$$\det\sigma(g_\lambda)=-g_\lambda^1g_\lambda^2-(g_\lambda^3)^2=-\tfrac{1}{4}.\tag{2.6}$$

This implies the explicit recursive formula for g_j^3 by comparing the coefficients of λ^{-s}. Thus we have

$$\begin{aligned}&g_{m+1}^1=-\partial g_m^1+2vg_m^3,\\ &g_{m+1}^2=\partial g_m^2+2ug_m^3,\\ &g_{m+1}^3=-\sum_{\substack{j+k=m\\ j,k\geqslant 0}}g_j^1g_k^2+g_j^3g_k^3.\end{aligned}\tag{2.7}$$

The first few members are:

$$g_{-1}=\begin{pmatrix}0\\ 0\\ \frac{1}{2}\end{pmatrix},\quad g_0=\begin{pmatrix}v\\ u\\ 0\end{pmatrix},\quad g_0=\begin{pmatrix}-v_x\\ u_x\\ -uv\end{pmatrix},$$

$$g_2=\begin{pmatrix} v_{xx}-2uv^2 \\ u_{xx}-2u^2v \\ uv_x-u_xv \end{pmatrix}, \quad g_3=\begin{pmatrix} -v_{xxx}+6uvv_x \\ u_{xxx}-6uvu_x \\ -u_{xx}v-uv_{xx}+u_xv_x+3u^2v^2 \end{pmatrix}, \tag{2.8}$$

$$X_0=\begin{pmatrix} u \\ -v \end{pmatrix}, \quad X_1=\begin{pmatrix} u_x \\ v_x \end{pmatrix}, \quad X_2=\begin{pmatrix} u_{xx}-2u^2v \\ -v_{xx}+2uv^2 \end{pmatrix}, \quad X_3=\begin{pmatrix} u_{xxx}-6uvu_x \\ v_{xxx}-6uvv_x \end{pmatrix}.$$

Using the bi-Hamiltonian structure $Jg_4=Kg_3$, we have

$$X_4=\begin{pmatrix} u_{xxxx}-8uvu_{xx}-6u_x^2v-4uu_xv_x-2u^2v_{xx}+6u^3v^2 \\ -v_{xxxx}+8uvv_{xx}+6uv_x^2+4vu_xv_x+2v^2u_{xx}-6u^2v^3 \end{pmatrix}.$$

III. THE ZS–BARGMANN SYSTEM

Consider N copies of the linear ZS equation (2.1):

$$\partial_x\begin{pmatrix} p_j \\ q_j \end{pmatrix}=\begin{pmatrix} \frac{1}{2}\alpha_j & u \\ v & -\frac{1}{2}\alpha_j \end{pmatrix}\begin{pmatrix} p_j \\ q_j \end{pmatrix}, \quad j=1,...,N, \tag{3.1}$$

with distinct eigenvalues $\lambda=\alpha_1,\dots\alpha_N$. Let $A=\mathrm{diag}(\alpha_1,...,\alpha_N)$. It is proved in Ref. 3 that the reflectionless potential is expressed by the squared sum of eigenfunctions:

$$\begin{aligned} u(x)&=-\langle p,p\rangle=-\sum_{j=1}^{N}\{p_j(x)\}^2, \\ v(x)&=\langle q,q\rangle=\sum_{j=1}^{N}\{q_j(x)\}^2. \end{aligned} \tag{3.2}$$

Thus in the reflectionless case, what the solution $(p_j,q_j)^T$ of the linear Eq. (3.1) satisfies, is actually a system of nonlinear equations:

$$\begin{aligned} p_x&=\frac{1}{2}Ap-\langle p,p\rangle q=-\frac{\partial H_1}{\partial q}, \\ q_x&=-\frac{1}{2}Aq+\langle q,q\rangle p=\frac{\partial H_1}{\partial p}, \\ H_1&=-\tfrac{1}{2}\langle Ap,q\rangle+\tfrac{1}{2}\langle p,p\rangle\langle q,q\rangle. \end{aligned} \tag{3.3}$$

This procedure is called nonlinearization of the eigenvalue problem, which is developed to a general approach to produce new finite-dimensional integrable systems from infinite-dimensional ones (soliton hierarchies).[2–4]

Now consider the problem of integrability of the ZS–Bargmann system (3.3). The functional gradient

$$\nabla\alpha_j=\begin{pmatrix} \delta\alpha_j/\delta u \\ \delta\alpha_j/\delta v \end{pmatrix}=\begin{pmatrix} q_j^2 \\ -p_j^2 \end{pmatrix}$$

is extended to $\nabla\alpha_j=(q_j^2,-p_j^2,p_jq_j)^T$, which satisfies the Lenard eigenvalue problem $(K-\alpha_jJ)\nabla\alpha_j=0$. The condition (3.2) is put in the general form (the Bargmann constraint):

$$g_0 + cg_{-1} = \sum_{j=1}^{N} \nabla \alpha_j, \tag{3.4}$$

where the third component $\langle p,q\rangle = c/2$ gives nothing essential since $\langle p,q\rangle$ is a conserved integral of the x flow. The solution of the Lenard eigenvalue problem with general parameter λ is constructed as

$$G_\lambda = g_{-1} + \sum_{j=1}^{N} \frac{1}{\lambda - \alpha_j} \nabla \alpha_j, \tag{3.5}$$

$$(K - \lambda J) G_\lambda = 0. \tag{3.6}$$

Actually,

$$(K - \lambda J) G_\lambda = J\left(g_0 - \sum_{j=1}^{N} \nabla \alpha_j \right) = J(cg_{-1}) = 0.$$

By the fundamental identity (2.2), the Lax equation along the x flow

$$V_x - [U,V] = 0 \tag{3.7}$$

has a solution $V_\lambda = \sigma(G_\lambda)$:

$$V_\lambda = \begin{pmatrix} \frac{1}{2} & 0 \\ 0 & -\frac{1}{2} \end{pmatrix} + \sum_{j=1}^{N} \frac{\epsilon_j}{\lambda - \alpha_j}, \quad \sigma(\nabla \alpha_j) = \epsilon_j = \begin{pmatrix} p_j q_j & -p_j^2 \\ q_j^2 & -p_j q_j \end{pmatrix}, \tag{3.8}$$

which is called the Lax matrix of the ZS–Bargmann system (3.3). Equation (3.7) implies that $F_\lambda = \det V_\lambda$ is invariant along the x flow. Therefore, we have the generating function of integrals of Eq. (3.3),

$$F_\lambda = -\frac{1}{4} - Q_\lambda(p,q) + Q_\lambda(p,p) Q_\lambda(q,q) - Q_\lambda^2(p,q) = -\frac{1}{4} + \sum_{k=0}^{\infty} \lambda^{-k-1} F_k, \tag{3.9}$$

where $Q_\lambda(\xi,\eta) = \langle (\lambda E - A)^{-1} \xi, \eta \rangle$, and

$$F_0 = -\langle p,q\rangle,$$

$$F_1 = -\langle Ap,q\rangle + \langle p,p\rangle\langle q,q\rangle - \langle p,q\rangle^2, \tag{3.10}$$

$$F_k = -\langle A^k p,q\rangle + \sum_{i+j=k-1} \langle A^i p,p\rangle\langle A^j q.q\rangle - \langle A^i p,q\rangle\langle A^j p,q\rangle.$$

Specifically,

$$H_1 = \tfrac{1}{2} F_1 + \tfrac{1}{2} F_0^2.$$

Regard the generating function F_λ as a Hamiltonian in the symplectic space $(\mathbb{R}^{2N}, dp \wedge dq)$. The canonical equation is

$$\frac{d}{dt_\lambda} \begin{pmatrix} p_k \\ q_k \end{pmatrix} = \frac{2}{\lambda - \alpha_k} V_\lambda \begin{pmatrix} p_k \\ q_k \end{pmatrix}, \quad k = 1,\ldots,N. \tag{3.11}$$

Proposition 3.1: The Lax matrix V_μ satisfies the Lax equation along the F_λ flow:

$$\frac{d}{dt_\lambda} V_\mu = \frac{2}{\lambda-\mu}[V_\lambda, V_\mu], \quad \forall \lambda, \mu \in \mathbb{C}. \tag{3.12}$$

Proof: Since

$$\epsilon_k = \begin{pmatrix} p_k \\ q_k \end{pmatrix} (p_k, q_k) \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix},$$

by Eq. (3.11) we have

$$\frac{d}{dt_\lambda}\epsilon_k = \frac{2}{\lambda-\alpha_k}[V_\lambda, \epsilon_k].$$

$$\begin{aligned}\frac{d}{dt_\lambda} V_\mu &= \sum_{k=1}^{N} \frac{1}{\mu-\alpha_k} \frac{2}{\lambda-\alpha_k}[V_\lambda, \epsilon_k] \\ &= \frac{2}{\lambda-\mu}\sum_{k=1}^{N}\left(\frac{1}{\mu-\alpha_k} - \frac{1}{\lambda-\alpha_k}\right)[V_\lambda, \epsilon_k] \\ &= \frac{2}{\lambda-\mu}[V_\lambda, V_\mu - V_\lambda] = \mathrm{RHS}.\end{aligned}$$

Corollary 3.2: $(F_\mu, F_\lambda) = 0, \quad \forall \lambda, \mu \in \mathbb{C};$

$$(F_j, F_k) = 0, \quad \forall j,k = 0,1,2,\ldots .$$

Proof: Equation (3.12) implies that $F_\mu = \det V_\mu$ is invariant along the t_λ flow. And the derivative of the function F_μ along the F_λ flow is exactly the Poisson bracket.

IV. ELLIPTIC COORDINATES AND FUNCTIONAL INDEPENDENCE

It is easy to see that each one of F_λ, V_λ^{12}, and V_λ^{21}, as a rational function of λ, has simple poles at α_j's, since the coefficient of $(\lambda-\alpha_j)^{-2}$ is zero in F_λ. We have

$$\begin{aligned} F_\lambda &= Q_\lambda(p,p)Q_\lambda(q,q) - \left\{Q_\lambda(p,q) + \frac{1}{2}\right\}^2 = -\frac{b(\lambda)}{4a(\lambda)}, \\ V_\lambda^{12} &= -Q_\lambda(p,p) = -\langle p,p\rangle \frac{m(\lambda)}{a(\lambda)}, \\ V_\lambda^{21} &= Q_\lambda(q,q) = \langle q,q\rangle \frac{n(\lambda)}{a(\lambda)}, \end{aligned} \tag{4.1}$$

where

$$a(\lambda) = \prod_{k=1}^{N} (\lambda-\alpha_k), \quad b(\lambda) = \prod_{k=1}^{N} (\lambda-\beta_k),$$

$$m(\lambda) = \prod_{k=1}^{N-1} (\lambda-\mu_k), \quad n(\lambda) = \prod_{k=1}^{N-1} (\lambda-\nu_k).$$

The roots $\{\mu_k\}$ and $\{\nu_k\}$ are defined as elliptic variables.

Proposition 4.1: The elliptic coordinates satisfy the evolution equations along the t_λ flow:

$$\frac{1}{2\sqrt{R(\mu_k)}}\frac{d\mu_k}{dt_\lambda}=\frac{m(\lambda)}{a(\lambda)(\lambda-\mu_k)m'(\mu_k)},$$
$$\frac{1}{2\sqrt{R(\nu_k)}}\frac{d\nu_k}{dt_\lambda}=\frac{-n(\lambda)}{a(\lambda)(\lambda-\nu_k)n'(\nu_k)}, \tag{4.2}$$

where

$$R(\lambda)=a(\lambda)b(\lambda)=\prod_{k=1}^{2N}(\lambda-\lambda_k), \tag{4.3}$$

with $\lambda_k=\alpha_k$, $\lambda_{N+k}=\beta_k$, $(k=1,...,N)$

Proof: Substitute $\lambda=\mu_k$, ν_k, respectively, in Eq. (4.1). We have

$$V^{11}_{\mu_k}=\frac{\sqrt{R(\mu_k)}}{2a(\mu_k)},\quad V^{11}_{\nu_k}=\frac{\sqrt{R(\nu_k)}}{2a(\nu_k)}.$$

In the second and third components of Eq. (3.12),

$$\frac{d}{dt_\lambda}V^{12}_\mu=\frac{-4}{\lambda-\mu}(V^{12}_\lambda V^{11}_\mu-V^{11}_\lambda V^{12}_\mu),$$

$$\frac{d}{dt_\lambda}V^{21}_\mu=\frac{4}{\lambda-\mu}(V^{21}_\lambda V^{11}_\mu-V^{11}_\lambda V^{21}_\mu),$$

let $\mu=\mu_k$ and $\mu=\nu_k$, respectively. After some calculations we have Eq. (4.2).

By means of the interpolation formula for polynomials with degree not more than $g-1=N-2$, we have $(s=1,...,g)$

$$\sum_{k=1}^{g}\frac{\mu_k^{g-s}}{2\sqrt{R(\mu_k)}}\frac{d\mu_k}{dt_\lambda}=\frac{\lambda^{g-s}}{a(\lambda)},$$

$$\sum_{k=1}^{g}\frac{\nu_k^{g-s}}{2\sqrt{R(\nu_k)}}\frac{d\nu_k}{dt_\lambda}=\frac{-\lambda^{g-s}}{a(\lambda)}.$$

For fixed λ_0, introduce the quasi-Abel–Jacobi coordinates:

$$\tilde{\phi}_s=\sum_{k=1}^{g}\int_{\lambda_0}^{\mu_k}\frac{\mu^{g-s}\,d\mu}{2\sqrt{R(\mu)}},\quad \tilde{\psi}_s=\sum_{k=1}^{g}\int_{\lambda_0}^{\nu_k}\frac{\nu^{g-s}\,d\nu}{2\sqrt{R(\nu)}},\quad (s=1,...,g). \tag{4.4}$$

Proposition 4.2: (Straightening of the F_λ flow)

$$\frac{d\tilde{\phi}_s}{dt_\lambda}=\frac{\lambda^{g-s}}{a(\lambda)},\quad \frac{d\tilde{\psi}_s}{dt_\lambda}=\frac{-\lambda^{g-s}}{a(\lambda)}. \tag{4.5}$$

Corollary 4.3: (Straightening of the F_k flow). Let t_k be the variable of the F_k flow. Then

$$\frac{d\tilde{\phi}}{dt_0}=0, \quad \left(\frac{d\tilde{\phi}}{dt_1},\frac{d\tilde{\phi}}{dt_2},\ldots,\frac{d\tilde{\phi}}{dt_{N-1}}\right)=\begin{pmatrix} 1 & A_1 & A_2 & \cdots & A_{N-2} \\ & 1 & A_1 & \cdots & A_{N-3} \\ & & \ddots & \ddots & \vdots \\ & & & \ddots & A_1 \\ & & & & 1 \end{pmatrix}, \tag{4.6}$$

and $d\tilde{\phi}/dt_k=-d\tilde{\psi}/dt_k$, where A_j's are the coefficient in the expansion

$$\frac{\lambda^N}{a(\lambda)}=\frac{1}{(1-\alpha_1\lambda^{-1})\cdots(1-\alpha_N\lambda^{-1})}=1+\sum_{j=1}^{\infty} A_j\lambda^{-j}, \tag{4.7}$$

which could be represented through the power sums of α_k, $s_l=\Sigma_{k=1}^{N}\alpha_k^l$:

$$A_1=s_1, \quad A_2=\tfrac{1}{2}(s_2+s_1^2), \quad A_3=\tfrac{1}{6}(2s_3+3s_2s_1+s_1^3),$$

with the recursive formula:

$$A_k=\frac{1}{k}\left(s_k+\sum_{\substack{i+j=k\\ i,j\geqslant 1}} s_iA_j\right). \tag{4.8}$$

Proof: According to the definition of the Poisson bracket:

$$\frac{d\tilde{\phi}}{dt_\lambda}=(\tilde{\phi},F_\lambda)=\sum_{k=0}^{\infty}\frac{1}{\lambda^{k+1}}(\tilde{\phi},F_k)=\sum_{k=0}^{\infty}\frac{1}{\lambda^{k+1}}\frac{d\tilde{\phi}}{dt_k}.$$

With the supplementary definition $A_0=1$, $A_{-j}=0$, $(j=1,2,3,...)$, the comparison of the coefficients of λ^{-k-1} in Eq. (4.5) yields $d\tilde{\phi}_s/dt_k=A_{k-s}$, and

$$\frac{d\tilde{\phi}}{dt_k}=(A_{k-1},A_{k-2},\ldots,A_{k-g})^T. \tag{4.9}$$

The proof of Eq. (4.8) is elementary, resorting to the expansion $\Sigma_1^\infty k^{-1}s_k\lambda^{-k}$ of the RHS of Eq. (4.7).

Proposition 4.4: $F_0,F_1,\ldots,F_{N-1}$ given in Eq. (3.10) are functionally independent.

Proof: We need only prove the linear independence of the differentials $dF_0,dF_1,\ldots,dF_{N-1}$. Recall the expression of the Poisson bracket by means of the symplectic structure $\omega^2=dp\wedge dq$:[18]

$$(H,F)=\omega^2(IdF,IdH).$$

Suppose $\Sigma_{k=0}^{N-1}c_kdF_k=0$. Let $H=\tilde{\phi}_s$, we have

$$0=\sum_{k=0}^{N-1}c_k\omega^2(IdF_k,Id\tilde{\phi}_s)=\sum_{k=0}^{N-1}c_k(\tilde{\phi}_s,F_k)=\sum_{k=1}^{N-1}c_k\frac{d\tilde{\phi}_s}{dt_k}.$$

Hence $c_1=\cdots=c_{N-1}=0$ since the coefficient determinant is equal to 1 by Eq. (4.6). Thus $c_0dF_0=0$. And $c_0=0$ since

$$dF_0=-\sum(q_kdp_k+p_kdq_k)\neq 0.$$

Note: Corollary 3.2 and the present Proposition complete the proof of the Liouville integrability of the ZS–Bargmann system (3.3) with the Hamiltonian $H_1=\frac{1}{2}F_1+\frac{1}{2}F_0^2$ and N integrals $F_0,F_1,\ldots,F_{N-1}$, which are involutive in pairs and functionally independent.

V. THE POLYNOMIAL INTEGRALS $\{H_k\}$

Introduce another set of polynomial integrals $\{H_k\}$ for the ZS–Bargmann system (3.3) recursively by:

$$\begin{gathered} H_0=\tfrac{1}{2}F_0, \\ H_{k+1}=\tfrac{1}{2}F_{k+1}+2\sum_{i+j=k} H_iH_j. \end{gathered} \tag{5.1}$$

The first few members are

$$\begin{gathered} H_0=\tfrac{1}{2}F_0, \quad H_1=\tfrac{1}{2}F_1+\tfrac{1}{2}F_0^2, \\ H_2=\tfrac{1}{2}F_2+F_1F_0+F_0^3, \\ H_3=\tfrac{1}{2}F_3+F_2F_0+\tfrac{1}{2}F_1^2+3F_1F_0^2+\tfrac{5}{2}F_0^4, \\ H_4=\tfrac{1}{2}F_4+F_3F_0+F_2F_1+3F_2F_0^2+3F_1^2F_0+10F_1F_0^3+7F_0^5. \end{gathered} \tag{5.2}$$

Here H_1 is exactly the Hamiltonian for the ZS–Bargmann system (3.3). Equation (5.1) is equivalent to

$$H_\lambda=\tfrac{1}{2}(F_\lambda+\tfrac{1}{4})+2H_\lambda^2,$$

or

$$-4F_\lambda=(1-4H_\lambda)^2, \tag{5.3}$$

where $H_\lambda=\Sigma_{k=0}^{\infty}H_k\lambda^{-k-1}$ is the generating function of $\{H_k\}$.

Proposition 5.1: $\{H_k\}$ satisfies the Liouville conditions of completely integrability:

$$\begin{gathered} \text{(i)} \quad (H_\lambda,H_\mu)=0, \quad \forall \lambda,\mu\in\mathbb{C}, \\ (H_j,H_k)=0, \quad \forall j,k=0,1,2,\ldots; \end{gathered} \tag{5.4}$$

$$\text{(ii)} \quad H_0,H_1,\ldots,H_{N-1} \text{ are functionally independent.}$$

Proof: Since $\{\alpha_j\}$ are the only poles of F_λ, the expansion

$$-4F_\lambda=1-4\sum_{k=0}^{\infty}F_k\lambda^{-k-1}=1+O\left(\frac{1}{\lambda}\right)$$

convergent absolutely outside the circle:

$$|\lambda|>\max(|\alpha_1|,\ldots,|\alpha_1|).$$

Thus for sufficiently large $|\lambda|$ we solve

$$1-4H_\lambda=\sqrt{-4F_\lambda}. \tag{5.5}$$

According to the Leibniz rule for the Poisson bracket, we obtain

$$(H_\lambda, H_\mu) = \frac{1}{16\sqrt{F_\lambda F_\mu}} (F_\lambda, F_\mu) = 0,$$

for sufficiently large $|\lambda|$ and $|\mu|$. By the principle of analytic continuation, Eq. (5.4) is valid for any λ and μ. From Eq. (5.3) we have

$$\tfrac{1}{2} dF_\lambda = (1 - 4H_\lambda) dH_\lambda,$$

$$\frac{1}{2}\begin{pmatrix} dF_0 \\ dF_1 \\ \vdots \\ dF_{N-1} \end{pmatrix} = \begin{pmatrix} 1 & & & \\ -4H_0 & 1 & & \\ \cdots & \cdots & \cdots & \\ -4H_{N-2} & \cdots & -4H_0 & 1 \end{pmatrix} \begin{pmatrix} dH_0 \\ dH_1 \\ \vdots \\ dH_{N-1} \end{pmatrix}.$$

Thus the linear independence of $dH_0, \ldots, dH_{N-1}$ is equivalent to that of $dF_0, \ldots, dF_{N-1}$, which completes the proof of the functional independence of $H_0, \ldots, H_{N-1}$.

The explicit form of H_k by means of canonical coordinates p,q is obtained through substituting the expression (3.10) into Eq. (5.2). The first few are as follows:

$$\begin{aligned} H_0 &= -\tfrac{1}{2}\langle p,q\rangle, \\ H_1 &= -\tfrac{1}{2}\langle Ap,q\rangle + \tfrac{1}{2}\langle p,p\rangle\langle q,q\rangle, \\ H_2 &= -\tfrac{1}{2}\langle A^2p,q\rangle + \tfrac{1}{2}\langle Ap,p\rangle\langle q,q\rangle + \tfrac{1}{2}\langle p,p\rangle\langle Aq,q\rangle - \langle p,p\rangle\langle p,q\rangle\langle q,q\rangle, \\ H_3 &= -\tfrac{1}{2}\langle A^3p,q\rangle + \tfrac{1}{2}\langle A^2p,p\rangle\langle q,q\rangle + \tfrac{1}{2}\langle Ap,p\rangle\langle Aq,q\rangle + \tfrac{1}{2}\langle p,p\rangle\langle A^2q,q\rangle - \langle Ap,p\rangle\langle p,q\rangle\langle q,q\rangle \\ &\quad - \langle p,p\rangle\langle Ap,q\rangle\langle q,q\rangle - \langle p,p\rangle\langle p,q\rangle\langle Aq,q\rangle + \tfrac{1}{2}\langle p,p\rangle^2\langle q,q\rangle^2 + 2\langle p,p\rangle\langle p,q\rangle^2\langle q,q\rangle. \end{aligned} \tag{5.6}$$

VI. RELATION OF H_k AND X_k

The kernel of J is of dimension 1 with the generator g_{-1}. Exerting $J^{-1}K$ on Eq. (3.4) k times gives

$$\sum_{j=1}^{N} \alpha_j^k \nabla \alpha_j = g_k + c_1 g_{k-1} + \cdots + c_k g_0 + c_{k+1} g_{-1}, \tag{6.1}$$

since each time there is an extra term $c_i g_{-1}$. Hence we have

$$0 = \sum_{j=1}^{N} a(\alpha_j)\nabla \alpha_j = g_N + c_{N1} g_{N-1} + \cdots + c_{NN} g_0 + c_{N,N+1} g_{-1}, \tag{6.2}$$

where

$$\begin{aligned} a(\lambda) &= \prod_{j=1}^{N} (\lambda - \alpha_j) = \sum_{k=0}^{N} a_{N-k}\lambda^k, \quad (a_0 = 1), \\ c_{N,N-i} &= \sum_{k=i}^{N} a_{N-k} c_{k-i}, \quad c_{N,N+1} = \sum_{k=0}^{N} a_{N-k} c_{k+1}. \end{aligned} \tag{6.3}$$

Acting with PJ on Eq. (6.2) yields:

Proposition 6.1: Let $(p(x), q(x))$ be a solution of the ZS–Bargmann system (3.3). Then

$$\begin{pmatrix} u \\ v \end{pmatrix} = f(p,q) = \begin{pmatrix} -\langle p,p\rangle \\ \langle q,q\rangle \end{pmatrix} \tag{6.4}$$

solves the Nth stationary AKNS equation

$$X_N + c_{N1}X_{N-1} + \cdots + c_{NN}X_0 = 0. \tag{6.5}$$

Proposition 6.2: The coefficients in Eq. (6.1) are given by:

$$c_k = -4H_{k-1}. \tag{6.6}$$

Furthermore,

$$g_\lambda = \frac{1}{1-4H_\lambda} G_\lambda . \tag{6.7}$$

Proof: Define the generating function of $\{c_k\}$ by

$$c_\lambda = 1 + \sum_{k=1}^{\infty} c_k \lambda^{-k}.$$

Multiplied by λ^{-k-1} and summed with respect to k from 0 to ∞, Eq. (6.1) becomes

$$G_\lambda = g_{-1} + \begin{pmatrix} Q_\lambda(q,q) \\ -Q_\lambda(p,p) \\ Q_\lambda(p,q) \end{pmatrix} = c_\lambda g_\lambda .$$

Thus $\sigma(G_\lambda) = c_\lambda \sigma(g_\lambda)$ and $F_\lambda = -\frac{1}{4}c_\lambda^2$ due to Eq. (2.6), which yields $c_\lambda = 1-4H_\lambda$ and Eq. (6.6) by comparing with Eq. (5.3).

Denote the solution variety of Eqs. (3.3) and (6.5) by $\mathcal{N}$ and $\mathcal{M}$, respectively. By Proposition 6.1 f maps $\mathcal{N}$ into $\mathcal{M}$. Consider the canonical equation of the H_k flow:

$$\frac{d}{d\tau_k}\begin{pmatrix} p \\ q \end{pmatrix} = \begin{pmatrix} -\dfrac{\partial H_k}{\partial q} \\ \dfrac{\partial H_k}{\partial p} \end{pmatrix} = I\nabla H_k \tag{6.8}$$

and the solution of the initial value problem:

$$\begin{pmatrix} p(\tau_k) \\ q(\tau_k) \end{pmatrix} = h_k^{\tau_k}\begin{pmatrix} p_0 \\ q_0 \end{pmatrix}. \tag{6.9}$$

Specifically, $\tau_1 = x$. It is well-known[18] that the involutivity $(H_j, H_k) = 0$ implies the commutativity of $h_j^{\tau_j}$ and $h_k^{\tau_k}$. Hence $I\nabla H_k$ can be regarded as a vector field on $\mathcal{N}$. The importance of H_k is that the differential f_* maps $I\nabla H_k$ exactly into the AKNS vector field X_k restricted to $\mathcal{M}$, where

$$f_*(p,q)\begin{pmatrix} \delta p \\ \delta q \end{pmatrix} = \frac{d}{d\epsilon}\bigg|_{\epsilon=0} f(p+\epsilon\delta p, q+\epsilon\delta q) = \begin{pmatrix} -2\langle p,\delta p\rangle \\ 2\langle q,\delta q\rangle \end{pmatrix}.$$

Proposition 6.3:

$$f_*(I\nabla H_\lambda) = PJg_\lambda|_{\mathcal{M}}, \quad \lambda \in \mathbb{C},$$
$$f_*(I\nabla H_k) = X_k|_{\mathcal{M}}, \quad k = 0,1,2,\ldots . \tag{6.10}$$

Proof: From the canonical Eq. (3.11) of the t_λ flow we get

$$\begin{aligned}\frac{d}{dt_\lambda}\langle p,p\rangle &= 4V_\lambda^{11}Q_\lambda(p,p)+4V_\lambda^{12}Q_\lambda(p,q)=2Q_\lambda(p,p),\\ \frac{d}{dt_\lambda}\langle q,q\rangle &= 4V_\lambda^{21}Q_\lambda(p,q)-4V_\lambda^{11}Q_\lambda(q,q)=-2Q_\lambda(q,q).\end{aligned} \tag{6.11}$$

Thus

$$f_*(I\nabla F_\lambda)=f_*\left\{\frac{d}{dt_\lambda}\begin{pmatrix}p\\q\end{pmatrix}\right\}=\frac{d}{dt_\lambda}\begin{pmatrix}-\langle p,p\rangle\\ \langle q,q\rangle\end{pmatrix}=-2\begin{pmatrix}Q_\lambda(p,p)\\ Q_\lambda(q,q)\end{pmatrix}.$$

By Eqs. (5.3), (3.5), and (6.7):

$$\nabla H_\lambda=\tfrac{1}{2}\nabla F_\lambda+4H_\lambda\nabla H_\lambda\,,$$

$$f_*(I\nabla H_\lambda)=\frac{1}{2(1-4H_\lambda)}f_*(I\nabla F_\lambda)=\frac{-1}{1-4H_\lambda}\begin{pmatrix}Q_\lambda(p,p)\\ Q_\lambda(q,q)\end{pmatrix}=\frac{1}{1-4H_\lambda}PJG_\lambda=PJg_\lambda\,.$$

Hence we have the first part of Eq. (6.10). The second part is obtained by comparing the coefficients of the same power λ^{-k-1}.

Corollary 6.4: (i) In the case $k=2$, denote $\tau_1=x,\ \tau_2=y$. Let $(p(x,y),q(x,y))$ be a compatible solution of

$$\begin{pmatrix}p\\q\end{pmatrix}_x=I\nabla H_1,\quad \begin{pmatrix}p\\q\end{pmatrix}_y=I\nabla H_2.$$

Then $u(x,y)=-\langle p,p\rangle, v(x,y)=\langle q,q\rangle$ solves the coupled NS equation:

$$\begin{pmatrix}u\\v\end{pmatrix}_y=X_2=\begin{pmatrix}u_{xx}-2u^2v\\ -v_{xx}+2uv^2\end{pmatrix}. \tag{6.12}$$

(ii) In the case $k=3$, denote $\tau_1=x,\ \tau_3=t$. Let $(p(x,t),q(x,t))$ be a compatible solution of

$$\begin{pmatrix}p\\q\end{pmatrix}_x=I\nabla H_1,\quad \begin{pmatrix}p\\q\end{pmatrix}_t=I\nabla H_3.$$

Then $u(x,t)=-\langle p,p\rangle,\ v(x,t)=\langle q,q\rangle$ solves the coupled mKdV equation:

$$\begin{pmatrix}u\\v\end{pmatrix}_t=X_3=\begin{pmatrix}u_{xxx}-6uu_xv\\ v_{xxx}-6uvv_x\end{pmatrix}. \tag{6.13}$$

VII. THE KP EQUATION

In this section, the special solution of the KP equation is first separated into two AKNS flows X_2 and X_3, and then into three confocal flows H_1,H_2,H_3.

Proposition 7.1: Let $u(x,y,t),v(x,y,t)$ be a compatible solution of the coupled NS equation (6.12) and the coupled mKdV (6.13). Then

$$w(x,y,t)=-2u(x,y,t)v(x,y,t) \tag{7.1}$$

solves the KP equation:

$$w_t=\tfrac{1}{4}(w_{xx}+3w^2)_x+\tfrac{3}{4}\partial_x^{-1}w_{yy}\,. \tag{7.2}$$

Proof: A direct calculation gives:

$$w_{tx}=w_{xxxx}+\tfrac{3}{2}(w^2)_{xx}+6(u_{xxx}v_x+u_xv_{xxx}+2u_{xx}v_{xx}),$$

$$\tfrac{3}{4}w_{yy}=\tfrac{3}{4}w_{xxxx}+\tfrac{3}{4}(w^2)_{xx}+6(u_{xxx}v_x+u_xv_{xxx}+2u_{xx}v_{xx}).$$

The difference gives Eq. (7.2)

Theorem 7.2: Let $(p(x,y,t),q(x,y,t))$ be a compatible solution of three systems of ODEs:

$$\begin{pmatrix}p\\q\end{pmatrix}_x=I\nabla H_1,\quad \begin{pmatrix}p\\q\end{pmatrix}_y=I\nabla H_2,\quad \begin{pmatrix}p\\q\end{pmatrix}_t=I\nabla H_3, \tag{7.3}$$

where H_j's are given explicitly by Eq. (5.6). Then

$$w(x,y,t)=2\langle p,p\rangle\langle q,q\rangle=2\langle Ap,q\rangle+4H_1 \tag{7.4}$$

solves the KP equation (7.2).

Proof: Since the flow operators defined by Eq. (6.9) h_1^x,h_2^y,h_3^t commute, we write the compatible solution in two ways:

$$\begin{pmatrix}p\\q\end{pmatrix}=h_1^xh_2^y\left\{h_3^t\begin{pmatrix}p_0\\q_0\end{pmatrix}\right\}=h_1^xh_3^t\left\{h_2^y\begin{pmatrix}p_0\\q_0\end{pmatrix}\right\}, \tag{7.5}$$

and regard the quantities in the parentheses $\{\cdot\}$ as initial values. Then, as a function of (x,y) and (x,t), respectively,

$$(u(x,y,t),v(x,y,t))=(-\langle p,p\rangle,\langle q,q\rangle)$$

Eqs. (6.12) and (6.13) simultaneously by Corollary 6.4. According to Proposition 7.1,

$$w=-2uv=2\langle p,p\rangle\langle q,q\rangle$$

is a solution to Eq. (7.2).

VIII. EVOLUTION PICTURE VIA THE ABEL–JACOBI COORDINATES

The shape of Eq. (4.4) suggests the consideration of the holomorphic differential

$$\tilde{\omega}_s=\frac{\lambda^{g-s}d\lambda}{2\sqrt{R(\lambda)}},\quad s=1,\dots,g, \tag{8.1}$$

on the hyperelliptic curve Γ:

$$\xi^2-4R(\lambda)=0, \tag{8.2}$$

with genus $g=N-1$ since $\deg R=2N$ by Eq. (4.3). For the same λ, there are two points on different sheets of the Riemann surface Γ:

$$\rho(\lambda)=(\lambda,2\sqrt{R(\lambda)}),\quad \rho_-(\lambda)=(\lambda,-2\sqrt{R(\lambda)}).$$

At infinity, the affine equation (8.2) is transformed into ($z=\lambda^{-1}$, $\hat{\xi}=z^N\xi$):

$$\hat{\xi}^2-4R_*(z)=0, \tag{8.3}$$

with

$$R_*(z)=z^{2N}R(z^{-1})=\prod_{j=1}^{2N}(1-\lambda_j z).$$

The two infinities are represented as:

$$\infty_l=(z=0,\hat{\xi}=(-1)^l 2),\quad l=1,2. \tag{8.4}$$

Take the canonical basis of cycles on $\Gamma: a_1,\ldots,a_g; b_1,\ldots,b_g$. Let $C=(C_{js})$ be the inverse of the periodic matrix (A_{sk}):

$$C=(A_{sk})^{-1}_{g\times g},\quad A_{sk}=\int_{a_k}\tilde{\omega}_s. \tag{8.5}$$

Then for the normalized holomorphic differential

$$\omega_j=\sum_{s=1}^{g}C_{js}\tilde{\omega}_s,\quad \omega=(\omega_1,\ldots,\omega_g)^T=C\tilde{\omega},$$

we have

$$\int_{a_k}\omega_j=\delta_{jk},\quad \int_{b_k}\omega_j=B_{jk}. \tag{8.6}$$

According to the Riemannian bilinear relation,[19] the matrix $B=(B_{jk})$ is symmetric and has positive definite imaginary part, and is used to construct the Riemannian theta function of Γ:

$$\theta(\zeta)=\sum_{z\in\mathcal{Z}^g}\exp\pi\sqrt{-1}(\langle Bz,z\rangle+2\langle\zeta,z\rangle),\quad \zeta\in\mathbb{C}^g.$$

For fixed λ_0, the Abel–Jacobi coordinates are defined as

$$\phi=\sum_{k=1}^{g}\int_{\rho(\lambda_0)}^{\rho(\mu_k)}\omega,\quad \psi=\sum_{k=1}^{g}\int_{\rho(\lambda_0)}^{\rho(\nu_k)}\omega. \tag{8.7}$$

Lemma 8.1: Let $S_k=\lambda_1^k+\cdots+\lambda_{2N}^k$. Then the coefficients of

$$\frac{1}{\sqrt{R_*(z)}}=\sum_{k=0}^{\infty}\Lambda_k z^k \tag{8.8}$$

satisfy the recursive formula:

$$\Lambda_0=1,\quad \Lambda_1=\tfrac{1}{2}S_1,$$
$$\Lambda_k=\frac{1}{2k}\left(S_k+\sum_{\substack{i+j=k\\ i,j\geqslant 1}}S_i\Lambda_j\right). \tag{8.9}$$

Proof: Since $-\ln(1-t)=\Sigma_{k=1}^{\infty}k^{-1}t^k$, we have

$$\ln\frac{1}{\sqrt{R_*(z)}}=-\frac{1}{2}\sum_{j=1}^{2N}\ln(1-\lambda_j z)=\sum_{k=1}^{\infty}\frac{1}{2k}S_k z^k.$$

By differentiating with regard to z and comparing the coefficients of z^k, we get Eq. (8.9).

Let $C_1,\ldots,C_g$ be the column vectors of C defined by Eq. (8.5). Then by direct calculations, the coefficients in

$$\frac{1}{2\sqrt{R_*(z)}}(C_1z+C_2z+\cdots+C_gz^g)=\sum_{k=1}^{\infty}\Omega_k z^k \tag{8.10}$$

are

$$\Omega_k=\tfrac{1}{2}(\Lambda_{k-1}C_1+\cdots+\Lambda_{k-g}C_g) \tag{8.11}$$

with additional defined $\Lambda_{-s}=0$, $(s=1,2,...)$. Specifically,

$$\begin{gathered}\Omega_0=0,\quad \Omega_1=\tfrac{1}{2}C_1,\\ \Omega_k=\tfrac{1}{2}(\Lambda_{k-1}C_1+\cdots+\Lambda_1C_{k-1}+C_k),\quad (k=1,...,g).\end{gathered} \tag{8.12}$$

Proposition 8.2: The τ_k flow is straightened by the Abel–Jacobi coordinates:

$$\frac{d\phi}{d\tau_k}=\Omega_k,\quad \frac{d\psi}{d\tau_k}=-\Omega_k. \tag{8.13}$$

Proof: By Eqs. (4.1), (4.3), and (5.3) we have

$$\sqrt{R(\lambda)}=a(\lambda)(1-4H_\lambda). \tag{8.14}$$

Since the derivative of a function along a Hamiltonian flow is equal to its Poisson bracket with the Hamiltonian, Eq. (5.3) implies

$$\frac{d}{d\tau_\lambda}=\frac{1}{2(1-4H_\lambda)}\frac{d}{dt_\lambda}. \tag{8.15}$$

Therefore, from Eqs. (4.5), (8.14), and (8.10) we get

$$\frac{d\tilde{\phi}}{d\tau_\lambda}=\frac{\lambda^g}{2\sqrt{R(\lambda)}}(\lambda^{-1},\ldots,\lambda^{-g})^T,$$

$$\frac{d\phi}{d\tau_\lambda}=C\frac{d\tilde{\phi}}{d\tau_\lambda}=\frac{\lambda^g}{2\sqrt{R(\lambda)}}(C_1\lambda^{-1}+\cdots+C_g\lambda^{-g})=\sum_{k=1}^{\infty}\Omega_k\lambda^{-k-1}.$$

Hence we obtain the first part of Eq. (8.13) after comparing the coefficients of λ^{-k-1}, while the second part is obtained similarly.

The straightened equations (8.13) are easily integrated by quadratures: $\phi=\phi_0+\Sigma\Omega_k\tau_k$. And the evolution picture of the confocal flow and AKNS flow becomes very simple through the ''window'' of the Abel–Jacobi coordinates ϕ (as well as ψ):

$$\begin{gathered}\text{confocal}\ \ H_k:\quad \phi=\phi_0+\Omega_k\tau_k,\\ \text{AKNS}\ \ X_k:\quad \phi=\phi_0+\Omega_1x+\Omega_k\tau_k.\end{gathered} \tag{8.16}$$

Specifically,

$$\left.\begin{array}{c}\text{ZS–Bargmann}\\ \text{Stationary AKNS}\end{array}\right\}:\quad \phi=\phi_0+\Omega_1x,$$

$$\text{coupled NS:}\quad \phi=\phi_0+\Omega_1 x+\Omega_2 y,$$
$$\text{coupled mKdV:}\quad \phi=\phi_0+\Omega_1 x+\Omega_3 t, \tag{8.17}$$
$$\text{KP:}\quad \phi=\phi_0+\Omega_1 x+\Omega_2 y+\Omega_3 t.$$

The corresponding explicit solutions are obtained by some inversion procedures from ϕ,ψ to the coordinates u, v, and w via the elliptic coordinates $\{\mu_k\}$ and $\{\nu_k\}$.

IX. INVERSION FROM ϕ,ψ TO $\{\mu_k\},\{\nu_k\}$

The Abel map $A:\mathrm{Div}(\Gamma)\to\mathcal{J}(\Gamma)=\mathbb{C}^g/\mathcal{T}$ is defined by:

$$A(P)=\int_{P_0}^{P}\omega,\quad A\left(\sum n_k P_k\right)=\sum n_k A(P_k), \tag{9.1}$$

where $P_0=\rho(\lambda_0)$ is fixed, $\mathrm{Div}(\Gamma)$ is the divisor group, and the lattice $\mathcal{T}$ is spanned by the periodic vectors $\{\delta_j;B_j\}$, which are the column vectors of E and (B_{js}) defined by Eq. (8.6). The definition of Abel–Jacobi coordinates is rewritten as

$$\phi=A\left\{\sum_{j=1}^{g}\rho(\mu_j)\right\},\quad \psi=A\left\{\sum_{j=1}^{g}\rho(\nu_j)\right\}. \tag{9.2}$$

According to the Riemann theorem,[19] there exists a constant vector K such that

(i) $\theta(A(\rho(\lambda))-\phi-K)$ has exactly g zeros at $\lambda=\mu_1,\ldots,\mu_g$;

(ii) $\theta(A(\rho(\lambda))-\psi-K)$ has exactly g zeros at $\lambda=\nu_1,\ldots,\nu_g$.

And we have the inversion formula:

$$\sum_{j=1}^{g}\mu_j^s=I_s(\Gamma)-\sum_{l=1}^{2}\operatorname*{Res}_{\lambda=\infty_l}\lambda^s d\ln\theta(A(\rho(\lambda))-\phi-K),$$
$$\sum_{j=1}^{g}\nu_j^s=I_s(\Gamma)-\sum_{l=1}^{2}\operatorname*{Res}_{\lambda=\infty_l}\lambda^s d\ln\theta(A(\rho(\lambda))-\psi-K), \tag{9.3}$$

where

$$I_s(\Gamma)=\sum_{j=1}^{g}\int_{a_j}\lambda^s\omega_j.$$

In the neighborhood of ∞_l $(l=1,2)$, since the two-valued function $\lambda^{-N}\sqrt{R(\lambda)}$ tends to $(-1)^l$ due to Eq. (8.4), we have $(z=\lambda^{-1})$:

$$\lambda^{-N}\sqrt{R(\lambda)}=(-1)^l\sqrt{R_*(z)},$$

By Eq. (8.1) we get:

$$\omega=C\tilde{\omega}=(-1)^{l-1}\frac{z^{-1}\,dz}{z\sqrt{R_*(z)}}(C_1 z+\cdots+C_g z^g).$$

With the help of Eq. (8.10) we obtain:

$$\omega=(-1)^{l-1}\sum_{k=1}^{\infty}\Omega_k z^{k-1}\,dz, \tag{9.4}$$

$$A(\rho(z^{-1}))=-\eta_l+(-1)^{l-1}\sum_{k=1}^{\infty}\frac{1}{k}\Omega_k z^k, \tag{9.5}$$

where

$$\eta_l=\int_{\infty_l}^{P_0}\omega.$$

Hence we have the power series expansions near ∞_l in the local coordinate $z=\lambda^{-1}$:

$$\ln\theta(A(\rho(\lambda))-\phi-K)=\ln\theta\left(\phi+K+\eta_l+(-1)^l\sum_{k=1}^{\infty}\frac{1}{k}\Omega_k z^k\right)=\ln\theta(\phi+K+\eta_l)+\sum_{k=1}^{\infty}f_k^l z^k,$$

$$\begin{aligned}\ln\theta(A(\rho(\lambda))-\psi-K)&=\ln\theta\left(-\psi-K-\eta_l+(-1)^{l-1}\sum_{k=1}^{\infty}\frac{1}{k}\Omega_k z^k\right)=\ln\theta(-\psi-K-\eta_l)\\&\quad+\sum_{k=1}^{\infty}\hat{f}_k^l z^k.\end{aligned} \tag{9.6}$$

Here the fact $\theta(\zeta)=\theta(-\zeta)$ is used. The power sums are obtained after substituting Eq. (9.6) into Eq. (9.3):

$$\begin{aligned}\sum_{j=1}^{g}\mu_j^s&=I_s(\Gamma)-sf_s^1-sf_s^2,\\ \sum_{j=1}^{g}\nu_j^s&=I_s(\Gamma)-s\hat{f}_s^1-s\hat{f}_s^2.\end{aligned} \tag{9.7}$$

The coefficients $f_k^l,\hat{f}_k^l$ in the Taylor expansions (9.6) are calculated by the chain rule of differentiation. Denote $\partial_j=\partial/\partial\zeta_j$, $\partial_{jk}^2=\partial^2/\partial\zeta_j\partial\zeta_k$, etc. Adopting the Einstein summation convention, finally we get:

$$\begin{aligned}\sum_{j=1}^{g}\mu_j&=I_1(\Gamma)+\Omega_1^j\partial_j\ln\frac{\theta_1}{\theta_2},\\
\sum_{j=1}^{g}\mu_j^2&=I_2(\Gamma)+\Omega_2^j\partial_j\ln\frac{\theta_1}{\theta_2}-\Omega_1^j\Omega_1^k\partial_{jk}^2\ln\theta_1\theta_2,\\
\sum_{j=1}^{g}\mu_j^3&=I_3(\Gamma)+\Omega_3^j\partial_j\ln\frac{\theta_1}{\theta_2}-\frac{3}{2}\Omega_2^j\Omega_1^k\partial_{jk}^2\ln\theta_1\theta_2+\frac{1}{2}\Omega_1^j\Omega_1^k\Omega_1^r\partial_{jkr}^3\ln\frac{\theta_1}{\theta_2},\\
\sum_{j=1}^{g}\mu_j^4&=I_4(\Gamma)+\Omega_4^j\partial_j\ln\frac{\theta_1}{\theta_2}-\left(\frac{4}{3}\Omega_3^j\Omega_1^k+\frac{1}{2}\Omega_2^j\Omega_2^k\right)\partial_{jk}^2\ln\theta_1\theta_2+\Omega_2^j\Omega_1^k\Omega_1^r\partial_{jkr}^3\ln\frac{\theta_1}{\theta_2}\\
&\quad-\frac{1}{6}\Omega_1^j\Omega_1^k\Omega_1^r\Omega_1^i\partial_{jkri}^4\ln\theta_1\theta_2,\\
\sum_{j=1}^{g}\nu_j&=I_1(\Gamma)-\Omega_1^j\partial_j\ln\frac{\theta_1^*}{\theta_2^*},\end{aligned} \tag{9.8}$$

$$\sum_{j=1}^{g} \nu_j^2 = I_2(\Gamma) - \Omega_2^j \partial_j \ln \frac{\theta_1^*}{\theta_2^*} - \Omega_1^j \Omega_1^k \partial_{jk}^2 \ln \theta_1^* \theta_2^* ,$$

$$\sum_{j=1}^{g} \nu_j^3 = I_3(\Gamma) - \Omega_3^j \partial_j \ln \frac{\theta_1^*}{\theta_2^*} - \frac{3}{2} \Omega_2^j \Omega_1^k \partial_{jk}^2 \ln \theta_1^* \theta_2^* - \frac{1}{2} \Omega_1^j \Omega_1^k \Omega_1^r \partial_{jkr}^3 \ln \frac{\theta_1^*}{\theta_2^*},$$

$$\sum_{j=1}^{g} \nu_j^4 = I_4(\Gamma) - \Omega_4^j \partial_j \ln \frac{\theta_1^*}{\theta_2^*} - \left(\frac{4}{3} \Omega_3^j \Omega_1^k + \frac{1}{2} \Omega_2^j \Omega_2^k \right) \partial_{jk}^2 \ln \theta_1^* \theta_2^* - \Omega_2^j \Omega_1^k \Omega_1^r \partial_{jkr}^3 \ln \frac{\theta_1^*}{\theta_2^*}$$
$$- \frac{1}{6} \Omega_1^j \Omega_1^k \Omega_1^r \Omega_1^i \partial_{jkri}^4 \ln \theta_1^* \theta_2^* ,$$

where $(l=1,2)$

$$\theta_l = \theta(\phi + K + \eta_l) = \theta\left(\sum \Omega_k \tau_k + \phi_0 + K + \eta_l \right),$$
$$\theta_l^* = \theta(-\psi - K - \eta_l) = \theta\left(\sum \Omega_k \tau_k - \psi_0 - K - \eta_l \right). \tag{9.9}$$

Since $\{\mu_j\}$ and $\{\nu_k\}$ appear symmetrically in Eq. (9.2), what we can expect to get in the inversion formula is only the symmetric function of $\{\mu_j\}$ or $\{\nu_j\}$.

Denote $x=\tau_1$, $y=\tau_2$, $t=\tau_3$. By the chain rule of differentiation for composition functions, Eq. (9.8) is further simplified as:

$$\sum_{j=1}^{g} \mu_j = I_1(\Gamma) + \partial_x \ln \frac{\theta_1}{\theta_2},$$

$$\sum_{j=1}^{g} \mu_j^2 = I_2(\Gamma) + \partial_y \ln \frac{\theta_1}{\theta_2} - \partial_x^2 \ln \theta_1 \theta_2 ,$$

$$\sum_{j=1}^{g} \mu_j^3 = I_3(\Gamma) + \left(\partial_t + \frac{1}{2} \partial_x^3 \right) \ln \frac{\theta_1}{\theta_2} - \frac{3}{2} \partial_y \partial_x \ln \theta_1 \theta_2 ,$$

$$\sum_{j=1}^{g} \mu_j^4 = I_4(\Gamma) + (\partial_{\tau_4} + \partial_y \partial_x^2) \ln \frac{\theta_1}{\theta_2} - \left(\frac{4}{3} \partial_t \partial_x + \frac{1}{2} \partial_y^2 + \frac{1}{6} \partial_x^4 \right) \ln \theta_1 \theta_2 ,$$

$$\sum_{j=1}^{g} \nu_j = I_1(\Gamma) - \partial_x \ln \frac{\theta_1^*}{\theta_2^*}, \tag{9.10}$$

$$\sum_{j=1}^{g} \nu_j^2 = I_2(\Gamma) - \partial_y \ln \frac{\theta_1^*}{\theta_2^*} - \partial_x^2 \ln \theta_1^* \theta_2^* ,$$

$$\sum_{j=1}^{g} \nu_j^3 = I_3(\Gamma) - \left(\partial_t + \frac{1}{2} \partial_x^3 \right) \ln \frac{\theta_1^*}{\theta_2^*} - \frac{3}{2} \partial_y \partial_x \ln \theta_1^* \theta_2^* ,$$

$$\sum_{j=1}^{g} \nu_j^4 = I_4(\Gamma) - (\partial_{\tau_4} + \partial_y \partial_x^2) \ln \frac{\theta_1^*}{\theta_2^*} - \left(\frac{4}{3} \partial_t \partial_x + \frac{1}{2} \partial_y^2 + \frac{1}{6} \partial_x^4 \right) \ln \theta_1^* \theta_2^* .$$

X. RELATION BETWEEN $\{\mu_k\}$, $\{\nu_k\}$, AND $(u,v)=f(p,q)$

Proposition 10.1: Let $u=-\langle p,p\rangle$, $v=\langle q,q\rangle$. Then

$$\frac{1}{u}\frac{du}{d\tau_\lambda}=\frac{m(\lambda)}{\sqrt{R(\lambda)}},\quad \frac{1}{v}\frac{dv}{d\tau_\lambda}=\frac{-n(\lambda)}{\sqrt{R(\lambda)}}. \tag{10.1}$$

Proof: By Eqs. (8.15), (6.11), (4.1), and (8.14), we have

$$\frac{d}{d\tau_\lambda}\langle p,p\rangle=\frac{1}{2(1-4H_\lambda)}\frac{d}{dt_\lambda}\langle p,p\rangle=\frac{Q_\lambda(p,p)}{1-4H_\lambda}=\frac{\langle p,p\rangle m(\lambda)}{(1-4H_\lambda)a(\lambda)}=\frac{\langle p,p\rangle m(\lambda)}{\sqrt{R(\lambda)}}.$$

The calculation for v is similar.

Proposition 10.2: Let

$$\sigma_k=\sum_{j=1}^{g}\mu_j^k,\quad \hat{\sigma}_k=\sum_{j=1}^{g}\nu_j^k,\quad S_k=\sum_{j=1}^{2N}\lambda_j^k. \tag{10.2}$$

Then

$$\frac{1}{u}\frac{du}{d\tau_k}=T_k,\quad \frac{1}{v}\frac{dv}{d\tau_k}=-\hat{T}_k\quad (k=0,1,2,...), \tag{10.3}$$

where $T_k,\hat{T}_k$ are determined, respectively, by the recursive formulas:

$$\begin{gathered}\text{(i)}\quad T_0=1,\quad T_1=\tfrac{1}{2}S_1-\sigma_1,\\ T_k=\frac{1}{k}\left(\frac{1}{2}S_k-\sigma_k\right)+\frac{1}{k}\sum_{\substack{i+j=k\\ i,j\geqslant 1}}\left(\frac{1}{2}S_i-\sigma_i\right)T_j,\end{gathered} \tag{10.4}$$

$$\begin{gathered}\text{(ii)}\quad \hat{T}_0=1,\quad \hat{T}_1=\tfrac{1}{2}S_1-\hat{\sigma}_1,\\ \hat{T}_k=\frac{1}{k}\left(\frac{1}{2}S_i-\hat{\sigma}_i\right)+\frac{1}{k}\sum_{\substack{i+j=k\\ i,j\geqslant 1}}\left(\frac{1}{2}S_i-\hat{\sigma}_i\right)\hat{T}_{j,}.\end{gathered} \tag{10.5}$$

Proof: By a way quite similar to the proof of Eq. (8.9), we have Eq. (10.4) based on Eq. (10.1) and the expansion:

$$\frac{m(\lambda)}{\sqrt{R(\lambda)}}=\lambda^{-1}\exp\left\{\sum_{k=1}^{\infty}k^{-1}\left(\frac{1}{2}S_k-\sigma_k\right)\lambda^{-k}\right\}=\sum_{k=0}^{\infty}T_k\lambda^{-k-1}.$$

Equation (10.5) is proved with slight adjustment.

Substituting Eq. (9.10) into Eq. (10.3) in the case of $k=1$, we have

$$\frac{u_x}{u}=N_1-\partial_x\ln\frac{\theta_1}{\theta_2},\quad \frac{v_x}{v}=-N_1-\partial_x\ln\frac{\theta_1^*}{\theta_2^*}, \tag{10.6}$$

with

$$N_1=\tfrac{1}{2}S_1-I_1(\Gamma). \tag{10.7}$$

Thus

$$u=u_0e^{N_1x}\frac{\theta_2}{\theta_1}=u_0e^{N_1x}\frac{\theta(\Sigma\Omega_k\tau_k+\phi_0+K+\eta_2)}{\theta(\Sigma\Omega_k\tau_k+\phi_0+K+\eta_1)},$$
$$v=v_0e^{-N_1x}\frac{\theta_2^*}{\theta_1^*}=v_0e^{-N_1x}\frac{\theta(\Sigma\Omega_k\tau_k-\psi_0-K-\eta_2)}{\theta(\Sigma\Omega_k\tau_k-\psi_0-K-\eta_1)}, \tag{10.8}$$

where u_0,v_0 are independent of $x=\tau_1$, but dependent (if we consider the next flows) upon $y=\tau_2$, $t=\tau_3,\tau_4,\ldots$. Nevertheless, for the H_1 flow, except $x=\tau_1$, no other independent variables $\tau_2,\tau_3,\ldots$ appear. Thus we have:

Proposition 10.1: The stationary AKNS equation (6.5) has solution

$$u(x)=u(0)e^{N_1x}\frac{\theta(\Omega_1x+\phi_0+K+\eta_2)\,\theta(\phi_0+K+\eta_1)}{\theta(\Omega_1x+\phi_0+K+\eta_1)\,\theta(\phi_0+K+\eta_2)},$$
$$v(x)=v(0)e^{-N_1x}\frac{\theta(\Omega_1x-\psi_0-K-\eta_2)\,\theta(\psi_0+K+\eta_1)}{\theta(\Omega_1x-\psi_0-K-\eta_1)\,\theta(\psi_0+K+\eta_2)}, \tag{10.9}$$

which is called the finite-band potential of the ZS spectral problem (2.1).

Consider the H_1, H_2, and H_3 flow. Substitute the expressions of u,v of Eq. (10.8) into $w=-2uv$. By Theorem 7.2, we have the solution of KP:

$$w(x,y,t)=C(y,t)\,\frac{\theta_2\theta_2^*}{\theta_1\theta_1^*}.$$

The ‘‘coefficient’’ $C(y,t)$ is determined by letting $x=0$. Thus we obtain:

$$w(x,y,t)=w(0,y,t)\,\frac{\theta_2\theta_2^*}{\theta_1\theta_1^*}\left(\frac{\theta_1\theta_1^*}{\theta_2\theta_2^*}\right)_{x=0}.$$

Proposition 10.2: The KP equation has a special solution in the form:

$$w(x,y,t)=w(0,y,t)\,\frac{\theta(\Omega_1x+\Omega_2y+\Omega_3t+\phi_0+K+\eta_2)\,\theta(\Omega_1x+\Omega_2y+\Omega_3t-\psi_0-K-\eta_2)}{\theta(\Omega_1x+\Omega_2y+\Omega_3t+\phi_0+K+\eta_1)\,\theta(\Omega_1x+\Omega_2y+\Omega_3t-\psi_0-K-\eta_1)}$$
$$\cdot\,\frac{\theta(\Omega_2y+\Omega_3t+\phi_0+K+\eta_1)\,\theta(\Omega_2y+\Omega_3t-\psi_0-K-\eta_1)}{\theta(\Omega_2y+\Omega_3t+\phi_0+K+\eta_2)\,\theta(\Omega_2y+\Omega_3t-\psi_0-K-\eta_2)}. \tag{10.10}$$

We list the first members of Eq. (10.3) for later use:

$$\frac{u_x}{u}=\Sigma_1,\quad \frac{u_y}{u}=\frac{1}{2}\Sigma_2+\frac{1}{2}\Sigma_1^2,$$
$$\frac{u_t}{u}=\tfrac{1}{3}\Sigma_3+\tfrac{1}{2}\Sigma_2\Sigma_1+\tfrac{1}{6}\Sigma_1^3, \tag{10.11}$$
$$\frac{u_{\tau_4}}{u}=\tfrac{1}{4}\Sigma_4+\tfrac{1}{3}\Sigma_3\Sigma_1+\tfrac{1}{8}\Sigma_2^2+\tfrac{1}{4}\Sigma_2\Sigma_1^2+\tfrac{1}{24}\Sigma_1^4,$$

where $\Sigma_k=\tfrac{1}{2}S_k-\sigma_k$. It is more convenient to represent the remainders in terms of u and its derivatives:

$$\frac{u_x}{u}=\left(\frac{S_1}{2}-\sigma_1\right),\quad \frac{u_y}{u}=\frac{1}{2}\left(\frac{S_2}{2}-\sigma_2\right)+\frac{1}{2}\left(\frac{u_x}{u}\right)^2,$$

$$\frac{u_t}{u}=\frac{1}{3}\left(\frac{S_3}{2}-\sigma_3\right)+\frac{u_y u_x}{u^2}-\frac{1}{3}\left(\frac{u_x}{u}\right)^3, \tag{10.12}$$

$$\frac{u_{\tau_4}}{u}=\frac{1}{4}\left(\frac{S_4}{2}-\sigma_4\right)+\frac{u_t u_x}{2}+\frac{1}{2}\left(\frac{u_y}{u}\right)^2-\frac{u_y u_x^2}{u^3}+\frac{1}{4}\left(\frac{u_x}{u}\right)^4.$$

XI. ANOTHER FORM OF ALGEBRO-GEOMETRIC SOLUTION OF KP

In order to derive another form of the explicit solution of KP, we take the initial value as $h_4^{\tau}(p_0,q_0)^T$ and consider

$$\begin{pmatrix} p \\ q \end{pmatrix}=h_1^x h_2^y h_3^t h_4^{\tau_4}\begin{pmatrix} p_0 \\ q_0 \end{pmatrix},$$

$$u=-\langle p,p\rangle,\quad v=\langle q,q\rangle,\quad w=-2uv.$$

The introduction of τ_4 is convenient in the proof of some important facts. Since in the final results there is no τ_4 and the initial data can be chosen arbitrarily, we may let $\tau_4=0$ in the end. Substitute Eq. (9.10) into the second of Eq. (10.12):

$$\begin{aligned} 2\frac{u_y}{u}&=\frac{S_2}{2}-I_2(\Gamma)-\partial_y \ln\frac{\theta_1}{\theta_2}+\partial_x^2 \ln\theta_1\theta_2+\left(\frac{u_x}{u}\right)^2 \\ &=\frac{S_2}{2}-I_2(\Gamma)-(\partial_y+\partial_x^2)\ln\frac{\theta_1}{\theta_2}+2\partial_x^2\ln\theta_1+\left(\frac{u_x}{u}\right)^2. \end{aligned} \tag{11.1}$$

By Eqs. (10.8) and (10.6) we have

$$-(\partial_y+\partial_x^2)\ln\frac{\theta_1}{\theta_2}=(\partial_y+\partial_x^2)\ln u-N_2,\quad N_2=\partial_y\ln u_0. \tag{11.2}$$

Substitute this into Eq. (11.1). By using Eq. (6.12), we have:

$$\partial_x^2\ln\theta_1+uv+\frac{1}{2}\left(\frac{S_2}{2}-I_2(\Gamma)-N_2\right)=0. \tag{11.3}$$

Hence we obtain the solution of the KP equation: $w=-2uv$.

Theorem 11.1: The KP equation (7.2) has the solution:

$$w(x,y,t)=2\partial_x^2\ln\theta(\Omega_1 x+\Omega_2 y+\Omega_3 t+D)+w_0, \tag{11.4}$$

where the constants D and w_0 are

$$D=\phi_0+K+\int_{\infty_1}^{P_0}\omega,\quad w_0=\frac{S_2}{2}-I_2(\Gamma)-N_2.$$

Proof: Since u_0 (therefore N_2) in Eq. (10.8) is independent of x, the only thing required to prove is the independence of N_2 with regard to y and t. Substitute Eq. (9.10) into the third equation of Eq. (10.11):

$$3\frac{u_t}{u}=\frac{S_3}{2}-I_3(\Gamma)-\left(\partial_t+\frac{1}{2}\partial_x^3\right)\ln\frac{\theta_1}{\theta_2}+\frac{3}{2}\partial_y\partial_x\ln\theta_1\theta_2+3\frac{u_yu_x}{u^2}-\left(\frac{u_x}{u}\right)^3$$
$$=\frac{S_3}{2}-I_3(\Gamma)-\left(\partial_t+\frac{1}{2}\partial_x^3+\frac{3}{2}\partial_y\partial_x\right)\ln\frac{\theta_1}{\theta_2}+3\partial_y\partial_x\ln\theta_1+3\frac{u_yu_x}{u^2}-\left(\frac{u_x}{u}\right)^3. \qquad (11.5)$$

Again by Eqs. (10.8) and (10.6) we have

$$-\left(\partial_t+\frac{1}{2}\partial_x^3+\frac{3}{2}\partial_y\partial_x\right)\ln\frac{\theta_1}{\theta_2}=\left(\partial_t+\frac{1}{2}\partial_x^3+\frac{3}{2}\partial_y\partial_x\right)\ln u-N_3,$$
$$N_3=\partial_t\ln u_0. \qquad (11.6)$$

Put it into Eq. (11.5). Taking advantage of Eqs. (6.12) and (6.13), after some calculations we get

$$\partial_y\partial_x\ln\theta_1+(u_xv-uv_x)+\frac{1}{3}\left(\frac{S_3}{2}-I_3(\Gamma)-N_3\right)=0. \qquad (11.7)$$

Note that N_3 is independent of x. Acting with ∂_y,∂_x on Eqs. (11.3) and (11.7), respectively, the difference of the results gives $\partial_yN_2=0$, which means N_2 is independent of y.

To prove the independence of N_2 with regard to t, we treat the fourth member of Eq. (10.11) with the expression σ_4 in Eq. (9.10):

$$4\frac{u_{\tau_4}}{u}=\frac{S_4}{2}-I_4(\Gamma)-(\partial_{\tau_4}+\partial_y\partial_x^2)\ln\frac{\theta_1}{\theta_2}+\left(\frac{4}{3}\partial_t\partial_x+\frac{1}{2}\partial_y^2+\frac{1}{6}\partial_x^4\right)\ln\theta_1\theta_2$$
$$+4\frac{u_tu_x}{u^2}+2\left(\frac{u_y}{u}\right)^2-\frac{4u_yu_x^2}{u^3}+\left(\frac{u_x}{u}\right)^4.$$

Once more by Eqs. (10.8) and (10.6) we get

$$-\left(\partial_{\tau_4}+\partial_y\partial_x^2+\frac{4}{3}\partial_t\partial_x+\frac{1}{2}\partial_y^2+\frac{1}{6}\partial_x^4\right)\ln\frac{\theta_1}{\theta_2}=\left(\partial_{\tau_4}+\partial_y\partial_x^2+\frac{4}{3}\partial_t\partial_x+\frac{1}{2}\partial_y^2+\frac{1}{6}\partial_x^4\right)\ln u-N_4,$$
$$N_4=\partial_{\tau_4}\ln u_0. \qquad (11.8)$$

With the same technique, after tedious calculations we obtain

$$\frac{1}{12}(8\partial_t\partial_x+3\partial_y^2+\partial_x^4)\ln\theta_1+\left(u_{xx}v+uv_{xx}-u_xv_x-\frac{5}{2}u^2v^2\right)+\frac{1}{4}\left(\frac{S_4}{2}-I_4(\Gamma)-N_4\right)=0. \qquad (11.9)$$

Exert $12\partial_x,8\partial_t+\partial_x^3,3\partial_y$ on Eqs. (11.9), (11.3), (11.7), respectively, and cancel the terms containing the derivatives of $\ln\theta_1$. Finally we have

$$0=4\partial_tN_2+\partial_yN_3=5\partial_tN_2,$$

since $\partial_tN_2=\partial_yN_3=\partial_t\partial_y\ln u_0$. Thus N_2 is independent of t. This completes the proof of the theorem.

Note: The algebro-geometric solution of the coupled NS is suggested by Eqs. (10.8) and (11.2):

$$u(x,y)=u(0,0)e^{N_1x+N_2y}\frac{\theta(\Omega_1x+\Omega_2y+\phi_0+K+\eta_2)\,\theta(\phi_0+K+\eta_1)}{\theta(\Omega_1x+\Omega_2y+\phi_0+K+\eta_1)\,\theta(\phi_0+K+\eta_2)},$$
$$v(x,y)=v(0,0)e^{-N_1x-N_2y}\frac{\theta(\Omega_1x+\Omega_2y-\psi_0-K-\eta_2)\,\theta(\psi_0+K+\eta_1)}{\theta(\Omega_1x+\Omega_2y-\psi_0-K-\eta_1)\,\theta(\psi_0+K+\eta_2)}. \tag{11.10}$$

The only thing which should be discussed is the constant N_2 in the expression of $v(x,y)$.

The solution of KP in the form of Eq. (11.4) is obtained in Ref. 9. And the solution of NS in the form of Eq. (11.10) coincides with those found in Refs. 20–23.

A new integrable Davey–Stewartson-type equation

Attilio Maccari
Technical Institute ''G. Cardano,'' Piazza della Resistenza 1, 00015 Monterotondo, Rome, Italy

(Received 9 December 1998; accepted for publication 12 March 1999)

A new integrable nonlinear partial differential equation (PDE) in $2+1$ dimensions is derived starting from the Konopelchenko–Dubrovsky equation. We use an asymptotically exact reduction method based on Fourier expansion and spatio-temporal rescaling and obtain a new integrable Davey–Stewartson-type equation. In order to demonstrate the integrability of the new equation by the inverse scattering method, we apply the reduction technique to the Lax pair of the Konopelchenko–Dubrovsky equation and find the corresponding Lax pair of the new equation. The new equation reduces to the Davey–Stewartson or the nonlinear Schrodinger equation by appropriate limits. © *1999 American Institute of Physics.* [S0022-2488(99)04407-2]

I. INTRODUCTION

As it has been known for some time, very large classes of nonlinear evolution partial differential equations (PDEs) in $1+1$ and $2+1$ dimensions, with a dispersive linear part, can be reduced, by a limiting procedure involving the wave modulation induced by weak nonlinear effects, to a very limited number of ''universal'' nonlinear evolution PDEs. These model equations [of which the nonlinear Schrodinger (NLS) equation in $1+1$ dimension is the most important] appear in many applicative fields (in plasma physics, nonlinear optics, hydrodynamics, etc.) because this reduction technique is able to take into account weakly nonlinear effects. The model equations are integrable, since it is sufficient that the very large class from which they are obtainable contain just one integrable equation, because it is clear from this method that the property of integrability is inherited through the limiting technique.[1–5] This last statement about the integrability is based on heuristic considerations and could not be characterized as rigorous theorem; indeed, no precise definition of integrability is available for nonlinear evolution PDEs.[5]

The reduction method provides a powerful tool to understand the integrability of known equations and to derive new integrable equations likely to be relevant in applicative contexts. It can be also applied to construct approximate solutions for weakly nonlinear ordinary differential equations.[6,7]

The first step of the reduction method is to consider the linearized equation, i.e., the equation obtained after neglecting all the nonlinear terms. The linear evolution is best described by Fourier modes, as they have a constant amplitude and a well defined group velocity (in $2+1$ dimensions) $\mathbf{V}=(V_1(K,K_2),V_2(K_1,K_2))$ depending on the wave numbers K_1,K_2. Subsequently, we introduce the slow variables

$$\xi=\epsilon^p(x-V_1t),\quad \eta=\epsilon^p(y-V_2t),\quad \tau=\epsilon^q t, \tag{1.1}$$

where $p,q>0$, and ϵ is the expansion parameter, supposed to be sufficiently small. If now we introduce the nonlinear terms, the amplitude of the Fourier mode becomes a slowly varying function of space and time and then the rescaled variables ξ,η,τ account for the need to look on larger space and time scales, in order to determine the effects of the nonlinear terms.

In precedent papers, this method has been applied to certain integrable equations in $2+1$ dimensions. The most interesting results are that the Davey–Stewarston equation[8,9] is the typical model equation in $2+1$ dimensions and new integrable nonlinear PDEs can be obtained together with their Lax pair.[10–12] Moreover, the reduction method has been used to derive an equation of applicative relevance in plasma physics.[13,14]

In this paper we consider the Konopelchenko–Dubrovsky (KD) equation[15,16] (integrable by means of the spectral transform[17,18])

$$U_t-U_{xxx}-6\beta UU_x+\tfrac{3}{2}\alpha^2U^2U_x-3W_y+3aU_xW=0, \tag{1.2a}$$

$$W_x=U_y, \tag{1.2b}$$

where $U=U(x,y,t)$, $W=W(x,y,t)$, the subscripts denote partial differentiation and α,β are real parameters.

Applying the reduction method, a new class of integrable equations depending on two real parameters (a,b) can be derived

$$i\Psi_\tau+L_1\Psi+\Psi\Phi+\Psi\chi=0, \tag{1.3a}$$

$$L_2\chi=L_3|\Psi|^2,\quad \Phi_\xi=\chi_\eta\mp(|\Psi|^2)_\eta, \tag{1.3b}$$

where the linear differential operators are given by

$$L_1=\left(\frac{b^2-a^2}{4}\right)\frac{\partial^2}{\partial\xi^2}-a\,\frac{\partial^2}{\partial\xi\partial\eta}-\frac{\partial^2}{\partial\eta^2}, \tag{1.3c}$$

$$L_2=\left(\frac{b^2+a^2}{4}\right)\frac{\partial^2}{\partial\xi^2}+a\,\frac{\partial^2}{\partial\xi\partial\eta}+\frac{\partial^2}{\partial\eta^2}, \tag{1.3d}$$

$$L_3=\pm\frac{1}{4}\left(b^2+a^2+\frac{8b^2(a-1)}{(a-2)^2-b^2}\right)\frac{\partial^2}{\partial\xi^2}\pm\left(a+\frac{2b^2}{(a-2)^2-b^2}\right)\frac{\partial^2}{\partial\xi\partial\eta}\pm\frac{\partial^2}{\partial\eta^2}, \tag{1.3e}$$

and $\Psi=\Psi(\xi,\eta,\tau)$ is complex while $\Phi=\Phi(\xi,\eta,\tau)$, $\chi=\chi(\xi,\eta,\tau)$ are real. If we take $\xi=\eta$, we recover the nonlinear Schrodinger (NLS) equation.

The paper is organized as follows. In the next section we apply the reduction method to the KD equation (1.2) and obtain the new Eq. (1.3). We demonstrate that the equation reduces to the Davey–Stewartson equation if $\alpha=0$, $\beta\neq0$ or $\alpha\neq0$, $\beta=0$ and to the NLS equation if $\xi=\eta$.

In Sec. III we discuss in some detail how the reduction method can be applied to the Lax pair of the KD equation. We demonstrate that the Lax pair of the new Eq. (1.3) is

$$L\hat{\varphi}=0,\quad \hat{\varphi}_\tau+A\hat{\varphi}=0, \tag{1.4a}$$

with

$$L=\begin{pmatrix} \partial_\eta+\dfrac{(a-ib)}{2}\partial_\xi & \dfrac{2-a-ib}{\sqrt{2|(a-2)^2-b^2|}}\Psi \\ \dfrac{2-a+ib}{\sqrt{2|(a-2)^2-b^2|}}\Psi^* & \partial_\eta+\dfrac{(a+ib)}{2}\partial_\xi \end{pmatrix},\quad \varphi=\begin{pmatrix}\varphi_+\\ \varphi_-\end{pmatrix}, \tag{1.4b}$$

and

$$A=\begin{pmatrix} a_1\partial_{\xi\xi}+a_2\chi+a_3|\Psi|^2+a_4\Phi & a_5\Psi_\xi+a_6\Psi\partial_\xi+a_7\Psi_\eta \\ b_5\Psi^*_\xi+b_6\Psi^*\partial_\xi+b_7\Psi^*_\eta & b_1\partial_{\xi\xi}+b_2\chi+b_3|\Psi|^2+b_4\Phi \end{pmatrix}, \tag{1.4c}$$

where

$$a_1=-\frac{ib^2}{2},\quad a_2=\mp\left(\frac{a}{2b}-\frac{a^2}{4b}-\frac{b}{4}+\frac{i}{2}\right),\quad a_3=\frac{a^2}{4b}-\frac{a}{2b}+\frac{b}{4}-\frac{b}{|(a-2)^2-b^2|},$$

$$a_4=\frac{a-2+ib}{2b},\quad a_5=\frac{(a-2+ib)(ia-b)}{2\sqrt{2|(a-2)^2-b^2|}},\quad a_6=\frac{(2-a-ib)b}{\sqrt{2|(a-2)^2-b^2|}},$$

$$a_7=i\frac{(a-2+ib)}{\sqrt{2|(a-2)^2-b^2|}},\quad b_1=\frac{ib^2}{2},\quad b_2=\mp\left(\frac{a}{2b}-\frac{a^2}{4b}-\frac{b}{4}-\frac{i}{2}\right),$$

$$b_3=a_3,\quad b_4=\frac{a-2-ib}{2b},\quad b_5=\frac{(2-a+ib)(ia+b)}{2\sqrt{2|(a-2)^2-b^2|}},$$

$$b_6=a_6,\quad b_7=i\frac{(2-a+ib)}{\sqrt{2|(a-2)^2-b^2|}}. \tag{1.4d}$$

II. A NEW INTEGRABLE NONLINEAR PDE IN 2+1 DIMENSIONS

The linear dispersive part of the Konopelchenko–Dubrovsky Eq. (1.2) admits as a solution a Fourier mode, with a group velocity $\mathbf{V(K)}=(V_1(K_1,K_2),V_2(K_1,K_2))$,

$$V_1(K_1,K_2)=3\left(K_1^2+\frac{K_2^2}{K_1^2}\right),\quad V_2(K_1,K_2)=-\frac{6K_2}{K_1}, \tag{2.1}$$

where

$$\mathbf{V(K)}=\frac{\partial\omega}{\partial\mathbf{K}}, \tag{2.2}$$

and $\omega=\omega(K_1,K_2)$ is the dispersion relation. The envelope of a wave packet concentrated around a value $\mathbf{K}$ travels with the constant group velocity (2.1) and gets slowly dispersed.

We introduce a formal asymptotic Fourier expansion

$$U(x,y,t)=\sum_{n=-\infty}^{n=+\infty}\epsilon^{\gamma_n}\psi_n(\xi,\eta,\tau;\epsilon)\exp\{in(K_1x+K_2y-\omega t)\}, \tag{2.3}$$

with $\gamma_n=|n|$, for $n\neq 0$, $\gamma_0=r$ rational number to be determined later on and $\psi_{-n}(\xi,\eta,\tau;\epsilon)=\psi_n^*(\xi,\eta,\tau;\epsilon)$ [recall that $U(x,y,t)$ is real]. An analogous treatment is assumed for $W(x,y,t)$,

$$W(x,y,t)=\sum_{n=-\infty}^{n=+\infty}\epsilon^{\gamma_n}\phi_n(\xi,\eta,\tau;\epsilon)\exp\{in(K_1x+K_2y-\omega t)\}. \tag{2.4a}$$

The functions $\psi_n(\xi,\eta,\tau,\epsilon)$'s depend on the parameter ϵ and we suppose that the ψ_n's remain finite in the limit $\epsilon\to 0$ and moreover they can be expanded in power series of ϵ, i.e.,

$$\psi_n(\xi,\eta,\tau;\epsilon)=\sum_{i=0}^{\infty}\epsilon^i\psi_n^{(i)}(\xi,\eta,\tau). \tag{2.4b}$$

In the following for simplicity we use the abbreviations $\psi_n^{(0)}=\psi_n$ for $n\neq 0,1$, $\psi_1^{(0)}=\Psi$, $\psi_0^{(0)}=\Psi_0$ (and $\phi_n^{(0)}=\phi_n$ for $n\neq 0,1$, $\phi_1^{(0)}=\phi$, $\phi_0^{(0)}=\Phi$).

The final goal is to obtain the evolution equation for the modulation amplitude $\Psi=\Psi(\xi,\eta,\tau)$ and to understand how it is modified by choosing different wave numbers. We insert the expansions (2.2)–(2.3) into the KD Eq. (1.2) and consider the different equations obtained considering the coefficients of the Fourier modes $\exp(in(K_1 x+K_2 y-\omega t))$. From Eq. (1.2b), we get

$$\phi=\frac{K_2}{K_1}\Psi, \quad \phi^{(p)}=\frac{i}{K_1}\left(\frac{K_2}{K_1}\Psi_{\xi}-\Psi_{\eta}\right), \quad \phi^{(2p)}=\frac{1}{K_1^2}\left(\Psi_{\xi\eta}-\frac{K_2}{K_1}\Psi_{\xi\xi}\right), \tag{2.5a}$$

$$\Phi_{\xi}=\Psi_{0,\eta}. \tag{2.5b}$$

In Eq. (1.2a), we separate the contributions from the linear and nonlinear parts, $\epsilon^{\gamma_n}D_n\psi_n=\epsilon^2F_n$, where D_n is a linear differential operator acting on $\psi_n(\xi,\eta,\tau)$ and F_n is the contribution of the nonlinear part. The operator D_n is

$$\begin{aligned} D_n=&(-in\omega+\epsilon^q\partial_{\tau}-V_1\epsilon^p\partial_{\xi}-V_2\epsilon^p\partial_{\eta})-(inK_1+\epsilon^p\partial_{\xi})^3 \\ &-3(inK_2+\epsilon^p\partial_{\eta})\left(\frac{K_2}{K_1}-\frac{i}{K_1}\epsilon^p\partial_{\eta}+\frac{iK_2}{K_1^2}\epsilon^p\partial_{\xi}+\frac{1}{K_1^2}\epsilon^{2p}\partial_{\xi\eta}-\frac{K_2}{K_1^3}\epsilon^{2p}\partial_{\xi\xi}\right)+o(\epsilon^{3p}). \end{aligned} \tag{2.6}$$

It is easily seen that the first F_n have the following explicit form:

$$F_0=6\left(\beta-\alpha\frac{K_2}{K_1}\right)(|\Psi|^2)_{\xi}\epsilon^p+3\alpha(|\Psi|^2)_{\eta}\epsilon^p+o(\epsilon^{p+2},\epsilon^{p+2r}), \tag{2.7a}$$

$$F_2=3i(\alpha K_2-2\beta K_1)\Psi^2+o(\epsilon^p), \tag{2.7b}$$

$$\begin{aligned} F_1=&-6i\beta K_1\Psi_0\Psi\epsilon^{r-1}+3i\alpha K_1\Phi\psi\epsilon^{r-1}+\tfrac{3}{2}\alpha^2 iK_1|\Psi|^2\Psi\epsilon \\ &+3i(\alpha K_2-2\beta K_1)\psi_2\Psi^*\epsilon+o(\epsilon^{p+r-1},\epsilon^{2p}). \end{aligned} \tag{2.7c}$$

After taking $q=2$, $p=1$, $r=2$ for the proper balance of terms, we obtain at the lowest order for $n=0$ and $n=2$,

$$V_1\Psi_{0,\xi}+V_2\Psi_{0,\eta}+3\Phi_{\eta}+3\alpha(|\Psi|^2)_{\eta}+6\left(\beta-\alpha\frac{K_2}{K_1}\right)(|\Psi|^2)_{\xi}=0, \tag{2.8a}$$

$$\psi_2^{(0)}=\left(\frac{\beta}{K_1^2}-\frac{\alpha K_2}{2K_1^3}\right)\Psi^2, \tag{2.8b}$$

and for $n=1$,

$$i\Psi_{\tau}+\left(3K_1-3\frac{K_2^2}{K_1^3}\right)\Psi_{\xi\xi}+6\frac{K_2}{K_1^2}\Psi_{\xi\eta}-\frac{3}{K_1}\Psi_{\eta\eta}-3\alpha K_1\Phi\Psi+\chi\Psi=0, \tag{2.8c}$$

where

$$\chi=6\beta K_1\Psi_0+N|\Psi|^2, \tag{2.9a}$$

and

$$N=-\frac{3}{2}\alpha^2K_1+\frac{3}{2}\alpha^2\frac{K_2^2}{K_1^3}-6\alpha\beta\frac{K_2}{K_1^2}+6\frac{\beta^2}{K_1}. \tag{2.9b}$$

From Eq. (2.5b), we get

$$6\beta K_1\Phi_{\xi}=\chi_{\eta}-N|\Psi|^2_{\eta}. \tag{2.10}$$

Substituting (2.9a) into (2.8a), we obtain

$$V_1\chi_{\xi\xi}+V_2\chi_{\xi\eta}+3\chi_{\eta\eta}=\left[36\beta K_1\left(\alpha\frac{K_2}{K_1}-\beta\right)+V_1N\right]\times(|\Psi|^2)_{\xi\xi}+[V_2N-18\alpha\beta K_1](|\Psi|^2)_{\xi\eta}+3N(|\Psi|^2)_{\eta\eta}. \quad (2.11)$$

If in Eqs. (2.8c)–(2.10)–(2.11) we set $\alpha=0$, $\beta\neq 0$ or $\alpha\neq 0$, $\beta=0$ then after trivial rescalings we obtain the Davey–Stewartson equation. Moreover, we get the unidimensional NLS equation if $\xi=\eta$.

If $\alpha\neq 0$, $\beta\neq 0$, after the cosmetic rescaling

$$\xi'=-\frac{\alpha}{2\sqrt{3}\beta}\xi,\quad \eta'=\frac{1}{\sqrt{3}}\eta,\quad \chi'=K_1\chi,\quad \Phi'=-3\alpha K_1^2\Phi, \quad (2.12a)$$

$$\tau'=\frac{\tau}{K_1},\quad \Psi'=\sqrt{|N|K_1}\Psi, \quad (2.12b)$$

and with the introduction of two real parameters,

$$a=\frac{\alpha K_2}{\beta K_1},\quad b=\frac{\alpha K_1}{\beta}, \quad (2.12c)$$

we arrive at the model equation of Davey–Stewartson-type (1.3).

Integrable Davey–Stewartson-type equations has been extensively investigated by many authors.[19–22] A very detailed list of Davey–Stewartson equations integrable by the inverse scattering method has been recently given.[23] Equation (1.3) does not appear in these papers. We expect that this new equation be integrable by the inverse scattering method, because it has been obtained from an integrable equation and the property of integrability is supposed to keep through the application of the reduction method. The integrability of Eq. (1.3) will be explicitly demonstrated in the next section.

III. THE LAX PAIR FOR THE MODEL NONLINEAR PDE

In order to demonstrate the integrability of the new Eq. (1.3) by the inverse scattering spectral transform, we apply the reduction method to the Lax pair of the KD equation. The Lax operators are

$$L=\frac{\partial}{\partial y}+\frac{\partial^2}{\partial x^2}+\alpha U(x,y,t)\frac{\partial}{\partial x}+\beta U(x,y,t),\quad L\varphi(x,y,t)=0, \quad (3.1)$$

$$A=-4\frac{\partial^3}{\partial x^3}-6\alpha U(x,y,t)\frac{\partial^2}{\partial x^2}-3\beta U_x(x,y,t)-\frac{3}{2}\alpha\beta U^2(x,y,t)+3\beta W(x,y,t)-3\alpha U_x(x,y,t)\frac{\partial}{\partial x}-\frac{3}{2}\alpha^2U^2(x,y,t)\frac{\partial}{\partial x}-6\beta U(x,y,t)\frac{\partial}{\partial x}+3\alpha W(x,y,t)\frac{\partial}{\partial x}, \quad (3.2)$$

$$\varphi_t(x,y,t)+A\varphi(x,y,t)=0. \quad (3.3)$$

We introduce an asymptotic Fourier expansion

$$\varphi(x,y,t)=\sum_{n=-\infty}^{n=+\infty}\epsilon^{\gamma_n}\varphi_n(\xi,\eta,\tau;\epsilon)\exp\left(i\frac{n}{2}z+(\lambda_1x+\lambda_2y+\lambda_3t)\right), \quad (3.4)$$

where n is odd, $z=K_1x+K_2y-\omega t$, $\gamma_{n+2}=1+\gamma_n$, $\gamma_n=\gamma_{-n}$ for $n>0$, the $\varphi_n(\xi,\eta,\tau;\epsilon)$'s are functions which parametrically depend on ϵ and remain finite if $\epsilon\rightarrow 0$ and $\lambda_1,\lambda_2,\lambda_3$ are real constants to be determined later on. Substituting the expression for $\varphi(x,y,t)$ in Eq. (3.1), the coefficients of the Fourier modes generate a series of relations. Obviously, each relation must be valid for a given order of approximation in ϵ. In particular, for the fundamental harmonics $\varphi_\pm(x,y,t)=\varphi_{\pm 1}(x,y,t)$, considering terms $O(\epsilon^0)$ in (3.1) and (3.3), the constants $\lambda_1,\lambda_2,\lambda_3$ can be fixed,

$$\left(\pm\frac{iK_1}{2}+\lambda_1\right)^2+\left(\pm\frac{iK_2}{2}+\lambda_2\right)=0, \tag{3.5a}$$

$$\left(\mp\frac{i\omega}{2}+\lambda_3\right)-4\left(\pm\frac{iK_1}{2}+\lambda_1\right)^3=0, \tag{3.5b}$$

and then

$$\lambda_1=-\frac{K_2}{2K_1},\quad \lambda_2=\frac{K_1^2}{4}-\frac{K_2^2}{4K_1^2},\quad \lambda_3=-\frac{K_2^3}{2K_1^3}+\frac{3}{2}K_2K_1. \tag{3.6}$$

The new spectral problem is obtained by means of the successive order ϵ for Eq. (3.1),

$$\varphi_{+,\eta}+\left(iK_1-\frac{K_2}{K_1}\right)\varphi_{+,\xi}+\left[\beta-\frac{\alpha}{2}\left(\frac{K_2}{K_1}+iK_1\right)\right]\Psi\varphi_-=0, \tag{3.7a}$$

$$\varphi_{-,\eta}-\left(iK_1+\frac{K_2}{K_1}\right)\varphi_{-,\xi}+\left[\beta-\frac{\alpha}{2}\left(\frac{K_2}{K_1}-iK_1\right)\right]\Psi^*\varphi_+=0. \tag{3.7b}$$

With the rescaling (2.12), we obtain

$$\varphi_{+,\eta}+\left(\frac{a-ib}{2}\right)\varphi_{+,\xi}+\frac{2-a-ib}{\sqrt{2|(a-2)^2-b^2|}}\Psi\varphi_-=0, \tag{3.8a}$$

$$\varphi_{-,\eta}+\frac{a+ib}{2}\varphi_{-,\xi}+\frac{2-a+ib}{\sqrt{2|(a-2)^2-b^2|}}\Psi^*\varphi_+=0. \tag{3.8b}$$

The spectral problem can be again obtained, when we consider the temporal evolution Eq. (3.3) at the same order ϵ. Only if we take into account the next orders of approximation of Eq. (3.3), i.e., the order ϵ^2, the temporal evolution can be determined. However, new quantities, the corrections $\tilde{\varphi}_\pm(\xi,\eta,\tau)$ of order ϵ to the fundamental harmonics $\varphi_\pm(\xi,\eta,\tau)$, appear. These unknown quantities can be eliminated in Eq. (3.3) taking advantage of the relation obtained from Eq. (3.1), considering terms of order ϵ^2. This elimination is possible only because Eqs. (3.1) and (3.3) are identical at the orders ϵ and ϵ^2. After a lengthy calculation we arrive at the final form for the operator A which is given in Eqs. (1.4c)–(1.4d). The compatibility condition between equations (1.4a),

$$L_\tau=[L,A]=LA-AL, \tag{3.9}$$

leads to the new integrable Eq. (1.3).

IV. CONCLUSION

The reduction method is a powerful tool to identify new nonlinear PDEs integrable that are also likely to be applicable in a regime of weak nonlinearity.

In this paper, we have derived a new integrable nonlinear evolution Davey–Stewartson-type equation from the KD equation, by means of a reduction method based on Fourier expansion and space–time rescalings. It reduces to the ordinary Davey–Stewartson equation for appropriate values of its parameters. Moreover, we have applied the reduction method to the Lax pair of the original equation and have demonstrated the integrability property of the new equation, by exhibiting the corresponding Lax pair.

Department of Fluid Mechanics, Polish Academy of Sciences,
Swietokrzyska 21, 00-049 Warsaw, Poland

(Received 20 October 1998; accepted for publication 10 March 1999)

In this paper we deal for the first time with gauge-invariant perturbations of anisotropic cosmological models of Bianchi types I and V from a unified point of view. Motivated by Ehlers' pioneering concepts, the key idea is to identify the gauge-invariant perturbations with the equivalence classes of tangents to one-parameter families of exact solutions to Einstein's field equations. For cases where these models are filled with a nonbarotropic perfect fluid, we show that a set of 26 ''geometrically'' independent, not identically vanishing gauge-invariant variables, denoted collectively by **D** and referred to as the complete set of basic variables, can be used to extract the equivalence classes of tangents from **D** in a unique way. The set **D** is complete because it has the following property: any gauge-invariant quantity is obtainable linearly from the basic variables through purely algebraic and differential operations. Mathematically, this approach to the gauge problem is a nontrivial example of the general scheme that we have described in our two previous papers [Int. J. Theor. Phys. **36**, 1787, 1817 (1997)], and the new concepts developed were also applied to the construction of a complete set of basic gauge-invariant variables for the cases of a fixed background de Sitter space–time and an almost-Robertson–Walker universe model. Arguments are given that there are a number of advantages to be gained by replacing the coordinate-based method of Bardeen or the covariant formalism of Ellis and Bruni by the present one. © *1999 American Institute of Physics.* [S0022-2488(99)03608-7]

I. INTRODUCTION

Beginning from Einstein's theory of gravity, considerable efforts have been expended in attempts to define gauge-invariant perturbations of homogeneous and isotropic cosmological models. The coordinate-based method of Bardeen[1] and the covariant formalism of Ellis and Bruni[2] are a selection of the more important comprehensive treatments. In the pioneering paper by Bardeen,[1] *before introducing a set of gauge-invariant variables*, a separation was made of the metric and matter perturbations into scalar, vector, and tensor parts. However, as noted already by Ellis and Matravers,[3] ''that separation is non-locally defined[4] and is in effect dependent on the coordinate choice made (for example, the Bardeen formalism is gauge invariant only if one restricts coordinate changes to the vector kinds when vector modes are investigated, and to the scalar kind when the scalar modes are the theme of interest).'' Consequently, the coordinate-based analysis of cosmological perturbations, while it helps us understand some important problems,[1] is not a fully gauge-invariant activity.

As an alternative to this line of development, Ellis and Bruni[2] proposed a covariant treatment of perturbations in Robertson–Walker space–times. After a brief outline of the Stewart–Walker approach to gauge-invariant perturbations (see Lemma 2.2 in Ref. 5), the basic idea of Ellis and Bruni was to introduce geometrically defined exact variables A (i.e., these variables are meaningful in any space–time) such that their values A_0 in a Robertson–Walker universe vanish. Then, because of Lemma 2.2 of Stewart and Walker,[5] the quantity A itself is a gauge-invariant perturbation in an almost-Robertson–Walker universe, and its physical significance is apparent through the covariant definition. As in the work of Bruni *et al.*[6] and Dunsby *et al.*[7] (see also the method of Ellis *et al.*[8]), we shall refer to such quantities as *covariant gauge-invariant variables*. It was the aim of Dunsby[9] to further extend this approach to perturbations of Bianchi type-I cosmological models. In his paper he illustrates one of the main advantages of using the covariant approach. Since the Stewart–Walker lemma is valid for any background space–time, one can often consider the same gauge-invariant variables in perturbing different universe models; in particular, covariant gauge-invariant variables can be easily identified in perturbing homogeneous anisotropic space–times. Thus, it is easy to see from Dunsby's analysis of the Bianchi type-I model that the covariant extension to Bianchi type V is very straightforward.

Recently, Banach and Piekarski[10,11] introduced new geometric techniques to develop linear perturbation theory for an arbitrary system of diffeomorphism-invariant, covariant field equations.[12,13] Given the nonlinear field equations of Einstein's gravity theory, these techniques were applied to the study of infinitesimal perturbations in Robertson–Walker universe models.[14–19] In this and the companion paper,[20] we demonstrate how the Banach–Piekarski formalism can be used to address the issue of describing the equivalence classes of perturbations (tangents) in a Bianchi type-I or Bianchi type-V universe[21,22] dominated by a nonbarotropic perfect fluid.[23,24] The crucial point to observe is that, for the aforementioned matter source and background models, a satisfactory (i.e., unique) characterization of cosmological perturbations can be obtained if one defines in a suitable way 26 ''geometrically'' independent, not identically vanishing gauge-invariant variables. The set consisting of these *basic variables*, denoted by **D** and referred to as the *complete set*, is important because it enables one to divide the infinitesimal perturbations into physically relevant equivalence classes: two infinitesimal perturbations $\delta\mathcal{F}_0$ and $\delta\mathcal{F}_0'$ are said to be equivalent if there is a vector field v on the space–time manifold X such that $\delta\mathcal{F}_0'$ differs from $\delta\mathcal{F}_0$ by the action of the Lie derivative $\mathcal{L}_v$ on the background solution $\mathcal{F}_0$ to nonlinear field equations.[25] Thus, it appears that $\delta\mathcal{F}_0$ and $\delta\mathcal{F}_0+\mathcal{L}_v\mathcal{F}_0$ represent the same perturbation of $\mathcal{F}_0$, and clearly $\delta\mathcal{F}_0$ satisfies the linearized field equations if and only if $\delta\mathcal{F}_0+\mathcal{L}_v\mathcal{F}_0$ does.[26] The situation may therefore be summarized as follows. The object of most physical interest is not just one perturbation $\delta\mathcal{F}_0$, but a whole equivalence class of all perturbations $\delta\mathcal{F}_0'$ that are equivalent to $\delta\mathcal{F}_0$. The equivalence class of $\delta\mathcal{F}_0$ is denoted $[\delta\mathcal{F}_0]$ and is called the *gauge-invariant perturbation* associated with $\delta\mathcal{F}_0$. Here, we prove that the complete set of basic variables, namely **D**, provides a mathematically simplest representation of the gauge-invariant perturbation $[\delta\mathcal{F}_0]$. As a matter of fact, $[\delta\mathcal{F}_0]$ is uniquely determined from **D** and vice versa. This important property of **D** serves to illustrate one of the key features of the present formalism: that is, because we start with a complete set of basic gauge-invariant variables, valid for an almost-Bianchi type-I or almost-Bianchi type-V universe model, it is possible to identify $[\delta\mathcal{F}_0]$ with **D** and thereby exploit the theory based on **D** as a *fundamental concept* for the description of infinitesimal perturbations.

Since the perturbations of anisotropic cosmological models have been studied before by several authors,[9,27–31] the natural question is the following: why do we need yet another formalism for cosmological perturbations when there are already so many on the market? First, note that in Refs. 9 and 27–31 the equivalence classes of perturbations (tangents) are not explicitly described. This is, without a doubt, a very important problem to consider.[25] Second, the previous papers concentrated upon the Bianchi type-I background model and thus did not analyze linear perturbations in a Bianchi type-V cosmology. Third, a decisive motivation for our work appears in the following crucial fact:[20] a knowledge of **D** is all one needs in the sense that if A denotes any gauge-invariant tensor field defined on X, then A is *obtainable linearly* from the basic gauge-invariant variables **D** through *purely algebraic and differential operations*. By contrast, as discussed in a companion paper,[20] one may observe that any description that chooses, at the outset, to introduce covariant gauge-invariant variables or to start with Lemma 2.2 of Stewart and Walker[5] is *necessarily incomplete*. Finally, the technique we present here could also be used to resolve disagreements between the results of different existing formalisms. Specifically, we are able to explain the coordinate-based method of Tomita and Den,[27] Den,[28,29] and Noh and Hwang[30,31] in such a way that the objections raised to this method by Ellis and Matravers[3] do not apply. For more details, one should consult Ref. 20. To sum up, in our opinion, the present formulation of linear perturbation theory is *canonical* because it provides a complete framework both for constructing all gauge-invariant variables and for determining the equivalence classes of perturbations.

In a separate paper,[32] we will derive a full set of propagation equations that involves only **D**. These equations are deterministic, i.e., the local existence and uniqueness of solutions can be demonstrated for ''arbitrary'' initial data. As a consequence, if we introduce $[\delta\mathcal{F}_0]$ and describe $[\delta\mathcal{F}_0]$ in terms of **D**, then we will remove the necessity for finding a satisfactory specific gauge or for referring to spurious ''gauge mode'' solutions. However, one expected feature from such an approach is that since the unperturbed shear tensor does not vanish, the dynamics of linearized perturbations will be extremely complicated. Thus, except for some particularly simple situations [e.g., the background spatial curvature is negligible (Bianchi type-I space–times), the metric is axially symmetric in both the background and the perturbed model, the ratio of pressure to energy density in the background is independent of time, etc.], we may be no longer able to analyze the propagation equations analytically. The implications of this observation are considered in some detail in Sec. V.

Here we proceed as follows. Restricting attention to the case of a nonbarotropic perfect fluid, in Sec. II a number of tensor fields appropriate to the specification of infinitesimal perturbations are introduced. Within the covariant formalism, in Sec. III the background models are briefly reviewed: Bianchi types I and V. The aim in Sec. IV is to prove that the equivalence classes of perturbations (tangents) can be described in terms of a finite set of gauge-invariant variables. Section V is for final remarks.

It is assumed throughout that the space–time metric has signature $(-,+,+,+)$, and the speed of light is taken to be unity $(c=1)$. We choose units so that the Einstein gravitational constant equals one $(\kappa=8\pi G=1)$. Lower case Greek characters $\alpha,\beta,\gamma,\ldots$, refer to space–time indices. By definition, $T_{\alpha\beta}$ is the energy–momentum tensor that takes the perfect fluid form.

II. LINEARIZATION PROCEDURE

A. Field equations for nonbarotropic perfect fluids

In general relativity, the metric of space–time is assumed to obey Einstein's field equations, given by

$$R_{\alpha\beta}-\tfrac{1}{2}R^{\mu}{}_{\mu}g_{\alpha\beta}+\Lambda g_{\alpha\beta}=T_{\alpha\beta}, \tag{2.1}$$

in the standard notation. Consider the case of a perfect fluid. If u^α is the four-velocity of the fluid (normalized by $u^\alpha u_\alpha=-1$), we find that the energy–momentum tensor $T_{\alpha\beta}$ can be decomposed as

$$T_{\alpha\beta}=(e+p)u_\alpha u_\beta+pg_{\alpha\beta}, \tag{2.2}$$

where e is the energy density and p is the pressure. Additionally, as we are considering nonbarotropic perfect fluids,[23,24] it will be natural to introduce a number flux density N^α. This density is required to satisfy the continuity equation:

$$N^\alpha{}_{;\alpha}=0. \tag{2.3}$$

Decomposing N^α with respect to u^α, we immediately see that

$$N^\alpha=nu^\alpha. \tag{2.4}$$

In the rest frame of the fluid, n is the number density. Another useful quantity is the temperature of the fluid; we denote this temperature by T. For nonbarotropic perfect fluids, we regard n and T as independent quantities and postulate the following equations of state:

$$e = e(n,T), \quad p = p(n,T). \tag{2.5}$$

Because of the first law of thermodynamics,[24] the problem of explicitly determining these equations of state reduces to the problem of explicitly expressing the specific free energy in terms of n and T [see, e.g., Eqs. (5.17) and (5.18) in Ref. 17]. However, the present general form of Eqs. (2.5) suffices for our purposes here.

It will be convenient to take the contravariant form $g^{\alpha\beta}$ of the metric $g_{\alpha\beta}$ to be more fundamental and the covariant form $g_{\alpha\beta}$ as derived from it by the relations

$$g^{\alpha\mu} g_{\mu\beta} = \delta^{\alpha}{}_{\beta}, \tag{2.6}$$

where $\delta^{\alpha}{}_{\beta}$ is the Kronecker delta. As a result of this convention, a perfect fluid flow in a curved space–time is described by giving the fields $g^{\alpha\beta}$, u^{α}, n, and T. For brevity, we denote these primary fields by $\mathcal{F}$:

$$\mathcal{F} := \{g^{\alpha\beta}, u^{\alpha}, n, T\}. \tag{2.7}$$

Ultimately, therefore, the system of equations for the specification of $\mathcal{F}$ consists of Eqs. (2.1)–(2.6), the others being only consequences of them.

B. Infinitesimal perturbations

Quite often, the treatment of nonbarotropic perfect fluids by means of exact, nonlinear field equations is far too cumbersome and unnecessarily detailed. Fortunately, the most practical problems can be adequately treated in the much simpler framework of linear perturbation theory. The basic assumption of this theory, *which seems necessary in order to give a clear idea of what the perturbation method is to be* (see, e.g., the discussion in Sec. 7.1 of Ref. 25), may be formulated as follows: Consider an open interval $I := (-d, d)$ of $\mathbb{R}$, $d > 0$; then, for each $\epsilon \in I$ there exists a *classical* solution,

$$\mathcal{F}_{\epsilon}(x^{\mu}) := \{g^{\alpha\beta}(x^{\mu}, \epsilon), u^{\alpha}(x^{\mu}, \epsilon), n(x^{\mu}, \epsilon), T(x^{\mu}, \epsilon)\} \tag{2.8}$$

of the exact, nonlinear field equations. The parameter ϵ appearing in this definition measures the size of the perturbation, in the sense that $\mathcal{F}_{\epsilon}(x^{\mu})$ depends continuously and differentiably on $\epsilon \in I$ for each (x^{μ}), and

$$\mathcal{F}_0(x^{\mu}) := \mathcal{F}_{\epsilon}(x^{\mu})_{|\epsilon=0} \tag{2.9}$$

is a background solution. Now, putting Eqs. (2.8) and (2.9) together, we have

$$\mathcal{F}_0(x^{\mu}) := \{q^{\alpha\beta}(x^{\mu}), w^{\alpha}(x^{\mu}), n_0(x^{\mu}), T_0(x^{\mu})\}, \tag{2.10}$$

where

$$q^{\alpha\beta}(x^{\mu}) := g^{\alpha\beta}(x^{\mu}, \epsilon)_{|\epsilon=0}, \quad w^{\alpha}(x^{\mu}) := u^{\alpha}(x^{\mu}, \epsilon)_{|\epsilon=0}, \tag{2.11a}$$

$$n_0(x^{\mu}) := n(x^{\mu}, \epsilon)_{|\epsilon=0}, \quad T_0(x^{\mu}) := T(x^{\mu}, \epsilon)_{|\epsilon=0}, \quad T_0 > 0. \tag{2.11b}$$

Here we postulate that $\mathcal{F}_0$ is obtainable from a solution of the ''unperturbed'' cosmological equations and that the forms of $q^{\alpha\beta}$, w^{α}, n_0, and T_0 are consistent with the background space–time geometry, which is that of a Bianchi type-I or Bianchi type-V space–time.[21,22]

Since $\mathcal{F}_{\epsilon}$ depends differentiably on $\epsilon \in I$, it will be possible to define the perturbation of $\mathcal{F}_0$ by the formula

$$\delta\mathcal{F}_0 := \{G^{\alpha\beta}, U^{\alpha}, n_0 M, T_0 K\}, \tag{2.12}$$

in which

$$G^{\alpha\beta} := \left(\frac{\partial g^{\alpha\beta}}{\partial \epsilon}\right)_{\epsilon=0}, \quad U^{\alpha} := \left(\frac{\partial u^{\alpha}}{\partial \epsilon}\right)_{\epsilon=0}, \tag{2.13a}$$

$$M := \frac{1}{n_0}\left(\frac{\partial n}{\partial \epsilon}\right)_{\epsilon=0}, \quad K := \frac{1}{T_0}\left(\frac{\partial T}{\partial \epsilon}\right)_{\epsilon=0}. \tag{2.13b}$$

We call $\delta\mathcal{F}_0$ the *infinitesimal perturbation* of $\mathcal{F}_0$. It is important to stress that the infinitesimal perturbation so defined has the absolute geometrical meaning independent of any particular choice of the coordinate system (x^{μ}) in X.[10,11] So as to derive a closed set of governing equations for perturbation for the system, we must first differentiate Einstein's field equations (2.1) and the equation of balance of number density (2.3) with respect to ϵ at $\epsilon=0$ and then apply the definitions of various quantities involved. In this way, we obtain a linear equation for $\delta\mathcal{F}_0$, i.e., an equation that can be expressed in the form[26]

$$\mathcal{Y}(\delta\mathcal{F}_0) = 0, \tag{2.14}$$

where $\mathcal{Y}$ is a linear differential space–time operator acting on $\delta\mathcal{F}_0$. As to the explicit characterization of $\mathcal{Y}$, it will be considered in a separate paper.[32]

Given the background space–time metric $q_{\alpha\beta}$ $(q^{\alpha\mu}q_{\mu\beta} = \delta^{\alpha}{}_{\beta})$ and a geometrically preferred (unperturbed) four-velocity w^{α} $(w_{\alpha} := q_{\alpha\mu}w^{\mu})$, the tensor $\gamma_{\alpha\beta} := q_{\alpha\beta} + w_{\alpha}w_{\beta}$ projects into the local rest spaces of comoving observers:

$$\gamma^{\alpha\beta} := q^{\alpha\beta} + w^{\alpha}w^{\beta}, \quad \gamma^{\alpha}{}_{\beta} := \delta^{\alpha}{}_{\beta} + w^{\alpha}w_{\beta}. \tag{2.15}$$

With the help of these projection tensors, we find that the metric and velocity perturbations, namely $G^{\alpha\beta}$ and U^{α}, have the covariant irreducible decompositions,

$$G^{\alpha\beta} = w^{\alpha}w^{\beta}Q + w^{\alpha}Q^{\beta} + w^{\beta}Q^{\alpha} + 2D\gamma^{\alpha\beta} + 2F^{\alpha\beta}, \tag{2.16a}$$

$$U^{\alpha} = Vw^{\alpha} + V^{\alpha}, \tag{2.16b}$$

where the scalars (Q,D,V), the spatial vectors (Q^{α},V^{α}), and a spatial two-tensor $F^{\alpha\beta}$ (which is symmetric and trace-free) are related to $\mathcal{F}_0$ and $\delta\mathcal{F}_0$ by

$$Q := w_{\mu}w_{\nu}G^{\mu\nu}, \quad Q^{\alpha} := -w_{\mu}\gamma^{\alpha}{}_{\nu}G^{\mu\nu}, \tag{2.17a}$$

$$D := \tfrac{1}{6}\gamma_{\mu\nu}G^{\mu\nu}, \quad F^{\alpha\beta} := \tfrac{1}{2}\gamma^{\alpha}{}_{\mu}\gamma^{\beta}{}_{\nu}G^{\mu\nu} - D\gamma^{\alpha\beta}, \tag{2.17b}$$

$$V := -w_{\mu}U^{\mu}, \quad V^{\alpha} := \gamma^{\alpha}{}_{\mu}U^{\mu}. \tag{2.17c}$$

Associated with $\delta\mathcal{F}_0$ is the object

$$J(\delta\mathcal{F}_0) := \{Q,Q^{\alpha},D,F^{\alpha\beta},V,V^{\alpha},M,K\}, \tag{2.18}$$

which we also call the *infinitesimal perturbation* of $\mathcal{F}_0$. This object contains the same information as $\delta\mathcal{F}_0$, and we can use $\mathbf{W} := J(\delta\mathcal{F}_0)$ in place of $\delta\mathcal{F}_0$. Such is indeed the case because, after specifying the background solution (i.e., $\mathcal{F}_0$), $\delta\mathcal{F}_0$ is uniquely determined from $\mathbf{W}$, and conversely. Defining $Y(\mathbf{W})$ by $Y(\mathbf{W}) := \mathcal{Y}(\delta\mathcal{F}_0)$, it follows that if $\mathcal{Y}(\delta\mathcal{F}_0) = 0$, then

$$Y(\mathbf{W}) = 0. \tag{2.19}$$

In the present paper, however, we consider the infinitesimal perturbations of $\mathcal{F}_0$ from a purely geometric point of view. Consequently, $\delta\mathcal{F}_0$ and $\mathbf{W}$ *are not necessarily assumed* to satisfy Eqs.

(2.14) and (2.19). This observation serves as an alternative, and in certain respects a more general and enlightening, starting point from which one could introduce and describe the equivalence classes of perturbations.[10,11]

III. CHARACTERIZATION OF THE BACKGROUND MODELS: BIANCHI TYPES I AND V

In this section we recall the more relevant properties of anisotropic background models of Bianchi types I and V; the discussion will be confined only to what is necessary for our aim. However, before briefly describing these background models, we have to define a few mathematical quantities. Thus, it is assumed that $\boldsymbol{\nabla}_\alpha$ is the covariant derivative based upon the background metric $q_{\alpha\beta}$. We use the standard kinematical decomposition of $\boldsymbol{\nabla}_\alpha$. More explicitly, a *dot* denotes the covariant derivative along the unperturbed fluid flow lines and a *slash* corresponds to the three-dimensional covariant derivative defined by totally projecting the covariant derivative $\boldsymbol{\nabla}_\alpha$ orthogonal to w^α, so, for example, $\dot{A}_{\alpha\cdots}:=w^\beta\,\boldsymbol{\nabla}_\beta A_{\alpha\cdots}$ and $A_{\alpha\cdots|\beta}:=\gamma^\mu{}_\alpha\gamma^\nu{}_\beta\cdots\boldsymbol{\nabla}_\nu A_{\mu\cdots}$. For $A_{\alpha\cdots|\beta}$, a certain care is needed if the tensor $A_{\alpha\ldots}$ itself is not totally orthogonal to w^α, but this will not be a problem here. As usual, round brackets enclosing indices denote symmetrization and square brackets denote antisymmetrization.

Let $h_{\alpha\beta}$ be the projection tensor into the tangent three-spaces orthogonal to u^α $(h_{\alpha\beta}:=g_{\alpha\beta}+u_\alpha u_\beta \Rightarrow h^\alpha{}_\mu h^\mu{}_\beta=h^\alpha{}_\beta$ and $h_\alpha{}^\beta u_\beta=0)$. Then the first covariant derivative of the four-velocity vector can be written as

$$u_{\alpha;\beta}=\omega_{\alpha\beta}+\sigma_{\alpha\beta}+\tfrac{1}{3}\theta h_{\alpha\beta}-a_\alpha u_\beta, \tag{3.1}$$

where $\omega_{\alpha\beta}$ is the vorticity tensor $(\omega_{\alpha\beta}=\omega_{[\alpha\beta]},\, \omega_{\alpha\beta}u^\beta=0)$, $\sigma_{\alpha\beta}$ is the shear tensor $(\sigma_{\alpha\beta}=\sigma_{(\alpha\beta)},\, g^{\alpha\beta}\sigma_{\alpha\beta}=0,\, \sigma_{\alpha\beta}u^\beta=0)$, θ is the expansion, and a_α is the acceleration $(a^\alpha u_\alpha=0)$. In an exact Bianchi type-I or Bianchi type-V universe model, the following conditions are automatically satisfied:

$$\omega_{\alpha\beta}=0, \quad a_\alpha=0, \tag{3.2a}$$

$$h^{\alpha\beta}\theta_{;\beta}=0, \quad h^{\alpha\beta}n_{;\beta}=0, \quad h^{\alpha\beta}T_{;\beta}=0. \tag{3.2b}$$

Moreover, if $d_{\alpha\beta}$ is the background shear tensor $[d_{\alpha\beta}:=(\sigma_{\alpha\beta})_{\epsilon=0}]$ and H is the average rate of expansion $[H:=\frac{1}{3}(\theta)_{\epsilon=0}]$, it will be possible to verify that[9,22]

$$\dot{d}_{\alpha\beta}+3Hd_{\alpha\beta}=0. \tag{3.3}$$

Setting $d^\alpha{}_\beta:=d_\beta{}^\alpha:=q^{\alpha\mu}d_{\mu\beta}$ (and $d^{\alpha\beta}:=q^{\alpha\mu}d_\mu{}^\beta$), focus now on the eigenvalue equation,

$$d^\alpha{}_\mu l_p^\mu=(H_p-H)l_p^\alpha, \quad p=1,2,3, \tag{3.4}$$

with eigenvectors l_p^μ $(l_p^\mu w_\mu=0)$ and eigenvalues H_p-H. We shall refer to H_p as the expansion in the p direction. Evidently, since H_p is a scalar,[33] the spatial gradient of H_p vanishes:

$$H_{p|\alpha}=0, \quad p=1,2,3. \tag{3.5}$$

Note that[21,22]

$$k(2H_1-H_2-H_3)=0, \tag{3.6}$$

where k is the constant. By an appropriate choice of units, the value of k can be made to be 0 or -1. The corresponding solutions for the background metric $q_{\alpha\beta}$ represent, respectively, a Bianchi type-I space–time and a Bianchi type-V space–time. If the eigenframe $\{l_p^\mu\}$ of $d_{\alpha\beta}$ is known, the objects l^p_μ dual to l_p^μ are completely determined from $l^p_\mu l_q^\mu=\delta^q{}_p$ and $l^p_\mu w^\mu=0$. However, owing to the fact that the eigenvectors l^μ_p are not uniquely defined by Eq. (3.4), the additional question arises of how to normalize l^μ_p. This question can be answered most easily in a special coordinate system in which the line element of Bianchi models takes the form[21,22]

$$ds^2=-dt^2+(R_1(t))^2(dx^1)^2+e^{2kx^1}[(R_2(t))^2(dx^2)^2+(R_3(t))^2(dx^3)^2], \tag{3.7}$$

where R_p, $p=1,2,3$, are the expansion factors related to H_p, $p=1,2,3$, by

$$H_p=\frac{1}{R_p}\frac{dR_p}{dt}=\dot{R}_p/R_p, \tag{3.8}$$

and where $t:=x^0$ and k is the (constant) spatial curvature $(k=0,-1)$. In such a coordinate system, both $d^\alpha{}_0$ and $d^0{}_\alpha$ vanish, $d^p{}_q$ equals $(H_p-H)\delta^p{}_q$ (where $p=1,2,3$ and $q=1,2,3$), w^α is given by $w^\alpha=\delta^\alpha{}_0$, and we postulate that $l^\mu_p=\delta^\mu{}_p$ (hence $l^p_\mu=\delta^p{}_\mu$).

Writing $B:=(\frac{1}{6})(2H_1-H_2-H_3)$ and $C:=(1/2\sqrt{3})(H_2-H_3)$ and remembering that $H:=(\frac{1}{3})\times(\theta)_{\epsilon=0}$, one finds the expansions H_p, $p=1,2,3$, to be

$$H_1=H+2B, \tag{3.9a}$$

$$H_2=H-B+\sqrt{3}C, \quad H_3=H-B-\sqrt{3}C. \tag{3.9b}$$

Now, let $\mathcal{R}_{\alpha\beta}$ be the Ricci tensor of the connection defined by the metric $q_{\alpha\beta}$, and suppose that $\mathcal{R}$ is the curvature scalar $(\mathcal{R}:=q^{\mu\nu}\mathcal{R}_{\mu\nu})$. Since the extrinsic curvature $k_{\alpha\beta}:=w_{\alpha|\beta}$ has the properties $k_{(\alpha\beta)}=k_{\alpha\beta}$ and $k_{[\alpha\beta]}=0$, there exists a family of three-surfaces $\Sigma_\perp$ everywhere orthogonal to the unperturbed fluid flow vector w^α; these are instantaneous surfaces of simultaneity for all the fundamental observers.[2] Motivated by the above observations, it proves useful to introduce the following quantity:

$$\frac{6k}{(R_1)^2}:=-6H^2+d^{\mu\nu}d_{\mu\nu}+\mathcal{R}+2w^\mu w^\nu\mathcal{R}_{\mu\nu}=-6H^2+6(B^2+C^2)+\mathcal{R}+2w^\mu w^\nu\mathcal{R}_{\mu\nu}. \tag{3.10}$$

This quantity acquires a special significance:[2] it is the Ricci scalar of the three-dimensional surfaces $(k=0,-1)$.

With these preparations behind us, the coupled system of governing equations for the background may be written as[21,22]

$$H^2-B^2-C^2+\frac{k}{(R_1)^2}=\frac{1}{3}(e_0+\Lambda), \tag{3.11a}$$

$$2\dot{H}+3(H^2+B^2+C^2)+\frac{k}{(R_1)^2}=-p_0+\Lambda, \tag{3.11b}$$

$$\dot{B}+3HB=0, \quad \dot{C}+3HC=0, \tag{3.11c}$$

$$kB=0, \quad kH=k(\dot{R}_1/R_1), \tag{3.11d}$$

$$\dot{n}_0+3n_0H=0, \tag{3.11e}$$

where [see Eqs. (2.5) and (2.11)]

$$e_0=e(n_0,T_0), \quad p_0=p(n_0,T_0). \tag{3.12}$$

Equation (3.11e) is the standard equation of balance of n_0. In the case when $k=0$, the conditions (3.6) and (3.11d) are automatically satisfied, and thus they are not needed to determine the propagation of interesting quantities along the flow lines. Note that the result of differentiating the first of Eqs. (3.11) with respect to time and then using (3.11b)–(3.11d) is the equation of the conservation of energy:

$$\dot{e}_0+3H(e_0+p_0)=0. \tag{3.13}$$

Another remark is also in order. Instead of considering Eq. (3.3), we may equivalently consider the scalar equations (3.11c).

This remark brings to an end our description of the background models.

IV. ANALYSIS OF THE GAUGE PROBLEM

A. Equivalence classes of perturbations (tangents)

In Einstein's theory of gravity, the action of the diffeomorphism group on the space–time manifold X induces an action on the space of field configurations on X, and the only thing that has an immediate physical meaning is the quotient space of orbits,[34] i.e., two field configurations are regarded as equivalent if they are connected by a diffeomorphism transformation. Within the framework of a linear approximation, these facts imply that two infinitesimal perturbations $\delta\mathcal{F}_0$ and $\delta\mathcal{F}_0'$, *not necessarily satisfying Eq. (2.14)*, characterize the same perturbation of the background solution $\mathcal{F}_0$ if (and only if) there exists a vector field $v=v^\mu(\partial/\partial x^\mu)$ on the space–time manifold X, such that $\delta\mathcal{F}_0'-\delta\mathcal{F}_0$ is the *Lie derivative* $\mathcal{L}_v\mathcal{F}_0$ of $\mathcal{F}_0$ with respect to v.[4,5] As to the explicit specification of $\mathcal{L}_v\mathcal{F}_0$, putting $w:=w^\mu(\partial/\partial x^\mu)$ and $q:=q^{\mu\nu}[(\partial/\partial x^\mu)\otimes(\partial/\partial x^\nu)]$ and recalling the definition (2.10) of $\mathcal{F}_0$, we obtain[35]

$$\mathcal{L}_v\mathcal{F}_0:=\{(\mathcal{L}_vq)^{\alpha\beta},(\mathcal{L}_vw)^\alpha,\mathcal{L}_vn_0,\mathcal{L}_vT_0\}, \tag{4.1}$$

where $(\mathcal{L}_vq)^{\alpha\beta}$ and $(\mathcal{L}_vw)^\alpha$ are the components of $\mathcal{L}_vq$ and $\mathcal{L}_vw$.

Let $\mathcal{P}$ be the set whose elements are arbitrary, linear perturbations of $\mathcal{F}_0$; thus $\delta\mathcal{F}_0\in\mathcal{P}$. Obviously, $\mathcal{P}$ carries a natural structure of a vector space. The set $\mathcal{P}_L$ consisting of $\mathcal{L}_v\mathcal{F}_0$ for all vector fields v on X may be considered as the subspace of $\mathcal{P}$. Given the object $J(\delta\mathcal{F}_0)$ as in Eq. (2.18), we denote by $\mathcal{W}$ the collection of $J(\delta\mathcal{F}_0)$, where $\delta\mathcal{F}_0\in\mathcal{P}$, and by $\mathbf{W},\mathbf{W}'$, and similar symbols the elements of $\mathcal{W}$. Moreover, we introduce the following subspace of $\mathcal{W}$:

$$\mathcal{W}_L:=\{J(\delta\mathcal{F}_0);\delta\mathcal{F}_0\in\mathcal{P}_L\}. \tag{4.2}$$

Knowing $\mathcal{F}_0$, elementary inspection shows that the correspondence $\delta\mathcal{F}_0\mapsto J(\delta\mathcal{F}_0)$ is a linear map that assigns to each $\delta\mathcal{F}_0\in\mathcal{P}$ an element $J(\delta\mathcal{F}_0)\in\mathcal{W}$; we denote this map by $J:\mathcal{P}\to\mathcal{W}$. Since for every $\mathbf{W}\in\mathcal{W}$ there is just one $\delta\mathcal{F}_0\in\mathcal{P}$ such that $\mathbf{W}=J(\delta\mathcal{F}_0)$, the map $J:\mathcal{P}\to\mathcal{W}$ can be said to be *one-to-one* and *onto*. The similar remark concerns the restriction of J to $\mathcal{P}_L$, still denoted by J. As suggested by the definition (4.2), the subspace $\mathcal{W}_L$ of $\mathcal{W}$ is the image of $\mathcal{P}_L$ under J. Clearly, $\mathbf{W}$ belongs to $\mathcal{W}_L$ if and only if $\mathbf{W}$ equals $J(\mathcal{L}_v\mathcal{F}_0)$ for some v. *In order to simplify our notation, we abbreviate* $J(\mathcal{L}_v\mathcal{F}_0)$ *as* $L_v\mathcal{F}_0$.

The next stage in the discussion is to calculate $L_v\mathcal{F}_0$. First of all, projecting the vector field v^α on X along and orthogonal to the background fluid four-velocity w^α, we obtain the decomposition of v^α, namely,

$$v^\alpha=\vartheta w^\alpha+\vartheta^\alpha, \tag{4.3}$$

in which the scalar ϑ and the spatial vector ϑ^α are given by

$$\vartheta:=-w_\mu v^\mu,\quad \vartheta^\alpha:=\gamma^\alpha{}_\mu v^\mu. \tag{4.4}$$

With the help of the definition of $\mathcal{L}_v$,[35] we then find from Eqs. (2.17) and (2.18) that $L_v\mathcal{F}_0$ can be written as

$$L_v\mathcal{F}_0=\{Q_v,Q_v^\alpha,D_v,F_v^{\alpha\beta},V_v,V_v^\alpha,M_v,K_v\}, \tag{4.5}$$

where

$$Q_v:=2\dot{\vartheta},\quad Q_v^\alpha:=\dot{\vartheta}^\alpha-H\vartheta^\alpha-d^\alpha{}_\mu\vartheta^\mu-\gamma^{\alpha\mu}\vartheta_{|\mu}, \tag{4.6a}$$

$$D_v:=-H\vartheta-\tfrac{1}{3}\vartheta^\mu{}_{|\mu}, \tag{4.6b}$$

$$F_v^{\alpha\beta}:=-d^{\alpha\beta}\vartheta+\tfrac{1}{3}\gamma^{\alpha\beta}\vartheta^\mu{}_{|\mu}-\gamma^{\mu(\alpha}\vartheta^{\beta)}{}_{|\mu}, \tag{4.6c}$$

$$V_v:=-\dot{\vartheta},\quad V_v^\alpha:=-\dot{\vartheta}^\alpha+H\vartheta^\alpha+d^\alpha{}_\mu\vartheta^\mu, \tag{4.6d}$$

$$M_v:=-3H\vartheta,\quad K_v:=\frac{1}{T_0}\dot{T}_0\vartheta. \tag{4.6e}$$

The notation and conventions are based on those of Secs. II and III. In obtaining Eqs. (4.6), we have used the fact that the form of $\mathcal{F}_0$ is consistent with exact anisotropic cosmological solutions of Einstein's field equations, namely spatially homogeneous cosmologies of Bianchi types I and V.

The net upshot of these considerations may be stated very neatly. In linear perturbation theory, the object of most physical interest is not just one perturbation $\delta\mathcal{F}_0\in\mathcal{P}$, but a whole equivalence class of all perturbations $\delta\mathcal{F}'_0\in\mathcal{P}$ that are equivalent to $\delta\mathcal{F}_0$: two infinitesimal perturbations $\delta\mathcal{F}_0\in\mathcal{P}$ and $\delta\mathcal{F}'_0\in\mathcal{P}$ are said to be equivalent if $\delta\mathcal{F}'_0-\delta\mathcal{F}_0$ equals $\mathcal{L}_v\mathcal{F}_0$ for some v. The equivalence class of $\delta\mathcal{F}_0\in\mathcal{P}$ is denoted $[\delta\mathcal{F}_0]$ and is called the *gauge-invariant perturbation* associated with $\delta\mathcal{F}_0$. In this way, we verify that the gauge-invariant perturbations are elements of $\mathcal{P}/\mathcal{P}_L$, the *quotient space* of $\mathcal{P}$ by $\mathcal{P}_L$. Another route to discussing the gauge problem is to introduce the equivalence class $[\mathbf{W}]$ of $\mathbf{W}\in\mathcal{W}$: two infinitesimal perturbations $\mathbf{W}\in\mathcal{W}$ and $\mathbf{W}'\in\mathcal{W}$, *not necessarily satisfying Eq. (2.19)*, will be taken to be equivalent if there is a vector field $v^\alpha=\vartheta w^\alpha+\vartheta^\alpha$ on X such that $\mathbf{W}'=\mathbf{W}+L_v\mathcal{F}_0$. Then we have the *gauge-invariant perturbation* $[\mathbf{W}]$ associated with $\mathbf{W}$ and the *quotient space* $\mathcal{W}/\mathcal{W}_L$, which consists of $[\mathbf{W}]$ for all $\mathbf{W}\in\mathcal{W}$.

The essential point in the theory of gauge-invariant perturbations is to describe the elements of $\mathcal{P}/\mathcal{P}_L$ or $\mathcal{W}/\mathcal{W}_L$ explicitly. These issues will be considered in Secs. IV B and IV C.

B. Basic gauge-invariant variables

In an almost-Bianchi type-I or almost-Bianchi type-V universe model, we have "absolute" or "prior geometric" elements (e.g., the background solution $\mathcal{F}_0$, the average rate of expansion H, the background shear tensor $d_{\alpha\beta}$, the eigenframe $\{l_p^\mu\}$ of $d_{\alpha\beta}$, etc.), and we can use these absolute elements and the equivalence classes of perturbations to introduce *local* gauge-invariant variables. By analogy with the general discussion in Sec. 4.2 of Ref. 10, the gauge-invariant quantity $\overline{A}(x,\mathbf{W})$ is such a linear and local algebropartial differential operation on $\mathbf{W}$ that, for each space–time point x and each vector field v on X, the "gauge mode" perturbation $L_v\mathcal{F}_0$ of $\mathcal{F}_0$ can be added to $\mathbf{W}$ without the need of replacing $\overline{A}(x,\mathbf{W})$ by $\overline{A}(x,\mathbf{W}+L_v\mathcal{F}_0)$:

$$\overline{A}(x,\mathbf{W})=\overline{A}(x,\mathbf{W}+L_v\mathcal{F}_0). \tag{4.7}$$

Because of this, the value of $\overline{A}(\cdot,\mathbf{W}')$ at $x\in X$ is independent of the choice of $\mathbf{W}'\in[\mathbf{W}]$ and the objects $A(x,[\mathbf{W}]):=\overline{A}(x,\mathbf{W})$ define a "function" $[\mathbf{W}]\mapsto A(\cdot,[\mathbf{W}])$ on the quotient space $\mathcal{W}/\mathcal{W}_L$. Here the most important examples of $x\mapsto A(x,[\mathbf{W}])$, which actually work and which provide the mathematically simplest representation of $[\mathbf{W}]$, are given by

$$\chi := Q + 2V, \quad \Gamma := K + \frac{1}{3HT_0}\dot{T}_0 M, \tag{4.8a}$$

$$\Omega := -\frac{1}{2}Q + \frac{1}{3H^2}(\dot{H}M - H\dot{M}), \tag{4.8b}$$

$$\Omega^\alpha := -3H(V^\alpha + Q^\alpha) + \gamma^{\alpha\mu}M_{|\mu}, \tag{4.8c}$$

$$\Omega^{\alpha\beta} := \ddot{Z}^{\alpha\beta} + 3H\dot{Z}^{\alpha\beta} + 2d_\mu{}^\alpha d^\beta{}_\nu Z^{\mu\nu} - 2d_\mu{}^{(\alpha} Z^{\beta)\nu} d^\mu{}_\nu + 2[\gamma^{\mu(\alpha}\dot{V}^{\beta)}]_{|\mu}$$
$$+ 4H\gamma^{\mu(\alpha}V^{\beta)}{}_{|\mu} - 4d^{\mu(\alpha}V^{\beta)}{}_{|\mu} + 2d_\mu{}^{(\alpha}\gamma^{\beta)\nu}V^\mu{}_{|\nu} + 2(2d^{\alpha\beta}{}_{|\mu} - \gamma^{\nu(\alpha}d^{\beta)}{}_{\mu|\nu})V^\mu, \tag{4.8d}$$

$$S^{\alpha\beta\mu\nu} := \frac{k}{(R_1)^2} Z^{\sigma[\alpha}\gamma^{\beta][\mu}\gamma^{\nu]}{}_\sigma + [(\gamma^{\sigma[\alpha}Z^{\beta][\mu}\gamma^{\nu]\lambda})_{|\sigma}]_{|\lambda}, \tag{4.8e}$$

$$\Theta^p := l^p_\mu l^p_\nu (\dot{Z}^{\mu\nu} + 2\gamma^{\lambda\mu}V^\nu{}_{|\lambda}), \tag{4.8f}$$

$$\Theta^{pq}_q := -l^\nu_q (l^q_\lambda l^p_{\mu|\nu} + l^p_\lambda l^q_{\mu|\nu})(\dot{Z}^{\mu\lambda} + 2\gamma^{\tau(\mu}V^{\lambda)}{}_{|\tau}) + l^\nu_q l^q_\lambda l^p_\mu [(\dot{Z}^{\lambda\mu} + 2\gamma^{\tau(\mu}V^{\lambda)}{}_{|\tau})_{|\nu}$$
$$-2d_\tau{}^{[\mu}Z^{\lambda]\tau}{}_{|\nu} + (d^{\mu\tau}\gamma_{\nu\sigma} - \gamma^{\mu\tau}d_{\nu\sigma})Z^{\sigma\lambda}{}_{|\tau} - d^\mu{}_{\nu|\tau}Z^{\tau\lambda}] \quad (p \neq q), \tag{4.8g}$$

$$\Omega^{pq}_r := l^\nu_r l^p_{(\lambda} l^q_{\mu)} [(\dot{Z}^{\lambda\mu} + 2\gamma^{\tau(\lambda}V^{\mu)}{}_{|\tau})_{|\nu} + 2(\gamma^\lambda{}_\sigma d^{\mu\tau} - d^\lambda{}_\sigma \gamma^{\mu\tau})\gamma_{\nu\kappa}Z^{\sigma\kappa}{}_{|\tau} + 2d^\lambda{}_{\nu|\sigma}Z^{\mu\sigma}] + l^\nu_r (l^p_\mu l^q_{\nu|\lambda}$$
$$+ l^q_\mu l^p_{\nu|\lambda})(\dot{Z}^{\lambda\mu} + 2\gamma^{\tau(\lambda}V^{\mu)}{}_{|\tau}) + l^\nu_{r|\nu} l^p_\lambda l^q_\mu (\dot{Z}^{\lambda\mu} + 2\gamma^{\tau(\lambda}V^{\mu)}{}_{|\tau}) \quad (p \neq q, r \neq p, r \neq q), \tag{4.8h}$$

where

$$Z^{\alpha\beta} := \frac{2}{3}(M - 3D)\gamma^{\alpha\beta} + \frac{2}{3H}Md^{\alpha\beta} - 2F^{\alpha\beta}. \tag{4.9}$$

In keeping with the notation of Sec. III, the quantity $\ddot{Z}^{\alpha\beta}$ is the covariant derivative of $\dot{Z}^{\alpha\beta}$ along w^μ and the tensor fields $l^\mu_{p|\nu}$ and $l^p_{\mu|\nu}$ are the spatially totally projected covariant derivatives of l^μ_p and l^p_μ. Also, it appears from Eqs. (4.8f) and (4.8g) that *we do not adopt* the Einstein summation convention for repeated Latin indices.

According to Eqs. (4.8g) and (4.8h), we have the condition $p \neq q$ for Θ^{pq}_q and the conditions $p \neq q$, $r \neq p$, and $r \neq q$ for Ω^{pq}_r; moreover, $\Omega^{pq}_r = \Omega^{qp}_r$. It is clear, from the manner in which the objects Θ^p, Θ^{pq}_q, and Ω^{pq}_r are defined [see Eqs. (4.8f)–(4.8h)], that the sets $\{\Theta^p\}$, $\{\Theta^{pq}_q\}$, and $\{\Omega^{pq}_r\}$ consist of *scalar* gauge-invariant variables; these sets may be written as

$$\{\Theta^p\} := \{\Theta^1, \Theta^2, \Theta^3\}, \tag{4.10a}$$

$$\{\Theta^{pq}_q\} := \{\Theta^{12}_2, \Theta^{13}_3, \Theta^{21}_1, \Theta^{23}_3, \Theta^{31}_1, \Theta^{32}_2\}, \tag{4.10b}$$

$$\{\Omega^{pq}_r\} := \{\Omega^{12}_3, \Omega^{13}_2, \Omega^{23}_1\}. \tag{4.10c}$$

Now, if we make use of Eq. (4.8e), we verify that a complete set of symmetry conditions for $S^{\alpha\beta\mu\nu}$ is $S^{\alpha\beta\mu\nu} = S^{[\alpha\beta][\mu\nu]}$, $S^{\alpha[\beta\mu\nu]} = 0$, and $w_\alpha S^{\alpha\beta\mu\nu} = 0$; thus, there are six linearly independent, not identically vanishing, components in $\{S^{\alpha\beta\mu\nu}\}$. An alternative viewpoint is to express $S^{\alpha\beta\mu\nu}$ in terms of

$$S := \gamma_{\mu\nu}\gamma_{\lambda\sigma}S^{\mu\lambda\sigma\nu} \tag{4.11a}$$

and

$$S^{\alpha\beta} := \gamma_{\mu\nu}(S^{\mu\alpha\beta\nu} - \tfrac{1}{3}\gamma^{\alpha\beta}\gamma_{\lambda\sigma}S^{\mu\lambda\sigma\nu}). \tag{4.11b}$$

The symmetries of $S^{\alpha\beta\mu\nu}$ imply

$$S^{\alpha\beta} = S^{\beta\alpha}, \quad \gamma_{\mu\nu}S^{\mu\nu} = 0, \quad w_\mu S^{\mu\alpha} = 0. \tag{4.12}$$

Through Eqs. (4.11a) and (4.11b), we can completely describe the tensor field $S^{\alpha\beta\mu\nu}$, since this tensor field is a *totally* spatial quantity:

$$S^{\alpha\beta\mu\nu} = -\tfrac{1}{3}S\,\gamma^{\mu[\alpha}\gamma^{\beta]\nu} - 2\,\gamma^{\mu[\alpha}S^{\beta]\nu} + 2\,\gamma^{\nu[\alpha}S^{\beta]\mu}. \tag{4.13}$$

Next, returning to the definitions (4.8c) and (4.8d) of Ω^α and $\Omega^{\alpha\beta}$, and using Eq. (4.8f) for Θ^p, we easily recognize that

$$w_\mu \Omega^\mu = 0, \quad w_\mu \Omega^{\mu\alpha} = 0, \quad \Omega^{\alpha\beta} = \Omega^{\beta\alpha}, \tag{4.14a}$$

$$l^p_\mu l^p_\nu \Omega^{\mu\nu} = \dot{\Theta}^p + (3H + 2H_p)\Theta^p \quad (p \text{ not summed}). \tag{4.14b}$$

Consequently, the formulas (4.8c) really provide only three independent equations for the determination of $\{\Omega^\alpha\}$, and the set $\{\Omega^{\alpha\beta}\}$ is uniquely specified by giving $\{\Theta^p\}$ and $\{l^p_\mu l^q_\nu \Omega^{\mu\nu}; p < q\}$. As regards the definition (4.8a) of χ, an equation for χ can be obtained from the relation $\chi = -[\partial(u^\alpha u_\alpha)/\partial\epsilon]_{\epsilon=0}$ with the result $\chi = Q + 2V = 0$, which is a direct consequence of $u^\mu u_\mu = -1$. Thus the gauge-invariant quantity χ will not be significant to us in considering linearization about the universe models of Bianchi types I and V.

Let us summarize the situation. For each $[\mathbf{W}]$, consider the set

$$\varphi([\mathbf{W}]) := \{\chi, \Gamma, \Omega, S, \Omega^\alpha, \Omega^{\alpha\beta}, S^{\alpha\beta}, \Theta^p, \Theta^{pq}_q, \Omega^{pq}_r\}. \tag{4.15}$$

From the discussion presented above it clearly follows that this set consists of gauge-invariant variables. Besides, the total number of independent, not identically vanishing, ''scalar functions'' in $\varphi([\mathbf{W}])$ is 26 $[f_n : X \to \mathbb{R}\ (n = 1,2,...,26)]$. For reasons to become clear later,[20] we shall refer to $\varphi([\mathbf{W}])$ as the *complete* set of *basic* gauge-invariant variables associated with $[\mathbf{W}]$. In order to obtain $\varphi([\mathbf{W}])$, we have used one representative member of $[\mathbf{W}]$, namely, the infinitesimal perturbation $\mathbf{W} = J(\delta\mathcal{F}_0)$ of $\mathcal{F}_0$ given by Eq. (2.18). However, the value of $\varphi([\mathbf{W}])$ does not depend on the choice of $\mathbf{W}' \in [\mathbf{W}]$ and the objects $\varphi([\mathbf{W}]), \mathbf{W} \in \mathcal{W}$, indeed define a function on the quotient space $\mathcal{W}/\mathcal{W}_L$:

$$[\mathbf{W}] \mapsto \varphi([\mathbf{W}]). \tag{4.16}$$

The key steps on which the derivation of this result rests are, first, the observation that the individual quantities appearing on the right-hand sides of Eqs. (4.8) are obtained by means of *linear*, algebropartial differential operations on $\mathbf{W}$, and second, the fact that all these quantities *vanish* if $\mathbf{W}$ is a trivial, ''gauge mode'' perturbation of $\mathcal{F}_0$, i.e., if $\mathbf{W}$ equals $L_v\mathcal{F}_0 := J(\mathcal{L}_v\mathcal{F}_0)$ for some v. Under the foregoing statements, our construction of $\varphi([\mathbf{W}])$ is valid in the class of spatially homogeneous, nonaxisymmetric cosmologies of Bianchi types I and V ($H_1 \neq H_2$, $H_1 \neq H_3$, $H_2 \neq H_3$) with a nonbarotropic perfect fluid as the source. Its usefulness will appear indisputably in Sec. IV C, where we prove that Eqs. (4.8)–(4.15) support an interpretation of $\mathbf{W} \mapsto \varphi([\mathbf{W}])$ as a ''coordinate system'' on $\mathcal{W}/\mathcal{W}_L$.

We now give a necessary word concerning the special cases. When $d_{\alpha\beta} = 0$, we reduce immediately to the situation in almost-Robertson–Walker universe models.[2] Surprisingly enough, the definition of $\varphi([\mathbf{W}])$ for this situation (see Refs. 18 and 19) differs considerably from that presented here. A similar remark holds for the case when the metric $q_{\alpha\beta}$ is axially symmetric ($R_1 \neq R_2 = R_3$); this case must be treated separately as well. We finally mention the following. If we begin from the *general* Bianchi type-I background model,[9] some of the formulas (4.8) simplify enormously; we can then set

$$k=0, \quad l^{\mu}_{p|\nu}=0, \quad l^{p}_{\mu|\nu}=0, \tag{4.17a}$$

$$d^{\alpha\beta}{}_{|\mu}=0, \quad d^{\alpha}{}_{\beta|\mu}=d_{\beta}{}^{\alpha}{}_{|\mu}=0, \quad d_{\alpha\beta|\mu}=0. \tag{4.17b}$$

Moreover, with this choice of the model, we can introduce

$$\Omega^{\alpha\beta}_{\mu}:=(\dot{Z}^{\alpha\beta}+2\gamma^{\nu(\alpha}V^{\beta)}{}_{|\nu})_{|\mu}+2(\gamma_{\sigma}{}^{(\alpha}d^{\beta)\nu}-d_{\sigma}{}^{(\alpha}\gamma^{\beta)\nu})\gamma_{\mu\lambda}Z^{\sigma\lambda}{}_{|\nu}, \tag{4.18}$$

in place of Eqs. (4.8g) and (4.8h). For $k=0$, the essential five properties of the quantity $\Omega^{\alpha\beta}_{\mu}$ are that it (a) is gauge invariant, (b) contains the same information as Θ^{pq}_{q} and Ω^{pq}_{r}, (c) is defined without making any explicit or implicit reference to the eigenframe $\{l^{\mu}_{p}\}$ of $d_{\alpha\beta}$, (d) has the symmetry properties $\Omega^{\alpha\beta}_{\mu}=\Omega^{\beta\alpha}_{\mu}$ and $w^{\mu}\Omega^{\alpha\beta}_{\mu}=w_{\mu}\Omega^{\mu\alpha}_{\nu}q^{\nu\beta}=0$, and (e) satisfies the condition of the form

$$l^{p}_{\alpha}l^{p}_{\beta}l^{\mu}_{q}\Omega^{\alpha\beta}_{\mu}=l^{\mu}_{q}\Theta^{p}{}_{|\mu} \quad (p \;\text{ not summed}). \tag{4.19}$$

Despite these conclusions, our motive for not preferring to replace Θ^{pq}_{q} and Ω^{pq}_{r} by $\Omega^{\alpha\beta}_{\mu}$ when $k=0$ is that we have not found a way to do so generally; if $k=-1$, the construction of $\varphi([\mathbf{W}])$ based on the shear eigenframe appears to us to be canonical.

C. Completeness of the set $\varphi([\mathbf{W}])$ of basic gauge-invariant variables

We denote by $\mathcal{D}$ the set consisting of $\varphi([\mathbf{W}])$ for all $[\mathbf{W}]\in\mathcal{W}/\mathcal{W}_L$ and by $\mathbf{D}$, $\mathbf{D}'$, and similar symbols the elements of $\mathcal{D}$. A function φ from $\mathcal{W}/\mathcal{W}_L$ onto $\mathcal{D}$, defined by Eqs. (4.8)–(4.15), is a linear map that assigns to each $[\mathbf{W}]\in\mathcal{W}/\mathcal{W}_L$ an element $\varphi([\mathbf{W}])\in\mathcal{D}$; thus, $\mathcal{D}$ carries a canonical structure of a vector space induced by that of $\mathcal{W}/\mathcal{W}_L$. More precisely, $\mathcal{D}$ is a function space in which the usual operations of addition and scalar multiplication are introduced. A necessary and sufficient condition that φ be a one-to-one mapping of $\mathcal{W}/\mathcal{W}_L$ onto $\mathcal{D}$ is that $\varphi([\mathbf{W}])$ equals a zero-vector of $\mathcal{D}$ if and only if $[\mathbf{W}]$ equals a zero-vector of the quotient space $\mathcal{W}/\mathcal{W}_L$, i.e., if and only if $[\mathbf{W}]$ can be identified with $[L_v\mathcal{F}_0]$, where v is an arbitrary vector field on the space–time manifold X. For essentially obvious reasons, it will be convenient to call this condition a *natural condition* for the existence of a ''coordinate system'' on $\mathcal{W}/\mathcal{W}_L$. Now, after these preparations, we are in a position to formulate the following theorem.

Theorem: Let $\mathcal{F}_0$ be a nonaxisymmetric Bianchi type-I or Bianchi type-V solution of the nonlinear field equations (2.1)–(2.6); in other words, suppose that this solution is such that $H_1\neq H_2$, $H_1\neq H_3$, and $H_2\neq H_3$. Then the linear mapping $\varphi:\mathcal{W}/\mathcal{W}_L\rightarrow\mathcal{D}$ defined as in Sec. IV B satisfies a *natural condition* for the existence of a ''coordinate system'' on $\mathcal{W}/\mathcal{W}_L$. Thus, for each $\mathbf{D}\in\mathcal{D}$ there is just one $[\mathbf{W}]\in\mathcal{W}/\mathcal{W}_L$ such that $\mathbf{D}=\varphi([\mathbf{W}])$, and the mapping $\varphi:\mathcal{W}/\mathcal{W}_L\rightarrow\mathcal{D}$ is one-to-one and onto. Put somewhat differently, one can introduce the inverse of φ, namely, $\varphi^{-1}:\mathcal{D}\rightarrow\mathcal{W}/\mathcal{W}_L$, by setting $\varphi^{-1}(\varphi([\mathbf{W}]))=[\mathbf{W}]$.

Sketch of the proof: A straightforward but tedious application of Eqs. (4.5)–(4.15) yields the identity $\varphi([L_v\mathcal{F}_0])=0$, so the proof of the theorem reduces to showing that if $[\mathbf{W}]\in\mathcal{W}/\mathcal{W}_L$ belongs to the *kernel* of φ, denoted by ker φ, then the representative member of $[\mathbf{W}]$, namely $\mathbf{W}$, is an element of $\mathcal{W}_L$. Thus, assume that $\mathbf{W}\in[\mathbf{W}]$, the infinitesimal perturbation of $\mathcal{F}_0$ has the property that $\varphi([\mathbf{W}])=0$, i.e., satisfies the conditions of the form

$$\chi=0, \quad \Gamma=0, \quad \Omega=0, \quad S=0, \tag{4.20a}$$

$$\Omega^{\alpha}=0, \quad \Omega^{\alpha\beta}=0, \quad S^{\alpha\beta}=0, \tag{4.20b}$$

$$\Theta^{p}=0, \quad \Theta^{pq}_{q}=0, \quad \Omega^{pq}_{r}=0, \tag{4.20c}$$

where the objects χ through Ω^{pq}_{r} are given by Eqs. (4.8) and (4.11). Under the foregoing conditions to guide us, we wish to demonstrate that there exists a vector field $v=v^{\alpha}(\partial/\partial x^{\alpha})$ on the space–time manifold X such that

$$\mathbf{W}:=\{Q,Q^{\alpha},D,F^{\alpha\beta},V,V^{\alpha},M,K\},$$

equals $L_v\mathcal{F}_0:=\{Q_v,Q^{\alpha}_v,D_v,F^{\alpha\beta}_v,V_v,V^{\alpha}_v,M_v,K_v\}$, i.e.,

$$Q=Q_v:=2\dot{\vartheta}, \tag{4.21a}$$

$$Q^{\alpha}=Q^{\alpha}_v:=\dot{\vartheta}^{\alpha}-H\vartheta^{\alpha}-d^{\alpha}{}_{\mu}\vartheta^{\mu}-\gamma^{\alpha\mu}\vartheta_{|\mu}, \tag{4.21b}$$

$$D=D_v:=-H\vartheta-\tfrac{1}{3}\vartheta^{\mu}{}_{|\mu}, \tag{4.21c}$$

$$F^{\alpha\beta}=F^{\alpha\beta}_v:=-d^{\alpha\beta}\vartheta+\tfrac{1}{3}\gamma^{\alpha\beta}\vartheta^{\mu}{}_{|\mu}-\gamma^{\mu(\alpha}\vartheta^{\beta)}{}_{|\mu}, \tag{4.21d}$$

$$V=V_v:=-\dot{\vartheta}, \tag{4.21e}$$

$$V^{\alpha}=V^{\alpha}_v:=-\dot{\vartheta}^{\alpha}+H\vartheta^{\alpha}+d^{\alpha}{}_{\mu}\vartheta^{\mu}, \tag{4.21f}$$

$$M=M_v:=-3H\vartheta, \tag{4.21g}$$

$$K=K_v:=\frac{1}{T_0}\dot{T}_0\vartheta. \tag{4.21h}$$

For our purposes here, we have used the definitions (4.6) and the decomposition $v^{\alpha}=\vartheta w^{\alpha}+\vartheta^{\alpha}$ of v^{α} with respect to the background fluid four-velocity w^{α}.

(a) To start with, let

$$\vartheta:=-\frac{1}{3H}M \tag{4.22}$$

be a candidate for the timelike part of v^{α}, and define the spacelike part ϑ^{α} of v^{α} by saying that it satisfies the differential equations[36]

$$\dot{\vartheta}^{\alpha}-H\vartheta^{\alpha}-d^{\alpha}{}_{\mu}\vartheta^{\mu}=-V^{\alpha}\quad(\alpha=0,\ldots,3). \tag{4.23}$$

The definitions (4.22) and (4.23) trivially prove Eq. (4.21g) for M and Eq. (4.21f) for V^{α}. Because of $\Gamma=0$ and $\Omega=0$, K equals $T_0^{-1}\dot{T}_0\vartheta$, Q equals $2\dot{\vartheta}$, and Eqs. (4.21h) and (4.21a) hold. Then we may conclude from $\chi=0$ that Eq. (4.21e) is valid for V as well. By using the definition (4.8c) of Ω^{α} and substituting the formulas (4.21f) and (4.21g) onto the left-hand side of $\Omega^{\alpha}=0$, we immediately derive Eq. (4.21b) for Q^{α}.

(b) At this stage of the proof, since the objects Q, Q^{α}, V, V^{α}, M, and K may be written in the desired form, it remains to show that the conditions $S=0, \Omega^{\alpha\beta}=0, S^{\alpha\beta}=0, \Theta^{p}=0, \Theta^{pq}_{q}=0$, and $\Omega^{pq}_{r}=0$ yield Eqs. (4.21c) and (4.21d) for D and $F^{\alpha\beta}$. The key step in the derivation of these two equations is simply this. According to the considerations in Sec. IV B, an equivalent statement to $S=0$ and $S^{\alpha\beta}=0$ is $S^{\alpha\beta\mu\nu}=0$. Given the definitions (4.8e) and (4.9) of $S^{\alpha\beta\mu\nu}$ and $Z^{\alpha\beta}$, we recognize $S^{\alpha\beta\mu\nu}=0$ as the condition for

$$Z^{\alpha\beta}:=\frac{2}{3}(M-3D)\gamma^{\alpha\beta}+\frac{2}{3H}Md^{\alpha\beta}-2F^{\alpha\beta}=-2(H\vartheta+D)\gamma^{\alpha\beta}-2\vartheta d^{\alpha\beta}-2F^{\alpha\beta}. \tag{4.24}$$

This condition implies that there exists a *spacelike* vector field z^{α} on X $(w_{\alpha}z^{\alpha}=0)$, *not necessarily equal to* ϑ^{α}, such that

$$Z^{\alpha\beta}=2\gamma^{\mu(\alpha}z^{\beta)}{}_{|\mu}. \tag{4.25}$$

For further details, and for the more general situations and conditions that also lead to the relation like Eq. (4.25), see the discussion on pp. 351–353 in Ref. 37. Now, in order to emphasize that z^α may differ from ϑ^α, we introduce the following vector field on X:

$$c^\alpha := z^\alpha - \vartheta^\alpha. \tag{4.26}$$

Using the obvious identities $\gamma_{\mu\nu} d^{\mu\nu} = 0$ and $\gamma_{\mu\nu} F^{\mu\nu} = 0$ and exploiting Eqs. (4.24)–(4.26), we then obtain

$$D = -H\vartheta - \tfrac{1}{3}\vartheta^\mu{}_{|\mu} - \tfrac{1}{3}(\gamma_{\mu\nu}\Delta^{\mu\nu}) \tag{4.27a}$$

and

$$F^{\alpha\beta} = -d^{\alpha\beta}\vartheta + \tfrac{1}{3}\gamma^{\alpha\beta}\vartheta^\mu{}_{|\mu} - \gamma^{\mu(\alpha}\vartheta^{\beta)}{}_{|\mu} + \tfrac{1}{3}\gamma^{\alpha\beta}(\gamma_{\mu\nu}\Delta^{\mu\nu}) - \Delta^{\alpha\beta}, \tag{4.27b}$$

where $\Delta^{\alpha\beta}$ is the spatial symmetric two-tensor related to c^α by

$$\Delta^{\alpha\beta} := \gamma^{\mu(\alpha} c^{\beta)}{}_{|\mu}. \tag{4.28}$$

If, without in any way restricting the generality of the conclusion, we demonstrate that $\Delta^{\alpha\beta}$ can be set equal to zero, Eqs. (4.21c) and (4.21d) will be derived, and this derivation will complete the proof of the theorem.

(c) To see how the identity $\Delta^{\alpha\beta} = 0$ can result from $\varphi([\mathbf{W}]) = 0$, by means of Eqs. (4.8d) and (4.8f)–(4.8h) we must carefully analyze the consequences of substituting $V^\alpha = -\dot{\vartheta}^\alpha + H\vartheta^\alpha + d^\alpha{}_\mu \vartheta^\mu$ and $Z^{\alpha\beta} = 2[\gamma^{\mu(\alpha}\vartheta^{\beta)}{}_{|\mu} + \Delta^{\alpha\beta}]$ onto the left-hand sides of $\Omega^{\alpha\beta} = 0$, $\Theta^p = 0$, $\Theta^{pq}_q = 0$, and $\Omega^{pq}_r = 0$; we are thereby led to a set of differential constraints for $\Delta^{\alpha\beta}$. However, before exploiting these constraints, some comments are in order. Equations (4.23) and (4.25) leave a residual ''gauge'' freedom in defining the spatial vector fields ϑ^α and z^α on X, i.e., ϑ^α and z^α are not uniquely determined from these equations. Thus, in particular, given any choice of ϑ^α consistent with Eq. (4.23), we can replace ϑ^α by $\vartheta^\alpha + a^\alpha$, where a^α is such that $w_\mu a^\mu = 0$ and $\dot{a}^\alpha - Ha^\alpha - d^\alpha{}_\mu a^\mu = 0$. Also, a significant feature follows immediately from Eq. (4.25). Let y^α be a vector field on X. Then, provided $w_\mu y^\mu = 0$ and $\gamma^{\mu(\alpha} y^{\beta)}{}_{|\mu} = 0$, the spacelike vector field z^α can be replaced by $z^\alpha + y^\alpha$.

(d) The gauge-invariant variables have as simple a form as possible if expressed in terms of a coordinate system (x^α) for which ds^2 is given by Eq. (3.7). Under this choice of coordinates, the differential conditions $\Omega^{\alpha\beta} = 0$, $\Theta^p = 0$, $\Theta^{pq}_q = 0$, and $\Omega^{pq}_r = 0$ can be solved for

$$\Delta^{\alpha\beta} := \gamma^{\mu(\alpha} z^{\beta)}{}_{|\mu} - \gamma^{\mu(\alpha}\vartheta^{\beta)}{}_{|\mu}, \tag{4.29}$$

by using Eqs. (3.6) and (3.11d), and then the tensor field,

$$\overline{\Delta}^{\alpha\beta} := \gamma^{\mu(\alpha}(z^{\beta)} + y^{\beta)})_{|\mu} - \gamma^{\mu(\alpha}(\vartheta^{\beta)} + a^{\beta)})_{|\mu} = \Delta^{\alpha\beta} + \gamma^{\mu(\alpha} y^{\beta)}{}_{|\mu} - \gamma^{\mu(\alpha} a^{\beta)}{}_{|\mu}, \tag{4.30}$$

can be set equal to zero by suitably constructing a^α and y^α:

$$\Delta^{\alpha\beta} \to \overline{\Delta}^{\alpha\beta} = 0. \tag{4.31}$$

Taken together with the previous results, this completes the proof of the theorem. ■

Remark: The detailed analysis of the differential constraints for $\Delta^{\alpha\beta}$, which is purely technical and requires the introduction of many auxiliary formulas, is available on request.

In virtue of the implication $([\mathbf{W}] \in \ker \varphi) \Rightarrow ([\mathbf{W}] = [L_v \mathcal{F}_0]$ for some $v)$, the mapping $[\mathbf{W}] \mapsto \varphi([\mathbf{W}])$ is very important: it establishes one possible sense in which the present approach to linear perturbation theory determines potentially everything, namely, that one can extract $[\mathbf{W}] \in \mathcal{W}/\mathcal{W}_L$ from $\mathbf{D} := \varphi([\mathbf{W}]) \in \mathcal{D}$ in a unique way. There is, however, another sense in which one would like to have the basic gauge-invariant variables,

$$\varphi([\mathbf{W}]) := \{\chi, \Gamma, \Omega, S, \Omega^{\alpha}, \Omega^{\alpha\beta}, S^{\alpha\beta}, \Theta^{p}, \Theta_{q}^{pq}, \Omega_{r}^{pq}\},$$

determine everything. This would be to show that any gauge-invariant tensor field defined on X is obtainable linearly from the basic variables through purely algebraic and differential operations. Moreover, we should ask the following questions. What is the relationship between the notion of basic gauge-invariant variables introduced here and in Refs. 10 and 11 and the notion of covariant gauge-invariant variables arising from consideration of the standard theory of Ellis and Bruni?[2] Is Lemma 2.2 of Stewart and Walker[5] sufficient to define an almost-Bianchi type-I or almost-Bianchi type-V universe model, or do new principles remain to be found? How do our ideas relate to the coordinate-based method of Tomita and Den,[27] Den,[28,29] and Noh and Hwang?[30,31] Within the framework here set up, can we find a closed set of linear ''propagation'' equations that involves only **D**? If it does exist and if **D** is a classical solution to these propagation equations, will one be able to construct **W**, which satisfies the condition (2.19), and is such that $\mathbf{D} = \varphi([\mathbf{W}])$? These and similar questions will be formulated and answered in separate papers (see, e.g., Ref. 20).

V. FINAL REMARKS

In this paper, we have developed a theory of cosmological perturbations in anisotropic background models of Bianchi types I and V, based on the geometric approach of Banach and Piekarski.[10,11] For the case of a nonbarotropic perfect fluid, we derived a complete set of basic gauge-invariant variables and concluded with an analysis showing how this set can be used to determine the equivalence class of perturbations (tangents). When considering an arbitrary system of diffeomorphism-invariant, covariant field equations, the establishment of an analytic description of the equivalence classes of tangents must be regarded as the primary problem in any complete formulation of linear perturbation theory, which is why a construction of the set $\varphi([\mathbf{W}])$ of basic gauge-invariant variables is of fundamental importance.[10,11] An additional reason for the mathematical and physical relevance of this construction arises from the fact that, as it will be discussed in a companion paper,[20] the appropriate local algebropartial differential operations on $\varphi([\mathbf{W}])$ enable us to define all gauge-invariant variables.

In the covariant approach[2,9] usually taken to the development of linear perturbation theory, the key result that makes the study of covariantly defined gauge-invariant quantities possible is the Stewart–Walker lemma (see Lemma 2.2 in Ref. 5). This states that if $\{A(x^{\mu},\epsilon); \epsilon \in I\}$ is a C^1 curve of geometrical objects determinable tensor algebraically from the fields $\mathcal{F}_{\epsilon}(x^{\mu}), \epsilon \in I$, and their first-, second-, or higher-order covariant derivatives with respect to $g_{\alpha\beta}(x^{\mu},\epsilon)$, then the linear perturbation δA_0 of a quantity $A_0 := (A)_{\epsilon=0}$ on $(X, q_{\alpha\beta})$, namely, $\delta A_0 := (\partial A/\partial\epsilon)_{\epsilon=0}$, is gauge invariant if and only if one of the following three conditions holds: (i) A_0 vanishes, (ii) A_0 is a constant scalar, or (iii) A_0 is a constant linear combination of products of Kronecker deltas.

How our variables are related with the gauge-invariant variables of Stewart and Walker.[5] To see this (more details will be given in Ref. 20), we need to compute δA_0 by differentiating $A(x^{\mu},\epsilon)$ with respect to ϵ at $\epsilon = 0$. Proceeding in this way and using the definition of a complete set, we can show that any of gauge-invariant variables δA_0 is uniquely determined from a knowledge of $\mathcal{F}_0$ and $\varphi([\mathbf{W}])$ alone. However, in the case of interest to us—namely the construction of $\varphi([\mathbf{W}])$ and $\{\delta A_0\}$ for anisotropic background models of Bianchi types I and V—the converse is not true. More precisely, while the set $\{\delta A_0\}$ Stewart and Walker[5] uses as a basic set consists of gauge-invariant quantities, it does not provide a complete framework for defining $\varphi([\mathbf{W}])$ (i.e., describing the equivalence classes of perturbations), unless supplemented by the extra condition $d_{\alpha\beta} = 0$ that restricts the space–time geometry to Robertson–Walker universe models. By what we have said above, the conclusion is simply this: the construction of $\varphi([\mathbf{W}])$ is superior to the construction of $\{\delta A_0\}$.

Another remark is also in order. The result of Stewart and Walker,[5] that the linear perturbation of some quantity only makes sense if the corresponding unperturbed quantity either is a constant scalar or vanishes or is a constant linear combination of products of Kronecker deltas, emerges as an immediate consequence of their definition of δA_0. Of course, this result has the well-known corollary that since the existence of $\{\delta A_0\}$ is completely dependent on the background chosen, a gauge-invariant formulation of linear perturbation theory by means of $\{\delta A_0\}$ will ''almost always'' be impossible. Fortunately, in our previous papers,[10,11] we introduced the notion of a complete set of basic gauge-invariant variables in a way that eliminated any explicit or implicit reference to the properties of the background and thus presented a satisfactory method of overcoming this apparent difficulty. Consequently, for an arbitrary choice of $\mathcal{F}_0$, linear perturbation theory can be formulated via the introduction of $\varphi([\mathbf{W}])$ in a manner that does not require the existence of $\{\delta A_0\}$.

Next, we mention the following. The considerations of Sec. 4.2 in Ref. 10 allow us to prove that nondegenerate linear perturbation theory for which sufficiently many gauge-invariant variables do exist that the equivalence classes of perturbations are completely determined by them (at least in principle) is a theory with sufficiently many tensor fields on X. Thus, when introducing the notion of a ''coordinate system'' on $\mathcal{W}/\mathcal{W}_L$, it is not necessary to impose restrictions on $\mathcal{F}_0$. Nevertheless, there is some confusion in the literature on this point since it is known mathematically that in the case of, for instance, almost-Robertson–Walker universe models, the set $\varphi([\mathbf{W}])$ differs considerably from that obtained here.[18,19] This point is resolved by remarking that the precise form of $\varphi([\mathbf{W}])$ is dependent on the choice of $\mathcal{F}_0$, while the existence of $\varphi([\mathbf{W}])$ is not.

Finally, because of the general results in Sec. 4 of Ref. 11, we should understand clearly that a complete set of propagation equations can be obtained directly in terms of the basic gauge-invariant variables. The mathematical description of these equations, while elementary, is formally too elaborate to present here. However, we plan to return to it in a later paper.[32] Compared with the Robertson–Walker case, we have one new feature of the cosmological perturbations in a spatially anisotropic background. The nonvanishing background shear causes extremely complicated couplings between (Γ,Ω,S), Ω^{α}, $(\Omega^{\alpha\beta},S^{\alpha\beta})$, and $(\Theta^{p},\Theta_{q}^{pq},\Omega_{r}^{pq})$. Thus, except for some particularly simple situations, the analytical solutions of the propagation equations are very difficult to get, and we have to content ourselves with the numerical analysis. Certain assumptions greatly simplify the discussion, e.g., the requirement that the metric is axially symmetric in the background. Unfortunately, from the viewpoint of the present paper, the typical consequence of these assumptions is that the symmetry properties of $\mathcal{F}_0$ and the definition of $\varphi([\mathbf{W}])$ are *substantially* changed, so it is not a generic strategy. Our basic philosophy was not to derive and solve a simple system of differential equations for the specific gauge-invariant variables, but rather to formulate the mathematical principles underlying the theory of gauge-invariant perturbations $[\mathbf{W}]\in\mathcal{W}/\mathcal{W}_L$ in anisotropic cosmological models.

Perhaps the most interesting concrete application of our findings is to the problem of a *semiclassical description* in which the background geometry is taken in the classical framework and the gauge-invariant perturbations are considered as *quantum variables*. For more details, one should consult Ref. 20.

ACKNOWLEDGMENTS

I am grateful to Dr. S. Piekarski for his continuous interest in my work and many discussions. Also, I would like to thank the anonymous referee for a critical reading of the original manuscript and valuable suggestions on clarifying the exposition.

Equivalence classes of perturbations in cosmologies of Bianchi types I and V: Interpretation

Zbigniew Banach
Centre of Mechanics, Institute of Fundamental Technological Research, Department of Fluid Mechanics, Polish Academy of Sciences, Swietokrzyska 21, 00-049 Warsaw, Poland

(Received 20 October 1998; accepted for publication 29 March 1999)

In the preceding paper, 26 gauge-invariant variables were defined that characterize an almost-Bianchi type I or almost-Bianchi type V universe filled with a nonbarotropic perfect fluid. One can think of these basic variables, denoted collectively by **D**, as having at least two aspects. First, **D** gives an explicit (i.e., analytical) representation of the equivalence class of perturbations. In fact, this equivalence class is uniquely determined from **D** and vice versa. Second, any gauge-invariant quantity with respect to a Bianchi type I or Bianchi type V background model is obtainable linearly from **D** through purely algebraic and differential operations. Among many other things, the above properties of **D** facilitate new insights into the question of why a standard and well-known formulation based on the Stewart–Walker lemma does not enable one to describe the equivalence classes of perturbations and to find gauge-invariant variables independent of **D**. If we pose an analogous question in regard to almost-Robertson–Walker universe models, a different but none-the-less instructive answer is obtained. In this case, the Stewart–Walker lemma provides a complete framework both for constructing all gauge-invariant variables and for determining the equivalence classes of perturbations. Because of the sometimes confusing statements in the literature, nontrivial comparisons with other work on linear perturbations in anisotropic background models are made. We also present what we believe are some interesting applications of our ideas to the subject of quantum field theory in curved space–time. © *1999 American Institute of Physics.* [S0022-2488(99)01607-2]

I. INTRODUCTION

In this paper, we continue the systematic investigation of an almost-Bianchi type I or type V universe dominated by a nonbarotropic perfect fluid, i.e., a general perfect fluid with two essential thermodynamic variables. Therefore, it should not be surprising that, to avoid the risk of appearing to be repetitive and even trite, *without further comment* we shall use here those symbols and notions which either appear for the first time in Ref. 1 or are reasonably standard, and the analysis proceeds in a way similar to that already made familiar.

Recalling the result of Banach,[1] one can show that a set of 26 ''geometrically'' independent, not identically vanishing gauge-invariant variables, denoted collectively by **D** and referred to as the complete set of basic variables, can be used to extract the equivalence classes of tangents (perturbations) from **D** in a unique way. This paper will focus upon the study of another important property of **D** which can be characterized by the following observation: any gauge-invariant quantity with respect to a Bianchi type I or type V background model is obtainable *linearly* from the basic variables **D** through *purely* local (i.e., algebraic and differential) operations. Among many other things, the above observation facilitates new insights into the question of why the Stewart–Walker lemma (see Lemma 2.2 in Ref. 2) *does not enable one* to find gauge-invariant variables independent of **D**. Denoting by δA_0 the linear perturbation of a geometric background quantity A_0, this lemma states that for δA_0 to be invariant under the action of an ''infinitesimal diffeomorphism''[3] A_0 must either be a constant scalar, vanish, or be a linear combination of products of Kronecker deltas with constant coefficients. However, if A_0 satisfies one of these three conditions, then the gauge-invariant quantity δA_0 can be expressed locally in terms of $\mathcal{F}_0$ and **D**, and a knowledge of δA_0 *is not necessary* to describe an almost-Bianchi type I or type V universe model.

For these models, the converse is not true. More precisely, a problem which begins: ''find a complete, finite set $\{\delta A_0\}$ of covariantly defined, gauge-invariant quantities δA_0 with a simple geometric and physical meaning, that code the information we need to determine the equivalence classes of perturbations, and extract **D** from $\mathcal{F}_0$ and $\{\delta A_0\}$ in a unique way'' *will be impossible to solve*. By what we have said above, the conclusion is simply this: the construction of **D** is superior to the construction of $\{\delta A_0\}$. However, if we pose an analogous question in regard to almost-Robertson–Walker universe models, a different but none-the-less instructive answer will be obtained.[4,5] In this case, the inverse problem *has a positive solution*, and we conclude that the Stewart–Walker lemma provides a complete framework both for constructing *all* ''geometrically'' independent, not identically vanishing gauge-invariant variables and for determining the equivalence classes of perturbations (see Ref. 5, pp. 289–292).

Various motivations lie behind such a careful analysis of the properties of **D**. To begin with, for an arbitrary background space–time $(X, q_{\alpha\beta})$, there does not appear to be any natural choice of δA_0, nor does there appear to be any unified treatment of the exact and the linearized theory. Thus in particular, the covariant formalism of Ellis and Bruni[6] cannot be extended to this case. It might seem that the lack of an acceptable method for obtaining sufficiently many covariant gauge-invariant variables[7] would pose an insurmountable obstacle to the formulation of linear perturbation theory in general. However, in our previous papers,[8,9] (see also Ref. 1), we introduced the notion of a gauge-invariant variable in a way that eliminated any explicit or implicit reference to Lemma 2.2 of Stewart and Walker[2] and thus presented a satisfactory means of overcoming these apparent difficulties. Moreover, we have found an intriguing result:[8,9] the construction of a ''coordinate system'' on $\mathcal{P}/\mathcal{P}_L$ or $\mathcal{W}/\mathcal{W}_L$ does not depend on the specific symmetry properties of the background space–time geometry chosen; in other words, the set **D** can be proven to exist for any possible choice of the background.

To define a set of gauge-invariant variables, most analysis of inhomogeneities in an expanding universe have categorized the metric and matter perturbations into three distinct types: scalar, vector, and tensor perturbations.[10–15] Such an approach to the gauge problem has been criticized by Ellis and Matravers[16] on the grounds that (i) they doubt the value of introducing the idea of ''gauge-invariant harmonic amplitudes'' into general relativity at all and (ii) if one is to introduce it, then one should accept a concept which is completely dependent on the coordinate choice made (for example, the Bardeen formalism[10] is gauge invariant only if one restricts coordinate changes to the vector kinds when vector modes are investigated, and to the scalar kind when the scalar modes are the theme of interest). The present formalism enables us to reformulate the coordinate-based method of Bardeen[10] in terms of properties of the complete set **D**. This reformulation is both *fully* covariant and gauge invariant; thus it sidesteps the usual problems and *resolves disagreements* between the results of different existing formalisms.

Are there at least possible concrete applications of our ideas? With regard to this question, it is an important—and conceptually and mathematically nontrivial—challenge to examine the effect of using a *semiclassical description*[17–21] in which the background geometry is taken in the classical framework and the gauge-invariant perturbations are considered as *quantum variables*. Progress towards this goal has been slow, mainly because of the fact that a ''presymplectic vector space structure''[19] $\overline{\omega}$ defined on the space $\mathcal{P}$ of infinitesimal perturbations $\delta\mathcal{F}_0$ is not necessarily nondegenerate. When it is degenerate, we must reduce $\mathcal{P}$ by taking the ''symplectic quotient'' of $(\mathcal{P}, \overline{\omega})$,[22] thereby producing a quotient space $\mathcal{P}/\mathcal{P}_L$ on which there is defined a nondegenerate symplectic vector space structure ω. The complete set **D** of basic gauge-invariant variables should be of great use in the study of these problems; up to the present, one has simply never succeeded in going beyond the self-evident observation that $\overline{\omega}$ always is gauge invariant, i.e., for any pair of linearized solutions $\delta\mathcal{F}_0$ and $\delta\mathcal{F}_0'$ of Eq. (2.14) in Ref. 1, the quantity $\overline{\omega}(\delta\mathcal{F}_0, \delta\mathcal{F}_0')$ depends only upon the gauge equivalence class of $\delta\mathcal{F}_0$ and $\delta\mathcal{F}_0'$. Indeed, it would appear that one is now in a position to formulate, for the first time, a sensible prescription—valid for an arbitrary Lagrangian field theory—for constructing ω from $\overline{\omega}$ and **D**.

The program of this paper is as follows. Section II introduces a number of geometric background quantities A_0 satisfying one of the three conditions in the Stewart–Walker lemma and then shows that from a knowledge of **D** alone, together with the information about $\mathcal{F}_0$, one can compute the linear perturbations of these quantities, namely $\{\delta A_0\}$. In Sec. III we compare our results with Bardeen's and with other treatments of gauge-invariant perturbations in anisotropic background models. Specifically, we relate our work to Tomita and Den,[11] Den,[12,13] and Noh and Hwang[14,15] on the Bardeen nonlocal approach,[10] and to Dunsby[23] on the Ellis–Bruni covariant method.[6] In Sec. IV we demonstrate how the entire formalism can be adapted naturally into a semiclassical description. Section V is for final remarks.

II. RELATIONSHIP WITH THE STEWART–WALKER LEMMA

Let $\{A(x^\mu,\epsilon);\ \epsilon\in I\}$ be a curve of geometrical objects determinable tensor-algebraically from the fields $\mathcal{F}_\epsilon(x^\mu)$, $\epsilon\in I$, and their first-, second-, or higher-order covariant derivatives with respect to $g_{\alpha\beta}(x^\mu,\epsilon)$, and suppose that $A(x^\mu,\epsilon)$ depends continuously and differentiably on ϵ. In this way of thinking, it will be convenient to regard $\{\mathcal{F}_\epsilon(\cdot);\ \epsilon\in I\}$ *not* as a one-parameter family of exact solutions to the nonlinear field equations, but rather as an arbitrary C^r curve (r sufficiently large) in the function space $\{\mathcal{F}(\cdot)\}$ passing through the background solution $\mathcal{F}_0(\cdot)$. With the notation $A_0 \coloneqq (A)_{\epsilon=0}$, we can introduce the quantity δA, denoted in the Introduction by δA_0, which represents the *linear perturbation* of A_0:

$$\delta A \coloneqq \left(\frac{\partial A}{\partial \epsilon}\right)_{\epsilon=0}. \tag{2.1}$$

As shown already by Ehlers,[24] this linear perturbation is gauge invariant (i.e., invariant under the action of an ''infinitesimal diffeomorphism''[3,25]) if and only if the following condition holds for each vector field v on X:[26]

$$\mathcal{L}_v A_0 = 0. \tag{2.2}$$

According to the Stewart–Walker lemma (see Lemma 2.2 in Ref. 2), in order to satisfy the above condition, it is necessary to use a scalar A that is constant in the unperturbed space–time $(X,q_{\alpha\beta})$, or any tensor $A_\alpha\ldots$ that vanishes in $(X,q_{\alpha\beta})$, or a tensor whose ''background value'' is a constant linear combination of products of Kronecker's deltas $\delta^\alpha{}_\beta$.

Having made these general remarks, we wish now to provide representative examples of the gauge-invariant quantities δA. Next, we will prove that, for the *general* Bianchi type I or type V background model $(k=0,-1)$, a knowledge of the complete set of basic variables, namely

$$\varphi([\mathbf{W}]) \coloneqq \{\chi,\Gamma,\Omega,S,\Omega^\alpha,\Omega^{\alpha\beta},S^{\alpha\beta},\Theta^p,\Theta^{pq}_q,\Omega^{pq}_r\}, \tag{2.3}$$

determines δA in a unique way. If the background spatial curvature k vanishes (Bianchi type I space–times), the set $\varphi([\mathbf{W}])$ can be replaced by

$$\varphi_1([\mathbf{W}]) \coloneqq \{\chi,\Gamma,\Omega,S,\Omega^\alpha,\Omega^{\alpha\beta},S^{\alpha\beta},\Omega^{\alpha\beta}_\mu,\Theta^p\}. \tag{2.4}$$

The mathematical details of our construction of $\varphi([\mathbf{W}])$ and $\varphi_1([\mathbf{W}])$ are given in Sec. IV B of Ref. 1 [see especially Eqs. (4.8), (4.11), and (4.18)]. For simplicity, we abbreviate $\varphi([\mathbf{W}])$ as **D** and $\varphi_1([\mathbf{W}])$ as $\mathbf{D}_1$.

A. Discussion of the case when $H_1\neq H_2\neq H_3\neq H_1$

From the above analysis plus the definition $h_{\alpha\beta}\coloneqq g_{\alpha\beta}+u_\alpha u_\beta$ and the decomposition of $u_{\alpha;\beta}$ [see Eq. (3.1) in Ref. 1] we conclude that the simplest physical objects $A(\cdot,\epsilon)$ satisfying for $\epsilon=0$ the condition (2.2) can be described as follows:

(1) The specific entropy:

$$s := \text{entropy per particle.} \tag{2.5}$$

(2) The normalized curvature scalars:

$$\mathcal{A} := \frac{1}{n^{2/3}} \left[-\frac{2}{3}(\theta)^2 + \sigma^{\mu\nu}\sigma_{\mu\nu} + R^{\mu}{}_{\mu} + 2u^{\mu}u^{\nu}R_{\mu\nu} \right], \tag{2.6a}$$

$$\mathcal{B} := \frac{1}{n^{2/3}} \left[-\frac{2}{3}(\theta)^2 + \sigma^{\mu\nu}\sigma_{\mu\nu} + 2(e+\Lambda) \right], \tag{2.6b}$$

$$\mathcal{C} := \frac{1}{n^{2/3}} [-2(\theta)^2 - 4u^{\mu}\theta_{;\mu} - 3\sigma^{\mu\nu}\sigma_{\mu\nu} - 6(p-\Lambda)]. \tag{2.6c}$$

(3) The orthogonal spatial gradients of n and $\theta := u^{\mu}{}_{;\mu}$:

$$X^{\alpha} := h^{\alpha\beta} n_{;\beta}, \quad Z^{\alpha} := h^{\alpha\beta}\theta_{;\beta}. \tag{2.7}$$

(4) The acceleration:

$$a^{\alpha} := u^{\beta} u^{\alpha}{}_{;\beta}. \tag{2.8}$$

(5) The spatial two-tensor associated with $\sigma_{\alpha\beta}$:

$$\mathcal{E}_{\alpha\beta} := h^{\mu}{}_{\alpha} h^{\nu}{}_{\beta} (u^{\lambda}\sigma_{\mu\nu;\lambda} + \theta\sigma_{\mu\nu}). \tag{2.9}$$

(6) The normalized trace-free curvature tensor:

$$\mathcal{A}^{\alpha\beta} := -\frac{1}{3}\mathcal{A}h^{\alpha\beta} + \frac{1}{n^{2/3}} \left[-\frac{2}{9}(\theta)^2 h^{\alpha\beta} - \frac{1}{3}\theta\sigma^{\alpha\beta} + \sigma^{\alpha}{}_{\mu}\sigma^{\mu\beta} + R_{\mu\nu}h^{\mu\alpha}h^{\nu\beta} + R^{\lambda}{}_{\mu\tau\nu}u_{\lambda}u^{\tau}h^{\mu\alpha}h^{\nu\beta} \right]. \tag{2.10}$$

Several points concerning these definitions should be noted. First, we assume that there exists the specific entropy, i.e., the entropy per particle. We denote this entropy by s. If $\mathcal{F}_{\epsilon}(\cdot)$ is a solution of the nonlinear field equations, and such is *certainly* the case when $\epsilon=0$, then $s:=s(\cdot,\epsilon)$ satisfies the property that $(nsu^{\alpha})_{;\alpha}=0$. After combining this property of s with the equation of balance of number density, we derive that the nonbarotropic perfect fluid is locally adiabatic:[27,28]

$$u^{\alpha}s_{;\alpha}=0. \tag{2.11}$$

That is, entropy is constant along the flow lines of the fluid. In this way, we arrive at the following conclusion: the specific entropy s is a scalar that is *constant* in the unperturbed space–time $(X,q_{\alpha\beta})$.

Second, it can be shown that the *same* conclusion concerns $\mathcal{A}$, $\mathcal{B}$, and $\mathcal{C}$. More precisely, if $\epsilon=0$, we have $kn_0 \sim k(R_1)^{-3}$ and $\mathcal{A}=\mathcal{B}=\mathcal{C}=(n_0)^{-2/3}[6k/(R_1)^2]=\text{constant}$; thus the Lie derivatives[26] $\mathcal{L}_v\mathcal{A}_0$, $\mathcal{L}_v\mathcal{B}_0$, and $\mathcal{L}_v\mathcal{C}_0$ vanish. For $\epsilon\neq 0$, provided $\mathcal{F}_{\epsilon}(\cdot)$ satisfies the nonlinear field equations, $\mathcal{A}$ equals $\mathcal{B}$ and $\mathcal{C}$ is dynamically related to $\mathcal{B}$, a^{μ}, and $\omega_{\mu\nu}$ by $\mathcal{C}=\mathcal{B}-4n^{-2/3}(a^{\mu}_{;\mu}+\omega^{\mu\nu}\omega_{\mu\nu})$. Under these circumstances, in the special case of vanishing vorticity (and only then) the quantity $n^{2/3}\mathcal{B}$ acquires a special significance:[6] it is the Ricci scalar ${}^3R$ of the three-dimensional spaces $\Sigma_{\perp}$ everywhere orthogonal to the fluid flow vector u^{α}; that is, $\omega_{\mu\nu}=0 \Rightarrow {}^3R=n^{2/3}\mathcal{B}$. For this reason, we call $\mathcal{B}$ (as well as $\mathcal{A}$ and $\mathcal{C}$) the normalized curvature scalar. (By way of digression, the meaning of $n^{2/3}\mathcal{B}$ when $\omega^{\mu\nu}\omega_{\mu\nu}\neq 0$ is discussed in Appendix B of Ref. 6.)

Third, the important physical variable turns out to be the orthogonal density gradient X^α defined by one of Eqs. (2.7). Ellis and Bruni,[6] Bruni *et al.*,[29] Dunsby *et al.*,[30] and Dunsby[23] gave the first systematic treatment of the properties of this variable. From the viewpoint of the formalism developed by Ellis and Bruni,[6] both quantities in Eqs. (2.7) are gauge invariant, as they vanish in the Bianchi type I and type V universes $[X^\alpha \cong \epsilon(\delta X^\alpha)$ and $Z^\alpha \cong \epsilon(\delta Z^\alpha)]$. Interpreting Eq. (2.8), this equation defines the standard kinematic quantity which vanishes in the background, and so is *gauge invariant*. As regards $\mathcal{E}_{\alpha\beta}$ [see Eq. (2.9)], this quantity is *also* gauge invariant, because of the condition[1] $(\mathcal{E}_{\alpha\beta})_{\epsilon=0} = \dot{d}_{\alpha\beta} + 3Hd_{\alpha\beta} = 0$. Note that $\mathcal{E}_{\alpha\beta}$ is constructed from the shear tensor $\sigma_{\alpha\beta}$ and that $\mathcal{E}_{\alpha\beta} = \mathcal{E}_{\beta\alpha}$, $g^{\alpha\beta}\mathcal{E}_{\alpha\beta} = 0$, and $\mathcal{E}_{\alpha\beta}u^\beta = 0$.

Next, using the definition (2.10) of $\mathcal{A}^{\alpha\beta}(\mathcal{A}^{\alpha\beta} = \mathcal{A}^{\beta\alpha}, g_{\alpha\beta}\mathcal{A}^{\alpha\beta} = 0, \mathcal{A}^{\alpha\beta}u_\beta = 0)$, we obtain $(\mathcal{A}^{\alpha\beta})_{\epsilon=0} = 0$; thus $\delta\mathcal{A}^{\alpha\beta}$ is *gauge invariant*. If $\omega_{\alpha\beta} = 0$, the tensor $\mathcal{A}^{\alpha\beta}$, which we call the normalized trace-free curvature tensor, is related to the trace-free part of the Ricci tensor ${}^3R_{\alpha\beta}$ of $\Sigma_\perp$. In fact, given a unit timelike vector u^α, we can define at each point the three-curvature tensor ${}^3R^\mu{}_{\alpha\nu\beta}$ and its trace ${}^3R_{\alpha\beta} := {}^3R^\mu{}_{\alpha\mu\beta}$. When u^α is hypersurface-orthogonal, these are the Riemann and Ricci tensors of three-surfaces $\Sigma_\perp$, but in general $\omega_{\alpha\beta} \neq 0 \Rightarrow {}^3R_{[\alpha\beta]} \neq 0$, and these tensors do not have all the usual symmetries of Riemann and Ricci (more details in Refs. 29 and 31). Let u^α be the fluid four-velocity and suppose that $\omega_{\alpha\beta} = 0$. Then we can split ${}^3R_{\alpha\beta}$ into its trace ${}^3R = n^{2/3}\mathcal{A}$ and its symmetric trace-free part ${}^3\mathcal{R}_{\alpha\beta} = n^{2/3}(g_{\alpha\mu}g_{\beta\nu}\mathcal{A}^{\mu\nu})$. The tensor field $(\mathcal{A}^{\alpha\beta})_{\epsilon=0}$ vanishes because $({}^3R^\mu{}_{\alpha\nu\beta})_{\epsilon=0}$ equals $[k/(R_1)^2](\gamma^\mu{}_\nu\gamma_{\alpha\beta} - \gamma^\mu{}_\beta\gamma_{\alpha\nu})$.

Finally, it is easy to find many further gauge-invariant quantities by finding more complex *invariantly* defined quantities that vanish in the background, for example, the vorticity; the orthogonal spatial gradients of $T, e, p, s, n^{2/3}\mathcal{A}, n^{2/3}\mathcal{B}$, and $n^{2/3}\mathcal{C}$; the divergence of the acceleration and its spatial gradient; and so on:

$$\omega_{\alpha\beta} := h^\mu{}_\alpha h^\nu{}_\beta u_{[\mu;\nu]}, \tag{2.12a}$$

$$\Pi^\alpha := h^{\alpha\beta}T_{;\beta}, \quad \overline{X}^\alpha := h^{\alpha\beta}e_{;\beta}, \tag{2.12b}$$

$$Y^\alpha := h^{\alpha\beta}p_{;\beta}, \quad \mathcal{E}^\alpha := h^{\alpha\beta}s_{;\beta}, \tag{2.12c}$$

$$C^\alpha := h^{\alpha\beta}(n^{2/3}\mathcal{A})_{;\beta}, \quad \overline{C}^\alpha := h^{\alpha\beta}(n^{2/3}\mathcal{B})_{;\beta}, \tag{2.12d}$$

$$\tilde{C}^\alpha := h^{\alpha\beta}(n^{2/3}\mathcal{C})_{;\beta}, \tag{2.12e}$$

$$\Xi := a^\mu{}_\mu, \quad \Xi^\alpha := h^{\alpha\beta}\Xi_{;\beta}. \tag{2.12f}$$

Together with the variables $\delta\mathcal{C}$ and Z^α, these will not be significant to us in considering linearization around the Bianchi type I and type V universes, for there are *simpler* gauge-invariant quantities which can be used to determine them [see Eqs. (2.17a)–(2.17k)].

Before calculating δA for the quantities defined by Eqs. (2.5)–(2.10) and (2.12), let us introduce the following notation:[1]

$$e_0 := e(n_0, T_0), \quad p_0 := p(n_0, T_0), \tag{2.13a}$$

$$e_T := \frac{\partial e_0}{\partial T_0}, \quad p_T := \frac{\partial p_0}{\partial T_0}, \tag{2.13b}$$

$$N := u^\mu n_{;\mu} + nu^\mu{}_{;\mu}, \tag{2.13c}$$

$$\vec{\gamma} \circ \vec{\Theta} := \sum_{p=1}^{3} [(l_p^\mu l_p^\nu \gamma_{\mu\nu})\Theta^p], \tag{2.13d}$$

$$\vec{d}\circ\vec{\Theta}:=\sum_{p=1}^{3}\,[(l_p^{\mu}l_p^{\nu}d_{\mu\nu})\Theta^p]. \tag{2.13e}$$

From Eq. (2.13c) we obtain $N_0:=(N)_{\epsilon=0}=0$, so that the linear perturbation δN of N_0 is gauge invariant. However, if $\{\mathcal{F}_\epsilon(\cdot);\ \epsilon\in I\}$ *is* a one-parameter family of exact solutions to the nonlinear field equations, then $N(\cdot,\epsilon)=0$ and δN *vanishes identically*. With all these preparatory remarks in mind, it is only a matter of labor to prove that

$$\delta N=\tfrac{1}{2}n_0(\vec{\gamma}\circ\vec{\Theta}) \tag{2.14a}$$

and that the linear perturbations of s, $\mathcal{A}$, $\mathcal{B}$, X^α, a^α, $\mathcal{E}_{\alpha\beta}$, and $\mathcal{A}^{\alpha\beta}$ at $\epsilon=0$ are related to the gauge-invariant variables Γ, Ω, S, Ω^α, $\Omega^{\alpha\beta}$, $S^{\alpha\beta}$, and Θ^p in $\mathbf{D}:=\varphi([\mathbf{W}])$ [see Eq. (2.3)] by[32]

$$\delta s=\frac{e_T}{n_0}\Gamma, \tag{2.14b}$$

$$\delta\mathcal{A}=\frac{2}{(n_0)^{2/3}}\left(\frac{2}{3}\Omega^{\mu}{}_{|\mu}-\frac{1}{3H}d^{\mu}{}_{\nu}\Omega^{\nu}{}_{|\mu}-S\right), \tag{2.14c}$$

$$\delta\mathcal{B}=\frac{2}{(n_0)^{2/3}}\left\{2\left[\frac{3k}{(R_1)^2}-e_0-\Lambda\right]\Omega-H(\vec{\gamma}\circ\vec{\Theta})+\frac{1}{2}(\vec{d}\circ\vec{\Theta})+T_0e_T\Gamma\right\}, \tag{2.14d}$$

$$\delta X^\alpha=n_0\Omega^\alpha, \tag{2.14e}$$

$$\delta a^\alpha=-\frac{1}{3H}\dot{\Omega}^\alpha+\frac{1}{3}\left(\frac{\dot{H}}{H^2}-1\right)\Omega^\alpha-\frac{1}{3H}d^{\alpha}{}_{\mu}\Omega^\mu-\gamma^{\alpha\mu}\Omega_{|\mu}, \tag{2.14f}$$

$$\begin{aligned}\delta\mathcal{E}_{\alpha\beta}=&-\frac{1}{6}\gamma_{\alpha\beta}(\vec{\gamma}\circ\vec{\Theta})^{\cdot}-\frac{1}{2}H\gamma_{\alpha\beta}(\vec{\gamma}\circ\vec{\Theta})+\dot{\Omega}d_{\alpha\beta}+\frac{1}{2}d_{\alpha\beta}(\vec{\gamma}\circ\vec{\Theta})\\&+\frac{1}{2}\gamma_{\alpha\mu}\gamma_{\beta\nu}\Omega^{\mu\nu}+\frac{1}{3H}d_{\mu(\alpha}\Omega^{\mu}{}_{|\beta)}-\frac{1}{3H}\gamma_{\nu(\alpha}d^{\mu}{}_{\beta)}\Omega^{\nu}{}_{|\mu},\end{aligned} \tag{2.14g}$$

$$\begin{aligned}\delta\mathcal{A}^{\alpha\beta}=-\frac{1}{(n_0)^{2/3}}\Bigg[&2S^{\alpha\beta}+\frac{1}{9}\gamma^{\alpha\beta}\Omega^{\mu}{}_{|\mu}-\frac{1}{3}\gamma^{\mu(\alpha}\Omega^{\beta)}{}_{|\mu}-\frac{1}{3H}d^{\alpha\beta}\Omega^{\mu}{}_{|\mu}\\&+\frac{1}{3H}\left(\gamma^{\mu(\alpha}d^{\beta)}{}_{\nu}-\frac{2}{3}\gamma^{\alpha\beta}d^{\mu}{}_{\nu}\right)\Omega^{\nu}{}_{|\mu}+\frac{1}{3H}d^{\mu(\alpha}\Omega^{\beta)}{}_{|\mu}+\frac{2}{3H}(\gamma^{\nu(\alpha}d^{\beta)}{}_{\mu|\nu}-d^{\alpha\beta}{}_{|\mu})\Omega^{\mu}\Bigg].\end{aligned} \tag{2.14h}$$

Equations (2.14g) and (2.14h) yield the conditions

$$\gamma^{\mu\nu}(\delta\mathcal{E}_{\mu\nu})=0,\quad \gamma_{\mu\nu}(\delta\mathcal{A}^{\mu\nu})=0 \tag{2.15a}$$

and

$$d^{\mu\nu}(\delta\mathcal{E}_{\mu\nu})=(d^{\mu\nu}d_{\mu\nu})\dot{\Omega}+\tfrac{1}{2}(d^{\mu\nu}d_{\mu\nu})(\vec{\gamma}\circ\vec{\Theta})+\tfrac{1}{2}(\vec{d}\circ\vec{\Theta})^{\cdot}+3H(\vec{d}\circ\vec{\Theta}), \tag{2.15b}$$

where we have used the identity (4.14b) of Ref. 1.

Given all these results, especially Eqs. (2.14a)–(2.14h), *it is now obvious mathematically* how to extract δN, δs, $\delta\mathcal{A}$, $\delta\mathcal{B}$, δX^α, δa^α, $\delta\mathcal{E}_{\alpha\beta}$, and $\delta\mathcal{A}^{\alpha\beta}$ from a knowledge of $\mathcal{F}_0$ and $\mathbf{D}$ *alone*. At the same time, we may interpret some of the above formulas in another way by noticing that Γ, Ω, S, Ω^{α}, $\Omega^{\alpha\beta}$, and $S^{\alpha\beta}$ are *uniquely* determined from $\mathcal{F}_0$, δs, $\delta\mathcal{A}$, $\delta\mathcal{B}$, δX^{α}, $\delta\mathcal{E}_{\alpha\beta}$, $\delta\mathcal{A}^{\alpha\beta}$, and Θ^p $(p=1,2,3)$. Thus, the set

$$\varphi_2([\mathbf{W}]) := \{\chi, \delta s, \delta\mathcal{B}, \delta\mathcal{A}, \delta X^{\alpha}, \delta\mathcal{E}_{\alpha\beta}, \delta\mathcal{A}^{\alpha\beta}, \Theta^p, \Theta^{pq}_q, \Omega^{pq}_r\} \tag{2.16}$$

constitutes a *new* complete set of basic gauge-invariant variables; this set contains all significant information about $[\mathbf{W}]$. Since the specification of $\varphi_2([\mathbf{W}])$ for each $[\mathbf{W}]$ is mathematically equivalent to the specification of $\mathbf{W} \mapsto \varphi([\mathbf{W}])$, it can also be interpreted as a construction of the *alternative* ''coordinate system''[1] on $\mathcal{W}/\mathcal{W}_L$. Nevertheless, it should be stressed that if $d^{\mu\nu}d_{\mu\nu} \neq 0$ and $\vec{d}\circ\vec{\Theta} \neq 0$, then Eqs. (2.14a), (2.14b), (2.14d), (2.14e), (2.14g), and (2.15b) *are not sufficient* to express Ω and $\Omega^{\alpha\beta}$ in terms of *only* $\mathcal{F}_0$, δN, δs, $\delta\mathcal{B}$, δX^{α}, and $\delta\mathcal{E}_{\alpha\beta}$. Similarly, in our model, *serious difficulties* would arise if we attempt to define a meaningful set of gauge-invariant variables δA for the determination of Θ^p, Θ^{pq}_q, and Ω^{pq}_r. Put somewhat differently, knowledge of the set $\mathbf{D}$ allows one to compute $\{\delta A\}$, but knowledge of the set $\{\delta A\}$ *does not permit one* inversely to compute $\mathbf{D}$. Moreover, except for some ''particularly simple'' situations ($d_{\alpha\beta}=0$; see Refs. 4 and 5), *we may be no longer able* to represent the equivalence classes of perturbations by means of $\{\delta A\}$.

Turning now to the formulas (2.12) and the quantities $\mathcal{C}$ and Z^{α} in Eqs. (2.6c) and (2.7), the corresponding linear perturbations δA are determined by the relations

$$\delta\omega_{\alpha\beta} = -\frac{1}{3Hn_0}\gamma_{\mu[\alpha}(\delta X^{\mu})_{|\beta]}, \tag{2.17a}$$

$$\delta\Pi^{\alpha} = -\frac{1}{3Hn_0}\dot{T}_0(\delta X^{\alpha}) + \frac{1}{e_T}n_0T_0\gamma^{\alpha\beta}(\delta s)_{|\beta}, \tag{2.17b}$$

$$\delta\overline{X}^{\alpha} = \frac{1}{n_0}(e_0+p_0)(\delta X^{\alpha}) + n_0T_0\gamma^{\alpha\beta}(\delta s)_{|\beta}, \tag{2.17c}$$

$$\delta Y^{\alpha} = -\frac{1}{3Hn_0}\dot{p}_0(\delta X^{\alpha}) + \frac{1}{e_T}n_0T_0p_T\gamma^{\alpha\beta}(\delta s)_{|\beta}, \tag{2.17d}$$

$$\delta Z^{\alpha} = -3H(\delta a^{\alpha}) - \frac{1}{n_0}[(\delta X^{\alpha})^{\cdot} + 4H(\delta X^{\alpha}) + d^{\alpha}{}_{\mu}(\delta X^{\mu}) - \gamma^{\alpha\mu}(\delta N)_{|\mu}], \tag{2.17e}$$

$$\delta\mathcal{E}^{\alpha} = \gamma^{\alpha\beta}(\delta s)_{|\beta}, \tag{2.17f}$$

$$\begin{aligned}\delta\mathcal{C} = \frac{1}{H}(\delta\mathcal{B})^{\cdot} + \delta\mathcal{B} - \frac{2}{H(n_0)^{2/3}}\Bigg\{ & d^{\mu\nu}(\delta\mathcal{E}_{\mu\nu}) - \frac{2}{n_0}\left[\frac{k}{(R_1)^2} - \frac{1}{2}(e_0+p_0)\right](\delta N) \\ & + n_0T_0(\delta s)^{\cdot} + \left(n_0\dot{T}_0 - \frac{1}{e_T}T_0p_T\dot{n}_0\right)(\delta s)\Bigg\},\end{aligned} \tag{2.17g}$$

$$\delta C^{\alpha} = \frac{4k}{n_0(R_1)^2}(\delta X^{\alpha}) + (n_0)^{2/3}\gamma^{\alpha\beta}(\delta\mathcal{A})_{|\beta}, \tag{2.17h}$$

$$\delta\overline{C}^{\alpha} = \frac{4k}{n_0(R_1)^2}(\delta X^{\alpha}) + (n_0)^{2/3}\gamma^{\alpha\beta}(\delta\mathcal{B})_{|\beta}, \tag{2.17i}$$

$$\delta\tilde{C}^{\alpha} = \frac{4k}{n_0(R_1)^2}(\delta X^{\alpha}) + (n_0)^{2/3}\gamma^{\alpha\beta}(\delta\mathcal{C})_{|\beta}, \tag{2.17j}$$

$$\delta\Xi=(\delta a^{\mu})_{|\mu}, \quad \delta\Xi^{\alpha}=\gamma^{\alpha\beta}[(\delta a^{\mu})_{|\mu}]_{|\beta}. \tag{2.17k}$$

Given these linear perturbations, we might now say justifiably that *they all can be generated from* $\mathcal{F}_0$, δN, δs, $\delta\mathcal{A}$, $\delta\mathcal{B}$, δX^{α}, δa^{α}, and $\delta\mathcal{E}_{\alpha\beta}$ via a local algebropartial differential transformation, so that, in linear perturbation theory, Eqs. (2.14) are *superior* to those just obtained.

The analysis so far has been for an almost-Bianchi type I or type V universe model ($k=0$, -1). However, in the case of a Bianchi type I cosmology ($k=0$), it proves useful, as we already mentioned,[1] both to replace Θ^{pq}_{q} and Ω^{pq}_{r} by a new gauge-invariant quantity $\Omega^{\alpha\beta}_{\mu}$ [see Eq. (4.18) in Ref. 1] and to write Eq. (2.16) in the more convenient form

$$\varphi_3([\mathbf{W}]):=\{\chi,\delta s,\delta\mathcal{B},\delta\mathcal{A},\delta X^{\alpha},\delta\mathcal{E}_{\alpha\beta},\delta\mathcal{A}^{\alpha\beta},\Omega^{\alpha\beta}_{\mu},\Theta^{p}\}. \tag{2.18}$$

Now, consider a tensor field $\mathcal{E}_{\alpha\beta\mu}$ ($\mathcal{E}_{[\alpha\beta]\mu}=0, g^{\alpha\beta}\mathcal{E}_{\alpha\beta\mu}=0, u^{\alpha}\mathcal{E}_{\alpha\beta\mu}=u^{\alpha}\mathcal{E}_{\beta\mu\alpha}=0$) defined in terms of the shear tensor $\sigma_{\alpha\beta}$ by

$$\mathcal{E}_{\alpha\beta\mu}:=h^{\tau}{}_{\alpha}h^{\lambda}{}_{\beta}h^{\nu}{}_{\mu}\sigma_{\tau\lambda;\nu}. \tag{2.19}$$

If $k=0$, this tensor field vanishes in the background, and we obtain the result that $\delta\mathcal{E}_{\alpha\beta\mu}$ is a *gauge-invariant* quantity. Proceeding through the same steps as lead to the formulas (2.14) and (2.17), we verify that a knowledge of $\mathcal{F}_0$ and $\{\Omega,\Omega^{\alpha},\Omega^{\alpha\beta}_{\mu},\Theta^{p}\}\subset\mathbf{D}_1$ *is all we need* to determine $\delta\mathcal{E}_{\alpha\beta\mu}$:

$$\delta\mathcal{E}_{\alpha\beta\mu}=\gamma_{\mu\nu}\Omega^{\nu}d_{\alpha\beta}+\frac{2}{3}[d_{\mu(\alpha}\gamma_{\beta)\nu}-\gamma_{\mu(\alpha}d_{\beta)\nu}]\Omega^{\nu}+\frac{2}{3H}[d^{\sigma}{}_{\mu}d_{\sigma(\alpha}\gamma_{\beta)\nu}-d_{\mu(\alpha}d_{\beta)\nu}]\Omega^{\nu}$$
$$-\frac{1}{6}\gamma_{\alpha\beta}(\vec{\gamma}\circ\vec{\Theta})_{|\mu}+d_{\alpha\beta}\Omega_{|\mu}+\frac{1}{2}\gamma_{\alpha\nu}\gamma_{\beta\sigma}\Omega^{\nu\sigma}_{\mu}. \tag{2.20}$$

Then, from Eq. (4.19) in Ref. 1, we get

$$\gamma^{\alpha\beta}(\delta\mathcal{E}_{\alpha\beta\mu})=0, \tag{2.21}$$

as it should be. Alternatively, within the framework here set up, $\Omega^{\alpha\beta}_{\mu}$ is obtainable from $\mathcal{F}_0$, δs, $\delta\mathcal{B}$, δX^{α}, $\delta\mathcal{E}_{\alpha\beta\mu}$, and Θ^{p} ($p=1,2,3$) through purely algebraic and differential operations, so that $[\mathbf{W}]$ can be described by means of the gauge-invariant variables Θ^{p} and χ ($\chi=-[\partial(u^{\alpha}u_{\alpha})/\partial\epsilon]_{\epsilon=0}=0$) and the following system of linear perturbations:

$$\mathbf{E}:=\{\delta s,\delta\mathcal{B},\delta\mathcal{A},\delta X^{\alpha},\delta\mathcal{E}_{\alpha\beta},\delta\mathcal{A}^{\alpha\beta},\delta\mathcal{E}_{\alpha\beta\mu}\}. \tag{2.22}$$

Thus, as in an almost-Bianchi type V universe model discussed before, the net upshot of these considerations is simply this. Since the *scalar* fields Θ^{p} ($p=1,2,3$) *are not expressible in terms of* $\{\delta A\}$ unless the background shear takes a simple form $[d_{\alpha\beta}:=(\sigma_{\alpha\beta})_{\epsilon=0}=0]$,

$$\Theta^{p}=2l^{p}_{\alpha}l^{p}_{\beta}\left[\frac{1}{3n_0}(\delta N)\gamma^{\alpha\beta}+\gamma^{\alpha\mu}\gamma^{\beta\nu}(\delta\sigma_{\mu\nu})\right], \tag{2.23}$$

the theory based on $\mathbf{E}$ or $\{\delta A\}=\mathbf{E}\cup\{\delta A\}$ alone seems to be *somewhat less complete* than that based on χ, $\mathbf{E}$, and Θ^{p} ($p=1,2,3$):

$$\varphi_4([\mathbf{W}]):=\{\chi,\mathbf{E},\Theta^{p}\}. \tag{2.24}$$

Focus now, for specifity, on the magnetic part $H_{\alpha\beta}$ of the Weyl tensor $C_{\alpha\beta\mu\nu}$. Restricting attention to the Bianchi type I background model, this part of $C_{\alpha\beta\mu\nu}$ vanishes in $(X,q_{\alpha\beta})$ since $(\omega_{\alpha\beta})_{\epsilon=0}=0$ and $(\mathcal{E}_{\alpha\beta\mu})_{\epsilon=0}=0$. By writing $H_{\alpha\beta}$ in the form [see, e.g., Eq. (4.19) in Ref. 33]

$$H_{\alpha\beta}=2a_{(\alpha}\omega_{\beta)}+u^{\nu}\eta^{\lambda\tau}{}_{\nu(\alpha}\mathcal{E}_{\beta)\lambda\tau}+h_{\alpha}{}^{\mu}h_{\beta}{}^{\sigma}u^{\nu}\eta^{\lambda\tau}{}_{\nu(\mu}\omega_{\sigma)\lambda;\tau}, \tag{2.25}$$

where $\eta_{\alpha\beta\mu\nu}$ is the space–time permutation tensor and $\omega^{\alpha}=g^{\alpha\beta}\omega_{\beta}$ is the vorticity vector ($\omega_{\alpha\beta}=\eta_{\alpha\beta\mu\nu}\omega^{\mu}u^{\nu}$), we then see that, *to linear order*, $H_{\alpha\beta}$ is *completely* determined by giving $\delta\omega_{\alpha\beta}$ and $\delta\mathcal{E}_{\alpha\beta\mu}$:

$$\delta H_{\alpha\beta}=\epsilon^{\lambda\tau}{}_{(\alpha}[\delta\mathcal{E}_{\beta)\lambda\tau}+(\delta\omega_{\beta)\lambda})_{|\tau}]. \tag{2.26}$$

Here $\epsilon^{\lambda\tau}{}_{\alpha}$ stands for the background value of $u^{\nu}\eta^{\lambda\tau}{}_{\nu\alpha}$.

To sum up, the notion of a gauge-invariant variable introduced by Banach[1] and Banach and Piekarski[8,9] *generalizes* the notion of a gauge-invariant variable arising from the approach of Stewart and Walker.[2] For the case of nonaxisymmetric cosmologies of Bianchi types I and V ($H_1\neq H_2, H_1\neq H_3, H_2\neq H_3$), it is this generalization which enables us to define satisfactorily the concept of a ''coordinate system'' on $\mathcal{W}/\mathcal{W}_L$ and to replace $\{\delta A\}$ by **D**. Our reasons for presenting the detailed construction of **D** are twofold. First, [**W**] is uniquely determined from **D** and conversely. Second, if $A_0:=(A)_{\epsilon=0}$ satisfies one of the three conditions in the Stewart–Walker lemma, then a knowledge of **D** consequently permits us to calculate δA. The natural question arises as to the possibility of recasting the mathematical formalism in such a way that **D** is obtainable from $\{\delta A\}$. However, we have seen that such a reformulation *is not possible*, i.e., the acceptance of $\{\delta A\}$ as fundamental gauge-invariant quantities in place of **D** involves the sacrifice of some information originally contained in our *complete* set **D**. Thus, despite the desirability of having only $\{\delta A\}$ as gauge-invariant variables, this sacrifice of the informational content of the formalism would be unacceptable, as far as the basic structure of the theory and the equivalence classes of perturbations are concerned.

B. Almost-Robertson–Walker universe models

In exact Robertson–Walker space–times ($k=0,\pm 1$), the shear tensor $d_{\alpha\beta}:=(\sigma_{\alpha\beta})_{\epsilon=0}$ vanishes identically, so that $\delta\sigma_{\alpha\beta}$ is a gauge-invariant quantity. If $d_{\alpha\beta}=0$, the formula (2.23) may be used to express Θ^{p} ($p=1,2,3$) in terms of δN and $\delta\sigma_{\alpha\beta}$, and from Eqs. (4.8d), (4.8g), (4.8h), and (4.18h) of Ref. 1 we obtain directly

$$\Omega^{\alpha\beta}=\frac{2}{n_0}\left[\frac{1}{3}(\delta N)^{\cdot}+2H(\delta N)\right]\gamma^{\alpha\beta}+2[(\delta\sigma_{\mu\nu})^{\cdot}+3H(\delta\sigma_{\mu\nu})]\gamma^{\mu\alpha}\gamma^{\nu\beta}, \tag{2.27a}$$

$$\Theta^{pq}_{q}=2l^{\nu}_{q}[-(l^{q}_{\lambda}l^{p}_{\mu})_{|\nu}(\delta\sigma_{\epsilon\tau})+l^{q}_{\lambda}l^{p}_{\mu}(\delta\sigma_{\epsilon\tau})_{|\nu}]\gamma^{\epsilon\mu}\gamma^{\tau\lambda}, \tag{2.27b}$$

$$\Omega^{pq}_{r}=2l^{p}_{\lambda}l^{q}_{\mu}\gamma^{\mu\epsilon}\gamma^{\lambda\tau}[l^{\nu}_{r}(\delta\sigma_{\epsilon\tau})]_{|\nu}-4l^{\nu}_{r|\lambda}l^{p}_{(\mu}l^{q}_{\nu)}\left[\frac{1}{3n_0}(\delta N)\gamma^{\mu\lambda}+\gamma^{\mu\epsilon}\gamma^{\lambda\tau}(\delta\sigma_{\epsilon\tau})\right], \tag{2.27c}$$

$$\Omega^{\alpha\beta}_{\mu}=2\left[\frac{1}{3n_0}(\delta N)\gamma^{\alpha\beta}+\gamma^{\alpha\lambda}\gamma^{\beta\tau}(\delta\sigma_{\lambda\tau})\right]_{|\mu}. \tag{2.27d}$$

These results are the statement that a knowledge of gauge-invariant variables δN and $\delta\sigma_{\alpha\beta}$ determines $\Omega^{\alpha\beta}$, Θ^{p}, Θ^{pq}_{q}, Ω^{pq}_{r}, and $\Omega^{\alpha\beta}_{\mu}$. Thus, for almost-Robertson–Walker universe models, we need not introduce the gauge-invariant objects $\Omega^{\alpha\beta}$, Θ^{p}, Θ^{pq}_{q}, Ω^{pq}_{r}, and $\Omega^{\alpha\beta}_{\mu}$ to represent [**W**], since the following set, much simpler than that appropriate for the nonaxisymmetric case [see Eqs. (2.16) and (2.18)], is found to give such a representation:[4,5]

$$\varphi_{\mathrm{RW}}([\mathbf{W}]):=\{\chi,\delta N,\delta s,\delta\mathcal{B},\delta\mathcal{A},\delta X^{\alpha},\delta\sigma_{\alpha\beta},\delta\mathcal{A}^{\alpha\beta}\}. \tag{2.28}$$

To the extent that $\{\mathcal{F}_{\epsilon}(\cdot);\epsilon\in I\}$ is an arbitrary curve in the function space $\{\mathcal{F}(\cdot)\}$ passing through the background solution $\mathcal{F}_0(\cdot)$ (i.e., that $\chi=0$ and $\delta N\neq 0$), this set consists of 17 ''geometrically'' independent, not identically vanishing gauge-invariant components.

As demonstrated in Sec. 4.2 of Ref. 5, any gauge-invariant quantity is obtainable linearly from $\varphi_{\mathrm{RW}}([\mathbf{W}])$ through purely algebraic and differential operations. To illustrate this property of $\varphi_{\mathrm{RW}}([\mathbf{W}])$, let $E_{\alpha\beta}$ be the electric part of the Weyl tensor. Then $(E_{\alpha\beta})_{\epsilon=0}=0$ and the linear perturbation $\delta E_{\alpha\beta}$ is gauge invariant. Appeal to the identity

$$E_{\alpha\beta}=\tfrac{1}{3}\theta\sigma_{\alpha\beta}-\sigma_{\alpha\mu}\sigma^{\mu}{}_{\beta}+\tfrac{1}{3}h_{\alpha\beta}(\sigma^{\mu\nu}\sigma_{\mu\nu})-\tfrac{1}{2}[R_{\mu\nu}h^{\mu}{}_{\alpha}h^{\nu}{}_{\beta}-\tfrac{1}{3}h_{\alpha\beta}(R_{\mu\nu}h^{\mu\nu})]+n^{2/3}h_{\alpha\mu}h_{\beta\nu}\mathcal{A}^{\mu\nu} \tag{2.29}$$

shows that

$$\delta E_{\alpha\beta}=H(\delta\sigma_{\alpha\beta})+(n_0)^{2/3}\gamma_{\alpha\mu}\gamma_{\beta\nu}(\delta\mathcal{A}^{\mu\nu})-\tfrac{1}{2}\,\delta[R_{\mu\nu}h^{\mu}{}_{\alpha}h^{\nu}{}_{\beta}-\tfrac{1}{3}h_{\alpha\beta}(R_{\mu\nu}h^{\mu\nu})], \tag{2.30}$$

where

$$\begin{aligned}\delta\left[R_{\mu\nu}h^{\mu}{}_{\alpha}h^{\nu}{}_{\beta}-\frac{1}{3}h_{\alpha\beta}(R_{\mu\nu}h^{\mu\nu})\right]=&(n_0)^{2/3}[\gamma_{\alpha\mu}\gamma_{\beta\nu}(\delta\mathcal{A}^{\mu\nu})]+(\delta\sigma_{\alpha\beta})^{\cdot}+3H(\delta\sigma_{\alpha\beta})\\&+\frac{1}{3Hn_0}\gamma_{\mu(\alpha}[(\delta X^{\mu})^{\cdot}]_{|\beta)}-\frac{1}{9Hn_0}\gamma_{\alpha\beta}[(\delta X^{\mu})^{\cdot}]_{|\mu}\\&+\frac{1}{3n_0}\left(4-\frac{\dot H}{H^2}\right)\gamma_{\mu(\alpha}(\delta X^{\mu})_{|\beta)}-\frac{1}{9n_0}\left(4-\frac{\dot H}{H^2}\right)\gamma_{\alpha\beta}(\delta X^{\mu})_{|\mu}\\&-\frac{1}{12H^2}(n_0)^{2/3}\left\{[(\delta\mathcal{B})_{|\alpha}]_{|\beta}-\frac{1}{3}\gamma_{\alpha\beta}\gamma^{\mu\nu}[(\delta\mathcal{B})_{|\mu}]_{|\nu}\right\}\\&-\frac{1}{3Hn_0}\left\{[(\delta N)_{|\alpha}]_{|\beta}-\frac{1}{3}\gamma_{\alpha\beta}\gamma^{\mu\nu}[(\delta N)_{|\mu}]_{|\nu}\right\}\\&+\frac{1}{6H^2}n_0T_0\left\{[(\delta s)_{|\alpha}]_{|\beta}-\frac{1}{3}\gamma_{\alpha\beta}\gamma^{\mu\nu}[(\delta s)_{|\mu}]_{|\nu}\right\}.\end{aligned} \tag{2.31}$$

Obviously, Eqs. (2.30) and (2.31) give a relationship for $\delta E_{\alpha\beta}$ in terms of $\varphi_{\mathrm{RW}}([\mathbf{W}])$. The extra assumption which can be made here is that $\delta\mathcal{F}_0$ satisfies the condition (2.14) of Ref. 1. Under these circumstances, the left-hand side of Eq. (2.31) equals zero and $\delta E_{\alpha\beta}$ is given by

$$\delta E_{\alpha\beta}=H(\delta\sigma_{\alpha\beta})+(n_0)^{2/3}\gamma_{\alpha\mu}\gamma_{\beta\nu}(\delta\mathcal{A}^{\mu\nu}). \tag{2.32}$$

The treatment of other gauge-invariant variables follows similar lines.

Since $\varphi_{\mathrm{RW}}([\mathbf{W}])$ is a subset of $\{\delta A\}$, it should be clear from our discussion above that the only essential structure of linear perturbation theory used in the definition of almost-Robertson–Walker universe models ($d_{\alpha\beta}=0$) was Lemma 2.2 of Stewart and Walker.[2] However, in more general cases—such as infinitesimal perturbations of anisotropic cosmological models ($d_{\alpha\beta}\neq 0$)—this lemma does not provide a complete framework for describing the equivalence classes of perturbations or for constructing all gauge-invariant quantities, and the basic concepts, notions, and ideas are qualitatively different (see, e.g., Refs. 8 and 9).

III. ANALYSIS OF OTHER APPROACHES

A. Covariant methods

Within the framework of a covariant formalism, the perturbations of homogeneous and isotropic cosmological models have been studied by several authors (Ellis and Bruni,[6] Ellis *et al.*,[31] Bruni *et al.*,[29] and Dunsby *et al.*[30]). Beginning from Eq. (2.2) and the Stewart–Walker lemma, the basic idea of these authors was to introduce a set $\{A\}$ of geometrically defined exact variables A such that $\mathcal{L}_v A_0=0$ for each vector field v on X. This definition of $\{A\}$ is relatively broad and includes, for example, studies of the meaning of $\mathcal{L}_v A_0 = 0$ when $A_0 \neq 0$. However, in practice, references to $\mathcal{L}_0 A_0$ usually include the assumption that A_0 *vanishes* in a Robertson–Walker universe model. Understood in this more limited sense, the quantity A itself is a gauge-invariant perturbation in an almost-Robertson–Walker universe, and its physical significance is apparent through the covariant definition. As in the work of Bruni *et al.*,[29] we shall refer to such quantities as *covariant gauge-invariant variables*.

The purpose of Dunsby[23] was to further extend this approach to perturbations of Bianchi type I cosmological models. His conclusion that it should be possible to give a more general argument for the utility of a covariant formalism relies on a number of observations: (i) that the Stewart–Walker lemma is valid for any background space-time; (ii) that one can often consider the same gauge-invariant variables in perturbing different universe models; (iii) that covariant gauge-invariant variables can be easily identified in perturbing homogeneous anisotropic space–times; (iv) that the differential equations governing these variables provide a unified treatment for the exact and the linearized theory; and (v) that the covariant extension to Bianchi type V is very straightforward. There may also be other important observations that we have failed to notice.

How do our concepts relate to the covariant method? If A is a gauge-invariant quantity with respect to homogeneous background space-times (i.e., if A has the property that $A_0 = 0$), then from a knowledge of $\varphi_{\mathrm{RW}}([\mathbf{W}])$ or $\varphi([\mathbf{W}])$ alone, together with a specification of $\mathcal{F}_0$, one can compute A approximately; the approximation takes place by neglecting higher-order terms in the exact expression for A $[A \cong \epsilon(\delta A)]$. As regards the details, the considerations of Secs. II A and II B were partly devoted to a systematic first-order expansion of the covariant gauge-invariant variables A $(A_0 = 0)$.

We see two main disadvantages in following this covariant approach. First, even in the case of Robertson–Walker background models, the covariant gauge-invariant variables do not provide a complete framework for determining the equivalence classes of perturbations and for identifying all gauge-invariant quantities. Specifically, by means of the definition (2.28) of $\varphi_{\mathrm{RW}}([\mathbf{W}])$, we obtain $s_0 \neq 0$ and $(n_0)^{2/3}\mathcal{A}_0 = (n_0)^{2/3}\mathcal{B}_0 = 6k/R^2$ $(k = 0, \pm 1)$. Second, the construction of Refs. 23 and 29–31 has the feature that it appears to depend on our choice of $(X, q_{\alpha\beta})$, and—as already remarked—in the absence of three-dimensional homogeneous hypersurfaces, simply no natural, ''preferred'' choice of covariant gauge-invariant variables is available. This poses a potential serious difficulty for the formulation of linear perturbation theory in general. Fortunately, given the alternative construction of Banach and Piekarski,[8,9] this difficulty can be resolved by modifying the definition of a gauge-invariant variable and by formulating the theory via the introduction of **D**.

B. Harmonic decompositions for an almost-Bianchi type I universe model

In a spatially flat anisotropic universe, a completely general perturbation of the gravitational field can be written as a linear combination of perturbations associated with individual spatial harmonics (for review see Refs. 10–15). The metric perturbations and the matter perturbations are classified into three types, i.e., scalar, vector, and tensor according to the properties of infinitesimal gauge transformations. For example, a scalar representation of the perturbation in the contravariant metric tensor is given by[1]

$$Q = Q_0 \mathcal{H}, \quad Q^\alpha = Q_L \mathcal{H}^\alpha, \quad D = D_L \mathcal{H}, \tag{3.1a}$$

$$F^{\alpha\beta} = \frac{1}{3} F_T \gamma^{\alpha\beta} \mathcal{H} - \frac{1}{n} F_T \gamma^{\mu(\alpha} \mathcal{H}^{\beta)}{}_{|\mu}, \tag{3.1b}$$

where Q_0, Q_L, D_L, and F_T are the expansion coefficients (amplitudes) whose covariant spatial gradients vanish. Explaining Eqs. (3.1) still further, n is a wave number (not to be confused with the number density, also denoted by n) which sets the spatial scale of the perturbation ($\dot{n} \neq 0, n_{|\alpha}=0$), $\mathcal{H}$ is a scalar harmonic independent of time ($\dot{\mathcal{H}}=0$), and $\mathcal{H}^\alpha$ is a spatial vector related to $\mathcal{H}$ by

$$\mathcal{H}^\alpha := -\frac{1}{n}\gamma^{\alpha\beta}\mathcal{H}_{|\beta}. \tag{3.2}$$

We can take the scalar harmonics as being eigenfunctions of the covariantly defined Laplace–Beltrami operator:[34]

$$\gamma^{\alpha\beta}[(\mathcal{H}_{|\alpha})_{|\beta}] = -n^2\mathcal{H}. \tag{3.3}$$

For zero background curvature ($k=0$), $\mathcal{H}$ is the usual plane wave.[12] Another remark is also in order. Since we study only the linear perturbations, there is no coupling between different wave numbers. Consequently, we drop the eigenvalue index n from the $\mathcal{H}$'s and omit the symbol Σ_n that could actually be a summation over a discrete set or an integral over a continuously varying index.[29]

The variations of expansion coefficients in Eqs. (3.1) under the gauge transformations $\mathbf{W} \to \mathbf{W}' := \mathbf{W} + L_v\mathcal{F}_0$ are obtained if we decompose the vector field v and the infinitesimal perturbation $\mathbf{W}'$ harmonically. Writing $\vartheta := -w_\alpha v^\alpha$ in the form $\vartheta = \vartheta_0\mathcal{H}$ ($\vartheta_{0|\alpha}=0$, $\dot{\vartheta}_0 \neq 0$) and denoting by $\vartheta_L\mathcal{H}^\alpha$ the scalar part of $\vartheta^\alpha := \gamma^\alpha{}_\beta v^\beta$ ($\vartheta_{L|\alpha}=0$, $\dot{\vartheta}_L \neq 0$), we conclude that the final result for the changes in the amplitudes of the metric perturbations is

$$Q_0' = Q_0 + 2\dot{\vartheta}_0, \tag{3.4a}$$

$$Q_L' = Q_L + n\vartheta_0 + \dot{\vartheta}_L + \frac{\dot{\Delta}}{2\Delta}\vartheta_L, \tag{3.4b}$$

$$D_L' = D_L - H\vartheta_0 - \frac{n}{3}\vartheta_L, \tag{3.4c}$$

$$F_T' = F_T - \frac{3}{2}\left(H + \frac{\dot{\Delta}}{2\Delta}\right)\vartheta_0 + n\vartheta_L, \tag{3.4d}$$

where $\Delta := n^2$.

For the scalar type, only two independent gauge-invariant quantities can be constructed from the metric tensor amplitudes alone, since there are two gauge functions and four metric tensor amplitudes. In our covariant notation, by inspection of Eqs. (3.4), these are conveniently taken as

$$\Phi_1 := \frac{1}{2}Q_0 + 2\left[\left(3H + \frac{\dot{\Delta}}{2\Delta}\right)^{-1}\left(D_L + \frac{1}{3}F_T\right)\right]^{\cdot}, \tag{3.5a}$$

$$\Phi_2 := -Q_L + \frac{1}{n}\dot{F}_T - 2n\left(3H + \frac{\dot{\Delta}}{2\Delta}\right)^{-1}\left(D_L + \frac{1}{3}F_T\right) - \frac{3}{n}\left[\left(3H + \frac{\dot{\Delta}}{2\Delta}\right)^{-1}\left(D_L + \frac{1}{3}F_T\right)\left(H + \frac{\dot{\Delta}}{2\Delta}\right)\right]^{\cdot}. \tag{3.5b}$$

The recognition that Φ_1 and Φ_2 are important in the context of an almost-Bianchi type I universe model goes back at least to Den,[12] and Eqs. (3.5a) and (3.5b) are equivalent to the central formulas (3.7) and (3.8) of his paper. We also define Φ by

$$\Phi := \frac{1}{n} H \Phi_2 . \tag{3.6}$$

This quantity is directly associated with the perturbation of the intrinsic curvature of a zero-shear hypersurface (i.e., Φ_H in Bardeen's paper[10]) in isotropic models:

$$d_{\alpha\beta} = 0 \Rightarrow \dot{\Delta} = -2H\Delta . \tag{3.7}$$

As emphasized in the Introduction (see also Ref. 1), there are a number of important *prima facie* questions that can be asked of any gauge-invariant formulation of linear perturbation theory. In the context of a harmonic decomposition of $\mathbf{W}$, the following question is particularly relevant: At what stage in the procedure is it ''necessary'' to make a harmonic decomposition corresponding to that made by Bardeen[10] and Den?[12] In particular, must this be done before defining a set $\mathbf{A}$ of gauge-invariant amplitudes, or can the objects[1] $\overline{A}(x,\mathbf{W})$ with a property $\overline{A}(x,\mathbf{W}) = \overline{A}(x,\mathbf{W} + L_v \mathcal{F}_0)$ be constructed first and then a notion of gauge-invariant amplitudes extracted afterwards? This is closely related to the question of whether the key quantities Φ_1 and Φ_2 are to be introduced before, or after, effectively describing the equivalence classes of perturbations. None of the previous approaches to this problem has yielded an argument which entirely carries conviction, although Ellis and Matravers[16] claim that the splitting of gauge-dependent quantities into scalar, vector, and tensor parts is of heuristic value only.

With the foregoing observations to guide us, we now seek an interpretation of how Den's variables Φ_1 and Φ_2 adapt to our formalism, and to this end introduce the following scalar representation of Ω, Ω^α, S, and $\vec{\gamma}\circ\vec{\Theta}$:

$$\Omega = \Omega_0 \mathcal{H}, \quad \Omega^\alpha = \Omega_1 \mathcal{H}^\alpha, \tag{3.8a}$$

$$S = S_0 \mathcal{H}, \quad \vec{\gamma}\circ\vec{\Theta} = \Theta_0 \mathcal{H}. \tag{3.8b}$$

It is important to stress that since Ω, Ω^α, S, and $\vec{\gamma}\circ\vec{\Theta}$ are gauge-invariant quantities, the amplitudes Ω_0, Ω_1, S_0, and Θ_0 are *automatically* gauge invariant. Thus the objections raised to harmonic decompositions by Ellis and Matravers,[16] that ''there is considerable effort going on at present into distinguishing if anisotropies are due to scalar, vector, or tensor modes; but this is not a fully covariant and gauge-invariant activity,'' do not apply here. Using the definitions of Ω, Ω^α, S, and $\vec{\gamma}\circ\vec{\Theta}$ [see Eq. (2.13d) and Eqs. (4.8) and (4.11a) of Ref. 1] and analyzing the gauge-dependent objects[1] Q, Q^α, D, $F^{\alpha\beta}$, V^α, and M harmonically, it is illustrative to express Φ_1 and Φ_2 in terms of Ω_0, Ω_1, S_0, and Θ_0. After a fair amount of algebraic calculation, we then obtain

$$\Phi_1 = -\Omega_0 + \left[\frac{1}{\Delta} \left(3H + \frac{\dot{\Delta}}{2\Delta} \right)^{-1} S_0 \right]^{\cdot} , \tag{3.9a}$$

$$\Phi_2 = \frac{1}{3H} \Omega_1 + \frac{1}{2n} \Theta_0 + \frac{3}{n} \left[\frac{H}{\Delta} \left(3H + \frac{\dot{\Delta}}{2\Delta} \right)^{-1} S_0 \right]^{\cdot} - \frac{1}{n} \left(3H + \frac{\dot{\Delta}}{2\Delta} \right)^{-1} S_0 . \tag{3.9b}$$

At first sight, these results seem highly mysterious, for how could one extract Φ_1 and Φ_2 from Ω_0, Ω_1, S_0, and Θ_0 in a unique way if Φ_1 and Φ_2 depend on the metric tensor amplitudes alone? The key is the general observation of Sec. II, showing that $\varphi([\mathbf{W}])$ *determines everything*.

In the case of other gauge-invariant amplitudes [see, e.g., Eqs. (3.9) and (3.10) in Ref. 12 or Eqs. (30)–(39) in Ref. 14], the procedure will be the same. First, separate $\varphi([\mathbf{W}])$ into scalar, vector, and tensor parts: this will define a complete set $\mathbf{A}_C$ of gauge-invariant amplitudes. Second, following the method outlined in Refs. 10–15, construct another set of gauge-invariant amplitudes that describes what one is interested in (e.g., energy density perturbation amplitudes, velocity perturbation amplitudes, etc.). Finally, show that this set is obtainable linearly from $\mathbf{A}_C$ through purely algebraic and differential operations.

It is clear from the above analysis that the existence of a set $\mathbf{A}$ of gauge-invariant amplitudes ($\mathbf{A}_C \subset \mathbf{A}$) is an immediate consequence of the existence of $\varphi([\mathbf{W}])$. Because of this, the issue of how to interpret decompositions like (3.1) is irrelevant to the geometric (i.e., intrinsic) definition of an almost-Bianchi type I universe. Put somewhat differently, the general theory of gauge-invariant perturbations[8,9] is a theory of *fields*, not amplitudes. Although in appropriate circumstances harmonic functions may be available and useful,[35] they play no fundamental role in either the formulation or interpretation of the theory.

IV. APPLICATION OF *D* TO QUANTUM FIELD THEORY IN CURVED SPACE–TIME

Among the issues that can be studied systematically *only* with this sort of approach, the examination of the effect of using a *semiclassical description* in which the background geometry is taken in the classical framework and the gauge-invariant perturbations are considered as *quantum variables* presents a most intriguing challenge. Clearly, there are many ways of performing this task, but a very natural way consists in applying the methods of symplectic geometry and geometric quantization.[18] For a Lagrangian formulation of covariant field theories,[17] the important object is a ''presymplectic form'' $\mathcal{F}_0 \mapsto \overline{\omega}(\mathcal{F}_0|\cdot,\cdot)$ defined on the space $\mathcal{G}$ of field configurations $\mathcal{F}_0$ on X. Such a presymplectic form can be used to construct a real-valued, bilinear functional of two ''infinitesimal perturbations'' $\delta\mathcal{F}_0 \in \mathcal{P}$ and $\delta\mathcal{F}_0' \in \mathcal{P}$ of $\mathcal{F}_0$, denoted $\overline{\omega}(\mathcal{F}_0|\delta\mathcal{F}_0,\delta\mathcal{F}_0')$. This functional satisfies the property that when $\mathcal{F}_0 \in \mathcal{G}$ is a solution to the nonlinear field equations and $\delta\mathcal{F}_0$ and $\delta\mathcal{F}_0'$ solve the linearized field equations, then $\overline{\omega}(\mathcal{F}_0|\delta\mathcal{F}_0,\delta\mathcal{F}_0')$ is gauge invariant, i.e., we have

$$\overline{\omega}(\mathcal{F}_0|\delta\mathcal{F}_0+\mathcal{L}_v\mathcal{F}_0,\delta\mathcal{F}_0'+\mathcal{L}_{v'}\mathcal{F}_0)=\overline{\omega}(\mathcal{F}_0|\delta\mathcal{F}_0,\delta\mathcal{F}_0'), \tag{4.1}$$

where v and v' are two arbitrary[36] vector fields on X. In other words, the two-form $\overline{\omega}(\cdot|\cdot,\cdot)$ fails to be a symplectic form on $\mathcal{G}_S \subset \mathcal{G}$, the space of solutions to the nonlinear field equations, because it is *degenerate*; equivalently, for each $\mathcal{F}_0 \in \mathcal{G}_S$, the set $\mathcal{P}_S \subset \mathcal{P}$ consisting of classical solutions to Eq. (2.14) of Ref. 1 is unsuitable to serve as phase space of linear perturbation theory because it is ''too large.''

However, with the help of a complete set $\mathbf{D}$ of basic gauge-invariant variables, we can try to prove that $\overline{\omega}(\mathcal{F}_0|\delta\mathcal{F}_0,\delta\mathcal{F}_0')$ depends only on[1] $\mathbf{D} := \varphi([J(\delta\mathcal{F}_0)])$ and $\mathbf{D}' := \varphi([J(\delta\mathcal{F}_0')])$, i.e., that there exists a bilinear functional $\omega(\mathcal{F}_0|\mathbf{D},\mathbf{D}')$ of $\mathbf{D} \in \mathcal{D}_S \subset \mathcal{D}$ and $\mathbf{D}' \in \mathcal{D}_S \subset \mathcal{D}$ related to $\overline{\omega}(\mathcal{F}_0|\delta\mathcal{F}_0,\delta\mathcal{F}_0')$ by

$$\omega(\mathcal{F}_0|\mathbf{D},\mathbf{D}')=\overline{\omega}(\mathcal{F}_0|\delta\mathcal{F}_0,\delta\mathcal{F}_0'). \tag{4.2}$$

If this reduction process gives rise to a *symplectic structure* $\omega(\mathcal{F}_0|\cdot,\cdot): \mathcal{D}_S \times \mathcal{D}_S \to \mathbb{R}$ via $(\mathbf{D},\mathbf{D}') \mapsto \omega(\mathcal{F}_0|\mathbf{D},\mathbf{D}')$, it will be possible to find a quantum theory in which the functions $\omega(\mathcal{F}_0|\mathbf{D},\cdot)$ on the ''classical phase space''

$$\mathcal{D}_S := \{\varphi([J(\delta\mathcal{F}_0)]); \quad \delta\mathcal{F}_0 \in \mathcal{P}_S\} \tag{4.3}$$

are represented (irreducibly) by operators $\hat{\omega}(\mathcal{F}_0|\mathbf{D},\cdot)$ satisfying the following commutation relations (see Ref. 19, p. 37):

$$[\hat{\omega}(\mathcal{F}_0|\mathbf{D},\cdot),\hat{\omega}(\mathcal{F}_0|\mathbf{D}',\cdot)]=-i\,\omega(\mathcal{F}_0|\mathbf{D},\mathbf{D}')\hat{I}, \tag{4.4}$$

where $\hat{I}$ denotes the identity operator and where we choose units so that $\hbar = 1$.

The above discussion has laid out the basic mathematical framework of the geometric formulation of quantum field theory on a background space–time. In attempting to find concrete examples of ω, our idea is to begin with the usual Hilbert Lagrangian density $L_H := \sqrt{-g}(R-2\Lambda)$

and the background metrics $q_{\alpha\beta}$ of constant curvature (de Sitter and anti-de Sitter space–times). However, since the construction of ω for these cases is not immediate, it will be presented in a separate paper.

V. FINAL REMARKS

The notion of a complete set of basic gauge-invariant variables has a number of independent connotations. One such connotation is that of being a representative of $[\mathbf{W}]$, the equivalence class of perturbations. In Sec. IV B of Ref. 1, we denoted this representative of $[\mathbf{W}]$ by $\varphi([\mathbf{W}])$ [see Eq. (4.15)]. Another connotation of the term ''complete set'' is one where the appropriate local algebropartial differential operations on $\varphi([\mathbf{W}])$ enable us to obtain all gauge-invariant quantities. There is yet a third connotation of this term arising from consideration of the dynamic equations governing linearized perturbations. As a matter of fact, if $\mathbf{W}$ satisfies the condition (2.19) of Ref. 1, a deterministic system of propagation equations can be derived that involves only $\varphi([\mathbf{W}])$. Conversely, if $\mathbf{D}$ is a classical solution to these propagation equations, one will be able to construct $\mathbf{W}$ which satisfies the condition (2.19) of Ref. 1 and is such that $\mathbf{D}=\varphi([\mathbf{W}])$.

Mathematically, this approach to the gauge problem is a nontrivial example of the general scheme that we have described in our two previous papers,[8,9] and the new concepts developed were also applied to the *explicit* definition of a complete set $\mathbf{D}$ of basic gauge-invariant variables for the case of an almost-Robertson–Walker universe model.[4,5] Details of the description of a gas of massive collisionless particles are given in Ref. 4, where we study the gauge problem in a broader context, i.e., for different general-relativistic models such as the Einstein–Liouville system. We can also obtain (see Sec. 5 in Ref. 9) an analytical form of $\mathbf{D}$ for the infinitesimal perturbation of the metric tensor itself (pure gravity) defined on a fixed background de Sitter space–time and obeying the linearized empty-space Einstein equations with non-negative cosmological constant Λ; the case $\Lambda=0$ corresponds to linear perturbation theory in Minkowski space–time.

On these grounds, it was possible to show that when the Stewart–Walker lemma[2] does not provide a completely satisfactory algorithm to describe $[\mathbf{W}]$ in terms of $\{\delta A\}$, this difficulty can be cured by working instead with $\mathbf{D}$. The construction of Ref. 1 gives rise to a significant enlargement of the class of gauge-invariant quantities admitted by the theory. Because of this, our method not only *generalizes* the covariant formalism of Ellis and Bruni,[6] but also *explains* in a fully covariant and gauge-invariant manner what Bardeen's major paper[10] is about. Moreover, the existence of $\mathbf{D}$ fits in well with the Hájíček–Isham view[21] of quantum field theory that *only* gauge-invariant objects should be quantized. Finally, it appears that our main ideas are broadly modifiable. For example, we can introduce the notion of an ''infinitesimal gauge-invariant variable'' for all Lagrangian field theories with local symmetries. Roughly speaking,[17] a local symmetry is a field variation on space–time about the field configuration $\mathcal{F}$—such as the gauge transformations of Yang–Mills theory or the diffeomorphisms of general relativity—that keeps the action $S[\mathcal{F}]$ invariant [see Eq. (2.1) in Ref. 17] and that is ''local'' in a suitable sense. This definition is certainly required for the deepest understanding of the gauge problem, and would be expected to be capable of yielding a natural generalization of the notion of a complete set $\mathbf{D}$ previously obtained ''only'' for the case of diffeomorphism-invariant, covariant field theories.[8,9]

To sum, the importance of $\mathbf{D}$ cannot be overemphasized. The information contained in a complete set is all-inclusive—it is equivalent to specifying all equivalence classes of perturbations, to constructing all gauge-invariant variables, and to obtaining all imaginable types of presentations of linear perturbation theory. If the set of basic gauge-invariant variables is known, there remains not a single perturbational attribute that is not completely and precisely determined.

ACKNOWLEDGMENTS

Gödel-type space–times in induced matter gravity theory

Centro Brasileiro de Pesquisas Físicas, Departamento de Relatividade e Partículas, Rua Dr. Xavier Sigaud 150, 22290-180 Rio de Janeiro—RJ, Brazil

(Received 2 March 1999; accepted for publication 26 April 1999)

Five-dimensional (5D) generalized Gödel-type manifolds are examined in the light of the equivalence problem techniques, as formulated by Cartan. The necessary and sufficient conditions for local homogeneity of these 5D manifolds are derived. The local equivalence of these homogeneous Riemannian manifolds is studied. It is found that they are characterized by three essential parameters k, m^2, and ω: identical triads (k, m^2, ω) correspond to locally equivalent 5D manifolds. An irreducible set of isometrically nonequivalent 5D locally homogeneous Riemannian generalized Gödel-type metrics are exhibited. A classification of these manifolds based on the essential parameters is presented, and the Killing vector fields as well as the corresponding Lie algebra of each class are determined. It is shown that the generalized Gödel-type 5D manifolds admit maximal group of isometry G_r with $r=7$, $r=9$, or $r=15$ depending on the essential parameters k, m^2, and ω. The breakdown of causality in all these classes of homogeneous Gödel-type manifolds are also examined. It is found that in three out of the six irreducible classes the causality can be violated. The unique generalized Gödel-type solution of the induced matter (IM) field equations is found. The question as to whether the induced matter version of general relativity is an effective therapy for these types of causal anomalies of general relativity is also discussed in connection with a recent work by Romero, Tavakol, and Zalaletdinov.

I. INTRODUCTION

The field equations of the general relativity theory, which in the usual notation are written in the form

$$G_{\alpha\beta}=\kappa T_{\alpha\beta}, \tag{1.1}$$

relate the geometry of the space–time to its source. The general relativity theory, however, does not prescribe the various forms of matter, and takes over the energy-momentum tensor $T_{\alpha\beta}$ from other branches of physics. In this sense, general relativity (GR) is not a closed theory. The separation between the gravitational field and its source has been often considered as one undesirable feature of GR.[1–3]

Recently, Wesson and co-workers[4,5] have introduced a new approach to GR in which the matter and its role in the determination of the space–time geometry are given from a purely five-dimensional geometrical point of view. In their five-dimensional (5D) version of general relativity the field equations are given by

$$\hat{G}_{AB}=0. \tag{1.2}$$

[a]Electronic mail: lenyj@cbpf.br
[b]Electronic mail: reboucas@cbpf.br
[c]Electronic mail: teixeira@cbpf.br

Henceforth, the five-dimensional geometrical objects are denoted by overhats, and Latin letters are 5D indices and run from 0 to 4. In this new approach to GR the 5D vacuum field equations (1.2) give rise to both curvature and matter in four dimensions. Indeed, it can be shown[5] that it is always possible to rewrite the 15 field equations (1.2) as a set of equations such that 10 of which are precisely Einstein's field equations (1.1) in four dimensions with an *induced* energy-momentum

$$\kappa T_{\alpha\beta}=\frac{\phi_{\alpha;\beta}}{\phi}-\frac{\varepsilon}{2\phi^2}\left\{\frac{\phi^* g^*_{\alpha\beta}}{\phi}-g^{**}_{\alpha\beta}+g^{\gamma\delta}g^*_{\alpha\gamma}g^*_{\beta\delta}-\frac{g^{\gamma\delta}g^*_{\gamma\delta}g^*_{\alpha\beta}}{2}+\frac{g_{\alpha\beta}}{4}[g^{*\gamma\delta}g^*_{\gamma\delta}+(g^{\gamma\delta}g^*_{\gamma\delta})^2]\right\}, \tag{1.3}$$

where the Greek letters denote 4D indices and run from 0 to 3, $g_{44}\equiv\varepsilon\phi^2$ with $\varepsilon=\pm 1$, $\phi_\alpha \equiv\partial\phi/\partial x^\alpha$, a star denotes $\partial/\partial x^4$, and a semicolon denotes the usual 4D covariant derivative. Obviously, the remaining five equations (a wave equation and four conservation laws) are automatically satisfied by any solution of the 5D vacuum equations (1.2). Thus, not only the matter but also its role in the determination of the geometry of the 4D space–time can be considered to have a five-dimensional geometrical origin. This approach unifies the gravitational field with its source (not just with a particular field) within a purely 5D geometrical framework. This 5D version of general relativity is often referred to as induced matter gravity theory (IM gravity theory, for short). The IM theory has become a focus of a recent research field.[6] The basic features of the theory have been explored by Wesson and others,[7–11] whereas the implications for cosmology and astrophysics have been investigated by a number of researchers.[12–32] For a fairly updated list of references on IM gravity theory and related issues we refer the reader to Ref. 6.

In general relativity, the causal structure of 4D space–time has locally the same qualitative nature as the flat space–time of special relativity—causality holds locally. The global question, however, is left open and significant differences can occur. On large scale, the violation of causality is not excluded. Actually, it has long been known that there are solutions to the Einstein field equations which possess causal anomalies in the form of closed timelike curves. The famous solution found by Gödel[33] in 1949 might not be the first, but it certainly is the best known example of a cosmological model which makes it apparent that general relativity, as it is normally formulated, does not exclude the existence of closed timelike world lines, despite its Lorentzian character which leads to the local validity of the causality principle. Owing to its striking properties, Gödel's model has a well-recognized importance and has to a certain extent motivated the investigations on rotating cosmological Gödel-type models and on causal anomalies in the framework of general relativity[34–52] and other theories of gravitation.[53–63]

Two recent articles have been concerned with *five-dimensional* Gödel-type space–times. First in Ref. 64 the main geometrical properties of five-dimensional Riemannian manifolds endowed with a 5D counterpart of the 4D Gödel-type metric of general relativity were investigated. Among several results, an irreducible set of isometrically nonequivalent 5D homogeneous (locally) Gödel-type metrics were exhibited. Therein it was also shown that, apart from the degenerated Gödel-type metric, in all classes of homogeneous Gödel-type geometries there is breakdown of causality. As no use of any particular field equations was made in this first paper, its results hold for any 5D Gödel-type manifolds regardless of the underlying 5D Kaluza–Klein gravity theory. In the second article[65] the classes of 5D Gödel-type space–times discussed in Ref. 64 were investigated from a more physical viewpoint. Particularly, the question was examined as to whether the induced matter theory of gravitation permits the family of noncausal solutions of Gödel-type metrics studied in Ref. 64. It was shown that the IM gravity excludes this class of 5D Gödel-type noncausal geometries as solution to its field equations.

In both articles[64,65] the 5D Gödel-type family of metrics discussed is the simplest 5D class of geometries for which the section $u=$const (u is the extra coordinate) is the 4D Gödel-type metric of general relativity. Actually, the 5D Gödel-type line element of both papers does not depend on the fifth coordinate u, and therefore, as regards the IM theory, a radiationlike equation of state is an underlying assumption of both articles. However, it is well known[6] that the dependence of the

5D metric on the extra coordinate is necessary to ensure that the 5D IM theory permits the induction of matter of a very general type in four dimensions.

In this work, on the one hand, we shall examine the main geometrical properties of a class of *generalized* Gödel-type geometries in which the 5D metric depends on the fifth coordinate, generalizing therefore the results found in Ref. 64. On the other hand, we shall also investigate the question as to whether the induced matter gravity theory, as formulated by Wesson and co-workers,[4,5] admits these generalized Gödel-type metrics as solutions to its field equations, thus also extending the investigations of Ref. 65.

The outline of this article is as follows. In the next section we present a summary of some important prerequisites for Sec. III, where using the equivalence problem techniques as formulated by Cartan[66] we derive the necessary and sufficient conditions for local homogeneity of this class of 5D generalized Gödel-type manifolds. In Sec. III we also exhibit an irreducible set of isometrically nonequivalent homogeneous generalized Gödel-type metrics. In Sec. IV we discuss the integration of the Killing equations and present the Killing vector fields as well as the corresponding Lie algebra for all homogeneous generalized Gödel-type metrics. In the last section we examine whether the IM field equations permit solutions of this generalized Gödel-type class of geometries. The unique solution of this type is found therein. The question as to whether the IM version of general relativity rules out the existence of closed timelike curves of Gödel type is also discussed (Sec. V) in connection with a recent paper by Romero *et al.*[67]

II. PREREQUISITES

The arbitrariness in the choice of coordinates in the metric theories of gravitation gives rise to the problem of deciding whether or not two manifolds whose metrics g and $\tilde{g}$ are given explicitly in terms of coordinates, viz.,

$$ds^2 = g_{\mu\nu} dx^\mu dx^\nu \quad \text{and} \quad d\tilde{s}^2 = \tilde{g}_{\mu\nu} d\tilde{x}^\mu d\tilde{x}^\nu, \tag{2.1}$$

are locally isometric. This is the so-called equivalence problem (see Ref. 66 for the local equivalence of n-dimensional Riemannian manifolds, and Refs. 68 and 69 for the special case $n=4$ of general relativity).

The Cartan solution[66] to the equivalence problem for Riemannian manifolds can be summarized as follows. Two n-dimensional Lorentzian Riemannian manifolds $\mathcal{M}_n$ and $\tilde{\mathcal{M}}_n$ are locally equivalent if there exist coordinate and generalized n-dimensional Lorentz transformations such that the following *algebraic* equations relating the frame components of the curvature tensor and their covariant derivatives:

$$\begin{aligned} R^A{}_{BCD} &= \tilde{R}^A{}_{BCD}\,, \\ R^A{}_{BCD;M_1} &= \tilde{R}^A{}_{BCD;M_1}, \\ R^A{}_{BCD;M_1 M_2} &= \tilde{R}^A{}_{BCD;M_1 M_2}, \\ &\vdots \\ R^A{}_{BCD;M_1 \ldots M_{p+1}} &= \tilde{R}^A{}_{BCD;M_1 \ldots M_{p+1}} \end{aligned} \tag{2.2}$$

are compatible as *algebraic* equations in (x^μ, ξ^A). Here and in what follows we use a semicolon to denote covariant derivatives. Note that x^μ are coordinates on the manifold $\mathcal{M}_n$ while ξ^A parametrize the group of allowed frame transformations [n-dimensional generalized Lorentz group usually denoted[70] by $O(n-1,1)$]. Reciprocally, Eqs. (2.2) imply local equivalence between the n-dimensional manifolds $\mathcal{M}_n$ and $\tilde{\mathcal{M}}_n$.

In practice, a fixed frame is chosen to perform the calculations so that only coordinates appear in the components of the curvature tensor, i.e., there is no explicit dependence on the parameters ξ^A of the generalized Lorentz group.

Another important practical point to be considered, once one wishes to test the local equivalence of two Riemannian manifolds, is that before attempting to solve Eqs. (2.2) one can extract and compare partial pieces of information at each step of differentiation as, for example, the number $\{t_0, t_1, \ldots, t_p\}$ of functionally independent functions of the coordinates x^μ contained in the corresponding set

$$I_p = \{R^A{}_{BCD}, R^A{}_{BCD;M_1}, R^A{}_{BCD;M_1M_2}, \ldots, R^A{}_{BCD;M_1M_2\ldots M_p}\}, \tag{2.3}$$

and the isotropy subgroup $\{H_0, H_1, \ldots, H_p\}$ of the symmetry group G_r under which the set corresponding I_p is invariant. They must be the same for each step $q = 0,1,...,p$ if the manifolds are locally equivalent.

In practice it is also important to note that in calculating the curvature and its covariant derivatives, in a chosen frame, one can stop as soon as one reaches a step at which the pth derivatives (say) are algebraically expressible in terms of the previous ones, and the residual isotropy group (residual frame freedom) at that step is the same isotropy group of the previous step, i.e., $H_p = H_{(p-1)}$. In this case further differentiation will not yield any new piece of information. Actually, if $H_p = H_{(p-1)}$ and, in a given frame, the pth derivative is expressible in terms of its predecessors, for any $q > p$ the qth derivatives can all be expressed in terms of the 0th,1st,$\ldots$,$(p-1)$th derivatives.[66,69]

Since there are t_p essential coordinates, in five dimensions clearly $5 - t_p$ are ignorable, so the isotropy group will have dimension $s = \dim(H_p)$, and the group of isometries of the metric will have dimension r given by (see Ref. 66)

$$r = s + 5 - t_p, \tag{2.4}$$

acting on an orbit with dimension

$$d = r - s = 5 - t_p. \tag{2.5}$$

III. HOMOGENEITY AND NONEQUIVALENT METRICS

The line element of the five-dimensional *generalized* Gödel-type manifolds $\mathcal{M}_5$ we are concerned with is given by

$$d\hat{s}^2 = dt^2 + 2H(x)dt\,dy - dx^2 - G(x)dy^2 - \tilde{F}^2(\tilde{u}) - (d\tilde{z}^2 + d\tilde{u}^2), \tag{3.1}$$

where $H(x)$, $G(x)$, and $\tilde{F}(\tilde{u})$ are arbitrary real functions. By a suitable choice of coordinates the line element (3.1) can be brought into the form

$$d\hat{s}^2 = [dt + H(x)dy]^2 - dx^2 - D^2(x)dy^2 - F^2(u)dz^2 - du^2, \tag{3.2}$$

where $D^2(x) = G + H^2$ and u clearly is a new fifth coordinate.

At an arbitrary point of $\mathcal{M}_5$ one can choose the following set of linearly independent one-forms $\hat{\Theta}^A$:

$$\hat{\Theta}^0 = dt + H(x)dy, \quad \hat{\Theta}^1 = dx, \quad \hat{\Theta}^2 = D(x)dy, \quad \hat{\Theta}^3 = F(u)dz, \quad \hat{\Theta}^4 = du, \tag{3.3}$$

such that the Gödel-type line element (3.2) can be written as

$$d\hat{s}^2 = \hat{\eta}_{AB}\hat{\Theta}^A\hat{\Theta}^B = (\hat{\Theta}^0)^2 - (\hat{\Theta}^1)^2 - (\hat{\Theta}^2)^2 - (\hat{\Theta}^3)^2 - (\hat{\Theta}^4)^2. \tag{3.4}$$

Here and in what follows capital letters are 5D Lorentz frame indices and run from 0 to 4; they are raised and lowered with Lorentz matrices $\hat{\eta}^{AB}=\hat{\eta}_{AB}=\text{diag}(+1,-1,-1,-1,-1)$, respectively.

Using as input the one-forms (3.3) and the Lorentz frame (3.4), the computer algebra package CLASSI,[6,71] e.g., gives the following nonvanishing Lorentz frame components $\hat{R}_{ABCD}$ of the curvature:

$$\hat{R}_{0101}=\hat{R}_{0202}=-\frac{1}{4}\left(\frac{H'}{D}\right)^2, \tag{3.5}$$

$$\hat{R}_{0112}=\frac{1}{2}\left(\frac{H'}{D}\right)', \tag{3.6}$$

$$\hat{R}_{1212}=\frac{D''}{D}-\frac{3}{4}\left(\frac{H'}{D}\right)^2, \tag{3.7}$$

$$\hat{R}_{3434}=\frac{\ddot{F}}{F}, \tag{3.8}$$

where the prime and the dot denote, respectively, derivative with respect to x and u.

For 5D (local) homogeneity from Eq. (2.5) one must have $t_q=0$ for $q=0,1,...,p$, that is, the number of functionally independent functions of the coordinates x^μ in the set I_p must be zero. Therefore, from Eqs. (3.5–3.8) we conclude that for 5D homogeneity it is necessary that

$$\frac{H'}{D}=\text{const}\equiv-2\omega, \tag{3.9}$$

$$\frac{D''}{D}=\text{const}\equiv m^2, \tag{3.10}$$

$$\frac{\ddot{F}}{F}=\text{const}\equiv k. \tag{3.11}$$

The above necessary conditions are also sufficient for 5D local homogeneity. Indeed, under these conditions the nonvanishing frame components of the curvature reduce to

$$\hat{R}_{0101}=\hat{R}_{0202}=-\omega^2, \tag{3.12}$$

$$\hat{R}_{1212}=m^2-3\omega^2, \tag{3.13}$$

$$\hat{R}_{3434}=k. \tag{3.14}$$

Following Cartan's method for the local equivalence, we calculate the first covariant derivative of the Riemann tensor. One obtains the following non-null covariant derivatives of the curvature:

$$\hat{R}_{0112;1}=\hat{R}_{0212;2}=\omega(m^2-4\omega^2). \tag{3.15}$$

Clearly, regardless of the value of the constant k, the first covariant derivative of the curvature is algebraically expressible in terms of the Riemann tensor. Moreover, the number of functionally independent functions of the coordinates x^μ among the components of the curvature and its first covariant derivative is zero ($t_0=t_1=0$). As far as the dimension of the residual isotropy group is concerned, we distinguish three different classes of locally homogeneous 5D generalized Gödel-type curved manifolds, according to the relevant parameters m^2, ω, and k, namely,[72]

(1) $\dim(H_0)=\dim(H_1)=2$ when

(a) $\omega\neq 0$, any real k, $m^2\neq 4\omega^2$;
(b) $\omega=0$, $k\neq 0$, $m^2\neq 0$;

(2) $\dim(H_0)=\dim(H_1)=4$ when

(a) $\omega\neq 0$, any real k, $m^2=4\omega^2$;
(b) $\omega=0$, $k=0$, $m^2\neq 0$;
(c) $\omega=0$, $k\neq 0$, $m^2=0$;

(3) $\dim(H_0)=\dim(H_1)=10$ when $\omega=k=m^2=0$.

Thus, from Eqs. (2.4) and (2.5) one finds that the locally homogeneous 5D generalized Gödel-type manifolds admit a (local) G_r, with either $r=7$, $r=9$, or $r=15$ acting on an orbit of dimension $d=5$, that is, on the manifold $\mathcal{M}_5$.

The above results can be collected together in the following theorems:

Theorem 1: *The necessary and sufficient conditions for a five-dimensional generalized Gödel-type manifold to be locally homogeneous are those given by Eqs. (3.9–3.11).*

Theorem 2: *The five-dimensional homogeneous generalized Gödel-type manifolds are locally characterized by three independent real parameters, ω, k, and m^2: identical triads (ω,k,m^2) specify locally equivalent manifolds.*

Theorem 3: *The five-dimensional locally homogeneous generalized Gödel-type manifolds admit group of isometry G_r with*

(i) $r=7$ *if either of the above conditions (1a) and (1b) is fulfilled;*
(ii) $r=9$ *if one of the above set of conditions (2a), (2b), and (2c) is fulfilled;* and
(iii) $r=15$ *if the above condition (3) is satisfied.*

We shall now focus our attention on the irreducible set of isometrically nonequivalent homogeneous generalized Gödel-type metrics. These nonequivalent classes of metrics can be obtained by a similar procedure to that used by Rebouças and Tiomno,[41] namely by integrating Eqs. (3.9–3.11), and eliminating through coordinate transformations the nonessential integration constants taking into account the relevant parameters according to the above Theorem 2. For the sake of brevity, however, we shall only present the irreducible classes without going into details of calculations. It turns out that one ought to distinguish six classes of metrics according to the following.

Class I: $m^2>0$, any real $k,\omega\neq 0$. The line element for this class of homogeneous generalized Gödel-type manifolds can always be brought [in cylindrical coordinates (r,ϕ,z)] into the form

$$d\hat{s}^2=[dt+H(r)d\phi]^2-D^2(r)d\phi^2-dr^2-F^2(u)dz^2-du^2 \tag{3.16}$$

with the metric functions given by

$$H(r)=\frac{2\omega}{m^2}[1-\cosh(mr)], \tag{3.17}$$

$$D(r)=m^{-1}\sinh(mr), \tag{3.18}$$

$$F(u)=\begin{cases}\alpha^{-1}\sin(\alpha u) & \text{if } k=-\alpha^2<0,\\ u & \text{if } k=0,\\ \alpha^{-1}\sinh(\alpha u) & \text{if } k=\alpha^2>0.\end{cases} \tag{3.19}$$

According to Theorem 3, the possible isometry groups for this class are either G_7 (for $m^2\neq 4\omega^2$) or G_9 (when $m^2=4\omega^2$), irrespective of the value of k.

Class II: $m^2=0$, any real $k,\omega\neq 0$. The line element for this class can be brought into the form (3.16), with the metric function $F(u)$ given by (3.19), but now the functions $H(r)$ and $D(r)$ are given by

$$H(r)=-\omega r^2 \quad \text{and} \quad D(r)=r. \tag{3.20}$$

For this class from Theorem 3 there is a group G_7 of isometries, regardless of the value of k.

Class III: $m^2\equiv-\mu^2<0$, any real $k,\omega\neq 0$. Similarly for this class the line element reduces to (3.16) with $F(u)$ given by (3.19) and

$$H(r)=\frac{2\omega}{\mu^2}[\cos(\mu r)-1], \tag{3.21}$$

$$D(r)=\mu^{-1}\sin(\mu r). \tag{3.22}$$

From Theorem 3, regardless of the value of k for this class there is a group G_7 of isometries.

Class IV: $m^2\neq 0$, any real k, and $\omega=0$. We shall refer to this class as degenerated Gödel-type manifolds, since the cross term in the line element, related to the rotation ω in 4D Gödel model, vanishes. By a trivial coordinate transformation one can make $H=0$ with $D(r)$ given, respectively, by (3.18) or (3.22) depending on whether $m^2>0$ or $m^2\equiv-\mu^2<0$. The function $F(u)$ depends on the sign of k and is again given by (3.19). For this class according to Theorem 3 one may have either a G_7 for $k\neq 0$, or a G_9 for $k=0$.

Class V: $m^2=0$, $k\neq 0$, and $\omega=0$. By a trivial coordinate transformation one can make $H=0$, $D=r$, and $F(u)=\alpha^{-1}\sin(\alpha u)$ or $F(u)=\alpha^{-1}\sinh(\alpha u)$ depending on whether $k<0$ or $k>0$, respectively. From Theorem 3 there is a group G_9 of isometries.

Class VI: $m^2=0$, $k=0$, and $\omega=0$. From (3.12–3.14) this corresponds to the 5D flat manifold. Therefore, one can make $H=0$, $D(r)=r$, and $F(u)=u$. Theorem 3 ensures that there is a group G_{15} of isometries.

IV. KILLING VECTOR FIELDS

In this section we shall present the infinitesimal generators of isometries of the 5D homogeneous generalized Gödel-type manifolds, whose line element (3.16) can be brought into the Lorentzian form (3.4) with $\hat{\Theta}^A$ given by

$$\hat{\Theta}^0=dt+H(r)d\phi, \quad \hat{\Theta}^1=dr, \quad \hat{\Theta}^2=D(r)d\phi, \quad \hat{\Theta}^3=F(u)dz, \quad \hat{\Theta}^4=du, \tag{4.1}$$

where the functions $H(r)$, $D(r)$, and $F(u)$ depend upon the essential parameters m^2, k, and ω according to the above classes of locally homogeneous manifolds.

Denoting the coordinate components of a generic Killing vector field $\hat{K}$ by $\hat{K}^u\equiv(Q,R,S,\overline{Z},U)$, where Q, R, S, $\overline{Z}$, and U are functions of all coordinates t,r,ϕ,z,u, then the 15 Killing equations

$$\hat{K}_{(A;B)}\equiv\hat{K}_{A;B}+\hat{K}_{B;A}=0 \tag{4.2}$$

can be written in the Lorentz frame (3.4)–(4.1) as

$$T_t=0, \quad T_u-U_t=0, \tag{4.3}$$

$$R_r=0, \quad U_r+R_u=0, \tag{4.4}$$

$$U_u=0, \tag{4.5}$$

$$D(T_r-R_t)-H_rP=0, \tag{4.6}$$

$$DP_u + U_\phi - HU_t = 0, \tag{4.7}$$

$$T_\phi + H_r R - DP_t = 0, \tag{4.8}$$

$$R_\phi - HR_t - D_r P + DP_r = 0, \tag{4.9}$$

$$P_\phi - HP_t + D_r R = 0, \tag{4.10}$$

$$T_z - FZ_t = 0, \tag{4.11}$$

$$FZ_r + R_z = 0, \tag{4.12}$$

$$Z_z + UF_u = 0, \tag{4.13}$$

$$U_z + FZ_u - ZF_u = 0, \tag{4.14}$$

$$DP_z + F(Z_\phi - HZ_t) = 0, \tag{4.15}$$

where the subscripts denote partial derivatives, and where we have made

$$T \equiv HS + Q, \quad P \equiv DS, \quad \text{and} \quad Z \equiv F\overline{Z} \tag{4.16}$$

to make easier the comparison and the use of the results obtained in Ref. 42. To this end we note that with the changes $u \to z$ and $U \to Z$ the above equations (4.3–4.10) are formally identical to the Killing equations (4)–(11) of Ref. 42. However, in the equations (4.3–4.10) the functions T,R,P,U depend additionally on the fifth coordinate u. Taking into account this similitude, the integration of the Killing equations (4.3–4.15) can be obtained in two steps as follows. First, by analogy with (4)–(11) of Ref. 42 one integrates (4.3–4.10), but at this step instead of the integration constants one has integration functions of the fifth coordinate u. Second, one uses the remaining equations (4.11–4.15) to achieve explicit forms for these integration functions and to obtain the last component U of the generic Killing vector K.

We have used the above two-step procedure to integrate the Killing equations (4.3–4.15) for all classes of homogeneous generalized Gödel-type manifolds. However, for the sake of brevity, we shall only present the Killing vector fields and the corresponding Lie algebras without going into details of calculations, which can be verified by using, for example, the computer algebra program KILLNF, written in CLASSI by Åman.[71]

Class I: $m^2 > 0$, any real $k, \omega \neq 0$. In the integration of the Killing equation for this general class one is led to distinguish two different subclasses of solutions depending on whether $m^2 \neq 4\omega^2$ or $m^2 = 4\omega^2$. We shall refer to these subclasses as classes Ia and Ib, respectively.

Class Ia: $m^2 > 0$, any real $k, m^2 \neq 4\omega^2$. In the coordinate basis in which (3.16) is given, a set of linearly independent Killing vector fields K_N (N is an enumerating index) is given by

$$K_1 = \partial_t, \quad K_2 = \frac{2\omega}{m}\partial_t - m\partial_\phi, \tag{4.17}$$

$$K_3 = -\frac{H}{D}\sin\phi\,\partial_t + \cos\phi\,\partial_r - \frac{D_r}{D}\sin\phi\,\partial_\phi, \tag{4.18}$$

$$K_4 = -\frac{H}{D}\cos\phi\,\partial_t - \sin\phi\,\partial_r - \frac{D_r}{D}\cos\phi\,\partial_\phi, \tag{4.19}$$

$$K_5 = \sin z\,\partial_u + \frac{F_u}{F}\cos z\,\partial_z, \tag{4.20}$$

$$K_6 = \cos z \partial_u - \frac{F_u}{F} \sin z \partial_z , \tag{4.21}$$

$$K_7 = \partial_z . \tag{4.22}$$

The Lie algebra has the following nonvanishing commutators:

$$[K_2, K_3] = -mK_4, \quad [K_2, K_4] = mK_3, \quad [K_3, K_4] = mK_2, \tag{4.23}$$

$$[K_5, K_6] = -kK_7, \quad [K_5, K_7] = -K_6, \quad [K_6, K_7] = K_5. \tag{4.24}$$

Therefore the corresponding algebra is $\mathcal{L}_{\mathrm{Ia}} = \mathcal{L}_k \oplus \tau \oplus \mathrm{so}(2,1)$. Here and in what follows the symbols $\oplus$ and $\in\!\!\!\!+$ denote and direct and semidirect sum of subalgebras, and the subalgebra $\mathcal{L}_k$ is so(3) for $k<0$, so(2,1) for $k>0$, and $t^2 \in\!\!\!\!+ \mathrm{so}(2)$ for $k=0$. For the present class $\mathcal{L}_k$ is generated by K_5, K_6, and K_7, the symbol τ is associated to the time translation K_1, and finally the infinitesimal generators of subalgebra so(2,1) are K_2, K_3, and K_4.

Class Ib: $m^2 = 4\omega^2$, any real $k, \omega \neq 0$. For this class the Killing vector fields are

$$K_1 = \partial_t, \quad K_2 = \partial_t - m\partial_\phi, \tag{4.25}$$

$$K_3 = -\frac{H}{D} \sin \phi \partial_t + \cos \phi \partial_r - \frac{D_r}{D} \sin \phi \partial_\phi , \tag{4.26}$$

$$K_4 = -\frac{H}{D} \cos \phi \partial_t - \sin \phi \partial_r - \frac{D_r}{D} \cos \phi \partial_\phi , \tag{4.27}$$

$$K_5 = -\frac{H}{D} \cos(mt + \phi) \partial_t + \sin(mt + \phi) \partial_r + \frac{1}{D} \cos(mt + \phi) \partial_\phi , \tag{4.28}$$

$$K_6 = -\frac{H}{D} \sin(mt + \phi) \partial_t - \cos(mt + \phi) \partial_r + \frac{1}{D} \sin(mt + \phi) \partial_\phi , \tag{4.29}$$

$$K_7 = \sin z \partial_u + \frac{F_u}{F} \cos z \partial_z , \tag{4.30}$$

$$K_8 = \cos z \partial_u - \frac{F_u}{F} \sin z \partial_z , \tag{4.31}$$

$$K_9 = \partial_z , \tag{4.32}$$

whose Lie algebra is given by

$$[K_1, K_5] = -mK_6, \quad [K_1, K_6] = mK_5, \quad [K_2, K_3] = -mK_4, \tag{4.33}$$

$$[K_2, K_4] = mK_3, \quad [K_3, K_4] = mK_2, \quad [K_5, K_6] = mK_1, \tag{4.34}$$

$$[K_7, K_8] = -kK_9, \quad [K_7, K_9] = -K_8, \quad [K_8, K_9] = K_7. \tag{4.35}$$

So, the corresponding algebra for this case is $\mathcal{L}_{\mathrm{Ib}} = \mathcal{L}_k \oplus \mathrm{so}(2,1) \oplus \mathrm{so}(2,1)$. As in the previous class, the subalgebra $\mathcal{L}_k$ depends on the sign of k, and here is generated by K_7, K_8, and K_9. The two subalgebras so(2,1) are generated by the Killing vector fields K_1, K_5, K_6 and K_2, K_3, K_4.

Class II: $m^2 = 0$, any real $k, \omega \neq 0$. For this class the Killing vector fields turn out to be the following:

$$K_1=\partial_t, \quad K_2=\partial_\phi, \tag{4.36}$$

$$K_3=-\omega r \sin\phi\partial_t-\cos\phi\partial_r+\frac{1}{r}\sin\phi\partial_\phi, \tag{4.37}$$

$$K_4=-\omega r \cos\phi\partial_t+\sin\phi\partial_r+\frac{1}{r}\cos\phi\partial_\phi, \tag{4.38}$$

$$K_5=\sin z\partial_u+\frac{F_u}{F}\cos z\partial_z, \tag{4.39}$$

$$K_6=\cos z\partial_u-\frac{F_u}{F}\sin z\partial_z, \tag{4.40}$$

$$K_7=\partial_z. \tag{4.41}$$

The Lie algebra has the following nonvanishing commutators:

$$[K_2,K_3]=K_4, \quad [K_2,K_4]=-K_3, \quad [K_3,K_4]=2\omega K_1, \tag{4.42}$$

$$[K_5,K_6]=-kK_7, \quad [K_5,K_7]=-K_6, \quad [K_6,K_7]=K_5. \tag{4.43}$$

Therefore, the corresponding algebra for this case is $\mathcal{L}_{\rm II}=\mathcal{L}_k\oplus\mathcal{L}_4$. The subalgebra $\mathcal{L}_4$ is generated by K_1, K_2, K_3, and K_4. This algebra $\mathcal{L}_4$ is soluble and does not contain Abelian 3D subalgebras; it is classified as type III with $q=0$ by Petrov.[73] The subalgebra $\mathcal{L}_k$ is the same as the previous classes and is generated by K_5, K_6, and K_7.

Class III: $m^2\equiv-\mu^2<0$, any real $k,\omega\neq0$. For this class the set of linearly independent Killing vector fields we have found is given by

$$K_1=\partial_t, \quad K_2=\frac{2\omega}{\mu}\partial_t+\mu\partial_\phi, \tag{4.44}$$

$$K_3=-\frac{H}{D}\sin\phi\partial_t+\cos\phi\partial_r-\frac{D_r}{D}\sin\phi\partial_\phi, \tag{4.45}$$

$$K_4=-\frac{H}{D}\cos\phi\partial_t-\sin\phi\partial_r-\frac{D_r}{D}\cos\phi\partial_\phi, \tag{4.46}$$

$$K_5=\sin z\partial_u+\frac{F_u}{F}\cos z\partial_z, \tag{4.47}$$

$$K_6=\cos z\partial_u-\frac{F_u}{F}\sin z\partial_z, \tag{4.48}$$

$$K_7=\partial_z. \tag{4.49}$$

The Lie algebra has the following nonvanishing commutators:

$$[K_2,K_3]=\mu K_4, \quad [K_2,K_4]=-\mu K_3, \quad [K_3,K_4]=\mu K_2, \tag{4.50}$$

$$[K_5,K_6]=-kK_7, \quad [K_5,K_7]=-K_6, \quad [K_6,K_7]=K_5. \tag{4.51}$$

Thus, the corresponding algebra for this case is $\mathcal{L}_{\rm III}=\mathcal{L}_k\oplus\tau\oplus{\rm so}(3)$. Here τ is associated to the Killing vector field K_1, whereas the subalgebra so(3) corresponds to K_2, K_3, and K_4. Again $\mathcal{L}_k$ is generated by K_5, K_6, and K_7.

Class IV: $m^2\neq 0$, any real $k,\omega=0$. In the integration of the Killing equation for this general class one is led to distinguish two different subclasses according to $k\neq 0$ or $k=0$. We shall denote these subclasses as classes IVa and IVb, respectively.

Class IVa: $m^2\neq 0$, $k\neq 0$, $\omega=0$. This class corresponds to the so-called degenerated Gödel-type manifolds. One obtains for this class the following Killing vector fields:

$$K_1=\partial_t, \quad K_2=\partial_\phi, \tag{4.52}$$

$$K_3=\cos\phi\,\partial_r-\frac{D_r}{D}\sin\phi\,\partial_\phi, \tag{4.53}$$

$$K_4=-\sin\phi\,\partial_r-\frac{D_r}{D}\cos\phi\,\partial_\phi, \tag{4.54}$$

$$K_5=\sin z\,\partial_u+\frac{F_u}{F}\cos z\,\partial_z, \tag{4.55}$$

$$K_6=\cos z\,\partial_u-\frac{F_u}{F}\sin z\,\partial_z, \tag{4.56}$$

$$K_7=\partial_z, \tag{4.57}$$

where $D(r)=(1/m)\sinh mr$ for $m^2>0$, or $D(r)=(1/\mu)\sin\mu r$ for $m^2\equiv-\mu^2<0$, and the function $F(u)$ for $k\neq 0$ is given by (3.19). The Lie algebra has the following nonvanishing commutators:

$$[K_2,K_3]=K_4, \quad [K_2,K_4]=-K_3, \quad [K_3,K_4]=-m^2K_2, \tag{4.58}$$

$$[K_5,K_6]=-kK_7, \quad [K_5,K_7]=-K_6, \quad [K_6,K_7]=K_5, \tag{4.59}$$

where one should substitute $-m^2$ by μ^2 if $m^2<0$. So, the corresponding Lie algebra is $\mathcal{L}_{\rm IVa}=\mathcal{L}_k\oplus\tau\oplus\mathcal{L}_m$, where $\mathcal{L}_m$ is so(2,1) for $m^2>0$, and so(3) for $m^2=-\mu^2<0$. The subalgebra $\mathcal{L}_k$ (generated by K_5, K_6, and K_7) is so(3) for $k<0$, and so(2,1) for $k>0$. Again τ is associated to the Killing vector field K_1.

Class IVb: $m^2\neq 0$, $k=0$, $\omega=0$. We shall refer to this class as doubly degenerated Gödel-type manifolds. One obtains for this class the following Killing vector fields:

$$K_1=\partial_t, \quad K_2=\partial_\phi, \tag{4.60}$$

$$K_3=\cos\phi\,\partial_r-\frac{D_r}{D}\sin\phi\,\partial_\phi, \tag{4.61}$$

$$K_4=-\sin\phi\,\partial_r-\frac{D_r}{D}\cos\phi\,\partial_\phi, \tag{4.62}$$

$$K_5=\sin z\,\partial_u+\frac{1}{u}\cos z\,\partial_z, \tag{4.63}$$

$$K_6=\cos z\,\partial_u-\frac{1}{u}\sin z\,\partial_z, \tag{4.64}$$

$$K_7=\partial_z\,, \tag{4.65}$$

$$K_8=u\sin z\,\partial_t+t\sin z\,\partial_u+\frac{1}{u}t\cos z\,\partial_z\,, \tag{4.66}$$

$$K_9=u\cos z\,\partial_t+t\cos z\,\partial_u-\frac{1}{u}t\sin z\,\partial_z\,, \tag{4.67}$$

where again $D(r)=(1/m)\sinh mr$ for $m^2>0$, or $D(r)=(1/\mu)\sin\mu r$ for $m^2\equiv-\mu^2<0$.

The Lie algebra has the following nonvanishing commutators:

$$[K_2,K_3]=K_4,\quad [K_2,K_4]=-K_3,\quad [K_3,K_4]=-m^2K_2, \tag{4.68}$$

$$[K_5,K_7]=-K_6,\quad [K_6,K_7]=K_5,\quad [K_1,K_8]=K_5, \tag{4.69}$$

$$[K_1,K_9]=K_6,\quad [K_5,K_8]=K_1,\quad [K_6,K_9]=K_1, \tag{4.70}$$

$$[K_7,K_8]=K_9,\quad [K_7,K_9]=-K_8,\quad [K_8,K_9]=-K_7, \tag{4.71}$$

where one should substitute $-m^2$ by μ^2 if $m^2<0$. So, the corresponding Lie algebra is $\mathcal{L}_{\mathrm{IVb}}=t^3 \mathbin{⋲} \mathrm{so}(2,1)\oplus\mathcal{L}_m$, where $\mathcal{L}_m$ is generated by K_2, K_3, K_4, and is either so(2,1) or so(3) depending on whether $m^2>0$ or $m^2=-\mu^2<0$. The subalgebra $t^3 \mathbin{⋲} \mathrm{so}(2,1)$ is generated by K_1,K_5,K_6,K_7,K_8,K_9.

Class V: $m^2=0$, $k\neq0$, $\omega=0$. A set of linearly independent Killing vector field for this class is

$$K_1=\partial_t\,,\quad K_2=\partial_\phi\,, \tag{4.72}$$

$$K_3=\cos\phi\,\partial_r-\frac{1}{r}\sin\phi\,\partial_\phi\,, \tag{4.73}$$

$$K_4=-\sin\phi\,\partial_r-\frac{1}{r}\cos\phi\,\partial_\phi\,, \tag{4.74}$$

$$K_5=\sin z\,\partial_u+\frac{F_u}{F}\cos z\,\partial_z\,, \tag{4.75}$$

$$K_6=\cos z\,\partial_u-\frac{F_u}{F}\sin z\,\partial_z\,, \tag{4.76}$$

$$K_7=\partial_z\,, \tag{4.77}$$

$$K_8=r\sin\phi\,\partial_t+t\sin\phi\,\partial_r+\frac{1}{r}t\cos\phi\,\partial_\phi\,, \tag{4.78}$$

$$K_9=r\cos\phi\,\partial_t+t\cos\phi\,\partial_r-\frac{1}{r}t\sin\phi\,\partial_\phi\,, \tag{4.79}$$

where $F(u)$ depends upon the sign of k and is given by Eq. (3.19).

The Lie algebra has the following nonvanishing commutators:

$$[K_2,K_3]=K_4,\quad [K_2,K_4]=-K_3,\quad [K_5,K_6]=-kK_7, \tag{4.80}$$

$$[K_5,K_7]=-K_6,\quad [K_6,K_7]=K_5,\quad [K_1,K_8]=-K_4, \tag{4.81}$$

$$[K_1, K_9]=K_3, \quad [K_4, K_8]=-K_1, \quad [K_3, K_9]=K_1, \tag{4.82}$$

$$[K_2, K_8]=K_9, \quad [K_2, K_9]=-K_8, \quad [K_8, K_9]=-K_2. \tag{4.83}$$

So, the corresponding Lie algebra is $\mathcal{L}_{\rm V}=t^3 \oplus\!\!\!\!\!\supset \mathrm{so}(2,1)\oplus\mathcal{L}_k$, where $\mathcal{L}_k$ is generated by K_5, K_6, K_7, and is either so(2,1) or so(3) depending on whether $k>0$ or $k<0$. The subalgebra $t^3 \oplus\!\!\!\!\!\supset \mathrm{so}(2,1)$ is generated by $K_1, K_2, K_3, K_4, K_8, K_9$.

Class VI: $m^2=0$, $k=0$, $\omega=0$. From (3.12)–(3.14) this case corresponds to the 5D flat manifold whose Lie algebra is $\mathcal{L}_{\rm VI}=\mathrm{so}(4,1)$ since it clearly has the well-known 15 Killing vector fields, namely five translations, four space–time rotations, and six space rotations.

It is worth noting that none of the above Lie algebras is semi-simple, but some of their subalgebras are. Besides, most of the simple subalgebras are noncompact. The 3D subalgebra so (3) present in all classes is compact, though.

The number of Killing vector fields we have found for each of the above six classes makes explicit that the 5D locally homogeneous generalized Gödel-type manifolds admit a group of isometry G_7 when (1a): $m^2\neq 4\omega^2$, any real $k,\omega\neq 0$, or when (1b): $m^2\neq 0$, $k\neq 0$, $\omega=0$. Groups G_9 of isometry occur when (2a): $m^2=4\omega^2$, any real $k,\omega\neq 0$, or (2b): $m^2\neq 0$, $k=0$, $\omega=0$, or when (2c): $m^2=0$, $k\neq 0$, $\omega=0$. Clearly when $m^2=\omega=k=0$ there is G_{15}. These possible groups are in agreement with Theorem 3 of the previous section. Actually the integration of the Killing equations constitutes a different way of deriving that theorem. Furthermore, these equations also show that the isotropy subgroup H of G_r is such that $\dim(H)=2$ when the above conditions (1a) and (1b) are satisfied, while the conditions (2a)–(2c) lead to $\dim(H)=4$, also in agreement with the previous section. Clearly $\dim(H)=10$ when $m^2=\omega=k=0$.

V. CAUSAL ANOMALIES AND FINAL REMARKS

In this section we shall initially be concerned with the problem of causal anomalies in the generalized Gödel-type manifolds. Then we proceed by examining whether the IM gravity allows solutions of generalized Gödel-type metrics (3.16). Finally, we conclude by addressing to the general question as to whether the IM gravity theory rules out the 4D noncausal Gödel-type solutions to Einstein's equations of general relativity.

In the first three of the six classes of homogeneous generalized Gödel-type manifolds we have discussed in Sec. III, there are closed timelike curves. Indeed, the analysis made in a previous paper[64] can be easily extended to the generalized 5D Gödel-type manifolds of the present article. To this end, we write the line element (3.16) in the form

$$ds^2=dt^2+2H(r)dt\,d\phi-dr^2-G(r)d\phi^2-F^2(u)dz^2-du^2, \tag{5.1}$$

where $G(r)=D^2-H^2$ and (r,ϕ,z) are cylindrical coordinates. Now, the existence of closed timelike curves of the Gödel-type depends on the behavior of $G(r)$. Indeed, if $G(r)<0$ for a certain range of r ($r_1<r<r_2$, say), Gödel's circles[74] $u,t,z,r=$const are closed timelike curves.

Since one can always make $H=0$ for the generalized Gödel-type manifolds of classes IV, V, and VI, then $G(r)>0$ for all $r>0$. Thus there are no closed timelike Gödel's circles in these classes of manifolds.

On the other hand, following the above-outlined reasoning it is easy to show (see Ref. 64 for details) that for each of the remaining three classes (classes I–III) one can always find a critical radius r_c such that for all $r>r_c$ one has $G(r)<0$, making clear that there are closed timelike curves in these families of homogeneous generalized Gödel-type manifolds. However, in what follows we shall show that these types of noncausal *curved* manifolds are not permitted in the context of the induced matter theory.

In the Lorentz frame $\hat{\Theta}^A$ given by (4.1) the nonvanishing frame components of the Einstein tensor $\hat{G}_{AB}=\hat{R}_{AB}-\frac{1}{2}R\,\hat{\eta}_{AB}$ are

$$\hat{G}_{00} = -\frac{D''}{D} + \frac{3}{4}\left(\frac{H'}{D}\right)^2 - \frac{\ddot{F}}{F}, \tag{5.2}$$

$$\hat{G}_{02} = \frac{1}{2}\left(\frac{H'}{D}\right)', \tag{5.3}$$

$$\hat{G}_{11} = \hat{G}_{22} = \frac{1}{4}\left(\frac{H'}{D}\right)^2 + \frac{\ddot{F}}{F}, \tag{5.4}$$

$$\hat{G}_{33} = \hat{G}_{44} = \frac{D''}{D} - \frac{1}{4}\left(\frac{H'}{D}\right)^2, \tag{5.5}$$

where the prime and dot denote derivative with respect to r and u, respectively.

The field equations (1.2) require that $\hat{G}_{02}=0$, which in turn implies that

$$\frac{H'}{D} = \text{const} \equiv -2\omega. \tag{5.6}$$

Inserting (5.6) into (5.4), (5.5), and (5.2) one easily finds that the IM field equations are fulfilled if and only if the independent parameters ω, k, and m^2 [see Eqs.(3.9) and (3.10)] vanish identically, which leads to the only solution given by

$$H = a, \quad D = br + c, \quad \text{and} \quad F = \beta u + \gamma, \tag{5.7}$$

where, a, b, c, β, and γ are arbitrary real constants. However, these constants have no physical meaning, and can be taken to be $a=c=\gamma=0$ and $b=\beta=1$ by a suitable choice of coordinates. Indeed, if one performs the coordinate transformations

$$t = \overline{t} - \frac{a}{b}\overline{\phi}, \quad r = \overline{r} - \frac{c}{b}, \tag{5.8}$$

$$\phi = \frac{\overline{\phi}}{b}, \quad z = \frac{\overline{z}}{\beta}, \quad u = \overline{u} - \frac{\gamma}{\beta}, \tag{5.9}$$

the line element (5.1) becomes

$$d\hat{s}^2 = d\overline{t}^2 - d\overline{r}^2 - \overline{r}^2 d\overline{\phi}^2 - d\overline{z}^2 - d\overline{u}^2, \tag{5.10}$$

in which we obviously have $G(\overline{r}) = \overline{r}^2 > 0$ for $\overline{r} \neq 0$. The line element (5.10) corresponds to a manifestly flat 5D manifold, making it clear that the underlying manifold can be taken to be the simply connected Euclidean manifold $\mathbb{R}^5$, and therefore as $G(\overline{r}) > 0$ no closed timelike circles are permitted. Furthermore, the above results clearly show that the IM theory does not admit any *curved* 5D Gödel-type metric (3.16) as solution to its field equations (1.2).

However, in a recent work McManus[17] has shown that a one-parameter family of solutions of the field equations (1.2) previously found by Ponce de Leon[75] was in fact flat in five dimensions. And yet, the corresponding 4D induced models were shown to be a perfect fluid family of Friedmann–Robertson–Walker curved models (see Refs. 11, 13, 19 and also 76–78, where other Riemann-flat solutions are also discussed).

Therefore a question which naturally arises here is whether the above 5D flat metric, which is the only solution to the IM field equations, can similarly give rise to any 4D *curved* space–time. However, from (5.10) one obviously has that the corresponding 4D space–time is nothing but the Minkowski flat space (this result can also be derived by using a computer algebra package as, e.g., CLASSI[71,69] to calculate the 4D curvature tensor for $m^2=\omega=0$). In brief, the only solution of the

IM field equations (1.2) of generalized Gödel-type is the 5D flat space (5.7), which gives rise only to the 4D Minkowski (flat) space–time, whose topology can be taken to be the simply connected Euclidean $\mathbb{R}^5$, in which no closed timelike curves are permitted.

Although the above results can be looked upon as if the induced matter theory works as an effective therapy for the causal anomalies which arise when one starts from the specific generalized 5D Gödel-type family of metrics (5.1), this does not ensure that the induced matter version of general relativity is an efficient treatment for the causal anomalies (solutions with closed timelike curves) in general relativity as it has been conjectured in Ref. 65. Actually, in a recent paper (which unfortunately was not initially noticed by Rebouças and Teixeira[65]) Romero *et al.*[67] (see also Ref. 79) have shown that the induced matter 5D scheme is indeed general enough to locally generate all solutions to 4D Einstein field equations. This is ensured by a theorem due to Campbell[80] which states that any analytic *n*-dimensional Riemannian space can be locally embedded in a $(n+1)$-dimensional Ricci-flat space. In our context this amounts to saying that there must exist a five-dimensional Ricci-flat space which locally gives rise to the 4D Gödel noncausal solution of Einstein equations of general relativity. Thus, what still remains to be done regarding Gödel-type spaces is to find out this 5D Ricci-flat space which gives rise (locally) to the 4D Gödel-type space–times of general relativity.

To conclude, it is worth stressing some features of the local underlying embedding of the induced matter theory. Any Riemann-flat manifold obviously is also Ricci-flat. The reverse, however, does not necessarily hold, and one can have Ricci-flat spaces which are not Riemann-flat. For the generalized 5D Gödel-type geometries we have discussed in this paper the condition for Ricci-flatness ($\hat{R}_{AB}=0$) necessarily leads to Riemann-flat spaces. Remarkably many solutions of the field equations (1.2) are indeed Riemann-flat (see Refs. 11, 17, 19, and 75–78). From a purely mathematical 5D point of view all Riemann-flat spaces are locally equivalent (locally isometric). However, from the viewpoint of the 5D induced matter gravity all the above-referred 5D Riemann-flat solutions give rise to physically (and geometrically) distinct 4D space–times.[11,17,19,75–78] On the other hand, in the light of the equivalence problem techniques we have discussed in Sec. II, these 5D Riemann-flat examples also show that all 5D Cartan scalars (2.3) can vanish identically, with or without the vanishing of the corresponding (induced) 4D Cartan scalars.

(Received 20 January 1999; accepted for publication 4 May 1999)

In this paper a theorem is derived in order to provide a wide sufficient condition for an orthogonally transitive cylindrical space–time to be singularity free. The applicability of the theorem is tested on examples provided by the literature that are known to have regular curvature invariants. © *1999 American Institute of Physics.* [S0022-2488(99)02708-5]

I. INTRODUCTION

The issue of establishing whether a Lorentzian manifold is geodesically complete is not in principle a simple one since there is no Hopf–Rinow theorem that could settle the matter as it happens in the Riemannian case. One could think that regularity of the curvature invariants might be helpful, but there are known examples of space–times with regular invariants, such as Taub-NUT,[1] that enclose geodesics that are not complete in their affine parametrization due to a phenomenon called imprisoned incompleteness.

Taking completeness of causal geodesics (g completeness) as a definition of the absence of singularities (no observer in free fall leaves the space–time in a finite proper time), one can resort to many theorems in the literature (cf. Refs. 1 and 2, and references therein) in order to determine whether a space–time is singular. But on the contrary, theorems that provide large families of nonsingular space–times are not very usual[3,4] and in principle the proof of geodesic completeness involves cumbersome calculations.[5]

Instead of dealing with general Lorentzian manifolds, we shall approach orthogonally transitive cylindrical space–times[6] since they have provided many examples of regular manifolds (cf. Refs. 7 and 8) in inhomogeneous cosmology.[9]

Our aim will be the generalization of the theorem on diagonal orthogonally transitive cylindrical space–times in Ref. 4 to nondiagonal models and thereby comprise all known nonsingular cylindrical perfect fluid space–times in the literature.

First we shall show that the second-order system of geodesic equations can be reduced by the use of constants of motion to three first-order equations plus two quadratures. This fact will simplify the analysis of the prolongability of the geodesics and will enable us to write a sufficient condition for completeness of orthogonally transitive cylindrical space–times in a theorem.

II. GEODESIC EQUATIONS

We shall write the metric of an orthogonally transitive cylindrical space–time in a chart using isotropic coordinates t, r for the subspace orthogonal to the orbits of the isometry group and coordinates ϕ, z adapted to the commuting generators of the group of isometries. The metric shall be determined by four functions, g, f, A, ρ, of the coordinates t, r,

$$ds^2=e^{2g(t,r)}\{-dt^2+dr^2\}+\rho^2(t,r)e^{2f(t,r)}d\phi^2+e^{-2f(t,r)}\{dz+A(r,t)d\phi\}^2 \tag{1}$$

and we shall assume that these functions are C^2 in their range,

[a)]Electronic mail: lfernandez@etsin.upm.es

$$-\infty<t,z<\infty, \quad 0<r<\infty, \quad 0<\phi<2\pi. \tag{2}$$

The axis will be located where the norm of the axial Killing field vanishes,

$$0=\Delta=g(\xi,\xi)=\rho^2(t,r)e^{2f(t,r)}+e^{-2f(t,r)}A^2(r,t), \tag{3}$$

which means that both A and ρ must vanish on the axis, since f is a smooth function.

Since the choice of isotropic coordinates is not unique, we can take advantage of this freedom to have $r=0$ as the equation for the axis. In order to avoid conical singularities, the usual requirement[10] will be imposed in order to have a well-defined axis,

$$\lim_{r\to 0}\frac{g(\mathrm{grad}\,\Delta,\mathrm{grad}\,\Delta)}{4\Delta}=1. \tag{4}$$

Denoting by a dot differentiation with respect to the affine parameter, two of the four second-order geodesic equations,

$$\ddot{x}^i+\Gamma^i_{jk}\dot{x}^j\dot{x}^k=0, \tag{5}$$

can be integrated, taking into account that there are two first integrals of the geodesic motion associated with the generators of the isometries. These are the angular momentum around the axis, L, and the linear momentum along the axis, P, of a test particle of unit mass,

$$L=e^{2f(t,r)}\rho^2(t,r)\dot{\phi}+e^{-2f(t,r)}A(t,r)\{\dot{z}+A(t,r)\dot{\phi}\}, \tag{6}$$

$$P=e^{-2f(t,r)}\{\dot{z}+A(t,r)\dot{\phi}\}. \tag{7}$$

The affine parametrization is determined, up to an affinity of the real line, by the prescription

$$\delta=e^{2g(t,r)}\{\dot{t}^2-\dot{r}^2\}-\{L-PA(t,r)\}^2\rho^{-2}(t,r)e^{-2f(t,r)}-P^2e^{2f(t,r)}, \tag{8}$$

where δ is one for timelike, zero for null, and minus one for spacelike geodesics. Since we are dealing just with causal geodesics, for our purposes δ will always be positive. After writing $\dot{z},\dot{\phi}$ as functions of L and P, the second-order equations in t and r,

$$\begin{aligned}\ddot{t}&+g_t(t,r)\dot{t}^2+2g_r(t,r)\dot{t}\dot{r}+g_t(t,r)\dot{r}^2-P^2e^{2\{f(t,r)-g(t,r)\}}f_t(t,r)\\&+e^{-2\{f(t,r)+g(t,r)\}}\frac{\{L-PA(t,r)\}^2}{\rho^2(t,r)}\left\{\frac{\rho_t(t,r)}{\rho(t,r)}+f_t(t,r)+\frac{PA_t(t,r)}{L-PA(t,r)}\right\},\end{aligned} \tag{9}$$

$$\begin{aligned}\ddot{r}&+g_r(t,r)\dot{t}^2+2g_t(t,r)\dot{t}\dot{r}+g_r(t,r)\dot{r}^2+P^2e^{2\{f(t,r)-g(t,r)\}}f_r(t,r)\\&-e^{-2\{f(t,r)+g(t,r)\}}\frac{\{L-PA(t,r)\}^2}{\rho^2(t,r)}\left\{\frac{\rho_r(t,r)}{\rho(t,r)}+f_r(t,r)+\frac{PA_r(t,r)}{L-PA(t,r)}\right\},\end{aligned} \tag{10}$$

can be rearranged in a form that will be useful afterwards,

$$\{e^{2g(t,r)}\dot{t}\}^{\cdot}-e^{-2g(t,r)}F(t,r)F_t(t,r)=0, \tag{11}$$

$$\{e^{2g(t,r)}\dot{r}\}^{\cdot}+e^{-2g(t,r)}F(t,r)F_r(t,r)=0, \tag{12}$$

$$F(t,r)=e^{g(t,r)}\sqrt{\delta+P^2e^{2f(t,r)}+\{L-PA(t,r)\}^2\frac{e^{-2f(t,r)}}{\rho^2(t,r)}}, \tag{13}$$

which have the same structure as in the diagonal case.

If at least one of the constants L, P, δ is different from zero, the system is equivalent to three equations of first order for future-pointing (past-pointing) geodesics,

$$\dot{t}=\pm e^{-2g(t,r)}F(t,r)\cosh\xi(t,r), \tag{14}$$

$$\dot{r}=e^{-2g(t,r)}F(t,r)\sinh\xi(t,r), \tag{15}$$

$$\dot{\xi}(t,r)=-e^{-2g(t,r)}\{\pm F_t(t,r)\sinh\xi(t,r)+F_r(t,r)\cosh\xi(t,r)\}, \tag{16}$$

parametrizing (8) by a function $\xi(t,r)$. More explicitly, the last equation takes the form,

$$\dot{\xi}=-\frac{e^{-g}}{\sqrt{\delta+\Lambda^2\rho^{-2}e^{-2f}+P^2e^{2f}}}\left\{\cosh\xi\left(\delta g_r+\Lambda^2\frac{e^{-2f}}{\rho^2}h_r+P^2e^{2f}q_r\right)\right.$$
$$\left.\pm\sinh\xi\left(\delta g_t+\Lambda^2\frac{e^{-2f}}{\rho^2}h_t+P^2e^{2f}q_t\right)\right\}, \tag{17}$$

$$h=g-f-\ln\rho+\ln|\Lambda|,\quad \Lambda=L-PA,\quad q=g+f, \tag{18}$$

which will be useful for deriving prolongability conditions for causal geodesics. The minus (plus) sign corresponds to past-pointing (future-pointing) geodesics.

Note that the general equations are obtained from those of the diagonal case just replacing L by Λ, which can be therefore considered as a sort of ''effective angular momentum'' in the case where the Killing fields are not orthogonal.

III. PROLONGABILITY OF THE GEODESICS

In this section we shall introduce two theorems on causal geodesic completeness of orthogonally transitive cylindrical space–times. Null coordinates,

$$u=\frac{t+r}{2},\quad v=\frac{t-r}{2}, \tag{19}$$

will play an important role in the results.

Theorem 1: An orthogonally transitive cylindrical space–time endowed with a metric whose local expression in terms of C^2 metric functions f, g, A, ρ is given by (1) such that the axis located at $r=0$ has complete future causal geodesics if the following set of conditions is fulfilled:

(1) For large values of t and increasing r,

$$\text{(a)}\quad \begin{cases} g_u\geqslant 0\\ h_u\geqslant 0\\ q_u\geqslant 0,\end{cases}$$

$$\text{(b) either}\quad \begin{cases} g_r\geqslant 0 \ \text{ or } \ |g_r|\lesssim g_u\\ h_r\geqslant 0 \ \text{ or } \ |h_r|\lesssim h_u\\ q_r\geqslant 0 \ \text{ or } \ |q_r|\lesssim q_u\,.\end{cases}$$

(2) For $L\neq 0$ and large values of t and decreasing r,

$$\text{(a)}\quad \delta g_v+P^2e^{2f}q_v+\Lambda^2\frac{e^{-2f}}{\rho^2}h_v\geqslant 0,$$

(b) either $\delta g_r + P^2 e^{2f} q_r + \Lambda^2 \frac{e^{-2f}}{\rho^2} h_r \leqslant 0$ or $\delta g_r + P^2 e^{2f} q_r$

$$+ \Lambda^2 \frac{e^{-2f}}{\rho^2} h_r \lesssim \delta g_v + P^2 e^{2f} q_v + \Lambda^2 \frac{e^{-2f}}{\rho^2} h_v .$$

(3) For large values of the time coordinate t, constants a, b exist such that

$$\text{that} \quad \left.\begin{matrix} 2g(t,r) \\ g(t,r)+f(t,r)+\ln\rho-\ln|\Lambda| \\ g(t,r)-f(t,r) \end{matrix}\right\} \geqslant -\ln|t+a|+b.$$

(4) The limit $\lim_{r\to 0}(A/\rho)$ exists.

A theorem can be obtained for past-pointing geodesics just changing the sign of the time derivatives in the previous one.

Theorem 2: An orthogonally transitive cylindrical space–time endowed with a metric whose local expression in terms of C^2 metric functions f, g, A, ρ is given by (1) such that the axis is located at $r=0$ has complete past causal geodesics if the following set of conditions is fulfilled:

(1) For small values of t and increasing r,

$$(\mathrm{a}) \quad \begin{cases} g_v \leqslant 0 \\ h_v \leqslant 0 \\ q_v \leqslant 0, \end{cases}$$

$$(\mathrm{b}) \text{ either } \begin{cases} g_r \geqslant 0 \text{ or } |g_r| \lesssim -g_v \\ h_r \geqslant 0 \text{ or } |h_r| \lesssim -h_v \\ q_r \geqslant 0 \text{ or } |q_r| \lesssim -q_v . \end{cases}$$

(2) For $L \neq 0$ and small values of t and decreasing r,

$$(\mathrm{a}) \quad \delta g_u + P^2 e^{2f} q_u + \Lambda^2 \frac{e^{-2f}}{\rho^2} h_u \leqslant 0$$

(b) either $\delta g_r + P^2 e^{2f} q_r + \Lambda \frac{2e^{-2f}}{\rho^2} h_r \leqslant 0$ or $\delta g_r + P^2 e^{2f} q_r$

$$+ \Lambda^2 \frac{e^{-2f}}{\rho^2} h_r \lesssim \left| \delta g_u + P^2 e^{2f} q_u + \Lambda^2 \frac{e^{-2f}}{\rho^2} h_u \right| .$$

(3) For small values of the time coordinate t, constants a, b exist such that

$$\text{that} \quad \left.\begin{matrix} 2g(t,r) \\ g(t,r)+f(t,r)+\ln\rho-\ln|\Lambda| \\ g(t,r)-f(t,r) \end{matrix}\right\} \geqslant -\ln|t+a|+b.$$

(4) The limit $\lim_{r\to 0}(A/\rho)$ exists.

The theorems in Ref. 4 can be seen to be subcases of the ones introduced here.

IV. PROOF OF THE THEOREMS

In order to achieve prolongability of causal geodesics we just have to impose that $\dot{t}$ remains finite for finite values of the affine parameter. The radial velocity, $\dot{r}$, need not be considered since it cannot become singular if $\dot{t}$ is not singular too. The other derivatives, $\dot{z}$ and $\dot{\phi}$, are quadratures of smooth functions of t and r and therefore they only may turn singular if t or r become so. We shall focus on future-pointing geodesics. The analysis for past-pointing geodesics is entirely similar.

A way of preventing the hyperbolic functions of ξ from becoming singular is to require that ξ does not grow indefinitely. Therefore for large values of ξ, $\dot{\xi}$ must eventually become negative. Since the constants, L, P, δ may vanish independently, one is not to expect compensations between them. Hence their respective terms in (17) have to become negative for large values of positive ξ as it is stated in conditions (1a) and (1b), taking into account that $\cosh\xi = \sinh\xi + e^{-\xi}$ and that therefore the terms in the negative exponential of ξ (1b) need not be negative but just of the same order as those in (1a).

By imposing condition (4) in the theorem, we require that the geometry of the space–time in the vicinity of the axis is determined by ρ and not by A. Hence for negative decreasing ξ the axis could be singular only for geodesics with $L \neq 0$, since the terms A/ρ are finite at the axis. Geodesics with zero angular momentum just cross $r=0$ and reappear with positive ξ and polar angle $\phi+\pi$ and hence need not be taken into account. In this case we can therefore allow compensations between the nonzero L term and the other ones. Splitting $\cosh\xi$ as $e^{\xi}-\sinh\xi$, the condition for $\dot{\xi}$ to become positive for large values of t and negative ξ is stated in (2a) for the terms in $\sinh\xi$ and in (2b) for the terms in e^{ξ}, that can be at most of the same order as the former ones since they are exponentially damped.

No further conditions need be imposed on $\dot{\xi}$. But $\dot{t}$ could turn singular also for the $e^{-2g}F$ term. A way of preventing it is to impose a growth slower than linear for $\dot{t}$ due to each of the three terms (δ,Λ,P) for large values of t. This is done in condition (3).

The condition on g must be refined since we have not yet considered the geodesics that cannot be parametrized by ξ. These are those with zero F, that is, null geodesics with zero $\dot{z}$ and $\dot{\phi}$. Since $\dot{t}=|\dot{r}|$ for such geodesics, the equations of geodesic motion,

$$\ddot{t}+g_t\dot{t}^2+2g_r\dot{t}\dot{r}+g_t\dot{r}^2=0, \tag{20}$$

$$\ddot{r}+g_r\dot{t}^2+2g_t\dot{t}\dot{r}+g_r\dot{r}^2=0, \tag{21}$$

can be reduced to a single one that can be integrated,

$$\ddot{t}+2g_t\dot{t}^2+2g_r\dot{t}\dot{r}=0 \Rightarrow (e^{2g}\dot{t})^{\cdot}=K, \tag{22}$$

which, in order to have t extendible to arbitrary values of the affine parameter, can be controlled by imposing at most linear growth for $\dot{t}$ as it is done in condition (3).

V. COMPLETENESS OF SEVERAL CYLINDRICAL MODELS

Since all known diagonal cylindrical perfect fluid models (Refs. 11–14) with regular curvature invariants have already been shown to be geodesically complete,[4] we shall only be concerned about the nondiagonal ones. To our knowledge there are just two, and both can be derived from Einstein space–times using the Wainwright–Ince–Marshman generation algorithm for stiff perfect fluids.[15]

(1) Mars:[16] It is the first known nonsingular nondiagonal cylindrical cosmological model in the literature. In another context it was previously published by Letelier.[17] In isotropic coordinates the metric functions can be written as

$$g(t,r)=\tfrac{1}{2}\ln\cosh(2at)+\tfrac{1}{2}\alpha a^2r^2, \quad f(t,r)=\tfrac{1}{2}\ln\cosh(2at),$$
$$\rho(t,r)=r, \quad A(t,r)=ar^2, \tag{23}$$

where a is a constant and $\alpha>1$. If $\alpha=1$ the pressure and the density of the fluid vanish.

All functions are even in t and therefore the analysis of past-pointing geodesics is equivalent to that of future-pointing ones and shall be omitted. The derivatives g_u, q_u in condition (1a) are positive for positive t whereas h_u also needs large radial coordinate.

The derivatives g_r, q_r in condition (1b) are positive regardless of t and h_r is positive for large r.

Conditions (2a), (2b) are satisfied when r is small and t is positive since the L term is dominant for small r.

The functions in condition (3) are all positive except for the $\ln r$ term in h when r decreases. But this can be bounded by a logarithm of t and therefore the condition is fulfilled. The ratio A/ρ tends to zero for decreasing r and hence condition (4) in theorem 1 is satisfied. Hence this space–time is causally g complete.

(2) Griffiths–Bičák:[18] The previous model is comprised in this one for $c=0$ after a redefinition of constants. The metric functions can be written as

$$g(t,r)=\tfrac{1}{2}\ln\cosh(2at)+\tfrac{1}{2}a^2r^2+\tfrac{1}{2}\Omega(t,r),\quad f(t,r)=\tfrac{1}{2}\ln\cosh(2at),$$
$$\rho(t,r)=r,\quad A(t,r)=ar^2, \tag{24}$$

where Ω is a function that is obtained from a solution, σ, of the wave equation

$$\Omega_r=r(\sigma_t^2+\sigma_r^2),\quad \Omega_t=2r\sigma_t\sigma_r,$$
$$\sigma(t,r)=bt+\sqrt{2}c\sqrt{\frac{\sqrt{(\alpha^2+r^2-t^2)^2+4\alpha^2t^2}+\alpha^2+r^2-t^2}{(\alpha^2+r^2-t^2)^2+4\alpha^2t^2}}. \tag{25}$$

The analysis of the geodesics of this space–time can be dealt with easily since

$$\Omega_u=r(\sigma_t+\sigma_r)^2,\quad \Omega_v=-r(\sigma_t-\sigma_r)^2, \tag{26}$$

and therefore Ω contributes with an additional positive term to conditions (1a), (1b) in theorem 1, that were already checked for Mars space–time. On the contrary, Ω adds a negative term in conditions (2a), (2b) but it is negligible for small r.

Finally, the contribution of Ω to g grows at most as $\sqrt{t}$ for large t and is therefore negligible compared to the other terms in condition (3).
A similar reasoning is valid for theorem 2, although the metric function Ω is not even in time.

Hence these space–times are geodesically complete.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 40, NUMBER 8 AUGUST 1999

Canonical angular supermomentum tensors in general relativity

Janusz Garecki[a)]
Institute of Physics, University of Szczecin, Wielkopolska 15, 70-451 Szczecin, Poland

(Received 9 April 1998; accepted for publication 9 December 1998)

We introduce *the canonical supermomentum tensors* ${}_mS^{ikl}(P;v^t)$ and ${}_gS^{ikl}(P;v^t)$ for matter and gravitation, respectively. These tensors give kinds of the *quasilocal quantities* which have recently been considered in the framework of general relativity though usually constructed in some special cases and for the mass only. Our method to construct the quasilocal quantities (i.e., superenergy and supermomentum tensors) is very general and does not require introducing any supplementary elements into general relativity. It merely *extracts covariant data* from the suitable canonical objects which exist in the framework of the standard general relativity. Having given a constructive definition of the canonical supermomentum tensors for gravitation and matter, we apply the canonical gravitational supermomentum tensor ${}_gS^{ikl}(P;v^t)$ for the local analysis of the *plane and plane-fronted* gravitational waves. Next, we apply the canonical supermomentum tensors ${}_gS^{ikl}(P;v^t)$ and ${}_mS^{ikl}(P;v^t)$, gravitation and matter, to local and global analysis of the Friedman, Schwarzschild, and Kerr space–times. We show that the canonical angular supermomentum tensors and integral angular supermomenta *have better geometric and physical properties* than the canonical objects which describe *densities* of the angular momenta and integral quantities determined by these densities. © *1999 American Institute of Physics.* [S0022-2488(99)02907-2]

I. INTRODUCTION

It is well known that in the framework of the *standard*[1] general relativity (**GR**) the gravitational field has *nontensorial strength* $\Gamma^i_{kl}=\{{}^{\,i}_{kl}\}$ as well as it has *no energy-momentum tensor*. One can only attribute to this field the so-called *gravitational energy-momentum pseudotensors*. The best of the possible gravitational energy-momentum pseudotensors seems to be the *canonical gravitational energy-momentum pseudotensor* ${}_Et_i^{\ k}$ proposed by Einstein.[2,3]

Some years ago[4,5] we introduced the *canonical gravitational superenergy tensor* into **GR** to avoid difficulties connected with a lack of any gravitational energy-momentum tensor in the theory. This tensor was generalized to matter fields, too.[4,5]

The superenergy tensors of gravitation and matter give a kind of so-called ''quasilocal quantities'' (see, e.g., Refs. 6–10) usually constructed in some particular cases and for mass (or energy) only. However, these ''quasilocal quantities'' usually demand introduction of some supplementary structures, apart from the metric, into **GR**.

Our method of construction of the ''quasilocal quantities''—the superenergy (and supermomentum) tensors—is very general and does not require introducing of any supplementary elements into **GR**. It is a generalization of an early idea by Pirani[11] and it only *extracts covariant data* from the suitable canonical objects which exist in the framework of the standard[1] **GR**.

In Refs. 12 and 13 the gravitational, canonical superenergy tensor ${}_gS_i^{\ k}(P;v^l)$ has been used to the local analysis of the *cylindrical, plane, and plane-fronted gravitational waves* and the canonical superenergy tensors ${}_mS_a^{\ b}(P;v^l)$ and ${}_gS_a^{\ b}(P;v^l)$ of matter and gravitation were used in Refs.

a)Electronic mail: garecki@wmf.univ.szczecin.pl

4,5,14,15 for local and global superenergetic analysis of the Friedman cosmological models and the Schwarzschild space–time.

In this paper we want to generalize the idea of the canonical superenergy tensors onto *angular momentum* and introduce *the canonical angular supermomentum tensors*.

As it is known,[16] the situation with the angular momentum in **GR** is much more difficult and obscure than with the energy-momentum.[17] For example, even matter field *does not possess any angular momentum tensor density* because coordinates $\{x^i\}$ *do not form* any radius vector in some general components.

The canonical angular supermomentum tensors which we introduce in this paper are *our proposal* for the nonexistent in **GR** angular momentum tensors, matter and gravitation.

Our convention is the same as in our previous paper,[15] i.e., we use the metric signature $(+---)$ and the Latin indices run over the values 0, 1, 2, 3; ∇_i means covariant derivative and ∂_i or $_{,i}$ denote partial derivative $\partial/\partial x^i$; and $:=$ means ''by definition.'' Round brackets mean symmetrization and square brackets mean alternation, i.e., $(a|c|b)=\frac{1}{2}(acb+bca)$ and $[a|c|b]=\frac{1}{2}[acb-bca]$. Our convention for the Riemann curvature and Ricci tensors and for the Einstein equations,

$$G_{ik}:=R_{ik}-\frac{1}{2}g_{ik}R=\frac{8\pi G}{c^4}T_{ik}=:\beta T_{ik},$$

follow the standard textbooks.[3]

In Sec. II we present our constructive definition of the canonical angular supermomentum tensors. This definition uses normal coordinates[18–20] and it is a straightforward generalization of our definition of the canonical superenergy tensors given in final form in Ref. 15. We calculate the analytic form of the canonical supermomentum tensors of gravitation ${}_gS^{abc}(P;v^l)$ and matter ${}_mS^{abc}(P;v^l)$.

In Sec. III we give the most natural physical interpretation of tensors ${}_gS^{abc}(P;v^l)$ and ${}_mS^{abc}(P;v^l)$. The physical interpretation follows the line developed in Ref. 15.

In Sec. IV we present some applications of the canonical angular supermomentum tensors ${}_gS^{abc}(P;v^l)$ and ${}_mS^{abc}(P;v^l)$. At first, we apply the canonical, gravitational angular supermomentum tensor ${}_gS^{abc}(P;v^l)$ to local analysis of the plane and plane-fronted gravitational waves. Then, we apply the both canonical angular supermomentum tensors ${}_gS^{abc}(P;v^l)$ and ${}_mS^{abc}(P;v^l)$, gravitation and matter, to analysis of the Friedman and Schwarzschild space–times. Finally, we apply the gravitational angular supermomentum tensor ${}_gS^{abc}(P;v^l)$ to the analysis of the stationary Kerr space–time.

In Sec. V we give conclusions.

In Appendix A we review the Bergmann–Thomson expression for the angular momentum in **GR**. In Appendix B we present the results of our calculations concerning plane and plane-fronted gravitational waves. Appendix C is devoted to the angular supermomentum in special relativity.

II. CANONICAL ANGULAR SUPERMOMENTUM TENSORS IN GENERAL RELATIVITY

In analogy with the definition of the canonical superenergy tensors given in Ref. 15 in the normal coordinates **NCS(P)** we define the *angular supermomentum tensor*

$$S^{(a)(b)(c)}(P):=\lim_{\Omega\to P}\frac{\int_\Omega[M^{(a)(b)(c)}(y)-M^{(a)(b)(c)}(P)]\,d\Omega}{1/2M}$$

$$=(-)\lim_{\Omega\to P}\frac{\int_\Omega[M^{(a)(b)(c)}(y)-M^{(a)(b)(c)}(P)]\,d\Omega}{1/2\int_\Omega\sigma(P;y)\,d\Omega},\qquad(1)$$

where

$$M^{(a)(b)(c)}(y) := M^{ikl}(y) e_i^{(a)}(y) e_k^{(b)}(y) e_l^{(c)}(y), \tag{2}$$

and

$$M^{(a)(b)(c)}(P) := M^{ikl}(P) e_i^{(a)}(P) e_k^{(b)}(P) e_l^{(c)}(P) = M^{ikl}(P)\, \delta_i^a \delta_k^b \delta_l^c = M^{abc}(P) \tag{3}$$

are *physical or tetrad components* of the field $M^{ikl} = (-) M^{kil}$ which describes angular momentum. Here $e^i_{(a)}(y)$, $e_k^{(b)}(y)$ are the components of the orthonormal tetrad $e^i_{(a)}(P) = \delta^i_a$ and its dual $e_k^{(b)}(P) = \delta_k^b$, respectively, such that $e^i_{(a)}(P) e_k^{(b)}(P) = \delta_a^b$ and the tetrads are parallelly propagated along geodesics through **P**. In (1) Ω is a sufficiently small domain which surrounds **P** and it has the following properties:

$$\int_\Omega y^i \, d\Omega = 0, \quad \int_\Omega y^i y^k \, d\Omega = \delta^{ik} M, \tag{4}$$

where

$$M = \int_\Omega (y^0)^2 \, d\Omega = \int_\Omega (y^1)^2 \, d\Omega = \int_\Omega (y^2)^2 \, d\Omega = \int_\Omega (y^3)^2 \, d\Omega \tag{5}$$

is a common value of the moments of inertia of the domain Ω with respect to the subspaces $y^i = 0$ $(i = 0,1,2,3)$.

Of course, we can write M in a covariant form as

$$M = (-) \int_\Omega \sigma(P;y) \, d\Omega, \tag{6}$$

where

$$\sigma(P;y) \doteq \tfrac{1}{2}(y^{0^2} - y^{1^2} - y^{2^2} - y^{3^2})$$

denotes the two-point *world function* introduced by J. L. Synge.[21] We have used this fact in Eq. (1) already. The symbol $\doteq$ means that an equation is valid only in some special coordinates.

For all quantities attached to the point **P** there is *an equality between tetrad and normal components*. We use this and skip tetrad brackets for indices of any quantities attached to the point **P**; for example, we will write $S^{abc}(P)$ instead of $S^{(a)(b)(c)}(P)$ and so on.

For matter, as ${}_mM^{ikl}(y) = (-)\, {}_mM^{ikl}(y)$, we take

$${}_mM^{ikl}(y) = \sqrt{|g|}(y^i T^{kl} - y^k T^{il}), \tag{7}$$

where $T^{ik} = T^{ki}$ are the components of the symmetric energy-momentum tensor of matter (the source terms in the Einstein equations) and $\{y^i\}$ denote normal coordinates. Equation (7) gives the *total matter angular momentum density*, spinorial and orbital.[22]

It is interesting to note that the normal coordinates $\{y^i\}$ form the components of the *local radius vector* originating from **P** (a global radius vector does not exist in **GR**). So, the components of the ${}_mM^{ikl}(y)$ form a tensor density.

For the gravitational field we prefer the formula given in Ref. 22, which is closely connected with the canonical energy-momentum complex (see, e.g., Ref. 15 and Appendix A)

$${}_gM^{ikl}(y) = {}_{\mathrm{F}}U^{k[li]}(y) - {}_{\mathrm{F}}U^{i[lk]}(y) + y^i \sqrt{|g|}\, {}_{\mathrm{BT}}t^{kl} - y^k \sqrt{|g|}\, {}_{\mathrm{BT}}t^{il}, \tag{8}$$

where

$${}_{\mathrm{F}}U^{k[li]} := g^{km}\, {}_{\mathrm{F}}U_m{}^{[li]} \tag{9}$$

and

$$ {}_{\mathrm{BT}}t^{kl} := g^{ki}_{\mathrm{E}} t_i{}^{l} + \frac{g^{mk}_{,p}}{\sqrt{|g|}}\, {}_{\mathrm{F}}U_m{}^{[lp]}. \tag{10} $$

Here

$$ {}_{\mathrm{F}}U_i{}^{[kl]} = \alpha \frac{g_{ia}}{\sqrt{|g|}} [(-g)(g^{ka}g^{lb} - g^{la}g^{kb})]_{,b} \tag{11} $$

are the so-called *von Freud superpotentials* and

$$ {}_{\mathrm{E}}t_i{}^{k} = \alpha\{\delta^k_i g^{ms}(\Gamma^l_{mr}\Gamma^r_{sl} - \Gamma^r_{ms}\Gamma^l_{rl}) + g^{ms}_{,i}[\Gamma^k_{ms} - \tfrac{1}{2}(\Gamma^k_{tp}g^{tp} - \Gamma^l_{tl}g^{kt})g_{ms} - \tfrac{1}{2}(\delta^k_s\Gamma^l_{ml} + \delta^k_m\Gamma^s_{sl})]\} \tag{12} $$

are the components of the *Einstein canonical energy-momentum pseudotensor* of the gravitational field. Here $\alpha = c^4/16\pi G = 1/2\beta$.

One can interpret (8) as a sum of the *spinorial and orbital angular momentum density* of the gravitational field (see Appendix A).

Remark: The Landau–Lifschitz formula

$$ {}_gM^{ikl} = (-g)(y^i{}_{\mathrm{LL}}t^{kl} - y^k{}_{\mathrm{LL}}t^{il}), \tag{13} $$

where ${}_{\mathrm{LL}}t^{kl} = {}_{\mathrm{LL}}t^{lk}$ denote the components of the so-called ''Landau–Lifschitz gravitational energy-momentum pseudotensor''[3] *is not useful for our purposes*. It is because, when applied to (1), it gives trivial result

$$ {}_gS^{ikl}(P;v^l) = 0, \tag{14} $$

which is *not satisfactory* from the physical point of view. This is a consequence of the following: the formula (13) *does not include any spinorial angular momentum of the gravitational field*.

Substituting the following expansions up to the third order,[23]

$$ M^{ikl}(y) = y^i\hat{T}^{kl} - y^k\hat{T}^{il} + \tfrac{1}{2}(2\hat{T}^{kl}{}_{,p}y^iy^p - 2\hat{T}^{il}{}_{,p}y^ky^p) + R_3, \tag{15} $$

$$ e^{(a)}_i(y) = \hat{e}^{(a)}_i - \tfrac{1}{6}\hat{R}^p{}_{lim}\hat{e}^{(a)}_p y^l y^m + R_3, \tag{16} $$

and so on into (1), we get the following components ${}_mS^{abc}(P)$ of the *matter angular supermomentum tensor*

$$ {}_mS^{abc}(P) = 2(\delta^{ap}\hat{T}^{bc}{}_{,p} - \delta^{bp}\hat{T}^{ac}{}_{,p}) = 2(\delta^{ap}\nabla_p\hat{T}^{bc} - \delta^{bp}\nabla_p\hat{T}^{ac}), \tag{17} $$

or, in a covariant form,

$$ {}_mS^{abc}(P;v^l) = 2[(2\hat{v}^a\hat{v}^p - \hat{g}^{ap})\nabla_p\hat{T}^{bc} - (2\hat{v}^b\hat{v}^p - \hat{g}^{bp})\nabla_p\hat{T}^{ac}]. \tag{18} $$

Here v^i is the four velocity $(v^iv_i = 1)$ of an observer **O** which is at rest at the beginning **P** of the normal coordinates **NCS(P)** and $g^{ab} \doteq \eta^{ab}$ denotes the components of the local metric. A hat over a quantity means the value of the quantity at the point **P**, for example, $\hat{T}^{ab} = T^{ab}(P)$.

After substitution expansion (8) (up to the third order) and (16) into (1), we get, for gravitational field,

$$ {}_gS^{abc}(P;v^l) = \delta^{lt}{}_g\hat{M}^{abc}{}_{,lt}. \tag{19} $$

Equation (19) can be covariantly written in the following form:

$$ {}_gS^{abc}(P;v^l)=\alpha(2\hat{v}^p\hat{v}^t-\hat{g}^{pt})[\beta(\hat{g}^{ca}\hat{g}^{br}-\hat{g}^{cb}\hat{g}^{ar})\nabla_{(t}\hat{E}_{pr)}+2\hat{g}^{ar}\nabla_{(t}\hat{R}^{(c}{}_r{}^{b)}{}_{p)}-2\hat{g}^{br}\nabla_{(t}\hat{R}^{(c}{}_r{}^{a)}{}_{p)} + \tfrac{2}{3}\hat{g}^{bc}(\nabla_r\hat{R}^r{}_{(t}{}^a{}_{p)}-\beta\nabla_{(p}\hat{E}^a_{t)})-\tfrac{2}{3}\hat{g}^{ac}(\nabla_r\hat{R}^r{}_{(t}{}^b{}_{p)}-\beta\nabla_{(p}\hat{E}^b_{t)})]. \quad (20) $$

We will call tensors (18) and (20) *the canonical, angular supermomentum tensors* of matter and gravitation, respectively.

It is very interesting to note that *only spinorial part* $S^{ikl}={}_{\mathrm{F}}U^{i[kl]}-{}_{\mathrm{F}}U^{k[il]}$ of the canonical angular momentum pseudotensor ${}_gM^{ikl}(y)$ gives nonzero contribution to the tensor ${}_gS^{abc}(P;v^l)$. The *orbital part* $O^{ikl}=y^i\sqrt{|g|}_{\mathrm{BT}}t^{kl}-y^k\sqrt{|g|}_{\mathrm{BT}}t^{il}$ gives *no contribution* to the tensor ${}_gS^{abc}(P;v^l)$.

In vacuum, when $T_{ik}=0\Rightarrow E_{ik}:=T_{ik}-\frac{1}{2}g_{ik}T=0$, the canonical angular supermomentum tensor ${}_gS^{abc}(P;v^l)$ given by (20) simplifies to give

$$ {}_gS^{abc}(P;v^l)=2\alpha(2\hat{v}^p\hat{v}^t-\hat{g}^{pt})[\hat{g}^{ar}\nabla_{(t}\hat{R}^{(b}{}_r{}^{c)}{}_{p)}-\hat{g}^{br}\nabla_{(t}\hat{R}^{(a}{}_r{}^{c)}{}_{p)}]. \quad (21) $$

Remarks:

(1) It follows from the formulas (18), (20), and (21) that the canonical angular supermomentum tensors ${}_mS^{abc}(P;v^l)$ and ${}_gS^{abc}(P;v^l)$ *do not require any radius vector* to be constructed.

(2) It also follows from the formulas (7) and (8)–(12) that

$$ {}_mM^{abc}(P)={}_m\hat{M}^{abc}=0, \quad {}_gM^{abc}(P)={}_g\hat{M}^{abc}=0. $$

Despite that the above quantities vanish, we have manifestly introduced them into the definition (1) of the canonical angular supermomentum tensors to emphasize their relative character.

III. PHYSICAL INTERPRETATION OF THE CANONICAL ANGULAR SUPERMOMENTUM TENSORS

Following the line developed in Ref. 15, we give, in our opinion, the most natural physical interpretation of the canonical angular supermomentum tensors ${}_gS^{abc}(P;v^l)=(-){}_gS^{bac}(P;v^l)$ and ${}_mS^{abc}(P;v^l)=(-){}_mS^{bac}(P;v^l)$.

A. Matter canonical angular supermomentum tensor ${}_mS^{abc}(P;v^l)$

In sufficiently small surroundings of the point **P**, we consider the differences

$$ \begin{aligned} {}_mM^{(a)(b)(c)}(y)-{}_mM^{(a)(b)(c)}(P) &= {}_mM^{ikl}(y)e_i^{(a)}(y)e_k^{(b)}(y)e_l^{(c)}(y)-{}_m\hat{M}^{ikl}\hat{e}_i^{(a)}\hat{e}_k^{(b)}\hat{e}_l^{(c)} \\ &= [y^i\hat{T}^{kl}-y^k\hat{T}^{il}+(y^i\hat{T}^{kl}{}_{,p}-y^k\hat{T}^{il}{}_{,p})y^p+R_3] \\ &\quad \times(\hat{e}_i^{(a)}-\tfrac{1}{6}\hat{R}^t{}_{ris}\hat{e}_t^{(a)}y^ry^s+R_3) \\ &\quad \times(\hat{e}_k^{(b)}-\tfrac{1}{6}\hat{R}^u{}_{ekd}\hat{e}_u^{(b)}y^ey^d+R_3)(\hat{e}_l^{(c)}-\tfrac{1}{6}\hat{R}^v{}_{flg}\hat{e}_v^{(c)}y^fy^g+R_3) \\ &\quad -{}_mM^{abc}(P) \\ &= y^a\hat{T}^{bc}-y^b\hat{T}^{ac}+(y^a\hat{T}^{bc}{}_{,p}-y^b\hat{T}^{ac}{}_{,p})y^p+R_3. \end{aligned} \quad (22) $$

In every previous expansion R_3 denotes the remainder of the third order.

Integrating the differences (22) over a sufficiently small domain Ω with the same properties as the domain Ω which occurs in the formulas (1), we obtain

$$ \begin{aligned} \int_\Omega[M^{(a)(b)(c)}(y)-M^{(a)(b)(c)}(P)]\,d\Omega &\approx {}_mS^{abc}(P;v^l)\cdot\tfrac{1}{2}\int_\Omega(y^d)^2\,d\Omega \\ &= {}_mS^{abc}(P;v^l)\cdot\tfrac{1}{2}M=:{}_mS^{abc}(P;v^l;\Omega). \end{aligned} \quad (23) $$

Here ${}_mS^{abc}(P;v^l;\Omega)=(-)_mS^{abc}(P;v^l;\Omega)$ is *a tensor* whose components give *the approximate values of the relative angular momentum* inside the domain Ω.

We can easily notice that this tensor ${}_mS^{abc}(P;v^l;\Omega)$ is the product of:

(1) the tensor ${}_mS^{abc}(P;v^l)$, which depends only on the matter and gravitational fields and four-velocity of the observer **O**, and,
(2) the term $\frac{1}{2}\int_\Omega (y^d)^2\, d\Omega=:\frac{1}{2}M$, which depends on the common value M of the moments of inertia of the domain Ω only.

The supermomentum tensor of matter ${}_mS^{abc}(P;v^l)$ is exactly the first term in this product.

B. Gravitational canonical angular supermomentum tensor ${}_g\boldsymbol{S}^{abc}(\boldsymbol{P};\boldsymbol{v}^l)$

For a gravitational field, the canonical angular momentum pseudotensor ${}_gM^{nmk}$ has the form given by (8)–(12), i.e.,

$$ {}_gM^{nmk}=\sqrt{|g|}(x^n g^{mi}{}_{\mathrm{E}}t_i{}^k - x^m g^{ni}{}_{\mathrm{E}}t_i{}^k)+x^n{}_{\mathrm{F}}U_i{}^{[kl]}g^{im}{}_{,l}-x^m{}_{\mathrm{F}}U_i{}^{[kl]}g^{in}{}_{,l}+g^{im}{}_{\mathrm{F}}U_i{}^{[kn]}-g^{in}{}_{\mathrm{F}}U_i{}^{[km]}. \tag{24}$$

As for the case of matter fields, let us consider the differences

$$\begin{aligned} {}_gM^{(a)(b)(c)}(y)-{}_gM^{(a)(b)(c)}(P)&={}_gM^{nmk}(y)e_n^{(a)}(y)e_m^{(b)}(y)e_k^{(c)}(y)-{}_g\hat{M}^{nmk}\hat{e}_n^{(a)}\hat{e}_m^{(b)}\hat{e}_k^{(c)}\\ &=[({}_{\mathrm{F}}\hat{U}^{m[kn]}{}_{,r}-{}_{\mathrm{F}}\hat{U}^{n[km]}{}_{,r})y^r+\tfrac{1}{2}({}_{\mathrm{F}}\hat{U}^{m[kn]}{}_{,rs}-{}_{\mathrm{F}}\hat{U}^{n[km]}{}_{,rs})y^r y^s+R_3]\\ &\quad\times(\hat{e}_n^{(a)}-\tfrac{1}{6}\hat{R}^e{}_{ind}\hat{e}_e^{(a)}y^i y^d+R_3)(\hat{e}_m^{(b)}-\tfrac{1}{6}\hat{R}^n{}_{fmg}\hat{e}_n^{(b)}y^f y^g+R_3)\\ &\quad\times(\hat{e}_k^{(c)}-\tfrac{1}{6}\hat{R}^j{}_{pkt}\hat{e}_j^{(c)}y^p y^t+R_3)-{}_gM^{abc}(P)\\ &=({}_{\mathrm{F}}\hat{U}^{b[ca]}{}_{,r}-{}_{\mathrm{F}}\hat{U}^{a[cb]}{}_{,r})y^r+\frac{1}{2!}({}_{\mathrm{F}}\hat{U}^{b[ca]}{}_{,pt}-{}_{\mathrm{F}}\hat{U}^{a[cb]}{}_{,pt})y^p y^t+R_3. \end{aligned}\tag{25}$$

Integrating these differences over the domain Ω with the same properties as the domain Ω used in Sec. III A, we have

$$\begin{aligned} \int_\Omega [{}_gM^{(a)(b)(c)}(y)-{}_gM^{(a)(b)(c)}(P)]\, d\Omega &\approx {}_gS^{abc}(P;v^l)\tfrac{1}{2}\int_\Omega (y^d)^2\, d\Omega\\ &={}_gS^{abc}(P;v^l)\tfrac{1}{2}M=:{}_gS^{abc}(P;v^l;\Omega). \end{aligned}\tag{26}$$

Here ${}_gS^{abc}(P;v^l;\Omega)=(-)_gS^{abc}(P;v^l;\Omega)$ is a tensor whose components give the *approximate values* of the (relative) *gravitational canonical angular momentum* inside the domain Ω.

The tensor ${}_gS^{abc}(P;v^l;\Omega)$ also factorizes onto a product of the two terms: the gravitational, canonical supermomentum tensor ${}_gS^{abc}(P;v^l)$ and the term $\frac{1}{2}M$ which depends on the (common) value of the moments of inertia of the domain Ω with respect to the subspaces $y^i=0$ $(i=0,1,2,3)$.

IV. APPLICATION OF THE CANONICAL, ANGULAR SUPERMOMENTUM TENSORS IN GR

A. Plane and plane-fronted gravitational waves (pp-waves)

By linearly polarized, plane gravitational wave we understand the solution to the Einstein vacuum equations which, in coordinates (t,x,y,z), has the line element of the form[24]

$$ds^2=dt^2-L^2(e^{2\beta}dx^2+e^{-2\beta}dy^2)-dz^2=du\,dv-L^2(e^{2\beta}dx^2+e^{-2\beta}dy^2), \tag{27}$$

where

$$L = L(u), \quad \beta = \beta(u), \quad u = t - z, \quad v = t + z.$$

The Einstein equations for (27) reduce just to one equation,

$$L'' + (\beta')^2 L = 0, \tag{28}$$

for the two *metric functions* $L = L(u)$, $\beta = \beta(u)$. Here $\beta' := d\beta/du$, $L' := dL/du$, and so on. A plane wave described by (27) and (28) propagates in the positive direction of the z axis.

By a suitable coordinate transformation (see, e.g., Ref. 14) one can bring the line element given by (27) and (28) to the following form:

$$ds^2 = 2(Y^2 - X^2)\frac{F(U)}{2}dU^2 + 2dUdV - dX^2 - dY^2 \tag{29}$$

with an arbitrary function $F = F(U) = F(t - z)$.

The *plane-fronted gravitational wave with parallel rays* (pp-wave; see, e.g., Ref. 25) is a generalization of the plane wave and has the following line element in coordinates ($U = t - z$, V, X, Y)

$$ds^2 = 2H(X,Y,U)dU^2 + 2dUdV - dX^2 - dY^2, \tag{30}$$

where

$$\Delta H := \left(\frac{\partial^2}{\partial X^2} + \frac{\partial^2}{\partial Y^2}\right)H = 0. \tag{31}$$

The vector field tangent to the V-lines is covariantly constant and null.

Let us calculate the components of the canonical, gravitational angular supermomentum tensor ${}_gS^{abc}(P;v^l)$ given by (21) for the line element (30) and (31). To simplify calculations we use the *null coreper*

$$\vartheta^0 = HdU + dV, \quad \vartheta^1 = dU, \quad \vartheta^2 = dX, \quad \vartheta^3 = dY. \tag{32}$$

After some tedious calculations we obtain that the components of the tensor

$${}_gS^{abc}(P;v^l) = (-)\,{}_gS^{bac}(P;v^l)$$

do not vanish in the null coreper and they do not vanish in *any other coreper, too* (for results of the performed calculations, see Appendix B). It means that the plane-fronted and plane gravitational waves *possess and carry* angular supermomentum. For the sake of comparison, we calculate the components of the canonical angular momentum pseudotensor (24) for pp and plane waves, which, in the null coreper (32), give

$${}_gM^{nmk} = 0, \tag{33}$$

i.e., they give *no angular momentum*. However, the components of the pseudotensor ${}_gM^{nmk}$ in the coordinates (t,x,y,z), for example, *do not vanish*. This is not surprising because the components ${}_gM^{nmk}$ form *neither a tensor nor any other geometric object*. On the contrary, the components of ${}_gS^{abc}(P;v^l)$, as being the components of a tensor, *do not vanish in any coordinates* and, therefore, they give *a coordinate independent, covariant characteristic* of the plane and plane-fronted gravitational waves. This characteristic depends on the gravitational field and on the four-velocity v^i of an observer **O** only.

B. Friedman universes

Friedman universes ($\equiv$ Friedman cosmological models) are the solutions to the Einstein equations with the Friedman–Lemaître–Robertson–Walker line element (**FLRW** line element) which, in the comoving coordinates $x^0=ct$, $x^1=r$, $x^2=\vartheta$, $x^3=\varphi$, reads

$$ds^2=c^2dt^2-R^2(t)\left[\frac{dr^2}{(1-kr^2)}+r^2(d\vartheta^2+\sin^2\vartheta d\varphi^2)\right], \tag{34}$$

where the *curvature index* $k=0,\pm1$ and $R=R(t)$ is the *scale factor*. The parameter t represents universal time called the *cosmic time*.

The scale factor $R(t)$ satisfies Einstein field equations (sometimes called *Friedman equations*)

$$\frac{3\dot{R}^2}{c^2R^2}+\frac{3k}{R^2}=\frac{\epsilon}{2\alpha}, \tag{35}$$

$$\frac{\dot{R}^2}{c^2R^2}+\frac{2\ddot{R}}{c^2R^2}+\frac{k}{R^2}=(-)\frac{p}{2\alpha}. \tag{36}$$

In (35) and (36) ϵ is the energy density of the cosmological fluid and p is the pressure; $\dot{R}:=dR/dt$, $\ddot{R}:=d^2R/dt^2$.

The canonical angular supermomentum tensors ${}_mS^{abc}(P;v^l)$ and ${}_gS^{abc}(P;v^l)$, similarly as with canonical superenergy tensors ${}_gS_i{}^k(P;v^l)$, ${}_mS_i{}^k(P;v^l)$, are *defined locally* and they depend on the four-velocity v^i ($v^iv_i=1$) of an observer **O** being at rest at the point **P**.

If the vector field v^i ($v^iv_i=1$) is given over a certain domain Ω of space–time or over the whole space–time, then one can uniquely determine tensor fields ${}_gS^{abc}(x;v^l)$ and ${}_mS^{abc}(x;v^l)$ [this is by performing the ''averaging'' given by (1) at every point of the domain Ω or at every point of the entire space–time and by using the field v^i to present the obtained results in a covariant way].

In the framework of Friedman cosmology *there always exists* such a vector field: it is just the four-velocity v^i of the *isotropic or fundamental observers* being at rest in comoving coordinates. This vector field is *geometrically and physically distinguished* in the case of Friedman cosmology: it forms timelike, geodesic, and hypersurface-orthogonal congruence.

So, in Friedman universes, one can introduce *unique* tensor fields ${}_gS^{abc}(x;v^l)$, ${}_mS^{abc}(x;v^l)$ and, in analogy to global superenergetic quantities considered in Refs. 4, 13, and 15, one can define *global angular supermomentum*

$$S^{ab}:=\frac{1}{c}\int_{t=\mathrm{const}}({}_gS^{ab0}+{}_mS^{ab0})\sqrt{|g|}\,dr\,d\vartheta\,d\varphi \tag{37}$$

of matter and gravitation.

As we restrict ourselves to the analysis of the global angular supermomentum components given by (37) in this paper, we just need to give the components

$${}_mS^{ab0}(x;v^l)=(-){}_mS^{ba0}(x;v^l) \quad \text{and} \quad {}_gS^{ab0}(x;v^l)=(-){}_gS^{ba0}(x;v^l) \tag{38}$$

of the tensors ${}_mS^{abc}(x;v^l)$ and ${}_gS^{abc}(x;v^l)$ which determine these global quantities.

After very simple but something lengthly calculations, we obtain, for Friedman universes

$${}_mS^{ab0}(x;v^l)=0={}_gS^{ab0}(x;v^l). \tag{39}$$

It follows from (39) that the components

$$S^{ab0}(x;v^l):={}_mS^{ab0}(x;v^l)+{}_gS^{ab0}(x;v^l) \tag{40}$$

and the components $S^{ab}=(-)S^{ba}$ of the global, canonical angular supermomentum of the Friedman universes *trivially vanish*. It can also be seen from (39) that the *global, canonical angular supermomenta* of gravitation

$$ {}_gS^{ab}:=\frac{1}{c}\int_{t=\mathrm{const}} {}_gS^{ab0}(x;v^l)\sqrt{|g|}\,dr\,d\vartheta\,d\varphi \tag{41} $$

and matter

$$ {}_mS^{ab}:=\frac{1}{c}\int_{t=\mathrm{const}} {}_mS^{ab0}(x;v^l)\sqrt{|g|}\,dr\,d\vartheta\,d\varphi \tag{42} $$

also *trivially vanish* for these universes since their integrands vanish. These results seem to be quite reasonable and somehow expected.

For the sake of comparison, we give here also the components ${}_gM^{ik0}$ and ${}_mM^{ik0}=\sqrt{|g|}(x^iT^{k0}-x^kT^{i0})$ of the canonical quantities which give the angular momentum of gravitation and matter, respectively.

The set $\{x^i\}$ $(i=0,1,2,3)$ here is the global, comoving coordinates (ct,x,y,z) in which the **FLRW** line element is given by

$$ ds^2=c^2dt^2-R^2(t)\,\frac{(dx^2+dy^2+dz^2)}{[1+k(x^2+y^2+z^2)/4]^2}. \tag{43} $$

Global coordinates (ct,x,y,z) are closely related to the Cartesian coordinates in a flat space–time. They have to be applied here if one wants to obtain any reasonable global results by using canonical angular momentum pseudotensor ${}_gM^{ikl}=(-)_gM^{kil}$ given by (8)–(12) or by (24) and by using matter angular momentum geometric object[26] ${}_mM^{ikl}=\sqrt{|g|}(x^iT^{kl}-x^kT^{il})$.

After some calculations [especially lengthy for components ${}_gM^{ik0}=(-)_gM^{ki0}$] we obtain

$$ \begin{gathered} {}_mM^{120}=(-)_mM^{210}=0,\quad {}_mM^{130}=(-)_mM^{310}=0,\quad {}_mM^{230}=(-)_mM^{320}=0,\\ {}_mM^{010}=(-)_mM^{100}=(-)\,\frac{xR^3\epsilon}{u^3}=(-)\,\frac{6\alpha Rx}{u^3}(\dot{R}^2+k),\\ {}_mM^{020}=(-)_mM^{200}=(-)\,\frac{yR^3\epsilon}{u^3}=(-)\,\frac{6\alpha Ry}{u^3}(\dot{R}^2+k),\\ {}_mM^{030}=(-)_mM^{300}=(-)\,\frac{zR^3\epsilon}{u^3}=(-)\,\frac{6\alpha Rz}{u^3}(\dot{R}^2+k), \end{gathered} \tag{44} $$

where

$$ u:=1+\frac{k(x^2+y^2+z^2)}{4}=:1+\frac{kr^2}{4}. \tag{45} $$

$$ \begin{gathered} {}_gM^{120}=(-)_gM^{210}=0,\quad {}_gM^{130}=(-)_gM^{310}=0,\quad {}_gM^{230}=(-)_gM^{320}=0,\\ {}_gM^{010}=(-)_gM^{100}=(-)\,\frac{2\alpha x}{u^2}\left[\frac{R}{u}\left(6\dot{R}^2-\frac{k^2r^2}{2}\right)+\dot{R}kt+kR\right],\\ {}_gM^{020}=(-)_gM^{200}=(-)\,\frac{2\alpha y}{u^2}\left[\frac{R}{u}\left(6\dot{R}^2-\frac{k^2r^2}{2}\right)+\dot{R}kt+kR\right], \end{gathered} \tag{46} $$

$$ {}_gM^{030}=(-)\,{}_gM^{300}=(-)\,\frac{2\alpha z}{u^2}\left[\frac{R}{u}\left(6\dot{R}^2-\frac{k^2r^2}{2}\right)+\dot{R}kt+kR\right]. $$

From (44)–(46) it follows that the components $M^{ik0}=(-)M^{ki0}$ of the canonical angular momentum complex of matter and gravitation $M^{ikl}:={}_MM^{ikl}+{}_gM^{ikl}$, which satisfies *local conservation laws*

$$ M^{ikl}{}_{,l}=0, $$

in coordinates (ct,x,y,z) are

$$ \begin{aligned} &M^{120}=M^{130}=M^{230}=0,\\ &M^{010}=(-)\,\frac{2\alpha x}{u^2}\left[\frac{R}{u}\left(9\dot{R}^2-\frac{k^2r^2}{2}\right)+\dot{R}kt+\frac{3kR}{u}\right],\\ &M^{020}=(-)\,\frac{2\alpha y}{u^2}\left[\frac{R}{u}\left(9\dot{R}^2-\frac{k^2r^2}{2}\right)+\dot{R}kt+kR=\frac{3kR}{u}\right],\\ &M^{030}=(-)\,\frac{2\alpha z}{u^2}\left[\frac{R}{u}\left(9\dot{R}^2-\frac{k^2r^2}{2}\right)+\dot{R}kt+kR+\frac{3kR}{u}\right]. \end{aligned} \tag{47} $$

This leads to the conclusion that the global, canonical angular momentum of the Friedman universes

$$ M^{ik}=\frac{1}{c}\int_{t=\mathrm{const}}({}_mM^{ik0}+{}_gM^{ik0})\,dxdydz \tag{48} $$

vanishes. The same results hold for the global *matter canonical angular momentum*

$$ {}_mM^{ik}=\frac{1}{c}\int_{t=\mathrm{const}}{}_mM^{ik0}\,dxdydz \tag{49} $$

and for the global *gravitational canonical angular momentum*

$$ {}_gM^{ik}=\frac{1}{c}\int_{t=\mathrm{const}}{}_gM^{ik0}\,dxdydz \tag{50} $$

separately: they all vanish in coordinates (ct,x,y,z), too. So, we have the same global results [in coordinates (ct,x,y,z)] for canonical angular momentum and canonical angular supermomentum in the case of the Friedman universes.

However, the canonical angular supermomenta possess much better geometric properties than the canonical angular momenta. Namely, we have the following.

(1) The components of ${}_gS^{ikl}(x;v^t)$ and ${}_mS^{ikl}(x;v^t)$ and the components of $S^{ikl}(x;v^t)={}_gS^{ikl}(x;v^t)+{}_mS^{ikl}(x;v^t)$ *form tensors*. Because of this the canonical angular supermomenta ${}_gS^{ikl}(P;v^t)$, ${}_mS^{ikl}(P;v^t)$, and $S^{ikl}(P;v^t)={}_gS^{ikl}(P;v^t)+{}_mS^{ikl}(P;v^t)$ *are localized* and

$$ {}_gS^{ik0}(x;v^t)=0,\quad {}_mS^{ik0}(x;v^t)=0,\quad S^{ik0}(x;v^t)={}_gS^{ik0}(x;v^t)+{}_mS^{ik0}(x;v^t)=0, \tag{51} $$

independent of the coordinates (x^1,x^2,x^3) which have been used for the parametrization of spaces $t=\mathrm{const}$. So, the global angular supermomenta vanish, i.e.,

$$ S^{ik}=0,\quad {}_gS^{ik}=0,\quad {}_mS^{ik}=0, \tag{52} $$

independent of the coordinates used within the spaces $t=\text{const}$.

(2) The components of the canonical angular supermomentum tensors *do not depend* on the so-called ''radius vector'' which *does not exist globally* in the framework of **GR**. On the contrary, the canonical angular momenta ${}_gM^{ikl}$ and $M^{ikl}={}_gM^{ikl}+{}_mM^{ikl}$ explicitly depend on ''radius vector'' and *form neither a tensor nor any other geometric objects*. So, they must be used only in *special coordinates* in order to give physically meaningful results. In the case of the Friedman universes these are the coordinates (ct,x,y,z) in which the **FLRW** line element is in the form given by (43). Moreover, even the matter canonical angular momentum object

$${}_mM^{ikl}=\sqrt{|g|}(x^iT^{kl}-x^kT^{il})$$

cannot be *any tensor density defined globally* because it needs a global *radius vector* $\vec{x}=x^i\partial_i$ to be a tensor density. However, radius vector *does not exist globally* in the framework of **GR**.

C. Schwarzschild space–time

The static, spherically symmetric space–time in the coordinates $(x^0=ct,\ x^1=r,\ x^2=\vartheta,\ x^3=\varphi)$ has the line element given by[3]

$$ds^2=e^{\nu(r)}c^2dt^2-e^{\lambda(r)}dr^2-r^2(d\vartheta^2+\sin^2\vartheta d\varphi^2). \tag{53}$$

In the exterior region $r\geqslant r_*$, the Einstein equations demand

$$e^{\nu}=e^{-\lambda}=1-\frac{2Gm}{c^2r}=:1-\frac{r_g}{r}, \tag{54}$$

where m is the mass of a spherical star (source of the gravitational field) having ''radius'' $r=r_*>r_g$. Here $r_g:=2Gm/c^2$ is the *Schwarzschild radius.*

As a source of the gravitational field we have taken a normal static and spherical star which consists of perfect fluid with the energy-momentum tensor $T^{ik}=T^{ki}$ in the form

$$T^{ik}=(\epsilon+p)u^iu^k-g^{ik}p. \tag{55}$$

It is known that one can join smoothly the interior and the exterior Schwarzschild solutions on the star surface and obtain *complete Schwarzschild space–time*. In the complete Schwarzschild space–time there exists a distinguished timelike unit vector field $v^i:v^iv_i=1$, orthogonal to the spatial slices $x^0=ct=\text{const}$. So, similarly as in the case of Friedman cosmological models, one can obtain unique tensor fields ${}_gS^{abc}(x)$ and ${}_mS^{abc}(x)$.

After some calculations, from (53), (54), and (21), outside of the star, i.e., in the domain $r>r_*$, where $T^{ik}=0$, we get

$${}_mS^{abc}(x)=0,\quad {}_gS^{010}(x)=(-){}_gS^{100}(x)=(-)\alpha\frac{r_g^2}{6r^4(r-r_g)}. \tag{56}$$

The other components of the ${}_gS^{ikl}(x)$ vanish in the domain.

On the other hand, inside the star, where $T^{ik}\neq 0$, for the line element (1) and for the energy-momentum tensor (55) we get from (18) and (20)

$$\begin{gathered}{}_mS^{010}=(-){}_mS^{100}\neq 0,\quad {}_mS^{122}=(-){}_mS^{212}={}_mS^{133}\sin^2\vartheta=(-){}_mS^{313}\sin^2\vartheta\neq 0,\\ {}_gS^{010}=(-){}_gS^{100}\neq 0,\quad {}_gS^{122}=(-){}_gS^{212}\neq 0,\quad {}_gS^{133}=(-){}_gS^{313}\neq 0,\end{gathered} \tag{57}$$

which is independent of any specific form of the interior solutions. The remaining components of the tensors ${}_mS^{abc}(x)$ and ${}_gS^{abc}(x)$ *vanish identically* in the case. It can be seen from (56) and (57) that physically most important, spatial components

$$S^{12}=(-)S^{21},\quad S^{13}=(-)S^{31},\quad S^{23}=(-)S^{32}$$

of the global angular supermomentum $S^{ik}=(-)S^{ki}$ (matter and gravitation) in the complete Schwarzschild space–time

$$S^{ik}:=\int_{x^0=ct=\mathrm{const}}({}_mS^{ik0}+{}_gS^{ik0})\sqrt{|g|}\,dr\,d\vartheta\,d\varphi \tag{58}$$

are trivially equal to zero. By *trivially* we mean by means of the fact that their integrands

$$S^{120}:={}_mS^{120}+{}_gS^{120},\quad S^{130}:={}_mS^{130}+{}_gS^{130},\quad S^{230}:={}_mS^{230}+{}_gS^{230}$$

identically vanish. We find this result quite reasonable. The same is correct for the *exterior* and *interior* Schwarzschild solutions separately. The analogical results can be obtained for the global *angular supermomentum of matter*

$${}_mS^{ik}:=\int_{x^0=\mathrm{const}}{}_mS^{ik0}\sqrt{|g|}\,dr\,d\vartheta\,d\varphi, \tag{59}$$

and *gravitation*

$${}_gS^{ik}:=\int_{x^0=ct=\mathrm{const}}{}_gS^{ik0}\sqrt{|g|}\,dr\,d\vartheta\,d\varphi. \tag{60}$$

The final results

$$S^{12}=S^{13}=S^{23}=0,\quad {}_gS^{12}={}_gS^{13}={}_gS^{23}=0,\quad {}_mS^{12}={}_mS^{13}={}_mS^{23}=0$$

are independent of the spatial coordinates used for parametrization of the slices $x^0=ct=\mathrm{const}$.

One can compare the above results with the results of calculations of the global angular momentum of the Schwarzschild space–time by using canonical, angular-momentum complex given by Bergmann and Thomson (see Appendix A)

$$M^{ijk}=(-)M^{jik}=x^i_{\mathrm{BT}}K^{jk}-x^j_{\mathrm{BT}}K^{ik}+{}_{\mathrm{F}}U^{i[jk]}-{}_{\mathrm{F}}U^{j[ik]}=(x^i_{\mathrm{F}}U^{j[kl]}-x^j_{\mathrm{F}}U^{i[kl]})_{,l}=:M^{[ij][kl]}{}_{,l}\,. \tag{61}$$

However, while using the complex (61), one should take the isotropic Cartesian coordinates ($x^0=ct, x^1=x,\ x^2=y, x^3=z$) (because the canonical angular momentum complex forms neither a tensor nor any other geometric object). In these coordinates the exterior Schwarzschild line element is of the form[3]

$$ds^2=\left[\frac{1-r_g/4\rho}{1+r_g/4\rho}\right]^2c^2dt^2-\left(1+\frac{r_g}{4\rho}\right)^4(dx^2+dy^2+dz^2), \tag{62}$$

where

$$\begin{aligned} r&=\rho\left(1+\frac{r_g}{4\rho}\right)^2,\\ \rho^2&=x^2+y^2+z^2, \end{aligned} \tag{63}$$

or, asymptotically, when $\rho\to\infty$ ($\Leftrightarrow r\to\infty$)

$$ds^2=\left(1-\frac{r_g}{\rho}\right)c^2dt^2-\left(1+\frac{r_g}{\rho}\right)(dx^2+dy^2+dz^2). \tag{64}$$

The asymptotic form (64) of the exterior Schwarzschild line element is sufficient to calculate the components $M^{ik}=(-)M^{ki}$ of the global angular momentum of the complete Schwarzschild space–time because they are determined by surface integrals over boundary of a spatial slice $x^0=ct=\text{const}$ (see Appendix A and Refs. 3 and 22):

$$M^{ik}=\oint_{\text{over a sphere } S^2 \text{ with } R\to\infty} M^{[ik][0\alpha]} n_\alpha r^2\, d\Omega. \tag{65}$$

From (64) and (65) we get, after some calculations,

$$M^{12}=M^{13}=M^{23}=0. \tag{66}$$

So, at least in asymptotically Lorentzian coordinates, we have equivalent global results concerning angular momentum and angular supermomentum. However, one should emphasize that the expressions (18), (20), and (21) of Sec. II *are tensorial* and are defined without *any use of radius vector*. This means they can be applied for any other spatial coordinates used for parametrization of the space $x^0=ct=\text{const}$ and give the same results, i.e.,

$$S^{12}=S^{13}=S^{23}=0, \quad {}_gS^{12}={}_gS^{13}={}_gS^{23}=0, \quad {}_mS^{12}+{}_mS^{13}={}_mS^{23}=0.$$

D. Stationary Kerr space–time

We use the Kerr space–time in *Boyer–Lindquist coordinates* $x^0=t$, $x^1=r$, $x^2=\theta$, $x^3=\varphi$ (see, e.g., Refs. 3 and 27) in which the line element reads as

$$ds^2=\left(1-\frac{r_g r}{\rho^2}\right)dt^2-\frac{\rho^2}{\Delta}dr^2-\rho^2 d\theta^2-\left(r^2+a^2+\frac{r_g r a^2}{\rho^2}\sin^2\theta\right)\sin^2\theta d\varphi^2+\frac{2r_g r a}{\rho^2}\sin^2\theta d\varphi dt, \tag{67}$$

where

$$\Delta:=r^2-r_g r+a^2, \quad \rho^2:=r^2+a^2\cos^2\theta, \quad r_g:=2mG. \tag{68}$$

Here m is the mass of the source and $M=ma$, its angular momentum.

The nonvanishing components[28] ${}_gS^{abc}(P;v^l)$ of the canonical gravitational angular supermomentum tensor (21) for the line element (67) and (68) are

$$\begin{aligned}
&{}_gS^{130}=(-)_gS^{310}, \quad {}_gS^{133}=(-)_gS^{313}, \quad {}_gS^{121}=(-)_gS^{211}\ {}_gS^{122}=(-)_gS^{212},\\
&{}_gS^{230}=(-)S^{320}, \quad {}_gS^{233}=(-)_gS^{323}, \quad {}_gS^{010}=(-)_gS^{100}, \quad {}_gS^{013}=(-)_gS^{103},\\
&{}_gS^{020}=(-)_gS^{200}, \quad {}_gS^{023}=(-)_gS^{203}, \quad {}_gS^{031}=(-)_gS^{301}, \quad {}_gS^{032}=(-)_gS^{302}.
\end{aligned} \tag{69}$$

One can get the components of ${}_gS^{abc}(P;v^l)$ in other coordinates by using the tensor transformation rule.

The analysis of the asymptotic behavior of the nonzero components of the tensor field ${}_gS^{abc}(x;v^l)$ determined by (69) shows that they are at least of the $0(r^{-4})$ order. So, the integrals[29]

$$S^{ik}=\frac{1}{c}\int_{x^0=t=\text{const}} {}_gS^{ik0}\sqrt{|g|}\,dr d\theta d\varphi, \quad \sqrt{|g|}=\rho^2\sin\theta, \tag{70}$$

which give the components of the global angular supermomentum for Kerr space–time *are convergent*. These components are also independent of time.

Of all the integrals (70), which give global angular supermomentum the *spatial components*

$$S^{12}=(-)S^{21}(=0), \quad S^{13}=(-)S^{31}\neq 0, \quad S^{23}=(-)S^{32}\neq 0,$$

are most physically important.

It is interesting to compare (69) with the components of the canonical angular momentum object (8) for Kerr space–time in Boyer–Lindquist coordinates. After some calculations[30] we get that the following components of the canonical angular momentum object ${}_gM^{ikl}=(-)_gM^{kil}$ given by (8) do not vanish:[31]

$$\begin{gathered}
{}_gM^{010}=(-)_gM^{100},\quad {}_gM^{011}=(-)_gM^{101},\quad {}_gM^{012}=(-)_gM^{102},\quad {}_gM^{013}=(-)_gM^{103},\\
{}_gM^{020}=(-)_gM^{200},\quad {}_gM^{021}=(-)_gM^{201},\quad {}_gM^{022}=(-)_gM^{202},\quad {}_gM^{023}=(-)_gM^{203},\\
{}_gM^{030}=(-)_gM^{300},\quad {}_gM^{033}=(-)_gM^{303},\\
{}_gM^{121}=(-)_gM^{211},\quad {}_gM^{122}=(-)_gM^{212},\\
{}_gM^{230}=(-)_gM^{320},\quad {}_gM^{231}=(-)_gM^{321},\quad {}_gM^{232}=(-)_gM^{322},\quad {}_gM^{233}=(-)_gM^{323},\\
{}_gM^{130}=(-)_gM^{310},\quad {}_gM^{131}=(-)_gM^{311},\quad {}_gM^{132}=(-)_gM^{312},\\
{}_gM^{133}=(-)_gM^{313}.
\end{gathered}\tag{71}$$

Here more compoments are different from zero than in (69). Moreover, these components are *nontensorial*. Therefore, the components of ${}_gM^{ikl}$ in any other system of coordinates must be calculated separately.

Having analyzed the asymptotic behavior of the components (71) at spatial infinity we conclude that the integrals[32]

$$M^{ik}=\frac{1}{c}\int_{x^0=t=\mathrm{const}} {}_gM^{ik0}\,dr\,d\theta d\varphi,\tag{72}$$

which represent the components of the global angular momentum are convergent *iff* $i,k=1,2,3$; $(M^{12}=0)$, i.e., only the integrals which represent *spatial components* of the global angular momentum are convergent. The convergent integrals are also independent of time.

So, for the most important spatial components M^{ik} we have similiar result as for the spatial components S^{ik}—the integrals which represent these components are convergent and independent of time. However, the values and dimension of the corresponding convergent integrals, except $S^{12}=M^{12}=0$, are, of course, different.

In order to conclude, we notice that the components of the ${}_gS^{abc}(P;v^l)$ have *better geometrical properties* (form a tensor) than the components of ${}_gM^{ikl}$ and *give better convergence* of the corresponding integrals which represent global quantities for Kerr space–time (all S^{ik} are convergent, but not all M^{ik}).

The superiority of the superenergetic quantities over canonical energetic quantities for Kerr geometry is more explicit if we compare the canonical superenergy and linear supermomentum with canonical energy and momentum, all calculated in the Boyer–Lindquist coordinates. Namely, we can see that the superenergy density ${}_g\epsilon_s := {}_gS_{ik}v^iv^k$ is a *positive-definite scalar* and the integrals

$$S_i=\frac{1}{c}\int_{x^0=\mathrm{const}} {}_gS_i{}^0(P;v^l)\sqrt{|g|}\,dr\,d\theta d\varphi,\tag{73}$$

which represent global superenegetic quantities are convergent $(S_0>0, S_1=S_2=0, S_3\neq 0)$. In consequence, they have very good physical sense.

On the other hand, the integrals

$$P_i=\frac{1}{c}\int_{x^0=t=\mathrm{const}} {}_EK_i{}^0\,dr\,d\theta d\varphi,\tag{74}$$

which give the global energetic quantities for Kerr space–time, *are divergent* in Boyer–Linquist coordinates (except $P_1 = P_2 = 0$). So, the integrals (74) *have no physical sense* in the Boyer–Lindquist coordinates. It is not surprising because canonical energy-momentum complex ${}_{\mathrm{E}}K_i^{\ k} = \sqrt{|g|}(T_i^k + {}_{\mathrm{E}}t_i^{\ k})$ can only be used in asymptotically flat coordinates.

V. CONCLUSION

In this paper we have generalized the idea of the canonical superenergy tensors and introduced *the canonical angular supermomentum tensors* for matter and for gravitation. Similarly as it was in the case of the canonical superenergy tensors, the canonical supermomentum tensors ${}_gS^{ikl}(P;v^t)$ and ${}_mS^{ikl}(P;v^t)$ which were introduced in the paper have much better geometrical properties than the canonical angular momentum pseudotensor ${}_gM^{ikl}$ and the canonical object ${}_mM^{ikl}$. Moreover, the canonical angular supermomentum tensors ${}_mS^{ikl}(P;v^t)$ and ${}_gS^{ikl}(P;v^t)$ of matter and gravitation, and their sum $S^{ikl} = {}_mS^{ikl} + {}_gS^{ikl}$ *do not require any radius vector* to be defined. The canonical angular supermomentum tensors, as well as canonical superenergy tensors considered in our previous papers, are *our proposal* as *substitutes* for the angular momentum tensors of matter and gravitation in **GR** (which actually do not exist). We want to emphasize that the canonical angular supermomentum tensors introduced and considered in the paper are *constructed locally*, defined pointwise, and explicitly depend on the four-velocity v^i of an observer **O** being at rest at the beginning **P** of the applied normal coordinates **NCS(P)**. This means they are the most appropriate for the *local analysis* of the gravitational and matter fields. However, if there exists a distinguished, unit, timelike vector field $\vec{v}$, then these tensors can also be used for the *global analysis* of the gravitational and matter fields. Such a situation appears to be valid for nearly all models of space–time (Friedman, Schwarzschild, and Kerr) we dealt with in this paper.

In the paper we applied the canonical angular supermomentum tensor ${}_gS^{ikl}(P;v^t) = (-){}_gS^{kil}(P;v^l)$ to the local analysis of the vacuum solutions to the Einstein equations which correspond to the *plane and plane-fronted* gravitational waves. We obtained *fully covariant results* in this case. Then, as already mentioned, we applied the canonical supermomentum tensor fields

$$ {}_mS^{ikl}(x;v^t), \quad {}_gS^{ikl}(x;v^t) $$

and their sum

$$ S^{ikl}(x;v^t) = {}_mS^{ikl}(x;v^t) + {}_gS^{ikl}(x;v^t) $$

for the global analysis of the Friedman universes and Schwarzschild space–time. These were extremely important applications since the Friedman universes are *a cornerstone* of relativistic cosmology and the Schwarzschild solution is of *primary astrophysical interest*. As a result of calculations, we obtained that the global, canonical angular supermomenta *trivially vanish* for both Friedman universes in all comoving coordinates and for Schwarzschild space–time. It seems to be a very reasonable result.

Comparing our results with the results obtained by using the canonical angular momentum pseudotensor ${}_gM^{ikl}$ and canonical angular momentum complex $M^{ikl} = {}_gM^{ikl} + {}_mM^{ikl}$, matter and gravitation, we conclude that in **GR**, the canonical angular supermomentum tensors are *much better tools* for the analysis (in particular, for the local analysis) of the gravitational and matter fields than the canonical angular momentum objects. The same is true when we compare the energetic and superenergetic quantities for Friedman universes[5,13,15] and for gravitational waves.[12,14]

Finally, we used the tensor ${}_gS^{abc}(P;v^l)$ for the analysis of the stationary Kerr space–time which is of great importance for relativistic astrophysics. This example can also be considered as a proof of the superiority of the canonical angular supermomentum tensor ${}_gS^{abc}(P;v^l)$ to canonical, angular momentum object ${}_gM^{ikl}$.

APPENDIX A: BERGMANN–THOMSON ANGULAR MOMENTUM IN GR

The canonical Bergmann–Thomson total angular momentum density, matter and gravitation, can most easily be obtained in the following way. At first, let us transform the Einstein equations written in mixed form and multiplied by $\sqrt{|g|}$,

$$\sqrt{|g|}G_i^k=\beta\sqrt{|g|}T_i^k, \tag{A1}$$

to the so-called *superpotential form*

$$_EK_i{}^k={}_FU_i{}^{[kl]}{}_{,l}, \tag{A2}$$

where

$$_EK_i{}^k:=\sqrt{|g|}(T_i{}^k+{}_Et_i{}^k)$$

is the *canonical, Einstein energy-momentum complex*, matter and gravitation, and $_FU_i{}^{[kl]}$ are *von Freud superpotentials*.

From (A2), after series of operations, we get the *Bergmann–Thomson energy-momentum complex* $_{\mathrm{BT}}K^{jk}$, matter and gravitation. At first, we form the following quantity:

$$g^{ij}{}_EK_i{}^k=g^{ij}{}_FU_i{}^{[kl]}{}_{,l}=(g^{ij}{}_FU_i{}^{[kl]})_{,l}-{}_FU_i{}^{[kl]}g^{ij}{}_{,l} \tag{A3}$$

or

$$g^{ij}{}_EK_i{}^k+{}_FU_i{}^{[kl]}g^l{}_{,l}={}_FU^{j[kl]}{}_{,l}. \tag{A4}$$

Then, we write (A4) in the form

$$_{\mathrm{BT}}K^{jk}={}_FU^{j[kl]}{}_{,l}, \tag{A5}$$

where

$$_{\mathrm{BT}}K^{jk}:={}_EK^{jk}+{}_FU_i{}^{[kl]}g^{ij}{}_{,l}=:\sqrt{|g|}(T^{jk}+{}_{\mathrm{BT}}t^{jk}) \tag{A6}$$

is the *Bergmann–Thomson energy-momentum complex*, matter and gravitation, which satisfies local conservation laws

$$_{\mathrm{BT}}K^{jk}{}_{,k}=0. \tag{A7}$$

Here $_{\mathrm{BT}}t^{jk}\neq{}_{\mathrm{BT}}t^{kj}$ are the components of the so-called *Bergmann–Thomson energy-momentum pseudotensor* of the gravitational field.[22]

Finally, from (A5) we get

$$x^i{}_{\mathrm{BT}}K^{jk}-x^j{}_{\mathrm{BT}}K^{ik}=x^i{}_FU^{j[kl]}{}_{,l}-x^j{}_FU^{i[kl]}{}_{,l}=(x^i{}_FU^{j[kl]}-x^j{}_FU^{j[kl]})_{,l}-{}_FU^{j[kl]}+{}_FU^{i[kj]}, \tag{A8}$$

or

$$x^i{}_{\mathrm{BT}}K^{jk}-x^j{}_{\mathrm{BT}}K^{ik}+{}_{\mathrm{BT}}S^{ijk}=M^{[ij][kl]}{}_{,l}, \tag{A9}$$

where

$$ {}_{\mathrm{BT}}S^{ijk} := {}_F U^{i[jk]} - {}_F U^{j[ik]} = \frac{\alpha}{\sqrt{|g|}}[(-g)(g^{kj}g^{il} - g^{ki}g^{jl})]_{,l} =: \frac{\alpha}{\sqrt{|g|}} g^{[ij][kl]}{}_{,l} \tag{A10} $$

and

$$ M^{[ij][kl]} := x^i{}_F U^{j[kl]} - x^j{}_F U^{i[kl]}. \tag{A11} $$

The quantity

$$ x^i{}_{\mathrm{BT}}K^{jk} - x^j{}_{\mathrm{BT}}K^{ik} + {}_{\mathrm{BT}}S^{ijk} =: {}_{\mathrm{BT}}M^{ijk} \tag{A12} $$

is the *Bergmann–Thomson angular momentum complex* (matter and gravitation) and the quantities $M^{[ij][kl]}$ are *superpotentials*.[22]

One can interpret physically the angular momentum complex (A12) as a sum of the *orbital part*

$$ x^i{}_{\mathrm{BT}}K^{jk} - x^j{}_{\mathrm{BT}}K^{ik} = \sqrt{|g|}(x^i T^{jk} - x^j T^{ik}) + \sqrt{|g|}(x^i{}_{\mathrm{BT}}t^{jk} - x^j{}_{\mathrm{BT}}T^{ik}) $$

of the angular momentum density of matter and gravitation (matter part includes also spin density[22]) and a *spinorial part*

$$ {}_{\mathrm{BT}}S^{ijk} = {}_F U^{i[jk]} - {}_F U^{j[ik]} = \frac{\alpha}{\sqrt{|g|}} g^{[ij][kl]}{}_{,l} \tag{A13} $$

of the gravitational angular momentum density given by (8) of Sec. II. From (A5) we have

$$ 2\,{}_{\mathrm{BT}}K^{[ij]} = \sqrt{|g|}({}_{\mathrm{BT}}t^{ij} - {}_{\mathrm{BT}}t^{ji}) = {}_{\mathrm{BT}}S^{ijk}{}_{,k} = \left(\frac{\alpha}{\sqrt{|g|}}\right)_{,k} g^{[ij][kl]}{}_{,l}, \tag{A14} $$

because the dynamical energy-momentum tensor of matter T^{ik} is symmetric: $T^{ik} = T^{ki}$. Equation (A14) justifies the above physical interpretation of the pseudotensor ${}_{\mathrm{BT}}S^{ijk} = (-)_{\mathrm{BT}}S^{jik}$ as a quantity which describes *canonical spin density* of the gravitational field.[33–35]

From (A9) we have the following expression for the components $M^{ik} = (-)M^{ki}$ of the global angular momentum (matter and gravitation) of an isolated system equipped with asymtotically Lorentzian coordinates

$$ {}_{\mathrm{BT}}M^{ik} = \frac{1}{c} \oint_{\text{over sphere having } R\to\infty} (x^i{}_F U^{j[0\alpha]} - x^j{}_F U^{i[0\alpha]}) n_\alpha r^2\, d\Omega, \tag{A15} $$

where $r^2 = x^2 + y^2 + z^2$, n_a are the components of the unit (exterior) normal to the sphere, and $d\Omega = \sin\theta d\theta d\varphi$.

APPENDIX B: COMPONENTS OF ${}_gS^{abc}(P;v^l)$ FOR GRAVITATIONAL WAVES

Here we give the components

$$ {}_gS^{abc}(P;v^l) = (-)_gS^{bac}(P;v^l) \tag{B1} $$

of the canonical, gravitational supermomentum tensor for the line element (30) and (31) and for the line element (29). In order to simplify the calculations we used the *null coreper*

$$ \vartheta^0 = HdU + dV, \quad \vartheta^1 = dU, \quad \vartheta^2 = dX, \quad \vartheta^3 = dY. \tag{B2} $$

After long (but rather simple) calculations, we obtain the following nonzero components ${}_gS^{abc}(P;v^l)$ in this coreper:

$$
\begin{aligned}
&{}_gS^{120}=(-)\,{}_gS^{210}=(-)\,\frac{4\alpha v^1}{3}(v^2H_{xxu}+v^3H_{xyu}),\\
&{}_gS^{121}=(-)\,{}_gS^{211}=0,\quad {}_gS^{122}=(-)\,{}_gS^{212}=(-)\,\frac{4}{3}\alpha(v^1)^2H_{xxu},\\
&{}_gS^{123}=(-)\,{}_gS^{213}=(-)\,\frac{4\alpha}{3}(v^1)^2H_{xyu},\\
&{}_gS^{130}=(-)\,{}_gS^{310}=(-)\,\frac{4\alpha}{3}v^1(v^2H_{xyu}+v^3H_{yyu}),\\
&{}_gS^{131}=(-)\,{}_gS^{311}=0,\quad {}_gS^{132}=(-)\,{}_gS^{312}=(-)\,\frac{4}{3}\alpha(v^1)^2H_{xyu},\\
&{}_gS^{133}=(-)\,{}_gS^{313}=(-)\,\frac{4\alpha}{3}(v^1)^2H_{yyu},\quad {}_gS^{230}=(-)\,{}_gS^{320}=0,\\
&{}_gS^{232}=(-)\,{}_gS^{322}=0,\quad {}_gS^{231}=(-)\,{}_gS^{321}=0,\quad {}_gS^{233}=(-)\,{}_gS^{323}=0,\\
&{}_gS^{010}=(-)\,{}_gS^{100}=\frac{4\alpha}{3}(v^2)^2H_{xxu}+\frac{4\alpha}{3}(v^3)^2H_{yyu}+\frac{8\alpha}{3}v^2v^3H_{xyu}+\frac{2\alpha}{3}(H_{xxu}+H_{yyu}),
\end{aligned}
\tag{B3}
$$

$$
\begin{aligned}
&{}_gS^{011}=(-)\,{}_gS^{101}=0,\quad {}_gS^{012}=(-)\,{}_gS^{102}=\frac{4\alpha}{3}v^1(v^2H_{xxu}+v^3H_{xyu}),\\
&{}_gS^{020}=(-)\,{}_gS^{200}=(-)\,\frac{16\alpha}{3}(v^2)^2H_{xxx}-\frac{16\alpha}{3}(v^3)^2H_{yyx}-4\alpha v^0v^2H_{xxu}-4\alpha v^0v^3H_{xyu}\\
&\qquad -\frac{32\alpha}{3}v^2v^3H_{xxy}-\frac{8\alpha}{3}(H_{xxx}+H_{yyx}),\\
&{}_gS^{021}=(-)\,{}_gS^{201}=0,\\
&{}_gS^{022}=(-)\,{}_gS^{202}=(-)4\alpha v^0v^1H_{xxu}-\frac{16\alpha}{3}v^1v^2H_{xxx}-\frac{16\alpha}{3}v^1v^3H_{xxy}+2\alpha H_{xxu},\\
&{}_gS^{023}=(-)\,{}_gS^{203}=(-)4\alpha v^0v^1H_{xyu}-\frac{16\alpha}{3}v^1v^2H_{yxx}-\frac{16\alpha}{3}v^1v^3H_{yyx}+2\alpha H_{xyu},\\
&{}_gS^{030}=(-)\,{}_gS^{300}=(-)4\alpha v^0v^2H_{xyu}-4\alpha v^0v^3H_{yyu}-\frac{32\alpha}{3}v^2v^3H_{yyx}-\frac{16\alpha}{3}(v^2)^2H_{xxy}\\
&\qquad -\frac{16\alpha}{3}(v^3)^2H_{yyy}-\frac{8\alpha}{3}(H_{xxy}+H_{yyy}),\\
&{}_gS^{031}=(-)\,{}_gS^{301}=0,
\end{aligned}
$$

$$ {}_gS^{032}=(-)_gS^{302}=(-)4\alpha v^0v^1H_{xyu}-\frac{16\alpha}{3}v^1v^2H_{xyx}-\frac{16\alpha}{3}v^1v^3H_{xyy}+2\alpha H_{xyu}, $$

$$ {}_gS^{033}=(-)_gS^{303}=(-)4\alpha v^0v^1H_{yyu}-\frac{16\alpha}{3}v^1v^2H_{yyx}-\frac{16\alpha}{3}v^1v^3H_{yyy}+2\alpha H_{yyu}. $$

In the above formulas (B3),

$$ H_x:=\frac{\partial H}{\partial X},\quad H_{xx}:=\frac{\partial^2 H}{\partial X^2},\quad H_{xy}:=\frac{\partial^2 H}{\partial X\partial Y}, $$

and so on; v^i, $(i=0,1,2,3)$ is the four-velocity of an observer **O** being at rest at the origin **P** of the **NCS(P)** adapted to the coordinates (t,x,y,z).

For the plane wave

$$ H(X,Y,U)=(Y^2-X^2)\frac{F(U)}{2} $$

in the null coreper we have

$$ {}_gS^{120}=(-)_gS^{210}=\frac{4\alpha}{3}v^1v^2F',\quad {}_gS^{121}=(-)_gS^{211}=0, $$

$$ {}_gS^{122}=(-)_gS^{212}=\frac{4\alpha}{3}(v^1)^2F',\quad {}_gS^{123}=(-)_gS^{213}=0, $$

$$ {}_gS^{130}=(-)_gS^{310}=(-)\frac{4\alpha}{3}v^1v^3F',\quad {}_gS^{131}=(-)_gS^{311}=0, $$

$$ {}_gS^{132}=(-)_gS^{312}=0,\quad {}_gS^{133}=(-)_gS^{313}=(-)\frac{4\alpha}{3}(v^1)^2F', $$

$$ {}_gS^{23k}=(-)_gS^{32k}=0,\quad k=0,1,2,3; $$

$$ {}_gS^{010}=(-)_gS^{100}=\frac{4\alpha}{3}F'(v^{3^2}-v^{2^2}),\quad {}_gS^{011}=(-)_gS^{101}=0, \tag{B4} $$

$$ {}_gS^{012}=(-)_gS^{102}=(-)\frac{4\alpha}{3}v^1v^2F',\quad {}_gS^{013}=(-)_gS^{103}=\frac{4\alpha}{3}v^1v^3F', $$

$$ {}_gS^{020}=(-)_gS^{200}=4\alpha v^0v^2F',\quad {}_gS^{021}=(-)_gS^{201}=0, $$

$$ {}_gS^{022}=(-)_gS^{202}=2\alpha F'(2v^0v^1-1),\quad {}_gS^{023}=(-)_gS^{203}=0, $$

$$ {}_gS^{030}=(-)_gS^{300}=(-)4\alpha v^0v^3F',\quad {}_gS^{031}=(-)_gS^{301}=0, $$

$$ {}_gS^{032}=(-)_gS^{302}=0,\quad {}_gS^{033}=(-)_gS^{303}=2\alpha F'(1-2v^0v^1), $$

$F':=dF/dU$.

It is seen from the above results that the plane-fronted and plane gravitational waves *possess and carry* angular supermomentum.

APPENDIX C: ANGULAR SUPERMOMENTUM IN SPECIAL RELATIVITY

In Minkowski space–time equipped with Lorentzian coordinates ($x^0=ct, x^1=x, x^2=y, x^3=z$) we have from (1)

$$
\begin{aligned}
{}_mS^{ikl}(P;v^t) &= 2(2v^iv^p-\eta^{ip})\partial_p\hat{T}^{kl}-2(2v^kv^p-\eta^{kp})\partial_p\hat{T}^{il}\\
&= 2(\delta^{ip}\partial_p\hat{T}^{kl}-\delta^{kp}\partial_p\hat{T}^{il})\\
&= 2(\partial^i\hat{T}^{kl}-\partial^k\hat{T}^{il}) = 2(\partial_i\hat{T}^{kl}-\partial_k\hat{T}^{il}) = 2(\nabla_i\hat{T}^{kl}-\nabla_k\hat{T}^{il}), \qquad \text{(C1)}
\end{aligned}
$$

where $v^i \doteq \delta^i_0$ and $T^{ik}=T^{ki}$ are the components of the energy-momentum tensor and $\delta^{ik} := 2v^iv^k - \eta^{ik}$ is an auxilliary, positive-definite metric.

By comparison of the structure of the angular supermomentum tensor ${}_mS^{ikl}(P;v^t) = (-)_mS^{kil}(P;v^t)$ given by (C1) with the structure of the angular momentum (Carthesian) tensor of matter

$$
{}_mM^{ikl} = (-)_mM^{kil} = x^iT^{kl} - x^kT^{il}, \qquad \text{(C2)}
$$

one can easily derive a simple rule of construction of the tensor ${}_mS^{ikl}(P;v^t)$ from the angular momentum (Cartesian) tensor of matter ${}_mM^{ikl}$:

$$
x^i \Rightarrow 2\partial_i = 2\nabla_i. \qquad \text{(C3)}
$$

Of course, one can consider the tensor field

$$
{}_mS^{ikl}(x) \doteq 2[\partial_iT^{kl}(x) - \partial_kT^{il}(x)] = 2[\nabla_iT^{kl}(x) - \nabla_kT^{il}(x)]
$$

and define the global angular supermomentum ${}_mS^{ik} = (-)_mS^{ki}$ of matter by means of the following integrals:

$$
{}_mS^{ik} := \frac{1}{c}\int_{x^0=ct=\text{const}} {}_mS^{ik0}(x)\, dxdydz. \qquad \text{(C4)}
$$

If the matter energy-momentum tensor $T^{ik}=T^{ki}$ is diagonal (for example, for a perfect fluid), then we have from (C4) (as a trivial result)

$$
{}_mS^{12} = {}_mS^{13} = {}_mS^{23} = 0. \qquad \text{(C5)}
$$

Similar results can be obtained in this case for the spatial components ${}_mM^{12}$, ${}_mM^{13}$, ${}_mM^{23}$ of the global (orbital) angular momentum of matter

$$
{}_mM^{ik} := \frac{1}{c}\int_{x^0=ct=\text{const}} {}_mM^{ik0}\, dxdydz, \qquad \text{(C6)}
$$

namely,

$$
{}_mM^{12} = {}_mM^{13} = {}_mM^{23} = 0. \qquad \text{(C7)}
$$

[1] By ''standard general relativity'' we mean general relativity without any supplementary element like tetrads, second metric, or an arbitrary vector field.
[2] Called *canonical* because it can be obtained as canonical one from a suitable Lagrangian (see Ref. 3).

Scale symmetries of spherical string fluids

E. N. Glass[a] and J. P. Krisch
Department of Physics, University of Michigan, Ann Arbor, Michigan 48109

(Received 8 March 1999; accepted for publication 18 May 1999)

We consider homothetic maps in a family of spherical relativistic star models. A generalization of Vaidya's radiating metric provides a fluid atmosphere of radiation and strings. The similarity structure of the string fluid is investigated. © *1999 American Institute of Physics.* [S0022-2488(99)03308-3]

I. INTRODUCTION

Metric symmetries have always played a large role in the development of exact solutions to the Einstein field equations. Often a choice of metric symmetry is made based on an assumed symmetry of the matter distribution, i.e., spherical symmetry for astrophysical objects or cylindrical symmetry for a simple string.[1] A homothetic motion (homothety) describes the symmetry of scale transformations, and homothetic symmetry has been called ''similarity of the first kind'' by Cahill and Taub.[2] One must distinguish between *geometrical* and *physical* self-similarity. Geometrical similarity is a property of the space–time metric, whereas physical similarity is a property of the matter fields. These need not be equivalent and the relationship between them also depends on the nature of the matter. Yavuz and Yilmaz[3] recently investigated inheritance symmetries wherein the stress energy inherits metric symmetries of the type

$$\mathcal{L}_\xi g_{ab} = 2\Psi g_{ab},$$

where $\mathcal{L}_\xi$ is the Lie derivative along the vector ξ. Some of the possibilities are

$\Psi = \Psi(x^a)$, ξ is a conformal Killing vector,

$\Psi = 1$, ξ is a homothetic vector,

$\Psi = 0$, ξ is a Killing vector.

Carter and Henriksen[4] have introduced the idea of *kinematic self-similarity* in the context of relativistic fluid mechanics and an extended analysis has been given by Coley.[5] A kinematic self-similarity vector satisfies the conditions

$$\mathcal{L}_\xi u_a = \text{const}\, u_a,$$

$$\mathcal{L}_\xi h_{ab} = 2h_{ab},$$

where $h_{ab} = g_{ab} - u_a u_b$ is the first fundamental form of the three-spaces orthogonal to u^a. The case const$\neq 1$ is called ''similarity of the second kind.''

In this work we apply the ideas of scaling and homothety to a string fluid atmosphere. Since our primary interest is in the extended Schwarzschild mass function $m(u,r)$ and the related string atmosphere, we apply scaling to the mass in two different ways. First, we assume diffusive mass transport and investigate the symmetries of the diffusion equation and second, we investigate the scaling properties of the metric and from those derive mass transport equations.

In Sec. II we briefly describe the Schwarzschild string fluid atmosphere. Section III studies the symmetry map which takes the diffusion equation to an ordinary differential equation. New

[a]Permanent address: Physics Department, University of Windsor, Ontario N9B 3P4, Canada.

diffusion solutions are found. Geometric symmetries, homothetic and conformal, are developed in Sec. IV. Mass transport is discussed in Sec. V. One of the results of the homothetic analysis are new self-similar solutions to the Einstein equations.

Our sign conventions are $2A_{c;[ab]}=A_e R^e{}_{cab}$, and $R_{ab}=R^e{}_{abe}$. Latin indices range over $(0,1,2,3)=(u,r,\vartheta,\varphi)$. Overdots abbreviate $\partial/\partial u$, and primes abbreviate $\partial/\partial r$. Overhead carets denote unit vectors. We use units where $G=c=1$. Einstein's field equations are $G_{ab}=-8\pi T_{ab}$, and the metric signature is $(+,-,-,-)$.

II. STRING FLUID ATMOSPHERE

Recently, Glass and Krisch[6,7] showed that there can be a spherically symmetric string fluid atmosphere outside a Schwarzschild horizon. The space–time metric is

$$ds^2_{\mathrm{GK}}=A\,du^2+2\,du\,dr-r^2(d\vartheta^2+\sin^2\vartheta\,d\varphi^2), \tag{1}$$

where $A=1-2m(u,r)/r$. Initially $m(u,r)=m_0$ provides the vacuum Schwarzschild solution in the region $r>2m_0$. The metric can be written in a natural basis as

$$g^{\mathrm{GK}}_{ab}=\hat{v}_a\hat{v}_b-\hat{r}_a\hat{r}_b-\hat{\vartheta}_a\hat{\vartheta}_b-\hat{\varphi}_a\hat{\varphi}_b, \tag{2}$$

where the unit vectors are defined by

$$\hat{v}_a dx^a=A^{1/2}\,du+A^{-1/2}\,dr,\quad \hat{v}^a\partial_a=A^{-1/2}\partial_u, \tag{3a}$$

$$\hat{r}_a\,dx^a=A^{-1/2}\,dr,\quad \hat{r}^a\partial_a=A^{-1/2}\partial_u-A^{1/2}\partial_r, \tag{3b}$$

$$\hat{\vartheta}_a\,dx^a=r\,d\vartheta,\quad \hat{\vartheta}^a\partial_a=-r^{-1}\partial_\vartheta, \tag{3c}$$

$$\hat{\varphi}_a\,dx^a=r\sin\vartheta\,d\varphi,\quad \hat{\varphi}^a\partial_a=-(r\sin\vartheta)^{-1}\partial_\varphi. \tag{3d}$$

$\hat{v}^a$ is hypersurface-orthogonal with h_{ab} the first fundamental form of the hypersurface,

$$h_{ab}dx^a dx^b=(g^{\mathrm{GK}}_{ab}-\hat{v}_a\hat{v}_b)dx^a dx^b=-A^{-1}dr^2-r^2(d\vartheta^2+\sin^2\vartheta\,d\varphi^2). \tag{4}$$

The kinematics of the $\hat{v}^a$ flow are described by

$$\hat{v}^a_{;b}=a^a\hat{v}_b+\sigma^a{}_b-(\Theta/3)(\hat{r}^a\hat{r}_b+\hat{\vartheta}^a\hat{\vartheta}_b+\hat{\varphi}^a\hat{\varphi}_b), \tag{5}$$

where

$$a^a=[\dot{m}/r+A\partial_r(m/r)]A^{-3/2}\hat{r}^a, \tag{6a}$$

$$\sigma^a{}_b=(\Theta/3)(-2\hat{r}^a\hat{r}_b+\hat{\vartheta}^a\hat{\vartheta}_b+\hat{\varphi}^a\hat{\varphi}_b), \tag{6b}$$

$$\Theta=(\dot{m}/r)A^{-3/2}. \tag{6c}$$

The string distribution is described by a string bivector Σ_{ab}. Spherical symmetry demands that the averaged string bivector will describe a world-sheet in either the (u,r) or the (ϑ,φ) plane. The string bivector is timelike and given by

$$\Sigma^{ac}=\hat{r}^a\hat{v}^c-\hat{r}^c\hat{v}^a, \tag{7}$$

where $\Sigma^{ac}\Sigma_c{}^b=\hat{v}^a\hat{v}^b-\hat{r}^a\hat{r}^b$. The two-surfaces spanned by Σ_{ab} are orthogonally transitive to the two-surfaces spanned by the dual bivector

$$\Sigma^*_{ab}=\hat{\vartheta}_a\hat{\varphi}_b-\hat{\vartheta}_b\hat{\varphi}_a, \tag{8}$$

which follows from the Frobenius surface-forming condition satisfied by Σ_{ab}. It is also true that $\Sigma_a^{*c}\Sigma_{cb}^{*}=\hat{\vartheta}_a\hat{\vartheta}_b+\hat{\varphi}_a\hat{\varphi}_b$.

The Einstein tensor computed from (1) can be written as a two-fluid system $G_{ab}^{\text{null}}+G_{ab}^{\text{matter}}$.

$$G_{ab}=(2\dot{m}/r^2)l_a l_b-(2m'/r^2)(\hat{v}_a\hat{v}_b-\hat{r}_a\hat{r}_b)+(m''/r)(\hat{\vartheta}_a\hat{\vartheta}_b+\hat{\varphi}_a\hat{\varphi}_b), \tag{9}$$

where $l_a dx^a=du$. The Einstein field equations $G^a{}_{b;a}=0$ are satisfied for arbitrary $m(u,r)$.

In Glass and Krisch[6,7] mass transport was modeled by diffusion, and the diffusion equation used is given by

$$\dot{\rho}=\mathcal{D}r^{-2}\partial_r(r^2\partial_r\rho), \tag{10}$$

where $\mathcal{D}$ is the positive coefficient of self-diffusion (taken to be constant).

III. SIMILARITY MAP OF THE DIFFUSION EQUATION

There is a similarity technique explained by Bluman and Cole[8] that maps the diffusion equation into an ordinary differential equation. Our primary interest is in the Schwarzschild mass function $m(u,r)$. New functional solutions for $m(u,r)$ are new solutions to the field equations for the parameter extended radiating atmosphere. The behavior of $m(u,r)$ describes the string fluid atmosphere beyond the Schwarzschild horizon through the relations $\dot{m}=4\pi\mathcal{D}r^2\rho'$ and $4\pi\rho=m'/r^2$. The mass function obeys a diffusion equation

$$\dot{m}=\mathcal{D}r^2\partial_r(r^{-2}\partial_r m) \tag{11}$$

with homogeneous solution $m_{\text{hom}}(r)=m_0+\frac{4}{3}\pi r^3\rho_0$ which can be added to each time-dependent solution.

The similarity technique (for a fully general analysis see Bluman and Kumei[9]) requires one to introduce an independent dimensionless variable. A standard choice in diffusion problems is the Boltzmann transformation:[10]

$$\eta=r(4\mathcal{D}u)^{-1/2}. \tag{12}$$

[Note that as a mapping from (u,r) to $(u^{-1/2},\eta)$ the Jacobian is singular implying a breakdown of the $1-1$ mapping along r.] The argument of the equation, $m(u,r)$, is replaced by a dimensionless function $F(\eta)$: We look for a general solution of the form

$$m(u,r):=c_0 r^\alpha u^\beta F(\eta). \tag{13}$$

The constant c_0 is intended to map the dimensions of $r^\alpha u^\beta$ to mass for arbitrary constants α and β. Upon substituting Eq. (13) into the diffusion equation (11) we obtain the ordinary differential equation

$$F_{\eta\eta}+2[(\alpha-1)\eta^{-1}+\eta]F_\eta+[\alpha(\alpha-3)\eta^{-2}-4\beta]F=0, \tag{14}$$

where F_η abbreviates $dF/d\eta$.

There are many analytic solutions of Eq. (14) which depend on the values of α and β. The choice $\alpha=\beta=0$ has the differential equation $F_{\eta\eta}+2(\eta-1/\eta)F_\eta=0$ with solution

$$F(\eta)=k_0+k_1[-\eta e^{-\eta^2}+(\sqrt{\pi}/2)\text{erf}(\eta)], \tag{15}$$

where $\text{erf}(\eta):=(2/\sqrt{\pi})\int_0^\eta \exp(-s^2)ds$, $\lim_{\eta\to 0}\text{erf}(\eta)=2\eta/\sqrt{\pi}$. This is the mass solution given in Eq. (40) of Glass and Krisch[7] (with $k_0=0$ and with the homogeneous solution m_{hom} added). At fixed time u, it describes a mass with value $m_{\text{hom}}+c_0k_1$ as $\eta\to\infty$. At late times c_0k_1 is radiated away. There is no length scale in this description so the m_{hom} atmosphere is unbounded.

Other choices can be made, for example $\alpha=n$, $\beta=-n/2$. This choice has $\text{const}\times r^n u^{-n/2}=\eta^n$ and one can solve Eq. (14) or see directly from Eq. (13) that

$$F(\eta)=\eta^{-n}.$$

If we write $F(\eta)=\eta^{-n}H(\eta)$ then $H(\eta)$ satisfies the case $\alpha=\beta=0$ and we have a new family of solutions parametrized by n:

$$F(\eta)=\eta^{-n}[k_0+k_1[-\eta e^{-\eta^2}+(\sqrt{\pi}/2)\text{erf}(\eta)]]. \tag{16}$$

Solution (15) is included here when $n=0$.

IV. SYMMETRIES

Because the string fluid naturally lives on a two-dimensional world sheet, the question of the symmetries of these two-dimensional subspaces is interesting. We examine how the mass distribution and stress energy content reflect the separate two-surface symmetries

$$\begin{aligned} \mathcal{L}_\xi(\hat{v}_a\hat{v}_b-\hat{r}_a\hat{r}_b)&=2\mu(\hat{v}_a\hat{v}_b-\hat{r}_a\hat{r}_b),\\ \mathcal{L}_\xi(\hat{\vartheta}_a\hat{\vartheta}_b+\hat{\varphi}_a\hat{\varphi}_b)&=2\nu(\hat{\vartheta}_a\hat{\vartheta}_b+\hat{\varphi}_a\hat{\varphi}_b). \end{aligned} \tag{17}$$

For similarity of the second kind, the map action must be

$$\begin{aligned} \mathcal{L}_\xi\hat{v}_a&=\gamma\hat{v}_a, \quad \gamma\neq 1,\\ \mathcal{L}_\xi\hat{r}_a&=\hat{r}_a,\\ \mathcal{L}_\xi(\hat{\vartheta}_a\hat{\vartheta}_b+\hat{\varphi}_a\hat{\varphi}_b)&=2(\hat{\vartheta}_a\hat{\vartheta}_b+\hat{\varphi}_a\hat{\varphi}_b). \end{aligned} \tag{18}$$

A. Homothetic map

The similarity vector which preserves the distinct two-surfaces of the matter distribution in Eq. (17) is

$$\xi^a\partial_a=[\nu u_0+(2\mu-\nu)u)]\partial_u+\nu r\partial_r, \tag{19}$$

with kinematic transformations

$$\mathcal{L}_\xi\hat{v}_a=\mu\hat{v}_a, \quad \mathcal{L}_\xi\hat{r}_a=\mu\hat{r}_a, \tag{20a}$$

$$\mathcal{L}_\xi\hat{\vartheta}_a=\nu\hat{\vartheta}_a, \quad \mathcal{L}_\xi\hat{\varphi}_a=\nu\hat{\varphi}_a, \tag{20b}$$

when the metric function A satisfies $(\kappa:=2\mu/\nu-1)$

$$\psi\dot{A}/A+rA'/A+\kappa-1=0, \tag{21}$$

with $\psi(u):=u_0+\kappa u$. The constraint (21) requires the mass function to have the form

$$r-2m(u,r)=\psi^{(2-\kappa)/\kappa}f(\psi/r^\kappa), \tag{22}$$

where f is an arbitrary function.

If $\mu=\nu=\kappa=1$ then the map is homothetic with $\mathcal{L}_\xi g_{ab}=2g_{ab}$.

B. Another homothetic map

The case $\kappa=0$ requires a separate solution. The metric function A satisfies

$$u_0\dot{A}/A+rA'/A=1. \tag{23}$$

Constraint (23) has the integral

$$r-2m(u,r)=r_1 e^{2u/u_0}\tilde{f}(e^{u/u_0}r_0/r) \tag{24}$$

with $\tilde{f}$ an arbitrary function. When $\nu=1$ and $\mu=1/2$ the u dependence is eliminated from ξ^a and the transformation acts on the (ϑ,φ) two-surfaces homothetically

$$\mathcal{L}_\xi(\hat{\vartheta}_a\hat{\vartheta}_b+\hat{\varphi}_a\hat{\varphi}_b)=2(\hat{\vartheta}_a\hat{\vartheta}_b+\hat{\varphi}_a\hat{\varphi}_b)$$

but preserves the scale of the string two-surfaces,

$$\mathcal{L}_\xi(\hat{v}_a\hat{v}_b-\hat{r}_a\hat{r}_b)=\hat{v}_a\hat{v}_b-\hat{r}_a\hat{r}_b\,.$$

C. Interpreting the scale parameter

Under the action of the homothety $\xi^a\partial_a=(u_0+u)\partial_u+r\partial_r$ the acceleration of $\hat{v}^a$, given in Eq. (6a), has the following Lie derivative: with $a^b=a\hat{r}^b$, $a:=[\dot{m}/r+A\partial_r(m/r)]A^{-3/2}$,

$$\mathcal{L}_\xi a^b=\left(\frac{a_\xi}{a}-1\right)a^b, \tag{25}$$

where $a_\xi:=[(u_0+u)\partial_u+r\partial_r]a$. Similarly the rate-of-shear given in Eqs. (6b) and (6c) obeys

$$\mathcal{L}_\xi\sigma^a{}_b=\left(\frac{\Theta_\xi}{\Theta}-1\right)\sigma^a{}_b\,, \tag{26}$$

where $\Theta_\xi=[(u_0+u)\partial_u+r\partial_r]\Theta$.

There is no information to be gained by analyzing the scaling properties of the Raychaudhuri equation

$$a^b_{;b}-\sigma_{ab}\sigma^{ab}-\Theta^2/3-\Theta_{,a}\hat{v}^a=-R_{ab}\hat{v}^a\hat{v}^b,$$

since it is identically satisfied by g^{GK}_{ab}.

D. Conformal map

The case $\mu=\nu=\kappa=1$, with $\psi=u_0+u$, has an interesting conformal symmetry. We see from Eq. (22) that $A=(\psi/r)f(\psi/r)=F(\psi/r)$. Metric (1) is written as

$$ds^2_{\mathrm{GK}}=F(\psi/r)du^2+2\,du\,dr-r^2\,d\Omega^2. \tag{27}$$

We define a new coordinate $y:=r/\psi$ and rewrite (27) as

$$ds^2_{\mathrm{GK}}=[F(1/y)+2y]du^2+2\psi\,du\,dy-y^2\psi^2\,d\Omega^2. \tag{28}$$

Now we factor out ψ^2 and introduce a new time coordinate $dw:=du/\psi$ to obtain

$$ds^2_{\mathrm{GK}}=\psi^2[(F+2y)dw^2+2\,dw\,dy-y^2\,d\Omega^2].$$

Upon choosing $F(1/y)=1-2M(y)/y-2y$, $M(y)$ arbitrary, we have

$$ds^2_{\rm GK}=e^{2w}[(1-2M/y)dw^2+2\,dw\,dy-y^2d\Omega^2]. \tag{29}$$

The argument above shows that the similarity transformation generated by vector $\xi^a\partial_a=(u_0+u)\partial_u+r\partial_r$ conformally relates the radiating string atmosphere of metric (1) to a previously identified family of static string atmospheres,[7] i.e.,

$$\mathcal{L}_\xi g^{\rm GK}_{ab}=2e^{2w}g^{\rm static}_{ab}. \tag{30}$$

E. Similarity of the second kind

For similarity vector $\xi^a\partial_a=(u+u_0)\partial_u+r\partial_r$ the metric function A must satisfy

$$(u_0+u)\dot{A}/A+rA'/A=\gamma-1. \tag{31}$$

Equation (31) has solution

$$r-2m(u,r)=r_2(u_0+u)^\gamma h[(u_0+u)/r], \tag{32}$$

where h is an arbitrary function and $\gamma\neq 1$.

V. MASS TRANSPORT

The mass functions found by similarity analysis obey certain transport equations. Most of the transport equations have the form of the ''telegrapher'' equation. This can describe dispersive and lossy electromagnetic wave motion.[11] Some forms have been interpreted by Kac[12] as a random Poisson process. Mass transport through the atmosphere is affected by the homothetic symmetries. The transport equations can be constructed from the similarity solutions of Sec. IV.

A. $\kappa=0$ homothety

Differentiation of Eq. (23), a constraint on the mass function, yields an inhomogeneous wave equation

$$\ddot{A}-3\dot{A}/u_0-(r/u_0)^2\nabla^2A=-2A/u_0^2. \tag{33}$$

B. $\kappa=1$ homothety

Recall metric function $A=1-2m(u,r)/r$. One can see directly from Eq. (22) that $A=(\psi/r)f(\psi/r)=F(\psi/r)$ with $\psi=u_0+u$. A, and thus m/r, satisfies a wave equation on the flat tangents to the $\hat{v}_a\hat{v}_b-\hat{r}_a\hat{r}_b$ two-spaces. Defining $\tau=\ln(\psi)$ and $z=\ln(r)$ we have

$$A=F(\tau-z). \tag{34}$$

It is clear that A, generated by homothety $\xi^a\partial_a=(u_0+u)\partial_u+r\partial_r$, satisfies the wave equation

$$\frac{\partial^2A}{\partial\tau^2}-\frac{\partial^2A}{\partial z^2}=0. \tag{35}$$

Alternatively, we can find a wave equation on the curved manifold by writing

$$\partial F/\partial u=(1/r)\hat{F},\quad \partial F/\partial r=-(\psi/r^2)\hat{F}$$

where $\hat{F}$ is the derivative of F with respect to its argument. It follows that

$$\ddot{A}=(1/r^2)\hat{\hat{F}},\quad (r^2A')'=(\psi^2/r^2)\hat{\hat{F}}.$$

Thus

$$\ddot{A}-v_s^2\nabla^2 A=0 \tag{36}$$

where $\nabla^2=r^{-2}(\partial/\partial r)r^2(\partial/\partial r)$ and $v_s=r/\psi$. The wave speed varies with u and r.

If v_s were constant v, then Eq. (36) would have the general solution

$$A(u,r)=\frac{f(r-vu)}{r}+\frac{g(r+vu)}{r} \tag{37}$$

in terms of two arbitrary functions f and g. Substituting $A=f/r$ into (36) one finds

$$(v^2-v_s^2)\hat{\hat{f}}=0.$$

This reflects ''damped, yet relatively undistorted, progressing wave solutions,'' [13] a special case of the telegrapher's equation.

For new time coordinate $t\mapsto u+u_0=e^{t/t_0}$ and with $A_t:=\partial A/\partial t$, Eq. (36) transforms to

$$A_{tt}-A_t/t_0-(r/t_0)^2\nabla^2 A=0. \tag{38}$$

C. $\kappa \geqslant 2$ two-surface symmetry

With $A=1-2m(u,r)/r=\psi^{(2-\kappa)/\kappa}r^{-1}f(\psi/r^\kappa)$ we can write

$$A=r^{1-\kappa}H(\psi/r^\kappa),\quad H:=(\psi/r^\kappa)^{(2-\kappa)/\kappa}f.$$

Differentiation yields

$$\ddot{A}=\kappa^2 r^{1-3\kappa}\hat{H}$$

and

$$(r^2A')'=(1-\kappa)(2-\kappa)r^{1-\kappa}H-3\kappa(1-\kappa)\psi r^{1-2\kappa}\hat{H}+\kappa^2\psi^2\hat{H}.$$

It follows that

$$(r^2A')'=(1-\kappa)(2-\kappa)A-3(1-\kappa)\psi\dot{A}+\psi^2\ddot{A}.$$

Transforming to a new time coordinate $e^{t/t_0}=\psi=u_0+\kappa u$ yields the inhomogeneous wave equation

$$A_{tt}+(2-3/\kappa)A_t/t_0-(r/t_0)^2\nabla^2 A=(1-1/\kappa)(2/\kappa-1)A/t_0^2, \tag{39}$$

where $A_t:=\partial A/\partial t$.

D. Similarity of the second kind

Differentiation of the constraint on metric function A, Eq. (31), yields the homogeneous wave equation

$$\ddot{A}+v_s\left(\frac{\gamma-1}{r}\right)\dot{A}-v_s^2\nabla^2 A+v_s^2\left(\frac{\gamma-1}{r^2}\right)(rA')=0, \tag{40}$$

where $v_s=r/(u_0+u)$ and $\gamma\neq 1$. As above, the wave speed varies with u and r.

VI. DISCUSSION

Similarity is physically important since scaling behavior may offer clues about possible relationships between macroscopic and microscopic physics (i.e., Ehrenfest's classical adiabatic invariants and quantization rules). Using scaling, one can model long term behaviors with single solutions to the field equations in which only the scaling variable changes as a function of time. Self-similar behavior is an important aspect of many evolutionary processes both linear and nonlinear.[14] The simplifications of the nonlinear field equations of general relativity are a good example of the value of similarity methods. In addition, we have seen that the special homothety of fluid two-surfaces can be associated with self-similar behavior in the fluid parameters.

In this paper our primary interest is in the extended Schwarzschild mass function $m(u,r)$ and the related string atmosphere. We applied scaling to the mass in two different ways. First, we assumed a mass transport and investigated the scaling properties and second, we investigated the scaling properties of the metric and from those derived mass transport equations. In the first case, assuming diffusive mass transport with a Boltzmann scaling variable, we developed a new family of diffusive mass functions and the associated family of string atmospheres. In the second case, we examined the scaling symmetries of the orthogonal two-surfaces (u,r) and (ϑ,φ). A two-parameter similarity generator acted separately on the (u,r) two-surface containing the string fluid and the orthogonal (ϑ,φ) two-surface subject to the mass parameter obeying a constraining first order differential equation. The similarity map affects all metric components equally when the parameters are both equal to 1. For this case, where the transformation is a homothety for the entire space–time, the mass constraint conformally relates a radiating string atmosphere and a static atmosphere. Other parameter choices could be made, for example, the choices which remove time dependence from the generator. This time independent mapping acts on the (ϑ,φ) two-surface homothetically while preserving the scale of the (u,r) string two-surface. For all the parameter choices associated with the scaling action of the generator, a mass transport equation is implied. This equation is, in general, the telegrapher's equation. The telegrapher's equation and the diffusion equation have both macroscopic and microscopic interpretations.[12,15,16] The appearance of both of these mass transport equations in conjunction with the description of a macroscopic string fluid atmosphere is suggestive of the quantum nature of the fundamental string fluid bits. The classical continuum fluid describes only the averaged fluid behavior, with the mass transport equations suggesting the underlying quantum nature of the fluid.

(Received 26 January 1999; accepted for publication 7 April 1999)

It is shown that the Levi-Civita metric can be obtained from a family of the Weyl metric, the γ metric, by taking the limit when the length of its Newtonian image source tends to infinity. In this process a relationship appears between two fundamental parameters of both metrics.
[S0022-2488(99)02507-4]

I. INTRODUCTION

One of the most interesting metrics of the family of Weyl solutions[1] is the so-called γ metric.[2,3] This metric, which is also known as the Zipoy–Voorhees metric,[4] is continuously linked to the Schwarzschild space–time through one of its parameters and corresponds to a solution of the Laplace equation in cylindrical coordinates. Its Newtonian image source[5] is given by a finite rod of matter. For a particular value of the mass density of the rod, the metric becomes spherically symmetric (Schwarzschild metric).

In this article we show that by extending the length of the rod to infinity we obtain the Levi-Civita space–time. At the same time a link is established between the parameter $\gamma/2$, measuring the mass density of the rod in the γ metric, and the parameter σ, which is thought to be related to the linear energy density of the source of the Levi-Civita space–time.[5] Since σ is the real source, not the Newtonian image source, and $\gamma/2$ measures the line mass density of the Newtonian image source, not of the real source, our result illustrates further the difficulties appearing in the interpretation of the Levi-Civita metric as representing an infinite line mass of density σ.[6]

In Sec. II we describe the γ metric. In Sec. III we show that it has a limit on the Levi-Civita space–time. In Sec. IV some other limits are studied in order to build a limiting diagram for the γ metric. Finally Sec. V presents our conclusions.

II. THE γ METRIC

In cylindrical coordinates, static axisymmetric solutions to Einstein's equations are given by the Weyl metric[1]

$$ds^2=e^{2\lambda}\,dt^2-e^{-2\lambda}[e^{2\mu}(d\rho^2+dz^2)+\rho^2\,d\phi^2], \tag{2.1}$$

[a)]Postal address: Apartado 80793, Caracas 1080A, Venezuela; electronic mail: laherrera@telcel.net.ve
[b)]Electronic mail: fmpaiva@symbcomp.uerj.br
[c)]Electronic mail: nos@lacesm.ufsm.br

with

$$\lambda_{,\rho\rho}+\rho^{-1}\lambda_{,\rho}+\lambda_{,zz}=0, \tag{2.2}$$

and

$$\mu_{,\rho}=\rho(\lambda_{,\rho}^2-\lambda_{,z}^2), \tag{2.3}$$

$$\mu_{,z}=2\rho\lambda_{,\rho}\lambda_{,z}, \tag{2.4}$$

where a comma denotes partial derivation. Observe the most amazing fact, as Synge writes,[1] that (2.2) is just the Laplace equation for λ in Euclidean space. The γ metric is defined by[2]

$$e^{2\lambda}=\left[\frac{R_1+R_2-2m}{R_1+R_2+2m}\right]^{\gamma}, \tag{2.5}$$

$$e^{2\mu}=\left[\frac{(R_1+R_2+2m)(R_1+R_2-2m)}{4R_1R_2}\right]^{\gamma^2}, \tag{2.6}$$

where

$$R_1^2=\rho^2+(z-m)^2, \quad R_2^2=\rho^2+(z+m)^2 \tag{2.7}$$

and γ is a constant. It is worth noticing that λ as given by (2.5) corresponds to the Newtonian potential of a line segment of mass density $\gamma/2$ and length $2m$, symmetrically distributed along the z axis. The particular case $\gamma=1$ corresponds to the Schwarzschild metric. This is more easily seen using Erez–Rosen coordinates,[4] given by

$$\rho^2=(r^2-2mr)\sin^2\theta, \quad z=(r-m)\cos\theta, \tag{2.8}$$

which yields the line element[2]

$$ds^2=F\,dt^2-F^{-1}[G\,dr^2+H\,d\theta^2+(r^2-2mr)\sin^2\theta\,d\phi^2], \tag{2.9}$$

where

$$F=\left(1-\frac{2m}{r}\right)^{\gamma}, \tag{2.10}$$

$$G=\left(\frac{r^2-2mr}{r^2-2mr+m^2\sin^2\theta}\right)^{\gamma^2-1}, \tag{2.11}$$

$$H=\frac{(r^2-2mr)^{\gamma^2}}{(r^2-2mr+m^2\sin^2\theta)^{\gamma^2-1}}. \tag{2.12}$$

Now, it is easy to check that $\gamma=1$ corresponds to the Schwarzschild metric. The total mass of the source is $M=\gamma m$,[2,3] and its quadrupole moment Q is given by

$$Q=\frac{\gamma}{3}M^3(1-\gamma^2), \tag{2.13}$$

so that $\gamma>1(\gamma<1)$ corresponds to an oblate (prolate) spheroid. We shall now show that *elongating* the Newtonian image source to infinity we obtain the Levi-Civita space–time. To achieve that, use will be made of the Cartan scalars. In Sec. III these scalars are obtained for the γ metric, and are compared to the corresponding quantities of the Levi-Civita metric in the limit $m\rightarrow\infty$.

III. THE LEVI-CIVITA LIMIT

Since the limit $m\rightarrow\infty$ taken on the γ metric in the form (2.1) diverges, we use the Cartan scalar approach to obtain a finite limit.[7,8]

It is known[9] that the so-called 14 algebraic invariants (and even all the polynomial invariants of any order) are not sufficient for locally characterizing a space–time, in the sense that two metrics may have the same set of invariants and not be equivalent. As an example, all these invariants vanish for both Minkowski and plane-wave[9] space–times and they are not the same. A complete local characterization of space–times may be done by the Cartan scalars. Briefly, the Cartan scalars are the components of the Riemann tensor and its covariant derivatives (up to possibly the tenth order) calculated in a constant frame.[10,9,11,12]

Therefore it is possible to establish unambiguously the local equivalence between two given metrics by comparing their respective Cartan scalars, in other words: Two metrics are equivalent if and only if there exist coordinate and Lorentz transformations which transform the Cartan scalars of one of the metrics into the Cartan scalars of the other. It should be stressed that, although the Cartan scalars provide a local characterization of the space–time, global properties such as topological defects do not probably appear in them.

In practice, the Cartan scalars are calculated with the Karlhede algorithm,[11] using the spinorial formalism. For the purpose here, the relevant quantities are the Weyl spinor Ψ_A, and its first covariant symmetrized derivative $\nabla\Psi_{AB'}$, which represent the Weyl tensor and its covariant derivative. Due to the amount of calculations, the computer algebra systems SHEEP/CLASSI[10,9] and MAPLE were used throughout this section.

In order to calculate the Cartan scalars for the γ metric, we take the line element in spherical coordinates [Eq. (2.9)] written in the same tetrad basis used in Ref. 2. In the zeroth order we find that the Ricci spinor and curvature scalar vanish and the Weyl spinor satisfies the relation: $\Psi_0=\Psi_4$, $\Psi_1=-\Psi_3$, $\Psi_2\neq 0$. It can be easily shown that this corresponds to a Petrov type I metric, which therefore has no isotropies. For putting these Cartan scalars in a canonical form, two tetrad transformations are done, which in the spinorial formalism are given by

$$\frac{1}{\sqrt{2}}\begin{bmatrix} 1 & i \\ i & 1 \end{bmatrix}, \quad \begin{bmatrix} A & 0 \\ 0 & 1/A \end{bmatrix}. \tag{3.1}$$

The first transformation puts the zeroth-order Cartan scalars in the form: $\Psi_0'\neq 0$, $\Psi_1'=0$, $\Psi_2'\neq 0$, $\Psi_3'=0$, $\Psi_4'\neq 0$. The second transformation with $A=(\Psi_4'/\Psi_0')^{1/8}$ gives finally: $\Psi_0''=\Psi_4''$, $\Psi_1''=0$, $\Psi_2''\neq 0$, $\Psi_3''=0$, which is the canonical form for Petrov type I metrics.

We come out with two independent functions of the coordinates r and θ [Eqs. (3.2) and (3.3)]. So, up to zeroth order, the isometry group is of dimension $4-2=2$ (where 4 is the dimension of the space–time). Since the metric is independent of the coordinates t and ϕ, its isometry group is of dimension 2. Therefore, the first-order Cartan scalars will present no new information about isometries and the Karlhede algorithm ends in the first order, with the Ψ_A, and $\nabla\Psi_{AB'}$ in the canonical basis defined by the transformation (3.1).

Instead of calculating the first-order Cartan scalars in the canonical basis, for computational reasons they were calculated in the initial basis and afterwards transformed to the canonical basis. Finally, to have the Cartan scalars in the cylindrical coordinate system one has to invert the coordinate transformation from cylindrical to spherical given by Eq. (2.8) (this leads to $r=[\sqrt{(z-m)^2+\rho^2}+\sqrt{(z+m)^2+\rho^2}+2m]/2$ and $\cos\theta=[\sqrt{(z+m)^2+\rho^2}-\sqrt{(z-m)^2+\rho^2}]/2m$) and apply it to the Cartan scalars, remembering that they transform like scalars.

In the canonical basis, in cylindrical coordinates, the zeroth-order Cartan scalars of the γ metric [Eqs. (2.1) and (2.5)–(2.7)] are (dropping the primes):

$$\Psi_2 = \frac{e^{2\lambda}}{e^{2\mu}} \frac{m\gamma(R_1+R_2-2\gamma m)}{(R_1+R_2+2m)(R_1+R_2-2m)R_1R_2}, \tag{3.2}$$

$$\Psi_0 = \Psi_4 = -\Psi_2 \frac{\sqrt{f^2+g^2}}{2R_1R_2(R_1+R_2-2\gamma m)}, \tag{3.3}$$

where

$$\begin{aligned} f^2 = \{ & [(R_1-R_2-2m)(R_1-R_2+2m)\gamma^2 \\ & -(R_1+R_2+2m)(R_1+R_2-2m)](R_1+R_2) \\ & -2(R_1+R_2-6\gamma m)R_1R_2\}^2, \end{aligned} \tag{3.4}$$

$$g^2 = (\gamma^2-1)^2(R_1-R_2)^2(R_1+R_2+2m)(R_1+R_2-2m)(R_1-R_2+2m)(R_1-R_2-2m) \tag{3.5}$$

and R_1 and R_2 are given by Eq. (2.7). The first-order Cartan scalars are too long and will not be shown.

Note that the Cartan scalars depend only on the coordinates ρ and z, while the line element depends on these coordinates and the differentials of the four coordinates. Also, they transform like scalars while the metric components transform like tensor components. Finally, the metric usually has features that are due to the nonessential coordinates (like the singularity on the Schwarzschild horizon) while, on the other hand, since only the essential coordinates appear on the Cartan scalars, they do not present such problems. So, in principle, a coordinate system can be found which provides a well-behaved limit for the Cartan scalars while the metric still diverges. Due to this fact it is easier to investigate limits using the Cartan scalars rather than using the line element.

The first step is to investigate the limits using Ψ_2; later we shall investigate whether the other Cartan scalars share the same limits. After a lengthy but straightforward calculation the leading term in the series expansion of Ψ_2 as $m\to\infty$ is:

$$2^{-(\gamma-1)} m^{2(\gamma^2-\gamma)} \rho^{-2(\gamma^2-\gamma+1)} \gamma(1-\gamma), \tag{3.6}$$

which is either divergent or finite depending on the value of γ. Nevertheless, this expression suggests that a finite limit may arise for all values of γ if we define a new radial coordinate $\overline{\rho}$ by $m^{2(\gamma^2-\gamma)}\rho^{-2(\gamma^2-\gamma+1)} = \overline{\rho}^{-2(\gamma^2-\gamma+1)}$ that is,

$$\rho = 2^{\beta} m^{\alpha} \overline{\rho}, \tag{3.7}$$

where

$$\alpha = \frac{\gamma^2-\gamma}{\gamma^2-\gamma+1} \tag{3.8}$$

and

$$\beta = \frac{-\gamma}{\gamma^2-\gamma+1}. \tag{3.9}$$

The constant β was introduced to provide the correct power of 2 in the limiting Cartan scalar.

Indeed, noting that $-\frac{1}{3} \leqslant \alpha < 1$ and using Eq. (3.7) in Eq. (3.2), a lengthy but straightforward calculation shows that in the $\{t, \overline{\rho}, z, \phi\}$ coordinate system one has:

$$\lim_{m\to\infty} \Psi_2 = \tfrac{1}{2}\bar{\rho}^{-2(\gamma^2-\gamma+1)}\gamma(1-\gamma), \tag{3.10}$$

which is finite. Similarly, one finds that all Cartan scalars have a finite limit in this new coordinate system. The question now is to find out to which metric this set of Cartan scalars belongs. This is not a straightforward task, but fortunately, calling

$$\gamma = 2\sigma \tag{3.11}$$

and $\bar{\rho} = r$ we are led to following set of Cartan scalars:

$$\psi_2 = (1-2\sigma)\sigma r^{-2(4\sigma^2-2\sigma+1)}, \tag{3.12}$$

$$\psi_0 = \psi_4 = (4\sigma-1)\psi_2, \tag{3.13}$$

$$\nabla\psi_{01'} = \nabla\psi_{50'} = \sqrt{2}(8\sigma^2-4\sigma+1)(4\sigma-1)(2\sigma-1)\sigma r^{-3(4\sigma^2-2\sigma+1)}, \tag{3.14}$$

$$\nabla\psi_{10'} = \nabla\psi_{41'} = \sqrt{2}(4\sigma-1)(2\sigma-1)\sigma r^{-3(4\sigma^2-2\sigma+1)}, \tag{3.15}$$

$$\nabla\psi_{21'} = \nabla\psi_{30'} = \sqrt{2}(4\sigma^2-2\sigma+1)(2\sigma-1)\sigma r^{-3(4\sigma^2-2\sigma+1)}, \tag{3.16}$$

which are the Cartan scalars of the Levi-Civita space–time[13]

$$ds^2 = r^{4\sigma}\,dt^2 - r^{8\sigma^2-4\sigma}(dr^2+dz^2) - \frac{r^{2-4\sigma}}{a}\,d\phi^2. \tag{3.17}$$

This shows that in the $\{t,\bar{\rho},z,\phi\}$ coordinate system, the limit of the γ metric as $m\to\infty$ is locally the Levi-Civita metric, provided the radial coordinates $\bar{\rho}$ and r are identified and the parameter γ divided by 2 of the γ metric is identified with the density parameter σ of the Levi-Civita metric, i.e., Eq. (3.11) holds.

We use the word *locally* since the Cartan scalars provide a local characterization of the metric. Furthermore, there is a parameter a in the Levi-Civita metric which does not appear in its Cartan scalars since it is a topological defect and can be eliminated by a coordinate transformation. For studying the global properties of the limit one has to investigate the metric (or the line element) directly. In fact one may ask whether, using the $\{t,\bar{\rho},z,\phi\}$ coordinate system, the Levi-Civita limit can be obtained directly from the line element of the γ metric.

In the $\{t,\bar{\rho},z,\phi\}$ coordinate system, the γ metric may be written as

$$ds^2 = e^{2\lambda}\,dt^2 - e^{-2\lambda}e^{2\mu}2^{2\beta}m^{2\alpha}\,d\bar{\rho}^2 - e^{-2\lambda}e^{2\mu}\,dz^2 - e^{-2\lambda}2^{2\beta}m^{2\alpha}\bar{\rho}^2\,d\phi^2, \tag{3.18}$$

where λ and μ are expressed with the $\bar{\rho}$ coordinate. The limit of the component $g_{\bar{\rho}\bar{\rho}}$ is precisely the g_{rr} of the Levi-Civita metric but the other metric components diverge. Now, the divergences can be easily removed by similar transformations on the coordinates t, z, and ϕ, given by

$$t = 2^{-\beta(\gamma^2+1)}m^{-\beta}\bar{t}, \tag{3.19}$$

$$z = 2^{\beta}m^{\alpha}\bar{z}, \tag{3.20}$$

$$\phi = 2^{\beta\gamma^2}m^{\beta\gamma}\frac{1}{\sqrt{a}}\bar{\phi}. \tag{3.21}$$

In the $\{\bar{t},\bar{\rho},\bar{z},\bar{\phi}\}$ coordinate system the γ metric becomes:

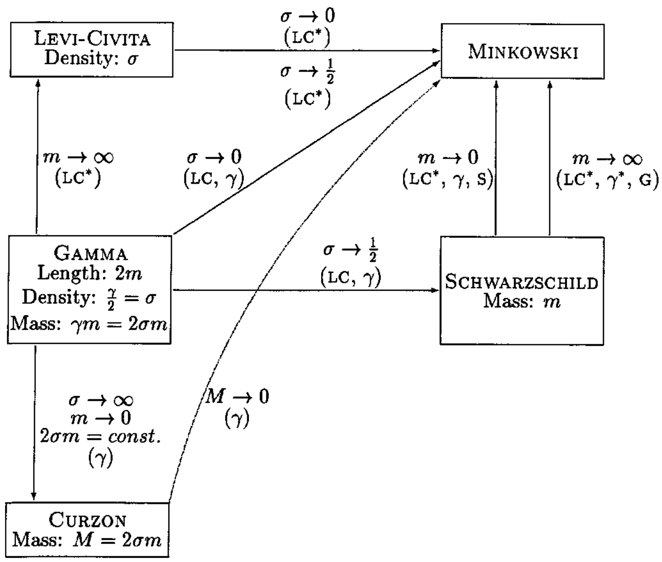

FIG. 1. Limiting diagram for the γ metric. In brackets are the coordinate systems where each limit works. γ means the original $\{t,\rho,z,\phi\}$ cylindrical coordinate system for the γ metric; LC means the Levi-Civita coordinate system $\{\bar{t},\bar{\rho},\bar{z},\bar{\phi}\}$, i.e., the γ coordinate system plus the coordinate transformation given by Eqs. (3.7) and (3.19)–(3.21); S means the usual Schwarszchild coordinates and G the Geroch coordinates first used to find the Minkowskian limit of Schwarzschild. The asterisk means that the limit is local, i.e., it was taken with the Cartan scalars and/or on the line element but a topological defect was found.

$$ds^2=e^{2\lambda}2^{-2(\gamma^2+1)\beta}m^{-2\beta}\,d\bar{t}^2-e^{-2\lambda}e^{2\mu}2^{2\beta}m^{2\alpha}\,d\bar{\rho}^2-e^{-2\lambda}e^{2\mu}2^{-2\beta}m^{-2\alpha}\,d\bar{z}^2$$
$$-e^{-2\lambda}2^{2(\beta+\gamma^2\beta)}m^{2(\alpha+\gamma\beta)}\bar{\rho}^2\frac{1}{a}\,d\bar{\phi}^2 \tag{3.22}$$

and its limit as $m\to\infty$ is precisely the Levi-Civita metric (3.17). The only drawback of this limit is the introduction of an infinite topological defect. In other words, the limit of the γ metric in the $\{\bar{t},\bar{\rho},\bar{z},\bar{\phi}\}$ coordinate system is the Levi-Civita metric only locally. This confirms the result we found previously with the Cartan scalars. Whether a coordinate system for the γ metric exists which provides a global limit into the Levi-Civita metric, i.e., with a finite topological defect, is still an open question.

IV. A LIMITING DIAGRAM FOR THE γ METRIC

We shall now study the limit we have just found, find other limits in the coordinate systems of Sec. III, and discuss some limits known in the literature in order to build the limiting diagram for the γ metric shown in Fig. 1.

A. Limits in the Schwarzschild coordinates

In the usual Schwarzschild coordinates, in the limit $m\to0$, the Schwarzschild line element tends to Minkowski. The limit $m\to\infty$ diverges. This can be easily checked by hand or from the Cartan scalars.[7]

B. The Geroch limits

In 1969 Geroch[14] showed that in the coordinate system (Geroch coordinates) defined by

$$x=r+m^{4/3},\quad \rho=m^{4/3}\theta,\quad t'=t,\quad \varphi'=\varphi, \tag{4.1}$$

the limit of the Schwarzschild metric as $m\rightarrow\infty$ is the Minkowski space–time. He also presented a coordinate system where the limit is a Kasner space–time. These results show that the limit of a space–time as some parameter goes to infinity is a coordinate-dependent process.

Later, Paiva, Rebouças, and MacCallum[7] reobtained these limits by using the Cartan scalar technique, and extended the results presenting new limits of the Schwarzschild metric and developing an approach to find all limits of a given space–time (see also Refs. 8, 15, and 16)

C. Limits in the γ coordinates

We shall call γ coordinates the original $\{t,\rho,z,\phi\}$ cylindrical coordinates used for the γ metric [Eqs. (2.1) and (2.5)–(2.7)]. Its is known[17] that in this coordinate system the limit $\gamma\rightarrow\infty$, $m\rightarrow 0$ with $\gamma m=\text{const}$ leads to the Curzon metric and, as shown in Sec. II, the limit $\gamma\rightarrow 1$ leads to Schwarzschild. Besides one can easily see that as $\gamma\rightarrow 0$ the γ metric tends to Minkowski. The coordinate systems in which the Curzon and Schwarzschild metrics are expressed when obtained as limit of the γ metric will also be called γ coordinates.

In the γ-coordinate system, the line elements of Curzon (see Ref. 17) and Schwarzschild tend to Minkowski as $m\rightarrow 0$ (this arises directly from the line element). Although the Schwarzschild line element in γ coordinates diverges as $m\rightarrow\infty$ it can be shown that its Cartan scalars (those of the γ metric with $\gamma=1$) tend to zero, which is locally Minkowski.

D. Limits in the LC coordinates

We have shown that in the coordinate system $\{\bar{t},\bar{\rho},\bar{z},\bar{\phi}\}$ the limit, as $m\rightarrow\infty$, of the γ metric is locally the Levi-Civita metric. This new coordinate system will therefore be called Levi-Civita coordinates or LC coordinates for short, for both the γ metric and the Levi-Civita metric (although the metric equivalence is only local). Coincidentally, this is the usual coordinate system for the Levi-Civita metric.

As $\gamma\rightarrow 0$ or $\gamma\rightarrow 1$, the γ metric in LC coordinates tends to Minkowski or Schwarzschild, as can be seen directly from the line element (3.22). The last one giving Schwarzschild in LC coordinates.

The limits of the Levi-Civita metric as $\sigma\rightarrow 0$ and $\sigma\rightarrow 1/2$ giving locally Minkowski can be directly found from the line element in LC coordinates.

As $m\rightarrow 0$, the Schwarzschild line element in LC coordinates diverge but its Cartan scalars tend to 0, i.e., locally Minkowski.

Finally, the LC-coordinate system turns out to be a new coordinate system (Geroch coordinates is the old one) where the Schwarzschild line element tends to Minkowski as $m\rightarrow\infty$. The equivalence is local since an infinite topological defect appears. This limit can also be done with the Cartan scalars.

One could point out that it is not proved that all limits found with the line element can be found with the Cartan scalars and vice-versa. Nevertheless, for our purposes, i.e., finding some specific limits, this proof is not necessary. In fact, both the line element and Cartan scalars are equivalent local representations of the space–time according to Cartan's equivalence theorem.[12] Therefore, limits found with one or the other are limits of the space–time. As a matter of fact, the Levi-Civita limit of the γ metric was found here using both approaches.

V. CONCLUSION

We have seen so far that by extending the length of the Newtonian image source of the γ metric to infinity we arrive at the Levi-Civita space–time. The amazing fact is that the finite rod does not represent the *real* source of the γ metric (it is just its Newtonian image source), whereas the infinite line singularity is thought to be the real source of the LC space–time. The link between the parameters γ and $\sigma(\gamma=2\sigma)$ appearing in the limiting process is quite consistent with previous results,[14,7] in the sense that the Schwarzschild metric ($\gamma=1$) leads (locally) to Minkowski space–

time as $m \to \infty$ and the Levi-Civita metric ($m \to \infty$) leads (locally) also to Minkowski if $\sigma = 1/2$. It should be interesting to find out if restrictions on σ, based on the existence of timelike circular geodesics[18] in LC ($\sigma < 1/4$), appear in the γ metric.

We shall now proceed to the interpretation of the limiting diagram of the γ metric (Fig. 1). In order to build this diagram, we introduced a new coordinate system for this metric (the LC coordinates) and found two new limits as $m \to \infty$: Schwarzschild $\to$ Minkowski in γ coordinates and LC coordinates and γ metric $\to$ Levi-Civita in LC coordinates.

One notices, that as it is presented, the diagram is quite consistent. It supports the current interpretations of σ as being the density in the Levi-Civita metric; $\gamma/2$ and $2m$, respectively, as the density and the length in the γ metric; m as the mass in the Schwarzschild solution, and M as the mass in the Curzon solution.

Note that from the γ metric one can reach Minkowski either through Levi-Civita by making $m \to \infty$ and then $\sigma \to 1/2$ or through Schwarzschild by making $\sigma \to 1/2$ and then $m \to \infty$. The limit $\sigma \to 0$ is similar; the difference being that, since the mass in the γ metric is $2\sigma m$, the limit $\sigma \to 0$ leads to Schwarzschild with zero mass, which is Minkowski.

To extend this work one should use the Cartan scalar techniques developed in Refs. 7 and 8 to find all limits of the γ metric. The main difficulty is computational, since in the present case too many Cartan scalars are different from zero and they depend on more than one coordinate and parameter. Afterwards one should do the same with the other metrics appearing on the diagram. Finally, one should find a single coordinate system which provides all the limits on the diagram and does not present an infinite topological defect. This would help the understanding of the topological defects in the Levi-Civita metric.

(Received 23 March 1998; accepted for publication 4 November 1998)

A subclass of a recently discovered class of solutions in multidimensional gravity with intersecting *p*-branes related to Lie algebras and governed by a set of harmonic functions is considered. This subclass in case of three Euclidean *p*-branes (one electric and two magnetic) contains a cosmological solution to $D=11$ supergravity related to hyperbolic Kac–Moody algebra $\mathcal{F}_3$ (of rank 3). This solution describes the non-Kasner power-law inflation. © *1999 American Institute of Physics.* [S0022-2488(99)02007-1]

I. INTRODUCTION

Here we consider a recently discovered class of solutions with intersecting *p*-branes.[1] These solutions are governed by a set of harmonic functions. The number of harmonic functions in general is less than the number of *p*-branes (as it takes place in orthogonal case[2–16]). The solutions correspond to a block-orthogonal set of *p*-brane vectors U^s [see (2.17) below] and may be considered as a Majumdar–Papapetrou type extension for the extremal limit of ''block-orthogonal'' black holes recently found in Ref. 17 (for ''orthogonal'' black holes see Refs. 18–23 and references therein.)

For the one-block case the solution is governed by one harmonic function and for a special configuration may be related to some simple finite dimensional Lie algebra or infinite dimensional hyperbolic Kac–Moody (KM) algebra.[24,25] The affine KM algebras do not appear among the solutions from Ref. 1.

Let us consider the simplest example of $D=11$ supergravity[26] (corresponding to M-theory[27]). It is known[3–5] that the orthogonal (or A_1+A_1) intersection rules for the M-theory read

$$3\cap 3=1, \quad 3\cap 6=2, \quad 6\cap 6=4 \tag{1.1}$$

(here we are counting dimensions of world sheets and their intersections). For the simplest $A_2=sl(3)$ Lie algebra the intersection rules are modified as follows:[1]

$$3\cap 3=0, \quad 3\cap 6=1, \quad 6\cap 6=3. \tag{1.2}$$

The rules (1.2) are obtained from (1.1) by a shift of one unit. (For $3\cap 3=0$ the ''truncated'' theory or without the Chern–Simons term should be considered). These modified rules may be written for a wide class of models and Lie algebras (finite or hyperbolic) and are defined by Dynkin diagrams.[1,23]

[a)]Electronic mail: ivas@rgs.phys.msu.su
[b)]Electronic mail: sungwon@mm.ewha.ac.kr
[c)]Electronic mail: rgs@com2com.ru

Hyperbolic algebras appeared in different areas of mathematical physics, e.g. in ordinary gravity[28] ($\mathcal{F}_3$ hyperbolic algebra), supergravity:[29,30] (E_{10} hyperbolic algebra),[31] ($\mathcal{F}_3$ hyperbolic algebra), strings, etc. (see also Ref. 32, and references therein). In Ref. 31 it was shown that the chiral reduction of a simple ($N=1$) supergravity from four dimensions to one dimension gives rise to the hyperbolic algebra of rank 3 (namely $\mathcal{F}_3$).

In Ref. 1 we considered some examples of hyperbolic intersection rules for the hyperbolic KM algebras of rank 2. These examples were suggested for so-called B_D models with $D\geqslant 14$,[23] containing $D-11$ scalar fields with negative kinetic terms. (B_{11} is the truncated bosonic sector of $D=11$ supergravity. B_{12} is the 12-dimensional model[33] corresponding to the low energy limit of F-theory.[34])

Here an example of cosmological solution in $D=11$ supergravity with three p-branes (two magnetic and one electric) that have intersection rules corresponding to the hyperbolic KM algebra $\mathcal{F}_3$ is constructed.

II. THE MODEL

We consider a model governed by the action[11]

$$S=\int d^Dz\sqrt{|g|}\left\{R[g]-h_{\alpha\beta}g^{MN}\partial_M\varphi^\alpha\partial_N\varphi^\beta-\sum_{a\in\Delta}\frac{\theta_a}{n_a!}\exp[2\lambda_a(\varphi)](F^a)^2\right\}, \tag{2.1}$$

where $g=g_{MN}\,dz^M\otimes dz^N$ is a metric, $\varphi=(\varphi^\alpha)\in\mathbf{R}^l$ is a vector of scalar fields, $(h_{\alpha\beta})$ is a symmetric nondegenerate $l\times l$ matrix $(l\in\mathbf{N})$, $\theta_a=\pm1$, $F^a=dA^a$ is a n_a-form $(n_a\geqslant1)$, λ_a is a one-form on $\mathbf{R}^l$: $\lambda_a(\varphi)=\lambda_{\alpha a}\varphi^\alpha$, $a\in\Delta$, $\alpha=1,\ldots,l$. Here Δ is some finite set.

We consider a manifold

$$M=M_0\times M_1\times\cdots\times M_n, \tag{2.2}$$

with a metric

$$g=e^{2\gamma(x)}g^0+\sum_{i=1}^n e^{2\phi^i(x)}g^i, \tag{2.3}$$

where $g^0=g^0_{\mu\nu}(x)dx^\mu\otimes dx^\nu$ is a metric on the manifold M_0, and $g^i=g^i_{m_in_i}(y_i)dy_i^{m_i}\otimes dy_i^{n_i}$ is a Ricci-flat metric on the manifold M_i ($\mathrm{Ric}[g^i]=0$), $i=1,\ldots,n$. Any manifold M_ν is oriented and connected and $d_\nu\equiv\dim M_\nu$, $\nu=0,\ldots,n$. Let

$$\tau_i\equiv\sqrt{|g^i(y_i)|}\,dy_i^1\wedge\ldots\wedge dy_i^{d_i},\quad \varepsilon(i)\equiv\mathrm{sign}(\det(g^i_{m_in_i}))=\pm1 \tag{2.4}$$

denote the volume d_i-form and signature parameter, respectively, $i=1,\ldots,n$. Let $\Omega=\Omega_n$ be a set of all subsets of $\{1,\ldots,n\}$, $|\Omega|=2^n$. For any $I=\{i_1,\ldots,i_k\}\in\Omega$, $i_1<\ldots<i_k$, we denote

$$\tau(I)\equiv\tau_{i_1}\wedge\ldots\wedge\tau_{i_k},\quad d(I)\equiv\sum_{i\in I}d_i,\quad \varepsilon(I)\equiv\prod_{i\in I}\varepsilon(i). \tag{2.5}$$

We also put $\tau(\emptyset)=\varepsilon(\emptyset)=1$ and $d(\emptyset)=0$.

For fields of forms we consider the following composite electromagnetic ansatz:

$$F^a=\sum_{I\in\Omega_{a,e}}\mathcal{F}^{(a,e,I)}+\sum_{J\in\Omega_{a,m}}\mathcal{F}^{(a,m,J)}, \tag{2.6}$$

where

$$\mathcal{F}^{(a,e,I)}=d\Phi^{(a,e,I)}\wedge\tau(I), \tag{2.7}$$

$$\mathcal{F}^{(a,m,J)} = e^{-2\lambda_a(\varphi)} * (d\Phi^{(a,m,J)} \wedge \tau(J)) \tag{2.8}$$

are elementary forms of electric and magnetic types, respectively, $a \in \Delta$, $I \in \Omega_{a,e}$, $J \in \Omega_{a,m}$, and $\Omega_{a,e} \subset \Omega$, $\Omega_{a,m} \subset \Omega$. In (2.8) $* = *[g]$ is the Hodge operator on (M,g). For scalar functions we put

$$\varphi^\alpha = \varphi^\alpha(x), \quad \Phi^s = \Phi^s(x), \tag{2.9}$$

$s \in S$.

Here and below

$$S = S_e \sqcup S_m, \quad S_v = \cup_{a \in \Delta} \{a\} \times \{v\} \times \Omega_{a,v}, \tag{2.10}$$

$v = e, m$.

Due to (2.7) and (2.8)

$$d(I) = n_a - 1, \quad d(J) = D - n_a - 1, \tag{2.11}$$

for $I \in \Omega_{a,e}$, $J \in \Omega_{a,m}$.

A. The sigma model

Let $d_0 \neq 2$ and

$$\gamma = \gamma_0(\phi) \equiv \frac{1}{2 - d_0} \sum_{j=1}^{n} d_j \phi^j, \tag{2.12}$$

i.e., the generalized harmonic gauge is used.

We impose the restriction on sets $\Omega_{a,v}$. These restrictions guarantee the block-diagonal structure of a stress-energy tensor (like for the metric) and the existence of σ-model representation.[11]

We denote $w_1 \equiv \{i | i \in \{1, \ldots, n\}, \quad d_i = 1\}$, and $n_1 = |w_1|$ (i.e., n_1 is the number of one-dimensional spaces among M_i, $i = 1, \ldots, n$).

Restriction 1: Let 1a) $n_1 \leqslant 1$ or (1b) $n_1 \geqslant 2$ and for any $a \in \Delta$, $v \in \{e, m\}$, $i, j \in w_1$, $i < j$, there are no $I, J \in \Omega_{a,v}$ such that $i \in I$, $j \in J$ and $I \setminus \{i\} = J \setminus \{j\}$.

Restriction 2 (only for $d_0 = 1,3$): Let (2a) $n_1 = 0$ or (2b) $n_1 \geqslant 1$ and for any $a \in \Delta$, $i \in w_1$ there are no $I \in \Omega_{a,m}$, $J \in \Omega_{a,e}$ such that $\bar{I} = \{i\} \sqcup J$ for $d_0 = 1$ and $J = \{i\} \sqcup \bar{I}$ for $d_0 = 3$. Here and in what follows

$$\bar{I} \equiv \{1, \ldots, n\} \setminus I. \tag{2.13}$$

It was proved in Ref. 11 that equations of motion for the model (2.1) and the Bianchi identities: $d\mathcal{F}^s = 0$, $s \in S_m$, for fields from (2.3) to (2.12), when Restrictions 1 and 2 are imposed, are equivalent to equations of motion for the σ-model governed by the action

$$S_\sigma = \int d^{d_0}x \sqrt{|g^0|} \left\{ R[g^0] - \hat{G}_{AB} g^{0\mu\nu} \partial_\mu \sigma^A \partial_\nu \sigma^B - \sum_{s \in S} \varepsilon_s e^{-2U_A^s \sigma^A} g^{0\mu\nu} \partial_\mu \Phi^s \partial_\nu \Phi^s \right\}, \tag{2.14}$$

where $(\sigma^A) = (\phi^i, \varphi^\alpha)$, the index set S from (2.10), target space metric

$$(\hat{G}_{AB}) = \begin{pmatrix} G_{ij} & 0 \\ 0 & h_{\alpha\beta} \end{pmatrix}, \tag{2.15}$$

with

$$G_{ij}=d_i\delta_{ij}+\frac{d_id_j}{d_0-2}, \tag{2.16}$$

vectors

$$(U^s_A)=(d_i\delta_{iI_s},-\chi_s\lambda_{\alpha a_s}), \tag{2.17}$$

where $s=(a_s,v_s,I_s)$, $\chi_e=+1$, $\chi_m=-1$;

$$\delta_{iI}=\sum_{j\in I}\delta_{ij} \tag{2.18}$$

is the indicator of i belonging to I: $\delta_{iI}=1$ for $i\in I$ and $\delta_{iI}=0$ otherwise; and

$$\varepsilon_s=(-\varepsilon[g])^{(1-\chi_s)/2}\varepsilon(I_s)\theta_{a_s}, \tag{2.19}$$

$s\in S$, $\varepsilon[g]\equiv\text{sign}\det(g_{MN})$. More explicitly (2.19) reads $\varepsilon_s=\varepsilon(I_s)\theta_{a_s}$ for $v_s=e$ and $\varepsilon_s=-\varepsilon[g]\varepsilon(I_s)\theta_{a_s}$ for $v_s=m$.

B. Exact solutions in a block-orthogonal case

Let us define the scalar product as follows:

$$(U,U')=\hat{G}^{AB}U_AU'_B, \tag{2.20}$$

for $U,U'\in\mathbf{R}^N$, where $(\hat{G}^{AB})=(\hat{G}_{AB})^{-1}$. The scalar products (2.20) for vectors U^s were calculated in 11

$$(U^s,U^{s'})=d(I_s\cap I_{s'})+\frac{d(I_s)d(I_{s'})}{2-D}+\chi_s\chi_{s'}\lambda_{\alpha a_s}\lambda_{\beta a_{s'}}h^{\alpha\beta}\equiv B^{ss'}, \tag{2.21}$$

where $(h^{\alpha\beta})=(h_{\alpha\beta})^{-1}$; $s=(a_s,v_s,I_s)$ and $s'=(a_{s'},v_{s'},I_{s'})$ belongs to S.

Let

$$S=S_1\sqcup\ldots\sqcup S_k, \tag{2.22}$$

$S_i\neq\emptyset$, $i=1,\ldots,k$, and

$$(U^s,U^{s'})=0 \tag{2.23}$$

for all $s\in S_i$, $s'\in S_j$, $i\neq j$; $i,j=1,\ldots,k$. Relation (2.22) means that the set S is a union of k nonintersecting (nonempty) subsets $S_1,\ldots,S_k$. According to (2.23) the set of vectors $(U^s,s\in S)$ has a block-orthogonal structure with respect to the scalar product (2.20), i.e., it splits into k mutually orthogonal blocks $(U^s,s\in S_i)$, $i=1,\ldots,k$.

Here we consider exact solutions in the model (2.1), when vectors $(U^s,s\in S)$ obey the block-orthogonal decomposition (2.22), (2.23) with scalar products defined in (2.21).[1] These solutions may be obtained from the corresponding solutions of the σ-model,[1] that are presented in the Appendix.

The solution reads:

$$g=U\left\{g^0+\sum_{i=1}^{n}U_ig^i\right\}, \tag{2.24}$$

$$U=\left(\prod_{s\in S} H_s^{2d(I_s)\varepsilon_s\nu_s^2}\right)^{1/(2-D)}, \tag{2.25}$$

$$U_i=\prod_{s\in S} H_s^{2\varepsilon_s\nu_s^2\delta_{iI_s}}, \tag{2.26}$$

$$\varphi^\alpha=-\sum_{s\in S}\lambda_{a_s}^{\alpha}\chi_s\varepsilon_s\nu_s^2\ln H_s, \tag{2.27}$$

$$F^a=\sum_{s\in S}\mathcal{F}^s\delta_{a_s}^a, \tag{2.28}$$

where $\mathrm{Ric}[g^0]=\mathrm{Ric}[g^i]=0$,

$$\mathcal{F}^s=\nu_s dH_s^{-1}\wedge\tau(I_s), \quad \text{for } v_s=e, \tag{2.29}$$

$$\mathcal{F}^s=\nu_s(*_0 dH_s)\wedge\tau(\bar{I}_s), \quad \text{for } v_s=m, \tag{2.30}$$

H_s are harmonic functions on (M_0,g^0) coinciding inside blocks of matrix $(B^{ss'})$ from (2.21) $(H_s=H_{s'},\ s,s'\in S_j,\ j=1,\ldots,k)$ and relations

$$\sum_{s'\in S} B^{ss'}\varepsilon_{s'}\nu_{s'}^2=-1 \tag{2.31}$$

for the matrix $(B^{ss'})$ (2.21), parameters ε_s (2.19) and ν_s are imposed, $s\in S$, $i=1,\ldots,n$; $\alpha=1,\ldots,l$. Here $\lambda_a^\alpha=h^{\alpha\beta}\lambda_{\beta a}$, $*_0=*[g^0]$ is the Hodge operator on (M_0,g^0) and $\bar{I}$ is defined in (2.13).

In deriving the solutions the following relations for contravariant components of U^s-vectors were used:[11]

$$U^{si}=\delta_{iI_s}-\frac{d(I_s)}{D-2}, \quad U^{s\alpha}=-\chi_s\lambda_{a_s}^{\alpha}, \tag{2.32}$$

$s=(a_s,v_s,I_s)$.

Thus, we obtained the generalization of the solutions from Ref. 11 to the block-orthogonal case [here we eliminate the misprint with sign in Eq. (5.19) in Ref. 11].

Remark 1: The solution is also valid for $d_0=2$, if Restriction 2 is replaced by Restriction 2*.

Restriction 2 (for $d_0=2$):* For any $a\in\Delta$ there are no $I\in\Omega_{a,m}$, $J\in\Omega_{a,e}$ such that $\bar{I}=J$ and for $n_1\geqslant 2$, $i,j\in w_1$, $i\neq j$, there are no $I\in\Omega_{a,m}$, $J\in\Omega_{a,e}$ such that $i\in I$, $j\in\bar{J}$, $I\setminus\{i\}=\bar{J}\setminus\{j\}$.

It may be proved using a more general form of the sigma-model representation (see Remark 2 in Ref. 11).

III. SOLUTIONS RELATED TO LIE ALGEBRAS AND INTERSECTION RULES

Here we put

$$(U^s,U^s)\neq 0 \tag{3.1}$$

for all $s\in S$ and introduce the quasi-Cartan matrix $A=(A^{ss'})$

$$A^{ss'}\equiv\frac{2(U^s,U^{s'})}{(U^{s'},U^{s'})}, \tag{3.2}$$

$s,s' \in S$. From (2.23) we get a block-orthogonal structure of A:

$$A = \begin{pmatrix} A_{(1)} & \dots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \dots & A_{(k)} \end{pmatrix}, \tag{3.3}$$

where $A_{(i)} = (A^{ss'}, s,s' \in S_i)$, $i=1,\dots,k$. Here we tacitly assume that the set S is ordered, $S_1 < \dots < S_k$ and the order in S_i is inherited by the order in S.

We note that due to (2.23) the relation (A5) may be rewritten as

$$\sum_{s' \in S_i} (U^s, U^{s'}) \varepsilon_{s'} \nu_{s'}^2 = -1, \tag{3.4}$$

$s \in S_i$, $i=1,\dots,k$. Hence, parameters $(\nu_s, s \in S_i)$ depend upon vectors $(U^s, s \in S_i)$, $i=1,\dots,k$.

For $\det A_{(i)} \neq 0$ relation (3.4) may be rewritten in the equivalent form

$$\varepsilon_s \nu_s^2 (U^s, U^s) = -2 \sum_{s' \in S} A_{ss'}^{(i)}, \tag{3.5}$$

$s \in S_i$, where $(A_{ss'}^{(i)}) = A_{(i)}^{-1}$. Thus, Eq. (3.4) may be resolved in terms of ν_s for certain $\varepsilon_s = \pm 1$, $s \in S_i$.

In what follows we consider the block-orthogonal decomposition to be irreducible, i.e., for any i the block $(U^s, s \in S_i)$ does not split into two mutually orthogonal subblocks. In this case any matrix $A_{(i)}$ is indecomposable (or irreducible) in the sense that there is no renumbering of vectors which would bring $A_{(i)}$ to the block diagonal form $A_i = \mathrm{diag}(A'_{(i)}, A''_{(i)})$.

Let A be the generalized Cartan matrix.[24,25] In this case

$$A^{ss'} \in -\mathbf{Z}_+ \equiv \{0,-1,-2, \dots\} \tag{3.6}$$

for $s \neq s'$ and A generates generalized symmetrizable Kac–Moody algebra.[24,25]

Now we fix $i \in \{1,\dots,k\}$. From (3.3) and (3.6) we get

$$A_{(i)}^{ss'} \in -\mathbf{Z}_+, \tag{3.7}$$

$s,s' \in S_i$, $s \neq s'$. There are three possibilities for $A_{(i)}$: (a) $\det A_{(i)} > 0$, (b) $\det A_{(i)} < 0$ and (c) $\det A_{(i)} = 0$. For $\det A_{(i)} \neq 0$ the corresponding Kac–Moody algebra is simple, since $A_{(i)}$ is indecomposable.[25]

A. Finite dimensional Lie algebras

Let $\det A_{(i)} > 0$. In this case $A_{(i)}$ is the Cartan matrix of a simple finite-dimensional Lie algebra and $A_{(i)}^{ss'} \in \{0,-1,-2,-3\}$, $s \neq s'$. The elements of inverse matrix $A_{(i)}^{-1}$ are positive (see Chap. 7 in Ref. 25) and hence we get from (3.5)

$$\varepsilon_s (U^s, U^s) < 0, \tag{3.8}$$

$s \in S_i$.

B. Hyperbolic Kac–Moody algebras

Let $\det A_{(i)} < 0$. Among irreducible symmetrizable matrices satisfying (3.7) there exists a large subclass of Cartan matrices, corresponding to infinite-dimensional simple hyperbolic generalized Kac–Moody (KM) algebras of ranks $r=2,\dots,10$.[24,25]

For the hyperbolic algebras the following relations are satisfied:

$$\varepsilon_s(U^s,U^s)>0, \tag{3.9}$$

$s \in S_i$. This relation is valid, since $(A^{-1}_{(i)})_{ss'} \leqslant 0$, $s,s' \in S$, for any hyperbolic algebra.[35]

It was shown in Ref. 1 that affine KM algebras with $\det A_{(i)}=0$ do not appear in the solutions.[1]

C. Intersection rules

From the orthogonality relation (2.23) and (2.21) we get

$$d(I_s \cap I_{s'}) = \Delta(s,s') \tag{3.10}$$

where $s \in S_i$, $s' \in S_j$, $i \neq j$, and

$$\Delta(s,s') \equiv \frac{d(I_s)d(I_{s'})}{D-2} - \chi_s \chi_{s'} \lambda_{a_s} \cdot \lambda_{a_{s'}}. \tag{3.11}$$

Here $\lambda \cdot \lambda' \equiv h^{\alpha\beta}\lambda_\alpha \lambda'_\beta$. Let

$$N(a,b) \equiv \frac{(n_a-1)(n_b-1)}{D-2} - \lambda_a \cdot \lambda_b, \tag{3.12}$$

$a,b \in \Delta$. The matrix (3.12) is called the fundamental matrix of the model (2.1).[23] For $s_1,s_2 \in S$, $s_1 \neq s_2$, the symbol of orthogonal intersection (3.11) may be expressed by means of the fundamental matrix[23]

$$\Delta(s_1,s_2) = \bar{D}\bar{\chi}_{s_1}\bar{\chi}_{s_2} + \bar{n}_{a_{s_1}}\chi_{s_1}\bar{\chi}_{s_2} + \bar{n}_{a_{s_2}}\chi_{s_2}\bar{\chi}_{s_1} + N(a_{s_1},a_{s_2})\chi_{s_1}\chi_{s_2}, \tag{3.13}$$

where $\bar{D}=D-2$, $\bar{n}_a = n_a - 1$, $\bar{\chi}_s = \frac{1}{2}(1-\chi_s)$. More explicitly (3.13) reads

$$\Delta(s_1,s_2) = N(a_{s_1},a_{s_2}), \quad v_{s_1}=v_{s_2}=e, \tag{3.14}$$

$$\Delta(s_1,s_2) = \bar{n}_{a_{s_1}} - N(a_{s_1},a_{s_2}), \quad v_{s_1}=e, \quad v_{s_2}=m, \tag{3.15}$$

$$\Delta(s_1,s_2) = \bar{D} - \bar{n}_{a_{s_1}} - \bar{n}_{a_{s_2}} + N(a_{s_1},a_{s_2}), \quad v_{s_1}=v_{s_2}=m. \tag{3.16}$$

This follows from the relations

$$d(I_s) = \bar{D}\bar{\chi}_s + \bar{n}_{a_s}\chi_s, \tag{3.17}$$

equivalent to (2.11). Let

$$K(a) \equiv n_a - 1 - N(a,a) = \frac{(n_a-1)(D-n_a-1)}{D-2} + \lambda_a \cdot \lambda_a, \tag{3.18}$$

$a \in \Delta$.

The parameters (3.18) play a rather important role in supergravitational theories, since they are preserved under Kaluza–Klein reduction[2] and define the norms of U^s vectors:

$$(U^s,U^s) = K(a_s), \tag{3.19}$$

$s \in S$.

Here we put $K(a) \neq 0$, $a \in \Delta$. Then, we obtain the general intersection rule formulas

$$d(I_{s_1}\cap I_{s_2})=\Delta(s_1,s_2)+\tfrac{1}{2}K(a_{s_2})A^{s_1s_2} \tag{3.20}$$

$s_1\neq s_2$, where $(A^{s_1s_2})$ is the quasi-Cartan matrix (3.2) (see also (6.32) from Ref. 23).

In most models including $D=11$ supergravity, $D=12$ theory,[33] $D<11$ supergravities,[2] $K(a)=2$ and (3.20) has the following form

$$d(I_{s_1}\cap I_{s_2})=\Delta(s_1,s_2)+A^{s_1s_2}, \tag{3.21}$$

$s_1\neq s_2$, and get $A^{s_1s_2}=A^{s_2s_1}$, i.e., the Cartan matrix is symmetric.

IV. EXAMPLES

A. Hyperbolic algebra of rank three

Now we consider the example of the solution corresponding to the hyperbolic KM algebra $\mathcal{F}_3$ with the Cartan matrix

$$A=\begin{pmatrix} 2 & -2 & 0 \\ -2 & 2 & -1 \\ 0 & -1 & 2 \end{pmatrix}. \tag{4.1}$$

The hyperbolic algebra $\mathcal{F}_3$ corresponding to (4.1), is an infinite dimensional Lie algebra generated by the (Serre) relations[24,25]

$$[h_i,h_j]=0, \quad [e_i,f_j]=\delta_{ij}h_j, \tag{4.2}$$

$$[h_i,e_j]=A_{ij}e_j, \quad [h_i,f_j]=-A_{ij}f_j, \tag{4.3}$$

$$(\mathrm{ad}e_i)^{1-A_{ij}}(e_j)=0 \quad (i\neq j), \tag{4.4}$$

$$(\mathrm{ad}f_i)^{1-A_{ij}}(f_j)=0 \quad (i\neq j). \tag{4.5}$$

$\mathcal{F}_3$ contains $A_1^{(1)}$ affine Kac–Moody subalgebra (it corresponds to the Geroch group) and A_2 subalgebra.

The calculation of inverse matrix gives us

$$A^{-1}=-\begin{pmatrix} \frac{3}{2} & 2 & 1 \\ 2 & 2 & 1 \\ 1 & 1 & 0 \end{pmatrix}, \tag{4.6}$$

and, hence,

$$\sum_{j=1}^{3} A_{ij}^{-1}=-\frac{9}{2},-5,-2, \tag{4.7}$$

for $i=1,2,3$, respectively.

Now we construct an example of the solution with the A-matrix (4.1) for $D=11$ supergravity governed by the action (in the bosonic sector)

$$S=\int d^{11}z\sqrt{|g|}\left\{R[g]-\frac{1}{4!}(F^4)^2\right\}+c\int A^3\wedge F^4\wedge F^4, \tag{4.8}$$

where $c=\mathrm{const}$, $F^4=dA^3$.

We consider a configuration with three p-branes, one electric and two magnetic. We denote $S=\{s_1,s_2,s_3\}$, $\nu_{s_1}=\nu_{s_3}=m$, $\nu_{s_2}=e$ and get $d(I_{s_1})=d(I_{s_3})=6$, $d(I_{s_2})=3$. From intersection rules (3.21) we obtain

$$d(I_{s_1}\cap I_{s_2})=0, \quad d(I_{s_2}\cap I_{s_3})=1, \quad d(I_{s_1}\cap I_{s_3})=4. \tag{4.9}$$

For the manifold (2.2) we put $n=5$ and $d_1=2$, $d_2=4$, $d_3=d_4=1$, $d_5=2$. The corresponding sets for p-branes are the following: $I_{s_1}=\{1,2\}$, $I_{s_2}=\{4,5\}$, $I_{s_3}=\{2,3,4\}$.

The corresponding solution reads

$$g=H^{-12}\{-dt\otimes dt+H^9g^1+H^{13}g^2+H^4g^3+H^{14}g^4+H^{10}g^5\}, \tag{4.10}$$

$$F^4=\frac{dH}{dt}\left\{\nu_{s_1}\tau_3\wedge\tau_4\wedge\tau_5+\frac{\nu_{s_2}}{H^2}dt\wedge\tau_4\wedge\tau_5+\nu_{s_3}\tau_1\wedge\tau_5\right\}, \tag{4.11}$$

where

$$\nu_{s_1}^2=\tfrac{9}{2}, \quad \nu_{s_2}^2=5, \quad \nu_{s_3}^2=2 \tag{4.12}$$

[see relations (3.5) and (4.7)], all metric g^i are Ricci-flat ($i=1,\ldots,5$) with the Euclidean signature [this agrees with relations (3.9) and (2.19)], and

$$H=ht+h_0>0, \tag{4.13}$$

h,h_0 are constants. [We remind that here $(U^s,U^s)=2$.]

The solution (4.10)–(4.13) satisfies not only equations of motion for the truncated model (without the Chern–Simons term), but also the equations of motion for the ''total'' model (4.8), since the only modification related to ''Maxwell's'' equations

$$d*F^4=\text{const}\,F^4\wedge F^4, \tag{4.14}$$

is trivial due to $F^4\wedge F^4=0$ (since $\tau_i\wedge\tau_i=0$).

The metric (4.10) may be also rewritten using the synchronous time variable t_s,

$$g=-dt_s\otimes dt_s+f^{3/5}g^1+f^{-1/5}g^2+f^{8/5}g^3+f^{-2/5}g^4+f^{2/5}g^5, \tag{4.15}$$

where $f=5ht_s=H^{-5}>0$, $h>0$, $t_s>0$. The metric describes the power-law ''inflation'' in $D=11$. It is singular for $t_s\to+0$. It is interesting to note that the powers in scale-factors $f^{2\alpha_i}$ do not satisfy Kasner-like relations:[36] $\Sigma_{i=1}^5 d_i\alpha_i=\Sigma_{i=1}^5 d_i(\alpha_i)^2=1$. For flat g^i the calculation of the Riemann tensor squared gives us (see Refs. 37, 38)

$$R_{MNPQ}[g]R^{MNPQ}[g]=At_s^{-4}, \tag{4.16}$$

where $A=2\times1.0714$.

B. A_3 Lie algebra

Here we present for comparison the solution of $D=11$ supergravity corresponding to A_3 Lie algebra with the Cartan matrix

$$A=\begin{pmatrix} 2 & -1 & 0 \\ -1 & 2 & -1 \\ 0 & -1 & 2 \end{pmatrix}. \tag{4.17}$$

The calculation of inverse matrix gives in this case

$$\sum_{j=1}^{3} A_{ij}^{-1} = \frac{3}{2}, 2, \frac{3}{2}, \tag{4.18}$$

for $i=1,2,3$, respectively.

Like in the example mentioned above we consider three p-branes, one electric and two magnetic, i.e., in this case $S=\{s_1, s_2, s_3\}$, $v_{s_1}=v_{s_3}=m$, $v_{s_2}=e$, $d(I_{s_1})=d(I_{s_3})=6$, $d(I_{s_2})=3$. From intersection rules (3.21) we obtain

$$d(I_{s_1}\cap I_{s_2})=1, \quad d(I_{s_2}\cap I_{s_3})=1, \quad d(I_{s_1}\cap I_{s_3})=4. \tag{4.19}$$

For the manifold (2.2) we put $n=5$ and $d_1=2$, $d_2=3$, $d_3=1$, $d_4=2$, $d_5=2$. The corresponding sets for p-branes are the following: $I_{s_1}=\{1,2,3\}$, $I_{s_2}=\{3,5\}$, $I_{s_3}=\{2,3,4\}$.

The corresponding solution reads

$$g = H^{16/3}\{d\rho\otimes d\rho + H^{-3}g^1 + H^{-6}g^2 + H^{-10}(-dt\otimes dt) + H^{-3}g^4 + H^{-4}g^5\} \tag{4.20}$$

$$F^4 = \frac{dH}{d\rho}\left\{ \nu_{s_1}\tau_4\wedge\tau_5 + \frac{\nu_{s_2}}{H^2} d\rho\wedge dt\wedge\tau_5 + \nu_{s_3}\tau_1\wedge\tau_5 \right\}, \tag{4.21}$$

where

$$\nu_{s_1}^2 = \tfrac{3}{2}, \quad \nu_{s_2}^2 = 2, \quad \nu_{s_3}^2 = \tfrac{3}{2}. \tag{4.22}$$

Here the metrics g^i are Ricci-flat $(i=1,2,4,5)$ with the Euclidean signature, and

$$H = c\rho + c_0 > 0, \tag{4.23}$$

c, c_0 are constants. So, we obtained the multidimensional ''cosmological'' solution with the Euclidean ''time'' ρ.

V. DISCUSSION

Here we obtained the example of the cosmological solution with three Euclidean intersecting p-branes (one electric and two magnetic) satisfying intersection rules for the hyperbolic Kac–Moody Lie algebra $\mathcal{F}_3$ [see (3.21) and (4.1)]. The corresponding A_3 solution contains three pseudo-Euclidean p-branes. The difference in sign rules (restriction on ε_s) for finite and hyperbolic algebras is a consequence of inequalities for elements of the inverse Cartan matrix: $A_{ij}^{-1} > 0$ for simple (or semisimple) finite dimensional Lie algebra and $A_{ij}^{-1} \leqslant 0$ (for simple hyperbolic KM algebra). In this paper the hyperbolic KM algebra $\mathcal{F}_3$ appeared only on the simplest level of the Cartan matrix (governing the intersection rules) but the full structure of the algebra, including Serre relations (4.4) and (4.5), was not used. We may suppose that at the second step a more deep penetrating into a ''structure'' of infinite dimensional hyperbolic algebras will be achieved when general cosmological solutions related to hyperbolic Toda-lattices will be considered.

1998. The authors are grateful to the organizers and participants of the Second Winter School on Branes, Fields and Mathematical Physics (APCTP, Seoul), where the results of this paper were reported.

APPENDIX: BLOCK-ORTHOGONAL SOLUTIONS IN THE σ-MODEL

Equations of motion corresponding to (2.14) have the following form:

$$R_{\mu\nu}[g^0]=\hat{G}_{AB}\partial_\mu\sigma^A\partial_\nu\sigma^B+\sum_{s\in S}\varepsilon_s e^{-2U_A^s\sigma^A}\partial_\mu\Phi^s\partial_\nu\Phi^s, \tag{A1}$$

$$\hat{G}_{AB}\Delta[g^0]\sigma^B+\sum_{s\in S}\varepsilon_s U_A^s e^{-2U_C^s\sigma^C}g^{0\mu\nu}\partial_\mu\Phi^s\partial_\nu\Phi^s=0, \tag{A2}$$

$$\partial_\mu(\sqrt{|g^0|}g^{0\mu\nu}e^{-2U_A^s\sigma^A}\partial_\nu\Phi^s)=0, \tag{A3}$$

$s\in S$. Here $\Delta[g^0]$ is the Laplace-Beltrami operator corresponding to g^0.

Proposition 1: Let (M_0,g^0) be Ricci-flat $R_{\mu\nu}[g^0]=0$. Then the field configuration

$$g^0, \quad \sigma^A=\sum_{s\in S}\varepsilon_s U^{sA}\nu_s^2\ln H_s, \quad \Phi^s=\frac{\nu_s}{H_s}, \tag{A4}$$

$s\in S$, satisfies the field equations (A1)–(A3) with $V=0$ if (real) numbers ν_s obey the relations

$$\sum_{s'\in S}(U^s,U^{s'})\varepsilon_{s'}\nu_{s'}^2=-1, \tag{A5}$$

$s\in S$, functions $H_s>0$ are harmonic, i.e.,

$$\Delta[g^0]H_s=0, \tag{A6}$$

$s\in S$ and H_s are coinciding inside blocks:

$$H_s=H_{s'} \tag{A7}$$

for $s,s'\in S_i$, $i=1,\ldots,k$.

The Proposition can be readily verified by a straightforward substitution of (A4)–(A7) into equations of motion (A1)–(A3). In the special (orthogonal) case, when any block contains only one vector (i.e., all $|S_i|=1$) the Proposition coincides with Proposition 1 of Ref. 11. In the general case vectors inside each block S_i are not orthogonal. The solution under consideration depends on k independent harmonic functions. For a given set of vectors $(U^s,s\in S)$ the maximal number k arises for the irreducible block-orthogonal decomposition (2.22), (2.23), when any block $(U^s,s\in S_i)$ does not split into two mutually-orthogonal subblocks.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 40, NUMBER 8 AUGUST 1999

Connection with torsion from Ashtekar–Barbero connection

Merced Montesinos[a)]
Department of Physics and Astronomy, University of Pittsburgh, Pittsburgh, Pennsylvania 15260, and Departamento de Física, Centro de Investigación y de Estudios Avanzados del I.P.N., Av. I.P.N. No. 2508, 07000 Ciudad de México, México

(Received 11 December 1998; accepted for publication 12 March 1999)

A natural three-dimensional covariant derivative with torsion emerges from the Ashtekar–Barbero connection in the canonical approach to general relativity. The torsion is related to the extrinsic curvature when the Barbero–Immirzi parameter β does not vanish. Alternatively, torsion can be avoided, but at the price of a nonvanishing covariant derivative of the triad field. The properties of both cases are discussed. © *1999 American Institute of Physics.* [S0022-2488(99)01108-1]

I. INTRODUCTION

Nonperturbative quantum gravity, or loop quantum gravity,[1] emerges from mixing general relativity and quantum mechanics. More precisely, it comes from implementing and extending the Dirac method[2] for constrained systems to the Hamiltonian formulation of general relativity in terms of the Ashtekar–Barbero variables[3,4] (for instance, the Dirac approach does not provide a mechanism for defining the measure of the Hilbert space). This theory has two non trivial aspects as a quantum theory of the gravitational field. First, it is a nonperturbative quantum approach[5] for describing the gravitational field. Second it shows that the quantum nature of the gravitational field is associated to loop-like excitations, as opposed to point-like ones from usual quantum field theory. When these nontrivial facts are put together, several striking results follow from the loop quantum gravity approach to the gravitational field (see Refs. 6, 7, and 8 for a complete review). All of them show a discrete nature of *space* at Planck length $l_{\mathrm{P}}=\sqrt{G\hbar/c^3}$.

The success of the quantum theory motivates us to investigate in detail the classical formulation on which the quantization is based and, in particular, the geometry defined by this formalism. In this paper therefore, we focus on some aspects of the geometry of general relativity in terms of real Ashtekar–Barbero variables.[3,4] In Sec. II, it is shown that a natural three-dimensional covariant derivative with torsion on Σ comes from the Ashtekar–Barbero connection, the torsion is related to the extrinsic curvature K^i_a. This covariant derivative kills (the inverse of) the triad field e^i_a. Alternatively, we introduce a mechanism for avoiding torsion related to the definition of a different covariant derivative. The relationship with the Cartan framework is clarified in both cases.

II. THE CONNECTION

We begin by recalling a few facts on affine connections (see for instance Ref. 9). Let $e^i = e^i_a\, dx^a$ $(i=1,2,3)$ be the set of 1-forms dual to the orthonormal frame $e_i = e^a_i(\partial/\partial x^a) = e^a_i \partial_a$ of the tangent space of a three-dimensional manifold Σ, where x^a $(a=1,2,3)$ are local coordinates on the manifold. If ∇ is an affine connection we have, in the orthonormal frame e_i,

$$\nabla_{e_i} e_j =: -\alpha_{ij}{}^k e_k; \tag{1}$$

[a)]Electronic mail: merced@fis.cinvestav.mx therefore the connection is completely determined by the $3\times3\times3=27$ coefficients of the affine connection $\alpha_{ij}{}^{k}$. By plugging the definition of e_i in Eq. (1) and using the properties of the affine connection, we get

$$e^k_c e^b_i(\partial_b e^c_j - A_{ba}{}^{c} e^a_j) = -\alpha_{ij}{}^{k},$$
$$\nabla_{\partial_b}\partial_a = : -A_{ba}{}^{c}\partial_c, \tag{2}$$

where the orthonormality condition $e^a_j e^i_a = \delta^i_j$ has been used. $A_{ba}{}^{c}$ are the coefficients of the affine connection with respect to the coordinate frame. The following step is to compute the antisymmetric and symmetric parts of $\alpha_{ij}{}^{k}$:

$$\alpha_{[ij]}{}^{k} := \tfrac{1}{2}(\alpha_{ij}{}^{k} - \alpha_{ji}{}^{k}) = e^a_{[i}e^b_{j]}\,\partial_a e^k_b + e^k_c e^a_i e^b_j T_{ab}{}^{c},$$
$$\alpha_{(ij)}{}^{k} := \tfrac{1}{2}(\alpha_{ij}{}^{k} + \alpha_{ji}{}^{k}) = e^a_{(i}e^b_{j)}\,\partial_a e^k_b + e^k_c e^a_i e^b_j K_{ab}{}^{c}. \tag{3}$$

$T_{ab}{}^{c} := \frac{1}{2}(A_{ab}{}^{c} - A_{ba}{}^{c})$ and $K_{ab}{}^{c} := \frac{1}{2}(A_{ab}{}^{c} + A_{ba}{}^{c})$ are the torsion tensor and the symmetric part of the coefficients $A_{ab}{}^{c}$, respectively. The set $\alpha_{[ij]}{}^{k}$ and $\alpha_{(ij)}{}^{k}$ determine $T_{ab}{}^{c}$ and $K_{ab}{}^{c}$ (and vice versa) through Eq. (3). Up to now we have been concerned with general aspects of affine connections. We now specialize to the Levi-Civita connection D. This connection is given in a coordinate frame by

$$T_{ab}{}^{c} = 0,$$
$$K_{ab}{}^{c} \equiv \Gamma_{ab}{}^{c} = -\tfrac{1}{2}q^{ce}(\partial_a q_{be} + \partial_b q_{ea} - \partial_e q_{ab}), \tag{4}$$

where $q_{ab} = e^i_a e^j_b \delta_{ij}$ is the three-dimensional metric on Σ. Therefore, in the case of the Levi-Civita connection Eq. (3) reduces to

$$\omega_{[ij]}{}^{k} := e^a_{[i}e^b_{j]}\,\partial_a e^k_b,$$
$$\omega_{(ij)}{}^{k} := e^a_{(i}e^b_{j)}\,\partial_a e^k_b + e^k_c e^a_i e^b_j \Gamma_{ab}{}^{c}. \tag{5}$$

Nevertheless, frequently it is necessary to compute covariant derivatives acting on both internal and space indices. The most general covariant derivative involving $SO(3)$ and space indices is given by

$$\mathcal{D}_a \lambda^i_b := \partial_a \lambda^i_b + \epsilon^i{}_{jk} A^j_a \lambda^k_b + A_{ab}{}^{c}\lambda^i_c, \tag{6}$$

so this expression can be computed once we have specified the rule to get the expressions of A^i_a and $A_{ab}{}^{c}$ $(9+27$ quantities). The usual way to specify them is through the *intrinsic* geometry of Σ. In this case we are forced to look at the action of the covariant derivative on the triad field e^a_i (or the inverse e^i_a). The most general allowed possibility is given by

$$\mathcal{D}_a e^i_b = \partial_a e^i_b + e^i{}_{jk} A^j_a e^k_b + A_{ab}{}^{c} e^i_c = t_{ab}{}^{i}, \tag{7}$$

where $t_{ab}{}^{i}$ is the *triadity* of the covariant derivative, i.e., the action of the covariant derivative on (the inverse of) the triad field e^i_b. Therefore, A^i_a and $A_{ab}{}^{c}$ are completely determined once the triadity $t_{ab}{}^{i}$ is given together with the other nine quantities, for instance, the value of the torsion tensor $T_{ab}{}^{c}$. One option is to choose $t_{ab}{}^{i} = 0$ and $T_{ab}{}^{c} = 0$. This election determines $A^i_a \equiv \Gamma^i_a = \Gamma^i_a[e]$ via

$$\partial_{[a} e^i_{b]} + \epsilon^i{}_{jk}\Gamma^j_{[a} e^k_{b]} = 0, \tag{8}$$

and $A_{ab}{}^{c}$ is given by

$$A_{ab}{}^{c}=\Gamma_{ab}{}^{c}=-\tfrac{1}{2}q^{ce}(\partial_a q_{be}+\partial_b q_{ea}-\partial_e q_{ab}), \tag{9}$$

with $q_{ab}=e^i_a e^j_b \delta_{ij}$.

Before continuing, it is important to emphasize some properties of the framework we are dealing with. In general, the covariant derivative (6) is well defined once we have A^i_a and $A_{ab}{}^c$ [which are obtained through (7)]. What are the differences between vanishing and nonvanishing triadity $t_{ab}{}^i$ in (7)? The difference is that when the covariant derivative kills (the inverse of) the triad, $\mathcal{D}_a e^i_b=0$ (and therefore we have vanishing triadity), we are in the Cartan framework, while when $t_{ab}{}^i\neq 0$ we are out the Cartan framework. This fact can be seen from (7). When $t_{ab}{}^i$ is vanishing, the antisymmetric part of (7) reads as

$$\partial_{[a}e^i_{b]}+\epsilon^i{}_{jk}A^j_{[a}e^k_{b]}+T_{ab}{}^c e^i_c=0, \tag{10}$$

which is one of Cartan's structure equations. When $t_{ab}{}^i\neq 0$ this last equation does not hold. We now relate these notions to the fields of canonical gravity.

Non perturbative quantum gravity is based on the following canonical pair of phase space variables,[3,4]

$$\begin{aligned} A^i_a &:= \Gamma^i{}_a+\beta K^i_a, \\ \tilde{E}^a_i &:= (\det(e^i_b))e^a_i, \end{aligned} \tag{11}$$

where A^i_a is the Ashtekar–Barbero connection [in fact, when $\beta=i$, the initial formulation due to Ashtekar, A^i_a comes from the ADM formalism of the (self-dual sector) of the Plebanski action[10]], $\tilde{E}^a_i$ is the densitized triad e^a_i, and β is the Barbero–Immirzi parameter.[4,11,12] In the Ashtekar formulation of general relativity the covariant derivative is defined to act on internal indices only. The extension of the covariant derivative to act on space indices is usually defined by choosing a torsion-free extension.[4,5] In this paper, we explore the different ways in which this extension can be made. As we have mentioned, we have the possibility of working within the Cartan framework or not. Therefore, we can define two covariant derivatives that act on space indices as well. Here we explore both alternatives. Let us consider first the Cartan framework. Here, the triadity must vanish and we need to specify the torsion in order to determine completely the full covariant derivative given by (6). It is clear that if we choose

$$\begin{aligned} t_{ab}{}^i &= 0, \\ T_{ab}{}^c &= A_{[ab]}{}^c=-\beta\epsilon^i{}_{jk}K^j_{[a}e^k_{b]}e^c_i, \end{aligned} \tag{12}$$

then [by using (7)] the connections A^i_a, $A_{ab}{}^c$ are

$$\begin{aligned} A^i_a &= \Gamma^i{}_a+\beta K^i_a, \\ A_{ab}{}^c &= K_{ab}{}^c+T_{ab}{}^c=\Gamma_{ab}{}^c-2T_{(a}{}^c{}_{b)}-\beta\epsilon^i{}_{jk}K^j_{[a}e^k_{b]}e^c_i. \end{aligned} \tag{13}$$

The covariant derivative $\mathcal{D}$ kills the metric q_{ab}, $\mathcal{D}_a q_{bc}=0$. Of course, we have also $\mathcal{D}_a\delta_{ij}=0$. Note that the torsion has here a geometric origin: it depends on the extrinsic curvature K^i_a. The fact that the Ashtekar–Barbero connection has torsion and that this is related to the extrinsic curvature means that the foliation of spacetime plays a double role: defining the new variables, through the connection A^i_a, and inducing geometric nonvanishing torsion on the three-dimensional connection. Of course, the torsion appears only in the case of a nonvanishing Barbero-Immirzi parameter.

There is a second possibility for defining the covariant derivative (6), taking into account the Ashtekar–Barbero connection A^i_a. This second covariant derivative has *no torsion*, but has nonvanishing triadity. In this sense there is a mechanism for avoiding torsion, but it should be clear that this is a different covariant derivative than the one considered before, and most important, we are *not* in the Cartan framework in this last case. Concretely,

$$t_{ab}{}^{i} = \beta \epsilon^{i}{}_{jk} K_{a}^{j} e_{b}^{k}, \qquad T_{ab}{}^{c} = A_{[ab]}{}^{c} = 0, \tag{14}$$

with A_a^i and $A_{ab}{}^c$ given [using (7)] by

$$A_a^i = \Gamma^i{}_a + \beta K^i{}_a, \qquad A_{ab}{}^c = \Gamma_{ab}{}^c. \tag{15}$$

Even though $\mathcal{D}$ has nonvanishing triadity, the covariant derivative kills the metric q_{ab}, $\mathcal{D}_a q_{bc} = 0$. Of course, also $\mathcal{D}_a \delta_{ij} = 0$ holds. On the other hand, as we have mentioned, the covariant derivative based in the Ashtekar–Barbero connection A_a^i acts only on internal indices. It is usually stated in the literature[4,5] that the covariant derivative can be extended to act on space indices as well, and that such an extension can be chosen free of torsion. The last covariant derivative we have defined is precisely this extension, but in this case the covariant derivative does not kill the triad field, i.e., the covariant derivative has *non*vanishing triadity.

III. CONCLUDING REMARKS

We have shown that two natural covariant derivatives arise from the Ashtekar–Barbero connection. One of these covariant derivatives kills the inverse triad field e_a^i (and of course the three-dimensional metric q_{ab}) and has torsion. The torsion is related to the extrinsic curvature of Σ. The Barbero–Immirzi parameter enters in the value of the torsion. Therefore, the torsion has a pure *geometric* origin as opposed to models where the torsion is put by hand. This structure sits in the Cartan framework. Alternatively, there is a way for avoiding torsion, which is related to the definition of a different covariant derivative. The covariant derivative is well defined, but this case sits outside the Cartan framework. A deeper analysis of the implications of these remarks was not made here, but it would be interesting to develop it in a future work. For instance, the role of the torsion in the $3+1$ decomposition of the spacetime needs to be clarified (the torsion might change the expressions of the constraints of the Hamiltonian formalism as well as the equations of motion for the canonical fields).

One-instanton prepotentials from WDVV equations in $N=2$ supersymmetric SU(4) Yang–Mills theory

Yűji Ohta
Research Institute for Mathematical Sciences, Kyoto University, Sakyoku, Kyoto 606, Japan

(Received 28 April 1999; accepted for publication 10 May 1999)

Prepotentials in $N=2$ supersymmetric Yang–Mills theories are known to obey nonlinear partial differential equations called Witten–Dijkgraaf–Verlinde–Verlinde (WDVV) equations. In this paper, the prepotentials at the one-instanton level in $N=2$ supersymmetric SU(4) Yang–Mills theory are studied from the standpoint of WDVV equations. Especially, it is shown that the one-instanton prepotentials are obtained from WDVV equations by assuming the perturbative prepotential and by using the scaling relation as a subsidiary condition but are determined without introducing the Seiberg–Witten curve. In this way, various one-instanton prepotentials which satisfy both WDVV equations and the scaling relation can be derived, but it turns out that among them there exist one-instanton prepotentials which coincide with the instanton calculus. © *1999 American Institute of Physics.* [S0022-2488(99)01708-9]

I. INTRODUCTION

A class of developments of quantum field theory in the 1990s may be represented by two keywords: $N=2$ supersymmetry and duality. For example, the mirror symmetry[1–4] established in the beginning of the nineties was based on the (trivial) isomorphism between left and right U(1) currents of (2,2)-superconformal field theory,[5,6] and this isomorphism predicted the existence of a pair of Calabi–Yau manifolds whose axes of the Hodge diamond were exchanged. Candelas *et al.*[3,4] skillfully used the consequence expected from this duality of the Hodge structure and showed that the number of rational curves on the Calabi–Yau quintic three-fold could be determined from mirror symmetry. The coincidence of their result with mathematically rigorous results[1,7,8] was a great surprise!

On the other hand, also in the recent studies of low-energy effective dynamics of $N=2$ supersymmetric Yang–Mills theory, $N=2$ supersymmetry and duality play a crucial role. Before the arrival of Seiberg and Witten's proposal of using electro-magnetic duality for the description of the low-energy effective action of SU(2) gauge theory,[9,10] though it has been known that the prepotential which is a generating function of the low-energy effective action is not renormalized beyond one-loop in perturbative calculation due to $N=2$ supersymmetry,[11–13] actually the prepotential was expected to receive instanton corrections.[14] Unfortunately, such corrections were not so extensively discussed, but thanks to their proposal, it made it possible to extract information on instanton effects from a Riemann surface and periods of meromorphic differential on it. Namely, the low-energy effective theory turned out to be parametrized by a Riemann surface. The validity of their proposal was discussed by Klemm *et al.*[15] with the aid of the Picard–Fuchs equation and the instanton corrections to the prepotential were revealed. The instanton corrections obtained in this way showed extremely good agreement with the prediction of instanton calculus.[16–21]

However, deeper and striking features of prepotentials of $N=2$ supersymmetric Yang–Mills theories may be nicely interpreted in terms of differential equations satisfied by prepotentials. For instance, it is well known that the prepotentials satisfy a Euler equation called a scaling relation,[22–26] and, in fact, this simple equation simplified and accelerated the study of prepotentials. As for another characteristic equation, we can mention that there is a nonlinear system of partial differential equations called Witten–Dijkgraaf–Verlinde–Verlinde (WDVV) equations[27–31] (rigorously speaking, the WDVV equations in $N=2$ Yang–Mills theory are not equivalent to those arising in two-dimensional topological field theory[32–35]). Actually, these equations hold not only in four-dimensional gauge theories but also in higher dimensions even if hypermultiplets are included.[28,29] Accordingly, it becomes possible to regard the prepotentials in various gauge theories as a member of solutions to WDVV equations. Then, what is the most general solution (function form of prepotentials) to the WDVV equations? Unfortunately, we cannot precisely know the answer to this question, but Braden *et al.*[36] partially found the answer. They assumed the function form of the prepotential which is expected from known examples and found a new prepotential which is considered as that in five-dimensional gauge theory, although their study was restricted to the perturbative part. Of course, among the solutions found by them we can see the existence of the prepotential in four-dimensional Yang–Mills theory. This seems to indicate that the prepotentials can be constructed without introducing the Riemann surface, provided the WDVV equations are used. Finding whether nonperturbative prepotentials are available from WDVV equations without using the Riemann surface is the subject of this paper.

The paper is organized as follows. In Sec. II, the construction of a perturbative solution to WDVV equations for SU(4) gauge theory in four dimensions discussed by Braden *et al.*[36] is summarized. We can see that the perturbative prepotential is, in fact, obtained from WDVV equations. In Sec. III, we add the nonperturbative part for this perturbative prepotential and try to solve the WDVV equations. Though the nonperturbative part satisfies a nonlinear differential equation, restricting it at the one-instanton level, we can reduce it to a linear differential equation satisfied by the one-instanton prepotential. For this reason, the one-instanton prepotential is investigated in this paper. To solve this equation, the scaling relation is used as a subsidiary condition, but it turns out that there are miscellaneous solutions which do not contradict both WDVV equations and the scaling relation. In Sec. IV we compare our result with the prediction of the one-instanton calculus. It is shown that among our one-instanton prepotentials obtained from WDVV equations there are one-instanton prepotentials which agree with the prediction of instanton calculus. In this way, we conclude that it is possible to obtain a nonperturbative prepotential from WDVV equations without relying on the Riemann surface. Section V is a brief summary.

II. PERTURBATIVE PREPOTENTIAL FROM WDVV EQUATIONS

In this section, we briefly outline the construction to get perturbative prepotential from WDVV equations in the SU(4) gauge theory presented by Braden *et al.*[36] Note that the SU(4) model is the simplest and nontrivial example for a study of WDVV equations.

In this case, the WDVV equations for the prepotential $\mathcal{F}$ take the form

$$(\mathcal{F}_i)(\mathcal{F}_k)^{-1}(\mathcal{F}_j)=(\mathcal{F}_j)(\mathcal{F}_k)^{-1}(\mathcal{F}_i), \quad i,j,k=1,...,3, \tag{2.1}$$

where

$$(\mathcal{F}_i)\equiv(\mathcal{F}_i)_{jk}=\frac{\partial^3\mathcal{F}}{\partial a_i\partial a_j\partial a_k} \tag{2.2}$$

are the matrix notations and in this paper the brackets are always added as $(\mathcal{F}_i)$ when "$\mathcal{F}_i$" mean matrices. The coordinates a_i are the periods of the SU(4) gauge theory (see the Appendix).

Braden *et al.*[36] considered the perturbative prepotential in the form

$$\mathcal{F}_{\text{per}}(a_1,a_2,a_3)=\sum_{i<j=1}^{4} f(a_{ij}), \quad a_{ij}=a_i-a_j, \quad \sum_{i=1}^{4} a_i=0. \tag{2.3}$$

Of course $\mathcal{F}_{\text{per}}$ may depend on the mass scale $\Lambda\equiv\Lambda_{SU(4)}^8$ of the theory, but we can ignore its dependence for the moment because Λ-differentiation is not included in the WDVV equations (2.1).

Under the assumption (2.3), we can find that when $\mathcal{F}_{\rm per}$ satisfies (2.1) there is a functional relation

$$g(a_{12})g(a_{34})-g(a_{13})g(a_{24})+g(a_{14})g(a_{23})=0, \tag{2.4}$$

where

$$g(a)\equiv\left(\frac{\partial^3 f}{\partial a^3}\right)^{-1}. \tag{2.5}$$

With the aid of several conditions, we can conclude that g is an odd function with

$$g(0)=g''(0)=0, \tag{2.6}$$

where the prime means the differentiation over the argument.[36]

There are several functions enjoying the properties (2.4) and (2.6), but a function which is necessary for us among them is the function of the form $g(a)=a$. Namely,

$$f(a)=\frac{a^2}{2}\ln a+O(a^2). \tag{2.7}$$

Note that $O(a^2)$ term cannot be fixed from the WDVV equations because they are third-order differential equations. Namely, the classical part is not fixed. It is easy to see that substituting (2.7) back to (2.3) in fact yields the perturbative part of the SU(4) prepotential (in a suitable normalization).

Marshakov *et al.*[29] give a general proof that the perturbative prepotentials in various gauge theories satisfy WDVV equations, but this is also confirmed by Ito and Yang[30] in their study of these equations.

III. ONE-INSTANTON PREPOTENTIALS

A. Differential equations for one-instanton prepotentials

Next, let us consider whether nonperturbative prepotential $\mathcal{F}$ is available from the WDVV equations by assuming the form

$$\mathcal{F}(a_1,a_2,a_3,\Lambda)=\mathcal{F}_{\rm per}(a_1,a_2,a_3)+\mathcal{F}_{\rm ins}(a_1,a_2,a_3,\Lambda), \tag{3.1}$$

where

$$\mathcal{F}_{\rm ins}(a_1,a_2,a_3,\Lambda)=\sum_{k=1}^{\infty}\mathcal{F}_k(a_1,a_2,a_3)\Lambda^k. \tag{3.2}$$

In order to derive differential equations for $\mathcal{F}_{\rm ins}$, we assume that $\mathcal{F}_{\rm per}$ is already given by (2.3) with (2.7).

Then substituting $\mathcal{F}$ into (2.1) we can obtain a single nonlinear differential equation for $\mathcal{F}_{\rm ins}$, but if we restrict only the case $k=1$ (one-instanton level), the equation reduces to

$$\begin{aligned}&\frac{\partial_1^3\mathcal{F}_1}{a_{12}a_{13}a_{14}}-\frac{\partial_2^3\mathcal{F}_1}{a_{12}a_{23}a_{24}}+\frac{\partial_3^3\mathcal{F}_1}{a_{13}a_{23}a_{34}}+\frac{6\partial_1\partial_2\partial_3\mathcal{F}_1}{a_{14}a_{24}a_{34}}-\frac{A_{012}\partial_2\partial_3^2\mathcal{F}_1+A_{021}\partial_2^2\partial_3\mathcal{F}_1}{a_{12}a_{13}a_{23}a_{24}a_{34}}\\&-\frac{A_{102}\partial_1\partial_3^2\mathcal{F}_1-A_{201}\partial_1^2\partial_3\mathcal{F}_1}{a_{12}a_{13}a_{14}a_{23}a_{34}}+\frac{A_{120}\partial_1\partial_2^2\mathcal{F}_1+A_{210}\partial_1^2\partial_2\mathcal{F}_1}{a_{12}a_{13}a_{14}a_{23}a_{24}}=0,\end{aligned} \tag{3.3}$$

where $\partial_i\equiv\partial/\partial a_i$ and

$$
\begin{aligned}
A_{012}&=a_1a_2-3a_2^2-2a_1a_3+4a_2a_3+a_1a_4+a_2a_4-2a_3a_4,\\
A_{021}&=2a_1a_2-a_1a_3-4a_2a_3+3a_3^2-a_1a_4+2a_2a_4-a_3a_4,\\
A_{102}&=3a_1^2-a_1a_2-4a_1a_3+2a_2a_3-a_1a_4-a_2a_4+2a_3a_4,\\
A_{201}&=2a_1a_2-4a_1a_3-a_2a_3+3a_3^2+2a_1a_4-a_2a_4-a_3a_4,\\
A_{120}&=3a_1^2-4a_1a_2-a_1a_3+2a_2a_3-a_1a_4+2a_2a_4-a_3a_4,\\
A_{210}&=4a_1a_2-3a_2^2-2a_1a_3+a_2a_3-2a_1a_4+a_2a_4+a_3a_4.
\end{aligned} \tag{3.4}
$$

B. The solutions

In order to solve (3.3), let us introduce the new variables

$$x=a_{12},\quad y=a_{13},\quad z=a_{14}. \tag{3.5}$$

In addition, using Euler derivatives $\theta_x=x\partial/\partial x$, etc., we can rewrite (3.3) as

$$L(\theta_x,\theta_y,\theta_z)\mathcal{F}_1=0, \tag{3.6}$$

where

$$
\begin{aligned}
L(\theta_x,\theta_y,\theta_z)=&\,yz(y-z)\theta_x(\theta_x-1)(\theta_x-2)+z(4xy-3y^2-2xz+yz)(\theta_x-1)\theta_x\theta_y\\
&+z(3x^2-4xy-xz+2yz)(\theta_y-1)\theta_x\theta_y-xz(x-z)\theta_y(\theta_y-1)(\theta_y-2)\\
&-y(3x^2-xy-4xz+2yz)(\theta_z-1)\theta_x\theta_y-y(4xz+yz-3z^2-2xy)(\theta_x-1)\theta_x\theta_z\\
&+6(x-y)(x-z)(y-z)\theta_x\theta_y\theta_z+x(xz+4yz-3z^2-2xy)(\theta_y-1)\theta_y\theta_z\\
&+x(3y^2+2xz-4yz-xy)(\theta_z-1)\theta_y\theta_z+xy(x-y)\theta_z(\theta_z-1)(\theta_z-2).
\end{aligned} \tag{3.7}
$$

Here, suppose that $\mathcal{F}_1$ is given by

$$\mathcal{F}_1=x^{\nu_1}y^{\nu_2}z^{\nu_3}F(x,y,z), \tag{3.8}$$

where

$$F(x,y,z)=\sum_{i,j,k=0}^{\infty} B_{\epsilon_x i,\epsilon_y j,\epsilon_z k}\, x^{\epsilon_x i}y^{\epsilon_y j}z^{\epsilon_z k} \tag{3.9}$$

and the expansion coefficients are assumed to be independent of x, y, and z. In (3.9), ϵ_x, etc. are signature symbols (the choice of signatures depends on where the convergence region is), e.g., $\epsilon_x=\pm$. Then from (3.3) we get the differential equation for F,

$$L(\theta_x+\nu_1,\theta_y+\nu_2,\theta_z+\nu_3)F=0, \tag{3.10}$$

and the indicial equations for ν_i:

$$
\begin{gathered}
\nu_1(\nu_1-2\nu_2-1)(\nu_1+\nu_2-3\nu_3-2)=0,\quad \nu_2(2\nu_1-\nu_2+1)(\nu_1+\nu_2-3\nu_3-2)=0,\\
\nu_2(\nu_2-2\nu_3-1)(3\nu_1-\nu_2-\nu_3+2)=0,\quad (\nu_2-\nu_3)(\nu_1^2-\nu_1-\nu_1\nu_2+\nu_2\nu_3)=0,\\
\nu_1(\nu_1^2-3\nu_1+5\nu_2-3\nu_1\nu_2+\nu_3-\nu_1\nu_3+4\nu_2\nu_3+2)=0,
\end{gathered} \tag{3.11}
$$

$$\nu_3^2(\nu_3-3\nu_2-3)+5\nu_1\nu_2\nu_3+3\nu_2\nu_3-2\nu_1^2\nu_3+2\nu_1\nu_3+2\nu_3+\nu_1\nu_2=0,$$

$$\nu_3^2(\nu_3-\nu_2-3)-2\nu_2^2\nu_3+3\nu_1\nu_2\nu_3+3\nu_2\nu_3+3\nu_1\nu_2+2\nu_3=0.$$

The sets of possible ν_i are thus given by

$$\boldsymbol{\nu}\equiv(\nu_1,\nu_2,\nu_3)=(-2,-2,-2),(-1,-1,-1),(0,-1,-1)^4,(0,0,0)^2,(0,0,1),(0,0,2)^2,$$
$$(0,1,0,),(0,1,1),(0,2,0)^2,(1,0,0)^2,(1,0,1),(1,0,2),(2,0,0)^2, \tag{3.12}$$

where the superscript means degeneracy, e.g., $(0,0,0)^2$ is composed of two (0, 0, 0), but we do not discuss the consequence of degeneracy in this paper. For the indices (3.12), it is straightforward to obtain F. Though we have expressed F in (3.9) as an infinite series, actually we can restrict possible terms in (3.9) by considering the degree counting of the one-instanton prepotential.

C. Scaling relation for one-instanton prepotential

If the WDVV equations can, in fact, yield a physically acceptable prepotential, the prepotential obtained from those equations must also satisfy the fundamental homogeneity condition called the scaling relation.[22–26] Therefore, we may use it as a subsidiary condition for the problem how to solve WDVV equations in gauge theory.

To see this, first, let us recall the scaling relation[22–26]

$$\sum_{i=1}^{3} a_i\frac{\partial\mathcal{F}}{\partial a_i}+\Lambda_{\mathrm{SU}(4)}\frac{\partial\mathcal{F}}{\partial\Lambda_{\mathrm{SU}(4)}}=2\mathcal{F}. \tag{3.13}$$

We need a scaling relation for $\mathcal{F}_1$, not for $\mathcal{F}$ itself, but in order to extract it from (3.13), the Λ-dependence of perturbative prepotential which cannot be fixed from WDVV equations must be included appropriately. For this, our choice here is

$$\mathcal{F}_{\mathrm{per}}=\sum_{i<j=1}^{4}\frac{a_{ij}^2}{2}\ln\frac{a_{ij}}{\Lambda_{\mathrm{SU}(4)}}. \tag{3.14}$$

Then from (3.13), $\mathcal{F}_1$ is found to satisfy

$$\sum_{i=1}^{3} a_i\frac{\partial\mathcal{F}_1}{\partial a_i}+6\mathcal{F}_1=0, \tag{3.15}$$

which indicates that $\mathcal{F}_1$ is a homogeneous function of degree -6.

In the variables (3.5), (3.15) becomes

$$x\partial_x\mathcal{F}_1+y\partial_y\mathcal{F}_1+z\partial_z\mathcal{F}_1+6\mathcal{F}_1=0. \tag{3.16}$$

Accordingly, from (3.8), (3.9), and (3.16) it must be always true that

$$\nu_1+\nu_2+\nu_3+\epsilon_x i+\epsilon_y j+\epsilon_z k=-6. \tag{3.17}$$

D. Examples of one-instanton prepotentials

We now have enough information to construct explicit one-instanton prepotentials which do not contradict WDVV equations and the scaling relation.

To begin with, let us consider the case $\boldsymbol{\epsilon}\equiv(\epsilon_x,\epsilon_y,\epsilon_z)=(+,+,+)$. In this case, we can easily find that there exists only one solution which satisfies (3.17). It is the solution with $\boldsymbol{\nu}=(-2,-2,-2)$, and thus

$$\mathcal{F}_1=\frac{B_{0,0,0}}{x^2y^2z^2}. \tag{3.18}$$

However, when $\boldsymbol{\epsilon}=(-,-,-)$ or one entry of $\boldsymbol{\epsilon}$ differs from the others, e.g., $\boldsymbol{\epsilon}=(-,-,+)$, the situation changes, in particular, drastically in the latter case. In the former case, it is easy to see that F consists of a finite number of terms for all indices in (3.12), but in the latter case F is generally represented by an infinite number of terms as long as (3.17) is satisfied. We do not know whether it is possible to find any physical meaning for this type of one-instanton prepotential, but it may be interesting to recall that a similar one was observed in the one-instanton prepotential in the five-dimensional gauge theory.[26]

Since the latter case mentioned above is slightly intractable, let us consider an example of the former case instead. In the case of $\boldsymbol{\nu}=(-1,-1,-1)$ with $\boldsymbol{\epsilon}=(-,-,-)$, for instance, we have

$$\mathcal{F}_1=\frac{1}{xyz}\left[B_{0,-1,-2}\left(\frac{1}{yz^2}+\frac{1}{y^2z}\right)+B_{-1,0,-2}\left(\frac{1}{xz^2}+\frac{1}{x^2z}\right)\right.$$
$$\left.+B_{-1,-2,0}\left(\frac{1}{x^2y}+\frac{1}{xy^2}\right)+B_{-1,-1,-1}\frac{1}{xyz}\right]. \tag{3.19}$$

Note that (3.19) includes the one-instanton prepotential of the form (3.18).

In a similar manner, we can construct one-instanton prepotentials for all other possible values of ν_i, which do not contradict both WDVV equations and the scaling relation, but it would not be necessary to explicitly show them here. However, we should point out that since (3.3) is a partial differential system, we can expect that there exist more and more various solutions. In fact, this observation is right, and we can show that also in the variables

$$(x,y,z)=(a_{12},a_{23},a_{24}),(a_{13},a_{23},a_{34}) \tag{3.20}$$

we can construct miscellaneous one-instanton prepotentials. Among them one-instanton prepotentials of the form (3.18) are included.

Remark: The function form of the one-instanton prepotentials can be determined by solving the WDVV equations, but its numerical factors, i.e., instanton expansion coefficients, are not obtained because they correspond to integration constants. In order to determine them, it is necessary to rewrite the scaling relation as a relation between prepotential and moduli. Then substituting the one-instanton prepotential obtained from WDVV equations into this scaling relation, we will be able to get the expansion coefficients. Of course, in this case the moduli must be represented as a function of periods and its expansion coefficients must be determined. However, since knowing moduli is equivalent to introducing a Seiberg-Witten curve, this method based on scaling relation represented by using moduli is not preferable in the formalism of WDVV equations because prepotentials available from WDVV equations should be determined without introduction of Seiberg–Witten curves. Accordingly, when the determination of instanton expansion coefficients is required, they should be determined from the result of instanton calculus.

IV. ONE-INSTANTON PREPOTENTIAL FROM INSTANTON CALCULUS

We have derived one-instanton prepotentials by solving the WDVV equations in the previous section. Though these one-instanton prepotentials satisfy the WDVV equations and the scaling relation, unfortunately, in view of WDVV equations, we cannot determine which ones are physically acceptable. For this reason, in order to extract physically meaningful one-instanton prepotentials among them, we must compare our result with the one-instanton prediction of instanton calculus.

In the case of SU(4) gauge theory, a one-instanton contribution for prepotential is given by[17,18]

$$\mathcal{F}_1=\frac{\Delta_4'}{\Delta_4}, \tag{4.1}$$

where we have omitted the numerical normalization factor and

$$\Delta_4'=\sum_{i=1}^{4}\prod_{\substack{k<l=1\\k,l\neq i}}^{4}(a_k-a_l)^2,\quad \Delta_4=\prod_{k<l=1}^{4}(a_k-a_l)^2. \tag{4.2}$$

The closed form of the one-instanton prepotential for SU(N_c) gauge theory is also obtained by solving Picard–Fuchs equations[37] and direct calculation of period integrals.[38,39]

Note that (4.1) is a sum of (3.18) and those for (3.20):

$$\mathcal{F}_1=\frac{1}{(a_{12}a_{13}a_{14})^2}+\frac{1}{(a_{12}a_{23}a_{24})^2}+\frac{1}{(a_{13}a_{23}a_{34})^2} \tag{4.3}$$

up to constant factors. Accordingly, we can conclude that the WDVV equations can yield physical prepotential without introducing a Riemann surface.

V. SUMMARY

In this paper, we have discussed the nonperturbative prepotential of $N=2$ supersymmetric SU(4) Yang–Mills theory from the standpoint of WDVV equations. Especially, we have found a differential equation for a one-instanton prepotential and constructed its solutions. The method to get prepotentials based on WDVV equations is fascinating in the point that the prepotentials can be obtained without introducing Seiberg–Witten curves, but it has been shown that unfortunately too many prepotentials exist in contrast with the approach based on Seiberg–Witten curves which uniquely determines a prepotential. Nevertheless, we have succeeded in showing that one-instanton prepotentials which coincide with the one-instanton calculus can be obtained from WDVV equations.

As for another aspect of WDVV equations, we should mention a connection to topological field theory in two dimensions. From the appearance of WDVV equations, it may be natural to think that the low-energy effective theory is actually a kind of topological field theory, but we must notice that *a priori* there is no reason that the effective theory must be a topological field theory. Therefore, topological or not topological: that is the question.

An approach to argue this implication more explicitly is to regard the Seiberg–Witten curves often identified with spectral curves of integrable system as if they were superpotentials of topological $\mathbf{CP}^1$ model.[31] Although this observation strongly relies on the existence of a Riemann surface (Seiberg–Witten curve), it enables us to find a connection to topological field theory, specifically, topological string theory at genus zero level.[31] Then, even if we do not assume a Riemann surface, can we find a topological nature of the effective theory? Probably WDVV equations give the answer, but the study is a subject in the future.

ACKNOWLEDGMENT

The author acknowledges Professor H. Kanno for discussions about WDVV equations.

APPENDIX: THE SU(4) SEIBERG–WITTEN SOLUTION

In this Appendix, we briefly summarize the SU(4) Seiberg–Witten solution. The SU(4) Seiberg–Witten curve is given by the hyperelliptic curve of genus three[40–43]

$$y^2=(x^4-ux^2-vx-w)^2-\Lambda_{\mathrm{SU}(4)}^8, \tag{A1}$$

where $(x,y)\in\mathbf{C}^2$ is the local coordinate, and u, v, and w are moduli of the theory. Then the Seiberg–Witten differential and its periods are given by

$$\lambda_{\mathrm{SW}}=\frac{x\partial_x W}{y}dx, \quad W=x^4-ux^2-vx-w \tag{A2}$$

and

$$a_i=\oint_{\alpha_i}\lambda_{\mathrm{SW}}, \quad a_{D_i}=\oint_{\beta_i}\lambda_{\mathrm{SW}}, \quad i=1,2,3, \tag{A3}$$

respectively, where α_i and β_i are the canonical bases of the one-cycles on the curve and the numerical normalization factor of the Seiberg–Witten differential is ignored. It is convenient to use the period vector

$$\Pi=\begin{pmatrix} a_{D_i} \\ a_i \end{pmatrix}. \tag{A4}$$

In general, these periods satisfy Fuchsian differential equations and in the case at hand they are given by[15,18,44,45]

$$\begin{aligned}
&\mathcal{L}_1\Pi\equiv[\partial_v^2-\partial_u\partial_w]\Pi=0,\\
&\mathcal{L}_2\Pi\equiv[4\partial_u^2-2u\partial_u\partial_w-v\partial_v\partial_w-\partial_w]\Pi=0,\\
&\mathcal{L}_3\Pi\equiv[v\partial_w^2+2u\partial_v\partial_w-4\partial_u\partial_v]\Pi=0,\\
&[4(u^2+24w)\partial_u^2+9v^2\partial_v^2-16(\Lambda_{\mathrm{SU}(4)}^8-w^2)\partial_w^2+12uv\partial_u\partial_v-32uw\partial_u\partial_w+3v\partial_v-16w\partial_w+1]\Pi\\
&\quad=0,
\end{aligned} \tag{A5}$$

which can be summarized as

$$\begin{aligned}
&\left[\theta_v(\theta_v-1)-\frac{v^2}{uw}\theta_u\theta_w\right]\Pi=0,\\
&\left[(2\theta_u+\theta_v+1)\theta_w-\frac{4w}{u^2}\theta_u(\theta_u-1)\right]\Pi=0,\\
&\left[(2\theta_u+3\theta_v+4\theta_w-1)^2-\frac{16\Lambda_{\mathrm{SU}(4)}^8}{w^2}\theta_w(\theta_w-1)\right]\Pi=0,
\end{aligned} \tag{A6}$$

where $\theta_w=w\partial_w$, etc., are Euler derivatives, provided the first, second, and last equations in (A5) are chosen as independent equations. Note that the third one in (A5) is not an independent equation because $(v\partial_w\mathcal{L}_1+\partial_v\mathcal{L}_2+\partial_u\mathcal{L}_3)\Pi=0$.

Introducing new variables x, y, and z by

$$x=\frac{\Lambda_{\mathrm{SU}(4)}^8}{4w^2}, \quad y=\frac{v^2}{4uw}, \quad z=\frac{w}{u^2}, \tag{A7}$$

we find that (A6) is converted into

$$[(8\theta_x+1)^2-64x(2\theta_x+\theta_y-\theta_z)(2\theta_x+\theta_y-\theta_z+1)]\Pi=0,$$

$$[\theta_y(2\theta_y-1)-2y(\theta_y+2\theta_z)(2\theta_x+\theta_y-\theta_z)]\Pi=0, \tag{A8}$$

$$[(2\theta_x+\theta_y-\theta_z)(4\theta_z-1)-4z(\theta_y+2\theta_z)(\theta_y+2\theta_z+1)]\Pi=0.$$

This system (A8) further simplifies to

$$[\theta_x^2-x(2\theta_x+\theta_y-\theta_z-1/2)(2\theta_x+\theta_y-\theta_z+1/2)]\tilde{\Pi}=0,$$

$$[\theta_y(\theta_y-1/2)-y(\theta_y+2\theta_z+1/2)(2\theta_x+\theta_y-\theta_z-1/2)]\tilde{\Pi}=0,$$

$$[(2\theta_x+\theta_y-\theta_z-1/2)\theta_z-z(\theta_y+2\theta_z+1/2)(\theta_y+2\theta_z+3/2)]\tilde{\Pi}=0 \tag{A9}$$

by $\Pi=x^{-1/8}z^{1/4}\tilde{\Pi}$. An analytic solution around $(x,y,z)=(0,0,0)$ is given by

$$\tilde{\Pi}=\sum_{m,n,p=0}^{\infty}\frac{(1/2)_{n+2p}(-1/2)_{2m+n-p}}{(1)_m(1/2)_n}\frac{x^m}{m!}\frac{y^n}{n!}\frac{z^p}{p!}, \tag{A10}$$

which is known as the type 54*b* Srivastava and Karlsson's (Gaussian) hypergeometric function in three variables,[46] and we denote it by

$$G_{54b}[\alpha,\beta;\gamma,\delta;x,y,z]=\sum_{m,n,p=0}^{\infty}\frac{(\alpha)_{n+2p}(\beta)_{2m+n-p}}{(\gamma)_m(\delta)_n}\frac{x^m}{m!}\frac{y^n}{n!}\frac{z^p}{p!}, \tag{A11}$$

which recovers Horn's $\mathcal{H}_4$ for $p=0$. Note that G_{54b} satisfies

$$[(\theta_x+\gamma-1)\theta_x-x(2\theta_x+\theta_y-\theta_z+\beta)(2\theta_x+\theta_y-\theta_z+\beta+1)]G_{54b}=0,$$

$$[(\theta_y+\delta-1)\theta_y-y(\theta_y+2\theta_z+\alpha)(2\theta_x+\theta_y-\theta_z+\beta)]G_{54b}=0, \tag{A12}$$

$$[(2\theta_x+\theta_y-\theta_z+\beta)\theta_z-z(\theta_y+2\theta_z+\alpha)(\theta_y+2\theta_z+\alpha+1)]G_{54b}=0.$$

(Received 2 February 1999; accepted for publication 21 April 1999)

It is shown that there exists a one-to-one correspondence between the real solutions of the Einstein vacuum field equations linearized about the Minkowski metric and the (complex) metric perturbations whose curvature to first order in the metric perturbation is self-dual. It is also shown that the self-duality condition of the curvature to first order in the metric perturbation is equivalent to a set of first-order equations for the metric perturbation whose solution is given by a scalar potential that obeys the wave equation.
[S0022-2488(99)00808-7]

I. INTRODUCTION

Every real solution of the source-free Maxwell equations, in flat or curved space–time, is the real part of a self-dual (or an anti-self-dual) Maxwell field. This fact allows us to find all the solutions of the source-free Maxwell equations (which constitute a set of second-order partial differential equations for the vector potential) by solving the self-duality conditions (which are a set of first-order partial differential equations for the vector potential) and in this manner one can demonstrate that in flat space–time or in a curved space–time that admits a geodetic and shear-free null congruence defined by a repeated principal null direction of the curvature, every solution of the source-free Maxwell equations can be locally expressed in terms of a single complex scalar potential.[1] The resulting expression coincides with one previously obtained by means of other approaches (see, e.g., Refs. 2–4).

The linearized Einstein vacuum field equations are similar to the source-free Maxwell equations in several ways. In fact, if the background space–time is flat, then the curvature tensor to first order in the metric perturbation, $K_{\alpha\beta\gamma\delta}$, obeys equations analogous to the source-free Maxwell equations. Moreover, in the case of a flat background, the tensor field $K_{\alpha\beta\gamma\delta}$ is invariant under the gauge transformations $h_{\alpha\beta}\mapsto h_{\alpha\beta}+2\nabla_{(\alpha}\xi_{\beta)}$ and, making use of spherical or cylindrical coordinates, it can be expressed in terms of a single complex scalar potential that satisfies the wave equation.[5,6] On the other hand, an expression for the metric perturbations of flat space–time or of an algebraically special solution of the Einstein vacuum field equations in terms of a complex scalar potential has been obtained by various approaches[7,3,8] which, however, do not demonstrate that every solution of the Einstein vacuum field equations linearized about these backgrounds can be written in that form. It may be recalled that, by contrast, in the standard treatment of the Einstein vacuum field equations linearized about the Minkowski metric, by imposing an appropriate gauge condition, one finds that each Cartesian component of the metric perturbation satisfies the wave equation (see, e.g., Refs. 9 and 10).

In this paper we show that, by analogy with the electromagnetic case, every real solution of the Einstein vacuum field equations linearized about the Minkowski metric is the real part of a metric perturbation whose curvature tensor to first order in the metric perturbation, $K_{\alpha\beta\gamma\delta}$, is self-dual (or anti-self-dual) and that if $K_{\alpha\beta\gamma\delta}$ is self-dual, then the metric perturbation can be expressed in terms of a complex scalar potential that satisfies the wave equation.

II. SELF-DUALITY AND THE LINEARIZED EINSTEIN VACUUM FIELD EQUATIONS

In the linearized Einstein theory it is assumed that, in a suitable coordinate system, the metric of the space–time can be written in the form

$$g_{\alpha\beta}=\eta_{\alpha\beta}+h_{\alpha\beta}, \tag{1}$$

where $h_{\alpha\beta}$, the metric perturbation, represents a small deviation of the metric $g_{\alpha\beta}$ from the Minkowski metric $(\eta_{\alpha\beta})=\mathrm{diag}(1,-1,-1,-1)$. The tensor field

$$K_{\alpha\beta\gamma\delta}\equiv\tfrac{1}{2}\{\partial_\alpha\partial_\gamma h_{\beta\delta}-\partial_\beta\partial_\gamma h_{\alpha\delta}+\partial_\beta\partial_\delta h_{\alpha\gamma}-\partial_\alpha\partial_\delta h_{\beta\gamma}\} \tag{2}$$

is the first-order contribution in $h_{\alpha\beta}$ to the curvature tensor corresponding to the metric $g_{\alpha\beta}$ and is invariant under the gauge transformations

$$h_{\alpha\beta}\mapsto h_{\alpha\beta}+\partial_\alpha\xi_\beta+\partial_\beta\xi_\alpha, \tag{3}$$

where ξ_α is an arbitrary vector field. From Eq. (2) it follows that $K_{\alpha\beta\gamma\delta}$ possesses the symmetries of the Riemann curvature tensor

$$K_{\alpha\beta\gamma\delta}=-K_{\beta\alpha\gamma\delta}=-K_{\alpha\beta\delta\gamma}=K_{\gamma\delta\alpha\beta}, \tag{4}$$

$$K_{\alpha\beta\gamma\delta}+K_{\alpha\delta\beta\gamma}+K_{\alpha\gamma\delta\beta}=0, \tag{5}$$

and

$$\partial_\alpha K_{\beta\gamma\delta\epsilon}+\partial_\beta K_{\gamma\alpha\delta\epsilon}+\partial_\gamma K_{\alpha\beta\delta\epsilon}=0. \tag{6}$$

Conversely, if $K_{\alpha\beta\gamma\delta}$ satisfies Eqs. (4)–(6), then there exists locally a symmetric tensor field $h_{\alpha\beta}$, defined up to the gauge transformations (3), such that Eq. (2) holds.

Defining the right dual $K^*_{\alpha\beta\gamma\delta}$ of $K_{\alpha\beta\gamma\delta}$ by means of

$$K^*_{\alpha\beta\gamma\delta}\equiv\tfrac{1}{2}K_{\alpha\beta}{}^{\rho\sigma}\epsilon_{\rho\sigma\gamma\delta}, \tag{7}$$

where $\epsilon_{\alpha\beta\gamma\delta}$ is completely antisymmetric with $\epsilon_{0123}=1$ and the indices are raised and lowered by means of $\eta^{\alpha\beta}$ and $\eta_{\alpha\beta}$, one finds that

$$K^*_{\alpha\beta\gamma\delta}=-K^*_{\beta\alpha\gamma\delta}=-K^*_{\alpha\beta\delta\gamma} \tag{8}$$

and

$$K^*_{\alpha\beta\gamma\delta}-K^*_{\gamma\delta\alpha\beta}=\tfrac{1}{2}(\epsilon_{\alpha\beta\delta\rho}K_\gamma{}^\rho+\epsilon_{\beta\alpha\gamma\rho}K_\delta{}^\rho+\epsilon_{\gamma\beta\delta\rho}K_\alpha{}^\rho+\epsilon_{\delta\alpha\gamma\rho}K_\beta{}^\rho), \tag{9}$$

where we have made use of the symmetric tensor field

$$K_{\alpha\beta}\equiv K_{\alpha\gamma\beta}{}^\gamma. \tag{10}$$

Moreover,

$$K^*_{\alpha\beta\gamma\delta}+K^*_{\alpha\delta\beta\gamma}+K^*_{\alpha\gamma\delta\beta}=-\epsilon_{\beta\gamma\delta\rho}K_\alpha{}^\rho \tag{11}$$

and

$$\partial_\alpha K^*_{\beta\gamma\delta\epsilon}+\partial_\beta K^*_{\gamma\alpha\delta\epsilon}+\partial_\gamma K^*_{\alpha\beta\delta\epsilon}=0. \tag{12}$$

Thus, $K^*_{\alpha\beta\gamma\delta}$ possesses all symmetries of $K_{\alpha\beta\gamma\delta}$ if and only if $K_{\alpha\beta}=0$, i.e., if the linearized Einstein vacuum field equations are satisfied.

Let $h_{\alpha\beta}$ be a real metric perturbation such that $K_{\alpha\beta}=0$. Then, the complex tensor field

$$P_{\alpha\beta\gamma\delta} \equiv K_{\alpha\beta\gamma\delta} - iK^{*}_{\alpha\beta\gamma\delta} \tag{13}$$

is self-dual,

$$P^{*}_{\alpha\beta\gamma\delta} = iP_{\alpha\beta\gamma\delta}, \tag{14}$$

and, according to the preceding paragraph, satisfies Eqs. (4)–(6). Hence, there exists a complex symmetric tensor field, $h^{c}_{\alpha\beta}$, such that

$$P_{\alpha\beta\gamma\delta} \equiv \tfrac{1}{2}\{\partial_\alpha\partial_\gamma h^{c}_{\beta\delta} - \partial_\beta\partial_\gamma h^{c}_{\alpha\delta} + \partial_\beta\partial_\delta h^{c}_{\alpha\gamma} - \partial_\alpha\partial_\delta h^{c}_{\beta\gamma}\} \tag{15}$$

and the original metric perturbation $h_{\alpha\beta}$ coincides with the real part of $h^{c}_{\alpha\beta}$ up to a gauge transformation (3).

Conversely, given a (complex) symmetric tensor field $h^{c}_{\alpha\beta}$ such that the tensor field (15) satisfies the self-duality condition [Eq. (14)], then the real and imaginary parts of $P_{\alpha\beta\gamma\delta}$, being linear combinations of $P_{\alpha\beta\gamma\delta}$ and its complex conjugate, satisfy Eqs. (4)–(6). If $K_{\alpha\beta\gamma\delta}$ denotes the real part of $P_{\alpha\beta\gamma\delta}$, then denoting the complex conjugation by a bar, from Eq. (14) we see that

$$K^{*}_{\alpha\beta\gamma\delta} = \frac{1}{2}(P^{*}_{\alpha\beta\gamma\delta} + \overline{P^{*}_{\alpha\beta\gamma\delta}}) = -\frac{1}{2i}(P_{\alpha\beta\gamma\delta} - \overline{P_{\alpha\beta\gamma\delta}}),$$

i.e., the right dual of the real part of $P_{\alpha\beta\gamma\delta}$ is minus the imaginary part of $P_{\alpha\beta\gamma\delta}$ and, therefore, $K_{\alpha\beta\gamma\delta}$ and $K^{*}_{\alpha\beta\gamma\delta}$ satisfy Eqs. (4)–(6), which implies that $K_{\alpha\beta} = 0$. Thus, the real part of $h^{c}_{\alpha\beta}$ satisfies the linearized Einstein field equations. The tensor $K_{\alpha\beta\gamma\delta}$ is related to the real part of $h^{c}_{\alpha\beta}$ according to Eq. (2).

III. INTEGRATION OF THE SELF-DUALITY CONDITIONS

In what follows, it will be convenient to make use of the spinor formalism. Letting

$$\partial_{AB'} \equiv \frac{\partial}{\partial x^{AB'}} \tag{16}$$

$(A,B,\ldots = 0,1;\ A',B',\ldots = 0',1')$ where the $x^{AB'}$ are (complex) coordinates such that the Minkowski metric is given by

$$ds^2 = \eta_{\alpha\beta}dx^\alpha dx^\beta = \epsilon_{AB}\epsilon_{C'D'}dx^{AC'}dx^{BD'}, \tag{17}$$

the spinor equivalent of Eq. (2) is given by

$$K_{AA'BB'}{}^{CC'DD'} = \tfrac{1}{2}\epsilon_{AB}\epsilon^{CD}\partial^{S}{}_{(A'}\partial^{R(C'}h_{|SR|B')}{}^{D')} + \tfrac{1}{2}\epsilon_{A'B'}\epsilon^{CD}\partial_{(A}{}^{S'}\partial^{R(C'}h_{B)RS'}{}^{D')}$$
$$+ \tfrac{1}{2}\epsilon_{AB}\epsilon^{C'D'}\partial^{S}{}_{(A'}\partial^{(C|R'|}h_{|S|}{}^{D)}{}_{B')R'} + \tfrac{1}{2}\epsilon_{A'B'}\epsilon^{C'D'}\partial_{(A}{}^{S'}\partial^{(C|R'|}h_{B)}{}^{D)}{}_{S'R'},$$

where $h_{ABA'B'} = h_{BAB'A'}$ is the spinor equivalent of $h_{\alpha\beta}$, the parentheses denote symmetrization on the indices enclosed, and the indices between bars are excluded from the symmetrization. Therefore, the self-duality conditions (14) amount to

$$\partial^{S}{}_{(A'}\partial^{(C|R'|}h_{|S|}{}^{D)}{}_{B')R'} = 0, \quad \partial_{(A}{}^{S'}\partial^{(C|R'|}h_{B)}{}^{D)}{}_{S'R'} = 0, \tag{18}$$

or, equivalently,

$$\partial^{S}{}_{(A'}H^{CD}{}_{|S|B')} = 0, \quad \partial_{(A}{}^{S'}H^{CD}{}_{B)S'} = 0 \tag{19}$$

with

$$H^{CD}{}_{AB'} \equiv \partial^{(C|R'|}h_A{}^{D)}{}_{B'R'} = \partial^{(C|R'|}h^{D)}{}_{AR'B'}\,. \tag{20}$$

Since the background metric is flat, Eqs. (19) are locally equivalent to the existence of a symmetric spinor field Λ_{AB} such that

$$H_{ABCD'} = \partial_{CD'}\Lambda_{AB}\,. \tag{21}$$

There always exists a (possibly complex) vector field $\xi_{AB'}$ such that

$$\Lambda_{AB} = -\partial_{(A}{}^{C'}\xi_{B)C'} \tag{22}$$

(actually, there are an infinite number of such vector fields). Then making use of Eqs. (20)–(22) one finds that under the gauge transformation $h_{ABA'B'} \mapsto h_{ABA'B'} + \partial_{AA'}\xi_{BB'} + \partial_{BB'}\xi_{AA'}$ [see Eq. (3)], $H_{ABCD'}$ is transformed into

$$\partial_{(A}{}^{R'}[h_{B)CR'D'} + \partial_{B)R'}\xi_{CD'} + \partial_{|CD'|}\xi_{B)R'}] = H_{ABCD'} + \partial_{CD'}\partial_{(A}{}^{R'}\xi_{B)R'} = H_{ABCD'} - \partial_{CD'}\Lambda_{AB} = 0. \tag{23}$$

Thus, by means of the gauge transformations (3), the self-duality conditions (18) can be reduced to the first-order differential equations

$$\partial_{(A}{}^{R'}h_{B)CR'D'} = 0. \tag{24}$$

Conditions (24) are similar to the (gauge-independent) equations for the vector potential of a self-dual electromagnetic field, $\nabla_{(A}{}^{R'}\Phi_{B)R'} = 0$ (see, e.g., Ref. 1), with an extra tensor index and, as in the case of the latter equations in a flat background, the solution of Eq. (24) is given, modulo gauge transformations, by a scalar potential that satisfies the wave equation. In order to prove this assertion, we start by considering Eq. (24) with $A = B = 0$, which yields $\partial_0{}^{R'}h_{0CR'D'} = 0$. These equations are locally equivalent to the existence of a set of functions, $M_{CD'}$, such that

$$h_{0CR'D'} = \partial_{0R'}M_{CD'}\,. \tag{25}$$

The symmetry of $h_{00R'D'}$ in the primed indices and Eq. (25) give $0 = h_{00}{}^{R'}{}_{R'} = \partial_0{}^{R'}M_{0R'}$, hence, there exists locally a function α such that

$$M_{0R'} = \partial_{0R'}\alpha. \tag{26}$$

Equation (24) with $A = 0$, $B = 1$, and $C = 0$ gives $\partial_0{}^{R'}h_{10R'D'} + \partial_1{}^{R'}h_{00R'D'} = 0$, or, making use of Eqs. (25) and (26), $0 = \partial_0{}^{R'}h_{10R'D'} + \partial_1{}^{R'}\partial_{0R'}\partial_{0D'}\alpha = \partial_0{}^{R'}(h_{10R'D'} - \partial_{1R'}\partial_{0D'}\alpha)$, which is locally equivalent to the existence of two functions $\mu_{A'}$ such that

$$h_{10R'D'} = \partial_{1R'}\partial_{0D'}\alpha + \partial_{0R'}\mu_{D'}\,. \tag{27}$$

Since $h_{10R'D'}$ must coincide with $h_{01D'R'}$, from Eqs. (25) and (27) it follows that $\partial_{1R'}\partial_{0D'}\alpha + \partial_{0R'}\mu_{D'} = \partial_{0D'}M_{1R'}$. Applying $\partial_0{}^{D'}$ to both sides of the last equation one finds that $\partial_{0R'}\partial_0{}^{D'}\mu_{D'} = 0$; hence,

$$\partial_0{}^{D'}\mu_{D'} = f(x^{1A'}), \tag{28}$$

where f is some function of two variables. By expressing Eq. (28) in the form $\partial_{0D'}(\mu^{D'} + \frac{1}{2}f(x^{1A'})x^{0D'}) = 0$, one finds that there exists locally a function β such that $\mu^{D'} + \frac{1}{2}f(x^{1A'})x^{0D'} = \partial_0{}^{D'}\beta$ and substituting this expression into Eq. (27) we obtain

$$h_{10R'D'} = \partial_{1R'}\partial_{0D'}\alpha + \partial_{0R'}(\partial_{0D'}\beta - \tfrac{1}{2}f(x^{1A'})x^0{}_{D'}). \tag{29}$$

Equation (24) with $A=0$ and $B=1=C$ yields $0=\partial_0{}^{R'}h_{11R'D'}+\partial_1{}^{R'}h_{01R'D'}$ or, equivalently, making use of Eq. (29), $0=\partial_0{}^{R'}h_{11R'D'}+\partial_1{}^{R'}h_{10D'R'}=\partial_0{}^{R'}(h_{11R'D'}-\partial_{1R'}\partial_{1D'}\alpha-\partial_{1R'}\partial_{0D'}\beta-\frac{1}{2}\partial_{1R'}f(x^{1A'})x^0{}_{D'})$, hence

$$h_{11R'D'}=\partial_{1R'}\partial_{1D'}\alpha+\partial_{1R'}\partial_{0D'}\beta+\tfrac{1}{2}\partial_{1R'}f(x^{1A'})x^0{}_{D'}+\partial_{0R'}\nu_{D'}\,, \tag{30}$$

where the $\nu_{D'}$ are some functions. From the symmetry of $h_{11R'D'}$ on the primed indices we obtain the condition $0=h_{11R'}{}^{R'}=\partial_{0R'}(\nu^{R'}-\partial_1{}^{R'}\beta+\frac{1}{6}\partial_{1S'}f(x^{1A'})x^{0S'}x^{0R'})$, therefore

$$\nu_{R'}=\partial_{1R'}\beta-\tfrac{1}{6}\partial_{1S'}f(x^{1A'})x^{0S'}x^0{}_{R'}+\partial_{0R'}\gamma, \tag{31}$$

where γ is some function. Substituting Eq. (31) into Eq. (30) we find that

$$\begin{aligned} h_{11R'D'}&=\partial_{1R'}\partial_{1D'}\alpha+\partial_{1R'}\partial_{0D'}\beta+\partial_{0R'}\partial_{1D'}\beta+\partial_{0R'}\partial_{0D'}\gamma\\ &\quad+\tfrac{1}{6}\partial_{1R'}f(x^{1A'})x^0{}_{D'}+\tfrac{1}{6}\partial_{1D'}f(x^{1A'})x^0{}_{R'}\,. \end{aligned} \tag{32}$$

Considering now Eq. (24) with $A=B=1$ and $C=0$, using Eq. (29) we obtain $0=\partial_1{}^{R'}h_{10R'D'}=\partial_{0D'}\partial_1{}^{R'}\partial_{0R'}\beta-\frac{1}{2}\partial_{1D'}f(x^{1A'})$, which implies that

$$\partial_1{}^{R'}\partial_{0R'}\beta=\tfrac{1}{2}\partial_{1D'}f(x^{1A'})x^{0D'}+g(x^{1A'}), \tag{33}$$

where g is some function of two variables, and from Eq. (24) with $A=B=C=1$ and Eqs. (32) and (33) it follows that $0=\partial_1{}^{R'}h_{11R'D'}=\partial_{0D'}(\partial_1{}^{R'}\partial_{0R'}\gamma+\frac{1}{6}\partial_{1R'}\partial_{1S'}f(x^{1A'})x^{0R'}x^{0S'}+\partial_{1S'}g(x^{1A'})x^{0S'})$, which implies that

$$\partial_1{}^{R'}\partial_{0R'}\gamma=-\tfrac{1}{6}\partial_{1R'}\partial_{1S'}f(x^{1A'})x^{0R'}x^{0S'}-\partial_{1S'}g(x^{1A'})x^{0S'}-b(x^{1A'}), \tag{34}$$

where b is some function of two variables.

Making use of the definitions

$$\tilde{\xi}_{0A'}\equiv-\tfrac{1}{2}\partial_{0A'}\alpha-\tfrac{1}{2}f_{A'}\,,\quad \tilde{\xi}_{1A'}\equiv-\tfrac{1}{2}\partial_{1A'}\alpha-\partial_{0A'}\beta+\tfrac{1}{2}\partial_{1S'}f_{A'}x^{0S'}+g_{A'}\,, \tag{35}$$

where $f_{A'}$ and $g_{A'}$ are functions of $x^{1A'}$ only such that

$$\partial_1{}^{A'}f_{A'}=f,\quad \partial_1{}^{A'}g_{A'}=g, \tag{36}$$

from Eqs. (25), (26), (29), (32), (35), and (36) we find that

$$\begin{aligned} h_{00R'D'}&=-\partial_{0R'}\tilde{\xi}_{0D'}-\partial_{0D'}\tilde{\xi}_{0R'}\,,\\ h_{10R'D'}&=-\partial_{1R'}\tilde{\xi}_{0D'}-\partial_{0D'}\tilde{\xi}_{1R'}\,,\\ h_{11R'D'}&=-\partial_{1R'}\tilde{\xi}_{1D'}-\partial_{1D'}\tilde{\xi}_{1R'}+\partial_{0R'}\partial_{0D'}\gamma+\partial_{1R'}\partial_{1D'}f_{S'}x^{0S'}\\ &\quad-\tfrac{1}{3}\partial_{1R'}fx^0{}_{D'}-\tfrac{1}{3}\partial_{1D'}fx^0{}_{R'}+\partial_{1R'}g_{D'}+\partial_{1D'}g_{R'}\\ &=-\partial_{1R'}\tilde{\xi}_{1D'}-\partial_{1D'}\tilde{\xi}_{1R'}+\partial_{0R'}\partial_{0D'}\psi, \end{aligned} \tag{37}$$

where

$$\psi\equiv\gamma+\tfrac{1}{6}\partial_{1A'}\partial_{1B'}f_{C'}x^{0A'}x^{0B'}x^{0C'}+\partial_{1A'}g_{B'}x^{0A'}x^{0B'}+b_{A'}x^{0A'}, \tag{38}$$

and $b_{A'}$ are functions of $x^{1A'}$ only such that

$$\partial_1{}^{A'} b_{A'} = b. \tag{39}$$

Then, from Eqs. (34), (36), (38), and (39) it follows that the scalar potential ψ satisfies the wave equation

$$\partial_1{}^{R'} \partial_{0R'} \psi = 0. \tag{40}$$

Thus, Eqs. (37) show that, in effect, the solution of Eqs. (24) and, therefore, of the self-duality conditions (18) is locally given, modulo gauge transformations, by a single scalar potential that obeys the wave equation.

It may be noticed that the complex vector field (35) satisfies the conditions $\partial_{(A}{}^{C'} \tilde{\xi}_{B)C'} = 0$, which means that $\tilde{\xi}_{AB'}$ is the vector potential of a self-dual electromagnetic field and that the condition $H_{ABCD'} = 0$ is preserved under the gauge transformation given by $\tilde{\xi}_{AB'}$ [cf. Eqs. (22) and (23)]; in other words, the metric perturbation $h_{ABA'B'} + \partial_{AA'} \tilde{\xi}_{BB'} + \partial_{BB'} \tilde{\xi}_{AA'}$ also satisfies Eq. (24), as can be directly verified.

The preceding result can also be expressed in a covariant form. If o_A is any *constant* spinor, then the solution of the self-duality conditions (14) and (15) is locally given, modulo gauge transformations, by

$$h_{ABC'D'} = \nabla^C{}_{C'} \nabla^D{}_{D'} (\psi o_A o_B o_C o_D), \tag{41}$$

where ψ is a solution of the wave equation

$$\nabla_{AA'} \nabla^{AA'} \psi = 0, \tag{42}$$

and any real solution of the Einstein vacuum field equations linearized about the Minkowski metric is locally given, modulo gauge transformations, by the real part of the perturbation given by Eq. (41). The covariant expression for the metric perturbations of an algebraically special solution of the Einstein vacuum field equations given in Ref. 8 (which is equivalent to the expressions found in Refs. 7 and 3) reduces to Eq. (41) when the multiple principal spinor of the background conformal curvature is constant. As pointed out in the Introduction, the derivations presented in Refs. 3, 7, and 8 do not demonstrate that all the metric perturbations of the algebraically special vacuum space–times are given by the formula obtained in those works. If the constant spinor o_A in Eq. (41) corresponds to the null direction $\partial_t + \partial_z$, then the first-order curvature $K_{\alpha\beta\gamma\delta}$ corresponding to the real part of the perturbation (41) agrees with the expression obtained in Ref. 6 by direct integration in circular cylindrical coordinates of the equations for the curvature in the linearized Einstein theory.

From Eq. (41) it also follows that $\nabla_{(M}{}^{D'} h_{AB)C'D'} = \nabla_{(M}{}^{D'} \nabla^C{}_{C'} \nabla^D{}_{D'} (\psi o_A o_{B)} o_C o_D)$ is (the spinor equivalent of) a Lanczos potential for the first-order curvature (see, e.g., Ref. 11). The metric perturbation, the Lanczos potential, and the curvature are given by second, third, and fourth derivatives, respectively, of the scalar potential ψ.

As a simple example, we can consider a potential ψ independent of $x^{00'}$. Then Eq. (40) reduces to $\partial_{01'} \partial_{10'} \psi = 0$, or, taking $u \equiv x^{11'}$, $v \equiv x^{00'}$, $\zeta \equiv x^{01'}$, and $\overline{\zeta} \equiv x^{10'}$,

$$\partial_\zeta \partial_{\overline{\zeta}} \psi(u, \zeta, \overline{\zeta}) = 0. \tag{43}$$

The only nonvanishing component of $h_{11R'D'} = \partial_{0R'} \partial_{0D'} \psi$ [cf. Eq. (37)] is

$$h_{111'1'} = \partial_\zeta \partial_\zeta \psi \equiv F(u, \zeta, \overline{\zeta}). \tag{44}$$

By virtue of Eq. (43), $\partial_{\overline{\zeta}} F = 0$; therefore, $F = F(u, \zeta)$ and

$$(\eta_{\alpha\beta}+h^{c}_{\alpha\beta})dx^{\alpha}dx^{\beta}=2du\,dv-2d\zeta d\overline{\zeta}+h_{111'1'}du^{2}$$
$$=2du\,dv-2d\zeta d\overline{\zeta}+F(u,\zeta)du^{2} \tag{45}$$

is a (possibly complex) solution of the linearized Einstein vacuum field equations, where $F(u,\zeta)$ is an arbitrary function. The real part of the metric (45),

$$2du\,dv-2d\zeta d\overline{\zeta}+\tfrac{1}{2}[F(u,\zeta)+\overline{F(u,\zeta)}]du^{2}, \tag{46}$$

is also a solution of the linearized Einstein vacuum field equations, which turns out to be an exact solution of the Einstein vacuum field equations, as can be easily seen by applying the Xanthopoulos theorem,[12] taking into account that the metric (46) is of the form $(\eta_{\alpha\beta}+l_{\alpha}l_{\beta})dx^{\alpha}dx^{\beta}$, with l_{α} being a null vector field with respect to the metric $\eta_{\alpha\beta}$. The metric (46) corresponds to the well-known pp waves.

IV. CONCLUDING REMARKS

As we have shown, the Einstein vacuum field equations linearized about the Minkowski metric, which are a set of second-order partial differential equations for the metric perturbation, can be reduced to a set of first-order partial differential equations whose solution is locally determined, modulo gauge transformations, by a scalar potential. It would be desirable to have analogous results in the case of curved backgrounds, but then the perturbation of the curvature is no longer gauge-invariant and, therefore, the self-duality of the curvature perturbation has no gauge-invariant meaning. Moreover, when the background is not flat, the self-duality of the curvature perturbation is a very strong condition that may not be satisfied, modulo gauge transformations, by all the solutions of the linearized Einstein vacuum field equations (see, e.g., Ref. 13).

Wybrzeże Wyspiańskiego 27, 50-370 Wrocław, Poland

(Received 5 February 1999; accepted for publication 17 March 1999)

The singular continuous spectrum of the Liouville operator of quantum statistical physics is, in general, properly included in the difference of the spectral values of the singular continuous spectrum of the associated Hamiltonian. The absolutely continuous spectrum of the Liouvillian may arise from a purely singular continuous Hamiltonian. We provide the correct formulas for the spectrum of the Liouville operator and show that the decaying states of the singular continuous subspace of the Hamiltonian do not necessarily contribute to the absolutely continuous subspace of the Liouvillian.
[S0022-2488(99)00208-X]

I. INTRODUCTION

The Liouville operator is the starting point of both classical and quantum statistical physics,[1,2] since it generates the evolution of states ρ:

$$\partial_t \rho = -i\mathbb{L}\rho.$$

The formal relation between the Liouville operator $\mathbb{L}$ and its corresponding Hamiltonian H is given by the Poisson brackets $\mathbb{L}\rho = i\{H,\rho\}$ for classical systems and by the commutator $\mathbb{L}\rho = [H, \rho]$ for quantum systems. Here ρ denotes the density function or the density operator.

It is well known that the Liouville operator $\mathbb{L}$ (also called the Liouvillian) corresponding to an essentially self-adjoint Hamiltonian H is also essentially self-adjoint.[3] Moreover, the spectrum $\sigma(H)$ of H determines the spectrum $\sigma(\mathbb{L})$ of $\mathbb{L}$ which consists of the differences between the spectral values of H:

$$\sigma(\mathbb{L}) = \{\lambda - \lambda' : \lambda, \lambda' \in \sigma(H)\}. \tag{1}$$

It may therefore be natural to expect a similar relation to hold separately for each part of the spectrum of the Hamiltonian and the Liouvillian, namely for the point spectrum, the absolutely continuous spectrum, and the singular continuous spectrum:

$$\sigma_{\mathrm{p}}(\mathbb{L}) = \{\lambda - \lambda' : \lambda, \lambda' \in \sigma_{\mathrm{p}}(H)\} \tag{2}$$

$$\sigma_{ac}(\mathbb{L})=\{\lambda-\lambda':\lambda,\lambda'\in\sigma_{ac}(H)\} \tag{3}$$

$$\sigma_{sc}(\mathbb{L})=\{\lambda-\lambda':\lambda,\lambda'\in\sigma_{sc}(H)\}. \tag{4}$$

Twenty years ago, Spohn[4] argued that formulas (2)–(4) hold true. The objective of this paper is to demonstrate that formulas (3) and (4) are not true. Spohn's proof concerning the singular spectrum (4) is based on the argument that the set $\{\lambda-\lambda':\lambda,\lambda'\in\sigma_{sc}(H)\}$ has Lebesgue measure zero, because the set $\sigma_{sc}(H)$ has Lebesgue measure zero. This is, however, not true, as can be shown on a simple example of an operator with Cantor spectrum. Another example contradicting explicitly Spohn's assertion has been found by L. Bos and B. S. Pavlov[5] who constructed an example of a Hamiltonian with purely singular spectrum for which the spectrum of its Liouvillian has an absolutely continuous component. Bos and Pavlov's example has been generalized further by M. Gadella and two of us (IA and ZS).[6]

Let us remark here that the problem of finding a Hamiltonian with pure singular spectrum such that the corresponding Liouvillian has nonempty absolutely continuous spectrum reduces to the problem of finding a singular measure on the real line with absolutely continuous convolution square. The answer to this problem is known since 1938 when N. Wiener and A. Wintner[7] constructed a singular continuous measure μ for which the convolution $\mu*\mu$ is absolutely continuous. However, the Wiener–Wintner paper[7] as well as many other refinements and generalizations of their construction[8] remained unnoticed by the physics community.

We show that it is always possible to find a Hamiltonian with purely continuous singular spectrum concentrated on an arbitrary thin set, precisely on the set of Hausdorff dimension zero, for which the spectrum of the Liouvillian has nontrivial absolutely continuous component. In fact, the Liouvillian corresponding to a Hamiltonian with purely singular continuous spectrum may have even a purely absolutely continuous spectrum.

The interest of this discussion goes beyond the result of Spohn. A possible consequence is the nonequivalence between the Hilbert space and the Liouville space description of quantum mechanics hinted by I. Prigogine.[9] For example, time and entropy operators do exist as superoperators on the Liouville space,[10,11] while they cannot exist as operators on the Hilbert space of wave functions.[12] This may also have profound consequences from the point of view of scattering theory and resonance behavior that are under present investigation.

In Sec. II we provide basic notion, facts, and notations from the spectral theory of self-adjoint Hamiltonian operators in Hilbert space and the associated Liouville operators in the Hilbert–Schmidt space, and establish the relation between the spectral measure of the Liouville operator and the spectral measure of the corresponding Hamiltonian operator. In Sec. III we provide a counterexample which shows that the singular continuous spectrum of the Liouvillian is properly included in the differences of the spectral values of the singular continuous spectrum of the Hamiltonian and correct formula (4). In Sec. IV we show that the absolutely continuous spectrum of the Liouvillian may arise from a pure singular continuous Hamiltonian and correct formula (3). Finally, we show that the decaying states of the singular spectrum of the Hamiltonian do not necessarily contribute to the possible absolutely continuous subspace of the associated Liouvillian.

II. BASIC FACTS FROM THE SPECTRAL THEORY OF THE HAMILTONIAN AND LIOUVILLIAN OPERATORS

We collect here the basic facts and notions and define the notation we employ.

Let $\mathcal{H}$ be a Hilbert space and H the self-adjoint Hamiltonian operator on $\mathcal{H}$. For a given Hamiltonian H we define the corresponding Liouvillian $\mathbb{L}$ as the essentially self-adjoint operator $\mathbb{L}=H\otimes I-I\otimes H$ defined on the Hilbert tensor product space $\mathcal{H}\otimes\mathcal{H}^{\times}$, where $\mathcal{H}^{\times}$ denotes the dual space of $\mathcal{H}$ (usually identified with $\mathcal{H}$) and I is the identity operator on $\mathcal{H}$. Recall that the space $\mathcal{H}\otimes\mathcal{H}^{\times}$ is isometrically isomorphic with the space $\mathcal{B}^2_{\mathcal{H}}$ of all Hilbert–Schmidt operators on $\mathcal{H}$ with the scalar product $(A,B)=\mathrm{tr}(A^{\dagger}B)$. In the sequel we shall use Dirac's notation $|f\rangle\langle g|$ for the tensor product of elements $f\in\mathcal{H}$, $g\in\mathcal{H}^{\times}$.

Let us denote by $\{E_\lambda\}$ the spectral family of H, i.e., $H=\int_{-\infty}^{\infty}\lambda\, dE_\lambda$, and let $\{\mathbb{E}_\lambda\}$ denote the the spectral family of the Liouvillian. Then we have

$$\mathbb{E}_\lambda|f\rangle\langle g|=\int_{-\infty}^{\infty}|E_{\lambda+\lambda'}f\rangle d\langle E_{\lambda'}g|. \tag{5}$$

Denote by $\mathcal{H}_{\rm p}$ the closed linear hull of all eigenvectors of H. The continuous subspace of H is $\mathcal{H}_{\rm c}=\mathcal{H}\ominus\mathcal{H}_{\rm p}$. Recall that the singular continuous subspace $\mathcal{H}_{\rm sc}$ of $\mathcal{H}_{\rm c}$ consists of all $f\in\mathcal{H}_{\rm c}$ for which there exists a Borel set B_0 of Lebesgue measure zero such that $\int_{B_0}dE_\lambda f=f$. By $\mathcal{H}_{\rm ac}=\mathcal{H}_{\rm c}\ominus\mathcal{H}_{\rm sc}$ we shall denote the absolutely continuous subspace of $\mathcal{H}_{\rm c}$. Recall also that $\mathcal{H}_{\rm p}$, $\mathcal{H}_{\rm c}$, $\mathcal{H}_{\rm sc}$, and $\mathcal{H}_{\rm ac}$ are closed linear subspaces of $\mathcal{H}$ which reduce the operator H. The spectra of the corresponding reductions of H will be called respectively point, continuous, singular continuous, and absolutely continuous spectrum of H, and will be denoted by $\sigma_{\rm p}(H)$, $\sigma_{\rm c}(H)$, $\sigma_{\rm sc}(H)$, and $\sigma_{\rm ac}(H)$ correspondingly.[13]

Let $\mu=\mu_f$ denote, for a given $f\in\mathcal{H}$, the spectral measure on $\sigma(H)$ determined by the nondecreasing function $\lambda\mapsto\langle f,E_\lambda f\rangle$. Let $f=f_{\rm p}+f_{\rm sc}+f_{\rm ac}$ be the decomposition of f corresponding to the direct sum $\mathcal{H}_{\rm p}\oplus\mathcal{H}_{\rm sc}\oplus\mathcal{H}_{\rm ac}$. Putting $\mu_{\rm p}=\mu_{f_{\rm p}}$, $\mu_{\rm sc}=\mu_{f_{\rm sc}}$, and $\mu_{\rm ac}=\mu_{f_{\rm ac}}$ we obtain the Jordan decomposition of μ,

$$\mu=\mu_{\rm p}+\mu_{\rm sc}+\mu_{\rm ac}, \tag{6}$$

onto the point, singular continuous, and absolutely continuous component. Conversely, given any three finite Borel measures $\mu_{\rm p}$, $\mu_{\rm sc}$, and $\mu_{\rm ac}$, where $\mu_{\rm p}$ is concentrated on a countable set of points and the other two measures are respectively singular and absolutely continuous, one can always construct a Hilbert space $\mathcal{H}$ and a self-adjoint operator H such that these measures are spectral measures associated with some $f\in\mathcal{H}$. Moreover, the point, singular, and absolutely continuous spectrum of H coincide with $\mu_{\rm p}$, $\mu_{\rm sc}$, and $\mu_{\rm ac}$, respectively. This can be proved by taking $\mathcal{H}$ as the direct sum $L^2(\mathbf{R},\mu_{\rm p})\oplus L^2(\mathbf{R},\mu_{\rm sc})\oplus L^2(\mathbf{R},\mu_{\rm ac})$ and H as the operator of multiplication by λ.[13]

The spectral measure of a self-adjoint operator $H=\int_{\sigma(H)}\lambda\, dE_\lambda$ on a Hilbert space $\mathcal{H}$ corresponding to an element $h\in\mathcal{H}$ is

$$F(\lambda)=\langle h,E_\lambda h\rangle \quad \text{for } \lambda\in\mathbf{R}. \tag{7}$$

Since the Liouville operator corresponding to this self-adjoint operator H is defined on $\mathcal{H}\otimes\mathcal{H}^\times$ by $\mathbb{L}=H\otimes I-I\otimes H$, it follows from (5) that

$$(|h\rangle\langle h|,\mathbb{E}_\lambda|h\rangle\langle h|)=\int_{-\infty}^{\infty}\langle h,E_{\lambda+\lambda'}h\rangle d\langle h,E_{\lambda'}h\rangle. \tag{8}$$

Formula (8) can be written as

$$\mathbb{F}(\lambda)=\int_{-\infty}^{\infty}F(\lambda+\lambda')dF(\lambda'), \tag{9}$$

where

$$\mathbb{F}(\lambda)=(|h\rangle\langle h|,\mathbb{E}_\lambda|h\rangle\langle h|) \tag{10}$$

is the distribution function associated with the Liouville operator $\mathbb{L}$ for the operator $|h\rangle\langle h|$.

The relation between the spectral measure $\mu_{\mathbb{L}}$ of the Liouville operator and the spectral measure of the Hamiltonian operator H is given by the following.

Lemma 1: The measure μ_{L} *associated to the distribution function (10) of the Liouville operator is the convolution of the measure* μ *associated to the distribution function (7) of the Hamiltonian operator with the reflection* $\overline{\mu}$ *of* μ *with respect to 0, i.e.,*

$$\mu_{\mathrm{L}} = \mu * \overline{\mu},$$

where $\overline{\mu}(\Delta) = \mu(-\Delta) = \mu(\{-x : x \in \Delta\})$, *for each Borel set* Δ.

We remind the reader that the convolution $\mu_1 * \mu_2$ of the Borel measure μ_1 with the Borel measure μ_2 is defined as the composition of the product $\mu_1 \times \mu_2$ with the measurable map $s:\mathbf{R} \times \mathbf{R} \to \mathbf{R}$ given by

$$s(x,y) = x + y, \tag{11}$$

i.e., $(\mu_1 * \mu_2)(\Delta) = \mu_1 \times \mu_2(s^{-1}\Delta)$, for every Borel subset Δ of the real line.

Proof: Let us denote by $\mu_1 \overline{*} \mu_2$ (μ_1 and μ_2 are Borel measures on $\mathbf{R}$) the composition of the measure $\mu_1 \times \mu_2$ with the measurable map $d:\mathbf{R} \times \mathbf{R} \to \mathbf{R}$ given by

$$d(x,y) = x - y. \tag{12}$$

Since we have

$$\mu_{\mathrm{L}} = \mu \overline{*} \mu,$$

the assertion of the lemma follows from a more general property

$$\mu_1 \overline{*} \mu_2 = \mu_1 * \overline{\mu_2}. \tag{13}$$

To prove (13) let us define (measurable) transformation $t:\mathbf{R} \times \mathbf{R} \to \mathbf{R} \times \mathbf{R}$:

$$t(x,y) = (x, -y). \tag{14}$$

We want to show first that

$$\mu_1 \times \overline{\mu_2} = (\mu_1 \times \mu_2) \circ t. \tag{15}$$

For that, we need only to show this identity for sets of the form $A \times B$, where A and B are measurable sets. Indeed, we have

$$\begin{aligned} ((\mu_1 \times \mu_2) \circ t)(A \times B) &= (\mu_1 \times \mu_2)[t^{-1}(A \times B)] \\ &= (\mu_1 \times \mu_2)(A \times (-B)) \\ &= \mu_1(A)\mu_2(-B) \\ &= \mu_1(A)\overline{\mu_2}(B) = (\mu_1 \times \overline{\mu_2})(A \times B), \end{aligned} \tag{16}$$

which proves (15). Therefore, taking any measurable set C we have

$$\begin{aligned} \mu_1 \overline{*} \mu_2(C) &= (\mu_1 \times \mu_2) d^{-1}(C) \\ &= \int \int_{\{(x,y): x - y \in C\}} d\mu_1 \times \mu_2 \\ &= \int \int_{t^{-1}\{(x,y): x + y \in C\}} d\mu_1 \times \mu_2 \\ &= \int \int_{\{(x,y): x + y \in C\}} d\mu_1 \times \overline{\mu_2} = \mu_1 \times \overline{\mu_2}(s^{-1}(C)) = \mu_1 * \overline{\mu_2}(C). \end{aligned} \tag{17}$$

■

III. THE SINGULAR CONTINUOUS SPECTRUM OF THE LIOUVILLIAN IS PROPERLY INCLUDED IN THE DIFFERENCES OF THE SPECTRAL VALUES OF THE SINGULAR CONTINUOUS SPECTRUM OF THE HAMILTONIAN

We provide a counterexample to formula (4) for the singular continuous spectrum of the Liouville operator, which shows that the singular continuous spectrum $\sigma_{sc}(\mathbb{L})$ of the Liouville operator is properly included in the differences of the spectral values of a Hamiltonian with purely singular continuous spectrum.

Consider a Hamiltonian operator H for which $\sigma(H)$ is a Cantor set. The existence of such operators is guaranteed by the above construction of the Hamiltonian with given spectral measure. Let us note, however, that there are more ''physical'' examples of Hamiltonians with Cantor-like spectrum. For example, there is an absolutely summable sequence $\{a_n\}$ such that the spectrum of the Hamiltonian

$$H=-\frac{d^2}{dx^2}+\sum_{n=0}^{\infty} a_n \cos(x2^{-n}) \tag{18}$$

is the Cantor set (see Ref. 14 and references therein). Suppose that $\sigma(H)=C$, where C is the Cantor set on the interval [0, 1]. According to the general property of spectra of functions of the Hamiltonian (see Ref. 3) we have (1).

However, according to a theorem of Steinhaus,[15] we have

$$\{\lambda-\lambda':\lambda,\lambda'\in C\}=[-1\ 1], \tag{19}$$

as $[-1, 1]$ is a set of nonzero Lebesgue measure. Formula (19) contradicts (4). This property of the Cantor set does not, however, imply that the spectrum of the Liouvillian is absolutely continuous. To show this let us consider the well-known ''devil's staircase'' distribution function $F(\lambda)$ on the Cantor set C.[16] We remind the reader that $F(\lambda)$ has constant value equal $k/2^n$ on each interval which is removed in the nth step of the iterative construction of the Cantor set[16] (k are such that the fraction $k/2^n$ is nonreducible). [The ''devil's staircase'' is defined as follows: it is $\frac{1}{2}$ on the interval $(\frac{1}{3}, \frac{2}{3})$, $\frac{1}{4}$ on $(\frac{1}{9}, \frac{2}{9})$, $\frac{3}{4}$ on $(\frac{7}{9}, \frac{8}{9})$, $\frac{1}{8}$ on $(\frac{1}{27}, \frac{2}{27})$, $\frac{3}{8}$ on $(\frac{7}{27}, \frac{8}{27})$, $\frac{5}{8}$ on $(\frac{19}{27}, \frac{20}{27})$, $\frac{7}{8}$ on $(\frac{25}{27}, \frac{26}{27})$, and so on.] It is well known and not difficult to check that $F(\lambda)$ is a nondecreasing continuous function such that $F(\lambda)=0$ for $\lambda\leqslant 0$ and $F(\lambda)=1$ for $\lambda\geqslant 1$.

The Hamiltonian with spectral measure $dF(\lambda)$ is the multiplication operator

$$Hf(\lambda)=\lambda f(\lambda) \tag{20}$$

on the Hilbert space $L([0,1],dF)$. The spectral projectors E_λ of H are

$$H=\int_0^1 \lambda\, dE_\lambda,$$

$$E_\lambda f(\lambda')=\mathbb{1}_{[0,\lambda)} f(\lambda'),$$

where

$$\mathbb{1}_{[0,\lambda)}(\lambda')=\begin{cases}1, & 0\leqslant\lambda'<\lambda\\ 0, & \text{otherwise.}\end{cases}$$

The spectral measure dF corresponds to the cyclic vector $e=1$:

$$F(\lambda)=\langle e,E_\lambda e\rangle.$$

The spectral measure of the Liouvillian which corresponds to H (20) is (10):

$$\mathbb{F}(\lambda)=(|e\rangle\langle e|,\mathbb{E}_\lambda|e\rangle\langle e|).$$

From the general properties of the convolution and Lemma 1, the function $\mathbb{F}(\lambda)$ is continuous. We shall show that it is, however, not absolutely continuous. In order to show this, let us consider the Fourier–Stieltjes transform

$$\hat{F}(t)=\int_0^1 e^{it\lambda}\,dF(\lambda). \tag{21}$$

Let us find the explicit expression for $\hat{F}(t)$:

$$\begin{aligned}\hat{F}(t)=\int_0^1 e^{it\lambda}\,dF(\lambda)&=\frac{1}{2}\int_0^{1/3} e^{it\lambda}\,dF(3\lambda)+\frac{1}{2}\int_{2/3}^1 e^{it\lambda}\,dF(3\lambda-2)\\&=\frac{1}{2}\int_0^1 e^{it\lambda/3}\,dF(\lambda)+\frac{1}{2}\int_0^1 e^{it\lambda/3}e^{it2/3}\,dF(\lambda)\\&=\frac{1}{2}[1+e^{2it/3}]\hat{F}\left(\frac{t}{3}\right)\\&=\frac{1}{2}[1+e^{2it/3}]\frac{1}{2}[1+e^{2it/3^2}]\hat{F}\left(\frac{t}{3^2}\right)\\&=\left(\prod_{k=1}^{\infty}\frac{1}{2}[1+e^{2it/3}]\right)\hat{F}(0).\end{aligned} \tag{22}$$

In the first identity in the second row, we have used the fact that $F(\lambda)$ satisfies functional equation of the De Rham type (compare with Ref. 17):

$$F(\lambda)=\begin{cases}\frac{1}{2}F(3\lambda), & 0\leqslant\lambda<\frac{1}{3},\\ \frac{1}{2}, & \frac{1}{3}\leqslant\lambda<\frac{2}{3},\\ \frac{1}{2}F(3\lambda-2)+\frac{1}{2}, & \frac{2}{3}\leqslant\lambda\leqslant 1.\end{cases} \tag{23}$$

Since $\hat{F}(0)=1$, we obtain

$$\hat{F}(t)=\prod_{k=1}^{\infty}[1+e^{2it/3}]. \tag{24}$$

Choosing $t_n=\pi 3^n$ we see that

$$\hat{F}(t_n)=\prod_{k=n+1}^{\infty}\frac{1}{2}[1+e^{2\pi i/3^{k-n}}]=\prod_{k=1}^{\infty}\frac{1}{2}[1+e^{2\pi i/3^k}] \tag{25}$$

does not depend on n. Moreover, $\hat{F}(t_n)$ is nonzero. Indeed, taking n_0 such that $\pi/3^n<1/2^n$, for $n>n_0$, and using the equality $\Pi_{n=1}^{\infty}\cos(t/2^n)=(\sin t)/t$ we have

$$
\begin{aligned}
|\hat{F}(t_n)| &= \prod_{k=1}^{\infty} \cos\frac{\pi}{3^k} > \prod_{k=1}^{n_0} \cos\frac{\pi}{3^k} \prod_{k=n_0+1}^{\infty} \cos\frac{1}{2^k} \\
&= \prod_{k=1}^{n_0} \cos\frac{\pi}{3^k} \prod_{k=1}^{\infty} \cos\frac{2^{-n_0}}{2^k} \\
&= 2^{n_0} \sin\frac{1}{2^{n_0}} \prod_{k=1}^{n_0} \cos\frac{\pi}{3^k} > 0.
\end{aligned} \tag{26}
$$

This means that the Fourier transform $\hat{F}(t)$ does not converge to zero as $t\to\infty$. The same is true for the Fourier transform $\hat{\mathbb{F}}(t)$ of $\mathbb{F}(\lambda)$ because $|\hat{\mathbb{F}}(t)| = |\hat{F}(t)|^2$. Therefore, in view of the Riemann–Lebesgue lemma, $F(\lambda)$ as well as $\mathbb{F}(\lambda)$ cannot be purely absolutely continuous. In fact, one can show, moreover, that $\mathbb{F}(\lambda)$ is purely singular continuous. The proof of this fact, which has been communicated to us by Professor O. G. Smolyanov, is given in the Appendix. Therefore, the singular continuous spectrum has Lebesgue measure zero.

Therefore, the singular continuous spectrum $\sigma_{\mathrm{sc}}(\mathbb{L})$ of the Liouville operator being a set with Lebesgue measure zero is properly included in the set of differences

$$\sigma_{\mathrm{sc}}(H) - \sigma_{\mathrm{sc}}(H) = [-1, 1].$$

Therefore formula (4) for the singular continuous spectrum of $\mathbb{L}$ should be corrected to

$$\sigma_{\mathrm{sc}}(\mathbb{L}) \subset \{\sigma_{\mathrm{sc}}(H) - \sigma_{\mathrm{sc}}(H)\}. \tag{4'}$$

IV. THE ABSOLUTELY CONTINUOUS SPECTRUM OF THE LIOUVILLIAN MAY ARISE FROM A PURE SINGULAR CONTINUOUS HAMILTONIAN

Using the results from Ref. 18 on convolutions of singular measures we shall show that it is possible to find Hamiltonians with purely singular spectral measures concentrated on a set of the Hausdorff dimension zero. Therefore, the associated Liouvillian has nontrivial absolutely continuous subspace.

Let us recall that the p-dimensional Hausdorff measure, $p \geqslant 0$, on subsets E of $\mathbf{R}$ is defined to be the number

$$\chi_p(E) = \lim_{\varepsilon\to 0} \inf\left\{ \sum_{n=1}^{\infty} |I_n|^p : E \subset \bigcup_{n=1}^{\infty} I_n, \ |I_n| < \varepsilon, \quad n = 1,2,... \right\}, \tag{27}$$

where the infimum is taken over the coverings of E by intervals of the length not greater than ε ($|I_n|$ denotes the length of the interval I_n).

An important property of the Hausdorff measure is that for each set E there is a value p_0 such that $\chi_p(E) = \infty$ for $p < p_0$ and $\chi_p(E) = 0$ for $p > p_0$. This value p_0 is called the *Hausdorff dimension* of the set E.

The Hausdorff dimension of any open subset of $\mathbf{R}$ is equal 1. Hausdorff dimensions smaller than one characterize fractal sets. For example, the Hausdorff dimension of the Cantor set is equal to $\log 2/\log 3$.

The key point in the further construction is a result on Ref. 18 which shows that one can construct two Cantor-type subsets E_1 and E_2 of the unit interval $I = [0, 1]$ such that

$$E_1 + E_2 = \{\lambda + \lambda' : \lambda \in E_1, \lambda' \in E_2\} = I \tag{28}$$

and

$$\chi_p(E_1) = \chi_p(E_2) = 0, \tag{29}$$

for any $p>0$. Moreover, the *natural* probability measures, i.e., constructed in the same way as the Cantor measure, μ_i, supported on E_i, $i=1,2$, have the property that the convolution $\mu_1*\mu_2$ is Lebesgue on I.

Let us take two such singular measures μ_1 and μ_2 on I and define

$$\mu=\mu_1+\overline{\mu_2},$$

which is a singular measure with support $E_1\cup E_2$.

We define, as before, a Hamiltonian with spectrum $E_1\cup E_2$ and μ as the spectral measure given by the multiplication operator $Hf(\lambda)=\lambda f(\lambda)$ on the Hilbert space $L^2(I,\mu)$. Its spectral resolution $H=\int_{\sigma(H)}\lambda\, dE_\lambda$ can be given explicitly if we define projectors E_λ as the operators of multiplication by the indicators $\mathbb{1}_{[0,\lambda]}$ {projectors on the spaces $L^2([0,\lambda],\mu)$}. Then $e\equiv 1$ is the corresponding cyclic vector and $\mu([0,\lambda])=\langle e,E_\lambda e\rangle$.

The Liouvillian corresponding to H has the spectral projectors $\mathbb{E}_\lambda$ and the measure generated by $(|e\rangle\langle e|,\mathbb{E}_\lambda|e\rangle\langle e|)$ is given by the convolution of μ and $\overline{\mu}$. We have

$$\mu*\overline{\mu}=(\mu_1+\overline{\mu_2})*\overline{(\mu_1+\overline{\mu_2})}=(\mu_1+\overline{\mu_2})*(\overline{\mu_1}+\mu_2)=\mu_1*\overline{\mu_2}+\mu_1*\mu_2+\overline{\mu_2}*\overline{\mu_1}+\overline{\mu_2}*\mu_2.$$

Here, $\mu_1*\mu_2$ is an absolutely continuous measure by the hypothesis. Because $\overline{\mu_2}*\overline{\mu_1}=\overline{\mu_1}*\overline{\mu_2}$ and $\overline{\mu_1},\overline{\mu_2}$ are reflections of μ_1,μ_2, then $\overline{\mu_2}*\overline{\mu_1}$ is also absolutely continuous. These two convolutions form the absolutely continuous part of the spectral measure of the Liouvillian.

In view of the result of the previous section, formula (3) for the absolutely continuous spectrum of $\mathbb{L}$ should be corrected to

$$\sigma_{\rm ac}(\mathbf{L})=\{\sigma_{\rm ac}(H)-\sigma_{\rm ac}(H)\}\cup\{[\sigma_{\rm sc}(H)-\sigma_{\rm sc}(H)]\setminus\sigma_{\rm sc}(\mathbb{L})\}. \qquad (3')$$

V. DECAYING STATES IN THE SINGULAR CONTINUOUS SUBSPACE OF THE HAMILTONIAN

The survival amplitude of a wave function ψ in the Hilbert space $\mathcal{H}$ is

$$\langle\psi,U_t\psi\rangle=\left\langle \psi,\int_{-\infty}^{\infty}e^{-i\lambda t}\,dE_\lambda\psi\right\rangle=\int_{-\infty}^{\infty}e^{-i\lambda t}\,d\|E_\lambda\psi\|^2=\hat{\mu}_\psi(t).$$

This is the Fourier transform $\hat{\mu}_\psi$ of the measure μ_ψ corresponding to the distribution function $\|E_\lambda\psi\|^2$. From the Riemann–Lebesgue lemma, if ψ is in the absolutely continuous subspace of H it decays:

$$\langle\psi,U_t\psi\rangle\to 0 \quad \text{as } t\to\infty.$$

This is well known in quantum mechanics. See, for example, Ref. 19.

There may exist, however, decaying states ψ, $\hat{\mu}_\psi\to 0$, as $t\to\infty$, in the singular continuous subspace of $\mathcal{H}$ as well. Do the decaying states in $\mathcal{H}_{\rm sc}$ give rise necessarily to absolutely continuous subspace of the associated Liouville operator? The following counterexample shows that there is no such necessity. We shall construct a Borel probability measure μ on $\mathbf{R}$ such that $\overline{\mu}=\mu$ (μ is symmetric with respect to zero), the measures μ and $\mu*\mu$ are singular continuous, and $\lim_{t\to\infty}\hat{\mu}(t)=0$, where $\hat{\mu}$ is the Fourier transform of μ.

Let μ_n be the Borel probability measure on $\mathbf{R}$ defined by the formula

$$\mu_n=\tfrac{1}{2}\delta_{(2/9)^n}+\tfrac{1}{2}\delta_{-(2/9)^n},$$

where δ_a denotes the normalized measure concentrated at the point a. The function $\cos(t(\frac{2}{9})^n)$ is the Fourier transform of the measure μ_n and the function

$$\mathcal{F}_N(t)=\prod_{n=0}^{N}\cos\left(t\left(\frac{2}{9}\right)^n\right)$$

is the Fourier transform of the convolution $\mu_0*\mu_1*\cdots*\mu_N$. Evidently, the sequence $\mathcal{F}_N(t)$ converges uniformly to the function

$$\mathcal{F}(t)=\prod_{n=0}^{\infty}\cos\left(t\left(\frac{2}{9}\right)^n\right) \tag{30}$$

on any segment in **R**. Therefore, the sequence $\mu_0*\mu_1*\cdots*\mu_N$ weakly converges to some Borel probability measure μ on **R** and the Fourier transform $\hat{\mu}$ of this measure coincides with $\mathcal{F}$.

Now we shall check that μ and $\mu*\mu$ are singular and that

$$\lim_{t\to\infty}\mathcal{F}(t)=0. \tag{31}$$

The continuity of the measures μ and $\mu*\mu$ follows from condition (31), which we shall prove below.

The support of the measure $\mu_0*\mu_1*\cdots*\mu_N$ is the set

$$\left\{\sum_{j=0}^{N}\frac{\varepsilon_j}{(9/2)^j}:\varepsilon_j\in\{0,1\}\right\}.$$

Hence, the compact set

$$K=\left\{\sum_{j=0}^{\infty}\frac{\varepsilon_j}{(\frac{9}{2})^j}:\varepsilon_j\in\{0,1\}\right\}$$

is the support of μ. From the last formula it is easy to see that for any $n\in\mathbf{Z}_+$ the set K is a subset of the union of 2^n segments of the length $\frac{18}{7}(\frac{2}{9})^n$ ($K\subset[-\frac{9}{7},\frac{9}{7}]$, $K\subset[-\frac{9}{7},-\frac{5}{7}]\cap[\frac{5}{7},\frac{9}{7}]$, $K\subset[-\frac{9}{7},-\frac{73}{63}]\cap[-\frac{53}{63},-\frac{5}{7}]\cap[\frac{5}{7},\frac{53}{63}]\cap[\frac{73}{63},\frac{9}{7}],\ldots$). Therefore, the set $K+K$ is contained in the union of 4^n segments of the length $\frac{36}{7}(\frac{2}{9})^n$. So, for any n, the Lebesgue measure of $K+K$ does not exceed $\frac{36}{7}(\frac{8}{9})^n$. Hence, the Lebesgue measure of $K+K$ is zero and, consequently, the measures μ and $\mu*\mu$ are singular ($K+K$ is the support of $\mu*\mu$). It remains to prove (31). This property was proved by Erdös[20] (see also Ref. 21) for a wide class of functions $\mathcal{F}(t)$ of the form (30), where the number $\frac{2}{9}$ can be any rational value which is not reciprocal of an integer.

Remark: The number 9 in the definitions of $\mathcal{F}$ and μ_n can be replaced by an arbitrary odd integer $n\geqslant 9$. The Hausdorff dimension of the support K of measure μ in this case is equal to $(\ln 2)/(\ln n)$ [the Hausdorff dimension of the support of the measure $\mu*\mu$ does not exceed $2(\ln 2)/(\ln n)$]. So there exists a measure with desired properties and with arbitrary small Hausdorff dimension of the support.

VI. CONCLUDING REMARKS

Our main result is to prove the correct relations between the spectra of the Liouville and Hamiltonian operator:

$$\sigma_{\mathrm{p}}(\mathbb{L})=\{\lambda-\lambda':\lambda,\lambda'\in\sigma_{\mathrm{p}}(H)\} \tag{2}$$

$$\sigma_{\mathrm{ac}}(\mathbb{L})=\{\sigma_{\mathrm{ac}}(H)-\sigma_{\mathrm{ac}}(H)\}\cup\{[\sigma_{\mathrm{sc}}(H)-\sigma_{\mathrm{sc}}(H)]\setminus\sigma_{\mathrm{sc}}(\mathbb{L})\}. \tag{3'}$$

$$\sigma_{\mathrm{sc}}(\mathbb{L})\subset[\sigma_{\mathrm{sc}}(H)-\sigma_{\mathrm{sc}}(H)]. \tag{4'}$$

The appearance of absolutely continuous spectrum of the Liouvillian from Hamiltonians with purely singular continuous spectra is very surprising. It shows that even in the conventional formulation the statistical description in Liouville space is not entirely equivalent to the wave function description in the original Hilbert space. This nonequivalence was mentioned to us by I. Prigogine several times.[9] In addition to the time and entropy operators[10,11] mentioned in the Introduction, our results show that it is always possible to construct Hamiltonians for which no scattering states may exist, because of the absence of absolutely continuous spectrum, while their corresponding Liouvillians may have scattering states because of the absolutely continuous spectrum, contrary to the general belief that scattering theory is equivalent in both Hilbert and Liouville space.[2]

These facts show that the Liouville space formulation of quantum mechanics contains more possibilities than the formulation in the Hilbert space of wave functions corresponding to a Hamiltonian operator. This is in fact true as the Liouville operator admits extensions beyond the Hilbert–Schmidt space which are nonreducible to wave function evolutions.[23]

ACKNOWLEDGMENTS

We want to thank Professor M. Gadella and Professor B. S. Pavlov for fruitful discussions and Professor I. Prigogine for his constant encouragement and support. We are grateful to Professor O. Smolyanov who kindly gave us the proof of the theorem in the Appendix. The support of the Belgian Government, Interuniversity Attraction Poles, and the European Commission Esprit Project No. 21042 CTIAC is acknowledged.

APPENDIX: SINGULARITY OF THE CONVOLUTION SQUARE OF THE CANTOR MEASURE

Theorem (O. G. Smolyanov): *Let μ be the Cantor measure on the interval $[0,1]$ and $\nu=\mu*\mu$. Then there exists a Borel set $A\subset[0,2]$ of the Lebesgue measure zero such that $\nu(A)=1$.*

Proof: Let $A_0=[0,1]$,

$$A_n=\tfrac{1}{3}A_{n-1}\cup(\{\tfrac{2}{3}\}+\tfrac{1}{3}A_{n-1}),\quad \text{for } n=1,2,...,$$

and put

$$f_n=(\tfrac{2}{3})^n \mathbb{1}_{A_n},\quad \text{for } n=0,1,2,... .$$

Denote by μ_n the measure with the density f_n, i.e.,

$$\mu_n(B)=\int_B f_n(x)\,dx,$$

where B is a Borel subset of $[0,1]$. It is easy to see that $g_n\overset{\text{df}}{=}f_n*f_n$ is the density of the convolution $\nu_n\overset{\text{df}}{=}\mu_n*\mu_n$.

The sequence $\{\mu_n\}$ converges weakly (see Ref. 22) to the Cantor measure μ and consequently $\nu_n\to\nu$ weakly.

To prove that ν is singular with respect to the Lebesgue measure it is enough to show that the sequence of densities $\{g_n\}$ converges to 0 in Lebesgue measure $|\cdot|$, i.e., for each $\varepsilon>0$,

$$|\{x:g_n(x)\geqslant\varepsilon\}|\to 0 \quad \text{as } n\to\infty.$$

Note that

$$g_0(x)=\begin{cases} x, & x\in[0,1],\\ 2-x, & x\in[1,2],\\ 0, & \text{otherwise,}\end{cases}$$

and

$$g_n(x)=\begin{cases} \tfrac{3}{4}g_{n-1}(3x), & x\in[0,\tfrac{2}{3}]\\ \tfrac{3}{2}g_{n-1}(3x-2), & x\in[\tfrac{2}{3},\tfrac{4}{3}]\\ \tfrac{3}{4}g_{n-1}(3x-4), & x\in[\tfrac{4}{3},2]\\ 0, & \text{otherwise.}\end{cases}$$

Observe that

$$|\{x:g_n(x)\geqslant\varepsilon\}|\leqslant 2\cdot 3^{-n}\,\mathrm{card}\{k:c_k^n\geqslant\varepsilon\},$$

where $c_k^n\overset{\mathrm{df}}{=}\max\{g_n(x):x\in[2(k-1)/3^n,2k/3^n]\}$, for $n=0,1,2,...,$ $k=1,...,3^n$. Therefore, in order to prove that $g_n\to 0$ in measure, it is sufficient to show that for each $r\in\mathbf{N}$

$$3^{-n}\,\mathrm{card}\{k:c_k^n\geqslant 2^{-r}\}\to 0 \quad \text{as} \quad n\to\infty.$$

Next observe that, for each n, c_k^n can only assume values $2^j(\tfrac{3}{4})^n$, $j=0,...,n$, and denote

$$\alpha_j^n=\mathrm{card}\{k:c_k^n=2^j(\tfrac{3}{4})^n\}.$$

Then

$$\mathrm{card}\{k:c_k^n\geqslant 2^{-r}\}=\sum_{\{j:2^j(\frac{3}{4})^n\geqslant 2^{-r}\}}\alpha_j^n.$$

Note that

$$2^j(\tfrac{3}{4})^n\geqslant 2^{-r}\Leftrightarrow j/n\geqslant 2-\log_2 3-r/n.$$

Since $2-\log_2 3>\tfrac{2}{5}$, then for each r there is $n_0(r)$ such that $2-\log_2 3-r/n>\tfrac{2}{5}$, for each $n>n_0(r)$. Therefore

$$\mathrm{card}\{k:c_k^n\geqslant 2^{-r}\}\leqslant\sum_{j>2n/5}\alpha_j^n,$$

for $n>n_0(r)$. Consequently, we need only to prove that

$$3^{-n}\sum_{j>2n/5}\alpha_j^n\to 0 \quad \text{as} \quad n\to\infty. \tag{A1}$$

Notice first that α_j^n are the coefficients in the binomial expansion of

$$\psi_n(x)\overset{\mathrm{df}}{=}(2+x)^n=\alpha_0^n+\alpha_1^n x+\cdots+\alpha_n^n x^n, \tag{A2}$$

i.e., $\alpha_j^m=2^{n-j}n!/j!(n-j)!$, which can be proved by induction. Indeed, (A2) is true for $n=0$. Now, assume that (A2) is true for some n. It is obvious that $\alpha_{n+1}^{n+1}=1$ and $\alpha_0^{n+1}=2\alpha_0^n=2^{n+1}$. If $j\in\{1,...,n\}$, then

$$\alpha_j^{n+1}=2\alpha_j^n+\alpha_{j-1}^n=2\cdot 2^{n-j}\frac{n!}{j!(n-j)!}+2^{n-j+1}\frac{n!}{(j-1)!(n-j+1)!}$$
$$=2^{n+1-j}\frac{(n+1)!}{j!(n+1-j)!},$$

which implies that (A2) is also true for $n+1$.

Let us now assume that $n/5\in\mathbf{N}$ and evaluate (A1) using the Cauchy form of the Taylor formula

$$3^{-n}\sum_{j>2n/5}\alpha_j^n=3^{-n}\frac{\psi_n^{(2n/5)}(\theta)(1-\theta)^{2n/5-1}}{(2n/5-1)!}$$
$$\leqslant 3^{-n}\frac{n!(2+\theta)^{3n/5}(1-\theta)^{2n/5-1}}{(3n/5)!(2n/5-1)!}$$
$$\leqslant 3^{-n}\frac{n!2^{3n/5}}{(3n/5)!(2n/5-1)!},$$

where $0<\theta<1$. Hence, using Stirling formula we get

$$3^{-n}\sum_{j>2n/5}\alpha_j^n=\frac{2n/5\sqrt{2\pi n}}{\sqrt{2\pi 3n/5}\sqrt{2n/5}}3^{-n}\frac{n^n2^{3n/5}}{(3n/5)^{3n/5}(2n/5)^{2n/5}}a(n)$$
$$=c(n)\left(3^{-1}\frac{2^{3/5}}{(3/5)^{3/5}(2/5)^{2/5}}\right)^n<c(n)p^n,$$

where $a(n)\to 1$ as $n\to\infty$, $c(n)\leqslant\text{const}\sqrt{n}$, and $p<1$. Since the right-hand side goes to 0, as $n\to\infty$, this ends the proof of the theorem.

(Received 1 February 1999; accepted for publication 2 April 1999)

The global additive and multiplicative properties of the Laplacian on j-forms and related zeta functions are analyzed. The explicit form of zeta functions on a product of closed oriented hyperbolic manifolds $\Gamma\backslash\mathbb{H}^d$ and of the multiplicative anomaly are derived. We also calculate in an explicit form the analytic torsion associated with a connected sum of such manifolds. © *1999 American Institute of Physics.* [S0022-2488(99)01407-3]

I. INTRODUCTION

The additive and multiplicative properties of (pseudo-) differential operators as well as properties of their determinants have been studied actively during recent years in the mathematical and physical literature. The anomaly associated with product of regularized determinants of operators can be expressed by means of the noncommutative residue, the Wodzicki residue[1] (see also Refs. 2 and 3). The Wodzicki residue, which is the unique extension of the Dixmier trace to the wider class of (pseudo-) differential operators,[4,5] has been considered within the noncommutative geometrical approach to the standard model of the electroweak interactions[6–8] and the Yang–Mills action functional. Some recent papers along these lines can be found in Refs. 9–12.

The product of two (or more) differential operators of Laplace type can arise in higher derivative field theories (for example, in higher derivative quantum gravity[13]). The zeta function associated to the product of Laplace-type operators acting in irreducible rank 1 symmetric spaces and the explicit form of the multiplicative anomaly have been derived in Ref. 11.

Under such circumstances we should note that the conformal deformation of a metric and the corresponding conformal anomaly can also play an important role in quantum theories with higher derivatives. It is well known that evaluation of the conformal anomaly is actually possible only for even-dimensional spaces and up to now its computation is extremely involved. The general structure of such an anomaly in curved d-dimensional spaces (d even) has been studied in Ref. 14. We briefly mention here analysis related to this phenomenon for constant curvature spaces. The conformal anomaly calculation for the d-dimensional sphere can be found, for example, in Ref. 15. The explicit computation of the anomaly (of the stress-energy tensor) in irreducible rank 1 symmetric spaces has been carried out in Refs. 16–18 using the zeta-function regularization and the Selberg trace formula.

Recently the topology of manifolds have been studied by means of quantum field theory methods. New invariants related to three-manifolds[19] can be constructed within the framework of Chern–Simons gauge theory and can be specified in terms of the axioms of topological quantum field theory. Also, an important role is played by semiclassical approximations for Chern–Simons theory associated with partition functions involving quadratic functionals. It has been shown, in fact, that the analytic or Ray–Singer torsion (a topological invariant)[20] occurs within quantum

field theory as the partition function of a certain quadratic functional.[21,22] Recall that Ray–Singer torsion $T_{\rm an}(X)$ is defined for every closed Riemannian manifold X and orthogonal representation χ of $\pi_1(X)$. The definition of the torsion involves the spectrum of the Laplacian on twisted j-forms. It has been proved in Refs. 23 and 24 that when χ is acyclic and orthogonal the value $T_{\rm an}(X)$ coincides with the so-called Reidemeister torsion, which can be computed from a twisted cochain complex of a finite complex by taking a suitable alternating product of determinants.[25]

The purpose of the present paper is to investigate the spectral zeta functions associated with a product and Krönecker sum of Laplacians on j-forms and to calculate in an explicit form the analytic torsion on closed oriented hyperbolic manifolds $\Gamma\backslash\mathbb{H}^d$ and on a connected sum of such manifolds.

II. THE SPECTRAL ZETA FUNCTION AND THE TRACE FORMULA

We shall be working with irreducible rank 1 symmetric spaces $X=G/K$ of noncompact type. Thus G will be a connected noncompact simple split rank 1 Lie group with finite center and $K\subset G$ will be a maximal compact subgroup. Up to local isomorphism we choose $X=\mathrm{SO}_1(d,1)/\mathrm{SO}(d)$. Thus the isotropy group K of the base point $(1,0,...,0)$ is $\mathrm{SO}(d)$; X can be identified with hyperbolic d-space $\mathbb{H}^d$, $d=\dim X$. It is possible to view $\mathbb{H}^d$, for example, as one sheet of the hyperboloid of two sheets in $\mathbb{R}^{d+1}$ given by $q(x)=-x_0^2+x_1^2+\cdots+x_d^2=-1$, $x_0>0$, with the metric induced by the quadratic form $q(x)$. Let $\Gamma\subset G$ be a discrete, co-compact, torsion free subgroup, and let $\chi(\gamma)=\mathrm{trace}(\chi(\gamma))$ be the character of a finite-dimensional unitary representation χ of Γ for $\gamma\in\Gamma$. Let $L^{(j)}\equiv\Delta_\Gamma^{(j)}$ be the Laplacian on j-forms acting on the vector bundle $V(X_\Gamma)$ over $X_\Gamma=\Gamma\backslash G/K$ induced by χ. Note that the nontwisted j-forms on X_Γ are obtained by taking $\chi=1$. One can define the heat kernel of the elliptic operator $\mathcal{L}^{(j)}=L^{(j)}+b^{(j)}$ by

$$\mathrm{Tr}(e^{-t\mathcal{L}^{(j)}})=\frac{-1}{2\pi i}\mathrm{Tr}\int_{\mathcal{C}_0}e^{-zt}(z-\mathcal{L}^{(j)})^{-1}\,dz, \tag{2.1}$$

where $\mathcal{C}_0$ is an arc in the complex plane $\mathbb{C}$; the $b^{(j)}$ are endomorphisms of the vector bundle $V(X_\Gamma)$. By standard results in operator theory there exist $\varepsilon,\delta>0$ such that for $0<t<\delta$ the heat kernel expansion holds

$$\omega_\Gamma^{(j)}(t,b^{(j)})=\sum_{l=0}^{\infty}n_l(\chi)e^{-(\lambda_l^{(j)}+b^{(j)})t}=\sum_{0\leqslant l\leqslant l_0}a_l(\mathcal{L}^{(j)})t^{-l}+\mathcal{O}(t^{\varepsilon}), \tag{2.2}$$

where $\{\lambda_l^{(j)}\}_{l=0}^{\infty}$ is the set of eigenvalues of operator $L^{(j)}$ and $n_l(\chi)$ denote the multiplicity of $\lambda_l^{(j)}$. Eventually we would also like to take $b^{(j)}=0$, but for now we consider only nonzero modes: $b^{(j)}+\lambda_l^{(j)}>0$, $\forall l:\lambda_0^{(j)}=0$, $b^{(j)}>0$.

Let a_0,n_0 denote the Lie algebras of A, N in an Iwasawa decomposition $G=KAN$. Since the rank of G is 1, $\dim a_0=1$ by definition, say $a_0=\mathbb{R}H_0$ for a suitable basis vector H_0. One can normalize the choice of H_0 by $\beta(H_0)=1$, where $\beta:a_0\rightarrow\mathbb{R}$ is the positive root which defines n_0; for more detail see Ref. 26. Since Γ is torsion free, each $\gamma\in\Gamma-\{1\}$ can be represented uniquely as some power of a primitive element $\delta:\gamma=\delta^{j(\gamma)}$, where $j(\gamma)\geqslant 1$ is an integer and δ cannot be written as γ_1^j for $\gamma_1\in\Gamma$, $j>1$ an integer. Taking $\gamma\in\Gamma$, $\gamma\neq 1$, one can find $t_\gamma>0$ and $m_\gamma\in M\overset{\mathrm{def}}{=}\{m_\gamma\in K|m_\gamma a=am_\gamma,\forall a\in A\}$ such that γ is G conjugate to $m_\gamma\exp(t_\gamma H_0)$, namely for some $g\in G$, $g\gamma g^{-1}=m_\gamma\exp(t_\gamma H_0)$. Additionally, let $\chi_\sigma(m)=\mathrm{trace}(\sigma(m))$ be the character of σ, for σ a finite-dimensional representation of M.

Theorem 2.1: *(Fried's trace formula[27]) For* $0\leqslant j\leqslant d-1$,

$$\mathrm{Tr}(e^{-t\mathcal{L}^{(j)}})=I^{(j)}(t,b^{(j)})+I^{(j-1)}(t,b^{(j-1)})+H^{(j)}(t,b^{(j)})+H^{(j-1)}(t,b^{(j-1)}), \tag{2.3}$$

where

$$I^{(j)}(t,b^{(j)})\overset{\text{def}}{=}\frac{\chi(1)\mathrm{Vol}(\Gamma\backslash G)}{4\pi}\int_{\mathbb{R}}\mu_{\sigma_j}(r)e^{-t[r^2+b^{(j)}+(\rho_0-j)^2]}dr, \tag{2.4}$$

$$H^{(j)}(t,b^{(j)})\overset{\text{def}}{=}\frac{1}{\sqrt{4\pi t}}\sum_{\gamma\in C_\Gamma-\{1\}}\chi(\gamma)t_\gamma j(\gamma)^{-1}C(\gamma)\chi_{\sigma_j}(m_\gamma)\exp\left\{-\left[b^{(j)}t+(\rho_0-j)^2t+\frac{t_\gamma^2}{4t}\right]\right\}, \tag{2.5}$$

$\rho_0=(d-1)/2$, *and the function* $C(\gamma),\ \gamma\in\Gamma$, *defined on* $\Gamma-\{1\}$ *by*

$$C(\gamma)\overset{\text{def}}{=}e^{-\rho_0 t_\gamma}|\det_{n_0}(\mathrm{Ad}(m_\gamma e^{t_\gamma H_0})^{-1}-1)|^{-1}. \tag{2.6}$$

For Ad *denoting the adjoint representation of G on its complexified Lie algebra, one can compute* t_γ *as follows:*[28]

$$e^{t_\gamma}=\max\{|c|\,|\,c=\text{an eigenvalue of }\mathrm{Ad}(\gamma)\}. \tag{2.7}$$

Here C_Γ is a complete set of representatives in Γ of its conjugacy classes; Haar measure on G is suitably normalized. In our case $K\simeq\mathrm{SO}(d)$, $M\simeq\mathrm{SO}(d-1)$. For $j=0$ (i.e., for smooth functions or smooth vector bundle sections) the measure $\mu_0(r)$ corresponds to the trivial representation of M. For $j\geqslant 1$ there is a measure $\mu_\sigma(r)$ corresponding to a general irreducible representation σ of M. Let σ_j be the standard representation of $M=\mathrm{SO}(d-1)$ on $\Lambda^j\mathbb{C}^{(d-1)}$. If $d=2n$ is even, then $\sigma_j(0\leqslant j\leqslant d-1)$ is always irreducible; if $d=2n+1$, then every σ_j is irreducible except for $j=(d-1)/2=n$, in which case σ_n is the direct sum of two (1/2)-spin representations $\sigma^\pm:\sigma_n=\sigma^+\oplus\sigma^-$. For $j=n$ the representation τ_n of $K=\mathrm{SO}(2n)$ on $\Lambda^n\mathbb{C}^{2n}$ is not irreducible, $\tau_n=\tau_n^+\oplus\tau_n^-$ is the direct sum of (1/2)-spin representations. The Harish-Chandra Plancherel measures $\mu_{\sigma_j}(r)$ are given by the following theorem.

Theorem 2.2: *Let the group* $G=\mathrm{SO}_1(2n,1)$. *Then*

$$\mu_{\sigma_j}(r)=\binom{2n-1}{j}\frac{\pi r}{2^{4n-4}\Gamma(n)^2}\prod_{i=2}^{j+1}\left[r^2+\left(n+\frac{3}{2}-i\right)^2\right]\times\prod_{i=j+2}^{n}\left[r^2+\left(n+\frac{1}{2}-i\right)^2\right]\tanh(\pi r)\quad\text{for }0\leqslant j\leqslant n-1, \tag{2.8}$$

$$\mu_{\sigma_j}(r)=\binom{2n-1}{j}\frac{\pi r}{2^{4n-4}\Gamma(n)^2}\prod_{i=2}^{2n-j}\left[r^2+\left(n+\frac{3}{2}-i\right)^2\right]\times\prod_{i=2n-j+1}^{n}\left[r^2+\left(n+\frac{1}{2}-i\right)^2\right]\tanh(\pi r)\quad\text{for }n\leqslant j\leqslant 2n-1, \tag{2.9}$$

and $\mu_{\sigma_j}(r)=\mu_{\sigma_{2n-j-1}}(r)$.

For the group $G=\mathrm{SO}_1(2n+1,1)$ *one has*

$$\mu_{\sigma_j}(r)=\binom{2n}{j}\frac{\pi}{2^{4n-2}\Gamma\left(n+\frac{1}{2}\right)^2}\prod_{i=1}^{j+1}[r^2+(n+1-i)^2]\prod_{i=j+2}^{n}[r^2+(n-i)^2]\quad\text{for }0\leqslant j<n, \tag{2.10}$$

$$\mu_{\sigma_j}(r)=\binom{2n}{j}\frac{\pi}{2^{4n-2}\Gamma\left(n+\frac{1}{2}\right)^2}\prod_{i=1}^{2n-j+1}[r^2+(n+1-i)^2]$$

$$\times\prod_{i=2n-j+2}^{n}[r^2+(n-i)^2]\quad \text{for } n+1\leqslant j\leqslant 2n-1. \tag{2.11}$$

We should note that the reason for the pair of terms $\{I^{(j)},I^{(j-1)}\}$, $\{H^{(j)},H^{(j-1)}\}$ in the trace formula Eq. (2.3) is that τ_j satisfies $\tau_j|_M=\sigma_j\oplus\sigma_{j-1}$.

Finally, using the result of Theorem 2.2, we have

$$\mu_{\sigma_j}(r)=C^{(j)}(d)P(r,d)\times\begin{cases}\tanh(\pi r) & \text{for } d=2n,\\ 1 & \text{for } d=2n+1,\end{cases}$$

$$=C^{(j)}(d)\times\begin{cases}\displaystyle\sum_{l=0}^{d/2-1} a_{2l}^{(j)}(d)r^{2l+1}\tanh(\pi r) & \text{for } d=2n,\\ \displaystyle\sum_{l=0}^{(d-1)/2} a_{2l}^{(j)}(d)r^{2l} & \text{for } d=2n+1,\end{cases} \tag{2.12}$$

$$C^{(j)}(d)=\binom{d-1}{j}\frac{\pi}{2^{2d-4}\Gamma(d/2)^2}, \tag{2.13}$$

where the $P(r,d)$ are even polynomials [with suitable coefficients $a_{2l}^{(j)}(d)$] of degree $d-1$ for $G\neq \mathrm{SO}(2n+1,1)$, and of degree $d=2n+1$ for $G=\mathrm{SO}_1(2n+1,1)$.[29,26]

A. Case of the trivial representation

For $j=0$ we take $I^{(-1)}=H^{(-1)}=0$. Since σ_0 is the trivial representation $\chi_{\sigma_0}(m_\gamma)=1$. In this case, Fried's formula (2.3) reduces exactly to the trace formula for $j=0$:[28,30]

$$\omega_\Gamma^{(0)}(t,b^{(0)})=\frac{\chi(1)\mathrm{vol}(\Gamma\backslash G)}{4\pi}\int_{\mathbb{R}}\mu_{\sigma_0}(r)e^{-(r^2+b^{(0)}+\rho_0^2)t}dr+H^{(0)}(t,b^{(0)}), \tag{2.14}$$

where ρ_0 is associated with the positive restricted (real) roots of G (with multiplicity) with respect to a nilpotent factor N of G in an Iwasawa decomposition $G=KAN$. The function $H^{(0)}(t,b^{(0)})$ has the form

$$H^{(0)}(t,b^{(0)})=\frac{1}{\sqrt{4\pi t}}\sum_{\gamma\in C_\Gamma-\{1\}}\chi(\gamma)t_\gamma j(\gamma)^{-1}C(\gamma)e^{-[b^{(0)}t+\rho_0^2t+t_\gamma^2/(4t)]}. \tag{2.15}$$

B. Case of zero modes

It can be shown[31] that the Mellin transform of $H^{(0)}(t,0)$ ($b^{(0)}=0$, i.e., the zero modes case),

$$\mathfrak{h}^{(0)}(s)\overset{\text{def}}{=}\int_0^\infty H^{(0)}(t,0)t^{s-1}dt, \tag{2.16}$$

is a holomorphic function on the domain $\mathrm{Re}\,s<0$. Then, using the result of Refs. 29 and 26 one can obtain on $\mathrm{Re}\,s<0$

$$\mathfrak{h}^{(0)}(s)=\sum_{\gamma\in C_\Gamma-\{1\}}\chi(\gamma)t_\gamma j(\gamma)^{-1}C(\gamma)\int_0^\infty \frac{e^{-(\rho_0^2 t+t_\gamma^2/(4t))}}{\sqrt{4\pi t}}t^{s-1}\,dt$$
$$=\frac{(2\rho_0)^{1/2-s}}{\sqrt{\pi}}\sum_{\gamma\in C_\Gamma-\{1\}}\chi(\gamma)t_\gamma j(\gamma)^{-1}C(\gamma)t_\gamma^{s+1/2}K_{1/2-s}(t_\gamma\rho_0), \tag{2.17}$$

where $K_\nu(s)$ is the modified Bessel function, and finally

$$\mathfrak{h}^{(0)}(s)=\frac{\sin(\pi s)}{\pi}\Gamma(s)\int_0^\infty \psi_\Gamma(t+2\rho_0;\chi)(2\rho_0 t+t^2)^{-s}\,dt. \tag{2.18}$$

Here $\psi_\Gamma(s;\chi)\equiv d(\log Z_\Gamma(s;\chi))/ds$, and $Z_\Gamma(s;\chi)$ is a meromorphic suitably normalized Selberg zeta function.[32–37,30,38,29]

III. THE MULTIPLICATIVE ANOMALY

In this section the product of the operators on j-forms $\otimes\mathcal{L}_p^{(j)}$, $\mathcal{L}_p^{(j)}=L^{(j)}+b_p^{(j)}$, $p=1,2$, will be considered. We are interested in multiplicative properties of determinants, the multiplicative anomaly.[39,2,3] The multiplicative anomaly $F(\mathcal{L}_1^{(j)},\mathcal{L}_2^{(j)})$ reads

$$F(\mathcal{L}_1^{(j)},\mathcal{L}_2^{(j)})=\det{}_\zeta[\otimes_p\mathcal{L}_p^{(j)}][\det{}_\zeta(\mathcal{L}_1^{(j)})\det{}_\zeta(\mathcal{L}_2^{(j)})]^{-1}, \tag{3.1}$$

where we assume a zeta-regularization of determinants, i.e.,

$$\det{}_\zeta(\mathcal{L}_p^{(j)})\overset{\text{def}}{=}\exp\left(-\frac{\partial}{\partial s}\zeta(s|\mathcal{L}_p^{(j)})\bigg|_{s=0}\right). \tag{3.2}$$

Generally speaking, if the anomaly related to elliptic operators is nonvanishing, then the relation $\log\det(\otimes\mathcal{L}_p^{(j)})=\mathrm{Tr}\log(\otimes\mathcal{L}_p^{(j)})$ does not hold.

A. The zeta function of the product of Laplacians

The spectral zeta function associated with the product $\otimes\mathcal{L}_p^{(j)}$ has the form

$$\zeta(s|\otimes_p\mathcal{L}_p^{(j)})=\sum_{l\geqslant 0}n_l\prod_p^2(\lambda_l^{(j)}+b_p^{(j)})^{-s}. \tag{3.3}$$

We shall always assume that $b_1^{(j)}\neq b_2^{(j)}$, say $b_1^{(j)}>b_2^{(j)}$. If $b_1^{(j)}=b_2^{(j)}$, then $\zeta(s|\otimes\mathcal{L}_p^{(j)})=\zeta(2s|\mathcal{L}^{(j)})$ is a well-known function. For $b_1^{(j)},b_2^{(j)}\in\mathbb{R}$, set $b_+\overset{\text{def}}{=}(b_1^{(j)}+b_2^{(j)})/2$, $b_-\overset{\text{def}}{=}(b_1^{(j)}-b_2^{(j)})/2$, thus $b_1^{(j)}=b_++b_-$ and $b_2^{(j)}=b_+-b_-$.

Theorem 3.1:[11] *The spectral zeta function can be written as follows:*

$$\zeta(s|\otimes_p\mathcal{L}_p^{(j)})=(2b_-)^{1/2-s}\frac{\sqrt{\pi}}{\Gamma(s)}\int_0^\infty \omega_\Gamma^{(j)}(t,b_+)I_{s-1/2}(b_-t)dt, \tag{3.4}$$

where the integral converges absolutely for $\mathrm{Re}\,s>d/4$.

This formula is a main starting point to study the zeta function. It expresses $\zeta(s|\otimes\mathcal{L}_p^{(j)})$ in terms of the Bessel function $I_{s-1/2}(b_-t)$ and $\omega_\Gamma^{(j)}(t,b_+)$, where the trace formula applies to $\omega_\Gamma^{(j)}(t,b_+)$. Let $B_p(j)=(\rho_0(p)-j)^2+b_p^{(j)}$ and $A\overset{\text{def}}{=}\chi(1)\mathrm{vol}(\Gamma\backslash G)C^{(j)}(d)/4$.

Theorem 3.2: *For* $\mathrm{Re}\,s>d/4$ *the explicit meromorphic continuation holds:*

$$\zeta(s|\otimes_p \mathcal{L}_p^{(j)}) = A\sum_{l=0}^{d/2-1} [a_{2l}^{(j)}(d)(\mathcal{F}_l^{(j)}(s)-E_l^{(j)}(s)) + a_{2l}^{(j-1)}(d)(\mathcal{F}_l^{(j-1)}(s)-E_l^{(j-1)}(s))] + \mathcal{I}^{(j)}(s)+\mathcal{I}^{(j-1)}(s), \tag{3.5}$$

where

$$E_l^{(j)}(s) \stackrel{\text{def}}{=} 4\int_0^\infty \frac{dr\, r^{2j+1}}{1+e^{2\pi r}} \prod_p (r^2+B_p(j))^{-s}, \tag{3.6}$$

which is an entire function of s,

$$\mathcal{F}_l^{(j)}(s) \stackrel{\text{def}}{=} (B_1(j)B_2(j))^{-s} \frac{l!(2B_1(j)B_2(j)/(B_1(j)+B_2(j)))^{l+1}}{(2s-1)(2s-2)\cdots(2s-(l+1))} \times F\left(\frac{l+1}{2},\frac{l+2}{2};s+\frac{1}{2};\left(\frac{B_1(j)-B_2(j)}{B_1(j)+B_2(j)}\right)^2\right), \tag{3.7}$$

$$\mathcal{I}^{(j)}(s) \stackrel{\text{def}}{=} (2b_-)^{1/2-s}\frac{\sqrt{\pi}}{\Gamma(s)}\int_0^\infty H^{(j)}(t,b_+)I_{s-1/2}(b_-t)t^{s-1/2}\,dt, \tag{3.8}$$

and $F(\alpha,\beta;\gamma;z)$ is the hypergeometric function.

The goal now is to compute the zeta function and its derivative at $s=0$. Thus we have

$$\mathcal{F}_l^{(j)}(0) = \frac{(-1)^{l+1}}{l+1}\left(\frac{2B_1(j)}{B_1(j)+B_2(j)}\right)^{l+1} F\left(\frac{l+1}{2},\frac{l+2}{2};\frac{1}{2};\left(\frac{B_1(j)-B_2(j)}{B_1(j)+B_2(j)}\right)^2\right) = \frac{(-1)^{l+1}}{2(l+1)}\sum_p^2 B_p(j)^{l+1}, \tag{3.9}$$

$$E_l^{(j)}(0) = 4\int_0^\infty \frac{dr\, r^{2l+1}}{1+e^{2\pi r}} = \frac{(-1)^l}{l+1}(1-2^{-2l-1})\mathcal{B}_{2l+2}, \tag{3.10}$$

$$\mathcal{I}^{(j)}(0)=0, \tag{3.11}$$

where $\mathcal{B}_{2n}$ are the Bernoulli numbers.

Proposition 3.3: A preliminary form of the zeta function $\zeta(s|\otimes_p\mathcal{L}_p^{(j)})$ at $s=0$ is

$$\zeta(0|\otimes_p\mathcal{L}_p^{(j)}) = A\sum_{l=0}^{(d/2)-1}\frac{(-1)^{l+1}}{2(l+1)}\Bigg[\sum_p (a_{2l}^{(j)}(d)B_p(j)^{l+1} + a_{2l}^{(j-1)}(d)B_p(j-1)^{l+1}) + (2-2^{-2l})\mathcal{B}_{2l+2}(a_{2l}^{(j)}(d)+a_{2l}^{(j-1)}(d))\Bigg]. \tag{3.12}$$

Proposition 3.4: The derivative of the zeta function at $s=0$ has the form

$$\zeta'(0|\otimes_p\mathcal{L}_p^{(j)}) = A\sum_{l=0}^{(d/2)-1}\left[\sum_m^4 (a_{2l}^{(j)}(d)\mathcal{E}_m^{(j)} + a_{2l}^{(j-1)}(d)\mathcal{E}_m^{(j-1)})\right], \tag{3.13}$$

where

$$\mathcal{E}_1^{(j)} = l!(B_1(j)^{l+1} + B_2(j)^{l+1}) \sum_{k=0}^{l} \frac{(-1)^{k+1}}{k!(l-k)!(j+1-k)!}, \tag{3.14}$$

$$\mathcal{E}_2^{(j)} = B_2(j)^{l+1} \left(\frac{B_1(j)-B_2(j)}{2B_1(j)} \right) \frac{(-1)^l}{(l+1)!} \sum_{k=1}^{\infty} \frac{(l+k+1)!}{(k+1)!} \sigma_n \left(\frac{B_1(j)-B_2(j)}{B_1(j)} \right)^k, \tag{3.15}$$

$$\mathcal{E}_3^{(j)} = \log(B_1(j)B_2(j)) \frac{(-1)^l}{2(l+1)} (B_1(j)^{l+1} + B_2(j)^{l+1}) - 4 \int_0^\infty \frac{r^{2l+1} \log((r^2+B_1(j))/(r^2+B_2(j)))dr}{1+e^{2\pi r}}, \tag{3.16}$$

$$\mathcal{E}_4^{(j)} \equiv \frac{d}{ds} \mathcal{I}^{(j)}(s) \bigg|_{s=0} = \int_0^\infty [H^{(j)}(t,b_1^{(j)}) + H^{(j)}(t,b_2^{(j)})] t^{-1}\, dt, \tag{3.17}$$

and $\sigma_n \overset{\text{def}}{=} \Sigma_{k=1}^n k^{-1}$.

B. The residue formula and the multiplicative anomaly

The value of $F(\mathcal{L}_1,\mathcal{L}_2)$ can be expressed by means of the noncommutative Wodzicki residue.[1] Let $\mathcal{O}_p$, $p=1$, 2, be invertible elliptic (pseudo-) differential operators of real nonzero orders α and β such that $\alpha+\beta\neq 0$. Even if the zeta functions for operators $\mathcal{O}_1$, $\mathcal{O}_2$ and $\mathcal{O}_1 \otimes \mathcal{O}_2$ are well defined and if their principal symbols satisfy the Agmon–Nirenberg condition (with appropriate spectra cuts), one has in general that $F(\mathcal{O}_1,\mathcal{O}_2)\neq 1$. For such invertible elliptic operators the formula for the anomaly of commuting operators holds:

$$\mathcal{A}(\mathcal{O}_1,\mathcal{O}_2) = \mathcal{A}(\mathcal{O}_2,\mathcal{O}_1) = \log(F(\mathcal{O}_1,\mathcal{O}_2)) = \frac{\text{res}[(\log(\mathcal{O}_1^\beta \otimes \mathcal{O}_2^{-\alpha}))^2]}{2\alpha\beta(\alpha+\beta)}. \tag{3.18}$$

More general formulas have been derived in Refs. 2 and 3. Furthermore, the anomaly can be iterated consistently. Indeed, using Eq. (3.18) we have

$$\begin{aligned}
\mathcal{A}(\mathcal{O}_1,\mathcal{O}_2) &= \zeta'(0|\mathcal{O}_1\mathcal{O}_2) - \zeta'(0|\mathcal{O}_1) - \zeta'(0|\mathcal{O}_2),\\
\mathcal{A}(\mathcal{O}_1,\mathcal{O}_2,\mathcal{O}_3) &= \zeta'(0|\overset{3}{\underset{j}{\otimes}}\mathcal{O}_j) - \sum_j^3 \zeta'(0|\mathcal{O}_j) - \mathcal{A}(\mathcal{O}_1,\mathcal{O}_2),\\
&\cdots\cdots\cdots\cdots \\
\mathcal{A}(\mathcal{O}_1,\mathcal{O}_2,\ldots,\mathcal{O}_n) &= \zeta'(0|\overset{n}{\underset{j}{\otimes}}\mathcal{O}_j) - \sum_j^n \zeta'(0|\mathcal{O}_j) - \mathcal{A}(\mathcal{O}_1,\mathcal{O}_2)\\
&\quad - \mathcal{A}(\mathcal{O}_1,\mathcal{O}_2,\mathcal{O}_3)\ldots - \mathcal{A}(\mathcal{O}_1,\mathcal{O}_2,\ldots,\mathcal{O}_{n-1}).
\end{aligned} \tag{3.19}$$

In particular, for $n=2$ and $\mathcal{O}_p \equiv \mathcal{L}_p^{(j)}$ the anomaly is given by the following theorem.

Theorem 3.5: *The explicit formula for the multiplicative anomaly is*

$$\mathcal{A}(\mathcal{L}_1^{(j)},\mathcal{L}_2^{(j)}) = A \sum_{l=0}^{(d/2)-1} [\Omega_l^{(j)} + \Omega_l^{(j-1)}], \tag{3.20}$$

where

$$\Omega_l^{(j)} = \frac{a_{2l}^{(j)}(d)(-1)^l}{2}\left[\frac{l}{2}(B_1(j)-B_2(j))^2 B_2(j)^{l-1} + \frac{l(l-1)}{4}(B_1(j)-B_2(j))^3 B_2(j)^{l-2} + \sum_{p=3}^{l} \frac{l!}{(p+1)p!(l-p)!}\left(\frac{1}{p}+\frac{1}{p-1}+\sum_{q=1}^{p-2}\frac{1}{p-q-1}\right)(B_1(j)-B_2(j))^{p+1}B_2(j)^{l-p}\right]. \tag{3.21}$$

We note that for the four-dimensional space with $G=\mathrm{SO}_1(4,1)$, one derives from Theorem 3.5 the result

$$\mathcal{A}(\mathcal{L}_1^{(j)},\mathcal{L}_2^{(j)} = -A_G^{(j)}(b_1^{(j)}-b_1^{(j)})^2 - A_G^{(j-1)}(b_1^{(j-1)}-b_1^{(j-1)})^2, \tag{3.22}$$

which also follows from Wodzicki's formula (3.18), where we should set $A_G^{(j)} = A a_{21}^{(j)}(4)/4$.

IV. THE CONFORMAL ANOMALY AND ASSOCIATED OPERATOR PRODUCTS

In this section we start with a conformal deformation of a metric and the conformal anomaly of the energy stress tensor. It is well known that (pseudo-) Riemannian metrics $\mathrm{g}_{\mu\nu}(x)$ and $\tilde{\mathrm{g}}_{\mu\nu}(x)$ on a manifold X are (pointwise) conformal if $\tilde{\mathrm{g}}_{\mu\nu}(x)=\exp(2f)\mathrm{g}_{\mu\nu}(x)$, $f\in C^\infty(\mathbb{R})$. For constant conformal deformations the variation of the connected vacuum functional (the effective action) can be expressed in terms of the generalized zeta function related to an elliptic self-adjoint operator $\mathcal{O}$:[13]

$$\delta W = -\zeta(0|\mathcal{O})\log\mu^2 = \int_{X_\Gamma}\langle T_{\mu\nu}(x)\rangle \delta \mathrm{g}^{\mu\nu}(x)dx, \tag{4.1}$$

where $\langle T_{\mu\nu}(x)\rangle$ means that all connected vacuum graphs of the stress-energy tensor $T_{\mu\nu}(x)$ are to be included. Therefore Eq. (4.1) leads to

$$\langle T_\mu^\mu(x)\rangle = (\mathrm{Vol}(X_\Gamma))^{-1}\zeta(0|\mathcal{O}). \tag{4.2}$$

The formulas (3.5) and (3.9)–(3.11) give an explicit result for the conformal anomaly, namely,

$$\langle T_\mu^\mu(x)\rangle_{(\mathcal{O}=\otimes\mathcal{L}_p^{(j)})} = \frac{1}{(4\pi)^{d/2}\Gamma(d/2)}\sum_{l=0}^{(d/2)-1}\frac{(-1)^{l+1}}{2(l+1)}\left\{\sum_p \left[a_{2l}^{(j)}(d)B_p(j)^{l+1} + a_{2l}^{(j-1)}(d)B_p(j-1)^{l+1}\right] + (2-2^{-2l})\mathcal{B}_{2l+2}(a_{2l}^{(j)}(d)+a_{2l}^{(j-1)}(d))\right\}, \tag{4.3}$$

where d is even. For $B_{1,2}(j)=B(j)$ and $B_{1,2}(j-1)=B(j-1)$, the anomaly (4.3) has the form

$$\langle T_\mu^\mu(x)\rangle_{(\mathcal{L}^{(j)}\otimes\mathcal{L}^{(j)})} = \frac{1}{(4\pi)^{d/2}\Gamma(d/2)}\sum_{l=0}^{(d/2)-1}\frac{(-1)^{l+1}}{2(l+1)}\{[a_{2l}^{(j)}(d)B(j)^{l+1} + a_{2l}^{(j-1)}(d)B(j-1)^{l+1}] + (2-2^{-2l})\mathcal{B}_{2l+2}(a_{2l}^{(j)}(d)+a_{2l}^{(j-1)}(d))\}. \tag{4.4}$$

Note that for a minimally coupled scalar field of mass m, $B(0)=\rho_0^2+m^2$. The simplest case is, for example, $G=\mathrm{SO}_1(2,1)\simeq \mathrm{SL}(2,\mathbb{R})$; besides $X=\mathbb{H}^2$ is a two-dimensional real hyperbolic space. Then we have $\rho_0^2=1/4$, $a_{20}^{(0)}=1$, and finally

$$\langle T_\mu^\nu(x\in\Gamma\backslash\mathbb{H}^2)\rangle_{(\mathcal{L}^{(0)}\otimes\mathcal{L}^{(0)})}=-\frac{1}{4\pi}\left(b+\frac{1}{3}\right). \tag{4.5}$$

For real d-dimensional hyperbolic space the scalar curvature is $R(x)=-d(d-1)$. In the case of the conformally invariant scalar field we have $B(0)=\rho_0^2+R(x)(d-2)/[4(d-1)]$. As a consequence, $B(0)=\frac{1}{4}$ and

$$\langle T_\mu^\mu(x\in\Gamma\backslash\mathbb{H}^d)\rangle_{(\mathcal{L}^{(0)}\otimes\mathcal{L}^{(0)})}=\frac{1}{(4\pi)^{d/2}\Gamma(d/2)}\times\sum_{l=0}^{(d/2)-1}\frac{(-1)^{l+1}}{l+1}a_{2l}^{(0)}(d)\{2^{-2l-2}+(1-2^{-2l-1})\mathcal{B}_{2l+2}\}. \tag{4.6}$$

Thus in conformally invariant scalar theory the anomaly of the stress tensor coincides with one associated with operator product. This statement holds not only for hyperbolic spaces considered above, but for all constant curvature manifolds as well.[17]

V. PRODUCT OF EINSTEIN MANIFOLDS

In this section we consider the problem of the global existence of zeta functions on (pseudo-) Riemannian product manifolds, a product of two Einstein manifolds[40,41]

$$(X,\mathbf{g},\mathcal{P})=(X_1,\mathbf{g}_1,\mathcal{P}_1)\otimes(X_2,\mathbf{g}_2,\mathcal{P}_2), \tag{5.1}$$

where $\mathbf{g}=\mathbf{g}_1\otimes\mathbf{g}_2$ and the metric $\mathbf{g}$ separates the variables, i.e.,

$$ds^2=\mathbf{g}_{\alpha\beta}(x)dx^\alpha\otimes dx^\beta+\mathbf{g}_{\mu\nu}(y)dy^\mu\otimes dy^\nu. \tag{5.2}$$

The tangent bundle splits as $TX=TX_1\oplus TX_2$ and $\mathcal{P}=\mathcal{P}_1+\mathcal{P}_2$, where $\mathcal{P}_p(p=1,2)$ are the corresponding projections on TX_p,

$$\mathcal{P}^2=\mathrm{Id},\quad \mathbf{g}(\mathcal{P}\mathcal{X},\mathcal{P}\mathcal{Y})=\mathbf{g}(\mathcal{X},\mathcal{Y}),\quad \mathcal{X},\mathcal{Y}\in\mathcal{G}(X), \tag{5.3}$$

$\mathcal{G}(X)$ being the Lie algebra of vector fields $\mathcal{X}$ and $\mathcal{Y}$ on X. The trivial examples of an almost-product structure are given by the choices $\mathcal{P}=\pm\mathrm{Id}$ ($\pm$ identity).

We recall some facts about Einstein manifolds. An almost-product (pseudo-) Riemannian structure $(X,\mathbf{g},\mathcal{P})$ is integrable iff $\Delta\mathcal{P}=0$ for the Levi–Civita connection Δ of $\mathbf{g}$. The two integrable complementary subbundles, i.e., both foliations, are totally geodesic.[40,41] Let X be a pseudo-Kähler manifold. Such a manifold is an Einstein manifold iff in any adapted coördinates (x^α,y^α) both metrics $\mathbf{g}_1$ and $\mathbf{g}_2$ are Einstein metrics for the same constant λ,[40–42] i.e.,

$$\mathrm{Ric}(\mathbf{g})=\lambda\mathbf{g}. \tag{5.4}$$

Our consideration will be restricted to only locally decomposable manifolds. A wide class of (pseudo-) Riemannian manifolds includes nonlocally decomposable manifolds as well, which are given by warped product space–times.[43–45] Note that many exact solutions of Einstein equations (associated with Schwarzschild, Robertson–Walker, Reissner–Nordström, de Sitter space–times) and p-brane solutions are, in fact, warped product space–times.

A. The explicit form of the zeta function

We study the zeta function

$$\zeta(s|\mathcal{L}^{(j)}\oplus\mathcal{L}^{(k)})=\zeta_{\Gamma_1\backslash X\otimes\Gamma_2\backslash X}(s)=\frac{1}{\Gamma(s)}\int_0^\infty\omega_{\Gamma_1}^{(j)}(t)\omega_{\Gamma_2}^{(k)}(t)t^{s-1}\,dt,\quad \mathrm{Re}\,s>d. \tag{5.5}$$

Let $B=B_1(j)+B_2(k)$, $A_p\overset{\text{def}}{=}\chi(1)\ \text{vol}\ (\Gamma_p\backslash G)C^{(j)}(d)/4$, $y_p(s;z)\overset{\text{def}}{=}s/2+(-1)^{p-1}z$, $p=1,2(s,z\in\mathbb{C})$. The explicit construction gives more, namely the following.

Theorem 5.1: *The function $\zeta(s|\mathcal{L}^{(j)}\otimes\mathcal{L}^{(k)})$ admits an explicit meromorphic continuation to $\mathbb{C}$ with at most a simple pole at $s=1,2,...,d$. In particular on the domain $\text{Re}\, s<1$,*

$$
\begin{aligned}
\zeta(s|\mathcal{L}^{(j)}\oplus\mathcal{L}^{(k)})=&\frac{\pi^2}{2}A_1A_2[C^{(j)}(d)+C^{(j-1)}(d)][C^{(k)}(d)+C^{(k-1)}(d)]\\
&\times\sum_{m=0}^{n-1}\sum_{l=0}^{m}\sum_{\mu=0}^{n-1}\sum_{\nu=0}^{\mu}\frac{[a_{2m}^{(j)}(d)+a_{2m}^{(j-1)}(d)][a_{2m}^{(k)}(d)+a_{2m}^{(k-1)}(d)]}{(m-l)!(\mu-\nu)!}\\
&\times\frac{\int_0^\infty r^{2(m-l)}\,\text{sech}^2(\pi r)\mathcal{K}_{\mu-\nu}(s-l-\nu-1;r^2+B,\pi)dr}{(s-1)(s-2)\cdots(s-(l+1))(s-(l+2))\cdots(s-(l+1+\nu+1))}\\
&+C^{(j)}(d)V_1\sin(\pi s)\sum_{m=0}^{n-1}[a_{2m}^{(j)}(d)+a_{2m}^{(j-1)}(d)]\int_{\mathbb{R}}r^{2m+1}\tanh(\pi r)\\
&\times\Bigg[\int_0^\infty\Psi_{\Gamma_2}(\rho_0-k+t+\sqrt{r^2+B};\chi_2)(2t\sqrt{r^2+B}+t^2)^{-s}\,dt+\int_0^\infty\Psi_{\Gamma_2}(\rho_0-k+1\\
&+t+\sqrt{r^2+B};\chi_2)(2t\sqrt{r^2+B}+t^2)^{-s}dt\Bigg]dr+C^{(j)}(d)V_2\sin(\pi s)\\
&\times\sum_{m=0}^{n-1}[a_{2m}^{(k)}(d)+a_{2m}^{(k-1)}(d)]\int_{\mathbb{R}}r^{2m+1}\tanh(\pi r)\Bigg[\int_0^\infty\Psi_{\Gamma_1}(\rho_0-j+t\\
&+\sqrt{r^2+B};\chi_1)(2t\sqrt{r^2+B}+t^2)^{-s}\,dt+\int_0^\infty\Psi_{\Gamma_1}(\rho_0-j+1+t+\sqrt{r^2+B};\chi_1)\\
&\times(2t\sqrt{r^2+B}+t^2)^{-s}dt\Bigg]dr+\frac{1}{2\pi^3 i\Gamma(s)}\int_{\text{Re}_{z=\varepsilon}}dz\left[\sin\pi\left(z+\frac{s}{2}\right)\right]\\
&\times\left[\sin\pi\left(\frac{s}{2}-z\right)\right]\Gamma\left(z+\frac{s}{2}\right)\Gamma\left(\frac{s}{2}-z\right)\Bigg[\int_0^\infty(\Psi_{\Gamma_1}(\rho_0-j+t+B_1^{1/2};\chi_1)(2tB_1^{1/2}\\
&+t^2)^{-y_1(s,z)}+\Psi_{\Gamma_1}(\rho_0-j+1+t+B_1^{1/2};\chi_1)(2tB_1^{1/2}+t^2)^{-y_1(s,z)})dt\Bigg]\\
&\times\Bigg[\int_0^\infty(\Psi_{\Gamma_2}(\rho_0-k+t+B_2^{1/2};\chi_2)(2tB_2^{1/2}+t^2)^{-y_2(s,z)}+\Psi_{\Gamma_2}(\rho_0-k+1+t\\
&+B_2^{1/2};\chi_2)(2tB_2^{1/2}+t^2)^{-y_2(s,z)})dt\Bigg],
\end{aligned}
\tag{5.6}
$$

for any $-\frac{1}{2}\leqslant\varepsilon\leqslant\frac{1}{2}$. For a, $\delta>0$, $\nu\in\mathbb{N}$, the entire function $\mathcal{K}_\nu(s;\delta,a)$ of s is defined by

$$
\mathcal{K}_\nu(s;\delta,a)\overset{\text{def}}{=}\int_{\mathbb{R}}\frac{r^{2\nu}\,\text{sech}^2(ar)dr}{(\delta+r^2)^s}.
\tag{5.7}
$$

All of the integrals are entire functions of s.

The simplest case is, for example, $G=SO_1(2,1)\simeq SL(2,\mathbb{R})$; besides $X=\mathbb{H}^2$ is a two-dimensional real hyperbolic space. Then for $j=k=0$, $\Gamma_1=\Gamma_2=\Gamma$, we have $a_{20}^{(0)}(2)=1$ and $\mu_{\sigma 0}(r)=\pi r\tanh(\pi r)$ and for $\text{Re}\, s<1$ we have

$$\zeta(s|\mathcal{L}^{(0)}\oplus\mathcal{L}^{(0)})=\frac{\pi A_1^2}{2(s-1)(s-2)}\int_0^\infty \mathrm{sech}^2(\pi r)\mathcal{K}_0(s-2;r^2+B,\pi)dr+\frac{2}{\pi}A_1\sin(\pi s)$$
$$\times\int_{\mathbb{R}} r\tanh(\pi r)dr\int_0^\infty \psi_\Gamma\left(\frac{1}{2}+t+\sqrt{r^2+B};\chi\right)(2t\sqrt{r^2+B}+t^2)^{-s}\,dt$$
$$+\frac{1}{2\pi^3 i\Gamma(s)}\int_{\mathrm{Re}_{z=\varepsilon}}\left[\sin\pi\left(z+\frac{s}{2}\right)\right]\left[\sin\pi\left(\frac{s}{2}-z\right)\right]\Gamma\left(z+\frac{s}{2}\right)$$
$$\times\Gamma\left(\frac{s}{2}-z\right)dz\int_0^\infty\psi_\Gamma\left(\frac{1}{2}+t+B_0^{1/2};\chi\right)(2tB_0^{1/2}+t^2)^{-y_1(s;z)}dt$$
$$\times\int_0^\infty\psi_\Gamma\left(\frac{1}{2}+t+B_0^{1/2};\chi\right)(2tB_0^{1/2}+t^2)^{-y_2(s;z)}\,dt, \tag{5.8}$$

where $B=\frac{1}{2}+2b^{(0)}$ and $B(0)=\frac{1}{2}+b^{(0)}$.

VI. QUADRATIC FUNCTIONAL WITH ELLIPTIC RESOLVENT AND ANALYTIC TORSION

Let $\chi:\pi_1(X_\Gamma)\mapsto O(V,\langle\cdot,\cdot\rangle v)$ be a representation of $\pi_1(X_\Gamma)$ on a real vector space V. The mapping χ determines (on the basis of a standard construction in differential geometry) a real flat vector bundle ξ over X_Γ and a flat connection map D on the space $\Omega(X_\Gamma,\xi)$ of differential forms on X_Γ with values in ξ. One can say that χ determines the space of smooth sections in the vector bundle $\Lambda(TX_\Gamma)^*\otimes\xi$.

Let D_j denote the restriction of D to the space $\Omega^j(X_\Gamma,\xi)$ of j- forms and let

$$H^j(D)=\ker(D_j)[\mathrm{Im}(D_{j-1})]^{-1} \tag{6.1}$$

be the corresponding cohomology spaces. There exists a canonical Hermitian structure on the bundle χ which we denote by $\langle\cdot,\cdot\rangle_V$. The above-mentioned Hermitian structure determines for each $x\in X_\Gamma$ a linear map $\langle\cdot,\cdot\rangle_x:\xi_x\otimes\xi_x\mapsto\mathbb{R}$, and the diagram for linear maps hold (see Ref. 46 for details)

$$(\Lambda^p(T_xX_\Gamma)^*\otimes\xi_x)\otimes(\Lambda^q(T_xX_\Gamma)^*\otimes\xi_x)\overset{\wedge}{\mapsto}\Lambda^{p+q}(T_xX_\Gamma)^*\otimes(\xi_x\otimes\xi_x)\overset{\langle\cdot,\cdot\rangle_x}{\mapsto}\Lambda^{p+q}(T_xX_\Gamma)^*, \tag{6.2}$$

where the image of $\omega_x\otimes\tau_x$ under the first map has been denote by $\langle\omega_x\wedge\tau_x\rangle_x$.

We define the quadratic functional S_D on $\Omega^j(X_\Gamma,\xi)$ by

$$S_D(\omega)=\int_{X_\Gamma}\langle\omega(x)\wedge(D_j\omega)(x)\rangle_x. \tag{6.3}$$

One can construct from the metric on X_Γ and Hermitian structure in ξ a Hermitian structure in $\Lambda(T_xX_\Gamma)^*\otimes\xi$ and the inner products $\langle\cdot,\cdot\rangle_j$ in the space $\Omega^j(X_\Gamma,\xi)$. Thus

$$S_D(\omega)=\langle\omega,T\omega\rangle_j,\quad T=*D_j, \tag{6.4}$$

where (*) is the Hodge-star map. Recall that the map T is formally self-adjoint with the property $T^2=D_j^*D_j$. Let $(\mathfrak{J}_p,D_p)$ be a complex, i.e., a sequence of vector space $\mathfrak{J}_p$ and linear operators D_p acting from the space $\mathfrak{J}_p$ to the space $\mathfrak{J}_{p+1}$ $(\mathfrak{J}_{-1}=\mathfrak{J}_{d+1})$ and satisfying $D_{p+1}D_p=0$ for all $p=0,1,...,d$. Let us define the adjoint operators $D_p^*:\mathfrak{J}_{p+1}\mapsto\mathfrak{J}_p$ by $\langle a,D_pb\rangle_{p+1}=\langle D_p^*a,b\rangle_p$. For the functional (6.3) there is a canonical topological elliptic resolvent $R(S_D)$ (a chain of linear maps)

$$0\overset{0}{\mapsto}\Omega^0(X_\Gamma,\xi)\overset{D_0}{\mapsto}\cdots\overset{D_{d-2}}{\mapsto}\Omega^{d-1}(X_\Gamma,\xi)\overset{D_{d-1}}{\mapsto}\ker(S_D)\overset{0}{\mapsto}0. \tag{6.5}$$

From Eq. (6.5) it follows that for $R(S_D)$ we have $H^p(R(S_D))=H^{d-p}(D)$ and $\ker(S_D)\equiv\ker(T)=\ker(D_j)$.

Let us choose an inner product $\langle\cdot,\cdot\rangle_{H^p}$ in each space $H^p(R(S_D))$. The partition function of S_D associated to points in the moduli space of flat gauge fields $\omega(x)$ on X_Γ with the resolvent (6.5) can be written in the form (see, for example, Ref. 46)

$$\mathcal{Z}(\beta)\equiv\mathcal{Z}(\beta;R(S_D),\langle\cdot,\cdot\rangle_H,\langle\cdot,\cdot\rangle)=\mathfrak{I}(\beta,\zeta,\eta)\,\tau(X_\Gamma,\chi,\langle\cdot,\cdot\rangle_H)^{1/2}, \tag{6.6}$$

where $\beta=i\lambda$, $\lambda\in\mathbb{R}$, $\mathfrak{I}(\beta,\zeta,\eta)$ is known function of β. The function ζ appearing in the partition function above can be expressed in terms of the dimensions of the cohomology spaces of D,

$$\zeta\equiv\zeta(0||T|)=-\sum_{p=0}^{d}(-1)^p\dim H^p(R(S))=(-1)^{n+1}\sum_{q=0}^{n}(-1)^q\dim H^q(D). \tag{6.7}$$

The dependence of $\eta=\eta(0|T_D)$ on the connection map D can be expressed with the help of formulas for the index of the twisted signature operator for a certain vector bundle over $X_\Gamma\otimes[0,1]$.[47] It can be shown that[46]

$$\eta(s|B^{(l)})=2\,\eta(s|T_{D^{(l)}}), \tag{6.8}$$

where the $B^{(l)}$ are elliptic self-adjoint maps on $\Omega(X_\Gamma,\xi)$ defined on j-forms by

$$B_j^{(l)}=(-i)^{\lambda(j)}(*D^{(l)}+(-1)^{j+1}D^{(l)}*). \tag{6.9}$$

In this formula $\lambda(j)=(j+1)(j+2)+n+1$ and for the Hodge star-map we have used that $*\alpha\wedge\beta=\langle\alpha,\beta\rangle_{\text{vol}}$. From the Hodge theory

$$\dim\ker B^{(l)}=\sum_{q=0}^{d}\dim H^q(D^{(l)}). \tag{6.10}$$

The metric dependence of η enters through $L^r(TX_\Gamma)$ and $\eta(0|T_{D^{(0)}})$, where $L^r(TX_\Gamma)$ is the r'th term in Hirzebruch's L-polynomial (see Ref. 47 for details) and $D^{(0)}$ is an arbitrary flat connection map on $\Omega(X_\Gamma,\xi)$. For $d=3$ the only contribution of the L-polynomial is $L_0=1$ and the metric dependence of η is determined alone by $\eta(0|T_{D^{(0)}})$.

The factor $\tau(X_\Gamma,\chi,\langle\cdot,\cdot\rangle_H)$ is independent of the choice of metric g on X.[46] In fact, this quantity is associated with the analytic (Ray–Singer) torsion $T_{\text{an}}(X_\Gamma)$ (Ref. 20) of the representation χ of $\pi_1(X_\Gamma)$ constructed using the metric g. If $H^0(D)\neq 0$ and $H^q(D)=0$ for $q=1,...,n$, $d=2n+1$ the dimension of X, then the product

$$\tau(X_\Gamma,\chi,\langle\cdot,\cdot\rangle_H)=T_{\text{an}}(X_\Gamma)\cdot\text{Vol}(X_\Gamma)^{-\dim H^0(D)}, \tag{6.11}$$

is independent of the choice of metric g, i.e., the metric dependence of the Ray–Singer torsion $T_{\text{an}}(X_\Gamma)$ factors out as $\text{Vol}(X_\Gamma)^{-\dim H^0(D)}$.

A. Connected sum of three-manifolds

Recall that an embedding of the cohomology $H(X_\Gamma;\xi)$ into $\Omega(X_\Gamma;\xi)$ as the space of harmonic forms induces a norm $|\cdot|^{\text{RS}}$ on the determinant line $\det H(X_\Gamma;\xi)$. The Ray–Singer norm $\|\cdot\|^{\text{RS}}$ on $\det H(X_\Gamma;\xi)$ is defined by[20]

$$\|\cdot\|^{\text{RS}}\overset{\text{def}}{=}|\cdot|\prod_{j=0}^{\dim X}\left[\exp\left(-\frac{d}{ds}\zeta(s|\mathcal{L}^{(j)})\bigg|_{s=0}\right)\right]^{(-1)^j j/2}, \tag{6.12}$$

where the zeta function $\zeta(s|\mathcal{L}^{(j)})$ of the Laplacian acting on the space of j-forms orthogonal to the harmonic forms has been used. For a closed connected orientable smooth manifold of odd dimension and for any Euler structure $\eta\in \mathrm{Eul}(X)$ the Ray–Singer norm of its cohomological torsion $T_{\rm an}(X_\Gamma,\eta)\in \det H(X_\Gamma;\xi)$ is equal to the positive square root of the absolute value of the monodromy of ξ along the characteristic class $c(\eta)\in H^1(X_\Gamma)$:[48] $\|T_{\rm an}(X_\Gamma)\|^{\rm RS}=|\det_\xi c(\eta)|^{1/2}$. In the special case where the flat bundle ξ is acyclic $[H^q(X_\Gamma;\xi)=0$ for all $q]$ we have

$$[T_{\rm an}(X_\Gamma,\eta)]^2=|\det_\xi c(\eta)|\prod_{j=0}^{\dim X}\left[\exp\left(-\frac{d}{ds}\zeta(s|\mathcal{L}^{(j)})\bigg|_{s=0}\right)\right]^{(-1)^{j+1}j}. \tag{6.13}$$

If ξ is unimodular, then $|\det_\xi c(\eta)|=1$ and the torsion $T_{\rm an}(X_\Gamma)$ does not depend on the choice of η. For odd-dimensional manifold the Ray–Singer norm is a topological invariant: it does not depend on the choice of metric on X and ξ, used in the construction. But for even-dimensional X this is not the case.[49]

Suppose the flat bundle ξ is acyclic. The analytic torsion $T_{\rm an}(\Gamma\backslash\mathbb{H}^3)$ can be expressed in terms of the Selberg zeta functions $Z_j(s,\chi_j)$. Indeed the Ruell zeta function in three dimensions associated with the closed oriented hyperbolic manifold $X_\Gamma=\Gamma\backslash\mathbb{H}^3$ has the form

$$\mathcal{R}_\chi(s)=\prod_{j=0}^{2}Z_j(j+s,\chi_j)^{(-1)^j}=\frac{Z_0(s,\chi_0)Z_2(2+s,\chi_2)}{Z_1(1+s,\chi_1)}. \tag{6.14}$$

The function $\mathcal{R}_\chi(s)$ extends meromorphically to the entire complex plane $\mathbb{C}$.[50] For the Ray–Singer torsion one gets[51]

$$[T_{\rm an}(\Gamma\backslash\mathbb{H}^3)]^2=\mathcal{R}_\chi(0)=\frac{[Z_0(2,\chi_0)]^2}{Z_1(1,\chi_1)}\exp\left(-\frac{\mathrm{Vol}(\mathcal{F})}{3\pi}\right), \tag{6.15}$$

where $\mathrm{Vol}(\mathcal{F})$ is a volume of the fundamental domain $\mathcal{F}$ of $\Gamma\backslash\mathbb{H}^3$. In the presence of nonvanishing Betti numbers $b_j=b_j(X_\Gamma)$ we have[51,52]

$$[T_{\rm an}(\Gamma\backslash\mathbb{H}^3)]^2=\frac{(b_1-b_0)![Z_0^{b_0}(2,\chi_0)]^2}{[b_0!]^2Z_1^{(b_1-b_0)}(1,\chi_1)}\exp\left(-\frac{\mathrm{Vol}(\mathcal{F})}{3\pi}\right). \tag{6.16}$$

In Chern–Simons theory the partition function at level k $(\lambda=2\pi k)$ depends on a framing (i.e., on a trivialization of the normal bundle to the link) of twice the tangent bundle as a Spin (6) bundle, henceforth referred to as two-framing. In particular, for the SU(2) theory in the large k-limit the partition function for a connected sum $\mathcal{X}=X_{\Gamma,1}\#X_{\Gamma,2}\#\cdots\#X_{\Gamma,N}$ can be written as follows:[53]

$$\mathcal{Z}(\mathcal{X})=\frac{\otimes_{l=1}^{N}\mathcal{Z}(X_{\Gamma,l})}{[\mathcal{Z}(S^3)]^{N-1}}. \tag{6.17}$$

Equation (6.17) holds for any given two-framings among $X_{\Gamma,p}$ and $X_{\Gamma,q}$, $p,q\leqslant N$, the induced two-framing on $X_{\Gamma,p}\#X_{\Gamma,q}$, and a canonical two-framing on $\mathbb{S}^3$. Since the Ray–Singer torsion on $\mathbb{S}^3$ is to be equal to one, $\mathcal{Z}(\mathbb{S}^3)=\sqrt{2}\pi k^{-3/2}$, the partition function associated with the semiclassical approximation $(k\to\infty)$ takes the form

$$\mathcal{Z}_{\rm sc}(\mathcal{X})=\left(\frac{k^3}{2\pi^2}\right)^{(N-1)/2}\bigotimes_{l=1}^{N}\mathcal{Z}_{\rm sc}(X_{\Gamma,l})=\sqrt{2}\pi k^{-3/2}\bigotimes_{l=1}^{N}|\mathcal{R}_{\chi(l)}(0)|^{1/2}, \tag{6.18}$$

while in the presence of nonvanishing Betti numbers $b_{jl}=b_j(X_{\Gamma,l})$ one gets

$$\mathcal{Z}_{\rm sc}(\mathcal{X})=\sqrt{2}\pi k^{-3/2}\bigotimes_{l=1}^{N}\left[\frac{(b_{1l}-b_{0l})!(Z_0^{(b_{0l})}(2,\chi_0))^2}{(b_{0l}!)^2Z_1^{(b_{1l}-b_{0l})}(1,\chi_1)}\right]^{1/4}\exp\left[-\frac{1}{12\pi}\bigoplus_{l=1}^{N}\mathrm{Vol}(\mathcal{F}_l)\right]. \tag{6.19}$$

In the case of nontrivial characters, $b_0(X_{\Gamma,l})=0$. If $b_1=0$, then Eq. (6.15) holds.

For the trivial character one has $b_0=1$ (for any closed manifold) and $b_1=0$ for an infinite number of $X_\Gamma=\Gamma\backslash\mathbb{H}^3$. The function $\mathcal{R}(s)$ has a zero at $s=0$ of order 4.[27] However, there is a class of compact sufficiently large hyperbolic manifolds which admit arbitrarily large values of $b_1(X_\Gamma)$. Sufficiently large manifolds X_Γ contain a surface S whose fundamental group $\pi_1(S)$ is infinite and such that $\pi_1(S)\subset\pi_1(X_\Gamma)$.

It seems that the most important problem in three-topology is the classification problem. In general, hyperbolic manifolds have not been completely classified and therefore a systematic computation is not yet possible. However, this is not the case for certain sufficiently large manifolds, the Haken manifolds.[54] There exists an algorithm for the enumeration of all Haken manifolds and there exists an algorithm for recognizing homeomorphy of the Haken manifolds.[55] Both algorithms depend on normal surface theory in the manifold, developed primarily by Haken. These manifolds give an essential contribution to the partition function (6.19).

VII. CONCLUDING REMARKS

We have obtained an explicit formula for the multiplicative anomaly (Theorem 3.5). The anomaly is equal to zero for $d=2$ and for the odd-dimensional cases. We have preferred to limit discussion here on various particular cases in detail and emphasize the general picture. It seems to us that the explicit results for the anomaly (3.20) and (3.22) are not only interesting as mathematical results, but are very important in several physical examples where the determinant of a product of differential operators is not equal to the product of the corresponding functional determinants (see, for example, Ref. 56). Because a large amount of recent activity has involved the calculation of the conformal anomaly of dilaton coupled matter, it would also be of great interest to generalize our results to the dilaton-dependent trace anomaly.

We have also considered product structures on closed real hyperbolic manifolds. In fact, the explicit form of the zeta function on product spaces (Theorem 5.1) is derived. As an example the zeta function associated with the Krönecker sum of Laplacians on twisted forms is calculated in the two-dimensional case.

Finally, the explicit formulas for analytic torsion $T_{\rm an}(X_\Gamma)$ (a topological invariant) on manifolds of the form $X_\Gamma=\Gamma\backslash\mathbb{H}^d$ and on a connected sum of such manifolds are derived. Thus our results enable one to calculate the Chern–Simons partition function appearing in the semiclassical approximation for the Witten invariant. We have also discussed briefly the fact that for Haken manifolds a larger influence, due to their Betti numbers, is exerted on the form of the partition function. We hope that proposed discussion of this invariant will be interesting in view of future applications to concrete problems in quantum field theory.

Matrix representation of octonions and generalizations

Jamil Daboul[a)] and Robert Delbourgo[b)]
School of Mathematics and Physics, University of Tasmania, Hobart, Australia

(Received 31 December 1998; accepted for publication 25 March 1999)

We define a special matrix multiplication among a special subset of $2N\times 2N$ matrices, and study the resulting (nonassociative) algebras and their subalgebras. We derive the conditions under which these algebras become alternative nonassociative, and when they become associative. In particular, these algebras yield special matrix representations of octonions and complex numbers; they naturally lead to the Cayley–Dickson doubling process. Our matrix representation of octonions also yields elegant insights into Dirac's equation for a free particle. A few other results and remarks arise as byproducts. © *1999 American Institute of Physics.* [S0022-2488(99)03108-4]

I. INTRODUCTION

Complex numbers and functions have played a pivotal role in physics for three centuries. On the other hand, their generalization to other Hurwitz algebras does not seem to have fired the interest of physicists to the same extent, because there is still no *compelling* application of them. Thus, despite the fascination of quaternions and octonions for over a century, it is fair to say that they still await universal acceptance. This is not to say that there have not been valiant attempts to find appropriate uses for them. One can point to their possible impact on quantum mechanics and Hilbert space,[1] relativity and the conformal group,[2] field theory and functional integrals,[3] internal symmetries in particle physics,[4] color field theories,[5] and formulations of wave equations.[6]

In all these cases, there is nothing that stands out and commands our attention; rather, the attempts to describe relativistic physics in terms of quaternions and octonions look rather contrived if not forced, especially for the case of octonions. In this paper we describe a generalization of octonions that allows for Lie algebras beyond the obvious SU(2) structure that is connected with quaternions. We do not presume that they will lead to new physics, but we do think they will at least provide a new avenue for investigation.

Since octonions are not associative, they cannot be represented by matrices with the usual multiplication rules. In this paper, we give representations of octonions and other nonassociative algebras by special matrices, which are endowed with very special multiplication rules; these rules can be regarded as an adaptation and generalization of Zorn's multiplication rule.[7] These matrix representations suggest generalizations of octonions to other nonassociative algebras, which, in turn, lead one almost automatically to a construction of new algebras from old ones, with double the number of elements; we have called these ''double algebras.'' Closer inspection reveals that our procedure can be made to correspond to the Cayley–Dickson construction method,[8] except that in our case the procedure seems rather natural, once one accepts the multiplication rule, whereas the Cayley–Dickson rule looks *ad hoc* at first sight.

II. DEFINITIONS, NOTATIONS, AND A REVIEW OF THE OCTONION ALGEBRA $\mathcal{O}$

The Cayley or the octonion algebra $\mathcal{O}$ is an eight-dimensional nonassociative algebra, which is defined in terms of the basis elements e_μ $(\mu=0,1,2,...,7)$ and their multiplication table. e_0

[a)]Permanent address: Department of Physics, Ben Gurion University of the Negev, 84105 Beer Sheva, Israel; electronic mail: daboul@bgumail.bgu.ac.il
[b)]Electronic mail: Bob.Delbourgo@utas.edu.au

stands for the unit element. We can efficiently summarize the table by introducing the following notation [in general, we shall use Greek indices ($\mu,\nu,...$) to include the 0 and latin indices $(i,j,k,\dots)$ when we exclude the 0]:

$$\hat{e}_k \equiv e_{4+k}, \quad \text{for } k=1,2,3. \tag{1}$$

The multiplication rules among the basis elements of octonions e_μ can be expressed in the form

$$-e_4 e_i = e_i e_4 = \hat{e}_i, \quad e_4 \hat{e}_i = -\hat{e}_i e_4 = e_i, \quad e_4 e_4 = -e_0, \tag{2}$$

$$e_i e_j = -\delta_{ij} e_0 + \epsilon_{ijk} e_k, \tag{3}$$

$$\hat{e}_i \hat{e}_j = -\delta_{ij} e_0 - \epsilon_{ijk} e_k \quad (i,j,k=1,2,3), \tag{4}$$

$$-\hat{e}_j e_i = e_i \hat{e}_j = -\delta_{ij} e_4 - \epsilon_{ijk} \hat{e}_k. \tag{5}$$

We can formally summarize the rules above by

$$e_\mu e_\nu = g_{\mu\nu} e_0 + \sum_{k=1}^{7} \gamma^k_{\mu\nu} e_k, \quad g_{\mu\nu} := \mathrm{diag}(1,-1,...,-1), \quad \gamma^k_{ij} = -\gamma^k_{ji}, \tag{6}$$

where $\mu,\nu=0,1,...,7$, and $i,j,k=1,...,7$. The multiplication properties are sometimes displayed graphically by a circle surrounded by a triangle, but we shall not bother to exhibit that.

The multiplication law (3) shows that the first four elements form a closed *associative* subalgebra of $\mathcal{O}$, which is known as the *quaternion algebra*,

$$\mathcal{Q} \equiv \langle e_0, e_1, e_2, e_3 \rangle_{\mathbb{R}}, \tag{7}$$

while the other rules (2), (4), and (5) show that $\mathcal{O}$ can be graded as follows:

$$\mathcal{O} = \mathcal{Q} \oplus \hat{\mathcal{Q}}, \quad \text{where } \hat{\mathcal{Q}} := e_4 \mathcal{Q}. \tag{8}$$

$\mathcal{O}$ is a nonassociative algebra. Now a measure of the nonassociativity in any algebra $\mathcal{A}$ is provided by the *associator*, which is defined for any three elements, as follows:

$$(x,y,z) := (xy)z - x(yz), \quad \text{for } x,y,z \in \mathcal{A}. \tag{9}$$

In particular, the associators for the octonion basis are

$$(e_i, e_j, e_k) = 2\epsilon_{ijkl} e_l, \tag{10}$$

where ϵ_{ijkl} are *totally* antisymmetric[9] and equal to unity for the following seven combinations:[5]

$$1247, \quad 1265, \quad 2345, \quad 2376, \quad 3146, \quad 3157, \quad \text{and} \quad 4576. \tag{11}$$

The quaternionic subalgebra $\mathcal{Q}$. It is very well known that the quaternions form an associative subalgebra $\mathcal{Q}$, which can be represented by the Pauli matrices:

$$e_0 \to \sigma_0 = 1, \quad \text{and} \quad e_j \to -i\sigma_j \quad (j=1,2,3), \tag{12}$$

where, as usual,

$$\sigma_0 = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad \sigma_1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \sigma_2 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}. \tag{13}$$

It is trivial to check that the above map is an isomorphism:

$$e_i e_j \Leftrightarrow -\sigma_i\sigma_j = -(\delta_{ij} + i\epsilon_{ijk}\sigma_k) \Leftrightarrow -\delta_{ij} + \epsilon_{ijk} e_k . \tag{14}$$

III. NONASSOCIATIVE MULTIPLICATION

In contrast to $\mathcal{Q}$, *the Cayley algebra* $\mathcal{O}$ *cannot be represented by matrices with the usual multiplication rules*, because $\mathcal{O}$ is not associative. However, as we demonstrate below, it is possible to represent octonions by matrices, provided one defines a special multiplication rule among them.

A. Zorn's representation of octonions

Zorn[7] gave a representation of the octonions[8] in terms of 2×2 matrices M, whose diagonal elements are scalars and whose off-diagonal elements are three-dimensional vectors:

$$\mathcal{O} \ni x \to \begin{pmatrix} \alpha & \mathbf{a} \\ \mathbf{b} & \beta \end{pmatrix}, \tag{15}$$

and invoked a peculiar multiplication rule for these matrices.[7] With a slight modification of the rule adopted by Humphreys,[10] p. 105, our rule is

$$\begin{pmatrix} \alpha & \mathbf{a} \\ \mathbf{b} & \beta \end{pmatrix} * \begin{pmatrix} \alpha' & \mathbf{a}' \\ \mathbf{b}' & \beta' \end{pmatrix} = \begin{pmatrix} \alpha\alpha' + \mathbf{a}\cdot\mathbf{b}' & \alpha\mathbf{a}' + \beta'\mathbf{a} - \mathbf{b}\times\mathbf{b}' \\ \alpha'\mathbf{b} + \beta\mathbf{b}' + \mathbf{a}\times\mathbf{a}' & \beta\beta' + \mathbf{b}\cdot\mathbf{a}' \end{pmatrix}. \tag{16}$$

We propose to adapt this multiplication law to octonions and also replace the necessary three-dimensional basis vectors $\hat{v}_k$ by Pauli matrices σ_k $(k=1,2,3)$, so that the octonions can be represented by the following ordinary 4×4 matrices:

$$\begin{gathered} e_0 \Leftrightarrow \Omega_0 \equiv \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad e_k \Leftrightarrow \Omega_k \equiv \begin{pmatrix} 0 & -\sigma_k \\ \sigma_k & 0 \end{pmatrix} \quad (k=1,2,3), \\ e_4 \Leftrightarrow \Omega_4 \equiv \begin{pmatrix} i & 0 \\ 0 & -1 \end{pmatrix}, \quad \hat{e}_k \Leftrightarrow \hat{\Omega}_k \equiv \begin{pmatrix} 0 & i\sigma_k \\ i\sigma_k & 0 \end{pmatrix}. \end{gathered} \tag{17}$$

[Note the equality of Ω_k $(k=1,2,3)$ to the Dirac matrices γ_k, and Ω_4 to $i\gamma_0$ in the Pauli–Dirac representation.] It can be shown by explicit multiplication, that the above map (17) becomes an isomorphism, provided we define the modified product rule, which we denote by ♥:

$$\begin{pmatrix} \alpha & A \\ B & \beta \end{pmatrix} \heartsuit \begin{pmatrix} \alpha' & A' \\ B' & \beta' \end{pmatrix} = \begin{pmatrix} \alpha\alpha' + \frac{1}{2}\mathrm{Tr}(AB') & \alpha A' + \beta' A + \dfrac{i}{2}[B,B'] \\ \alpha' B + \beta B' - \dfrac{i}{2}[A,A'] & \beta\beta' + \frac{1}{2}\mathrm{Tr}(BA') \end{pmatrix}, \tag{18}$$

where $[A,B] \equiv AB - BA$ is the commutator of A and B. Of course, $A = \mathbf{a}\cdot\boldsymbol{\sigma}$ and $B = \mathbf{b}\cdot\boldsymbol{\sigma}$ are traceless: $\mathrm{Tr}\,A = \mathrm{Tr}\,B = 0$.

In particular, the above multiplication rule yields the following relations:

$$\begin{aligned} \begin{pmatrix} 0 & \eta\sigma_i \\ \xi\sigma_i & 0 \end{pmatrix} \heartsuit \begin{pmatrix} 0 & \eta'\sigma_j \\ \xi'\sigma_j & 0 \end{pmatrix} &= \begin{pmatrix} \eta\xi'\delta_{ij} & \xi\xi'\dfrac{i}{2}[\sigma_i,\sigma_j] \\ -\eta\eta'\dfrac{i}{2}[\sigma_i,\sigma_j] & \xi\eta'\delta_{ij} \end{pmatrix} \\ &= \delta_{ij}\begin{pmatrix} \eta\xi' & 0 \\ 0 & \xi\eta' \end{pmatrix} + \epsilon_{ijk}\begin{pmatrix} 0 & -\xi\xi'\sigma_k \\ \eta\eta'\sigma_k & 0 \end{pmatrix}, \end{aligned} \tag{19}$$

which are helpful for checking the multiplication rules (2)–(5), by substituting the appropriate coefficients, η and ξ.

B. The standard conjugate of octonions

Usually, octonions are studied over the field of real numbers $\mathbb{R}$,

$$x=\sum_{\mu=0}^{7} x_\mu e_\mu \equiv x_0+\mathbf{x}, \quad \text{for } x_\mu \in \mathbb{R}, \tag{20}$$

although later we will find it interesting to deal with their complex extension. The standard *conjugate* $\overline{x}$ of an octonion over $\mathbb{R}$ is defined by

$$\overline{x}:=x_0e_0-\sum_{i=1}^{7} x_ie_i \equiv x_0-\mathbf{x}. \tag{21}$$

The reason for this definition is that the product of $\overline{x}$ with x yields a positive definite norm:

$$n(x)=x\overline{x}=\overline{x}x=\sum_{\mu=0}^{7} x_\mu^2 \geqslant 0. \tag{22}$$

Moreover, this norm obeys the decomposition law,

$$n(xy)=n(x)n(y). \tag{23}$$

However, with complex octonions [real $x \rightarrow$complex z in (20)], we shall still formally define the *conjugate* $\overline{z}$ of z, to be

$$\overline{z}:=z_0e_0-\sum_{i=1}^{7} z_ie_i, \quad \text{for } z_\mu \in \mathbb{C}. \tag{24}$$

It follows that the product $z\overline{z}$ is again proportional to unity:

$$n(z)=z\overline{z}=\overline{z}z=\sum_{\mu=0}^{7} z_\mu^2 \in \mathbb{C}, \tag{25}$$

but $n(z)$ ceases to be real, in general; therefore $n(z)$ should simply be regarded as a scalar function, but not a norm.

It is interesting to calculate $n(z)$ by using the matrix representation (26): First, we note that if z is mapped into the matrix Z, then $\overline{z}$ will be mapped into $\overline{Z}$, as follows:

$$z \rightarrow Z \equiv \sum_{\mu=0}^{7} z_\mu \Omega_\mu = \begin{pmatrix} \alpha & A \\ B & \beta \end{pmatrix}, \quad \overline{z} \rightarrow \overline{Z} \equiv \begin{pmatrix} \beta & -A \\ -B & \alpha \end{pmatrix}, \tag{26}$$

where $A=\mathbf{a}\cdot\boldsymbol{\sigma}$ and $B=\mathbf{b}\cdot\boldsymbol{\sigma}$, with

$$\alpha=z_0+iz_4, \quad \beta=z_0-iz_4, \quad a_k=-z_k+iz_{4+k}, \quad b_k=z_k+iz_{4+k} \quad (k=1,2,3). \tag{27}$$

Second,

$$z\overline{z} \leftrightarrow Z \heartsuit \overline{Z} = \begin{pmatrix} \alpha & A \\ B & \beta \end{pmatrix} \heartsuit \begin{pmatrix} \beta & -A \\ -B & \alpha \end{pmatrix} = \left(\alpha\beta - \frac{1}{2}\mathrm{Tr}(AB) \right) \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} = n(z) I_{4\times 4}. \tag{28}$$

Therefore, we reproduce the expression (25), as expected:

$$n(z):=\frac{1}{4}\operatorname{Tr}(Z\heartsuit\overline{Z})=\alpha\beta-\frac{1}{2}\operatorname{Tr}(AB)=\alpha\beta-\mathbf{a}\cdot\mathbf{b}=\sum_{\mu=0}^{7} z_\mu^2. \tag{29}$$

C. Hermitian conjugate of octonions

Since σ_i are Hermitian matrices, *all our representation matrices* Ω_k *are anti-Hermitian, with the exception of the identity* Ω_0 (which is Hermitian, of course):

$$\Omega_k^\dagger=-\Omega_k,\quad k=1,2,...,7. \tag{30}$$

This fact enables us to prove that the following ''hermiticity'' property also holds for the ♥ products:

$$(\Omega_\mu\heartsuit\Omega_\nu)^\dagger=\Omega_\nu^\dagger\heartsuit\Omega_\mu^\dagger,\quad\text{for }\ \mu,\nu=0,1,...,7. \tag{31}$$

First, we note that this equality holds trivially for $(\Omega_0\heartsuit\Omega_\mu)^\dagger=\Omega_\mu^\dagger=\Omega_\mu^\dagger\heartsuit\Omega_0^\dagger$. Second, we prove (31) for $j,k\neq 0$ by using (6) and noting that γ_{ij}^k are real and antisymmetric in *j*, *k*, so that

$$(\Omega_j\heartsuit\Omega_k)^\dagger=-\delta_{jk}\Omega_0+\sum_{i=1}^{7}\gamma_{jk}^i\Omega_i^\dagger=-\delta_{kj}\Omega_0+\sum_{i=1}^{7}\gamma_{kj}^i\Omega_i=\Omega_k\heartsuit\Omega_j=\Omega_k^\dagger\heartsuit\Omega_j^\dagger,\quad j,k=1,...,7. \tag{32}$$

The conjugation property (31) of Ω_μ suggests the following formal definition for the *Hermitian conjugate* of the octonionic basis:

$$e_0^\dagger=e_0,\quad e_j^\dagger=-e_j\quad(j=1,2,...,7), \tag{33}$$

whereupon the ''*number operators*'' become equal to the identity element:

$$N_\mu:=e_\mu^\dagger e_\mu=e_\mu e_\mu^\dagger=e_0=1\quad(\text{no summation})\quad(\mu=0,1,...,7). \tag{34}$$

We can now define the *Hermitian conjugate* of the complex octonions *z* in a natural way, by

$$z^\dagger:=\sum_{\mu=0}^{7}\overline{z_\mu}e_\mu^\dagger=\overline{z_0}e_0-\sum_{i=1}^{7}\overline{z_i}e_i\equiv\overline{z_0}-\overline{\mathbf{z}},\quad\text{where }\ z_i\in\mathbb{C}. \tag{35}$$

We then calculate

$$\begin{aligned}zz^\dagger&\equiv(z_0+\mathbf{z})(\overline{z_0}-\overline{\mathbf{z}})=|z_0|^2+(\overline{z_0}\mathbf{z}-z_0\overline{\mathbf{z}})-\mathbf{z}\overline{\mathbf{z}}\\&=\sum_{\mu=0}^{7}|z_\mu|^2-\sum_{k=1}^{7}(z_0\overline{z_k}-z_k\overline{z_0})e_k+\sum_{1\leqslant i<j}(z_i\overline{z_j}-z_j\overline{z_i})e_ie_j\\&=N(z)+2i\sum_{k=i}^{7}\mathfrak{I}\left(\overline{z_0}z_k+\sum_{1\leqslant i<j\leqslant 7}z_i\overline{z_j}\gamma_{ij}^k\right)e_k,\end{aligned} \tag{36}$$

where

$$N(z)=\sum_{\mu=0}^{7}|z_\mu|^2. \tag{37}$$

The definition $N(z)$ is perfectly reasonable for a norm, although the decomposition law (23) is *not* satisfied. We see that the ''space components'' $(zz^\dagger)_i$ of $zz^\dagger$ are pure imaginary. To understand why this is expected on general grounds, it is useful to introduce the concept of a *Hermitian octonion:* $y^\dagger = y$, which signifies that

$$\overline{y_0} = y_0, \quad \overline{y_i} = -y_i \quad (i=1,...,7), \tag{38}$$

so that y_0 must be real and all the space components must be pure imaginary.

Since $zz^\dagger$ is Hermitian by (31), we see that its space components can only be pure imaginary. If we wish to get rid of these components and retain only the zero component, we must add the standard conjugate. Thus, we may define the *Hermitian norm* by

$$N(z) = (zz^\dagger + \overline{zz^\dagger})/2. \tag{39}$$

Hence, if z is mapped into Z, then $z^\dagger$ will be mapped into $Z^\dagger$, which is obtained by the standard Hermitian conjugation of the matrix Z.

One of the main insights gained by using the matrix representation is when we calculate the Hermitian norm. If

$$z \to Z = z^\mu \Omega_\mu = \begin{pmatrix} \alpha & A \\ B & \beta \end{pmatrix}, \quad \text{then} \quad z^\dagger \to Z^\dagger = \begin{pmatrix} \overline{\alpha} & B^\dagger \\ A^\dagger & \overline{\beta} \end{pmatrix}. \tag{40}$$

The product

$$Z \heartsuit Z^\dagger = \begin{pmatrix} \alpha & A \\ B & \beta \end{pmatrix} \heartsuit \begin{pmatrix} \overline{\alpha} & B^\dagger \\ A^\dagger & \overline{\beta} \end{pmatrix} = \begin{pmatrix} \alpha\overline{\alpha} + \frac{1}{2}\mathrm{Tr}(AA^\dagger) & \alpha\beta^\dagger + \overline{\beta}A + \dfrac{i}{2}[B,A^\dagger] \\ \overline{\alpha}\beta + \beta A^\dagger - \dfrac{i}{2}[A,B^\dagger] & \beta\overline{\beta} + \frac{1}{2}\mathrm{Tr}(BB^\dagger) \end{pmatrix}. \tag{41}$$

The zero component of $zz^\dagger$ is proportional to the trace of $Z \heartsuit Z^\dagger$, so that the new *Hermitian norm* can be expressed in terms of the representation matrices Z as follows:

$$\begin{aligned} N(z) &= \tfrac{1}{4}\mathrm{Tr}(Z \heartsuit Z^\dagger) = \tfrac{1}{2}(|\alpha|^2 + |\beta|^2) + \tfrac{1}{4}(\mathrm{Tr}(AA^\dagger) + \mathrm{Tr}(BB^\dagger)) \\ &= \frac{1}{2}\left(|\alpha|^2 + |\beta|^2 + \sum_{k=1}^{3} (|a_k|^2 + |b_k|^2) \right) = \sum_{\mu=0}^{7} |z_\mu|^2, \end{aligned} \tag{42}$$

in accordance with (37). For real z_μ we get $\beta \to \overline{\alpha}$, $B \to -A^\dagger$ in (26). Therefore, $AB \to -AA^\dagger = -\mathbf{a}\cdot\boldsymbol{\sigma}\overline{\mathbf{a}}\cdot\boldsymbol{\sigma} = -\mathbf{a}\cdot\overline{\mathbf{a}}$. Thus, the formally defined scalar reduces to a conventional norm:

$$N(z) = \alpha\beta - A\cdot B = |\alpha|^2 + \mathbf{a}\cdot\overline{\mathbf{a}} \to |\alpha|^2 + \sum_{k=1}^{3} |a_k|^2 = \sum_{\mu=0}^{7} x_\mu^2 \equiv n(z) \geqslant 0. \tag{43}$$

D. Nonassociative algebras from Lie algebras

The main advantage of our matrix representation over the Zorn vector representation is that our multiplication rule can be generalized to *any number n of dimensions*, whereas the Zorn rule is restricted, since it is defined in terms of vector product $\mathbf{a}\times\mathbf{b}$, which only applies to 3-vectors!

In particular, given *any* representation of an n-dimensional Lie algebra $\mathbf{g}$ in terms of Hermitian $N\times N$ matrices $\lambda_k (k=1,2,...,n)$, we can then define $2n+2$ different $2N$-dimensional matrices,

$$e_0 \Leftrightarrow \Omega_0 \equiv \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad e_k \Leftrightarrow \Omega_k \equiv \begin{pmatrix} 0 & -\lambda_k \\ \lambda_k & 0 \end{pmatrix} \quad (k=1,...,n),$$

$$\hat{e}_0 \Leftrightarrow \Omega_{n+2} \equiv \begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix}, \quad \hat{e}_k \Leftrightarrow \hat{\Omega}_k \equiv \begin{pmatrix} 0 & i\lambda_k \\ i\lambda_k & 0 \end{pmatrix}. \tag{44}$$

If we multiply these matrices using the ♥ rule, we end up with a closed algebra, which we shall call the *double algebra* g^D, with the following product rules for their basis elements ($\hat{\Omega}_0 \equiv \Omega_{n+2}$):

$$-\hat{\Omega}_0\Omega_k = \Omega_k\hat{\Omega}_0 = \hat{\Omega}_k, \quad \hat{\Omega}_0\hat{\Omega}_k = -\hat{\Omega}_k\hat{\Omega}_0 = \Omega_k, \quad \hat{\Omega}_0\hat{\Omega}_0 = -\Omega_0,$$

$$\Omega_i\Omega_j = -\delta_{ij}\Omega_0 + f_{ijk}\Omega_k, \quad \hat{\Omega}_i\hat{\Omega}_j = -\delta_{ij}\Omega_0 - f_{ijk}\Omega_k, \tag{45}$$

$$-\hat{\Omega}_j\Omega_i = \Omega_i\hat{\Omega}_j = -\delta_{ij}\hat{\Omega}_0 - f_{ij}\hat{\Omega}_k.$$

Above, the f_{ijk} are the structure constants of the Lie algebra **g**, defined as usual by

$$[L_i, L_j] = i f_{ijk} L_k. \tag{46}$$

The matrices (44) can be regarded as the ♥- matrix representation of the following (nonassociative) abstract algebra:

$$-\hat{e}_0 e_k = e_k \hat{e}_0 = \hat{e}_k, \quad \hat{e}_0\hat{e}_k = -\hat{e}_k\hat{e}_0 = e_k, \quad \hat{e}_0\hat{e}_0 = -e_0, \quad \text{where } \hat{e}_0 \equiv e_{n+2}, \tag{47}$$

$$e_i e_j = -\delta_{ij} e_0 + f_{ijk} e_k, \tag{48}$$

$$\hat{e}_i \hat{e}_j = -\delta_{ij} e_0 - f_{ijk} e_k, \tag{49}$$

$$-\hat{e}_j e_i = e_i \hat{e}_j = -\delta_{ij}\hat{e}_0 - f_{ijk}\hat{e}_k. \tag{50}$$

These rules (47)–(50) can all be summarized by $(\mu,\nu = 0,1,2,...,2n+2)$,

$$e_\mu e_\nu = g_{\mu\nu} e_0 + \sum_{k=1}^{2n+2} \gamma^k_{\mu\nu} e_k, \quad g_{\mu\nu} := \text{diag}(1,-1,...,-1), \quad \gamma^k_{ij} = -\gamma^k_{ji}. \tag{51}$$

We note from (44) that the e_μ, $\mu = 0,1,...,n$ correspond to a *subalgebra* $\mathbf{g}_+$ of $\mathbf{g}^D$. The rules (47) show that the double algebra $\mathbf{g}^D$ is obtained from $\mathbf{g}_+$ simply by adding a new element, called $\hat{e}_0$, and defining the other $\hat{e}_k$. This Lie algebra example then automatically leads us to a more general doubling procedure, which can be applied to *any algebra* and not just to those constructed from Lie algebras. In fact, this doubling idea is exactly the procedure that is known as the *Cayley–Dickson process*, as we shall see below.

IV. DEFORMED MULTIPLICATION AND THE $\mathcal{A}^♥$ ALGEBRA

Begin with the following subset of $2N\times 2N$-matrices:

$$\mathcal{A} := \left\{ \begin{pmatrix} \alpha & A \\ B & \beta \end{pmatrix} \middle| A, B \in M_{N\times N} \right\}, \tag{52}$$

where the $N\times N$ matrices α and β in the first and fourth quadrants are proportional to unit matrices.

Among these matrices we may define a more general multiplication rule than that given in (18).[11] We shall still denote it by ♥ since it only introduces two complex *deformation parameters* λ_0 and λ (their values will be restricted as we impose further conditions on the subalgebras):

$$X \heartsuit X' \equiv \begin{pmatrix} \alpha & A \\ B & \beta \end{pmatrix} \heartsuit \begin{pmatrix} \alpha' & A' \\ B' & \beta' \end{pmatrix} := \begin{pmatrix} \alpha\alpha' + \lambda_0 A\cdot B' & \alpha A' + \beta' A - \lambda[B,B'] \\ \alpha' B + \beta B' + \lambda[A,A'] & \beta\beta' + \lambda_0 B\cdot A' \end{pmatrix}. \tag{53}$$

As before, $[A,B] \equiv AB - BA$ denotes the commutator, but $A\cdot B$ may now be chosen to be any suitable *bilinear map* into an appropriate field F. For example, one might define $A\cdot B$ by $A\cdot B \equiv \mathrm{Tr}(AB)/N$, or if A and B belong to a Lie algebra, then one could take $A\cdot B$ to be the adjoint trace: $A\cdot B := \mathrm{Tr}(\mathrm{ad}\,A\ \mathrm{ad}\,B)$, where ad denotes the adjoint representation.[12]

When $\lambda = 0$ and $\lambda_0 = 1$ the multiplication rule (53) looks *almost* like the usual one for matrices. However, it still yields nonassociativity, since we are replacing matrix products, such as AB, by $A\cdot B$ times the unit matrix. But in any case, it is evident that with the ♥ product the set $\mathcal{A}$ becomes a closed algebra, which we denote by $\mathcal{A}^\heartsuit$.[13]

A. Complex numbers from real

Before continuing, let us consider the simplest example of the above matrices, namely, the case $N=1$. In this circumstance, the matrices A and B become simple *commuting* numbers, a and b. If we specialize further, and choose $\beta = \alpha$ and $b = -a$ to be real, we end up with two-parameter matrices. Their products are

$$X \heartsuit X' \equiv \begin{pmatrix} \alpha & a \\ -a & \alpha \end{pmatrix} \heartsuit \begin{pmatrix} \alpha' & a' \\ -a' & \alpha' \end{pmatrix} := \begin{pmatrix} \alpha\alpha' - \lambda_0 a a' & \alpha a' + \alpha' a \\ \alpha' a + \alpha a' & \alpha\alpha' - \lambda_0 a a' \end{pmatrix}, \tag{54}$$

and this is nothing but the multiplication rule of two complex numbers z and z', provided that we set $\lambda_0 = 1$ and identify α and a with the real and imaginary parts of z. Thus, a *subalgebra* of $\mathcal{A}^\heartsuit$ for $N = \lambda_0 = 1$ becomes isomorphic to the complex numbers $\mathbb{C}$:

$$\mathcal{A}^\heartsuit \ni X = \begin{pmatrix} \alpha & a \\ -a & \alpha \end{pmatrix} \Leftrightarrow z \equiv \alpha + i a \in \mathbb{C}. \tag{55}$$

B. Simple and Hermitian conjugates

The attractive feature of the generalization (53) is that most results and definitions needed for octonions apply almost automatically to $\mathcal{A}^\heartsuit$. For example, for every element $X \in \mathcal{A}^\heartsuit$ we can define a conjugate element $\overline{X}$, as follows:

$$\overline{X} = \overline{\begin{pmatrix} \alpha & A \\ B & \beta \end{pmatrix}} := \begin{pmatrix} \beta & -A \\ -B & \alpha \end{pmatrix}. \tag{56}$$

By substituting $A' \to -A$, $B' \to -B$, $\alpha' \to \beta$, and $\beta' \to \alpha$ in (53), we get immediately

$$X \heartsuit \overline{X} = \begin{pmatrix} \alpha & A \\ B & \beta \end{pmatrix} \heartsuit \begin{pmatrix} \beta & -A \\ -B & \alpha \end{pmatrix} = (\alpha\beta - \lambda_0 A\cdot B) \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \equiv n(X) I_{2N\times 2N}, \tag{57}$$

where $n(X) \in \mathbb{C}$. In the meantime, we should again look upon $n(X)$ simply as a scalar function, defined by the map $\mathcal{A}^\heartsuit \to \mathbb{C}$ in (58). Later, we shall study the conditions on $\mathcal{A}^\heartsuit$ under which $n(X)$ becomes a norm.

V. SUBALGEBRAS OF $\mathcal{A}^\heartsuit$

The algebra $\mathcal{A}^\heartsuit$ has several interesting subalgebras.

(i) An obvious subalgebra is the one obtained by choosing both matrices A and B to be traceless:

$$\mathcal{A}_0^{\heartsuit} := \left\{ \begin{pmatrix} \alpha & A \\ B & \beta \end{pmatrix} \middle| \mathrm{Tr}\, A = \mathrm{Tr}\, B = 0 \right\}. \tag{58}$$

(ii) This subalgebra has, in turn, another subalgebra $\mathcal{A}_A^{\heartsuit} \subset \mathcal{A}_0^{\heartsuit}$, in which A and B become antisymmetric matrices.

(iii) A third subalgebra, which we denote by $\mathcal{A}_+^{\heartsuit}$, is obtained by choosing $\beta = \alpha$ and $B = -A$:

$$\mathcal{A}_+^{\heartsuit} := \left\{ \begin{pmatrix} \alpha & A \\ -A & \alpha \end{pmatrix} \right\}. \tag{59}$$

It is easily verified that products of such matrices stay in the same class:

$$\begin{aligned} X \heartsuit X' &= \begin{pmatrix} \alpha & A \\ -A & \alpha \end{pmatrix} \heartsuit \begin{pmatrix} \alpha' & A' \\ -A' & \alpha' \end{pmatrix} \\ &= \begin{pmatrix} \alpha\alpha' - \lambda_0 A \cdot A' & \alpha A' + \alpha' A - \lambda [A, A'] \\ -\alpha A' - \alpha' A + \lambda [A, A'] & \alpha\alpha' - \lambda_0 A \cdot A' \end{pmatrix} \in \mathcal{A}_+^{\heartsuit}. \end{aligned} \tag{60}$$

Moreover, $\mathcal{A}_+^{\heartsuit}$ has an interesting property.

Proposition 1: The subalgebra $\mathcal{A}_+^{\heartsuit}$ is flexible for all matrices A.

To put this result into perspective, we note that all Abelian or anticommutative algebras are flexible; thus, if $yx = \pm xy$, then $x(yx) = \pm (yx)x = (xy)x$, so that $(x,y,x) = 0$. Therefore, it is of interest to show that $\mathcal{A}_+^{\heartsuit}$, which is neither Abelian nor anticommutative, is also flexible.

Proof: We shall prove the above assertion by explicit multiplication. However, to simplify the calculations we first note that the multiples of unity added to each element do not affect the associators:

$$(X + \alpha 1, Y + \beta 1, Z + \gamma 1) = (X, Y, Z), \tag{61}$$

where 1 is the identity matrix. This follows immediately from the linearity of associators:

$$(X + \alpha 1, Y, Z) = (X, Y, Z) + \alpha (1, Y, Z) = (X, Y, Z). \tag{62}$$

The property (61) is helpful for calculating associators of the subalgebra $\mathcal{A}_+^{\heartsuit}$, since we can set the α's equal to zero, when calculating the associators.

We now calculate explicitly the associator (X_1, X_2, X_3) for general matrices from $\mathcal{A}_+^{\heartsuit}$, but using only those with $\alpha_i = 0$, i.e.,

$$X_i = \begin{pmatrix} 0 & A_i \\ -A_i & 0 \end{pmatrix} \in \mathcal{A}_+^{\heartsuit}, \quad \text{for } i = 1,2,3. \tag{63}$$

We get

$$(X_1, X_2, X_3) \equiv (X_1 X_2) X_3 - X_1 (X_2 X_3) = \begin{pmatrix} p & P \\ -P & p \end{pmatrix} - \begin{pmatrix} q & Q \\ -Q & q \end{pmatrix} = \begin{pmatrix} p - q & P - Q \\ Q - P & p - q \end{pmatrix}, \tag{64}$$

where

$$p = \lambda \lambda_0 ([A_1, A_2] \cdot A_3), \tag{65}$$

$$P=-\lambda_0(A_1\cdot A_2)A_3+\lambda^2[[A_1,A_2],A_3] \tag{66}$$

and

$$q=\lambda\lambda_0(A_1\cdot[A_2,A_3]), \tag{67}$$

$$Q=-\lambda_0(A_2\cdot A_3)A_1+\lambda^2[A_1,[A_2,A_3]]. \tag{68}$$

Therefore, the elements of the associator (X_1,X_2,X_3) are

$$p-q=\lambda\lambda_0([A_1,A_2]\cdot A_3-A_1\cdot[A_2,A_3])=0, \tag{69}$$

$$\begin{aligned}P-Q&=-\lambda_0((A_1\cdot A_2)A_3-(A_2\cdot A_3)A_1)+\lambda^2([[A_1,A_2],A_3]-[A_1,[A_2,A_3]])\\&=-\lambda_0((A_1\cdot A_2)A_3-(A_2\cdot A_3)A_1)+\lambda^2[A_2,[A_3,A_1]].\end{aligned} \tag{70}$$

In other words, *the associator* (X,Y,X) *vanishes identically, for any* λ, λ_0, $A_1=A_3$ and A_2,

$$(X,Y,X)=0,\quad \text{for } X,Y\in\mathcal{A}_+^{\heartsuit}. \tag{71}$$

□

(iv) As a fourth subalgebra, let $\mathbf{g}$ be a given Lie algebra of dimension n, and let $V_{\mathbf{g}}$ be the algebra spanned by the representation matrices of $\mathbf{g}$. Then, we can define a subalgebra of $\mathcal{A}^{\heartsuit}$ via

$$\mathbf{g}^D:=\left\{\begin{pmatrix}\alpha & A\\ B & \beta\end{pmatrix}\middle| A,B\in V_{\mathbf{g}}\right\}. \tag{72}$$

Clearly the off-diagonal elements, such as $\alpha A'+\beta' A+\lambda[B,B']$, of the products, $X\heartsuit X'$ belong to $V_{\mathbf{g}}$. Hence, $\mathbf{g}^D$ are subalgebras of $\mathcal{A}_0$. Moreover, half of $\mathbf{g}^D$, obtained by the intersection of $\mathbf{g}^D$ with $\mathcal{A}_+^{\heartsuit}$, will be a subalgebra of $\mathbf{g}^D$:

$$\mathbf{g}_0^D:=\left\{\begin{pmatrix}\alpha & A\\ -A & \alpha\end{pmatrix}\middle| A\in V_{\mathbf{g}}\right\}\subset\mathbf{g}^D\subset\mathcal{A}_+^{\heartsuit}. \tag{73}$$

The commutators of the elements of $\mathbf{g}_0^D$ constitute a Lie algebra, which is isomorphic to the original algebra $\mathbf{g}$.

VI. GRADING OF $\mathcal{A}^{\heartsuit}$

Proposition 2: The algebra $\mathcal{A}^{\heartsuit}$ *can be graded, as follows:*

$$\mathcal{A}^{\heartsuit}=\mathcal{A}_+^{\heartsuit}\oplus\mathcal{A}_-^{\heartsuit}=\mathcal{A}_+^{\heartsuit}\oplus K\mathcal{A}_+^{\heartsuit}=A_+^{\heartsuit}\oplus K\heartsuit\mathcal{A}_+^{\heartsuit}, \tag{74}$$

where the ''grading matrix'' is

$$K\equiv\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}. \tag{75}$$

Observe that $K\heartsuit X=KX$ for any $X\in A^{\heartsuit}$. Also, of course,

$$\mathcal{A}_{\eta}^{\heartsuit}\heartsuit\mathcal{A}_{\eta'}^{\heartsuit}\subseteq\mathcal{A}_{\eta\eta'}^{\heartsuit}. \tag{76}$$

Proof: Every matrix $X\in\mathcal{A}^{\heartsuit}$ can be decomposed, as follows:

$$X\equiv\begin{pmatrix}\alpha & A\\ B & \beta\end{pmatrix}=\begin{pmatrix}\alpha_+ & A_+\\ -A_+ & \alpha_+\end{pmatrix}+\begin{pmatrix}\alpha_- & A_-\\ A_- & -\alpha_-\end{pmatrix}\equiv X_++\hat{X}_- \tag{77}$$

$$\equiv X_+ + KX_- , \tag{78}$$

where

$$\alpha_\pm \equiv \frac{1}{2}(\alpha \pm \beta), \quad A_\mp \equiv \frac{1}{2}(A \pm B), \quad K \equiv \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}. \tag{79}$$

The first set of matrices (with $\beta = \alpha$ and $B = -A$) constitutes the subalgebra $\mathcal{A}_+^\heartsuit$, which we defined earlier in (59). The second set of matrices (with $\beta = -\alpha$ and $B = A$) will be called $\mathcal{A}_-^\heartsuit$. Since $\mathcal{A}_+^\heartsuit$ is a subalgebra of $\mathcal{A}^\heartsuit$, clearly $\mathcal{A}_+^\heartsuit \mathcal{A}_+^\heartsuit = \mathcal{A}_+^\heartsuit$. The rest of the inclusion relations (76), namely,

$$\hat{X} \heartsuit \hat{X}' \in \mathcal{A}_+^\heartsuit , \quad X \heartsuit \hat{X}' \in \mathcal{A}_-^\heartsuit , \quad \hat{X} \heartsuit X' \in \mathcal{A}_-^\heartsuit , \tag{80}$$

follow immediately from the equalities (85)–(87), which we shall prove below. □

Proposition 3: The following equalities hold for any $X, X' \in \mathcal{A}_+^\heartsuit$:

$$KXK = \overline{X}, \tag{81}$$

$$(KX) \heartsuit (KX') = X' \heartsuit \overline{X}, \tag{82}$$

$$X \heartsuit (KX') = K(\overline{X} \heartsuit X'), \tag{83}$$

$$(KX) \heartsuit X' = K(X' \heartsuit X). \tag{84}$$

Proof: The proof follows simply by explicit matrix multiplication, using (60):

$$KX \heartsuit KX' = \begin{pmatrix} \alpha & A \\ A & -\alpha \end{pmatrix} \heartsuit \begin{pmatrix} \alpha' & A' \\ A' & -\alpha' \end{pmatrix} = \begin{pmatrix} \alpha\alpha' + \lambda_0 A \cdot A' & \alpha A' - \alpha' A - \lambda[A,A'] \\ -\alpha A' + \alpha' A + \lambda[A,A'] & \alpha\alpha' + \lambda_0 A \cdot A' \end{pmatrix}$$

$$= \begin{pmatrix} \alpha' & A' \\ -A' & \alpha' \end{pmatrix} \heartsuit \begin{pmatrix} \alpha & -A \\ A & \alpha \end{pmatrix} \equiv X' \heartsuit \overline{X} \in \mathcal{A}_+^\heartsuit , \tag{85}$$

$$X \heartsuit (KX') = \begin{pmatrix} \alpha & A \\ -A & \alpha \end{pmatrix} \heartsuit \begin{pmatrix} \alpha' & A' \\ A' & -\alpha' \end{pmatrix} = \begin{pmatrix} \alpha\alpha' + \lambda_0 A \cdot A' & \alpha A' - \alpha' A + \lambda[A,A'] \\ \alpha A' - \alpha' A + \lambda[A,A'] & -\alpha\alpha' - \lambda_0 A \cdot A' \end{pmatrix}$$

$$= \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \left\{ \begin{pmatrix} \alpha & -A \\ A & \alpha \end{pmatrix} \heartsuit \begin{pmatrix} \alpha' & A' \\ -A' & \alpha' \end{pmatrix} \right\} = K(\overline{X} \heartsuit X') \equiv \widehat{\overline{X} \heartsuit X'} \in \mathcal{A}_-^\heartsuit , \tag{86}$$

$$KX \heartsuit X' = \begin{pmatrix} \alpha & A \\ A & -\alpha \end{pmatrix} \heartsuit \begin{pmatrix} \alpha' & A' \\ -A' & \alpha' \end{pmatrix} = \begin{pmatrix} \alpha\alpha' - \lambda_0 A \cdot A' & \alpha A' - \alpha' A + \lambda[A,A'] \\ \alpha A' - \alpha' A + \lambda[A,A'] & -\alpha\alpha' - \lambda_0 A \cdot A' \end{pmatrix}$$

$$= \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \left\{ \begin{pmatrix} \alpha' & A' \\ -A' & \alpha' \end{pmatrix} \heartsuit \begin{pmatrix} \alpha & A \\ -A & \alpha \end{pmatrix} \right\} = K(X' \heartsuit X) \in \mathcal{A}_-^\heartsuit . \tag{87}$$

A. Matrix representation of the Cayley–Dickson process

If we multiply the grading matrix K by a real or complex scalar v, and let $\mu \equiv v^2$, we get

$$v_{\text{op}} := vK, \quad v_{\text{op}} v_{\text{op}} := v^2 1 = \mu 1. \tag{88}$$

Therefore, using the relations (81)–(84), we get the multiplication rule

$$(X_1 + v_{\text{op}} X_2) \heartsuit (X_3 + v_{\text{op}} X_4) = (X_1 \heartsuit X_3 + \mu X_4 \heartsuit \overline{X_2}) + v_{\text{op}}(\overline{X_1} \heartsuit X_4 + X_3 \heartsuit X_2), \quad \forall X_i \in \mathcal{A}_+^{\heartsuit}. \tag{89}$$

This is exactly the multiplication rule given by Cayley and Dickson, where one starts with an abstract algebra $\mathcal{B}$ and defines an abstract operator v_{op}, and essentially *postulates* the following multiplication rule:[8]

$$(b_1 + v_{\text{op}} b_2)(b_3 + v_{\text{op}} b_4) = (b_1 b_3 + \mu b_4 \overline{b_2}) + v_{\text{op}}(\overline{b_1} b_4 + b_3 b_2), \quad b_i \in \mathcal{B}, \tag{90}$$

where $\overline{b_i} \in \mathcal{B}$ is the conjugate of b_i, and $v_{\text{op}} \notin \mathcal{B}$, such that $v_{\text{op}}^2 = \mu \cdot 1$.

Observe that the $\heartsuit$ multiplication rule provides an explicit matrix representation of the Cayley–Dickson process,[8] provided that the original algebra $\mathcal{B}$ can be represented by $\mathcal{A}_+^{\heartsuit}$.

B. Composition algebras from 2×2 matrices

One may wonder what happens if we allow the rudimentary 2×2 matrices to contain arbitrary complex elements. Since

$$X \heartsuit X' \equiv \begin{pmatrix} \alpha & a \\ b & \beta \end{pmatrix} \heartsuit \begin{pmatrix} \alpha' & a' \\ b' & \beta' \end{pmatrix} := \begin{pmatrix} \alpha\alpha' + \lambda_0 a b' & \alpha a' + \beta' a \\ \alpha' b + \beta b' & \beta b' + \lambda_0 b a' \end{pmatrix}, \tag{91}$$

when $X' = \overline{X}$ this product yields a ''norm,''

$$X * \overline{X} = n(X) \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad \text{where } n(x) = \alpha\beta - \lambda_0 ab. \tag{92}$$

It is easy to check, by explicit multiplication, that the following identity holds for any $\lambda_0 \in \mathbb{C}$:

$$\begin{aligned} n(x)n(x') &= (\alpha\beta - \lambda_0 ab)(\alpha'\beta' - \lambda_0 a'b') \\ &= (\alpha\alpha' + \lambda_0 ab')(\beta\beta' + \lambda_0 ba') - \lambda_0(\alpha a' + \beta' a)(\alpha' b + \beta b') = n(xx'), \end{aligned} \tag{93}$$

which informs us that the standard norm (92) for $N=1$ obeys the composition law.

Clearly, the norm (92) is degenerate for any $\lambda_0 \in \mathbb{C}$, if we allow X to be any 2×2 matrix. [For example, simply choosing $\beta = a = b = 1$ and $\alpha = \lambda_0$ will yield an $x \neq 0$ with $n(x) = \alpha\beta - \lambda_0 ab = 0$.] The question then arises, when is the norm $n(x)$ in (92) nondegenerate? We can certainly guarantee that $n(x)$ is nondegenerate, if we restrict X to have the following special form:

$$X = \begin{pmatrix} z & w \\ -\overline{w} & \overline{z} \end{pmatrix}, \quad \text{and} \quad \Re\lambda_0 > 0, \tag{94}$$

whence

$$n(x) = |z|^2 + \lambda_0 |w|^2 \neq 0, \quad \text{for } \Re\lambda_0 \neq 0. \tag{95}$$

[Of course, there exist a few equivalent variations of the conditions (94). For instance, we can replace $-\overline{w}$ by $\overline{w}$, but demand that $\Re\lambda_0 < 0$.]

Anyhow, this means that we are dealing with a division algebra, which must therefore be one of the four possibilities. Because $X \in M_{2\times 2}$, we may expand it in terms of Pauli matrices, getting

$$X=\begin{pmatrix} z & w \\ -\overline{w} & \overline{z} \end{pmatrix}=z_1\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}+iw_2\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}+iw_1\begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}+iz_2\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$$

$$\equiv x_0\sigma_0 - i\mathbf{x}\cdot\boldsymbol{\sigma} \leftrightarrow x_0 e_0 + \sum_{k=1}^{3} x_k e_k, \quad \text{where } w_i, z_i \in \mathbb{R}. \tag{96}$$

Since $e_0 \rightarrow \sigma_0$ and $e_j \rightarrow -i\sigma_j$ $j=1,2,3$ are known representations of the quaternions, we conclude that this is the quaternion algebra over the *real* field $\mathbb{R}$, as expected. Indeed, the matrix (96) is the usual representation of $\mathcal{Q}$ in terms of standard matrices. Later on we shall describe another representation by nonstandard matrices.

VII. CONDITIONS ON DEFORMATION PARAMETERS

Previously we showed that $\mathcal{A}_+^{\heartsuit}$ is flexible. We now ask under what conditions $\mathcal{A}_+^{\heartsuit}$ can become alternative.

For this, we must have $(X_1, X_1, X_3)=0$. By setting $X_2 = X_1$ and noting Eq. (70), we get the condition

$$[A_1,[A_3,A_1]] = \frac{\lambda^2}{\lambda_0} = ((A_1\cdot A_1)A_3 - (A_1\cdot A_3)A_1). \tag{97}$$

This condition can be satisfied if $\lambda^2 = \lambda_0/4$ and $A_i = \mathbf{a}_i\cdot\boldsymbol{\sigma}$: Indeed, for such A_i, we get

$$\begin{aligned}[A_2,[A_3,A_1]] &= [\mathbf{a}_2\cdot\boldsymbol{\sigma}, 2i[\mathbf{a}_3\times\mathbf{a}_1]\cdot\boldsymbol{\sigma}] = -4[\mathbf{a}_2\times[\mathbf{a}_3\times\mathbf{a}_1]]\cdot\boldsymbol{\sigma} \\ &= 4((\mathbf{a}_2\cdot\mathbf{a}_3)\mathbf{a}_1 - (\mathbf{a}_2\cdot\mathbf{a}_1)\mathbf{a}_3)\cdot\boldsymbol{\sigma} \\ &= 4((A_1\cdot A_2)A_3 - (A_2\cdot A_3)A_1), \end{aligned} \tag{98}$$

where we used $(A\cdot B)=\frac{1}{2}\mathrm{Tr}(AB)$. Hence, we can have $\lambda = \pm\frac{1}{2}\sqrt{\lambda_0}$. For the special choice $\lambda_0 = -1$, we get $\lambda = \pm 1/2$.

This sign ambiguity is the origin of the nonuniqueness of the ♥ product.[14]

VIII. SUMMARY

Our algebras provide concrete the matrix representation of a big class of nonassociative algebras. They may suggest new constructions in the future. One such possibility, which leads to notions of triality, is described in Appendix A, but anyhow the formulation (18) and its deformations (53) permit generalizations that have an obvious affinity to higher symmetry groups, rather than the simple case of SU(2). We also believe that our treatment of hermiticity and norm for the complex case is reasonable; we illustrate their utility with reference to the Dirac equation in Appendix B.

ACKNOWLEDGMENTS

We are extremely grateful to Dr. G. Joshi for supplying us with a comprehensive list of references in this vast topic and for pointing us in the right direction, and to Dr. B. Gardner for useful comments.

APPENDIX A: THE ◇ PRODUCT

In this appendix we try another type of product, which we denote by ◇, where the commutators $[B,B']$ in the ♥ product are now replaced by the standard matrix products BB'.

Let us first consider the simplest case, $N=1$, where the matrices A and B become scalars, so that we shall first deal with 2×2 matrices:

$$X\equiv\begin{pmatrix}\alpha & a\\ b & \beta\end{pmatrix}. \tag{A1}$$

We define the new matrix product, as follows:

$$X\diamondsuit X'\equiv\begin{pmatrix}\alpha & a\\ b & \beta\end{pmatrix}\diamondsuit\begin{pmatrix}\alpha' & a'\\ b' & \beta'\end{pmatrix}:=\begin{pmatrix}\alpha\alpha'+\lambda_0 ab & \alpha a'+\beta' a+\lambda bb'\\ \alpha' b+\beta b'+\eta\lambda aa' & \beta\beta'+\lambda_0 ba'\end{pmatrix}, \tag{A2}$$

where η, λ, λ_0 are arbitrary complex numbers. We now ask the question, whether for such a product, we can define for every X a conjugate $\overline{X}$, such that $X\diamondsuit\overline{X}=n(X)\cdot 1$, where $n(X)$ is some quadratic form of X, i.e., $n(sX)=s^2n(X)$.

Let us try the following ansatz:

$$\overline{X}\equiv\begin{pmatrix}\beta+\gamma & -a\\ -b & \alpha+\delta\end{pmatrix}. \tag{A3}$$

We want to determine γ and δ, and derive conditions on α, β, a,b, by demanding that $X\diamondsuit\overline{X}\propto 1$:

$$X\diamondsuit\overline{X}=\begin{pmatrix}\alpha & a\\ b & \beta\end{pmatrix}\diamondsuit\begin{pmatrix}\beta+\gamma & -a\\ -b & \alpha+\delta\end{pmatrix}=\begin{pmatrix}\alpha(\beta+\gamma)-\lambda_0 ab & \delta a-\lambda b^2\\ \gamma b-\eta\lambda a^2 & \beta(\alpha+\delta)-\lambda_0 ab\end{pmatrix}$$
$$=n(X)\begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix},\quad\text{where}\quad n(X)=\alpha(\beta+\gamma)-\lambda_0 ab. \tag{A4}$$

This condition is obeyed, if

$$\delta a-\lambda b^2=0,\quad \gamma b-\eta\lambda a^2=0,\quad\text{and}\quad \alpha\gamma=\beta\delta. \tag{A5}$$

We cannot satisfy these conditions for general a and b. (For example, if $a=0$ and $b\neq 0$, then δ would be infinite.) Thus, for $\eta\neq 0$ we must assume that either both a and b are zero or both are unequal to zero. But for $\eta=0$ we must demand $b=0$. With these restrictions, we get

$$\delta(X)=\lambda\frac{b^2}{a},\quad \gamma(X)=\eta\lambda\frac{a^2}{b},\quad\text{and}\quad \frac{\beta}{\alpha}=\frac{\gamma}{\delta}=\eta\frac{a^3}{b^3}. \tag{A6}$$

An additional condition can be obtained by demanding that the adjoint operation is an involution, so that $\bar{\bar{X}}=X$, whence

$$\bar{\bar{X}}=\begin{pmatrix}\alpha+\delta(X)+\gamma(\overline{X}) & a\\ b & \beta+\gamma(X)+\delta(\overline{X})\end{pmatrix}$$

$$=\begin{pmatrix}\alpha+\lambda\left(\frac{b^2}{a}-\eta\frac{a^2}{b}\right) & a\\ b & \beta+\lambda\left(\eta\frac{a^2}{b}+\frac{b^2}{-a}\right)\end{pmatrix}$$

$$=\begin{pmatrix}\alpha & a\\ b & \beta\end{pmatrix}=X. \tag{A7}$$

Thus, we get the new condition

$$b^3=\eta a^3, \quad \text{or} \quad b=\xi a, \quad \text{where} \quad \xi=\eta^{1/3}. \tag{A8}$$

Note that for each η we have three cubic roots ξ. Substituting (A8) into the third equality in (A6), we get

$$\alpha=\beta \quad \text{and} \quad \gamma=\delta. \tag{A9}$$

Hence, a can be any complex number as long as $b=\xi a$. Finally, by noting all the above conditions, we get for every $\eta\in\mathbb{C}$ three sets of 2×2 matrices, which are closed algebras under the product $\diamondsuit$:

$$X(\xi)=\left\{\begin{pmatrix}\alpha & a\\ \xi a & \alpha\end{pmatrix}\right\}, \quad \xi=\eta^{1/3}\in\mathbb{C}. \tag{A10}$$

For these matrices, the adjoint and the corresponding quadratic form are

$$\overline{X}\equiv\begin{pmatrix}\alpha+\xi^2\lambda\alpha & -a\\ -\xi a & \alpha+\xi^2\lambda a\end{pmatrix}, \tag{A11}$$

and

$$n(X)=\alpha(\beta+\gamma)-\lambda_0 ab=\alpha^2+\eta\lambda\alpha\frac{a^2}{b}-\lambda_0 ab=\alpha^2+\xi^2\lambda\alpha a-\xi\lambda_0 a^2. \tag{A12}$$

Note that $n(X)$ is quadratic in X, i.e., $N(sX)=s^2N(X)$, $s\in\mathbb{C}$.

For the special case $b=-a$, or $\xi=-1$, we obtain a known quadratic form,[11]

$$n(X)=\alpha^2+\lambda\alpha a+\lambda_0 a^2. \tag{A13}$$

Proceeding to larger matrices, let

$$X\diamondsuit X'\equiv\begin{pmatrix}\alpha & A\\ B & \beta\end{pmatrix}\diamondsuit\begin{pmatrix}\alpha' & A'\\ B' & \beta'\end{pmatrix}:=\begin{pmatrix}\alpha\alpha'+\lambda_0 A\cdot B' & \alpha A'+\beta' A+\lambda BB'\\ \alpha' B+\beta B'+\eta\lambda AA' & \beta\beta'+\lambda_0 B\cdot A'\end{pmatrix}, \quad \eta\in\mathbb{C}. \tag{A14}$$

One can readily check that such matrices yield closed algebras with respect to the above $\diamondsuit$ product. By restricting B to be ξA, we get the following subalgebra:

$$X(\xi)=\left\{\begin{pmatrix}\alpha & A\\ \xi A & \alpha\end{pmatrix}\right\}, \quad \xi=\eta^{1/3}\in\mathbb{C}. \tag{A15}$$

We can check, using (A14), that products of two such matrices yield a matrix of the same type:

$$X \diamondsuit X' \equiv \begin{pmatrix} \alpha & A \\ \xi A & \alpha \end{pmatrix} \diamondsuit \begin{pmatrix} \alpha' & A' \\ \xi A' & \alpha' \end{pmatrix} = \begin{pmatrix} \alpha\alpha' + \xi\lambda_0 A\cdot A' & \alpha A' + \alpha' A + \xi^2\lambda A A' \\ \xi(\alpha' A + \alpha A') + \eta\lambda A A' & \alpha\alpha' + \xi\lambda_0 A\cdot A' \end{pmatrix}. \tag{A16}$$

However, if we replace the *scalar a* in Eqs. (A11) and (A12) by a *matrix A*, we do not get an adjoint nor a bilinear form, since the appropriate items do not stay scalar, as they should.

Finally, we note that if we replace the simple products AA' in (A16) by anticommutators $\{A,A'\}/2$, and if we make the scalar products $A\cdot A'$ symmetric, i.e.,

$$\begin{pmatrix} \alpha & A \\ \xi A & \alpha \end{pmatrix} \diamondsuit_S \begin{pmatrix} \alpha' & A' \\ \xi A' & \alpha' \end{pmatrix} := \begin{pmatrix} \alpha\alpha' + \xi\lambda_0 A\cdot A' & \alpha A' + \alpha' A + \xi^2\lambda\{A,A'\}/2 \\ \xi(\alpha' A + \alpha A') + \eta\lambda\{A,A'\}/2 & \alpha\alpha' + \xi\lambda_0 A\cdot A' \end{pmatrix},$$

then the product becomes Abelian. Therefore the new algebra will automatically become *flexible*. One can similarly symmetrize the more general product (112) by defining, $X \diamondsuit_S X' := (X \diamondsuit X' + X' \diamondsuit X)/2$, and also get a flexible algebra.

APPENDIX B: APPLICATION TO THE DIRAC EQUATION

In momentum space, the free Dirac equation reads as

$$P\Psi \equiv (p_0 - \mathbf{p}\cdot\boldsymbol{\alpha} - m\beta)\Psi = \begin{pmatrix} p_0 - m & -\mathbf{p}\cdot\boldsymbol{\sigma} \\ -\mathbf{p}\cdot\boldsymbol{\sigma} & p_0 + m \end{pmatrix}\Psi = 0, \tag{B1}$$

and it can be rewritten in terms of octonions as follows:

$$p\psi \equiv (p_0 + i\mathbf{p}\cdot\hat{\mathbf{e}} + ime_4)\psi = 0, \tag{B2}$$

where we have used the correspondence

$$\alpha_k = \begin{pmatrix} 0 & \sigma_k \\ \sigma_k & 0 \end{pmatrix} = -i\hat{\Omega}_k \Leftrightarrow -i\hat{e}_k, \quad \beta = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} = -i\Omega_4 \Leftrightarrow -ie_4. \tag{B3}$$

Notice that we cannot write the Dirac equation in terms of quaternions alone, since we require five different basis elements: $(e_0, e_4, \hat{e}_k;\ k=1,2,3)$ or $(e_0, e_4, e_k;\ k=1,2,3)$.

The octonion p is nicely Hermitian $(p = p^\dagger)$ and has zero norm:

$$p\overline{p} = n(p) = p_0^2 - \mathbf{p}^2 - m^2 = 0. \tag{B4}$$

Therefore the solution ψ of the *Dirac octonionic equation* (B2) is elegantly given by the standard conjugate of p, namely,

$$\psi = \overline{p} \equiv p_0 - i\mathbf{p}\cdot\hat{\mathbf{e}} - ime_4 \Leftrightarrow \Psi = \overline{P} = \begin{pmatrix} p_0 + m & \mathbf{p}\cdot\boldsymbol{\sigma} \\ \mathbf{p}\cdot\boldsymbol{\sigma} & p_0 - m \end{pmatrix}. \tag{B5}$$

The first and second columns of Ψ are proportional to the positive energy solutions $u^1(p)$ and $u^2(p)$, while the third and fourth columns yield the negative energy solutions $v^1(p)$ and $v^2(p)$, if we replace m by $-m$, because

$$(p_0 - \mathbf{p}\cdot\boldsymbol{\alpha} - m\beta)u^i(p) = 0, \quad (p_0 - \mathbf{p}\cdot\boldsymbol{\alpha} + m\beta)v^i(p) = 0 \quad (i=1,2). \tag{B6}$$

Therefore the *physical* and *normalizable* solutions can be expressed as

$$\Psi_p \equiv (u^1|u^2|v^1|v^2) = \frac{1}{\sqrt{2m(p_0+m)}}\begin{pmatrix} p_0+m & \mathbf{p}\cdot\boldsymbol{\sigma} \\ \mathbf{p}\cdot\boldsymbol{\sigma} & p_0+m \end{pmatrix} \Leftrightarrow \frac{p_0+m-i\mathbf{p}\cdot\hat{\mathbf{e}}}{\sqrt{2m(p_0+m)}}, \tag{B7}$$

ensuring that

$$\overline{u}^{\dagger}(p)u^j(p) \equiv u^{i\dagger}(p)\beta u^j(p) = \delta_{ij} \quad \text{and} \quad \overline{v}^{\dagger}(p)v^j(p) \equiv v^{i\dagger}(p)\beta v^j(p) = -\delta_{ij} \quad (i,j=1,2). \tag{B8}$$

[9] The complete antisymmetry of ϵ_{ijkl} in its first three indices is an immediate consequence of the fact that $\mathcal{O}$ is an alternative algebra, such algebras being defined by the two ''*alternative conditions*.'' $x^2y = x(xy)$, and $(yx)x = yx^2$, $\forall x,y \in \mathcal{A}$. These conditions can be expressed in terms of associators as $(x,x,y) = (y,x,x) = 0$, $\forall x,y \in \mathcal{A}$. They enable one to prove that the associator (x,y,z) of an alternative algebra is totally antisymmetric in its three arguments. The proof is based on the ''*linearization technique*,'' which consists of replacing one or more of the arguments, say x, by $x + \lambda w$. By these means we get $(x+\lambda w, x+\lambda w, y) = (x,x,y) + \lambda^2(w,w,y) + \lambda(w,x,y) + \lambda(x,w,y) = \lambda((w,x,y) + (x,w,y)) = 0$, so that $(w,x,y) = -(x,w,y)$. One can similarly prove the antisymmetry among the other arguments. In particular, the total antisymmetry yields $(x,y,x) = 0$, or $(z,y,x) + (x,y,z) = 0$, where the second equality follows the first, again by linearization. Algebras that obey these last conditions are called *flexible*. These conditions are much less restrictive than the alternative conditions. In fact, most of the interesting nonassociative algebras are flexible. For example, both the Lie and Jordan algebras are flexible, the *Jordan algebras* $\mathcal{T}$ being defined by the (Jordan) identities: $(x^2,y,x) = (x,y,x^2) = 0$, $\forall x,y \in \mathcal{T}$. See N. Jacobson, *Structure and Representations of Jordan Algebras*, (American Mathematical Society, 1968). We shall find another class of flexible algebras below.

[11] K. A. Zhevlakov, A. M. Slin'ko, I. P. Shestakov, and A. I. Shirshov, *Rings That Are Nearly Associative* (Academic, New York, 1982).

[12] Note, that although $X_i \cdot X_j = -2\delta_{ij}$ $(i,j=1,2,3)$ for $X_i \in so(3)$, the diagonal elements of $X_i \cdot X_j$ can have different signs, as in $so(2,1)$, where $(X_i \cdot X_j) = \text{diag}(-2,-2,2)$.

[13] Actually we can generalize $\mathcal{A}^{\heartsuit}$ further, by replacing the product of the complex numbers $\alpha\beta$ with a bilinear product $\alpha\beta \leftrightarrow \alpha\cdot\beta = \alpha_+^2 + \lambda_1\alpha_-^2$, where $\alpha_\pm = (\alpha \pm \beta)/\sqrt{2}$. We have refrained from doing so in the text.

[14] Thus, if we reverse the sign in front of the σ in (17), we only need to change the sign of the commutators in (18) to fix the multiplication rule.

On Lie algebras all nilpotent subalgebras of which are Abelian

(Received 2 February 1998; accepted for publication 8 June 1998)

By Kirillov's theorem, every non-Abelian nilpotent Lie algebra contains the three-dimensional Heisenberg algebra $H(3)$ as a subalgebra. [R. Schimming, Arch. Math. **24**, 65–74 (1988)]. Here we are interested in a sufficient condition for a non-nilpotent Lie algebra to contain a subalgebra isomorphic to $H(3)$. Explicitly, we show: Every indecomposable non-nilpotent Lie algebra L of dimension dim $L \geqslant 3$ with a nonvanishing center $Z(L) \neq \{0\}$ contains a non-Abelian nilpotent subalgebra and hence a copy of $H(3)$. *© 1999 American Institute of Physics.* [S0022-2488(98)02410-4]

I. MOTIVATION BY THE YANG–MILLS EQUATIONS

The given problem stems from the study of constant Yang–Mills potentials. These give examples of Huygens's-type differential equations with constant coefficients and examples of harmonic differential operators.[1]

The Yang–Mills equations on a Riemannian manifold (E,g) for a potential $A = A_\alpha dx^\alpha$ with values in some Lie algebra L are given by

$$D_\alpha F^{\alpha\beta} \equiv \partial_\alpha F^{\alpha\beta} + [A_\alpha, F^{\alpha\beta}] = 0,$$

where $[\cdot,\cdot]$ denotes the commutator in L, $F_{\alpha\beta} = \partial_\alpha A_\beta - \partial_\beta A_\alpha + [A_\alpha, A_\beta]$ are the field strength components, $\partial_\alpha = \partial/\partial x^\alpha$ the partial derivatives with respect to local coordinates x^α of $x \in E$, $g = g_{\alpha\beta} dx^\alpha dx^\beta$ denotes a Riemannian metric, and D_α is the corresponding covariant derivative. If the Yang–Mills potential A has constant components A_α then the Yang–Mills equations $D_\alpha F^{\alpha\beta} = 0$ collapse to the algebraic equations

$$[A_\alpha, F^{\alpha\beta}] = [A_\alpha, [A^\alpha, A^\beta]] = 0.$$

A general solution of the Yang–Mills equations is not available. It depends on the structure of the Lie algebra L and the signature of the metric g whether or not there exists a nontrivial solution of these equations (i.e., potentials A with $F_{\alpha\beta} \equiv [A_\alpha, A_\beta] \neq 0$ and $D_\alpha F^{\alpha\beta} = 0$). One should consider the structure of Lie algebras in detail. For special types of Lie algebras, like Abelian, nilpotent, compact, and for all Lie algebras of dim $L \leqslant 5$ we can decide whether or not there exists a nontrivial solution for the constant Yang–Mills equations.[2–4] The following holds true:

(1) If a subalgebra M of a Lie algebra L admits a nontrivial solution of the Yang–Mills equations then so does L.
(2) Every Yang–Mills potential A with values in a two-step nilpotent Lie algebra L is a constant Yang–Mills potential.

Example: The Heisenberg algebra $H = H(2m+1)$ has as the only nonvanishing structure relations $[X_j, Y_j] = Z$ for $j = 1,...,m$ with respect to a base $\{X_1, \ldots, X_m, Y_1, \ldots, Y_m, Z\}$. Hence it is two-step nilpotent, i.e.,

$$[H,[H,H]] = 0,$$

and so every element of $H(2m+1)$ is a constant Yang–Mills potential.

Corollary: Every non-Abelian nilpotent Lie algebra L admits a nontrivial solution of the Yang–Mills equations.

It would be desirable to know if a given non-nilpotent Lie algebras contains a (non-Abelian) nilpotent subalgebra, because then it is easy to find out whether or not there exists a nontrivial solution of the constant Yang–Mills equations. The work on low-dimensional Lie algebras[5,6] leads to the conjecture that an indecomposable Lie algebra with a nonvanishing center contains a non-Abelian nilpotent subalgebra. This conjecture will be the subject of the present paper.

II. PRELIMINARIES ON THE STRUCTURE OF LIE ALGEBRAS

In this section we give a brief survey of the most important definitions and theorems which we need in the following. We refer the reader to the literature for the proofs of the lemmas and theorems.

We denote the direct sum of vector spaces by $\dot{+}$, the direct sum of Lie algebras by $\oplus$, and the semidirect sum of Lie algebras by $\niplus$.

Definition: A Lie algebra L is called *decomposable* if we can decompose it into the direct sum of two ideals. Otherwise L is called *indecomposable*.

Now we define solvable and nilpotent Lie algebras.

Definition: Let L be a Lie algebra. Let $L^{(0)}:=L$ and $L^{(n+1)}:=[L^{(n)},L^{(n)}]$ with $n\in\mathbb{N}$. Then $(L^{(n)})_{n\in\mathbb{N}}$ is called the *derived series* of L. The Lie algebra L is called *solvable* if there exists a $k\in\mathbb{N}$ such that $L^{(k)}=\{0\}$. Let $L^0:=L$ and $L^{n+1}:=[L,L^n]$ with $n\in\mathbb{N}$. Then $(L^n)_{n\in\mathbb{N}}$ is called the *lower central series* of L. The Lie algebra L is called *nilpotent* if there exists a $k\in\mathbb{N}$ such that $L^k=\{0\}$.

Remark: There holds $L^{(1)}=L^1=:L'$. L' is called the *commutator algebra of L*.

Lemma 2: Nilpotent and solvable Lie algebras satisfy the following:

(i) Let $L\neq\{0\}$ be a nilpotent Lie algebra. Then $Z(L)\neq\{0\}$ (Ref. 7, p. 111).
(ii) A Lie algebra L is solvable if and only if $[L,L]$ is nilpotent (Ref. 7, p. 117).
(iii) There exists a maximal solvable ideal in L, the so-called *radical* $R=R_L$. Similarly there exists a maximal nilpotent ideal in L, the so-called *nilradical* $N=N_L$ (Ref. 7, pp. 114, 175).

Lemma 3: The center $Z(L)=\{X\in L|(\forall Y\in L)[X,Y]=0\}$, the nilradical N_L and the radical R_L are *characteristic ideals* of a Lie algebra L, i.e., they are invariant under all derivations of L (Ref. 8, pp. 155, 210).

Beyond this we need the following.

Lemma 4: A characteristic ideal in an ideal of L is an ideal of L as well (Ref. 8, p. 155). Nilpotent and solvable Lie algebras contain—in contrast to semisimple or simple Lie algebras—many ideals.

Definition: A Lie algebra L is called *semisimple* if the radical is trivial, $R_L=\{0\}$, and it is called *simple* if it is not Abelian and contains no ideals except L and $\{0\}$.

Obviously, every simple Lie algebra is semisimple as well. One can show that every semisimple Lie algebra is the direct sum of simple ideals (Ref. 7, p. 126). Furthermore, we need the following.

Lemma 5: Let $L\neq\{0\}$ be a semisimple Lie algebra. Then there holds:

(i) $[L,L]=L$ (Ref. 7, p. 127).
(ii) $Z(L)=\{0\}$ (Ref. 8, p. 201).

All (finite-dimensional) Lie algebras are composed from semisimple and solvable Lie algebras.

Levi's theorem: Every Lie algebra L is isomorphic to a semidirect sum of its radical R with a semisimple subalgebra S, i.e., $L\cong R\niplus S$ (Ref. 7, p. 146).

Thus, Lie algebras can be classified by means of classification of the following objects:

(1) solvable Lie algebras R,
(2) semisimple Lie algebras S (or rather simple Lie algebras, since every semisimple Lie algebra can be decomposed into the direct sum of simple ideals),

(3) semidirect sums of solvable Lie algebras with a semisimple one.

Simple Lie algebras are completely classified nowadays. The solution of the other two problems is still lacking.[5,6,9]

One important result in the theory of representations of Lie algebras is the following.

Weyl's theorem: A finite-dimensional representation $\phi: S \rightarrow gl(V)$ of a semisimple Lie algebra S on a finite-dimensional vector space V is completely reducible (Ref. 10, p. 28).

Corollary: Let S be a semisimple Lie algebra, V a finite-dimensional S-module. The vector spaces

$$V_0 := \{ v \in V | S.v = 0 \}, \quad V_{\text{eff}} := \text{span } S \cdot V$$

are S-invariant subspaces and $V = V_0 \dot{+} V_{\text{eff}}$.

Proof: The action of S on V, $S \times V \rightarrow V$, $(X,v) \mapsto X \cdot v =: \phi(X)(v)$, defines a representation ϕ of S in V. By the Weyl's theorem this representation is completely reducible, i.e., every submodule has a complement. Obviously, V_0 and V_{eff} are S-submodules of V. We show that V is the direct sum $V = V_0 \dot{+} V_{\text{eff}}$: Choose a subspace $V_1 \subseteq V_{\text{eff}}$ such that $V_{\text{eff}} = (V_0 \cap V_{\text{eff}}) \dot{+} V_1$. Then $S \cdot V = S \cdot V_{\text{eff}} = S \cdot V_1 \subseteq V_1$, hence $V_{\text{eff}} \subseteq V_1$ and therefore $V_0 \cap V_{\text{eff}} = \{0\}$. On the other side $V = V_0 + V_{\text{eff}}$: Choose a submodule $W \subseteq V$ such that $V = (V_0 + V_{\text{eff}}) \dot{+} W$. Then $S \cdot W \subseteq W \cap V_{\text{eff}} = \{0\}$. Therefore $W \subseteq V_0$, hence $W = \{0\}$. □

We will also need the following:

Lemma 6: Let H be a nilpotent subalgebra of L and let $M \subseteq L$ be an $(\text{ad } H)$-invariant subspace. Then

$$M_0 := \{ Y \in M | (\forall X \in H) \exists n \in \mathbb{N}: \ (\text{ad } X)^n Y = 0 \}$$

is an $(\text{ad } H)$-invariant subspace of M with a complement in M, i.e., there exists an $(\text{ad } H)$-invariant subspace $M_1 \subseteq M$ such that $M = M_0 \dot{+} M_1$.

Proof: We use the weight-decomposition of a (real) Lie algebra with respect to a nilpotent subalgebra. For details see Ref. 11, Chap. VII and Ref. 13, Chap. I.10. First we consider the complexification $M^{\mathbb{C}} = M \otimes_{\mathbb{R}} \mathbb{C}$ of M and its generalized weight-decomposition with respect to $H^{\mathbb{C}} = H \otimes_{\mathbb{R}} \mathbb{C}$:

$$M^{\mathbb{C}} = \sum_{\lambda \in \Lambda} M_{\lambda}^{\mathbb{C}},$$

where

$$M_{\lambda}^{\mathbb{C}} = \{ X \in M^{\mathbb{C}} | (\forall Y \in H^{\mathbb{C}}) \exists n \in \mathbb{N}: \quad (\text{ad } Y - \lambda(Y) \text{Id}_{M^{\mathbb{C}}})^n X = 0 \},$$

and Λ is the set of complex weights with respect to $H^{\mathbb{C}}$. More precisely there holds:

$$M^{\mathbb{C}} = M_0^{\mathbb{C}}(H^{\mathbb{C}}) \dot{+} \sum_{j=1}^{m} M_{\lambda_j}^{\mathbb{C}}(H^{\mathbb{C}}), \quad \lambda_j \neq 0 \quad \text{for } 1 \leq j \leq m.$$

We also know that

$$M_0(H) \otimes_{\mathbb{R}} \mathbb{C} \cong M_0^{\mathbb{C}}(H) \cong M_0^{\mathbb{C}}(H^{\mathbb{C}}).$$

We define the conjugation c on the complexification $L^{\mathbb{C}} = L \otimes_{\mathbb{R}} \mathbb{C}$ of the Lie algebra L by $c(X + iY) = X - iY$ with $X, Y \in L$. Further, we use the following.

Lemma:

(i) If $\lambda \in \Lambda$ is a weight then so is $\overline{\lambda} \circ c$. Moreover, $c(L_{\lambda}^{\mathbb{C}}) = L_{\overline{\lambda} \circ c}^{\mathbb{C}}$.

(ii) $L_{\lambda}^{\mathbb{C}} \dot{+} L_{\overline{\lambda} \circ c}^{\mathbb{C}}$ is c-invariant.

(iii) Let $X \in L_\lambda^{\mathbb{C}}$, then the real and imaginary parts of X are in $L \cap (L_\lambda^{\mathbb{C}} \dot{+} L_{\overline{\lambda \circ c}}^{\mathbb{C}})$.

With λ also $\overline{\lambda \circ c}$ is in Λ and the two root spaces are conjugated to each other in the real case. We define the class $[\lambda] := \{\lambda, \overline{\lambda \circ c}\}$ and the corresponding real root spaces of M by $M_{[\lambda]} := M \cap (M_\lambda^{\mathbb{C}} \dot{+} M_{\overline{\lambda \circ c}}^{\mathbb{C}})$.

Hence in the real case we have the following generalized weight-decomposition:

$$M = M_0 \dot{+} \sum_{j=1}^{m} M_{[\lambda_j]} =: M_0 \dot{+} M_1, \quad \lambda_j \neq 0 \quad \text{for } 1 \leqslant j \leqslant m. \qquad \square$$

III. THE RESULT ON LIE ALGEBRAS WITH ONLY ABELIAN NILPOTENT SUBALGEBRAS

In this section we prove our main result:

Theorem: An indecomposable non-nilpotent Lie algebra L of dimension $\dim L \geqslant 3$ with a nontrivial center $Z(L) \neq \{0\}$ contains a non-Abelian nilpotent subalgebra.

The following is logically equivalent:

Theorem: A non-nilpotent Lie algebra L of dimension $\dim L \geqslant 3$ with a nontrivial center $Z(L) \neq \{0\}$ all of whose nilpotent subalgebras are Abelian is decomposable. Moreover, $Z(L)$ is a direct summand of L, i.e., there exists an ideal I in L with $L = Z(L) \oplus I$.

Proof: By Levi's theorem the following cases have to be considered:

(1) L is non-nilpotent and solvable.
(2) L is isomorphical to a semidirect sum of its radical $R \neq \{0\}$ and a semisimple subalgebra $S \neq \{0\}$, i.e., $L \cong R \oplus\!\!\!\!\supset S$.

Notice that the case of a semisimple Lie algebra L is canceled, because then the assumption $Z(L) \neq \{0\}$ is not satisfied.

Case 1: Let L be a non-nilpotent solvable Lie algebra and denote the nilradical of L by N. Generally, $[R,L] \subseteq N$ (Ref. 7, p. 175). In particular, for solvable L we have $L' \subseteq N$. Let us consider the factor algebra L/N. For X, $Y \in L$ there holds

$$[X+N, Y+N] = [X,Y] + N \subseteq L' + N \subseteq N + N = N,$$

i.e., the quotient L/N is Abelian. Next we consider the canonical projection $\pi: L \rightarrow L/N$. Let H be a Cartan subalgebra of L. The image of a Cartan subalgebra under a subjective Lie algebra homomorphism is a Cartan subalgebra and a nilpotent Lie algebra is its only Cartan subalgebra (Ref. 7, p. 131). Since L/N is an Abelian Lie algebra it is the only Cartan subalgebra in L/N and therefore $\pi(H) = L/N$. Thus $L = N + H$, on the one hand. On the other hand we have $L \cong N \dot{+} L/N$. So we find in H a subalgebra $\overline{H}$ that is isomorphic to $\pi(H)$, because by assumption H is Abelian. Hence we get a direct sum of vector spaces $L = N \dot{+} \overline{H}$. In particular, $[N, \overline{H}] \subseteq N$ and N is an ideal in L. Therefore $L = N \oplus\!\!\!\!\supset \overline{H}$ is a semidirect sum of Lie subalgebras of L.

Let us apply Lemma 6 to the case $M = N$. The vector space

$$N_0 = \{Y \in N \,|\, (\forall X \in \overline{H}) \exists n \in \mathbb{N} : (\text{ad } X)^n Y = 0\}$$

is an $(\text{ad } \overline{H})$-invariant subspace with a complement N_1 in N: $N = N_0 \dot{+} N_1$, where N_1 is $(\text{ad } \overline{H})$-invariant as well. We show: $L_1 := N_0 \oplus\!\!\!\!\supset \overline{H}$ is nilpotent, i.e., there exists an $n \in \mathbb{N}$ with $L_1^n = \{0\}$. Namely, $L_1^1 = [L_1, L_1] = [\overline{H}, N_0]$, because $\overline{H}$ and N_0 are Abelian. Further, $L_1^1 = [\overline{H}, N_0] \subseteq N_0$ because N_0 is invariant under the action of ad $\overline{H}$. Induction with respect to n gives $L_1^n = [L_1, L_1^{n-1}] = [\overline{H}, L_1^{n-1}] = (\text{ad } \overline{H})^n N_0$, since $L_1^{n-1} \subseteq N_0$ for $n > 1$. By definition of N_0 we know that for every $Y \in N_0$ there exists an $n \in \mathbb{N}$ such that $(\text{ad } \underline{X})^n Y = 0$ for all $X \in \overline{H}$. Thus $N_0 \oplus\!\!\!\!\supset \overline{H}$ is nilpotent, and so by assumption Abelian. Therefore, $[N_0, \overline{H}] = \{0\}$. Next we show: $N_0 = Z(L)$. By definition of N_0 we obtain the inclusion $Z(L) \subseteq N_0$. The other inclusion $N_0 \subseteq Z(L)$ is proved as follows:

$$[N_0,L]=[N_0,N\oplus\overline{H}]=[N_0,N]+[N_0,\overline{H}]=0,$$

since $[N_0,\overline{H}]=\{0\}$ and N, and therefore also N_0, is Abelian by assumption. Hence $N_0\subseteq Z(L)$.

Our next goal is to show: $N_1=L'$. On the one hand,

$$L'=[L,L]=[N\oplus\overline{H},N\oplus\overline{H}]=[N,N]+[\overline{H},\overline{H}]+[\overline{H},N]=[\overline{H},N],$$

$$[\overline{H},N]=[\overline{H},N_0\dotplus N_1]=[\overline{H},N_0]+[\overline{H},N_1]\subseteq N_1,$$

because $N_0\oplus\overline{H}$ is Abelian and N_1 is invariant under the action of $(\mathrm{ad}\ \overline{H})$. One the other hand, let us apply the construction of N_1 by the proof of Lemma 6. Namely,

$$N_\alpha^{\mathbb{C}}:=\{Y\in N^{\mathbb{C}}|(\forall X\in\overline{H}^{\mathbb{C}})\exists n\in\mathbb{N}:(\mathrm{ad}\ X-\alpha(X))^nY=0\}$$

with a complex weight $0\neq\alpha\in(\overline{H}^{\mathbb{C}})^*$. Then for a $Y\in N_\alpha^{\mathbb{C}}$ there exists a $X\in\overline{H}^{\mathbb{C}}$ with $\alpha(X)\neq 0$ and an $n\in\mathbb{N}$ with

$$0=(\alpha(X)-\mathrm{ad}\ X)^nY=\sum_{k=0}^{n}\binom{n}{k}\alpha(X)^{n-k}(-\mathrm{ad}\ X)^kY=\alpha(X)^nY$$

$$-\sum_{k=1}^{n}\binom{n}{k}\alpha(X)^{n-k}(-\mathrm{ad}\ X)^{k-1}[X,Y].$$

From this it follows

$$Y=\alpha(X)^{-n}\sum_{k=1}^{n}\binom{n}{k}\alpha(X)^{n-k}(-\mathrm{ad}\ X)^{k-1}[X,Y].$$

Therefore $N_\alpha^{\mathbb{C}}\subseteq L'^{\mathbb{C}}$ and hence

$$N_1^{\mathbb{C}}:=\sum_{0\neq\alpha\in(\overline{H}^{\mathbb{C}})^*}N_\alpha^{\mathbb{C}}\subseteq L'^{\mathbb{C}}\quad\text{and so}\quad N_1\subseteq L'.$$

Finally, we get the decomposition $N=Z(L)\oplus L'$ with $N_0=Z(L)$ and $N_1=L'$ as well as

$$L=N\oplus\overline{H}=(N_0\oplus N_1)\oplus\overline{H}=N_0\oplus(N_1\oplus\overline{H})=Z(L)\oplus(L'\oplus\overline{H}).$$

(Note: $[N_0,N_1\oplus\overline{H}]=0$ and $N_1\oplus\overline{H}$ is a subalgebra of L.) Therefore, here $Z(L)\neq\{0\}$ is direct summand in L.

Case 2: We consider the Levi decomposition $L=R\oplus S$ with a radical $R=R_L\neq\{0\}$ and a semisimple subalgebra $S\neq\{0\}$. There holds $[R,L]\subseteq R$ and $[S,S]=S$.

From case 1 we know $R=N_R\oplus\overline{H}_R$ with $N_R=Z(R)\oplus R'$, and therefore $R=(Z(R)\oplus R')\oplus\overline{H}_R$. In particular, $Z(R)\cap R'=\{0\}$. Thus,

$$\begin{aligned}L'=[L,L]=[R\oplus S,R\oplus S]=[R,R]+[S,S]+[S,R]\\ &=R'+S+[S,R]=R'+S+[S,N_R\oplus\overline{H}_R]=R'+S+[S,N_R]+[S,\overline{H}_R]\\ &=R'+S+[S,Z(R)\oplus R']+[S,\overline{H}_R]\\ &=R'+S+[S,Z(R)]+[S,R']+[S,\overline{H}_R].\end{aligned}$$

From the Jacobi identity it follows $[S,R']=[S,[R,R]]\subseteq[[S,R],R]\subseteq[R,R]=R'$. Therefore

$$L'=R'+S+[S,Z(R)]+[S,\overline{H}_R].$$

We can take R as an S-module with respect to the action of ad, because $[S,R]\subseteq[L,R]\subseteq R$. It follows that $[S,N_R]\subseteq N_R$, since N_R is a characteristic ideal in R, i.e., N_R is a S-submodule of R. By Weyl's theorem it follows that N_R has a S-module complement. As we know from case 1, we can assume that $\overline{H}_R$ is this module complement. Therefore, we obtain

$$R=N_R\dot{+}\overline{H}_R,\quad [S,\overline{H}_R]\subseteq\overline{H}_R.$$

There holds $[S,Z(R)]\subseteq Z(R)$ because $Z(R)$ is a characteristic ideal in R. By Weyl's theorem we conclude that $Z(R)=V_0\dot{+}V_{\text{eff}}$ with

$$\begin{aligned}V_0&=\{X\in Z(R)\,|\,(\text{ad } S)\cdot X=0\}\\&=\{X\in Z(R)\,|\,(\forall U\in S)[X,U]=0\}\\&=\{X\in R\,|\,(\forall V\in R)[X,V]=0\wedge(\forall U\in S)[S,U]=0\}\\&=\{X\in L\,|\,(\forall Y\in L)[X,Y]=0\}=Z(L)\end{aligned}$$

and

$$V_{\text{eff}}=\text{span}(\text{ad } S).Z(R)=[S,Z(R)],$$

i.e., $Z(R)=Z(L)\dot{+}[S,Z(R)]$ and, in particular, $Z(L)\cap[S,Z(R)]=\{0\}$. Since $Z(R)\cap R'=\{0\}$, $[S,Z(R)]\subseteq Z(R)$ and $[S,\overline{H}_R]\subseteq\overline{H}_R$, we obtain

$$L'=R'\dot{+}S\dot{+}[S,Z(R)]\dot{+}[S,\overline{H}_R],$$

i.e., the sum is direct. With $Z(R)=Z(L)+[S,Z(R)]$ then we conclude $L'\cap Z(L)=\{0\}$. So, we obtain L as the direct sum of vector spaces:

$$L=R\dot{+}S=Z(L)\dot{+}[S,Z(R)]\dot{+}R'\dot{+}\overline{H}_R\dot{+}S=Z(L)\dot{+}I.$$

If $L'\subseteq I$ with $L=Z(L)\dot{+}I$ then I is an ideal in L: $[I,L]\subseteq L'\subseteq I$, and hence $L=Z(L)\oplus I$ is a direct sum of ideals in L.

Actually, we have shown the assertion that $Z(L)$ is a direct summand in L, if every nilpotent subalgebra of L is abelian. The theorem is proven. □

ACKNOWLEDGMENTS

I am greatly indebted to Herrn Professor K.-H. Neeb from the University of Erlangen for many valuable comments. Also I want to thank my mentor Professor R. Schimming from the University of Greifswald for drawing my attention to the problem on constant Yang–Mills potentials and for helpful discussions.

Hopf algebra extension of a Zamolochikov algebra and its double

Jintai Ding
Department of Mathematical Sciences, University of Cincinnati, Cincinnati, Ohio 45221

(Received 20 April 1998; accepted for publication 29 January 1999)

The particles with a scattering matrix $R(x)$ are defined as operators $\Phi_i(z)$ satisfying the relation $\Sigma_{i',j'} R_{i,j}^{j',i'}(x_1/x_2)\Phi_{i'}(x_1)\Phi_{j'}(x_2)=\Phi_i(x_2)\Phi_j(x_1)$. The algebra generated by those operators is called a Zamolochikov algebra. We construct a new Hopf algebra by adding half of the Faddeev–Reshetikhin–Takhtajan–Semenov-Tian-Shansky (FRTS) construction of a quantum affine algebra with this $R(x)$. Then we double it to obtain a new Hopf algebra such that the full FRTS construction of a quantum affine algebra is a Hopf subalgebra inside. Drinfeld realization of quantum affine algebras is included as an example. © *1999 American Institute of Physics.* [S0022-2488(99)04107-9]

I. INTRODUCTION

In physics, the particles with a scattering matrix $R(x)$ in $\mathrm{End}(V)\otimes\mathrm{End}(V)$ are defined with the operators $\Phi_i(x)$ index by a linear independent basis of V such that

$$\sum_{i',j'} R_{i,j}^{j',i'}(x_1/x_2)\Phi_{i'}(x_1)\Phi_{j'}(x_2)=\Phi_i(x_2)\Phi_j(x_1),$$

where V is a vector space and x is a parameter in $\mathbb{C}$. This naturally gives an algebra with these current generators $\Phi_i(x)$, which we will call a Zamolochikov algebra. However this algebra is not given a Hopf algebra structure. We construct a Hopf algebra on this algebra by adding structures coming from the structures of the affine quantum groups.

The definition of quantum groups discovered by Drinfeld and Jimbo is presented as a deformation of the simple Lie algebra by the basic generators and the relations based on the data coming from the corresponding Cartan matrix. The extension of the realization of the affine Kac–Moody algebra $\hat{\mathfrak{g}}$ associated to a simple Lie algebra $\mathfrak{g}$ as a central extension of the corresponding loop algebra $\mathfrak{g}\otimes\mathbb{C}[t,t^{-1}]$ has two different approaches. The first approach was given by Faddeev, Reshetikhin, and Takhtajan,[1] who obtained a realization of the quantum loop algebra $U_q(\mathfrak{g}\otimes\mathbb{C}[t,t^{-1}])$ via a canonical solution of the Yang–Baxter equation depending on a parameter $z\in\mathbb{C}$. This approach was completed by Reshetikhin and Semenov-Tian-Shansky[2] by incorporating the central extension in the previous realization. We call this approach FRTS construction. The second approach was given by Drinfeld, who[3] gave a realization of the quantum affine algebra $U_q(\mathfrak{g})$ and its special degeneration called the Yangian. As an algebra, this realization is equivalent to the FRTS construction[4] through certain Gauss decomposition for the case of $U_q(\widehat{\mathfrak{gl}}(n))$. Although we cannot extend the conventional comultiplication to the current operators of Drinfeld to derive a closed comultiplication formula, Drinfeld also gave the Hopf algebra structure for such a formulation,[4] which[5,6] we used to study vertex operators and zeros and poles of the quantum current operators. In the Drinfeld realization of quantum affine algebras, the structure constants are certain rational functions $g_{ij}(z)$. In Ref. 6, we generalize this type of Hopf algebras by substituting $g_{ij}(z)$ by other functions that satisfy the functional property of $g_{ij}(z)$.

In this paper, we will use the idea of FRTS construction to define a Hopf algebra generated by a current operator valued matrix on $V,L(x)$, such that

$$R(x_1/x_2)L_1(x_1)L_2(x_2)=L_2(x_2)L_1(x_1)R(x_1/x_2),$$

where $L_1(x)=L(x)\otimes 1$ and $L_2(x)=1\otimes L(x)$; and the commutation relation between the particles and this new operator matrix $L(x)$ is presented as

$$\Phi(x_1)_1 L(x_2)_2 = R((x_1/x_2)q^{c/2})^{-1} L(x_2)_2 \Phi(x_1)_1 .$$

This relation can be interpreted as that $\Phi(x)$ is an intertwiner for the algebra generated by $L(x)$.[7] With this we can define a comultiplication on the algebra generated by $L(x)$ and $\Phi(x)$, where the comultiplication for $L(z)$ comes from FRTS construction and the comultiplication of $\Phi(x)$ is defined as

$$\Delta(\Phi(z)) = \Phi(x)\otimes 1 + L(xq^{c_1/2})\otimes \Phi(zq^{c_1}),$$

which is a generalization of Drinfeld construction. Then combining the idea of FRTS construction and Drinfeld realization, we give a double for such a construction, where the FRTS construction is a Hopf subalgebra and Drinfeld realization is a special case of our realization with certain diagonal $R(x)$. This paper is basically a result of the combination of the two approaches, the FRTS construction and the Drinfeld realization.

This paper contains two additional sections. In Sec. II we define the Zamolochikov algebra and present its Hopf algebra extension. Section III describes the double of such a construction and the related examples.

II. HOPF ALGEBRA EXTENSION OF A ZAMOLOCHIKOV ALGEBRA

Let V be the vector space $\mathbb{C}^n$. Let x be a parameter in $\mathbb{C}$. A function valued R-matrix $R(x)$ is a function valued operator in $\mathrm{End}(V)\otimes \mathrm{End}(V)$, which satisfies the so-called Yang–Baxter equation:

$$R_{12}(z)R_{13}(z/w)R_{23}(w) = R_{23}(w)R_{13}(z/w)R_{12}(z),$$

where $R_{12}(x)\Sigma_{ij} = f_{ij}(x)a_i\otimes b_j\otimes 1 = R(x)\otimes 1$, $R_{13}(x)=\Sigma_{ij} f_{ij}(x)a_i\otimes 1\otimes b_j$, $R_{23}(x)=\Sigma_{ij} f_{ij}(x)1\otimes a_i\otimes b_j = 1\otimes R$, and $R(x)=f_{ij}(x)\Sigma_{ij}\, a_i\otimes b_j$. We also require that $R(x)$ satisfies the unitary condition

$$R_{21}(z)^{-1} = R(z^{-1}),$$

where $R_{21}(z)=f_{ij}(x)\Sigma_{ij}\, b_j\otimes a_i$.

Definition 2.1: The associative algebra $P[R(x)]$ is an algebra generated by operators $\Phi_i(x)$ index by a linear independent basis e_i of V. Let $\Phi(x)=\Sigma \Phi_i(x)\otimes e_i$. The commutation relations are presented as

$$R(x_1/x_2)\Phi(x_1)_1\Phi(x_2)_2 = \Phi(x_2)_2\Phi(x_1)_1 ,$$

where

$$\Phi(x_1)_1\Phi(x_2)_2 = \sum \Phi_i(x_1)\Phi_j(x_2)e_i\otimes e_j , \quad \Phi(x_2)_2\Phi(x_1)_1 = \sum \Phi_j(x_2)\Phi_i(x_1)e_i\otimes e_j .$$

As explained in Sec. I, this system is used in the description particles $(\Phi_i(x))$ in physics with the scattering matrix $R(x)$ and in some other context. This relation is also satisfied by the vertex operators for quantum affine algebras,[7,8] etc., and this type of system also appeared in describing the elliptic type of algebras.[9] However, they are all described as algebras, not Hopf algebras. Following the idea in Refs. 6, 10–12 we would like to extend this algebra with additional current operators coming from the FRTS construction to give a Hopf algebra structure to such a system.

Definition 2.2: The algebra $EP[R(x)]$ is an associative algebra generated by $\Phi_i(x)$ indexed by a linear independent basis e_i of $V, l_{ij}(x)$ indexed by the linear independent basis e_{ij} of $\mathrm{End}(V)$

and a central element c. Let $\Phi(x)=\Phi_i(x)\otimes e_i$ and the operator valued matrix $L(x)=\Sigma l_{ij}(x)\otimes e_{ij}$, such that $L(x)$ is invertible. They satisfy the commutation relations:

$$R(x_1/x_2)\Phi(x_1)_1\Phi(x_2)_2=\Phi(x_2)_2\Phi(x_1)_1,$$

$$\Phi(x_1)_1L(x_2)_2=R(q^{c/2}x_1/x_2)^{-1}L(x_2)_2\Phi_i(x_1)_1,$$

$$R(x_1/x_2)L(x_1)_1L(x_2)_2=L(x_2)_2L(x_1)_1R(x_1/x_2).$$

Here

$$\Phi(x_1)_1L(x_2)_2=\sum \Phi_i(x_1)L_{kl}(x_2)e_i\otimes e_{kl}, \quad L(x_2)_2\Phi_i(x_1)_1=\sum L_{kl}(x_2)\Phi_i(x_1)e_i\otimes e_{kl},$$

$$L(x_1)_1L(x_2)_2=PL(x_1)_2L(x_2)_1P=\sum L_{ij}(x_1)L_i(x_2)e_{ij}\otimes e_{kl},$$

and P is the permutation operator.

Theorem 2.1: *The algebra $EP[R(x)]$ has a Hopf algebra structure, which is given by the following formulas.*

Coproduct Δ,

$$(0) \quad \Delta(q^c)=q^c\otimes q^c,$$

$$(1) \quad \Delta(\Phi_i(z))=\Phi_i(z)\otimes 1+\sum L_{ij}(zq^{c_1/2})\otimes\Phi_j(zq^{c_1}),$$

$$(2) \quad \Delta(L_{ij}(z))=\sum L_{ik}(zq^{-c_2/2})\otimes L_{kj}(zq^{c_1/2}),$$

where $c_1=c\otimes 1$ and $c_2=1\otimes c$.

Counit ϵ,

$$\epsilon(q^c)=1, \quad \epsilon(L_{ij}(z))=\delta_{ij},$$

$$\epsilon(\Phi_i^{\pm}(z))=0.$$

Antipode a,

$$(0) \quad a(q^c)=q^{-c},$$

$$(1) \quad a(\Phi_i(z))=\sum -(L(zq^{-c/2})^{-1})_{ij}\Phi_j(zq^{-c}),$$

$$(2) \quad a(L(z))=(L(z))^{-1}.$$

We will use the notation to denote the comultiplication,

$$\Delta\Phi(x_1)=\Phi(x_1)\overline{\otimes}1+L(x_1q^{c_1/2})\overline{\otimes}\Phi(x_1q^{c_1}),$$

$$\Delta(L(x_2)=(L(x_2q^{-c_2/2})\overline{\otimes}L(x_2q^{c_1/2}))$$

Proof: For the comultiplication above we have that

$$\Delta\Phi(x_1)_1\Delta L(x_2)_2=(\Phi(x_1)\overline{\otimes}1+L(x_1q^{c_1/2})\overline{\otimes}\Phi(x_1q^{c_1}))_1(L(x_2q^{-c_2/2})\overline{\otimes}L(x_2q^{c_1/2})_2$$
$$=R(x_1/x_2q^{(c_1+c_2)/2})^{-1}(L(x_2q^{-c_2}/2)\overline{\otimes}L(x_2q^{c_1/2}))_2(\Phi(z)\overline{\otimes}1)_1$$
$$+R(x_2/x_1q^{(c_1+c_2)/2})^{-1}(L(x_2q^{-c_2/2})\overline{\otimes}L(x_2q^{c_1/2}))_2(L(x_1q^{c_1/2})$$
$$\overline{\otimes}\Phi(x_1q^{c_1}))_1,$$

$$R(x_1/x_2)\Delta\Phi(x_1)_1\Delta\Phi(x_2)_2=R(x_1/x_2)(\Phi(x_1)\overline{\otimes}1+L(x_1q^{c_1/2})\overline{\otimes}\Phi(x_1q^{c_1}))_1(\Phi(x_2)\overline{\otimes}1$$
$$+L(x_2q^{c_1/2})\overline{\otimes}\Phi(x_2q^{c_1}))_2$$
$$=(\Phi(x_2)\overline{\otimes}1)_2(\Phi(x_1)\overline{\otimes}1)_1$$
$$+(L(x_2q^{c_1/2})\overline{\otimes}\Phi(x_2q^{c_1}))_2(\Phi(x_1)\overline{\otimes}1)_1+(L(x_1q^{c_1/2})$$
$$\overline{\otimes}\Phi(x_1q^{c_1}))_1(L(x_2q^{c_1/2})\overline{\otimes}\Phi(x_2q^{c_1}))_2+R_{21}(x_2/x_1)^{-1}L(x_1q^{c_1/2})$$
$$\overline{\otimes}\Phi(x_1q^{c_1}))_1(\Phi(x_2)\overline{\otimes}1)_2$$
$$=\Delta\Phi(x_2)_2\Phi(x_1)_1.$$

Similarly, we can prove the rest of the theorem by direct calculation.

This construction of comultiplication follows partially the idea of constructing comultiplications for the quantum Lie algebra,[10] where the cases without the parameter x are given. With our construction, we can extend the Hopf algebra structures to the special Zamolochikov algebra $Z_{n,k}(\xi,\tau)$, which is defined as the algebra generated $\Phi(z)$ with a Belavin elliptic R-matrix $R(z)$.[9] We expect that the new Hopf algebra structure should be very useful in the study of the representation theory of the elliptic Zamolochikov algebras and hopefully even the related Sklyanin elliptic algebras.

III. THE DOUBLE OF $EP[R(x)]$

In this section, we will present a double of the algebra $EP[R(x)]$ following the Drinfeld realization of the quantum affine algebra $U_q(\widehat{\mathfrak{sl}}(2))$.

Definition 3.1: The algebra $DEP[R(x)]$ is an associative algebra generated by $\Phi_i(x)$ indexed by a linear independent basis e_i of $V, l_{ij}(x)$ and $l^*_{ij}(x)$ indexed by the linear independent basis e_{ij} of End(V), $\Phi^*(x)$ indexed by a linear independent basis e^*_i of V^*, the dual space of V, and a central element c. Let $\Phi(x)=\Phi_i(x)\otimes e_i$, $\Phi^*(x)=\Phi^*_i(x)\otimes e^*_i$ the operator valued matrix $L(x)=\Sigma l_{ij}(x)\otimes e_{ij}$, $L^*(x)=\Sigma l^*_{ij}(x)\otimes e_{ij}$, such that $L(x)$ and $L^*(x)$ are invertible. They satisfy the commutation relations:

$$R(x_1/x_2)\Phi(x_1)_1\Phi(x_2)_2=\Phi(x_2)_2\Phi(x_1)_1,$$

$$\Phi(x_1)_1L(x_2)_2=R(q^{c/2}x_1/x_2)^{-1}L(x_2)_2\Phi_i(x_1)_1,$$

$$R(x_1/x_2)L(x_1)_1L(x_2)_2=L(x_2)_2L(x_1)_1R(x_1/x_2).$$

$$R(x_1/x_2)L^*(x_1)_1L^*(x_2)_2=L^*(x_2)_2L^*(x_1)_1R(x_1/x_2),$$

$$R(x_1/x_2q^{-c})L(x_1)_1L^*(x_2)_2=L^*(x_2)_2L^*(x_1)_1R(x_1/x_2q^{c}),$$

$$\Phi^*(x_2)_2\Phi^*(x_1)_1=\Phi^*(x_1)_1\Phi^*(x_2)_2R_{21}(x_2/x_1),$$

$$L^*(x_2)_2\Phi^*(x_1)_1=\Phi^*(x_1)_1L^*(x_2)_2R_{21}(q^{-c/2}x_2/x_1),$$

$$\Phi(x_1)_1\Phi(x_2)_2^* - \Phi^*(x_2)_2\Phi(x_1)_1 = 1/(q-q^{-1})(L^*(wq^{c/2})\delta(z/wq^{-c}) - \delta(z/wq^{c})L^*(zq^{c/2}),$$

$$L(x_1)_1\Phi^*(x_2)_2R_{21}(q^{-c/2}x_2/x_1) = \Phi^*(x_2)_2L(x_1)_1,$$

$$R(q^{c/2}x_1/x_2)L^*(x_1)_1\Phi(x_2)_2 = \Phi(x_2)_2L^*(x_1)_1.$$

Here $\Phi(x_1)_1L(x_2)_2 = \Sigma\Phi_i(x_1)L_{kl}(x_2)e_i\otimes e_{kl}$, $L(x_2)_2\Phi_i(x_1)_1 = \Sigma L_{kl}(x_2)\Phi_i(x_1)e_i\otimes e_{kl}$, $L(x_1)_1L(x_2)_2 = PL(x_1)_2L(x_2)_1P = \Sigma L_{ij}(x_1)L_i(x_2)e_{ij}\otimes e_{kl}$, and the others are defined in the same way. P is the permutation operator. $\delta(z)$ is the distribution with the support at 1.

Theorem 3.1: *$DEP[R(x)]$ has an Hopf algebra structure. The comultiplication Δ, the counit ϵ and the antipode a are given by the following formulas.*

Coproduct Δ,

$$(0)\quad \Delta(q^c) = q^c\otimes q^c,$$

$$(1)\quad \Delta(\Phi_i(z)) = \Phi_i(z)\otimes 1 + \sum L_{ij}(zq^{c_1/2})\otimes\Phi_j(zq^{c_1}),$$

$$(2)\quad \Delta(L_{ij}(z)) = \sum L_{ik}(zq^{-c_2/2})\otimes L_{kj}(zq^{c_1/2}),$$

$$(3)\quad \Delta(\Phi_i^*(z)) = 1\otimes\Phi_i^*(z) + \sum \Phi_j^*(zq^{c_2})\otimes L_{ij}^*(zq^{c_2/2}),$$

$$(2)\quad \Delta(L_{ij}^*(z)) = \sum L_{ik}^*(zq^{c_2/2})\otimes L_{kj}^*(zq^{-c_1/2}),$$

where $c_1 = c\otimes 1$ and $c_2 = 1\otimes c$.

Counit ϵ,

$$\epsilon(q^c) = 1\,\epsilon(L(z)) = \epsilon(L^*(z)) = I,$$

$$\epsilon(\Phi(z)) = 0 = \epsilon(\Phi^*(z)).$$

Antipode a,

$$(0)\quad a(q^c) = q^{-c},$$

$$(1)\quad a(\Phi(z)) = -L(zq^{-c/2})^{-1}\Phi(zq^{-c}),$$

$$(2)\quad a(\Phi^*(z)) = -\Phi^*(zq^{-c})L^*(zq^{-c/2})^{-1},$$

$$(3)\quad a(L(z)) = L(z)^{-1},$$

$$(4)\quad a(L^*(z)) = L^*(z)^{-1}.$$

Proof:

$$\begin{aligned}\Delta\Phi^*(z)_1\Delta\Phi(w)_2^*R_{21}(w/z) &= (1\otimes\Phi^*(z) + \Phi^*(zq^{c_2})\otimes L^*(zq^{c_2/2}))_1(1\otimes\Phi^*(w) + \Phi^*(wq^{c_2})\\ &\quad\otimes L^*(wq^{c_2/2}))_2R_{21}(x_1/x_2)\\ &= (1\otimes\Phi^*(w)_2(1\otimes\Phi^*(z)_1 + (\Phi^*(wq^{c_2})\otimes L^*(wq^{c_2/2}))_2(1\\ &\quad\otimes\Phi^*(z))_1 + (\Phi^*(zq^{c_2})\otimes L^*(zq^{c_2/2}))_1(1\otimes\Phi^*(w))_2R(z/w)^{-1}\end{aligned}$$

$$+(1\otimes\Phi^*(w)+\Phi^*(wq^{c_2})\otimes L^*(wq^{c_2/2}))_2(1\otimes\Phi^*(z)+\Phi^*(zq^{c_2})\otimes L^*(zq^{c_2/2}))_1+(\Phi^*(wq^{c_2})\otimes L^*(wq^{c_2/2}))_2(\Phi^*(zq^{c_2})\otimes L^*(zq^{c_2/2}))_1,$$

$$\Delta\Phi^*(z)_1\Delta L^*(w)_2R_{21}(q^{-(c_1+c_2)/2}w/z)=(1\otimes\Phi^*(z)+\Phi^*(zq^{c_2})\otimes L^*(zq^{c_2/2}))_1(L^*(wq^{c_2/2})\otimes L^*(wq^{-c_1/2}))_2R_{21}(q^{-(c_1+c_2)/2}w/z)$$
$$=\Delta L^*(w)_2\Delta\Phi^*(z)_1,$$

$$\Delta L(z)_1\Delta\Phi^*(w)_2R_{21}(q^{-(c_1+c_2)/2}w/z)=(L(zq^{-c_2/2})\otimes L(zq^{c_1/2})_1(1\otimes\Phi^*(w)+\Phi^*(wq^{c_2})\otimes L^*(wq^{c_2/2}))_2R_{21}(q^{-(c_1+c_2)/2}w/z)$$
$$=(1\otimes\Phi^*(w))_2(L(zq^{-c_2/2})\otimes L(zq^{c_1/2})_1+(L(zq^{-c_2/2})\otimes L(zq^{c_1/2})_1(\Phi^*(wq^{c_2})\otimes L^*(wq^{c_2/2}))_2R_{21}(q^{-(c_1+c_2)/2}w/z)$$
$$=(1\otimes\Phi^*(w))_2(L(zq^{-c_2/2})\otimes L(zq^{c_1/2})_1+(\Phi^*(wq^{c_2})\otimes L^*(wq^{c_2/2}))_2(L(zq^{-c_2/2})\otimes L(zq^{c_1/2})_1$$
$$=\Delta(\Phi^*(w))_2\Delta(L(x_1))_1,$$

$$R(q^{(c_1+c_2)/2}z/w)\Delta L^*(z)_1\Delta\Phi(w)_2=R(q^{(c_1+c_2)/2}z/w)(L^*(zq^{c_2/2})\otimes L^*(zq^{-c_1/2}))_1(\Phi(w)\otimes 1+L(wq^{c_1/2})\otimes\Phi(wq^{c_1}))_2$$
$$=(\Phi(w)\otimes 1)_2(L^*(zq^{c_2/2})\otimes L^*(zq^{-c_1/2}))_1+R_{21}(q^{-(c_1+c_2)/2}w/z)(L^*(zq^{c_2/2})\otimes L^*(zq^{-c_1/2}))_1L(wq^{c_1/2})\otimes\Phi(wq^{c_1}))_2$$
$$=\Delta\Phi(w)_2\Delta L^*(z)_1,$$

$$\Delta\Phi(z)_1\Delta\Phi(w)_2^*-\Delta\Phi^*(w)_2\Delta\Phi(z)_1=(\Phi(z)\otimes 1+L(zq^{c_1/2})\otimes\Phi(zq^{c_1}))_1(1\otimes\Phi^*(w)+\Phi^*(wq^{c_2})\otimes L^*(wq^{c_2/2}))_2-(1\otimes\Phi^*(w)+\Phi^*(wq^{c_2})\otimes L^*(wq^{c_2/2}))_2(\Phi(z)1+L(zq^{c_1/2})\otimes\Phi(zq^{c_1}))_1$$
$$=0+1/(q-q^{-1})(L^*(wq^{c_1/2+c_2})\delta(z/wq^{-c_1-c_2})\otimes L^*(wq^{c_2/2})-\delta(z/wq^{c_1-c_2})L(zq^{c_1/2}))\otimes L^*(wq^{c_2/2})+L(zq^{c_1/2})\otimes(1/(q-q^{-1})(L^*(wq^{c_2/2})\delta(z/wq^{-c_2+c_1})-\delta(z/wq^{c_1+c_2})L(zq^{c_1+c_2/2})+(L(zq^{c_1/2})\otimes\Phi(zq^{c_1}))_1(\Phi^*(wq^{c_2})\otimes L^*(wq^{c_2/2}))_2-(\Phi^*(wq^{c_2})\otimes L^*(wq^{c_2/2}))_2(L(zq^{c_1/2})\otimes\Phi(zq^{c_1}))_1.$$

Because

$$(L(zq^{c_1/2}\otimes 1)_1(\Phi^*(wq^{c_2}))\otimes 1)_2R_{21}(q^{-c_1+c_2}w/z)=(\Phi^*(wq^{c_2}))\otimes 1)_2(L(zq^{c_1/2}\otimes 1)_1,$$

and

$$(R_{21}(q^{-c_1+c_2}w/z))^{-1}(1\otimes\Phi(zq^{c_1}))_1L^*(wq^{c_2/2}))_2=L^*(wq^{c_2/2}))_2(1\otimes\Phi(zq^{c_1}))_1,$$

we have that

$$\Delta\Phi(z)_1\Delta\Phi(w)_2^*-\Delta\Phi^*(w)_2\Delta\Phi(z)_1$$
$$=1/(q-1^{-1})(\Delta L(z/wq^{(c_1+c_2)/2}\delta(z/wq^{-(c_1+c_2)})-\delta(z/wq^c)\Delta L^*(zq^{(c_1+c_2)/2}).$$

Similar calculation gives the complete proof for the theorem.

In all the setting above, $l_{ij}(z)$, $l_{ij}^*(z)$, $\Phi_i(z)$, and $\Phi_i^*(z)$ are functional operators, namely the operator depending the variable z. On the other hand, we can assume that z is a formal variable and $l_{ij}(z)=\Sigma_{n\in\mathbb{Z}}l_{ij}(n)z^{-n}$, $l_{ij}^*(z)=\Sigma_{n\in\mathbb{Z}}l_{ij}^*(n)z^{-n}$, $\Phi_i(z)=\Sigma_{n\in\mathbb{Z}}\Phi_i(n)z^{-n}$, $\Phi_i^*(z)=\Sigma_{n\in\mathbb{Z}}\Phi_i^*(n)z^{-n}$. We can define an algebra $DZP[R(x)]$.

We assume that the entries of $R(z)$ are meromorphic functions. Let $R'(z)=R(z)f(z)$, where $f(z)$ is the common divisor of all the functions $F(z)$, such that $F(z)R(z)$ has no poles.

Definition 3.2: The algebra $DZP[R(x)]$ is an associative algebra generated by $\Phi_i(x)$ indexed by a linear independent basis e_i of $V,l_{ij}(x)$, and $l_{ij}^*(x)$ indexed by the linear independent basis e_{ij} of End(V), $\Phi^*(x)$ indexed by a linear independent basis e_i^* of V^*, the dual space of V, and a central element c. Let $\Phi(x)=\Phi_i(x)\otimes e_i$, $\Phi^*(x)=\Phi_i^*(x)\otimes e_i^*$ the operator valued matrix $L(x)=\Sigma l_{ij}(x)\otimes e_{ij}$, $L^*(x)=\Sigma l_{ij}^*(x)\otimes e_{ij}$, such that $L(x)$ and, $L^*(x)$ are invertible. They satisfy the commutation

$$R'(x_1/x_2)\Phi(x_1)_1\Phi(x_2)_2=f(x_1/x_2)\Phi(x_2)_2\Phi(x_1)_1,$$

$$\Phi(x_1)_1L(x_2)_2=R(q^{c/2}x_1/x_2)^{-1}L(x_2)_2\Phi_i(x_1)_1,$$

$$R(x_1/x_2)L(x_1)_1L(x_2)_2=L(x_2)_2L(x_1)_1R(x_1/x_2).$$

$$R(x_1/x_2)L^*(x_1)_1L^*(x_2)_2=L^*(x_2)_2L^*(x_1)_1R(x_1/x_2),$$

$$R(x_1/x_2q^{-c})L(x_1)_1L^*(x_2)_2=L^*(x_2)_2L^*(x_1)_1R(x_1/x_2q^c),$$

$$f(x_2/x_1)\Phi^*(x_2)_2\Phi^*(x_1)_1=\Phi^*(x_1)_1\Phi^*(x_2)_2R'_{21}(x_2/x_1),$$

$$L^*(x_2)_2\Phi^*(x_1)_1=\Phi^*(x_1)_1L^*(x_2)_2R_{21}(q^{-c/2}x_2/x_1),$$

$$\Phi(x_1)_1\Phi(x_2)_2^*-\Phi^*(x_2)_2\Phi(x_1)_1=1/(q-q^{-1})(L^*(wq^{c/2})\delta(z/wq^{-c})-\delta(z/wq^c)L^*(zq^{c/2}),$$

$$L(x_1)_1\Phi^*(x_2)_2R_{21}(q^{-c/2}x_2/x_1)=\Phi^*(x_2)_2L(x_1)_1,$$

$$R(q^{c/2}x_1/x_2)L^*(x_1)_1\Phi(x_2)_2=\Phi(x_2)_2L^*(x_1)_1.$$

Here $\Phi(x_1)_1L(x_2)_2=\Sigma\Phi_i(x_1)L_{kl}(x_2)e_i\otimes e_{kl}$, $L(x_2)_2\Phi_i(x_1)_1=\Sigma L_{kl}(x_2)\Phi_i(x_1)e_i\otimes e_{kl}$, $L(x_1)_1L(x_2)_2=PL(x_1)_2L(x_2)_1P=\Sigma L_{ij}(x_1)L_i(x_2)e_{ij}\otimes e_{kl}$, and the others are defined in the same way as above. P is the permutation operator. $\delta(z)=\Sigma_{n\in\mathbb{Z}}z^n$. The operator $R(z)$ and $R_21(z)$ are expanded in appropriate directions.

If the poles of the matrix of $R(z)$ are beyond a finite disk around zero, we can always impose the condition that $l_{kl}(n)=0=l_{kl}^*(-n)=l_{ij}(0)=l_{ji}^*(0)$, for $n<0$, $i<j$. Then the condition of the invertibility is equivalent and requires that $l_{ii}(0)$ and $l_{ii}^*(0)$ are invertible.

Example 3.1: Let V be one dimensional, and $R(z)=z-wq^2/zq^2-w$. Let $l_{11}(n)=0=l_{11}^*(-n)$, for $n<0$. Then the algebra $DZP[R(x)]$ is the quantum affine algebra $U_q(\widehat{\mathfrak{sl}}(2))$. If we choose $R(z)$ to be other functions with the property $R(z)=(R(z^{-1})^{-1}$, then it is an algebra defined in Ref. 6 as a generalization of the the quantum affine algebra $U_q(\widehat{\mathfrak{sl}}(2))$.

Example 3.2: Let $V=C^n$ and $R(z)=\Sigma(z-wq^2)/(zq^2-w)e_{ii}\otimes e_{ii}+\Sigma_{|i-j|=1}(z-wq^{-1})/(zq^{-1}-w)(e_{j,j}\otimes e_{i,i})+\Sigma_{|i-j|>1}e_{ii}\otimes e_{jj}$. Let $l_{kl}(n)=0=l^*_{kl}(-n)=l_{ij}(0)=l^*_{ji}(0)$, for $n<0$, $i<j$. Then the algebra $DZP[R(x)]$ is an algebra, whose quotient (modular the cubic relations) is $U_q(\widehat{\mathfrak{sl}}(n))$. If we substitute $z-wq^2/zq^2-w$ and $(z-wq^{-1})/(zq^{-1}-w)$ by other functions, it will be the generalization of $U_q(\widehat{\mathfrak{sl}}(n))$ without the cubic relations.[6]

Example 3.3: Let $V=C^n$ and $R(z)$ be the projection of the universal R-matrix $\mathfrak{R}$ of $U_q(\widehat{\mathfrak{sl}}(n))$. Let $l_{kl}(n)=0=l^*_{kl}(-n)=l_{ij}(0)=l^*_{ji}(0)$, for $n<0$, $i<j$. The operator $L(z)$ can be identified with the operator $(\mathrm{id}\otimes\pi_V)\mathfrak{R}_21(zq^{c/2})$ and $L^*(z)$ with the operator $(\mathrm{id}\otimes\pi_V)\mathfrak{R}^{-1}(z^{-1}q^{-c/2})$. The subalgebra generated by $L(z)$ and $L^*(z)$ is isomorphic to $U_q(\widehat{\mathfrak{sl}}(n))$. We conjecture that the algebra $DZP[R(x)]$ is isomorphic to $U_q(\widehat{\mathfrak{sl}}(n+1))$. This is because when q goes to 1, this algebra degenerates into $\widehat{\mathfrak{sl}}(n+1)$. Such a formulation should have application in construction of quantum W-algebras.[13] Also if we take $z=0$, it becomes that in Refs. 11 and 14.

From the definition, we can see both the subalgebra generated by $\Phi(z)$, $L(z)$, and $L^*(z)$ and the subalgebra generated by $\Phi^*(z)$, $L(z)$, and $L^*(z)$ are the Hopf algebras. If we take $R(z)$ to be the projection of the universal R-matrix $\mathfrak{R}$ of $U_q(\widehat{\mathfrak{sl}}(n))$ on finite dimensional representations, we will derive unconventional Hopf algebras from those subalgebras.

Our new algebras can be viewed as a simple generalization of the Drinfeld realization of the quantum affine algebra $U_q(\widehat{\mathfrak{sl}}(2))$, where the function $g(z)$ is substitute by a matrix $R(z)$, the operators are substituted by the vector valued operators and the relations looks the same. However such a generalization is highly nontrivial in the sense that all the Hopf algebra structures are preserved, in the other words, those new algebras are Hopf algebras, whose comultiplication, counit, and antipode symbolically are the same. These new Hopf algebras should be very useful in various applications in mathematics and physics, for example, the study of the representation theory of the elliptic Zamolochikov algebras.[15]

(Received 29 April 1999; accepted for publication 11 May 1999)

The properties of linear equations on braided linear spaces are investigated and conservation laws for them are derived. The conserved currents are given in the explicit form. The procedure is then applied to scalar wave equations on a quantum plane and on q-Minkowski space. © *1999 American Institute of Physics.* [S0022-2488(99)02208-2]

I. INTRODUCTION

In the classical field theory we can derive conservation laws for linear equations using the Takahashi–Umezawa method.[1] We have shown previously that it can be extended to models on lattices[2–4] and on quantum Minkowski spaces by Podleś and Woronowicz.[5–10] The aim in this paper is to develop a similar procedure for linear equations on braided linear spaces.

The class of braided linear spaces was introduced by Majid[11] as braided Hopf groups with a full structure of the Hopf group consistent with a braided tensor product:

$$(a\otimes c)(b\otimes d)=a\Psi(c\otimes b)d.$$

The important examples of braided linear spaces are q-Euclidean and q-Minkowski space endowed, respectively, with action of the $SO_q(4)$ and q-Poincaré algebra. For q-Minkowski space investigated equations include the scalar, spinor and vector wave equations.[12,13] In the last section we show how to obtain the conserved currents for a scalar wave equation on q-Minkowski space.

Let us notice that technically the procedure of the derivation of the conserved currents is very similar to the method introduced for discrete space and for quantum Minkowski spaces mentioned earlier.

The paper is organized as follows: In Secs. II and III we reformulate the Leibnitz rule for braided differential calculus. It appears that the deformation is given by a certain transformation operator. This operator differs from the ones investigated earlier in discrete and noncommutative models. Nevertheless, the properties of the transformation operator are analogous. There also exists the inverse transformation operator due to the bi-invertibility of the R matrix. This operator is then used in the modification of the Leibnitz rule. In Sec. IV we solve uniquely and explicitly a certain operator equation for the operator Γ_μ that enables us to construct the conserved currents in Sec. V. Section VI includes an application of the presented method to wave equations on the quantum plane and on q-Minkowski space.

II. BRAIDED LINEAR SPACES

Let us begin with a brief sketch of properties of braided covector space. This structure is a braided Hopf algebra defined by generators 1, x_i ($i=1,...,n$) and relations of the braided group structure:

$$x_i x_j=(R')^{kl}_{ij}x_l x_k, \tag{1}$$

[a)]Electronic mail: klimek@matinf.pcz.czest.pl

$$\Delta x_i = x_i \otimes 1 + 1 \otimes x_i \,, \tag{2}$$

$$\epsilon x_i = 0, \quad S x_i = -x_i \,, \tag{3}$$

$$\Psi(x_i \otimes x_j) = x_k \otimes x_l R^{lk}_{ij} \,, \tag{4}$$

where bi-invariant matrix R fulfills QYBE and besides the first inverse R^{-1} there also exists the second inverse $\widetilde{R}$:

$$(R^{-1})^{ij}_{kl} R^{kl}_{ab} = R^{ij}_{kl} (R^{-1})^{kl}_{ab} = \delta^i_a \delta^j_b \,, \tag{5}$$

$$\widetilde{R}^{ib}_{al} R^{ak}_{jb} = R^{ib}_{al} \widetilde{R}^{ak}_{jb} = \delta^i_j \delta^k_l \,. \tag{6}$$

The matrix R' defining the commutation rule for coordinates (1) is an invertible matrix given by the formula[11]

$$R' = P + P \Pi_{j \neq i} (PR - \lambda_j), \tag{7}$$

with P the permutation matrix and λ_i the nonzero eigenvalue of the minimal polynomial of PR:

$$\Pi_j (PR - \lambda_j) = 0.$$

Differentiation on braided linear space was defined by Majid[14,15] as an infinitesimal translation, and this leads to the following properties of partial derivatives:

$$\partial^i \partial^j = (R')^{ij}_{kl} \partial^l \partial^k, \tag{8}$$

$$\partial^i x_j = \delta^i_j + R^{ki}_{jl} x_k \partial^l. \tag{9}$$

We shall consider the functions of coordinates on braided linear spaces understood as a formal power series:

$$f(\vec{x}) = \sum_{l=0}^{\infty} a^{k_0 \cdots k_l} x_{k_0} \cdots x_{k_l}. \tag{10}$$

For functions, the commutation rule (9) transforms into the Leibnitz rule given by Majid[11,14,15] in the form

$$\partial^i (fg) = (\partial^i f) g + \cdot \Psi^{-1} (\partial^i \otimes f) g, \tag{11}$$

where the inverse braiding looks as follows on monomials of arbitrary order [e^i is a basic covector that means $(e^i)_j = \delta^i_j$]:

$$\Psi^{-1}(\partial^i \otimes x_1 \cdots x_k) = e^i_1 x_2 \cdots x_k x_{k+1} (PR)_{12} \cdots (PR)_{k,k+1} \otimes \partial^{k+1}. \tag{12}$$

It is easy to deduce that the Leibnitz rule (11) can be rewritten similarly to the ones appearing in the discrete calculus[4] and in the differential calculus on quantum Minkowski space by Podleś and Woronowicz.[5,10] In this formula the deformation of the classical Leibnitz rule is described by the transformation operator ζ^i_j:

$$\partial^i (fg) = (\partial^i f) g + (\zeta^i_j f) \partial^j g. \tag{13}$$

The transformation operator for braided differential calculus is defined by formula (12) and on an arbitrary monomial of the first order is given by

$$\zeta^i_j x_k = R^{li}_{kj} x_l . \tag{14}$$

We extend the ζ operator to arbitrary function (10) using its multiplicity property, namely,

$$\zeta^i_j(fg) = (\zeta^i_k f)(\zeta^k_j g). \tag{15}$$

Let us be reminded that in the classical differential calculus the transformation operator is the identity operator:

$$\zeta^i_j = \delta^i_j .$$

For the discrete calculus it is the shift operator on the lattice in the given direction,[4] while on the quantum Minkowski space it is defined by its multiplicity and action on monomials of the first order.[5]

Now we can modify the Leibnitz rule (13) in such a way as to obtain on the right-hand side operators acting only on one of the functions in the product. To this aim we use the inverse transformation operator ζ^-:

$$\zeta^k_j \zeta^{-\ i}_k = \zeta^{-\ k}_j \zeta^i_k = \delta^i_j . \tag{16}$$

The existence of the inverse operator is due to the bi-invertibility of the R matrix, and it is defined by its action on monomials of the first order:

$$\zeta^{-\ i}_j x_k = \tilde{R}^{li}_{kj} x_l , \tag{17}$$

and the multiplicity property:

$$\zeta^{-\ i}_j(fg) = (\zeta^{-\ k}_j f)(\zeta^{-\ i}_k g). \tag{18}$$

The properties of the transformation operators ζ and ζ^- imply the following modified Leibnitz rule:

$$\partial^k[(\zeta^{-\ i}_k f)g] = (-\partial^{\dagger\ i} f)g + f(\partial^i g) = f(-\overleftarrow{\partial}^{\dagger\ i} + \partial^i)g, \tag{19}$$

where we have denoted as a conjugated derivative,

$$\partial^{\dagger\ i} := -\partial^k \zeta^{-\ i}_k . \tag{20}$$

We see that after modification we deal with the Leibnitz rule, where the right-hand side is analogous to the classical differential calculus:

$$\partial^i(fg) = f(-\overleftarrow{\partial}^{\dagger\ i} + \partial^i)g,$$

with the exception that classically $\partial^{\dagger\ i} = -\partial^i$, while in our noncommutative case it is deformed by the inverse transformation operator (19), (20).

Let us notice that the form of the modified Leibnitz rule for braided differential calculus (19) is identical with the formulas derived for discrete and quantum models; the only difference is enclosed in the explicit formula for the transformations operators ζ and ζ^-.

III. LINEAR EQUATIONS ON BRAIDED LINEAR SPACES

We shall consider equations of the form

$$\Lambda(\partial)\Phi = 0, \tag{21}$$

$$\Lambda(\partial)=\Lambda_0+\sum_{l=1}^{N}\Lambda_{\mu_1\cdots\mu_l}\partial^{\mu_1}\cdots\partial^{\mu_l}. \tag{22}$$

They are linear equations with coefficients (which may be matrices) fulfilling the following conditions:

$$\sum_{\mu_k}\partial^{\mu_k}\Lambda_{\mu_1\cdots\mu_k\cdots\mu_l}=0, \tag{23}$$

$$\sum_{\mu_k}\zeta_j^{\mu_k}\Lambda_{\mu_1\cdots\mu_k\cdots\mu_l}=\Lambda_{\mu_1\cdots j\cdots\mu_l}, \tag{24}$$

where $l=1,...,N,\ k=1,...,l$.

The class of equations obeying (23), (24), in general, admits the coefficients depending on coordinates. It includes equations with constant coefficients such as, for example, a scalar, spinor, and vector wave equation on q-Minkowski space.[12,13] For constant coefficients the condition (23) can be replaced with stronger one:

$$\partial^i\Lambda_{\mu_1\cdots\mu_l}=0, \tag{25}$$

for $l=1,...,N$ and $i=1,...,N$.

Finally, due to the commutation relation for partial derivatives (8), the coefficients of Eq. (21) fulfill the symmetry condition, namely,

$$(R')^{\mu_k\mu_{k+1}}{}_{ij}\Lambda_{\mu_1\cdots\mu_k\mu_{k+1}\cdots\mu_l}=\Lambda_{\mu_1\cdots ji\cdots\mu_l},\quad l=1,...,N. \tag{26}$$

In earlier papers we investigated an analogous class of equations on discrete spaces and on quantum Minkowski space. The properties (23), (24) of coefficients together with the modified Leibnitz rule (19) allowed us to derive the conservation laws for arbitrary linear equation fulfilling these conditions. The crucial point in the construction, just as in the classical procedure of Takahashi and Umezawa,[1] is the solution of an operator equation for the operator Γ_μ:

$$\sum_{\mu}(-\overleftarrow{\partial}^{\dagger\,\mu}+\partial^\mu)\circ\Gamma_\mu(\partial,\overleftarrow{\partial}^\dagger)=\Lambda(\partial)-\Lambda(\overleftarrow{\partial}^\dagger), \tag{27}$$

where the operator $\Lambda(\overleftarrow{\partial}^\dagger)$ of the conjugated equation looks as follows:

$$\Lambda(\overleftarrow{\partial}^\dagger)=\Lambda_0+\sum_{l=1}^{N}\overleftarrow{\partial}^{\dagger\,\mu_1}\cdots\overleftarrow{\partial}^{\dagger\,\mu_l}\Lambda_{\mu_1\cdots\mu_l}. \tag{28}$$

We introduced the notation for the product "$\circ$" to underline the way it acts on monomials of derivatives:

$$\begin{aligned}(-\overleftarrow{\partial}^{\dagger\,\mu}+\partial^\mu)\circ\overline{[\nu_1,\ldots,\nu_l]}a(\vec{x})[\rho_1,\ldots,\rho_k]:=&-\overline{[\nu_1,\ldots,\nu_l,\mu]}a(\vec{x})[\rho_1,\ldots,\rho_k]\\&+\overline{[\nu_1,\ldots,\nu_l]}\partial^\mu a(\vec{x})[\rho_1,\ldots,\rho_k],\end{aligned} \tag{29}$$

where we have denoted the monomials of derivatives as follows:

$$[\rho_1,\ldots,\rho_k]:=\partial^{\rho_1}\cdots\partial^{\rho_k}, \tag{30}$$

$$\overline{[\nu_1,\ldots,\nu_l]}:=\overleftarrow{\partial}^{\dagger\,\nu_1}\cdots\overleftarrow{\partial}^{\dagger\,\nu_l}. \tag{31}$$

IV. THE CONSTRUCTION OF THE Γ_μ OPERATOR

The above equation (27) for the Γ_μ operator can be uniquely solved according to the following proposition.

Proposition 4.1: The unique solution of (27) in the class of polynomials of derivatives $\overleftarrow{\partial}^\dagger$ and ∂ for the equation operator Λ fulfilling (23), (24) is of the form

$$\Gamma_\mu(\partial,\overleftarrow{\partial}^\dagger)=\Lambda_\mu+\sum_{l=1}^{N-1}\sum_{k=0}^{l}\overleftarrow{\partial}^{\dagger\,\mu_1}\cdots\overleftarrow{\partial}^{\dagger\,\mu_k}\Lambda_{\mu_1\cdots\mu_k\mu\mu_{k+1}\cdots\mu_l}\partial^{\mu_{k+1}}\cdots\partial^{\mu_l}. \tag{32}$$

Proof: the proof for braided differential calculus is analogous to the one conducted in Refs. 4, 5 for discrete and quantum differential calculi so we enclose the shortened version in Appendix A.

Additionally, as the condition (23) is weaker than the condition for constant coefficients (25), we conclude that for this case the Γ_μ operator is given by the analogous proposition.

Proposition 4.2: The unique solution of (27) in the class of polynomials of derivatives $\overleftarrow{\partial}^\dagger$ and ∂ for the equation operator Λ with constant coefficients fulfilling (24), (25) is of the form

$$\Gamma_\mu(\partial,\overleftarrow{\partial}^\dagger)=\Lambda_\mu+\sum_{l=1}^{N-1}\sum_{k=0}^{l}\overleftarrow{\partial}^{\dagger\,\mu_1}\cdots\overleftarrow{\partial}^{\dagger\,\mu_k}\Lambda_{\mu_1\cdots\mu_k\mu\mu_{k+1}\cdots\mu_l}\partial^{\mu_{k+1}}\cdots\partial^{\mu_l}. \tag{33}$$

Proof: this is a corollary valid by Proposition 4.1.

The construction of the Γ_μ operator enables us to derive the conservation laws for linear equations in classical commutative models. This is not the case for equations on the discrete and noncommutative spaces due to the deformation of the Leibnitz rule.

We introduce the operator $\hat{\Gamma}_\mu$,

$$\hat{\Gamma}_\mu(\partial,\overleftarrow{\partial}^\dagger)=\overleftarrow{\zeta}_\mu^{-\,j}\Lambda_j+\sum_{l=1}^{N-1}\sum_{k=0}^{l}\overleftarrow{\partial}^{\dagger\,\mu_1}\cdots\overleftarrow{\partial}^{\dagger\,\mu_k}\overleftarrow{\zeta}_\mu^{-\,j}\Lambda_{\mu_1\cdots\mu_k j\mu_{k+1}\cdots\mu_l}\partial^{\mu_{k+1}}\cdots\partial^{\mu_l}, \tag{34}$$

which for a pair of arbitrary functions F and G is connected with the Γ_μ operator by the equality

$$\sum_\mu \partial^\mu F\,\hat{\Gamma}_\mu(\partial,\overleftarrow{\partial}^\dagger)G=\sum_\mu F(-\overleftarrow{\partial}^{\dagger\,\mu}+\partial^\mu)\circ\Gamma_\mu(\partial,\overleftarrow{\partial}^\dagger)G. \tag{35}$$

The operator $\hat{\Gamma}_\mu$ shall be used in an explicit construction of the conserved currents in the same way the operator Γ_μ was applied in the classical procedure for commutative differential calculus.

V. THE CONSERVATION LAWS FOR LINEAR EQUATIONS ON BRAIDED LINEAR SPACES

We use the properties of the $\hat{\Gamma}_\mu$ operator derived in the previous section to prove the following proposition which allows us to obtain the conservation law for arbitrary equation obeying conditions (23), (24).

Proposition 5.1: Let us assume that function Φ is an arbitrary solution of equation (21) with coefficients fulfilling (23), (24), which means

$$\Lambda(\partial)\Phi=0, \tag{36}$$

and function Φ' solves the conjugated equation

$$\Phi'\Lambda(\overleftarrow{\partial}^\dagger)=0. \tag{37}$$

Then

$$J_\mu = \Phi' \hat{\Gamma}_\mu(\partial, \bar{\partial}^\dagger)\Phi, \tag{38}$$

where the operator $\hat{\Gamma}_\mu$ *is defined by (34), is a current that obeys the conservation law on braided linear space:*

$$\sum_\mu \partial^\mu J_\mu = 0. \tag{39}$$

Proof: The conservation law results from the modified Leibnitz rule (19), and from the properties of the $\hat{\Gamma}$ and Γ operators:

$$\sum_\mu \partial^\mu J_\mu = \sum_\mu \partial^\mu \Phi' \hat{\Gamma}_\mu(\partial, \bar{\partial}^\dagger)\Phi = \Phi' \left(\sum_\mu (-\bar{\partial}^{\dagger\,\mu} + \partial^\mu)\circ\Gamma_\mu(\partial, \bar{\partial}^\dagger) \right)\Phi = \Phi'(\Lambda(\partial) - \Lambda(\bar{\partial}^\dagger))\Phi$$
$$= 0. \tag{40}$$

Thus, the conservation law for an arbitrary linear equation fulfilling (23), (24) is valid provided functions Φ' and Φ are solutions of the corresponding equations:

$$\Lambda(\partial)\Phi = 0, \quad \Phi'\Lambda(\bar{\partial}^\dagger) = 0. \tag{41}$$

Let us notice that for Eqs. (21) with constant coefficients fulfilling stronger conditions (24), (25) the Proposition 5.1 is also valid due to Proposition 4.2. The formula (38) shall be used in examples enclosed in the next section.

VI. APPLICATIONS

We shall now apply the general formulas of Propositions 4.2 and 5.1 to scalar wave equations on two braided linear spaces: on quantum plane and on the q-Minkowski space, which is the most interesting from the physical point of view.

A. The conserved currents for scalar wave equation on a quantum plane

The commutation relations for derivatives and coordinates on a quantum plane look as follows:[11]

$$yx = qxy, \quad \partial^y \partial^x = q^{-1}\partial^x \partial^y. \tag{42}$$

The Leibnitz rule (13) in differential calculus is defined by the following R matrix:

$$R = \begin{bmatrix} q^2 & 0 & 0 & 0 \\ 0 & q & q^2-1 & 0 \\ 0 & 0 & q & 0 \\ 0 & 0 & 0 & q^2 \end{bmatrix}, \quad R' = q^{-2}R. \tag{43}$$

It is easy to check the explicit form of the transformation operator for monomials of the first order:

$$\zeta_x^x x = q^2 x, \quad \zeta_x^x y = qy, \quad \zeta_y^x x = (q^2-1)y, \quad \zeta_y^x y = 0, \tag{44}$$

$$\zeta_y^y y = q^2 y, \quad \zeta_y^y x = qx, \quad \zeta_x^y y = 0, \quad \zeta_x^y x = 0. \tag{45}$$

These formulas together with the condition (16), yield the inverse transformation operator, which can be described explicitly on monomials of the first order as

$$\zeta_x^{-\,x} x = q^{-2}x, \quad \zeta_x^{-\,x} y = q^{-1}y, \quad \zeta_y^{-\,x} x = (q^{-2}-1)y, \quad \zeta_y^{-\,x} y = 0, \tag{46}$$

$$\zeta_y^{-\ y} y = q^{-2} y, \quad \zeta_y^{-\ y} x = q^{-1} x, \quad \zeta_x^{-\ y} y = 0, \quad \zeta_x^{-\ y} x = 0. \tag{47}$$

We shall investigate the wave equation on a quantum plane:

$$\Box \Phi = \partial^a \partial^b g_{ba} \Phi = (\partial^x \partial^y + q \partial^y \partial^x) \Phi = 0. \tag{48}$$

From the general formula for the Γ_μ operator (32), we obtain in our case the following operator of the first order:

$$\Gamma_x = q \overleftarrow{\partial}^{\dagger\, y} + \partial^y, \quad \Gamma_y = \overleftarrow{\partial}^{\dagger\, x} + q \partial^x. \tag{49}$$

The modified Γ operator looks as follows (34):

$$\hat{\Gamma}_x = \overleftarrow{\partial}^{\dagger\, x} \overleftarrow{\zeta}_x^{-\ y} + q\, \overleftarrow{\partial}^{\dagger\, y} \overleftarrow{\zeta}_x^{-\ x} + q \overleftarrow{\zeta}_x^{-\ y} \partial^x + \overleftarrow{\zeta}_x^{-\ x} \partial^y, \tag{50}$$

$$\hat{\Gamma}_y = \overleftarrow{\partial}^{\dagger\, x} \overleftarrow{\zeta}_y^{-\ y} + q\, \overleftarrow{\partial}^{\dagger\, y} \overleftarrow{\zeta}_y^{-\ x} + q \overleftarrow{\zeta}_y^{-\ y} \partial^x + \overleftarrow{\zeta}_y^{-\ x} \partial^y. \tag{51}$$

Having constructed the $\hat{\Gamma}_\mu$ operator we are able to derive the conservation laws and explicit conserved currents for the wave equation. To this aim we need the solutions of (48) and of its conjugation:

$$\Phi' \overleftarrow{\Box}^{\dagger} = \Phi' (\overleftarrow{\partial}^{\dagger\, y} \overleftarrow{\partial}^{\dagger\, x} + q \overleftarrow{\partial}^{\dagger\, x} \overleftarrow{\partial}^{\dagger\, y}) = 0. \tag{52}$$

Let us notice that the function

$$\Phi(x,y) = \phi_1(x) + \phi_2(y), \tag{53}$$

where ϕ_1 and ϕ_2 are arbitrary functions is always a solution for the equation (48). More solutions can be produced from the above solution Φ using the symmetry operators that transform solutions into solutions. The set of symmetry operators for (48) includes momenta $P^x = \partial^x$, $P^y = \partial^y$; rotation operator $M = x \partial^x - y \partial^y$; dilatation operator $D = x \partial^x + y \partial^y$; and conformal boosts $K^x = (xy) \partial^x - qyD$ and $K^y = (xy) \partial^y - xD$.

These operators are quantum deformations for conformal algebra on two-dimensional space. Additionally, one can show that the operators from infinite-dimensional set:

$$L^m = x^m \partial^x, \quad \tilde{L}^n = y^n \partial^y, \quad n,m > 1, \tag{54}$$

also produces the solution from the solution of the wave equation (48).

According to Proposition 5.1 we obtain the currents connected with deformed conformal algebra $\delta^\omega \in \{P^x, P^y, M, D, K^x, K^y\}$:

$$J_\mu^\omega = \Phi' \hat{\Gamma}_\mu (\partial, \overleftarrow{\partial}^{\dagger}) \delta^\omega \Phi, \tag{55}$$

which fulfill the conservation law:

$$\partial^x J_x^\omega + \partial^y J_y^\omega = 0. \tag{56}$$

The operators L^m and $\tilde{L}^n$ add to the set of conserved currents the following expressions:

$$J_\mu^m = \Phi' \hat{\Gamma}_\mu (\partial, \overleftarrow{\partial}^{\dagger}) L^m \Phi, \quad \tilde{J}_\mu^n = \Phi' \hat{\Gamma}_\mu (\partial, \overleftarrow{\partial}^{\dagger}) \tilde{L}^n \Phi, \quad n,m > 1. \tag{57}$$

B. The conserved currents for scalar wave equation on *q*-Minkowski space

Let us now pass to the scalar wave equation on q-Minkowski space. We have studied this equation in Ref. 16 within the framework given by Azcárraga, Kulish, and Rodenas.[17,18] Now we would like to derive conservation laws using the formalism by Majid, the more interesting that in Ref. 19 he introduced q-conformal algebra in the scalar and spinor representation and showed that it is also a braided Hopf algebra.

We shall follow the notations of Majid from the mentioned paper. The momenta fulfill the conditions

$$p^i p^j = (R')^{ij}_{kl} p^l p^k, \tag{58}$$

$$p^i x_j = -\delta^i_j + x_k (R^{-1})^{ik}_{lj} p^l. \tag{59}$$

The q-conformal algebra includes momenta $\mathbf{p}$, rotations $\mathbf{l}^+$ and $\mathbf{l}^-$, dilatation operator $\mathbf{s}$, and special conformal generators $\mathbf{c}$. They form braided Hopf algebra with algebraic relations (written in vector form):

$$\mathbf{l}_1^\pm \mathbf{l}_2^\pm \mathbf{R} = \mathbf{R} \mathbf{l}_2^\pm \mathbf{l}_1^\pm, \quad \mathbf{l}_1^+ \mathbf{l}_2^- \mathbf{R} = \mathbf{R} \mathbf{l}_2^- \mathbf{l}_1^+, \tag{60}$$

$$\mathbf{l}_1^+ \mathbf{p}_2 = \frac{1}{\lambda} \mathbf{R}_{21}^{-1} \mathbf{p}_2 \mathbf{l}_1^+, \quad \mathbf{l}_1^- \mathbf{p}_2 = \lambda \mathbf{R} \mathbf{p}_2 \mathbf{l}_1^-, \tag{61}$$

$$\mathbf{s}\mathbf{p} = \frac{\mathbf{1}}{\lambda} \mathbf{p}\mathbf{s}, \quad \mathbf{l}^\pm \mathbf{s} = \mathbf{s} \mathbf{l}^\pm, \tag{62}$$

and for special conformal generators we have

$$\mathbf{c}_2 \mathbf{c}_1 = \mathbf{c}_1 \mathbf{c}_2 \mathbf{R}', \quad \mathbf{s}\mathbf{c} = \lambda \mathbf{c}\mathbf{s}, \tag{63}$$

$$\mathbf{l}_1^+ \mathbf{c}_2 = \lambda \mathbf{c}_2 \mathbf{l}_1^+ \mathbf{R}_{21}, \quad \mathbf{l}_1^- \mathbf{c}_2 = \frac{1}{\lambda} \mathbf{c}_2 \mathbf{l}_1^{-1} \mathbf{R}^{-\mathbf{1}}, \tag{64}$$

with the following commutation relation between momenta and special conformal generators:

$$\mathbf{p}\mathbf{c} = \mathbf{c}\mathbf{p} + \frac{\mathbf{l}^+ \mathbf{s}^{-\mathbf{1}} - \mathbf{l}^- \mathbf{s}}{q - q^{-1}}. \tag{65}$$

We see from (59) that in our case the transformation operators ζ and ζ^- for $-\mathbf{p}$ look as follows:

$$\zeta^i_j x_m = (R^{-1})^{ik}_{jm} x_k, \tag{66}$$

$$\zeta^{-\ i}_j x_m = \hat{R}^{ik}_{jm} x_k, \tag{67}$$

where the matrix $\hat{R}$ is the second inverse of R^{-1} fulfilling the condition

$$\hat{R}^{ib}_{al} (R^{-1})^{ak}_{jb} = (R^{-1})^{ib}_{al} \hat{R}^{ak}_{jb} = \delta^i_j \delta^k_l. \tag{68}$$

Now, the scalar wave equation on q-Minkowski space is of the form

$$\Box \Phi = p^i p^j g_{ji} \Phi = 0. \tag{69}$$

The set of symmetry operators for the above equation includes momenta $\mathbf{p}$, rotation operators $\mathbf{l}^\pm$, dilatation $\mathbf{s}$, and conformal boosts $\mathbf{K} = \mathbf{c} + (\mathbf{x}_1 \mathbf{l}_1^+ \mathbf{s}^{-\mathbf{1}} - \mathbf{x}_1 \mathbf{l}_1^- \mathbf{s})/(q - q^{-1})$, where $\mathbf{x}_1 \mathbf{l}_1^\pm$ is a vector with components $(\mathbf{x}_1 \mathbf{l}_1^\pm)_k = x_m l^{\pm\ m}_k$.

The momenta and rotations commute with the d'Alembert operator (69) due to the following properties of R and R' matrices,[11]

$$g_{ka}R^{ia}_{jl}=\frac{1}{\lambda^2}(R^{-1})^{ia}_{jk}g_{al}, \quad g_{ka}\tilde{R}^{ia}_{jl}=\lambda^2 R^{ia}_{jk}g_{al}, \tag{70}$$

$$g_{ai}R^{ak}_{jl}=\frac{1}{\lambda^2}(R^{-1})^{ak}_{il}g_{ja}, \quad g_{ai}\tilde{R}^{ak}_{jl}=\lambda^2 R^{ak}_{il}g_{ja}, \tag{71}$$

$$R'^{ak}_{jl}g_{ai}=(R'^{-1})^{ak}_{il}g_{ja}. \tag{72}$$

The above formulas also yield the explicit expression for the matrix $\hat{R}$ used in the construction of the inverse operator (67):

$$\hat{R}^{ij}_{kl}=\frac{1}{\lambda^2}g^{ja}g_{lb}(R^{-1})^{ib}_{ka}. \tag{73}$$

The dilatation operator does not commute with the d'Alembert operator, but it belongs to the set of symmetry operators due to the relation

$$\Box \mathbf{s}=\lambda^2 \mathbf{s}\Box. \tag{74}$$

Let us notice that we have modified the special conformal generators so as to obtain the symmetry operators $\mathbf{K}$ without imposing any condition on rotation operators $\mathbf{l}^{\pm}$.

To derive the conservation law we construct the Γ_μ operator

$$\Gamma_\mu(\mathbf{p},\overleftarrow{\mathbf{p}}^\dagger)=\overleftarrow{p}^{\dagger j}g_{j\mu}+g_{\mu j}p^j, \tag{75}$$

where

$$p^{\dagger j}=-p^k\zeta^{-\,j}_k.$$

The modified operator $\hat{\Gamma}_\mu$ includes the ζ^- operator (67):

$$\hat{\Gamma}_\mu(\mathbf{p},\overleftarrow{\mathbf{p}}^\dagger)=\overleftarrow{p}^{\dagger k}\overleftarrow{\zeta}^{-\,j}_\mu g_{kj}+\overleftarrow{\zeta}^{-\,j}_\mu g_{jk}p^k. \tag{76}$$

Now we can write down the currents following Proposition 5.1:

$$J^\omega_\mu=\Phi'\hat{\Gamma}_\mu(\mathbf{p},\overleftarrow{\mathbf{p}}^\dagger)\,\delta^\omega\Phi, \tag{77}$$

with $\delta^\omega\in\{\mathbf{p},\mathbf{l}^+,\mathbf{l}^-,\mathbf{s},\mathbf{K}\}$.

They obey the conservation law:

$$\sum_\mu p^\mu J^\omega_\mu=0. \tag{78}$$

VII. FINAL REMARKS

Let us notice that noncommutative spaces were studied by Doplicher, Fredenhagen, Roberts[20,21] and Madore and Mourad in Ref. 22 in the context of quantization of Minkowski space–time.

In the paper we have considered the fundamental properties of free field-theoretic models on a class of noncommutative spaces including q-Minkowski space. We obtained the conservation laws for a wide class of linear equations on braided linear spaces. In this paper we have extended the results derived in Refs. 3–6 for discrete spaces and for quantum Minkowski spaces.

The next step after the construction of conserved currents is to investigate the integrals of motion. In classical field theory as well as for discrete spaces,[3,4] they are produced from the time component of conserved current by integrating over space-like dimensions. In the noncommutative case the rules of integration still need further development. For braided linear spaces the global integration was introduced in papers by Chryssomalakos[23,24] and Kempf and Majid.[25] In the mentioned construction the main feature of global integration is its invariance with respect to translations. Thus, integrals of the functions that have a proper asymptotic behavior yield the vanishing boundary terms. In the derivation of integrals of motion we should apply the global integral over space-like dimensions. To this aim we shall formulate the Fubini theorem in which we express the global integral over whole space as a sequence of the iterated integrals. Having constructed iterated integrals, we will be able to follow the classical method and use conserved currents in the derivation of an analog of the integral of motion for specific noncommutative spaces.

APPENDIX: THE UNIQUE SOLUTION OF THE OPERATOR EQUATION (27)

Proof of the Proposition 4.1: We denote the monomials of derivatives by formulas (30), (31). Due to the modified Leibnitz rule (19), we should consider the solution of the operator equation (27) in the form of the polynomial of order $N-1$ with arbitrary coefficients:

$$\Gamma_\mu(\partial,\overleftarrow{\partial}^\dagger)=a^0_\mu+\sum_{l=1}^{N-1}\sum_{k=0}^{l}\overline{[\mu_1,\ldots,\mu_k]}a^k_{\mu\mu_1\cdots\mu_l}[\mu_{k+1},\ldots,\mu_l], \tag{A1}$$

where the coefficients a^k can depend on coordinates of covectors $\vec{x}$.

The condition (27) applied to the above polynomial yields the equations for coefficients $a^k_{\mu\mu_1\cdots\mu_l}$:

$$\begin{aligned}\sum_\mu(-\overleftarrow{\partial}^{\dagger\,\mu}+\partial^\mu)\circ\Gamma_\mu(\partial,\overleftarrow{\partial}^\dagger)=&-\sum_{l=1}^{N-1}\sum_{k=0}^{l}\sum_\mu\overline{[\mu_1,\ldots,\mu_k,\mu]}a^k_{\mu\mu_1\cdots\mu_l}[\mu_{k+1},\ldots,\mu_l]\\&+\sum_{l=1}^{N-1}\sum_{k=0}^{l}\overline{[\mu_1,\ldots,\mu_k]}\sum_\mu(\zeta^\mu_\nu a^k_{\mu\mu_1\cdots\mu_l})[\nu,\mu_{k+1},\ldots,\mu_l]\\&+\sum_{l=1}^{N-1}\sum_{k=0}^{l}\overline{[\mu_1,\ldots,\mu_k]}\sum_\mu(\partial^\mu a^k_{\mu\mu_1\cdots\mu_l})[\mu_{k+1},\ldots,\mu_l]-\sum_\mu\overline{[\mu]}a^0_\mu\\&+\sum_\mu(\zeta^\mu_\nu a^0_\mu)[\nu]+\sum_\mu(\partial^\mu a^0_\mu)=\Lambda(\partial)-\Lambda(\overleftarrow{\partial}^\dagger).\end{aligned} \tag{A2}$$

The resulting set of equations for functions $a^k_{\mu\mu_1\cdots\mu_l}$ is of the form

$$a^0_\mu=\Lambda_\mu, \tag{A3}$$

$$\partial^\alpha a^0_{\alpha\mu}+\zeta^\nu_\mu a^0_\nu=\Lambda_\mu, \tag{A4}$$

$$\zeta^\alpha_\mu a^0_{\alpha\mu_1\ldots\mu_l}+\partial^\alpha a^0_{\alpha\mu\mu_1\ldots\mu_l}=\Lambda_{\mu\mu_1\cdots\mu_l}, \tag{A5}$$

$$-a^k_{\mu\mu_1\cdots\mu_l}+\zeta^\alpha_{\mu_{k+1}}a^{k+1}_{\alpha\mu_1\cdots\mu_k\mu\mu_{k+2}\cdots\mu_l}+\partial^\alpha a^{k+1}_{\alpha\mu_1\cdots\mu_k\mu\mu_{k+1}\cdots\mu_l}=0, \tag{A6}$$

$$a^l_{\mu\mu_1\cdots\mu_l}+\partial^\alpha a^l_{\alpha\mu_1\cdots\mu_l\mu}=\Lambda_{\mu_1\cdots\mu_l\mu}, \tag{A7}$$

with $l=1,\ldots,N-1$, $k=0,\ldots,l-1$.

We begin to solve this set of equations by deriving the coefficients $a^0_{\mu\mu_1\cdots\mu_l}$ from Eqs. (3)–(5). Namely, for $l=N-1$ we have

$$\zeta_\mu^\alpha a^0_{\alpha\mu_1\cdots\mu_{N-1}} = \Lambda_{\mu\mu_1\cdots\mu_{N-1}}. \tag{A8}$$

Applying the inverse operator ζ^- and using the property of coefficients (24), we obtain:

$$a^0_{\mu\mu_1\cdots\mu_{N-1}} = \Lambda_{\mu\mu_1\cdots\mu_{N-1}}. \tag{A9}$$

We insert this solution into (A5) for $l=N-2$ and solve the next equation:

$$\zeta_\mu^\alpha a^0_{\alpha\mu_1\cdots\mu_{N-2}} + \partial^\alpha \Lambda_{\alpha\mu\mu_1\cdots\mu_{N-2}} = \Lambda_{\mu\mu_1\cdots\mu_{N-2}}. \tag{A10}$$

By assumption (23) after using ζ^- operator and (24), we derive $a^0_{\mu\mu_1\cdots\mu_{N-2}}$ as

$$a^0_{\mu\mu_1\cdots\mu_{N-2}} = \Lambda_{\mu\mu_1\cdots\mu_{N-2}}. \tag{A11}$$

Passing to the next equation from the subset (A5) and solving them in the similar way, we obtain the unique solution for coefficients a^0:

$$a^0_\mu = \Lambda_\mu, \quad a^0_{\mu\mu_1\cdots\mu_l} = \Lambda_{\mu\mu_1\cdots\mu_l}, \quad l=1,...,N-1. \tag{A12}$$

This R'-symmetric solution for initial coefficients allows us to evaluate the remaining ones using (A6), (A7), namely, we obtain the a^1 coefficients after writing the subset (A6) for $k=0$ and solving it the way we solved the subset (A3)–(A5) for a^0. The result is unique and looks as follows:

$$a^1_{\mu\mu_1\mu_2\cdots\mu_l} = \Lambda_{\mu_1\mu\mu_2\cdots\mu_l}, \quad l=1,...,N-1. \tag{A13}$$

The same method applied to subsets of (A6), (A7) for $k=1,...,N-2$ produces the unique solution of the set of equations for coefficients in the form

$$a^k_{\mu\mu_1\cdots\mu_l} = \Lambda_{\mu_1\cdots\mu_k\mu\mu_{k+1}\cdots\mu_l}, \quad l=1,...,N-1. \tag{A14}$$

The derivation of the explicit formulas for a unique solution of the coefficients of the operator Γ_μ concludes the proof of Proposition 4.1.

Let us notice once more that in the derivation of coefficients for the Γ_μ operator the crucial factors were the properties of coefficients of the equation (21), which enabled us to solve the equation (27) in the explicit form.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 40, NUMBER 8 AUGUST 1999

Comment on ''The complete Schwarzschild interior and exterior solution in the harmonic coordinate system'' [J. Math. Phys. 39, 6086 (1998)]

László Á. Gergely
Laboratoire de Physique Théorique, Université Louis Pasteur, 3-5 rue de l'Université 67084 Strasbourg Cedex, France[a)]
and KFKI Research Institute for Particle and Nuclear Physics, Budapest 114, P.O. Box 49, H-1525 Hungary

(Received 18 November 1998; accepted for publication 17 March 1999)

[S0022-2488(99)01408-5]

In a recent paper Liu[1] considered the complete Schwarzschild interior and exterior solution in harmonic coordinates. There he argued about the necessity to keep the integration constant C_1 in R_{ex}, in contrast with previous treatments (Refs. 1–5 and 8 of Ref. 1). The purpose of this comment is to show that the above conclusion cannot be traced from the matching conditions between the vacuum exterior and the uniform density interior perfect fluid, as claimed in Ref. 1. The reason for this is that the last condition in Eqs. (7) of Ref. 1, namely $R'_{in}(a) = R'_{ex}(a)$, is *not* required by the junction conditions at $r=a$, as will be shown in what follows.

The junction of two space–times along a timelike hypersurface Σ can be done applying the Darmois–Israel matching procedure,[2,3] which requires the continuity across the junction of both the first and second fundamental forms (induced metric and extrinsic curvature) *of the junction hypersurface.*

In the standard coordinates, the metric (1) of Ref. 1 induces the three-metric given by the line element

$$ds^2_\Sigma = E(r)dt^2 - r^2(d\theta^2 + \sin^2\ \theta d\phi^2) \tag{1}$$

on the junction hypersurface $r=a$, which has the normal $n=1/\sqrt{G}\partial/\partial r$ and the nonvanishing extrinsic curvature components

$$K_{00} = -\frac{E'}{2\sqrt{G}}, \quad K_{22} = \frac{r}{\sqrt{G}}, \quad K_{33} = \frac{r}{\sqrt{G}} \sin^2\theta. \tag{2}$$

The continuity of both (1) and (2) implies that the metric function G is continuous and E is $\mathcal{C}^1$ across the junction. It is not to be expected that starting from the metrics written in other coordinate systems the conditions on E and G will be weakened. However, constraints on the new function R introduced by the coordinate transformation (2)–(5) of Ref. 1 will also emerge.

In the harmonic coordinate system the normal vector to Σ has the components $n^\mu = (\ln R)'/\sqrt{G}(0,X_1,X_2,X_3)$. The metric (6) of Ref. 1 (with a missing square on the last bracket corrected) induces the first fundamental form

$$ds^2_\Sigma = E(r)dt^2 - \frac{r^2}{R^2(r)}\, d\mathbf{X}^2. \tag{3}$$

This is still expressed in terms of the four space–time coordinates. When written in terms of the coordinates t, θ, and ϕ, intrinsic to Σ, the continuity of the induced metric again implies the

[a)]Visiting position, supported by the Hungarian State Eötvös Fellowship.

continuity of the metric function E alone. The extrinsic curvature tensor in the new coordinate system is found either by direct computation or by transforming its components (2) from standard to harmonic coordinates. The nonvanishing components are K_{00} given in (2) and

$$K_{ii}=\frac{(X_j^2+X_k^2)r}{R^4\sqrt{G}}\,, \quad K_{ij}=-\frac{X_iX_jr}{R^4\sqrt{G}}\,, \tag{4}$$

where $i\neq j\neq k$ take the values 1,2,3. The junction condition on the extrinsic curvature at arbitrary radius implies that G, R, and E' should be continuous. Altogether we find that G and R are $\mathcal{C}^0$ and E is $\mathcal{C}^1$. Thus the last relation in (7) of Ref. 1 does not hold.

The condition

$$E'_{in}=E'_{ex}\,, \tag{5}$$

though not listed among the continuity conditions (7) of Ref. 1, was fulfilled when imposing that the pressure vanishes on the junction. Indeed, Eq. (5) is a substitute for the requirement that the radial pressures on the two sides of Σ are equal, which was demonstrated for generic spherically symmetric static space–times in another context.[4]

Our criticism does not affect the main result of Ref. 1, which is the solution of R_{in} of the second-order differential equation (22) of Ref. 1. The arguments about the integration constants, however, should be reviewed. Requiring only the continuity of R and nothing more, one of the constants C_1 and C_2 can be freely specified, in particular $C_1=0$ can be chosen, in accordance with Refs. 1–5 and 8 of Ref. 1. Of course, the continuity of R' across the junction of the interior and exterior Schwarzschild solutions can be imposed as an additional requirement for other purposes [e.g., for having a smooth function $R(r)$ as in Ref. 1], but it is not a consequence of the junction conditions.

Response to ''Comment on 'The complete Schwarzschild interior and exterior solution in the harmonic coordinate system' '' [J. Math. Phys. 40, 4177 (1999)]

Quan-Hui Liu
Department of Physics, Hunan University, Changsha 410082, People's Republic of China and Institute of Theoretical Physics, Academia Sinica, P.O. Box 2735, Beijing 100080, People's Republic of China[a)]

(Received 10 March 1999; accepted for publication 17 March 1999)

[S0022-2488(99)01508-X]

The preceding comment[1] applied the Darmois–Israel matching condition to the Schwarzschild interior and exterior solution in the harmonic coordinate system, and correctly pointed out that from this matching condition, one of the constants C_1 and C_2 in Eqs. (13) and (23) of my paper[2] can be freely specified, in particular $C_1=0$ can be chosen.

If only imposing the Darmois-Israel matching condition on the complete harmonic coordinates,[2] there are in fact infinite choices. I agree with Weinberg[3] that the particular choice $C_1=0$ is a ''convenient'' one. But we cannot use only this choice while keeping silent on the other possibilities. I used one half of the Darmois–Israel matching condition, the extrinsic-curvature and an *ad hoc* condition, the metric components, are continuous. It is equivalent to impose $R'_{in}(a)=R'_{ex}(a)$ on the Darmois–Israel matching condition to uniquely determine C_1 and C_2. We are confident that it is a good and reasonable choice. Furthermore, even C_1 and C_2 can be freely specified; we must carefully specify them. For example, a bad choice $C_2=0$ is presented in the Darmois–Israel matching condition. For our purpose of treating a star of $r=a$ with $a=9M/4\neq 0$,[2] this choice means that all the interior coordinates vanish, the metric components are singular, the proper time undefinable, and the whole interior gravitational field appears singular.

(Received 13 April 1999; accepted for publication 13 April 1999)

[S0022-2488(99)02308-7]

There are some mistakes in Eqs. (11), (12), (15) and the formula (A4). The correct ones should be

$$u_t(n+1)+u_t(n-1)+u_t(n)+\tfrac{3}{4}(u(n+1)-u(n-1))^2+\tfrac{1}{4}(u(n+1)+u(n-1)-2u(n))^2 +\tfrac{1}{4}(v(n)-1)=0, \tag{11}$$

$$[(3D_t^2e^{D_n}+3D_t^2-e^{D_n}+1)f(n)\cdot f(n)]f(n)^2-[(1-e^{D_n})f(n)\cdot f(n)](D_t^2 f(n)\cdot f(n)) +D_t^2[(e^{D_n}-1)f(n)\cdot f(n)]\cdot f^2(n)=0, \tag{12}$$

$$u_t(n)+(T_++T_-+1)^{-1}[\tfrac{3}{4}(u(n+1)-u(n-1))^2+\tfrac{1}{4}(u(n+1)+u(n-1)-2u(n))^2 +\tfrac{1}{4}(v(n)-1)]=0, \tag{15}$$

$$(D_t^3D_z a\cdot a)a^2-(D_zD_t a\cdot a)(D_t^2 a\cdot a)=D_t^2(D_zD_t a\cdot a)\cdot a^2. \tag{A4}$$

In this case, (10) and (11) can be reduced to the equation found in Ref. 1. However, we can derive the following z flow from (13) and (14) by viewing t as an auxiliary variable:

$$U_{zz}(n)+U_z(n)(U_z(n-1)-U_z(n+1))=4e^{U(n+2)-U(n-1)}-4e^{U(n+1)-U(n-2)},$$

where $U(n)=\ln(f(n+1)/f(n))$. A Lax pair for it could be easily obtained from the bilinear Bäcklund transformation (16)–(18):

$$4\lambda^2e^{U(n+3)-U(n)}\psi_{n+3}+\lambda U_z(n+1)\psi_{n+2}-\psi_{n+1}+(\omega+2\lambda^{-1}\gamma^3)\psi_n=0,$$

$$\psi_{nz}+U_z(n)\psi_n+\lambda^{-1}\psi_{n-1}+\mu\psi_n=0,$$

where we have set $U(n)=\ln(g(n+1)/g(n))$, $f(n)=\psi_n g(n+1)$.

The mistakes that appeared in (11), (12), (15), and (A4) do not affect all the other deductions and calculations in the paper.

Point and line boundaries in scalar Casimir theory

Alfred Actor[a)]
Department of Physics, The Pennsylvania State University, Fogelsville, Pennsylvania 18051

(Received 6 February 1998; accepted for publication 16 April 1999)

A simple image-charge construction enables one to insert point or line boundaries (or planar or hyperplanar boundaries when sufficiently many spatial dimensions are available) at or into the central point, line, plane etc., of a great range of spatial backgrounds in quantum field theory which have appropriate symmetry. This nontrivial construction (which provides among other things the exact vacuum stress tensor $T_{\mu\nu}$ of the quantum field if $T_{\mu\nu}$ can be computed for the original background prior to point, line,..., insertion) works if all directions x_i perpendicular to the inserted object are symmetric under $x_i \rightarrow -x_i$. In other respects the symmetric spatial background can be quite arbitrary. While the inserted object experiences (by symmetry) no net Casimir force from the background, it does exert Casimir forces throughout this background which were originally not present. In addition to general theory, detailed examples are given (which include exact field $T_{\mu\nu}$'s and exact Casimir force densities) for arbitrary spatial dimension. First: point and line boundaries in otherwise empty space; then a planar boundary with a semi-infinite line extending from one side; finally, parallel planar boundaries with a point boundary halfway between them. Only scalar quantum fields are analyzed here; however the extension to the electromagnetic Casimir effect is discussed qualitatively. [S0022-2488(99)03807-4]

I. INTRODUCTION

A simple image-charge construction enables one to insert a point boundary or a line boundary into existing appropriately symmetric spatial backgrounds in quantum field theory (QFT). This construction involves reflection through the point or line to be occupied by the inserted boundary and the required background symmetry is thereby determined: The spatial background must be invariant under $x_i \rightarrow -x_i$ in all directions x_i perpendicular to the inserted object. (All spatial directions are perpendicular to a point.) Otherwise the spatial background can be quite arbitrary. Image-charge constructions are, of course, very familiar for planar boundary surfaces. The method here is an extension, of what one routinely does for planar surfaces, to reflections in two and more dimensions. Hyperplanes can similarly be inserted into appropriate backgrounds when sufficiently many dimensions are available. However, our attention here will be limited to point and line boundaries in scalar QFT.

By symmetry the inserted object (point, line,...) experiences no *net* Casimir force from the symmetric background into which it has been inserted. This balanced situation keeps the mathematics manageable and enables our simple but general construction to work. (In a nonsymmetric background the inserted object will experience a net Casimir force and one is confronted with a far more difficult problem.) The inserted object will, of course, exert (symmetrically in directions perpendicular to itself) Casimir forces throughout the original background which were nonexistent prior to its insertion. These additional Casimir forces may be complicated. Nonetheless, as we shall see, if one can calculate the vacuum stress tensor $T_{\mu\nu}$ for the original background, then one can also calculate $T_{\mu\nu}$ for the substantially more complicated system with inserted point or line boundary. From $T_{\mu\nu}$ all Casimir forces can straightforwardly be obtained, including the new forces exerted by the point or line boundary.

[a)]Electronic mail: aaa2@psu.edu

The image-charge construction presented here at a far more general level was first noticed[1] for the symmetric background called empty space. Otherwise these point and line boundary constructions can (to the author's knowledge) be found nowhere in the literature. Because this method provides quantitative access to many Casimir systems that could not previously be solved exactly, its description in some detail should be of interest to other workers in this area of QFT.

A secondary topic in this article will be the use of point and line boundary insertions into a scalar quantum field already distorted by an existing background to test the following hypotheses: (1) Distinct Dirichlet boundary (or background) objects mutually *attract*. (2) Distinct Neumann boundary objects mutually *attract*. (3) Distinct Dirichlet and Neumann objects mutually *repel*. This behavior has been observed for a variety of boundary geometries (in Refs. 2 and 3 and related unpublished calculations[4]). A typical Dirichlet (Neumann)—hereafter we use $D(N)$—object is understood to be a spatial surface on which the scalar quantum field $\hat{\phi}$ must satisfy $D(N)$ boundary conditions. The characterization ''distinct'' used above is important and means the object is, in a geometrical sense, uniquely defined. For comparison, in this context a cylindrical or spherical surface should *not* be imagined as consisting of two or more (obviously quite nonunique) pieces glued together. However, a plane with a line projecting from one side can reasonably be thought of as consisting of two distinct pieces, even though these pieces touch.

As will be seen, in the explicit examples considered in this paper rules (1)–(3) above hold unambiguously. This gives us additional confidence in the robustness of these rules and their (qualitative) independence of the geometric details of the boundaries involved.

The author has a preference for D over N boundary conditions in scalar QFT. One reason is that the notion of a D object can be generalized in an apparently deep way by introducing[3,5] a potential $V=V(\vec{x},t)\geqslant 0$ into the wave equation $\Box\hat{\phi}=0$ for a massless scalar field;

$$[\Box+V(\vec{x},t)]\hat{\phi}=0. \tag{1.1}$$

This brings great flexibility into the subtle process of coupling a quantum field to background structures which (partially or completely) expel it from those regions of space they occupy. Such a natural and compelling generalization of N boundary conditions seems to be impossible.

Another point to mention concerning N boundary conditions is an occasional sensitivity of the Casimir forces associated with them to one's choice of stress tensor. Scalar fields do not have a unique stress tensor. Commonly employed are the canonical ($T_{\mu\nu}$) and improved ($\theta_{\mu\nu}$) tensors. In the past (see Ref. 2 and unpublished work) one has noticed the existence of (a few) boundary geometries for which $T_{\mu\nu}$ and $\theta_{\mu\nu}$ yield different Casimir force densities when N conditions are involved. However, this seems never to happen when only D conditions are involved. This line of inquiry will be continued here for backgrounds with point and line boundaries. Again we find no evidence for ambiguous Casimir forces in pure Dirichlet systems, but some indication of such ambiguity when one or more boundary objects are Neumann.

The contents of this paper are now described. Section II presents the construction of isolated point and line boundaries in free space (of arbitrary dimension d) for a massless scalar field. Nonzero field mass $M>0$ does not introduce any particular problems and we choose $M=0$ merely for simplicity. Reference 1 discussed this same problem for $M\geqslant 0$ but only in terms of heat kernels. Here we present a more complete discussion beginning with the field modes and ending with the vacuum stress tensor of a scalar field distorted by an isolated point or line boundary in d-dimensional (and otherwise empty) space. Periodic arrays of these objects are also easily constructed and this is briefly discussed.

In Sec. III we show how in d dimensions to insert a line boundary perpendicular to an existing arbitrary one-dimensional (1D) background—say a 1D potential $V=V(x_d)$ with the line boundary parallel to the x_d axis. This is illustrated by a simple example: an infinite planar boundary with a semi-infinite line boundary extending from one side. The $T_{\mu\nu}$ and $\theta_{\mu\nu}$ of the distorted field are calculated and the nonuniform Casimir force density exerted by the projecting line on the plane is determined.

Section IV discusses and solves the problem of inserting point and line boundaries into the symmetry midplane of a symmetric (but otherwise arbitrary) 1D background—say a 1D symmetric potential $V=f(x_1^2)$ with midplane $x_1=0$. This is illustrated by a fairly complicated example: parallel planar boundaries with a point boundary in the midplane. $T_{\mu\nu}$ and $\theta_{\mu\nu}$ for the distorted quantum field between the planes are calculated, and from these the nonuniform Casimir force densities exerted by the point boundary on the planes are found.

Section V outlines the general point and line boundary construction procedure for an arbitrary background potential $V=V(\vec{x})$ having the required symmetry. Interesting examples here would include the insertion of a point boundary at the center of a spherical or rectangular cavity, or a line boundary through the center of these cavities, or a line boundary along the axis of a circular or rectangular waveguide, and so on. All of these calculations and many others are straightforward by our method, but for lack of space no additional examples can be presented here.

Further discussion will be found in Sec. VI, including comments on the relevance of these scalar field considerations to the electromagnetic case.

II. POINT AND LINE BOUNDARIES IN FREE SPACE

To illustrate the construction procedure for point and line boundaries consider what can be done with the ordinary plane-wave modes of QFT in d spatial dimensions.

Free space:

$$\phi(\vec{x}|\vec{k})_{0d}=(2\pi)^{-d/2}e^{i\vec{k}\cdot\vec{x}},$$

$$\text{all } \vec{x}, \quad -\infty<k_{1,2,\ldots,d}<\infty. \tag{2.1}$$

Planar boundary at $x_1=0$: $\eta_{D,N}=\mp 1$,

$$\phi(\vec{x}|\vec{k})_{1,d-1}\equiv(2\pi)^{-d/2}[e^{ik_1x_1}+\eta e^{-ik_1x_1}]e^{i(k_2x_2+\cdots+k_dx_d)},$$

$$k_1\geqslant 0, \quad -\infty<k_{2,\ldots,d}<\infty,$$

$$x_1\geqslant 0 \text{ or } \leqslant 0, \quad -\infty<x_{2,\ldots,d}<\infty,$$

$$D: \ \phi(x_1=0)_{1,d-1}=0,$$

$$N: \ \partial_1\phi(x_1=0)_{1,d-1}=0, \quad \forall\vec{k}. \tag{2.2}$$

Line boundary along the x_d *axis* $\vec{u}=(x_1,x_2,\ldots,x_{d-1})=0$: $\eta_{D,N}=\mp 1$,

$$\phi(\vec{x}|\vec{k})_{d-1,1}\equiv(2\pi)^{-d/2}[e^{i\vec{k}\cdot\vec{u}}+\eta e^{-i\vec{k}\cdot\vec{u}}]e^{ik_dx_d},$$

$$k_1\geqslant 0, \quad -\infty<k_{2,\ldots,d}<\infty,$$

$$x_1\geqslant 0 \text{ or } \leqslant 0, \quad -\infty<x_{2,\ldots,d}<\infty,$$

$$D: \ \phi(\vec{u}=0)_{d-1,1}=0, \quad \forall\vec{k},$$

$$N: \ \partial_i\phi(\vec{u}=0)_{d-1,1}=0, \quad i=1,2,\ldots,d-1. \tag{2.3}$$

Point boundary at $\vec{x}=0$: $\eta_{D,N}=\mp 1$,

$$\phi(\vec{x}|\vec{k})_{d0}\equiv(2\pi)^{-d/2}[e^{i\vec{k}\cdot\vec{x}}+\eta e^{-i\vec{k}\cdot\vec{x}}],$$

$$k_1\geqslant 0, \quad -\infty<k_{2,\ldots,d}<\infty,$$

$$x_1 \geqslant 0 \quad \text{or} \quad \leqslant 0, \quad -\infty < x_{2,...,d} < \infty,$$

$$D: \quad \phi(\vec{x}=0)=0, \quad \forall \vec{k}$$

$$N: \quad \partial_i \phi(\vec{x}=0)=0, \quad i=1,...,d. \tag{2.4}$$

In Eqs. (2.2)–(2.4) and throughout this paper the symbol η distinguishes Dirichlet (D) from Neumann (N) boundary conditions: $\eta_D=-1$ and $\eta_N=+1$. Moreover a label $pq=(0,d),(1,d-1),(2,d-2),\ldots,(d-1,1)$, $(d,0)$ is attached to ϕ_{pq} to emphasize the systematics. p represents the number of dimensions $x_1,x_2,\ldots,x_p$ in which an image-charge construction is used, and $q=d-p$ the remaining dimensions $x_{p+1},\ldots,x_d$ unused for this purpose. Between Eqs. (2.2) and (2.3) a number of boundary (hyper) objects in $d>3$ dimensions have been left out: specifically those with $p=2,...,d-2$. We could work with these objects exactly as we do with plane, line, and point boundaries. However, having no interest in these objects at this time we shall leave them entirely out of our discussion. Note that the D modes (2.2)–(2.4) all vanish on the objects on which they are supposed to vanish, while the N modes have vanishing normal derivatives on these same objects. (All directions are normal to a point.) Moreover the choice $\eta=0$ in Eqs. (2.2)–(2.4) eliminates the boundary objects altogether.

The complete orthonormal sets of modes (2.1)–(2.4) are delta-function normalized:

$$\int d^d k \, \phi(\vec{x}|\vec{k}) \overline{\phi}(\vec{y}|\vec{k}) = \delta(\vec{x}-\vec{y}), \tag{2.5}$$

where $k_1,\ldots,k_d$ have the ranges given in Eqs. (2.1)–(2.4) for $\phi=\phi_{pq}(\vec{x}|\vec{k})$. It is understood in Eq. (2.5) that $\vec{x}$ and $\vec{y}$ lie in the same spatial hemisphere, i.e., both $x_1,y_1\geqslant 0$ or both $x_1,y_1\leqslant 0$. Thus $\delta(x_1+y_1)$ vanishes and Eq. (2.5) results. Similarly,

$$\int d^d k \, \phi(\vec{x}|\vec{k}) \overline{\phi}(\vec{x}|\vec{k}') = \delta(\vec{k}-\vec{k}'), \tag{2.6}$$

where terms containing $\delta(\vec{k}+\vec{k}')$ vanish because $\delta(k_1+k_1')$ vanishes. Completeness and orthonormality are the reasons why $\vec{x}$ and $\vec{k}$ in each of Eqs. (2.2)–(2.4) are restricted to a hemisphere: $x_1\geqslant 0$ or $x_1\leqslant 0$ and $k_1\geqslant 0$.

Some standard information on spatial heat kernels is restated briefly in the Appendix. The definition (A1) becomes here

$$K(t|\vec{x},\vec{y})_{pq} \equiv \int d^d k \, e^{-t\vec{k}^2} \phi(\vec{x}|\vec{k})_{pq} \overline{\phi}(\vec{y}|\vec{k})_{pq}.$$

With the help of the formula

$$\frac{1}{2\pi}\int_{-\infty}^{\infty} dk \, e^{-tk^2} e^{ik(x-y)} = \frac{1}{\sqrt{4\pi t}} e^{-(x-y)^2/4t}, \tag{2.7}$$

one easily verifies from modes (2.1) to (2.4) the spatial heat kernels listed below.

Free space:

$$K(t|\vec{x},\vec{y})_{0d} \equiv k_d(t|\vec{x}-\vec{y}) = (2\pi)^{-d}\int_{-\infty}^{\infty} d^d k \, e^{i\vec{k}\cdot(\vec{x}-\vec{y})} e^{-t\vec{k}^2} = (4\pi t)^{-d/2} e^{-(\vec{x}-\vec{y})^2/4t}. \tag{2.8}$$

Planar boundary at $x_1=0$:

$$K(t|\vec{x},\vec{y})_{1,d-1} \equiv [k_1(t|x_1-y_1) + \eta k_1(t|x_1+y_1)] k_{d-1}(t|x_2-y_2,\ldots,x_d-y_d). \tag{2.9}$$

Line boundary along the x_d axis:

$$K(t|\vec{x},\vec{y})_{d-1,1}\equiv\{k_{d-1}(t|x_1-y_1,\ldots,x_{d-1}-y_{d-1}) + \eta k_{d-1}(t|x_1+y_1,\ldots,x_{d-1}+y_{d-1})\}k_1(t|x_d-y_d). \tag{2.10}$$

Point boundary at $\vec{x}=0$:

$$K(t|\vec{x},\vec{y})_{d0}\equiv k_d(t|\vec{x}-\vec{y})+\eta k_d(t|\vec{x}+\vec{y}). \tag{2.11}$$

Again, in these formulas $\eta=-1$ for D and $\eta=+1$ for N boundary conditions. Also k_n always means the free-space heat kernel (2.8) for n spatial dimensions. One verifies that k_1 satisfies the free 1D heat equation

$$(-\partial_x^2)k_1(t|x\pm y)=(-\partial_y^2)k_1(t|x\pm y)=\partial_t k_1(t|x\pm y). \tag{2.12}$$

Each of the heat kernels (2.8)–(2.11) therefore satisfies the free-space heat equation

$$(-\Delta_x)K_{pq}=(-\Delta_y)K_{pq}=\partial_t K_{pq}. \tag{2.13}$$

Moreover the K_{pq} all fulfill the boundary conditions they are supposed to satisfy. Thus they are the correct heat kernels for these systems.

The heat kernels (2.9)–(2.11) were deduced in Ref. 1 without any discussion of the modes ϕ_{pq}. The derivation here is more complete. In Ref. 1 it was observed that the heat kernels for infinite arrays of equally spaced points or lines can also be obtained quite simply. For example, in mode language the isolated-point modes (2.4) can be replaced by

$$\phi(\vec{x}|\vec{k})_{d0}\equiv(2\pi)^{-d/2}\sum_{b=-\infty}^{\infty}[e^{i\vec{k}\cdot(\vec{x}+b\vec{B})}+\eta e^{i\vec{k}\cdot(-\vec{x}+b\vec{B})}], \tag{2.14}$$

where $\vec{B}$ is any constant vector. Here $\phi(\vec{x}=m\vec{B}|\vec{k})_{d0}^D=0$ for any integer m; also $\partial_i\phi(\vec{x}=m\vec{B}|\vec{k})_{d0}^N=0$ for $i=1,\ldots,d$ and any integer m. Thus the $D(N)$ modes (2.14) represent infinite arrays of Dirichlet (Neumann) points at $\vec{x}=m\vec{B}$. More complicated arrays of point boundaries can be similarly introduced.[1] The heat kernel obtained from modes (2.14) and Eq. (2.7) is

$$K(t|\vec{x},\vec{y})_{d0}=(4\pi t)^{-d/2}\sum_b \{e^{-(\vec{x}-\vec{y}+b\vec{B})^2/4t}+\eta e^{-(\vec{x}+\vec{y}+b\vec{B})^2/4t}\}.$$

Actually one obtains here a double sum $\Sigma_{b,b'}$ rather than Σ_b and $(b-b')\vec{B}$ in the exponents rather than $b\vec{B}$. But the sum over b' is totally redundant and can simply be discarded, this step amounting to nothing more than a constant (infinite) renormalization of K_{d0} which has no effect on boundary conditions, the heat equation, or other essential properties of K_{d0}.

The same device with slight modification in Eqs. (2.3) and (2.10) leads to explicit modes and heat kernels for infinite arrays of line boundaries with equal spacing. Due to a lack of space no further discussion of arrays of point and line boundaries will be given in this article.

A. Vacuum stress tensor for an isolated point boundary

It is helpful to know the vacuum stress tensors of isolated point and line boundaries as these are, after all, prototypical boundary objects. Let us consider the point boundary at $\vec{x}=0$ in d dimensions, using some formulas collected in the Appendix for the canonical and improved stress tensors $T_{\mu\nu}$ and $\theta_{\mu\nu}$. The calculations are fairly similar to ones presented in Ref. 2. Ultraviolet regularization is performed by discarding the free-space term $k_d(t|\vec{x}-\vec{y})$ in Eq. (2.11). From the remaining (purely boundary) term

$$\eta K(t|\vec{x},\vec{y})_{\text{point}}\equiv\eta k_d(t|\vec{x}+\vec{y}) \tag{2.15}$$

in K_{d0} we obtain using Eq. (A3) and the convenient formula

$$(r^2)^s\Gamma(-s)=\int_0^\infty dt\, t^{s-1}e^{-r^2/t}, \tag{2.16}$$

the regularized mode sum

$$\sum_n (w_n^2)^{-s}\phi_n(\vec{x})\overline{\phi_n}(\vec{y})_{\text{reg}}=\frac{1}{\Gamma(s)}\int_0^\infty dt\, t^{s-1}\eta(4\pi t)^{-d/2}e^{-(\vec{x}+\vec{y})^2/4t}$$
$$=\eta\frac{\Gamma(-s+d/2)}{\Gamma(s)(4\pi)^{d/2}}\left[\frac{1}{4}(\vec{x}+\vec{y})^2\right]^{s-d/2}. \tag{2.17}$$

Henceforth we drop the label ''reg'' on the mode sum. From Eq. (2.17) one verifies

$$\sum_n \frac{1}{\omega_n}\partial_i\phi_n(\vec{x})\partial_j\overline{\phi_n}(\vec{x})=-\eta\frac{\Gamma\left(\frac{d+1}{2}\right)}{(\sqrt{4\pi}r)^{d+1}}\left[\delta_{ij}-(d+1)\frac{x_ix_j}{r^2}\right],\quad r=|\vec{x}|.$$

Here the right-hand side is unchanged when $\partial_i\phi_n(\vec{x})\partial_j\overline{\phi_n}(\vec{x})$ on the left is replaced by $(\partial_i\partial_j\phi_n(\vec{x}))\overline{\phi_n}(\vec{x})$ or by $\phi_n(\vec{x})\partial_i\partial_j\overline{\phi_n}(\vec{x})$. Then using mode-sum formulas for $T_{\mu\nu},\theta_{\mu\nu}$ in the Appendix we find

$$T_{00}=0,\quad \theta_{00}=-\eta\frac{1}{2d}(d-1)\frac{\Gamma\left(\frac{d+1}{2}\right)}{(\sqrt{4\pi}r)^{d+1}}; \tag{2.18}$$

$$T_{ii}=d\,\theta_{ii}=-\eta\frac{1}{2}\frac{\Gamma\left(\frac{d+1}{2}\right)}{(\sqrt{4\pi}r)^{d+1}}\left[2-(d+1)\frac{x_i^2}{r^2}\right]; \tag{2.19}$$

$$T_{ij}=d\,\theta_{ij}=\eta\frac{\Gamma\left(\frac{d+3}{2}\right)}{(\sqrt{4\pi}r)^{d+1}}\frac{x_ix_j}{r^2};\quad i\neq j \tag{2.20}$$

with $T_{0i}=\theta_{0i}=0$. $\theta_{\mu\nu}$ is traceless as it should be. Both $T_{\mu\nu}$ and $\theta_{\mu\nu}$ are conserved as they should be: $\partial_iT_{ij}=0$.

The results (2.18)–(2.20) of course display the physical boundary divergences (see, e.g., Refs. 6–8) known to be inseparable from boundaries (unless these divergences cancel away). Here $T_{00}=0$ merely because of cancellation. $T_{00}=0$ does *not* mean the point boundary has no effect on the vacuum energy distribution in its vicinity. There is no unique stress tensor for a scalar field, and θ_{00} does not vanish. Dimensionally $T_{\mu\nu}$ and $\theta_{\mu\nu}$ must be constructed from $1/r^{d+1}$ and x_ix_j/r^{d+3} making the presence of these $r\to 0$ divergences in Eqs. (2.18)–(2.20) inevitable. Physically, boundary divergences represent the extreme distortion of the quantum field by the point boundary away from the spatial uniformity it would possess in the absence of this boundary object.

Before leaving the point boundary we mention the connection between the exact boundary term (2.15) in the heat kernel and the heat kernel expansion for boundary problems (see, e.g., Ref. 9)

$$K(t|\vec{x},\vec{x}) \sim \sum_{n\geqslant 0} (4\pi t)^{(n-d)/2}[a_n(\vec{x})+b_n(\vec{x})], \quad t\to 0+$$

where $a_0=1$, $b_0=0$. Here the $a_n(\vec{x})$ are *functions* of $\vec{x}$ characterizing bulk properties of the distorted quantum field. The $b_n(\vec{x})$ are *distributions* defined only on the boundary surfaces, each distribution characterizing the field distortion near that particular boundary surface (but less well than the exact heat kernel does this). From the exact heat kernel

$$K(t|\vec{x},\vec{x})_{d0} = (4\pi t)^{-d/2}[1+\eta e^{-\vec{x}^2/t}]$$

and the limit

$$\lim_{t\to 0+} \frac{1}{\sqrt{\pi t}} e^{-x^2/t} = \delta(x),$$

we see that for the isolated point boundary $a_0=1$ (as it must) while

$$b_d(\vec{x}) = \eta 2^{-d}\delta(x_1)\,\delta(x_2)\cdots\delta(x_d).$$

All other a_n, b_n vanish.

B. Vacuum stress tensor for an isolated line boundary

The heat kernel (2.10) for the infinite line boundary along the x_d axis is UV regularized by discarding the free-space term. What remains is

$$\eta K(t|\vec{x},\vec{y})_{\text{line}} \equiv \eta k_{d-1}(t|\vec{u}+\vec{v})k_1(t|x_d-y_d),$$
$$\vec{u}=(x_1,\ldots,x_{d-1}), \quad \vec{v}=(y_1,\ldots,y_{d-1}), \tag{2.21}$$

leading to the regularized mode sum for the isolated line boundary

$$\sum_n (\omega_n^2)^{-s}\phi_n(\vec{x})\overline{\phi}_n(\vec{y}) = \eta\frac{\Gamma(-s+d/2)}{\Gamma(s)(4\pi)^{d/2}} 2^{d-2s}[(\vec{u}+\vec{v})^2+(x_d-y_d)^2]^{s-d/2}. \tag{2.22}$$

Thus

$$\sum_n \frac{1}{\omega_n}\partial_i\phi_n(\vec{x})\partial_j\overline{\phi}_n(\vec{x}) = -\eta\frac{\Gamma\left(\frac{d+1}{2}\right)}{(\sqrt{4\pi}u)^{d+1}}\left[\delta_{ij}-(d+1)\frac{x_ix_j}{u^2}\right], \quad i,j\neq d,$$
$$u^2=x_1^2+x_2^2+\cdots+x_{d-1}^2, \tag{2.23}$$

$$\sum_n \frac{1}{\omega_n}\partial_d\phi_n(\vec{x})\partial_d\overline{\phi}_n(\vec{x}) = -\sum_n \omega_n|\phi_n|^2 = \eta\frac{\Gamma\left(\frac{d+1}{2}\right)}{(\sqrt{4\pi}u)^{d+1}}, \tag{2.24}$$

$$\sum_n \frac{1}{\omega_n}\partial_i\phi_n(\vec{x})\partial_j\overline{\phi}_n(\vec{x}) = 0 \quad \text{for } i=d, \quad j\neq d \text{ or } i\neq d, \quad j=d. \tag{2.25}$$

The right-hand sides of Eqs. (2.23) and (2.25) are unchanged when on the left $\partial_i\phi_n\partial_j\overline{\phi_n}$ is replaced by $(\partial_i\partial_j\phi_n)\overline{\phi_n}$ or by $\phi_n(\partial_i\partial_j\overline{\phi_n})$. The right-hand side of Eq. (2.24) changes sign when $\partial_d\phi_n\partial_d\overline{\phi_n}$ is replaced by $(\partial_d\partial_d\phi_n)\overline{\phi_n}$ or by $\phi_n(\partial_d\partial_d\overline{\phi_n})$. One then verifies the vacuum stress tensors

$$T_{00}=-T_{dd}=\eta\frac{1}{2}\frac{\Gamma\left(\frac{d+1}{2}\right)}{(\sqrt{4\pi}u)^{d+1}}, \tag{2.26}$$

$$\theta_{00}=-\theta_{dd}=\eta\frac{2-d}{2d}\frac{\Gamma\left(\frac{d+1}{2}\right)}{(\sqrt{4\pi}u)^{d+1}}, \tag{2.27}$$

$$T_{ii}=d\theta_{ii}=-\eta\frac{1}{2}\frac{\Gamma\left(\frac{d+1}{2}\right)}{(\sqrt{4\pi}u)^{d+1}}\left[3-(d+1)\frac{x_i^2}{u^2}\right],\quad i<d, \tag{2.28}$$

$$T_{ij}=d\theta_{ij}=\eta\frac{\Gamma\left(\frac{d+3}{2}\right)}{(\sqrt{4\pi}u)^{d+1}}\frac{x_ix_j}{u^2},\quad i\neq j,\quad i,j<d, \tag{2.29}$$

$$T_{id}=\theta_{id}=0,\quad i<d, \tag{2.30}$$

with $T_{0\mu}=\theta_{0\mu}=0$ for $\mu=1,2,...,d$. Here $\theta_{\mu\nu}$ is traceless as it should be and both $T_{\mu\nu}$ and $\theta_{\mu\nu}$ are conserved as they should be.

From the exact heat kernel (2.10) for the isolated line boundary

$$K(t|\vec{x},\vec{x})_{d-1,1}=(4\pi t)^{-d/2}[1+\eta e^{-\vec{u}^2/t}]\sim(4\pi t)^{-d/2}+\eta\frac{1}{2^d\sqrt{\pi t}}\delta(x_1)\cdots\delta(x_{d-1}),$$

$$t\to 0+$$

we can read off the coefficients a_n, b_n in the heat-kernel expansion for this system.

III. LINE BOUNDARY PERPENDICULAR TO EXISTING ONE-DIMENSIONAL BACKGROUND

Our line boundary construction works when, in all spatial directions perpendicular to the line, space is symmetric. If the line boundary is to be positioned along the x_d axis then we need symmetry under $x_i\to -x_i$ for $i=1,...,d-1$. There is no need for spatial symmetry along x_d. In fact we can insert the line boundary into an arbitrary background potential $V(x_d)$.

The modes for a line boundary parallel to x_d in an arbitrary 1D background potential $V=V(x_d)$ are

$$\phi(\vec{x}|\vec{q},n)=(2\pi)^{(1-d)/2}[e^{i\vec{q}\cdot\vec{u}}+\eta e^{-i\vec{q}\vec{u}}]\phi_n(x_d),$$

$$\vec{u}=(x_1,\ldots,x_{d-1}),\quad \vec{q}=(k_1,\ldots,k_{d-1}),$$

$$k_1\geqslant 0,\quad -\infty<k_i<\infty,$$

$$x_1\geqslant 0 \text{ or } \leqslant 0,\quad -\infty<x_i<\infty,\quad i=2,...,d-1, \tag{3.1}$$

where $\phi_n(x_d)$ satisfies

$$[-\partial_d^2+V(x_d)]\phi_n(x_d)=k_n^2\phi_n(x_d). \tag{3.2}$$

The set $\{\phi_n(x_d)\}$ is complete in x_d. With momentum allowed to have the range indicated the modes (3.1) are orthonormal and complete. The heat kernel is

$$K(t|\vec{x},\vec{y})_{d-1,1}=K_1(t|x_d,y_d)\{k_{d-1}(t|\vec{u}-\vec{v})+\eta k_{d-1}(t|\vec{u}+\vec{v})\}, \tag{3.3}$$

$$K_1(t|x_d,y_d)\equiv\sum_n e^{-tk_n^2}\phi_n(x_d)\overline{\phi_n}(y_d), \tag{3.4}$$

where $\vec{v}=(y_1,\ldots,y_{d-1})$ and k_{d-1} is the free-space heat kernel. If the factor (3.4) is known one can compute $T_{\mu\nu},\theta_{\mu\nu}$ directly from Eq. (A3).

As a simple but nontrivial example of this construction let us attach a perpendicular semi-infinite line boundary to one side of an infinite plane. The plane is positioned at $x_d=0$ and the line lies along the positive x_d axis. Our goal is to calculate $T_{\mu\nu}$ and $\theta_{\mu\nu}$ in the half space $x_d>0$. These tensors are known (see, e.g., Ref. 2) in $x_d<0$ where there are no boundary objects. From $T_{\mu\nu},\theta_{\mu\nu}$ we can find the Casimir force density on the plane exerted by the projecting semi-infinite line boundary.

The x_d mode factor $\phi_n(x_d)$ in Eq. (3.1) is, in $x_d\geqslant0$,

$$\phi_d(x_d)=\frac{1}{\sqrt{2\pi}}[e^{ik_dx_d}+\gamma e^{-ik_dx_d}] \tag{3.5}$$

where $\gamma=-1(+1)$ for a Dirichlet (Neumann) plane at $x_d=0$. The heat kernel in $x_d,y_d\geqslant0$ is

$$K(t|\vec{x},\vec{y})_{d-1,1}=[k_1(t|x_d-y_d)+\gamma k_1(t|x_d+y_d)]\{k_{d-1}(t|\vec{u}-\vec{v})+\eta k_{d-1}(t|\vec{u}+\vec{v})\}. \tag{3.6}$$

Discarding the free-space term we are left with

$$K(t|\vec{x},\vec{y})_{d-1,d}=\gamma K_{\text{plane}}+\eta K_{\text{line}}+\eta\gamma K_{\text{point}}, \tag{3.7}$$

where K_{point} and K_{line} are defined by Eqs. (2.15) and (2.21) and

$$\gamma K(t|\vec{x},\vec{y})_{\text{plane}}\equiv\gamma k_1(t|x_d+y_d)k_{d-1}(t|\vec{u}-\vec{v}) \tag{3.8}$$

is the regularized heat kernel for an isolated plane positioned at $x_d=0$. The vacuum stress tensors computed from Eq. (3.7) obviously have the form

$$T_{\mu\nu}=T^{\gamma}_{\mu\nu\ \text{plane}}+T^{\eta}_{\mu\nu\ \text{line}}+T^{\eta\gamma}_{\mu\nu\ \text{point}} \tag{3.9}$$

with a similar formula for $\theta_{\mu\nu}$. Each term in Eq. (3.9) is separately conserved as are the separate terms in $\theta_{\mu\nu}$. The latter are separately traceless as well.

Perhaps the most interesting quantity to look at is the perpendicular Casimir force/area

$$F(x_1,\ldots,x_{d-1})/A\equiv\lim_{\epsilon\to0}[T_{dd}(x_d=-\epsilon)-T_{dd}(x_d=\epsilon)] \tag{3.10}$$

on the boundary plane at $x_d=0$. Because $T_{dd\ \text{plane}}=0$ for any $x_d\neq0$,[2] this plane's distortion of the quantum field does not contribute to the Casimir force acting on either side of it (quite appropriately). This leaves the Casimir force acting on the plane due to the field distortion in $x_d>0$ caused by the semi-infinite line, and by the pointlike juncture of this line with the plane. As Eq. (3.9) displays very explicitly this juncture acts as an independent boundary object in addition to the plane and the line. We find

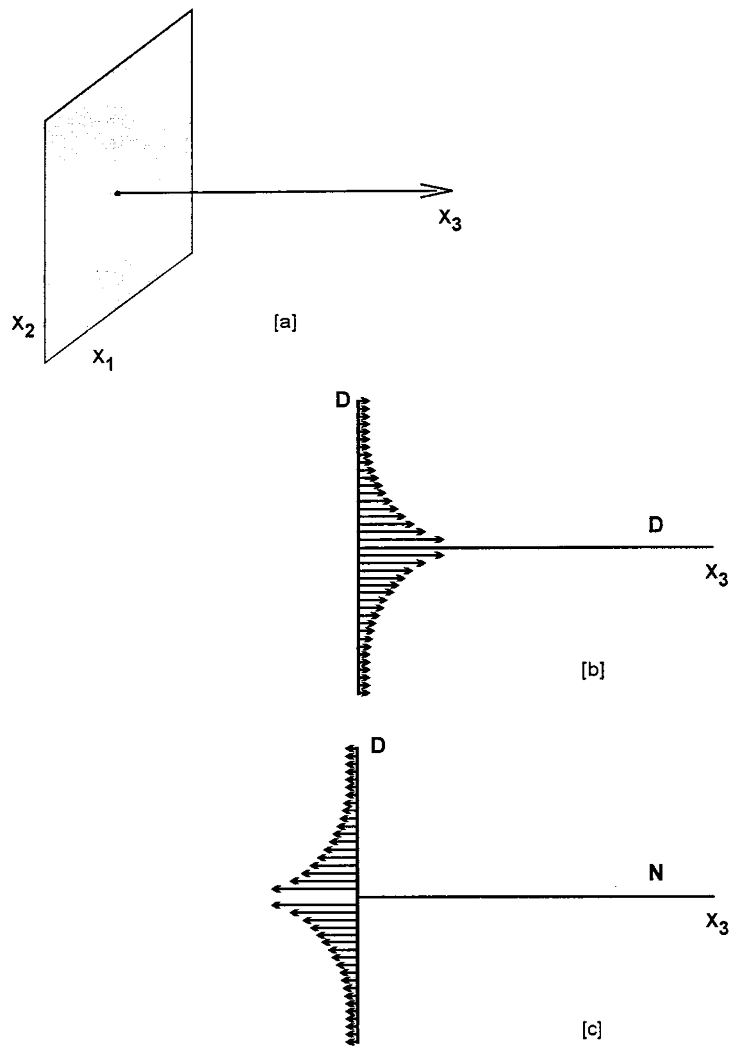

FIG. 1. The example in Sec. III for $d=3$ spatial dimensions. (a) A semi-infinite line boundary (along the positive x_3 axis) extends at right angles from one side of an infinite planar boundary (occupying the x_1x_2 plane). (b), (c) Side view: The semi-infinite $D(N)$ line attracts (repels) the D plane according to Eq. (3.11) (force density not to scale).

$$F(x_1,\ldots,x_{d-1})/A=\eta\frac{1}{2}(1+2\gamma)\frac{\Gamma\left(\frac{d+1}{2}\right)}{(\sqrt{4\pi}u)^{d+1}},\tag{3.11}$$

where $u^2=x_1^2+\cdots+x_{d-1}^2$. Thus $T_{\mu\nu}$ predicts that a D line and a D plane attract, as do a N line and a N plane. However, a D line repels a N plane, and a N line repels a D plane. See Fig. 1.

Using Eq. (3.10) with $T_{dd}\rightarrow\theta_{dd}$ we obtain the Casimir force/area on the plane at $x_d=0$ predicted by the improved vacuum stress tensor,

$$F'(x_1,\ldots,x_{d-1})/A=\eta\frac{1}{2d}(2-d+2\gamma)\frac{\Gamma\left(\frac{d+1}{2}\right)}{(\sqrt{4\pi}u)^{d+1}}.\tag{3.12}$$

Using the symbol $F'_{\text{plane,line}}$ we see here that F'_{NN} is (attractive, 0, repulsive) for ($d<4$, $d=4$, $d>4$) and F'_{ND} is (repulsive, 0, attractive) for ($d<4$, $d=4$, $d>4$). The force densities F_{NN} and F_{ND} disagree with this. On the other hand, $F'_{DD}=F_{DD}$ and $F'_{DN}=F_{DN}$ for all spatial dimensions $d\geqslant 2$.

IV. POINT OR LINE BOUNDARY IN THE CENTRAL PLANE OF A SYMMETRIC ONE-DIMENSIONAL BACKGROUND

We now consider a background in d-dimensional space represented by an arbitrary potential of the form $V=f(x_1^2)$. The directions $x_2,\ldots,x_d$ are translation invariant and free. The non-negative potential function $f(x_1^2)\geqslant 0$ can be otherwise quite arbitrary, but it is symmetric under $x_1\to -x_1$. This symmetry enables one to easily insert a planar,..., line or point boundary into the central plane $x_1=0$. We show how to calculate $T_{\mu\nu},\theta_{\mu\nu}$ for the resulting system from the heat kernel for the original background. Then as a detailed example we perform these calculations for a point boundary midway between two parallel planes. This system and others like it have never been investigated to our knowledge. The exact stress-tensor results agree with our qualitative expectations concerning Casimir forces acting between distinct D and N objects.

A. Arbitrary background

The modes for the original spatial background *prior* to inserting the point or line boundary into the plane $x_1=0$ have the form

$$\phi(\vec{x}|n,\vec{q})=\phi_n(x_1)(2\pi)^{(1-d)/2}e^{i\vec{q}\cdot\vec{u}},$$

$$\vec{u}=(x_2,\ldots,x_d),\quad \vec{q}=(k_2,\ldots,k_d),\tag{4.1}$$

$$-\infty<k_i<\infty,\quad i=2,...,d$$

$$[-\partial_1^2+f(x_1^2)]\phi_n(x_1)=k_n^2\phi_n(x_1).\tag{4.2}$$

The corresponding background heat kernel is

$$K(t|\vec{x},\vec{y})=K_1(t|x_1,y_1)k_{d-1}(t|\vec{u}-\vec{v}),\tag{4.3}$$

$$K_1(t|x_1,y_1)\equiv\sum_n e^{-tk_n^2}\phi_n(x_1)\overline{\phi_n}(y_1),\tag{4.4}$$

where $\vec{v}=(y_2,\ldots,y_d)$ and k_{d-1} is the free-space heat kernel. The x_1 heat kernel (4.4) satisfies

$$[-\partial_1^2+f(x_1^2)]K_1(t|x_1,y_1)=\partial_t K_1(t|x_1,y_1)\tag{4.5}$$

and similarly in y_1. Because of the symmetry of the operator $-\partial_1^2+f(x_1^2)$ under $x_1\to -x_1$ it follows that $\phi_n(-x_1)$ is also a solution of Eq. (4.2), and $K_1(t|-x_1,y_1)$ is a solution of Eq. (4.5). Obvious properties of the free-space factor k_{d-1} in Eq. (4.3) then lead to the conclusion that both $K(t|\pm\vec{x},\vec{y})$ satisfy the full heat equation $[-\Delta_x+V]\ K=\partial_t K$ for this system, and similarly in $\vec{y}$.

1. Point boundary at $\vec{x}=0$

To insert a point boundary at $\vec{x}=0$ we define the new heat kernel

$$K(t|\vec{x},\vec{y})_{d0}\equiv K(t|\vec{x},\vec{y})+\eta K(t|\mp\vec{x},\pm\vec{y})\tag{4.6}$$

with $\eta_D=-1$, $\eta_N=+1$ as usual. This heat kernel satisfies the full heat equation as well as D or N boundary conditions at the point $x_1,\ldots,x_d=0$. Thus it represents the modified system with a point boundary at $\vec{x}=0$ in addition to the 1D background structure described by $V=f(x_1^2)$. The (orthonormal, complete) modes for the same system are

$$\phi(\vec{x}|n,\vec{q})_{d0}=(2\pi)^{(1-d)/2}[\phi_n(x_1)e^{i\vec{q}\cdot\vec{u}}+\eta\phi_n(-x_1)e^{-i\vec{q}\cdot\vec{u}}] \tag{4.7}$$

with now $k_2\geqslant 0$, $x_2\geqslant 0$ or $\leqslant 0$. K_{d0} can be obtained directly from these modes.

Using Eq. (A3) we can now compute $T_{\mu\nu},\theta_{\mu\nu}$ for the modified system if $K_1(t|x_1,y_1)$ for the original system without point boundary is known. Even if K_1 is unknown, Eq. (4.6) reveals a very fundamental property of Casimir forces: Inserted D and N point boundaries exert equal but opposite Casimir forces throughout the symmetric background into which they have been inserted. This is evident from the structure of Eq. (4.6). Consider the canonical vacuum stress tensor computed from Eq. (4.6),

$$T_{\mu\nu}=T_{\mu\nu\ \text{background}}+\eta T_{\mu\nu\ \text{point}}, \tag{4.8}$$

where the notation is hopefully obvious. $T_{\mu\nu\ \text{background}}$ is computed from $K(t|\vec{x},\vec{y})$ and $T_{\mu\nu\ \text{point}}$ from $K(t|-\vec{x},\vec{y})$. These tensors are separately conserved. Clearly the contribution from the point boundary to any Casimir force/area acting on a boundary surface, or to any Casimir force density acting on diffuse (Dirichlet-like) background structure represented by $V=f(x_1^2)$, will be equal but opposite for D,N points simply because $\eta_D=-1$ and $\eta_N=+1$. Exactly the same statements can be made about the improved vacuum stress tensor $\theta_{\mu\nu}$.

Another comment on Eq. (4.8) concerns UV renormalization. The free-space part of $T_{\mu\nu}$ will be found in $T_{\mu\nu\ \text{background}}$ and only this part of the tensor (4.8) needs UV renormalization. $T_{\mu\nu\ \text{point}}$ is UV finite by construction. This will be illustrated by the example to follow.

2. Line boundary along the x_d axis

To insert a line boundary into the symmetry plane $x_1=0$ (along the x_d axis) we define the heat kernel

$$K(t|\vec{x},\vec{y})_{d-1,1}=k_1(t|x_d,y_d)\{K_1(t|x_1,y_1)k_{d-2}(t|\vec{\alpha}-\vec{\beta})+\eta K_1(t|\mp x_1,\pm y_1)k_{d-2}(t|\vec{\alpha}+\vec{\beta})\},$$
$$\vec{\alpha}=(x_2,\ldots,x_{d-1}),\quad \vec{\beta}=(y_2,\ldots,y_{d-1}). \tag{4.9}$$

$K_{d-1,1}$ satisfies both the heat equation and D or N boundary conditions along the x_d axis. The corresponding modes are

$$\phi(\vec{x}|n,\vec{q})_{d-1,1}=(2\pi)^{(1-d)/2}e^{ik_dx_d}[\phi_n(x_1)e^{i\vec{q}\cdot\vec{\alpha}}+\eta\phi_n(-x_1)e^{-i\vec{q}\cdot\vec{\alpha}}]. \tag{4.10}$$

From $K_{d-1,1}$ we can calculate $T_{\mu\nu},\theta_{\mu\nu}$ for the new system with line boundary along the x_d axis if we know K_1 for the original background without this line. As for an inserted point it is obvious that D and N boundary lines exert equal but opposite Casimir forces throughout the original background.

B. Parallel-plane background

Let us now specialize to a familiar background: two static parallel planar boundaries at $x_1=\pm L/2$. The distortion of the quantum field between and outside these walls is such that each wall experiences an inward uniform force/area[10,2] (the same for D or N conditions)

$$F/A=\frac{d\Gamma\left(\frac{d+1}{2}\right)\zeta(d+1)}{(\sqrt{4\pi}L)^{d+1}}. \tag{4.11}$$

After point or line boundary insertion in the central plane $x_1=0$ the local Casimir force $F_1(x_2,\ldots,x_d)/A$ on the planes is nonuniform. Far from the point/line boundary F_1/A becomes of course the uniform force (4.11). However near the point/line boundary $F_1(x_2,\ldots,x_d)/A$ is significantly position dependent. As we shall see, if a $D(N)$ point is positioned between parallel D walls the attractive Casimir force/area between the latter is locally strengthened (weakened). If a $D(N)$ point is positioned between parallel N walls the attractive force/area between the latter is locally weakened (strengthened).

Note that we assume $d\geqslant 2$ henceforth, specifically *excluding* one spatial dimension $d=1$ from discussion. The obvious reason is that all boundaries are points in one dimension. Because one knows how to handle the static two-boundary problem for $d=1$, one can as easily deal with N static boundaries at arbitrary positions. There is no reason to apply the far more powerful but equally more specialized method of this paper.

The modes for the parallel-plane background are given by Eq. (4.1) with

$$\phi_n(x_1)=\frac{1}{\sqrt{2L}}[e^{in(\pi/L)(x_1+L/2)}+\gamma e^{-in(\pi/L)(x_1+L/2)}],$$

$$D:\quad \gamma=-1,\quad n=1,2,3,...,$$

$$N:\quad \gamma=1,\quad n=0,1,2,... . \tag{4.12}$$

All the D modes vanish at $x_1=\pm L/2$, and beyond these planes at $x_1=(p+1/2)L$ with p any integer where one might imagine other D planes if one so chooses. However we shall imagine empty space out beyond the planes at $x_1=\pm L/2$, so modes other than the ones (4.12) are appropriate in these regions. For the N modes $\partial_1\partial_n$ vanishes at $x_1=(p+1/2)L,\ p$ any integer.

The heat kernel for the parallel-plane background is (see, e.g., Ref. 2) given by Eq. (4.3) with

$$K_1(t|x_1,y_1)=(4\pi t)^{-1/2}\sum_{n=-\infty}^{\infty}[e^{-(n2L+x_1-y_1)^2/4t}+\gamma e^{-(n2L+L+x_1+y_1)^2/4t}]. \tag{4.13}$$

Here we discard a constant term for Neumann planes coming from the $n=0$ constant mode in Eq. (4.12), which seems to play no physical role. Note that $K_{1\mathrm{D}}$ with $\gamma=-1$ vanishes at $x_1=\pm L/2$ or $y_1=\pm L/2$. Also $\partial_1 K_{1N}$ vanishes at $x_1=\pm L/2$ or $y_1=\pm L/2$. Both of $K_1(t|\pm x_1,y_1)$ satisfy the 1D free heat equation in x_1, and similarly in y_1. Consequently $K(t|\pm\vec{x},\vec{y})$ satisfies the complete heat equation in $\vec{x}$, and likewise for $K(t|\vec{x},\pm\vec{y})$ in variable $\vec{y}$.

Inserting a point boundary between the planes at $\vec{x}=0$ by means of Eq. (4.6) we obtain a canonical vacuum stress tensor for the resulting system having the form (4.8);

$$T_{\mu\nu}=T_{\mu\nu\ \text{planes}}+\eta T_{\mu\nu\ \text{point}},\quad -L/2\leqslant x_1\leqslant L/2 \tag{4.14}$$

and similarly for $\theta_{\mu\nu}$. The field tensor $T_{\mu\nu\,\text{planes}}$ between parallel planes computed (with UV renormalization) from the background heat kernel (4.3) with factor (4.13) is well known (again see, e.g., Ref. 2). This tensor is conserved; therefore the remaining tensor $T_{\mu\nu\,\text{point}}$ describing the additional distortion of the quantum field by the inserted point boundary is separately conserved. $T_{\mu\nu\,\text{planes}}$ contains the only free-space contribution to $T_{\mu\nu}$ and only this part of $T_{\mu\nu}$ needs renormalization. The uniform force (4.11) is obtained from $T_{\mu\nu\,\text{planes}}$.

$T_{\mu\nu\,\text{point}}$ is computed without renormalization from

$$\eta K(t|-\vec{x},\vec{y})_{\text{point}}=\eta(4\pi t)^{-d/2}\sum_{n=-\infty}^{\infty}\{e^{-(n2L+x_1+y_1)^2/4t}+\gamma e^{-(n2L+L+x_1-y_1)^2/4t}\}e^{-(\vec{u}+\vec{v})^2/4t}. \tag{4.15}$$

From Eq. (A3) and this heat kernel we find

$$\eta\sum_n (\omega_n^2)^{-s}\phi_n(\vec{x})\overline{\phi_n}(\vec{y})_{\text{point}}=\eta\frac{\Gamma(-s+d/2)}{\Gamma(s)(4\pi)^{d/2}}2^{d-2s}\sum_{n=-\infty}^{\infty}\{[(n2L+x_1+y_1)^2+(\vec{u}+\vec{v})^2]^{s-d/2}+\gamma[(n2L+L+x_1-y_1)^2+(\vec{u}+\vec{v})^2]^{s-d/2}\}. \tag{4.16}$$

This basic mode sum yields all terms in $T_{\mu\nu\,\text{point}}$. UV renormalization is unnecessary because of the presence of $(\vec{u}+\vec{v})^2$ in every term on the right. Thus $[0]^{s-d/2}$ never occurs in the limit $\vec{x}\to\vec{y}$ (except at $\vec{x}=\vec{y}=0$, which produces the boundary divergences inseparable from the point boundary). In the corresponding mode sum for $T_{\mu\nu\,\text{planes}}$ one has $[(n2L+x_1-y_1)^2+(\vec{u}-\vec{v})^2]^{s-d/2}$ under the sum and the $n=0$ term needs renormalization. Because $[0]^{s-d/2}$ never occurs in Eq. (4.16) on the boundary planes $x_1=\pm L/2$, $T_{\mu\nu\,\text{point}}$ is finite on these planes. The boundary divergences in $T_{\mu\nu}$ inseparable from the boundary planes are found only in $T_{\mu\nu\,\text{planes}}$, just as the boundary divergences associated with the point boundary are found only in $T_{\mu\nu\,\text{point}}$. These comments can be repeated for the improved vacuum stress tensor $\theta_{\mu\nu}$.

Some helpful intermediate formulas in a moderately tedious calculation are

$$\eta\sum_n \frac{1}{\omega_n}\left\{\begin{matrix}|\partial_1\phi_n|^2\\ (\partial_1^2\phi_n)\overline{\phi_n}\ \text{ or }\ \phi_n(\partial_1^2\overline{\phi_n})\end{matrix}\right\}_{\text{point}}$$
$$=\eta\frac{\Gamma\left(\frac{d+1}{2}\right)}{(4\pi)^{(d+1)/2}}\sum_{n=-\infty}^{\infty}\left\{[d(nL+x_1)^2-u^2][(nL+x_1)^2+u^2]^{-(d+3)/2}\mp\gamma\left[d\left(nL+\frac{L}{2}\right)^2-u^2\right]\left[\left(nL+\frac{L}{2}\right)^2+u^2\right]^{-(d+3)/2}\right\}, \tag{4.17}$$

$$\eta\sum_n \frac{1}{\omega_n}\left\{\begin{matrix}\partial_i\phi_n\partial_1\overline{\phi_n}\quad \text{or}\quad \phi_n\partial_i\partial_1\overline{\phi_n}\\ \partial_1\phi_n\partial_i\overline{\phi_n}\quad \text{or}\quad (\partial_1\partial_i\phi_n)\overline{\phi_n}\end{matrix}\right\}_{\text{point}}$$
$$=\eta\frac{\Gamma\left(\frac{d+3}{2}\right)}{(4\pi)^{(d+1)/2}}(2x_i)\sum_{n=-\infty}^{\infty}\left\{(nL+x_1)[(nL+x_1)^2+u^2]^{-(d+3)/2}\mp\gamma\left(nL+\frac{L}{2}\right)\left[\left(nL+\frac{L}{2}\right)^2+u^2\right]^{-(d+3)/2}\right\}\quad \text{for } i>1, \tag{4.18}$$

$$\eta\sum_n \frac{1}{\omega_n}\{\partial_i\phi_n\partial_j\overline{\phi_n}\ \text{ or }\ (\partial_i\partial_j\phi_n)\overline{\phi_n}\ \text{ or }\ \phi_n\partial_i\partial_j\overline{\phi_n}\}_{\text{point}}$$
$$=\eta\frac{\Gamma\left(\frac{d+1}{2}\right)}{(4\pi)^{(d+1)/2}}\sum_{n=-\infty}^{\infty}\left\{-\delta_{ij}[(nL+x_1)^2+u^2]^{-(d+1)/2}-\gamma\delta_{ij}\left[\left(nL+\frac{L}{2}\right)^2+u^2\right]^{-(d+1)/2}+(d+1)x_ix_j[(nL+x_1)^2+u^2]^{-(d+3)/2}+\gamma(d+1)x_ix_j\left[\left(nL+\frac{L}{2}\right)^2+u^2\right]^{-(d+3)/2}\right\}\quad i,j>1. \tag{4.19}$$

As a check on these expressions one can verify that each satisfies any D or N boundary condition on the planes it should satisfy. The identity (for $p=$integer)

$$\sum_{n=-\infty}^{\infty}\left(nL+\frac{L}{2}\right)^{2p+1}\left[\left(nL+\frac{L}{2}\right)^2+u^2\right]^{-s}=0 \tag{4.20}$$

is helpful. Another useful intermediate formula is

$$\eta\sum_n \frac{1}{\omega_n}|\vec{\nabla}\phi_n|^2_{\text{point}}=\eta\frac{\Gamma\left(\frac{d+1}{2}\right)}{(4\pi)^{(d+1)/2}}\sum_{n=-\infty}^{\infty}\left\{[(nL+x_1)^2+u^2]^{-(d+1)/2}\right.$$
$$\left.+\gamma\left[(1-2d)\left(nL+\frac{L}{2}\right)^2+3u^2\right]\left[\left(nL+\frac{L}{2}\right)^2+u^2\right]^{-(d+3)/2}\right\}. \tag{4.21}$$

From the mode-sum formulas in the Appendix we now find relatively easily the components of $T_{\mu\nu\,\text{point}}$ in the region $-L/2\leqslant x_1\leqslant L/2$:

$$T_{00\ \text{point}}=\eta\gamma\frac{\Gamma\left(\frac{d+1}{2}\right)}{2(4\pi)^{(d+1)/2}}\sum_{n=-\infty}^{\infty}\left[-d\left(nL+\frac{L}{2}\right)^2+u^2\right]\left[\left(nL+\frac{L}{2}\right)^2+u^2\right]^{-(d+3)/2}, \tag{4.22}$$

$$T_{11\ \text{point}}=\eta\frac{\Gamma\left(\frac{d+1}{2}\right)}{2(4\pi)^{(d+1)/2}}\sum_{n=-\infty}^{\infty}\{[(d-1)(nL+x_1)^2-2u^2]$$
$$\times[(nL+x_1)^2+u^2]^{-(d+3)/2}-\gamma[(nL+L/2)^2+u^2]^{-(d+1)/2}\}, \tag{4.23}$$

$$T_{ii\ \text{point}}=\eta\frac{\Gamma\left(\frac{d+1}{2}\right)}{2(4\pi)^{(d+1)/2}}\sum_{n=-\infty}^{\infty}\{[(nL+x_1)^2+u^2]^{-(d+3)/2}$$
$$\times[-2(nL+x_1)^2-2u^2+(d+1)x_i^2]+\gamma[(nL+L/2)^2+u^2]^{-(d+3)/2}$$
$$\times[(d-2)(nL+L/2)^2-3u^2+(d+1)x_i^2]\},\quad i>1,\ i\ \text{not summed}, \tag{4.24}$$

$$T_{1i\ \text{point}}=\eta x_i\frac{\Gamma\left(\frac{d+3}{2}\right)}{(4\pi)^{(d+1)/2}}\sum_{n=-\infty}^{\infty}(nL+x_1)[(nL+x_1)^2+u^2]^{-(d+3)/2},\quad i>1, \tag{4.25}$$

$$T_{ij\ \text{point}}=\eta\frac{\Gamma\left(\frac{d+3}{2}\right)}{(4\pi)^{(d+1)/2}}x_ix_j\sum_{n=-\infty}^{\infty}\left\{[(nL+x_1)^2+u^2]^{-(d+3)/2}+\gamma\left[\left(nL+\frac{L}{2}\right)^2+u^2\right]^{-(d+3)/2}\right\},$$
$$i\neq j\quad\text{and}\quad i,j>1, \tag{4.26}$$

$$T_{0i}=0,\quad i\geqslant 1. \tag{4.27}$$

In the limit $L\to\infty$ the tensor $T_{\mu\nu\,\text{point}}$ becomes the tensor (2.18)–(2.20) for an isolated point boundary at $\vec{x}=0$. $T_{\mu\nu\,\text{point}}$ is conserved as it should be.

The improved vacuum stress tensor $\theta_{\mu\nu\,\text{point}}$ is

$$\theta_{00\ \mathrm{point}}=\eta\frac{\Gamma\left(\frac{d+1}{2}\right)}{2d(4\pi)^{(d+1)/2}}\sum_{n=-\infty}^{\infty}\{[(nL+x_1)^2+u^2]^{-(d+1)/2}(1-d)$$

$$+\gamma[(nL+L/2)^2+u^2]^{-(d+3)/2}[(1-2d)(nL+L/2)^2-(d-2)u^2]\},\qquad(4.28)$$

$$\theta_{11\ \mathrm{point}}=\eta\frac{\Gamma\left(\frac{d+1}{2}\right)}{2d(4\pi)^{(d+1)/2}}\sum_{n=-\infty}^{\infty}\{[(nL+x_1)^2+u^2]^{-(d+3)/2}[(d-1)(nL+x_1)^2-2u^2]$$

$$+\gamma[(nL+L/2)^2+u^2]^{-(d+3)/2}[-(d^2-d+1)(nL+L/2)^2+(d-2)u^2]\},\qquad(4.29)$$

$$\theta_{ii\ \mathrm{point}}=\frac{1}{d}T_{ii\ \mathrm{point}},$$

$$i>1,\quad i\ \text{not summed},\qquad(4.30)$$

$$\theta_{i1\ \mathrm{point}}=\frac{1}{d}T_{i1\ \mathrm{point}},\quad i>1,\qquad(4.31)$$

$$\theta_{ij\ \mathrm{point}}=\frac{1}{d}T_{ij\ \mathrm{point}},$$

$$i\neq j\quad\text{and}\ i,j>1.\qquad(4.32)$$

$\theta_{\mu\nu\ \mathrm{point}}$ is conserved, and for $L\to\infty$ this tensor reduces to the isolated point boundary tensor given in Eqs. (2.18)–(2.20).

From the formula $f_i(\vec{x})=-\partial_j T_{ij}(\vec{x})$ for the local force density within the boundary-distorted quantum field we see that $f_1(\vec{x})=0$ (because $\partial^\mu T_{\mu\nu}=0$) everywhere away from the boundaries (i.e., in empty space). However $T_{\mu\nu}$ and $\theta_{\mu\nu}$ are discontinuous across the boundary planes and Casimir forces act on these planes. The Casimir force/area on the plane at $x_1=-L/2$ computed from $T_{\mu\nu}$ is

$$F_1(u)/A\equiv\lim_{\epsilon\to0}\left[T_{11}\left(x_1=-\frac{L}{2}-\epsilon\right)-T_{11}\left(x_1=-\frac{L}{2}+\epsilon\right)\right]$$

$$=d\,\frac{\Gamma\left(\frac{d+1}{2}\right)\zeta(d+1)}{(\sqrt{4\pi}L)^{d+1}}-T_{11\ \mathrm{point}}\left(x_1=-\frac{L}{2}\right)\qquad(4.33)$$

with

$$T_{11\ \mathrm{point}}(x_1=-L/2)=\eta\frac{\Gamma\left(\frac{d+1}{2}\right)}{2(4\pi)^{(d+1)/2}}\sum_{n=-\infty}^{\infty}\left[\left(nL+\frac{L}{2}\right)^2+u^2\right]^{-(d+3)/2}$$

$$\times\left\{(d-1-\gamma)\left(nL+\frac{L}{2}\right)^2-(2+\gamma)u^2\right\}.\qquad(4.34)$$

Here we remind the reader that $T_{11}=0$ outside the parallel planes, and the first term on the right in Eq. (4.33) (second equality), i.e., the uniform force (4.11) between parallel planes, comes from $T_{11\ \mathrm{planes}}$. The negative of Eq. (4.34) gives the additional nonuniform force/area on the left boundary plane due to the point boundary in the middle. At position $u=0$ on this plane ''beneath'' or nearest the point boundary the force/area (4.34) is strongest, and larger in magnitude than the first term in Eq. (4.33),

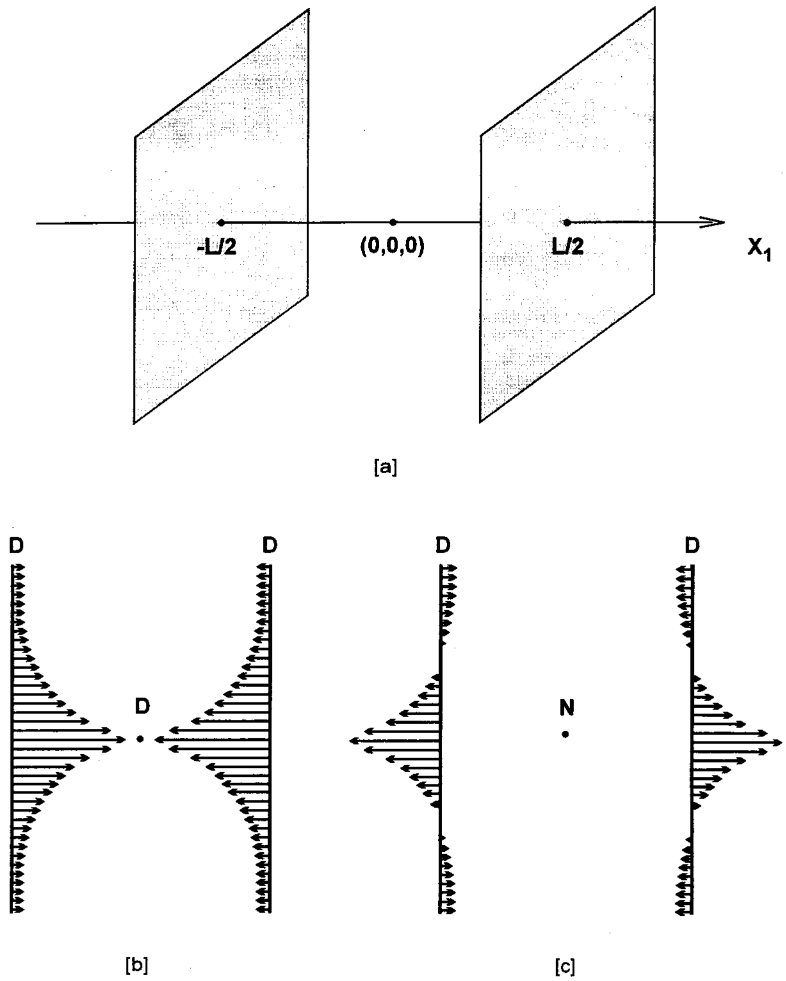

FIG. 2. The example in Sec. IV B for $d=3$ spatial dimensions. (a) A point boundary midway between parallel infinite boundary planes. (b), (c) Side view: A $D(N)$ point boundary attracts (repels) the parallel D planes enclosing it according to Eq. (4.33) (force density not to scale).

$$T_{11\ \mathrm{point}}(x_1=-L/2)|_{u=0}=\eta(d-1-\gamma)\frac{\Gamma\left(\frac{d+1}{2}\right)\zeta(d+1)}{(\sqrt{4\pi}L)^{d+1}}[2^{d+1}-1].$$

The identity

$$\sum_{n=-\infty}^{\infty}(n+1/2)^{-s}=2[2^s-1]\zeta(s)$$

is useful here. Figure 2 depicts the situation for parallel Dirichlet planes with a Dirichlet or Neumann point midway between them.

The Casimir force/area on the plane at $x_1=-L/2$ computed from $\theta_{\mu\nu}$ is given by

$$F_1'(u)/A=d\frac{\Gamma\left(\frac{d+1}{2}\right)\zeta(d+1)}{(\sqrt{4\pi}L)^{d+1}}-\theta_{11\ \mathrm{point}}\left(x_1=-\frac{L}{2}\right) \tag{4.35}$$

with

$$\theta_{11\ \text{point}}(x_1=-L/2)=\eta\frac{\Gamma\left(\frac{d+1}{2}\right)}{2(4\pi)^{(d+1)/2}}\sum_{n=-\infty}^{\infty}\left[\left(nL+\frac{L}{2}\right)^2+u^2\right]^{-(d+3)/2}$$
$$\times\left\{\frac{1}{d}[d-1-\gamma(d^2-d+1)]\left(nL+\frac{L}{2}\right)^2+\frac{1}{d}[-2+\gamma(d-2)]u^2\right\}. \tag{4.36}$$

The constant term in eq. (4.35)—again the uniform force (4.11)—comes from $\theta_{11\ \text{planes}}$. The additional nonuniform force/area on the left plane due to the point boundary at $\vec{x}=0$ is the negative of Eq. (4.36).

An important question is: For what backgrounds do $T_{\mu\nu}$ and $\theta_{\mu\nu}$ predict the same nonuniform force density on the boundary planes due to the point, and for which backgrounds are these force densities different? A comparison of Eqs. (4.34) and (4.36) shows that for $\gamma=-1$

$$T_{11\ \text{point}}\left(x_1=-\frac{L}{2}\right)=\theta_{11\ \text{point}}\left(x_1=-\frac{L}{2}\right),\quad \gamma=-1 \tag{4.37}$$

while for $\gamma=1$ these two functions of u^2 are somewhat different. Thus for parallel Dirichlet planes with a Dirichlet or Neumann point halfway between them, $T_{\mu\nu}$ and $\theta_{\mu\nu}$ predict identical Casimir force densities on the planes. For parallel Neumann planes the predicted force densities are not identical. The *total* force F_{point} on the $x_1=-L/2$ plane due to the point boundary is finite;

$$F_{\text{point}}\equiv\int_{-\infty}^{\infty}dx_2\cdots dx_d\left[-T_{11\ \text{point}}\left(x_1=-\frac{L}{2}\right)\right]=\eta\gamma\frac{\pi}{2^{d+2}L^2}.$$

Interestingly the force computed from $-\theta_{11\ \text{point}}(x_1=-L/2)$ is exactly the same. Note that F_{point} is an attractive inward force for $\eta\gamma=1$ (D planes and D point or N planes and N point) and a repulsive outward force for $\eta\gamma=-1$ (D planes and N point or N planes and D point).

V. GENERAL CASE

For completeness we now summarize the most general versions of the point boundary and line boundary constructions.

A. Point boundary insertion

If the spatial background is symmetric under $\vec{x}\to-\vec{x}$ [in particular if this background is described by a potential $V(\vec{x})$ with the property $V(-\vec{x})=V(\vec{x})$] then a point boundary can be inserted at $\vec{x}=0$. By now it should be quite obvious how. The heat kernel $K(t|\vec{x},\vec{y})$ for the original background satisfies by assumption

$$[-\Delta_x+V(\vec{x})]K(t|\pm\vec{x},\vec{y})=\partial_t K(t|\pm\vec{x},\vec{y}) \tag{5.1}$$

and similarly in $\vec{y}$. Moreover

$$K(t|-\vec{x},-\vec{y})=K(t|\vec{x},\vec{y}). \tag{5.2}$$

Thus the modified heat kernel

$$K(t|\vec{x},\vec{y})_{d0}\equiv K(t|\vec{x},\vec{y})+\eta K(t|\mp\vec{x},\pm\vec{y}) \tag{5.3}$$

satisfies the background heat equation (5.1). It also manifestly vanishes at $\vec{x}=0$ for $\eta_D=-1$, while $\vec{\nabla}K_{d0}$ vanishes at $\vec{x}=0$ for $\eta_N=+1$. Thus K_{d0} correctly represents the modified system of original background+point boundary at $\vec{x}=0$.

B. Line boundary insertion

If the spatial background is symmetric under $\vec{u}\rightarrow-\vec{u}$ where $\vec{u}=(x_1,x_2,\ldots,x_{d-1})$, then a line boundary can be inserted along the x_d axis. The background can be arranged in any fashion parallel to the x_d axis. The background heat kernel $K(t|\vec{u},x_d;\vec{v},y_d)$ has to satisfy

$$[-\Delta_x+V(\vec{u},x_d)]K(t|\pm\vec{u},x_d;\vec{v},y_d)=\partial_t K(t|\pm\vec{u},x_d;\vec{v},y_d) \tag{5.4}$$

and similarly in $\vec{y}=(\vec{v},y_d)$. The potential V satisfies $V(-\vec{u},x_d)=V(\vec{u},x_d)$ and consequently

$$K(t|-\vec{u},x_d;-\vec{v},y_d)=K(t|\vec{u},x_d;\vec{v},y_d). \tag{5.5}$$

Then the modified heat kernel

$$K(t|\vec{x},\vec{y})_{d-1,1}\equiv K(t|\vec{u},x_d;\vec{v},y_d)+\eta K(t|\mp\vec{u},x_d;\pm\vec{v},y_d) \tag{5.6}$$

satisfies the background heat equation (5.5) and moreover D or N boundary conditions along the x_d axis.

The heat kernels (5.3) and (5.6) obviously lead to vacuum stress tensors of the form

$$T_{\mu\nu}=T_{\mu\nu}^{\mathrm{BG}}+\eta\Delta T_{\mu\nu}. \tag{5.7}$$

Here $\eta\Delta T_{\mu\nu}$ is computed from the second term in Eqs. (5.3) and (5.6) and $T_{\mu\nu}^{\mathrm{BG}}$ from $K(t|\vec{x},\vec{y})$ for the original background. UV renormalization has to be performed on $T_{\mu\nu}^{\mathrm{BG}}$, not on $\Delta T_{\mu\nu}$. Point and line boundary insertion does not affect UV renormalization, and this is expressed by the UV-finite nature of $\Delta T_{\mu\nu}$. The additional Casimir force density $f_i(\vec{x})$ acting throughout the quantum field due to this field's additional distortion by the point or line boundary is given by

$$f_i(\vec{x})=-\eta\partial_j\Delta T_{ij}.$$

Equal but opposite force densities are exerted by D and N point or line boundaries.

VI. DISCUSSION

A. Quantum scalar field

In this article we have shown quite explicitly how to insert point and line boundaries into the central point, line, plane,..., of symmetric (but otherwise arbitrary) backgrounds in scalar QFT. The spatial background is required to be invariant under reflection through the inserted object along every direction x_i perpendicular to this object. Such a construction is familiar for planar boundaries but not for point and line boundaries. If one is able to compute the heat kernel $K(t|\vec{x},\vec{y})$ for the original background system—and therefore the vacuum stress tensor $T_{\mu\nu}$ and all Casimir force densities within this system—then one can also calculate $K,T_{\mu\nu}$, and all Casimir force densities for the substantially more complicated system with a point or line boundary at its center.

We used point and line boundary insertion to investigate the conjectured rules for scalar Casimir theory discussed in Sec. I: Distinct D objects attract; distinct N objects do the same; distinct D and N objects repel. These rules were found to be obeyed in the detailed examples of Secs. III and IV. Strong indications that these rules hold at a very general level could be discerned in the general mathematics.

Are global Casimir energy considerations at all useful for studying point and line boundaries? Let us return to the parallel planes (*DD* or *NN*) with a *D* or *N* point boundary between them. The four boundary configurations *DDD*,*DND*,*NDN*,*NNN* produce identical spectra in the quantum field. Consequently the (unrenormalized) global vacuum energy $E_{\text{vac}}=\Sigma\,\omega_n/2$ between the planes cannot distinguish among them. One soon realizes this is only to be expected. The point boundary between the planes causes a *finite* shift in the *infinite* (even after renormalization) vacuum energy between the infinite planes. (For finite planes one might wish to rethink this—see below.)

Another way to formulate the preceeding comment is as follows: Imagine displacing slowly the point boundary (keeping it in the midplane between the parallel planar boundaries) away to infinity. Done slowly this costs no energy because no field excitation occurs. Yet with the point boundary out of sight at infinity the system appears to be just two parallel planes distorting the quantum field everywhere. Evidently no change in vacuum energy is involved. Exactly the same argument applies to a line boundary inserted between parallel planes.

These remarks for the parallel-plane example have an obvious extension to more complicated backgrounds. If an inserted point or line boundary *is not* ''confined'' by its symmetric background in the sense that it *can* (at least in one direction) be displaced away to infinity with no expenditure of energy, then global vacuum energy considerations will be insensitive to the insertion of the point or line boundary.

On the other hand, if an inserted point or line boundary *is* confined by its symmetric background in the sense that it *cannot* be displaced to infinity without expenditure of energy, then global vacuum energy considerations should be helpful. Take for example a finite spherical cavity. The method of this paper enables one to insert a point boundary at the center of this cavity, or a line boundary diametrically through the center. Neither the point nor the line can be displaced without expending energy. The vacuum energy within the cavity is finite and therefore quite capable of detecting the insertion of either point or line. Very similar comments apply to finite cavities with other shapes.

The method of this paper can very straightforwardly be extended to scalar QFT at finite temperature. The notation the author would choose for this purpose is reviewed in Ref. 11.

B. Quantum electromagnetic field

What about fields other than scalar ones? Fermion boundary conditions on planes and other extended surfaces are not a clearly organized subject. Thus we leave these aside and mention gauge fields—especially the electromagnetic field in four space–time dimensions. Many Casimir calculations in electromagnetic theory have been done using Green functions. The latter are, of course, bilocal functions closely related to heat kernels and mode sums like (A3) with $s=1$. Thus the constructions presented in this paper can be applied to the electromagnetic field, much as one uses the image-charge constructions associated with planar metallic surfaces. This is, of course, important because the electromagnetic (EM) field is the one quantum field everyone believes in. The EM vacuum state is understood to pervade all of space, and the Casimir effect provides a wonderfully direct way to locally access and manipulate this vacuum state, and hence to further verify its existence. Naturally, when studying the static EM Casimir effect one chooses space to be three dimensional.

Technically it is clear that the methods of this paper straightforwardly modified to the EM problem enable one to insert metal point and line boundaries into preexisting appropriately symmetric metal and/or dielectric spatial backgrounds. We cannot undertake a technical discussion of this here; however we hope to present a relatively full account elsewhere. Still there are useful and general things which can be said about the EM problem.[4] The present article concludes with a brief account of these aspects.

A vacuum EM fluctuation can be any classical EM field, including ones which do not satisfy the vacuum Faraday's and Ampere's laws. [Of course, the further a given quantum fluctuation is from being a solution of these Maxwell equations, the more brief will be its existence, which reduces its influence.] Vacuum EM fluctuations of course have to satisfy charge conservation. In the presence of backgrounds one can think in terms of distinct electric and magnetic sectors, and discuss quantum fluctuations in these sectors separately as we shall do. It is known (although nowhere in the literature adequately discussed) that the electric and magnetic sectors in the EM Casimir effect *compete*, with electric quantum fluctuations giving rise to attractive Casimir forces and magnetic quantum fluctuations to repulsive Casimir forces between metal boundary objects. (See, e.g., Refs. 12 and 13 for early work suggesting this.) The seemingly unpredictable dependence of the static EM Casimir effect on boundary geometry[14–17] arises from this competition between electric and magnetic sectors.

There exists an interesting analogy between the scalar and EM Casimir effects. A scalar field interacting with a Dirichlet object is in some sense analogous to the electric vacuum sector interacting with a usual (i.e., electric charge) metal object. Just as distinct D objects have an attractive Casimir effect in scalar QFT, the electric vacuum sector always gives rise to attraction between distinct metal objects.[4,12,13]

Distinct N objects in scalar QFT also have an attractive Casimir effect. Such objects correspond to ''magnetic monopole metal'' objects in EM theory, with the magnetic vacuum sector in the role of the scalar field. Of course the magnetic vacuum sector interacting with monopole-metal objects is just the dual of the electric sector with metal objects, so it must have the same behavior.[18]

The Casimir repulsion[2,3] between distinct D and N objects in scalar QFT has an analog in electromagnetism. For example, parallel metal and monopole-metal planes repel.[18] This system is the only one discussed in the literature known to the author involving both metal and monopole metal boundaries. However, basic physical arguments[4] rather convincingly reveal that distinct metal and monopole metal objects must necessarily have a repulsive Casimir effect.

Returning to the insertion of metal point and line boundaries into symmetric backgrounds, the reader might ask how physically relevant such small boundaries can be. The answer to this question provides useful insight into the electromagnetic Casimir effect.

1. Metal point boundary

Idealized as a tiny metal sphere, such a boundary has little effect on the magnetic vacuum sector. The boundary condition on the magnetic field at the surface of metal is $B_\perp = 0$. Essentially all field lines of any vacuum fluctuation are already parallel to the ''surface'' of the metal point; thus $B_\perp = 0$ causes little distortion of any nearby quantum fluctuation of the magnetic field. Presumably there is no room on the surface of a metal point for currents to flow to cancel intruding $B_\perp$ from vacuum fluctuations—but neither are such induced currents needed. It is such induced surface currents on metal objects (which cancel intruding $B_\perp$ from magnetic vacuum fluctuations) which make the magnetic vacuum sector exert repulsive forces between distinct metal objects. For metal points we see this magnetic repulsion mechanism is strongly suppressed.

The effect of the metal point boundary on the electric vacuum sector is quite pronounced. The metal boundary condition $E_\parallel = 0$ at the metal point strongly distorts nearby vacuum fluctuations of the electric field, bending field lines so they radially approach the metal point. Induced electric surface charges are of course responsible for this. It seems physically reasonable for induced surface charges to find room to exist even where surface currents cannot. In general the closed electric field lines of vacuum fluctuations can be ''opened'' by induced charges on a given metal object, or by induced charges on two distinct metal objects. The latter mechanism is what makes the electric vacuum sector attractive. This mechanism still functions for metal point boundaries, while as we have seen magnetic vacuum repulsion is hardly present for metal points. Thus one expects that small metal objects will always experience attractive Casimir forces from other nearby metal objects. For example, two metal points attract,[12] and a metal point will be attracted to a metal plane.[13] Moreover, a small metal object between parallel metal planes should attract these planes much as in the scalar example of Sec. IV B.

Such considerations suggest an interesting modification of the standard experiment,[19,20] verifying the static Casimir force between parallel uncharged metal plates. Let these plates have area A and separation L. Insertion into the midplane of a small uncharged metal object should modify the usual Casimir force $F_{\mathrm{Cas}} = A[c/L^4]$ on one plane[19,20] as follows:

$$F_{\mathrm{Cas}} = A\,\frac{c}{L^4} + \frac{d}{L^2}. \tag{6.1}$$

Here the constant $d>0$ fixing the strength of the metal point's attraction to either metal plate can be approximately calculated. Even if the second term in Eq. (6.1) is small relative to the first, it may well be detectable because of the quite different power of L involved. Moreover, one could displace the small metal object nearer to one plane than the other and observe the resulting change in $F_{\rm Cas}$. Further, this object could be moved laterally through the space between the parallel planes, which should result in a transient increase in $F_{\rm Cas}$. Successful observation of any of these effects would make the already convincing experimental Casimir effect even more compelling.

2. Metal line boundary

Idealized as a thin long wire, a metal line boundary also has little effect on the magnetic vacuum sector, but a strong effect on the electric vacuum sector. Thus metal wires will experience attractive Casimir forces from other nearby metal objects. Additional modifications of the standard Casimir effect suggest themselves, e.g., positioning an uncharged metal wire between the parallel planes, or moving the wire laterally through the space between these planes.

A final comment recalls the different (for some boundary configurations) Casimir forces obtained from $T_{\mu\nu}$ and $\theta_{\mu\nu}$ for a scalar quantum field. A similar situation exists in EM theory. One way to view this situation is that the Casimir effect provides in principle a way to distinguish experimentally between different stress tensors.

An article discussing the EM Casimir effect from the perspective presented above is in preparation.

ACKNOWLEDGMENTS

The author thanks I. Bender for his advice and influence on these calculations. APPENDIX: MODE SUMS FOR THE VACUUM STRESS TENSOR

In a convenient and general notation the spatial heat kernel for a scalar field interacting with a static background is defined by

$$K(t|\vec{x},\vec{y})\equiv\sum_n e^{-t\omega_n^2}\phi_n(\vec{x})\,\overline{\phi_n}(\vec{y}), \tag{A1}$$

$$[-\Delta_x+V(\vec{x})]\phi_n(\vec{x})=\omega_n^2\phi_n(\vec{x}). \tag{A2}$$

The spatial modes $\phi_n(\vec{x})$ are understood to comprise a complete orthonormal set, selected from other such sets by the background potential $V(\vec{x})$. This potential represents either softened Dirichlet boundary structure, or actual Dirichlet boundary conditions on one or more surfaces. [In a formal way one might also think of $V(\vec{x})$ as representing Neumann boundary conditions as well.] In any case $V(\vec{x})$ couples the quantum field to the classical background. The heat kernel (A1) by construction satisfies Eq. (A2) in $\vec{x}$ and in $\vec{y}$ separately.

From the heat kernel (A1) one can obtain quite directly a number of important local physical quantities, in particular the canonical and improved vacuum stress tensors $T_{\mu\nu}$ and $\theta_{\mu\nu}$. These tensors consist of a number of terms, each having a mode-sum representation which can be gotten directly from

$$\sum_n (\omega_n^2)^{-s}\phi_n(\vec{x})\,\overline{\phi_n}(\vec{y})=\frac{1}{\Gamma(s)}\int_0^\infty dt\,t^{s-1}K(t|\vec{x},\vec{y}). \tag{A3}$$

Here the Mellin transform of K introduces ultraviolet singularities at $t=0$ which must be removed from the mode sum on the left (UV regularization). Aside from this, an explicit calculation of the bilocal mode sum (A3) for a given system yields straightforwardly $T_{\mu\nu}$ and $\theta_{\mu\nu}$, Casimir force densities throughout the spatial background of this system, and so on.

Explicit mode-sum formulas for $T_{\mu\nu}$ and $\theta_{\mu\nu}$ are given in Ref. 2. We list these again here for a massless scalar field with $V(\vec{x})=0$:

$$T_{00}=\frac{1}{4}\sum_n \omega_n|\phi_n|^2+\frac{1}{4}\sum_n \frac{1}{\omega_n}|\vec{\nabla}\phi_n|^2,$$

$$T_{ii}=\frac{1}{2}\sum_n \frac{1}{\omega_n}|\partial_i\phi_n|^2-\frac{1}{4}\sum_n \frac{1}{\omega_n}|\vec{\nabla}\phi_n|^2+\frac{1}{4}\sum_n \omega_n|\phi_n|^2, \quad i \text{ not summed},$$

$$T_{0i}=\theta_{0i}=\frac{i}{4}\sum_n [(\partial_i\phi_n)\overline{\phi_n}-\phi_n(\partial_i\overline{\phi_n})],$$

$$T_{ij}=\frac{1}{4}\sum_n \frac{1}{\omega_n}[\partial_i\phi_n\partial_j\overline{\phi_n}+\partial_j\phi_n\partial_i\overline{\phi_n}], \quad i\neq j$$

$$\theta_{00}=\frac{2d-1}{4d}\sum_n \omega_n|\phi_n|^2+\frac{1}{4d}\sum_n \frac{1}{\omega_n}|\vec{\nabla}\phi_n|^2,$$

$$\theta_{ii}=\frac{d+1}{4d}\sum_n \frac{1}{\omega_n}|\partial_i\phi_n|^2+\frac{1}{4d}\sum_n \omega_n|\phi_n|^2-\frac{1}{4d}\sum_n \frac{1}{\omega_n}|\vec{\nabla}\phi_n|^2$$
$$-\frac{d-1}{8d}\sum_n \frac{1}{\omega_n}[\phi_n\partial_i^2\overline{\phi_n}+(\partial_i^2\phi_n)\overline{\phi_n}],$$
$$i \text{ not summed},$$

$$\theta_{ij}=\frac{d+1}{8d}\sum_n \frac{1}{\omega_n}[\partial_i\phi_n\partial_j\overline{\phi_n}+\partial_j\phi_n\partial_i\overline{\phi_n}]-\frac{d-1}{8d}\sum_n \frac{1}{\omega_n}[\phi_n\partial_i\partial_j\overline{\phi_n}+(\partial_i\partial_j\phi_n)\overline{\phi_n}],$$
$$i\neq j.$$

A simple technique employed almost three decades ago to manufacture partially solvable quantum many-body problems is revisited. [A quantum problem is "partially solvable" if (only) some of its eigenvalues and eigenfunctions can be exhibited]. The models thereby generated are characterized by Hamiltonians of normal form, i.e., standard kinetic plus momentum-independent potential energy; in most cases the latter features three-body, in addition to two-body and one-body, interactions. The setting refers to D-dimensional space; the examples focus on $D=1$, $D=2$, and $D\geqslant 2$, and include generalizations of, and additional results on, cases recently discussed in the literature, as well as new models. [S0022-2488(99)02409-3]

I. INTRODUCTION

Several recent papers[1–8] have presented and discussed partially solvable quantum many-body problems. (We call "partially solvable" a quantum problem if some of, but not all, its eigenvalues and eigenfunctions can be exhibited; for simplicity attention is hereafter restricted to bound states and discrete eigenvalues.) This prompted us to revisit a simple technique employed almost three decades ago[9] to manufacture partially solvable quantum many-body problems. We thereby generate a variety of such models. They are characterized by Hamiltonians of normal form, with standard kinetic energy and momentum-independent potential energy; in most cases the latter features three-body, in addition to two-body and one-body (and possibly some special "N-body"), interactions. The setting refers to D-dimensional space, and attention is restricted to rotation-invariant Hamiltonians. The examples focus on $D=1$, $D=2$, and $D\geqslant 2$. We exhibit a fairly general class of models, which is then specialized to specific examples. These include generalized versions of cases discussed in the literature,[1–10] as well as new partially solvable quantum many-body problems. Moreover, in some cases, our treatment of known models goes beyond previous findings, inasmuch as the collection of eigenstates we exhibit is larger than that previously known.

In Sec. II we display for convenience a representative list of the partially solvable models treated in this paper. Section III explains the main idea and reports the basic formulas from which the various models are then easily obtained, and exhibited as specific examples, in Sec. IV. Section V contains some concluding remarks and hints at future developments.

The relations of the specific models exhibited herein with previous findings[1–11] are discussed below, in Sec. IV, on a case-by-case basis. The notation is defined at the beginning of Sec. III, but it is sufficiently self-evident to allow direct browsing through Sec. II.

II. A REPRESENTATIVE LIST OF PARTIALLY SOLVABLE QUANTUM MANY-BODY PROBLEMS IN D-DIMENSIONAL SPACE

In this section we present, for convenience, a representative list of the partially solvable quantum many-body problems treated in this paper. We only report here those with one-, two-, and three-body interactions, for whose definition the reader is referred, if need be, to (3.1) with (3.2) [and let us also recall that *partial solvability* entails the capability to exhibit at least one solution of the stationary Schrödinger equation (3.3)]. These results are derived, and explained in somewhat more detail, in Sec. IV, where we also report more general models than those displayed here, including some that include certain special ''N-body'' potentials.

The first model we report [see (4.1b), (4.3b), and (4.3c)] is characterized by translation-invariant interactions:

$$u_j^{(1)}(\vec{r})=0, \tag{2.1a}$$

$$u_{jk}^{(2)}(\vec{r}_1,\vec{r}_2)=u_{jk}^{(2)}(r_{12})=[(m_j+m_k)/(4m_jm_k)][\alpha_{jk}(\alpha_{jk}+D-2)/r_{12}{}^2-\beta_{jk}(2\alpha_{jk}+D-1)/r_{12}], \tag{2.1b}$$

$$u_{j_1j_2j_3}^{(3)}(\vec{r}_1,\vec{r}_2,\vec{r}_3)=u_{j_1j_2j_3}^{(3)}(\vec{r}_{12},\vec{r}_{13})$$
$$=(m_{j_1})^{-1}[(\vec{r}_{12}\cdot\vec{r}_{13})/(r_{12}r_{13})^2][\alpha_{j_1j_2}-\beta_{j_1j_2}r_{12}][\alpha_{j_1j_3}-\beta_{j_1j_3}r_{13}]. \tag{2.1c}$$

Here and below D is the dimensionality of space and m_j are the particle masses; the $N(N-1)$ constants $\alpha_{jk}=\alpha_{kj}$, $\beta_{jk}=\beta_{kj}$ are largely arbitrary (say, nonnegative), and $\vec{r}_{jk}\equiv\vec{r}_j-\vec{r}_k$.

The second and third models [see (4.7c) with (4.10b) and (4.10d), and again (4.7c) but with (4.11b) and (4.11d)] read

$$u_j^{(1)}(r)=2m_j\alpha^2r^2, \tag{2.2a}$$

$$u_{jk}^{(2)}(\vec{r}_1,\vec{r}_2)=u_{jk}^{(2)}(r_1,r_2)$$
$$=g_{jk}a\{[(m_j+m_k)/(8m_jm_k)]\{(g_{jk}-1)a\cosh[2a(r_1-r_2)]/\sinh^2[a(r_1-r_2)]$$
$$-2(D-1)\{r_2-r_1\exp[a(r_1-r_2)]\}/[r_1r_2\{1-\exp[a(r_1r_2)]\}]\}$$
$$+\alpha\{r_1-r_2\exp[a(r_1-r_2)]\}/\{1-\exp[a(r_1-r_2)]\}\}, \tag{2.2b}$$

$$u_{j_1j_2j_3}^{(3)}(\vec{r}_1,\vec{r}_2,\vec{r}_3)=u_{j_1j_2j_3}^{(3)}(r_1,r_2,r_3)$$
$$=(m_{j_1})^{-1}g_{j_1j_2}g_{j_1j_3}\{1-\exp[a(r_1-r_2)]\}^{-1}\{1-\exp[a(r_1-r_3)]\}^{-1}; \tag{2.2c}$$

and, with $u_j^{(1)}(r)$ given again by (2.2a),

$$u_{jk}^{(2)}(\vec{r}_1,\vec{r}_2)=u_{jk}^{(2)}(r_1,r_2)$$
$$=g_{jk}b[(m_j+m_k)/(4m_jm_k)]\{(g_{jk}-1)b[r_1{}^{2(b-1)}+r_2{}^{2(b-1)}]/(r_1{}^b-r_2{}^b)^2$$
$$+(b+D-2)[r_1{}^{b-2}-r_2{}^{b-2}]/(r_1{}^b-r_2{}^b)\}, \tag{2.3a}$$

$$u_{j_1j_2j_3}^{(3)}(\vec{r}_1,\vec{r}_2,\vec{r}_3)=u_{j_1j_2j_3}^{(3)}(r_1,r_2,r_3)=(m_{j_1})^{-1}g_{j_1j_2}g_{j_1j_3}r_1{}^{2(b-1)}/[(r_1{}^b-r_2{}^b)(r_1{}^b-r_3{}^b)]. \tag{2.3b}$$

Here the $N(N-1)/2$ constants $g_{jk}=g_{kj}$ are also largely arbitrary (nonnegative), as well as the two constants a and b.

The fourth model we report [see (4.14a)–(4.14c)] reads

$$u_j^{(1)}(\vec{r})=u_j^{(1)}(r)=v_j(r), \tag{2.4a}$$

$$u_{jk}^{(2)}(\vec{r}_1,\vec{r}_2)=[(m_j+m_k)/(4m_jm_k)]g_{jk}(g_{jk}-1)(r_1{}^2+r_2{}^2)/(\vec{r}_1\cdot\vec{r}_2)^2, \tag{2.4b}$$

$$u_{j_1j_2j_3}^{(3)}(\vec{r}_1,\vec{r}_2,\vec{r}_3)=(m_{j_1})^{-1}g_{j_1j_2}g_{j_1j_3}(\vec{r}_2\cdot\vec{r}_3)/[(\vec{r}_1\cdot\vec{r}_2)(\vec{r}_1\cdot\vec{r}_3)]. \tag{2.4c}$$

In these formulas $v_j(r)$ are rotation-invariant one-body potentials (arbitrary, but solvable in D-dimensional space for arbitrary angular momentum), and the $N(N-1)/2$ constants $g_{jk}=g_{kj}$ are again arbitrary nonnegative numbers.

The fifth model we report [see (4.21a)–(4.21c)]

$$u_{jk}^{(2)}(\vec{r}_1,\vec{r}_2)=[(m_j+m_k)/(4m_jm_k)](r_1{}^2+r_2{}^2)[g_{jk}(g_{jk}-1)/(\vec{r}_1\cdot\vec{r}_2)^2+\tilde{g}_{jk}(\tilde{g}_{jk}-1)/(\hat{z}\cdot\vec{r}_1\wedge\vec{r}_2)^2], \tag{2.5a}$$

$$\begin{aligned} u_{j_1j_2j_3}^{(3)}(\vec{r}_1,\vec{r}_2,\vec{r}_3)=(m_{j_1})^{-1}[&(\vec{r}_2\cdot\vec{r}_3)\{g_{j_1j_2}g_{j_1j_3}/[(\vec{r}_1\cdot\vec{r}_2)(\vec{r}_1\cdot\vec{r}_3)]\\ &+\tilde{g}_{j_1j_2}\tilde{g}_{j_1j_3}/[(\hat{z}\cdot\vec{r}_1\wedge\vec{r}_2)(\hat{z}\cdot\vec{r}_1\wedge\vec{r}_3)]\}\\ &+(\hat{z}\cdot\vec{r}_2\wedge\vec{r}_3)\{g_{j_1j_2}\tilde{g}_{j_1j_3}/[(\vec{r}_1\cdot\vec{r}_2)(\hat{z}\cdot\vec{r}_1\wedge\vec{r}_3)]\\ &-\tilde{g}_{j_1j_2}g_{j_1j_3}/[(\hat{z}\cdot\vec{r}_1\wedge\vec{r}_2)(\vec{r}_1\cdot\vec{r}_3)]\}], \end{aligned} \tag{2.5b}$$

again with (2.4a), see above, and the $N(N-1)$ constants $g_{jk}=g_{kj}$, $\tilde{g}_{jk}=\tilde{g}_{kj}$ arbitrary nonnegative numbers. In this case $D=2$ (while in the other cases displayed above the dimensionality D of space is arbitrary), and we employ the definition $\hat{z}\cdot\vec{r}_j\wedge\vec{r}_k\equiv x_jy_k-y_jx_k$.

In the case of the first three models, exact formulas are given in Sec. IV for (at least) one eigenvalue and the corresponding eigenfunction; for the last two, large families of eigenvalues and eigenfunctions are given, depending on N quantum numbers (the *complete* energy spectrum and set of eigenfunctions depends generally on ND quantum numbers).

Finally let us re-emphasize that not all these models are quite new; for a discussion of this aspect on a case-by-case basis, including of course the attribution of due credits, see Sec. IV.

III. MAIN IDEA AND BASIC RESULTS

Notation: D-dimensional vectors are denoted by superimposed arrows, say $\vec{r}_j$, with the usual (Euclidean) definitions for the scalar product $\vec{r}_j\cdot\vec{r}_k$ and the modulus $r_j\equiv(\vec{r}_j\cdot\vec{r}_j)^{1/2}$. Indices generally run from 1 to N, for N-body problems. Unless otherwise indicated, both D and N are *arbitrary positive integers*. We denote by m_j the mass of the jth particle, and generally write the quantum many-body Hamiltonian as follows:

$$H=-\sum_{j=1}^{N}(2m_j)^{-1}\Delta_j+U(\vec{r}_1,\ldots,\vec{r}_N), \tag{3.1}$$

with $\Delta_j\equiv\vec{\nabla}_j\cdot\vec{\nabla}_j$, $\vec{\nabla}_j\equiv\partial/\partial\vec{r}_j$ (hence we have chosen units so that $\hbar=1$). The potential energy $U(\vec{r}_1,\ldots,\vec{r}_N)$ will be conveniently split up into multibody contributions as follows:

$$U(\vec{r}_1,\ldots,\vec{r}_N)=\sum_{n=1}^{N}U^{(n)}(\vec{r}_1,\ldots,\vec{r}_N), \tag{3.2a}$$

$$U^{(1)}(\vec{r}_1,\ldots,\vec{r}_N)=\sum_{j=1}^{N}u_j^{(1)}(\vec{r}_j), \tag{3.2b}$$

$$U^{(2)}(\vec{r}_1,\ldots,\vec{r}_N)=(1/2)\sum_{j,k=1;j\neq k}^{N}u_{jk}^{(2)}(\vec{r}_j,\vec{r}_k)=\sum_{1\leqslant j<k\leqslant N}u_{jk}^{(2)}(\vec{r}_j,\vec{r}_k), \tag{3.2c}$$

$$U^{(3)}(\vec{r}_1,\ldots,\vec{r}_N)=(1/2)\sum_{j_1,j_2,j_3=1;j_1\neq j_2,j_2\neq j_3,j_3\neq j_1}^{N} u^{(3)}_{j_1j_2j_3}(\vec{r}_{j_1},\vec{r}_{j_2},\vec{r}_{j_3})$$
$$=\sum_{j_1,j_2,j_3=1;j_1\neq j_2,j_1\neq j_3,j_2<j_3}^{N} u^{(3)}_{j_1j_2j_3}(\vec{r}_{j_1},\vec{r}_{j_2},\vec{r}_{j_3}), \tag{3.2d}$$

and so on (but in fact consideration will be mainly focused on problems with up to three-body interactions, except possibly for some special ''N-body'' contributions, see below). Note that, as indicated by these formulas, $u^{(2)}_{jk}(\vec{r}_1,\vec{r}_2)=u^{(2)}_{kj}(\vec{r}_2,\vec{r}_1)$, $u^{(3)}_{j_1j_2j_3}(\vec{r}_1,\vec{r}_2,\vec{r}_3)=u^{(3)}_{j_1j_3j_2}(\vec{r}_1,\vec{r}_3,\vec{r}_2)$. We do not assume *a priori* all particles to be equal, indeed we allow them to have different masses and interactions; and for simplicity we pay no attention hereafter to the statistics obeyed by identical particles (this gap can be easily filled by the diligent reader).

We seek solutions of the stationary Schrödinger equation

$$[H-E]\Psi(\vec{r}_1,\ldots,\vec{r}_N)=0, \tag{3.3}$$

using for the eigenfunction $\Psi(\vec{r}_1,\ldots,\vec{r}_N)$ the *ansatz*

$$\Psi(\vec{r}_1,\ldots,\vec{r}_N)=F(\vec{r}_1,\ldots,\vec{r}_N)\,\psi(\vec{r}_1,\ldots,\vec{r}_N), \tag{3.4a}$$

$$F(\vec{r}_1,\ldots,\vec{r}_N)=\prod_{n=1}^{N} F^{(n)}(\vec{r}_1,\ldots,\vec{r}_N), \tag{3.4b}$$

$$F^{(1)}(\vec{r}_1,\ldots,\vec{r}_N)=\prod_{j=1}^{N} f^{(1)}_j(\vec{r}_j)=\exp\left[\sum_{j=1}^{N}\varphi^{(1)}_j(\vec{r}_j)\right], \tag{3.4c}$$

$$F^{(2)}(\vec{r}_1,\ldots,\vec{r}_N)=\prod_{j=1,k=1;j\neq k}^{N}[f^{(2)}_{jk}(\vec{r}_j,\vec{r}_k)]^{1/2}$$
$$=\prod_{1\leq j<k\leq N}[f^{(2)}_{jk}(\vec{r}_j,\vec{r}_k)]$$
$$=\exp\left[(1/2)\sum_{j,k=1;j\neq k}^{N}\varphi^{(2)}_{jk}(\vec{r}_j,\vec{r}_k)\right]$$
$$=\exp\left[\sum_{1\leq j<k\leq N}\varphi^{(2)}_{jk}(\vec{r}_j,\vec{r}_k)\right], \tag{3.4d}$$

and so on (in fact we shall hardly go beyond, see below). Note that these formulas imply $f^{(2)}_{jk}(\vec{r}_1,\vec{r}_2)=f^{(2)}_{kj}(\vec{r}_2,\vec{r}_1)$ and likewise $\varphi^{(2)}_{jk}(\vec{r}_1,\vec{r}_2)=\varphi^{(2)}_{kj}(\vec{r}_2,\vec{r}_1)$, as well as

$$f^{(1)}_j(\vec{r})=\exp[\varphi^{(1)}_j(\vec{r})],\quad f^{(2)}_{jk}(\vec{r}_1,\vec{r}_2)=\exp[\varphi^{(2)}_{jk}(\vec{r}_1,\vec{r}_2)], \tag{3.5a}$$

entailing

$$\vec{\nabla}f^{(1)}_j(\vec{r})=f^{(1)}_j(\vec{r})\vec{\nabla}\varphi^{(1)}_j(\vec{r}),\quad \Delta f^{(1)}_j(\vec{r})=f^{(1)}_j(\vec{r})\{\Delta\varphi^{(1)}_j(\vec{r})+[\vec{\nabla}\varphi^{(1)}_j(\vec{r})]^2\}, \tag{3.5b}$$

and analogous formulas for $f^{(2)}_{jk}(\vec{r}_1,\vec{r}_2)$ and $\varphi^{(2)}_{jk}(\vec{r}_1,\vec{r}_2)$. In the following we employ the f or φ notation according to convenience.

The *ansatz* (3.4) is of course highly redundant; we take advantage of this by making appropriate choices for the ''correlation factors'' $F^{(n)}(\vec{r}_1,\ldots,\vec{r}_N)$, see below. The idea is to impose that $\Psi(\vec{r}_1,\ldots,\vec{r}_N)$, see (3.4), satisfy the Schrödinger equation (3.3), and to identify the corresponding potential $U(\vec{r}_1,\ldots,\vec{r}_N)$, see (3.1) and (3.2), and the energy eigenvalue E; there will be cases when, to a specific potential $U(\vec{r}_1,\ldots,\vec{r}_N)$, there correspond different eigenfunctions $\Psi_{\mu_1,\mu_2,\ldots}(\vec{r}_1,\ldots,\vec{r}_N)$, labeled by one or more quantum numbers $\mu_1,\mu_2,\ldots$, and correspondingly energy eigenvalues $E_{\mu_1,\mu_2,\ldots}$ (possibly degenerate, see below).

Let us then insert the *ansatz* (3.4) into the Schrödinger equation (3.3). There are two approaches, which we like to set out explicitly so as to avoid misunderstandings. Firstly we obtain, via (3.1), the following formulas:

$$(\tilde{H}-\tilde{E})\psi=0, \tag{3.6}$$

with

$$\tilde{H}=-\sum_{j=1}^{N}(2m_j)^{-1}\Delta_j-i\sum_{j=1}^{N}[\vec{W}_j(\vec{r}_1,\ldots,\vec{r}_N)\cdot\vec{\nabla}_j+\vec{\nabla}_j\cdot\vec{W}_j(\vec{r}_1,\ldots,\vec{r}_N)]+\tilde{U}(\vec{r}_1,\ldots,\vec{r}_N), \tag{3.7a}$$

$$\tilde{U}(\vec{r}_1,\ldots,\vec{r}_N)-\tilde{E}=U(\vec{r}_1,\ldots,\vec{r}_N)-E-\sum_{j=1}^{N}(2m_j)^{-1}[\vec{V}_j(\vec{r}_1,\ldots,\vec{r}_N)]^2, \tag{3.7b}$$

where

$$\vec{V}_j(\vec{r}_1,\ldots,\vec{r}_N)=[F(\vec{r}_1,\ldots,\vec{r}_N)]^{-1}\vec{\nabla}_jF(\vec{r}_1,\ldots,\vec{r}_N), \tag{3.7c}$$

$$\vec{W}_j(\vec{r}_1,\ldots,\vec{r}_N)=-i(2m_j)^{-1}\vec{V}_j(\vec{r}_1,\ldots,\vec{r}_N). \tag{3.7d}$$

Note that in the right-hand-side of (3.7a) $\vec{\nabla}_j$ is an operator, so that

$$\vec{\nabla}_j\cdot\vec{W}_j\psi=\vec{W}_j\cdot(\vec{\nabla}_j\psi)+\psi(\vec{\nabla}_j\cdot\vec{W}_j). \tag{3.8}$$

These formulas entail the following (trivial) Remark: *If the Schrödinger equation (3.3) with (3.1) is solvable, also solvable is the Schrödinger equation (3.6) with (3.7).* Indeed the two problems are related by the unitary transformation $F^{-1}(H-E)F=(\tilde{H}-\tilde{E})$ [we allow for the possibility to chose $\tilde{E}\neq E$, so that neither $U(\vec{r}_1,\ldots,\vec{r}_N)$ nor $\tilde{U}(\vec{r}_1,\ldots,\vec{r}_N)$ contain an *additive constant*; a requirement which makes sense only if both potentials vanish asymptotically]. The (also trivial) classical counterpart of this *Remark* states that *the two classical problems characterized by the Hamiltonians*

$$H(\vec{p}_1,\ldots,\vec{p}_N;\vec{r}_1,\ldots,\vec{r}_N)=\sum_{j=1}^{N}(2m_j)^{-1}p_j^{\,2}+U(\vec{r}_1,\ldots,\vec{r}_N), \tag{3.9a}$$

$$\tilde{H}(\vec{P}_1,\ldots,\vec{P}_N;\vec{r}_1,\ldots,\vec{r}_N)=\sum_{j=1}^{N}(2m_j)^{-1}P_j^{\,2}+2\sum_{j=1}^{N}\vec{P}_j\cdot\vec{W}_j(\vec{r}_1,\ldots,\vec{r}_N)+\tilde{U}(\vec{r}_1,\ldots,\vec{r}_N), \tag{3.9b}$$

are equivalent [they entail the same evolution for the particle positions $\vec{r}_j(t)$]. Indeed they are related by the *canonical transformation* $\vec{p}_j=\vec{P}_j-i\vec{V}_j(\vec{r}_1,\ldots,\vec{r}_N)$, $\vec{r}_j=\vec{R}_j$, with $\vec{W}_j(\vec{r}_1,\ldots,\vec{r}_N)$ related to $\vec{V}_j(\vec{r}_1,\ldots,\vec{r}_N)$ by (3.7d), and of course $\tilde{U}(\vec{r}_1,\ldots,\vec{r}_N)$ related to $U(\vec{r}_1,\ldots,\vec{r}_N)$ by (3.7b). Note that these *Remarks* hold for an *arbitrary* choice of the N D-vector functions $\vec{V}_j(\vec{r}_1,\ldots,\vec{r}_N)$, provided they admit the representation (3.7c). They entail the possibility to introduce solvable many-body problems, by starting from a trivially solvable problem [say, from (3.1) with

$U(\vec{r}_1,\ldots,\vec{r}_N)$ given by (3.2a) where $U^{(n)}(\vec{r}_1,\ldots,\vec{r}_N)=0$ for $n>1$ and $u_j^{(1)}(r)$ in (3.2b) are solvable one-body potentials] and getting a new, *apparently* nontrivial, Hamiltonian via (3.7) or (3.9). This is not the route we follow below.

The second approach is, perhaps, less trivial. It is based on another set of formulas [also equivalent, via (3.4), to (3.3) with (3.1)]:

$$-\sum_{j=1}^{N}(2m_j)^{-1}[\Delta_j+2\vec{V}_j(\vec{r}_1,\ldots,\vec{r}_N)\cdot\vec{\nabla}_j]\psi(\vec{r}_1,\ldots,\vec{r}_N)=0, \tag{3.10}$$

$$\vec{V}_j(\vec{r}_1,\ldots,\vec{r}_N)=\sum_{n=1}^{N}\vec{V}_j^{(n)}(\vec{r}_1,\ldots,\vec{r}_N), \tag{3.11}$$

$$U(\vec{r}_1,\ldots,\vec{r}_N)-E=\sum_{j=1}^{N}(2m_j)^{-1}\sum_{n=1}^{N}[F(\vec{r}_1,\ldots,\vec{r}_N)]^{-1}\Delta_j F(\vec{r}_1,\ldots,\vec{r}_N), \tag{3.12a}$$

$$U(\vec{r}_1,\ldots,\vec{r}_N)-E=\sum_{j=1}^{N}(2m_j)^{-1}\left\{\sum_{n=1}^{N}[F^{(n)}(\vec{r}_1,\ldots,\vec{r}_N)]^{-1}\Delta_j F^{(n)}(\vec{r}_1,\ldots,\vec{r}_N)\right.$$
$$\left.+\sum_{m,n=1;m\neq n}^{N}\vec{V}_j^{(m)}(\vec{r}_1,\ldots,\vec{r}_N)\cdot\vec{V}_j^{(n)}(\vec{r}_1,\ldots,\vec{r}_N)\right\}, \tag{3.12b}$$

$$U(\vec{r}_1,\ldots,\vec{r}_N)-E=\sum_{j=1}^{N}(2m_j)^{-1}\left\{\sum_{n=1}^{N}\vec{\nabla}_j\cdot\vec{V}_j^{(n)}(\vec{r}_1,\ldots,\vec{r}_N)\right.$$
$$\left.+\sum_{m,n=1}^{N}\vec{V}_j^{(m)}(\vec{r}_1,\ldots,\vec{r}_N)\cdot\vec{V}_j^{(n)}(\vec{r}_1,\ldots,\vec{r}_N)\right\}, \tag{3.12c}$$

where

$$\vec{V}_j^{(n)}(\vec{r}_1,\ldots,\vec{r}_N)=[F^{(n)}(\vec{r}_1,\ldots,\vec{r}_N)]^{-1}\vec{\nabla}_j F^{(n)}(\vec{r}_1,\ldots,\vec{r}_N)=\vec{\nabla}_j\log[F^{(n)}(\vec{r}_1,\ldots,\vec{r}_N)]. \tag{3.13}$$

The equivalence among (3.12a) and (3.12b) is consistent with the definition (3.4b); likewise, the equivalence among (3.12b) and (3.12c) is entailed by the definition (3.13) [note that in the double sum in the right-hand-side of (3.12b) the ''diagonal'' term with $m=n$ is omitted while it is instead present in the double sum in the right-hand-side of (3.12c)].

The modified Schrödinger equation (3.10) provides a convenient starting point for the treatment of *completely solvable* models, including the well-known *one-dimensional* case with *equal particles* and *two-body inverse-square potentials* (possibly with an additional interaction, for instance a harmonic oscillator potential, or a ''Coulomb-type'' potential, depending only on the global coordinate $\Sigma_{j=1}^{n}x_j{}^2$).[11,7] Hereafter we set instead $\psi(\vec{r}_1,\ldots,\vec{r}_N)=1$, and thereby satisfy (3.10) trivially. We moreover set $F^{(n)}(\vec{r}_1,\ldots,\vec{r}_N)=1$ for $2<n<N$, namely we restrict only to $F^{(1)}(\vec{r}_1,\ldots,\vec{r}_N)$, $F^{(2)}(\vec{r}_1,\ldots,\vec{r}_N)$ and $F^{(N)}(\vec{r}_1,\ldots,\vec{r}_N)$ (with a special *ansatz* for this latter, see below) our freedom to chose, compatibly with the *ansatzen* (3.4c), (3.4d) etc., nontrivial ''correlation factors'' $F^{(n)}(\vec{r}_1,\ldots,\vec{r}_N)$ [which then determine the ''partially solvable'' potential $U(\vec{r}_1,\ldots,\vec{r}_N)$ via (3.12), see below]. To explain this restriction let us emphasize that, for $2n-1\leqslant N$, a nontrivial presence of the ''correlation factor'' $F^{(n)}(\vec{r}_1,\ldots,\vec{r}_N)$ yields up to $(2n-1)$-body interactions in the corresponding partially solvable potential [see (3.12) and below].

Hence [from (3.12b)]

$$U(\vec{r}_1,\ldots,\vec{r}_N)-E=\sum_{j=1}^{N}(2m_j)^{-1}\{[F^{(1)}]^{-1}\Delta_jF^{(1)}+[F^{(2)}]^{-1}\Delta_jF^{(2)}$$
$$+[F^{(N)}]^{-1}\Delta_jF^{(N)}+2\vec{V}_j^{(1)}\cdot\vec{V}_j^{(2)}+2\vec{V}_j^{(1)}\cdot\vec{V}_j^{(N)}+2\vec{V}_j^{(2)}\cdot\vec{V}_j^{(N)}\}. \tag{3.14}$$

To preserve rotation-invariance we moreover set [see (3.4c)]

$$f_j^{(1)}(\vec{r})=f_j^{(1)}(r)=\exp[\varphi_j^{(1)}(\vec{r})]=\exp[\varphi_j^{(1)}(r)] \tag{3.15a}$$

so that

$$[F^{(1)}(\vec{r}_1,\ldots,\vec{r}_N)]^{-1}\Delta_jF^{(1)}(\vec{r}_1,\ldots,\vec{r}_N)=[f_j^{(1)\prime\prime}(r_j)+(D-1)f_j^{(1)\prime}(r_j)/r_j]/f_j^{(1)}(r_j)$$
$$=\varphi_j^{(1)\prime\prime}(r_j)+[\varphi_j^{(1)\prime}(r_j)]^2+(D-1)\varphi_j^{(1)\prime}(r_j)/r_j, \tag{3.15b}$$

$$\vec{V}_j^{(1)}=\vec{r}_jf_j^{(1)\prime}(r_j)/[r_jf_j^{(1)}(r_j)]=\varphi_j^{(1)\prime}(r_j)\vec{r}_j/r_j. \tag{3.15c}$$

Of course appended primes denote differentiations with respect to the argument r_j.

We moreover set

$$F^{(N)}(\vec{r}_1,\ldots,\vec{r}_N)=F^{(N)}(\rho)=\exp[\Phi(\rho)], \tag{3.16a}$$

$$\rho^2=\sum_{j=1}^{N}2m_jr_j^2, \tag{3.16b}$$

so that

$$\sum_{j=1}^{N}(2m_j)^{-1}[F^{(N)}(\rho)]^{-1}\Delta_jF^{(N)}(\rho)=[\ddot{F}^{(N)}(\rho)+(ND-1)\dot{F}^{(N)}(\rho)/\rho]/F^{(N)}(\rho)$$
$$=\ddot{\Phi}(\rho)+[\dot{\Phi}(\rho)]^2+(ND-1)\dot{\Phi}(\rho)/\rho, \tag{3.16c}$$

$$\vec{V}_j^{(N)}=2m_j\vec{r}_j\dot{\Phi}(\rho)/\rho, \tag{3.16d}$$

where of course superimposed dots denote differentiation with respect to the argument ρ. In particular in the following we generally set (unless we state otherwise)

$$F^{(N)}(\rho)=\exp(-\alpha\rho^2/2),\quad \Phi(\rho)=-\alpha\rho^2/2,\quad \dot{\Phi}(\rho)=-\alpha\rho,\quad \ddot{\Phi}(\rho)=-\alpha, \tag{3.17a}$$

so that

$$\sum_{j=1}^{N}(2m_j)^{-1}[F^{(N)}(\rho)]^{-1}\Delta_jF^{(N)}(\rho)=\alpha^2\rho^2-\alpha ND, \tag{3.17b}$$

$$\vec{V}_j^{(N)}=-2m_j\alpha\vec{r}_j. \tag{3.17c}$$

To complete the construction of the potential $U(\vec{r}_1,\ldots,\vec{r}_N)$, see (3.14), we must still assign the two-body correlation functions $f_{jk}^{(2)}(\vec{r}_1,\vec{r}_2)$ or $\varphi_{jk}^{(2)}(\vec{r}_1,\vec{r}_2)$, see (3.4d). The discussion of various specific choices for these functions, as well as for the functions $f_j^{(1)}(r)$ or $\varphi_j^{(1)}(r)$, is postponed to the following section.

We end this section by rewriting the expression for $U(\vec{r}_1,\ldots,\vec{r}_N)$ and E, see (3.14), entailed by the choices made so far, see (3.15) and (3.16) with (3.17):

$$U(\vec{r}_1,\ldots,\vec{r}_N)=\sum_{j=1}^{N} u_j^{(1)}(r_j)+\sum_{j,k=1;j<k}^{N} u_{jk}^{(2)}(\vec{r}_j,\vec{r}_k)+\sum_{j_1,j_2,j_3=1;j_1\neq j_2,j_1\neq j_3,j_2<j_3}^{N} u_{j_1j_2j_3}^{(3)}(\vec{r}_{j_1},\vec{r}_{j_2},\vec{r}_{j_3}), \tag{3.18a}$$

$$E=\sum_{j=1}^{N} E_j^{(1)}+\sum_{j,k=1j:j<k}^{N} E_{jk}^{(2)}+\sum_{j_1,j_2,j_3=1;j_1\neq j_2,j_1\neq j_3,j_2<j_3}^{N} E_{j_1j_2j_3}^{(3)}, \tag{3.18b}$$

$$u_j^{(1)}(r)=2m_j\alpha^2r^2-\alpha D+\{(2m_j)^{-1}[f_j^{(1)\prime\prime}(r)+(D-1)f_j^{(1)\prime}(r)/r]$$
$$-2\alpha r f_j^{(1)\prime}(r)+E_j^{(1)}f_j^{(1)}\}/f_j^{(1)}(r), \tag{3.18c}$$

$$u_{jk}^{(2)}(\vec{r}_1,\vec{r}_2)=[f_{jk}^{(2)}(\vec{r}_1,\vec{r}_2)]^{-1}\{[(m_j+m_k)/(4m_jm_k)][(\Delta_1+\Delta_2)f_{jk}^{(2)}(\vec{r}_1,\vec{r}_2)$$
$$+2\{[\varphi_j^{(1)\prime}(r_1)/r_1](\vec{r}_1\cdot\vec{\nabla}_1)+[\varphi_k^{(1)\prime}(r_2)/r_2](\vec{r}_2\cdot\vec{\nabla}_2)\}f_{jk}^{(2)}(\vec{r}_1,\vec{r}_2)]$$
$$-\alpha[(\vec{r}_1\cdot\vec{\nabla}_1)+(\vec{r}_2\cdot\vec{\nabla}_2)]f_{jk}^{(2)}(\vec{r}_1,\vec{r}_2)+E_{jk}^{(2)}f_{jk}^{(2)}(\vec{r}_1,\vec{r}_2)\}, \tag{3.18d}$$

$$u_{j_1j_2j_3}^{(3)}(\vec{r}_1,\vec{r}_2,\vec{r}_3)=E_{j_1j_2j_3}^{(3)}+(m_{j_1})^{-1}[\vec{\nabla}_1\varphi_{j_1j_2}^{(2)}(\vec{r}_1,\vec{r}_2)]\cdot[\vec{\nabla}_1\varphi_{j_1j_3}^{(2)}(\vec{r}_1,\vec{r}_3)]. \tag{3.18e}$$

Let us re-emphasize that we are still free to choose at our convenience the one-body functions $f_j^{(1)}(r)$ [or $\varphi_j^{(1)}(r)$, see (3.5a)] and the two-body functions $f_{jk}^{(2)}(\vec{r}_1,\vec{r}_2)$ [or $\varphi_{jk}^{(2)}(\vec{r}_1,\vec{r}_2)$, see (3.5a)], as well as the energy constants $E_j^{(1)}$, $E_{jk}^{(2)}$, and $E_{j_1j_2j_3}^{(3)}$; we have on the other hand committed ourselves to the simple choice (3.17) for $\Phi(\rho)$. Cases in which a more general choice for $\Phi(\rho)$ is convenient will also be specially mentioned and considered below. It is easily seen that this shall entail the following modifications: in (3.18c) the term $2m_j\alpha^2r^2-\alpha D$ must be replaced by $\{\ddot{\Phi}(\rho)+[\dot{\Phi}(\rho)]^2+(ND-1)\dot{\Phi}(\rho)/\rho\}/N$ [see (3.17b) and (3.16c)], and in the other two places, in (3.18c) and (3.18d), where the constant α appears, it must be replaced by $-\dot{\Phi}(\rho)/\rho$ [see (3.17c) and (3.16d)], of course always with ρ defined by (3.16b). These modifications mar the interpretation of $u_j^{(1)}(r),u_{jk}^{(2)}(\vec{r}_1,\vec{r}_2)$, respectively, $u_{j_1j_2j_3}^{(3)}(\vec{r}_1,\vec{r}_2,\vec{r}_3)$ as one-, two- respectively three-body potentials; this is why we prefer to write (3.18) as we did, rather than in the more general form entailed by these modifications. But we must also emphasize that, even though the formula (3.18) seems to provide a natural distinction between one-, two- and three-body interactions, there also are cases (see below) when parts, say, of the potential $u_{jk}^{(2)}(\vec{r}_1,\vec{r}_2)$ are more naturally interpreted as one-body contributions: this is generally the case whenever $u_{jk}^{(2)}(\vec{r}_1,\vec{r}_2)$, or parts of it, separate into additive contributions of two functions each depending only upon one of the two arguments $\vec{r}_1$ and $\vec{r}_2$. Hence a more complete analysis, including a proper separation in one-, two-, three- and possibly *N*-body potentials, can only be made after we specify, in the following section, various choices for the functions $f_j^{(1)}(r)$ and $f_{jk}^{(2)}(\vec{r}_1,\vec{r}_2)$.

IV. EXAMPLES

In this section we derive various examples of partially solvable quantum many-body problems. Our main tool are the equations (3.18) displayed at the end of the preceding Sec. III, which are now implemented by making specific choices for the two-body ‘‘correlation functions’’ $f_{jk}^{(2)}(\vec{r}_1,\vec{r}_2)$ and the ‘‘one-body’’ functions $f_j^{(1)}(r)$ [or equivalently $\varphi_{jk}^{(2)}(\vec{r}_1,\vec{r}_2)$ and $\varphi_j^{(1)}(r)$, see (3.5a)]. Let us re-emphasize the large freedom in the choice of these functions, and correspondingly of the ‘‘energies’’ $E_j^{(1)}$, $E_{jk}^{(2)}$, and $E_{j_1j_2j_3}^{(3)}$; the only restriction is that the wave function $\Psi(\vec{r}_1,\ldots,\vec{r}_N)$, see (3.4), be *normalizable* (possibly up to the free motion of the center of mass of the many-body system, see below).

We conveniently subdivide this section into four parts, treating thereby four different classes of partially solvable many-body problems.

A. Models of type A (translation invariant)

Let us set

$$E_j^{(1)}=E_{j_1j_2j_3}^{(3)}=0,\quad \alpha=0,\quad f_j^{(1)}(r)=1,\quad \varphi_j^{(1)}(r)=0, \tag{4.1a}$$

entailing [see (3.18c)]

$$u_j^{(1)}(r)=0, \tag{4.1b}$$

and let us moreover set

$$f_{jk}^{(2)}(\vec{r}_j,\vec{r}_k)=f_{jk}^{(2)}(r_{jk})=f_{kj}^{(2)}(r_{jk}), \tag{4.1c}$$

where we introduce the convenient short-hand notation

$$\vec{r}_{jk}\equiv\vec{r}_j-\vec{r}_k,\quad r_{jk}\equiv(\vec{r}_{jk}\cdot\vec{r}_{jk})^{1/2}\equiv r_{kj}. \tag{4.1d}$$

Then [see (3.18d)]

$$\begin{aligned}u_{jk}^{(2)}(\vec{r}_1,\vec{r}_2)&=u_{jk}^{(2)}(r_{12})\\&=\{[(m_j+m_k)/(4m_jm_k)][f_{jk}^{(2)\prime\prime}(r_{12})+(D-1)f_{jk}^{(2)\prime}(r_{12})/r_{12}]\\&\quad+E_{jk}^{(2)}f_{jk}^{(2)}(r_{12})\}/f_{jk}^{(2)}(r_{12}),\end{aligned} \tag{4.1e}$$

and (see (3.18e))

$$u_{j_1j_2j_3}^{(3)}(\vec{r}_1,\vec{r}_2,\vec{r}_3)=u_{j_1j_2j_3}^{(3)}(\vec{r}_{12},\vec{r}_{13})=(m_{j_1})^{-1}[(\vec{r}_{12}\cdot\vec{r}_{13})/(r_{12}r_{13})]\varphi_{j_1j_2}^{(2)\prime}(r_{12})\varphi_{j_1j_3}^{(2)\prime}(r_{13}). \tag{4.1f}$$

Hence, by choosing $f_{jk}^{(2)}(r)$ as an (appropriate; see examples below) solution of the equation

$$[(m_j+m_k)/(4m_jm_k)][f_{jk}^{(2)\prime\prime}(r)+(D-1)f_{jk}{}'(r)/r]+E_{jk}^{(2)}f_{jk}^{(2)}(r)=v_{jk}(r)f_{jk}^{(2)}(r), \tag{4.2a}$$

with $v_{jk}(r)$ arbitrarily given (and $E_{jk}^{(2)}$ appropriately chosen, see examples below), one obtains

$$u_{jk}^{(2)}(r)=v_{jk}(r). \tag{4.2b}$$

Note that (4.2a) is just the two-body D-dimensional Schrödinger equation (after separation of the two-body center-of-mass motion) for the jth and kth particles, with the pair potential $u_{jk}^{(2)}(r)=v_{jk}(r)$, r being the (scalar) interparticle distance. It is thus seen that solutions (i.e., eigenvalues and eigenfunctions) of *many-body problems* with arbitrary translation- and rotation-invariant pair potentials can be found, provided solutions of the corresponding problem are known *in the two-body context*, and additional, *appropriate* three-body interactions are also present. On the other hand *partially solvable two-body problems* can easily be manufactured by choosing appropriately a two-body wave function and computing the corresponding potential. In this manner it is easy to manufacture a large zoo of *partially solvable rotation- and translation-invariant quantum many-body problems*.

For instance by choosing

$$f_{jk}^{(2)}(r)=r^{\alpha_{jk}}\exp(-\beta_{jk}r), \tag{4.3a}$$

we conclude that the N-body problem without one-body interactions, with the long-range two-body interactions

$$u_{jk}^{(2)}(r)=[(m_j+m_k)/(4m_jm_k)][\alpha_{jk}(\alpha_{jk}+D-2)/r^2-\beta_{jk}(2\alpha_{jk}+D-1)/r], \tag{4.3b}$$

and the long-range three-body interactions

$$u^{(3)}_{j_1j_2j_3}(\vec{r}_1,\vec{r}_2,\vec{r}_3)=u^{(3)}_{j_1j_2j_3}(\vec{r}_{12},\vec{r}_{13})$$
$$=(m_{j_1})^{-1}[(\vec{r}_{12}\cdot\vec{r}_{13})/(r_{12}r_{13})^2][\alpha_{j_1j_2}-\beta_{j_1j_2}r_{12}][\alpha_{j_1j_3}-\beta_{j_1j_3}r_{13}], \quad (4.3c)$$

is *partially solvable*, possessing a ground state with energy

$$E=-\sum_{j,k=1;j<k}^{N}[(m_j+m_k)/(4m_jm_k)]\beta_{jk}{}^2 \quad (4.3d)$$

and eigenfunction

$$\Psi(\vec{r}_1,\ldots,\vec{r}_N)=\exp\left[-\sum_{j,k=1;j<k}^{N}\beta_{jk}r_{jk}\right]\prod_{j,k=1;j<k}^{N}(r_{jk})^{\alpha_{jk}}. \quad (4.3e)$$

Here the $N(N-1)$ constants $\alpha_{jk}=\alpha_{kj}$ and $\beta_{jk}=\beta_{kj}$ are *arbitrary*, except for the conditions

$$\alpha_{jk}>0, \quad \sum_{k=1,k\neq j}^{N}\beta_{jk}>0, \quad (4.3f)$$

which are sufficient to guarantee that the eigenfunction (4.3e) be normalizable (in the N-body center-of-mass frame).

Let us however emphasize that these results are not new: they essentially coincide with those of Ref. 9, except for the specific example given above, and the fact that here we kept arbitrary the dimensionality D of space (in Ref. 9 attention focused on the physical $D=3$ case, although it was emphasized there that the extension to different space dimensionality is easy). Let us also note that the results, as given here, hold only for $D\geqslant 2$; the one-dimensional case requires a (marginally) modified treatment because in that case the derivative of $r_{12}=|x_1-x_2|$ with respect to x_1 or x_2 has a discontinuity at $x_1=x_2$ (for an example belonging to this case see Ref. 10).

Let us finally focus on the special case with

$$f^{(2)}_{jk}(r)=r^{g_{jk}}, \quad \varphi^{(2)}_{jk}{}'(r)=g_{jk}/r, \quad \varphi^{(2)}_{jk}{}''(r)=-g_{jk}/r^2 \quad (4.4)$$

[namely, the case (4.3a) with $\beta_{jk}=0$ and, for notational convenience, $\alpha_{jk}=g_{jk}=g_{kj}$], but now without setting $\Phi(\rho)=0$ [as entailed above by the choice (3.17) with $\alpha=0$]. As noted above [see after (3.18e)], and using (4.4), this entails the replacement

$$[f^{(2)}_{jk}(\vec{r}_1,\vec{r}_2)]^{-1}\{-\alpha[(\vec{r}_1\cdot\vec{\nabla}_1)+(\vec{r}_2\cdot\vec{\nabla}_2)]f^{(2)}_{jk}(\vec{r}_1,\vec{r}_2)\}\Rightarrow g_{jk}\dot{\Phi}(\rho)/\rho \quad (4.5a)$$

on the right-hand side of (3.18d), as well as the replacement

$$2m_j\alpha^2r^2-\alpha D\Rightarrow\{\ddot{\Phi}(\rho)+[\dot{\Phi}(\rho)]^2+(ND-1)\dot{\Phi}(\rho)/\rho\}/N \quad (4.5b)$$

on the right-hand side of (3.18c). Hence in this special case the partially solvable potential can be written as follows:

$$U(\vec{r}_1,\ldots,\vec{r}_N)=\alpha^2\sum_{j=1}^{N}2m_jr_j{}^2+\sum_{j,k=1;j<k}^{N}[(m_j+m_k)/(2m_jm_k)]g_{jk}(g_{jk}+D-2)/r_{jk}{}^2$$
$$+\sum_{j_1,j_2,j_3=1;j_1\neq j_2,j_1\neq j_3,j_2<j_3}^{N}(m_{j_1})^{-1}g_{j_1j_2}g_{j_1j_3}[(\vec{r}_{j_1j_2}\cdot\vec{r}_{j_1j_3})/(r_{j_1j_2}r_{j_1j_3})^2]$$
$$+u^{(N)}(\rho), \quad (4.6a)$$

with ρ defined by (3.16b), and $u^{(N)}(\rho)$ a (largely arbitrary) function (''N-body potential''). The corresponding eigenfunction [see (3.3)] reads

$$\Psi(\vec{r}_1,\ldots,\vec{r}_N)=\chi_\mu(\rho)\prod_{j,k=1;j<k}^{N}(r_{jk})^{g_{jk}}, \tag{4.6b}$$

with energy, see (3.3),

$$E=E_\mu, \tag{4.6c}$$

the two quantities $\chi_\mu(\rho)=\log[\Phi(\rho)]$ and E_μ being related by the eigenvalue equation

$$-\ddot{\chi}_\mu(\rho)-(ND-1+G)\dot{\chi}_\mu(\rho)/\rho+[\alpha^2\rho^2+u^{(N)}(\rho)]\chi_\mu(\rho)=E_\mu\chi_\mu(\rho), \tag{4.6d}$$

or equivalently, via $\chi_\mu(\rho)=\rho^{(1-ND-G)/2}\psi_\mu(\rho)$, by the Schrödinger-type equation

$$-\ddot{\psi}_\mu(\rho)[(ND+G-1)(ND+G-3)/4+\alpha^2\rho^2+u^{(N)}(\rho)]\psi_\mu(\rho)=E_\mu\psi_\mu(\rho). \tag{4.6e}$$

Here

$$G=\sum_{j,k=1;j<k}^{N} g_{jk}, \tag{4.6f}$$

α is an arbitrary constant [which has been conveniently reintroduced on the right-hand side of (4.6a) as well as in (4.6d) and (4.6e)], the dots denote of course differentiation with respect to the global radial variable ρ, see (3.16b), μ is a quantum number, and the eigenvalue equation (4.6d) and (4.6e) is constrained by the requirements that (4.6b) be *normalizable*, sufficient conditions for the existence of a discrete infinity of such solutions, parametrized, say, by $\mu=0,1,2,\ldots$, are the requirement that all the ''coupling constants'' g_{jk} be non-negative, $g_{jk}\geqslant 0$, and that the potential $\alpha^2\rho^2+u^{(N)}(\rho)$ be confining. The two (well-known) cases in which the solutions $\chi_\mu(\rho)$ or $\psi_\mu(\rho)$ can be explicitly exhibited in terms of known functions (in fact, elementary functions and Laguerre polynomials), and the corresponding eigenvalues easily computed, for *all* values of the quantum number μ, are those characterized by the presence of centrifugal and harmonic or attractive Coulomb potentials (this latter not being confining, but possessing an infinite sequence of bound states due to its long range), corresponding, respectively, to $\alpha\neq 0$, $u^{(N)}(\rho)=\lambda^2/\rho^2$, or $\alpha=0$, $u^{(N)}(\rho)=\lambda^2/\rho^2-q^2/\rho$; but in these two cases the partial solvability of this N-body problem, as detailed above, is not a new result: it had already been demonstrated (in the equal-particle case: $m_j=m$, $g_{jk}=g$) by Khare.[8]

B. Models of type B

Let us set

$$f_j^{(1)}(r)=1,\quad \varphi_j^{(1)}(r)=0,\quad E_j^{(1)}=\alpha D,\quad E_{j_1j_2j_3}^{(3)}=0, \tag{4.7a}$$

and

$$f_{jk}^{(2)}(\vec{r}_1,\vec{r}_2)=f_{jk}^{(2)}(r_1,r_2),\quad \varphi_{jk}^{(2)}(\vec{r}_1,\vec{r}_2)=\varphi_{jk}^{(2)}(r_1,r_2). \tag{4.7b}$$

Then

$$u_j^{(1)}(r)=2m_j\alpha^2r^2, \tag{4.7c}$$

$$u_{jk}^{(2)}(\vec{r}_1,\vec{r}_2)=u_{jk}^{(2)}(r_1,r_2)=[(m_j+m_k)/(4m_jm_k)]\{\varphi_{jk,11}^{(2)}(r_1,r_2)+[\varphi_{jk,1}^{(2)}(r_1,r_2)]^2+\varphi_{jk,22}^{(2)}(r_1,r_2)+[\varphi_{jk,2}^{(2)}(r_1,r_2)]^2+(D-1)[\varphi_{jk,1}^{(2)}(r_1,r_2)/r_1+\varphi_{jk,2}^{(2)}(r_1,r_2)/r_2]\}-\alpha[r_1\varphi_{jk,1}^{(2)}(r_1,r_2)+r_2\varphi_{jk,2}^{(2)}(r_1,r_2)]+E_{jk}^{(2)}, \tag{4.7d}$$

$$u_{j_1j_2j_3}^{(3)}(\vec{r}_1,\vec{r}_2,\vec{r}_3)=u_{j_1j_2j_3}^{(3)}(r_1,r_2,r_3)=(m_{j_1})^{-1}\varphi_{j_1j_2,1}^{(2)}(r_1,r_2)\varphi_{j_1j_3,1}^{(2)}(r_1,r_3), \tag{4.7e}$$

where of course $\varphi_{jk,1}^{(2)}(r_1,r_2)\equiv\partial\varphi_{jk}^{(2)}(r_1,r_2)/\partial r_1$, $\varphi_{jk,2}^{(2)}(r_1,r_2)\equiv\partial\varphi_{jk}^{(2)}(r_1,r_2)/\partial r_2$, $\varphi_{jk,11}^{(2)}(r_1,r_2)\equiv\partial^2\varphi_{jk}^{(2)}(r_1,r_2)/\partial r_1{}^2$ and so on.

We now specialize further the choice of the functions $f_{jk}^{(2)}(r_1,r_2)$ [or $\varphi_{jk}^{(2)}(r_1,r_2)$, see (3.5a)] by setting

$$f_{jk}^{(2)}(r_1,r_2)=f_{jk}^{(2)}[\chi_j(r_1)-\chi_k(r_2)],\quad \varphi_{jk}^{(2)}(r_1,r_2)=\varphi_{jk}^{(2)}[\chi_j(r_1)-\chi_k(r_2)], \tag{4.8a}$$

so that

$$\varphi_{jk,1}^{(2)}(r_1,r_2)=\chi_j{}'(r_1)\dot{\varphi}_{jk}^{(2)}, \tag{4.8b}$$

$$\varphi_{jk,11}^{(2)}(r_1,r_2)=[\chi_j{}'(r_1)]^2\ddot{\varphi}_{jk}^{(2)}+\chi_j''(r_1)\dot{\varphi}_{jk}^{(2)}, \tag{4.8c}$$

$$\varphi_{jk,2}^{(2)}(r_1,r_2)=-\chi_k{}'(r_2)\dot{\varphi}_{jk}^{(2)}, \tag{4.8d}$$

$$\varphi_{jk,22}^{(2)}(r_1,r_2)=[\chi_k{}'(r_2)]^2\ddot{\varphi}_{jk}^{(2)}-\chi_k''(r_2)\dot{\varphi}_{jk}^{(2)}, \tag{4.8e}$$

where the superimposed dots denote differentiation with respect to the argument of the $\varphi_{jk}^{(2)}$ functions, which is always the quantity $[\chi_j(r_1)-\chi_k(r_2)]$, and appended primes denote differentiation with respect to r_1 or r_2, as the case may be.

With this choice

$$\begin{aligned}u_{jk}^{(2)}(\vec{r}_1,\vec{r}_2)&=u_{jk}^{(2)}(r_1,r_2)\\&=[(m_j+m_k)/(4m_jm_k)][\{[\chi_j{}'(r_1)]^2+[\chi_k{}'(r_2)]^2\}\{\ddot{\varphi}_{jk}^{(2)}+[\dot{\varphi}_{jk}^{(2)}]^2\}\\&\quad+\{\chi_j''(r_1)-\chi_k''(r_2)+(D-1)[\chi_j{}'(r_1)/r_1-\chi_k{}'(r_2)/r_2]\}\dot{\varphi}_{jk}^{(2)}]\\&\quad-\alpha[r_1\chi_j{}'(r_1)-r_2\chi_k{}'(r_2)]\dot{\varphi}_{jk}^{(2)}+E_{jk}^{(2)},\end{aligned} \tag{4.8f}$$

where the argument of the functions $\varphi_{jk}^{(2)}$ is always $[\chi_j(r_1)-\chi_k(r_2)]$, and

$$u_{j_1j_2j_3}^{(3)}(\vec{r}_1,\vec{r}_2,\vec{r}_3)=u_{j_1j_2j_3}^{(3)}(r_1,r_2,r_3)=(m_{j_1})^{-1}[\chi_{j_1}{}'(r_1)]^2\dot{\varphi}_{j_1j_2}^{(2)}\dot{\varphi}_{j_1j_3}^{(2)}, \tag{4.8g}$$

where the argument of $\varphi_{j_1j_2}^{(2)}$ is $\chi_{j_1}(r_1)-\chi_{j_2}(r_2)$ and likewise the argument of $\dot{\varphi}_{j_1j_3}^{(2)}$ is $\chi_{j_1}(r_1)-\chi_{j_3}(r_3)$.

Let us now make the choice

$$f_{jk}^{(2)}(x)=x^{g_{jk}},\quad \dot{\varphi}_{jk}^{(2)}(x)=g_{jk}/x,\quad \ddot{\varphi}_{jk}^{(2)}(x)=-g_{jk}/x^2, \tag{4.9a}$$

where the $N(N-1)/2$ constants $g_{jk}=g_{kj}\geqslant 0$ are non-negative but otherwise arbitrary. Then

$$u_{jk}^{(2)}(r_1,r_2)=[(m_j+m_k)/(4m_jm_k)][g_{jk}(g_{jk}-1)[\chi_j(r_1)-\chi_k(r_2)]^{-2}\{[\chi_j{}'(r_1)]^2+[\chi_k{}'(r_2)]^2\}$$
$$+g_{jk}[\chi_j(r_1)-\chi_k(r_2)]^{-1}\{\chi_j''(r_1)-\chi_k''(r_2)+(D-1)[\chi_j{}'(r_1)/r_1-\chi_k{}'(r_2)/r_2]\}]$$
$$-\alpha g_{jk}[\chi_j(r_1)-\chi_k(r_2)]^{-1}[r_1\chi_j{}'(r_1)-r_2\chi_k{}'(r_2)]+E_{jk}^{(2)}, \tag{4.9b}$$

$$u_{j_1j_2j_3}^{(3)}(r_1,r_2,r_3)=(m_{j_1})^{-1}g_{j_1j_2}g_{j_1j_3}[\chi_{j_1}{}'(r_1)]^2[\chi_{j_1}(r_1)-\chi_{j_2}(r_2)]^{-1}[\chi_{j_1}(r_1)-\chi_{j_3}(r_3)]^{-1}. \tag{4.9c}$$

Let us finally make two simple choices for the functions $\chi_j(r)$, namely

$$\chi_j(r)=\exp(-ar) \tag{4.10a}$$

or

$$\chi_j(r)=r^b \tag{4.11a}$$

[we leave as an exercise for the diligent reader to explore the more general choice $\chi_j(r)=c_jr^{b_j}\exp(-a_jr)$ involving $3N$ arbitrary constants]. The first choice, (4.10a), yields

$$u_{jk}^{(2)}(r_1,r_2)=g_{jk}\alpha\{[(m_j+m_k)/(8m_jm_k)]\{(g_{jk}-1)a\cosh[2a(r_1-r_2)]\sinh^2[a(r_1-r_2)]$$
$$-2(D-1)\{r_2-r_1\exp[a(r_1-r_2)]\}/[r_1r_2\{1-\exp[a(r_1-r_2)]\}]\}$$
$$+\alpha\{r_1-r_2\exp[a(r_1-r_2)]\}/\{1-\exp[a(r_1-r_2)]\}\}, \tag{4.10b}$$

$$E_{jk}^{(2)}=-[(m_j+m_k)/(4m_jm_k)]g_{jk}a^2, \tag{4.10c}$$

$$u_{j_1j_2j_3}^{(3)}(r_1,r_2,r_3)=(m_{j_1})^{-1}g_{j_1j_2}g_{j_1j_3}\{1-\exp[a(r_1-r_2)]\}^{-1}\{1-\exp[a(r_1-r_3)]\}^{-1}. \tag{4.10d}$$

These potentials, which must be complemented by (4.7c), of course lack translation invariance, and they are singular whenever two particles are at the same distance from the origin (the two-body potential is however nonsingular in the special case $g_{jk}=1$). It is easily seen that the conditions $g_{jk}\geqslant 0$, $\alpha>0$, $a\geqslant 0$ are *sufficient* to guarantee normalizability of the (ground-state) eigenfunction $\Psi(\vec{r}_1,\ldots,\vec{r}_N)$, given by (3.4) with $\psi=1$, $F^{(n)}=1$ for all values of n except $n=2$ and $n=N$, $F^{(N)}$ given by (3.17a) with (3.16b) and $F^{(2)}$ given by (3.4d) with (4.8a), (4.9a), and (4.10a). (*Necessary and sufficient* conditions can also be easily obtained; this is left as an easy exercise for the diligent reader.) The corresponding (ground-state) energy is given by (3.18b) with $E_j^{(1)}=\alpha D$, $E_{j_1j_2j_3}^{(3)}=0$ [see (4.7a)] and $E_{jk}^{(2)}$ given by (4.10c).

The second choice, (4.11a), yields

$$u_{jk}^{(2)}(r_1,r_2)=g_{jk}b[(m_j+m_k)/(4m_jm_k)]\{(g_{jk}-1)b[r_1^{2(b-1)}+r_2^{2(b-1)}]/(r_1^b-r_2^b)^2$$
$$+(b+D-2)[r_1^{b-2}-r_2^{b-2}]/(r_1^b-r_2^b)\}, \tag{4.11b}$$

$$E_{jk}^{(2)}=\alpha bg_{jk}, \tag{4.11c}$$

$$u_{j_1j_2j_3}^{(3)}(r_1,r_2,r_3)=(m_{j_1})^{-1}g_{j_1j_2}g_{j_1j_3}r_1^{2(b-1)}/[(r_1^b-r_2^b)(r_1^b-r_3^b)]. \tag{4.11d}$$

Likewise these potentials, which must again be complemented by (4.7c), lack translation invariance and are singular whenever two particles are at the same distance from the origin; again, the two-body potential becomes nonsingular (except at the origin) in the special case $g_{jk}=1$. And it is again easily seen that the conditions $g_{jk}\geqslant 0$, $\alpha>0$, $b\geqslant 0$ are *sufficient* to guarantee normalizability of the (ground-state) eigenfunction $\Psi(\vec{r}_1,\ldots,\vec{r}_N)$, given by (3.4) with $\psi=1$, $F^{(n)}=1$ for all values of n except $n=2$ and $n=N$, $F^{(N)}$ given by (3.17a) with (3.16b) and $F^{(2)}$ given by (3.4d) with

(4.8a), (4.9a) and (4.11a). (*Necessary and sufficient* conditions can also be easily obtained; this is left as an easy exercise for the diligent reader.) The corresponding (ground-state) energy is given by (3.18b) with $E_j^{(1)}=\alpha D$, $E_{j_1j_2j_3}^{(3)}=0$ [see (4.7a)] and $E_{jk}^{(2)}$ given by (4.11c).

The special case of equal particles, $m_j=m$, $g_{jk}=g$, is particularly interesting, but it is not new; it was introduced and discussed by Ghosh,[4] who moreover made the very interesting observation that the three-body contributions cancel out neatly for $b=1$ or $b=2$ [in these two cases $U^{(3)}(\vec{r}_1,\ldots,\vec{r}_N)$, as given by (3.2d) with (4.11d), vanishes]. Hence in these special cases the Hamiltonian (3.1) only features one-body and two-body interactions, see (4.7c) (with $m_j=m$) and (4.11b) (with $m_j=m$, $g_{jk}=g$).

Let us finally emphasize that the eigenstate constructed herein is again the ground state. It would be easy to also construct a sequence of other eigenstates for this ''Ghosh model,'' see (4.11), by using the more general *ansatz* (3.16) rather than the special choice (3.17); but since this has already been done by Ghosh,[4] we do not discuss this development here (the diligent reader may easily extend the Ghosh result to the case of unequal particles treated here). It would moreover be easy, in this case (4.11a), to introduce more general N-body potentials depending on the global radius ρ, see (3.16b), in analogy with the treatment given at the end of the preceding Sec. IV A [the main change would be the replacement in (4.6b) of G with bG, see (4.6f)]. But such an extension of the Ghosh treatment is not new; it has been given, in the equal particles case ($m_j=m$, $g_{jk}=g$), and for the two explicitly solvable potentials (centrifugal plus harmonic or plus Coulomb) by Khare.[8] Further extensions to the case of unequal particles, and of more general potentials—for which an analytic solution would however be generally available only for one discrete eigenvalue—are left for the diligent reader.

C. Models of type C

Let us set $\alpha=0$ [entailing $F^{(N)}=1$, see (3.17); the choice $\alpha\neq 0$ yields no additional generality, see below], $E_{jk}^{(2)}=E_{j_1j_2j_3}^{(3)}=0$, and

$$f_{jk}^{(2)}(\vec{r}_j,\vec{r}_k)=(c_{jk})^{g_{jk}} \tag{4.12a}$$

with

$$c_{jk}=c_{kj}\equiv\vec{r}_j\cdot\vec{r}_k, \tag{4.12b}$$

so that

$$[f_{jk}^{(2)}(\vec{r}_1,\vec{r}_2)]^{-1}[\Delta_1+\Delta_2]f_{jk}^{(2)}(\vec{r}_1,\vec{r}_2)=g_{jk}(g_{jk}-1)(r_1^2+r_2^2)/c_{12}^2, \tag{4.12c}$$

$$\vec{\nabla}_1\varphi_{jk}^{(2)}(\vec{r}_1,\vec{r}_2)=g_{jk}\vec{r}_2/c_{12},\quad \vec{\nabla}_2\varphi_{jk}^{(2)}(\vec{r}_1,\vec{r}_2)=g_{jk}\vec{r}_1/c_{12}, \tag{4.12d}$$

$$(\vec{r}_1\cdot\vec{\nabla}_1)\varphi_{jk}^{(2)}(\vec{r}_1,\vec{r}_2)=(\vec{r}_2\cdot\vec{\nabla}_2)\varphi_{jk}^{(2)}(\vec{r}_1,\vec{r}_2)=g_{jk}. \tag{4.12e}$$

[The diligent reader is invited to explore the results that obtain by setting, more generally,

$$f_{jk}^{(2)}(\vec{r}_j,\vec{r}_k)=f_{jk}^{(2)}(c_{jk}), \tag{4.13}$$

rather than (4.12a).]

Hence from (3.18d) we get

$$u_{jk}^{(2)}(\vec{r}_1,\vec{r}_2)=[(m_j+m_k)/(4m_jm_k)]\{g_{jk}(g_{jk}-1)(r_1^2+r_2^2)/c_{12}^2+2g_{jk}[\varphi_j^{(1)}(r_1)/r_1+\varphi_k^{(1)}(r_2)/r_2]\}, \tag{4.12f}$$

and from (3.18e)

$$u^{(3)}_{j_1j_2j_3}(r_1,r_2,r_3)=(m_{j_1})^{-1}g_{j_1j_2}g_{j_1j_3}c_{23}/(c_{12}c_{13}). \tag{4.12g}$$

Via (3.18a) it is clear that the second term on the right-hand side of (4.12f) should actually be included in the one-body potential. Hence we conclude that the partially solvable potential is in this case given by (3.18a) with

$$u^{(1)}_j(\vec{r})=u^{(1)}_j(r)=v_j(r), \tag{4.14a}$$

$$u^{(2)}_{jk}(\vec{r}_1,\vec{r}_2)=[(m_j+m_k)/(4m_jm_k)]g_{jk}(g_{jk}-1)(r_1^2+r_2^2)/(\vec{r}_1\cdot\vec{r}_2)^2, \tag{4.14b}$$

$$u^{(3)}_{j_1j_2j_3}(\vec{r}_1,\vec{r}_2,\vec{r}_3)=(m_{j_1})^{-1}g_{j_1j_2}g_{j_1j_3}(\vec{r}_2\cdot\vec{r}_3)/[(\vec{r}_1\cdot\vec{r}_2)(\vec{r}_1\cdot\vec{r}_3)]. \tag{4.14c}$$

In these formulas $v_j(r)$ are arbitrary (rotation-invariant) one-body potentials, and the $N(N-1)/2$ constants g_{jk} are arbitrary non-negative numbers. The eigenvalues are given by (3.18b) with $E^{(2)}_{jk}=E^{(3)}_{j_1j_2j_3}=0$, and the corresponding eigenfunctions $\Psi(\vec{r}_1,\ldots,\vec{r}_N)$ are given by (3.4), with $\psi=1$, $F^{(n)}=1$ for $n>2$ and $f^{(2)}_{jk}(\vec{r}_j,\vec{r}_k)$ given by (4.12a) and (4.12b). The ''one-body eigenvalues and eigenfunctions'' $E^{(1)}_j$ and $f^{(1)}_j(r)$ are the solutions of the one-body problem that obtains from (4.14a), (4.12f), (3.18a), and (3.18c):

$$-(2m_j)^{-1}[f^{(1)\prime\prime}_j(r)+(D-1+G_j)f^{(1)\prime}_j(r)/r]+v_j(r)f^{(1)}_j(r)=E^{(1)}_jf^{(1)}_j(r), \tag{4.15a}$$

with

$$G_j=\sum_{k=1;k\neq j}^{N}[(m_j+m_k)/(2m_k)]g_{jk}, \tag{4.15b}$$

or equivalently, via $f^{(1)}_j(r)=r^{(1-D-G_j)/2}\psi_j(r)$,

$$-(2m_j)^{-1}\{\psi_j''(r)-[(D+G_j-1)(D+G_j-3)/4]r^{-2}\psi_j(r)\}+v_j(r)\psi_j(r)=E^{(1)}_j\psi_j(r). \tag{4.15c}$$

For given one-body potentials $v_j(r)$, these one-body Schrödinger equations possess generally an infinity of eigenvalues and correspondingly of eigenfunctions, parametrized by quantum numbers μ_j, that take discrete values, say $\mu_j=0,1,2,...$, if the potential $v_j(r)$ is confining. Hence we see that the partially solvable potential we have manufactured, (3.18a) with (4.14), has a known set of eigenvalues and eigenfunctions [assuming the one-dimensional Schrödinger equations (4.15) are solvable] which is parametrized by N quantum numbers; while the *complete* spectrum, and the corresponding *complete* set of eigenfunctions, is generally parametrized by ND quantum numbers. [The fact that one gets *all* eigenvalues and eigenstates for $D=1$ is trivial: it is clear from (4.14b) and (4.14c) that for $D=1$ the two-body and three-body potentials reduce to one-body potentials, hence the N-body problem separates into N decoupled one-body problems.]

For instance for

$$v_j(r)=2m_j\alpha_j^2r^2, \tag{4.16a}$$

the eigenvalues of (4.15) are

$$E^{(1)}_j=\alpha_j(D+G_j+2\mu_j), \tag{4.16b}$$

with $\mu_j=0,1,2,...$, and the corresponding eigenfunctions $\psi_j(r)$ are the well-known harmonic oscillator wave functions, see (4.15c) with (4.16a). Of course if some of the (non-negative) quantities α_j coincide, or are integer multiples of each other, the spectrum of the many-body problem, see (3.3) and (3.18b) with $E^{(2)}_{jk}=E^{(3)}_{j_1j_2j_3}=0$, is degenerate.

There is a variant of the approach of this Sec. IV C which is worth mentioning. It is obtained by setting

$$f_j^{(1)}(r)=1, \quad \varphi_j^{(1)}(r)=0, \quad E_j^{(1)}=0, \tag{4.17a}$$

namely eliminating the one-body contributions, and using [instead of (3.17) with $\alpha=0$, see above], the ''N-body'' *ansatz* (3.16). The corresponding partially solvable potential then reads

$$U(\vec{r}_1,\ldots,\vec{r}_N)=\alpha^2\sum_{j=1}^{N} 2m_j r_j^2+\sum_{j,k=1;j<k}^{N} u_{jk}^{(2)}(\vec{r}_j,\vec{r}_k) + \sum_{j_1,j_2,j_3=1;j_1\neq j_2,j_1\neq j_3,j_2<j_3}^{N} u_{j_1j_2j_3}^{(3)}(\vec{r}_{j_1},\vec{r}_{j_2},\vec{r}_{j_2})+u^{(N)}(\rho), \tag{4.17b}$$

with $u_{jk}^{(2)}(\vec{r}_1,\vec{r}_2)$, respectively, $u_{j_1j_2j_3}^{(3)}(\vec{r}_1,\vec{r}_2,\vec{r}_3)$ given by (4.14b), respectively, (4.14c), ρ defined by (3.16b), and $u^{(N)}(\rho)$ a (largely arbitrary) ''N-body potential.'' The corresponding eigenfunction [see (3.3)] reads

$$\Psi_\mu(\vec{r}_1,\ldots,\vec{r}_N)=\chi_\mu(\rho)\prod_{j,k=1;j<k}^{N}(\vec{r}_j\cdot\vec{r}_k)^{g_{jk}}, \tag{4.17c}$$

and the corresponding equations for the energy eigenvalue E, see (3.3), and for the functions $\varphi_\mu(\rho)=\log[\Phi(\rho)]$, are exactly the same as in Sec. IV A, see (4.6c)–(4.6f). Hence in this variant, as in the analogous model treated at the end of Sec. IV A, the set of eigenvalues and eigenfunctions is parametrized by only one quantum number μ [rather than by N of them, see for instance (4.16b)]; moreover, only for the choice $\alpha=0$, $u^{(N)}(\rho)=-q^2/\rho$ is it possible to obtain explicitly *all* the eigenvalues and eigenfunctions of (4.6d) and (4.6e) [the other solvable case, $\alpha\neq 0$, $u^{(N)}(\rho)=0$, is of no interest here, since it is a special case of the ''less partially'' solvable case discussed above, see (4.14) with (4.16a)].

The models considered in this Sec. IV C are, to the best of our knowledge, new.

D. Models of type D

In this section we restrict attention to *two-dimensional* space, $D=2$, and we set, as above,

$$c_{jk}=c_{kj}\equiv\vec{r}_j\cdot\vec{r}_k\equiv x_jx_k+y_jy_k, \tag{4.18a}$$

and, in addition,

$$s_{jk}=-s_{kj}\equiv\hat{z}\cdot\vec{r}_j\wedge\vec{r}_k\equiv x_jy_k-y_jx_k. \tag{4.18b}$$

The notation $\hat{z}\cdot\vec{r}_j\wedge\vec{r}_k$ is formally *three-dimensional*, with the unit vector $\hat{z}\equiv(0,0,1)$ orthogonal to the plane in which all the vectors $\vec{r}_j\equiv(x_j,y_j,0)$ lie, and the symbol $\wedge$ denoting the standard *three-dimensional* vector product; it entails $\hat{z}\wedge\vec{r}_j\equiv(-y_j,x_j,0)$ and it underlines the rotation-invariant character of the (pseudoscalar) quantity s_{jk}, see (4.18b).

We then set $\alpha=0$ (as in the preceding Sec. IV C, the choice of an arbitrary value for α entails no increase in generality, see below), and, as a natural generalization of (4.12a),

$$f_{jk}^{(2)}(\vec{r}_j,\vec{r}_k)=(c_{jk})^{g_{jk}}|s_{jk}|^{\tilde{g}_{jk}}, \tag{4.18c}$$

so that

$$[f_{jk}^{(2)}(\vec{r}_1,\vec{r}_2)]^{-1}[\Delta_1+\Delta_2]f_{jk}^{(2)}(\vec{r}_1,\vec{r}_2)=(r_1^2+r_2^2)[g_{jk}(g_{jk}-1)/c_{12}^2+\tilde{g}_{jk}(\tilde{g}_{jk}-1)/s_{12}^2], \tag{4.18d}$$

$$\vec{\nabla}_1\varphi_{jk}^{(2)}(\vec{r}_1,\vec{r}_2)=g_{jk}\vec{r}_2/c_{12}-\tilde{g}_{jk}(\hat{z}\wedge\vec{r}_2)/s_{12}, \quad \vec{\nabla}_2\varphi_{jk}^{(2)}(\vec{r}_1,\vec{r}_2)=g_{jk}\vec{r}_1/c_{12}+\tilde{g}_{jk}(\hat{z}\wedge\vec{r}_1)/s_{12}, \tag{4.18e}$$

$$(\vec{r}_1\cdot\vec{\nabla}_1)\varphi_{jk}^{(2)}(\vec{r}_1,\vec{r}_2)=(\vec{r}_2\cdot\vec{\nabla}_2)\varphi_{jk}^{(2)}(\vec{r}_1,\vec{r}_2)=g_{jk}+\tilde{g}_{jk}. \tag{4.18f}$$

[Again, as in the preceding Sec. IV C, the diligent reader is invited to explore the results that obtain by setting, more generally,

$$f_{jk}^{(2)}(\vec{r}_j,\vec{r}_k)=f_{jk}^{(2)}(c_{jk},s_{jk}), \tag{4.19}$$

rather than (4.18c).]

Hence from (3.18d) we get

$$u_{jk}^{(2)}(\vec{r}_1,\vec{r}_2)=[(m_j+m_k)/(4m_jm_k)]\{(r_1^2+r_2^2)[g_{jk}(g_{jk}-1)/c_{12}^2+\tilde{g}_{jk}(\tilde{g}_{jk}-1)/s_{12}^2] \\ +2(g_{jk}+\tilde{g}_{jk})[\varphi_j^{(1)}(r_1)/r_1+\varphi_k^{(1)}(r_2)/r_2]\}, \tag{4.20a}$$

and from (3.18e) we get

$$u_{j_1j_2j_3}^{(3)}(r_1,r_2,r_3)=(m_{j_1})^{-1}[g_{j_1j_2}g_{j_1j_3}c_{23}/(c_{12}c_{13})+\tilde{g}_{j_1j_2}\tilde{g}_{j_1j_3}c_{23}/(s_{12}s_{13}) \\ +g_{j_1j_2}\tilde{g}_{j_1j_3}s_{23}/(c_{12}s_{13})-\tilde{g}_{j_1j_2}g_{j_1j_3}s_{23}/(s_{12}c_{13})]. \tag{4.20b}$$

As in the preceding Sec. IV C, via (3.18a) it is again clear that the second term on the right-hand side of (4.20a) should be considered part of the one-body potential. Hence we conclude that the partially solvable potential is now given by (3.18a) with

$$u_j^{(1)}(\vec{r})=u_j^{(1)}(r)=v_j(r), \tag{4.21a}$$

$$u_{jk}^{(2)}(\vec{r}_1,\vec{r}_2)=[(m_j+m_k)/(4m_jm_k)](r_1^2+r_2^2)[g_{jk}(g_{jk}-1)/(\vec{r}_1\cdot\vec{r}_2)^2+\tilde{g}_{jk}(\tilde{g}_{jk}-1)/(\hat{z}\cdot\vec{r}_1\wedge\vec{r}_2)^2], \tag{4.21b}$$

$$\begin{aligned} u_{j_1j_2j_3}^{(3)}(\vec{r}_1,\vec{r}_2,\vec{r}_3)=(m_{j_1})^{-1}[(\vec{r}_2\cdot\vec{r}_3)\{&g_{j_1j_2}g_{j_1j_3}/[(\vec{r}_1\cdot\vec{r}_2)(\vec{r}_1\cdot\vec{r}_3)] \\ &+\tilde{g}_{j_1j_2}\tilde{g}_{j_1j_3}/[(\hat{z}\cdot\vec{r}_1\wedge\vec{r}_2)(\hat{z}\cdot\vec{r}_1\wedge\vec{r}_3)]\} \\ &+(\hat{z}\cdot\vec{r}_2\wedge\vec{r}_3)\{g_{j_1j_2}\tilde{g}_{j_1j_3}/[(\vec{r}_1\cdot\vec{r}_2)(\hat{z}\cdot\vec{r}_1\wedge\vec{r}_3)] \\ &-\tilde{g}_{j_1j_2}g_{j_1j_3}/[(\hat{z}\cdot\vec{r}_1\wedge\vec{r}_2)(\vec{r}_1\cdot\vec{r}_3)]\}]. \end{aligned} \tag{4.21c}$$

In these formulas the N functions $v_j(r)$ are arbitrary (rotation-invariant) one-body potentials, and the $N(N-1)$ constants g_{jk} and $\tilde{g}_{jk}$ are arbitrary nonnegative numbers. The eigenvalues are given by (3.18b) with $E_{jk}^{(2)}=E_{j_1j_2j_3}^{(3)}=0$, and the corresponding eigenfunctions $\Psi(\vec{r}_1,\ldots,\vec{r}_N)$ are given by (3.4), with $\psi=1$, $F^{(n)}=1$ for $n>2$ and $f_{jk}^{(2)}(\vec{r}_j,\vec{r}_k)$ given by (4.18a)–(4.18c). The ''one-body eigenvalues and eigenfunctions'' $E_j^{(1)}$ and $f_j^{(1)}(r)$ are the solutions of the one-body problem that obtains from (4.21a), (4.20a), and (3.18c):

$$-(2m_j)^{-1}[f_j^{(1)\prime\prime}(r)+(1+G_j)f_j^{(1)\prime}(r)/r]+v_j(r)f_j^{(1)}(r)=E_j^{(1)}f_j^{(1)}(r), \tag{4.22a}$$

with

$$G_j=\sum_{k=1;k\neq j}^{N}[(m_j+m_k)/(2m_k)](g_{jk}+\tilde{g}_{jk}), \tag{4.22b}$$

or equivalently, via $f_j^{(1)}(r)=r^{-(1+G_j)/2}\psi_j(r)$,

$$-(2m_j)^{-1}\{\psi_j''(r)-[(G_j^2-1)/4]r^{-2}\psi_j(r)\}+v_j(r)\psi_j(r)=E_j^{(1)}\psi_j(r). \tag{4.22c}$$

These last developments have followed closely the analogous treatment given in the preceding Sec. IV C. Also applicable, practically *verbatim*, are the subsequent observations given there, except that one must now set $D=2$. It is thus seen that for the potential we have now manufactured, see (4.21), *partial solvability* generally entails the possibility to exhibit eigenvalues and eigenfunctions depending on N quantum numbers, while *complete solvability* would require knowledge of eigenvalues and eigenfunctions depending on $2N$ quantum numbers. In particular, for the one-body potential (4.16a), the treatment of the preceding Sec. IV C remains applicable [including (4.16b)], up to trivial modifications.

The special case with equal particles, $m_j=m$, $\alpha_j=\alpha$ [see (4.16a)], $\tilde{g}_{jk}=g$, and moreover $g_{jk}=0$, is not new: the partially solvable potential corresponding to this case has been introduced and discussed by Murthy, Bhaduri, and Sen.[1,5] The set of eigenvalues and eigenfunctions exhibited in these papers is however, for large N, much smaller than the set exhibited herein: it depends on 3, rather than N, quantum numbers.

There also is, in close analogy to the elaboration reported at the end of the preceding Sec. IV C, the variant of this treatment that is obtained by adopting (4.17a) and using the *ansatz* (3.16) instead of (3.17). We leave the derivation of the corresponding formulas to the diligent reader: the changes relative to the treatment given at the end of Sec. IV C entail essentially the replacement of (4.14) with (4.21), the insertion of an additional factor $(s_{jk})^{\tilde{g}_{jk}}$ in (4.17c), and the replacement of g_{jk} with $g_{jk}+\tilde{g}_{jk}$ in the definition (4.6f) of G (and of course the specialization $D=2$). But the results so obtained are not quite new: they have been previously given by Khare,[8] in the case of equal particles ($m_j=m$, $\tilde{g}_{jk}=g$) with moreover $g_{jk}=0$, and with special attention focused on the completely solvable ''N-body'' Coulomb and centrifugal potentials.

V. FINAL REMARKS AND OUTLOOK

Clearly the technique described in this paper yields easily a much larger gamut of partially solvable quantum many-body problems than the examples presented above. In selecting these examples, we have been mainly motivated by ''aesthetic'' considerations, and/or the intent to demonstrate how to cover in a unified manner several cases recently treated in the literature.[1–8] Applications have not been discussed: this is of course the most interesting direction for future developments.

We did not treat ''few-body'' problems, such as those characterized by a relatively small number of particles, say $N=3$ or $N=4$. For some special variants, applicable to such problems, of the technique used herein the interested reader is referred to the original paper where this technique was introduced.[9]

Another technique to manufacture completely or partially solvable quantum many-body problems, so much investigated in the literature that we refrain from mentioning any reference here since any appropriate list should be too long, relies on the introduction of (collective) coordinates such that the many-body Schrödinger equation becomes *separable*. These models tend to be farther from physics, because they generally give rise to many-body forces that do not seem to have any counterpart in nature, or break important invariance properties such as physical (i.e., three-dimensional) rotation invariance. We have, by and large, avoided to present models of this type, except to the extent we used the overall radial coordinate ρ, see (3.16b), mainly to make contact with the recent literature.

Let us finally emphasize that several of the examples presented above are characterized by potentials which are homogeneous functions of degree -2 in the particle coordinates [see for instance (2.1) with $\beta_{jk}=0$, (2.3), as well as (2.4) and (2.5) with an appropriate choice—''centrifugal''—of the one-body potentials $v_j(r)$]. Obviously for such potentials the introduction of an overall radial coordinate such as ρ, see (3.16b), allows separation of the problem into a (generally easily solvable) ''radial'' part involving a single coordinate and a (generally much more difficult) ''angular'' part, for which sometimes one very simple (generally, just constant) solution can be found (in fact the potentials may be adjusted so that such a solution exist). Several classes of partially solvable potentials which have appeared in the literature are of this kind. In the examples provided above it has been generally possible to go somewhat beyond this simple approach.

(Received 23 May 1997; accepted for publication 2 June 1999)

We introduce a class of quantum pure state models called the coherent models. A coherent model is an even-dimensional manifold of pure states whose tangent space is characterized by a symplectic structure. In a rigorous framework of noncommutative statistics, it is shown that a coherent model inherits and expands the original spirit of the minimum uncertainty property of coherent states. © *1999 American Institute of Physics.* [S0022-2488(99)02509-8]

I. INTRODUCTION

Quantum estimation theory, originated in optical communications, offers a rigorous approach toward the optimization of detection processes in quantum communication systems.[1,2] It aims to find, for a given smooth parametric family of density operators (a model) $\mathcal{P}=\{\rho_\theta;\theta=(\theta^1,\ldots,\theta^n)\in\Theta\subset\mathbf{R}^n\}$, the optimum measurement (positive operator-valued measure) $M=\{M(B);B$ is a Borel set in $\mathbf{R}^n\}$ for the parameter θ under the unbiasedness condition: For all $\theta\in\Theta$,

$$\int \hat{\theta}^j \,\mathrm{Tr}\,\rho_\theta M(d\hat{\theta})=\theta^j, \quad j=1,...,n.$$

Here Tr denotes the operator trace. Normally a more tractable (weaker) condition is adopted, called the local unbiasedness condition: A measurement M is called locally unbiased at a given point θ if M satisfies at θ the above equality and its formal differentiation,

$$\frac{\partial}{\partial\theta^i}\int \hat{\theta}^j \,\mathrm{Tr}\,\rho_\theta M(d\hat{\theta})=\delta_i^j, \quad i,j=1,...,n.$$

It is well known that when $n=1$, the quantum Cramér–Rao inequality with respect to the symmetric logarithmic derivative (SLD) offers the achievable lower bound (i.e., the bound attained by a certain measurement) of the variance of estimation. This is also regarded as a rigorous modification of the uncertainty relation. When $n\geqslant 2$, on the other hand, a matrix version of the SLD Cramér–Rao inequality itself does not always have an absolute significance because the lower bound cannot be attained, in general, unless the model has commutative SLDs. We therefore often deal with the minimization problem of the scalar quantity $\mathrm{tr}\,GV_\theta[M]$ with respect to M, where tr denotes the matrix trace on the parameter space Θ, G a real symmetric positive matrix representing the weight, and $V_\theta[M]$ the covariance matrix at θ with respect to a locally unbiased measurement M whose $(i,\,j)$ entry is

[b)]Electronic mail: nagaoka@is.uec.ac.jp

$$(V_\theta[M])^{ij}=\int(\hat\theta^i-\theta^i)(\hat\theta^j-\theta^j)\mathrm{Tr}\,\rho_\theta M(d\hat\theta).$$

If there is a number C such that $\mathrm{tr}\,GV_\theta[M]\geqslant C$ holds for all M, C is called a Cramér–Rao-type bound or simply a CR bound. The CR bound C may depend on both G and θ. The problem of finding the achievable CR bound is, in general, a hard one and has been solved only in a few special models such as the quantum Gaussian model[3,2] and the two-dimensional spin-$\frac{1}{2}$ model.[4,5]

Holevo showed that if a model having the right logarithmic derivative (RLD) exhibits a certain ''nice'' property of a tangent space, the CR bound based on the RLD is expressed only in terms of the SLDs (Ref. 2, p. 280). Moreover it was shown that this gives the achievable CR bound for the Gaussian model of quantum oscillators. Motivated by these facts and that the SLD Fisher information is well defined also for pure state models,[6] we will introduce a class of pure state models called the coherent models,[7] each having a ''nice'' tangent space, and will explore their parameter estimation theory.

The construction of the paper is as follows. In Sec. II, we explore some basic characteristics inherent in pure state models that are closely related with Holevo's commutation operator. In Sec. III, a special class of pure state models, called the coherent models, is introduced of which the SLD tangent space forms an invariant subspace with respect to the commutation operator. In Sec. IV, we derive a CR bound, called the generalized RLD bound, for a model that has an invariant SLD tangent space with respect to the commutation operator. Here the model is not assumed to be pure. In Sec. V, we show that for a coherent model, there exists a random measurement that attains the generalized RLD bound. In Sec. VI, the above results are demonstrated in two simple coherent models: a canonical squeezed state model and a spin coherent state model. In the final section we give conclusions.

II. COMMUTATION OPERATOR

In the study of noncommutative statistics, Holevo introduced useful mathematical tools called the square summable operators and the commutation operators associated with quantum states. We here give a brief summary: for details, consult Ref. 2. Let $\mathcal{H}$ be a separable complex Hilbert space that corresponds to a physical system of interest, and let ρ be a fixed density operator. We define a real Hilbert space $\mathcal{L}_h^2(\rho)$ associated with ρ by the completion of $\mathcal{B}_h(\mathcal{H})$, the set of bounded self-adjoint operators, with respect to the pre-inner product $\langle X,Y\rangle_\rho=\mathrm{Re}\,\mathrm{Tr}\,\rho XY$. Letting $\rho=\sum_j s_j|\psi_j\rangle\langle\psi_j|$ be the spectral representation, an element $X\in\mathcal{L}_h^2(\rho)$ can be regarded as an equivalence class of such self-adjoint operators (called square summable operators) satisfying $\sum_j s_j\|X\psi_j\|^2<\infty$ [so that $\psi_j\in\mathrm{Dom}(X)$ if $s_j\neq 0$] under the identification $X_1\sim X_2$ if $X_1\psi_j=X_2\psi_j$ for $s_j\neq 0$. The space $\mathcal{L}_h^2(\rho)$ thus provides a convenient tool to cope with unbounded observables. Let $\mathcal{L}^2(\rho)$ be the complexification of $\mathcal{L}_h^2(\rho)$. Note that $\mathcal{L}^2(\rho)$ is also regarded as the completion of $\mathcal{B}(\mathcal{H})$, the set of bounded operators, with respect to the pre-inner product,

$$\langle X,Y\rangle_\rho=\tfrac{1}{2}\mathrm{Tr}\,\rho(YX^*+X^*Y).$$

Thus $\mathcal{L}^2(\rho)$ is regarded as a complex Hilbert space with the inner product $\langle\cdot,\cdot\rangle_\rho$. We further introduce two sesquilinear forms on $\mathcal{B}(\mathcal{H})$ by

$$(X,Y)_\rho=\mathrm{Tr}\,\rho YX^*,\quad [X,Y]_\rho=\frac{1}{2i}\mathrm{Tr}\,\rho(YX^*-X^*Y),$$

and extend them to $\mathcal{L}^2(\rho)$ by continuity.

The *commutation operator* $\mathcal{D}_\rho:\mathcal{L}^2(\rho)\to\mathcal{L}^2(\rho)$ with respect to ρ is defined by $[X,Y]_\rho=\langle X,\mathcal{D}_\rho Y\rangle_\rho$, which is formally represented by the operator equation $\rho(\mathcal{D}_\rho X)+(\mathcal{D}_\rho X)\rho=(1/i)\times(\rho X-X\rho)$. (To be precise, this definition is different from Holevo's original definition by a factor of 2.) The operator $\mathcal{D}_\rho$ is a complex-linear bounded skew-adjoint operator. Moreover, since the forms $[\cdot,\cdot]_\rho$ and $\langle\cdot,\cdot\rangle_\rho$ are real on the real subspace $\mathcal{L}_h^2(\rho)$, this subspace is invariant under the operation of $\mathcal{D}_\rho$. Thus, $\mathcal{D}_\rho$ can also be regarded as a real-linear bounded skew-adjoint operator when restricted to $\mathcal{L}_h^2(\rho)$ as $\mathcal{D}_\rho:\mathcal{L}_h^2(\rho)\to\mathcal{L}_h^2(\rho)$.

Our main concern lies in the case where ρ is pure. In this case the above setting is considerably simplified as follows: Let $\rho=|\psi\rangle\langle\psi|$. Then, for $X,Y\in\mathcal{L}^2(\rho)$,

$$\langle X,Y\rangle_\rho=\tfrac{1}{2}\{\langle Y^*\psi|X^*\psi\rangle+\langle X\psi|Y\psi\rangle\},$$

$$[X,Y]_\rho=\frac{1}{2i}\{\langle Y^*\psi|X^*\psi\rangle-\langle X\psi|Y\psi\rangle\},$$

$$(X,Y)_\rho=\langle Y^*\psi|X^*\psi\rangle.$$

Here $X\psi$, for example, stands for the vector $X_1\psi$, where X_1 is an arbitrary representative of X. (It is independent of the choice of a representative.) In particular, if $X,Y\in\mathcal{L}_h^2(\rho)$, we have

$$\langle X,Y\rangle_\rho=\mathrm{Re}\langle Y\psi|X\psi\rangle=\mathrm{Re}\langle X\psi|Y\psi\rangle, \tag{1}$$

$$[X,Y]_\rho=\mathrm{Im}\langle Y\psi|X\psi\rangle=-\mathrm{Im}\langle X\psi|Y\psi\rangle, \tag{2}$$

$$(X,Y)_\rho=\langle Y\psi|X\psi\rangle=\overline{\langle X\psi|Y\psi\rangle}. \tag{3}$$

It should be noted that operators X and Y (whether bounded or not) are identified with each other in $\mathcal{L}^2(\rho)$ iff $X\psi=Y\psi$ and $X^*\psi=Y^*\psi$. In particular, self-adjoint operators X and Y are identified in $\mathcal{L}_h^2(\rho)$ iff $X\psi=Y\psi$.

Lemma 1: Let $\rho=|\psi\rangle\langle\psi|$. *Then for all* $X\in\mathcal{L}_h^2(\rho)$,

$$(\mathcal{D}_\rho X)\psi=i(X-\langle\psi|X\psi\rangle I)\psi,$$

where I denotes the identity in $\mathcal{L}_h^2(\rho)$.

Proof: For $X\in\mathcal{L}_h^2(\rho)$, let Z be the element in $\mathcal{L}_h^2(\rho)$ having a representative $Z_1=i(|X\psi\rangle\times\langle\psi|-|\psi\rangle\langle X\psi|)$. Then $Z\psi=i(X-\langle\psi|X\psi\rangle I)\psi$. On the other hand, for $Y\in\mathcal{L}_h^2(\rho)$, we have

$$\langle Y\psi|Z\psi\rangle=i\{\langle Y\psi|X\psi\rangle-\langle\psi|X\psi\rangle\langle\psi|Y\psi\rangle\},$$

and hence $\langle Y,Z\rangle_\rho=[Y,X]_\rho$ because of (1) and (2). Thus $Z=\mathcal{D}_\rho X$, which completes the proof.□

Note that Lemma 1 does not imply $\mathcal{D}_\rho X=i(X-\langle\psi|X\psi\rangle I)$, since the right-hand side is not a self-adjoint element in $\mathcal{L}^2(\rho)$ unless it equals 0.

Let us introduce a linear subspace,

$$\mathcal{T}_h(\rho)=\{X\in\mathcal{L}_h^2(\rho);\langle I,X\rangle_\rho=0\},$$

of $\mathcal{L}_h^2(\rho)$. Here ρ is not necessarily pure. This subspace is itself a real Hilbert space with the inner product $\langle\cdot,\cdot\rangle_\rho$. Now consider again the special case that ρ is pure: $\rho=|\psi\rangle\langle\psi|$. Then from Lemma 1, we obtain the important relation:

$$(\mathcal{D}_\rho X)\psi=(iX)\psi,\quad X\in\mathcal{T}_h(\rho). \tag{4}$$

This equation, combined with (1), implies that $\mathcal{D}_\rho$ is a unitary transformation on $(\mathcal{T}_h(\rho),\langle\cdot,\cdot\rangle_\rho)$. In particular, $\mathcal{D}_\rho$ is nondegenerate on $\mathcal{T}_h(\rho)$, and so is the skew-symmetric bilinear form $[\cdot,\cdot]_\rho$. In other words, the real linear space $\mathcal{T}_h(\rho)$ is regarded as a symplectic space[8] with the symplectic form $[\cdot,\cdot]_\rho$. We also note that $\mathcal{D}_\rho^2=-\mathcal{I}$ on $\mathcal{T}_h(\rho)$ [$\mathcal{I}$ denotes the identity operator acting on $\mathcal{T}_h(\rho)$], since $\mathcal{D}_\rho$ is unitary and skew adjoint. Indeed, Eq. (4) immediately leads to $(\mathcal{D}_\rho^2X)\psi=-X\psi$, and hence $\mathcal{D}_\rho^2X=-X$ for all $X\in\mathcal{T}_h(\rho)$, whereas $\mathcal{D}_\rho X\neq iX$, as mentioned earlier. In other words, $\mathcal{D}_\rho$ is an almost complex structure on $\mathcal{T}_h(\rho)$.

III. COHERENT MODEL

Let $\mathcal{P}=\{\rho_\theta;\theta=(\theta^1,\ldots,\theta^n)\in\Theta\}$ be an n-dimensional model, where ρ_θ are not necessarily pure for the present, and Θ is an open subset of $\mathbf{R}^n$. We assume the following regularity conditions.

(a) The parametrization $\theta\mapsto\rho_\theta$ is assumed to be appropriately smooth and nondegenerate so that the derivatives $\{\partial\rho_\theta/\partial\theta^j\}_{j=1}^n$ exist in trace class and form a linearly independent set at each point θ.

(b) There exists a constant c such that

$$\left|\frac{\partial}{\partial\theta^j}\mathrm{Tr}\,\rho_\theta X\right|^2\leqslant c\langle X,X\rangle_{\rho_\theta},$$

for all $X\in\mathcal{B}(\mathcal{H})$ and j.

From the condition (b), the linear functionals $X\mapsto(\partial/\partial\theta^j)\mathrm{Tr}\,\rho_\theta X$ can be extended to continuous linear functionals on $\mathcal{L}^2(\rho_\theta)$.

Given a model that satisfies (a) and (b), the *symmetric logarithmic derivative* (SLD) $L^S_{\theta,j}$ in the jth direction is defined by the requirement that

$$\frac{\partial}{\partial\theta^j}\mathrm{Tr}\,\rho_\theta X=\langle L^S_{\theta,j},X\rangle_{\rho_\theta},\quad L^S_{\theta,j}\in\mathcal{L}^2(\rho_\theta),$$

for all $X\in\mathcal{L}^2(\rho_\theta)$. It is easily verified that $L^S_{\theta,j}\in\mathcal{L}^2_h(\rho_\theta)$; so the definition is formally written as $\partial\rho_\theta/\partial\theta^j=1/2(L^S_{\theta,j}\rho_\theta+\rho_\theta L^S_{\theta,j})$. The SLDs belong to $\mathcal{T}_h(\rho_\theta)$, since $\langle I,L^S_{\theta,j}\rangle_{\rho_\theta}=(\partial/\partial\theta^j)\mathrm{Tr}\,\rho_\theta=0$, and the SLD Fisher information matrix defined by $J^S_\theta=[\langle L^S_{\theta,j},L^S_{\theta,k}\rangle_{\rho_\theta}]$ gives a Cramér–Rao inequality $V_\theta[M]\geqslant(J^S_\theta)^{-1}$, where M is an arbitrary locally unbiased measurement for the parameter θ; see Ref. 2, p. 276.

In the rest of this section, we restrict ourselves to pure state models. Some remarks are in order. First, by differentiating the identity $\rho_\theta^2=\rho_\theta$, we see that the element in $\mathcal{L}^2_h(\rho_\theta)$ having a representative $2\,\partial\rho_\theta/\partial\theta^j$ gives the SLD $L^S_{\theta,j}$. Thus, for a pure state model, the condition (a) implies (b). Second, associated with a pure state model $\{\rho_\theta;\theta\in\Theta\}$ is, at least locally, a smooth family $\{\psi_\theta;\theta\in\Theta\}$ of normalized vectors in $\mathcal{H}$ such that $\rho_\theta=|\psi_\theta\rangle\langle\psi_\theta|$. In what follows, we shall frequently use this representation.

A convenient way of finding SLDs for a pure state model ρ_θ is as follows: Let $L^A_{\theta,j}$ be the antisymmetric logarithmic derivative (ALD) satisfying

$$\frac{\partial}{\partial\theta^j}\mathrm{Tr}\,\rho_\theta X=[L^A_{\theta,j},X]_{\rho_\theta},\quad L^A_{\theta,j}\in\mathcal{T}_h(\rho_\theta),$$

for all $X\in\mathcal{L}^2(\rho_\theta)$, or formally $\partial\rho_\theta/\partial\theta^j=(L^A_{\theta,j}\rho_\theta-\rho_\theta L^A_{\theta,j})/2i$. (This definition is different from Ref. 6 by a factor of i.) Then the SLD is given by $L^S_{\theta,j}=-\mathcal{D}_\theta L^A_{\theta,j}$, where $\mathcal{D}_\theta=\mathcal{D}_{\rho_\theta}$, since $\langle L^S_{\theta,j},X\rangle_{\rho_\theta}=[L^A_{\theta,j},X]_{\rho_\theta}$. Note that since $\mathcal{D}_\theta^2=-\mathcal{I}$ on $\mathcal{T}_h(\rho_\theta)$, then $L^A_{\theta,j}=\mathcal{D}_\theta L^S_{\theta,j}$, which assures the existence and the uniqueness of the ALD for a pure state model. The advantage of the use of the ALD is this: Every pure state model can be expressed in the form $\rho_\theta=U_\theta\rho_0U_\theta^*$, where $\{U_\theta\}_\theta$ is a smooth family of unitary operators (which do not necessarily form a group representation), so that the ALD is explicitly given by

$$L^A_{\theta,j}=2i(A_{\theta,j}-\langle I,A_{\theta,j}\rangle_{\rho_\theta}),$$

where $A_{\theta,j}$ is the skew-adjoint element in $\mathcal{L}^2(\rho_\theta)$ having a representative $(\partial U_\theta/\partial\theta^j)U_\theta^*$, the local generator of U_θ. For a group covariant pure state model, the generator of the group is usually obvious.

Let $\mathcal{T}_\theta^S(\mathcal{P})$ be the real-linear subspace of $\mathcal{T}_h(\rho_\theta)$ spanned by the SLDs $\{L_{\theta,j}^S\}_j$. Since the tangent vectors of the manifold $\mathcal{P}$ at the point ρ_θ are faithfully represented by the elements of $\mathcal{T}_\theta^S(\mathcal{P})$ via the correspondence $(\partial/\partial\theta^j)_\theta \mapsto L_{\theta,j}^S$, we call $\mathcal{T}_\theta^S(\mathcal{P})$ the *SLD tangent space* of the model $\mathcal{P}$ at θ. A pure state model $\mathcal{P}=\{\rho_\theta;\theta\in\Theta\}$ is called *locally coherent* at θ if $\mathcal{T}_\theta^S(\mathcal{P})$ is $\mathcal{D}_\theta$ invariant. The model is called *coherent* if it is locally coherent for all $\theta\in\Theta$.

When the Hilbert space $\mathcal{H}$ is finite dimensional, the totality of pure states forms a complex projective space and is an example of coherent model. The Riemannian metric on the model induced by the SLD Fisher information matrix J_θ^S is identical to the Fubini–Study metric up to a constant factor[6] and hence is a Kähler metric. The associated fundamental 2-form[9] in this case is nothing but the symplectic structure $[\cdot,\cdot]_\rho$.

Theorem 2: *Consider a pure state model of the form $\rho_\theta=U_{g(\theta)}\rho_0 U_{g(\theta)}^*$, where $\{U_g;g\in\mathcal{G}\}$ is a projective unitary representation of a Lie group $\mathcal{G}$ and $g(\cdot):\theta\mapsto g(\theta)$ is the parametrization of the elements of $\mathcal{G}$ by a local coordinate system satisfying $g(0)=e$ (: the unit element). This model is coherent iff it is locally coherent at ρ_0.*

Proof: We only need to prove the if part. Let $\Lambda_\theta:\mathcal{G}\to\mathcal{G}$ be the left translation by $g(\theta)^{-1}$ that maps $h\mapsto g(\theta)^{-1}h$. Then its differential $(d\Lambda_\theta)_{g(\theta)}:T_{g(\theta)}(\mathcal{G})\to T_e(\mathcal{G})$ is represented by a nonsingular real matrix $a_j^k(\theta)$ such that $(d\Lambda_\theta)_{g(\theta)}([\partial g(\theta)/\partial\theta^j]_\theta)=\Sigma_k a_j^k(\theta)[\partial g(\theta)/\partial\theta^k]_{\theta=0}$. Now since $\rho_{\theta+\Delta\theta}=U_{g(\theta)}\rho_{\Delta\theta'}U_{g(\theta)}^*$, where $\Lambda_\theta(g(\theta+\Delta\theta))=g(\Delta\theta')$, we find that $\partial\rho_\theta/\partial\theta^j =\Sigma_k a_j^k(\theta)U_\theta[\partial\rho_\theta/\partial\theta^k]_{\theta=0}U_\theta^*$. This implies that the SLDs at θ are given by $L_{\theta,j}^S =\Sigma_k a_j^k(\theta)U_\theta L_{0,k}^S U_\theta^*$. As a consequence,

$$L_{\theta,j}^S\psi_\theta=\sum_k a_j^k(\theta)U_\theta L_{0,k}^S\psi_0. \tag{5}$$

Here we have set as $\rho_\theta=|\psi_\theta\rangle\langle\psi_\theta|$ with $\psi_\theta=U_\theta\psi_0$. Now suppose $\mathcal{P}$ is locally coherent at ρ_0. Then the vector $(\mathcal{D}_0 L_{0,k}^S)\psi_0=iL_{0,k}^S\psi_0$ [see (4)] belongs to the real linear span of $\{L_{0,k'}^S\psi_0\}_{k'=1}^n$; hence, the vector $(\mathcal{D}_\theta L_{\theta,j}^S)\psi_\theta=iL_{\theta,j}^S\psi_\theta$ belongs to the real linear span of $\{L_{\theta,j'}^S\psi_\theta\}_{j'=1}^n$ because of (5) and the nonsingularity of the matrix $a_j^k(\theta)$. This implies that $\mathcal{P}$ is locally coherent at every point θ. □

It is clear from the definition that if $\mathcal{P}$ is locally coherent at θ, then $\mathcal{T}_\theta^S(\mathcal{P})$ forms a symplectic space with the symplectic form being the restriction of $[\cdot,\cdot]_{\rho_\theta}$. In particular, the dimensionality of $\mathcal{T}_\theta^S(\mathcal{P})$ is necessarily even (say $n=2m$), and it has a symplectic basis $\{\tilde{L}_{\theta,j}^S\}_{j=1}^{2m}$, satisfying

$$[\tilde{L}_{\theta,j}^S,\tilde{L}_{\theta,k}^S]_{\rho_\theta}=\begin{cases}-1, & \text{if } j \text{ is odd and } k=j+1,\\ 1, & \text{if } j \text{ is even and } k=j-1,\\ 0, & \text{otherwise.}\end{cases}$$

Furthermore, since $\mathcal{D}_\theta$ is unitary on $\mathcal{T}_\theta^S(\mathcal{P})$ with respect to the inner product $\langle\cdot,\cdot\rangle_{\rho_\theta}$, we can take $\{\tilde{L}_{\theta,j}^S\}$ to be orthonormal. Such a basis, which we shall call a *normalized ρ_θ-symplectic basis*, satisfies

$$\mathcal{D}_\theta\begin{bmatrix}\tilde{L}_{\theta,1}^S\\ \tilde{L}_{\theta,2}^S\\ \tilde{L}_{\theta,3}^S\\ \tilde{L}_{\theta,4}^S\\ \vdots\\ \tilde{L}_{\theta,2m-1}^S\\ \tilde{L}_{\theta,2m}^S\end{bmatrix}=\begin{bmatrix}0 & 1 & & & & & \\ -1 & 0 & & & & & \\ & & 0 & 1 & & & \\ & & -1 & 0 & & & \\ & & & & \ddots & & \\ & & & & & 0 & 1\\ & & & & & -1 & 0\end{bmatrix}\begin{bmatrix}\tilde{L}_{\theta,1}^S\\ \tilde{L}_{\theta,2}^S\\ \tilde{L}_{\theta,3}^S\\ \tilde{L}_{\theta,4}^S\\ \vdots\\ \tilde{L}_{\theta,2m-1}^S\\ \tilde{L}_{\theta,2m}^S\end{bmatrix}. \tag{6}$$

Thus, the SLD tangent space of a coherent model is decomposed into two-dimensional $\mathcal{D}_\theta$-invariant subspaces. This suggests the importance of studying two-dimensional coherent models.

Now, let us characterize a two-dimensional coherent model.

Theorem 3: *For a two-dimensional pure state model* $\mathcal{P}=\{\rho_\theta=|\psi_\theta\rangle\langle\psi_\theta|;\theta\in\Theta\}$, *the following three conditions are equivalent.*

(α) $\mathcal{P}$ *is locally coherent at* θ.
(β) $L^S_{\theta,1}\psi_\theta$ *and* $L^S_{\theta,2}\psi_\theta$ *are linearly dependent.*
(γ) $L^A_{\theta,1}\psi_\theta$ *and* $L^A_{\theta,2}\psi_\theta$ *are linearly dependent.*

Before going to the proof, we should remark that the condition (β) does not conflict with the fact that $L^S_{\theta,1}$ and $L^S_{\theta,2}$ are linearly independent due to the nondegeneracy of the parametrization $\theta\mapsto\rho_\theta$. Indeed, the linear independence of $\{L^S_{\theta,1},L^S_{\theta,2}\}$ is concerned with the real linear structure of $\mathcal{L}^2_h(\rho_\theta)$ and is equivalent to the real linear independence of $\{L^S_{\theta,1}\psi_\theta,L^S_{\theta,2}\psi_\theta\}$. On the other hand, the condition (β) asserts the complex linear dependence of the same vectors.

Proof: The proof relies essentially on (4). We only need to show that $(\alpha)\Leftrightarrow(\beta)$, since $(\beta)\Leftrightarrow(\gamma)$ is obvious from the identity $L^S_{\theta,j}\psi_\theta=-(\mathcal{D}_\theta L^A_{\theta,j})\psi_\theta=-iL^A_{\theta,j}\psi_\theta$. Let $\varphi_j:=L^S_{\theta,j}\psi_\theta$, and assume ($\alpha$) first. Then there exist real numbers x, y such that $\mathcal{D}_\theta L^S_{\theta,1}=xL^S_{\theta,1}+yL^S_{\theta,2}$. This is equivalent to $i\varphi_1=x\varphi_1+y\varphi_2$ and leads to (β). Assume (β) in turn. Recalling the real linear independence of $\{\varphi_1,\varphi_2\}$, we see that there exist real numbers x, y satisfying $\varphi_2=(x+iy)\varphi_1$ with $y\neq0$. It then follows that $i\varphi_1=-(x/y)\varphi_1+(1/y)\varphi_2$ and $\mathcal{D}_\theta L^S_{\theta,1}=-(x/y)L^S_{\theta,1}+(1/y)L^S_{\theta,2}$. Similarly, $\mathcal{D}_\theta L^S_{\theta,2}$ is shown to be a real linear combination of $\{L^S_{\theta,1},L^S_{\theta,2}\}$, and thus ($\alpha$) is verified. □

The following corollary, whose proof is now straightforward from Theorem 3 and (4), offers a mostly useful method to treat group covariant coherent models as exemplifed in Sec. VI. Moreover, Eq. (7) in the corollary reveals a close connection with the conventional definition of coherent states.[10] Indeed, this fact gave a motive for the nomenclature of the coherent model.

Corollary 4: Let $\mathcal{P}=\{\rho_\theta=|\psi_\theta\rangle\langle\psi_\theta|;\theta\in\Theta\}$ *be a two-dimensional pure state model and let* $\mathcal{T}^A_\theta(\mathcal{P})$ *be the real linear span of ALDs* $\{L^A_{\theta,1},L^A_{\theta,2}\}$ *at* θ. *Then* $\mathcal{P}$ *is locally coherent at* θ *iff there exist nonzero elements* X_1,X_2 *in* $\mathcal{T}^A_\theta(\mathcal{P})$, *satisfying*

$$(X_1+iX_2)\psi_\theta=0. \tag{7}$$

Moreover, (7) is also necessary and sufficient for $\{cX_j\}_{j=1,2}$ *to form a normalized* ρ_θ*-symplectic basis of* $\mathcal{T}^S_\theta(\mathcal{P})[=\mathcal{T}^A_\theta(\mathcal{P})]$ *with a common normalizing constant c. Under the condition (7), the linear relations,*

$$L^A_{\theta,1}=c_{11}X_1+c_{12}X_2,\quad L^A_{\theta,2}=c_{21}X_1+c_{22}X_2,$$

imply

$$L^S_{\theta,1}=c_{12}X_1-c_{11}X_2,\quad L^S_{\theta,2}=c_{22}X_1-c_{21}X_2.$$

IV. GENERALIZED RLD BOUND

Throughout this section we consider an n-dimensional model $\mathcal{P}=\{\rho_\theta\}$ of general (i.e., not necessarily pure) states satisfying the regularity conditions (a) and (b) presented in Sec. III.

Let $\mathcal{L}^2_+(\rho)$ denote the completion of $\mathcal{B}(\mathcal{H})$ with respect to the preinner product $(\cdot,\cdot)_\rho$. Since $(X,X)_\rho\leqslant2\langle X,X\rangle_\rho$, then $\mathcal{L}^2(\rho)\subset\mathcal{L}^2_+(\rho)$. The *right logarithmic derivative* (RLD) $L^R_{\theta,j}$ in the jth direction of a model $\mathcal{P}=\{\rho_\theta\}$, when it exists, is defined by the requirement that

$$\frac{\partial}{\partial\theta^j}\mathrm{Tr}\,\rho_\theta X=(L^R_{\theta,j},X)_{\rho_\theta},\quad L^R_{\theta,j}\in\mathcal{L}^2_+(\rho_\theta),$$

for all $X\in\mathcal{L}_+^2(\rho_\theta)$, or, formally, $\partial\rho_\theta/\partial\theta^j=(L_{\theta,j}^R)^*\rho_\theta=\rho_\theta L_{\theta,j}^R$. The covariance matrix of an arbitrary locally unbiased estimator M is then bounded from below as

$$V_\theta[M]\geqslant(J_\theta^R)^{-1}, \tag{8}$$

where $J_\theta^R=[(L_{\theta,j}^R,L_{\theta,k}^R)_{\rho_\theta}]$ is the RLD Fisher information matrix (Ref. 2, p. 279). When a real positive definite matrix G is specified as the weight for the estimation accuracy, the total deviation is bounded from below as

$$\operatorname{tr} GV_\theta[M]\geqslant C^R:=\operatorname{tr} G\operatorname{Re}(J_\theta^R)^{-1}+\operatorname{tr}\operatorname{abs} G\operatorname{Im}(J_\theta^R)^{-1}, \tag{9}$$

where $\operatorname{tr}\operatorname{abs} A$ denotes the absolute sum of the eigenvalues of matrix A; see Ref. 2, p. 284. The RLD thus gives a CR bound and plays a crucial role in optical communication theory.[3,2]

The RLD exists iff there is a constant c such that

$$\left|\frac{\partial}{\partial\theta^j}\operatorname{Tr}\rho_\theta X\right|^2\leqslant c(X,X)_{\rho_\theta}, \tag{10}$$

for all $X\in\mathcal{B}(\mathcal{H})$. Thus, the RLD does not always exist for a model satisfying the weaker condition (b). In particular, it never exists for a pure state model $\rho_\theta=|\psi_\theta\rangle\langle\psi_\theta|$. To see this, let us fix a θ arbitrarily and take a vector $x\in\mathcal{H}$ such that $\langle\psi_\theta|x\rangle=0$ and $\langle\partial\psi_\theta/\partial\theta^j|x\rangle\neq 0$. [This is indeed possible because ψ_θ and $\partial\psi_\theta/\partial\theta^j$ are linearly independent, owing to $(\partial/\partial\theta^j)\langle\psi_\theta|\psi_\theta\rangle=0$ and $(\partial/\partial\theta^j)|\psi_\theta\rangle\langle\psi_\theta|\neq 0$.] Then $X=|x\rangle\langle\psi_\theta|$ satisfies $(X,X)_{\rho_\theta}=0$ and $(\partial/\partial\theta^j)\operatorname{Tr}\rho_\theta X\neq 0$. It is, however, important to notice that what is needed in estimation theory is not the RLD itself but the inverse of the RLD Fisher information matrix, as indicated by (8) and (9).

In his book (Ref. 2, p. 280), Holevo has shown that when a model satisfying the regularity conditions (a) and (10) has a $\mathcal{D}_\theta$-invariant SLD tangent space, the $(J_\theta^R)^{-1}$ is expressed only in terms of SLDs; so is the CR bound (9). We generalize this result to a wider class of models that satisfy only the weaker conditions (a) and (b).

Theorem 5: *Suppose we are given an n-dimensional model $\mathcal{P}=\{\rho_\theta\}$ having a $\mathcal{D}_\theta$-invariant SLD tangent space $\mathcal{T}_\theta^S(\mathcal{P})$. Then for all locally unbiased measurements M at θ,*

$$V_\theta[M]\geqslant(J_\theta^S)^{-1}+i(J_\theta^S)^{-1}D_\theta(J_\theta^S)^{-1},$$

where $D_\theta=[[L_{\theta,j}^S,L_{\theta,k}^S]_{\rho_\theta}]$.

Proof: Let us introduce a family of inner products on $\mathcal{L}^2(\rho_\theta)$ having a parameter $\epsilon\in(0,1]$:

$$(X,Y)_{\rho_\theta}^{(\epsilon)}=(1-\epsilon)(X,Y)_{\rho_\theta}+\epsilon\langle X,Y\rangle_{\rho_\theta}.$$

Since

$$\epsilon\langle X,X\rangle_{\rho_\theta}\leqslant(X,X)_{\rho_\theta}^{(\epsilon)}\leqslant(2-\epsilon)\langle X,X\rangle_{\rho_\theta},$$

there exists, for each ϵ, a unique operator $L_{\theta,j}^{(\epsilon)}\in\mathcal{L}^2(\rho_\theta)$ that satisfies

$$\frac{\partial}{\partial\theta^j}\operatorname{Tr}\rho_\theta X=(L_{\theta,j}^{(\epsilon)},X)_{\rho_\theta}^{(\epsilon)},$$

for all $X\in\mathcal{L}^2(\rho_\theta)$. Then, in a quite similar way to the derivation of the quantum Cramér–Rao inequality, we have

$$V_\theta[M]\geqslant(J_\theta^{(\epsilon)})^{-1},\quad J_\theta^{(\epsilon)}=[(L_{\theta,j}^{(\epsilon)},L_{\theta,k}^{(\epsilon)})_{\rho_\theta}^{(\epsilon)}]. \tag{11}$$

Now, observing the identity $(X,Y)^{(\epsilon)}_{\rho_\theta}=\langle X,Y\rangle_{\rho_\theta}+i(1-\epsilon)[X,Y]_{\rho_\theta}$, and using the definition of $\mathcal{D}_{\rho_\theta}=\mathcal{D}_\theta$, we see that, for all $Y\in\mathcal{L}^2(\rho_\theta)$,

$$\frac{\partial}{\partial\theta^j}\operatorname{Tr}\rho_\theta Y=\langle L^S_{\theta,j},Y\rangle_{\rho_\theta}=(L^{(\epsilon)}_{\theta,j},Y)^{(\epsilon)}_{\rho_\theta}=\langle\{\mathcal{I}+i(1-\epsilon)\mathcal{D}_\theta\}L^{(\epsilon)}_{\theta,j},Y\rangle_{\rho_\theta}.$$

Then $L^S_{\theta,j}=\{\mathcal{I}+i(1-\epsilon)\mathcal{D}_\theta\}L^{(\epsilon)}_{\theta,j}$; hence $(L^{(\epsilon)}_{\theta,j},L^{(\epsilon)}_{\theta,k})^{(\epsilon)}_{\rho\theta}=\langle L^S_{\theta,j},\{\mathcal{I}+i(1-\epsilon)\mathcal{D}_\theta\}^{-1}L^S_{\theta,k}\rangle_{\rho_\theta}$. Let us introduce Dirac's notation $|L^S_{\theta,j}\rangle$ for the Hilbert space $(\mathcal{L}^2(\rho_\theta),\langle\cdot,\cdot\rangle_{\rho_\theta})$, and let $\Gamma_\theta:=[|L^S_{\theta,1}\rangle,\ldots,|L^S_{\theta,n}\rangle]$. Then $\Gamma^*_\theta\Gamma_\theta=J^S_\theta$ and $\Gamma^*_\theta\mathcal{D}_\theta\Gamma_\theta=D_\theta$. And the matrix $J^{(\epsilon)}_\theta$ can be written in the form $J^{(\epsilon)}_\theta=\Gamma^*_\theta\{\mathcal{I}+i(1-\epsilon)\mathcal{D}_\theta\}^{-1}\Gamma_\theta$. Thus, from the assumption that $\mathcal{T}^S_\theta(\mathcal{P})$ is $\mathcal{D}_\theta$ invariant, the inverse of $J^{(\epsilon)}_\theta$ is explicitly given by

$$(J^{(\epsilon)}_\theta)^{-1}=(J^S_\theta)^{-1}\Gamma^*_\theta\{\mathcal{I}+i(1-\epsilon)\mathcal{D}_\theta\}\Gamma_\theta(J^S_\theta)^{-1}=(J^S_\theta)^{-1}+i(1-\epsilon)(J^S_\theta)^{-1}D_\theta(J^S_\theta)^{-1}. \quad (12)$$

Combining (11) and (12), and taking the limit $\epsilon\downarrow 0$, we have the theorem. □

Theorem 5 asserts that even for a model that does not have the RLDs, the $\lim_{\epsilon\downarrow 0}(J^{(\epsilon)}_\theta)^{-1}$ indeed gives a generalization of $(J^R_\theta)^{-1}$ as long as the SLD tangent space is $\mathcal{D}_\theta$ invariant. Then, by using Theorem 5 and an analogous argument to the derivation of (9), we obtain the CR bound,

$$C^R=\operatorname{tr}G(J^S_\theta)^{-1}+\operatorname{tr}\operatorname{abs}G(J^S_\theta)^{-1}D_\theta(J^S_\theta)^{-1}, \quad (13)$$

for models each having a $\mathcal{D}_\theta$-invariant SLD tangent space $\mathcal{T}^S_\theta(\mathcal{P})$. This may be called a generalized RLD bound. We will show in the next section that this bound is achievable in a coherent model.

V. OPTIMAL ESTIMATION FOR TWO-DIMENSIONAL COHERENT MODELS

We now proceed to a parameter estimation for a pure coherent model. In particular, taking into account the symplectic structure (6) of the SLD tangent space, we restrict ourselves to a two-dimensional case. We note that as long as we are concerned with the achievable CR bound at each point on the model $\{\rho_\theta\}$, we can take the weight as $G=I$ without loss of generality. In fact, let M be a locally unbiased measurement for the parameter $\theta=(\theta^1,\theta^2)$ and let $p(\hat\theta^1,\hat\theta^2)d\hat\theta=\operatorname{Tr}\rho_\theta M(d\hat\theta)$ be the corresponding joint distribution. The coordinate transformation $\eta^i=\Sigma_j h^i_j\theta^j$, where $H=[h^i_j]$ is a real regular matrix, then induces another measurement $N(d\hat\eta)$, which corresponds to the joint distribution $q(\hat\eta^1,\hat\eta^2)d\hat\eta=p(\hat\theta^1,\hat\theta^2)d\hat\theta$ and is locally unbiased for the parameter $\eta=(\eta^1,\eta^2)$. In this case, $\operatorname{tr}V_\eta[N]=\operatorname{tr}({}^tHH)V_\theta[M]$. Thus, the parameter estimation for θ with the weight $G={}^tHH$ is equivalent to that for η with the weight I.

Now suppose we are given a two-dimensional coherent model $\mathcal{P}=\{\rho_\theta;\theta=(\theta^1,\theta^2)\in\Theta\}$. Let $\{L^i\}$ be the dual basis of the SLDs: $L^i=\Sigma_j J^{ij}L^S_{\theta,j}$ with J^{ij} being the (i,j) entry of $(J^S_\theta)^{-1}$. Then

$$(J^S_\theta)^{-1}=\begin{bmatrix}\langle L^1,L^1\rangle_{\rho_\theta} & \langle L^1,L^2\rangle_{\rho_\theta}\\ \langle L^2,L^1\rangle_{\rho_\theta} & \langle L^2,L^2\rangle_{\rho_\theta}\end{bmatrix}$$

and

$$(J^S_\theta)^{-1}D_\theta(J^S_\theta)^{-1}=\begin{bmatrix}0 & [L^1,L^2]_{\rho_\theta}\\ [L^2,L^1]_{\rho_\theta} & 0\end{bmatrix}.$$

Thus the generalized RLD bound (13) for $G=I$ can be rewritten in the form

$$C^R=\langle L^1,L^1\rangle_{\rho_\theta}+\langle L^2,L^2\rangle_{\rho_\theta}+2|[L^1,L^2]_{\rho_\theta}|. \quad (14)$$

We will show that the bound C^R is achievable. In what follows, we fix a $\theta=(\theta^1,\theta^2)$ arbitrarily.

Let us consider a random measurement as follows. We first introduce a linear transformation ϕ: $\mathcal{T}_\theta^S(\mathcal{P})\to\mathcal{T}_\theta^S(\mathcal{P})$ by

$$\phi(X)=\langle L^1,X\rangle_{\rho_\theta}L^1+\langle L^2,X\rangle_{\rho_\theta}L^2.$$

Since ϕ is symmetric and positive definite, it has positive eigenvalues λ_1,λ_2, and mutually orthogonal unit eigenvectors A_1,A_2 satisfying $\phi(A_\nu)=\lambda_\nu A_\nu$, $\nu=1,2$. We next take positive numbers p_1,p_2 satisfying $p_1+p_2=1$. Now letting

$$\int \xi E_\nu(d\xi), \quad \nu=1,2$$

be the spectral decompositions of arbitrarily fixed representatives of A_ν, we define a generalized measurement,

$$M(\nu,d\xi)=p_\nu E_\nu(d\xi).$$

This has the following physical interpretation: Select one of the two ''observables'' A_1,A_2 according to the probability p_1,p_2, respectively, and measure it in a usual sense.

Now suppose we have selected A_ν and have obtained an outcome ξ. We identify this result with a pair of real quantities,

$$\hat\theta^i(\nu,\xi)=\theta^i+\frac{\xi}{p_\nu}\langle L^i,A_\nu\rangle_{\rho_\theta}, \quad i=1,2.$$

The pair $\{\hat\theta^i(\nu,\xi)\}_{i=1,2}$ satisfies the local unbiasedness condition at θ:

$$\sum_{\nu=1}^{2}\int \hat\theta^i(\nu,\xi)\mathrm{Tr}\,\rho_\theta M(\nu,d\xi)=\theta^i, \quad i=1,2, \tag{15}$$

$$\sum_{\nu=1}^{2}\int \hat\theta^i(\nu,\xi)\frac{\partial}{\partial\theta^j}\mathrm{Tr}\,\rho_\theta M(\nu,d\xi)=\delta_j^i, \quad i,j=1,2. \tag{16}$$

To prove (15), we used the fact that $A_\nu\in\mathcal{T}_\theta^S(\mathcal{P})$, i.e., $\langle I,A_\nu\rangle_{\rho_\theta}=0$. To prove (16), observe that

$$\int \xi\frac{\partial}{\partial\theta^j}\mathrm{Tr}\,\rho_\theta E_\nu(d\xi)=\langle L_{\theta,j}^S,A_\nu\rangle_{\rho_\theta},$$

so that the left-hand side of (16) becomes

$$\sum_{\nu=1}^{2}\langle L^i,A_\nu\rangle_{\rho_\theta}\langle L_{\theta,j}^S,A_\nu\rangle_{\rho_\theta}=\langle L^i,L_{\theta,j}^S\rangle_{\rho_\theta}=\delta_j^i.$$

With this measurement M,

$$\begin{aligned}\mathrm{tr}\,V_\theta[M]&=\sum_{\nu=1}^{2}\int[(\hat\theta^1(\nu,\xi)-\theta^1)^2+(\hat\theta^2(\nu,\xi)-\theta^2)^2]\mathrm{Tr}\,\rho_\theta M(\nu,d\xi)\\&=\sum_{\nu=1}^{2}\frac{1}{p_\nu}[\langle L^1,A_\nu\rangle_{\rho_\theta}^2+\langle L^2,A_\nu\rangle_{\rho_\theta}^2].\end{aligned}$$

In the second equality, we used the fact that

$$\int \xi^2 \,\mathrm{Tr}\,\rho_\theta E_\nu(d\xi)=\langle A_\nu ,A_\nu\rangle_{\rho_\theta}=1.$$

Since, for given $\mu_1,\mu_2>0$, $\mu_1/p_1+\mu_2/p_2$ takes the minimum $(\sqrt{\mu_1}+\sqrt{\mu_2})^2$ at $p_\nu=\sqrt{\mu_\nu}/(\sqrt{\mu_1}+\sqrt{\mu_2})$, we see

$$\begin{aligned}\min_{\{p_\nu\}} \mathrm{tr}\, V_\theta[M]&=\left[\sqrt{\langle L^1,A_1\rangle_{\rho_\theta}^2+\langle L^2,A_1\rangle_{\rho_\theta}^2}+\sqrt{\langle L^1,A_2\rangle_{\rho_\theta}^2+\langle L^2,A_2\rangle_{\rho_\theta}^2}\right]^2\\ &=\left[\sqrt{\langle A_1,\phi(A_1)\rangle_{\rho_\theta}}+\sqrt{\langle A_2,\phi(A_2)\rangle_{\rho_\theta}}\right]^2\\ &=\left[\sqrt{\lambda_1}+\sqrt{\lambda_2}\right]^2\\ &=\langle L^1,L^1\rangle_{\rho_\theta}+\langle L^2,L^2\rangle_{\rho_\theta}+2\sqrt{\langle L^1,L^1\rangle_{\rho_\theta}\langle L^2,L^2\rangle_{\rho_\theta}-\langle L^1,L^2\rangle_{\rho_\theta}^2}. \end{aligned}\tag{17}$$

The last equality follows from the fact that the trace $\lambda_1+\lambda_2$ and the determinant $\lambda_1\lambda_2$ of the linear transformation ϕ are independent of the choice of the basis that represents ϕ in a matrix form.

The random measurement presented above was first introduced in Ref. 5 by one of the present authors. In that paper, it was also shown that the problem of finding the achievable CR bound for an arbitrary two-parameter faithful spin-$\frac{1}{2}$ model can be reduced to an easy minimization problem. Interestingly, the explicit solution of the minimization problem, i.e., the achievable CR bound, turns out to be identical to the quantity (17), although the model treated there is not pure nor has, in general, a $\mathcal{D}_\rho$-invariant tangent space.

Now we establish the relation between (14) and (17) for a coherent model.

Theorem 6: *For a two-dimensional coherent model* $\{\rho_\theta=|\psi_\theta\rangle\langle\psi_\theta|\}$, *the lower bound (14) is identical to (17). In other words, the generalized RLD bound (14) is achievable.*

Proof: By Theorem 3, $L^1\psi_\theta$ and $L^2\psi_\theta$ are linearly dependent. Therefore

$$\det\begin{bmatrix}\langle L^1\psi_\theta|L^1\psi_\theta\rangle & \langle L^1\psi_\theta|L^2\psi_\theta\rangle\\ \langle L^2\psi_\theta|L^1\psi_\theta\rangle & \langle L^2\psi_\theta|L^2\psi_\theta\rangle\end{bmatrix}=0,$$

which leads to

$$(\mathrm{Im}\langle L^1\psi_\theta|L^2\psi_\theta\rangle)^2=\langle L^1\psi_\theta|L^1\psi_\theta\rangle\langle L^2\psi_\theta|L^2\psi_\theta\rangle-(\mathrm{Re}\langle L^1\psi_\theta|L^2\psi_\theta\rangle)^2.$$

By (1) and (2), this can be read as

$$|[L^1,L^2]_{\rho_\theta}|^2=\langle L^1,L^1\rangle_{\rho_\theta}\langle L^2,L^2\rangle_{\rho_\theta}-\langle L^1,L^2\rangle_{\rho_\theta}^2,$$

which proves the theorem.

It should be noted that a more convincing result has been obtained by Matsumoto.[11] He proved that the CR bound (13) is achievable for a $2m$-dimensional coherent model with an arbitrary weight G.

It is also worth noting that the achievability of (14) is closely related to the Heisenberg uncertainty relation. By a coordinate transformation, we can assume that the SLD Fisher information matrix is diagonal at a fixed $\rho_\theta=|\psi_\theta\rangle\langle\psi_\theta|$. Then there exist nonzero real numbers c_1,c_2 and a normalized ρ_θ-symplectic basis $\{\tilde{L}_1^S,\tilde{L}_2^S\}$ such that $L_j^S=c_j\tilde{L}_j^S$. Then $L^j=\tilde{L}_j^S/c_j$, and, by (7),

$$(c_1L^1+ic_2L^2)\psi_\theta=0.$$

This is nothing but the equality condition for the Heisenberg uncertainty relation. So we have

$$\langle L^1,L^1\rangle_{\rho_\theta}\langle L^2,L^2\rangle_{\rho_\theta}=|[L^1,L^2]_{\rho_\theta}|^2.$$

This equation, combined with the assumption that $\langle L^1,L^2\rangle_{\rho_\theta}=0$, gives another proof of Theorem 6 for an orthogonal parametrization at ρ_θ.

VI. EXAMPLES

In this section we calculate the achievable CR bounds for canonical and spin coherent models. Throughout this section, adjoint operators and complex conjugate numbers are denoted by † and *, respectively, according to the convention in physics. Also, we use the same letter for both a square summable operator and the corresponding element in $\mathcal{L}_h^2(\rho)$.

A. Canonical squeezed state model

The canonical squeezed state[12,13] is defined by

$$\rho_{q,p}=D(q,p)|0\rangle_{\xi\xi}\langle 0|D^\dagger(q,p) \quad (q,p\in\mathbf{R}),$$

where $D(q,p)=\exp(za^\dagger - z^* a)$ denotes the shift operator with $z=(q+ip)/\sqrt{2}$, and a and $a^\dagger$ are annihilation and creation operators, respectively, with $a=(Q+iP)/\sqrt{2}$. Further, $|0\rangle_\xi=\exp[(\xi a^{\dagger 2}-\xi^* a^2)/2]|0\rangle$ is the squeezed vacuum with $|0\rangle$ the Fock vacuum, and ξ is a complex number that represents the squeezing ratio: let $\xi=se^{i\theta}$.

Comparing the identity $b|z\rangle_\xi=\beta|z\rangle_\xi$ with Corollary 4, where $|z\rangle_\xi=D(q,p)|0\rangle_\xi$, $b=a\cosh s - a^\dagger e^{i\theta}\sinh s$, and $\beta=z\cosh s - z^* e^{i\theta}\sinh s$, we see that $\rho_{q,p}$ is a two-dimensional coherent model, and a normalized $\rho_{q,p}$-symplectic basis is given by

$$\tilde{L}_1^S=\sqrt{2}[(Q-qI)(\cosh s-\cos\theta\sinh s)-(P-pI)\sin\theta\sinh s],$$

$$\tilde{L}_2^S=\sqrt{2}[(P-pI)(\cosh s+\cos\theta\sinh s)-(Q-qI)\sin\theta\sinh s].$$

The SLDs at $\rho_{q,p}$ are calculated by operating $-\mathcal{D}_{q,p}$ to ALDs at $\rho_{q,p}$. By expanding ALDs, $L_q^A=2(P-pI)$, $L_p^A=-2(Q-qI)$ into linear combinations of $\tilde{L}_1^S$, $\tilde{L}_2^S$, and using the relations $\mathcal{D}_{q,p}\tilde{L}_1^S=\tilde{L}_2^S$, $\mathcal{D}_{q,p}\tilde{L}_2^S=-\tilde{L}_1^S$, we have

$$L_q^S=2[(Q-qI)(\cosh 2s-\cos\theta\sinh 2s)-(P-pI)\sin\theta\sinh 2s],$$

$$L_p^S=2[(P-pI)(\cosh 2s+\cos\theta\sinh 2s)-(Q-qI)\sin\theta\sinh 2s].$$

The corresponding SLD Fisher information matrix becomes

$$J_{q,p}^S=2\begin{bmatrix}\cosh 2s-\cos\theta\sinh 2s & -\sin\theta\sinh 2s\\ -\sin\theta\sinh 2s & \cosh 2s+\cos\theta\sinh 2s\end{bmatrix}.$$

Then from (17), we have

$$\min_M \operatorname{tr} V_{q,p}[M]=\cosh 2s+1.$$

B. Spin coherent state model

The spin coherent state[14,15] in the spin j representation is defined by

$$\rho_{\theta,\varphi}=R(\theta,\varphi)|j\rangle\langle j|R^\dagger(\theta,\varphi), \quad (0\le\theta\le\pi,\ 0\le\varphi<2\pi),$$

where (θ,φ) is the polar coordinate system (the north pole is $\theta=0$ and the x axis corresponds to $\varphi=0$), $R(\theta,\varphi)=\exp[i\theta(J_x\sin\varphi-J_y\cos\varphi)]$ the rotation through an angle $-\theta$ about an axis $(\sin\varphi,-\cos\varphi,0)$, and $|j\rangle$ the highest weight state with respect to J_z that corresponds to the north pole.

Since $J_+|j\rangle=(J_x+iJ_y)|j\rangle=0$, we find that $\rho_{\theta,\varphi}$ is a two-dimensional coherent model, and a normalized $\rho_{0,0}$-symplectic basis is $\tilde{L}_1^S(0,0)=\sqrt{2/j}J_x$, $\tilde{L}_2^S(0,0)=\sqrt{2/j}J_y$. A normalized $\rho_{\theta,\varphi}$-symplectic basis is then calculated as

$$\tilde{L}_k^S(\theta,\varphi)=R(\theta,\varphi)\tilde{L}_k^S(0,0)R^\dagger(\theta,\varphi),$$

where $k=1,2$.

On the other hand, the generators of rotations about axes $(\sin\varphi,-\cos\varphi,0)$ and $(\cos\varphi,\sin\varphi,0)$ at $\theta=0$ are $i(J_x\sin\varphi-J_y\cos\varphi)$ and $i(J_x\cos\varphi+J_y\sin\varphi)$, respectively. Therefore ALDs for the model at $\rho_{\theta,\varphi}$ are given by

$$\begin{aligned}L_\theta^A(\theta,\varphi)&=R(\theta,\varphi)\{-2(J_x\sin\varphi-J_y\cos\varphi)\}R^\dagger(\theta,\varphi)\\&=-\sqrt{2j}\{\tilde{L}_1^S(\theta,\varphi)\sin\varphi-\tilde{L}_2^S(\theta,\varphi)\cos\varphi\},\end{aligned}$$

$$\begin{aligned}L_\varphi^A(\theta,\varphi)&=R(\theta,\varphi)\{-2(J_x\cos\varphi+J_y\sin\varphi)\sin\theta\}R^\dagger(\theta,\varphi)\\&=-\sqrt{2j}\{\tilde{L}_1^S(\theta,\varphi)\sin\theta\cos\varphi+\tilde{L}_2^S(\theta,\varphi)\sin\theta\sin\varphi\}.\end{aligned}$$

The SLDs at $\rho_{\theta,\varphi}$ are calculated by operating $-\mathcal{D}_{\theta,\varphi}$ to ALDs, to obtain

$$L_\theta^S(\theta,\varphi)=\sqrt{2j}\{\tilde{L}_1^S(\theta,\varphi)\cos\varphi+\tilde{L}_2^S(\theta,\varphi)\sin\varphi\},$$

$$L_\varphi^S(\theta,\varphi)=-\sqrt{2j}\{\tilde{L}_1^S(\theta,\varphi)\sin\theta\sin\varphi-\tilde{L}_2^S(\theta,\varphi)\sin\theta\cos\varphi\}.$$

Since $\rho_{\theta,\varphi}$-symplectic basis $\{\tilde{L}_k^S(\theta,\varphi)\}_{k=1,2}$ is orthonormal, the SLD Fisher information matrix and the matrix D are easily calculated:

$$J_{\theta,\varphi}^S=\begin{bmatrix}2j & 0\\ 0 & 2j\sin^2\theta\end{bmatrix},\quad D_{\theta,\varphi}=\begin{bmatrix}0 & -2j\sin\theta\\ 2j\sin\theta & 0\end{bmatrix}.$$

We thus have

$$\min_M \operatorname{tr} V_{\theta,\varphi}[M]=\frac{1}{2j}\left(1+\frac{1}{\sin\theta}\right)^2.$$

VII. CONCLUSIONS

We introduced a class of quantum pure state models called the coherent models. They are characterized by a symplectic structure of the tangent space, and have a close connection with the conventional generalized coherent states in mathematical physics. A Cramér–Rao-type bound for a coherent model was derived by an analogous argument to the derivation of the right logarithmic derivative bound. Moreover, by an argument of random measurement, this lower bound was found to be achievable.

ACKNOWLEDGMENT

We thank Keiji Matsumoto for helpful suggestions, with which the manuscript has been improved as compared with the early version[16] of this paper.

Exact solutions of the Dirac equation in a chiral representation for neutrinos in the presence of external stresses are investigated in terms of special functions, using the algebraic method of the separation of variables in Cartesian, cylindrical, and spherical coordinates.
[S0022-2488(99)02408-1]

I. INTRODUCTION

It is in the neutrino physics domain that most inconsistencies with the standard model are found. From the results presented in the standard model, it seems clear that neutrinos have opened a window toward new physics. It is nowadays very interesting to study the neutrino beams by means of electromagnetic fields in order to understand their space distributions and to give exacts solutions of the Dirac equation for them.

The investigations of methods giving exact solutions of the Dirac equation with or without external interactions[1–30] have excited great interest in the past few years because of the usefulness of solvable problems to build a consistent and comprehensible theory, and to find an adequate mathematical framework for the interpretation of numerous experimental results.

The methods used in the most fundamental works on this Dirac equation in the presence of external interaction are essentially based on the quaternionic approach proposed by Hautot,[29] the Stäckel separation method developed by Bagrov *et al.*,[22] the shift operator method,[25] the algebraic method proposed by Komarov and Romanov,[30] and the algebraic method of the separation of variables adopted by Shishkin *et al.*[6] Our aim in this paper is to present the theory of neutrinos in external fields from this latter point of view.

Despite the remarkable results attained in these previous works, using one or the other of the mentioned methods, the large set of representations adapted to various situations does not permit us to elaborate on a unified mathematical framework for the exact solutions in the standard system of coordinates like Cartesian, cylindrical, and spherical.

Clearly, it is not often explained in these works why a matrix or geometric representation used to solve the Dirac equation in one system of coordinates is not quite adapted to solve the same problem in other systems of coordinates! What kind of mathematical difficulties occur and oblige us to choose specific representations for a specific system of coordinates! To discuss this equation, we opt here to work in a unique representation, whatever the coordinate system considered.

The algebraic method of the separation of variables[6] consists of reducing the Dirac operator to a sum of two commuting differential operators following the scheme

$$\{H_{\mathrm{D}}\}\Psi \Rightarrow \{H_{\mathrm{D}}\}\Gamma\Gamma^{-1}\Psi \Rightarrow \{\hat{K}_1+\hat{K}_2\}\Phi, \quad \text{with } \Psi=\Gamma\Phi, \tag{1}$$

$$\{\hat{K}_1+\hat{K}_2\}\Phi=0, \tag{2}$$

$$[\hat{K}_1,\hat{K}_2]_-=\hat{K}_1\hat{K}_2-\hat{K}_2\hat{K}_1=0, \tag{3}$$

[a)]Electronic mail: hounkon@syfed.bj.refer.org

where H_D is the initial Dirac operator; and $\hat{K}_1$ and $\hat{K}_2$, the searched commuting differential operators, depend on a set of variables.

Ψ and Φ are the initial spinor, solution of the Dirac equation, and the searched spinor, corresponding to the operator $\hat{K}_1+\hat{K}_2$, respectively.

Thus the initial problem is equivalently reduced to solve the following:

$$\hat{K}_1\Phi=\lambda\Phi=-\hat{K}_2\Phi, \tag{4}$$

where λ is a constant of separation.

Here, we have shown that, adapting this algebraic method of separation of variables in a chiral representation, it is possible to give exact solutions in terms of special functions to Dirac equation with various external fields in different systems of coordinates such as a Cartesian, cylindrical, and spherical one.

The paper is organized as follows. In Sec. II, considering the system of Cartesian coordinates, exact solutions to the Dirac equation in the presence of four types of external fields are given in terms of confluent hypergeometric functions. In Sec. III, the same problem is considered in cylindrical coordinates. In Sec. IV, we discuss the difficulties arising when the spherical coordinates are considered in a chiral representation.

II. CARTESIAN COORDINATES

In Cartesian coodinates, the Dirac equation for a neutrino of mass m in external electromagnetic field reads as follows in chiral representation:

$$\{\gamma_\chi^0\partial_t+\gamma_\chi^1\partial_x+\gamma_\chi^2\partial_y+\gamma_\chi^3\partial_z+m+g\epsilon_{ijk}\gamma_\chi^i\gamma_\chi^jH_k\}\Psi_\chi=0, \tag{5}$$

where

$$\gamma_\chi^0=\begin{pmatrix}0 & I\\ I & 0\end{pmatrix},\qquad \gamma_\chi^k=\begin{pmatrix}0 & -\sigma^k\\ \sigma^k & 0\end{pmatrix},\qquad (k=1,2,3); \tag{6}$$

g is the coupling constant; H_k the external electromagnetic field; and Ψ_χ the spinor solution of the Dirac equation;

$$\epsilon_{ijk}=\begin{cases}+1, & \text{if } (ijk) \text{ is an even permutation of } (123);\\ -1, & \text{if } (ijk) \text{ is an odd permutation of } (123);\\ 0, & \text{otherwise.}\end{cases}$$

Using the algebraic method of the separation of variables, we can write Eq. (5) as follows:

$$\{\hat{K}_{xy}+\hat{K}_{zt}\}\Phi_\chi=0,\quad \hat{K}_{xy}\Phi_\chi=\lambda\Phi_\chi=-\hat{K}_{zt}\Phi_\chi, \tag{7}$$

where

$$\hat{K}_{xy}=\gamma_\chi^1\partial_y-\gamma_\chi^2\partial_x+m\gamma_\chi^1\gamma_\chi^2-gH_z(x,y), \tag{8}$$

$$\hat{K}_{zt}=\gamma_\chi^0\gamma_\chi^1\gamma_\chi^2\partial_t+\gamma_\chi^3\gamma_\chi^1\gamma_\chi^2\partial_z-gH_z(z,t), \tag{9}$$

and

$$\Psi_\chi=\gamma_\chi^1\gamma_\chi^2\Phi_\chi. \tag{10}$$

The magnetic vector H_z reads as

$$H_z = H_z(x,y) + H_z(z,t). \tag{11}$$

Applying the condition $\nabla \underline{H}_z = 0$ on Eq. (11), we find that $H_z(z,t) = H_z(t)$, and if we fix our attention to time-independent fields, this term can be omitted.

$\lambda \Phi_\chi = -\hat{K}_{zt}\Phi_\chi$ establishes the relationship between the different spinor composents of Φ_χ and Ψ_χ, and the value of the constant of separation λ, which satisfies the relation $\lambda^2 = E^2 - k_z^2$.

From $\lambda \Phi_\chi = -\hat{K}_{zt}\Phi_\chi$, we find

$$\Phi_\chi = \begin{pmatrix} \xi_1 \\ \xi_2 \\ \eta_1 \\ \eta_2 \end{pmatrix} = \begin{pmatrix} \dfrac{E+k_z}{\lambda}\eta_1 \\ \dfrac{-E+k_z}{\lambda}\eta_2 \\ \eta_1 \\ \eta_2 \end{pmatrix}. \tag{12}$$

Substituting Eqs. (6) and (11) in (7), we obtain

$$[\gamma_\chi^1 \partial_y - \gamma_\chi^2 \partial_x + m\gamma_\chi^1 \gamma_\chi^2 - gH_z(x,y) - \lambda]\Phi_\chi = 0. \tag{13}$$

This equation splits into a system of ordinary differential equations, mixing the two-component spinors η and ξ as follows:

$$(\sigma^2 d_x - ik_y\sigma^1)\eta - (gH_z(x) + \lambda + im\sigma^3)\xi = 0, \tag{14}$$

$$(-\sigma^2 d_x + ik_y\sigma^1)\xi - (gH_z(x) + \lambda + im\sigma^3)\eta = 0. \tag{15}$$

Now, we are going to solve these equations to obtain the explicit expressions of η_1, η_2, ξ_1, and ξ_2, for some relevant external fields H_z.

(i) H_z is a constant magnetic field: $H_z = \beta$.

In this case, Eqs. (14) and (15) become

$$(\sigma^2 d_x - ik_y\sigma^1)\eta - (g\beta + \lambda + im\sigma^3)\xi = 0, \tag{16}$$

$$(-\sigma^2 d_x + ik_y\sigma^1)\xi - (g\beta + \lambda + im\sigma^3)\eta = 0. \tag{17}$$

Inserting (12) into the spinor equation (16), and using the standard representation for the Pauli matrices, we obtain

$$(d_x + k_y)\eta_2 - i(g\beta + \lambda + im)\left(\frac{E+k_z}{\lambda}\right)\eta_1 = 0, \tag{18}$$

$$(d_x - k_y)\eta_1 - i(g\beta + \lambda + im)\left(\frac{E-k_z}{\lambda}\right)\eta_2 = 0, \tag{19}$$

where

$$\eta = \begin{pmatrix} \eta_1 \\ \eta_2 \end{pmatrix}. \tag{20}$$

From (19), we have

$$\eta_2=\frac{-i}{(g\beta+\lambda+im)\left(\frac{E-k_z}{\lambda}\right)}(d_x-k_y)\,\eta_1, \tag{21}$$

which we insert into (18) to obtain a second-order differential equation for η_1,

$$\left[\frac{d^2}{dx^2}-k_y^2+(g\beta+\lambda+im)^2\right]\eta_1=0. \tag{22}$$

The solution of this equation reads as

$$\eta_1=c_1\exp[\sqrt{k_y^2-(g\beta+\lambda+im)^2}x]+c_2\exp[-\sqrt{k_y^2-(g\beta+\lambda+im)^2}x]. \tag{23}$$

Substituting (23) into (21), and using (12), we have

$$\eta_2=\frac{-i}{(g\beta+\lambda+im)\left(\frac{E-k_z}{\lambda}\right)}\{c_1[\sqrt{k_y^2-(g\beta+\lambda+im)^2}-k_y]\exp[\sqrt{k_y^2-(g\beta+\lambda+im)^2}x]$$
$$-c_2[\sqrt{k_y^2-(g\beta+\lambda+im)^2}+k_y]\exp[-\sqrt{k_y^2-(g\beta+\lambda+im)^2}x]\}, \tag{24}$$

$$\xi_1=\frac{E+k_z}{\lambda}\{c_1\exp[\sqrt{k_y^2-(g\beta+\lambda+im)^2}x]+c_2\exp[-\sqrt{k_y^2-(g\beta+\lambda+im)^2}x]\}, \tag{25}$$

$$\xi_2=\frac{i}{(g\beta+\lambda+im)}\{c_1[\sqrt{k_y^2-(g\beta+\lambda+im)^2}-k_y]\exp[\sqrt{k_y^2-(g\beta+\lambda+im)^2}x]$$
$$-c_2[\sqrt{k_y^2-(g\beta+\lambda+im)^2}+k_y]\exp[-\sqrt{k_y^2-(g\beta+\lambda+im)^2}x]\}. \tag{26}$$

(ii) H_z linearly depends on spatial coordinate x: $H_z=\beta x$.

Substituting the field expression into the spinor equation (14) with the standard representation for Pauli matrices, and taking into account (12), we obtain

$$(d_x+k_y)\,\eta_2-i(g\beta x+\lambda+im)\left(\frac{E+k_z}{\lambda}\right)\eta_1=0, \tag{27}$$

$$(d_x-k_y)\,\eta_1-i(g\beta x+\lambda+im)\left(\frac{E-k_z}{\lambda}\right)\eta_2=0. \tag{28}$$

From (28), we have

$$\eta_2=\frac{-i}{(g\beta x+\lambda+im)\left(\frac{E-k_z}{\lambda}\right)}(d_x-k_y)\,\eta_1, \tag{29}$$

which we insert into (27) to obtain a second-order ordinary differential equation for η_1,

$$\left[\frac{d^2}{dx^2}-k_y^2+(g\beta x+\lambda+im)^2\right]\eta_1=0. \tag{30}$$

Making the change of variables,

$$g\beta x+\lambda+im=\sqrt{\frac{g\beta}{2}}y, \tag{31}$$

we reduce (30) to a parabolic cylinder equation,[31]

$$\left[\frac{d^2}{dy^2}+\frac{y^2}{4}-\frac{k_y^2}{2g\beta}\right]\eta_1=0, \tag{32}$$

whose solution can be written in terms of confluent hypergeometric functions $M(a,b,z)$:[31]

$$\eta_1=c_1\exp\left(\frac{-iy^2}{4}\right)M\left(\frac{1}{4}-\frac{ik_y^2}{4g\beta},\frac{1}{2},\frac{i}{2}y^2\right)+y\exp\left(\frac{i\pi}{4}\right)c_2\exp\left(\frac{-iy^2}{4}\right)M\left(\frac{3}{4}-\frac{ik_y^2}{4g\beta},\frac{3}{2},\frac{i}{2}y^2\right). \tag{33}$$

Substituting (33) into (29), and using (12) and the recurrence relation

$$M'(a,b,z)=\frac{a}{b}M(a+1,b+1,z), \tag{34}$$

we obtain explicit expressions for other components of the 4-spinor Φ_χ:

$$\eta_2=\frac{i\exp\left(\frac{-iy^2}{4}\right)}{\sqrt{\frac{g\beta}{2}}y\left(\frac{E-k_z}{\lambda}\right)}\left[c_1\left(M\left(\frac{1}{4}-\frac{ik_y^2}{4g\beta},\frac{1}{2},\frac{i}{2}y^2\right)\left(i\sqrt{\frac{g\beta}{2}}y+k_y\right)-iy\sqrt{2g\beta}\left(\frac{1}{2}-\frac{ik_y^2}{2g\beta}\right)\right.\right.$$
$$\left.\times M\left(\frac{5}{4}-\frac{ik_y^2}{4g\beta},\frac{3}{2},\frac{i}{2}y^2\right)\right)-c_2\exp\left(\frac{i\pi}{4}\right)\left(M\left(\frac{3}{4}-\frac{ik_y^2}{4g\beta},\frac{3}{2},\frac{i}{2}y^2\right)\left(\sqrt{2g\beta}-i\sqrt{\frac{g\beta}{2}}y^2\right.\right.$$
$$\left.\left.\left.-yk_y\right)-i\sqrt{2g\beta}\left(\frac{3}{6}-\frac{ik_y^2}{6g\beta}\right)y^2M\left(\frac{7}{4}-\frac{ik_y^2}{4g\beta},\frac{5}{2},\frac{i}{2}y^2\right)\right)\right], \tag{35}$$

$$\xi_1=\frac{E+k_z}{\lambda}\left[c_1\exp\left(\frac{-iy^2}{4}\right)M\left(\frac{1}{4}-\frac{ik_y^2}{4g\beta},\frac{1}{2},\frac{i}{2}y^2\right)+y\exp\left(\frac{i\pi}{4}\right)c_2\exp\left(\frac{-iy^2}{4}\right)\right.$$
$$\left.\times M\left(\frac{3}{4}-\frac{ik_y^2}{4g\beta},\frac{3}{2},\frac{i}{2}y^2\right)\right], \tag{36}$$

$$\xi_2=-i\frac{\exp\left(\frac{-iy^2}{4}\right)}{\sqrt{\frac{g\beta}{2}}y}\left[c_1\left(M\left(\frac{1}{4}-\frac{ik_y^2}{4g\beta},\frac{1}{2},\frac{i}{2}y^2\right)\left(i\sqrt{\frac{g\beta}{2}}y+k_y\right)-iy\sqrt{2g\beta}\left(\frac{1}{2}-\frac{ik_y^2}{2g\beta}\right)\right.\right.$$
$$\left.\times M\left(\frac{5}{4}-\frac{ik_y^2}{4g\beta},\frac{3}{2},\frac{i}{2}y^2\right)\right)-c_2\exp\left(\frac{i\pi}{4}\right)\left(M\left(\frac{3}{4}-\frac{ik_y^2}{4g\beta},\frac{3}{2},\frac{i}{2}y^2\right)\right.$$
$$\left.\left.\times\left(\sqrt{2g\beta}-i\sqrt{\frac{g\beta}{2}}y^2-yk_y\right)-i\sqrt{2g\beta}\left(\frac{3}{6}-\frac{ik_y^2}{6g\beta}\right)y^2M\left(\frac{7}{4}-\frac{ik_y^2}{4g\beta},\frac{5}{2},\frac{i}{2}y^2\right)\right)\right]. \tag{37}$$

(iii) The magnetic field H_z is inversely proportional to the spatial coordinate x: $H_z(x)=\beta/x$. Substituting the field expression into (14) and taking into account (12), we obtain

$$(d_x+k_y)\eta_2-i\left(\frac{g\beta}{x}+\lambda+im\right)\left(\frac{E+k_z}{\lambda}\right)\eta_1=0, \tag{38}$$

$$(d_x-k_y)\eta_1-i\left(\frac{g\beta}{x}+\lambda+im\right)\left(\frac{E-k_z}{\lambda}\right)\eta_2=0. \tag{39}$$

If we eliminate η_2 from (39) and (38), we find a second-order differential equation as follows:

$$\left[\frac{d^2}{dx^2}-k_y^2+\left(\frac{g\beta}{x}+\lambda+im\right)^2\right]\eta_1=0, \tag{40}$$

whose solution can be expressed in terms of confluent hypergeometric functions as follows:

$$\eta_1=\exp\left(\frac{-y}{2}\right)\left[a_1y^{1/2+\mu}M\left(\frac{1}{2}+\mu-\tilde{k},1+2\mu,y\right)+a_2y^{1/2-\mu}M\left(\frac{1}{2}-\mu-\tilde{k},1-2\mu,y\right)\right], \tag{41}$$

where

$$y=2\sqrt{k_y^2-(\lambda+im)^2}x, \quad \tilde{k}=\frac{g\beta(\lambda+im)}{\sqrt{k_y^2-(\lambda+im)^2}},$$

$$\mu=\sqrt{\frac{1}{4}-g^2\beta^2}. \tag{42}$$

Inserting (41) into (39), and using (12) and the recurrence relation (34), the other components of the 4-spinor are explicitly determined as

$$\begin{aligned}\eta_2=&\frac{-i\lambda\tilde{k}y\exp\left(\frac{-y}{2}\right)}{(2g^2\beta^2+\tilde{k}y)(\lambda+im)(E-k_z)}\left[a_1\left(M\left(\frac{1}{2}+\mu-\tilde{k},1+2\mu,y\right)\right.\right.\\&\times\left(\frac{-g\beta(\lambda+im)}{\tilde{k}}y^{1/2+\mu}+\frac{2g\beta(\lambda+im)}{\tilde{k}}\left(\frac{1}{2}+\mu\right)y^{-1/2+\mu}-k_yy^{1/2+\mu}\right)\\&\left.+\frac{2g\beta(\lambda+im)}{\tilde{k}}\frac{(\frac{1}{2}+\mu-\tilde{k})}{1+2\mu}y^{1/2+\mu}M\left(\frac{3}{2}+\mu-\tilde{k},2+2\mu,y\right)\right)+a_2\left(M\left(\frac{1}{2}-\mu-\tilde{k},1-2\mu,y\right)\right.\\&\times\left(\frac{-g\beta(\lambda+im)}{\tilde{k}}y^{1/2-\mu}+\frac{2g\beta(\lambda+im)}{\tilde{k}}\left(\frac{1}{2}-\mu\right)y^{-1/2-\mu}-k_yy^{1/2-\mu}\right)\\&\left.\left.+\frac{2g\beta(\lambda+im)}{\tilde{k}}\frac{(\frac{1}{2}-\mu-\tilde{k})}{1-2\mu}y^{1/2-\mu}M\left(\frac{3}{2}-\mu-\tilde{k},2-2\mu,y\right)\right)\right],\end{aligned} \tag{43}$$

$$\xi_1=\frac{(E+k_z)\exp\left(\frac{-y}{2}\right)}{\lambda}\left[a_1y^{1/2+\mu}M\left(\frac{1}{2}+\mu-\tilde{k},1+2\mu,y\right)+a_2y^{1/2-\mu}M\left(\frac{1}{2}-\mu-\tilde{k},1-2\mu,y\right)\right], \tag{44}$$

$$\xi_2=\frac{i\tilde{k}y\exp\left(\frac{-y}{2}\right)}{(2g^2\beta^2+\tilde{k}y)(\lambda+im)}\left[a_1\left(M\left(\frac{1}{2}+\mu-\tilde{k},1+2\mu,y\right)\left(\frac{-g\beta(\lambda+im)}{\tilde{k}}y^{1/2+\mu}\right.\right.\right.$$

$$+\frac{2g\beta(\lambda+im)}{\tilde{k}}\left(\frac{1}{2}+\mu\right)y^{-1/2+\mu}-k_y y^{1/2+\mu}\Bigg)$$

$$+\frac{2g\beta(\lambda+im)}{\tilde{k}}\frac{(\frac{1}{2}+\mu-\tilde{k})}{1+2\mu}y^{1/2+\mu}M\left(\frac{3}{2}+\mu-\tilde{k},2+2\mu,y\right)\Bigg)$$

$$+a_2\left(M\left(\left(\frac{1}{2}-\mu-\tilde{k},1-2\mu,y\right)\left(\frac{-g\beta(\lambda+im)}{\tilde{k}}y^{1/2-\mu}\right.\right.\right.$$

$$+\frac{2g\beta(\lambda+im)}{\tilde{k}}\left(\frac{1}{2}-\mu\right)y^{-1/2-\mu}-k_y y^{1/2-\mu}\Bigg)$$

$$\left.+\frac{2g\beta(\lambda+im)}{\tilde{k}}\frac{(\frac{1}{2}-\mu-\tilde{k})}{1-2\mu}y^{1/2-\mu}M\left(\frac{3}{2}-\mu-\tilde{k},2-2\mu,y\right)\Bigg)\Bigg)\right]. \tag{45}$$

(iv) The magnetic field depends exponentially on the spatial coordinate x: $H_z(x)=\beta\exp\alpha x$. Here, substituting field expression into (14) and taking into account (12), we obtain

$$(d_x+k_y)\eta_2-i(g\beta\exp\alpha x+\lambda+im)\left(\frac{E+k_z}{\lambda}\right)\eta_1=0, \tag{46}$$

$$(d_x-k_y)\eta_1-i(g\beta\exp\alpha x+\lambda+im)\left(\frac{E-k_z}{\lambda}\right)\eta_2=0. \tag{47}$$

Making the change of variables $v=\exp\alpha x$, and eliminating η_2 from (47) and (46), leads to

$$\left[\frac{d^2}{dv^2}+\frac{1}{v}\frac{d}{dv}+\frac{(\lambda+im)^2-k_y^2}{\alpha^2v^2}+\frac{2g\beta(\lambda+im)}{\alpha^2v}+\frac{g^2\beta^2}{\alpha^2}\right]\eta_1=0. \tag{48}$$

Writing

$$\eta_1=c(v)\zeta, \tag{49}$$

reduces Eq. (48) to a canonic form:

$$\left[\frac{d^2}{dv^2}+q(v)\right]\zeta=0. \tag{50}$$

Then, the change of variables $z=(-2ig\beta/\alpha)v$ permits us to obtain the solution of the Whittaker equation[31] as follows:

$$\eta_1=a_1\exp\left(\frac{ig\beta}{\alpha}v\right)v^{\mu}M\left(\frac{1}{2}+\mu-k,1+2\mu,\frac{-2ig\beta}{\alpha}v\right)$$

$$+a_2\exp\left(\frac{ig\beta}{\alpha}v\right)v^{-\mu}M\left(\frac{1}{2}-\mu-k,1-2\mu,\frac{-2ig\beta}{\alpha}v\right), \tag{51}$$

where

$$\mu=\sqrt{\frac{k_y^2-(\lambda+im)^2}{\alpha^2}},\quad k=\frac{(i\lambda-m)}{\alpha}. \tag{52}$$

Putting (51) into (47), and using (12) and the recurrence relation (34), we explicitly determine the other components of Φ_χ:

$$\eta_2=\frac{-i\lambda\,\exp\left(\frac{ig\beta}{\alpha}v\right)}{(g\beta v+\lambda+im)(E-k_z)}\Bigg[a_1M\left(\frac{1}{2}+\mu-k,1+2\mu,\frac{-2ig\beta}{\alpha}v\right)(ig\beta v^{1+\mu}+\alpha\mu v^{\mu}-k_yv^{\mu})$$
$$+a_1\alpha' v^{1+\mu}\left(\frac{\frac{1}{2}+\mu-k}{1+2\mu}\right)M\left(\frac{3}{2}+\mu-k,2+2\mu,\frac{-2ig\beta}{\alpha}v\right)$$
$$+a_2M\left(\frac{1}{2}-\mu-k,1-2\mu,\frac{-2ig\beta}{\alpha}v\right)(ig\beta v^{1-\mu}-\alpha\mu v^{-\mu}-k_yv^{-\mu})$$
$$+a_2\alpha' v^{1-\mu}\left(\frac{\frac{1}{2}-\mu-k}{1-2\mu}\right)M\left(\frac{3}{2}-\mu-k,2-2\mu,\frac{-2ig\beta}{\alpha}v\right)\Bigg], \tag{53}$$

$$\xi_1=\frac{E+k_z}{\lambda}\Bigg[a_1\exp\left(\left(\frac{ig\beta}{\alpha}v\right)v^{\mu}M\left(\frac{1}{2}+\mu-k,1+2\mu,\frac{-2ig\beta}{\alpha}v\right)\right.$$
$$+a_2\exp\left(\frac{ig\beta}{\alpha}v\right)v^{-\mu}M\left(\frac{1}{2}-\mu-k,1-2\mu,\frac{-2ig\beta}{\alpha}v\right)\Bigg], \tag{54}$$

$$\xi_2=\frac{i\,\exp\left(\frac{ig\beta}{\alpha}v\right)}{(g\beta v+\lambda+im)}\Bigg[a_1M\left(\frac{1}{2}+\mu-k,1+2\mu,\frac{-2ig\beta}{\alpha}v\right)(ig\beta v^{1+\mu}+\alpha\mu v^{\mu}-k_yv^{\mu})$$
$$+a_1\alpha' v^{1+\mu}\left(\frac{\frac{1}{2}+\mu-k}{1+2\mu}\right)M\left(\frac{3}{2}+\mu-k,2+2\mu,\frac{-2ig\beta}{\alpha}v\right)$$
$$+a_2M\left(\frac{1}{2}-\mu-k,1-2\mu,\frac{-2ig\beta}{\alpha}v\right)(ig\beta v^{1-\mu}-\alpha\mu v^{-\mu}-k_yv^{-\mu})$$
$$+a_2\alpha' v^{1-\mu}\left(\frac{\frac{1}{2}-\mu-k}{1-2\mu}\right)M\left(\frac{3}{2}-\mu-k,2-2\mu,\frac{-2ig\beta}{\alpha}v\right)\Bigg], \tag{55}$$

where $\alpha'=-2ig\beta$.

III. CYLINDRICAL COORDINATES

The Dirac equation in cylindrical coordinates for the neutrino of mass m in an external magnetic field, expressed in chiral representation, reads as

$$\left\{\gamma_\chi^0\partial_t+\gamma_\chi^1\partial_r+\frac{\gamma_\chi^2}{r}\partial_\theta+\gamma_\chi^3\partial_z+m+g\gamma_\chi^1\gamma_\chi^2H\right\}\Psi_\chi=0. \tag{56}$$

Following the pairwise scheme of variable separation, we transform Eq. (56) to

$$\left[-\gamma_\chi^2\partial_r+\frac{\gamma_\chi^1}{r}\partial_\theta+m\gamma_\chi^1\gamma_\chi^2-gH+\lambda\right]\Phi_\chi=0, \tag{57}$$

$$[\gamma_\chi^0\gamma_\chi^1\gamma_\chi^2\partial_t+\gamma_\chi^3\gamma_\chi^1\gamma_\chi^2\partial_z-\lambda]\Phi_\chi=0, \tag{58}$$

where Φ_χ is related to Ψ_χ by

$$\Psi_\chi=\gamma_\chi^1\gamma_\chi^2\Phi_\chi. \tag{59}$$

From Eq. (58), we find the following relations:

$$\lambda^2=E^2-k_z^2, \quad \Phi_\chi=\begin{pmatrix}\xi_1\\ \xi_2\\ \eta_1\\ \eta_2\end{pmatrix}=\begin{pmatrix}-\dfrac{E+k_z}{\lambda}\eta_1\\ \dfrac{E-k_z}{\lambda}\eta_2\\ \eta_1\\ \eta_2\end{pmatrix}. \tag{60}$$

The Eq. (57) splits into a system of ordinary differential equations, mixing the two-component spinors η and ξ as follows:

$$\left(\sigma^2 d_r-\frac{ik_\theta}{r}\sigma^1\right)\eta-(gH-\lambda+im)\xi=0, \tag{61}$$

$$\left(-\sigma^2 d_r+\frac{ik_\theta}{r}\sigma^1\right)\xi-(gH-\lambda+im)\eta=0, \tag{62}$$

involving the new system of equations,

$$\left(d_r+\frac{k_\theta}{r}\right)\eta_2+i(gH-\lambda+im)\left(\frac{E+k_z}{\lambda}\right)\eta_1=0, \tag{63}$$

$$\left(d_r-\frac{k_\theta}{r}\right)\eta_1+i(gH-\lambda+im)\left(\frac{E-k_z}{\lambda}\right)\eta_2=0, \tag{64}$$

which are more adapted to our situation.

Let us now analyze its solutions in terms of special functions, providing a concrete prescription for the external magnetic field.

(i) H is a constant magnetic field: $H=\beta$.

From (64), we have

$$\eta_2=\frac{i\lambda}{(g\beta-\lambda+im)(E-k_z)}\left(d_r-\frac{k_\theta}{r}\right)\eta_1, \tag{65}$$

which we insert into (63) to obtain a second-order differential equation for η_2,

$$\left[\frac{d^2}{dr^2}-\frac{k_\theta(k_\theta-1)}{r^2}+(g\beta-\lambda+im)^2\right]\eta_1=0, \tag{66}$$

whose solution can be written as follows:

$$\eta_1=cr^{1/2}H^{(1)}_{k_\theta-1/2}[(g\beta-\lambda+im)r]; \tag{67}$$

$H_\alpha^{(1)}(r)$ is the Hankel function of the first kind. Substituting (67) into (65), and using (60) and the following recurrence relation:

$$H'^{(1)}_{\mu}(z)=H^{(1)}_{\mu-1}(z)-\frac{\mu}{z}H^{(1)}_{\mu}(z), \tag{68}$$

we completely defined the three other components of the 4-spinor Φ_χ:

$$\eta_2=\frac{i\lambda}{E-k_z}cr^{-1/2}H^{(1)}_{k_\theta+1/2}[(g\beta-\lambda+im)r], \tag{69}$$

$$\xi_1=-\frac{E+k_z}{\lambda}cr^{1/2}H^{(1)}_{k_\theta-1/2}[(g\beta-\lambda+im)r], \tag{70}$$

$$\xi_2=icr^{1/2}H^{(1)}_{k_\theta+1/2}[(g\beta-\lambda+im)r]. \tag{71}$$

(ii) The magnetic field H is inversely proportional to the spatial coordinate r: $H=\alpha/r$. Substituting the field expression into (63) and (64), and if eliminating η_2 from these equations, we find a second-order differential equation:

$$\left[\frac{d^2}{dr^2}-\frac{k_\theta(k_\theta-1)-g^2\alpha^2}{r^2}-2(\lambda-im)g\frac{\alpha}{r}+(\lambda-im)^2\right]\eta_1=0. \tag{72}$$

Then, the change of variables $\rho=2i(\lambda-im)r$ permits us to obtain the solution

$$\eta_1=c_0\exp\left(\frac{-\rho}{2}\right)\rho^{1/2+\mu}M\left(\frac{1}{2}+\mu-k,1+2\mu,\rho\right)+c_1\exp\left(\frac{-\rho}{2}\right)\rho^{1/2-\mu}M\left(\frac{1}{2}-\mu-k,1-2\mu,\rho\right), \tag{73}$$

where

$$\mu=\sqrt{k_\theta(k_\theta-1)-g^2\alpha^2+\tfrac{1}{4}},\quad k=ig\alpha. \tag{74}$$

Inserting (73) into (63), and using (60) and the recurrence relation (34), we have the three other components of the 4-spinor Φ_χ,

$$\begin{aligned}\eta_2=\frac{-2\lambda\rho\exp\left(\frac{-\rho}{2}\right)}{(2ig\alpha-\rho)(E-k_z)}\Bigg[&c_0\Bigg(M\left(\frac{1}{2}+\mu-k,1+2\mu,\rho\right)\left(\frac{-1}{2}\rho^{1/2+\mu}+\left(\frac{1}{2}+\mu\right)\rho^{\mu-1/2}-k_\theta\rho^{\mu-1/2}\right)\\&+\frac{\frac{1}{2}+\mu-k}{1+2\mu}\rho^{1/2+\mu}M\left(\frac{3}{2}+\mu-k,2+2\mu,\rho\right)\Bigg)\\&+c_1\Bigg(M\left(\frac{1}{2}-\mu-k,1-2\mu,\rho\right)\left(\frac{-1}{2}\rho^{1/2-\mu}+\left(\frac{1}{2}-\mu\right)\rho^{-\mu-1/2}-k_\theta\rho^{-\mu-1/2}\right)\\&+\frac{\frac{1}{2}-\mu-k}{1-2\mu}\rho^{1/2-\mu}M\left(\frac{3}{2}-\mu-k,2-2\mu,\rho\right)\Bigg)\Bigg],\end{aligned} \tag{75}$$

$$\xi_1 = -\frac{E+k_z}{\lambda}\left[c_0 \exp\left(\frac{-\rho}{2}\right)\rho^{1/2+\mu} M\left(\frac{1}{2}+\mu-k,1+2\mu,\rho\right) + c_1 \exp\left(\frac{-\rho}{2}\right)\rho^{1/2-\mu} M\left(\frac{1}{2}-\mu-k,1-2\mu,\rho\right)\right], \tag{76}$$

$$\xi_2 = \frac{-2\rho\exp\left(\frac{-\rho}{2}\right)}{2ig\alpha-\rho}\left[c_0\left(M\left(\frac{1}{2}+\mu-k,1+2\mu,\rho\right)\left(\frac{-1}{2}\rho^{1/2+\mu}+\left(\frac{1}{2}+\mu\right)\rho^{\mu-1/2}-k_\theta\rho^{\mu-1/2}\right) + \frac{\frac{1}{2}+\mu-k}{1+2\mu}\rho^{1/2+\mu}M\left(\frac{3}{2}+\mu-k,2+2\mu,\rho\right)\right) + c_1\left(M\left(\frac{1}{2}-\mu-k,1-2\mu,\rho\right)\left(\frac{-1}{2}\rho^{1/2-\mu}+\left(\frac{1}{2}-\mu\right)\rho^{-\mu-1/2}-k_\theta\rho^{-\mu-1/2}\right) + \frac{\frac{1}{2}-\mu-k}{1-2\mu}\rho^{1/2-\mu}M\left(\frac{3}{2}-\mu-k,2-2\mu,\rho\right)\right)\right]. \tag{77}$$

Now, we are going to solve the Dirac equation for a neutrino with anomalous electric interaction.

(iii) The electric field $\mathbf{E}=\epsilon$ is applied along the z axis.

The Dirac equation takes the form

$$\left\{ \gamma_\chi^0\partial_t + \gamma_\chi^1\partial_r + \frac{\gamma_\chi^2\partial_\theta}{r} + \gamma_\chi^3\partial_z + m + g\gamma_\chi^3\gamma_\chi^0\epsilon \right\}\Psi_\chi = 0. \tag{78}$$

Applying the pairwise scheme of variable separation, we can write Eq. (78) as follows:

$$\left(\gamma_\chi^1\gamma_\chi^3\gamma_\chi^0\partial_r + \frac{\gamma_\chi^2\gamma_\chi^3\gamma_\chi^0\partial_\theta}{r} + g\epsilon - \lambda \right)\Phi_\chi = 0, \tag{79}$$

$$(\gamma_\chi^3\partial_t + \gamma_\chi^0\partial_z - m\gamma_\chi^3\gamma_\chi^0 - \lambda)\Phi_\chi = 0, \tag{80}$$

where Φ_χ is related to Ψ_χ by

$$\Psi_\chi = \gamma_\chi^3\gamma_\chi^0\Phi_\chi. \tag{81}$$

From Eq. (80), we find the relations

$$\lambda^2 = E^2 - k_z^2 + m^2, \qquad \Phi_\chi = \begin{pmatrix} \xi_1 \\ \xi_2 \\ \eta_1 \\ \eta_2 \end{pmatrix} = \begin{pmatrix} \frac{-i(E+k_z)}{m-\lambda}\eta_1 \\ \frac{-i(E-k_z)}{m+\lambda}\eta_2 \\ \eta_1 \\ \eta_2 \end{pmatrix}. \tag{82}$$

The 4-spinor Eq. (79) splits into a system of ordinary differential equations, mixing the two-component spinors η and ξ as follows:

$$\left(\sigma^2\partial_r+\frac{\partial_\theta}{r}\sigma^1\right)\eta+i(g\epsilon-\lambda)\xi=0, \tag{83}$$

$$\left(\sigma^2\partial_r+\frac{\partial_\theta}{r}\sigma^1\right)\xi+i(g\epsilon-\lambda)\eta=0, \tag{84}$$

which can be transformed to a simple system,

$$\left(d_r-\frac{k_\theta}{r}\right)\eta_2+i(g\epsilon-\lambda)\left(\frac{E+k_z}{m-\lambda}\right)\eta_1=0, \tag{85}$$

$$\left(d_r+\frac{k_\theta}{r}\right)\eta_1-i(g\epsilon-\lambda)\left(\frac{E-k_z}{m+\lambda}\right)\eta_2=0. \tag{86}$$

If we eliminate η_2 from (86) and (85), we find a second-order ordinary differential equation,

$$\left[\frac{d^2}{dr^2}-\frac{k_\theta(k_\theta+1)}{r^2}+(g\epsilon-\lambda)^2\right]\eta_1=0, \tag{87}$$

whose solution is given by

$$\eta_1=cr^{1/2}H^{(1)}_{k_\theta+1/2}[(g\epsilon-\lambda)r]. \tag{88}$$

Substituting (88) into (86), and using (82) and the recurrence relation (68), we determine the other components of the 4-spinor Φ_χ:

$$\eta_2=\frac{i(m+\lambda)}{k_z-E}cr^{1/2}H^{(1)}_{k_\theta-1/2}[(g\epsilon-\lambda)r], \tag{89}$$

$$\xi_1=\frac{i(E+k_z)}{\lambda-m}cr^{1/2}H^{(1)}_{k_\theta+1/2}[(g\epsilon-\lambda)r], \tag{90}$$

$$\xi_2=cr^{1/2}H^{(1)}_{k_\theta-1/2}[(g\epsilon-\lambda)r]. \tag{91}$$

IV. DISCUSSIONS

In each case, the original Dirac spinor Ψ_χ in chiral representation should be faithfully recovered using relations (6) and (10) in Cartesian coordinates or (59), (81) in cylindrical coordinates and the explicit expressions for the 4-spinor Φ_χ components, obtained in the various system of coordinates for a specific applied field.

For instance, in the cylindrical coordinates, the explicit structure of the Dirac 4-spinor Ψ_χ for the neutrino with an anomalous electric interaction is given by

$$\Psi_\chi=\gamma_\chi^3\gamma_\chi^0\Phi_\chi=\begin{pmatrix}\xi_{1\chi}\\ \xi_{2\chi}\\ \eta_{1\chi}\\ \eta_{2\chi}\end{pmatrix}, \tag{92}$$

where

$$\xi_{1\chi}=\frac{i(E+k_z)}{m-\lambda}cr^{1/2}H^{(1)}_{k_\theta+1/2}[(g\epsilon-\lambda)r], \tag{93}$$

$$\xi_{2\chi}=-cr^{1/2}H^{(1)}_{k_\theta-1/2}[(g\epsilon-\lambda)r], \tag{94}$$

$$\eta_{1\chi}=cr^{1/2}H^{(1)}_{k_\theta+1/2}[(g\epsilon-\lambda)r], \tag{95}$$

$$\eta_{2\chi}=\frac{i(m+\lambda)}{E-k_z}cr^{1/2}H^{(1)}_{k_\theta-1/2}[(g\epsilon-\lambda)r]. \tag{96}$$

At the opposite of Cartesian and cylindrical coordinates that have been worked out to give standard ordinary differential equations whose solutions are obtained in terms of special mathematical functions for the set of magnetic field expressions, the system of spherical coordinates showed some difficulties in exhibiting exact finite physical analytical solutions. The introduction of spherical symmetry in a chiral representation has contributed to elevating the order of ordinary differential equations governing a single spinor component. From a second-order differential equation in the case of Cartesian and cylindrical coordinate systems, we return back to a more complicated greater order differential equation.

Indeed, in spherical coordinates, the Dirac equation for a neutrino with anomalous electric interaction takes the form

$$\left\{\gamma_\chi^0\partial_t+\gamma_\chi^1\partial_r+\frac{\gamma_\chi^2}{r}\partial_\theta+\frac{\gamma_\chi^3}{r\sin\theta}\partial_\varphi+m+g\gamma_\chi^1\gamma_\chi^0\mathbf{E}\right\}\Psi_\chi=0. \tag{97}$$

By the pairwise scheme of variable separation, we transform (97) to

$$\left[-\gamma_\chi^1\partial_t-\gamma_\chi^0\partial_r+m\gamma_\chi^1\gamma_\chi^0+g\mathbf{E}+\frac{k}{r}\right]\Phi_\chi=0, \tag{98}$$

$$\left[-\gamma_\chi^2\gamma_\chi^1\gamma_\chi^0\partial_\theta+\frac{\gamma_\chi^3\gamma_\chi^1\gamma_\chi^0}{\sin\theta}\partial_\varphi-k\right]\Phi_\chi=0, \tag{99}$$

and

$$\Psi_\chi=\gamma_\chi^1\gamma_\chi^0\Phi_\chi. \tag{100}$$

If we consider, for example, a field inversely varying with respect to the spatial coordinate r: $\mathbf{E}=\epsilon/r$, and substituting it into (98), we obtain

$$(i\sigma^1 E + d_r)\,\eta - \left(\frac{g\epsilon+k}{r} - m\sigma^1\right)\xi = 0, \tag{101}$$

$$(i\sigma^1 E - d_r)\xi + \left(\frac{g\epsilon+k}{r} + m\sigma^1\right)\eta = 0, \tag{102}$$

which can be reduced to

$$\left\{\frac{m}{\frac{(g\epsilon+k)^2}{r^2}-m^2}\left[-\frac{d^2}{dr^2}+\frac{(g\epsilon+k)}{r^2}\left(iE+\frac{2m\frac{(g\epsilon+k)}{r}}{\frac{(g\epsilon+k)^2}{r^2}-m^2}\right)\frac{d}{dr}+\frac{\frac{2imE}{r}\frac{(g\epsilon+k)^3}{r^3}}{\frac{(g\epsilon+k)^2}{r^2}-m^2}-E^2\right]+m\right\}$$
$$\times\eta_1+\left\{\frac{m}{\frac{(g\epsilon+k)^2}{r^2}-m^2}\left[-\frac{(g\epsilon+k)}{r}\frac{d^2}{dr^2}+\frac{(g\epsilon+k)}{r^2}\left(1+\frac{2m\frac{(g\epsilon+k)^2}{r^2}}{\frac{(g\epsilon+k)^2}{r^2}-m^2}\right)\frac{d}{dr}\right.\right.$$
$$\left.\left.+\frac{g\epsilon+k}{r}\left(-E^2+\frac{\frac{2imE}{r}\frac{(g\epsilon+k)}{r}}{\frac{(g\epsilon+k)^2}{r^2}-m^2}\right)\right]+\frac{g\epsilon+k}{r}\right\}\eta_2=0, \tag{103}$$

and

$$\left\{\frac{m}{\frac{(g\epsilon+k)^2}{r^2}-m^2}\left[-\frac{d^2}{dr^2}+\frac{(g\epsilon+k)}{r^2}\left(iE+\frac{2m\frac{(g\epsilon+k)}{r}}{\frac{(g\epsilon+k)^2}{r^2}-m^2}\right)\frac{d}{dr}+\frac{\frac{2imE}{r}\frac{(g\epsilon+k)^3}{r^3}}{\frac{(g\epsilon+k)^2}{r^2}-m^2}-E^2\right]+m\right\}$$
$$\times\eta_2+\left\{\frac{m}{\frac{(g\epsilon+k)^2}{r^2}-m^2}\left[-\frac{(g\epsilon+k)}{r}\frac{d^2}{dr^2}+\frac{(g\epsilon+k)}{r^2}\left(1+\frac{2m\frac{(g\epsilon+k)^2}{r^2}}{\frac{(g\epsilon+k)^2}{r^2}-m^2}\right)\frac{d}{dr}\right.\right.$$
$$\left.\left.+\frac{g\epsilon+k}{r}\left(-E^2+\frac{\frac{2imE}{r}\frac{(g\epsilon+k)}{r}}{\frac{(g\epsilon+k)^2}{r^2}-m^2}\right)\right]+\frac{g\epsilon+k}{r}\right\}\eta_1=0. \tag{104}$$

These equations can be solved using either numerical integration methods or infinite series solutions.

Thus, the spherical coordinates clearly show the limitation of using a chiral representation to find exact solutions in terms of special functions for a Dirac equation in the presence of external fields.

The results obtained in this paper prove again that the general algebraic method of the separation of variables developed by Shishkin *et al.*[7] constitutes one of the most appropriate and powerful techniques in searching for exact solutions to the Dirac equation.

(Received 20 January 1999; accepted for publication 23 March 1999)

We introduce and perform a systematic study of a new exactly solvable model of sphere interactions in quantum mechanics : the δ' interaction, formally given by $-\Delta+\alpha\delta'(|\mathbf{x}|-R)$, $\mathbf{x}\in\mathbb{R}^3$, $R>0$, $\alpha\in\mathbb{R}$. We also consider the cases of a δ' plus a Coulomb interaction and finitely many δ'-sphere interactions with support on concentric spheres. For all these models, we provide basic properties and discuss the stationary scattering theory. We also briefly discuss the δ'-sphere interaction of the second type. [S0022-2488(99)02508-6]

I. INTRODUCTION

In recent years, there has been a lot of interest in the study of sphere interactions in quantum mechanics, both from the mathematical point of view and for their application in modelling physical phenomena.[1–11]

So far, these studies focused on the δ-sphere interactions and their various generalizations. In this paper we provide a new exactly solvable model of sphere interactions : the δ'-sphere interaction formally given in three dimensions by the Hamiltonian

$$H=-\Delta+\alpha\delta'(|\mathbf{x}|-R),\quad \mathbf{x}\in\mathbb{R}^3,\quad R>0,\quad \alpha\in\mathbb{R}.$$

As indicated in Ref. 12, this model is different from the δ-sphere interaction of the second type introduced in Refs. 1,3 and inadequately called the ''δ'-sphere interaction.''

The paper is organized as follows. In Sec. II, we give a rigorous mathematical definition of H using the theory of self-adjoint extensions of symmetric closed operators in Hilbert spaces. We obtain the basic properties of H, including the resolvent equation, the spectral properties, and the scattering data. In Secs. III and IV, we generalize the results of Sec. II to the case of a δ'-sphere plus a Coulomb interaction and finitely many δ'-sphere interactions, respectively. In Sec. V, we introduce and briefly discuss the δ'-sphere interaction of the second type.

II. THE δ'-SPHERE INTERACTION

A. Definition of the Hamiltonian

Consider the radial Schrödinger equation for a δ'-sphere interaction given by the formal expression

[a)]Electronic mail: hounkon@syfed.bj.refer.org
[b)]On leave of absence from University of Burundi, Faculty of Science, B. P. 2700 Bujumbura, Burundi.

$$h_{l,\alpha_l} f_l(k,r) \equiv \left[-\frac{d^2}{dr^2} + \frac{l(l+1)}{r^2} + \alpha_l \delta'(r-R) \right] f_l(k,r) = k^2 f_l(k,r), \tag{1}$$

and assume that the function $f_l(k,r)$ is continuous at $r=R$, i.e.,

$$f_l(k,R_+) = f_l(k,R_-) \equiv f_l(k,R). \tag{2}$$

This assumption implies that the derivative $f_l'(k,r)$ is discontinuous at $r=R$, since otherwise the operator h_{l,α_l} would coincide with the free Hamiltonian corresponding to the partial wave l.

Therefore, at $r=R$, the function $f_l'(k,r)$ may be defined by

$$f_l'(k,R) \equiv \tfrac{1}{2}[f_l'(k,R_+) + f_l'(k,R_-)]. \tag{3}$$

Let us integrate Eq. (1) from $r=R-\varepsilon$ to $r=R+\varepsilon$ and take the limit when $\varepsilon \to 0_+$. We obtain the following boundary condition:

$$\left(1+\frac{\alpha_l}{2}\right) f_l'(k,R_+) - \left(1-\frac{\alpha_l}{2}\right) f_l'(k,R_-) = 0. \tag{4}$$

From the above discussion, it follows that a δ'-sphere interaction may be fully characterized by the boundary conditions (2) and (4).

Let us now provide a rigorous mathematical definition of a quantum Hamiltonian describing a δ'-sphere interaction.

Consider in $L^2(\mathbb{R}^3)$ the closed and non-negative operator,

$$\dot{H} = -\Delta,$$

$$\mathcal{D}(\dot{H}) = \{ f \in H^{2,2}(\mathbb{R}^3) | f(\partial \overline{K(O,R)) = f'}(\partial \overline{K(O,R)) = 0} \}, \tag{5}$$

where $H^{m,n}(\Omega)$ is the Sobolev space of indices (m,n) and $\overline{K(O,R)}$ is the closed ball of radius R centered at the origin of $\mathbb{R}^3$.

We decompose $L^2(\mathbb{R}^3)$ with respect to angular momenta,

$$L(\mathbb{R}^3) = L^2((0,\infty); r^2 dr) \otimes L^2(S^2), \tag{6}$$

and introduce the unitary transformation,

$$U: \begin{cases} L^2((0,\infty); r^2 dr) \to L^2((0,\infty); dr) \equiv L^2((0,\infty)), \\ f \mapsto (Uf)(r) = r f(r), \end{cases} \tag{7}$$

in order to get the following representation of $L^2(\mathbb{R}^3)$:

$$L^2(\mathbb{R}^3) = \bigoplus_{l=0}^{\infty} U^{-1} L^2((0,\infty)) \otimes [Y_l^{-l}, \dots, Y_l^l], \tag{8}$$

where $[\cdots]$ denotes the linear span of spherical harmonics.

With respect to the decomposition (8), $\dot{H}$ reads as

$$\dot{H} = \bigoplus_{l=0}^{\infty} U^{-1} \dot{h}_l U \otimes 1, \tag{9}$$

where

$$\dot{h}_l = -\frac{d^2}{dr^2} + \frac{l(l+1)}{r^2},$$

$$\mathcal{D}(\dot{h}_l) = \{f \in L^2((0,\infty))/f, \quad f' \in AC_{\rm loc}((0,\infty)); \quad f(0_+)=0, \quad \text{if } l=0;$$
$$f(R_\pm) = f'(R_\pm) = 0; \quad -f'' + l(l+1)r^{-2}f \in L^2((0,\infty))\}; \quad l \in \mathbb{N}_0, \tag{10}$$

and $AC_{\rm loc}(\Omega)$ denotes the set of the locally absolutely continuous functions on $\Omega \subset \mathbb{R}$.

Thus, the adjoint $\dot{H}^\star$ of $\dot{H}$ is

$$\dot{H}^\star = \bigoplus_{l=0}^{\infty} U^{-1}\dot{h}_l^\star U \otimes 1, \tag{11}$$

where

$$\dot{h}_l^\star = -\frac{d^2}{dr^2} + \frac{l(l+1)}{r^2},$$

$$\mathcal{D}(\dot{h}_l^\star) = \{f \in L^2((0,\infty))/f, f' \in AC_{\rm loc}((0,\infty)\setminus\{R\}); \quad f(0_+)=0, \quad \text{if } l=0;$$
$$-f'' + l(l+1)r^{-2}f \in L^2((0,\infty))\}; \; l \in \mathbb{N}_0. \tag{12}$$

In particular, the equation

$$\dot{h}_l^\star \psi_l(k) = k^2 \psi_l(k), \;\; \text{Im}(k) > 0, \;\; l \in \mathbb{N}_0, \tag{13}$$

has two linearly independent solutions,

$$\psi_l^{(1)}(k,r) = \begin{cases} G_l(k,R)F_l(k,r) & ; \quad r<R, \\ 0 & ; \quad r>R, \end{cases} \tag{14}$$

$$\psi_l^{(2)}(k,r) = \begin{cases} 0 & ; \quad r<R, \\ F_l(k,R)G_l(k,r) & ; \quad r>R, \end{cases} \tag{15}$$

where

$$F_l(k,r) = \Gamma\left(l+\frac{3}{2}\right)\left(\frac{k}{2}\right)^{-l-1/2} r^{1/2} J_{l+1/2}(kr), \tag{16}$$

$$G_l(k,r) = \frac{i\pi}{2}\Gamma\left(l+\frac{3}{2}\right)^{-1}\left(\frac{k}{2}\right)^{l+1/2} r^{1/2} H_{l+1/2}^{(1)}(kr), \tag{17}$$

and $J_\nu(.)$, [resp., $H_\nu(\cdot)$] denote the Bessel (resp., Hankel) functions of order ν.[13] Therefore $\dot{h}_l$ has deficiency indices (2,2), and consequently all self-adjoint (s.a.) extensions of $\dot{h}_l$ are given by a 4-parameter family of s.a. operators.[14]

In this paper, we consider a special one-parameter family h_{l,α_l} of s.a. extensions of $\dot{h}_l$ defined by

$$h_{l,\alpha_l} = -\frac{d^2}{dr^2} + \frac{l(l+1)}{r^2},$$

$$\mathcal{D}(h_{l,\alpha_l})=\Big\{ f\in L^2((0,\infty))/f,f'\in AC_{\mathrm{loc}}((0,\infty)\backslash\{R\});$$
$$f(0_+)=0\,,\quad \text{if}\quad l=0\,;\qquad f(R_+)=f(R_-)=f(R);$$
$$\left(1+\frac{\alpha_l}{2}\right)f'(R_+)-\left(1-\frac{\alpha_l}{2}\right)f'(R_-)=0;$$
$$-f''+l(l+1)r^{-2}f\in L^2((0,\infty))\Big\}\,;\qquad -\infty<\alpha_l<\infty\,,\qquad l\in\mathbb{N}_0 \tag{18}$$

The case $\alpha_l=0$ coincides with the free kinetic energy Hamiltonian $h_{l,o}$ for a fixed angular momentum l.

Let $\alpha=\{\alpha_l\}_{l\in\mathbb{N}_0}$ and introduce in $L^2(\mathbb{R}^3)$ the operator

$$H_\alpha=\bigoplus_{l=0}^{\infty} U^{-1}h_{l,\alpha_l}U\otimes 1\,. \tag{19}$$

By definition, H_α is the rigorous mathematical formulation of the formal expression $H=-\Delta+\alpha\delta'(|x|-R)$. Actually, it provides a slight generalization of H, since α may depend on $l\in\mathbb{N}_0$.

The case $\alpha=0$ leads to the free Hamiltonian,

$$H_o=-\Delta,\qquad \mathcal{D}(H_o)=H^{2,2}(\mathbb{R}^3). \tag{20}$$

Next, we introduce the free resolvent,

$$g_{l,k}=(h_{l,o}-k^2)^{-1},\qquad \mathrm{Im}(k)>0, \tag{21}$$

with integral kernel

$$g_{l,k}(r,r')=\begin{cases} F_l(k,r')G_l(k,r) & ;\quad r'\leqslant r,\\ F_l(k,r)G_l(k,r') & ;\quad r'\geqslant r.\end{cases} \tag{22}$$

B. The resolvent equation

Theorem 2.1:

(i) The resolvent of h_{l,α_l} is given by

$$(h_{l,\alpha_l}-k^2)^{-1}=(h_{l,o}-k^2)^{-1}+\lambda_l(k)(\tilde{\phi}_l(-\overline{k}),.)\phi_l(k),$$
$$k^2\in\rho(h_{l,\alpha_l})\,,\qquad \mathrm{Im}(k)>0\,,\qquad l\in\mathbb{N}_0, \tag{23}$$

where

$$\lambda_l(k)=\alpha_l\left[1-\frac{\alpha_l}{2}g'_{l,k}(R,R)\right]^{-1}, \tag{24}$$

$$\phi_l(k,r)=\begin{cases} G_l(k,R)F_l(k,r) & ;\quad r\leqslant R,\\ F_l(k,R)G_l(k,r) & ;\quad r\geqslant R,\end{cases} \tag{25}$$

$$\tilde{\phi}_l(k,r)=\begin{cases} G'_l(k,R)F_l(k,r) & ;\quad r< R,\\ F'_l(k,R)G_l(k,r) & ;\quad r> R,\end{cases} \tag{26}$$

we note that $\phi_l(k,r)=g_{l,k}(R,r)$, $\mathrm{Im}(k)>0$.

(ii) The resolvent of H_α is given by

$$(H_\alpha-k^2)^{-1}=(H_o-k^2)^{-1}+\bigoplus_{l=0}^{\infty}\bigoplus_{m=-l}^{l}\lambda_l(k)\times(|\cdot|^{-1}\tilde{\phi}_l(-\overline{k})Y_l^m,\cdot)|\cdot|^{-1}\phi_l(k)Y_l^m$$

$$k^2\in\rho(H_\alpha),\quad \mathrm{Im}(k)>0. \tag{27}$$

Proof: Since $\dot{h}_l$ has deficiency indices (2,2), it follows from Krein's formula[14] that the resolvent of h_{l,α_l} is given by

$$(h_{l,\alpha_l}-k^2)^{-1}=(h_{l,o}-k^2)^{-1}+\sum_{i,j=1}^{2}\mu_{ij}(k)(\psi_l^{(j)}(-\overline{k}),.)\psi_l^{(i)}(k),$$

$$k^2\in\rho(h_{l,\alpha_l}),\quad \mathrm{Im}(k)>0,\quad l\in\mathbb{N}_0, \tag{28}$$

where $\psi_l^{(m)}$; $m=1,2$ are defined by (14) and (15), respectively.

For the determination of the μ_{ij}, we proceed as follows. Let $g\in L^2((0,\infty))$ and define the function

$$\chi_l(k,r)=((h_{l,\alpha_l}-k^2)^{-1}g)(r). \tag{29}$$

Since $\chi_l\in\mathcal{D}(h_{l,\alpha_l})$, it follows that χ_l should satisfy the boundary conditions in (18).

The implementation of these boundary conditions gives

$$\mu(k)=\frac{\alpha_l}{1-\dfrac{\alpha_l}{2}g'_{l,k}(R,R)}\begin{pmatrix}G_l(k,R)G'_l(k,R) & G_l(k,R)F'_l(k,R)\\ F_l(k,R)G'_l(k,R) & F_l(k,R)F'_l(k,R)\end{pmatrix}. \tag{30}$$

Inserting (30) into (28), we reduce the expression (28) to (23).

Equation (27) follows from (19) and (23).

We note that $\det[\mu(k)]=0$. This means that $\dot{h}_l$ is not the maximal commun part of h_{l,α_l} and $h_{l,o}$.

Next, we should like to provide some additional information on the domain of h_{l,α_l} and to show that the δ'-sphere interaction is in fact a local interaction.

Theorem 2.2: The domain $\mathcal{D}(h_{l,\alpha_l})$ consists of functions of the type

$$\varphi_l(k,r)=F_l(k,r)+\lambda_l(k)F'_l(k,R)g_{l,k}(R,r), \tag{31}$$

where $\lambda_l(k)$ is defined by (24), $F_l\in\mathcal{D}(h_{l,o})$, and $k^2\in\rho(h_{l,\alpha_l})$, $\mathrm{Im}(k)>0$.

The decomposition (31) is unique and with $\varphi_l\in\mathcal{D}(h_{l,\alpha_l})$ of this form, we obtain

$$(h_{l,\alpha_l}-k^2)\varphi_l=(h_{l,o}-k^2)F_l. \tag{32}$$

Furthermore, if $\varphi_l\in\mathcal{D}(h_{l,\alpha_l})$ and $\varphi_l=0$ in an open set $\mathcal{O}\subset(0,\infty)$, then $h_{l,\alpha_l}\varphi_l=0$ in $\mathcal{O}$ which means that the δ'-sphere interaction is a local interaction.

Proof: One may follow step by step[15] where a similar result was obtained for point interactions.

C. Spectral properties

Spectral properties of h_{l,α_l} are provided by the following theorem where $\sigma(.)$, $\sigma_{\mathrm{ess}}(.)$, $\sigma_{\mathrm{ac}}(.)$, $\sigma_{\mathrm{sc}}(.)$ and $\sigma_p(.)$ denote the spectrum, essential spectrum, absolutely continuous spectrum, singularly continuous spectrum, and point spectrum, respectively.

Theorem 2.3: For all $\alpha_l \in (-\infty,\infty)$, we have the following results:

- $$\sigma_{\mathrm{ess}}(h_{l,\alpha_l}) = \sigma_{\mathrm{ac}}(h_{l,\alpha_l}) = [0,\infty), \tag{33}$$
- $$\sigma_{\mathrm{sc}}(h_{l,\alpha_l}) = \emptyset, \tag{34}$$
- $$\sigma_p(h_{l,\alpha_l}) \cap [0,\infty) = \emptyset. \tag{35}$$

Negative eigenvalues of h_{l,α_l} are obtained from the equation

$$1 - \frac{\alpha_l}{2} g'_{l,i\sqrt{-E}}(R,R) = 1 - \frac{\alpha_l}{2} \frac{d}{dr}[rI_{l+1/2}(\sqrt{-E}r)K_{l+1/2}(\sqrt{-E}r)]_{r=R} = 0; \quad E<0, \tag{36}$$

which implies that

$$\sigma_p(h_{l,\alpha_l}) = \begin{cases} \emptyset, & \text{if} \quad \alpha_l \leqslant 2(2l+1), \\ \{E_o\}, & \text{if} \quad \alpha_l > 2(2l+1), \end{cases} \tag{37}$$

where E_o is a solution of (36) and $I_\nu(\cdot)$, $K_\nu(\cdot)$ are modified Bessel functions.[13]

Proof: Equations (33) and (34) follow from Weyl's theorem Ref. 16, p. 112 and Ref. 16, theorem XIII.20, respectively.

For $k \geqslant 0$, consider the function $f_l(k,r) \in \mathcal{D}(h_{l,\alpha_l})$. By inspection, we may show that the equation

$$-f_l''(k,r) + l(l+1)r^{-2} f_l(k,r) = k^2 f_l(k,r) \tag{38}$$

can be solved uniquely in terms of Bessel functions which do not belong to $L^2((0,\infty))$. This yields Eq. (35).

The bound state equation (36) obtained by using a Bessel function ansatz in (38) and the boundary conditions in (18) can be analyzed using monotonicity properties of the modified Bessel functions, and indeed one proves Eq. (37).

Next we briefly discuss resonances of h_{l,α_l}.

Following, e.g., Ref. 17 we define the resonances of h_{l,α_l} as the poles of the resolvent (23) in the unphysical sheet $\mathrm{Im}(k)<0$, i.e., as solutions of the equation

$$1 - \frac{\alpha_l}{2} g'_{l,k}(R,R) = 0, \quad \mathrm{Im}(k)<0. \tag{39}$$

First we discuss the solutions located on the negative imaginary k axis. Let $k=ix$, $x>0$. Then analytic continuation of Bessel functions in (39) yields

$$-\frac{2}{\alpha_l} = \frac{d}{dr}[rI_{l+1/2}(xr)K_{l+1/2}(xr)]_{r=R}. \tag{40}$$

This equation can be analyzed using monotonicity properties of the modified Bessel functions.

We prove that in each fixed partial wave, Eq. (40) has exactly one solution $x>0$ if $\alpha_l < 2(2l+1)$. The case $\alpha_l = 2(2l+1)$ gives a zero energy resonance, i.e., $x_o = 0$.

A systematic study of the solutions located off the imaginary axis can be carried out following, e.g., the techniques used in Ref. 1 in the case of δ-sphere interactions.

Here, we simply note that in each fixed partial wave, h_{l,α_l} has an infinite number of resonances off the imaginary axis.

D. Stationary scattering theory for the pair $(h_{l,\alpha_l};\ h_{l,o})$

For $k \geqslant 0$, let us define the functions

$$\mathcal{F}_{l,\alpha_l}(k,r) = F_l(k,r) + \lambda_l(k) F_l'(k,R) g_{l,k}(R,r), \tag{41}$$

where $F_l \in \mathcal{D}(h_{l,o})$ and $g_{l,k}$ and $\lambda_l(k)$ are defined by (22) and (24) respectively.

By inspection, we show that the function $\mathcal{F}_{l,\alpha_l}$ fulfills the following conditions:

$$\mathcal{F}_{l,\alpha_l}(k,R_+) = \mathcal{F}_{l,\alpha_l}(k,R_-) \equiv \mathcal{F}_{l,\alpha_l}(k,R), \tag{42}$$

$$\left(1+\frac{\alpha_l}{2}\right)\mathcal{F}'_{l,\alpha_l}(k,R_+) - \left(1-\frac{\alpha_l}{2}\right)\mathcal{F}'_{l,\alpha_l}(k,R_-) = 0, \tag{43}$$

$$-\mathcal{F}''_{l,\alpha_l}(k,r) + l(l+1)r^{-2}\mathcal{F}_{l,\alpha_l}(k,r) = k^2 \mathcal{F}_{l,\alpha_l}(k,r). \tag{44}$$

Consequently, the functions $\mathcal{F}_{l,\alpha_l}(k,r)$ constitute a set of generalized eigenfunctions associated with h_{l,α_l} or in other words, $\mathcal{F}_{l,\alpha_l}(k,r)$ are the scattering wave functions of h_{l,α_l}.

As usual, the phase shifts of h_{l,α_l} may be obtained through the asymptotic behavior of $\mathcal{F}_{l,\alpha_l}(k,r)$ as $r \to \infty$. Indeed, one has[18]

$$\begin{aligned}
\mathcal{F}_{l,\alpha_l}(k,r) \underset{r\to\infty}{\overset{k>0,}{\to}} & A_l(k)\sin\left(kr-\frac{l\pi}{2}\right) + \lambda_l(k)F_l(k,R)F_l'(k,R)B_l(k)\exp\left[-i\left(kr-\frac{l\pi}{2}\right)\right] \\
&= [A_l(k) - iB_l(k)\lambda_l(k)F_l(k,R)F_l'(k,R)]\sin\left(kr-\frac{l\pi}{2}\right) \\
&\quad + \lambda_l(k)B_l(k)F_l(k,R)F_l'(k,R)\cos\left(kr-\frac{l\pi}{2}\right) \\
&= [C_{1,l}^2(k) + C_{2,l}^2(k)]^{1/2} \sin\left(kr-\frac{l\pi}{2}+\delta_{l,\alpha_l}(k)\right) + o(1),
\end{aligned} \tag{45}$$

which defines the phase shifts by

$$\begin{aligned}
\delta_{l,\alpha_l}(k) &= -\arctan\frac{C_{2,l}(k)}{C_{1,l}(k)}, \\
&= -\arctan\frac{B_l(k)\lambda_l(k)F_l(k,R)F_l'(k,R)}{A_l(k) - iB_l(k)\lambda_l(k)F_l(k,R)F_l'(k,R)},
\end{aligned} \tag{46}$$

where we have used the notations[18]

$$A_l(k) = 2^{-l}k^{-l-1}\Gamma(2l+2)\Gamma(l+1)^{-1}, \tag{47}$$

$$B_l(k) = \frac{1}{kA_l(k)}. \tag{48}$$

The on-shell scattering matrix is defined by

$$\begin{aligned} S_{l,\alpha_l}(k) &= \exp[2i\delta_{l,\alpha_l}(k)] \\ &= 1-2ikB_l^2(k)\lambda_l(k)F_l(k,R)F_l'(k,R). \end{aligned} \tag{49}$$

The corresponding effective range expansion reads[19] as

$$[(2l+1)!!]^2k^{2l+1}\cot\delta_{l,\alpha_l}(k) = -a_{l,\alpha_l}^{-1}+\frac{1}{2}r_{l,\alpha_l}k^2+o(k^4), \tag{50}$$

where the coefficients a_{l,α_l} and r_{l,α_l} are called the partial wave scattering length and effective range parameters, respectively.

A straightforward computation yields

$$a_{l,\alpha_l}=\lambda_l(0)(l+1)R^{2l+1}\cdots \quad . \tag{51}$$

The on-shell scattering amplitude $f_\alpha(k,\omega,\omega')$ corresponding to H_α is given by

$$\begin{aligned} f_\alpha(k,\omega,\omega') &= 4\pi\sum_{l=0}^{\infty}\sum_{m=-l}^{l}\frac{S_{l,\alpha_l}(k)-1}{2ik}\overline{Y_l^m(\omega')Y_l^m(\omega)} \\ &= 4\pi\sum_{l=0}^{\infty}\sum_{m=-l}^{l} f_{l,\alpha_l}(k)\overline{Y_l^m(\omega')Y_l^m(\omega)} \\ & k\geqslant 0; \quad \omega,\ \omega'\in S^2, \end{aligned} \tag{52}$$

where the partial wave scattering amplitude $f_{l,\alpha_l}(k)$ is given by

$$f_{l,\alpha_l}(k) = -B_l^2(k)\lambda_l(k)F_l(k,R)F_l'(k,R). \tag{53}$$

The on-shell scattering operator $S_\alpha(k)$ in $L^2(S^2)$ corresponding to H_α is defined by

$$\begin{aligned} (S_\alpha(k)\phi)(\omega) &= \phi(\omega)-\frac{k}{2\pi i}\int_{S^2}d\omega' f_\alpha(k,\omega,\omega')\phi(\omega') \\ & k\geqslant 0; \quad \omega,\ \omega'\in S^2, \end{aligned} \tag{54}$$

which means that $S_\alpha(k)$ reads as

$$S_\alpha(k)=1+2ik\sum_{l=0}^{\infty}\sum_{m=-l}^{l} f_{l,\alpha_l}(k)(Y_l^m,.)Y_l^m(\omega). \tag{55}$$

III. THE δ'-SPHERE PLUS COULOMB INTERACTION

In this section we consider the system formally given by

$$-\Delta+\gamma|\mathbf{x}|^{-1}+\alpha\delta'(|\mathbf{x}|-R), \quad \gamma\in\mathbb{R}, \quad R>0, \quad \mathbf{x}\in\mathbb{R}^3. \tag{56}$$

A. Defintion of the Hamiltonian

Consider in $L^2(\mathbb{R}^3)$ the operator

$$\begin{aligned} \dot{H}_\gamma &= -\Delta+\gamma|x|^{-1} \\ \mathcal{D}(\dot{H}_\gamma) &= \{f\in H^{2,2}(\mathbb{R}^3)/f(\overline{\partial K(O,R))=f'}(\overline{\partial K(O,R))=0}\}. \end{aligned} \tag{57}$$

Using the decomposition (8) we can write $\dot{H}_\gamma$ in the form

$$\dot{H}_\gamma = \bigoplus_{l=0}^{\infty} U^{-1}\dot{h}_{l,\gamma}U\otimes 1, \tag{58}$$

where

$$\dot{h}_{l,\gamma} = -\frac{d^2}{dr^2} + \frac{l(l+1)}{r^2} + \frac{\gamma}{r},$$

$$\mathcal{D}(\dot{h}_{l,\gamma}) = \{f\in L^2((0,\infty))/f,f'\in AC_{\mathrm{loc}}((0,\infty));$$
$$f(0_+)=0 \text{ if } l=0;\quad f(R_\pm)=f'(R_\pm)=0;$$
$$-f''+l(l+1)r^{-2}f+\gamma r^{-1}f\in L^2((0,\infty))\},\quad \gamma\in\mathbb{R}, l\in\mathbb{N}_0. \tag{59}$$

The adjoint $\dot{H}^\star_\gamma$ of $\dot{H}_\gamma$ is defined by

$$\dot{H}^\star_\gamma = \bigoplus_{l=0}^{\infty} U^{-1}\dot{h}^\star_{l,\gamma}U\otimes 1, \tag{60}$$

where

$$\dot{h}^\star_{l,\gamma} = -\frac{d^2}{dr^2} + \frac{l(l+1)}{r^2} + \frac{\gamma}{r},$$

$$\mathcal{D}(\dot{h}^\star_{l,\gamma}) = \{f\in L^2((0,\infty))/f,f'\in AC_{\mathrm{loc}}((0,\infty)\setminus\{R\});\quad f(0_+)=0\quad \text{if}\ \ l=0;$$
$$-f''+l(l+1)r^{-2}f+\gamma r^{-1}f\in L^2((0,\infty))\};\ \ \gamma\in\mathbb{R},\ \ l\in\mathbb{N}_0. \tag{61}$$

A direct computation shows that the equation

$$\dot{h}^\star_{l,\gamma}\psi_{l,\gamma}(k) = k^2\psi_{l,\gamma}(k),\ \ \mathrm{Im}(k)>0,\quad l\in\mathbb{N}_0, \tag{62}$$

has two linearly independent solutions:

$$\psi^{(1)}_{l,\gamma}(k,r) = \begin{cases} G_{l,\gamma}(k,R)F_{l,\gamma}(k,r) & ;\quad r<R,\\ 0 & ;\quad r>R, \end{cases} \tag{63}$$

$$\psi^{(2)}_{l,\gamma}(k,r) = \begin{cases} 0 & ;\quad r<R,\\ F_{l,\gamma}(k,R)G_{l,\gamma}(k,r) & ;\quad r>R, \end{cases} \tag{64}$$

where

$$F_{l,\gamma}(k,r) = r^{l+1}\exp(ikr)\ {}_1F_1\left(l+1+\frac{i\gamma}{2k};2l+2;-2ikr\right), \tag{65}$$

$$G_{l,\gamma}(k,r) = \Gamma(2l+2)^{-1}\Gamma\left(l+1+\frac{i\gamma}{2k}\right)(-2ik)^{2l+1}\exp(ikr)\times U\left(l+1+\frac{i\gamma}{2k};\ \ 2l+2;\ \ 2ikr\right), \tag{66}$$

and ${}_1F_1(a;b;z)$, $U(a;b;z)$ denote (ir)regular confluent hypergeometric functions, respectively.[13]

As in the short range case ($\gamma=0$), $\dot{h}_{l,\gamma}$ has deficiency indices (2,2) and consequently all its self-adjoint (s.a.) extensions are given by a four-parameter family of s.a. operators.

In this section we will consider the following one-parameter family of s.a. extensions of $\dot{h}_{l,\gamma}$,

$$h_{l,\gamma,\alpha_l}=-\frac{d^2}{dr^2}+\frac{l(l+1)}{r^2}+\frac{\gamma}{r},$$

$$\begin{aligned}\mathcal{D}(h_{l,\gamma,\alpha_l})=\Big\{& f\in L^2((0,\infty))/f,f'\in AC_{\mathrm{loc}}((0,\infty)\backslash\{R\});\\ & f(0_+)=0,\quad \text{if } l=0;\quad f(R_+)=f(R_-)\equiv f(R);\\ & \left(1+\frac{\alpha_l}{2}\right)f'(R_+)-\left(1-\frac{\alpha_l}{2}\right)f'(R_-)=0;\\ & -f''+l(l+1)r^{-2}f+\gamma r^{-1}f\in L^2((0,\infty))\Big\};\\ & -\infty<\alpha_l<\infty,\quad \gamma\in\mathbb{R},\quad l\in\mathbb{N}_0.\end{aligned} \tag{67}$$

The case $\alpha_l=0$ yields the free Coulomb Hamiltonian $h_{l,\gamma,o}$ for a fixed angular momentum l. The formal expression (56) is therefore represented by the following Hamiltonian in $L^2(\mathbb{R}^3)$:

$$H_{\gamma,\alpha}=\bigoplus_{l=0}^{\infty} U^{-1}h_{l,\gamma,\alpha_l}U\otimes 1. \tag{68}$$

The case $\alpha=0$ leads to the Coulomb Hamiltonian

$$H_{\gamma,o}\equiv H_\gamma=-\Delta+\frac{\gamma}{|x|};\quad \mathcal{D}(H_\gamma)=H^{2,2}(\mathbb{R}^3). \tag{69}$$

Next we introduce the free resolvent,

$$g_{l,\gamma,k}=(h_{l,\gamma}-k^2)^{-1},\ k\neq-\frac{i\gamma}{2n},\ n\in\mathbb{N},\ \mathrm{Im}(k)>0,\ l\in\mathbb{N}_0, \tag{70}$$

with integral kernel

$$g_{l,\gamma,k}(r,r')=\begin{cases}F_{l,\gamma}(k,r')G_{l,\gamma}(k,r) & ;\quad r'\leqslant r,\\ F_{l,\gamma}(k,r)G_{l,\gamma}(k,r') & ;\quad r'\geqslant r.\end{cases} \tag{71}$$

B. The resolvent equation

Theorem 3.1: The resolvent of h_{l,γ,α_l} is given by

$$\begin{aligned}&(h_{l,\gamma,\alpha_l}-k^2)^{-1}=(h_{l,\gamma}-k^2)^{-1}+\lambda_{l,\gamma}(k)(\tilde{\phi}_{l,\gamma}(-\bar{k}),.)\phi_{l,\gamma}(k),\\ &k^2\in\rho(h_{l,\gamma,\alpha_l}),\quad \mathrm{Im}(k)>0,\quad l\in\mathbb{N}_0,\quad \gamma\in\mathbb{R},\end{aligned} \tag{72}$$

where

$$\lambda_{l,\gamma}(k)=\alpha_l\left[1-\frac{\alpha_l}{2}g'_{l,\gamma,k}(R,R)\right]^{-1}, \tag{73}$$

$$\phi_{l,\gamma}(k,r)=\begin{cases} G_{l,\gamma}(k,R)F_{l,\gamma}(k,r) & ; \quad r\leqslant R, \\ F_{l,\gamma}(k,R)G_{l,\gamma}(k,r) & ; \quad r\geqslant R, \end{cases} \tag{74}$$

$$\tilde{\phi}_{l,\gamma}(k,r)=\begin{cases} G'_{l,\gamma}(k,R)F_{l,\gamma}(k,r) & ; \quad r< R, \\ F'_{l,\gamma}(k,R)G_{l,\gamma}(k,r) & ; \quad r> R, \end{cases} \tag{75}$$

we note that $\phi_{l,\gamma}(k,r)=g_{l,\gamma,k}(R,r)$, $\mathrm{Im}(k)>0$.

Proof: One can follow step by step the proof of Theorem 2.1.

Theorem 3.2: The domain $\mathcal{D}(h_{l,\gamma,\alpha_l})$ consists of functions of the type

$$\varphi_{l,\gamma}(k,r)=F_{l,\gamma}(k,r)+\lambda_{l,\gamma}(k)F'_{l,\gamma}(k,R)g_{l,\gamma,k}(R,r); \tag{76}$$

$F_{l,\gamma}\in\mathcal{D}(h_{l,\gamma,\alpha_l})$ and $k^2\in\rho(h_{l,\gamma,\alpha_l})$, $\mathrm{Im}(k)>0$.

The decomposition (76) is unique and with $\varphi_{l,\gamma}\in\mathcal{D}(h_{l,\gamma,\alpha_l})$ of this form, we obtain

$$(h_{l,\gamma,\alpha_l}-k^2)\varphi_{l,\gamma}=(h_{l,\gamma}-k^2)F_{l,\gamma}. \tag{77}$$

Moreover, if $\varphi_{l,\gamma}\in\mathcal{D}(h_{l,\gamma,\alpha_l})$ and $\varphi_{l,\gamma}=0$ in an open set $\mathcal{O}\subset(0,\infty)$, then $h_{l,\gamma,\alpha_l}\varphi_l=0$ in $\mathcal{O}$.

C. Spectral properties

In a similar way to Sec. II, we obtain the following results.

Theorem 3.3: For all $\alpha_l\in(-\infty,\infty)$ and $\gamma\in\mathbb{R}$, we have the following:

- $\sigma_{\mathrm{ess}}(h_{l,\gamma,\alpha_l})=\sigma_{\mathrm{ac}}(h_{l,\gamma,\alpha_l})=[0,\infty)$, (78)
- $\sigma_{\mathrm{sc}}(h_{l,\gamma,\alpha_l})=\varnothing$, (79)
- $\sigma_p(h_{l,\gamma,\alpha_l})\cap[0,\infty)=\varnothing$. (80)

The negative eigenvalues of h_{l,γ,α_l} are obtained from the equation

$$1-\frac{\alpha_l}{2}g'_{l,\gamma,i\sqrt{-E}}(R,R)=0, \quad E<0, \tag{81}$$

which has at most one solution $E_o<0$ for $\gamma\geqslant 0$ and infinitely many for $\gamma<0$.

Proof: Similar to the proof of Theorem 2.3

D. Stationary scattering theory for the pair $(h_{l,\gamma,\alpha_l};h_{l,\gamma})$

For $k\geqslant 0$ let us define the function

$$\mathcal{F}_{l,\gamma,\alpha_l}(k,r)=F_{l,\gamma}(k,r)+\lambda_{l,\gamma}(k)F'_{l,\gamma}(k,R)g_{l,\gamma,k}(R,r), \tag{82}$$

where $F_{l,\gamma}$ and $\lambda_{l,\gamma}(k)$ are defined by (65) and (73), respectively.

A straightforward calculation shows that $\mathcal{F}_{l,\gamma,\alpha_l}(k,r)$ are the scattering wave functions of h_{l,γ,α_l}.

For the determination of the phase shifts of h_{l,γ,α_l}, we follow the strategy of Sec. II D and use the asymptotic behavior of hypergeometric functions given in Ref. 18.

The Coulomb modified phase shift $\delta^{(c)}_{l,\gamma,\alpha_l}(k)$ is given by

$$\delta^{(c)}_{l,\gamma,\alpha_l}(k)=-\arctan\frac{B_{l,\gamma}(k)\lambda_{l,\gamma}(k)F_{l,\gamma}(k,R)F'_{l,\gamma}(k,R)}{A_{l,\gamma}(k)-iB_{l,\gamma}(k)\lambda_{l,\gamma}(k)F_{l,\gamma}(k,R)F'_{l,\gamma}(k,R)}, \tag{83}$$

where we have used the notations[19]

$$A_{l,\gamma}(k)=2^{-l}\exp(\pi\gamma/4k)k^{-l-1}\Gamma(2l+2)\left|\Gamma\left(l+1+\frac{i\gamma}{2k}\right)\right|, \tag{84}$$

$$B_{l,\gamma}(k)=\frac{1}{kA_{l,\gamma}(k)}. \tag{85}$$

We note that the total phase shift $\delta_{l,\gamma,\alpha_l}(k)$ corresponding to h_{l,γ,α_l} splits up into

$$\delta_{l,\gamma,\alpha_l}(k)=\delta^{(c)}_{l,\gamma,\alpha_l}(k)+\delta_{l,\gamma}(k), \quad k>0, \quad \gamma\in\mathbb{R}, \tag{86}$$

where

$$\delta_{l,\gamma}(k)=\arg\Gamma\left(l+1+\frac{i\gamma}{2k}\right), \quad k>0, \quad \gamma\in\mathbb{R} \tag{87}$$

represents the pure Coulomb phase shift.

The Coulomb modified on-shell scattering matrix elements are given by

$$S^{(c)}_{l,\gamma,\alpha_l}(k)=\exp[2i\delta^{(c)}_{l,\gamma,\alpha_l}(k)]=1-2ikB^2_{l,\gamma}(k)\lambda_{l,\gamma}(k)F_{l,\gamma}(k,R)F'_{l,\gamma}(k,R). \tag{88}$$

The corresponding partial wave scattering amplitudes are given by

$$f^{(c)}_{l,\gamma,\alpha_l}(k)=(2ik)^{-1}(S^{(c)}_{l,\gamma,\alpha_l}(k)-1)=-B^2_{l,\gamma}(k)\lambda_{l,\gamma}(k)F_{l,\gamma}(k,R)F'_{l,\gamma}(k,R). \tag{89}$$

The Coulomb modified effective range expansion corresponding to h_{l,γ,α_l} reads[20] as

$$\Gamma(2l+2)^{-1}(2k)^{2l}\left|\Gamma\left(l+1+\frac{i\gamma}{2k}\right)\right|\exp(-\pi\gamma/2k)\times[k\cot\delta^{(c)}_{l,\gamma,\alpha_l}(k)-ik+\exp(\pi\gamma/2k)h_\gamma(k)]$$

$$=-\frac{1}{a^{(c)}_{l,\gamma,\alpha_l}}+o(k^2) \quad k>0, \quad \gamma\in\mathbb{R}, \tag{90}$$

where $a^{(c)}_{l,\gamma,\alpha_l}$ is the Coulomb modified scattering length and the function $h_\gamma(k)$ is defined by

$$h_\gamma(k)=\gamma\left|\Gamma\left(1+\frac{i\gamma}{2k}\right)\right|^2\left[\frac{ik}{\gamma}+\ln\left(\frac{2k}{i|\gamma|}\right)+\Psi\left(1+\frac{i\gamma}{2k}\right)\right]. \tag{91}$$

In Eq. (91), $\Psi(z)$ denotes a digamma function.[13]

In the short range case ($\gamma=0$), Eq. (90) simplifies to

$$\Gamma\left(l+\frac{3}{2}\right)\left(\frac{k}{2}\right)^{2l+1}\frac{\pi}{2}\cot\delta_{l,\alpha_l}(k)=-\frac{1}{a_{l,\alpha_l}}+o(k^2), \tag{92}$$

where a_{l,α_l} is given by (51).

Using the properties of the hypergeometric functions, one may obtain explicitly $a^{(c)}_{l,\gamma,\alpha_l}$ in the expansion (90).

Indeed, a tedious but straightforward calculation gives

$$-\frac{1}{a^{(c)}_{l,\gamma,\alpha_l}}=\begin{cases}\dfrac{1-\alpha_l[rI_\nu(y)K_\nu(y)]'_{r=R}}{\alpha_l\gamma^{-\nu}\Gamma(2l+2)^2[r^{1/2}I_\nu(y)]'_{r=R}[r^{1/2}I_\nu(y)]_{r=R}} & ;\quad \gamma\geqslant 0,\\[2ex] \dfrac{2+i\pi\alpha_l[rJ_\nu(z)H^{(2)}_\nu(z)]'_{r=R}}{2\alpha_l|\gamma|^{-\nu}\Gamma(2l+2)^2[r^{1/2}J_\nu(z)]'_{r=R}[r^{1/2}J_\nu(z)]_{r=R}} & ;\quad \gamma\leqslant 0\,,\end{cases}\tag{93}$$

where we have used the notations $\nu=2l+1$, $y=(4\gamma r)^{1/2}$ and $z=(4|\gamma|r)^{1/2}$.

In the short range case $\gamma=0$, we obtain

$$-a^{-1}_{l,\alpha_l}=\frac{2-\dfrac{\alpha_l}{2l+1}}{2\alpha_l(l+1)R^{2l+1}}=-[\lambda_l(0)(l+1)R^{2l+1}]^{-1}.\tag{94}$$

IV. FINITELY MANY δ'-INTERACTIONS WITH SUPPORT ON CONCENTRIC SPHERES

In this section, we study in dimensions $n=3$ the case of $N-\delta'$-interactions with support on concentric spheres of radii $0<R_1<\cdots<R_N$ formally given by

$$-\Delta+\sum_{j=1}^{N}\alpha_j\delta'(|\mathbf{x}|-R_j),\quad R_j>0,\ \mathbf{x}\in R^3.\tag{95}$$

A. Defintion of the Hamiltonian

Consider in $L^2(\mathbb{R}^3)$ the closed, symmetric and non-negative operator,

$$\tilde{H}=-\Delta,$$

$$\mathcal{D}(\tilde{H})=\{f\in H^{2,2}(\mathbb{R})/f(\overline{\partial K(O,R_j)})=f'(\overline{\partial K(O,R_j)})=0\,,\quad 1\leqslant j\leqslant N\}.\tag{96}$$

Using the decomposition (8), we can write $\tilde{H}$ in the form

$$\tilde{H}=\bigoplus_{l=0}^{\infty}U^{-1}h_{l,\{R\}}U\otimes 1,\tag{97}$$

where

$$h_{l,\{R\}}=-\frac{d^2}{dr^2}+\frac{l(l+1)}{r^2},$$

$$\mathcal{D}(h_{l,\{R\}})=\{f\in L^2((0,\infty))/f,f'\in AC_{\mathrm{loc}}((0,\infty));f(0_+)=0\quad\text{if}\quad l=0;$$
$$f(R_{j\pm})=f'(R_{j\pm})=0;\quad -f''+l(l+1)r^{-2}f\in L^2((0,\infty))\}.\tag{98}$$

The adjoint $\tilde{H}^\star$ of $\tilde{H}$ is given by

$$\tilde{H}^\star=\bigoplus_{l=0}^{\infty}U^{-1}h^\star_{l,\{R\}}U\otimes 1,\tag{99}$$

where

$$h^{\star}_{l,\{R\}} = -\frac{d^2}{dr^2} + \frac{l(l+1)}{r^2},$$

$$\mathcal{D}(h^{\star}_l) = \{f \in L^2((0,\infty))/f, f' \in AC_{loc}((0,\infty)\backslash\{R\}); \quad f(0_+) = 0 \quad \text{if} \quad l = 0;$$
$$-f'' + l(l+1)r^{-2} f \in L^2((0,\infty))\}; \quad l \in \mathbb{N}_0,$$

$$\{R\} = \{R_1, \ldots, R_N\}, \tag{100}$$

A straightforward computation shows that the equation

$$h^{\star}_{l,\{R\}} \psi_l(k) = k^2 \psi_l(k), \quad \text{Im}(k) > 0, \tag{101}$$

has $2N$ linearly independent solutions,

$$\psi^{(1)}_{l,j}(k,r) = \begin{cases} G_l(k,R_j) F_l(k,r) & ; \quad r < R_j, \\ 0 & ; \quad r > R_j, \end{cases} \tag{102}$$

$$\psi^{(2)}_{l,j}(k,r) = \begin{cases} 0 & ; \quad r < R_j, \\ F_l(k,R_j) G_l(k,r) & ; \quad r > R_j, \end{cases} \tag{103}$$

Therefore $h_{l,\{R\}}$ has deficiency indices $(2N,2N)$ and consequently all self-adjoint (s.a.) extensions of $h_{l,\{R\}}$ are given by a $4N^2$-parameter family of s.a. operators.

In this paper, we consider a special N-parameter family of s.a extensions of $h_{l,\{R\}}$ corresponding to the formal expression (95).

We introduce in $L^2((0,\infty))$ the following family of closed extensions of $h_{l,\{R\}}$:

$$h_{l,\{\alpha_l\},\{R\}} = -\frac{d^2}{dr^2} + \frac{l(l+1)}{r^2},$$

$$\mathcal{D}(h_{l,\{\alpha_l\},\{R\}}) = \{f \in L^2((0,\infty))/f, f' \in AC_{\text{loc}}((0,\infty)\backslash\{R\});$$

$$f(0_+) = 0 \quad \text{if} \quad l = 0\,; f(R_{j^+}) = f(R_{j^-}) \equiv f(R_j);$$

$$\left(1 + \frac{\alpha_{jl}}{2}\right) f'(R_{j^+}) - \left(1 - \frac{\alpha_{jl}}{2}\right) f'(R_{j^-}) = 0\,;$$

$$-f'' + l(l+1)r^{-2} f \in L^2((0,\infty))\}\,;$$

$$\{\alpha_l\} = \{\alpha_{1l}, \ldots, \alpha_{Nl}\}, \, -\infty < \alpha_{jl} < \infty, \, l \in \mathbb{N}_0. \tag{104}$$

Following, e.g., Ref. 15, Chap. II 3 we note that there exists an intermediate operator in $L^2((0,\infty))$ with deficiency indices (N,N) which is a proper extension of $h_{l,\{R\}}$.

A simple integration by parts shows that $h_{l,\{\alpha_l\},\{R\}}$ is symmetric. Moreover, since $h_{l,\{\alpha_l\},\{R\}}$ may be obtained as an extension of an operator with deficiency (N,N) and the N boundary conditions in (104) are symmetric and linearly independent, it follows from Ref. 21, Theorem XII, p. 4.30 that $h_{l,\{\alpha_l\},\{R\}}$ is self-adjoint.

The case $\alpha_{jl} = 0$ for all $j = 1, \ldots, N$ (i.e., $\{\alpha_l\} = 0$) coincides with the free kinetic energy Hamiltonian $h_{l,o,\{R\}} \equiv h_{l,o}$ for a fixed angular momentum l.

By definition the operator $H_{\{\alpha_l\},\{R\}}$ given in $L^2(\mathbb{R}^3)$ by

$$H_{\{\alpha_l\},\{R\}}=\bigoplus_{l=0}^{\infty} U^{-1}h_{l,\{\alpha_l\},\{R\}}U\otimes 1 \tag{105}$$

describes $N-\delta'$-interactions with support on concentric spheres of radii $0<R_1<\ldots<R_N$. The case $\{\alpha_l\}=0$ yields the free Hamiltonian

$$H_{o,\{R\}}\equiv H_o=-\Delta,\quad \mathcal{D}(H_o)=H^{2,2}(\mathbb{R}^3). \tag{106}$$

B. The resolvent equation

Theorem 4.1: The resolvent of $h_{l,\{\alpha_l\},\{R\}}$ is given by

$$(h_{l,\{\alpha_l\},\{R\}}-k^2)^{-1}=(h_{l,o}-k^2)^{-1}+\sum_{j,j'=1}^{N}\lambda_{jj'}(k)(\tilde{\phi}_{l,j'}(-\overline{k}),.)\phi_{l,j}(k)$$
$$k^2\in\rho(h_{l,\{\alpha_l\},\{R\}}),\quad \mathrm{Im}(k)>0,\quad l\in\mathbb{N}_0, \tag{107}$$

where

$$[\lambda(k)]^{-1}_{jj'}=\left[\alpha_{jl}^{-1}\delta_{jj'}-\frac{1}{2}g'_{l,k}(R_j,R_{j'})\right], \tag{108}$$

$$\phi_{l,j}(k,r)=\begin{cases}G_l(k,R_j)F_l(k,r) & ;\quad r\leqslant R_j,\\ F_l(k,R_j)G_l(k,r) & ;\quad r\geqslant R_j,\end{cases} \tag{109}$$

$$\tilde{\phi}_{l,j}(k,r)=\begin{cases}G'_l(k,R_j)F_l(k,r) & ;\quad r<R_j,\\ F'_l(k,R_j)G_l(k,r) & ;\quad r>R_j,\end{cases} \tag{110}$$

$$1\leqslant j\leqslant N.$$

Proof: Equation (107) follows from Krein's formula.[14]
In order to determine the factors $\lambda_{jj'}(k)$ we proceed as follows
Let $g\in L^2((0,\infty))$ and define the function

$$\tilde{\chi}_l(k,r)=((h_{l,\{\alpha_l\},\{R\}}-k^2)^{-1}g)(r), \tag{111}$$

where k is chosen in such a way that $\det[\lambda(k)]\neq 0$. Since $\tilde{\chi}_l\in\mathcal{D}(h_{l,\{\alpha_l\},\{R\}})$, it follows from Eq. (104) that $\tilde{\chi}$ satisfies the following conditions:

$$\tilde{\chi}_l\in AC_{\mathrm{loc}}((0,\infty)), \tag{112}$$

$$\left(1+\frac{\alpha_{jl}}{2}\right)\tilde{\chi}'_l(k,R_{j+})-\left(1-\frac{\alpha_{jl}}{2}\right)\tilde{\chi}'_l(k,R_{j-})=0, \tag{113}$$

$$((h_{l,\{\alpha_l\},\{R\}}-k^2)\tilde{\chi}_l)(r)=-\tilde{\chi}''_l(k,r)+\frac{l(l+1)}{r^2}\tilde{\chi}_l(k,r)-k^2\tilde{\chi}_l(k,r)=g(r),$$
$$r>0,\quad r\neq R_j,\quad 1\leqslant j\leqslant N. \tag{114}$$

The implementation of these conditions gives the factors $\lambda_{jj'}(k)$.

The resolvent of $H_{\{\alpha_l\},\{R\}}$ may be easily obtained using Eq. (105) and (107). We get

$$(H_{\{\alpha_l\},\{R\}}-k^2)^{-1}=(H_o-k^2)^{-1}+\bigoplus_{l=0}^{\infty}\bigoplus_{m=-l}^{l}\sum_{j,j'=1}^{N}\lambda_{jj'}(k)\times(|\cdot|^{-1}\widetilde{\phi}_{l,j'}(-\overline{k})Y_l^m,.)|\cdot|^{-1}\phi_{l,j}(k)Y_l^m$$

$$k\in\rho(H_{\{\alpha_l\},\{R\}}),\quad \mathrm{Im}(k)>0,\ l\in\mathbb{N}_0. \tag{115}$$

The following theorem provides additional information on the domain of $h_{l,\{\alpha_l\},\{R\}}$ and shows that $h_{l,\{\alpha_l\},\{R\}}$ describes a local interaction.

Theorem 4.2: The domain $\mathcal{D}(h_{l,\{\alpha_l\},\{R\}})$ consists of functions of the type

$$\widetilde{\varphi}_l(k,r)=F_l(k,r)+\sum_{j,j'=1}^{N}\lambda_{jj'}(k)F_l'(k,R_{j'})g_{l,k}(R_j,r), \tag{116}$$

where $F_l\in\mathcal{D}(h_{l,\{\alpha_l\},\{R\}})$ and $k^2\in\rho(h_{l,\{\alpha_l\},\{R\}})$, $\mathrm{Im}(k)>0$.

The decomposition (116) is unique and with $\widetilde{\varphi}_l\in\mathcal{D}(h_{l,\{\alpha_l\},\{R\}})$ of this form, we obtain

$$(h_{l,\{\alpha_l\},\{R\}}-k^2)\widetilde{\varphi}_l=(h_{l,o}-k^2)F_l. \tag{117}$$

Moreover if $\widetilde{\varphi}_l\in\mathcal{D}(h_{l,\{\alpha_l\},\{R\}})$ and $\widetilde{\varphi}_l=0$ in an open set $\mathcal{O}\subset(0,\infty)$, then $h_{l,\{\alpha_l\},\{R\}}\widetilde{\varphi}_l=0$ in $\mathcal{O}$, which means that $h_{l,\{\alpha_l\},\{R\}}$ describes a local interaction.

C. Spectral properties

Theorem 4.3: For all $j=1,\ldots,N$, let $\alpha_{jl}\in(-\infty,\infty)$ and assume that $\alpha_{jl}\neq 0$. Then $h_{l,\{\alpha_l\},\{R\}}$ has at most N eigenvalues which are all negative and simple. The remaining part of the spectrum is purely absolutely continuous and covers the non-negative real axis,

$$\sigma_{\mathrm{ess}}(h_{l,\{\alpha_l\},\{R\}})=\sigma_{\mathrm{ac}}(h_{l,\{\alpha_l\},\{R\}})=[0,\infty), \tag{118}$$

$$\sigma_{\mathrm{sc}}(h_{l,\{\alpha_l\},\{R\}})=\emptyset. \tag{119}$$

Proof: One may follow step by step[2] where a similar result was obtained for finitely many δ-interactions with support on concentric spheres.

D. Stationary scattering theory for the pair $(h_{l,\{\alpha_l\},\{R\}};h_{l,o})$

For $k\geqslant 0$, let us define the functions

$$\mathcal{F}_{l,\{\alpha_l\},\{R\}}(k,r)=F_l(k,r)+\sum_{j,j'=1}^{N}\lambda_{jj'}(k)F_l'(k,R_{j'})g_{l,k}(R_j,r). \tag{120}$$

One can easily show that $\mathcal{F}_{l,\{\alpha_l\},\{R\}}$ are the scattering wave functions of $h_{l,\{\alpha_l\},\{R\}}$.

As usual, the phase shifts of $h_{l,\{\alpha_l\},\{R\}}$ may be obtained through the asymptotic behavior of $\mathcal{F}_{l,\{\alpha_l\},\{R\}}(k,r)$ as $r\rightarrow\infty$. Indeed, using Ref. 18, we obtain

$$\mathcal{F}_{l,\{\alpha_l\},\{R\}}(k,r) \underset{r\rightarrow\infty}{\overset{k>0}{\rightarrow}} A_l(k)\sin\left(kr-\frac{l\pi}{2}\right)$$

$$+\sum_{j,j'=1}^{N} \lambda_{jj'}(k)F_l(k,R_j)F_l'(k,R_{j'})B_l(k)\exp\left[-i\left(kr-\frac{l\pi}{2}\right)\right]$$

$$=\left[A_l(k)-iB_l(k)\sum_{j,j'=1}^{N} \lambda_{jj'}(k)F_l(k,R_j)F_l'(k,R_{j'})\right]\sin\left(kr-\frac{l\pi}{2}\right)$$

$$+B_l(k)\sum_{j,j'=1}^{N} \lambda_{jj'}(k)F_l(k,R_j)F_l'(k,R_{j'})\cos\left(kr-\frac{l\pi}{2}\right)$$

$$=[\tilde{C}_{1,l}^2(k)+\tilde{C}_{2,l}^2(k)]^{1/2}\sin\left(kr-\frac{l\pi}{2}+\delta_{l,\{\alpha_l\},\{R\}}(k)\right)+o(1), \tag{121}$$

which defines the phase shifts by

$$\delta_{l,\{\alpha_l\},\{R\}}(k)=-\arctan\frac{\tilde{C}_{2,l}(k)}{\tilde{C}_{1,l}(k)}$$

$$=-\arctan\frac{B_l(k)\sum_{j,j'=1}^{N} \lambda_{jj'}(k)F_l(k,R_j)F_l'(k,R_{j'})}{A_l(k)-iB_l(k)\sum_{j,j'=1}^{N} \lambda_{jj'}(k)F_l(k,R_j)F_l'(k,R_{j'})}, \tag{122}$$

where $A_l(k)$ and $B_l(k)$ are defined by (47) and (48), respectively.

Using Eq. (122), we can now compute the other scattering data. Indeed, we obtain the following results.

(i) The on-shell scattering matrix,

$$S_{l,\{\alpha_l\},\{R\}}(k)=\exp[2i\delta_{l,\{\alpha_l\},\{R\}}(k)]$$

$$=1-2ikB_l^2(k)\sum_{j,j'=1}^{N} \lambda_{jj'}(k)F_l(k,R_j)F_l'(k,R_{j'}). \tag{123}$$

(ii) The partial wave scattering length,

$$a_{l,\{\alpha_l\},\{R\}}=\sum_{j,j'=1}^{N} \lambda_{jj'}(0)(l+1)R_j^{l+1}R_{j'}^{l}. \tag{124}$$

(iii) The partial wave scattering amplitude,

$$f_{l,\{\alpha_l\},\{R\}}(k)=-B_l^2(k)\sum_{j,j'=1}^{N} \lambda_{jj'}(k)F_l(k,R_j)F_l'(k,R_{j'}). \tag{125}$$

V. THE δ'-SPHERE INTERACTION OF THE SECOND TYPE

In this section, following Refs. 1,12, we provide another exactly solvable model that we call the δ'-sphere interaction of the second type.

This model is obtained by formally interchanging the role of f and f' in the boundary conditions at $r=R$ in (18).

The radial quantum Hamiltonian describing this model is therefore defined by

$$h_{l,\beta_l} = -\frac{d^2}{dr^2} + \frac{l(l+1)}{r^2},$$

$$\begin{aligned}
\mathcal{D}(h_{l,\beta_l}) = \{ & f \in L^2((0,\infty))/f,f' \in AC_{\text{loc}}((0,\infty)\backslash\{R\}); \quad f(0_+)=0, \quad \text{if} \quad l=0; \\
& f'(R_+) = f'(R_-) \equiv f'(R); \\
& \left(1+\frac{\beta_l}{2}\right) f(R_+) - \left(1-\frac{\beta_l}{2}\right) f(R_-) = 0; \\
& -f'' + l(l+1)r^{-2} f \in L^2((0,\infty))\}; \; -\infty < \beta_l < \infty, \; l \in \mathbb{N}_0.
\end{aligned} \tag{126}$$

Now we can apply the techniques used in the previous sections in order to carry out a systematic study of this model.

In particular, we can show that the resolvent of h_{l,β_l} is given by

$$\begin{aligned}
(h_{l,\beta_l} - k^2)^{-1} = (h_{l,o} - k^2)^{-1} + \hat{\lambda}_l(k) (\phi_l(-\overline{k}), \cdot) \tilde{\phi}_l(k), \\
k^2 \in \rho(h_{l,\beta_l}), \quad \text{Im}(k) > 0, \quad l \in \mathbb{N}_0,
\end{aligned} \tag{127}$$

where

$$\hat{\lambda}_l(k) = -\beta_l \left[1 + \frac{\beta_l}{2} g'_{l,k}(R,R) \right]^{-1}, \tag{128}$$

and ϕ_l, $\tilde{\phi}_l$ are defined by (25) and (26), respectively.

We also note that the domain $\mathcal{D}(h_{l,\beta_l})$ consists of functions of the form

$$\hat{\varphi}_l(k,r) = F_l(k,r) + \hat{\lambda}_l(k) F_l(k,R) \tilde{\phi}_l(k,r), \tag{129}$$

and that h_{l,β_l} describes a local interaction.

(Received 2 February 1999; accepted for publication 19 February 1999)

The quantum mechanics of a spin $\frac{1}{2}$ particle on a locally spatial constant curvature part of a $(2+1)$-space–time in the presence of a constant magnetic field of a magnetic monopole has been investigated. It has been shown that these two-dimensional Hamiltonians have the degeneracy group of $SL(2,c)$, and para-supersymmetry of arbitrary order or shape invariance. Using this symmetry we have obtained its spectrum algebraically. The Dirac's quantization condition has been obtained from the representation theory. Also, it is shown that the presence of angular deficit suppresses both the degeneracy and shape invariance. © *1999 American Institute of Physics.* [S0022-2488(99)00409-0]

I. INTRODUCTION

Quantum theories, particularly quantum gravity in $(2+1)$-dimensions provide us with a useful field of investigation not only for theoretical and mathematical issues, but also in some cases, for actual physical problems.[1,2] In the past decade many interesting physical problems in $(2+1)$-gravity have been solved, such as classical scattering, quantum scattering, bound states of a scalar and spinor point particle both in the presence and absence of a magnetic monopole and also magnetic vortex.[3–6] In Ref. 6 some interesting results have been obtained in studying quantum scattering and bound states of a scalar charged particle in the background metric corresponding to $(2+1)$-manifold both with local and global constant curvature in the presence of a magnetic monopole, which satisfy the coupled Einstein–Maxwell equations.

Here in this article we investigate the quantum mechanics of a charged spin $\frac{1}{2}$ point particle on a $(2+1)$-space–time with spatial part of local constant curvature in the presence of a constant magnetic field of a magnetic monopole. We show that these two-dimensional Hamiltonians have the degeneracy group of $SL(2,c)$ type and para-supersymmetry of arbitrary order or shape invariance. Using these symmetries we have obtained their spectra algebraically. Also, the Dirac quantization follows naturally from the representation theory. In the case of local constancy of the curvature, the presence of angular deficit suppresses both the degeneracy and shape invariance.

The paper is organized as follows: In Sec. II we briefly describe the $(2+1)$-space–time metric of Ref. 6 and assume that angular deficit is absent. Section III is devoted to the algorithm of the manipulation of the Dirac operator in these spacetimes. The Dirac operator has been given in terms of the generators of the $sl(2,c)$ Lie algebra, which reduces the familiar Dirac operator on the S^2 in special case.[7] In Sec. IV we obtain the left and right invariant generators of the $SL(2,c)$ Lie group in terms of Euler's angles,[8] where after eliminating the ψ coordinate we get the eigenspectrum of massless Dirac operator together with its degeneracy which is in agreement with those of Ref. 7 in the special case of S^2. Also, as a special case, we obtain the massless Dirac operator in the presence of a magnetic vortex.[5,9] In Sec. V we add the constant magnetic field of

[a)]Electronic mail: jafarzadeh@ark.tabrizu.ac.ir
[b)]Electronic mail: moayedi@ark.tabrizu.ac.ir

the magnetic monopole. Using again the representation of the $SL(2,c)$ Lie group we obtain the eigenspectrum of a charged spin $\frac{1}{2}$ particle algebraically together with its degeneracy group. As a special case we obtain the monopole harmonics.[10–12] Also we obtain the familiar Dirac quantization from the representation theory. In Sec. VI, using the right invariant generators and eliminating the coordinate ψ, we obtain the raising and lowering operators of the magnetic charge. Using them we show the presence of the para-supersymmetry of arbitrary order p, or equivalently, the shape invariance symmetry associated with the Dirac operator in the presence of a magnetic monopole. Finally in Sec. VII we add the angular deficit to the background space–time metric which leads to the suppression of both degeneracy and the shape invariance symmetry. Thus we obtain the eigenspectrum by solving the Dirac operator by usual method which is in agreement with the result of Ref. 4 for the special case of the cone.

II. (2+1)-SPACE–TIME WITH LOCAL SPATIAL CONSTANT CURVATURE

In $(2+1)$ dimensions the Einstein–Hilbert action of gravity coupled to matter and electromagnetic field, together with the cosmological term can be written as[6]

$$S=\int d^3x\sqrt{|\det g_{\mu\nu}|}\left\{\frac{1}{4\pi G}(R+2\Lambda)+\frac{1}{4}F_{\mu\nu}F^{\mu\nu}-\mathcal{L}_M\right\}, \tag{2.1}$$

where $\mathcal{L}_M$ is the matter Lagrangian corresponding to a very massive point particle with mass M located in the origin. We have rescaled G by a factor of 4. As it is shown in Ref. 6, the following $(2+1)$-space–time metric corresponds to a massive point mass M together with non-negative cosmological constant Λ and magnetic monopole field

$$ds^2=dt^2-\frac{1}{2\lambda}\left(d\theta^2+(1-GM)^2\frac{\sin^2\alpha\theta}{\alpha^2}d\phi^2\right), \tag{2.2}$$

where α and λ satisfy the following relation:

$$\Lambda=\alpha^2\lambda, \tag{2.3}$$

and GM satisfies the condition $GM<1$. The parameter α in Eq. (2.3) chooses one of the values 0,1, i. In the case of $\alpha=1$, λ is a positive real number and we have

$$0\leqslant\theta<\pi,\quad 0\leqslant\phi<2\pi.$$

For $\alpha=i$, λ is a negative real number and $(2+1)$-space–time metric (2.2) is Euclidean. In this case we have $0\leqslant\theta<\infty$ and the range of ϕ is the same as $\alpha=1$ case. Finally for $\alpha=0$, λ is a positive real number again and θ plays the role of the radial variable[6] and the range of the coordinate ϕ is the same as $\alpha=1$, i case. The magnetic monopole field corresponding to the system (2.1) is

$$\mathcal{B}=g(1-GM)\alpha\sin\alpha\theta, \tag{2.4}$$

with

$$g=\begin{cases}\dfrac{1}{2\sqrt{\pi G\lambda}} & \text{if } \alpha=0 \text{ and } 1\\[2ex] \dfrac{-1}{2\sqrt{\pi G|\lambda|}} & \text{if } \alpha=i\end{cases} \tag{2.5}$$

which extremizes the Einstein–Hilbert action given in (2.1). In other words they are the solution of the Einstein–Maxwell equation which extremizes this action. The magnetic field given in (2.4) is the magnetic field of a magnetic monopole located in the origin of the R^3 Euclidean space where the constant curvature spatial part of the space–time is embedded in it. The corresponding magnetic potential one-form A in the coordinates θ and ϕ is

$$A = -g(1-GM)\cos\alpha\theta d\phi. \tag{2.6}$$

In the next section after introducing the abstract Dirac operator we write it on the spatial part of metric (2.2) in the case $M=0$.

III. DIRAC OPERATOR ON TWO-DIMENSIONAL SPACES WITH GLOBAL CONSTANT CURVATURE

The massless Dirac operator on a given d-dimensional Riemannian manifold with metric $g_{\mu\nu}$ can be written as[7,8]

$$D = -i\gamma^a E_a^\mu \left(\partial_\mu + \tfrac{1}{8}\omega_{\mu ab}[\gamma^a,\gamma^b]\right), \tag{3.1}$$

where γ^a, s are the generators of the flat Clifford algebra which satisfy the following anticommutation relation,

$$\{\gamma^a,\gamma^b\} = 2\delta^{ab}, \quad a,b = 1,...,d. \tag{3.2}$$

Also $E_a^\mu, \omega_{\mu ab}$ are d-beins and spin connections, respectively, which satisfy the following relations:

$$\begin{gathered} E_a^\mu g_{\mu\nu} E_b^\nu = \delta_{ab}, \quad E_a^\mu e_\mu^b = \delta_a^b, \\ \partial_\mu e_\nu^a - \Gamma_{\mu\nu}^\lambda e_\lambda^a + \omega_{\mu ab} e_\nu^b = 0. \end{gathered} \tag{3.3}$$

Here in this article we are concerned with the manifolds described by metric (2.2) and gauge potential (2.6). We also assume that M vanishes in the rest of the article except in the last section. Then the spatial part of the metric (2.2) reads

$$ds_{(2)}^2 = \frac{1}{2\lambda}\left(d\theta^2 + \frac{\sin^2\alpha\theta}{\alpha^2} d\phi^2\right), \tag{3.4}$$

it is clear from the above metric that the spatial part consists of a two-dimensional manifold of global constant curvature. Using Eqs. (3.3) we obtain the following expression for the nonvanishing components of zwei-beins and spin connections associated with metric (3.4):

$$\begin{gathered} E_1^\theta = \sqrt{2\lambda}, \quad E_2^\phi = \sqrt{2\lambda}\frac{\alpha}{\sin\alpha\theta}, \\ \omega_{\phi 12} = -\cos\alpha\theta. \end{gathered} \tag{3.5}$$

By using Eq. (3.1), we obtain the Dirac operator on a manifold described by metric (3.4) as follows:

$$D_2 = -i\sqrt{2\lambda}\gamma^1\left(\partial_\theta + \frac{1}{2}\frac{\alpha}{\tan\alpha\theta}\right) - i\sqrt{2\lambda}\gamma^2\frac{\alpha}{\sin\alpha\theta}\partial_\phi. \tag{3.6}$$

For $\alpha=1$, D_2 becomes the Dirac operator on the two-dimensional sphere S^2.[7] It is more convenient to consider the two-dimensional manifold (3.4) as a submanifold of the three-dimensional manifold M_3 with the line element,

$$ds^2_{(3)}=dr^2+\alpha^2r^2\left(d\theta^2+\frac{\sin^2\alpha\theta}{\alpha^2}d\phi^2\right), \tag{3.7}$$

which is parametrized with the following local coordinates:

$$x_1=r\sin\alpha\theta\cos\phi,\quad x_2=r\sin\alpha\theta\sin\phi,\quad x_3=r\cos\alpha\theta. \tag{3.8}$$

Now we consider $r=\text{constant}$ submanifold of M_3 with the following metric:

$$ds^2_{(2)}=\alpha^2r^2\left(d\theta^2+\frac{\sin^2\alpha\theta}{\alpha^2}d\phi^2\right). \tag{3.9}$$

For $\alpha=1$ and $r=(1/\sqrt{2\lambda})>0$ this submanifold coincides with the special case of $\alpha=1$ of the two-dimensional manifold with metric (3.4), while for $\alpha=0$, with the assumption of $\lim_{\alpha\to 0,r\to\infty}\alpha r=\text{finite}=(1/\sqrt{2\lambda})$, it is the same as the $\alpha=0$ case of metric (3.4). Finally for $\alpha=i$, with the assumption $r=(1/\sqrt{2|\lambda|})>0$ it changes to the $\alpha=i$ case of metric (3.4). Now we try to define the Dirac operator on the manifold M_3. Using Eq. (3.3), for nonvanishing components of 3-beins and spin connections we get

$$E_1^\theta=\frac{1}{\alpha r},\quad E_2^\phi=\frac{1}{r\sin\alpha\theta},\quad E_3^r=1,$$

$$\omega_{\theta 13}=\alpha,\omega_{\phi 21}=\cos\alpha\theta,\omega_{\phi 23}=\sin\alpha\theta. \tag{3.10}$$

Finally, using the relations (3.1) and (3.10) the Dirac operator associated with metric (3.7) reads

$$D_3=-i\gamma^1\frac{1}{\alpha r}\left(\partial_\theta+\frac{1}{2}\frac{\alpha}{\tan\alpha\theta}\right)-i\gamma^2\frac{1}{\alpha r}\frac{\alpha}{\sin\alpha\theta}\partial_\phi-i\gamma^3\left(\partial_r+\frac{1}{r}\right). \tag{3.11}$$

It is straightforward to see that the Dirac operator D_3 yields

$$\left(-i\gamma^3D_3+\frac{1}{r}\right)\Bigg|_{r=\text{constant}}=-i\Gamma^1\frac{1}{\alpha r}\left(\partial_\theta+\frac{1}{2}\frac{\alpha}{\tan\alpha\theta}\right)-i\Gamma^2\frac{1}{\alpha r}\frac{\alpha}{\sin\alpha\theta}\partial_\phi, \tag{3.12}$$

with Γ^a defined as

$$\Gamma^a=-i\gamma^3\gamma^a,\quad a=1,2,$$

which satisfy the following Clifford algebra

$$\{\Gamma^a,\Gamma^b\}=2\delta^{ab}. \tag{3.13}$$

Assuming the equivalence of the metric of submanifold given in (3.9) with the two-dimensional metric (3.4) and also replacing αr with $1/\sqrt{2\lambda}$, we can deduce that the operator (3.12) is the same as Dirac operator D_2 given in (3.6). In terms of local coordinates (3.8) the operator D_3 can be written as

$$D_3=-i\sigma_i\partial_i, \tag{3.14}$$

where σ_i, s are Pauli matrices. Using the identity $(\sigma_ix_i/r)^2=I$, we have

$$D_3=\left(\frac{\sigma_ix_i}{r}\right)^2D_3=-i\frac{\sigma_ix_i}{r}\left(\partial_r+\frac{i}{r}\epsilon_{ijk}\sigma_ix_j\partial_k\right). \tag{3.15}$$

Now, comparing the operator (3.15) with (3.11), it follows that the operator γ^3 has the following form:

$$\gamma^3 = \frac{\sigma_i x_i}{r}. \tag{3.16}$$

Using the relations (3.12) and (3.15) together with the relation (3.11) the Dirac operator D_2 over two dimensional manifold with metric (3.4) can be represented as

$$D_2 = \frac{1}{r} - \frac{i}{r}\epsilon_{ijk}\sigma_i x_j \partial_k = \sqrt{2\lambda}(\sigma_1 I_1 + \sigma_2 I_2 + \alpha\sigma_3 I_3 + \alpha I), \tag{3.17}$$

where I is a 2×2 identity matrix and the differential operators I_i with $i=1,2,3$ in (3.17) have the following form:

$$\begin{aligned} I_1 &= i\left(\sin\phi\partial_\theta + \frac{\alpha}{\tan\alpha\theta}\cos\phi\partial_\phi\right),\\ I_2 &= i\left(-\cos\phi\partial_\theta + \frac{\alpha}{\tan\alpha\theta}\sin\phi\partial_\phi\right),\\ I_3 &= -i\partial_\phi, \end{aligned} \tag{3.18}$$

and satisfy the following $sl(2,c)$ Lie algebra:

$$[I_1,I_2] = i\alpha^2 I_3, \quad [I_2,I_3] = iI_1, \quad [I_3,I_1] = iI_2. \tag{3.19}$$

It is clear that for $\alpha=1$ this algebra becomes an $su(2)$ Lie algebra, for $\alpha=i$ we get $su(1,1)$ Lie algebra, and finally for $\alpha=0$ we get $iso(2)$ Lie algebra.[6,13]

IV. DEGENERACY GROUP OF THE DIRAC OPERATOR ON TWO-DIMENSIONAL MANIFOLDS WITH GLOBAL CONSTANT CURVATURE

In order to obtain the degeneracy group of the Dirac operator D_2 over the two-dimensional manifold with metric (3.4) we need to know the left and right invariant generators of $SL(2,c)$ group which have the following form in the Eulerean coordinates:[6]

$$\begin{aligned} L_1^{(L)} &= i\left(\sin\phi\partial_\theta + \frac{\alpha}{\tan\alpha\theta}\cos\phi\partial_\phi - \frac{\alpha}{\sin\alpha\theta}\cos\phi\partial_\psi\right),\\ L_2^{(L)} &= i\left(-\cos\phi\partial_\theta + \frac{\alpha}{\tan\alpha\theta}\sin\phi\partial_\phi - \frac{\alpha}{\sin\alpha\theta}\sin\phi\partial_\psi\right),\\ L_3^{(L)} &= -i\partial_\phi,\\ L_1^{(R)} &= i\left(\sin\psi\partial_\theta + \frac{\alpha}{\tan\alpha\theta}\cos\psi\partial_\psi - \frac{\alpha}{\sin\alpha\theta}\cos\psi\partial_\phi\right),\\ L_2^{(R)} &= i\left(-\cos\psi\partial_\theta + \frac{\alpha}{\tan\alpha\theta}\sin\psi\partial_\psi - \frac{\alpha}{\sin\alpha\theta}\sin\psi\partial_\phi\right),\\ L_3^{(R)} &= -i\partial_\psi, \end{aligned} \tag{4.1}$$

where $0\leqslant\phi<2\pi$, $0\leqslant\psi<4\pi$ and $0\leqslant\theta<\pi$ for $\alpha=1$, while $0\leqslant\theta<\infty$ when $\alpha=0,i$. It is rather well known that both left and right invariant generators satisfy $sl(2,c)$ Lie algebra denoted by $sl(2,c)_L$ and $sl(2,c)_R$, respectively and also they commute with each other. That is we have

$$\begin{gathered}[L_1^{(L)},L_2^{(L)}]=i\alpha^2L_3^{(L)},\quad [L_2^{(L)},L_3^{(L)}]=iL_1^{(L)},\quad [L_3^{(L)},L_1^{(L)}]=iL_2^{(L)},\\ [L_1^{(R)},L_2^{(R)}]=i\alpha^2L_3^{(R)},\quad [L_2^{(R)},L_3^{(R)}]=iL_1^{(R)},\quad [L_3^{(R)},L_1^{(R)}]=iL_2^{(R)},\\ [\mathbf{L^{(L)}},\mathbf{L^{(R)}}]=0.\end{gathered}\tag{4.2}$$

Now, using the generators (4.1) we define the following new bases:

$$\begin{gathered}K_1^{(L)}:=L_1^{(L)}\otimes I+\tfrac{1}{2}\alpha\sigma_1\quad K_2^{(L)}:=L_2^{(L)}\otimes I+\tfrac{1}{2}\alpha\sigma_2,\quad K_3^{(L)}:=L_3^{(L)}\otimes I+\tfrac{1}{2}\sigma_3,\\ K_1^{(R)}:=L_1^{(R)}\otimes I,\quad K_2^{(R)}:=L_2^{(R)}\otimes I,\quad K_3^{(R)}:=L_3^{(R)}\otimes I.\end{gathered}\tag{4.3}$$

Using the commutation relations (4.2) and the properties of Pauli matrices it is rather straightforward to show that the newly defined left and right invariant operators (4.3) also satisfy $sl(2,c)$ Lie algebra separately and commute with each other. Now, the operator F defined as

$$F:=\sqrt{2\lambda}(\sigma_1L_1^{(L)}+\sigma_2L_2^{(L)}+\alpha\sigma_3L_3^{(L)}+\alpha I),\tag{4.4}$$

commute with all the generators given in (4.3), that is

$$[F,\mathbf{K^{(L)}}]=0,\quad [F,\mathbf{K^{(R)}}]=0.\tag{4.5}$$

Therefore, in order to obtain the eigenspectrum of operator F, we need the set of commutative operators expressed in terms of operators (4.3), which are

$$\{K_3^{(R)},K_3^{(L)},K_1^{(L)2}+K_2^{(L)2}+\alpha^2K_3^{(L)2},K_1^{(R)2}+K_2^{(R)2}+\alpha^2K_3^{(R)2}\}.$$

Then, we have the following simultaneous eigenvalue equations:

$$\begin{gathered}K_3^{(R)}\Psi=q\Psi,\quad K_3^{(L)}\Psi=m\Psi,\\ (K_1^{(R)2}+K_2^{(R)2}+\alpha^2K_3^{(R)2})\Psi=\alpha^2l(l+1)\Psi,\\ (K_1^{(L)2}+K_2^{(L)2}+\alpha^2K_3^{(L)2})\Psi=\alpha^2j(j+1)\Psi.\end{gathered}\tag{4.6}$$

Obviously the operators $K_3^{(R)}$ and $\dot{K}_3^{(L)}$ have the following differential form;

$$\begin{gathered}K_3^{(R)}=\begin{pmatrix}-i\partial_\psi & 0\\ o & -i\partial_\psi\end{pmatrix},\\ K_3^{(L)}=\begin{pmatrix}-i\partial_\phi+\frac{1}{2} & 0\\ o & -i\partial_\phi-\frac{1}{2}\end{pmatrix}.\end{gathered}\tag{4.7}$$

Therefore, the two component spinor Ψ reads

$$\Psi=\begin{pmatrix}ae^{i(m-1/2)\phi+iq\psi}f_1(\theta)\\ be^{i(m+1/2)\phi+iq\psi}f_2(\theta)\end{pmatrix}.\tag{4.8}$$

In Eq. (4.8) a and b are constants and f_1 and f_2 are functions of variable θ. In order the spinor Ψ to become a periodic function of ϕ with period 2π, the quantum number m must be a half-integer number. Now, using the left and right invariant generators (4.1) we have

$$L_1^{(L)2}+L_2^{(L)2}+\alpha^2 L_3^{(L)2}=L_1^{(R)2}+L_2^{(R)2}+\alpha^2 L_3^{(R)2}$$
$$=-\left\{\partial_\theta^2+\frac{\alpha}{\tan\alpha\theta}\partial_\theta+\frac{\alpha^2}{\sin^2\alpha\theta}(\partial_\phi^2+\partial_\psi^2-2\cos\alpha\theta\partial_\phi\partial_\psi)\right\}. \tag{4.9}$$

The operator (4.9) yields the following eigenvalue equation:[14]

$$-\left\{\partial_\theta^2+\frac{\alpha}{\tan\alpha\theta}\partial_\theta+\frac{\alpha^2}{\sin^2\alpha\theta}(\partial_\phi^2+\partial_\psi^2-2\cos\alpha\theta\partial_\phi\partial_\psi)\right\}Y_{nq}^l(\theta,\phi,\psi)=\alpha^2 l(l+1)Y_{nq}^l(\theta,\phi,\psi), \tag{4.10}$$

where the eigenfunction (4.10), that is $Y_{nq}^l(\theta,\phi,\psi)$ reads

$$Y_{nq}^l(\theta,\phi,\psi)=e^{in\phi+iq\psi}P_{nq}^l(\cos\alpha\theta). \tag{4.11}$$

On the other hand, the operators $K_1^{(L)2}+K_2^{(L)2}+\alpha^2K_3^{(L)2}$ and $K_1^{(R)2}+K_2^{(R)2}+\alpha^2K_3^{(R)2}$ may be represented in the form

$$K_1^{(R)2}+K_2^{(R)2}+\alpha^2K_3^{(R)2}=\begin{pmatrix} L_1^{(R)2}+L_2^{(R)2}+\alpha^2L_3^{(R)2} & 0\\ 0 & L_1^{(R)2}+L_2^{(R)2}+\alpha^2L_3^{(R)2}\end{pmatrix},$$
$$K_1^{(L)2}+K_2^{(L)2}+\alpha^2K_3^{(L)2}$$
$$=\begin{pmatrix} L_1^{(L)2}+L_2^{(L)2}+\alpha^2L_3^{(L)2}+\frac{3}{4}\alpha^2+\alpha^2L_3^{(L)} & \alpha(L_1^{(L)}-iL_2^{(L)})\\ \alpha(L_1^{(L)}+iL_2^{(L)}) & L_1^{(L)2}+L_2^{(L)2}+\alpha^2L_3^{(L)2}+\frac{3}{4}\alpha^2-\alpha^2L_3^{(L)}\end{pmatrix}, \tag{4.12}$$

where the operators $L_1^{(L)}+iL_2^{(L)}$ and $L_1^{(L)}-iL_2^{(L)}$ are the raising and lowering operators of index n of eigenfunction (4.11), that is we have

$$(L_1^{(L)}+iL_2^{(L)})Y_{nq}^l(\theta,\phi,\psi)=\sqrt{\alpha^2(l+n+1)(l-n)}\,Y_{n+1q}^l(\theta,\phi,\psi),$$
$$(L_1^{(L)}-iL_2^{(L)})Y_{nq}^l(\theta,\phi,\psi)=\sqrt{\alpha^2(l-n+1)(l+n)}\,Y_{n-1q}^l(\theta,\phi,\psi).$$

Summarizing the above explanation the eigenfunction Ψ of eigenvalue Eq. (4.6) read

$$\Psi=\Psi_{l,j=l\pm\frac{1}{2},m,q}(\theta,\phi,\psi)=\Omega\begin{pmatrix}\pm\sqrt{l\pm m+\frac{1}{2}}\,Y_{m-(1/2)q}^l(\theta,\phi,\psi)\\ \sqrt{l\mp m+\frac{1}{2}}\,Y_{m+(1/2)q}^l(\theta,\phi,\psi)\end{pmatrix}, \tag{4.13}$$

where Ω is constant of normalization. Note that in Eq. (4.13), q takes integer values because m can take on only half-integer values as said before.[14] Now, by taking the operator F of Eq. (4.4) to the power 2 we arrive at

$$F^2=2\lambda(K_1^{(L)2}+K_2^{(L)2}+\alpha^2K_3^{(L)2}+\tfrac{1}{4}\alpha^2 I)=2\lambda(j+\tfrac{1}{2})^2\alpha^2 I.$$

Therefore, we have the following eigenvalue equation:

$$F\Psi_{l,j=l\pm1/2,m,q}(\theta,\phi,\psi)=\pm\sqrt{2\lambda(j+\tfrac{1}{2})^2\alpha^2}\,\Psi_{l,j=l\pm1/2,m,q}(\theta,\phi,\psi). \tag{4.14}$$

Now, transfering the factor $e^{iq\psi}$ which appears in the wave function (4.13) to the left of the operator F and eliminating it from both sides of Eq. (4.14), we get

$$F(q)\Psi_{l,j=l\pm 1/2,m,q}(\theta,\phi)=\pm\sqrt{2\lambda(j+\tfrac{1}{2})^2\alpha^2}\Psi_{l,j=l\pm 1/2,m,q}(\theta,\phi), \tag{4.15}$$

where $F(q)$ and $\Psi_{l,j=l\pm\frac{1}{2},m,q}(\theta,\phi)$ are

$$F(q)=\sqrt{2\lambda}\begin{pmatrix} \alpha(1-i\partial_\phi) & e^{-i\phi}\left(-\partial_\theta+i\,\dfrac{\alpha}{\tan\alpha\theta}\,\partial_\phi+q\,\dfrac{\alpha}{\sin\alpha\theta}\right) \\ e^{i\phi}\left(\partial_\theta+i\,\dfrac{\alpha}{\tan\alpha\theta}\,\partial_\phi+q\,\dfrac{\alpha}{\sin\alpha\theta}\right) & \alpha(1+i\partial_\phi) \end{pmatrix},$$

$$\Psi_{l,j=l\pm 1/2,m,q}(\theta,\phi)=\Omega\begin{pmatrix} \pm\sqrt{l\pm m+\frac{1}{2}}e^{i(m-1/2)\phi}P^l_{m-(1/2)\,q}(\cos\alpha\theta) \\ \sqrt{l\mp m+\frac{1}{2}}e^{i(m+1/2)\phi}P^l_{m+(1/2)\,q}(\cos\alpha\theta) \end{pmatrix}. \tag{4.16}$$

Now we consider the limiting case of $q\to 0$. In this limit the operator $F(q)$ becomes the same as the operator D_2 in (3.17), that is we have

$$\lim_{q\to 0} F(q)=D_2.$$

Specially for $\alpha=1$ we get the Dirac operator on S^2,[7] and the eigenfunction introduced in (4.16) becomes the wellknown spinor harmonics.[10]

There is another interesting limiting case: to let $\alpha\to 0$ and $l\to\infty$ but αl to remain finite, that is

$$\lim_{\alpha\to 0, l\to\infty} \alpha l=k.$$

In this limit θ plays the role of radial coordinate and we have[14]

$$\lim_{\alpha\to 0, l\to\infty} P^l_{nq}(\cos\alpha\theta)=J_{|n-q|}(kr),$$

where $J_{|n-q|}(kr)$ is the Bessel function with index $|n-q|$. In brief, we have

$$Z_{k,m,q}(r,\phi)=\lim_{\alpha\to 0, l\to\infty}\Psi_{l,j=l\pm 1/2,m,q}(\theta,\phi)=\Omega'\begin{pmatrix} \pm e^{i(m-1/2)\phi}J_{|m-1/2-q|}(kr) \\ e^{i(m+1/2)\phi}J_{|m+1/2-q|}(kr) \end{pmatrix}, \tag{4.17}$$

where Ω' is the new constant of normalization. The operator $F(q)$, in the limit of $\alpha\to 0$ reads

$$\lim_{\alpha\to 0}F(q)=\sqrt{2\lambda}\begin{pmatrix} 0 & e^{-i\phi}\left(-\partial_r+\dfrac{i}{r}\,\partial\phi+\dfrac{q}{r}\right) \\ e^{i\phi}\left(\partial r+\dfrac{i}{r}\,\partial\phi+\dfrac{q}{r}\right) & 0 \end{pmatrix}. \tag{4.18}$$

In this limit the operator $F(q)$ has the following eigenvalue:

$$E=\pm\sqrt{2\lambda}k.$$

The operator (4.18) is exactly the Dirac operator of a very light spin $\frac{1}{2}$ particle in the presence of magnetic vortex with gauge potential $\mathbf{A}=e_\phi q/r$.[9] The wave function (4.17) is the eigenstate associated with the scattering of a massless fermion from a vortex. It is obvious that in the case $q=0$, (4.17) and (4.18) represent the wave function and the Dirac operator of a free massless fermion on two dimensional flat space, respectively. In the next section we obtain the eigenspectrum of the Dirac operator in the presence of the magnetic monopole (2.4) for the special case of $M=0$.

V. THE DIRAC OPERATOR ON A TWO-DIMENSIONAL MANIFOLD WITH GLOBAL CONSTANT CURVATURE IN THE PRESENCE OF THE MAGNETIC FIELD OF A MAGNETIC MONOPOLE

The massless Dirac operator on a Riemannian manifold with metric $g_{\mu\nu}$ in the presence of gauge field A_μ is[15]

$$D(A)=-i\gamma^a E_a^\mu\left(\partial_\mu+\tfrac{1}{8}\omega_{\mu ab}[\gamma^a,\gamma^b]+ieA_\mu\right). \tag{5.1}$$

Therefore, using the beins and spin connections given in (3.5) and considering the gauge potential $A=-g\cos\alpha\theta d\phi$ we obtain the following expression for the Dirac operator:

$$D_2(A)=-i\sqrt{2\lambda}\,\gamma^1\left(\partial_\theta+\frac{1}{2}\frac{\alpha}{\tan\alpha\theta}\right)-i\sqrt{2\lambda}\,\gamma^2\frac{\alpha}{\sin\alpha\theta}(\partial_\phi-ieg\cos\alpha\theta). \tag{5.2}$$

Now we try to obtain the Dirac operator $D_2(A)$ given in (5.2) from the Dirac operator on the manifold described by the metric (3.7) and by the gauge field with connection

$$A_r=0,\quad A_\theta=0,\quad A_\phi=-g\cos\alpha\theta. \tag{5.3}$$

Using the beins and spin connections given in (3.10) and gauge field connection (5.3), the Dirac operator on the manifold (3.7) in the presence of gauge field (5.3) reads

$$D_3(A)=-i\gamma^1\frac{1}{\alpha r}\left(\partial_\theta+\frac{1}{2}\frac{\alpha}{\tan\alpha\theta}\right)-i\gamma^2\frac{1}{\alpha r}\frac{\alpha}{\sin\alpha\theta}(\partial_\phi-ieg\cos\alpha\theta)-i\gamma^3\left(\partial_r+\frac{1}{r}\right). \tag{5.4}$$

It is straightforward to show that the following relation between the operators $D_2(A)$ and $D_3(A)$ holds,

$$D_2(A)=\left.\left(-i\gamma^3D_3(A)+\frac{1}{r}\right)\right|_{r=\text{constant}}. \tag{5.5}$$

The gauge field (5.3) has the following form in the Cartesian-type coordinates (3.8),

$$A_i=g\epsilon_{ij3}\frac{x_jx_3}{r(x_1^2+x_2^2)},\quad i,j=1,2,3, \tag{5.6}$$

where it satisfies the following gauge condition:

$$\mathbf{r}\cdot\mathbf{A}=0.$$

In the local coordinates (3.8) together with the gauge connection (5.6), the Dirac operator can be written as

$$D_3(A)=\sigma_i\left(\frac{1}{i}\partial_i+eA_i\right). \tag{5.7}$$

With further little algebra one can show that the Dirac operator given in (5.7) takes the following form:

$$D_3(A)=\left(\frac{\sigma_ix_i}{r}\right)^2D_3(A)=-i\gamma^3\left(\partial_r-\frac{1}{r}\boldsymbol{\sigma}.\mathbf{r}\times\left(\frac{1}{i}\boldsymbol{\nabla}+e\mathbf{A}\right)\right). \tag{5.8}$$

Finally using the relation (5.5) between the operators $D_2(A)$ and $D_3(A)$, the Dirac operator on the two-dimensional manifold (3.4) and in the presence of magnetic field of a magnetic monopole is

$$D_2(A)=F(eg)-\alpha\sqrt{2\lambda}eg\gamma^3. \tag{5.9}$$

Therefore, according to Sec. IV, we have the following eigenvalue equation:

$$D_2(A)\Psi_{l,j=l\pm 1/2,m,q}(\theta,\phi)=\pm\sqrt{2\lambda\alpha^2[(j+\tfrac{1}{2})^2-q^2]}\Psi_{l,j=l\pm 1/2,m,q}(\theta,\phi), \tag{5.10}$$

where q is equal to the product of electric and magnetic charge, that is

$$q=eg.$$

Therefore, the Dirac quantization condition follows naturally from the finite representation of the $SL(2,c)$ Lie group. Also $j+\frac{1}{2}\geqslant q$ and for $j+\frac{1}{2}=q$ the operator (5.9) becomes noninvertible. It is clear that for $\alpha=1$, the operator $D_2(A)$ becomes the Dirac operator on S^2 in the presence of magnetic field of magnetic monopole[11,12] with monopole harmonics as its eigenfunctions.

VI. PARA-SUPERSYMMETRY AND SHAPE INVARIANCE OF THE DIRAC EQUATION

In this section using the left and right invariant generators introduced in Sec. IV, we try to investigate the shape invariance symmetry and para-supersymmetry of the two-dimensional Dirac operator. Here it is more convenient to work with bases $\{J_+^{(R)},J_-^{(R)},J_3^{(R)}\}$ rather than with $\{L_1^{(R)},L_2^{(R)},L_3^{(R)}\}$ which are defined as

$$\begin{aligned}J_\pm^{(R)}&=L_1^{(R)}\pm iL_2^{(R)}=e^{\pm i\psi}\left(\pm\partial_\theta+i\frac{\alpha}{\tan\alpha\theta}\partial_\psi-i\frac{\alpha}{\sin\alpha\theta}\partial_\phi\right),\\ J_3^{(R)}&=L_3^{(R)}=-i\partial_\psi.\end{aligned} \tag{6.1}$$

Clearly these new bases have the following commutation relations:

$$\begin{aligned}[][J_+^{(R)},J_-^{(R)}]&=2\alpha^2J_3^{(R)},\\ [J_3^{(R)},J_\pm^{(R)}]&=\pm J_\pm^{(R)}.\end{aligned} \tag{6.2}$$

Using the relations (4.9) and (4.10) we arrive at

$$\begin{aligned}(J_+^{(R)}\otimes I)(J_-^{(R)}\otimes I)\Psi_{l,j=l\pm 1/2,m,q}(\theta,\phi,\psi)&=\alpha^2(l-q+1)(l+q)\Psi_{l,j=l\pm 1/2,m,q}(\theta,\phi,\psi),\\ (J_-^{(R)}\otimes I)(J_+^{(R)}\otimes I)\Psi_{l,j=l\pm 1/2,m,q}(\theta,\phi,\psi)&=\alpha^2(l+q+1)(l-q)\Psi_{l,j=l\pm 1/2,m,q}(\theta,\phi,\psi).\end{aligned} \tag{6.3}$$

The above relations indicate that $J_+^{(R)}\otimes I$ and $J_-^{(R)}\otimes I$ are raising and lowering operators of index q, respectively, that is,

$$\begin{aligned}J_+^{(R)}\otimes I\Psi_{l,j=l\pm 1/2,m,q}(\theta,\phi,\psi)&=\sqrt{\alpha^2(l+q+1)(l-q)}\Psi_{l,j=l\pm 1/2,m,q+1}(\theta,\phi,\psi),\\ J_-^{(R)}\otimes I\Psi_{l,j=l\pm 1/2,m,q}(\theta,\phi,\psi)&=\sqrt{\alpha^2(l-q+1)(l+q)}\Psi_{l,j=l\pm 1/2,m,q-1}(\theta,\phi,\psi).\end{aligned} \tag{6.4}$$

Now by transfering $e^{iq\psi}$, which is only ψ dependent factor in the eigenspinor $\Psi_{l,j=l\pm 1/2,m,q}(\theta,\phi,\psi)$, to the left-hand sides of the lowering and raising operator in (6.4) we arrive at

$$J_+^{(R)}(q)\otimes I\Psi_{l,j=l\pm 1/2,m,q}(\theta,\phi)=\sqrt{\alpha^2(l+q+1)(l-q)}\Psi_{l,j=l\pm 1/2,m,q+1}(\theta,\phi),$$
$$J_-^{(R)}(q)\otimes I\Psi_{l,j=l\pm 1/2,m,q}(\theta,\phi)=\sqrt{\alpha^2(l-q+1)(l+q)}\Psi_{l,j=l\pm 1/2,m,q-1}(\theta,\phi), \tag{6.5}$$

where $J_\pm^{(R)}(q)$ read

$$J_\pm^{(R)}(q)=\pm\frac{\partial}{\partial\theta}-i\frac{\alpha}{\sin\alpha\theta}\frac{\partial}{\partial\phi}-q\frac{\alpha}{\tan\alpha\theta}. \tag{6.6}$$

But $J_+^{(R)}(q)\otimes I$ and $J_-^{(R)}(q)\otimes I$ are still raising and lowering operators of index q of the eigenspinors $\Psi_{l,j=l\pm 1/2,m,q}(\theta,\phi)$ and the relations (6.5) indicate that $\Psi_{l,j=l\pm 1/2,m,q}(\theta,\phi)$ can form the basis for a representation of para-supersymmetry of order p, where p is an arbitrary integer. According to Refs. 13 and 16, the nonunitary para-supersymmetric algebra of order p can be generated by parafermionic generators of order p, denoted by Q_1 and Q_2 and a bosonic generator H, which satisfy the following relations:

$$Q_1^pQ_2+Q_1^{p-1}Q_2Q_1+\cdots+Q_1Q_2Q_1^{p-1}+Q_2Q_1^p=2pQ_1^{p-1}H, \tag{6.7a}$$

$$Q_2^pQ_1+Q_2^{p-1}Q_1Q_2+\cdots+Q_2Q_1Q_2^{p-1}+Q_1Q_2^p=2pQ_2^{p-1}H, \tag{6.7b}$$

$$Q_1^{p+1}=Q_2^{p+1}=0, \tag{6.7c}$$

$$[H,Q_1]=[H,Q_2]=0. \tag{6.7d}$$

By introducing the operators,

$$X_+(q):=J_+^{(R)}(q)\otimes I,\quad X_-(q):=J_-^{(R)}(q)\otimes I,\quad \mathcal{H}_q:=H_q\otimes I, \tag{6.8}$$

we can represent the generators Q_1, Q_2, and H by the following $(p+1)\times(p+1)$ matrices of the form:

$$(Q_1)_{qq'}:=X_-(q)\delta_{q+1,q'},$$
$$(Q_2)_{qq'}:=X_+(q'-1)\delta_{q,q'+1}, \tag{6.9}$$
$$(H)_{qq'}:=\mathcal{H}_q\delta_{q,q'}\quad q,q'=1,\ldots,p+1,$$

where each element of these matrices is a 2×2 matrix. In (6.9) we need to choose the Hamiltonians $\mathcal{H}$, with $q=1,...,p+1$ so that the generators (6.9) satisfy the para-supersymmetric algebraic relations (6.7). The generators Q_1, Q_2, and H, as defined in (6.9), satisfy the Eq. (6.7c), but Eqs. (6.7a) and (6.7b) lead to the following equations:

$$X_+(p-2)\cdots X_+(1)X_+(0)X_-(1)+\cdots+X_+(p-2)X_-(p-1)X_+(p-2)X_-(p-3)\cdots X_+(0)$$
$$+X_-(p)X_+(p-1)X_+(p-2)\cdots X_+(0)=2pX_+(p-2)X_+(p-3)\cdots X_+(0)\mathcal{H}_1, \tag{6.10a}$$

$$X_+(p-1)\cdots X_+(1)X_+(0)X_-(1)+X_+(p-1)\cdots X_+(2)X_+(1)X_-(2)X_+(1)+\cdots$$
$$+X_+(p-1)X_-(p)X_+(p-1)X_+(p-2)\cdots X_+(1)=2pX_+(p-1)X_+(p-2)\cdots X_+(1)\mathcal{H}_2, \tag{6.10b}$$

$$X_-(1)\cdots X_-(p-1)X_-(p)X_+(p-1)+X_-(1)\cdots X_-(p-2)X_-(p-1)X_+(p-2)X_-(p-1)$$
$$+\cdots+X_-(1)X_+(0)X_-(1)X_-(2)\cdots X_-(p-1)=2pX_-(1)X_-(2)\cdots X_-(p-1)\mathcal{H}_p, \tag{6.10c}$$

$$X_-(2)\cdots X_-(p-1)X_-(p)X_+(p-1)X_-(p)+\cdots+X_-(2)X_+(1)X_-(2)X_-(3)\cdots X_-(p)$$
$$+X_+(0)X_-(1)X_-(2)\cdots X_-(p)=2pX_-(2)X_-(3)\cdots X_-(p)\mathcal{H}_{p+1}. \tag{6.10d}$$

Finally Eq. (6.7d) imply the following equations:

$$\mathcal{H}_q X_-(q)=X_-(q)\mathcal{H}_{q+1},$$
$$\mathcal{H}_{q+1}X_+(q-1)=X_+(q-1)\mathcal{H}_q. \tag{6.11}$$

Now, defining the Hamiltonians $\mathcal{H}_q$, $q=1,...,p$ as

$$\mathcal{H}_q=\tfrac{1}{2}X_-(q)X_+(q-1)+\tfrac{1}{2}C_qI \quad q=1,2,...,p,$$
$$\mathcal{H}_{p+1}=\tfrac{1}{2}X_+(p-1)X_-(p)+\tfrac{1}{2}C_pI. \tag{6.12}$$

By definitions (6.12) relations (6.11) are satisfied for the special case $q=p$. In order for the relations (6.11) to be satisfied for $q=1,...,p-1$, too, we need to choose the constants C_q as

$$E_{q+1}-E_q=C_q-C_{q+1}, \tag{6.13}$$

where

$$E_q:=\alpha^2[l(l+1)-q(q-1)]. \tag{6.14}$$

To obtain the relation (6.13) we have used the following shape invariance property between the operators $X_\pm(q)$:

$$X_+(q-1)X_-(q)-X_-(q+1)X_+(q)=E_q-E_{q+1}. \tag{6.15}$$

Substituting (6.12) in formula (6.10a), and also using the shape invariance property (6.15) we obtain

$$C_1=\frac{1}{p}[(1-p)E_1+E_2+E_3+\cdots+E_p]. \tag{6.16}$$

Finally combining (6.13) with (6.16) we obtain

$$C_q=\frac{1}{p}\sum_{q'=1}^{p}E_{q'}-E_q. \tag{6.17}$$

From (6.17) we can see that the following relation among the constants C_q holds

$$C_1+C_2+\cdots+C_p=0.$$

Using the substitution (6.12) and the shape invariance property (6.15) together with the constants C_q given in (6.17) one can straightforwardly show that Eqs. (6.10b), (6.10c), (6.10d) are satisfied, too. Also using the result given in (6.17) and the shape invariance relation (6.15) it follows that the Hamiltonians $\mathcal{H}_q$ are isospectral and we have

$$\mathcal{H}_q\Psi_{l,j=l\pm 1/2,m,q-1}(\theta,\phi)=E\Psi_{l,j=l\pm 1/2,m,q-1}(\theta,\phi), \quad q=1,...,p+1, \tag{6.18}$$

with

$$E=\frac{1}{2p}\sum_{q=1}^{p}E_q. \tag{6.19}$$

Substituting E_q in (6.19) and by using the relation (6.14) we get

$$E=\tfrac{1}{6}\alpha^2[3l(l+1)+1-p^2]. \tag{6.20}$$

In a similar manner by substituting (6.14) in (6.17) we have

$$C_q=\tfrac{1}{3}\alpha^2[3q(q-1)+1-p^2]. \tag{6.21}$$

Substituting the constants C_q in (6.21), and also using the relations (6.6) and (6.8) after the substituting (6.12) we obtain the explicit differential form of the Hamiltonian $\mathcal{H}_q$ as

$$\mathcal{H}_q=-\frac{1}{2}\left[\frac{\partial^2}{\partial\theta^2}+\frac{\alpha}{\tan\alpha\theta}\frac{\partial}{\partial\theta}+\frac{\alpha^2}{\sin^2\alpha\theta}\frac{\partial^2}{\partial\phi^2}-\frac{2i(q-1)\alpha^2}{\sin\alpha\theta\tan\alpha\theta}\frac{\partial}{\partial\phi}-\frac{(q-1)^2\alpha^2}{\sin^2\alpha\theta}+\frac{1}{3}\alpha^2(p^2-1)\right]\otimes I. \tag{6.22}$$

The bases of the representation of para-supersymmetric algebra of order p can be represented by column matrix with $(p+1)$ row, that is

$$(\Psi_{l,j=l\pm 1/2,m}(\theta,\phi))_q:=\Psi_{l,j=l\pm 1/2,m,q}(\theta,\phi),\quad q=0,1,...,p, \tag{6.23}$$

where $\Psi_{l,j=l\pm 1/2,m}(\theta,\phi)$ is the eigenvector of paraboson operator H with eigenvalue E, that is

$$H\Psi_{l,j=l\pm 1/2,m}(\theta,\phi)=E\Psi_{l,j=l\pm 1/2,m}(\theta,\phi). \tag{6.24}$$

It follows rather trivially from the commutation relations (6.7d) and also from the relations (6.7c) that $Q_1^q\Psi_{l,j=l\pm 1/2,m}(\theta,\phi)$ and $Q_2^q\Psi_{l,j=l\pm 1/2,m}(\theta,\phi)$ for $q=1,...,p$ are eigenstates of the bosonic generator H with the corresponding eigenvalue E. Hence, it follows that

$$\Psi_{l,j=l\pm 1/2,m,q}(\theta,\phi)=\frac{X_-(q+1)}{\sqrt{E_{q+1}}}\frac{X_-(q+2)}{\sqrt{E_{q+2}}}\cdots\frac{X_-(q'+q)}{\sqrt{E_{q'+q}}}\Psi_{l,j=l\pm 1/2,m,q'+q}(\theta,\phi),$$
$$q=0,1,...,p-q'. \tag{6.25}$$

The representation of para-supersymmetry algebra of order p is valid even for the special case of $\alpha=0$. Using the relation (4.17) in the limiting cases of $\alpha\to 0$ and $l\to\infty$ we arrive at the following shape invariance relations:

$$\begin{aligned}\left(\frac{\partial}{\partial r}-\frac{i}{r}\frac{\partial}{\partial\phi}-\frac{q}{r}\right)\otimes IZ_{k,m,q}(r,\phi)&=kZ_{k,m,q+1}(r,\phi),\\ \left(-\frac{\partial}{\partial r}-\frac{i}{r}\frac{\partial}{\partial\phi}-\frac{q}{r}\right)\otimes IZ_{k,m,q}(r,\phi)&=kZ_{k,m,q-1}(r,\phi).\end{aligned} \tag{6.26}$$

Note that in the limiting case of $\alpha=0$ there is neither any highest nor lowest state in the realization of para-supersymmetry, since there is no first order differential operator which can kill any of the Bessel functions. In this case we can have a para-supersymmetry of infinite order where the Bessel functions form its bases.

VII. SOLUTION OF THE DIRAC EQUATION ON THREE-DIMENSIONAL MANIFOLDS WITH A LOCAL CONSTANT CURVATURE

For nonvanishing M, the spatial part of the metric given in (2.2) describes a two-dimensional manifold with local constant curvature. In this section we try to solve the Dirac equation of a point mass $\mathcal{M}$ and charge e on the manifold with metric (2.2), in the presence of magnetic field with connection (2.6). The angular deficit due to the presence of a very heavy point mass M destroys the global constancy of the curvature, hence we lose both the degeneracy and para-supersymmetry. Therefore, we cannot solve the Dirac equation by the algebraic methods any longer. Thus we have to solve it by an ordinary method of solution of coupled first order differential equations. In a flat $(2+1)$-space–time one can represent the Dirac γ matrices as[4,5]

$$\gamma^0=\sigma_3, \quad \gamma^1=i\sigma_2, \quad \gamma^2=-i\sigma_1, \tag{7.1}$$

where γ^a, $a=0,1,2$ close the Clifford algebra as

$$\{\gamma^a,\gamma^b\}=2\eta^{ab}, \quad a,b=0,1,2. \tag{7.2}$$

The Minkowski metric η_{ab} has the following signature:

$$\eta_{ab}=\mathrm{diag}(+,-,-).$$

One can write the metric (2.2) in the following form:

$$ds^2=dt^2-\rho^2\left(\beta^{-2}d\theta^2+\frac{\sin^2\alpha\theta}{\alpha^2}d\phi^2\right), \tag{7.3}$$

where ρ^2 and β are defined as

$$\beta=1-GM,$$

$$\rho^2=\frac{(1-GM)^2}{2\lambda}.$$

Since λ is negative when $\alpha=i$ we have $\rho^2<0$, hence the metric (7.3) is Euclidean while for other values of α it is Minkowskian. We can choose the three-beins associated with the metric (7.3) as

$$e^a_\mu=\begin{pmatrix} 1 & 0 & 0 \\ 0 & \rho\dfrac{1}{\beta}\cos\phi & \rho\dfrac{1}{\beta}\sin\phi \\ 0 & -\rho\dfrac{\sin\alpha\theta}{\alpha}\sin\phi & \rho\dfrac{\sin\alpha\theta}{\alpha}\cos\phi \end{pmatrix}. \tag{7.4}$$

With the above choice of 3-beins we can compare our results in a special case with those of Ref. 4. The inverse of matrix (7.4) is

$$E^\mu_a=\begin{pmatrix} 1 & 0 & 0 \\ 0 & \dfrac{\beta}{\rho}\cos\phi & -\dfrac{1}{\rho}\dfrac{\alpha}{\sin\alpha\theta}\sin\phi \\ 0 & \dfrac{\beta}{\rho}\sin\phi & \dfrac{1}{\rho}\dfrac{\alpha}{\sin\alpha\theta}\cos\phi \end{pmatrix}. \tag{7.5}$$

According to Ref. 4, the Dirac equation in $(2+1)$-space–time for a fermion with mass $\mathcal{M}$ and electric charge e, in the presence of a gauge field with gauge connection A_μ is

$$\left[i\gamma^a E^\mu_a\left(\partial_\mu-\frac{i}{2}\omega^b_\mu\gamma_b+ieA_\mu\right)-\mathcal{M}\right]\Psi(t,\theta,\phi)=0, \tag{7.6}$$

where ω^a_μ is given by

$$\epsilon^{\kappa\mu\nu}\partial_\mu e^a_\nu=\epsilon^{\kappa\mu\nu}\epsilon^a_{bc}\omega^b_\mu e^c_\nu. \tag{7.7}$$

Hence

$$\omega_\mu^a = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ \beta\cos\alpha\theta - 1 & 0 & 0 \end{pmatrix}. \tag{7.8}$$

Therefore, the Dirac Eq. (7.6) can be written as

$$\left\{ i\left[\gamma^0\partial_t + \frac{1}{\rho}\gamma^\theta\left(\beta\partial_\theta - \frac{\alpha}{2\sin\alpha\theta}(1-\beta\cos\alpha\theta)\right) + \frac{1}{\rho}\frac{\alpha}{\sin\alpha\theta}\gamma^\phi(\partial_\phi + ieA_\phi)\right] - \mathcal{M}\right\}\Psi(t,\theta,\phi) = 0, \tag{7.9}$$

where γ^θ and γ^ϕ are defined as

$$\gamma^\theta = \cos\phi\,\gamma^1 + \sin\phi\,\gamma^2, \quad \gamma^\phi = -\sin\phi\,\gamma^{1+}\cos\phi\,\gamma^2.$$

In the limiting case of $\alpha \to 0$, the coordinate θ becomes similar to a radial coordinate r and the Dirac equation (7.9) in the absence of gauge field A_ϕ becomes exactly the Dirac equation associated with a massive fermion on a $(2+1)$-space–time dimension with conical spatial part.[4] Now let the Dirac spinor have the following time dependence

$$\Psi(t,\theta,\phi) = e^{-iEt}\Psi(\theta,\phi),$$

together with the following ϕ dependence:

$$\Psi(\theta,\phi) = \begin{pmatrix} e^{i(m-1/2)\phi} f_1(\theta) \\ e^{i(m+1/2)\phi} f_2(\theta) \end{pmatrix}, \tag{7.10}$$

where m is a half-integer number. One can show that the functions $f_1(\theta)$ and $f_2(\theta)$ satisfy the following differential equations:

$$\left\{ (1-z^2)\frac{d^2}{dz^2} - 2z\frac{d}{dz} - \frac{1}{1-z^2}\left(\left(\frac{m}{\beta}\right)^2 + \left(eg \pm \frac{1}{2}\right)^2 - 2\frac{m}{\beta}\left(eg \pm \frac{1}{2}\right)z\right)\right\} f_{1,2}(z)$$
$$= -\left(\frac{\rho^2}{\alpha^2\beta^2}(E^2 - \mathcal{M}^2) + \left(e^2g^2 - \frac{1}{4}\right)\right) f_{1,2}(z), \tag{7.11}$$

with z defined as

$$z = \cos\alpha\theta.$$

Now defining

$$\frac{\rho^2}{\alpha^2\beta^2}(E^2 - \mathcal{M}^2) + (e^2g^2 - \tfrac{1}{4}) = c(c+1),$$

with c as a real number, one can give the solutions of Eq. (7.11) in terms of hypergeometric functions.[17] In the limiting cases of $\alpha, e \to 0$ and $c \to \infty$ such that the product αc remains constant we obtain[17]

$$\lim_{\alpha\to 0, c\to\infty, e\to 0} f_{1,2}(\theta) = J_{|m/\beta \mp \frac{1}{2}|}(\alpha c r). \tag{7.12}$$

Writing the half-integer number m as

$$m = n + \tfrac{1}{2},$$

with n as an arbitrary integer the Dirac Eq. (7.9) takes the following solution in the above mentioned limit:

$$\Psi(t,r,\phi)=e^{-iEt}\exp i\left(n+\tfrac{1}{2}-\tfrac{1}{2}\sigma_3\right)\phi\begin{pmatrix} AJ_{|(1/\beta)(n+(1-\beta)/2)|}(\alpha c r) \\ BJ_{|(1/\beta)(n+(1-\beta)/2)+1|}(\alpha c r)\end{pmatrix}, \tag{7.13}$$

where A and B are arbitrary constants. The solution (7.13) is eigenstate of Dirac Hamiltonian associated with a fermion on $(2+1)$ spacetime with conical spatial part[4] with corresponding eigenvalues,

$$E=\pm\sqrt{\mathcal{M}^2+\frac{1}{\rho^2}\beta^2\alpha^2c^2}. \tag{7.14}$$

(Received 22 April 1998; accepted for publication 5 March 1999)

It is widely believed that Bell has proved there can be no consistent local extension of the quantum formalism. Against this, Angelidis has presented a hidden variable theory which, he claims, makes precisely the same predictions as the quantum formalism and which also satisfies locality. In this note, we argue that Angelidis' theory does not live up to its inventor's claims. © *1999 American Institute of Physics.* [S0022-2488(99)02607-9]

I. INTRODUCTION

Since the early days of quantum mechanics, a number of physicists have doubted whether quantum mechanics was a complete theory and wondered whether it was possible to extend the quantum formalism by adjoining hidden variables.[1] In 1952, Bohm answered this question in the affirmative[2] and in doing so refuted von Neumann's influential yet flawed proof that no such extension was possible.[3] However, Bohm's hidden variable theory has not won wide support partly because the theory is *nonlocal*: there is instantaneous action at a distance. Since there is an obvious problem reconciling such nonlocal theories with Relativity, hidden variable theories would look much more promising if they also satisfied locality. Accordingly, the question as to whether or not *local* hidden variable theories are possible assumes great significance. In 1964 Bell appeared to prove that this question had a negative answer:[4] He showed that any local hidden variables theory is incompatible with certain quantum mechanical predictions. Since these predictions have been borne out by the experiments of Aspect and others[5] the prospects for hidden variable theories have looked grim.

Angelidis disagrees.[6] He claims to have done to Bell what Bohm did to von Neumann: He has found a theory which is local and which generates a family of probability functions converging uniformly to the probability function generated by quantum mechanics. If this were true, then Angelidis' theory would be a counterexample to Bell's theorem and a promising path would once again be open to hidden variable theorists.

Unfortunately, Angelidis' theory fails to live up to his claims: As formulated, the theory does not make the same predictions as quantum mechanics, and while there is a natural extension of his theory which does make the same predictions, the extension is *not* local. Bell's Theorem stands.

II. ANGELIDIS' THEORY

The disagreement between Angelidis and Bell can most easily be understood by considering the following thought experiment, due originally to Einstein, Podolsky, and Rosen and later simplified by Bohm.[7] In this experiment, photons γ_1 and γ_2, created by the spontaneous annihilation decay of the nonfactorizable singlet state $|\gamma_1\gamma_2\rangle$, are emitted in opposite directions and arrive at polarizers P_1 and P_2, respectively. Behind each polarizer lies a photon detector. If α and β represent the angles of polarization of P_1 and P_2 then, according to quantum mechanics, the probability that both detectors register a photon is $1/2\cos^2(\alpha-\beta)$. Could a local hidden variable theory assign the same probabilities to this experiment as quantum mechanics?

To answer this, we need to know just what locality entails. First, let us fix our terminology. Let QF stand for the classical quantum formalism. Let $p^T{}_{12}(\alpha,\beta)$ be the probability that a theory

T assigns to both detectors registering a photon given that the angles of polarization are α and β. Let λ represent our hidden variable and Λ the set of values the hidden variable could take. Let $p^*{}_1(\lambda,\alpha)(p_2^*(\lambda,\beta))$ be the chance that the photon passes through $P_1(P_2)$ given that the system is in state λ and the angle of polarization is $\alpha(\beta)$. Finally, let $\rho(\lambda)$ be a weight function which represents the chance that the hidden variable takes the value λ.

Bell and Angelidis agree that any local theory should meet the following constraints:

$$\text{(L1)}\ p^T{}_{12}(\alpha,\beta)=\int_\Lambda \rho(\lambda)p^*{}_1(\lambda,\alpha)p^*{}_2(\lambda,\beta),$$

where the function $p^*{}_1$ must not depend upon the variable β and the function $p^*{}_2$ must not depend upon the variable α.

(L2) The specified range Λ of the variable λ must depend upon neither the variable α nor the variable β.

(L3) The function ρ must depend upon neither the variable α nor the variable β.[8]

Bell's claim is that no hidden variable theory which meets constraints (L1)–(L3) can yield the same statistical predictions as QF. According to Bell, the QF probability function $p^{\mathrm{QF}}{}_{12}$ cannot be represented, either precisely or arbitrarily closely in the form

$$\forall\alpha,\beta\left[1/2\cos^2(\alpha-\beta)=\int_\Lambda \rho(\lambda)p^*{}_1(\lambda,\alpha)p^*{}_2(\lambda,\beta)d\lambda.\right.$$

According to Angelidis, you can. Consider the theory T which consists of the following four postulates:

$$(\Pi_1)\quad p^*{}_1(\lambda,\alpha)=\cos^2(\lambda-\alpha),$$

$$(\Pi_2)\quad p^*{}_2(\lambda,\beta)=\cos^2(\lambda-\beta),$$

$$(\Pi_3)\quad \rho(\lambda,\mu):=1/2\left[\delta(\lambda-\mu)+\delta\left(\lambda-\mu+\frac{\pi}{2}\right)\right],$$

$$(\Pi_4)\quad \Lambda:=\{\lambda|-\infty<\lambda<+\infty\}.$$

One can think of the hidden variable λ as a common plane of polarization of the two photons emitted when the atom decays. The functions $p^*{}_i(\lambda,\gamma)$ represent the probabilities that a photon will be detected at wing i ($i=1$ or $i=2$) given that the photons are plane polarized in the λ direction *or* in the $\lambda-\frac{1}{2}\pi$ direction, and the polarizer P_i is set in the γ direction.

The third postulate is the ''conditional probability distribution for the spherically symmetric singlet state $|\gamma_1,\gamma_2\rangle$ to spontaneously disintegrate into two back to back photons plane-polarized in a *specific* but randomly chosen direction, given by a variable μ, out of *all* the equally likely choices of directions...''[9] δ is simply the Dirac delta function and the final postulate does nothing more than specify the range of λ.

T generates a family of functions $p^\mu{}_{12}$ such that

$$p^\mu{}_{12}(\alpha,\beta)=\int_\Lambda \rho(\lambda,\mu)p^*{}_1(\lambda,\alpha)p^*{}_2(\lambda,\beta)d\lambda=1/4[1+\cos 2(\mu-\alpha)\cos 2(\mu-\beta)],$$

and families of functions $p^\mu{}_1$ and $p^\mu{}_2$ such that

$$p^\mu{}_1=\int_\Lambda \rho(\lambda,\mu)p^*{}_1(\lambda,\alpha)d\lambda=\tfrac{1}{2},$$

$$p^{\mu}{}_2=\int_{\Lambda}\rho(\lambda,\mu)p^{*}{}_2(\lambda,\beta)d\lambda=\tfrac{1}{2}.$$

Finally, theory T entails the following important sentence (Σ):

$$(\Sigma)\quad (\forall\epsilon>0)(\exists\eta>0)(\forall\mu\in M)(\forall\alpha,\beta\in D)[(|\mu-\alpha|<\eta)\vee(|\mu-\beta|<\eta)\rightarrow|p^{\mu}{}_{12}(\alpha,\beta)-p_{12}(\alpha,\beta)|<\epsilon].$$

A logically equivalent way of writing this sentence is

$$(\Sigma)\quad (\forall\epsilon>0)(\exists\eta>0)(\forall\mu\in M)(\forall\alpha,\beta\in D)[(\mu\in S_{\alpha}\cup S_{\beta})\rightarrow|p^{\mu}{}_{12}(\alpha,\beta)-p_{12}(\alpha,\beta)|<\epsilon]$$

where $S_{\alpha}=\{\mu|-\eta+\alpha<\mu<\alpha+\eta\}$ and $S_{\beta}=\{\mu|-\eta+\beta<\mu<\beta+\eta\}$.

According to Angelidis, (Σ) ''expresses the *formal definition* of the uniform convergence of the family of functions $\{p^{\mu}{}_{12}|\mu\in M\}$ to the function $p^{\mathrm{QF}}{}_{12}$.''

Angelidis bases his physical interpretation of this theory around (Σ): ''For *any* chosen values of α and β, whenever a value of μ, characterising the random direction of the common plane of polarization of a single pair of back to back photons, *happens by pure chance* to belong to subset S_{α} or S_{β}, this single pair of back to back photons gets through polarisers P_1 and P_2 *and causes* a coincidence count with probability given by a *value* of the QF probability function $p^{\mathrm{QF}}{}_{12}$.'' [10]

So if μ is close to either α or β, then the chance of a coincidence count is close to the chance predicted by QF. But what if μ is not close to α or β? Well, in that case, (Σ) is still true just because the antecedant is false. However, we cannot infer that the ''single pair of back to back photons with $\mu_1\in M$ causes a coincidence count with probability $\frac{1}{2}\cos^2(\alpha_1-\beta_1)$. But the single pair of back to back photons with $\mu_1\in M$ may fall inside another subset, say, $S_{\alpha 4}$ or $S_{\beta 4}$ of the set M... so that it causes a coincidence count with a different probability $\frac{1}{2}\cos^2(\alpha_4-\beta_4)$.'' Angelidis concludes that ''The universal quantifiers $(\forall\mu\in M)$ and $(\forall\alpha,\beta\in D)$ occurring in the prefix of the sentence Σ take into account the *whole* array of such possibilities... so that the detectors accordingly register coincidence (and single) counts with the same probabilities as those given by QF for *each* and *every* pair of back to back photons emitted by the source.'' [11]

This ends the summary of Angelidis' theory. I shall now argue that the paper contains two flaws: (1) Angelidis' family of functions does *not* converge uniformly to the QF probability function; (2) Angelidis' theory does not predict the same probability count as those given by QF for each and every pair of back to back photons emitted by the source.

III. UNIFORM CONVERGENCE

Let us examine a little more closely Angelidis' notion of uniform convergence.

We know when a countable sequence of functions $\{q^n|n\in N\}$ defined on some domain D uniformly converges to q: they converge uniformly if, for any small number ϵ we please, there is an n such that any $q^{n'}$ (with n' larger than n) is within an ϵ of q for *any* value of q and $q^{n'}$. More formally:

$$(\forall\epsilon>0)(\exists n\in N)(\forall n'\in N)(n'>n\rightarrow\forall\alpha\beta\{|q^n(\alpha,\beta)-q(\alpha,\beta)|<\epsilon\}).$$

However, since Angelidis' theory deals with the uniform convergence of an *uncountable* family of functions, the definition must be extended to cover this case. So when does the set $\{f^{\mu}|\mu\in M\}$, with M uncountable, converge to g?

Angelidis extends the definition of uniform convergence by introducing the notion of a direction: N is a *direction* in X precisely when (a) N is a set of subsets of X partially ordered by reverse inclusion; (b) for any $x,y\in N$ there is a $z\in N$ with $z\subseteq x$ and $z\subseteq y$. Example: if X is the set of real numbers, then the set of basic neighborhoods containing the number 0 is a direction in X.[12]

Then Angelidis' definition of *uniform convergence* is as follows: Let D^2 be a subset of R^2, and let N be a direction in M. The family of functions $\{f^{\mu}|\mu\in M\}$ is said to converge uniformly to g on D^2 if for every $\epsilon>0$ there exists an $\eta>0$ (with η depending only on ϵ) corresponding to a basic neighborhood N_η in N such that for any μ in M and any x in D^2 *whenever* the values of μ are in N_η then $|f^\mu(x)-g(x)|<\epsilon$ holds. In symbols this becomes,

$$(\forall \epsilon>0)(\exists \eta>0)(\forall \mu \in M)(\forall x \in D^2)(\mu \in N_\eta \rightarrow |p^\mu{}_{12}(\alpha,\beta)-p_{12}(\alpha,\beta)|<\epsilon].$$

Now, it isn't at all clear what the N_η are supposed to be here. Angelidis tells us that they are basic neighborhoods (unlike Angelidis' N_x) and it is natural to think that they are basic neighborhoods of η. But then, why quantify over the variable η? And indeed, it would be perfectly all right to say that $\{f^\mu|\mu \in M\}$ uniformly converges to f^η iff, for any ϵ there is some basic neighborhood of η such that any μ in N_η, $|f^\mu(x)-f^\eta(x)|<\epsilon$. But here η is a *name* for an element of R—it is not a free variable which can be quantified over; nor is there any reason why η has to be greater than zero.

The ambiguity of the N_η allows Angelidis to make a serious mistake in his formal definition of uniform convergence. Angelidis claims that sentence (Σ) expresses the formal definition of uniform convergence. Recall that this sentence is

$$(\Sigma) \quad (\forall \epsilon>0)(\exists \eta>0)(\forall \mu \in M)(\forall \alpha,\beta \in D)[(|\mu-\alpha| < \eta)\vee(|\mu-\beta|<\eta)\rightarrow|p^\mu{}_{12}(\alpha,\beta)-p_{12}(\alpha,\beta)|<\epsilon].$$

.

In this case $N_\eta=\{\mu|\alpha-\eta<\mu<\alpha+\eta\}$. Again, this significantly differs from Angelidis' own definition of S_α on p. 1645, where $S_\alpha=\{\mu|\alpha-2\epsilon<\mu<\alpha+2\epsilon\}$. For N_η the subscript is an index of the distance from α that the μ in N_η are allowed to be. For S_α the subscript tells us which value of D the μ in S_α are close to.

Worse still, (Σ) does *not* express the notion of uniform convergence. For (Σ) says that if μ is close to α or is close to β then $p^\mu{}_{12}$ is close to p_{12} *at* (α,β). We require something more of uniform convergence—we require that if μ be close to α or β then $p^\mu{}_{12}$ be close to p_{12} for *all* values of these functions. To see how short of uniform convergence Angelidis' definition falls, consider the family of functions $\{q^\mu(\alpha):=\alpha-\mu\}$. Let $q(\alpha)$ be the zero function (so $q(\alpha)=0$ for all α). Now, by letting $\eta=\epsilon$ it is easy to see that

$$(\forall \epsilon>0)(\exists \eta>0)(\forall \mu \in R)(\forall \alpha \in R)(|\mu-\alpha|<\eta\rightarrow|q^\mu(\alpha)-q(\alpha)|<\epsilon).$$

So, if μ is close to α then q^μ is close to q *at* α. But there is no reasonable sense of *uniform convergence* on which the family of functions can be said to converge to the zero function. True, for any μ and for any x, if μ is sufficiently close to x then the function q^μ is sufficiently close to the function q *at the point* α—but this is a far cry from implying that the function q^μ is close to q for all values of α.

It is clear that a family of functions f^μ will *not* uniformly converge to the function g if there is some ϵ such that, for every μ there is some α,β with $|f^\mu(\alpha,\beta)-g(\alpha,\beta)|\geqslant\epsilon$. For in such a case, the family is always at least an ϵ away from g at some point $\langle\alpha,\beta\rangle$. In Angelidis' theory, we can find an ϵ such that ϵ equals 1/4. For, for any μ let $\alpha=\mu+45$ and let $\beta=\mu-45$. Now,

$$p^{\mathrm{QF}}{}_{12}(\alpha,\beta)=1/2\cos^2(\alpha-\beta)=1/2\cos^2(90)=0$$

while

$$p^\mu{}_{12}(\alpha,\beta)=1/4[1+\cos 2(\mu-\alpha)\cos 2(\mu-\beta)]=1/4[1+\cos 2(-45)\cos 2(45)]=1/4.$$

Since every one of Angelidis' functions is at least 1/4 away from the QF function at some point $\langle\alpha,\beta\rangle$, the set does not uniformly converge to the QF function.

IV. ON THE STATISTICAL PREDICTIONS OF ANGELIDIS' THEORY

In this section we argue that Angelidis' theory does not make the same statistical predictions for the EPRB experiment as the quantum formalism.

Suppose we fix an α and a β and repeat the EPRB experiment many times. Then what proportion of coincidence counts does Angelidis' theory say we should expect? There has been a suspicious change of notation in Angelidis' paper which makes this question surprisingly difficult to answer. $p^{\mathrm{QF}}{}_{12}(\alpha,\beta)$, is the chance that both detectors fire given the polarizers are set at angles α and β, respectively, according to QF. We would expect any rival theory to QF to yield a similar probability function. But Angelidis' theory actually yields a set of probability functions $p^{\mu}{}_{12}(\alpha,\beta)$. Moreover, the superscript μ no longer represents a *theory* (as it does in ''$p^{\mathrm{QF}}{}_{12}(\alpha,\beta)$''). Rather, it has come to represent the direction of polarization of the two photons.

This is odd. We expected any competitor of QF to produce a function $p^{T}{}_{12}(\alpha,\beta)$ as close to $p^{\mathrm{QF}}{}_{12}(\alpha,\beta)$ as is compatible with experimental error. But $p^{\mu}{}_{12}(\alpha,\beta)$ tells us only the chance of a coincidence *given* that the common plane of polarization of the two photons is μ. In order to work out the chance of a coincidence full stop, we need a weight function $\rho^{*}(\mu)$ which tells us how likely it is that the atom will decay into two photons plane polarized in the μ direction. The chance of a coincidence will then be equal to $\int_{\mu}\rho^{*}(\mu)p^{\mu}{}_{12}(\alpha,\beta)d\mu$. But Angelidis never tells us what this weight function is. Accordingly, it is hard to see how his theory manages to make any statistical predictions at all for the EPRB experiment he is attempting to model.

Angelidis seems to think that there is no need for him to specify this weight function. He seems to think that sentence (Σ) contains all the information we need to know. Recall that (Σ) says that, when hidden variable μ happens by pure chance to be close to α or β, then the two photons get through their respective polarizers with a probability close to $p^{\mathrm{QF}}{}_{12}(\alpha,\beta)$. But, as Angelidis admits, the conditional sentence (Σ) tells us nothing about what happens when μ is *not* close to either α or β. However, ''the single pair of back-to-back photons with $\mu\in M$ may fall inside another subset, say, $S_{\alpha 4}$ or $S_{\beta 4}$ of the set M, that is, $\mu\in S_{\alpha 4}$ OR $\mu\in S_{\beta 4}$, so that it causes a coincidence count with a different probability $\frac{1}{2}\cos^2(\alpha_4-\beta_4)$, determined by the consequent in Σ deduced from Σ (by *modus ponens*) under another value assignment.''[13] He goes on to add ''The universal quantifiers $(\forall\mu\in M)$ and $(\forall\alpha,\beta\in D)$ occurring in the prefix of the sentence Σ take into account the *whole* array of such possibilities so that the detectors accordingly register coincidence (and single counts) with the same probabilities as those given by QF for *each* and *every* pair of back to back photons emitted by the source.''

This is not so. Angelidis' explanation of how to interpret the physical significance of Σ is not complete. Standard quantum mechanics tells us that if a particular α and β are chosen so that α and β are at right angles then we will never, no matter how many times we repeat the experiment, register photons at both polarizers. Now, it is true that, on those particular occasions when the back to back photons are emitted so that their common plane of polarization μ is very close to either α or β, then the chance of a correlation will be very small. But what happens on those occasions where μ is not close to the settings of either of the polarizers? It is true, as Angelidis says, that there *exists* an α^{*} such that α^{*} is close to $\mu\alpha\nu\delta$ that, *had been the case* that the polarizer had been placed at angle α^{*} then the probabilities ascribed by T to a coincidence count are the same as that ascribed by quantum mechanics. But this does not tell us what we wanted to know! The situations where polarizer 1 is set at angle α^{*} is a *different* physical situation from the one that was under consideration. We need to know what happens when polarizers are at the particular settings α and β and the hidden variable μ is not close to either. Angelidis' advice that we choose an α^{*} close to μ simply dodges the question. In effect, Angelidis is only considering experiments where μ *is* close to one of the two polarizer settings. This information is not sufficient to tell us what proportion of coincidences we should expect if the polarizers are set at α and β and the experiment repeated many times.

Perhaps, though, Angelidis could augment his theory so that μ always *is* close to one of the two polarizer settings. Should Angelidis accept the postulate the value of the hidden variable μ is always close to the angle of one of the two polarizers, then his theory would both ascribe a probability to a coincidence count and, since $p^{\mu}{}_{12}(\alpha,\beta)$ approaches arbitrarily close to

$p^{QF}{}_{12}(\alpha,\beta)$, this probability can be made arbitrarily close to the probabilities ascribed by QF. The trouble with this proposal is that it straightforwardly violates the postulates of locality. In particular, it violates (L3), which effectively forbids that the angle of polarization of the two back to back photons be a function of the settings of the polarizers themselves.

V. CONCLUSION

The conclusion of this paper is clear: Angelidis has failed to provide us with a theory which is both local and which makes the same predictions as the standard quantum formalism. As such, Angelidis' theory simply leaves Bell's theorems untouched and the prospects for a local extension of the quantum formalism look as slim as ever.

[11] T. D. Angelidis, ''A local extension of the quantum formalism,'' J. Math. Phys. **34**, 1646 (1993).
[12] Angelidis makes a mess of the definition of N. He lets each N_x be the *set* of basic neighborhoods containing x, and then defines direction N as $\{N_x | x \in X\}$ thus making a direction a set of sets of subsets of X. This conflicts with his own use of the symbol N_x in the very next paragraph. Moreover, it is not true that for any two N_x and N_y there is an N_z which is contained in both. N is not even a directed set.

On one generalization for the projection matrices method in the *S*-matrix factorization problem

Dmitry I. Muravyev
Samara State Architecture and Civil Engineering Academy, Department of Physics, Molodogvardeyskaya 194, Samara 443001, Russia

(Received 20 August 1998; accepted for publication 22 January 1999)

A boundary value problem for a 2×2 *S*-matrix is solved by the method of projection matrices. The *S*-matrix is assumed to be diagnoalized by orthogonal matrix $U(k^2)=\Omega(k^2)/\sqrt{\det \Omega(k^2)}$, where matrix elements of $\Omega(k^2)$ are polynomials. The equation $\det \Omega(k^2)=0$ has roots of any order. The example is considered for the roots with order 2.
[S0022-2488(99)00605-2]

I. INTRODUCTION

The factorization of the *S*-matrix into Jost matrices can be considered as the Riemann–Hilbert boundary value problem for a half-plane. Its solution can be expressed in terms of an infinite integral in the scalar case.[1] The boundary value problem is reduced to a system of singular integral equations in the matrix case.[2] It does not seem to be the most optimal way for physical applications.

Projection matrices were used for factorization of the 2×2 rational *S*-matrix in Ref. 3. Thus, the boundary value problem was solved without using a system of the singular integral equations. It follows from Ref. 4 that projection matrices can be applied in other cases.

In Ref. 5 the boundary value problem was solved with the following assumption. The 2×2 *S*-matrix can be diagonalized by orthogonal matrix $U(k^2)$ on the real axis:

$$U(k^2)=\begin{pmatrix} \cos\varepsilon(k^2) & \sin\varepsilon(k^2) \\ -\sin\varepsilon(k^2) & \cos\varepsilon(k^2) \end{pmatrix}=\frac{1}{\sqrt{\det \Omega(k^2)}}\Omega(k^2), \tag{1}$$

$$\Omega(k^2)=\begin{pmatrix} Q_N(k^2) & P_M(k^2) \\ -P_M(k^2) & Q_N(k^2) \end{pmatrix}, \tag{2}$$

where $P_M(k^2)$ and $Q_N(k^2)$ are the polynomials in k of the degree $2M$ and $2N$, respectively, and $\operatorname{Im} P_M(k^2)$ and $\operatorname{Im} Q_N(k^2)=0$ at $\operatorname{Im} k=0$. In addition, all roots of the equation

$$\det \Omega(k^2)=Q_N^2(k^2)+P_M^2(k^2)=0 \tag{3}$$

have order 1. However, the formulas for the projection matrices are not obtained in the case when the roots have any other order.

It should be pointed out that the minimum order of roots can be set in advance. For example, if $\tan[\varepsilon(k^2)/j]$ is approximated by rational function, then the minimum order of any root of Eq. (3) is j, $j=1,2,...,j<+\infty$.

In this paper generalization of the results of Ref. 5 is suggested. The boundary value problem is solved by method of projection matrices in the case when the roots of Eq. (3) have any order.

The formulation of the problem is presented in Sec. II. The general form of the solution is discussed in Sec. III. Projection matrices are calculated in Sec. IV. The example for the roots with order 2 is considered in Sec. V. Section VI contains conclusions.

II. THE FORMULATION OF THE PROBLEM

Let us assume that the matrix $S(k)$ is known on the real k axis:

$$S(k)=U(k^2)S^{(0)}(k)U^T(k^2), \quad \operatorname{Im} k=0, \tag{4}$$

where $U(k^2)$ is defined by (1) and (2). Without generality loss one can suppose that the polynomials $P_M(k^2)$, and $Q_N(k^2)$ have no zeros simultaneously. The matrix $S^{(0)}(k)$ has the form

$$S^{(0)}(k)=\begin{pmatrix} \exp[i2\delta_1(k)] & 0 \\ 0 & \exp[i2\delta_2(k)] \end{pmatrix}, \quad \operatorname{Im} k=0,$$

where

$$\delta_j(\pm\infty)=0, \quad \delta_j(-k)=-\delta_j(k), \quad \operatorname{Im}\delta_j(k)=0, \quad j=1,2, \quad \operatorname{Im} k=0.$$

The Hölder condition should be assumed to be valid for the diagonal elements $[S^{(0)}(k)]_{jj}$ on the real axis:

$$|[S^{(0)}(k_1)]_{jj}-[S^{(0)}(k_2)]_{jj}|\leqslant A|k_1-k_2|^{\mu}, \quad A>0, \; 0<\mu\leqslant 1, \quad j=1,2.$$

Let there be two numerical sets as well:

$$\Delta_j=\{\kappa_j^{(i)}\}_{i=1}^{m_j}, \quad 0<\kappa_j^{(1)}<\kappa_j^{(2)}<\cdots<\kappa_j^{(m_j)}<+\infty, \quad m_j<+\infty, \quad j=1,2.$$

The number of the elements in the set Δ_j and behavior of $\delta_j(k)$ at the point $k=0$ are related according to the Levinson's theorem:

$$\delta_j(+0)=\begin{cases} 0, & \Delta_j=\varnothing, \\ \pi m_j, & \Delta_j\neq\varnothing, \end{cases} \quad j=1,2.$$

Here, the case when $0\in\Delta_1$ or $0\in\Delta_2$ is not considered because it is not significant to the matrix problem.

The piecewise analytical matrix $F(k)$ (i.e., when matrix elements are the piecewise analytical functions) has to be constructed in the complex k-plane. The boundary values of $F(k)$ must be continuous on the real axis and they meet the condition

$$F_+(k)=S^{-1}(k)F_-(k), \quad \operatorname{Im} k=0, \tag{5}$$

where $F_+(k)$ is analytical at $\operatorname{Im} k>0$, $F_-(k)$ at $\operatorname{Im} k<0$. In addition,

$$F_+^*(k)=F_+(-k^*)=F_-(k^*), \tag{6}$$

$$\det F_+(i\kappa_j^{(\beta)})=0, \quad \beta=1,2,...,m_j, \quad j=1,2, \tag{7}$$

$$\lim_{k\to\pm\infty} F_+(k)=E, \tag{8}$$

where E is the matrix unit.

III. THE GENERAL FORM OF THE SOLUTION.

Let us consider properties of the roots of Eq. (3). Since the polynomials $P_M(k^2)$ and $Q_N(k^2)$ depend on k^2 and $\operatorname{Im} P_M(k^2)$ and $\operatorname{Im} Q_N(k^2)=0$ at $\operatorname{Im} k=0$, the following statement takes place.

If $i\lambda_1$ is any root of Eq. (3), $-i\lambda_1$, $i\lambda_1^*$, $-i\lambda_1^*$ are the roots of this equation.

It is easy to prove that

$$\mathrm{Re}\,(i\lambda_1)\neq 0 \tag{9}$$

and

$$\mathrm{Im}\,(i\lambda_1)\neq 0. \tag{10}$$

If (9) or (10) is false, then $P_M^2(-\lambda_1^2)$, $Q_N^2(-\lambda_1^2)\geqslant 0$. The polynomials $P_M(k^2)$ and $Q_N(k^2)$ have no common zeros, thus

$$Q_N^2(-\lambda_1^2)+P_M^2(-\lambda_1^2)>0,$$

i.e., $i\lambda_1$ is not a root of Eq. (3). Consequently, conditions (9) and (10) are true for any root of Eq. (3).

Let γ_1 be an order of the roots $i\lambda_1$, $-i\lambda_1$, $i\lambda_1^*$, $-i\lambda_1^*$. Based on Eq. (3),

$$\sum_{j=1}^{\alpha}\gamma_j=L, \quad L=\max\{M,N\}, \tag{11}$$

and α is of particular importance for the solution of the boundary value problem.

For convenience Eq. (3) is rewritten as two equations:

$$Q_N(k^2)+iP_M(k^2)=0, \tag{12}$$

$$Q_N(k^2)-iP_M(k^2)=0.$$

For definiteness, let $i\lambda_j$ be the root of (12) and $\mathrm{Im}(i\lambda_j)>0$, $j=1,2,...,\alpha$

Let us find the solution of the boundary value problem in the form

$$F_+(k)=\Omega(k^2)G_+(k)W_1(k^2)\times\cdots\times W_\alpha(k^2)C, \tag{13}$$

$$C=[\lim_{k\to\pm\infty}k^{-2L}\Omega(k^2)]^{-1}, \tag{14}$$

$$W_j(k^2)=W_j^{(1)}(k^2)\times\cdots\times W_j^{(\gamma_j)}(k^2), \quad j=1,2,...\alpha, \tag{15}$$

$$W_j^{(i)}(k^2)=P_j^{(i)}\frac{1}{k^2+\lambda_j^2}+(E-P_j^{(i)})\frac{1}{k^2+\lambda_j^{*2}}, \quad i=1,2,...,\gamma_j, \quad j=1,2,...,\alpha, \tag{16}$$

$$(P_j^{(i)})^2=P_j^{(i)}, \quad P_j^{(i)}\neq E,0, \ \ i=1,2,...,\gamma_j, \quad j=1,2,...,\alpha, \tag{17}$$

$$(P_j^{(i)})^*=E-P_j^{(i)}, \quad i=1,2,...,\gamma_j, \quad j=1,2,...,\alpha. \tag{18}$$

$G_+(k)$ is the diagonal matrix. It satisfies to conditions

$$G_+(k)=(S^{(0)}(k))^{-1}G_-(k), \quad \mathrm{Im}\,k=0, \tag{19}$$

$$G_+^*(k)=G_+(-k^*)=G_-(k^*), \tag{20}$$

$$\det G_+(i\kappa_j^{(\beta)})=0, \quad \beta=1,2,...,m_j, \quad j=1,2, \tag{21}$$

$$\lim_{k\to\pm\infty}G_+(k)=E. \tag{22}$$

The matrix elements $[G_+(k)]_{jj}$ can be calculated with the formulas of the scalar boundary value problem:

$$[G_+(k)]_{jj}=\Pi_\pm(j,k)\exp\left(\frac{1}{i2\pi}\int_{-\infty}^{+\infty}\ln[\exp(-i2\delta_j(k'))\Pi_-^2(j,k')]\frac{dk'}{k'-k\mp i0}\right),\quad j=1,2, \tag{23}$$

$$\Pi_\pm(j,k)=\begin{cases}1, & \Delta_j=\varnothing,\\ \prod_{\beta=1}^{m_j}(k\mp i\kappa_j^{(\beta)})/(k\pm i\kappa_j^{(\beta)}), & \Delta_j\neq\varnothing,\end{cases}\quad j=1,2. \tag{24}$$

Let us show that $F_+(k)$ in the form (13) satisfies to conditions (5)–(8). Really, taking into account (1), (4), and (19) it is easy to check (5). To convince oneself that (6) is correct, we must use (2), (14)–(16), (18), and (20). Some steps are required for the proof of (7). From (17),

$$\det P_j^{(i)}=0,\quad \mathrm{Sp}\,P_j^{(i)}=1,\quad i=1,2,\ldots,\gamma_j,\quad j=1,2,\ldots,\alpha. \tag{25}$$

Furthermore, from (16) and (25)

$$\det W_j^{(i)}(k^2)=(k^2+\lambda_j^2)^{-1}(k^2+\lambda_j^{*2})^{-1},\quad i=1,2,\ldots,\gamma_j,\quad j=1,2,\ldots,\alpha. \tag{26}$$

Property (7) is true since (2), (15), (16), (21), and (26) are valid. Condition (8) is evident because of (2), (11), (14)–(16), and (22).

The explicit form of the projection matrices $P_j^{(\beta)}$ must be chosen in such a way that $F_+(k)$ will have no poles in the points $k=i\lambda_j$, $i\lambda_j^*$, $\beta=1,2,\ldots,\gamma_j$, $j=1,2,\ldots,\alpha$.

IV. THE CONSTRUCTION OF THE PROJECTION MATRICES

Let us prove that

$$\Omega(k^2)\left[P_0\prod_{j=1}^{\alpha}\frac{1}{(k^2+\lambda_j^2)^{\gamma_j}}+(E-P_0)\prod_{j=1}^{\alpha}\frac{1}{(k^2+\lambda_j^{*2})^{\gamma_j}}\right]C=E, \tag{27}$$

where

$$P_0=\frac{1}{2}\begin{pmatrix}1 & -i\\ i & 1\end{pmatrix},\quad P_0^2=P_0,\quad P_0^*=E-P_0. \tag{28}$$

Since $i\lambda_j$ and $-i\lambda_j$, $j=1,2,\ldots,\alpha$, are the roots of Eq. (12) and taking into account (2), (14), and (28)

$$\Omega(k^2)P_0\prod_{j=1}^{\alpha}\frac{1}{(k^2+\lambda_j^2)^{\gamma_j}}C=[Q_N(k^2)+iP_M(k^2)]P_0\prod_{j=1}^{\alpha}\frac{1}{(k^2+\lambda_j^2)^{\gamma_j}}C=P_0. \tag{29}$$

The complex conjugation of (29) at $\mathrm{Im}\,k=0$ produces

$$\Omega(k^2)(E-P_0)\prod_{j=1}^{\alpha}\frac{1}{(k^2+\lambda_j^{*2})^{\gamma_j}}C=[Q_N(k^2)-iP_M(k^2)](E-P_0)\prod_{j=1}^{\alpha}\frac{1}{(k^2+\lambda_j^{*2})^{\gamma_j}}C=E-P_0. \tag{30}$$

Thus, (27) results from (29) and (30). Formula (27) gives an important presentation of the matrix $\Omega(k^2)$:

$$\Omega(k^2)=C^{-1}\left[P_0\prod_{j=1}^{\alpha}(k^2+\lambda_j^2)^{\gamma_j}+(E-P_0)\prod_{j=1}^{\alpha}(k^2+\lambda_j^{*2})^{\gamma_j}\right]. \tag{31}$$

Let us fix four roots $i\lambda_1$, $-i\lambda_1$, $i\lambda_1^*$, and $-i\lambda_1^*$. Their order is γ_1. Let us consider the matrix

$$X_{1+}^{(1)}(k)=\Omega(k^2)A_1^{(1)}(k), \tag{32}$$

$$A_1^{(1)}(k)=G_+(k)W_1^{(1)}(k^2)=G_+(k)\left[P_1^{(1)}\frac{1}{k^2+\lambda_1^2}+(E-P_1^{(1)})\frac{1}{k^2+\lambda_1^{*2}}\right], \tag{33}$$

where the projection matrix $P_1^{(1)}$ is computed from the formulas

$$P_1^{(1)}=\frac{1}{\mathrm{Sp}\,Y_1^{(1)}}Y_1^{(1)}, \tag{34}$$

$$Y_1^{(1)}=[G_+(i\lambda_1)]^{-1}P_0[G_+(i\lambda_1)]^*. \tag{35}$$

Formulas (34) and (35) are in complete accordance with condition (18).

Let us show that

$$(E-P_0)G_+(i\lambda_1)P_1^{(1)}=0. \tag{36}$$

Insertion of (34) and (35) into (36) proves the validity of this equation. The complex conjugation of (36) in terms of (18), (20), and (28) results in

$$P_0G_+(i\lambda_1^*)(E-P_1^{(1)})=0. \tag{37}$$

It will be obvious from (31)–(33), (36), and (37) that matrix $X_{1+}^{(1)}(k)$ has no poles at the points $k=i\lambda_1$, $i\lambda_1^*$. Thus $X_{1+}^{(1)}(k)$ is analytical at $\mathrm{Im}\,k>0$ except the cases when $k=\infty$ (in a general case).

Let us rewrite the matrix $X_{1+}^{(1)}(k)$ in the form

$$X_{1+}^{(1)}(k)=C^{-1}\left[P_0(k^2+\lambda_1^2)^{\gamma_1-1}\prod_{j=2}^{\alpha}(k^2+\lambda_1^2)^{\gamma_1}+(E-P_0)(k^2+\lambda_1^{*2})^{\gamma_1-1}\prod_{j=2}^{\alpha}(k^2+\lambda_1^{*2})^{\gamma_1}\right]Z_{1+}^{(1)}\times(k), \tag{38}$$

$$Z_{1+}^{(1)}(k)=[P_0(k^2+\lambda_1^2)+(E-P_0)(k^2+\lambda_1^{*2})]A_1^{(1)}(k), \tag{39}$$

where (31) should be taken into account. According to (33), (36), (37), and (39), the matrix $Z_{1+}^{(1)}(k)$ has no poles at the points $k=i\lambda_1$, $i\lambda_1^*$. In addition, it follows from (21), (26), (33), and (39) that

$$\det Z_{1+}^{(1)}(i\lambda_1)=\det G_+(i\lambda_1)\neq 0. \tag{40}$$

For all projection matrices $P_j^{(i)}$, $i=1,2,...,\gamma_j$, $j=1,2,...,\alpha$, the formulas can be written now based on (31)–(40).

Let us assume that the matrix $X_{n+}^{(j)}(k)$ is computed:

$$X_{n+}^{(j)}(k)=\Omega(k^2)A_n^{(j)}(k),\quad j=0,1,2,...,\gamma_n-1,$$

where

$$A_n^{(j)}(k)=G_+(k)W_1(k^2)\times\cdots\times W_{n-1}(k^2)\times W_n^{(1)}(k^2)\times\cdots\times W_n^{(j)}(k^2),\quad j=0,1,2,...,\gamma_n-1, \tag{41}$$

$$A_n^{(\gamma_n)}(k)\equiv A_{n+1}^{(0)}(k),\quad n<\alpha,\quad A_1^{(0)}(k)\equiv G_+(k),\quad W_0(k^2)\equiv E,\quad W_n^{(0)}(k^2)\equiv E. \tag{42}$$

The projection matrix $P_n^{(j+1)}$ can be computed from the formulas

$$P_n^{(j+1)}=\frac{1}{\mathrm{Sp}\,Y_n^{(j+1)}}Y_n^{(j+1)},\quad j=0,1,2,...,\gamma_n-1, \tag{43}$$

$$Y_n^{(j+1)}=[Z_{n+}^{(j)}(i\lambda_n)]^{-1}P_0[Z_{n+}^{(j)}(i\lambda_n)]^*,\quad j=0,1,2,...,\gamma_n-1, \tag{44}$$

$$Z_{n+}^{(j)}(k)=[P_0(k^2+\lambda_n^2)^j+(E-P_0)(k^2+\lambda_n^{*2})^j]A_n^{(j)}(k),\quad j=0,1,2,...,\gamma_n-1. \tag{45}$$

It should be pointed out that

$$\det Z_{n+}^{(j)}(i\lambda_j)\neq 0,\quad j=0,1,2,...,\gamma_n-1.$$

So far as $F_+(k)$ can be written in the form

$$F_+(k)=X_{a+}^{(\gamma_a)}(k)C,$$

the formulas (13)–(16), (23), (24), and (41)–(45) give the solution of the boundary value problem given in Sec. II.

V. THE EXAMPLE

Let us assume that

$$S^{(0)}(k)=\begin{pmatrix}\dfrac{(k+i\kappa)(k+i\varphi)}{(k-i\kappa)(k-i\varphi)} & 0\\ 0 & 1\end{pmatrix},\quad \varphi,\kappa>0,\quad \tan\frac{\varepsilon(k^2)}{2}=\frac{k^2}{ak^2+b},\quad \mathrm{Im}\,a,\mathrm{Im}\,b=0.$$

The function $\tan\varepsilon(k^2)$ has the form

$$\tan\varepsilon(k^2)=P_2(k^2)/Q_2(k^2),\quad P_2(k^2)=2k^2(ak^2+b),\quad Q_2(k^2)=(ak^2+b)^2-k^4.$$

Equation (12) is rewritten as

$$[k^2(a+i)+b]^2=0.$$

Let $i\lambda_1$ and $-i\lambda_1$ be the roots of this equation and $\mathrm{Im}(i\lambda_1)>0$. The order of $i\lambda_1$ is $\gamma_1=2$. Since $\gamma_1=L=\max\{2,2\}=2$, two projection matrices have to be constructed [see (11), (13), (15), and (16)].

The solution of the boundary value problem has the form

$$F_+(k)=\Omega(k^2)G_+(k)\left[P_1^{(1)}\frac{1}{k^2+\lambda_1^2}+(E-P_1^{(1)})\frac{1}{k^2+\lambda_1^{*2}}\right]\left[P_1^{(2)}\frac{1}{k^2+\lambda_1^2}+(E-P_1^{(2)})\frac{1}{k^2+\lambda_1^{*2}}\right]C,$$

$$G_+(k)=\begin{pmatrix}\dfrac{k-i\kappa}{k+i\varphi} & 0\\ 0 & 1\end{pmatrix},\quad C=\frac{1}{1+4a^2}\begin{pmatrix}-1 & -2a\\ 2a & -1\end{pmatrix}.$$

The matrix $P_1^{(1)}$ is computed from (34) and (35):

$$P_1^{(1)}=\frac{1}{(\lambda_1+\varphi)(\lambda_1^*-\kappa)+(\lambda_1^*+\varphi)(\lambda_1-\kappa)}\begin{pmatrix}(\lambda_1+\varphi)(\lambda_1^*-\kappa) & -i(\lambda_1+\varphi)(\lambda_1^*-\varphi)\\ i(\lambda_1-\kappa)(\lambda_1^*-\kappa) & (\lambda_1^*+\varphi)(\lambda_1-\kappa)\end{pmatrix}.$$

According to (41), (42), and (45):

$$Z_{1+}^{(1)}(k)=[P_0(k^2+\lambda_1^2)+(E-P_0)(k^2+\lambda_1^{*2})]G_+(k)\left[P_1^{(1)}\frac{1}{k^2+\lambda_1^2}+(E-P_1^{(1)})\frac{1}{k^2+\lambda_1^{*2}}\right].$$

L'Hospital's rule is convenient to be used to compute $Z_{1+}^{(1)}(i\lambda_1)$:

$$Z_{1+}^{(1)}(i\lambda_1)=P_0B+H,$$

$$B=G_+(i\lambda_1)P_1^{(1)},\quad H=\frac{\lambda_1^{*2}-\lambda_1^2}{i2\lambda_1}(E-P_0)\frac{d}{dk}G_+(k)\bigg|_{k=i\lambda_1}P_1^{(1)}+(E-P_0)G_+(i\lambda_1)(E-P_1^{(1)}).$$

The matrix H has the structure

$$H=\frac{1}{4\lambda_1(\lambda_1+\varphi)^2}\begin{pmatrix} h_{11} & ih_{22}\\ -ih_{11} & h_{22}\end{pmatrix},$$

and its elements can be computed using formulas

$$\begin{aligned}h_{11}&=-(\lambda_1^{*2}-\lambda_1^2)(\varphi+\kappa)[P_1^{(1)}]_{11}+2\lambda_1(\lambda_1+\varphi)([P_1^{(1)}]_{11}^*(\lambda_1-\kappa)-i[P_1^{(1)}]_{21}(\lambda_1+\varphi))\\ &=-(\lambda_1^{*2}-\lambda_1^2)(\varphi+\kappa)[P_1^{(1)}]_{11}+2\lambda_1(\lambda_1+\varphi)(\lambda_1-\kappa),\end{aligned}$$

$$\begin{aligned}h_{22}&=i(\lambda_1^{*2}-\lambda_1^2)(\varphi+\kappa)[P_1^{(1)}]_{12}+2\lambda_1(\lambda_1+\varphi)([P_1^{(1)}]_{11}(\lambda_1+\varphi)+i[P_1^{(1)}]_{12}(\lambda_1-\kappa))\\ &=i(\lambda_1^{*2}-\lambda_1^2)(\varphi+\kappa)[P_1^{(1)}]_{12}+2\lambda_1(\lambda_1+\varphi)^2.\end{aligned}$$

The matrix (P_0B) does not impact on the final result. However, it is required to compute $[Z_{1+}^{(1)}\times(i\lambda_1)]^{-1}$. The result is [see (43) and (44)]

$$P_1^{(2)}=\frac{1}{h_{11}h_{22}^*+h_{11}^*h_{22}}\begin{pmatrix} h_{22}h_{11}^* & -ih_{22}h_{22}^*\\ ih_{11}h_{11}^* & h_{22}^*h_{11}\end{pmatrix}.$$

VI. CONCLUSION

The discussion above showed that the projection matrices method appears to perform well in the case when the roots of Eq. (3) have any order. This is especially important because the minimum order of the roots can be set in advance. In addition, the class of the unitary matrices for which the boundary value problem can be solved without using the system of the singular integral equations is extended.

(Received 7 December 1998; accepted for publication 2 February 1999)

We discuss the classical mechanics on the Grassmannian and the disc modeled on the ideal $\mathcal{L}^{(2,\infty)}$. We apply methods of geometric quantization to these systems. Their relation to a flat symplectic space is also discussed. © *1999 American Institute of Physics.* [S0022-2488(99)01808-3]

I. INTRODUCTION

We will analyze geometric quantization of a classical system which has as its phase space the infinite-dimensional Grassmannian or the disc modeled on the ideal $\mathcal{L}^{(2,\infty)}(\mathcal{H}_+,\mathcal{H}_-)$. There are two motivations for our work. The classical dynamics studied should correspond to the large-N_c limit of a quantum system which requires a logarithmic renormalization. Its quantization should give us an understanding of this system in the Schrödinger picture. This picture has some advantages over the scattering matrix, as is well known in the physics literature. The second is to study and understand infinite-dimensional systems; their quantization should lead to some interesting mathematical questions. A good example is typical two-dimensional field theory models, which do not require a renormalization but only a normal ordering.[1,2] It will be interesting to develop the necessary tools for a more complicated systems, and perhaps give a more precise meaning to renormalized field theories. We should add that, in this article, we do not study any particular Hamiltonian or associated delicate domain problems. In some sense we have only made an attempt to study part of the kinematics. The full understanding will require studying a specific model.

II. THE DISC AND THE GRASSMANNIAN

Our approach is inspired from the discussion of the Grassmannian in the book by Pressley and Segal[3] and closely follows our previous work.[2] We will extend some of our previous ideas to this case.

Let $\mathcal{H}$ be a separable infinite-dimensional complex Hilbert space; $\mathcal{H}_-$ and $\mathcal{H}_+$ are two orthogonal isomorphic subspaces with $\mathcal{H}=\mathcal{H}_-\oplus\mathcal{H}_+$. Physically, one can think of these two spaces as the decomposition of the one-particle Hilbert space into positive and negative energy states.

Define the disc $D_{1+}(\mathcal{H}_-,\mathcal{H}_+)$ to be the set of all operators $Z:\mathcal{H}_+\rightarrow\mathcal{H}_-$ such that $1-Z^\dagger Z>0$ and Z is in $\mathcal{L}^{(2,\infty)}(\mathcal{H}_+,\mathcal{H}_-)$. We refer to the Appendix for the ideals $\mathcal{L}^{(2,\infty)}$ and $\mathcal{L}^{(1,\infty)}$.

Since the space $\mathcal{L}^{(2,\infty)}(\mathcal{H}_+,\mathcal{H}_-)$ is contractible, the set of Z for the disc can be taken as a coordinate system. It is an infinite-dimensional complex manifold, modeled on a Banach space.

In a similar spirit, we define the Grassmannian to be the set of closed subspaces W of $\mathcal{H}$, such that the projection $\mathrm{Pr}_+:W\rightarrow\mathcal{H}_+$ is Fredholm and the projection $\mathrm{Pr}_-:W\rightarrow\mathcal{H}_-$ is in $\mathcal{L}^{(2,\infty)}(W,\mathcal{H}_-)$. We first define natural group actions on these spaces. These group actions are used to prove that these are manifolds. (Generalizations of this kind have been pointed out in Ref. 3, and explored in Ref. 4 for the ideals $\mathcal{L}^p$. See also Ref. 5.)

We introduce the following pseudo-unitary group which is a subset of the invertible operators from $\mathcal{H}$ to $\mathcal{H}$:

[a]After March 1999.

$$\mathrm{U}_{1+}(\mathcal{H}_-,\mathcal{H}_+)=\{g|g\epsilon g^\dagger=\epsilon,\quad g^{-1}\ \text{exists and}\ [\epsilon,g]\in\mathcal{L}^{(2,\infty)}\}. \tag{1}$$

Here $\epsilon=\begin{pmatrix}-1&0\\0&1\end{pmatrix}$ with respect to the decomposition $\mathcal{H}=\mathcal{H}_-\oplus\mathcal{H}_+$. If we decompose the matrix into block forms,

$$g=\begin{pmatrix}a&b\\c&d\end{pmatrix}, \tag{2}$$

we have $a:\mathcal{H}_-\to\mathcal{H}_-$, $b:\mathcal{H}_+\to\mathcal{H}_-$, $c:\mathcal{H}_-\to\mathcal{H}_+$, and $d:\mathcal{H}_+\to\mathcal{H}_+$. Then, the off-diagonal elements b and c are in $\mathcal{L}^{(2,\infty)}$ and the diagonal elements a and d are bounded operators. In fact, they are invertible operators, since their spectrum does not contain zero. The conditions on the off-diagonal elements imply some control over how much $\mathcal{H}_+$ and $\mathcal{H}_-$ mix with each others.

We define an action of $\mathrm{U}_{1+}(\mathcal{H}_-,\mathcal{H}_+)$ on the disc D_{1+}:

$$Z\mapsto g\circ Z=(aZ+b)(cZ+d)^{-1}. \tag{3}$$

The condition $1-Z^\dagger Z>0$ implies that $cZ+d$ is invertible and bounded. Since the space of $\mathcal{L}^{(2,\infty)}$ is a two-sided ideal, $(aZ+b)(cZ+d)^{-1}$ is still in $\mathcal{L}^{(2,\infty)}$. Thus our action is well defined.

The stability subgroup of the point $Z=0$ is $\mathrm{U}(\mathcal{H}_-)\times\mathrm{U}(\mathcal{H}_+)$,$\mathrm{U}(\mathcal{H}_\pm)$ being the group of *all* unitary operators on $\mathcal{H}_\pm$. Moreover, any point Z is the image of 0 under the action of the group, $g\circ(Z=0)=bd^{-1}$. [Note that bd^{-1} is in $\mathcal{L}^{(2,\infty)}$ and $d^\dagger d=1+b^\dagger b$ implies that $1-(bd^{-1})^\dagger bd^{-1}>0$.] We therefore see that D_{1+} is a homogeneous space and given by the quotient

$$\mathrm{D}_{1+}=\mathrm{U}_{1+}(\mathcal{H}_-,\mathcal{H}_+)/\mathrm{U}(\mathcal{H}_-)\times\mathrm{U}(\mathcal{H}_+). \tag{4}$$

It is possible to view Gr_{1+} as a coset space of complex Lie groups. Incidentally this will define a complex structure on Gr_{1+} which will be useful for geometric quantization. Define a subset of the general linear group

$$\mathrm{GL}_{1+}=\{\gamma|\gamma\ \text{is invertible};\quad[\epsilon,\gamma]\in\mathcal{L}^{(2,\infty)}\}. \tag{5}$$

When we decompose g into 2×2 submatrices $\gamma_{12},\gamma_{21}\in\mathcal{L}^{(2,\infty)}$ while γ_{11} and γ_{22} are Fredholm. This is a Banach–Lie group modeled on $\mathcal{L}^{(2,\infty)}(\mathcal{H}_+,\mathcal{H}_-)$. We take the space of all endomorphisms on $\mathcal{H}$ with the same condition on the off-diagonals, $\mathrm{End}_{\mathcal{L}^{(2,\infty)}}(\mathcal{H})$, and give it the natural topology under the norm $\|A\|_+=\|[\epsilon,A]_+\|+\|[\epsilon,A]\|_{\mathcal{L}^{(2,\infty)}}$. The invertible elements of $\mathrm{End}_{\mathcal{L}^{(2,\infty)}}(\mathcal{H})$ are a group, open under this topology, and it has a tangent space which comes from the natural imbedding. It is straightforward to define the "Borel subgroup"

$$\mathrm{B}_{1+}=\left\{\beta=\begin{pmatrix}\beta_{11}&\beta_{12}\\0&\beta_{22}\end{pmatrix}\middle|\beta\in\mathrm{GL}_{1+}\right\}. \tag{6}$$

This is the stability group of $\mathcal{H}_-$ under the action of GL_{1+} on $\mathcal{H}$. Thus the Grassmannian (which is the orbit of $\mathcal{H}_-$) is the complex coset space,

$$\mathrm{Gr}_{1+}=\mathrm{GL}_{1+}/\mathrm{B}_{1+}. \tag{7}$$

It will be convenient to use the following operators for the points on D_{1+},$\Phi:\mathcal{H}\to\mathcal{H}$,

$$\Phi=1-2\begin{pmatrix}(1-ZZ^\dagger)^{-1}&-(1-ZZ^\dagger)^{-1}Z\\Z^\dagger(1-ZZ^\dagger)^{-1}&-Z^\dagger(1-ZZ^\dagger)^{-1}Z\end{pmatrix}. \tag{8}$$

One can see that under the transformation $Z\mapsto g\circ Z,\Phi\mapsto g^{-1}\Phi g$. Here Φ satisfies $\epsilon\Phi^\dagger\epsilon=\Phi$ and $\Phi^2=1$. Also, $\Phi-\epsilon\in\mathcal{L}^{(2,\infty)}$, so that as an operator Φ does not differ from ϵ in an arbitrary way.

We can equivalently define the Grassmannian to be the following set of operators on $\mathcal{H}$:

$$\mathrm{Gr}_{1+}=\{\Phi|\Phi=\Phi^{\dagger};\Phi^{2}=1;\Phi-\epsilon\in\mathcal{L}^{(2,\infty)}\}. \tag{9}$$

Since $\Phi^2=1$ and it is self-adjoint, it can be diagonalized by the action of

$$\mathrm{U}_{1+}(\mathcal{H})=\{g|g^{\dagger}g=1;[\epsilon,g]\in\mathcal{L}^{(2,\infty)}\}. \tag{10}$$

Let us split g into 2×2 blocks:

$$g=\begin{pmatrix} g_{11} & g_{12}\\ g_{21} & g_{22}\end{pmatrix}. \tag{11}$$

The convergence condition on $[\epsilon,g]$ is the statement that the off-diagonal blocks g_{12} and g_{21} are in $\mathcal{L}^{(2,\infty)}$. It then follows that g_{11} and g_{22} are Fredholm operators. The Fredholm index of g_{11} is opposite to that of g_{22}; this integer is a homotopy invariant of g and we can decompose $\mathrm{U}_{1+}(\mathcal{H})$ into connected components labeled by this integer.

We can see that $\mathrm{U}_{1+}(\mathcal{H})$ is a real form of this group. $\mathrm{GL}_{1+}(\mathcal{H})$ is the topological product of $\mathrm{U}_{1+}(\mathcal{H})$ and the contractible space of positive definite elements by using the fact that $\mathrm{End}_{\mathcal{L}^{(2,\infty)}}(\mathcal{H})$ has the square root of positive elements well defined and continuous under its topology. (We can show that U_{1+} is a deformation retract of GL_{1+}, similar to the finite-dimensional case.)

With the projection $g\rightarrow g\epsilon g^{\dagger}$, we see that Gr_{1+} is a homogeneous space of $\mathrm{U}_{1+}(\mathcal{H})$:

$$\mathrm{Gr}_{1+}=\mathrm{U}_{1+}(\mathcal{H})/\mathrm{U}(\mathcal{H}_{-})\times\mathrm{U}(\mathcal{H}_{+}). \tag{12}$$

Any $\Phi\in\mathrm{Gr}_{1+}$ can be diagonalized by an element of $\mathrm{U}_{1+}(\mathcal{H})$, $\Phi=g\epsilon g^{\dagger}$; this g is ambiguous up to right multiplication by an element that commutes with ϵ. Such elements form the subgroup

$$\mathrm{U}(\mathcal{H}_{-})\times\mathrm{U}(\mathcal{H}_{+})=\left\{h\middle|h=\begin{pmatrix} h_{11} & 0\\ 0 & h_{22}\end{pmatrix};\quad h_{11}^{\dagger}h_{11}=1=h_{22}^{\dagger}h_{22}\right\}. \tag{13}$$

Each point $\Phi\in\mathrm{Gr}_{1+}$ corresponds to a subspace of $\mathcal{H}$: the eigenspace of Φ with eigenvalue -1. Thus Gr_{1+} consists of all subspaces obtained from $\mathcal{H}_{-}$ by an action of U_{1+}.

To define the tangent space at each point we can use the action of the group on itself. For our purposes it is better to take the group action on the left. Since the stability subgroup of ϵ is $\mathrm{U}(\mathcal{H}_{-})\times\mathrm{U}(\mathcal{H}_{+})$, in both cases the tangent space is isomorphic to the corresponding off-diagonal algebras. In each case this is equivalent to $\mathcal{L}^{(2,\infty)}(\mathcal{H}_{+},\mathcal{H}_{-})$ as a vector space, due to the Hermiticity (or pseudo-Hermiticity) condition.

Any given $u\in\mathrm{U}_{1+}$ defines a vector at a given point, and a vector field can be expanded in terms of the local set of vectors. The action of a vector field on Φ is given by $V_{u(\Phi)}(\Phi)=[u(\Phi),\Phi]=g[g^{-1}u(\Phi)g,\epsilon]g^{-1}$. The tangent space has a set of vectors which are given by the completion of the finite rank operators inside $\mathcal{L}^{(2,\infty)}$. This is also an ideal inside $\mathcal{B}=B(\mathcal{H})$ and is a separable Banach space under the same norm as $\mathcal{L}^{(2,\infty)}$; we will denote this set by $(\mathcal{L}^{(2,\infty)})^{(0)}$. The tangent space has a noncanonical decomposition at each point which is isomorphic to $(\mathcal{L}^{(2,\infty)})^{(0)}+\mathcal{L}^{(2,\infty)}/(\mathcal{L}^{(2,\infty)})^{(0)}$; the second part is a "transversal piece." As we will see, this quotient will be important for the dynamical system we have in mind.

We introduce the cotangent space as a formal expression $d\Phi$ via its contraction with the vector field at a given point; $d\Phi(V_{u(\Phi)})=V_{u(\Phi)}(\Phi)$. (The dual space requires more care in infinite dimensions. We can think of the norm dual of $\mathcal{L}^{(2,\infty)}$, yet this space does not have a simple characterization. If we assume that the tangent space is, in fact, the norm dual of the cotangent space, we have a simple description of the cotangent space. We refer to Gohberg and Krein for the details.[6] In this article we will leave the question of the dual open, and use one-forms only when we have an explicit formula.)

We would like to think of the D_{1+} and Gr_{1+} as classical phase spaces. To do this we need to introduce a Poisson bracket. We will search for a symplectic form on this space. It is tempting to generalize the finite-dimensional formula to this case. If we write down $\Omega=(i/4)\mathrm{Tr}\Phi d\Phi\wedge d\Phi$ we see that the trace, in general, does not exist. However, one can see that the divergence is logarithmic, in fact the formal expression $\Phi d\Phi\wedge d\Phi$ belongs to $\mathcal{L}^{(1,\infty)}$. Hence we can replace the ordinary trace by the Dixmier trace. The Dixmier trace is used in noncommutative geometry; for a masterful presentation of its properties we refer to the book and lecture notes by Connes.[7]

Each choice of the trace will give another symplectic form. They all agree on the ''measurable'' part of the ideal $\mathcal{L}^{(1,\infty)}$. Since the ''measurable'' elements do not form an ideal, we cannot assume that the symplectic form is independent of the choice of the limit point.

Another important point is to remember that the Dixmier trace vanishes on the ideal generated by the completion of finite rank operators, $(\mathcal{L}^{(1,\infty)})^{(0)}$. In the applications one expects that the operators we have to consider are pseudo-differential operators on manifolds. The physically relevant group of transformations is modeled on pseudo-differential operators which belong to the specific ideals that we have defined. In the case of classical pseudo-differential operators, the Dixmier trace is uniquely defined; it is equal to the Wodzicki residue of the pseudo-differential operator, as shown by Connes.[8] An interesting application of a new trace to the class of elliptic pseudodifferential operators is given in Ref. 9, and to chiral anomaly in Ref. 10. An interesting discussion of the central extensions and Schwinger terms are given in Ref. 11.

In this article we will consider the general case, and show the dependence of the symplectic form to this limiting process ω explicitly on our definition of the symplectic form:

$$\Omega_\omega=\frac{i}{4}\mathrm{Tr}_\omega\,\Phi d\Phi\wedge d\Phi. \tag{14}$$

The existence of such a trace is the reason for our choice $\mathcal{L}^{(2,\infty)}$. One can check that the above form is closed; it is not so obvious that it is nondegenerate. In fact, it vanishes whenever the result of the contractions with the vectors at a given point is in the completion of the finite rank operators inside $\mathcal{L}^{(2,\infty)},(\mathcal{L}^{(2,\infty)})^{(0)}\neq\mathcal{L}^{(2,\infty)}$. This completion is a separable Banach space, and an ideal inside $\mathcal{B}$ as well, whereas $\mathcal{L}^{(2,\infty)}$ is a nonseparable Banach space.

The above form is invariant under the action of $\mathrm{U}_{1+}(\mathcal{H})$ for the Gr_{1+} and invariant under the action of $\mathrm{U}_{1+}(\mathcal{H}_-,\mathcal{H}_+)$ for the D_{1+}. The formal expression is defined as

$$i_{V_u}i_{V_v}\Omega_\omega=\frac{i}{8}\mathrm{Tr}_\omega\,\Phi[[u,\Phi],[v,\Phi]]. \tag{15}$$

One can show the invariance using this expression immediately (see below). Thus, Gr_{1+} and D_{1+} are both homogeneous manifolds with an invariant closed two-form similar to the finite-dimensional case.

Unfortunately, this form is degenerate; it vanishes on the part of the tangent space which corresponds to $(\mathcal{L}^{(2,\infty)})^{(0)}$. (This means that we throw away a large part of the symplectic manifold. Perhaps a physically more appropriate choice is to use a combination, which keeps the information about the ''small'' directions. Although this can be done we will focus on the above symplectic form.) To see this let us calculate the contraction of Ω_ω at a point Φ, with a vector field which belongs to the part $(\mathcal{L}^{(2,\infty)})^{(0)}$. Let us assume that this vector is generated by u acting from the left. The condition for the vector of be in $(\mathcal{L}^{(2,\infty)})^{(0)}$ is simply $[\epsilon,g^{-1}ug]\in(\mathcal{L}^{(2,\infty)})^{(0)}$ at the point $\Phi=g\epsilon g^{-1}$:

$$i_{V_u}\Omega_\omega=\frac{i}{8}\mathrm{Tr}_\omega\,\Phi[[u,\Phi],d\Phi]. \tag{16}$$

We will show that the contraction of this one-form with an arbitrary vector on the tangent space at the same point Φ is zero, hence the form is zero. Any such vector on the tangent is again generated by the left action with a Lie algebra element v,

$$i_{V_v} i_{V_u} \Omega_\omega = \frac{i}{8} \mathrm{Tr}_\omega\, \epsilon [[\epsilon, g^{-1} u g], [\epsilon, g^{-1} v g]]. \tag{17}$$

Using

$$\left[\epsilon, \begin{pmatrix} \mathcal{B} & \mathcal{L}^{(2,\infty)} \\ \mathcal{L}^{(2,\infty)} & \mathcal{B} \end{pmatrix} \right] = \begin{pmatrix} 0 & \mathcal{L}^{(2,\infty)} \\ \mathcal{L}^{(2,\infty)} & 0 \end{pmatrix}$$

and similarly for the other part, we have

$$\begin{pmatrix} 0 & \mathcal{L}^{(2,\infty)} \\ \mathcal{L}^{(2,\infty)} & 0 \end{pmatrix} \begin{pmatrix} 0 & (\mathcal{L}^{(2,\infty)})^{(0)} \\ (\mathcal{L}^{(2,\infty)})^{(0)} & 0 \end{pmatrix} = \begin{pmatrix} (\mathcal{L}^{(1,\infty)})^{(0)} & 0 \\ 0 & (\mathcal{L}^{(1,\infty)})^{(0)} \end{pmatrix}, \tag{18}$$

where we use $(\mathcal{L}^{(2,\infty)})^{(0)} \mathcal{L}^{(2,\infty)} \in (\mathcal{L}^{(1,\infty)})^{(0)}$ (see the Appendix for a proof). The Dixmier trace vanishes on $(\mathcal{L}^{(1,\infty)})^{(0)}$ and this shows that the form is zero. In general, since the tangent space has the direction given by $(\mathcal{L}^{(2,\infty)})^{(0)}$, the cotangent space has one-forms which do not vanish on them. If Λ is a form such that $\Lambda(V_u) \neq 0$, then $\Lambda = i_Y \Omega_\omega$ has no solution for the vector Y. If we assume that the de Rham theory makes sense on these spaces, since D_{1+} is contractible, and $\pi_1(\mathrm{Gr}_{1+}) = 0$, we would expect that there is a function f such that $\Lambda = df$, and this will show that one cannot obtain a Hamiltonian vector field for any given function f in general. Nevertheless, as we will see, for the relevant part of the space, that is for ''large'' motions, directions which belong to $\mathcal{L}^{(2,\infty)}/(\mathcal{L}^{(2,\infty)})^{(0)}$, the form is nondegenerate. This will allow us to define classical dynamics for certain systems.

Before we continue, let us point out an important observation. For clarity let us concentrate on Gr_{1+}. There is an interesting leaf of Gr_{1+} which corresponds to the orbit of ϵ under the following subgroup:

$$\mathrm{U}_{1+}^{(0)} = \begin{pmatrix} \mathcal{B} & (\mathcal{L}^{(2,\infty)})^{(0)} \\ (\mathcal{L}^{(2,\infty)})^{(0)} & \mathcal{B} \end{pmatrix}. \tag{19}$$

We denote this orbit by $\mathrm{Gr}_{1+}^{(0)}$. Since the connected components are still labeled by the integers, each connected component of Gr_{1+} has the connected component of $\mathrm{Gr}_{1+}^{(0)}$ inside. If we take $\mathrm{Gr}_{1+}^{(0)}$'s own tangent space, generated by $\mathrm{U}_{1+}^{(0)}$, the symplectic form vanishes on this orbit using the fact that $(\mathcal{L}^{(2,\infty)})^{(0)} \mathcal{L}^{(2,\infty)} \in (\mathcal{L}^{(1,\infty)})^{(0)}$ (see the Appendix for a proof). The same remarks apply to the disc D_{1+}, and we spare the reader the details.

Since the group action preserves the two from Ω_ω the Lie derivative along the direction of any vector field generated by the group action gives us zero. This raises the possibility of finding the moment maps which would generate the infinitesimal action of $\mathrm{U}_{1+}(\mathcal{H}_-, \mathcal{H}_+)$ and $\mathrm{U}_{1+}(\mathcal{H})$, respectively. We can start with the finite-dimensional answer; one can check that to avoid the divergence the finite-dimensional answer has to be modified as $-\mathrm{Tr}_\omega^\epsilon u(\Phi - \epsilon)$, where u is a Hermitian matrix which is in the Lie algebra of $\mathrm{U}_+(\mathcal{H})$ for the Gr_{1+} and a pseudo-Hermitian ($u^\dagger = \epsilon u \epsilon$) operator which belongs to $\mathrm{U}_{1+}(\mathcal{H}_-, \mathcal{H}_-)$ for D_{1+}. We use a conditionally convergent trace for the variable $\Phi - \epsilon$ if we think of the group acting from the left. To see that the above expression makes sense consider $u \in \left(\begin{smallmatrix} \mathcal{B} & \mathcal{L}^{(2,\infty)} \\ \mathcal{L}^{(2,\infty)} & \mathcal{B} \end{smallmatrix}\right)$, and $\Phi - \epsilon \in \left(\begin{smallmatrix} \mathcal{L}^{(1,\infty)} & \mathcal{L}^{(2,\infty)} \\ \mathcal{L}^{(2,\infty)} & \mathcal{L}^{(1,\infty)} \end{smallmatrix}\right)$. (Here $\mathcal{B}$ is the space of bounded operators). As a result, $u(\Phi - \epsilon) \in \left(\begin{smallmatrix} \mathcal{L}^{(1,\infty)} & \mathcal{L}^{(2,\infty)} \\ \mathcal{L}^{(2,\infty)} & \mathcal{L}^{(1,\infty)} \end{smallmatrix}\right)$. Let us define $M = \Phi - \epsilon$. Formally the equation for the group action is satisfied,

$$-\mathrm{Tr}_\omega^\epsilon\, u\, d\Phi = \Omega_\omega(V_u, \ ), \quad V_u(\Phi) = [u, \Phi], \tag{20}$$

but we must be careful since if $g^{-1} u g \in (\mathcal{L}^{(2,\infty)})^{(0)}$, the right-hand side vanishes as we have shown. The only way to satisfy this equation is to show that whenever the right-hand side vanishes, the left vanishes as well. This can be checked as follows:

$$df_u(V_v)=\mathrm{Tr}^{\epsilon}_{\omega}\, u[v,\Phi]=\mathrm{Tr}^{\epsilon}_{\omega}\, g^{-1}ug[\epsilon,g^{-1}vg], \tag{21}$$

for any $v\in \mathrm{U}_{1+}$. By the same argument as above, we see that the resulting expression inside the trace is of class $(\mathcal{L}^{(1,\infty)})^{(0)}$. Hence the trace is also zero.

We notice that the form corresponding to the moment map $-\mathrm{Tr}^{\epsilon}_{\omega}(uM^{(0)})$ for any $u\in \mathrm{U}_{1+}$ when contracted with the elements of the tangent space of $D_1^{(0)}$ or $Gr_{1+}^{(0)}$ also gives zero. This is in some sense the orbit one can neglect; we can think of it as the null orbit. This shows that we cannot take the separable part in our definition of the group U_{1+}, denoted as $(\mathrm{U}_{1+})^{(0)}$, if we use the Dixmier trace. In a recent preprint,[12] it is argued that there is no positive trace on the ideal $(\mathcal{L}^{(2,\infty)})^{(0)}$. This implies that a similar construction cannot be achieved for the group $(\mathrm{U}_{1+})^{(0)}$.

However, it is not enough to show that the moment functions satisfy a consistent equation. Normally in the Hamiltonian formalism we are given a function and asked to find the vector field generated by this function. Our discussion shows that this vector field at every point is only determined in the equivalence class $\mathcal{L}^{(2,\infty)}/(\mathcal{L}^{(2,\infty)})^{(0)}$. It is easy to see that if we take, instead of u, a vector generated by $u+v$ such that $g^{-1}vg\in(\mathcal{L}^{(2,\infty)})^{(0)}$, $-df_u=i/8\,\mathrm{Tr}_{\omega}\Phi[[u+v,\Phi],d\Phi]$ $=i/8\,\mathrm{Tr}_{\omega}\Phi[[u,\Phi],d\Phi]+i/8\,\mathrm{Tr}_{\omega}[[v,\Phi],d\Phi]$ for the last piece is zero by the previous argument. This implies that the moment functions do not have unique vector fields; they generate the motions in the ''transversal direction'' $\mathcal{L}^{(2,\infty)}/(\mathcal{L}^{(2,\infty)})^{(0)}$ with an undetermined piece in $(\mathcal{L}^{(2,\infty)})^{(0)}$. Let us look at the infinitesimal part of this evolution for two different choices of the vector field in the equivalence class, $\Delta\Phi=t[u,\Phi]$ and $\Delta'\Phi=t[u',\Phi]$. The difference of these two infinitesimal evolutions is given by $\Delta\Phi-\Delta'\Phi=[u-u',\Phi]=g[g^{-1}(u-u')g,\epsilon]g^{-1}$. Since the ambiguity is a result of the difference, which satisfies $[g^{-1}(u-u')g,\epsilon]\in(\mathcal{L}^{(2,\infty)})^{(0)}$, this term is in the orbit $D_{1+}^{(0)}$, or in the same connected component of $\mathrm{Gr}_{1+}^{(0)}$. Thus the difference of the infinitesimal evolutions can be conjugated to the orbit $\mathrm{D}_{1+}^{(0)}$, or to the same connected component of $\mathrm{Gr}_{1+}^{(0)}$. This implies that the relevant space for the classical dynamics is not the original quotient we look for, but a smaller one, given by $\mathrm{U}_{1+}/\mathrm{U}_{1+}^{(0)}$. In fact as we will see later on, this reduction has an interesting consequence. But, for the moment, we will continue to use the ''unreduced phase space.''

To talk about classical evolution, we will make the proposal that this type of classical systems is defined through an equivalence relation. We will assume that two dynamical evolutions are equivalent if they could be conjugated to the ''null'' orbit, $\mathrm{D}_{1+}^{(0)}$, for D_{1+}, and to the same connected component of $\mathrm{Gr}_{1+}^{(0)}$, for Gr_{1+}. Another way to think about this is that the dynamics in the ''small'' directions cannot be determined. The moment functions we consider only determine the evolution under equivalence.

This feature will affect the dynamics generated by Hamiltonians of more complicated functions. The generic Hamiltonians we have in mind are quadratic functions of the variable $M=\Phi-\epsilon$ plus a moment map. We think of the moment map as the free part of the Hamiltonian since it generates the group action up to an equivalence, and the quadratic piece as an ''interaction.''

Formally we can write the Hamiltonians as

$$h=i\,\mathrm{Tr}^{\epsilon}_{\omega}\, uM+\mathrm{Tr}^{\epsilon}_{\omega}\,\hat{K}(M)M, \tag{22}$$

where $\hat{K}$ is a linear operator which acts on the variable M. If we specify a basis, it can be expressed as $(\hat{K}(M)M)^k_p=\Sigma_{ijk}K^{ik}_{jl}M^j_iM^l_p$. The summability properties of the kernel K^{ik}_{jl} should be such that the resulting operator is in the ideal $\mathcal{L}^{(1,\infty)}$. For example, this can be achieved if the map $\hat{K}$ produces an operator in the group U_{1+}. Notice that it is important to use the Dixmier trace again. As we mentioned in the moment maps, since the symplectic form Ω_{ω} vanishes upon contraction with elements of the tangent space in the ''small'' directions, the interaction Hamiltonian must have the same property. As one can check, this form of the Hamiltonian, when differentiated, gives a form which vanishes on the same subspace. This will impose certain conditions on the choice of kernels. Interactions which are ''too weak'' will not affect the equations of motion.

Let us give a typical interaction Hamiltonian. We can take two moment functions and take their products

$$\sum_{ij} K^{ij}\,\mathrm{Tr}_\omega^\epsilon\, u_i M\ \mathrm{Tr}_\omega^\epsilon\, u_j M. \tag{23}$$

If the sum is over a finite number of terms, then clearly this is a well-defined expression. In general, one should be able to choose K^{ij} such that the above expression is finite. For these Hamiltonians, one can directly calculate the equations of motion by using the Poisson bracket relations among the moment functions only. As we will see later on, they also have a simpler description in the quantum case.

A word of caution should be said here. Typically, the Hamiltonians are more singular than the symplectic form, and they require further renormalizations. This implies a choice of domain for the Hamiltonian. This should restrict the accessible regions of the phase space, or the true phase space of the theory, and it may change the formulation of the problem drastically. In real physical systems, we expect these problems to modify the precise formulation of the field theory. In this work, we do not discuss this more difficult problem. In some sense this is part of the kinematics, although interactions may even change this.

There will always be vector fields generating the equations of motion up to equivalence. In infinite dimensions determination of the integral curves and their completeness are highly nontrivial issues; the answer depends on the Hamiltonian as well. This is the classical version of the unitarity condition in quantum mechanics.

From general principles we expect that the Poisson brackets of the moment functions will provide a realization of the corresponding Lie algebra possibly with a central extension. We can calculate the Poisson bracket of two moment functions using a formal manipulation and it gives us

$$\{f_u, f_v\} = f_{-i[u,v]} - i\,\mathrm{Tr}_\omega^\epsilon[\epsilon, u]v. \tag{24}$$

This is a central extension of the full group, indexed by the choice of limit process ω. (Note that there is no ambiguity in this relation since the right-hand side is the same for equivalent choices of the vector fields.) One can explicitly check that $c_\omega(u,v) = \mathrm{Tr}_\omega^\epsilon[\epsilon, u]v$ satisfies $c_\omega(u,v) = -c_\omega(v,u)$ and the cocycle condition, $c_\omega(u,[v,w]) + c_\omega(v,[w,u]) + c_\omega(w,[u,v]) = 0$. Since the central term vanishes on the ideal $(\mathcal{L}^{(1,\infty)})^{(0)}$ it will not be there when u or $v \in \mathrm{U}_{1+}^{(0)}$. The actual computation should be done with care, due to infinite dimensionality. One can see that the both sides of the equation after explicit calculation give the same result, hence they are identical. We will leave the details to the reader.

This gives us a symplectic realization of the Lie algebra of $\mathrm{U}_{1+}(\mathcal{H})$ for Gr_{1+} and $\mathrm{U}_{1+}(\mathcal{H}_-, \mathcal{H}_+)$ for D_{1+} except a central term. Since the calculation of the both sides are actually zero whenever $g^{-1}ug$ or $g^{-1}vg \in \mathrm{U}_{1+}^{(0)}$, this expression should be thought of as a realization of the ''large'' part of the Lie algebra. [It is more natural to look into the spaces which are modeled on the quotients $\mathcal{L}^{(2,\infty)}/(\mathcal{L}^{(2,\infty)})^{(0)}$. Since $(\mathcal{L}^{(2,\infty)})^{(0)}$ is closed, the quotient is well defined. Later on we will consider this point of view.] Let us consider this central extension for the pseudodifferential operators (pointed out to me by Mickelsson); then we have $\mathrm{Tr}_\omega[\epsilon,u]v = \mathrm{Res}([\epsilon,u]v)$. We recall that the residue is actually defined for all pseudodifferential operators and it satisfies $\mathrm{Res}[A,B] = 0$.[13,14] This implies that, in fact $\mathrm{Tr}_\omega[\epsilon,u]v = \partial\phi(u,v)$, for $\phi(u) = \mathrm{Res}(\epsilon u)$, hence the central extension is trivial.

Because of the infinite dimensionality, an attempt to remove the central term, in the general case, will result in a divergent expression. This gives us the Lie algebra of the nontrivial central extension of U_{1+} corresponding to ω. We expect that these extensions are not equivalent, in general, for different choices of ω, but they all agree on the subset modeled on the ''measureable'' elements—this is not a subalgebra of $\underline{U_{1+}}$, so one cannot reduce it to this case.

III. QUANTIZATION

We continue to think of classical mechanics in geometric terms.[15,16] Let us assume that the phase space, Γ, is a smooth manifold. If we have a Poisson structure on the algebra of smooth functions $C^\infty(\Gamma)$, we can introduce classical dynamics. Quantization of this classical system is given by a representation of the Poisson algebra of smooth functions by self-adjoint operators on a Hilbert space. This is an overambitious program; in general, there is no way to find such a representation. The difficulties and various methods have been well explained in the literature.[17–19] In this article we will follow our point of view in Ref. 2. We will find a representation of the Poisson algebra of moment functions. Any composite function, which is related to the product of two moment maps, can be quantized by giving an ordering rule. We will not attempt to establish this idea in the present article.

Before we proceed further, we need to make a digression and introduce a generalized ''determinant.'' It does not satisfy all the properties of a determinant. As we will see, to think of it as a determinant simplifies the calculations. Let us define $\det_\omega(1+A)$ for $A\in\mathcal{L}^{(1,\infty)}$ as

$$\det_\omega(1+A)=\exp(\mathrm{Tr}_\omega(A)). \tag{25}$$

[One way to motivate this definition is the following. Let us take the determiant formula, $\log\det(1+A)=\mathrm{Tr}\log(1+A)$. We replace the trace by the Dixmier trace, and define $\log\det_\omega(1+A)=:\mathrm{Tr}_\omega\log(1+A)=\mathrm{Tr}_\omega(A-\frac{1}{2}A^2+\frac{1}{3}A^3-\cdots)=\mathrm{Tr}_\omega(A)$ since all the higher terms are in $\mathcal{L}^1$ and the Dixmier trace vanishes on them. This gives the above formula again.] One can see that it satisfies the multiplicative property of the determinants,

$$\det_\omega((1+A)(1+B))=\det_\omega(1+A)\det_\omega(1+B), \tag{26}$$

due to $\mathcal{L}^{(1,\infty)}\mathcal{L}^{(1,\infty)}\in\mathcal{L}^1$ and Tr_ω vanishes on the trace class operators $\mathcal{L}^1$. An interesting property is that $\det_\omega$ never vanishes.

We will use this to provide a representation of the Borel subroup on **C**, and attempt to follow the geometric quantization program.

We will introduce an *ad hoc* representation, which comes from the geometric quantization performed in Ref. 2, of the Lie algebra of the group $U_{1+}(\mathcal{H}_-,\mathcal{H}_+)$ on the space of ''holomorphic functions'' on D_{1+}:

$$\hat{f}_{-u}\Psi(Z)=-i\hbar\left[\mathcal{L}_{V_u}\Psi(Z)-\frac{1}{\hbar}\mathrm{Tr}_\omega(\gamma Z)\Psi(Z)\right], \tag{27}$$

where $u\in \underline{U}_1(\mathcal{H}_-,\mathcal{H}_+)$, and $V_u=V_u^Z\partial_Z+V_u^{Z^\dagger}\partial_{Z^\dagger}$ is the formal vector field generated by the action of $-u$. (The author is not aware of a well-established definition of holomorphicity for infinite dimensions. We assume that the algebraic operations on the coordinate Z after the application of a dual element, if it is finite, provides a holomorphic function. This will be used for the Grassmannian as well. It is easier to define the Lie derivative directly, by using the action of the Lie algebra on the disc. We define this as

$$\mathcal{L}_{V_u}\Psi(Z)=\lim_{t\to 0}\frac{\Psi(Z+t(\alpha Z+\beta-Z\gamma Z-Z\delta))-\Psi(Z)}{t}, \tag{28}$$

where

$$u=\begin{pmatrix}\alpha & \beta\\ \gamma & \delta\end{pmatrix} \tag{29}$$

is the decomposition of u into block form; $\alpha^\dagger=-\alpha$, $\beta^\dagger=\gamma$, and $\delta^\dagger=-\delta$; and, further, $\gamma,\beta\in\mathcal{L}^{(2,\infty)}$. We notice that this differs from the finite-dimensional answer by a constant term, which is infinite in this case. The changes introduced in the functions are all ‘‘holomorphic,’’ so the action of the operators corresponding to the moment functions preserve the ‘‘holomorphicity condition.’’ In order to show that this is the correct representation, we need to prove that the commutation relations are satisfied acting on these set of functions.

Let us check that the commutation relations will give us a realization of the Poisson bracket relations satisfied by the moment maps:

$$[\hat{f}_{-u_1},\hat{f}_{-u_2}]\Psi(Z)=i\hbar\hat{f}_{[u_1,u_2]}\Psi(Z)+i\hbar\,\mathrm{Tr}_\omega^\epsilon([\epsilon,u_1]u_2)\Psi(Z). \tag{30}$$

A calculation shows that

$$[\hat{f}_{-u_1},\hat{f}_{-u_2}]\Psi(Z)=\hbar^2(\mathcal{L}_{u_1}\mathcal{L}_{u_2}-\mathcal{L}_{u_2}\mathcal{L}_{u_1})\Psi(Z)+\hbar[(\mathcal{L}_{u1}\,\mathrm{Tr}_\omega\,\gamma_2 Z)-(\mathcal{L}_{u_2}\,\mathrm{Tr}_\omega\,\gamma_1 Z)]\Psi(Z). \tag{31}$$

For simplicity we use $\mathcal{L}_u$ instead of $\mathcal{L}_{V_u}$. This is equal to

$$[\hat{f}_{-u_1},\hat{f}_{-u_2}]\Psi(Z)=\hbar^2\mathcal{L}_{[u_1,u_2]}\Psi(Z)+\hbar\,\mathrm{Tr}_\omega\{\gamma([u_1,u_2])Z\}\Psi(Z)+\hbar\,\mathrm{Tr}_\omega(\gamma_1\beta_2-\gamma_2\beta_1)\Psi(Z). \tag{32}$$

The last term, which is a constant multiple, can be rewritten as $\mathrm{Tr}_\omega^\epsilon[\epsilon,u_1]u_2$. Hence we see that it is a representation of the Poisson bracket relations (24).

This representation can, in fact, be integrated to a representation of the group action on the space of holomorphic functions:

$$\rho_\omega(g^{-1})\Psi=\mathrm{det}_\omega^{-1/\hbar}(d^{-1}cZ+1)\Psi((aZ+b)(cZ+d)^{-1}). \tag{33}$$

These representations are labeled by ω, the choice of limit point, and $\hbar$. Since the determinant never vanishes and is actually given by an exponential, $\hbar$ is any real number. (This point of view on quantization for finite-dimensional homogeneous spaces appeared in Ref. 20.) To justify this, we will compute the infinitesimal form of the representation and show that it is given by the operators corresponding to the moment maps. We write explicitly

$$\rho(g^{-1})\Psi(Z)=e^{-(1/\hbar)\mathrm{Tr}_\omega(d^{-1}cZ)}\Psi(g\circ Z) \tag{34}$$

and evaluate

$$\lim_{t\to 0}\left\{\frac{\rho_\omega(1+tu)-\rho_\omega(1)}{t}\right\}\Psi(Z)=\hbar\left[\mathcal{L}_{V_u}-\frac{1}{\hbar}\mathrm{Tr}_\omega(\gamma Z)\right]\Psi(Z). \tag{35}$$

So, we see that the infinitesimal form is given by the moment map operators. We still have to check that this is a representation:

$$\rho_\omega(g_1)\rho_\omega(g_2)\Psi(Z)=c_\omega(g_1,g_2)\rho_\omega(g_1g_2)\Psi(Z), \tag{36}$$

where $c_\omega(g_1,g_2)$ is a central term, which satisfies $c_\omega(g_1g_2,g_3)c_\omega(g_1,g_2)=c_\omega(g_1,g_2g_3)c_\omega(g_2,g_3)$. Since the disc is topologically trivial, the central extension can be described by specifying a function from the Cartesian product of the group to **C**. An explicit calculation, which is given in the Appendix, shows that the group property is satisfied with a central term,

$$c_\omega(g_1,g_2)=\mathrm{det}_\omega^{1/\hbar}[(d_1d_2)^{-1}c_1b_2+1]=\exp\left(\frac{1}{\hbar}\mathrm{Tr}_\omega[(d_1d_2)^{-1}c_1b_2]\right). \tag{37}$$

However, there is still one more point we need to consider. Recall that the orbit of ϵ corresponding to the subgroup $U_{1+}^{(0)}, D_{1+}^{(0)}$, when considered as a submanifold with its own tangent space, has no dynamics under our choice of the symplectic form. Hence the Poisson algebra of moment maps restricted on this submanifold is trivially true, being zero on both sides, whereas the representation space we choose, when restricted to the subspace $D_{1+}^{(0)}$, provides a nontrivial representation of the Poisson algebra of moment maps. This can be rectified by selecting a subspace of holomorphic functions which remain constant on the orbit $D_{1+}^{(0)}$. As a result, we define the quantum Hilbert space to be

$$\mathcal{H}_Q=\{\Psi(Z)|\Psi(Z) \quad \text{holomorphic on } \mathrm{D}_{1+} \quad \text{and} \quad \Psi|_{\mathrm{D}_{1+}^{(0)}}=\text{constant}\}. \tag{38}$$

This condition is consistent with the assumption that the dynamics along the directions $(\mathcal{L}^{(2,\infty)})^{(0)}$ is unimportant. If we consider ϵ to be the ''vacuum'' configuration, its orbit under $\mathrm{U}_{1+}^{(0)}$ is equivalent to this ''vacuum'' configuration.

For this choice of the quantum Hilbert space, we will exhibit a class of wave functions. We are unable to prove that these are the only possible ones. Since the wave functions should be constant on the orbit $\mathrm{D}_{1+}^{(0)}$, it suggests the use of the Dixmier trace again.

We can compose polynomials in the variable Z. The interesting thing is to note that we can go up to quadratic terms only inside the Dixmier trace. For any choice of $A_i \in \mathcal{L}^{(2,\infty)}$, and any two $B_j, B_k \in B(\mathcal{H})$, we can form

$$\mathrm{Tr}_\omega(A_i Z) \;\text{ and }\; \mathrm{Tr}_\omega(B_j Z B_k Z). \tag{39}$$

Using the generalized Hölder inequality,[21] we have the inequalities

$$|\mathrm{Tr}_\omega(A_i Z)| \le \|A_i\|_{\mathcal{L}^{(2,\infty)}}\|Z\|_{\mathcal{L}^{(2,\infty)}} \quad \text{and} \quad |\mathrm{Tr}_\omega(B_k Z B_j Z)| \le \|B_k\|\|B_j\|\|Z\|^2_{\mathcal{L}^{(2,\infty)}}. \tag{40}$$

These show the continuity in Z and with respect to A_i and B_j, B_k. We can compose products of these kinds of functions:

$$\Psi(Z)=\prod_{i,j,k} \mathrm{Tr}_\omega(B_j Z B_k Z)\mathrm{Tr}_\omega(A_i Z). \tag{41}$$

The reader can verify that any higher power of Z is irrelevant, so these are the only combinations we can make. Various superpositions of these functions will give us the set of wave functions. [One should perhaps compare this with the analysis given in Ref. 2. There, the holomorphic wave functions can be constructed using the analogy with the finite-dimensional case. We can use the fact that the dual of $\mathcal{L}^2$ is itself and the dual of $\mathcal{L}^1$ is $\mathrm{B}(\mathcal{H})$. We can write down a general holomorphic function as sums and products of the expressions of the form, $\mathrm{Tr}(AZ), \mathrm{Tr}(B_1 Z B_2 Z \cdots B_m Z)$, where $A \in \mathcal{L}^2$ and $B_k \in \mathrm{B}(\mathcal{H})$ for all $k=1,...,m$. Not all of them are linearly independent of course. With the appropriate inner product the quantum Hilbert space constructed out of these functions is isomorphic to the usual Fock space and it is a separable Hilbert space.]

We also would like to point out an interesting property of our wave functions. Since we have obtained them through the Dixmier trace, we effectively perform ''logarithmic wave function renormalization.''

The quantum Hilbert space may be very large, or maybe very small; it depends on the size of the space of ''holomorphic functions'' on D_{1+}, and the inner product. It is not clear how one should introduce a measure to define an inner product in this quantum Hilbert space. The term Hilbert space is only justified by thinking of this as a quantization of a classical system. It should be possible to extend the work in Ref. 22 to this case. Once this is done, the completion of the above set of wave functions with respect to this measure will be the quantum Hilbert space, $\mathcal{H}_Q$.

Next we will construct the quantum operators for the Gr_{1+}. Our approach will be somewhat *ad hoc* again. Since Gr_{1+} is topologically nontrivial, it may not be possible to represent wave functions as functions on the Grassmannian. It is natural to introduce them as sections of a complex line bundle. However, we will see that there are nonconstant holomorphic functions on this Grassmannian. (This can be contrasted with Refs. 3 and 2. There, the finite-dimensional Grassmannians are dense inside the full Grassmannian, and it is well known that on a compact complex manifold there are no nonconstant holomorphic functions. In our case, completion of finite rank objects will not be equal to the full space.) For the quantization of our classical system, we actually need the sections of a line bundle. For this it is better to think of Gr_{1+} as a quotient of another pair of groups as in the case discussed by Refs. 3 and 2. It is possible that the extension is nontrivial both topologically and algebraically. Essentially, we will enlarge ''numerator'' and ''denominator'' by the same amount. This will keep the same ratio. We define the group $\tilde{\mathrm{G}}_{1+}$:

$$\tilde{\mathrm{G}}_{1+}=\{(\gamma,q)|q\in \mathrm{GL}(\mathcal{H}_-);\quad \gamma\in \mathrm{GL}_{1+}(\mathcal{H}),\quad \gamma_{11}q^{-1}-1\in\mathcal{L}^{(1,\infty)}\}. \tag{42}$$

Here, γ_{11} denotes the mapping $\gamma_{11}:\mathcal{H}_-\to\mathcal{H}_-$ in the block form of the matrix $\gamma\in\mathrm{GL}_{1+}(\mathcal{H})$. One can prove that the set of q's which satisfies this condition is not empty using the definition of the group GL_{1+} following Pressley and Segal.[3] We can give a topology to this space using the two topologies inherited from the bounded and $\mathcal{L}^{(1,\infty)}$. (Notice that the extension for any two-sided ideal is mentioned in Ref. 3 on p. 98.)

Here $\tilde{\mathrm{G}}_{1+}$ is a complex Banach–Lie group under the multiplication $(\gamma,q)(\gamma',q')=(\gamma\gamma',qq')$. We introduce $\tilde{\mathrm{B}}_{1+}$, a closed complex subgroup of $\tilde{\mathrm{G}}_{1+}$;

$$\tilde{\mathrm{B}}_{1+}=\{(\beta,t)|\beta\in \mathrm{B}_{1+},\quad t\in\mathrm{GL}(\mathcal{H}_-),\quad \beta_{11}t^{-1}-1\in\mathcal{L}^{(1,\infty)}\}. \tag{43}$$

There is an action of $\tilde{\mathrm{B}}_{1+}$ on $\tilde{\mathrm{G}}_{1+}$. Since this action does not involve anything but multiplication in the group, it is holomorphic. We enlarged $\mathrm{GL}_{1+}(\mathcal{H})$ and B_{1+} with the same set of elements, thus the quotient is still the same:

$$\tilde{\mathrm{B}}_{1+}\to\tilde{\mathrm{G}}_{1+}\to\mathrm{Gr}_{1+}. \tag{44}$$

In this case as well, there are subgroups corresponding to completions of the finite rank elements. These subgroups now can be written as

$$\tilde{\mathrm{G}}_{1+}^{(0)}=\{(\gamma^{(0)},q)|q\in\mathrm{GL}(\mathcal{H}_-);\quad \gamma^{(0)}\in\mathrm{GL}_{1+}^{(0)}(\mathcal{H}),\quad \gamma_{11}^{(0)}q^{-1}-1\in(\mathcal{L}^{(1,\infty)})^{(0)}\}. \tag{45}$$

Existence can be proved along the same lines. The stability subgroup also changes to $\tilde{\mathrm{B}}_{1+}^{(0)}$, which is defined similarly. One can see that $\tilde{\mathrm{G}}_{1+}^{(0)}\subset\tilde{\mathrm{G}}_{1+}$ as a closed subset. This subgroup will correspond to the null orbit, and it will not have any extension.

Now, we can introduce the holomorphic line bundle corresponding to the representation $\rho(\beta,r)=\det_\omega^{1/\hbar}(\beta_{11}r^{-1})$. There is no condition for the number $\hbar$ to be an integer at this stage, since our definition for $\det_\omega$ has an exponential, it never vanishes, and the value of $\hbar$ could be any real number. We denote the line bundle as $(\tilde{\mathrm{G}}_{1+}\times_\rho\mathbf{C})/\tilde{\mathrm{B}}_{1+}$. A section of this line bundle can be identified with equivariant functions:

$$\psi:\tilde{\mathrm{G}}_{1+}\to\mathbf{C}\quad\text{such that}\quad\psi(\gamma\beta,qr)=\rho(\beta,r)\psi(\gamma,q). \tag{46}$$

Let us exhibit the functions which would satisfy this condition. They are given by generalized determinants very similar to the case discussed in Ref. 2. As an example we start with

$$\psi(\gamma,q)=\det_\omega^{1/\hbar}(\gamma_{11}q^{-1}). \tag{47}$$

One can see that this is an equivariant function on the space $\tilde{\mathrm{G}}_{1+}$, using the properties of the Dixmier trace. There is no restriction on the value of $\hbar$ due to holomorphicity, since the exponential is an entire function except possibly due to a topological obstruction. We can compose more functions of this type, if we allow ''mixing'' of the elements of γ_{11} with the elements of γ_{21}, in a controlled way. One can see that if we assume that the mixing is allowed by finite rank operators, the result will not change. More than that, it will not change if we use elements of $(\mathcal{L}^{(2,\infty)})^{(0)}$. To get different functions we need to mix them by elements of $\mathcal{L}^{(2,\infty)}/(\mathcal{L}^{(2,\infty)})^{(0)}$:

$$\det_\omega((1-A_iS)\gamma_{11}q^{-1}+A_i\gamma_{21}q^{-1}) \tag{48}$$

for $A_i\in\mathcal{L}^{(2,\infty)}(\mathcal{H}_+,\mathcal{H}_-)$ and the mapping $S:\mathcal{H}_-\to\mathcal{H}_+$ is an isometric isomorphism which is given by mapping one set of orthonormal basis elements into the other (it can simply be taken as sending $e_{-i}\to e_i$). This form is guessed from the system studied in Refs. 2 and 3. However, we have two problems with this form. When we use $A_iS\gamma_{11}$, this expression is not convergent under the Dixmier trace. The second is that we want our wave functions to be constant when they are restricted to the null orbit. As we will see, this is not possible for the above form of the functions due to the term $A_iS\gamma_{11}$. One can see that dropping this term does not change the equivariance condition thanks to the Dixmier trace again. This means an infinite multiplicative renormalization. At the same time we see that it is simpler to just multiply with the function $\mathrm{Tr}_\omega(A_i\gamma_{21}q^{-1})$, since it is invariant under the action of B_{1+}, hence it descends to a function on the quotient, Gr_{1+}. A similar argument shows that we can do better, we may add even a nonlinear term, which is still invariant. Any higher-order addition vanishes. We can write down a general expression,

$$\det_\omega^{1/\hbar}(\gamma_{11}q^{-1})\mathrm{Tr}_\omega(A_i\gamma_{21}q^{-1})\mathrm{Tr}_\omega(B_j\gamma_{21}q^{-1}B_k\gamma_{21}q^{-1}), \tag{49}$$

where $B_j,B_k\in\mathrm{B}(\mathcal{H}_+,\mathcal{H}_-)$. For clarity, we will prove that this form is equivariant and satisfies all the requirements.

Let us look at the action by an element of B_{1+};

$$\begin{aligned}&\det_\omega^{1/\hbar}((\gamma\beta)_{11}(qr)^{-1})\mathrm{Tr}_\omega(A_i(\gamma\beta)_{21}(qr)^{-1})\mathrm{Tr}_\omega(B_j(\gamma\beta)_{21}(qr)^{-1}B_k(\gamma\beta)_{21}(qr)^{-1})\\&\quad=\det_\omega^{1/\hbar}(\gamma_{11}\beta_{11}r^{-1}q^{-1})\mathrm{Tr}_\omega(A_i\gamma_{21}\beta_{11}r^{-1}q^{-1})\mathrm{Tr}_\omega(B_j\gamma_{21}\beta_{11}r^{-1}q^{-1}B_k\gamma_{21}\beta_{11}r^{-1}q^{-1})\\&\quad=\det_\omega^{1/\hbar}(\gamma_{11}(1+I)q^{-1})\mathrm{Tr}_\omega(A_i\gamma_{21}(1+I)q^{-1})\mathrm{Tr}_\omega(B_j\gamma_{21}(1+I)q^{-1}B_k\gamma_{21}(1+I)q^{-1})\end{aligned}$$

using $\beta_{11}r^{-1}=1+I$ for $I\in\mathcal{L}^{(1,\infty)}$;

$$\begin{aligned}&\det_\omega^{1/\hbar}(\gamma_{11}q^{-1}(1+qIq^{-1}))\mathrm{Tr}_\omega(A_i\gamma_{21}q^{-1}+A_i\gamma_{21}Iq^{-1})\mathrm{Tr}_\omega((B_j\gamma_{21}q^{-1}+B_j\gamma_{21}Iq^{-1})\\&\qquad\times(B_k\gamma_{21}q^{-1}+B_k\gamma_{21}Iq^{-1}))\\&\qquad=\det_\omega(\gamma_{11}q^{-1}(1+qIq^{-1}))\mathrm{Tr}_\omega(A_i\gamma_{21}q^{-1})\mathrm{Tr}_\omega(B_j\gamma_{21}q^{-1}B_k\gamma_{21}q^{-1})).\end{aligned}$$

In the last line we have used $\mathcal{L}^{(1,\infty)}\mathcal{L}^{(2,\infty)}\in\mathcal{L}^1$ and the Dixmier trace vanishes on them. As a result we get

$$\exp\frac{1}{\hbar}(\mathrm{Tr}_\omega(\gamma_{11}g^{-1}-1)+\mathrm{Tr}_\omega(\beta_{11}r^{-1}-1))\mathrm{Tr}_\omega(A_i\gamma_{21}q^{-1})\mathrm{Tr}_\omega(B_j\gamma_{21}q^{-1}B_k\gamma_{21}q^{-1}), \tag{50}$$

where we use $(1+I)(1+qIq^{-1})=1+I+qJq^{-1}+IqJq^{-1}$ and the last term is zero inside the Dixmier trace for $\gamma_{11}q^{-1}=1+I$, $I\in\mathcal{L}^{(1,\infty)}$. This is the equivariance condition we want. We can take a product over the trace part only, and this will not change the result.

We need to check that when we reduce the wave function onto the ''small'' orbit, that is to the subgroup $\tilde{\mathrm{G}}_{1+}^{(0)}$, the resulting wave functions are just constant. This is necessary for consistency with the classical Poisson bracket calculation as we will see. Let us note the following: in fact, our system is invariant under a larger symmetry. This will be discussed in the next section, and we will see that the correct phase space is smaller.

One can see that we can compose a product wave function; in general, we define, as in the case of D_{1+},

$$\det_{\omega}^{1/\hbar}(\gamma_{11}q^{-1})\prod_{i,j,k}\ \mathrm{Tr}_{\omega}(A_i\gamma_{21}q^{-1})\mathrm{Tr}_{\omega}(B_j\gamma_{21}q^{-1}B_k\gamma_{21}q^{-1}). \tag{51}$$

These and their various superpositions are the most general wave functions we can construct. The next step is to complete these sets of wave functions with respect to an inner product to get the quantum Hilbert space. (Notice that in our previous work[2] we could have used the trace class operators for the mixing of γ_{11} and γ_{21}, not only the finite rank ones. Various superpositions of the wave functions described in that work will lead to a similar general form given here with a finite rank matrix used for the mixing. The finite rank operators are dense in the trace class and the determinant uses the ordinary trace. We can extend the wave functions in that case to the one with mixing elements in the trace class operators. This should actually be done by using the inner product in the quantum Hilbert space, but we expect some dominance property with respect to the parameters. In fact, the above claim is known to be true, hence there is no loss of generality in that case.) Notice that still there could be an integrality condition on $\hbar$, due to the fact that the first Chern class of the line bundle corresponding to the representation ρ should be in $H^2(\mathrm{Gr}_{1+},\mathbf{Z})$.

Let us note that the form of the wave function for the disc and the Grassmannian are quite the same—this is unlike the previous case studied in Ref. 2. We can, in fact, set up a one-to-one correspondence between the elements of the two quantum Hilbert spaces; for any choices of $A_i \in \mathcal{L}^{(2,\infty)}$ and B_j, B_k, which are operators in $\mathrm{B}(\mathcal{H}_-,\mathcal{H}_+)$ we have a wave function on the disc and on the Grassmannian. This suggests in some natural sense a boson–fermion correspondence, if we think of the disc corresponding to a bosonic and the Grassmannian to a fermionic system. Of course, this correspondence is only at a formal level, since we only have a set theoretical relation between the two quantum Hilbert spaces. One also has to check the inner products, to make sure that the linearly independent choices are mapped to each other in the same manner. This seems to be a reasonable expectation. Its physical meaning is not so obvious to the author; it maybe due to the fact that we have thrown away a large part of the phase space, which may have a lot of physical information about the system. We will see some further evidence of the equivalence of these two systems in this quantization scheme, when we look at these problems in a different way in the next section. (There is larger stability subgroup as we will see in the next section, and it seems to suggest a simpler solution.)

The above wave functions carry a representation of the group $\tilde{\mathrm{G}}_{1+}$ which comes from the left action;

$$\mathbf{r}(\gamma',q')\psi(\gamma,q)=\psi(\gamma'^{-1}\gamma,q^{-1}q'). \tag{52}$$

This group action is well defined. We give a proof for completeness: Let us denote the inverse element acting from the left by $(\lambda,r)\in \mathrm{G}_{1+}$. For simplicity we drop the products and compute the following expression:

$$\det_{\omega}^{1/\hbar}((\lambda\gamma)_{11}q^{-1}r^{-1})\mathrm{Tr}_{\omega}(A_i(\lambda\gamma)_{21}q^{-1}r^{-1})\mathrm{Tr}_{\omega}(B_j(\lambda\gamma)_{21}q^{-1}r^{-1}B_k(\lambda\gamma)_{21}q^{-1}r^{-1}). \tag{53}$$

We expand the products

$$\begin{aligned}
&\det_{\omega}^{1/\hbar}((\lambda_{11}\gamma_{11}+\lambda_{12}\gamma_{21})q^{-1}r^{-1})\mathrm{Tr}_{\omega}(A_i(\lambda_{21}\gamma_{11}+\lambda_{22}\gamma_{21})q^{-1}r^{-1})\\
&\quad\times\mathrm{Tr}_{\omega}(B_j(\lambda_{21}\gamma_{11}+\lambda_{22}\gamma_{21})q^{-1}r^{-1}B_k(\lambda_{21}\gamma_{11}+\lambda_{22}\gamma_{21})q^{-1}r^{-1}))\\
&\quad=\det_{\omega}^{1/\hbar}((1+I)(1+rJr^{-1})+\lambda_{12}\gamma_{21}q^{-1}r^{-1})\\
&\qquad\times\mathrm{Tr}_{\omega}(A_i\lambda_{21}(1+I)r^{-1}+A_i\lambda_{22}\gamma_{21}q^{-1}r^{-1})\\
&\qquad\times\mathrm{Tr}_{\omega}[B_j\lambda_{21}(1+I)r^{-1}+B_j\lambda_{22}\gamma_{21}q^{-1}r^{-1}][B_k\lambda_{21}(1+I)r^{-1}+B_k\lambda_{22}\gamma_{21}q^{-1}r^{-1}]\\
&\quad=\det_{\omega}^{1/\hbar}(1+I+J+\lambda_{12}\gamma_{21}q^{-1}r^{-1})\times\mathrm{Tr}_{\omega}(A_i(\lambda_{21}r^{-1}+\lambda_{22}\gamma_{21})q^{-1}r^{-1}\\
&\qquad\times\mathrm{Tr}_{\omega}[B_j\lambda_{21}r^{-1}+B_j\lambda_{22}\gamma_{21}q^{-1}r^{-1}][B_k\lambda_{21}r^{-1}+B_k\lambda_{22}\gamma_{21}q^{-1}r^{-1}],
\end{aligned}$$

where we use $\gamma_{11}q^{-1}=1+I$ and $\lambda_{11}r^{-1}=1+J$. Notice also that we used the vanishing of the Dixmier trace whenever the resulting multiplication is in the trace class operators—and this is the case, for example, for products of the kind $\lambda_{21}I$ and for other similar terms. All the terms in the above expression are actually in the ideal $\mathcal{L}^{(1,\infty)}$ except 1, hence we have the result well defined.

Clearly the action of a group element on a general wave function follows directly from this result. It follows immediately from the above formula that when we restrict to the subspace $\tilde{\mathrm{G}}_{1+}^{(0)}$ for the wave function elements and the group element multiplying from the left, the expression inside the determinant gives us 1. This shows that the representation is trivial.

For completeness we will prove that we have a true representation of the group $\tilde{\mathrm{G}}_{1+}$ on this space of wave functions. This is a technical step and it can be skipped. We will compare the action of the group elements and show that

$$\psi(\lambda(\sigma\gamma),r(sq))=\psi((\lambda\sigma)\gamma,(rs)q), \tag{54}$$

hence when we apply the left multiplication on the left this gives us a representation. We have the group action by (λ,r) given by the above formula that we have already calculated:

$$\det{}_{\omega}^{1/\hbar}(\lambda_{11}r^{-1})\det{}_{\omega}^{1/\hbar}(\gamma_{11}q^{-1}+\lambda_{12}\gamma_{21}q^{-1}r^{-1})\mathrm{Tr}_{\omega}A_i(\lambda_{21}r^{-1}+\lambda_{22}\gamma_{21}q^{-1}r^{-1})$$
$$\times\mathrm{Tr}_{\omega}(B_j(\lambda_{21}r^{-1}+\lambda_{22}\gamma_{21}q^{-1}r^{-1})B_k(\lambda_{21}r^{-1}+\lambda_{22}\gamma_{21}q^{-1}r^{-1})).$$

We can act with the element (σ,s) on this; it is better to break the terms into separate parts:

$$\det{}_{\omega}^{1/\hbar}(\lambda_{11}r^{-1})\det{}_{\omega}^{1/\hbar}((\sigma_{11}\gamma_{11}+\sigma_{12}\gamma_{21})q^{-1}s^{-1}+\lambda_{12}(\sigma_{21}\gamma_{11}+\sigma_{22}\gamma_{21})q^{-1}(rs)^{-1})$$
$$\times\det{}_{\omega}^{1/\hbar}(\lambda_{11}r^{-1})\det{}_{\omega}^{1/\hbar}(\sigma_{11}s^{-1})\det{}_{\omega}^{1/\hbar}(\gamma_{11}q^{-1}+\sigma_{12}\gamma_{21}q^{-1}s^{-1}$$
$$+\lambda_{12}\sigma_{21}(rs)^{-1}+\lambda_{12}\sigma_{22}\gamma_{21}q^{-1}(rs)^{-1}).$$

We compare this with the action of the group element $(\lambda\sigma,rs)$ on the same wave function:

$$\det{}_{\omega}^{1/\hbar}((\lambda\sigma)_{11}(rs)^{-1})\det{}_{\omega}^{1/\hbar}(\gamma_{11}q^{-1}+(\lambda\sigma)_{12}\gamma_{21}q^{-1}(rs)^{-1})$$
$$=\det{}_{\omega}^{1/\hbar}(\lambda_{11}\sigma_{11}s^{-1}r^{-1}+\lambda_{12}\sigma_{21}s^{-1}r^{-1})\det{}_{\omega}^{1/\hbar}(\gamma_{11}q^{-1}+\lambda_{11}\sigma_{12}\gamma_{21}q^{-1}s^{-1}r^{-1}$$
$$+\lambda_{12}\sigma_{22}\gamma_{21}q^{-1}(rs)^{-1})$$
$$=\det{}_{\omega}^{1/\hbar}(\lambda_{11}r^{-1})\det{}_{\omega}^{1/\hbar}(\sigma_{11}s^{-1})\det{}_{\omega}^{1/\hbar}(\gamma_{11}q^{-1}+\lambda_{12}\sigma_{21}(rs)^{-1}+\sigma_{12}\gamma_{21}q^{-1}s^{-1}$$
$$+\lambda_{12}\sigma_{22}\gamma_{21}q^{-1}(rs)^{-1}).$$

These two expressions are the same, hence we have a group action on this part of the wave function.

Let us check the next term:

$$\mathrm{Tr}_{\omega}(A_i(\lambda_{21}r^{-1}+\lambda_{22}(\sigma_{21}\gamma_{11}+\sigma_{22}\gamma_{21})q^{-1}(rs)^{-1}))$$
$$=\mathrm{Tr}_{\omega}(A_i(\lambda_{21}r^{-1}+\lambda_{22}\sigma_{21}(rs)^{-1}+\lambda_{22}\sigma_{22}\gamma_{21}q^{-1}(rs)^{-1})).$$

Let us compare this with the direct application of the product:

$$\mathrm{Tr}_{\omega}(A_i((\lambda\sigma)_{21}(rs)^{-1}+(\lambda\sigma)_{22}\gamma_{21}q^{-1}(rs)^{-1}))$$
$$=\mathrm{Tr}_{\omega}(A_i(\lambda_{21}\sigma_{11}s^{-1}r^{-1}++\lambda_{22}\sigma_{21}(rs)^{-1}+\lambda_{21}\sigma_{12}\gamma_{21}q^{-1}(rs)^{-1}+\lambda_{22}\sigma_{22}\gamma_{21}q^{-1}(rs)^{-1}))$$
$$=\mathrm{Tr}_{\omega}(A_i(\lambda_{21}r^{-1}+\lambda_{22}\sigma_{21}(rs)^{-1}+\lambda_{22}\sigma_{22}\gamma_{21}q^{-1}(rs)^{-1})).$$

These two expressions are the same. Let us look at the last type of term:

$$\begin{aligned}
&\mathrm{Tr}_\omega(B_j(\lambda_{21}r^{-1}+\lambda_{22}(\sigma_{21}\gamma_{11}+\sigma_{22}\gamma_{21})q^{-1}(rs)^{-1})B_k(\lambda_{21}r^{-1}+\lambda_{22}(\sigma_{21}\gamma_{11}+\sigma_{22}\gamma_{21})q^{-1}(rs)^{-1}))\\
&\quad=\mathrm{Tr}_\omega(B_j(\lambda_{21}r^{-1}+\lambda_{22}\sigma_{21}(rs)^{-1}+\lambda_{22}\sigma_{22}\gamma_{21}q^{-1}(rs)^{-1})B_k(\lambda_{21}r^{-1}+\lambda_{22}\sigma_{21}(rs)^{-1}\\
&\qquad+\lambda_{22}\sigma_{22}\gamma_{21}q^{-1}(rs)^{-1})).
\end{aligned}$$

If we look at the action of the product,

$$\begin{aligned}
&\mathrm{Tr}_\omega(B_j((\lambda\sigma)_{21}(rs)^{-1}+(\lambda\sigma)_{22}\gamma_{21}q^{-1}(rs)^{-1})B_k((\lambda\sigma)_{21}(rs)^{-1}+(\lambda\sigma)_{22}\gamma_{21}q^{-1}(rs)^{-1}))\\
&\quad=\mathrm{Tr}_\omega(B_j(\lambda_{21}r^{-1}+\lambda_{22}\sigma_{21}(rs)^{-1}+(\lambda_{21}\sigma_{12}+\lambda_{22}\sigma_{22})\gamma_{21}q^{-1}(rs)^{-1})B_k(\lambda_{21}r^{-1}\\
&\qquad+\lambda_{22}\sigma_{21}(rs)^{-1}+(\lambda_{21}\sigma_{12}+\lambda_{22}\sigma_{22})\gamma_{21}q^{-1}(rs)^{-1}))\\
&\quad=\mathrm{Tr}_\omega(B_j(\lambda_{21}r^{-1}+\lambda_{22}\sigma_{21}(rs)^{-1}+\lambda_{22}\sigma_{22}\gamma_{21}q^{-1}(rs)^{-1})\\
&\qquad\times B_k(\lambda_{21}r^{-1}+\lambda_{22}\sigma_{21}(rs)^{-1}+\lambda_{22}\sigma_{22}\gamma_{21}q^{-1}(rs)^{-1})),
\end{aligned}$$

where we used the vanishing of the Dixmier trace on $\mathcal{L}^1$ and some rearrangements on all the above calculations. We see that this term also respects the group action.

The above representation factors through the subgroup which corresponds to the elements s of $\mathrm{GL}(\mathcal{H}_-)$, with $\det_\omega(s)$ well defined. These are the elements in the subgroup, $s\in 1+\mathcal{L}^{(1,\infty)}$. Notice that for a fixed element γ, the freedom we have to choose different q's which satisfy the determinant condition is isomorphic to $\mathrm{GL}^{1+}=\{q\in \mathrm{GL}(\mathcal{H}_-)|q=1+\mathcal{L}^{(1,\infty)}\}$, although we could not find a way to reduce it to this group everywhere. Hence our representations can actually be reduced to the representations of another group, which is a central extension of the group GL_{1+}. The extension is trivial on the subgroup $\mathrm{GL}_{1+}^{(0)}$; this can be seen by noticing that $s\in 1+(\mathcal{L}^{(1,\infty)})^{(0)}$ will give us $\det_\omega(s)=1$. We can construct a commutative diagram, as we have done in Ref. 2, to show that this gives us a representation of a central extension of the group GL_{1+}. This is more transparent if we look in the Lie algebra level, and also this gives us a chance to compare the central term we have in the case of moment maps. The Lie algebra we need to consider is clearly $\{(u,r)|r\in \mathrm{End}(\mathcal{H}_-)\ \ u_{11}-r\in\mathcal{L}^{(1,\infty)}\}$. One can see that the Lie bracket $[(u,r),(v,s)]=([u,v],[r,s])$ is well defined, and this is the infinitesimal form of the group $\widetilde{\mathrm{G}}_{1+}$. One can see immediately that the set of possible r's is isomorphic to the set of $r\in \mathrm{GL}(\mathcal{H}_-)$ such that $r\in\mathcal{L}^{(1,\infty)}$. We can construct a central extension of the original Lie algebra by using, $(u,r)\mapsto(u,\mathrm{Tr}_\omega(u_{11}-r))$. We give the trivial Lie bracket to the complex numbers. Under this map, the commutator goes to

$$([u,v],\mathrm{Tr}_\omega([u,v]_{11}-[r,s]))=([u,v],\mathrm{Tr}_\omega^\epsilon([\epsilon,u]v)),\tag{55}$$

where we used

$$\begin{aligned}
&\mathrm{Tr}_\omega(u_{11}v_{11}-v_{11}u_{11}+u_{12}v_{21}-v_{12}u_{21}-[r,s])\\
&\quad=\mathrm{Tr}_\omega(u_{11}v_{11}-rs-v_{11}u_{11}+sr)+\mathrm{Tr}_\omega(u_{12}v_{21}-v_{12}u_{21})\\
&\quad=\mathrm{Tr}_\omega((u_{11}-r)v_{11}+r(v_{11}-s))-\mathrm{Tr}_\omega(v_{11}(u_{11}-r)+(v_{11}-s)r)+\mathrm{Tr}_\omega^\epsilon([\epsilon,u]v)\\
&\quad=\mathrm{Tr}_\omega^\epsilon([\epsilon,u]v)
\end{aligned}$$

since all the terms, as grouped, are in $\mathcal{L}^{(1,\infty)}$ and we use the Dixmier trace properties. Note that this is the same central extension in the case of moment maps that we have been using. We will show by an explicit calculation that our representations can be reduced to representations of this algebra. Let us first compute the infinitesimal action; for simplicity we drop the product signs:

$$\mathcal{L}_{(u,r)}\det_\omega^{1/\hbar}(\gamma_{11}q^{-1})\mathrm{Tr}_\omega(A_i\gamma_{21}q^{-1})\mathrm{Tr}_\omega(B_j\gamma_{21}q^{-1}B_k\gamma_{21}q^{-1}).\tag{56}$$

It is again easier to use the derivation property of the Lie derivative and compute individual terms:

$$\mathcal{L}_{(u,r)}\,\det_\omega^{1/\hbar}(\gamma_{11}q^{-1})=\frac{-1}{\hbar}\mathrm{Tr}_\omega((u_{11}\gamma_{11}+u_{12}\gamma_{21})q^{-1}-\gamma_{11}q^{-1}r)\det_\omega^{1/\hbar}(\gamma_{11}q^{-1})$$

$$=\left(-\frac{1}{\hbar}\mathrm{Tr}_\omega(u_{11}-r)-\frac{1}{\hbar}\mathrm{Tr}_\omega(u_{12}\gamma_{21}q^{-1})\right)\det_\omega^{1/\hbar}(\gamma_{11}q^{-1}).$$

In a similar way we get

$$\mathcal{L}_{(u,r)}\,\mathrm{Tr}_\omega(A_i\gamma_{21}q^{-1})=\mathrm{Tr}_\omega(A_i(u_{21}+u_{22}\gamma_{21}q^{-1}-\gamma_{21}q^{-1}r)) \tag{57}$$

and

$$\mathcal{L}_{(u,r)}\,\mathrm{Tr}_\omega(B_j\gamma_{21}q^{-1}B_k\gamma_{21}q^{-1})=\mathrm{Tr}_\omega(B_j(u_{21}+u_{22}\gamma_{21}q^{-1}-\gamma_{21}q^{-1}r)B_k(u_{21}+u_{22}\gamma_{21}q^{-1}-\gamma_{21}q^{-1}r)).$$

We define a new representation and, using the above expressions, check that it is, in fact, independent of the choice of the Lie algebra element r:

$$\hat{\mathrm{r}}[(u,r)]=\mathcal{L}_{(u,r)}+\frac{1}{\hbar}\mathrm{Tr}_\omega(u_{11}-r), \tag{58}$$

acting on the same set of wave functions. Using the above expression, we compute the action of the Lie algebra element $(u,r+s)$, where $s\in\mathcal{L}^{(1,\infty)}$ and this is the freedom we have. It is again simpler to check this on each basic piece:

$$(\hat{\mathrm{r}}[(u,r+s)]\det_\omega^{1/\hbar}(\gamma_{11}q^{-1}))\phi(A_i,B_j,B_k,\gamma,q)$$

$$=\left[\mathcal{L}_{(u,r+s)}+\frac{1}{\hbar}\mathrm{Tr}_\omega(u_{11}-(r+s))\right]\det_\omega^{1/\hbar}(\gamma_{11}q^{-1})\phi(A_i,B_j,B_k,\gamma,q)$$

$$=-\frac{1}{\hbar}\mathrm{Tr}_\omega(u_{12}\gamma_{21}q^{-1})\det_\omega^{1/\hbar}(\gamma_{11}q^{-1})\phi(A_i,B_j,B_k,\gamma,q).$$

For the other terms we only use the Lie derivative part since the scalar part is used in the above expression already:

$$\mathcal{L}_{(u,r+s)}\mathrm{Tr}_\omega(A_i\gamma_{21}q^{-1})=\mathrm{Tr}_\omega(A_i(u_{21}+u_{22}\gamma_{21}q^{-1}-\gamma_{21}q^{-1}(r+s)))$$

$$=\mathrm{Tr}_\omega(A_i(u_{21}+u_{22}\gamma_{21}q^{-1})-A_i\gamma_{21}q^{-1}r)$$

$$=\mathcal{L}_{(u,r)}\,\mathrm{Tr}_\omega(A_i\gamma_{21}q^{-1})$$

by using the fact that, everytime s is multiplied with an element, the resulting term is in the ideal of trace class operators, and the Dixmier trace vanishes on them. The other term,

$$\mathcal{L}_{(u,r+s)}\,\mathrm{Tr}_\omega(B_j\gamma_{21}q^{-1}B_k\gamma_{21}q^{-1}), \tag{59}$$

can be shown to be independent of s by using the same reasoning as above. Hence, we can denote the representation we have as $\hat{\mathbf{r}}(u)$.

If we compute the commutator,

$$(\hat{\mathrm{r}}(u)\hat{\mathrm{r}}(v)-\hat{\mathrm{r}}(v)\hat{\mathrm{r}}(v))\psi(\gamma,q)=\left[\hat{\mathrm{r}}([v,u])-\frac{1}{\hbar}\mathrm{Tr}_\omega([u,v]_{11}-[r,p])\right]\psi(\gamma,q). \tag{60}$$

The last term is independent of the choices of r,p and equal to $-(1/\hbar)\mathrm{Tr}_\omega^\epsilon[\epsilon,u]v$ as we have seen before.

Hence the representations that we have obtained can be reduced to the representations of the central extension of the Lie group $U_{1+}(\mathcal{H})$. This is the quantization of our classical system; it may not be possible to express the central term corresponding to the group in this form, since the extension may have a topological twist in general. We are not able to answer this question, although the discussion in the last section hints that the correct phase space is topologically trivial. This will imply that the central extension actually comes from a central term, globably defined.

IV. FLAT GEOMETRY AND QUANTIZATION

In this section we will introduce a classical system which appears to be unrelated at first sight. This point of view was suggested by Rajeev in our discussions. We consider the set of elements $\overline{Z}$ such that they belong to the following quotient space $\mathcal{L}^{(2,\infty)}(\mathcal{H}_+,\mathcal{H}_-)/(\mathcal{L}^{(2,\infty)}(\mathcal{H}_+,\mathcal{H}_-))^{(0)}$ [equivalence classes of $Z:\mathcal{H}_+\rightarrow\mathcal{H}_-$ and $Z\in\mathcal{L}^{(2,\infty)}(\mathcal{H}_+,\mathcal{H}_-)$ under $Z-Z'\in(\mathcal{L}^{(2,\infty)}(\mathcal{H}_+,\mathcal{H}_-))^{(0)}$]. There is a natural quotient norm,

$$\||\overline{Z}|\|=\inf_{Z_0\in(\mathcal{L}^{(2,\infty)})^{(0)}}\|Z+Z_0\|_{\mathcal{L}^{(2,\infty)}}, \tag{61}$$

where Z is a representative in the equivalence class of $\overline{Z}$.

There is a natural product from $\mathcal{L}^{(2,\infty)}\times\mathcal{L}^{(2,\infty)}\rightarrow\mathcal{L}^{(1,\infty)}$, and this reduces to the quotients $\mathcal{L}^{(2,\infty)}/(\mathcal{L}^{(2,\infty)})^{(0)}\times\mathcal{L}^{(2,\infty)}/(\mathcal{L}^{(2,\infty)})^{(0)}\rightarrow\mathcal{L}^{(1,\infty)}/(\mathcal{L}^{(1,\infty)})^{(0)}$ given by $\overline{ZZ'}=\overline{Z}\overline{Z}'$. The natural product $B(\mathcal{H})\times\mathcal{L}^{(2,\infty)}\rightarrow\mathcal{L}^{(2,\infty)}$ also descends to the quotient $B(\mathcal{H})\times(\mathcal{L}^{(2,\infty)}/(\mathcal{L}^{(2,\infty)})^{(0)})\rightarrow\mathcal{L}^{(2,\infty)}/(\mathcal{L}^{(2,\infty)})^{(0)}$.

The Dixmier trace is nondegenerate on this quotient space. We will use this important fact to introduce an obvious symplectic form,

$$\tilde{\Omega}_\omega=i\,\mathrm{Tr}_\omega\, d\overline{Z}\wedge d\overline{Z}^\dagger. \tag{62}$$

This flat geometry has a simple symmetry group given by rotations and translations. (This may not be the most general action, but it is the obvious one.) Due to the quotient we can allow for slight deviations from unitary transformations and write a general transformation as

$$\overline{Z}\mapsto\overline{eZf^{-1}+l}, \tag{63}$$

where $e\in GL(\mathcal{H}_-)$, $f\in GL(\mathcal{H}_+)$ such that $e^\dagger e-1$, $f^\dagger f-1\in K(\mathcal{H})$, and $l\in\mathcal{L}^{(2,\infty)}$. One can check that this is, in fact, a group under the obvious composition law, which we call as the affine group, $\mathcal{A}_{1+}$. This action is well defined and transitive. One can immediately check that the group action preserves the symplectic form due to the extra conditions we have:

$$\tilde{\Omega}_\omega=i\,\mathrm{Tr}_\omega\, ed\overline{Z}f^{-1}\wedge f^{-1\dagger}d\overline{Z}^\dagger e^\dagger=i\,\mathrm{Tr}_\omega(e^\dagger e)d\overline{Z}\wedge(f^\dagger f)^{-1}d\overline{Z}^\dagger=\tilde{\Omega}_\omega, \tag{64}$$

using the fact that the product $e^\dagger ed\overline{Z}\approx d\overline{Z}$ and the same for f (see the Appendix for a proof).

It is again natural to find the moment maps generating this action. We can find them using the infinitesimal form of the group action, $\tilde{V}_{(e,f,l)}(\overline{Z})=\overline{\alpha Z}-\overline{Z}\delta+\overline{\beta}$. [Here we denote the Lie algebra elements by the same letter α,β,δ, but they now satisfy $\alpha^\dagger+\alpha=1+K$, $\delta^\dagger+\delta=1+K$ where K is a compact operator, and $\overline{\beta}\in\mathcal{L}^{(2,\infty)}/(\mathcal{L}^{(2,\infty)})^{(0)}$, yet we denote the moment maps by $F_{(e,f,l)}$ to imply that they are coming from the affine action. We hope that this does not cause too much confusion.] Hence,

$$F_{(e,f,l)}=i\,\mathrm{Tr}_\omega(\alpha\overline{ZZ}^\dagger-\overline{Z}\delta\overline{Z}^\dagger+\overline{\beta Z}^\dagger+\overline{Z\beta}^\dagger). \tag{65}$$

If we compute $\{F_{(e_1,f_1,l_1)},F_{(e_2,f_2,l_2)}\}$, we will see that there is a central term. Since we will do this calculation below to make connection with the previous section, we postpone the result.

Geometric quantization gives us immediately the following general set of wave functions:

$$\Psi(\overline{Z},\overline{Z}^{\dagger})=e^{-(1/\hbar)\mathrm{Tr}_{\omega}\overline{ZZ^{\dagger}}}\prod_{i,j,k}\mathrm{Tr}_{\omega}(\overline{A_i}\overline{Z})\mathrm{Tr}_{\omega}(B_j\overline{Z}B_k\overline{Z}), \tag{66}$$

where $\overline{A_i}\in\mathcal{L}^{(2,\infty)}$ and $B_{j,k}$ are bounded. Naturally, this set of wave functions carries a representation of the central extension of the above group action, via the same type of operators we have found before:

$$\hat{F}\psi(\overline{Z})=\left(\mathcal{L}_{(\alpha,\delta,\beta)}-\frac{1}{\hbar}\mathrm{Tr}_{\omega}(\overline{\beta}^{\dagger}\overline{Z})\right)\psi(\overline{Z}). \tag{67}$$

(We skip a detailed derivation of this formula, but the reader can verify it by using standard geometric quantization).

This system has an interesting connection to our discussions on the previous section. Let us recall the disc case. One can recover the symplectic form for the disc using the following Kähler potential, $i\mathrm{Tr}_{\omega}\log(1-ZZ^{\dagger})$, just as in the finite-dimensional case. Let us expand the Kähler form, and use the properties of the Dixmier trace. We see that the result is a simple expression: $i\mathrm{Tr}_{\omega}ZZ^{\dagger}$. This is the result for a flat system, except for degeneracies. If we look at the quotient, as above, the result is the same as the Kähler potential of the above system.

We can also apply the quotient homomorphism to our pseudo-unitary group action; this gives

$$\overline{Z}\mapsto\overline{aZd^{-1}}+\overline{bd^{-1}}. \tag{68}$$

Let us show that the group property is preserved under this mapping:

$$\begin{aligned}\overline{g_2\circ(g_1\circ Z)}&=a_2(a_1\overline{Z}d_1^{-1}+\overline{b_1d_1^{-1}})d_2^{-1}+\overline{b_2d_2^{-1}}\\&=a_2a_1\overline{Z}(d_2d_1)^{-1}+a_2\overline{b_1(d_2d_1)^{-1}}\\&=\overline{(a_2a_1+b_2b_1)Z(d_2d_1+c_2c_1)^{-1}}+\overline{(a_2b_1+b_2d_1)(d_2d_1+c_2c_1)^{-1}}\\&=\overline{(g_2g_1)\circ Z}.\end{aligned}$$

This gives us an embedding of $\mathrm{U}_{1+}(\mathcal{H}_-,\mathcal{H}_+)$ into the affine group. Another interesting point is to look at the moment maps, and expand $\mathrm{Tr}_{\omega}u(\Phi-\epsilon)$ in the variable Z, by using the expression of Φ in terms of Z. The properties of the Dixmier trace can be used to see that most of the terms vanish; the result is the same as the moment maps of the flat system:

$$f_u=i\,\mathrm{Tr}_{\omega}(\alpha ZZ^{\dagger}-Z\delta Z^{\dagger}+\beta Z+Z^{\dagger}\beta^{\dagger}). \tag{69}$$

Of course, it is natural to go to the quotient again, and we get $F_u=F_{(a,d,bd^{-1})}$. We can now compute to see the Poisson bracket of these two moment maps, using the flat Poisson bracket:

$$\begin{aligned}\{F_u,F_v\}=i\,\mathrm{Tr}_{\omega}([\alpha_1,\alpha_2]\overline{ZZ^{\dagger}}-\overline{Z}[\delta_1,\delta_2]\overline{Z^{\dagger}}+(\alpha_2\beta_1-\alpha_1\beta_2+\beta_1\delta_2-\beta_2\delta_1)\overline{Z}^{\dagger}+\overline{Z}(\alpha_2\beta_1-\alpha_1\beta_2\\+\beta_1\delta_2-\beta_2\delta_1)^{\dagger})+i\,\mathrm{Tr}_{\omega}(\overline{\beta_1\beta_2^{\dagger}-\beta_2\beta_1^{\dagger}}).\end{aligned}$$

One can verify that the last term is a central term which is equal to the central term we have found before.

The above set of wave functions is equivalent to the wave functions on the disc and they carry the same representation of the central extension of the quotient group. This shows that the system we studied without the reduction can be put into a slightly bigger flat system.

The same question then arises for the Grassmannian. Its coordination will show that in each coordinate neighborhood, the symplectic form is given by the flat one, and similarly the moment functions will look like the flat geometry. Certainly, the quotient point of view, using $U_{1+}/(U_{1+})^{(0)}$, implies that there is a similar simplification. Now we will try to present an alternative point of view in the Grassmannian which keeps the complex structure. Consider the following subgroup:

$$\tilde{G}_{(1+,0)} = \left\{ (g,q) \middle| g \in \begin{pmatrix} \mathcal{B} & \mathcal{L}^{(2,\infty)} \\ (\mathcal{L}^{(2,\infty)})^{(0)} & \mathcal{B} \end{pmatrix} \right\}. \tag{70}$$

This is a closed subgroup, hence the quotient is a holomorphic manifold. Notice that the representation we have introduced for the subgroup $\tilde{B}_{1+}$ actually extends to a representation of this larger group:

$$\det{}_{\omega}^{1/\hbar}((\gamma\lambda)_{11}s^{-1}q^{-1}) = \det{}_{\omega}^{1/\hbar}(\gamma_{11}\lambda_{11}s^{-1}q^{-1} + \gamma_{12}\lambda_{21}s^{-1}q^{-1}). \tag{71}$$

Notice that the last term is actually zero under the Dixmier trace and the rest follows as before, showing that it is a one-dimensional holomorphic representation. The next thing is to check that the remaining part of the wave function is, in fact, invariant under the group $\tilde{G}_{(1+,0)}$. Thus, we will have a line bundle on this smaller quotient, which is the physically relevant phase space. Let us only check one of the terms,

$$\mathrm{Tr}_{\omega}(A_i(\gamma\lambda)_{21}s^{-1}q^{-1}) = \mathrm{Tr}_{\omega}(A_i(\gamma_{21}\lambda_{11}s^{-1}q^{-1} + \gamma_{22}\lambda_{21}s^{-1}q^{-1})) = \mathrm{Tr}_{\omega}(A_i\gamma_{21}q^{-1}),$$

by using the fact that the last term is in $(\mathcal{L}^{(1,\infty)})^{(0)}$ (and similarly for the other type of term). Hence we can consider the set of functions as the sections of a line bundle on the quotient, $\tilde{G}_{1+}/\tilde{G}_{(1+,0)}$. Since we already know that for B_{1+} the quotient cancels out the q parts, for the above form also we get

$$\tilde{G}_{1+}/\tilde{G}_{(1+,0)} \approx GL_{1+}/GL_{(1+,0)} = \begin{pmatrix} \mathcal{B} & \mathcal{L}^{(2,\infty)} \\ \mathcal{L}^{(2,\infty)} & \mathcal{B} \end{pmatrix} \bigg/ \begin{pmatrix} \mathcal{B} & \mathcal{L}^{(2,\infty)} \\ (\mathcal{L}^{(2,\infty)})^{(0)} & \mathcal{B} \end{pmatrix} \approx \mathcal{L}^{(2,\infty)}/(\mathcal{L}^{(2,\infty)})^{(0)}. \tag{72}$$

This shows that the relevant part of the phase spaces for the disc and the Grassmannian are of equal size. We are not able to provide a link with this and the coordinate description at the present moment. Our guess is that Grassmannian also has the same embedding into a flat system; this manifests the possible equivalence of the two systems. We hope to clarify some of these issues in a future publication.

ACKNOWLEDGMENTS

Most of this paper owes a lot to several conversations with S. G. Rajeev, and shows his guidance and influence. We thank J. Mickelsson for reading and suggesting corrections, M. Wodzicki for a series of marvelous lectures on traces, and E. Langmann for perusing through and several comments. We also would like to thank J. Brodzki, P. Bongaart, K. Gawedzki, G. Landi, and M. Walze, for many useful discussions. The author gratefully acknowledges the hospitality of S. Majid and his group, and the kind invitation of P. Goddard and D. Crighton to DAMTP, where most of this work was done during the author's stay in Cambridge. During this project the author was supported by the EPDI grant, and we thank IHES for the excellent help and working environment provided.

APPENDIX: MISCELLANEOUS RESULTS

The definitions of the operator ideals will be given. Let us start with the definition of $\mathcal{L}^{(2,\infty)}$. Operator ideals contain compact operators, thus they are given by the summability properties of the singular values of the operators. If $\mu_n(A) = n$th eigenvalue of $|A|$, then we define a new norm:

$$\|A\|_{\mathcal{L}^{(2,\infty)}}=\sup_N\frac{\Sigma_{n=1}^N\mu_n(A)}{\Sigma_{i=1}^N 1/n^{1/2}}. \tag{A1}$$

The set of all $A\in K(\mathcal{H})$ for which the above norm is finite is denoted by $\mathcal{L}^{(2,\infty)}$. It is a symmetrically normed ideal.[6] Since the sequence $1/n^{1/2}$ is regular, the same ideal can be defined through the asymptotic behavior of the singular values. In fact, the set of operators in $\mathcal{L}^{(2,\infty)}$ can be defined as $A\in K(\mathcal{H})$ such that $\mu_n(A)=O(n^{-1/2})$. This also gives a simple characterization of the completion of the finite rank operators inside $\mathcal{L}^{(2,\infty)}$, denoted as $(\mathcal{L}^{(2,\infty)})^{(0)}$; $A\in(\mathcal{L}^{(2,\infty)})^{(0)}$ iff $\mu_n(A)=o(n^{-1/2})$. [The symbol $\mu_n=O(\pi_n)$ means that, $\limsup_{n\to\infty}\mu_n/\pi_n<\infty$ and $\mu_n=o(\pi_n)$ iff $\lim_{n\to\infty}\mu_n/\pi_n=0$.] One can define the norm for $\mathcal{L}^{(1,\infty)}$ in the same way replacing the sequence $1/n^{1/2}$ by $1/n$. This is not a regular sequence, so the completions of finite rank operators are given by the behavior of the partial sums; $\sigma_N(A)=\Sigma_{n=1}^N\mu_n(A)$, $\sigma_N(A)=O(\log N)$. If $\mu_n(B)=o(1/n)$, then it implies that $\sigma_N(B)=o(\log N)$, hence $B\in(\mathcal{L}^{(1,\infty)})^{(0)}$. However, the converse is not true.

We give a proof that $A,B\in\mathcal{L}^{(1,\infty)}$, then $AB\in\mathcal{L}^1$. Let us assume that the hypothesis is true. It implies that $A,B\in\mathcal{L}^2$ as well. However, we know that $\mathcal{L}^2\mathcal{L}^2\in\mathcal{L}^1$, hence the result.

Next, we will prove that if $A\in\mathcal{L}^{(2,\infty)}$ and $B\in(\mathcal{L}^{(2,\infty)})^{(0)}$, then $AB\in(\mathcal{L}^{(1,\infty)})^{(0)}$.

We will use the inequalities satisfied by the singular values:

$$\mu_{n+m}(AB)\leq\mu_n(A)\mu_m(B). \tag{A2}$$

Choose $n+m=2N+j$, where $j=0,1$ and look at the following limit:

$$\limsup_{N\to\infty}(2N+j)\mu_{2N+j}(AB)\leq\limsup_{N\to\infty}(2N+j)^{1/2}\mu_N(A)(2N+j)^{1/2}\mu_{N+j}(B). \tag{A3}$$

Now we can use

$$\lim_{N\to\infty}(N^{1/2}\mu_N(A))=a<\infty \quad\text{and}\quad \lim_{N\to\infty}((N^{1/2}\mu_N(B))=0 \tag{A4}$$

in the above expression to get

$$\lim_{N\to\infty}(2N+j)\mu_{2N+j}(AB)=0, \tag{A5}$$

and this implies that the product is in the closure, $AB\in(\mathcal{L}^{(1,\infty)})^{(0)}$. One can imitate the above proof to show that $A,B\in\mathcal{L}^{(2,\infty)}$, then $AB\in\mathcal{L}^{(1,\infty)}$; we leave this to the reader.

Let us use the same idea to show that $K(\mathcal{H})\mathcal{L}^{(2,\infty)}\subset(\mathcal{L}^{(2,\infty)})^{(0)}$:

$$\limsup_{2N+j}(2N+j)^{1/2}\mu_{2N+j}(AK)\leq\limsup_{2N+j}(2N+j)^{1/2}\mu_N(A)\mu_{N+j}(K)=0 \tag{A6}$$

by using the fact that $\lim_N\mu_N(K)=0$ for a compact operator K.

In the second part we will prove some of the properties of the conditional Dixmier traces, which are identical to the usual trace conditions. We define the conditional trace as

$$\mathrm{Tr}_\omega^\epsilon A=\mathrm{Tr}_\omega^\epsilon\begin{pmatrix}a_{11} & a_{12}\\ a_{21} & a_{22}\end{pmatrix}=\frac{1}{2}(\mathrm{Tr}_\omega(a_{11})+\mathrm{Tr}_\omega(a_{22}))=\frac{1}{4}\mathrm{Tr}_\omega[A+\epsilon A\epsilon] \tag{A7}$$

for $A=\left(\begin{smallmatrix}a_{11} & a_{12}\\ a_{21} & a_{22}\end{smallmatrix}\right)$. Notice that we have absorbed a factor of $\frac{1}{2}$ into the definition to make the formulas involving this trace look simpler. First property,

$$\mathrm{Tr}_\omega^\epsilon AB=\mathrm{Tr}_\omega^\epsilon BA \tag{A8}$$

if all the individual terms in the products $\Sigma_k a_{ik} b_{ki}$ are in the ideal $\mathcal{L}^{(1,\infty)}$. This is easy to see if we use the definition of the conditional trace, and

$$\begin{pmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{pmatrix}\begin{pmatrix} b_{11} & b_{12} \\ b_{21} & b_{22} \end{pmatrix}=\begin{pmatrix} a_{11}b_{11}+a_{12}b_{21} & * \\ * & a_{21}b_{12}+a_{22}b_{22} \end{pmatrix}. \tag{A9}$$

If each of the terms appearing in the diagonal parts is independently in $\mathcal{L}^{(1,\infty)}$, we can use $\mathrm{Tr}_\omega\, ab=\mathrm{Tr}_\omega\, ba$ and see that the result is the same when one takes the product in the opposite order.

We will show that the group representation is satisfied up to a central term. It is more convenient to use $\det_\omega$ instead of e^{Tr_ω} and the power $1/\hbar$ is not written since it is easy to put back. We compare the two ways of applying the representation, $\rho(g_2^{-1})\rho(g_1^{-1})\Psi(Z)$ and $\rho((g_1g_2)^{-1})\Psi(Z)$. The first expression gives

$$\det{}_\omega(d_1^{-1}c_1(a_2Z+b_2)(c_2Z+d_2)^{-1}+1)\det{}_\omega(d_2^{-1}c_2Z+1)\Psi((g_1g_2)\circ Z), \tag{A10}$$

and the second

$$\det{}_\omega((d_1d_2+c_1b_2)^{-1}(c_1a_2+d_1c_2)Z+1)\Psi((g_1g_2)^{-1}\circ Z). \tag{A11}$$

It is enough to compare the ''determinant'' pieces because the other parts are the same. Let us check the following:

$$\begin{aligned}
&\det{}_\omega(d_1^{-1}c_1(a_2Z+b_2)(c_2Z+d_2)^{-1}+1)\det{}_\omega(d_2^{-1}c_2Z+1)\\
&\quad=\det{}_\omega(d_2^{-1}d_1^{-1}c_1(a_2Z+b_2)(d_2^{-1}c_2Z+1)^{-1}+1)\det{}_\omega(d_2^{-1}c_2Z+1)\\
&\quad=\det{}_\omega((d_1d_2)^{-1}c_1(a_2Z+b_2)(d_2^{-1}c_2Z+1)^{-1}(d_2^{-1}c_2Z+1)+d_2^{-1}c_2Z+1)\\
&\quad=\det{}_\omega((d_1d_2)^{-1}c_1(a_2Z+b_2)+d_2^{-1}c_2Z+1)\\
&\quad=\det{}_\omega((d_1d_2)^{-1}(c_1a_2+d_1c_2)Z+(d_1d_2)^{-1}c_1b_2+1).
\end{aligned}$$

We used the multiplicative property of the $\det_\omega$, which comes from the properties of the Dixmier trace. The equalities are true by adding terms which give zero under the Dixmier trace; this is the advantage of using the symbol $\det_\omega$. Let us compare this with

$$\begin{aligned}
&\det{}_\omega((d_1d_2+c_1b_2)^{-1}(c_1a_2+d_1c_2)Z+1)\\
&\quad=\det{}_\omega[((d_1d_2)^{-1}c_1b_2+1)^{-1}(d_1d_2)^{-1}(c_1a_2+d_1c_2)Z+1]\\
&\quad=\det{}_\omega((d_1d_2)^{-1}c_1b_2+1)^{-1}\det{}_\omega((d_1d_2)^{-1}(c_1a_2+d_1c_2)Z+(d_1d_2)^{-1}c_1b_2+1),
\end{aligned}$$

hence they differ by a constant multiple which never vanishes,

$$c_\omega(g_1,g_2)=\det{}_\omega((d_1d_2)^{-1}c_1b_2+1). \tag{A12}$$

This trace is well defined as one can check, and, since it never vanishes, the two sides are equal. We need to further check that it obeys the cocyle condition,

$$\begin{aligned}
c_\omega(g_1g_2,g_3)c_\omega(g_1,g_2)&=c_\omega(g_1,g_2g_3)c_\omega(g_2,g_3)\\
&=\det{}^{1/\hbar}[(d_1d_2d_3)^{-1}c_1a_2b_3+(d_2d_3)^{-1}c_2b_3+(d_1d_2)^{-1}c_1b_2+1].
\end{aligned} \tag{A13}$$

The sum of all the terms except 1 inside the determinant sign are in the ideal $\mathcal{L}^{(1,\infty)}$, hence the Dixmier trace is well defined. The cocycle c_ω, in the finite-dimensional case, can be obtained from $\phi(g)=\det(d)$, as $c(g_1,g_2)=\phi(g_1)\phi(g_2)\phi(g_1g_2)^{-1}$. Clearly it is not well defined in infinite dimensions; in fact, the extension is nontrivial. Thus, we obtain a representation of a central extension $\hat{\mathrm{U}}_{1+}(\mathcal{H}_-,\mathcal{H}_+)$ in the quantum Hilbert space of holomorphic sections.

The w_∞ algebra is a higher-spin extension of the Virasoro algebra. In this paper, we construct the gauge theory of *w* symmetry in terms of its representations. [S0022-2488(99)03508-2]

I. INTRODUCTION

The Virasoro algebra and its extensions play a fundamental role in the study of two-dimensional conformal field theories. The w_∞ algebra[1] is a higher-spin extension of the Virasoro algebra. It can be regarded as the algebra of smooth area-preserving diffeomorphisms of the cylinder. It is known that two-dimension gravity can be thought of as the result of gauging the Virasoro algebra. *W* gravity is the gauge theory of local *W* algebra symmetry. The study of *W* gravity has been guided by the analogy with two-dimension gravity. The w_3 gravity was first constructed in the *W* gravity.[2] It was begun from a free action realizing a chiral w_3 symmetry, and Noether-coupled it to spin-2 and spin-3 background gauge fields. Schoutens *et al.*[3] extended this work to a nonchiral gauged theory of w_3. In terms of these methods, chiral and nonchiral w_∞ gravity was constructed by Bergshoeff *et al.*[4] We know that it is difficult to construct a gauge theory of the Virasoro symmetry through the conventional method. The reason is that the Virasoro group is not only noncompact, but also does not admit any bi-invariant Cartan–Killing metric. For the Virasoro group, the representation that we know well is the highest-weight representation. But this representation is of no use to construct the gauge theory of the Virasoro group because the gauge field must form an adjoint representation. One must consider the other representation. In order to construct the wanted gauge theory, Cho generalized the Kaplansky–Feigin–Fuks (KFF) representation of the Virasoro algebra[5,6] and constructed the invariant tensors. With all of these elements, he gave a gauge theory of the Virasoro group.[7,8]

As a higher-spin extension of the Virasoro algebra, the generators of the w_∞ algebra can be expressed linearly in terms of the generators of the ''Virasoro-like'' algebras. From the representations of the ''Virasoro-like'' algebras, we can obtain the representations of the w_∞ algebra that we need for the gauge theory. In this paper, we will construct the gauge theory of *w* symmetry from its representations.

II. w_∞ ALGEBRA AND ITS REPRESENTATIONS

The w_∞ algebra is an infinite-dimensional algebra. Its commutation relation is given by[4]

$$[v_{m_1,m_2},v_{n_1,n_2}]\equiv[v_{\bar{m}},v_{\bar{n}}]=f_{\bar{m}\bar{n}}^{\bar{k}}v_{\bar{k}}=[(n_2+1)m_1-(m_2+1)n_1]v_{\bar{m}+\bar{n}}, \tag{1}$$

where

$$\bar{m}=(m_1,m_2). \tag{2}$$

The generators are given on a two-dimensional space (x,y) as follows:

[a)]Electronic mail: Zhaowz100@263.net

$$v_{\overline{m}}=e^{(im_1x)}[m_1y^{m_2+1}\partial_y+i(m_2+1)y^{m_2}\partial_x], \tag{3}$$

where m_2 is the index of the conformal spins satisfying $m_2+2\geqslant 2$ and $m_1\in Z$. The generators $v_{m,0}$ are just the Virasoro generators L_m. If we take $z=e^{ix}$, then the generators become

$$v_{\overline{m}}=(m_2+1)L^{1,0}_{m_1,m_2}-m_1L^{0,1}_{m_1,m_2}, \tag{4}$$

where

$$L^{1,0}_{m_1,m_2}=-z^{m_1+1}y^{m_2}\frac{d}{dz}, \tag{5}$$

and

$$L^{0,1}_{m_1,m_2}=-z^{m_1}y^{m_2+1}\frac{d}{dy}. \tag{6}$$

The generators $L^{1,0}_{m_1,m_2}$ and $L^{0,1}_{m_1,m_2}$ satisfy the ''Virasoro-like'' algebra, respectively, i.e.,

$$[L^{1,0}_{m_1,m_2},L^{1,0}_{n_1,n_2}]=(m_1-n_1)L^{1,0}_{m_1+n_1,m_2+n_2}, \tag{7}$$

$$[L^{0,1}_{m_1,m_2},L^{0,1}_{n_1,n_2}]=(m_2-n_2)L^{0,1}_{m_1+n_1,m_2+n_2}. \tag{8}$$

From the above commutation relations, we obtain the following adjoint representations of the ''Virasoro-like'' algebras:

$$(L^{1,0}_{m_1,m_2})^{k_1,k_2}_{n_1,n_2}=(m_1-n_1)\,\delta^{\overline{k}}_{\overline{m}+\overline{n}}, \tag{9}$$

$$(L^{0,1}_{m_1,m_2})^{k_1,k_2}_{n_1,n_2}=(m_2-n_2)\,\delta^{\overline{k}}_{\overline{m}+\overline{n}}, \tag{10}$$

where

$$\delta^{\overline{k}}_{\overline{m}+\overline{n}}=\delta^{k_1}_{m_1+n_1}\delta^{k_2}_{m_2+n_2}. \tag{11}$$

As the case of the Virasoro algebra,[7] we introduce the following KFF representations of the ''Virasoro-like'' algebras:

$$(L^{1,0}_{m_1,m_2})^{k_1,k_2}_{n_1,n_2}=[(\alpha+1)m_1+\beta-k_1]\,\delta^{\overline{k}}_{\overline{m}+\overline{n}}, \tag{12}$$

$$(L^{0,1}_{m_1,m_2})^{k_1,k_2}_{n_1,n_2}=[(\alpha+1)m_2-k_2]\,\delta^{\overline{k}}_{\overline{m}+\overline{n}}, \tag{13}$$

where α and β are arbitrary complex numbers. One can easily show that the KFF representations (12), (13) satisfy the following relations:

$$\begin{aligned}([L^{1,0}_{m_1,m_2},,L^{1,0}_{n_1,n_2}])^{k_1,k_2}_{l_1,l_2}&=(L^{1,0}_{m_1,m_2})^{k_1,k_2}_{h_1,h_2}(L^{1,0}_{n_1,n_2})^{h_1,h_2}_{l_1,l_2}-(L^{1,0}_{n_1,n_2})^{k_1,k_2}_{h_1,h_2}(L^{1,0}_{m_1,m_2})^{h_1,h_2}_{l_1,l_2}\\&=(m_1-n_1)(L^{1,0}_{m_1+n_1,m_2+n_2})^{k_1,k_2}_{l_1,l_2},\end{aligned} \tag{14}$$

$$([L^{0,1}_{m_1,m_2}, ,L^{0,1}_{n_1,n_2}])^{k_1,k_2}_{l_1,l_2}=(L^{0,1}_{m_1,m_2})^{k_1,k_2}_{h_1,h_2}(L^{0,1}_{n_1,n_2})^{h_1,h_2}_{l_1,l_2}-(L^{0,1}_{n_1,n_2})^{k_1,k_2}_{h_1,h_2}(L^{0,1}_{m_1,m_2})^{h_1,h_2}_{l_1,l_2}$$
$$=(m_2-n_2)(L^{0,1}_{m_1+n_1,m_2+n_2})^{k_1,k_2}_{l_1,l_2}. \tag{15}$$

In fact, the adjoint representations (9), (10) correspond to the $(\alpha=1,\ \beta=0)$ representation of the KFF representations (12), (13), respectively. From the adjoint representations of the ''Virasoro-like'' algebras, we have

$$(v_{\bar{m}})^{\bar{k}}_{\bar{n}}=(m_2+1)(L^{1,0}_{m_1,m_2})^{k_1,k_2}_{n_1,n_2}-m_1(L^{0,1}_{m_1,m_2})^{k_1,k_2}_{n_1,n_2}=[(n_2+1)m_1-(m_2+1)n_1]\,\delta^{\bar{k}}_{\bar{m}+\bar{n}}. \tag{16}$$

It is obvious that the above representation is the adjoint representation of the w_∞ algebra. It acts on an infinite-dimensional vector $\phi^{\bar{k}}$ as

$$(v_{\bar{m}}\phi)^{\bar{k}}=-f^{\bar{k}}_{\bar{m}\bar{n}}\phi^{\bar{n}}=-[(k_2+2)m_1-(m_2+1)k_1]\,\phi^{\bar{k}-\bar{m}}. \tag{17}$$

Using the KFF representations (12), (13), we have the KFF representation of the *w* symmetry,

$$(v_{\bar{m}})^{\bar{k}}_{\bar{n}}=\{(m_2+1)[(\alpha+1)m_1+\beta-k_1]-m_1[(\alpha+1)m_2-k_2]\}\,\delta^{\bar{k}}_{\bar{m}+\bar{n}}. \tag{18}$$

One can show that the above representation satisfies the relation

$$([v_{\bar{m}},v_{\bar{n}}])^{\bar{k}}_{\bar{l}}=(v_{\bar{m}})^{\bar{k}}_{\bar{h}}(v_{\bar{n}})^{\bar{h}}_{\bar{l}}-(v_{\bar{n}})^{\bar{k}}_{\bar{h}}(v_{\bar{m}})^{\bar{h}}_{\bar{l}}=[(n_2+1)m_1-(m_2+1)n_1](v_{\bar{m}+\bar{n}})^{\bar{k}}_{\bar{l}}. \tag{19}$$

If we take $m_2=n_2=k_2=0$, then the representation (18) gives the KFF representation of the Virasoro algebra.[7] This is the reason that we require $\beta=0$ in Eq. (13). The representation (18) acts on an infinite-dimensional vector space $V_{(\alpha,\beta)}$ as

$$(v_{\bar{m}}\phi)^{\bar{k}}=-(v_{\bar{m}})^{\bar{k}}_{\bar{n}}\phi^{\bar{n}}=-\{(m_2+1)[(\alpha+1)m_1+\beta-k_1]-m_1[(\alpha+1)m_2-k_2]\}\,\phi^{\bar{k}-\bar{m}}, \tag{20}$$

where $\phi^{\bar{k}}$ is an element of $V_{(\alpha,\beta)}$. We introduce the dual representation of the KFF representation of the *w* symmetry that acts on the vector space $V^*_{\alpha,\beta}$ dual to $V_{\alpha,\beta}$ as follows:

$$(v_{\bar{m}}\omega)_{\bar{k}}=(v_{\bar{m}})^{\bar{n}}_{\bar{k}}\omega_{\bar{n}}=[(m_2+1)(\alpha m_1+\beta-k_1)-m_1(\alpha m_2-k_2)]\,\omega_{\bar{k}+\bar{m}}, \tag{21}$$

where $w_{\bar{k}}$ is an element of $V^*_{\alpha,\beta}$. In terms of the dual representation, we have the following contraction between $\phi^{\bar{k}}$ and $w_{\bar{k}}$:

$$\phi\cdot\omega=\phi^{\bar{k}}\omega_{\bar{k}}, \tag{22}$$

which is invariant under the *w* transformation. From Eqs. (20) and (21), it is noted that there is an isomorphism $V^*_{\alpha,\beta}\cong V_{-1-\alpha,-\beta}$ if $\omega_{\bar{k}}=\phi^{-\bar{k}}$. We can generalize the KFF representation of the *w* symmetry to a $(\bar{p},\bar{q})$ tensor $T_{(\bar{p},\bar{q})}$ and define the tensor representation by

$$v_{\bar{m}}t^{\bar{i}\cdots\bar{j}}_{\bar{k}\cdots\bar{l}}=-(v_{\bar{m}})^{\bar{i}}_{\bar{n}}t^{\bar{n}\cdots\bar{j}}_{\bar{k}\cdots\bar{l}}-\cdots-(v_{\bar{m}})^{\bar{j}}_{\bar{n}}t^{\bar{i}\cdots\bar{n}}_{\bar{k}\cdots\bar{l}}+(v_{\bar{m}})^{\bar{n}}_{\bar{k}}t^{\bar{i}\cdots\bar{j}}_{\bar{n}\cdots\bar{l}}+\cdots+(v_{\bar{m}})^{\bar{n}}_{\bar{l}}t^{\bar{i}\cdots\bar{j}}_{\bar{k}\cdots\bar{n}}, \tag{23}$$

where $t^{\bar{i}\cdots\bar{j}}_{\bar{k}\cdots\bar{l}}$ is an infinite-dimensional $(\bar{p},\bar{q})$ tensor, and define a tensor module of mixed type $\hat{T}_{p,q}$ by allowing each of the $p+q$ indices to transform according to a different (α,β) representation. For example, we can define a (0,2) tensor of mixed type $\hat{t}_{\bar{n}\bar{k}}$, which transforms as

$$(v_{\bar{m}}\hat{t})_{\bar{n}\bar{k}}=[(m_2+1)(\alpha m_1+\beta-n_1)-m_1(\alpha m_2-n_2)]\hat{t}_{\bar{n}+\bar{m},\bar{k}}+[(m_2+1)(\alpha' m_1+\beta'-k_1)$$
$$-m_1(\alpha' m_2-k_2)]\hat{t}_{\bar{n},\bar{k}+\bar{m}}. \tag{24}$$

In terms of these generalizations, we have the invariant tensors $\hat{d}^{\bar{k}}_{\bar{i}\bar{j}\cdots\bar{l}}$, $\hat{f}^{\bar{k}}_{\bar{i}\bar{j}}$ and $g_{\bar{i}\bar{j}}$, where

$$\hat{d}^{\bar{k}}_{\bar{i}\bar{j}\cdots\bar{l}}=\delta^{\bar{k}}_{\bar{i}+\bar{j}+\cdots\bar{l}}. \tag{25}$$

The indices $\overline{i,j,\ldots,l,k}$ belong to (α_1,β_1), $(\alpha_2,\beta_2),\ldots$, (α_n,β_n) and $(\alpha_1+\alpha_2+\cdots+\alpha_n,\beta_1+\beta_2+\cdots+\beta_n)$ representations, respectively,

$$\hat{f}^{\bar{k}}_{\bar{i}\bar{j}}=(v_{\bar{i}})^{\bar{k}}_{\bar{j}}=\{(i_2+1)[(\alpha+1)i_1+\beta-k_1]-i_1[(\alpha+1)i_2+\beta-k_2]\}\delta^{\bar{k}}_{\bar{i}+\bar{j}}. \tag{26}$$

The indices $\overline{i,j,k}$ belong to $(\alpha=1,\ \beta=0)$, (α,β) and (α,β) representations, respectively. The metric $g_{\bar{i}\bar{j}}=\delta^0_{\bar{i}+\bar{j}}$ is an invariant tensor of the $(\alpha=-\frac{1}{2},\ \beta=0)$ representation. The invariant tensors $\hat{d}^{\bar{k}}_{\bar{i}\bar{j}},\hat{f}^{\bar{k}}_{\bar{i}\bar{j}}$ can be used to define the vector products. The invariant metric $g_{\bar{i}\bar{j}}$ allow us to define the index raising of the tensors and the scalar product. For example, with the invariant metric, one can obtain the index raising of the tensor,

$$\phi_{\bar{k}}=g_{\bar{k}\bar{l}}\phi^{\bar{l}}=\delta^0_{\bar{k}+\bar{l}}\phi^{\bar{l}}=\phi^{-\bar{k}}, \tag{27}$$

and the scalar product

$$\phi_{\bar{k}}\phi^{\bar{k}}=g_{\bar{k}\bar{l}}\phi^{\bar{l}}\phi^{\bar{k}}=\sum_{\bar{k}}\phi^{-\bar{k}}\phi^{\bar{k}}\equiv\phi^{-\bar{k}}\phi^{\bar{k}}. \tag{28}$$

With the invariant tensor $\hat{d}^{\bar{k}}_{\bar{i}\bar{j}\cdots\bar{l}}$, one can define the nth power $(\phi^n)^{\bar{k}}$ by

$$(\phi^n)^{\bar{k}}=\hat{d}^{\bar{k}}_{\bar{k}_1\bar{k}_2\cdots\bar{k}_n}\phi^{\bar{k}_1}\phi^{\bar{k}_2}\cdots\phi^{\bar{k}_n}=\sum_{\bar{k}_1+\cdots+\bar{k}_n=\bar{k}}\phi^{\bar{k}_1}\phi^{\bar{k}_2}\cdots\phi^{\bar{k}_n}. \tag{29}$$

These invariant tensors are very useful in our gauge theory. The concepts of hermiticity and the unitarity of the representation take the important roles in the gauge theory. We call a tensor field $t^{\bar{i}\cdots\bar{j}}_{\bar{k}\cdots\bar{l}}$ Hermitian[8] if

$$(t^{\bar{i}\cdots\bar{j}}_{\bar{k}\cdots\bar{l}})^*=t^{-\bar{i}\cdots-\bar{j}}_{-\bar{k}\cdots-\bar{l}}. \tag{30}$$

As the case of the Virasoro symmetry,[8] we can introduce the following complex conjugate KFF representations of the ‘‘Virasoro-like’’ algebras:

$$(\overline{L}^{1,0}_{m_1,m_2})^{k_1,k_2}_{n_1,n_2}=[(\alpha^*+1)m_1-\beta^*+k_1]\delta^{\bar{k}}_{\bar{n}-\bar{m}}, \tag{31}$$

and

$$(\overline{L}^{0,1}_{m_1,m_2})^{k_1,k_2}_{n_1,n_2}=[(\alpha^*+1)m_2+k_2]\delta^{\bar{k}}_{\bar{n}-\bar{m}}. \tag{32}$$

With the above complex conjugate representations, we have the conjugate KFF representation of w symmetry,

$$(\overline{v_{\bar m}})_{\bar n}^{\bar k} = (m_2+1)(\overline{L}_{m_1,m_2}^{1,0})_{n_1,n_2}^{k_1,k_2} - m_1(\overline{L}_{m_1,m_2}^{0,1})_{n_1,n_2}^{k_1,k_2}$$

$$= \{(m_2+1)[(\alpha^*+1)m_1 - \beta^* + k_1] - m_1[(\alpha^*+1)m_2+k_2]\}\delta_{\bar n - \bar m}^{\bar k}, \tag{33}$$

which acts on an infinite-dimensional complex conjugate vector space $\overline{V}_{\alpha,\beta}$ as

$$v_{\bar m}(\phi^{\bar k})^* = -(\overline{v_{\bar m}})_{\bar n}^{\bar k}(\phi^{\bar n})^*$$

$$= -\{(m_2+1)[(\alpha^*+1)m_1 - \beta^* + k_1] - m_1[(\alpha^*+1)m_2+k_2]\}(\phi^{\bar k + \bar m})^*, \tag{34}$$

where $(\phi^{\bar k})^*$ is an element of $\overline{V}_{\alpha,\beta}$.

Let us consider the following Hermitian product (φ,ϕ), defined by

$$(\varphi,\phi) = (\varphi^{\bar k})^*\phi^{\bar k}; \tag{35}$$

then we have

$$v_{\bar m}(\varphi,\phi) = -(\overline{v_{\bar m}})_{\bar n}^{\bar k}(\varphi^{\bar n})^*\phi^{\bar k} - (\varphi^{\bar k})^*(v_{\bar m})_{\bar n}^{\bar k}\phi^{\bar n}$$

$$= -[(\alpha+\alpha^*+1)m_1 + (m_2+1)(\beta-\beta^*)](\varphi^{\bar k})^*\phi^{\bar k - \bar m}. \tag{36}$$

So the Hermitian product becomes invariant under *w* symmetry if and only if

$$\alpha+\alpha^*+1=0, \tag{37}$$

and

$$\beta-\beta^*=0. \tag{38}$$

We call an (α,β) representation unitary if the above condition is satisfied. Clearly, the $(\alpha=-\frac{1}{2}, \beta=0)$ representation is unitary. This representation is important in the following gauge theory.

III. THE GAUGE THEORY OF *W* SYMMETRY

Let $A_\mu^{\bar k}$ be the Hermitian gauge potential that forms an adjoint representation, the matter field $\phi^{\bar k}$ is a Hermitian scalar multiplet that forms a $(\alpha=-\frac{1}{2}, \beta=0)$ representation, and the infinitesimal gauge parameter of *w* symmetry forms an adjoint representation. Under the infinitesimal gauge transformation, we require

$$\delta A_\mu^{\bar k} = -\frac{1}{g}[\partial_\mu\theta^{\bar k} + ig(A_\mu\times\theta)^{\bar k}] = -\frac{1}{g}\{\partial_\mu\theta^{\bar k} + ig[m_1(k_2+2) - k_1(m_2+1)]A_\mu^{\bar m}\theta^{\bar k - \bar m}\}, \tag{39}$$

$$\delta\phi^{\bar k} = i(\theta\times\phi)^{\bar k} = i\hat f_{\bar m \bar n}^{\bar k}\theta^{\bar m}\phi^{\bar n} = i[(m_2+1)(\tfrac{1}{2}m_1 - k_1) - m_1(\tfrac{1}{2}m_2 - k_2)]\theta^{\bar m}\phi^{\bar k - \bar m}. \tag{40}$$

The field strength $F_{\mu\nu}^{\bar k}$ and the covariant derivative D_μ are, respectively, defined by

$$F_{\mu\nu}^{\bar k} = \partial_\mu A_\nu^{\bar k} - \partial_\nu A_\mu^{\bar k} + ig(A_\mu\times A_\nu)^{\bar k} = \partial_\mu A_\nu^{\bar k} - \partial_\nu A_\mu^{\bar k} + ig[m_1(k_2+2) - k_1(m_2+1)]A_\mu^{\bar m}A_\nu^{\bar k - \bar m}, \tag{41}$$

$$D_\mu\phi^{\bar k} = \partial_\mu\phi^{\bar k} + ig(A_\mu\times\phi)^{\bar k} = \partial_\mu\phi^{\bar k} + ig[(m_2+1)(\tfrac{1}{2}m_1 - k_1) - m_1(\tfrac{1}{2}m_2 - k_2)]A_\mu^{\bar m}\phi^{\bar k - \bar m}, \tag{42}$$

where g is the coupling constant. For the Hermitian fields $D_\mu\phi^{\bar k}$ and $F_{\mu\nu}^{\bar k}$, we have

$$(D_\mu \phi^{\bar{k}})^* = D_\mu \phi^{-\bar{k}}, \tag{43}$$

and

$$(F_{\mu\nu}^{\bar{k}})^* = F_{\mu\nu}^{-\bar{k}}, \tag{44}$$

so here the coupling constant g is required to be real. Under the gauge transformations (39), (40), we have

$$\delta F_{\mu\nu}^{\bar{k}} = i[m_1(k_2+2) - k_1(m_2+1)]\theta^{\bar{m}} F_{\mu\nu}^{\bar{k}-\bar{m}}, \tag{45}$$

and

$$\delta(D_\mu \phi^{\bar{k}}) = i[(m_2+1)(\tfrac{1}{2}m_1 - k_1) - m_1(\tfrac{1}{2}m_2 - k_2)]\theta^{\bar{m}}(D_\mu \phi^{\bar{k}-\bar{m}}). \tag{46}$$

Clearly $F_{\mu\nu}^{\bar{k}}$ and $D_\mu \phi^{\bar{k}}$ transform covariantly as an adjoint representation and a $(\alpha=-1/2, \beta=0)$ representation, respectively. With the above definitions, we can construct the following Lagrangian:

$$\begin{aligned} L &= -\frac{1}{4}\kappa^6 d_{\bar{i}\bar{j}}^{\bar{k}} (\phi^6)_{\bar{k}} F_{\mu\nu}^{\bar{i}} F_{\mu\nu}^{\bar{j}} + \frac{1}{2}(D_\mu \phi_{\bar{k}})(D^\mu \phi^{\bar{k}}) + \frac{1}{2}\mu^2(\phi_{\bar{k}})\phi^{\bar{k}} - \frac{\lambda}{4}(\phi_{\bar{k}}\phi^{\bar{k}})^2 \\ &= -\frac{1}{4}\kappa^6 (\phi^6)^{-\bar{i}-\bar{j}} F_{\mu\nu}^{\bar{i}} F_{\mu\nu}^{\bar{j}} + \frac{1}{2}(D_\mu \phi^{\bar{k}})^*(D^\mu \phi^{\bar{k}}) + \frac{1}{2}\mu^2(\phi^{\bar{k}})^*\phi^{\bar{k}} - \frac{\lambda}{4}(\phi^{\bar{k}*}\phi^{\bar{k}})^2, \end{aligned} \tag{47}$$

where the scale parameter κ is to keep $\kappa\phi^{\bar{k}}$ dimensionless. One can easily show that this Lagrangian is invariant under the gauge transformations (39), (40). The form of this Lagrangian is the same as the case of the gauge theory of the Virasoro symmetry.[7] If we take the conformal spin indices $i_2 = j_2 = k_2 = 0$, then the Lagrangian (47) comes back to the case of the Virasoro symmetry.

IV. SUMMARY

It is not as the general method[4] of the gauge theory of w symmetry. In this paper, the gauge theory of w symmetry is constructed in terms of its representations. It is known that the gauge theory of the Virasoro symmetry from its representation[7] can be described as an effective field theory of the string theory. As a higher-spin extension of the Virasoro algebra, the w_∞ algebra possesses more symmetry. This gauge theory will be useful in further explorations for the string theory.

Method of handling the divergences in the radiation theory of sources that move faster than their waves

H. Ardavan
Institute of Astronomy, University of Cambridge, Madingley Road, Cambridge CB3 0HA, England

(Received 16 April 1999; accepted for publication 19 June 1999)

The nonintegrable singularities that arise when the retarded potentials associated with supersonically or superluminally moving sources are differentiated are closely related to those encountered in the context of the Cauchy problem for hyperbolic equations over odd-dimensional space-times. The purpose of this paper is to point out that the field components are given in these cases by Hadamard's finite parts of the resulting divergent integrals, as in the case of the Cauchy problem, and to show that the procedure familiar from the subluminal regime—which is used by Hannay—is not applicable when there are source elements that approach the observer with the wave speed and zero acceleration at the retarded time. © *1999 American Institute of Physics.* [S0022-2488(99)01809-5]

I. INTRODUCTION

The emission of waves by a moving point source whose speed exceeds the wave speed is generally described by a Lienard–Wiechert potential that has extended singularities. These singularities occur on the envelope of the emitted wave fronts and its cusps, where the waves interfere constructively and so form caustics. A well-understood example is the emission of acoustic waves by a point source that moves along a straight line with a constant supersonic speed. In this case a simple caustic forms along a cone issuing from the source, the so-called Mach cone, and the Lienard–Wiechert potential describing the sound amplitude diverges algebraically as this cone is approached from inside.

Neither supersonically nor superluminally moving sources can ever be pointlike.[1] However, the retarded potential due to any physically realizable source of this kind consists of the superposition of the potentials of the moving volume elements that constitute it, so that the Lienard–Wiechert potentials in question act as Green's functions for the calculation of the potentials of viable extended sources.

Thus, the integral representing the superposition of the contributions of the various volume elements of a supersonically or superluminally moving extended source to its potential would generally entail an integrand with algebraic singularities, singularities that have extended loci but are as a rule integrable. If (in order to calculate the field) this integral representation of the potential is differentiated with respect to the space-time coordinates of the observer, therefore, there results a new integral with an integrand that has a higher order singularity and so is no longer integrable (see, e.g., Ref. 2). A question that thus arises, and has been a source of some confusion in the literature,[3] is how to handle such nonintegrable singularities.

II. RADIATION INTEGRALS INVOLVING SINGULAR KERNELS AND THEIR HADAMARD'S FINITE PARTS

Green's functions with algebraic singularities also arise when the wave equation is solved over a space-time that has an even number of spatial dimensions. For example, the solution of the two-dimensional wave equation

$$\partial^2 G_{2D}/\partial x^2+\partial^2 G_{2D}/\partial y^2-\partial^2 G_{2D}/\partial(ct)^2=-4\pi\delta(x-\xi)\delta(y-\eta)\delta(t-\tau), \qquad (1)$$

in the absence of boundaries, has the form

$$G_{2D}=2c[c^2(t-\tau)^2-R_{2D}^2]^{-1/2}\theta(t-\tau-R_{2D}/c), \tag{2}$$

where $R_{2D}\equiv[(x-\xi)^2+(y-\eta)^2]^{1/2}$, δ is the Dirac delta function and $\theta(x)$ is unity for $x>0$ and zero for $x<0$ (see Ref. 4, p. 842).

The square-root singularity of this Green's function over the space-time cone $t-\tau=R_{2D}/c$ is integrable. However, to solve the initial-boundary-value problem for the two-dimensional wave equation with Cauchy data that are prescribed on a space-like surface (such as $t=$const) in the (x,y,t)-space, one needs to evaluate an integral over this surface whose integrand consists of the product of the normal derivative of G_{2D} (e.g., $\partial G_{2D}/\partial t$) with the initial value of the wave amplitude (see Ref. 4, p. 893). The singularity of the kernel of the required integral at the intersection of the cone $t-\tau-R_{2D}/c=0$ with the space-like surface on which the Cauchy data is prescribed is consequently like that of $(t-t_0)^{-3/2}$ at $t-t_0=0$ and so is not integrable.

The first systematic discussion of such nonintegrable singularities was given by Hadamard in his general treatment of the Cauchy problem for hyperbolic partial differential equations that have an odd number of independent variables. From his work, and from a modern version of it featuring in the theory of generalized functions, it is well known that the way to handle the nonintegrable singularities of the derivatives of the Green's functions that appear in the solutions to the Cauchy problem is to take the so-called Hadamard finite part of the divergent integrals in question.[5,6]

There is a close analogy between the Lienard–Wiechert potentials for sources that move faster than their waves and the Green's functions for hyperbolic differential equations that govern the propagation of waves in two spatial dimensions. For example, the potential for a point source of unit strength that moves along a straight line ($x=$const, $y=$const) with a supersonic speed u ($>c$) is given, at an observation point P with the space-time coordinates $(x_P,y_P,z_P;t_P)$, by

$$G_M=2[(\tilde{z}-\tilde{z}_P)^2-(M^2-1)R_{2D}^2]^{-1/2}\theta[\tilde{z}-\tilde{z}_P-(M^2-1)^{1/2}R_{2D}], \tag{3}$$

where $\tilde{z}$ is defined as $z-ut$ and M stands for the Mach number u/c (see, e.g., Ref. 7). The Lienard–Wiechert potential G_M has precisely the same mathematical structure as the Green's function G_{2D} of the two-dimensional wave equation (1).

This analogy stems from the fact that the density ρ of a rectilinearly moving supersonic source with a fixed distribution pattern depends on z and t in only the combination $z-ut=\tilde{z}$, i.e., is of the form $\rho(x,y,z,t)=\rho(x,y,\tilde{z})$. In the absence of space-time boundaries, this symmetry of the source $(\partial\rho/\partial t=-u\,\partial\rho/\partial z)$ imposes a corresponding symmetry $(\partial\psi/\partial t=-u\,\partial\psi/\partial z)$ on the potential so that the wave equation governing the potential $\psi(x,y,\tilde{z})$ of such a source,

$$\partial^2\psi/\partial x^2+\partial^2\psi/\partial y^2-(M^2-1)\partial^2\psi/\partial\tilde{z}^2=-4\pi\rho(x,y,\tilde{z}), \tag{4}$$

has only three rather than four independent variables. Thus the functions G_{2D} and G_M are analogous because the differential operators in Eqs. (1) and (4) can be rendered identical by a mere rescaling of the coordinates.

Unlike some other symmetries (e.g., $\partial\psi/\partial t=0$) that alter the type of the differential equation governing the potential from hyperbolic to elliptic or parabolic at the same time as reducing the number of its independent variables, the symmetry imposed by the rigidity of a moving source distribution does not affect the type of the equation when the speed of the source exceeds the wave speed: for $M>1$, the coefficient of $\partial^2\psi/\partial\tilde{z}^2$ in (4) is negative and so the variable $\tilde{z}$ is time-like. Thus, the well-known singularity associated with the ray conoid of the two-dimensional wave equation[8] is mathematically identical to the caustic singularity that occurs on the envelope of the wave fronts emanating from a moving point source in three dimensions.

Inasmuch as the origins of the two types of singularity are mathematically the same, it is clear that the techniques for handling the analogous divergences that they cause in the contexts of radiation theory and of Cauchy problem should also be the same. The technique used in the context of the Cauchy problem has been known for some time,[5] but the applicability of this same technique to the corresponding problems in radiation theory does not seem to have been noted until recently.[2]

From the standpoint of the theory of generalized functions, there is a well-defined procedure for obtaining the physically relevant values of the divergent integrals that appear when the integral representations of the retarded potential are differentiated, a procedure involving integration by parts that extracts the so-called Hadamard finite part of the resulting divergent integrals (see, e.g., Ref. 6). Hadamard's finite part of the convolution of the density of a supersonically or superluminally moving extended source with the nonintegrable derivative of an associated Lienard–Wiechert potential yields the value that we would have obtained if we had first evaluated the original integral representing the retarded potential of the source as an explicit function of the spaec-time coordinates of the observer and then differentiated it.

What we have illustrated here with the aid of a simple source motion holds true also when the motion of the source is neither uniform nor rectilinear. Consider, for instance, an extended source with a rigidly rotating distribution pattern whose outer parts move with linear speeds exceeding the wave speed. The density of such a source depends on the azimuthal angle φ and the time t in only the combination $\varphi-\omega t \equiv \hat{\varphi}$, i.e., has the form $\rho(r,\varphi,z,t)=\rho(r,\hat{\varphi},z)$ where (r,φ,z) are the cylindrical polar coordinates based on the axis of rotation. The potential ψ that arises from the source in question is likewise subject to the symmetry $\partial\psi/\partial t=-\omega\partial\psi/\partial\varphi=-\omega\partial\psi/\partial\hat{\varphi}$ and so is governed by the following reduced version of the wave equation in cylindrical coordinates:

$$\frac{1}{r}\frac{\partial}{\partial r}\left(r\frac{\partial\psi}{\partial r}\right)+\frac{\partial^2\psi}{\partial z^2}+\left(\frac{1}{r^2}-\frac{\omega^2}{c^2}\right)\frac{\partial^2\psi}{\partial\hat{\varphi}^2}=-4\pi\rho(r,\hat{\varphi},z). \tag{5}$$

This is an equation of the mixed type. In the domain $r>c/\omega$, where the coefficient of $\partial^2\psi/\partial\hat{\varphi}^2$ is negative and the variable $\hat{\varphi}$ acts as a time-like coordinate, it is a hyperbolic differential equation in *two* spatial dimensions.

Just as the spherical wave fronts emanating from a rectilinearly moving supersonic point source form a Mach cone, so the envelope of the wave fronts from a corresponding circularly moving point source (Ref. 2, Figs. 1 and 4) constitutes a caustic that coincides with the ray conoid of (5) in its domain of hyperbolicity (Ref. 9, Sec. 6). The Lienard–Wiechert potential describing the amplitudes of these waves is identical to the Green's function G_0 of (5) in unbounded space (Ref. 10, Appendix). The divergences that arise in the context of the initial-boundary-value problem for the above two-dimensional equation, and from the differentiation of its solution

$$\psi(\mathbf{x}_P,t_P)=\int r\,dr\,d\hat{\varphi}\,dz\,\rho(r,\hat{\varphi},z)G_0(r,r_P,\hat{\varphi}-\hat{\varphi}_P,z-z_P) \tag{6}$$

in the radiation theory of rapidly rotating extended sources, once again have the same origins, therefore, and should be handled by the same technique.[2]

III. DERIVATIVES OF THE RETARDED POTENTIAL IN THE CASE OF A RAPIDLY ROTATING EXTENDED SOURCE

Improper handling of the divergences discussed above has led to erroneous conclusions in the analysis of certain radiation problems. Hannay[3] bases his analysis of the emission from rapidly rotating extended sources on the following form of the retarded potential

$$\psi(\mathbf{x}_P,t_P)=\int \rho(\mathbf{x},t_P-|\mathbf{x}-\mathbf{x}_P|/c)/|\mathbf{x}-\mathbf{x}_P|d^3\mathbf{x} \tag{7}$$

and contends that since the only singularity of the integrand in this expression is that at the point $\mathbf{x}=\mathbf{x}_P$, which is inoffensive, one can differentiate (7) under the integral sign to obtain

$$\frac{\partial \psi}{\partial \mathbf{x}_P} = \int \frac{\partial}{\partial \mathbf{x}_P}\left[\frac{\rho(\mathbf{x}, t_P - |\mathbf{x}-\mathbf{x}_P|/c)}{|\mathbf{x}-\mathbf{x}_P|}\right] d^3\mathbf{x} = \int \frac{\nabla \rho(\mathbf{x}, t_P - |\mathbf{x}-\mathbf{x}_P|/2)}{|\mathbf{x}-\mathbf{x}_P|} d^3\mathbf{x} \tag{8}$$

[see Ref. 3, Eqs. (1.2), (1.5), and (1.6)]. Having thus ''avoided'' the singularities that arise when the alternative form (6) of the retarded potential is differentiated, Hannay then uses (8) to derive an upper bound on the intensity of the resulting radiation.

The result claimed by Hannay[3] is erroneous because the steps, familiar from the subluminal regime, that are taken in Eq. (8) are not mathematically permissible when the moving source has volume elements that approach the observer with the wave speed and zero acceleration at the retarded time. To demonstrate this, here we shall render these steps explicit by taking them in the case of a specific source distribution, a source distribution that is bounded and smooth but entails motion at speeds exceeding the wave speed.

Let us consider a spherical source with the radius λ whose center moves on a circle of radius r_0 with the constant angular frequency ω and whose density smoothly reduces from a maximum ρ_0 at its center to zero at its boundary, e.g., has the form

$$\rho(r,\hat{\varphi},z) = \begin{cases} \rho_0 \cos^2[\pi X/(2\lambda)] & \text{if } X \leqslant \lambda, \\ 0 & \text{otherwise,} \end{cases} \tag{9}$$

where

$$X \equiv (z^2 + r^2 + r_0^2 - 2rr_0 \cos\hat{\varphi})^{1/2}$$

is the distance of a point $(r,\hat{\varphi},z) = (r,\varphi - \omega t, z)$ that is stationary in the rotating frame from the center $(r = r_0,\ \hat{\varphi} = 0,\ z = 0)$ of the sphere. The circle in broken lines in Fig. 1 shows the intersection, with the plane $z = 0$, of the boundary of the above source in the $(r,\hat{\varphi},z)$-space for $r_0 = \frac{3}{2}c/\omega$ and $\lambda = \frac{1}{2}c/\omega$. (The axes in this figure are marked in units of c/ω and the larger dotted circles designate the sonic or the light cylinder $r = c/\omega$ and the orbit $r = \frac{3}{2}c/\omega$ of the center of the source, respectively.)

Once the quantities $|\mathbf{x}-\mathbf{x}_P|$ and $d^3\mathbf{x}$ in (7) are expressed in terms of cylindrical coordinates and the above expression for the source density is inserted in this form of the retarded potential, there results an integral over the (r,φ,z)-space for which the domain of integration is automatically bounded.[11] Not only do we need to replace $\hat{\varphi}$ in the above expression for ρ by its retarded value

$$\hat{\varphi} = (\varphi - \omega t)|_{t = t_P - |\mathbf{x}-\mathbf{x}_P|/c} = \varphi - \omega t_P + [(z - z_P)^2 + r^2 + r_P^2 - rr_P \cos(\varphi - \varphi_P)]^{1/2}\omega/c \tag{10}$$

when substituting (9) in (7), but in addition we need to delineate the domain of integration in (7), by mapping the source boundary $X = \lambda$ from the $(r,\hat{\varphi},z)$-space onto the (r,φ,z)-space. The image of the source boundary under the mapping $\hat{\varphi} \rightarrow \varphi$ expressed in (10) is a surface whose shape is different for different observers, or at different observation times, and bears no direct relationship with the sphere $X = \lambda$ that appears in (9).

To specify the boundary of the domain of integration in (7), we need to solve the transcendental equation (10) for φ at every point $(r,\hat{\varphi},z)$ of the sphere $X = \lambda$. In the case of the source depicted in Fig. 1, and of an observer that is located at $(r_P, \varphi_P, z_P) = (\frac{5}{2}c/\omega, 0, 0)$ at the observation time $t_P = (2\pi - \arccos\frac{2}{5} + \sqrt{21}/2)\omega^{-1}$, the intersection of this domain of integration with the plane $z = 0$ has the shape shown by the solid curve in Fig. 1.

The boundary of the irregular volume occupied by the source in the (r,φ,z)-space intersects a circle $r = \text{const}$, $z = \text{const}$, (with $1 < r\omega/c < 2$ and $-\frac{1}{2} < z\omega/c < \frac{1}{2}$) at either two, four, or six values of φ. If we let $(\varphi_l^{(n)}, \varphi_u^{(n)})$, with $n = 1,2,\ldots$, denote the various intervals in φ that are occupied by the retarded distribution of the source at any given $(r,z;r_P,\varphi_P,z_P,t_P)$, then the volume integral in (7) may be written as a triple integral over the variables φ, z, and r, respectively, in which the functions $\varphi_l^{(n)}(r,z;r_P,\varphi_P,z_P,t_P)$ and $\varphi_u^{(n)}(r,z;r_P,\varphi_P,z_P,t_P)$ constitute the

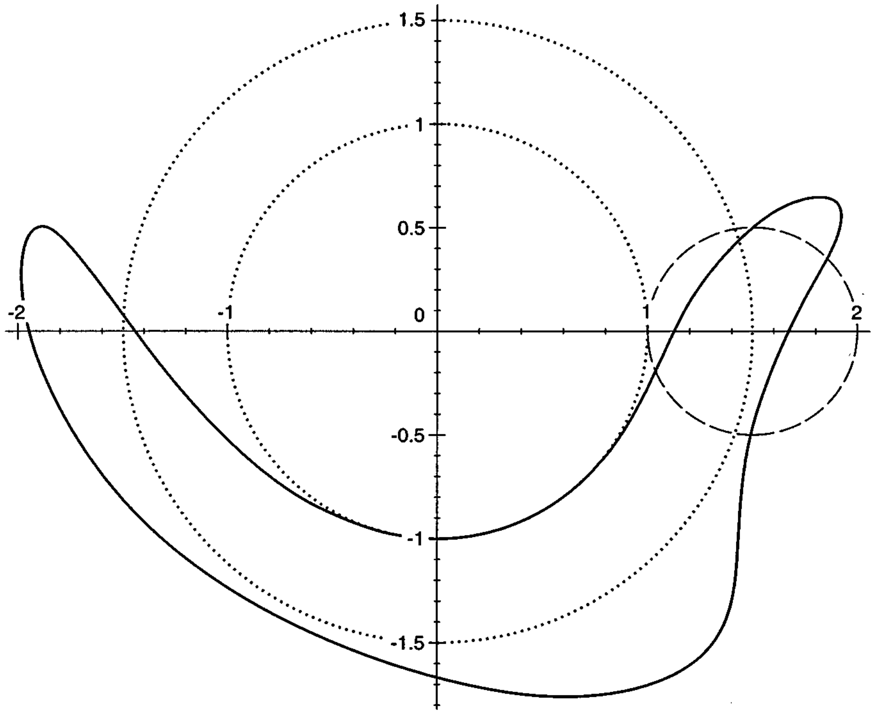

FIG. 1. The retarded shape of the source boundary in the (r,φ,z)-space (the solid curve) compared to its original shape in the $(r,\hat{\varphi},z)$-space (the smallest circle in broken lines).

various limits of integration with respect to φ. Differentiation of the integral in question entails the differentiation of these limits of integration, limits that are given by the solutions φ of (10) for a point $(r,\hat{\varphi},z)$ on the boundary of the source distribution.

Differentiating (10) with respect to $\mathbf{x}_P$ while holding $(r,\hat{\varphi},z)$ and the observation time $\hat{\varphi}_P$ constant, we find that the gradient of any of the $\varphi_l^{(n)}$ or $\varphi_u^{(n)}$ is given by an expression

$$\nabla_P\varphi=r_P^{-1}\hat{e}_{\varphi_P}-(\omega/c)\{[r_P-r\cos(\varphi-\varphi_P)]\hat{e}_{r_P}+(z_P-z)\hat{e}_{z_P}\}$$
$$\times\{[(z-z_P)^2+r^2+r_P^2-rr_P\cos(\varphi-\varphi_P)]^{1/2}-rr_P\omega\sin(\varphi_P-\varphi)/c\}^{-1}, \qquad (11)$$

whose denominator both vanishes and has a vanishing derivative at the boundary points that approach the observer with the wave speed and zero acceleration (see Ref. 2, Appendix B).

In Eq. (8), Hannay[3] applies Leibniz's formula for the differentiation of a definite integral assuming that there are no contributions from the limits of integration. Leibniz's formula, on the other hand, is not applicable if there are any points at which the limits of integration are not differentiable.[12] In the case considered here, where the derivatives of the limits of integration are singular, the gradient of the integral in question does not consist solely of the integral of the gradient of its kernel, as claimed by Hannay.[3] There is an additional contribution to the gradient of the potential: that which arises from the singularities of the gradients of the limits of integration in (7) and which comprises the boundary contribution to the Hadamard finite part of the gradient of the integral in (6).

The singularities of the gradients of the limits of integration in (7) are the images, under the mapping $\hat{\varphi}\rightarrow\varphi$, of the singularities of the integrand of the gradient of (6): They both arise from those source elements that approach the observer with the wave speed and zero acceleration at the retarded time.[2] By overlooking the contribution from the limits of integration in (8), Hannay[3] has discarded the boundary term in Hadamard's finite part of the divergent integral that results from the differentiation of the alternative form (6) of the retarded potential.

Note that it makes no difference if we extend the domain of integration in (7) over all (r,φ,z) by introducing a Heaviside step function that incorporates the vanishing of ρ outside $X=\lambda$ into the expression for ρ. Differentiation of such a step function results in a delta function, the gradient of whose argument vanishes—and so itself diverges—*algebraically* at those points of the boundary that approach the observer with the wave speed and zero acceleration. The product of this delta function and the vanishing value of ρ on the boundary is neither zero nor infinite; it is an *indeterminate* quantity that would have to be evaluated by means of a physically meaningful procedure. Far from ''avoiding'' the divergence that needs to be handled by Hadamard's technique, therefore, the adoption of this form of the retarded potential would merely replace the divergence in question by a closely related indeterminacy.

The contribution from the limits of integration to the right-hand side of (8) is zero, as assumed by Hannay,[3] only in the familiar subsonic or subluminal regimes where the derivatives of these limits are singularity free. In the case of a supersonically or superluminally moving accelerated source, this contribution is nonvanishing and has a value that may be calculated by means of Hadamard's method.[2] The upper bound derived by Hannay[3] applies only to the contribution to the derivative of the potential that arises from the derivative of its integrand, i.e., to the contribution that is retained by Hannay,[3] not to the contribution from the limits of integration that is overlooked by him.

[11] The analysis in Ref. 3 is based on the assumption that the domain of integration in Eq. (7) extends over all space regardless of what the expression for the source density may be. That this is not so may be seen by writing out the explicit form of the integral in Eq. (7) for any source distribution—such as the one considered here—whose density vanishes outside a finite volume. For such source distributions, the integration in (7) does not extend over all space unless we introduce step functions that would incorporate the finiteness of their support into the mathematical expressions for their densities. The contributions of the required step functions toward the derivatives of the integral in (7), on the other hand, are the same as those of the original limits of integration.

(Received 5 March 1999; accepted for publication 21 April 1999)

We discuss the existence and uniqueness of nonequilibrium dynamics of infinitely many particles interacting via superstable pair interactions in one and two dimensions. The interaction is allowed to be of infinite range and singular at the origin. Under suitable regularity conditions on the interaction potential, we show that if the potential decreases polynomially as the distance between interacting two particles increases, then the tempered solution to the system of Hamiltonian equations exists. Moreover, if the potential satisfies further that either it has a subexponential decreasing rate or it is everywhere two-times continuously differentiable, then we show that the tempered solution is unique. The results extend those of Dobrushin and Fritz obtained for finite range interactions. © *1999 American Institute of Physics.* [S0022-2488(99)01609-6]

I. INTRODUCTION

Our aim in this paper is to show the existence and uniqueness of nonequilibrium dynamics of infinitely many particles interacting via (infinite range) superstable interactions in dimensions one and two. In this paper we extend the results obtained by Dobrushin and Fritz in Refs. 1–3 where the interaction range is assumed to be finite. By suitably modifying and extending the methods given in Refs. 1–3, we remove the finite range assumption. The time evolution will be constructed in an explicitly defined set $\bar{\Omega}$ of allowed configurations characterized by a logarithmic order of energy fluctuations. The extension of the results for finite range interactions to infinite range interactions must be meaningful in the sense of practical and aesthetic points of view.

This study may be considered as being in the extension of the line of investigation on the dynamics of infinitely many particles that has been studied by various authors.[1–10] The main point in this study would be to show the existence of solutions to the infinite system of Hamiltonian equations [see (1.1)] and then to investigate the detailed properties of the solution such as the uniqueness of the solution and the essential self-adjointness of the generator of the evolution semigroup of the dynamics. While various techniques for showing the existence of the solutions have been developed in the papers including the above mentioned ones (see, e.g., Refs. 3 and 8 for further references), the method to show the energy bound of the solutions has not been fully developed for general dimensions. Only up to one and two dimensions and for finite range interactions, such an aim has been fulfilled in Refs. 1–3 and 5 for explicitly characterized initial conditions. The method of the energy bound has been also used to show the essential self-adjointness of the Liouville operator.[3,11]

In Ref. 8, Siegmund–Schultze has shown that in any dimension, for a given translation invariant probability measure on the phase space such that the particle density and specific energy are finite, there is a class of configurations which carries a full measure such that the solutions with initial conditions from that class exist provided that the potential is not singular and has a finite interaction range. However, the method of Siegmund–Schultze do not yet permit us to prove the uniqueness of the solution and to control the properties of the solution. See also Refs. 9–10 and the references in Ref. 8 for earlier works.

We would like to mention the works related to the infinite system of Hamiltonian equations. In Ref. 12, Lang initiated to consider the system of first order differential equations for the system with additional white-noise terms.[12,13] Recently the system of stochastic differential equations related to the particle systems has been investigated using the Dirichlet form approach.[14–19]

Let us briefly describe the contents of this paper. We are going to consider the motion of a countable collection of identical particles of unit mass in the d-dimensional Euclidean space $\mathbb{R}^d$ with $d=1,2$. Let I be the index set for the particles. Configurations of the system are represented as infinite sequences $\omega=(q_k,\, p_k)_{k\in I}$, where $q_k\in\mathbb{R}^d$ and $p_k\in\mathbb{R}^d$ are the position and velocity of the particle labeled by $k\in I$, respectively. Sometimes we will use more informative notations $q_k=q_k(\omega)$, $p_k=p_k(\omega)$. Only locally finite configurations are allowed, i.e., the sequence $(q_k)_{k\in I}$ of positions can not have limit points at all, but some additional restrictions are necessary too. We assume that our particles interact by a symmetric pair potential $U:\mathbb{R}^d\to(-\infty,\infty]$ and $U(x)=U(-x)$. The potential U is allowed to be of an infinite range. Let $\operatorname{grad} U$ denote the gradient of U. The equations of motion read as

$$\frac{dp_k}{dt}=-\sum_{j\neq k}\operatorname{grad} U(q_k-q_j),\qquad \frac{dq_k}{dt}=p_k,\quad k\in I. \tag{1.1}$$

We will impose to the potential that it is superstable in the sense of Ruelle.[20,21] We allow that U is possibly singular at the origin and is of an infinite range. See Sec. II for the details.

The space $\overline{\Omega}$ of allowed configurations on which the evolution of the dynamics shall be constructed is defined in the following way. Let

$$g(u):=(1+\log(1+u))^{1/d},\quad u\geqslant 0, \tag{1.2}$$

and let $H(\omega,\mu,\sigma)$ denote the total energy plus a multiple of particle numbers in the sphere with center $\mu\in\mathbb{R}^d$ and radius $\sigma>0$, i.e.,

$$H(\omega,\mu,\sigma):=\frac{1}{2}\sum_{|q_k-\mu|\leqslant\sigma}\left[|p_k|^2+A+\sum_{j\neq k;|q_j-\mu|\leqslant\sigma}U(q_k-q_j)\right], \tag{1.3}$$

where $A\geqslant 0$ is a constant appearing in the superstable condition [see (2.1)] and makes $H(\omega,\mu,\sigma)$ non-negative numbers. Let us define

$$\overline{H}(\omega):=\sup_{\mu}\sup_{\sigma\geqslant g(|\mu|)}\sigma^{-d}H(\omega,\mu,\sigma). \tag{1.4}$$

$\overline{H}(\omega)$ is called the logarithmic fluctuation of energy of ω.[3] The allowed configuration space is defined by

$$\overline{\Omega}:=\{\omega:\omega \text{ is locally finite and } \overline{H}(\omega)<\infty\}. \tag{1.5}$$

It turns out that $\overline{\Omega}$ carries a large class of probability measures including Gibbs random fields with interaction U.[1,11,16]

We will show that in dimensions one and two, under proper conditions on the potential, there exists a tempered solution (see Sec. II for the definition) ω_t to (1.1) with any initial configuration $\omega\in\overline{\Omega}$. This solution can be obtained as the limit of solutions to finite subsystems. Furthermore, the tempered solution is unique when the potential U is either everywhere two-times continuously differentiable or subexponentially decreasing (see Theorem 2.2) when it is singular at the origin. The main idea used in this paper is to decompose the potential U into two parts:

$$U(x)=U^{(1)}(x)+U^{(2)}(x),$$

where $U^{(1)}$ is of finite range and $U^{(2)}$ is a smooth potential which decreases polynomially. See (2.2) and (2.6). For $U^{(1)}$, we use the method developed in Ref. 3 with suitable modifications and for $U^{(2)}$, we utilize the decay properties of $U^{(2)}$ stated in (2.6).

Employing the method developed in Sec. VI and using an appropriate modification of the method in Sec. 5 of Ref. 3, it may be possible to show the (anti) self-adjointness of the corresponding Liouville operator.[3,11] However we do not pursue the proof here and leave it to further study.

We organize this paper as follows. In Sec. II, we give necessary notations, impose conditions to the potential, and give main results of this paper. In Sec. III, we discuss the cutoff of total energy. In Sec. IV, we present the *a priori* bound which is a core in proving the results of this paper. We prove the existence and the uniqueness of the tempered solution in Sec. V and Sec. VI, respectively.

II. NOTATIONS AND MAIN RESULTS

In this section we give conditions to the interaction and state our main results. As mentioned in the Introduction, we will consider a symmetric pair potential U: $\mathbb{R}^d \to (-\infty,\infty]$, $d=1,2$, allowing the possibility of being of an infinite range and of singularity at the origin. We need, however, some regularity conditions on the potential in order to show the existence and uniqueness of the solutions to (1.1). First, we need superstability of the interaction to control the number of particles, just as in equilibrium theory.[20,21] There exist $A \geqslant 0$ and $B>0$ such that for any finite collection $q_1,q_2,\ldots,q_n$ of points of $\mathbb{R}^d$,

$$\sum_{k=1}^{n}\sum_{j\neq k} U(q_k-q_j) \geqslant -An+B\sum_{i\in\mathbb{Z}^d} n_i^2, \tag{2.1}$$

where $\mathbb{Z}^d$ is the d-dimensional integer lattice and for each site $i\in\mathbb{Z}^d$, n_i denotes the number of particles within the unit box with center i. This condition can be verified under natural assumptions, e.g., that U is not integrable near zero and integrable outside the origin.[21] We assume that $U(x)$ is continuously differentiable outside the origin and suppose that U is decomposed into two parts of singular and analytic potentials;

$$U(x)=U^{(1)}(x)+U^{(2)}(x). \tag{2.2}$$

Furthermore, we assume that $U^{(1)} \geqslant 0$ for all x and there exists a positive number r such that

$$U^{(1)}(x)=0, \quad \text{if } |x|\geqslant r. \tag{2.3}$$

It is important that singularity of U can not be too strong. Sometimes the velocity depends on the strength of the interaction and this velocity can become arbitrarily large in the extreme case. Thus, as in Ref. 3, we assume that there exist positive constants a and b such that

$$|x|\,|\mathrm{grad}\, U^{(1)}(x)| \leqslant a+b\, U^{(1)}(x). \tag{2.4}$$

From a mathematical point of view, (2.4) means that the singularity can not be stronger than that of $|x|^{-b}$. Also we need local Lipschitz condition. Let $L>1$ and suppose that

$$|\mathrm{grad}\, U^{(1)}(x)-\mathrm{grad}\, U^{(1)}(y)| \leqslant L[L+U^{(1)}(x)+U^{(1)}(y)]^c\,|x-y| \tag{2.5}$$

holds for all $x,y\neq 0$ with some constant $c>1$. (2.5) means that the singularity can not be too weak, logarithmic singularities are excluded. Finally we assume that the analytic potential $U^{(2)}(x)$ is everywhere two times continuously differentiable and decreases polynomially: There exist a decreasing function $\psi:\mathbb{R}^+\to\mathbb{R}^+$ and constants $\gamma>2d+3$ and $0<M$ such that

$$\psi(u)\leqslant M(1+u)^{-\gamma},\quad u\geqslant 0,$$

and

$$|U^{(2)}(x)|+|\mathrm{grad}\,U^{(2)}(x)|+\sum_{l,k=1}^{d}\left|\frac{\partial^2}{\partial x^{(l)}\,\partial x^{(k)}}U^{(2)}(x)\right|\leqslant\psi(|x|). \tag{2.6}$$

Notice that $U^{(2)}(x)\geqslant -M$, and hence $U(x)\geqslant -M$. We refer to Ref. 3 for the detailed accounting for the conditions on the potential.

We recall the notion of the logarithmic energy fluctuation $\bar{H}(\omega)$ of a given configuration ω and the possible configuration space given in (1.4)–(1.5). The configuration space $\bar{\Omega}$ is equipped with the product topology and with an associated Borel structure.[3] If $\omega_t^{(n)}$ is a sequence of trajectories in $\bar{\Omega}$, then convergence of $\omega_t^{(n)}$ means the uniform convergence on compact intervals of time of each of the components $q_k(\omega_t^{(n)})$ and $p_k(\omega_t^{(n)})$. This convergence need not be uniform in $k\in I$. A continuous trajectory $\omega_t:\mathbb{R}\to\bar{\Omega}$ is called a *tempered* solution to (1.1) with initial configuration $\omega\in\bar{\Omega}$ if $\omega_0=\omega$, $\bar{H}(\omega_t)$ is bounded in bounded intervals of time, and the components $q_k(t)=q_k(\omega_t)$, $p_k(t)=p_k(\omega_t)$ are continuously differentiable and satisfy (1.1) for all $k\in I$ and $t\in\mathbb{R}$. See Ref. 3 for the details.

As usual in the theory of infinite systems, solutions to (1.1) are constructed as limits of solutions to finite subsystems of (1.1). The passage to the infinite system is based on an *a priori* bound expressing a local version of the law of energy conservation. Just as in Refs. 1–3, energy flow will be controlled by means of a partial differential inequality formulated in terms of a spatial cutoff of total energy. Let us mention that the *a priori* bound can be obtained from this inequality only in dimensions one and two.

Our first main result concerns the existence of tempered solutions to (1.1).

Theorem 2.1: *Suppose that the hypotheses on the potential given in (2.1)–(2.6) are satisfied. Then, for any $\omega\in\bar{\Omega}$ there exists at least a tempered solution to (1.1) with initial configuration ω.*

The proof of the above theorem will be given in Sec. V. Next, we discuss the uniqueness of the solution. When the potential is singular at the origin, the method developed in this paper demands that the decreasing rate of the potential must be stronger than that given in (2.6), at least it must be of sub-exponential, in order that the tempered solution to (1.1) is unique. Recall the constant $c>1$ appearing in (2.5) for the Lipschitz condition of the potential.

Theorem 2.2: *Suppose that the conditions (2.1)–(2.5) for the potential hold. Suppose further that there exists a constant $\epsilon_0>0$ such that the function ψ in the right hand side of (2.6) satisfies $\psi(u)\leqslant\exp[-(\log u)^{c+\epsilon_0}]$ for large values of $u>0$. Then the tempered solution to (1.1) exists uniquely.*

When the potential is not singular at the origin, the polynomial decreasing rate is enough to insure the uniqueness.

Theorem 2.3: *Suppose that the potential $U(x)$ satisfies (2.1) and everywhere two-times continuously differentiable with a decreasing rate given in* (2.6) [*$U^{(2)}(x)$ being replaced by $U(x)$*]. Then the tempered solution to (1.1) exists uniquely.

The proofs of Theorem 2.2 and Theorem 2.3 will be given in Sec. VI.

III. CUTOFF OF TOTAL ENERGY

In this section, we introduce a smooth version of the energy functions $H(\omega,\mu,\sigma)$ defined in (1.3). In Ref. 3, exponentially decreasing functions have been used as a smooth version of the indicator functions. In order to deal with polynomially decreasing interaction potentials, we will use polynomially decreasing functions which satisfy all of the desired properties (Lemma 3.1).

Let $0<\lambda<1$. We will choose λ sufficiently small. Choose $\varphi:\mathbb{R}^+\to(0,1]$, continuously differentiable such that for $p>d+1$,

(i) $\varphi(u)=(1+\lambda u)^{-p}, \; u\geqslant 2$;
(ii) φ is concave for $u\leqslant 2$;
(iii) $\varphi(u)=\varphi(2)-\frac{1}{2}\varphi'(2)=(1/1+2\lambda)^p(1+(\lambda p/2(1+2\lambda)))$, for $u\leqslant 1$.

Notice that $\varphi(u)\leqslant(1+\lambda u)^{-p}$ and $0\leqslant-\varphi'(u)\leqslant p\lambda(1+\lambda u)^{-(p+1)}$.

Define

$$f(x,\sigma):=\int_{\mathbb{R}^d}\varphi\left(\frac{|x-y|}{\sigma}\right)\left(\frac{1}{1+\lambda|y|}\right)^{p+1}dy, \tag{3.1}$$

where $\sigma>0$. The definition (3.1) and the following lemma work well for $p>d$ but we need the condition $p>d+1$ for a later use (Lemma 3.3). In the proof of the *a priori* bound, $f(x-\mu,\sigma)$ will be used as a smooth version of the indicator function of the d-dimensional ball with center $\mu\in\mathbb{R}^d$ and radius σ. From now on we assume that $\sigma\geqslant 2$.

Lemma 3.1: There exist positive constants $c_1,\overline{c_1}$, and c_2 depending only on λ and p such that the following properties hold:

(a) $f(x-\mu,\sigma)\leqslant c_1(1+\lambda|x-\mu|/\sigma)^{-p}$ and $f(x,\sigma)\geqslant\overline{c_1}(1+|x|)^{-p}$ for all σ.
(b) $f(x-\mu,\sigma)\geqslant c_2>0$, if $|x-\mu|\leqslant\sigma$.
(c) $f(x,\sigma)\leqslant(1+\lambda|x-y|)^{p+1}f(y,\sigma)$.
(d) Denote by f' the derivative of f w.r.t. σ. Then $f'(x,\sigma)\leqslant(1+\lambda|x-y|)^{p+1}f'(y,\sigma)$.
(e) $|\mathrm{grad}\, f(x,\sigma)|\leqslant f'(x,\sigma)$.
(f) $g(|x|)\,|\mathrm{grad}\, f(x-\mu,\sigma)|\leqslant 4g(|\mu|+\sigma)f'(x-\mu,\sigma)$.

Proof: (a) We may assume $\mu=0$. Notice that

$$\left(1+\frac{\lambda|x|}{\sigma}\right)^p f(x,\sigma)\leqslant\int\left(\frac{\sigma+\lambda|x|}{\sigma+\lambda|x-y|}\right)^p\left(\frac{1}{1+\lambda|y|}\right)^{p+1}dy.$$

Using the inequality $|x|\leqslant|x-y|+|y|$, one can check that the right hand side of the inequality is finite uniformly in x and σ. This implies the first bound.

To obtain second bound, notice that $f(x,\sigma)\geqslant f(x,2)$. Since φ is concave for $u\leqslant 2$, there exist positive numbers $c>0$ and $\overline{c_1}$ such that the bound

$$\begin{aligned}(1+|x|)^p f(x,2)&\geqslant c\,(1+|x|)^p\int\left(\frac{1}{1+\lambda\,(|x-y|/2)}\right)^p\left(\frac{1}{1+\lambda|y|}\right)^{p+1}dy\\&\geqslant\overline{c_1}>0\end{aligned}$$

holds.

(b) Suppose $|x|\leqslant\sigma$. Then there exists a constant $c>0$ such that

$$\begin{aligned}f(x,\sigma)&\geqslant c\int_{|x-y|\leqslant\sigma}\left(\frac{1}{1+\lambda|y|}\right)^{p+1}dy\\&\geqslant c\int_{B_\sigma(0)\cap B_\sigma(x)}\left(\frac{1}{1+\lambda|y|}\right)^{p+1}dy,\\&\geqslant c\int_D\left(\frac{1}{1+\lambda|y|}\right)^{p+1}dy=:c_2>0,\end{aligned}$$

where $D=B_2(0)\cap B_2(z_1)$ and $z_1=2x/|x|$.

(c) The bound follows from the following relations:

$$f(x,\sigma)=\int_{\mathbb{R}^d}\varphi\left(\frac{|z|}{\sigma}\right)\left(\frac{1}{1+\lambda|x-z|}\right)^{p+1}dz$$

and

$$\frac{1+\lambda|y-z|}{1+\lambda|x-z|}\leqslant 1+\lambda|x-y|.$$

(d) Since

$$f'(x,\sigma)=-\int \varphi'\left(\frac{|x-y|}{\sigma}\right)\frac{|x-y|}{\sigma^2}\left(\frac{1}{1+\lambda|y|}\right)^{p+1}dy,$$

the result follows by the method same as that used in (c).

(e) This follows from a direct computation.

(f) We first show that

$$|x|\,|\mathrm{grad}\, f(x,\sigma)|\leqslant 4\sigma f'(x,\sigma). \tag{3.2}$$

In view of the fact (e), we may assume that $|x|\geqslant 4\sigma$. Let $D_1=\{y\in\mathbb{R}^d:|y|\leqslant|x-y|\}$ and $D_2=\mathbb{R}^d\setminus D_1$. Then $|y|\geqslant|x|/2$ if $y\in D_2$ and $-\varphi'(u)\leqslant p\lambda/(1+\lambda u)^{p+1}$.

We assert that for $y\in D_1$,

$$-\varphi'\left(\frac{|y|}{\sigma}\right)\left(\frac{1}{1+\lambda|x-y|}\right)^{p+1}\leqslant-\varphi'\left(\frac{|x-y|}{\sigma}\right)\left(\frac{1}{1+\lambda|y|}\right)^{p+1}. \tag{3.3}$$

Notice that $|y-x|\geqslant 2\sigma$ for $|y|\leqslant|x-y|$. One needs to show that for $y\in D_1$,

$$\left(\frac{1}{1+\lambda|y|/\sigma}\right)\left(\frac{1}{1+\lambda|x-y|}\right)\leqslant\left(\frac{1}{1+\lambda|x-y|/\sigma}\right)\left(\frac{1}{1+\lambda|y|}\right),$$

which is equivalent to

$$\frac{\sigma+\lambda|x-y|}{\sigma+\lambda|y|}\leqslant\frac{1+\lambda|x-y|}{1+\lambda|y|}.$$

Since $(\sigma+\lambda|x-y|)/(\sigma+\lambda|y|)$ is monotonic decreasing w.r.t. σ if $|y|\leqslant|x-y|$, this proves (3.3). Now (3.2) follows from the method used in Ref. 3, p. 545 and (f) follows from (3.2) by the method the same as that given in Ref. 3. □

From now on we will fix p such that $\gamma>2p+1>2(d+1)+1$ in the definition of φ in (3.1). The smooth version of total energy corresponding to $H(\omega,\mu,\sigma)$ given in (1.3) is defined as

$$W(\omega,\mu,\sigma)=\sum_{k\in I} f(q_k-\mu,\sigma)W_k(\omega), \tag{3.4}$$

where $q_k=q_k(\omega)$, $p_k=p_k(\omega)$, and

$$W_k(\omega)=2A+|p_k|^2+\sum_{j\neq k} U(q_k-q_j), \tag{3.5}$$

where A is the same as in (2.1). Define the logarithmic fluctuation of W by

$$\overline{W}(\omega)=\sup_{\mu}\sup_{\sigma\geqslant 2g(|\mu|)}\sigma^{-d}W(\omega,\mu,\sigma). \tag{3.6}$$

Recall that for any $i\in\mathbb{Z}^d$ and $\omega\in\overline{\Omega}$, $n_i(\omega)$ is the number of particles of ω in the unit box with a center at i. The superstability of U implies the following:

Lemma 3.2: There exists $0<\lambda<1$ *such that*

$$W(\omega,\mu,\sigma)\geqslant\frac{B}{4}\sum_{i\in\mathbb{Z}^d}f(i-\mu,\sigma)\,n_i(\omega)^2$$

and

$$\frac{\partial}{\partial\sigma}W(\omega,\mu,\sigma)\geqslant\frac{B}{4}\sum_{i\in\mathbb{Z}^d}f'(i-\mu,\sigma)\,n_i(\omega)^2.$$

Proof: Let $R>0$ be a sufficiently large natural number which will be fixed later and write the potential $U(x)$ as

$$U(x):=U^{(R,1)}(x)+U^{(R,2)}(x), \tag{3.7}$$

where $U^{(R,1)}(x):=U(x)1_{[0,R]}(|x|)$ and $U^{(R,2)}(x):=U(x)-U^{(R,1)}(x)$. We write

$$W(\omega,\mu,\sigma):=W^{(R,1)}(\omega,\mu,\sigma)+W^{(R,2)}(\omega,\mu,\sigma), \tag{3.8}$$

$$W^{(R,1)}(\omega,\mu,\sigma):=\sum_{k\in I}f(q_k-\mu,\sigma)\left[2A+|p_k|^2+\sum_{j\neq k}U^{(R,1)}(q_k-q_j)\right],$$

$$W^{(R,2)}(\omega,\mu,\sigma):=\sum_{k\in I}f(q_k-\mu,\sigma)\sum_{j\neq k}U^{(R,2)}(q_k-q_j).$$

It is easy to check that there is a positive constant c_3 such that

$$|W^{(R,2)}(\omega,\mu,\sigma)|\leqslant c_3\left(\sum_{k\in\mathbb{Z}^d}n_k(\omega)f(k-\mu,\sigma)\right)\left(\sum_{j\in\mathbb{Z}^d;|k-j|\geqslant R-2}n_j(\omega)(1+|k-j|)^{-\gamma}\right).$$

We use the fact that $n_k(\omega)n_j(\omega)\leqslant(1/2)(n_k(\omega)^2+n_j(\omega)^2)$, Lemma 3.1(c), $\gamma>2p+1$ and $p>d+1$ to obtain that

$$\begin{aligned}|W^{(R,2)}(\omega,\mu,\sigma)|&\leqslant c_3\left[\sum_{j\in\mathbb{Z}^d:|j|\geqslant R-2}(1+|j|)^{(-\gamma+p+1)}\right]\left[\sum_{k\in\mathbb{Z}^d}f(k-\mu,\sigma)n_k(\omega)^2\right]\\&\leqslant\frac{B}{4}\sum_{k\in\mathbb{Z}^d}f(k-\mu,\sigma)n_k(\omega)^2,\end{aligned} \tag{3.9}$$

where we have chosen R large enough.

On the other hand, by a similar method used above, it is not hard to see that if R is sufficiently large, then $U^{(R,1)}(x)$ is also superstable and satisfies that for any finite collection $q_1,\dots,q_n$ of points in $\mathbb{R}^d$,

$$\sum_{k=1}^{n}\sum_{j\neq k}U^{(R,1)}(q_k-q_j)\geqslant -A\sum_{k\in\mathbb{Z}^d}n_k+\frac{3}{4}B\sum_{k\in\mathbb{Z}^d}n_k^2, \tag{3.10}$$

where $A\geqslant 0$ and $B>0$ are the same constants that appeared in (2.1).

In order to control $W^{(R,1)}$, we modify the method used in the proof of Lemma 3.1 of Ref. 3. Introduce

$$\Lambda_u := \{x \in \mathbb{R}^d : u^{(i)} \leqslant x^{(i)} < u^{(i)} + mR, \quad 1 \leqslant i \leqslant d\},$$

where $x^{(i)}$ and $u^{(i)}$ are the coordinates of $x, u \in \mathbb{R}^d$, and m is a large natural number. Let P denote the set of pairs $[k,j]$ such that $|q_k - q_j| \leqslant R$ and let P_u be the set of $[k,j] \in P$ such that $k,j \in I_u$, where I_u is the set of particles in Λ_u. Put $\mathbb{Z}_u = \mathbb{Z}^d \cap \Lambda_u$. If ρ_u denotes the minimum of $f_k = f(q_k - \mu, \sigma)$ for $k \in I_u$, and $\lambda m R \sqrt{d} < \epsilon$, i.e., the diameter of Λ_u is less than ϵ/λ, then using Lemma 3.1 (c) and $U^{(R,1)}(x) \geqslant -M$, we obtain for each $[k,j] \in P_u$,

$$\begin{aligned}(f_k + f_j) U^{(R,1)}(q_k - q_j) &= 2\rho_u U^{(R,1)}(q_k - q_j) + (f_k + f_j - 2\rho_u) U^{(R,1)}(q_k - q_j)\\ &\geqslant 2\rho_u U^{(R,1)}(q_k - q_j) - 2M\rho_u((1+\epsilon)^{(p+1)} - 1),\end{aligned}$$

and so it follows from the above bound, (3.10) and Lemma 3.1 (c) that

$$\begin{aligned}\sum_{[k,j]\in P_u} (f_k + f_j) U^{(R,1)}(q_k - q_j) &\geqslant -A \sum_{k \in \mathbb{Z}_u} \rho_u n_k + \frac{3}{4} B \sum_{k\in\mathbb{Z}_u} \rho_u n_k^2\\ &\quad - \left(2M((1+\epsilon)^{(p+1)} - 1) \sum_{[k,j]\in P_u} \rho_u \right)\\ &\geqslant -A \sum_{k\in\mathbb{Z}_u} \rho_u n_k + \left(\frac{3}{4} B (1+\epsilon)^{-(p+1)} \sum_{k\in\mathbb{Z}_u} f(k-\mu,\sigma) n_k^2 \right)\\ &\quad - \left(M((1+\epsilon)^{(p+1)} - 1) \sum_{[k,j]\in P_u} (f_k + f_j) \right).\end{aligned}$$

Now let $z \in \Lambda_0 \cap R\ \mathbb{Z}^d$ be given. Then $\{\Lambda_u : u \in z + Rm\mathbb{Z}^d\}$ is a partition of $\mathbb{R}^d$. Let Q_z be the union of all P_u such that $u \in z + Rm\mathbb{Z}^d$. By the above estimate and $U^{(R,1)}(x) \geqslant -M$, we see that

$$\begin{aligned}W^{(R,1)}(\omega, \mu.\sigma) &\geqslant \left(\frac{3}{4} B(1+\epsilon)^{-(p+1)} \sum_{k\in\mathbb{Z}^d} f(k-\mu,\sigma) n_k^2 \right) - M \sum_{[k,j]\in P\setminus Q_z} (f_k + f_j)\\ &\quad - \left(M((1+\epsilon)^{(p+1)} - 1) \sum_{[k,j]\in Q_z} (f_k + f_j) \right)\\ &\geqslant \left(\frac{3}{4} B(1+\epsilon)^{-(p+1)} \sum_{k\in\mathbb{Z}^d} f(k-\mu,\sigma) n_k^2 \right)\\ &\quad - M \sum_{[k,j]\in P\setminus Q_z} (f_k + f_j) - \left(M((1+\epsilon)^{(p+1)} - 1) \sum_{[k,j]\in P} (f_k + f_j) \right). \end{aligned} \tag{3.11}$$

We notice that

$$\sum_{[k,j]\in P} (f_k + f_j) \leqslant c_4 \sum_{k\in\mathbb{Z}^d} \sum_{j\in\mathbb{Z}^d; |k-j| \leqslant R+2} n_k n_j f(k-\mu,\sigma).$$

Since $f(k-\mu,\sigma) \leqslant f(j-\mu,\sigma)\ (1+\lambda(R+2))^{(p+1)}$ if $|k-j| \leqslant R+2$, by Lemma 3.1 (c), and the number of j such that $|k-j| \leqslant R+2$ has an order of $(R+2)^d$, we use the Schwarz inequality to obtain

$$\sum_{[k,j]\in P}(f_k+f_j)\leqslant c_5\,(3+R)^{p+1+d}\sum_{k\in\mathbb{Z}^d} f(k-\mu,\sigma)\; n_k(\omega)^2. \tag{3.12}$$

Hence, inserting (3.12) into (3.11), we have

$$W^{(R,1)}(\omega,\mu.\sigma)\geqslant\left(\frac{3}{4}B(1+\epsilon)^{-(p+1)}-M((1+\epsilon)^{(p+1)}-1)\,c_5(3+R)^{p+1+d}\right)\sum_{k\in\mathbb{Z}^d} f(k-\mu,\sigma)n_k^2$$
$$-M\sum_{[k,j]\in P\setminus Q_z}(f_k+f_j). \tag{3.13}$$

We are going to sum both sides of the inequality (3.13) over $z\in\Lambda_0\cap R\mathbb{Z}^d$. The term in the left hand side and the first term in the right hand side of (3.13) are independent of z. Thus we consider the last term in the right hand side of (3.13). Given $[k,j]\in P$, the number of $z\in\Lambda_0\cap R\mathbb{Z}^d$ such that $[k,j]\in Q_z$ is larger than $(m-2)^d$, thus the number of z with $[k,j]\notin Q_z$ is less than $m^d-(m-2)^d\leqslant 2\,dm^{(d-1)}$. Consequently, summing both sides of (3.13) over $z\in\Lambda_0\cap R\;\mathbb{Z}^d$ we have

$$m^d\,W^{(R,1)}(\omega,\mu.\sigma)\geqslant\left[m^d\left(\frac{3}{4}B(1+\epsilon)^{-(p+1)}-M\big((1+\epsilon)^{(p+1)}-1\big)\,c_5(3+R)^{p+1+d}\right)\right.$$
$$\left.\times\sum_{k\in\mathbb{Z}^d} f(k-\mu,\sigma)n_k^2\right]-\left[M2\,dm^{(d-1)}\sum_{[k,j]\in P}(f_k+f_j)\right]. \tag{3.14}$$

Therefore, inserting (3.12) into (3.14) and dividing both sides of (3.14) by m^d, we get

$$W^{(R,1)}(\omega,\mu,\sigma)\geqslant C(R,\epsilon,m)\sum_{k\in\mathbb{Z}^d} f(k-\mu,\sigma)n_k(\omega)^2, \tag{3.15}$$

where

$$C(R,\epsilon,m)=\left(\frac{3}{4}B(1+\epsilon)^{-(p+1)}-M\big((1+\epsilon)^{(p+1)}-1\big)\,c_5(3+R)^{p+1+d}\right)$$
$$-c_5\frac{M2d}{m}(3+R)^{(p+1+d)}.$$

Now we choose and fix a sufficiently large R so that (3.9) and (3.10) hold. Then fix $\epsilon>0$ to be sufficiently small and fix m sufficiently large so that

$$C(R,\epsilon,m)\geqslant\tfrac{1}{2}B. \tag{3.16}$$

Finally we take and fix $0<\lambda<1$ so small that $\lambda mR\sqrt{d}<\epsilon$. By (3.8)–(3.9), (3.15)–(3.16), the first statement in the Lemma follows directly. Using Lemma 3.1 (d) instead of Lemma 3.1 (c), we obtain the second inequality in the same way. □

In the rest of this paper $\lambda>0$ will be fixed such that Lemma 3.2 holds. Finally, let us remark that H and W are equivalent in the following sense.

Lemma 3.3: There exist positive constants M_1 and M_2 such that

$$M_1\overline{H}(\omega)\leqslant\overline{W}(\omega)\leqslant M_2\overline{H}(\omega),$$

for all $\omega\in\overline{\Omega}$.

Proof: To prove the first part it is enough to show that

$$H(\omega,\mu,\sigma)\leqslant c\, W(\omega,\mu,\sigma), \tag{3.17}$$

for some constant $c>0$. By (2.6), $U(q_k-q_j)\geqslant -M(1+|q_k-q_j|)^{-\gamma}$ for all k,j. It follows from Lemma 3.1 (b) that

$$W(\omega,\mu,\sigma)\geqslant c_2 H(\omega,\mu,\sigma)-M\sum_k \sum_{j\neq k} f(q_k-\mu,\sigma)(1+|q_k-q_j|)^{-\gamma}.$$

By a simple computation and Lemma 3.2, we see that

$$\sum_k \sum_{j\neq k} f(q_k-\mu,\sigma)(1+|q_k-q_j|)^{-\gamma}\leqslant c_6 \sum_{k\in\mathbb{Z}^d} f(k-\mu,\sigma)n_k(\omega)^2$$
$$\leqslant c_6'\ W(\omega,\mu,\sigma).$$

Thus (3.17) follows from the above bounds.

Let us consider the second inequality. By the superstability of potential, one has that

$$\sum_{|j-\mu|\leqslant\sigma} n_j(\omega)^2\leqslant \frac{2}{B}H(\omega,\mu,\sigma+1). \tag{3.18}$$

We use the decomposition $U(x)=U^{(1)}(x)+U^{(2)}(x)$ in (2.2), so that $U^{(1)}(x)\geqslant 0$ and $U^{(1)}(x)=0$ if $|x|\geqslant r$, and $|U^{(2)}(x)|\leqslant M\ (1+|x|)^{-\gamma}$. We write

$$W(\omega,\mu,\sigma)=\sum_k f(q_k-\mu,\sigma)\left(2A+|p_k|^2+\sum_{j\neq k} U^{(1)}(q_k-q_j)\right)$$
$$+\sum_k f(q_k-\mu,\sigma)\sum_{j\neq k} U^{(2)}(q_k-q_j)$$
$$\equiv W_1+W_2.$$

Using Lemma 3.1 (a) and (c), and (3.18), we have that

$$|W_2|=\left|\sum_k f(q_k-\mu,\sigma)\sum_{j\neq k} U^{(2)}(q_k-q_j)\right|$$
$$\leqslant c_7 \sum_{k,j\in\mathbb{Z}^d;k\neq j} f(k-\mu,\sigma)\ n_k(\omega)\ n_j(\omega)\ (1+|k-j|)^{-\gamma}\leqslant c_7' \sum_{k\in\mathbb{Z}^d} f(k-\mu,\sigma)\ n_k(\omega)^2$$
$$\leqslant \tilde{c}\sum_{n=1}^{\infty} n^{-p} \sum_{k\in\mathbb{Z}^d;|k-\mu|\leqslant n\sigma} n_k(\omega)^2\leqslant \tilde{c}_1\sum_{n=1}^{\infty} n^{-p}H(\omega,\mu,n\sigma+1). \tag{3.19}$$

On the other hand, since $U^{(1)}(q_k-q_j)\geqslant 0$ and equals 0 for $|q_k-q_j|\geqslant r$, and since $f(q_k-\mu,\sigma)\leqslant f(q_j-\mu,\sigma)(1+\lambda|q_k-q_j|)^{(p+1)}$, we use Lemma 3.1 (a) to see that

$$W_1\leqslant c_8\sum_{n=1}^{\infty} n^{-p}\left(\sum_{|q_k-\mu|\leqslant n\sigma}\left(A+|p_k|^2+\sum_{|q_j-\mu|\leqslant n\sigma} U^{(1)}(q_k-q_j)\right)\right).$$

By adding and subtracting $U^{(2)}(q_k-q_j)$ to the last summand, we get that

$$W_1\leqslant c_8\sum_{n=1}^{\infty} n^{-p}\left(H(\omega,\mu,n\sigma)+\sum_{|q_k-\mu|\leqslant n\sigma,|q_j-\mu|\leqslant n\sigma} |U^{(2)}(q_k-q_j)|\right). \tag{3.20}$$

Observe that

$$\sum_{|q_k-\mu|\leqslant n\sigma,|q_j-\mu|\leqslant n\sigma} |U^{(2)}(q_k-q_j)|\leqslant c_9 \sum_{k,j\in\mathbb{Z}^d;|k-\mu|\leqslant n\sigma+1,|j-\mu|\leqslant n\sigma+1} n_k(\omega)\ n_j(\omega)(1+|k-j|)^{-\gamma}$$

$$\leqslant c_9' \sum_{|k-\mu|\leqslant n\sigma+1} n_k(\omega)^2\leqslant c_9''\ H(\omega,\mu,n\sigma+2). \tag{3.21}$$

It follows from (3.19)–(3.21) that

$$W(\omega,\mu,\sigma)\leqslant c_{10}\sum_{n=1}^{\infty} n^{-p}\ H(\omega,\mu,n\sigma+2)\leqslant c_{10}'\ \sigma^d\left(\sum_{n=1}^{\infty} n^{-(p-d)}\right)\ \overline{H}(\omega). \tag{3.22}$$

Dividing both sides of (3.22) by σ^d and using the fact that $p-d>1$, we get the desired result. □

IV. *A PRIORI* BOUND

Recall that a continuous trajectory $\omega_t:\mathbb{R}\to\overline{\Omega}$ is called a tempered solution to (1.1) with initial configuration ω if $\omega_0=\omega$ and the components $q_k(t)=q_k(w_t)$, $p_k(t)=p_k(w_t)$ are continuously differentiable and satisfy (1.1) for all $k\in I$ and $t\in\mathbb{R}$. We assume the dimension $d\leqslant 2$. The following is a local version of the law of energy conservation.

Proposition 4.1: There exists a constant $K>0$ *such that along any tempered solution* ω_t *to (1.1) we have*

$$\frac{\partial}{\partial t}W(\omega_t,\mu,\sigma)\leqslant K\ g(|\mu|+\sigma)[\overline{W}(\omega_t)]^{1/2}\frac{\partial}{\partial\sigma}W(\omega_t,\mu,\sigma),$$

for all $t\in\mathbb{R}$, $\mu\in\mathbb{R}^d$, *and* $\sigma\geqslant 2$.

Proof: In order to prove the proposition, we modify and extend the method used in the proof of Proposition 4.1 of Ref. 3. Recall the decomposition $U(x)=U^{(1)}(x)+U^{(2)}(x)$ in (2.2) and the inequality (2.4). A direct computation gives

$$\frac{\partial W}{\partial t}=\sum_{k\in I}\langle \operatorname{grad} f_k,p_k\rangle\ W_k+\frac{1}{2}\sum_k \sum_{j\neq k;|q_k-q_j|\leqslant r}(f_j-f_k)\langle \operatorname{grad} U^{(1)}(q_k-q_j),p_k+p_j\rangle$$

$$+\frac{1}{2}\sum_k \sum_{j\neq k;|q_k-q_j|\geqslant r}(f_j-f_k)\langle \operatorname{grad} U^{(2)}(q_k-q_j),p_k+p_j\rangle\equiv D_1+D_2+D_3, \tag{4.1}$$

where $f_k=f(q_k-\mu,\sigma)$.

For D_1, it is not hard to see that $|W_k|\leqslant W_k+M\ \Sigma_{j\neq k}(1+|q_k-q_j|)^{-\gamma}$. Thus

$$|D_1|\leqslant\sum_{k\in I}|\operatorname{grad} f_k|\ |p_k|\left[W_k+M\sum_{j\neq k}(1+|q_k-q_j|)^{-\gamma}\right].$$

Since $|p_k|\leqslant K_1\ g(|q_k|)\ [\overline{W}(\omega_t)]^{1/2}$, we use Lemma 3.1 (f) to get

$$|D_1|\leqslant 4K_1\ g(|\mu|+\sigma)[\overline{W}(\omega_t)]^{1/2}\sum_k f_k'\left[W_k(\omega_t)+M\sum_{j\neq k}(1+|q_k-q_j|)^{-\gamma}\right]. \tag{4.2}$$

By Lemma 3.1 (d), $f_k'\leqslant(1+\lambda|q_k-q_j|)^{p+1}\ f_j'$. Thus using Schwarz inequality and the fact that $\gamma>2p$, we get

$$\sum_{k\in I} f_k'\sum_{j\neq k}(1+|q_k-q_j|)^{-\gamma}\leqslant K_2\sum_{k\in\mathbb{Z}^d} f'(k-\mu,\sigma)\ n_k(\omega)^2. \tag{4.3}$$

From (4.2)–(4.3) and Lemma 3.2, one obtains

$$|D_1|\leqslant K_3\, g(|\mu|+\sigma)\,[\overline{W}(\omega_t)]^{1/2}\frac{\partial}{\partial\sigma}W(\omega_t,\mu,\sigma). \tag{4.4}$$

For D_3, since $|\text{grad}\, U^{(2)}(q_k-q_j)|\leqslant M\ (1+|q_k-q_j|)^{-\gamma}$, we have

$$|D_3|\leqslant K_4\sum_k\sum_{j\neq k}|\text{grad}\, f(z_{kj}-\mu,\sigma)|\,|q_k-q_j|\,(1+|q_k-q_j|)^{-\gamma}\ (g(|q_k|)+g(|q_j|))[\overline{W}(\omega_t)]^{1/2},$$

where z_{kj} is at some point between q_k and q_j. Note that, by Lemma 3.1 (f),

$$|\text{grad}\, f(z_{kj}-\mu,\sigma)|\leqslant\frac{1}{g(|z_{kj}|)}\ 4\ g(|\mu|+\sigma)\, f'(z_{kj}-\mu,\sigma).$$

We note that $g(x+y)\leqslant g(x)g(y)$ for any $x,y\geqslant 0$, and so $g(|q_k|)+g(|g_j|)\leqslant 2g(|z_{kj}|)g(|q_k-q_j|)$. Using Schwarz inequality, Lemma 3.1 (d), and Lemma 3.2, we obtain

$$\begin{aligned}|D_3|&\leqslant K_5\ g(|\mu|+\sigma)[\overline{W}(\omega_t)]^{1/2}\sum_{k\in\mathbb{Z}^d}\sum_{j\in\mathbb{Z}^d}[n_k(\omega)\ n_j(\omega)\ f'(l_{kj}-\mu,\sigma)|k-j|(1+|k-j|)^{-\gamma}\\&\quad\times(1+\log(1+|k-j|))]\\&\leqslant K_5'\ g(|\mu|+\sigma)[\overline{W}(\omega_t)]^{1/2}\\&\quad\times\sum_{k\in\mathbb{Z}^d}f_k'\ n_k^2(\omega)\left[\sum_{j\in\mathbb{Z}^d}|k-j|\,(1+|k-j|)^{-\gamma}\ (1+\log(1+|k-j|)\ (1+\lambda|k-j|)^{p+1}\right]\\&\leqslant K_5''\ g(|\mu|+\sigma)\,[\overline{W}(\omega_t)]^{1/2}\frac{\partial}{\partial\sigma}W(\omega_t,\mu,\sigma),\end{aligned}\tag{4.5}$$

where l_{kj} is a point between k and j. Here we have used $\gamma>2p+1$ to get the last inequality.

Finally for D_2, we use (2.4) to obtain the following bound:

$$\begin{aligned}|D_2|&\leqslant K_6\sum_k\sum_{j\neq k;|q_k-q_j|\leqslant r}|\text{grad}\, f(z_{kj}-\mu,\sigma)|\,(a+b\ U^{(1)}(q_k-q_j))\ g(|q_k|)\ [\overline{W}(\omega_t)]^{1/2}\\&\leqslant K_6'\ g(|\mu|+\sigma)[\overline{W}(\omega_t)]^{1/2}\sum_k\sum_{j\neq k;|q_k-q_j|\leqslant r}f'(z_{kj}-\mu,\sigma)\ (a+b\ U^{(1)}(q_k-q_j|))\frac{g(|q_k|)}{g(|z_{kj}|)}.\end{aligned}$$

Notice that if $|q_k-q_j|<r$, $g(|q_k|)\leqslant K_7\ g(|z_{kj}|)$. By Lemma 3.1 (d),

$$\sum_k\sum_{j\neq k;|q_k-q_j|\leqslant r}f'(z_{kj}-\mu,\sigma)\leqslant K_8\sum_{k\in\mathbb{Z}^d}\sum_{|j-k|\leqslant r}n_k\ n_j\ f_k'\leqslant K_8'\sum_{k\in\mathbb{Z}^d}f_k'\ n_k^2. \tag{4.6}$$

Moreover, a direct computation yields

$$
\begin{aligned}
&\sum_k \sum_{j\neq k;|q_k-q_j|\leqslant r} f'(z_{kj}-\mu,\sigma)U^{(1)}(q_k-q_j)\\
&\quad\leqslant K_9\sum_k f'_k \sum_{j\neq k;|q_k-q_j|\leqslant r} U^{(1)}(q_k-q_j)\\
&\quad\leqslant K_9\sum_k f'_k\left[2A+|p_k|^2+\sum_{j\neq k}U(q_k-q_j)\right]+K_{10}\sum_k f'_k \sum_{j\neq k;|q_k-q_j|\leqslant r}(1+|q_k-q_j|)^{-\gamma}\\
&\quad\leqslant K_9\sum_k f'_k\, W_k(\omega_t)+K_{11}\sum_{k\in\mathbb{Z}^d} f'(k-\mu,\sigma)\; n_k^2(\omega).
\end{aligned}\tag{4.7}
$$

Using (4.6)–(4.7) and Lemma 3.2, we see that

$$|D_2|\leqslant K_{12}\; g(|\mu|+\sigma)\;[\overline{W}(\omega_t)]^{1/2}\frac{\partial}{\partial\sigma}W(\omega_t,\mu,\sigma). \tag{4.8}$$

Thus the proof of the proposition follows from (4.4), (4.5), and (4.8). □

By the method in Proposition 4.2 of Ref. 3 and Lemma 3.3 one can prove the following proposition.

Proposition 4.2: For each $h>0$ *and* $T>0$ *there exists a finite* $\overline{h}=\overline{h}(h,T)$ *such that* $\overline{H}(\omega_0)\leqslant h$ *implies* $\overline{H}(\omega_t)\leqslant\overline{h}$ *for all* $|t|\leqslant T$ *provided that* ω_t *is a tempered solution to (1.1).*

As a consequence we have the following localization of particles.

Proposition 4.3: If ω_t *is a tempered solution to (1.1) and* $\overline{H}(\omega_0)<h$*, then there is a constant* $c(h,T)$ such that

$$|q_k(\omega_{t_1})-q_k(\omega_{t_2})|\leqslant c(h,T)\, g(|q_k(\omega_{t_1})|),$$

for all $k\in I,|t_1|\leqslant T,|t_2|\leqslant T$.

Proof: Let us simply write $q_k(\omega_t):=q_k(t)$. By Proposition 4.2, we have

$$\left|\frac{dq_k}{dt}\right|\leqslant g(|q_k|)\; c_1(h,T). \tag{4.9}$$

Define

$$q_{\max}:=\max_{|t|\leqslant T}|q_k(t)| \quad\text{and}\quad q_{\min}:=\min_{|t|\leqslant T}|q_k(t)|.$$

It follows from (4.9) that

$$|q_k(t_2)-q_k(t_1)|\leqslant 2\;T\,c_1(h,T)\;g(q_{\max}). \tag{4.10}$$

Similarly we have also

$$q_{\min}\geqslant q_{\max}-2\;T\,c_1(h,T)\;g(q_{\max}). \tag{4.11}$$

(4.11) implies the existence of $c_2(h,T)$ such that

$$\frac{g(q_{\max})}{g(q_{\min})}\leqslant c_2(h,T). \tag{4.12}$$

Inserting (4.12) into (4.10) and using the fact that $g(u)$ is an increasing function, we get the desired result. □

V. EXISTENCE

We are going to show the existence of tempered solutions to (1.1). For that purpose we have to investigate a kind of uniform boundedness. Let $(r_n)_{n=1}^{\infty}$ be any increasing sequence of positive numbers such that $r_n \to \infty$ as $n \to \infty$. Let $\omega_0 \in \overline{\Omega}$ be any initial configuration. For each $n \geqslant 1$, let $\omega_0^{(n)}$ be the configuration obtained by discarding the particles outside the r_n-ball with center the origin. Let $\omega^{(n)}(t) = (q_k^{(n)}(t), p_k^{(n)}(t))$ be the (finite system) solution of (1.1) with initial condition $\omega^{(n)}(0) = \omega_0^{(n)}$. We start with the following lemma saying that the energy densities of cutoff sub-systems are uniformly bounded.

Lemma 5.1: Let $\omega_0 \in \overline{\Omega}$ *and* $\omega_0^{(n)}$, $n \geqslant 1$, *be defined as above. There exists a constant* $c_0 > 0$ *independent of* ω_0 *such that the bounds*

$$\overline{H}(\omega_0^{(n)}) \leqslant c_0 \, \overline{H}(\omega_0)$$

hold uniformly in $n \in \mathbb{N}$.

Proof: For any $\mu \in \mathbb{R}^d$ and $\sigma > 0$, let us compare $H(\omega_0^{(n)}, \mu, \sigma)$ to $H(\omega_0, \mu, \sigma)$. For our purpose it is sufficient to consider the cases where the σ-ball $B_\sigma(\mu)$ touches the boundary of r_n-ball $B_{r_n}(0)$. In that case we see that

$$H(\omega_0^{(n)}, \mu, \sigma) \leqslant H(\omega_0, \mu, \sigma) - \sum^{*} U(q_k - q_l), \tag{5.1}$$

where $q_k = q_k(\omega_0)$, $p_k = p_k(\omega_0)$, and

$$\sum^{*} U(q_k - q_l) = \frac{1}{2}\left(\sum_{k \in \Lambda_1} \sum_{l \in \Lambda_2} U(q_k - q_l) + \sum_{k,l \in \Lambda_2} U(q_k - q_l) \right), \tag{5.2}$$

where $\Lambda_1 := B_{r_n}(0) \cap B_\sigma(\mu)$, $\Lambda_2 := B_\sigma(\mu) \setminus \Lambda_1$. By the superstability of the potential, we see that

$$\sum_{k,l \in \Lambda_2} U(q_k - q_l) \geqslant -A \sum_{l \in \Lambda_2 \cap \mathbb{Z}^d} n_l(\omega_0) \geqslant -A \sum_{l \in B_\sigma(\mu) \cap \mathbb{Z}^d} n_l(\omega_0)^2 \geqslant -\frac{2A}{B} H(\omega_0, \mu, \sigma + 1). \tag{5.3}$$

Here we have used (3.18) to get the last inequality. On the other hand, by using the decomposition of $U = U^{(1)} + U^{(2)}$ in (2.2), let us put

$$\sum_{k \in \Lambda_1} \sum_{l \in \Lambda_2} U(q_k - q_l) = \sum_{k \in \Lambda_1} \sum_{l \in \Lambda_2} U^{(1)}(q_k - q_l) + \sum_{k \in \Lambda_1} \sum_{l \in \Lambda_2} U^{(2)}(q_k - q_l). \tag{5.4}$$

Since $U^{(1)} \geqslant 0$ and $U^{(1)}(x) \geqslant -M(1 + |x|)^\gamma$, it is not hard to see that

$$\sum_{k \in \Lambda_1} \sum_{l \in \Lambda_2} U(q_k - q_l) \geqslant -c_{11} \sum_{k \in B_\sigma(\mu) \cap \mathbb{Z}^d} n_k(\omega_0)^2 \geqslant -c_{11}' H(\omega_0, \mu, \sigma + 1). \tag{5.5}$$

Inserting (5.3) and (5.5) into (5.1), we proved the lemma. □

When $q_k(0)$ is outside of the r_n-ball, define $q_k^{(n)}(t) \equiv q_k(0)$ and $p_k^{(n)}(t) \equiv 0$ for all $t \geqslant 0$.

Lemma 5.2: For each $k \in I$, *and* $T > 0$, *the sequence of continuous functions* $(q_k^{(n)}(\cdot))_{n=1}^{\infty}$ *and* $(p_k^{(n)}(\cdot))_{n=1}^{\infty}$ *on* $[0,T]$ *are equi-continuous.*

Proof: For any $-T \leqslant t_1 \leqslant t_2 \leqslant T$, it follows from Lemma 5.1, Proposition 4.2, and Proposition 4.3 that

$$|q_k^{(n)}(t_2)-q_k^{(n)}(t_1)|\leqslant\int_{t_1}^{t_2}|p_k^{(n)}(s)|\,ds\leqslant c_{12}\,g(|q_k(\omega_0)|)\ |t_2-t_1|. \tag{5.6}$$

On the other hand,

$$|p_k^{(n)}(t_2)-p_k^{(n)}(t_1)|\leqslant\sum_{j\neq k}\int_{t_1}^{t_2}|\mathrm{grad}U(q_j^{(n)}(s)-q_k^{(n)}(s))|\,ds.$$

We again decompose $U=U^{(1)}+U^{(2)}$ as in (2.2). By (2.5), we may assume that there exist $c>1$ and $L>1$ such that

$$|\mathrm{grad}U(x)|\leqslant L(L+U^{(1)}(x))^c. \tag{5.7}$$

Thus we have

$$\begin{aligned}\sum_{l\neq k}|\mathrm{grad}U(q_j^{(n)}-q_k^{(n)})|&\leqslant\sum_{j\neq k}L[L+U^{(1)}(q_j^{(n)}-q_k^{(n)})]^c\\&\leqslant L\left(\sum_{j\neq k:|q_j^{(n)}-q_k^{(n)}|\leqslant r}[L+U^{(1)}(q_j^{(n)}-q_k^{(n)})]\right)^c\\&\leqslant L\left(\sum_{j,l\in I_{k,n}}[L+U^{(1)}(q_j^{(n)}-q_l^{(n)})]\right)^c,\end{aligned} \tag{5.8}$$

where $I_{k,n}=\{j\in I:|q_j^{(n)}-q_k^{(n)}|\leqslant r\}$. By direct computations, we have that

$$\sum_{j,l\in I_{k,n}}L\leqslant L\ r^d\sum_{j\in\mathbb{Z}^d\cap B_r(q_k^{(n)})}(1+n_j^2)\leqslant c_{13}Lr^dH(\omega^{(n)},q_k^{(n)},r), \tag{5.9}$$

and

$$\begin{aligned}&\sum_{j,l\in I_{k,n}}U^{(1)}(q_j^{(n)}-q_l^{(n)})\\&\leqslant\sum_{j:|q_j^{(n)}-q_k^{(n)}|\leqslant r}\left(|p_j^{(n)}|^2+A+\sum_{l:|q_l^{(n)}-q_k^{(n)}|\leqslant r}U(q_j^{(n)}-q_l^{(n)})\right)+c_{14}\sum_{j,l\in I_{k,n}}(1+|q_j^{(n)}-q_l^{(n)}|)^{-\gamma}\\&\leqslant c_{14}'H(\omega^{(n)},q_k^{(n)},r).\end{aligned} \tag{5.10}$$

Inserting (5.9) and (5.10) into (5.8) and using Lemma 5.1, Proposition 4.2, and Proposition 4.3, we have that

$$|p_k^{(n)}(t_2)-p_k^{(n)}(t_1)|\leqslant c_{15}\,g(|q_k(\omega_0)|)^{cd}\ |t_2-t_1|. \tag{5.11}$$

Thus the lemma follows from (5.6) and (5.11). □

We are now ready to prove the existence of tempered solutions to (1.1). The method of the proof is given in Theorem 5.1 of Ref. 3, but we provide it for completeness.

Proof of Theorem 2.1: For each $n=1,2,\ldots$, let $\omega^{(n)}(t)$ be the tempered solution corresponding to the cutoff finite subsystem introduced above. By Lemma 5.2, for any finite $T>0$ and $k\in I$, the sequences $(q_k^{(n)}(t))_{n=1}^{\infty}$ and $(p_k^{(n)}(t))_{n=1}^{\infty}$ are equi-continuous. Thus by the Arzela–Ascoli theorem, after a diagonal procedure, we see that there exists a subsequence n_i, $i=1,2,\ldots$, such that for all $k\in I$, the sequences $(q_k^{(n_i)}(t))_{i=1}^{\infty}$ and $(p_k^{(n_i)}(t))_{i=1}^{\infty}$ uniformly converge on $[0,T]$ and define continuous functions $q_k(t)$ and $p_k(t)$. Since $T>0$ is arbitrary we can extend these functions to all $t\in\mathbb{R}$. Since $\overline{H}$ is lower semicontinuous, the *a priori* bounds remain in force for $\omega_t := (q_k, p_k)_{k\in I}$. Exploiting the continuity of the r.h.s. of the integral version of (1.1), we conclude that ω_t really satisfies (1.1). □

VI. UNIQUENESS

In order to prove uniqueness of tempered solution, we use an iteration method which turns out to be much more complicated compared to that used in Sec. 5 of Ref. 3. Consider a sequence $\delta(t,m)$, $m=0,1,\ldots,$ of non-negative and continuous functions on $[0,T]$ such that the bounds

$$\delta(t,m)\leqslant\delta(0,m)+L_1 a_m\int_0^t\delta(s,m+1)\,ds+L_2 b_m \tag{6.1}$$

hold for all $t\in[0,T]$ and m with some constants L_1 and L_2 (independent of m) and positive, increasing sequences $(a_m)_{m\geqslant 0}$ and $(b_m)_{m\geqslant 0}$. If

$$\delta(t,m)\leqslant Q_T\exp(mQ_T), \tag{6.2}$$

for $t\leqslant T$ and for all $m\geqslant 0$, and, furthermore, if the infinite series

$$\sum_{m=0}^{\infty}\frac{1}{m!}[(a_m)^m\ b_m]^{\alpha}<\infty \tag{6.3}$$

converges for any $\alpha\geqslant 1$, then (6.1) can be iterated infinitely many times to obtain

$$\delta(t,0)\leqslant\sum_{m=0}^{\infty}\ \delta(0,m)\frac{(L_1 t)^m}{m!}(a_m)^m+\sum_{m=0}^{\infty}\frac{(L_1 t)^m}{m!}(a_m)^m\ (L_2 b_m). \tag{6.4}$$

Recall the decomposition $U(x)=U^{(1)}(x)+U^{(2)}(x)$ in (2.2). $U^{(1)}(x)$ satisfies (2.3)–(2.5) and $U^{(2)}(x)$ satisfies (2.6).

Proof of Theorem 2.2: Let $f_0:\mathbb{R}\to[0,1]$ be a continuously differentiable nonincreasing function such that $f_0(u)=1$ if $u\leqslant 1$, $f_0(u)=0$ if $u\geqslant 2$, and $-f_0'(u)\leqslant f_0(u-1)$ for all $u\in\mathbb{R}$. Recall that the singular part of the interaction has finite range $r<\infty$. For each $R\geqslant r+1$ let $f_R(u) := f_0(u/R), u\in\mathbb{R}$. Then $f_R(u)$ also satisfies

$$f_R(u)=1\ \text{ if }\ u\leqslant R,\quad f_R(u)=0\ \text{ if }\ u\geqslant 2R,\quad\text{and }\ -f_R'(u)\leqslant f_R(u-R). \tag{6.5}$$

Suppose now that $\omega_t=(q_k(t),p_k(t))_{k\in I}$ and $\overline{\omega}_t=(\overline{q}_k(t),\overline{p}_k(t))_{k\in I}$ are two tempered solutions of (1.1) with the same initial condition $\omega_0=(q_k(0),p_k(0))\in\overline{\Omega}$. For each $R\geqslant r+1$, let us define

$$\begin{aligned} d_R(\omega_t,\overline{\omega}_t,m) &:= \sum_{k\in I} f_R(|q_k|-2\tilde{c}R(1+mg(m)))\ f_R(|\overline{q}_k|-2\tilde{c}R(1+mg(m)))\\ &\quad\times[|q_k-\overline{q}_k|_1+|p_k-\overline{p}_k|_1], \end{aligned} \tag{6.6}$$

where $\tilde{c}\geqslant 1$ is a sufficiently large fixed number that will be characterized later. We have used also the norm $|x|_1 := |x^{(1)}|+\cdots+|x^{(d)}|$ for each $x=(x^{(1)},\ldots,x^{(d)})\in\mathbb{R}^d$. We would like to show that for each $R\geqslant r+1$ the sequence of functions $\delta_R(t,m) := d_R(\omega_t,\overline{\omega}_t,m)$ satisfies (6.1)–(6.3) with suitably chosen sequences $(a_m)_{m\geqslant 0}$, $(b_m)_{m\geqslant 0}$ and constants $L_1(R)$, $L_2(R)$. Given $R\geqslant r+1$ and $T>0$, the r.h.s. of (6.6) is an absolutely continuous function of $t\in[0,T]$, thus we can differentiate it almost everywhere. By a notational convenience, let us drop the subscript R in $f_R(\cdot)$; $f(\cdot)\equiv f_R(\cdot)$ [cf. $f(x,\sigma)$ in (3.1)] and denote $f(t,k,m) := f(|q_k|-2\tilde{c}R(1+mg(m)))$, $\overline{f(t,k,m)} := f(|\overline{q}_k|-2\tilde{c}R(1+mg(m)))$. By differentiating the right hand side of (6.6), we have

$$\frac{d}{dt}(\delta_R(t,m)) = A^{(1)}(t,m) + A^{(2)}(t,m) + A^{(3)}(t,m) + A^{(4)}(t,m), \tag{6.7}$$

where

$$\begin{aligned} A^{(1)}(t,m) &= \sum_{k\in I} \left(\frac{d}{dt} f(t,k,m)\right)\overline{f}(t,k,m)(|q_k - \overline{q_k}|_1 + |p_k - \overline{p_k}|_1), \\ A^{(2)}(t,m) &= \sum_{k\in I} f(t,k,m)\left(\frac{d}{dt}\overline{f}(t,k,m)\right)(|q_k - \overline{q_k}|_1 + |p_k - \overline{p_k}|_1), \\ A^{(3)}(t,m) &= \sum_{k\in I} f(t,k,m)\overline{f}(t,k,m)\frac{d}{dt}|q_k - \overline{q_k}|_1, \\ A^{(4)}(t,m) &= \sum_{k\in I} f(t,k,m)\overline{f}(t,k,m)\frac{d}{dt}|p_k - \overline{p_k}|_1. \end{aligned} \tag{6.8}$$

Below, we will estimate each term in (6.8).

Since the bound

$$|p_k| \leqslant H(\omega, q_k, g(|q_k|))^{1/2} \leqslant c_{16}\, g(|q_k|)^{d/2} \tag{6.9}$$

holds for any $k \in I$, we use (6.5) to see that

$$\left|\frac{d}{dt} f(t,k,m)\right| \leqslant c_{17} f(t,k,m+1)\ (g(R)\, g(m))^{d/2}, \tag{6.10}$$

and

$$\left|\frac{d}{dt}\overline{f}(t,k,m)\right| \leqslant c_{17}\, \overline{f}(t,k,m+1)\ (g(R)\, g(m))^{d/2}. \tag{6.11}$$

Obviously,

$$\left|\frac{d}{dt}\right| q_k - \overline{q_k}|_1\, | \leqslant |p_k - \overline{p_k}|_1. \tag{6.12}$$

Thus, it follows from (6.9)–(6.12) that

$$|A^{(1)}(t,m) + A^{(2)}(t,m) + A^{(3)}(t,m)| \leqslant c_{18}(g(R) g(m))^{d/2} \delta_R(t,m+1). \tag{6.13}$$

Finally, let us consider the last term $A^{(4)}(t,m)$ in (6.8). Observe that

$$\begin{aligned} \left|\frac{d}{dt}\right| p_k - \overline{p_k}|_1\, | \leqslant & \sum_{l\neq k} |\operatorname{grad} U^{(1)}(q_l - q_k) - \operatorname{grad} U^{(1)}(\overline{q_l} - \overline{q_k})| \\ & + \sum_{l\neq k} |\operatorname{grad} U^{(2)}(q_l - q_k) - \operatorname{grad} U^{(2)}(\overline{q_l} - \overline{q_k})|. \end{aligned} \tag{6.14}$$

Thus

$$|A^{(4)}(t,m)| \leqslant Q_1(t,m) + Q_2(t,m), \tag{6.15}$$

where

$$Q_1(t,m)=\sum_{k\in I}\left(f(t,k,m)\overline{f}(t,k,m)\sum_{l\neq k}(|\operatorname{grad}U^{(1)}(q_l-q_k)-\operatorname{grad}U^{(1)}(\overline{q_l}-\overline{q_k})|)\right),\quad(6.16)$$

$$Q_2(t,m)=\sum_{k\in I}\left(f(t,k,m)\overline{f}(t,k,m)\sum_{l\neq k}(|\operatorname{grad}U^{(2)}(q_l-q_k)-\operatorname{grad}U^{(2)}(\overline{q_l}-\overline{q_k})|)\right).$$

In order to control the first term $Q_1(t,m)$, we use (2.5) to see that

$$\sum_{l\neq k}|\operatorname{grad}U^{(1)}(q_l-q_k)-\operatorname{grad}U^{(1)}(\overline{q_l}-\overline{q_k})|$$
$$\leqslant L\sum_{l\neq k}[L+U^{(1)}(q_l-q_k)+U^{(1)}(\overline{q_l}-\overline{q_k})]^c[|q_l-\overline{q_l}|_1+|q_k-\overline{q_k}|_1].\quad(6.17)$$

Following the method similar to that used to obtain (5.11), one can check that

$$\begin{aligned}&\sum_{l\neq k}[L+U^{(1)}(q_l-q_k)+U^{(1)}(\overline{q_l}-\overline{q_k})]^c\,|q_k-\overline{q_k}|_1\\&\leqslant c_{19}[H(\omega_t,q_k,r)+H(\overline{\omega_t},\overline{q_k},r)]^c\,|q_k-\overline{q_k}|_1\\&\leqslant c_{19}'[g(|q_k|)^{cd}+g(|\overline{q_k}|)^{cd}]\,|q_k-\overline{q_k}|_1\\&\leqslant c_{19}''\,g(R)^{cd}\,g(m)^{cd}\,|q_k-\overline{q_k}|_1.\end{aligned}\quad(6.18)$$

On the other hand, since $U^{(1)}$ has interaction range $r<R$, we see that

$$\begin{aligned}&\sum_{k\in I}f(|q_k|-2\tilde{c}R(1+mg(m)))\;f(|\overline{q_k}|-2\tilde{c}R(1+mg(m)))\\&\times\sum_{l\neq k}[L+U^{(1)}(q_l-q_k)+U^{(1)}(\overline{q_l}-\overline{q_k})]^c\,|q_l-\overline{q_l}|_1\\&\leqslant\sum_{l\in I}f(|q_l|-2\tilde{c}R(1+(m+1)g(m+1)))\;f(|\overline{q_l}|-2\tilde{c}R(1+(m+1)g(m+1)))\\&\quad\times|q_l-\overline{q_l}|_1\sum_{k\neq l}[L+U^{(1)}(q_l-q_k)+U^{(1)}(\overline{q_l}-\overline{q_k})]^c\\&\leqslant c_{20}\,g(R)^{cd}\,g(m)^{cd}\;\delta_R(t,m+1).\end{aligned}\quad(6.19)$$

Hence by (6.16)–(6.19), we obtain that

$$Q_1(t,m)\leqslant c_{21}\,g(R)^{cd}g(m)^{cd}\delta_R(t,m+1).\quad(6.20)$$

Let us estimate the second term $Q_2(t,m)$ in (6.16). We use (2.6) to obtain

$$\sum_{l\neq k} |\operatorname{grad} U^{(2)}(q_l-q_k)-\operatorname{grad} U^{(2)}(\overline{q_l}-\overline{q_k})|$$

$$\leqslant \sum_{l\neq k} (\psi(|q_l-q_k|)+\psi(|\overline{q_l}-\overline{q_k}|))\,[|q_l-\overline{q_l}|_1+|q_k-\overline{q_k}|_1]$$

$$=\left(\sum_{l\neq k}\psi(|q_l-q_k|)+\psi(|\overline{q_l}-\overline{q_k}|)\right)|q_k-\overline{q_k}|_1+\sum_{l\neq k}(\psi(|q_l-q_k|)+\psi(|\overline{q_l}-\overline{q_k}|))|q_l-\overline{q_l}|_1$$

$$\equiv S_1(t,k)+S_2(t,k). \tag{6.21}$$

Thus, by the definition of $Q_2(t,m)$ in (6.16), we have

$$Q_2(t,m)\leqslant\sum_{k\in I} f(t,k,m)\overline{f(}t,k,m)S_1(t,k)+\sum_{k\in I} f(t,k,m)\overline{f(}t,k,m)\,S_2(t,k)$$

$$\equiv Q_2^{(1)}(t,m)+Q_2^{(2)}(t,m). \tag{6.22}$$

In order to control $Q_2^{(1)}(t,m)$, we notice that by Lemma 3.1 (a) and (2.6), the bound

$$\psi(|q_l-q_k|)\leqslant c_{22}\,f(q_l-q_k,g(|q_k|)) \tag{6.23}$$

holds. We then use the above bound, the Schwarz inequality, and Lemma 3.2 to see that

$$\sum_{l\neq k}\psi(|q_l-q_k|)\leqslant c_{23}\,W(\omega_t,q_k,g(|q_k|))^{d/2}. \tag{6.24}$$

Repeating the same calculation after a change ω_t by $\overline{\omega_t}$, we conclude that

$$S_1(t,k)\leqslant c_{24}\,(g(R)\,g(m))^{d/2}\,|q_k-\overline{q_k}|_1,$$

and so

$$Q_2^{(1)}(t,m)\leqslant c_{24}\,(g(R)g(m))^{d/2}\delta_R(t,m+1). \tag{6.25}$$

Next, we consider $Q_2^{(2)}(t,m)$. We write

$$S_2(t,k)=\sum_{l\neq k}\psi(|q_l-q_k|)\;|q_l-\overline{q_l}|_1+\sum_{l\neq k}\psi(|\overline{q_l}-\overline{q_k}|)\;|q_l-\overline{q_l}|_1\equiv S_{2,1}(t,k)+S_{2.2}(t,k), \tag{6.26}$$

and

$$Q_2^{(2)}(t,m)=\sum_{k\in I} f(t,k,m)\overline{f(}t,k,m)\,S_{2,1}(t,k)+\sum_{k\in I} f(t,k,m)\overline{f(}t,k,m)\,S_{2,2}(t,k)$$

$$\equiv Q_2^{(2,1)}(t,m)+Q_2^{(2,2)}(t,m). \tag{6.27}$$

By symmetry, it is enough to control only $Q_2^{(2,1)}(t,m)$. For that purpose, let us further decompose $S_{2,1}$ as follows:

$$S_{2,1}(t,k)=\sum_{l\neq k:|q_l-q_k|\leqslant R}\psi(|q_l-q_k|)\;|q_l-\overline{q_l}|_1+\sum_{l:\,|q_l-q_k|>R}\psi(|q_l-q_k|)\;|q_l-\overline{q_l}|_1.$$

Substituting the above decomposition into the definition of $Q_2^{(2,1)}(t,m)$ in (6.27), one has that

$$Q_2^{(2,1)}(t,m)=\sum_{k\in I} f(t,k,m)\overline{f}(t,k,m)\sum_{l\neq k:|q_l-q_k|\leqslant R} \psi(|q_l-q_k|)\ |q_l-\overline{q_l}|_1$$
$$+\sum_{k\in I} f(t,k,m)\overline{f}(t,k,m)\sum_{l:|q_l-q_k|>R} \psi(|q_l-q_k|)\ |q_l-\overline{q_l}|_1\equiv D_1(t,m)+D_2(t,m). \tag{6.28}$$

By Proposition 4.3, it is not hard (and very important) to see that if $f(|q_k|-2\tilde{c}R(1+mg(m)))\neq 0$, $f(|\overline{q_k}|-2\tilde{c}R(1+mg(m)))\neq 0$, and $|q_l-q_k|\leqslant R$, then $f(|q_l|-2\tilde{c}R(1+(m+1)g(m+1)))=1$ and $f(|\overline{q_l}|-2\tilde{c}R(1+(m+1)g(m+1)))=1$ when $\tilde{c}\geqslant 1$ is a large enough constant. Thus, by interchanging the order of summation and using the argument used in deriving (6.24), we have the bound for $D_1(t,m)$ in (6.28):

$$D_1(t,m)\leqslant c_{25}\,(g(R)\,g(m))^{d/2}\ \delta_R(t,m+1). \tag{6.29}$$

Finally, let us consider $D_2(t,m)$. If $f(|q_k|-2\tilde{c}R(1+mg(m)))\neq 0$, it follows from Proposition 4.3 that

$$|q_l-\overline{q_l}|_1\leqslant c_{26}\,g(|q_l|)\leqslant c'_{26}\,g(|q_k|)\ g(|q_l-q_k|)\leqslant c''_{26}\,g(R)\ g(m)\ g(|q_l-q_k|).$$

Thus, using (6.23) and Lemma 3.2, we obtain that

$$\sum_{l:|q_l-q_k|>R} \psi(|q_l-q_k|)\ |q_l-\overline{q_l}|_1$$
$$\leqslant c_{27}\,g(R)g(m)\sum_{l\in\mathbb{Z}^d:|l-q_k|\geqslant R} n_l(\omega_t)\ \psi(|l-q_k|)\ g(|l-q_k|)$$
$$\leqslant c_{27}\,g(R)g(m)\left(\sum_{l:|l-q_k|\geqslant R}\psi(|l-q_k|)g(|l-q_k|)^2\right)^{1/2}\left(\sum_{l\in\mathbb{Z}^d} n_l(\omega_t)^2 f(l-q_k,g(|q_k|))\right)^{1/2}$$
$$\leqslant c'_{27}\,g(R)g(m)[\psi(R)R^{d+\epsilon_1}]^{1/2}[g(R)g(m)]^{d/2},$$

where $0<\epsilon_1<1$ is a small constant. Substituting the above bound into the expression of $D_2(t,m)$ in (6.28), we conclude that

$$D_2(t,m)\leqslant c'_{28}\,g(R)^2g(m)^2[\psi(R)R^{d+\epsilon_1}]^{1/2}\sum_{l\in\mathbb{Z}^d:|l|\leqslant 2\tilde{c}R(1+mg(m))+3R} n_l(\omega_t)$$
$$\leqslant c_{28}\,g(R)^2g(m)^2[\psi(R)R^{d+\epsilon_1}]^{1/2}[Rmg(m)]^d. \tag{6.30}$$

Here we have used superstability to get the last inequality [see (3.18)]. Thus it follows from (6.22), (6.25), and (6.28)–(6.30) that

$$Q_2(t,m)\leqslant c_{29}\,(g(R)g(m))^{d/2}\,\delta_R(t,m+1)\,+c_{28}\,g(R)^2g(m)^2\,[\psi(R)R^{d+\epsilon_1}]^{1/2}[Rmg(m)]^d. \tag{6.31}$$

Therefore from (6.13), (6.15), (6.20), and (6.31) we conclude that

$$\left|\frac{d}{dt}\delta_R(t,m)\right| \le \overline{C}_1[g(R)^{cd}g(m)^{cd}+(g(R)g(m))^{d/2}]\,\delta_R(t,m+1)$$
$$+\overline{C}_2\,g(R)^2g(m)^2\,[\psi(R)R^{d+\epsilon_1}]^{1/2}\,[Rmg(m)]^d$$
$$\le C_1(g(R)^{cd}\,g(m)^{cd})\;\delta_R(t,m+1)+C_2\,m^{2d}\,[\psi(R)]^{1/2}R^{d+(2/3)\,d}, \qquad (6.32)$$

where $\overline{C}_1, C_1, \overline{C}_2$, and C_2 are positive constants.

To use the iteration method, we see that for all $0\le t\le T$, the sequence $\delta_R(t,m) := d_R(\omega_t,\overline{\omega}_t,m)$ satisfies the relation (6.1) with $L_1=C_1\,g(R)^{cd}$, $L_2=T\;C_2\,[\psi(R)]^{1/2}R^{d+(2/3)d}$, $a_m=g(m)^{cd}$, and $b_m=m^{2d}$. It is easy to check that the conditions in (6.2)–(6.3) are fulfilled. Thus by (6.4) we have

$$\delta_R(\omega_t,\overline{\omega}_t,m)\le\sum_{m=0}^{\infty}\,\delta_R(\omega_0,\overline{\omega}_0,m)\,\frac{1}{m!}(C_1\,g(R)^{cd}t)^m\;g(m)^{cdm}$$
$$+C_3\,[\psi(R)]^{1/2}R^{d+(2/3)\,d}\sum_{m=0}^{\infty}\frac{1}{m!}(C_1\;g(R)^{cd}t)^m\;g(m)^{cdm}m^{2d}, \qquad (6.33)$$

where C_3 is a positive constant. Notice that $\delta_R(\omega_0,\overline{\omega}_0,m)=0$ for all $m=0,1,\ldots$. By using Hölder's inequality with conjugate pair $p=(1+\epsilon)$ and $p'=(1/\epsilon)\,p$ with small $\epsilon>0$, we obtain

$$\delta_R(\omega_t,\overline{\omega}_t,m)\le C_3\;[\psi(R)]^{1/2}R^{d+(2/3)\,d}(\exp[(C_1t)^{1+\epsilon}g(R)^{cd(1+\epsilon)}])^{1/(1+\epsilon)}$$
$$\times\left(\sum_{m=0}^{\infty}\frac{1}{m!}[g(m)^{cdm}m^{2d}]^{p'}\right)^{1/p'}. \qquad (6.34)$$

Notice that the last term converges to a constant. We check here that when R is large, $g(R)$ is similar to $(\log R)^{1/d}$ [see (1.2)]. On the other hand, when the potential is singular at the origin, then $c>1$ [see (2.5)]. Thus the exponential term in the r.h.s. of (6.34) increases faster than any polynomial order, but slower than any exponential order as $R\to\infty$. But, since we are assuming that $|U^{(2)}(x)|\le\psi(|x|)\le\exp[-(\log|x|)^{c+\epsilon_0}]$ for some $\epsilon_0>0$ and since the function $R\to\delta_R(\omega_t,\overline{\omega}_t,m)$ is increasing as R increases, by taking ϵ such that $c(1+\epsilon)<c+\epsilon_0$ and letting R go to infinity, we conclude from (6.34) that

$$\delta_{R_0}(\omega_t,\overline{\omega}_t,0)=0, \quad \text{for all} \quad R_0\ge r+1. \qquad (6.35)$$

Since $R_0\ge r+1$ can be taken arbitrarily large, (6.35) concludes the uniqueness. □

When the potential is not singular at the origin, the proof of uniqueness under the condition of the polynomial decreasing rate follows as a simple corollary to the method given in the above.

Proof of Theorem 2.3: Since the potential $U(x)$ is everywhere two-times continuously differentiable, i.e., $U^{(1)}(x)\equiv 0$, the terms concerning to $U^{(1)}$ disappear in the proof of Theorem 2.2. For example, we may discard the terms of (6.20). Thus, observing the derivation of (6.32), we have the bound

$$\left|\frac{d}{dt}\delta_R(t,m)\right|\le C_1\,(g(R)g(m))^{d/2}\delta_R(t,m+1)+C_2[\psi(R)]^{1/2}R^{d+(2/3)\,d}m^{2d}. \qquad (6.36)$$

That is, we may replace the constant cd by $d/2$ in (6.34). Notice again that $g(R)$ is similar to $(\log R)^{1/d}$ for large values of R. Since $\exp[(C_1T)^{1+\epsilon}(\log R)^{(1+\epsilon/2)}]$ increases slower than $(1+R)^{\alpha}$ for any $\alpha>0$ as $R\to\infty$, we see that the uniqueness holds with $\psi(R)=(1+R)^{-\gamma}$, the appropriate rate used to derive the *a priori* bound. □

(Received 1 June 1998; accepted for publication 11 December 1998)

With use of the invariant imbedding method and Markov process approximation, the statistical characteristics of the backscattering field from the impulse point source in a nonstationary multidimensional random medium are considered. The equations for the characteristic function and the density of the probability in the functional space of the backscattering are obtained. The equations for the statistical moments of the field are yielded and then solutions are presented in the matrix form. The additional averaging of the fast field variations is used for the simplification of the statistical equations. The procedures for the investigation of the direct and inverse statistical problem are proposed. The role of the phenomenological transfer theory is discussed from the statistical point of view. © *1999 American Institute of Physics.* [S0022-2488(99)00809-9]

I. INTRODUCTION

The invariant imbedding method[1–3] gives a good approach for the investigation of the wave problem in the determinant media and it allows applying the Markov process approximation[3–5] for the research of the statistical wave characteristics as well.

The recently developed method[4] of the wave problem inversion in a random medium is based on the assumption that the backscattering (reflected) field is approximately a Gaussian process. The direct solutions[5–7] of the wave statistical problem in the various cases show that this assumption takes place only in the single backscattering area, therefore it is interesting to extend this method on the multiple backscattering without the hypothesis of the Gaussian field and for the general case of a medium. This widening is needed for the remote sounding of the physical media with the large scattering depth as the dense plasma, the atmosphere clouds, and the light scattering layers of the ocean.

As the example, for the typical seawater,[8] the depth of the single backscattering is 35–50 m. At the same time, the active upper ocean layer, where the main dynamic processes take place, is 100–150 m. This layer is accessible for the modern light detection and ranging (lidar) systems but not for the known data lidar processing methods. The development of these methods is an actual problem now.

The hypothesis of the Gaussian field for the multiple backscattering leads to the noncorrect transport equations describing the transient signals with the mistake for the long time area.[9,10] The better alternative instead this hypothesis for the statistical inverse problem will be discussed below.

In the current paper, the scattering in the nonstationary multidimensional random medium of the scalar wave from the point impulsive source will be considered. We shall address the results[1] obtained for a determine inverse problem by using the invariant embedding method, which allows us to develop the analogous inverse procedure for the statistical case.

Following the work,[1] the next mathematical model accepted in statistical theory will be employed. The scalar wave propagates in the layer of the inhomogeneous nonstationary medium, which occupies the part of the space $L_0 \leqslant x \leqslant L$. The wave is created by the point impulsive source on the boundary of the layer $x=L$ and is described by the equation

[a)]Electronic mail: wave@online.vladivostok.ru

$$\left[\frac{\partial^2(\mathbf{1}+\epsilon(x,\rho,t))}{\partial t^2}-c^2\Delta\right]G(x,\rho,t;L,\rho_0,t_0)=\delta(x-L)\,\delta(\rho-\rho_0)\,\delta(t-t_0), \tag{1}$$

where $\epsilon(x,\rho,t)$ is the continuous and smooth characteristic of the scattering medium in the layer $L_0 \leqslant x \leqslant L$, ρ and ρ_0 are the vectors in the plane of constant x, c is the signal velocity in the homogeneous medium outside of the layer, where $\epsilon=0$, Δ is Laplacian; the product of the Dirac δ functions is in the right part of this equation.

Equation (1) has many applications in the different areas of physics, for example, in optics, acoustics, radio science, etc. It will be assumed that $-1<\epsilon(x,\rho,t)<\mu$ and all first partial derivatives of $\epsilon(x,\rho,t)$ exist and are bounded. When the statistical model of a medium will be discussed, the smallness of the fluctuations of the nonhomogeneity characteristic ($|\epsilon(x,\rho,t)| \ll 1$) will be supposed.

The solution of the mixed (initial and boundary values) problem for Eq. (1) named the Green's function will be used. The initial value is $G=0$ for $t<t_0$. The boundary conditions are the availability of the going away waves outside of the layer only, and the continuities of G and $\partial G/\partial x$ on two planes $x=L_0$ and $x=L$, where $\epsilon(x,\rho,t)$ breaks. The solution of Eq. (1) is the generalized function[11] and, for the homogeneous medium $[\epsilon(x,\rho,t)=0]$ has the form

$$\begin{aligned} g(x-L,\rho-\rho_0,t-t_0)&=\frac{\theta(t-t_0)}{4\pi c^2(t-t_0)}\,\delta\!\left(c(t-t_0)-\sqrt{(x-L)^2+(\rho-\rho_0)^2}\right)\\ &\equiv\frac{\theta(t-t_0)}{2\pi c}\,\delta(c^2(t-t_0)^2-(x-L)^2-(\rho-\rho_0)^2), \end{aligned} \tag{2}$$

where $\theta(t-t_0)$ is the Heaviside function.

In a nonhomogeneous medium, the solution $G(x,\rho,t;L,\rho_0,t_0)$ of the above problem is described by the system of the evolution equations[1] obtained in the frames of the imbedding method with the assumption that L is a variable parameter,

$$\begin{aligned} &\left[\frac{\partial}{\partial L}+\hat{M}(\rho_0,t_0)\right]G(x,\rho,t;L,\rho_0,t_0)\\ &\quad=-\int d\rho_1\,dt_1\,G(x,\rho,t;L,\rho_1,t_1)\,\frac{\partial^2}{\partial t_1^2}\,\epsilon(L,\rho_1,t_1)G_L(\rho_1,t_1;\rho_0,t_0), \end{aligned} \tag{3}$$

with the initial condition $G(x,\rho,t;L,\rho_0,t_0)|_{L=x}=G_x(\rho,t;\rho_0,t_0)$ and

$$\begin{aligned} &\left[\frac{\partial}{\partial L}+\hat{M}(\rho,t)+\hat{M}(\rho_0,t_0)\right]G_L(\rho,t;\rho_0,t_0)\\ &\quad=\frac{1}{c^2}\,\delta(\rho-\rho_0)\,\delta(t-t_0)-\int_1 d\rho\,dt_1\,G_L(\rho,t;\rho_1,t_1)\,\frac{\partial^2}{\partial t_1^2}\,\epsilon(L,\rho_1,t_1)G_L(\rho_1,t_1;\rho_0,t_0), \end{aligned} \tag{4}$$

with the initial data $G_L(\rho,t;\rho_0,t_0)|_{L=L_0}=g_0(\rho-\rho_0,t-t_0)$, where $g_0(\rho-\rho_0,t-t_0)=g(x-L,\rho-\rho_0,t-t_0)|_{x=L}$, the integral operators $\hat{M}(\rho,t)$ and $\hat{M}(\rho_0,t_0)$ are the inversions[1] of the Neumann[2] operator in a free space and have the kernels[1]

$$M(\rho-\rho_1,t-t_1)=-\frac{2}{(t-t_1)}\,\frac{\partial}{\partial t}\,g_0(\rho-\rho_1,t-t_1) \tag{5a}$$

and

$$M^{-1}(\rho-\rho_1,t-t_1)=2c^2 g_0(\rho-\rho_1,t-t_1). \tag{5b}$$

$G_L(\rho,t;\rho_0,t_0)$ is an impotent value in the inverse problem.[1] It may be presented in the composition $G_L(\rho,t;\rho_0,t_0)=g_0(\rho-\rho_0,t-t_0)+R_L(\rho,t;\rho_0,t_0)$, where the second term in the right part is the backscattering (reflected) field. The equation for $R_L(\rho,t;\rho_0,t_0)$ may be obtained from (4) with respect to the relation[1]

$$\hat{M}(\rho,t)g_0(\rho-\rho_0,t-t_0)=(1/2c^2)\,\delta(\rho-\rho_0)\,\delta(t-t_0). \tag{6}$$

Introducing the notations $\tau=\{q,q_0\}$, and $q=\{\rho,t\}$, and $q_0=\{\rho_0,t_0\}$ we can write the equation for $R_L(\rho,t;\rho_0,t_0)$ in the form

$$\frac{\partial}{\partial L}R_L(\tau)+[\hat{M}(q)+\hat{M}(q_0)]R_L(\tau)=-\int dq_1[g_0(q,q_1)+R_L(q,q_1)]\frac{\partial^2}{\partial t_1^2}\epsilon(L,q_1)[g_0(q_1,q_0)+R_L(q_1,q_0)], \tag{7}$$

with the initial condition $R_L(\tau)|_{L=L_0}=0$.

Amongst the four terms that took place under the integral in the right part of Eq. (7), the summand g_0g_0 describes the single scattering process, two cross-items g_0R_L and R_Lg_0 are associated with the multiple forward scattering when the backscattering is single and R_LR_L corresponds to the multiple backscattering. All the enumerated above items are the components of the inverse Neumann operator[2] in the nonhomogeneous medium. The nonlinear on R_L item in Eq. (7) creates the principal difficulties in the statistical analysis and leads to the non-Gaussian reflected field and to the nonclosed transport equation. At the same time, the linear on R_L cross-items do not create the problems with the closing of the statistical expressions. They correspond to the affect of the medium nonhomogeneities on the transport of the radiation and may be considered in the group with the linear items in the left part of Eq. (7). Having in mind the relation (5b), Eq. (7) may be rewritten as

$$\begin{aligned}&\frac{\partial}{\partial L}R_L(\tau)+\Bigg\{\hat{M}^{-1}(q)\left[\frac{1}{c^2}\frac{\partial^2}{\partial t^2}\left(1+\frac{1}{2}\epsilon(L,q)\right)-\Delta_\rho\right]\\&\quad+\hat{M}^{-1}(q_0)\left[\left(1+\frac{1}{2}\epsilon(L,q_0)\right)\frac{1}{c^2}\frac{\partial^2}{\partial t_0^2}-\Delta_{\rho_0}\right]\Bigg\}R_L(\tau)\\&\quad=-\int dq_1\left[g_0(q,q_1)\frac{\partial^2}{\partial t_1^2}\epsilon(L,q_1)g_0(q_1,q_0)+R_L(q,q_1)\frac{\partial^2}{\partial t_1^2}\epsilon(L,q_1)R_L(q_1,q_0)\right].\end{aligned} \tag{8}$$

In a single backscattering area, the last item in Eq. (8) may be ignored and the generalized parabolic equation is obtained. In a small angle approximation, which gives the usual parabolic equation, which may be employed for the investigation of the radio or optic wave propagation in the turbulent atmosphere[3,12–14] with the limitation on a distance.

The roles in the statistical analysis of the enumerated above items under the integral in Eq. (7) depend from the size of the layer $L-L_0$. Two scales characterize the medium: the length of the single scattering l_s and the length of the single backscattering l_{SB}. For the anisotropic scattering medium, $l_s \ll l_{SB}$ and three scattering areas take place. Each of the enumerated above items in (7) is associated with one of these areas. The deference between forward and backward scattering is absent in the isotropic scattering medium ($l_s=l_{SB}$), and the linear and quadratic on R_L items under the integral in Eq. (7) contribute equally.

The structure of the solution singularities has to be considered for the discussion of the direct and inverse procedure. Performing the solution in the form

$$G_L(\rho,t;\rho_0,t_0)=\theta(t-t_0)\tilde{G}_L(\rho,t;\rho_0,t_0), \tag{9}$$

where $\theta(t-t_0)$ is the Heaviside function, substituting (9) in (4) and comparing the coefficients before two kinds of singularities $\theta(t-t_0)$ and $\delta(t-t_0)$ to zero, we obtain two equations:[1]

$$\frac{\partial}{\partial L}\tilde{G}_L(\rho;t;\rho_0,t_0)+\frac{1}{c}\frac{\partial}{\partial t}\tilde{G}_L(\rho,t;\rho_0,t_0)-\frac{1}{c}\frac{\partial}{\partial t_0}\tilde{G}_L(\rho,t;\rho_0,t_0)-\frac{2c}{\pi}\int_{t_0}^{t}dt_1\int d\rho_1\,\delta'(c^2(t-t_1)^2$$
$$-(\rho-\rho_1)^2)\tilde{G}_L(\rho_1,t_1;\rho_0,t_0)-\frac{2c}{\pi}\int_{t_0}^{t}dt_1\int d\rho\tilde{G}_L(\rho,t;\rho_1,t_1)\,\delta'(c^2(t_1-t_0)^2-(\rho_1-\rho_0)^2)$$
$$=h_L(\rho_0,t_0)\epsilon(L,\rho_0,t_0)\frac{\partial}{\partial t_0}\tilde{G}_L(\rho,t;\rho_0,t_0)-h_L(\rho,t)\frac{\partial}{\partial t}\epsilon(L,\rho,t)\tilde{G}_L(\rho,t;\rho_0,t_0)$$
$$+\int_{t_0}^{t}dt_1\int_1 d\rho_1\frac{\partial\tilde{G}_L(\rho,t;\rho_1,t_1)}{\partial t_1}\cdot\frac{\partial\epsilon(L,\rho_1,t_1)\tilde{G}_L(\rho_1,t_1;\rho_0,t_0)}{\partial t_1}, \tag{10}$$

where $\delta'(\cdots)$ is the derivative of the δ functions,

$$c^2\epsilon(L,\rho_0,t_0)h_L^2(\rho_0,t_0)+2c\cdot h_L(\rho_0,t_0)-1=0, \tag{11}$$

where $h_L(\rho_0,t_0)$ is the amplitude of the wave in the initial moment. This value is introduced with the use of the relationship $\tilde{G}_L(\rho,t;\rho_0,t_0)|_{t\to t_0}=h_L(\rho_0,t_0)\delta(\rho-\rho_0)$ and is determined by the characteristic of the medium in the point of the source in the initial moment through the solution of Eq. (11),

$$h_L(\rho_0,t_0)=\frac{\sqrt{1+\epsilon(L,\rho_0,t_0)}-1}{c\epsilon(L,\rho_0,t_0)}=\frac{n_L(\rho_0,t_0)-1}{c\epsilon(L,\rho_0,t_0)}, \tag{12}$$

where $n_L(\rho,t)=\sqrt{1+\epsilon(L,\rho,t)}$; it is a refractive index in electrodynamics.

In the homogeneous medium, $g_0(\rho-\rho_0,t-t_0)=\theta(t-t_0)\tilde{g}_0(\rho-\rho_0,t-t_0)$ and $\tilde{g}_0(\rho-\rho_0,t-t_0)|_{t\to t_0}=(1/2c)\delta(\rho-\rho_0)$ take off the sign ambiguity of (12).

The analogous equations for the backscattering can be obtained, if $\tilde{G}_L=\tilde{g}_0+\tilde{R}_L$ is substituted in (10) and $h_L=(1/2c)+r_L$ in (11), where $r_L(\rho_0,t_0)$ is the amplitude of the backscattering wave in the initial moment.

Equation (10) may be integrated along the characteristics,[2] which are defined for the partial differential equation, which is obtained from (10) in the first approximation on $t-t_0\to 0$,

$$\frac{\partial}{\partial L}\tilde{G}_L(\rho,t;\rho_0,t_0)+\frac{n_L(\rho,t)}{c}\frac{\partial}{\partial t}\tilde{G}_L(\rho,t;\rho_0,t_0)-\frac{n_L(\rho_0,t_0)}{c}\frac{\partial}{\partial t_0}\tilde{G}_L(\rho,t;\rho_0,t_0)$$
$$+h_L(\rho,t)\left[\frac{\partial}{\partial t}\epsilon(L,\rho,t)\right]\tilde{G}_L(\rho,t;\rho_0,t_0)\approx 0,$$

where $\tilde{G}_L(\rho,t;\rho_0,t_0)$ has the asymptotic behavior[2] for this time.

The integration process for Eq. (10) starts from $L=L_0$ and the point initial condition, which is given by the expression (12). The support of $\tilde{G}_L(\rho,t;\rho_0,t_0)$ expands, when $L-L_0$ increases. The characteristics multiply every step on L. In each point of the multiplying, the initial condition (12) is used and the definition of $\tilde{G}_L(\rho,t;\rho_0,t_0)$ for $t=t_0$ is completed through $\epsilon(L,\rho_0,t_0)$. This is a direct procedure. The inversion is obtained, if Eq. (10) is reintegrated (integrated in the inverse order) along the characteristics and $\epsilon(L,\rho_0,t_0)$ is defined through $\tilde{G}_L(\rho,t;\rho_0,t_0)$ for $t=t_0$. The inversion procedure is known as the ‘‘layer stripping’’ process.[2]

II. STATISTICAL MODEL

We suppose additionally the smallness ($|\epsilon(L,\rho,t)|\ll 1$) of the medium characteristic fluctuations, that will allow us to use the Markov apparatus[5–7] and to realize the diffusion approximation.[5–7] We assume that $\epsilon(L,\rho,t)$ is the Gaussian field with the statistical properties

$$\langle \epsilon(L,\rho,t)\rangle = 0 \quad \text{and} \quad \langle \epsilon(L,\rho,t)\epsilon(L',\rho',t')\rangle = B(L,\rho,t;L',\rho',t'). \tag{13}$$

For a characteristic functional of the backscattering $\Psi_L[\upsilon(\tau)] = \langle \exp[i\int d\tau R_L(\tau)\upsilon(\tau)]\rangle$, the equation is obtained by using (7)

$$\begin{aligned}\frac{\partial}{\partial L}\Psi_L[\upsilon(\tau)] &= \left\langle \left[i\int d\tau' \left[\frac{\partial}{\partial L}R_L(\tau')\right]\upsilon(\tau')\right]\exp\left[i\int d\tau R_L(\tau)\upsilon(\tau)\right]\right\rangle \\ &= -\int d\tau'\, \upsilon(\tau')[\hat{M}(q')+\hat{M}(q_0')]\frac{\delta}{\delta\upsilon(\tau')}\Psi_L[\upsilon(\tau)] \\ &\quad - i\int d\tau'\, \upsilon(\tau')\int dq_1\left[g_0(q',q_1)+\frac{\delta}{i\,\delta\upsilon(q',q_1)}\right] \\ &\quad \cdot \frac{\partial^2}{\partial t_1^2}\left[g_0(q_1,q_0')+\frac{\delta}{i\,\delta\upsilon(q_1,q_0')}\right]\left\langle \epsilon(L,q_1)\exp\left[i\int d\tau R_L(\tau)\upsilon(\tau)\right]\right\rangle,\end{aligned} \tag{14}$$

where the notation $\langle\cdots\rangle$ is the averaging on the realization set of the random value $\epsilon(L,q)$.

Note that the integral $\int d\tau R_L(\tau)\upsilon(\tau)$ is implied in the interval $[-\infty,\infty]$ of the variable t. We shall consider the divergent $R_L(\tau)$ and convergent $R_L^*(\tau)$ waves. The latter is found by Eq. (7) with the changes $\hat{M}(q)\to -\hat{M}(q)$ and $g_0(\tau)\to g_0^*(\tau)$, where $g_0^*(\tau)$ is the convergent wave in the free space. The convergent waves have the inversion course in time and may be placed formally on the negative semiaxis of t. The necessity of this expansion will be seen below.

In agreement with Furutsu–Novikov formula,[3,5]

$$\begin{aligned}\left\langle \epsilon(L,q_1)\exp\left[i\int d\tau R_L(\tau)\upsilon(\tau)\right]\right\rangle &= \int_{L_0}^{L}dx\int dq_2\, B(L,q_1;x,q_2)\left\langle \frac{\delta \exp[i\int d\tau R_L(\tau)\upsilon(\tau)]}{\delta\epsilon(x,q_2)}\right\rangle \\ &= \int_{L_0}^{L}dx\int dq_2\, B(L,q_1;x,q_2) \\ &\quad \times\left\langle i\int d\tau''\frac{\delta R_L(\tau'')}{\delta\epsilon(x,q_2)}\upsilon(\tau'')\exp\left[i\int d\tau R_L(\tau)\upsilon(\tau)\right]\right\rangle.\end{aligned} \tag{15}$$

Varying (7), we obtain the equation for the variational derivative,

$$\begin{aligned}\frac{\partial}{\partial L}\frac{\partial R_L(\tau'')}{\delta\epsilon(x,q_2)} &= -[\hat{M}(q'')+\hat{M}(q_0'')]\frac{\delta R_L(\tau'')}{\delta\epsilon(x,q_2)} - \int dq_3\frac{\delta R_L(q'',q_3)}{\delta\epsilon(x,q_2)}\frac{\partial^2}{\partial t_3^2}\epsilon(L,q_3)G_L(q_3,q_0'') \\ &\quad - \int dq_3\, G_L(q'',q_3)\frac{\partial^2}{\partial t_3^2}\epsilon(L,q_3)\frac{\delta R_L(q_3,q_0'')}{\delta\epsilon(x,q_2)},\end{aligned} \tag{16}$$

with the initial condition

$$\left.\frac{\delta R_L(\tau'')}{\delta\epsilon(x,q_2)}\right|_{L=x+0} = -\left[\frac{\partial^2}{\partial t_2^2}G_x(q'',q_2)\right]G_x(q_2,q_0'').$$

The comparison of Eq. (16) with (3) shows that the solution of (16) may be expressed though the solution of (3) as

$$\frac{\delta R_L(\tau'')}{\delta\epsilon(x,q_2)} = -\left[\frac{\partial^2}{\partial t_2^2} G(L,q'',x,q_2)\right] G(x,q_2;L,q_0'')$$

$$= -\hat{\Omega}_x^L(q'',\tilde{q})\left[\frac{\partial^2}{\partial t_2^2} G_x(\tilde{q},q_2)\right] G_x(q_2,\tilde{q}_0)\hat{\Omega}_x^L(\tilde{q}_0,q_0''), \tag{17}$$

where $\hat{\Omega}_x^L$ are the matriciants of the operators with the kernels, which may be defined from (16), a new value $G(L,q'';x,q_2)$ in the first line of (17) is the field on the right boundary of the layer, when the source takes place into the medium. The equation for this value may be produced like (3) by the invariant embedding method.[5] This equation differs from (3) by the operator $\hat{M}(\rho,t)$ instead of $\hat{M}(\rho_0,t_0)$. In the second of (17), the solution of (16) is presented in the symbolic operator form. The result (17) is well known for the one-dimensional problem.[5]

We see from (17) that the statistical problem is not local in general, and the closed equation for the backscattering field cannot be derived. The expression (17) demands that we consider two additional values (the field in the medium from the source on the right boundary and the field on the boundary from the source in the medium). Only for the case $B(L,q_1;x,q_2)=B(q_1;q_2)\delta(L-x)$, when $x=L$ in (17), the relation (17) yields the close equation for the backscattering. However, the δ-correlation model is not satisfactory for some real situations. The generalization of this model on the case of the nonzero correlation radius will be considered below.

If $|\epsilon(L,\rho,t)|\ll 1$, the internal field and the variational derivative vary not essentially on the size of the scatters, and we can take the solutions of Eqs. (16) and (7) in a zero approximation with respect to $\epsilon(L,q)$. Then we have for the variational derivative,

$$\frac{\delta R_L(\tau'')}{\delta\epsilon(x,q_2)} \approx -\exp\{-[\hat{M}(q'')+\hat{M}(q_0'')](L-x)\}$$

$$\cdot\left\{\frac{\partial^2}{\partial t_2^2}[g_0(q'',q_2)+\exp\{[\hat{M}(q'')+\hat{M}(q_2)](L-x)\}R_L(q'',q_2)]\right\}$$

$$\cdot[g_0(q_2,q_0'')+\exp\{[\hat{M}(q_2)+\hat{M}(q_0'')](L-x)\}R_L(q_2,q_0'')]. \tag{18}$$

This approach is associated with the perturbation theory[15] employed on the distance $L-x$ defined by the radius correlation of the medium, which is small in comparison with the size of the layer $L-L_0$. This approach is known as Chernov's local method[16] and allows us to obtain the close equation for the characteristic functional of the backscattering field,

$$\frac{\partial}{\partial L}\Psi_L[v(\tau)] = -\int d\tau'\, v(\tau')[\hat{M}(q')+\hat{M}(q_0')]\frac{\delta}{\delta v(\tau')}\Psi_L[v(\tau)]$$

$$-\int d\tau'\, v(\tau')\int dq_1\left\{\frac{\partial^2}{\partial t_1^2}\left[g_0(q',q_1)+\frac{\delta}{i\,\delta v(q',q_1)}\right]\right\}$$

$$\cdot\left[g_0(q_1,q_0')+\frac{\delta}{i\,\delta v(q_1,q_0')}\right]$$

$$\cdot\int_{L_0}^{L}dx\int dq_2\, B(L,q_1;x,q_2)\int d\tau''\, v(\tau'')\left\{\frac{\partial^2}{\partial t_2^2}\left[e^{-\hat{M}(q'')(L-x)}g_0(q'',q_2)\right.\right.$$

$$\left.\left.+e^{\hat{M}(,q_2)(L-x)}\frac{\delta}{i\,\delta v(q'',q_2)}\right]\right\}\cdot\left[e^{-\hat{M}(q_0'')(L-x)}g_0(q_2,q_0'')\right.$$

$$\left.+e^{\hat{M}(q_2,)(L-x)}\frac{\delta}{i\,\delta v(q_2,q_0'')}\right]\Psi_L[v(\tau)], \tag{19}$$

with the initial condition $\Psi_L[v(\tau)]|_{L=L_0}=1$. The operators $\hat{M}(\ ,q_2)$ and $\hat{M}(q_2,\ )$ in (19) are deferent by the action on the right and left arguments of the functions.

For the density of the probability in the backscattering functional space $P_L[\omega(\tau)]$, which is introduced here through the Fourier transformation,

$$\Psi_L[v(\tau)]=\int\ldots\int\prod_\tau d\omega(\tau)P_L[\omega(\tau)]\exp\left[i\int\tau\,\omega(\tau)v(\tau)\right], \tag{20}$$

the Fokker–Planck equation[3,5] may be obtained from (19),

$$\begin{aligned}\frac{\partial}{\partial L}P_L[\omega(\tau)]=&\int d\tau'\frac{\delta}{\delta\omega(\tau')}[\hat{M}(q')+\hat{M}(q_0')]\omega(\tau')P_L[\omega(\tau)]\\&+\int d\tau'\frac{\delta}{\delta\omega(\tau')}\int dq_1\left\{\frac{\partial^2}{\partial t_1^2}[g_0(q',q_1)+\omega(q',q_1)]\right\}\\&\cdot[g_0(q_1,q_0')+\omega(q_1,q_0')]\cdot\int_{L_0}^{L}dx\int dq_2\,B(L,q_1;x,q_2)\\&\times\int d\tau''\frac{\delta}{\delta\omega(\tau'')}\left\{\frac{\partial^2}{\partial t_2^2}[e^{-\hat{M}(q'')(L-x)}g_0(q'',q_2)+e^{\hat{M}(,q_2)(L-x)}\omega(q'',q_2)]\right\}\\&\cdot[e^{-\hat{M}(q_0'')(L-x)}g_0(q_2,q_0'')+e^{\hat{M}(q_2,)(L-x)}\omega(q_2,q_0'')]P_L[\omega(\tau)],\end{aligned} \tag{21}$$

with the obvious initial condition $P_L[\omega(\tau)]|_{L=L_0}=\Pi_\tau\delta(\omega(\tau))$.

With respect to the type of the latter equation, the considered above approach is known in statistical theory as the diffusion approximation.[5–7] The application condition of this method may be mounted, if we return to second and third lines of the expression (17), and notice that the nonaccounted for above two terms in (17) are the additional variation of the wave ''phase'' on the scatter. This variation is small in comparison with the unit that is really, if $|\epsilon(L,\rho,t)|\ll 1$.

Otherwise, Eq. (21) may be obtained from (7) through the Liouville equation[3,5] for the value $\varphi_L[\omega(\tau)]=\Pi_\tau\delta(R_L(\tau)-\omega(\tau))$. The functional $P_L[\omega(\tau)]=\langle\varphi_L[\omega(\tau)]\rangle$ will satisfy this equation after the averaging with respect to $\epsilon(L,\rho,t)$, if the approximation (18) will be used.

The statistical equation for $\tilde{R}_L(\rho,t;\rho_0,t_0)$ may be yielded by the change $\int dt'\to\int_{t_0}^{t}dt'+\int_{-t}^{t_0}dt'$ in (19) and (21) as Eqs. (4) and (10) are different only by the limits of the integral, when $|\epsilon(L,q)|\ll 1$.

III. THE STATISTICAL CHARACTERISTICS OF THE MEDIUM

Equation (21) for the value $P_L[\omega(\tau)]$ consists of 16 terms that are proportionally the correlation function of the medium. They may be collected in four groups with the deferent operator coefficients that are the Laplace transformation of the correlation function with the parameter of the transformation in the form of the operator,

$$\begin{aligned}\hat{K}_i=&\int_{L_0}^{L}dx\,B(L,q_1;x,q_2)\frac{\partial^2}{\partial t_2^2}e^{\hat{N}_i(L-x)},\quad i=1,2,3,4;\\\hat{N}_1=&-\hat{M}(q'')-\hat{M}(q_0''),\quad \hat{N}_2=-\hat{M}(q'')+\hat{M}(q_2,),\\\hat{N}_3=&\hat{M}(,q_2)-\hat{M}(q_0''),\quad \hat{N}_4=\hat{M}(,q_2)+\hat{M}(q_2,).\end{aligned} \tag{22}$$

If the Fourier transformation with respect to the difference argument q_1-q_2 is performed in (22), these four operator coefficients are the Born's expression[15] for the scattering characteristic of the medium (in first order of the perturbation theory). They are named in the suitable calibration as an indicatrix of the scattering or a phase function. The value $\hat{K}_1$ describes the scattering of the wave from the right hemisphere to back, $\hat{K}_4$—from the left hemisphere to back, $\hat{K}_2$ and $\hat{K}_3$ correspond to the wave scattering with the change of the hemisphere (from right to left and from left to right). The scattering takes place in the thin layer $L-x$, which is equal approximately to the correlation radius of the medium nonhomogeneities and is little more than $L-L_0$; therefore we can put $L_0=-\infty$ in (21) and (22). If the graphs for $g_0(q,q_0)$ and $\omega(q,q_0)$ are introduced, all 16 terms under the integral in (21) may be presented in the form of the Feynman four-tail diagram.[15]

For the isotropic medium, $\hat{K}_1=\hat{K}_4$ and $\hat{K}_2=\hat{K}_3$. For the medium with the isotropic scattering, all coefficients are equal. The medium with the point and δ correlation in time scatters has $B(L,q_1;x,q_2)=\sigma^2(L,q_1)\,\delta(L-x)\,\delta(q_1-q_2)$. For these scatters and the statistical layered medium, $\sigma^2(L,q_1)=\sigma^2(L)$, in the statistical homogeneous one, $\sigma^2(L,q_1)=\text{const}$ and so on, the classification of the media may be continued through the properties of the correlation function.

It is important for the statistical inverse problem. If $\hat{K}_1$ is defined by some way, the rest coefficients $\hat{K}_i$ may be known through the inverse and direct Laplace transformation too. For the determination of the correlation function through the statistical properties of the backscattering, Eq. (21) will be considered for the short time. The scales of the problem have to be discussed before.

The correlation function $B(L,q_1;x,q_2)$ has two sets of the scales l_x,l_y,l_z,τ and $\tilde{l}_x,\tilde{l}_y,\tilde{l}_z,\tilde{\tau}$. The first is that the set of the correlation radiuses measured the deference of the arguments $L-x$ and q_1-q_2. The second is the sizes of the variables L and q_1 (the spatial-time alterations of l_x,l_y,l_z,τ). The first set with the intensity of the medium fluctuations defines the third scale set of the problem, the lengths of the scattering l_S and l_{SB}, which is discussed above. We assume that the second scale is less than the third (the inverse case corresponds to the condition for the statistical quasihomogenous medium) and bigger than the first.

The term ''short time'' is associated with the value $t-t_0$ and the appropriate depth of the wave penetration into the medium, which are intermediate between the first and second scales of the problem. For this time, the same simplifications may be carried out in (21).

The short time corresponds to the single scattering; then the change $g_0+\omega\rightarrow g_0$ can be made in (21). The short time is less than the second scale of the problem, therefore the diffusion equation (21) has the constant coefficients in the chosen time interval. For the short time, this equation has the intermediate stationary ($\partial P_L/L\approx 0$) solution in the form of the Gaussian distribution defined by the next expression

$$\int d\tau'\frac{\delta}{\delta\omega(\tau')}[\hat{M}(q')+\hat{M}(q_0')]\omega(\tau')P_L[\omega(\tau)]+\int d\tau'\frac{\delta}{\delta\omega(\tau')}\int dq_1\left[\frac{\partial^2}{\partial t_1^2}g_0(q',q_1)\right]$$
$$\cdot[g_0(q_1,q_0')]\cdot\int_{-\infty}^{L}dx\int dq_2\,B(L,q_1;x,q_2)\int d\tau''\frac{\delta}{\delta\omega(\tau'')}\left[\frac{\partial^2}{\partial t_2^2}e^{-\hat{M}(q'')(L-x)}g_0(q'',q_2)\right]$$
$$\cdot[e^{-\hat{M}(q_0'')(L-x)}g_0(q_2,q_0'')]P_L[\omega(\tau)]\approx 0, \tag{23}$$

where the change $\int dt'\rightarrow\int_{t_0}^{t}dt'+\int_{-t}^{t_0}dt'$ is implied and the value $t-t_0$ corresponds to the short time interval.

The physical meaning of (23) may be explained. For the short time after the fast field variations, the solution of (21) takes the intermediate stationary form defined by (23).

This equation gives the locale relation between the correlation function and the statistical characteristics of the backscattering. The found relation (23) is very important for the inverse procedure in the statistical problem and plays the role of Eq. (11), which gives the point relation between the field and the medium characteristic in the determinant problem.

IV. THE ADDITIONAL AVERAGING OF THE FAST FIELD VARIATIONS

The solution of the evolution equation (21) contains the detailed statistical information that may be surplus for some cases, for example, if the average field in the point is not interested.

The more simple evolution equation for the statistical problem may be obtained from (21), if the additional averaging of the fast field variation on the first problem scale is carried out there. This operation is the passage to the slowly varying amplitude of the backscattering. It may be realized formally so.

For the simplification of the obtained above expressions, the normalized backscattering $\mathfrak{R}_L(\tau)=2c^2M(q)R_L(\tau)$ has to be introduced. This value satisfies Eq. (7) with the changes $g_0(q,q_0)\rightarrow\delta(q-q_0)$ and $\epsilon(L,q_1)\rightarrow\tilde{\epsilon}(L,q_1)=[\partial^2\epsilon(L,q_1)/\partial t_1^2]\hat{M}^{-1}(q_1)/2c^2$, where $\tilde{\epsilon}(L,q_1)$ is the effective characteristic of the medium. Presenting the normalized backscattering in the form $\mathfrak{R}_L(\tau)=\exp\{-[\hat{M}(q)+\hat{M}(q_0)](L-L_0)\}\overline{\mathfrak{R}}_L(\tau)$ and repeating the derivation of the Fokker–Planck equation, we come to the new expression instead (21),

$$\begin{aligned}\frac{\partial}{\partial L}P_L[\overline{\omega}(\tau)]=&\int d\tau'\frac{\delta}{\delta\overline{\omega}(\tau')}\int dq_1[e^{\hat{M}(q')(L-L_0)}\delta(q'-q_1)+e^{-\hat{M}(,q_1)(L-L_0)}\overline{\omega}(q',q_1)]\\&\cdot[e^{\hat{M}(q_0')(L-L_0)}\delta(q_1-q_0')+e^{-\hat{M}(q_1,)(L-L_0)}\overline{\omega}(q_1,q_0')]\\&\cdot\int_{L_0}^{L}dx\int dq_2\,\tilde{B}(L,q_1;x,q_2)\int d\tau''\frac{\delta}{\delta\overline{\omega}(\tau'')}\cdot[e^{-\hat{M}(q'')(L-x)}e^{\hat{M}(q'')(L-L_0)}\delta(q''-q_2)\\&+e^{\hat{M}(,q_2)(L-x)}e^{-\hat{M}(,q_2)(L-L_0)}\overline{\omega}(q'',q_2)]\cdot[e^{-\hat{M}(q_0'')(L-x)}e^{\hat{M}(q_0'')(L-L_0)}\delta(q_2-q_0'')\\&+e^{\hat{M}(q_2,)(L-x)}e^{-\hat{M}(q_2,)(L-L_0)}\overline{\omega}(q_2,q_0'')]P_L[\overline{\omega}(\tau)],\end{aligned}\tag{24}$$

where $\overline{\omega}(\tau)$ is the parameter of the distribution of the slowly vary normalized backscattering amplitude $\overline{\mathfrak{R}}_L(\tau)$ and $\tilde{B}(L,q_1;x,q_2)=\langle\tilde{\epsilon}(L,q_1)\tilde{\epsilon}(x,q_2)\rangle$.

Having in mind that $P_L[\overline{\omega}(\tau)]$ varies slowly on the first scale of the problem, and averaging additionally the expression (24) by the operation $(1/\Delta L)\int_L^{L+\Delta L}dL'$, where ΔL is bigger than the first problem scale, we obtain the equation

$$\begin{aligned}\frac{\partial}{\partial L}P_L[\overline{\omega}(\tau)]=&\int d\tau'\int d\tau''\int_{L_0}^{L}dx\int dq_1\int dq_2\,\hat{B}(L,q_1;x,q_2)\\&\times\frac{\delta}{\delta\overline{\omega}(\tau')}\Bigg(\frac{\overline{\omega}(q',q_1)\,\delta(q_1-q_0')}{\delta^*(q_0''-\check{q}_2)\,\delta^*(\hat{q}_2-q_0'')}+\frac{\overline{\omega}(q',q_1)\,\overline{\omega}(q_1,q_0')}{\delta^*(q_0''-\check{q}_2)\,\overline{\omega}^*(\check{q}_2,q_0'')}\\&+\frac{\delta(q'-q_1)\,\delta(q_1-q_0')}{\delta(q_0''-\hat{q}_2)\,\overline{\omega}(\hat{q}_2,q_0'')}+\frac{\delta(q'-q_1)\,\overline{\omega}(q_1,q_0')}{\delta(q_0''-\hat{q}_2)\,\delta(\check{q}_2-q_0'')}+\frac{\delta(q'-q_1)\,\overline{\omega}(q_1,q_0')}{\delta^*(q''-\hat{q}_2)\,\delta^*(\check{q}_2-q'')}\\&+\frac{\overline{\omega}(q',q_1)\,\overline{\omega}(q_1,q_0')}{\overline{\omega}^*(q'',\check{q}_2)\,\delta^*(\check{q}_2-q'')}+\frac{\delta(q'-q_1)\,\delta(q_1-q_0')}{\overline{\omega}(q'',\hat{q}_2)\,\delta(\hat{q}_2-q'')}\\&+\frac{\overline{\omega}(q',q_1)\,\delta(q_1-q_0')}{\delta(q''-\hat{q}_2)\,\delta(\check{q}_2-q'')}\Bigg)P_L[\overline{\omega}(\tau)]\\&+\int d\tau'\int d\tau''\int_{L_0}^{L}dx\int dq_1\int dq_2\,\tilde{B}(L,q_1;x,q_2)\\&\times\frac{\delta}{\delta\overline{\omega}(\tau')}\Bigg(\frac{\delta(q'-q_1)\,\delta(q_1-q_0')}{\delta^*(q''-\hat{q}_2)\,\delta^*(\hat{q}_2-q_0'')}+\frac{\delta(q'-q_1)\,\overline{\omega}(q_1,q_0')}{\delta^*(q''-\hat{q}_2)\,\overline{\omega}^*(\check{q}_2,q_0'')}\end{aligned}$$

$$+\frac{\overline{\omega}(q',q_1)\,\delta(q_1-q_0')}{\overline{\omega}^*(q'',\check{q}_2)\,\delta^*(\hat{q}_2-q_0'')}+\frac{\overline{\omega}(q',q_1)\,\overline{\omega}(q_1,q_0')}{\overline{\omega}^*(q'',\check{q}_2)\,\overline{\omega}^*(\hat{q}_2,q_0'')}+\frac{\delta(q'-q_1)\,\delta(q_1-q_0')}{\overline{\omega}(q'',\hat{q}_2)\,\overline{\omega}(\hat{q}_2,q_0'')}$$

$$+\frac{\overline{\omega}(q',q_1)\,\overline{\omega}(q_1,q_0')}{\delta(q''-\check{q}_2)\,\delta(\check{q}_2-q_0'')}+\frac{\delta(q'-q_1)\,\overline{\omega}(q_1,q_0')}{\overline{\omega}(q'',\hat{q}_2)\,\delta(\check{q}_2-q_0'')}$$

$$+\left.\frac{\overline{\omega}(q',q_1)\,\delta(q_1-q_0')}{\delta(q''-\check{q}_2)\,\overline{\omega}(\hat{q}_2,q_0'')}\right)\frac{\delta}{\delta\overline{\omega}(\tau'')}P_L[\overline{\omega}(\tau)], \tag{25}$$

where $f_1f_2/f_3f_4=f_1f_2f_3f_4$ is the compact form of the product notation, which shows the connection of (25) with (24) and the analogy of the equation coefficients with the Feynman diagrams, $f(q,\hat{q}_2)=e^{\hat{M}(,q_2)(L-x)}f(q,q_2)$ and $f(q,\check{q}_2)=e^{-\hat{M}(,q_2)(L-x)}f(q,q_2)$ are the actions of the displacement operator, f and f^* are the divergent and convergent waves.

The simplification of (25) depends from the model of the medium characteristic $\widetilde{B}(L,q_1;x,q_2)$. This function has the cofactor $\delta(\rho_1-\rho_2)$ for the layered medium and has the cofactor $\delta(t_1-t_2)$ for the time δ-correlation medium; then the some integrals in the coefficients of Eq. (25) may be calculated. The passage to the plane waves allows us to get rid of the dependence on ρ_1 and ρ_2.

For the three-dimensional medium, we have to average additionally Eq. (25) on ρ and t. The biquadratic coefficients in Eq. (25) are kept in the result (the others fall out)

$$\frac{\partial}{\partial L}P_L[\overline{\omega}(\tau)]=+\int d\tau'\int d\tau''\int_{L_0}^{L}dx\int dq_1\int dq_2\,\widetilde{B}(L,q_1;x,q_2)$$

$$\times\frac{\delta}{\delta\overline{\omega}(\tau')}\left(\frac{\delta(q'-q_1)\,\delta(q_1-q_0')}{\delta^*(q''-\hat{q}_2)\,\delta^*(\hat{q}_2-q_0'')}+\frac{\delta(q'-q_1)\,\overline{\omega}(q_1,q_0')}{\delta^*(q''-\hat{q}_2)\,\overline{\omega}^*(\check{q}_2,q_0'')}\right.$$

$$\left.+\frac{\overline{\omega}(q',q_1)\,\delta(q_1-q_0')}{\overline{\omega}^*(q'',\check{q}_2)\,\delta^*(\hat{q}_2-q_0'')}+\frac{\overline{\omega}(q',q_1)\,\overline{\omega}(q_1,q_0')}{\overline{\omega}^*(q'',\check{q}_2)\,\overline{\omega}^*(\check{q}_2,q_0'')}\right)\frac{\delta}{\delta\overline{\omega}(\tau'')}P_L[\overline{\omega}(\tau)]. \tag{26}$$

Note, for the three-dimensional medium, $q_1\approx q_2$ and $\tau'\approx\tau''$. It means that the expression in the right part of (26) is approximately diagonal and the consideration of the many-dimensional problem may be reduced to the analysis of the one-dimensional case. This fact was noticed earlier in the solution of the backscattering moment equations[14,15] (the solution of the many-dimensional problem was obtained as an analytical continuation of the one-dimensional result) and may be the base for the digital simulation of Eq. (26).

We have to remark that the passage to the layered medium in (26) is not possible, as this action is not permutable with the averaging on ρ.

V. STATISTICAL INVERSE PROBLEM

The local relation (23) allows integrating or reintegrating Eq. (21) along the characteristics of the transport operator, and how it is made for Eq. (10) with the use of (11). Equation (10) and the local relation (23) in a statistical problem play accordingly the roles of Eq. (11) and the point relation (11) in the determinant one. The direct and inverse procedures are realized the same in both cases. The difference is in the type of the evolution equations (10) and (21).

Equation (25) or (26) for the slowly varying statistical characteristic of the backscattering may be used instead of (21), if the weak effects of the fast field variations are fallen out. As the evolution equations for the direct and inverse problem investigation, the equations for the statistical moments of the backscattering field may be chosen, which will be considered below.

VI. THE MOMENT EQUATIONS

The characteristic functional of the backscattering may be decomposed in the Taylor series,

$$\Psi_L[\upsilon(\tau)]=\sum_{n=0}^{\infty}\frac{i^n}{n!}\int_{\dots}\int d\tau_1\cdots d\tau_n\, M_n(L;\tau_1,\dots,\tau_n)\upsilon(\tau_1)\cdots\upsilon(\tau_n), \tag{27}$$

with the coefficients represented through the density of the probability in the backscattering functional space as

$$M_n(L;\tau_1,\dots,\tau_n)=\left\langle \prod_{i=1}^{n} R_L(\tau_i)\right\rangle=\int_{\dots}\int \prod_{\tau} d\omega(\tau)\prod_{i=1}^{n}\omega(\tau_i)P_L[\omega(\tau)], \tag{28}$$

and named as the statistical moments of the backscattering. The equations are obtained from (21),

$$\begin{aligned}\frac{\partial}{\partial L}M_n(L;\tau_1,\dots,\tau_n)=&-\sum_{i=1}^{n}[\hat{M}(q^i)+\hat{M}(q_0^i)]M_n(L;\tau_1,\dots,\tau_n)\\&+\int_{\dots}\int\prod_{\tau} d\omega(\tau)\sum_{j=1}^{n}\int dq_1\left\{\frac{\partial^2}{\partial t_1^2}[g_0(q^j,q_1)+\omega(q^j,q_1)]\right\}\cdot[g_0(q_1,q_0^j)\\&+\omega(q_1,q_0^j)]\cdot\int_{L_0}^{L}dx\int dq_2\, B(L,q_1;x,q_2)\sum_{\substack{k=1\\k\neq j}}^{n}\left\{\frac{\partial^2}{\partial t_2^2}[e^{-\hat{M}(q^k)(L-x)}g_0(q^k,q_2)\right.\\&\left.+e^{\hat{M}(,q_2)(L-x)}\omega(q^k,q_2)]\right\}\cdot[e^{-\hat{M}(q_0^k)(L-x)}g_0(q_2,q_0^k)\\&+e^{\hat{M}(q_2,)(L-x)}\omega(q_2,q_0^k)]\frac{\Pi_{i=1}^{n}\omega(\tau_i)}{\omega(\tau_j)\omega(\tau_k)}P_L[\omega(\tau)].\end{aligned} \tag{29}$$

The expression under the integral in (29) gives 32 terms, which may be collected into five groups:

$$\begin{aligned}\frac{\partial}{\partial L}M_n(L;\tau_1,\dots,\tau_n)=&-\hat{Q}_n(\tau_1,\dots,\tau_n)M_n(L;\tau_1,\dots,\tau_n)\\&+\hat{D}_{n-2}(L;\tau_1,\dots,\tau_{n-2})M_{n-2}(L;\tau_1,\dots,\tau_{n-2})\\&+\hat{D}_{n-1}(L;\tau_1,\dots,\tau_{n-1})M_{n-1}(L;\tau_1,\dots,\tau_{n-1})\\&+\hat{D}_{n}(L;\tau_1,\dots,\tau_{n})M_{n}(L;\tau_1,\dots,\tau_{n})\\&+\hat{D}_{n+1}(L;\tau_1,\dots,\tau_{n+1})M_{n+1}(L;\tau_1,\dots,\tau_{n+1})\\&+\hat{D}_{n+2}(L;\tau_1,\dots,\tau_{n+2})M_{n+2}(L;\tau_1,\dots,\tau_{n+2}),\end{aligned} \tag{30}$$

where $\hat{Q}_n=\Sigma_{i=1}^{n}[\hat{M}(q^i)+\hat{M}(q_0^i)]$, $\hat{D}_n(L;\tau_1,\dots,\tau_n)$ is the operator coefficients, the explicit expressions of which may be yielded from (29). The initial conditions for (30) are $M_0=1$ and $M_n=0$, if $n>0$.

Eq. (30) can be rewritten in the matrix form

$$\frac{\partial}{\partial L}\mathbf{M}_L=\hat{\mathbf{A}}_L\mathbf{M}_L+\mathbf{B}_L,\quad \hat{\mathbf{A}}_L=\hat{\mathbf{Q}}+\hat{\mathbf{D}}_L,$$

$$\mathbf{M}_L=\begin{pmatrix} M_1\\ M_2\\ \cdots\\ M_n\\ \cdots \end{pmatrix},\quad \mathbf{B}_L=\begin{pmatrix} B_{1-1}\\ B_{2-2}\\ 0\\ 0\\ \cdots \end{pmatrix},\quad \hat{\mathbf{Q}}=\begin{pmatrix} \hat{Q}_1 & & \dots & 0 & \dots & & \\ 0 & \hat{Q}_2 & \dots & 0 & \dots & & \\ & & \dots & & & & \\ \dots & 0 & \dots & \hat{Q}_n & \dots & 0 & \dots \\ & & & & \dots & & \end{pmatrix},$$

$$\hat{\mathbf{D}}_L=\begin{pmatrix} \hat{D}_1 & \hat{D}_{1+1} & \hat{D}_{1+2} & \dots 0 \dots & & & \\ \hat{D}_{2-1} & \hat{D}_2 & \hat{D}_{2+1} & \hat{D}_{2+2} & \dots 0 \dots & & \\ \hat{D}_{3-2} & \hat{D}_{3-1} & \hat{D}_3 & \hat{D}_{3+1} & \hat{D}_{3+2} & \dots 0 \dots & \\ & & & \dots & & & \\ \dots 0 \dots & \hat{D}_{n-2} & \hat{D}_{n-1} & \hat{D}_n & \hat{D}_{n+1} & \hat{D}_{n+2} & \dots 0 \dots \\ & & & & \dots & & \end{pmatrix}, \tag{31}$$

where $\mathbf{B}_L$ is the vector function, $B_{1-1}=\hat{D}_{1-1}M_0$, $B_{2-2}=\hat{D}_{2-2}M_0$ are the known values expressed through the correlation function of the medium, $M_0=1$. The numeration for the elements of the five diagonal D matrix (31) is chosen as in Eqs. (30).

VII. EQUATIONS FOR THE SLOWLY EVOLVED MOMENTS

After the additional averaging of the fast field variations on L in (31), the equations for the even slowly evolved moments $\overline{M}_{2n}$ ($n=0,1,...$) are obtained. This result may be yielded from (25) as (31) was produced from (21). If the input is (31) we fall out the fast-evolved moments there. It means to put formally $\hat{\mathbf{Q}}=0$ and to delete the $n-1$ and $n+1$ diagonals of the D matrix and B_{1-1} in (31). For the many-dimensional medium, after the additional averaging of the fast field variations on ρ and t, the even coefficients of the D matrix are simplified essentially otherwise, compare (25) and (26). Equations for the slowly moments may be written as

$$\begin{aligned}\frac{\partial}{\partial L}\overline{M}_{2n}(L;\tau_2,\dots,\tau_{2n})=&\hat{D}_{2n-2}(L;\tau_1,\dots,\tau_{2n-2})\overline{M}_{2n-2}(L;\tau_1,\dots,\tau_{2n-2})\\ &+\hat{D}_{2n}(L;\tau_1,\dots,\tau_{2n})\overline{M}_{2n}(L;\tau_1,\dots,\tau_{2n})\\ &+\hat{D}_{2n+2}(L;\tau_1,\dots,\tau_{2n+2})\overline{M}_{2n+2}(L;\tau_1,\dots,\tau_{2n+2}).\end{aligned} \tag{32}$$

VIII. TRANSPORT EQUATION

The expression (32) for second moment of the backscattering is implied as the transport equation,

$$\begin{aligned}\frac{\partial}{\partial L}\overline{M}_2(L;\tau_1,\tau_2)=&B_{2-2}(L;\tau_1,\tau_2)+\hat{D}_2(L;\tau_1,\tau_2)\overline{M}_2(L;\tau_1,\tau_2)\\ &+\hat{D}_{2+2}(L;\tau_1,\dots,\tau_4)\overline{M}_4(L;\tau_1,\dots,\tau_4).\end{aligned} \tag{33}$$

The ''Gaussian hypothesis'' is the assumption that the relation between $\overline{M}_4$ and $\overline{M}_2$ is as for the Gaussian field. It is formally the noncorrect supposition about the absence of the correlation between the couples of the counterwaves, $\overline{M}_4=\langle RR^*RR^*\rangle\approx\langle RR^*\rangle\langle RR^*\rangle=\overline{M}_2\overline{M}_2$. If the approximate relation $\overline{M}_4\approx\overline{M}_2\overline{M}_2$ is put in (33), a closed equation for $\overline{M}_2$ is obtained,

$$\frac{\partial}{\partial L}\overline{M}_2(L;\tau_1,\tau_2)=B_{2-2}(L;\tau_1,\tau_2)+\hat{D}_2(L;\tau_1,\tau_2)\overline{M}_2(L;\tau_1,\tau_2)$$
$$+\hat{D}_{2+2}(L;\tau_1,\ldots,\tau_4)\overline{M}_2(L;\tau_1,\tau_2)\overline{M}_2(L;\tau_3,\tau_4), \tag{34}$$

where the operator $\hat{D}_{2+2}$ sorts out the couples of τ and sums; see (29).

Equation (34) is the statistical analog of the phenomenological transport equation[17] written for the backscattering wave. As an example, this equation was used for the layered media.[9] Its solution showed that the error of such an approach grows in comparison with the strong statistical theory as $\sqrt{t}$ in the multiple backscattering regimes, where the correlation between the couples of the counterwaves plays the essential role, and it cannot be thrown. However, Eq. (34) may be used efficiently for the single backscattering.

Note that Eq. (34) is quadratic on $\overline{M}_2$ and is formally the determinant equation (4), or (7) and (10). It mean that we can solve the statistical inverse problem as the determinant one by the use of Eq. (34) and the locale relation from (23) for the single backscattering regime.

For the further discussion of the moments, let us consider the solution for the equations.

IX. SOLUTION OF THE MOMENT EQUATIONS

The solution of (31) or (32) may be presented through a matriciant,

$$\hat{\Omega}_{L_0}^{L}=E+\int_{L_0}^{L}dL'\,\hat{\mathbf{A}}_{L'}+\int_{L_0}^{L}dL'\,\hat{\mathbf{A}}_{L'}\int_{L_0}^{L'}dL''\,\hat{\mathbf{A}}_{L''}+\cdots,$$

where E is the unit matrix, and $\hat{\mathbf{A}}_L$ is defined in (31). With the use of a Cauchy matrix $\hat{\mathbf{K}}(L,L')=\hat{\Omega}_{L_0}^{L}[\hat{\Omega}_{L_0}^{L'}]^{-1}$ and with respect to the zero initial condition for R_L, the solution of the moment equations (31) may be written as

$$\mathbf{M}_L=\int_{L_0}^{L}dL'\,\hat{\mathbf{K}}(L,L')\mathbf{B}_{L'}. \tag{35}$$

The solution of the slow moment equations (32) has the form of (35) with the simplification of $\hat{\mathbf{A}}_L$ and $\mathbf{B}_L$, as discussed above.

Every line of (35) with the component $M_n(L,\tau_1,\ldots,\tau_n)$ in the left part may be considered as the equation for the statistical characteristic of the medium $B(L,q_1;x,q_2)$, which is included in $\hat{\mathbf{A}}_L$ and $\mathbf{B}_L$. These equations are integrodifferential and nonline with respect to the unknown function $B(L,q_1;x,q_2)$. Any from them may be used for the solving of the inverse problem, for the determination of $B(L,q_1;x,q_2)$, in principal. It means that the any moment contains the full information about the random medium. And more, any moment may be expressed through any other by the use of (35), if the inverse operator to the corresponding line of the expression (35) will be yielded. The all moments are tied stringently between themselves, and this connection is defined by the properties of the medium. As an example, the connection between the slow moments for the statistic homogeneous media can be defined easy from (32) putting $\partial\overline{M}_{2n}/L=0$ (the stationary solution exists for these media) and obtaining the recurrent relation there. For the full system of the moments, it cannot be yielded since five, not three, moments are tied in (30).

We can yield the exact closed statistical transport equation expressing $\overline{M}_4$ through $\overline{M}_2$ by use of (35) and substituting it into (33). However, the relation between $\overline{M}_4$ and $\overline{M}_2$ is dependent on $B(L,q_1;x,q_2)$ in the all layers $[L_0,L]$, and the transport equation will be not local and will not be comfortable for the inverse procedure in the form of the ‘‘layer stripping’’ process[2] as in (10), (21), (25), (26), (30), and (32). The first approximation of the exact statistical transport equation is (34), which is comfortable for the ‘‘layer stripping’’ process,[2] but it is not correct for the multiple backscattering.

If the application for the lidar remote sounding is had in mind, the second line of (35) can be named as the lidar equation.[18]

As a result, if we know one of the moments, using (35) we can solve the inverse problem in principal and reconstruct the full statistic information of the backscattering (the characteristic functional). What the moment (first, second, or any more) we have to select for the solving of the inverse problem? It will be decided. In general, all the moments are not different in this meaning. The second slow moment $\langle RR^* \rangle$ can be chosen from the convenience, because it is the energy characteristic of the field and it can be measured directly, it is described in more simple equations than the full moment system.

In the nondissipative medium, which is the subject of this paper, one of the moments has to be known for the solving of the inverse problem. In the opposite case, it is not enough. Two moments and two equations (35) are necessary for the determination of the statistical and dissipative medium characteristics simultaneously. It was shown in the experimental work[19] with use of the statistical solution.[10]

X. THE FIRST MOMENT OF THE FIELD

It is of interest to consider $\langle R \rangle$ as one of the fast-varied statistical moments and to understand their role. Using (12) we can compare the first moment with the second in the initial time $t = t_0$. For $|\epsilon| \ll 1$, $r_L(\rho_0, t_0) \approx [-\epsilon(L,\rho_0,t_0) + \epsilon^2(L,\rho_0,t_0)/2]/8c$ from (12). Whence $\langle r_L \rangle \approx \langle \epsilon^2 \rangle /16c$ [the nonline form of (12) leads to the detection effect] and $\langle r_L^2 \rangle \approx \langle \epsilon^2 \rangle/(8c)^2$. The energy of the average field is less than the average energy of the field, $\langle r_L \rangle^2 \ll \langle r_L^2 \rangle$. In this sense, the fast statistical moments are associated with the weak random effects and the additional averaging of the fast variation of the field is justified.

XI. CONCLUSION

The statistical characteristics of the backscattering and the relation with the parameters of the random medium were considered above. Six ways of the inverse problem solving were shown (three with use of the full statistical characteristics system and three with the slow varied one). In every three, the inverse procedures are the ''layer stripping'' process[2] for the Fokker–Planck equation (21) or (25) and the same process for the moment equations (30) or (32) as the two equivalent approach and the inversion of the moment equations solution (35) as the alternative method.

The initial experimental data for the ''layer stripping'' process are the density of the probability in the backscattering functional space or the respective system of the statistical moments. Let us consider the case with the slow varied statistical characteristics $P_L[\overline{\omega(\tau)}]$ and $\overline{M}_{2n} = \langle \Pi_{i=1,j=1}^{n} \bar{\mathfrak{R}}_L(q_i, q_{0,i}), \bar{\mathfrak{R}}_L^*(q_j, q_{0,j}) \rangle$. It requires the measurement of the stochastic value $\bar{\mathfrak{R}}_L(q_i, q_{0,i}) \bar{\mathfrak{R}}_L^*(q_j, q_{0,j})$. The Fourier transformation of which with respect to $q_i - q_j$ and $q_{0,i} - q_{0,j}$ is the stochastic spectral transfer function from the point $(q_{0,i} + q_{0,j})/2$ to the point $(q_i + q_j)/2$, which may be measured[20] by the multiple canal analyzer. The realizations of $\bar{\mathfrak{R}}_L(q_i, q_{0,i}) \bar{\mathfrak{R}}_L^*(q_j, q_{0,j})$ are reproduced from the measured spectral data though the inverse Fourier transformation. The averaging on the set of the $\bar{\mathfrak{R}}_L(q_i, q_{0,i}) \bar{\mathfrak{R}}_L^*(q_j, q_{0,j})$ realizations gives $\overline{M}_{2n}$ and $P_L[\overline{\omega(\tau)}]$. In the result, the ''layer stripping'' process may be used.

As the alternative method, $\overline{M}_2$ is employed for the inversion of the moment equation solution (35).

Solution of a discrete inverse scattering problem and of the Cauchy problem of a class of discrete evolution equations

Henning Blohm[a)]
Fakultät für Mathematik und Informatik, Friedrich-Schiller-Universität Jena, Ernst-Abbe-Platz 1-4, D-07743 Jena, Germany

(Received 25 February 1999; accepted for publication 18 May 1999)

The Cauchy problem of a class of nonlinear evolution equations is solved by finding explicit solutions of a discrete inverse scattering problem that are not restricted to the pure soliton case and implementing appropriate time evolution of the scattering data. This yields operator-valued functions, which are shown to solve a hierarchy of operator evolution equations by applying methods similar to those in Marchenko's work. In addition the relation to canonical Lax constructions is investigated. Using methods introduced by Aden and Carl and Schiebold, one obtains scalar solutions to corresponding scalar equations, sometimes representable by determinants on operator ideals.
[S0022-2488(99)03008-X]

I. INTRODUCTION

The inverse scattering problem of the Schrödinger operator, investigated by Marchenko[1] and many others, lead to the so-called inverse scattering method for the Korteweg–de Vries equation

$$u_t = u_{xxx} + 6uu_x, \tag{1}$$

which provides a method for solving the Cauchy problem of (1). This was discovered by Gardner, *et al.*[2] in 1967. A discrete analog was developed by Flaschka[3] in 1974 and was used to solve the discrete nonlinear evolution equation

$$\partial_{tt} y_n = e^{-(y_n - y_{n-1})} - e^{-(y_{n+1} - y_n)} \quad (n \in \mathbb{Z}),$$

called the toda lattice equation.

As Flaschka did, we focus on reconstructing real sequences $a = (a_n)_{n\in\mathbb{Z}}$ and $b = (b_n)_{n\in\mathbb{Z}}$ from spectral information, the scattering data, of an operator $L \in \mathcal{L}(\ell_2(\mathbb{Z}))$ defined by

$$(Lx)_n = a_{n-1}x_{n-1} + b_n x_n + a_n x_{n+1} \quad (x \in \ell_2(\mathbb{Z}), n \in \mathbb{Z})$$

in the process of discrete inverse scattering. Here $\ell_2(\mathbb{Z})$ denotes the Hilbert space of square summable complex sequences over the integers $\mathbb{Z}$ and $\mathcal{L}(\ell_2(\mathbb{Z}))$ the space of all linear and continuous operators on $\ell_2(\mathbb{Z})$. Under the assumptions

$$a_n > 0 \quad (n \in \mathbb{Z}), \qquad \sum_{n=-\infty}^{\infty} |n|(|1-a_n^2| + |b_n|) < \infty, \tag{2}$$

we show how a and b can be represented as sequences of traces of one-dimensional operators, constructed from the scattering data, and therefore obtain an explicit solution of the described discrete inverse scattering problem. This is done in the first part of the paper.

[a)]Electronic mail: blohm@minet.uni-jena.de

The traditional way of construction of solutions of some evolution equation by solving an inverse scattering problem is to assume that the function under consideration already solves that equation and to determine the resulting time evolution of the scattering data. Equations that allow the effective application of this procedure are usually given by Lax pairs[4] or zero-curvature conditions (see, e.g., Faddeev[5] or Ablowitz[6]). Although that analysis is not carried out in this article, the method of Lax pairs was used to come up with the time evolution of the scattering data we implement in Sec. III. Employing ideas similar to those in Marchenko's book,[7] we find operator-valued functions that solve evolution equations easily accessible by an algorithm. Equivalent scalar equations are achieved by application of the trace operator defined on the finite-dimensional operators. Next we show that there is indeed a straight relation to a family of Lax pairs, as indicated above. Note that this suggests uniqueness assertions regarding the solution of the initial value problem solved, a question that is not subject to a rigorous investigation here. A short presentation of possible representations by determinants on operator ideals follows.

Finally, we demonstrate the solution of the Cauchy problem of the Toda lattice equation and the Langmuir lattice equation.

The method of representation of solutions of soliton equations by traces and determinants on operator ideals was introduced by Aden and Carl[8] and Schiebold.[9,10]

II. DISCRETE INVERSE SCATTERING

Our aim here is to derive a discrete version of the so-called Gelfand–Levitan–Marchenko equation found in the literature.

A. Derivation of the fundamental equation

There are many papers on discrete scattering. For a technically more detailed but somewhat different discussion we refer to Geronimo and Case.[11]

Under the hypothesis (2), L has essential spectrum

$$\sigma_e(L)=[-2,2]$$

and discrete spectrum in $\mathbb{R}\backslash[-2,2]$. This can be proved by observing that L is the sum of a right and left shift operator and an additional compact self-adjoint operator and by consulting, for example, Berthier.[12] We consider the linear differences equation

$$\lambda\varphi_n=a_{n-1}\varphi_{n-1}+b_n\varphi_n+a_n\varphi_{n+1}\quad(n\in\mathbb{Z}),\tag{3}$$

where $\lambda\in\mathbb{C}$ is fixed. Asymptotically (3) becomes

$$\lambda\varphi_n=\varphi_{n-1}+\varphi_{n+1}\quad(n\in\mathbb{Z}).\tag{4}$$

If $\lambda\neq0$, a fundamental system of solutions of (4) is given by $(z^n)_{n\in\mathbb{Z}}$ and $(z^{-n})_{n\in\mathbb{Z}}$ where $\lambda=z+z^{-1}$. Solutions of (3) that behave asymptotically similarly, the so-called Jost solutions, are of special interest to us. These can be obtained by solving the following linear summation equation:

$$\frac{1}{\beta_n}\Phi_n=z^n-\sum_{k=n}^{\infty}(1-a_k^2)\left(\frac{z^{n-k-1}-z^{-(n-k-1)}}{z-z^{-1}}\right)\frac{1}{\beta_k}\Phi_k+\sum_{k=n}^{\infty}b_k\left(\frac{z^{n-k}-z^{-(n-k)}}{z-z^{-1}}\right)\frac{1}{\beta_k}\Phi_k$$

using the method of successive approximation. Here we set $\beta_n:=\Pi_{j=n}^{\infty}a_j$ and assumed $z\in\overline{U}$, $U:=\{x\in\mathbb{C}\,|\,|z|<1\}$. This gives solutions

$$\Phi_n^+(z)=\sum_{m=n}^{\infty}k(n,m)z^m\quad(n\in\mathbb{Z})$$

of (3) for $\lambda := z + z^{-1}$ such that the series converges absolutely and $\lim_{n\to\infty} z^{-n}\Phi_n^+(z) = 1$ uniformly on $\overline{U}$. Similarly, or simply by a transformation of coordinates, we get another family of solutions

$$\Psi_n^-(z) = \sum_{m=-n}^{\infty} \ell(n,m) z^m \quad (n \in \mathbb{Z})$$

such that the series converges absolutely and $\lim_{n\to-\infty} z^n \Psi_n^-(z) = 1$ uniformly on $\overline{U}$.

Substituting the Jost solutions into (3), using our hypotheses (2), and comparing coefficients we get:

$$a_n = \frac{k(n+1,n+1)}{k(n,m)}, \quad k(n,n) = \prod_{j=n}^{\infty} \frac{1}{a_j} \neq 0,$$
$$b_n = \frac{k(n,n+1)}{k(n,n)} - \frac{k(n-1,n)}{k(n-1,n-1)} \, (n \in \mathbb{Z}). \tag{5}$$

In the particular case where $|z| = 1$, $z \neq \pm 1$ we define another set of solutions of (3) by

$$\Phi_n^-(z) = \Phi_n^+(z^{-1}) \quad (n \in \mathbb{Z}), \quad \Psi_n^+(z) = \Psi_n^-(z^{-1}) \quad (n \in \mathbb{Z}).$$

From the linear independence of $\Phi^+(z)$ and $\Phi^-(z)$ we infer the existence of coefficients $\alpha(z)$ and $\beta(z)$ such that

$$\Psi_n^-(z) = \beta(z)\Phi_n^+(z) + \alpha(z)\Phi_n^-(z) \quad (n \in \mathbb{Z}). \tag{6}$$

We call $r(z) := \beta(z)/\alpha(z)$ the reflection coefficient. By substitution of (6) into (3) and some computation, it is not hard to see that

$$\overline{\alpha(z)} = \alpha(\overline{z}), \quad \overline{\beta(z)} = \beta(\overline{z}), \quad \overline{r(z)} = r(\overline{z}), \tag{7}$$

and

$$|\alpha(z)|^2 - |\beta(z)|^2 = 1,$$

in particular

$$|r(z)|^2 = 1 - 1/|\alpha(z)|^2 < 1 \tag{8}$$

for all $|z| = 1$, $z \neq \pm 1$. Furthermore, α has the analytical continuation

$$\alpha(z) := \frac{z a_n (\Psi_n^-(z)\Phi_{n+1}^+(z) - \Psi_{n+1}^-(z)\Phi_n^+(z))}{z^2 - 1}$$

onto the open unit disk U. The zeros of α in U are simple and correspond via $\lambda = z + z^{-1}$ to the discrete eigenvalues of L. More precisely, if $\alpha(z) = 0$, then $\Phi^+(z)$ and $\Psi^-(z)$ are linearly dependent eigenvectors of L, and

$$\alpha'(z) = -\rho(z)/z \|\Phi^+(z)\|_2^2, \tag{9}$$

where $\Psi^-(z) = \rho(z)\Phi^+(z)$.

A nontrivial fact is that α has at most finitely many zeros in U. This can be seen by splitting L into two operators, one acting on $\ell_2(\{\dots,-2,-1\})$ and one acting on $\ell_2(\{0,1,2,...\})$. For either one we apply the results of Geronimo and Case and in turn, using the very same techniques, show that L can have only finitely many eigenvalues of magnitude greater than 2.

Let $z_1,\ldots,z_N$ denote the zeros of α in U, $\gamma_i := \|\Phi^+(z_i)\|_2^{-2}$ $(i=1,...,N)$. Integrating the expression $\Psi_n^-(z)z^{m-1}\alpha(z)^{-1}$ along the boundary of a ball of radius $0<\epsilon<1$ and applying the residue theorem to one side, using (9), while considering the limit as ϵ tends to one and using (6) on the other side, yields the following discrete version of the famous Gelfand–Levitan–Marchenko equation:

$$\frac{\delta_{nm}}{k(n,n)} = k(n,m) + \sum_{j=n}^{\infty} k(n,j) f(m+j) \quad (m \geqslant n \in \mathbb{Z}), \tag{10}$$

where

$$f(m) = \sum_{i=1}^{N} z_i^m \gamma_i + \frac{1}{2\pi i} \int_{\partial U} r(z) z^{m-1}\, dz \quad (m \in \mathbb{Z})$$

and δ is the Kronecker–Delta function. The numbers $z_1,\ldots,z_N$ together with the normalization constants $\gamma_1,\ldots,\gamma_N$ and the reflection coefficient r are called the scattering data. By setting $\kappa(n,m) := k(n,m)/k(n,n)$ for $m>n$, Eq. (10) can be reformulated as

$$0 = \kappa(n,m) + f(m+n) + \sum_{j=n+1}^{\infty} \kappa(n,j) f(m+j) \quad (m>n \in \mathbb{Z}). \tag{11}$$

We will focus on solving Eq. (11), that is, as we will see, uniquely solvable. Once we found κ, one can use

$$k(n,n)^{-2} = 1 + f(2n) + \sum_{j=n+1}^{\infty} \kappa(n,j) f(n+j)$$

to compute $k(n,n)$. By the definition of κ, all other values $k(n,m)$ for $m>n$ are accessible, and via (5) the values of a and b are thereby determined by κ. Finally, we state a consequence of (11) proved by Geronimo and Case:[11]

$$\sum_{m=0}^{\infty} |f(m)| < \infty$$

and in particular

$$\sum_{m=0}^{\infty} \left| \int_{\partial U} r(z) z^{m-1} dz \right| < \infty. \tag{12}$$

B. Solution of the inverse scattering problem

The following theorem shows how to solve Eq. (11) abstractly, using the trace operator tr, defined on the operator ideal of finite-dimensional operators.[13] We write $(\cdot|\cdot)$ for the inner product on a Hilbert space and $h \otimes g$ for the one-dimensional operator on a vector space V, defined for a linear functional h on V and an element g of V by

$$h \otimes g x := h(x) g \quad (x \in V).$$

An important property of the trace operator, that is used here and in later sections, is that it is multiplicative on operators of the form $T(h \otimes g)$, that is,

$$\mathrm{tr}(T(h\otimes g) S(h\otimes g)) = \mathrm{tr}(T(h\otimes g))\,\mathrm{tr}(S(h\otimes g))$$

for any two linear operators S and T on V. If H is a Hilbert space, its dual will be canonically identified with the space itself. By e_n we denote the vector of $\ell_2(\mathbb{Z})$ that has nth coordinate one and zero otherwise.

Theorem II.B.1: Let H be a Hilbert space, $V\in\mathcal{L}(H)$, $h,g\in H$, and let $B\in\mathcal{L}(H)$ be such that

$$(Bx|y)=-\sum_{k=0}^{\infty}(V^kx|h)(V^kg|y)\quad\text{for all}\quad x,y\in H.$$

Then:

(i) $VBV-B=h\otimes g$.

(ii) Assuming that V and $(1+V^{2n}B)$ are invertible for every $n\in\mathbb{Z}$ and setting

$$K(n,m):=V^{m-n}(1+V^{2n+1}BV)^{-1}V^{2n}(h\otimes g),\quad F(m):=-V^m(h\otimes g)\quad(n,m\in\mathbb{Z}),$$

it is

$$0=\mathrm{tr}(K(n,m))+\mathrm{tr}(F(m+n))+\sum_{j=n+1}^{\infty}\mathrm{tr}(F(m+j))\mathrm{tr}(K(n,j))\quad(n,m\in\mathbb{Z},m\geqslant n).$$

(iii) Under the hypotheses of *(ii)*, $\kappa(n,m):=\mathrm{tr}(K(n,m))$ $(n,m\in\mathbb{Z},m>n)$ defines a solution of Eq. (11) with kernel $f(m):=\mathrm{tr}(F(m))$ $(m\in\mathbb{Z})$.

Proof: For arbitrary $x,y\in H$ it is

$$(VBVx-Bx|y)=(VBVx|y)-(Bx|y)=-\sum_{k=0}^{\infty}(V^{k+1}x|h)(V^{k+1}g|y)-(Bx|y)$$
$$=(x|h)(g|y)=(h\otimes gx|y),$$

which implies (i). We set $L_n:=V^{2n}B$ and $W(n):=(1+VL_nV)^{-1}V^{2n}(h\otimes g)$ and compute

$$\sum_{j=n}^{\infty}\mathrm{tr}(F(m+j))\mathrm{tr}(K(n,j))=-\sum_{j=n}^{\infty}(V^{m+j}g|h)(V^{j-n}(1+VL_nV)^{-1}V^{2n}g|h)$$
$$=-\sum_{j=0}^{\infty}(V^j(1+VL_nV)^{-1}V^{2n}g|h)(V^{m+n+j}g|h)$$
$$=(V^{m+n}B(1+VL_nV)^{-1}V^{2n}g|h)=\mathrm{tr}(V^{m+n}BW(n))$$

and

$$F(m+n)+K(n,m)-F(m+n)K(n,n)+V^{m+n}BW(n)$$
$$=-V^{m+n}(h\otimes g)+V^{m-n}W(n)+V^{m+n}(h\otimes g)W(n)+V^{m+n}BW(n)$$
$$=-V^{m+n}(h\otimes g)+V^{m-n}(1+V^{2n}(h\otimes g)+V^{2n}B)W(n)$$
$$=-V^{m+n}(h\otimes g)+V^{m-n}(1+V^{2n+1}BV)W(n)=0.$$

Now, application of the trace operator to the last equation gives (ii), and statement (iii) is an immediate consequence of it. □

The theorem just proved suggests the following model for the solution of Eq. (11): We choose $H_1:=\ell_2^N$, $H_2:=L_2(T)$, $H:=H_1\oplus^2H_2$, where $T:=\partial U$ is the complex unit sphere equipped with the normalized Haar-measure μ. In addition let

(1) $V_1\in\mathcal{L}(H_1)$ such that $(V_1x)_i:=z_ix_i(x\in\ell_2^N)$;
(2) $V_2\in\mathcal{L}(H_2)$ multiplication with the identical mapping on T;

(3) $h_1, g_1 \in H_1$ such that $-\overline{h_1} g_1 = \gamma = (\gamma_1, \ldots, \gamma_N)$;
(4) $h_2, g_2 \in H_2 \cap L_\infty(T)$ such that $-\overline{h_2} g_2 = r$.

After setting $V := V_1 \oplus V_2$, $g := g_1 \oplus g_2$, $h := h_1 \oplus h_2$, we observe:

$$\begin{aligned}\operatorname{tr}(V^m(h \otimes g)) = (V^m g|h) = (V_1^m g_1|h_1) + (V_2^m g_2|h_2) \\ &= -\sum_{i=1}^{N} z_i^m \gamma_i - \int_T r(z) z^m \, d\mu(z) \\ &= -\left(\sum_{i=1}^{N} z_i^m \gamma_i + \frac{1}{2\pi i} \int_{\partial U} r(z) z^{m-1} \, dz \right) = -f(m).\end{aligned}$$

Consequently, we are going to show:

(1) The operator equation $VBV - B = h \otimes g$ can be solved as desired for Theorem II.B.1.
(2) The operator $1 + V^{2n} B$ is invertible for every $n \in \mathbb{Z}$.

We proceed with the solution of the first problem:

Lemma II.B.2: Suppose that $g, h \in L_2(T) \cap L_\infty(T)$ and that $V \in \mathcal{L}(L_2(T))$ is the multiplication with the identical mapping on T. Then there is exactly one operator $B \in \mathcal{L}(L_2(T))$ such that

$$(Bx|y) = -\sum_{k=0}^{\infty} (V^k x|h)(V^k g|y) \quad \text{for every } x, y \in L_2(T).$$

It follows that $\|B\| \leqslant \|g|L_\infty(T)\| \|h|L_\infty(T)\|$, and that B factors through $\ell_2(\mathbb{N}_0)$, $B = SR$ where $S \in \mathcal{L}(\ell_2(\mathbb{N}_0), L_2(T))$ is such that

$$(Sx|y) = -\sum_{n=0}^{\infty} (x|e_n)(V^n g|y) \quad \text{for every } x \in \ell_2(\mathbb{N}_0), y \in L_2(T)$$

and $\|S\| \leqslant \|g|L_\infty(T)\|$, as well as $R \in \mathcal{L}(L_2(T), \ell_2(\mathbb{N}_0))$ is such that

$$(Rx|y) = \sum_{k=0}^{\infty} (V^k x|h)(y|e_k) \quad \text{for every } x \in L_2(T), y \in \ell_2(\mathbb{N}_0)$$

and $\|R\| \leqslant \|h|L_\infty(T)\|$.

Proof: Since

$$\begin{aligned}\sum_{k=0}^{\infty} |(V^k x|h)(V^k g|y)| = \sum_{k=0}^{\infty} \left| \int_T (x\overline{h}) z^k \, d\mu(z) \right| \left| \int_T (g\overline{y}) z^k \, d\mu(z) \right| \\ \leqslant \|x\overline{h}|L_2(T)\| \|g\overline{y}|L_2(T)\| \leqslant \|x\| \|h|L_\infty(T)\| \|g|L_\infty(T)\| \|y\|\end{aligned}$$

for arbitrary $x, y \in L_2(T)$,

$$[x|y] := -\sum_{k=0}^{\infty} (V^k x|h)(V^k g|y)$$

defines a continuous sesquilinear form on $L_2(T)$. We conclude that for each $y \in L_2(T)$ there exists exactly one $Ay \in L_2(T)$ satisfying

$$[\cdot|y] = (\cdot|Ay). \tag{13}$$

Obviously $\|Ay\| \leqslant \|g|L_\infty(T)\|\|h|L_\infty(T)\|\|y\|$. Hence $B=A^*$ is the right choice. It is clear that B is uniquely determined through A by (13). Similarly S and R are given by their required properties. Finally, since

$$(SRx|y) = -\sum_{n=0}^{\infty} (Rx|e_n)(V^n g|y) = -\sum_{n=0}^{\infty} (V^n x|h)(V^n g|y)$$

for all $x,y \in L_2(T)$, $B=SR$. □

It is easier to solve the corresponding operator equation over $H_1 = \ell_2^N$ for V_1. Because of $\|V_1\| < 1$, we can simply choose

$$B_1 := -\sum_{n=0}^{\infty} V_1^n (h_1 \otimes g_1) V_1^n.$$

In this case we have an analogous factorization through $\ell_2(\mathbb{N}_0)$ by

$$S_1 := -\sum_{n=0}^{\infty} e_n \otimes (V_1^n g_1), \quad R_1 := \sum_{k=0}^{\infty} ((V_1^*)^k h_1) \otimes e_k .$$

The operators received from the application of Lemma II.B.2 to V_2, g_2, h_2 will be denoted by B_2, S_2, R_2 from now on. We define

$$K_1 := R_1 S_1, \quad K_2 := R_2 S_2$$

and write $I_i : H_i \hookrightarrow H$ and $P_i : H \to H_i$ for the canonical inclusion and projection operators, respectively. Let

$$R := R_1 P_1 + R_2 P_2 \in \mathcal{L}(H, \ell_2(\mathbb{N}_0)), \quad S := I_1 S_1 + I_2 S_2 \in \mathcal{L}(\ell_2(\mathbb{N}_0), H),$$

$$K := K_1 + K_2 \in \mathcal{L}(\ell_2(\mathbb{N}_0)), \quad B := SR \in \mathcal{L}(H).$$

It is easily checked that $K = RS$. For arbitrary $x = x_1 \oplus x_2 \in H$ and $y = y_1 \oplus y_2 \in H$ we compute

$$\begin{aligned}
(Bx|y) &= (I_1 S_1 R_1 x_1 + I_1 S_1 R_2 x_2 + I_2 S_2 R_1 x_1 + I_2 S_2 R_2 x_2 | y) \\
&= (S_1 R_1 x_1 | y_1) + (S_1 R_2 x_2 | y_1) + (S_2 R_1 x_1 | y_2) + (S_2 R_2 x_2 | y_2) \\
&= -\sum_{n=0}^{\infty} ((V_1^n x_1 | h_1)(V_1^n g_1 | y_1) + (V_2^n x_2 | h_2)(V_1^n g_1 | y_1) \\
&\quad + (V_1^n x_1 | h_1)(V_2^n g_2 | y_2) + (V_2^n x_2 | h_2)(V_2^n g_2 | y_2)) \\
&= -\sum_{n=0}^{\infty} (V^n x | h)(V^n g | y).
\end{aligned}$$

Thus B is the solution of the operator equation sought for.

Next we take care of the existence of the inverse operators. A by-product is the unique solvability of Eq. (11): Set $K^{(n)} := R V^{2n} S$. An easy computation shows that

$$(K^{(n+1)} x)_k = \sum_{j=0}^{\infty} f(2n+k+j+2) x_j ,$$

where $f(m) = -\mathrm{tr}(V^m (h \otimes g))$. Hence solving Eq. (11) is equivalent to solving

$$(1 + K^{(n+1)}) \kappa(n, n+1+\cdot) = -f(2n+1+\cdot)$$

for every $n\in\mathbb{Z}$. As we will see soon, $1+K^{(n)}$ is invertible and therefore (11) possesses at most one solution κ. The following lemma collects important properties of the operators $K^{(n)}$. Similar statements can be found in other settings in scattering theory.

Lemma II.B.3: Assuming the situation of our model, it is $\|K^{(n)}\|\leqslant\Sigma_{j=0}^{\infty}|f(2n+j)|$, $K^{(n)}$ is compact, and $-1\notin\sigma(K^{(n)})$ for every $n\in\mathbb{Z}$.

Proof: Let $N\in\mathbb{N}_0$ and $x\in\ell_2(\mathbb{N}_0)$, $\|x\|\leqslant 1$. It is

$$\left(\sum_{k=N}^{\infty}\left|\sum_{j=0}^{\infty}f(2n+k+j)x_j\right|^2\right)^{1/2}=\left(\sum_{k=N}^{\infty}\left|\sum_{j=k}^{\infty}f(2n+j)x_{j-k}\right|^2\right)^{1/2}$$
$$\leqslant\sum_{j=N}^{\infty}\left(\sum_{k=N}^{j}|f(2n+j)x_{j-k}|^2\right)^{1/2}$$
$$\leqslant\sum_{j=N}^{\infty}|f(2n+j)|.$$

Choosing $N=0$ gives the norm estimate. In addition we showed that for any $\epsilon>0$ there exists an $N\geqslant 0$ such that

$$\left(\sum_{j=N}^{\infty}|y_j|^2\right)^{1/2}<\epsilon$$

uniformly for all $y=K^{(n)}x$, $x\in\ell_2(\mathbb{N}_0)$, $\|x\|\leqslant 1$. We infer that $K^{(n)}$ is compact. Define

$$K_1^{(n)}:=R_1V_1^{2n}S_1,\quad K_2^{(n)}:=R_2V_2^{2n}S_2.$$

Then $K^{(n)}=K_1^{(n)}+K_2^{(n)}$, and for arbitrary $i,j\in\mathbb{N}_0$ we have

$$(K_1^{(n)}e_j|e_i)=(R_1V_1^{2n}S_1e_j|e_i)=(V_1^{2n+i}S_1e_j|h_1)=-(V_1^{2n+i+j}g_1|h_1).$$

If $x\in\ell_2(\mathbb{N}_0)$, this implies

$$(K_1^{(n)}x|x)=-\sum_{k=0}^{\infty}\sum_{j=0}^{\infty}x_j(V_1^{n+j}g_1|(V_1^*)^{n+k}h_1)\overline{x_k}=-\sum_{i=1}^{N}g_{1,i}\overline{h_{1,i}}\left|\sum_{k=0}^{\infty}x_kz_i^{k+n}\right|^2\geqslant 0,$$

and therefore $K_1^{(n)}$ is a positive operator. Let us turn to the second operator: Since

$$(K_2^{(n)}e_j|e_i)=\cdots=-(V_2^{2n+j+i}g_2|h_2)=\int_T r(z)z^{2n+i+j}\,d\mu(z),$$

we see for arbitrary $x\in\ell_2(\mathbb{N}_0)$ that

$$(K_2^{(n)}x|x)=\sum_{k=0}^{\infty}\sum_{j=0}^{\infty}\int_T r(z)z^{2n+i+j}x_j\overline{x_k}\,d\mu(z)=\int_T r(z)q(z)\overline{p(z)}d\mu(z)$$

where $q(z)=\Sigma_{j=0}^{\infty}x_jz^{n+j}$, $p(z)=\Sigma_{k=0}^{\infty}x_kz^{-(n+k)}$ [in $L_2(T)$]. Thus:

$$|(K_2^{(n)}x|x)|\leqslant\|rp|L_2(T)\|\|q|L_2(T)\|\leqslant\|p|L_2(T)\|\|q|L_2(T)\|=\|x\|^2,$$

because $|r|\leqslant 1$ almost everywhere. Assuming $\|rp|L_2(T)\|=\|p|L_2(T)\|$ leads to

$$\int_T(1-|r(z)|^2)|p(z)|^2\,d\mu(z)=0,$$

which, taking Eq. (8) into account, implies that p vanishes μ almost everywhere and thus that $x=0$. Hence we have shown:

$$x\neq 0 \Rightarrow |(K_2^{(n)}x|x)|<\|x\|^2.$$

Now it is easy to see that $1+K^{(n)}$ is one-to-one. Indeed, if $x\neq 0$, we know that

$$((1+K^{(n)})x|x)=\|x\|^2+(K_1^{(n)}x|x)+(K_2^{(n)}x|x)>0,$$

and in particular it follows that $(1+K^{(n)})x\neq 0$. Now, as shown in Riesz theory of functional analysis, the fact that $K^{(n)}$ is compact implies that $1+K^{(n)}$ is invertible. □

Lemma II.B.4: In the situation of our model, the operators $1+V^nB$ are invertible for every $n\in\mathbb{Z}$ and

$$\lim_{n\to\infty}((1+V^nB)^{-1}-(1-V^nB))=0.$$

Proof: This is implied by the next lemma. □

Lemma II.B.5: Suppose $R\in\mathcal{L}(E,F)$ and $S\in\mathcal{L}(F,E)$ where E and F are Banach spaces. Then:

(i) $1+RS$ is invertible if and only if $1+SR$ is invertible, and in that case: $(1+RS)^{-1}=1-R(1+SR)^{-1}S$.

(ii) $\rho(SR)\backslash\{0\}=\rho(RS)\backslash\{0\}$, $\sigma(SR)\backslash\{0\}=\sigma(RS)\backslash\{0\}$.

Proof: Assertion *(i)* is easily proved using the stated formula, and *(ii)* is a simple consequence of it. □

Now we have essentially solved our discrete inverse scattering problem and close this section with a main result:

Theorem II.B.6: In the situation of our model the following assertions are true:

(i) Equation (11) possesses exactly one solution $\kappa(n,n+\cdot)$ in $\ell_2(\mathbb{N}_0)$ for each $n\in\mathbb{Z}$.

(ii) The operators $1+V^{2n}B$ and $1+V^{2n+1}BV$ are invertible for every $n\in\mathbb{Z}$.

(iii) $\kappa(n,m):=\mathrm{tr}(V^{m-n}(1+V^{2n+1}BV)^{-1}V^{2n}(h\otimes g))(m>n)$ gives the solution of Eq. (11) with kernel

$$f(m)=-\mathrm{tr}(V^m(h\otimes g))=\sum_{i=1}^{N} z_i^m\gamma_i+\frac{1}{2\pi i}\int_{\partial U} r(z)z^{m-1}\,dz \quad (m\in\mathbb{Z}).$$

(iv) Let $Q_n:=(1+V^{2n}B)^{-1}V^{2n}(h\otimes g)$, $q_n:=\mathrm{tr}(Q_n)$, and let k denote the function of the coefficients of the Jost solution Φ^+. Then:

$$0<k(n,n)=\prod_{j=n}^{\infty}\frac{1}{a_j}=\sqrt{1+q_n} \quad (n\in\mathbb{Z})$$

and $k(n,m)=\sqrt{1+q_n}\,\kappa(n,m)(m>n)$.

(v) For every $n\in\mathbb{Z}$:

$$a_n=\left(\frac{1+q_{n+1}}{1+q_n}\right)^{1/2}=\frac{k(n+1,n+1)}{k(n,n)}$$

and

$$b_n=\frac{k(n,n+1)}{k(n,n)}-\frac{k(n-1,n)}{k(n-1,n-1)}=\kappa(n,n+1)-\kappa(n-1,n)$$
$$=\mathrm{tr}(V(1+Q_n)^{-1}Q_n-V(1+Q_{n-1})^{-1}Q_{n-1}).$$

Proof: Almost everything has been proved before. Only assertion *(iv)* still calls for some consideration: Using the techniques of the proof of Theorem II.B.1, we see that

$$\begin{aligned}\frac{1}{k(n,n)^2} &= 1+f(2n)+\sum_{j=n+1}^{\infty}\kappa(n,j)f(n+j)\\ &= 1-\kappa(n,n)\\ &= 1-\mathrm{tr}((1+V^{2n+1}BV)^{-1}V^{2n}(h\otimes g))\\ &= 1-\mathrm{tr}((1+Q_n)^{-1}Q_n)\\ &= 1-\frac{q_n}{1+q_n}=\frac{1}{1+q_n}.\end{aligned}$$

We know that $k(n,n)>0$, and by the last computation, it is $1+q_n>0$. Hence:

$$k(n,n)=\sqrt{1+q_n}. \qquad \square$$

III. SOLUTION OF EVOLUTION EQUATIONS

In this section we implement a certain time development of the scattering data and show what evolution equation can be solved by the resulting functions a and b. From now on we will always use the constructions and notations of our model. For real numbers $\sigma_1,\ldots,\sigma_M$ set

$$A:=\sum_{k=1}^{M}\sigma_k(V^k-V^{-k}),\quad g(t):=e^{tA}g\quad (t\in\mathbb{R}). \tag{14}$$

We assume that g was given by initial values a and b that satisfy (2). All operators and functions, defined using g before, will from now on be defined for all $t\in\mathbb{R}$ by substitution of $g(t)$ for g. Consequently they will depend on an additional parameter t. The next Lemma shows that everything works out well. Note that, in the words of scattering theory, (14) just means that the discrete eigenvalues of L stay constant in time, while the reflection coefficient and the normalization constants γ_i have exponential time evolution.

Lemma III.1: For arbitrary $t\in\mathbb{R}$ the following statements are true:
(i) $B(t)=e^{tA}B(0)$;
(ii) $\forall n\in\mathbb{Z}$: $-1\notin\sigma(V^{2n}B(t))\cup\sigma(V^{2n+1}B(t)V)\cup\sigma(K^{(n)}(t))\cup\sigma(Q_n(t))$;
(iii) $\forall n\in\mathbb{Z}$: $\kappa(n,n+\cdot,t)\in\ell_2(\mathbb{N}_0)$;
(iv) $\forall m\in\mathbb{Z}$: $f(m,t):=\mathrm{tr}(F(m,t))\in\mathbb{R}$;
(iv) $\forall n\in\mathbb{Z}$: $1+q_n(t)>0$.
Proof: Let $x,y\in H$. Since

$$(e^{tA}Bx|y)=-\sum_{n=0}^{\infty}(V^nx|h)(V^ng|e^{tA^*}y)=-\sum_{n=0}^{\infty}(V^nx|h)(V^ne^{tA}g|y),$$

the uniqueness assertion of Lemma II.B.2 implies that $B(t)=e^{tA}B$. In order to prove *(ii)*, we return our attention to the proof of Lemma II.B.3: It is necessary that the negative Fourier coefficients of $\overline{h_2}g_2(t)$ are absolutely summable. This will be shown in the following Lemma III.2. Furthermore,

$$g_2(t)(z)=\exp\left(t2\sum_{k=1}^{M}\sigma_k(z^k-\overline{z}^k)\right)g_2(z)=\exp\left(t4i\sum_{k=1}^{M}\sigma_k\mathfrak{J}z^k\right)g_2(z)\quad (z\in T),$$

and so $|\overline{h_2}g_2(t)|$ is constant in t. From

$$g_1(t)_n = \exp\left(t2\sum_{k=1}^{M}\sigma_k(z_n^k - z_k^{-k})\right)g_{1,n} \quad (n=1,...,N),$$

we conclude that $\overline{h_1}g_1(t)$ has constant sign. These properties allow us to infer the assertions of Lemma II.B.3 for all $t\in\mathbb{R}$. Assertion *(iii)* follows easily from $\|V_1\|<1$ and noting that $h_2 \in L_\infty(T)$. Since

$$\overline{\mathrm{tr}(V^m(h\otimes g(t)))} = -\sum_{i=1}^{N}\exp\left(t\sum_{k=1}^{M}\sigma_k(z_i - z_i^{-1})\right)z_i^m\gamma_i - \int_T \exp\left(t\sum_{k=1}^{M}\sigma_k\overline{(z-z^{-1})}\right)\overline{r(z)z^m}\,d\mu(z),$$

Eq. (7) and the properties of the Haar measure μ give *(iv)*. In order to prove *(v)*, we observe that $-1\notin\sigma(Q_n(t))$ implies $1+q_n(t)\neq 0$ for all real t. By *(iii), (iv)* and by the construction of the operators $K^{(n)}$, not only κ gives solutions to the Eq. (11) but also its conjugate. Hence, by the uniqueness of solutions implied by *(ii)*, $\kappa(n,m,t)$ must be real for all t and $m>n$. As in the proof of Theorem II.B.6, it is

$$\frac{1}{1+q_n(t)} = 1-\kappa(n,n,t) = 1+f(2n,t)+\sum_{j=n+1}^{\infty}\kappa(n,j,t)f(n+j,t).$$

Therefore $q_n(t)$ is real. Now, since $1+q_n(0)>0$, $1+q_n(t)\neq 0$ for all $t\in\mathbb{R}$, assertion *(v)* follows from the continuity of q_n. □

We needed:

Lemma III.2: Suppose $g\in L_2(T)$ is such that $C:=\Sigma_{n=-\infty}^{0}|(g|f_n)|<\infty$, where $(f_n)_{n\in\mathbb{Z}}$ denotes the canonical orthonormal basis in $L_2(T)$, and let $c\in\mathbb{R}$, $m\in\mathbb{Z}$ be arbitrarily chosen. Furthermore define $h(z):=e^{cz^m}g(z)$ $(z\in T)$. Then: $\Sigma_{n=-\infty}^{0}|(h|f_n)|<\infty$.

Proof: Since

$$(h|f_n) = \int_T g(z)e^{cz^m}z^{-n}d\mu(z) = \sum_{k=0}^{\infty}\frac{c^k}{k!}\int_T g(z)z^{mk-n}\,d\mu(z),$$

$$\sum_{n=-\infty}^{0}|(h|f_n)| \leqslant \sum_{k=0}^{\infty}\frac{c^k}{k!}\sum_{n=-\infty}^{0}|(g|f_{n-mk})|.$$

For the case $m\geqslant 0$ we have $\Sigma_{n=-\infty}^{0}|(h|f_n)|\leqslant Ce^c$. Otherwise we use Hölder's inequality and Bessel's inequality to show

$$\sum_{n=-\infty}^{0}|(h|f_n)| \leqslant \sum_{k=0}^{\infty}\frac{c^k}{k!}\left(\sum_{n=1}^{-mk}|(g|f_n)|+C\right) \leqslant \sum_{k=0}^{\infty}\frac{c^k}{k!}(-mk)\left(\sum_{n=1}^{-mk}|(g|f_n)|^2\right)^{1/2}+Ce^c \leqslant -mce^c\|g\|+Ce^c.$$ □

Now we are in the position to define

$$a_n(t) := \left(\frac{1+q_{n+1}(t)}{1+q_n(t)}\right)^{1/2}$$

and

$$b_n(t) := \mathrm{tr}(V(1+Q_n(t))^{-1}Q_n(t) - V(1+Q_{n-1}(t))^{-1}Q_{n-1}(t))$$

for $n \in \mathbb{Z}$, $t \in \mathbb{R}$. These functions are differentiable in t, b_n and a_n^2 are even analytical in t. From now on we will frequently omit the parameter t in computations and definitions.

A. Derivation of evolution equations

Without necessary relation to the model introduced in Sec. II B, we show a derivation of a class of operator evolution equations that will—of course—later be shown to combine with our previous work.

Consider a family of operators $F_n(t)$ where $n \in \mathbb{Z}$ and t is real or complex and possibly confined to an open set. We require that $F_n(t)$ is invertible for all admissible t and that F_n is differentiable in t such that

$$\partial_t F_n = \sum_{k=1}^{M} \sigma_k F_{n+k} \quad (n \in \mathbb{Z}), \tag{15}$$

where $\sigma_1, \ldots, \sigma_M$ are some fixed scalars. Furthermore we demand that the expression

$$(F_{m+k} + F_{m-k}) F_m^{-1} \tag{16}$$

is independent of $m \in \mathbb{Z}$ for fixed k. Define

$$\Gamma_n := F_n^{-1} F_{n+1}, \quad B_n := \Gamma_{n+1} - \Gamma_n, \quad C_n := \Gamma_n^{-1} \Gamma_{n+1}$$

for $n \in \mathbb{Z}$. Under the two hypotheses above, we derive evolution equations for B_n and C_n. First note that trivially

$$B_n = \Gamma_{n+1} - \Gamma_n = \Gamma_n(\Gamma_n^{-1}\Gamma_{n+1} - 1) = \Gamma_n(C_n - 1), \tag{17}$$

and as a consequence of property (16):

$$B_n = \Gamma_n^{-1}(\Gamma_{n-1}^{-1} - \Gamma_n^{-1})\Gamma_n = \Gamma_n^{-1}(C_{n-1} - 1). \tag{18}$$

After setting

$$X_{j,n}^{(k)} = \begin{cases} 1 & \text{if } j = k \\ \Gamma_{n+1} - \Gamma_{n-k+1} & \text{if } j = k-1 \\ \Gamma_{n+1} \cdots \Gamma_{n+k-j-1}(\Gamma_{n+k-j} - \Gamma_{n-j}) & \text{if } 0 \leqslant j < k-1 \\ 0 & \text{otherwise;} \end{cases}$$

for $n, j \in \mathbb{Z}$, $1 \leqslant k \leqslant M$ and noting that $F_{n+k} = F_n \Gamma_n \cdots \Gamma_{n+k-1}$ for $k \geqslant 1$, we arrive at

$$\partial_t \Gamma_n = -F_n^{-1} \partial_t F_n \Gamma_n + F_n^{-1} \partial_t F_{n+1} = \sum_{k=1}^{M} \sigma_k (\Gamma_n \cdots \Gamma_{n+k-1}(\Gamma_{n+k} - \Gamma_n)) = \sum_{k=1}^{M} \sigma_k \Gamma_n X_{0,n}^{(k)} = \Gamma_n W_{0,n},$$

where $W_{j,n} := \sum_{k=1}^{M} \sigma_k X_{j,n}^{(k)}$. Therefore:

$$\partial_t C_n = -\Gamma_n^{-1} \partial_t \Gamma_n C_n + \Gamma_n^{-1} \partial_t \Gamma_{n+1} = C_n W_{0,n+1} - W_{0,n} C_n. \tag{19}$$

Similarly, since $\partial_t(\Gamma_n^{-1}) = -\Gamma_n^{-1} \partial_t \Gamma_n \Gamma_n^{-1} = -W_{0,n} \Gamma_n^{-1}$, it is

$$\Gamma_n^{-1}(\partial_t(\Gamma_{n-1}^{-1}) - \partial_t(\Gamma_n^{-1}))\Gamma_n = \Gamma_n^{-1} W_{0,n-1} \Gamma_{n-1}^{-1} \Gamma_n + \Gamma_n^{-1} W_{0,n} = -W_{1,n} C_{n-1} + C_n W_{1,n+1}.$$

Hence, by Eq. (18):

$$\partial_t B_n = C_n W_{1,n+1} - W_{1,n} C_{n-1} - W_{0,n} B_n + B_n W_{0,n} = C_n W_{1,n+1} - W_{1,n} C_{n-1} + [B_n, W_{0,n}]. \quad (20)$$

The point is that we can state an easy algorithm that lets us formulate the $X_{j,n}^{(k)}$ in terms of the $C_n - 1$ and B_n. Equation (18) together with Eq. (17) gives:

$$\Gamma_m B_m = (\Gamma_m - \Gamma_n) B_n + \Gamma_n B_n = \begin{cases} (B_{m-1} + \cdots + B_n) B_n + C_{n-1} - 1 & \text{if } m > n \\ C_{n-1} - 1 & \text{if } m = n \\ -(B_{n-1} + \cdots + B_m) B_n + C_{n-1} - 1 & \text{if } m < n; \end{cases}$$

and

$$\begin{aligned} \Gamma_m (C_n - 1) &= (\Gamma_m - \Gamma_n)(C_n - 1) + \Gamma_n (C_n - 1) \\ &= \begin{cases} (B_{m-1} + \cdots + B_n)(C_n - 1) + B_n & \text{if } m > n \\ B_n & \text{if } m = n \\ -(B_{n-1} + \cdots + B_m)(C_n - 1) + B_n & \text{if } m < n. \end{cases} \end{aligned}$$

All that remains to realize is, that after we start with $X_{k-1,n}^{(k)} = B_n + \cdots + B_{n-k+1}$, we can iterate over $X_{j,n}^{(k)} = \Gamma_{n+1} X_{j+1,n+1}^{(k)}$ $(0 \leqslant j < k)$, applying the equations above, to derive formulas of all $X_{j,n}^{(k)}$ in terms of the B_n, $C_n - 1$. We will do the computations for $k = 3$: Starting with $X_{2,n}^{(3)} = B_n + B_{n-1} + B_{n-2}$, we get

$$\begin{aligned} X_{1,n}^{(3)} = \Gamma_{n+1} X_{2,n+1}^{(3)} &= \Gamma_{n+1}(B_n + B_{n-1} + B_{n-2}) \\ &= B_n^2 + B_{n-1}^2 + B_n Bn - 1 + (C_n - 1) + (C_{n-1} - 1) + (C_{n-2} - 1). \end{aligned}$$

Similarly,

$$\begin{aligned} X_{0,n}^{(3)} = \Gamma_{n+1} X_{1,n+1}^{(3)} &= B_n^3 + (C_n - 1)(B_{n+1} + 2B_n) + B_{n+1} \\ &\quad + B_n + B_{n-1} + B_n (C_n - 1) + (B_n + B_{n-1})(C_{n-1} - 1). \end{aligned}$$

Let us return to the situation of our model: Consider

$$F_n(t) := V^{-n} e^{t\tilde{Z}} + V^n e^{tZ} B,$$

where $n \in \mathbb{Z}$, $t \in \mathbb{R}$ and $Z := \Sigma_{k=1}^M \sigma_k V^k$, $\tilde{Z} := \Sigma_{k=1}^M \sigma_k V^{-k}$, and define Γ_n, C_n, B_n, $X_{j,n}^{(k)}$ and $W_{j,n}$ just as before. It is readily seen that $\Gamma_n V = (1 + Q_n)$. Clearly, property (15) is satisfied, whereas property (16) is a consequence of the relation $F_{m+k} F_m^{-1} = V^{-m}(V^{-k} - V^k) e^{t\tilde{Z}} F_m^{-1} + V^k$, which in turn gives $F_{m+k} F_m^{-1} = -F_{m-k} F_m^{-1} + V^k + V^{-k}$ for all $m, k \in \mathbb{Z}$. The eventual goal is to derive evolution equations for the scalars a_n and b_n. The relation to our construction is as follows:

$$\begin{aligned} c_n := a_n^2 = \frac{1 + q_{n+1}}{1 + q_n} &= 1 + \operatorname{tr}((1 + Q_n)^{-1}(Q_{n+1} - Q_n)) \\ &= 1 + \operatorname{tr}(V^{-1} \Gamma_n^{-1} (\Gamma_{n+1} - \Gamma_n) V) \\ &= 1 + \operatorname{tr}(\Gamma_n^{-1} \Gamma_{n+1} - 1) = 1 + \operatorname{tr}(C_n - 1). \end{aligned} \quad (21)$$

From (17) we infer

$$(1 + Q_{n-1})^{-1} - (1 + Q_n)^{-1} = V^{-1}(\Gamma_{n-1}^{-1} - \Gamma_n^{-1}) = V^{-1} \Gamma_n (\Gamma_{n+1} - \Gamma_n) \Gamma_n^{-1}$$

and hence

$$b_n = \mathrm{tr}(V((1+Q_{n-1})^{-1} - (1+Q_n)^{-1})) = \mathrm{tr}(\Gamma_{n+1} - \Gamma_n) = \mathrm{tr}(B_n). \tag{22}$$

Note that the operators $X_{j,n}^{(k)}$ for $0 \leqslant j \leqslant k-1$ are one dimensional, of the form $T(((V^*)^{-1}h) \otimes g)$ for some operator T. The same holds for the operators $C_n - 1$, B_n. This allows us to obtain scalar evolution equations for c_n, b_n from Eqs. (19) and (20) by Eqs. (21) and (22), and by application of the trace operator.

For example, assuming $A = \Sigma_{j=1}^{3} \sigma_j (V^j - V^{-j})$ we arrive after some computation at the following scalar evolution equations:

$$\begin{aligned}\partial_t c_n = c_n(&\sigma_3(b_{n+1}^3 - b_n^3 - 3(b_{n+1} - b_n) + c_{n+1}(2b_{n+1} + b_{n+2}) \\ &+ c_n(b_{n+1} - b_n) + c_{n-1}(-2b_n - b_{n-1})) \\ &+ \sigma_2(b_{n+1}^2 - b_n^2 + c_{n+1} - c_{n-1}) + \sigma_1(b_{n+1} - b_n))\end{aligned} \tag{23}$$

and

$$\begin{aligned}\partial_t b_n = &c_n(\sigma_3(b_{n+1}^2 + b_n^2 + b_{n+1}b_n + c_{n+1} + c_n + c_{n-1} - 3) + \sigma_2(b_{n+1} + b_n) + \sigma_1) \\ &- c_{n-1}(\sigma_3(b_n^2 + b_{n-1}^2 + b_n b_{n-1} + c_n + c_{n-1} + c_{n-2} - 3) + \sigma_2(b_n + b_{n-1}) + \sigma_1).\end{aligned} \tag{24}$$

B. Relation to the Lax approach

In this section we show that there is a straight relation between the method presented in the previous parts of the paper and the method of Lax pairs.

Define

$$\partial_t L(t) e_n := \partial_t a_{n-1}(t) e_{n-1} + \partial_t b_n(t) e_n + \partial_t a_n(t) e_{n+1} \quad (n \in \mathbb{Z}).$$

This is a densely defined operator in $\ell_2(\mathbb{Z})$, which is indeed the strong derivative of L on $E := \mathrm{span}\{e_n | n \in \mathbb{Z}\}$. An additional operator $U(t)$ in $\ell_2(\mathbb{Z})$ shall be defined by

$$U(t) e_n := 1/2 \sum_{j=1}^{M} (d_{j,n}(t) e_{n-j} - d_{j,n+j}(t) e_{n+j}) \quad (n \in \mathbb{Z})$$

for some numbers $d_{j,n}$ that are to be determined later. We will see that the equation

$$[L,U] + \partial_t L = 0 \tag{25}$$

is equivalent to a system of evolution equations for a and b. The pair (L,U) is then called a Lax pair for these equations. This method of construction of evolution equations has been studied by many authors. A version for the Toda lattice equation can be found for example in Ref. 3. Define $d_{j,n} := 0$ if $j > M$ or $j \leqslant 0$, respectively. An easy computation shows that (25) is equivalent to the following system of equations:

$$a_{n-1} d_{j,n-1} + b_n d_{j+1,n} + a_n d_{j+2,n+1} - a_{n-j-1} d_{j,n} - b_{n-j-1} d_{j+1,n} - a_{n-j-2} d_{j+2,n} = 0, \tag{26}$$

for $j \geqslant 1$,

$$a_{n+1} d_{2,n+2} - a_{n-1} d_{2,n+1} + (b_{n+1} - b_n) d_{1,n+1} = 2 \partial_t a_n \tag{27}$$

and

$$(a_n d_{1,n+1} - a_{n-1} d_{1,n}) = \partial_t b_n. \tag{28}$$

This indeed determines a couple of evolution equations for a_n and b_n. A reformulation of (26) is

$$a_{n-j-1}d_{j,n}-a_{n-1}d_{j,n-1}=(b_n-b_{n-j-1})d_{j+1,n}+a_n d_{j+2,n+1}-a_{n-j-2}d_{j+2,n} \quad (j=1,...,M).$$

The ansatz $d_{j,n}=r_{j,n}(a_{n-1}\cdots a_{n-j})$ leads to:

$$r_{j,n}-r_{j,n-1}=(b_n-b_{n-j-1})r_{j+1,n}+a_n^2 r_{j+2,n+1}-a_{n-j-2}^2 r_{j+2,n} \quad (j=1,...,M), \tag{29}$$

$$r_{j,n}=0 \quad (j>M). \tag{30}$$

Obviously, the sequence $(r_{j,n})_{n\in\mathbb{Z}}$ is uniquely determined up to a constant for every $j=1,...,M$. Equations (27) and (28) now become

$$\partial_t a_n=1/2 a_n(a_{n+1}^2 r_{2,n+2}-a_{n-1}^2 r_{2,n+1}+(b_{n+1}-b_n)r_{1,n+1}) \tag{31}$$

and

$$\partial_t b_n=(a_n^2 r_{1,n+1}-a_{n-1}^2 r_{1,n}). \tag{32}$$

The upshot is that we can explicitly find a fundamental system of solutions of Eqs. (29) and (30).

Theorem III.B.1: For each $1\leqslant k\leqslant M$, the family $X_{j,n}^{(k)}$ of operators satisfies

$$X_{j,n}^{(k)}-X_{j,n-1}^{(k)}=B_n X_{j+1,n}^{(k)}-X_{j+1,n}^{(k)}B_{n-j-1}+C_n X_{j+2,n+1}^{(k)}-X_{j+2,n}^{(k)}C_{n-j-2},$$

where $n\in\mathbb{Z},\ j\geqslant 0$.

Proof: This is the result of a tedious but nevertheless easy computation after rewriting the equation in terms of the operators F_m and using the fact that $(F_{m+k}+F_{m-k})F_m^{-1}$ is independent of m. □

Let $x_{j,n}^{(k)}:=\mathrm{tr}(X_{j,n}^{(k)})$ if $j\neq k$ and $x_{k,n}^{(k)}:=1$. Then $r_{j,n}:=\Sigma_{k=1}^{M}\sigma_k x_{j,n}^{(k)}$ gives the general solution of Eqs. (29) and (30). In addition, Eqs. (31) and (32) are also satisfied as a consequence of Eqs. (19) and (20) and of Theorem III.B.1.

We have seen now that the evolution equations derived in Sec. III A correspond to Lax pairs constructed in this section. The Lax approach provides a second method of derivation of evolution equations by solving Eqs. (29) and (30) directly and substituting the results into Eqs. (31) and (32). Faced with a specific Lax pair, one can obtain the coefficients $\sigma_1,\ldots,\sigma_M$ by taking limits as n grows to infinity. This is implied by the following lemma:

Lemma III.B.2: If $0\leqslant j<k$, then $\lim_{n\to\infty}\mathrm{tr}(X_{j,n}^{(k)})=0$.

Proof: It is

$$BV^m f=(S_1(R_1V_1^m f_1+R_2V_2^m f_2))\oplus(S_2(R_2V_2^m f_2+R_1V_1^m f_1))$$

for arbitrary $f=f_1\oplus f_2\in H$. Clearly $\lim_{m\to\infty}V_1^m=0$. But also $(R_2V_2^m f_2|e_j)=(V_2^{m+j}f_2|h_2)$ and therefore

$$\|R_2V_2^m f_2\|=\left(\sum_{k=0}^{\infty}\left|\int_T \overline{h_2}f_2 z^{m+k}d\mu(z)\right|^2\right)^{1/2}\to 0 \quad (m\to\infty).$$

Thus $\lim_{m\to\infty}BV^m f=0$. Furthermore, we have that $(V^m g|h)\to 0$ as $n\to\infty$, since $g_2\overline{h_2}\in L_2(T)$. It requires a little computation to check that

$$\mathrm{tr}(X_{j,n}^{(k)})=\mathrm{tr}((1+V^{2n+1}BV)^{-1}V^j(V^k-V^{-k})(1+V^{2(n-j)})^{-1}V^{2(n-j)}(h\otimes g)).$$

Now, using the asymptotics assertion of Lemma II.B.4,

$$\lim_{n\to\infty}((1+V^{2n+1}BV)^{-1}V^j(V^k-V^{-k})(1+V^{2(n-j)}B)^{-1}V^{2(n-j)}$$
$$-(1-V^{2n+1}BV)V^j(V^k-V^{-k})(1-V^{2(n-j)}B)V^{2(n-j)})=0,$$

and we infer

$$\lim_{n\to\infty}\operatorname{tr}(X_{j,n}^{(k)})=\lim_{n\to\infty}\operatorname{tr}((1-V^{2n+1}BV)V^j(V^k-V^{-k})(1-V^{2(n-j)}B)V^{2(n-j)}(h\otimes g))=0.$$

□

Concluding this section, we show how to derive Eqs. (23) and (24) by a Lax ansatz for $M=3$: Obviously, $r_{3,n}=\sigma_3$. From

$$r_{2,n}-r_{2,n-1}=(b_n-b_{n-3})r_{3,n}=(b_n-b_{n-3})\sigma_3$$

it follows that $r_{2,n}=\sigma_3(b_n+b_{n-1}+b_{n-2})+\sigma_2$. It remains to solve

$$r_{1,n}-r_{1,n-1}=(b_n-b_{n-2})r_{2,n}+a_n^2r_{3,n+1}-a_{n-3}^2r_{3,n}.$$

Rewriting it as

$$r_{1,n}-r_{1,n-1}=\sigma_3(b_n^2-b_{n-2}^2+b_nb_{n-1}-b_{n-1}b_{n-2}+a_n^2-a_{n-3}^2)+\sigma_2(b_n-b_{n-2})$$

leads to

$$r_{1,n}=\sigma_3(b_n^2+b_{n-1}^2+b_nb_{n-1}+a_n^2+a_{n-1}^2+a_{n-2}^2)+\sigma_2(b_n+b_{n-1})+\tilde r$$

for some constant $\tilde r$. Since then $\lim_{n\to\infty}r_{1,n}=3\sigma_3+\tilde r$, it must be $\tilde r=\sigma_1-3\sigma_3$, and hence:

$$r_{1,n}=\sigma_3(b_n^2+b_{n-1}^2+b_nb_{n-1}+a_n^2+a_{n-1}^2+a_{n-2}^2-3)+\sigma_2(b_n+b_{n-1})+\sigma_1.$$

Now substitution into Eqs. (31) and (32) gives the evolution Eqs. (23) and (24).

At this point we note again the fact that the Lax equations are satisfied gives a plausible hint on the necessary time evolution of the scattering data of the operator L, as investigated in many books and articles on inverse scattering methods. This in turn suggests uniqueness assertions for solutions. However, a rigorous proof or investigation is omitted here.

C. Representation of solutions by determinants

In some cases, it is possible to represent the scalar functions a and b by determinants on operator ideals. Although, under the restrictions of the model we chose in this paper, we can restrict ourselves to ordinary determinants, we still give an outlook onto some generalizations. For the theory of traces and determinants on operator ideals we refer to Pietsch.[13]

Theorem III.C.1: Suppose $B\in\mathcal{A}$ where $\mathcal{A}$ is an quasi-Banach operator ideal admitting a continuous trace τ and a continuous determinant δ, and define $L_n:=V^{2n}B$ for $n\in\mathbb{Z}$. Then

$$c_n=\frac{\delta(1+L_{n+2})\,\delta(1+L_n)}{\delta(1+L_{n+1})^2}.$$

and

$$b_n:=\frac{\delta(1+L_{n+1}+VL_{n+1}-L_{n+1}V^{-1})}{\delta(1+L_{n+1})}-\frac{\delta(1+L_n+VL_n-L_nV^{-1})}{\delta(1+L_n)}.$$

Proof: By the one dimensionality of Q_n:

$$\begin{aligned}1+q_n=1+\mathrm{tr}(Q_n)=1+\tau(Q_n)&=\delta(1+Q_n)\\&=\delta(1+(1+L_n)^{-1}(VL_nV-L_n))\\&=\delta((1+L_n)^{-1}(1+VL_nV))\\&=\frac{\delta(1+VL_nV)}{\delta(1+L_n)}=\frac{\delta(1+L_{n+1})}{\delta(1+L_n)},\end{aligned}$$

which implies the first formula. It is $b_n=\mathrm{tr}(\Gamma_{n+1}-\Gamma_n)=\mathrm{tr}(Q_{n+1}V^{-1}-Q_nV^{-1})$. Similarly to above, we compute

$$\begin{aligned}1+\mathrm{tr}(Q_nV^{-1})=\delta(1+Q_nV^{-1})&=\delta((1+L_n)^{-1}(1+L_n+VL_n-L_nV^{-1}))\\&=\frac{\delta(1+L_n+VL_n-L_nV^{-1})}{\delta(1+L_n)}\end{aligned}$$

and the assertion follows. □

In the reflectionless case, that is if the reflection coefficient vanishes everywhere, the theorem above is applicable inserting the usual determinant on the finite-dimensional operators, viewed, for example, as a restriction of the continuous trace on the quasi-Banach operator ideal of the p-nuclear operators for $0<p\leqslant 2/3$. However, it should be pointed out that the methods of Sec. III A work under the stated requirements, and that one can construct solutions of the derived evolution equations that are not bound to the restrictions of our model.

D. Examples of solved equations

Finally, we use the presented methods to solve the Cauchy problem of two well-known evolution equations.

The Toda lattice equation as stated in Sec. I is given by

$$\partial_{tt}y_n=e^{-(y_n-y_{n-1})}-e^{-(y_{n+1}-y_n)}\quad(n\in\mathbb{Z}).\tag{33}$$

Choosing $\sigma_3:=\sigma_2:=0$ and $\sigma_1:=1$ in Eqs. (23) and (24) they become

$$\partial_tc_n=c_n(b_{n+1}-b_n)\tag{34}$$

and

$$\partial_tb_n=c_n-c_{n-1}.\tag{35}$$

Now, formally substituting $b_n=-\partial_ty_n$, $c_n=\exp(-(y_{n+1}-y_n))$ leads to Eq. (33). Rigorously: We intend to solve Eq. (33) for given initial values y and ∂_ty. For that purpose we assume that

$$b_n(0):=-\partial_ty_n,\quad a_n^2(0)=c_n(0):=e^{-(y_{n+1}-y_n)}$$

satisfy (2). Suppose now that z_n such that $\partial_tz_n=-b_n$ and $z_n(0)=y_n$. Then Eq. (34) implies that:

$$c_n=\gamma_ne^{-(z_{n+1}-z_n)}$$

for some constants γ_n. By the choice of $c_n(0)$, it must be $\gamma_n=1$. From Eq. (35) we finally conclude:

$$\partial_{tt}z_n=e^{-(z_n-z_{n-1})}-e^{-(z_{n+1}-z_n)},$$

i.e., that z is a solution of the initial value problem.

The Langmuir lattice equation can, without loss of generality, be written as:

$$\partial_t g_n = (1+g_n)(g_{n+1}-g_{n-1}) \quad (n\in\mathbb{Z}). \tag{36}$$

Formally: Choose $\sigma_3=0$, $\sigma_2=1$, and $\sigma_1=0$ to obtain the evolution equations

$$\partial_t c_n = c_n(c_{n+1}-c_{n-1}+b_{n+1}^2-b_n^2) \tag{37}$$

and

$$\partial_t b_n = c_n(b_{n+1}+b_n)-c_{n-1}(b_n+b_{n-1}). \tag{38}$$

Substituting $b_n=0$ and $c_n=1+g_n$ gives Eq. (36). Suppose now we are given initial values $1+g_n$. We set $a_n^2(0)=c_n(0):=1+g_n$, $b_n(0):=0$ and require that (2) is fulfilled. In order to have solved the initial value problem, we need to show that $b_n(t)=0$ also for $t\neq 0$:

Step 1. Suppose that $t_0\in\mathbb{R}$ is such that $b_n(t_0)=0$ for all $n\in\mathbb{Z}$. Repeated differentiation and application of Eq. (38) implies that:

$$\left(\frac{d}{dt}\right)^k b_n(t_0)=0 \quad \text{for all } k\in\mathbb{N}_0, n\in\mathbb{Z}.$$

Since b_n is analytical in t, there must be an open neighborhood of t_0 where b_n vanishes for each fixed n.

Step 2. Define

$$N:=\left\{ t\in\mathbb{R} \,\middle|\, \left(\frac{d}{dt}\right)^k b_n(t)=0 \quad \text{for all } k\in\mathbb{N}_0, n\in\mathbb{Z}\right\}.$$

Then N is a closed set, and since $0\in N$, it is not empty. Suppose $t_0\in N$. As we have seen above, there is an open neighborhood U of t_0 such that $b_0(t)=b_1(t)=0$ for all $t\in U$. But then all derivatives of b_0 and b_1 must vanish on U too. Since $c_n(t)\neq 0$ for all $n\in\mathbb{Z}$ and $t\neq 0$, Eq. (38) shows that b_2 as well as b_{-1} and all their derivatives must equal zero on U. Continuing this way we get $U\subset N$. Hence N is open. By the connectedness of $\mathbb{R}$, this means $N=\mathbb{R}$.

Hence the initial value problem of the Langmuir lattice equation is solved.

Note that here, unlike the Toda case, where arbitrary scattering data—unless inversion of the operators fails or $1+q_n(0)\leqslant 0$ for some n—leads to solutions of Eq. (33) via

$$y_n:=-\log(1+q_n),$$

the requirement that $b_n(0)=0$ for the Langmuir model poses a nontrivial restriction on the choice of the scattering data. One can indeed verify by computation, that in general the formula

$$g_n:=c_n-1=\frac{q_{n+1}-q_n}{1+q_n}=\operatorname{tr}((1+Q_n)^{-1}(Q_{n+1}-Q_n)),$$

even if all the inverse operators exist, does not yield solutions of Eq. (36).

IV. CONCLUSION

It has been shown that the methods presented here give solutions of a discrete inverse scattering problem and of the initial value problem of a class of evolution equations that, via the Lax approach, correspond in a rather direct manner to their linear problem. Similar work can be done for different inverse scattering problem and classes of nonlinear evolution equation and is on the way. It is possible, explicitly using the form of the solutions constructed here, to find solutions of the same evolution equations that are not subject to the restrictions of the chosen model. For example, inserting well-chosen diagonal operators and some C_0-semigroup theory in our construction, one can easily derive soliton solutions possessing an infinite number of solitons with interesting properties.

We derive a generalized Gel'fand–Levitan integral equation for two block Ablowitz–Kaup–Newell–Segur systems. This is possible if we suppose that the matrix coupling coefficients are invertible and come from simple zeroes of the determinant of the diagonal blocks of the scattering matrix. © *1999 American Institute of Physics.* [S0022-2488(99)02908-4]

I. INTRODUCTION

The coupled nonlinear Schrödinger (NLS) equations, a nonlinear evolution equation system, have been solved by means of a generalized Riemann–Hilbert problem[1] before it, in its classical form, were one of the more important ways of recovering the soliton solutions. ''Pseudopotentials'' (integrable coefficients of first-order differential form relation)[2–4] and prolongation structure of Lie groups[5,6] were essential ingredients in the beginnings of the inverse scattering method. By introducing the classical general principle of associating nonlinear evolution equations to linear operators,[7] the inverse scattering method was simplified, improved, and formulated via a Gel'fand–Levitan (GL) integral equation[8] (an approach different from the Riemann–Hilbert problem). Finding suitable linear operators become the focus of the inverse scattering method, which naturally is carried not only to classical but also to matrix GL integral equations;[9,10] in addition, the discovery of connections among matrix linear operators with nonlinear evolution equations contributed to exploring inverse scattering problems for nonlinear evolution equation systems. For instance, systems associated with the matrix operator

$$D_x(J,z)=\frac{d}{dx}-zJ-q, \tag{1}$$

with J an $n\times n$ constant diagonal matrix, have been called in the literature $n\times n$ Ablowitz–Kaup–Newell–Segur (AKNS) systems, which AKNS[11] used to systematically solve the NLS equation via a generalized GL approach with the 2×2 diagonal matrix $J=i\,\mathrm{diag}(1,-1)$.

The first-order linear operator in (1) with the 3×3 constant matrix

$$J=i\begin{pmatrix}2&0&0\\0&-1&0\\0&0&-1\end{pmatrix}$$

is connected with the coupled NLS equations. It has been naturally approached by Riemann–Hilbert problems.[12,13]

High dimensional nonlinear evolution equation systems are closely connected with multidimensional inverse scattering problems,[14] which eventually led to the $\overline{\partial}$ method.[15–18] In general, the GL approach has not been successfully established for dimensions higher than two,[15] generalized

[a)]Electronic mail: ccg@hp9000a1.uam.mx

Riemann–Hilbert problems have been the natural way to formulate the $\overline{\partial}$ approach. However, the relatively complicated structure of generalized GL equations makes them of some interest.

II. THE TWO BLOCK AKNS SYSTEMS

In this paper, generalizing the idea of deriving a GL equation for the NLS equation,[9,10] we shall derive a generalized GL equation for two block AKNS systems,[19] i.e., for the first order $n\times n$ linear operator in (1) with the constant diagonal $n\times n$ matrix

$$J=i\begin{pmatrix} p_-\mathbb{I}_{p_+} & 0_{p_+\times p_-} \\ 0_{p_-\times p_+} & -p_+\mathbb{I}_{p_-} \end{pmatrix}$$

being $p_\pm$ positive integers whose sum is n; $\mathbb{I}_{p_\pm}$ are the $p_\pm\times p_\pm$ identity matrices, respectively; and $0_{p_\pm\times p_\mp}$ are the $p_\pm\times p_\mp$ null matrices, respectively. The two block $n\times n$ AKNS potential q is a $n\times n$ matrix-valued function defined on the real line

$$q=\begin{pmatrix} 0_{p_+} & r_+ \\ r_- & 0_{p_-} \end{pmatrix}, \tag{2}$$

whose entries are in the Schwartz class where $0_{p_\pm}$ are the $p_\pm\times p_\pm$ null matrices and $r_\pm$ are $(p_\pm\times p_\mp)$ matrix-valued functions, respectively. In the sequel, we refer to them as the two block AKNS systems.

The method used here for deriving generalized GL equations cannot be generalized for $n\times n$ AKNS systems, $n\geqslant 2$, where the constant diagonal matrix J has all of its entries distinct, but we use it here to derive a GL equation for the present case provided the coupling matrix coefficients of the potential are invertible and come from simple zeroes of the determinant of the J-diagonal blocks of the scattering matrix.[19] We shall obtain a generalized GL equation by coupling two integral matrix equations into one equation system.

III. COUPLED MATRIX INTEGRAL EQUATIONS

We need to get suitable representations for the wave functions of the two block AKNS system. For this purpose, let us adopt the same notation as that used in Ref. 19 and recall some results established there: construct the wave functions $\psi_\pm$ with asymptotic behavior $\psi_\pm \sim e^{\pm ip_\pm xz}e_\pm$ as $x\to\infty$ for the two block AKNS systems.

With this at hand, we may get the representations for these wave functions,

$$\psi_\pm(x,z)=e_\pm e^{\pm ip_\pm xz}+\int_x^\infty G_\pm(x,\zeta)e^{\pm ip_\pm z\zeta}\,d\zeta, \tag{3}$$

where $e_\pm$ are $n\times p_\pm$ constant matrices such that the identity matrix $I_n=\|e_+e_-\|$.[19]

The kernels $G_\pm$ both have support in the region $\zeta>x$. For example, the matrix-valued function $\psi_-e^{ip_-xz}-e_-$ tends to zero, as z tends to infinity, in the upper half plane, so by the Paley–Wiener theorem,

$$\psi_-e^{ip_-xz}-e_-=\frac{1}{2\pi}\int_{-\infty}^0 K_-(x,\zeta)e^{iz\zeta}\,d\zeta,$$

that is,

$$\psi_- = e_- e^{-ip_- xz} + \int_{-\infty}^{0} K_-(x,\zeta) e^{iz\zeta - ip_- zx}\, d\zeta$$
$$= e_- e^{-ip_- xz} + \int_{-\infty}^{0} K_-(x,\zeta) e^{iz(\zeta - p_- x)} d\zeta$$
$$= e_- e^{-ip_- xz} + p_- \int_{x}^{\infty} K_-(x, p_-(x-\zeta)) e^{-izp_- \zeta}\, d\zeta.$$

So the result for ψ_- follows by taking

$$G_-(x,\zeta) = \frac{p_-}{2\pi} K_-(x, p_-(x-\zeta)).$$

The matrix functions $G_\pm$ are $n \times p_\pm$-matrix valued functions, respectively.

Write the relations[19] between the wave functions $\psi_\pm$ and those $\phi_\pm$ with asymptotic behavior $\phi_\pm \sim e^{\mp ip_\mp xz} e_\mp$ as $x \to -\infty$ in the following form:

$$\phi_+ d^{-1} = \psi_+ b d^{-1} + \psi_-,$$
$$\phi_- a^{-1} = \psi_+ + \psi_- c a^{-1}, \tag{4}$$

where a,b,c,d are the J-blocks of the scattering matrix[12]

$$s = \begin{pmatrix} a & b \\ c & d \end{pmatrix}.$$

Combining the first relation with the representations for $\psi_\pm$, write the first equation as

$$\phi_+ d^{-1} - e_- e^{-ip_- xz} = \int_x^{\infty} G_-(x,\zeta) e^{-ip_- z\zeta}\, d\zeta + \left(e_+ e^{ip_+ xz} + \int_x^{\infty} G_+(x,\zeta) e^{ip_+ z\zeta}\, d\zeta \right) b d^{-1}. \tag{5}$$

Multiplying by $(2\pi)^{-1} e^{ip_- z\zeta}$ and integrating with respect to z over the real line, an integral matrix integral equation may be derived. To do this, we define the matrix valued function and the rational number, respectively, by

$$f_1^+(\zeta) = \frac{1}{2\pi} \int_{-\infty}^{\infty} b d^{-1} e^{ip_+ \zeta z}\, dz, \quad p = \frac{p_+}{p_-}.$$

With this at hand, we get the following relations for each term in (4):

$$\frac{1}{2\pi} \int_{-\infty}^{\infty} e^{ip_- z\zeta} \int_x^{\infty} G_-(x,\eta) e^{-ip_- z\eta}\, d\eta\, dz = G_-(x,\zeta),$$

$$\frac{1}{2\pi} \int_{-\infty}^{\infty} b d^{-1} e^{ip_- \zeta z} e^{ip_+ xz}\, dz = f_1^+(x + p^{-1}\zeta),$$

$$\frac{1}{2\pi} \int_{-\infty}^{\infty} e^{ip_- z\zeta} \int_x^{\infty} G_+(x,\eta) e^{ip_+ z\eta} b d^{-1}\, d\eta\, dz = \int_x^{\infty} G_+(x,\zeta) \frac{1}{2\pi} \int_{-\infty}^{\infty} e^{ip_+ z\eta} e^{ip_- z\zeta} b d^{-1} dz\, d\eta$$
$$= \int_x^{\infty} G_+(x,\eta) f_1^+(\eta + p^{-1}\zeta) d\eta.$$

The left-hand side can be evaluated by closing the contour in the upper half plane for $\zeta > x$ and using the residue theorem:

$$\frac{1}{2\pi}\int_{-\infty}^{\infty} e^{ip_-z\zeta}(\phi_+ d^{-1} - e_- e^{-ip_-xz})dz$$
$$= \frac{1}{2\pi}\int_{-\infty}^{\infty} e^{i(\zeta-x)p_-z}(\phi_+ d^{-1}e^{ip_-xz} - e_-)dz = i\sum_{j=1}^{N} \phi_{+j}d'^{-1}(z_j)e^{ip_-z_j\zeta}$$
$$= -\sum_{j=1}^{N} \phi_{+j}(id')^{-1}(z_j)e^{ip_-z_j\zeta} = -\sum_{j=1}^{N} \psi_{+j}c_j^+(id')^{-1}(z_j)e^{ip_-z_j\zeta}$$
$$= -\sum_{j=1}^{N}\left(e_+e^{ip_+xz_j} + \int_x^\infty G_+(x,\eta)e^{ip_+z_j\eta}\,d\eta\right)c_j^+(id')^{-1}e^{ip_-z_j\zeta}$$
$$= -e_+\sum_{j=1}^{N} c_j^+(id')^{-1}e^{i(p_+x+p_-\zeta)z_j} - \int_x^\infty G_+(x,\eta)\left(\sum_{j=1}^{N} c_j^+(id')^{-1}e^{i(p_+\eta+p_-\zeta)z_j}\right)d\eta$$
$$= -f_2^+(x+p^{-1}\zeta) - \int_x^\infty G_+(x,\eta)f_2^+(\eta+p^{-1}\zeta)\,d\eta,$$

where the $p_+\times p_-$ matrix function

$$f_2^+(\zeta) = \sum_{j=1}^{N} c_j^+(id')^{-1}e^{ip_+z_j\zeta}.$$

Putting this together, we get

$$f_+(x+p^{-1}\zeta) + G_-(x,\zeta) + \int_x^\infty G_+(x,\eta)f_+(\eta+p^{-1}\zeta)\,d\eta = 0 \tag{6}$$

with $f_+ = f_1^+ + f_2^+$. Here, z_j^+ are the (simple) zeroes of d in the upper half plane and c_j^+ are the coupling coefficients[19]

$$\phi_+(x,z_j^+) = \psi_+(x,z_j^+)c_j^+ .$$

Now combining the second relation with the representations for $\psi_\pm$, we can write the second equation as

$$\phi_- a^{-1} = \psi_+ + \psi_- c a^{-1}.$$

Consequently,

$$\phi_- a^{-1} - e_+e^{ip_+xz} = \int_x^\infty G_+(x,\zeta)e^{ip_+z\zeta}\,d\zeta + \left(e_-e^{-ip_-xz} + \int_x^\infty G_-(x,\zeta)e^{-ip_-z\zeta}\,d\zeta\right)ca^{-1}.$$

Another integral equation system involving the matrix-valued functions $G_\pm$ is obtained by multiplying by $(2\pi)^{-1}e^{-ip_+z\zeta}$ and integrating with respect to z over the real line. Write

$$f_1^-(\zeta) = \frac{1}{2\pi}\int_{-\infty}^{\infty} ca^{-1}e^{-ip_-\zeta z}\,dz.$$

Using this definition, we arrive at

$$\frac{1}{2\pi}\int_{-\infty}^{\infty} e^{-ip_+ z\zeta}\int_x^{\infty} G_+(x,\eta)e^{ip_+ z\eta}\,d\eta\,dz = G_+(x,\zeta),$$

$$\frac{1}{2\pi}\int_{-\infty}^{\infty} ca^{-1}e^{-ip_+\zeta z}e^{-ip_- xz}\,dz = f_1^-(x+p\zeta),$$

and

$$\frac{1}{2\pi}\int_{-\infty}^{\infty} e^{-ip_+ z\zeta}\int_x^{\infty} G_+(x,\eta)e^{-ip_- z\eta}bd^{-1}\,d\eta\,dz$$
$$=\int_x^{\infty} G_+(x,\zeta)\frac{1}{2\pi}\int_{-\infty}^{\infty} e^{-ip_+ z\eta}e^{-ip_-\zeta\eta}\,bd^{-1}\,dz\,d\eta$$
$$=\int_x^{\infty} G_+(x,\eta)f_1^-(\eta+p\zeta)d\eta.$$

The left-hand side can be evaluated by closing the contour in the lower half plane for $\zeta > x$ and using the residue theorem:

$$\frac{1}{2\pi}\int_{-\infty}^{\infty} e^{-ip_+ z\zeta}(\phi_- a^{-1} - e_+ e^{ip_+ xz})dz$$
$$=\frac{1}{2\pi}\int_{-\infty}^{\infty} e^{-i(\zeta-x)p_+ z}(\phi_- a^{-1}e^{-ip_+ xz} - e_-)dz = i\sum_{j=1}^{N}\phi_{-j}a'^{-1}(z_j)e^{-ip_+ z_j\zeta}$$
$$=-\sum_{j=1}^{N}\phi_{-j}(ia')^{-1}(z_j)e^{-ip_+ z_j}\zeta$$
$$=-\sum_{j=1}^{N}\psi_{-j}c_j^-(ia')^{-1}(z_j)e^{-ip_+ z_j\zeta}$$
$$=-\sum_{j=1}^{N}\left(e_- e^{-ip_- xz_j} + \int_x^{\infty} G_-(x,\eta)e^{-ip_- z_j\eta}\,d\eta\right)c_j^-(ia')^{-1}e^{-ip_+ z_j\zeta}$$
$$=-e_+\sum_{j=1}^{N}c_j^-(ia')^{-1}e^{-i(p_- x+p_+\zeta)z_j} - \int_x^{\infty} G_-(x,\eta)\left(\sum_{j=1}^{N}c_j^-(ia')^{-1}e^{-i(p_-\eta+p_+\zeta)z_j}\right)d\eta$$
$$=-e_- f_2^-(x+p\zeta) - \int_x^{\infty} G_-(x,\eta)f_2^-(\eta+p\zeta)d\eta,$$

where the $p_-\times p_+$ matrix function $f_2^-(\zeta)=\Sigma_{j=1}^{N} c_j^+(ia')^{-1}e^{-ip_- z_j\zeta}$. Proceeding as before, we get

$$f_-(x+p\zeta)+G_-(x,\zeta)+\int_x^{\infty} G_+(x,\eta)f_-(\eta+p\zeta)d\eta = 0$$

with $f_- = f_1^- + f_2^-$. Here, z_j^- are the (simple) zeroes of d in the upper half plane and c_j^- are the coupling coefficients:[19]

$$\phi_-(x,z_j^-) = \psi_-(x,z_j^-)c_j^-.$$

IV. GENERALIZED GEL'FAND–LEVITAN INTEGRAL EQUATION

Coupling the integral equations, we get the generalized GL equation

$$f(x+p^{\pm}\zeta)+G(x,\zeta)\tau+\int_x^{\infty}G(x,\eta)f(\eta+p^{\pm}\zeta)d\eta=0, \tag{7}$$

where

$$f(x+p^{\pm}\zeta)=\begin{pmatrix} f_+(x+p^{-1}\zeta) & 0_{p_+\times p_+} \\ 0_{p_-\times p_-} & f_-(x+p\zeta) \end{pmatrix},$$
$$\tau=\begin{pmatrix} 0_{p_+\times p_-} & \mathbb{I}_{p_+\times p_+} \\ \mathbb{I}_{p_-\times p_-} & 0_{p_-\times p_+} \end{pmatrix}. \tag{8}$$

On the other hand, taking into account Eq. (3) and the definition in (8) for the matrix-valued function G, get

$$\Psi(x,z)=\|\psi_-(x,z)\psi_+(x,z)\|=e^{xzJ}+\int_x^{\infty}G(x,\zeta)e^{z\zeta J}\,d\zeta.$$

Evaluating $D_x(J,z)\Psi$ in two ways, one obtains after reducing terms

$$[G(x,x)+q]e^{xzJ}+\int_x^{\infty}[zJG(x,\zeta)+qG(x.\zeta)-G_x(x,\zeta)]e^{z\zeta J}d\zeta=0.$$

Now integrating by parts $\int_x^{\infty}zJG(x,\zeta)e^{z\zeta J}\,d\zeta$ and replacing it in the above equation, write

$$[G(x,x)+q-JG(x.x)J^{-1}]+\int_x^{\infty}[qG(x.\zeta)-G_x(x,\zeta)-JG_z(x,\zeta)J^{-1}]e^{z(\zeta-z)J}\,d\zeta=0.$$

If the potential has compact support, then the integrand is in $L_1(x,\infty)$. So by the Riemann–Lebesgue Lemma the integral term goes to zero as z goes to ∞. Since the first term is independent of z, we have that both terms must vanish. Hence

$$q(x)=J^{-1}[J,G(x,x,)],\quad q(x)G(x,z)=G_x(x,z)J+JG_z(x,z). \tag{9}$$

Since the potentials of compact support are dense and G, G_x, G_z depends continuously[19] on q, the equations in (9) are valid for other potentials.

To state our next result, we denote by $\mathbf{P}$[19] the set of the matrix-valued functions q defined on the real line given by (2).

Theorem: *If the potential q is in* **P** *then the entries of the matrix f of (5) are in the Schwartz class. In addition if the coupling coefficients*[19] *associated with q are invertible and come from simple zeroes of the determinant J-diagonal entries*[12] *of the scattering matrix, the matrix-valued function G satisfies the GL integral equation system (7) and q is related to G by the formulas in (9).*

Remark: Since the entries of the matrix f in (7) are rational functions of the entries of the scattering matrix then their denominators are lower bounded.[18] So the entries of f are in the Schwartz class because of belonging scattering matrix ones to the same class

Comment: Calling a type of integral equation as that given in (7) the ''Gel'fand–Levitan–Marchenko equation'' is common in the nonlinear evolution literature, however, Gel'fand–Levitan and Marchenko integral equations are different and describe distinct problems. For details see, e.g., Ref. 20.

V. CONCLUSIONS

It is possible to approach the two block AKNS systems by a generalized GL equation integral system under the hypothesis that the coupling matrix coefficients are invertible and come from simple zeroes of the determinant of $\det a$ and $\det d$. In fact, we can relate the potential q with the solution G of the GL equation system in (7) by the formulas in (9). The case $p_+ = 1$ and $p_- = 2$ is involved with the coupled nonlinear Schrödinger equations for which Riemann–Hilbert approaches have been formulated. In general, generalized GL equations are not successfully formulated for nonlinear evolution equation systems of dimension greater that two,[21] but for present $n \times n$ AKNS systems, this is possible with a relative simpleness and by a short calculation.

(Received 2 March 1999; accepted for publication 9 April 1999)

A general discussion is given of weak limits of classical dynamical systems depending on a parameter. The resulting maps are shown to be invertible if and only if they define a group of measure preserving point transformations. The irreversible case automatically leads to positive bistochastic maps and is characterized in terms of convergence properties of the corresponding automorphisms of the observable algebra. Necessary and sufficient conditions are given for the limit to define a time-independent Markov process. Two models are discussed, for a particle in a periodic potential, and for a particle interacting with fixed configurations of external obstacles. © *1999 American Institute of Physics.* [S0022-2488(99)03208-9]

I. INTRODUCTION

Irreversible time evolution plays a major and generic role in the phenomenology of macroscopic systems. While its general description seems to be well established and understood in terms of stochastic maps and processes,[1–3] the derivation of irreversible behavior in dynamical systems usually makes reference to specific physical situations, and is under mathematical control only in special cases;[4,5] it is therefore not clear whether the mechanisms observed in such models may provide a general mathematical explanation of the origin of irreversibility on the same level as its general characterization.[6–9]

Many different structures are in fact present in models, i.e., a large (infinite) number of degrees of freedom, dynamical instabilities, restrictions on the states appearing ''at time zero,''[10–14] distinctions between ''macroscopic'' and ''microscopic'' observables, or between ''subsystem of interest'' and ''environment,''[15] moreover statistical arguments always play a critical role, starting with Boltzman's analysis.[16,12,13]

Since in all cases irreversible behavior is obtained as a limit description in the variation of some parameter, it is worthwhile to ask whether this ingredient is also sufficient, i.e., whether stochastic maps and processes *are the generic result of taking such limits*. The other ingredients can then be interpreted as characterizing specific classes of physical situations, where specific parameters and limits may play a significant physical role.

In models, the above-mentioned parameters appear in the description of the structure of the system (the number of particles in the Boltzmann–Grad case), of the states (the correlation functions at time zero), and of the dynamics (the rescaling of the particle radius); since dynamical instabilities seem to be an essential ingredient of irreversibility, it is reasonable to concentrate the attention on parameters which appear in the time evolution, leaving for the moment the system and its states invariant. Such a possibility is not even far from the situation in the Boltzmann–Grad limit since, in the spatially homogeneous case, that limit can be formulated in terms of an infinite system of hard spheres, in a fixed time zero configuration, in terms of a suitable rescaling of the radius ($r \to \lambda r$) and of the time scale ($t \to \lambda^{-2} t$ in three space dimensions).

One is therefore led to investigate limits of sequences of reversible dynamical systems. On the basis of the general interpretation of dynamical systems in terms of observables and states, the most general relevant limit is the limit for the result of measurements of fixed observables, given any state in some relevant class.

In the Hamiltonian case, observables may be identified with regular functions on the phase space, states with probability measures, and one has to take limits of mean values of observables over states evolved in time under groups of transformations defined by Hamiltonians depending on a parameter. More generally, i.e., for quantum systems and infinite systems, observables may be identified (see, e.g., Ref. 17) with the Hermitean elements of a C^* algebra, states with positive linear functionals, time evolution with a group of automorphisms of the observable algebra, and the relevant limit is the weak limit of the time evolution automorphisms, taken with respect to a subspace of the state space, interpreted as the set of states of interest.

In this form, the problem is similar to the one that appears in the framework of the algebraic formulation of quantum field theory and statistical mechanics,[17–18] in relation with the construction of the time evolution of infinite quantum systems in the presence of long-range interactions. In fact, a general analysis of limits of automorphisms arising in that context has been developed in Refs. 19–22. The relatively strong assumptions which had to be required in that analysis in order that the limit still give rise to a group of automorphisms, i.e., to a reversible dynamical system, leave open the possibility that the result of such limits may be interpreted, in some generality, in terms of irreversible time evolution.

The purpose of the present paper is to show that this is the case, and that in fact only two possibilities arise for weak limits of classical dynamical systems: either they still define groups of measure preserving transformations, or they give rise to positive ''bistochastic'' maps, and to stochastic processes if the limits exist for the results of observations at different times.

We restrict our attention in this paper to classical dynamical systems, under assumptions which typically hold for Hamiltonian models with a finite number of degrees of freedom. Our discussion covers the (realistic) case of noncompact phase space, with infinite invariant measure. In the case of a *finite* invariant measure, part of the results of Proposition 1 has been derived, in a rather different context, by Brown,[23] together with a density result which implies that, under suitable restrictions on the structure of the measure, *all* bistochastic maps arise as a weak limit of measure preserving invertible transformations. We also discuss the implications of the group structure in the time parameter, which is preserved if and only if the limit maps are invertible, the necessity of dynamical instability for an irreversible limit, and show that stochastic processes arise in general from taking weak limits at different times, providing a characterization of the Markov case.

In Sec. II we make our framework more precise and give the main results; Sec. III contains the proofs; in Sec. IV two models are discussed, the first exhibiting the role of weak limits in simple Hamiltonian systems, the second bearing some similarity to the Lorentz gas. In both cases, stochastic maps are obtained in explicit form, as weak limits of strictly deterministic and reversible dynamical systems, reproducing the general structures discussed in Sec. II; for the second model the result defines a time-independent Markov process.

II. ASSUMPTIONS AND RESULTS

We consider classical dynamical systems, defined as in Ref. 24 by groups of continuous transformations Γ_t, $t \in \mathbb{R}$ of a locally compact Hausdorff topological space X. We will discuss continuous transformations Γ_n^t depending on a parameter $n \in \mathbb{N}$, and their limits as $n \to \infty$.

The observables of the system are identified with the C^* algebra of the continuous functions on X vanishing at infinity, $C^0(X)$, i.e., the completion, in the sup norm, of $C_0^0(X)$, the space of continuous functions of compact support. The transformations Γ_n^t define as usual groups of automorphism α_n^t of $C^0(X)$, $\alpha_n^t f(x) = f(\Gamma_n^t(x))$.

Conversely, by Gelfand's isomorphism,[25] any group of automorphisms of a commutative C^* algebra defines a group of continuous transformation of its spectrum, a locally compact Hausdorff space (the set of multiplicative linear functionals being clearly left invariant by the transpose of an automorphism).

The states of the system are the positive normalized linear functional ω on $C^0(X)$, i.e., by the Riesz–Markov theorem, the regular Borel probability measures on X.

The only restrictions on α_n^t that we will assume are the existence of a common invariant measure, and a condition which keeps the time evolution ''far from infinity'' uniformly in n; more specifically, we will assume:

(M) a σ finite regular Borel measure μ is defined on X, and left invariant by all Γ_n^t, $n \in \mathbb{N}$;

(F) for all real t and compact set $K \subset X$ there is a compact set $M(K,t) \subset X$ such that

$$\Gamma_n^t(K) \subset M(K,t), \qquad \forall n \in \mathbb{N}.$$

Given the invariant measure μ, a distinguished class of states is given by the set of probability measures ν which are continuous with respect to μ: $\nu(x) = h(x)\mu(x)$, $h(x) \in L^1(X,d\mu)$. The set $\mathcal{F}$ of such states, which will be called ''regular,'' is the positive part of a closed subspace of the dual of $C^0(X)$, and defines a ''full folium'' of states in the sense of Ref. 26. Regular states will be identified in the following with functions in $L^1(X,d\mu)$.

The invariance of $d\mu$ implies that $\mathcal{F}$ is left invariant by the transpose α_n^{t*} of α_n^t, defined by $\alpha_n^{t*}\omega(f) = \omega(\alpha_n^t f)$. It also implies that time evolution can be formulated ''a la Koopman''[27] in $L^2(X,d\mu)$: $\forall g \in L^1 \cap L^2$, $U_n^t g$ is defined by $\alpha_n^{t*} g$, and extends by continuity to a unitary group in $L^2(X,d\mu)$.

The above general structure covers in particular the case of Hamiltonian systems, for which X is the phase space, Γ^t the Hamiltonian time evolution, $d\mu$ the (infinite) Liouville measure, and the regular states are the probability measures on the phase space with well-defined (L^1) density.

We do not assume that $d\mu$ is a finite measure; in fact, even in the Hamiltonian case, a sequence of groups of transformations does not in general leave invariant a common compact subspace, and there is no common invariant finite measure. For the same reason, X is assumed to be only locally compact.

Continuity of Γ_n^t is assumed only for simplicity [it allows for a discussion in terms of $C^0(X)$]. Propositions 1–5 still hold, with minor changes in the proofs, for groups Γ_n^t of *measurable* transformations; in this case, $\alpha_n^t(f) \equiv f(\Gamma_n^t(x))$ obviously define automorphisms of $L^\infty(X,d\mu)$.

The advantage of the above formulation is to make explicit the role of the observables and of the states of the system, so that the discussion of the limit $n \to \infty$ can be done with a clear physical interpretation.

The existence of a *limit description* of the dynamical systems (X,Γ_n^t) as $n \to \infty$, given a time zero state ω, amounts in fact to convergence of all the mean values $\omega(\alpha_n^t f)$, $f \in C^0(X)$. As we will see (Proposition 1), this is also equivalent to convergence of $\omega(\alpha_n^t \chi)$, for all characteristic functions χ of μ measurable subsets of X, i.e., convergence of the frequence of answers for all yes–no experiments based on μ measurable subsets of X, given the state ω.

Since we will admit as time zero states all regular states, we will investigate the limit of α_n^t in the weak topology $\tau_{\mathcal{F}}$ defined by $\mathcal{F}$ on $C^0(X)$. $\tau_{\mathcal{F}}$ can also be described as the ultraweak topology[28] associated with the representation of $C^0(X)$ as multiplication operators in $L^2(X,d\mu)$, and the $\tau_{\mathcal{F}}$ closure of $C^0(X)$ can be identified with $L^\infty(X,d\mu)$.

In the following, we will also use the strong and ultrastrong topologies defined on $C^0(X)$ and $L^\infty(X,d\mu)$ by the same representation; for bounded sequences f_n, the strong and ultrastrong topology coincide, and f_n converge to f iff

$$\int |f_n(x) - f(x)|^2 h(x) d\mu(x) \to 0, \quad \forall h(x) \in L^1(X,d\mu).$$

We will assume that the $\tau_{\mathcal{F}}$ weak limit of α_n^t exists for all t, and investigate under which condition it can be interpreted as an irreversible time evolution. More detailed results, which do not assume convergence for all times, are given in Ref. 29. The following result holds for any $\tau_{\mathcal{F}}$ convergent sequence of automorphisms of $C^0(X)$:

Proposition 1: If a sequence of automorphisms α_n^t of $C^0(X)$, satisfying M, converges in the weak topology $\tau_{\mathcal{F}}$, for all $t\in\mathbb{R}$, then

(i) the limit defines $\tau_{\mathcal{F}}$ continuous linear positive maps α^t of $C^0(X)$ into $L^\infty(X,d\mu)$, with norm at most one;

(ii) the transpose α^{t*} of α^t leaves $\mathcal{F}$ invariant;

(iii) α^t extends by continuity to a linear positive mapping of all $L^\infty(X,d\mu)$ into itself.

(iv) $\alpha^{t*}=\alpha^{-t}$ on $L^1\cap L^\infty$;

(v) $\forall p\in[1,\infty)$, $\forall h\in L^p\cap L^1$, $\|\alpha^{t*}h\|_p\leqslant\|h\|_p$.

If the sequence α_n^t also satisfies property F, then

(vi) α^{t*} preserve the L^1 norm on $(L^1\cap L^\infty)^+$, and α^t leaves the identity invariant;

(vii) the $\tau_{\mathcal{F}}$ continuous extension of α_n^t to $L^\infty(X,d\mu)$ also converges $\tau_{\mathcal{F}}$ for $n\to\infty$ to α^t on L^∞.

Positive maps are well-known candidates for the description of irreversible evolution. Moreover, property (vi) characterizes *bistochastic* maps, and it is generally assumed as fundamental[2,3] for an axiomatic description of irreversible processes.

Proposition 1 is however compatible with limits still defining groups of automorphisms of $L^\infty(X,d\mu)$. In order to characterize the irreversible case, one must ask whether the mapping α^t are invertible, and whether the group law $\alpha^t\alpha^s=\alpha^{t+s}$ is satisfied. *A priori*, as candidates for the description of irreversible time evolution arising in the above limit we have therefore:

(i) failure of the group law for α^t,

(ii) failure of invertibility of α^t.

It is also clear that

(iii) failure of the morphism property of α^t

gives a relevant notion of irreversible behavior. In fact, the transpose α^{t*} of a linear positive map α^t of any Abelian C^* algebra, with invariant identity, sends pure states into pure states if and only if α^t is a morphism, as is easily seen by using the Gelfand construction. Property (iii) therefore has, in general, the interpretation of a loss of information on the system, corresponding to a transformation of pure into mixed states. More concretely, a linear bounded transformation of $L^\infty(X,d\mu)$ is a morphism iff it maps characteristic functions of measurable sets into themselves, i.e., iff all yes–no questions are transformed into yes–no questions, equivalently, no information is lost in the time evolution.

Moreover, in the same generality, both *(ii)* and *(iii)* imply *(i)*. Only *(iii)* ⇒ *(i)* is in fact nontrivial, and follows from the fact that if the α^t satisfies the group law, then α^{-t} inverts α^t and is a positive map, so that α^{-t*} sends mixed states into mixed states, and therefore invertibility implies that α^{t*} sends pure states into pure states.

The following Proposition shows that in the present framework the notions (i)–(iii) coincide, so that *there is a unique notion of irreversibility for weak limits of classical dynamical systems*; it also provides necessary and sufficient conditions for the appearance of irreversibility.

Proposition 2: The following properties are equivalent for the weak limit α^t of a sequence of automorphisms α_n^t of $C^0(X)$, satisfying M:

(i) $\forall t\in\mathbb{R}$, α^t is an automorphism of $L^\infty(X,d\mu)$;

(ii) α^t, $t\in\mathbb{R}$, is a one parameter group of automorphisms of $L^\infty(X,d\mu)$;

(iii) $\forall t\in\mathbb{R}$, α_n^t converges in the ultrastrong topology associated to the representation of $C^0(X)$ as multiplication operators in $L^2(X,d\mu)$, and $\alpha^t(1)=1$.

(iv) For some $p\in(1,\infty)$ $\alpha^t:C_0^0(X)\mapsto L^\infty(X,d\mu)$ preserves the L^p norm, for all t,

$$\|\alpha^t f\|_p=\|f\|_p \quad \forall f\in C_0^0\,(X),\quad t\in\mathbb{R}.$$

(v) For some $p\in(1,\infty)$ α^{t*} preserves the L^p norm, for all t:

$$\|\alpha^{t*}h\|_p=\|h\|_p \quad \forall h\in L^1\cap L^p,\quad t\in\mathbb{R}.$$

(vi) For all $p\in[1,\infty]$, for all t, α^{t*} preserves the L^p norm.

Similar results hold for the convergence of the unitary group U_n^t which implement the time evolution in $L^2(X,d\mu)$:

Proposition 3: Assuming M, weak $\tau_{\mathcal{F}}$ convergence of α_n^t is equivalent to convergence of U_n^t in the weak operator topology in $L^2(X,d\mu)$. Assuming convergence and denoting by U^t the weak limit of U_n^t, conditions (i)–(vi) of Proposition 2 are equivalent to each of the following:

(i) $\forall t \in \mathbb{R}$ the operators U_n^t converge strongly in $L^2(X,d\mu)$;

(ii) $\forall t \in \mathbb{R}$ the operators U^t are unitary.

(iii) The operators U^t form a one-parameter unitary group.

The following result shows that dynamical instabilities growing with n (at fixed time) are necessary for irreversible behavior to take place in the limit $n \to \infty$:

Proposition 4: Assume that X is a metric space, with distance $d(x,y)$, and that the maps Γ_n^t, satisfying M and F, are stable, at fixed time, uniformly in n, except possibly on ''locally small subsets''; i.e., assume: $\forall$ compact $K \subset X$, $\epsilon > 0$, $t \in \mathbb{R}$, $\exists M(K,\epsilon,t) \in \mathbb{R}$ such that

$$d(\Gamma_n^t(x),\Gamma_n^t(y)) < M d(x,y) \quad \forall n \in \mathbb{N}, \quad \forall x,y \in K \backslash S,$$

$S = S(K,\epsilon,t)$ an open subset of K of μ measure smaller than ϵ.
Then, if the sequence α_n^t converges in the weak $\tau_{\mathcal{F}}$ topology, it also converges strongly and α^t is a group of automorphisms of $L^\infty(X,d\mu)$.

In general, the map α^t has an immediate probabilistic interpretation: Given any state $h \in L^1(X,d\mu)$ and denoting by χ_B the characteristic function of a Borel set $B \subset X$, the mean value

$$\int h(x) \alpha^t \chi_B(x) \, d\mu(x)$$

gives by definition the probability that a point distributed with $h(x) d\mu(x)$ at time 0 ends in B at time *t*. $\alpha^t \chi_B(x)$ is therefore interpreted as a probability $P_t(x,B)$ that a point starting at x at time 0 falls in B at time *t*.

Since $\alpha^t \chi_B$ is the characteristic function of a measurable set for all B if and only if α^t is an automorphism of $L^\infty(X,d\mu)$ (see Proposition 2), $P_t(x,B)$ takes values in $\{0, 1\}$ ($d\mu$ almost every) if and only if there is no irreversibility.

The situation is therefore very close to that of a stochastic process, and an examination of limits at different times is of interest. Consider in fact finite sequences of measurements at different times, $t_1 \cdots t_k$, of observables $f_1 \cdots f_k$, and assume that, given a regular state $\omega \in \mathcal{F}$, the mean values

$$\omega(\alpha_n^{t_1} f_1 \cdots \alpha_n^{t_k} f_k)$$

converge for $n \to \infty$.

The following Proposition shows that, if such a limit exists, it defines a stochastic process, i.e., a measure $d\rho_\omega(x(t))$ on trajectories in X, and gives necessary and sufficient condition for the process to be Markov.

Proposition 5: Let α_n^t satisfy M and F and converge weakly for $n \to \infty$; assume that for a fixed $\omega \in \mathcal{F}$, and for all finite sequences $f_1 \cdots f_k \in C^0(X)$ and $0 \leq t_1 < t_2 < \ldots < t_k \in \mathbb{R}$

$$\omega(\alpha_n^{t_1} f_1 \cdots \alpha_n^{t_k} f_k)$$

converge for $n \to \infty$.
Then, there exists a unique regular Borel probability measure $d\rho_\omega$ on $\Pi_{t \in \mathbb{R}^+} \dot{X}_t$, $\dot{X}$ the one point compactification of X, such that

$$\lim_n \omega(\alpha_n^{t_1} f_1 \cdots \alpha_n^{t_k} f_k) = \int d\rho_\omega(x(t)) \, f_1(x(t_1)) \cdots f_k(x(t_k)).$$

For $\omega(x)$ of compact support K, the measure $d\rho_\omega$ is supported on a product of compact sets K_t, $t>0$.
The process defined by $d\rho_\omega$ is Markov, with time-independent transition function $P_t(x,B) = \alpha^t \chi_B(x)$, if

$$\lim_n \omega(\alpha_n^{t_1} f_1 \cdots \alpha_n^{t_k} f_k) = \lim_{n_k} \cdots \lim_{n_2} \lim_{n_1} \omega(\alpha_{n_1}^{t_1}(f_1 \alpha_{n_2}^{t_2-t_1}(\cdots(f_{k-1}\alpha_{n_k}^{t_k-t_{k-1}} f_k)\cdots))).$$

This condition is also necessary for the time-independent Markov property if $\omega(x)$ is almost everywhere different from zero.

III. PROOFS

Identifying states ω in $\mathcal{F}$ with representative function h in $L^1(X,d\mu)$, we will write $\alpha_n^{t*}h$ for the representative of $\alpha_n^{t*}\omega$. The norm of the dual $C^0(X)^*$ of $C^0(X)$ coincides on $\mathcal{F}$ with the $L^1(X,d\mu)$ norm. Since $d\mu$ is sigma finite, the continuous functions with compact support are dense in $L^1(X,d\mu)$; $L^1 \cap C^0$ is therefore dense in $L^1 = \mathcal{F}$.

By weak and strong $\tau_{\mathcal{F}}$ topology we will denote, respectively, the weak topology defined on $C^0(X)$ by the linear functionals in $\mathcal{F}$ and the ultrastrong topology defined as above by the representation of $C^0(X)$ in $L^2(X,d\mu)$, identical to the strong topology for bounded sets. By $\tau_{\mathcal{F}}$ topology and $\tau_{\mathcal{F}}$ continuity we will refer to the weak one. The following facts are preliminary:

Lemma 6: (i) $\forall t \in \mathbb{R}$, α_n^{t*} maps $\mathcal{F}$ into $\mathcal{F}$ and

$$\alpha_n^{t*}h(x) = h(\Gamma_n^{-t}x), \tag{3.1}$$

(ii) α_n^t is continuous in the weak (and in the strong) $\tau_{\mathcal{F}}$ topology, and extends therefore by continuity to an automorphism of the Von Neumann algebra $L^\infty(X,d\mu)$;

(iii) $\forall f \in L^1 \cap L^\infty$ $\alpha_n^{t*} f = \alpha_n^{-t} f$;

(iv) $\forall p \in [1,\infty]$, $\forall f \in L^1 \cap L^p \|\alpha_n^{t*}f\|_p = \|f\|_p$.

Proof. Equation (3.1) follows immediately from the invariance of $d\mu$: $\forall h \in L^1(X,d\mu)$, $h(\Gamma_n^t x) \in L^1(X,d\mu)$ and

$$\int h(\Gamma_n^{-t}x) f(x)\, d\mu = \int h(x) f(\Gamma_n^t x)\, d\mu = \int h(x) \alpha_n^t f\, d\mu \quad \forall f \in C^0(X). \tag{3.2}$$

Invariance of $d\mu$ implies conservation of all L^p norms. Invariance of $\mathcal{F}$ implies (see, e.g., Ref. 22) weak $\tau_{\mathcal{F}}$ continuity of α_n^t, which extends by continuity to the weak closure L^∞ of $C^0(X)$.

Proof of Proposition 1: (i) For all f in $C^0(X)$, the weak $\tau_{\mathcal{F}}$ limit of $\alpha_n^t f$ defines a continuous linear functional on $L^1(X,d\mu)$, with norm bounded by $\sup|f|$, i.e., an element of $L^\infty(X,d\mu)$; the limit α^t of α_n^t therefore defines a linear map of $C^0(X)$ into $L^\infty(X,d\mu)$, of norm at most one; its transpose α^{t*} *a priori* maps $\mathcal{F}$ into $C^0(X)^*$, and is continuous in the norm of $C^0(X)^*$, denoted by $\|\cdot\|_*$: $\forall h \in L^1$,

$$\|\alpha^{t*}h\|_* = \sup_{f \in C^0(X)\, \|f\|_\infty = 1} \left|\lim_n \int h\alpha_n^t f\, d\mu\right| \leq \|h\|_1.$$

Weak $\tau_{\mathcal{F}}$ continuity of α^t is equivalent[22] to stability of $\mathcal{F}$ under α^{t*}, i.e., point *(ii);* for positivity see *(iii)* below.

(ii) Consider first states represented by functions $h \in L^1 \cap C^0$; by Lemma 1, $\alpha_n^{t*}h = \alpha_n^{-t}h$, which $\tau_{\mathcal{F}}$ converges for $n \to \infty$ to $\alpha^{-t}h$. This means that $\forall f \in C_0^0(X)$,

$$\int \alpha^{t*}h\, f\, d\mu = \lim_n \int \alpha_n^{t*}h\, f\, d\mu = \lim_n \int \alpha_n^{-t}h\, f\, d\mu = \int \alpha^{-t}h\, f\, d\mu, \tag{3.3}$$

so that

$$\alpha^{t*}h = \alpha^{-t}h \quad \forall h \in L^1 \cap C^0. \tag{3.4}$$

Moreover,

$$\|\alpha^{-t}h\|_1 = \|\alpha^{t*}h\|_1 = \|\alpha^{t*}h\|_* . \tag{3.5}$$

Equation (3.5), continuity in $C^0(X)^*$ norm of α^{t*} and density of $L^1 \cap C^0$ in $\mathcal{F}$ imply the stability of $\mathcal{F}$ under α^{t*}.

(*iii*) α^t extends by $\tau_{\mathcal{F}}$ continuity to the Von Neumann algebra L^∞. Positivity of α^t is equivalent to

$$\int h(x)\alpha^t f(x) d\mu \geqslant 0, \quad \forall f \geqslant 0, \quad f \in L^\infty, \quad h \geqslant 0, \quad h \in L^1. \tag{3.6}$$

For $f \in C^0(X)$, Eq. (3.6) follows from the positivity of the same expression with α_n^t replacing α^t, for $f \in L^\infty$, by definition of continuous extension of α^t.

(*iv*) Equation (3.5) extends to all $h \in L^1 \cap L^\infty$ since, $\forall h \in L^1 \cap L^\infty$, $f \in L^1 \cap C^0$,

$$\int \alpha^{t*}h \, f \, d\mu = \int h \alpha^t f \, d\mu = \int h \alpha^{-t*} f \, d\mu = \int \alpha^{-t} h \, f \, d\mu \tag{3.7}$$

and $L^1 \cap C^0$ is dense in $C^0(X)$;
(*v*) follows from Hölder inequality:

$$\int \alpha_n^{t*} h f \, d\mu \leqslant \|h\|_p \|f\|_q \quad \forall h \in L^1 \cap L^p, \quad f \in C^0 \cap L^q, \quad n \in \mathbb{N},$$

which implies

$$\int \alpha^{t*} h \, f \, d\mu \leqslant \|h\|_p \|f\|_q$$

so that, by density of $C^0 \cap L^q$ in L^q,

$$\|\alpha^{t*}h\|_p \leqslant \|h\|_p . \tag{3.8}$$

(*vi*) In order to prove

$$\|\alpha^{t*}h\|_1 = \|h\|_1 \quad \forall h \in L^{1+}, \tag{3.9}$$

consider first $h \in C_0^0(X)$. Denote by χ_K the characteristic function of a compact set $K \subset X$; using Lemma 1, condition F implies

$$\int \chi_K \, \alpha_n^{-t} h \, d\mu = \int \chi_K \, h \, d\mu \quad \forall n \tag{3.10}$$

if K is sufficiently large, depending only h and t. Given the support L of h, it is in fact enough to take $K \supset L$ such that $\Gamma_n^t(L) \subset K \forall n$. Using Eqs. (3.4) and (3.10) it follows

$$\int \alpha^{t*} h \, d\mu = \lim_K \int \chi_K \, \alpha^{-t} h \, d\mu = \lim_K \lim_n \int \chi_K \, \alpha_n^{-t} h \, d\mu = \lim_K \int \chi_K \, h \, d\mu = \int h \, d\mu.$$

Equation (3.9) then follows from density in L^1 of $C_0^0(X)$ and L^1 continuity of α^{t*}. Equation (3.9) also implies $\alpha^t 1 = 1$.

(vii) Using Lemma 1 and Eq. (3.4), $\forall h \in L^1 \cap L^\infty$, $f \in L^1 \cap C^0$,

$$\int \alpha_n^t h\ f\,d\mu = \int h\ \alpha_n^{t*} f\,d\mu = \int h\ \alpha_n^{-t} f\,d\mu \to \int h\ \alpha^{-t} f\,d\mu = \int h\ \alpha^{t*} f\,d\mu = \int \alpha^t h\ f\,d\mu \tag{3.11}$$

and $\tau_{\mathcal{F}}$ convergence of $\alpha_n^t h$ to $\alpha^t h$ follows from density of $L^1 \cap C^0$ in L^1 and uniform boundedness of $\alpha_n^t h$ in L^∞.

To obtain $\tau_{\mathcal{F}}$ convergence of $\alpha_n^t h$ to $\alpha^t h$ for all $h \in L^\infty$ consider a sequence $\{K_i\}$ of compact sets with χ_{K_i} converging $\tau_{\mathcal{F}}$ to 1 (it exists because μ is σ finite); then, $\forall h \in L^{\infty +}$, $\forall l \in L^{1+}$,

$$\int \alpha_n^t (h - h\chi_{K_i})\ l\ d\mu \leqslant \|h\|_\infty \int (1 - \alpha_n^t \chi_{K_i})\ l\ d\mu \tag{3.12}$$

but $\tau_{\mathcal{F}}$ convergence of α_n^t on $L^1 \cap L^\infty$, $\tau_{\mathcal{F}}$ continuity of α^t and $\alpha^t 1 = 1$ imply

$$\lim_i \lim_n \text{rhs of } (3.12) = 0;$$

on the other hand, by $\tau_{\mathcal{F}}$ continuity of α^t,

$$\lim_i \lim_n \int \alpha_n^t (h\chi_{K_i})\ l\ d\mu = \int \alpha^t h\ l\ d\mu$$

and therefore,

$$\lim_n \int \alpha_n^t h\ l\ d\mu = \int \alpha^t h\ l\ d\mu,$$

which extends by linearity to $h \in L^\infty$ and $l \in L^1$.

Proof of Proposition 2: $(vi) \Rightarrow (v)$ and $(ii) \Rightarrow (i)$ are obvious; $(iv) \Leftrightarrow (v)$ and $(i) \Rightarrow (vi)$ immediately follow from Proposition 1, (for the latter implication, see the proof of Lemma 6); it is therefore enough to prove $(v) \Rightarrow (i)$ and $(vi) \Rightarrow (iii) \Rightarrow (ii)$.

$(v) \Rightarrow (i)$: For any Borel set B of finite measure $d\mu$, $\alpha^{t*}\chi_B$ is real, non-negative, and

$$\|\alpha^{t*}\chi_B\|_\infty \leqslant \|\chi_B\|_\infty \leqslant 1,$$

so that

$$(\alpha^{t*}\chi_B)^p \leqslant \alpha^{t*}\chi_B; \tag{3.13}$$

(v) implies that for some $p \in (1,\infty)$,

$$\int (\alpha^{t*}\chi_B)^p d\mu = \int \chi_B^p\,d\mu = \int \chi_B\,d\mu \geqslant \int \alpha^{t*}\chi_B\,d\mu, \tag{3.14}$$

the last equality following from Proposition 1, *(v)*. Equations (3.13) and (3.14) imply

$$\alpha^{t*}\chi_B = (\alpha^{t*}\chi_B)^p$$

$d\mu$ almost every, so that $\alpha^{t^*}\chi_B$ is a measurable function taking values in {0, 1}, i.e., it is the characteristic function of a measurable set $B' \subset X$, and by Eqs. (3.13) and (3.14), $\mu(B') = \mu(B)$.

From linearity and the fact that L^∞ norms do not increase [Proposition 1, *(i)*], it follows that disjoint sets *B*, *C* have disjoint images B', C'; α^t, coinciding with α^{-t*} on $L^1 \cap L^\infty$, [Proposition 1, (iv)] is therefore a morphism of the algebra of simple functions based on sets of finite measure, and, by a density argument, of $L^\infty(X, d\mu)$. It also follows that α^{t*} preserves the L^1 norm on L^{1+}, which implies invertibility of α^t, actually $\alpha^{-t}\alpha^t = \alpha^t\alpha^{-t} = 1$; in fact, for all positive simple functions *f*, *g*,

$$\int f\ \alpha^{-t}\alpha^t g\, d\mu = \int \alpha^t f\ \alpha^t g\, d\mu = \int \alpha^t(fg)\ d\mu = \int f\ g\, d\mu.$$

The same holds for $\alpha^t\alpha^{-t}$, and invertibility of α^t follows by a density argument.

$(vi)\Rightarrow(iii)$: Convergence in the strong and ultrastrong topologies is equivalent for a bounded sequence,[28] and amounts to

$$\int |\alpha_n^t f - \alpha^t f|^2 h\, d\mu \to 0 \quad \forall h \in L^1(X, d\mu). \tag{3.15}$$

By a density argument, it is enough to obtain Eq. (3.15) for all f in $C_0^0(X) \subset L^1 \cap L^\infty$; in this case, $\alpha_n^t f = \alpha_n^{-t*} f$ converges to $\alpha^t f = \alpha^{-t*} f$ strongly in $L^2(X, d\mu)$, as a consequence of weak L^2 convergence and of conservation of the L^2 norms in the limit. $\alpha^t 1 = 1$ immediately follows from conservation of the L^1 norm.

$(iii)\Rightarrow(ii)$: Strong convergence implies in general that α^t is a morphism. The group property follows since for all f, g in $C_0^0(X)$,

$$\int f\ \alpha^{t+s} g\, d\mu = \lim_n \int f\ \alpha_n^t \alpha_n^s g\, d\mu = \lim_n \int \alpha_n^{-t} f\ \alpha_n^s g\, d\mu; \tag{3.16}$$

strong convergence in L^2 of $\alpha_n^{-t} f$ and $\alpha_n^s g$ imply in fact

$$\lim_n \int \alpha_n^{-t} f\ \alpha_n^s g\, d\mu = \int \alpha^{-t} f\ \alpha^s g\, d\mu = \int f\ \alpha^t \alpha^s g\, d\mu. \tag{3.17}$$

Proof of Proposition 3: The algebra $C_0^0(X)$ of continuous functions of compact support is dense in $C^0(X)$ and in $L^1(X, d\mu)$ in the respective norms. Moreover, the sequence $\alpha_n^t h$ is uniformly bounded in L^1 and in C^0. $\tau_{\mathcal{F}}$ convergence of α_n^t for all $f \in C^0$ is therefore equivalent to convergence on $C_0^0(X)$.

In the same way, since $C_0^0(X)$ is dense in L^2 and U_n^t preserves the L^2 norm, $\tau_{\mathcal{F}}$ convergence is equivalent to

$$\forall h_1,\ h_2 \in L^2 \quad \exists \lim_n \int h_1^* U_n^t h_2\, d\mu,$$

i.e., to convergence of U_n^t in the weak topology w_{op} for operators in L^2.
Denoting $U^t \equiv w_{\mathrm{op}} - \lim_n U_n^t$, $\forall h_1,\ h_2 \in C_0^0(X)$,

$$\int h_1^* U^t h_2\, d\mu = \lim_{n\to\infty} \int h_1^* \alpha_n^t h_2\, d\mu = \int h_1^* \alpha^t h_2\, d\mu, \tag{3.18}$$

which implies $U^t h = \alpha^t h$ for $h \in C_0^0(X)$ and, by L^2 continuity of both U^t and α^t (Proposition 1, v), for $h \in L^1 \cap L^\infty$. The rest of the proof of Proposition 3 is then reduced to the following simple fact: $\forall n \in \mathbb{N}$ let U_n^t be a one-parameter group of unitary operators on a Hilbert space $\mathcal{H}$, converging weakly for $n \to \infty$, $\forall t \in \mathbb{R}$, $w_{\mathrm{op}} - \lim_n U_n^t \equiv U^t$. Then the following are equivalent:
(a) $\forall t \in \mathbb{R}$, U_n^t converges strongly to U^t,
(b) $\forall t \in \mathbb{R}\ \forall h \in \mathcal{H} \|U^t h\| = \|h\|$,
(c) $\forall t \in \mathbb{R} U^t$ is unitary,
(d) U^t is a group of unitary operators.

In fact, $(a)\Leftrightarrow(b)$ is well known, and $(d)\Rightarrow(c)\Rightarrow(b)$ are trivial.
To prove $(a)\Rightarrow(d)$, we have, from Schwarz inequality,

$$\begin{aligned}|(h,(U_n^tU_n^s-U^tU^s)h)|&=|(h,(U_n^tU_n^s-U_n^tU^s+U_n^tU^s-U^tU^s)h)|\\&\leqslant|(h,U_n^t(U_n^s-U^s)h)|+|(h,(U_n^t-U^t)U^sh)|\\&\leqslant\|h\|\|(U_n^s-U^s)h\|+|(h,(U_n^t-U^t)U^sh)|,\end{aligned}$$

which implies the group property. In particular U^t is invertible, and unitarity follows since $(a)\Rightarrow(b)$.

Proof of Proposition 4: For fixed compact $K\subset X$, $\epsilon>0$, $t\in\mathbb{R}$, $f\in C_0^0(X)$ with support in K, by property F all the functions $\alpha_n^tf(x)=f(\Gamma_n^t(x))$ have support contained in a compact set K'. By assumption, there exists an open set S, of measure smaller than ϵ, such that

$$d(\Gamma_n^t(x),\Gamma_n^t(y))\;<\;M(K',\varepsilon,t)d(x,y)$$

for $x,y\in K'\backslash S$. Since f is of compact support and therefore uniformly continuous, it follows that the functions $\alpha_n^tf(x)$ are equicontinuous on $K'\backslash S$.

Since $K'\backslash S$ is closed and therefore compact, by the Ascoli–Arzelà theorem there exists a subsequence $\alpha_{n_k}^tf$ which converges there uniformly; its limit coincides, on $K'\backslash S$ with α^tf, as a consequence of weak convergence of $\alpha_n^tf(x)$ to α^tf. On compact sets, uniform convergence implies convergence in L^2; moreover, the functions $\alpha_n^tf(x)$ are bounded by $\sup|f|$, and therefore their L^2 norm coincides with the norm of their restriction to $K'\backslash S$ up to an error of order ϵ, and the same is true for $\alpha^tf(x)$; this implies

$$|\|\alpha^tf\|_{L^2}^2-\|f\|_{L^2}^2|\;\leqslant\;2\,\sup|f|^2\varepsilon\quad\forall\varepsilon>0.$$

It follows that α^t preserves the L^2 norm on $C_0^0(X)$, for all t, and therefore, by Proposition 2, (iv), it is a group of automorphisms of $L^\infty(X,d\mu)$.

Proof of Proposition 5: We will use the shorthand $\{t_j\}_{1,k}$ for $0\leqslant t_1<t_2<\cdots<t_k$, and $\{t_j\}_{1,]m[,k}$ for the same sequence without t_m; $X^{\{t_j\}_{1,k}}$ will denote the product of k copies of X, X_{t_j} the copy at time t_j; the state ω will be represented by the measure $\omega(x)d\mu$, $\omega(x)\in L^1(X,d\mu)$.

For fixed $\{t_j\}_{1,k}$, consider the algebra C^{sp} of functions $f\in C^0(X^{\{t_j\}_{1,k}})$ which are finite sums of products, i.e., $f(x_{1,k})=\Sigma_ic_if_1^i(x_1)\cdots f_k^i(x_k)$ with $f_j^i(x_j)\in C^0(X_{t_j})$. For fixed n the linear map of C^{sp} into itself

$$f(x_{1,k})\rightarrow\sum_i\;c_i\prod_{j=1}^k\;\alpha_n^{t_j}f_j^i(x_j)$$

is $\|\;\|_\infty$ preserving and extends to an automorphism of the completion $\overline{C^{sp}}$ of C^{sp} in the sup norm; in particular, it is positive.

It follows that $\rho_\omega^{\{t_j\}_{1,k}}$, defined by

$$\rho_\omega^{\{t_j\}_{1,k}}(f)\equiv\lim_n\int_X\sum_i\;c_i\prod_{j=1}^k\;\alpha_n^{t_j}\;f_j^i(x)\omega(x)\;d\mu(x)\tag{3.19}$$

is a bounded positive linear functional over C^{sp}, with $\|\rho_\omega\|\leqslant\|\omega\|$. Since by the Stone–Weierstrass theorem $\overline{C^{sp}}=C^0(X^{\{t_i\}_{1,k}})$, ρ_ω has a unique extension to C^0, with the same bound.

The functional so obtained defines, by the Riesz–Markov theorem, a finite regular Borel measure, which we indicate with $\rho_\omega^{\{t_j\}_{1,k}}$, over $X^{\{t_j\}_{1,k}}$. If X is not compact it is technically convenient to consider $\rho_\omega^{\{t_j\}_{1,k}}$ over $\dot{X}^{\{t_j\}_{1,k}}$, the product of the 1-point compactified spaces $\dot{X}_{t_j}$. However, if ω has compact support K, the construction also lives in $\Pi_{t\geqslant0}K_t$ with K_t the compact sets given by condition F, $\alpha_n^t\chi_K\leqslant\chi_{K_i}\forall n$. The measures $\rho_\omega^{\{t_j\}_{1,k}}$, for all k-tuples $0\leqslant t_1<t_2<\cdots<t_k$, define a (unique) measure over $\Pi_{t\geqslant0}\dot{X}_t$ iff they are compatible, i.e.,

$$\rho_\omega^{\{t_j\}_{1,k}}\,(f_1(x_1)\cdots f_{m-1}(x_{m-1})f_{m+1}(x_{m+1})\cdots f_k(x_k))$$
$$=\rho_\omega^{\{t_j\}_{1,]m[,k}}\,(f_1(x_1)\cdots f_{m-1}(x_{m-1})f_{m+1}(x_{m+1})\cdots f_k(x_k)).$$

Compatibility obviously holds for X compact, since then $1\in C^0(X)$, and $\alpha_n^t 1=1$. For noncompact X, compatibility follows from $\tau_{\mathcal{F}}$ continuity of α^t together with $\alpha^t 1=1$; take in fact an increasing sequence of positive functions $g_\nu\in C_0^0(X_{t_m})$ converging to 1 $d\mu$ almost everywhere. Clearly, for any positive $f_j\in C^0(X_{t_j}),\ j=1,...,k,\ j\neq m,$

$$\lim_\nu \lim_n \omega\left((1-\alpha_n^{t_m}g_\nu)\prod_j \alpha_n^{t_j}f_j\right)\leqslant \lim_\nu \lim_n \omega(1-\alpha_n^{t_m}g_\nu)\prod_j \|f_j\|_\infty . \tag{3.20}$$

By the monotone convergence theorem, $g_\nu\Pi_j f_j$ converge in $\|\ \|_{L^1(X^{\{t_j\}_{1,k}},\rho_\omega^{\{t_j\}_{1,k}})}$ to $\Pi_j f_j$, and therefore the left-hand side of Eq. (3.20) converges to

$$\rho_\omega^{\{t_j\}_{1,]m[,k}}\left(\prod_j f_j\right)-\rho_\omega^{\{t_j\}_{1,k}}\left(\prod_j f_j\right);$$

since g_ν converge in $\|\ \|_{L^1(X,\alpha^{t_m}*\omega)}$ to 1, the right-hand side converges to 0.
This implies the compatibility condition, since linear combinations of products of positive functions are dense in $C^0(X^{\{t_j\}_{1,]m[,k}})$.
From compatibility it also follows $\rho_\omega^{\{t_j\}_{1,k}}(1)=\omega(1)=1$.
For the Markov property, let us indicate by

$$p(t_1,x_1;\ldots;t_{k-1},x_{k-1}|t_k,f_k)\in L^\infty(\dot{X}^{\{t_j\}_{1,k-1}},\rho_\omega^{\{t_j\}_{1,k-1}})$$

the conditional expectations of the process, characterized by

$$\forall k\geqslant 2,\quad \forall j=1,...,k,\quad \forall f_j\in L^\infty(\dot{X}_{t_j},\rho_\omega^{t_j})$$

$$\int f_1(x_1)\cdots f_k(x_k)d\rho_\omega^{\{t_j\}_{1,k}}=\int f_1(x_1)\ \cdots\ f_{k-1}(x_{k-1})\ p(t_1,x_1;\ldots;t_{k-1},x_{k-1}|t_k,f_k)\ d\rho_\omega^{\{t_j\}_{1,k-1}}.$$

The process is Markov iff

$$p(t_1,x_1;\ldots;t_{k-1},x_{k-1}|t_k,f_k)=p(t_{k-1},x_{k-1}|t_k,f_k)$$

and it is also time independent iff

$$p(t_1,x_1|t_2,f_2)=p(0,x_1|(t_2-t_1)f_2).$$

Hence, for a time-independent Markov process, by iteration we obtain

$$\int f_1(x_1)\ \cdots\ f_k(x_k)\ d\rho_\omega^{\{t_j\}_{1,k}}$$
$$=\int p(0,x_0|t_1,f_1p(0,\cdot|t_2-t_1,f_2\ \cdots\ f_{k-1}p(0,\cdot|t_k-t_{k-1},f_k)\cdots))\omega(x_0)d\mu. \tag{3.21}$$

Notice now that, since the α_n^t are automorphisms,

$$\lim_{n_k} \cdots \lim_{n_2} \lim_{n_1} \omega\ (\alpha_{n_1}^{t_1} f_1 \cdots \alpha_{n_k}^{t_k} f_k) = \lim_{n_k} \cdots \lim_{n_2} \lim_{n_1} \omega\ (\alpha_{n_1}^{t_1}\ (f_1 \alpha_{n_2}^{t_2 - t_1}(\cdots(f_{k-1} \alpha_{n_k}^{t_k - t_{k-1}} f_k)\cdots))) \tag{3.22}$$

which, by definition and continuity of α^t, converges to

$$\omega(\alpha^{t_1}(f_1 \alpha^{t_2 - t_1}\ (\cdots\ (f_{k-1} \alpha^{t_k - t_{k-1}} f_k)\ \cdots))). \tag{3.23}$$

So, if the limit (3.19) coincides with (3.22), then the stochastic process ρ is Markov and time independent, with $p(0,x|t,f) = \alpha^t f(x)$.

The converse follows if $\omega(x)$ only vanishes on a set of zero measure; in fact, for $\omega(x) \neq 0$, $p(0,x|t,f) = \alpha^t f(x)$, and therefore, if the process is time-independent Markov, i.e., if (3.21) holds, then it is also given by the limit (3.22) and (3.23).

IV. MODELS

We consider two models for the general structures and results of Sec. II. For both models, we will prove weak convergence to positive maps, and for the second model the limit will be shown to define a time-independent Markov process.

The first model is a Hamiltonian system with one degree of freedom, namely a particle in a periodic potential, which is scaled so that its period converges to zero. The phase space is $\mathbb{R}^2$, with canonical variables p, q; the dynamics is defined by the Hamiltonian

$$H_n \equiv p^2/\ 2m + V(nq), \tag{4.1}$$

with $V(q) = V(q+1) \in C^2(\mathbb{R}^2)$, and $dV/dq = 0$ only for a finite number of points.

We will consider the maps defined on $\mathbb{R}^2$ by the solutions $p_t^{(n)}(p,q)$, $q_t^{(n)}(p,q)$ of the Hamiltonian equations of motion, with Hamiltonians (4.1) and initial conditions p, q, and denote by α_n^t the corresponding map on $C^0(\mathbb{R}^2)$, the space of continuous functions vanishing at infinity,

$$\alpha_n^t f(p,q) \equiv f(p_t^{(n)}(p,q), q_t^{(n)}(p,q)). \tag{4.2}$$

For $n = 1$, we denote

$$p_t(p,q) \equiv p_t^{(1)}(p,q), \quad q_t(p,q) \equiv q_t^{(1)}(p,q).$$

From the properties of $V(q)$ it follows that $p_t(p,q)$ and $q_t(p,q)$ mod $\mathbb{Z}$ are periodic in q, with period 1, and in t, with period $T(p,q)$ differentiable and periodic in q, for fixed p, except for q mod $\mathbb{Z}$ in a finite set $\{q_{i,\infty}(p)\}$.

We will assume nondegeneracy, i.e., for all p, $\partial/\partial q T(p,q) \neq 0$, except for a finite number of points $q_{i,0}(p)$ (in [0, 1)). It follows that, $\forall p \in \mathbb{R}$, $\forall \delta > 0$,

$$T(p,q)\ \leqslant\ 1/\delta, \quad |\partial/\partial q T(p,q)|\ \geqslant\ \delta \quad \forall q \in [0,1] \backslash I_\delta(p), \tag{4.3}$$

with $I_\delta(p)$ the union of a finite number of intervals, with total length converging to zero for $\delta \to 0$, and $\cap_\delta I_\delta(p) = \{q_{i,0}(p), q_{i,\infty}(p)\}$.

Proposition 7: Under the above assumptions, the automorphisms α_n^t*, Eq. (4.2), converge for all* $t \in \mathbb{R}$*, in the weak topology defined by Lebesgue absolutely continuous finite measures in* $\mathbb{R}^2$*, to positive bistochastic maps* α^t*, given by*

$$\alpha^t f(p,q) = \int_0^1 dx\ 1/T(p,x) \int_0^{T(p,x)} d\tau\ f(p_\tau(p,x), Q_t(p,x) + q) \tag{4.4}$$

with

$$Q_t(p,x)\ = \lim_{n\to\infty} 1/n\ q_{nt}(p,x)\ \equiv\ \beta(p,x)t. \tag{4.5}$$

The limit (4.5) exists pointwise for all p, x, and it is uniform, at fixed p, for $x \in [0,1] \backslash I_\delta(p)$, $\forall \delta > 0$.

Proof: It is easy to see that

$$p_t^{(n)}(p,q) = p_{nt}(p,nq), \quad q_t^{(n)}(p,q) = 1/n \; q_{nt}(p,nq). \tag{4.6}$$

It is enough to prove weak convergence of

$$\alpha_n^t f(p,q) = f(p_{nt}(p,nq), 1/n \, q_{nt}(p,nq)) \tag{4.7}$$

for f in $\mathcal{D}$, the space of C^∞ functions of compact support.
We introduce the convolutions

$$f_{k,n}^t(p,q) \equiv \int ds \, h_k(q-s) \; \alpha_n^t f(p,s), \tag{4.8}$$

with

$$0 \leqslant h_k \in \mathcal{D}, \quad \mathrm{Supp}(h_k) \subset [-1/k, 1/k], \quad \int h_k(s) ds = 1.$$

We will show that

$$\lim_k \lim_n f_{k,n}^t(p,q) \tag{4.9}$$

exists pointwise almost everywhere, and it is given by the right-hand side of Eq. (4.4).
Existence of the limit $n \to \infty$ in Eq. (4.9) implies convergence, for $n \to \infty$, of

$$\int dp \, ds \left(\int d \; q g(p,q) \; h_k(q-s) \right) \alpha_n^t f(p,s) \tag{4.10}$$

$\forall g \in \mathcal{D}$, i.e., weak convergence of $\alpha_n^t f$ with respect to a dense subspace of $L^1(\mathbb{R}^2)$ and therefore, by uniform boundedness of $\alpha_n^t f$, weak convergence. The weak limit is identified by the value taken on it by the measures with density in $\mathcal{D}$, and therefore by the limit, $k \to \infty$, of Eq. (4.10), which is given by the pointwise limit (4.9), $f_{k,n}^t$ being uniformly bounded.

In order to control the limit (4.9), for fixed $p \in \mathbb{R}$ and $h \in \mathcal{D}$, we use the periodicity properties of p_t, q_t,

$$p_t(p,q+n) = p_t(p,q), \quad q_t(p,q+n) = q_t(p,q) + n \quad \forall n \in \mathbb{Z} \tag{4.11}$$

to estimate, denoting $x(s) \equiv ns - [ns]$, $[\;]$ the integer part,

$$\begin{aligned} &\int ds \, h_k(q-s) f(p_{nt}(p,ns), 1/n \, q_{nt}(p,ns)) \\ &\quad = \int ds \, h_k(q-s) \; f(p_{nt}(p,x(s)), 1/n \; (q_{nt}(p,x(s)) + [ns])) \\ &\quad \simeq \int_0^1 dx \, f(p_{nt}(p,x), 1/n \, q_{nt}(p,x) + q), \end{aligned} \tag{4.12}$$

with an error bounded by $\epsilon_k + C(k)\epsilon_n$, ϵ_i denoting, here and in the following, a suitable infinitesimal sequence.

Periodicity in t of $q_t(p,q)$ mod $\mathbb{Z}$, more precisely, for $x \notin \{q_{i,\infty}(p)\}$,

$$q_{t+T(p,x)}(p,x) = q_t(p,x) + \sigma(p,x) \tag{4.13}$$

with

$$\sigma(p,x)=\pm 1 \quad \text{if } H(p,x) > \max V(q)$$

and otherwise vanishing, implies pointwise convergence of $1/n\, q_{nt}(p,x)$, uniform in $[0,1]\backslash I_\delta(p)$, $\forall \delta>0$, to

$$Q_t(p,x) \equiv \sigma(p,x)\ t/T(p,x). \tag{4.14}$$

Since $T(p,x)\to\infty$ for $x\to q_{i,\infty}(p)$, $Q_t(p,x)$ is continuous in x, at fixed p.
It follows that the right-hand side of Eq. (4.12) can be estimated as

$$\int_0^1 dx\, f(p_{nt}(p,x),\ Q_t(p,x)+q) \tag{4.15}$$

apart from an error ϵ_n.

By extending $Q_t(p,x)$ to a (continuous) periodic function of $x\in\mathbb{R}$, of period 1, the right-hand side of Eq. (4.15) can be written, with h_j as before,

$$\int_0^1 dx \int dy\, h_j(x-y)\ f(p_{nt}(p,y),Q_t(p,y)+q) \simeq \int_0^1 dx \int dy\, h_j(x-y)\ f(p_{nt}(p,y),Q_t(p,x)+q) \tag{4.16}$$

with an error ϵ_j.

By periodicity in time, $p_{nt}(p,y)=p_{\tau_n(p,y)}(p,y)$, with

$$\tau_n(p,y) \equiv nt \bmod T(p,y). \tag{4.17}$$

By continuity in x, uniform for t bounded, of $p_t(p,x)$, $p_{\tau_n(p,y)}(p,y)$ can be replaced, with an error $C(\delta)\epsilon_j$, by $p_{\tau_n(p,y)}(p,x)$, for $y\in[0,1]\backslash I_\delta(p)$, $\forall\delta>0$. Since $I_\delta(p)$ is the union of a finite number of intervals, restricting x to $[0,1]\backslash I_{\delta/2}(p)$ implies that, for large j, the domain of integration in y is contained in $[0,1]\backslash I_\delta(p)$; replacing in the right-hand side of (4.16) $p_{nt}(p,y)$ with $p_{\tau_n(p,y)}(p,x)$ therefore gives an error $\epsilon(\delta)+C(\delta)\epsilon_j$. Moreover, $\tau_n(p,y)$ is differentiable in y, apart from a finite number of points, with derivative

$$-[nt/T(p,y)]\ \partial/\partial y T(p,y)$$

large in modulus, uniformly in $y\in[0,1]\backslash I_\delta(p)$, $\forall\delta>0$. It follows that integration in y (in $[x-j^{-1},x+j^{-1})$ in the right-hand side of Eq. (4.16) can be replaced by a mean in τ, with an error $\epsilon_j+C(j,\delta)\epsilon_n+\epsilon(\delta)$; the result is then the right-hand side of Eq. (4.4).

From the fact that the sum of the errors made in the above estimates can be written as $\epsilon_k+C(\delta)\epsilon_j+(C(k)+C(j,\delta)\epsilon_n+\epsilon(\delta))$, it follows that the limit (4.9) exists and is given by the right-hand side of Eq. (4.4). ■

The second model is defined by a particle moving horizontally in $\mathbb{R}^2$ with speed 1, and interacting with fixed vertical ''rods,'' of equal height; the interaction is assumed only to change of the ''spin'' of the particle, taking values ± 1.

The space X of the configurations of the system is thus $\mathbb{R}^2\times\{-1,1\}$, on which we take the measure $\mu=d^2\mathbf{x}\otimes d\sigma$, with $\sigma(\{1\})=\sigma(\{-1\})=1$. As space of states we will take $L^1(\mathbb{R}^2\times\{-1,1\},\mu)$, i.e., the set of states defined by measures space which are absolutely continuous with respect to the Lebesgue measure. The dynamics will depend on a parameter n through a suitable scaling of the positions and of the height of the rods *in one given and fixed configuration* in a set to be specified in the following.

In general, a configuration ξ of rods is determined by their height h and by the set of their centers, $\xi\equiv\cup_{i\in\mathbb{N}}\{(x_i,y_i)\}$; we will consider only configurations with a finite number of rods in any compact subset of $\mathbb{R}^2$, and denote by Ξ the set of all such configurations. For fixed $\xi \in \Xi$, and $h > 0$, we will study the limit $n \to \infty$ of the dynamics α_n^t defined by the interaction with rods of height $n^{-2}h$ in the scaled configuration $n^{-1}\xi \equiv \cup_{i \in \mathbb{N}} \{(n^{-1}x_i, n^{-1}y_i)\}$. The limit will be taken in the weak topology defined by the state space $\mathcal{F} \equiv L^1(\mathbb{R}^2 \times \{-1,1\}, \mu)$. We will prove the following:

Proposition 8: Let $n_k \to \infty$, with $\Sigma 1/n_k < \infty$. For any denumerable set of positive times, for almost all choices of the configuration ξ with respect to the independent Poisson distribution (the measure ρ defined below), the dynamical systems defined as above by the configuration ξ converge weakly, for $k \to \infty$, with respect to the set $\mathcal{F}$ of states, to positive maps, and define, as in Proposition 5, a time-independent Markov process.

It is of course essential that *no integration* is performed over ρ; performing such an integration would in fact amount to *assuming* a stochastic process, indexed by the sample space of the distribution of the obstacles. On the contrary, Proposition 7 *implies* that *the same* stochastic process correctly describes the *result of all measurements, in the limit $n \to \infty$*, for ρ almost all *fixed* configurations of obstacles. The model is therefore relevant in order to clarify the basis for the use of stochastic maps and processes for the description of perfectly reversible dynamical systems, and it is worthwhile to control it with all mathematical details.

For completeness, we recall the construction of the probability measure ρ corresponding to the independent Poisson distribution of points in a plane, with unit mean density: following Ref. 30, Sec. 7.1.2, one considers the family of measures on Λ^j,

$$d\rho_\Lambda^j \equiv \frac{e^{-|\Lambda|}}{j!} \, d\mathbf{x}_1 \cdots d\mathbf{x}_j \tag{4.18}$$

with $j \in \mathbb{N}$ and Λ bounded Borel $\subset \mathbb{R}^2$; they define a positive linear functional

$$\rho(f) \equiv \sum_{j=0}^{\infty} \frac{e^{-|\Lambda|}}{j!} \int_{\Lambda^j} d\mathbf{x}_1 \cdots d\mathbf{x}_j \, f(\xi), \tag{4.19}$$

where $f: \Xi \to \mathbb{C}$ depends only on the points, $\mathbf{x}_1 \ldots \mathbf{x}_j$, of ξ inside Λ, over a suitable algebra $\mathcal{B}$ of functions on Ξ. The spectrum $\mathcal{E}$ of the $\| \|_\infty$ closure of $\mathcal{B}$ turns out be the $* - w$ closure of Ξ (the $*$ weak topology being the weakest one which makes the weak topology being the weakest one which makes the functions in $\mathcal{B}$ continuous). By the Riesz–Markov theorem, the positive functional ρ defines a Borel regular measure on $\mathcal{E}$, denoted again by ρ, and it is not difficult to see that ρ is in fact concentrated on Ξ, i.e., $\rho(\Xi) = \rho(\mathcal{E}) = 1$.[29] For functions depending only on a finite number of points, integration with the measure ρ is simply given by Eq. (4.19).

Proof of Proposition 8: The time evolution is given by

$$\Gamma_n^t(x,y,\sigma) \equiv (x+t,y,\sigma \cdot (-1)^{|n^{-1}\xi \cap B_{\mathbf{x},t,n^{-2}h}|}) = (x+t,y,\sigma \cdot (-1)^{|(\xi \cap B_{n\mathbf{x},nt,n^{-1}h}|}, \tag{4.20}$$

$|I|$ being the number of points in the finite set I, $\mathbf{x} \equiv (x,y)$, and

$$B_{\mathbf{x},t,h} \equiv \{(\alpha,\beta) \in \mathbb{R}^2 | \beta \in [y-h/2, y+h/2),$$

$$\alpha \in [x, x+t) \quad \text{for } t>0, \quad \alpha \in [x+t, x) \quad \text{for } t<0\}.$$

For the observables we have therefore:

$$\forall f \in C^0(X), \quad \alpha_n^t \, f(x,y,\sigma) = f(x+t,y,\sigma \cdot (-1)^{|\xi \cap B_{n\mathbf{x},nt,n^{-1}h}|}). \tag{4.21}$$

Clearly, μ is left invariant by the Γ_n^t, for all n and t. The lack of continuity of the maps Γ_n^t (a consequence of the discreteness of the ''spin'' variable) is not a problem since, as already remarked, measurability of Γ_n^t is enough for all the results of Sec. II. Here, α_n^t maps C^0 into $L^1 \cap L^\infty$, and defines automorphisms of the closure of this space, with the Sup norm.

We denote by $g_{\pm 1,\mathbf{x},t,h}(\xi)$ the characteristic functions of the sets

$$\left\{ \mathbf{x}\in\mathbb{R}^2 : |\xi\cap B_{\mathbf{x},t,h}| \text{ is } \begin{matrix}\text{even}\\ \text{odd}\end{matrix}\right\}.$$

From Eq. (4.21), using the density of the finite linear combinations of the characteristic functions of bounded Borel subsets of $\mathbb{R}^2$ in $L^1(\mathbb{R}^2,d^2\mathbf{x})$, it follows that the existence of the weak limit for α_n^t,

$$\forall f\in C^0(X), \quad \forall l\in L^1(X,d\mu) \quad \lim_n \int l\ \alpha_n^t f\, d\mu \equiv \int l\ \alpha^t f\, d\mu$$

is equivalent to the existence of the limit

$$\lim_n \int \chi_B(\mathbf{x})\ g_{\sigma,n\mathbf{x},nt,n^{-1}h}(\xi)\ d^2\mathbf{x}. \tag{4.22}$$

$\forall B$ bounded Borel subset of $\mathbb{R}^2$, and $\sigma=\pm 1$.

Moreover, calling $G_{\sigma,\mathbf{x},t,h}(\xi)$ the weak limit of $g_{\sigma,n\mathbf{x},nt,n^{-1}h}(\xi)$, α^t will be given by

$$\alpha^t f(\mathbf{x},\sigma) = \sum_{\tau=\pm 1} G_{\tau,\mathbf{x},t,h}(\xi)\ f(\mathbf{x}+t,\tau\cdot\sigma),$$

with $\mathbf{x}+t\equiv(x+t,y)$.

In the same way it turns out that the existence of the limit for the measurement of k observables at k successive times $0\leqslant t_1<t_2<\cdots<t_k$ is equivalent to weak convergence of the products $\Pi_{i=1}^k g_{\sigma_i,n\mathbf{x},nt_i,n^{-1}h}(\xi)$. Denoting $t_0\equiv 0$ and $\tau_i\equiv\Pi_{j\leqslant i}\sigma_j$, it follows

$$\prod_{i=1}^k g_{\sigma_i,n(\mathbf{x}+t_{i-1}),n(t_i-t_{i-1}),n^{-1}h}(\xi) = \prod_{i=1}^k g_{\tau_i,n\mathbf{x},nt_i,n^{-1}h}(\xi),$$

and we may write the request of convergence in a form that will be more suitable to demonstrate the Markov time-independent property for the limit stochastic process:

$\forall B$ bounded Borel set $\subset\mathbb{R}^2$, $\quad\forall k=1,2,...,\quad \forall\sigma_i=\pm 1,\quad i=1,...,k$

$$\exists \lim_n \int \chi_B(\mathbf{x}) \prod_{i=1}^k g_{\sigma_i,n(\mathbf{x}+t_{i-1}),n(t_i-t_{i-1}),n^{-1}h}(\xi)\ d^2\mathbf{x}. \tag{4.23}$$

Now, from the definition of ρ it follows that the characteristic functions of the sets $\{\mathbf{x}\in\mathbb{R}^2 : |\xi\cap B_{\mathbf{x},t,h}|=n\}$, denoted by $\tilde{g}_{n,\mathbf{x},t,h}(\xi)$, are in $L^1(\Xi,\rho)$, and their integral is given by

$$\int_\Xi \tilde{g}_{n,\mathbf{x},t,h}(\xi)\ d\rho(\xi) = \sum_{j=0}^\infty \frac{e^{-|\Lambda|}}{j!}\int_{\Lambda^j} d\mathbf{x}_1\ldots d\mathbf{x}_j\ \tilde{g}_{n,\mathbf{x},t,h}(\xi) = e^{-|t|h}\frac{|th|^n}{n!}.$$

Expressing the functions $g_{\sigma,\mathbf{x},t,h}$ in terms of the $\tilde{g}_{n,\mathbf{x},t,h}$, we obtain

$$\int_\Xi g_{\pm 1,\mathbf{x},t,h}(\xi)\ d\rho(\xi) = \frac{1\pm e^{-2|t|h}}{2}$$

and, for $B_{\mathbf{x}_i,t_i,h_i}\cap B_{\mathbf{x}_j,t_j,h_j}=\emptyset,\ \ i\neq j$,

$$\int_\Xi \prod_{i=1}^k g_{\sigma_i,\mathbf{x}_i,t_i,h_i}(\xi)\ d\rho(\xi) = \prod_{i=1}^k \int_\Xi g_{\sigma_i,\mathbf{x}_i,t_i,h_i}(\xi)\ d\rho(\xi) = \prod_{i=1}^k \frac{1+\sigma_i\cdot e^{-2|t_i|h_i}}{2}.$$

The aim is now to show that the conditions in Eqs. (4.22) and (4.23) are fulfilled for ρ—almost all $\xi \in \Xi$. We will show that those limits exist in the $L^1(\Xi,\rho)$ norm, and hence pointwise, ρ-almost everywhere on Ξ, for any subsequence n_k with $\Sigma_k 1/n_k < \infty$. Consider first the single time case: $\forall B$ bounded Borel $\subset \mathbb{R}^2$:

$$\int_\Xi d\rho(\xi) \left| \int_B d^2\mathbf{x}\, g_{\sigma,n\mathbf{x},nt,n^{-1}h}(\xi) - |B| \frac{1+\sigma\cdot e^{-2|t|h}}{2} \right|^2$$
$$= \int_\Xi d\rho(\xi) \int_B d^2\mathbf{x}\, g_{\sigma,n\mathbf{x},nt,n^{-1}h}(\xi) \int_B d^2\mathbf{x}'\, g_{\sigma,n\mathbf{x}',nt,n^{-1}h}(\xi) - \int_\Xi d\rho(\xi) \left(|B| \frac{1+\sigma\cdot e^{-2|t|h}}{2} \right)^2,$$

where we applied Fubini's theorem to g, which is measurable over $(\mathbb{R}^2\times\Xi, d^2\mathbf{x}\otimes d\rho)$, since it is pointwise approximated by a sequence of finite linear combinations of products $\phi_i(\mathbf{x})\chi_i(\xi)$, with $\phi_i(\mathbf{x})$ and $\chi_i(\xi)$ measurable.

Since the points of ξ are ρ uncorrelated, in the above integration no contribution comes from the set

$$Q \equiv \{(\mathbf{x},\mathbf{x}') \in B\times B : n|y-y'| \geq n^{-1}h\}.$$

As $n\to\infty$, Q becomes all of $B\times B$; more precisely, taken a rectangle in $\mathbb{R}^2$ of base Δ_1 and height Δ_2 which contains B, it is

$$|(B\times B)\backslash Q| \leq \int_B d^2\mathbf{x}\, \Delta_1 \int_{y-n^{-2}h}^{y+n^{-2}h} dy' \leq n^{-2} 2h \Delta_1^2 \Delta_2$$

and therefore, since $\|g\|_\infty = 1$, we conclude

$$\int_\Xi d\rho(\xi) \left| \int_B d^2\mathbf{x}\, g_{\sigma,n\mathbf{x},nt,n^{-1}h}(\xi) - |B| \frac{1+\sigma\cdot e^{-2|t|h}}{2} \right|^2 \leq n^{-2} 2h \Delta_1^2 \Delta_2. \tag{4.24}$$

The same reasoning and the same inequality apply for functions of the form

$$\prod_{i=1}^k g_{\sigma_i, n(\mathbf{x}+t_{i-1}), n(t_i - t_{i-1}), n^{-1}h}(\xi) \quad \text{with} \quad t_0 = 0 < t_1 < \cdots < t_k,$$

which describe all measurements at k successive times. Moreover, since the g's in the above product depend on ξ only through points in disjoint sets, and since the points of ξ are ρ uncorrelated, it follows that

$$\int_B d^2\mathbf{x} \prod_{i=1}^k g_{\sigma_i, n(\mathbf{x}+t_{i-1}), n(t_i-t_{i-1}), n^{-1}h}(\xi)$$

converges, for the moment in $\| \,\|_2$ over (Ξ,ρ), to the product of the limits, i.e., to

$$|B| \prod_{i=1}^k \frac{1+\sigma_i\cdot e^{-2(t_i-t_{i-1})h}}{2}.$$

Since $\rho(\Xi)=1$, convergence also takes place in the L^1 norm. Now, if a sequence $\{f_j\}$ converges in $\| \,\|_1$ to f and $\Sigma_{j=1}^\infty \|f_j - f_{j-1}\|_1 \leq \infty$, then f_j converge pointwise almost everywhere to f,[27] and in our case it is sufficient to take a subsequence with $\Sigma 1/n_j < \infty$ to assure ρ—almost everywhere pointwise convergence.

Therefore, for any denumerable family $\mathcal{R}$ of bounded Borel sets $B\subset\mathbb{R}^2$, $\forall k=1,2,\ldots$, $\forall \rho_i = \pm 1$, $i=1,\ldots,k$, $\forall t_0 = 0 < t_1 < \cdots < t_k$ in a denumerable set, for ρ-almost all $\xi\in\Xi$,

$$\lim_j \int_B d^2\mathbf{x} \prod_{i=1}^{k} g_{\sigma_i, n_j(\mathbf{x}+t_{i-1}), n_j(t_i-t_{i-1}), n_j^{-1}h}(\xi) = |B| \prod_{i=1}^{k} \frac{1+\sigma_i \cdot e^{-2(t_i-t_{i-1})h}}{2}.$$

By taking $\mathcal{R}$ such that the linear combinations of characteristic functions χ_B are dense in $L^1(\mathbb{R}^2, d^2\mathbf{x})$, and using the $\| \|_\infty$ boundedness of the integrand, uniform in j, convergence follows for any bounded Borel subset of $\mathbb{R}^2$; as discussed above, this implies weak convergence of α_n^t, and convergence of the means at different times to a stochastic process, for times in a denumerable set, for ρ—almost all (fixed) configurations of obstacles.
The weak limit is given by

$$\alpha^t f(\mathbf{x},\sigma) = \sum_{\tau=\pm 1} f(\mathbf{x}+t, \tau\cdot\sigma) \frac{1+\tau e^{-2|t|h}}{2}. \tag{4.25}$$

Convergence of $\Pi_{i=1}^k g$ to $\Pi_{i=1}^k G$ implies that limits of measurements at successive times define a time-independent Markov process, with transition function

$$P_t((\mathbf{x},\sigma),(B,\tau)) = \alpha^t \chi_{B,\tau}(\mathbf{x},\sigma) = \sum_{\rho=\pm 1} \chi_{B,\tau}(\mathbf{x}+t, \rho\cdot\sigma) \frac{1+\rho e^{-2|t|h}}{2}.$$

In fact,

$$\alpha_n^t f(\mathbf{x},\sigma) = \sum_{\tau=\pm 1} f(\mathbf{x}+t, \tau\cdot\sigma)\; g_{\tau, n\mathbf{x}, nt, n^{-1}h}(\xi),$$

so that

$$\begin{aligned}
&\alpha_n^{t_1}(f_1 \alpha_n^{t_2-t_1}(f_2 \alpha_n^{t_3-t_2} \cdots (f_{k-1}\alpha_n^{t_k-t_{k-1}} f_k) \cdots))(\mathbf{x},\sigma) \\
&= \prod_{i=1}^{k} \sum_{\tau_i=\pm 1} f_i\left(\mathbf{x}+t_i, \sigma\cdot \prod_{j=1}^{i} \tau_j\right) g_{\tau_i, n(\mathbf{x}+t_{i-1}), n_j(t_i-t_{i-1}), n^{-1}h}(\xi)
\end{aligned}$$

which $\tau_{\mathcal{F}}$ converges as $n\to\infty$ to

$$\begin{aligned}
&\prod_{i=1}^{k} \sum_{\tau_i=\pm 1} f_i\left(\mathbf{x}+t_i, \sigma\cdot\prod_{j=1}^{i} \tau_j\right) \frac{1+\tau_i e^{-2(t_i-t_{i-1})h}}{2} \\
&= \alpha^{t_1}(f_1 \alpha^{t_2-t_1}(f_2 \alpha^{t_3-t_2} \cdots (f_{k-1}\alpha^{t_k-t_{k-1}} f_k) \cdots))(\mathbf{x},\sigma),
\end{aligned} \tag{4.26}$$

which is the condition for the stochastic process to be Markov and time independent. The process is defined by the left-hand side of Eq. (4.26) for all positive times, and the restriction to a denumerable set of times is only involved in the construction of a fixed set of configurations of rods (of ρ-measure one) for which weak convergence holds.

(Received 29 July 1998; accepted for publication 30 April 1999)

A coupled AKNS–Kaup–Newell hierarchy of systems of soliton equations is proposed in terms of hereditary symmetry operators resulted from Hamiltonian pairs. Zero curvature representations and tri-Hamiltonian structures are established for all coupled AKNS–Kaup–Newell systems in the hierarchy. Therefore all systems have infinitely many commuting symmetries and conservation laws. Two reductions of the systems lead to the AKNS hierarchy and the Kaup–Newell hierarchy, and thus those two soliton hierarchies also possess tri-Hamiltonian structures.
 [S0022-2488(99)01209-8]

I. INTRODUCTION

Systems of soliton equations usually come in hierarchies. This kind of hierarchy possesses many nice properties, for instance, Lax representations or zero curvature representations, infinitely many commuting symmetries and conservation laws, hereditary recursion structures, bi-Hamiltonian formulations, and even multiple Hamiltonian formulations, etc., and they are often called soliton hierarchies. Well-known examples of such soliton hierarchies (for example, see Refs. 1, 2) contain the KdV hierarchy, the MKdV hierarchy, the AKNS hierarchy, the Kaup–Newell hierarchy, the Benjamin–Ono hierarchy,[3] the Tu hierarchy,[4] the Dirac hierarchy,[5] the coupled KdV hierarchies,[6,7] the coupled Harry–Dym hierarchies,[8] the coupled Burgers hierarchies,[9] and so on. It is very interesting to search for new soliton hierarchies, even hierarchies of systems that possess only infinitely many commuting symmetries.

An idea that allows us to achieve this is to construct soliton hierarchies of coupled systems of equations. It could be divided into two aspects in view of types of soliton equations. The one is to construct soliton hierarchies by coupling systems of the same type. Such examples are the coupled KdV hierarchies,[6,7] the coupled Harry–Dym hierarchies,[8] the coupled Burgers hierarchies,[9] and the perturbation systems of the KdV hierarchy,[10] etc. The other is to construct soliton hierarchies by coupling systems of different types. There are few examples in this aspect. A coupled AKNS–Kaup–Newell hierarchy of a complex form, recently introduced by Zhang,[11] is such an example.

In this paper, motivated by Zhang's coupled AKNS–Kaup–Newell hierarchy of a complex form, we would like to propose a hierarchy of coupled AKNS–Kaup–Newell evolution equations of real form. The hierarchy will be established in the second section, in terms of hereditary symmetry operators. The required hereditary symmetry operators can be generated by observing a set of Hamiltonian operators. Zero curvature representations will be computed in the third section for all systems in the hierarchy. Interestingly the discussion of the fourth section shows that all the systems have not only bi-Hamiltonian structures but also tri-Hamiltonian structures, although Zhang did not present Hamiltonian structures and consequent conservation laws due to a failure in determining Hamiltonian operators.[11] Therefore the resulting hierarchy has infinitely many commuting symmetries and conservation laws. Some concluding remarks are given in the last section.

II. HEREDITARY SYMMETRY OPERATORS

We want to establish a coupled AKNS–Kaup–Newell hierarchy in terms of hereditary symmetry operators resulted from Hamiltonian pairs. To this end, let us introduce a set of 2×2 matrix integrodifferential operators:

$$M=M(u)=\begin{pmatrix} \alpha_1 q\,\partial^{-1}q & \alpha_2+\alpha_3\partial-\alpha_1 q\,\partial^{-1}r \\ -\alpha_2+\alpha_3\partial-\alpha_1 r\,\partial^{-1}q & \alpha_1 r\,\partial^{-1}r \end{pmatrix},\quad u=\begin{pmatrix} q \\ r \end{pmatrix}, \tag{1}$$

where $\partial=\partial/\partial x$, $q=q(x,t)$, $r=r(x,t)$, and $\alpha_1,\alpha_2,\alpha_3$ are three arbitrary constants, and consider their Hamiltonian property. They are simple generalizations of the Hamiltonian operators in the AKNS case.[12] The following proposition shows that they are still Hamiltonian, indeed.

Proposition 1: The 2×2 *matrix integrodifferential operators defined by* (1) *are all Hamiltonian for any constants* $\alpha_1,\alpha_2,\alpha_3$.

Proof: Assume that

$$X=(X_1,X_2)^T,\quad Y=(Y_1,Y_2)^T,\quad Z=(Z_1,Z_2)^T,\quad W=(W_1,W_2)^T,$$

are two-dimensional vectors of functions. Since M is skew symmetric, we only need to prove that the Jacobi identity,

$$\langle Z,M'[MX]Y\rangle+\text{cycle}(X,Y,Z)\equiv 0(\text{mod}\,\partial), \tag{2}$$

holds for any X,Y,Z, where $\langle\cdot,\cdot\rangle$ denotes the standard inner product of $\mathbb{R}^2$. By (1), we immediately have

$$MX=\begin{pmatrix} \alpha_2X_2+\alpha_3X_{2x}+\alpha_1 qP(X) \\ -\alpha_2X_1+\alpha_3X_{1x}-\alpha_1 rP(X) \end{pmatrix}:=\begin{pmatrix} W_1(X) \\ W_2(X) \end{pmatrix},$$

where $P(X)=\partial^{-1}(qX_1-rX_2)$. Following the definition of the Gateaux derivative, two objects $M'[W]$ and $M'[W]Y$ are computed as follows:

$$M'[W]=\begin{pmatrix} \alpha_1 q\,\partial^{-1}W_1+\alpha_1W_1\,\partial^{-1}q & -\alpha_1 q\,\partial^{-1}W_2-\alpha_1W_1\,\partial^{-1}r \\ -\alpha_1 r\,\partial^{-1}W_1-\alpha_1W_2\,\partial^{-1}q & \alpha_1 r\,\partial^{-1}W_2+\alpha_1W_2\,\partial^{-1}r \end{pmatrix},$$

$$M'[W]Y=\begin{pmatrix} \alpha_1 q\partial^{-1}(W_1Y_1-W_2Y_2)+\alpha_1W_1\partial^{-1}(qY_1-rY_2) \\ -\alpha_1 r\partial^{-1}(W_1Y_1-W_2Y_2)-\alpha_1W_2\partial^{-1}(qY_1-rY_2) \end{pmatrix}.$$

Now we can have

$$\begin{aligned}\langle Z,M'[MX]Y\rangle&=\alpha_1(qZ_1-rZ_2)\partial^{-1}(W_1(X)Y_1-W_2(X)Y_2)\\&\quad+\alpha_1(W_1(X)Z_1-W_2(X)Z_2)\partial^{-1}(qY_1-rY_2).\end{aligned} \tag{3}$$

Upon observing that

$$\begin{aligned}W_1(X)Y_1-W_2(X)Y_2&=(\alpha_2X_2+\alpha_3X_{2x}+\alpha_1 qP(X))Y_1-(-\alpha_2X_1+\alpha_3X_{1x}-\alpha_1 rP(X))Y_2\\&=\alpha_1P(X)(qY_1+rY_2)+\alpha_2(X_2Y_1+X_1Y_2)+\alpha_3(X_{2x}Y_1-X_{1x}Y_2),\end{aligned}$$

we can make a decomposition,

$$\langle Z,M'[MX]Y\rangle=R(X,Y,Z)+S(X,Y,Z)+T(X,Y,Z), \tag{4}$$

where R,S,T are defined by

$$R(X,Y,Z)=\alpha_1^2(qZ_1-rZ_2)\partial^{-1}[P(X)(qY_1+rY_2)]+\alpha_1^2P(X)(qZ_1+rZ_2)\partial^{-1}(qY_1-rY_2), \tag{5}$$

$$S(X,Y,Z)=\alpha_1\alpha_2(qZ_1-rZ_2)\partial^{-1}(X_2Y_1+X_1Y_2)+\alpha_1\alpha_2(X_2Z_1+X_1Z_2)\partial^{-1}(qY_1-rY_2), \tag{6}$$

$$T(X,Y,Z)=\alpha_1\alpha_3(qZ_1-rZ_2)\partial^{-1}(X_{2x}Y_1-X_{1x}Y_2)+\alpha_1\alpha_3(X_{2x}Z_1-X_{1x}Z_2)\partial^{-1}(qY_1-rY_2). \tag{7}$$

For these three functions R,S,T, we can compute that

$$R(X,Y,Z)+\text{cycle}(X,Y,Z)=\alpha_1^2\partial\{P(Z)\partial^{-1}[P(X)(qY_1+rY_2)]\}+\text{cycle}(X,Y,Z), \tag{8}$$

$$S(X,Y,Z)+\text{cycle}(X,Y,Z)=\alpha_1\alpha_2\partial[P(Z)\partial^{-1}(X_2Y_1+X_1Y_2)]+\text{cycle}(X,Y,Z), \tag{9}$$

$$\begin{aligned}T(X,Y,Z)&+\text{cycle}(X,Y,Z)\\ &=\alpha_1\alpha_3(qZ_1-rZ_2)(X_2Y_1-X_1Y_2)+\alpha_1\alpha_3(qZ_1-rZ_2)\partial^{-1}(X_1Y_{2x}-X_2Y_{1x})\\ &\quad+\alpha_1\alpha_3(Z_1X_{2x}-Z_2X_{1x})\partial^{-1}(qY_1-rY_2)+\text{cycle}(X,Y,Z)\\ &=\alpha_1\alpha_3(qZ_1-rZ_2)(X_1Y_{2x}-X_2Y_{1x})+\alpha_1\alpha_3(Z_1X_{2x}-Z_2X_{1x})\partial^{-1}(qY_1-rY_2)\\ &\quad+\text{cycle}(X,Y,Z)\\ &=\alpha_1\alpha_3\partial[P(Z)\partial^{-1}(X_1Y_{2x}-X_2Y_{1x})]+\text{cycle}(X,Y,Z).\end{aligned} \tag{10}$$

They are all total derivatives and thus combining the decomposition (4) and the equalities (8), (9), (10) leads to the Jacobi identity (2). This completes the proof. ■

Now we would like to discuss some special cases of Hamiltonian pairs starting from the above Hamiltonian operators defined by (1), which allows us to generate hereditary symmetry operators and further soliton hierarchies. This idea has been successfully used to construct bi-Hamiltonian coupled KdV systems.[13,14] An important phenomenon we want to point out is that different soliton hierarchies can be derived from Hamiltonian operators of the same type. The following discussion shows an example of such phenomenon. It is also important to realize that not all Hamiltonian pairs may generate hereditary symmetry operators. Thus, care must be taken to restrict our attention to the cases where there exists at least one invertible Hamiltonian operator for each Hamiltonian pair. The required invertibility guarantees that Hamiltonian pairs can yield hereditary symmetry operators.[15]

Case 1: We make a choice of an invertible Hamiltonian operator,

$$J=\begin{pmatrix}0 & 1\\ -1 & 0\end{pmatrix}, \tag{11}$$

which has an inverse operator,

$$J^{-1}=\begin{pmatrix}0 & -1\\ 1 & 0\end{pmatrix}.$$

It follows from Proposition 1 that this operator J constitutes a Hamiltonian pair with M defined by (1). Therefore we can have a hereditary symmetry operator,

$$\Phi=MJ^{-1}=\begin{pmatrix}\alpha_2+\alpha_3\partial-\alpha_1q\,\partial^{-1}r & -\alpha_1q\,\partial^{-1}q\\ \alpha_1r\,\partial^{-1}r & \alpha_2-\alpha_3\partial+\alpha_1r\,\partial^{-1}q\end{pmatrix}, \tag{12}$$

where α_1, α_2, and α_3 are arbitrary. The reduction of $\alpha_1=-1$, $\alpha_2=0$ and $\alpha_3=\frac{1}{2}$ leads to the recursion operator for the normal AKNS hierarchy.[1,2,16]

Case 2: We make a choice of a Hamiltonian pair,

$$J=\begin{pmatrix} \beta_1 q\,\partial^{-1}q & 1-\beta_1 q\partial^{-1}r \\ -1-\beta_1 r\,\partial^{-1}q & \beta_1 r\,\partial^{-1}r \end{pmatrix},\quad M=\begin{pmatrix} 0 & \alpha_3\partial \\ \alpha_3\partial & 0 \end{pmatrix}. \tag{13}$$

The above proposition ensures that they constitute a Hamiltonian pair, indeed. Since the operator J has an invertible operator,

$$J^{-1}=\begin{pmatrix} \beta_1 r\,\partial^{-1}r & -1+\beta_1 r\,\partial^{-1}q \\ 1+\beta_1 q\,\partial^{-1}r & \beta_1 q\,\partial^{-1}q \end{pmatrix},$$

we can obtain the corresponding hereditary symmetry operator,

$$\Phi=MJ^{-1}=\begin{pmatrix} \alpha_3\partial+\alpha_3\beta_1\partial q\,\partial^{-1}r & \alpha_3\beta_1\partial q\,\partial^{-1}q \\ \alpha_3\beta_1\partial r\,\partial^{-1}r & -\alpha_3\partial+\alpha_3\beta_1 r\,\partial^{-1}r \end{pmatrix}, \tag{14}$$

where α_3 and β_1 are arbitrary. The reduction of $\alpha_3=\frac{1}{2}$ and $\beta_1=-1$ leads to the recursion operator for the normal Kaup–Newell hierarchy (for example, see Ref. 17).

More generally, we have the following case, which combines the above two cases.

Case 3: We make a choice of an invertible Hamiltonian operator,

$$J=\begin{pmatrix} \beta_1 q\,\partial^{-1}q & \beta_2-\beta_1 q\,\partial^{-1}r \\ -\beta_2-\beta_1 r\,\partial^{-1}q & \beta_1 r\,\partial^{-1}r \end{pmatrix}, \tag{15}$$

whose inverse operator can be given by

$$J^{-1}=\frac{1}{\beta_2^2}\begin{pmatrix} \beta_1 r\,\partial^{-1}r & -\beta_2+\beta_1 r\,\partial^{-1}q \\ \beta_2+\beta_1 q\,\partial^{-1}r & \beta_1 q\,\partial^{-1}q \end{pmatrix}.$$

It follows from Proposition 1 that the operator J constitutes a Hamiltonian pair with the Hamiltonian operator M defined by (1). In this case, we can generate the following corresponding hereditary symmetry operator:

$$\Phi=MJ^{-1}=\frac{1}{\beta_2^2}\begin{pmatrix} \alpha_2\beta_2+\alpha_3\beta_2\partial+(\alpha_2\beta_1-\alpha_1\beta_2)q\,\partial^{-1}r+\alpha_3\beta_1\,\partial q\,\partial^{-1}r, & (\alpha_2\beta_1-\alpha_1\beta_2)q\,\partial^{-1}q+\alpha_3\beta_1\,\partial q\,\partial^{-1}q \\ (\alpha_1\beta_2-\alpha_2\beta_1)r\,\partial^{-1}r+\alpha_3\beta_1\,\partial r\,\partial^{-1}r, & \alpha_2\beta_2-\alpha_3\beta_2\partial+(\alpha_1\beta_2-\alpha_2\beta_1)r\,\partial^{-1}q+\alpha_3\beta_1\,\partial r\,\partial^{-1}q \end{pmatrix}, \tag{16}$$

where five constants are arbitrary but $\beta_2\neq 0$.

Let us pick out a special subcase of $\alpha_2=0$ and $\beta_2=1$ from the third case. If $\alpha_3=0$, we just obtain a simple hereditary symmetry operator,

$$\Phi=\begin{pmatrix} -\alpha q\,\partial^{-1}r & -\alpha q\,\partial^{-1}q \\ \alpha r\,\partial^{-1}r & \alpha r\,\partial^{-1}q \end{pmatrix}, \tag{17}$$

where $\alpha=\alpha_1$ is arbitrary. This is equivalent to the first case with $\alpha_2=\alpha_3=0$.

If $\alpha_3\neq 0$, upon resetting $\alpha_3=\gamma$, $\alpha_1=\alpha$, $\alpha_3\beta_1=\beta$, we obtain a hereditary symmetry operator,

$$\Phi=\begin{pmatrix} \gamma\partial-\alpha q\,\partial^{-1}r+\beta\,\partial q\,\partial^{-1}r & -\alpha q\,\partial^{-1}q+\beta\,\partial q\,\partial^{-1}q \\ \alpha r\,\partial^{-1}r+\beta\,\partial r\,\partial^{-1}r & -\gamma\partial+\alpha r\,\partial^{-1}q+\beta\,\partial r\,\partial^{-1}q \end{pmatrix}, \tag{18}$$

where α,β,γ are arbitrary but $\gamma\neq 0$. Note that if we let the constant γ go to zero, the hereditary condition for Φ with a general constant γ becomes the one for Φ with $\gamma=0$. Therefore the constant γ can be chosen as zero, which does not affect the hereditary property of Φ. However, if $\gamma=0$, we do not know whether the operator Φ defined by (18) is decomposable, i.e, whether there exists any Hamiltonian pair J and M so that $\Phi=MJ^{-1}$.

We will focus on discussing a soliton hierarchy generated by the hereditary symmetry operator in (18) because of its generality. For $\gamma\neq 0$, we can rescale three constants to put a general case into a special case of the operator Φ defined by (18), and thus we pick out the following special case:

$$\Phi=MJ^{-1}=\begin{pmatrix} \frac{1}{2}\partial-\alpha q\,\partial^{-1}r-\frac{1}{2}\beta\,\partial q\,\partial^{-1}r & -\alpha q\,\partial^{-1}q-\frac{1}{2}\beta\,\partial q\,\partial^{-1}q \\ \alpha r\,\partial^{-1}r-\frac{1}{2}\beta\,\partial r\,\partial^{-1}r & -\frac{1}{2}\partial+\alpha r\,\partial^{-1}q-\frac{1}{2}\beta\,\partial r\,\partial^{-1}q \end{pmatrix}, \tag{19}$$

to discuss without loss of generality. To this special case, the corresponding hierarchy of evolution equations,

$$\begin{pmatrix} q_t \\ r_t \end{pmatrix}=\begin{pmatrix} \frac{1}{2}\partial-\alpha q\,\partial^{-1}r-\frac{1}{2}\beta\,\partial q\,\partial^{-1}r & -\alpha q\,\partial^{-1}q-\frac{1}{2}\beta\,\partial q\,\partial^{-1}q \\ \alpha r\,\partial^{-1}r-\frac{1}{2}\beta\,\partial r\,\partial^{-1}r & -\frac{1}{2}\partial+\alpha r\,\partial^{-1}q-\frac{1}{2}\beta\,\partial r\,\partial^{-1}q \end{pmatrix}^n \begin{pmatrix} q_x \\ r_x \end{pmatrix}, \quad n\geqslant 0, \tag{20}$$

contains two important reductions. If $\alpha\neq 0$ but $\beta=0$, the hierarchy reduces to the AKNS hierarchy. If $\alpha=0$ but $\beta\neq 0$ but $\beta=0$, the hierarchy reduces to the Kaup–Newell hierarchy. Thus, the hierarchy (20) generated by the hereditary symmetry operator (19) is called a coupled AKNS–Kaup–Newell hierarchy. All systems in the hierarchy (20) are real. Therefore the hierarchy (20) is a soliton hierarchy that we want to construct.

III. ZERO CURVATURE REPRESENTATIONS

In the previous section, we generated a coupled AKNS–Kaup–Newell hierarchy of real form by observing Hamiltonian operators. More importantly, the resulting hierarchy shares some common integrable properties. In this section, we want to show zero curvature representations for all systems in the hierarchy, and in the next section, we will establish tri-Hamiltonian structures.

To show zero curvature representations, let us impose a spectral problem,

$$\phi_x=U\phi, \quad U=U(u,\lambda)=\begin{pmatrix} \lambda & q \\ (\alpha+\beta\lambda)r & -\lambda \end{pmatrix}, \quad \phi=\begin{pmatrix} \phi_1 \\ \phi_2 \end{pmatrix}, \tag{21}$$

where λ is a spectral parameter, and α and β are arbitrary constants. It is customary to solve the stationery zero curvature equation $V_x=[U,V]$ first. Suppose that

$$V=V(u,\lambda)=\begin{pmatrix} a & b \\ (\alpha+\beta\lambda)c & -a \end{pmatrix}=\sum_{i\geqslant 0}\begin{pmatrix} a_i & b_i \\ (\alpha+\beta\lambda)c_i & -a_i \end{pmatrix}\lambda^{-i}, \tag{22}$$

and then the stationary zero curvature equation becomes

$$a_x=(\alpha+\beta\lambda)(qc-rb), \quad b_x=2\lambda b-2qa, \quad c_x=2ra-2\lambda c. \tag{23}$$

Notice that a recursion relation to determine b and c may be found if we fix $a=(\alpha+\beta\lambda)\partial^{-1}(qc-rb)$. Actually, we have

$$b_x=2\lambda b-2(\alpha+\beta\lambda)q\partial^{-1}(qc-rb), \quad c_x=2(\alpha+\beta\lambda)r\partial^{-1}(qc-rb)-2\lambda c, \tag{24}$$

which equivalently leads to

$$\begin{pmatrix} -2\beta q\,\partial^{-1}q & 2+2\beta q\,\partial^{-1}r \\ -2+2\beta r\,\partial^{-1}q & -2\beta r\,\partial^{-1}r \end{pmatrix}\begin{pmatrix} c_{i+1} \\ b_{i+1} \end{pmatrix}=\begin{pmatrix} 2\alpha q\,\partial^{-1}q & \partial-2\alpha q\,\partial^{-1}r \\ \partial-2\alpha r\,\partial^{-1}q & 2\alpha r\,\partial^{-1}r \end{pmatrix}\begin{pmatrix} c_i \\ b_i \end{pmatrix}, \tag{25}$$

where $i \geqslant 0$. If we set

$$J = \begin{pmatrix} -2\beta q\,\partial^{-1} q & 2+2\beta q\,\partial^{-1} r \\ -2+2\beta r\,\partial^{-1} q & -2\beta r\,\partial^{-1} r \end{pmatrix}, \quad M = \begin{pmatrix} 2\alpha q\,\partial^{-1} q & \partial - 2\alpha q\,\partial^{-1} r \\ \partial - 2\alpha r\,\partial^{-1} q & 2\alpha r\,\partial^{-1} r \end{pmatrix}, \tag{26}$$

the operators J and M constitute a Hamiltonian pair, based on the result in the previous section. It is apparent that the corresponding hereditary symmetry operator $\Phi = MJ^{-1}$ is exactly the same as the one defined by (19), having noted that

$$J^{-1} = \frac{1}{2}\begin{pmatrix} -\beta\,\partial r\,\partial^{-1} r & -1-\beta\,\partial r\,\partial^{-1} q \\ 1-\beta\,\partial q\,\partial^{-1} r & -\beta\,\partial q\,\partial^{-1} q \end{pmatrix}.$$

The conjugate operator of Φ reads as

$$\Psi = \Phi^{\dagger} = J^{-1}M = \begin{pmatrix} -\frac{1}{2}\partial + \alpha r\,\partial^{-1} q - \frac{1}{2}\beta r\,\partial^{-1} q\,\partial & -\alpha r\,\partial^{-1} r - \frac{1}{2}\beta r\,\partial^{-1} r\,\partial \\ \alpha q\,\partial^{-1} q - \frac{1}{2}\beta q\,\partial^{-1} q\,\partial & \frac{1}{2}\partial - \alpha q\,\partial^{-1} r - \frac{1}{2}\beta q\,\partial^{-1} r\,\partial \end{pmatrix}. \tag{27}$$

Therefore upon noting (23) and choosing $a_0 = 1$, we obtain a solution to the stationary zero curvature equation $V_x = [U,V]$:

$$a_0 = 1, \quad b_0 = c_0 = 0; \quad b_1 = q, \quad c_1 = r;$$

$$\begin{pmatrix} c_{i+1} \\ b_{i+1} \end{pmatrix} = \Psi \begin{pmatrix} c_i \\ b_i \end{pmatrix}, \quad i \geqslant 1,$$

$$a_i = \alpha\partial^{-1}(qc_i - rb_i) + \beta\partial^{-1}(qc_{i+1} - rb_{i+1}), \quad i \geqslant 1; \tag{28}$$

from which we can get

$$\begin{pmatrix} c_2 \\ b_2 \end{pmatrix} = \Psi \begin{pmatrix} r \\ q \end{pmatrix} = \frac{1}{2}\begin{pmatrix} -r_x - \beta q r^2 \\ q_x - \beta q^2 r \end{pmatrix},$$

and

$$a_1 = \beta\partial^{-1}(qc_2 - rb_2) = -\tfrac{1}{2}\beta q r.$$

It should be noted that we always need to select zero constants for integration in deriving a_i, b_i, c_i, $i \geqslant 1$. That is, we require that $a_i|_{[u]=0} = b_i|_{[u]=0} = c_i|_{[u]=0} = 0$, $i \geqslant 1$, where $[u] = (u, u_x, \ldots)$.

Now we can express the coupled AKNS–Kaup–Newell hierarchy (20) in another way. Let us define

$$u_t = K_n := J\begin{pmatrix} c_{n+1} \\ b_{n+1} \end{pmatrix} = \Phi^n \begin{pmatrix} 2q \\ -2r \end{pmatrix}, \quad n \geqslant 0, \tag{29}$$

where Φ is defined by (19). The first three systems of the hierarchy (29) are

$$u_t = \begin{pmatrix} q_t \\ r_t \end{pmatrix} = K_0 = J\begin{pmatrix} c_1 \\ b_1 \end{pmatrix} = \begin{pmatrix} 2q \\ -2r \end{pmatrix},$$

$$u_t = \begin{pmatrix} q_t \\ r_t \end{pmatrix} = K_1 = J\begin{pmatrix} c_2 \\ b_2 \end{pmatrix} = \begin{pmatrix} q_x \\ r_x \end{pmatrix},$$

$$u_t=\begin{pmatrix} q_t \\ r_t \end{pmatrix}=K_2=J\begin{pmatrix} c_3 \\ b_3 \end{pmatrix}=\frac{1}{2}\begin{pmatrix} q_{xx}-2\alpha q^2r-\beta(q^2r)_x \\ -r_{xx}+2\alpha qr^2-\beta(qr^2)_x \end{pmatrix}. \tag{30}$$

Since $K_1=u_x$, all systems in the hierarchy (29), except the first system $u_t=K_0$, are exactly the coupled AKNS–Kaup–Newell systems in the hierarchy (20). Therefore (29) is another expression for the coupled AKNS–Kaup–Newell hierarchy (20).

Let us turn to the construction of zero curvature representations for all coupled AKNS–Kaup–Newell systems in the soliton hierarchy (29). We need a condition of $\alpha^2+\beta^2\neq 0$. With this condition, we have the injective property of the Gateaux derivative of U with respect to u, which is required in deriving systems of evolution equations from zero curvature equations. If the condition of $\alpha^2+\beta^2\neq 0$ is not satisfied, then the systems defined by (29) are linear and separated, and thus they are all trivial.

We choose Lax operators $V^{(n)}$ for $n\geqslant 0$ as

$$V^{(n)}=V^{(n)}(u,\lambda)=\overline{V}^{(n)}+\Delta_n, \quad \Delta_n=\begin{pmatrix} \delta_{1n} & 0 \\ 0 & \delta_{2n} \end{pmatrix}, \tag{31}$$

$$\overline{V}^{(n)}=\sum_{j=0}^{n}\begin{pmatrix} a_j & b_j \\ (\alpha+\beta\lambda)c_j & -a_j \end{pmatrix}\lambda^{n-j}=\begin{pmatrix} (\lambda^n a)_+ & (\lambda^n b)_+ \\ (\alpha+\beta\lambda)(\lambda^n c)_+ & -(\lambda^n a)_+ \end{pmatrix}, \tag{32}$$

where the subscript denotes choosing the polynomial part in λ, and δ_{1n} and δ_{2n} are two functions to be determined. At this moment, we can compute that

$$\overline{V}_x^{(n)}-[U,\overline{V}^{(n)}]=\begin{pmatrix} a_{nx}-\alpha(qc_n-rb_n) & b_{nx}+2qa_n \\ (\alpha+\beta\lambda)(c_{nx}-2ra_n) & -a_{nx}+\alpha(qc_n-rb_n) \end{pmatrix},$$

$$\Delta_{nx}-[U,\Delta_n]=\begin{pmatrix} \delta_{1n,x} & q(\delta_{1n}-\delta_{2n}) \\ -(\alpha+\beta\lambda)r(\delta_{1n}-\delta_{2n}) & \delta_{2n,x} \end{pmatrix}.$$

Therefore, if we take a choice,

$$\delta_{1n}=-\delta_{2n}=-a_n+\alpha\partial^{-1}(qc_n-rb_n), \quad n\geqslant 1, \tag{33}$$

then noting the injective property of U' under $\alpha^2+\beta^2\neq 0$, the zero curvature equation,

$$U_t-V_x^{(n)}+[U,V^{(n)}]=0, \tag{34}$$

equivalently yields the coupled AKNS–Kaup–Newell system,

$$u_t=K_n=M\begin{pmatrix} c_n \\ b_n \end{pmatrix}=J\begin{pmatrix} c_{n+1} \\ b_{n+1} \end{pmatrix},$$

for each $n\geqslant 1$. Moreover, it is easy to see that $u_t=K_0$ has a Lax pair U and $\overline{V}^{(0)}$. Therefore each coupled AKNS–Kaup–Newell system $u_t=K_n$ has a zero curvature representation with the Lax pair U and $V^{(n)}$ if we adopt $\delta_{10}=\delta_{20}=0$. We remark that for the systems $u_t=K_n$ with $\alpha=\beta=0$, $n\geqslant 0$, the above zero curvature representations still hold, but they are not sufficient, because we lose the injective property of U' in the case of $\alpha=\beta=0$.

IV. TRI-HAMILTONIAN STRUCTURES

To establish some kind of tri-Hamiltonian structures for the coupled AKNS–Kaup–Newell hierarchy, let us impose a third Hamiltonian operator,

$$N=M\Psi=\begin{pmatrix} -\alpha q\,\partial^{-1}q\,\partial+\alpha\,\partial q\,\partial^{-1}q-\frac{1}{2}\beta\,\partial q\,\partial^{-1}q\,\partial, & \frac{1}{2}\partial^2-\alpha q\,\partial^{-1}r\,\partial-\alpha\,\partial q\,\partial^{-1}r-\frac{1}{2}\beta\,\partial q\,\partial^{-1}r\,\partial \\ -\frac{1}{2}\partial^2+\alpha\,\partial r\,\partial^{-1}q+\alpha r^{-1}q\partial-\frac{1}{2}\beta\,\partial r\,\partial^{-1}q\,\partial, & -\alpha\,\partial r\,\partial^{-1}r+\alpha r\,\partial^{-1}r\,\partial-\frac{1}{2}\beta\,\partial r\,\partial^{-1}r\,\partial \end{pmatrix}. \tag{35}$$

It constitutes a Hamiltonian triple with J and M defined by (26), for any constants α, β, γ. That is, any linear combination of J, M, and N is still a Hamiltonian operator, which is automatically satisfied since J and M are a Hamiltonian pair.

Let us consider the first nonlinear system in the coupled AKNS–Kaup–Newell hierarchy (20):

$$u_t=K_2=M\begin{pmatrix} c_2\\ b_2\end{pmatrix}=\frac{1}{2}\begin{pmatrix} q_{xx}-2\alpha q^2r-\beta(q^2r)_x\\ -r_{xx}+2\alpha qr^2-\beta(qr^2)_x\end{pmatrix}. \tag{36}$$

It is apparent that this system could be written in three ways as

$$u_t=K_2=J\begin{pmatrix} c_3\\ b_3\end{pmatrix}=M\begin{pmatrix} c_2\\ b_2\end{pmatrix}=N\begin{pmatrix} c_1\\ b_1\end{pmatrix}.$$

Moreover, a direct calculation can show three gradient vectors,

$$\begin{pmatrix} c_1\\ b_1\end{pmatrix}=\begin{pmatrix} r\\ q\end{pmatrix}=\frac{\delta H_0}{\delta u},\quad H_0=qr; \tag{37}$$

$$\begin{pmatrix} c_2\\ b_2\end{pmatrix}=\Psi\begin{pmatrix} c_1\\ b_1\end{pmatrix}=\frac{1}{2}\begin{pmatrix} -r_x-\beta qr^2\\ q_x-\beta q^2r\end{pmatrix}=\frac{\delta H_1}{\delta u},$$

$$H_1=-\tfrac{1}{4}\beta q^2r^2-\tfrac{1}{4}qr_x+\tfrac{1}{4}q_xr; \tag{38}$$

$$\begin{pmatrix} c_3\\ b_3\end{pmatrix}=\Psi\begin{pmatrix} c_2\\ b_2\end{pmatrix}=\frac{1}{4}\begin{pmatrix} r_{xx}-2\alpha qr^2+3\beta qrr_x+\frac{3}{2}\beta^2q^2r^3\\ q_{xx}-2\alpha q^2r-3\beta qq_xr+\frac{3}{2}\beta^2q^3r^2\end{pmatrix}=\frac{\delta H_2}{\delta u},$$

$$H_2=\tfrac{1}{8}qr_{xx}+\tfrac{1}{8}q_{xx}r-\tfrac{1}{4}\alpha q^2r^2+\tfrac{3}{16}\beta q^2rr_x-\tfrac{3}{16}\beta qq_xr^2+\tfrac{1}{8}\beta^2q^3r^3. \tag{39}$$

Therefore a tri-Hamiltonian structure for the coupled AKNS–Kaup–Newell system (36) can be given by

$$u_t=K_2=J\,\frac{\delta H_2}{\delta u}=M\,\frac{\delta H_1}{\delta u}=N\,\frac{\delta H_0}{\delta u}, \tag{40}$$

where three Hamiltonian functions H_0, H_1, and H_2 are defined by (37), (38), and (39), respectively. Based on the recursion scheme in Refs. 18, 19, this leads to a tri-Hamiltonian structure for each nonlinear system in the coupled AKNS–Kaup–Newell hierarchy,

$$u_t=K_n=J\,\frac{\delta H_n}{\delta u}=M\,\frac{\delta H_{n-1}}{\delta u}=N\,\frac{\delta H_{n-2}}{\delta u},\quad n\geqslant 2. \tag{41}$$

The existence of all Hamiltonian functions H_n to satisfy $\delta H_n/\delta u=\Psi^n(\delta H_0/\delta u)$, $n\geqslant 0$, is guaranteed by the hereditary property of the hereditary symmetry operator Φ. They are all common conserved densities for the whole AKNS–Kaup–Newell hierarchy and commute with each other under three Poisson brackets associated with J, M, and N. This is because, for example, we can compute that

$$\{H_m,H_n\}_J:=\int\left\langle\frac{\delta H_m}{\delta u},J\frac{\delta H_n}{\delta u}\right\rangle dx=\int\left\langle\frac{\delta H_m}{\delta u},J\Psi\frac{\delta H_{n-1}}{\delta u}\right\rangle dx=\int\left\langle\frac{\delta H_m}{\delta u},\Phi J\frac{\delta H_{n-1}}{\delta u}\right\rangle dx$$
$$=\int\left\langle\Psi\frac{\delta H_m}{\delta u},J\frac{\delta H_{n-1}}{\delta u}\right\rangle dx=\{H_{m+1},H_{n-1}\}_J=\cdots=\{H_n,H_m\}_J,$$
$$m<n,\quad m,n\geqslant 0.$$

It gives rise to the commutativity of the conserved densities H_n, $n\geqslant 0$, by combining the skew-symmetric property of the Poisson brackets. Furthermore, we have

$$[K_m,K_n]=J\frac{\delta}{\delta u}\{H_m,H_n\}=0,\quad m,n\geqslant 0,\tag{42}$$

which implies that each coupled AKNS–Kaup–Newell system has infinitely many commuting symmetries. This may also be seen from a zero Lie derivative $L_{u_x}\Phi=0$. The property of $L_{u_x}\Phi=0$ also guarantees that the hereditary symmetry operator defined by (19) is a common recursion operator for all systems in the coupled AKNS–Kaup–Newell hierarchy (29).

V. CONCLUDING REMARKS

We have introduced a set of Hamiltonian operators and presented some corresponding hereditary symmetry operators. Therefore a coupled AKNS–Kaup–Newell hierarchy of systems of soliton equations of a real form is proposed. Zero curvature representations and tri-Hamiltonian structures are established for all systems in the hierarchy.

Interestingly, this coupled AKNS–Kaup–Newell hierarchy contains two different reductions of the AKNS hierarchy and the Kaup–Newell hierarchy. A natural problem we want to ask is what conditions could be found for the existence of similar coupled soliton hierarchies associated with two or more given soliton hierarchies and how one constructs such coupled soliton hierarchies if they exist.

Because our coupled AKNS–Kaup–Newell hierarchy includes the AKNS hierarchy and the Kaup–Newell hierarchy as two simple reductions, tri-Hamiltonian structures can be constructed for the AKNS hierarchy and the Kaup–Newell hierarchy, based on the obtained tri-Hamiltonian structures of the coupled AKNS–Kaup–Newell hierarchy. The corresponding tri-Hamiltonian structure for the Kaup–Newell system of nonlinear derivative Schrödinger equations has been raised recently in Ref. 20 and a nonlinearization problem has been manipulated for the associated spectral problem.[21] We believe that some other nice properties may also be achieved for the the coupled AKNS–Kaup–Newell hierarchy.

It is worthy pointing out that by using a similar deduction to the one in Section III, a general hereditary symmetry operator defined by (18) can be constructed from the following spectral problem:

$$\phi_x=U\phi,\quad U=U(u,\lambda)=\begin{pmatrix}\frac{1}{2\gamma}\lambda & q\\ \frac{1}{2\gamma}\left(\alpha-\frac{\beta}{\gamma}\lambda\right)r & -\frac{1}{2\gamma}\lambda\end{pmatrix},\tag{43}$$

with the same constants α, β, γ as ones in (18). It is apparent that the condition of $\gamma\neq 0$ is required, but α and β may be equal to zero. Only a condition of $\alpha^2+\beta^2\neq 0$ is needed for α and β, in order to guarantee the injective property of the Gateaux derivative U'. It also deserves to mention that the Hamiltonian operators defined by (1) can lead to other hierarchies of systems of evolution equations. For example, a hierarchy of bi-Hamiltonian systems $u_t=\Phi^n u_x$, $n\geqslant 0$, can be generated from a hereditary symmetry operator Φ defined by (17). What is more, we can make another choice of an invertible Hamiltonian operator,

$$J=\begin{pmatrix} 0 & \partial \\ \partial & 0 \end{pmatrix}, \tag{44}$$

which has an inverse operator

$$J^{-1}=\begin{pmatrix} 0 & \partial^{-1} \\ \partial^{-1} & 0 \end{pmatrix}.$$

It constitutes a Hamiltonian pair together with M defined by (1). Thus we can have the corresponding hereditary symmetry operator,

$$\Phi=MJ^{-1}=\begin{pmatrix} \alpha_2\partial^{-1}+\alpha_3-\alpha_1 q\partial^{-1}r\partial^{-1} & \alpha_1 q\partial^{-1}q\partial^{-1} \\ \alpha_1 r\partial^{-1}r\partial^{-1} & -\alpha_2\partial^{-1}+\alpha_3-\alpha_1 r\partial^{-1}q\partial^{-1} \end{pmatrix}. \tag{45}$$

This generates a new hierarchy $u_t=\Phi^n u_x$, $n\geqslant 0$, which is an inverse hierarchy of the Kaup–Newell hierarchy. In conclusion, Hamiltonian operators of the same type may lead to soliton hierarchies of different types.

(Received 28 July 1998; accepted for publication 2 April 1999)

Spatially homogeneous field theories are studied in the framework of dynamical system theory. In particular, we consider a model of inflationary cosmology and a Yang–Mills–Higgs system. We discuss also the role of quantum chaos and its application to field theories.
[S0022-2488(99)00209-1]

I. INTRODUCTION

Quantum field theory offers a wide variety of applications, in particular for condensed matter[1] and elementary particle physics.[2] Field theoretic ideas also reach for the cosmos through the development of the inflationary scenario—a speculative, but completely physical analysis of the early universe, which appears to be consistent with available observations.[3]

In the last years there has been much interest in the chaotic behavior of field theories.[4–8] In this paper we discuss and extend our recent results on instability and chaos[9–11] in classical and quantum field theory.[12–17] In Sec. II we show how spatially homogeneous field theories can be studied by using the dynamical system theory, and we introduce some basic definitions for the regular and chaotic dynamics of classical and quantum systems. In Sec. III we analyze the local stability of an inflationary scalar field minimally coupled to gravity and its point attractors in the phase space. The value of the scalar field in the vacuum is a bifurcation parameter, and we discuss the existence of a stable limit cycle. Finally, in Sec. IV we study the spatially homogeneous SU(2) Yang–Mills–Higgs system. We show that for this system a classical order–chaos transition occurs both in classical and quantum mechanics.

II. FIELD THEORIES AS DYNAMICAL SYSTEMS

In this section we introduce some basic ideas of the dynamical system theory. We clarify the concept of ergodic system giving a hierarchy of chaos.

Let us consider a classical relativistic scalar field theory with action

$$S[\phi]=\int d^4x\, L(\phi,\partial_\mu\phi), \tag{1}$$

where L is the Lagrangian density of the system, $\partial_\mu=(\partial/\partial t,\boldsymbol{\nabla})$ is the covariant derivative, and $\phi=\phi(x)$ is a real scalar field with $x_\mu=(t,\mathbf{x})$ the space–time position.[2] It is well known that by imposing the Hamilton's Least Action Principle,

$$\delta S[\phi]=0, \tag{2}$$

we obtain the Euler–Lagrange equation of motion of the system

[a)]Electronic mail: salasnich@mi.infm.it

$$\frac{\partial L}{\partial \phi} - \partial_\mu \frac{\partial L}{\partial(\partial_\mu \phi)} = 0. \tag{3}$$

The homogeneous space approximation means that we can neglect the spatial dependence of the field, thus we can perform the following substitution:

$$\phi(t,\mathbf{x}) \to \phi(t), \tag{4}$$

and the resulting equation of motion is given by

$$\frac{\partial L}{\partial \phi} - \frac{d}{dt}\frac{\partial L}{\partial \dot{\phi}} = 0. \tag{5}$$

By introducing the momentum

$$\chi = \frac{\partial L}{\partial \dot{\phi}}, \tag{6}$$

and the Hamiltonian

$$H(\chi,\phi) = \dot{\phi}\chi - L(\phi,\dot{\phi}), \tag{7}$$

the second-order equation of motion can be written as a system of two first-order Hamilton's equations,

$$\dot{\mathbf{z}} = \mathbf{f}(\mathbf{z}), \tag{8}$$

where $\mathbf{z} = (\phi,\chi)$ is a point in a two-dimensional phase space and $\mathbf{f} = (f_1, f_2)$ is given by

$$f_1(\phi,\chi) = \frac{\partial H}{\partial \phi}, \quad f_2(\phi,\chi) = -\frac{\partial H}{\partial \chi}. \tag{9}$$

This is a general result: any homogenous field theory can be written as a system of N first-order differential equations, i.e., a dynamical system. In the next sections we shall consider nonconservative and non-Abelian field theories.

A. Dynamical system theory

A dynamical system is defined by N first-order differential equations,

$$\dot{\mathbf{z}}(t) = \mathbf{f}(\mathbf{z}(t),t), \tag{10}$$

where the variables $\mathbf{z} = (z_1,\ldots,z_N)$ are in the phase space Ω (the Euclidean space R^N, unless otherwise specified). These equations describe the time evolution of the variables and the system they represent.[9–11]

A solution of the dynamical system is a vector function $\mathbf{z}(\mathbf{z}_0,t)$, which satisfies (10) and the initial condition

$$\mathbf{z}(\mathbf{z}_0,0) = \mathbf{z}_0 . \tag{11}$$

Usually one writes simply $\mathbf{z}(t)$ without the initial condition dependence.

The time evolution of $\mathbf{z} \in \Omega$ is obtained with the one-parameter group of diffeomorphism $g^t : \Omega \to \Omega$, such that

$$\frac{d}{dt}(g^t\mathbf{z})|_{t=0}=\mathbf{f}(\mathbf{z},0). \tag{12}$$

The group g^t is called phase flux and the solution is called orbit. The system is called Hamiltonian, if the dimension of Ω is even and there exists a function $H(\mathbf{z},t)$, given by

$$\mathbf{f}(\mathbf{z}(t),t)=J\,\nabla H(\mathbf{z},t), \tag{13}$$

where

$$J=\begin{pmatrix} 0 & I \\ -I & 0 \end{pmatrix} \tag{14}$$

is the symplectic matrix and $H(\mathbf{z},t)$ is the Hamiltonian function.

On the phase space Ω one usually defines a probability measure $\mu:\Omega\rightarrow\Omega$, such that $\mu(\Omega)=1$. If we choose a subspace A of Ω, the system is measure preserving if

$$\mu(g^tA)=\mu(A). \tag{15}$$

We observe that for measure preserving dynamical systems one gets $\mathrm{div}(\mathbf{f})=0$. It is well known that Hamiltonian systems preserve their measure: the Liouville measure. Dynamical systems that do not preserve their measure are called dissipative, and usually have a measure contraction in time evolution.

The dynamics of a system is called regular if the orbits are stable to infinitesimal variations of initial conditions. It is called chaotic if the orbits are unstable to infinitesimal variations of initial conditions. Useful quantities to calculate this behavior are the Lyapunov exponents, which give the stability of a single orbit.

A vector of the tangent space $T\Omega_{\mathbf{z}}$ to the phase space Ω in the position $\mathbf{z}$ is given by

$$\omega(\mathbf{z})=\lim_{s\rightarrow 0}\frac{\mathbf{r}(s)-\mathbf{r}(0)}{s}, \tag{16}$$

where $\mathbf{r}(0)=\mathbf{z}$ and $\mathbf{r}(s)\in\Omega$. The tangent space vectors are the velocity vectors of the curves on M; there are obviously N independent vectors.

Now we can define the Lyapunov exponent,

$$\lambda(\mathbf{z})=\lim_{t\rightarrow\infty}\frac{1}{t}\ln|\omega(t)|, \tag{17}$$

where $\omega(t)$ is a tangent vector to $\mathbf{z}(t)$ with the condition that $|\omega(0)|=1$.

It can be demonstrated that the limit given by the previous equation exists for a compact phase space, and that it is metric independent. Fixing an orbit in the N-dimensional phase space, there are N distinct exponents $\lambda_1,\ldots,\lambda_N$, called first-order Lyapunov exponents. If the orbit has positive Lyapunov exponents, it is chaotic.

To characterize globally the chaoticity of a system, we can introduce the Kolmogorov–Sinai entropy, which is given by

$$h_{\mathrm{KS}}(\mu)=\int_A d\mu(\mathbf{z})\sum_{\lambda_i>0}\lambda_i(\mathbf{z}), \tag{18}$$

with an A subspace of Ω and λ_i Lyapunov exponents. The Kolmogorov–Sinai entropy is a very useful tool for showing chaotic behavior in the region A.

A system is called ergodic if the time average is equal to the phase space average,

$$\lim_{t\to\infty}\frac{1}{t}\int_0^t dt\, f(g^t\mathbf{z}(t))=\int_\Omega d\mu(\mathbf{z})f(\mathbf{z}). \tag{19}$$

Incidentally, as is well known, Boltzmann started from the ''ergodic hypothesis'' to obtain statistical mechanics of equilibrium. But ergodicity is not sufficient to reach an equilibrium state: one must consider mixing systems.

In a mixing system, every finite element of the phase space occupies for $t\to\infty$ the entire phase space Ω; more precisely: $\forall A, B\subset\Omega$ with $\mu(A)$ and $\mu(B)\neq 0$,

$$\lim_{t\to\infty}\frac{\mu(B\cap g^t A)}{\mu(B)}=\mu(A). \tag{20}$$

To have quantitative information of orbit separations, we must introduce K systems (Kolmogorov), which are mixing systems with a positive metric entropy, i.e., $h_{\mathrm{KS}}>0$. Such systems are typical chaotic systems. Among the K systems, the most unpredictable ones are the B systems (Bernoulli), which have the Kolmogorov–Sinai entropy equal to the entropy of every partition, i.e., $h_{\mathrm{KS}}=h(A_i(0),\mu),\forall A_i(0)$.

B. Hamiltonian dynamics

Let us consider a Hamiltonian system with n degrees of freedom described by the Hamiltonian function $H(\mathbf{z})$, where $\mathbf{z}=(q_1,\ldots,q_n,p_1,\ldots,p_n)$ so that the phase space is $N=2n$ dimensional. The Hamiltonian system is called integrable if there are N functions $F_i=F_i(\mathbf{z})$ defined on Ω in involution:

$$[F_i,F_j]_{\mathrm{PB}}=\sum_{k=1}^{n}\frac{\partial F_i}{\partial q_k}\frac{\partial F_j}{\partial p_k}-\frac{\partial F_j}{\partial q_k}\frac{\partial F_i}{\partial p_k}=0, \quad \forall i,j, \tag{21}$$

and linearly independent. $[,]_{\mathrm{PB}}$ are the Poisson brackets.

For conservative systems we have $F_1=H(\mathbf{z})$, and also

$$\frac{dF_i}{dt}=[H,F_i]_{\mathrm{PB}}=0. \tag{22}$$

Because there are n constants of motion, every orbit can explore only the n-dimensional manifold $\Omega_f=\{\mathbf{z}:F_i(\mathbf{z})=f_i,\, i=1,\ldots,n\}$. If Ω_f is compact and connected, it is equivalent to an n-dimensional torus $T^n=\{(Q_1,\ldots,Q_n)\bmod 2\pi\}$. There are n irreducible and independent circuits γ_i on Ω_f and there exists a canonical transformation $(\mathbf{p},\mathbf{q})\to(\mathbf{P},\mathbf{Q})$, generated by the function $S(\mathbf{q},\mathbf{P})$, such that

$$P_i=\oint_{\gamma i} d\mathbf{q}\cdot\mathbf{p}, \quad Q_i=\frac{\partial S}{\partial P_i}. \tag{23}$$

The P_i are called action variables and the Q_i are called angle variables. The moments $\mathbf{p}$ and coordinates $\mathbf{q}$ are periodic functions of $\mathbf{Q}$ with period 2π. The Hamiltonian depends only on action variables, i.e., $H=H(\mathbf{P})$.

Adding a small perturbation $V(\mathbf{P},\mathbf{Q})$ to an integrable Hamiltonian $H_0(\mathbf{P})$, the total Hamiltonian can be written as

$$H(\mathbf{P},\mathbf{Q})=H_0(\mathbf{P})+gV(\mathbf{P},\mathbf{Q}), \tag{24}$$

and, generically, the integrability is destroyed. As a consequence, parts of phase space become filled with chaotic orbits, while in other parts the toroidal surfaces of the integrable system are deformed but not destroyed; thus we have a quasi-integrable system. By growing g, chaotic motion develops near the regions of phase space, where all the frequencies on the torus $\omega_i = \partial H(\mathbf{P})/\partial P$ are commensurate. Conversely, tori of the integrable system, on which the ω_i are incommensurate, are deformed, but not destroyed immediately [Kolmogorov–Arnold–Moser (KAM) theorem].[9,18] As g increases, the phase space generically develops a highly complex structure, with islands of regular motion (filled with quasiperiodic orbits) interspersed in regions of chaotic motion, but containing in turn more regions of chaos. As g grows further, the fraction of phase space filled with chaotic orbits grows until it reaches unity as the last KAM surface is destroyed. Then the motion is completely chaotic everywhere, except possibly for isolated periodic orbits.[9,18]

It is very useful to plot a $2n-1$ surface of section $\mathcal{P}\subset\Omega$, called a Poincaré section. For an integrable system with two degrees of freedom, the $q_1=0$ Poincaré section of a rational (resonant) torus is a finite number of points along a closed curve, while the section of an irrational (nonresonant) torus is a continuous closed curve. Adding a perturbation, in the section we present closed curves (KAM tori), whose points are stable (elliptic), and also curves formed by substructures, residua of resonant tori, whose points are unstable (hyperbolic). As the perturbation parameter increases, the closed curves are distorted and reduced in number.

C. Quantum chaos

We use the term quantum chaotic system in the precise and restricted sense of a quantum system whose classical analog is chaotic. In particular, we concentrate on energy levels of quantum systems (see, for example, Refs. 18 and 19).

Let us consider a classical regular Hamiltonian system. The short-range properties of the corresponding quantal spectrum tend to resemble those of a spectrum of randomly distributed numbers. This is because regular classical motion is associated with integrability or separability of the classical equations of motion. In quantum mechanics the separability corresponds to a number of independent conserved quantities (such as angular momentum), and each energy level can be characterized by the associated quantum numbers. Superimposing the terms arising from the various quantum numbers, a spectrum is generated like that of random numbers, at least over short intervals. In particular, the distribution $P(s)$ of nearest-neighbor spacings $s_i=(\epsilon_{i+1}-\epsilon_i)/d$, where d is the mean level spacing, is expected to follow the Poisson limit, i.e., $P(s)=\exp(-s)$.

Instead, when the classical dynamics of a physical system is chaotic, the system cannot be integrable, and there must be fewer constants of motion than degrees of freedom. Quantum mechanically, this means that once all good quantum numbers due to obvious symmetries, etc., are accounted for, the energy levels cannot simply be labeled by quantum numbers associated with certain constants of motion. The short-range properties of the energy spectrum then tend to resemble those of eigenvalue spectra of matrices with randomly chosen elements, and one gets a result very close to $P(s)=(\pi/2)s\exp[-(\pi/4)s^2]$, which is the so-called Wigner distribution.

The distribution $P(s)$ is the best spectral statistics to analyze a shorter series of energy levels and the intermediate regions between order and chaos. This distribution can be compared to the Brody distribution,

$$P(s,\omega)=\alpha(\omega+1)s^{\omega}\exp(-\alpha s^{\omega+1}), \tag{25}$$

with

$$\alpha=\left(\Gamma\left[\frac{\omega+2}{\omega+1}\right]\right)^{\omega+1}. \tag{26}$$

The Brody distribution interpolates between the Poisson distribution ($\omega=0$) of integrable systems and the Wigner distribution ($\omega=1$) of chaotic ones, and thus the parameter ω can be used as a simple quantitative measure of the degree of chaoticity.

III. A MODEL FOR INFLATIONARY COSMOLOGY

In this section we study the stability of a scaler inflation field[12,13] and analyze its bifurcation properties in the framework of the dynamical system theory.

It is generally believed that the universe, at a very early stage after the big bang, exhibited a short period of exponential expansion, the so-called inflationary phase. In fact, the assumption of an inflationary universe solves three major cosmological problems: the flatness problem, the homogeneity problem, and the formation of a structure problem.[3]

The Friedmann–Robertson–Walker metric of a homogeneous and isotropic expanding universe is given by

$$ds^2 = dt^2 - a^2(t)\left[\frac{dr^2}{1-kr^2} + r^2(d\theta^2 + \sin^2\theta\, d\varphi^2)\right], \tag{27}$$

where $k=1$, -1, or 0 for a closed, open, or flat universe, and $a(t)$ is the scale factor of the universe.

The evolution of the scale factor $a(t)$ is given by the Einstein equations

$$\ddot{a} = -\frac{4\pi}{3}G(\rho+3p)a, \quad \left(\frac{\dot{a}}{a}\right)^2 + \frac{k}{a^2} = \frac{8\pi}{3}G\rho, \tag{28}$$

where ρ is the energy density of matter in the universe, and p its pressure. The gravitational constant $G=M_p^{-2}$ (with $\hbar=c=1$), where $M_p=1.2\times 10^{19}$ GeV is the Plank mass, and $H_u=\dot{a}/a$ is the Hubble "constant," which, in general, is a function of time.

The inflationary models postulate the existence of a scalar field ϕ, the so-called inflation field, with Lagrangian

$$L = \tfrac{1}{2}\partial_\mu\phi\,\partial^\mu\phi - V(\phi), \tag{29}$$

where the potential $V(\phi)$ depends on the type of inflation model considered. The scalar field, if minimally coupled to gravity, satisfies the equation

$$\Box\phi = \ddot{\phi} + 3\left(\frac{\dot{a}}{a}\right)\dot{\phi} - \frac{1}{a^2}\nabla^2\phi = -\frac{\partial V}{\partial\phi}, \tag{30}$$

where $\Box$ is the covariant d'Alembertian operator. The Hubble "constant" H_u is related to the energy density of the field by

$$H_u^2 + \frac{k}{a^2} = \left(\frac{\dot{a}}{a}\right)^2 + \frac{k}{a^2} = \frac{8\pi G}{3}\left[\frac{\dot{\phi}^2}{2} + \frac{(\nabla\phi)^2}{2} + V(\phi)\right]. \tag{31}$$

In a flat universe $k=0$ and, if the inflation field is sufficiently uniform [i.e., $\dot{\phi}^2, (\nabla\phi)^2 \ll V(\phi)$], we obtain a homogeneous field theory in one dimension,

$$\ddot{\phi} + 3H_u(\phi)\dot{\phi} + \frac{\partial V}{\partial\phi} = 0, \tag{32}$$

where the Hubble "constant" H_u is an explicit function of ϕ:

$$H_u^2 = \frac{8\pi G}{3}V(\phi). \tag{33}$$

A. Local instability for the inflationary self-energy

The second-order equation of motion of our cosmological model can be written as a system of two first-order differential equations,

$$\dot{\mathbf{z}} = \mathbf{f}(\mathbf{z}), \tag{34}$$

where $\mathbf{z} = (\phi, \chi)$ is a point in the two-dimensional phase space and $\mathbf{f} = (f_1, f_2)$ is given by

$$f_1(\phi,\chi) = \chi, \quad f_2(\phi,\chi) = -3H_u(\phi)\chi - \frac{\partial V(\phi)}{\partial \phi}. \tag{35}$$

The system is nonconservative, because the function

$$\mathrm{div}(\mathbf{f}) = \frac{\partial g_1}{\partial \phi} + \frac{\partial g_2}{\partial \chi} = -3H_u(\phi), \tag{36}$$

is not identically zero. The fixed points of the system are those for which $f_1(\phi,\chi) = 0$ and $f_2(\phi,\chi) = 0$, i.e.,

$$\chi = 0, \quad \frac{\partial V(\phi)}{\partial \phi} = 0. \tag{37}$$

The deviation $\delta\mathbf{z}(t) = \hat{\mathbf{z}}(t) - \mathbf{z}(t)$ from the two initially neighboring trajectories $\mathbf{x}$ and $\hat{\mathbf{x}}$ in the phase space satisfies the linearized equations of motion,

$$\frac{d}{dt}\delta\mathbf{z}(t) = \Gamma(t)\,\delta\mathbf{z}, \tag{38}$$

where $\Gamma(t)$ is the stability matrix

$$\Gamma(t) = \begin{pmatrix} 0 & 1 \\ -\dfrac{\partial^2 V}{\partial \phi^2} - 3\chi \dfrac{\partial H}{\partial \phi} & -3H_u(\phi) \end{pmatrix}. \tag{39}$$

At least if an eigenvalue of $\Gamma(t)$ is real, the separation of the trajectories grows exponentially and the motion is unstable. Imaginary eigenvalues correspond to stable motion. In the limit of time that goes to infinity, from the eigenvalues of the stability matrix, we can obtain the Lyapunov exponents. For a two-dimensional dynamical system, the Lyapunov exponents cannot be positive[9] and so the system is not chaotic, i.e., there is not global instability. However, we can be assured that the universe is crowded with many interacting fields of which the inflation is but one. The nonlinear nature of these interactions can result in a complex chaotic evolution of the universe and the local instability of the inflation field is a precursor phenomenon of chaotic motion.

The eigenvalues of the stability matrix are given by

$$\sigma_{1,2} = -\frac{3}{2}H_u(\phi) \pm \frac{1}{2}\sqrt{9H_u^2(\phi) - 4\frac{\partial^2 V}{\partial \phi^2} - 12\chi\frac{\partial H_u}{\partial \phi}}. \tag{40}$$

The pair of eigenvalues become real and there is exponential separation of neighboring trajectories, i.e., unstable motion, if

$$\frac{\partial^2 V}{\partial \phi^2} + 3\chi\frac{\partial H_u}{\partial \phi} < 0. \tag{41}$$

Particularly when $\chi = 0$, e.g., the fixed points, we obtain local instability when

$$\frac{\partial^2 V}{\partial \phi^2} < 0, \tag{42}$$

i.e., for negative curvature of the potential energy. The fixed points are stable if they are a point of the local minimum of $V(\phi)$ and unstable if they are points of the local maximum.

The potential $V(\phi)$ depends on the type of inflation model considered, and it is usually some kind of double-well potential. We choose a symmetric double-well potential,

$$V(\phi)=\frac{\lambda}{4}(\phi^2-v^2)^2, \tag{43}$$

where $\pm v$ are the values of the inflaton field in the vacuum, i.e., the points of minimal energy of the system.

We observe that the inflation field value in the vacuum v is a bifurcation parameter. Bifurcation is used to indicate a qualitative change in the features of the system under the variation of one or more parameters on which the system depends. First of all we consider the case $v=0$, i.e., $V(\phi)=(\lambda/4)\phi^4$. In this situation there is only one fixed point $(\phi^*=0,\chi^*=0)$ which is a stable one being

$$\frac{\partial^2 V}{\partial \phi^2}=3\lambda\phi^2\geqslant 0. \tag{44}$$

The fixed point $(\phi^*=0,\chi^*=0)$ is a point attractor.

Instead, for $v\neq 0$, there are three fixed points:

$$(\phi^*=0,\chi^*=0),\quad (\phi^*=v,\chi^*=0),\quad (\phi^*=-v,\chi^*=0), \tag{45}$$

and the condition for the instability becomes

$$-\frac{v}{\sqrt{3}}<\phi<\frac{v}{\sqrt{3}}. \tag{46}$$

Obviously $(\phi^*=0,\chi^*=0)$ is an unstable fixed point, and, in particular, a saddle point because the stability matrix has real and opposite eigenvalues. On the other hand $(\phi^*=\pm v,\chi^*=0)$ are stable fixed points.

There are four possible functions for the Hubble ''constant:''

$$H_u(\phi)=\pm\gamma|\phi^2-v^2|, \tag{47}$$

but also

$$H_u(\phi)=\pm\gamma(\phi^2-v^2), \tag{48}$$

where $\gamma=\sqrt{2\pi G\lambda/3}$ is the dissipation parameter. The choice of the Hubble function is crucial for the dynamical evolution of the system.

In certain nonconservative systems, we could find closed trajectories or limit cycles toward which the neighboring trajectories spiral on both sides. It is sometimes possible to know that no limit cycle exists and the Bendixson criterion,[20] which establishes a condition for the nonexistence of closed trajectories, is useful in some cases. Bendixson criterion is as follows: if div(**f**) is not zero and does not change its sign within a domain D of the phase space, no closed trajectories can exist in that domain. In our case we have $\text{div}(\mathbf{f})=-3H_u(\phi)$, and so the presence of periodic orbit is related to the sign of $H_u(\phi)$.

If $H_u(\phi)=\gamma|\phi^2-v^2|$ we do not find periodic orbits and the inflation field goes to one of its two stable fixed points, which are points attractors (see Fig. 1). The vacuum is degenerate, but if we choose an initial condition around the saddle point, there is a dynamical symmetry breaking toward the positive v or negative $-v$ value of the inflation field in the vacuum. This symmetry breaking is unstable because neighbor initial conditions can go in different point attractors.

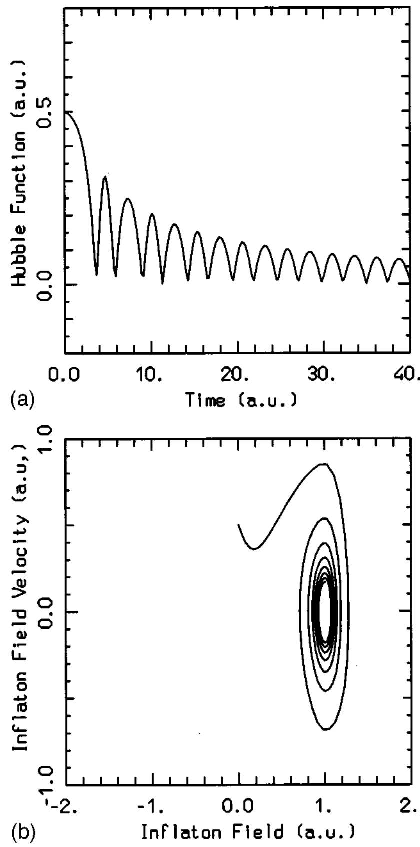

FIG. 1. The Hubble function versus time (top) and the phase space trajectory of the inflation field (bottom); for $H_u(\phi)=\gamma|\phi^2-v^2|$ with $\gamma=\frac{1}{2}$, $\lambda=3$, and $v=1$. Initial conditions: $\phi=0$ and $\dot{\phi}=\frac{1}{2}$.

Instead, if we choose $H_u(\phi)=\gamma(\phi^2-v^2)$, the numerical calculations of Fig. 2 show that a limit cycle exists, the two stable fixed points are not point attractors, and the inflaton field oscillates forever. Obviously the larger v is the larger the limit cycle.

B. A limit cycle in the cosmological model

The equation of motion of the inflation field with $H_u(\phi)=\gamma(\phi^2-v^2)$ reads as

$$\ddot{\phi}+3\gamma(\phi^2-v^2)\dot{\phi}+\lambda\phi(\phi^2-v^2)=0. \tag{49}$$

This equation can be written as

$$\frac{d}{dt}\left[\dot{\phi}+3\gamma\int_0^{\phi}(u^2-v^2)du\right]+\lambda\phi(\phi^2-v^2)=0, \tag{50}$$

and if we put

$$F(\phi)=3\int_0^{\phi}(u^2-v^2)du=\phi(\phi^2-3v^2), \quad G(\phi)=\phi(\phi^2-v^2), \tag{51}$$

and also $\omega=\dot{\phi}+\gamma F(\phi)$, we obtain the system

$$\dot{\phi}=\omega-\gamma F(\phi), \quad \dot{\omega}=-\lambda G(\phi). \tag{52}$$

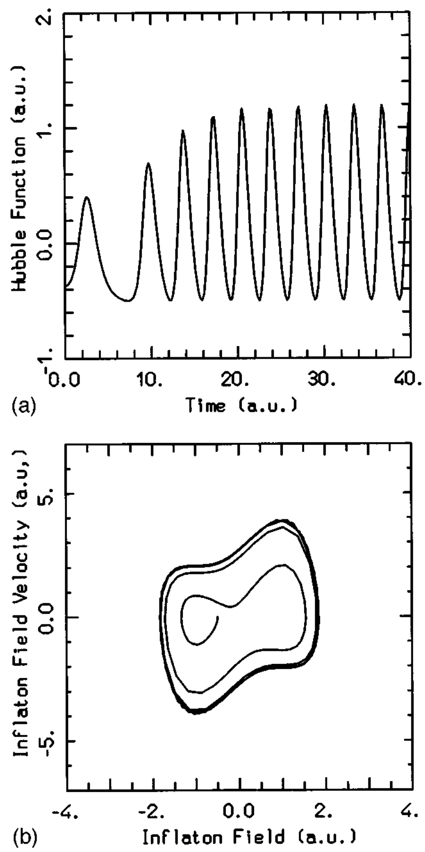

FIG. 2. The Hubble function versus time (top) and the phase space trajectory of the inflation field (bottom); for $H_u(\phi) = \gamma(\phi^2 - v^2)$ with $\gamma = \frac{1}{2}$, $\lambda = 3$, and $v = 1$. Initial conditions: $\phi = -\frac{1}{2}$ and $\dot{\phi} = 0$.

For systems of this kind, the Lienard theorem[21] states that there is a unique and stable limit cycle if the following conditions are satisfied: $F(\phi)$ is an odd function and $F(\phi) = 0$ only at $\phi = 0$ and $\phi = \pm\alpha$; $F(\phi) < 0$ for $0 < \phi < \alpha$, $F(\phi) > 0$ and is increasing for $\phi > \alpha$; $G(\phi)$ is an odd function and $\phi G(\phi) > 0$ for all $\phi > \alpha$. It is easy to check that the functions $F(\phi)$ and $G(\phi)$ satisfy all the conditions of the Lienard theorem with $\alpha = v$. The cubic force $G(\phi)$ tends to reduce any displacement for large $|\phi|$, whereas the damping $F(\phi)$ is negative at small $|\phi|$ and positive at large $|\phi|$. Since small oscillations are pumped up and large oscillations are damped down, it is not surprising that the system tends to settle into a self-sustained oscillation of some intermediate amplitude.

Let us consider a typical trajectory of the system. After the scaling $\psi = \lambda\omega$, we obtain

$$\dot{\phi} = \lambda\left[\psi - \frac{\gamma}{\lambda}F(\phi)\right], \quad \dot{\psi} = -G(\phi). \tag{53}$$

The cubic nullcline $\psi = (\gamma/\lambda)F(\phi)$ is the key to understanding the motion. Suppose that $\lambda \gg 1$ and the initial condition is far from the cubic nullcline, then we have $|\dot{\phi}| \sim O(\lambda) \gg 1$; hence, the velocity is enormous in the horizontal direction and tiny in the vertical direction, so trajectories move practically horizontally. If the initial condition is above the nullcline, then $\dot{\phi} > 0$; thus the trajectory moves sideways toward the nullcline. However, once the trajectory gets so close that $\psi \simeq (\lambda/\gamma)F(\phi)$ then the trajectory crosses the nullcline vertically and moves slowly along the backside of the branch until it reaches the knee and can jump sideways again. The period T of the limit cycle is essentially the time required to travel along the two slow branches, since the time spent in the jumps is negligible for large λ. By symmetry, the time spent on each branch is the same, so we have

$$T \simeq 2 \int_{t_A}^{t_B} dt, \tag{54}$$

where A and B are the initial and final points on the positive slow branch. To derive an expression for dt, we note that on the slow branches with a good approximation $\psi \simeq (\gamma/\lambda) F(\phi)$, and thus

$$\frac{d\psi}{dt} \simeq \frac{\gamma}{\lambda} F'(\phi) \frac{d\phi}{dt} = 3 \frac{\gamma}{\lambda} (\phi^2 - v^2) \frac{d\phi}{dt}. \tag{55}$$

Since $d\psi/dt = -\phi(\phi^2 - v^2)$, we obtain $dt \simeq -3(\gamma/\lambda)(d\phi/\phi)$, on the slow branches. The slow positive branch begins at $\phi_A = 2\gamma v/\lambda$ and ends at $\phi_B = \gamma v/\lambda$. Because $\gamma = \sqrt{2\pi G \lambda/3}$ we get $T \simeq 2 \ln 2 \sqrt{6\pi G/\lambda}$.

IV. THE HOMOGENEOUS SU(2) YMH SYSTEM

Now we study the suppression of classical chaos in the spatially homogeneous SU(2) Yang–Mills–Higgs (YMH) system induced by the Higgs field.[4,14,15] We analyze also the energy fluctuation properties of the system, which give a clear quantum signature of the classical chaos–order transition of the system.

The SU(2) YMH system describes the interaction between a scalar Higgs field ϕ and three non-Abelian Yang–Mills fields A_μ^a, $a = 1,2,3$. The Lagrangian density of the YMH system is given by

$$L = \tfrac{1}{2}(D_\mu \phi)^+ (D^\mu \phi) - V(\phi) - \tfrac{1}{4} F_{\mu\nu}^a F^{\mu\nu a}, \tag{56}$$

where

$$(D_\mu \phi) = \partial_\mu \phi - i g A_\mu^b T^b \phi, \tag{57}$$

$$F_{\mu\nu}^a = \partial_\mu A_\nu^a - \partial_\nu A_\mu^a + g \epsilon^{abc} A_\mu^b A_\nu^c, \tag{58}$$

with $T^b = \sigma^b/2$, $b = 1,2,3$, generators of the SU(2) algebra, and where the potential of the scalar field (the Higgs field) is

$$V(\phi) = \mu^2 |\phi|^2 + \lambda |\phi|^4. \tag{59}$$

We work in the $(2+1)$-dimensional Minkowski space ($\mu = 0,1,2$) and choose spatially homogeneous Yang–Mills and the Higgs fields,

$$\partial_i A_\mu^a = \partial_i \phi = 0, \quad i = 1,2, \tag{60}$$

i.e., we consider the system in the region in which space fluctuations of fields are negligible compared to their time fluctuations.

In the gauge $A_0^a = 0$ and using the real triplet representation for the Higgs field, we obtain

$$L = \dot{\phi}^2 + \tfrac{1}{2}(\dot{A}_1^2 + \dot{A}_2^2) - g^2 [\tfrac{1}{2} A_1^2 A_2^2 - \tfrac{1}{2}(A_1 \cdot A_2)^2 + (A_1^2 + A_2^2)\phi^2 - (A_1 \cdot \phi)^2 - (A_2 \cdot \phi)^2] - V(\phi), \tag{61}$$

where $\phi = (\phi^1, \phi^2, \phi^3)$, $A_1 = (A_1^1, A_1^2, A_1^3)$, and $A_2 = (A_2^1, A_2^2, A_2^3)$.

When $\mu^2 > 0$, the potential V has a minimum at $|\phi| = 0$, but for $\mu^2 < 0$ the minimum is at

$$|\phi_0| = \sqrt{\frac{-\mu^2}{4\lambda}} = v,$$

which is the nonzero Higgs vacuum. This vacuum is degenerate and after spontaneous symmetry breaking the physical vacuum can be chosen as $\phi_0=(0,0,v)$. If $A_1^1=q_1$, $A_2^2=q_2$ and the other components of the Yang–Mills fields are zero, in the Higgs vacuum the Hamiltonian of the system reads as

$$H=\tfrac{1}{2}(p_1^2+p_2^2)+g^2v^2(q_1^2+q_2^2)+\tfrac{1}{2}g^2q_1^2q_2^2, \tag{62}$$

where $p_1=\dot{q}_1$ and $p_2=\dot{q}_2$. Here $w^2=2g^2v^2$ is the mass term of the Yang–Mills fields. This YMH Hamiltonian is a toy model for classical nonlinear dynamics, with the attractive feature that the model emerges from particle physics.

A. From chaos to order in the YMH system

The chaotic behavior of the YMH system can be studied by using the Toda criterion of the Gaussian curvature of the potential energy.[22,23] For our YMH system the potential energy is given by

$$V(q_1,q_2)=g^2v^2(q_1^2+q_2^2)+\tfrac{1}{2}g^2q_1^2q_2^2. \tag{63}$$

At low energy, the motion near the minimum of the potential, where the Gaussian curvature is positive, is periodic or quasiperiodic and is separated from the instability region by a line of zero curvature; if the energy is increased, the system will be, for some initial conditions, in a region of negative curvature, where the motion is chaotic. According to this scenario, the energy E_c of the chaos–order transition is equal to the minimum value of the line of zero Gaussian curvature $K_{\mathrm{G}}(q_1,q_2)$ on the potential-energy surface. For our potential the Gaussian curvature vanishes at the points that satisfy the equation,

$$(2g^2v^2+g^2q_2^2)(2g^2v^2+g^2q_1^2)-4g^4q_1^2q_2^2=0. \tag{64}$$

It is easy to show that the minimal energy on the zero-curvature line is given by

$$E_c=V_{\mathrm{min}}(K_{\mathrm{G}}=0,\overline{q_1})=6g^2v^4, \tag{65}$$

and by inverting this equation we obtain $v_c=(E/6g^2)^{1/4}$. Thus the curvature criterion suggest that there is a order–chaos transition by increasing the energy E of the system and a chaos–order transition by increasing the value v of the Higgs field in the vacuum. Thus, there is only one transition regulated by the parameter $E/(g^2v^4)$.

It is important to stress that the Toda criterion is not a fully reliable indicator of chaos.[23] In fact, the local instability of the Toda Criterion does not necessarily imply the global one, and the idea of an order–chaos transition with a critical energy is not strictly correct. The Toda curvature criterion should therefore be combined with the Poincaré sections, which are shown in Fig. 3. The numerical results confirm the analytical predictions of the curvature criterion: with $E=10$ and $g=1$ we get the critical value of the onset of chaos $v_c=(E/6g^2)^{1/4}\simeq 1.14$.

B. Spectral statistics of the YMH system

In quantum mechanics the generalized coordinates of the YMH system satisfy the usual commutation rules $[\hat{q}_k,\hat{p}_l]=i\delta_{kl}$, with $k,l=1,2$. Introducing the creation and destruction operators,

$$\hat{a}_k=\sqrt{\frac{\omega}{2}}\,\hat{q}_k+i\sqrt{\frac{1}{2\omega}}\,\hat{p}_k, \quad \hat{a}_k^+=\sqrt{\frac{\omega}{2}}\,\hat{q}_k-i\sqrt{\frac{1}{2\omega}}\,\hat{p}_k, \tag{66}$$

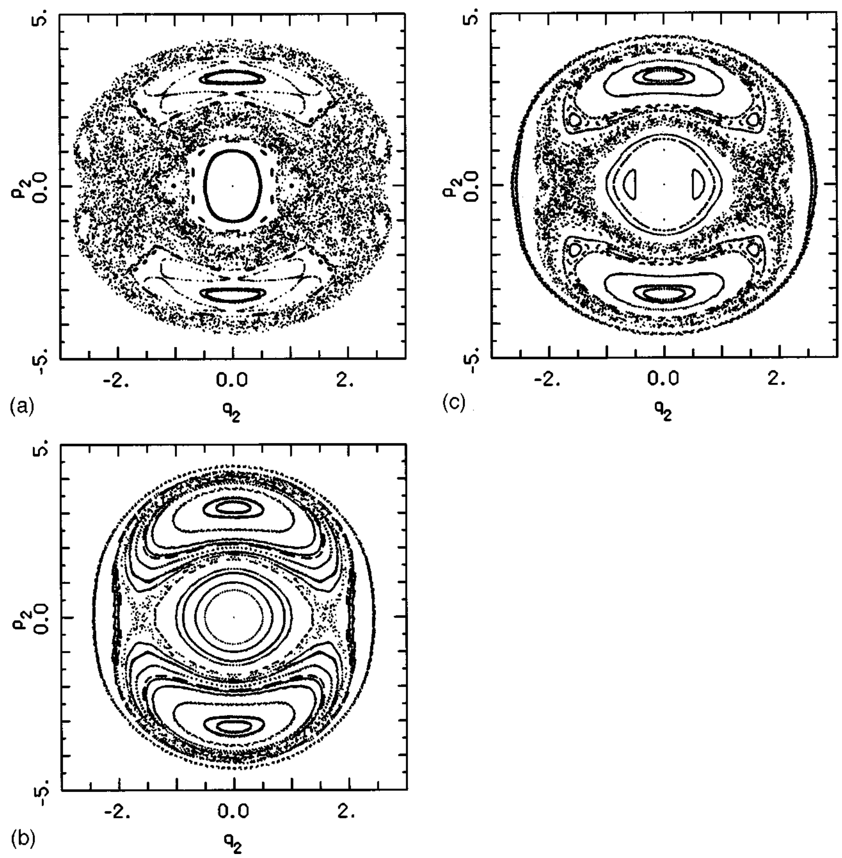

FIG. 3. The Poincarè sections of the YMH system. From the top: $v=1$, $v=1.1$, and $v=1.2$. Energy $E=10$ and interaction $g=1$.

the quantum YMH Hamiltonian can be written as

$$\hat{H}=\hat{H}_0+\tfrac{1}{2}g^2\hat{V}, \tag{67}$$

where

$$\hat{H}_0=\omega(\hat{a}_1^+\hat{a}_1+\hat{a}_2^+\hat{a}_2+1), \tag{68}$$

$$\hat{V}=\frac{1}{4\omega^2}(\hat{a}_1+\hat{a}_1^+)^2(\hat{a}_2+\hat{a}_2^+)^2, \tag{69}$$

with $\omega^2=2g^2v^2$ and $[\hat{a}_k,\hat{a}_l^+]=\delta_{kl}$, $k,l=1,2$.

We compute the energy levels of the YMH system with a numerical diagonalization of the truncated matrix of the quantum YMH Hamiltonian in the basis of the harmonic oscillators (see also Refs. 16 and 17). If $|n_1n_2\rangle$ is the basis of the occupation numbers of the two harmonic oscillators, the matrix elements are

$$\langle n_1'n_2'|\hat{H}_0|n_1n_2\rangle=\omega(n_1+n_2+1)\,\delta_{n_1'n_1}\delta_{n_2'n_2}, \tag{70}$$

and

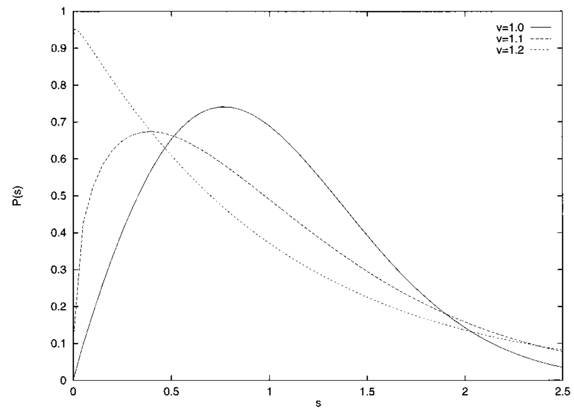

FIG. 4. The $P(s)$ distribution of Brody of the YMH system. The first 100 energy levels and $g=1$. The best fit Brody parameter is given by $\omega=0.92$ for $v=1.0$, $\omega=0.34$ for $v=1.1$, and $\omega=0.01$ for $v=1.2$.

$$\langle n_1' n_2' | \hat{V} | n_1 n_2 \rangle = \frac{1}{4\omega^2} [\sqrt{n_1(n_1-1)}\,\delta_{n_1' n_1 -2} + \sqrt{(n_1+1)(n_1+2)}\,\delta_{n_1' n_1+2} + (2n_1+1)\,\delta_{n_1' n_1}] \times [\sqrt{n_2(n_2-1)}\,\delta_{n_2' n_2-2} + \sqrt{(n_2+1)(n_2+2)}\,\delta_{n_2' n_2+2} + (2n_2+1)\,\delta_{n_2' n_2}]. \quad (71)$$

The symmetry of the potential enables us to split the Hamiltonian matrix into four submatrices reducing the computer storage required. These submatrices are related to the parity of the two occupation numbers n_1 and n_2: even–even, odd–odd, even–odd, and odd–even. The numerical energy levels depend on the dimension of the truncated matrix: we compute the numerical levels in double precision increasing the matrix dimension until the first 100 levels converge within eight digits (matrix dimension 1156×1156).

We have seen previously that the most used quantity to study the local fluctuations of the energy levels is the distribution $P(s)$ of nearest-neighbor spacings s_i of the energy levels. It is obtained by accumulating the number of spacings that lie within the bin $(s, s+\Delta s)$ and then normalizing $P(s)$ to unit.

We use the first 100 energy levels of the four submatrices to calculate the $P(s)$ distribution. In order to remove the secular variation of the level density as a function of the energy E, for each value of the coupling constant the corresponding spectrum is mapped into one that has a constant level density.

Figure 4 shows the $P(s)$ distribution of Brody for three different values of the Higgs vacuum v. The best fit Brody parameter ω is obtained by using the nearest-neighbor spacings of the first 100 unfolded energy levels of the YMH system. There is a Wigner–Poisson transition by increasing the value v of the Higgs field in the vacuum. Thus, by using the $P(s)$ distribution, it is possible to give a quantitative measure of the degree of quantal chaoticity of the system. Our numerical calculations show clearly the quantum chaos–order transition and its correspondence to the classical one.

V. CONCLUSIONS

We have seen that spatially homogeneous field theories can be studied as dynamical systems. After a brief review of the dynamical system theory, we have discussed two schematic models of field theory.

First, we have considered the stability of a nonconservative scalar inflation field. The value of the inflation field in the vacuum is a bifurcation parameter that changes dramatically the phase space structure. The main point is that for some functional solutions of the Hubble ''constant'' the system goes to a limit cycle, i.e., to a periodic orbit. The inflation field is not chaotic, but its local instability can give rise to a complex chaotic evolution of the universe due to its nonlinear interactions with other fields. In the future it will be very interesting to study these effects, which can perhaps lead to some observable implications like a fractal pattern in the spectrum of density fluctuations.

We have then analyzed the non-Abelian SU(2) Yang–Mills–Higgs system. We have given an analytical estimation (confirmed by numerical results of Poincaré sections) of the classical chaos–order transition as a function of the Higgs vacuum, the Yang–Mills coupling constant, and the energy of the system. A quantum signature of a chaos–order transition has been obtained by using the distribution $P(s)$ of nearest-neighbor spacings. The Wigner–Poisson transition of the $P(s)$ distribution follows very well the classical results of the Poincaré sections.

To conclude, we observe that there are yet many open problems about chaos in field theory. We make a list of some of them: (i) spatial chaos and space–time chaos; (ii) classical and quantum chaos in more realistic systems, for example, in QCD (some results can be found in Refs. 7 and 8); (iii) the connection between chaos and critical phenomena (finite temperature field theory).

Dimension of the global attractor for damped semilinear wave equations with critical exponent

Zhou Shengfan[a)]
Department of Mathematics, Sichuan University, Chengdu 610064, People's Republic of China

(Received 28 January 1999; accepted for publication 21 April 1999)

We obtain an estimate of the upper bound of the Hausdorff dimension of the global attractor for damped semilinear wave equations with a critical exponent. The obtained Hausdorff dimension decreases as the damping grows for large damping. © *1999 American Institute of Physics.* [S0022-2488(99)01509-1]

I. INTRODUCTION

Our aim in this paper is to estimate the upper bound of the Hausdorff dimension of the attractor for damped semilinear wave equations with a homogeneous Dirichlet boundary condition when the nonlinearity satisfies the critical growth condition. Let Ω be an open bounded set of R^3 with a smooth boundary $\partial\Omega$, we consider the initial-boundary value problem of the equation

$$u_{tt}+\alpha u_t-\Delta u+f(u)=g, \quad x\in\Omega, \quad t>0, \tag{1.1}$$

$$u(x,t)|_{x\in\partial\Omega}=0, \quad t>0, \tag{1.2}$$

$$u(x,0)=u_0(x), \quad \frac{\partial u}{\partial t}(x,0)=u_1(x), \quad x\in\Omega, \tag{1.3}$$

where $u=u(x,t)$ is a real-valued function on $\Omega\times[0,+\infty)$, $g\in L^2(\Omega)$, $\alpha>0$, $f(u)=f_1(u)+f_2(u)\in C^1(R;R)$.

Let $G_i(s)=\int_0^s f_i(r)dr$, $i=1,2$. We make the following assumptions on functions $G_i(s)$, $f_i(s)$, $i=1,2$.

(i)

$$f_1(s)s\geqslant 0, \quad \lim_{|s|\to+\infty}\inf\frac{G_2(s)}{s^2}\geqslant 0, \quad \forall s\in R. \tag{1.4}$$

(ii) There exist constants $c_{1i}>0$, $c_{2i}>0$, $i=1,2$ such that

$$\lim_{|s|\to+\infty}\inf\frac{sf_i(s)-c_{1i}G(s)}{s^2}\geqslant 0, \quad i=1,2 \quad \forall s\in R, \tag{1.5}$$

$$|f_1'(s)|\leqslant c_{21}(1+|s|^2), \quad |f_2'(s)|\leqslant c_{22}(1+|s|^p), \quad \text{with } 0\leqslant p<2, \quad \forall s\in R. \tag{1.6}$$

(iii) For every $M>0$, there exists $c_3=c_3(M)$ such that

$$\|f'(u_1)-f'(u_2)\|_{L(H_0^1(\Omega),L^2(\Omega))}\leqslant c_3\|u_1-u_2\|^{\delta_1}, \quad \forall u_1,u_2\in H_0^1(\Omega), \quad \|u_1\|\leqslant M, \quad \|u_2\|\leqslant M, \tag{1.7}$$

[a)]Electronic mail: nic2601@scu.edu.cn

where $\delta_1>0$, $\|\cdot\|$ and $\|\cdot\|_{L(H_0^1(\Omega),L^2(\Omega))}$ denote the norms of $H_0^1(\Omega)$ and $L(H_0^1(\Omega),L^2(\Omega))$ [the space of linear continuous operators from $H_0^1(\Omega)$ into $L^2(\Omega)$], respectively.

The existence of the global attractor for (1.1)–(1.3) with the critical exponent has been studied by many authors,[1–7] of those, Yu[7] obtained an estimate of the upper bound of the Hausdorff dimension of attractors, but this upper bound of the Hausdorff dimension is directly proportional to the coefficient α of damping for $\alpha\geqslant\sqrt{2\lambda_1}$ and tends to infinity as $\alpha\to+\infty$, which does not conform to the physics. In the noncritical case, the author[8] showed the boundedness of the dimension of an attractor for large damping. In this article, we obtain an upper bound of the Hausdorff dimension of attractor of (1.1) for large damping when the functions $f(u)$ satisfies the conditions (1.4)–(1.7), which generates the result in Ref. 8. The main result is the following theorem.

Theorem 1.1: *If the function $f(u)$ satisfies the conditions (1.4)–(1.7), then for any $\alpha\geqslant\alpha_0>0$, the Hausdorff dimension d_{H} of the global attractor for system (1.1)–(1.3) satisfies*

$$d_{\mathrm{H}}\leqslant\min\left\{ m \,\middle|\, m\in N,\ \frac{1}{m}\sum_{j=1}^{m}\lambda_j^{-4\nu_0}\leqslant\frac{2\lambda_1\alpha^2}{k\sqrt{\alpha^2+4\lambda_1}(\alpha+\sqrt{\alpha^2+4\lambda_1})}\right\}$$
$$\leqslant\min\left\{ m \,\middle|\, m\in N,\ \frac{1}{m}\sum_{j=1}^{m}\lambda_j^{-4\nu_0}\leqslant\frac{2\lambda_1\alpha_0^2}{k\sqrt{\alpha_0^2+4\lambda_1}(\alpha_0+\sqrt{\alpha_0^2+4\lambda_1})}\right\},\qquad(1.8)$$

where $\{\lambda_j\}_{j\in N}:0<\lambda_1\leqslant\lambda_2\leqslant\cdots\leqslant\lambda_m\leqslant\cdots$, are the eigenvalues of operator $-\Delta$ with the Dirichlet boundary condition on Ω and $k=k(\alpha_0)$ is a positive constant, $0<\nu_0<\min\{(2-p)/4,\frac{1}{4}\}$, $p\in[0,2)$ is as in (1.6).

Obviously, the upper bound of d_{H} in (1.8) is a decreasing function of α because

$$h(\alpha)=\frac{2\lambda_1\alpha^2}{k\sqrt{\alpha^2+4\lambda_1}(\alpha+\sqrt{\alpha^2+4\lambda_1})}$$

increases as α grows and

$$\lim_{m\to+\infty}\frac{1}{m}\sum_{j=1}^{m}\lambda_j^{-4\nu_0}=0,\qquad\lim_{\alpha\to+\infty}\frac{2\lambda_1\alpha^2}{k\sqrt{\alpha+4\lambda_1}(\alpha+\sqrt{\alpha^2+4\lambda_1})}=\frac{\lambda_1}{k^2}.$$

II. EXISTENCE OF THE GLOBAL ATTRACTOR

It is known that the operator $A=-\Delta:D(A)=H_0^1(\Omega)\cap H^2(\Omega)\to L^2(\Omega)$ is a self-adjoint positive linear, and its eigenvalues $\{\lambda_i\}_{i\in N}$ satisfy

$$0<\lambda_1\leqslant\lambda_2\leqslant\cdots\leqslant\lambda_m\leqslant\cdots,\quad\text{and}\quad\lambda_m\to+\infty,\quad\text{as }m\to+\infty.$$

Let

$$E=H_0^1(\Omega)\times L^2(\Omega),$$

$$(u,v)=\int_\Omega uv\,dx,\quad|u|=(u,u)^{1/2},\quad\forall u,v\in L^2(\Omega),$$

$$((u,v))=\int_\Omega\nabla u\cdot\nabla v\,dx,\quad\|u\|=((u,u))^{1/2},\quad\forall u,v\in H_0^1(\Omega),$$

$$(y_1,y_2)_E=((u_1,u_2))+(v_1,v_2),\quad\forall y_i=(u_i,v_i)^T\in E,\quad i=1,2,$$

$$|y|_E=(y,y)_E^{1/2},\quad\forall y=(u,v)^T\in E$$

denote the usual inner products and norms in $L^2(\Omega)$, $H_0^1(\Omega)$, and E, respectively.

From the assumptions (1.4)–(1.7), it is easy to obtain the existence and uniqueness of the solution of (1.1)–(1.3), which defines a continuous semigroup of mapping,

$$S(t):E\to E, \quad \{u_0,u_1\}\mapsto\{u,u_t\}, \quad \text{for } t\geqslant 0 \tag{2.1}$$

(see, e.g., Ref. 4 or Ref. 6 for detail).

It is convenient to reduce (1.1) to an evolution equation of the first order in time. Let $\varphi=(u,v)^T$, $v=\dot{u}+\epsilon u$, where ϵ is chosen as

$$\epsilon=\frac{\lambda_1\alpha}{\alpha^2+4\lambda_1}, \tag{2.2}$$

then (1.1)–(1.3) can be written as

$$\dot{\varphi}+\Lambda\varphi=F(\varphi), \quad \varphi(0)=(u_0,u_1+\epsilon u_0), \tag{2.3}$$

where

$$F(\varphi)=\begin{pmatrix} 0 \\ -f(u)+g \end{pmatrix}, \quad \Lambda=\begin{pmatrix} \epsilon I & -I \\ A-\epsilon(\alpha-\epsilon)I & (\alpha-\epsilon)I \end{pmatrix}. \tag{2.4}$$

It is easy to see that the semigroup,

$$S_\epsilon(t):(u_0,u_1+\epsilon u_0)^T\to(u(t),u_t(t)+\epsilon u(t))^T, \quad E\to E, \tag{2.5}$$

defined by (2.3), has the following relation with $S(t)$:

$$S_\epsilon(t)=R_\epsilon S(t)R_{-\epsilon}, \tag{2.6}$$

where $R_\epsilon:\{u,v\}\to\{u,v+\epsilon u\}$ is an isomorphism of E. So, we need consider the equivalent system (2.3) only.

Lemma 2.1: For any $\varphi=(u,v)^T\in E$,

$$(\Lambda\varphi,\varphi)_E\geqslant\sigma|\varphi|_E^2+(\alpha/2)|v|^2, \tag{2.7}$$

where

$$\sigma=\frac{\lambda_1\alpha}{\sqrt{\alpha^2+4\lambda_1}(\alpha+\sqrt{\alpha^2+4\lambda_1})}. \tag{2.8}$$

Proof: See Lemma 1 in Ref. 8.

Lemma 2.2: Suppose $0<\alpha_0\leqslant\alpha<+\infty$ and $f(u)$ satisfies conditions (1.4)–(1.5). There exists a positive constant $r_0=r_0(\alpha_0)>0$ such that the bounded ball B_0 of E, $B_0=B_E(0,r_0)$, centered at 0 of radius r_0, is an absorbing set of the semigroup $S_\epsilon(t)$, $t\geqslant 0$ in E, that is, for any bounded set B of E, there exists $T_0(B)\geqslant 0$ such that the solution $\varphi(t)=(u(t),v(t))^T$ of (2.3) starting at B satisfies

$$|\varphi(t)|_E=(\|u(t)\|^2+|v(t)|^2)^{1/2}\leqslant r_0, \quad \forall t\geqslant T_0(B), \tag{2.9}$$

in which $v=u_t+\epsilon u$.

Proof: Let $G(s)=\int_0^s f(r)dr=G_1(s)+G_2(s)$. By (1.4) and (1.5), we have

$$G_1(s)\geqslant 0, \quad \liminf_{|s|\to+\infty}\frac{G(s)}{s^2}\geqslant 0, \quad \forall s\in R. \tag{2.10}$$

and there exists a constant $c_4>0$ such that

$$\lim_{|s|\to+\infty}\inf\frac{sf(s)-c_4G(s)}{s^2}\geqslant 0,\quad \forall s\in R. \tag{2.11}$$

Let $\overline{G}(u)=\int_\Omega G(u)dx$. Following the procedure leading to (23) in Ref. 8, we have

$$|\varphi|_E^2\leqslant 2[|\varphi(0)|_E^2+2\overline{G}(u_0)+2k_1]e^{-\beta t}+\frac{4}{\theta}\left(\frac{\alpha^2+4\lambda_1}{\lambda_1\alpha^2}|g|^2+2(c_1k_1+k_2)\right), \tag{2.12}$$

where k_1, $k_2\geqslant 0$, $\beta>0$, $\theta=\min\{1,2c_4\}$ are constants. Thus

$$\lim_{t\to+\infty}\sup|\varphi|_E^2\leqslant\frac{4}{\theta}\left(\frac{\alpha_0^2+4\lambda_1}{\lambda_1\alpha_0^2}|g|^2+2(c_1k_1+k_2)\right)=\frac{1}{2}r_0(\alpha_0). \tag{2.13}$$

The proof is completed.

Lemma 2.3: For any initial value $u_0\in H_0^1(\Omega)$, $u_1\in L^2(\Omega)$ with

$$\|u_0\|^2+|u_1+\epsilon u_0|^2\leqslant r_0^2, \tag{2.14}$$

there exists a constant $r_1=r_1(r_0)$ such that the solution of (2.3) $\varphi(t)=(u(t),v(t))^T$ in which $v=u_t+\epsilon u$ satisfies

$$|\varphi(t)|_E\leqslant r_1,\quad \forall t\geqslant 0. \tag{2.15}$$

Proof: By (2.11),

$$\overline{G}(u_0)\leqslant\frac{1}{c_4}\left[|f(u_0)|\cdot|u_0|+\frac{1}{8}\|u_0\|^2+k_3\right],\quad \forall u\in H_0^1(\Omega). \tag{2.16}$$

By (1.6),

$$|f'(s)|\leqslant c_5(1+|s|^2),\quad \forall s\in R,\quad c_5\geqslant 0. \tag{2.17}$$

By (2.17) and the Sobolev embedding theorem, $H_0^1(\Omega)\subset L^6(\Omega)$,

$$|f(u_0)|^2\leqslant c_6^2\int_\Omega(1+|u_0(x)|^3)^2\,dx\leqslant c_7(r_0). \tag{2.18}$$

By the inequality (2.12), we obtain (2.15). The proof is completed.

Let $u(t)$ be a solution of system (1.1)–(1.3) with the initial value u_0, u_1 satisfying (2.14). We decompose $u(t)$ into $u(t)=z(t)+w(t)$, where $z(t)$ and $w(t)$ satisfy, respectively,

$$z_{tt}+\alpha z_t-\Delta z+f_1(z)=0,$$

$$z(x,t)|_{x\in\partial\Omega}=0,\quad z(0)=u_0,\quad z_t(0)=u_1, \tag{2.19}$$

$$w_{tt}+\alpha w_t-\Delta w+f_1(u)-f_1(z)=g-f_2(u(t)),$$

$$w(x,t)|_{x\in\partial\Omega}=0,\quad w(0)=w_t(0)=0. \tag{2.20}$$

Lemma 2.4: There exist two positive constants $M_1(r_0)$ and $\sigma_1(r_0)$ such that

$$\|z(t)\|^2+|z_t(t)|^2\leqslant M_1(r_0)\exp(-\sigma_1(r_0)t),\quad \forall t\geqslant 0. \tag{2.21}$$

Proof: Let $z' = z_t + \epsilon z$, $\phi = (z,z')^T$, where ϵ is as in (2.2); then (2.19) can be written as

$$\phi_t + \Lambda\phi + F_1(\phi) = 0, \quad \phi(0) = (u_0, u_1 + \epsilon_1 u_0)^T, \tag{2.22}$$

where $F_1(\phi) = (0, f_1(z))^T$, Λ is as in (2.4). Write $\overline{G}_1(z) = \int_\Omega G_1(z)dx$. Taking the inner product $(\cdot,\cdot)_E$ of (2.22) with $\phi = (z,z')^T$, we find

$$\frac{d}{dt}[|\phi|_E^2 + 2\overline{G}_1(z)] + 2(\Lambda\phi,\phi)_E + 2\epsilon(f_1(z),z) = 0. \tag{2.23}$$

Similar to Lemma 2.3, there exists a constant $c_8 = c_8(r_0) \geqslant 0$ such that

$$|\phi(t)|_E^2 = \|z(t)\|^2 + |z_t(t) + \epsilon z(t)|^2 \leqslant c_8^2, \quad \forall t \geqslant 0. \tag{2.24}$$

From (1.4) and (1.6), we deduce that $f_1(0) = 0$ and $|f_1(s)| \leqslant c_9(|s|^3 + |s|)(c_9 > 0)$. Hence, for every $z \in H_0^1(\Omega)$, by the Sobolev embedding $H_0^1(\Omega) \subset L^4(\Omega)$ and (2.24), we have

$$0 \leqslant \overline{G}_1(z) \leqslant c_{10}(\|z\|_{L^4}^4 + \|z\|_{L^2}^2) \leqslant c_{11}\|z\|^2(\|z\|^2 + 1) \leqslant c_{12}(r_0)\|z\|^2, \tag{2.25}$$

i.e.,

$$\sigma\|z\|^2 \geqslant \frac{\sigma}{c_{12}(r_0)}\overline{G}_1(z). \tag{2.26}$$

By (1.4),

$$\epsilon(f_1(z),z) \geqslant 0. \tag{2.27}$$

Plugging (2.7), (2.26), and (2.27) into (2.23), we obtain

$$\frac{d}{dt}[|\phi|_E^2 + 2\overline{G}_1(z)] + \sigma|\phi|_E^2 + \frac{\sigma}{c_{12}(r_0)}\overline{G}_1(z) \leqslant 0. \tag{2.28}$$

By the Gronwall inequality, (2.24) and (2.28), we have

$$|\phi|_E^2 \leqslant (|\phi(0)|_E^2 + 2\overline{G}_1(z(0))\exp(-\sigma_1(r_0)t) \leqslant M_0(r_0)\exp(-\sigma_0(r_0)t), \quad \forall t \geqslant 0, \tag{2.29}$$

where $\sigma_0(r_0) = \min\{\sigma, \sigma/2c_{12}(r_0)\}$, $M_0(r_0) = r_0^2(1 + 2c_{12}(r_0))$. It follows that (2.21) holds. The proof is completed.

Lemma 2.5: There exist constants $M_2(r_0) > 0$ and $0 < \nu_0 < \min\{(2-p)/4, \frac{1}{4}\}$ such that $w(t)$ satisfies

$$|A^{\nu_0 + 1/2}w(t)|^2 + |A^{\nu_0}w_t(t)|^2 \leqslant M_2(r_0), \quad \forall t \geqslant 0, \tag{2.30}$$

where p is as in (1.6).

Proof: We make use of the space $D(A^{\nu/2}), \nu \geqslant 0$, which is a Hilbert space with the scalar product and the norm

$$((w_1, w_2))_\nu = (A^{\nu/2}w_1, A^{\nu/2}w_2), \quad \|w\|_\nu = ((w,w))_\nu; \tag{2.31}$$

then

$$H_0^\nu(\Omega) \subset D(A^{\nu/2}) \subset H^\nu(\Omega). \tag{2.32}$$

Set $0 \leqslant \nu \leqslant \frac{1}{4}$, we multiply the equation (2.20) by $A^{2\nu}w$ and integrate by parts to deduce

$$|A^{\nu}w_t(t)|^2+|A^{\nu+1/2}w(t)|^2+\alpha\int_0^t(A^{\nu}w_t(s),A^{\nu}w_t(s))ds$$
$$\leqslant\int_\Omega[|(f_1(u(t))-f_1(z(t)))|+|(g-f_2(u(t)))|]\cdot|A^{2\nu}w(t)|dx$$
$$+\int_0^t\int_\Omega[|(f_1'(u(s))-f_1'(z(s)))z_t(s)|+|f_1'(u(s))w_t(s)|$$
$$+|f_2'(u(s))u_t(s)|]\cdot|A^{2\nu}w(s)|dx\,ds. \tag{2.33}$$

From Lemma 2.3 and Lemma 2.4, we observe that $\|w(t)\|$ and $|w_t(t)|$ are uniformly bounded, i.e., $\|w(t)\|\leqslant c_{13}(r_0)$, $|w_t(t)|\leqslant c_{14}(r_0)$, $\forall t\geqslant 0$. By the embedding relation

$$H^{\nu_1}(\Omega)\subset H^{\nu_2}(\Omega),\quad \text{if}\quad \nu_1\geqslant\nu_2\quad\text{and}\quad H^{\nu}(\Omega)\subset L^q(\Omega),\quad\text{where}\quad \frac{1}{q}=\frac{1}{2}-\frac{\nu}{3}, \tag{2.34}$$

$$\int_\Omega|(f_1(u(t))-f_1(z(t)))A^{2\nu}w(t)|dx\leqslant|f_1(u(t))-f_1(z(t))||A^{2\nu}w(t)|\leqslant c_{15}(r_0),\quad\forall t\geqslant 0. \tag{2.35}$$

$$\int_\Omega|(g-f_2(u(t)))\cdot A^{2\nu}w(t)|dx\leqslant|g-f_2(u(t))||A^{2\nu}w(t)|\leqslant c_{16}(r_0),\quad\forall t\geqslant 0. \tag{2.36}$$

By the Holder inequality, (2.34), and (1.6), we have

$$\|f_2'(u(s))u_t(s)\|_{L^r}\leqslant c_{17}(r_0), \tag{2.37}$$

$$\|(f_1'(u(s))-f_1'(z(s)))z_t(s)\|_{L^\delta}\leqslant c_{18}(r_0)|A^{\nu+1/2}w(s)|, \tag{2.38}$$

$$\|f_1'(u(s))w_t(s)\|_{L^\delta}\leqslant c_{19}(r_0)|A^{\nu}w_t(s)|, \tag{2.39}$$

$$\|A^{2\nu}w(s)\|_{L^r}=\|A^{\nu-1/2}A^{\nu+1/2}w(s)\|_{L^r}\leqslant c_{20}|A^{\nu+1/2}w(s)|, \tag{2.40}$$

where $\tau=6/(3+p)$, $p\in[0,2)$ is as in (1.6), $1/\delta=\frac{5}{6}-2\nu/3$, and $1/r=1-1/\delta$. Setting $0<\nu<\min\{(2-p)/4,\frac{1}{4}\}$, plugging above estimates into (2.33), we have

$$|A^{\nu}w_t(t)|^2+|A^{\nu+1/2}w(t)|^2\leqslant c_{21}(r_0)+c_{22}(r_0)\int_0^t[|A^{\nu}w_t(s)|^2+|A^{\nu+1/2}w(s)|^2]ds. \tag{2.41}$$

By applying the Gronwall inequality and zero initial value conditions (2.20), we obtain (2.30). The proof is completed.

Lemma 2.6: If $f(u)$ satisfies (1.4)–(1.7), then the semigroup $S_\epsilon(t),t\geqslant 0$ possesses a global attractor β in E and β is included in the bounded ball B_0 of E.

Proof: It is a direct consequence of Lemmas 2.2, 2.4, 2.5, and Theorem I.1.1 in Ref. 9.

III. PROOF OF THEOREM 1.1

To estimate the Hausdorff dimension of the global attractor β for (2.3) in E, we consider the first variation equation of (2.3) with the initial value condition,

$$\Psi'=-\Lambda\Psi+F'(\varphi)\Psi,\quad \Psi(0)=(\xi,\eta)^T\in E, \tag{3.1}$$

where $\Psi=(U,V)^T\in E$, and $\varphi=(u,v)^T$ is a solution of (2.3) and

$$F'(\varphi)=\begin{pmatrix} 0 & 0 \\ -f'(u) & 0 \end{pmatrix}.$$

Lemma 3.1: The system (3.1) is a well-posed problem in E; the mapping $S_\epsilon(t)$ defined by (2.3) is Fréchet differentiable on E for any $t>0$; its differential at $\varphi=(u_0,u_1+\epsilon u_0)^T$ is the linear operator on E, $(\xi,\eta)^T\mapsto(U(t),V(t))^T$, where $(U,V)^T$ is the solution of (3.1).

Proof: It is a direct consequence of (1.7), (2.6), and Lemma VI. 6.1 in Ref. 9.

Lemma 3.2: Consider the system (2.3). Let Φ denote a set of m vectors $\{\Phi_1,\Phi_2,\ldots,\Phi_m\}$ that are orthonormal in E. If

$$q_m=\overline{\lim_{t\to+\infty}}\ \sup_{\Phi\subset E}\ \sup_{\varphi\in ß}\frac{1}{t}\int_0^t\sum_{j=1}^m\left((-\Lambda+F'(\varphi(\tau)))\Phi_j(\tau),\quad \Phi_j(\tau)\right)_E d\tau\leqslant 0, \tag{3.2}$$

then the Hausdorff dimension of the global attractor β is less than or equal to m.

Proof: This is a direct consequence of Theorem V. 3.3., Eqs. (V. 3.47)–(V. 3.49) of Ref. 9.

Lemma 3.3: For any orthonormal family of elements of E, $\{(\xi_j,\eta_j)^T\}_{j=1}^m$, we have

$$\sum_{j=1}^m |A^{(1/2)\nu}\xi_j|^2\leqslant\sum_{j=1}^m \lambda_j^{\nu-1},\quad \forall\nu\in[0,1). \tag{3.3}$$

Proof: See Lemma VI, 6.3 in Ref. 9.

Lemma 3.4: If the functions $f(u)$ satisfy assumptions (1.4)–(1.7), then for any $\alpha\geqslant\alpha_0>0$, the Hausdorff dimension $d_H(ß)$ of the global attractor ß for system (2.3) in E satisfies

$$d_H(ß)\leqslant\min\left\{m\,\middle|\, m\in N,\frac{1}{m}\sum_{j=1}^m \lambda_j^{-4\nu_0}\leqslant\frac{2\alpha\sigma}{k}\right\}, \tag{3.4}$$

where $k=k(\alpha_0)$ is a positive constant that is independent of α, σ is as in (2.8), $0<\nu_0<\min\{(2-p)/4,\frac{1}{4}\}$, and p is as in (1.6).

Proof: Let $m\in N$ be fixed. Consider m solutions $\Psi_1,\Psi_2,\ldots,\Psi_m$ of (5.1). At a given time τ, let $Q_m(\tau)$ denote the orthogonal projection in E onto the space span $\{\Psi_1(\tau),\Psi_2(\tau),\ldots,\Psi_m(\tau)\}$. Let $\Phi_j(\tau)=(\xi_j,\eta_j)^T\in E$, $j=1,2,...,m$, be an orthonormal basis of $Q_m(\tau)E$.

Suppose $\varphi(\tau)=(u(\tau),v(\tau))^T\in ß$; then $|\varphi(\tau)|_E\leqslant r_0$ (r_0 is defined by Lemma 2.2). By Lemma 2.1 and $|\Phi_j|_E=1$,

$$-(\Lambda\Phi_j,\Phi_j)_E\leqslant-\sigma-\frac{\alpha}{2}\|\eta_j\|^2, \tag{3.5}$$

$$(F'(\varphi(\tau))\Phi_j(\tau),\Phi_j(\tau))_E=(-f'(u(\tau))\xi_j(\tau),\eta_j(\tau))\leqslant|f'(u(\tau))\xi_j(\tau)|\cdot|\eta_j|. \tag{3.6}$$

By (2.17), (2.21), the Young inequality, and Hölder inequality,

$$\begin{aligned}
|f'(u(t)))\xi_j(t)|^2&\leqslant c_5^2\int_\Omega[1+(z(t)+w(t))^2]^2\xi_j^2(t)dx\\
&\leqslant c_{23}\int[1+z^4(t)+w^4(t)]\xi_j^2(t)dx\\
&\leqslant c_{24}[\|z(t)\|_{L^6}^4\cdot\|\xi_j(t)\|_{L^6}^2+|\xi_j(t)|^2+\|w(t)\|^4_{L^{6/(1-4\nu_0)}}\cdot\|\xi_j(t)\|L^{6/(1+8\nu_0)}]\\
&\leqslant c_{25}(r_0)(e^{-4\sigma_1(r_0)t}\|\xi_j(t)\|^2+|\xi_j(t)|^2+\|A^{\nu_0+1/2}w(t)\|^4\cdot\|A^{(1-4\nu_0)/2}\xi_j(t)\|^2)\\
&\leqslant c_{26}(r_0)(e^{-4\sigma_1(r_0)t}\|\xi_j(t)\|^2+\|A^{(1-4\nu_0)/2}\xi_j(t)\|^2),\quad\forall t\geqslant 0,
\end{aligned} \tag{3.7}$$

where $0<\nu_0<\min\{(2-p)/4,1/4\}$ is defined by Lemma 2.4. By (3.6) and (3.7), there exists a constant $k=k(\alpha_0)=c_{26}^2(r_0)>0$, which is independent of α, such that

$$(F'(\varphi(\tau))\Phi_j(\tau),\Phi_j(\tau))_E\leqslant\frac{k}{2\alpha}(e^{-4\sigma_1(r_0)\tau}\|\xi_j(\tau)\|^2+\|A^{(1-4\nu_0)/2}\xi_j(\tau)\|^2)+\frac{\alpha}{2}|\eta_j(t)|^2. \tag{3.8}$$

Thus, by $\|\xi_j(\tau)\|^2\leqslant|\Phi_j|_E^2=1$ and (3.2), (3.5) and (3.8),

$$\begin{aligned}q_m&=\overline{\lim_{t\to+\infty}}\sup_{\Phi\subset E}\sup_{\varphi\in ß}\frac{1}{t}\int_0^t\sum_{j=1}^m((-\Lambda+F'(\varphi(\tau)))\Phi_j(\tau),\Phi_j(\tau)_E\,d\tau\\&\leqslant\overline{\lim_{t\to+\infty}}\left(-m\sigma+\frac{km}{8\sigma_1(r_0)\alpha t}(1-e^{-4\sigma_1(r_0)t})+\frac{k}{2\alpha}\sum_{j=1}^m\lambda_j^{-4\nu_0}\right)\\&\leqslant-\frac{mk}{2\alpha}\left(\frac{2\alpha\sigma}{k}-\frac{1}{m}\sum_{j=1}^m\lambda_j^{-4\nu_0}\right).\end{aligned}$$

If

$$\frac{1}{m}\sum_{j=1}^m\lambda_j^{-4\nu_0}\leqslant\frac{2\alpha\sigma}{k},$$

then $q_m\leqslant0$; hence, (3.4) holds. The proof is completed.

Combining with Lemma 3.4 and (2.8), we complete the proof of Theorem 1.1.

(Received 2 October 1998; accepted for publication 14 June 1999)

It is shown how to construct an infinite number of families of quasi-bi-Hamiltonian (QBH) systems by means of the constrained flows of soliton equations. Three explicit QBH structures are presented for the first three families of the constrained flows. The Nijenhuis coordinates defined by the Nijenhuis tensor for the corresponding families of QBH systems are proved to be exactly the same as the separated variables introduced by mean of the Lax matrices for the constrained flows. © *1999 American Institute of Physics.* [S0022-2488(99)02909-6]

I. INTRODUCTION

As is known, some integrable systems possess bi-Hamiltonian structure. We recall some known results. Let M be a differential manifold, TM and T^*M its tangent and cotangent bundle, and θ_0 and θ_1: $T^*M \rightarrow TM$ two compatible Poisson tensors on M.[1] A vector field X is said to be bi-Hamiltonian (BH) with respect to θ_0 and θ_1, if two smooth functions, $H,F \in C^\infty(M)$, exist such that

$$X = \theta_0\, dH = \theta_1\, dF, \tag{1.1}$$

where dF denotes the differential of F (gradient ∇F for finite system and variation δF for field system). If θ_0 is invertible, the tensor $\Phi = \theta_1 \theta_0^{-1}$ is a Nijenhuis tensor or hereditary operator. The operator Φ maps a given BH vector field into another BH vector field. Hence having a Nijenhuis tensor, one can construct a hierarchy of Hamiltonian symmetries, and a related hierarchy of integrals of motion for the underlying system. The BH structure (1.1) ensures that the resulting integrals of motion are pairwise in involution with respect to both Poisson brackets. Thus the BH structure of a given system is important for its integrability.

Unfortunately, for a majority of the BH finite-dimensional systems, none of the θ_0 and θ_1 is invertible. In fact, all the known BH finite-dimensional systems arising from the constrained flows or stationary flows of soliton equations usually exist in an extended phase space and both θ_0 and θ_1 are degenerated (see, for example, Refs. 2–8). In their natural phase space these systems may satisfy a weaker condition than the BH one. The notion of a quasi-bi-Hamiltonian (QBH) system was introduced.[9,10] According to,[10] for $\dim M = 2n$, a vector field, X, is said to be a QBH vector field with respect to Poisson tensors, θ_0 and θ_1, if there exist three smooth functions H, F, ρ, such that

$$X = \theta_0 \nabla H = \frac{1}{\rho}\, \theta_1 \nabla F, \tag{1.2}$$

[a)]Electronic mail: yzeng@tsinghua.edu.cn
[b)]Electronic mail: mawx@cityu.edu.hk

where two Poisson tensors θ_0 and θ_1 are compatible and nondegenerated (invertible). The function ρ is called an integrating factor. On a $2n$-dimensional symplectic manifold M, let ($\mathbf{q}=(q_1,\ldots,q_n)$, $\mathbf{p}=(p_1,\ldots,p_n)$) be a set of canonical coordinates and θ_0 the canonical Poisson matrix $\theta_0=\begin{pmatrix} 0 & I \\ -I & 0\end{pmatrix}$ (I denoting the $n\times n$ identity matrix). As θ_0 and θ_1 are compatible and invertible, the Nijenhuis tensor $\Phi=\theta_1\theta_0^{-1}$ is maximal, i.e., it has n distinct eigenvalues $\boldsymbol{\mu}=(\mu_1,\ldots,\mu_n)$. As is known,[11] in a neighborhood of a regular point, where the eigenvalues $\boldsymbol{\mu}$ are distinct, one can construct a canonical transformation $(\mathbf{q},\mathbf{p})\rightarrow(\boldsymbol{\mu},\boldsymbol{\nu})$(($\boldsymbol{\mu},\boldsymbol{\nu}$) referred to as the Nijenhuis coordinates) such that θ_1 and Φ take the Darboux form

$$\theta_1=\begin{pmatrix} 0 & \Lambda_1 \\ -\Lambda_1 & 0\end{pmatrix}, \quad \Phi=\begin{pmatrix} \Lambda_1 & 0 \\ 0 & \Lambda_1\end{pmatrix}, \quad \Lambda_1=\mathrm{diag}(\mu_1,\ldots,\mu_n). \tag{1.3}$$

A QBH vector field is said to be Pfaffian[10] if, in the Nijenhuis coordinates, an integrating factor ρ in Eq. (1.2) is the product of the eigenvalues of Φ, i.e.,

$$\rho=\prod_{i=1}^{n}\mu_i\,. \tag{1.4}$$

In the Pfaffian case, the general solutions, H and F, of Eq. (1.2) are obtained and the Hamilton–Jacobi equation for H is shown to be separable by verifying the Levi–Civita conditions.[12] Some relationship between BH and QBH structure is discussed in Ref. 13. Several QBH systems are presented.[9,10,12–14] It is in general quite difficult to directly construct a BH or QBH structure for a given integrable Hamiltonian vector field. In recent years much work has been devoted to the constrained flows of soliton equations (see, for example, Refs. 2–8, 15–24). One of the aims of this paper is to show how to construct an infinite number of families of QBH systems from the constrained flows of soliton equations. We have presented some families of the constrained flows in order to study the dynamical r-matrices in Ref. 24. We now describe the explicit QBH structures for these families of the constrained flows.

The Lax representation for the constrained flows of soliton equations can always be deduced from the adjoint representation of the Lax pair for soliton equations.[16,17] There is an effective way for the separation of variables for some finite-dimensional integrable Hamiltonian systems with some kind of Lax matrices.[25,26] The separated variables for some constrained flows can be introduced and the Jacobi inversion problems for the constrained flows can be established by means of the Lax representation.[27,28] We are interested in the relationship between the two methods for the separability mentioned above. Another main aim of this paper is to prove that the Nijenhuis coordinates for the underlying families of QBH systems are usually the same as the separated variables introduced by the Lax matrices.

The paper is organized as follows.

In Sec. II we present a new QBH system. We directly construct the second compatible Poisson tensor by using a map relating this system to its modified version, and prove that the Nijenhuis coordinates for this system is equivalent to the separated variables defined by Lax matrix. We make some comparison of the two methods for separability. In Secs. III and IV, by using the constrained flows associated with the polynomial second-order spectral problems and the higher-order symmetry constraints, we propose a way to construct an infinite number of families of QBH systems. The explicit QBH structures of the first two families of constrained flows are given. The equivalence of the Nijenhuis coordinates and the separated variables is proved. In Sec. V we point out that the two compatible Poisson tensors θ_0, θ_1 and the integrating factor ρ given by the QBH structure (2.28) and (2.29a) are just that for the third family of QBH systems. Also some conclusions and a conjucture are given.

II. NEW QBH SYSTEM

In this section we present a new QBH system. By using a map relating this system to its modified version, the second compatible Poisson tensor is obtained from the image of the Poisson tensor for the modified version under the map. We use this system to illustrate how to prove the equivalence of the Nijenhuis coordinates and the separated variables introduced by the Lax matrix.

A. New finite-dimensional integrable Hamiltonian system

For Jaulent–Miodek (JM) spectral problem[29]

$$\psi_x = U(u,\lambda)\psi, \quad U(u,\lambda) = \begin{pmatrix} 0 & 1 \\ \lambda^2 - u_1\lambda - u_0 & 0 \end{pmatrix}, \quad \psi = \begin{pmatrix} \psi_1 \\ \psi_2 \end{pmatrix}, \quad u = \begin{pmatrix} u_1 \\ u_0 \end{pmatrix}, \tag{2.1}$$

its adjoint representation is defined by[30]

$$V_x = [U,V] \equiv UV - VU, \tag{2.2}$$

where V is taken as

$$V = \sum_{i=0}^{\infty} V_i \lambda^{-i}, \quad V_i = \begin{pmatrix} a_i & b_i \\ c_i & -a_i \end{pmatrix}. \tag{2.3}$$

Then Eq. (2.2) and (2.3) yield

$$a_0 = a_1 = a_2 = b_0 = b_1 = 0, \quad b_2 = 1, \quad b_3 = \tfrac{1}{2}u_1,$$

$$a_3 = -\tfrac{1}{4}u_{1,x}, \quad c_0 = 1, \quad c_1 = -\tfrac{1}{2}u_1, \ldots,$$

and in general

$$\begin{pmatrix} b_{k+2} \\ b_{k+1} \end{pmatrix} = L \begin{pmatrix} b_{k+1} \\ b_k \end{pmatrix}, \quad k = 1,2,..., \tag{2.4a}$$

$$a_k = -\tfrac{1}{2}b_{k,x}, \quad c_k = a_{k,x} - u_0 b_k - u_1 b_{k+1} + b_{k+2}, \quad k = 1,2,..., \tag{2.4b}$$

where

$$L = \begin{pmatrix} u_1 - \tfrac{1}{2}D^{-1}u_{1,x} & \tfrac{1}{4}D^2 + u_0 - \tfrac{1}{2}D^{-1}u_{0,x} \\ 1 & 0 \end{pmatrix}, \quad D = \frac{\partial}{\partial x}, \quad DD^{-1} = D^{-1}D = 1.$$

The Jaulent–Miodek hierarchy associated with (2.1) can be written as an infinite-dimensional Hamiltonian system

$$u_{t_n} = \begin{pmatrix} u_1 \\ u_0 \end{pmatrix}_{t_n} = J \begin{pmatrix} b_{n+2} \\ b_{n+1} \end{pmatrix} = J \frac{\delta H_n}{\delta u}, \quad n = 1,2,..., \tag{2.5}$$

where the Hamiltonian H_n and the Hamiltonian operator J are given by

$$J = \begin{pmatrix} 0 & 2D \\ 2D & -u_{1x} - 2u_1 D \end{pmatrix}, \quad H_n = \frac{1}{n}(2b_{n+3} - u_1 b_{n+2}).$$

Under zero boundary condition we have

$$\frac{\delta\lambda}{\delta u} = \begin{pmatrix} \lambda\psi_1^2 \\ \psi_1^2 \end{pmatrix}, \quad L\frac{\delta\lambda}{\delta u} = \lambda\frac{\delta\lambda}{\delta u}. \tag{2.6}$$

The constrained flow of (2.5) consists of the equations obtained from the spectral problem (2.1) for N distinct λ_j and the restriction of the variational derivatives for conserved quantities H_l (for any fixed l) and λ_j:[15–17]

$$\Psi_{1,x}=\Psi_2, \quad \Psi_{2,x}=\Lambda^2\Psi_1-u_1\Lambda\Psi_1-u_0\Psi_1, \tag{2.7a}$$

$$\frac{\delta H_l}{\delta u}-\frac{1}{2}\sum_{j=1}^{N}\frac{\delta\lambda_j}{\delta u}=\begin{pmatrix} b_{l+2}\\ b_{l+1}\end{pmatrix}-\frac{1}{2}\begin{pmatrix}\langle\Lambda\Psi_1,\Psi_1\rangle\\ \langle\Psi_1,\Psi_1\rangle\end{pmatrix}=0, \tag{2.7b}$$

which has been recognized as a symmetry constraint.[18–20] Hereafter we denote the inner product in R^N by $\langle.,.\rangle$ and $\Psi_i=(\psi_{i1},\dots,\psi_{iN})^T$, $i=1,2$, $\Lambda=\mathrm{diag}(\lambda_1,\dots,\lambda_N)$.

For $l=4$, we have

$$H_4=\tfrac{7}{128}u_1^5+\tfrac{5}{16}u_1^3u_0-\tfrac{5}{32}u_{1x}^2u_1+\tfrac{3}{8}u_0^2u_1-\tfrac{1}{8}u_{1x}u_{0x}. \tag{2.8}$$

By introducing the Jacobi–Ostrogradsky coordinates

$$q_1=u_1, \quad q_2=u_0,$$

$$p_1=\frac{\delta H_4}{\delta u_{1x}}=-\frac{5}{16}u_1u_{1x}-\frac{1}{8}u_{0x}, \quad p_2=\frac{\delta H_4}{\delta u_{0x}}=-\frac{1}{8}u_{1x}, \tag{2.9}$$

the Eqs. (2.7) for $l=4$ are transformed into a finite-dimensional Hamiltonian system (FDHS)

$$\Psi_{1x}=\frac{\partial F_1}{\partial\Psi_2}=\Psi_2, \quad q_{1x}=\frac{\partial F_1}{\partial p_1}=-8p_2, \quad q_{2x}=\frac{\partial F_1}{\partial p_2}=-8p_1+20q_1p_2, \tag{2.10a}$$

$$\Psi_{2x}=-\frac{\partial F_1}{\partial\Psi_1}=\Lambda^2\Psi_1-q_1\Lambda\Psi_1-q_2\Psi_1, \tag{2.10b}$$

$$p_{1x}=-\frac{\partial F_1}{\partial q_1}=\frac{35}{128}q_1^4+\frac{15}{16}q_1^2q_2-10p_2^2+\frac{3}{8}q_2^2-\frac{1}{2}\langle\Lambda\Psi_1,\Psi_1\rangle, \tag{2.10c}$$

$$p_{2x}=-\frac{\partial F_1}{\partial q_2}=\frac{5}{16}q_1^3+\frac{3}{4}q_1q_2-\frac{1}{2}\langle\Psi_1,\Psi_1\rangle, \tag{2.10d}$$

or equivalently

$$P_x=\theta_0\nabla F_1,$$

where

$$P=(\Psi_1^T,q_1,q_2,\Psi_2^T,p_1,p_2)^T, \quad \theta_0=\begin{pmatrix}0 & I_{(N+2)\times(N+2)}\\ -I_{(N+2)\times(N+2)} & 0\end{pmatrix},$$

$$\begin{aligned}F_1={}&\tfrac{1}{2}\langle\Psi_2,\Psi_2\rangle-\tfrac{1}{2}\langle\Lambda^2\Psi_1,\Psi_1\rangle+\tfrac{1}{2}q_1\langle\Lambda\Psi_1,\Psi_1\rangle+\tfrac{1}{2}q_2\langle\Psi_1,\Psi_1\rangle\\ &-8p_1p_2+10q_1p_2^2-\tfrac{5}{16}q_1^3q_2-\tfrac{3}{8}q_1q_2^2-\tfrac{7}{128}q_1^5.\end{aligned} \tag{2.11}$$

The Lax representation for FDHS (2.10) can be deduced from the adjoint representation (2.2) by using the method in Refs. 16 and 17 which is sketched as follows. Due to (2.4a), (2.6), and (2.7b), we may define

$$\tilde{b}_m=\tfrac{1}{2}\langle\Lambda^{m-5}\Psi_1,\Psi_1\rangle, \quad m=5,6,\dots,$$

which together with (2.4b) and (2.10) yields

$$\tilde{a}_m = -\tfrac{1}{2}\langle \Lambda^{m-5}\Psi_1, \Psi_2\rangle, \quad \tilde{c}_m = -\tfrac{1}{2}\langle \Lambda^{m-5}\Psi_2, \Psi_2\rangle, \quad m=5,6,\ldots .$$

Set

$$\tilde{a}_m = a_m, \quad \tilde{b}_m = b_m, \quad \tilde{c}_m = c_m, \quad m=0,1,2,3,4.$$

Then the construction of $\tilde{a}_m, \tilde{b}_m, \tilde{c}_m$ ensures that under (2.10),

$$\tilde{V} = \sum_{i=0}^{\infty} \tilde{V}_i \lambda^{-i}, \quad \tilde{V}_i = \begin{pmatrix} \tilde{a}_i & \tilde{b}_i \\ \tilde{c}_i & -\tilde{a}_i \end{pmatrix},$$

also satisfies (2.2). Notice that

$$\sum_{m=5}^{\infty} \tilde{a}_m \lambda^{-m+4} = -\frac{1}{2}\sum_{m=0}^{\infty}\sum_{j=1}^{N}\left(\frac{\lambda_j}{\lambda}\right)^m \psi_{1j}\psi_{2j} = -\frac{1}{2}\sum_{j=1}^{N}\frac{\psi_{1j}\psi_{2j}}{\lambda-\lambda_j},$$

set

$$Q \equiv \begin{pmatrix} A(\lambda) & B(\lambda) \\ C(\lambda) & -A(\lambda) \end{pmatrix} = \lambda^4 \tilde{V}, \tag{2.12a}$$

we have

$$A(\lambda) = 2p_2\lambda + 2p_1 - 2q_1p_2 - \frac{1}{2}\sum_{j=1}^{N}\frac{\psi_{1j}\psi_{2j}}{\lambda-\lambda_j}, \tag{2.12b}$$

$$B(\lambda) = \lambda^2 + \frac{1}{2}q_1\lambda + \frac{3}{8}q_1^2 + \frac{1}{2}q_2 + \frac{1}{2}\sum_{j=1}^{N}\frac{\psi_{1j}^2}{\lambda-\lambda_j}, \tag{2.12c}$$

$$\begin{aligned} C(\lambda) = {} & \lambda^4 - \frac{1}{2}q_1\lambda^3 - \left(\frac{1}{2}q_2 + \frac{1}{8}q_1^2\right)\lambda^2 + \left(\frac{1}{4}q_1^3 + \frac{1}{2}q_1q_2 - \frac{1}{2}\langle\Psi_1,\Psi_1\rangle\right)\lambda \\ & + \frac{1}{4}q_2^2 - \frac{5}{64}q_1^4 - 4p_2^2 - \frac{1}{2}\langle\Lambda\Psi_1,\Psi_1\rangle + \frac{1}{2}q_1\langle\Psi_1,\Psi_1\rangle - \frac{1}{2}\sum_{j=1}^{N}\frac{\psi_{2j}^2}{\lambda-\lambda_j}. \end{aligned} \tag{2.12d}$$

Since $\tilde{V}$ under (2.10) satisfies (2.2), then Q under (2.10) satisfies (2.2), too, namely

$$Q_x = [U, Q], \tag{2.13}$$

which presents the Lax representation for (2.10). This can also be verified by a direct calculation. Equation (2.13) implies that $\frac{1}{2}\operatorname{Tr} Q^2(\lambda) = A^2(\lambda) + B(\lambda)C(\lambda)$ is the generating function of the integrals of motion for (2.10). We have

$$A^2(\lambda) + B(\lambda)C(\lambda) = \lambda^6 - F_1\lambda + F_2 + \sum_{i=1}^{N}\frac{F^{(i)}}{\lambda-\lambda_i}, \tag{2.14}$$

$$\begin{aligned} F_2 = {} & -\tfrac{1}{2}\langle\Lambda\Psi_2,\Psi_2\rangle + \tfrac{1}{2}\langle\Lambda^3\Psi_1,\Psi_1\rangle - \tfrac{1}{4}q_1\langle\Lambda^2\Psi_1,\Psi_1\rangle + \left(\tfrac{1}{8}q_1^3 + \tfrac{1}{4}q_1q_2 - \tfrac{1}{4}\langle\Psi_1,\Psi_1\rangle\right) \\ & \times\langle\Psi_1,\Psi_1\rangle - \tfrac{1}{4}q_1\langle\Psi_2,\Psi_2\rangle + \left(\tfrac{3}{8}q_1^2 + \tfrac{1}{2}q_2\right)\left(-4p_2^2 - \tfrac{5}{64}q_1^4 + \tfrac{1}{4}q_2^2 - \tfrac{1}{2}\langle\Lambda\Psi_1,\Psi_1\rangle\right. \\ & \left. + \tfrac{1}{2}q_1\langle\Psi_1,\Psi_1\rangle\right) - \left(\tfrac{1}{4}q_2 + \tfrac{1}{16}q_1^2\right)\langle\Lambda\Psi_1,\Psi_1\rangle - 2p_2\langle\Psi_1,\Psi_2\rangle + 4(p_1 - q_1p_2)^2, \end{aligned} \tag{2.15}$$

$$F^{(i)}=(-2p_2\lambda_i+2q_1p_2-2p_1)\psi_{1i}\psi_{2i}-\tfrac{1}{2}(\lambda_i^2+\tfrac{1}{2}q_1\lambda_i+\tfrac{3}{8}q_1^2+\tfrac{1}{2}q_2)\psi_{2i}^2+\tfrac{1}{2}[\lambda_i^4-\tfrac{1}{2}q_1\lambda_i^3$$
$$-(\tfrac{1}{8}q_1^2+\tfrac{1}{2}q_2)\lambda_i^2+(\tfrac{1}{4}q_1^3+\tfrac{1}{2}q_1q_2-\tfrac{1}{2}\langle\Psi_1,\Psi_1\rangle)\lambda_i+\tfrac{1}{4}q_2^2-4p_2^2-\tfrac{5}{64}q_1^4-\tfrac{1}{2}\langle\Lambda\Psi_1,\Psi_1\rangle$$
$$+\tfrac{1}{2}q_1\langle\Psi_1,\Psi_1\rangle]\psi_{1i}^2+\tfrac{1}{4}\sum_{k\neq i}\frac{(\psi_{1i}\psi_{2k}-\psi_{1k}\psi_{2i})^2}{\lambda_k-\lambda_i},\quad i=1,...,N, \tag{2.16}$$

where $F^{(i)}$, $i=1,...,N$, F_1,F_2 are $N+2$ independent integrals of motion for (2.10). Notice that $\{A^2(\lambda)+B(\lambda)C(\lambda),\ A^2(\mu)+B(\mu)C(\mu)\}=0$, it can be shown that the equation (2.10) is a finite-dimensional integrable Hamiltonian system (FDIHS).

In order to find the QBH structure for (2.10), we need to use the modified system of (2.10). Let us consider the modified Jaulent–Miodek (MJM) spectral problem[31]

$$\phi_x=U(v,\lambda)\phi,\quad U(v,\lambda)=\begin{pmatrix} v_0 & \lambda \\ \lambda-v_1 & -v_0\end{pmatrix},\quad \phi=\begin{pmatrix}\phi_1\\ \phi_2\end{pmatrix},\quad v=\begin{pmatrix}v_0\\ v_1\end{pmatrix}. \tag{2.17}$$

Equations (2.2) and (2.3) yield

$$a_0=0,\quad b_0=1,\quad b_1=\tfrac{1}{2}v_1,\quad a_1=v_0,\quad c_0=1,\quad c_1=-\tfrac{1}{2}v_1,\ldots,$$
$$\begin{pmatrix}2a_{k+1}\\ -b_{k+1}\end{pmatrix}=L\begin{pmatrix}2a_k\\ -b_k\end{pmatrix},\quad k=1,2,...,$$
$$L=\begin{pmatrix}0 & -2v_0+D\\ \tfrac{1}{4}D+\tfrac{1}{2}D^{-1}v_0D & \tfrac{1}{2}v_1+\tfrac{1}{2}D^{-1}v_1D\end{pmatrix}. \tag{2.18}$$

The MJM hierarchy associated with (2.17) can also be written as a infinite-dimensional Hamiltonian system

$$v_{t_n}=\begin{pmatrix}v_0\\ v_1\end{pmatrix}_{t_n}=J\begin{pmatrix}2a_n\\ -b_n\end{pmatrix}=J\frac{\delta H_n}{\delta v},\quad n=1,2,..., \tag{2.19}$$

where the Hamiltonian H_n and the Hamiltonian operator J are given by

$$J=\begin{pmatrix}\tfrac{1}{2}D & 0\\ 0 & -2D\end{pmatrix},\quad H_n=\frac{-1}{n}[a_{n,x}-v_1b_n+2b_{n+1}].$$

Also we have

$$\frac{\delta\lambda}{\delta v}=\begin{pmatrix}2\phi_1\phi_2\\ \phi_1^2\end{pmatrix}. \tag{2.20}$$

In the similar way as for (2.7), the constrained flow of (2.19) is defined by

$$\Phi_{1,x}=v_0\Phi_1+\Lambda\Phi_2,\quad \Phi_{2,x}=(\Lambda-v_1)\Phi_1-v_0\Phi_2, \tag{2.21a}$$

$$\frac{\delta H_1}{\delta v}+\frac{1}{2}\begin{pmatrix}2\langle\Phi_1,\Phi_2\rangle\\ \langle\Phi_1,\Phi_1\rangle\end{pmatrix}=0, \tag{2.21b}$$

where $\Phi_i=(\phi_{i1},\ldots,\phi_{iN})^T$, $i=1,2$.

For $l=3$,

$$H_3=-(\tfrac{1}{4}v_{0x}^2-\tfrac{1}{16}v_{1x}^2+\tfrac{1}{4}v_0^4+\tfrac{5}{64}v_1^4-\tfrac{3}{8}v_{0x}v_1^2-\tfrac{3}{8}v_0^2v_1^2).$$

By introducing the Jacobi–Ostrogradsky coordinates

$$\tilde{q}_1 = v_1, \quad \tilde{q}_2 = v_0, \tag{2.22a}$$

$$\tilde{p}_1 = -\frac{\delta H_3}{\delta v_{1x}} = -\frac{1}{8} v_{1x}, \quad \tilde{p}_2 = -\frac{\delta H_3}{\delta v_{0x}} = \frac{1}{2} v_{0x} - \frac{3}{8} v_1^2, \tag{2.22b}$$

the equations (2.21) for $l=3$ are transformed into a FDHS

$$\Phi_{1,x} = \frac{\partial \tilde{F}_1}{\partial \Phi_2} = \tilde{q}_2 \Phi_1 + \Lambda \Phi_2, \quad \tilde{q}_{1x} = \frac{\partial \tilde{F}_1}{\partial \tilde{p}_1} = -8\tilde{p}_1, \quad \tilde{q}_{2x} = \frac{\partial \tilde{F}_1}{\partial \tilde{p}_2} = 2\tilde{p}_2 + \frac{3}{4}\tilde{q}_1^2, \tag{2.23a}$$

$$\Phi_{2,x} = -\frac{\partial \tilde{F}_1}{\partial \Phi_1} = \Lambda \Phi_1 - \tilde{q}_1 \Phi_1 - \tilde{q}_2 \Phi_2, \tag{2.23b}$$

$$\tilde{p}_{1x} = -\frac{\partial \tilde{F}_1}{\partial \tilde{q}_1} = -\frac{3}{2}\tilde{q}_1 \tilde{p}_2 - \frac{3}{4}\tilde{q}_1 \tilde{q}_2^2 - \frac{1}{4}\tilde{q}_1^3 - \frac{1}{2}\langle \Phi_1, \Phi_1 \rangle, \tag{2.23c}$$

$$\tilde{p}_{2x} = -\frac{\partial \tilde{F}_1}{\partial \tilde{q}_2} = \tilde{q}_2^3 - \frac{3}{4}\tilde{q}_1^2 \tilde{q}_2 - \langle \Phi_1, \Phi_2 \rangle, \tag{2.23d}$$

or

$$\tilde{P}_x = \theta_0 \nabla \tilde{F}_1,$$

where

$$\tilde{P} = (\Phi_1^T, \tilde{q}_1, \tilde{q}_2, \Phi_2^T, \tilde{p}_1, \tilde{p}_2)^T,$$

$$\tilde{F}_1 = -4\tilde{p}_1^2 + \tilde{p}_2^2 + \tfrac{3}{4}\tilde{q}_1^2 \tilde{p}_2 + \tfrac{3}{8}\tilde{q}_1^2 \tilde{q}_2^2 + \tfrac{1}{16}\tilde{q}_1^4 - \tfrac{1}{4}\tilde{q}_2^4 + \tilde{q}_2 \langle \Phi_1, \Phi_2 \rangle$$
$$+ \tfrac{1}{2}\langle \Lambda \Phi_2, \Phi_2 \rangle - \tfrac{1}{2}\langle \Lambda \Phi_1, \Phi_1 \rangle + \tfrac{1}{2}\tilde{q}_1 \langle \Phi_1, \Phi_1 \rangle.$$

B. The QBH structure for the FDIHS (2.10)

We now establish a map relating FDIHS (2.10) to (2.23), then use the map to construct the second compatible Poisson tensor for the FDIHS (2.10).

It is known[31] that a gauge transformation between the JM and MJM spectral problem is as follows

$$\psi_1 = \phi_1, \quad \psi_2 = \lambda \phi_2 + v_0 \phi_1, \quad u_1 = v_1, \quad u_0 = -v_{0x} - v_0^2, \tag{2.24}$$

which, together with (2.9) and (2.22), gives rise to the map relating (2.10) to (2.23), i.e., $P = M(\tilde{P})$:

$$\Psi_1 = \Phi_1, \quad \Psi_2 = \Lambda \Phi_2 + \tilde{q}_2 \Phi_1, \quad q_1 = \tilde{q}_1,$$
$$q_2 = -2\tilde{p}_2 - \tfrac{3}{4}\tilde{q}_1^2 - \tilde{q}_2^2, \quad p_1 = \tilde{q}_1 \tilde{p}_1 + \tfrac{1}{4}\tilde{q}_2^3 + \tfrac{1}{2}\tilde{q}_2 \tilde{p}_2 - \tfrac{1}{4}\langle \Phi_1, \Phi_2 \rangle, \quad p_2 = \tilde{p}_1. \tag{2.25}$$

The map M given by (2.25) transforms all equations in (2.10) except for (2.10c) into the corresponding equations in (2.23) except for (2.23c). In fact, the equation (2.10c) with an additive constant term $c = -\frac{1}{2}\tilde{F}_1$ is transformed into (2.23c) under the map (2.25). However, the second Poisson tensor constructed later by using the map (2.25) is valid for an arbitrary c, therefore we can take $c=0$. The Jacobi M' of the map M take the form

$$M'(\tilde{P})=\begin{pmatrix} I & 0 & 0 & 0 & 0 & 0\\ 0 & 1 & 0 & 0 & 0 & 0\\ 0 & -\frac{3}{2}\tilde{q}_1 & -2\tilde{q}_2 & 0 & 0 & -2\\ \tilde{q}_2 I & 0 & \Phi_1 & \Lambda & 0 & 0\\ -\frac{1}{4}\Phi_2^T & \tilde{p}_1 & \frac{3}{4}\tilde{q}_2^2+\frac{1}{2}\tilde{p}_2 & -\frac{1}{4}\Phi_1^T & \tilde{q}_1 & \frac{1}{2}\tilde{q}_2\\ 0 & 0 & 0 & 0 & 1 & 0 \end{pmatrix}. \tag{2.26}$$

According to the standard procedure,[32] the image of the Poisson tensor θ_0 for the FDIHS (2.23) under the map M gives rise to the second compatible Poisson tensor for the FDIHS (2.10). That is

$$\theta_1=M'\theta_0 M'^T|_{P=M(\tilde{P})}=\begin{pmatrix} 0_{(N+2)\times(N+2)} & A_1\\ -A_1^T & B_1 \end{pmatrix}, \tag{2.27a}$$

$$A_1=\begin{pmatrix} \Lambda & -\frac{1}{4}\Psi_1 & 0_{N\times 1}\\ 0_{1\times N} & q_1 & 1\\ 2\Psi_1^T & -\frac{1}{2}q_2-\frac{15}{8}q_1^2 & -\frac{3}{2}q_1 \end{pmatrix},\quad B_1=\begin{pmatrix} 0_{N\times N} & \frac{1}{4}\Psi_2 & 0_{N\times 1}\\ -\frac{1}{4}\Psi_2^T & 0 & p_2\\ 0_{1\times N} & -p_2 & 0 \end{pmatrix}. \tag{2.27b}$$

Furthermore, by a straightforward calculation, we can show the following proposition.

Proposition 1: The system (2.10) possesses the QBH *representation*

$$P_x=\theta_0\nabla F_1=\frac{1}{\rho}\,\theta_1\nabla E_1, \tag{2.28}$$

where

$$\rho=B(\lambda)|_{\lambda=0}=\tfrac{3}{8}q_1^2+\tfrac{1}{2}q_2-\tfrac{1}{2}\langle\Lambda^{-1}\Psi_1,\Psi_1\rangle, \tag{2.29a}$$

$$\begin{aligned} E_1&=[A^2(\lambda)+B(\lambda)C(\lambda)]|_{\lambda=0}=F_2-\sum_{i=1}^{N}\lambda_i^{-1}F^{(i)}=(\tfrac{3}{16}q_1^2+\tfrac{1}{4}q_2)(\langle\Lambda^{-1}\Psi_2,\Psi_2\rangle-\langle\Lambda\Psi_1,\Psi_1\rangle)\\ &\times(\tfrac{3}{16}q_1^3+\tfrac{1}{4}q_1q_2)\langle\Psi_1,\Psi_1\rangle+2(p_1-q_1p_2)\langle\Lambda^{-1}\Psi_1,\Psi_2\rangle+(2p_2^2+\tfrac{5}{128}q_1^4-\tfrac{1}{8}q_2^2+\tfrac{1}{4}\langle\Lambda\Psi_1,\Psi_1\rangle\\ &-\tfrac{1}{4}q_1\langle\Psi_1,\Psi_1\rangle)\langle\Lambda^{-1}\Psi_1,\Psi_1\rangle+(\tfrac{3}{8}q_1^2+\tfrac{1}{2}q_2)(\tfrac{1}{4}q_2^2-4p_2^2-\tfrac{5}{64}q_1^4)+4(p_1-q_1p_2)^2\\ &+\tfrac{1}{4}[\langle\Lambda^{-1}\Psi_1,\Psi_2\rangle^2-\langle\Lambda^{-1}\Psi_1,\Psi_1\rangle\langle\Lambda^{-1}\Psi_2,\Psi_2\rangle]. \end{aligned} \tag{2.29b}$$

C. The Nijenhuis coordinates

We now prove that the Nijenhuis coordinates for QBH system (2.28) are the same as the separated variables defined by means of the Lax matrix (2.12b). As θ_0 and θ_1 are compatible and invertible, the matrix $\theta_1\theta_0^{-1}$ is maximal, it has $N+2$ distinct eigenvalues $\boldsymbol{\mu}=(\mu_1,\ldots,\mu_{N+2})$. The explicit form of the canonical transformation from P to the Nijenhuis coordinates $(\boldsymbol{\mu},\boldsymbol{\nu})$ is given in what follows. The eigenvalues $\mu_1,\ldots,\mu_{N+2}$ are defined by the roots of the equation

$$f(\lambda)=|\lambda I-A_1|=0, \tag{2.30}$$

which, since A_1 depends only on (Ψ_1,q_1,q_2), gives rise to

$$\mu_j=f_j(\Psi_1,q_1,q_2),\quad j=1,\ldots,N+2, \tag{2.31}$$

$$\psi_{1j}=g_j(\boldsymbol{\mu}),\quad j=1,\ldots,N,\quad q_1=g_{N+1}(\boldsymbol{\mu}),\quad q_2=g_{N+2}(\boldsymbol{\mu}). \tag{2.32}$$

Then we introduce the generating function by

$$S=\sum_{j=1}^{N} \psi_{2j}g_j(\boldsymbol{\mu})+p_1 g_{N+1}(\boldsymbol{\mu})+p_2 g_{N+2}(\boldsymbol{\mu}), \tag{2.33a}$$

such that

$$\psi_{1j}=\frac{\partial S}{\partial \psi_{2j}}, \quad j=1,...,N, \quad q_1=\frac{\partial S}{\partial p_1}, \quad q_2=\frac{\partial S}{\partial p_2}, \tag{2.33b}$$

$$\nu_j=\frac{\partial S}{\partial \mu_j}=\sum_{j=1}^{N} \psi_{2j}\frac{\partial g_j}{\partial \mu_j}+p_1\frac{\partial g_{N+1}}{\partial \mu_j}+p_2\frac{\partial g_{N+2}}{\partial \mu_j}, \quad j=1,...,N+2. \tag{2.33c}$$

The equations (2.33b) reconstruct (2.31) or (2.32), the equations (2.33c) give the expression for ν_j. The system (2.10) written in terms of $(\boldsymbol{\mu},\boldsymbol{\nu})$ can be shown to be separable.

On the other hand, the separated variables $(\overline{\boldsymbol{\mu}},\overline{\boldsymbol{\nu}})$ for (2.10) can be constructed by means of the Lax matrix in the following way.[27,28] The coordinates $\overline{\mu}_1,\ldots,\overline{\mu}_{N+2}$ are introduced by the zeros of $B(\lambda)$:

$$B(\lambda)=\lambda^2+\frac{1}{2}q_1\lambda+\frac{3}{8}q_1^2+\frac{1}{2}q_2+\frac{1}{2}\sum_{j=1}^{N}\frac{\psi_{1j}^2}{\lambda-\lambda_j}=\frac{R(\lambda)}{K(\lambda)}, \tag{2.34}$$

with

$$R(\lambda)=\prod_{k=1}^{N+2}(\lambda-\overline{\mu}_k)=\sum_{k=0}^{N+2}\beta_k\lambda^{N+2-k}, \quad K(\lambda)=\prod_{k=1}^{N}(\lambda-\lambda_k)=\sum_{k=0}^{N}\alpha_k\lambda^{N-k}, \tag{2.35}$$

$$\alpha_0=1, \quad \alpha_1=-\sum_{j=1}^{N}\lambda_j, \quad \cdots, \quad \alpha_N=(-1)^N\prod_{j=1}^{N}\lambda_j,$$

$$\beta_0=1, \quad \beta_1=-\sum_{j=1}^{N+2}\overline{\mu}_j, \quad \cdots, \quad \beta_{N+2}=(-1)^N\prod_{j=1}^{N+2}\overline{\mu}_j,$$

and the canonically conjugate coordinates $\overline{\nu}_1,\ldots,\overline{\nu}_{N+2}$ are defined by

$$\overline{\nu}_k=-A(\overline{\mu}_k)=-2p_2\overline{\mu}_k-2p_1+2q_1p_2+\frac{1}{2}\sum_{j=1}^{N}\frac{\psi_{1j}\psi_{2j}}{\overline{\mu}_k-\lambda_j}, \quad k=1,...,N+2. \tag{2.36}$$

The FDIHS (2.10) in terms of the coordinates $(\overline{\boldsymbol{\mu}},\overline{\boldsymbol{\nu}})$ will be shown to be separable later. We have the following proposition.

Proposition 2: The Nijenhuis coordinates $(\boldsymbol{\mu},\boldsymbol{\nu})$ *defined by (2.30) and (2.33) are exactly the same as the separated variables* $(\overline{\boldsymbol{\mu}},\overline{\boldsymbol{\nu}})$ *defined by (2.34) and (2.36). The* QBH *vector field (2.28) is Pfaffian in the Nijenhuis coordinates.*

Proof: We first show that

$$f(\lambda)=B(\lambda)K(\lambda)=R(\lambda). \tag{2.37}$$

We denote $f(\lambda)$ by $f_N(\lambda;\lambda_1,\ldots,\lambda_N)$ in order to prove (2.37) by induction. Obviously, (2.37) holds for $N=1$. Then we have by induction

$$f_N(\lambda;\lambda_1,\ldots,\lambda_N)=\begin{vmatrix} \lambda-\lambda_1 & 0 & \ldots & 0 & \frac{1}{4}\psi_{11} & 0\\ 0 & \lambda-\lambda_2 & \ldots & 0 & \frac{1}{4}\psi_{12} & 0\\ \vdots & \vdots & \ddots & \vdots & \vdots & \vdots\\ 0 & 0 & \ldots & \lambda-\lambda_N & \frac{1}{4}\psi_{1N} & 0\\ 0 & 0 & \ldots & 0 & \lambda-q_1 & -1\\ -2\psi_{11} & -2\psi_{12} & \ldots & -2\psi_{1N} & \frac{1}{2}q_2+\frac{15}{8}q_1^2 & \lambda+\frac{3}{2}q_1 \end{vmatrix}$$

$$=(\lambda-\lambda_1)f_{N-1}(\lambda;\lambda_2,\ldots,\lambda_N)+\frac{1}{2}\psi_{11}^2\prod_{k=2}^{N}(\lambda-\lambda_k)$$

$$=\left(\lambda^2+\frac{1}{2}q_1\lambda+\frac{3}{8}q_1^2+\frac{1}{2}q_2+\frac{1}{2}\sum_{j=2}^{N}\frac{\psi_{1j}^2}{\lambda-\lambda_j}\right)K(\lambda)+\frac{1}{2}\frac{\psi_{11}^2}{\lambda-\lambda_1}K(\lambda)$$

$$=B(\lambda)K(\lambda). \tag{2.38}$$

Equation (2.38) implies that λ_1, similarly λ_k, $k=2,\ldots,N$, is not the zero of $f(\lambda)$. Thus (2.37) indicates that $f(\lambda)$ and $B(\lambda)$ have the same zeros, i.e., $\mu_k=\overline{\mu_k}$.

It follows from (2.34) that

$$\psi_{1j}^2=2\frac{R(\lambda_j)}{K'(\lambda_j)},\quad q_1=2(\beta_1-\alpha_1), \tag{2.39a}$$

$$\frac{1}{2}q_2+\frac{3}{8}q_1^2=\frac{1}{2}\langle\Lambda^{-1}\Psi_1,\Psi_1\rangle+\frac{\beta_{N+2}}{\alpha_N}, \tag{2.39b}$$

where the prime denotes differentiation with respect to λ. The equations (2.39a) and (2.39b) yield

$$q_2=2\sum_{j=1}^{N}\frac{R(\lambda_j)}{\lambda_jK'(\lambda_j)}-3(\beta_1-\alpha_1)^2+2\frac{\beta_{N+2}}{\alpha_N}. \tag{2.39c}$$

According to (2.33a), one gets

$$S=\sum_{j=1}^{N}\psi_{2j}\sqrt{\frac{2R(\lambda_j)}{K'(\lambda_j)}}+2p_1(\beta_1-\alpha_1)+p_2\left[\sum_{j=1}^{N}\frac{2R(\lambda_j)}{\lambda_jK'(\lambda_j)}-3(\beta_1-\alpha_1)^2+2\frac{\beta_{N+2}}{\alpha_N}\right].$$

Notice that

$$\frac{\partial}{\partial\mu_k}\sum_{j=1}^{N}\psi_{2j}\sqrt{\frac{2R(\lambda_j)}{K'(\lambda_j)}}=\sum_{j=1}^{N}\frac{\psi_{2j}R(\lambda_j)}{\sqrt{2R(\lambda_j)K'(\lambda_j)}(\mu_k-\lambda_j)}=\frac{1}{2}\sum_{j=1}^{N}\frac{\psi_{1j}\psi_{2j}}{\mu_k-\lambda_j},$$

$$\frac{\partial}{\partial\mu_k}\sum_{j=1}^{N}\frac{2R(\lambda_j)}{\lambda_jK'(\lambda_j)}=\sum_{j=1}^{N}\frac{2R(\lambda_j)}{\lambda_jK'(\lambda_j)(\mu_k-\lambda_j)}=\frac{1}{\mu_k}\sum_{j=1}^{N}\left[\frac{2R(\lambda_j)}{\lambda_jK'(\lambda_j)}+\frac{2R(\lambda_j)}{(\mu_k-\lambda_j)K'(\lambda_j)}\right]$$

$$=\frac{1}{\mu_k}\left(\langle\Lambda^{-1}\Psi_1,\Psi_1\rangle+\sum_{j=1}^{N}\frac{\psi_{1j}^2}{\mu_k-\lambda_j}\right),$$

$$\frac{\partial\beta_{N+2}}{\partial\mu_k}=\frac{\beta_{N+2}}{\mu_k},\quad \frac{\partial(\beta_1-\alpha_1)^2}{\partial\mu_k}=-q_1,\quad \frac{\partial(\beta_1-\alpha_1)}{\partial\mu_k}=-1,$$

and using $B(\mu_k)=0$, one finds from (2.33c) that ν_k,μ_k satisfy (2.36). Finally, it follows from (2.39b) that

$$\rho=B(\lambda)|_{\lambda=0}=\frac{1}{2}q_2+\frac{3}{8}q_1^2-\frac{1}{2}\langle\Lambda^{-1}\Psi_1,\Psi_1\rangle=\frac{\beta_{N+2}}{\alpha_N}=\frac{(-1)^N}{\alpha_N}\prod_{j=1}^{N+2}\mu_j. \tag{2.40}$$

This completes the proof.

D. Comparison of the two methods for separability

For the FDIHS with QBH structure, the separated variables, i.e., the Nijenhuis coordinates, can be introduced by the Nijenhuis tensor. Then the separability of the Hamilton–Jacobi equation for the system can be shown by verifying the Levi-Civita conditions. For the FDIHS with some kind of Lax representation, the separated variables can be found and the separability of the Hamilton Jacobi equation for the system can be shown by means of the Lax representation. So far there is not an effective way to define separated variables for the FDIHSs with some kind of Lax matrices, such as the 3×3 Lax matrices[22] or the Lax matrices admitting dynamical r-matrix. However, if the separated variables can be introduced by the Lax matrix, one can further establish the Jacobi inversion problem for the system by means of the Lax representation. By using the standard Jacobi inversion technique, the solution to the system can be found.

We now use the Lax representation (2.12) to construct the Jacobi inversion problem for (2.10). Set

$$A^2(\lambda)+B(\lambda)C(\lambda)=\frac{W(\lambda)}{K(\lambda)},\quad W(\lambda)=\sum_{i=0}^{N+6}P_i\lambda^i, \tag{2.41}$$

then P_i are also the integrals of motion for (2.10). By substituting (2.13) and using (2.14), (2.41) leads to

$$P_{N+6}=1,\quad P_{N+6-i}=\alpha_i,\quad i=1,2,3,4,$$
$$F_1=-P_{N+1}+\alpha_5,\quad F_2=P_N-\alpha_1P_{N+1}+\alpha_1\alpha_5-\alpha_6,\dots. \tag{2.42}$$

The equations (2.34), (2.36), and (2.41) give rise to

$$\nu_k=\sqrt{\frac{W(\mu_k)}{K(\mu_k)}},\quad k=1,\dots,N+2, \tag{2.43}$$

which indicates that the Hamilton–Jacobi equation is separable. Replacing ν_k by $\partial S_k/\partial\mu_k$ and interpreting the P_i as integration constants, one gets the generating function S of the canonical transformation from (2.43)

$$S(\mu_1,\dots,\mu_{N+2};P_0,\dots,P_{N+1})=\sum_{k=1}^{N+2}\int^{\mu_k}\sqrt{\frac{W(\lambda)}{K(\lambda)}}\,d\lambda. \tag{2.44}$$

The linearizing coordinates are then

$$Q_i=\frac{\partial S}{\partial P_i}=\frac{1}{2}\sum_{k=1}^{N+2}\int^{\mu_k}\frac{\lambda^i}{\sqrt{W(\lambda)K(\lambda)}}\,d\lambda,\quad i=0,1,\dots,N+1. \tag{2.45}$$

The linear flow induced by (2.10) is then given by [using (2.42)]

$$Q_i=\gamma_i+x\frac{\partial F_1}{\partial P_i}=\gamma_i-x\,\delta_{i,N+1},\quad i=0,1,\dots,N+1, \tag{2.46}$$

where γ_i are arbitrary constants. Combining the equation (2.45) with the equation (2.46) leads to the Jacobi inversion problem for the FDIHS (2.10)

$$\frac{1}{2}\sum_{k=1}^{N+2}\int^{\mu_k}\frac{\lambda^i}{\sqrt{W(\lambda)K(\lambda)}}d\lambda=\gamma_i-x\,\delta_{i,N+1},\quad i=0,1,\ldots,N+1. \tag{2.47}$$

Since ψ_{1j},q_1,q_2 defined by (2.39) are the symmetric functions of μ_k, $k=1,\ldots,N+2$, by using the standard Jacobi inversion technique,[33] they can be solved in terms of Riemann theta functions from (2.47). After having ψ_{1j},q_1,q_2, the ψ_{2j},p_1,p_2 can be found by using (2.10a). In this way the solution to (2.10) is obtained.

III. THE FIRST FAMILY OF QBH SYSTEMS

In the following sections, by using the method described in the preceding section, we will present QBH representation for some families of FDIHSs given in Ref. 24, and prove the equivalence of two sets of separated variables.

A. The first family of FDIHSs

We first recall the constrained flows of the hierarchy of nonlinear evolution equations (NLEE) associated with the following polynomial second order spectral problem[31]

$$\psi_x=U(u,\lambda)\psi,\quad U(u,\lambda)=\begin{pmatrix}0 & 1\\ -\sum_{i=0}^{m}u_i\lambda^i & 0\end{pmatrix},\quad \psi=\begin{pmatrix}\psi_1\\ \psi_2\end{pmatrix}, \tag{3.1}$$

where $u_m=-1$, $u=(u_{m-1},\ldots,u_0)^T$. The adjoint representation (2.2) of (3.1) yields

$$a_0=\cdots=a_m=b_0=\cdots=b_{m-1}=0,\quad b_m=1,\quad b_{m+1}=\tfrac{1}{2}u_{m-1},$$

$$a_{m+1}=-\tfrac{1}{4}u_{m-1,x},\quad c_0=1,\quad c_1=-\tfrac{1}{2}u_{m-1},\ldots,$$

and in general

$$\begin{pmatrix}b_{k+m}\\ \vdots\\ b_{k+1}\end{pmatrix}=L\begin{pmatrix}b_{k+m-1}\\ \vdots\\ b_k\end{pmatrix}, \tag{3.2a}$$

$$a_k=-\tfrac{1}{2}b_{k,x},\quad c_k=-\tfrac{1}{2}b_{k,xx}-\sum_{i=0}^{m}u_ib_{k+i},\quad k=1,2,\ldots, \tag{3.2b}$$

where

$$L=\begin{pmatrix}L_{m-1} & L_{m-2} & \ldots & L_1 & L_0\\ 1 & 0 & \ldots & 0 & 0\\ 0 & 1 & \ldots & 0 & 0\\ \vdots & \vdots & \ddots & \vdots & \vdots\\ 0 & 0 & \ldots & 1 & 0\end{pmatrix},$$

$$L_0=\tfrac{1}{4}D^2+u_0-\tfrac{1}{2}D^{-1}u_{0,x},\quad L_i=u_i-\tfrac{1}{2}D^{-1}u_{i,x},\quad i=1,\ldots,m-1.$$

The hierarchy of NLEEs associated with (3.1) can be written as an infinite-dimensional Hamiltonian system

$$u_{t_n}=\begin{pmatrix} u_{m-1}\\ \vdots \\ u_0\end{pmatrix}_{t_n}=J\begin{pmatrix} b_{n+m}\\ \vdots \\ b_{n+1}\end{pmatrix}=J\,\frac{\delta H_n}{\delta u},\quad n=1,2,..., \tag{3.3}$$

where the Hamiltonian H_n and the Hamiltonian operator J are defined by

$$J=\begin{pmatrix} 0 & 0 & \dots & 0 & 2D\\ 0 & 0 & \dots & 2D & J_{m-1}\\ 0 & 0 & \dots & J_{m-1} & J_{m-2}\\ \vdots & \vdots & \ddots & \vdots & \vdots\\ 2D & J_{m-1} & \dots & J_1 & J_0\end{pmatrix},$$

$$J_i=-u_{i,x}-2u_iD,\quad i=0,1,...,m-1,\quad H_n=\frac{2}{m-2n-2}\sum_{i=1}^{m} iu_ib_{n+i+1}.$$

Under zero boundary condition we have

$$\frac{\delta\lambda}{\delta u}=(\lambda^{m-1}\psi_1^2,\lambda^{m-2}\psi_1^2,\dots,\psi_1^2)^T,\quad L\,\frac{\delta\lambda}{\delta u}=\lambda\,\frac{\delta\lambda}{\delta u}. \tag{3.4}$$

Similarly, the constrained flows of the NLEEs (3.3) are defined by[24]

$$\Psi_{1,x}=\Psi_2,\quad \Psi_{2,x}=\Lambda^m\Psi_1-\sum_{i=0}^{m-1} u_i\Lambda^i\Psi_1, \tag{3.5a}$$

$$\frac{\delta H_l}{\delta u}-\frac{1}{2}\sum_{j=1}^{N}\frac{\delta\lambda_j}{\delta u}=\begin{pmatrix} b_{m+l}\\ \vdots\\ b_{l+1}\end{pmatrix}-\frac{1}{2}\begin{pmatrix}\langle\Lambda^{m-1}\Psi_1,\Psi_1\rangle\\ \vdots\\ \langle\Psi_1,\Psi_1\rangle\end{pmatrix}=0. \tag{3.5b}$$

For $l=m$, (3.5b) leads to

$$u_{m-k}=\sum_{j=1}^{k}(-1)^{j-1}\frac{j+1}{2^j}\sum_{l_1+\dots+l_j=k-j}\langle\Lambda^{l_1}\Psi_1,\Psi_1\rangle\cdots\langle\Lambda^{l_j}\Psi_1,\Psi_1\rangle,\quad k=1,...,m, \tag{3.6}$$

where $l_1\geqslant 0,...,l_j\geqslant 0$. By substituting (3.6) into (3.5a), the first constrained flow of (3.3) can be written as a canonical FDHS

$$\Psi_{1,x}=\frac{\partial F_0}{\partial\Psi_2},\quad \Psi_{2,x}=-\frac{\partial F_0}{\partial\Psi_1}, \tag{3.7}$$

or

$$P_x=\theta_0\nabla F_0,$$

where

$$P=(\Psi_1^T,\Psi_2^T)^T,\quad \theta_0=\begin{pmatrix} 0 & I_{N\times N}\\ -I_{N\times N} & 0\end{pmatrix},$$

$$F_0=\frac{1}{2}\langle\Psi_2,\Psi_2\rangle+\sum_{j=0}^{m}\left(\frac{-1}{2}\right)^{j+1}\sum_{l_1+\cdots+l_{j+1}=m-j}\langle\Lambda^{l_1}\Psi_1,\Psi_1\rangle\cdots\langle\Lambda^{l_{j+1}}\Psi_1,\Psi_1\rangle.$$

The entries of the Lax matrix for (3.7) are given by[24]

$$A(\lambda)=-\frac{1}{2}\sum_{j=1}^{N}\frac{\psi_{1j}\psi_{2j}}{\lambda-\lambda_j},\quad B(\lambda)=1+\frac{1}{2}\sum_{j=1}^{N}\frac{\psi_{1j}^2}{\lambda-\lambda_j}, \tag{3.8a}$$

$$C(\lambda)=\lambda^m+\sum_{k=1}^{m}\lambda^{m-k}\sum_{j=1}^{k}\left(-\frac{1}{2}\right)^j\sum_{l_1+\cdots+l_j=k-j}\langle\Lambda^{l_1}\Psi_1,\Psi_1\rangle\cdots\langle\Lambda^{l_j}\Psi_1,\Psi_1\rangle-\frac{1}{2}\sum_{j=1}^{N}\frac{\psi_{2j}^2}{\lambda-\lambda_j}. \tag{3.8b}$$

We have

$$A(\lambda)^2+B(\lambda)C(\lambda)=\lambda^m+\sum_{i=1}^{N}\frac{F^{(i)}}{\lambda-\lambda_i},$$

$$F^{(i)}=\frac{1}{2}\left[\lambda_i^m+\sum_{k=1}^{m}\lambda_i^{m-k}\sum_{j=1}^{k}\left(-\frac{1}{2}\right)^j\sum_{l_1+\cdots+l_j=k-j}\langle\Lambda^{l_1}\Psi_1,\Psi_1\rangle\cdots\langle\Lambda^{l_j}\Psi_1,\Psi_1\rangle\right]\psi_{1i}^2$$
$$-\frac{1}{2}\psi_{2i}^2+\frac{1}{4}\sum_{k\neq i}\frac{(\psi_{1i}\psi_{2k}-\psi_{1k}\psi_{2i})^2}{\lambda_k-\lambda_i},\quad i=1,\ldots,N, \tag{3.9}$$

where $F^{(i)}$, $i=1,\ldots,N$, are independent integrals of motion for (3.7) and $F_0=\Sigma_{i=0}^{N}F^{(i)}$. It can be shown that the system (3.7) is integrable in the Liouville's sense. The systems with $m=1,2,\ldots$ give rise to a family of FDIHSs which include the well-known Garnier system as the first member $(m=1)$. This family of FDIHSs was first given in Ref. 34.

In order to find the QBH structure for (3.7), we need to consider the following modified polynomial second-order spectral problem[31]

$$\phi_x=U(v,\lambda)\phi,\quad U(v,\lambda)=\begin{pmatrix} v_0 & \lambda\\ -\sum_{i=1}^{m}v_i\lambda^{i-1} & -v_0\end{pmatrix},\quad \phi=\begin{pmatrix}\phi_1\\ \phi_2\end{pmatrix}, \tag{3.10}$$

where $v_m=-1$, $v=(v_0,\ldots,v_{m-1})^T$. The equations (2.2) and (2.3) yield

$$a_0=\cdots=a_{m-2}=b_0=\cdots=b_{m-3}=0,\quad b_{m-2}=1,\quad b_{m-1}=\tfrac{1}{2}v_{m-1},$$

$$a_{m-1}=v_0,\quad c_0=1,\quad c_1=-\tfrac{1}{2}v_{m-1},\ldots,$$

and in general

$$\begin{pmatrix}2a_{k+1}\\ -b_{k+1}\\ \vdots\\ -b_{k+m-1}\end{pmatrix}=L\begin{pmatrix}2a_k\\ -b_k\\ \vdots\\ -b_{k+m-2}\end{pmatrix}, \tag{3.11a}$$

$$c_{k+1}=a_{k,x}-\sum_{i=1}^{m}v_ib_{k+i-1},\quad k=1,2,\ldots, \tag{3.11b}$$

where

$$L=\begin{pmatrix} 0 & -2v_0+D & 0 & \dots & 0 & 0 \\ 0 & 0 & 1 & \dots & 0 & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & \dots & 0 & 1 \\ L_0 & L_1 & L_2 & \dots & L_{m-2} & L_{m-1} \end{pmatrix},$$

$$L_0=\tfrac{1}{4}D+\tfrac{1}{2}D^{-1}v_0D, \quad L_i=\tfrac{1}{2}v_i+\tfrac{1}{2}D^{-1}v_iD, \quad i=1,...,m-1.$$

The hierarchy of NLEEs associated with (3.10) is

$$v_{t_n}=\begin{pmatrix} v_0 \\ \vdots \\ v_{m-1} \end{pmatrix}_{t_n}=J\begin{pmatrix} 2a_n \\ -b_n \\ \vdots \\ -b_{n+m-2} \end{pmatrix}=J\frac{\delta H_n}{\delta u}, \quad n=1,2,..., \tag{3.12}$$

where the Hamiltonian H_n and the Hamiltonian operator J are given by

$$J=\begin{pmatrix} \frac{1}{2}D & 0 & 0 & \dots & 0 & 0 \\ 0 & J_2 & J_3 & \dots & J_{m-1} & -2D \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & J_{m-1} & -2D & \dots & 0 & 0 \\ 0 & -2D & 0 & \dots & 0 & 0 \end{pmatrix},$$

$$J_i=v_{i,x}+2v_iD, \quad i=0,1,...,m-1, \quad H_n=\frac{2}{m-2n-2}\left[a_{n,x}-\sum_{i=1}^{m} iv_ib_{n+i-1}\right].$$

Also we have

$$\frac{\delta\lambda}{\delta u}=(2\phi_1\phi_2,\phi_1^2,\lambda\phi_1^2,\dots,\lambda^{m-2}\phi_1^2)^T. \tag{3.13}$$

The constrained flows of (3.12) are defined by

$$\Phi_{1,x}=v_0\Phi_1+\Lambda\Phi_2, \quad \Phi_{2,x}=\left(\Lambda^{m-1}-\sum_{i=1}^{m-1} v_i\Lambda^{i-1}\right)\Phi_1-v_0\Phi_2, \tag{3.14a}$$

$$\frac{\delta H_l}{\delta v}+\frac{1}{2}\sum_{j=1}^{N}\frac{\delta\lambda_j}{\delta v}=\begin{pmatrix} 2a_l \\ -b_l \\ \vdots \\ -b_{l+m-2} \end{pmatrix}+\frac{1}{2}\begin{pmatrix} 2\langle\Phi_1,\Phi_2\rangle \\ \langle\Phi_1,\Phi_1\rangle \\ \vdots \\ \langle\Lambda^{m-2}\Phi_1,\Phi_1\rangle \end{pmatrix}=0. \tag{3.14b}$$

For $l=m-1$, (3.14b) leads to

$$v_0=-\tfrac{1}{2}\langle\Phi_1,\Phi_2\rangle, \tag{3.15a}$$

$$v_{m-k}=\sum_{j=1}^{k}(-1)^{j-1}\frac{j+1}{2^j}\sum_{l_1+\dots+l_j=k-j}\langle\Lambda^{l_1}\Phi_1,\Phi_1\rangle\dots\langle\Lambda^{l_j}\Phi_1,\Phi_1\rangle, \quad k=1,...,m-1. \tag{3.15b}$$

By substituting (3.15) into (3.14a), the first constrained flow of NLEE (3.12) can be written as a canonical FDHS

$$\Phi_{1,x}=\frac{\partial\widetilde{F}_0}{\partial\Phi_2},\quad \Phi_{2,x}=-\frac{\partial\widetilde{F}_0}{\partial\Phi_1}, \tag{3.16a}$$

or

$$\widetilde{P}_x=\theta_0\nabla\widetilde{F}_0,$$

where

$$\widetilde{P}=(\Phi_1^T,\Phi_2^T)^T,\quad \theta_0=\begin{pmatrix}0 & I_{N\times N}\\ -I_{N\times N} & 0\end{pmatrix},$$

$$\widetilde{F}_0=\tfrac{1}{2}\langle\Lambda\Phi_2,\Phi_2\rangle-\tfrac{1}{4}\langle\Phi_1,\Phi_2\rangle^2+\sum_{j=1}^{m}(-\tfrac{1}{2})^j\sum_{l_1+\ldots+l_j=m-j}\langle\Lambda^{l_1}\Phi_1,\Phi_1\rangle\cdots\langle\Lambda^{l_j}\Phi_1,\Phi_1\rangle. \tag{3.16b}$$

B. The QBH structure for the family of FDIHD (3.7)

It is known[31] that the gauge transformation between the spectral problems (3.1) and (3.10) is given by

$$\psi_1=\phi_1,\quad \psi_2=\lambda\phi_2+v_0\phi_1,$$
$$u_i=v_i,\quad i=1,...,m-1,\quad u_0=-v_{0x}-v_0^2, \tag{3.17}$$

which, together with (3.6) and (3.15), gives rise to the map relating (3.7) to (3.16), i.e., $P=M(\widetilde{P})$:

$$\Psi_1=\Phi_1,\quad \Psi_2=\Lambda\Phi_2-\tfrac{1}{2}\langle\Phi_1,\Phi_2\rangle\Phi_1. \tag{3.18}$$

In fact the map M transforms the first equation and the second equation with an additive term, $-c\Psi_1(c=\widetilde{F}_0)$, in (3.7) into the corresponding equations in (3.16). Since the θ_1 constructed in the following is valid for an arbitrary c, so we can take $c=0$. The Jacobi M' of the map M takes the form

$$M'(\widetilde{P})=\begin{pmatrix}I_{N\times N} & 0_{N\times N}\\ -\tfrac{1}{2}\langle\Phi_1,\Phi_2\rangle I_{N\times N}-\tfrac{1}{2}\Phi_1\Phi_2^T & \Lambda-\tfrac{1}{2}\Phi_1\Phi_1^T\end{pmatrix}. \tag{3.19}$$

Then the second compatible Poisson tensor for the vector field (3.7) is

$$\theta_1=M'\theta_0M'^T|_{P=M(\widetilde{P})}=\begin{pmatrix}0_{N\times N} & A_1\\ -A_1^T & B_1\end{pmatrix},$$
$$A_1=\Lambda-\tfrac{1}{2}\Psi_1\Psi_1^T,\quad B_1=\tfrac{1}{2}\Psi_2\Psi_1^T-\tfrac{1}{2}\Psi_1\Psi_2^T. \tag{3.20}$$

By a straightforward calculation, we have the following proposition.

Proposition 3: The system (3.7) possesses the QBH *representation*

$$P_x=\theta_0\nabla F_0=\frac{1}{\rho}\theta_1\nabla E_1, \tag{3.21a}$$

where

$$\rho = B(\lambda)|_{\lambda=0} = 1 - \tfrac{1}{2}\langle \Lambda^{-1}\Psi_1, \Psi_1\rangle, \tag{3.21b}$$

$$\begin{aligned} E_1 &= [A^2(\lambda) + B(\lambda)C(\lambda)]|_{\lambda=0} \\ &= -\sum_{i=1}^{N} \lambda_i^{-1} F^{(i)} \\ &= \tfrac{1}{2}\langle \Lambda^{-1}\Psi_2, \Psi_2\rangle + \tfrac{1}{4}[\langle \Lambda^{-1}\Psi_1, \Psi_2\rangle^2 - \langle \Lambda^{-1}\Psi_1, \Psi_1\rangle\langle \Lambda^{-1}\Psi_2, \Psi_2\rangle] \\ &\quad + \sum_{j=0}^{m} (-\tfrac{1}{2})^{j+1} \sum_{l_1+\ldots+l_{j+1}=m-j} \langle \Lambda^{l_1}\Psi_1, \Psi_1\rangle \ldots \langle \Lambda^{l_{j+1}-1}\Psi_1, \Psi_1\rangle. \end{aligned} \tag{3.21c}$$

C. The Nijenhuis coordinates

In the same way as for (2.30)–(2.33), the eigenvalues of the Nijenhuis tensor $\mu_1, \ldots, \mu_N$ are defined by the roots of the equation

$$f(\lambda) = |\lambda I - A_1| = 0, \tag{3.22a}$$

which gives

$$\psi_{1j} = g_j(\boldsymbol{\mu}), \quad j = 1,\ldots,N.$$

Then one defines

$$\nu_j = \frac{\partial S}{\partial \mu_j} = \sum_{j=1}^{N} \psi_{2j} \frac{\partial g_j}{\partial \mu_j}, \quad j = 1,\ldots,N. \tag{3.22b}$$

On the other hand, the generalized elliptic coordinates $(\overline{\boldsymbol{\mu}}, \overline{\boldsymbol{\nu}})$ are defined by means of the Lax matrix in the following way.[24] The coordinates $\overline{\mu}_1, \ldots, \overline{\mu}_N$ are introduced by the zeros of $B(\lambda)$:

$$B(\lambda) = 1 + \frac{1}{2}\sum_{j=1}^{N} \frac{\psi_{1j}^2}{\lambda - \lambda_j} = \frac{R(\lambda)}{K(\lambda)}, \tag{3.23a}$$

where $K(\lambda)$ is defined by (2.35) and

$$R(\lambda) = \prod_{k=1}^{N} (\lambda - \overline{\mu}_k) = \sum_{k=0}^{N} \beta_k \lambda^{N-k},$$

$$\beta_0 = 1, \quad \beta_1 = -\sum_{j=1}^{N} \overline{\mu}_j, \ldots, \quad \beta_N = (-1)^N \prod_{j=1}^{N} \overline{\mu}_j, \tag{3.23b}$$

and the canonically conjugate coordinates $\overline{\nu}_1, \ldots, \overline{\nu}_N$ are defined by

$$\overline{\nu}_k = -A(\overline{\mu}_k) = \frac{1}{2}\sum_{j=1}^{N} \frac{\psi_{1j}\psi_{2j}}{\overline{\mu}_k - \lambda_j}, \quad k = 1,\ldots,N. \tag{3.23c}$$

We have the following proposition.

Proposition 4: The Nijenhuis coordinates $(\boldsymbol{\mu}, \boldsymbol{\nu})$ *defined by (3.22) are exactly the same as the generalized elliptic coordinates* $(\overline{\boldsymbol{\mu}}, \overline{\boldsymbol{\nu}})$ *defined by (3.23). The* QBH *vector field (3.21) is Pfaffian in the Nijenhuis coordinates.*

Proof: Similarly, we have by induction

$$f_N(\lambda;\lambda_1,\ldots,\lambda_N)=|\lambda I-A_1|$$
$$=\begin{vmatrix} \lambda-\lambda_1+\frac{1}{2}\psi_{11}^2 & \frac{1}{2}\psi_{11}\psi_{12} & \cdots & \frac{1}{2}\psi_{11}\psi_{1N} \\ \frac{1}{2}\psi_{12}\psi_{11} & \lambda-\lambda_2+\frac{1}{2}\psi_{12}^2 & \cdots & \frac{1}{2}\psi_{12}\psi_{1N} \\ \vdots & \vdots & \ddots & \vdots \\ \frac{1}{2}\psi_{1N}\psi_{11} & \frac{1}{2}\psi_{1N}\psi_{12} & \cdots & \lambda-\lambda_N+\frac{1}{2}\psi_{1N}^2 \end{vmatrix}$$
$$=(\lambda-\lambda_1)f_{N-1}(\lambda;\lambda_2,\ldots,\lambda_N)+\tfrac{1}{2}\psi_{11}^2\prod_{k=2}^{N}(\lambda-\lambda_k)$$
$$=B(\lambda)K(\lambda), \tag{3.24}$$

which shows that $\mu_k=\overline{\mu_k}$. It follows from (3.23a) that

$$\psi_{1j}^2=2\,\frac{R(\lambda_j)}{K'(\lambda_j)},\quad j=1,\ldots,N. \tag{3.25}$$

Thus we have

$$\nu_k=\sum_{j=1}^{N}\psi_{2j}\frac{\partial}{\partial\mu_k}\sqrt{\frac{2R(\lambda_j)}{K'(\lambda_j)}}=\sum_{j=1}^{N}\frac{\psi_{2j}R(\lambda_j)}{\sqrt{2R(\lambda_j)K'(\lambda_j)}(\mu_k-\lambda_j)}=\frac{1}{2}\sum_{j=1}^{N}\frac{\psi_{1j}\psi_{2j}}{\mu_k-\lambda_j}, \tag{3.26}$$

which implies that $\nu_k=\overline{\nu_k}$, since $\mu_k=\overline{\mu_k}$. Finally, it is found from (3.23a) that

$$\rho=B(\lambda)|_{\lambda=0}=1-\frac{1}{2}\langle\Lambda^{-1}\Psi_1,\Psi_1\rangle=\frac{\beta_N}{\alpha_N}.$$

This completes the proof.

IV. THE SECOND FAMILY OF QBH SYSTEMS

For $l=m+1$, it is found from (3.5b)[24] that

$$u_{m-k}=(-\tfrac{1}{2})^k u_{m-1}^k+\sum_{i=0}^{k-2}u_{m-1}^i\sum_{j=1}^{[(k-i)/2]}E_{i,j}\sum_{l_1+\ldots+l_j=k-i-2j}\langle\Lambda^{l_1}\Psi_1,\Psi_1\rangle\cdots\langle\Lambda^{l_j}\Psi_1,\Psi_1\rangle,$$
$$k=2,\ldots,m, \tag{4.1a}$$

$$L_0u_{m-1}=\langle\Lambda^{m-1}\Psi_1,\Psi_1\rangle-\sum_{i=1}^{m-1}L_i\langle\Lambda^{i-1}\Psi_1,\Psi_1\rangle, \tag{4.1b}$$

where

$$E_{i,j}=-(i+j+1)\beta_{i,j},\quad \beta_{i,j}=\left(-\frac{1}{2}\right)^{i+j}\frac{(i+j)!}{i!j!}.$$

Denote

$$q=u_{m-1},\quad p=-\tfrac{1}{8}u_{m-1,x}.$$

By substituting (4.1a), (3.5a) and (4.1b) become a canonical FDHS

$$P_x=\theta_0\nabla F_1, \tag{4.2a}$$

where

$$P=(\Psi_1^T,q,\Psi_2^T,p)^T, \quad \theta_0=\begin{pmatrix} 0 & I_{(N+1)\times(N+1)} \\ -I_{(N+1)\times(N+1)} & 0 \end{pmatrix},$$

$$F_1=\tfrac{1}{2}\langle\Psi_2,\Psi_2\rangle+(-\tfrac{1}{2}q)^{m+2}-4p^2 + \sum_{i=0}^{m} q^i \sum_{j=1}^{[(m+2-i)/2]} \beta_{i,j} \sum_{l_1+\cdots+l_j=m+2-i-2j} \langle\Lambda^{l_1}\Psi_1,\Psi_1\rangle\cdots\langle\Lambda^{l_j}\Psi_1,\Psi_1\rangle. \tag{4.2b}$$

The entries of the Lax matrix Q for (4.2) are of the form[24]

$$A(\lambda)=2p-\frac{1}{2}\sum_{j=1}^{N}\frac{\psi_{1j}\psi_{2j}}{\lambda-\lambda_j}, \quad B(\lambda)=\lambda+\frac{1}{2}q+\frac{1}{2}\sum_{j=1}^{N}\frac{\psi_{1j}^2}{\lambda-\lambda_j}, \tag{4.3a}$$

$$C(\lambda)=\sum_{k=0}^{m+1}\lambda^{m+1-k}\tilde{c}_k-\frac{1}{2}\sum_{j=1}^{N}\frac{\psi_{2j}^2}{\lambda-\lambda_j}, \tag{4.3b}$$

where

$$\tilde{c}_k=\left(-\frac{1}{2}q\right)^k+\sum_{i=0}^{k-2}q^i\sum_{j=1}^{[(k-i)/2]}\beta_{i,j}\sum_{l_1+\ldots+l_j=k-i-2j}\langle\Lambda^{l_1}\Psi_1,\Psi_1\rangle\ldots\langle\Lambda^{l_j}\Psi_1,\Psi_1\rangle,$$

$$k=1,\ldots,m+1, \tag{4.3c}$$

$$\tilde{c}_{m+2+k}=-\tfrac{1}{2}\langle\Lambda^k\Psi_2,\Psi_2\rangle, \quad k=0,1,\ldots. \tag{4.3d}$$

Similarly, the equality

$$A^2(\lambda)+B(\lambda)C(\lambda)=\lambda^{m+2}-F_1+\sum_{i=1}^{N}\frac{F^{(i)}}{\lambda-\lambda_i},$$

$$F^{(i)}=-2p\psi_{1i}\psi_{2i}-\frac{1}{2}\left(\lambda_i+\frac{1}{2}q\right)\psi_{2i}^2+\frac{1}{2}\sum_{k=0}^{m+1}\tilde{c}_k\lambda_i^{m+1-k}\psi_{1i}^2+\frac{1}{4}\sum_{k\neq i}\frac{(\psi_{1i}\psi_{2k}-\psi_{1k}\psi_{2i})^2}{\lambda_k-\lambda_i}, \tag{4.4}$$

$$i=1,\ldots,N,$$

determines $N+1$ independent integrals of motion F_0, $F^{(i)}$, $i=1,\ldots,N$, for the FDHS (4.2). The systems (4.2) for $m=1,2,\ldots$, give the second family of FDIHSs. By taking $m=1$ (4.2) gives rises to the multidimensional Henon–Heiles system. The system (4.2) was also studied by a recurrence relation in Ref. 35, however no explicit expressions like (4.2b) and (4.3) were given in that paper.

In the exactly the same way as we did in the preceding section, we can obtain another FDHS from (3.14) for $l=m$, find the map relating this FDHS to the FDHS (4.2) and finally, by using this map, obtain the second compatible Poisson tensor for the vector field for (4.2)

$$\theta_1=\begin{pmatrix} 0_{(N+1)\times(N+1)} & A_1 \\ -A_1^T & B_1 \end{pmatrix},$$

$$A_1=\begin{pmatrix} \Lambda & -\frac{1}{4}\Psi_1 \\ 2\Psi_1^T & -\frac{1}{2}q \end{pmatrix}, \quad B_1=\begin{pmatrix} 0_{N\times N} & \frac{1}{4}\Psi_2 \\ -\frac{1}{4}\Psi_2^T & 0 \end{pmatrix}. \tag{4.5}$$

By a straightforward calculation, we can show the following proposition.

Proposition 5: The system (4.2) possesses the QBH *representation*

$$P_x=\theta_0\nabla F_1=\frac{1}{\rho}\,\theta_1\nabla E_1, \tag{4.6}$$

where

$$\rho=B(\lambda)|_{\lambda=0}=\tfrac{1}{2}q-\tfrac{1}{2}\langle\Lambda^{-1}\Psi_1,\Psi_1\rangle, \tag{4.7a}$$

$$\begin{aligned}E_1&=[A^2(\lambda)+B(\lambda)C(\lambda)]|_{\lambda=0}\\ &=-F_1-\sum_{i=1}^{N}\lambda_i^{-1}F^{(i)}=2p\langle\Lambda^{-1}\Psi_1,\Psi_2\rangle+\frac{1}{4}\,q\langle\Lambda^{-1}\Psi_2,\Psi_2\rangle+4p^2-\left(-\frac{1}{2}\,q\right)^{m+2}\\ &\quad-\sum_{i=0}^{m}q^i\sum_{j=1}^{[(m+2-i)/2]}\beta_{i,j}\sum_{l_1+\ldots+l_j=m+2-i-2j}\langle\Lambda^{l_1}\Psi_1,\Psi_1\rangle\cdots\langle\Lambda^{l_j}\Psi_1,\Psi_1\rangle\\ &\quad+\frac{1}{4}[\langle\Lambda^{-1}\Psi_1,\Psi_2\rangle^2-\langle\Lambda^{-1}\Psi_1,\Psi_1\rangle\langle\lambda^{-1}\Psi_2,\Psi_2\rangle]\\ &\quad-\frac{1}{2}\sum_{i=0}^{m+1}q^i\sum_{j=0}^{[(m+1-i)/2]}\beta_{i,j}\sum_{l_1+\ldots+l_{j+1}=m+1-i-2j}\langle\Lambda^{l_1}\Psi_1,\Psi_1\rangle\cdots\langle\Lambda^{l_j}\Psi_1,\Psi_1\rangle\\ &\quad\times\langle\Lambda^{l_{j+1}-1}\Psi_1,\Psi_1\rangle.\end{aligned} \tag{4.7b}$$

In the same way, $\mu_1,\ldots,\mu_{N+1}$ in the Nijenhuis coordinates are defined by the roots of the equation

$$f(\lambda)=|\lambda I-A_1|=0, \tag{4.8a}$$

which gives

$$\psi_{1j}=g_j(\boldsymbol{\mu}),\quad j=1,\ldots N,\quad q=g_{N+1}(\boldsymbol{\mu}).$$

Then one defines

$$\nu_j=\frac{\partial S}{\partial\mu_j}=\sum_{j=1}^{N}\psi_{2j}\frac{\partial g_j}{\partial\mu_j}+p\,\frac{\partial g_{N+1}}{\partial\mu_j},\quad j=1,\ldots,N+1. \tag{4.8b}$$

On the other hand, the generalized parabolic coordinates $(\overline{\boldsymbol{\mu}},\overline{\boldsymbol{\nu}})$ are defined by means of the Lax matrix in the following way.[24] The coordinates $\overline{\mu}_1,\ldots,\overline{\mu}_{N+1}$ are introduced by the zeros of $B(\lambda)$:

$$B(\lambda)=\lambda+\frac{1}{2}q+\frac{1}{2}\sum_{j=1}^{N}\frac{\psi_{1j}^2}{\lambda-\lambda_j}=\frac{R(\lambda)}{K(\lambda)}, \tag{4.9a}$$

where $K(\lambda)$ is defined by (2.35) and $R(\lambda)$ by

$$R(\lambda)=\prod_{k=1}^{N+1}(\lambda-\overline{\mu}_k)=\sum_{k=0}^{N+1}\beta_k\lambda^{N+1-k},$$

$$\beta_0=1,\quad\beta_1=-\sum_{j=1}^{N}\overline{\mu}_j,\ldots,\quad\beta_{N+1}=(-1)^{N+1}\prod_{j=1}^{N+1}\overline{\mu}_j,$$

and the canonically conjugate coordinates $\overline{\nu}_1,\dots,\overline{\nu}_{N+1}$ are defined by

$$\overline{\nu}_k=-A(\overline{\mu}_k)=-2p+\frac{1}{2}\sum_{j=1}^{N}\frac{\psi_{1j}\psi_{2j}}{\overline{\mu}_k-\lambda_j},\quad k=1,\dots,N+1. \tag{4.9b}$$

We have the following proposition.

Proposition 4: The Nijenhuis coordinates ($\boldsymbol{\mu},\boldsymbol{\nu}$) *defined by (4.8) are exactly the same as the generalized parabolic coordinates* ($\overline{\boldsymbol{\mu}},\overline{\boldsymbol{\nu}}$) *defined by (4.9). The* QBH *vector field (4.6) is Pfaffian in the Nijenhuis coordinates*.

Proof: In a similar way, we can show by induction that

$$f(\lambda)=B(\lambda)K(\lambda). \tag{4.10}$$

It follows from (4.9a) that

$$\psi_{1j}^2=2\frac{R(\lambda_j)}{K'(\lambda_j)},\quad j=1,\dots,N,$$

$$q=\langle\Lambda^{-1}\Psi_1,\Psi_1\rangle+2\frac{\beta_{N+1}}{\alpha_N}=\sum_{j=1}^{N}\frac{2R(\lambda_j)}{\lambda_jK'(\lambda_j)}+2\frac{\beta_{N+1}}{\alpha_N}. \tag{4.11}$$

Then it is similar to find that

$$\nu_k=-A(\mu_k),$$

$$\rho=B(\lambda)|_{\lambda=0}=\frac{1}{2}q-\frac{1}{2}\langle\Lambda^{-1}\Psi_1,\Psi_1\rangle=\frac{\beta_{N+1}}{\alpha_N}.$$

This completes the proof.

V. CONCLUDING REMARKS

In the exact same way as we did in the preceding two sections, we can construct the third family of QBH systems from the constrained flows (3.5) for $l=m+2$, $m=1,2,\dots$. The QBH system (2.28) is just the second member ($m=2$) in the third family of QBH systems, and θ_1 and ρ given by (2.27) and (2.29a) are the second compatible Poisson tensor and the integrating factor for the third family of QBH systems.

In general, the constrained flow (3.5) for $l=m+k$ can be transformed into a FDIHS by introducing the Jacobi–Ostrogradsky coordinates. Under the map relating this FDIHS to that obtained from the modified constrained flow (3.14) for $l=m+k-1$, the image of the Poisson tensor θ_0 for the latter gives rise to the second compatible Poisson tensor θ_1 for the former. In this way, for each k we can obtain a family of QBH systems with $m=1,2,\dots$. The results obtained in the preceding sections suggest the following conjecture: each family of QBH systems ($l=m+k$, $m=1,2,\dots$) shares the same θ_1 and ρ for the QBH structure

$$\theta_0\nabla F_1=\frac{1}{\rho}\theta_1\nabla E_1,$$

and, in general, by means of the Lax matrix $Q=\begin{pmatrix}A(\lambda) & B(\lambda)\\ C(\lambda) & -A(\lambda)\end{pmatrix}$ and the expression

$$A^2(\lambda)+B(\lambda)C(\lambda)=\sum_{i=0}^{m+2k}\overline{F}_i\lambda^i+\sum_{i=1}^{N}\frac{F^{(i)}}{\lambda-\lambda_i},$$

we have

$$\rho = B(\lambda)|_{\lambda=0}, \quad E_1 = [A^2(\lambda) + B(\lambda)C(\lambda)]|_{\lambda=0} = \overline{F_0} - \sum_{i=1}^{N} F^{(i)} \lambda_i^{-1}.$$

For $k=1,2,...$, we find an infinite number of families of QBH systems. Furthermore we can show in a similar way that the Nijenhuis coordinates introduced by the Nijenhuis tensor are exactly the same as the separated variables defined by means of the Lax matrix for the QBH system in the family, and each QBH vector field is Pfaffian in the Nijenhuis coordinates.

We show that the resonant interaction of sound waves is a source of gravitational waves in general relativity. We derive an asymptotic equation that describes this process, and compute the interaction coefficient for the quadratically nonlinear coupling between sound waves and gravitational waves. © *1999 American Institute of Physics.* [S0022-2488(99)01709-0]

I. INTRODUCTION

We consider the propagation of two sound waves through a fluid that is contained in a relativistic space–time. If the interference pattern of the sound waves moves at the speed of light, then they resonate with a gravitational wave, and the resulting variations of the fluid energy–momentum tensor act as the source of a free gravitational wave. We will derive simplified, asymptotic equations that describe the generation of a gravitational wave by this resonant interaction.

Equations that describe the interaction between gravitational waves and waves in another field have been derived for scalar fields,[1] electromagnetic fields,[2] and Yang–Mills fields.[3] In these cases, the nongravitational waves propagate at the speed of light, so they resonate directly with a gravitational wave. The propagation speed of sound waves is less than the speed of light, so a single sound wave cannot generate a gravitational wave.[4] Thus, the resonant interaction of two sound waves is the simplest mechanism for the generation of gravitational waves by sound waves. In the Introduction, we summarize the equations that describe this process, and estimate the strength of the resulting gravitational wave.

We consider weak gravitational waves whose metric is a small perturbation of the flat Minkowski metric. Linearization of the Einstein field equations about the Minkowski metric leads to equations of the form

$$\mathcal{G}[\mathbf{h}] = \frac{8\pi G}{c^4}\mathbf{T}, \tag{1.1}$$

where $\mathbf{h}$ is the perturbation of the metric from the Minkowski metric, $\mathbf{T}$ is the energy–momentum tensor of the fluid, $\mathcal{G}$ is a linear partial differential operator acting on $\mathbf{h}$, c is the speed of light, and G is the gravitational constant. This linearization is valid provided that the background curvature of space–time caused by the unperturbed fluid is negligible over the region in which the waves interact.

[a)]Electronic mail: jkhunter@ucdavis.edu

First, we suppose that the sound waves are small-amplitude, harmonic acoustic wave packets. We denote the wave number four-vectors of the two acoustic waves by $k^{(J)}=(k_\alpha^{(J)})$, where $J=1,2$ and Greek indices run over 0, 1, 2, 3. We define associated phases θ_J by

$$\theta_J=k_\alpha^{(J)}x^\alpha. \tag{1.2}$$

We will not use the summation convention over the wave index J, and will indicate any sums with respect to J explicitly. According to linearized acoustics, the density perturbation ρ' in the acoustic wave field is given by

$$\rho'=(\overset{0}{\rho}+\overset{0}{p}/c^2)\sum_{J=1}^{2}\{A_J(x)e^{i\theta_J}+A_J^*(x)e^{-i\theta_J}\}+\cdots\ . \tag{1.3}$$

In (1.3), the dimensionless function A_J is a complex wave amplitude, and the quantities $\overset{0}{\rho}$ and $\overset{0}{p}$ are the unperturbed fluid density and pressure, repectively.

The energy–momentum tensor associated with the acoustic wave field (1.3) has the form

$$\begin{aligned}\mathbf{T}=\overset{0}{\mathbf{T}}&+\sum_{J=1}^{2}\{A_Je^{i\theta_J}\mathbf{P}_J+A_J^*e^{-i\theta_J}\mathbf{P}_J^*\}\\&+\sum_{J,K=1}^{2}\{A_JA_Ke^{i(\theta_J+\theta_K)}\mathbf{Q}_{JK}+A_J^*A_K^*e^{-i(\theta_J+\theta_K)}\mathbf{Q}_{JK}^*\\&+A_JA_K^*e^{i(\theta_J-\theta_K)}\mathbf{R}_{JK}+A_J^*A_Ke^{-i(\theta_J-\theta_K)}\mathbf{R}_{JK}^*\}+\cdots\ ,\end{aligned}$$

where $\mathbf{P}_J$, $\mathbf{Q}_{JK}$, and $\mathbf{R}_{JK}$ are constant, complex-valued tensors. This energy–momentum tensor is a source term for the gravitational field in Eq. (1.1), which, in essence, is a forced wave equation for the metric perturbation $\mathbf{h}$. When an acoustic source term is resonant, it generates a gravitational wave, provided that an appropriate interaction coefficient is nonzero. With a suitable choice of the signs of the wave number vectors, the condition for three-wave resonance to occur is that

$$k^{(1)}+k^{(2)}+k^{(3)}=0, \tag{1.4}$$

where $k^{(1)}$, $k^{(2)}$ satisfy the dispersion relation of acoustic waves, and $k^{(3)}$ is a null vector. The quantum mechanical interpretation of this triresonance condition is the conservation of energy and momentum in the resonant scattering of two phonons into a graviton.

It is convenient to use Lorentzian coordinates in which the fluid is at rest,

$$x=(t,\vec{x}),\quad \vec{x}=(x^1,x^2,x^3).$$

In these coordinates, the Minkowski metric components $\eta_{\alpha\beta}$ are given by

$$(\eta_{\alpha\beta})=\begin{pmatrix}-1&0&0&0\\0&1/c^2&0&0\\0&0&1/c^2&0\\0&0&0&1/c^2\end{pmatrix}.$$

We write a wave number four-vector k as

$$k=(-\omega,\vec{k}),\quad \vec{k}=(k_1,k_2,k_3),$$

where ω is the angular frequency and $\vec{k}$ is the spatial wave number vector. The dispersion relation of acoustic waves is

$$\omega^2 = c_s^2 \vec{k}^2, \tag{1.5}$$

where c_s is the sound speed of the unperturbed fluid, and the dispersion relation of gravitational waves is

$$\omega^2 = c^2 \vec{k}^2. \tag{1.6}$$

The triresonance condition (1.4) may be written as

$$\omega^{(1)} + \omega^{(2)} + \omega^{(3)} = 0, \quad \vec{k}^{(1)} + \vec{k}^{(2)} + \vec{k}^{(3)} = 0. \tag{1.7}$$

This condition implies that the spatial wave number vectors of the three waves are coplanar. We can therefore choose coordinates so that the propagation directions of the acoustic waves lie in the (x^1,x^2) plane and the propagation direction of the gravitational wave lies in the x^1 direction. As we will show, the gravitational wave generated by the resonant interaction is then plane polarized in the (x^2,x^3) directions. We may write the spatial wave number vectors explicitly as

$$\begin{aligned}\vec{k}^{(1)} &= \frac{\omega^{(1)}}{c_s}(\cos\varphi_1, \sin\varphi_1, 0),\\ \vec{k}^{(2)} &= \frac{\omega^{(2)}}{c_s}(\cos\varphi_2, \sin\varphi_2, 0),\\ \vec{k}^{(3)} &= \frac{\omega^{(3)}}{c}(1,0,0),\end{aligned} \tag{1.8}$$

where φ_1, φ_2 are the angles of the acoustic wave number vectors to the gravitational wave number vector, and $\varphi_1 \neq \varphi_2$. It follows from (1.7) and (1.8) that three-wave resonance occurs when the angles satisfy

$$c \sin(\varphi_1 - \varphi_2) = c_s(\sin\varphi_1 - \sin\varphi_2).$$

In a transverse, traceless gauge, the metric perturbation $h_{\alpha\beta}$ of the gravitational wave is given by

$$(h_{\alpha\beta}) = \{A_3(x)e^{i\theta_3} + A_3^*(x)e^{-i\theta_3}\}\begin{pmatrix} 0 & 0 & 0 & 0\\ 0 & 0 & 0 & 0\\ 0 & 0 & 1/c^2 & 0\\ 0 & 0 & 0 & -1/c^2\end{pmatrix}.$$

As we will show, the gravitational wave amplitude A_3 satisfies the equation

$$i\omega^{(3)}(\partial_t A_3 + c\,\partial_{x^1} A_3) + \Gamma A_1^* A_2^* = 0, \tag{1.9}$$

where the interaction coefficient Γ is given by

$$\Gamma = \frac{8\pi G c_s^2}{c^2}(\overset{0}{\rho} + \overset{0}{p}/c^2)\sin\varphi_1 \sin\varphi_2. \tag{1.10}$$

The sound wave amplitudes A_J in Eq. (1.3) satisfy

$$\partial_t A_J + C_J^j\,\partial_{x^j} A_J = 0, \quad J = 1,2, \tag{1.11}$$

where lower case latin indices run over $1,\ 2,\ 3$, and C_J^j is the spatial group velocity of the Jth wave,

$$C_J^j = \frac{c_s^2 k_j^{(J)}}{\omega^{(J)}}, \quad J = 1,2. \tag{1.12}$$

Equation (1.9) describes the forcing of the gravitational wave by the resonant interaction of the acoustic waves. If the acoustic waves collide head on in the rest frame of the fluid, then $\varphi_1 = 0$, $\varphi_2 = \pi$, and $\Gamma = 0$, so no gravitational wave is generated by the three-wave resonance. The interaction coefficient Γ is nonzero for the resonant interaction of oblique acoustic waves. The angular dependence of the interaction coefficient is explained by the fact that the component of the velocity perturbation of the Jth longitudinal sound wave in the x^2 direction transverse to the gravitational wave is proportional to $\sin \varphi_J$. The resonant component of the transverse momentum tensor, which forces the gravitational wave, is therefore proportional to $\sin \varphi_1 \sin \varphi_2$.

The form of the resonant interaction equations (1.9), (1.11) differs from the usual form of the three-wave resonant interaction equations for Hamiltonian systems,[5] because there is no forcing of an acoustic wave by the resonant interaction between the other acoustic wave and the gravitational wave. From the Lagrangian point of view, the asymmetry between the gravitational and acoustic equations is a consequence of the unusual structure of the variational principle for the Einstein field equations, which provides variational equations for the metric but no variational equations for the fluid. Instead, the fluid equations follow from the metric equations on account of the Bianchi identities. One consequence of this asymmetry is that the resonant interaction equations do not conserve energy exactly. The lack of exact energy conservation for the resonant interaction equations is not physically inconsistent, however. The amplitude of the gravitational wave is much smaller than the amplitudes of the acoustic waves, as can be seen from Eq. (1.18) below, so the depletion of energy of the acoustic waves due to the generation of the gravitational wave is negligible for the time scales over which the resonant interaction equations apply.

In the above discussion, we have described our results for the case of harmonic acoustic waves. In the following sections, we derive the resonant-interaction equations for the more general case of weakly nonlinear sound waves, where the nonlinear self-interaction of the waves leads to the distortion of the wave profiles. Harmonic waves are obtained as a limiting case of weakly nonlinear waves in which their wave amplitudes tends to zero.

The density perturbation for a sum of two weakly nonlinear sound waves is given by

$$\rho' = (\overset{0}{\rho} + \overset{0}{p}/c^2) \sum_{J=1}^{2} a_J(x, \theta_J) + \cdots , \tag{1.13}$$

where a_J is a 2π-periodic function of θ_J whose dependence on the phase variable θ_J describes the local profile of the sound wave. Expansion of the fluid equations implies that a_J satisfies an inviscid Burgers equation,

$$\partial_t a_J + C_J^j \, \partial_{x^j} a_J + \partial_{\theta_J}\left(\tfrac{1}{2}\,\omega^{(J)} \Lambda_J a_J^2\right) = 0, \tag{1.14}$$

where, for a barotropic fluid,

$$\Lambda_J = 1 - \frac{c_s^2}{c^2}. \tag{1.15}$$

The metric perturbation of the gravitational wave is given by

$$(h_{\alpha\beta}) = a_3(x,\theta_3)\begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 1/c^2 & 0 \\ 0 & 0 & 0 & -1/c^2 \end{pmatrix}, \tag{1.16}$$

where the gravitational wave amplitude a_3 satisfies

$$\omega^{(3)}\partial_{\theta_3}(\partial_t a_3 + c\,\partial_{x^1} a_3) + \Gamma\langle a_1 a_2\rangle = 0. \tag{1.17}$$

Here, Γ is defined in (1.10), and the bracket $\langle\cdot\rangle$ denotes a phase average with respect to θ_1 or θ_2 in which θ_3 is held fixed and $\theta_1+\theta_2+\theta_3=0$, in view of (1.2) and (1.4). That is,

$$\langle a_1 a_2\rangle(x,\theta_3) = \frac{1}{2\pi}\int_0^{2\pi} a_1(x,\xi)a_2(x,-\xi-\theta_3)\,d\xi.$$

For very small-amplitude sound waves, we can neglect the nonlinear term in (1.14), and consider harmonic waves with

$$a_J(x,\theta_J) = A_J(x)e^{i\theta_J} + A_J^*(x)e^{-i\theta_J}, \quad J=1,2,3.$$

In that case, (1.14) reduces to (1.11), and (1.17) reduces to (1.9).

The coupling between sound waves and gravitational waves is weak, but the volume of the source region in which the resonant interaction takes place can be large, so that it is possible for the sound waves to generate a significant flux of low-frequency gravitational waves. This mechanism contrasts with the rapid collapse of a massive object, which provides a strong, localized source of gravitational waves.[6]

To estimate the strength of a gravitational wave generated by such a resonant interaction, we suppose that the dimensionless amplitudes a_J of the sound waves are of the order ϵ, and that their interaction time is of the order T. Integration of (1.17) implies that the dimensionless gravitational wave amplitude a_3 is of the order $\epsilon^2 T\Gamma/\omega^{(3)}$. Using the expression in (1.10) for Γ, writing $\omega^{(3)}=2\pi f$, where f is the frequency of the gravitational wave, and neglecting the order one geometrical factor $\sin\varphi_1 \sin\varphi_2$, we find that the gravitational wave amplitude is of the order α, where

$$\alpha = \frac{4\epsilon^2 c_s^2 G T}{c^2 f}(\overset{0}{\rho} + \overset{0}{p}/c^2). \tag{1.18}$$

An upper limit on the interaction time T is the shock formation time of the sound waves, which is of the order

$$T = \frac{1}{\epsilon f}.$$

In that case, we have

$$\alpha = \frac{4\epsilon c_s^2 G}{c^2 f^2}(\overset{0}{\rho} + \overset{0}{p}/c^2). \tag{1.19}$$

In the present, matter-dominated era of the universe, this amplitude is too small for the resonant interaction of sound waves to be a significant source of gravitational waves. However, much stronger gravitational waves may have been generated in the radiation-dominated era. The equation of state for a radiation-dominated universe is

$$p = \tfrac{1}{3}\rho c^2.$$

Thus, from (1.19), the strength α of the gravitational wave is of the order

$$\alpha = \frac{16\epsilon G \overset{0}{\rho}}{9f^2}.$$

For example, in a flat Robertson–Walker universe, the density is given as a function of the age of the universe τ by[7]

$$\overset{0}{\rho} = \frac{3}{32\pi G\tau^2},$$

so that

$$\alpha = \frac{\epsilon}{6\pi\tau^2 f^2}.$$

The gravitational wave amplitude is therefore significant at sufficiently low frequencies.

II. THE FIELD EQUATIONS

We use units in which

$$8\pi G = 1, \quad c = 1. \tag{2.1}$$

The Einstein field equations are

$$G_{\alpha\beta} = T_{\alpha\beta}, \tag{2.2}$$

where $G_{\alpha\beta}$ is the Einstein tensor and $T_{\alpha\beta}$ is the energy–momentum tensor. The Einstein tensor $G_{\alpha\beta}$ is given in terms of the Ricci curvature tensor $R_{\alpha\beta}$, the scalar curvature $R = R^{\alpha}_{\alpha}$, the metric tensor $g_{\alpha\beta}$, and the associated connection coefficients $\Gamma^{\alpha}_{\beta\gamma}$ by

$$G_{\alpha\beta} = R_{\alpha\beta} - \tfrac{1}{2} R g_{\alpha\beta},$$

$$R_{\alpha\beta} = \partial_\lambda \Gamma^{\lambda}_{\alpha\beta} - \partial_\lambda \Gamma^{\lambda}_{\beta\lambda} + \Gamma^{\lambda}_{\alpha\beta}\Gamma^{\mu}_{\lambda\mu} - \Gamma^{\mu}_{\alpha\lambda}\Gamma^{\lambda}_{\beta\mu},$$

$$\Gamma^{\alpha}_{\beta\gamma} = \tfrac{1}{2} g^{\alpha\lambda}(\partial_\beta g_{\lambda\gamma} + \partial_\gamma g_{\lambda\beta} - \partial_\lambda g_{\beta\gamma}).$$

The Einstein equations (2.2) may be written in the equivalent form

$$R_{\alpha\beta} = T_{\alpha\beta} - \tfrac{1}{2} T g_{\alpha\beta}, \tag{2.3}$$

where T is the trace of the energy–momentum tensor.

We study weak gravitational waves for which the metric tensor $g_{\alpha\beta}$ is a small perturbation of the Minkowski metric $\eta_{\alpha\beta}$. We therefore write

$$g_{\alpha\beta} = \eta_{\alpha\beta} + h_{\alpha\beta}, \tag{2.4}$$

where the metric perturbation $h_{\alpha\beta}$ is small. Use of (2.4) in (2.3) and linearization of the result with respect to $h_{\alpha\beta}$ implies that

$$\mathcal{L}[h]_{\alpha\beta} = T_{\alpha\beta} - \tfrac{1}{2} T \eta_{\alpha\beta}, \tag{2.5}$$

where the linearized gravitational wave operator $\mathcal{L}$ is given by

$$\mathcal{L}[h]_{\alpha\beta}=\tfrac{1}{2}(-\partial^{\lambda}\partial_{\lambda}h_{\alpha\beta}-\partial_{\alpha}\partial_{\beta}h^{\lambda}_{\lambda}+\partial_{\beta}\partial_{\lambda}h^{\lambda}_{\alpha}+\partial_{\alpha}\partial_{\lambda}h^{\lambda}_{\beta}), \tag{2.6}$$

and

$$T=\eta^{\alpha\beta}T_{\alpha\beta}. \tag{2.7}$$

Throughout the paper, we use the Minkowski metric to raise and lower indices.

Computation of the divergence of (2.5) implies that the energy–momentum tensor satisfies the conservation laws,

$$\partial_{\alpha}T^{\alpha\beta}=0. \tag{2.8}$$

After evaluation at the Minkowski metric, the energy–momentum tensor of the fluid is given by

$$T^{\alpha\beta}=(\rho+p)u^{\alpha}u^{\beta}+p\,\eta^{\alpha\beta}, \tag{2.9}$$

where ρ is the mass–energy density, p is the pressure, and u^{α} is the four-velocity of the fluid. The four-velocity satisfies

$$u^{\alpha}u_{\alpha}=-1. \tag{2.10}$$

In a barotropic fluid, the pressure and density are related by

$$p=c_s^2\rho, \tag{2.11}$$

where the constant c_s is the sound speed. Fluids with more general equations of state could be treated in a similar way.

In Secs. III–IV, we derive an asymptotic solution of the fluid equations (2.8)–(2.11), which describes the sum of two weakly nonlinear sound waves. In Secs. V–VI, we solve the gravitational equations (2.5) for the metric perturbation.

In dimensioned variables, the length scale L of the variation of the background space–time metric caused by the presence of the fluid is given by

$$L=\left[\frac{8\pi G}{c^2}(\overset{0}{\rho}+\overset{0}{p}/c^2)\right]^{-1/2}.$$

The Einstein equations can be linearized about the Minkowski metric, provided that the length scale δ of the interaction region is small compared with L. To carry out the linearization in a systematic way, we use dimensionless variables in which $L=1$, and denote the corresponding space–time variables by y^{α}. The solution for the metric in a region of order δ about the origin is given by an expansion of the form

$$g_{\alpha\beta}(y;\delta)=\eta_{\alpha\beta}+\delta^2h_{\alpha\beta}(x)+O(\delta^3),\qquad x^{\alpha}=\frac{y^{\alpha}}{\delta}. \tag{2.12}$$

The corresponding expansion of the fluid's energy–momentum tensor $T_{\alpha\beta}(\mathbf{g})$ is

$$T_{\alpha\beta}(\mathbf{g})=T_{\alpha\beta}+O(\delta^2), \tag{2.13}$$

where the energy–momentum tensor $T_{\alpha\beta}$ on the right-hand side of (2.13) is evaluated at the Minkowski metric. Using (2.12) and (2.13) in (2.3), and setting $\delta=0$, we obtain the linearized equations (2.6)–(2.7).

III. EXPANSION OF THE FLUID EQUATIONS

The fluid variables are the pressure p, the density ρ, and the four-velocity u^α. We denote the constant fluid variables in the unperturbed state by

$$p=\overset{0}{p},\quad \rho=\overset{0}{\rho},\quad u^\alpha=\overset{0}{u}{}^\alpha.$$

We use a reference frame in which the unperturbed fluid is at rest, so that

$$(\overset{0}{u}{}^\alpha)=(1,0,0,0),\quad (\overset{0}{u}{}_\alpha)=(-1,0,0,0). \tag{3.1}$$

We look for small-amplitude, high-frequency asymptotic solutions of (2.8)–(2.11) of the form

$$\begin{aligned} p&=\overset{0}{p}+\epsilon\overset{1}{p}(x,\theta_1,\theta_2)+\epsilon^2\overset{2}{p}(x,\theta_1,\theta_2)+O(\epsilon^3),\\ \rho&=\overset{0}{\rho}+\epsilon\overset{1}{\rho}(x,\theta_1,\theta_2)+\epsilon^2\overset{2}{\rho}(x,\theta_1,\theta_2)+O(\epsilon^3),\\ u^\alpha&=\overset{0}{u}{}^\alpha+\epsilon\overset{1}{u}{}^\alpha(x,\theta_1,\theta_2)+\epsilon^2\overset{2}{u}{}^\alpha(x,\theta_1,\theta_2)+O(\epsilon^3), \end{aligned} \tag{3.2}$$

where the phase variable θ_J is given by

$$\theta_J=\frac{k_\alpha^{(J)}x^\alpha}{\epsilon},\quad J=1,2. \tag{3.3}$$

Here, $k^{(J)}$ is the scaled wave number vector of the Jth wave.

In (3.2)–(3.3), the small dimensionless parameter ϵ measures both the amplitude and the wavelength of the sound waves. This scaling is the appropriate one for the description of small-amplitude sound waves that propagate over a distance comparable with their shock-formation distance.[8,9] Once shocks form, the sound waves decay, or other physical effects become important, so the shock-formation distance effectively limits the length scale of the interaction region.

Because of the algebraic relations (2.10)–(2.11), there are four independent fluid variables, which we take to be the pressure p and the spatial velocity components u_j. Use of (3.1) and (3.2) in (2.10), and expansion of the result with respect to ϵ, implies that the timelike component of the four-velocity is given in terms of the spatial components by (3.2), with

$$\overset{1}{u}{}^0=0,\quad \overset{2}{u}{}^0=\tfrac{1}{2}\overset{1}{u}{}^j\overset{1}{u}{}_j. \tag{3.4}$$

From (2.11), the density perturbations are given in terms of the pressure perturbations by

$$\overset{1}{\rho}=\frac{\overset{1}{p}}{c_s^2},\quad \overset{2}{\rho}=\frac{\overset{2}{p}}{c_s^2}. \tag{3.5}$$

Use of (3.2) in the expression (2.9) for the energy–momentum tensor implies that

$$T^{\alpha\beta}=\overset{0}{T}{}^{\alpha\beta}+\epsilon\overset{1}{T}{}^{\alpha\beta}(x,\theta_1,\theta_2)+\epsilon^2\overset{2}{T}{}^{\alpha\beta}(x,\theta_1,\theta_2)+O(\epsilon^3), \tag{3.6}$$

where

$$\overset{0}{T}{}^{\alpha\beta}=\begin{pmatrix} \overset{0}{\rho} & 0 \\ 0 & \overset{0}{p}\,\delta^{jk} \end{pmatrix},$$

$$\overset{1}{T}{}^{\alpha\beta}=\begin{pmatrix} \overset{1}{\rho} & (\overset{0}{\rho}+\overset{0}{p})\overset{1}{u}{}^{k} \\ (\overset{0}{\rho}+\overset{0}{p})\overset{1}{u}{}^{j} & \overset{1}{p}\,\delta^{jk} \end{pmatrix}, \tag{3.7}$$

$$\overset{2}{T}{}^{\alpha\beta}=\begin{pmatrix} \overset{2}{\rho}+2(\overset{0}{\rho}+\overset{0}{p})\overset{2}{u}{}^{0} & (\overset{1}{\rho}+\overset{1}{p})\overset{1}{u}{}^{k}+(\overset{0}{\rho}+\overset{0}{p})\overset{2}{u}{}^{k} \\ (\overset{1}{\rho}+\overset{1}{p})\overset{1}{u}{}^{j}+(\overset{0}{\rho}+\overset{0}{p})\overset{2}{u}{}^{j} & \overset{2}{p}\,\delta^{jk}+(\overset{0}{\rho}+\overset{0}{p})\overset{1}{u}{}^{j}\overset{1}{u}{}^{k} \end{pmatrix}.$$

Use of (3.3) and (3.6) in the conservation law (2.8) implies that

$$\left(\frac{1}{\epsilon}\sum_{J=1}^{2} k_{\alpha}^{(J)}\partial_{\theta_J}+\partial_{\alpha}\right)(\overset{0}{T}{}^{\alpha\beta}+\epsilon\overset{1}{T}{}^{\alpha\beta}+\epsilon^{2}\overset{2}{T}{}^{\alpha\beta}+O(\epsilon^{3}))=0. \tag{3.8}$$

Expanding and equating the coefficients of ϵ^{-1} and ϵ^{0} to zero in (3.8), we obtain that

$$\sum_{J=1}^{2} k_{\alpha}^{(J)}\,\partial_{\theta_J}\overset{1}{T}{}^{\alpha\beta}=0, \tag{3.9}$$

$$\sum_{J=1}^{2} k_{\alpha}^{(J)}\,\partial_{\theta_J}\overset{2}{T}{}^{\alpha\beta}+\partial_{\alpha}\overset{1}{T}{}^{\alpha\beta}=0. \tag{3.10}$$

In order to write these equations in a more convenient form, we define a four-component vector field $\mathbf{U}=(U_{\alpha})$ of independent fluid variables by

$$\mathbf{U}=\begin{pmatrix} p \\ u_j \end{pmatrix}. \tag{3.11}$$

From (3.1), (3.2), and (3.11),

$$\mathbf{U}=\overset{0}{\mathbf{U}}+\epsilon\overset{1}{\mathbf{U}}(x,\theta_1,\theta_2)+\epsilon^{2}\overset{2}{\mathbf{U}}(x,\theta_1,\theta_2)+O(\epsilon^{3}), \tag{3.12}$$

$$\overset{0}{\mathbf{U}}=\begin{pmatrix} \overset{0}{p} \\ 0 \end{pmatrix}, \quad \overset{1}{\mathbf{U}}=\begin{pmatrix} \overset{1}{p} \\ \overset{1}{u}_j \end{pmatrix}, \quad \overset{2}{\mathbf{U}}=\begin{pmatrix} \overset{2}{p} \\ \overset{2}{u}_j \end{pmatrix}. \tag{3.13}$$

We define tensor-valued functions $B=(B^{\alpha\beta})$, $C=(C^{\alpha\beta})$ of $\mathbf{U}=(\rho,u_j)^{T}$ by

$$B(\mathbf{U})=\begin{pmatrix} p/c_s^{2} & (\overset{0}{\rho}+\overset{0}{p})u^{k} \\ (\overset{0}{\rho}+\overset{0}{p})u^{j} & p\,\delta^{jk} \end{pmatrix}, \tag{3.14}$$

$$C(\mathbf{U},\mathbf{U})=\begin{pmatrix} (\overset{0}{\rho}+\overset{0}{p})u^{j}u_{j} & (\rho+p)u^{k} \\ (\rho+p)u^{j} & (\overset{0}{\rho}+\overset{0}{p})u^{j}u^{k} \end{pmatrix}. \tag{3.15}$$

Since we are using a Lorentzian coordinate frame, we have $u_j = u^j$. From (3.14)–(3.15), $B(\mathbf{U})$ is a linear function of $\mathbf{U}$, and

$$C(\mathbf{U},\mathbf{V}) = \tfrac{1}{4}[C(\mathbf{U}+\mathbf{V},\mathbf{U}+\mathbf{V}) - C(\mathbf{U}-\mathbf{V},\mathbf{U}-\mathbf{V})]$$

is a bilinear function of $(\mathbf{U},\mathbf{V})$.

It follows from (3.4), (3.5), (3.7), (3.14), and (3.15) that

$$\overset{1}{T}{}^{\alpha\beta} = B^{\alpha\beta}(\overset{1}{\mathbf{U}}), \tag{3.16}$$

$$\overset{2}{T}{}^{\alpha\beta} = B^{\alpha\beta}(\overset{2}{\mathbf{U}}) + C^{\alpha\beta}(\overset{1}{\mathbf{U}},\overset{1}{\mathbf{U}}). \tag{3.17}$$

Therefore, Eqs. (3.9)–(3.10) can be written in the form

$$\sum_{J=1}^{2} k_\alpha^{(J)} \partial_{\theta_J} B^{\alpha\beta}(\overset{1}{\mathbf{U}}) = 0, \tag{3.18}$$

$$\sum_{J=1}^{2} k_\alpha^{(J)} \partial_{\theta_J} B^{\alpha\beta}(\overset{2}{\mathbf{U}}) + \partial_\alpha B^{\alpha\beta}(\overset{1}{\mathbf{U}}) + \sum_{J=1}^{2} k_\alpha^{(J)} \partial_{\theta_J} C^{\alpha\beta}(\overset{1}{\mathbf{U}},\overset{1}{\mathbf{U}}) = 0. \tag{3.19}$$

IV. SOLUTION OF THE FLUID EQUATIONS

We nondimensionalize the fluid variables so that

$$\overset{0}{\rho} + \overset{0}{p} = 1. \tag{4.1}$$

It follows from (3.11), (3.14), (3.15), and (4.1) that

$$k_\alpha^{(J)} B^{\alpha\beta}(\mathbf{U}) = A_J^{\beta\alpha} U_\alpha, \tag{4.2}$$

where the four-by-four matrices $A_J = (A_J^{\beta\alpha})$ are given by

$$A_J = \begin{pmatrix} k_0^{(J)}/c_s^2 & k^{(J)k} \\ k^{(J)j} & k_0^{(J)} \delta^{jk} \end{pmatrix}, \qquad J = 1,2. \tag{4.3}$$

Use of (4.2) in (3.18) implies that

$$A_1\, \partial_{\theta_1} \overset{1}{\mathbf{U}} + A_2\, \partial_{\theta_2} \overset{1}{\mathbf{U}} = 0. \tag{4.4}$$

Equation (4.4) is a symmetric hyperbolic system for $\overset{1}{\mathbf{U}}$ in two independent variables (θ_1, θ_2). The ''slow'' variables x occur in (4.4) as parameters.

The determinant of A_J is given by

$$\det A_J = \frac{(k_0^{(J)})^2}{c_s^2} \{(k_0^{(J)})^2 - c_s^2 k^{(J)j} k_j^{(J)}\}.$$

In order for θ_J to be the phase of a sound wave, we require that $k^{(J)}$ satisfies the acoustic dispersion relation,

$$(k_0^{(J)})^2 = c_s^2 k^{(J)j} k_j^{(J)}, \tag{4.5}$$

in which case A_J is singular. We denote a normalized null vector by $\mathbf{R}_J$, where

$$A_J\mathbf{R}_J=0, \qquad J=1,2. \tag{4.6}$$

From (4.3), (4.5), and (4.6), we find that

$$\mathbf{R}_J=\begin{pmatrix} k_0^{(J)} \\ -k_j^{(J)} \end{pmatrix}, \quad J=1,2. \tag{4.7}$$

From (4.6), a solution of (4.4) is given by

$$\overset{1}{\mathbf{U}}=b_1(x,\theta_1)\mathbf{R}_1+b_2(x,\theta_2)\mathbf{R}_2, \tag{4.8}$$

where $b_J(x,\theta_J)$ is an arbitrary scalar-valued function, which we assume is a 2π-periodic, zero-mean function of θ_J. The solution (4.8) describes a sum of two oscillatory sound waves. We will derive an equation for the amplitude function b_J from the solvability conditions for the second-order perturbation equation, (3.19).

Using (4.2), we can write (3.19) as

$$A_1\,\partial_{\theta_1}\overset{2}{\mathbf{U}}+A_2\,\partial_{\theta_2}\overset{2}{\mathbf{U}}=\mathbf{F}(\overset{1}{\mathbf{U}}), \tag{4.9}$$

where $\mathbf{F}=(F^\beta)$ with

$$F^\beta(\overset{1}{\mathbf{U}})=-\left\{\partial_\alpha B^{\alpha\beta}(\overset{1}{\mathbf{U}})+\sum_{J=1}^{2}k_\alpha^{(J)}\partial_{\theta_J}C^{\alpha\beta}(\overset{1}{\mathbf{U}},\overset{1}{\mathbf{U}})\right\}. \tag{4.10}$$

Equation (4.9) is a linear, nonhomogeneous hyperbolic equation for $\mathbf{U}2$ that we solve by the method of characteristics.

The line

$$\frac{d\theta_1}{ds}=\mu_1, \quad \frac{d\theta_2}{ds}=\mu_2,$$

is a characteristic of (4.9) if there is an eigenvector $\mathbf{R}$, such that

$$(\mu_2A_1-\mu_1A_2)\mathbf{R}=0.$$

Using (4.3), we find that

$$\det(\mu_2A_1-\mu_1A_2)=\frac{2(q-1)k_0^{(1)}k_0^{(2)}}{c_s^2}\mu_1\mu_2(\mu_2k_0^{(1)}-\mu_1k_0^{(2)})^2,$$

where

$$q=\frac{k_j^{(1)}k^{(2)j}c_s^2}{k_0^{(1)}k_0^{(2)}}. \tag{4.11}$$

Thus, Eq. (4.9) has two simple characteristics, given by $\mu_1=0$ and $\mu_2=0$, with associated eigenvectors $\mathbf{R}=\mathbf{R}_1$ and $\mathbf{R}=\mathbf{R}_2$, respectively. These characteristics correspond to acoustic waves. Equation (4.9) also has a double characteristic, given by

$$\mu_2k_0^{(1)}-\mu_1k_0^{(2)}=0,$$

which corresponds to vorticity waves. The associated eigenspace is two dimensional, but only one eigenvector is required to solve (4.9) because the acoustic wave interaction forces velocity perturbations that are coplanar with the acoustic wave number vectors. The relevant eigenvector $\mathbf{R} = \mathbf{R}_0$ is given by

$$\mathbf{R}_0 = \begin{pmatrix} 0 \\ k_0^{(1)} k_j^{(2)} + k_0^{(2)} k_j^{(1)} \end{pmatrix}. \tag{4.12}$$

We look for a solution of Eq. (4.9) of the form

$$\overset{2}{\mathbf{U}} = w_0(x,\theta_1,\theta_2)\mathbf{R}_0 + w_1(x,\theta_1,\theta_2)\mathbf{R}_1 + w_2(x,\theta_1,\theta_2)\mathbf{R}_2. \tag{4.13}$$

We use (4.13) in (4.9) and, after some algebra,[10] find that it is a solution, provided that the scalar-valued coefficients w_0, w_1, w_2 satisfy the equations

$$\sum_{J=1}^{2} k_0^{(J)} \partial_{\theta_J} w_0 = \sum_{J=1}^{2} k_0^{(J)} \{ V_J \partial_{\theta_J}(b_J)^2 + W \partial_{\theta_J}(b_1 b_2) + H^\alpha \partial_\alpha b_J \}, \tag{4.14}$$

$$\begin{aligned} \partial_{\theta_2} w_1 = {} & M_1(\partial_{\theta_1} b_1) b_2 + N_1 b_1 (\partial_{\theta_1} b_1) \\ & + P_1 b_1 (\partial_{\theta_2} b_2) + Q_2 b_2 (\partial_{\theta_2} b_2) + Y_1^\alpha \partial_\alpha b_1 + Z_1^\alpha \partial_\alpha b_2, \end{aligned} \tag{4.15}$$

$$\begin{aligned} \partial_{\theta_1} w_2 = {} & M_2 b_1 (\partial_{\theta_2} b_2) + N_2 b_2 (\partial_{\theta_2} b_2) \\ & + P_2 (\partial_{\theta_1} b_1) b_2 + Q_1 b_1 (\partial_{\theta_1} b_1) + Y_2^\alpha \partial_\alpha b_2 + Z_2^\alpha \partial_\alpha b_1. \end{aligned} \tag{4.16}$$

The coefficients in (4.14)–(4.16) are given by

$$\begin{gathered} V_J = \frac{(k_0^{(J)})^2}{2k_0^{(1)} k_0^{(2)}}, \quad W = \frac{2c_s^2 + 1 - q}{2c_s^2}, \quad H^\alpha = \frac{h^\alpha}{k_0^{(1)} k_0^{(2)} (1+q)}, \\ M_J = \frac{k_0^{(J)} q (1-c_s^2)}{c_s^2 (1-q)}, \quad N_J = \frac{(k_0^{(J)})^3 (1-c_s^2)}{c_s^2 k_0^{(1)} k_0^{(2)} (1-q)}, \quad P_J = \frac{k_0^{(1)} k_0^{(2)} (1 + q^2 - 2qc_s^2)}{2k_0^{(J)} c_s^2 (1-q)}, \\ Q_J = \frac{(k_0^{(J)})^3 (1 - qc_s^2)}{c_s^2 k_0^{(1)} k_0^{(2)} (1-q)}, \quad Y_J^\alpha = -\frac{k_0^{(J)} C_J^\alpha}{k_0^{(1)} k_0^{(2)} (1-q)}, \quad Z_J^\alpha = -\frac{h^\alpha}{2k_0^{(J)} (1-q)}. \end{gathered} \tag{4.17}$$

Here, q is defined in (4.11), and the four-vectors $h = (h^\alpha)$ and $C_J = (C_J^\alpha)$ are given by

$$h = \begin{pmatrix} 1+q \\ -c_s^2 k_j^{(1)}/k_0^{(1)} - c_s^2 k_j^{(2)}/k_0^{(2)} \end{pmatrix}, \tag{4.18}$$

$$C_J = \begin{pmatrix} 1 \\ -c_s^2 k_j^{(J)}/k_0^{(J)} \end{pmatrix}. \tag{4.19}$$

Integration of (4.14)–(4.16) implies that

$$w_0 = \sum_{J=1}^{2} \{ H^\alpha \partial_\alpha B_J + V_J b_J^2 \} + W b_1 b_2 + f_0, \tag{4.20}$$

$$w_1=(N_1 b_1\,\partial_{\theta_1} b_1+Y_1^\alpha\,\partial_\alpha b_1)\,\theta_2+M_1(\partial_{\theta_1} b_1)B_2$$
$$+P_1 b_1 b_2+\tfrac{1}{2}Q_2(b_2)^2+Z_1^\alpha\,\partial_\alpha B_2+f_1, \tag{4.21}$$

$$w_2=(N_2 b_2\,\partial_{\theta_2} b_2+Y_2^\alpha\,\partial_\alpha b_1)\,\theta_1+M_2(\partial_{\theta_2} b_2)B_1$$
$$+P_2 b_1 b_2+\tfrac{1}{2}Q_1(b_1)^2+Z_2^\alpha\,\partial_\alpha B_1+f_2. \tag{4.22}$$

Here, $f_0(x,k_0^{(2)}\theta_1-k_0^{(1)}\theta_2)$, $f_1(x,\theta_1)$, and $f_2(x,\theta_2)$ are arbitrary functions of integration, and

$$B_J(x,\theta_J)=\int_0^{\theta_J} b_J(x,\xi)\,d\xi-\frac{1}{2\pi}\int_0^{2\pi}\int_0^{\eta} b_J(x,\xi)d\xi\,d\eta \tag{4.23}$$

denotes the zero-mean integral of b_J with respect to θ_J.

Terms in w_J that grow linearly in θ_J are secular terms that invalidate the asymptotic solution. We therefore require that the coefficients of θ_2 and θ_1 in (4.21) and (4.22) are zero. It follows that

$$Y_J^\alpha\,\partial_\alpha b_J+N_J b_J\,\partial_{\theta_J} b_J=0,\quad J=1,2. \tag{4.24}$$

After using (4.11) and (4.17) in (4.24), we obtain an an inviscid Burgers equation for b_J,

$$C_J^\alpha\,\partial_\alpha b_J-\partial_{\theta_J}\left(\frac{(k_0^{(J)})^2}{2c_s^2}\Lambda_J b_J^2\right)=0, \tag{4.25}$$

where Λ_J is given in (1.15). The solutions for w_1, w_2 in (4.21)–(4.22) then reduce to

$$w_1=M_1(\partial_{\theta_1} b_1)B_2+P_1 b_1 b_2+\tfrac{1}{2}Q_2(b_2)^2+Z_1^\alpha\,\partial_\alpha B_2+f_1, \tag{4.26}$$

$$w_2=M_2(\partial_{\theta_2} b_2)B_1+P_2 b_1 b_2+\tfrac{1}{2}Q_1(b_1)^2+Z_2^\alpha\,\partial_\alpha B_1+f_2. \tag{4.27}$$

In summary, an asymptotic solution as $\epsilon\to 0$ of (2.8)–(2.11) for the fluid variables $\mathbf{U}$ in (3.11) is given by

$$\mathbf{U}=\overset{0}{\mathbf{U}}+\epsilon\{b_1(x,\theta_1)\mathbf{R}_1+b_2(x,\theta_2)\mathbf{R}_2\}+\epsilon^2\{w_0(x,\theta_1,\theta_2)\mathbf{R}_0$$
$$+w_1(x,\theta_1,\theta_2)\mathbf{R}_1+w_2(x,\theta_1,\theta_2)\mathbf{R}_2\}+O(\epsilon^3), \tag{4.28}$$

where the eigenvectors $\mathbf{R}_0$, $\mathbf{R}_1$, $\mathbf{R}_2$ are defined in (4.12) and (4.7), b_J satisfies (4.25), w_0, w_1, w_2 are given in (4.20) and (4.26)–(4.27), the phase variable θ_J is defined in (3.3), and the wave number vector $k^{(J)}$ satisfies the acoustic dispersion relation (4.5). From (3.5), (3.11), (4.7), and (4.8), we may write

$$\overset{1}{\rho}=\sum_{J=1}^{2} a_J,\quad a_J=\frac{k_0^{(J)}}{c_s^2}b_J. \tag{4.29}$$

Reintroducing dimensioned variables, and removing the expansion parameter ϵ by setting $\epsilon=1$, we find from (4.25) and (4.29) that the leading-order density perturbation ρ' is given by (1.13), where a_J satisfies (1.14).

The use of (4.8) and (4.13) in (3.16)–(3.17) implies that the terms in the expansion (3.6) of the energy–momentum tensor are given by

$$\overset{1}{T}{}^{\alpha\beta}(x,\theta_1,\theta_2)=\sum_{J=1}^{2} b_J(x,\theta_J)B^{\alpha\beta}(\mathbf{R}_J), \tag{4.30}$$

$$\overset{2}{T}{}^{\alpha\beta}(x,\theta_1,\theta_2)=\sum_{J=1}^{3} w_J(x,\theta_1,\theta_2)B^{\alpha\beta}(\mathbf{R}_J)+\sum_{J,K=1}^{2} b_J(x,\theta_J)b_K(x,\theta_K)C^{\alpha\beta}(\mathbf{R}_J,\mathbf{R}_K), \tag{4.31}$$

where B and C are defined in (3.14) and (3.15).

V. EXPANSION OF THE GRAVITATIONAL EQUATIONS

We suppose that the acoustic wave number vectors satisfy the triresonance condition (1.4). We define a gravitational phase variable by

$$\theta_3=\frac{k_\alpha^{(3)}x^\alpha}{\epsilon}, \tag{5.1}$$

where the gravitational wave number vector $k^{(3)}$ satisfies the dispersion relation

$$k_\alpha^{(3)}k^{(3)\alpha}=0. \tag{5.2}$$

The triresonance condition (1.4) implies that the phases are related by

$$\theta_1+\theta_2+\theta_3=0. \tag{5.3}$$

If $h(x;\epsilon)=h(x,\theta_1,\theta_2,\theta_3)$, where the phase variables θ_J are given by (3.3) and (5.1), then it follows from the chain rule that

$$\partial_\alpha h=\frac{1}{\epsilon}\sum_{J=1}^{3} k_\alpha^{(J)}\,\partial_{\theta_J}h+\partial_\alpha h. \tag{5.4}$$

The partial derivative ∂_α on the right-hand side of (5.4) is taken with respect to x^α holding θ_J fixed. Using (5.4) to expand partial derivatives in the linearized gravitational wave operator $\mathcal{L}$ given in (2.6), we find that

$$\mathcal{L}[h]_{\alpha\beta}=\frac{1}{\epsilon^2}\mathcal{A}[h]_{\alpha\beta}+\frac{1}{\epsilon}\mathcal{B}[h]_{\alpha\beta}+\mathcal{C}[h]_{\alpha\beta}, \tag{5.5}$$

where the linear operators $\mathcal{A}$, $\mathcal{B}$, and $\mathcal{C}$ are given by

$$\mathcal{A}[h]_{\alpha\beta}=\frac{1}{2}\sum_{J,K=1}^{3}\partial_{\theta_J}\partial_{\theta_K}\{-k_\lambda^{(J)}k^{(K)\lambda}h_{\alpha\beta}-k_\alpha^{(J)}k_\beta^{(K)}h_\lambda^\lambda+k_\lambda^{(J)}k_\beta^{(K)}h_\alpha^\lambda+k_\alpha^{(J)}k_\lambda^{(K)}h_\beta^\lambda\}, \tag{5.6}$$

$$\begin{aligned}\mathcal{B}[h]_{\alpha\beta}=\frac{1}{2}\sum_{J=1}^{3}\partial_{\theta_J}\{&-2k^{(J)\lambda}\partial_\lambda h_{\alpha\beta}-(k_\alpha^{(J)}\partial_\beta+k_\beta^{(J)}\partial_\alpha)h_\lambda^\lambda\\&+(k_\lambda^{(J)}\partial_\beta+k_\beta^{(J)}\partial_\lambda)h_\alpha^\lambda+(k_\alpha^{(J)}\partial_\lambda+k_\lambda^{(J)}\partial_\alpha)h_\beta^\lambda\},\end{aligned} \tag{5.7}$$

$$\mathcal{C}[h]_{\alpha\beta}=\tfrac{1}{2}(-\partial_\lambda\,\partial^\lambda h_{\alpha\beta}-\partial_\alpha\,\partial_\beta h_\lambda^\lambda+\partial_\alpha\,\partial_\lambda h_\alpha^\lambda+\partial_\beta\,\partial_\lambda h_\beta^\lambda). \tag{5.8}$$

We look for an asymptotic expansion of the metric perturbation h as $\epsilon\to 0$ of the form

$$h_{\alpha\beta}=\overset{0}{h}_{\alpha\beta}(x)+\epsilon^2\overset{2}{h}_{\alpha\beta}(x)+\epsilon^3\overset{3}{h}_{\alpha\beta}(x,\theta_1,\theta_2,\theta_3)+\epsilon^4\overset{4}{h}_{\alpha\beta}(x,\theta_1,\theta_2,\theta_3)+O(\epsilon^5). \tag{5.9}$$

We use (3.6), (5.5), and (5.9) in (2.5), expand, and equate coefficients of ϵ^0, ϵ^1, and ϵ^2 in the result. This yields the perturbation equations

$$\mathcal{C}[\overset{0}{h}]_{\alpha\beta}=\overset{0}{T}_{\alpha\beta}-\tfrac{1}{2}\overset{0}{T}\eta_{\alpha\beta}, \tag{5.10}$$

$$\mathcal{A}[\overset{3}{h}]_{\alpha\beta}=\overset{1}{T}_{\alpha\beta}-\tfrac{1}{2}\overset{1}{T}\eta_{\alpha\beta}, \tag{5.11}$$

$$\mathcal{A}[\overset{4}{h}]_{\alpha\beta}+\mathcal{B}[\overset{3}{h}]_{\alpha\beta}+\mathcal{C}[\overset{2}{h}]_{\alpha\beta}=\overset{2}{T}_{\alpha\beta}-\tfrac{1}{2}\overset{2}{T}\eta_{\alpha\beta}. \tag{5.12}$$

Equation (5.10) is a linearized Einstein field equation for the leading-order metric perturbation $\overset{0}{h}$ in which the source term is the constant energy–momentum tensor of the unperturbed fluid. The solution describes the small background space–time curvature caused by the presence of the fluid. Since our aim is to determine the propagating part of the metric, we will not consider this equation further. The source term in Eq. (5.11) is a linear sum of nonresonant acoustic terms, and it can be solved without the appearance of secular terms. The solution includes a gravitational wave that satisfies the homogeneous equation. The source term in Eq. (5.12) contains resonant terms that are quadratically nonlinear in the sound wave amplitudes. The imposition of solvability conditions leads to an equation for the amplitude of the gravitational wave included in the solution of (5.11). This equation describes the generation of a gravitational wave by the sound wave interaction, and is our main result. We carry out the detailed computations in the next section.

VI. SOLUTION OF THE GRAVITATIONAL EQUATIONS

A solution of the order ϵ perturbation equation (5.11) has the form

$$\overset{3}{h}_{\alpha\beta}=f_{\alpha\beta}(x,\theta_1,\theta_2)+h'_{\alpha\beta}(x,\theta_3)+\overline{h}_{\alpha\beta}(x), \tag{6.1}$$

where $f_{\alpha\beta}$ is a particular solution of (5.11) that corresponds to an oscillatory metric perturbation forced by the acoustic waves, $h'_{\alpha\beta}$ is a solution of the homogeneous equation that corresponds to the metric perturbation of a gravitational wave, and $\overline{h}_{\alpha\beta}$ is an arbitrary function of x. We assume that $h'_{\alpha\beta}$ is 2π periodic in θ_3 and, without loss of generality, we choose $\overline{h}_{\alpha\beta}$ so that $f_{\alpha\beta}$ and $h'_{\alpha\beta}$ have zero mean with respect to the phase variables.

From (4.30) and (5.6), a particular solution of (5.11) is given by

$$f_{\alpha\beta}(x,\theta_1,\theta_2)=\sum_{J=1}^{2} c_J(x,\theta_J)F^{(J)}_{\alpha\beta}, \tag{6.2}$$

where $\partial^2_{\theta_J}c_J=b_J$ and

$$\begin{aligned}&\tfrac{1}{2}(-k^{(J)}_\lambda k^{(J)\lambda}F^{(J)}_{\alpha\beta}-k^{(J)}_\alpha k^{(J)}_\beta F^{(J)\lambda}_\lambda+k^{(J)}_\lambda k^{(J)}_\beta F^{(J)\lambda}_\alpha+k^{(J)}_\alpha k^{(J)}_\lambda F^{(J)\lambda}_\beta)\\&\quad=B_{\alpha\beta}(\mathbf{R}_J)-\tfrac{1}{2}B^\lambda_\lambda(\mathbf{R}_J)\eta_{\alpha\beta}.\end{aligned}$$

This algebraic equation for $F^{(J)}_{\alpha\beta}$ is nonsingular whenever the wave number vector $k^{(J)}$ is not a null vector. The precise form of the solution is unimportant for our purposes, so we omit a detailed expression.

The term $h'_{\alpha\beta}(x,\theta_3)$ in (6.1) satisfies the homogeneous equation

$$\mathcal{A}[h']_{\alpha\beta}=0. \tag{6.3}$$

Using (5.6), we can write (6.3) as

$$\tfrac{1}{2}\partial^2_{\theta_3}(k^{(3)}_\alpha \Phi_\beta + k^{(3)}_\beta \Phi_\alpha)=0, \tag{6.4}$$

where

$$\Phi_\alpha = k^{(3)\lambda} h'_{\alpha\lambda} - \tfrac{1}{2} k^{(3)}_\alpha h'^{\lambda}_{\ \lambda}. \tag{6.5}$$

Since $h'_{\alpha\beta}$ is a zero-mean, 2π-periodic function of θ_3, it follows from (6.4), after two integrations with respect to θ_3, that

$$\Phi_\alpha = 0. \tag{6.6}$$

We use Lorentzian coordinates in which the gravitational wave propagates in the $(-x^1)$ direction. The covariant wave number four-vector of the wave is then

$$(k^{(3)}_\alpha) = \kappa_3(1,1,0,0), \tag{6.7}$$

where κ_3 is a constant scalar. It follows from (6.5), (6.6), and (6.7) that the metric $h'_{\alpha\beta}$ has the form

$$(h'_{\alpha\beta}) = \begin{pmatrix} h'_{00} & (h'_{00}+h'_{11})/2 & h'_{02} & h'_{03} \\ (h'_{00}+h'_{11})/2 & h'_{11} & h'_{02} & h'_{03} \\ h'_{02} & h'_{02} & h'_{22} & h'_{23} \\ h'_{03} & h'_{03} & h'_{23} & -h'_{22} \end{pmatrix}.$$

We can eliminate h'_{00}, h'_{11}, h'_{02}, and h'_{03} by means of an appropriate gauge transformation.[11] The metric perturbation associated with the gravitational wave is then given by

$$(h'_{\alpha\beta}) = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & h'_{22} & h'_{23} \\ 0 & 0 & h'_{23} & -h'_{22} \end{pmatrix}. \tag{6.8}$$

Equations for the second-order mean-field perturbation $\overset{2}{h}_{\alpha\beta}$ and the third-order gravitational wave perturbation $h'_{\alpha\beta}$ follow from the requirement that Eq. (5.12) has a solution for $\overset{4}{h}_{\alpha\beta}$ that is a periodic function of the phase variables. There are two solvability conditions for (5.12). The first condition is obtained by averaging the equation with respect to all the phase variables, and leads to an equation for the perturbation in the background gravitational field caused by the mean energy–momentum density of the sound waves. The second condition is obtained by averaging (5.12) with respect to θ_1 subject to the constraint (5.3) with θ_3 held fixed, and leads to an equation for the amplitude of the gravitational wave. Similar arguments have been used in the study of resonant wave interactions for hyperbolic conservation laws.[12,13] To derive these solvability conditions, we first introduce some notation.

Suppose that $f(x,\theta_1,\theta_2,\theta_3)$ is a 2π-periodic function of each of the phase variables θ_J $(J=1,2,3)$. We define

$$\overline{f}(x) = \frac{1}{(2\pi)^3}\int_0^{2\pi}\int_0^{2\pi}\int_0^{2\pi} f(x,\xi_1,\xi_2,\xi_3)\, d\xi_1 d\xi_2 d\xi_3, \tag{6.9}$$

$$\langle f\rangle(x,\theta_3) = \frac{1}{2\pi}\int_0^{2\pi} f(x,\xi,-\xi-\theta_3,\theta_3)\, d\xi. \tag{6.10}$$

Thus, $\overline{f}$ is the mean of f with respect to the phase variables $(\theta_1,\theta_2,\theta_3)$, while $\langle f\rangle$ is the mean of f with respect to θ_1, or θ_2, in which θ_3 is held fixed and the three phase variables satisfy the constraint (5.3).

It follows from these definitions that

$$\overline{\partial_{\theta_J} f}=0, \quad J=1,2,3. \tag{6.11}$$

If $F(x)$ is independent of the phases, then $\overline{F}=F$, and if $f_J(x,\theta_J)$ is a periodic function of a single phase variable θ_J, then

$$\langle f_J\rangle=\overline{f_J}, \quad J=1,2, \quad \langle f_3\rangle=f_3. \tag{6.12}$$

Since $f(x,\theta_1,\theta_2,\theta_3)$ is periodic, we have

$$\begin{aligned}\langle \partial_{\theta_1} f-\partial_{\theta_2} f\rangle &= \frac{1}{2\pi}\int_0^{2\pi}\{\partial_{\theta_1} f(x,\xi,-\xi-\theta_3,\theta_3)-\partial_{\theta_2} f(x,\xi,-\xi-\theta_3,\theta_3)\}d\xi\\ &=\frac{1}{2\pi}\int_0^{2\pi}\partial_\xi f(x,\xi,-\xi-\theta_3,\theta_3)\,d\xi\\ &=0.\end{aligned}$$

Hence,

$$\langle \partial_{\theta_1} f\rangle=\langle \partial_{\theta_2} f\rangle. \tag{6.13}$$

We write (5.12) as

$$\mathcal{A}[\overset{4}{h}]_{\alpha\beta}+\mathcal{B}[\overset{3}{h}]_{\alpha\beta}+\mathcal{C}[\overset{2}{h}]_{\alpha\beta}=S_{\alpha\beta}, \tag{6.14}$$

where

$$S_{\alpha\beta}=\overset{2}{T}_{\alpha\beta}-\tfrac{1}{2}\overset{2}{T}\eta_{\alpha\beta}. \tag{6.15}$$

From (5.6) and (5.7), we see that each term in $\mathcal{A}[h]_{\alpha\beta}$ and $\mathcal{B}[h]_{\alpha\beta}$ is a derivative with respect to a phase variable, so (6.11) implies that

$$\overline{\mathcal{A}[h]_{\alpha\beta}}=0, \quad \overline{\mathcal{B}[h]_{\alpha\beta}}=0.$$

Therefore, averaging (6.14) with respect to all the phase variables, we obtain the first solvability condition,

$$\mathcal{C}[\overset{2}{h}]_{\alpha\beta}=\overline{S}_{\alpha\beta}. \tag{6.16}$$

To derive an expression for $\overline{S}_{\alpha\beta}$, we use (4.31) in (6.15), which gives

$$\begin{aligned}\overline{S}_{\alpha\beta}=&\sum_{J=1}^{3}\overline{w}_J\left\{B_{\alpha\beta}(\mathbf{R}_J)-\frac{1}{2}B^{\lambda}_{\lambda}(\mathbf{R}_J)\,\eta_{\alpha\beta}\right\}\\ &+\sum_{J=1}^{2}\overline{b_J^2}\left\{C_{\alpha\beta}(\mathbf{R}_J,\mathbf{R}_J)-\frac{1}{2}C^{\lambda}_{\lambda}(\mathbf{R}_J,\mathbf{R}_J)\,\eta_{\alpha\beta}\right\}.\end{aligned} \tag{6.17}$$

Averaging (4.20) and (4.26)–(4.27), and supposing for simplicity that the arbitrary functions of integration f_J have zero mean, we find that

$$\overline{w_0}=\sum_{J=1}^{2} V_J\overline{b_J^2}, \quad \overline{w_J}=\frac{1}{2}Q_J\overline{b_J^2}, \quad J=1,2.$$

Use of these expressions in (6.17) gives

$$\overline{S}_{\alpha\beta}=\sum_{J=1}^{2} \overline{b_J^2}M_{\alpha\beta}^{(J)},$$

$$M_{\alpha\beta}^{(J)}=C_{\alpha\beta}(\mathbf{R}_J,\mathbf{R}_J)-\tfrac{1}{2}C_\lambda^\lambda(\mathbf{R}_J,\mathbf{R}_J)\eta_{\alpha\beta} + V_J\{B_{\alpha\beta}(\mathbf{R}_0)-\tfrac{1}{2}B_\lambda^\lambda(\mathbf{R}_0)\eta_{\alpha\beta}\}+\tfrac{1}{2}Q_J\{B_{\alpha\beta}(\mathbf{R}_J)-\tfrac{1}{2}B_\lambda^\lambda(\mathbf{R}_J)\eta_{\alpha\beta}\}.$$

Equation (6.16) is a linearized Einstein equation for the second-order metric perturbation in (5.9) in which the source term is given by the mean energy–momentum tensor of the sound waves. This mean energy–momentum tensor leads to a small change in the background curvature of space time, in addition to the background curvature caused by the energy–momentum tensor of the unperturbed fluid.

To derive the second solvability condition, we average Eq. (6.14) with respect to θ_1, subject to the constraint (5.3) with θ_3 held fixed. After subtracting the mean equation (6.16) from the result, we obtain that

$$\langle \mathcal{A}[\overset{4}{h}]\rangle_{\alpha\beta}+\langle \mathcal{B}[\overset{3}{h}]\rangle_{\alpha\beta}=\langle S'\rangle_{\alpha\beta}, \tag{6.18}$$

where

$$S'_{\alpha\beta}=S_{\alpha\beta}-\overline{S}_{\alpha\beta}. \tag{6.19}$$

We will compute explicit expressions for each of the means in (6.18). The final result is given in (6.34) below.

First, we compute $\langle S'\rangle_{\alpha\beta}$. From (4.31), (6.15), (6.17), and (6.19) we have

$$\langle S'\rangle_{\alpha\beta}=\sum_{J=1}^{3}\langle w_J'\rangle\left\{B_{\alpha\beta}(\mathbf{R}_J)-\frac{1}{2}B_\lambda^\lambda(\mathbf{R}_J)\eta_{\alpha\beta}\right\} +2\langle b_1b_2\rangle\{C_{\alpha\beta}(\mathbf{R}_1,\mathbf{R}_2)-\tfrac{1}{2}C_\lambda^\lambda(\mathbf{R}_1,\mathbf{R}_2)\eta_{\alpha\beta}\}, \tag{6.20}$$

where

$$w_J'=w_J-\overline{w}_J. \tag{6.21}$$

Averaging (4.20) and (4.26)–(4.27), we find that

$$\langle w_0'\rangle=W\langle b_1b_2\rangle, \quad \langle w_J'\rangle=(M_J+P_J)\langle b_1b_2\rangle, \quad J=1,2, \tag{6.22}$$

where W, M_J, and P_J are defined in (4.17). In deriving (6.22), we have used the fact that

$$\langle b_1b_2\rangle=\langle(\partial_{\theta_1}b_1)B_2\rangle=\langle B_1(\partial_{\theta_2}b_2)\rangle,$$

which follows from (6.13), since Eq. (4.23) implies that $\partial_{\theta_J}B_J=b_J$. Substitution of (6.22) into (6.20) gives

$$\langle S'\rangle_{\alpha\beta}=\langle b_1b_2\rangle J_{\alpha\beta}, \tag{6.23}$$

where

$$J_{\alpha\beta}=W\{B_{\alpha\beta}(\mathbf{R}_0)-\tfrac{1}{2}B_\lambda^\lambda(\mathbf{R}_0)\,\eta_{\alpha\beta}\}+\sum_{J=1}^{2}(M_J+P_J)\left\{B_{\alpha\beta}(\mathbf{R}_J)-\frac{1}{2}B_\lambda^\lambda(\mathbf{R}_J)\,\eta_{\alpha\beta}\right\}+2\{C_{\alpha\beta}(\mathbf{R}_1,\mathbf{R}_2)-\tfrac{1}{2}C_\lambda^\lambda(\mathbf{R}_1,\mathbf{R}_2)\,\eta_{\alpha\beta}\}. \tag{6.24}$$

Using (3.14), (3.15), (4.7), (4.12), and (4.17) in (6.24), and simplifying the result with the aid of (1.4) and (6.7), we get[10]

$$(J_{\alpha\beta})=\begin{pmatrix} J_{00} & (J_{00}+J_{11})/2 & J_{02} & J_{03}\\ (J_{00}+J_{11})/2 & J_{11} & J_{02} & J_{03}\\ J_{02} & J_{02} & J_{22} & J_{23}\\ J_{03} & J_{03} & J_{23} & -J_{22}\end{pmatrix},$$

$$J_{00}=\left(\frac{1+3c_s^2+q+7qc_s^2}{2c_s^4}\right)k_0^{(1)}k_0^{(2)},\quad J_{11}=\left(\frac{3-3c_s^2+3q+qc_s^2}{2c_s^4}\right)k_0^{(1)}k_0^{(2)},$$

$$J_{01}=\left(\frac{1+q+2qc_s^2}{c_s^4}\right)k_0^{(1)}k_0^{(2)},\quad J_{02}=-\frac{1}{c_s^2}k_2^{(1)}(k_0^{(1)}-k_0^{(2)}), \tag{6.25}$$

$$J_{03}=-\frac{1}{c_s^2}k_3^{(1)}(k_0^{(1)}-k_0^{(2)}),\quad J_{22}=k_2^{(1)}k_2^{(2)}-k_3^{(1)}k_3^{(2)},\quad J_{23}=k_2^{(1)}k_3^{(2)}+k_3^{(1)}k_2^{(2)}.$$

Next, we consider the terms on the left-hand side of (6.18). From (5.6),

$$\langle\mathcal{A}[\overset{4}{h}]\rangle_{\alpha\beta}=\frac{1}{2}\sum_{J,K=1}^{3}\langle\partial_{\theta_J}\partial_{\theta_K}(k_\lambda^{(J)}k_\beta^{(K)}\overset{4}{h}{}_\alpha^\lambda+k_\alpha^{(J)}k_\lambda^{(K)}\overset{4}{h}{}_\beta^\lambda-k_\alpha^{(J)}k_\beta^{(K)}\overset{4}{h}{}_\lambda^\lambda)\rangle. \tag{6.26}$$

If f is any periodic function of the phases, then use of (6.13) and the triresonance condition (1.4) implies that

$$\begin{aligned}\left\langle\sum_{J,K=1}^{3}k_\alpha^{(J)}k_\beta^{(K)}\partial_{\theta_J}\partial_{\theta_K}f\right\rangle&=(k_\alpha^{(1)}+k_\alpha^{(2)})\left\langle\sum_{K=1}^{3}k_\beta^{(K)}\partial_{\theta_1}\partial_{\theta_K}f\right\rangle+k_\alpha^{(3)}\left\langle\sum_{K=1}^{3}k_\beta^{(K)}\partial_{\theta_3}\partial_{\theta_K}f\right\rangle\\&=k_\alpha^{(3)}\left\langle\sum_{K=1}^{3}k_\beta^{(K)}\partial_{\theta_K}(-\partial_{\theta_1}f+\partial_{\theta_3}f)\right\rangle\\&=k_\alpha^{(3)}(k_\beta^{(1)}+k_\beta^{(2)})\langle\partial_{\theta_1}(-\partial_{\theta_1}f+\partial_{\theta_3}f)\rangle+k_\alpha^{(3)}k_\beta^{(3)}\langle\partial_{\theta_3}(-\partial_{\theta_1}f+\partial_{\theta_3}f)\rangle\\&=k_\alpha^{(3)}k_\beta^{(3)}\langle\partial_{\theta_1}^2f-2\partial_{\theta_1}\partial_{\theta_3}f+\partial_{\theta_3}^2f\rangle.\end{aligned}$$

Using this result to compute the averages in (6.26), we find that

$$\langle\mathcal{A}[\overset{4}{h}]\rangle_{\alpha\beta}=\hat{A}_{\alpha\beta}, \tag{6.27}$$

where

$$\hat{A}_{\alpha\beta}=k_\lambda^{(3)}k_\beta^{(3)}\hat{h}_\alpha^\lambda+k_\alpha^{(3)}k_\lambda^{(3)}\hat{h}_\beta^\lambda-k_\alpha^{(3)}k_\beta^{(3)}\hat{h}_\lambda^\lambda, \tag{6.28}$$

$$\hat{h}_{\alpha\beta}=\tfrac{1}{2}\langle\partial^2_{\theta_1}\overset{4}{h}_{\alpha\beta}-2\partial_{\theta_1}\partial_{\theta_3}\overset{4}{h}_{\alpha\beta}+\partial^2_{\theta_3}\overset{4}{h}_{\alpha\beta}\rangle. \tag{6.29}$$

We can rewrite (6.28) as

$$\hat{A}_{\alpha\beta}=k^{(3)}_\alpha\Psi_\beta+k^{(3)}_\beta\Psi_\alpha,\quad \Psi_\alpha=k^{(3)}_\lambda\hat{h}^\lambda_\alpha-\tfrac{1}{2}k^{(3)}_\alpha\hat{h}^\lambda_\lambda. \tag{6.30}$$

The use of (6.7) in (6.30) gives

$$(\hat{A}_{\alpha\beta})=\begin{pmatrix}\hat{A}_{00} & (\hat{A}_{00}+\hat{A}_{11})/2 & \hat{A}_{02} & \hat{A}_{03}\\ (\hat{A}_{00}+\hat{A}_{11})/2 & \hat{A}_{11} & \hat{A}_{02} & \hat{A}_{03}\\ \hat{A}_{02} & \hat{A}_{02} & 0 & 0\\ \hat{A}_{03} & \hat{A}_{03} & 0 & 0\end{pmatrix}, \tag{6.31}$$

$$\hat{A}_{00}=2\kappa_3\Psi_0,\quad \hat{A}_{11}=2\kappa_3\Psi_1,\quad \hat{A}_{02}=\kappa_3\Psi_2,\quad \hat{A}_{03}=\kappa_3\Psi_3.$$

Finally, from (5.7), (6.1), (6.2), (6.11), and (6.12) we have

$$\langle\mathcal{B}[\overset{3}{h}]\rangle_{\alpha\beta}=\mathcal{B}[h']_{\alpha\beta}. \tag{6.32}$$

The use of (5.7), (6.7), and (6.8) implies that

$$\mathcal{B}[h']_{\alpha\beta}=\hat{B}_{\alpha\beta},$$

$$\hat{B}_{\alpha\beta}=\begin{pmatrix}0 & 0 & 0 & 0\\ 0 & 0 & 0 & 0\\ 0 & 0 & \hat{B}_{22} & \hat{B}_{23}\\ 0 & 0 & \hat{B}_{23} & -\hat{B}_{22}\end{pmatrix}, \tag{6.33}$$

$$\hat{B}_{22}=\kappa_3\partial_{\theta_3}(\partial_0-\partial_1)h'_{22},\quad \hat{B}_{23}=\kappa_3\partial_{\theta_3}(\partial_0-\partial_1)h'_{23}.$$

Using (6.23), (6.25), (6.27), (6.31), (6.32), and (6.33), we may rewrite Eq. (6.18) as

$$\begin{pmatrix}\hat{A}_{00} & (\hat{A}_{00}+\hat{A}_{11})/2 & \hat{A}_{02} & \hat{A}_{03}\\ (\hat{A}_{00}+\hat{A}_{11})/2 & \hat{A}_{11} & \hat{A}_{02} & \hat{A}_{03}\\ \hat{A}_{02} & \hat{A}_{02} & 0 & 0\\ \hat{A}_{03} & \hat{A}_{03} & 0 & 0\end{pmatrix}+\begin{pmatrix}0 & 0 & 0 & 0\\ 0 & 0 & 0 & 0\\ 0 & 0 & \hat{B}_{22} & \hat{B}_{23}\\ 0 & 0 & \hat{B}_{23} & -\hat{B}_{22}\end{pmatrix}$$

$$=\langle b_1b_2\rangle\begin{pmatrix}J_{00} & (J_{00}+J_{11})/2 & J_{02} & J_{03}\\ (J_{00}+J_{11})/2 & J_{11} & J_{02} & J_{03}\\ J_{02} & J_{02} & J_{22} & J_{23}\\ J_{03} & J_{03} & J_{23} & -J_{22}\end{pmatrix}. \tag{6.34}$$

Equating the (2,3)-components in (6.34), we obtain the second solvability condition for (6.14),

$$\begin{pmatrix}\hat{B}_{22} & \hat{B}_{23}\\ \hat{B}_{23} & -\hat{B}_{22}\end{pmatrix}=\langle b_1b_2\rangle\begin{pmatrix}J_{22} & J_{23}\\ J_{23} & -J_{22}\end{pmatrix}. \tag{6.35}$$

The remaining components of (6.34) can be satisfied by a suitable choice of the higher-order metric perturbation $\overset{4}{h}$. The use of (6.25) and (6.33) in (6.35) implies that the metric components of the gravitational wave satisfy

$$\kappa_3 \partial_{\theta_3}(\partial_0 - \partial_1)\begin{pmatrix} h'_{22} & h'_{23} \\ h'_{23} & -h'_{22} \end{pmatrix} = \langle b_1 b_2 \rangle \begin{pmatrix} k_2^{(1)}k_2^{(2)} - k_3^{(1)}k_3^{(2)} & k_2^{(1)}k_3^{(2)} + k_3^{(1)}k_2^{(2)} \\ k_2^{(1)}k_3^{(2)} + k_3^{(1)}k_2^{(2)} & -(k_2^{(1)}k_2^{(2)} - k_3^{(1)}k_3^{(2)}) \end{pmatrix}. \quad (6.36)$$

It follows from (6.8) and (6.36) that the gravitational wave generated by the resonant interaction is plane polarized with a metric perturbation given by

$$(h'_{\alpha\beta}) = b_3(x,\theta_3)\begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & k_2^{(1)}k_2^{(2)} - k_3^{(1)}k_3^{(2)} & k_2^{(1)}k_3^{(2)} + k_3^{(1)}k_2^{(2)} \\ 0 & 0 & k_2^{(1)}k_3^{(2)} + k_3^{(1)}k_2^{(2)} & -(k_2^{(1)}k_2^{(2)} - k_3^{(1)}k_3^{(2)}) \end{pmatrix}, \quad (6.37)$$

where the gravitational wave amplitude b_3 satisfies the equation

$$\kappa_3 \partial_{\theta_3}(\partial_0 b_3 - \partial_1 b_3) = \langle b_1 b_2 \rangle. \quad (6.38)$$

When the spatial acoustic wave number vectors lie in the (x^1, x^2) plane, so that $k_3^{(1)} = k_3^{(2)} = 0$, the expression in (6.37) for the gravitational wave metric reduces to

$$(h'_{\alpha\beta}) = a_3(x,\theta_3)\begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & -1 \end{pmatrix}, \quad a_3 = k_2^{(1)}k_2^{(2)} b_3. \quad (6.39)$$

From (6.39), the metric perturbation $h_{\alpha\beta} = \epsilon^3 h'_{\alpha\beta}$ associated with the gravitational wave is given by (1.16), after we remove the expansion parameter ϵ by setting $\epsilon = 1$, and restore dimensioned variables. Moreover, using (6.39) in (6.38), and changing $x^1 \to -x^1$ to obtain equations for a gravitational wave that propagates in the x^1 direction, we get Eq. (1.17) stated in the Introduction, with $\omega^{(3)} = -\kappa_3$.

(Received 31 July 1998; accepted for publication 25 May 1999)

All nontwisting Petrov-type N solutions of vacuum Einstein field equations with cosmological constant Λ are summarized. They are shown to belong either to the nonexpanding Kundt class or to the expanding Robinson–Trautman class. Invariant subclasses of each class are defined and the corresponding metrics are given explicitly in suitable canonical coordinates. Relations between the subclasses and their geometrical properties are analyzed. In the subsequent paper these solutions are interpreted as exact gravitational waves propagating in de Sitter or anti-de Sitter spacetimes. © *1999 American Institute of Physics.* [S0022-2488(99)00509-5]

I. INTRODUCTION AND SUMMARY

Our purpose in this and the subsequent paper is to analyze all nontwisting type N solutions of Einstein's vacuum equations with Λ. There are several basic works on these solutions available in literature, in particular Refs. 1–3 (for pre-1980 works, see Ref. 4). None of them, however, discusses the physical interpretation of the solutions. Such an interpretation, based on the study of the deviation of geodesics, will be presented in the following paper. In this part we summarize, compare, classify, and generalize the mathematical results of Refs. 1–3.

We consider type N solutions in which the Debever–Penrose null vector field $\mathbf{k}$ is quadruple.[4] The vector field defines a congruence of null geodesics $x^\alpha(v)$ such that $dx^\alpha/dv=k^\alpha$, $k_\alpha k^\alpha=0$, $k_{\alpha;\beta}k^\beta=0$, v being an affine parameter. In general, a geodesic congruence is characterized by its expansion, $\Theta=\frac{1}{2}k^\alpha_{;\alpha}$, shear $|\sigma|=\sqrt{\frac{1}{2}k_{(\alpha;\beta)}k^{\alpha;\beta}-\Theta^2}$ and twist $\omega=\sqrt{\frac{1}{2}k_{[\alpha;\beta]}k^{\alpha;\beta}}$.[4] The Bianchi identities and the Kundt-Thompson theorem for type N solutions (see Ref. 5, and Theorem 7.5 in Ref. 4) imply $\sigma=0$ since $C^{\;;\delta}_{\alpha\beta\gamma\delta}=R^{\;;\delta}_{\alpha\beta\gamma\delta}=0$ for solutions of $R_{\alpha\beta}=\Lambda g_{\alpha\beta}$. In the following we assume $\omega=0$. Therefore, with (possibly) nonvanishing Λ we are left with two cases to consider: (i) the Kundt class of nonexpanding gravitational waves, $\Theta=0$ (cf. Ref. 6, Chap. 27 in Ref. 4); and (ii) the Robinson–Trautman class of expanding gravitational waves of type N, $\Theta\neq 0$ (cf. Ref. 7, Chap. 24 in Ref. 4). Hereafter we denote the Kundt class by $KN(\Lambda)$ and the Robinson–Trautman class by $RTN(\Lambda)$.

In Sec. II we analyze the class $KN(\Lambda)$ in detail. We do not present any new solution of this type, but we extend the results of Ref. 3 by giving the explicit forms of the transformations that leave the metrics of $KN(\Lambda)$ invariant. These enable us to give the *explicit* transformations to different canonical subclasses of $KN(\Lambda)$, which have not been given in the literature so far. We also introduce a convenient new notation for these subclasses and demonstrate how they are interconnected. In particular, we show that one of the subclasses is identical to the "Lobatchewski waves" studied by Siklos.[8] We also formulate the proposition (proven in the Appendix) that all vacuum solutions with Λ that are conformal to the "Kundt waves with $\Lambda=0$" belong to one specific subclass of $KN(\Lambda)$; we thus generalize the result of an analogous theorem for the *pp* waves.[8]

[b]Electronic mail: podolsky@mbox.troja.mff.cuni.cz

In Sec. III the Robinson–Trautman solutions[7] of type N with Λ are discussed. The transformation between two standard forms of the metric (those of Refs. 4 and 1) is presented, and then transformations preserving the metric form given in Ref. 1 are generalized and used to demonstrate how the nonradiative part of the structural function of these solutions can be transformed away.

II. THE KUNDT CLASS OF SOLUTIONS $KN(\Lambda)$

This class has been investigated in detail by Ozsváth, Robinson, and Rózga.[3] They have shown that in this case the vector $\mathbf{k}$ can be normalized such that $\frac{1}{2}\mathcal{L}_{\mathbf{k}}g_{\alpha\beta}=\frac{1}{2}(k_{\alpha;\beta}+k_{\beta;\alpha})=Lk_\alpha k_\beta$, where $\mathcal{L}_{\mathbf{k}}$ is the Lie derivative and L is a scalar. Denoting $L'=\mathcal{L}_{\mathbf{k}}L$, we find $\mathcal{L}_{\mathbf{k}}L'=0$ so that L' is invariant under the renormalization of $\mathbf{k}$. A suitable coordinate system $(v,\xi,\bar{\xi},u)$, where $\xi,\bar{\xi}$ are space-like coordinates, v is a parameter along the null geodesics, and u is a retarded time with u=const. being a wavefront, $\mathbf{k}\equiv\psi(u)\partial_v$, can be introduced[3] in which the $KN(\Lambda)$ metrics have the form

$$ds^2=2\frac{1}{p^2}d\xi\, d\bar{\xi}-2\frac{q^2}{p^2}du\, dv+F\, du^2, \tag{1}$$

where

$$p=1+\frac{\Lambda}{6}\xi\bar{\xi},\quad q=\left(1-\frac{\Lambda}{6}\xi\bar{\xi}\right)\alpha+\bar{\beta}\xi+\beta\bar{\xi},$$

$$F=\kappa\frac{q^2}{p^2}v^2-\frac{(q^2)_{,u}}{p^2}v-\frac{q}{p}H,\quad \kappa=\frac{\Lambda}{3}\alpha^2+2\beta\bar{\beta}.$$

Here $\alpha(u)$ and $\beta(u)$ are *arbitrary* real and complex functions of u, respectively. These functions play the role of two arbitrary ''parameters,'' i.e., we can denote the Kundt class by $KN(\Lambda)\equiv KN(\Lambda)[\alpha,\beta]$. The parameter κ is related to the invariant L' by

$$L'=\kappa\frac{p^2}{q^2}. \tag{2}$$

The function $H=H(\xi,\bar{\xi},u)$ entering F is restricted by Einstein's equations, $H_{,\xi\bar{\xi}}+(\Lambda/3p^2)H=0$. There exists a general solution to this equation,

$$H(\xi,\bar{\xi},u)=(f_{,\xi}+\bar{f}_{,\bar{\xi}})-\frac{\Lambda}{3p}(\bar{\xi}f+\xi\bar{f}), \tag{3}$$

where $f(\xi,u)$ is an arbitrary function of ξ and u, analytic in ξ. The space–time is conformally flat if and only if the structural function H is of the form

$$H=H_c=\frac{1}{p}\left[\left(1-\frac{\Lambda}{6}\xi\bar{\xi}\right)\mathcal{A}+\bar{\mathcal{B}}\xi+\mathcal{B}\bar{\xi}\right], \tag{4}$$

with $\mathcal{A}(u)$ and $\mathcal{B}(u)$ being arbitrary real and complex functions, respectively. Since H_c of this form corresponds to (3) for f quadratic in ξ we easily infer the following.

Lemma 1: The $KN(\Lambda)$ solutions (1), (3) with $f=f_c=c_0(u)+c_1(u)\xi+c_2(u)\xi^2$, where $c_i(u)$ are arbitrary complex functions of u, are isometric to Minkowski (if $\Lambda=0$), de Sitter $(\Lambda>0)$ and anti-de Sitter spacetime $(\Lambda<0)$.

It can be proven by straightforward but tedious calculations that the following lemma (which is not formulated in Ref. 3 but is a consequence of results therein) is true.

Lemma 2: The metric of the $KN(\Lambda)[\alpha,\beta]$ class preserves its form (1) under the transformations $(v,\xi,\bar{\xi},u)\rightarrow(w,\eta,\bar{\eta},t)$, given by

$$v=a(t)\left[w+\frac{\left(1-\frac{\Lambda}{6}\eta\bar{\eta}\right)\gamma+\delta\bar{\eta}+\bar{\delta}\eta}{\left(1-\frac{\Lambda}{6}\eta\bar{\eta}\right)\alpha'+\beta'\bar{\eta}+\bar{\beta}'\eta}\right]+\Delta(t),$$

$$\xi=\frac{\bar{B}(t)+A(t)\eta}{\bar{A}(t)-\frac{\Lambda}{6}B(t)\eta},\quad u=u(t), \tag{5}$$

where $A(t),B(t)$ are arbitrary complex and $a(t),u(t)$ are real functions of t, respectively.

In the new coordinates $(w,\eta,\bar{\eta},t)$ the resulting metric $KN(\Lambda)[\alpha',\beta']$ has

$$\alpha'=\frac{\sqrt{a\dot{u}}}{\Phi}\left[\left(A\bar{A}-\frac{\Lambda}{6}B\bar{B}\right)\alpha+\bar{A}B\beta+A\overline{B\beta}\right],$$

$$\beta'=\frac{\sqrt{a\dot{u}}}{\Phi}\left[-\frac{\Lambda}{3}\overline{AB}\alpha+\bar{A}^2\beta-\frac{\Lambda}{6}\bar{B}^2\bar{\beta}\right], \tag{6}$$

with $\Phi=A\bar{A}+(\Lambda/6)B\bar{B}$ and the dot denotes d/dt. The remaining real functions $\gamma(t),\Delta(t)$ and a complex function $\delta(t)$ in (5) must satisfy the equations

$$\alpha'\delta-\beta'\gamma=\frac{1}{\Phi}(\bar{A}\dot{\bar{B}}-\dot{\bar{A}}\bar{B})\equiv C,$$

$$\bar{\beta}'\delta-\beta'\bar{\delta}=\frac{1}{\Phi}\left(\dot{A}\bar{A}-A\dot{\bar{A}}+\frac{\Lambda}{6}\dot{B}\bar{B}-\frac{\Lambda}{6}B\dot{\bar{B}}\right)\equiv D, \tag{7}$$

$$\frac{\kappa'}{a}\Delta=\frac{1}{2}\left(\frac{\dot{a}}{a}-\frac{\ddot{u}}{\dot{u}}\right)-\left(\frac{\Lambda}{3}\alpha'\gamma+\bar{\beta}'\delta+\beta'\bar{\delta}\right).$$

The structural function $H'(\eta,\bar{\eta},t)$ then takes the form

$$p'H'=\left(1-\frac{\Lambda}{6}\eta\bar{\eta}\right)E+\bar{F}\eta+F\bar{\eta}+\frac{\dot{u}}{\Phi}\sqrt{\frac{\dot{u}}{a}}\left(A-\frac{\Lambda}{6}\overline{B\eta}\right)\left(\bar{A}-\frac{\Lambda}{6}B\eta\right)pH, \tag{8}$$

where

$$E(t)\equiv2\dot{\gamma}+\frac{2}{a}(\alpha'\Delta)^{\cdot}-\alpha'\kappa'\frac{\Delta^2}{a^2}-2\frac{\Delta}{a}\left[\frac{1}{2}\alpha'\left(\frac{\dot{a}}{a}+\frac{\ddot{u}}{\dot{u}}\right)+C\bar{\beta}'+\bar{C}\beta'\right]$$
$$-\alpha'\left(2\delta\bar{\delta}-\frac{\Lambda}{3}\gamma^2\right)+2\gamma(\beta'\bar{\delta}+\bar{\beta}'\delta),$$

$$F(t)\equiv 2\dot{\delta}+\frac{2}{a}(\beta'\Delta)^{\cdot}-\beta'\kappa'\frac{\Delta^2}{a^2}-2\frac{\Delta}{a}\left[\frac{1}{2}\beta'\left(\frac{\dot a}{a}+\frac{\ddot u}{\dot u}\right)-\frac{\Lambda}{3}C\alpha'-D\beta'\right]$$
$$-\frac{\Lambda}{3}\gamma(\beta'\gamma-2\alpha'\delta)+2\overline{\beta'}\delta^2.$$

The transformation (5) is also important in connection with Lemma 1. Comparing Eq. (4) with Eq. (8), we see that we can 'generate' $H=H_c$ from $H=0$ by a coordinate transformation. Therefore, the conformally flat part, H_c, of H generated by f_c cannot represent a radiative field. Only if the function f is at least cubic in ξ, the resulting spacetime is of type N and can be interpreted as radiative (see the subsequent paper).

Another important application of the coordinate freedom (5) was suggested in Ref. 3: it is possible to use the transformation to get 'canonical' subclasses of $KN(\Lambda)[\alpha,\beta]$ corresponding to special values of parameters α and β. Without loss of generality we can assume $\alpha\geqslant 0$. In addition, the transformation (5) of a special form,

$$\xi=\eta,\quad v=a(t)w,\quad u=\int a(t)dt, \tag{9}$$

for $a(t)\neq 0$ results in scaling $\alpha(u)=\alpha'(t)/|a(t)|$, $\beta(u)=\beta'(t)/|a(t)|$ so that *we can always assume either* $\alpha=1$ *or* $\alpha=0$. Since the parameter L' (2) is invariant, the sign of κ is also an invariant. We can thus base the invariant canonical classification of all $KN(\Lambda)$ solutions on the sign of κ and the sign of Λ. There are nine possible cases (κ and Λ can both be positive, zero or negative). However, subclasses $\kappa<0,\Lambda>0$ and $\kappa=0,\Lambda>0$ and $\kappa<0,\Lambda=0$ are forbidden since they violate the relation $\kappa=(\Lambda/3)\alpha^2+2\beta\bar{\beta}$. The remaining possibilities are six subclasses which we shall now discuss.

A. Subclass $\kappa=0,\Lambda=0$

The equation $\kappa=0$ implies $\beta=0$ so that $\alpha=1$. A canonical representative of this subclass can be denoted as $PP\equiv KN(\Lambda=0)[\alpha=1,\beta=0]$. We are now using the notation PP since the corresponding metric,

$$PP:\ ds^2=2\,d\xi\,d\bar{\xi}-2\,du\,dv-(g+\bar{g})du^2, \tag{10}$$

with arbitrary $g(\xi,u)=f_{,\xi}$ analytic in ξ, describes well-known *pp* waves investigated by many authors (for details and references see Sec. 21.5 in Ref. 4).

B. Subclass $\kappa>0,\Lambda=0$

Since $0<\kappa=2\beta\bar{\beta}$, we have $\beta\neq 0$. Then Eqs. (5) with $A=\sqrt{\beta}$, $B=-(\alpha/2\beta)+i(J/\beta))A$, $a=1/\beta\bar{\beta}$, $\gamma=(1/2)(\alpha/\sqrt{\beta\bar{\beta}})^{\cdot}+(2J/\alpha)(J/\sqrt{\beta\bar{\beta}})^{\cdot}$, $\delta=\dot{A}/A$, $\Delta=\frac{1}{2}\dot{a}$, $u=t$, where J is a real function satisfying $(J/\sqrt{\beta\bar{\beta}})^{\cdot}=(i/4)(\alpha/\sqrt{\beta\bar{\beta}})(\bar{\beta}/\beta)(\beta/\bar{\beta})^{\cdot}$, transform any solution of this subclass to $KN\equiv KN(\Lambda=0)[\alpha=0,\ \beta=1]$. The metric,

$$KN:\ ds^2=2\,d\xi\,d\bar{\xi}+2(\xi+\bar{\xi})^2\left[-dv+\left(v^2-\frac{g+\bar{g}}{\xi+\bar{\xi}}\right)du\right]du, \tag{11}$$

with arbitrary $g(\xi,u)=\frac{1}{2}f_{,\xi}$, describes solutions discovered by Kundt.[6] This is a *special* ''Kundt solution'' in the ''Kundt class'' of nonexpanding waves. For details see Ref. 4, Chap. 27; the transformation between $\tilde{v}$ used there and v above is $v=\tilde{v}/(\xi+\bar{\xi})^2$.

C. Subclass $\kappa>0,\Lambda>0$

If $\alpha=1$ we can use (5) with $A=\exp(-(i/2)\chi)$, $B=cA$, $a=(\Lambda/6+\beta\bar{\beta})^{-1}$, $\gamma=-[\dot{W}+\frac{1}{2}(\dot{V}\exp(-i\chi)+\dot{\bar{V}}\exp(i\chi))]/(1+(\Lambda/6)c\bar{c})$, $\delta=\dot{A}/A+(\Lambda/6)\dot{c}\bar{c}/(1+(\Lambda/6)c\bar{c})$, $\Delta=\frac{1}{4}\dot{a}-(\Lambda/12)\times(c\bar{c})^{\cdot}(1+(\Lambda/6)c\bar{c})^{-1}a$, $u=t$, where $c\equiv V+W\bar{A}/A$, $V\equiv(6/\Lambda)\bar{\beta}$, $W\equiv-(6/\Lambda)\sqrt{\Lambda/6+\beta\bar{\beta}}$, χ is a real function satisfying $\dot{\chi}=(i/2)(\dot{V}\exp(-i\chi)-\dot{\bar{V}}\exp(i\chi))/W$ to obtain $\alpha'=0$, $\beta'=1$. If $\alpha=0$ the scaling (9) makes $|\beta|=1$ and then we put $\xi=(6/\Lambda)\beta/\eta$, $v=w+\frac{1}{2}(\dot{\beta}\bar{\beta}\eta+\beta\dot{\bar{\beta}}\bar{\eta})/(\eta+\bar{\eta})$, $u=t$. In both cases the representative of this subclass is $KN(\Lambda)I\equiv KN(\Lambda)[\alpha=0,\beta=1]$. The metric reads as

$$KN(\Lambda)I{:}\,ds^2=2\frac{d\xi\,d\bar{\xi}}{\left(1+\frac{\Lambda}{6}\xi\bar{\xi}\right)^2}-2\left(\frac{\xi+\bar{\xi}}{1+\frac{\Lambda}{6}\xi\bar{\xi}}\right)^2 du\,dv+\left[2\left(\frac{\xi+\bar{\xi}}{1+\frac{\Lambda}{6}\xi\bar{\xi}}\right)^2 v^2-\frac{\xi+\bar{\xi}}{1+\frac{\Lambda}{6}\xi\bar{\xi}}H\right]du^2. \tag{12}$$

$KN(\Lambda)I$ indicates that this solution is a generalization of the KN waves to the case $\Lambda\neq0$, ''I'' means ''of the first kind.'' The $KN(\Lambda)I$ solutions were first discovered by García Díaz and Plebański,[1,9] transformation between their coordinates and those used here is $\xi=\sqrt{6/\Lambda}\tanh\sqrt{\Lambda/6}\tilde{\xi}$, $v=r/\sinh\sqrt{\Lambda/6}(\tilde{\xi}+\bar{\tilde{\xi}})$, $u=-\sqrt{\Lambda/6}t$. However, in Refs. 1 and 9 not all $KN(\Lambda\neq0)$ solutions were found since (invariantly different) Subclasses E and F mentioned below were omitted.

D. Subclass $\kappa>0,\Lambda<0$

The same transformation as in the previous case leads to the metric (12) which has thus the same form for $\Lambda<0$. The transformation to the coordinates used in Ref. 1 is $\xi=\sqrt{-6/\Lambda}\tan\sqrt{-\Lambda/6}\tilde{\xi}$, $v=r/\sin\sqrt{-\Lambda/6}(\tilde{\xi}+\bar{\tilde{\xi}})$, $u=-\sqrt{-\Lambda/6}t$.

E. Subclass $\kappa<0,\Lambda<0$

Now $\kappa<0$ implies $\alpha=1$. Using (5) with $A=\exp(i\phi)$, $B=cA$, $a=(1+(6/\Lambda)\beta\bar{\beta})^{-1}$, $\gamma=0$, $\delta=\bar{A}^2\dot{\bar{c}}/(1+(\Lambda/6)c\bar{c})$, $\Delta=(3/2\Lambda)\dot{a}$, $u=t$, where $c\equiv(1/\beta)(\sqrt{1+(6/\Lambda)\beta\bar{\beta}}-1)$, ϕ is a real function satisfying $\dot{\phi}=i(\Lambda/12)(\dot{c}\bar{c}-c\dot{\bar{c}})/(1+(\Lambda/6)c\bar{c})$, we find $\beta'=0$ and the canonical representative, denoted by $KN(\Lambda^-)II\equiv KN(\Lambda<0)[\alpha=1,\beta=0]$, is

$$KN(\Lambda^-)II{:}\; ds^2=2\frac{d\xi\,d\bar{\xi}}{\left(1+\frac{\Lambda}{6}\xi\bar{\xi}\right)^2}-2\left(\frac{1-\frac{\Lambda}{6}\xi\bar{\xi}}{1+\frac{\Lambda}{6}\xi\bar{\xi}}\right)^2 du\,dv+\left[\frac{\Lambda}{3}\left(\frac{1-\frac{\Lambda}{6}\xi\bar{\xi}}{1+\frac{\Lambda}{6}\xi\bar{\xi}}\right)^2 v^2-\frac{1-\frac{\Lambda}{6}\xi\bar{\xi}}{1+\frac{\Lambda}{6}\xi\bar{\xi}}H\right]du^2. \tag{13}$$

Here $KN(\Lambda^-)II$ means generalized Kundt waves ''of the second kind'' with $\Lambda<0$. This class was first discovered by Ozsváth *et al.*[3] Observe that with $\kappa>0$, $\Lambda>0$, $KN(\Lambda^+)II\equiv KN(\Lambda^+)I$, since transformation (5) where $A=1/\sqrt{2}$, $B=\sqrt{3/\Lambda}$, $a=1$, $\gamma=\delta=\Delta=0$, $u=(\Lambda/6)t$ identifies $KN(\Lambda^+)[\alpha=0,\beta=1]$ with $KN(\Lambda^+)[\alpha'=1,\beta'=0]$.

F. Subclass $\kappa=0,\Lambda<0$

The relation $\kappa=0$ implies $\alpha=1$. Thus, $|\beta|=\sqrt{-\Lambda/6}$ and the representative can be denoted by $KN(\Lambda^-)III\equiv KN(\Lambda<0)[\alpha=1,\beta=\sqrt{-\Lambda/6}e^{i\omega(u)}]$, $\omega(u)$ being an arbitrary real function of u. The metric takes the form of (1) with $q=(1+\sqrt{-\Lambda/6}\xi e^{-i\omega(u)})(1+\sqrt{-\Lambda/6}\bar{\xi}e^{i\omega(u)})$. This class was also first discovered in Ref. 3. One can distinguish *two subsubclasses* of $KN(\Lambda^-)III$ according to the value of L: 1. $L\neq 0$ (**k** is not a Killing vector). 2. $L=0$ (**k** is a Killing vector). In case 2, β=const and the transformation $\xi=\sqrt{\beta/\bar{\beta}}\eta$ leads to $KN(\Lambda^-)III_K\equiv KN(\Lambda<0)[\alpha=1,\beta=\sqrt{-\Lambda/6}]$, where the suffix ''$K$'' stands for ''Killing:''

$$KN(\Lambda^-)III_{\rm K}:\ ds^2=2\frac{d\xi\, d\bar{\xi}}{\left(1+\frac{\Lambda}{6}\xi\bar{\xi}\right)^2}-2\left(\frac{\left(1+\sqrt{-\frac{\Lambda}{6}}\xi\right)\left(1+\sqrt{-\frac{\Lambda}{6}}\bar{\xi}\right)}{1+\frac{\Lambda}{6}\xi\bar{\xi}}\right)^2 du\, dv$$
$$-\frac{\left(1+\sqrt{-\frac{\Lambda}{6}}\xi\right)\left(1+\sqrt{-\frac{\Lambda}{6}}\bar{\xi}\right)}{1+\frac{\Lambda}{6}\xi\bar{\xi}}H\, du^2. \tag{14}$$

This subsubclass can be shown to be identical with the ''Lobatchevski waves'' studied by Siklos:[8] indeed, the transformation $\xi=-\sqrt{-6/\Lambda}(x+\frac{1}{2}+iy)/(x-\frac{1}{2}+iy)$, $v=(12/\Lambda)r$, brings the metric (14) into the form

$$ds^2=-\frac{3}{\Lambda}\cdot\frac{1}{x^2}(dx^2+dy^2+2\,du\,dr+\tilde{H}\,du^2), \tag{15}$$

where $\tilde{H}\equiv-(\Lambda/6)xH$. This is the Siklos metric.[8] Recently we analyzed in detail the behavior of test particles in these solutions and interpreted them as waves in the anti-de Sitter spacetime.[10] Impulsive waves of this type were investigated in Ref. 11.

G. Relations of the subclasses

Using the above results we can summarize the invariant canonical classification of the $KN(\Lambda)$ class of solutions in the following diagram:

$$KN(\Lambda)\begin{cases}\Lambda=0\begin{cases}\kappa=0: PP,\\ \kappa>0: KN,\end{cases}\\[2ex] \Lambda\neq 0\begin{cases}\kappa>0: KN(\Lambda)I,\\ \kappa<0: KN(\Lambda^-)II,\\ \kappa=0: KN(\Lambda^-)III\rightarrow KN(\Lambda^-)III_{\rm K}.\end{cases}\end{cases}$$

There is an asymmetry with respect to the sign of Λ: there are *three* distinct classes of nonexpanding waves for $\Lambda<0$ whereas there is only *one* such class for $\Lambda>0$. The reason is in the condition $\kappa=(\Lambda/3)\alpha^2+2\beta\bar{\beta}$ which for $\Lambda>0$ excludes the cases $\kappa<0$ and $\kappa=0$. Intuitively, fewer nonexpanding waves ''fit'' into the de Sitter universe which admits closed spacelike sections than into the anti-de Sitter space.

There exist natural relations between the $\Lambda=0$ and $\Lambda\neq 0$ subclasses. The metrics (12), (13) and (14) do not diverge as $\Lambda\rightarrow 0$, we can set $\Lambda=0$ and thus find

$$KN(\Lambda=0)I=KN,\quad KN(\Lambda^{-}=0)II=PP,\quad KN(\Lambda^{-}=0)III=PP. \tag{16}$$

Thus, it is natural to consider the $KN(\Lambda)I$ class as a generalization of the Kundt solution KN, and the classes $KN(\Lambda^{-})II$ and $KN(\Lambda^{-})III$ as generalizations of PP waves. There exists *no* generalization of PP waves to the case of $\Lambda>0$.

From metrics (10) and (15), with $\xi=(1/\sqrt{2})(x+iy)$, and from (11) and (12) we find $ds^2_{KN(\Lambda^{-})III_{\mathrm{K}}}=-(6/\Lambda)(\xi+\bar{\xi})^{-2}ds^2_{PP}$, and $ds^2_{KN(\Lambda)I}=(1+(\Lambda/6)\xi\bar{\xi})^{-2}ds^2_{KN}$. Therefore, the class $KN(\Lambda^{-})III_{\mathrm{K}}$ is conformal to the PP-class, and the class $KN(\Lambda)I$ is conformal to the KN-class. In fact, the solutions $KN(\Lambda^{-})III_{\mathrm{K}}$ and $KN(\Lambda)I$ are the only nontrivial spacetimes conformal to PP and KN, respectively. The theorem proven by Siklos[8] states that the only vacuum solutions (other than PP solutions themselves) which are properly (with a nonconstant factor) conformal to nonflat PP metrics are $KN(\Lambda^{-})III_{\mathrm{K}}$ metrics. However, we see from (16) that PP metrics are a special case of metrics $KN(\Lambda^{-})III_{\mathrm{K}}$ for $\Lambda=0$, and Siklos' theorem may just be formulated as follows.

Proposition 1: The only vacuum solutions conformal to nonflat PP metrics are $KN(\Lambda^{-})III_{\mathrm{K}}$ metrics.

In addition, the following analogous proposition can be proven for the KN solutions.

Proposition 2: The only vacuum solutions conformal to KN metrics are $KN(\Lambda)I$ metrics.

The proof is contained in the Appendix.

The conformal, homothetic and isometric symmetries of the $KN(\Lambda)$ solutions have been systematically investigated by Salazar, Garcı́a and Plebański[2] and by Siklos.[8] It is only in the subclasses PP and $KN(\Lambda^{-})III_{\mathrm{K}}$ that the vector $\mathbf{k}=\partial_v$ is a Killing vector; $k_{\alpha;\beta}=0$ only in the PP subclass. Let us finally summarize the classification of all $KN(\Lambda)$ solutions and compare our notation with notations used in the literature:

Notation in this paper	Notations in literature
$KN(\Lambda)$	$R(\Lambda,\alpha,\beta)$[3]
PP	pp, R[4,3] for Refs.
KN	K[6,4]
$KN(\Lambda)I$	$K(\Lambda)$[1,3]
$KN(\Lambda^{-})II$	$R(\Lambda)$[3]
$KN(\Lambda^{-})III$	$(IV)_1$[3]
$KN(\Lambda^{-})III_K$	$(IV)_0$[8,3]

Impulsive waves in the $KN(\Lambda)$ spacetimes were recently studied in Ref. 12.

III. THE ROBINSON–TRAUTMAN CLASS OF SOLUTIONS $RTN(\Lambda,\epsilon)$

The Robinson–Trautman solutions[7] satisfying the vacuum equations with Λ can be written as (see Ref. 4)

$$ds^2=2\frac{r^2}{P^2}d\zeta\,d\bar{\zeta}-2\,du\,dr-\left[\Delta\ln P-2r(\ln P)_{,u}-\frac{2m}{r}-\frac{\Lambda}{3}r^2\right]du^2, \tag{17}$$

where ζ is a complex spatial coordinate, r is an affine parameter along the rays generated by the vector field $\mathbf{k}$, u is a retarded time, m is a function of u which in some cases can be interpreted as mass, and $\Delta\equiv 2P^2\partial^2/\partial\zeta\partial\bar{\zeta}$. The function $P\equiv P(\zeta,\bar{\zeta},u)$ satisfies the equation $\Delta\Delta(\ln P)+12m(\ln P)_{,u}-4m_{,u}=0$. Here we restrict attention to the solutions of type N and denote these as $RTN(\Lambda)$. In this case $m=0$ and $\Delta\ln P=K(u)$. By a transformation $u=g(\tilde{u})$, $r=\tilde{r}/\dot{g}$, where $\dot{g}=dg/d\tilde{u}$, we can set the Gaussian curvature $K(u)$ of the 2-surfaces $2P^{-2}\,d\zeta\,d\bar{\zeta}$ to be $K=2\epsilon$, where $\epsilon=+1,0,-1$ (since $\tilde{P}=\dot{g}P$ and $\tilde{K}=\dot{g}^2K$, the sign of K is invariant). Thus, the different subclasses can be denoted as $RTN(\Lambda,\epsilon)$. The corresponding metrics can be written as

$$ds^2=2\frac{r^2}{P^2}d\zeta\, d\bar{\zeta}-2\,du\,dr-2\left[\epsilon-r(\ln P)_{,u}-\frac{\Lambda}{6}r^2\right]du^2. \tag{18}$$

Since $\epsilon=+1,0,-1$ and $\Lambda>0$, $\Lambda=0$, $\Lambda<0$, there are 9 invariant subclasses.

Another coordinate for the $RTN(\Lambda,\epsilon)$ class, suitable for physical interpretation, has been given by García Díaz and Plebański.[1] Their metric is expressed in terms of a function $f(\xi,u)$ which is an arbitrary function of u, analytic in spatial coordinate ξ,

$$ds^2=2v^2\,d\xi\,d\bar{\xi}+2v\bar{\mathrm{A}}\,d\xi\,du+2v\mathrm{A}\,d\bar{\xi}\,du+2\psi\,du\,dv+2(\mathrm{A}\bar{\mathrm{A}}+\psi\mathrm{B})du^2, \tag{19}$$

where

$$\mathrm{A}=\epsilon\xi-vf,\quad \mathrm{B}=-\epsilon+\frac{v}{2}(f_{,\xi}+\bar{f}_{,\bar{\xi}})+\frac{\Lambda}{6}v^2\psi,\quad \psi=1+\epsilon\xi\bar{\xi}.$$

It can be shown that the transformation relating (18) with (19) has the form

$$\xi=F(\zeta,u)=\int f(\xi(\zeta,u),u)du,$$

$$v=\frac{r}{1+\epsilon F\bar{F}}, \tag{20}$$

$$u\to -u,\quad P=(1+\epsilon F\bar{F})(F_{,\zeta}\bar{F}_{,\bar{\zeta}})^{-1/2}.$$

If f does not depend on ξ, we put $\xi=F(\zeta,u)=\zeta+\int f(u)du$.

The nonvanishing Weyl tensor components are proportional to $f_{,\xi\xi\xi}$ so that the solutions are conformally flat if f is quadratic in ξ. Thus, we can formulate

Lemma 3: The $RTN(\Lambda,\epsilon)$ solutions (19) with $f=f_c=c_0(u)+c_1(u)\xi+c_2(u)\xi^2$, where $c_i(u)$ are arbitrary complex functions of u, are isometric to Minkowski (if $\Lambda=0$), de Sitter ($\Lambda>0$) and anti-de Sitter spacetime ($\Lambda<0$).

Transformations preserving the form of (19) were studied in Ref. 2. However, more general transformations [Eq. (2.4) in Ref. 2 follows from Eqs. (21), (24) if we put $\Delta=0$ and $\alpha\bar{\alpha}+\epsilon\beta\bar{\beta}=1$] are given in the following.

Lemma 4: The coordinate transformations $(v,\xi,\bar{\xi},u)\to(w,\eta,\bar{\eta},t)$, which maintain invariant the form of the $RTN(\Lambda,\epsilon)$ metric (19), are

$$\xi=\frac{\alpha\eta+\beta}{\gamma\eta+\delta},$$

$$v=\frac{(\gamma\eta+\delta)(\overline{\gamma\eta}+\bar{\delta})}{\sqrt{(\alpha\delta-\beta\gamma)(\overline{\alpha\delta}-\overline{\beta\gamma})}}w, \tag{21}$$

$$u=\int\frac{\sqrt{(\alpha\delta-\beta\gamma)(\overline{\alpha\delta}-\overline{\beta\gamma})}}{\delta\bar{\delta}+\epsilon\beta\bar{\beta}}dt,$$

where $\alpha(t),\beta(t),\gamma(t),\delta(t)$ are arbitrary complex functions of t which satisfy the conditions

$$\bar{\gamma}\delta=-\epsilon\bar{\alpha}\beta,\quad \gamma\bar{\gamma}+\epsilon\alpha\bar{\alpha}=\epsilon(\delta\bar{\delta}+\epsilon\beta\bar{\beta}). \tag{22}$$

In the coordinates $(w,\eta,\bar{\eta},t)$, the new structural function $f'(\eta,t)$ is related to f as follows:

$$f' = \frac{\overline{\alpha\delta} - \overline{\beta\gamma}}{\delta\bar{\delta} + \epsilon\beta\bar{\beta}} \frac{(\gamma\eta+\delta)^2}{\sqrt{(\alpha\delta-\beta\gamma)(\overline{\alpha\delta}-\overline{\beta\gamma})}} f - \frac{1}{\alpha\delta-\beta\gamma}[(\dot{\beta}\delta-\beta\dot{\delta}) + (\dot{\alpha}\delta - \alpha\dot{\delta} + \dot{\beta}\gamma - \beta\dot{\gamma})\eta + (\dot{\alpha}\gamma - \alpha\dot{\gamma})\eta^2]. \tag{23}$$

From this relation and Lemma 3 we see that the conformally flat part f_c is indeed unimportant since it can be generated from $f=0$ by the coordinate transformation (21).

If $\epsilon \neq 0$, Eq. (22) implies that $|\alpha| = |\delta|$, $|\beta| = |\gamma|$ so that $\sqrt{(\alpha\delta-\beta\gamma)(\overline{\alpha\delta}-\overline{\beta\gamma})} = \delta\bar{\delta} + \epsilon\beta\bar{\beta}$. Equations (21)–(23) then simplify to

$$\xi = \frac{\alpha\eta+\beta}{\gamma\eta+\delta}, \quad v = \frac{(\gamma\eta+\delta)(\overline{\gamma\eta}+\bar{\delta})}{\alpha\bar{\alpha}+\epsilon\beta\bar{\beta}} w, \quad u=t, \tag{24}$$

where $\alpha(t)$ and $\beta(t)$ are arbitrary complex functions of t and $\gamma(t) = \bar{\beta}(t)e^{i\Gamma(t)}$, $\delta(t) = \bar{\alpha}(t)e^{i\Delta(t)}$, with $\Gamma(t)$, $\Delta(t)$ being arbitrary real functions of t satisfying $\Delta - \Gamma = (1+\epsilon)(\pi/2)$. The structural function is given by $f' = \{(\gamma\eta+\delta)^2 f - [(\dot{\beta}\delta-\beta\dot{\delta}) + (\dot{\alpha}\delta-\alpha\dot{\delta}+\dot{\beta}\gamma-\beta\dot{\gamma})\eta + (\dot{\alpha}\gamma-\alpha\dot{\gamma})\eta^2]\}e^{-i\Delta}/(\alpha\bar{\alpha}+\epsilon\beta\bar{\beta})$.

For $\epsilon=0$, Eqs. (22) imply $\gamma=0$ so that the transformations (21) yield

$$\xi = A(t)\eta + B(t), \quad v = \frac{w}{\sqrt{A(t)\bar{A}(t)}}, \quad u = \int \sqrt{A(t)\bar{A}(t)}\,dt, \tag{25}$$

where $A(t)$ and $B(t)$ are arbitrary complex functions of t. The relation (23) between the structural functions is now $f' = \sqrt{\bar{A}/A} f - (\dot{B}/A + \dot{A}/A\,\eta)$, so that, in contrast to the case $\epsilon \neq 0$, the term quadratic in η vanishes. Hence, Eq. (25) does not enable us to transform away the complete conformally flat part f_c. [We tried but without success to generalize (25) so that quadratic terms could be removed.]

Symmetries of the $RTN(\Lambda,\epsilon)$ solutions have been investigated in Ref. 13 (see also Ref. 4, Table 33.2) and, more systematically, in Ref. 2. The solutions which are not conformally flat allow the existence of at most two Killing vectors.

Note added in proof. We noticed that transformation (20) has been given in D. B. Singleton, ‘‘Homothetic motions and vacuum Robinson–Trautman solutions,’’ Gen. Relativ. Gravit. **22**, 1239 (1990).

APPENDIX: PROOF OF PROPOSITION 2

For the conformally related metrics $g_{\alpha\beta}$ and $\hat{g}_{\alpha\beta}$, $\hat{g}_{\alpha\beta} = \Omega^{-2} g_{\alpha\beta}$, the trace-free Ricci tensors are related by[4]

$$S_{\alpha\beta} = R_{\alpha\beta} - \tfrac{1}{4} R g_{\alpha\beta},$$
$$\hat{S}_{\alpha\beta} = \hat{R}_{\alpha\beta} - \frac{1}{4}\hat{R}\hat{g}_{\alpha\beta} = S_{\alpha\beta} + \frac{2}{\Omega}\left(\Omega_{;\alpha\beta} - \frac{1}{4} g_{\alpha\beta}\Box\Omega\right), \tag{A1}$$

where $\Box\Omega = g^{\mu\nu}\Omega_{;\mu\nu}$, the covariant derivative is taken with respect to $g_{\alpha\beta}$ and the scalar curvature is

$$\hat{R}=\Omega^2 R+6\Omega\Box\Omega-12g^{\alpha\beta}\Omega_{;\alpha}\Omega_{;\beta}. \tag{A2}$$

Since $\hat{R}_{\alpha\beta}=\Lambda\hat{g}_{\alpha\beta}$, $\hat{R}=4\Lambda$, we have $\hat{S}_{\alpha\beta}=0$. In coordinates $(v,\xi,\bar{\xi},u)$,

$$g_{12}=1,\ g_{03}=-(\xi+\bar{\xi})^2,\ \ g_{33}=2(\xi+\bar{\xi})^2\left(v^2-\frac{1}{2}\frac{H}{\xi+\bar{\xi}}\right), \tag{A3}$$

$R_{33}=(\xi+\bar{\xi})H_{,\xi\bar{\xi}}$ and the other Ricci tensor components vanish. Therefore, $R=0$ and (A1) can be written as

$$\Omega_{,\alpha\beta}-\Gamma^{\gamma}_{\alpha\beta}\Omega_{,\gamma}-\tfrac{1}{4}g_{\alpha\beta}\Box\Omega+\tfrac{1}{2}\Omega R_{\alpha\beta}=0, \tag{A4}$$

which gives

$$\left(\frac{\Omega_{,v}}{\xi+\bar{\xi}}\right)_{,\xi}=0=\left(\frac{\Omega_{,v}}{\xi+\bar{\xi}}\right)_{,\bar{\xi}}, \tag{A5}$$

$$\Omega_{,vv}=0, \tag{A6}$$

$$\Omega_{,\xi\xi}=0=\Omega_{,\bar{\xi}\bar{\xi}}, \tag{A7}$$

$$\Omega_{,vu}+2v\Omega_{,v}-(\xi+\bar{\xi})(\Omega_{,\xi}+\Omega_{,\bar{\xi}})+\tfrac{1}{4}(\xi+\bar{\xi})^2\Box\Omega=0, \tag{A8}$$

$$\Omega_{,\xi\bar{\xi}}=\tfrac{1}{4}\Box\Omega, \tag{A9}$$

$$\Omega_{,\xi u}-\frac{\Omega_{,u}}{\xi+\bar{\xi}}-\frac{1}{2}\left(\frac{H}{\xi+\bar{\xi}}\right)_{,\xi}\Omega_{,v}=0=\Omega_{,\bar{\xi}u}-\frac{\Omega_{,u}}{\xi+\bar{\xi}}-\frac{1}{2}\left(\frac{H}{\xi+\bar{\xi}}\right)_{,\bar{\xi}}\Omega_{,v}, \tag{A10}$$

$$\begin{aligned}&\Omega_{,uu}-2v\Omega_{,u}-\left[2v\left(2v^2-\frac{H}{\xi+\bar{\xi}}\right)+\tfrac{1}{2}\left(\frac{H}{\xi+\bar{\xi}}\right)_{,u}\right]\Omega_{,v}\\&-\tfrac{1}{2}[(\xi+\bar{\xi})H]_{,\bar{\xi}}\Omega_{,\xi}-\tfrac{1}{2}[(\xi+\bar{\xi})H]_{,\xi}\Omega_{,\bar{\xi}}+2v^2(\xi+\bar{\xi})(\Omega_{,\xi}+\Omega_{,\bar{\xi}})\\&-\frac{1}{2}(\xi+\bar{\xi})^2\left(v^2-\frac{1}{2}\frac{H}{\xi+\bar{\xi}}\right)\Box\Omega+\frac{1}{2}(\xi+\bar{\xi})H_{,\xi\bar{\xi}}\Omega=0.\end{aligned} \tag{A11}$$

By using (A9), Eq. (A2) takes the form

$$\Omega\Omega_{,\xi\bar{\xi}}-\Omega_{,\xi}\Omega_{,\bar{\xi}}+\frac{\Omega_{,v}}{(\xi+\bar{\xi})^2}\left[\Omega_{,u}+\left(v^2-\frac{1}{2}\frac{H}{\xi+\bar{\xi}}\right)\Omega_{,v}\right]=\frac{\Lambda}{6}. \tag{A12}$$

Equations (A5) imply $\Omega_{,v}=A(u,v)(\xi+\bar{\xi})$. Equation (A6) gives $A_{,v}=0$ so that $\Omega=A(u)(\xi+\bar{\xi})v+B(\xi,\bar{\xi},u)$. By virtue of Eq. (A7) it must be of the form $\Omega=A(u)(\xi+\bar{\xi})v+C(u)\xi\bar{\xi}+D_1(u)\xi+D_2(u)\bar{\xi}+E(u)$. Equation (A8) combined with Eq. (A9) gives $dA/du=D_1+D_2$ so that $\Omega=A(u)(\xi+\bar{\xi})v+C(u)\xi\bar{\xi}+\tfrac{1}{2}dA/du(\xi+\bar{\xi})+D(u)(\xi-\bar{\xi})+E(u)$ with A,C,E being real functions of u, and $D(u)$ being pure imaginary. We distinguish the possibilities:

$$(1)\ \ A=0.$$

In this case Eq. (A10) implies $\Omega=C\xi\bar{\xi}+D(\xi-\bar{\xi})+E$, with C,E real constants, D a pure imaginary constant. Let (i) $C\neq 0$. Without loss of generality we can set $D=0$ by transformation ξ

$\rightarrow\xi'=\xi-D/C$. If $E\neq 0$, we can set $E=1$ by $\xi'=\xi/E$ which implies $\Omega=C\xi\bar{\xi}+1$. Equation (A12) gives $C=\Lambda/6$ so that $\Omega=1+(\Lambda/6)\xi\bar{\xi}$, and the metric $\hat{g}_{\alpha\beta}$ takes the canonical form (12) of the $KN(\Lambda)I$ metric. If $E=0$ we can make transformation $\xi'=1/(C\xi)$, after which $\hat{g}_{\alpha\beta}$ takes the canonical form (11) of the KN metric. Now (ii) $C=0$. If $D\neq 0$ we can set $E=0$ by $\xi'=\xi+E/(2D)$. The relation (A12) gives $\Omega=\sqrt{\Lambda/6}(\xi-\bar{\xi})$, with Λ necessarily being negative. It represents just another coordinate form of the $KN(\Lambda)I$ metric since by $\xi=(\xi'+i\sqrt{-6/\Lambda})/(i\xi'+\sqrt{-6/\Lambda})$ we get the $KN(\Lambda^-)I$ metric in the canonical form (12). If $D=0$ then $\Omega=E$ so that $\hat{g}_{\alpha\beta}$ is the KN metric by transformation $\xi'=|E|\xi$,

$$(2)\quad A\neq 0.$$

Without loss of generality we can assume $A=1$ by using transformation $w=A(u)v+\frac{1}{2}dA/du$, $t=\int A^{-1}(u)du$. Therefore, $\Omega=(\xi+\bar{\xi})v+C(u)\xi\bar{\xi}+D(u)(\xi-\bar{\xi})+E(u)$. In this case Eq. (A10) implies $H=2[(dC/du)\xi\bar{\xi}+\alpha(u)(\xi+\bar{\xi})+(dD/du)(\xi-\bar{\xi})+(dE/du)]$, with α being an arbitrary real function of u. Equation (A12) reduces to $\alpha(u)=C(u)E(u)+D(u)^2-\Lambda/6$, whereas Eq. (A11) is satisfied identically. The solution given by $\hat{g}_{\alpha\beta}$ is then conformally flat since $g_{\alpha\beta}$ for H of this form is conformally flat ($C_{\alpha\beta\gamma\delta}=0$). Therefore, the solution describes Minkowski, de Sitter or anti-de Sitter spacetime, according to the sign of Λ. It is interesting to notice that although $\hat{g}_{\alpha\beta}$ of this form describes a conformally flat vacuum solution, the KN solution to which it is conformal (given by $g_{\alpha\beta}$ with H of the same form) is conformally flat but *not* necessarily a vacuum solution. In general, it is a pure radiation solution, becoming a vacuum solution (Minkowski) only for $C=$const. In particular, if $\alpha=0$ and $D,E=$const, then the conformally flat KN pure radiation solution given by $H=2(dC/du)\,\xi\bar{\xi}$ is Wils' solution (3.10)[14] for $N=0$ [where $Q+\bar{Q}=dC/du$, $v\rightarrow v/(\xi+\bar{\xi})^2$]. The solution was used by Wils as an explicit counterexample of Theorem 32.17 in Ref. 4 according to which there are no other conformally flat pure radiation solutions besides the special PP wave of McLenaghan *et al.*[15]

We have thus shown that all vacuum solutions conformal to the KN class are (1) $KN(\Lambda)I$ solutions, (2) KN solutions themselves [$KN=KN(\Lambda=0)I$], (3) Minkowski, de Sitter and anti-de Sitter spacetimes (these are special cases of $KN(\Lambda)I$ given by $KN(\Lambda)I[H=H_c]$). Therefore, *all vacuum solutions conformal to the KN class belong to the $KN(\Lambda)I$ class*, which proves Proposition 2 in Sec. II.

Gravitational waves in vacuum spacetimes with cosmological constant. II. Deviation of geodesics and interpretation of nontwisting type *N* solutions

Jiří Bičák[a)] and Jiří Podolský[b)]
Department of Theoretical Physics, Faculty of Mathematics and Physics, Charles University, V Holešovičkách 2, 180 00 Prague 8, Czech Republic

(Received 31 July 1998; accepted for publication 25 May 1999)

In a suitably chosen essentially unique frame tied to a given observer in a general spacetime, the equation of geodesic deviation can be decomposed into a sum of terms describing specific effects: isotropic (background) motions associated with the cosmological constant, transverse motions corresponding to the effects of gravitational waves, longitudinal motions and Coulomb-type effects. Conditions under which the frame is parallelly transported along a geodesic are discussed. Suitable coordinates are introduced and an explicit coordinate form of the frame is determined for spacetimes admitting a nontwisting null congruence. Specific properties of all nontwisting type *N* vacuum solutions with cosmological constant Λ (nonexpanding Kundt class and expanding Robinson–Trautman class) are then analyzed. It is demonstrated that these spacetimes can be understood as exact transverse gravitational waves of two polarization modes ''+'' and ''×,'' shifted by $\pi/4$, which propagate ''on'' Minkowski, de Sitter or anti-de Sitter backgrounds. It is also shown that the solutions with $\Lambda>0$ may serve as exact demonstrations of the cosmic ''no-hair'' conjecture in radiative spacetimes with no symmetry. © *1999 American Institute of Physics.* [S0022-2488(99)00609-X]

I. INTRODUCTION AND SUMMARY

In the preceding paper[1] we classified nontwisting type *N* solutions of the vacuum Einstein's equations with a nonvanishing cosmological constant Λ and analyzed their geometrical properties. Here we wish to discuss their physical properties. We shall show that these solutions can be interpreted as gravitational waves propagating in spacetimes of constant curvature—in Minkowski, de Sitter or anti-de Sitter spaces. In our treatment we focus on the analysis of the equation of geodesic deviation.

We first discuss the equation of geodesic deviation in general spacetimes (Sec. II), briefly reviewing and extending[2–4] by using both a Newman–Penrose null tetrad and a physical frame of four independent vectors $\{\mathbf{e}_{(a)}\}$ tied to the geodesic with respect to which the relative motion is studied. In type *N* solutions only the Newman–Penrose scalar Ψ_4 is nonvanishing.

Starting from Sec. III we study nontwisting type *N* solutions with Λ. As shown in Ref. 1, they comprise the nonexpanding Kundt class $KN(\Lambda)$ and the expanding Robinson–Trautman class $RTN(\Lambda,\epsilon)$. By analyzing the geodesic deviation in these spacetimes we demonstrate that they can be interpreted as exact transverse gravitational waves with two polarization modes (shifted by $\pi/4$) propagating ''on'' Minkowski, de Sitter or anti-de Sitter space (depending on the values of Λ). In the Appendix we calculate the exact forms of wave amplitudes.

At the end of Sec. IV we discuss, for $\Lambda>0$, special timelike geodesics explicitly. We demonstrate that observers moving along these geodesics see waves decaying exponentially fast and the spacetimes to approach locally the de Sitter space—in agreement with the cosmic no-hair

[a)]Electronic mail: bicak@mbox.troja.mff.cuni.cz
[b)]Electronic mail: podolsky@mbox.troja.mff.cuni.cz

conjecture (see, e.g., Ref. 5, and references therein). As in our previous work,[6,7] this is an explicit demonstration of the conjecture under the presence of waves within exact theory.

II. THE RELATIVE MOTION OF FREE PARTICLES IN A GENERAL SPACETIME

It is natural to base the local characterization of radiative spacetimes on the equation of geodesic deviation,[2–4]

$$\frac{D^2Z^\mu}{d\tau^2}=-R^\mu_{\alpha\beta\gamma}u^\alpha Z^\beta u^\gamma, \tag{1}$$

where $\mathbf{u}=d\mathbf{x}/d\tau$, $\mathbf{u}\cdot\mathbf{u}=-1$ is the four-velocity of a free test particle (observer), τ is the proper time and $\mathbf{Z}(\tau)$ is the displacement vector. In order to obtain invariant results one sets up a frame $\{\mathbf{e}_{(a)}\}$ along the geodesic. The frame components $Z^{(a)}(\tau)$, $\mathbf{Z}=Z^{(a)}\mathbf{e}_{(a)}$, are invariant quantities. Choosing $\mathbf{e}_{(0)}=\mathbf{u}$ and perpendicular spacelike unit vectors $\{\mathbf{e}_{(1)},\mathbf{e}_{(2)},\mathbf{e}_{(3)}\}$ in the local hypersurface orthogonal to $\mathbf{u}$, we have $\mathbf{e}_{(a)}\cdot\mathbf{e}_{(b)}\equiv g_{\alpha\beta}e^\alpha_{(a)}e^\beta_{(b)}=\eta_{(a)(b)}=\mathrm{diag}(-1,1,1,1)$. The dual basis is $\mathbf{e}^{(0)}=-\mathbf{u}$ and $\mathbf{e}^{(i)}=\mathbf{e}_{(i)}$, $i=1,2,3$. By projecting (1) onto the frame we get

$$\ddot{Z}^{(i)}=-R^{(i)}_{(0)(j)(0)}Z^{(j)}, \tag{2}$$

where $Z^{(j)}=\mathbf{e}^{(j)}\cdot\mathbf{Z}=e^{(j)}_\mu Z^\mu$ determine directly the distance between close test particles,

$$\ddot{Z}^{(i)}\equiv\mathbf{e}^{(i)}\cdot\frac{D^2\mathbf{Z}}{d\tau^2}=e^{(i)}_\mu\frac{D^2Z^\mu}{d\tau^2}, \tag{3}$$

are physical relative accelerations, and $R_{(i)(0)(j)(0)}=e^\alpha_{(i)}u^\beta e^\gamma_{(j)}u^\delta R_{\alpha\beta\gamma\delta}$. Equation (1) also implies $d^2Z^{(0)}/d\tau^2=-u_\mu D^2Z^\mu/d\tau^2=R_{\mu\alpha\beta\gamma}u^\mu u^\alpha Z^\beta u^\gamma=0$ so that $Z^{(0)}=a_0\tau+b_0$, a_0,b_0 are constants. Setting $Z^{(0)}=0$, all test particles are "synchronized" by τ (they always stay in the same local hypersurface). From the definition of the Weyl tensor we get $R_{(i)(0)(j)(0)}=C_{(i)(0)(j)(0)}+\frac{1}{2}(\delta_{ij}R_{(0)(0)}-R_{(i)(j)})+\frac{1}{6}R\delta_{ij}$. Using Einstein's equations,

$$R_{(i)(0)(j)(0)}=C_{(i)(0)(j)(0)}-\frac{\Lambda}{3}\delta_{ij}-\frac{\kappa}{2}\left[T_{(i)(j)}-\delta_{ij}\left(T_{(0)(0)}+\frac{2}{3}T\right)\right], \tag{4}$$

$T=T^{(a)}_{(a)}$. Following Ref. 8 we introduce the null complex tetrad $\{\mathbf{e}_{\hat{a}}\}=\{\mathbf{e}_{\hat{1}},\mathbf{e}_{\hat{2}},\mathbf{e}_{\hat{3}},\mathbf{e}_{\hat{4}}\}=\{\mathbf{m},\bar{\mathbf{m}},\mathbf{l},\mathbf{k}\}$,

$$\mathbf{m}=\frac{1}{\sqrt{2}}(\mathbf{e}_{(1)}+i\mathbf{e}_{(2)}),\quad \bar{\mathbf{m}}=\frac{1}{\sqrt{2}}(\mathbf{e}_{(1)}-i\mathbf{e}_{(2)}),$$
$$\mathbf{l}=\frac{1}{\sqrt{2}}(\mathbf{u}-\mathbf{e}_{(3)}),\quad \mathbf{k}=\frac{1}{\sqrt{2}}(\mathbf{u}+\mathbf{e}_{(3)}). \tag{5}$$

Null tetrad components of the Weyl tensor are (see, e.g., Refs. 8 and 9)

$$\Psi_0=C_{\alpha\beta\gamma\delta}k^\alpha m^\beta k^\gamma m^\delta,\quad \Psi_1=C_{\alpha\beta\gamma\delta}k^\alpha l^\beta k^\gamma m^\delta,$$
$$\Psi_2=\tfrac{1}{2}C_{\alpha\beta\gamma\delta}k^\alpha l^\beta(k^\gamma l^\delta-m^\gamma\bar{m}^\delta), \tag{6}$$
$$\Psi_3=C_{\alpha\beta\gamma\delta}l^\alpha k^\beta l^\gamma\bar{m}^\delta,\quad \Psi_4=C_{\alpha\beta\gamma\delta}l^\alpha\bar{m}^\beta l^\gamma\bar{m}^\delta.$$

Regarding expressions (6) and inverting relations (5) we obtain

$$C_{(1)(0)(1)(0)}=\tfrac{1}{2}\mathcal{R}e\Psi_0+\tfrac{1}{2}\mathcal{R}e\Psi_4-\mathcal{R}e\Psi_2,\quad C_{(2)(0)(2)(0)}=-\tfrac{1}{2}\mathcal{R}e\Psi_0-\tfrac{1}{2}\mathcal{R}e\Psi_4-\mathcal{R}e\Psi_2,$$
$$C_{(1)(0)(2)(0)}=\tfrac{1}{2}\mathcal{I}m\Psi_0-\tfrac{1}{2}\mathcal{I}m\Psi_4,\quad C_{(3)(0)(3)(0)}=2\mathcal{R}e\Psi_2, \tag{7}$$
$$C_{(1)(0)(3)(0)}=-\mathcal{R}e\Psi_1+\mathcal{R}e\Psi_3,\quad C_{(2)(0)(3)(0)}=-\mathcal{I}m\Psi_1-\mathcal{I}m\Psi_3.$$

Substituting Eqs. (4) and (7) into Eq. (2) we arrive at

$$\ddot{Z}^{(1)}=\frac{\Lambda}{3}Z^{(1)}-\frac{\kappa}{2}\left(T_{(0)(0)}+\frac{2}{3}T\right)Z^{(1)}+\frac{\kappa}{2}T_{(1)(j)}Z^{(j)}+\mathcal{G}_1,$$
$$\ddot{Z}^{(2)}=\frac{\Lambda}{3}Z^{(2)}-\frac{\kappa}{2}\left(T_{(0)(0)}+\frac{2}{3}T\right)Z^{(2)}+\frac{\kappa}{2}T_{(2)(j)}Z^{(j)}+\mathcal{G}_2, \tag{8}$$
$$\ddot{Z}^{(3)}=\frac{\Lambda}{3}Z^{(3)}-\frac{\kappa}{2}\left(T_{(0)(0)}+\frac{2}{3}T\right)Z^{(3)}+\frac{\kappa}{2}T_{(3)(j)}Z^{(j)}+\mathcal{G}_3,$$

where

$$\mathcal{G}_1\equiv+\mathcal{C}Z^{(1)}-(\mathcal{L}_1-\mathcal{M}_1)Z^{(3)}-(\mathcal{A}_++\mathcal{B}_+)Z^{(1)}+(\mathcal{A}_\times-\mathcal{B}_\times)Z^{(2)},$$
$$\mathcal{G}_2\equiv+\mathcal{C}Z^{(2)}+(\mathcal{L}_2+\mathcal{M}_2)Z^{(3)}+(\mathcal{A}_++\mathcal{B}_+)Z^{(2)}+(\mathcal{A}_\times-\mathcal{B}_\times)Z^{(1)},$$
$$\mathcal{G}_3\equiv-2\mathcal{C}Z^{(3)}-(\mathcal{L}_1-\mathcal{M}_1)Z^{(1)}+(\mathcal{L}_2+\mathcal{M}_2)Z^{(2)},$$

and

$$\mathcal{C}=\mathcal{R}e\Psi_2,\quad \mathcal{L}_1=\mathcal{R}e\Psi_3,\quad \mathcal{L}_2=\mathcal{I}m\Psi_3,\quad \mathcal{M}_1=\mathcal{R}e\Psi_1,\quad \mathcal{M}_2=\mathcal{I}m\Psi_1,$$
$$\mathcal{A}_+=\tfrac{1}{2}\mathcal{R}e\Psi_4,\quad \mathcal{A}_\times=\tfrac{1}{2}\mathcal{I}m\Psi_4,\quad \mathcal{B}_+=\tfrac{1}{2}\mathcal{R}e\Psi_0,\quad \mathcal{B}_\times=\tfrac{1}{2}\mathcal{I}m\Psi_0. \tag{9}$$

Equations (8) are well suited for physical interpretation. The relative motions depend on 1. the cosmological constant Λ responsible for overall background isotropic motions; 2. the energy–momentum tensor $T_{(a)(b)}$ terms describing interaction with matter-content; 3. the terms depending on the local free gravitational field, and consisting of Coulomb, longitudinal and transverse (outgoing/ingoing) components with amplitudes given by Ψ_A's. In the following we put $T_{(a)(b)}=0$. Individual terms in Eq. (8) can be interpreted as follows.

Λ-term: Assuming $T_{(a)(b)}=0=\Psi_A$, Eq. (8) reduces to

$$\ddot{Z}^{(i)}=\frac{\Lambda}{3}Z^{(i)}. \tag{10}$$

Considering a sphere of test particles each having a position vector $\mathbf{Z}$, Eq. (10) implies that the acceleration of each particle is in the direction $\mathbf{Z}$ and has the same magnitude. Assume the frame $\{\mathbf{e}_{(i)}\}$ to be parallelly transported so that $\ddot{Z}^{(i)}=D^2(\mathbf{e}^{(i)}\cdot\mathbf{Z})/d\tau^2=d^2Z^{(i)}/d\tau^2$. Equations (10) have solutions

$$Z^{(i)}(\tau)=A_i\tau+B_i,\quad \text{for }\Lambda=0,$$
$$Z^{(i)}(\tau)=A_i\exp(\sqrt{\Lambda/3}\,\tau)+B_i\exp(-\sqrt{\Lambda/3}\,\tau),\quad \text{for }\Lambda>0, \tag{11}$$
$$Z^{(i)}(\tau)=A_i\cos(\sqrt{-\Lambda/3}\tau)+B_i\sin(\sqrt{-\Lambda/3}\tau),\quad \text{for }\Lambda<0,$$

where A_i, B_i are constants. As expected, conformally flat ($\Psi_A=0$) vacuum backgrounds (Minkowski, de Sitter or anti-de Sitter) are homogeneous and isotropic, so that the relative motion of test particles is isotropic.

Ψ_4-term: Assuming $\Lambda=0=T_{(a)(b)}$ and $\Psi_0=\Psi_1=\Psi_2=\Psi_3=0$, Eq. (8) reduces to

$$\ddot{Z}^{(1)}=-\mathcal{A}_+Z^{(1)}+\mathcal{A}_\times Z^{(2)},\quad \ddot{Z}^{(2)}=\mathcal{A}_+Z^{(2)}+\mathcal{A}_\times Z^{(1)},\quad \ddot{Z}^{(3)}=0, \tag{12}$$

which describe the influence of ''+'' and ''×'' polarization modes of a transverse gravitational wave with amplitudes $\mathcal{A}_+$ and $\mathcal{A}_\times$. If particles, initially at rest, lie in the $(\mathbf{e}_{(1)},\mathbf{e}_{(2)})$ plane, there is no motion in the longitudinal direction of $\mathbf{e}_{(3)}$. The ring of particles is deformed into an ellipse, the axes of different polarizations are shifted once with respect to the other by $\pi/4$ (such behavior is typical for linearized gravitational waves — cf., e.g., Ref. 10). Making a rotation in the transverse plane by an angle ϑ,

$$\mathbf{e}'_{(1)}=\cos\vartheta\,\mathbf{e}_{(1)}+\sin\vartheta\,\mathbf{e}_{(2)},\quad \mathbf{e}'_{(2)}=-\sin\vartheta\,\mathbf{e}_{(1)}+\cos\vartheta\,\mathbf{e}_{(2)} \tag{13}$$

— which corresponds to $\mathbf{m}'=\mathbf{e}^{-i\vartheta}\mathbf{m}$ — and using Eqs. (6) and (9), we find

$$\mathcal{A}'_+(\tau)=\cos 2\vartheta\mathcal{A}_+-\sin2\vartheta\mathcal{A}_\times,\quad \mathcal{A}'_\times(\tau)=\sin 2\vartheta\mathcal{A}_++\cos 2\vartheta\mathcal{A}_\times. \tag{14}$$

Taking $\vartheta=\vartheta_+(\tau)=-\frac{1}{2}\text{Arg}\,\Psi_4$, then $\mathcal{A}'_+=\frac{1}{2}|\Psi_4|$, $\mathcal{A}'_\times=0$—the wave is purely ''+'' polarized for an observer using $\mathbf{m}_+=e^{-i\vartheta_+}\mathbf{m}$; if $\vartheta=\vartheta_\times(\tau)=\vartheta_++\pi/4$, then $\mathcal{A}'_+=0$, $\mathcal{A}'_\times=\frac{1}{2}|\Psi_4|$—the wave is purely ''×'' polarized for an observer using $\mathbf{m}_\times=e^{-i\vartheta_\times}\mathbf{m}$. The amplitude $\mathcal{A}=\frac{1}{2}|\Psi_4|$ is invariant under the rotation. A general observer sees a superposition of the two polarization modes shifted by $\pi/4$.

One can similarly show[4,8] that Ψ_3 and Ψ_2 terms describe longitudinal modes and Coulomb-type effects; Ψ_1 and Ψ_0 terms are equivalent to Ψ_3 and Ψ_4 terms (if $\mathbf{k}\leftrightarrow\mathbf{l}$).

For given principal null vector $\mathbf{k}$ and observer's $\mathbf{u}$ we have chosen the frame vector $\mathbf{e}_{(3)}$ according to Eq. (5), which implies $k_{(1)}=0=k_{(2)}$, $k_{(3)}\neq0$, and makes the physical interpretation based on Eq. (8) simpler. This leads to essentially unique $\mathbf{k}$ and $\mathbf{l}$. More precisely, we easily show the following.

Proposition 1: Let $\mathbf{u}$ be the four-velocity ($\mathbf{u}\cdot\mathbf{u}=-1$) and $\mathbf{k}$ be the null vector. Then there exists a unit spacelike vector $\mathbf{e}_{(3)}$ which is the projection of the null direction given by $\mathbf{k}$ into the hypersurface orthogonal to $\mathbf{u}$. Such $\mathbf{e}_{(3)}$ is unique (up to reflections $\mathbf{e}_{(3)}\to-\mathbf{e}_{(3)}$) and is given by $\mathbf{e}_{(3)}=-\mathbf{u}+\sqrt{2}\mathbf{k}$, where $\mathbf{k}$ satisfies $\mathbf{k}\cdot\mathbf{u}=-1/\sqrt{2}$. Another null vector $\mathbf{l}$ in the plane $(\mathbf{u},\mathbf{e}_{(3)})$ such that $\mathbf{l}\cdot\mathbf{k}=-1$ is then given by $\mathbf{l}\equiv\sqrt{2}\mathbf{u}-\mathbf{k}$. The only remaining freedoms are rotations in the plane $(\mathbf{e}_{(1)},\mathbf{e}_{(2)})$ perpendicular to $\mathbf{e}_{(3)}$.

In what follows the orthonormal tetrad and the corresponding null frame (5) determined according to Proposition 1 will always be assumed.

Notice that Eqs. (8) represent possible motions seen by an observer with a given $\mathbf{u}$. By making the Lorentz boosts to other observers with $\mathbf{u}'$, Ψ_A change (see, e.g., Ref. 8). Thus, the ''strength of gravitational field'' is strongly observer dependent [cf. Refs. 2, 11, 12 and point 5 in the discussion following Eq. (34)].

III. THE CHOICE OF COORDINATES AND PARALLELLY PROPAGATED FRAMES

We shall now express our frames in coordinates suitable for spacetimes admitting a *nontwisting* null congruence and give the conditions for the frames to be parallelly transported. The field $\mathbf{k}$ is orthogonal to null hypersurfaces, say u=const., so that $k^\mu=g^{\mu\nu}u_{,\nu}$. It is convenient (cf. Refs. 9, 13) to choose as coordinates $u=x^3$, parameter $v=x^0$ along the null geodesics generated by k^μ, and two complex spacelike coordinates $\xi=x^1$ and $\bar{\xi}=x^2$ that label the geodesics on each surface u=const. The metric then takes the form

$$g_{\mu\nu}=\begin{pmatrix} 0 & 0 & 0 & g_{03} \\ 0 & g_{11} & g_{12} & g_{13} \\ 0 & g_{12} & g_{22} & g_{23} \\ g_{03} & g_{13} & g_{23} & g_{33} \end{pmatrix}, \tag{15}$$

where $g_{22}=\overline{g_{11}}$, $g_{23}=\overline{g_{13}}$ since $x^2=\overline{x^1}$; all other components are real, and

$$g_{12}>0,\ \ D=g_{12}^2-g_{11}g_{22}>0, \tag{16}$$

since the subspace $(\xi,\overline{\xi})$ is spacelike. The vector $\mathbf{k}$ is simply

$$k^\mu=(k^0,0,0,0), \tag{17}$$

and the four-velocity $\mathbf{u}$ of a particle moving along a geodesic $x^\mu(\tau)$, is given by $u^\mu=(\dot{v},\dot{\xi},\dot{\overline{\xi}},\dot{u})$, where the overdot is $d/d\tau$ and $\dot{u}\neq 0$ (otherwise the geodesic would not be timelike).

Proposition 2: In coordinates $(v,\xi,\overline{\xi},u)$ the interpretation null tetrad introduced in Proposition 1 has the form

$$\begin{aligned} m^\mu&=\Bigg(\frac{1}{g_{03}\dot{u}}[(g_{12}\dot{\xi}+g_{22}\dot{\overline{\xi}}+g_{23}\dot{u})g_+-(g_{11}\dot{\xi}+g_{12}\dot{\overline{\xi}}+g_{13}\dot{u})g_-\exp(-i\operatorname{Arg}g_{11})],\\ &\qquad g_-\exp(-i\operatorname{Arg}g_{11}),-g_+,0\Bigg),\\ \overline{m}^\mu&=\Bigg(\frac{1}{g_{03}\dot{u}}[(g_{11}\dot{\xi}+g_{12}\dot{\overline{\xi}}+g_{13}\dot{u})g_+-(g_{12}\dot{\xi}+g_{22}\dot{\overline{\xi}}+g_{23}\dot{u})g_-\exp(i\operatorname{Arg}g_{11})],\\ &\qquad -g_+,g_-\exp(i\operatorname{Arg}g_{11}),0\Bigg),\\ l^\mu&=\left(\sqrt{2}\dot{v}+\frac{1}{\sqrt{2}}\frac{1}{g_{03}\dot{u}},\sqrt{2}\dot{\xi},\sqrt{2}\dot{\overline{\xi}},\sqrt{2}\dot{u}\right),\\ k^\mu&=\left(-\frac{1}{\sqrt{2}}\frac{1}{g_{03}\dot{u}},0,0,0\right), \end{aligned} \tag{18}$$

where $g_\pm=\sqrt{(g_{12}\pm\sqrt{D})/(2D)}$. The tetrad is unique up to trivial reflections and rotations $m^\mu\to m^\mu e^{i\vartheta}$. The corresponding orthonormal frame obtained from Eqs. (18) using Eq. (5) is

$$\begin{aligned} e_{(0)}^\mu&=u^\mu=(\dot{v},\dot{\xi},\dot{\overline{\xi}},\dot{u}),\\ e_{(1)}^\mu&=\frac{1}{\sqrt{2}}\left(\frac{2}{g_{03}\dot{u}}\mathcal{R}e\{(g_{12}\dot{\xi}+g_{22}\dot{\overline{\xi}}+g_{23}\dot{u})G_-\},-\overline{G}_-,-G_-,0\right),\\ e_{(2)}^\mu&=\frac{1}{\sqrt{2}}\left(\frac{2}{g_{03}\dot{u}}\mathcal{I}m\{(g_{12}\dot{\xi}+g_{22}\dot{\overline{\xi}}+g_{23}\dot{u})G_+\},-i\overline{G}_+,iG_+,0\right),\\ e_{(3)}^\mu&=-\left(\dot{v}+\frac{1}{g_{03}\dot{u}},\dot{\xi},\dot{\overline{\xi}},\dot{u}\right), \end{aligned} \tag{19}$$

where $G_{\pm}=g_{+}\pm g_{-}\exp(i\mathrm{Arg}g_{11})$. The expressions (18) and (19) simplify considerably if $g_{11}=0$ since in this case $g_{-}=0$ and $g_{+}=1/\sqrt{g_{12}}=G_{+}=G_{-}$.

Proof: The last equation in (18) follows from Eq. (17) and $\mathbf{k}\cdot\mathbf{u}=-1/\sqrt{2}$, the equation for l^{μ} follows from $\mathbf{l}=\sqrt{2}\mathbf{u}-\mathbf{k}$. Vectors $\mathbf{m}$ and $\overline{\mathbf{m}}$ can then be determined from $\mathbf{e}_{\hat{a}}\cdot\mathbf{e}_{\hat{b}}=g_{\mu\nu}e^{\mu}_{\hat{a}}e^{\nu}_{\hat{b}}=g_{\hat{a}\hat{b}}$. The conditions $\mathbf{m}\cdot\mathbf{k}=g_{\hat{1}\hat{4}}=0=g_{\hat{2}\hat{4}}=\overline{\mathbf{m}}\cdot\mathbf{k}$ imply $m^3=0=\overline{m^3}$, $\mathbf{m}\cdot\mathbf{l}=g_{\hat{1}\hat{3}}=0$ implies $m^0=-(l_1m^1+l_2m^2)/l_0$. In given coordinates we have $\overline{m^1}=\overline{m^2}$ and $\overline{m^2}=\overline{m^1}$. Denoting $X=m^1$ and $Y=m^2$ we get $m^{\mu}=(-(l_1X+l_2Y)/l_0,X,Y,0)$ and $\overline{m}^{\mu}=(-(l_1\overline{Y}+l_2\overline{X})/l_0,\overline{Y},\overline{X},0)$. Functions *X, Y* can be determined as solutions of equations $\mathbf{m}\cdot\mathbf{m}=g_{\hat{1}\hat{1}}=0=g_{\hat{2}\hat{2}}=\overline{\mathbf{m}}\cdot\overline{\mathbf{m}}$ and $\mathbf{m}\cdot\overline{\mathbf{m}}=g_{\hat{1}\hat{2}}=1$,

$$g_{11}X^2+2g_{12}XY+g_{22}Y^2=0, \tag{20}$$

$$g_{11}X\overline{Y}+g_{12}(X\overline{X}+Y\overline{Y})+g_{22}\overline{X}Y=1. \tag{21}$$

(i) Assume $g_{11}\neq 0$. Then $X\neq 0$, and introducing a complex function C such that $Y=CX$, Eq. (20) implies $C=(-g_{12}\pm\sqrt{D})/g_{22}$, and Eq. (21) gives $X\overline{X}=|X|^2=(g_{12}\pm\sqrt{D})/(2D)$. Since $X=|X|e^{i\varphi}$, φ being a real function, we have $m^1=\sqrt{(g_{12}\pm\sqrt{D})/(2D)}\exp(i(\vartheta-\mathrm{Arg}g_{11}))$, $m^2=-\sqrt{(g_{12}\mp\sqrt{D})/(2D)}\exp(i\vartheta)$, where $\vartheta=\varphi+\mathrm{Arg}g_{11}$. The change from the upper to lower signs accompanied by $\vartheta\to-\vartheta+\pi+\mathrm{Arg}g_{11}$ results just in $\mathbf{m}\leftrightarrow\overline{\mathbf{m}}$, corresponding to a reflection $\mathbf{e}_{(2)}\leftrightarrow-\mathbf{e}_{(2)}$. By performing rotation $m^{\mu}\to m'^{\mu}=e^{-i\vartheta}m^{\mu}$ we can write the representatives of $\mathbf{m}$ and $\overline{\mathbf{m}}$ given by $\vartheta=0$ so that we arrive at Eq. (18).

(ii) If $g_{11}=0$, we simply find $m^1=0$ and $m^2=-1/\sqrt{g_{12}}$. Hence, the null tetrad has the form (18), and this implies the orthonormal frame (19).

In general, the frames $\{\mathbf{e}_a\}$ and $\{\mathbf{e}_{\hat{a}}\}$, related by Eq. (5), are not parallelly transported along the geodesic with tangent $\mathbf{u}=\mathbf{e}_{(0)}$. However, they are if $D\mathbf{k}/d\tau=0=D\mathbf{m}/d\tau$. Starting with an arbitrary $\mathbf{m}$, the second condition can always be satisfied by choosing $\mathbf{m}_{\parallel}=e^{i\vartheta_{\parallel}}\mathbf{m}$, where $\vartheta_{\parallel}=i\int_0^{\tau}\overline{\mathbf{m}}\cdot(D\mathbf{m}/d\tau)\,d\tau+\vartheta_0$, $\vartheta_0=\mathrm{const}$. We thus arrive at the following.

Proposition 3: Consider a geodesic $x^{\mu}(\tau)=(v,\xi,\overline{\xi},u)$ in spacetime with metric (15). Then the orthonormal frame $\{\mathbf{e}_a\}$ given by Eq. (19) and the null tetrad $\{\mathbf{e}_{\hat{a}}\}$ given by Eqs. (18) are parallelly transported along the geodesic if

$$g_{12,0}\dot{\xi}+g_{22,0}\dot{\overline{\xi}}+(g_{23,0}-g_{03,2})\dot{u}=0, \tag{22}$$

and

$$\begin{aligned}\dot{\vartheta}_{\parallel}(\tau)=\frac{i}{2D}[&(G_1\overline{G}_1-G_2\overline{G}_2)E\\&+G_1(2D\dot{m}^1+m^1(g_{12}\dot{g}_{12}-g_{22}\dot{g}_{11})+m^2(g_{12}\dot{g}_{22}-g_{22}\dot{g}_{12}))\\&+G_2(2D\dot{m}^2+m^1(g_{12}\dot{g}_{11}-g_{11}\dot{g}_{12})+m^2(g_{12}\dot{g}_{12}-g_{11}\dot{g}_{12}))],\end{aligned} \tag{23}$$

where $G_1=g_{12}g_{-}\exp(i\,\mathrm{Arg}\,g_{11})-g_{11}g_{+}$, $G_2=g_{22}g_{-}\exp(i\,\mathrm{Arg}\,g_{11})-g_{11}g_{+}$, $E=(g_{12,1}-g_{11,2})\dot{\xi}+(g_{22,1}-g_{12,2})\dot{\overline{\xi}}+(g_{23,1}-g_{13,2})\dot{u}=-\overline{E}$, $m^1=g_{-}\exp(-i\,\mathrm{Arg}\,g_{11})$, and $m^2=-g_{+}$. If, in addition, $g_{11}=0$, then $G_1=0$, $G_2=-\sqrt{g_{12}}$, and Eqs. (22), (23) reduce to

$$g_{12,0}\dot{\xi}+(g_{23,0}-g_{03,2})\dot{u}=0, \tag{24}$$

and

$$\dot{\vartheta}_{\parallel}(\tau)=-\frac{i}{2}\frac{1}{g_{12}}[g_{12,1}\dot{\xi}-g_{12,2}\dot{\overline{\xi}}+(g_{23,1}-g_{13,2})\dot{u}]. \tag{25}$$

Proof: Using $k_\mu k^\mu = 0$ and $k_\mu u^\mu = -1/\sqrt{2}$, it can be shown that **k** is parallelly transported if $\Gamma^1_{0\alpha} u^\alpha = 0$. Calculating the Christoffel symbols for the metric (15) we find (22). For proving Eq. (23) we use $m^3 = 0$ and $\overline{m}_0 = 0$; again the condition $\Gamma^1_{0\alpha} u^\alpha = 0$ and other Christoffel symbols for the metric (15).

IV. DEVIATION OF GEODESICS IN THE VACUUM NONTWISTING TYPE *N* SPACETIMES WITH COSMOLOGICAL CONSTANT

In this section we apply results given above to the nontwisting type N vacuum spacetimes with nonvanishing Λ. In the preceding paper[1] we showed that all such solutions belong either to the Kundt class of nonexpanding gravitational waves which we denoted by symbol $KN(\Lambda)$, or to the Robinson–Trautman class of expanding gravitational waves $RTN(\Lambda,\epsilon)$.

The class $KN(\Lambda)$ can be divided into six invariant canonical subclasses $KN(\Lambda)[\alpha,\beta]$, and the class $RTN(\Lambda,\epsilon)$ into nine invariant canonical subclasses, as analyzed in detail in Ref. 1. All $KN(\Lambda)$ metrics can be written in the form of Eq. (1, I), all $RTN(\Lambda,\epsilon)$ are described by Eq. (19, I). Both classes of metrics are of the form (15) in coordinates $x^\mu = (v,\xi,\overline{\xi},u)$. In the $KN(\Lambda)$ class we have

$$g_{12} = \frac{1}{p^2}, \quad g_{03} = -\frac{q^2}{p^2}, \quad g_{33} = F, \tag{26}$$

where $p = 1 + \Lambda/6\xi\overline{\xi}$, $q = (1-(\Lambda/6)\xi\overline{\xi})\alpha + \overline{\beta}\xi + \beta\overline{\xi}$, $F = \kappa(q^2/p^2)v^2 - ((q^2)_{,u}/p^2)v - (q/p)H$, $\kappa = (\Lambda/3)\alpha^2 + 2\beta\overline{\beta}$, $H = (f_{,\xi} + \overline{f}_{,\overline{\xi}}) - (\Lambda/3p)(\overline{\xi} f + \xi\overline{f})$; and in the $RTN(\Lambda,\epsilon)$ class,

$$g_{12} = v^2, \quad g_{13} = v\overline{\mathrm{A}}, \quad g_{23} = v\mathrm{A}, \quad g_{03} = \psi, \quad g_{33} = 2(\mathrm{A}\overline{\mathrm{A}} + \psi\mathrm{B}), \tag{27}$$

where $\mathrm{A} = \epsilon\xi - vf$, $\mathrm{B} = -\epsilon + (v/2)(f_{,\xi} + \overline{f}_{,\overline{\xi}}) + (\Lambda/6)v^2\psi$, $\psi = 1 + \epsilon\xi\overline{\xi}$, $\epsilon = -1,0,+1$, respectively.

Hence, for the $KN(\Lambda)$ solutions the orthonormal frame (19) is given by

$$\begin{aligned} e^\mu_{(0)} &= (\dot{v},\dot{\xi},\dot{\overline{\xi}},\dot{u}),\\ e^\mu_{(1)} &= -\frac{p}{\sqrt{2}}\left(\frac{2}{q^2}\,\frac{\mathcal{R}e\,\dot{\xi}}{\dot{u}},1,1,0\right),\\ e^\mu_{(2)} &= -\frac{p}{\sqrt{2}}\left(\frac{2}{q^2}\,\frac{\mathcal{I}m\,\dot{\xi}}{\dot{u}},i,-i,0\right),\\ e^\mu_{(3)} &= -\left(\dot{v} - \frac{p^2}{\dot{u}q^2},\dot{\xi},\dot{\overline{\xi}},\dot{u}\right), \end{aligned} \tag{28}$$

and for the $RTN(\Lambda,\epsilon)$ solutions we have

$$\begin{aligned} e^\mu_{(0)} &= (\dot{v},\dot{\xi},\dot{\overline{\xi}},\dot{u}),\\ e^\mu_{(1)} &= \frac{1}{\sqrt{2}}\,\frac{1}{v}\left(\frac{2v}{\psi\dot{u}}\mathcal{R}e\{v\dot{\xi} + \mathrm{A}\dot{u}\},-1,-1,0\right),\\ e^\mu_{(2)} &= \frac{1}{\sqrt{2}}\,\frac{1}{v}\left(\frac{2v}{\psi\dot{u}}\mathcal{I}m\{v\dot{\xi} + \mathrm{A}\dot{u}\},-i,i,0\right), \end{aligned} \tag{29}$$

$$e^{\mu}_{(3)}=-\left(\dot{v}+\frac{1}{\psi\dot{u}},\dot{\xi},\dot{\bar{\xi}},\dot{u}\right).$$

According to Proposition 3 these frames are parallelly transported along timelike geodesics $x^{\mu}(\tau)=(v,\xi,\bar{\xi},u)$ in the $KN(\Lambda)[\alpha,\beta]$ spacetimes if

$$\left(\frac{q}{p}\right)_{,\xi}=0=\left(\frac{q}{p}\right)_{,\bar{\xi}},\quad \dot{\vartheta}_{\parallel}(\tau)=i\left(\frac{p_{,\xi}}{p}\dot{\xi}-\frac{p_{,\bar{\xi}}}{p}\dot{\bar{\xi}}\right), \tag{30}$$

and in the case of $RTN(\Lambda,\epsilon)$ solutions if

$$\dot{\xi}=f\dot{u},\quad \dot{\bar{\xi}}=\bar{f}\dot{u},\quad \dot{\vartheta}_{\parallel}(\tau)=\frac{i}{2}(f_{,\xi}-\bar{f}_{,\bar{\xi}})\dot{u}. \tag{31}$$

The equation of geodesic deviation is now given by Eq. (8) with $T_{(a)(b)}=0$. The amplitudes (9) for both classes of spacetimes are calculated in the Appendix. We find that the invariant form of the equation of geodesic deviation with respect to the interpretation frame along any timelike geodesic in the $KN(\Lambda)$ and $RTN(\Lambda,\epsilon)$ spacetimes takes the form

$$\begin{aligned}\ddot{Z}^{(1)}&=\frac{\Lambda}{3}Z^{(1)}-\mathcal{A}_{+}Z^{(1)}+\mathcal{A}_{\times}Z^{(2)},\\ \ddot{Z}^{(2)}&=\frac{\Lambda}{3}Z^{(2)}+\mathcal{A}_{+}Z^{(2)}+\mathcal{A}_{\times}Z^{(1)},\\ \ddot{Z}^{(3)}&=\frac{\Lambda}{3}Z^{(3)},\end{aligned} \tag{32}$$

where the amplitudes of the transverse gravitational wave are given by

$$\mathcal{A}_{+}(\tau)=\tfrac{1}{2}pq\dot{u}^{2}\mathcal{R}e\{f_{,\xi\xi\xi}\},\quad \mathcal{A}_{\times}(\tau)=\tfrac{1}{2}pq\dot{u}^{2}\mathcal{I}m\{f_{,\xi\xi\xi}\}, \tag{33}$$

for the $KN(\Lambda)$ spacetimes, and by

$$\mathcal{A}_{+}(\tau)=-\frac{1}{2}\frac{\psi}{v}\dot{u}^{2}\mathcal{R}e\{f_{,\xi\xi\xi}\},\quad \mathcal{A}_{\times}(\tau)=-\frac{1}{2}\frac{\psi}{v}\dot{u}^{2}\mathcal{I}m\{f_{,\xi\xi\xi}\}, \tag{34}$$

in the $RTN(\Lambda,\epsilon)$ spacetimes [see Eqs. (A5) and (A10) in Appendix]. Equations (32)–(34) give relative accelerations of the free test particles in terms of their actual positions. They enable us to draw a number of simple conclusions.

(1) All particles move isotropically, one with respect to the other according to Eqs. (11) if no gravitational wave is present, i.e., if $f_{,\xi\xi\xi}=0$. In this case both the $KN(\Lambda)$ and $RTN(\Lambda,\epsilon)$ spacetimes are vacuum conformally flat [cf. (A3), (A8)], and therefore Minkowski ($\Lambda=0$), de Sitter ($\Lambda>0$) and anti-de Sitter ($\Lambda<0$) (see Lemma 1 and 3 in Ref. 1). Such spaces are maximally symmetric, homogeneous, isotropic, and they represent a natural background for other ''nontrivial'' $KN(\Lambda)$ and $RTN(\Lambda,\epsilon)$ type N solutions.

(2) If amplitudes $\mathcal{A}_{+}$ and $\mathcal{A}_{\times}$ do not vanish ($f_{,\xi\xi\xi}\neq 0$), the particles are influenced by the wave [see Eq. (12) and subsequent discussions] in a similar way as they are affected by a standard gravitational wave on Minkowski background (cf. Ref. 10). However, if $\Lambda\neq 0$, the influence of the wave adds with the (anti-) de Sitter isotropic expansion (contraction). This makes plausible our interpretation of the $KN(\Lambda)$ and $RTN(\Lambda,\epsilon)$ metrics as *exact gravitational waves propagating on the constant curvature backgrounds*.

(3) The wave propagates in the spacelike direction of $\mathbf{e}_{(3)}$ and has a *transverse character*, since only motions in the perpendicular directions of $\mathbf{e}_{(1)}$ and $\mathbf{e}_{(2)}$ are affected. The propagation direction given by $\mathbf{e}_{(3)}$ coincides with the projection of the Debever-Penrose vector $\mathbf{k}$ on the hypersurface orthogonal to the observer's velocity $\mathbf{u}$ (cf. Proposition 1).

(4) There are *two polarization modes* of the wave — ''+'' and ''×,'' $\mathcal{A}_+$ and $\mathcal{A}_\times$ being the amplitudes. Under rotation (13) in the transverse plane they transform according to Eq. (14) so that the helicity of the wave is 2, as with linearized waves on a Minkowski background. For the special choice of the frame given by $\vartheta(\tau)=\vartheta_+=-\frac{1}{2}pq\dot{u}^2\,\mathrm{Arg}\{f_{,\xi\xi\xi}\}$ for the $KN(\Lambda)$, and by $\vartheta_+=\frac{1}{4}(\psi/v)\dot{u}^2\,\mathrm{Arg}\{f_{,\xi\xi\xi}\}$ for the $RTN(\Lambda,\epsilon)$ spacetimes, the observer views pure ''+'' polarization, and for $\vartheta_\times=\vartheta_+ + \pi/4$ — pure ''×'' polarization.

(5) The waves have amplitude $\mathcal{A}=\frac{1}{2}pq\dot{u}^2|f_{,\xi\xi\xi}|$ for the $KN(\Lambda)$ class and $\mathcal{A}=\frac{1}{2}(\psi/v)\dot{u}^2|f_{,\xi\xi\xi}|$ for $RTN(\Lambda,\epsilon)$; this is invariant under rotations (13). However, the amplitude changes under Lorentz transformations to another observer $\mathbf{u}'$ with a spatial velocity $\vec{v}=(v_1,v_2,v_3)$ with respect to the original observer. For type N solutions we get $\mathcal{A}'=(1-v_3)^2/(1-v_1^2-v_2^2-v_3^2)\,\mathcal{A}$. By increasing speed in the wave-propagation direction $\mathbf{e}_{(3)}$ $(v_1=v_2=0,\ v_3>0)$, he experiences a weakening of the wave amplitude by factor $(1-v_3)/(1+v_3)$ $(\mathcal{A}'\to 0$ as $v_3\to 1)$, and by moving in the opposite direction, an increase of the amplitude $(\mathcal{A}'\to\infty$ as $v_3\to -1)$. By increasing speed in the transverse directions $\mathbf{e}_{(1)}$, $\mathbf{e}_{(2)}$, $(v_1^2+v_2^2=0,\ v_3=0)$, she experiences an increase by the factor $1/(1-v_1^2-v_2^2)$.

In general, all $KN(\Lambda)$ spacetimes contain singularities except for the homogeneous pp-waves[8] given by $p=1=q$ and $f_{,\xi\xi\xi}=6c_3(u)$, where $c_3(u)$ is a finite function of u. All other $KN(\Lambda)$ spacetimes are singular at $|\xi|=\infty$ where the amplitudes $\mathcal{A}_+$, $\mathcal{A}_\times$ diverge. Additional singularities in the amplitudes may occur if the coefficients $c_n(u)$, $n\geqslant 3$, of the analytic expansion of function $f(\xi,u)$ are badly behaved at some u.

$RTN(\Lambda,\epsilon)$ spacetimes also contain singularities. The character of the singularities depends on parameter ϵ and on the form of the function $f(\xi,u)$. As follows from Eq. (34), there is always a singularity at $v=0$. Another singularity is given by $\psi=\infty$ which occurs only for $\epsilon\neq 0$ at $|\xi|=\infty$. There may be singularities for special forms of f, namely, if $f_{,\xi\xi\xi}=\infty$. This occurs at $|\xi|=\infty$ if f contains the terms $c_n\xi^n$, $n\geqslant 4$. Another type of singularity may appear if some of the coefficients $c_n(u)$ diverge for some values of u. Singularities might be considered as ''sources'' of waves; however, it is far from certain whether nonsingular sources ''covering'' the regions in which singularities occur can be constructed. The singularities of the $RTN(\Lambda,\epsilon)$ spacetimes can invariantly be characterized by the nonvanishing invariant constructed recently[14] from the second derivatives of the Riemann tensor.

Finally, we shall discuss a special class of geodesics explicitly. Since for $f=f_c=c_0(u)+c_1(u)\xi+c_2(u)\xi^2$ the metrics represent Minkowski, de Sitter or anti-de Sitter space there always exists a transformation of coordinates which brings $g_{\mu\nu}[f=f_c]$ to $g_{\mu\nu}[f=0]$ (see Lemmas 2 and 4 in Ref. 1). It is thus sufficient to consider only the nontrivial part $f_w\equiv f-f_c$ of function $f(\xi,u)$. Moreover, one can always rearrange its analytic expansion so that $f=\Sigma_{n=0}^{\infty}c_n(u)\xi^n=\Sigma_{n=0}^{\infty}\tilde{c}_n(u)(\xi-\xi_0)^n=\Sigma_{n=3}^{\infty}\tilde{c}_n(u)(\xi-\xi_0)^n+\tilde{f}_c$, ξ_0 being an arbitrary complex constant. Therefore, it is natural to consider structural functions of the form

$$f_w=c_3(u)(\xi-\xi_0)^3+c_4(u)(\xi-\xi_0)^4+\cdots. \tag{35}$$

Consider a *special class of geodesics* characterized by $\xi=\xi_0=\text{const}$. For the $RTN(\Lambda,\epsilon)$ solutions these are geometrically privileged since the interpretation frame (29) is parallelly propagated along them [Eq. (31) is satisfied]. One can also find special geodesics for some subclasses of $KN(\Lambda)$: $\xi=\xi_0$ for the PP subclass, $\xi_0=\pm\sqrt{6/\Lambda}$ for $KN(\Lambda)I$, and $\xi_0=0$ for $KN(\Lambda^-)II$. The geodesics $\xi=\xi_0$ have the same forms as geodesics in the ''background'' since Christoffel symbols for $f=f_w$ and $\xi=\xi_0$ coincide with those for $f=0$. However, the test particles feel the tidal forces proportional to $\mathcal{A}_+$ and $\mathcal{A}_\times$ given by Eqs. (33), (34). The amplitudes do not vanish since $f_{w,\xi\xi\xi}=6c_3(u)$ is nonvanishing.

The timelike geodesics $\xi=\xi_0=\text{const}$ in the $RTN(\Lambda>0,\epsilon)[f_w]$ spacetimes are given by

$$v=\frac{\alpha}{1+\epsilon\xi_0\bar{\xi}_0}\left(C_1\cosh\frac{\tau}{\alpha}+C_2\sinh\frac{\tau}{\alpha}\right),\quad \dot{u}=-\left(C_1\sinh\frac{\tau}{\alpha}+C_2\cosh\frac{\tau}{\alpha}+C_3\right)^{-1},\tag{36}$$

where $\alpha=\sqrt{3/\Lambda}$, C_1, C_2, C_3 are real constants satisfying $C_1^2-C_2^2+C_3^2=2\epsilon$. The integration of Eq. (36) can be performed explicitly but we do not give it here since only $\dot{u}$ enters the amplitudes. The wave amplitudes (34) are $\mathcal{A}_+=\mathcal{R}e\,\mathcal{A}$ and $\mathcal{A}_\times=\mathcal{I}m\,\mathcal{A}$ where

$$\mathcal{A}(\tau)=-\frac{3}{\alpha}(1+\epsilon\xi_0\bar{\xi}_0)^2\left(C_1\cosh\frac{\tau}{\alpha}+C_2\sinh\frac{\tau}{\alpha}\right)^{-1}\left(C_1\sinh\frac{\tau}{\alpha}+C_2\cosh\frac{\tau}{\alpha}+C_3\right)^{-2}c_3(u(\tau)).\tag{37}$$

As proper time τ along geodesics increases, $\tau\rightarrow\infty$, particles recede from $v=0$ and amplitudes decay as $\mathcal{A}\sim\exp(-3\sqrt{\Lambda/3}\,\tau)$, i.e., *waves are damped exponentially*. The spacetime locally approaches the de Sitter universe. This is an explicit demonstration of the *cosmic no-hair conjecture* (see, e.g., Ref. 5) under the presence of waves within exact model spacetimes. (For a cosmic no-hair conjecture in the Robinson–Trautman spacetimes of Petrov type *II*, see Refs. 6, 7.)

Similarly, for the $KN(\Lambda>0)I[f_w]$ subclass [representing the only spacetimes of the $KN(\Lambda)$ type admitting $\Lambda>0$] the geodesics $\xi=\xi_0=\pm\sqrt{6/\Lambda}$ are given by

$$v=C_1\exp\left(\frac{\tau}{\alpha}\right),\quad u=-\frac{1}{2C_1}\exp\left(-\frac{\tau}{\alpha}\right)+C_2,\tag{38}$$

and

$$v=C_1\sinh\left(\frac{\tau}{\alpha}+2\tau_0\right),\quad u=\frac{1}{2C_1}\tanh\left(\frac{\tau}{2\alpha}+\tau_0\right)+C_2,\tag{39}$$

with C_1, C_2, τ_0 constants. For observers moving along these geodesics,

$$\mathcal{A}(\tau)=\pm12\sqrt{\frac{6}{\Lambda}}\dot{u}^2(\tau)c_3(u(\tau)).\tag{40}$$

After substitution of the explicit dependence of $u(\tau)$, we see that as $\tau\rightarrow+\infty$ the amplitudes behave like $\mathcal{A}\sim\exp(-2\sqrt{\Lambda/3}\,\tau)$. Again, gravitational waves are damped exponentially and the cosmic no-hair conjecture is confirmed.

APPENDIX: GRAVITATIONAL WAVE AMPLITUDES

We calculate amplitudes $\mathcal{A}_+=\frac{1}{2}\mathcal{R}e\Psi_4$ and $\mathcal{A}_\times=\frac{1}{2}\mathcal{I}m\Psi_4$ by using differential forms. Let $\{\mathbf{e}_{\hat{a}}\}=\{\mathbf{m},\bar{\mathbf{m}},\mathbf{l},\mathbf{k}\}$ be a null tetrad, $\mathbf{m}=\mathbf{e}_{\hat{1}}=m^\mu\partial_\mu$, $\bar{\mathbf{m}}=\mathbf{e}_{\hat{2}}=\bar{m}^\mu\partial_\mu$, $\mathbf{l}=\mathbf{e}_{\hat{3}}=l^\mu\partial_\mu$, $\mathbf{k}=\mathbf{e}_{\hat{4}}=k^\mu\partial_\mu$. The dual basis $\{\boldsymbol{\omega}^{\hat{a}}\}$ is given by one-forms $\boldsymbol{\omega}^{\hat{1}}=\bar{m}_\mu\,dx^\mu$, $\boldsymbol{\omega}^{\hat{2}}=m_\mu\,dx^\mu$, $\boldsymbol{\omega}^{\hat{3}}=-k_\mu\,dx^\mu$, $\boldsymbol{\omega}^{\hat{4}}=-l_\mu\,dx^\mu$; the metric is $ds^2=g_{\hat{a}\hat{b}}\boldsymbol{\omega}^{\hat{a}}\boldsymbol{\omega}^{\hat{b}}=2\boldsymbol{\omega}^{\hat{1}}\boldsymbol{\omega}^{\hat{2}}-2\boldsymbol{\omega}^{\hat{3}}\boldsymbol{\omega}^{\hat{4}}$ with $g_{\hat{1}\hat{2}}=\mathbf{e}_{\hat{1}}\cdot\mathbf{e}_{\hat{2}}=1$ and $g_{\hat{3}\hat{4}}=\mathbf{e}_{\hat{3}}\cdot\mathbf{e}_{\hat{4}}=-1$. The natural choice of the null basis for the metric $KN(\Lambda)$ is

$$\boldsymbol{\omega}^{\hat{1}}=\frac{d\bar{\xi}}{p},\quad \boldsymbol{\omega}^{\hat{2}}=\frac{d\xi}{p},\quad \boldsymbol{\omega}^{\hat{3}}=\frac{q^2}{p^2}du,\quad \boldsymbol{\omega}^{\hat{4}}=dv-\frac{1}{2}\frac{p^2}{q^2}F\,du;\tag{A1}$$

in coordinates $x^\mu=(v,\xi,\bar{\xi},u)$ we have

$$
\begin{aligned}
m^\mu&=(0,0,p,0),\quad \bar{m}^\mu=(0,p,0,0),\\
k^\mu&=(1,0,0,0),\quad l^\mu=\left(\frac{1}{2}\,\frac{p^4}{q^4}F,0,0,\frac{p^2}{q^2}\right).
\end{aligned}
\tag{A2}
$$

The nonvanishing components of the Weyl tensor in this null tetrad are

$$
C_{\hat{3}\hat{2}\hat{3}\hat{2}}\equiv\Psi_4=\frac{1}{2}\,\frac{p^5}{q^3}f_{,\xi\xi\xi}=\overline{C_{\hat{3}\hat{1}\hat{3}\hat{1}}}.
\tag{A3}
$$

The interpretation null tetrad for the $KN(\Lambda)$ spacetimes, given by Eq. (18), reads as

$$
\begin{aligned}
m^\mu&=\left(-\frac{p}{q^2}\,\frac{\dot{\xi}}{\dot{u}},0,-p,0\right),\quad \bar{m}^\mu=\left(-\frac{p}{q^2}\,\frac{\dot{\bar{\xi}}}{\dot{u}},-p,0,0\right),\\
k^\mu&=\left(\frac{1}{\sqrt{2}\dot{u}}\,\frac{p^2}{q^2},0,0,0\right),\quad l^\mu=\left(\sqrt{2}\dot{v}-\frac{1}{\sqrt{2}\dot{u}}\,\frac{p^2}{q^2},\sqrt{2}\dot{\xi},\sqrt{2}\dot{\bar{\xi}},\sqrt{2}\dot{u}\right).
\end{aligned}
\tag{A4}
$$

The relation between tetrads (A2) and (A4) is given by the Lorentz transformation, $\mathbf{k}_{\mathrm{natur}}=A\mathbf{k}_{\mathrm{interp}}$, $\mathbf{l}_{\mathrm{natur}}=(\mathbf{l}_{\mathrm{interp}}+Be^{i\vartheta}\bar{\mathbf{m}}_{\mathrm{interp}}+\bar{B}e^{-i\vartheta}\mathbf{m}_{\mathrm{interp}}+B\bar{B}\mathbf{k}_{\mathrm{interp}})/A$, $\mathbf{m}_{\mathrm{natur}}=e^{-i\vartheta}\mathbf{m}_{\mathrm{interp}}+B\mathbf{k}_{\mathrm{interp}}$, where $A=\sqrt{2}\dot{u}\,q^2/p^2$, $B=-\sqrt{2}\,\dot{\xi}/p$, $\vartheta=\pi$. The coefficients Ψ_A transform (see Ref. 8)

$$
\begin{aligned}
\Psi_4^{\mathrm{interp}}&=A^2\Psi_4^{\mathrm{natur}}=pq\dot{u}^2f_{,\xi\xi\xi},\\
\Psi_3^{\mathrm{interp}}&=\Psi_2^{\mathrm{interp}}=\Psi_1^{\mathrm{interp}}=\Psi_0^{\mathrm{interp}}=0.
\end{aligned}
\tag{A5}
$$

Similarly, the natural choice of null basis for the $RTN(\Lambda,\epsilon)$ metric is

$$
\boldsymbol{\omega}^{\hat{1}}=v\ d\bar{\xi}+\ \bar{\mathrm{A}}\ du,\quad \boldsymbol{\omega}^{\hat{2}}=v\,d\xi+\mathrm{A}\ du,\quad \boldsymbol{\omega}^{\hat{3}}=\psi\ du,\quad \boldsymbol{\omega}^{\hat{4}}=-dv-\mathrm{B}\ du,
\tag{A6}
$$

so that

$$
\begin{aligned}
m^\mu&=\left(0,0,\frac{1}{v},0\right),\quad \bar{m}^\mu=\left(0,\frac{1}{v},0,0\right),\\
k^\mu&=(-1,0,0,0),\quad l^\mu=\left(-\frac{\mathrm{B}}{\psi},-\frac{\mathrm{A}}{v\psi},-\frac{\bar{\mathrm{A}}}{v\psi},\frac{1}{\psi}\right).
\end{aligned}
\tag{A7}
$$

For this tetrad we obtain nonvanishing components,

$$
C_{\hat{3}\hat{2}\hat{3}\hat{2}}\equiv\Psi_4=-\frac{1}{2v\psi}f_{,\xi\xi\xi}=\overline{C_{\hat{3}\hat{1}\hat{3}\hat{1}}}.
\tag{A8}
$$

The interpretation null tetrad (18) reads as

$$
\begin{aligned}
m^\mu&=\left(\frac{1}{\psi\dot{u}}(v\dot{\xi}+\mathrm{A}\dot{u}),0,-\frac{1}{v},0\right),\quad \bar{m}^\mu=\left(\frac{1}{\psi\dot{u}}(v\dot{\bar{\xi}}+\bar{\mathrm{A}}\dot{u}),-\frac{1}{v},0,0\right),\\
k^\mu&=\left(-\frac{1}{\sqrt{2}}\,\frac{1}{\psi\dot{u}},0,0,0\right),\ l^\mu=\left(\sqrt{2}\dot{v}+\frac{1}{\sqrt{2}}\,\frac{1}{\psi\dot{u}},\sqrt{2}\dot{\xi},\sqrt{2}\dot{\bar{\xi}},\sqrt{2}\dot{u}\right).
\end{aligned}
\tag{A9}
$$

The relation between the tetrads (A7) and (A9) is again given by the Lorentz transformation with $A=\sqrt{2}\,\dot{u}\psi$, $B=-\sqrt{2}\,(v\dot{\xi}+\mathrm{A}\dot{u})$, $\vartheta=\pi$. We thus get

$$\Psi_4^{\text{interp}}=A^2\Psi_4^{\text{natur}}=-\frac{\psi}{v}\dot{u}^2 f_{,\xi\xi\xi},$$
$$\Psi_3^{\text{interp}}=\Psi_2^{\text{interp}}=\Psi_1^{\text{interp}}=\Psi_0^{\text{interp}}=0. \tag{A10}$$

(Received 23 July 1998; accepted for publication 25 May 1999)

We derive simple general expressions for the explicit Killing spinors on the n-sphere, for arbitrary n. Using these results we also construct the Killing spinors on various AdS×Sphere supergravity backgrounds, including $AdS_5 \times S^5$, $AdS_4 \times S^7$, and $AdS_7 \times S^4$. In addition, we extend previous results to obtain the Killing spinors on the hyperbolic spaces H^n. *© 1999 American Institute of Physics.* [S0022-2488(99)00309-6]

I. INTRODUCTION

Finding the explicit form of Killing spinors on curved spaces can be an involved task. Often, one merely uses integrability conditions to establish their existence and to determine their multiplicities. In this way it is easy to show that spheres and anti-de Sitter spacetimes preserve all supersymmetries, i.e., they admit the maximum number of Killing spinors. However, one does not obtain explicit solutions by this method. Although establishing their existence is often sufficient, there are situations where it is necessary to know their explicit forms.

There exists a very simple explicit construction of the Killing spinors on n-dimensional anti-de Sitter spacetime AdS_n, for arbitrary n.[1] This exploits the fact that AdS_n can be written in horospherical coordinates, in terms of which the metric takes the simple form

$$ds^2 = dr^2 + e^{2r}\eta_{\alpha\beta}\,dx^\alpha\,dx^\beta, \tag{1}$$

where $\eta_{\alpha\beta}$ is the Minkowski metric in $(n-1)$ dimensions, and the Ricci tensor satisfies $R_{\mu\nu} = -(n-1)g_{\mu\nu}$. It was shown in Ref. 1 that the Killing spinors, satisfying $D_\mu \epsilon = \frac{1}{2}\Gamma_\mu \epsilon$, are then expressible as

$$\epsilon = e^{(1/2)r}\epsilon_0^+, \quad \text{or} \quad \epsilon = (e^{(-1/2)r} + e^{(1/2)r}x^\alpha \Gamma_\alpha)\epsilon_0^-, \tag{2}$$

where $\epsilon_\pm$ are arbitrary constant spinors satisfying $\Gamma_r \epsilon_0^\pm = \pm \epsilon_0^\pm$. One can alternatively write the two kinds of Killing spinors together in one equation, as

$$\epsilon = e^{(1/2)r\Gamma_r}(1 + \tfrac{1}{2}x^\alpha \Gamma_\alpha(1-\Gamma_r))\epsilon_0, \tag{3}$$

where ϵ_0 is an arbitrary constant spinor. It is therefore manifest that the number of independent Killing spinors is equal to the number of components in the spinors. (The Killing spinors for AdS_4, written in the standard AdS coordinate system, were obtained in Ref. 2.) It is worth remarking that the horospherical metric (1) can equally well have other spacetime signatures $(p, n-p)$, by taking other signatures $(p, n-p-1)$ for the metric $\eta_{\alpha\beta}$. The isometry group is $SO(p+1, n-p)$. The case $p=1$ gives AdS_n, with $SO(2, n-1)$, while $p=0$ gives the positive-

[a)]Electronic mail: rahmfeld@leland.stanford.edu definite hyperbolic metric on H^n, with $SO(1,n)$. [Expressions for the Killing spinors on H^2 and H^3, which are special cases of (3), were given in Ref. 3.] Thus, Eq. (3) gives the Killing spinors on all of the AdS_n spacetimes, hyperbolic spaces H^n, and the other maximally symmetric spacetimes with a $(p,n-p)$ signature.

There is an alternative Killing spinor equation that one can consider when n is even, namely, $D_\mu\epsilon=(i/2)\gamma\Gamma_\mu\epsilon$, where γ is the chirality operator, expressed as an appropriate product over the Γ_μ, with $\gamma^2=1$. We easily see that the solutions of this equation can be written as

$$\epsilon=e^{(i/2)r\gamma\Gamma_r}\left(1+\frac{i}{2}\gamma x^\alpha\Gamma_\alpha(1-i\gamma\Gamma_r)\right)\epsilon_0. \tag{4}$$

Note that in all the cases above, we considered a ''unit radius'' AdS_n, or H^n, etc., given by (1). It is trivial to extend the results to an arbitrary scale size, by replacing (1) by $ds^2=\lambda^{-2}(dr^2+e^{2r}\eta_{\alpha\beta}\,dx^\alpha\,dx^\beta)$, which has the Ricci tensor $R_{\mu\nu}=-(n-1)\lambda^2 g_{\mu\nu}$. The Killing spinor equations then become $D_\mu\epsilon=\frac{1}{2}\lambda\Gamma_\mu\epsilon$, etc. It is easily seen that the solutions are given by precisely the same expressions (3), etc., with no modifications whatsoever. (In Ref. 1 a different coordinatization of the general-radius AdS_n was used, in which the expressions for the Killing spinors *do* depend upon the scale-setting parameter.)

In this paper, we find an explicit construction of the Killing spinors on S^n. (Explicit results for $n=2$ and $n=3$ were obtained in Ref. 3.) One might think that since AdS_n can be related to S^n by appropriate complexifications of coordinates, it should be possible to obtain expressions for the Killing spinors on S^n that are analogous to those given above. However, things are not quite so simple, because the ability to write the metric on AdS_n in the simple form (1) depends rather crucially on the fact that its isometry group $SO(2,n-1)$ is noncompact. (One can easily see that (1) has $(n-1)$ commuting Killing vectors ∂_μ, which exceeds the rank $[(n+1)/2]$ of the isometry group when $n>3$. This is not possible for compact groups.) We shall thus present a different construction for the Killing spinors of S^n, which, although more complicated, is still explicit, and of an essentially simple structure. Our main result is contained in Eq. (7) in Sec. II, which also contains a detailed proof. In Sec. III we combine the results for AdS and spheres, to give the explicit expressions for Killing spinors in various $\mathrm{AdS}_m\times S^n$ supergravity backgrounds, with $(m,n)=(4,7)$, (7, 4), (5, 5), (3, 3), (3, 2), (2, 3), (2, 2). In Appendix A, we collect some useful expressions for the representation and decomposition of Dirac matrices.

II. KILLING SPINORS ON S^n

A. Results

We begin by writing the metric on a unit S^n in terms of that for a unit S^{n-1} as

$$ds_n^2=d\theta_n^2+\sin^2\theta_n\,ds_{n-1}^2, \tag{5}$$

with $ds_1^2=d\theta_1^2$. This has a Ricci tensor given by $R_{ij}=(n-1)g_{ij}$. We then consider the Killing spinor equation on the unit n-sphere, for arbitrary n, namely,

$$D_j\epsilon=\frac{i}{2}\Gamma_j\epsilon. \tag{6}$$

We shall first present our results for the solutions to this equation, and then present the proof later. We find that the Killing spinors can be written as

$$\epsilon=e^{(i/2)\theta_n\Gamma_n}\left(\prod_{j=1}^{n-1}e^{(-1/2)\theta_j\Gamma_{j,j+1}}\right)\epsilon_0, \tag{7}$$

where ϵ_0 is an arbitrary constant spinor, and the indices on the Dirac matrices are vielbein indices. We use the convention that the Γ matrices are Hermitian, satisfying the Clifford algebra

$\{\Gamma_i,\Gamma_j\}=2\delta_{ij}$. Note that here, and in all other analogous formulas in the paper, the factors in the product in (7) are ordered antilexigraphically i.e., starting with the θ_{n-1} term at the left. Note also that the exponential factors in (7) can be written as

$$e^{(i/2)\theta_n\Gamma_n}=\mathbb{1}\cos\tfrac{1}{2}\theta_n+i\Gamma_n\sin\tfrac{1}{2}\theta_n,\quad e^{(-1/2)\theta_j\Gamma_{j,j+1}}=\mathbb{1}\cos\tfrac{1}{2}\theta_j-\Gamma_{j,j+1}\sin\tfrac{1}{2}\theta_j. \tag{8}$$

One can also consider the Killing spinor equation with the opposite sign for the Γ_j term, namely,

$$D_j\epsilon_-=-\frac{i}{2}\Gamma_j\epsilon_-. \tag{9}$$

The previous solution (7) is easily modified to give solutions of this equation. One finds

$$\epsilon_-=e^{(-i/2)\theta_n\Gamma_n}\left(\prod_{j=1}^{n-1}e^{(-1/2)\theta_j\Gamma_{j,j+1}}\right)\epsilon_0. \tag{10}$$

This is immediately verified by noting that (9) is obtained from (6) by changing the sign of the gamma matrices.

The Killing spinors discussed above exist on S^n for any n. When n is even, there is an alternative equation that can also be considered, namely,

$$D_j\epsilon=\tfrac{1}{2}\gamma\Gamma_j\epsilon, \tag{11}$$

where γ is the chirality operator formed from the product of the Γ matrices, satisfying $\gamma^2=1$. In this case, we find that the corresponding Killing spinors can be written as

$$\epsilon=e^{(1/2)\theta_n\gamma\Gamma_n}\left(\prod_{j=1}^{n-1}e^{(-1/2)\theta_j\Gamma_{j,j+1}}\right)\epsilon_0. \tag{12}$$

We may again also consider the Killing spinors satisfying (11) with the sign of the Γ_j term reversed, namely,

$$D_j\epsilon=-\tfrac{1}{2}\gamma\Gamma_j\epsilon. \tag{13}$$

The solutions are again obtained by sending $\theta_n\to-\theta_n$, giving

$$\epsilon_-=e^{(-1/2)\theta_n\gamma\Gamma_n}\left(\prod_{j=1}^{n-1}e^{(-1/2)\theta_j\Gamma_{j,j+1}}\right)\epsilon_0. \tag{14}$$

As in the AdS and H^m cases discussed in Sec. I, we may again trivially extend the results to an n-sphere of arbitrary radius, with metric $ds_n^2=\lambda^{-2}(d\theta_n^2+\sin^2\theta_n\,ds_{n-1}^2)$ and Ricci tensor $R_{ij}=(n-1)\lambda^2 g_{ij}$. The Killing spinor equations are modified to $D_j\epsilon=(i/2)\lambda\Gamma_j\epsilon$, etc., but again the expressions (7), etc. for the Killing spinors receive no modification whatsoever.

B. Proofs

The proofs of these results proceed by substituting our expressions into the corresponding Killing spinor equations. We begin by showing that in the orthonormal basis $e^n=d\theta_n$, $e^a=\sin\theta_n e^a_{(n-1)}$, the spin connection for the metric (5) is given by

$$\omega^{ab}=\omega^{ab}_{(n-1)},\quad \omega^{a,n}=\cos\theta_n e^a_{(n-1)}, \tag{15}$$

where $a \leqslant n-1$, and $e^a_{(n-1)}$, and $\omega^{ab}_{(n-1)}$ are the vielbein and spin connection for S^{n-1}. (Note that the index n always denotes the specific value n of the dimension of the n-sphere.) Thus we can write the vielbein and spin connection on S^n as

$$e^j = \left(\prod_{k=j+1}^{n} \sin \theta_k \right) d\theta_j ,$$

$$\omega^{jk} = \cos \theta_k \left(\prod_{l=j+1}^{k-1} \sin \theta_l \right) d\theta_j , \quad 1 \leqslant j < k \leqslant n. \tag{16}$$

The Killing spinor equation (6) can be written as

$$\partial_j \epsilon + \frac{1}{4} \omega_j^{kl} \Gamma_{kl} \epsilon = \frac{i}{2} e_j^k \Gamma_k \epsilon, \tag{17}$$

where ω_j^{kl} and e_j^k are the coordinate-index components of ω^{kl} and e^k, i.e., $\omega^{kl} = \omega_j^{kl}\, d\theta_j$ and $e^k = e_j^k\, d\theta^j$. These can be read off from (16). Note that the indices on the Γ matrices in (17) are vielbein indices.

We now make the following two definitions:

$$U_j^k \equiv \left(\prod_{l=j+1}^{k} e^{(-1/2)\theta_l \Gamma_{l,l+1}} \right) \Gamma_{j,j+1} \left(\prod_{l=j+1}^{k} e^{(-1/2)\theta_l \Gamma_{l,l+1}} \right)^{-1}, \quad k \geqslant j, \tag{18}$$

$$V_j \equiv e^{(i/2)\theta_n \Gamma_n} U_j^{n-1} e^{(-i/2)\theta_n \Gamma_n}, \tag{19}$$

where, as usual, the factors with the larger l values in the product sit to the left of those with smaller l values. (Note that if the upper limit on the product is less than the lower limit, then it is defined to be 1.) It is now evident that verifying that the expression (7) gives a solution to the Killing spinor equation (6) amounts to proving that

$$V_j = -i e_j^j \Gamma_j + \sum_{k>j}^{n} \omega_j^{jk} \Gamma_{jk} . \tag{20}$$

We prove this by first establishing two lemmata. The first, whose proof is elementary, states that if X and Y are matrices such that $[X,Y] = 2Z$, and $[X,Z] = -2Y$, then

$$e^{(1/2)\theta X} Y e^{(-1/2)\theta X} = \cos \theta Y + \sin \theta Z. \tag{21}$$

The second lemma states that

$$U_j^k = \sec \theta_{k+1} \omega_j^{j,k+1} \Gamma_{j,k+1} + \sum_{l>j}^{k} \omega_j^{jl} \Gamma_{jl} , \quad k \geqslant j. \tag{22}$$

We prove this by induction. From the definition (18), we know that $U_j^j = \Gamma_{j,j+1}$, which clearly satisfies (22) since $\omega_j^{j,j+1} = \cos \theta_{j+1}$. Assuming then that (22) holds for a specific $k \geqslant j$, we will have that

$$U_j^{k+1} \equiv e^{(-1/2)\theta_{k+1}\Gamma_{k+1,k+2}} U_j^k e^{(+1/2)\theta_{k+1}\Gamma_{k+1,k+2}},$$

$$= \sec \theta_{k+1} \omega_j^{j,k+1} e^{(-1/2)\theta_{k+1}\Gamma_{k+1,k+2}} \Gamma_{j,k+1} e^{(1/2)\theta_{k+1}\Gamma_{k+1,k+2}} + \sum_{l>j}^{k} \omega_j^{jl} \Gamma_{jl} , \tag{23}$$

where we have made use of the fact that the Γ_{jl} in the last term all commute with $\Gamma_{k+1,k+2}$, since $l\leqslant k$. The first term can be evaluated using Lemma 1, giving

$$U_j^{k+1}=\sec\theta_{k+1}\omega_j^{j,k+1}(\cos\theta_{k+1}\Gamma_{j,k+1}+\sin\theta_{k+1}\Gamma_{j,k+2})+\sum_{l>j}^{k}\omega_j^{jl}\Gamma_{jl},$$
$$=\tan\theta_{k+1}\omega_j^{j,k+1}\Gamma_{j,k+2}+\sum_{l>j}^{k+1}\omega_j^{jl}\Gamma_{jl}. \tag{24}$$

Now, it follows from (16) that $\omega_j^{j,k+2}=\cos\theta_{k+2}\tan\theta_{k+1}\omega_j^{j,k+1}$. Using this, we then obtain (22) with k replaced by $k+1$, completing the inductive proof.

Having established the lemmata, we can substitute the expression U_j^{n-1} from (22) into the definition of V_j given in (18), giving

$$V_j=\sec\theta_n\omega_j^{jn}e^{(i/2)\theta_n\Gamma_n}\Gamma_{jn}e^{(-i/2)\theta_n\Gamma_n}+\sum_{l>j}^{n-1}\omega_j^{jl}\Gamma_{jl},$$
$$=-i\tan\theta_n\omega_j^{jn}\Gamma_j+\sum_{l>j}^{n}\omega_j^{jl}\Gamma_{jl}, \tag{25}$$

where we have used Lemma 1 to derive the second line. Since $e_j^j=\tan\theta_n\omega_j^{jn}$, as can be seen from (16), it follows that (25) gives (20). This completes the proof that (7) satisfies the Killing spinor equation (6). An essentially identical proof shows that (12) satisfies the alternative Killing spinor equation (11) in even dimensions.

III. KILLING SPINORS ON ADS×SPHERE

An application of the formulas obtained in this paper is to construct the explicit forms of the Killing spinors in the full D-dimensional spacetime of a supergravity theory that admits an $\mathrm{AdS}_m\times S^n$ solution, where $D=m+n$. Consider, for example, the $\mathrm{AdS}_4\times S^7$ solution of $D=11$ supergravity. This is obtained by taking $F_{\mu\nu\rho\sigma}=6m\epsilon_{\mu\nu\rho\sigma}$ with $\mu=0$, 8, 9, 10, implying that the Ricci tensors on AdS_4 and S^7 satisfy $R_{\mu\nu}=-12m^2g_{\mu\nu}$ and $R_{mn}=6m^2g_{mn}$, respectively.[4] The Killing spinors ϵ must satisfy

$$0=\delta\psi_M=D_M\epsilon-\tfrac{1}{288}(\hat\Gamma_{MNPQR}F^{NPQR}-8F_{MNPQ}\hat\Gamma^{NPQ})\epsilon. \tag{26}$$

Using the appropriate decomposition of Dirac matrices given in Appendix A, this implies that on AdS_4 and S^7 we must have

$$\mathrm{AdS}_4{:}D_\mu\epsilon_{AdS}=im\gamma\Gamma_\mu\epsilon_{\mathrm{AdS}},$$
$$S^7{:}D_j\eta=\frac{i}{2}m\Gamma_j\eta, \tag{27}$$

with $j=1,...,7$. From the results obtained in this paper, we find that the Killing spinors on $\mathrm{AdS}_4\times S^7$ can be written as

$$\mathrm{AdS}_4\times S^7{:}\epsilon=e^{(i/2)r\hat\gamma\hat\Gamma_r}\left(1+\frac{1}{2}x^\alpha(i\hat\gamma\hat\Gamma_\alpha+\hat\Gamma_r\hat\Gamma_\alpha)\right)e^{(i/2)\theta_7\hat\gamma\hat\Gamma_7}\left(\prod_{j=1}^{6}e^{(-1/2)\theta_j\hat\Gamma_{j,j+1}}\right)\epsilon_0, \tag{28}$$

where $\hat\gamma\equiv(-i/24)\epsilon^{\mu\nu\rho\sigma}\hat\Gamma_{\mu\nu\rho\sigma}=\gamma\otimes\mathbf{1}$ is a ‘‘pseudo chirality operator,’’ and ϵ_0 is an arbitrary 32-component constant spinor in $D=11$. Note that the explicit numerically assigned indices refer to the seven directions on the 7-sphere. Also, as implied by (27), the AdS_4 and S^7 have different radii, which are related by the 11-dimensional field equations. However, as noted before, in our coordinatization the Killing spinors are independent of the scale sizes.

In $D=11$ supergravity there is also a solution, $\mathrm{AdS}_7\times S^4$. An analogous calculation gives the result that the Killing spinors in this background can be written as

$$\mathrm{AdS}_7\times S^4\colon \epsilon=e^{(1/2)r\hat{\gamma}\hat{\Gamma}_r}(1+\tfrac{1}{2}x^{\alpha}(\hat{\gamma}\hat{\Gamma}_{\alpha}+\hat{\Gamma}_r\hat{\Gamma}_{\alpha}))e^{(1/2)\theta_4\hat{\gamma}\hat{\Gamma}_4}\left(\prod_{j=1}^{3} e^{(-1/2)\theta_j\hat{\Gamma}_{j,j+1}}\right)\epsilon_0, \tag{29}$$

where $\hat{\gamma}\equiv\hat{\Gamma}_{1234}=\mathbf{1}\otimes\gamma$, and all numerically assigned indices refer to the four directions on S^4. Again, ϵ_0 is an arbitrary 32-component constant spinor in $D=11$.

As another explicit example let us look at Type IIB supergravity on $\mathrm{AdS}_5\times S^5$. The gravitino transformation rules are

$$0=\delta\psi_M=D_M\epsilon+\frac{i}{1920}\hat{\Gamma}^{NPQRS}\hat{\Gamma}_M F_{NPQRS}\epsilon, \tag{30}$$

where ϵ is a ten-dimensional spinor of positive chirality, satisfying

$$\hat{\Gamma}_0\cdots\hat{\Gamma}_9\epsilon=\epsilon. \tag{31}$$

Choosing now $F_{\mu\nu\rho\lambda\sigma}=4m\epsilon_{\mu\nu\rho\lambda\sigma}$ and $F_{ijklm}=4m\epsilon_{ijklm}$, Eq. (30) reduces to

$$D_M\epsilon-\tfrac{1}{2}m(\sigma_1\times\mathbf{1}\times\mathbf{1})\hat{\Gamma}_M\epsilon=0, \tag{32}$$

where we are using the (odd, odd) decomposition of Dirac matrices given in Appendix A. With the ansatz

$$\epsilon=\begin{pmatrix}1\\0\end{pmatrix}\otimes\epsilon_{AdS}\otimes\eta, \tag{33}$$

for a spinor of positive chirality, we obtain the equations for the AdS_5 and S^5 subspaces:

$$\mathrm{AdS}_5: D_\mu\epsilon_{AdS}=\tfrac{1}{2}m\Gamma_\mu\epsilon_{AdS},$$

$$S^5: D_j\eta=\frac{i}{2}m\Gamma_j\eta, \tag{34}$$

which are the standard Killing spinor equations. Putting the AdS and S^n results together, we obtain the explicit expression for the Killing spinors on $\mathrm{AdS}_5\times S^5$,

$$\mathrm{AdS}_5\times S^5\colon \epsilon=e^{(i/2)r\hat{\gamma}\hat{\Gamma}_r}(1+\tfrac{1}{2}x^{\alpha}(i\hat{\gamma}\hat{\Gamma}_{\alpha}+\hat{\Gamma}_r\hat{\Gamma}_{\alpha}))e^{(-i/2)\theta_5\hat{\gamma}\hat{\Gamma}_5}\left(\prod_{j=1}^{4} e^{(-1/2)\theta_j\hat{\Gamma}_{j,j+1}}\right)\epsilon_0, \tag{35}$$

where ϵ_0 is an arbitrary 32-component constant spinor of positive chirality, and $\hat{\gamma}\equiv\hat{\Gamma}^{12345}=-\sigma_2\otimes\mathbf{1}\otimes\mathbf{1}$, where the numerical indices lie in S^5.

Four further analogous examples that arise in lower-dimensional supergravities are

$$\mathrm{AdS}_3\times S^3\colon \epsilon=e^{(-i/2)r\hat{\tilde{\gamma}}\hat{\Gamma}_r}(1+\tfrac{1}{2}x^{\alpha}(-i\hat{\tilde{\gamma}}\hat{\Gamma}_{\alpha}+\hat{\Gamma}_r\hat{\Gamma}_{\alpha}))e^{(-i/2)\theta_3\hat{\gamma}\hat{\Gamma}_3}\left(\prod_{j=1}^{2} e^{(-1/2)\theta_j\hat{\Gamma}_{j,j+1}}\right)\epsilon_0,$$

$$\mathrm{AdS}_3\times S^2\colon \epsilon=e^{(1/2)r\hat{\gamma}\hat{\Gamma}_r}(1+\tfrac{1}{2}x^{\alpha}(\hat{\gamma}\hat{\Gamma}_{\alpha}+\hat{\Gamma}_r\hat{\Gamma}_{\alpha}))e^{(1/2)\theta_2\hat{\gamma}\hat{\Gamma}_2}e^{(-1/2)\theta_1\hat{\Gamma}_{12}})\epsilon_0,$$

$$\mathrm{AdS}_2\times S^3: \epsilon = e^{(i/2)r\hat{\gamma}\hat{\Gamma}_r}(1+\tfrac{1}{2}x(i\hat{\gamma}\hat{\Gamma}_x+\hat{\Gamma}_r\hat{\Gamma}_x))e^{(i/2)\theta_3\hat{\gamma}\hat{\Gamma}_3}\left(\prod_{j=1}^{2} e^{(-1/2)\theta_j\hat{\Gamma}_{j,j+1}}\right)\epsilon_0,$$

$$\mathrm{AdS}_2\times S^2: \epsilon = e^{(i/2)r\hat{\gamma}\hat{\Gamma}_r}(1+\tfrac{1}{2}x(i\hat{\gamma}\hat{\Gamma}_x+\hat{\Gamma}_r\hat{\Gamma}_x))e^{(i/2)\theta_2\hat{\gamma}\hat{\Gamma}_2}e^{(-1/2)\theta_1\hat{\Gamma}_{12}}\epsilon_0,$$

or

$$\epsilon = e^{(1/2)r\hat{\gamma}\hat{\Gamma}_r}(1+\tfrac{1}{2}x(\hat{\gamma}\hat{\Gamma}_x+\hat{\Gamma}_r\hat{\Gamma}_x))e^{(1/2)\theta_2\hat{\gamma}\hat{\Gamma}_2}e^{(-1/2)\theta_1\hat{\Gamma}_{12}}\epsilon_0, \tag{36}$$

where the Dirac matrices are the ones appropriate to the total spacetime dimension in each case. In the case where one or another space in the factored product is even dimensional, $\hat{\gamma}$ is the pseudochirality operator given by the appropriate product of the overcareted Dirac matrices in the even-dimensional factor. For this reason, there are two possibilities in the $\mathrm{AdS}_2\times S^2$ example, reflecting the two possibilities for the Dirac matrix decomposition given in Appendix A. The first corresponds to taking $\hat{\gamma}$ to be the pseudochirality operator in AdS_2, and the second to taking it instead to be in S^2. In the case of $\mathrm{AdS}_3\times S^3$, $\hat{\gamma}\equiv\hat{\Gamma}^{123}=-i\sigma_2\otimes\mathbf{1}\otimes\mathbf{1}$, where the numerical indices lie in S^3, while $\hat{\hat{\gamma}}\equiv\frac{1}{6}\epsilon_{\mu\nu\rho}\hat{\Gamma}^{\mu\nu\rho}=\sigma_1\otimes\mathbf{1}\otimes\mathbf{1}$. In all the examples, ϵ_0 is an arbitrary constant spinor in the total space. It will be subject to a chirality condition in the $\mathrm{AdS}_3\times S^3$ example, if the $D=6$ supergravity is chosen to be the minimal chiral theory, and $\hat{\hat{\gamma}}$ can then be replaced by $\hat{\gamma}$ in the expression for the Killing spinors.

IV. DISCUSSION

In this paper, we have obtained explicit expressions for the Killing spinors on S^n for all n. We then used the results to obtain the full Killing spinors on various $\mathrm{AdS}_m\times S^n$ spacetimes that arise as solutions in supergravity theories. These are of considerable interest owing to the conjectured duality relation to conformal theories on the AdS boundaries. One further application of these results is to construct the Killing vectors, and conformal Killing vectors, from appropriate bilinear products $\epsilon'^{\dagger}\Gamma_i\epsilon$ of Killing spinors. As discussed in Ref. 3, products where the Killing spinors ϵ' and ϵ on S^n either both satisfy (6) or both satisfy (9) give Killing vectors, while products where one satisfies (6) and the other satisfies (9) give conformal Killing vectors. In general, it is necessary to use both of the Killing-vector constructions in order to obtain all the Killing vectors on S^n. At large n there is a considerable redundancy in the construction, since the number of Killing spinors grows exponentially with n, while the number of Killing vectors grows only quadratically with n. In certain low dimensions, there is a more elegant exact spanning of the Killing vectors using this construction, such as for S^7 where the antisymmetric products $\overline{\epsilon^{\alpha}}\Gamma_i\epsilon^{\beta}$ of the eight Killing spinors ϵ^{α} give the 28 Killing vectors of $SO(8)$.[4]

We shall present just one simple example here, for the case of S^2. From the matrix expression (B1) in the appendix, we find that from the Killing spinors $\epsilon=\Omega_2\binom{a}{b}$ and $\epsilon'=\Omega_2\binom{a'}{b'}$, we obtain the Killing vectors,

$$K=K^i\partial_i=E^i_j\epsilon'^{\dagger}\Gamma^j\epsilon=(b\overline{b'}-a\overline{a'})\frac{\partial}{\partial\theta_1}+i(a\overline{b'}e^{-i\theta_1}-\overline{a'}be^{i\theta_1})\frac{\partial}{\partial\theta_2}$$
$$+(a\overline{b'}e^{-i\theta_1}+\overline{a'}be^{i\theta_1})\cot\theta_2\frac{\partial}{\partial\theta_1}, \tag{37}$$

where E^i_j are the components of the inverse vielbein $E_j=E^i_j\partial_i$. Choosing different values for the constants a, b, a', b' spans the complete set of three Killing vectors of $SO(3)$.

ACKNOWLEDGMENTS

We are grateful to Renata Kallosh for posing the question of whether simple explicit expressions for the Killing spinors on S^n can be obtained. J. R. thanks Arvind Rajaraman for useful discussions. APPENDIX A: DIRAC MATRICES AND THEIR DECOMPOSITION ON PRODUCT SPACES

It is useful in general to represent the Dirac matrices in terms of the 2×2 Pauli matrices $\{\sigma_1,\sigma_2,\sigma_3\}$ as follows. In even dimensions $D=2n$, we have

$$\begin{aligned}
\Gamma_1 &= \sigma_1\otimes \mathbb{1}\otimes \mathbb{1}\otimes\cdots\otimes \mathbb{1},\\
\Gamma_2 &= \sigma_2\otimes \mathbb{1}\otimes \mathbb{1}\otimes\cdots\otimes \mathbb{1},\\
\Gamma_3 &= \sigma_3\otimes \sigma_1\otimes \mathbb{1}\otimes\cdots\otimes \mathbb{1},\\
\Gamma_4 &= \sigma_3\otimes \sigma_2\otimes \mathbb{1}\otimes\cdots\otimes \mathbb{1},\\
\Gamma_5 &= \sigma_3\otimes \sigma_3\otimes \sigma_1\otimes\cdots\otimes \mathbb{1},\\
&\ldots,\\
\Gamma_{2n-1} &= \sigma_3\otimes\sigma_3\otimes\cdots\otimes\sigma_3\otimes\sigma_1,\\
\Gamma_{2n} &= \sigma_3\otimes\sigma_3\otimes\cdots\otimes\sigma_3\otimes\sigma_2.
\end{aligned} \tag{A1}$$

In odd dimensions $D=2n+1$, we use the above construction for the Dirac matrices of $2n$ dimensions, and take

$$\Gamma_{2n+1} = \sigma_3\otimes\sigma_3\otimes\sigma_3\otimes\cdots\otimes\sigma_3. \tag{A2}$$

When performing Kaluza–Klein reductions, it is necessary to decompose the Dirac matrices of D dimensions in terms of those of the lower-dimensional spacetime M_m, and the internal space K_n, whose respective dimensions m and n add up to D. There are four cases that arise, namely, $(m,n)=$(even, odd), (odd, even), (even, even) and (odd, odd). If we denote the Dirac matrices of the spacetime M_m by Γ_μ, and those of the internal space K_n by Γ_i, then the Dirac matrices $\hat\Gamma_A$ of $M_m\times K_n$ can be written as

$$\begin{aligned}
&(\text{even, odd}): \hat\Gamma_\mu = \Gamma_\mu\otimes\mathbb{1}, \quad \hat\Gamma_i = \gamma\otimes\Gamma_i,\\
&(\text{odd, even}): \hat\Gamma_\mu = \Gamma_\mu\otimes\gamma, \quad \hat\Gamma_i = \mathbf{1}\otimes\Gamma_i,\\
&(\text{even, even}): \hat\Gamma_\mu = \Gamma_\mu\otimes\mathbb{1}, \quad \hat\Gamma_i = \gamma\otimes\Gamma_i,\\
&\qquad \text{or}\\
&\qquad \hat\Gamma_\mu = \Gamma_\mu\otimes\gamma, \quad \hat\Gamma_i = \mathbf{1}\otimes\Gamma_i,\\
&(\text{odd, odd}): \hat\Gamma_\mu = \sigma_1\otimes\Gamma_\mu\otimes\mathbf{1}, \quad \hat\Gamma_i = \sigma_2\otimes\mathbf{1}\otimes\Gamma_i.
\end{aligned} \tag{A3}$$

Note that in the final case the extra Pauli matrices σ_1 and σ_2 are needed in order to satisfy the Clifford algebra, in view of the fact that the Dirac matrices of D dimensions are twice the size of the simple tensor products of those in M_m and K_n. Note also in this case that the chirality operator in the total space is $\sigma_3 \otimes \mathbf{1} \times \mathbf{1}$.

APPENDIX B: SOME LOW-DIMENSIONAL EXAMPLES

In this appendix, we give explicit matrix expressions for the Killing spinors on the spheres S^2, S^3, S^4, and S^5. These examples arise in the near-horizon structures of Reißner–Nordstrøm black holes, dyonic strings, M5-branes, and D3-branes, respectively. In each case, we may write the expression (7) for the Killing spinors on S^n as $\epsilon = \Omega_n \epsilon_0$. For S^2, taking $\Gamma_i = \sigma_i$, where σ_i are the usual Pauli matrices, we find

$$\Omega_2 = \begin{pmatrix} e^{(-i/2)\theta_1} \cos\frac{1}{2}\theta_2 & e^{(i/2)\theta_1} \sin\frac{1}{2}\theta_2 \\ -e^{(-i/2)\theta_1} \sin\frac{1}{2}\theta_2 & e^{(i/2)\theta_1} \cos\frac{1}{2}\theta_2 \end{pmatrix}. \tag{B1}$$

To avoid clumsy expressions later, we may define $t_k = e^{(i/2)\theta_k}$, $\bar{t}_k = e^{(-i/2)\theta_k}$, $c_k = \cos\frac{1}{2}\theta_k$, $s_k = \sin\frac{1}{2}\theta_k$. The matrix Ω_2 thus becomes

$$\Omega_2 = \begin{pmatrix} \bar{t}_1 c_2 & t_1 s_2 \\ -\bar{t}_1 s_2 & t_1 c_2 \end{pmatrix}. \tag{B2}$$

For S^3, S^4, and S^5 we obtain

$$\Omega_3 = \begin{pmatrix} \bar{t}_1 t_3 c_2 & -i t_1 t_3 s_2 \\ -i \bar{t}_1 \bar{t}_3 s_2 & t_1 \bar{t}_3 c_2 \end{pmatrix}, \tag{B3}$$

$$\Omega_4 = \begin{pmatrix} \bar{t}_1 \bar{t}_3 c_2 c_4 & \bar{t}_1 \bar{t}_3 c_2 s_4 & -i t_1 \bar{t}_3 s_2 s_4 & -i t_1 \bar{t}_3 c_4 s_2 \\ -\bar{t}_1 \bar{t}_3 c_2 s_4 & \bar{t}_1 \bar{t}_3 c_2 c_4 & -i t_1 \bar{t}_3 c_4 s_2 & i t_1 \bar{t}_3 s_2 s_4 \\ i \bar{t}_1 t_3 s_2 s_4 & -i \bar{t}_1 t_3 c_4 s_2 & t_1 t_3 c_2 c_4 & -t_1 t_3 c_2 s_4 \\ -i \bar{t}_1 t_3 c_4 s_2 & -i \bar{t}_1 t_3 s_2 s_4 & t_1 t_3 c_2 s_4 & t_1 t_3 c_2 c_4 \end{pmatrix}, \tag{B4}$$

$$\Omega_5 = \begin{pmatrix} \bar{t}_1 \bar{t}_3 \bar{t}_5 c_2 c_4 & -i \bar{t}_1 \bar{t}_3 \bar{t}_5 c_2 s_4 & -t_1 \bar{t}_3 \bar{t}_5 s_2 s_4 & -i t_1 \bar{t}_3 \bar{t}_5 c_4 s_2 \\ -i \bar{t}_1 \bar{t}_3 \bar{t}_5 c_2 s_4 & \bar{t}_1 \bar{t}_3 \bar{t}_5 c_2 c_4 & -i t_1 \bar{t}_3 \bar{t}_5 c_4 s_2 & -t_1 \bar{t}_3 \bar{t}_5 s_2 s_4 \\ -\bar{t}_1 t_3 t_5 s_2 s_4 & -i \bar{t}_1 t_3 t_5 c_4 s_2 & t_1 t_3 t_5 c_2 c_4 & -i t_1 t_3 t_5 c_2 s_4 \\ -i \bar{t}_1 t_3 t_5 c_4 s_2 & -\bar{t}_1 t_3 t_5 s_2 s_4 & -i t_1 t_3 t_5 c_2 s_4 & t_1 t_3 t_5 c_2 c_4 \end{pmatrix}. \tag{B5}$$

In these examples we have used the representations of Dirac matrices given in Eqs. (A1) and (A2) of appendix A.

Gauge fixation and global phase time for minisuperspaces

Claudio Simeone[a)]

(Received 22 March 1999; accepted for publication 16 April 1999)

Homogeneous and isotropic cosmological models whose Hamilton–Jacobi equation is separable are deparametrized by turning their action functional into that of an ordinary gauge system. Canonical gauge conditions imposed on the gauge system are used to define a global phase time in terms of the canonical coordinates and momenta of the minisuperspaces. The procedure clearly shows how the geometry of the constraint surface restricts the choice of time; the consequences that this has on the path integral quantization are discussed. © *1999 American Institute of Physics.* [S0022-2488(99)00709-4]

I. INTRODUCTION

While in ordinary mechanics the time is an absolute parameter, and this allows for the existence of a unitary quantum theory, in General Relativity the time is an arbitrary label of spacelike hypersurfaces, and physical quantities are invariant under diffeomorfisms. The gravitational field in General Relativity is a parametrized system, its evolution given in terms of a parameter τ which does not have physical significance.

A possible way to obtain a unitary quantum theory of gravitation is to consider that the time is hidden among the coordinates and momenta of the system, which then must be deparametrized by identifying the time as a first step before quantization. The identification of time is closely related to gauge fixation.[1] In the theory of gravitation the dynamical evolution is embodied in the motion of a spacelike hypersurface moving in space–time along the timelike direction; this motion includes arbitrary local deformations which yield a multiplicity of times. From a different point of view, the same motion can be generated by general gauge transformations. Hence, the gauge fixation is not only a way to select one path from each class of equivalent paths in phase space, but also a reduction procedure identifying a time for the system.

In the present work we exploit this fact to identify a global phase time[2] for minisuperspace models whose Hamilton–Jacobi (H–J) equation is solvable. We define a canonical transformation which turns the cosmological models into ordinary gauge systems by matching their Hamiltonian constraint $H\approx 0$ to one of the new momenta, namely P_0, of the gauge system.[3,4] Then we are able to avoid derivative gauges involving Lagrange multipliers,[5,6,7] and to use gauge conditions given in terms of only the coordinates and momenta (*canonical gauges*) to identify a time in terms of the original phase space variables of the cosmological models. The results of Ref. 8 are easily reproduced. We show how the geometry of the constraint surface determines restrictions on the existence of an intrinsic time;[9] we also discuss the consequences that these restrictions have for the path integral quantization of minisuperspaces, making more precise the analysis of Ref. 3.

II. PARAMETRIZED SYSTEMS AND ORDINARY GAUGE SYSTEMS

The action functional of a parametrized system described by the coordinates and momenta (q^i,p_i) has the form

[a)]Electronic mail: simeone@tandar.cnea.gov.ar

$$S[q^i,p_i,N]=\int_{\tau_1}^{\tau_2}\left(p_i\frac{dq^i}{d\tau}-NH\right)d\tau, \tag{1}$$

where N is a Lagrange multiplier enforcing the Hamiltonian constraint

$$H(q^i,p_i)\approx 0; \tag{2}$$

the constraint reflects the reparametrization invariance of the system, i.e., that its evolution is given in terms of the arbitrary parameter τ which does not have physical meaning.

The parametrized system described by (1) can be turned into an ordinary gauge system, that is, a system with a true Hamiltonian and a constraint which is linear and homogeneous in the momenta if the H–J equation is solvable.[3] Consider $W(q^i,\alpha_\mu,E)$ a complete solution of the τ-independent H–J equation,

$$H\left(q^i,\frac{\partial W}{\partial q^i}\right)=E, \tag{3}$$

which is obtained by matching the integration constants (α_μ,E) to $(\overline{P}_\mu,\overline{P}_0)$. The solution W generates a canonical transformation

$$p_i=\frac{\partial W}{\partial q^i},\quad \overline{Q}^i=\frac{\partial W}{\partial \overline{P}_i},\quad \overline{K}=N\overline{P}_0=NH, \tag{4}$$

which identifies the constraint H with the new momentum $\overline{P}_0$. The variables $(\overline{Q}^\mu,\overline{P}_\mu)$ are conserved observables because $[\overline{Q}^\mu,H]=[\overline{P}_\mu,H]=0$, so that they would not be appropriate to characterize the dynamical evolution. A second transformation generated by the function

$$F=P_0\overline{Q}^0+f(\overline{Q}^\mu,P_\mu,\tau) \tag{5}$$

gives

$$\begin{aligned}\overline{P}_0&=\frac{\partial F}{\partial \overline{Q}^0}=P_0,\quad \overline{P}_\mu=\frac{\partial f}{\partial \overline{Q}^\mu},\\ Q^0&=\frac{\partial F}{\partial P_0}=\overline{Q}^0,\quad Q^\mu=\frac{\partial f}{\partial P_\mu},\end{aligned} \tag{6}$$

and a new nonvanishing Hamiltonian

$$K=NP_0+\frac{\partial f}{\partial \tau}=NH+\frac{\partial f}{\partial \tau}, \tag{7}$$

so that (Q^μ,P_μ) are nonconserved observables. The two successive transformations $(q^i,p_i)\to(\overline{Q}^i,\overline{P}_i)\to(Q^i,P_i)$ lead to the action

$$\mathcal{S}=\int_{\tau_1}^{\tau_2}\left(P_i\frac{dQ^i}{d\tau}-NP_0-\frac{\partial f}{\partial \tau}\right)d\tau \tag{8}$$

which in terms of the original variables reads[3]

$$\mathcal{S}=\int_{\tau_1}^{\tau_2}\left(p_i\frac{dq^i}{d\tau}-NH\right)d\tau+[\overline{Q}^i\overline{P}_i-W+Q^\mu P_\mu-f]_{\tau_1}^{\tau_2}, \tag{9}$$

so that $\mathcal{S}$ and S differ only in surface terms and then yield the same dynamics. The action (8) contains a linear and homogeneous constraint $P_0 \approx 0$ and a nonzero Hamiltonian $(\partial f/\partial \tau)$ and is then that of an ordinary gauge system.

III. GAUGE FIXATION AND GLOBAL PHASE TIME

The constraint $P_0 \approx 0$ in Eq. (8) acts as a generator of gauge transformations yielding an infinite number of physically equivalent paths in the (Q^i, P_i) phase space. To select one path from each class of equivalent paths we must impose a gauge condition $\chi = 0$, the choice being restricted by

(1) The gauge condition must can be reached from any path by means of gauge transformations leaving the action unchanged.
(2) Only one point of each orbit (that is, each set of points on the constraint surface connected by gauge transformations) must be on the manifold defined by $\chi = 0$.

To accomplish with (1) the symmetries of the action must be examined; under a gauge transformation generated by a constraint G,

$$\delta_\epsilon Q^i = \epsilon(\tau)[Q^i, G], \quad \delta_\epsilon P_i = \epsilon(\tau)[P_i, G], \quad \delta_\epsilon N = \frac{\partial \epsilon(\tau)}{\partial \tau}, \tag{10}$$

the variation of the action $\mathcal{S}$ is

$$\delta_\epsilon \mathcal{S} = \left[\epsilon(\tau) \left(P_i \frac{\partial G}{\partial P_i} - G \right) \right]_{\tau_1}^{\tau_2} \tag{11}$$

and we have $\delta_\epsilon \mathcal{S} = 0$ for $G = P_0$. Therefore the action $\mathcal{S}$ is gauge invariant over the whole trajectorie and canonical gauge conditions $\chi(Q^i, P_i, \tau) = 0$ are admissible.[3] We should emphasize that if we worked with the original action S, as the constraint in S is $H \approx 0$ and H is not linear and homogeneous in the momenta for a parametrized system, then we should fix the gauge by means of a noncanonical condition involving a derivative of the multiplier N;[5,6] this is clearly not a good choice if we want to define a global phase time in terms of the phase space variables.

Condition (2) requires that a gauge transformation moves a point of an orbit off the surface $\chi = 0$, so that[10]

$$\delta_\epsilon \chi = \epsilon(\tau)[\chi, G] \neq 0$$

unless $\epsilon = 0$; this holds if

$$[\chi, G] \neq 0. \tag{12}$$

As Q^0 and P_0 are conjugate variables,

$$[Q^0, P_0] = 1, \tag{13}$$

so that a gauge condition of the form

$$\chi \equiv Q^0 - T(\tau) = 0 \tag{14}$$

with T a monotonic function is a good choice. Strictly speaking, Eq. (12) only ensures that the orbits are not tangent to the surface $\chi = 0$; however, as (14) defines a plane $Q^0 =$ constant for each τ, if at any τ any orbit was intersected more than once (then yielding Gribov copies[10]) at another τ it should be $[\chi, P_0] = 0$. Therefore our gauge fixation procedure avoids the Gribov problem.

Given a parametrized system with coordinates and momenta (q^i, p_i) a smooth function $t(q^i, p_i)$ fulfilling

$$[t,H]>0 \tag{15}$$

is a global phase time[2] for the system, and its values along any classical trajectory can parametrize its evolution. As the Poisson bracket is invariant under a canonical transformation, from (13) and (15) it follows that a globally good gauge choice given in terms of the coordinate Q^0 of the gauge system can be used to define a global phase time t for the parametrized system in terms of the coordinates and momenta (q^i,p_i). In other words, a gauge choice for the gauge system defines a particular foliation of space–time for the parametrized system. We shall see that for certain minisuperspace models a τ-dependent gauge condition of the form $\chi\equiv Q^0-T(\tau)=0$ defines an extrinsic time, that is, a time which is a function not only of the coordinates q^i but also of the momenta p_i, while an intrinsic time, i.e., a function of the coordinates q^i only, can be defined by means of a gauge condition like $\chi\equiv\eta Q^0P-T(\tau)$ with $\eta=\pm1$ if the potential of the model under consideration has a definite sign; in this situation, the constraint surface splits into two disjoint surfaces, and η is determined by the sheet on which the system evolves.

IV. MINISUPERSPACES

The action of an homogeneous and isotropic Friedmann–Robertson–Walker (FRW) universe is

$$S=\int_{\tau_1}^{\tau_2}(\pi_\phi\dot{\phi}+\pi_\Omega\dot{\Omega}-NH)d\tau \tag{16}$$

where ϕ is the matter field, $\Omega=\sqrt{(4/3\pi\mathcal{G})}\ln a(\tau)$ with $a(\tau)$ the scale factor in the FRW metric, and π_ϕ and π_Ω are their conjugate momenta; N is a Lagrange multiplier enforcing the Hamiltonian constraint[11]

$$H=G(\Omega)(\pi_\phi^2-\pi_\Omega^2)+v(\phi,\Omega)\approx0, \tag{17}$$

where $G(\Omega)>0$ and $v(\phi,\Omega)$ is the potential. Our aim is not to study the separability of the H–J equation in general, but to get a clear understanding of the details and also of the restrictions of deparametrizing minisuperspaces by imposing canonical gauge conditions; then we shall limit our analysis to easily solvable models.

A. A toy model

Consider the Hamiltonian constraint

$$H=-\tfrac{1}{4}e^{-3\Omega}\pi_\Omega^2+e^\Omega\approx0 \tag{18}$$

which corresponds to an open ''universe'' with null cosmological constant. For this model the authors of Ref. 8 found a time of the form

$$t\sim-e^{-4\Omega/3}\pi_\Omega \tag{19}$$

by matching the model to the parametrized system called ''ideal clock,'' whose Hamiltonian is $\tilde{H}=p_t-t^2\approx0$. They did it by performing a canonical transformation $(t,p_t)\rightarrow(\Omega,\pi_\Omega)$ and multiplying $\tilde{H}$ by a positive definite function of the form $\sim e^{-\Omega/3}$ to obtain H. Then we shall apply our procedure to the constraint $H'=e^{\Omega/3}H$,

$$H'=-\tfrac{1}{4}e^{-8\Omega/3}\pi_\Omega^2+e^{4\Omega/3}\approx0. \tag{20}$$

The constraint H' is equivalent to H because they differ only in a positive definite factor (see below). The τ-independent H–J equation associated with the Hamiltonian H' is

$$-\left(\frac{\partial W}{\partial \Omega}\right)^2 + 4e^{4\Omega} = 4e^{8\Omega/3}E, \tag{21}$$

and then matching $E=\overline{P}_0$ we have

$$W(\Omega,\overline{P}_0) = \pm \int 2\sqrt{e^{4\Omega} - \overline{P}_0 e^{8\Omega/3}}\, d\Omega, \tag{22}$$

with $+$ for $\pi_\Omega > 0$ and $-$ for $\pi_\Omega < 0$. According to Eq. (6), on the constraint surface

$$Q^0 = \overline{Q}^0 = \left[\frac{\partial W}{\partial \overline{P}_0}\right]_{\overline{P}_0=0} = \mp e^{2\Omega/3}. \tag{23}$$

The system described by Q^0 and P_0 has a constraint which is linear and homogeneous in the momenta. Its action functional is then invariant under general gauge transformations, so that there is gauge freedom at the end points and canonical gauges are admissible. If we choose $\chi \equiv Q^0 - T(\tau) = 0$ with T a monotonic function of τ then we have a global phase time that can be written in terms of the coordinate Ω only, the expression given by the sheet of the constraint surface on which the system evolves,

$$\begin{aligned} t(\Omega) &= -e^{2\Omega/3} \quad \text{if} \quad \pi_\Omega > 0, \\ t(\Omega) &= +e^{2\Omega/3} \quad \text{if} \quad \pi_\Omega < 0. \end{aligned} \tag{24}$$

As on the constraint surface we have

$$\pi_\Omega = \pm 2e^{2\Omega}, \tag{25}$$

then we can write

$$t(\Omega,\pi_\Omega) = -\tfrac{1}{2} e^{-4\Omega/3} \pi_\Omega, \tag{26}$$

which clearly agrees with (19).

B. True degrees of freedom

Let us go back to the general constraint (17). We shall restrict our analysis to the cases in which the potential $v(\phi,\Omega)$ has a definite sign. As the cases $v>0$ and $v<0$ are formally analogous, to simplify the notation we shall consider only $v>0$. Define the coordinates

$$x = x(\phi+\Omega), \quad y = y(\phi-\Omega), \tag{27}$$

so that $(\partial x/\partial\phi) = (\partial x/\partial\Omega)$, $(\partial y/\partial\phi) = -(\partial y/\partial\Omega)$. The momenta π_x, π_y are given by

$$\pi_\phi = \frac{\partial x}{\partial \phi}\pi_x + \frac{\partial y}{\partial \phi}\pi_y, \quad \pi_\Omega = \frac{\partial x}{\partial \Omega}\pi_x + \frac{\partial y}{\partial \Omega}\pi_y, \tag{28}$$

and then $\pi_\phi^2 - \pi_\Omega^2 = 4(\partial x/\partial\phi)(\partial y/\partial\phi)\pi_x\pi_y = -4(\partial x/\partial\Omega)(\partial y/\partial\Omega)\pi_x\pi_y$. If it is possible to choose the coordinates x and y so that $4(\partial x/\partial\phi)(\partial y/\partial\phi) = (v/G)$, as $(v/G)>0$ then we can multiply the constraint H by $(4G(\partial x/\partial\phi)(\partial y/\partial\phi))^{-1}$ and obtain a constraint H' which is equivalent to H because it differs only in a positive definite factor,

$$H' = \pi_x\pi_y + 1 \approx 0. \tag{29}$$

We shall turn the system described by (x,y,π_x,π_y) into an ordinary gauge system. The τ-independent H–J equation for the constraint (29) is

$$\frac{\partial W}{\partial x}\frac{\partial W}{\partial y}+1=E'$$

and matching the integration constants α, E' to the new momenta $\overline{P},\overline{P}_0$ it has the solution

$$W(x,y,\overline{P}_0,\overline{P})=\overline{P}x+y\left(\frac{\overline{P}_0-1}{\overline{P}}\right); \tag{30}$$

then

$$\begin{gathered}\pi_x=\frac{\partial W}{\partial x}=\overline{P},\quad \pi_y=\frac{\partial W}{\partial y}=\frac{\overline{P}_0-1}{\overline{P}},\\ \overline{Q}^0=\frac{\partial W}{\partial \overline{P}_0}=\frac{y}{\overline{P}},\quad \overline{Q}=\frac{\partial W}{\partial \overline{P}}=x+y\left(\frac{1-\overline{P}_0}{\overline{P}^2}\right).\end{gathered} \tag{31}$$

To go from the set $(\overline{Q}^i,\overline{P}_i)$ to (Q^i,P_i) we define

$$F=\overline{Q}^0P_0+\overline{Q}P+\frac{T(\tau)}{P} \tag{32}$$

with $T(\tau)$ a monotonic function (see the next section for a discussion about this choice). Then we have the canonical variables of the gauge system in terms of those of the minisuperspace,

$$\begin{gathered}P_0=\pi_x\pi_y+1,\quad P=\pi_x,\\ Q^0=\frac{y}{P},\quad Q=x+\left(\frac{y(1-P_0)-T(\tau)}{P^2}\right).\end{gathered} \tag{33}$$

There is no problem with P as a denominator because $P=\pi_x$ cannot be zero on the constraint surface.

As $[Q^0,P_0]=1$ we have $[y/\pi_x,H']=1$; H' differs from H in a positive definite factor, namely a, so that $1=[y/\pi_x,H']=[y/\pi_x,aH]=[y/\pi_x,a]H+[y/\pi_x,H]a\approx[y/\pi_x,H]a$; hence

$$[y/\pi_x,H]>0 \tag{34}$$

and a canonical gauge condition of the form $\chi\equiv Q^0-T(\tau)=0$ with T a monotonic function of τ, when imposed on the gauge system described by Q^i and P_i defines a global phase time $t\equiv y/\pi_x$ for the minisuperspace described by ϕ, Ω, π_ϕ, π_Ω. From (28) we have $\pi_x=(\pi_\phi+\pi_\Omega)(2(\partial x/\partial\phi))^{-1}$ and therefore

$$t(\phi,\Omega,\pi_\phi,\pi_\Omega)=2\,\frac{y(\phi-\Omega)}{\pi_\phi+\pi_\Omega}\,\frac{\partial x(\phi+\Omega)}{\partial\phi}. \tag{35}$$

The monotonic function of τ given by (35) depends on the coordinates and also on the momenta of the cosmological model, and is then an extrinsic time.

We can also identify a time in terms of the coordinates only, but, as we shall see, the definition depends on the sheet of the constraint surface on which the system evolves. The gauge choice

$$\chi \equiv \eta Q^0 P - T(\tau) = 0 \tag{36}$$

with $\eta = \pm 1$ gives

$$[\chi, P_0] = \eta P \tag{37}$$

and as $\eta Q^0 P = \eta y$ and $P = \pi_x$ we have

$$[\eta y, H'] = \eta \pi_x . \tag{38}$$

As before, as H' and H differ in a positive definite factor, if we can define η so that $[\eta y, H'] > 0$ then $[\eta y, H] > 0$ and ηy is a global phase time. We can chose $(\partial x/\partial \phi)$ as a positive definite function (and appropriately adjust the sign of $(\partial y/\partial \phi)$) to yield sign$(\pi_x) =$ sign$(\pi_\phi + \pi_\Omega)$. From the constraint equation we have

$$\pi_\Omega = \pm \sqrt{\frac{v(\phi,\Omega)}{G(\Omega)} + \pi_\phi^2} \tag{39}$$

and because v/G is positive definite, $\pi_\Omega \neq 0$ and the evolution of the system is restricted to one of the two disjoint surfaces (39), each one topologically equivalent to half a plane. Moreover, from (39) we have $|\pi_\Omega| > |\pi_\phi|$, yielding sign$(\pi_x) > 0$ for $\pi_\Omega > 0$ and sign$(\pi_x) < 0$ for $\pi_\Omega < 0$. Hence we can have a good definition of time on each sheet of the constraint surface by appropriately choosing η, the choice dictated by the sign of the momentum π_Ω,

$$\begin{aligned} t(\phi,\Omega) &= +y(\phi - \Omega) \quad \text{if} \quad \pi_\Omega > 0, \\ t(\phi,\Omega) &= -y(\phi - \Omega) \quad \text{if} \quad \pi_\Omega < 0. \end{aligned} \tag{40}$$

Therefore, even though we can not write a single expression which holds for both sheets of the constraint surface, if v has a definite sign, once we have on which sheet the system evolves we can identify a time in terms of the coordinates (intrinsic time). If, instead, we want an expression which holds automatically, that is, which does not depend on the sign of π_Ω, we must choose a time like that given in (35).

Examples:

(1) Consider a flat model with massless scalar field ϕ and a cosmological ''constant'' which decays with ϕ as $\Lambda = \Lambda_0 e^{-6\phi}$,

$$H = \tfrac{1}{4} e^{-3\Omega}(\pi_\phi^2 - \pi_\Omega^2) + \Lambda_0 e^{-6\phi} e^{3\Omega} \approx 0. \tag{41}$$

This constraint is equivalent to

$$H' = \pi_\phi^2 - \pi_\Omega^2 + 4\Lambda_0 e^{-6(\phi-\Omega)} \approx 0,$$

making the choice of variables $x = \phi + \Omega$, $y = -(\Lambda_0/6) e^{-6(\phi-\Omega)}$ obvious; by turning the system into an ordinary gauge system with coordinates and momenta (Q^0, Q, P_0, P) and fixing the gauge with the canonical condition $\chi \equiv Q^0 - T(\tau) = 0$ with T monotonic function we obtain the time

$$t(\phi,\Omega,\pi_\phi,\pi_\Omega) = -\frac{1}{3}\frac{\Lambda_0 e^{-6(\phi-\Omega)}}{\pi_\phi + \pi_\Omega}, \tag{42}$$

which on the constraint surface is equivalent to

$$t(\pi_\phi, \pi_\Omega) = \tfrac{1}{2}(\pi_\phi - \pi_\Omega).$$

The system also has an intrinsic time, which according to (40) can be written as

$$t=\mp\frac{\Lambda_0}{6}e^{-6(\phi-\Omega)},$$

with $-$ if the system is on the sheet $\pi_\Omega>0$ and $+$ if it is on the sheet $\pi_\Omega<0$.

(2) A closed ($k=1$) model with cosmological constant $\Lambda>0$ and massless scalar field ϕ, whose Hamiltonian constraint is

$$H=\tfrac{1}{4}e^{-3\Omega}(\pi_\phi^2-\pi_\Omega^2)-e^{\Omega}+\Lambda e^{3\Omega}\approx 0 \tag{43}$$

is not separable in terms of the variables $x(\phi+\Omega)$, $y(\phi-\Omega)$; moreover, its potential has not a definite sign. However, it is easy to show that the time obtained for the case $k=0$ (flat model) is also a global phase time for the case $k=1$. Then consider the constraint

$$H_0=\tfrac{1}{4}e^{-3\Omega}(\pi_\phi^2-\pi_\Omega^2)+\Lambda e^{3\Omega}\approx 0 \tag{44}$$

which is equivalent to

$$H_0'=\pi_\phi^2-\pi_\Omega^2+4\Lambda e^{6\Omega}\approx 0.$$

By choosing $y=-(1/3)e^{3(\Omega-\phi)}$, $x=(1/3)e^{3(\Omega+\phi)}$ the same procedure used in the preceding example gives the extrinsic time

$$t=-2/3\,\frac{\Lambda e^{6\Omega}}{\pi_\phi+\pi_\Omega}\approx\frac{1}{6}(\pi_\phi-\pi_\Omega). \tag{45}$$

Note that if we want to verify that this function is a global phase time also for the case $k=1$ we should not write it as $\tfrac{1}{6}(\pi_\phi-\pi_\Omega)$ because the last equality holds only on the surface $H_0\approx 0$. If we calculate the Poisson bracket of $t=-2/3[\Lambda e^{6\Omega}/(\pi_\phi+\pi_\Omega)]$ with the constraint $H'=4e^{3\Omega}H$ we obtain $[t,H']=[t,H_0']+[t,-4e^{4\Omega}]$, which, as it is easy to check, is the sum of two positive terms. As the constraints H and H' are equivalent, then we have

$$[t,H]>0,$$

and t is a global phase time also for the model given by (43).

C. Geometry of the constraint surface

Our deparametrization procedure gives a simple way to examine how the geometrical properties of the constraint surface impose restrictions on the definition of a global phase time. Consider the Hamiltonian constraint of the most general case of a FRW empty cosmological model,

$$H=-\tfrac{1}{4}e^{-3\Omega}\pi_\Omega^2-ke^{\Omega}+\Lambda e^{3\Omega}\approx 0 \tag{46}$$

with $k=\pm 1$ and $\Lambda>0$. For this model the authors of Ref. 8 found an extrinsic time

$$t\sim -e^{-2\Omega}\pi_\Omega \tag{47}$$

after performing a canonical transformation on the ideal clock and multiplying the constraint by a positive definite function of the form $\sim e^{\Omega}$. Then we shall apply our procedure to the constraint $H'=e^{-\Omega}H$,

$$H'=-\tfrac{1}{4}e^{-4\Omega}\pi_\Omega^2-k+\Lambda e^{2\Omega}\approx 0. \tag{48}$$

The constraints H and H' are equivalent because they differ only in a positive definite factor. The τ-independent H–J equation for the Hamiltonian H' is

$$-\left(\frac{\partial W}{\partial \Omega}\right)^2 - 4ke^{4\Omega} + 4\Lambda e^{6\Omega} = 4e^{4\Omega}E \tag{49}$$

and matching $E=\overline{P_0}$ we obtain the solution

$$W(\Omega,\overline{P_0}) = \pm \int 2e^{2\Omega}\sqrt{\Lambda e^{2\Omega} - k - \overline{P_0}}\, d\Omega, \tag{50}$$

with + for $\pi_\Omega > 0$ and − for $\pi_\Omega < 0$. According to Eq. (6), on the constraint surface we have

$$Q^0 = \overline{Q}^0 = \left[\frac{\partial W}{\partial \overline{P_0}}\right]_{\overline{P_0}=0} = \mp \Lambda^{-1}\sqrt{\Lambda e^{2\Omega} - k}. \tag{51}$$

If we fix the gauge by means of the canonical condition $\chi \equiv Q^0 - T(\tau) = 0$ with T a monotonic function of τ then we have that

$$t = \theta(-\pi_\Omega)\Lambda^{-1}\sqrt{\Lambda e^{2\Omega} - k} - \theta(\pi_\Omega)\Lambda^{-1}\sqrt{\Lambda e^{2\Omega} - k} \tag{52}$$

is a global phase time for the system. As on the constraint surface we have

$$\pi_\Omega = \pm 2e^{2\Omega}\sqrt{\Lambda e^{2\Omega} - k} \tag{53}$$

[so that in the case $k=1$ the natural size of the configuration space is given by $\Omega \geqslant -\ln(\sqrt{\Lambda})$ (Ref. 2)] then we can write

$$t(\Omega,\pi_\Omega) = -\tfrac{1}{2}\Lambda^{-1}e^{-2\Omega}\pi_\Omega, \tag{54}$$

which is in agreement with (47). Now an important difference between the cases $k=-1$ and $k=1$ arises; for $k=-1$ the potential has a definite sign, and the constraint surface splits into two disjoint sheets given by (53). In this case the evolution can be parametrized by a function of the coordinate Ω only, the choice given by the sheet on which the system remains, and we then say that it has an intrinsic time; if the system is on the sheet $\pi_\Omega > 0$ the time is $t = -\Lambda^{-1}\sqrt{\Lambda e^{2\Omega} - k}$, and if it is on the sheet $\pi_\Omega < 0$ we have $t = \Lambda^{-1}\sqrt{\Lambda e^{2\Omega} - k}$. For $k=1$, instead, the potential can be zero and the topology of the constraint surface is no more analogous to that of two disjoint planes. Although for $\Omega = -\ln(\sqrt{\Lambda})$ we have $v(\Omega)=0$ and $\pi_\Omega = 0$, it is easy to verify that $\dot{\pi}_\Omega \neq 0$ at this point. Hence, in this case the coordinate Ω does not suffice to parametrize the evolution, because the system can go from (Ω,π_Ω) to $(\Omega,-\pi_\Omega)$; therefore we must necessarily define a global phase time as a function of the coordinate and the momentum (extrinsic time); $t=t(\Omega,\pi_\Omega)$. This, of course, generalizes to the case of models with true degrees of freedom.

A remark should be made, and it is that we have multiplied H by different positive functions to make calculations simpler, or to obtain times that we could compare with previous results; different rescalings of the Hamiltonian constraint would lead to different times, but—at least at the classical level—they would be equivalent.

D. Path integral quantization

Suppose that we want to quantize a cosmological model described by (q^i,p_i) by means of a path integral in terms of the variables (Q^i,P_i) given by (33). As we showed in a previous paper,[4] this has practical advantages, for example, when trying to avoid the Gribov problem. If we pretend the quantum amplitude $\langle Q_2^i | Q_1^i \rangle$ to be equivalent to $\langle q_2^i | q_1^i \rangle$ we should verify that the paths in the integral are weighted by the action $\mathcal{S}$ in the same way that they are weighted by S, and that the quantum states $|Q^i\rangle$ are equivalent to $|q^i\rangle$. As the path integral in the variables (Q^i,P_i) is gauge invariant, this requirement is fulfilled if it is possible to impose a—globally good—gauge condition $\overline{\chi}=0$ such that $\tau=\tau(q^i)$ is defined, and such that the boundary terms in (9) vanish. This is the reason why we chose the generating function for $\overline{X^i}\to X^i$ as in (32); with this choice the boundary terms in (9) vanish if we fix the gauge by means of $\chi\equiv\eta PQ^0-T(\tau)=0;$ when written in terms of the original variables, this gauge condition involves only the coordinates q^i, and is associated to the identification of an intrinsic time.

An intrinsic time, however, can be defined only if the constraint surface splits into two disjoint sheets, that is, if the potential has a definite sign. In the most general case the definition of a global phase time must necessarily involve also the momenta, and then we cannot fix the gauge in the path integral in such a way that $\tau=\tau(q^i)$ [see the last example, where $t=-1/2\Lambda^{-1}e^{-2\Omega}\pi_\Omega \approx T(\tau)$, so that $\tau=\tau(\Omega,\pi_\Omega)$]. Hence, if we want to quantize the system by imposing canonical gauges in the path integral, in the most general case of a potential with a nondefinite sign we must admit the possibility of identifying the quantum states in the original phase space not by q^i but by a complete set of functions of the coordinates and momenta q^i and p_i.

V. CONCLUSIONS

Although gauge fixation and the identification of a global phase time are closely related, as the action of parametrized systems—like the gravitational field—is not gauge invariant at the boundaries, we could not, in principle, use this fact to obtain a direct procedure to deparametrize minisuperspaces; while ordinary gauge systems admit gauge conditions of the type $\chi(q^i,p_i,\tau)=0$, only derivative gauges would be admissible for parametrized systems. Then we would not be able to identify a time for a cosmological model as a function of its canonical variables by imposing on the system a gauge condition which is compatible with the symmetries of the action.

However, if the H–J equation is separable, a parametrized system described by (q^i,p_i) can be turned into an ordinary gauge system described by (Q^i,P_i) by matching H with P_0, and canonical gauges are therefore admissible. Then we are able to identify a global phase time for cosmological models in terms of their coordinates and momenta by imposing τ-dependent canonical gauge conditions on the ordinary gauge system. We have illustrated our procedure with simple models whose H–J equation is easily solvable. We have been able to show that sometimes a global phase time for a quite trivial model is also a good time for a more physical system (example 2); however, we believe that this is not the best way to proceed, because in a general case it would only work if we impose restrictions on the parameters of the model (as it happens when we consider a massive scalar field, when a relation between Λ and m should exist). Of course, a complete solution of the H–J equation is, in general, difficult to obtain; an example of a more interesting model to be studied could be the Bianchi type-IX universe, which is the anisotropic generalization of the closed FRW model, and whose H–J equation is solvable.[12]

Our procedure clearly shows the restrictions arising from the geometry of the constraint surface; a global phase time in terms of the coordinates q^i can be defined only if the potential of the model has a definite sign; in this case, the choice is determined by the sheet of the constraint surface on which the system evolves. In the most general case, a global phase time must be a function of the coordinates and the momenta; at the quantum level, our method completes the analysis of Ref. 3, clearly showing the relation existing between the geometrical properties of the constraint surface and the possibility of identifying the quantum states in the path integral by means of only the original coordinates.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 40, NUMBER 9 SEPTEMBER 1999

Exact solutions to sourceless charged massive scalar field equation on Kerr–Newman background

S. Q. Wu[a)] and X. Cai[b)]
Institute of Particle Physics, Hua-Zhong Normal University, Wuhan 430079, People's Republic of China

(Received 18 February 1999; accepted for publication 30 April 1999)

The covariant Klein–Gordon equation in the Kerr–Newman black hole geometry is separated into a radial part and an angular part. It is discovered that in the nonextreme case, these two equations belong to a generalized spin-weighted spheroidal wave equation. Then general exact solutions in integral forms and several special solutions with physical interest are given. While in the extreme case, the radial equation can be transformed into a generalized Whittaker–Hill equation. In both cases, five-term recurrence relations between coefficients in power series expansion of general solutions are presented. Finally, the connection between the radial equations in both cases is discussed.
[S0022-2488(99)01608-4]

I. INTRODUCTION

Since the Hawking effect[1] on a black hole was found, the evaporation of a black hole has been investigated in several coordinates by miscellaneous methods such as the path integral approach,[2] tortoise coordinate (r_*) transformation,[3,4] and r_*-coordinate analytical extension,[4] etc. Among these methods, the generalized tortoise transformation method has been used widely in the discussions, not only on the evaporation of a static black hole and a stationary black hole, but also on that of nonstationary ones.[3] Much more progress has been made. But this method cannot give an exact solution of the radial (r_*) equation, the radial wave function, which can be analyzed only in an asymptotic expression.

Couch[5] obtained a series of exact solutions by transforming the separated radial equation into a modified Whittaker–Hill equation under some special conditions. But these solutions seem to have nothing to do with the discussion on black hole evaporation.

Solutions to the generalized spheroidal wave equation have been studied to some extent[6,7] by using power series expansions around regular singular points, so that three-term recurrence relations between coefficients can be manipulated in terms of the continued fraction method. Leaver[6] has shown that Teukolsky master equations in Kerr geometry are, in fact, spin-weighted generalized spheroidal wave equations.

It appears to be more important to obtain an exact solution to the radial equation, for this is crucial in discussing the Hawking effect of a black hole. However, it is very difficult to do so. It is this motivation that stimulates our present research. Our main aim in this paper is to show that the separated radial part of a massive covariant Klein–Gordon equation on the Kerr–Newman black hole (KNBH) background is a generalized spin-weighted spheroidal wave equation of imaginary number order. In this paper, we shall discuss the solutions to a massive complex scalar field in the KNBH geometry with three parameters. In the nonextreme case, its general solutions of the separated parts are spin-weighted generalized spheroidal wave functions,[6–8] and some special solutions to the radial equation with physical interest are given. General solutions to the radial equation in the extreme case shall be briefly discussed. Finally, we show that the radial

[a)]Electronic mail: emu@iopp.ccnu.edu.cn
[b)]Electronic mail: xcai@wuhan.cngb.com

equation in the extreme case is a confluent equation of that in the nonextreme case.

In Sec. II we deal with the variable separation of a sourceless complex scalar field on KNBH and solutions to the angular part. In Sec. III and IV, the radial equation is solved in both nonextreme and extreme cases, respectively. In Sec. III A we reduce the radial equation to standard form, and in Secs. III B and III C we obtain general solutions and special ones including case $(\omega=\mu=0)$, respectively. Five-term recurrences between coefficients of solutions in power series forms are given in both cases. In addition, we give solutions in integral forms and some special solutions of physical interest in the nonextreme case. Conditions for general solutions exist and are given in these two cases. Section V is devoted to discussing the connection between the radial equation in the extreme case and that in the nonextreme case. Finally, we point out some probable applications and generalization of exact solutions in Sec. VI.

In the Appendix, three-term recurrence relations between coefficients in power series expansions around regular singular points for a generalized spheroidal wave equation are presented.

II. SEPARATION OF KLEIN–GORDON EQUATION AND SOLUTION TO THE ANGULAR EQUATION

The Kerr–Newman line element and electromagnetic one-form are given in the Boyer-Lindquist coordinates as follows:[4,9]

$$\begin{aligned} ds^2 &= g_{\mu\nu}\,dx^\mu\,dx^\nu \\ &= -\frac{\Delta}{\Sigma}(dt-a\sin^2\theta\,d\varphi)^2+\frac{\sin^2\theta}{\Sigma}[a\,dt-(r^2+a^2)d\varphi]^2+\Sigma\left(\frac{dr^2}{\Delta}+d\theta^2\right), \end{aligned} \tag{1}$$

$$\mathcal{A}=A_\mu\,dx^\mu=\frac{-er}{\Sigma}(dt-a\sin^2\theta\,d\varphi), \tag{2}$$

with event horizon function $\Delta=r^2-2Mr+a^2+e^2$, and $\Sigma=r^2+a^2\cos^2\theta$, where mass M, charge e, specific angular momentum $a=J/M$ being three parameters to describe KNBH. (Use Planck units system $G=\hbar=c=1$, and denote $\partial_\mu=\partial/\partial x^\mu$).

The determinant of the KNBH metric tensor is $g=\det(g_{\mu\nu})=-\Sigma^2\sin^2\theta$, while the electromagnetic four-vector potential A_μ apparently satisfies the following covariant Lorentz gauge condition:

$$\nabla_\mu A^\mu=\frac{1}{\sqrt{-g}}\partial_\mu(\sqrt{-g}g^{\mu\nu}A_\nu)=0. \tag{3}$$

In curved spacetime, a sourceless scalar field Φ with mass μ and charge q obeys the covariant Klein–Gordon equation (KGE):

$$(\Box_c-\mu^2)\Phi=0, \tag{4}$$

where the d'Alembert operator $\Box_c$ on the KNBH background is given by

$$\begin{aligned} \Box_c &\equiv \frac{1}{\sqrt{-g}}D_\mu(\sqrt{-g}g^{\mu\nu}D_\nu) \\ &= \frac{1}{\Sigma}\left\{\frac{-1}{\Delta}[(r^2+a^2)\partial_t+a\partial_\varphi+iqer]^2+\partial_r(\Delta\partial_r)\right. \\ &\quad \left.+\left(a\sin\theta\partial_t+\frac{1}{\sin\theta}\partial_\varphi\right)^2+\frac{1}{\sin\theta}\partial_\theta(\sin\theta\partial_\theta)\right\}, \end{aligned} \tag{5}$$

the covariant gauge differential operator here being $D_\mu=\partial_\mu-iqA_\mu$.

The scalar wave function Φ for the KGE of Eq. (4) has a solution of variables separable form $\Phi(t,r,\theta,\varphi)=R(r)S(\theta)e^{i(m\varphi-\omega t)}$:[9]

$$\frac{1}{\Delta}[\omega(r^2+a^2)-qer-ma]^2\Phi+\partial_r(\Delta\,\partial_r\Phi)-\mu^2\Sigma\Phi -\left(a\omega\sin\theta-\frac{m}{\sin\theta}\right)^2\Phi+\frac{1}{\sin\theta}\partial_\theta(\sin\theta\,\partial_\theta\Phi)=0. \tag{6}$$

The separated results of the above equation are

$$\partial_r[\Delta\,\partial_r R(r)]+\left\{\frac{[\omega(r^2+a^2)-qer-ma]^2}{\Delta}-\mu^2(r^2+a^2)-\lambda+2ma\omega\right\}R(r)=0 \tag{7}$$

and

$$\frac{1}{\sin\theta}\partial_\theta[\sin\theta\,\partial_\theta S(\theta)]+\left[\lambda-\frac{m^2}{\sin^2\theta}+(\mu^2-\omega^2)a^2\sin^2\theta\right]S(\theta)=0, \tag{8}$$

where λ is a separation constant.

The general solutions to the angular part are ordinary spheroidal angular wave functions[8,10] with spin weight $s=0$. When $a^2(\omega^2-\mu^2)=0$, these solutions degenerate to Legendre spherical functions.

Let $x=\cos\theta$, $S(\theta)=S(x)=(1-x^2)^{m/2}\Theta(x)$, Eq. (8) should take the following forms:

$$(1-x^2)S''(x)-2xS'(x)+\left[\lambda-\frac{m^2}{1-x^2}+a^2(\omega^2-\mu^2)(x^2-1)\right]S(x)=0 \tag{9}$$

and

$$(1-x^2)\Theta''(x)-2(1+m)x\Theta'(x)+[\lambda-m(m+1)+a^2(\omega^2-\mu^2)(x^2-1)]\Theta(x)=0. \tag{10}$$

Here and after, $S'(x)=\partial S(x)/\partial x$, etc.

The eigenfunctions to Eqs. (9) and (10) are generalized spheroidal wave functions[6–8] $S(x)=S_l^{m,0}(c,x)$ with eigenvalue $\lambda=\lambda_{ml}+c^2$, $c^2=a^2(\mu^2-\omega^2)$. When $\mu=0$, Eqs. (9) and (10) are special cases ($s=0$) of the following spin-weighted spheroidal wave equations:[6–8,10]

$$(1-x^2)P''(x)-2xP'(x)+\left[a^2\omega^2x^2-2a\omega sx-\frac{(m+sx)^2}{1-x^2}+s+\lambda'\right]P(x)=0 \tag{11}$$

and

$$(1-x^2)Q''(x)-2[s+(1+m)x]Q'(x) +[\lambda'-(m-s)(m+s+1)-2a\omega sx+a^2\omega^2x^2]Q(x)=0, \tag{12}$$

where $P(x)=(1-x)^{|m+s|/2}(1+x)^{|m-s|/2}Q(x)$ and $x=\cos\theta$.

When $a\omega=0$, the solutions to the above equations are Jacobi ultrasphere D functions[10] $D_{m,s}^l(x)$ or spin-weighted spherical harmonic functions[11] with eigenvalue $\lambda'=l(l+1)-s(s+1)$, $l=\max(|m|,|s|)$. In the general case, the solutions should be the generalized spin-weighted spheroidal wave functions[6–8] $P(x)=P_{m,s}^l(c,x)$, $c^2=-a^2\omega^2$. By taking account of some reasonable boundary conditions, these solutions could be a set of orthogonal polynomials.

In the following, we shall assume that all parameters, M,e,a,μ,q,m, are nonzero, and discuss the radial equation of Eq. (7) according to two cases, namely, the nonextreme case $(M^2\neq a^2+e^2)$ and the extreme case $(M^2=a^2+e^2)$. The special case $(\omega=\mu=0)$ will be included in Sec. III C.

III. SOLUTIONS TO THE RADIAL EQUATION IN THE NONEXTREME CASE $(M^2\neq a^2+e^2)$

A. Simplification of the radial equation in the case $(\epsilon\neq 0)$

In this case, we put $\epsilon=\sqrt{M^2-a^2-e^2}$ $(0<\epsilon<M)$. After making substitutions of $r=M+\epsilon z$ and $R(r)=R(z)=(z-1)^{i|B+A|/2}(z+1)^{i|B-A|/2}F(z)$, the exterior horizon and interior horizon are located at points $r_\pm=M\pm\epsilon$, $(z=\pm 1)$, respectively, the radial equation of Eq. (7) can be reduced to the following standard forms:

$$(z^2-1)R''+2zR'+\left[\epsilon^2(\omega^2-\mu^2)(z^2-1)+2\epsilon(A\omega-M\mu^2)z+\frac{(Az+B)^2}{z^2-1}\right.$$
$$\left.+(2\omega^2-\mu^2)(2M^2-e^2)-2qeM\omega-\lambda\right]R=0 \quad (1<z<\infty) \tag{13}$$

and

$$(z^2-1)F''+2[iA+(1+iB)z]F'+[\epsilon^2(\omega^2-\mu^2)(z^2-1)+2\epsilon(A\omega-M\mu^2)z$$
$$+(2\omega^2-\mu^2)(2M^2-e^2)-2qeM\omega-\lambda+A^2-B^2+iB]F=0 \quad (1<z<\infty), \tag{14}$$

where $A=2M\omega-qe$, $\epsilon B=\omega(2M^2-e^2)-qeM-ma$.

In order to study behaviors of solutions to Eqs. (13) and (14) in the interval $(-1<z<1)$, we rotate first T from the real axis to the imaginary axis $T=i\tau$ after making substitution of $z=\cosh T=\cosh(i\tau)=\cos\tau$, then return to the real z axis $z=\cos\tau$. Therefore, Eqs. (13) and (14) have corresponding forms in the interval $(|z|<1)$ as follows:

$$(1-z^2)R''-2zR'+\left[\epsilon^2(\omega^2-\mu^2)(z^2-1)+2\epsilon(A\omega-M\mu^2)z-\frac{(Az+B)^2}{1-z^2}\right.$$
$$\left.+(2\omega^2-\mu^2)(2M^2-e^2)-2qeM\omega-\lambda\right]R=0 \quad (-1<z<1) \tag{15}$$

and

$$(1-z^2)G''-2[A+(1+B)z]G'+[\epsilon^2(\omega^2-\mu^2)(z^2-1)+2\epsilon(A\omega-M\mu^2)z$$
$$+(2\omega^2-\mu^2)(2M^2-e^2)-2qeM\omega-\lambda+A^2-B^2-B]G=0 \quad (|z|<1), \tag{16}$$

where we have made a function transformation,

$$R(z)=(1-z)^{|B+A|/2}(1+z)^{|B-A|/2}G(z).$$

The essence of our manipulation is that we extend the domain of z from the real axis to the complex z plane $z=x+iy$ at first and then make an analytical extension on the complex z plane from the region outside the unit circle $(|z|>1)$ to that inside it $(|z|<1)$. The handled issue is that only derivative terms change to a negative sign, while the nonderivative terms, namely, terms in square brackets, make no change in symbol. This method is equivalent to that Eqs. (13)–(16) are solved initially and then the solutions are made an analytical extension on the complex z plane.

Both Eqs. (13) and (14) are the generalized spin-weighted spheroidal wave equation[6–8] with an imaginary number order, while both Eqs. (15) and (16) with a real number order. The formers are suitable, especially to study problems about the scattering state, whereas the latters are more convenient to investigate energy levels of bound states. Furthermore, we can apparently find out the connection between poles of scattering amplitudes and energy levels of bound states. Actually, the domain in which z takes values in Eqs. (13) and (14) is on the x axis, while those in Eqs. (15) and (16) on the y axis. So these equations can be thought of as equivalence. However, to be convenient, we have made a restriction on intervals that z takes values of $1<z<\infty$ in Eqs. (13) and (14), while of $|z|<1$ in Eqs. (15) and (16).

When $\mu=0$ or $M=0$, if taking $R_1(z_1)$ as the first solution to Eq. (15) in the interval of $|z|<1$, then $R_2(z_2)$, the second one to the same equation in that of $|z|>1$, might be

$$R_2(z_2)=(z_2-1)^{|B+A|/2}(z_2+1)^{|B-A|/2}\int_{-1}^{+1}e^{i\epsilon\omega z_2 z_1}(1-z_1)^{|B+A|/2}(1+z_1)^{|B-A|/2}R(z_1)dz_1. \tag{17}$$

Here, we have assumed that $\omega>0$. The integral equation of Eq. (17) connects the irregular solution $R_2(z_2)$ with the regular solution $R_1(z_1)$.

Comparing Eqs. (9)–(12) with Eqs. (13)–(16), especially Eqs. (11) and (12) with Eqs. (15) and (16), we can draw a conclusion that the separated angular and radial equations are ordinary differential equations of the same type, generalized spin-weighted spheroidal wave equations.[6–8] Furthermore, we discover that ϵ, A, B correspond to $-a$, $-s$, $-m$, respectively, when $\mu=0$. There may exist three pairs of power series solutions to generalized spheroidal wave equations around singular points $z=\pm1,\infty$, respectively. Added with some proper boundary conditions, these power series expansions of spheroidal wave functions can be cut off to be polynomials.

Therefore, in the following section, we shall only study the generalized spheroidal wave equation. The reader who has more interest in this equation can find more information in Refs. 6 and 7 (and references cited therein).

B. General solutions to the radial equation ($\epsilon\neq 0$)

The standard generalized spin-weighted spheroidal wave equation that we reduce to study is as follows:

$$(1-z^2)W''(z)-2[\alpha+(\beta+1)z]W'(z)+[\gamma^2(z^2-1)+2\,\delta z+\bar{\lambda}-\beta]W(z)=0, \tag{18}$$

where $\bar{\lambda}$ is a redefined eigenvalue that could make $W(z)$ finite at $z=\pm1$, and the region of z' taking values could be the whole complex z plane.

(i) For the radial equation of Eq. (16), we have

$$\alpha=A, \quad \beta=B, \quad \gamma^2=\epsilon^2(\omega^2-\mu^2), \quad \delta=\epsilon(A\omega-M\mu^2).$$

(ii) For the angular equation of Eq. (12), we have

$$\alpha=s, \quad \beta=m, \quad \gamma^2=a^2\omega^2, \quad \delta=-as\omega.$$

(iii) For the angular equation of Eq. (10), we have

$$\alpha=0, \quad \beta=m, \quad \gamma^2=a^2(\omega^2-\mu^2), \quad \delta=0.$$

The form of Eq. (18) is invariant both under the Laplace transformation and by changing parameters $\alpha,\beta,\gamma^2,\delta,z$ into $-\alpha,\beta,\gamma^2,-\delta,-z$, respectively. Namely, $W(z)=W(\alpha,\beta,\gamma,\delta;z)$ satisfies the following integral equation:

$$\int_0^{+\infty}e^{-tz}W(\alpha,\beta,\gamma,\delta;z)dz=W\left(\frac{\delta}{\gamma},-\beta,\gamma,-\alpha\gamma;\frac{t}{\gamma}\right)=W\left(\frac{-\delta}{\gamma},-\beta,\gamma,\alpha\gamma;\frac{-t}{\gamma}\right), \tag{19}$$

$$W(\alpha,\beta,\gamma,\delta;z)=W(-\alpha,\beta,\gamma,-\delta;-z)=\int_0^{+\infty}e^{-\gamma zt}W\left(\frac{-\delta}{\gamma},-\beta,\gamma,\alpha\gamma;t\right)dt. \tag{20}$$

The above formulas are integral solutions to Eq. (18). If one knows a solution, then he can obtain another by integral transformations of Eqs. (19) and (20). It is obvious that solutions are symmetry under the following condition:

$$\alpha=\delta=0 \quad (\gamma\neq 0).$$

This just is the case (iii). At this moment, the symmetric solutions are ordinary spheroidal angular wave functions.[10]

Now, we consider a solution to the generalized spheroidal equation of Eq. (18), which is in power series form in the interval of $-1<z<1$. According to the knowledge of an ordinary differential equation, one can know that Eq. (18) has two regular singularities $(z=\pm 1)$ and one confluently irregular singular point $(z=\infty)$. As $z=0$ is its ordinary point, we can make a Taylor expansion of $W(z)$ in the vicinity of ordinary point $(z=0)$:

$$W(z)=W_n(z)=\sum_{n=0}^{\infty}a_nz^n \quad (|z|<1). \tag{21}$$

Substituting the power series of Eq. (21) into Eq. (18), we obtain five-term recurrence relations between coefficients as follows:

$$(\bar{\lambda}-\gamma^2-\beta)a_0-2\alpha a_1+2a_2=0,$$

$$2\delta a_0+[\bar{\lambda}-\gamma^2-\beta-(2+2\beta)]a_1-4\alpha a_2+a_3=0,$$

$$\gamma^2a_0+2\delta a_1+[\bar{\lambda}-\gamma^2-\beta-2(3+2\beta)]a_2-6\alpha a_3+12a_4=0,$$

$$\cdots\cdots$$

$$\gamma^2a_{n-2}+2\delta a_{n-1}+[\bar{\lambda}-\gamma^2-\beta-n(n+1+2\beta)]a_n-2(n+1)\alpha a_{n+1}+(n+2)(n+1)a_{n+2}=0.$$

Redefine coefficients:

$$A_n=\frac{\gamma^2}{\bar{\lambda}-\gamma^2-\beta-n(n+1+2\beta)},$$

$$B_n=\frac{2\delta}{\bar{\lambda}-\gamma^2-\beta-n(n+1+2\beta)},$$

$$C_n=\frac{-2(n+1)\alpha}{\bar{\lambda}-\gamma^2-\beta-n(n+1+2\beta)},$$

$$D_n=\frac{(n+2)(n+1)}{\bar{\lambda}-\gamma^2-\beta-n(n+1+2\beta)}.$$

When taking limits $n\to\infty$, we have A_n, B_n, $C_n\to 0$, and $D_n\to -1$.

Then, five-term recurrence relations become

$$A_na_{n-2}+B_na_{n-1}+a_n+C_na_{n+1}+D_na_{n+2}=0. \tag{22}$$

After arranging coefficients A_n, B_n, C_n, D_n and making up them into a quasidiagonal band matrix Λ and $a_0, a_1, \ldots, a_n, \ldots,$ into a column vector $\vec{a} = (a_0, a_1, \ldots, a_n, \ldots)$, the above recurrence relations become an infinite tridiagonal matrix equation:

$$\Lambda \vec{a} = h \vec{a}. \tag{23}$$

The condition for solutions of Eq. (23) exist is that determinant of Λ is zero,

$$\det(\Lambda) = \begin{vmatrix} 1 & C_0 & 0 & 0 & 0 & 0 & 0 & 0\cdots \\ B_1 & 1 & C_1 & D_1 & 0 & 0 & 0 & 0\cdots \\ A_2 & B_2 & 1 & C_2 & D_2 & 0 & 0 & 0\cdots \\ 0 & A_3 & B_3 & 1 & C_3 & D_3 & 0 & 0\cdots \\ & & & \cdots & \cdots & & & \\ 0 & 0 & A_n & B_n & 1 & C_n & D_n & 0\cdots \\ & & & \cdots & \cdots & & & \end{vmatrix} = 0. \tag{24}$$

In fact, this condition could be satisfied, and we have $\det(\Lambda) \to 0$ when $n \to \infty$.

Matrix equation of Eq. (23), together with the determinant equation of Eq. (24) determines coefficients $a_0, a_1, \ldots, a_n, \ldots,$ and eigenvalue $\bar{\lambda}$, hence, eigenvalue $\bar{\lambda}$ will be a complicated function of $\alpha, \beta, \gamma, \delta$, as well as n. The second power series solution around the same point $z = 0$ can be obtained by Frobenius' method. To be finite at $z = \pm 1$, power series $W(z)$ could be truncated to be polynomial, and $\alpha, \beta, \gamma, \delta$ could be integers or half-integers. While in the general case, solutions to spin-weighted generalized spheroidal equation of Eq. (18) are transcendental functions.[6,7]

Absolutely, solution $W_n(z) = W_n(\alpha, \beta, \gamma, \delta; z)$ of Eq. (18) can be orthonormalized to constitute a set of complete functions:

$$\int_{-1}^{1} (1-z)^{\beta+\alpha} (1+z)^{\beta-\alpha} W_n(z) W_{n'}(z) dz = \delta_{n,n'}. \tag{25}$$

Solutions $W_n(z)$ at infinity can have asymptotic forms $W_n(z) \to e^{\mp \gamma z}$, $(z \to \pm \infty,\ \gamma > 0)$. This is consistent with that the Minkowski spacetime is an asymptotic spacetime of the Kerr–Newmann black hole. Thus, an ingoing wave and an outgoing wave at infinity can take the form of plane waves.

C. Special solutions to the radial equation in the case ($\epsilon \neq 0$)

In this section, we will base our discussion upon Eq. (15), namely,

$$(1-z^2) R''(z) - 2z R'(z) + \left[\gamma^2 (z^2 - 1) + 2\delta z - \frac{(\beta + \alpha z)^2}{z^2 - 1} \right.$$
$$\left. + (2\omega^2 - \mu^2)(2M^2 - e^2) - 2qeM\omega - \lambda \right] R(z) = 0 \quad (|z| < 1), \tag{26}$$

where

$$\gamma^2 = \epsilon^2 (\omega^2 - \mu^2), \quad \delta = \epsilon (A\omega - M\mu^2),$$

$$\alpha = A = 2M\omega - qe, \quad \beta = B = \frac{\omega(2M^2 - e^2) - qeM - ma}{\epsilon}.$$

Case 1: when $\gamma=\delta=0$, there exist three situations:
(i) $\omega=\pm\mu=qe/M\neq 0$ $(\alpha\neq 0)$; (ii) $\omega=\mu=qe/M=0$ $(\alpha=0)$ (This case can be thought of as a special one in the above-head case); (iii) $\omega=\mu=0$, $qeM\neq 0$ $(\alpha\neq 0)$.

Solutions in situations (i) and (iii) are Jacobi ultrasphere functions $R(z)=P_n^{(\beta+\alpha,\beta-\alpha)}(z)$,[10] whereas solutions in situation (ii) degenerate to be Legendre functions, $R(z)=P_n^{\beta}(z)$, or $Q_n^{\beta}(z)$.

Case 2: when $M\mu^2=0$, $\omega\neq 0$, $\delta/(\epsilon\omega)=\alpha$, this case has been considered in detail by Leaver.[6]

Case 3: when $\alpha=\delta=0$, $\gamma\neq 0$, Eqs. (26) is an ordinary spheroidal wave equation,[10] and its solutions are Prolate spheroidal angular wave functions $R(z)=S_n^{\beta,0}(\gamma,z)$.

Obviously, all these solutions are special cases of general solutions $R_n^{(\beta+\alpha,\beta-\alpha)}(\gamma,\delta;z)=(1-z)^{(\beta+\alpha)/2}(1+z)^{(\beta-\alpha)/2}W_n(\alpha,\beta,\gamma,\delta;z)$.

Solutions in Case 1 will be particularly important in physics to black hole evaporation, as a scattering cross section, stationary state energy levels, emission coefficients of black hole radiation, etc., could be analytically computed at an exact theoretical level by the use of Jacobi polynomials. Furthermore, there maybe exist special symmetry in such a case.

IV. SOLUTIONS TO THE RADIAL EQUATION IN THE EXTREME CASE $(M^2=a^2+e^2)$

In the extreme KNBH case $(\epsilon=0)$, we make the substitution $r=M(1+x)$; then the event horizon is located at a single point $(r_h=M)$, namely, $x=0$; hence the radial equation of Eq. (7) can be transformed into the following confluent equation:

$$x^2R''(x)+2xR'(x)+\Big[(\omega^2-\mu^2)M^2x^2+2(A\omega-M\mu^2)Mx + \left(A+\frac{\mathcal{B}}{x}\right)^2+(2\omega^2-\mu^2)(2M^2-e^2)-2qeM\omega-\lambda\Big]R(x)=0, \tag{27}$$

where $A=2M\omega-qe$, $M\mathcal{B}=B\epsilon=\omega(2M^2-e^2)-qeM-ma$.

Defining

$$C^2=M^2(\omega^2-\mu^2),\quad D=M(A\omega-M\mu^2),$$

$$\lambda_e=(2\omega^2-\mu^2)(2M^2-e^2)-2qeM\omega-\lambda-\tfrac{1}{4}+A^2,$$

and making substitutions

$$x=e^{i\nu\xi},\quad R(x)=R(\xi)=e^{-i\nu\xi/2}H(\xi);$$

then Eq. (27) is transformed into the generalized Whittaker–Hill equation (GWHE):

$$-\nu^{-2}H''(\xi)+[C^2e^{2i\nu\xi}+2De^{i\nu\xi}+2A\mathcal{B}e^{-i\nu\xi}+\mathcal{B}^2e^{-2i\nu\xi}+\lambda_e]H(\xi)=0. \tag{28}$$

Solutions of GWHE of Eq. (28) can be regarded formally as

$$H(\xi)=\sum_{n=-\infty}^{+\infty}g_ne^{in\nu\xi},\quad n=0,\pm 1,\pm 2,\ldots. \tag{29}$$

Substituting Eq. (29) into Eq. (28), we obtain five-term recurrence relations between coefficients:

$$C^2g_{n-2}+2Dg_{n-1}+(\lambda_e+n^2)g_n+2A\mathcal{B}g_{n+1}+\mathcal{B}^2g_{n+2}=0,$$

$$E\vec{g}=h_e\vec{g}=\sum_{n=-\infty}^{+\infty}\sum_{m=n-2}^{n+2}E_{m,n}g_n, \tag{30}$$

where we have recast recurrence relations in matrix form in Eq. (30), and defined matrix elements,

$$E_{n,n-2}=\frac{C^2}{\lambda_e+n^2},\quad E_{n,n-1}=\frac{2D}{\lambda_e+n^2},$$

$$E_{n,n}=1,\quad E_{n,n+1}=\frac{2A\mathcal{B}}{\lambda_e+n^2},\quad E_{n,n+2}=\frac{\mathcal{B}^2}{\lambda_e+n^2}.$$

The condition that solutions of simultaneous equations in Eq. (30) exist is that determinant det(E) must be zero, that is,

$$\det(E)=0, \tag{31}$$

$$\det|E-h_eI|=0. \tag{32}$$

The secular equation of Eq. (32) is a characteristic equation that determines the existence of periodic solutions of Eq. (29). Solutions $R(\xi)$ could be functions with period $4\pi/\xi$. There exist four series of periodic functions according to the period being odd or even. Equation (27) has two confluently irregular singular points $x=0,\infty$. Behaviors of its solutions at event horizon $r_h=0$ $(x=0)$ depend upon that of $R(\xi)$ at $\xi\rightarrow\pm i\infty$ (according to ν being a negative number or a positive number).

V. CONNECTION BETWEEN THE RADIAL EQUATION IN NONEXTREME CASE AND THAT IN EXTREME CASE

In this section, we illustrate that the radial equation of Eq. (27) in the extreme case is a confluent form of Eq. (13) in the nonextreme case, and give an expression to the first thermodynamic law in the extreme KNBH case.

After making substitutions of $\epsilon=M\varepsilon$, $\varepsilon z=x$, $\epsilon z=Mx$, $\mathcal{B}=\varepsilon B$, $(0<\varepsilon<1)$ in Eq. (13), we have

$$r=M+\epsilon z=M(1+x),\quad \Delta=\epsilon^2(z^2-1)=M^2(x^2-\varepsilon^2),$$

$$A=2M\omega-qe,\quad \epsilon B=M\mathcal{B}=\omega(2M^2-e^2)-qeM-ma.$$

Then Eq. (13) is equivalent to the following one in the nonextreme case:

$$\frac{\partial}{\partial x}\left[(x^2-\varepsilon^2)\frac{\partial R(x)}{\partial x}\right]+\left[M^2(\omega^2-\mu^2)(x^2-\varepsilon^2)+2M(A\omega-M\mu^2)x\right.$$
$$\left.+\frac{(Ax+\mathcal{B})^2}{x^2-\varepsilon^2}+(2\omega^2-\mu^2)(2M^2-e^2)-2qeM\omega-\lambda\right]R(x)=0. \tag{33}$$

Equation (33) has two regular singular points $x=\pm\varepsilon$ $(z=\pm1)$ that are located at the exterior horizon and the interior horizon (Cauchy surface) $r_\pm=M\pm\epsilon=M(1\pm\varepsilon)$, respectively, along with another irregular singular point $x=\infty$. After taking limits $\varepsilon\rightarrow0$, $x^2-\varepsilon^2\rightarrow x^2$, Eq. (33) in the nonextreme case tends to Eq. (27) in the extreme case. The latter has two confluently irregular singular points $x=0,\infty$. The irregular singular point $x=0$ that is located at event horizon $r_h=M$ in the extreme case is just one to which two irregular singular points $x=\varepsilon$ and $x=-\varepsilon$ in the nonextreme case concur when ε or $\epsilon\rightarrow0$.

In the extreme KNBH case $(M^2=a^2+e^2)$, surface gravity $\kappa_h=0$, event horizon $r_h=M$, reduced event horizon area $A_h=M^2+a^2=2M^2-e^2$, the first thermodynamic law of the extreme Kerr–Newman black hole is expressed as follows:

$$dM=\Omega_h\,dJ+\Phi_h de, \tag{34}$$

where $\Phi_h=(er_h)/A_h$, and $\Omega_h=a/A_h$ are the electric potential and angular velocity at the event horizon $(r_h=M)$, respectively.

VI. CONCLUSION

In this paper, a sourceless charged massive scalar Klein–Gordon field equation has been separated into the angular and radial parts. The separated equations are all generalized spin-weighted spheroidal wave equations. In the nonextreme case, we present general solutions in power series expansion and that of integral forms, as well as several special solutions with physical interest for the radial equation. These solutions can be orthonormalized to a set of complete functions. In addition, they have asymptotic behaviors of plane waves at infinity. On the base of these orthogonal functions or polynomials, we can expand the wave function of a complex scalar field to a quantized Klein–Gordon field on the Kerr–Newman background. In the extreme case, the radial equation can be reduced to a modified Whittaker–Hill equation. In both cases, we obtain five-term recurrence relations between coefficients in power series expansions.

At the base of this work, the quantum conservation laws about the Hawking process and the probable generalization to black hole thermodynamic laws can be discussed further. It is anticipated that the separated parts of the Dirac equation in the Kerr–Newman geometry could be reduced to the forms of a generalized spheroidal wave equation.

APPENDIX

In this appendix, we present three-term recurrence relations between coefficients in power series expansions around regular singular points $(z=\pm 1)$ for spin-weighted spheroidal wave equation of Eq. (18), namely,

$$(1-z^2)W_n''(z)-2[a+(b+1)z]W_n'(z)+[c^2(z^2-1)+2\,dz+\lambda_n-b]W_n=0 \quad (-1<z<1). \tag{A1}$$

Equation (A1) has two regular singular points $z=1$ and $z=-1$, with indices $\rho_-=0,-a-b$ and $\rho_+=0,a-b$, respectively. When $c,d\to 0$, $W_n(z)$ must tend to Jacobi polynomials.

Introducing a symbol $\epsilon=\mp 1$, we denote these two regular singular points $z=\pm 1=-\epsilon$. Then, we make power series expansions around regular singular points $z=-\epsilon$, respectively, where we have written them in a united manner:

$$W_n(z)=e^{-cz}\sum_{n=0}^{\infty} f_n(1+\epsilon z)^n. \tag{A2}$$

Substituting the above regular solutions of Eq. (A2) into Eq. (A1), we obtain three-term recurrence relations between coefficients as follows:

$$(1+b-\epsilon a)f_1+[\lambda_0+2ac-b-2\epsilon(bc+c+d)]f_0=0,$$

$$\cdots$$

$$(n+1)(n+1+b-\epsilon a)f_{n+1}+[\lambda_n+2ac-b-2\epsilon(bc+c+d)$$
$$-n(n+1+2b+4\epsilon c)]f_n+4\epsilon(nc+bc+d)f_{n-1}=0.$$

After defining coefficients,

$$A_n=\lambda_n+2ac-b-2\epsilon(bc+c+d)-n(n+1+2b+4\epsilon c),$$

$$B_n=(n+1)(n+1+b-\epsilon a),$$

$$C_n=4\epsilon[(n+b)c+d],$$

recurrence relations for the first term and the nth term can be written as

$$B_0 f_1+A_0 f_0=0,$$

$$B_n f_{n+1}+A_n f_n+C_n f_{n-1}=0. \tag{A3}$$

Three-term recurrence relations of Eq. (A3) can be handled by the continued fraction method,[6,7] or by the matrix method (see Liu's paper in Ref. 7) as we can array A_n, B_n, C_n to make up a generalized Jacobi tridiagonal band matrix. Similar three-term recurrence relations can also be obtained by expansions in the light of Jacobi polynomials, but the coefficients A_n, B_n, C_n will be more complicated than those presented here.

The second regular solutions around the same points can be easily obtained by Frobenius' method, and we have not presented them here. Irregular solutions are connected with these regular ones by integrals similar to those in Eqs. (19) and (20).

In order to make $W_n(z)$ finite at $z=\pm 1$, $W_n(z)$ must be truncated to be polynomials, then $W_n(z)$ is orthonormalized with eigenvalue λ_n and weight $(1-z)^{b+a}(1+z)^{b-a}$. Hence we have

$$\int_{-1}^{+1}(1-z)^{b+a}(1+z)^{b-a}W_m(z)W_n(z)dz=\delta_{m,n}. \tag{A4}$$

The Battle–Lemarié wavelet or Daubechies' compact support wavelets[12] can be used in numerical computation for the matrix equation of Eq. (A3) and to prove the convergence of polynomials $W_n(z)$, but we do not pursue this goal here.

(Received 16 October 1998; accepted for publication 16 June 1999)

We study a pair of commuting difference operators arising from the elliptic $C_2^{(1)}$-face model. The operators, whose coefficients are expressed in terms of the Jacobi's elliptic theta function, act on the space of meromorphic functions on the weight space of the C_2-type simple Lie algebra. We show that the space of functions spanned by the level one characters of the affine Lie algebra $\widehat{\mathfrak{sp}}(4,\mathbb{C})$ is invariant under the action of the difference operators. © *1999 American Institute of Physics.* [S0022-2488(99)03109-6]

I. INTRODUCTION

In Ref. 1, one of the authors constructed an L operator for Belavin's elliptic quantum R matrix[2] acting on the space of meromorphic functions on the weight space of the A_n-type simple Lie algebra. The traces of the L operator, the transfer matrices, give rise to a family of commuting difference operators with an elliptic theta function coefficient. In Ref. 3, they are actually equivalent to Rnijsenaars' operators,[4] which are elliptic extensions of Macdonald's q-difference operators.[5] Our aim in the present paper is to take a step toward a generalization of the above construction to the root systems other than the type A. In this paper, we construct a pair of commuting difference operators acting on the space of functions on the C_2-type weight space.

In the construction of Refs. 1 and 3, a relation between Belavin's elliptic quantum R matrix and the face-type solution of the Yang–Baxter equation (YBE),[6] especially the *intertwining vectors*,[7,8] played the central role. For the root systems other than type A, it is known that no vertex-type R-matrices nor the intertwining vectors. Nevertheless, the face-type solutions of the YBE are known for all classical Lie algebras and their vector representations.[6] We will utilize this type of solution to introduce the difference operators. We take traces (see Sec. V) of the fused Boltzmann weights to obtain a pair of difference operators (Theorem 1).

We also show that the space that is spanned by the level one characters of the affine Lie algebra $\widehat{\mathfrak{sp}}(4,\mathbb{C})$ is invariant under the action of the difference operators (Theorem 2).

The plan of this paper is as follows. In Sec. II, we prepare the notation used in the text and state the main results. In Sec. III, we review the $C_n^{(1)}$-face model[6] in the vector representation, which was given by a set of functions called Boltzmann weights. In Sec. IV, we introduce the *path space*, on which the set of Boltzmann weights act naturally as linear maps and thereby explain the notion of the so-called *fusion procedure* (see, for example, Ref. 3 and references therein). We also give a set of formulas for *fused* Boltzmann weights, which leads to the explicit formula of our difference operators [Theorem 1,(ii)]. In Sec. V, we prove the commutativity of the difference operators. In Sec. VI, we prove a property that the difference operators preserve a three-

[a)]Electronic mail: kojihas@math.tohoku.ac.jp
[b)]Electronic: mail: ike@xmath.ous.ac.jp
[c)]Electronic mail: tkikuchi@math.tohoku.ac.jp

dimensional subspace spanned by the level one characters of the affine Lie algebra $\widehat{\mathfrak{sp}}(4,\mathbb{C})$.[9] In the Appendix, we give a formula of a similarity transformation of the Boltzmann weights.

Our result can be seen as a type C generalization of the Felder and Varchenko work,[10] where they showed that the Ruijsenaars system of difference operators can be recovered from the dynamical R matrices, which is nothing but the face-type solution of the YBE.

On the other hand, a BC_n generalization of the Macdonald polynomial theory is studied by Koornwinder.[11] In Ref. 12, van Diejen constructed the corresponding family of q-difference operators and he studied its elliptic extension in Ref. 13. He succeeded in constructing two elliptic commuting operators: one is of the first order and the other is of the nth order, so that they give rise to an elliptic extension of difference quantum Calogero–Moser system of type BC_2[12] in $n=2$. It is likely that our operators can be identified with his system with a special choice of parameters. We hope to report on this issue in the near future.

Extending this work by van Diejen, Hikami and Komori recently obtained a general family of n-commuting difference operators with elliptic function coefficients.[14,15] Besides the step parameter of difference operators and the modulus of elliptic functions, the family contains ten arbitrary parameters. Their construction uses the Shibukawa–Ueno elliptic R operator,[16] together with the elliptic K operators,[17,18] the elliptic solution to the reflection equation, and can be regarded as an elliptic generalization of the Dunkl-type operator approach to those systems, which have been extensively used by Cherednik[19] (see Ref. 20 for the BC_n case). It would be interesting if one can find an explicit relationship between their approach and ours.

II. NOTATION AND RESULTS

Let $\mathfrak{h}$ be a fixed Cartan subalgebra of the simple Lie algebra $\mathfrak{g}:=\mathfrak{sp}(4,\mathbb{C})$ and denote by $\mathfrak{h}^*$ the dual space of $\mathfrak{h}$. We realize the root system R for $(\mathfrak{g},\mathfrak{h})$ as $R:=\{\pm(\epsilon_1\pm\epsilon_2),\pm 2\epsilon_1,\pm 2\epsilon_2\}\subset\mathfrak{h}^*$. A normalized Killing form (,) is given by $(\epsilon_j,\epsilon_k)=\frac{1}{2}\delta_{jk}$. We will often identify the space $\mathfrak{h}$ and its dual $\mathfrak{h}^*$ via the form (,). The fundamental weights are given by $\varpi_1=\epsilon_1$, $\varpi_2=\epsilon_1+\epsilon_2$. Let $\mathcal{P}_d$ be the set of weights for the fundamental representation $L(\varpi_d)$. We have

$$\mathcal{P}_1=\{\pm\epsilon_1,\pm\epsilon_2\},\quad \mathcal{P}_2=\{\pm(\epsilon_1\pm\epsilon_2),0\}. \tag{2.1}$$

Note that, in these cases, the multiplicity of the weights are all one.

Fix an elliptic modulus τ in the upper half-plane $\Im\tau>0$ and a generic nonzero complex number $\hbar$. Let $[u]$ denote the Jacobi theta function with elliptic nome $p:=e^{2\pi i r}(\Im\tau>0)$, defined by

$$[u]:=ip^{1/8}\sin\pi u\prod_{m=1}^{\infty}(1-2p^m\cos 2\pi u+p^{2m})(1-p^m).$$

This is an odd function and has the following quasiperiodicity:

$$[u+m]=(-1)^m[u],\quad [u+m\tau]=(-1)^m e^{-\pi i m^2\tau-2\pi i m u}[u]\quad (m\in\mathbb{Z}). \tag{2.2}$$

Let d,d' be 1 or 2. Then the $C_2^{(1)}$-type Boltzmann weights of the type (d,d') are given as follows. For any square

$$\begin{pmatrix}\lambda & \mu\\ \kappa & \nu\end{pmatrix}\quad (\lambda,\mu,\nu,\kappa\in\mathfrak{h}^*)$$

of weights, the Boltzmann weight

$$W_{dd'}\left(\begin{matrix}\lambda & \mu\\ \kappa & \nu\end{matrix}\middle| u\right)$$

is given as a function of the spectral parameter $u \in \mathbb{C}$. See the next section for the explicit formula for W_{11}, which are expressed by the Jacobi theta function.

They satisfy the condition:

$$W_{dd'}\left(\begin{matrix} \lambda & \mu \\ \kappa & \nu \end{matrix}\middle| u\right)=0, \quad \text{unless} \quad \mu-\lambda, \nu-\kappa \in 2\hbar\mathcal{P}_d, \quad \kappa-\lambda, \nu-\mu \in 2\hbar\mathcal{P}_{d'},$$

and solve the YBE,

$$\sum_\eta W_{dd'}\left(\begin{matrix} \rho & \eta \\ \sigma & \kappa \end{matrix}\middle| u-v\right) W_{dd''}\left(\begin{matrix} \lambda & \mu \\ \rho & \eta \end{matrix}\middle| u-w\right) W_{d'd''}\left(\begin{matrix} \mu & \nu \\ \eta & \kappa \end{matrix}\middle| v-w\right)$$
$$=\sum_\eta W_{d'd''}\left(\begin{matrix} \lambda & \eta \\ \rho & \sigma \end{matrix}\middle| v-w\right) W_{dd''}\left(\begin{matrix} \eta & \nu \\ \sigma & \kappa \end{matrix}\middle| u-w\right) W_{dd'}\left(\begin{matrix} \lambda & \mu \\ \eta & \nu \end{matrix}\middle| u-v\right). \tag{2.3}$$

The original Boltzmann weights in Ref. 6 are of the type (1,1) in the above terminology. We generalized it by the fusion procedure (see Sec. IV) for the present purpose.

For $\lambda \in \mathfrak{h}^*$ and $p \in \mathcal{P}_d (d=1,2)$, we put

$$\lambda_p := (\lambda, p).$$

Theorem 1: *Let* $M_d(u)$ $(u \in \mathbb{C}, d=1,2)$ *be the following difference operators acting on the space of functions on* $\mathfrak{h}^*$,

$$(M_d(u)f)(\lambda) := \sum_{p \in \mathcal{P}_d} W_{d2}\left(\begin{matrix} \lambda & \lambda+2\hbar p \\ \lambda & \lambda+2\hbar p \end{matrix}\middle| u\right) T_{\hat{p}} f(\lambda),$$

where $T_{\hat{p}} f(\lambda) := f(\lambda+2\hbar p)$.

(i) *We have* $M_d(u)M_{d'}(v)=M_{d'}(v)M_d(u)$ $(u,v \in \mathbb{C}, d,d'=1,2)$.

(ii) *Let us define the following difference operators independent of the spectral parameter* u:

$$\tilde{M}_1 := \sum_{p \in \mathcal{P}_1} \prod_{\substack{q \in \mathcal{P}_1 \\ q \neq \pm p}} \frac{[\lambda_{p+q}-\hbar]}{[\lambda_{p+q}]} T_{\hat{p}},$$

$$\tilde{M}_2 := \sum_{\substack{p=\pm\epsilon_1 \\ q=\pm\epsilon_2}} \left(\frac{[\lambda_{p+q}-\hbar]}{[\lambda_{p+q}+\hbar]} T_{\hat{p}} T_{\hat{q}} + \frac{[2\hbar]}{[6\hbar]} \frac{[2\lambda_p+2\hbar]}{[2\lambda_p]} \frac{[2\lambda_q+2\hbar]}{[2\lambda_q]} \frac{[\lambda_{p+q}-5\hbar]}{[\lambda_{p+q}+\hbar]} \frac{[\lambda_{p+q}+2\hbar]}{[\lambda_{p+q}]} \right).$$

Then we have $M_1(u)=F(u)\tilde{M}_1$, $M_2(u)=G(u)(\tilde{M}_2-H(u))$, *where*

$$F(u) := \frac{[u][u+2\hbar]^2[u+4\hbar]}{[-3\hbar]^2[\hbar]^2},$$

$$G(u) := \frac{[u-\hbar][u]^2[u+\hbar][u+2\hbar][u+3\hbar]^2[u+4\hbar]}{[-3\hbar]^4[\hbar]^4}, \tag{2.4}$$

and

$$H(u) := \frac{[u+6\hbar][u-3\hbar][2\hbar]}{[u][u+3\hbar][6\hbar]}.$$

In Sec. VI, we introduce a space of Weyl group-invariant theta functions, which are preserved by the actions of the difference operators. For $\beta\in\mathfrak{h}^*$, we introduce the following operators $S_{\tau\beta}$, S_β acting on the functions on $\mathfrak{h}^*$:

$$(S_{\tau\beta}f)(\lambda):=\exp[2\pi i((\lambda,\beta)+\tau(\beta,\beta)/2)]f(\lambda+\tau\beta),$$

$$(S_\beta f)(\lambda):=f(\lambda+\beta).$$

They satisfy Heisenberg's relations,

$$S_\beta S_\gamma=S_\gamma S_\beta,\quad S_{\tau\beta}S_{\tau\gamma}=S_{\tau\gamma}S_{\tau\beta},\quad S_\gamma S_{\tau\beta}=e^{2\pi i(\gamma,\beta)}S_{\tau\beta}S_\gamma \tag{2.5}$$

$(\gamma,\beta,\in\mathfrak{h}^*)$.

Let $Q^\vee$, $P^\vee$ be the coroot and coweight lattice, respectively. Let $W\subset GL(\mathfrak{h}^*)$ denote the Weyl group for $(\mathfrak{g},\mathfrak{h})$. Let Th^W be a space of W-invariant theta functions, defined by

$$Th^W:=\left\{ f \text{ is a holomorphic function over } \mathfrak{h}^* \left| \begin{array}{ll} S_{\tau\alpha}f=S_\alpha f=f & (\forall\alpha\in Q^\vee) \\ f(w\lambda)=f(\lambda) & (\forall w\in W) \end{array}\right. \right\}.$$

It is well known that the space is spanned by the level one characters of the affine Lie algebra $\widehat{\mathfrak{sp}}(4,\mathbb{C})$, and the dimension of this space is three.

Theorem 2: *We have*

$$\tilde{M}_d(Th^W)\subset Th^W\quad(d=1,2).$$

The corresponding facts in the case of the A type are proved in Refs. 21 and 3.

III. THE $C_n^{(1)}$-FACE MODEL

Fix an integer $n\geqslant 2$. We review the definition of the $C_n^{(1)}$-face model given in Ref. 6. We realize the root system R of the type C_n as

$$R:=\{\pm(\epsilon_j\pm\epsilon_k),\pm 2\epsilon_l | 1\leqslant j<k\leqslant n, 1\leqslant l\leqslant n\},$$

where $\{\epsilon_j\}_{j=1}^n$ is a basis of a complex vector space denoted by $\mathfrak{h}^*$ with a bilinear form (,), defined by

$$(\epsilon_j,\epsilon_k):=\tfrac{1}{2}\delta_{jk}.$$

The vector space $\mathfrak{h}^*$ can be identified with the dual space of a Cartan subalgebra $\mathfrak{h}$ of the simple Lie algebra $\mathfrak{sp}(2n,\mathbb{C})$. The fundamental weights $\varpi_j(1\leqslant j\leqslant n)$ are given by $\varpi_j=\epsilon_1+\epsilon_2+\cdots+\epsilon_j$. Let $\mathcal{P}$ denote the set of weights that belongs to the vector representation $L(\varpi_1)$ of $\mathfrak{sp}(2n,\mathbb{C})$. We have

$$\mathcal{P}=\{\pm\epsilon_1,\pm\epsilon_2,\dots,\pm\epsilon_n\}.$$

Note that the multiplicity of the weights in $\mathcal{P}$ are all one.

We shall use the following notation frequently:

$$\hat{\mathcal{P}}:=2\hbar\mathcal{P}\quad\text{and}\quad\hat{p}:=2\hbar p\quad(p\in\mathcal{P}).$$

The Boltzmann weights are given by a set of functions of spectral parameter $u\in\mathbb{C}$ defined for any square

$$\begin{pmatrix} \lambda & \mu \\ \kappa & \nu \end{pmatrix}$$

of elements of $\mathfrak{h}^*$. Let us denote the functions by

$$W\left(\begin{matrix} \lambda & \mu \\ \kappa & \nu \end{matrix}\middle| u\right).$$

They satisfy the condition

$$W\left(\begin{matrix} \lambda & \mu \\ \kappa & \nu \end{matrix}\middle| u\right)=0, \quad \text{unless} \quad \mu-\lambda, \nu-\mu, \kappa-\lambda, \nu-\kappa \in \hat{\mathcal{P}}.$$

For p, q, r, $s \in \mathcal{P}$ such that $p+q=r+s$, we will write

$$s \overset{p}{\underset{r}{\boxed{u}}} q = W\left(\begin{matrix} \lambda & \lambda+\hat{p} \\ \lambda+\hat{s} & \lambda+\hat{p}+\hat{q} \end{matrix}\middle| u\right).$$

They are explicitly given as follows:

$$p \overset{p}{\underset{p}{\boxed{u}}} p = \frac{[c-u][u+\hbar]}{[c][\hbar]}, \tag{3.1}$$

$$p \overset{p}{\underset{q}{\boxed{u}}} q = \frac{[c-u][\lambda_{p-q}-u]}{[c][\lambda_{p-q}]} \quad (p \neq \pm q), \tag{3.2}$$

$$p \overset{q}{\underset{q}{\boxed{u}}} p = \frac{[c-u][u][\lambda_{p-q}+\hbar]}{[c][\hbar][\lambda_{p-q}]} \quad (p \neq \pm q), \tag{3.3}$$

$$p \overset{q}{\underset{-p}{\boxed{u}}} -q = -\frac{[u][\lambda_{p+q}+\hbar+c-u]}{[c][\lambda_{p+q}+\hbar]} \frac{[2\lambda_p+2\hbar]}{[2\lambda_q]} \frac{\Pi_{r\neq \pm p}[\lambda_{p+r}+h]}{\Pi_{r\neq \pm q}[\lambda_{q+r}]} \quad (p \neq q), \tag{3.4}$$

$$p \overset{p}{\underset{-p}{\boxed{u}}} -p = \frac{[c-u][2\lambda_p+\hbar-u]}{[c][2\lambda_p+\hbar]} - \frac{[u][2\lambda_p+\hbar+c-u]}{[c][2\lambda_p+\hbar]} \frac{[2\lambda_p+2\hbar]}{[2\lambda_p]} \prod_{q\neq \pm p} \frac{[\lambda_{p+q}+\hbar]}{[\lambda_{p+q}]}. \tag{3.5}$$

The *crossing parameter* c in the above formulas are fixed to be

$$c := -(n+1)\hbar. \tag{3.6}$$

Proposition 1: The Boltzmann weights (3.1),(3.2),(3.3),(3.4),(3.5) enjoy the following properties.

Initial condition:

$$\sum_{\eta} W\left(\begin{matrix} \lambda & \mu \\ \kappa & \nu \end{matrix}\middle| 0\right) = \delta_{\mu\kappa}. \tag{3.7}$$

Inversion relation:

$$\sum_{\eta} W\left(\begin{matrix}\lambda & \eta \\ \kappa & \nu\end{matrix}\middle| -u\right) W\left(\begin{matrix}\lambda & \mu \\ \eta & \nu\end{matrix}\middle| -u\right) = \delta_{\mu\kappa}\frac{[c+u][c-u][\hbar+u][\hbar-u]}{[c]^2[\hbar]^2}. \tag{3.8}$$

Crossing symmetry:

$$W\left(\begin{matrix}\lambda & \mu \\ \kappa & \nu\end{matrix}\middle| u\right) = \frac{g(\lambda,\kappa)}{g(\mu,\nu)} W\left(\begin{matrix}\kappa & \lambda \\ \nu & \mu\end{matrix}\middle| c-u\right), \tag{3.9}$$

where we put

$$g(\lambda,\mu) := [2\mu_p] \prod_{\substack{q\in\mathcal{P} \\ q\neq \pm p}} [\mu_{p+q}] \quad (\mu=\lambda+\hat{p}, p\in\mathcal{P}).$$

Reflection symmetry:

$$W\left(\begin{matrix}\lambda & \mu \\ \kappa & \nu\end{matrix}\middle| u\right) = \frac{g(\lambda,\kappa)g(\kappa,\nu)}{g(\lambda,\mu)g(\mu,\nu)} W\left(\begin{matrix}\lambda & \kappa \\ \mu & \nu\end{matrix}\middle| u\right). \tag{3.10}$$

Proof: The equation (3.7) is trivial. The two types of symmetries (3.9), (3.10) are easily checked by the explicit form. In the case of $\lambda=\nu$ the equation (3.8) is reduced to the following:

$$\begin{aligned}&\sum_{r\in\mathcal{P}} \frac{[\lambda_p+\lambda_r+\hbar+c-u][\lambda_q+\lambda_r+\hbar+c+u]}{[\lambda_p+\lambda_r+\hbar][\lambda_q+\lambda_r+\hbar]} G_{\lambda r} \\ &\quad = \delta_{p,q}\frac{[c-u][c+u][2\lambda_p][2\lambda_q+2\hbar]}{[\hbar]^2[2\lambda_p+\hbar]^2} G_{\lambda p}^{-1} + \frac{[c+u][2\lambda_p+\hbar+u][\lambda_p+\lambda_q+\hbar+c-u]}{[u][2\lambda_p+\hbar][\lambda_p+\lambda_q+\hbar]} \\ &\qquad - \frac{[c-u][2\lambda_q+\hbar-u][\lambda_p+\lambda_q+\hbar+c+u]}{[u][2\lambda_q+\hbar][\lambda_p+\lambda_q+\hbar]}.\end{aligned} \tag{3.11}$$

Here we denote by $G_{\lambda p}$ the following function:

$$G_{\lambda p} := -\frac{[2\lambda_p+2\hbar]}{[2\lambda_p]} \prod_{\substack{r\in\mathcal{P} \\ r\neq \pm p}} \frac{[\lambda_{p+r}+\hbar]}{[\lambda_{p+r}]} \quad (p\in\mathcal{P}). \tag{3.12}$$

One can find a proof of the equation (3.11) in Ref. 6 [see (3.5) and Lemma 3]. The cases $\nu=\lambda+2\hat{p}(p\in\mathcal{P})$ are trivial. The remaining cases are easily checked by using the following *three-term identity*:

$$[u+x][u-x][v+y][v-y]-[u+y][u-y][v+x][v-x]=[x+y][x-y][u+v][u-v] \tag{3.13}$$

$(u,v,x,y\in\mathbb{C})$. □

We adopted a slightly different formulas (3.3),(3.4) from the original ones [see (A1),(A2)] in Ref. 6. In the Appendix, we will give a similarity transformation (A3),(A4) which transforms our Boltzmann weights into the original ones. Thus, one has a way to prove the YBE for our Boltzmann weights, since such a transformation does not destroy the varidity of the YBE. If we follow this track, however, we must specify the arguments of the square roots contained in the expressions of the original formulas and the transformation. This way of proof may require a rather complicated discussion. In this paper, we will give a proof of the YBE for our Boltzmann weights directly without using the similarity transformation. In fact, our proof here goes quite parallel to the proof given in Ref. 6.

Theorem 3: *The Boltzmann weights*

$$W\begin{pmatrix} \lambda & \mu \\ \kappa & \nu \end{pmatrix} u \Bigg)$$

(3.1),(3.2),(3.3),(3.4),(3.5) solve the YBE *(2.3) for* $d=d'=d''=1$.

Proof: Set

$$X(\lambda,\mu,\nu,\kappa,\sigma,\rho|u,v) := \sum_\eta W\left(\begin{matrix}\rho & \eta\\ \sigma & \kappa\end{matrix}\middle| u\right) W\left(\begin{matrix}\lambda & \mu\\ \rho & \eta\end{matrix}\middle| u+v\right) W\left(\begin{matrix}\mu & \nu\\ \eta & \kappa\end{matrix}\middle| v\right), \tag{3.14}$$

$$Y(\lambda,\mu,\nu,\kappa,\sigma,\rho|u,v) := \sum_\eta W\left(\begin{matrix}\lambda & \eta\\ \rho & \sigma\end{matrix}\middle| v\right) W\left(\begin{matrix}\eta & \nu\\ \sigma & \kappa\end{matrix}\middle| u+v\right) W\left(\begin{matrix}\lambda & \mu\\ \eta & \nu\end{matrix}\middle| u\right), \tag{3.15}$$

and

$$Z(\lambda,\mu,\nu,\kappa,\sigma,\rho,|u,v) := X(\lambda,\mu,\nu,\kappa,\sigma,\rho|u,v) - Y(\lambda,\mu,\nu,\kappa,\sigma,\rho|u,v). \tag{3.16}$$

Regarding $Z(\lambda,\mu,\nu,\kappa,\sigma,\rho|u,v)$ as a function of u, we denote it by $Z(u)$.

The equations (3.7) and (3.8) imply $Z(0)=Z(-v)=0$. Since we have

$$Z(\lambda,\mu,\nu,\kappa,\sigma,\rho|u,v) = -\frac{g(\lambda,\rho)}{g(\nu,\kappa)} Z(\rho,\lambda,\mu,\nu,\kappa,\sigma|c-u-v,u) \tag{3.17}$$

by (3.9), this shows $Z(c-v)=Z(c)=0$ also. Thus, we have found the four zeros at $u=0, -v, c, c-v$ of $Z(u)$. By the exactly same argument in Ref. 6 using the quasiperiodicity property of $Z(u)$, (3.17), and the following symmetry [this follows from (3.10)]:

$$Z(\lambda,\mu,\nu,\kappa,\sigma,\rho|u,v) = \frac{g(\lambda,\rho)g(\rho,\sigma)g(\sigma,\kappa)}{g(\lambda,\mu)g(\mu,\nu)g(\nu,\kappa)} Z(\lambda,\rho,\sigma,\kappa,\nu,\mu|v,u),$$

we can reduce the proof of the YBE to the following two special cases:

$$Z(\lambda,\lambda+\hat{p},\lambda+\hat{p}+\hat{q},\lambda+\hat{p}+\hat{q}+\hat{r},\lambda+\hat{q}+\hat{r},\lambda+\hat{r}|u,v)=0, \tag{3.18}$$

where $r\neq\pm p,\pm q, p\neq\pm q$ and

$$Z(\lambda,\lambda+\hat{p},\lambda,\lambda+\hat{p},\lambda,\lambda+\hat{p}|u,v)=0. \tag{3.19}$$

In the case of the equation (3.18), each side of the YBE contains only one term, and they are manifestly the same. A proof of the last case (3.19) can be found in the original literature.[6] However, since the proof is brief and seems to contain some typographical errors, we will describe details of it in the following for the readers' convenience.

We will prove $Z(\lambda,\lambda+\hat{p},\lambda,\lambda+\hat{p},\lambda,\lambda+\hat{p}|u,v)=0$. Regarding $Y(\lambda,\lambda+\hat{p},\lambda,\lambda+\hat{p},\lambda,\lambda+\hat{p}|u,v)$ as a function of λ_p, we denote it by $f(\lambda_p)$. It reads as

$$f(\lambda_p)=G_{\lambda p}\frac{[u][v][w]}{[c]^3}\sum_{q\in\mathcal{P}}\frac{[\lambda_q+\lambda_p+\hbar+\tilde{u}][\lambda_q+\lambda_p+\hbar+\tilde{v}][\lambda_q+\lambda_p+\hbar+\tilde{w}]}{[\lambda_q+\lambda_p+\hbar]^3}G_{\lambda q}$$
$$+G_{\lambda p}^{-1}\frac{[\tilde{u}][\tilde{v}][\tilde{w}]}{[c]^3}\frac{[2\lambda_p+\hbar-u][2\lambda_p+\hbar-v][2\lambda_p+\hbar-w]}{[2\lambda_p+\hbar]^3}$$
$$+\sum_{\text{cyclic}}\frac{[u][\tilde{v}][\tilde{w}]}{[c]^3}\frac{[2\lambda_p+\hbar+\tilde{u}][2\lambda_p+\hbar-v][2\lambda_p+\hbar-w]}{[2\lambda_p+\hbar]^3}$$
$$+G_{\lambda p}\sum_{\text{cyclic}}\frac{[\tilde{u}][v][w]}{[c]^3}\frac{[2\lambda_p+\hbar-u][2\lambda_p+\hbar+\tilde{v}][2\lambda_p+\hbar+\tilde{w}]}{[2\lambda_p+\hbar]^3},$$

where we put $w=c-u-v$, $\tilde{u}=c-u$, $\tilde{v}=c-v$, $\tilde{w}=c-w$ and the summation Σ_{cyclic} is over the cyclic permutations of the three variables (u,v,w). From the explicit form, one can see that $X(\lambda,\lambda+\hat{p},\lambda,\lambda+\hat{p},\lambda,\lambda+\hat{p}|u,v)=f(-\lambda_p-\hbar)$. We will prove $f(\lambda_p)=f(-\lambda_p-\hbar)$.

Now consider a function,

$$\Phi(z):=\frac{[z+\lambda_p+\hbar+\tilde{u}][z+\lambda_p+\hbar+\tilde{v}][z+\lambda_p+\hbar+\tilde{w}]}{[z+\lambda_p+\hbar]^3}\frac{[0]'}{[\hbar]}\frac{[2z+2\hbar]}{[2z+\hbar]}\prod_{q\in\mathcal{P}}\frac{[z+\lambda_q+\hbar]}{[z+\lambda_q]}.$$

One sees that $\Phi(z)$ is a doubly periodic function of the periods 1 and τ. Its poles are located at $z=-\lambda_p-h$, $\lambda_q(q\in\mathcal{P})$, $-\hbar/2+\omega(\omega=0,1/2,\tau/2,(1+\tau)/2)$. The pole at $z=-\lambda_p-\hbar$ is of the second order, and the others are simple.

Let $f_i(\lambda_p)(i=1,2,3,4)$ denote the ith term of the above function $f(\lambda_p)$. Since we have

$$\operatorname*{Res}_{z=\lambda_q}\Phi(z)dz=-\frac{[\lambda_q+\lambda_p+\hbar+\tilde{u}][\lambda_q+\lambda_p+\hbar+\tilde{v}][\lambda_q+\lambda_p+\hbar+\tilde{w}]}{[\lambda_q+\lambda_p+\hbar]^3}G_{\lambda_q},$$

the relation $\Sigma\,\mathrm{Res}\,\Phi(z)dz=0$ implies $f_1(\lambda_p)=a(\lambda_p)+b(\lambda_p)$, where we set

$$a(\lambda_p):=G_{\lambda p}\frac{[u][v][w]}{[c]^3}\sum_{\omega}\operatorname*{Res}_{z=-\hbar/2+\omega}\Phi(z)dz, \tag{3.20}$$

$$b(\lambda_p):=G_{\lambda p}\frac{[u][v][w]}{[c]^3}\operatorname*{Res}_{z=-\lambda_p-\hbar}\Phi(z)dz. \tag{3.21}$$

Here the summation Σ_ω is over the half-periods $\omega=0,1/2,\tau/2,(1+\tau)/2$.

From (2.2) and (3.6), we have, for $\omega=0,1/2,\tau/2,(1+\tau)/2$.

$$\operatorname*{Res}_{z=-\hbar/2+\omega}\Phi(z)dz=\frac{1}{2}\frac{\left[\lambda_p+\frac{\hbar}{2}+\omega+\tilde{u}\right]\left[\lambda_p+\frac{\hbar}{2}+\omega+\tilde{v}\right]\left[\lambda_p+\frac{\hbar}{2}+\omega+\tilde{w}\right]}{\left[\lambda_p+\frac{\hbar}{2}+\omega\right]^3}e^{2\pi i\xi(\omega)}, \tag{3.22}$$

where we put $\xi(0)=\xi(\frac{1}{2})=0$, $\xi(\tau/2)=\xi((1+\tau)/2)=c$. Combining (3.20), (3.22), and Lemma 3 in Ref. 6, we can verify

$$a(\lambda_p)+f_4(\lambda_p)-f_2(-\lambda_p-\hbar)=-a(-\lambda_p-\hbar)+f_2(\lambda_p)-f_4(-\lambda_p-\hbar)=0. \tag{3.23}$$

Set $\phi(u)=(d/du)\log[u]$, then the residue $\mathrm{Res}_{z=-\lambda_p-\hbar}\Phi(z)dz$ can be expressed as

$$\operatorname*{Res}_{z=-\lambda_p-\hbar} \Phi(z)dz = G_{\lambda p}^{-1} \frac{[\tilde{u}][\tilde{v}][\tilde{w}]}{[0]'[\hbar]^2} \frac{[2\lambda_p+2\hbar][2\lambda_p]}{[2\lambda_p+\hbar]^2}$$
$$\times \left(\sum_{\text{cyclic}} \phi(\tilde{u}) - 3\phi(2\lambda_p) + 3\phi(2\lambda_p+\hbar) + \phi(\hbar) \right.$$
$$\left. + \sum_{\substack{q\in\mathcal{P} \\ q\neq\pm p}} \{\phi(-\lambda_p+\lambda_q) - \phi(-\lambda_p+\lambda_q-\hbar)\} \right). \tag{3.24}$$

Since $\phi(u)$ is an odd function, we have, from (3.21) and (3.24),

$$b(\lambda_p) - b(-\lambda_p-\hbar) = -3 \frac{[u][v][w]}{[c]^3} \frac{[\tilde{u}][\tilde{v}][\tilde{w}]}{[0]'[\hbar]^2} \frac{[2\lambda_p+2\hbar][2\lambda_p]}{[2\lambda_p+\hbar]^2}$$
$$\times \{\phi(2\lambda_p) + \phi(2\lambda_p+2\hbar) - 2\phi(2\lambda_p+\hbar)\}. \tag{3.25}$$

On the other hand, using the identity [see (3.13)]

$$[2\lambda_p+\hbar+\tilde{u}][2\lambda_p+\hbar-v][2\lambda_p+\hbar-w] - [2\lambda_p+\hbar-\tilde{u}][2\lambda_p+\hbar+v][2\lambda_p+\hbar+w]$$
$$= [\tilde{u}][v][w] \frac{[4\lambda_p+2\hbar]}{[2\lambda_p+\hbar]},$$

and its cyclic permutations of (u,v,w), we have

$$f_3(\lambda_p) - f_3(-\lambda_p-\hbar) = 3 \frac{[u][v][w][\tilde{u}][\tilde{v}][\tilde{w}]}{[c]^3} \frac{[4\lambda_p+2\hbar]}{[2\lambda_p+\hbar]^4}. \tag{3.26}$$

Now from (3.25) and (3.26), we have

$$b(\lambda_p) + f_3(\lambda_p) = b(-\lambda_p-\hbar) + f_3(-\lambda_p-\hbar), \tag{3.27}$$

where we used the following identity (Lemma 4 in Ref. 6):

$$\phi(u+\hbar) + \phi(u-\hbar) - 2\phi(u) = \frac{[\hbar]^2[2u][0]'}{[u]^2[u-\hbar][u+\hbar]}.$$

Combining (3.23) and (3.27), we obtained $f(\lambda_p) = f(-\lambda_p-h)$. □

IV. PATH SPACE AND FUSION PROCEDURE

In the previous section we introduced the Boltzmann weights $W(u)$ of the type (1,1) and proved that they satisfy the YBE. In what follows, we treat only the case of $n=2$. To construct commuting difference operators, we need the general types of the Boltzmann weights $W_{dd'}(u)$, which we call the fused Boltzmann weights.

First let us introduce the notion of the path space. Let $d=1,2$. For any $u\in\mathbb{C}$ and $\lambda,\mu\in\mathfrak{h}^*$ such that $\mu-\lambda\in 2\hbar\mathcal{P}_d$, we introduce a formal symbol,

$$g_\lambda^\mu(u) := \begin{cases} e_\lambda^\mu(u) & :d=1, \\ f_\lambda^\mu(u) & :d=2. \end{cases}$$

See (2.1) for the notation $\mathcal{P}_1$ and $\mathcal{P}_2$. We define the complex vector space,

$$\hat{\mathcal{P}}(\varpi_d^u)_\lambda^\mu := \begin{cases} \mathbb{C} g_\lambda^\mu(u) & : \mu-\lambda \in 2\hbar \mathcal{P}_d, \\ 0 & : \text{otherwise}, \end{cases}$$

for each $u \in \mathbb{C}$, and the *space of paths* from λ to μ of the type $(d_1,\dots,d_k;u_1,\dots,u_k)$,

$$\hat{\mathcal{P}}(\varpi_{d_1}^{u_1}\otimes\cdots\otimes\varpi_{d_k}^{u_k})_\lambda^\nu := \bigoplus_{\mu_1,\dots,\mu_{k-1}\in\mathfrak{h}^*} \hat{\mathcal{P}}(\varpi_{d_1}^{u_1})_\lambda^{\mu_1}\otimes\hat{\mathcal{P}}(\varpi_{d_2}^{u_2})_{\mu_1}^{\mu_2}\otimes\cdots\otimes\hat{\mathcal{P}}(\varpi_{d_k}^{u_k})_{\mu_{k-1}}^\nu. \tag{4.1}$$

The following set:

$$\{g_\lambda^{\mu_1}(\mu_1)\otimes g_{\mu_1}^{\mu_2}(u_2)\otimes\cdots\otimes g_{\mu_{k-1}}^\nu(u_k) \,|\, \mu_i-\mu_{i-1}\in 2\hbar\mathcal{P}_d(1\leqslant i\leqslant k), \mu_0=\lambda, \mu_k=\nu\},$$

of *paths* forms a basis of the space (4.1). Set also

$$\hat{\mathcal{P}}(\varpi_{d_1}^{u_1}\otimes\cdots\otimes\varpi_{d_k}^{u_k})_\lambda := \bigoplus_{\nu\in\mathfrak{h}^*}\hat{\mathcal{P}}(\varpi_{d_1}^{u_1}\otimes\cdots\otimes\varpi_{d_k}^{u_k})_\lambda^\nu$$

and

$$\hat{\mathcal{P}}(\varpi_{d_1}^{u_1}\otimes\cdots\otimes\varpi_{d_k}^{u_k}) := \bigoplus_{\lambda\in\mathfrak{h}^*}\hat{\mathcal{P}}(\varpi_{d_1}^{u_1}\otimes\cdots\varpi_{d_k}^{u_k})_\lambda.$$

In the following, we will construct the linear operators:

$$W_{dd'}(u-v): \hat{\mathcal{P}}(\varpi_d^u\otimes\varpi_{d'}^v)\to\hat{\mathcal{P}}(\varpi_{d'}^v,\otimes\varpi_d^u),$$

which satisfy the following YBE $(d,d',d''=1,2)$:

$$\begin{aligned}&(\mathrm{id}\otimes W_{dd'}(u-v))(W_{dd''}(u-w)\otimes\mathrm{id})(\mathrm{id}\otimes W_{d'd''}(v-w))\\ &\quad=(W_{d'd''}(v-w)\otimes\mathrm{id})(\mathrm{id}\otimes W_{dd''}(u-w))(W_{dd'}(u-v)\otimes\mathrm{id})\\ &\quad:\hat{\mathcal{P}}(\varpi_d^u\otimes\varpi_{d'}^v\otimes\varpi_{d''}^w)\to\hat{\mathcal{P}}(\varpi_{d''}^w\otimes\varpi_{d'}^v\otimes\varpi_d^u).\end{aligned} \tag{4.2}$$

First we define a linear operator $W(\varpi_1^u,\varpi_1^v):\hat{\mathcal{P}}(\varpi_1^u\otimes\varpi_1^v)\to\hat{\mathcal{P}}(\varpi_1^v\otimes\varpi_1^u)$ by

$$W(\varpi_1^u,\varpi_1^v)e_\lambda^\mu(u)\otimes e_\mu^\nu(v) := \sum_{\kappa\in\mathfrak{h}^*} W\left(\begin{matrix}\lambda & \mu\\ \kappa & \nu\end{matrix}\middle| u-v\right) e_\lambda^\kappa(v)\otimes e_\kappa^\nu(u).$$

Put $W_{11}(u-v) := W(\varpi_1^u,\varpi_1^v)$, then the YBE (4.2) for $d=d'=d''=1$ is nothing but (2.3).

To construct $W_{dd'}(u-v)$ other than $W_{11}(u-v)$, we will formulate the fusion procedure. Put

$$\begin{aligned}W(\varpi_1^{u_1}\otimes\varpi_1^{u_2}\otimes\cdots\otimes\varpi_1^{u_k},\varpi_1^v) &:= W^{1,2}(\varpi_1^{u_1},\varpi_1^v)W^{2,3}(\varpi_1^{u_2},\varpi_1^v)\cdots W^{k,k+1}(\varpi_1^{u_k},\varpi_1^v)\\ &:\hat{\mathcal{P}}(\varpi_1^{u_1}\otimes\varpi_1^{u_2}\otimes\cdots\otimes\varpi_1^{u_k}\otimes\varpi_1^v)\to\hat{\mathcal{P}}(\varpi_1^v\otimes\varpi_1^{u_1}\otimes\varpi_1^{u_2}\cdots\otimes\varpi_1^{u_k}),\end{aligned}$$

where

$$\begin{aligned} W(\varpi_1^{u_j},\varpi_1^{v})^{j,j+1} &:= \mathrm{id}^{\otimes(j-1)}\otimes W(\varpi_1^{u_j},\varpi_1^{v})\otimes \mathrm{id}^{\otimes(k-j)} \\ &: \hat{\mathcal{P}}(\varpi_1^{u_1}\otimes\cdots\otimes\varpi_1^{u_{j-1}}\otimes \underbrace{\varpi_1^{u_j}\otimes\varpi_1^{v}}\otimes\varpi_1^{u_{j+1}}\otimes\cdots\otimes\varpi_1^{u_k}) \\ &\to \hat{\mathcal{P}}(\varpi_1^{u_1}\otimes\cdots\otimes\varpi_1^{u_{j-1}}\otimes \underbrace{\varpi_1^{v}\otimes\varpi_1^{u_j}}\otimes\varpi_1^{u_{j+1}}\otimes\cdots\otimes\varpi_1^{u_k}). \end{aligned}$$

We also put

$$\begin{aligned} &W(\varpi_1^{u_1}\otimes\varpi_1^{u_2}\otimes\cdots\otimes\varpi_1^{u_k},\varpi_1^{v_1}\otimes\varpi_1^{v_2}\otimes\cdots\otimes\varpi^{v_l}) \\ &:= \overleftarrow{\prod_{1\leqslant j\leqslant l}} W(\varpi_1^{u_1}\otimes\varpi_1^{u_2}\otimes\cdots\otimes\varpi_1^{u_k},\varpi_1^{v_j})^{[j,k+j]} \\ &: \hat{\mathcal{P}}(\varpi_1^{u_1}\otimes\cdots\otimes\varpi_1^{u_k}\otimes\varpi_1^{v_1}\otimes\cdots\otimes\varpi_1^{v_l}) \to \hat{\mathcal{P}}(\varpi_1^{v_1}\otimes\cdots\otimes\varpi_1^{v_l}\otimes\varpi_1^{u_1}\otimes\cdots\otimes\varpi_1^{u_k}), \end{aligned}$$

where

$$\begin{aligned} &W(\varpi_1^{u_1}\otimes\cdots\otimes\varpi_1^{u_k},\varpi_1^{v_j})^{[j,k+j]} \\ &:= \mathrm{id}^{\otimes(j-1)}\otimes W(\varpi_1^{u_1}\otimes\cdots\otimes\varpi_1^{u_k},\varpi_1^{v_j})\otimes\mathrm{id}^{\otimes(l-j)} \\ &: \hat{\mathcal{P}}(\varpi_1^{v_1}\otimes\cdots\otimes\varpi_1^{v_{j-1}}\otimes\underbrace{\varpi_1^{u_1}\otimes\cdots\otimes\varpi_1^{u_k}\otimes\varpi_1^{v_j}}\otimes\varpi_1^{v_{j+1}}\otimes\cdots\otimes\varpi_1^{v_l}) \\ &\to \hat{\mathcal{P}}(\varpi_1^{v_1}\otimes\cdots\otimes\varpi_1^{v_{j-1}}\otimes\underbrace{\varpi_1^{v_j}\otimes\varpi_1^{u_1}\otimes\cdots\otimes\varpi_1^{u_k}}\otimes\varpi_1^{v_{j+1}}\otimes\cdots\otimes\varpi_1^{v_l}). \end{aligned}$$

We will realize the space $\hat{\mathcal{P}}(\varpi_2^u)$ as a subspace of $\hat{\mathcal{P}}(\varpi_1^u\otimes\varpi_1^{u-\hbar})$. For this purpose, let us introduce the *fusion projector* $\pi_{\varpi_2^u}$ by specializing the parameter in $W(\varpi_1^u,\varpi_1^v)$:

$$\pi_{\varpi_2^u} := W(\varpi_1^{u-\hbar},\varpi_1^u) : \hat{\mathcal{P}}(\varpi_1^{u-\hbar}\otimes\varpi_1^u)\to\hat{\mathcal{P}}(\varpi_1^u\otimes\varpi_1^{u-\hbar}). \tag{4.3}$$

Lemma 1: The space $\pi_{\varpi_2^u}(\hat{\mathcal{P}}(\varpi_1^{u-\hbar}\otimes\varpi_1^u)_\lambda)$ has a basis $\{\overline{f_\lambda^{\lambda+\hat{r}}}(u)\}_{r\in\mathcal{P}_2}$, given by

$$\overline{f_\lambda^{\lambda+\hat{p}+\hat{q}}}(u) := [\lambda_{p-q}+\hbar]e_\lambda^{\lambda+\hat{p}}(u)\otimes e_{\lambda+\hat{p}}^{\lambda+\hat{p}+\hat{q}}(u-\hbar)+[\lambda_{q-p}+\hbar]e_\lambda^{\lambda+\hat{q}}(u)\otimes e_{\lambda+\hat{q}}^{\lambda+\hat{p}+\hat{q}}(u-\hbar), \tag{4.4}$$

where $p=\pm\epsilon_1$, $q=\pm\epsilon_2$, and

$$\overline{f_\lambda^{\lambda}}(u) := \sum_{p\in\mathcal{P}_1}[2\lambda_p+2\hbar]e_\lambda^{\lambda+\hat{p}}(u)\otimes e_{\lambda+\hat{p}}^{\lambda}(u-\hbar). \tag{4.5}$$

Proof: For $p,q\in\mathcal{P}_1$, $q\neq\pm p$, we have

$$\pi_{\varpi_2^u}(e_\lambda^{\lambda+\hat{p}}(u-\hbar)\otimes e_{\lambda+\hat{p}}^{\lambda+2\hat{p}}(u)) = \begin{pmatrix} & p & \\ p & \boxed{-\hbar} & p \\ & p & \end{pmatrix} e_\lambda^{\lambda+\hat{p}}(u)\otimes e_{\lambda+\hat{p}}^{\lambda+2\hat{p}}(u-h)=0,$$

$$\pi_{\varpi_2^u}(e_\lambda^{\lambda+\hat{p}}(u-\hbar)\otimes e_{\lambda+\hat{p}}^{\lambda+\hat{p}+\hat{q}}(u))=\left(\begin{matrix} & p & \\ p & \boxed{-\hbar} & q \\ & q & \end{matrix}\right) e_\lambda^{\lambda+\hat{p}}(u)\otimes e_{\lambda+\hat{p}}^{\lambda+\hat{p}+\hat{q}}(u-\hbar)$$

$$+\left(\begin{matrix} & p & \\ q & \boxed{-\hbar} & q \\ & p & \end{matrix}\right) e_\lambda^{\lambda+\hat{q}}(u)\otimes e_{\lambda+\hat{q}}^{\lambda+\hat{p}+\hat{q}}(u-\hbar)$$

$$=\frac{[-2\hbar]}{[-3\hbar][\lambda_{p-q}]}([\lambda_{p-q}+\hbar]e_\lambda^{\lambda+\hat{p}}(u)\otimes e_{\lambda+\hat{p}}^{\lambda+\hat{p}+\hat{q}}(u-\hbar)$$

$$+[\lambda_{q-p}+\hbar]e_\lambda^{\lambda+\hat{q}}(u)\otimes e_{\lambda+\hat{q}}^{\lambda+\hat{p}+\hat{q}}(u-\hbar)),$$

and

$$\pi_{\varpi_2^u}(e_\lambda^{\lambda+\hat{p}}(u-\hbar)\otimes e_{\lambda+\hat{p}}^{\lambda}(u))=\sum_{r\in\mathcal{P}_1}\left(\begin{matrix} & p & \\ r & \boxed{-\hbar} & -p \\ & -r & \end{matrix}\right) e_\lambda^{\lambda+\hat{r}}(u)\otimes e_{\lambda+\hat{r}}^{\lambda}(u-\hbar)$$

$$=\frac{[-\hbar][\lambda_{p+q}-\hbar][\lambda_{p-q}-\hbar]}{[-3\hbar][\lambda_{p+q}][\lambda_{p-q}][2\lambda_p]}$$

$$\times\left(\sum_{r\in\mathcal{P}_1}[2\lambda_r+2\hbar]e_\lambda^{\lambda+\hat{r}}(u)\otimes e_{\lambda+\hat{r}}^{\lambda}(u-\hbar)\right).$$

Here we have used the three-term identity (3.13). □

Thus, we know the subspace $\pi_{\varpi_2^u}(\hat{\mathcal{P}}(\varpi_1^{u-\hbar}\otimes\varpi_1^u)_\lambda)$ is naturally isomorphic to the space $\hat{\mathcal{P}}(\varpi_2^u)_\lambda$. In the following, we will identify the image $\mathrm{Im}(\pi_{\varpi_2^u})\subset\hat{\mathcal{P}}(\varpi_1^u\otimes\varpi_1^{u-\hbar})$ with the space $\hat{\mathcal{P}}(\varpi_2^u)$ via $\overline{f_\lambda^\mu}(u)\leftrightarrow f_\lambda^\mu(u)$.

Proposition 2: Define the operators $\tilde{W}_{dd'}(u-v)$ by

$$\tilde{W}_{21}(u-v):=W(\varpi_1^u\otimes\varpi_1^{u-\hbar},\varpi_1^v),\quad \tilde{W}_{12}(u-v):=W(\varpi_1^u,\varpi_1^v\otimes\varpi_1^{v-\hbar}) \tag{4.6}$$

and

$$\tilde{W}_{22}(u-v):=W(\varpi_1^u\otimes\varpi_1^{u-\hbar},\varpi_1^v\otimes\varpi_1^{v-h}).$$

We have

$$\tilde{W}_{dd'}(u-v)(\hat{\mathcal{P}}(\varpi_d^u\otimes\varpi_{d'}^v)_\lambda^\mu)\subset\hat{\mathcal{P}}(\varpi_{d'}^v\otimes\varpi_d^v)_\lambda^\mu.$$

Proof: From the definition of $\pi_{\varpi_2^u}$ (4.3) and the YBE (2.3),

$$W^{1,2}(u-v)W^{2,3}(u-v-\hbar)(\pi_{\varpi_2^u}\otimes\mathrm{id})=(\mathrm{id}\otimes\pi_{\varpi_2^u})W^{1,2}(u-v-\hbar)W^{2,3}(u-v). \tag{4.7}$$

Applying this to the definition of $\tilde{W}_{21}(u-v)$, we get

$$\tilde{W}_{21}(u-v)(\hat{\mathcal{P}}(\varpi_2^u\otimes\varpi_1^v)_\lambda^\mu)\subset\hat{\mathcal{P}}(\varpi_1^v\otimes\varpi_2^u)_\lambda^\mu.$$

By a same argument, we have

$$W^{2,3}(u-v+\hbar)W^{1,2}(u-v)(\mathrm{id}\otimes\pi_{\varpi_2^u})=(\pi_{\varpi_2^u}\otimes\mathrm{id})W^{2,3}(u-v)W^{1,2}(u-v+\hbar), \tag{4.8}$$

and

$$\widetilde{W}_{12}(u-v)(\hat{\mathcal{P}}(\varpi_1^u \otimes \varpi_2^v)_\lambda^\mu) \subset \hat{\mathcal{P}}(\varpi_2^v \otimes \varpi_1^u)_\lambda^\mu.$$

Together with the equations (4.7), (4.8) and the definition of $\widetilde{W}_{22}(u-v)$, we obtain

$$\widetilde{W}_{22}(u-v)(\hat{\mathcal{P}}(\varpi_2^u \otimes \varpi_2^v)_\lambda^\mu) \subset \hat{\mathcal{P}}(\varpi_2^v \otimes \varpi_2^u)_\lambda^\mu.$$

□

We denote by $W_{dd'}(u-v)$ the restricted operators $\widetilde{W}_{dd'}(u-v)|_{\hat{\mathcal{P}}(\varpi_d^u \otimes \varpi_{d'}^v)}$ and introduce their matrix coefficients by the following equation:

$$W_{dd'}(u-v) g_\lambda^\mu(u) \otimes g_\mu^\nu(v) = \sum_{\kappa \in \mathfrak{h}^*} W_{dd'}\left(\begin{matrix} \lambda & \mu \\ \kappa & \nu \end{matrix} \middle| u-v \right) g_\lambda^\kappa(v) \otimes g_\kappa^\nu(u).$$

By the construction, the operators $W_{dd'}(u-v)$ clearly satisfies the YBE (4.2) in operator form, and their coefficients

$$W_{dd'}\left(\begin{matrix} \lambda & \mu \\ \kappa & \nu \end{matrix} \middle| u-v \right)$$

satisfies the YBE (2.3). For $p,r \in \mathcal{P}_d$ and $s,q \in \mathcal{P}_{d'}$ $(d,d'=1,2)$ such that $p+q=r+s$, we write for brevity (as long as confusion does not arise)

$$\begin{matrix} & p & \\ s & \boxed{u} & q \\ & r & \end{matrix} = W_{dd'}\left(\begin{matrix} \lambda & \lambda+\hat{p} \\ \lambda+\hat{s} & \lambda+\hat{p}+\hat{q} \end{matrix} \middle| u \right). \tag{4.9}$$

We calculate the coefficients of the operator $W_{21}(u)$ as an example. In what follows, we will often omit the dependence of $g_\lambda^\mu(u) \in \hat{\mathcal{P}}(\varpi_d^u)$ on u (the spectral parameter) for brevity. Let $p \in \mathcal{P}_1$. From the definitions of f_λ^λ (4.5) and $\widetilde{W}_{21}$ (4.6), we have

$$\begin{aligned} W_{21}(u) f_\lambda^\lambda \otimes e_\lambda^{\lambda+\hat{p}} &= \widetilde{W}_{21}(u) f_\lambda^\lambda \otimes e_\lambda^{\lambda+\hat{p}} \\ &= \widetilde{W}_{21}(u)\left(\sum_{r \in \mathcal{P}_1} [2\lambda_r + 2\hbar] e_\lambda^{\lambda+\hat{r}} \otimes e_{\lambda+\hat{r}}^\lambda \otimes e_\lambda^{\lambda+\hat{p}} \right) \\ &= \sum_{q \in \mathcal{P}_1} e_\lambda^{\lambda+\hat{q}} \otimes \left(\sum_{\substack{s,t \in \mathcal{P}_1 \\ s+t=p-q}} V_q(\lambda;s,t;u) e_{\lambda+\hat{q}}^{\lambda+\hat{q}+\hat{s}} \otimes e_{\lambda+\hat{q}+\hat{s}}^{\lambda+\hat{p}} \right), \end{aligned}$$

where we denote by $V_q(\lambda;s,t;u)$ the following function:

$$\sum_{r \in \mathcal{P}_1} [2\lambda_r + 2\hbar] W_{11}\left(\begin{matrix} \lambda & \lambda+\hat{r} \\ \lambda+\hat{q} & \lambda+\hat{q}+\hat{s} \end{matrix} \middle| u \right) W_{11}\left(\begin{matrix} \lambda+\hat{r} & \lambda \\ \lambda+\hat{q}+\hat{s} & \lambda+\hat{p} \end{matrix} \middle| u-\hbar \right).$$

If $q \in \mathcal{P}_1$ such that $q \neq \pm p$, then the functions $V_q(\lambda;s,t;u)$ vanish except for $(s,t)=(p,-q)$ or $(-q,p)$, and one can easily show that

$$\frac{V_q(\lambda;p,-q;u)}{[(\lambda+\hat{q})_{p+q}+\hbar]} = \frac{V_q(\lambda;-q,p;u)}{[(\lambda+\hat{q})_{-q-p}+\hbar]}. \tag{4.10}$$

This equation implies that the vector

$$V_q(\lambda;p,-q;u) e_{\lambda+\hat{q}}^{\lambda+\hat{q}+\hat{p}} \otimes e_{\lambda+\hat{q}+\hat{p}}^{\lambda+\hat{p}} + V_q(\lambda;-q,p;u) e_{\lambda+\hat{q}}^{\lambda} \otimes e_\lambda^{\lambda+\hat{p}}$$

is proportional to $f^{\lambda+\hat{p}}_{\lambda+\hat{q}}$ and its coefficient [the both-hand sides of (4.10)] is calculated as

$$\frac{[u-\hbar][u+\hbar][u+3\hbar][2\hbar]}{[-3\hbar]^2[\hbar]^2}\,\frac{[\lambda_{q-p}-\hbar-u][2\lambda_q+2\hbar]}{[\lambda_{q-p}-\hbar][\lambda_{q+p}+\hbar]},$$

by using the three-term identity (3.13). This function is labeled by [see (4.9)]

$$\begin{array}{ccc} & 0 & \\ q & \boxed{u} & p \\ & p-q & \end{array} \quad (q\neq \pm p).$$

Let us consider the term for $q=p$. For all $s\in\mathcal{P}_1$ we have from the three-term identity,

$$\frac{V_p(\lambda;s,-s;u)}{[2(\lambda+\hat{p})_s+2\hbar]}=\frac{[u-\hbar][u+\hbar][u+3\hbar]}{[-3\hbar]^2[\hbar]}\,\frac{[u+\hbar]}{[\hbar]}\prod_{\substack{r\in\mathcal{P}_1\\ r\neq\pm p}}\frac{[\lambda_{p+r}+2\hbar]}{[\lambda_{p+r}+\hbar]}. \tag{4.11}$$

The right-hand side of this equation is independent of $s\in\mathcal{P}_1$. Thus, we see that the vector,

$$\sum_{s\in\mathcal{P}_1} V_p(\lambda;s,-s;u)e^{\lambda+\hat{p}+\hat{s}}_{\lambda+\hat{p}}\otimes e^{\lambda+\hat{p}}_{\lambda+\hat{p}+\hat{s}},$$

is proportional to $f^{\lambda+\hat{p}}_{\lambda+\hat{p}}$ and its coefficient is equal to the right-hand side of (4.11), which is labeled by

$$\begin{array}{ccc} & 0 & \\ p & \boxed{u} & p. \\ & 0 & \end{array}$$

Here we write all fused Boltzmann weights [the coefficients of the operator $W_{21}(u)$]. They are obtained by the three-term identity (3.13). We assume that $p,q\in\mathcal{P}_1$ satisfy $p\neq\pm q$. The common factor $[u-\hbar][u+\hbar][u+3\hbar][-3\hbar]^{-2}[\hbar]^{-1}$ is dropped:

$$\begin{array}{ccc} & p+q & \\ q & \boxed{u} & q \\ & p+q & \end{array}=\frac{[u+2\hbar]}{[\hbar]},$$

$$\begin{array}{ccc} & p-q & \\ q & \boxed{u} & q \\ & p-q & \end{array}=\frac{[u]}{[\hbar]}\,\frac{[2\lambda_q+2\hbar]}{[2\lambda_q]}\,\frac{[\lambda_{p-q}-\hbar]}{[\lambda_{p-q}+\hbar]},$$

$$\begin{array}{ccc} & 0 & \\ q & \boxed{u} & q \\ & 0 & \end{array}=\frac{[u+\hbar]}{[\hbar]}\prod_{\substack{r\in\mathcal{P}_1\\ r\neq\pm q}}\frac{[\lambda_{q+r}+2\hbar]}{[\lambda_{q+r}+\hbar]}, \tag{4.12}$$

$$\begin{array}{ccc} & q-p & \\ q & \boxed{u} & p \\ & 0 & \end{array}=\frac{[\lambda_{q-p}-u][\lambda_{q+p}+2\hbar]}{[2\lambda_p][\lambda_{q-p}+\hbar]}, \tag{4.13}$$

$$\begin{array}{ccc} & 0 & \\ q & \boxed{u} & p \\ & p-q & \end{array}=\frac{[2\hbar]}{[\hbar]}\,\frac{[2\lambda_{q-p}-\hbar-u][2\lambda_q+2\hbar]}{[2\lambda_{q-p}-\hbar][\lambda_{q+p}+\hbar]}, \tag{4.14}$$

$$\begin{array}{ccc} & p+q & \\ q & \boxed{u} & -q \\ & p-q & \end{array} = \frac{[2\hbar]}{[\hbar]}\frac{[2\lambda_q-u][\lambda_{p-q}-\hbar]}{[2\lambda_q][\lambda_{p+q}+\hbar]}.$$

Next, we give the example of W_{12}. In this case, the common factor $[u][u+2\hbar][u+4\hbar][-3\hbar]^{-2}[\hbar]^{-1}$ is dropped. To obtain them, we use only the three-term identity (3.13):

$$\begin{array}{ccc} & p & \\ p+q & \boxed{u} & p+q \\ & p & \end{array} = \frac{[u+3\hbar]}{[\hbar]},$$

$$\begin{array}{ccc} & p & \\ q-p & \boxed{u} & q-p \\ & p & \end{array} = \frac{[u+\hbar]}{[\hbar]}\frac{[2\lambda_p-2\hbar]}{[2\lambda_p]}\frac{[\lambda_{q-p}+2\hbar]}{[\lambda_{q-p}]},$$

$$\begin{array}{ccc} & p & \\ 0 & \boxed{u} & 0 \\ & p & \end{array} = \frac{[u+2\hbar]}{[\hbar]}\prod_{\substack{r\in\mathcal{P}_1\\ r\neq\pm p}}\frac{[\lambda_{p+r}-\hbar]}{[\lambda_{p+r}]}, \tag{4.15}$$

$$\begin{array}{ccc} & p & \\ 0 & \boxed{u} & q-p \\ & q & \end{array} = \frac{[\lambda_{p-q}-2\hbar-u][\lambda_{p+q}-\hbar]}{[2\lambda_p][\lambda_{q-p}]},$$

$$\begin{array}{ccc} & p & \\ p-q & \boxed{u} & 0 \\ & q & \end{array} = \frac{[2\hbar]}{[\hbar]}\frac{[\lambda_{p-q}-\hbar-u][2\lambda_q-2\hbar]}{[\lambda_{q-p}][\lambda_{p+q}]},$$

$$\begin{array}{ccc} & p & \\ p+q & \boxed{u} & q-p \\ & -p & \end{array} = \frac{[2\hbar]}{[\hbar]}\frac{[2\lambda_p-\hbar-u][\lambda_{p+q}+2\hbar]}{[2\lambda_p][\lambda_{q-p}]}.$$

Finally, we give the example of W_{22}. They are equivalent to the Boltzmam weights associated to the vector representation of the type B_2 Lie algebra (see Ref. 6). We write only two cases as an example, which is used to define the difference operator $M_2(u)$. We will drop the common factor $G(u)$ (2.4) here:

$$\begin{array}{ccc} & p+q & \\ 0 & \boxed{u} & 0 \\ & p+q & \end{array} = \frac{[\lambda_{p+q}-\hbar]}{[\lambda_{p+q}+\hbar]}, \tag{4.16}$$

$$\begin{array}{ccc} & 0 & \\ 0 & \boxed{u} & 0 \\ & 0 & \end{array} = \frac{[2\hbar]}{[6\hbar]}\left(\sum_{\substack{r=\pm\epsilon_1\\ s=\pm\epsilon_2}}\frac{[2\lambda_r+2\hbar][2\lambda_s+2\hbar]}{[2\lambda_r][2\lambda_s]}\frac{[\lambda_{r+s}-5\hbar][\lambda_{r+s}+2\hbar]}{[\lambda_{r+s}][\lambda_{r+s}+\hbar]}-\frac{[u+6\hbar][u-3\hbar]}{[u][u+3\hbar]}\right). \tag{4.17}$$

The formulas (4.15), (4.16), and (4.17) together give the explicit form of $\widetilde{M}_d$ [Theorem 1 (ii)].

We explain how to calculate the fused Boltzmann weight

$$\begin{array}{ccc} & 0 & \\ 0 & \boxed{u} & 0. \\ & 0 & \end{array}$$

According to the definition of the operator $W_{22}(u)$ and the vector f_λ^λ (4.5), the coefficient of $W_{22}(u)f_\lambda^\lambda\otimes f_\lambda^\lambda$ with respect to $f_\lambda^\lambda\otimes f_\lambda^\lambda$ is equal to

$$\frac{1}{[2\lambda_p+2\hbar]}\sum_{r\in\mathcal{P}_1}[2\lambda_r+2\hbar]W_{21}\left(\begin{matrix}\lambda & \lambda\\ \lambda+\hat{p} & \lambda+\hat{r}\end{matrix}\middle| u\right)W_{21}\left(\begin{matrix}\lambda+\hat{p} & \lambda+\hat{r}\\ \lambda & \lambda\end{matrix}\middle| u+\hbar\right). \tag{4.18}$$

In this summation, if r is equal to $-p$, then

$$W_{21}\left(\begin{matrix}\lambda & \lambda\\ \lambda+\hat{p} & \lambda-\hat{p}\end{matrix}\middle| u\right)=0,$$

so that (4.18) can be rewritten as

$$W_{21}\left(\begin{matrix}\lambda & \lambda\\ \lambda+\hat{p} & \lambda+\hat{p}\end{matrix}\middle| u\right)W_{21}\left(\begin{matrix}\lambda+\hat{p} & \lambda+\hat{p}\\ \lambda & \lambda\end{matrix}\middle| u+\hbar\right)$$
$$+\sum_{\substack{q\in\mathcal{P}_1\\ q\neq\pm p}}\frac{[2\lambda_q+2\hbar]}{[2\lambda_p+2\hbar]}W_{21}\left(\begin{matrix}\lambda & \lambda\\ \lambda+\hat{p} & \lambda+\hat{q}\end{matrix}\middle| u\right)W_{21}\left(\begin{matrix}\lambda+\hat{p} & \lambda+\hat{q}\\ \lambda & \lambda\end{matrix}\middle| u+\hbar\right).$$

By means of (4.12), (4.13), and (4.14), this function is equal to

$$\frac{[u-\hbar][u][u+\hbar][u+2\hbar][u+3\hbar][u+4\hbar][2\hbar]}{[-3\hbar]^3[\hbar]^4}$$
$$\times\left(\frac{[u+\hbar][u+2\hbar]}{[2\hbar][-3\hbar]}\prod_{\substack{q\in\mathcal{P}_1\\ q\neq\pm p}}\frac{[\lambda_{p+q}-\hbar][\lambda_{p+q}+2\hbar]}{[\lambda_{p+q}][\lambda_{p+q}+\hbar]}\right.$$
$$\left.+\frac{[\hbar]}{[-3\hbar]}\sum_{\substack{q\in\mathcal{P}_1\\ q\neq\pm p}}\frac{[2\lambda_q-2\hbar]}{[2\lambda_q]}\frac{[\lambda_{p+q}+2\hbar+u][\lambda_{p+q}-\hbar-u][\lambda_{p-q}-\hbar]}{[\lambda_{p+q}][\lambda_{p+q}-\hbar][\lambda_{p-q}+\hbar]}\right).$$

To obtain the formula (4.17), we use the following lemma.

Lemma 2: For any $p\in\mathcal{P}_1$, we have

$$\frac{[u+\hbar][u+2\hbar]}{[2\hbar][-3\hbar]}\prod_{\substack{q\in\mathcal{P}_1\\ q\neq\pm p}}\frac{[\lambda_{p+q}-\hbar]}{[\lambda_{p+q}]}\frac{[\lambda_{p+q}+2\hbar]}{[\lambda_{p+q}+\hbar]}$$
$$+\frac{[\hbar]}{[-3\hbar]}\sum_{\substack{q\in\mathcal{P}_1\\ q\neq\pm p}}\frac{[2\lambda_q-2\hbar]}{[2\lambda_q]}\frac{[\lambda_{p+q}+2\hbar+u][\lambda_{p+q}-\hbar-u][\lambda_{p-q}-\hbar]}{[\lambda_{p+q}][\lambda_{p+q}-\hbar][\lambda_{p-q}+\hbar]}$$
$$=\frac{[u][u+3\hbar]}{[6\hbar][-3\hbar]}\sum_{\substack{r=\pm\epsilon_1\\ s=\pm\epsilon_2}}\frac{[2\lambda_r+2\hbar][2\lambda_s+2\hbar]}{[2\lambda_r][2\lambda_s]}\frac{[\lambda_{r+s}-5\hbar][\lambda_{r+s}+2\hbar]}{[\lambda_{r+s}][\lambda_{r+s}+\hbar]}+\frac{[u+6\hbar][u-3\hbar]}{[6\hbar][u+3\hbar]}. \tag{4.19}$$

Proof: Let $f(\lambda_p)$ be (the left-hand side)−(the right-hand side) of (4.19), regarded as a function of λ_p. It is doubly periodic function of the periods $1,\tau$. Let us show that it is entire. The apparent poles of $f(\lambda_p)$ are located at

$$\lambda_p=\lambda_q,\quad \lambda_p=\lambda_q\pm h(p,q\in\mathcal{P}_1,p+q\neq 0),\quad \lambda_p=0(p\in\mathcal{P}_1).$$

Note that the left-hand side of (4.19) is clearly invariant under $\lambda_q \mapsto -\lambda_q$, and the right-hand side is W invariant. In view of the symmetry, it suffices to check the regularity at $\lambda_p=\lambda_q$, $\lambda_p=\lambda_q-\hbar$, and $\lambda_p=0$. By the three-term identity (3.13), it is easy to see that the residue of $f(\lambda_p)$ at $\lambda_p=\lambda_q-\hbar$ vanishes. Manifestly, the point $\lambda_p=\lambda_q$ and $\lambda_p=0$ is regular.

Now we have proved that $f(\lambda_p)$ is independent of λ_p. We will show $f(-\lambda_q-2\hbar)=0$. This can be directly checked by using the identity (3.13) twice, and the proof completes. □

V. COMMUTATIVITY OF THE DIFFERENCE OPERATORS

This section is devoted to the proof of commutativity of the difference operators [Theorem 1(i)]. For $t\in\mathcal{P}_d+\mathcal{P}_{d'}$ we will introduce the matrices $A_t(\lambda|u,v)$, $B_t(\lambda|v,u)$ whose index set is $I_t:=\{(p,q)\in\mathcal{P}_d\times\mathcal{P}_{d'}|p+q=t\}$:

$$A_t(\lambda|u,v)^{(p,q)}_{(r,s)}:=W_{d2}\left(\begin{matrix}\lambda & \lambda+\hat{p}\\ \lambda & \lambda+\hat{r}\end{matrix}\middle| u\right)W_{d'2}\left(\begin{matrix}\lambda+\hat{p} & \lambda+\hat{t}\\ \lambda+\hat{r} & \lambda+\hat{t}\end{matrix}\middle| v\right),$$

$$B_t(\lambda|v,u)^{(p,q)}_{(r,s)}:=W_{d'2}\left(\begin{matrix}\lambda & \lambda+\hat{q}\\ \lambda & \lambda+\hat{s}\end{matrix}\middle| v\right)W_{d2}\left(\begin{matrix}\lambda+\hat{q} & \lambda+\hat{t}\\ \lambda+\hat{s} & \lambda+\hat{t}\end{matrix}\middle| u\right).$$

With these matrices, we can write down both the left- and right-hand sides as

$$M_d(u)M_{d'}(v)=\sum_{t\in\mathcal{P}_d+\mathcal{P}_{d'}}\operatorname{tr}A_t(\lambda|u,v)T_{\hat{t}},\quad M_{d'}(v)M_d(u)=\sum_{t\in\mathcal{P}_d+\mathcal{P}_{d'}}\operatorname{tr}B_t(\lambda|v,u)T_{\hat{t}}.$$

Let us also define the matrix $W_t(\lambda|u-v)$ with the same index set:

$$W_t(\lambda|u-v)^{(p,q)}_{(r,s)}:=W_{dd'}\left(\begin{matrix}\lambda & \lambda+\hat{p}\\ \lambda+\hat{s} & \lambda+\hat{t}\end{matrix}\middle| u-v\right).$$

The YBE (2.3) implies

$$W_t(\lambda|u-v)A_t(\lambda|u,v)=B_t(\lambda|v,u)W_t(\lambda|u-v).$$

By the inversion relation (3.8), it can be seen that $W_t(\lambda|u-v)$ is invertible for generic $u,v\in\mathbb{C}$. It follows that $\operatorname{tr}A_t(\lambda|u,v)=\operatorname{tr}B_t(\lambda|v,u)$ for all $u,v\in\mathbb{C}$. Hence, we have $M_d(u)M_{d'}(v)=M_{d'}(v)M_d(u)$ for all $u,v\in\mathbb{C}$.

VI. SPACE OF WEYL GROUP-INVARIANT THETA FUNCTIONS

This section is devoted to the proof of Theorem 2. Let $Q^\vee$, $P^\vee$ be the coroot and coweight lattice, respectively. Under the identification $\mathfrak{h}=\mathfrak{h}^*$ via the form (,), these are given by

$$Q^\vee=\mathbb{Z}2\epsilon_1\oplus\mathbb{Z}2\epsilon_2,\quad P^\vee=Q^\vee+\mathbb{Z}(\epsilon_1+\epsilon_2).$$

Lemma 3: For all $\beta\in P^\vee$ and d=1,2, we have

$$[S_{\tau\beta},M_d(u)]=[S_\beta,M_d(u)]=0. \tag{6.1}$$

Proof: Note that if $p,q\in\mathcal{P}_1\,(q\neq\pm p)$ and $\beta\in P^\vee$ then $\beta_{p+q}\in\mathbb{Z}$. By the quasiperiodicity (2.2), we have

$$\frac{[(\lambda+\tau\beta)_{p+q}-\hbar]}{[(\lambda+\tau\beta)_{p+q}]}=e^{2\pi i\beta_{p+q}\hbar}\frac{[\lambda_{p+q}-\hbar]}{[\lambda_{p+q}]},\quad \frac{[(\lambda+\beta)_{p+q}-\hbar]}{[(\lambda+\beta)_{p+q}]}=\frac{[\lambda_{p+q}-\hbar]}{[\lambda_{p+q}]}.$$

Using these equations, we have, for all $p\in\mathcal{P}_1$,

$$S_{\tau\beta}\prod_{q\neq\pm p}\frac{[\lambda_{p+q}-\hbar]}{[\lambda_{p+q}]}T_{\hat{p}}f(\lambda)=e^{2\pi i((\lambda,\beta)+\tau(\beta,\beta)/2)}\prod_{q\neq\pm p}\frac{[(\lambda+\tau\beta)_{p+q}-\hbar]}{[(\lambda+\tau\beta)_{p+q}]}f(\lambda+\tau\beta+\hat{p})$$
$$=e^{2\pi i((\lambda,\beta)+\tau(\beta,\beta)/2+2\beta_p\hbar)}\prod_{q\neq\pm p}\frac{[\lambda_{p+q}-\hbar]}{[\lambda_{p+q}]}f(\lambda+\tau\beta+\hat{p})$$
$$=\prod_{q\neq\pm p}\frac{[\lambda_{p+q}-\hbar]}{[\lambda_{p+q}]}T_{\hat{p}}S_{\tau\beta}f(\lambda),$$

and

$$S_{\beta}\prod_{q\neq\pm p}\frac{[\lambda_{p+q}-\hbar]}{[\lambda_{p+q}]}T_{\hat{p}}f(\lambda)=\prod_{q\neq\pm p}\frac{[(\lambda+\beta)_{p+q}-\hbar]}{[(\lambda+\beta)_{p+q}]}f(\lambda+\beta+\hat{p})$$
$$=\prod_{q\neq\pm p}\frac{[\lambda_{p+q}-\hbar]}{[\lambda_{p+q}]}f(\lambda+\beta+\hat{p})$$
$$=\prod_{q\neq\pm p}\frac{[\lambda_{p+q}-\hbar]}{[\lambda_{p+q}]}T_{\hat{p}}S_{\beta}f(\lambda).$$

Note that $2\beta_p\hbar=(\hat{p},\beta)$, etc. Hence, we have $[S_{\tau\beta},M_1(u)]=[S_\beta,M_1(u)]=0$. In the same way, we can see that the principal part of $\widetilde{M}_2$ commutes with $S_{\tau\beta}$ and S_β, using the equations

$$\frac{[(\lambda+\tau\beta)_{p+q}-\hbar]}{[(\lambda+\tau\beta)_{p+q}+\hbar]}=e^{2\pi i(2\beta_{p+q}\hbar)}\frac{[\lambda_{p+q}-\hbar]}{[\lambda_{p+q}+\hbar]},\quad \frac{[(\lambda+\beta)_{p+q}-\hbar]}{[(\lambda+\beta)_{p+q}+\hbar]}=\frac{[\lambda_{p+q}-\hbar]}{[\lambda_{p+q}+\hbar]}.$$

Using (2.2) it is easy to see that the function,

$$C_{p,q}(\lambda):=\frac{[2\hbar]}{[6\hbar]}\frac{[2\lambda_p+2\hbar]}{[2\lambda_p]}\frac{[2\lambda_q+2\hbar]}{[2\lambda_q]}\frac{[\lambda_{p+q}-5\hbar]}{[\lambda_{p+q}+\hbar]}\frac{[\lambda_{p+q}+2\hbar]}{[\lambda_{p+q}]}\quad (p,q\in\mathcal{P}_1,p+q\neq 0),$$

satisfies $C_{p,q}(\lambda+\beta)=C_{p,q}(\lambda+\tau\beta)=C_{p,q}(\lambda)(\forall\beta\in P^\vee)$. This means that $S_{\tau\beta}$, $S_\beta\,(\beta\in P^\vee)$ commute with a multiplication by $C_{p,q}(\lambda)$. □

Lemma 4: For all $\gamma\in P^\vee$, *we have*

$$S_{\tau\gamma}Th^W\subset Th^W,\quad S_\gamma Th^W\subset Th^W. \tag{6.2}$$

Proof: Let $f\in Th^W$ and $\gamma\in P^\vee$. Since the bilinear form (,) is W invariant, we have $(S_{\tau\gamma}f)(w\lambda)=(S_{\tau w^{-1}(\gamma)}f)(\lambda)$. Using (2.5), we can write this as $(S_{\tau\gamma}S_{\tau(w^{-1}(\gamma)-\gamma)}f)(\lambda)$, which is equal to $S_{\tau\gamma}f(\lambda)$ in view of $w^{-1}(\gamma)-\gamma\in Q^\vee$. In the same way, we can show that $(S_\gamma f)(w\lambda)=(S_\gamma f)(\lambda)$.

Evidently, $S_{\tau\gamma}f$ and $S_\gamma f$ are holomorphic. For all $\alpha\in Q^\vee$, using (2.5) and $(\gamma,\alpha)\in\mathbb{Z}$, it can be seen that the operators S_α, $S_{\tau\alpha}$ commute with S_γ, $S_{\tau\gamma}$. Hence, $S_{\tau\gamma}f$ or $S_\gamma f$ are fixed by $S_{\tau\alpha}$ and S_α. □

Here we prove Theorem 2.

Proof of Theorem 2: Let f be any function in Th^W. In view of (6.1), we have $S_\alpha\widetilde{M}_d f=S_{\tau\alpha}\widetilde{M}_d f=\widetilde{M}_d f$ for all $\alpha\in Q^\vee\subset P^\vee$. It is clear from the explicit form of $\widetilde{M}_d$ that $\widetilde{M}_d f(w\lambda)=\widetilde{M}_d f(\lambda)$ for all $w\in W$.

Let us show that the function $\widetilde{M}_d f$ is holomorphic on $\mathfrak{h}^*$. For $\mu\in\mathfrak{h}^*$ and $z\in\mathbb{C}$, we denote by D_μ^z the line in $\mathfrak{h}^*$, defined by

$$D_\mu^z:=\{\lambda\in\mathfrak{h}^*|(\lambda,\mu)+z=0\}.$$

The coefficients of the difference operators $\tilde{M}_d$ have their possible simple poles along $D+P^\vee+\tau P^\vee$, where we put

$$D:=\bigcup_{p\in R_+} D_p^0 \ \cup \bigcup_{q\in\mathcal{P}_2-\{0\}} D_q^\hbar,$$

and R_+ is a fixed set of positive roots.

Next we will show that for any function f in Th^W, $\tilde{M}_d f$ is regular along D. Let us consider the meromorphic function $g:=(\Pi_{p\in R_+}[\lambda_p])\,\tilde{M}_d f$, which is regular along $D^0:=\cup_{p\in R_+}D_p^0$. Since $\tilde{M}_d f$ is W invariant, it is clear that g is W anti-invariant. This implies that g has zero along D^0 and hence $\tilde{M}_d f$ is regular along D^0.

The holomorphy along $\cup_{q\in\mathcal{P}_2-\{0\}}D_q^\hbar$ is somewhat nontrivial. Let $p=\pm\epsilon_1$, $q=\pm\epsilon_2$. Clearly, $\tilde{M}_1 f$ is regular along $D_{p+q}^\hbar$. Let us consider the function $\tilde{M}_2 f$. It suffices to show that the following function is regular along $D_{p+q}^\hbar$:

$$\frac{[\lambda_{p+q}-\hbar]}{[\lambda_{p+q}+\hbar]}T_{\hat{p}}T_{\hat{q}}f(\lambda)+\frac{[2\hbar]}{[6\hbar]}\frac{[2\lambda_p+2\hbar]}{[2\lambda_p]}\frac{[2\lambda_q+2\hbar]}{[2\lambda_q]}\frac{[\lambda_{p+q}-5\hbar]}{[\lambda_{p+q}+\hbar]}\frac{[\lambda_{p+q}+2\hbar]}{[\lambda_{p+q}]}f(\lambda).$$

We note that, for any W-invariant function f, we have $(T_{\hat{p}}T_{\hat{q}}f-f)|_{D_{p+q}^\hbar}=0$. In view of this, the residue of the above function along $D_{p+q}^\hbar$ is easily seen to vanish. Thus, we have proved that for any function f in Th^W, the functions $\tilde{M}_d f(d=1,2)$ are regular along D.

For $\beta,\gamma\in P^\vee$, we have, by the definitions of $S_{\tau\beta}$, S_γ, and (6.1),

$$\tilde{M}_d f(\lambda+\beta\tau+\gamma)=e^{-2\pi i((\lambda,\beta)+\tau(\beta,\beta)/2)}S_{\tau\beta}S_\gamma\tilde{M}_d f(\lambda)=e^{-2\pi i((\lambda,\beta)+\tau(\beta,\beta)/2)}\tilde{M}_d S_{\tau\beta}S_\gamma f(\lambda). \tag{6.3}$$

Since $S_{\tau\beta}S_\gamma f$ belongs to Th^W by (6.2), $\tilde{M}_d S_{\tau\beta}S_\gamma f$ is regular along D. Then (6.3) implies that $\tilde{M}_d f$ is regular along $D+\beta\tau+\gamma$. The proof is completed. □

ACKNOWLEDGMENTS

The authors are grateful to Masato Okado and Michio Jimbo who kindly let them know detailed points in the proof of the YBE of the Boltzmann weight. They also thank Toshiki Nakashima for useful information and Gen Kuroki, Masatoshi Noumi, Hiroyuki Ochiai, Yasuhiko Yamada, Yasushi Komori, and Kazuhiro Hikami for fruitful discussions and kind interest. Much of the work was done when T. I. was a postdoctral student at the Mathematical Institute, Tohokn University. He would like to thank the staff of the Institute for their support.

APPENDIX: SIMILARITY TRANSFORMATION

Our Boltzmann weights in Sec. III and the original form in Ref. 6 are slightly different. The original form of type (3.3) and (3.4) are given as follows:

$$p\underset{q}{\overset{q}{\boxed{u}}}p=\frac{[c-u][u]}{[c][\hbar]}\left(\frac{[\lambda_{p-q}+\hbar][\lambda_{p-q}-\hbar]}{[\lambda_{p-q}]^2}\right)^{1/2}\quad(p\neq\pm q), \tag{A1}$$

$$p\underset{-p}{\overset{q}{\boxed{u}}}-q=\frac{[u][\lambda_{p+q}+\hbar+c-u]}{[c][\lambda_{p+q}+\hbar]}(G_{\lambda p}G_{\lambda q})^{1/2}\quad(p\neq q). \tag{A2}$$

All the other Boltzmann weights [(3.1),(3.2),(3.5)] are the same as the ones we adopted in Sec. III. We denote these weights by

$$W_{JMO}\left(\begin{matrix}\lambda & \mu \\ \kappa & \nu\end{matrix}\middle| u\right).$$

Our Boltzmann weights are obtained from those by the following way. We introduce an ordering on the set $\mathcal{P}$ as

$$\epsilon_1 \prec \epsilon_2 \prec \cdots \prec \epsilon_n \prec -\epsilon_n \prec \cdots \prec -\epsilon_2 \prec -\epsilon_1 .$$

For $\lambda, \mu \in \mathfrak{h}^*$, such that $\mu - \lambda = \hat{q} \in 2\hbar\mathcal{P}$, we define the function $s(\lambda,\mu)$ by

$$s(\lambda,\mu) := \prod_{\substack{p\in\mathcal{P} \\ p\prec q}} [\lambda_{p-q}]^{-1/2}[\mu_{p-q}]^{-1/2}. \tag{A3}$$

The relation between the Boltzmann weights W in Sec. III and the ones in Ref. 6 is as follows:

$$W\left(\begin{matrix}\lambda & \mu \\ \kappa & \nu\end{matrix}\middle| u\right) = \frac{s(\lambda,\mu)s(\mu,\nu)}{s(\lambda,\kappa)s(\kappa,\nu)} W_{JMO}\left(\begin{matrix}\lambda & \mu \\ \kappa & \nu\end{matrix}\middle| u\right). \tag{A4}$$

(Received 24 June 1998; accepted for publication 9 April 1999)

Jordanian quantizations of Lie algebras are studied using the factorizable twists. For a restricted Borel subalgebra $\mathbf{B}^\vee$ of $\mathrm{sl}(N)$ the explicit expressions are obtained for the twist element $\mathcal{F}$, universal $\mathcal{R}$-matrix and the corresponding canonical element $\mathcal{T}$. It is shown that the twisted Hopf algebra $\mathcal{U}_{\mathcal{F}}(\mathbf{B}^\vee)$ is self-dual. The cohomological properties of the involved Lie bialgebras are studied to justify the existence of a contraction from the Dinfeld–Jimbo quantization to the Jordanian one. The construction of the twist is generalized to a certain type of inhomogenious Lie algebras. © *1999 American Institute of Physics.* [S0022-2488(99)02707-3]

I. INTRODUCTION

The thorough formulation of the theory of quantum groups by Drinfeld[1] includes two types of Hopf algebras: triangular (with the universal $\mathcal{R}$-matrix satisfying the relation $\mathcal{R}_{21}\mathcal{R}=1$) and quasitriangular (with $\mathcal{R}_{21}\mathcal{R}\neq 1$). Deformations of universal enveloping of simple Lie algebras initiated by the quantum inverse scattering method and discovered by Drinfeld and Jimbo[1,2] belong to the latter class. In the framework of the deformation quantization theory[3] these quantum algebras correspond to Lie bialgebras with classical r-matrix

$$r_{\mathrm{DJ}}=\sum_{i=1}^{k} t_{ij}H_i\otimes H_j+\sum_{\alpha\in\Phi_+} E_\alpha\otimes E_{-\alpha},$$

where k is the rank, t_{ij} is the inverse Cartan matrix, and Φ_+ is the set of positive roots. This r_{DJ} is one of the multitude of solutions to the classical Yang–Baxter equation. The detailed classification of solutions was performed for simple Lie algebras in Ref. 4, only for some of these classical r-matrices the corresponding quantum R-matrices are known explicitly.

Although the existence of quantization for any Lie bialgebra is now proved,[5] the explicit knowledge of the R-matrix as an algebraic element $\mathcal{R}$ or a matrix in some irreducible representations is required in the FRT approach[6] and in a variety of applications of quantum groups. One can mention the universal R-matrix of the quantum algebra $\mathcal{U}_q(\mathrm{sl}(2))$ (Ref. 1) which is a building block for the universal R-matrices for other simple Lie and Kac–Moody algebras. As about triangular quantum groups and twistings,[7,8] the well-known example is the Jordanian quantization of sl(2) or, more exactly, of its Borel subalgebra $\mathbf{B}_+(\{h,x|[h,x]=2x\})$ with $r=h\otimes x-x\otimes h=h\wedge x$ (Ref. 1) and the triangular R-matrix $\mathcal{R}=\mathcal{F}_{21}\mathcal{F}^{-1}$ defined by the twisting element[9,10]

$$\mathcal{F}=\exp\{\tfrac{1}{2}h\otimes\ln(1+2\xi x)\}. \tag{1}$$

This quantum algebra $\mathcal{U}_\xi(\mathrm{sl}(2))$ also found numerous applications from the deformed Heisenberg XXX-spin chain to the quantum Minkowski space (see e.g., Ref. 11) and in a few other cases.[12,13]

In the present paper we propose various extensions of this twist element. The suggested construction implies the existence (in the universal enveloping algebra to be deformed) of a subalgebra **L** with special properties of multiplication. This is a solvable subalgebra with at least four generators. All simple Lie algebras except sl(2) contain such **L** and in any of them a deformation induced by twist of **L** can be performed. In particular we study a Jordanian deformation of $\mathcal{U}(\mathrm{sl}(N))$, reaching a closed form of deformed compositions lacking in Ref. 9. Using the notion of factorizible twist,[14] we prove that the element $\mathcal{F}\in\mathcal{U}(\mathrm{sl}(N))^{\otimes 2}$,

$$\mathcal{F}=\exp\left\{2\xi\sum_{i=2}^{N-1} E_{1i}\otimes E_{iN}e^{-\sigma}\right\}\exp\{H\otimes\sigma\},\tag{2}$$

where $x=E_{1N}$, $H=E_{11}-E_{NN}$, $\sigma=\frac{1}{2}\ln(1+2\xi x)$, satisfies the twist equation. Hence, it defines a triangular deformation of $\mathcal{U}(\mathrm{sl}(N))$. In such Hopf algebras deformed by Jordanian twist the subset of Cartan generators $\{E_{ii}-E_{jj}\}$ with $i<j$, $i,j\neq 1,N$, remains untouched. Hence there is a possibility to perform additional multiparametric deformation using the Reshetikhin twist.[15]

The main ingredients of the quantum group theory[1] are constructed: the universal R-matrix, the dual Hopf algebra [quantized function algebra on $\mathrm{SL}(N)$], the universal $\mathcal{T}$-matrix (canonical element) for the subalgebra which induces the twist of $\mathcal{U}(\mathrm{sl}(N))$ and the self-duality of **L**. Cohomological interpretation of the interrelation between the Drinfeld–Jimbo (or standard) quantum algebra $\mathcal{U}_q(\mathrm{sl}(N))$ and the Jordanian (or nonstandard) one $\mathcal{U}_\xi(\mathrm{sl}(N))$ is discussed. The real form and the corresponding quantum linear space are given. We present also further generalization in which the subalgebra **L** is substituted by a certain type of inhomogeneous Lie algebras.

The connection of the Drinfeld–Jimbo deformation[1,2] with the Jordanian deformation was already pointed out in Ref. 9. The similarity transformation of the classical matrix r_{DJ} performed by the operator $\exp(\xi\mathrm{ad}E_{1N})$ (with the highest root generator E_{1N}) turns r_{DJ} into the sum $r_{\mathrm{DJ}}+\xi r_j$.[9] Hence,

$$r_j=-\xi\left(H_{1N}\wedge E_{1N}+2\sum_{k=2}^{N-1} E_{1k}\wedge E_{kN}\right)\tag{3}$$

is a classical r-matrix too, which defines the corresponding deformation. A contraction of the quantum plane $xy=qyx$ of $\mathcal{U}_q(\mathrm{sl}(2))$ with the above-mentioned transformation in the fundamental representation $M=1+\theta\rho(E_{1N})$, $\theta=\xi(1-q)^{-1}$, results in the Jordanian plane $x'y'=y'x'+\xi y'^2$ of $\mathcal{U}_\xi(\mathrm{sl}(2))$.[10] Later, this contraction in the fundamental representation of sl(3) and sl(N) was used in many papers (cf. Refs. 16 and 17 and references therein). Let us point out that in our formulas we do not refer to any particular representation of deformed algebras.

The paper is organized as follows. After recalling briefly the basic material on twisting of Hopf algebras (Sec. II), we construct an extended Jordanian twist $\mathcal{F}$ for a four-generator Lie algebra and apply it to twist the universal enveloping algebra $\mathcal{U}(\mathrm{sl}(N))$ (Sec. III). The next section contains a cohomological explanation of the connection between the Drinfeld–Jimbo and Jordanian quantization. The main objects of the theory of quantum groups are constructed in Sec. V. Further generalization of the extended Jordanian twist to a special class of inhomogenious Lie algebras and possible research topics are given in Sec. VI and in the Conclusion.

II. TWISTING OF HOPF ALGEBRAS

A Hopf algebra $\mathcal{A}(m,\Delta,\epsilon,S)$ with multiplication $m:\mathcal{A}\otimes\mathcal{A}\rightarrow\mathcal{A}$, coproduct $\Delta:\mathcal{A}\rightarrow\mathcal{A}\otimes\mathcal{A}$, counit $\epsilon:\mathcal{A}\rightarrow C$, and antipode $S:\mathcal{A}\rightarrow\mathcal{A}$ (see definitions in Refs. 1, 6, and 18) can be transformed[7] with an invertible element $\mathcal{F}\in\mathcal{A}\otimes\mathcal{A}$, $\mathcal{F}=\sum f_i^{(1)}\otimes f_i^{(2)}$ into a twisted one $\mathcal{A}_t(m,\Delta_t,\epsilon,S_t)$. This Hopf algebra $\mathcal{A}_t$ has the same multiplication and counit maps but the twisted coproduct and antipode:

$$\Delta_t(a)=\mathcal{F}\Delta(a)\mathcal{F}^{-1},\quad S_t(a)=vS(a)v^{-1},\quad v=\sum f_i^{(1)}S(f_i^{(2)}),\quad a\in\mathcal{A}.$$

The twisting element has to satisfy the equations

$$(\epsilon\otimes\mathrm{id})(\mathcal{F})=(\mathrm{id}\otimes\epsilon)(\mathcal{F})=1, \tag{4}$$

$$\mathcal{F}_{12}(\Delta\otimes\mathrm{id})(\mathcal{F})=\mathcal{F}_{23}(\mathrm{id}\otimes\Delta)(\mathcal{F}), \tag{5}$$

where the first one is just a normalizing condition and follows from the second relation modulo a nonzero scalar factor.

A quasitriangular Hopf algebra $\mathcal{A}(m,\Delta,\epsilon,S,\mathcal{R})$ has additionally an element $\mathcal{R}\in\mathcal{A}\otimes\mathcal{A}$ (a universal R-matrix) satisfying[1]

$$(\Delta\otimes\mathrm{id})(\mathcal{R})=\mathcal{R}_{13}\mathcal{R}_{23},\quad (\mathrm{id}\otimes\Delta)(\mathcal{R})=\mathcal{R}_{13}\mathcal{R}_{12}. \tag{6}$$

The coproduct Δ and its opposite Δ^{op} are related by the similarity transformation (twisting) with $\mathcal{R}$

$$\Delta^{\mathrm{op}}(a)=\mathcal{R}\Delta(a)\mathcal{R}^{-1},\quad a\in\mathcal{A},$$

and in this case the relation (5) is just the Yang–Baxter equation.

A twisted quasitriangular quantum algebra $\mathcal{A}_t(m,\Delta_t,\epsilon,S_t,\mathcal{R}_t)$ has the twisted universal R-matrix

$$\mathcal{R}_t=\tau(\mathcal{F})\mathcal{R}\mathcal{F}^{-1}, \tag{7}$$

where τ means the permutation of the tensor factors: $\tau(f\otimes g)=(g\otimes f)$, $\tau(\mathcal{F})=\mathcal{F}_{21}$.

Although, in principle, the possibility to quantize an arbitrary Lie bialgebra has been proved,[5] an explicit formulation of Hopf operations remains a nontrivial task. In particular, the knowledge of the explicit form of the twisting cocycle is a rare case even for classical universal enveloping algebras, despite the advanced Drinfeld theory.[8] Most of the such explicitly known twisting elements have the factorization property with respect to comultiplication [cf. (6)],

$$(\Delta\otimes\mathrm{id})(\mathcal{F})=\mathcal{F}_{23}\mathcal{F}_{13}\quad\text{or}\quad(\Delta\otimes\mathrm{id})(\mathcal{F})=\mathcal{F}_{13}\mathcal{F}_{23},$$

and a similar property involving $(\mathrm{id}\otimes\Delta)$. To satisfy the twist equation, these identities are to be combined with additional requirement $\mathcal{F}_{12}\mathcal{F}_{23}=\mathcal{F}_{23}\mathcal{F}_{12}$ or the Yang–Baxter equation on $\mathcal{F}$.[14,15]

An important subclass of factorizable twists consists of elements satisfying the following equations:

$$(\Delta\otimes\mathrm{id}(\mathcal{F})=\mathcal{F}_{13}\mathcal{F}_{23}, \tag{8}$$

$$(\mathrm{id}\otimes\Delta_t)(\mathcal{F})=\mathcal{F}_{12}\mathcal{F}_{13}. \tag{9}$$

It is easy to see that the universal R-matrix $\mathcal{R}$ satisfies these equations for $\Delta_t=\Delta^{\mathrm{op}}$. Another well-developed case is the Jordanian twist of sl(2) with $\mathcal{F}$ described by (1).[10] Due to the fact that the Cartan element h is primitive in $\mathrm{sl}(2):\Delta(h)=h\otimes 1+1\otimes h$, and σ is primitive in the Jordanian $\mathcal{U}_\xi(\mathrm{sl}(2)):\Delta_t(\sigma)=\sigma\otimes 1+1\otimes\sigma$, one gets

$$(\Delta\otimes\mathrm{id})e^{h\otimes\sigma}=e^{h\otimes 1\otimes\sigma}e^{1\otimes h\otimes\sigma},$$

$$(\mathrm{id}\otimes\Delta_t)e^{h\otimes\sigma}=e^{h\otimes\sigma\otimes 1}e^{h\otimes 1\otimes\sigma}.$$

It will be shown in the next section that the element $\mathcal{F}(2)$ also satisfies the factorization equations (8) and (9) and can be used to twist the universal enveloping algebra of $\mathrm{sl}(N)$.

Let us mention that the composition of appropriate twists can be defined $\mathcal{F}=\mathcal{F}_2\mathcal{F}_1$. The element $\mathcal{F}_1$ has to satisfy the twist equation with the coproduct of the original Hopf algebra, while $\mathcal{F}_2$ must be its solution for Δ_{t_1} of the intermediate Hopf algebra twisted by $\mathcal{F}_1$. In particular, if $\mathcal{F}$ is a solution to the twist equation (5), then $\mathcal{F}^{-1}$ satisfies this equation with $\Delta\rightarrow\Delta_t$.

III. FACTORIZABLE TWISTS

Now we shall propose a new factorizable twist similar to (1) and defined on the abstract set of generators.

Let $\mathbf{L}$ be a four-dimensional Lie algebra with generators $\{H,A,B,E\}$ containing $\mathbf{B}_+$ and representable in a form of semidirect sum of one-dimensional space V_H with basic element H and a Heisenberg subalgebra $\mathcal{H}(A,B,E)$:$\mathbf{L}=V_H\triangleright\mathcal{H}$:

$$\begin{gathered}[H,E]=2E,\\ [H,A]=\alpha A,\quad [H,B]=\beta B,\quad \alpha+\beta=2,\\ [E,A]=[E,B]=0,\\ [A,B]=\gamma E.\end{gathered}\tag{10}$$

Extending the twist deformation $\mathcal{U}_t(\mathbf{B}_+)$ performed by

$$\Phi=\exp\left(\tfrac{1}{2}H\otimes\ln(1+\gamma E)\right)=e^{H\otimes\sigma}$$

to the universal enveloping $\mathcal{U}(\mathbf{L})$, one gets the twisted algebra $\mathcal{U}_\Phi(\mathbf{L})$. It retains the initial multiplication defined by (10) while its coproduct $\Delta_\Phi=\Phi\Delta\Phi^{-1}$ becomes noncocommutative:

$$\begin{gathered}\Delta_\Phi(H)=H\otimes e^{-2\sigma}+1\otimes H,\\ \Delta_\Phi(A)=A\otimes e^{\alpha\sigma}+1\otimes A,\\ \Delta_\Phi(B)=B\otimes e^{\beta\sigma}+1\otimes B,\\ \Delta_\Phi(E)=E\otimes e^{2\sigma}+1\otimes E,\end{gathered}\tag{11}$$

We shall show that the algebra $\mathcal{U}(\mathbf{L})$ allows a more complicated twist deformation containing Φ as a factor.

Theorem 1: *The element*

$$\mathcal{F}=\Phi\Phi_1=\exp(H\otimes\sigma)\exp(A\otimes Be^{-2\sigma})\tag{12}$$

is a twist for $\mathcal{U}(\mathbf{L})$.

Proof: We shall show that $\mathcal{F}=\Phi\Phi_1$ belongs to the subclass defined by the equations (8) and (9). The equation (8) is obviously true: H and A are the primitive elements and B commutes with σ in $\mathcal{U}(\mathbf{L})$. To check the second equation (9) let us consider the coproducts $\Delta_{\mathcal{F}}(\sigma)$ and $\Delta_{\mathcal{F}}(B)$. It is known that in twisted (by Φ) universal enveloping of a Borel subalgebra the element σ is primitive.[10] The element σ commutes not only with B, but also with A, so σ remains primitive with respect to $\Delta_{\mathcal{F}}$. Using the properties of ''roots'' $\alpha-2=-\beta$, the twisted coproduct of B can be written in the following form:

$$\begin{aligned}\Delta_{\mathcal{F}}(B)&=\exp\left(\mathrm{ad}(A\otimes Be^{-\beta\sigma})\right)\circ\exp\left(\mathrm{ad}(H\otimes\sigma)\right)\circ(B\otimes 1+1\otimes B)\\ &=\exp\left(\mathrm{ad}(A\otimes Be^{-\beta\sigma})\right)\circ(B\otimes e^{\beta\sigma}+1\otimes B)\\ &=\exp\left(\mathrm{ad}(A\otimes Be^{-\beta\sigma})\right)\circ(B\otimes e^{\beta\sigma})+1\otimes B.\end{aligned}$$

From (10) one can see that $(\mathrm{ad}_A)^2 \circ B = 0$. So the obtained expression can be simplified,

$$\Delta_{\mathcal{F}}(B) = B \otimes e^{\beta\sigma} + (1 + [A,B]) \otimes B = B \otimes e^{\beta\sigma} + e^{2\sigma} \otimes B.$$

Now using the coproduct

$$\Delta_{\mathcal{F}}(Be^{-2\sigma}) = Be^{-2\sigma} \otimes e^{-\alpha\sigma} + 1 \otimes Be^{-2\sigma},$$

one can easily see that

$$\exp(\mathrm{ad}\,(H \otimes 1 \otimes \sigma)) \circ (A \otimes Be^{-2\sigma} \otimes e^{-\alpha\sigma}) = A \otimes Be^{-2\sigma} \otimes 1.$$

The latter guarantees the validity of the equation (9) for the twisting element $\mathcal{F}$. ●

The deformed algebra $\mathcal{U}_{\mathcal{F}}(\mathbf{L})$ has initial commutation relations generated by (10) and twisted coproducts:

$$\begin{aligned} \Delta_{\mathcal{F}}(H) &= H \otimes e^{-2\sigma} + 1 \otimes H - 2A \otimes Be^{(\alpha-4)\sigma}, \\ \Delta_{\mathcal{F}}(A) &= A \otimes e^{-\beta\sigma} + 1 \otimes A, \\ \Delta_{\mathcal{F}}(B) &= B \otimes e^{\beta\sigma} + e^{2\sigma} \otimes B, \\ \Delta_{\mathcal{F}}(E) &= E \otimes e^{2\sigma} + 1 \otimes E. \end{aligned} \tag{13}$$

Let us rewrite the twisting element $\mathcal{F}$ in the reverse order:

$$\mathcal{F} = \widetilde{\Phi_1}\Phi = \exp(A \otimes Be^{-\beta\sigma}) \exp(H \otimes \sigma) \tag{14}$$

Now we know that both $\mathcal{F}$ and Φ are twists for $\mathcal{U}(\mathbf{L})$ and both satisfy the equations (8) and (9). Hence $\widetilde{\Phi_1}$ is also a twist element with respect to the algebra $\mathcal{U}_{\Phi}(\mathbf{L})$. Using the coalgebra relations (11), it is easy to check that $\widetilde{\Phi_1}$ satisfies the general twist equation (5),

$$(\widetilde{\Phi_1})_{12}(\Delta_{\Phi} \otimes \mathrm{id})\widetilde{\Phi_1} = (\widetilde{\Phi_1})_{23}(\mathrm{id} \otimes \Delta_{\Phi})\widetilde{\Phi_1}.$$

Note that, contrary to the properties of $\mathcal{F}$ and Φ, this twist $(\widetilde{\Phi_1})$ does not belong to the subclass of factorizable twists defined by the equations (8) and (9).

Subalgebras of the type $\mathbf{L}$ exist in a large class of Lie algebras. They can also be found in any simple Lie algebra of rank greater than 1. Such simple algebras contain at least one pair of roots λ_1 and λ_2 such that $\lambda_3 = \lambda_1 + \lambda_2$ is also a root. The corresponding generators X_1, X_2, X_3 together with the Cartan element H_3 dual to the root λ_3 form the subalgebra equivalent to $\mathbf{L}$. As we have shown above such a subalgebra can be twisted with the element $\mathcal{F}$ and the corresponding deformation can be extended to the whole algebra $\mathcal{U}$ and its twisted version $\mathcal{U}_{\mathcal{F}}$ can be thus constructed.

We shall demonstrate the deformations generated by these twists in the case of simple algebras of series A_{N-1}. For our purposes it will be convenient to use the canonical basis of $\mathrm{gl}(N)$ for the compositions of $\mathcal{U}(\mathrm{sl}(N))$

$$[E_{ik}, E_{lm}] = \delta_{kl}E_{im} - \delta_{im}E_{lk}, \quad i,k,l,m = 1,\ldots N. \tag{15}$$

The Cartan elements of $\mathcal{U}(\mathrm{sl}(N))$ will be fixed as $H_{ik} = E_{ii} - E_{kk}$.

Let $H \in \mathbf{L}$ be identified with the Cartan element dual to the highest root of $\mathrm{sl}(N)$. This root will be denoted by λ_H. Collecting all the pairs of roots with the property $\lambda_H = \lambda_1 + \lambda_2$ one can get the multiparametric twist of the type $\mathcal{F}$ with

$$H=H_{1N},\quad E=E_{1N},$$
$$A=\sum_k \,(a^{1k}E_{1k}+a^{kN}E_{kN}), \tag{16}$$

$$B=\sum_k \,(b^{1k}E_{1k}+b^{kN}E_{kN}),$$
$$\{k=2,...,N-1;a^{mn},b^{nm}\in \mathbb{C}\}. \tag{17}$$

Here it is convenient to put $\gamma=2\xi$,

$$\sigma(E)=\tfrac{1}{2}\ln(1+2\xi E).$$

In these terms the consistency condition would take the form

$$[A,B]=e^{2\sigma}-1=2\xi E, \tag{18}$$

and the only nontrivial commutator of σ with the basic elements of **L** is

$$[H,\sigma]=1-e^{-2\sigma}. \tag{19}$$

According to Theorem 1, the element

$$\mathcal{F}=\Phi\Phi_1=\exp(H\otimes\sigma)\exp(A\otimes Be^{-2\sigma}) \tag{20}$$

is twisting for $\mathcal{U}(\mathrm{sl}(N))$. Using the particular properties of **L** one can apply the Cambell–Hausdorff formula to rewrite this twisting element in the following form:

$$\mathcal{F}=\exp(A\otimes Be^{-\sigma})\exp(H\otimes\sigma)=\exp(H\otimes\sigma+A\otimes B\sigma e^{-2\sigma}(1-e^{-\sigma})^{-1}). \tag{21}$$

Note: Any number of factors of the type Φ_1 can appear in the expression (20):

$$\mathcal{F}=\Phi\prod_j \Phi_j=\exp(H\otimes\sigma)\prod_j \exp(A_j\otimes B_j e^{-2\sigma}) \tag{22}$$

with A_j and B_j as in (17) and (16) and subject to the additional conditions

$$[A_{j1},A_{j2}]=[B_{j1},B_{j2}]=0,$$

while the correlation equation (18) takes the form

$$[A_j,B_k]=\delta_{jk}(e^{2\sigma}-1). \quad \bullet \tag{23}$$

Using the twist (20) with the sole factor Φ_1 one gets the maximal number of free parameters—the relation (18) imposes the only condition on the coefficients a's and b's,

$$\sum_{k=2}^{N-1}(a^{1k}b^{kN}-a^{kN}b^{1k})=2\xi. \tag{24}$$

On the contrary, supplying $\mathcal{F}$ with the maximal number $(N-2)$ of factors Φ_j one gets the $(N-2)^2$ conditions (23). In particular, one can satisfy $(N-2)(N-3)$ of these conditions using the basic relations (15) and the specific choice of A_j and B_j (one root λ_j for each factor Φ_j):

$$A_j=a^{1j}E_{1j}+a^{jN}E_{jN}\quad B_j=(b^{1j}E_{1j}+b^{jN}E_{jN}),\quad (\text{with no summation on } j). \tag{25}$$

Here the essential relations rest

$$a^{1j}b^{jN}-a^{jN}b^{1j}=2\xi \quad \{j=2,...N-1\}. \tag{26}$$

The equation (24) [as well as (26)] shows that it is natural to renormalize the element A (or the elements A_j) putting

$$A=2\xi\tilde{A}$$

so that

$$[\tilde{A},B]=E.$$

In these notations the twisting elements

$$\mathcal{F}=\exp(H\otimes\sigma)\exp(2\xi\tilde{A}\otimes Be^{-2\sigma}), \tag{27}$$

$$\mathcal{F}=\exp(H\otimes\sigma)\prod_{j}\exp(2\xi\widetilde{A_j}\otimes B_j e^{-2\sigma}) \tag{28}$$

have the trivial limit $\lim_{\xi\to 0}\mathcal{F}=1$. So does the universal R-matrix ($\mathcal{R}=\mathcal{F}_{21}\mathcal{F}^{-1}$) and one can easily write down the corresponding classical r-matrices

$$r=-(H\wedge E+2\tilde{A}\wedge B) \tag{29}$$

or

$$r=-\left(H\wedge E+2\sum \tilde{A}_j\wedge B_j\right). \tag{30}$$

Their form clearly indicates that twisting by $\mathcal{F}$ corresponds to the quantization of the self-dual Lie bialgebra ($\mathbf{L},\mathbf{L}^*\approx\mathbf{L}$) just as in the case of the Jordanian twist of $\mathbf{B}(1)$.[10,12] The same is true for the twisted Hopf algebra $\mathcal{U}_{\mathcal{F}}(\mathbf{L})$, it is self-dual. We shall discuss this property in the next section and prove it in Sec. V where the canonical element will be constructed.

For the special case of $\mathcal{U}(\mathrm{sl}(N))$, according to Theorem 1, the following form of twisting element $\mathcal{F}$ can be chosen:

$$\mathcal{F}=\exp(H_{1N}\otimes\sigma)\prod_{j=2}^{N-1}\exp(2\xi E_{1j}\otimes E_{jN}e^{-2\sigma}).$$

This twist of $\mathcal{U}(\mathrm{sl}(N))$ is generated by the twist of $\mathcal{U}(\mathbf{L})$ [here $\mathbf{L}$ is the restricted Borel subalgebra $\mathbf{B}^\vee$ of $\mathrm{sl}(N)$ with the basic elements $\{H_{1N},E_{1N},E_{1j},E_{jN}\}_{j=2,\dots,N-1}$] leading to the Hopf algebra $\mathcal{U}_\xi(\mathbf{B}^\vee)$ with the initial commutation relations [as in (15)], the twisted coproducts

$$\begin{aligned}
\Delta_{\mathcal{F}}H_{1N}&=H_{1N}\otimes e^{-2\sigma}+1\otimes H_{1N}-4\xi\sum_{j=2}^{N-1}E_{1j}\otimes E_{jN}e^{-3\sigma},\\
\Delta_{\mathcal{F}}E_{1i}&=E_{1i}\otimes e^{-\sigma}+1\otimes E_{1i},\\
\Delta_{\mathcal{F}}E_{iN}&=E_{iN}\otimes e^{\sigma}+e^{2\sigma}\otimes E_{iN},\\
\Delta_{\mathcal{F}}E_{1N}&=E_{1N}\otimes e^{2\sigma}+1\otimes E_{1N};
\end{aligned} \tag{31}$$

antipodes

$$S_{\mathcal{F}}(\sigma) = -\sigma, \quad S_{\mathcal{F}}(E_{1i}) = -E_{1i}e^{\sigma},$$
$$S_{\mathcal{F}}(E_{iN}) = -E_{iN}e^{-3\sigma}, \quad S_{\mathcal{F}}(E_{1N}) = -E_{1N}e^{-2\sigma}, \tag{32}$$
$$S_{\mathcal{F}}(H_{1N}) = -H_{1N}e^{2\sigma} - 4\xi \sum_{j=2}^{N-1} E_{1j}E_{jN};$$

and the universal R-matrix of the form

$$\mathcal{R} = \mathcal{F}_{21}\mathcal{F}^{-1} = \prod_j \exp(2\xi E_{jN}e^{-\sigma} \otimes E_{1j}) \exp(\sigma \otimes H_{1N})$$
$$\times \exp(-H_{1N} \otimes \sigma) \prod_j \exp(-2\xi E_{1j} \otimes E_{jN}e^{-\sigma}). \tag{33}$$

The coproducts and antipodes for other elements of $\mathcal{U}_{\xi}(\mathrm{sl}(N))$ can be calculated using the standard formulas. The obtained expressions are rather cumbersome. Thus, for example, in the case of $\mathcal{U}_{\xi}(\mathrm{sl}(3))$, the coproduct of E_{32} looks like

$$\Delta_{\mathcal{F}}E_{32} = E_{32} \otimes e^{-\sigma} + 1 \otimes E_{32} + \xi H_{13} \otimes E_{12}e^{-2\sigma} + 2\xi E_{12} \otimes H_{23}e^{-\sigma}$$
$$-\xi H_{13}E_{12} \otimes (e^{-\sigma} - e^{-3\sigma}) - 4\xi^2 E_{12} \otimes E_{23}E_{12}e^{-3\sigma} - 4\xi^2 E_{12}^2 \otimes E_{23}e^{-4\sigma}.$$

Twisting the coproducts is acting by the exponential of the adjoint operator defined on the tensor product $\mathcal{U}(\mathrm{sl}(N)) \otimes \mathcal{U}(\mathrm{sl}(N))$. One can check that this operator is nilpotent and all the twisted coproducts can be expressed through the finite number of its powers.

IV. CONNECTIONS BETWEEN STANDARD AND JORDANIAN DEFORMATIONS

It is well known that some sorts of Jordanian deformations can be treated as limiting structures for certain sequences of standard quantizations.[9,10,16,17] As will be shown below, this is due to the specific properties of Lie bialgebras involved in the quantizations. These properties are more transparent when formulated for quantum groups rather than for quantum algebras. For this reason, in the current section we use the dual picture to treat Lie bialgebraic characteristics.

The generators of the standard (FRT deformed) quantum group $\mathrm{Fun}_h(\mathrm{SL}(N))$ ($h = \ln q$) will be described by the entries of the $N \times N$ matrix T. Let T be subject to the similarity transformation with the matrix

$$M = 1 + \frac{\xi}{q-1}\rho(E_{1N}) \tag{34}$$

[for the generators the canonical coproduct ($\Delta T = T \otimes T$) is conserved]. For $q \neq 1$ the transformed quantum group $\mathrm{Fun}_{h;\xi}(\mathrm{SL}(N))$ is equivalent to the original one. Compare the corresponding Lie bialgebras: $(g, g^*_{h;0}) = (\mathrm{sl}(N), (\mathrm{sl}(N))^*)$ and $(g, g^*_{h;\xi})$. Here the Lie algebra $g = \mathrm{sl}(N)$ is not changed, the transformation $T \to MTM^{-1}$ does not touch the canonical coproduct for the generators of the Hopf algebra $\mathrm{Fun}_h(\mathrm{SL}(N))$. Only the second Lie multiplication ($\mu^*_{h;0}: V_{g*} \wedge V_{g*} \to V_{g*}$) changes:

$$\mu^*_{h;0} \to \mu^*_{h;\xi}.$$

The structure of the similarity transformation shows that the new Lie product decomposes as

$$\mu^*_{h;\xi} = \mu^*_{h;0} + \xi\mu'. \tag{35}$$

The component μ' is fixed by the commutation relations that can be extracted from the transformed $RTT=TTR$ equations. For this purpose one has to change the coordinate functions of SL(N) arranged in matrix T for the exponential ones $T=\exp(\epsilon Y)$ and also change the parameters $h\mapsto\epsilon h$, $\xi\mapsto\epsilon\xi$. Tending ϵ to zero one gets both summands in (35). The second one of them looks as follows:

$$\begin{aligned}
\mu'(Y_{1k},Y_{ij})&=2\delta_{ik}Y_{Nj}, \quad \text{for } k,j<N, \quad i>1;\\
\mu'(Y_{ij},Y_{lN})&=-2\delta_{jl}Y_{Nj}, \quad \text{for } j<N, \quad i,l>1;\\
\mu'(Y_{ij},Y_{1N})&=-\delta_{j1}Y_{i1}-\delta_{iN}Y_{Nj}, \quad \text{for } j<N, \quad i>1;
\end{aligned}\tag{36}$$

$$\begin{aligned}
\mu'(Y_{1i},Y_{1N})&=-Y_{1i}, \quad \text{for } N>i>1;\\
\mu'(Y_{1N},Y_{kN})&=Y_{kN}, \quad \text{for } 1<k<N;\\
\mu'(Y_{11},Y_{1N})=\mu'(Y_{1N},Y_{NN})&=-(Y_{11}-Y_{NN});\\
\mu'(Y_{1i},Y_{1k})&=\delta_{i1}Y_{Nk}, \quad \text{for } k,i<N,k>1;\\
\mu'(Y_{iN},Y_{kN})&=-\delta_{kN}Y_{i1}, \quad \text{for } k,i>1,i<N;\\
\mu'(Y_{1i},Y_{kN})&=\delta_{i1}Y_{k1}-\delta_{kN}Y_{Ni}-2\delta_{ik}(Y_{11}-Y_{NN}), \quad \text{for } i<N, \quad k>1.
\end{aligned}\tag{37}$$

Here for simplicity of exposition we use the canonical gl(N) basis. One can check that this deforming function μ' not only defines the infinitesimal deformation of $\mu^*_{h;0}$, but is itself a Lie multiplication.

Consider the decomposition (35) as a deformation equation for the initial dual Lie algebra $g^*_{h;0}$. Its main property is that μ' does not depend on h or ξ. So the transformed law has the form

$$\mu^*_{h;\xi}=\mu^*_{h;0}+\mu^*_{0;\xi}.\tag{38}$$

This means that $\mu^*_{h;\xi}$ is a Lie multiplication deformed in the first order. Both summands are Lie maps and at the same time can be considered as deforming functions of each other. As a result, both deforming functions are two-cocycles for the corresponding Lie algebras ($g^*_{0;\xi}$ with the multiplication $\mu^*_{0;\xi}$ and $g^*_{h;0}$ defined by $\mu^*_{h;0}$)

$$\mu^*_{h;0}\in Z^2(g^*_{0;\xi},g^*_{0;\xi}),$$

$$\mu^*_{0;\xi}\in Z^2(g^*_{h;0},g^*_{h;0}).$$

The equivalence of the algebraic structures in $\mathrm{Fun}_{h;\xi}(\mathrm{SL}(N))$ and $\mathrm{Fun}_h(\mathrm{SL}(N))$ (for $h\neq 0$) signifies that $\mu^*_{0;\xi}$ is, in fact, a coboundary,

$$\mu^*_{0;\xi}\in B^2(g^*_{h;0},g^*_{h;0}).$$

On the contrary, the composition $\mu^*_{h;0}$ corresponds to a nontrivial cohomology class

$$\mu^*_{h;0}\in H^2(g^*_{0;\xi},g^*_{0;\xi});$$

the deformation of $\mu^*_{0;\xi}$ by $\mu^*_{h;0}$ is essential.[19]

Notice that the multiplication maps here have certain cohomological properties also with respect to cochain complex C of maps $C^n:\wedge^n V_g\rightarrow V_g\wedge V_g$, where the g-module is chosen to be $\wedge^2 V_g$ with the canonically extended adjoint action on it. The dualization of spaces $V_g\Leftrightarrow V_{g*}$ converts the map μ^* into the chain $\mu^*\in C^1(g,g\wedge g)$. As it was mentioned above, the initial coproduct for the generators of $\mathrm{Fun}_h(\mathrm{SL}(N))$ rests unchanged under the transformation. All the Lie algebras $g^*_{h;\xi}$ are dual to one and the same $g=\mathrm{sl}(N)$. Thus both $\mu^*_{h;0}$ and $\mu^*_{0;\xi}$ are one-cocycles for the complex C.

This set of characteristics necessarily indicates that the classical r-matrix of $\mathcal{U}_{h;\xi}(\mathrm{sl}(N)) \approx (\mathrm{Fun}_{h;\xi}(\mathrm{SL}(N)))^*$ must also exhibit this decomposition property:

$$\begin{aligned} r_{h;\xi} &= r_{h;0} + r_{0;\xi} \\ &= \frac{h}{N}\left(\sum_{k=1}^{N-1} k(N-k) H_{k,k+1}\otimes H_{k,k+1} + \sum_{k<l}^{N-1} (N-l)k(H_{k,k+1}\otimes H_{l,l+1} + H_{l,l+1}\otimes H_{k,k+1}) \right) \\ &\quad + 2h\sum_{k<l} (E_{lk}\otimes E_{kl}) - \xi H_{1N}\wedge E_{1N} - 2\xi \sum_{k=2}^{N-1} E_{1k}\wedge E_{kN}. \end{aligned} \tag{39}$$

In the limit $h \to 0$ one gets the element

$$\lim_{h\to 0} r_{h;\xi} = r_{0;\xi} = -\xi\left(H_{1N}\wedge E_{1N} + 2\sum_{k=2}^{N-1} E_{1k}\wedge E_{kN}. \right) \tag{40}$$

that coincides with r-matrix that can be obtained from $\mathcal{R}$ presented above (33). So the Jordanian quantum group $\mathrm{Fun}_{0;\xi}(\mathrm{SL}(N))$ corresponds to the same r-matrix as the twisted algebra $\mathcal{U}_{\mathcal{F}}(\mathrm{sl}(N))$ [with $\mathcal{F}$ as in (28) and $\tilde{A}_j$, B_j as in (25) and (26)].

The r-matrices (39) and (40) are known for a long time. In Ref. 9 $r_{0;\xi}$ was obtained by applying $\mathrm{ad}_{E_{1N}}$ to the canonical antisymmetric $r_\wedge = \Sigma_{i<j} E_{ij}\wedge E_{ji}$. It was stressed that $r_{0;\xi}$ lay in the boundary of the dense set of orbits of standard quantizations induced by $r_\wedge$. The r-matrix (40) was also obtained in the discussion of conformal algebra deformations.[20]

The r-matrix $r_{0;\xi}$ is the element of the space $\mathbf{B}^\vee \wedge \mathbf{B}^\vee$. Its structure suggests the renumbering of the basic elements of $\mathbf{B}^\vee$; we shall describe the corresponding basis as the set

$$\{P_\alpha, X_\beta\}_{\alpha,\beta=1,\dots,N-1} \quad \text{with } \begin{cases} P_1 = E_{1N}, & P_i = E_{iN}; \\ X_1 = H_{1N}, & X_j = 2E_{1j}; \end{cases} \quad i,j=2,\dots,N-1.$$

In these notations $r_{0;\xi}$ takes the form

$$r_{0;\xi} = -\xi X_\alpha \wedge P_\alpha .$$

The basic exponential coordinate functions $\{Y_{1N}, Y_{iN}, Y_{1i}, Y_{11}-Y_{NN}\}$ are chosen so that they are canonically dual to those of $\{P_\alpha, X_\beta\}$. Let us apply the homomorphism

$$r_{0;\xi}: Y \to -\xi X_\alpha \wedge \langle P_\alpha, Y\rangle \tag{41}$$

to the Lie algebra $(\mathbf{B}^\vee)^*$ described by the last six compositions μ' [see (37)]. As a result we shall get the Lie algebra $\mathbf{B}^\vee$. The significant fact is that (41) is an isomorphism, that is, $\mathbf{B}^\vee \approx (\mathbf{B}^\vee)^*$. The twist $\mathcal{F}$ induces the self-dual Lie bialgebra $(\mathbf{B}^\vee, \mathbf{B}^\vee)$.

It is useful to compare this situation with that of a classical double of dual Lie algebras (g,g^*). There, the composition law of the double can also be presented as a sum of two multiplications with independent linear parameters. But in that case both summands are cohomologically nontrivial. What is more important, such parametrization (and subdivision) cannot be performed in only one algebra of a Lie bialgebra (g,g^*) corresponding to a classical double. In fact, these are the Lie bialgebras that can be parametrized in that case so that their arbitrary linear combination is again a Lie bialgebra.[21] When a Lie bialgebra is nontrivially decomposed (that is, the decomposition goes parallel in both dual algebras), the r-matrix for a linear combination of Lie bialgebras does not inherit the decomposition property.

To clarify the contraction properties of $\mathrm{Fun}_{h;\xi}(\mathrm{SL}(N))$, let us consider the one-parameter subvariety $\{g^*_{h;1-h}\}$ of Lie algebras $g^*_{h;\xi}$ [putting $\xi=1-h$ in (38)]. Each dual pair $(\mathrm{sl}(N),g^*_{h;1-h})$ is a Lie bialgebra and thus is quantizable.[5] The result is the set $\mathcal{A}_{s;h}$ of deformation quantizations parametrized by h and the deformation parameter s. This set can be considered smooth in the sense compatible with the formal series topology[22]—close Lie bialgebras give rise to close deformations. The one-dimensional boundaries $\mathcal{A}_{0;h}$ and $\mathcal{A}_{s;0}$ of $\mathcal{A}_{s;h}$ are formed respectively by the quantizations of $(\mathrm{sl}(N),g^*_{1;0})$ (the standard Lie bialgebra) and $(\mathrm{sl}(N),g^*_{0;1})$ (the Jordanian one). Each internal point in $\mathcal{A}_{s;h}$ can be connected with a boundary by a smooth parametric curve $a(u)$. One can choose it so that it starts in $\mathcal{A}_{0;h}$ and ends in $\mathcal{A}_{s;0}$. So a Jordanian Hopf algebra obtained by twisting deformation can be also treated as a limit point of a smooth one-dimensional subvariety $a(u)$. This does not necessarily mean that this limit is a faithful contraction—it may be impossible to attribute the curve $a(u)$ to an orbit of some Hopf algebra in $\mathcal{A}$. This is just what happens when the transformation M is applied to $\mathrm{Fun}_{h;0}(\mathrm{SL}(N))$. For every positive h fixed, the subset $\{\mathrm{Fun}_{h;\xi}(\mathrm{SL}(N))\}$ is in the $\mathrm{GL}(N^2)$-suborbit of the corresponding $\mathrm{Fun}_{h;0}(\mathrm{SL}(N))$. To attain the points $\mathrm{Fun}_{0;\xi}(\mathrm{SL}(N))$ one must tend h to zero and this can be done only by crossing the set of orbits refering to inequivalent Hopf algebras. These specific interrelations of different types of quantizations where noted in Ref. 9. It was demonstrated for the case of $\mathrm{sl}(N)$ that the standard deformation $\mathrm{Fun}_{h;0}(\mathrm{SL}(N))$ can be accompanied by a smooth transformation of a Jordanian deformation so that the latter reaches the orbit of $\mathrm{Fun}_{h;0}(\mathrm{SL}(N))$. Applying the operator M to an element of the set $\{\mathrm{Fun}_{h;0}(\mathrm{SL}(N))\}$ one gets an intersection point of an orbit and of a curve parametrized by ξ.

One of the principle conclusions is that the possibility of obtaining the Jordanian deformation $\mathrm{Fun}_{0;\xi}(\mathrm{SL}(N))$ as a limiting transformation of the standard quantum group $-\mathrm{Fun}_{h;0}(\mathrm{SL}(N))$ is provided by the fact that the one-cocycle $\mu^*_{0;\xi}\in Z^1(\mathrm{sl}(N),\ \mathrm{sl}(N)\wedge\mathrm{sl}(N))$ [that characterizes the Lie bialgebra for $\mathcal{U}_{\mathcal{F}}(\mathrm{sl}(N))$] is at the same time the two-coboundary $\mu^*_{0;\xi}\in B^2(g^*_{h;0},g^*_{h;0})$, the Lie algebra $g^*_{h;0}$ being the standard dual of $\mathrm{sl}(N)$. The same scenario can be performed on the dual list to get the twisted q-algebra $\mathcal{U}_{\mathcal{F}}(\mathrm{sl}(N))$ as a limit of the variety of standardly quantized algebras $\mathcal{U}_q(\mathrm{sl}(N))$.

V. CANONICAL ELEMENT AND JORDANIAN QUANTUM SPACE

The set $\{P_\alpha,X_\beta\}$ forms the basis appropriate to deal with the Lie bialgebras $(\mathbf{L},\mathbf{L}^*)$. To study the properties of R-matrix $\mathcal{R}$ and the canonical element $\mathcal{T}$ it is reasonable to perform the corresponding rearrangement of basis for the whole Hopf algebra $\mathcal{U}_\xi(\mathbf{B}^\vee)$. We shall consider the set

$$\{z_k\}_{k=1,\ldots,2(N-1)}=\{x_\alpha,\pi_\beta\}_{\alpha,\beta=1,\ldots,N-1} \tag{42}$$

as the generators of $\mathcal{U}_\xi(\mathbf{B}^\vee)$ with

$$x_1=H_{1N},\quad x_i=2E_{1i},$$

$$\pi_1=\frac{1}{\xi}\sigma=\frac{1}{2\xi}\ln(1+2\xi E_{1N}),\quad \pi_i=E_{iN}e^{-2\sigma}.$$

The basis will be formed by the set of ordered monomials:

$$\{z_{\vec{k}}\}_{\vec{k}=\{\vec{m},\vec{n}\}=\{m_1,\ldots,m_{N-1},n_1,\ldots,n_{N-1}\}}=\{x_1^{m_1}\cdots x_{N-1}^{m_{N-1}}\pi_1^{n_1}\cdots\pi_{N-1}^{n_{N-1}}\}. \tag{43}$$

In these terms the R-matrix (33) can be rewritten as

$$\mathcal{R}=\prod_{\alpha=1,\ldots,N-1}^{<}\exp(\pi_\alpha\otimes\xi x_\alpha)\prod_{\alpha=1,\ldots,N-1}^{>}\exp(-\xi x_\alpha\otimes\pi_\alpha), \tag{44}$$

where sybmols $<$ and $>$ mean that the factors in the products are ordered correspondingly. We shall use the standard Hopf algebra homomorphism $\mathcal{R}:\mathcal{A}^*\to\mathcal{A}_-$ where, in our case, $\mathcal{A}$ is the twisted algebra $\mathcal{U}_\xi(\mathbf{B}^\vee)$ and ''$-$'' indicates the opposite multiplication. It would be appropriate to consider $\mathcal{R}$ as belonging to $\mathcal{A}_-\otimes\mathcal{A}$ with the decomposition

$$\mathcal{R}=\sum R^{\vec{k}\vec{l}}y_{\vec{k}}\otimes z_{\vec{l}}. \tag{45}$$

It is implied that the basic monomials $y_{\vec{k}}\in\mathcal{A}_-$ contain the same sequences of generators z_k as the corresponding basic elements $z_{\vec{k}}\in\mathcal{A}$ [see (43)], but the multiplication that glue them is opposite to that of $\mathcal{A}$. Let $\{z^{\vec{k}}\}$ be the canonical dual basis of $\mathcal{A}^*$, $\langle z^{\vec{k}},z_{\vec{l}}\rangle=\delta^{\vec{k}}_{\vec{l}}$. The morphism $\mathcal{R}$ can be defined by its values on the basic elements:

$$\mathcal{R}(z^{\vec{k}})=\sum R^{\vec{l}\vec{k}}y_{\vec{l}}. \tag{46}$$

Let us extract the first terms of the decomposition (45) for the R-matrix (44):

$$\mathcal{R}=1\otimes 1+R^{kl}z_k\otimes z_l+\cdots. \tag{47}$$

(Note that in such a presentation the second term is not proportional to the classical r-matrix; the generators z_l do not form a Lie algebra.) The terms written explicitly in (47) are the only ones containing the first powers of generators. Thus the images $\mathcal{R}(z^k)$ are the linear combinations of the generators z_l. In our case the matrix $\{R^{kl}\}$ is invertible,

$$R=\xi\begin{pmatrix}0 & -I\\ I & 0\end{pmatrix}\Rightarrow\begin{cases}\mathcal{R}(x^\alpha)=\xi\pi_\alpha,\\ \mathcal{R}(\pi^\alpha)=-\xi x_\alpha,\end{cases}$$

$$R^{-1}=-\frac{1}{\xi^2}R\Rightarrow\begin{cases}\mathcal{R}^{-1}(x_\alpha)=-\dfrac{1}{\xi}\pi^\alpha,\\ \mathcal{R}^{-1}(\pi_\alpha)=\dfrac{1}{\xi}x^\alpha.\end{cases}$$

Reversing the formula (46) we get the expression for the elements of the dual basis in terms of generators $z^k{}_{|k=1,\ldots,2(N-1)}$:

$$z^{\vec{k}}=\sum R^{\vec{l}\vec{k}}\mathcal{R}^{-1}(y_{\vec{l}})=\sum R^{\vec{l}\vec{k}}((R^{-1})_{k_1 1}z^{k_1})^{l_1}\cdots((R^{-1})_{k_{2(N-1)}2(N-1)}z^{k_{2(N-1)}})^{l_{2(N-1)}}. \tag{48}$$

The basic decomposition for the R-matrix (44) can be written explicitly:

$$\mathcal{R}=\sum\frac{(-\xi)^{|\vec{n}|}\xi^{|\vec{m}|}}{c_{\vec{m}}c_{\vec{n}}}x_1^{n_1}\cdots x_{N-1}^{n_{N-1}}(\pi_1)^{m_1}\cdots(\pi_{N-1})^{m_{N-1}}\otimes x_1^{m_1}\cdots x_{N-1}^{m_{N-1}}(\pi_1)^{n_1}\cdots(\pi_{N-1})^{n_{N-1}},$$
$$|\vec{n}|=n_1+\cdots+n_{N-1}. \tag{49}$$

Here we used the inclusion $\mathcal{R}\in\mathcal{A}_-\otimes\mathcal{A}$ and the fact that all the generators π_α commute. The structure of $\mathcal{R}$-morphism is clearly seen here. It states the one-to-one correspondence between the basic monomials of $\mathcal{A}^*$ and $\mathcal{A}_-$. This evidently signifies that the Hopf algebras $\mathcal{A}^*$ and $\mathcal{A}_-$ are equivalent. One must also take into account that in our case $\mathcal{A}_-$ is the twisted universal enveloping algebra $\mathcal{U}_\xi(\mathbf{B}^\vee)$ with the opposite product. The result is

$$\mathcal{A}^*\approx\mathcal{A}_-\approx\mathcal{A}.$$

The Hopf algebra $\mathcal{U}_\xi(\mathbf{B}^\vee)$ is self-dual.

The structure constants $R^{\vec{l}\vec{k}}$ presented in the decomposition (49) can be substituted in the expression (48) to fix explicitly the form of the dual basis. Hence the canonical element $\mathcal{T}$ is completely defined

$$\mathcal{T}=\sum_{\vec{k}=(\vec{m},\vec{n})} z^{\vec{k}}\otimes z_{\vec{k}}$$
$$=\sum \frac{1}{c_{\vec{m}}c_{\vec{n}}}(\pi^1)^{n_1}\cdots(\pi^{N-1})^{n_{N-1}}(x^1)^{m_1}\cdots(x^{N-1})^{mN-1}$$
$$\otimes x_1^{m_1}\cdots x_{N-1}^{m_{N-1}}\pi_1^{n_1}\cdots\pi_{N-1}^{n_{N-1}}.$$

We can recollect this expansion into the ordered product using the following property of the $\mathcal{T}$-matrix, $(id\otimes S)(\mathcal{T})=\mathcal{T}^{-1}$:

$$\mathcal{T}^{-1}=\sum_{(\vec{m},\vec{n})}\frac{1}{c_{\vec{m}}c_{\vec{n}}}(\pi^{1n_1}\cdots(\pi^{N-1})^{n_{N-1}}(x^1)^{m_1}\cdots(x^{N-1})^{m_{N-1}}$$
$$\otimes(S(\pi_{N-1}))^{n_{N-1}}\cdots(S(\pi_1))^{n_1}(S(x_1))^{m_1}\cdots(S(x_{N-1}))^{m_{N-1}}.$$

The antipodes used here can be easily found using the expressions (32) given in Sec. III:

$$S(\pi_1)=-\pi_1,\quad S(\pi_i)=-\pi_i e^{\xi\pi_1},$$

$$S(x_1)=-x_1e^{2\xi\pi_1}-4\xi\sum x_i\pi_ie^{2\xi\pi_1},\quad S(x_i)=-x_ie^{\xi\pi_1}.$$

Note that the homomorphic image in $\mathcal{A}^*$ of the Abelian subalgebra generated by elements $\{\pi_\alpha\}$ is itself a commutative subalgebra. This enables us to write the final formula for the canonical element

$$\mathcal{T}=\prod_\alpha^{<}\exp(-x^\alpha\otimes S(x_\alpha))\prod_\alpha^{>}\exp(-\pi^\alpha\otimes S(\pi_\alpha)).\tag{50}$$

The corresponding constructions for Jordanian deformations of the Lie superalgebras of the type $\mathrm{sl}(M|N)$ can be easily performed.

Let us present a real form for $\mathcal{U}_\mathcal{F}(\mathrm{sl}(N))$. We focus first on the subalgebra $\mathbf{B}^\vee$ in the general setting of the previous section and with the basis $\{z_k\}$ [see (42)]. The antialgebraic antilinear transformation given on the generators by

$$\theta(x_\alpha)=-x_\alpha,\quad \theta(\pi_\alpha)=\pi_\alpha$$

respects the classical comultiplication and defines a real form on $\mathcal{U}(\mathbf{L})$. At the same time, the twisting element $\mathcal{F}$ turns into $\mathcal{F}^{-1}$. Henceforth, θ is a real form (cohomomorphic and antihomomorphic) for the twisted algebra $\mathcal{U}_\mathcal{F}(\mathbf{L})$ as well. Turning to the specific case of $\mathrm{sl}(N)$, the question is whether θ can be extended from the subalgebra $\mathbf{B}^\vee$ to the entire $\mathrm{sl}(N)$. This is possible, and the corresponding transformation is

$$\theta(E_{ij})=-E_{ij},\quad i,j<N \text{ or } i,j=N;\quad \theta(E_{kN})=E_{kN},\quad \theta(E_{Nk})=E_{Nk},\quad k<N.$$

It is evident that θ is a Lie algebra antiautomorphism. The real form for the $N=2$ case of the Jordanian $\mathcal{U}_\xi(\mathrm{sl}(2))$ was given in Ref. 23.

Twisting of a symmetry Hopf algebra $\mathcal{A}$ of a manifold $\mathcal{M}$ induces a deformation of its whole geometry, so that the notion of symmetry is conserved in the framework of the noncommutative geometry. Such deformation includes that of function algebras (vector bundles, $*$-structure, and so on) expressing new objects in terms of the nontwisted ones by explicit formulas involving twisting two-cocycle $\mathcal{F}$. Here we present, as an application of the developed Jordanian-type quantization of $\mathrm{sl}(N)$, the corresponding noncommutative space $\mathcal{M}_{\mathcal{F}}$. We deduce commutation relations for generators of $\mathcal{M}_{\mathcal{F}}$, and the differential calculus. The basic formula connecting multiplications in $\mathcal{A}$-modules $\mathcal{M}_{\mathcal{F}}$ and $\mathcal{M}$ (the twisted and the nontwisted ones) is[8]

$$f*g=\mathcal{F}^{-1}_{(1)}(f)\cdot\mathcal{F}^{-1}_{(2)}(g),\quad f,g\in\mathcal{M}. \tag{51}$$

The star stands for the new product on $\mathcal{M}_{\mathcal{F}}$ defined through the old one ''$\cdot$'' and the element $\mathcal{F}$. If $\mathcal{M}$ is classical, the twisting cocycle is represented by a bidifferential operator according to the corresponding representation of $\mathcal{F}$. Thus $\mathcal{M}_{\mathcal{F}}$ and $\mathcal{M}$ coincide as linear spaces, but they are endowed with different algebraic structures. The transformation is performed in such a way that the symmetry property $h(f\cdot g)=h_{(1)}(f)\cdot h_{(2)}(g)$, $h\in\mathcal{A}$, f, $g\in\mathcal{M}$, is inherited by the twisted algebra $\mathcal{A}_{\mathcal{F}}$.

Let x^α, $\alpha=1,...N$, be the generators of $\mathcal{M}_{\mathcal{F}}$. The representation of $\mathrm{sl}(N)$ is given by $E^m_n\to x^m\partial_n$. To evaluate commutation relations among the generators, it is sufficient to retain only the following terms:

$$\mathcal{F}=1\otimes 1+\xi(x^1\partial_1-x^N\partial_N)\otimes x^1\partial_N+2\xi\sum_{k=2}^{N-1}x^1\partial_k\otimes x^k\partial_N+\cdots,$$

with the rest of the series vanishing on the products $x^\mu\cdot x^\nu$. Resolving formula (51) (twisting is an invertible operation) we come to

$$\mathcal{F}_{(1)}(x^\mu)*\mathcal{F}_{(2)}(x^\nu)=x^\mu\cdot x^\nu=x^\nu\cdot x^\mu=\mathcal{F}_{(1)}(x^\nu)*\mathcal{F}_{(2)}(x^\mu).$$

This gives (commutators are understood in terms of the twisted product ''$*$'')[9]

$$[x^1,x^N]=-\xi x^1*x^1,\quad [x^i,x^k]=0,$$

$$[x^k,x^N]=-2\xi x^1*x^k,\quad [x^k,x^1]=0.$$

We use the convention that the small Latin indices run from 2 to $N-1$. Similarly, for the contravariant entities p_μ we have

$$[p_1,p_N]=-\xi p_N*p_N,\quad [p_i,p_k]=0,$$

$$[p_1,p_k]=-2\xi p_k*p_N,\quad [p_k,p_N]=0.$$

Let us note that after the quantization the bases p_μ and x^μ are no longer dual. The invariant canonical element turns out to be $p_\mu\cdot x^\mu=p_\mu*x^\mu+\xi p_1*x^N$. Nontrivial cross relations between coordinates and momenta are expressed by

$$[p_1,x^N]=\xi\left(x^N*p_N+2\sum_{k=2}^{N-1}p_k*x^k+p_1*x^1\right)$$

$$[p_1,x^1]=-\xi x^1*p_N,\quad [p_k,x^k]=-2\xi x^1*p_N,\quad [p_N,x^N]=-\xi x^1*p_N.$$

Partial derivatives ∂_μ satisfies the same identities as p_μ, whereas the cross relations are modified accordingly:

$$[\partial_1, x^N] = \xi\left(x^N * \partial_N + 2\sum_{k=2}^{N-1} \partial_k * x^k + \partial_1 * x^1 \right)$$

$$[\partial_1, x^1] = 1 - \xi x^1 * \partial_N, \quad [\partial_k, x^k] = 1 - 2\xi x^1 * \partial_N, \quad [\partial_N, x^N] = 1 - \xi x^1 * \partial_N.$$

VI. GROUP COCYCLES AND TWISTING

To generalize the construction of Sec. III let us arrange the generators of $\mathbf{B}^\vee$ into the two sets (H, A_j) and (E, B_j) spanning two mutually complementary Lie subalgebras. We denote them $\mathbf{H}$ and $\mathbf{H}^*$, respectively, regarding as dual linear spaces. Subalgebra $\mathbf{H}$ acts on $\mathbf{H}^*$, thus endowing $\mathbf{B}^\vee$ with the semidirect sum $\mathbf{L} = \mathbf{H} \triangleright \mathbf{H}^*$ structure. In this section we explain the twist quantization of interest in terms of a one-cocycle on the Lie algebra $\mathbf{H}$ and its formal Lie group $\mathbf{G} = \exp \mathbf{H}$.

Let H_μ be basic elements of a Lie algebra $\mathbf{H}$ and X^ν be their duals. Commutation relations in $\mathbf{H}$ are specified by the structure constants $C^\sigma_{\mu\nu}$:

$$[H_\mu, H_\nu] = C^\sigma_{\mu\nu} H_\sigma. \tag{52}$$

Suppose a left action of $\mathbf{H}$ on $\mathbf{H}^*$.

$$[H_\mu, X^\nu] = -L^{\nu}_{\mu\sigma} X^\sigma, \tag{53}$$

which enables us to build the semidirect sum $\mathbf{L} = \mathbf{H} \triangleright \mathbf{H}^*$ where $\mathbf{H}^*$ is assumed to be an abelian subalgebra. The element

$$r = X^\nu \otimes H_\nu - H_\nu \otimes X^\nu \in \mathbf{L} \wedge \mathbf{L} \tag{54}$$

is a solution to the classical Yang–Baxter equation if and only if

$$C^\sigma_{\mu\nu} = L^\sigma_{\mu\nu} - L^\sigma_{\nu\mu}. \tag{55}$$

The structure constants $L^\sigma_{\mu\nu}$ define also a left action of $\mathbf{H}$ on itself according to the rule

$$H_\mu \triangleright H_\nu = L^\sigma_{\mu\nu} H_\sigma.$$

The equality (55) implies that the following quasi-associativity property holds:

$$(H_\mu \triangleright H_\nu) \triangleright H_\sigma - (H_\nu \triangleright H_\mu) \triangleright H_\sigma = H_\mu \triangleright (H_\nu \triangleright H_\sigma) - H_\nu \triangleright (H_\mu \triangleright H_\sigma), \tag{56}$$

which is the pre-Lie structure due to Gerstenhaber.[24] Conversely, if a bilinear pairing $\triangleright$ on $\mathbf{H}$ satisfies this condition, the skew-symmetric operation

$$[H_\mu, H_\nu] = (H_\mu \triangleright H_\nu) - (H_\nu \triangleright H_\mu) \tag{57}$$

fulfills the Jacobi identity, and $\triangleright$ becomes a left representation of the Lie algebra $\mathbf{H}$ [equipped with the Lie bracket (57)] on itself.

Lie algebra action $\triangleright$ induces an action of the Lie group $\mathbf{G}$ turning $\mathbf{H}$ into the left $\mathbf{G}$-module. Consider now a one-cocycle φ on the group $\mathbf{G}$ with values in $\mathbf{H}$.[25] This means that φ obeys the equation

$$\varphi(xy) = \varphi(y) + y^{-1} \triangleright \varphi(x), \quad x, y \in \mathbf{G}. \tag{58}$$

The Lie algebra one-cocycle $\partial\varphi$ is in one-to-one correspondence with φ, being its derivative taken at the group identity.[25] It satisfies the equation

$$\partial\varphi([H_\mu, H_\nu]) = H_\mu \triangleright \partial\varphi(H_\nu) - H_\nu \triangleright \partial\varphi(H_\mu)$$

[cf. (57)]. Suppose the linear map $\delta\varphi$ to be nondegenerate. Then the identity map id:$\mathbf{H}\rightarrow\mathbf{H}$ is a one-cocycle with respect to the new action defined as $(\partial\varphi)^{-1}\circ\triangleright\circ\partial\varphi$. Thus nondegenerate one-cocycles of Lie algebras are in one-to-one correspondence with bilinear quasi-associative, in the sense of (56), operations on $\mathbf{H}$. Only nondegenerate cocycles are suitable for our purposes, so we will think of them as of identity maps, and all the freedom will be encoded in the choice of action $\triangleright$. Note that a one-coboundary normalized to id implies the existence of the right unity H_e, that is,

$$H_\mu \triangleright H_e = H_\mu .$$

The group cocycle in terms of Lie algebra coordinates ξ^μ in a neighborhood of the origin reads

$$\varphi^\mu(\xi) = \left(\frac{e^{-L(\xi)}-1}{-L(\xi)} \right)^\mu_\nu \xi^\nu,$$

and the coboundary can be written as

$$\varphi^\mu(\xi) = (1-e^{-L(\xi)})^\mu_\nu \xi^\nu_e, \quad H_\nu \xi^\nu_e = H_e .$$

Consider the semidirect sum $\mathbf{L}=\mathbf{H}\triangleright\mathbf{H}^*$ with the Lie bracket given by (52) and (53) such that the condition (55) holds. Since $\partial\varphi = id$ is nondegenerate, the function φ is invertible in a neighborhood of the origin in $\mathbf{H}$. Its inverse ψ as well as φ itself are treated as columns whose components are formal series in coordinate functions generating $\mathcal{U}(\mathbf{H}^*)$.

Theorem 2: *The element*

$$\mathcal{F} = \exp\big(H_\nu \otimes \psi^\nu(X)\big) \tag{59}$$

is a twist for the semidirect sum $\mathbf{L}=\mathbf{H}\triangleright\mathbf{H}^*$

Proof: The element $\exp\big(H_\nu\otimes\psi^\nu(X)\big)$ satisfies the identity (8). If we prove the second identity (9), the theorem will be stated. Denote $\tilde{X}^\mu = \psi^\mu(X)$ and evaluate $\Delta_{\mathcal{F}}(X)$:

$$\Delta_{\mathcal{F}}(X^\mu) = \exp(H\otimes\tilde{X})(X^\mu\otimes 1 + 1\otimes X^\mu)\exp(-H\otimes\tilde{X}) = X^\nu\otimes(e^{-L(\tilde{X})})^\mu_\nu + 1\otimes X^\mu. \tag{60}$$

The map $\Delta_{\mathcal{F}}(h)=\mathcal{F}\Delta(h)\mathcal{F}^{-1}$ is an algebra homomorphism $\mathcal{U}(\mathbf{L})\rightarrow\mathcal{U}(\mathbf{L})^{\otimes 2}$. Henceforth, the relation (60) entails the equation

$$\varphi\big(\Delta_{\mathcal{F}}(\tilde{X})\big) = e^{-L(1\otimes\tilde{X})}\varphi(\tilde{X}\otimes 1) + \varphi(1\otimes\tilde{X}). \tag{61}$$

Since φ is invertible as a map of $\mathbf{H}$ on $\mathbf{H}$, we find $\Delta_{\mathcal{F}}(\tilde{X}^\mu) = \mathcal{D}^\mu(\tilde{X}\otimes 1, 1\otimes\tilde{X})$ where $\mathcal{D}^\mu(\xi_1,\xi_2)$ is the Campbell—Hausdorff series. This yields (9) and therefore the twist equation (5) for $\exp\big(H_\nu \otimes \psi^\nu(X)\big)$ is valid. ●

Now we can evaluate the twisted coproducts in terms of new generators $\tilde{X}^\mu$. Straightforward calculations show that

$$\Delta_{\mathcal{F}}(H_\mu) = H_\nu \otimes g(\tilde{X})^\nu_\mu + 1\otimes H_\mu , \tag{62}$$

where $g(\xi):\mathbf{H}\rightarrow\mathbf{H}$ is a map to be found. Imposing coassociativity conditions we find that the function g realizes a left group action on $\mathbf{H}$ which is generated by a Lie algebra representation. To evaluate this action let us perform the following Lie algebra isomorphism $H_\mu \rightarrow H_\mu$, $X^\mu\rightarrow\xi X^\mu$. The specific form of the classical r-matrix allows us to consider ξ as a deformation parameter. Taking into account $(d/d\xi)\tilde{X}^\mu(0)=X^\mu$, $\tilde{X}^\mu(0)=0$, and calculating $(d/d\xi)\mathcal{F}\Delta(H_\nu)\mathcal{F}^{-1}|_{\xi=0}$ we come to

$$\frac{d}{d\xi}\Delta_{\mathcal{F}}(H_\nu)|_{\xi=0}=[H_\sigma\otimes X^\sigma,H_\nu\otimes 1+1\otimes H_\nu]=C^\mu_{\sigma\nu}H_\mu\otimes X^\sigma+L^\mu_{\nu\sigma}H_\mu\otimes X^\sigma=L^\mu_{\sigma\nu}H_\mu\otimes X^\sigma.$$

Performing this for the coproduct (62) and comparing the results we obtain $g(\tilde{X})=e^{L(\tilde{X})}$. Thus the coproduct on generators H_μ, $\tilde{X}_\nu$ reads

$$\Delta_{\mathcal{F}}(\tilde{X}^\mu)=\mathcal{D}^\mu(\tilde{X}\otimes 1,1\otimes\tilde{X}),\quad \Delta_{\mathcal{F}}(H_\mu)=H_\nu\otimes(e^{L(\tilde{X})})^\nu_\mu+1\otimes H_\mu. \tag{63}$$

Using these relations it is easy to find also the antipodes,

$$S_{\mathcal{F}}(\tilde{X}^\mu)=-\tilde{X}^\mu,\quad S_{\mathcal{F}}(H_\mu)=-H_\nu(e^{-L(\tilde{X})})^\nu_\mu. \tag{64}$$

Writing $\tilde{X}^\mu$ in terms of X^ν we can evaluate the twisted antipode on the classical generators as well.

VII. CONCLUSION

The triangular deformation of the universal enveloping algebra of sl(N), discussed already by Gerstenhaber *et al.*,[9] was realized in this paper as a twisted algebra with the explicit form (2) of the twisting element $\mathcal{F}$ (extended Jordanian twist). The Hopf subalgebra of the type $\mathcal{U}_{\mathcal{F}}(\mathbf{B}^\vee)$ generated by the twist is self-dual. The twisted coproduct of the sl(N) generators can be expressed as finite sums of classical generators and such a function σ of the highest root vector that is primitive with respect to the twisted coproduct. The commutation relations of the quantum space generators were defined using the twisting element action on the commutative coordinates. The cohomological properties of the involved Lie bialgebra permit the explanation of the connection of the Drinfeld–Jimbo (standard) quantization with this twisting.

The explicit expression of the twisting element $\mathcal{F}$ gives rise to a possibility to evaluate the Clebsch–Gordan coefficients (CGC) of the twisted sl(N) in terms of the original CGC and the entries of the matrix $F=(\rho_1\otimes\rho_2)\mathcal{F}$,[11] as well as to get the relations among the FTR-approach generators $L^{(\pm)}$ of the twisted algebra and the generators of the original algebras. It can be used also to construct the quantum double.[1,12]

The construction of the extended Jordanian twist was generalized to a certain class of inhomogenious Lie algebras, using properties of the Campbell–Hausdorff series. Further generalizations, in particular to Lie superalgebras, twisting of the corresponding Yangians, and new integrable models, twisting elements for other boundary solutions to the classical Yang–Baxter equation[26] are under study.

On the root mean square quantitative chirality and quantitative symmetry measures

Michel Petitjean[a)]
ITODYS (CNRS, ESA 7086), 1 rue Guy de la Brosse, 75005 Paris, France

(Received 22 February 1999; accepted for publication 22 March 1999)

The properties of the root mean square chiral index of a d-dimensional set of n points, previously investigated for planar sets, are examined for spatial sets. The properties of the root mean squares direct symmetry index, defined as the normalized minimized sum of the n squared distances between the vertices of the d-set and the permuted d-set, are compared to the properties of the chiral index. Some most dissymetric figures are analytically computed. They differ from the most chiral figures, but the most dissymetric 3-tuples and the most chiral 3-tuples have a common remarkable geometric property: the squared lengths of the sides are each equal to three times a squared distance vertex to the mean point. © *1999 American Institute of Physics.* [S0022-2488(99)01009-9]

I. INTRODUCTION

Chirality and symmetry properties of a solid body can be viewed as a continuous varying quantity taking values over [0;1] rather than a logical property, i.e., the body is or is not symmetric or chiral. The use of a chirality measure seems to be introduced by Rassat.[1] Then, various quantitative chirality or symmetry measures have been used.[2–12] This concept has received applications in physics, proposed mostly by the Avnir group.[2–4]

The root mean square chiral index CHI of a d-dimensional set of n points was defined[12] as the sum of the n squared distances between the vertices of the set and those of its inverted image, normalized to $4T/d$, T being the inertia of the set. This index is computed after minimization of the sum of the squared distances in respect to all rotations and translations and all permutations between equivalent vertices. It was shown to be a second kind of continuous chirality measure taking values over [0;1], the zero value corresponding to an achiral compound perfectly superposed to its inverted image. Similarly, the direct symmetry index DSI of a d-dimensional set of n points is defined here as follows. When all vertices are unequivalent, DSI is undefined. When there are at least two equivalent vertices, the sum of the n squared distances between the vertices and those of the permuted set is minimized for all rotations and translations and permutations (excluding the identity permutation) between equivalent vertices. DSI is the ratio of this minimized sum to twice the inertia T of the set.

The quantitative symmetry and chirality concepts used here are fully different from those of Avnir *et al.* for the following reasons: no achiral reference is needed to compute CHI, no symmetry assumptions are needed to compute CHI and DSI, no folding and unfolding process[5] are needed here, the normalization are different, and the farthest point from the centroid is not needed here, and, of course, the extremal figures are different.

The properties of CHI were examined for monodimensional sets and planar sets.[12] They are now examined for spatial sets. Hyperspatial sets (i.e., d is any positive integer) are examined when all vertices are unequivalent. The major difference between planar, spatial, and hyperspatial sets lies in the expression of the optimal rotation. The properties of DSI are also examined. For clarity, a set of $n=3$ points will be called a triangle. The most dissymetric triangles, i.e., those maximizing DSI, are here analytically computed when there are two or three equivalent vertices.

II. NOTATIONS

The notations are those used in Ref. 12. X0 and X1 are the n rows and d columns arrays of coordinates. X0 is the fixed set and X1 is to move. The quote denotes the transposition operator. All vectors are written as one-column matrices. $\langle x|y\rangle$ is the scalar product of the vectors x and y, and when $d=3$, $x\wedge y$ is their cross product. The trace and the determinant operators are denoted, respectively, Tr and Det. Y1 is the rotated and translated image of X1, and $D^2=\mathrm{Tr}((\mathrm{X0}-\mathrm{Y1})\cdot(\mathrm{X0}-\mathrm{Y1})')$ is the sum of the squared distances. D^2 is minimized for rotation plus translation when X0 and X1 are centered before computing the optimal rotation. Translations will be no longer considered, and the centering condition will not be assumed unless otherwise mentioned. The following matrices are used: $\mathrm{V00}=\mathrm{X0}'\cdot\mathrm{X0}$, $\mathrm{V11}=\mathrm{X1}'\cdot\mathrm{X1}$, $\mathrm{V10}=\mathrm{X1}'\cdot\mathrm{X0}$, $\mathrm{V01}=\mathrm{V10}'$, and $T=(\mathrm{T0}+\mathrm{T1})/2$, $\mathrm{T0}=\mathrm{Tr(V00)}$ and $\mathrm{T1}=\mathrm{Tr(V11)}$ being the respective inertia of X0 and X1, reducing to the usual inertia when the arrays are centered. The identity matrix is **I**, and R is a rotation matrix, such that $\mathrm{Y1}=\mathrm{X1}\cdot R'$.

The correspondence between X0 and X1 is handled via an n-dimensional square permutation matrix P. Let be $\mathrm{Z1}=P\cdot\mathrm{Y1}$. When X1 is the inverted image of X0 and when the centering condition is satisfied, the chiral index of a spatial set is $\mathrm{CHI}=D^2/(4T/d)$, with $D^2=\mathrm{Tr}((\mathrm{X0}-P\cdot\mathrm{X1}\cdot R')\cdot(\mathrm{X0}-P\cdot\mathrm{X1}\cdot R')')$ being minimized over all rotations R and allowed permutations P. When X1 is a rotated and translated image of X0 and when the centering condition is satisfied, $\mathrm{DSI}=D^2/2T$, D being minimized over all rotations and allowed nonidentity permutations.

The computation of either CHI or DSI requires the optimal rotation superimposing two sets. When $d=3$, the analytical expression of the optimal rotation superposing X1 on X0, X0 and X1 being any n rows and 3 columns arrays of coordinates, is given in the Appendix.

III. THE OPTIMAL ROTATION FOR 3D ENANTIOMERS

In this section, the centering condition is not assumed and three-dimensional enantiomers are considered. For clarity, X0 is noted $\sim X$ and its inverted image is $\mathrm{X1}=-P\cdot X$, and we define $V=X'\cdot P\cdot X=-\mathrm{V01}$. From Appendix A, we have

$$D^2=D0^2-2\langle q|Bq\rangle, \tag{1}$$

the optimal quaternion q being the eigenvector associated to L1, the highest eigenvalue of B:

$$B=\begin{pmatrix} 0 & c' \\ c & A \end{pmatrix}, \tag{2}$$

$$A=\mathrm{Tr}(V+V')\cdot\mathbf{I}-(V+V'), \tag{3}$$

$$c=\begin{pmatrix} \mathrm{V(2,3)-V(3,2)} \\ \mathrm{V(3,1)-V(1,3)} \\ \mathrm{V(1,2)-V(2,1)} \end{pmatrix}. \tag{4}$$

When P is a symmetric permutation, c is null, and the eigenvalues of B are the three eigenvalues of A and zero.

IV. ENANTIOMERS WITH ALL VERTICES UNEQUIVALENT

All the conditions of the preceding section are assumed to stand, and the vertices are all unequivalent, i.e., the only allowed permutation is $P=\mathbf{I}$. $V=X'\cdot X$ is symmetric and c is therefore null. The sum of squares prior rotation is $\mathrm{D0}^2=4\,\mathrm{Tr}(V)$, which is the maximized D^2 value because zero is the smallest eigenvalue of B. We have $A=2(\mathrm{Tr}(V)\cdot\mathbf{I}-V)$. Let v1, v2, v3 be the eigenvalues of V arranged in decreasing order. The largest eigenvalue of B is $\mathrm{L1}=\mathrm{d1}=2(\mathrm{v1}+\mathrm{v2})$ and the optimal rotation of $-X$ is 180 degrees around the principal axis associated to the smallest eigenvalue of V. Now we have $D^2=4\,\mathrm{Tr}(V)-4(\mathrm{v1}+\mathrm{v2})$, i.e.,

$$D^2 = 4\mathrm{v}3. \tag{5}$$

We assume now that X is centered, i.e., V is n times its variance matrix. The chiral index of the set of n vertices is therefore:

$$\mathrm{CHI} = 3\mathrm{v}3/(\mathrm{v}1+\mathrm{v}2+\mathrm{v}3). \tag{6}$$

CHI is d times the percentage of inertia associated to the smallest eigenvalue of V. Looking at Eqs. (3) and (7) in Ref. 12 and Appendix 1 in Ref. 12, we can see that this is also true for planar sets $(d=2)$ and unidimensional sets $(d=1)$.

The eigenvalues of V being positive and in decreasing order, CHI is maximized for $\mathrm{v}1=\mathrm{v}2=\mathrm{v}3=v$, i.e., $\mathrm{CHI}=1$ and $V=v\cdot\mathbf{I}$. When X has only 4 vertices, it is therefore a regular tetrahedron (see Appendix 2 in Ref. 12).

V. HYPERSPATIAL SETS WITH ALL UNEQUIVALENT VERTICES

The optimal rotation superimposing two d-dimensional sets is unknown when $d>3$, except for enantiomers with all unequivalent vertices, as shown hereafter. The sum of squares to be minimized is $D^2=\mathrm{Tr}((X-X\cdot Q')\cdot(X-X\cdot Q')')=2(\mathrm{Tr}(X'\cdot X)-\mathrm{Tr}(Q\cdot X'\cdot X))$, X being the (n,d) array of coordinates and Q being an orthogonal matrix with $\det(Q)=-1$. Thus, $\mathrm{Tr}(Q\cdot X'\cdot X)$ has to be maximized. Assuming that X is in its principal components axis (i.e., $V=X'\cdot X$ is diagonal), we have to find the maximum of $E=\mathrm{v}(1)\cdot\mathrm{Q}(1,1)+\mathrm{v}(2)\cdot\mathrm{Q}(2,2)+...+\mathrm{v}(d)\cdot\mathrm{Q}(d,d)$, $\mathrm{v}(1),...,\mathrm{v}(d)$ being the eigenvalues of V in decreasing order.

$$E=[(\mathrm{v}(1)-\mathrm{v}(d))\cdot\mathrm{Q}(1,1)+(\mathrm{v}(2)-\mathrm{v}(d))\cdot\mathrm{Q}(2,2)+\cdots+(\mathrm{v}(d-1)-\mathrm{v}(d))\cdot\mathrm{Q}(d-1,d-1)]+\mathrm{v}(d)\cdot\mathrm{Tr}(Q).$$

The eigenvalues of Q can be either $+1$, or -1, or pairs of conjugate complex roots of 1. It follows that $\mathrm{Tr}(Q)$ is maximized when $d-1$ eigenvalues are $+1$ and one is -1. Obviously, the sum of the $d-1$ terms $(\mathrm{v}(i)-\mathrm{v}(d))\cdot Q(i,i)$ is also maximized for $\mathrm{Q}(i,i)=1$ when $i<d$. Thus E is maximized and D^2 is minimized when X and its enantiomer have opposite coordinates on the principal axis with smallest inertia. Thus, Eqs. (5) and (6) are generalized:

$$D^2=4\mathrm{v}(d), \tag{7}$$

and assuming X centered:

$$\mathrm{CHI}=d\cdot\mathrm{v}(d)/(\mathrm{v}(1)+\mathrm{v}(2)+\cdots+\mathrm{v}(d)). \tag{8}$$

As previously, CHI is maximized when all eigenvalues of V are equal. When $n=d+1$, CHI is therefore maximized when X is a regular d-simplex. (See Appendix 2 in Ref. 12.)

From Eq. (8), it is possible to compare practical CHI values with the distribution of CHI when X is an isotropic multinormal sample. V is a Wishart matrix,[13] from which the joint density of the percentages of inertia can be derived,[14] leading to the distribution[15] of CHI/d. Unfortunately, the final expression is not trivial when $d>2$.

VI. THE DIRECT SYMMETRY INDEX

In this section, d-dimensional sets are considered and the centering condition is not assumed. The situation where all vertices are unequivalent precludes the existence of direct symmetry in the set. This situation should not be confused with the purely geometric situation where all vertices are equivalent (i.e., undistinct), for which symmetry properties are potentially observable. Thus, we consider now only sets with at least two equivalent vertices. As for the chiral index, the sum D^2

of the n squared distances between the vertices and those of the permuted set is minimized for all rotations and all authorized permutations, excluding of course the identity permutation $P=\mathbf{I}$. When the set is centered DSI$=D^2/(2T)$.

P being fixed, the sum of the squared distances to minimize is, as previously, $D^2=\mathrm{Tr}((\mathrm{X0}-P\cdot\mathrm{X1}\cdot R')\cdot(\mathrm{X0}-P\cdot\mathrm{X1}\cdot R')')$. Setting X0=X1=$X$ and $V=X'\cdot P\cdot X$, we get

$$D^2=2(T-\mathrm{Tr}(V\cdot R')). \tag{9}$$

There are at least two equivalent points x and y. Thus the minimum of D^2 for all rotations and permutations cannot exceed the minimum of D^2 for all rotations and for the permutation exchanging x and y, i.e., P is such that $V=x\cdot y'+y\cdot x'+Z'\cdot Z$, with Z being the $(n-2,d)$ block extracted from X by elimination of x and y. For this permutation,

$$\mathrm{Tr}(V\cdot R')=y'\cdot R'\cdot x+x'\cdot R'\cdot y+\mathrm{Tr}(Z'\cdot Z\cdot R'). \tag{10}$$

Assuming $d>1$, a rotation exists R which rotates from $+90$ degrees the first axis toward the second axis, i.e., $R(2,1)=-R(1,2)=1$, $R(i,i)=1$ for $i>2$, all other elements of R being null. Thus, $R+R'=0$, $y'\cdot R'\cdot x+x'\cdot R'\cdot y=0$ and $-\mathrm{Tr}(Z'\cdot Z\cdot R')=\mathrm{Tr}(Z'\cdot Z\cdot R)=\mathrm{Tr}(R'\cdot Z'\cdot Z)=\mathrm{Tr}(Z'\cdot Z\cdot R')=0$, which means that $\mathrm{Tr}(V\cdot R')$ is null. Because a permutation and a rotation exist such that $\mathrm{Tr}(V\cdot R')=0$, it follows from (9) that the minimum of D^2 is upper bounded by $2T$, and then DSI pertains to $[0;1]$ when $d>1$.

The following centered set containing three points is such that DSI$=1$ for all $d>1$: $x=e1\cdot(-1-\sqrt{3})/2$, $y=e1\cdot(-1+\sqrt{3})/2$, $z=e1$, $e1$ being the first base vector, x and y being equivalent and z being not.

When $d=1$, x and y are numbers, Z is a vector, $T=x^2+y^2+Z'\cdot Z$, $R=1$, and $\mathrm{Tr}(V\cdot R')=2x\cdot y+Z'\cdot Z$. Thus, $4T-D^2=2\cdot(T+\mathrm{Tr}(V\cdot R'))=2(x+y)^2+4\cdot Z'\cdot Z$, which cannot be negative. Thus, for $d=1$, D^2 varies from 0 to $4T$ and the direct symmetry index pertains to $[0;2]$, the extremal value DSI$=2$ being reached for a centered set containing two opposite values. But of course, direct rotational symmetry has little interest for $d=1$.

Computing simultaneously CHI and DSI for spatial sets is easy, since they both lead to the same quadratic form defined by Eqs. (1)–(4), except that the quadratic form associated to DSI now takes the opposite sign, because X1 was set to X rather than to $-X$. It means that the smallest eigenvalue L4 should be used to compute DSI rather than L1 for CHI, the minimized sum of squared distances being now

$$D^2=\mathrm{D0}^2+2\mathrm{L4}. \tag{11}$$

As shown in the Appendix, L4 is always nonpositive. Another difference between CHI and DSI is that the normalizing coefficients are, respectively, $4T/d$ and $2T$, but this is not a crucial difference.

VII. THE DIRECT SYMMETRY INDEX OF PLANAR TRIANGLES

We assume that $d=2$. Let x be the column vector of the abscissas, and y the column vector of their ordinates: $x'=(x_1,x_2,\ldots,x_n)$ and $y'=(y_1,y_2,\ldots,y_n)$. The points will be $p_1,p_2,\ldots,p_n$. The image of (x,y) through the permutation P is (Px,Py). P being fixed, the distance D minimized for all rotations is known:[12]

$$D^2=2(T-E), \tag{12}$$

E being the non-negative number, such that

$$E^2=(x'P'x)^2+(x'P'y)^2+(y'P'x)^2+(y'P'y)^2+2(x'P'x)(y'P'y)-2(y'P'x)(x'P'y).$$

Thus,

$$E^2=(x'Px+y'Py)^2+(y'Px-x'Py)^2. \tag{13}$$

The minimization for rotations plus translations is reached when the set is centered. The inertia is thus $T=x'x+y'y$. We assume T non-null, i.e., there are at least two distinct points. Let $\mathbf{1}$ be the n-vector such that all its n components are 1. Centering means $\mathbf{1}'x=\mathbf{1}'y=0$. We define also $M=(P+P')/2$ and $N=(P-P')/2$, which implies that $x'Nx=y'Ny=0$.

We assume now that $n=3$, and that all vertices are equivalents. d_{12}, d_{23} and d_{31} are the respective lengths of the sides of the triangle. $\|p_1\|$, $\|p_2\|$ and $\|p_3\|$ are the lengths of the segments joining the barycenter to the vertices at the opposite of the sides with respective lengths d_{23}, d_{31} and d_{12}. The inertia can be also written as $T=\|p_1\|^2+\|p_2\|^2+\|p_3\|^2$, or $T=(d_{23}^2+d_{31}^2+d_{12}^2)/3$.

The surface S of the triangle is such that $16S^2=2(d_{12}^2d_{23}^2+d_{23}^2d_{31}^2+d_{31}^2d_{12}^2)-(d_{12}^4+d_{23}^4+d_{31}^4)$.

A. Extremal values for a given permutation

Using M and N, Eq. (13) becomes

$$E^2=(x'Mx+y'My)^2+4(x'Ny)^2. \tag{14}$$

The gradient of $(1-D^2/2T)^2=(E^2/T^2)$ if set to zero for x, then for y,

$$T(x'Mx+y'My)Mx+2T(x'Ny)Ny=E^2x, \tag{15}$$

$$T(x'Mx+y'My)My-2T(x'Ny)Nx=E^2y. \tag{16}$$

Multiplying on the left (15) by x' then (16) by y', and substracting,

$$T(x'Mx)^2-T(y'My)^2=E^2(x'x-y'y). \tag{17}$$

Then from (15) or (16),

$$T(x'Mx+y'My)(x'My)=E^2(x'y). \tag{18}$$

From (17) and (18), it comes

$$E^2(x'My)(x'x-y'y)=E^2(x'y)(x'Mx-y'My). \tag{19}$$

When $n=3$,5 permutations are possible: 3 are symmetric and 2 are circular.

When P is symmetric, $M=P$, $N=0$, and Eqs. (15) and (16) reduce to the same eigenvalues equations: $T^2Px=E^2x$ and $T^2Py=E^2y$. For $n=3$, the eigenvalues of P are $+1$, $+1$ and -1. Only the solution such that $E^2=T^2$ is possible, implying $D=0$, leading to a minimum for DSI, rather to a maximum.

When P is one of the 2 circular permutations (the other being its transposed), we have: $2\mathbf{M}=\mathbf{1}\cdot\mathbf{1}'-\mathbf{I}$, implying that $x'Mx=-x'x/2$ and $y'My=-y'y/2$, and then $E^2=4(x'Ny)^2+T^2/4$. Moreover, $2x'Ny$ is equal to the determinant of the matrix $[\mathbf{1}|x|y]$ or to the opposite of this determinant, depending on which circular permutation is used. That implies $E^2=4S^2+T^2/4$. The minimum is therefore reached by a null-area triangle: the points are aligned.

B. Maximizing DSI

Let us consider the symmetric permutation associating p_1 to itself. The following comes: $N=0$ and $E^2=2x_2x_3+x_1^2+2y_2y_3+y_1^2=(T-d_{23}^2)^2$. Similarly, the E values associated with the symmetric permutations associating p_2 with p_2 and p_3 with p_3 are such that $E^2=(T-d_{31}^2)^2$ and $E^2=(T-d_{12}^2)^2$. Both circular permutations lead to $E^2=4S^2+T^2/4$, S^2 and T being homogeneous polynomials of d_{12}^2, d_{23}^2 and d_{31}^2. The 4 expressions of E^2 are homogeneous polynomials of 3 variables, returning non-negative values.

For a given triangle, the optimal permutation is that which leads to the highest E value. Thus a maximum of DSI, or a minimum of $[\mathrm{Max}(E^2)/T^2]$, should be searched either among the extrema of E^2/T^2 associated with a permutation, or at the intersection of at least two of the 4 polynomials associated with the permutations, T being the same for all permutations.

It was shown above that only one extremum of E^2/T^2 is useful, and it is such that $E=T/2$ and $S=0$. This is possible only if the length of a side is equal to the sum of the two others. Assuming for example, that $d_{23}=d_{31}+d_{12}$, and reporting it in $E=|T-d_{23}^2|=|d_{12}^2+d_{31}^2-2d_{23}^2|/3$. The following comes: $E=(d_{23}^2+2d_{12}d_{31})/3$, or $E=(T/2)+d_{12}d_{31}$. The circular permutation could be optimal only if $d_{12}d_{31}=0$, which should imply that $\mathrm{DSI}=0$ (degenerate isocele triangle). Similar conclusions should be reached if d_{31} or d_{12} have been used: the extrema of E^2/T^2 associated to a given permutation are not adequate.

Thus, it is needed to look at the intersection of the polynomials. Noting that the E/T values depend only on the distances ratios, we can work with only two independent variables, and we search the minimum at the intersection of 3 among the 4 polynomials. There are at least 2 among 3 symmetric permutations which lead to the same value. Assuming, for example, that $E=|T-d_{12}^2|=|T-d_{31}^2|$, thus, $|d_{23}^2+d_{31}^2-2d_{12}^2|=|d_{12}^2+d_{23}^2-2d_{31}^2|$. Either we get $d_{12}^2=d_{31}^2$, which does not work because the triangle should be isocele ($\mathrm{DSI}=0$), or we get $2d_{23}^2=d_{31}^2+d_{12}^2$, and thus $E=|d_{12}^2-d_{31}^2|/2$. In this situation, the E value associated to the third symmetric permutation is null, and the E value associated to circular permutations is $E=d_{12}d_{31}$. The equality between the 3 nonzero E^2 values give the desired relation: $(d_{12}^2-d_{31}^2)^2=4d_{12}^2d_{31}^2$. Reusing $2d_{23}^2=d_{31}^2+d_{12}^2$, the ratios of the squared lengths of the sides are deduced: $(d_{12}^2/d_{23}^2)=1+\sqrt{2}/2$, $(d_{31}^2/d_{23}^2)=1-\sqrt{2}/2$, and $E^2/T^2=(1-\mathrm{DSI})^2=1/2$.

C. Remarkable geometric properties of the optimal triangles

Using the distances, we get the angles associated, respectively, to the points p_1, p_2 and p_3: $\pi/4$, $\pi/8$ and $5\pi/8$.

A possible set of coordinates of the most dissymetric triangle is

$$X=\begin{pmatrix} \sqrt{2}/3 & 1/3 \\ (-3-\sqrt{2})/6 & -1/6 \\ (3-\sqrt{2})/6 & -1/6 \end{pmatrix}. \tag{20}$$

It is easy to see that $d_{23}^2=3\|p_1\|^2$, $d_{12}^2=3\|p_2\|^2$, and $d_{31}^2=3\|p_3\|^2$. It should be pointed out that this relation is symmetric only for p_2 and p_3. This remarkable proportionality exists also for the degenerate triangle with only two equivalent vertices, which was cited in Sec. VI, and corresponding to the maximal value $\mathrm{DSI}=1$, for any dimension $d>1$. For $d=2$, the most chiral triangles also offer this remarkable proportionality, discarding which vertices are equivalent,[12] but none of them has the shape of the most dissymmetric triangle. The shape of the most dissymmetric triangle has been measured using random triangles, with vertices uniformly distributed over a square. The results (Table I) are in accordance with the theory.

VIII. DISCUSSION AND CONCLUSION

The properties of the RMS (root mean square) chiral index have been examined for spatial sets. As for planar sets, it is easily analytically computed, but the expression of the optimal 3D rotation is fully different from those of the 2D one. The optimal rotation is unknown for hyperspatial sets, except when X is superposed with its unpermuted enantiomer. When $d>3$, it is proposed to extend the iterative procedure[16] to compute the optimal rotation superposing two d-dimensional sets, and to use it for permuted enantiomers. Similarly, computing the RMS direct symmetry index is easy for 2D and 3D sets, but suffers from the same limitation than the chiral index when $d>3$.

Looking at Eq. (8), it is clear that the RMS chiral index is also extendible to continuous distributions with all distinct points, provided that the variance exists. When there are subsets of

undistinct points, handling continuous sets is more difficult, because the set of authorized permutations must be redefined. This latter remark applies to the direct symmetry index. Thus, the extension of CHI and DSI to continuous sets will be examined in a further work.

The most chiral triangles and the most dissymmetric triangles offer the same remarkable geometric property. Its extension to higher-dimensional simplices is an open problem.

The chiral index and the direct symmetry index provides a coherent quantification of rotational symmetries carrying more information than a boolean value indicating the presence or absence of such symmetries. Although a perfect symmetry can be destroyed when a small perturbation is applied, the ability to quantify proper and improper rotational symmetries provides a robust tool to overcome this problem. As a by-product of computing CHI or DSI, the axe and angle associated to the optimal quaternion locate nonambiguously the symmetry element. When computing either CHI or DSI, if more than one permutation leads to small values of the indices, the set of optimal quaternions provides informations about the existence of more than one symmetry element. Building an automated procedure returning all symmetry elements of a perturbated symmetric set is currently investigated.

ACKNOWLEDGMENT

The author thanks Professor D. Avnir for useful discussions and encouragement to publish this work.

APPENDIX: THE OPTIMAL ROTATION FOR SPATIAL SETS

In this section, the centering condition is not assumed, and $d=3$. X0 and X1 are any n rows and 3 columns arrays of coordinates. The identity permutation $P=\mathbf{I}$ is assumed, but the final result will be valid for any P with replacing X1 by $P\cdot\text{X1}$. The well-known Procrustes algorithm[16,17] used to find the optimal orthogonal transformation superposing two d-sets does not work for enantiomers, because it leads always to $D=0$ and the optimal orthogonal matrix has a negative determinant $(\text{Det}=-1)$. Some iterative procedures are available,[18,19] but the final expression of the optimal rotation was found by Diamond,[20] leading to express D^2 with a quadratic form of the quaternion associated to the rotation. This quadratic form is maximized by an orthonormal basis of four quaternions. For convenience, the expression of the optimal rotation is retrieved here following a different presentation.

A 3D-rotation R is associated to a 3D rotation axis u and to a rotation angle r. This is expressed with a quaternion $q=(p,u)$, with $p=\cos(r/2)$ and $\|u\|=\langle u|u\rangle^{1/2}=\sin(r/2)$. Thus $\langle q|q\rangle=1$, and the image of a point x through R is[21] $Rx=(1-2\langle u|u\rangle)x+2\langle u|x\rangle u+2p(u\wedge x)$. Because $(-p,-u)$ is the same rotation than (p,u), p is always taken non-negative, i.e., r takes values from 0 to 180 degrees.

Let c be the sum of the n vectors $x1_i\wedge x0_i$. Thus, we have $c(1)=\mathrm{V10}(2,3)-\mathrm{V10}(3,2)$, $c(2)=\mathrm{V10}(3,1)-\mathrm{V10}(1,3)$, and $c(3)=\mathrm{V10}(1,2)-\mathrm{V10}(2,1)$. The matrix A is defined as $A=(\mathrm{V10}+\mathrm{V01})-\mathrm{Tr}(\mathrm{V10}+\mathrm{V01})\cdot\mathbf{I}$. Let $\mathrm{D0}^2$ be the initial sum of squares, prior to rotating X1. Now, we have the following equalities: $\langle \mathrm{R}x1_i|x0_i\rangle=(1-2\langle u|u\rangle)\langle x1_i|x0_i\rangle+2\langle u|x1_i\rangle\langle u|x0_i\rangle+2p\langle u\wedge x1_i|x0_i\rangle=(1-2\langle u|u\rangle)\langle x1_i|x0_i\rangle+\langle u|(x1_i\cdot x0_i'+x0_i\cdot x1_i')u\rangle+2p\langle u|x1_i\wedge x0_i\rangle$. V10 is the sum of the n matrices $x1_i\cdot x0_i'$, and $\mathrm{Tr}(V10)$ is the sum of the n quantities $\langle x1_i|x0_i\rangle$. Thus we get $D^2=\mathrm{D0}^2-2\langle u|Au\rangle-4p\langle u|c\rangle$. Let us define the 4×4 matrix B:

$$B=\begin{pmatrix}0 & c'\\ c & A\end{pmatrix},$$

$q=(p,u)$ being the unknown quaternion; it follows that: $D^2=\mathrm{D0}^2-2\langle q|Bq\rangle$.

B is a constant symmetric matrix depending only on the input data, and the quadratic form $\langle q|Bq\rangle$ has to be maximized, q being a unit vector. This problem has a well-known solution:[17] the stationary points are an othonormal basis eigenvectors of B, and the associated eigenvalues are the optimal values of the quadratic form. The sense of each eigenvector is known because p must be non-negative. It is unimportant to get $+u$ or $-u$ when $p=0$. Let L1, L2, L3, L4 be the eigenvalues arranged in decreasing order.

B is the sum of two 4×4 symmetric matrices. One contains only A and zeros on the first row and column. Let B1 be this matrix. The other contains only c' on the right of the first row and c on the bottom of the first column, zero as a first diagonal element, and nine zeros in the remaining 3×3 block. Let B2 be this one-rank matrix, of which the four eigenvalues are obviously $\|c\|$ and zero with three as multiplicity. Let d1, d2, d3 be the eigenvalues of A arranged in decreasing order. Thus, the following inequalities stand:[22] the eigenvalues of A separate those of B: $\mathrm{L1}\geqslant\mathrm{d1}\geqslant\mathrm{L2}\geqslant\mathrm{d2}\geqslant\mathrm{L3}\geqslant\mathrm{d3}\geqslant\mathrm{L4}$, and $|\mathrm{Li}-\mathrm{di}'|\leqslant\|c\|$ for $i=1,2,3,4$, di' being the ith greatest value among $(0,\mathrm{d1},\mathrm{d2},\mathrm{d3})$.

Two situations may arise. If d1 and d3 have not the same sign, the first set of inequalities means that L1 and L4 have not the same sign. If d1 and d3 have the same sign, let us look at the determinant of B expressed after diagonalization of A. The components of c become c(1), c(2), c(3), and $\det(B)=-\mathrm{c}(1)^2\cdot\mathrm{d2}\cdot\mathrm{d3}-\mathrm{c}(2)^2\cdot\mathrm{d1}\cdot\mathrm{d3}-\mathrm{c}(3)^2\cdot\mathrm{d1}\cdot\mathrm{d2}$. This determinant cannot be positive, thus again L1 and L4 cannot have the same sign.

Thus L1 is always non-negative and L4 is always non-positive. The rotation minimizing D^2 is those associated to the quaternion q1, such that $D^2=\mathrm{D0}^2-2\mathrm{L1}$, and the rotation associated to q4 such that $D^2=\mathrm{D0}^2-2\mathrm{L4}$ is that which maximizes D^2. D^2 has one saddle point associated to q2 and one associated to q3.

Some minor properties of the four optimal quaternions are obtained from their othonormality. Considering the first row of the equation Bq=Lq, it comes that $\mathrm{D0}^2-D^2=2\mathrm{L}=2\langle v|c\rangle$, with $v=u/p$. It shows than only a positive L value leads to $D^2<\mathrm{D0}^2$. The three others equations may be rewritten: $(A-\langle v|n\rangle\mathbf{I})v+n=0$, but this is neither an eigenvector equation nor a linear system. Two distinct directions ui and uj are generally not orthogonal: $\cos(ui,uj)=-pi\cdot pj/((1-pi^2)\cdot(1-pj^2))^{1/2}=-\cot g(ri)\cdot\cot g(rj)$, ri and rj being the 2D-angles associated, respectively, to qi and qj.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 40, NUMBER 9 SEPTEMBER 1999

Operator representations of a *q*-deformed Heisenberg algebra

Konrad Schmüdgen[a)]
Universität Leipzig, Fakultät für Mathematik und Informatik und NTZ, Augustusplatz 10/11, D-04109 Leipzig, Germany

(Received 3 June 1998; accepted for publication 9 July 1998)

A class of well-behaved $*$-representations of a q-deformed Heisenberg algebra previously introduced [Phys. Lett. B **291**, 273 (1992); Z. Phys. C **64**, 335 (1994)] is studied and classified.
[S0022-2488(99)02008-3]

I. INTRODUCTION

The idea to develop a q-deformed quantum mechanics by using quantum groups has been investigated in several papers.[1–5] Such approaches are usually based on a q-deformed phase space algebra which is derived from the noncommutative differential calculus of the q-deformed configuration space.[6,7] Following the standard procedure in quantum mechanics one has to represent the q-deformed position and momentum operators by essentially self-adjoint operators acting on a Hilbert space. More precisely, one has to find appropriate $*$-representations of the phase space $*$-algebra by unbounded operators in a Hilbert space. In the case of general Euclidean or Minykowski phase spaces the study and classification of these $*$-representations turns out to be technically complicated because of the many relations and also because of the various difficulties concerning unbounded operators.

The aim of this paper is to give a rigorous treatment of well-behaved operator representations for one of the simplest example—the one-dimensional q-deformed Heisenberg algebra which was invented in Refs. 4 and 2. Representations of this algebra have been investigated in Ref. 2. Since this $*$-algebra occurs as a subalgebra of other larger $*$-algebras, the study of general not necessarily irreducible $*$-representations seems to be important as well. We shall develop and analyze an operator-theoretic model for such general representations of the q-deformed Heisenberg algebra. This model might be used as a tool kit for the study of representations of larger $*$-algebras.

This paper is organized as follows. Section II contains the definition and some simple algebraic properties of the q-deformed Heisenberg algebra $\mathcal{A}(q)$. In Sec. III we develop a general operator-theoretic model for certain triples of operators which will lead in Sec. VI to representations of the $*$-algebra $\mathcal{A}(q)$. In Sec. IV the irreducibility and the unitary equivalence of these operator triples are investigated and a number of examples are treated. In Sec. V we give a characterization of these operator triples by a number of natural conditions. In Sec. VI we define the self-adjoint $*$-representations of the $*$-algebra $\mathcal{A}(q)$ obtained by means of these operator triples.

In a forthcoming paper we shall study the spectrum of the operator X. For this analysis the q-Fourier transform[8,9] will play a crucial role.

II. THE *q*-HEISENBERG ALGEBRA

For a positive real number $q \neq 1$, let $\mathcal{A}(q)$ denote the complex unital algebra with four generators $\mathbf{p},\mathbf{x},\mathbf{u},\mathbf{u}^{-1}$ subject to the defining relations

$$\mathbf{up} = q\mathbf{pu}, \quad \mathbf{ux} = q^{-1}\mathbf{xu}, \quad \mathbf{uu}^{-1} = \mathbf{u}^{-1}\mathbf{u} = 1, \tag{1}$$

[a)]Electronic mail: schmuedgen@mathematik.uni-leipzig.de

$$\mathbf{px}-q\mathbf{xp}=\mathrm{i}(q^{3/2}-q^{-1/2})\mathbf{u},\quad \mathbf{xp}-q\mathbf{px}=-\mathrm{i}(q^{3/2}-q^{-1/2})\mathbf{u}^{-1},\tag{2}$$

where i denotes the imaginary unit. An equivalent set of relations is obtained if (2) is replaced by

$$\mathbf{px}=\mathrm{i}q^{1/2}\mathbf{u}^{-1}-\mathrm{i}q^{-1/2}\mathbf{u},\quad \mathbf{xp}=\mathrm{i}q^{-1/2}\mathbf{u}^{-1}-\mathrm{i}q^{1/2}\mathbf{u}.\tag{2$'$}$$

From (1) and (2)$'$ it follows that the set of elements $\{\mathbf{p}^r\mathbf{u}^n,\mathbf{x}^s\mathbf{u}^n;\ r\in\mathbb{N}_0,\ s\in\mathbb{N},\ n\in\mathbb{Z}\}$ is a vector space basis of $\mathcal{A}(q)$.

The algebra $\mathcal{A}(q)$ becomes a $*$-algebra with involution defined on the generators by

$$\mathbf{p}=\mathbf{p}^*,\quad \mathbf{x}=\mathbf{x}^*,\quad \mathbf{u}^*=\mathbf{u}^{-1}.\tag{3}$$

Indeed, it suffices to check that the defining relations (1) and (2)$'$ of $\mathcal{A}(q)$ are invariant under the involution (3) which is easily done.

From (1), (2)$'$, and (3) we conclude that there are $*$-isomorphisms ρ_1 and ρ_2 of the $*$-algebras $\mathcal{A}(q)$ and $\mathcal{A}(q^{-1})$ such that

$$\rho_1(\mathbf{x})=\mathbf{p},\quad \rho_1(\mathbf{p})=\mathbf{x},\quad \rho_1(\mathbf{u})=\mathbf{u},\quad \text{and}\quad \rho_2(\mathbf{x})=\mathbf{x},\quad \rho_2(\mathbf{p})=\mathbf{p},\quad \rho_2(\mathbf{u})=-\mathbf{u}^*.$$

Because the $*$-algebras $\mathcal{A}(q)$ and $\mathcal{A}(q^{-1})$ are isomorphic, we shall assume in what follows that $0<q<1$.

III. AN OPERATOR-THEORETIC MODEL

(1) Let μ_1 be a finite positive Borel measure on the interval $[q,1)$. The measure μ_1 extends uniquely to a Borel measure μ on the half-axis $\mathbb{R}_+=(0,+\infty)$ by setting $\mu(q^n\mathcal{M}):=q^n\mu_1(\mathcal{M})$ for any Borel subset $\mathcal{M}$ of $[q,1)$. Then μ has the property that $\mu(q\mathcal{N})=q\mu(\mathcal{N})$ for an arbitrary Borel subset $\mathcal{N}$ of $\mathbb{R}_+$ or equivalently that $d\mu(qt)/qt=d\mu(t)/t$ for $t\in\mathbb{R}_+$. We shall work with the Hilbert spaces $\mathcal{H}:=L^2(\mathbb{R}_+,\mu)$ and $\mathfrak{H}:=L^2([q,1),\mu_1)$. First we define three linear operators *U, P*, and *X* on the Hilbert space $\mathcal{H}$:

(i) $(Uf)(t)=q^{1/2}f(qt)$ for $f\in\mathcal{H}$,
(ii) $(Pf)(t)=tf(t)$ for $f\in\mathcal{D}(P):=\{f\in\mathcal{H}:tf(t)\in\mathcal{H}\}$,
(iii) $(Xf)(t)=\mathrm{i}t^{-1}(f(q^{-1}t)-f(qt))$ for $f\in\mathcal{D}(X):=\{f\in\mathcal{H}:t^{-1}f(t)\in\mathcal{H}\}$.

These operators will play a crucial role throughout this paper. Roughly speaking and ignoring technical subtleties (domains, boundary conditions, etc.), we shall show that for all ''well-behaved'' $*$-representations of the q-deformed Heisenberg algebra $\mathcal{A}(q)$ the images of the generators **u, p**, and **x** act by the same formulas as the operators *U, P*, and *X*, respectively.

Obviously, P is an unbounded self-adjoint operator on $\mathcal{H}$. Using the relation $d\mu(qt)/qt=d\mu(t)/t$ one easily verifies that U is a unitary operator and that X is a symmetric operator on $\mathcal{H}$. Let $\mathcal{D}_0$ be the set of functions $f\in\mathcal{H}$ such that supp $f\in[a,b]$ for some $a>0$ and $b>0$. (Note that a and b may depend on f.) Clearly, $\mathcal{D}_0$ is dense linear subspace of $\mathcal{H}$ which is invariant under *U, P*, and *X*. It is straightforward to check that the operators *P, X*, and *U* applied to functions $f\in\mathcal{D}_0$ satisfy the defining relations (1), (2), and (3) of the $*$-algebra $\mathcal{A}(q)$. In turns out that the symmetric operator X is not essentially self-adjoint. Our next aim is to characterize the domain of the adjoint operator X^*.

For $f\in\mathfrak{H}=L^2([q,1),\mu_1)$ let f^e and f^o be the functions on $\mathbb{R}_+$ defined by

$$f^e(q^{2n}t)=f^o(q^{2n+1}t)=f(t)\quad \text{for } n\in\mathbb{N}_0,\quad t\in[q,1),\quad \text{and } f^e(t)=f^o(t)=0\ \text{ otherwise.}\tag{4}$$

Clearly, f^e and f^o are in $\mathcal{H}=L^2(\mathbb{R}_+,\mu)$ and we have $U(f^e)-q^{1/2}f\in\mathcal{D}(X)$ and $U(f^o)-q^{1/2}f^e\in\mathcal{D}(X)$. Let $\mathfrak{H}_e$ and $\mathfrak{H}_o$ denote the set of functions f^e and f^o, respectively, where $f\in\mathfrak{H}=L^2([q,1),\mu_1)$.

Lemma 1: The domain $\mathcal{D}(X^*)$ *is the direct sum of vector spaces* $\mathcal{D}(X)$, $\mathfrak{H}_e$ *and* $\mathfrak{H}_o$.

Proof: It is straightforward to check that $\mathcal{D}(X)+\mathfrak{H}_e+\mathfrak{H}_o\subseteq\mathcal{D}(X^*)$. In order to prove the converse, let $g\in\mathcal{D}(X^*)$. Then, by definition there is an $h\in\mathcal{H}$ such that $\langle Xf,g\rangle=\langle f,h\rangle$ for all $f\in\mathcal{D}(X)$. Inserting the definition of X and using once more the fact that $\mu(q\mathcal{N})=q\mu(\mathcal{N})$ for an arbitrary Borel subset $\mathcal{N}$ of $\mathbb{R}_+$ we easily conclude that $h(t)=it^{-1}(g(q^{-1}t)-g(qt))$. For a function $f\in\mathcal{H}$ let f_n denote the function in $L^2([q,1),\mu_1^+)$ given by $f_n(t)=f(q^nt)$. Then we get

$$\|h\|^2_{L^2(\mathbb{R}_+,\mu)}=\sum_{n=-\infty}^{\infty}\|h_n\|^2q^n\geqslant\sum_{n=0}^{\infty}\frac{\|g_{n+1}-g_{n-1}\|^2}{q^{2n}}q^n.$$

For $n\in\mathbb{N}$ we set $\alpha_n:=\|g_{n+1}-g_{n-1}\|q^{-n/2}$. Since $h\in L^2(\mathbb{R},\mu)$, the sequence (α_n) is in l_2. From the inequality

$$\|g_{2r}-g_{2s}\|\leqslant\alpha_{2r+1}q^{(2r+1)/2}+\cdots+\alpha_{2s+1}q^{(2s+1)/2}$$

we obtain

$$\|g_{2r}-g_{2s}\|^2\leqslant\left(\sum_{i=2s+1}^{\infty}|\alpha_i|^2\right)q^{2s+1}(1-q^2)^{-1},\quad r\geqslant s. \tag{5}$$

Since $(\alpha_n)\in l_2$, this implies that the sequence $(g_{2n})_{n\in\mathbb{N}}$ converges in the Hilbert space $L^2([q,1),\mu_1)$. Let us denote its limit by ξ. We extend ξ to a function ξ^e on $\mathbb{R}_+$ by setting $\xi^e(q^{2n}t):=\xi(t)$ and $\xi^e(q^{2n+1}t):=0$ for $n\in\mathbb{N}_0$, $t\in[q,1)$, and $\xi^e(t)=0$ for $t\geqslant1$. Replacing even indices by odd indices, a similar reasoning yields functions $\zeta\in L^2([q,1),\mu_1)$ and ζ^o on $\mathbb{R}_+$ such that $\zeta^o(q^{2n+1}t)=\zeta(t)$ and $\zeta^o(q^{2n}t)=0$ for $n\in\mathbb{N}$, $t\in[q,1)$, and $\zeta^o(t)=0$ for $t\geqslant1$. By construction, $\xi^e\in\mathfrak{H}_e$ and $\zeta^o\in\mathfrak{H}_o$. Our proof is complete once we have shown that $f:=g-\xi^e-\zeta^o$ belongs to the domain $\mathcal{D}(X)$ of the operator X.

Letting $r\to\infty$ in (5), we get

$$\|\xi-g_{2s}\|^2\leqslant q^{2s+1}(1-q^2)^{-1}\sum_{n=0}^{\infty}|\alpha_{2n}|^2. \tag{6}$$

From (6) and the corresponding estimation of $\|\zeta-g_{2s+1}\|^2$ we obtain

$$\sum_{n=0}^{\infty}\|t^{-1}f_n(t)\|^2q^n\leqslant\sum_{n=0}^{\infty}\frac{\|f_n\|^2}{q^{2n+2}}q^n=\sum_{r=0}^{\infty}\frac{\|\xi-g_{2r}\|^2}{q^{2r+2}}+\frac{\|\zeta-g_{2r+1}\|^2}{q^{2r+3}}=(q-q^3)^{-1}\sum_{n=0}^{\infty}|\alpha_n|^2<\infty.$$

Since $f(t)=g(t)$ for $t\geqslant1$, this inequality implies that the functions $t^{-1}f(t)$ and $f(t)$ are in $L^2(\mathbb{R}^+,\mu)$. Thus, $f\in\mathcal{D}(X)$. ∎

As shown in the preceding proof, for any function $g\in\mathcal{D}(X^*)$ the "even components" g_{2n} and the "odd components" g_{2n+1} both have "boundary limits" ξ and ζ in $L^2([q,1),\mu_1)$. By Lemma 1, any element $f\in\mathcal{D}(X^*)$ is of the form $f=f_X+f^e+f^o$ with uniquely determined functions $f_X\in\mathcal{D}(X)$, $f^e\in\mathcal{H}_e$ and $f^o\in\mathcal{H}_o$. By the definition of $\mathcal{H}_e$ and $\mathcal{H}_o$, there exist unique functions f_e, $f_o\in\mathfrak{H}=L^2([q,1),\mu_1)$ such that $(f_e)^e=f^e$ and $(f_o)^o=f^o$, where the function $(f_e)^e$ and $(f_o)^o$ on $\mathbb{R}$ are given by (4). This notation will be kept in the sequel.

Let $\langle\cdot,\cdot\rangle$ and $(\cdot,\cdot)$ denote the scalar products of the Hilbert spaces $L^2(\mathbb{R}_+,\mu)$ and $L^2([q,1),t^{-1}\mu_1)$, respectively.

Lemma 2: For arbitrary functions $f,g\in\mathcal{D}(X^*)$ we have

$$\langle X^*f,g\rangle-\langle f,X^*g\rangle=\frac{1}{2\mathrm{i}}\{(f_e+f_o,g_e+g_o)-(f_e-f_o,g_e-g_o)\}. \tag{7$_+$}$$

Proof: Let $h\in L^2(([q,1),\mu_1)$. From the definitions of the operator X and of the functions $h^e,h^o\in L^2(\mathbb{R},\mu)$ we easily derive that $(X^*h^e)(t)=-it^{-1}h(qt)$ for $t\in[1,q^{-1})$, $(X^*h^e)(t)=0$ for t

$\in \mathbb{R}_+ \backslash [1,q^{-1})$, $(X^* h^o)(t) = -it^{-1}h(t)$ for $t \in [q,1)$, and $(X^* h^o)(t) = 0$ for $t \in \mathbb{R}_+ \backslash [q,1)$. Inserting these expressions and using the symmetry of the operator X we compute

$$\langle X^* f,g\rangle - \langle f,X^* g\rangle = \langle X^* f_o, g_e\rangle - \langle f_e, X^* g_o\rangle$$
$$= -\mathrm{i}\int_q^1 (f_o(t)\overline{g_e(t)} + f_e(t)\overline{g_o(t)})t^{-1}\, d\mu(t)$$
$$= -\mathrm{i}\{(f_o, g_e) + (f_e, g_o)\} = \frac{1}{2\mathrm{i}}\{(f_e + f_o, g_e + g_o) - (f_e - f_o, g_e - g_o)\}.$$

■

Let us illustrate the preceding by the simplest example.

Example 1: Let μ_1 be the Delta measure δ_a, where a is a fixed number from the interval $[q,1)$. Then the measure μ is supported on the points $aq^n, n \in \mathbb{Z}$, and we have $\mu(\{aq^n\}) = q^n \mu(\{a\}) = q^n$. Hence the scalar product of the Hilbert space $\mathcal{H} = L^2(\mathbb{R}_+, \mu)$ is given by the Jackson integral

$$\langle f,g\rangle = \sum_{n=-\infty}^{+\infty} f(aq^n)\overline{g(aq^n)}q^n.$$

Let $e_n \in \mathcal{H}$ be the function $e_n(t) = q^{-n/2}\delta^t_{aq^n}$, where δ^t_s is the usual Kronecker symbol. Then the vectors $e_n, n \in \mathbb{Z}$, form an orthonormal basis of $\mathcal{H}$ and the actions of the operators U, P, and X on these vectors are given by

$$Ue_n = e_{n-1}, \quad Pe_n = aq^n e_n, \quad Xe_n = \frac{\mathrm{i}}{aq^n}(q^{-1/2}e_{n+1} - q^{1/2}e_{n-1}).$$

These equations are in accordance with formulas (5) in Ref. 2. If f is the function in $L^2([q,1),\mu_1) \cong \mathbb{C}$ with $f(a) = 1$, then by definition $f^e(aq^{2n}) = f^o(aq^{2n+1}) = 1$, $f^e(aq^{2n+1}) = f^o(aq^{2n}) = 0$ for $n \in \mathbb{N}_0$, and $f^e(t) = f^o(t) = 0$ for $t \geqslant 1$. Then we have $\mathcal{D}(X^*) = \mathcal{D}(X) + \mathbb{C}\cdot f^e + \mathbb{C}\cdot f^o$ by Lemma 1 and formula $(7)_+$ reads as

$$\langle X^*(\varphi + \alpha_1 f^e + \beta_1 f^o), \psi + \alpha_2 f^e + \beta_2 f^o\rangle - \langle \varphi + \alpha_1 f^e + \beta_1 f^o, X^*(\psi + \alpha_2 f^e + \beta_2 f^o)\rangle$$
$$= -\mathrm{i}a^{-1}\{\beta_1\overline{\alpha_2} + \alpha_1\overline{\beta_2}\}$$
$$= \frac{1}{2\mathrm{i}a}\{(\alpha_1 + \beta_1)\overline{(\alpha_2 + \beta_2)} - (\alpha_1 - \beta_1)\overline{(\alpha_2 - \beta_2)}\}$$

for $\alpha_1, \beta_1, \alpha_2, \beta_2 \in \mathbb{C}$. ■

(2) The above considerations carry over almost verbatim to the case where the positive half-axis $\mathbb{R}_+$ is replaced by the negative half-axis $\mathbb{R}_- = (-\infty,0)$. Any positive finite Borel measure μ_1 on the interval $[q,1)$ induces a positive Borel measure μ on $\mathbb{R}_-$ by defining $\mu(-q^n\mathcal{M}) := q^n\mu_1(\mathcal{M})$ for a Borel subset $\mathcal{M}$ of $[q,1)$. The operators U, P, and X on the Hilbert space $\mathcal{H}_- := L^2(\mathbb{R}_-, \mu)$ are defined by the same formulas as in the preceding subsection and Lemma 1 and its proof remain valid in this case as well. However, there is an essential difference which will be crucial in the sequel: Since in the proof of Lemma 2 the integration is over the interval $(-1,-q]$, the expression on the right-hand side of $(7)_+$ must be multiplied by -1. That is, instead of $(7)_+$ we now have

$$\langle X^* f,g\rangle - \langle f,X^* g\rangle = \frac{1}{2\mathrm{i}}\{(f_e + f_o, g_e + g_o) - (f_e - f_o, g_e - g_o)\} \qquad (7)_-$$

for $f,g \in \mathcal{D}(X^*)$.

(3) After the preceding preparations we are now able to develop the operator-theoretic model for the description of $*$-representations of the q-Heisenberg algebra $\mathcal{A}(q)$. For this let us fix two families $\{\mu_1^{j,+};j\in I_+\}$ and $\{\mu_1^{j,-};j\in I_-\}$ of finite positive Borel measures on the interval $[q,1)$.

As above, we define the Hilbert spaces $\mathcal{H}_{j,\pm}:=L^2(\mathbb{R}_\pm,\mu^{j,\pm})$, $j\in I_\pm$, and the operators $U_{j,\pm}$, $P_{j,\pm}$, and $X_{j,\pm}$ acting therein. We shall work with the representation Hilbert space $\mathcal{H}=\mathcal{H}_+\oplus\mathcal{H}_-$, where $\mathcal{H}_+:=\oplus_{j\in I_+}\mathcal{H}_{j,+}$ and $\mathcal{H}_-:=\oplus_{j\in I_-}\mathcal{H}_{j,-}$. The elements of $\mathcal{H}$ are pairs $\mathfrak{f}=(\mathfrak{f}^+,\mathfrak{f}^-)$, where $\mathfrak{f}^+=(f^{j,+};j\in I_+)\in\mathcal{H}_+$ and $\mathfrak{f}^-=(f^{j,-};j\in I)\in\mathcal{H}_-$. Let U, P, and X denote the operators on $\mathcal{H}$ which are defined as the direct sums of the operators $U_{j,+},U_{j,-}$; $P_{j,+},P_{j,-}$; and $X_{j,+},X_{j,-}$, respectively. Clearly, U is a unitary operator and P is a self-adjoint operator on $\mathcal{H}$. The operator X is only symmetric, but not self-adjoint. Our next aim is to describe all self-adjoint extensions $\tilde{X}$ of X on $\mathcal{H}$ which have the property that $U\tilde{X}U^{-1}=q\tilde{X}$.

Let V and W be two unitary linear transformations of the Hilbert space $\mathfrak{H}_-:=\oplus_{j\in I_-}L^2([q,1),t^{-1}\mu_1^{j,-})$ on the Hilbert space $\mathfrak{H}_+:=\oplus_{j\in I_+}L^2([q,1),t^{-1}\mu_1^{j,+})$. We define a linear operator $X_{V,W}$ as being the restriction of the adjoint operator X^* to the domain

$$\mathcal{D}(X_{V,W}):=\{\mathfrak{f}=\mathfrak{f}_X+\mathfrak{f}^e+\mathfrak{f}^o\in\mathcal{D}(X^*):\mathfrak{f}_X\in\mathcal{D}(X),$$
$$\mathfrak{f}_e^+=V(\mathfrak{f}_e^-+\mathfrak{f}_0^-)+W(\mathfrak{f}_e^--\mathfrak{f}_0^-),\ \ \mathfrak{f}_0^+=V(\mathfrak{f}_e^++\mathfrak{f}_0^-)-W(\mathfrak{f}_e^--\mathfrak{f}_0^-). \tag{8}$$

Proposition 1: $X_{V,W}$ is a self-adjoint operator on $\mathcal{H}$ such that $X\subseteq X_{V,W}$ and $UX_{V,W}U^*=qX_{V,W}$. In particular, we have $U\mathcal{D}(X_{V,W})=\mathcal{D}(X_{V,W})$. Conversely, for any self-adjoint extension $\tilde{X}$ of X satisfying $U\mathcal{D}(\tilde{X})\subseteq\mathcal{D}(\tilde{X})$ there exist unitary transformations V,W of $\mathfrak{H}_+$ onto $\mathfrak{H}_-$ such that $\tilde{X}=X_{V,W}$.

Proof: From $(7)_+$ and $(7)_-$ we obtain

$$-2\mathrm{i}(\langle X^*\mathfrak{f},\mathfrak{g}\rangle-\langle\mathfrak{f},X^*\mathfrak{g}\rangle)=(\mathfrak{f}_e^++\mathfrak{f}_o^+,\mathfrak{g}_e^++\mathfrak{g}_o^+)+(\mathfrak{f}_e^--\mathfrak{f}_o^-,\mathfrak{g}_e^--\mathfrak{g}_o^-)-(\mathfrak{f}_e^-+\mathfrak{f}_o^-,\mathfrak{g}_e^-+\mathfrak{g}_o^-)$$
$$-(\mathfrak{f}_e^+-\mathfrak{f}_o^+,\mathfrak{g}_e^+-\mathfrak{g}_o^+) \tag{9}$$

for arbitrary elements $\mathfrak{f}=\mathfrak{f}_X+\mathfrak{f}^e+\mathfrak{f}^o$ and $\mathfrak{g}=\mathfrak{g}_X+\mathfrak{g}^e+\mathfrak{g}^o$ of $\mathcal{D}(X^*)$. Here $\mathfrak{f}_e^+$ denotes the sequence $(f_e^{j,+};j\in I_+)\in\mathfrak{H}_+$ with $f_e^{j,+}\in L^2([q,1),\mu_1^j)$ such that the extension $(f_e^{j,+})^e$ of $f_e^{j,+}$ to $\mathbb{R}_+$ by means of formula (4) is just the $(j,+)$-component of the vector $\mathfrak{f}^e\in\mathcal{H}$. A similar meaning attached to the other symbols $f_e^-,f_o^+,f_o^-,\mathfrak{g}_e^+,\mathfrak{g}_o^-,\mathfrak{g}_o^+,\mathfrak{g}_o^-$ occuring in (9). If $\mathfrak{f},\mathfrak{g}\in\mathcal{D}(X_{V,W})$, then we have $f_e^++\mathfrak{f}_o^-=V(\mathfrak{f}_e^-+\mathfrak{f}_o^-)$, $\mathfrak{g}_e^++\mathfrak{g}_o^-=V(\mathfrak{g}_e^-+\mathfrak{g}_o^-)$, $\mathfrak{f}_e^+-\mathfrak{f}_o^+=W(\mathfrak{f}_e^--\mathfrak{f}_o^-)$, and $\mathfrak{g}_e^+-\mathfrak{g}_o^+=W(\mathfrak{g}_e^--\mathfrak{g}_o^-)$ by (8). Since $X_{V,W}\subseteq X^*$, we therefore obtain that $\langle X_{V,W}\mathfrak{f},\mathfrak{g}\rangle-\langle\mathfrak{f},X_{V,W}\mathfrak{g}\rangle=0$ by (9), that is, the operator $X_{V,W}$ is symmetric. Now let $\mathfrak{g}\in\mathcal{D}((X_{V,W})^*)$. Since $X\subseteq X_{V,W}\subseteq(X_{V,W})^*\subseteq X^*$, we then have $\langle X^*\mathfrak{f},\mathfrak{g}\rangle=\langle\mathfrak{f},X^*\mathfrak{g}\rangle$ and hence

$$(\mathfrak{f}_e^++\mathfrak{f}_o^+,\mathfrak{g}_e^++\mathfrak{g}_o^+)+(\mathfrak{f}_e^--\mathfrak{f}_o^-,\mathfrak{g}_e^--\mathfrak{g}_o^-)=(\mathfrak{f}_e^-+\mathfrak{f}_o^-,\mathfrak{g}_e^-+\mathfrak{g}_o^-)+(\mathfrak{f}_e^+-\mathfrak{f}_o^+,\mathfrak{g}_e^+-\mathfrak{g}_o^+) \tag{10}$$

for all $\mathfrak{f}\in\mathcal{D}(X_{V,W})$ by (9). Inserting (8) into (10), we get

$$(f_e^-+\mathfrak{f}_o^-,V^*(\mathfrak{g}_e^++\mathfrak{g}_o^-))+(\mathfrak{f}_e^--\mathfrak{f}_o^-,\mathfrak{g}_e^--\mathfrak{g}_o^-)=(\mathfrak{f}_e^-+\mathfrak{f}_o^-,\mathfrak{g}_e^-+\mathfrak{g}_o^-)+(\mathfrak{f}_e^--\mathfrak{f}_o^-,W^*(\mathfrak{g}_e^+-\mathfrak{g}_o^+)). \tag{11}$$

From the construction it is clear that for arbitrary $\mathfrak{h},\mathfrak{k}\in\mathfrak{H}_-$ there exists $\mathfrak{f}\in\mathcal{D}(X_{V,W})$ such that $\mathfrak{f}_e^-+\mathfrak{f}_o^-=\mathfrak{h}$ and $\mathfrak{f}_e^--\mathfrak{f}_o^-=\mathfrak{k}$. Therefore, it follows from (11) that $V^*(\mathfrak{g}_e^++\mathfrak{g}_o^+)=\mathfrak{g}_e^++\mathfrak{g}_o^-$ and $W^*(\mathfrak{g}_e^+-\mathfrak{g}_o^+)=\mathfrak{g}_e^--\mathfrak{g}_o^-$, which in turn implies that $\mathfrak{g}\in\mathcal{D}(X_{V,W})$. Thus we have shown that the operator $X_{V,W}$ is self-adjoint. From the relations $U(\mathfrak{f}_e)-q^{1/2}\mathfrak{f}_o\in\mathcal{D}(X)$ and $U(\mathfrak{f}_o)-q^{1/2}\mathfrak{f}_e\in\partial(X)$ we see that $U\mathcal{D}(X_{V,W})=\mathcal{D}(X_{V,W})$. Since $UXU^*=qX$ and hence $UX^*U^*=qX^*$ and $X_{V,W}$ is the restriction of X^* to $\mathcal{D}(X_{V,W})$, the latter yields $UX_{V,W}U^*=qX_{V,W}$.

Conversely, suppose that $\tilde{X}$ is a self-adjoint extension of X such that $U\mathcal{D}(\tilde{X}) \subseteq \mathcal{D}(\tilde{X})$. Since $\tilde{X}$ is symmetric, we have Eq. (10) for arbitrary elements $\mathfrak{f},\mathfrak{g} \in \mathcal{D}(\tilde{X})$. By assumption, $U\mathfrak{f} \in \mathcal{D}(\tilde{X})$ for all $\mathfrak{f} \in \mathcal{D}(\tilde{X})$. Replacing $\mathfrak{f}$ by $U\mathfrak{f}$ in (10) we get

$$(\mathfrak{f}_e^+ + \mathfrak{f}_o^+, \mathfrak{g}_e^+ + \mathfrak{g}_o^+) + (\mathfrak{f}_o^- - \mathfrak{f}_e^-, \mathfrak{g}_e^- - \mathfrak{g}_o^-) = (\mathfrak{f}_e^- + \mathfrak{f}_o^-, \mathfrak{g}_e^- + \mathfrak{g}_o^-) + (\mathfrak{f}_o^+ - \mathfrak{f}_e^+, \mathfrak{g}_e^+ - \mathfrak{g}_o^+). \tag{12}$$

Setting $\mathfrak{f} = \mathfrak{g}$ and combining formulas (10) and (12) we obtain

$$\|\mathfrak{f}_e^+ + \mathfrak{f}_o^+\| = \|\mathfrak{f}_e^- + \mathfrak{f}_o^-\| \quad \text{and} \quad \|\mathfrak{f}_e^+ - \mathfrak{f}_o^+\| = \|\mathfrak{f}_e^- - \mathfrak{f}_o^-\| \tag{13}$$

for all $\mathfrak{f} \in \mathcal{D}(\tilde{X})$.

For $\mathfrak{f} \in \mathcal{D}(X^*)$ we abbreviate $B_\pm(\mathfrak{f}) = (\mathfrak{f}_e^\pm + \mathfrak{f}_0^\pm, \mathfrak{f}_e^\pm - \mathfrak{f}_o^\pm)$. The vector space $B_\pm(\tilde{X}) = \{B_\pm(\mathfrak{f}) : \mathfrak{f} \in \mathcal{D}(\tilde{X})\}$ is called the ''boundary space'' of the operator $\tilde{X}$. We shall show that $B_+(\tilde{X}) = \mathfrak{H}_+ \oplus \mathfrak{H}_+$ and $B_-(\tilde{X}) = \mathfrak{H}_- \oplus \mathfrak{H}_-$. First let us note that the spaces $B_\pm(\tilde{X})$ are closed in $\mathfrak{H}_\pm \oplus \mathfrak{H}_\pm$. Otherwise, let $\tilde{\tilde{X}}$ denote the restriction of X^* to the domain $\mathcal{D}(\tilde{\tilde{X}}) = \{\mathfrak{f} \in \mathcal{D}(X^*) : B_\pm(\mathfrak{f}) \in \overline{B_\pm(\tilde{X})}\}$, where the bar means the closure in the Hilbert space $\mathfrak{H}_\pm \oplus \mathfrak{H}_\pm$. The symmetry of an operator Y such that $X \subseteq Y \subseteq X^*$ is equivalent to the validity of Eq. (10) for all $\mathfrak{f},\mathfrak{g} \in \mathcal{D}(Y)$. Hence $\tilde{\tilde{X}}$ is symmetric, because $\tilde{X}$ is so. Since a self-adjoint operator has no proper symmetric extension, we conclude that $\tilde{X} = \tilde{\tilde{X}}$ which means that $B_+(\tilde{X})$ and $B_-(\tilde{X})$ are closed. Next let us suppose that $(\xi,\zeta) \perp B_+(\tilde{X})$ in $\mathfrak{H}_+ \oplus \mathfrak{H}_+$. We then choose a vector $\mathfrak{g} \in \mathcal{D}(\tilde{X})$ such that $\xi = \mathfrak{g}_e^+ + \mathfrak{g}_o^+$, $\zeta = \mathfrak{g}_e^+ - \mathfrak{g}_o^+$ and $\mathfrak{g}_e^- = \mathfrak{g}_0^- = 0$. Then the right-hand side of (9) vanishes for all $\mathfrak{f} \in \mathcal{D}(\tilde{X})$, so that $\langle \tilde{X}\mathfrak{f}, \mathfrak{g} \rangle = \langle X^*\mathfrak{f}, \mathfrak{g} \rangle = \langle \mathfrak{f}, X^*\mathfrak{g} \rangle$ for all $\mathfrak{f} \in \mathcal{D}(\tilde{X})$ by (9). Consequently, $\mathfrak{g} \in \mathcal{D}(\tilde{X}^*)$. Since $\tilde{X}$ is self-adjoint, $\mathfrak{g}$ must be in $\mathcal{D}(\tilde{X})$. Because $(\xi,\zeta) \perp B_+(\tilde{X})$, this implies that $\xi = \zeta = 0$. This proves that $B_+(\tilde{X}) = \mathfrak{H}_+ \oplus \mathfrak{H}_+$. Similarly $B_-(\tilde{X}) = \mathfrak{H}_- \oplus \mathfrak{H}_-$.

Since $B_\pm(\tilde{X}) = \mathfrak{H}_\pm \oplus \mathfrak{H}_\pm$ as just shown, it follows from (13) that there are unitary operators V and W of $\mathfrak{H}_-$ onto $\mathfrak{H}_+$ such that $\mathfrak{f}_e^+ + \mathfrak{f}_o^+ = V(\mathfrak{f}_e^- + \mathfrak{f}_o^-)$ and $\mathfrak{f}_e^+ - \mathfrak{f}_o^+ = W(\mathfrak{f}_e^- - \mathfrak{f}_o^-)$ for all $\mathfrak{f} \in \mathcal{D}(\tilde{X})$. That is, $\mathcal{D}(\tilde{X}) \subseteq \mathcal{D}(X_{V,W})$. Since $\tilde{X}$ and $X_{V,W}$ are self-adjoint, we conclude that $\tilde{X} = X_{V,W}$. ■

IV. IRREDUCIBILITY AND UNITARY EQUIVALENCE

(1) The next two propositions decide when a triple of operators $\{P, X_{V,W}, U\}$ defined in the preceding section is irreducible and when two such triples are unitarily equivalent. Here we shall say that the triple $\{P, X_{V,W}, U\}$ on $\mathcal{H}$ is *irreducible* if any bounded operator A on $\mathcal{H}$ satisfying

$$PA \supseteq AP, \quad X_{V,W}A \supseteq AX_{V,W}, \quad \text{and} \quad AU = UA \tag{14}$$

is a scalar multiple of the identity operator on $\mathcal{H}$.

Recall that the operator triple $\{P, X_{V,W}, U\}$ depends on the two families $\{\mu_1^{j,\pm}; j \in I_\pm\}$ of measures on the interval $[q,1)$ and on the two unitary operators $V,W : \mathfrak{H}_- \to \mathfrak{H}_+$. In order to formulate the corresponding conditions it is convenient to work with the Hilbert spaces $\mathfrak{K}_\pm = \oplus_{j \in I_\pm} L^2([q,1), \mu_1^{j,\pm})$ rather than with $\mathfrak{H}_\pm = \oplus_{j \in I_\pm} L^2([q,1), t^{-1}\mu_1^{j,\pm})$. Further, let $P_\pm$ denote the self-adjoint operator on $\mathfrak{K}_\pm$ which acts componentwise as the multiplication by the variable t. Clearly, V and W are bounded linear operators of $\mathfrak{K}_-$ to $\mathfrak{K}_+$ such that

$$V' := P_+^{1/2} V P_-^{-1/2} \quad \text{and} \quad W' := P_+^{1/2} W P_-^{-1/2} \tag{15}$$

are unitary.

Proposition 2: The triple $\{P, X_{V,W}, U\}$ as defined above is irreducible if and only if any bounded self-adjoint operators A_+ on $\mathfrak{K}_+$ and A_- on $\mathfrak{K}_-$ satisfying

$$A_+P_+ = P_+A_+, \quad A_-P_- = P_-A_-, \quad A_+V' = V'A_-, \quad A_+W' = W'A_- \tag{16}$$

or equivalently

$$A_+P_+=P_+A_+\,,\ \ A_-P_-=P_-A_-\,,\ \ A_+V=VA_-\,,\ \ A_+W=WA_- \tag{17}$$

are scalar multiples of the identity.

Proof: We only show that the above condition implies the irreducibility of the triple. The proof of the converse implication is easier and will be omitted. Suppose that A is a bounded operator on $\mathcal{H}$ satisfying (14). Since the set of such A is invariant under the involution, we can assume that A is self-adjoint. Let $E(\cdot)$ denote the spectral projections of P. Since $PA\supseteq AP$, the subspace $\mathfrak{K}_+=E([q,1))\mathcal{H}$ of $\mathcal{H}$ reduces A and the restriction A_+ of A to $\mathfrak{K}_+$ commutes with the restriction P_+ of P to $\mathfrak{K}_+$. Similarly, the restrictions $\tilde{A}_-$ of A and $\tilde{P}_-$ of P to the reducing subspace $E((-1,q])\mathcal{H}$ commute. Changing the variable from t to $-t$, the Hilbert space $E((-1,q])\mathcal{H}$ and the operator $\tilde{P}_-$ become $\mathfrak{K}_-$ and P_-, respectively, and the operator $\tilde{A}_-$ goes into an operator, say A_-, on $\mathfrak{K}_-$. Thus, $A_-P_-=P_-A_-$. From the assumptions $AU=UA$ and $X_{V,W}A\subseteq AX_{V,W}$ it follows easily that $(A\mathfrak{f})_e^\pm=A_\pm\mathfrak{f}_e^\pm$ and $(A\mathfrak{f})_o^\pm=A_\pm\mathfrak{f}_o^\pm$ for $\mathfrak{f}\in\mathcal{D}(X_{V,W})$. Since $A\mathfrak{f}\in\mathcal{D}(X_{V,W})$ has to satisfy the relation (8), we obtain $A_+V=VA_-$ and $A_+W=WA_-$. Therefore, by the above condition, $A_\pm=\lambda_\pm I$ for some $\lambda_\pm\in\mathbb{C}$. Since $A_+V=VA_-$ and $AU=UA$, it follows that $\lambda_+=\lambda_-$ and $A=\lambda_+\cdot I$ on $\mathcal{H}$. ■

Using similar operator-theoretic arguments it is not difficult to prove the following.

Proposition 3: Two triples $\{P,X_{V,W},U\}$ *and* $\{\tilde{P},X_{\tilde{V},\tilde{W}},\tilde{U}\}$ *are unitarily equivalent if and only if there are unitary operators* A_+ *of* $\mathfrak{K}_+$ *to* $\tilde{\mathfrak{K}}_+$ *and* A_- *of* $\mathfrak{K}_-$ *to* $\tilde{\mathfrak{K}}_-$ *such that*

$$A_+P_+=\tilde{P}_+A_+\,,\ \ A_-P_-=\tilde{P}_-A_-\,,\ \ A_+V=\tilde{V}A_-\quad\text{and}\quad A_+W=\tilde{W}A_-\,, \tag{18}$$

where the tilde refers to the corresponding operators and spaces for the triple $\{\tilde{P},X_{\tilde{V},\tilde{W}},\tilde{U}\}$.

(2) We shall illustrate the preceding by describing a few examples of irreducible representations. We begin with the simplest possible case.

Example 2: Suppose that the Hilbert spaces $\mathfrak{K}_+$ and $\mathfrak{K}_-$ are one-dimensional. Then the families of measure $\{\mu_i^{j,+};\in I_+\}$ and $\{\mu_1^{j,-};j\in I_-\}$ consist only of single Dirac measures δ_a and δ_b, respectively, where $a,b\in[q,1)$. Then the triples $\{P,X_{V,W},U\}$ are parametrized by complex numbers $V=V'=e^{i\varphi}$ and $W=W'=e^{i\psi},\varphi,\psi\in\mathbb{R}$. The self-adjoint extension $X_{V,W}$ is then characterized by the boundary condition (8), that is,

$$\mathfrak{f}_e^+ + \mathfrak{f}_o^+ = e^{i\varphi}(\mathfrak{f}_e^- + \mathfrak{f}_o^-),\quad \mathfrak{f}_e^+ - \mathfrak{f}_o^+ = e^{i\psi}(\mathfrak{f}_e^- - \mathfrak{f}_o^-).$$

Each such triple is irreducible because the condition in Proposition 2 is trivially fulfilled. Two triples with different numbers VW^{-1} are not unitarily equivalent. The case where $e^{i\varphi}=e^{i\psi}=1$ and $a=b$ has been treated in detail in Ref. 3.

Example 3: Let P_+ be a self-adjoint operator and Z a unitary operator on a Hilbert space $\mathfrak{K}_+$ such that the commutant $\{P_+,Z\}'$ is equal to $\mathbb{C}\cdot I$. Such operators exist on any separable Hilbert space.[10] Upon scaling we can assume that the spectrum of P_+ is contained in $[q,1)$. By the spectral representation theorem (Ref. 11, chap. X, 5), we can represent P_+ up to unitary equivalence as the multiplication operator by the independent variable t on some direct sum Hilbert space $\mathfrak{K}_+=\oplus_{j\in I_+}L^2([q,1);\mu_1^{j,+})$. Let $\{\mu_1^{j,-};j\in I\}$ be an arbitrary family of measures on $[q,1)$ such that $\dim\mathfrak{K}_+=\dim\mathfrak{K}_-$, where $\mathfrak{K}_-:=\oplus_{j\in I_-}L^2([q,1);\mu_1^{j,-})$. Let W' be a unitary operator from $\mathfrak{K}_-$ to $\mathfrak{K}_+$. We set $V':=ZW'$ and define V and W by (15). Then the triple $\{P,X_{V,W},U\}$ is irreducible.

Indeed, if A_+ and A_- be bounded self-adjoint operators satisfying (17), then we have $A_+Z=A_+V'W'^*=V'A_-W'^*=V'W'^*A_+=ZA_+$ and $A_+P_+=P_+A_+$, so that $A_+=\lambda\cdot I$ for some $\lambda\in\mathbb{C}$ and hence $A_-=V'^*A_+V'=\lambda\cdot I$. By Proposition 2, the triple is irreducible. ■

Example 4: For this example we assume that there exist numbers $a,b\in[q,1)$ such that $\mu_1^{j,+}=\delta_a$ and $\mu_1^{k,-}=\delta_b$ for all $j\in I_+$ and $k\in I_-$. We shall show that in this case an irreducible triple $\{P,X_{V,W},U\}$ can be only obtained if both index sets I_+ and I_- are singletons or equivalently if $\dim\mathfrak{K}_+=\dim\mathfrak{K}_-=1$. Indeed, otherwise we take a self-adjoint operator A_+ on $\mathfrak{K}_+$ such that

$A_+V'W'^* = V'W'^*A_+$ and $A_+ \notin \mathbb{C}\cdot I$ and set $A_- := V'^*A_+V'$. Then the conditions (16) are fulfilled, hence the triple is not irreducible. ■

Example 5: If the spectra of the operators P_+ on $\mathfrak{K}_+$ and P_- on $\mathfrak{K}_-$ are singletons, then we have seen in Example 4 that irreducible triples exist only in the trivial case where I_+ and I_- are singletons. We now show that this is no longer true if both spectra consist of two points. To be more precise, we shall consider the following situation: The index sets $I_\pm$ are disjoint unions of two countable infinite sets $I_\pm^1$ and $I_\pm^2$ and there are numbers $a_1, a_2, b_1, b_2 \in [q,1)$, $a_1 \neq a_2$, such that $\mu_1^{j,+} = \delta_{a_1}$ for $j \in I_+^1$, $\mu_1^{j,+} = \delta_{a_2}$ for $j \in I_+^2$, $\mu_1^{j,-} = \delta_{b_1}$ for $j \in I_-^1$, and $\mu_1^{j,-} = \delta_{b_2}$ for $j \in I_-^2$. By identifying $I_\pm^j$ with the natural numbers the Hilbert spaces $\mathfrak{K}_+$ and $\mathfrak{K}_-$ become the direct sum $l_2(\mathbb{N}) \oplus l_2(\mathbb{N})$ of two l_2-spaces. We choose a bounded operator T on $l_2(\mathbb{N})$ such that $\{T,T^*\}' = \mathbb{C}\cdot I$ and $I \leqslant 3T^*T \leqslant 2\cdot I$. It is well known (see Ref. 12, Anhang, §4) that the operator matrix

$$Z = \begin{pmatrix} T & \sqrt{I-TT^*} \\ -\sqrt{I-T^*T} & T^* \end{pmatrix}$$

defines a unitary operator Z on $\mathfrak{K}_+ = \mathfrak{K}_- = l_2(\mathbb{N}) \oplus l_2(\mathbb{N})$. Let W' be an arbitrary unitary operator on $\mathfrak{K}_+ = \mathfrak{K}_-$ and set $V' := ZW'$. Then the triple $(P, X_{V,W}, U)$ is irreducible.

Indeed, let A_+ and A_- be self-adjoint bounded operators on $\mathfrak{K}_+ = \mathfrak{K}_-$ satisfying (17). Since $a_1 \neq a_2$, the relation $A_+P_+ = P_+A_+$ implies that A_+ is given by a diagonal operator matrix

$$A_+ = \begin{pmatrix} B & 0 \\ 0 & C \end{pmatrix}.$$

From (17) we get $A_+Z = ZA_+$. Comparing the matrix entries of the first line yields $BT = TB$ and $B\sqrt{I-T^*T} = \sqrt{I-T^*T}C$. Since $B = B^*$, we have $BT^* = T^*B$. Therefore, B commutes with T and T^* and so with $\sqrt{I-T^*T}$ which in turn gives $\sqrt{I-T^*T}B = \sqrt{I-T^*T}C$. Because $\sqrt{I-T^*T}$ is invertible, we get $B = C$. Since $B \in \{T,T^*\}'$, we obtain $B = C = \lambda\cdot I$ for some $\lambda \in \mathbb{C}$. Thus, $A_+ = \lambda\cdot I$ and $A_- = V'^*A_+V' = \lambda\cdot I$, so that the triple is irreducible by Proposition 2. ■

V. A CHARACTERIZATION OF THE OPERATOR TRIPLES

Let $\{P, X_{V,W}, U\}$ be an operator triple as in Sec. II and let $\mathcal{D}_1$ be the set of all vectors $\mathfrak{f} = \mathfrak{f}_X + \mathfrak{f}^e + \mathfrak{f}^o \in \mathcal{D}(X_{V,W})$ with $\mathfrak{f}_X \in \mathcal{D}_o$, where $\mathcal{D}_o$ is as defined in Sec. II. Then $\mathcal{D}_1$ is a dense linear subspace of the Hilbert space $\mathcal{H}$ such that $\mathcal{D}_1$ is invariant under the operators P, $X_{V,W}$, and U and the restrictions of P and $X_{V,W}$ to $\mathcal{D}_1$ are essentially self-adjoint. Further, the three operators P, $X_{V,W}$, and U applied to vectors $\mathfrak{f} \in \mathcal{D}_1$ satisfy the relations (1) and (2). From the construction it is clear that the range $E([q,1))\mathcal{H} (\cong \mathfrak{K}_+)$ of the spectral projection $E([q,1))$ of the operator P is contained in $\mathcal{D}_1$. Our next proposition says that the operator triples $\{P, X_{V,W}, U\}$ can be characterized by some of the properties just mentioned.

Proposition 4: Let $\{P', X', U'\}$ be a triple of two self-adjoint operators P' and X' and a unitary operator U' on a Hilbert space $\mathcal{H}'$. Let $E(\cdot)$ denote the spectral measure of P'. Suppose that there exists a linear subspace $\mathcal{D}_1 \subseteq \mathcal{D}(P'X') \cap \mathcal{D}(X'P')$ of $\mathcal{H}$ such that

(i) $E([q,1))\mathcal{H} \subseteq \mathcal{D}_1$ *and* $E((-1,-q])\mathcal{H} \subseteq \mathcal{D}_1$.
(ii) *The operators P', X', U' satisfy the relations (1) and (2) for vectors in $\mathcal{D}_1$.*
(iii) *The restrictions $P' \lceil \mathcal{D}_1$ and $X' \lceil \mathcal{D}_1$ of P' and X' to $\mathcal{D}_1$ are essentially self-adjoint. Then $\{P', X', U'\}$ is unitarily equivalent to an operator triple $\{P, X_{V,W}, U\}$ defined in Sec. II.*

Sketch of proof: The restriction P_1' of P' to the invariant subspace $\mathcal{H}_1 := E([q,1))\tilde{\mathcal{H}}$ is obviously a bounded self-adjoint operator on the Hilbert space $\mathcal{H}_1$ with spectrum contained in the interval $[q,1]$. By the spectral representation theorem[11], there is a family $\{\mu_1^{j,+}; j \in I_+\}$ of finite positive Borel measures on $[q, 1]$ and a unitary isomorphism of $\mathcal{H}_1$ on $\mathfrak{K}_+ := \oplus_j L^2([q, 1], \mu_1^{j,+})$

such that P_1' is unitarily equivalent to the operator P_1 on $\mathfrak{K}_+$ which acts componentwise as the multiplication by the variable t. Since 1 is not an eigenvalue of P_1' by construction, we have $\mu_1^{j,+}(\{1\})=0$ for all $j\in I_+$. For simplicity let us identify $\mathcal{H}_1$ with $\mathfrak{K}_+$ and P_1' with P_1.
