$, satisfying the rules (i), (ii), (iii). The calculation of the number of distinct primitive words $V^{(1)}\times(n,\mu)$ of given primitive length μ is now straightforward,

$$V^{(1)}(n,\mu)=\sum_{m=0}^{\mu-1}2^{m+1}\binom{\mu-1}{m}\theta_n(m). \tag{8}$$

The combinatorial factor $2^{m+1}\binom{\mu-1}{m}$ in Eq. (8) is the number of all primitive words of length μ written in a normal order form for the *fixed sequence* of $m+1$ generators.

Our approach to the computation of $\theta_n(m)$ is based on the consideration of a "correlation function" $\theta_n(x,x_0,m)$ which is defined as the number of all distinct sequences of $m+1$ generators satisfying the rules (i), (ii), (iii), beginning with the generator f_{x_0} and ending with the generator f_x. It is easy to write an evolution equation for $\theta(x,m)\equiv\theta_n(x,x_0,m)$ with the "time" m,

$$\theta(x,m+1)=\theta(x-1,m)+\sum_{y=x+1}^{n}\theta(y,m). \tag{9}$$

This equation should be completed by initial and boundary conditions

$$\begin{gathered}\theta(x,0)=\delta_{x,x_0}\\ \theta(0,m)=\theta(n+1,m)=0.\end{gathered} \tag{10}$$

We solve the boundary problems (9)–(10) in the limit $n\gg 1$ supposing the periodical boundary conditions on the segment $[0,n+1]$. Namely, we have

$$\theta(x+1,m+1)-\theta(x,m+1)=\theta(x,m)-\theta(x-1,m)-\theta(x+1,m)$$
$$\theta(x,0)=\delta_{x_0,x} \tag{11}$$
$$\theta(0,m)=\theta(n+1,m)=0.$$

The substitution

$$\theta(n,m)=\sum_{k=1}^{n} A_k \lambda_k^m \alpha_k(x) \tag{12}$$

enables us to pass to the following recursion relations

$$(\lambda_k+1)\alpha_k(x+1)-(\lambda_k+1)\alpha_k(x)+\alpha_k(x-1)=0$$
$$\alpha_k(0)=\alpha_k(n+1)=0. \tag{13}$$

One can readily find the eigenvalues and eigenfunctions of (13),

$$\lambda_k=4\cos^2\frac{\pi k}{n+1}-1,$$
$$\alpha_k(x)=\frac{\sin\frac{\pi k x}{n+1}}{\left(2\cos\frac{\pi k}{n+1}\right)^x}, \quad k=1,...,n. \tag{14}$$

As the function (13) is not symmetric, the set of eigenfunctions is not orthogonal on the segment $[0,n+1]$ and it is difficult to ensure the initial condition. It is convenient to pass from (13) to symmetric problem. Consider a generating function

$$Z(x,s)=\sum_{m=0}^{\infty} s^m\theta(x,m). \tag{15}$$

The equation for the function $Z(x,s)$ reads

$$(s+1)Z(x+1,s)-(s+1)Z(x,s)+sZ(x-1,s)=\delta_{x,x_0-1}-\delta_{x,x_0}$$
$$Z(0,s)=Z(n+1,s)=0. \tag{16}$$

The last equation can be symmetrized via the substitution $Z(x,s)=A^x\varphi(x,s)$, where $A=\sqrt{s/(s+1)}$. Thus, we get

$$\varphi(x+1,s)-\frac{1}{A}\varphi(x,s)+\varphi(x-1,s)=\frac{A^{-x}}{\sqrt{s(s+1)}}(\delta_{x,x_0-1}-\delta_{x,x_0})$$
$$\varphi(0,s)=\varphi(n+1,s)=0. \tag{17}$$

Making use of the sin-Fourier transform, $f(k,s)=\sum_{x=1}^{n}\varphi(x,s)\sin[\pi kx/(n+1)]$, let us rewrite (17) in the form

$$\left(2\cos\frac{\pi k}{n+1}-\frac{1}{A}\right)f(k,s)=\frac{A^{-x_0}}{\sqrt{s(s+1)}}\left(A\sin\frac{\pi k(x_0-1)}{n+1}-\sin\frac{\pi k x_0}{n+1}\right).$$

The final explicit expression of the function $Z(x,s)$ reads as follows:

$$Z(x,s)=\frac{2}{(n+1)(s+1)}\left(\frac{s}{s+1}\right)^{(x-x_0)/2}\sum_{k=1}^{n}\frac{\sqrt{\frac{s+1}{s}}\sin\frac{\pi k x_0}{n+1}-\sin\frac{\pi k(x_0-1)}{n+1}}{\sqrt{\frac{s+1}{s}}-2\cos\frac{\pi k}{n+1}}\sin\frac{\pi k x}{n+1}.$$

Now we can restore the function $\theta(x,m)$ via contour integration

$$\theta(x,m)=\frac{1}{2\pi i}\oint_C\frac{Z(x,s)}{s^{m+1}}ds,$$

where the contour C surrounds the point $s=0$ and is displaced in the regularity area of the function $Z(s)\equiv Z(x,s)$. Hence

$$\theta(x,m)=-\sum_{s_k}\mathrm{Res}\left(\frac{Z(x,s_k)}{s_k^{m+1}}\right),$$

where s_k are the poles out of the regularity area,

$$s_k=\frac{1}{4\cos^2\frac{\pi k}{n+1}-1}$$

(compare to (14)). We are interested only in the asymptotic behavior $m\gg 1$ of the function $\theta_n(x,x_0,m)$ which is determined by the poles nearest to the origin, $s_1=s_n=\frac{1}{3}$ for $n\gg 1$. So we get

$$\theta_n(x,x_0,m)=\frac{4}{n+1}\sin\frac{\pi(x_0+1)}{n+1}\sin\frac{\pi x}{n+1}2^{x_0-x}3^m. \tag{18}$$

To find the function $\theta_n(m)$ we should sum up $\theta(x,x_0,m)$ over all x and x_0; $\theta_n(m)=\Sigma^n{}_{x,x_0=1}\theta_n(x,x_0,m)$. We obtain in the limit for $n=\text{const}\gg 1$ the following expression:

$$\theta_n(m)=\frac{16\pi^2}{\log^4 2}\frac{2^n}{n^3}3^m. \tag{19}$$

The whole number of nonequivalent words follows from Eq. (8) in the limits $n=\text{const}\gg 1$, $\mu\gg 1$,

$$V^{(1)}(n,\mu)=\frac{32\pi^2}{\log^4 2}\frac{2^n}{n^3}7^{\mu-1}. \tag{20}$$

2. The group $\mathcal{LF}_{n+1}^{(2)}$

It is convenient to enumerate the generators $f_{ij}^{(\alpha)}$, $i,j=1,...,n^2$, $\alpha=x,y$, ordering them in a sequence, $(f_{11}^{(x)},f_{11}^{(y)}),\ldots,(f_{1n}^{(x)},f_{1n}^{(y)}),\ldots,(f_{n1}^{(x)},f_{n1}^{(y)}),\ldots,\ (f_{nn}^{(x)},f_{nn}^{(y)})$. For any such sequence we define the ''normal order'' according to the prescriptions (i)–(iii). Let z be the serial number of the pair $(f_{ij}^{(x)},f_{ij}^{(y)})$. Consider the functions $a(z,m)$ and $b(z,m)$ defined as numbers of all distinct sequences of $m+1$ generators satisfying the rules (i)–(iii) and ending with $f_{ij}^{(x)}$ and $f_{ij}^{(y)}$, respectively. One can readily write the evolution equations for $a(z,m)$ and $b(z,m)$ similar to (9),

$$a(z,m+1)=a(z-1,m)+b(z-n,m)+b(z-n+1,m)+b(z,m)+\sum_{z'=z+1}^{n^2}(a(z',m)+b(z',m))$$
$$b(z,m+1)=b(z-n,m)+a(z-1,m)+a(z,m)+\sum_{z'=z+1}^{n^2}(a(z',m)+b(z',m)). \tag{21}$$

Analogous to the case of the group $\mathcal{LF}_{n+1}^{(1)}$ let us suppose in the limit $n\gg 1$ the periodical boundary conditions on the segment $[0,n^2+1]$. So we have

$$\begin{aligned}a(z+1,m+1)-a(z,m+1)&=b(z-n+2,m)-b(z-n,m)\\&\quad-b(z,m)+a(z,m)-a(z-1,m)-a(z+1,m),\\ b(z+1,m+1)-b(z,m+1)&=b(z-n+1,m)-b(z-n,m)-a(z-1,m)-b(z+1,m),\\ a(0,m)=b(0,m)&=a(n^2+1,m)=b(n^2+1,m)=0,\quad m=0,1,...,\\ a(z,0)=b(z,0)&=1,\quad z=1,...,n^2.\end{aligned} \tag{22}$$

The initial conditions differ from (11) because in (22) we do not fix the first generator in the sequence involved.

Assuming that $|a(z,m)-b(z,m)|\to 0(n\to\infty)$ uniformly for z and m, we may pass from (22) to a single closed equation for the function $b(z,m)$. (The self-consistency of this supposition we check at the end of our computations.) So, we get

$$\begin{aligned}b(z+1,m+1)-b(z,m+1)&=b(z-n+1,m)-b(z-n,m)-b(z-1,m)-b(z+1,m),\\ b(0,m)=b(n^2+1,m)&=0,\quad m=0,1,...,\\ b(z,0)&=1,\quad z=1,...,n^2.\end{aligned} \tag{23}$$

Performing the decomposition $b(z,m)=\sum_{k=1}^{n^2}B_k\lambda_k^m\beta_k(z)$, we arrive at the following boundary problem:

$$\begin{aligned}(\lambda_k+1)\beta_k(z+1)-\lambda_k\beta_k(z)+\beta_k(z-1)+\beta_k(z-n)-\beta_k(z-n+1)&=0\\ \beta_k(0)=\beta_k(n^2+1)&=0.\end{aligned} \tag{24}$$

Let us look for the solution of Eq. (24) in the form $\beta_k(z)=p_k^z\sin[\pi kz/(n^2+1)]$. Substituting this ansatz in (24) we obtain an equation for p_k as well as an expression for λ_k,

$$\begin{aligned}&\sin\frac{\pi k}{n^2+1}p_k^{n+1}+\sin\frac{2nk}{n^2+1}p_k^n-\sin\frac{\pi k}{n^2+1}p_k^{n-1}-\sin\frac{\pi kn}{n^2+1}p_k^2\\&+2\cos\frac{\pi k}{n^2+1}\sin\frac{\pi kn}{n^2+1}p_k-\sin\frac{\pi kn}{n^2+1}=0,\\ &\lambda_k=p_k^{-2}-1-p_k^{-n}\frac{\sin\frac{\pi k(n-1)}{n^2+1}}{\sin\frac{\pi k}{n^2+1}}+p_k^{-n-1}\frac{\sin\frac{\pi kn}{n^2+1}}{\sin\frac{\pi k}{n^2+1}}.\end{aligned} \tag{25}$$

In Eq. (25) each root $p_k^{(i)}$ corresponds to different values of $\lambda_k^{(i)}$. However, we are interested only in the asymptotic behavior of $b(z,m)(m\gg 1)$ determined by the largest value of $\lambda_k^{(i)}$ for $k=1$. (Compare to the case of the group $\mathcal{LF}_{n+1}^{(1)}$, Eq. (14).) Equation (25) at $k=1$ and $n\gg 1$ reads

$$\begin{aligned} &p_1^{n+1}+2p_1^n-p_1^{n-1}-n(p_1-1)^2=0,\\ &\lambda_1=p_1^{-2}-1+np_1^{-n-1}-(n-1)p_1^{-n}. \end{aligned} \tag{26}$$

One can easily check that the smallest positive root corresponding to the largest value of $\lambda_1^{(i)}$ is

$$p_1=1-\frac{\log n}{n}+o\left(\frac{\log n}{n}\right), \quad n=\text{const}\gg 1,$$

and

$$\lambda_1=\frac{n}{\log n}+o\left(\frac{n}{\log n}\right), \quad n=\text{const}\gg 1. \tag{27}$$

In the $1+1$-dimensional case the same value of λ_k was given by the right edge of the spectrum, but in $2+1$-dimensional case one can prove that Eq. (25) for any $i>1$ has no solution $\lambda_{n^2}^{(i)}$ growing as fast as λ_1. The coefficients B_k should be found from the initial condition

$$\sum_{k=1}^{n^2} B_k\beta_k(z)=1.$$

As $p_1\to 1$ $(n\gg 1)$ we can expect the set $\beta_k(z)$ to be orthogonal in the vicinity of the left edge of the spectrum, so B_1 is determined basically by the expression

$$B_1=\frac{\int_0^{n^2+1}\beta_1(z)dz}{\int_0^{n^2+1}\beta_1^2(z)dz}, \quad n\gg 1.$$

Now we have the following equation for the function for $b(z,m)$ in the limits $n=\text{const}\gg 1$ and $m\gg 1$,

$$b(z,m)=\frac{4}{\pi}\sin\frac{\pi z}{n^2+1}\left(\frac{n}{\log n}\right)^m. \tag{28}$$

If we suppose the equality $a(z,m)=b(z,m)$, where $b(z,m)$ is given by (28), it is easy to check that $a(z,m)$ and $b(z,m)$ really satisfy Eqs. (22) in the limits $n\gg 1$, $m\gg 1$. This fact proves our assumption about the behaviors of $a(z,m)$ and $b(z,m)$ in a self-consistent way.

The limiting expression of the function $\tilde{\theta}_n(m)$ which is defined similar to the function $\theta_n(m)$ in the $1+1$-dimensional case reads

$$\tilde{\theta}_n(m)=\sum_{z=1}^{n^2} a(z,m)+b(z,m)=\frac{16n^2}{\pi^2}\left(\frac{n}{\log n}\right)^m.$$

Thus, the asymptotics of the number of nonequivalent words of given irreducible length, μ in the limit $n=\text{const}\gg 1$, $\mu\gg 1$ is

$$V^{(2)}(n,\mu)=\sum_{m=0}^{\mu-1} 2^{m+1}\binom{\mu-1}{m}\tilde{\theta}_n(m)=\frac{32n^2}{\pi^2}\left(\frac{2n}{\log n}\right)^{\mu-1} \tag{29}$$

(compare to Eq. (20).)

III. CONCLUSION

The principal difference between the limiting behavior of the partition functions $V^{(1)}(n,\mu)$ and $V^{(2)}(n,\mu)$ (and, hence, between the upper boundaries of the sets $\Omega^{(1)}(n,\mu)$ and $\Omega^{(2)}(n,\mu)$) becomes at most illuminating in the limit $n=\text{const}\gg 1$ and $\mu\to\infty$ if we consider the following limit:

$$f_{1,2}=\left[\lim_{\mu\to\infty}\frac{\log V^{(1,2)}(n,\mu)}{\mu}\right]_{n=\text{const}\gg 1}. \tag{30}$$

Using Eqs. (20) and (29), we get

$$f_1=\log 7$$

$$f_2=\frac{2n}{\log n}.$$

Thus, we can conclude, that with the exponential accuracy in the limit $n=\text{const}\gg 1$ and $\mu\to\infty$ the set $\Omega^{(1)}(n,\mu)$ is bounded from above by the n-independent estimate, i.e., $\Omega^{(1)}(n,\mu)$ is ''representation-independent;'' while the set $\Omega^{(2)}(n,\mu)$ with the same accuracy and in the same limit depends strongly on the braid representation (i.e., on the number of strings, n).

Equations (20) and (29) enable us to make some conclusions about the structure of the graphs corresponding to the groups $\mathcal{LF}_n^{(1)}$ and $\mathcal{LF}_n^{(2)}$. These graphs can be viewed as follows. Take the *free* $1+1$- or $2+1$-groups, where all generators do not commute at all. The graphs of these groups have structures of $2n$- and $2n^2$-branching Cayley trees, where the number of distinct words of length μ is equal to

$$V_{\text{free}}^{(1)}(n,\mu)=2n(2n-1)^{\mu-1} \quad \text{for } 1+1-\text{free group}$$

$$V_{\text{free}}^{(2)}(n,\mu)=2n^2(2n^2-1)^{\mu-1} \quad \text{for } 2+1-\text{free group.}$$

The graphs corresponding to the groups $\mathcal{LF}_n^{(1,2)}$ can be constructed from the graphs of the free groups in accordance with the following recursion procedure:

(i) Take the root vertex of the free group graph and consider all vertices on the distance $\mu=2$. Identify those vertices which correspond to the equivalent words in groups $\mathcal{LF}_n^{(1,2)}$;

(ii) Repeat this procedure taking all vertices on the distance $\mu=(1,2,...)$ and ''gluing'' them on the distance $\mu+2$ according to the definition of the locally free groups.

By means of this procedure we raise a graph which in average has $z_{\text{eff}}^{(1,2)}-1$ distinct branches leading from the level μ to the level $\mu+1$. We may easily find the expressions of $z_{\text{eff}}^{(1,2)}$ using Eqs. (20) and (29). We have in the limit $n=\text{const}\gg 1$ and $\mu\to\infty$,

$$z_{\text{eff}}^{(1,2)}=\frac{V^{(1,2)}(n,\mu+1)}{V^{(1,2)}(n,\mu)}+1=\begin{cases} 8 & \text{for } 1+1-\text{locally free group} \\ \dfrac{2n}{\log n} & \text{for } 2+1-\text{locally free group.}\end{cases}$$

We see that the graph of the group $\mathcal{LF}_n^{(1)}$ coincides (in average) with ($z_{\text{eff}}=8$)-branching Cayley tree for any $n\gg 1$, while the effective coordinational number of the graph of the group $\mathcal{LF}_n^{(2)}$ depends on n and does not ''saturate'' for $n\gg 1$.

ACKNOWLEDGMENTS

We are very grateful to A. Comtet, J. Desbois, and A. M. Vershik for fruitful discussions and useful suggestions.

(Received 1 June 1999; accepted for publication 16 August 1999)

We study the graded derivation-based noncommutative differential geometry of the $\mathbb{Z}_2$-graded algebra $\mathbb{M}(n|m)$ of complex $(n+m)\times(n+m)$-matrices with the ''usual block matrix grading'' (for $n\neq m$). Beside the (infinite-dimensional) algebra of graded forms, the graded Cartan calculus, graded symplectic structure, graded vector bundles, graded connections and curvature are introduced and investigated. In particular we prove the universality of the graded derivation-based first-order differential calculus and show that $\mathbb{M}(n|m)$ is a ''noncommutative graded manifold'' in a stricter sense: There is a natural body map and the cohomologies of $\mathbb{M}(n|m)$ and its body coincide (as in the case of ordinary graded manifolds). © *1999 American Institute of Physics.* [S0022-2488(99)03811-6]

I. INTRODUCTION

The basic idea of noncommutative geometry,[1] which is the formulation of differential geometric concepts on more general algebras than the algebras of $\mathcal{C}^\infty$ functions on differentiable manifolds, is at least conceptionally rooted in the fact that all the information about the differentiable manifold and its sheaf of differentiable functions is encoded in its algebra of global $\mathcal{C}^\infty$-functions such that differential geometry can be formulated in terms of the latter algebras. Although the $\mathbb{Z}_2$-graded algebra of global sections of the structure sheaf of a graded manifold is a ''baby-noncommutative geometry,'' the differential geometry of graded manifolds is treated and interpreted in the spirit of classical differential and algebraic geometry. So graded manifolds should not be seen as specific noncommutative geometries to which the general methods of noncommutative geometry applies, but rather as a conceptional starting point of a ''supergeneralization'' of noncommutative geometry. Because graded manifolds are completely determined by the $\mathbb{Z}_2$-graded algebra of global sections of their structure sheafs,[2] the natural class of objects to which such a generalization applies are $\mathbb{Z}_2$-graded real and complex algebras, respectively.

There exist already several articles and books in the literature dealing with various aspects of $\mathbb{Z}_2$-graded $\mathbb{C}$-algebras, supersymmetry, and noncommutative geometry. Examples, are Refs. 3 and 4, where notions such as cyclic cohomology and Fredholm modules are treated in the $\mathbb{Z}_2$-graded setting; Ref. 5, where supersymmetry is employed to establish metric, Kähler, and symplectic structures in noncommutative geometry; Ref. 6, where the concept of a spectral triple is extended to algebras which contain bosonic and fermionic degrees of freedom, and Refs. 7 and 8, where the possibility of generalizing matrix geometry to the $\mathbb{Z}_2$-graded framework is presented. Here we want to adopt a somewhat different point of view.

If $\mathcal{O}(X)$ is the $\mathbb{Z}_2$-graded algebra of global sections of the (complexified) structure sheaf of some graded manifold (complex) global graded vector fields on the graded manifold are by definition graded derivations of $\mathcal{O}(X)$. All global graded vector fields $\mathfrak{D}^g(X)$ from a complex Lie

a)Electronic mail: grosse@doppler.thp.univie.ac.at
b)Electronic mail: reiter@itp.tu-graz.ac.at

subsuperalgebra and a graded module over the graded center $\mathcal{Z}^g(\mathcal{O}(X))$. (Complex) global graded p-forms for $p \in \mathbb{N}$ are defined as p-fold $\mathcal{Z}^g(\mathcal{O}(X))$-graded-multilinear, graded-alternating maps from $\mathfrak{D}^g(X)$ to $\mathcal{O}(X)$ and one can form the $\mathbb{N}_0 \times \mathbb{Z}_2$-bigraded $\mathbb{C}$-vector space $\Omega^g(X)$ of global graded forms as the direct sum of all $\mathbb{Z}_2$-graded $\mathbb{C}$-vector spaces $\Omega^{g,p}(X)$ of global graded p forms. The graded wedge product as well as the whole graded Cartan calculus on $\Omega^g(X)$ can be introduced (see Refs. 2 and 9, for example) by employing only the facts that $\mathfrak{D}^g(X)$ is a $\mathbb{C}$-Lie superalgebra and $\mathbb{Z}_2$-graded $\mathcal{Z}^g(\mathcal{O}(X))$-module and that $\mathcal{O}(X)$ is a $\mathbb{Z}_2$-graded $\mathbb{C}$-algebra.

The important feature of the recipe for the construction of the graded deRham complex and the graded Cartan calculus formulated above is that it uses only the graded algebra structure of $\mathcal{O}(X)$. In particular it does not use the graded commutativity of $\mathcal{O}(X)$ and we can define on arbitrary $\mathbb{Z}_2$-graded $\mathbb{C}$ algebras noncommutative graded differential calculi.

What we have just described is mutatis mutandis the basic idea of the so-called derivation-based differential calculi[10–13] transposed to the $\mathbb{Z}_2$-graded setting. Such graded derivation-based differential calculi were investigated for arbitrary, but graded-commutative $\mathbb{Z}_2$-graded algebras in the framework of $\mathbb{Z}_2$-graded Lie–Cartan pairs.[3,4,14]

Motivated by the rich differential geometric structure of ordinary matrix algebras[10,11,15] and by our previous investigation of the fuzzy supersphere,[16,17] where each truncated supersphere was a graded matrix algebra in particular, we will investigate especially the differential calculus based on all graded derivations on the $\mathbb{Z}_2$-graded $\mathbb{C}$-algebra $\mathbb{M}(n|m)$ of complex $(n+m)\times(n+m)$-matrices $(n,m \in \mathbb{N}_0, n+m \in \mathbb{N})$, $\mathbb{Z}_2$-graded by declaring the vector subspace

$$\mathbb{M}(n|m)_{\bar{0}} := \left\{ M = \begin{pmatrix} M_1 & 0 \\ 0 & M_4 \end{pmatrix} \middle| M_1 \in \mathbb{M}(n), M_4 \in \mathbb{M}(m) \right\} \tag{1}$$

of $\mathbb{M}(n|m)$ as even and the vector subspace

$$\mathbb{M}(n|m)_{\bar{1}} := \left\{ M = \begin{pmatrix} 0 & M_2 \\ M_3 & 0 \end{pmatrix} \middle| M_2 \in \mathbb{M}(n,m), M_3 \in \mathbb{M}(m,n) \right\} \tag{2}$$

of $\mathbb{M}(n|m)$ as odd. Here $\mathbb{M}(n,m)$ and $\mathbb{M}(n)$ denote the vector space of $n \times m$, respectively, the algebra of $n \times n$-matrices and we will always assume $n \neq m$.

Section II is devoted to the precise definition of the graded derivation-based differential calculus on $\mathbb{M}(n|m)$ as described in Sec. I and its immediate consequences. The resulting complexes are nothing else than the complexes of Lie superalgebra cohomology with values in $\mathbb{M}(n|m)$ and typically infinite. The latter fact shows, in particular, that the complex is completely different from that proposed in Refs. 7 and 8.

In Sec. III we continue the investigation of the differential calculus using the facts that there exist graded-commutative homogeneous bases in the $\mathbb{Z}_2$-graded $\mathbb{M}(n|m)$-modules of all graded p-forms and that all graded derivations of $\mathbb{M}(n|m)$ are inner. In particular, we construct an invariant graded one-form, which determines the differential of graded matrices in terms of graded commutators (within the graded algebra of graded forms) and show that the first-order differential calculus is universal.

Associated with every graded manifold there exists an even, surjective algebra homomorphism β_X from the $\mathbb{Z}_2$-graded algebra of global sections of the (complexified) structure sheaf of the graded manifold $\mathcal{O}(X)$ to the algebra $\mathcal{C}^\infty(X)$ of (complex) $\mathcal{C}^\infty$-functions on its body manifold X. We call this map, which is the key to all further developments in graded manifold theory, the body map. In Sec. IV we show that there exists a natural noncommutative analog to the body map. It induces an isomorphism between the graded derivation-based cohomology of $\mathbb{M}(n|m)$ and the derivation-based cohomology of its body, such that the situation described by a theorem of Kostant[9] is generalized to the noncommutative case.

In Sec. V we study the graded symplectic geometry of $\mathbb{M}(n|m)$. As for ordinary matrix geometry,[10,11,18,19] which is included as special case, there exists a graded symplectic structure such that the induced graded Poisson bracket on $\mathbb{M}(n|m)$ is (i times) the graded commutator on $\mathbb{M}(n|m)$.

In Sec. VI we investigate the noncommutative generalization of graded vector bundles over graded manifolds. Graded vector bundles over a graded manifold $(X,\mathcal{O})$ are usually introduced as locally graded-free $\mathcal{O}$-modules.[2,9,20] In the spirit of noncommutative geometry[1,21] we concentrate on the module of global sections and introduced graded vector bundles over $\mathbb{M}(n|m)$ as $\mathbb{Z}_2$-graded, finitely generated (graded-projective) $\mathbb{M}(n|m)$-modules. Concepts like connections and curvature can be generalized to the $\mathbb{Z}_2$-graded noncommutative setting.

In addition we have included an appendix in which we analyze the associative product of supertrace-free, graded matrices. The results of this analysis are used for a minimality proof in Sec. III.

There will appear lots of $\mathbb{Z}_2$-graded objects. If the object is denoted by $\mathcal{A}$ its even part is denoted by $\mathcal{A}_{\bar{0}}$, its odd part by $\mathcal{A}_{\bar{1}}$. If a is some homogeneous element of such an object its degree will be denoted by $\overline{a}$. Speaking of grading in the context of an ungraded object, we mean that the object is endowed with its trivial graduation. If for some construction the $\mathbb{Z}_2$-grading is indicated by an index ''g'', we omit this index in the case of trivial graduation.

II. GRADED DERIVATION-BASED DIFFERENTIAL CALCULUS ON GRADED MATRIX ALGEBRAS

We will interpret the $\mathbb{C}$-Lie superalgebra and $\mathbb{Z}_2$-graded $\mathcal{Z}^g(\mathbb{M}(n|m))$-module $\mathfrak{Der}^g(\mathbb{M}(n|m))$ of all graded derivations of $\mathbb{M}(n|m)$ as ''noncommutative graded vector fields'' on $\mathbb{M}(n|m)$. Because $\mathbb{M}(n|m)$ is graded central,

$$\mathcal{Z}^g(\mathbb{M}(n|m)) = \mathcal{Z}^g(\mathbb{M}(n|m))_{\bar{0}} = \mathbb{C}1_{n+m} \cong \mathbb{C}, \tag{3}$$

the concept of graded $\mathcal{Z}^g(\mathbb{M}(n|m))$ multilinearity reduces to ordinary $\mathbb{C}$ multilinearity and we can employ ideas and results of Lie superalgebra cohomology (see Refs. 22 and 23) for the construction of the graded derivation-based differential calculus on $\mathbb{M}(n|m)$.

For every natural number $p \in \mathbb{N}$ let us denote by $\mathrm{Hom}^p(\mathfrak{Der}^g(\mathbb{M}(n|m));\mathbb{M}(n|m))$ the $\mathbb{Z}_2$-graded $\mathbb{C}$-vector space of all p-linear maps $\mathfrak{Der}^g(\mathbb{M}(n|m)) \times \dots_p \times \mathfrak{Der}^g(\mathbb{M}(n|m)) \to \mathbb{M}(n|m)$ and by $\mathfrak{S}_p$ the symmetric group of p letters. Introducing a commutation factor $\gamma_p : \mathfrak{S}_p \times \mathbb{Z}_2 \times \dots_p \times \mathbb{Z}_2 \to \{\pm 1\}$ via

$$\gamma_p(\sigma;\overline{\underline{\imath}_1},\dots,\overline{\underline{\imath}_p}) := \prod_{\substack{r,s=1,\cdots p;r<s \\ \sigma^{-1}(r)>\sigma^{-1}(s)}} (-1)^{\overline{\underline{\imath}_r}\,\overline{\underline{\imath}_s}}, \tag{4}$$

we can define a representation π of $\mathfrak{S}_p$ on $\mathrm{Hom}^p(\mathfrak{Der}^g(\mathbb{M}(n|m));\mathbb{M}(n|m))$ by

$$(\pi_\sigma \omega)(D_1,\dots,D_p) := \gamma_p(\sigma;\overline{D_1},\dots,\overline{D_p})\,\omega(D_{\sigma(1)},\dots,D_{\sigma(p)}) \tag{5}$$

for all $\omega \in \mathrm{Hom}^p(\mathfrak{Der}^g(\mathbb{M}(n|m));\mathbb{M}(n|m))$, all homogeneous $D_1,\dots,D_p \in \mathfrak{Der}^g(\mathbb{M}(n|m))$, and all $\sigma \in \mathfrak{S}_p$. Now by definition a p-linear map $\omega \in \mathrm{Hom}^p(\mathfrak{Der}^g(\mathbb{M}(n|m));\mathbb{M}(n|m))$ is called graded alternating if

$$\pi_\sigma \omega = \mathrm{sgn}\,\sigma\,\omega \tag{6}$$

is fulfilled for all $\sigma \in \mathfrak{S}_p$ and we interpret such maps as graded p-forms on $\mathbb{M}(n|m)$. All graded p-forms on $\mathbb{M}(n|m)$ form a graded vector subspace of $\mathrm{Hom}^p(\mathfrak{Der}^g(\mathbb{M}(n|m));\mathbb{M}(n|m))$, which we will denote by $\Omega^{g,p}(\mathbb{M}(n|m))$.

A general graded form on $\mathbb{M}(n|m)$ is an element of the direct sum

$$\Omega^g(\mathbb{M}(n|m)) := \bigoplus_{p\in N_0} \Omega^{g,p}(\mathbb{M}(n|m)), \tag{7}$$

where we set $\Omega^{g,0}(\mathbb{M}(n|m)) := \mathbb{M}(n|m)$. Employing the multiplicative structure of $\mathbb{M}(n|m)$ we can proceed exactly as in the case of graded manifolds[2,9] (respectively, graded Lie–Cartan pairs[3,4,14]) to introduce a graded wedge product on $\Omega^g(\mathbb{M}(n|m))$. So we first define for all $p,p' \in \mathbb{N}_0, \overline{\imath}, \overline{i'} \in \mathbb{Z}_2$ a bilinear map $\wedge : \Omega^{g,p}(\mathbb{M}(n|m))_{\overline{\imath}} \times \Omega^{g,p}(\mathbb{M}(n|m))_{\overline{i'}} \to \Omega^{g,p+p'}(\mathbb{M}(n|m))_{\overline{i+i'}}$ by

$$(\omega\wedge\omega')(D_1,\ldots,D_{p+p'}) := \frac{1}{p!p'!} \sum_{\sigma\in\mathfrak{S}_{p+p'}} \operatorname{sgn}\sigma\, \gamma_{p+p'}(\sigma;\overline{D}_1,\ldots,\overline{D}_{p+p'}) \cdot (-1)^{\overline{i'}\sum_{l=1}^{p}\overline{D}_{\sigma(l)}} \omega(D_{\sigma(1)},\ldots,D_{\sigma(p)})\,\omega'(D_{\sigma(p+1)},\ldots,D_{\sigma(p+p')}). \tag{8}$$

for all homogeneous $D_1,\ldots,D_{p+p'} \in \mathfrak{Der}^g(\mathbb{M}(n|m))$ and extend these by bilinearity to $\Omega^g(\mathbb{M}(n|m))$. With respect to it, $\Omega^g(\mathbb{M}(n|m))$ becomes a $\mathbb{N}_0\times\mathbb{Z}_2$-bigraded $\mathbb{C}$ algebra.

Via

$$(L_{D_0}\omega)(D_1,\ldots,D_p) := D_0(\omega(D_1,\ldots,D_p)) - \sum_{l=1}^{p} (-1)^{\overline{D}_0(\overline{\omega}+\sum_{l'=1}^{l-1}\overline{D}_{l'})} \omega(D_1,\ldots,[D_0,D_l]_g,\ldots,D_p), \tag{9}$$

$$(\iota_{D_1}\omega)(D_2,\ldots,D_p) := \omega(D_1,D_2,\ldots,D_p) \tag{10}$$

and

$$d\omega(D_0,\ldots,D_p) = \sum_{l=0}^{p} (-1)^{l+\overline{D}_l(\overline{\omega}+\sum_{l'=0}^{l-1}\overline{D}_{l'})} L_{D_l}(\omega(D_0,\ldots,\check{D}_l,\ldots,D_p)) + \sum_{0\le l<l'\le p} (-1)^{l'+\overline{D}_{l'}\sum_{l''=l+1}^{l'-1}\overline{D}_{l''}} \omega(D_0,\ldots,D_{l-1},[D_l,D_{l'}]_g,\ldots,\check{D}_{l'},\ldots,D_p) \tag{11}$$

for all homogeneous $D_0,D_1,\ldots,D_p \in \mathfrak{Der}^g(\mathbb{M}(n|m))$ and all homogeneous $\omega \in \Omega^{g,p}(\mathbb{M}(n|m))$ ($\vee$ denotes omission), one defines homogeneous endomorphisms $\Omega^g(\mathbb{M}(n|m)) \to \Omega^g(\mathbb{M}(n|m))$ of bidegree $(0,\overline{D}_0)$, $(-1,\overline{D}_0)$, and $(1,\overline{0})$ respectively. The assignments $D\mapsto\iota_D$ and $D\mapsto L_D$ extend to $\mathbb{C}$-linear maps $\mathfrak{Der}^g(\mathbb{M}(n|m)) \to \mathrm{End}(\Omega^g(\mathbb{M}(n|m)))$ and L is a graded representation of $\mathfrak{Der}^g(\mathbb{M}(n|m))$ in particular. Furthermore the relations

$$d\circ d = 0, \quad d\circ L_D = L_D\circ d, \tag{12}$$

as well as

$$\begin{aligned} &\iota_D\iota_{D'} + (-1)^{\overline{DD'}}\iota_{D'}\circ\iota_D = 0,\\ &(L_D\circ\iota_{D'} - \iota_{D'}\circ L_D)\omega = (-1)^{\overline{D}\overline{\omega}}\iota_{[D,D']_g}\omega,\\ &(\iota_D\circ d + d\circ\iota_D)\omega = (-1)^{\overline{D}\overline{\omega}}L_D\omega \end{aligned} \tag{13}$$

for all homogeneous $D,D' \in \mathfrak{Der}^g(\mathbb{M}(n|m))$ and all bihomogeneous $\omega \in \Omega^g(\mathbb{M}(n|m))$ are known from Lie superalgebra cohomology.[23]

By analogy with the case of graded manifolds we call d, L_D, and ι_D the exterior derivative, Lie derivative and interior product (with respect to a graded vector field $D \in \mathfrak{Der}^g(\mathbb{M}(n|m))$). (12) and (13) tell us that they fulfill exactly the same relations as in the ''graded-commutative case'', but this observation remains also true for the graded wedge product (8) of graded forms.

Proposition 1: The relations

$$L_D(\omega \wedge \omega') = (L_D\omega)\wedge \omega' + (-1)^{\bar{D}\bar{\omega}}\omega \wedge L_D\omega',$$

$$\iota_D(\omega\wedge\omega') = (-1)^{\bar{D}\bar{\omega}'}(\iota_D\omega)\wedge\omega' + (-1)^p \omega \wedge \iota_D\omega', \tag{14}$$

$$d(\omega\wedge\omega') = (d\omega)\wedge\omega' + (-1)^p\omega\wedge d\omega'$$

are fulfilled for all homogeneous $D \in \mathfrak{Der}^g(\mathbb{M}(n|m)), \omega \in \Omega^{g,p}(\mathbb{M}(n|m)), \omega' \in \Omega^{g,p'}(\mathbb{M}(n|m))$.

Proof: This can be shown exactly as in the case of graded manifolds. That is, one starts with a direct proof of the second relation and proofs the other equations inductively using the last two relations (13).

Because we interpret d as exterior derivative, the Lie superalgebra cohomology of $\mathfrak{Der}^g(\mathbb{M}(n|m))$ with values in $\mathbb{M}(n|m)$,

$$H(\mathbb{M}(n|m)) \equiv \bigoplus_{p\in N_0} H^p(\mathbb{M}(n|m)) := \frac{\ker d}{\operatorname{im} d}, \tag{15}$$

has to be seen as analogous to the graded deRham cohomology on graded manifolds. Via

$$[\omega]\wedge[\omega'] := [\omega\wedge\omega'], \tag{16}$$

the above graded derivation-based cohomology of $\mathbb{M}(n|m)$ becomes a $\mathbb{N}_0\times\mathbb{Z}_2$-bigraded $\mathbb{C}$-algebra and we will continue to study it in Sec. IV.

III. HOMOGENEOUS BASES AND THE CANONICAL GRADED ONE-FORM

Whereas the definitions and results of the preceding considerations apply to each $\mathbb{Z}_2$-graded, graded-central $\mathbb{C}$-algebra we shall now employ more specific properties of $\mathbb{M}(n|m)$. There will result similar formulas as in ''ordinary'' matrix geometry,[10,11,15] which is included as a special case.

The sets $\Omega^{g,p}_{\mathcal{Z}g}(\mathbb{M}(n|m))$ of graded p-forms with values in the graded center of $\mathbb{M}(n|m)$ form graded vector subspaces of $\Omega^{g,p}(\mathbb{M}(n|m))$ for all $p\in\mathbb{N}$ and one can introduce

$$\Omega^{g}_{\mathcal{Z}g}(\mathbb{M}(n|m)) := \bigoplus_{p\in N_0}\Omega^{g,p}_{\mathcal{Z}g}(\mathbb{M}(n|m)) \tag{17}$$

with $\Omega^{g,0}_{\mathcal{Z}g}(\mathbb{M}(n|m)) = \mathcal{Z}^g(\mathbb{M}(n|m))$. $\Omega^{g}_{\mathcal{Z}g}(\mathbb{M}(n|m))$ is a bigraded subalgebra of $\Omega^g(\mathbb{M}(n|m))$, whose product fulfills

$$\omega\wedge\omega' = (-1)^{pp' + \overline{\omega\omega'}}\omega'\wedge\omega \tag{18}$$

for all homogeneous $\omega\in\Omega^{g,p}_{\mathcal{Z}g}(\mathbb{M}(n|m)), \omega'\in\Omega^{g,p'}_{\mathcal{Z}g}(\mathbb{M}(n|m))$, and which is stable with respect to the whole Cartan calculus.

Now let us introduce a homogeneous basis $\{\partial_A\}_{A=1,\dots,n'+m'}$ of $\mathfrak{Der}^g(\mathbb{M}(n|m))$ with $\partial_1,\dots,\partial_{n'}\in\mathfrak{Der}^g(\mathbb{M}(n|m))_{\bar{0}}$, $\partial_{n'+1},\dots,\partial_{n'+m'}\in\mathfrak{Der}^g(\mathbb{M}(n|m))_{\bar{1}}$, where we set $n' := \dim_{\mathbb{C}}\mathfrak{Der}^g(\mathbb{M}(n|m))_{\bar{0}}$ and $m' := \dim_{\mathbb{C}}\mathfrak{Der}^g(\mathbb{M}(n|m))_{\bar{1}}$. If $\{\eta^A\}_{A=1,\dots,n'+m'}$ denotes the dual basis to $\{\partial_A\}_{A=1,\dots,n'+m'}$ we can introduce a homogeneous basis $\{\theta^A\}_{A=1,\dots,n'+m'}$ of $\Omega^{g,1}_{\mathcal{Z}g}(\mathbb{M}(n|m))$ by

$$\theta^A(D) := \eta^A(D) 1_{n+m} \tag{19}$$

for all $D \in \mathfrak{Der}^g(\mathbb{M}(n|m))$. Employing the standard isomorphisms between graded-alternating maps and the graded exterior algebra,[2,23] one deduces that

$$\{\theta^{A_1} \wedge \cdots \wedge \theta^{A_p} | (A_1, \ldots, A_p) \in \mathcal{J}_p^{n'|m'}\} \tag{20}$$

with

$$\mathcal{J}_p^{n'|m'} := \{(k_1, \ldots, k_{p'}, \alpha_{p'+1}, \ldots, \alpha_p) | 0 \leqslant p' \leqslant p; k_1, \ldots, k_{p'} = 1, \ldots, n'; \tag{21}$$

$$\alpha_{p'+1}, \ldots, \alpha_p = n'+1, \ldots, n'+m'; k_1 < k_2 < \cdots < k_{p'} < \alpha_{p'+1} \leqslant \cdots \leqslant \alpha_{p-1} \leqslant \alpha_p\}$$

is an homogeneous basis of $\Omega_{\mathcal{Z}g}^{g,p}(\mathbb{M}(n|m)), p \in \mathbb{N}$.

Because of

$$M \wedge \omega = (-1)^{\bar{M}\bar{\omega}} \omega \wedge M, \tag{22}$$

for all homogeneous $M \in \mathbb{M}(n|m)$ and all bihomogeneous $\omega \in \Omega_{\mathcal{Z}g}^g(\mathbb{M}(n|m))$, the $\mathbb{N}_0 \times \mathbb{Z}_2$-bigraded $\mathbb{C}$-algebras $\Omega^g(\mathbb{M}(n|m))$ and $\mathbb{M}(n|m) \hat{\otimes}_{\mathbb{C}} \Omega_{\mathcal{Z}g}^g(\mathbb{M}(n|m))$, where $\hat{\otimes}$ denotes the tensor product of $\mathbb{Z}_2$-graded algebras, are canonically isomorphic. In particular we can conclude:

Proposition 2: The $\mathbb{Z}_2$-graded $\mathbb{M}(n|m)$-bimodules $\Omega^{g,p}(\mathbb{M}(n|m))$ are graded-free for both multiplications and for all $p \in \mathbb{N}_0$. The set (20) determines a homogeneous basis of the left (right), $\mathbb{Z}_2$-graded $\mathbb{M}(n|m)$-module $\Omega^{g,p}(\mathbb{M}(n|m))$.

Consequently every $\omega \in \Omega^{g,p}(\mathbb{M}(n|m))$ can be written as

$$\omega = \sum_{(A_1, \ldots, A_p) \in \mathcal{J}_p^{n'|m'}} \omega_{A_1 \ldots A_p} \wedge \theta^{A_1} \wedge \cdots \wedge \theta^{A_p} \tag{23}$$

with unique coefficients $\omega_{A_1 \ldots, A_p} \in \mathbb{M}(n|m)$. Explicitly these coefficients are given by

$$\omega_{A_1 \ldots A_p} = (-1)^{(1/2)p''(p''-1)} \frac{1}{\Pi_{l=1}^{n'+m'} N_l!} \omega(\partial_{A_1}, \ldots, \partial_{A_p}), \tag{24}$$

where p'' is the number of entries in $(A_1, \ldots, A_p)$ greater than n' and N_l is the number of entries in $(A_1, \ldots, A_p)$ being equal to l.

In order to investigate graded derivations of $\mathbb{M}(n|m)$ (we include the case $n=m$ for the moment) let us denote by $\mathfrak{gl}(n|m)$ the (complex) general linear Lie superalgebra and by $\mathfrak{sl}(n|m)$ the (complex) special linear Lie superalgebra. The adjoint representation of $\mathfrak{gl}(n|m)$ is at the same time a Lie superalgebra homomorphism $\mathrm{ad}: \mathfrak{gl}(n|m) \to \mathfrak{Der}^g(\mathbb{M}(n|m))$ and, as we will see, the structure of $\mathfrak{Der}^g(\mathbb{M}(n|m))$ and its Lie subsuperalgebras is determined by this homomorphism.

Proposition 3: If $\mathfrak{L}$ is a Lie subsuperalgebra of $\mathfrak{gl}(n|m)$ then

$$\mathcal{L}^{\mathrm{ad}} := \mathrm{im}\, \mathrm{ad}|_{\mathcal{L}} \tag{25}$$

is a Lie *subsuperalgebra of $\mathfrak{Der}^g(\mathbb{M}(n|m))$. Conversely every Lie subsuperalgebra of $\mathfrak{Der}^g(\mathbb{M}(n|m))$ is of this form. There are two different cases.*

(i) *For $n \neq m$ the restriction of* ad *to $\mathfrak{sl}(n|m)$ is a Lie superalgebra isomorphism onto $\mathfrak{Der}^g(\mathbb{M}(n|m))$ and the various restrictions of* ad *induce a bijective correspondence between Lie subsuperalgebras of $\mathfrak{sl}(n|m)$ and Lie subsuperalgebras of $\mathfrak{Der}^g(\mathbb{M}(n|m))$.*

(ii) *For $n=m$ there is no Lie subsuperalgebra $\mathcal{L}$ of $\mathfrak{gl}(n|n)$ such that the restriction of* ad *to $\mathcal{L}$ becomes a Lie superalgebra isomorphism onto $\mathfrak{Der}^g(\mathbb{M}(n|m))$.*

Proof: An even graded derivation of $\mathbb{M}(n|m)$ is just an ordinary derivation of the $\mathbb{C}$-algebra $\mathbb{M}(n+m)$ and these are inner, because the first Hochschild cohomology group of $\mathbb{M}(n+m)$ with values in $\mathbb{M}(n+m)$ is trivial.[24] Introducing

$$\Gamma := \begin{pmatrix} 1_n & 0 \\ 0 & -1_m \end{pmatrix}$$

we find for some $D \in \mathfrak{Der}^g(\mathbb{M}(n|m))_1^-$ and all homogeneous $M \in \mathbb{M}(n|m)$,

$$DM = \mathrm{ad}(\tfrac{1}{2}(D\Gamma)\Gamma)(M),$$

from which we can conclude that D is inner. Consequently, if $\mathfrak{D}$ is a Lie subsuperalgebra of $\mathfrak{Der}^g(\mathbb{M}(n|m))$, then $\mathfrak{L} := \mathrm{ad}^{-1}(\mathfrak{D})$ is a Lie subsuperalgebra of $\mathfrak{gl}(n|m)$ with $\mathfrak{L}^{\mathrm{ad}} = \mathfrak{D}$. (i) and (ii) are consequences of $1_{n+m} \notin \mathfrak{sl}(n|m)$ for $n \neq m$, respectively, $1_{2n} \in [\mathfrak{gl}(n|n)_1^-, \mathfrak{gl}(n|n)_1^-]_g$. □

The ultimate reason for restricting our geometric investigation to the case $n \neq m$ lies in the existence of the Lie superalgebra isomorphism $\mathrm{ad}: \mathfrak{sl}(n|m) \to \mathfrak{Der}^g(\mathbb{M}(n|m))$. The elements of every homogeneous basis $\{\partial_A\}_{A=1,\ldots,n'+m'}$ of $\mathfrak{Der}^g(\mathbb{M}(n|m))$ are given by

$$\partial_A = \mathrm{ad}\, E_A, \tag{26}$$

where $\{E_A\}_{A=1,\ldots,n'+m'}$ is a homogeneous basis of $\mathfrak{sl}(n|m)$ and we have $n' = n^2 + m^2 - 1$, $m' = 2nm$ in particular. Moreover, the structure constants c_{AB}^C appearing in

$$[\partial_A, \partial_B]_g = \sum_{C=1}^{(n+m)^2-1} c_{AB}^C \partial_C \tag{27}$$

are the structure constants of the homogeneous $\mathfrak{sl}(n|m)$-basis $\{E_A\}_{A=1,\ldots,(n+m)^2-1}$ and one deduces the nice formulas

$$dE_A = -\sum_{B,C=1}^{(n+m)^2-1} c_{AB}^C E_C \wedge \theta^B \tag{28}$$

and

$$d\theta^A = \frac{1}{2} \sum_{B,C=1}^{(n+m)^2-1} c_{BC}^A \theta^C \wedge \theta^B. \tag{29}$$

The even graded one-form

$$\Theta := \sum_{A=1}^{(n+m)^2-1} E_A \wedge \theta^A \tag{30}$$

will be called the canonical graded one-form, because it plays a distinguished role.

Proposition 4: The definition of Θ is independent of the choice of the homogeneous basis of $\mathfrak{Der}^g(\mathbb{M}(n|m))$ and

$$\Theta(\mathrm{ad}\, M) = M - \frac{1}{n-m} \mathrm{Tr}_s(M) 1_{n+m} \tag{31}$$

for all $M \in \mathbb{M}(n|m)$. Θ is $(\mathfrak{Der}^g(\mathbb{M}(n|m))$-invariant and this property determines Θ up to constant multiples. Furthermore its exterior differential fulfills

$$d\Theta = \Theta \wedge \Theta \tag{32}$$

and the exterior differential of each $M \in \mathbb{M}(n|m)$ *can be expressed according to*

$$dM = [\Theta, M]_g \equiv \Theta \wedge M - M \wedge \Theta. \tag{33}$$

Proof: Beside the uniqueness statement only simple calculations are involved [for which one can use (28) and (29) advantageously]. The irreducibility of the adjoint representation of $\mathfrak{sl}(n|m)$[25] guarantees that

$$L_D \omega = 0, \quad \omega \in \Omega^{g,1}(\mathbb{M}(n|m)),$$

for all $D \in \mathfrak{Der}^g(\mathbb{M}(n|m))$ implies $\omega = c\Theta$, $c \in \mathbb{C}$. □

Finally we note that $\Omega^g(\mathbb{M}(n|m))$ is in a certain sense minimal (for the ungraded case see Refs. 12 and 15).

Proposition 5: (28) can be inverted according to

$$\theta^A = 4(n-m)^2 \sum_{B,C,D=1}^{(n+m)^2-1} (-1)^{\bar{E}_B \bar{E}_D} K^{AB} K^{CD} E_C E_B \wedge dE_D, \tag{34}$$

where K is the Killing form of $\mathfrak{sl}(n|m)$ *and* K^{AB} *denote the components of the inverse matrix of* $(K(E_A, E_B))$. *Consequently, if* Ω *is differential subalgebra of* $\Omega^g(\mathbb{M}(n|m))$ *containing* $\mathbb{M}(n|m)$, *then* $\Omega = \Omega^g(\mathbb{M}(n|m))$.

Proof: The minimality statement follows from (34) because of proposition 2. In order to show (34) one uses (28) and expands the threefold product of the basis elements E_A according to (A4). Using the results of proposition A (34) follows.

The second part of proposition 5 can be stated differently: The canonical even algebra homomorphisms from the (intrinsic) $\mathbb{Z}_2$-graded universal differential envelope of $\mathbb{M}(n|m)$ to $\Omega^g(\mathbb{M}(n|m))$ (see Refs. 3 and 26 for a precise definition) is onto. The restriction of this homomorphism to the corresponding first-order differential calculi is an isomorphism.

IV. COHOMOLOGY AND THE NONCOMMUTATIVE BODY MAP

We will call the even, surjective $\mathbb{C}$-linear map

$$\beta: \mathbb{M}(n|m) \to \mathbb{M}(\underline{n}) \quad \text{with } \underline{n} := \begin{cases} n & \text{if } n > m \\ m & \text{if } n < m, \end{cases} \tag{35}$$

defined by

$$\beta(M) \equiv \beta\left(\begin{pmatrix} M_1 & M_2 \\ M_3 & M_4 \end{pmatrix} \right) := \begin{cases} M_1 & \text{if } \underline{n} = n \\ M_4 & \text{if } \underline{n} = m \end{cases} \tag{36}$$

canonical body map of $\mathbb{M}(n|m)$. A justification for choosing this terminology will result from the investigation of its properties: They are completely analogous to the corresponding map of graded manifolds if one takes the noncommutativity of $\mathbb{M}(n|m)$ and its ''body'' $\mathbb{M}(\underline{n})$ appropriately into account. In order to distinguish between ''objects'' on $\mathbb{M}(n|m)$ and corresponding ''objects'' on the body we underline the latter.

The restriction of β to $\mathcal{Z}^g(\mathbb{M}(n|m))$ is an even algebra homomorphism onto $\mathcal{Z}(\mathbb{M}(\underline{n}))$ and by

$$\iota(\underline{M}) := \begin{cases} \begin{pmatrix} \underline{M} & 0 \\ 0 & \frac{1}{n}\operatorname{Tr}(\underline{M}) 1_m \end{pmatrix} & \text{if } \underline{n}=n \\ \begin{pmatrix} \frac{1}{m}\operatorname{Tr}(\underline{M}) 1_n & 0 \\ 0 & \underline{M} \end{pmatrix} & \text{if } \underline{n}=m \end{cases} \tag{37}$$

we can introduce an even, injective $\mathbb{C}$-linear map $\iota:\mathbb{M}(\underline{n})\to\mathbb{M}(n|m)$, which is right inverse to β on the one hand and whose restriction to $\mathcal{Z}(\mathbb{M}(\underline{n}))$ is an even algebra homomorphism into $\mathcal{Z}^g(\mathbb{M}(n|m))$ on the other hand.

Analogous to the body map of graded manifolds β induces a Lie algebra homomorphism $\hat{\beta}:\mathfrak{Der}^g(\mathbb{M}(n|m))_{\bar{0}}\to\mathfrak{Der}(\mathbb{M}(\underline{n}))$ via

$$\hat{\beta}(D)\beta(M) := \beta(DM) \tag{38}$$

for all $M\in\mathbb{M}(n|m)$. $\hat{\beta}$ is surjective because of

$$\hat{\beta}(\operatorname{ad} E) = \operatorname{ad}\beta(E) \tag{39}$$

for all $E\in\mathfrak{sl}(n|m)_{\bar{0}}$ and in addition $\hat{\iota}:\mathfrak{Der}(\mathbb{M}(\underline{n}))\to\mathfrak{Der}^g(\mathbb{M}(n|m))_{\bar{0}}$,

$$\hat{\iota}(\operatorname{ad}\underline{E}) := \operatorname{ad}\iota(\underline{E}) \tag{40}$$

is a Lie algebra homomorphism right-inverse to $\hat{\beta}$.
Now we can introduce even $\mathbb{C}$-linear maps $\beta^{(p)}:\Omega^{g,p}(\mathbb{M}(n|m))\to\Omega^p(\mathbb{M}(\underline{n}))$, $p\in\mathbb{N}$ by

$$(\beta^{(p)}(\omega))(\underline{D}_1,\ldots,\underline{D}_p) := \beta(\omega(\hat{\iota}(\underline{D}_1),\ldots,\hat{\iota}(\underline{D}_p))) \tag{41}$$

for all $\underline{D}_1,\ldots,\underline{D}_p\in\mathfrak{Der}(\mathbb{M}(\underline{n}))$. $\mathfrak{sl}(n|m)_{\bar{0}}$ is canonically isomorphic to $\mathfrak{sl}(n)\oplus\mathfrak{gl}(1)\oplus\mathfrak{sl}(m)$ and we can choose a homogeneous basis $\{E_A\}_{A=1,\ldots,(n+m)^2-1}$ of $\mathfrak{sl}(n|m)$ such that $E_1,\ldots,E_{\underline{n}^2-1}$ lie in the isomorphic copy of $\mathfrak{sl}(\underline{n})$ and $E_{\underline{n}^2},\ldots,E_{n^2+m^2-1}$ in the isomorphic copy of $\mathfrak{gl}(1)\oplus\mathfrak{sl}(\underline{m})$ with $\underline{m}:=\min\{n,m\}$. Then the elements $\beta(E_k) := \underline{E}_k$, $k=1,\ldots,\underline{n}^2-1$ form a basis of $\mathfrak{sl}(\underline{n})$. Denoting the elements of the basis of $\Omega^1(\mathbb{M}(\underline{n}))$ corresponding to $\{\underline{E}_k\}_{k=1,\ldots,\underline{n}^2-1}$ according to (19) and (26) by $\underline{\theta}^k$ the action of the maps $\beta^{(p)}$ can be described alternatively by

$$\begin{aligned} \beta^{(p)}(\omega) &\equiv \beta^{(p)}\left(\sum_{(A_1,\ldots,A_p)\in\mathcal{J}_p^{n^2+m^2-1|2nm}} \omega_{A_1,\ldots,A_p}\wedge\theta^{A_1}\wedge\cdots\wedge\theta^{A_p}\right) \\ &= \sum_{(k_1,\ldots,k_p)\in\mathcal{J}_p^{\underline{n}^2-1|0}} \beta(\omega_{k_1,\ldots,k_p})\wedge\underline{\theta}^{k_1}\wedge\cdots\wedge\underline{\theta}^{k_p}. \end{aligned} \tag{42}$$

If we set $\beta^{(0)}\equiv\beta$ the maps $\beta^{(p)}$, $p\in\mathbb{N}_0$, extend uniquely to a bihomogeneous, $\mathbb{C}$-linear map $\Omega^g(\mathbb{M}(n|m))\to\Omega(\mathbb{M}(\underline{n}))$ of bidegree $(0,\bar{0})$, which we again denote by β. Because of (42) β is onto and its restriction to $\Omega^g_{\mathcal{Z}^g}(\mathbb{M}(n|m))$ is a surjective homomorphism of bigraded $\mathbb{C}$-algebras onto $\Omega_{\mathcal{Z}}(\mathbb{M}(\underline{n}))$. Furthermore β fulfills

$$\beta\circ L_D = L_{\hat{\beta}(D)}\circ\beta \tag{43}$$

for all $D\in\mathfrak{Der}^g(\mathbb{M}(n|m))_{\bar{0}}$ as well as

$$\beta\circ d = d\circ\beta. \tag{44}$$

Consequently β induces a homomorphism $H(\beta):H(\mathbb{M}(n|m))\to H(\mathbb{M}(\underline{n}))$ of cohomologies in the usual way. Analogous to graded manifold theory[9] this map is an isomorphism.

Proposition 6: $H(\beta)$ is an isomorphism of bigraded $\mathbb{C}$-algebras, such that both cohomologies $H(\mathbb{M}(n|m))$ *and* $H(\mathbb{M}(n))$ *are isomorphic to the Lie algebra cohomology* $H(\mathfrak{sl}(n);\mathbb{C})$ *of* $\mathfrak{sl}(n)$ *with trivial coefficients.*

Proof: Using the results of Ref. 23 as well as $\mathfrak{Der}^g(\mathbb{M}(n|m))=\mathfrak{sl}(n|m)^{\mathrm{ad}}$ we find the sequence

$$\begin{aligned}H(\mathbb{M}(n|m))&\cong H(\mathfrak{sl}(n|m);\mathbb{M}(n|m))\\&\cong H(\mathfrak{sl}(n|m);\mathbb{C}1_{n+m})\oplus H(\mathfrak{sl}(n|m);\mathfrak{sl}(n|m))\\&\cong H(\mathfrak{sl}(n|m);\mathbb{C}1_{n+m})\cong H(\mathfrak{sl}(n|m;\mathbb{C})\end{aligned}$$

of natural isomorphisms between Lie superalgebra cohomologies. In particular we have $H(\mathbb{M}(n))\cong H(\mathfrak{sl}(\underline{n});\mathbb{C})$ (as $\mathbb{N}_0$-graded $\mathbb{C}$-algebra), which is well known from matrix geometry.[10–12] Combining the above-mentioned result with the calculations of the cohomology of $\mathfrak{sl}(n|m)$ with trivial coefficients[22,27] one can conclude that $H(\beta)$ is an isomorphism of bigraded $\mathbb{C}$-algebras.

V. NONCOMMUTATIVE GRADED SYMPLECTIC GEOMETRY

Generalizing the situation on graded manifolds[9] as well as the one of ordinary matrix algebras[10,11,18,19] we call an even, closed graded two-form $\omega\in\Omega^{g,2}(\mathbb{M}(n|m))$ graded symplectic structure on $\mathbb{M}(n|m)$, if the equation

$$\omega(D,D_M)=DM \tag{45}$$

for all $D\in\mathfrak{Der}^g(\mathbb{M}(n|m))$ possesses a unique solution $D_M\in\mathfrak{Der}^g(\mathbb{M}(n|m))$ for each $M\in\mathbb{M}(n|m)$. The graded vector fields $D_M\in\mathfrak{Der}^g(\mathbb{M}(n|m))$ are called Hamiltonian and the set of all graded Hamiltonian vector fields is denoted by $\mathfrak{Ham}^g(\omega)$.

If $\omega\in\Omega^{g,2}(\mathbb{M}(n|m))$ is a graded symplectic structure on $\mathbb{M}(n|m)$ the assignment $M\mapsto D_M$ defines an even $\mathbb{C}$-linear map $D^\omega:\mathbb{M}(n|m)\to\mathfrak{Ham}^g(\omega)\subseteq\mathfrak{Der}^g(\mathbb{M}(n|m))$ and one can conclude that (45) is equivalent to

$$\iota_{D_M}\omega+dM=0. \tag{46}$$

Using (13) we find

$$L_{D_M}\omega=0 \tag{47}$$

for all $D_M\in\mathfrak{Ham}^g(\omega)$, that is a graded symplectic structure on $\mathbb{M}(n|m)$ is—as usual—invariant with respect to all graded Hamiltonian vector fields.

Via

$$\{M,M'\}_g^\omega:=\omega(D_M,D_{M'}) \tag{48}$$

for all $M,M'\in\mathbb{M}(n|m)$ we can introduce a graded Poisson bracket, which has the analogous properties as its graded-commutative pendant.

Proposition 7: $(\mathbb{M}(n|m),\{\cdot,\cdot\}_g^\omega)$ *is a* $\mathbb{C}$*-Lie superalgebra and the graded Poisson bracket fulfills in addition*

$$\begin{aligned}\{M,M'M''\}_g^\omega&=\{M,M'\}_g^\omega M''+(-1)^{\overline{MM'}}M'\{M,M''\}_g^\omega,\\\{1_{n+m},M\}_g^\omega&=0\end{aligned} \tag{49}$$

for all homogeneous $M,M',M''\in\mathbb{M}(n|m)$. *Moreover, the map* $D^\omega:\mathbb{M}(n|m)\to\mathfrak{Ham}^g(\omega)$ *is a homomorphism of Lie superalgebras and*

$$\mathfrak{Ham}^g(\omega) = \mathfrak{Der}^g(\mathbb{M}(n|m)). \tag{50}$$

Proof: The properties of $\{\cdot,\cdot\}_g^\omega$ and of D^ω result from the defining properties of the graded symplectic structure ω. From the irreducibility of the adjoint representation of $\mathfrak{sl}(n|m)$ one can deduce $\ker D^\omega = \mathbb{C}1_{n+m}$ on the one hand and the injectivity of $D^\omega|_{\mathfrak{sl}(n|m)}$ on the other hand. Then (50) follows because of $\mathfrak{Der}^g(\mathbb{M}(n|m)) = \mathfrak{sl}(n|m)^{\mathrm{ad}}$. □

There exists an essentially unique graded symplectic structure on $\mathbb{M}(n|m)$.

Proposition 8: $d\Theta$ is a graded symplectic structure on $\mathbb{M}(n|m)$ and up to complex multiples it is the only one. The corresponding graded Poisson bracket is given by

$$\{M,M'\}_g^{d\Theta} = [M,M']_g \tag{51}$$

for all $M,M' \in \mathbb{M}(n|m)$.

Proof: The exact, even graded two-form $c\,d\Theta, c \in \mathbb{C}\setminus\{0\}$ induces via (45) a homomorphism $D^{c\,d\Theta}: \mathbb{M}(n|m) \to \mathfrak{Der}^g(\mathbb{M}(n|m))$,

$$D^{c\,d\Theta}(M) = \frac{1}{c}\,\mathrm{ad}\,M \tag{52}$$

of Lie superalgebras and the corresponding graded Poisson bracket is given by $\{M,M'\}_g^{c\,d\Theta} = c^{-1}[M,M']_g$. The uniqueness property is a consequence of proposition 3, (50), and Schur's Lemma. □

Consequently the extension of the body map β maps a graded symplectic structure ω onto a symplectic structure $\beta(\omega)$. Moreover one has

$$\hat{\beta}(D^\omega(M)) = D^{\beta(\omega)}(\beta(M)) \tag{53}$$

for all even graded (Hamiltonian) vector fields as well as

$$\beta(\{M,M'\}_g^\omega) = \{\beta(M),\beta(M')\}^{\beta(\omega)} \tag{54}$$

for the graded Poisson bracket of $M,M' \in \mathbb{M}(n|m)_{\bar{0}}$. That is, the relation between $\mathbb{M}(n|m)$ and its body is analogous to the one for graded symplectic manifolds and their respective underlying manifolds.

VI. GRADED VECTOR BUNDLES OVER GRADED MATRIX ALGEBRAS

As a synthesis of the definition of graded vector bundles over graded manifolds[2,9,20] and the idea how to introduce vector bundles in noncommutative geometry[1,21] we interpret left, $\mathbb{Z}_2$-graded, finitely generated (graded-projective) $\mathbb{M}(n|m)$ modules as graded vector bundles over $\mathbb{M}(n|m)$ and even $\mathbb{M}(n|m)$-module homomorphisms between such modules as graded vector bundle homomorphisms. We note that the specifying property of graded projectivity is redundant in the context of left, $\mathbb{Z}_2$-graded $\mathbb{M}(n|m)$-modules, because on the one hand graded-projective means $\mathbb{Z}_2$-graded plus projective[28] and on the other hand every left $\mathbb{M}(n+m)$-module is projective.[24]

Let us denote by $\mathbb{M}(n|m,r|s), r,s \in \mathbb{N}_0, r+s \in \mathbb{N}$, the $\mathbb{C}$-vector space $\mathbb{M}(n+m,r+s)$ together with the $\mathbb{Z}_2$-grading defined by

$$\begin{aligned}\mathbb{M}(n|m,r|s)_{\bar{0}} &:= \left\{ v = \begin{pmatrix} v_1 & 0 \\ 0 & v_4 \end{pmatrix} \middle| v_1 \in \mathbb{M}(n,r), v_4 \in \mathbb{M}(m,s) \right\},\\ \mathbb{M}(n|m,r|s)_{\bar{1}} &:= \left\{ v = \begin{pmatrix} 0 & v_2 \\ v_3 & 0 \end{pmatrix} \middle| v_2 \in \mathbb{M}(n,s), v_3 \in \mathbb{M}(m,r) \right\}.\end{aligned} \tag{55}$$

With respect to ordinary matrix multiplication $\mathbb{M}(n|m,r|s)$ becomes a left, $\mathbb{Z}_2$-graded, finitely generated $\mathbb{M}(n|m)$-module and these examples constitute essentially all graded vector bundles over $\mathbb{M}(n|m)$.

Proposition 9: If $\mathcal{V}$ is a graded vector bundle over $\mathbb{M}(n|m)$ then there exist unique numbers $r,s\in\mathbb{N}_0, r+s\in\mathbb{N}$ and a graded vector bundle isomorphism $\phi:\mathcal{V}\to\mathbb{M}(n|m,r|s)$. $\mathcal{V}$ is graded-free if and only if there are natural numbers $p,q\in\mathbb{N}_0, p+q\in\mathbb{N}$, such that

$$pn+qm=r,\quad pm+qn=s. \tag{56}$$

Proof: The existence of the isomorphisms are implied by the graded simplicity of $\mathbb{M}(n|m,1|0)$ and $\mathbb{M}(n|m,0|1)$ and the fact, that every left, $\mathbb{Z}_2$-graded, finitely generated $\mathbb{M}(n|m)$ module is the homomorphic image of a left, $\mathbb{Z}_2$-graded, graded-free $\mathbb{M}(n|m)$-module with homogeneous basis of suitable cardinality $p|q$. Because all $\mathbb{M}(n|m)$-module isomorphisms are $\mathbb{C}$-vector space isomorphisms in particular, the uniqueness statement and (56) follow. □

After this ''miniature-classification'' we develop graded differential geometry on a fixed graded vector bundle $\mathcal{V}$ generalizing the treatment of noncommutative geometry[1,10,13,21] on the one hand and the one of supergeometry[2] on the other hand.

So we first define the set $\Omega^g(\mathcal{V})$ of $\mathcal{V}$-valued graded forms according to

$$\Omega^g(\mathcal{V})\equiv\bigoplus_{p\in\mathbb{N}_0}\Omega^{g,p}(\mathcal{V}):=\Omega^g(\mathbb{M}(n|m))\hat{\otimes}_{M(n|m)}\mathcal{V}. \tag{57}$$

$\Omega^g(\mathcal{V})$ is a left $\mathbb{N}_0\times\mathbb{Z}_2$-bigraded $\Omega^g(\mathbb{M}(n|m))$-module in a natural way and each $\Omega^{g,p}(\mathcal{V}),p\in\mathbb{N}_0$, is a left, $\mathbb{Z}_2$-graded, finitely generated $\mathbb{M}(n|m)$ module, in particular. The product will again be denoted by $\wedge$.

A connection on $\mathcal{V}$ is an even $\mathbb{C}$-linear map $\nabla:\mathcal{V}\to\Omega^{g,1}(\mathcal{V})$ such that

$$\nabla(Mv)=dM\otimes v+M\wedge\nabla v \tag{58}$$

is fulfilled for all $M\in\mathbb{M}(n|m), v\in\mathcal{V}$. Connections always exist due to (graded) projectivity.

Proposition 10: Let $\mathcal{V}$ be a graded vector bundle over $\mathbb{M}(n|m)$. Then there exists a graded-free vector bundle $\mathcal{V}^{p|q}$ over $\mathbb{M}(n|m)$ with homogeneous basis $\{\epsilon_A|\epsilon_A\in\mathcal{V}^{p|q}_0,\ A=1,...,p;\epsilon_A\in\mathcal{V}^{p|q}_1,\ A=p+1,...,p+q\}$, $p,q\in\mathbb{N}_0, p+q\in\mathbb{N}$, together with an even, idempotent endomorphism $P:\mathcal{V}^{p|q}\to\mathcal{V}^{p|q}$ and an isomorphism $\varphi:\mathcal{V}\to\operatorname{im}P$ of $\mathbb{Z}_2$-graded $\mathbb{M}(n|m)$ modules. The map $\nabla_d:\mathcal{V}^{p|q}\to\Omega^{g,1}(\mathcal{V}^{p|q})$ defined by

$$\nabla_d(v)\equiv\nabla_d\left(\sum_{A=1}^{p+q}v^A\epsilon_A\right):=\sum_{A=1}^{p+q}dv^A\otimes\epsilon_A \tag{59}$$

is a connection on $\mathcal{V}^{p|q}$ and

$$\nabla_{Pd}:=\mathrm{Id}_{\Omega^{g,1}(\mathbb{M}(n|m))}\otimes\varphi^{-1}\circ\mathrm{Id}_{\Omega^{g,1}(\mathbb{M}(n|m))}\otimes P\circ\nabla_d\circ\varphi \tag{60}$$

is a connection on $\mathcal{V}$. A map $\nabla:\mathcal{V}\to\Omega^{g,1}(\mathcal{V})$ is a connection on $\mathcal{V}$ if and only if it is of the form

$$\nabla=\nabla_{Pd}+\alpha, \tag{61}$$

where $\alpha:\mathcal{V}\to\Omega^{g,1}(\mathcal{V})$ is an even homomorphism of $\mathbb{Z}_2$-graded $\mathbb{M}(n|m)$ modules.

Proof: Analogous to the ungraded case.[1,21] □

We note that the existence of connections on $\mathcal{V}$ can also be shown without using (graded) projectivity (see Refs. 10, 11, 13, 15 for the ungraded case): According to (33),

$$\nabla_\Theta(v):=\Theta\otimes v \tag{62}$$

for all $v\in\mathcal{V}$ defines a connection on $\mathcal{V}$.

Quite generally we will denote the $\mathbb{Z}_2$-graded $\mathbb{M}(n|m)$-bimodule of graded $(p+q)\times(p+q)$-matrices over a $\mathbb{Z}_2$-graded $\mathbb{M}(n|m)$-bimodule $\mathcal{B}$ with $\mathbb{M}(p|q;\mathcal{B})$. It is an $\mathbb{M}(n|m)$ bimodule in a natural way and $\mathbb{Z}_2$-graded by declaring those matrices with even diagonal entries and odd off-diagonal entries as even and those with odd diagonal entries and even off-diagonal entries as odd. Adopting the notation of the above proposition we introduce homogeneous generators

$$\eta_A := \varphi^{-1}\circ P(\epsilon_A) \tag{63}$$

of $\mathcal{V}$ as well as an even matrix $(P_A^B)\in\mathbb{M}(p|q;\mathbb{M}(n|m))_{\bar{0}}$ via

$$P(\epsilon_A) =: \sum_{B=1}^{p+q} P_A^B \epsilon_B . \tag{64}$$

Then

$$(\nabla-\nabla_{Pd})(\eta_A)=\alpha(\eta_A)=:\sum_{B=1}^{p+q} \alpha_A^B\otimes\eta_B . \tag{65}$$

establishes a bijective correspondence between the set of all connections on $\mathcal{V}$ and the set $P\mathbb{M}(p|q;\Omega^{g,1}(\mathbb{M}(n|m)))_{\bar{0}}P$, which consists of those $(\alpha_A^B)\in\mathbb{M}(p|q;\Omega^{g,1}(\mathbb{M}(n|m)))_{\bar{0}}$ fulfilling $\alpha_A^B=\sum_{C,D=1}^{p+q} P_A^C\wedge\alpha_C^D\wedge P_D^B$ (for $\mathcal{V}=\mathcal{V}^{p|q}$ set $P=\varphi=\mathrm{Id}_{\mathcal{V}^{p|q}}$). The graded one-forms α_A^B are called connection forms of the connection $\nabla=\nabla_{Pd}+\alpha$.

If ∇ is a connection on a graded vector bundle $\mathcal{V}$ we can introduce a $\mathbb{C}$-linear map $\Omega^g(\mathcal{V})\to\Omega^g(\mathcal{V})$, again denoted by ∇, via

$$\nabla(\omega\otimes v)=d\omega\otimes v+(-1)^p\omega\wedge\nabla v \tag{66}$$

for all $v\in\mathcal{V},\omega\in\Omega^{g,p}(\mathbb{M}(n|m)),p\in\mathbb{N}_0$. This homogeneous map of bidegree $(1,\bar{0})$ extends the original connection if we identify $\mathcal{V}$ with $\Omega^{g,0}(\mathcal{V})$. Moreover it fulfills

$$\nabla(\omega'\wedge\omega\otimes v)=d\omega'\wedge(\omega\otimes v)+(-1)^{p'}\omega'\wedge\nabla(\omega\otimes v) \tag{67}$$

for all $v\in\mathcal{V},\omega\in\Omega^{g,p}(\mathbb{M}(n|m)),\omega'\in\Omega^{g,p'}(\mathbb{M}(n|m)),p,p'\in\mathbb{N}_0$, and this property determines the extension of the connection uniquely.

The curvature of a connection ∇ on a graded vector bundle $\mathcal{V}$ is defined as

$$\nabla^2\equiv\nabla\circ\nabla:\mathcal{V}\to\Omega^{g,2}(\mathcal{V}). \tag{68}$$

It is an even homomorphism of $\mathbb{Z}_2$-graded $\mathbb{M}(n|m)$ modules and one can describe its action on an element $v=\sum_{A=1}^{p+q}\varphi(v)^A\eta_A\in\mathcal{V}$ according to

$$\nabla^2(v)=:\sum_{A,B=1}^{p+q}\varphi(v)^A\wedge R_A^B\otimes\eta_B \tag{69}$$

with a uniquely determined matrix $(R_A^B)\in P\mathbb{M}(p|q;\Omega^{g,2}(\mathbb{M}(n|m)))_{\bar{0}}P$. The graded two-forms R_A^B are called curvature forms and they can be expressed according to

$$R_A^B=-\sum_{C=1}^{p+q}\alpha_A^C\wedge\alpha_C^B+\sum_{C,D=1}^{p+q}(P_A^C\wedge d\alpha_C^D\wedge P_D^B-P_A^C\wedge dP_C^D\wedge dP_D^B) \tag{70}$$

in terms of the connection forms α_A^B of the connection. Moreover they have to fulfill the Bianchi identity

$$\sum_{C,D=1}^{p+q} P_A^C \wedge dR_C^D \wedge P_D^B - \sum_{C=1}^{p+q} (\alpha_A^C \wedge R_C^B - R_A^C \wedge \alpha_C^B) = 0. \tag{71}$$

Let us finally analyze the space of flat connections, that is the set of all connections with vanishing curvature. We will not do this in complete generality but only for a graded-free vector bundle $\mathcal{V}^{1|0}$ with an even basis element ϵ.

Proposition 11: A connection on $\mathcal{V}^{1|0}$ *is flat if and only if its connection form* $\alpha \in \Omega^{g,1}(\mathbb{M}(n|m))_0^-$ *is either given by*

$$\alpha = \Theta \tag{72}$$

or by

$$\alpha = \Theta - \sum_{A=1}^{(n+m)^2-1} f(E_A) \wedge \theta^A, \tag{73}$$

where $\{E_A\}$ *is the homogeneous basis of* $\mathfrak{sl}(n|m)$ *"corresponding" to* $\{\theta^A\}$ *and f is some automorphism of* $\mathfrak{sl}(n|m)$.

Proof: Let us introduce an even graded one-form $\rho = \Sigma_{A=1}^{(n+m)^2-1} \rho_A \wedge \theta^A$ according to $\alpha =: \Theta - \rho$. Using proposition 4 we find that the curvature form is given by

$$R = \frac{1}{2} \sum_{A,B=1}^{(n+m)^2-1} \Omega_{AB} \wedge \theta^A \wedge \theta^B \tag{74}$$

with

$$\Omega_{AB} = [\rho_b, \rho_A]_g - \sum_{C=1}^{(n+m)^2-1} C_{BA}^C \rho_C. \tag{75}$$

Because the vanishing of the curvature is equivalent to $\Omega_{AB} = 0$ the proposition follows from the simplicity of $\mathfrak{sl}(n|m)$. □

That is, we have the same situation as in ordinary matrix geometry:[10,11,13,15] There exist different "classes" of flat connections. Here "class" refers to the action of the group of automorphisms of the graded vector bundle on the space of connections, which can be introduced similar to the ungraded case. The connection ∇_d and the one associated with the connection form Θ will lie in different classes, because the latter is invariant. However, if one does not restrict the space of connections by a suitable compatibility requirement with respect to a graded Hermitian structure there will exist even more than two classes of flat connections.

VII. CONCLUDING REMARKS

We have developed the graded differential geometry of graded matrix algebras and shown that the results of matrix geometry[10,11,13,15] carry over to the $\mathbb{Z}_2$-graded setting. In addition we found a natural noncommutative analog of the body map, which allows us to view graded matrix geometries as true noncommutative generalizations of graded manifolds.

Whereas in ordinary differential geometry one integrates forms this is not true in supergeometry. Except from the before mentioned body map, which plays a central role in the global theory of Berezin integration,[29] we completely excluded the integral geometry of graded matrix algebras. We plan to treat this together with metric aspects in a separate work.

Beside its immediate application for the construction of (graded) differential calculi on fuzzy (super) manifolds[15,17] the developments of this article offer another perspective. The extension of space–time by matrix geometries led to interesting new gauge models. In particular the existence of different gauge orbits of flat connections in matrix geometry is the origin of the appearance of the Higgs effect.[10,13,15,30] The possibility of extending the structures of matrix geometry to $\mathbb{Z}_2$-graded matrix algebras suggests thinking about similar ''supersymmetric'' noncommutative extensions of space–time.

APPENDIX: ASSOCIATIVE PRODUCT OF SUPERTRACE-FREE, GRADED MATRICES

Let $\{E_A | E_A \in \mathfrak{sl}(n|m)_0^-, A=1,...,n^2+m^2-1; E_A \in \mathfrak{sl}(n|m)_1^-, A=n^2+m^2,\ldots,(n+m)^2-1\}$ be a homogeneous basis of $\mathfrak{sl}(n|m), n\neq m$. The aim of this Appendix is to investigate the associative product of the homogeneous matrices E_A in a similar way as was done in Ref. 31 for trace-free, Hermitian matrices.

If we introduce a graded anticommutator

$$[M,M']_g^+ := MM' + (-1)^{\overline{MM'}} M'M \tag{A1}$$

of two homogeneous $M,M' \in \mathbb{M}(n|m)$ we find the relations

$$\begin{aligned} &[M,[M',M'']_g]_g - [M,[M',M'']_g^+]_g^+ + (-1)^{\bar{M}'\bar{M}''}[[M,M'']_g^+, M']_g^+ = 0,\\ &[[M,M']_g^+, M'']_g - [M,[M',M'']_g]_g^+ - (-1)^{\bar{M}'\bar{M}''}[[M,M'']_g, M']_g^+ = 0 \end{aligned} \tag{A2}$$

between the graded commutator and the graded anticommutator of homogeneous $M,M',M'' \in \mathbb{M}(n|m)$.

Because $\{E_A, 1_{n+m}\}_{A=1,\ldots,(n+m)^2-1}$ forms a homogeneous basis of $\mathbb{M}(n|m)$ the graded anticommutator of E_A and E_B can be written according to

$$[E_A, E_B]_g^+ = \sum_{C=1}^{(n+m)^2-1} d_{AB}^C E_C + g_{AB} 1_{n+m} \tag{A3}$$

with uniquely determined coefficients $d_{AB}^C, g_{AB} \in \mathbb{C}$. Then the associative product of E_A and E_B is given by

$$E_A E_B = \frac{1}{2} \sum_{C=1}^{(n+m)^2-1} (c_{AB}^C + d_{AB}^C) E_C + \frac{1}{2} g_{AB} 1_{n+m}. \tag{A4}$$

Independent of the specific choice of the homogeneous basis $\{E_A\}_{A=1,\ldots,(n+m)^2-1}$ there exist a lot of relations between the ''structure constants'' c_{AB}^C, d_{AB}^C, and g_{AB} which we summarize in

Proposition A: (i) c_{AB}^C *and* d_{AB}^C *vanish if* $\bar{E}_A + \bar{E}_B + \bar{E}_C = \bar{1}$ *and* g_{AB} *vanishes if* $\bar{E}_A + \bar{E}_B = \bar{1}$.

$$\text{(ii)} \qquad \sum_{B=1}^{(n+m)^2-1} (-1)^{\bar{E}_B} c_{AB}^B = 0, \qquad \sum_{B=1}^{(n+m)^2-1} (-1)^{\bar{E}_B} d_{AB}^B = 0. \tag{A5}$$

(iii) c_{ABC} *and* d_{ABC}, *defined via*

$$c_{ABC} := \sum_{D=1}^{(n+m)^2-1} c_{AB}^D g_{DC}, \quad d_{ABC} := \sum_{D=1}^{(n+m)^2-1} d_{AB}^D g_{DC}, \tag{A6}$$

are totally antisymmetric, respectively, totally symmetric in the $\mathbb{Z}_2$-graded sense.

(iv) $$\sum_{E=1}^{(n+m)^2-1} \{(-1)^{\bar{E}_A\bar{E}_C}C^E_{BC}C^D_{AE}+(-1)^{\bar{E}_B\bar{E}_A}c^E_{CA}c^D_{BE}+(-1)^{\bar{E}_C\bar{E}_B}c^E_{AB}c^D_{CE}\}=0,$$

$$\sum_{E=1}^{(n+m)^2-1} \{c^E_{BC}c^D_{AE}-d^E_{AB}d^D_{EC}+(-1)^{\bar{E}_A\bar{E}_C+\bar{E}_B\bar{E}_C}d^E_{CA}d^D_{EB}\}$$
$$+2(-1)^{\bar{E}_A\bar{E}_C+\bar{E}_B\bar{E}_C}g_{CA}\delta^D_B-2g_{AB}\delta^D_C=0, \tag{A7}$$

$$\sum_{E=1}^{(n+m)^2-1} \{d^E_{AB}c^D_{EC}-c^E_{BC}d^D_{AE}-(-1)^{\bar{E}_B\bar{E}_C}c^E_{AC}d^D_{EB}\}=0.$$

(v) *If $K_{AB}:=K(E_A,E_B)$, where K is the Killing form of $\mathfrak{sl}(n|m)$, then*

$$K_{AB}=(n-m)^2g_{AB}=\sum_{C,D=1}^{(n+m)^2-1}(-1)^{\bar{E}_C}c^C_{AD}c^D_{BC}=\frac{(n-m)^2}{(n-m)^2-4}\sum_{C,D=1}^{(n+m)^2-1}(-1)^{\bar{E}_C}d^C_{AD}d^D_{BC}. \tag{A8}$$

(vi) *Denoting by g^{AB} the components of the matrix inverse to (g_{AB}), then*

$$\sum_{B,C=1}^{(n+m)^2-1} g^{BC}c^A_{BC}=0, \qquad \sum_{B,C=1}^{(n+m)^2-1} g^{BC}d^A_{BC}=0. \tag{A9}$$

(vii) $$\sum_{C,D,E=1}^{(n+m)^2-1} g^{CD}c^A_{CE}c^E_{DB}=(n-m)^2\delta^A_B,$$

$$\sum_{C,D,E=1}^{(n+m)^2-1} g^{CD}c^A_{CE}d^E_{DB}=0, \tag{A10}$$

$$\sum_{C,D,E=1}^{(n+m)^2-1} g^{CD}d^A_{CE}d^E_{DB}=((n-m)^2-4)\delta^A_B.$$

(viii) $$\sum_{D,E,F,G=1}^{(n+m)^2-1}(-1)^{\bar{E}_A\bar{E}_E}g^{DE}c^F_{EB}c^G_{AF}c^C_{DG}=\frac{1}{2}(n-m)^2c^C_{AB},$$

$$\sum_{D,E,F,G=1}^{(n+m)^2-1}(-1)^{\bar{E}_A\bar{E}_E}g^{DE}c^F_{EB}c^G_{AF}c^C_{DG}=-\frac{1}{2}(n-m)^2c^C_{AB},$$

$$\sum_{D,E,F,G=1}^{(n+m)^2-1}(-1)^{\bar{E}_A\bar{E}_E}g^{DE}c^F_{EB}d^G_{AF}d^C_{DG}=-\frac{1}{2}((n-m)^2-4)c^C_{AB}, \tag{A11}$$

$$\sum_{D,E,F,G=1}^{(n+m)^2-1}(-1)^{\bar{E}_A\bar{E}_E}g^{DE}d^F_{EB}d^G_{AF}d^C_{DG}=\frac{1}{2}((n-m)^2-12)d^C_{AB}.$$

Proof: (i) is a reformulation of the homogeneity of $\{E_A\}$. The first line of (A8) as well as (iii) result from $K_{AB}=2(n-m)\mathrm{Tr}_s(E_AE_B)$. (ii) is a consequence of $\mathrm{Tr}_s(\mathrm{ad}\,E_A)=0$ and of

$\Sigma_{B,C}\,\mathrm{Tr}_s(g^{BC}[E_B,E_C]_g^+E_A)=0$. (iv) is a reformulation of the graded Jacobi identity and (A2). Using the second equation (A7) one deduces the second line of (A8). (vi) follows from (ii) and (iii). The left-hand side of the first equation (A10) is essentially the second-order Casimir operator of $\mathfrak{sl}(n|m)$ in the adjoint representation. The second part of (A10) follows from (iii), whereas the third equation is a consequence of the first part together with (iv) and (vi). The relations (viii) are results of calculations using (iii), (iv), (vi), and (vii). □

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 40, NUMBER 12 DECEMBER 1999

Even moments of a polymer chain distribution

Gary G. Hoffman[a)]
Theoretical Division, Los Alamos National Laboratory, Los Alamos, New Mexico 87545

(Received 25 February 1999; accepted for publication 17 September 1999)

An algorithm is presented for the evaluation of the even moments of the end-to-end separation of a polymer chain. The only assumption made in the distribution function is that the energy of the chain depends only on the individual bond lengths of the chain. This assumption covers many of the commonly used distribution functions. © *1999 American Institute of Physics.* [S0022-2488(99)02512-8]

I. INTRODUCTION

Recent investigations[1] into the stress–strain behavior of polymer network solids have led to an expression for the stress tensor in the form of an expansion in moments of the distribution of end-to-end separations of a polymer chain. Practical implementation of the expression requires, specifically, the even moments for chain lengths ranging from one on up to arbitrary numbers of bonds. It was found that moments up to at least the eighth were needed to obtain a reasonable description of the stress–strain behavior. It was found, further, that the non-Gaussian nature of the distribution was a critical ingredient in the computations and that the contributions of the shorter chains were found to be important, especially for the larger strains. It was therefore desired to have a model distribution for polymer chain end-to-end separations that reasonably describes the molecular nature of the material and expressions for the associated moments that are accurate for all chain lengths. For sufficiently long chain lengths, the probability distribution is well approximated by a Gaussian chain distribution. In such a case, the moments could be profitably obtained from such a distribution or a correction to it. However, a Gaussian distribution would not be appropriate for the shorter chain lengths. Since the stress–strain studies involved chain lengths as short as one bond, more accurate expressions were needed. In this paper, an algorithm for deriving exact expressions for the moments is presented and specific expressions for the lower order moments are given.

While the moments can be evaluated by brute force, each order being considered in turn, the procedure becomes increasingly difficult for higher orders. In trying to recognize patterns and simplifications, a general procedure was developed that can be applied to arbitrary orders. With this procedure, closed form expressions were readily generated for the moments up to the twelfth order. It was further noted that the procedure is applicable to a more general class of distribution than the one originally considered. In the event that the evaluation of higher moments of such distributions is desired, the general procedure will be presented in this paper.

This procedure uses a diagrammatic approach and has some similarities to the treatment used for the cluster expansion of the two-body distribution function in the classical statistical mechanics of many-body systems[2] or the quantum mechanical treatment of many-fermion systems.[3] Although the spirit of the development is the same, however, the details are different.

II. MATHEMATICAL FORMULATION

Consider a polymer chain that contains N equivalent bonds. The direction and length of the jth bond is given by the bond vector, $\mathbf{Q}_j$, and the full set of N such vectors is represented by $\mathbf{Q}^N$. It is assumed that the energy of the polymer chain depends only on the lengths of the bonds. Mathematically, the energy of a polymer chain in a particular configuration is then given by

[a)]Permanent address: Department of Chemistry, Florida International University, Miami, FL 33199.

$$E(\mathbf{Q}^N)=E_0+\sum_{j=1}^{N} f(Q_j), \tag{1}$$

where E_0 is a reference energy associated with the relaxed chain, and $f(Q)$ is an arbitrary function of the vector magnitude, Q. Recent work[4] has focused specifically on a chain of harmonic springs, where $f(Q)=\frac{1}{2}H(Q-a)^2$. The equilibrium probability of end-to-end separations of the chain at absolute temperature, T, is then given by

$$P_{\mathrm{eq}}^{(N)}(r)=\frac{1}{Z_1^N}\int \delta\left(\mathbf{r}-\sum_{j=1}^{N}\mathbf{Q}_j\right)\exp\left[-\sum_{n=1}^{N} f(Q_n)/kT\right]d^3Q_1\cdots d^3Q_N, \tag{2}$$

where k is Boltzmann's constant and

$$Z_1=\int e^{-f(Q)/kT}d^3Q. \tag{3}$$

It is easily shown that the distribution (2) depends only on the magnitude of the separation and not its direction.

The objective of this paper is to evaluate the even moments of this distribution:

$$\langle r^{2j}\rangle_0\equiv\int r^{2j}P_{\mathrm{eq}}^{(N)}(r)d^3r. \tag{4}$$

The subscript ''0'' denotes the use of the equilibrium distribution, as opposed to the distribution for a system under a deformation. In the course of the development, averages over bond vectors will be needed and it is convenient to introduce the shorthand notation

$$\langle F(\mathbf{Q}^N)\rangle_Q\equiv\frac{1}{Z_1^N}\int F(\mathbf{Q}^N)\exp\left[-\sum_{n=1}^{N} f(Q_n)/kT\right]d^3Q_1\cdots d^3Q_N \tag{5}$$

for arbitrary functions of the bond vectors. The subscript ''Q'' is used to distinguish this average from those over r. Although the details vary with the choice for the function, $f(Q)$, it will be assumed that the specific averages

$$\langle Q^{2j}\rangle_Q\equiv\frac{1}{Z_1}\int Q^{2j}e^{-f(Q)/kT}d^3Q \tag{6}$$

are available by some other means. For instance, in the above-mentioned case of the chain of harmonic springs, it is readily worked out that

$$\langle Q^{2j}\rangle_Q=\left(\frac{a^2}{\epsilon}\right)^j\frac{(2j+2)!}{2}\,\frac{D_{-(2j+3)}(-\sqrt{\epsilon})}{D_{-3}(-\sqrt{\epsilon})}, \tag{7}$$

where $\epsilon=Ha^2/kT$ and $D_\nu(z)$ is a parabolic cylinder function.

If Eq. (2) is substituted into Eq. (4), the integrations over $\mathbf{r}$ can be evaluated immediately, and there results

$$\langle r^{2j}\rangle_0=\sum_{k_1=1}^{N}\cdots\sum_{k_{2j}=1}^{N}\langle(\mathbf{Q}_{k_1}\cdot\mathbf{Q}_{k_2})\cdots(\mathbf{Q}_{k_{2j-1}}\cdot\mathbf{Q}_{k_{2j}})\rangle_Q \tag{8}$$

Consider each term in the sum separately. The distribution function does not depend on the orientation of the bond vectors, so that the directions of the bond vectors are manifest solely in the combination of dot products in the average. In any one term, a specific vector may appear once, twice, or even more times. Since each vector is odd under inversion and the overall integral must be invariant under an inversion, the nonvanishing terms in the sum must have the indices paired up. The complication is that there are many distinct ways that the indices can be paired up, so that it is not valid to just pick j of the indices and then set them equal to the other j.

A schematic way to represent this constraint on the indices is with the formula

$$\langle r^{2j}\rangle_0=\sum_{k_1=1}^{N}\cdots\sum_{k_{2j}=1}^{N}\langle(\mathbf{Q}_{k_1}\cdot\mathbf{Q}_{k_2})\cdots(\mathbf{Q}_{k_{2j-1}}\cdot\mathbf{Q}_{k_{2j}})\times\{\delta_{k_1k_2}\cdots\delta_{k_{2j-1}k_{2j}}+\text{all distinct permutations}\}\rangle_Q. \tag{9}$$

The phrase ''all distinct permutations'' needs some elaboration. There is a total of $(2j)!$ possible permutations of the indices, but a large number of them yield identical terms. For instance, interchanging k_1 and k_2 in the first product of Krönecker deltas yields exactly the same combination of Krönecker deltas and really does not provide a distinct term in the average. It should not be included in the sum of ''distinct permutations.'' Similarly, the interchange of the pair k_1,k_2 with the pair k_3,k_4 in the first term yields an identical product of Krönecker deltas and should also not be included in the sum of distinct permutations. One may imagine a large number of such equivalences, not necessarily involving the first product of Krönecker deltas. Further complications arise when considering terms in which more than one pair are the same. Suppose that $k_1=k_3$, so that this implies that $k_1=k_2=k_3=k_4$ in the first term of the sum of Krönecker deltas. Any permutation of these four indices, even one that would have yielded distinct terms if $k_1\neq k_3$ were true, should not be viewed as a distinct permutation in this case.

A second thing to notice is that the distribution of bond vectors is symmetric with respect to all permutations of the N vectors. Any terms in the sum, therefore, which differ only by a permutation of the particular labels used on the vectors must have the same value. This allows the grouping of similar terms and an elimination of the sums over the indices. This also is not a trivial matter, but depends on the number of pairs of indices that are equal as well as how they are paired in the dot products. If only terms where j indices are different and where only the first product of Krönecker deltas in Eq. (9) is considered, there results

$$\begin{aligned}&\sum_{\substack{k_1=1\\k_1\neq k_3\neq\cdots\neq k_{2j-1}}}^{N}\cdots\sum_{k_{2j}=1}^{N}\langle(\mathbf{Q}_{k_1}\cdot\mathbf{Q}_{k_2})\cdots(\mathbf{Q}_{k_{2j-1}}\cdot\mathbf{Q}_{k_{2j}})\delta_{k_1k_2}\cdots\delta_{k_{2j-1}k_{2j}}\rangle_Q\\&=\sum_{\substack{k_1=1\\k_1\neq k_2\neq\cdots\neq k_j}}^{N}\cdots\sum_{k_j=1}^{N}\langle Q_{k_1}^2Q_{k_2}^2\cdots Q_{k_j}^2\rangle_Q\\&=N(N-1)\cdots(N-j+1)\langle Q^2\rangle_Q^j.\end{aligned} \tag{10}$$

Clearly, there are many more terms to consider and it is important to properly categorize terms as well as determine how many times they occur.

Before getting to the diagrammatic treatment, it is instructive to see how the first two even moments can be evaluated by brute force. For $j=1$, there are only two sums in Eq. (8), and it is clear that only terms with $k_2=k_1$ will contribute. Further, every term in the remaining sum has the same value so that

$$\langle r^2\rangle_0=N\langle Q^2\rangle_Q. \tag{11}$$

For $j=2$, there are four sums, and k_1 may equal either k_2, k_3, or k_4. Whichever one k_1 equals, the remaining two must then be equal to each other. In addition, if k_1 equals k_2, the dot product $\mathbf{Q}_{k_1}\cdot\mathbf{Q}_{k_1}$ eliminates the angular dependence of the vectors; the dot product of the other pair will likewise eliminate any angular dependence. On the other hand, if k_1 equals either k_3 or k_4 and the two pairs are distinct, there results $(\mathbf{Q}_{k_1}\cdot\mathbf{Q}_{k_2})^2$ and the angular dependence of the vectors must be taken into account. There is a further distinction in that the two pairs may be different or equal. Proceeding in detail, there results

$$\langle r^4\rangle_0=\sum_{\substack{k_1=1\\k_1\neq k_2}}^{N}\sum_{k_2=1}^{N}\langle Q_{k_1}^2Q_{k_2}^2\rangle_Q+2\sum_{\substack{k_1=1\\k_1\neq k_2}}^{N}\sum_{k_2=1}^{N}\langle(\mathbf{Q}_{k_1}\cdot\mathbf{Q}_{k_2})^2\rangle_Q+\sum_{k_1=1}^{N}\langle Q_{k_1}^4\rangle_Q$$
$$=N(N-1)\{\langle Q^2\rangle_Q^2+2\langle(\mathbf{Q}_1\cdot\mathbf{Q}_2)^2\rangle_Q\}+N\langle Q^4\rangle_Q. \quad (12)$$

There are three different types of terms and each has its own associated coefficient. The evaluation over the angles of the bond vectors will be taken up later.

The types of complications that arise are already evident for $j=2$, but the above-mentioned procedure illustrates the general approach that must be taken for an arbitrary term. First, the types of terms that can occur must be identified. The indices must all be paired, but terms differ in how many pairs of indices are equal and in how the indices are connected in the dot products. All distinct arrangements lead to different results and so, should be considered separately. The second task is to determine how many times each type of term occurs to get the correct associated coefficient. Finally, the terms must be evaluated and combined.

III. CATEGORIZATION OF TERMS

Equation (9) contains summations of a large number of terms, in general. The objective of categorizing them is to group together equivalent terms and evaluate them all together. This reduces the overall number of terms to consider. The $2j$ indices must all be paired, so that a first step is to group the indices together into j pairs. It is possible for all pairs to be distinct, or for any number of pairs to be the same. The types of terms can be further distinguished by how they are linked through the dot products.

The categorization is broken down into two steps, which will be called the primary and secondary categorizations. The primary categorization involves finding all the possible sets of ‘‘cluster’’ sizes. After pairing up the indices, clusters can be made that contain one or more equal pairs. All possible arrangements of cluster sizes can occur and must be treated separately. For instance, for $j=2$, there are two pairs and it is possible for the pairs to be different or the same. In the first case, there will be two clusters, both of size one. In the second case, there is just one cluster of size two. The number of possibilities, naturally, increases with j.

The secondary categorization determines how many distinct ways the pairs of indices can be linked given a set of cluster sizes. For instance, for $j=2$ and two clusters of size one, there are terms where each pair consists of a dot product with itself and other terms where a member of each pair has a dot product with a member of the other. The general procedure for categorizing the terms will now be presented and the specific case for $j=5$ will be used for illustrative purposes.

The primary categorization can be reduced to a recursive procedure that is easily programed on a computer. Each primary categorization is labeled by a set of cluster sizes. For a given j, the clusters can have sizes from 1 to j. Let g_m denote the number of clusters with size m. Each categorization is then labeled by a unique set of integers, $\{g_m,\ m=1,...,j\}$. It is only necessary that

$$\sum_{m=1}^{i} mg_m=j. \quad (13)$$

The following procedure can be followed to generate all possible sets.

(a) Begin with $g_1=j$, the rest of the g_m's being zero.
(b) Evaluate the quantity $J_k=\Sigma_{m=1}^{k} mg_m$, starting with $k=1$ and continuing to successively higher values of k until $J_k-(k+1)>0$.

TABLE I. Clusters and coefficients associated with $j=5$.

Set	g_1	g_2	g_3	g_4	g_5	Factor	N_l
1	5	0	0	0	0	$N(N-1)(N-2)(N-3)(N-4)$	945
2	3	1	0	0	0	$N(N-1)(N-2)(N-3)$	3150
3	1	2	0	0	0	$N(N-1)(N-2)$	1575
4	2	0	1	0	0	$N(N-1)(N-2)$	630
5	0	1	1	0	0	$N(N-1)$	210
6	1	0	0	1	0	$N(N-1)$	45
7	0	0	0	0	1	N	1

(c) With this value of k, set $g_m=0$ for all $m\leqslant k$, increase g_{k+1} by one, and set $g_1=J_k-(k+1)$.

(d) Perform steps (b) and (c) repeatedly until the final case, where $g_j=1$ and the rest are zero, is achieved.

For $j=5$, the seven sets of clusters listed in Table I are obtained.

The secondary categorization looks at how the indices are connected through the dot products. This is where the diagrams are helpful. Begin by constructing a representation for the primary categorizations; call these the primary diagrams. Each pair of indices is assigned a dot. If any pairs are equal, the corresponding dots are joined to form a ''star.'' A star is a filled-in object with the number of points representing the number of equal-index pairs. For generality, a dot may be viewed as a star with one point. Each pair of indices is then associated with a point on a star. For $j=5$, the sets of stars associated with all the primary categorizations is shown in Fig. 1. With practice, generation of these primary diagrams may be performed by inspection and is often easier than following the set of rules outlined in the previous paragraph. However, the set of rules is more amenable for writing a computer program to perform the task.

Once these primary diagrams are generated, a new symbol is introduced that represents the arrangement of the dot products. Each point on a star represents a pair of bond vectors. Each bond vector is connected with another through a dot product, so each point on a star can make two connections. These connections are represented in the diagrams by directed lines. Every point of a star in the diagram must have one directed line coming in and one going out. It is possible to have a point with a single directed line coming in and going out of it; this corresponds to a dot product of the vector with itself.

There are some complications that can arise, and so some care is needed to construct a set of rules for the full generation of allowable diagrams. First of all, to avoid cluttering up the diagram, single lines that leave and enter the same point are left out. Any unconnected points are assumed to represent dot products of the vector with itself. Second, a star with more than one point must be treated specially to avoid generating more than one equivalent diagram. Because all the points on a star represent the same vector, there is some arbitrariness in choosing where lines come in and

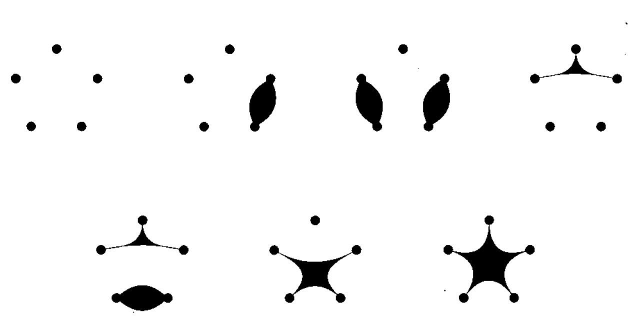

FIG. 1. The primary diagrams for $j=5$.

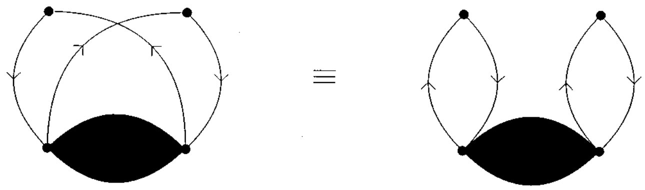

FIG. 2. Two equivalent diagrams, only one of which is acceptable.

where they leave. To avoid confusion, if a line comes into one point of a star from another star, a line must leave by the same point to another star. Lines should not connect two different points of the same star. Since such lines would represent the dot product of a vector with itself, they should be represented as points without any directed lines connected.

Another restriction needs to be made regarding stars of more than one point. Directed lines may be followed to form closed loops. Because of the equivalence of points on a star, it is possible to manipulate lines in a diagram so that a given loop contacts the star at only one point. To illustrate this, Fig. 2 shows two equivalent diagrams for $j=4$. In the first diagram, there is one loop that contacts the two-point star at two points. In the second, the lines have been rearranged so that there are two loops, each contacting the star at only one point. For any general set of equivalent diagrams, only one has closed loops that contact each star at no more than one point. The rule is therefore made that any loop of an acceptable diagram may contact a given star at no more than one point. With this rule, only the second diagram in Fig. 2 would be acceptable.

It must also be kept in mind that stars with the same number of points are equivalent. Diagrams which differ only by a rearrangement of such stars are equivalent and only one should be included.

A moment can be represented by a sum of diagrams. A set of rules for constructing the diagrams can be stated as follows.

(a) Given j, the set of all primary diagrams is generated as described above.

(b) Starting with each primary diagram, directed lines are added to construct all topologically distinct diagrams such that:

(i) a point may have no lines connected to it,

(ii) if a line enters a point, another line must leave it,

(iii) a line may not leave and enter the same point, and

(iv) the lines form closed loops which can connect to any star at no more than one point.

Following these rules, all distinct diagrams may be constructed. These represent the types of terms that will be encountered. As an example, all the diagrams associated with $j=5$ are shown in Fig. 3.

IV. EVALUATION OF THE DIAGRAMS

The moment is now expressed as a sum of diagrams. It only remains to evaluate these diagrams and combine them for the final result. To interpret the diagrams, label each star with an index. These represent labels for the bond vectors. The directed lines are used to form dot products between the vectors and unconnected points represent vectors that have dot products with themselves. The full list of terms for $j=5$ is rather long, so only the terms for $j=5$ and the first primary categorization, with $g_1=5$, will be presented. The bond vector averages that go with these diagrams are given in Table II. Aside from evaluating these averages, it is necessary to determine the coefficients that go with each term.

Each primary categorization has associated with it a certain number of distinct indices. For instance, set 1 in Table I contains five distinct indices, set 2 contains four, and so on. Denote the number of distinct indices in a given set by M. As already mentioned, terms which differ only in the indices used to label the vectors have the same value. Therefore, with a given primary categorization, the sum over all appropriate indices can be performed explicitly. For instance, for set

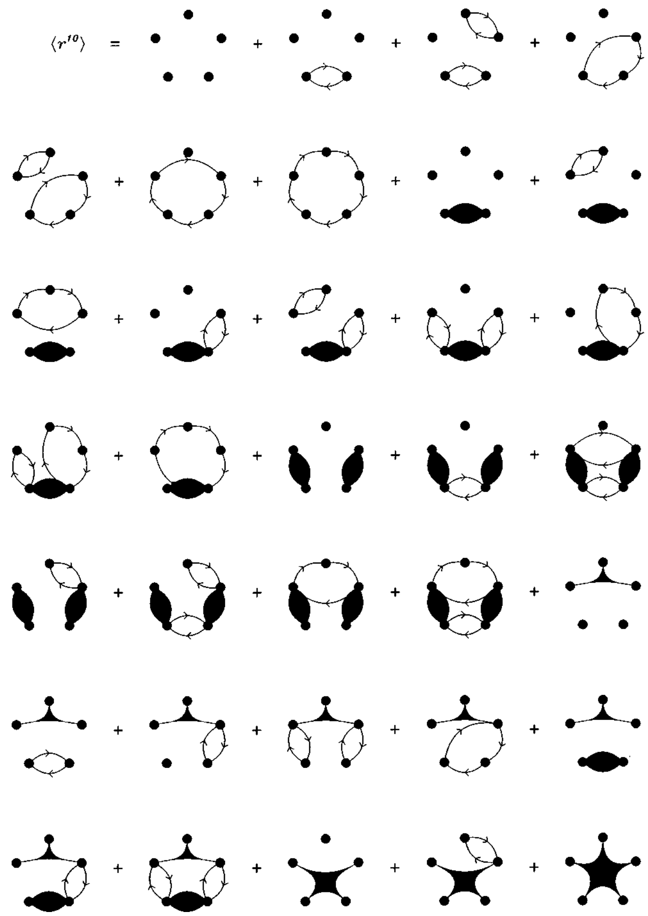

FIG. 3. The full set of diagrams for $j=5$.

1 in Table I, all sets of five distinct indices give the same set of terms corresponding to this primary categorization. It is then possible to extract one such set of terms—say for $k_1=1$, $k_2=2$, $k_3=3$, $k_4=4$, and $k_5=5$—and pull it out of the sums completely. It is then necessary to sum over all sets of five distinct indices, none of which may be equal, to arrive at the coefficient, $N(N-1)(N-2)(N-3)(N-4)$, which must multiply all diagrams associated with this primary categorization. More generally, with M different indices in a given categorization, the sums over indices yield a factor of $N!/(N-M)!$. The factors for $j=5$ are included in Table I.

A useful quantity for checking the generation of secondary diagrams is the number of terms associated with each primary categorization. This is associated with the number of distinct permutations of the delta functions in Eq. (9) that correspond to a given categorization. This is a

TABLE II. Evaluated terms for the $g_1=5$ cluster diagrams for $j=5$.

Term	Coefficient
$Q_1^2Q_2^2Q_3^2Q_4^2Q_5^2$	1
$Q_1^2Q_2^2Q_3^2(\mathbf{Q}_4\cdot\mathbf{Q}_5)^2$	20
$Q_1^2(\mathbf{Q}_2\cdot\mathbf{Q}_3)^2(\mathbf{Q}_4\cdot\mathbf{Q}_5)^2$	60
$Q_1^2Q_2^2(\mathbf{Q}_3\cdot\mathbf{Q}_4)(\mathbf{Q}_4\cdot\mathbf{Q}_5)(\mathbf{Q}_5\cdot\mathbf{Q}_3)$	80
$(\mathbf{Q}_1\cdot\mathbf{Q}_2)^2(\mathbf{Q}_3\cdot\mathbf{Q}_4)(\mathbf{Q}_4\cdot\mathbf{Q}_5)(\mathbf{Q}_5\cdot\mathbf{Q}_3)$	160
$Q_1^2(\mathbf{Q}_2\cdot\mathbf{Q}_3)(\mathbf{Q}_3\cdot\mathbf{Q}_4)(\mathbf{Q}_4\cdot\mathbf{Q}_5)(\mathbf{Q}_5\cdot\mathbf{Q}_2)$	240
$(\mathbf{Q}_1\cdot\mathbf{Q}_2)(\mathbf{Q}_2\cdot\mathbf{Q}_3)(\mathbf{Q}_3\cdot\mathbf{Q}_4)(\mathbf{Q}_4\cdot\mathbf{Q}_5)(\mathbf{Q}_5\cdot\mathbf{Q}_1)$	384

simple problem in combinatorics, being equal to the number of distinct permutations of the j pairs of integers in the list among j boxes, each being able to hold only two integers. For an arbitrary set l, this is given by

$$N_l = \frac{(2j)!}{\Pi_m (m!)^{g_m} g_m!} \tag{14}$$

For $j=5$, the values are included in Table I.

A coefficient is also associated with each diagram based on the secondary categorization. These coefficients represent the number of times such a term appears in the sum of Krönecker deltas. Determining these coefficients leads to exercises in combinatorics. The indices are viewed as pairs of labels that are to go into j boxes, each being able to hold two labels. Vectors that are connected by a dot product have their indices paired. It is necessary to determine how many distinct ways a particular set of pairings may be accomplished. It is important to keep in mind, though, that overall permutations of the labels has already been performed in the sums over the indices. If a simple permutation of labels leads to an indistinguishable term, this permutation must not be included in the coefficient.

For example, the first term in Table II contains the five pairings (11), (22), (33), (44), and (55). The only permutations that yield equivalent pairings are those where a pair is interchanged completely with another. There are $5!=120$ such permutations. However, note that all simple permutations of the five labels also lead to equivalent terms. Therefore, the value of 120 must be divided by the number of such permutations, i.e., 120, to get the correct coefficient of 1.

Consider, now, the second term in Table II. This has the five pairings (11), (22), (33), (45), and (45). One way to count the possible permutations is to note that the pair (11) has five possible positions. Once this placement is taken care of, the pair (22) has four possible positions. Then, the pair (33) has three possible positions. This then fixes where the two pairs (45) must go. The indices in each of these two final pairs may be interchanged, meaning there are four possible arrangements of them. Specifically, these are (45)(45), (45)(54), (54)(45), and (54)(54). Overall, then, there are $5\times4\times3\times4=240$ appropriate permutations. However, permutations of the labels 1, 2, and 3 among themselves lead to indistinguishable terms; there are six such permutations. Further, permutation of 4 and 5 lead to indistinguishable terms; there are two such permutations. No other permutations of the labels yield indistinguishable terms. Therefore, the result of 240 must be divided by $2\times6=12$ to give 20. The other terms can be worked out in an analogous way and the coefficients for the diagrams listed in Table II are given there.

As a check, it should be noted that the sum of coefficients for all the diagrams associated with a given primary categorization should equal the quantity, N_l, defined in Eq. (14). Note that the sum of coefficients in Table II equals 945, the number given in Table I for this primary categorization.

The general procedure has been given. The details for the specific cases can be worked out with little difficulty. The final step involves performing the averages over the dot products. This requires integrals over angles, which are readily performed, the procedure being outlined in the Appendix. For the first few moments, there results

$$\langle r^2\rangle_0 = N\langle Q^2\rangle_Q, \tag{15a}$$

$$\langle r^4\rangle_0 = \tfrac{5}{3}N(N-1)\langle Q^2\rangle_Q^2 + N\langle Q^4\rangle_Q, \tag{15b}$$

$$\langle r^6\rangle_0 = \tfrac{35}{9}N(N-1)(N-2)\langle Q^2\rangle_Q^3 + 7N(N-1)\langle Q^2\rangle_Q^2\langle Q^4\rangle_Q + N\langle Q^6\rangle_Q, \tag{15c}$$

$$\begin{aligned}\langle r^8\rangle_0 = {}& \tfrac{35}{3}N(N-1)(N-2)(N-3)\langle Q^2\rangle_Q^4 + 42N(N-1)(N-2)\langle Q^2\rangle_Q^2\langle Q^4\rangle_Q \\ & + \tfrac{63}{5}N(N-1)\langle Q^4\rangle_Q^2 + 12N(N-1)\langle Q^2\rangle_Q\langle Q^6\rangle_Q + N\langle Q^8\rangle_Q,\end{aligned} \tag{15d}$$

$$\langle r^{10}\rangle_0=\tfrac{385}{9}N(N-1)(N-2)(N-3)(N-4)\langle Q^2\rangle_Q^5+\tfrac{770}{3}N(N-1)(N-2)(N-3)\langle Q^2\rangle_Q^3\langle Q^4\rangle_Q$$
$$+231N(N-1)(N-2)\langle Q^2\rangle_Q\langle Q^4\rangle_Q^2+110N(N-1)(N-2)\langle Q^2\rangle_Q^2\langle Q^6\rangle_Q+66N(N-1)$$
$$\times\langle Q^4\rangle_Q\langle Q^6\rangle_Q+\tfrac{55}{3}N(N-1)\langle Q^2\rangle_Q\langle Q^8\rangle_Q+N\langle Q^{10}\rangle_Q, \tag{15e}$$

$$\langle r^{12}\rangle_0=\tfrac{5005}{27}N(N-1)(N-2)(N-3)(N-4)(N-5)\langle Q^2\rangle_Q^6+\tfrac{5005}{3}N(N-1)(N-2)(N-3)(N-4)$$
$$\times\langle Q^2\rangle_Q^4\langle Q^4\rangle_Q+3003N(N-1)(N-2)(N-3)\langle Q^2\rangle_Q^2\langle Q^4\rangle_Q^2+\tfrac{2860}{3}N(N-1)(N-2)(N$$
$$-3)\langle Q^2\rangle_Q^3\langle Q^6\rangle_Q+\tfrac{3003}{5}N(N-1)(N-2)\langle Q^4\rangle_Q^3+1716N(N-1)(N-2)$$
$$\times\langle Q^2\rangle_Q\langle Q^4\rangle_Q\langle Q^6\rangle_Q+\tfrac{715}{3}N(N-1)(N-2)\langle Q^2\rangle_Q^2\langle Q^8\rangle_Q+\frac{858}{7}N(N-1)\langle Q^6\rangle_Q^2$$
$$+143N(N-1)\langle Q^4\rangle_Q\langle Q^8\rangle_Q+26N(N-1)\langle Q^2\rangle_Q\langle Q^{10}\rangle_Q+N\langle Q^{12}\rangle_Q. \tag{15f}$$

Note that these expressions reduce to those for the Kramers chain[5] when $\langle Q^{2j}\rangle_Q=a^{2j}$.

V. CONCLUSIONS

A general procedure has been given for the closed form evaluation of the even moments of the distribution of end-to-end separations of a polymer chain. The only assumption made is that the energy of the polymer chain depends only on the lengths of the polymer bonds. The procedure can be applied to any order, although it is acknowledged that the procedure becomes increasingly tedious with higher orders. Nevertheless, the procedure is considerably easier than the brute force approach.

It may be noted that the terms in Eq. (15) to leading order in N are identical to what would be obtained from the Gaussian chain model:

$$\langle r^{2j}\rangle_G=\frac{(2j+1)!!}{3^j}N^j\langle Q^2\rangle_Q^j. \tag{16}$$

The expressions derived here would therefore converge to the Gaussian chain results as N gets larger, corrections being of the order $1/N$. This may be viewed simply as a statement of the central limit theorem.[6] A general expression for the distribution function of polymer chain end-to-end separations may be derived as a Gaussian chain distribution times a series expansion correction, successive terms being of higher orders in $1/N$.[7] The moments would therefore be expected to be expansions in $1/N$ as well, as is clear from the equations derived here. As noted in Sec. I, it was desired to have moments for all possible chain lengths. The expressions derived here were therefore found to be quite useful in the stress–strain studies.[1] The expansion derived in that work was truncated so that moments only up to the eighth were needed. If a truncation at the next higher order were desired, moments up to the twelfth would be needed, and the appropriate expressions are presented in closed form here. Higher orders, if needed, could be derived by the procedure outlined in this paper.

This procedure is restricted to a specific type of energy dependence of the polymer chain, and the possibility of generalization may be worth investigating. As it turns out, the procedure is unchanged if the energy depends not only on the length, but also on the direction of each bond, except that the evaluation of the angular integrals as described in the Appendix is more complicated. The restriction of bond angles and even dihedral angles would lead to more realistic distribution functions. The methods for evaluating the moments of such distributions with rigid bonds in the rotational isomeric state approximation[8,9] seem rather cumbersome and generally require numerical evaluation. The extension of these models to chains where bonds may bend and stretch away from their equilibrium values would be extremely difficult using these methods. However, there may be some hope for the diagrammatic approach presented here.

There is another intriguing possibility associated with this procedure that is worth mentioning. The diagrammatic approach used here has analogies with that used in cluster expansions of the two-body distribution function of many-body systems.[2,3] Not only does the diagrammatic treatment aid in the identification and evaluation of terms in the cluster expansions, it is also helpful in deriving relationships between the various types of terms that arise. These relationships allow a resummation of the expansion to infinite order resulting in either the hypernetted chain (HNC)[10] equations in the classical case or the fermion hypernetted chain (FHNC)[11,12] equations in the many-fermion case. The importance of these equations is realized when it is noted that the terms of the cluster expansion may either converge slowly or even diverge at low orders. The resummation removes these difficulties. The moments of the polymer equilibrium distribution function can be used in an expansion of the distribution function for a polymer network under strain[13] and subsequently in an expansion of the free energy density associated with the material. A resummation along the lines of the HNC or FHNC equations might prove valuable for an improved theory of polymer networks. The method to be presented may serve as a starting point for such a development.

APPENDIX: EVALUATION OF THE ANGULAR INTEGRALS

The evaluation of an angular integral can be reduced to an exercise in tensor analysis. Since the distribution of vector bonds depends only on their magnitudes, the general average can be reduced to

$$\langle(\mathbf{Q}_{k_1}\cdot\mathbf{Q}_{k_2})\cdots(\mathbf{Q}_{k_{2j-1}}\cdot\mathbf{Q}_{k_{2j}})\rangle_Q=\langle Q_{k_1}Q_{k_2}\cdots Q_{k_2}\rangle_{jQ}\langle(\mathbf{u}_{k_1}\cdot\mathbf{u}_{k_2})\cdots(\mathbf{u}_{k_{2j-1}}\cdot\mathbf{u}_{k_{2j}})\rangle_a, \tag{A1}$$

where $\mathbf{u}_i$ is a unit vector in the direction of $\mathbf{Q}_i$ and the subscript ''a'' on the final averaged quantity indicates that the average is taken only over angles. A generic way to write this is

$$\langle F(\mathbf{u}^N)\rangle_a\equiv\frac{1}{(4\pi)^N}\int F(\mathbf{u}^N)d\Omega_1\cdots d\Omega_N \tag{A2}$$

for an arbitrary function of the unit vectors.

The functions of interest here are simply dot products of the unit vectors. In general, there will be unit vectors appearing as various powers and connected with each other through the dot products. The angular average then reduces to a product of averages over single unit vectors, which are then connected through tensor products. For instance, there is the simple average

$$\langle(\mathbf{u}_1\cdot\mathbf{u}_2)^2\rangle_a=\langle\mathbf{u}_1\mathbf{u}_1\rangle_a:\langle\mathbf{u}_2\mathbf{u}_2\rangle_a \tag{A3}$$

or, getting a little more complicated, there is

$$\langle(\mathbf{u}_1\cdot\mathbf{u}_3)^2(\mathbf{u}_2\cdot\mathbf{u}_3)^2\rangle_a=\langle\mathbf{u}_1\mathbf{u}_1\rangle_a\langle\mathbf{u}_2\mathbf{u}_2\rangle_a\vdots\langle\mathbf{u}_3\mathbf{u}_3\mathbf{u}_3\mathbf{u}_3\rangle_a. \tag{A4}$$

An important first step is therefore the evaluation of the average of a particular power of a unit vector.

An elegant procedure for performing these averages has been presented by Brenner.[14] The general results is

$$\langle \mathbf{u}^p \rangle_a = \begin{cases} 0 & \text{if } p \text{ is odd} \\ \dfrac{1}{(p+1)!} (\boldsymbol{\nabla})^p r^p & \text{if } p \text{ is even.} \end{cases} \tag{A5}$$

As already noted in the main part of the paper, only even powers should appear in these averages. The above result makes this explicit.

This formal result can be made a bit more convenient. First, note that the successive gradients reduce the power of the coordinates by one, so that the final result is independent of r. Two successive gradients, though, will yield a nonzero result only if a particular coordinate appears twice. This leads to a pairing of the coordinate indices. This pairing, though, can occur in many different ways. A careful analysis leads to

$$\langle u_{j_1} \cdots u_{j_{2n}} \rangle_a = \frac{1}{(2n+1)!!} \{ \delta_{j_1 j_2} \cdots \delta_{j_{2n-1} j_{2n}} + \text{all proper permutations} \}, \tag{A6}$$

where the indices in Eq. (A6) indicate specific coordinates of the unit vectors: u_1, u_2, and u_3. The phrase ''all proper permutations'' has a slightly different meaning than the phrase ''all distinct permutations'' used in the main part of the paper. All indices, $\{j_1,\ldots,j_{2n}\}$ are viewed as distinct and all distinct permutations of the first product of delta functions is included in the sum. In all, there are $(2n-1)!!$ such permutations. Several examples might help see how this works.

The average for $n=1$ is given explicitly by

$$\langle \mathbf{uu} \rangle_a = \tfrac{1}{3} \boldsymbol{\delta}, \tag{A7}$$

where $\boldsymbol{\delta}$ is the unit tensor. For $n=2$, there results

$$\langle \mathbf{uuuu} \rangle_a = \tfrac{1}{15} \{ \boldsymbol{\delta\delta} + \mathbf{I} + \mathbf{I}^\dagger \}, \tag{A8}$$

where $\mathbf{I}$ is a fourth-rank tensor with elements $I_{ijkl} = \delta_{ik}\delta_{jl}$. Similarly, the transpose has elements $I^\dagger_{ijkl} = \delta_{il}\delta_{jk}$. The result for $n=3$ requires more space, but is obtained in a straightforward way,

$$\begin{aligned}(\langle \mathbf{uuuuuu} \rangle_a)_{ijklmn} = \tfrac{1}{105} \{ & \delta_{ij}\delta_{kl}\delta_{mn} + \delta_{ij}\delta_{km}\delta_{ln} + \delta_{ij}\delta_{kn}\delta_{lm} + \delta_{ik}\delta_{jl}\delta_{mn} + \delta_{ik}\delta_{jm}\delta_{ln} \\ & + \delta_{ik}\delta_{jn}\delta_{lm} + \delta_{il}\delta_{jk}\delta_{mn} + \delta_{il}\delta_{jm}\delta_{kn} + \delta_{il}\delta_{jn}\delta_{km} + \delta_{im}\delta_{jk}\delta_{ln} \\ & + \delta_{im}\delta_{jl}\delta_{kn} + \delta_{im}\delta_{jn}\delta_{kl} + \delta_{in}\delta_{jk}\delta_{lm} + \delta_{in}\delta_{jl}\delta_{km} + \delta_{in}\delta_{jm}\delta_{kl} \}. \end{aligned} \tag{A9}$$

The results for higher orders should be apparent. The procedure is readily programmed on a computer.

These results can now be used, the appropriate summations over indices being performed to obtain the final results. Several examples can illustrate this. First, consider

$$\langle (\mathbf{Q}_1 \cdot \mathbf{Q}_2)^2 \rangle_Q = \langle Q_1^2 Q_2^2 \rangle_Q \langle \mathbf{u}_1 \mathbf{u}_1 \rangle_a : \langle \mathbf{u}_2 \mathbf{u}_2 \rangle_a = \tfrac{1}{9} \langle Q^2 \rangle_Q^2 \boldsymbol{\delta} : \boldsymbol{\delta} = \tfrac{1}{3} \langle Q^2 \rangle_Q^2. \tag{A10}$$

A more general result is given by

$$\langle (\mathbf{Q}_1 \cdot \mathbf{Q}_2)^{2n} \rangle_Q = \frac{1}{2n+1} \langle Q^n \rangle_Q^2. \tag{A11}$$

Another example is

$$\langle (\mathbf{Q}_1 \cdot \mathbf{Q}_2)(\mathbf{Q}_2 \cdot \mathbf{Q}_3)(\mathbf{Q}_3 \cdot \mathbf{Q}_1) \rangle_Q = \langle Q_1^2 Q_2^2 Q_3^2 \rangle_Q \, \mathrm{tr} \{ \tfrac{1}{3} \boldsymbol{\delta} \cdot \tfrac{1}{3} \boldsymbol{\delta} \cdot \tfrac{1}{3} \boldsymbol{\delta} \} = \tfrac{1}{9} \langle Q^2 \rangle_Q^3. \tag{A12}$$

Generalizing this,

$$\langle(\mathbf{Q}_1\cdot\mathbf{Q}_2)(\mathbf{Q}_2\cdot\mathbf{Q}_3)\cdots(\mathbf{Q}_n\cdot\mathbf{Q}_1)\rangle_Q=\frac{1}{3^{n-1}}\langle Q^2\rangle_Q^n. \tag{A13}$$

The procedure is readily applied to any of the angular averages that arise.

Zeros of the Jimbo, Miwa, Ueno tau function

John Palmer[a)]
Department of Mathematics, University of Arizona, Tucson, Arizona 85721

(Received 2 March 1999; accepted for publication 30 August 1999)

We introduce a family of local deformations for meromorphic connections on $\mathbf{P}^1$ in the neighborhood of a higher rank (simple) singularity. Following the scheme in Malgrange [*Mathematique et Physique*, Progress in Mathematics (Birkhäuser, Boston, 1983), Vol. 37, pp. 381–400, *ibid.*, pp. 401–426; *ibid.*, pp. 427–438] we use these local models to prove that the zeros of the tau function, introduced by Jimbo, Miwa, and Ueno in their pioneering work on ''Birkhoff'' deformations at irregular singular points [Physica D **2**, 306–352; **2**, 407–448 (1981); **4**, 26–46 (1983); Publ. RIMS Kyoto Univ. **17-2**, 703–721 (1981)], occur at precisely those points in the deformation space at which a certain Birkhoff–Riemann–Hilbert problem fails to have a solution. [S0022-2488(99)01112-3]

I. INTRODUCTION

A. The Riemann–Hilbert problem and monodromy preserving deformations

Suppose that $A(x)$ is a $p\times p$ matrix with entries that are rational functions of x on $\mathbf{P}^1$. Linear differential equations,

$$\frac{d\psi}{dx}=A(x)\psi, \tag{1.0}$$

arise in many important applications and have been studied intensively for more than 100 years. The nature of the singularities in the coefficient matrix $A(x)$ at its poles has a lot to do with the character of the solutions to (1.0). For example, in the neighborhood of a point a where $A(x)$ has but a simple pole, it is well known that the equation (1.0) has a fundamental solution, $\Psi(x)$, with polynomially limited growth as $x\rightarrow a$ (by which we mean that solutions are dominated near $x=a$ by $c|x-a|^{-N}$ where c and N are constants). Higher-order poles in $A(x)$ typically produce local fundamental solutions with more complicated exponential–polynomial growth near the pole. Fundamental solutions to the equation (1.0) are usually not single valued. If one has a fundamental solution $\Psi(x)$ defined for x in some small ball not containing any of the poles, $\{a_1,a_2,\ldots,a_n\}$, of $A(x)$, then it is possible to analytically continue $\Psi(x)$ along paths in $\mathbf{P}^1$ that avoid these poles. The analytic continuation depends only on the homotopy class of the path, so that the resulting function, $\Psi(x)$, is defined not on $\mathbf{P}^1$ but for x in the simply connected covering space, $\mathcal{R}(X)$, of $X:=\mathbf{P}^1\backslash\{a_1,a_2,\ldots,a_n\}$ with projection $\pi:\mathcal{R}(X)\rightarrow X$. If $x_0\in\mathcal{R}(X)$ and γ is a closed path in X with base point $\pi(x_0)$ then

$$\Psi(\gamma\cdot x_0)=\Psi(x_0)M(\gamma)^{-1},$$

where $x_0\rightarrow\gamma\cdot x_0$ is the natural action of the homotopy class of the path γ on $x_0\in\mathcal{R}(X)$, and $\gamma\rightarrow M(\gamma)$ is an n-dimensional representation of the fundamental group $\pi_1(X,\pi(x_0))$. Riemann's analysis of the solutions of the hypergeometric equation in terms of its *monodromy representation* $M(\cdot)$ led to the general problem of determining if any representation of the fundamental group of the punctured sphere could arise as the monodromy representation for a linear differential equation (1.0). It is clear from simple examples that there will not be a unique association between a

[a)]Electronic mail: Palmer@math.arizona.edu

representation of π_1 and a differential equation (1.0) without some further restriction on the differential equation. It is possibly most natural to look for a differential equation with *simple poles* to realize a given monodromy representation. It is not always possible to solve this problem,[1] but if one relaxes the condition on the differential equation to admit *regular singular points* then it is classical that the inverse monodromy problem always has a solution (a good discussion of the confusion about the status of the solution to this problem can also be found in Ref. 1). A pole a of $A(x)$ in (1.0) is said to be a regular singular point if fundamental solutions to (1.0) have, at worst, polynomial growth at a. Because the fundamental solutions are defined on the simply connected covering and paths that wind around the point a pick up powers of the local monodromy, the precise notion of polynomial growth requires some restriction to sectors in the covering space.[1] More important for us, however, is *a deformation* variant of the simple pole condition. Suppose that for some collection of points $\{a_1^0,a_2^0,\ldots,a_n^0\}$, a given representation of

$$\pi_1(\mathbf{P}^1\backslash\{a_1^0,a_2^0,\ldots,a_n^0\},a_0),$$

can be realized by a differential equation (1.0) with *simple poles* at a_j^0 $j=1,2,...,n$ and a fundamental solution $\Psi(x)$ normalized to $\Psi(a_0)=I$ at the base point a_0. In this case, we write $A^0(x)$ for the matrix coefficient in the differential equation (1.0) that realizes the appropriate monodromy representation. Since $A^0(x)$ has simple poles,

$$A^0(x)=\sum_{\nu=1}^{n}\frac{A_\nu^0}{x-a_\nu^0}.$$

The problem, first formulated by Schlesinger,[2] is to ask whether it is possible to deform the coefficients A_ν^0 in $A^0(x)$ as functions of the pole locations a_ν so that the differential equation (1.0) with coefficient matrix.

$$A(x)=\sum_{\nu=1}^{n}\frac{A_\nu(a)}{x-a_\nu}$$

realizes the *same* monodromy representation as as the differential equation with coefficient matrix (1.1) (we will be more precise about what this means later on). Note that we have written $a=(a_1,a_2,\ldots,a_n)$, and we want

$$A_\nu(a^0)=A_\nu(a_1^0,a_2^0,\ldots,a_n^0)=A_\nu^0.$$

When the point at infinity is a regular point and $a_0=\infty$, Schlesinger showed that if such a deformation exits the coefficients A_ν must satisfy a nonlinear system of differential equations,

$$dA_\mu=-\sum_{\nu\neq\mu}\frac{A_\mu A_\nu-A_\nu A_\mu}{a_\mu-a_\nu}d(a_\mu-a_\nu),$$

now called the Schlesinger equations. A modern treatment of the existence question can be found in Ref. 3. If we write $a\in\mathbf{C}^n$ then, as might be guessed from looking at the Schlesinger equations, it is important to remove the points at which $a_\mu=a_\nu$ from consideration. Let

$$\Delta_{\mu\nu}=\{a\in\mathbf{C}^n | a_\nu=a_\mu\},$$

and define

$$Z^n=\mathbf{C}^n\backslash\cup_{\nu\neq\mu}\Delta_{\mu\nu}.$$

As observed by Malgrange, an appropriate place to seek monodromy preserving deformations is the simply connected covering space $\mathcal{R}(Z^n)\to Z^n$. Because this same space will enter our considerations with a different significance later on, it will be useful at this point to introduce distinctive notation for elements in $\mathcal{R}(Z^n)$ and their projection onto Z^n. We will write $t\in\mathcal{R}(Z^n)$ and $a(t)\in Z^n$ for the projection of t on $Z^n\subset C^n$. We write $a_j(t)$ for the jth component of $a(t)$.

As pointed out in Refs. 3 and 4, the space $\mathcal{R}(Z^n)$ has a number of advantages as a deformation space. Not only is it simply connected but since Z^n is contractible[5] the long exact sequence associated with the fiber bundle projection,

$$a:\mathcal{R}(Z^n)\rightarrow Z^n,$$

shows that all the higher homotopy groups of $\mathcal{R}(Z^n)$ are also trivial and hence that $\mathcal{R}(Z^n)$ is contractible. Since Z^n is the complement of the zero set of an an analytic function on $\mathbf{C}^n$, it is a Stein space, and since $\mathcal{R}(Z^n)$ is an unramified covering of Z^n it too is a Stein space.[6] The consequent triviality of the sheaf cohomology $H^1(\mathcal{R}(Z^n),\mathcal{O}^*)$ plays a role in giving a global definition of tau functions following Ref. 4. Finally, although it will not be the principal focus of the deformations we consider in this paper, we indicate the crucial property used to construct the Schlesinger deformations considered in Refs. 3, 4. Let Y_k denote the subset of $\mathbf{P}^1\times\mathcal{R}(Z^n)$, given by

$$Y_k=\{(x,t)|x=a_k(t)\}.$$

Let

$$Y_\infty=\{(\infty,t)|t\in\mathcal{R}(Z^n)\},$$

and

$$Y=Y_\infty\cup Y_1\cup Y_2\cup\ldots\cup Y_n. \tag{1.1}$$

Then the property that is exploited in Ref. 3 to construct the Schlesinger deformations, is that for any choice of $t_0\in\mathcal{R}(Z^n)$, the injection

$$\mathbf{P}^1\backslash\{a_1^0,a_2^0,\ldots a_n^0,\infty\}\ni x\rightarrow(x,t^0)\in\mathbf{P}^1\times\mathcal{R}(Z^n)\backslash Y$$

induces an isomorphism of fundamental groups (where $a_j^0=a_j(t^0)$ is the jth coordinate of the projection). Using the correspondence between flat connections and representations of the fundamental group from Ref. 7, this allows one to prolong the original connection from $\mathbf{P}^1\backslash\{a_1^0,a_2^0,\ldots,a_n^0,\infty\}$ to $\mathbf{P}^1\times\mathcal{R}(Z^n)\backslash Y$ in a holonomy preserving fashion. The crux of the existence proof for the Schlesinger deformations is then to extend this connection to a neighborhood of Y so that it has *logarithmic poles* along Y. In Ref. 3 (and by a similar construction in Ref. 4) this is accomplished by exhibiting local deformations in a neighborhood of each Y_k and then proving that these can be fit together to provide a solution to the deformation problem if and only if a certain Fredholm integral equation has a solution. We will consider a related construction later on in this paper.

Some further analysis then leads to the existence of a holomorphic function τ defined on $\mathcal{R}(Z^n)$ whose 0 set is an exceptional set for the solution of the original deformation problem. In this paper we wish to use similar constructions to examine a somewhat different class of deformations. Our goal will be to show that the τ function introduced by Jimbo, Miwa, and Ueno[8] in a study of such deformations has a similar property. Namely, that the zeros of these tau functions are exceptional sets for the solution of a deformation problem.

B. Birkhoff deformations

The deformations we wish to consider are associated with Birkhoff's generalization of the Riemann–Hilbert problem.[9] To understand what is involved, it is useful to review the analysis of solutions to linear differential equations,

$$\frac{d\psi}{dx}=A(x)\psi,$$

with a rational matrix-valued coefficient $A(x)$ in a neighborhood of an irregular singular point. A helpful modern review of this subject can be found in Ref. 10. Suppose that $x=a$ is a pole of $A(x)$ of order $r+1$; then we have

$$A(x)=A_r(x-a)^{-r-1}+A_{r-1}(x-a)^{-r}+\cdots.$$

The integer r is called the rank of the singularity and for the moment we will confine our attention to the case $r\geqslant 1$. The theory of *formal* solutions to (1.0) is much simplified by one further assumption that we will make from now on. We require the following.

Standing Assumption (1.2). The coefficient, A_r, of the leading singularity in the Laurent expansion of $A(x)$ at $x=a$ has distinct eigenvalues.

This assumption, of course, guarantees that A_r can be diagonalized by a nonsingular matrix G,

$$G^{-1}A_rG=\Lambda_r,$$

where Λ_r is a diagonal matrix with distinct complex entries. In such circumstances (1.0) has a unique *formal* fundamental solution,

$$\hat{\Psi}(x,t)=G\hat{\alpha}(x)e^{H(x)},$$

where $\hat{\alpha}(x)$ is an $n\times n$ matrix-valued formal power series,

$$\hat{\alpha}(x)=I+\beta_1(x-a)^1+\beta_2(x-a)^2+\cdots$$

and

$$H(x)=\Lambda_r\frac{(x-a)^{-r}}{-r}+\Lambda_{r-1}\frac{(x-a)^{-r+1}}{-r+1}\cdots+\Lambda_1\frac{(x-a)^{-1}}{-1}+\Lambda_0\log(x-a),$$

where all the matrices Λ_k are diagonal with diagonal entries,

$$\Lambda_{k,j}:=(\Lambda_k)_{jj}.$$

The construction of this formal solution hinges on the inversion of $\mathrm{ad}(A_r)$ acting on the off-diagonal matrices. Since the eigenvalues of $\mathrm{ad}(A_r)$ acting on the off-diagonal matrices are differences of distinct eigenvalues for A_r, our standing assumption guarantees that this can be done. It is quite typical that the series for $\hat{\alpha}$ does not converge and this leads to some complication in making a connection between the formal solution to (1.0) and genuine solutions to this equation. Before we turn to this matter we mention a slightly different way of looking at this result that will make it simpler for the reader to connect this way of thinking with the developments in Refs. 3, 4, and 10.

Now write $\partial=\partial/\partial x$ and $\overline{\partial}=\partial/\partial\overline{x}$ and instead of the differential equation (1.0) one regards the connection

$$dx\otimes(\partial-A(x))+d\overline{x}\otimes\overline{\partial}, \tag{1.3}$$

on the trivial bundle

$$\mathbf{P}^1\times\mathbf{C}^p\rightarrow\mathbf{P}^1,$$

as the fundamental object. If $\{a_1,a_2,\dots,a_n\}$ is the set of poles for $A(x)$, then flat sections, ψ, for (1.3) defined locally in $\mathbf{P}^1\backslash\{a_1,a_2,\dots,a_n\}$ are solutions to the differential equation (1.0).

Gauge transformations (e.g., multiplication by smooth invertible matrix-valued functions of x) which are holomorphic (or meromorphic) in x do not change the $d\overline{x}\otimes\overline{\partial}$ part of the connection (at least away from the singularities) and the solution of the differential equation (1.0) is effectively accomplished by gauging $\partial - A(x)$ into diagonal form by such a gauge transformation. The formal gauge substitution,

$$\psi \leftarrow G\hat{\alpha}\psi,$$

can then be seen to reduce the connection (1.3) to the diagonal form

$$dx\otimes(\partial - h(x)) + d\overline{x}\otimes\overline{\partial},$$

where $h(x) := dH/dx$. A fundamental solution to the differential equation

$$(\partial - h(x))\psi = 0, \tag{1.4}$$

is given by

$$\Psi = e^{H(x)},$$

which is well defined modulo the possible appearance of a multivalued log term in $H(x)$. This accounts for the structure of the formal fundamental solution above but the relation between this formal solution and a genuine fundamental solution is complicated by Stokes' phenomena, which we will now describe.

We first adopt some notation and definitions from Ref. 10. Σ will denote a sector with a vertex at the origin, consisting of points $re^{i\theta}$ with $r>0$ and argument $\theta\in(a,b)$ with $0\leqslant a<b<2\pi$. For $\delta>0$, we write Σ_δ for the subset of Σ with $r<\delta$. If Σ and Σ' are two sectors we write $\Sigma'\subset\subset\Sigma$ if the bounding rays for Σ' are contained in Σ. An open set $\Omega\subset\Sigma$ is said to be asymptotic to the sector Σ, if for each $\Sigma'\subset\subset\Sigma$ we have $\Sigma'_\delta\subset\Omega$ for all sufficiently small δ. We introduce $\mathcal{A}(\Sigma)$, the complex algebra of germs of analytic functions defined on open sets asymptotic to Σ consisting of functions that are asymptotic to a formal meromorphic series. The asymptotic condition on $f\in\mathcal{A}(\Sigma)$ is understood to mean that there exists a formal series,

$$\hat{f}(x) \sim \sum_{k\geqslant m} f_k x^k,$$

with $m>-\infty$, so that for any $\Sigma'\subset\subset\Sigma$ and any integer M one has

$$f(x) = \sum_{k\geqslant m}^{M} f_k x^k + \mathcal{O}(|x|^{M+1}), \quad \text{as} \quad x\rightarrow 0 \quad \text{in} \quad \Sigma'.$$

The basic local existence result for solutions of (1.0) near a pole $x=a$ of $A(x)$ (and we take $a=0$ for convenience) with leading singularity diagonalized by G is that if a sector Σ is chosen appropriately, there is a function (or germ) $\alpha_\Sigma\in\mathcal{A}(\Sigma)$ that is asymptotic to $\hat{\alpha}$ with the property that the gauge transformation by $\alpha_\Sigma^{-1}G^{-1}$ reduces the differential equation (1.0) to the diagonal form (1.4) in an open set Ω asymptotic to Σ. For simplicity in the following local analysis, we will suppose that a trivialization has been chosen so that $G=I$. To describe the nonuniqueness for α_Σ, upon which the Stokes' phenomena hinges, we introduce

$$\alpha_{\Sigma,k} = k\text{th column of } \alpha_\Sigma,$$

and

$$H_k(x) = k\text{th diagonal entry of } H(x).$$

Another way to state the existence result mentioned above is that the n vector-valued functions,

$$\psi_k(x) = \alpha_{\Sigma,k}(x) e^{H_k(x)},$$

are independent solutions to (1.0) in some open set Ω asymptotic to the sector Σ. Because the functions $\alpha_{\Sigma,k}(x)$ are asymptotic to the power series, the ''growth'' of the functions $\psi_k(x)$ as $x \to 0$ is controlled by the exponential factors $e^{H_k(x)}$, which have absolute value $e^{\Re H_k(x)}$ (where $\Re x =$ real part of x). Now let

$$\Delta H_{jk}(x) = \Re(H_j(x) - H_k(x)).$$

The curves along which

$$\Delta H_{jk}(x) = 0, \tag{1.5}$$

play an important role in understanding the relationship between formal solutions and analytic solutions near the singularity at $x=0$. To get an idea of what such curves look like near 0, it is enough to consider the leading-order equivalent of (1.5). This is

$$\Re(\Lambda_{r,j} - \Lambda_{r,k}) x^{-r} = 0. \tag{1.6}$$

Since each difference $\Lambda_{r,j} - \Lambda_{r,k} \neq 0$, it follows that there are $2r$ rays emanating from 0 that satisfy (1.6), given by

$$\arg x = \frac{1}{r}\left(\arg(\Lambda_{r,j} - \Lambda_{r,k}) + \left(n + \frac{1}{2}\right)\pi\right), \quad \text{for } n = 0,...,2r-1.$$

These rays are called Stokes lines. Near $x=0$ the family of solutions to (1.5) consists of $2r$ curves, each asymptotic to one of the Stokes lines (1.6). The property of the Stokes lines that will be important for us is that any open sector that contains one of the Stokes lines (1.6) will contain points with $\Delta H_{jk} < 0$ and also points with $\Delta H_{jk} > 0$.

Now suppose that one crosses such a Stokes line going from $\Delta H_{jk} < 0$ to $\Delta H_{jk} > 0$. One moves from a region in which $\psi_k(x)$ dominates $\psi_j(x)$ as $x \to 0$ to a region in which this dominance relation is reversed. For the purpose of illustration assume that $\Delta H_{jk}(x) < 0$ for x in some truncation Σ_δ of Σ. Then for any constant c, one finds

$$\psi_k + c\psi_j = (\alpha_{\Sigma,k} + c\alpha_{\Sigma,j} e^{H_j - H_k}) e^{H_k},$$

and because $e^{H_j - H_k}$ is exponentially small in Σ_δ, it follows that

$$\alpha_{\Sigma,k} + c\alpha_{\Sigma,j} e^{H_j - H_k} \sim \hat{\alpha}_k,$$

where $\hat{\alpha}_k$ is the kth column of the formal series $\hat{\alpha}$. Thus, the less dominant solution ψ_j may be freely mixed in with ψ_k without affecting the asymptotics of $\alpha_{\Sigma,k}$. In this way one sees that genuine solutions with a given exponential behavior are not uniquely determined by the asymptotics of their ''power series component.'' One obvious way to ''cure'' this particular nonuniqueness would be to include a Stokes line from the family $\Delta H_{jk} = 0$ in the sector Σ. The exchange of dominance across the line makes it impossible to alter ψ_k by adding in multiples of ψ_j without changing the asymptotics of $\alpha_{\Sigma,k}$, and *vice versa*. In fact, if one includes *exactly one Stokes line from each of the families (1.6) for* $j<k$, then a simple argument[11] shows that a genuine fundamental solution,

$$\Psi = \alpha_\Sigma e^H,$$

in Σ_δ, is uniquely determined by the condition that the asymptotic expansion of α_Σ is given by $\hat{\alpha}$. What is more, there is also an existence result for such sectors that can be proved using a variant of the usual integral equation technique but employing different contours for the each of the matrix elements in the solution (see the references in Ref. 12). Following Ref. 13 we call such sectors *good sectors*. It is not hard to see that a punctured neighborhood of 0 can be covered by $2r$ (truncated) good sectors $\Sigma_{i,\delta}$ that we will take to be arranged in counterclockwise order, starting with $\Sigma_{1,\delta}$. Because each good sector contains exactly one Stokes line from each family (1.5), it follows that the intersections $\Sigma_{i,\delta}\cap\Sigma_{i+1,\delta}$ do not contain any Stokes lines. On this overlap the two local fundamental solutions $\alpha_{\Sigma_i}e^H$ and $\alpha_{\Sigma_{i+1}}e^H$ of (1.0) necessarily differ by a constant invertible $p\times p$ matrix $S_{i,i+1}$,

$$\alpha_{\Sigma_{i+1}}e^H=\alpha_{\Sigma_i}e^H S_{i,i+1}. \tag{1.7}$$

The matrices $S_{i,i+1}$ are called Stokes multipliers and must satisfy a triangularity property that we will now explain. Since $\Sigma_{i,\delta}\cap\Sigma_{i+1,\delta}$ does not contain any Stokes lines, it follows that for each fixed choice of (j,k) the quantity ΔH_{jk} is either always positive or always negative in $\Sigma_{i,\delta}\cap\Sigma_{i+1,\delta}$ (at least if δ is small enough so that the Stokes lines are good ''stand ins'' for the curves $\Delta H_{jk}=0$). Thus there is a fixed dominance ordering,

$$\Re\Lambda_{r,i_1}x^{-r}>\Re\Lambda_{r,i_2}x^{-r}>\cdots>\Re\Lambda_{r,i_n}x^{-r},$$

for $x\in\Sigma_{i,\delta}\cap\Sigma_{i+1,\delta}$, and some permutation $(i_1,i_2,\ldots,i_n)$ of 1,2,....,n. If we write (1.7) in matrix form relative to the ordered basis $\{e_{i_1},e_{i_2},\ldots,e_{i_n}\}$, then the matrix of $S_{i,i+1}$ relative to this ordered basis must be lower triangular with 1's on the diagonal in order that $S_{i,i+1}$ should only alter α_{Σ_i} by exponentially small terms. Another (basis-independent) version of the same observation is that

$$e^H S_{i,i+1}e^{-H}=I+O(|x|^N),\quad \text{for } x\to 0 \quad \text{in} \quad \Sigma_{i,\delta}\cap\Sigma_{i+1,\delta},$$

for some $\epsilon>0$ and all positive integers N. The relation (1.7) allows us to construct a fundamental solution Ψ to (1.0) in a neighborhood of $x=a$ by analytically continuing the fundamental solution $\alpha_{\Sigma_1}e^H$ from $\Sigma_{1,\delta}$ to $\Sigma_{2,\delta}$ to $\Sigma_{3,\delta}$ and etc. The result is

$$\Psi(x)=\begin{cases}\alpha_{\Sigma_1}(x)e^{H(x)}, & \text{for } x\in\Sigma_{1,\delta},\\ \alpha_{\Sigma_2}(x)e^{H(x)}S_{1,2}^{-1}, & \text{for } x\in\Sigma_{2,\delta},\\ \cdots, & \\ \alpha_{\Sigma_{2r}}(x)e^{H(x)}S_{1,2r}^{-1}, & \text{for } x\in\Sigma_{2r,\delta},\end{cases} \tag{1.8}$$

where we have written

$$S_{1,k}=S_{1,2}S_{2,3}\cdots S_{k-1,k},$$

and it is understood that the logarithmic term in $H(x)$ is analytically continued from Σ_1 to Σ_2 to $\cdots$ to Σ_{2r}. If we write $S_{2r,1}$ for the Stokes multiplier connecting Σ_{2r} with Σ_1 then it is not hard to see that the analytic continuation of $\alpha_{\Sigma_1}(x)e^{H(x)}$ around $x=a$ comes back to its original value multiplied on the right by

$$e^{H(e^{2\pi i}x)-H(x)}(S_{1,2r}S_{2r,1})^{-1}=e^{2\pi i\Lambda_0}(S_{1,2r}S_{2r,1})^{-1}. \tag{1.9}$$

The matrix (1.9) is thus the local monodromy for the fundamental solution (1.8). We will refer to the *exponent of formal monodromy* Λ_0, together with the Stokes multipliers $S_{i,i+1}$ as the generalized monodromy data for (1.0) at $x=a$. Roughly speaking the deformations of (1.0) we are interested in are those that fix the local generalized monodromy data at each of the singularities for (1.0) and fix the global monodromy for (1.0) but permit the formal expansion coefficients $\{\Lambda_r,\Lambda_{r-1},\ldots,\Lambda_1\}$ at each singularity to vary. The global monodromy is precisely the representation of the fundamental group described earlier and we will say more about this later on, following the presentation in Malgrange[3] and Helmink.[4] Generalizations of the Schlesinger deformations in which the location of the poles are varied are also quite interesting; however, the issues we wish to pursue have already been treated for these deformations in Refs. 3 and 4, and so for the moment we confine our attention to deformations of the local exponents $\{\Lambda_r,\Lambda_{r-1},\ldots,\Lambda_1\}$. Our strategy in studying these deformations will follow closely the developments in Ref. 14. In fact, in Ref. 14 Malgrange already proves existence results for such deformations in the irregular singular case. However, we did not understand how to make use of his results to establish the connection with the JMU tau function that is the principal object in this paper. Instead, we will adapt an integral equation technique from Flaschka and Newell[15] to produce local models for the desired deformation at each of the poles. These local deformations are then fit together by solving the same Toeplitz integral equations that one finds in Ref. 3. The tau function is introduced by identifying its log derivative as the connection one-form for a flat connection on an appropriate determinant bundle. A computation shows that this connection one-form differs from the JMU connection one-form by a regular term, and so the tau function we have introduced and the JMU tau functions have the same 0 set. We show that this 0 set is precisely the exceptional set for the existence of the deformations we are considering.

C. Local analysis and Stokes multipliers

It will be useful at this point to be a little more precise about the nature of the generalized local monodromy data that is to be ''fixed'' under the deformations that are of interest to us. These deformations concern the local model for our connections. Suppose that one starts with a holomorphic connection $\bar{\boldsymbol{\nabla}}^0$ defined on a trivial bundle over a punctured neighborhood of the point $a\in\mathbf{P}^1$ with a singularity of type r at a (*note*: we will put a bar over connections defined on subsets of $\mathbf{P}^1$ to distinguish them from the connections in many variables that will soon appear as deformations). Suppose that the connection satisfies our standing assumption and that the trivialization is chosen so that the leading singularity in the one-form for $\bar{\boldsymbol{\nabla}}^0$ has a diagonal matrix coefficient. Then $\bar{\boldsymbol{\nabla}}^0$ is formally gauge equivalent to the diagonal form,

$$d_x - d_x\mathbf{H}_0 - \Lambda_0\frac{dx}{x-a}, \tag{1.10}$$

where

$$\mathbf{H}_0=\sum_{j=1}^{r}\frac{\Lambda_j^0}{-j}(x-a)^{-j}, \tag{1.11}$$

where Λ_j^0 and Λ_0 are diagonal matrices. More precisely there is a formal gauge transformation,

$$\hat{\alpha}^0(x)=I+\beta_1^0(x-a)+\beta_2^0(x-a)^2+\cdots,$$

so that

$$\bar{\boldsymbol{\nabla}}^0=\hat{\alpha}^0\cdot\left[d_x-d_x\mathbf{H}_0-\Lambda_0\frac{dx}{x-a}\right],$$

where $\hat{\alpha}\cdot[X]=\hat{\alpha}[X]\hat{\alpha}^{-1}$. Note that it is actually the inverse of $\hat{\alpha}^0$ that reduces $\bar{\boldsymbol{\nabla}}^0$ to diagonal form. This is just how things work out if the relationship between $\hat{\alpha}^0$ and a fundamental solution to $\bar{\boldsymbol{\nabla}}^0$ is given along the lines explained above.

The local analytic equivalence class of $\bar{\boldsymbol{\nabla}}^0$ is determined by further data, which can be specified by choosing a covering of the punctured neighborhood of a by good sectors, $\Sigma_1,\Sigma_2,\ldots,\Sigma_{2r}$ (to somewhat unburden the notation we will write Σ_k for the truncated sector $\Sigma_{k,\delta}$ when the precise value of δ is not an issue). For simplicity in the following discussion we will always suppose that such a covering is obtained by first choosing a good sector Σ_1. The other sectors Σ_j are obtained from Σ_1 by rotating counterclockwise by $j\pi/r$ radians. The Stokes multipliers $S_{j,j+1}$ that connect local fundamental solutions with fixed asymptotics in the sectors Σ_j and Σ_{j+1} (with $\Sigma_{2r+1}=\Sigma_1$) then determine the local holomorphic equivalence class of $\bar{\nabla}^0$. The deformations we wish to focus on allow the local model

$$\bar{\nabla}_\Lambda := d_x - d_x\mathbf{H} - \Lambda_0 \frac{dx}{x-a}, \tag{1.12}$$

with

$$\mathbf{H} = \sum_{j=1}^{r} \frac{\Lambda_j}{-j}(x-a)^{-j}, \tag{1.13}$$

to vary in the sense that the diagonal coefficient matrices $\Lambda_r, \Lambda_{r-1}, \ldots, \Lambda_1$ vary in a neighborhood of $\Lambda_r^0, \Lambda_{r-1}^0, \ldots, \Lambda_1^0$ with Λ_r maintaining distinct eigenvalues and Λ_0 held fixed. In what follows Λ_0 will always denote a fixed diagonal $p\times p$ matrix.

The Stokes multipliers are to remain fixed under our deformations. However, since the Stokes multipliers are significant relative to some choice of a covering by good sectors $\{\Sigma_1, \Sigma_2, \ldots, \Sigma_{2r}\}$ we must either fix this covering for all values of the deformation parameters (this is what is done in Refs. 11 and 8) or say how the choice of covering affects the notion of ''fixed'' Stokes multipliers. We follow Malgrange in adopting the second alternative. The choice of a good sector Σ_1 is nearly equivalent to the selection of a suitable collection of ''consecutive'' Stokes lines [one from each of the families (1.6)]. Once one has selected such a collection of Stokes lines any open sector that contains these Stokes lines could serve as a good sector. However, we wish to put a further limitation on our good sectors. No Stokes line should lie on the boundary of a good sector. The reason for this is that for a fixed connection, the Stokes multipliers associated with such a good sector are not stable under small rotations of the sector; Stokes lines can rotate in or out of the sector and this changes the associated Stokes multipliers. Another way of saying this is that the local analytic equivalence class associated with a choice of a covering by good sectors and associated Stokes multipliers is not stable under small rotations of the good sectors unless the sectors do not have Stokes lines on their boundary. We will say that a covering $\{\Sigma_1, \Sigma_2, \ldots, \Sigma_{2r}\}$ of a punctured neighborhood of a by good sectors is *stable* if the good sector Σ_1 has no Stokes lines on its boundary.

We now define a configuration space, $\mathcal{C}$, for our local models (1.12):

$$\mathcal{C} := Z^p \times \mathbf{C}^p \times \cdots \times \mathbf{C}^p,$$

where there are $r-1$ factors $\mathbf{C}^p$. The first factor Z^p is, of course, the configuration space for the leading coefficient Λ_r, and the remaining factors $\mathbf{C}^p$ are associated with the Λ_j, $j=r-1,\ldots,1$. Following Malgrange, we now introduce a fiber bundle, $\mathcal{M}\to\mathcal{C}$. The fiber $\mathcal{M}_\Lambda$ over each point $\Lambda := (\Lambda_r, \Lambda_{r-1}, \ldots, \Lambda_1)$ in $\mathcal{C}$ is the moduli space of all holomorphic gauge equivalence classes of locally defined type r connections on the trivial bundle $\{x : |x-a| < \epsilon\} \times \mathbf{C}^p$ (for some $\epsilon > 0$) that are formally equivalent to the connection (1.12)–(1.13). Or put another way, if $\bar{\nabla}_1$ and $\bar{\nabla}_2$ are two type r connections at a and they are formally equivalent to $\bar{\nabla}_\Lambda$ via $\hat{\alpha}_1$ and $\hat{\alpha}_2$, then $\bar{\nabla}_1 \simeq \bar{\nabla}_2$ if $\hat{\alpha}_2^{-1}\hat{\alpha}_1$ is convergent in a neighborhood of a (see Ref. 14). Next, we want to show that

$$\mathcal{M} \xrightarrow{\pi} \mathcal{C}, \tag{1.14}$$

is a fiber bundle with a natural flat connection. This connection will play a role in providing a global significance for monodromy preserving deformations. We first discuss local trivializations for (1.14). Suppose that $\Lambda^0 \in \mathcal{C}$ and write $\bar{\nabla}^0$ for the connection (1.12) associated with Λ^0.

Suppose that $\{\Sigma_1,\Sigma_2,\ldots,\Sigma_{2r}\}$ is a covering of a punctured neighborhood of a by stable good sectors for $\bar{\boldsymbol{\nabla}}^0$. Then we can find a neighborhood U of Λ^0 in $\mathcal{C}$ so that $\{\Sigma_1,\Sigma_2,\ldots,\Sigma_{2r}\}$ is a stable covering at a for all $\bar{\boldsymbol{\nabla}}_\Lambda$ with $\Lambda\in U$ (in fact, it is clear that U can be taken to be of the form $U_r\times\mathbf{C}^p\times\ldots\times\mathbf{C}^p$, where U_r is a sufficiently small neighborhood of Λ_r^0 in Z^p). It is a result of Malgrange and Sibuya,[14,16] that for any $\Lambda\in U$ and suitable choice of Stokes multipliers $S_{j,j+1}$ there exists a type r connection at a with local model $\bar{\boldsymbol{\nabla}}_\Lambda$ and Stokes multipliers $S_{j,j+1}$ relative to the covering $\{\Sigma_1,\Sigma_2,\ldots,\Sigma_{2r}\}$. This connection is not unique but its local holomorphic gauge equivalence class is unique. To be ''suitable'' the Stokes multipliers must be 1 on the diagonal and lower triangular relative to the dominance ordering of $\Re(\Lambda_{r,j}x)$ for $x\in\Sigma_j\cap\Sigma_{j+1}$. This identifies the fiber of $\mathcal{M}$ as $\mathbf{C}^{rp(p-1)}$, since there are $2r$ intersections $\Sigma_j\cap\Sigma_{j+1}$ and $p(p-1)/2$ arbitrary coefficients for each Stokes multiplier. The choice of a neighborhood U and a covering $\{\Sigma_1,\Sigma_2,\ldots,\Sigma_{2r}\}$, which is stable for all $\boldsymbol{\nabla}_\Lambda$ with $\Lambda\in U$, thus produces a trivialization,

$$\pi^{-1}(U)\simeq U\times\mathbf{C}^{rp(p-1)}.$$

Note: The fiber $\mathcal{M}_\Lambda$ is more invariantly defined in Ref. 14, as $H^1(S^1,\mathrm{St}(\bar{\boldsymbol{\nabla}}_\Lambda))$, the first cohomology of the Stokes sheaf associated with the connection $\bar{\boldsymbol{\nabla}}_\Lambda$ (see also Ref. 10).

We will now show that $\mathcal{M}$ is a fiber bundle by determining that the transition maps between trivializations are given by polynomial diffeomorphisms in the fiber. Suppose that U' is a neighborhood in $\mathcal{C}$ with $\{\Sigma_1',\Sigma_2',\ldots,\Sigma_{2r}'\}$ a covering by sectors at a that is stable for all $\bar{\boldsymbol{\nabla}}_\Lambda$ with $\Lambda\in U'$. Now suppose that $\Lambda\in U\cap U'$. Then since $\{\Sigma_1,\Sigma_2,\ldots,\Sigma_{2r}\}$ and $\{\Sigma_1',\Sigma_2',\ldots,\Sigma_{2r}'\}$ are both good stable coverings for $\bar{\boldsymbol{\nabla}}_\Lambda$ it follows that, up to small changes in the opening angle of Σ_1', which do not affect the Stokes multipliers, Σ_1' can be obtained from Σ_1 by rotating Σ_1 counterclockwise through an angle θ. To emphasize this we will write $\Sigma_j'=\Sigma_j^\theta$. Now let $\bar{\boldsymbol{\nabla}}$ denote a connection of type r at a that is formally equivalent to $\bar{\boldsymbol{\nabla}}_\Lambda$ [i.e., $\pi(\bar{\boldsymbol{\nabla}})=\Lambda$]. Suppose $\hat{\alpha}$ is a formal series with

$$\bar{\boldsymbol{\nabla}}=\hat{\alpha}\cdot[\bar{\boldsymbol{\nabla}}_\Lambda],$$

in the sense of formal series at a. Suppose that $\alpha_j^\theta\in\mathcal{A}(\Sigma_j^\theta)$ is asymptotic to $\hat{\alpha}$ and $\bar{\boldsymbol{\nabla}}=\alpha_j^\theta\cdot[\bar{\boldsymbol{\nabla}}_\Lambda]$ analytically in the sector Σ_j^θ. Then the Stokes multipliers $S_{j,j+1}^\theta$ are defined by,

$$\alpha_{j+1}^\theta(x)e^{H_\Lambda(x)}=\alpha_j^\theta(x)e^{H_\Lambda(x)}S_{j,j+1}^\theta, \tag{1.15}$$

where

$$H_\Lambda(x)=\sum_{j=1}^{r}\frac{\Lambda_j}{-j}(x-a)^{-j}+\Lambda_0\log(x-a). \tag{1.16}$$

There is a slight ambiguity in the definition of the Stokes multipliers in (1.15) associated with the choice of $x\to\log(x-a)$ in (1.16). To deal with this ambiguity we require that the data that specifies a local trivialization for $\mathcal{M}\to\mathcal{C}$ includes not only the choice of a stable good covering $\{\Sigma_1,\Sigma_2,\ldots,\Sigma_{2r}\}$ but also a branch of the function $x\to\log(x-a)$ in the sector Σ_1. One may analytically continue this choice from Σ_1 to Σ_2 to Σ_3 and so on to fix a choice of log in (1.16) and render (1.15) an unambiguous defining relation for $S_{j,j+1}^\theta$. In the rank $r=1$ case there are only two sectors Σ_1 and Σ_2 and the intersection $\Sigma_1\cap\Sigma_2$ is disconnected. In this case we suppose that the analytic continuation from Σ_1 to Σ_2 is accomplished so that the function is smooth on counterclockwise oriented circles passing from Σ_1 into Σ_2.

In the special case $\theta=0$ we will simply write $\alpha_j^0=\alpha_j$ and $S_{j,j+1}^0=S_{j,j+1}$.

Now we turn to the proof that $\mathcal{M}\to\mathcal{C}$ is a fiber bundle. As noted above our trivializations depend on a choice of $\log(x-a)$ in Σ_1^θ. However, different choices will simply alter $S_{j,j+1}^\theta$ by conjugation with powers of $\exp(2\pi i\Lambda_0)$. Since this is a linear transformation in the fiber constant in the base, we may as well suppose that this choice of $\log(x-a)$ has been fixed in Σ_1^θ (and Σ_1). The Stokes multipliers (1.15) are thus well defined and the transition map we wish to compute takes $\{S_{j,j+1}\}$ to $\{S_{j,j+1}^\theta\}$. It is enough to compute the transition in the fiber for $0<\theta<\pi/r$ since a larger rotation may be realized as a composition of rotations satisfying this condition. Suppose now that $0<\theta<\pi/r$. Because the rotation θ is smaller than π/r, it follows that $\Sigma_j\cap\Sigma_j^\theta$ is not empty. We may thus compare the local fundamental solutions $\alpha_j e^{H_\Lambda}$ and $\alpha_j^\theta e^{H_\Lambda}$ on this intersection,

$$\alpha_j e^{H_\Lambda}=\alpha_j^\theta e^{H_\Lambda}S_j(\theta), \tag{1.17}$$

where $S_j(\theta)$ is a constant $p\times p$ matrix. Combining (1.16) and (1.17), one finds that

$$S_{j,j+1}^\theta=S_j(\theta)S_{j,j+1}S_{j+1}(\theta)^{-1}. \tag{1.18}$$

Thus, to find $S_{j,j+1}^\theta$ in terms of the Stokes multipliers $\{S_{k,k+1}\}$ it will suffice to determine $S_k(\theta)$ in terms of $\{S_{k,k+1}\}$.

By relabling the eigenvalues, $\Lambda_{r,j}j=1,...,p$, of Λ_r we may suppose that the dominance ordering in $\Sigma_j\cap\Sigma_{j+1}$ is the ‘‘natural’’ one,

$$\Re(\Lambda_{r,1}x)<\Re(\Lambda_{r,2}x)<\cdots<\Re(\Lambda_{r,p}x),$$

for $x\in\Sigma_j\cap\Sigma_{j+1}$. It is not hard to see what happens to this dominance ordering as one rotates $\Sigma_j\cap\Sigma_{j+1}$ counterclockwise. As $\Sigma_j\cap\Sigma_{j+1}$ crosses a ‘‘simple’’ Stokes line, say

$$\Re(\Lambda_{r,1}x)<\Re(\Lambda_{r,2}x)=\Re(\Lambda_{r,3}x)<\Re(\Lambda_{r,3}x),$$

then the dominance ordering permutes 2 and 3 leaving the rest of the indices in sequence. If one crosses a Stokes line with ‘‘higher multiplicity,’’ say

$$\Re(\Lambda_{r,1}x)<\Re(\Lambda_{r,2}x)=\Re(\lambda_{r,3}x)=\Re(\Lambda_{r,4}x)<\Re(\Lambda_{r,5}x),$$

then the (2, 3, 4) part of the ordering is inverted to (4, 3, 2).

For the purpose of illustration suppose that $p=5$ and that in going from $\Sigma_j\cap\Sigma_{j+1}$ to $\Sigma_j^\theta\cap\Sigma_{j+1}^\theta$ one passes through the simple Stokes line $\Re(\Lambda_{r,1}x)=\Re(\Lambda_{r,2}x)$ and the higher multiplicity Stokes line $\Re(\Lambda_{r,3}x)=\Re(\Lambda_{r,4}x)=\Re(\Lambda_{r,5}x)$. Then it is not hard to see that the Stokes multiplier for $\Sigma_j^\theta\cap\Sigma_{j+1}^\theta$ must have the following ‘‘triangularity,’’

$$S_{j,j+1}^\theta=\begin{bmatrix}1&*&0&0&0\\0&1&0&0&0\\ *&*&1&*&*\\ *&*&0&1&*\\ *&*&0&0&1\end{bmatrix}, \tag{1.19}$$

relative to the basis for $\mathbf{C}^5$ in which $S_{j,j+1}$ is lower triangular. The $*$'s represent possibly nonzero entries. Next consider (1.17). Since α_j and α_j^θ have the same asymptotics in the sector $\Sigma_j\cap\Sigma_j^\theta$, it follows that $S_j(\theta)$ must have 1's on the diagonal and cannot have nonzero off-diagonal elements for any of the pairs associated with Stokes lines in the intersection $\Sigma_j\cap\Sigma_j^\theta$. In the example (1.19) this means that the (l,m) matrix elements for $S_j(\theta)$ are zero for

$$(l,m)\in\{(k,1),(k,2),(1,k),(2,k):k=3,4,5\}.$$

Since $\theta < \pi/r$ it follows that $\Sigma_j \cap \Sigma_{j+1}$ is contained in $\Sigma_j \cap \Sigma_j^\theta$ (provided at least one Stokes line is crossed, which is the only interesting case). Thus one can also say of $S_j(\theta)$ that it is lower triangular with respect to the dominance ordering in $\Sigma_j \cap \Sigma_{j+1}$. Thus, for our example, the matrix of $S_j(\theta)$ must have the form

$$S_j(\theta) = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ a & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & b & 1 & 0 \\ 0 & 0 & c & d & 1 \end{bmatrix}. \tag{1.20}$$

In a similar fashion $\Sigma_j^\theta \cap \Sigma_{j+1}^\theta$ is contained in $\Sigma_{j+1} \cap \Sigma_{j+1}^\theta$, and it follows that $S_{j+1}(\theta)$ must be lower triangular with respect to the dominance ordering for $\Sigma_j^\theta \cap \Sigma_{j+1}^\theta$. In our example, if we rewrite (1.17) in the form $S_{j,j+1}^\theta S_{j+1}(\theta) = S_j(\theta) S_{j,j+1}$ and make use of the lower triangularity of the product $S_{j,j+1}^\theta S_{j+1}(\theta)$ with respect to the dominance ordering in $\Sigma_j^\theta \cap \Sigma_{j+1}^\theta$. We find

$$\begin{bmatrix} 1 & * & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ * & * & 1 & * & * \\ * & * & 0 & 1 & * \\ * & * & 0 & 0 & 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ a & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & b & 1 & 0 \\ 0 & 0 & c & d & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ * & 1 & 0 & 0 & 0 \\ * & * & 1 & 0 & 0 \\ * & * & * & 1 & 0 \\ * & * & * & * & 1 \end{bmatrix}. \tag{1.21}$$

The (2,1) matrix element of $S_j(\theta)$ can be determined simply by equating the (2,1) matrix elements on both sides of (1.21). One finds

$$a = S_j(\theta)_{2,1} = -(S_{j,j+1})_{2,1}.$$

The same thing can be done for the matrix elements b and d for $S_j(\theta)$ on the subdiagonal. For example,

$$d = S_j(\theta)_{5,2} = -(S_{j,j+1})_{5,2}.$$

Once one knows the subdiagonal elements one can move out to the diagonal below the subdiagonal. Equating (5,3) matrix elements for (1.21), one finds

$$0 = c + d(S_{j,j+1})_{4,3} + (S_{j,j+1})_{5,3}.$$

From the earlier relation for d one finds that c is a polynomial function of the matrix elements of $S_{j,j+1}$. Thus, the entries of $S_j(\theta)$ are polynomials in the entries for $S_{j,j+1}$ and it is clear that this is true quite generally and does not depend on anything special in our example. From (1.18) it then follows that $S_{j,j+1}^\theta$ is a polynomial in the entries of $S_{j,j+1}$ and $S_{j+1,j+2}$. Since this relation is invertible by construction it follows that the map from $\{S_{k,k+1}\}$ to $\{S_{k,k+1}^\theta\}$ is a polynomial diffeomorphism on $\mathbf{C}^{rp(p-1)}$.

We have seen that π: $\mathcal{M} \to \mathcal{C}$ is a fiber bundle and that there is a natural family of trivializations for this bundle that are related by polynomial diffeomorphisms in the fiber that are constant in the base. Recall that the vertical vectors in the tangent space to $\mathcal{M}$ at $p, T_p(\mathcal{M})$, are those killed by $d\pi_p$. A connection on $\mathcal{M}$ is determined by a one-form ω on $\mathcal{M}$ whose value $\omega_p(v)$ at a vector $v \in T_p(\mathcal{M})$ is a vertical vector in $T_p(\mathcal{M})$ at p; ω must have the further property that $\omega_p(v) = v$ if v is a vertical vector in $T_p(\mathcal{M})$. Our trivializations single out a flat connection on $\mathcal{M}$. If $\pi^{-1}(U)$ has trivialization $U \times \mathbf{C}^N$ and $f_1, f_2, \ldots, f_N$ are the natural coordinate functions on $\mathbf{C}^N$ then it is easy to see that

$$\omega = \sum_{k=1}^{N} \frac{\partial}{\partial f_k} df_k$$

defines a connection one-form independent of the choice of trivialization (among the special class of trivializations that we have been considering for $\mathcal{M}$ in which the fiber coordinates transform among themselves). The curve $\hat{\gamma}(t)$ in $\mathcal{M}$ is the horizontal lift of $\gamma(t) = \pi\hat{\gamma}(t)$ provided that $\omega(\hat{\gamma}'(t)) = 0$. Relative to one of our distinguished trivializations this translates into

$$\hat{\gamma}(t) = (\gamma(t), f),$$

where $f \in \mathbf{C}^N$ is constant in t. The curvature of this connection is clearly 0 and locally parallel sections look like

$$\sigma(x) = (x, f),$$

where f is independent of x. Now let $\mathcal{R}(\mathcal{C})$ denote the simply connected covering space of $\mathcal{C}$. As was the case for $\mathcal{R}(Z^n)$ above it will be convenient to introduce special notation for projection from $\mathcal{R}(\mathcal{C})$ to $\mathcal{C}$. We will write $\lambda \in \mathcal{R}(\mathcal{C})$ and $\Lambda(\lambda) \in \mathcal{C}$ for the projection of λ onto $\mathcal{C}$.

The bundle $\mathcal{M}$ over $\mathcal{C}$ with flat connection ω pulls back to a bundle over $\mathcal{R}(\mathcal{C})$ (which we will continue to denote by $\mathcal{M}$) with a flat connection (which we will continue to denote by ω). Because $\mathcal{R}(\mathcal{C})$ is simply connected, the bundle

$$\mathcal{M} \to \mathcal{R}(\mathcal{C})$$

has globally defined parallel sections. The existence of these global sections, which are the analogs of the local notion of ''constant Stokes multipliers'' in $\mathcal{C}$ is the reason for working here in $\mathcal{R}(\mathcal{C})$ instead of just locally in $\mathcal{C}$ (*note*: the theory of local systems explained in Ref. 10 also applies to $\mathcal{M}$ and could be used to bypass the introduction of a connection in the fiber bundle $\mathcal{M}$).

D. Local models for integrable deformations

Before we state our global result for $\mathcal{R}(\mathcal{C})$ deformations we introduce some notation from Ref. 14 concerning connections in several complex variables. Suppose that X is a complex analytic variety of dimension n, Y is a smooth hypersurface in X, E is a rank p complex vector bundle over X, $\boldsymbol{\nabla}$ is a holomorphic connection on $X \backslash Y$, and Ω is the one form for $\boldsymbol{\nabla}$ in a local frame for E.

Definition 1.22: For $r \geqslant 0$ an integer one says that $\boldsymbol{\nabla}$ is of type r along Y, if in a system of local coordinates $x_1, x_2, \ldots, x_n$ for X with Y locally defined by $x_1 = 0$ one has

$$\Omega = \sum_{j=1}^{n} M_j \, dx_j,$$

where M_1 has a pole of order $r+1$ in x_1, M_j for $j \geqslant 2$ has a pole of order r in x_1, and M_j is holomorphic in $x_2, x_3, \ldots, x_n$ for all j.

Suppose that

$$M_1 = \sum_{-r-1}^{\infty} M_{1,k} x_1^k.$$

Our standing assumption (1.2) for type $r \geqslant 1$ connections, translates into this situation as the assumption that $M_{1,-r-1}(x_2, x_3, \ldots, x_n)$ has distinct eigenvalues. We will refer to such connections as *simple* type r connections along Y. When $r = 0$ we will say that a type 0 connection is *simple* if $M_{1,-1}(x_2, x_3, \ldots, x_n)$ has distinct eigenvalues, which, in addition, *do not differ by integers*. Malgrange has shown how to develop the theory of Schlesinger deformations without this assumption, but it will be convenient for us to insist on it so that we may work with regular and irregular singular points in parallel. Propositions 1.23a and 1.23b below are the principal reason that this is possible and will permit us to present the ''unified'' formula for $d \log \tau$, which can be found in Ref. 8.

We recall some results of Malgrange for simple *integrable* type r connections. Suppose that one has a simple integrable type r connection ∇ along Y and that, as above, Y is locally defined by $x_1=0$. Let $y=(x_2,x_3,\ldots,x_n)$ denote the local coordinates on Y. Then one has the following local version of Proposition 1.3 in Ref. 14.

Proposition 1.23a: Suppose that (E,∇*) is a vector bundle with a simple integrable connection* ∇ *of type* $r\geqslant 1$ *along Y. There exists a local trivialization in a neighborhood of* $x=0$ *so that* $M_{1,-r-1}$ *is diagonal in this trivialization. Let* Ω *denote the connection form for* ∇ *in this trivialization. Then in a sufficiently small neighborhood* $|y|<\epsilon$ *there exists a formal power series* $\hat{\alpha}$ *in* x_1,

$$\hat{\alpha}(x)=I+\beta_1(y)x_1+\beta_2(y)x_1^2+\cdots,$$

with matrix coefficients $\beta_j(y)$, *which are holomorphic in y for* $|y|<\epsilon$, *with the property that*

$$\hat{\alpha}\cdot[\nabla_\Lambda]=d+\Omega,$$

where $\hat{\alpha}\cdot[\nabla_\Lambda]=\hat{\alpha}\,\nabla_\Lambda\hat{\alpha}^{-1}$ *is the formal gauge transformation by* $\hat{\alpha}$,

$$\nabla_\Lambda=d-d(\mathbf{H})-\Lambda_0\frac{dx_1}{x_1},$$

d is the exterior derivative in the x variables, Λ_0 *is a constant diagonal matrix,*

$$\mathbf{H}=\sum_{j=1}^{r}\Lambda_j(y)\frac{x_1^{-j}}{-j},$$

with $\Lambda_j(y)$ *a diagonal matrix with entries that are holomorphic functions of y, and* $\Lambda_r(y)$ *a diagonal matrix with distinct entries [note: in the statement of this Proposition* Λ *does not denote the projection* $\mathcal{R}(\mathcal{C})\rightarrow\mathcal{C}$ *described above].*

There is an analog of this result for simple type 0 connections, which is the principal reason we work with such connections.

Proposition 1.23b: Suppose that (E,∇*) is a vector bundle with a simple integrable type 0 connection* ∇ *along Y. There exists a local trivialization near* $x=0$ *so that* $M_{1,-1}$ *is diagonal. Let* Ω *denote the one form for* ∇ *in this trivialization. Then in a sufficiently small neighborhood of* $x=0$ *there exists a* $\mathrm{GL}(p,C)$*-valued holomorphic function,*

$$\alpha(x)=I+\beta_1(y)x_1+\beta_2(y)x_1^2+\cdots,$$

so that

$$\alpha\left(d-\frac{\Lambda_0}{x_1}dx_1\right)\alpha^{-1}=d+\Omega,$$

where Λ_0 *is a diagonal matrix that is independent of x.*

Remark: The conclusion of this theorem is simply that the connection ∇ is given by $d-(\Lambda_0/x_1)dx_1$ in a suitable local trivialization. The analogy with Proposition 1.23a is not so apparent in this formulation, however.

Proof (of Proposition 1.23b): Let $\Omega=\Sigma_{j=1}^{n}M_j\,dx_j$ denote the connection one-form for ∇ relative to some trivialization in a neighborhood of $x=0$. Suppose $M_{1,-1}(y)$ is the residue of M_1

at $x_1=0$. Then the matrix $M_{1,-1}(0)$ has distinct eigenvalues, and this remains true for $M_{1,-1}(y)$ for x in a sufficiently small neighborhood of 0. Because its eigenvalues are distinct one may diagonalize $M_{1,-1}(y)$ by a holomorphic similarity transformation,

$$Q(y)M_{1,-1}(y)Q(y)^{-1}=\Lambda_0(y),$$

where $Q(y)$ is holomorphic and $\Lambda_0(y)$ is diagonal. Making a gauge transformation by Q, one finds that the connection ∇ becomes

$$d-\frac{\Lambda_0(y)}{x_1}dx_1-\sum_{j=1}^{n} B^j(x)dx_j,$$

where the $B^j(x)$ is holomorphic in x. By assumption, the eigenvalues of $\Lambda_0(0)$ do not differ by integers and so the same is true for $\Lambda_0(y)$ if y remains in a sufficiently small neighborhood of 0. Now let $z=x_1$ and consider the connection

$$d_z-\frac{\Lambda_0(y)}{z}dz-B^1(z,y)dz,$$

depending on the parameter y. Since the eigenvalues of $\Lambda_0(y)$ are distinct and do not differ by integers, the standard construction of a fundamental solution [which depends on the inversion of $\mathrm{ad}(\Lambda_0)-nI$ where $n=1,2,...,$ is an integer] shows that one can find a gauge transformation $\beta(z,y)=I+O(z)$, which depends holomorphically on the parameters y and that transforms this connection to

$$d_z-\frac{\Lambda_0(y)}{z}dz.$$

The gauge transformation of the complete connection by this transform gives one

$$d-\frac{\Lambda_0(y)}{z}dz-\sum_{j=1}^{n-1} B^{j+1}(z,y)dy_j, \tag{1.23}$$

where $y_j=x_{j+1}$. Now we express the integrability of this connection $(d\Omega+\Omega\wedge\Omega=0)$ expanding $B^k(z,y)$ in powers of z,

$$B^k(z,y)=\sum_{j=0}^{\infty} B_j^k(y)z^j.$$

Equating the coefficients of z^{-1} in the integrability condition, we find that

$$\frac{\partial\Lambda_0(y)}{\partial y_j}=[B_0^j,\Lambda_0].$$

Since Λ_0 is diagonal the right-hand side vanishes on the diagonal and this shows that $\Lambda_0(y)=\Lambda_0=\text{const}$. The left-hand side vanishes off the diagonal and since the entries of Λ_0 are distinct this implies that B_0^j must be diagonal. Equating the coefficients of $z^j dz\wedge dy_j$ in the integrability condition, one finds

$$nB_n^j=[\Lambda_0,B_n^j], \quad \text{for } n=1,2...,$$

which implies that $B_n^j=0$ for $n=1,2,...$. Thus, the connection ∇ has the form

$$d_z - \frac{\Lambda_0}{z}dz + d_y - \sum_{j=1}^{n-1} B_0^{j+1}(y)dy_j .$$

The connection

$$d_y - \sum_{j=1}^{n-1} B_0^{j+1}(y)dy_j$$

is integrable and so a gauge transformation, $\gamma(y)$, in the y variables reduces this connection to d_y. Since $B_0^{j+1}(y)$ is diagonal this gauge transformation may be chosen to be diagonal and also may be chosen so that $\gamma(y)=I+O(y)$. Since γ is diagonal, it does not alter the dz part of the connection. Composing β and γ we get a gauge transformation $\alpha=I+O(z)$, which reduces (1.23) to

$$d - \frac{\Lambda_0}{z}dz,$$

and this finishes the proof. QED

Although we do not require the result until the next section it will be convenient here to recall Theorem 2.1 from Ref. 14. Suppose that $(E,\boldsymbol{\nabla})$ is a vector bundle with a connection $\boldsymbol{\nabla}$ that has a simple type r pole along the hypersurface Y defined by $x_1=0$. Let $y=(x_2,\ldots,x_n)$ denote the coordinates along Y. Suppose that in a neighborhood of a point $x^0\in Y$, with coordinates $x_1=0$ and $y=0$, and relative to some local trivialization of the bundle one has a formal isomorphism,

$$\boldsymbol{\nabla} = \hat{\alpha}\cdot[\boldsymbol{\nabla}_\Lambda],$$

where $\boldsymbol{\nabla}_\Lambda$ is the diagonal connection described in Proposition 1.23a and $\hat{\alpha}$ is the formal power series described in that same proposition. Suppose that Σ is a good stable sector (in the x_1 variable) for the connection $\boldsymbol{\nabla}$ restricted to $y=0$. Suppose that $\epsilon>0$ is chosen small enough so that for all y_1 with $|y_1|<\epsilon$, the sector Σ remains a good stable sector for the restriction of $\boldsymbol{\nabla}$ to $y=y_1$.

Then one has (Theorem 2.1 in Ref. 14).

Proposition 1.23c: There exists a uniquely determined invertible holomorphic map $\alpha_\Sigma \in \mathcal{A}(\Sigma_\epsilon\times|y|<\epsilon)$ *such that on* $\Sigma_\epsilon\times|y|<\epsilon$ *and in an appropriate trivialization for E, one has*

$$\boldsymbol{\nabla} = \alpha_\Sigma\cdot[\boldsymbol{\nabla}_\Lambda],$$

and such that the map α_Σ *extends* $\hat{\alpha}$ *in the sense that* α_Σ *has an asymptotic development along Y, which is equal to* $\hat{\alpha}$.

Remark: The consequence of this result that is of interest for us is that the formal isomorphism class $\boldsymbol{\nabla}_\Lambda$ together with the Stokes multipliers determine the local holomorphic equivalence class of a simple, integrable, type r connection. Two collections, α_{Σ_k} and α'_{Σ_k}, associated with the same good stable cover $\{\Sigma_1,\ldots,\Sigma_{2r}\}$ with the same Stokes multipliers, and the same asymptotics $\hat{\alpha}$ clearly differ by an invertible holomorphic map.

We are now prepared to state an existence result for a global version of a "Stokes multiplier preserving deformation," which is, however, local in the x_1 variable. The space we will work on is $D\times\mathcal{R}(\mathcal{C})$, where D is the unit disk about $x=a$ in $\mathbf{C}$ and the connection whose existence we wish to demonstrate is a simple integrable type r connection along $\{a\}\times\mathcal{R}(\mathcal{C})$, which has formal reduction to

$$\boldsymbol{\nabla}_\lambda = d - d(\mathbf{H}) - \Lambda_0\frac{dx}{x-a}, \tag{1.24}$$

where $d=d_x+d_\lambda$ is the exterior derivative in the $(x,\lambda)\in D\times\mathcal{R}(\mathcal{C})$ variables and

$$\mathbf{H}=\sum_{j=1}^{r}\Lambda_k(\lambda)\frac{(x-a)^{-j}}{-j}. \tag{1.25}$$

Note that $\nabla_\lambda=e^H de^{-H}$, is the gauge transform of the connection d by e^H, with H given by $\mathbf{H}+\Lambda_0\log(x-a)$. However, since H is singular at $x=a$ and multivalued this is not properly a global statement, but does make sense locally.

Theorem 1.26: *Suppose that σ is a parallel section for $\mathcal{M}\rightarrow\mathcal{R}(\mathcal{C})$. Let D denote the unit disk in* $\mathbf{C}$ *centered at a. Then there exists a holomorphic integrable connection* ∇ *defined on the trivial vector bundle,*

$$D\times\mathcal{R}(\mathcal{C})\times\mathbf{C}^p\rightarrow D\times\mathcal{R}(\mathcal{C}), \tag{1.27}$$

which has a singularity of type $r\geqslant 1$ along the hypersurface $Y=\{a\}\times\mathcal{R}(\mathcal{C})$ such that the restriction of the connection ∇ to $D\backslash\{a\}\times\mathcal{R}(\mathcal{C})$ is formally equivalent to the diagonal model ∇_λ defined in (1.24) and such that the the holomorphic equivalence class of the restriction of ∇ to $(D\backslash\{a\})\times\{\lambda\}$ is given by $\sigma(\lambda)$.

Proof: We first recall a result of Malgrange and Sibuya, for which one can also find a detailed proof in Ref. 17. Suppose that $\lambda\in\mathcal{R}(\mathcal{C})$ and $\sigma\in\mathcal{M}_\lambda$, where $\mathcal{M}_\lambda$ is the fiber in $\mathcal{M}$ over λ. Then on the trivial bundle $D\times\mathbf{C}^p\rightarrow D$ there exists a simple type r connection $\overline{\nabla}$ singular at $x=a$ in D, which has formal reduction to the diagonal model,

$$\overline{\nabla}_\lambda:=d_x-d_x\mathbf{H}(\lambda)-\Lambda_0\frac{dx}{x-a}, \tag{1.28}$$

and which has ''Stokes multipliers'' given by σ. In the version of this result that is proved in Ref. 17 the connection is shown to exist on a disk, D_δ, of small radius δ. It is not difficult to use the Birkhoff factorization theorem to produce a connection defined on $D\backslash\{a\}$ with the same properties. Suppose then that one has a connection $\overline{\nabla}$ defined on the trivial bundle over D_δ and satisfying the conditions above. There exists a connection $\overline{\nabla}_{\text{ext}}$ defined on the trivial bundle $\mathbf{C}\backslash\{a\}\times\mathbf{C}^p\rightarrow\mathbf{C}\backslash\{a\}$ with the same holonomy about $x=a$ as the connection $\overline{\nabla}$ (it is easy to produce such a connection with a logarithmic pole at $x=a$). Because the holonomy of $\overline{\nabla}$ and of $\overline{\nabla}_{\text{ext}}$ about $x=a$ are equal it follows that there is an annulus A containing the circle, $S_{\delta/2}$, of radius $\delta/2$ on which the two connections are gauge equivalent. Thus there exists a holomorphic map $g:A\rightarrow\text{GL}(p,\mathbf{C})$ such that

$$g\cdot[\overline{\nabla}]=\overline{\nabla}_{\text{ext}}.$$

The Birkhoff theorem gives us a factorization,

$$g=g_\infty^{-1}(x-a)^N g_0,$$

where g_0 is holomorphic and invertible in a neighborhood of $x=a$ containing the annulus A, g_∞ is holomorphic and invertible in a neighborhood of ∞ that contains the annulus, A, and N is a diagonal matrix with integer entries. The equality

$$g_0\cdot[\overline{\nabla}]=(x-a)^{-N}g_\infty\cdot[\overline{\nabla}_{\text{ext}}], \tag{1.29}$$

on the annulus A, shows that the connection $g_0\cdot[\overline{\nabla}]$ extends to the punctured unit disk, and since it is in the same local holomorphic equivalence class as $\overline{\nabla}$, we have finished the demonstration that we may work on the unit disk, D, rather than D_δ.

To complete the proof of Theorem 1.26 we proceed in two steps. First, we show that if we confine our attention to a sufficiently small neighborhood U of $\lambda \in \mathcal{R}(\mathcal{C})$, then we can find a connection $\boldsymbol{\nabla}_U$ defined over $D\backslash\{a\}\times U$ that satisfies the conclusions of Theorem 1.26, with σ_U the unique local flat section of $\mathcal{M}$ with $\sigma_U(\lambda)=\sigma$. We will prove this using a variant of the Flaschka–Newell integral equation to produce a ''perturbation'' of the connection $\overline{\boldsymbol{\nabla}}$. We defer the proof of this result to Proposition 1.35 below. The second step is to put together the ''local'' solutions $\boldsymbol{\nabla}_U$ to get something defined on all of $\mathcal{R}(\mathcal{C})$. We will now show how to do this.

Let $\lambda \rightarrow \sigma(\lambda)$ denote a flat section of $\mathcal{M}\rightarrow\mathcal{R}(\mathcal{C})$. For each point $\lambda\in\mathcal{R}(\mathcal{C})$ there exists a neighborhood $U(\lambda,\sigma)$ of λ in which the construction of Proposition 1.35 applies. Let $\mathcal{U}$ denote a subcollection of such open neighborhoods that is a covering for $\mathcal{R}(\mathcal{C})$ and for which $U\cap V$ is contractible for each pair U, $V\in\mathcal{U}$. We also suppose that each neighborhood $U\in\mathcal{U}$ is chosen sufficiently small so that for $\delta>0$ small enough there exists a sectorial covering $\{\Sigma_{1,\delta},\Sigma_{2,\delta},\ldots,\Sigma_{2r,\delta}\}$ of the punctured neighborhood $D_\delta\backslash\{a\}$ that is stable and good for the all connections,

$$d_x - d_x\mathbf{H}(\lambda) - \Lambda_0\frac{dx}{x-a},$$

with $\lambda\in U$. The construction of Proposition 1.35 shows that there exist holomorphic maps,

$$\alpha_k^U:\Sigma_{k,\delta}\times U\rightarrow \mathrm{GL}(p,\mathbf{C}),$$

so that

$$\alpha_k^U\cdot[\boldsymbol{\nabla}_\lambda]=\boldsymbol{\nabla}_U,\quad \text{on}\ \ \Sigma_{k,\delta}\times U.$$

Furthermore, the maps α_k^U are related to one another,

$$\alpha_{k+1}^U=\alpha_k^U S_{k,k+1}(x,\lambda),$$

where $S_{k,k+1}:\Sigma_{k,\delta}\cap\Sigma_{k+1,\delta}\times U\rightarrow\mathrm{GL}(p,\mathbf{C})$ is a gauge automorphism of $\boldsymbol{\nabla}_\lambda$ that is asymptotic to the identity *to all orders* at $x=a$. Recall that

$$S_{k,k+1}(x,\lambda)=e^H S_{k,k+1}e^{-H},$$

where $S_{k,k+1}$ is a constant matrix and e^H is well defined once a choice of $x\rightarrow\log(x-a)$ is made for $x\in\Sigma_{1,\delta}$. Suppose that U, $V\in\mathcal{U}$; then for $\lambda\in U\cap V$, the fact that $S_{k,k+1}$ does not depend on U implies that the collection of holomorphic maps,

$$\alpha_k^U(\alpha_k^V)^{-1}\quad\text{for}\ \ k=1,2,...,2r,$$

defines a holomorphic map, g_{UV}, in a punctured neighborhood, $D_\delta\backslash\{a\}\times U\cap V$, and the fact that $S_{k,k+1}(x,\lambda)$ is asymptotic to the identity to all orders in $(x-a)$ implies that g_{UV} asymptotic to a power series near $x=a$ that does not depend on the sector. This implies that g_{UV} is actually holomorphic on $D_\delta\times U\cap V$. By construction,

$$g_{UV}\cdot[\boldsymbol{\nabla}_V]=\boldsymbol{\nabla}_U,\quad\text{on}\ \ D_\delta\backslash\{a\}\times U\cap V. \tag{1.30}$$

This shows that the holonomy of the connection $\boldsymbol{\nabla}_U$ and the holonomy of the connection $\boldsymbol{\nabla}_V$ agree on $D\backslash\{a\}\times U\cap V$ (since $U\cap V$ is contractible the fundamental group of the product $D\backslash\{a\}\times U\cap V$ is determined by the first factor) and hence that they are holomorphically equivalent on all of $D\backslash\{a\}\times U\cap V$. The map g_{UV} has an invertible holomorphic extension to all of $D\times U\cap V$ with the property that $g(a,\lambda)=I$ for all $\lambda\in U\cap V$. It is not difficult to see that the gauge transformation g_{UV} is uniquely determined by (1.30) and this normalization. Because of this $g_{UV}g_{VW}=g_{UW}$. Thus, the collection $\{g_{UV}|U,V\in\mathcal{U}\}$ is a collection of transition functions for a holomorphic vector bundle over $D\times\mathcal{R}(\mathcal{C})$. But $D\times\mathcal{R}(\mathcal{C})$ is contractible since both factors are, and every bundle on $D\times\mathcal{R}(\mathcal{C})$, is thus topologically trivial. But $D\times\mathcal{R}(\mathcal{C})$ is a Stein space. It is a theorem of Grauert that on a Stein space every topologically trivial holomorphic bundle is holomorphically trivial.[18] Thus, the bundle defined by these transition functions is holomorphically trivial. Thus, there exists invertible holomorphic maps $g_U:D\times U\rightarrow \mathrm{GL}(p,\mathbf{C})$, so that

$$g_{UV}=g_U^{-1}g_V.$$

Equation (1.30) becomes

$$g_V\cdot[\boldsymbol{\nabla}_V]=g_U\cdot[\boldsymbol{\nabla}_U],$$

and we see that $g_U\cdot[\boldsymbol{\nabla}_U]$ defines a global connection on $D\backslash\{a\}\times\mathcal{R}(\mathcal{C})$ that satisfies the conditions of Theorem 1.26. QED

Now we turn to the proof of the perturbation result used in the proof of the preceeding theorem. Suppose that $\overline{\boldsymbol{\nabla}}^0$ is a simple type r connection on the trivial bundle,

$$D\times\mathbf{C}^p\rightarrow D,$$

with singularity at $x=a$ in D. For the purpose of a technical result later on, it will be convenient to choose a special trivialization in which to consider the connection $\overline{\boldsymbol{\nabla}}^0$. Choose $\rho<1$ and let A denote the annulus,

$$A=\{x:\rho<|x-a|<1\}\subset D.$$

Choose a point $q\in A$ and let M denote the $p\times p$ invertible matrix, which gives the holonomy of the connection $\overline{\boldsymbol{\nabla}}^0$ (with respect to the initial trivialization) along a counterclockwise oriented circle of radius $|q-a|$ about a. Let

$$m:=\frac{1}{2\pi i}\log M,$$

for some choice of a logarithm for M. The connection

$$\overline{\boldsymbol{\nabla}}^\infty:=d_x-\frac{m}{x-a},$$

defined on the trivial bundle $\mathbf{P}^1\times\mathbf{C}^p$, has regular singular points at 0 and ∞ and its restriction to A has the same holonomy representation as $\overline{\boldsymbol{\nabla}}^0$. Hence, there exists an invertible holomorphic map $g:A\rightarrow\mathrm{GL}(p,\mathbf{C})$ so that

$$g\cdot\overline{\boldsymbol{\nabla}}^0=\overline{\boldsymbol{\nabla}}^\infty,\quad \text{on } A.$$

Let $g=g_\infty^{-1}(x-a)^{-N}g_0$ denote the Birkhoff factorization of g, with g_0 holomorphic and invertible in D, g_∞ holomorphic and invertible in $\{x:|x-a|>\rho\}\cup\{\infty\}$, and N a diagonal matrix with integer entries. Thus,

$$g_0\cdot\overline{\boldsymbol{\nabla}}^0=(x-a)^N g_\infty\cdot\overline{\boldsymbol{\nabla}}^\infty,$$

and we see that by adjusting the trivialization on $D\times\mathbf{C}^p$ by g_0 we may suppose that our connection $\overline{\boldsymbol{\nabla}}^0$ extends to a connection on the trivial bundle $\mathbf{P}^1\times\mathbf{C}^p\rightarrow\mathbf{P}^1$ with a regular singular point at ∞ (the resulting connection may not be of a simple type at ∞, however). In what follows we suppose that we are looking at $\overline{\boldsymbol{\nabla}}^0$ in just such a trivialization.

Now suppose that the leading singularity in the connection one-form for $\bar{\boldsymbol{\nabla}}^0$ is diagonal and that for the formal power series,

$$\hat{\alpha}^0 = I + \beta_1^0(x-a) + \beta_2^0(x-a)^2 + \cdots,$$

we have

$$\bar{\boldsymbol{\nabla}}^0 = \hat{\alpha}^0 \cdot \left[d_x - d_x \mathbf{H}(\lambda^0) - \Lambda_0 \frac{dx}{x-a} \right], \tag{1.31}$$

where $\mathbf{H}$ is given by (1.25) and λ^0 is some fixed element in $\mathcal{R}(\mathcal{C})$ covering $\Lambda(\lambda^0)$. Note that the projection $\Lambda^0 = \Lambda(\lambda^0)$ is determined by $\bar{\boldsymbol{\nabla}}^0$ through (1.31). Let $\{\Sigma_{1,\delta}, \Sigma_{2,\delta}, \ldots, \Sigma_{2r,\delta}\}$ denote a stable good covering of a punctured neighborhood of $x=a$ for the diagonal connection $\bar{\boldsymbol{\nabla}}_{\lambda^0}$ [see (1.28)]. Let $\alpha_k^0 = \alpha_{\Sigma_k}^0 \in \mathcal{A}(\Sigma_k)$ be a holomorphic function whose asymptotics are given by $\hat{\alpha}^0$ and for which one has the analytical relation

$$\bar{\boldsymbol{\nabla}}^0 = \alpha_k^0 \cdot \left[d_x - d_x \mathbf{H}(\lambda^0) - \Lambda_0 \frac{dx}{x-a} \right], \tag{1.32}$$

in the sector $\Sigma_{k,\delta}$. Finally, suppose that on $\Sigma_{k,\delta} \cap \Sigma_{k+1,\delta}$, we have

$$\alpha_{k+1}^0 = \alpha_k^0 S_{k,k+1}(x, \lambda^0), \tag{1.33}$$

where

$$S_{k,k+1}(x,\lambda) = e^{H(\lambda)} S_{k,k+1}^0 e^{-H(\lambda)}. \tag{1.34}$$

Here H is given by (1.16) and a choice of $\log(x-a)$ is fixed for $x \in \Sigma_{1,\delta}$ to make H well defined. The Stokes multiplier $S_{k,k+1}^0$ is independent of x and λ^0. Let Ω^0 denote the connection form for $\bar{\boldsymbol{\nabla}}^0$ and let pr denote the natural projection,

$$D \times \mathcal{R}(\mathcal{C}) \to D.$$

Define

$$\boldsymbol{\nabla}^0 = d + \mathrm{pr}^* \, \Omega^0,$$

with $d = d_x + d_\lambda$, so that $\boldsymbol{\nabla}^0$ defines a connection on the trivial bundle,

$$D \times \mathcal{R}(\mathcal{C}) \times \mathbf{C}^p \to D \times \mathcal{R}(\mathcal{C}).$$

The following proposition demonstrates the existence of local ''Birkhoff deformations'' of the connection $\bar{\boldsymbol{\nabla}}^0$ in the space $D \times \mathcal{R}(\mathcal{C})$.

Proposition 1.35: For a sufficiently small neighborhood U of λ^0 there exists a simple integrable type r connection $\boldsymbol{\nabla}_U$ defined on the trivial bundle,

$$D \times U \times \mathbf{C}^p \to D \times U,$$

so that we have the following.

(i) $\boldsymbol{\nabla}_U$ is formally reducible to the diagonal form (1.28),

$$\boldsymbol{\nabla}_U = \hat{\alpha} \cdot [\boldsymbol{\nabla}_\lambda], \tag{1.36}$$

where

$$\hat{\alpha}=I+\beta_1(\lambda)(x-a)+\beta_2(\lambda)(x-a)^2+\cdots \tag{1.37}$$

is a formal power series with holomorphic matrix-valued coefficients $\beta_k(\lambda)$*. The sectors* $\Sigma_k \times U$ *are good stable sectors for* ∇_U*; there exist holomorphic maps,*

$$\alpha_k \in \mathcal{A}(\Sigma_k, U), \tag{1.38}$$

with asymptotics given by $\hat{\alpha}$*, so that on open sets asymptotic to* $\Sigma_k \times U$*.*

$$\nabla_U=\alpha_k\cdot[\nabla_\lambda], \tag{1.39}$$

(ii) ∇_U *is a ''Birkhoff deformation'' of* $\overline{\nabla}^0$*, in that the restriction of* ∇_U *to* $D\backslash\{a\}\times\{\lambda^0\}$ *is equivalent to* $\overline{\nabla}^0$ *and*

$$\alpha_{k+1}(x,\lambda)=\alpha_k(x,\lambda)S_{k,k+1}(x,\lambda), \tag{1.40}$$

on $\Sigma_{k,\delta}\cap\Sigma_{k+1,\delta}\times U$ *[see (1.34)].*

(iii) On the punctured neighborhood $D\backslash\{a\}\times U$*, the connections* ∇_U *and* ∇^0 *are gauge equivalent,*

$$\nabla_U=\Phi\cdot[\nabla^0], \tag{1.41}$$

by a gauge transformation $x\to\Phi(x,\lambda)$ *that is holomorphic in the exterior of the disk D and asymptotic to I as* $x\to\infty$*.*

(iv) If $\overline{\nabla}^0$ *extends to a connection on the trivial bundle* $\mathbf{P}^1\times\mathbf{C}^p\to\mathbf{P}^1$ *with a regular singular point at infinity; then*

$$d_\lambda \operatorname{Res}_{x=a} \operatorname{Tr}\{\hat{\alpha}^{-1}\, d_x\hat{\alpha}\, d_\lambda H(\lambda)\}=0. \tag{1.42}$$

Proof: To construct ∇_U through Eq. (1.39) it will suffice to construct functions α_k satisfying (1.40) with $\alpha_k(x,\lambda^0)=\alpha_k^0(x)$. Our strategy will be to look for solutions

$$\alpha_k(x,\lambda)=\varphi_k(x,\lambda)\,\alpha_k^0(x),$$

with $\varphi_k:\Sigma_{k,\delta}\times U\to \mathrm{GL}(p,\mathbf{C})$ a holomorphic map with appropriate asymptotics. Condition (1.40) for $\{\alpha_k\}$ translates into

$$\varphi_{k+1}(x,\lambda)=\varphi_k(x,\lambda)(I+\Delta s_{k,k+1}(x,\lambda)), \tag{1.43}$$

for (x,λ) in $\Sigma_{k,\delta}\cap\Sigma_{k+1,\delta}\times U$, where

$$I+\Delta s_{k,k+1}(x,\lambda)=\alpha_k^0(x)S_{k,k+1}(x,\lambda)S_{k,k+1}(x,\lambda^0)^{-1}\alpha_k^0(x)^{-1}.$$

The important property of $\Delta s_{k,k+1}$ for us is that for any fixed $\delta>0$ one can make $\Delta s_{k,k+1}$ as close to zero as one likes by choosing $\lambda\in U$, with U a sufficiently small neighborhood of λ^0.

The condition (1.40) [or its translation (1.43)] does not determine α_k uniquely. We will impose a further condition on α_k that will uniquely determine it. The extra condition is that the ''fundamental solutions'' $\Psi(x,\lambda)$ and $\Psi^0(x)$ associated to $\{\alpha_k\}$ and $\{\alpha_k^0\}$ by (1.8) differ on the circle of radius δ by a map that is holomorphic in the exterior of the circle of radius δ about $x=a$ and asymptotic to the identity at ∞. More precisely, $\Psi(x,\lambda)\Psi^0(x)^{-1}$ should be holomorphic in x outside the circle of radius δ and

$$\Psi(x,\lambda)\Psi^0(x)^{-1}=I+O(x^{-1}).$$

Note that $\Phi(x,\lambda)=\Psi(x,\lambda)\Psi^0(x)^{-1}$ will be the gauge transformation in (iii) of Proposition 1.35. We will now translate the conditions we have outlined into an integral equation for the functions

φ_k. It will be useful to begin by describing the pieces that make up the integration contours we will use. Let $\sigma_{k,k+1}$ denote an oriented ray segment that lies in the intersection $\Sigma_{k,\delta}\cap\Sigma_{k+1,\delta}$, joins the point a to the circle of radius δ about a, and separates the Stokes lines in the sector $\Sigma_{k,\delta}$ from the Stokes lines in the sector $\Sigma_{k+1,\delta}$ for all $\lambda\in U$ [Stokes lines are associated with the function $\Lambda_r(\lambda)$]. It is always possible to do this if δ is small enough and U is chosen to be a sufficiently small neighborhood of λ^0. Let γ_k denote the counterclockwise oriented segment of the circle of radius δ about a that joins the end point of $\sigma_{k-1,k}$ to the end point of $\sigma_{k,k+1}$. Finally, let σ_k denote the open wedge that is bounded by $\sigma_{k-1,k}$, γ_k, and $\sigma_{k,k+1}$. Then clearly $\sigma_k\subset\Sigma_{k,\delta}$, and the oriented boundary of σ_k is given by

$$\partial\sigma_k=\sigma_{k-1,k}+\gamma_k-\sigma_{k,k+1}.$$

If we now compare Ψ and Ψ^0 defined by (1.8) on the circle of radius δ about a we find

$$\Psi(x,\lambda)\Psi^0(x)^{-1}=\varphi_k(x,\lambda)(I+\Delta m_k(x,\lambda))\quad\text{for }x\in\gamma_k, \tag{1.44}$$

where $k=1,2,...,2r$, with

$$I+\Delta m_k(x,\lambda):=\alpha_k^0(x)e^{H(x,\lambda)-H(x,\lambda^0)}\alpha_k^0(x)^{-1}. \tag{1.45}$$

We have written (1.45) in the special form $I+\Delta m_k$ to emphasize the fact that for fixed δ the right-hand side of (1.45) can be made as close to the identity as one pleases by choosing $\lambda\in U$, with U a sufficiently small neighborhood of λ^0. Next we will obtain a system of integral equations for φ_k following Flaschka and Newell.[15] Suppose that $y\in\sigma_1$; then by Cauchy's theorem,

$$\varphi_1(y,\lambda)=\int_{\partial\sigma_1}\frac{\varphi_1(x,\lambda)}{x-y}\frac{dx}{2\pi i}=\int_{\sigma_{0,1}}\frac{\varphi_1(x,\lambda)}{x-y}\frac{dx}{2\pi i}+\int_{\gamma_1}\frac{\varphi_1(x,\lambda)}{x-y}\frac{dx}{2\pi i}-\int_{\sigma_{1,2}}\frac{\varphi_1(x,\lambda)}{x-y}\frac{dx}{2\pi i}. \tag{1.46}$$

On $\sigma_{1,2}$ we can use (1.43) to write

$$\varphi_1(x,\lambda)=\varphi_1(x,\lambda)-\varphi_2(x,\lambda)+\varphi_2(x,\lambda)=-\varphi_1\Delta s_{1,2}(x,\lambda)+\varphi_2(x,\lambda), \tag{1.47}$$

where for brevity we have written $\varphi_1\,\Delta s_{1,2}(x,\lambda)$ for $\varphi_1(x,\lambda)\Delta s_{1,2}(x,\lambda)$ (we will use this notation without further comment in what follows). Substituting this expression in the $\sigma_{1,2}$ integral in (1.46), one finds

$$\varphi_1(y,\lambda)=\int_{\sigma_{0,1}}\frac{\varphi_1(x,\lambda)}{x-y}\frac{dx}{2\pi i}+\int_{\gamma_1}\frac{\varphi_1(x,\lambda)}{x-y}\frac{dx}{2\pi i}+\int_{\sigma_{1,2}}\frac{\varphi_1\Delta s_{1,2}(x,\lambda)}{x-y}\frac{dx}{2\pi i}-\int_{\sigma_{1,2}}\frac{\varphi_2(x,\lambda)}{x-y}\frac{dx}{2\pi i}. \tag{1.48}$$

Since $\varphi_2(x,\lambda)$ is holomorphic in σ_2 and $y\in\sigma_1$, which is outside of σ_2 it follows that

$$-\int_{\sigma_{1,2}}\frac{\varphi_2(x,\lambda)}{x-y}\frac{dx}{2\pi i}=\int_{\gamma_2}\frac{\varphi_2(x,\lambda)}{x-y}\frac{dx}{2\pi i}-\int_{\sigma_{2,3}}\frac{\varphi_2(x,\lambda)}{x-y}\frac{dx}{2\pi i}. \tag{1.49}$$

We substitute (1.49) for the last integral to appear in (1.48). In the expression that results we observe that the integral,

$$\int_{\sigma_{2,3}}\frac{\varphi_2(x,\lambda)}{x-y}\frac{dx}{2\pi i}=-\int_{\sigma_{2,3}}\frac{\varphi_2\,\Delta s_{2,3}(x,\lambda)}{x-y}\frac{dx}{2\pi i}+\int_{\sigma_{2,3}}\frac{\varphi_3(x,\lambda)}{x-y}\frac{dx}{2\pi i},$$

and one may continue this last integral to γ_3 and $\sigma_{3,4}$ by Cauchy's theorem as above. Proceeding all the way around the circle in this fashion, one finds

$$\varphi_1(y,\lambda)-\sum_{k=1}^{2r}\left\{\int_{\gamma_k}\frac{\varphi_k(x,\lambda)}{x-y}\frac{dx}{2\pi i}+\int_{\sigma_{k,k+1}}\frac{\varphi_k\Delta s_{k,k+1}(x,\lambda)}{x-y}\frac{dx}{2\pi i}\right\}=0. \tag{1.50}$$

Now we formulate the condition that the right-hand side of (1.44) should be holomorphic in the exterior of the circle of radius δ about a and asymptotic to the identity at ∞. This can be expressed as

$$\sum_{k=1}^{2r}\int_{\gamma_k}\frac{\varphi_k(x,\lambda)(I+\Delta m_k(x,\lambda))}{x-y}\frac{dx}{2\pi i}=I. \tag{1.51}$$

Adding this result to the preceding equation, one finds

$$\varphi_1(y,\lambda)+K_1\varphi(y,\lambda)=I, \tag{1.52}$$

where

$$K_1\varphi(y,\lambda)=\sum_{k=1}^{2r}\left\{\int_{\gamma_k}\frac{\varphi_k\,\Delta m_k(x,\lambda)}{x-y}\frac{dx}{2\pi i}-\int_{\sigma_{k,k+1}}\frac{\varphi_k\,\Delta s_{k,k+1}(x,\lambda)}{x-y}\frac{dx}{2\pi i}\right\}, \tag{1.53}$$

and $\varphi=(\varphi_1,\varphi_2,\ldots,\varphi_{2r})$. We ''derived'' (1.52) with y chosen to be in the interior of σ_1. However, we now choose to think of (1.52) as an integral equation for the restriction of φ_1 to $\partial\sigma_1$. In this case the integral operator K_1 defined in (1.52) is understood to involve nontangential limits for y on $\partial\sigma_1$ from the interior of σ_1. There is was nothing special about φ_1 in the arguments above, and so we find that the vector φ satisfies the system of integral equations,

$$\varphi_k(y,\lambda)+K_k\varphi(y,\lambda)=I, \tag{1.54}$$

where the integral operators K_k are defined by the same formula as K_1 but the y variable that occurs in (1.53) takes values in $\partial\sigma_k$ (with the integral operator defined by nontangential limits from the interior). It might be instructive for the reader to compare the system (1.54) of singular integral equations with the standard translation of a Riemann–Hilbert problem into a singular integral equation to be found in (3.17) below.

It is well known that nontangential limits for the Cauchy kernel $(x-y)^{-1}$ determine a bounded operator on $L^2(\partial\sigma_k)$ in case both x and y are in $\partial\sigma_k$. It is not hard to see from this that the integral operator

$$K\varphi=(K_1\varphi,K_2\varphi,\ldots,K_{2r}\varphi)$$

is a bounded operator on

$$\mathcal{H}=L^2(\partial\sigma_1)\oplus L^2(\partial\sigma_2)\oplus\cdots\oplus L^2(\partial\sigma_{2r}).$$

Furthermore, it is clear that because $\Delta m_k(x,\lambda)$ and $\Delta s_{k,k+1}(x,\lambda)$ can be made uniformly small by choosing λ close enough to λ^0, the system of integral equations (1.54) has a unique solution in $\mathcal{H}$ provided the neighborhood U is small enough.

Next, we wish to show that the solution of (1.54) satisfies (1.43). Suppose then that φ is a solution to (1.54) in $\mathcal{H}$. One calculates that, for $y\in\sigma_{j,j+1}$,

$$\varphi_{j+1}(y,\lambda)-\varphi_j(y,\lambda)=K_j\varphi(y,\lambda)-K_{j+1}\varphi(y,\lambda)$$
$$=\int_{\sigma_{j,j+1}}\left\{\frac{\varphi_j\,\Delta s_{j,j+1}(x,\lambda)}{x-y(\sigma_j)}-\frac{\varphi_j\,\Delta s_{j,j+1}(x,\lambda)}{x-y(\sigma_{j+1})}\right\}\frac{dx}{2\pi i}, \tag{1.55}$$

where we have written $y(\sigma_k)$ for the boundary value on $\sigma_{j,j+1}$ taken from the interior of σ_k for $k=j$ and $k=j+1$. Since

$$\frac{1}{2\pi i}\left\{\frac{1}{x-y(\sigma_j)}-\frac{1}{x-y(\sigma_{j+1})}\right\}=\delta(x-y),\quad \text{for } y\in\sigma_{j,j+1},$$

it follows from (1.55) that

$$\varphi_{j+1}(y,\lambda)-\varphi_j(y,\lambda)=\varphi_j(y,\lambda)\Delta s_{j,j+1}(y,\lambda),\quad \text{for } y\in\sigma_{j,j+1}. \tag{1.56}$$

This is a ''boundary value'' version of (1.43), that we will now extend to a sectorial neighborhood of $\sigma_{j,j+1}$. As a simple consequence of satisfying the integral equation (1.54), we know that $\varphi_j(y,\lambda)$ for $y\in\sigma_{j,j+1}$ is the boundary value of a holomorphic function $\varphi_j(y,\lambda)$ for $y\in\sigma_j$. Also, $\varphi_{j+1}(y,\lambda)$ for $y\in\sigma_{j,j+1}$ is the boundary value of a holomorphic function $\varphi_{j+1}(y,\lambda)$ for $y\in\sigma_{j+1}$. Solving (1.56) for $\varphi_{j+1}(y,\lambda)$, we see this function has an analytic continuation into a sector containing $\sigma_{j,j+1}$, since Eq. (1.43) shows that the function $I+\Delta s_{j,j+1}(y,\lambda)$ (and its inverse) has an analytic continuation into such a sector. One can use Morera's theorem to show that the function obtained by gluing together L^2 boundary values along $\sigma_{j,j+1}$ is actually holomorphic in a neighborhood of $\sigma_{j,j+1}$. The same argument works for $\varphi_j(y,\lambda)$ and Eq. (1.56) extends to a sectorial neighborhood of $\sigma_{j,j+1}$. This is (1.43).

It is easy to see that the operator K depends analytically on λ in the operator norm on $\mathcal{H}$. It follows that the iterative solution to (1.54) produces an analytic function of λ with values in $\mathcal{H}$. We would like to know that the solution $\varphi_k(x,\lambda)$ is jointly analytic in x and λ in the usual sense. We know already that for fixed $\lambda\in U$, the function $\varphi_k(x,\lambda)$ is analytic in a sectorial neighborhood of σ_k. It is a theorem (Hartog's theorem) that separate analyticity in each argument implies joint analyticity; thus, it will suffice to show that for x_0 chosen in a suitable sectorial neighborhood of σ_k, the function $\lambda\to\varphi_k(x_0,\lambda)$ is holomorphic in λ. We can argue for this analyticity in the following way. If necessary, enlarge the opening of the wedge σ_k to produce a wedge σ_k' so that the point x_0 becomes an interior point of the region σ_k', and σ_k' remains inside the region of analyticity for $x\to\varphi_k(x,\lambda)$ $(\lambda\in U)$. Since we have confirmed that $\varphi(x,\lambda)$ satisfies (1.43) the arguments leading up to (1.53) now show that $\varphi(x,\lambda)$ satisfies the integral equation (1.53) with the contours adjusted to accommodate σ_k' (σ_{k-1} and σ_{k+1} are a bit smaller). In particular, $U\ni\lambda\to\varphi_k(\cdot,\lambda)$ is an analytic function of λ with values in $L^2(\partial\sigma_k')$. Cauchy's theorem shows that

$$\varphi_k(x_0,\lambda)=\frac{1}{2\pi i}\int_{\partial\sigma_k'}\frac{\varphi_k(x,\lambda)}{x-x_0}\,dx.$$

Since $x\to 1/(x-x_0)$ is in $L^2(\partial\sigma_k')$ the result is analytic in λ. This proves separate analyticity in λ.

The asymptotics for φ_j are obtained by substituting

$$\frac{1}{x-y}=\frac{1}{x}\sum_{n=0}^{N}\left(\frac{y}{x}\right)^n+y^{N+1}\frac{x^{-N-1}}{x-y}$$

into the integral equation (1.54) and noting that the functions

$$\varphi_j(x,\lambda)x^{-k}\,\Delta s_{j,j+1}(x,\lambda),$$

are integrable in x on $\sigma_{j,j+1}$ for all integers $k\geqslant 0$ with integrals that are analytic in λ.

This finishes the proof of (i), (ii). To establish (iii) note that we have shown that each solution φ_k to (1.54) extends to a holomorphic function in a sector containing σ_k, with controlled asymptotic behavior as $x \to a$. This is all that is needed to establish the analog of (1.50) for φ_k. Subtracting this from (1.54), one obtains the analog of (1.51) for φ_k. As noted above, this is an expression of the holomorphic character of the gauge transformation $\Phi(x,\lambda) := \Psi(x,\lambda)\Psi^0(x)^{-1}$ in the exterior of *D*, and this finishes the proof of (iii).

To establish (iv) (which will play an important role in a tau function calculation in Sec. III) write

$$\Omega = \Omega_x + \Omega_\lambda ,$$

for the one-form associated with ∇_U. Here Ω_x is the *dx* term in the one-form and Ω_λ is a sum,

$$\Omega_\lambda = \sum_k \Omega_{\lambda,k}\, d\lambda_k .$$

The $d\lambda$ component of the formal equivalence $\nabla_U = \hat{\alpha}\cdot[\nabla_\lambda]$ is

$$-d\hat{\alpha}\hat{\alpha}^{-1} - \hat{\alpha}\, dH\, \hat{\alpha}^{-1} = \Omega_\lambda ,$$

or

$$d\hat{\alpha} = -\hat{\alpha}\, dH - \Omega_\lambda \hat{\alpha}. \tag{1.57}$$

For simplicity, we write $d = d_\lambda$ and calculate

$$\begin{aligned} d\, \mathrm{Res}_{x=a} \mathrm{Tr}(\hat{\alpha}^{-1} d_x\hat{\alpha}\, dH) &= \mathrm{Res}_{x=a} \mathrm{Tr}(-\hat{\alpha}^{-1} d\hat{\alpha}\, \hat{\alpha}^{-1} d_x\hat{\alpha}\, dH - \hat{\alpha}^{-1} d_x d\hat{\alpha}\, dH) \\ &= \mathrm{Res}_{x=a} \mathrm{Tr}(d_x(dH)dH + \hat{\alpha}^{-1} d_x\Omega_\lambda\, \hat{\alpha}\, dH), \end{aligned}$$

where to get from the second to the the third line we substituted (1.57) for $d\hat{\alpha}$ did an obvious cancellation in the result and made use of the fact that $dH\, dH = 0$ since *dH* is diagonal. But

$$\mathrm{Res}_{x=a} \mathrm{Tr}(d_x(dH)dH) = 0,$$

since the Laurent series for $d_x(dH)dH$ begins with terms $C(x-a)^{-3}$, and so we find

$$d\, \mathrm{Res}_{x=a} \mathrm{Tr}(\hat{\alpha}^{-1} d_x\hat{\alpha}\, dH) = \mathrm{Res}_{x=a} \mathrm{Tr}(d_x\Omega_\lambda\, \hat{\alpha}\, dH\, \hat{\alpha}^{-1}). \tag{1.58}$$

A straightforward calculation now shows that

$$\mathrm{Res}_{x=a} \mathrm{Tr}(d_x(\hat{\alpha}\, dH\, \hat{\alpha}^{-1})\hat{\alpha}\, dH\, \hat{\alpha}^{-1}) = \mathrm{Res}_{x=a} \mathrm{Tr}(d_x(dH)dH) = 0. \tag{1.59}$$

In (1.59) we replace $\hat{\alpha}\, dH\, \hat{\alpha}^{-1}$ by $-d\hat{\alpha}\, \hat{\alpha}^{-1} - \Omega_\lambda$ from (1.57), and find

$$\mathrm{Res}_{x=a} \mathrm{Tr}(d_x(\Omega_\lambda)\Omega_\lambda) + 2\, \mathrm{Res}_{x=a} \mathrm{Tr}(d_x(\Omega_\lambda)d\hat{\alpha}\, \hat{\alpha}^{-1}) = 0, \tag{1.60}$$

where we made use of the fact that $d_x(d\hat{\alpha}\, \hat{\alpha}^{-1})d\hat{\alpha}\, \hat{\alpha}^{-1}$ is ''regular'' at $x=a$ and so has 0 residue, and that

$$\mathrm{Res}_{x=a}\, d_x\, \mathrm{Tr}(\Omega_\lambda\, d\hat{\alpha}\, \hat{\alpha}^{-1}) = 0.$$

Now substitute $-d\hat{\alpha}\, \hat{\alpha}^{-1} - \Omega_\lambda$ for $\hat{\alpha}\, dH\, \hat{\alpha}^{-1}$ in (1.58) and make use of (1.60), to get

$$d\, \mathrm{Res}_{x=a} \mathrm{Tr}(\hat{\alpha}^{-1} d_x\hat{\alpha}\, dH) = -\tfrac{1}{2}\mathrm{Res}_{x=a} \mathrm{Tr}(d_x(\Omega_\lambda)\Omega_\lambda). \tag{1.61}$$

Now for the first time we use the fact that $\overline{\nabla}^0$ is looked at in a trivialization in which it extends to a connection on $\mathbf{P}^1$ with an additional regular singularity at ∞. We see from this and (iii) that

$$\Omega_\lambda = -d\Phi\,\Phi^{-1},$$

is holomorphic in a neighborhood of ∞. Since $\mathrm{Tr}(d_x(\Omega_\lambda)\Omega_\lambda)$ is meromorphic on $\mathbf{P}^1$ with a single pole at $x=a$, it follows that the residue at this pole must be 0. With (1.61), this finishes the proof of (iv) (incidentally, the argument here follows the argument in Ref. 8 used to show that the Jimbo, Miwa, Ueno expression for $d\log\tau$ is closed). QED

II. THE VECTOR BUNDLE DEFORMATION OF MALGRANGE

A. Representations of the fundamental group and flat connections

In this section we are interested in constructing an integrable deformation of a connection on a bundle over $\mathbf{P}^1$ that is monodromy preserving and that respects the local character of the connection near its singular points.

The principal tool in the construction of this deformation away from the singular set is a correspondence between representations of the fundamental group and vector bundles with flat connections. More precisely, suppose that X is a connected complex manifold with base point x^0. Suppose that $E\to X$ is a complex vector bundle with a flat holomorphic connection ∇. Suppose that $\gamma:[0,1]\to X$ is a piecewise smooth curve in X and let $\mathcal{P}_{\nabla}(\gamma)$ denote parallel translation with respect to ∇ along γ. Then

$$\mathcal{P}\nabla(\gamma):E_{\gamma(0)}\to E_{\gamma(1)},$$

is a linear isomorphism between the fibers of E at the end points $\gamma(0)$ and $\gamma(1)$. Now suppose that γ is a piecewise smooth closed loop based at x^0 and let $g=[\gamma]$ denote the homotopy class of γ. Then

$$\rho(g) := \mathcal{P}_{\nabla}(\gamma)^{-1}, \tag{2.1}$$

defines a representation of $\pi_1(X,x^0)$ on E_{x^0}. The right-hand side depends only on the homotopy class of γ because the curvature of ∇ is zero. The equivalence class of the representation ρ actually determines the pair (E,∇) up to an isomorphism. Before we turn to the main theorem of this section we digress to sketch a construction that takes one from ρ to (E,∇). Let $\pi:\mathcal{R}(X)\to X$ denote the simply connected covering space of X and suppose that (E,∇) is a vector bundle with flat connection over X as above. The pull-back bundle $\pi^*(E)\to\mathcal{R}(X)$ is necessarily trivial since the base $\mathcal{R}(X)$ is simply connected. The natural projection $\tilde{\pi}:\pi^*(E)\to E$ is a local diffeomorphism, and since $d\tilde{\pi}_{\tilde{p}}$ is an isomorphism of tangent spaces that maps the vertical vectors in $T_{\tilde{p}}(\pi^*(E))$ bijectively onto the vertical vectors in $T_p(E)$ we may use $d\tilde{\pi}_{\tilde{p}}$ to lift the horizontal subspace in $T_p(E)$ that comes from ∇ to a horizontal subspace in $T_{\tilde{p}}(\pi^*(E))$. We write $\pi^*(\nabla)$ for the resulting connection on $\pi^*(E)$, and note that since the pull-back connection $\pi^*(\nabla)$ is related to ∇ by a local diffeomorphism, it is also a flat connection. We may thus produce a trivialization for $\pi^*(E)$ consisting of flat sections for $\pi^*(\nabla)$. Let $\tilde{x}^0$ denote a base point in $\mathcal{R}(X)$ such that $\pi(\tilde{x}^0)=x^0$. For $u\in\pi^*(E)_{\tilde{x}^0}$ let $\tilde{x}\to\mathcal{P}(\tilde{x},u)\in\pi^*(E)_{\tilde{x}}$ denote the parallel section of $\pi^*(E)$, which agrees with u at $\tilde{x}^0$. Writing $E_0 := \pi^*(E)_{\tilde{x}^0}$ (which is naturally isomorphic to E_{x^0}), we have

$$\mathcal{R}(X)\times E_0 \ni (x,u)\to\mathcal{P}(x,u)\in\pi^*(E),$$

is an isomorphism between the bundle $\pi^*(E)$ and the trivial bundle $\mathcal{R}(X)\times E_0$. If we compose this map $\mathcal{P}$ with the vector bundle projection,

$$\tilde{\pi}:\pi^*(E)\to E,$$

one obtains a vector bundle map,

$$\tilde{\pi}\mathcal{P}:R(X)\times E_0\to E, \tag{2.2}$$

which covers the projection $\pi:\mathcal{R}(X)\to X$.

The representation ρ from (2.1) determines a left action of $\pi_1(X,x^0)$ on $R(X)\times E_0$ given by

$$g\cdot(\tilde{x},u)=(g\cdot\tilde{x},\rho(g)u), \tag{2.3}$$

where $g\cdot\tilde{x}$ is just the usual action of π_1 on the simply connected covering space $\mathcal{R}(X)$. We will show that the quotient bundle $\pi_1(X,x^0)\backslash\mathcal{R}(X)\times E_0\to\pi_1(X,x^0)\backslash\mathcal{R}(X)$ is isomorphic to $E\to X$ as a vector bundle with connection.

We begin by showing that the map $\tilde{\pi}\mathcal{P}$ is equivariant for this action of $\pi_1(X,x^0)$. To see this suppose that $\tilde{x}=[\chi]$, where χ is a smooth curve joining x^0 to x in X. Let $\tilde{x}^0$ denote the class of the constant path starting and ending at x^0. Write $\tilde{\chi}$ for the lift of χ into $\mathcal{R}(X)$ with initial point $\tilde{x}^0$. Let $g=[\gamma]$ where γ is a smooth closed path in X based at x^0. Then one finds

$$\begin{aligned}\tilde{\pi}\mathcal{P}(g\cdot\tilde{x},\rho(g)u)&=\tilde{\pi}\mathcal{P}_{\pi^*(\nabla)}(\widetilde{\gamma\chi})\rho(g)u\\&=\mathcal{P}_{\nabla}(\gamma\chi)\rho(g)u\\&=\mathcal{P}_{\nabla}(\chi)\mathcal{P}_{\nabla}(\gamma)\rho(g)u=\mathcal{P}_{\nabla}(\chi)u=\tilde{\pi}\mathcal{P}(\tilde{x},u),\end{aligned}$$

which shows the equivariance of the map $\tilde{\pi}\mathcal{P}$. In the third and last equality we used the fact that $\tilde{\pi}\mathcal{P}_{\pi^*(\nabla)}(\tilde{\gamma})u=\mathcal{P}_{\nabla}(\gamma)u$, where $\tilde{\gamma}$ is a lift of γ and $u\in E_{\gamma(0)}$. This is obvious if the curve γ stays in a neighborhood U in X, which is evenly covered by the projection on X from $\mathcal{R}(X)$; the general result follows from the fact that parallel translation is an antihomomorphism under homotopy composition.

Since the vector bundle action (2.3) covers the standard left action of $\pi_1(X,x^0)$ on $\mathcal{R}(X)$, and since $\pi_1(X,x^0)\backslash\mathcal{R}(X)\simeq X$, one finds that

$$\pi_1(X,x^0)\backslash\mathcal{R}(X)\times E_0 := \mathcal{R}(X)\times_\rho E_0,$$

is a vector bundle over X isomorphic to E through the map induced by (2.2). Since the construction of the bundle

$$\mathcal{R}(X)\times_\rho E_0\to X \tag{2.4}$$

depends only on the representation ρ, it follows that this representation determines the bundle $E\to X$ up to isomorphism. In fact, the bundle (2.4) has a naturally defined flat connection ∇_ρ so that the map induced by (2.2) determines an isomorphism,

$$(\mathcal{R}(X)\times_\rho E_0,\nabla_\rho)\simeq(E,\nabla). \tag{2.5}$$

In order to define ∇_ρ we introduce a family of trivializations for the vector bundle,

$$\pi_\rho:\mathcal{R}(X)\times_\rho E_0\to X. \tag{2.6}$$

Let $\mathcal{F}$ denote a covering of X by open sets, with the following properties.

(1) If $U\in\mathcal{F}$, then U is evenly covered by $\pi:\mathcal{R}(X)\to X$. That is there exist disjoint sets $U_\alpha\subset X$ such that $\pi^{-1}(U)=\cup_\alpha U_\alpha$ and $\pi:U_\alpha\to U$ is a diffeomorphism for each α.

(2) If U, $V\in\mathcal{F}$ and $U\cap V\neq\phi$, then $U\cup V$ is evenly covered by π.

The existence of such a covering is an easy consequence of the fact that X has a metric topology. Now suppose that $U\in\mathcal{F}$ and $U_\alpha\subset\mathcal{R}(X)$ is such that $\pi:U_\alpha\to U$ is a diffeomorphism. We define a trivialization, $\phi(U_\alpha)$ of $\pi_\rho^{-1}(U)$, by sending each equivalence class,

$$[(\tilde{x},u)] := \{(y,v):(\tilde{y},v)=g\cdot(\tilde{x},u)\quad\text{for }\ g\in\pi_1(X,x^0)\},$$

in $\pi_\rho^{-1}(U)$ into the unique representative of the form $(\tilde{x},u)$ with $\tilde{x}\in U_\alpha$ and $u\in E_0$. Then

$$\phi(U_\alpha)[(\tilde{x},u)]:=(\pi(\tilde{x}),u)=(x,u)\in U\times E_0.$$

Now suppose that $U, V\in\mathcal{F}$ and $\pi:U_\alpha\to U$ and $\pi:V_\beta\to V$ are diffeomorphisms (note that $U=V$ is a possibility). Then if $U\cap V\neq\phi$, it follows that there exists a unique $g_{\alpha\beta}\in\pi_1(X,x^0)$ so that $U_\alpha\cap g_{\alpha\beta}V_\beta\neq\phi$. The existence of such a $g_{\alpha\beta}$ is trivial and uniqueness is equivalent to the assertion that if $U_\alpha\cap V_\beta\neq\phi$ and $U_\alpha\cap gV_\beta\neq\phi$ for some $g\in\pi_1(X,x^0)$ then $g=1$. Suppose then that $U_\alpha\cap V_\beta\neq\phi$ and $U_\alpha\cap gV_\beta\neq\phi$. Then since $U\cup V$ is evenly covered, we have $(U_\alpha\cup V_\beta)\cap g(U_\alpha\cup V_\beta)=\phi$ if $g\neq 1$. But evidently,

$$U_\alpha\cap gV_\beta\subset(U_\alpha\cup V_\beta)\cap g(U_\alpha\cup V_\beta)=\phi,$$

so $U_\alpha\cap gV_\beta=\phi$ if $g\neq 1$. Uniqueness follows. One may now easily compute

$$\phi(U_\alpha)\phi(V_\beta)^{-1}(x,u)=(x,\rho(g_{\alpha\beta})u). \tag{2.7}$$

Since these transition functions are constant in the base variables there is a globally defined flat connection $\boldsymbol{\nabla}_\rho$ on $\mathcal{R}(X)\times_\rho E_0$ that is obtained by gluing together the exterior derivative in the base variables defined in each of the trivializations $\phi(U_\alpha)$. In these trivializations it is not hard to check the isomorphism of connections (2.5).

To finish this account of the reconstruction of a bundle with a flat connection and prescribed holonomy it is still necessary to check that $(\mathcal{R}(X)\times_\rho E_0,\boldsymbol{\nabla}_\rho)$ has a holonomy at x^0 given by ρ. Suppose that γ is a piecewise smooth loop in X based at x^0 with $g=[\gamma]\in\pi_1(X,x^0)$. Let $\gamma^{-1}(\mathcal{F})$ be the open covering of the interval $[0, 1]$ by the inverse image of sets from $\mathcal{F}$ under γ. Let $\delta>0$ be a Lebesque number for this covering and suppose that $0=t_0<t_1\cdots<t_n=1$ is a partition of $[0, 1]$ with $t_{j+1}-t_j<\delta$ for all j. Then each curve segment $\{\gamma(t):t\in[t_j,t_{j+1}]\}$ lies inside some $U_j\in\mathcal{F}$. For each j one can find $U_{\alpha_j}\subset\mathcal{R}(X)$ so that $\pi:U_{\alpha_j}\to U_j$ is a diffeomorphism and one can also arrange that $U_{\alpha_{j+1}}\cap U_{\alpha_j}\neq\phi$ for $j=0,...,n-1$. Then parallel translation of a vector u in E_0 along γ is constant in the trivializations $\phi(U_{\alpha_j})$ for $j=0,...,n-1$. To compute the holonomy one must only compute what the vector u in the trivialization $\phi(U_{\alpha_{n-1}})$ looks like in the trivialization $\phi(U_{\alpha_0})$. However, it is clear from the construction that $gU_{\alpha_0}\cap U_{\alpha_{n-1}}\neq\phi$. Thus, the parallel transport of $u\in E_0$ along γ gives $\rho(g)^{-1}u\in E_0$. This finishes our sketch of the reconstruction of a vector bundle with flat connection (up to equivalence) from its holonomy representation. We now begin to explain the setting for Theorem 2.9 below.

B. The vector bundle deformation

Suppose that $\{a_1^0,a_2^0,\dots,a_n^0\}$ is a collection of n distinct points in $\mathbf{C}$. In this section we will construct a global deformation for a connection $\overline{\boldsymbol{\nabla}}^0$ defined on the trivial bundle $E^0:=\mathbf{P}^1\times\mathbf{C}^p$, with a simple type r_j singularity at a_j^0 and a regular point or simple type r_∞ singularity at ∞. For simplicity in stating results, when $\overline{\boldsymbol{\nabla}}^0$ has a regular point at ∞ we put $r_\infty=-1$ and say that $\overline{\boldsymbol{\nabla}}^0$ has a simple type 1 singularity.

Roughly speaking the deformation we consider will preserve the local type of the singularities for $\overline{\boldsymbol{\nabla}}^0$ and also the local and global monodromy data for the connection $\overline{\boldsymbol{\nabla}}^0$. We now make this more precise.

By relabling the points if necessary we may suppose that $r_j\geqslant 1$ for $j=1,2,...,m$ and $r_j=0$ for $j=m+1,m+2,...,n$. It could happen that $m=0$ or $m=n$. The point ∞ is somewhat special in this context since it does not contribute to the space of pole deformations, $\mathcal{R}(Z^n)$, which we defined in Sec. I. We will mention special considerations concerning ∞ when we encounter them.

For $j=1,...,m$ let

$$\mathcal{C}_j:=Z^p\times\mathbf{C}^p\times\cdots\times\mathbf{C}^p \quad \text{with } r_j-1 \quad \text{factors } \mathbf{C}^\rho,$$

denote the local configuration space at a_j^0, as described in Sec. I. Recall that each point in $\mathcal{C}_j$ corresponds to a formal equivalence class for a simple type r_j connection at a_j^0. Write $\mathcal{C}_\infty$ for the corresponding configuration space at ∞, defined if $r_\infty \geqslant 1$.

Write $\Lambda_j^0 \in \mathcal{C}_j$ for the data associated to $\overline{\boldsymbol{\nabla}}^0$ at a_j^0, for $j=1,...,m$. Recall that $\mathcal{R}(X)$ is just the simply connected cover of X, and define

$$\mathcal{D} := \mathcal{R}(Z^n) \times \prod_{j=1}^{m} \mathcal{R}(\mathcal{C}_j) \times \mathcal{R}(\mathcal{C}_\infty), \tag{2.8}$$

where the product is just the Cartesian product, and the final factor $\mathcal{R}(\mathcal{C}_\infty)$ only appears if $r_\infty \geqslant 1$.

The space $\mathcal{D}$ will serve as our ''deformation space.'' In the first factor, Z^n, is the space of pole locations and in each of the subsequent factors, $\mathcal{C}_j$, is the space of local formal equivalence classes at a_j^0. We must pass to the simply connected cover in $\mathcal{D}$ to guarantee global existence for the sort of deformation we are about to describe.

Let $\mathcal{M}_j \to \mathcal{C}_j$ denote the fiber bundle over $\mathcal{C}_j$ whose fiber over $\Lambda \in \mathcal{C}_j$ is the holomorphic equivalence class of connections formally equivalent to the diagonal model (1.12) associated to the base point Λ (defined in Sec. I). As in Sec. I we also write $\mathcal{M}_j \to \mathcal{R}(\mathcal{C}_j)$ for the pull-back of $\mathcal{M}_j$ under the projection $\mathcal{R}(\mathcal{C}_j) \to \mathcal{C}_j$. Let $\sigma_j^0 \in \mathcal{M}_j$ denote the point in the fiber associated to the class of $\overline{\boldsymbol{\nabla}}^0$ in a neighborhood of $x=a_j^0$ (σ_∞^0 is also defined if $r_\infty \geqslant 1$). Let $\lambda \to \sigma_j(\lambda)$ denote the unique flat section of $\mathcal{M}_j \to \mathcal{R}(\mathcal{C}_j)$ with $\sigma_j(\Lambda_j^0) = \sigma_j^0$ [$\sigma_\infty(\lambda)$ is defined in a similar fashion if $r_\infty \geqslant 1$].

Recall that Y_k is the subset of points $(x,t) \in \mathbf{P}^1 \times \mathcal{R}(Z^n)$ with $x=a_k(t)$, and for $j=1,2,...,n$ define

$$\mathcal{Y}_k = Y_k \times \prod_{j=1}^{m} \mathcal{R}(\mathcal{C}_j) \times \mathcal{R}(\mathcal{C}_\infty) \subset \mathbf{P}^1 \times \mathcal{D},$$

where the factor $\mathcal{R}(\mathcal{C}_\infty)$ is present only if $r_\infty \geqslant 1$. Let $t^0 \in \mathcal{R}(Z^n)$ denote a point in the covering space of Z^n such that $a_j(t^0) = a_j^0$, let $\lambda_j^0 \in \mathcal{R}(\mathcal{C}_j)$ denote a point in the covering space of $\mathcal{C}_j$ such that $\Lambda_j^0 = \Lambda_j(\lambda_j^0)$ [where Λ_j is the projection from $\mathcal{R}(\mathcal{C}_j)$ to $\mathcal{C}_j$] and write

$$\mathbf{P}^1 \ni x \to i(x) := (x, t^0, \lambda^0) \in \mathbf{P}^1 \times \mathcal{D},$$

where

$$\lambda^0 = (\lambda_1^0, \ldots, \lambda_m^0, \lambda_\infty^0),$$

and, as above, λ_∞^0 only occurs when $r_\infty \geqslant 1$.

The following theorem is due to Malgrange (Ref. 14, Theorem 3.1).

Theorem 2.9: *There exists a rank p holomorphic vector bundle* $E \to \mathbf{P}^1 \times \mathcal{D}$ *and an integrable connection* $\boldsymbol{\nabla}$ *on E with a simple type* r_j *singularity along* $\mathcal{Y}_j$ *for* $j=1,...,n$ *and a simple type* r_∞ *singularity along* $\mathcal{Y}_\infty$ *such that the restriction of* $(E, \boldsymbol{\nabla})$ *to* $\mathbf{P}^1 \times \{(t^0, \lambda^0)\}$ is equivalent to $(E^0, \overline{\boldsymbol{\nabla}}^0)$ [that is, $i^*(E,\boldsymbol{\nabla}) \simeq (E^0, \overline{\boldsymbol{\nabla}}^0)$]. *Furthermore, for* $j=1,...,m$ *the restriction of* $(E, \boldsymbol{\nabla})$ to $\mathbf{P}^1 \times \{(t,\lambda)\}$ *is formally equivalent to the model connection* $\overline{\boldsymbol{\nabla}}_{\Lambda_j(\lambda_j)}$ (1.12) *near* $x=a_j(t)$ *and is in the holomorphic equivalence class* $\sigma_j(\lambda_j) \in \mathcal{M}_j$.

Proof: We will prove this result as Malgrange does by first constructing the deformation in the complement of

$$\mathcal{Y} = \cup_{j=1}^{n} \mathcal{Y}_j \cup \mathcal{Y}_\infty \subset \mathbf{P}^1 \times \mathcal{D},$$

and then extending the connection $\overline{\nabla}^0$ to a tubular neighborhood $\mathcal{T}(\mathcal{Y}_j)(\mathcal{T}(\mathcal{Y}_\infty))$ of each singular set $\mathcal{Y}_j(\mathcal{Y}_\infty)$ so that it has the right local characteristics. In particular, one finds that the two constructions must be holomorphically equivalent on $\mathcal{T}(\mathcal{Y}_k)\backslash\mathcal{Y}_k$ and this equivalence allows one to define a bundle over all $\mathbf{P}^1\times D$ together with a connection that has the right global and local properties.

An important result for the construction of the deformation on $\mathbf{P}^1\times D\backslash\mathcal{Y}$ is the following observation of Malgrange. Choose some point $x^0\in\mathbf{C}$ so that $x^0\neq a_j(t^0)$ for all $j=1,...,n$. Define $p^0=(x^0,t^0,\lambda^0)$. Then the map

$$\mathbf{P}^1\backslash\{a_1^0,a_2^0,\ldots,a_n^0,\infty\}\ni x\rightarrow(x,t^0,\lambda^0)\in\mathbf{P}^1\times\mathcal{D}\backslash\mathcal{Y}, \tag{2.10}$$

induces an isomorphism of fundamental groups,

$$\pi_1(\mathbf{P}^1\backslash\{a_1^0,a_2^0,\ldots,a_n^0,\infty\},x^0)\simeq\pi_1(\mathbf{P}^1\times\mathcal{D}\backslash\mathcal{Y},p^0). \tag{2.11}$$

This is explained in both Refs. 3 and 4, where the deformation space does not include the factors $\mathcal{R}(\mathcal{C}_j)$. However, the product of these factors is simply connected so it does not influence the result. The holonomy of the connection $\overline{\nabla}^0$ at the base point x^0 determines a representation, ρ, of $\pi_1(\mathbf{P}^1\backslash\{a_1^0,a_2^0,\ldots,a_n^0,\infty\},x^0)$ on $\mathrm{GL}(p,\mathbf{C})$. The isomorphism (2.11) and the representation ρ determines a $\mathrm{GL}(p,\mathbf{C})$ representation of $\pi_1(\mathbf{P}^1\times\mathcal{D}\backslash\mathcal{Y},p^0)$ that we continue to denote by ρ. Associated with this representation is a vector bundle $E_\rho:=(\mathbf{P}^1\times\mathcal{D}\backslash\mathcal{Y})\times_\rho\mathbf{C}^p$ with connection ∇_ρ whose holonomy representation is given by ρ.

Next we turn to the construction of the local deformations. Suppose that $a=(a_1,a_2,\ldots,a_n)\in Z^n$ and let $\delta(a)$ denote the minimum of the distances, $\{|a_i-a_j|,|a_i^0-a_j^0|\}_{i\neq j}$ [the reason for insisting that $\delta(a)\leqslant\min\{|a_i^0-a_j^0|\}_{i\neq j}$ will appear below]. Let $D_j(a)$ denote the disk of radius $\delta(a)/3$ about the point a_j. Let $D_\infty(a)$ denote the open complement of the closed disk of radius $\delta(a)+\max_i\{|a_i|,|a_i^0|\}$. It is clear by construction that the disks $\{D_\infty(a),D_j(a),j=1,...,n\}$ are pairwise disjoint for each $a\in Z^n$. Define a tubular neighborhood, $\mathcal{T}(\mathcal{Y}_j)$, of $\mathcal{Y}_j$ by

$$\mathcal{T}(\mathcal{Y}_j)=\{(x,t,\lambda)\in\mathbf{P}^1\times\mathcal{D}|x\in D_j(a(t))\},$$

and a tubular neighborhood of $\mathcal{Y}_\infty$ by

$$\mathcal{T}(\mathcal{Y}_\infty):=\{(x,t,\lambda)\in\mathbf{P}^1\times\mathcal{D}|x\in D_\infty(a(t))\}.$$

Then the neighborhoods $\{\mathcal{T}(\mathcal{Y}_\infty),\mathcal{T}(\mathcal{Y}_j),j=1,...,n\}$ are pairwise disjoint. Following the scheme that can be found in Malgrange[3] we define a connection on the trivial bundle $\mathcal{T}(\mathcal{Y}_j)\times\mathbf{C}^p\rightarrow\mathcal{T}(\mathcal{Y}_j)$ by lifting the connection on the trivial bundle over $D_j(a^0)\times\mathcal{R}(\mathcal{C}_j)$ that one obtains from Theorem 1.26 above. Recall that $\lambda\rightarrow\sigma_j(\lambda)$ is the unique flat section of $\mathcal{M}_j\rightarrow\mathcal{R}(\mathcal{C}_j)$ with $\sigma_j(\Lambda_j^0)=\sigma_j^0$. For $j=1,...,m$ let ∇_j denote the integrable connection on the trivial bundle,

$$D_j(a^0)\times\mathcal{R}(\mathcal{C}_j)\times\mathbf{C}^p\rightarrow D_j(a^0)\times\mathcal{R}(\mathcal{C}_j),$$

with a simple type r_j singularity along $\{a_j^0\}\times\mathcal{R}(\mathcal{C}_j)$, whose existence is guaranteed by Theorem 1.26. This connection naturally extends to a connection on the trivial bundle,

$$D_j(a^0)\times\mathcal{R}(\mathcal{C})\times\mathbf{C}^p\rightarrow D_j(a^0)\times\mathcal{R}(\mathcal{C}),$$

by pulling back the connection one-form under the natural projection,

$$D_j(a_0)\times\mathcal{R}(\mathcal{C})\rightarrow D_j(a_0)\times\mathcal{R}(\mathcal{C}_j),$$

where we have written

$$\mathcal{R}(\mathcal{C}) := \prod_{j=1}^{m} \mathcal{R}(\mathcal{C}_j) \times \mathcal{R}(\mathcal{C}_\infty).$$

We continue to denote this connection by $\boldsymbol{\nabla}_j$. Now define a map,

$$\mathrm{pr}_j : \mathcal{T}(\mathcal{Y}_j) \to D_j(a^0) \times \mathcal{R}(\mathcal{C}), \tag{2.12}$$

by $\mathrm{pr}_j(x,t,\lambda) = (x - a_j(t) + a_j^0, \lambda)$ [the extra condition that $\delta(a) \leqslant \min\{|a_i^0 - a_j^0|\}_{i\neq j}$ now guarantees that $x - a_j(t) + a_j^0 \in D_j(a^0)$ for $x \in D_j(a^0)$. Let $\Omega_j(x,\lambda_j)$ denote the one-form for $\boldsymbol{\nabla}_j$ [and we have written $\Omega_j(x,\lambda_j)$ to emphasize the fact that Ω_j only depends on the variables (x,λ_j)],

$$\boldsymbol{\nabla}_j = d + \Omega_j(x,\lambda_j), \tag{2.13}$$

and define a connection (that we again call $\boldsymbol{\nabla}_j$!) on the trivial bundle $E_j := \mathcal{T}(\mathcal{Y}_j) \times \mathbf{C}^p \to \mathcal{T}(\mathcal{Y}_j)$ by

$$\boldsymbol{\nabla}_j := d + \mathrm{pr}_j^*(\Omega_j), \tag{2.14}$$

where d denotes the exterior derivative on $\mathcal{T}(\mathcal{Y}_j)$ (acting on $\mathbf{C}^p$-valued functions). It is easy to check that connection (2.14) is integrable and has a simple type r_j singularity along $\mathcal{Y}_j$ as a consequence of (2.13) being integrable with a simple type r_j singularity along $\{a_j^0\} \times \mathcal{R}(\mathcal{C})$. Now we wish to determine the holonomy for $\boldsymbol{\nabla}_j$ on $\mathcal{T}(\mathcal{Y}_j)\backslash\mathcal{Y}_j$. The map

$$\mathcal{T}(\mathcal{Y}_j)\backslash\mathcal{Y}_j \ni (x,t,\lambda) \to t \in \mathcal{R}(Z^n), \tag{2.15}$$

is surjective with fiber over t given by $D_j(a(t))\backslash\{a(t)\} \times \mathcal{R}(\mathcal{C})$ [which is homeomorphic to $D_j(a^0)\backslash\{a_j^0\} \times \mathcal{R}(\mathcal{C})$]. The first part of the homotopy exact sequence for this fiber bundle reads as

$$\to \pi_2(\mathcal{R}(Z^n)) \to \pi_1(\mathcal{T}(\mathcal{Y}_j)\backslash\mathcal{Y}_j) \to \pi_1(D_j(a^0)\backslash\{a_j^0\}) \to \pi_1(\mathcal{R}(Z^n)) \to 0,$$

where we substituted $\pi_1(D_j(a^0)\backslash\{a_j^0\})$ for $\pi_1(D_j(a^0)\backslash\{a_j^0\} \times \mathcal{R}(\mathcal{C}))$. Thus, we have

$$\pi_1(\mathcal{T}(\mathcal{Y}_j)\backslash\mathcal{Y}_j) \simeq \pi_1(D_j(a^0)\backslash\{a_j^0\}). \tag{2.16}$$

Let

$$(\mathcal{T}(\mathcal{Y}_j)\backslash\mathcal{Y}_j)_{t=t^0} = \{(x,t^0,\lambda) \in \mathcal{T}(\mathcal{Y}_j)\backslash Y_j\} \simeq D_j(a^0)\backslash\{a_j^0\} \times \mathcal{R}(\mathcal{C}),$$

Then the restriction of pr_j,

$$\mathrm{pr}_j : (\mathcal{T}(\mathcal{Y}_j)\backslash\mathcal{Y}_j)_{t=t^0} \to D_j(a^0)\backslash\{a_j^0\} \times \mathcal{R}(\mathcal{C}), \tag{2.17}$$

is essentially the identity. Since (2.16) shows that representatives of all the homotopy classes of curves in $\mathcal{T}(\mathcal{Y}_j)\backslash\mathcal{Y}_j$ can be found among the loops that stay in the section $(\mathcal{T}(\mathcal{Y}_j)\backslash\mathcal{Y}_j)_{t=t^0}$, it follows that the holonomy of the connection $\boldsymbol{\nabla}_j$ can be computed from its restriction to $(\mathcal{T}(\mathcal{Y}_j)\backslash\mathcal{Y}_j)_{t=t^0}$. But the identification (2.16) shows that this holonomy is the same as the holonomy of the connection coming from Theorem 1.26 on the the space $D_j(a^0)\backslash\{a_j^0\} \times \mathcal{R}(\mathcal{C})$. Since $\pi_1(\mathcal{R}(\mathcal{C})) = 0$ we may compute this holonomy by restricting to $\lambda = \lambda^0$ where the connection agrees with $\overline{\boldsymbol{\nabla}}^0$ by construction.

We also need to construct a model connection in the tubular neighborhoods $\mathcal{T}(\mathcal{Y}_j)\backslash\mathcal{Y}_j$ for $j = m+1,...,n$ and $\mathcal{T}(\mathcal{Y}_\infty)\backslash\mathcal{Y}_\infty$. In the first instance, we are looking for a connection on $\mathcal{T}(\mathcal{Y}_j)$ with a simple type 0 singularity along $\mathcal{Y}_j$, which is equivalent to $\overline{\boldsymbol{\nabla}}^0$ in a neighborhood of a_j^0. Since $\overline{\boldsymbol{\nabla}}^0$ is a simple type 0 connection, Proposition 1.25b shows that in a neighborhood of $x = a_j^0$ there exists a diagonal matrix Λ_j so that in the appropriate local trivialization about $x = a_j^0$, $\overline{\boldsymbol{\nabla}}^0$ is represented by

$$d_x+\Omega_j\,,$$

on the trivial bundle

$$D_j(a^0)\times\mathbf{C}^p\to D_j(a^0), \tag{2.18}$$

where

$$\Omega_j=-\frac{\Lambda_j d_x(x-a_j^0)}{x-a_j^0}.$$

Define a connection ∇_j on the trivial bundle over $\mathcal{T}(\mathcal{Y}_j)\backslash\mathcal{Y}_j$ by

$$\nabla_j=d-\frac{\Lambda_j d(x-a_j(t))}{x-a_j(t)},$$

where $d=d_x+d_t+d_\lambda$ is the exterior derivative on $\mathcal{T}(\mathcal{Y}_j)$. It is easy to check that ∇_j is a simple integrable connection with type 0 singularity along $\mathcal{Y}_j$ that has a restriction to $D_j(a^0)\times\{(t^0,\lambda^0)\}$ that is equivalent to $\overline{\nabla}^0$ by construction. The same argument given above for $j=1,...,m$ applies here, and one sees that the connection ∇_j defined on the trivial bundle,

$$\mathcal{T}(\mathcal{Y}_j)\times\mathbf{C}^p\to\mathcal{T}(\mathcal{Y}_j),$$

has holonomy determined by its restriction to $t=t^0$ and $\lambda=\lambda^0$, where it is essentially $\overline{\nabla}^0$. To extend the connection to $\mathcal{T}(\mathcal{Y}_\infty)\backslash\mathcal{Y}_\infty$ so that it is regular along $\mathcal{Y}_\infty$, or has a logarithmic pole along $\mathcal{Y}_\infty$, or a higher rank simple singularity one proceeds as above with some simplification arising from the fact that ∞ adds no component to the space of pole deformations. One should use the local parameter $w=1/x$ with

$$\mathrm{pr}_\infty(w,t,\lambda)=(w,\lambda).$$

We leave the details to the reader.

What we have now is a bundle E_ρ over $\mathbf{P}^1\times\mathcal{D}\backslash\mathcal{Y}$, bundles E_j over $\mathcal{T}(\mathcal{Y}_j)$, and E_∞ over $\mathcal{T}(\mathcal{Y}_\infty)$ with bundle isomorphisms,

$$b_j:E_\rho|_{\mathcal{T}(\mathcal{Y}_j)\backslash\mathcal{Y}_j}\to E_j|_{\mathcal{T}(\mathcal{Y}_j)\backslash\mathcal{Y}_j}, \tag{2.19}$$

and

$$b_\infty:E_\rho|_{\mathcal{T}(\mathcal{Y}_\infty)\backslash\mathcal{Y}_\infty}\to E_\infty|_{\mathcal{T}(\mathcal{Y}_\infty)\backslash\mathcal{Y}_\infty}, \tag{2.20}$$

which take the connection ∇_ρ into ∇_j and ∇_∞. We define a vector bundle E over $\mathbf{P}^1\times\mathcal{D}$ by forming the union $E_\rho\cup E_1\cup\cdots\cup E_n\cup E_\infty$ modulo the equivalence relations determined by (2.19) and (2.20). By construction the bundle E and the connection ∇ obtained by gluing together the connections ∇_ρ, ∇_j, and ∇_∞ have the properties asserted in the formulation of Theorem 2.9. This finishes the proof. QED

III. TAU FUNCTIONS

In this section we will first follow Helmink[4] to define a tau function associated with the deformation construction of Theorem 2.0 above. Let (E,∇) be the integrable deformation of $(E^0,\overline{\nabla}^0)$ constructed in Theorem 2.9. Recall that $\mathcal{D}=\mathcal{R}(Z^n)\times\mathcal{R}(\mathcal{C})$ and define

$$\Theta:=\{(t,\lambda)\in\mathcal{D},E|_{\mathbf{P}^1\times\{(t,\lambda)\}}\text{is nontrivial}\}.$$

Theorem 3.0: *There exists a nonvanishing holomorphic map $\tau:\mathcal{D}\rightarrow\mathbf{C}$ so that Θ is equal to the zero set of τ.*

This is basically a result of Malgrange[14] and Helmink[4] that we will sketch a proof of following the arguments for Proposition 3.2 in Ref. 4.

Sketch of Proof (more details can be found in Ref. 4): Choose $0<\rho_1<1<\rho_2$ and set

$$D_1 := \{x | x\in\mathbf{P}^1, |x|>\rho_1\}, D_2 := \{x | x\in\mathbf{P}^1, |x|<\rho_2\}.$$

Then $D_k\times\mathcal{D}$ for $k=1,2$ is a contractible Stein space, and hence $E|_{D_k\times\mathcal{D}}$ is holomorphically trivial for $k=1,2$. Let $\mathbf{f}:=(f_1,f_2,\ldots,f_p)$ be a row vector of sections for the restriction of E to $D_1\times\mathcal{D}$ that trivializes this restriction. Let $\mathbf{g}:=(g_1,g_2,\ldots,g_p)$ be a row vector of sections for the restriction of E to $D_2\times\mathcal{D}$ that trivializes this restriction. Then there exists a holomorphic map $S:D_1\cap D_2\times\mathcal{D}\rightarrow GL(p,\mathbf{C})$ so that

$$\mathbf{g}=\mathbf{f}S$$

on $D_1\cap D_2\times\mathcal{D}$. Write $S(x,t,\lambda)=S_{t,\lambda}(x)$. Then the restriction of E to $\mathbf{P}^1\times\{(t,\lambda)\}$ will be trivial if and only if there are holomorphic maps $S^-_{t,\lambda}:D_1\rightarrow \mathrm{GL}(p,\mathbf{C})$ and $S^+_{t,\lambda}:D_2\rightarrow \mathrm{GL}(p,\mathbf{C})$, so that for all $x\in D_1\cap D_2$,

$$S_{t,\lambda}(x)=S^-_{t,\lambda}(x)S^+_{t,\lambda}(x)^{-1}. \tag{3.1}$$

A p vector of sections that trivializes E is then given by the appropriate extension of

$$\mathbf{g}S^+_{t,\lambda}=\mathbf{f}S^-_{t,\lambda},$$

from $D_1\cap D_2$. Let S^1 denote the unit circle, write $\mathcal{H}:=L^2(S^1,\mathbf{C}^p)$, and let $\mathcal{H}_+$ be the closed subspace of $\mathcal{H}$ consisting of those functions that are boundary value functions holomorphic inside the unit disk. Let $\mathcal{H}_-=\mathcal{H}_+^\perp$. Suppose that $S^1\ni x\rightarrow S(x)$ is a smooth $p\times p$ matrix-valued function on the circle and let $\mathcal{H}\ni f\rightarrow Sf$ denote the associated multiplication operator on $\mathcal{H}$. Let

$$S=\begin{bmatrix} a(S) & b(S)\\ c(S) & d(S)\end{bmatrix},$$

denote the decomposition of S relative to the direct sum decomposition $\mathcal{H}=\mathcal{H}_+\oplus\mathcal{H}_-$. It is well known[1] that the factorization (3.1) exists if and only if $a(S_{t,\lambda}):\mathcal{H}_+\rightarrow\mathcal{H}_+$ is invertible. Since $(t,\lambda)\rightarrow a(S_{t,\lambda})$ is continuous in the uniform norm topology for $a(S_{t,\lambda})$ and $a(S)$ is known to be Fredholm if S is smooth, it follows that the index of $a(S_{t,\lambda})$ is independent of (t, λ). Since $a(S_{t^0,\lambda^0})$ is invertible by construction, it follows that the index of $a(S_{t,\lambda})$ is 0 for all $(t,\lambda)\in\mathcal{D}$. Fix (t, λ) for the moment. Then since $a(S_{t,\lambda})$ has index 0, there exists a finite rank operator $k:\mathcal{H}_+\rightarrow\mathcal{H}_+$ so that $k+a(S_{t,\lambda})$ is invertible. In fact, there exists a neighborhood $V_{t,\lambda}$ of (t, λ) so that for all $(s,\mu)\in V_{t,\lambda}$ the operator $q_{s,\mu}:=k+a(S_{s,\mu})$ is invertible. Note that $q_{s,\mu}$ is a parametrix for $a(S_{s,\mu})$ for $(s,\mu)\in V_{t,\lambda}$ in that

$$a(S_{s,\mu})q^{-1}_{s,\mu}=I+F_{s,\mu},$$

where $F_{s,\mu}$ is a finite rank operator that depends holomorphically on (s,μ). Now we show that it is possible to make a coherent choice of parametrices $q_{s,\mu}$ following the argument in Helmink.[4] Let $\{V_i\}$ be a locally finite covering of $\mathcal{D}$ with $q_i(s,\mu)$ a holomorphic parametrix for $a(S_{s,\mu})$ for all $(s,\mu)\in V_i$. For each i,j such that $V_i\cap V_j\neq\phi$ define $q_iq_j^{-1}=\phi_{ij}$. Note that each ϕ_{ij} is a finite rank perturbation of the identity. The maps $V_i\cap V_j\ni(s,\mu)\rightarrow\det\phi_{ij}(s,\mu)$ are the transition functions for a holomorphic line bundle on $\mathcal{D}$. Since $\mathcal{D}$ is a Stein space we have $H^1(\mathcal{D},\mathcal{O}^*)=0$, and it follows that this line bundle must be trivial. Hence there exist holomorphic maps $\tau_i:V_i\rightarrow\mathbf{C}^*$ so that $\tau_i^{-1}\tau_j = \det \phi_{ij}$. Now define $t_i : \mathcal{H}_+ \to \mathcal{H}_+$ by $t_i 1 = \tau_i$ and $t_i(e^{in\theta}) = e^{in\theta}$ for $n = 1,2,\ldots$. Now define $\mathbf{q}_i = t_i q_i$. Then $\mathbf{q}_i(s,\mu)$ remains a holomorphic parametrix for $a(S_{s,\mu})$ for $(s,\mu)\in V_i$ and since

$$\det \mathbf{q}_i \mathbf{q}_j^{-1} = \det t_i t_j^{-1} \det q_i q_j^{-1} = \tau_i \tau_j^{-1} \det \phi_{ij} = 1,$$

it follows that

$$\tau(s,\mu) := \det(a(S_{s,\mu})\mathbf{q}_i(s,\mu)^{-1}),$$

is a well-defined holomorphic function on all of $\mathcal{D}$ whose 0 set is equal to Θ. QED

Next, we will make a connection with the tau function defined by Jimbo, Miwa, and Ueno.[8] We follow Malgrange by computing the regularized logarithmic derivative of the determinant of a Toeplitz operator, the invertibility of which determines if $E|_{\mathbf{P}^1\times\{(t,\lambda)\}}$ is trivial or not. The bundle E is first realized in terms of a system of transition functions that relate local models for the connection ∇ in a neighborhood of the singularities to a model for the connection ∇ in a complement of a neighborhood of the singularities. We will spend some effort to choose the local models carefully [so that (3.7) is satisfied], even though this is not important for the calculation of the regularized logarithmic derivative of the Toeplitz operator. We do it because it will simplify a curvature calculation later on.

First fix a point $(t^0,\lambda^0)\in\mathcal{D}$. We will examine the restriction of E to $\mathbf{P}^1\times W$, where W is a suitably small neighborhood of (t^0,λ^0). We will cover $\mathbf{P}^1\times W$ by neighborhoods $B_j\times W$ that contain the singular sets $x = a_j(t)$ (including $x=\infty$ for $j=\infty$) and a complementary set $B_{\text{ex}}\times W$. We will choose trivializations for E over each of these sets and understand the bundle E in terms of the transition maps between these trivializations.

Now we turn to the identification of a suitable local model for the connection ∇ in a neighborhood of each singularity.

For each $j=1,\ldots,m$ choose a connected, simply connected product neighborhood $W_j = U_j \times V_j$ of (t_j^0,λ_j^0), with compact closure. For $j=m+1,\ldots,n (j=\infty)$ choose a connected, simply connected neighborhood of $t_j^0(\lambda_\infty^0)$ with compact closure. Let

$$W = \prod_{j=1}^{n} W_j \times W_\infty .$$

Let $D_j(a^0)$ denote the disk of radius $\delta(a^0)/3$ defined in Sec. II and let $D_j'(a^0)\subseteq D_j(a^0)$ denote the disk of radius $\delta(a^0)/6$. Choose a trivialization, $\mathbf{g}^j$, for the restriction $E|_{D_j(a^0)\times W}$ and suppose that relative to this trivialization the connection ∇ is given by

$$d + \Omega_j .$$

Let Ω_j^0 denote the restriction of Ω_j to $(t_j,\lambda_j) = (t_j^0,\lambda_j^0)$. As in the developments preceding Theorem 1.35, it is possible to adjust the trivialization $\mathbf{g}^j$ by a gauge transformation in the x variables alone so that $d_x + \Omega_j^0$ extends to a connection on the trivial bundle $\mathbf{P}^1\times\mathbf{C}^p\to\mathbf{P}^1$ with a simple type r singularity at a_j^0 and a regular singularity at ∞. In what follows we suppose that this has been done. For $j=1,\ldots,m$ choose V_j small enough so that the Birkhoff deformation of $d_x+\Omega_j^0$ constructed in Proposition 1.35 exists on $D_j(a^0)\times V_j$. Thus there exists an integrable connection,

$$d_x + d_{\lambda_j} + \Omega_j^{\text{loc}}, \tag{3.2}$$

which is a Birkhoff deformation of $d_x+\Omega_j^0$ in the sense of Proposition 1.35 (i) and (ii) and such that on $D_j(a^0)\backslash\{a_j^0\}\times V_j$ one has the gauge equivalence

$$d_x + d_{\lambda_j} + \Omega_j^{\text{loc}} = \varphi_j \cdot [d_x + d_{\lambda_j} + \Omega_j^0], \tag{3.3}$$

where $x \to \varphi_j(x,\lambda_j)$ is holomorphic in the punctured disk $D_j(a^0)\backslash\{a_j^0\}$ and asymptotic to the identity as $x\to\infty$. Now choose the neighborhood U_j of $\{t_j^0\}$ small enough so that the map p_j, defined by

$$D_j'(a^0)\times U_j\times V_j \ni (x,t,\lambda)\to p_j(x,t,\lambda):=(x-a_j(t)+a_j^0,\lambda),$$

maps into $D_j(a^0)\times V_j$. Let $d_j=d_x+d_{t_j}+d_\lambda$, where d_λ is the exterior derivative on $\Pi_{k=1}^n \mathcal{R}(\mathcal{C}_k)\times\mathcal{R}(\mathcal{C}_\infty)$ and define the connection

$$d_j+p_j^*\Omega_j^{\text{loc}}, \tag{3.4}$$

on the trivial $\mathbf{C}^p$ bundle over

$$X_j:=D_j'(a^0)\times W.$$

It is a consequence of Proposition 1.26c above that the connection (3.4) on the trivial bundle over X_j is equivalent to $\boldsymbol{\nabla}$ on $E|_{X_j}$ (they have the same formal reduction and Stokes multipliers). Possibly shrinking the open neighborhood U_j, we can ensure that there is an annular region,

$$A_j=\{x|\rho_j<|x-a_j^0|<\rho_j'\}\subset D_j'(a^0),$$

with the property that $x-a_j(t)\neq 0$ for $(x,t)\in A_j\times U_j$. The integrable connection (3.4) and the integrable connection,

$$d_j+\Omega_j^{\text{loc}},$$

have the same holonomy on $A_j\times W_j$. They are thus related by a holomorphic gauge transformation, ψ_j, defined on $A_j\times W_j$, so that

$$d_j+p_j^*\Omega_j^{\text{loc}}=\psi_j\cdot[d_j+\Omega_j^{\text{loc}}], \tag{3.5}$$

which can be normalized so that $\psi_j(x,t_j^0,\lambda_j^0)=I$ for $x\in A_j$. By choosing W_j small enough, we may ensure that ψ_j is a sufficiently small perturbation of the identity so that it has a ''canonical factorization'' $\psi_j=\psi_j^+\psi_j^-$, where $\psi_j^+(x,t_j,\lambda_j)$ is holomorphic for $|x-a_j^0|<\rho_j'$ and $\psi_j^-(x,t_j,\lambda_j)$ is holomorphic for $|x-a_j^0|>\rho_j$, with $\psi_j^-(\infty,t_j,\lambda_j)=I$. Now, define the gauge transform of $d_j+p_j^*\Omega_j^{\text{loc}}$ by $(\psi_j^+)^{-1}$,

$$\boldsymbol{\nabla}_j:=(\psi^+)^{-1}\cdot[d_j+p_j^*\Omega_j^{\text{loc}}]=\psi_j^-\cdot[d_j+\Omega_j^{\text{loc}}]. \tag{3.6}$$

Combining (3.6) with the extension of (3.3) to

$$d_j+\Omega_j^{\text{loc}}=\varphi_j\cdot[d_j+\Omega_j^0],$$

which follows from (3.3), since φ_j does not depend on t_j, or λ_k for $k\neq j$, we also have

$$\boldsymbol{\nabla}_j=\phi_j\cdot[d_j+\Omega_j^0], \tag{3.7}$$

where $\phi_j(x,t_j,\lambda_j)$ is holomorphic for $|x-a_j^0|>\rho_j$. The connection $\boldsymbol{\nabla}_j$ is equivalent to the restriction of $\boldsymbol{\nabla}$ to $E|_{X_j}$ and so is a good local model for $\boldsymbol{\nabla}$. Thus, we can choose a trivialization $\mathbf{f}^j$ for $E|_{X_j}$ so that in this trivialization $\boldsymbol{\nabla}$ is represented by $\boldsymbol{\nabla}_j$.

Now we wish to do something similar for $j=m+1,...,n$. W_j should be small enough so the map

$$D_j'(a^0)\times W_j\ni(x,t)\to p_j(x,t):=x-a_j(t)+a_j^0,$$

maps into $D_j(a^0)$. Choose a trivialization for $E|_{D_j(a^0)\times W}$ and write Ω_j for the connection one-form for ∇ in this trivialization. Thus, ∇ is represented by

$$d+\Omega_j,$$

in this trivialization.

Let Ω_j^0 denote the restriction of Ω_j to $(t,\lambda)=(t^0,\lambda^0)$. Again, using the same argument to be found in the preliminaries to Proposition 1.35, we may suppose that the trivialization of $E|_{D_j(a^0)\times W}$ has been chosen so that $d_x+\Omega_j^0$ extends to a meromorphic connection on the trivial bundle $\mathbf{P}^1\times\mathbf{C}^p\rightarrow\mathbf{P}^1$ with a simple type 0 singularity at $x=a$ and a regular singularity at $x=\infty$.

As above, consider the connection,

$$d_j+p_j^*\Omega_j^0.$$

One can choose W_j small enough so that there exists an annular region $A_j=\{x|\rho_j<|x-a_j^0|<\rho_j'\}$ contained in $D_j'(a^0)$ with the property that $x-a_j(t)\neq 0$ for $(x,t_j)\in A_j\times W_j$. The connection $d_j+p_j^*\Omega_j^0$ and $d_j+\Omega_j^0$ then have the same holonomy over $A_j\times W$ and so there exists a holomorphic gauge transformation ψ_j defined on $A_j\times W$ so that

$$d_j+p_j^*\Omega_j^0=\psi_j\cdot[d_j+\Omega_j^0].$$

One can normalize ψ_j so that $\psi_j(x,t^0,\lambda^0)=I$ and by choosing W sufficiently small we can guarantee that ψ_j has a canonical factorization $\psi_j^+\psi_j^-$ as above. We define

$$\nabla_j:=(\psi_j^+)^{-1}\cdot[d_j+p_j^*\Omega_j^0]=\psi_j^-\cdot[d_j+\Omega_j^0], \tag{3.8}$$

where $\psi_j^-(x,t,\lambda)$ is holomorphic for $|x-a_j^0|>\rho_j$ and asymptotic to the identity I as $x\rightarrow\infty$. As above, we can find a trivialization $\mathbf{f}^j$ for the restriction of E to $D_j(a^0)\times W$ so that ∇ is represented by ∇_j.

The local connection at infinity, ∇_∞, might be regular, or have a simple type r_∞ singularity. It does not matter much for the calculation we are going to do, but for definiteness we suppose $r_\infty\geqslant 1$. Then W_∞ is a neighborhood of λ_∞^0 (no pole deformation parameters). Proceeding in close analogy with the first case discussed above, we choose a trivialization $\mathbf{g}^\infty$ for E restricted to $D_\infty(a^0)\times W$ so that the connection ∇ is represented by

$$d_x+d_\lambda+\Omega_\infty.$$

We further suppose that the trivialization $\mathbf{g}^\infty$ has been chosen so that the restriction of this connection to $\lambda=\lambda^0$, given by $d_x+\Omega_\infty^0$, extends to a connection on the trivial bundle $\mathbf{P}^1\times\mathbf{C}^p\rightarrow\mathbf{P}^1$ with a simple type r_∞ singularity at ∞ and a regular singular point at 0.

Now let

$$d_x+d_{\lambda_\infty}+\Omega_\infty^{\mathrm{loc}}$$

denote the Birkhoff deformation of $d_x+\Omega_\infty^0$ constructed in Proposition 1.35 (with the slight alterations needed to locate the singularity at ∞). Let p_∞ denote the projection $(x,\lambda)\rightarrow(x,\lambda_\infty)$ and define

$$\nabla_\infty:=d_x+d_\lambda+p_\infty^*\Omega_\infty^{\mathrm{loc}}. \tag{3.9}$$

Choose ρ_∞ and ρ_∞' so that ∇_∞ and $d_x+d_\lambda+\Omega_\infty^0$ are holomorphically equivalent on the annulus,

$$A_\infty=\{x|\rho_\infty<x<\rho_\infty'\}\subset D_\infty(a^0),$$

by a gauge transformation ϕ_∞,

$$\nabla_\infty = \phi_\infty \cdot [d_x + d_\lambda + \Omega_\infty^0], \tag{3.10}$$

which can be chosen so that $\phi_\infty(x,\lambda)$ is holomorphic for $|x| < \rho'_\infty$.

In contrast to Theorem 2.9 we do *not* assume that the restriction

$$E|_{\mathbf{P}^1 \times \{t^0,\lambda^0\}}$$

is holomorphically trivial. Let $B_j(\rho) = \{x : |x - a_j^0| < \rho\}$ denote the open ball of radius ρ about a_j^0. Let $B_\infty(\rho) = \{x : |x| > \rho\}$, and define

$$B_j := B_j(\rho'_j),$$

$$B_\infty := B_\infty(\rho_\infty),$$

$$B := B_1(\rho_1) \cup B_2(\rho_2) \cup \cdots \cup B_n(\rho_n) \cup B_\infty(\rho'_\infty),$$

$$B_{\text{ex}} := \mathbf{P}^1 \backslash \overline{B}, \tag{3.11}$$

where $\overline{X}$ denotes the closure of X. Then

$$\{B_1, B_2, \ldots, B_n, B_\infty, B_{\text{ex}}\} \tag{3.12}$$

is an open covering of $\mathbf{P}^1$.

We now wish to show that there is a holomorphic trivialization of the bundle E over $B_{\text{ex}} \times W$. Since we have seen that Θ is the zero set of a holomorphic function, τ which is not identically 0, it follows that there is some $(t^1,\lambda^1) \in W$ so that $E|_{\mathbf{P}^1 \times \{(t^1,\lambda^1)\}}$ is holomorphically trivial. Since $B_{\text{ex}} \times W$ does not intersect any of the singular sets (3.2) or $\{\infty\} \times W$ it follows that the integrable connection ∇ on E is smooth over $B_{\text{ex}} \times W$, and since W is connected and simply connected one may integrate ∇ over W to extend the trivialization over $B_{\text{ex}} \times \{(t^1,\lambda^1)\}$ to a holomorphic trivialization of E over $B_{\text{ex}} \times W$. We wish to pick a trivialization so that the connection form for ∇ is particularly simple. Suppose that relative to some choice of a trivialization for the restriction of E to $\mathbf{P}^1 \times \{(t^1,\lambda^1)\}$, the connection ∇ is

$$d_x + \Omega_{\text{ex}}(x),$$

where $\Omega_{\text{ex}}(x)$ depends only on x. Write $d = d_x + d_t + d_\lambda$; then, since W is connected and simply connected it is easy to see that the connection,

$$d + \Omega_{\text{ex}}(x), \tag{3.13}$$

defined on the trivial bundle over $B_{\text{ex}} \times W$ with fiber $\mathbf{C}^p$ has the same holonomy representation as ∇ on the restriction of E to $B_{\text{ex}} \times W$. The holomorphic equivalence of these two connections implies that we can choose a trivialization $\mathbf{f}^{\text{ex}}$ for $E|_{B_{\text{ex}} \times W}$ so that relative to this trivialization the connection ∇ is given by (3.13). Observe that this connection form has no dt or $d\lambda$ components.

For each $j = 1,...,n$ there exists a holomorphic map $S^j : A_j \times W \to \text{GL}(p,\mathbf{C})$ so that

$$\mathbf{f}^{\text{ex}} = \mathbf{f}^j S^j, \tag{3.14}$$

and a holomorphic map $S^\infty : A_\infty \times W \to \text{GL}(p,\mathbf{C})$ so that

$$\mathbf{f}^{\text{ex}} = \mathbf{f}^\infty S^\infty, \tag{3.15}$$

where we think of each trivialization $\mathbf{f} = (f_1, \ldots, f_p)$ as a row vector of sections.

Define

$$B_{\text{in}} = \cup_j B_j \cup B_\infty.$$

Let S denote the holomorphic map from $B_{\mathrm{in}}\cap B_{\mathrm{ex}}\times W$ into $\mathrm{GL}(p,\mathbf{C})$ that restricts to S^j on $A_j\times W$ and S^∞ on $A_\infty\times W$. Then for $(t,\lambda)\in W$, $E|_{\mathbf{P}^1\times\{(t,\lambda)\}}$ will be holomorphically trivial if and only if there exists a factorization,

$$S(x,t,\lambda)=\Phi_{\mathrm{in}}(x,t,\lambda)^{-1}\Phi_{\mathrm{ex}}(x,t,\lambda), \tag{3.16}$$

where $x\to\Phi_{\mathrm{in}}(x,t,\lambda)$ is holomorphic and invertible in B_{in} and $x\to\Phi_{\mathrm{ex}}(x,t,\lambda)$ is holomorphic and invertible in B_{ex}. Let $C_j(C_\infty)$ denote a counterclockwise oriented circle contained in $A_j(A_\infty)$, and define the oriented curve,

$$C=C_\infty-C_1-C_2-\cdots-C_n.$$

Choose a point $z_0\in B_{\mathrm{ex}}$ with $z_0\notin\overline{B_{\mathrm{in}}}$ and define a projection P_{ex} on $L^2(C)$ by

$$P_{\mathrm{ex}}f(z)=\int_C f(x)\left\{\frac{1}{x-z}-\frac{1}{x-z_0}\right\}\frac{dx}{2\pi i},$$

where $z\in C$ is a nontangential limit from B_{ex}. This projects onto the subspace of $L^2(C)$, which has a holomorphic extension into the connected part of B_{ex} bounded by the curve C, with the further property that this holomorphic extension vanishes at $z=z_0$. We can make the factorization (3.16) unique (when it exists) by normalizing

$$\Phi_{\mathrm{ex}}(z_0,t,\lambda)=\mathrm{identity}=I.$$

Rewriting (3.16), we have

$$\Phi_{\mathrm{in}}S=\Phi_{\mathrm{ex}},$$

and writing $P_{\mathrm{in}}=I-P_{\mathrm{ex}}$ we find

$$P_{\mathrm{in}}(\Phi_{\mathrm{in}}S)=I. \tag{3.17}$$

Regarding this as an equation for the rows of Φ_{in}, the solution of this equation is equivalent to the existence of the factorization (3.16). Suppose that (3.16) has a solution Φ_{in}, Φ_{ex}. Then the Toeplitz operator T_S defined by

$$T_Sf=P_{\mathrm{in}}(fS),$$

where f is a row vector in the range of P_{in}, has an inverse,

$$T_S^{-1}g=P_{\mathrm{in}}(g\Phi_{\mathrm{ex}}^{-1})\Phi_{\mathrm{in}}.$$

Following Malgrange, we now calculate the regularized trace,

$$\omega:=\mathrm{Tr}(T_S^{-1}T_{dS}-T_{dS\,S^{-1}}), \tag{3.18}$$

where for brevity we write $d=d_{t,\lambda}$.

Note: because the multiplication operator in our Toeplitz operator is acting on the right it is $T_{RS}-T_ST_R$, which is compact when R and S are smooth.

We will eventually show that (3.18) differs from $d\log\tau$, defined above, by a regular term, and this will allow us to make a connection with the formula for the tau function given by Jimbo, Miwa, and Ueno in Ref. 8.

We compute

$$T_S^{-1}T_{dS}f=P_{\rm in}((f\,dS)\Phi_{\rm ex}^{-1})\Phi_{\rm in}=P_{\rm in}(f\,dS\Phi_{\rm ex}^{-1})\Phi_{\rm in}=P_{\rm in}\big(f(\Phi_{\rm in}^{-1}\,d\Phi_{\rm ex}\,\Phi_{\rm ex}^{-1}$$
$$-\Phi_{\rm in}^{-1}\,d\Phi_{\rm in}\,\Phi_{\rm in}^{-1})\big)\Phi_{\rm in}, \tag{3.19}$$

and

$$T_{dS\,S^{-1}}f=P_{\rm in}(f\,dS\,S^{-1})=P_{\rm in}\big(f(\Phi_{\rm in}^{-1}\,d\Phi_{\rm ex}\,\Phi_{\rm ex}^{-1}\Phi_{\rm in}-\Phi_{\rm in}^{-1}\,d\Phi_{\rm in})\big). \tag{3.20}$$

Now let

$$R_qf=fq,$$

denote right multiplication by q, and define

$$Q=\Phi_{\rm in}^{-1}\,d\Phi_{\rm ex}\,\Phi_{\rm ex}^{-1}-\Phi_{\rm in}^{-1}\,d\Phi_{\rm in}\,\Phi_{\rm in}^{-1}.$$

Then from (3.19) and (3.20), one sees that

$$T_S^{-1}T_{dS}-T_{dS\,S^{-1}}=R_{\Phi_{\rm in}}P_{\rm in}R_Q-P_{\rm in}R_{\Phi_{\rm in}}R_Q=[R_{\Phi_{\rm in}},P_{\rm in}]R_Q=[P_{\rm ex},R_{\Phi_{\rm in}}]R_Q.$$

Thus, the trace of interest is

$$\mathrm{Tr}[P_{\rm ex},R_{\Phi_{\rm in}}]R_Q, \tag{3.21}$$

and one computes

$$[P_{\rm ex},R_{\Phi_{\rm in}}]R_Qf(z)=\int_C f(x)Q(x)(\Phi_{\rm in}(x)-\Phi_{\rm in}(z))\left\{\frac{1}{x-z}-\frac{1}{x-z_0}\right\}\frac{dx}{2\pi i}.$$

Writing $d_x\Phi=\Phi'\,dx$, the integral of the (finite-dimensional) trace over the diagonal is then

$$\int_C \mathrm{Tr}\big(Q(x)\Phi_{\rm in}'(x)\big)\frac{dx}{2\pi i}=\int_C \mathrm{Tr}(d\Phi_{\rm ex}\,\Phi_{\rm ex}^{-1}\Phi_{\rm in}'\Phi_{\rm in}^{-1}-d\Phi_{\rm in}\,\Phi_{\rm in}^{-1}\Phi_{\rm in}'\Phi_{\rm in}^{-1})\frac{dx}{2\pi i}$$
$$=\int_C \mathrm{Tr}(d\Phi_{\rm ex}\,\Phi_{\rm ex}^{-1}\Phi_{\rm in}'\Phi_{\rm in}^{-1})\frac{dx}{2\pi i}, \tag{3.22}$$

where the second equality follows from Cauchy's theorem and the fact that $\Phi_{\rm in}$ is holomorphic in $B_{\rm in}$. To make a connection between (3.22) and the JMU[8] formula for the log derivative of the tau function we replace $\Phi_{\rm in}$ and $\Phi_{\rm ex}$ in (3.22) with quantities more intimately related to the connection $\boldsymbol{\nabla}$. First, choose $j\in\{1,...,n,\infty\}$, and let $\boldsymbol{\nabla}_j$ denote the representation for $\boldsymbol{\nabla}$ in the trivialization $\mathbf{f}^j$. Let $\boldsymbol{\nabla}_{\rm ex}$ denote the representation of $\boldsymbol{\nabla}$ in the trivialization $\mathbf{f}^{\rm ex}$. Then, in the trivialization $\mathbf{f}^j\Phi_{\rm in}^{-1}=\mathbf{f}^{\rm ex}\Phi_{\rm ex}^{-1}$ for the restriction of E to $\mathbf{P}^1\times(W\backslash\Theta)$, we find that the connection $\boldsymbol{\nabla}$ is given by

$$\boldsymbol{\nabla}=\Phi_{\rm ex}\cdot[\boldsymbol{\nabla}_{\rm ex}]=\Phi_j\cdot[\boldsymbol{\nabla}_j], \tag{3.23}$$

on $A_j\times W\backslash\Theta$ (or $A_\infty\times W\backslash\Theta$ for $j=\infty$).

Now fix $j\in\{1,...,m,\infty\}$ and let $\hat\alpha_j$ be the formal power series near $x=a_j(t)$ (or ∞ if $j=\infty$) for which

$$\hat\alpha_j\cdot[\boldsymbol{\nabla}_{\lambda_j}]=\boldsymbol{\nabla}. \tag{3.24}$$

Let $\hat\alpha_j(\mathrm{loc})$ denote the formal power series near $x=a_j(t)$, such that

$$\hat\alpha_j(\mathrm{loc})\cdot[\boldsymbol{\nabla}_{\lambda_j}]=\boldsymbol{\nabla}_j. \tag{3.25}$$

Equating (3.24) with the first term of (3.23) and recalling that $\Omega_{\rm ex}$ does not have any dt or $d\lambda$ terms, one finds

$$d\Phi_{\rm ex}\,\Phi_{\rm ex}^{-1}=d\,\hat{\alpha}_j\hat{\alpha}_j^{-1}-\hat{\alpha}_j\,dH_j\,\hat{\alpha}_j^{-1}, \tag{3.26}$$

which should be understood in the following sense. Replacing $\hat{\alpha}_j$ by $\alpha_{\Sigma,j}$ defined in a suitable sector Σ with vertex at $x=a_j(t)$, one finds a sectorial version of (3.26). This shows that the function $d\Phi_{\rm ex}\,\Phi_{\rm ex}^{-1}$ that is analytic in an annular region about $x=a_j(t)$ extends holomorphically into the sector Σ. Since this is true for a collection of sectors that cover a punctured neighborhood of $x=a_j(t)$, it follows that $d\Phi_{\rm ex}\,\Phi_{\rm ex}^{-1}$ is holomorphic in a punctured neighborhood of $x=a_j(t)$. Equation (3.26) may then be understood as an equality of formal Laurent series (which, in fact, converge since the left-hand side has a convergent Laurent series).

Applying $\hat{\Phi}_{\rm in}$ (the formal power series associated to $\Phi_{\rm in}$) to both sides of (3.25) and comparing the result with (3.23) and (3.24), one finds

$$\hat{\Phi}_{\rm in}\hat{\alpha}_j(\mathrm{loc})=\hat{\alpha}_j c_j\,,$$

where c_j is a diagonal constant matrix (the only gauge automorphisms of $\boldsymbol{\nabla}_{\lambda_j}$ are diagonal constants). Thus

$$\hat{\Phi}_{in}=\hat{\alpha}_j c_j\hat{\alpha}_j(\mathrm{loc})^{-1}, \tag{3.27}$$

for $j=1,2,...,m,\infty$. This is to be understood in the sense of a formal power series at $x=a_j(t)$.

For $j=m+1,...,n$ let α_j denote the local holomorphic gauge transformation constructed in Proposition 1.25b such that

$$\alpha_j\cdot\left[d_x+d-\frac{\Lambda_j}{x-a_j(t)}\,d(x-a_j(t))\right]=\boldsymbol{\nabla}, \tag{3.28}$$

where Λ_j is a constant diagonal matrix. Let $\alpha_j(\mathrm{loc})$ denote the local holomorphic gauge transformation so that

$$\alpha_j(\mathrm{loc})\cdot\left[d_x+d-\frac{\Lambda_j}{x-a_j(t)}\,d(x-a_j(t))\right]=\boldsymbol{\nabla}_j\,. \tag{3.29}$$

Comparing this with the first term in (3.23) and making use of the fact that $\Omega_{\rm ex}$ has no dt or $d\lambda$ components, one finds

$$d\Phi_{\rm ex}\,\Phi_{\rm ex}^{-1}=d\,\alpha_j\,\alpha_j^{-1}+\alpha_j\frac{\Lambda_j d a_j(t)}{x-a_j(t)}\,\alpha_j^{-1}. \tag{3.30}$$

If we write $dH_j=\Lambda_j d(x-a_j(t))/(x-a_j(t))$ for $j=m+1,...,n$ (remember $d=d_t+d_\lambda$), then (3.30) can be written as

$$d\Phi_{\rm ex}\,\Phi_{\rm ex}^{-1}=d\,\alpha_j\,\alpha_j^{-1}-\alpha_j\,dH_j\,\alpha_j^{-1}, \tag{3.31}$$

which is analogous to (3.26).

Applying $\Phi_{\rm in}$ to both sides of (3.29) and comparing with (3.28), we find

$$\Phi_{\rm in}=\alpha_j c_j\alpha_j(\mathrm{loc})^{-1},\quad \text{for }\ j=m+1,...,n, \tag{3.32}$$

which is analogous to (3.27).

The formal power series expansion for (3.26) and the powers series expansion for (3.30) shows that the integral,

$$\int_{C_j} \mathrm{Tr}(d\Phi_{\mathrm{ex}}\, \Phi_{\mathrm{ex}}^{-1} \Phi_{\mathrm{in}}' \Phi_{\mathrm{in}}^{-1})\, \frac{dx}{2\pi i},$$

can be ''done'' by residues to get

$$\pm \mathrm{Res}_{x=a_j(t)}\, \mathrm{Tr}(d\Phi_{\mathrm{ex}}\, \Phi_{\mathrm{ex}}^{-1} \Phi_{\mathrm{in}}' \Phi_{\mathrm{in}}^{-1}), \tag{3.33}$$

with the $+$ choice for $j=1,...,n$ and the $-$ choice for $j=\infty$. We now substitute (3.26), (3.27), (3.31), and (3.32) into (3.33). The first term in (3.26) and (3.30) does not make a contribution to the formal residue in (3.28) since $d\hat{\alpha}_j\, \hat{\alpha}_j^{-1}$ and $\Phi_{\mathrm{in}}' \Phi_{\mathrm{in}}^{-1}$ both have formal power series expansions at $x=a_j(t)$. After some simplification (using $c_j^{-1}\, dH_j\, c_j = dH_j$), one finds

$$\int_{C_j} \mathrm{Tr}(d\Phi_{\mathrm{ex}}\, \Phi_{\mathrm{ex}}^{-1} \Phi_{\mathrm{in}}' \Phi_{\mathrm{in}}^{-})\, \frac{dx}{2\pi i} = \pm \mathrm{Res}_j\, \mathrm{Tr}(\hat{\alpha}_j^{-1} \hat{\alpha}_j'\, dH_j - \hat{\alpha}_j(\mathrm{loc})^{-1} \hat{\alpha}_j'(\mathrm{loc}) dH_j), \tag{3.34}$$

where Res_j is the residue at $x=a_j(t)$ or ∞ if $j=\infty$, and the sign $\pm$ is $+$ for $j=1,...,n$ and $-$ for $j=\infty$. Combining (3.22) with (3.34), one finds that

$$\mathrm{Tr}(T_S^{-1} T_{dS} - T_{dS\, S^{-1}}) = -\sum_j \mathrm{Res}_j\, \mathrm{Tr}(\hat{\alpha}_j^{-1} \hat{\alpha}_j'\, dH_j - \hat{\alpha}_j(\mathrm{loc})^{-1} \hat{\alpha}_j'(\mathrm{loc}) dH_j), \tag{3.35}$$

where the sum is over $j \in \{1,...,n,\infty\}$.

Next, we make use of the special choice we made for the local models $\boldsymbol{\nabla}_j$ that is reflected in (3.7), (3.8), and (3.10). Following the arguments for the proof of part (iv) of Proposition 1.35, we find that

$$d_{t,\lambda}\, \mathrm{Res}_j\, \mathrm{Tr}(\hat{\alpha}_j(\mathrm{loc})^{-1} \hat{\alpha}_j'(\mathrm{loc}) dH_j) = 0, \tag{3.36}$$

for $j=1,...,n,\infty$ follows from (3.7), (3.8), and (3.10) in the same way that (1.42) follows from (1.41).

We will now make use of (3.36) to show that the one form in (3.35) is closed off the singular set Θ. One easily computes

$$d\, \mathrm{Tr}(T_S^{-1} T_{dS} - T_{dS\, S^{-1}}) = -\frac{1}{2} \sum_{j>k} \mathrm{Tr}([T_S^{-1} T_{\partial_k S}, T_S^{-1} T_{\partial_j S}] + T_{[\partial_j S S^{-1}, \partial_k S\, S^{-1}]}) ds_j \wedge ds_k,$$

where $s := (t,\lambda)$ and $\partial_k = \partial/\partial s_k$. This last expression can be computed as in Malgrange,[3] and one finds

$$\frac{1}{2} \sum_{j>k} \int_C \frac{dx}{2\pi i} \mathrm{Tr}(\partial_j S\, S^{-1} (\partial_k S\, S^{-1})') ds_j \wedge ds_k. \tag{3.37}$$

If $(t^0,\lambda^0) \notin \Theta$, then we may take $(t^1,\lambda^1) = (t^0,\lambda^0)$ in the construction above. Note that Eq. (3.35) shows that $\mathrm{Tr}(T_S^{-1} T_{dS} - T_{dS\, S^{-1}})$ is actually independent of the choice of (t^1,λ^1), though it does depend on (t^0,λ^0) through $\hat{\alpha}_j(\mathrm{loc})$. With this choice for (t^1,λ^1), Eqs. (3.7), (3.8) and (3.10) take on added significance. In this case one may choose a global trivialization for $E|_{\mathbf{P}^1 \times \{(t^0,\lambda^0)\}}$. If Ω_j^0 denotes the one-form for $\boldsymbol{\nabla}$ relative to this trivialization, then (3.7), (3.8), and (3.9) show that the transition function S_j can be chosen so that it has a holomorphic continuation into the exterior of C_j in $\mathbf{P}^1$ (including $j=\infty$). Each of the integrals,

$$\int_{C_j} \frac{dx}{2\pi i} \mathrm{Tr}(\partial_l S_j\, S_j^{-1} (\partial_k S_j\, S_j^{-1})'),$$

then vanishes by Cauchy's theorem. This shows that if $(t^0,\lambda^0)\notin\Theta$, then

$$d\,\mathrm{Tr}(T_S^{-1}T_{dS}-T_{dS\,S^{-1}})=0, \tag{3.38}$$

at least for the special constructions associated with $(t^0,\lambda^0)=(t^1,\lambda^1)$. But we can now use (3.35) and (3.36) to show that $\mathrm{Tr}(T_S^{-1}T_{dS}-T_{dS\,S^{-1}})$ is closed even without this restriction. Define

$$\omega_{\mathrm{JMU}}:=-\sum_j \mathrm{Res}_j\,\mathrm{Tr}(\hat{\alpha}_j^{-1}\hat{\alpha}_j'\,dH_j),$$

which is the one-form introduced by Jimbo, Miwa, and Ueno in Ref. 4. Then (3.38), (3.35), and (3.36) together show that

$$d\omega_{\mathrm{JMU}}=0, \tag{3.39}$$

for $(t,\lambda)\notin\Theta$. This result and (3.36) [which is not restricted to the special choice $(t^0,\lambda^0)=(t^1,\lambda^1)$] then show that the right-hand side of (3.35) is closed, in general, and we conclude that $\mathrm{Tr}(T_S^{-1}T_{dS}-T_{dS\,S^{-1}})$ is closed even when (t^1,λ^1) is different from (t^0,λ^0). We are now prepared to state the principal result of this paper.

Theorem 3.40: *Suppose that $\bar{\nabla}^0$ is a connection on the trivial bundle, $\mathbf{P}^1\times\mathbf{C}^p\to\mathbf{P}^1$, with simple type r_j singularities at the distinct points $a_j\in\mathbf{P}^1$ for $j\in\{1,2,...,n,\infty\}$ with $a_\infty:=\infty$. Let (E,∇) denote the vector bundle with connection constructed as a deformation of $\bar{\nabla}^0$ in Theorem 2.9. Let Θ denote the set of $(t,\lambda)\in\mathcal{D}$ such that $E|_{\mathbf{P}^1\times\{(t,\lambda)\}}$ is not trivial. For $(t,\lambda)\notin\Theta$ let $\hat{\alpha}_j$ and α_j be defined as in (3.24) and (3.28). Then we have the following.*

(i) *The form defined by*

$$\omega_{\mathrm{JMU}}=-\sum_j \mathrm{Res}_j\,\mathrm{Tr}(\hat{\alpha}_j^{-1}\hat{\alpha}_j'\,dH_j), \tag{3.41}$$

is a closed one-form on $\mathcal{D}\backslash\Theta$ and there exists a holomorphic function τ_{JMU} on $\mathcal{D}$ such that

$$\omega_{\mathrm{JMU}}=d\log\tau_{\mathrm{JMU}}.$$

(ii) *The point $(t,\lambda)\in\mathcal{D}$ is a zero of τ_{JMU} if and only if $(t,\lambda)\in\Theta$.*

Proof: Let S denote the transition function defined by (3.14) and (3.15). Then, as in the proof of Theorem 3.0, one can find an invertible holomorphic parametrix,

$$W\ni(t,\lambda)\to q(t,\lambda),$$

so that

$$T_{S(t,\lambda)}q(t,\lambda)^{-1}=I+\text{trace class},$$

for $(t,\lambda)\in W$. Define

$$\tau_q(t,\lambda):=\det(T_{S(t,\lambda)}q(t,\lambda)^{-1}).$$

Then it is clear that $\tau_q(t,\lambda)=0$ if and only if $(t,\lambda)\in\Theta$. As above, write $d=d_t+d_\lambda$. Then the usual formula for the derivative of a determinant gives

$$d\log\tau_q=\mathrm{Tr}(T_S^{-1}T_{dS}-dq\,q^{-1}), \tag{3.42}$$

off the singular set Θ. Comparing this with ω defined by (3.18) above, we find that

$$\omega-d\log\tau_q=\mathrm{Tr}(dq\,q^{-1}-T_{dS\,S^{-1}}). \tag{3.43}$$

The left-hand side is a closed form on $W\backslash\Theta$ and the right-hand side is holomorphic on W. Thus, the right hand side of (3.43) is a closed form on W. Since W is simply connected, it follows that there exists a holomorphic function ϕ on W so that

$$\omega - d\log\tau_q = d\phi. \tag{3.44}$$

Consulting the definition (3.41) for ω_{JMU} and the result (3.35) for ω, one finds

$$\omega_{\mathrm{JMU}} - \omega = -\sum_j \mathrm{Res}_j\,\mathrm{Tr}(\hat{\alpha}_j(\mathrm{loc})^{-1}\hat{\alpha}_j'(\mathrm{loc})dH_j). \tag{3.45}$$

The right-hand side of (3.45) is a holomorphic one-form on W and by (3.36) it is closed. Thus, there exists a holomorphic function φ on W so that

$$\omega_{\mathrm{JMU}} - \omega = d\varphi. \tag{3.46}$$

Adding (3.44) and (3.46) and writing $\Phi = \phi + \varphi$, we find

$$\omega_{\mathrm{JMU}} = d\log\tau_q + d\Phi = d\log(e^{\Phi}\tau_q). \tag{3.47}$$

Thus, for some constant, c, we have

$$\tau_{\mathrm{JMU}} = c e^{\Phi}\tau_q\,.$$

From this it follows immediately that $\tau_{\mathrm{JMU}}(t,\lambda)=0$ if and only if $(t,\lambda)\in\Theta$ and this finishes the proof of the theorem. QED

A note on the Morse index theorem for geodesics between submanifolds in semi-Riemannian geometry

Paolo Piccione[a] and Daniel V. Tausk[b]
Departamento de Matemática, Universidade de São Paulo, Brazil

(Received 26 April 1999; accepted for publication 24 August 1999)

The computation of the index of the Hessian of the action functional in semi-Riemannian geometry at geodesics with two variable endpoints is reduced to the case of a *fixed* final endpoint. Using this observation, we give an elementary proof of the Morse index theorem for Riemannian geodesics with two variable endpoints, in the spirit of the original Morse proof. This approach reduces substantially the effort required in the proofs of the theorem given previously [Ann. Math. **73**(1), 49–86 (1961); J. Diff. Geom **12**, 567–581 (1977); Trans. Am. Math. Soc. **308**(1), 341–348 (1988)]. Exactly the same argument works also in the case of timelike geodesics between two submanifolds of a Lorentzian manifold. For the extension to the lightlike Lorentzian case, just minor changes are required and one obtains easily a proof of the focal index theorem previously presented [J. Geom. Phys. **6**(4), 657–670 (1989)].

I. INTRODUCTION

A geodesic in a semi-Riemannian manifold $(\mathcal{M},g)$ is a smooth curve $\gamma:[a,b]\mapsto\mathcal{M}$ that is a stationary point for the action functional $f(z)=\frac{1}{2}\int_a^b g(\dot z,\dot z)\,dt$ defined in the set of paths z joining two given points of $\mathcal{M}$. If $(\mathcal{M},g)$ is Riemannian, i.e., if g is positive definite, given one such critical point γ, the celebrated Morse index theorem relates some analytical properties of the second variation of f at γ with some geometrical properties of γ. More precisely, the *index* of Hess_f at γ, that gives the number of *essentially different* directions in which γ can be deformed to obtain a shorter curve, equals the number of conjugate points along γ counted with multiplicity, excluding the endpoints $\gamma(a)$ and $\gamma(b)$.

The index theorem opened a very active field of research for both geometers and analysts, and the original result of Morse was successively extended in several directions. Beem and Ehrlich extended the results to the case of timelike Lorentzian geodesics (see Ref. 1) and to the lightlike Lorentzian case.[1,2] The case of a Riemannian geodesic with endpoints variable in two submanifolds of $\mathcal{M}$ has been treated by several authors, including Ambrose, Bolton and Kalish, (see Refs. 3–5, see also Ref. 6); Kalish's result (Ref. 5) has successively been extended in Ref. 7 to the case that each end manifold lies at a focal point of the other. Following the approach of Ref. 5, Ehrlich and Kim have then proven in Ref. 8 the Morse index theorem for lightlike geodesics with endpoints varying on two spacelike submanifolds of a Lorentzian manifold. The case of spacelike geodesics in semi-Riemannian manifolds was treated by Helfer in Ref. 9, where an extension of the index theorem was proven in terms of the *Maslov* index of a curve, and by the introduction of a notion of *signature* for conjugate points. Edwards extended in Ref. 10 the Morse Index Theorem to the case of formally self-adjoint linear systems of ordinary differential equations (ODEs), and Smale proved in Ref. 11 a general version of the Index Theorem for strongly elliptic operators on a Riemannian manifold.

The key point in the original Morse's proof of the theorem was the introduction of a function

[a]Electronic mail: piccione@ime.usp.br
[b]Electronic mail: tausk@ime.usp.br

$i:[a,b]\mapsto\mathbb{N}$ that gives the index of the form I_t, which is the Hessian Hess_f restricted to the geodesic $\gamma|_{[a,t]}$. Using a suitable subdivision of the interval $[a,b]$ and some geometrical arguments (see Refs. 12 and 13) Morse proved that i is nondecreasing and left continuous, with discontinuities precisely at the conjugate points, and that the jump of i at each discontinuity point t_0 is given by the value of the multiplicity of the conjugate point $\gamma(t_0)$.

When passing to the case of variable endpoints, i.e., when one admits variations with curves having endpoints varying on two fixed submanifolds P and Q of $\mathcal{M}$, in which case a stationary point of f is a geodesic γ that is orthogonal to P and Q at its endpoints, some obstructions to the use of the original argument of Morse arise, due mainly to the fact that the restricted index form I_t does not detect the influence of the final manifold Q.

Ambrose[3] gave a proof of the Index Theorem that uses the subdivision argument by introducing a family Q_t of *localized end manifolds* along γ, constructed with the help of the geodesic flow of the normal bundle of P around $(\gamma(a),\dot\gamma(a))$. This construction leads to technical difficulties (see also Ref. 6), due to the fact that the submanifold Q_t may lose dimension and differentiability. The proof of Bolton[4] also uses a subdivision argument, and it avoids the introduction of the manifolds Q_t, but it employs a restricted index function which is no longer nondecreasing.

The passage to a restricted index function is avoided in Kalish's proof of the index theorem in the variable endpoints case (see Ref. 5). In this article, it is given an explicit direct sum decomposition of the space $\mathcal{H}^{(P,Q)}=B\oplus B_+^c\oplus B_-^c$ of vector fields along γ which are everywhere orthogonal to γ and tangent to P and Q respectively at $\gamma(a)$ and $\gamma(b)$. The index theorem is deduced with a study of the sign of the index form in each of the three spaces; the definition of such decomposition is not very natural, and the remaining calculations are rather involved.

Ehrlich and Kim[8] have adapted Kalish's proof to the case of lightlike Lorentzian geodesics, where a suitable quotient space is used, in analogy with the null Morse index theorem of Refs. 1 and 2.

The aim of this paper is to show that the proof of the Morse index theorem for geodesics with two variable endpoints is a simple adaptation of the classical proof for the fixed endpoints case, in the spirit of the original proof of Morse, which is well understood. To this goal, the key observation is that the case of a geodesic with final point varying on a submanifold Q can be deduced immediately from the case of a fixed final endpoint (see Theorem II.6) by using a natural splitting of the space $\mathcal{H}^{(P,Q)}$. Moreover, we emphasize that the case of causal (nonspacelike) Lorentzian geodesics is essentially analogous to the Riemannian case.

We try to keep all the statements and proofs of the paper at the maximum level of generality; in particular, we present an approach that unifies the Riemannian and the causal Lorentzian case, obtaining a proof of all the results for Riemannian and causal Lorentzian geodesics at the same time. In Remark II.7, among other things we observe that, in the Lorentzian lightlike case, the use of the quotient bundle employed in Refs. 1, 2, and 8 is not really essential for the computation of the (nonaugmented) index, which allows to give an easier statement of the focal index theorem. The possibility of circumventing the quotient bundle construction had already been emphasized in Ref. 14, where the author's idea was to consider vector fields which are perpendicular to the given lightlike geodesic but never tangential to it.

It is also important to observe that the result of Theorem II.6 applies to a great number of situations in semi-Riemannian geometry where the Morse index theorem may *not* work, such as, for instance, in the case of spacelike geodesics in stationary Lorentzian manifolds (see Remark II.8).

II. THE INDEX THEOREM

Let $(\mathcal{M},g)$ be a semi-Riemannian manifold, $m=\dim(\mathcal{M})$, $P\subset\mathcal{M}$ be a smooth submanifold of $\mathcal{M}$, and $\gamma:[a,b]\mapsto\mathcal{M}$ be a nonconstant geodesic in $\mathcal{M}$, with $\gamma(a)\in P$ and $\dot\gamma(a)\in T_{\gamma(a)}P^\perp$. We will say that γ is spacelike, timelike, or lightlike according to $g(\dot\gamma,\dot\gamma)$ positive, negative, or zero, respectively; by *causal* we will mean either timelike or lightlike.

Let ∇ denote the Levi-Civita connection of g and let $R(X,Y)=\nabla_X\nabla_Y-\nabla_Y\nabla_X-\nabla_{[X,Y]}$ be the curvature tensor of ∇; moreover, for all $p \in P$ and all $n \in T_pP^\perp$, let $\mathcal{S}_n^P$ be the second fundamental form of P in the orthogonal direction *n*, which is the following symmetric bilinear form on T_pP:

$$\mathcal{S}_n^P(v_1, v_2) = g(n, \nabla_{v_1} V_2),$$

where V_2 is any extension of v_2 to a vector field tangent to P. Observe that we are *not* in principle making any nondegeneracy assumption on P, but if the metric is nondegenerate on T_pP, then we can also define a linear map $\mathcal{S}_n^P: T_pP \mapsto T_pP$ such that $g(\mathcal{S}_n^P(v_1), v_2) = \mathcal{S}_n^P(v_1, v_2)$.

Given a (piecewise) smooth vector field V along γ, we denote by V' the covariant derivative of V along γ.

If $(\mathcal{M}, g)$ is Lorentzian, i.e., if the index of g is 1, and γ is timelike, we have that $T_{\gamma(a)}P$ is spacelike, in the sense that the restriction of g to $T_{\gamma(a)}P$ is positive definite. More in general, the restriction of the metric g to the orthogonal space $\dot\gamma(t)^\perp$ is positive definite for all $t \in [a,b]$. If γ is lightlike, the restriction of the metric to the orthogonal space is just positive semi-definite [having a one-dimensional kernel spanned by $\dot\gamma(t)$]. We will assume *henceforth* that $\dot\gamma(a) \notin T_{\gamma(a)}P$, so that, again, $T_{\gamma(a)}P$ is spacelike.

Let $\tilde{\mathcal{H}}^P$ denote the vector space of all piecewise smooth vector fields V along γ such that $V(a) \in T_{\gamma(a)}P$ and let $\mathcal{H}^P$ be the subspace of $\tilde{\mathcal{H}}^P$ consisting of those V such that $g(V, \dot\gamma) \equiv 0$ and $V(b) = 0$. Moreover, let $I^P: \tilde{\mathcal{H}}^P \times \tilde{\mathcal{H}}^P \mapsto \mathbb{R}$ be the symmetric bilinear form given by

$$I^P(V,W) = \int_a^b [g(V',W') + g(R(\dot\gamma, V)\dot\gamma, W)]\,dt - \mathcal{S}^P_{\dot\gamma(a)}(V(a), W(a)). \tag{1}$$

Observe that if the submanifold P consists of just one point, the term involving its second fundamental form $\mathcal{S}^P_{\dot\gamma(a)}$ in (1) disappears. In this case we will write just I instead of I^P.

We will be concerned with the *index* of I^P in $\mathcal{H}^P$, defined as follows. If $\mathcal{K}$ is a vector subspace of $\tilde{\mathcal{H}}^P$, then the index $i(I^P, \mathcal{K})$ of I^P in $\mathcal{K}$ is the number

$$\mathrm{ind}\,(I^P, \mathcal{K}) = \sup\{\dim(\mathcal{V}) : \mathcal{V} \text{ subspace of } \mathcal{K} \ with \ I^P|_{\mathcal{V}} < 0\},$$

and we set

$$\mathrm{ind}\,(I^P) = \mathrm{ind}\,(I^P, \mathcal{H}^P). \tag{2}$$

The number $\mathrm{ind}\,(I^P)$ will be called the *Morse index* of γ.

A Jacobi field along γ is a smooth vector field J satisfying the linear equation $J'' - R(\dot\gamma, J)\dot\gamma = 0$. We say that J is a P-Jacobi field if it satisfies in addition

$$J(a) \in T_{\gamma(a)}P \quad \text{and} \quad g(J'(a), w) + \mathcal{S}^P_{\dot\gamma(a)}(J(a), w) = 0, \quad \text{for all } w \in T_{\gamma(a)}P. \tag{3}$$

If the metric is nondegenerate on $T_{\gamma(a)}P$ we can rewrite the second condition in (3) as

$$J'(a) + \mathcal{S}^P_{\dot\gamma(a)}(J(a)) \in T_{\gamma(a)}P^\perp.$$

In this case, a simple counting argument shows that the dimension of the vector space of P-Jacobi fields along γ is precisely equal to m and that the dimension of P-Jacobi fields satisfying $g(J, \dot\gamma) = 0$ is equal to $m-1$ [for P-Jacobi fields the condition $g(J, \dot\gamma) = 0$ is equivalent to $g(J'(a), \dot\gamma(a)) = 0$]. Observe that if P is a point, then a P-Jacobi field is simply a Jacobi field J along γ such that $J(a) = 0$.

Two points $q_0 = \gamma(t_0)$ and $q_1 = \gamma(t_1)$, t_0, $t_1 \in [a,b]$, are said to be *conjugate* along γ if there exists a non-null Jacobi field J along γ with $J(t_0) = 0$ and $J(t_1) = 0$. A point $q_0 = \gamma(t_0), t_0 \in [a,b]$ is said to be a *P-focal point* along γ if there exists a non-null P-Jacobi field J along γ such that $J(t_0)=0$; the *geometrical multiplicity* $\mu^P(t_0)$ of a P-focal point $\gamma(t_0)$ is the dimension of the vector space of all P-Jacobi fields along γ that vanish at t_0. If $\gamma(t_0)$ is not P-focal, we set $\mu^P(t_0)=0$.

It is well known that, if γ is either Riemannian or causal Lorentzian, then the set of P-focal points along γ is discrete, hence finite. (As proved in Ref. 9, along a spacelike Lorentzian geodesic, or more in general along a semi-Riemannian geodesic the conjugate points may accumulate.) Namely, if $J_1,\ldots,J_m$ is a linear basis for the space of P-Jacobi fields along γ and $E_1,\ldots,E_m$ is a parallelly transported orthogonal basis along γ, then the smooth function $r(t)=\det(g(J_i,E_j))$ has only simple zeroes on $[a,b]$, i.e., zeroes of finite multiplicity, exactly at those points $t_0\in[a,b]$ such that $\gamma(t_0)$ is a P-focal point along γ [see for instance (Ref. 15, Ex. 8, p. 299)]. Similarly, for all $q_0=\gamma(t_0)$, the set of points q_1 that are conjugate to q_0 along γ is finite.

We are interested in the kernel of the restriction of I^P to $\mathcal{H}^P$. To this aim, we introduce the spaces $\mathcal{N}$ and $\mathcal{J}_0$ as follows:

$$\mathcal{N}=\{f\dot\gamma : f:[a,b]\mapsto\mathbb{R} \quad \text{piecewise smooth}, \quad f(a)=f(b)=0\};$$
$$\mathcal{J}_0=\{P\text{-Jacobi fields } J \text{ along } \gamma : J(b)=0\}. \tag{4}$$

If γ is lightlike we have $\mathcal{N}\subset\mathcal{H}^P$, and in fact $\mathcal{N}$ is contained in the kernel of I^P in $\mathcal{H}^P$, as follows directly from (1). We now compute this kernel in the case of Riemannian or causal Lorentzian geodesics.

Lemma II.1: Let $(\mathcal{M},g)$ be either Riemannian or Lorentzian; in the latter case assume that γ is causal. The kernel of the restriction of the bilinear form I^P to $\mathcal{H}^P$ is equal to $\mathcal{J}_0$ if $(\mathcal{M},g)$ is Riemannian or if $(\mathcal{M},g)$ is Lorentzian and γ is timelike. If γ is lightlike, this kernel is equal to $\mathcal{J}_0\oplus\mathcal{N}$.

Proof: It follows by standard integration by parts of (1) and simple arguments involving the Fundamental lemma of calculus of variations. □

The proof of the index theorem for Riemannian or causal Lorentzian geodesics with initial endpoint varying on a submanifold and fixed endpoint is a simple adaptation of the classical Morse proof of the index theorem in the case of fixed endpoints (see, for instance, Refs. 12 and 13). For the reader's convenience, we outline briefly such adaptation.

We start with the following:

Lemma II.2: Let $J_1,J_2,\ldots,J_n$ be any family of P-Jacobi fields (not necessarily linearly independent) and $\phi_1,\ldots,\phi_n,\psi_1,\ldots,\psi_n$ be piecewise smooth real functions on $[a,b]$. Then,

$$I^P\left(\sum_{i=1}^n \phi_i\cdot J_i,\sum_{j=1}^n \psi_j\cdot J_j\right)=\int_a^b g\left(\sum_{i=1}^n \phi_i'\cdot J_i,\sum_{j=1}^n \psi_j'\cdot J_j\right)dt + g\left(\sum_{i=1}^n \phi_i(b)\cdot J_i'(b),\sum_{j=1}^n \psi_j(b)\cdot J_j(b)\right). \tag{5}$$

Proof: It is a simple computation that uses the Jacobi equation, formulas (3), (1), and the fact that, for P-Jacobi fields J_i and J_j, one has $g(J_i',J_j)=g(J_i,J_j')$. □

For Riemannian or causal Lorentzian geodesics, the above Lemma gives immediately the following Corollary:

Corollary II.3: Let $(\mathcal{M},g)$ be either Riemannian or Lorentzian; in the latter case assume that γ is causal. Suppose there are no P-focal points along γ. Let $V,J\in\tilde{\mathcal{H}}^P$ be vector fields orthogonal to γ, with J a P-Jacobi field and such that $V(b)=J(b)$. Then $I^P(V,V)\geqslant I^P(J,J)$. In the Riemannian and timelike Lorentzian case equality holds if and only if $V=J$, and in the lightlike Lorentzian case it holds if and only if $V-J\in\mathcal{N}$.

Proof: By standard arguments, the absence of P-focal points along γ implies that V can be written as a linear combination of P-Jacobi fields with piecewise smooth coefficients. The conclusion follows directly from Lemma II.2. □

We give the following definition:

Definition II.4: A partition $a=t_0<t_1<\cdots<t_N=b$ of $[a,b]$ is said to be *normal* if the following conditions are satisfied:

(a) for all $i\geqslant 1$ and all $t\in]t_i,t_{i+1}]$, the point $\gamma(t)$ is not conjugate to $\gamma(t_i)$ along γ;
(b) (b) for all $t\in]t_0,t_1]$, the point $\gamma(t)$ is not P-focal along γ.

If γ is either Riemannian or causal Lorentzian, since the set of P-focal points along γ is finite, it is easy to see that there exists $\delta>0$ such that every partition $t_0,\ldots,t_N$ of $[a,b]$ with $t_{i+1}-t_i\leqslant\delta$ for all i is normal. Namely, in order to (b) be satisfied, one can take δ to be the Lebesgue number of a covering of γ by *totally normal neighborhoods* (see Ref. 13).

Given a normal partition, we define the following two subspaces of $\mathcal{H}^P$:

$$\mathcal{H}_0^P=\{V\in\mathcal{H}^P:V(t_i)=0,\forall i\geqslant 1\};$$
$$\mathcal{H}_J^P=\{V\in\mathcal{H}^P:V|_{[t_i,t_{i+1}]}\text{ is Jacobi }\forall i\geqslant 1,\text{ and }V|_{[t_0,t_1]}\text{ is }P\text{-Jacobi}\}. \tag{6}$$

Observe that there exists an isomorphism:

$$\phi:\mathcal{H}_J^P\mapsto\bigoplus_{i=1}^{N-1}\dot\gamma(t_i)^\perp \tag{7}$$

given by setting $\phi(V)=(V(t_1),V(t_2),\ldots,V(t_{N-1}))$. By using the isomorphism (7) one proves that $\mathcal{H}_0^P\cap\mathcal{H}_J^P=\{0\}$ and that $\mathcal{H}_0^P+\mathcal{H}_J^P=\mathcal{H}^P$, hence we have

$$\mathcal{H}_0^P\oplus\mathcal{H}_J^P=\mathcal{H}^P. \tag{8}$$

Using standard integration by parts in (1) one sees that the above decomposition is I^P-orthogonal; moreover, it follows directly from Corollary II.3 that I^P is non-negative on $\mathcal{H}_0^P$. Thus, the index of I^P on $\mathcal{H}^P$ is finite, and it equals the index of I^P on $\mathcal{H}_J^P$.

For the proof of the Morse index theorem for Riemannian or causal Lorentzian geodesics with variable initial point we will follow the outline of the proof of Ref. 13, Theorem 2.2, §11:

Theorem II.5: *Let $(\mathcal{M},g)$ be either Riemannian or Lorentzian, P a smooth submanifold of $\mathcal{M}$, and $\gamma:[a,b]\mapsto\mathcal{M}$ a geodesic [causal, if (M,g) is Lorentzian] with $\gamma(a)\in P$ and $\dot\gamma(a)\in T_{\gamma(a)}P^\perp\setminus T_{\gamma(a)}P$. Then,* $\operatorname{ind}(I^P)=\Sigma_{t_0\in]a,b[}\mu^P(t_0)<+\infty$.

Proof: Let I_t be the index form of the restricted geodesic $\gamma|_{[a,t]}$ and denote by $i(t)$ its index. By classical arguments, one sees that $i(t)=0$ for t near a, and that $i:]a,b[\mapsto\mathbb{N}$ is non decreasing. Let $\bar t\in]a,b[$ be fixed; in order to study the behavior of i near $\bar t$ we consider a normal partition $t_0=a<t_1<\ldots<t_N=b$, with $t_j<\bar t<t_{j+1}$ for some $j\geqslant 1$ (or $t_j<\bar t\leqslant t_{j+1}$ if $\bar t=b$). Replacing N with $j+1$ in (7), for $t\in]t_j,t_{j+1}[$ we obtain an isomorphism ϕ_t onto the *fixed* space $\Theta=\oplus_{i=1}^j\dot\gamma(t_i)^\perp$; we regard I_t as a family of symmetric bilinear forms on Θ. As we have already observed, the index of I_t on Θ equals $i(t)$; we also observe that I_t depends continuously on t.

Since negativity is an open condition, it follows that $i(t)\geqslant i(\bar t)$ for t near $\bar t$; the monotonicity of i implies then that $i(t)=i(\bar t)$ for $t<\bar t$ near $\bar t$.

If γ is Riemannian or timelike Lorentzian, Lemma II.1 implies that $\dim(\operatorname{Ker}(I_{\bar t}))=\mu^P(\bar t)$. If γ is lightlike Lorentzian, again by Lemma II.1, we see that the subspace $\phi_t(\mathcal{N}\cap\mathcal{H}_J^P)$ of Θ is contained in the kernel of I_t; this space consists of the j-tuples of vectors parallel to $\dot\gamma$, and therefore it does not depend on $t\in]t_j,t_{j+1}[$.

Since positivity is an open condition, then $i(t)\leqslant i(\bar t)+\mu^P(\bar t)$ for $t>\bar t$ near $\bar t$; to conclude the proof we now show the opposite inequality. For, a standard argument that uses Corollary II.3 shows that

$$I_t(\theta,\theta)\leqslant I_{\bar t}(\theta,\theta),\quad \forall t\in]\bar t,t_{j+1}[,\quad \forall\theta\in\Theta,$$

where the inequality is strict if $V=\phi_t^{-1}(\theta)$ is a nonzero P-Jacobi field such that $V(\overline{t})=0$. This concludes the proof. □

We now want to extend the Morse index theorem to the case of two variable endpoints. To this end, we now assume that P and Q are smooth submanifolds of $\mathcal{M}$, and that $\gamma:[a,b]\mapsto\mathcal{M}$ is a geodesic with $\gamma(a)\in P$, $\dot\gamma(a)\in T_{\gamma(a)}P^\perp$, $\gamma(b)\in Q$ and $\dot\gamma(b)\in T_{\gamma(b)}Q^\perp$.

We denote by $\mathcal{H}^{(P,Q)}$ the vector space of all piecewise smooth vector fields V along γ, with $g(V,\dot\gamma)\equiv 0$, $V(a)\in T_{\gamma(a)}P$, and $V(b)\in T_{\gamma(b)}Q$. Moreover, we will consider the symmetric bilinear form $I^{(P,Q)}$ on $\mathcal{H}^{(P,Q)}$, given by

$$I^{(P,Q)}(V,W)=I^P(V,W)+\mathcal{S}^Q_{\dot\gamma(b)}(V(b),W(b)). \tag{9}$$

Let $\mathcal{J}^Q$ denote the subspace of $\mathcal{H}^{(P,Q)}$ consisting of P-Jacobi fields, and let $\mathcal{A}$ be the symmetric bilinear form on $\mathcal{J}^Q$ obtained by the restriction of $I^{(P,Q)}$. Then, it is easily computed from (1) using integration by parts:

$$\mathcal{A}(J_1,J_2)=\mathcal{S}^Q_{\dot\gamma(b)}(J_1(b),J_2(b))+g(J_1'(b),J_2(b)),\quad J_1,J_2\in\mathcal{J}^Q.$$

Moreover, for $t\in[a,b]$, we introduce the space $\mathcal{J}[t]$:

$$\mathcal{J}[t]=\{J(t):J\ \text{ is }\ P\text{-Jacobi}\}\subset T_{\gamma(t)}\mathcal{M};$$

observe that, for $t\in]a,b],\gamma(t)$ is not P-focal if and only if $\mathcal{J}[t]=T_{\gamma(t)}\mathcal{M}$.

We can now state and prove the following extension of the Morse Index Theorem for geodesics between submanifolds:

Theorem II.6: *Let* $(\mathcal{M}, g)$ *be a semi-Riemannian manifold, P, Q submanifolds of* $\mathcal{M}$ and $\gamma:[a,b]\mapsto\mathcal{M}$ *be a geodesic such that* $\gamma(a)\in P$, $\dot\gamma(a)\in T_{\gamma(a)}P^\perp$, $\gamma(b)\in Q$, *and* $\dot\gamma(b)\in T_{\gamma(b)}Q^\perp$. *Assume that* $\mathcal{J}[b]\subseteq T_{\gamma(b)}Q$. *Let* $\mathcal{V}$ *be a subspace of* $\mathcal{H}^{(P,Q)}$ *that contains the space* $\mathcal{J}^Q$ *of P-Jacobi fields along* γ *in* $\mathcal{H}^{(P,Q)}$. *Then,* $\mathrm{ind}(I^{(P,Q)},\mathcal{V})=\mathrm{ind}(I_P,\mathcal{H}_P\cap\mathcal{V})+\mathrm{ind}(\mathcal{A},\mathcal{J}^Q)$.

Proof: The space $\mathcal{H}^P$ is given by the subspace of $\mathcal{H}^{(P,Q)}$ consisting of those vector fields V such that $V(b)=0$; moreover, the restriction of $I^{(P,Q)}$ to $\mathcal{H}^P$ is precisely I^P. Defining $\mathcal{J}_0$ as in formula (4), let $\mathcal{J}_1$ be any subspace of $\mathcal{J}^Q$ such that $\mathcal{J}^Q=\mathcal{J}_0\oplus\mathcal{J}_1$. Clearly, $\mathcal{H}^{(P,Q)}=\mathcal{H}^P\oplus\mathcal{J}_1$, because $\mathcal{J}[b]\supset T_{\gamma(b)}Q$; moreover, from (9) it follows immediately that this decomposition is $I^{(P,Q)}$-orthogonal, i.e., $I^{(P,Q)}(V,J)=0$ for all $V\in\mathcal{H}^P$ and all $J\in\mathcal{J}_1$. Since $\mathcal{V}$ contains $\mathcal{J}_1$, then $\mathcal{V}=(\mathcal{V}\cap\mathcal{H}^P)\oplus\mathcal{J}_1$. Hence, $\mathrm{ind}(I^{(P,Q)},\mathcal{V})=\mathrm{ind}(I^P,\mathcal{H}^P\cap\mathcal{V})+\mathrm{ind}(\mathcal{A},\mathcal{J}_1)$. To conclude the proof, we simply observe that $\mathrm{ind}(\mathcal{A},\mathcal{J}_1)=\mathrm{ind}(\mathcal{A},\mathcal{J})$, because $\mathcal{J}_0\subset\mathrm{Ker}(\mathcal{A})$. □

Remark II.7: If $(\mathcal{M}, g)$ is Riemannian and $\mathcal{V}=\mathcal{H}^{(P,Q)}$, then Theorems II.5 and II.6 give as a particular case the Index Theorem of Ref. 5, p. 342, and the older versions of the Morse Index Theorem presented in Refs. 3 and 4. In Ref. 8 the fact was briefly mentioned that results analogous to the Riemannian case could apply to the Lorentzian timelike case. As to the lightlike case, in Refs. 1, 2, and 8 the authors consider the index of $I^{(P,Q)}$ in the quotient space $\mathcal{H}^{(P,Q)}/\mathcal{N}$ [recall formula (4)]; in this situation, $\mathcal{N}$ is contained in the kernel of $I^{(P,Q)}$. By a simple linear algebra argument one proves that the index of a bilinear form in a quotient space by a subspace of its kernel is the same as the index of the form in the original space. Hence, Theorems II.5 and II.6 generalize the results of Refs. 1, 2, and 8. In Ref. 14 (2.2 Null Index Lemma) the quotient bundle construction had been avoided by taking into consideration only those vector fields along a null geodesic which are orthogonal but never tangential to it.

Remark II.8: The result of Theorem II.6 becomes significant when the subspace $\mathcal{V}$ of $\mathcal{H}^{(P,Q)}$ is chosen in such a way that $\mathrm{ind}(I^P,\mathcal{H}^P\cap\mathcal{V})$ is finite; observe that ind $(\mathcal{A}, \mathcal{J}^Q)$ is always finite. If one considers geodesics in semi-Riemannian manifolds with metric of index greater or equal to 2, or spacelike geodesics in Lorentzian manifolds, then $\mathrm{ind}(I^P,\mathcal{H}^P)$ is in general infinite (see Refs. 9 and 16 for further results in this direction). Nevertheless, the restriction to suitable subspaces may yield the finiteness of the index, and, possibly, weaker versions of the Morse Index Theorem may apply. For instance (see Ref. 17), let us consider the case of a stationary Lorentzian manifold $(\mathcal{M}, g)$, i.e., a Lorentzian manifold endowed with a timelike Killing vector field Y. Let γ be a spacelike geodesic. The Killing vector field Y induces the conservation law $g(\dot\gamma,Y)\equiv C_\gamma$ for all geodesic γ; then, one can consider only variations γ_s of γ such that $g(\dot\gamma_s,Y)\equiv C_s$, and the corresponding variational field $V=(d/ds)|_{s=0}\gamma_s$ belongs to the space

$$\mathcal{V}=\{V:\exists C_V\in\mathbb{R}\quad\text{such that}\quad g(V',Y)-g(V,Y')\equiv C_V\}.$$

It is a simple observation that $\mathcal{V}$ contains all the Jacobi fields along γ; moreover, using the Sobolev Embedding Theorem one proves that the bilinear form I^P is given by a self-adjoint operator T on the closure of $\mathcal{V}\cap\mathcal{H}^P$ in a suitable Sobolev space completion of $\mathcal{H}^P$, where T is a *compact perturbation* of the identity (see Ref. 18). Thus, $\mathcal{V}\cap\mathcal{H}^{(P,Q)}$ satisfies the hypothesis of Theorem II.6 and it is such that $\mathrm{ind}(I^P,\mathcal{V}\cap\mathcal{H}^P)$ is finite. The value of this index has been recently proven to be equal to the sum of the signature of the restriction of g to $T_{\gamma(a)}P$ with the *Maslov* index of γ (see Ref. 19 for details).

Another proof of the triple sum formula for Wigner $9j$-symbols

(Received 5 April 1999; accepted for publication 23 August 1999)

We give a simple proof of the Ališauskas–Jucys triple sum formula for Wigner $9j$-symbols. © *1999 American Institute of Physics.* [S0022-2488(99)00412-0]

In Ref. 1 we gave a new simple proof of the triple sum formula for Wigner $9j$-symbols due to Ališauskas and Jucys.[2] In this note we give an even more simple proof. We will use the notation of Ref. 1. In particular, we will work with the Lie group SU(1, 1) (and its covering groups), though the same proof works in the physically more important case of SU(2).

We will denote the (unnormalized) Racah coefficients or $6j$-symbols by

$$R_{qr}^{tu}(\nu_1,\nu_2,\nu_3)=\langle(((1,1)_q,1)_r,(1,(1,1)_t)_u\rangle_{\mathcal{A}^{\nu_1}\otimes\mathcal{A}^{\nu_2}\otimes\mathcal{A}^{\nu_3}}$$

(where $q+r=t+u$) and use notation such as

$$x_{12}=x_1+x_2,\quad |x|=x_1+\cdots+x_n$$

for a vector $x=(x_1,\dots,x_n)$. As in Ref. 1 we denote Wigner $9j$-symbols by

$$W_{pqr}^{tuv}=W_{pqr}^{tuv}(\nu_1,\nu_2,\nu_3,\nu_4),$$

where $p+q+r=t+u+v=s$. It is not hard to derive the expression

$$W_{pqr}^{tuv}=\sum_{j=0}^{\min(p+r,t+v)}\frac{(-1)^{p+r+j+u}}{C_{p+r-j}^{\nu_2,\nu_{34}+2q}C_j^{\nu_1,\nu_{234}+2s-2j}C_{t+v-j}^{\nu_3,\nu_{24}+2u}}R_{pr}^{p+r-j,j}(\nu_1,\nu_2,\nu_{34}+2q)$$
$$\times R_{q,p+r-j}^{u,t+v-j}(\nu_3,\nu_4,\nu_2)R_{t+v-j,j}^{t,v}(\nu_{24}+2u,\nu_3,\nu_1);\tag{1}$$

in fact this (or rather the corresponding formula for SU(2)) is often taken as the definition of Wigner $9j$-symbols. We will prove the triple sum formula by inserting appropriate single sum expressions for the Racah coefficients and changing the order of summation.

There is a large number of expressions for Racah coefficients as terminating ${}_4F_3$ series, including

$$R_{qr}^{tu}(\nu_1,\nu_2,\nu_3)=(\nu_1)_u(\nu_2)_t(\nu_3)_r(\nu_{12}+q-1)_q(\nu_{23}+r+t)_q(|\nu|+2q+r-1)_r$$
$$\times\frac{r!u!}{(u-q)!}\,{}_4F_3\left(\left.\begin{matrix}-q,1-\nu_1-q,1+r,\nu_3+r\\1+u-q,\nu_{23}+r+t,2-\nu_{12}-2q\end{matrix}\right|1\right)$$
$$=(\nu_1)_u(\nu_2)_q(\nu_2)_t(\nu_3)_s(\nu_{12}+s)_q(|\nu|+2q+r-1)_r$$
$$\times r!\,{}_4F_3\left(\left.\begin{matrix}-q,1-\nu_3-t,\nu_2+t,\nu_{12}+q-1\\\nu_2,1-\nu_3-s,\nu_{12}+s\end{matrix}\right|1\right)$$
$$=(\nu_1)_q(\nu_2)_t(\nu_3)_t(\nu_{12}+q-1)_u(\nu_{23}+2t)_u(|\nu|+2q+r-1)_r$$

[a)]Electronic mail: hjalmar@maths.lth.se

$$\times\frac{(-1)^{q+u}q!t!}{(q-u)!}\,{}_4F_3\left(\left.\begin{matrix}-u,1-\nu_1-u,1+t,\nu_3+t\\ 1+q-u,\nu_{23}+2t,2-\nu_{12}-q-u\end{matrix}\right|1\right),$$

where $q+r=t+u=s$. In the first and third expression we use the ${}_4F_3$ notation somewhat formally; for instance the first ${}_4F_3$ should be interpreted as in

$$\frac{1}{(u-q)!}\,{}_4F_3\left(\left.\begin{matrix}-q,a,b,c\\ 1+u-q,d,e\end{matrix}\right|1\right)=\sum_{k=\max(0,q-u)}^{q}\frac{(-q)_k(a)_k(b)_k(c)_k}{k!(u-q+k)!(d)_k(e)_k},$$

where one may have $u<q$. Inserting these three expressions, in this order, in (1) gives

$$\begin{aligned}W_{pqr}^{tuv}=&\sum_{j=0}^{\min(p+r,t+v)}\frac{(-1)^{q+v}r!t!(\nu_1)_t(\nu_2)_{s-j}(\nu_3)_t(\nu_4)_q(\nu_4)_u(\nu_{12}+p-1)_p(\nu_{13}+2t)_v}{(\nu_{34})_{s-j}(\nu_{234}+2s-2j)_j(\nu_{234}+2u+t+v-j-1)_{t+v-j}}\\&\times(\nu_{34})_{2q+r}(\nu_{234}+2q+2r+p-j)_p(\nu_{234}+2u+t+v-j-1)_v(|\nu|+2p+2q+r-1)_r\\&\times\frac{1}{(j-p)!}\,{}_4F_3\left(\left.\begin{matrix}-p,1-\nu_1-p,1+r,\nu_{34}+2q+r\\ 1+j-p,\nu_{234}+2q+2r+p-j,2-\nu_{12}-2p\end{matrix}\right|1\right)\\&\times{}_4F_3\left(\left.\begin{matrix}-q,1-\nu_2-u,\nu_4+u,\nu_{34}+q-1\\ \nu_4,1-\nu_2-s+j,\nu_{34}+s-j\end{matrix}\right|1\right)\\&\times\frac{1}{(t-j)!}\,{}_4F_3\left(\left.\begin{matrix}-v,1-\nu_{24}-2u-v,1+t,\nu_1+t\\ 1+t-j,\nu_{13}+2t,2-\nu_{234}-2u-t-2v+j\end{matrix}\right|1\right).\end{aligned}$$

By Karlsson's summation formula[3] the second ${}_4F_3$ vanishes if $p+r<j\leqslant t+v$; therefore the condition $j\leqslant p+r$ is superfluous. Let us now expand the ${}_4F_3$ functions and rearrange the terms according to

$$\sum_{j=0}^{t+v}\sum_{k=\max(0,p-j)}^{p}\sum_{l=0}^{q}\sum_{m=\max(0,j-t)}^{v}C_{jklm}=\sum_{\substack{0\leqslant k\leqslant p,0\leqslant l\leqslant q,\\ 0\leqslant m\leqslant v,k+m\geqslant p-t}}\sum_{j=0}^{t-p+k+m}C_{t+m-j,klm}.$$

This gives

$$\begin{aligned}W_{pqr}^{tuv}=&(-1)^{q+v}r!t!(\nu_1)_t(\nu_2)_{u+v}(\nu_3)_t(\nu_4)_q(\nu_4)_u(\nu_{12}+p-1)_p(\nu_{13}+2t)_v(\nu_{34}+q+r)_q\\&\times(|\nu|+2p+2q+r-1)_r\\&\times\sum_{\substack{0\leqslant k\leqslant p,0\leqslant l\leqslant q,\\ 0\leqslant m\leqslant v,k+m\geqslant p-t}}\frac{1}{(\nu_{34}+q+r)_{k+l}(1-\nu_2-u-v)_{l+m}(t-p+k+m)!}\\&\times\frac{(-p)_k(1-\nu_1-p)_k(1+r)_k(\nu_{34}+2q+r)_k}{k!(2-\nu_{12}-2p)_k}\,\frac{(-q)_l(1-\nu_2-u)_l(\nu_4+u)_l(\nu_{34}+q-1)_l}{l!(\nu_4)_l}\\&\times\frac{(-v)_m(1-\nu_{24}-2u-v)_m(1+t)_m(\nu_1+t)_m}{m!(\nu_{13}+2t)_m}\\&\times\frac{(\nu_{34}+u+v+l-m)_{t-p+k+m}}{(\nu_{234}+2s-2t-2m)_{t-p+k+m}}\sum_{j=0}^{t-p+k+m}\frac{\nu_{234}+2s-2t-2m-1+2j}{\nu_{234}+2s-2t-2m-1}\\&\times\frac{(p-t-k-m)_j(\nu_{234}+2s-2t-2m-1)_j(\nu_2+u+v-l-m)_j}{j!(\nu_{34}+u+v+l-m)_j(\nu_{234}+2s-p-t+k-m)_j}\,(-1)^j,\end{aligned}$$

where, by the summation formula[4]

$$\sum_{k=0}^{n} \frac{a+2k}{a} \frac{(-n)_k(a)_k(b)_k}{k!(1+a-b)_k(1+a+n)_k}(-1)^k = {}_4F_3\left(\begin{matrix} a,1+\frac{1}{2}a,b,-n \\ \frac{1}{2}a,1+a-b,1+a+n \end{matrix} \middle| -1 \right) = \frac{(1+a)_n}{(1+a-b)_n},$$

the inner sum equals

$$\frac{(\nu_{234}+2s-2t-2m)_{t-p+k+m}}{(\nu_{34}+u+v+l-m)_{t-p+k+m}}.$$

This leads to the expression

$$\begin{aligned} W_{pqr}^{tuv} &= (-1)^{q+v} r!t!(\nu_1)_t(\nu_2)_{u+v}(\nu_3)_t(\nu_4)_q(\nu_4)_u(\nu_{12}+p-1)_p(\nu_{13}+2t)_v(\nu_{34}+q+r)_q \\ &\quad \times(|\nu|+2p+2q+r-1)_r \\ &\quad \times \sum_{\substack{0\leqslant k\leqslant p, 0\leqslant l\leqslant q, \\ 0\leqslant m\leqslant v, k+m\geqslant p-t}} \frac{1}{(\nu_{34}+q+r)_{k+l}(1-\nu_2-u-v)_{l+m}(t-p+k+m)!} \\ &\quad \times \frac{(-p)_k(1-\nu_1-p)_k(1+r)_k(\nu_{34}+2q+r)_k}{k!(2-\nu_{12}-2p)_k} \frac{(-q)_l(1-\nu_2-u)_l(\nu_4+u)_l(\nu_{34}+q-1)_l}{l!(\nu_4)_l} \\ &\quad \times \frac{(-v)_m(1-\nu_{24}-2u-v)_m(1+t)_m(\nu_1+t)_m}{m!(\nu_{13}+2t)_m} \end{aligned} \tag{2}$$

which is a version of the Ališauskas–Jucys formula.

Finally we remark that Corollary 3.2 of Ref. 1 has previously been obtained (in the case of the group SU(2)) by Masao Nomura.[5] We owe this reference to Sigitas Ališauskas.

Invariance groups of transformations of basic hypergeometric series

J. Van der Jeugt[a)]
Department of Applied Mathematics and Computer Science, University of Ghent, Krijgslaan 281-S9, B-9000 Gent, Belgium

K. Srinivasa Rao
Institute of Mathematical Sciences, CIT Campus, Madras 600113, India

(Received 26 April 1999; accepted for publication 31 August 1999)

We show that certain two-term transformation formulas between basic hypergeometric series can easily be described by means of invariance groups. For the transformations of nonterminating ${}_3\phi_2$ series, and those of terminating balanced ${}_4\phi_3$ series, these invariance groups are symmetric groups. For transformations of ${}_2\phi_1$ series the invariance group is the dihedral group of order 12. Transformations of terminating ${}_3\phi_2$ series are described by means of some subgroup of S_6, and finally the invariance group of transformations of very-well-poised nonterminating ${}_8\phi_7$ series is shown to be isomorphic to the Weyl group of a root system of type D_5.
 [S0022-2488(99)00512-5]

I. INTRODUCTION

This article deals with two-term transformation formulas for basic hypergeometric series. Our aim is to identify the (finite) invariance group structures underlying known transformation formulas. Examining these invariance groups is not only an interesting problem by itself but it enables a whole list of (known) transformation formulas to be summarized as elegant one-line statements!

Anyone working with (basic) hypergeometric series is bound to encounter sooner or later transformation formulas which express a series into another. A summary of the most commonly used transformation formulas can be found in Appendix III of Gasper and Rahman.[1] A required, specific transformation formula, not listed in this appendix, can be derived by iterative use of one or more of the given transformation formulas. This can be done by hand, or even simpler by a computer algebra package such as HYP or HYPQ that performs these transformations consecutively.[2] This process of iteration is not new. Already in 1923 Whipple[3] showed that by iterating Thomae's ${}_3F_2$ transformation formula, one obtains a set of 120 such series, and he tabulated the parameters of these 120 series. He did not, however, recognize any group structure behind these 120 series. In some way, this group comes naturally into the picture, once a transformation formula between two (basic) hypergeometric series is translated into a linear transformation between the set of parameters (and/or variables) of the two series. The application of two transformation formulas then translates into the composition (or product) of two linear transformations, and this is how a group structure emerges, (see, for example, Refs. 4 and 5). This group is then called the invariance group of the transformations of (basic) hypergeometric series.

For the transformations of nonterminating ${}_3\phi_2$ series, and those of terminating balanced ${}_4\phi_3$ series, it is established in Sec. II that the invariance groups are the symmetric groups, S_5 and S_6, respectively. This result is not surprising, and essentially the same as in the classical case of the transformations of the (ordinary) hypergeometric series of unit argument, ${}_3F_2(1)$ and ${}_4F_3(1)$, respectively.[4] Our aim in proving these results is twofold: that the results can be established

[a)]Research Associate of the Fund for Scientific Research—Flanders (Belgium). Electronic mail: Joris.VanderJeugt @rug.ac.be simply, *à la* Hardy,[6] and, more importantly, they pave the way for a study of other cases. In Sec. III, Heine's transformations for ${}_2\phi_1$ series are considered, and it is shown that the invariance group is the dihedral group of order 12, D_{12}. Next, transformations of terminating ${}_3\phi_2$ series are considered. The invariance group is a nonsimple group of order 72, which can be described in terms of extended symmetries of the hexagon. Finally, in Sec. V it is established that the invariance group of transformations of very-well-poised nonterminating ${}_8\phi_7$ series is WD_5, a group of signed permutations isomorphic to the Weyl group of a root system of type D_5.

Apart from the mathematical interest, our motivation for studying these invariance groups also stems from a number of examples illustrating the usefulness of the transformations of the ordinary and basic hypergeometric series in physics and quantum groups. Louck *et al.* used the invariance group related to the ${}_4F_3(1)$ series to discuss the symmetries of extended 6-j coefficients.[6,7] Rajeswari and Srinivasa Rao used Thomae transformations of the ${}_3F_2(1)$ to derive the well-known Wigner, Racah, and Majumdar forms of the 3-j angular momentum coefficient[8] of quantum mechanics from the Van der Waerden form. They also derived the q analog of the Van der Waerden form of the 3-j coefficient and the q analogs of the aforesaid Wigner, Racah, and Majumdar forms of the 3-j coefficient.[9] They showed[10] that the transformation theory for basic hypergeometric functions, ${}_3\phi_2$, provides the necessary framework to relate the explicit forms for the Clebsch–Gordan coefficient of the quantum group $\mathrm{SU}_q(2)$.

We end this Introduction by fixing some notation. For (basic) hypergeometric series, our notation is the standard one of Ref. 1. Throughout the paper, the base q satisfies $|q|<1$. The q-shifted factorial is

$$(a;q)_n=\begin{cases}1, & n=0,\\ \prod_{k=0}^{n-1}(1-aq^k), & n=1,2,...,\infty,\end{cases}$$

and $(a_1,\ldots,a_m;q)_n=(a_1;q)_n\cdots(a_m;q)_n$. The basic hypergeometric series appearing here are

$${}_{r+1}\phi_r\left[\begin{matrix}a_1,a_2,\ldots,a_{r+1}\\ b_1,b_2,\ldots,b_r\end{matrix};q,z\right]=\sum_{k=0}^{\infty}\frac{(a_1,a_2,\ldots,a_{r+1};q)_k}{(q,b_1,b_2,\ldots,b_r;q)_k}z^k,$$

and for $r=1$ we shall usually write ${}_2\phi_1(a_1,a_2;b_1;q,z)$.

It is also useful to establish some notation about permutations here. A permutation on n elements can be denoted by its cycle structure (see, e.g., Ref. 11, Chap. 1). For example, the permutation $p\in S_5$ with $p(1)=2$, $p(2)=3$, $p(3)=1$, $p(4)=5$, $p(5)=4$ is simply denoted by (123) (45). For the action of p on an array of n symbols, we use by abuse of notation again p; thus for the above example,

$$p\cdot(x_1,x_2,x_3,x_4,x_5)=p\cdot x=(x_2,x_3,x_1,x_5,x_4).$$

With a permutation, an $n\times n$ monomial matrix (this is a matrix with exactly one nonzero element in every row and column) is associated with nonzero entries equal to 1. For the above example, this matrix is

$$\begin{pmatrix}0&1&0&0&0\\0&0&1&0&0\\1&0&0&0&0\\0&0&0&0&1\\0&0&0&1&0\end{pmatrix};$$

the action $p\cdot x$ can then be interpreted as a multiplication of this permutation matrix with a column vector x. We will also encounter ''signed permutations;'' here the nonzero entries of the monomial matrices are ± 1. If, for example, the matrix of a signed permutation p is given by

$$\begin{pmatrix} 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & -1 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & -1 \\ 0 & 0 & 0 & 1 & 0 \end{pmatrix},$$

then we define its action on an array of n variables by

$$p\cdot(x_1,x_2,x_3,x_4,x_5)=p\cdot x=\left(x_2,\frac{1}{x_3},x_1,\frac{1}{x_5},x_4\right).$$

II. TRANSFORMATIONS OF NONTERMINATING ${}_3\phi_2$ SERIES, AND SEARS' TRANSFORMATIONS OF TERMINATING BALANCED ${}_4\phi_3$ SERIES

Thomae[12] obtained a number of transformations for hypergeometric series of type ${}_3F_2$ with unit argument (see also Ref. 13, Sec. 3.2) through the calculus of finite differences. Whipple[3] introduced a new notation in order to simplify the numerous formulas obtained by Thomae, and showed there are 120 such series related to each other. Still, it was not recognized that an invariance group (the symmetric group S_5) can describe all these relations. To our knowledge, the existence of such an invariance group was first stated by Hardy (Ref. 14, footnote on p. 111). Being unaware of Hardy's result, this property was later rediscovered by Beyer *et al.*.[4]

Here, the q analogs of Thomae's transformations are considered. These transformations were derived by Sears (Ref. 15, Sec. 10), and two of them are given by (III.9) and (III. 10) of Ref. 1. It is easy to show that for these transformations of nonterminating ${}_3\phi_2$ series, the invariance group is S_5.

Proposition 1: The function

$$f(x)=f(x_1,x_2,x_3,x_4,x_5)=\left(\frac{x_1x_2x_3}{x_4x_5},x_4^2,x_5^2;q\right)_\infty \times {}_3\phi_2\left[\begin{matrix}\frac{x_1}{x_2x_3}x_4x_5,\frac{x_2}{x_1x_3}x_4x_5,\frac{x_3}{x_1x_2}x_4x_5\\ x_4^2,x_5^2\end{matrix};q,\frac{x_1x_2x_3}{x_4x_5}\right] \tag{1}$$

is symmetric in the variables (x_1,x_2,x_3,x_4,x_5).

Proof: Clearly, $f(x)$ is invariant under permutations of (x_1,x_2,x_3) [resp. (x_4,x_5)], since these do not change the factor in front of the ${}_3\phi_2$, and on the ${}_3\phi_2$ they have the effect of permuting numerator (resp. denominator) parameters. Next, consider the permutation $p=(14325)$ (in cycle notation: $x_1\to x_4\to x_3\to x_2\to x_5\to x_1$), which is a permutation of order 5. Upon relabeling the parameters of the ${}_3\phi_2$ in $f(x)$ by

$${}_3\phi_2\left[\begin{matrix}a,b,c\\ d,e\end{matrix};q,\frac{de}{abc}\right],$$

it is easy to see that equation (III.10) of Ref. 1 is equivalent to $f(x)=f(p\cdot x)$. So $f(x)$ is invariant under the permutation p, and under the transposition $x_4\leftrightarrow x_5$. However, since p is a permutation of order 5, the group generated by p and this transposition is the complete group of permutations on five elements (see, for example, Ref. 16, p. 5), i.e., the symmetric group S_5. □

For convergence of all the 120 series in (1) it is sufficient that all x_i satisfy $\alpha^{3/2}<|x_i|<\alpha$, with $\alpha<1$ a positive real number.

Next, we consider transformations of terminating balanced ${}_4\phi_3$ series. This is the q-analog of Bailey's transformations for terminating Saalschützian hypergeometric series of type ${}_4F_3$ with unit argument [Ref. 13, Sec. 7.2(1)]. All 720 transformations of this type were already obtained by Bailey (Ref. 13, Chap. VII), and the fact that the invariance group for these transformations is the symmetric group S_6 was established by Beyer *et al.*[4] For the corresponding basic series, the essential transformation was first given by Sears [Ref. 15, (8.3)] [see also (III.15) and (III.16) of Ref. 1]. Here again, it is not difficult to show that also for these transformations of terminating balanced ${}_4\phi_3$ series, the invariance group is the symmetric group S_6.

Proposition 2: Let $x_1,\ldots,x_6$ be six parameters satisfying

$$x_1x_2x_3x_4x_5x_6=q^{1-n} \tag{2}$$

for some non-negative integer n. Then the function

$$f(x)=f(x_1,x_2,x_3,x_4,x_5,x_6)=q^{\binom{n}{2}}(x_1x_2x_3x_4,x_1x_2x_3x_5,x_1x_2x_3x_6;q)_n/(x_1x_2x_3)^n$$
$$\times{}_4\phi_3\left[\begin{matrix}q^{-n},x_2x_3,x_1x_3,x_1x_2\\ x_1x_2x_3x_4,x_1x_2x_3x_5,x_1x_2x_3x_6\end{matrix};q,q\right] \tag{3}$$

is symmetric in the variables $(x_1,x_2,x_3,x_4,x_5,x_6)$.

Proof: Again $f(x)$ is obviously invariant under permutations of (x_1,x_2,x_3) [resp. (x_4,x_5,x_6)]. Next, consider the cyclic permutation $p=(164253)$, which is a permutation of order 6. Upon relabeling the parameters of the ${}_4\phi_3$ in $f(x)$ by

$${}_4\phi_3\left[\begin{matrix}q^{-n},a,b,c\\ d,e,f\end{matrix};q,q\right],$$

it is easy to see that equation (III.16) of Ref. 1 is equivalent to $f(x)=f(p\cdot x)$. A similar argument as in the previous proof then implies the current proposition, i.e., the invariance group is S_6. □

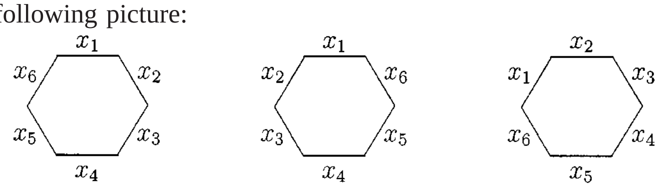
Note that in this context equation (III.15) of Ref. 1 corresponds to $f(x)=f(p\cdot x)$ with $p=(14)(23)(56)$.

III. HEINE'S TRANSFORMATIONS OF ${}_2\phi_1$ SERIES

Heine[17] showed that

$${}_2\phi_1(a,b;c;q,z)=\frac{(a,bz;q)_\infty}{(c,z;q)_\infty}\,{}_2\phi_1(c/a,z;bz;q,a); \tag{4}$$

see [Ref. 1, (III.1)–(III.3)] for this and similar transformations. In (4), $|z|<1$ and $|a|<1$ is required for convergence. When iterating this transformation, using the symmetry of the numerator parameters of the ${}_2\phi_1$, a set of 12 transformation formulas is obtained. This observation is not new, and can already be found in Ref. 15, Sec. 11. However, the identification of the invariance group behind these 12 transformations has never been made. Here, we shall show that the invariance group is the dihedral group D_{12} (sometimes also denoted by D_6), i.e., the group of symmetries of the hexagon. In terms of a hexagon with sides labeled $x_1,\ldots,x_6$, the group consists of all rotations and reflections that map the hexagon into itself. The hexagon and two of its symmetries are shown in the following picture:



(5)

The second hexagon is obtained from the first one by a reflection about the vertical axis; the third one is obtained from the first one by a rotation through angle $\pi/3$. In all, there are 12 such symmetries. The group D_{12}, a subgroup of S_6, is generated by the two elements described above.

Proposition 3: The function

$$f(x)=f(x_1,x_2,x_3,x_4,x_5)=\left(x_1x_4,\frac{x_2x_6}{x_1};q\right)_\infty {}_2\phi_1\left(\frac{x_1x_3}{x_2},\frac{x_1x_5}{x_6};x_1x_4;q,\frac{x_2x_6}{x_1}\right) \tag{6}$$

is invariant under the dihedral group D_{12} acting on the variables $(x_1,x_2,x_3,x_4,x_5,x_6)$.

Proof: It is clear that the only effect of the permutation (26)(35) (in cycle notation), i.e., $x_2\leftrightarrow x_6$ and $x_3\leftrightarrow x_5$, on (6) is a transposition of the two numerator parameters in the ${}_2\phi_1$. Next, consider the permutation (123456), or explicitly

$$p\cdot(x_1,x_2,x_3,x_4,x_5,x_6)=(x_2,x_3,x_4,x_5,x_6,x_1). \tag{7}$$

Upon relabeling the parameters of the ${}_2\phi_1$ in $f(x)$ by ${}_2\phi_1(a,b;c;q,z)$, it is easy to see that (4) is equivalent to $f(x)=f(p\cdot x)$. The two permutations considered here correspond to the two symmetries of the hexagon described in (5), and they form a set of generators for the group D_{12}. □

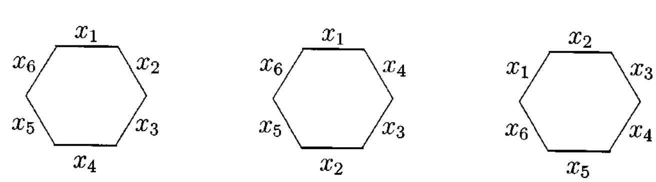
For convergence of all the 12 series in (6) it is sufficient that all x_i satisfy $\alpha^2<|x_i|<\alpha$, with $\alpha<1$ a positive real number.

IV. TRANSFORMATIONS OF TERMINATING ${}_3\phi_2$ SERIES

Whipple[3] not only showed that there are 120 nonterminating ${}_3F_2$ series of unit argument, he also established that there are 72 terminating ${}_3F_2(1)$ series (see also Ref. 13, §3.9). In Ref. 5 the 72-element group associated with these series transformations was examined. The q-analogs of these transformation formulas were given by Sears.[15] The essential transformations are summarized in Ref. 1, (III.11)–(III.13), and others can be obtained from these by iteration. For example, from (III.11) and (III.13) one can deduce that

$${}_3\phi_2\left[\begin{matrix}q^{-n},b,c\\ d,e\end{matrix};q,q\right]=\frac{(c,de/bc;q)_n}{(d,e;q)_n}(b)^n{}_3\phi_2\left[\begin{matrix}q^{-n},d/c,e/c\\ de/bc,q^{1-n}/c\end{matrix};q,\frac{q}{b}\right]. \tag{8}$$

In the present case the group G associated with the transformations is somewhat more difficult to describe. By Cayley's and Lagrange's theorems,[18] it is obvious that the 72-element group G cannot be a subgroup of S_5 (since 72 is not a factor of 120), but it is a subgroup of S_6 generated by the two elements (24) and (123456). One way to see that the subgroup generated by these two elements has order 72 is by extending the 12 classical symmetries of the hexagon described in the previous section. The new transformations that are allowed on the hexagon are the interchange of two sides that are next to nearest neighbors, such as $x_1\leftrightarrow x_3$, $x_2\leftrightarrow x_4$, $x_3\leftrightarrow x_5$, etc. Superposed on the 12 classical symmetries, this enlarges the total number of allowed transformations to $12\times6=72$. The two generating elements of G, (24) and (123456), are described by the second and third hexagons in the following picture:



Another way to describe the elements of G is by calling x_2, x_4, and x_6 the even labels (or even sides), and x_1, x_3, and x_5 the odd labels (or odd sides) of the hexagon. Then the elements of G consist of the symmetries of the hexagon on which permutations of even labels (resp. odd labels) are superposed. As a consequence, G has a subgroup H consisting of permutations of (x_1,x_3,x_5) and of (x_2,x_4,x_6). Thus H is isomorphic to $S_3\times S_3$ and its order is 36.

The description of the invariance itself is also slightly more complicated in this case, mainly because the argument z of the ${}_3\phi_2$ is equal to q only in 36 cases, and different from q in the other 36 cases.

Proposition 4: Let $x_1,\dots,x_6$ be six parameters satisfying

$$x_1x_2x_3x_4x_5x_6=q^{1-n} \tag{10}$$

for some non-negative integer n. Consider the functions

$$\begin{aligned} f_0(x)&=f_0(x_1,x_2,x_3,x_4,x_5,x_6)\\ &=(x_1x_2x_3x_4,x_1x_2x_4x_5;q)_n/(x_1x_2x_4)^n\,{}_3\phi_2\left[\begin{matrix} q^{-n},x_1x_2,x_1x_4\\ x_1x_2x_3x_4,x_1x_2x_4x_5\end{matrix};q,q\right], \end{aligned} \tag{11}$$

$$\begin{aligned} f_1(x)&=f_1(x_1,x_2,x_3,x_4,x_5,x_6)\\ &=(-1)^nq^{\binom{n}{2}}(x_1x_2x_3x_4,x_1x_2x_4x_5;q)_n(x_6)^n\,{}_3\phi_2\left[\begin{matrix} q^{-n},x_1x_2,x_1x_4\\ x_1x_2x_3x_4,x_1x_2x_4x_5\end{matrix};q,\frac{q}{x_1x_6}\right]. \end{aligned} \tag{12}$$

Then $f_i(x)=f_i(p\cdot x)$ if $p\in H(i=0,1)$, and $f_0(x)=f_1(p\cdot x)$ (or $f_1(x)=f_0(p\cdot x)$) if $p\in G-H$.

Proof: The permutation (24) (in cycle notation) only transposes two of the numerator parameters in the ${}_3\phi_2$ of $f_0(x)$ or $f_1(x)$. Next, consider the permutation (123456), or explicitly

$$p\cdot(x_1,x_2,x_3,x_4,x_5,x_6)=(x_2,x_3,x_4,x_5,x_6,x_1). \tag{13}$$

This is an element of $G-H$, and it is straightforward to verify that (8) is equivalent to $f_0(x)=f_1(p\cdot x)$. The two permutations considered here generate G, hence G is the invariance group of the terminating ${}_3\phi_2$ series transformations. □

Consider the permutations (in cycle notation) $p_1=(13)(24)$ and $p_2=(1432)(56)$. Thus $p_1\in H$ and $p_2\in G-H$. As an extra verification, one can check that (III.11), (III.12), and (III.13) of Ref. 1 correspond to $f_0(x)=f_0(p_1\cdot x)$, $f_0(x)=f_1(p_2\cdot x)$, and $f_1(x)=f_0(p_2\cdot x)$, respectively.

V. TRANSFORMATIONS OF VERY-WELL-POISED ${}_8\phi_7$ SERIES

The last type of transformation considered here is for very-well-poised ${}_8\phi_7$ series. These transformations can be obtained as a limiting case of Bailey's terminating ${}_{10}\phi_9$ series transformations[19] [see also Ref. 1, (III.23) and (III.24)]. Such transformations are the q-analog of transformations of ''unrestricted well-poised ${}_7F_6$ series'' of unit argument (see Ref. 13, Sec. 7.5).

For our purposes, we define

$$\begin{aligned} &w(a;b,c,d,e,f)\\ &=\frac{(aq/b,aq/c,aq/d,aq/e,aq/f,a^2q^2/bcdef;q)_\infty}{(aq;q)_\infty}\\ &\times{}_8\phi_7\left[\begin{matrix} a, & q\sqrt{a}, & -q\sqrt{a}, & b, & c, & d, & e, & f\\ & \sqrt{a}, & -\sqrt{a}, & aq/b, & aq/c, & aq/d, & aq/e, & aq/f\end{matrix};q,\frac{a^2q^2}{bcdef}\right]. \end{aligned} \tag{14}$$

Clearly, w is invariant under permutations of (b,c,d,e,f), and hence S_5 is going to be a subgroup of the invariance group. In order to find the complete invariance group, we make again a relabelling as follows:

$$f(x_0,x_1,x_2,x_3,x_4,x_5)=w\left(x_0^3x_1x_2x_3x_4x_5/q;\frac{x_0x_2x_3x_4x_5}{x_1},\frac{x_0x_1x_3x_4x_5}{x_2},\right.$$
$$\left.\times\frac{x_0x_1x_2x_4x_5}{x_3},\frac{x_0x_1x_2x_3x_5}{x_4},\frac{x_0x_1x_2x_3x_4}{x_5}\right). \tag{15}$$

Thus permutations of (b,c,d,e,f) in w correspond to permutations of (x_1,x_2,x_3,x_4,x_5) in f. On examining the transformations given in Ref. 1, one finds that (III.23) is equivalent to

$$f(x_0,x_1,x_2,x_3,x_4,x_5)=f(x_0,x_1,x_2,x_3,1/x_5,1/x_4), \tag{16}$$

and that (III.24) is equivalent to

$$f(x_0,x_1,x_2,x_3,x_4,x_5)=f(x_0,1/x_2,1/x_3,1/x_4,1/x_5,x_1). \tag{17}$$

This implies that the invariance group will be a subgroup of the group WB_5 of signed permutations on five letters. In general, the group WB_n of signed permutations on n letters is the semidirect product of the symmetric group S_n operating as permutations on a standard basis e_i and $(\mathbf{Z}_2)^n$ operating as $e_i\rightarrow\pm e_i$, so its order is $n!2^n$. WB_n can also be seen as the group of $n\times n$ signed permutation matrices [cf. Sec. I, also for the action of such a signed permutation on the array (x_1,x_2,x_3,x_4,x_5)]. Since the invariance group is generated by the elements of S_5 and the elements corresponding to (16) and (17), we are dealing with a subgroup WD_5 of WB_5 consisting of those elements with an even number of (-1)'s in their matrix representation. Therefore the order of G is $5!2^4=1920$. We have used the notation WB_n and WD_n because WB_n is the Weyl group of a root system of type B_n (or C_n), and WD_n is the Weyl group of a root system of type D_n (see, e.g., Ref. 20).

Thus we have the following result:

Proposition 5: The function $f(x_0,x)=f(x_0,x_1,x_2,x_3,x_4,x_5)$ *satisfies* $f(x_0,x)=f(x_0,p\cdot x)$ *for every element p of* WB_5 *that has an even number of minus signs in its matrix representation. Hence the invariance group of the very-well-poised* ${}_8\phi_7$ *transformations is the group* WD_5.

For convergence of all the 1920 series it is sufficient that all $x_i (i=1,...,5)$ satisfy $1/\alpha<|x_i|<\alpha$ and $|x_0|<1/\alpha^5$ for some real number $\alpha>1$.

VI. SUMMARY AND REMARKS

The seminal remark of Hardy in his *Notes on Lecture VII*:[14]

''Formula (7.3.3) is equivalent to (1), §3.2, of Bailey's tract. It is an expression of the theorem that

$$\frac{1}{\Gamma(\beta_1)\Gamma(\beta_2)\Gamma(\beta_1+\beta_2-\alpha_1-\alpha_2-\alpha_3)}F\begin{pmatrix}\alpha_1,\alpha_2,\alpha_3\\ \beta_1,\beta_2\end{pmatrix}$$

is a symmetric function of the five arguments

$$\beta_1,\beta_2,\beta_1+\beta_2-\alpha_2-\alpha_3,\quad \beta_1+\beta_2-\alpha_3-\alpha_1,\quad \beta_1+\beta_2-\alpha_1-\alpha_2\text{''}$$

clearly implies a group theoretical interpretation for formula (7.3.3), which is a ${}_3F_2(1)$ transformation of Thomae:[12]

$$\frac{\Gamma(x+y+s+1)}{\Gamma(x+s+1)\Gamma(y+s+1)}F\begin{pmatrix}-a,-b,x+y+s+1\\ x+s+1,y+s+1\end{pmatrix}$$
$$=\frac{\Gamma(a+b+s+1)}{\Gamma(a+s+1)\Gamma(b+s+1)}F\begin{pmatrix}-x,-y,a+b+s+1\\ a+s+1,b+s+1\end{pmatrix}.$$

Forty-seven years later, Beyer *et al.*[4] rediscovered that Thomae's identity between two ${}_3F_2(1)$ hypergeometric series of unit argument, together with the trivial invariance under separate permutations of the numerator and denominator parameters, implies the symmetry group S_5 is an invariance group of this series. They also showed that Bailey's identity for Saalschützian ${}_4F_3(1)$ series has S_6 as its invariance group. Srinivasa Rao *et al.*[5] studied the group theory of terminating ${}_3F_2(1)$ series—a case not considered by Beyer *et al.*[4]—and found all the invariant subgroups of the 72-element group.

In this article, taking the cue from Hardy's remark, the group theoretical basis of well-known basic hypergeometric transformations has been studied, for the first time. We have constructed explicit functions $f(x)$, where x is a multi-dimensional parameter, expressed in terms of a basic hypergeometric series for the given transformation, and established the appropriate symmetry group. The transformations are then given by

$$f(x)=f(p\cdot x), \tag{18}$$

where p is any element of the symmetry group. The constructed functions (1), (3), and (6) together with (18) are succinct, quintessential one-line statements for Sears' nonterminating ${}_3\phi_2$, Sears' terminating balanced ${}_4\phi_3$, and Heine's ${}_2\phi_1$ transformations of basic hypergeometric series, respectively, which have as their corresponding invariance groups the symmetric groups S_5, S_6 and the dihedral group D_{12}.

In the case of the Sears' terminating ${}_3\phi_2$ transformations, the 72-element invariance group G (being a subgroup of S_6), a 36-element subgroup H of G, and two functions (instead of one) $f_0(x)$ and $f_1(x)$ were necessary to give a complete description. In terms of these all the transformations were generated by

$$f_i(x)=f_j(p\cdot x), \quad i,j=0,1,$$

where $i=j$ if $p\in H$ and $i\neq j$ if $p\in G-H$.

Finally, in the case of transformations of very-well-poised ${}_8\phi_7$ series, though the constructed function $f(x)$ is a function of six parameters, the invariance group is a subgroup WD_5 of WB_5, which is the Weyl group of a root system of type B_n (or, equivalently, the group of $n\times n$ signed permutation matrices).

Kählerian supermanifolds

S. Varsaie
Department of Mathematics, University of Tehran, Tehran, Iran

(Received 12 August 1998; accepted for publication 27 July 1999)

In this paper the concepts of almost Hermitian and Kählerian supermanifolds are introduced. Using the classical Newlander–Nirenberg theorm, it is shown that an almost complex structure J is integrable if it is compatible with Δ_L, the supermanifold analog of the Levi-Civita connection. It is proved that an almost Hermitian supermanifold is Kählerian if and only if Δ_L is compatible with J. [S0022-2488(99)00211-X]

I. INTRODUCTION

The concepts of differential geometry on a smooth manifold are based on the sheaf of germs of functions which is a sheaf of commutative algebras. Most of these concepts can be extended to a supermanifold which is a manifold and a sheaf of $\mathbb{Z}_2$-graded commutative algebras with certain local conditions. Although a unified theory of strong, weak, electromagnetic and gravitational intraction can be constructed in the language of supermanifolds (see Ref. 1, and references therein), from a purely mathematical point of view there exists certain open questions on the theory of supermanifolds. A main problem is that the natural definition of characteristic classes does not provide new invariants and this may be due to the lack of a suitable (co)homology theory which carries the new invariants (see the Introduction to Ref. 2). In commutative geometry, it is known that the space of harmonic forms represents cohomology groups. Therefore, it is natural to expect that an appropriate harmonicity for pseudodifferential forms can be related with a new cohomology theory.[3] As a first step in this direction, we introduce the concept of almost Hermitian supermanifolds. This leads to a new proof of integrability of an almost complex structure on almost Hermitian supermanifolds (see Theorem 4.4). Using this result a necessary and sufficient condition that an almost Hermitian supermanifold be Kählerian is obtained.

II. PRELIMINARIES

Let $\mathcal{A}$ be a sheaf of $\mathbb{Z}_2$-graded commutative (i.e., supercommutative) rings on a topological space M. Thus $\mathcal{A}=\mathcal{A}_0\oplus\mathcal{A}_1$ with $\mathcal{A}_i\mathcal{A}_j\subset\mathcal{A}_{(i+j)\text{mod }2}$, and on each open set U for $a\in\mathcal{A}_i(U)$, $b\in\mathcal{A}_j(U)$, we have $ab=(-1)^{ij}ba$. The index i is called the parity of a and is denoted by $\tilde{a}$. The pair $(M, \mathcal{A})$ is called a supercommutative ringed space.

A morphism of supercommutative ringed spaces $(M, \mathcal{A})$ to $(N, \mathcal{B})$ is a pair (τ, φ) of a continuous map $\tau:M\to N$ and a morphism $\varphi:\mathcal{B}\to\tau_*\mathcal{A}$ of sheaves of $\mathbb{Z}_2$-graded commutative rings on N.

A complex (real) supermanifold of dimension (m, n) is a supercommutative ringed space $(M, \mathcal{A})$ such that:

(i) $(M, \mathcal{A}/\mathcal{N})$ is an m-dimensional complex (respectively, real) manifold, where $\mathcal{N}$ is the sheaf of nilpotents of $\mathcal{A}$.
(ii) $\mathcal{E}=\mathcal{N}/\mathcal{N}^2$ is a locally free $\mathcal{A}/\mathcal{N}$-module of finite rank n.
(iii) $\mathcal{A}$ is locally isomorphic to the Grassman algebra $\wedge\mathcal{E}$.

Any open set U on which the ringed spaces in (iii) are isomorphic is said to be a splitting neighborhood. Let $x^1,\ldots,x^m$ be a system of coordinates of M on U and let $e^1,\ldots,e^n$ be a basis for the sections of $\mathcal{E}$ on U. The x^i's are called the even coordinates, and e^j's are called the odd coordinates. According to (i), $\mathcal{A}/\mathcal{N}$ will be denoted by $\mathcal{O}(M)$ in the complex case and by $C^\infty(M)$ in the real case in the sequel.

Let $\mathrm{Der}\,\mathcal{A}$ be the sheaf of derivations on $\mathcal{A}$. This is a $\mathbb{Z}_2$-graded $\mathcal{A}$-module and $\mathrm{Der}\,\mathcal{A} = (\mathrm{Der}\,\mathcal{A})_0 \oplus (\mathrm{Der}\,\mathcal{A})_1$. If (x^i, e^j) is a system of coordinates of $(M, \mathcal{A})$ on U, then $\mathrm{Der}\,\mathcal{A}$ is a free $\wedge\mathcal{E}$-module with basis $\{\partial/\partial x^i, \partial/\partial e^j\}$.

An almost complex structure on the real supermanifold $(M, \mathcal{A})$ is an even automorphism J on $\mathrm{Der}\,\mathcal{A}$ such that $J^2 = -1$. On the underlying real supermanifold of a complex supermanifold, there exists a natural almost complex structure (Ref. 4, step 1). Let (z^i, u^j) be a system of coordinates on the complex supermanifold $(M, \mathcal{A})$. With $z^i = x^i + \sqrt{-1}y^i$ and $u^j = v^j + \sqrt{-1}w^j$, let

$$J\left(\frac{\partial}{\partial x^i}\right) = \frac{\partial}{\partial y^i}, \quad J\left(\frac{\partial}{\partial y^i}\right) = -\frac{\partial}{\partial x^i},$$
$$J\left(\frac{\partial}{\partial v^j}\right) = \frac{\partial}{\partial w^j}, \quad J\left(\frac{\partial}{\partial w^j}\right) = -\frac{\partial}{\partial v^j}. \tag{1}$$

Obviously, J is an almost complex structure.

III. ALMOST HERMITIAN SUPERMANIFOLDS

In this section, the concept of a (Riemannian) supermetric is introduced. Due to the $\mathbb{Z}_2$-graded structure and hence the existence of zero divisors, in contrast with the commutative case, a supermetric cannot be commutative and positive definite. Instead, some other substitute conditions will be imposed.

Definition 3.1: By a supermetric on a real supermanifold $(M, \mathcal{A})$ we mean an $\mathcal{A}$-linear even map $g:\mathrm{Der}\,\mathcal{A}\otimes_{\mathcal{A}}\mathrm{Der}\,\mathcal{A}\to\mathcal{A}$ such that:

(i) $g(X\otimes Y) = (-1)^{\tilde{X}\tilde{Y}} g(Y\otimes X)$,
(ii) g induces a Riemannian metric on M, i.e., the map g_M with $g_M(\partial/\partial x^i, \partial/\partial x^k) = g(\partial/\partial x^i \otimes \partial/\partial x^k) \bmod \mathcal{N}$ is a Riemannian metric,
(iii) g induces a symplectic form on $\mathcal{E}$, i.e., the map $g_{\mathcal{E}}$ with $g_{\mathcal{E}}(e^j, e^l) = g(\partial/\partial e^j \otimes \partial/\partial e^l) \bmod \mathcal{N}$, is a symplectic form.

Definition 3.2: Let $(M, \mathcal{A})$ be a real supermanifold and let J be an almost complex structure on $(M, \mathcal{A})$. A supermetric g on $(M, \mathcal{A})$ is called a Hermitian supermetric if $g(JX\otimes JY) = g(X\otimes Y)$ for every $X, Y \in \mathrm{Der}\,\mathcal{A}$. Under these circumstances, $(M, \mathcal{A})$ is called an almost Hermitian supermanifold.

As in commutative case, any Hermitian supermetric g can be extended on $\mathrm{Der}\,\mathcal{A}\otimes\mathbb{C}$. Since J preserves g, on any splitting neighborhood U, g can be written as

$$g = dz^i d\overline{z}^k g_{ik} + dz^i d\overline{u}^j t_{ij} + du^j d\overline{z}^k s_{jk} + du^j d\overline{u}^l h_{jl}, \tag{2}$$

where $dz^i = dx^i + \sqrt{-1}J^*(dx^i)$, $du^j = de^j + \sqrt{-1}J^*(de^j)$ and $d\overline{z}^i$, $d\overline{u}^j$ are their conjugations, respectively, and (x^i, e^j) is a coordinate system on U and J^* is the automorphism induced by J on the dual of $\mathrm{Der}\,\mathcal{A}$.

Obviously every complex supermanifold admits a Hermitian supermetric. More precisely, by the existence of partition of unity for supermanifolds, it is sufficient to find a Hermitian supermetric locally. Let U be a spilitting neighborhood of a complex supermanifold $(M, \mathcal{A})$. If $z^i = x^i + \sqrt{-1}y^i$, $u^j = v^j + \sqrt{-1}w^j$ are coordinates on U then $J^*(dx^i) = dy^i$, $J^*(dv^j) = dw^j$, where J is the natural almost complex structure on the underlying real supermanifold of $(M, \mathcal{A})$ defined by (1). Thus $dz^i = dx^i + \sqrt{-1}dy^i$ and $du^j = dv^j + \sqrt{-1}dw^j$. On U we set

$$g_U = dz^i d\overline{z}^i + \sqrt{-1}du^j\, d\overline{u}^j,$$

then g_U gives a Hermitian supermetric.

Definition 3.3: Let g be a Hermitian supermetric. Set $\omega(X,Y)=g(X, JY)$ for all X, $Y \in \mathrm{Der}\,\mathcal{A}$. The supermetric g is called Kählerian if $d\omega=0$. By a Kählerian supermanifold, we mean a complex supermanifold equipped with a Kählerian supermetric.

On a splitting neighborhood U, g is given by (2), and hence on U,

$$\omega=\sqrt{-1}(dz^i\wedge d\overline{z^k}g_{ik}+dz^i\wedge d\overline{e^j}t_{ij}+de^j\wedge d\overline{z^k}s_{jk}+de^j\wedge d\overline{e^l}h_{jl}).$$

We now give an example of a Kählerian supermanifold.

Example 3.4: The complex projective superspace of dimension (m, n) is the supermanifold $\mathbb{P}_{m|n}=(\mathbb{P}_m,\wedge(\mathbb{C}^n\otimes_{\mathbb{C}}\mathcal{O}(-1)))$, where $\mathcal{O}(-1)$ is the sheaf of sections of the tautological line bundle over the complex projective space $\mathbb{P}_m$. Let $\mathbb{P}_m=\cup_{i=0}^m U_i$ where $U_i=\{[z^0,\ldots,z^m],z^i\neq 0\}$. If a system of coordinates of $\mathbb{P}_m$ on U_i is denoted by $z^k_{(i)}$ where $k\in\{0,1,...,m\}\backslash\{i\}$ and if $\{u_i^1,\ldots,u_i^n\}$ is a basis for sections of $\mathbb{C}^n\otimes_{\mathbb{C}}\mathcal{O}(-1)$ on U_i, then $(z^k_{(i)},u^j_{(i)})$ is a system of coordinates of $\mathbb{P}_{m|n}$ on U_i and the transition rules are $z^k_{(l)}=(z^l_{(i)})^{-1}z^k_{(i)}$ and $u^j_{(l)}=(z^l_{(i)})^{-1}u^j_{(i)}$ (Ref. 5, Chap. 4, Sec. 3).

In fact the Fubini–Study metric on $\mathbb{P}_m$ (see Ref. 6) can be naturally extended on $\mathbb{P}_{m|n}$. Let

$$f_i=\log\left(1+\sum_k z^k_{(i)}\overline{z^k_{(i)}}+\sqrt{-1}\sum_j u^j_{(i)}\overline{u^j_{(i)}}\right),$$

where $\log(1+t)=t-t^2/2+t^3/3-\cdots$. Since $u^l_{(i)}\cdot u^l_{(i)}=0$, it follows that

$$f_i=\log\left(1+\sum_k z^k_{(i)}\overline{z^k_{(i)}}\right)+\sqrt{-1}\left(\sum_j u^j_{(i)}\overline{u^j_{(i)}}\right)\left(\frac{1}{1+\Sigma_k z^k_{(i)}\overline{z^k_{(i)}}}\right). \tag{3}$$

Thus f_i is a well-defined section of $\mathbb{C}^n\otimes_{\mathbb{C}}\mathcal{O}(-1)$ on U_i and

$$f_i-f_k=\log|z^k_{(i)}|^2.$$

Therefore,

$$\partial\overline{\partial}f_i=\partial\overline{\partial}f_k. \tag{4}$$

Let $\omega=\partial\overline{\partial}f_i$. By (4) it follows that ω is a 1-1 form defined on $\mathbb{P}_{m|n}$. Since $d\omega=0$, the supermetric corresponding to ω is Kählerian.

Remark: Expression (3) first appeared in Ref. 7.

IV. CONNECTIONS

In this section the concept of a left connection on a supermanifold is given. It is shown that there exists a unique torsion free left connection on a supermanifold equipped with a supermetric. Then it is shown that an almost complex structure is integrable if it is parallel to Δ_L. Here Δ_L is the supermanifold analog of the Levi-Civita connection. Finally a necessary and sufficient condition that an almost Hermitian supermanifold is Kählerian will be presented.

Let $(M, \mathcal{A})$ be a real supermanifold and let $\mathcal{F}$ be a locally free sheaf of $\mathcal{A}$-modules over M. By $D_{\leqslant 1}$ we mean the $\mathcal{A}$-module of differential operators of rank $\leqslant 1$.

Definition 4.1: A left connection on $\mathcal{F}$ is a map $\Delta_L:D_{\leqslant 1}\otimes\mathcal{F}\to\mathcal{F}$ such that:

(i) $\Delta_L(a\otimes f)=af$,
(ii) $\Delta_L(Y\otimes af)=\Delta_L(Y\circ a\otimes f)$,
(iii) $\Delta_L(aY\otimes f)=a\Delta_L(Y\otimes f)$,

where $a\in\mathcal{A}(U)$, $Y\in\mathrm{Der}\,\mathcal{A}(U)$, and $f\in\mathcal{F}(U)$, and U is any open subset.

The natural left connection on $\mathcal{A}$ given by

$$Y\otimes a \mapsto Y(a)$$

will be denoted by d.

The torsion of a connection Δ_L is the map T:Der $\mathcal{A}\otimes$Der $\mathcal{A}\rightarrow$Der $\mathcal{A}$ defined by

$$T(X\otimes Y)=\Delta_L(X\otimes Y)-(-1)^{\tilde{X}\tilde{Y}}\Delta_L(Y\otimes X)-[X,Y].$$

Obviously, T is even and $\mathcal{A}$-linear.

Let g be a supermetric on $(M, \mathcal{A})$ and let Δ_L be a connection on Der $\mathcal{A}$ [in this case we say that Δ_L is a left connection on $(M, \mathcal{A})$]. Then Δ_L is said to be compatible with g if:

$$d(X\otimes g(Y\otimes Z))=g(\Delta_L(X\otimes Y)\otimes Z)+(-1)^{\tilde{X}\tilde{Y}}g(Y\otimes\Delta_L(X\otimes Z)). \tag{5}$$

Theorem 4.2: Let $(M, \mathcal{A})$ be a real supermanifold with supermetric g. There is a unique torsion free left connection on $(M, \mathcal{A})$ compatible with g.

Proof (The uniqueness): Let Δ_L be one such connection. By (5), for every $X,Y,Z\in$ Der $\mathcal{A}$ we have

$$g(\Delta_L(X\otimes Y)\otimes Z)=d(X\otimes g(Y\otimes Z))-(-1)^{\tilde{X}\tilde{Y}}g(Y\otimes\Delta_L(X\otimes Z)).$$

Since Δ_L is torsion free, it follows that

$$g(\Delta_L(X\otimes Y)\otimes Z)=d(X\otimes g(Y\otimes Z))-(-1)^{\tilde{X}\tilde{Y}}g(Y\otimes[X,Z])-(-1)^{\tilde{X}\tilde{Y}+\tilde{X}\tilde{Z}}g(Y\otimes\Delta_L(Z\otimes X)).$$

By (5) and similar substitution as above we get

$$\begin{aligned}g(\Delta_L(X\otimes Y)\otimes Z)=\tfrac{1}{2}[&d(X\otimes g(Y\otimes Z))-(-1)^{\tilde{X}\tilde{Z}+\tilde{Y}\tilde{Z}}d(Z\otimes g(X\otimes Y))\\&+(-1)^{\tilde{X}\tilde{Y}+\tilde{X}\tilde{Z}}d(Y\otimes g(Z\otimes X))-g(X\otimes[Y,Z])\\&+(-1)^{\tilde{X}\tilde{Z}+\tilde{Y}\tilde{Z}}g(Z\otimes[X,Y])+(-1)^{\tilde{X}\tilde{Y}+\tilde{X}\tilde{Z}}g(Y\otimes[Z,X])].\end{aligned} \tag{6}$$

The conditions (ii) and (iii) in Definition 3.1 imply that g is nondegenerate. Thus by (6), the uniqueness of Δ_L follows.

(*The existence*). Every $X\in$ Der $\mathcal{A}$ determines an element of Hom (Der $\mathcal{A}$, $\mathcal{A}$) which is denoted by the same X and is defined as

$$X(Y)=g(X\otimes Y).$$

This correspondence is 1-1 and onto. Since g is nondegenerate, (6) determines $\Delta_L(X\otimes Y)$ as a derivation on $\mathcal{A}$. With direct computation, it can be shown that $g(T(X,Y)\otimes Z)=0$ for every $Z\in$ Der $\mathcal{A}$. Again as g is nondegenerate, $T(X,Y)=0$. □

The connection Δ_L is the supermanifold analog of the Levi-Civita connection.

Definition 4.3: Let Δ_L be a left connection and let J be an almost complex structure on $(M, \mathcal{A})$. By compatibility of Δ_L and J we mean

$$\Delta_L(X\otimes JY)-J\Delta_L(X\otimes Y)=0$$

for every $X,Y\in$ Der $\mathcal{A}$.

By (6) it is obvious that the left connection corresponding to a Kählerian supermetric on a complex supermanifold is compatible with the natural almost complex structure. On the other hand, if the left connection corresponding to an almost Hermitian supermanifold given by Theorem 4.2 is compatible with the almost complex structure J, then the supermanifold has a complex structure, i.e., there exist local coordinates (x^i,e^j), $i=1,...,2m$; $j=1,...,2n$, such that $J(\partial/\partial x^i)=\partial/\partial x^{m+i}$, $J(\partial/\partial e^j)=\partial/\partial e^{n+j}$. In this case J is called integrable.

Theorem 4.4: Let $(M, \mathcal{A})$ be a real supermanifold with almost complex structure J and let g be a Hermitian supermetric. If Δ_L, the left connection corresponding to g, is compatible with J then J is integrable.

Proof: Let $\{U_\alpha\}$ be an open covering consisting of splitting neighborhoods on M and let $\varphi_\alpha:\mathcal{A}(U_\alpha)\to\wedge\mathcal{E}$ be the isomorphisms of $\mathbb{Z}_2$-graded algebras. If (x^i_α, e^j_α) is a system of coordinates on U_α, we set:

$$\Delta_M\frac{\partial}{\partial x^i_\alpha}:=\Delta_L\frac{\partial}{\partial x^i_\alpha}\bmod \mathcal{N}\left\langle\frac{\partial}{\partial x^k_\alpha}\right\rangle\oplus\left\langle\frac{\partial}{\partial e^j_\alpha}\right\rangle_{\mathcal{A}},$$

where $\langle\partial/\partial e^j_\alpha\rangle_{\mathcal{A}}$ means the $\mathcal{A}$-module generated by $\partial/\partial e^j_\alpha$. Obviously, Δ_M is compatible with the induced metric and the induced almost complex structure on M. Thus, by a well-known theorem on smooth manifolds,[8] the induced almost complex structure on M is integrable. Therefore, M is a complex manifold.

Similarly, it can be seen that P, the total space of the vector bundle $\mathcal{E}$, is also a complex manifold. Set

$$\Delta_P\frac{\partial}{\partial x^i_\alpha}=\Delta_L\frac{\partial}{\partial x^i_\alpha}\bmod \mathcal{N}\left\langle\frac{\partial}{\partial x^k_\alpha},\frac{\partial}{\partial e^l_\alpha}\right\rangle_{\substack{k=1,\dots,2m\\ l=1,\dots,2n}},$$

$$\Delta_P\frac{\partial}{\partial e^j_\alpha}=\Delta_L\frac{\partial}{\partial e^j_\alpha}\bmod \mathcal{N}\left\langle\frac{\partial}{\partial x^k_\alpha},\frac{\partial}{\partial e^l_\alpha}\right\rangle_{\substack{k=1,\dots,2m;\\ l=1,\dots,2n}}.$$

Then Δ_P is a well-defined connection on P compatible with the induced almost complex structure on P. Since Δ_P is torsion free, by Ref. 8, Corollary 3.5, P is a complex manifold. In particular, every point of P has a neighborhood on which there exist holomorphic coordinates z^t and u^s, $t=1,\dots,m;\ s=1,\dots,n$.

Let E_x be the fiber of the vector bundle $\mathcal{E}$ over $x\in M$. Identifying E_x with T_pE_x, where $\pi(p)=x$ and $\pi:P\to M$ is the projection map associated with $\mathcal{E}$, we can regard the derivation of the inclusion map $E_x\to P$ as a linear isomorphism $\rho_p:E_x\to V_p$ where V_p is the fiber of the vertical bundle over $p\in P$. Let κ be the vertical projection associated with the linear connection $\Delta_{\mathcal{E}}$ defined by

$$\Delta_{\mathcal{E}}e^j_\alpha=\Delta_L\frac{\partial}{\partial e^j_\alpha}\bmod \mathcal{A}\left\langle\frac{\partial}{\partial x^i_\alpha}\right\rangle_{i=1,\dots,2m}+\mathcal{N}\left\langle\frac{\partial}{\partial e^l_\alpha}\right\rangle_{l=1,\dots,2n}.$$

In order to obtain a section of $\mathcal{E}$, after applying mod in the above congruence, we need to substitute $\partial/\partial e^l_\alpha$ by e^l_α in the resulting expression. Observe that since the transition map on the intersection of any two splitting neighborhoods is a polynomial map in terms of anticommutative coordinates, the definition of $\Delta_{\mathcal{E}}$ is independent of the choice of sections e^j_α. Set:

$$v^s(x)=\rho_p^{-1}\circ\kappa\circ\frac{\partial}{\partial u^s}(o_x),\quad w^t(x)=\rho_p^{-1}\circ\kappa\circ\frac{\partial}{\partial z^t}(o_x),$$

where o_x is the null element of the vector space E_x. Obviously, $\{w^t, v^s\}$ is varied holomorphically, so that $\mathcal{E}$ is a holomorphic vector bundle.

Now consider the algebra of holomorphic sections of $\wedge\mathcal{E}(U_\alpha)\otimes\mathbb{C}$. If the inverse image of this algebra under the isomorphism $\varphi_\alpha\otimes i:\mathcal{A}(U_\alpha)\otimes\mathbb{C}\to\wedge\mathcal{E}(U_\alpha)\otimes\mathbb{C}$ is denoted by $\mathcal{B}(U_\alpha)$, then $(M, \mathcal{B})$ is a complex supermanifold and $(M, \mathcal{A})$ is the underlying real supermanifold. □

Remark: Theorem 4.4 can be obtained by invoking an extended Newlander–Nirenberg theorem proved by Mc Hugh.[9] Indeed, since Δ_L is torsion free and is compatible with g and J, straightforward computations reveal that

$$[JX,JY]=[X,Y]+J[JX,Y]+J[X,JY],$$

where $X,Y\in \mathrm{Der}\,\mathcal{A}$. Therefore by the extended Newlander–Nirenberg theorem for supermanifolds in Ref. 9, J is integrable. However, in our proof of Theorem 4.2 we have avoided the use of the extended Newlander–Nirenberg theorem.

Let $(M,\mathcal{A})$, g, J and Δ_L be as specified in Theorem 4.4 under the same hypotheses.

Theorem 4.5: $(M,\mathcal{A})$ is a Kählerian supermanifold.

Proof: It is sufficient to show that ω is closed, where ω is the associated 1-1 form to the Hermitian supermetric g. By Ref. 10, Theorem 4-3-7, $d\omega=0$ if and only if

$$(-1)^{\tilde{X}\tilde{Z}}d(X\otimes_{\omega}(Y,Z))+(-1)^{\tilde{X}\tilde{Y}}d(Y\otimes_{\omega}(Z,X))+(-1)^{\tilde{Y}\tilde{Z}}d(Z\otimes_{\omega}(X,Y))$$
$$=(-1)^{\tilde{X}\tilde{Z}}\omega([X,Y],Z)+(-1)^{\tilde{X}\tilde{Y}}\omega([Y,Z],X)+(-1)^{\tilde{Y}\tilde{Z}}\omega([Z,X],Y).$$

By the definition of ω and the properties of Δ_L, the validity of the last equation follows.

Theorem 4.6: Let $(M,\mathcal{A},g)$ be a Kählerian supermanifold as defined in Definition 3.3. Then Δ_L, the left connection associated to g, is compatible with J.

Proof: It is sufficient to show that

$$g(\Delta_L(X\otimes JY)-J\Delta_L(X\otimes Y),Z)=0 \tag{7}$$

for every $Z\in \mathrm{Der}\,\mathcal{A}$. By (6), adding and subtracting suitable terms, the left-hand side of the last equation is equal to

$$\tfrac{1}{2}[-d(X,\omega(Y,Z))+(-1)^{\tilde{X}\tilde{Y}}d(Y,\omega(X,Z))-(-1)^{\tilde{X}\tilde{Z}+\tilde{Y}\tilde{Z}}d(Z,\omega(X,Y))$$
$$+\omega([X,Y],Z)+(-1)^{\tilde{X}\tilde{Y}+\tilde{X}\tilde{Z}}\omega([Y,Z],X)-(-1)^{\tilde{Y}\tilde{Z}}\omega([X,Z],Y)]$$
$$+\tfrac{1}{2}[d(X,\omega(JY,JZ))-(-1)^{\tilde{X}\tilde{Y}}d(JY,\omega(X,JZ))+(-1)^{\tilde{X}\tilde{Z}+\tilde{Y}\tilde{Z}}d(JZ,\omega(X,JY))$$
$$-\omega([X,JY],JZ)-(-1)^{\tilde{X}\tilde{Y}+\tilde{X}\tilde{Z}}\omega([JY,JZ],X)+(-1)^{\tilde{Z}\tilde{Y}}\omega([X,JZ],JY)].$$

By Ref. 10, pp. 252 the first and the second brackets above are equal to $d\omega(X,Y,Z)$ and $-d\omega(X,JY,JZ)$, respectively. Thus (7) follows. □

ACKNOWLEDGMENT

The author would like to thank Professor Rahim Zaare-Nahandi for his encouragement and in particular, for his help on the final version of this paper.

[S0022-2488(99)00212-1]

Dr. van Hemmen has pointed out to me that except for the minor extension to odd and even numbers of sites, the argument leading to Herring's formula, Eq. (3.11) of my paper, appears in the same form in Ref. 1. I regret the omission.

Secondly, condition (2.10) for the validity of the discrete WKB method is too weak, and should be replaced by

$$|dq(j)/dj| \leqslant \sin^2 q(j).$$

Lastly, the second of Eqs. (5.8) contains a sign error. The correct equation is

$$\cos \theta_1 = \cos \theta_0 + \sin^2 \theta_0 / 2S \cos \theta_0 + \cdots.$$

The conclusions are unaffected by either error.
