The set Γ contains unbounded operators such as J. In particular, the operators Z_τ in the proofs of the chaos theorems are not bounded. It may happen that the domain of $A\in\Gamma$ is a proper subset of K^2 and that the domain of $A(t)$ depends on t. In that case the intersection $\cap_{t\geqslant 0}\mathrm{Dom}[A(t)]$ could be very small, so that there would be few vectors f allowing $(A(t)f,g)$ to be followed over the entire interval $0\leqslant t<\infty$. On the other hand, the operator $[A(t)]^{1/2}$ can be applied to every $f\in K^2$ at all times $t\geqslant 0$. Hence the notation of Eq. (6.1) can be used at all positive times, expressing the matrix elements of $A(t)\in\Gamma$ in the form

$$\langle f|A(t)|g\rangle = ([A(t)]^{1/2}f, [A(t)]^{1/2}g).$$

VIII. CHAOTIC OBSERVABLES

The previous sections provide the framework to show that the time evolution of a large class of observables in quantum mechanics exhibits chaos in the spirit of Devaney's definition of chaos in classical dynamical systems.[3] Among the three components of chaos listed in Sec. I, properties (T) and (P) are strictly topological. According to Devaney[3] a map $F: X \to X$ on a topological space X is topologically transitive if for any pair of open sets $V,\ W \in X$ there exists $n>0$ such that $F^{(n)}(V) \cap W \neq 0$. We replace points $x \in X$ by operators $A \in X$. The iterated map $x \to F^{(n)}(x)$ is replaced by the time evolution $A \to A(t)$. Our results on topological transitivity and periodic points are as follows.

Theorem T: (Topological transitivity) Given $A, B \in X$, there is a net $\{Z_\tau\} \in X(\tau \geqslant 0)$ such that

$$\lim_{\tau \to \infty} Z_\tau = A, \quad \lim_{\tau \to \infty} Z_\tau(\tau) = B.$$

The interpretation is that the time evolution takes Z_τ in a neighborhood V of A into $Z_\tau(\tau)$ in a neighborhood W of B.

Theorem P: (Existence of a dense set of periodic points) Given $A \in X$, there is a net $\{Z_\tau\} \in X(\tau \geqslant 0)$ such that

$$\lim_{\tau \to \infty} Z_\tau = A,$$

$$Z_\tau(t + n\tau) = Z_\tau(t), \quad \text{if } t \geqslant 0,\ n = 0,1,2,\ldots.$$

This theorem states that there is an operator $Z_\tau \in X$ with semiperiodic $Z_\tau(t)$ in any neighborhood of any $A \in X$.

According to Devaney[3] a map $F: X \to X$ on a metric space X has sensitive dependence on initial conditions if there exists $\delta > 0$ such that, for any $x \in X$ and any neighborhood V of x, there exists $y \in V$ and $n \geqslant 0$ such that $|F^{(n)}(x) - F^{(n)}(y)| > \delta$. Given $x, y \in X$ and the map $F^{(n)}$, the distance $|F^{(n)}(x) - F^{(n)}(y)|$ is determined by the metric that defines the topology of Devaney's X. Typical examples allow scaling, so that the actual magnitude of δ is not important. In our transcription δ may be any positive number. Because our X is not a metric space, we have to introduce a distance between operators as an additional quantity. Since one would like the distance between $A \in X$ and $B \in X$ to be large when the difference between expectation values is large, regardless of the wave function $f \in K^2$, we define

$$|A - B| := \inf_{f \in K^2} \|f\|^{-2} |\|A^{1/2} f\|^2 - \|B^{1/2} f\|^2|.$$

Notice that $|A - B|$ does not satisfy the triangle inequality, and hence does not determine a metric.

Theorem S: (Sensitive dependence on initial conditions). Given $A \in X$ and $\delta > 0$, there is a net $\{Z_{\delta\tau}\} \in X(\tau \geqslant 0)$ such that

$$\lim_{\tau \to \infty} Z_{\delta\tau} = A,$$

$$|\|A^{1/2}(t) f\|^2 - \|Z_{\delta\tau}^{1/2}(t) f\|^2| > \delta \|f\|^2 \quad \text{if } t \geqslant \tau, \text{ for all } f \in K^2.$$

Assuming that τ and δ are sufficiently large, Theorem S says that the expectation values of $A(t)$ and $Z_{\delta\tau}(t)$ are very close at time $t = 0$, yet very different at times $t \geqslant \tau$.

According to Devaney's definition, a map $F: X \to X$ is chaotic on X if F has sensitive dependence on initial conditions, is topologically transitive, and has a dense set of periodic points. Due to Theorems S, T, and P, the time evolution of operators $A(t) \in X$ is chaotic in the sense of Devaney.

Among Devaney's conditions for chaos, sensitive dependence is probably best known, suggesting that it is the most important concept. In actual fact, if the map F is continuous and X is a metric space, the two topological conditions imply sensitive dependence.[22] Alternative definitions of chaos have been proposed by several authors. As shown in a recent review with a comparison table,[23] various definitions are not equivalent. On the other hand, all definitions are meant to capture the same set of essential features, and these have been retained in Theorems S, T, and P.

The wording of Theorems S, T, and P is the same as in Ref. 2, only the space X and the time evolution $U(t)$ are different. The proofs in Ref. 2 construct operators $\tilde{Z}_\tau$ with suitable properties, then invoke the map γ to find operators Z_τ that satisfy the theorems. The sole relation used in the construction of $\tilde{Z}_\tau$ is the counterpart in Ref. 2 of Eqs. (7.6) and (7.7) for the time evolution. Because this counterpart is the same as the current equations, the proofs in Ref. 2 may be copied unchanged. To illustrate how the theorems work, we quote the respective operators $\tilde{Z}_\tau$. Further details are in Ref. 2.

The proof of Theorem S uses

$$\tilde{Z}_{\delta\tau} := \tilde{A} + (1+\tau)^{-1} + \delta Q(\tau).$$

The term $(1+\tau)^{-1}$ guarantees that the form $\langle \tilde{Z}_{\delta\tau} f, g\rangle$ on ΠL^2 with form domain K^2 is closed for every δ; τ. When τ is sufficiently large and f is fixed, $|||Q(\tau)f|||$ is small so that $\langle \tilde{Z}_{\delta\tau} f, g\rangle$ is close to $\langle \tilde{A} f, g\rangle$. At time $t \geqslant \tau$ we have to examine $U^\dagger(t)\tilde{Z}_{\delta\tau}U(t)$. By Eqs. (7.1) and (7.6)

$$U^\dagger(t)Q(\tau)U(t) = \begin{cases} Q(\tau - t) & \text{if } 0 \leqslant t \leqslant \tau \\ I & \text{if } 0 \leqslant \tau \leqslant t, \end{cases}$$

where I is the identity operator. Hence

$$|\langle \tilde{A}(t)f, f\rangle - \langle \tilde{Z}_{\delta\tau}(t)f, f\rangle| > \delta |||f|||^2 \geqslant \delta |||f|||^2$$

$$\text{if } t \geqslant \tau, \text{ for all } f \in K^2.$$

Theorem S now follows easily. Moreover, we see that the error term $\delta\langle U^\dagger(t)Q(\tau)U(t)f, f\rangle$ is a nondecreasing function of $t \geqslant 0$ which reaches its maximum $\delta |||f|||^2$ at time $t = \tau$.

The proof of Theorem T uses

$$\tilde{Z}_\tau := [1 - Q(\tau)]\tilde{A}[1 - Q(\tau)] + U(\tau)\tilde{B}U^\dagger(\tau) + (1+\tau)^{-1}.$$

Since $|||U^\dagger(\tau)f||| = |||Q(\tau)f|||$, the matrix element $\langle \tilde{Z}_\tau f, g\rangle$ is close to $\langle \tilde{A} f, g\rangle$ if τ is large. On the other hand, at time $t = \tau$ the operator $\tilde{A}$ acts on $[1 - Q(\tau)]U(\tau) = 0$ while $\tilde{B}$ acts on $U^\dagger(\tau)U(\tau) = I$. As a result $\langle \tilde{Z}_\tau(\tau) f, g\rangle$ is close to $\langle \tilde{B} f, g\rangle$.

The proof of Theorem P uses

$$\tilde{Z}_\tau = \sum_{n=0}^{\infty} U(n\tau)[1 - Q(\tau)]\tilde{A}[1 - Q(\tau)]U^\dagger(n\tau) + (1+\tau)^{-1}.$$

Write this in the form

$$\tilde{Z}_\tau = \sum_{n=0}^{\infty} \tilde{Z}_{\tau n} + (1+\tau)^{-1}.$$

The sum converges in the strong operator topology. Since

$$Q(\tau)U(n\tau) = U(n\tau) \quad \text{if } n \geqslant 1,$$

the terms $\tilde{Z}_{\tau n}$ with $n \geqslant 1$ are equal to $Q(\tau)\tilde{Z}_{\tau n}Q(\tau)$, and hence tend strongly to 0 if $\tau \to \infty$. For any fixed f and sufficiently large τ the norm $\|\|\tilde{Z}_\tau f - \tilde{Z}_{\tau 0} f\|\|$ is close to 0. Hence $\langle \tilde{Z}_\tau f, g\rangle$ is close to $\langle \tilde{A} f, g\rangle$.

Now examine $\Sigma_n U^\dagger(\tau)\tilde{Z}_{\tau n}U(\tau)$. The term with $n=0$ contains a factor $[1-Q(\tau)]U(\tau)$. Since this vanishes $\tilde{Z}_{\tau 0}(\tau)=0$. In the term with $n=1$ the operator $\tilde{A}$ acts on

$$[1-Q(\tau)]U^\dagger(\tau)U(\tau)=1-Q(\tau).$$

Hence $\tilde{Z}_{\tau 1}(\tau)=\tilde{Z}_{\tau 0}$. By a similar reasoning $\tilde{Z}_{\tau n}(\tau)=\tilde{Z}_{\tau,n-1}$ $(n=1,2,...)$. Also $U^\dagger(\tau)(1+\tau)^{-1}U(\tau)=(1+\tau)^{-1}$. It follows that $\tilde{Z}_\tau(\tau)=\tilde{Z}_\tau$. The argument can be repeated to show that $\tilde{Z}_\tau(t+m\tau)=\tilde{Z}_\tau(t)$ if $t \geqslant 0$ and $m=0,1,2,...$. Hence the operator $\tilde{Z}_\tau(t)$ is semiperiodic.

IX. NOTES AND REMARKS

The chaos concept in this paper was developed with the idea in mind that *K*-maps and *K*-flows are classical dynamical systems with chaotic properties that are well understood. The proofs of Theorems S, T, and P are inspired by the symbolic dynamics used in chaos proofs for Bernoulli systems and other *K*-maps in which the dynamics can be represented by a shift on sequences of symbols.[24–28] Wave functions in this paper are assumed to belong to the space K^2 because the time evolution $\{U(t)|0 \leqslant t < \infty\}$ on K^2 is unitarily equivalent to a semigroup of shift operators, as shown by Eq. (7.5). The semigroup on K^2 is probably our best substitute for a *K*-flow. By a result due to Sinai[29] the nonequilibrium part of a *K*-flow can be represented in terms of Hilbert spaces N and $L^2(\mathbb{R})\otimes N$ and a unitary group $\{V(t)|-\infty<t<\infty\}$ such that $\hat{g}(s) \in L^2(\mathbb{R})\otimes N$ transforms according to

$$(V(t)\hat{g})(s)=\hat{g}(s-t). \tag{9.1}$$

The same canonical form is used extensively in the Lax–Phillips scattering theory for the wave equation.[30]

The group $\{V(t)\}$ in Eq. (9.1) has self-adjoint generator $-id/ds$ with spectrum $(-\infty, \infty)$. We want to contrast this with the semigroup $\{U(t)\}$ on K^2 generated by H. To this end, we apply the reasoning developed in Ref. 2 to the resolvent $(H-\lambda)^{-1}$. By Eq. (5.6)

$$\langle (H-\lambda)^{-1}f, g\rangle = \sum_\alpha \langle (k_\alpha^2 + E_\alpha - \lambda)^{-1} f_\alpha, g_\alpha\rangle. \tag{9.2}$$

A function $(k_\alpha^2+E_\alpha-\lambda)^{-1}f_\alpha$ belongs to K_α^2 if and only if it has a square-integrable analytic continuation taking the k_α^2-variable into the lower half-plane. It follows that each operator $(k_\alpha^2 + E_\alpha - \lambda)^{-1}$ on the right-hand side in Eq. (9.2) is bounded if and only if $\mathrm{Im}\,\lambda > 0$. Hence $(H-\lambda)^{-1}$ is bounded if and only if $\mathrm{Im}\,\lambda > 0$. The spectrum of H on K^2 is the half-plane $\mathrm{Im}\,\lambda \leqslant 0$.

The foregoing implies that H cannot represent the energy on K^2. If there is an energy operator $\tilde{H}$ on K^2, it must have the same spectrum as H on ΠL^2. To identify $\tilde{H}$, we examine the form

$$q[f,g] := (Hf,g) = \langle (1+J^2)^{-1}Hf, g\rangle$$

as a quadratic form on K^2 with form domain $\mathrm{Dom}\,(q)$ consisting of all $f \in K^2$ with the property that $Hf \in \Pi L^2$. Since $\mathrm{Dom}\,(q)$ contains all $f \in K^2$ that can be written as $\Sigma_\alpha \Omega_\alpha \psi_\alpha f_\alpha$ with functions $f_\alpha(k_\alpha, \omega) \in K_\alpha^2$ such that $k_\alpha^2 f_\alpha(k_\alpha, \omega) \in L^2(\mathbb{R}^\nu)$, properties of the spaces K_α^2 can be used to show that $\mathrm{Dom}\,(q)$ is dense in K^2. Now consider the operator $(1+J^2)^{-1}H$ on K^2 with domain $\mathrm{Dom}\,(q)$. This operator is symmetric and bounded below, due to properties of H on ΠL^2. Hence the form q has a well-defined closure $\overline{q}$ (Ref. 20, see Chap. VI, Sec. 1). The closed form $\overline{q}$ determines a self-adjoint operator $\tilde{H}$ on K^2 satisfying

$$\overline{q}[f,g]=\langle \tilde{H}f,g\rangle$$

for every $f\in \mathrm{Dom}\,(\tilde{H})\subset \mathrm{Dom}\,(\overline{q})$ and $g\in \mathrm{Dom}\,(\overline{q})$. The operator $\tilde{H}$ is the Friedrichs extension of $(1+J^2)^{-1}H$ (Ref. 20, see Chap. VI, Sec. 2). Since $\tilde{H}$ is an extension, $\mathrm{Dom}\,(\tilde{H})\supset \mathrm{Dom}\,(q)$. For $f,g\in \mathrm{Dom}\,(q)$,

$$(Hf,g)=\langle \tilde{H}f,g\rangle.$$

It is a significant property of the space K^2 that it gives rise to a time evolution whose generator H differs from the energy operator $\tilde{H}$.

If $A\in X$ is a bounded operator on ΠL^2, then $\tilde{A}$ defined by Eq. (6.3) equals $(1+J^2)^{-1}A$. By the same token, if $\tilde{A}\in\tilde{X}$ is the identity operator on K^2, then $A^{1/2}$ equals $(1+J^2)^{1/2}$, so that $A\in X$ equals $1+J^2$. It follows that the terms $(1+\tau)^{-1}$ in the operators $\tilde{Z}_\tau$ make unbounded contributions to the corresponding Z_τ on ΠL^2. The terms in question are included to guarantee that the form $\langle \tilde{Z}_\tau f,g\rangle$ on ΠL^2 with form domain K^2 is closed. It appears that we cannot avoid unbounded operators on ΠL^2. To take advantage of the special properties of the space K^2, we have to allow operators such as J whose domains are no larger than K^2. Such operators are not bounded on ΠL^2.

X. OTHER CHAOS CONCEPTS

Since operators in X have to be positive and are not necessarily bounded on ΠL^2, the elements of X do not give rise to an algebra. Hence the set of operators in this paper differs substantially from the operator algebras used by several authors to define noncommutative K-systems.[31–34] In an algebraic K-system[31,32,34] a sequence of operator-subalgebras replaces the σ-subalgebras of measurable sets that determine a classical K-system. An entropic K-system[33] is characterized in terms of its quantum dynamical entropy.[35] While these definitions are not equivalent,[36] all authors report mixing behavior characteristic of chaos.[31,32,37–42] In cases where spectral properties were investigated[31,32,39,41] there was agreement with Eq. (9.1).

Examples include a quantum version of the Arnold cat map.[39–42] Several statistical-mechanics models were shown[43] to be entropic K-systems. Because classically the Kolmogorov–Sinai entropy being positive indicates chaos, it was proposed[44] that quantum chaos is related to a positive quantum dynamical entropy. It was found, however,[44] that the quantum dynamical entropy vanishes in the case of a system of finitely many particles described by a density matrix with unitary time evolution. Such a system is therefore not chaotic from the dynamical-entropy point of view.

In typical papers on quantum chaos the question is not whether a system is chaotic in the sense of a mathematical definition. Starting from a chaotic classical system, one constructs a quantum counterpart and looks for characteristic features that would be different if the underlying classical system were integrable.[45–49] The distribution of energy-level spacings is an example. Computer calculations[50,51] show that the energy levels of a classically chaotic quantum billiard agree with a level-spacing distribution that is well established in nuclear physics[52] and in that context can be derived from random matrix theory.[53] If the billiard is classically integrable, a Poisson distribution applies.[54] That the classically chaotic case agrees with the predictions of random matrix theory has been explained[55] with the help of semiclassical path integrals that relate periodic orbits of a classical system to spectral properties of its quantum counterpart.[46] A more recent argument[56] arrives at the same conclusion on the basis of a supersymmetric field theory.[57]

Since a particle on a quantum billiard is confined to a bounded region in space, its energy spectrum is purely discrete. To investigate continuous spectra, several authors have developed scattering theories for classically chaotic systems in unbounded regions.[58–62] In this context random matrix theory was shown to apply to statistical properties of scattering amplitudes. These investigations are of practical interest because billiards with external leads are used as models for mesoscopic semiconductor devices.[49,63]

Since there is strong evidence that random matrix theory applies to nuclear physics[52] it might apply as well to a system of N distinguishable particles. One would like to know whether the results of this paper can be related to quantum chaos as studied in the literature.

XI. DENSITY OPERATORS

Whether chaos is related to irreversible behavior is a question with a long history. Boltzmann[64] implicitly invoked the assumption of molecular chaos in the 1872 proof of his H-theorem. Since K-systems are both chaotic and reversible, it is clear that chaos is not sufficient for irreversible behavior, yet many authors believe that chaos at the microscopic level promotes macroscopic irreversibility. Essentially, however, this is an open problem.

It is shown in the following sections that states in the space K^2 give rise to irreversible behavior that can be characterized in terms of an increasing entropy. Although chaos as such does not play a role in the proof, there is a connection in that the space K^2 provides the framework to describe chaotic as well as irreversible properties of scattering systems.

Let ρ be a positive operator in the trace class on ΠL^2 with time evolution $\rho(t)$ defined by Eq. (1.1). Since the entropy $S[\rho(t)]$ does not depend on t, we want to replace $\rho(t)$ by the density operator $\sigma(t)$ defined by Eq. (1.5) and show that $S[\sigma(t)]$ increases. With this objective in mind, we first examine the set of all positive operators R in the trace class on ΠL^2. Any R in this set acts on $f \in \Pi L^2$ according to

$$Rf = \sum_n \mu_n \phi_n (f, \phi_n),$$

where $\{\phi_n\}$ is an orthonormal set on ΠL^2 and the μ_n are positive numbers satisfying $\mathrm{Tr}\, R = \Sigma_n \mu_n < \infty$.

Given the set $\{\phi_n\}$ on ΠL^2, the set $\{(1+J^2)^{-1/2}\phi_n\}$ is orthonormal on K^2. Hence $\tilde{\rho}$ acting on $f \in K^2$ as

$$\tilde{\rho} f = \sum_n \mu_n (1+J^2)^{-1/2} \phi_n \langle f, (1+J^2)^{-1/2} \phi_n \rangle \tag{11.1}$$

belongs to the trace class on K^2, satisfying

$$\langle \mathrm{Tr}\, \tilde{\rho} \rangle = \mathrm{Tr}\, R. \tag{11.2}$$

Given R and $\tilde{\rho}$, we now consider ρ acting on $f \in \Pi L^2$ as

$$\rho f = \sum_n \mu_n (1+J^2)^{-1/2} \phi_n (f, [1+J^2]^{-1/2} \phi_n). \tag{11.3}$$

This operator satisfies

$$\rho = (1+J^2)^{-1/2} R (1+J^2)^{-1/2}. \tag{11.4}$$

It can be shown as in Ref. 1 that a density operator ρ on ΠL^2 is of the form (11.4) with some positive operator R in the trace class if and only if ρ and $J\rho$ belong to the trace class and ρJ and $J\rho J$ have closures in the trace class. The operator R is the closure of $(1+J^2)^{1/2}\rho(1+J^2)^{1/2}$, and

$$\mathrm{Tr}\, R = \mathrm{Tr}\, \rho + \mathrm{Tr}\, J\rho J. \tag{11.5}$$

The relation (1.4) follows from Eqs. (11.2) and (11.5). Henceforth we simply refer to $J\rho J$ when we actually mean its closure, and similarly for operators such as ρJ and $\rho(1+J^2)^{1/2}$.

If A is an operator in Γ, then $A^{1/2}(1+J^2)^{-1/2}$ is bounded. Assuming that ρ is of the form (11.4) we examine the operator

$$T := A^{1/2}(1+J^2)^{-1/2} R [A^{1/2}(1+J^2)^{-1/2}]^*.$$

Since R belongs to the trace class, so does T. When applied to an element of K^2, the operator T acts as $A^{1/2}\rho A^{1/2}$. Hence $A^{1/2}\rho A^{1/2}$ is closable with closure T. In the following we simply write $A^{1/2}\rho A^{1/2}$ when the closure is meant.

If ρ is normalized so that $\mathrm{Tr}\,\rho = 1$, then $\mathrm{Tr}(A^{1/2}\rho A^{1/2})$ is the expectation value of the observable A in the state ρ. To show this, we assume that ρ has orthonormal eigenvectors r_n with eigenvalues λ_n. If ρ is of the form (11.4) each r_n belongs to K^2. Hence for any $f \in \Pi L^2$,

$$A^{1/2}\rho A^{1/2} f = \sum_n \lambda_n A^{1/2} r_n (f, A^{1/2} r_n).$$

It follows easily that

$$\mathrm{Tr}(A^{1/2}\rho A^{1/2}) = \sum_n \lambda_n (A^{1/2} r_n, A^{1/2} r_n).$$

The eigenvalue λ_n is the probability that the system is in the state r_n. The expectation value of A in this state is $(A^{1/2} r_n, A^{1/2} r_n)$. Hence $\mathrm{Tr}(A^{1/2}\rho A^{1/2})$ can be interpreted as the expectation value of A in the mixed state ρ.

Let $\{\chi_m\}$ be a complete orthonormal set on ΠL^2. If we expand ρ as in Eq. (11.3), the expectation value of A takes the form

$$\begin{aligned}
\mathrm{Tr}(A^{1/2}\rho A^{1/2}) &= \sum_m (A^{1/2}\rho A^{1/2}\chi_m, \chi_m) \\
&= \sum_m \sum_n \mu_n |(A^{1/2}[1+J^2]^{-1/2}\phi_n, \chi_m)|^2 \\
&= \sum_n \mu_n \|A^{1/2}(1+J^2)^{-1/2}\phi_n\|^2 \\
&= \sum_n \mu_n \|\,|(1+J^2)^{-1/2} A^{1/2}(1+J^2)^{-1/2}\phi_n|\,\|^2 \\
&= \sum_n \mu_n \langle \tilde{A}(1+J^2)^{-1/2}\phi_n, (1+J^2)^{-1/2}\phi_n\rangle = \langle \mathrm{Tr}\,\tilde{A}\tilde{\rho}\rangle.
\end{aligned}$$

This generalizes Eq. (6.4) and indicates that $\tilde{\rho}$ is the density operator on K^2 that matches ρ of the form (11.4) on ΠL^2.

Our problem is that the entropy $S[\rho(t)]$ does not depend on t if ρ is a density operator on ΠL^2. The time evolution on K^2 replaces $(1+J^2)^{-1/2}\phi_n$ by $U(t)(1+J^2)^{-1/2}\phi_n$. As a result $\tilde{\rho}$ is replaced by $U(t)\tilde{\rho}U^\dagger(t)$. Since $U(t)$ is an isometry on K^2, the entropy $-\langle \mathrm{Tr}\tilde{\rho}(t)\ln\tilde{\rho}(t)\rangle$ does not depend on $t \geqslant 0$ either. In Sec. XII we therefore take a partial trace of $\tilde{\rho}$ as in Eq. (1.5). This defines the density operator $\sigma(t)$ with increasing entropy $S[\sigma(t)]$.

XII. THE DENSITY OPERATOR σ

If ρ is of the form (11.4) and $t > 0$, there is an operator $R(t)$ in the trace class on ΠL^2 such that $\rho(t)$ satisfies Eq. (11.4) with $R(t)$ instead of R. Moreover,

$$J\rho(t)J = \exp(iHt) W(t) J\rho J W^*(t) \exp(-iHt). \tag{12.1}$$

These properties follow from Eq. (5.4). A formal proof with attention to all domain questions can be conducted as in Ref. 1. Since $W(t)$ is unitary, $\mathrm{Tr}\, J\rho(t)J$ does not depend on t. Hence $\mathrm{Tr}\,\sigma(t)$ does not depend on t.

While $\mathrm{Tr}\,\rho^2(t)$ does not depend on t either, $\mathrm{Tr}\,\sigma^2(t)$ is a decreasing function of $t \geqslant 0$,

$$\mathrm{Tr}\,\sigma^2(s) > \mathrm{Tr}\,\sigma^2(t) \quad \text{if} \quad 0 \leqslant s < t. \tag{12.2}$$

To show this, we deduce from Eq. (5.5) that

$$\Omega_\alpha \Omega_\alpha^* J^{1/2} \exp(-iHt) f = W^{1/2}(t)\Omega_\alpha \exp(-k_\alpha^2 t) J_\alpha^{1/2} \Omega_\alpha^* f$$

for every $f \in K^2$. This relation can be used to prove that

$$\Omega_\alpha \Omega_\alpha^* J^{1/2} \rho(t) J^{1/2} \Omega_\beta \Omega_\beta^* = W^{1/2}(t)\Omega_\alpha \exp(-k_\alpha^2 t) T_{\alpha\beta} \exp(-k_\beta^2 t) \Omega_\beta^* [W^{1/2}(t)]^*,$$

where we have used the abbreviation

$$T_{\alpha\beta} := J_\alpha^{1/2} \Omega_\alpha^* \rho \Omega_\beta J_\beta^{1/2}.$$

As in Ref. 1,

$$\mathrm{Tr}\,\rho(t)J\rho(t)J = \mathrm{Tr}[J^{1/2}\rho(t)J^{1/2}][J^{1/2}\rho(t)J^{1/2}]. \tag{12.3}$$

Let us define

$$\Pi_n := \sum_{\alpha \leqslant n} \Omega_\alpha \Omega_\alpha^*. \tag{12.4}$$

Even if the number of channels is not finite, Π_n tends strongly to the identity operator on ΠL^2 as $n \to \infty$. Hence it follows from known properties of the trace class (Ref. 65, Chap III, Theorem 6.3) that

$$\mathrm{Tr}\,\Pi_n [J^{1/2}\rho(t)J^{1/2}]\Pi_n [J^{1/2}\rho(t)J^{1/2}]\Pi_n \tag{12.5}$$

tends to the right-hand side of Eq. (12.3) when $n \to \infty$. We want to prove that $\mathrm{Tr}\,\rho(t)J\rho(t)J$ is a decreasing function of t. For this it is sufficient to show that

$$\mathrm{Tr}\,\Omega_\alpha \exp(-k_\alpha^2 t) T_{\alpha\beta} \exp(-k_\beta^2 t) \Omega_\beta^* \Omega_\beta \exp(-k_\beta^2 t) T_{\beta\alpha} \exp(-k_\alpha^2 t) \Omega_\alpha^* \tag{12.6}$$

is decreasing for every fixed α, β.

The projection operator $\Omega_\beta^* \Omega_\beta$ commutes with $\exp(-k_\beta^2 t)$ and with the operator $J_\beta^{1/2}$ included in $T_{\beta\alpha}$. Hence it can be absorbed in $T_{\beta\alpha}$. With a similar procedure for $\Omega_\alpha^* \Omega_\alpha$, it follows that expression (12.6) is equal to

$$\mathrm{Tr} \exp(-k_\alpha^2 t) T_{\alpha\beta} \exp(-2k_\beta^2 t) T_{\beta\alpha} \exp(-k_\alpha^2 t).$$

In an obvious notation, we denote this quantity by $\mathrm{Tr}\,\Theta_{\alpha\beta\alpha}(t)$. It is equal to $\mathrm{Tr}\,\Theta_{\beta\alpha\beta}(t)$.

Now suppose $0 \leqslant s < t$ and examine

$$\begin{aligned}
&\mathrm{Tr}\,\Theta_{\alpha\beta\alpha}(s) + \mathrm{Tr}\,\Theta_{\beta\alpha\beta}(s) - \mathrm{Tr}\,\Theta_{\alpha\beta\alpha}(t) - \mathrm{Tr}\,\Theta_{\beta\alpha\beta}(t) \\
&\quad = \mathrm{Tr} \exp(-k_\alpha^2 s) T_{\alpha\beta} [\exp(-2k_\beta^2 s) - \exp(-2k_\beta^2 t)] T_{\beta\alpha} \exp(-k_\alpha^2 s) \\
&\qquad + \mathrm{Tr} \exp(-k_\beta^2 s) T_{\beta\alpha} [\exp(-2k_\alpha^2 s) - \exp(-2k_\alpha^2 t)] T_{\alpha\beta} \exp(-k_\beta^2 s) \\
&\qquad + \mathrm{Tr} \exp(-k_\alpha^2 t) T_{\alpha\beta} [\exp(-2k_\beta^2 s) - \exp(-2k_\beta^2 t)] T_{\beta\alpha} \exp(-k_\alpha^2 t) \\
&\qquad + \mathrm{Tr} \exp(-k_\beta^2 t) T_{\beta\alpha} [\exp(-2k_\alpha^2 s) - \exp(-2k_\alpha^2 t)] T_{\alpha\beta} \exp(-k_\beta^2 t).
\end{aligned} \tag{12.7}$$

If $s<t$, the operators $\exp(-2k_\beta^2 s)-\exp(-2k_\beta^2 t)$ and $\exp(-2k_\alpha^2 s)-\exp(-2k_\alpha^2 t)$ are strictly positive. Since $T_{\beta\alpha}=T_{\alpha\beta}^*$, expression (12.7) vanishes if and only if $T_{\alpha\beta}=0$. If $T_{\alpha\beta}\neq 0$, the traces in Eq. (12.7) are positive. Repeating this reasoning for all α, β, we see that expression (12.5) is a decreasing function of t unless $T_{\alpha\beta}=0$ for all $\alpha,\beta\leqslant n$. Since any positive ρ gives rise to some nonvanishing operators $T_{\alpha\beta}$, it follows with Eq. (12.3) that

$$\operatorname{Tr}\rho(s)J\rho(s)J>\operatorname{Tr}\rho(t)J\rho(t)J \quad \text{if} \quad 0\leqslant s<t,$$

whenever ρ is of the form (11.4) with a positive trace-class operator R.

By Eq. (12.1) $\operatorname{Tr}[J\rho(t)J][J\rho(t)J]$ does not depend on t. Hence

$$\operatorname{Tr}\sigma^2(t)=\operatorname{Tr}\rho^2+\operatorname{Tr}\rho(t)J\rho(t)J+\operatorname{Tr}J\rho(t)J\rho(t)+\operatorname{Tr}(J\rho J)(J\rho J).$$

Two terms on the right do not depend on t while the remaining two are decreasing. Hence $\operatorname{Tr}\sigma^2(t)$ is decreasing, as we wanted to show.

Let $v(t)$ be a positive operator satisfying $\operatorname{Tr}v(t)=1$. The quantities

$$S_\alpha[v(t)]:=(1-\alpha)^{-1}\ln\operatorname{Tr}[v(t)]^\alpha \quad (\alpha>0;\alpha\neq 1)$$

are called Rényi entropies or α-entropies. [Ref. 66, Definition 2.2.2, Remark 2.2.5; Ref. 67, Eq. (7.14).] Taking $\alpha=2$ and $v(t)=\sigma(t)/\operatorname{Tr}\sigma(t)$, we have an increasing Rényi entropy $S_2[\sigma(t)/\operatorname{Tr}\sigma(t)]$.

XIII. THE ENTROPY

If T is any positive compact operator, we denote by $\gamma_n(T)$ the nth largest eigenvalue of T, counting multiplicity. If ρ and $J\rho J$ belong to the trace class

$$\sum_n \gamma_n(\rho)<\infty, \quad \sum_n \gamma_n(J\rho J)<\infty. \tag{13.1}$$

With a view to the entropy, we define

$$s(\gamma):=\begin{cases}-\gamma\ln\gamma & \text{if} \quad \gamma>0\\ 0 & \text{if} \quad \gamma=0\end{cases}$$

and assume

$$\begin{aligned}S(\rho)&:=\sum_n s[\gamma_n(\rho)]<\infty,\\ S(J\rho J)&:=\sum_n s[\gamma_n(J\rho J)]<\infty.\end{aligned} \tag{13.2}$$

Due to Eq. (5.4) and the fact that $\exp(iHt)$ and $W(t)$ are unitary, $S[\rho(t)]$ and $S[J\rho(t)J]$ do not depend on t.

By general entropy inequalities[68]

$$S[\sigma(t)]\leqslant S[\rho(t)]+S[J\rho(t)J] \tag{13.3}$$

with equality if and only if

$$\rho(t)J\rho(t)J=0, \quad J\rho(t)J\rho(t)=0.$$

The sum $S(\rho)+S(J\rho J)$ is finite by Eq. (13.2). It is an upper bound for $S[\sigma(t)]$ by Eq. (13.3). We claim that

$$\lim_{t\to\infty} S[\sigma(t)] = S(\rho) + S(J\rho J). \tag{13.4}$$

Typically, $\rho J\rho J \neq 0$, hence $S[\sigma(t)]$ has to increase, approaching its least upper bound as $t\to\infty$.

The relations (13.3) and (13.4) are compatible due to the fact that $\rho(t)J\rho(t)J$ and its adjoint $J\rho(t)J\rho(t)$ tend to 0 in the trace norm as $t\to\infty$. To show this, we denote the trace norm of an operator T in the trace class by $\|T\|_1$. By Eq. (5.4)

$$\begin{aligned}\|J\rho(t)J[\Pi_n\rho(t)-\rho(t)]\|_1 &= \|\exp(iHt)W(t)J\rho JW^*(t)\exp(-2iHt)(\Pi_n\rho-\rho)\exp(iHt)\|_1 \\ &\leqslant \|J\rho J\|\|\Pi_n\rho-\rho\|_1,\end{aligned}$$

where Π_n is the projection defined by Eq. (12.4). Since the right-hand side tends to 0 as $n\to\infty$, uniformly in t, it is sufficient to show that $J\rho(t)J\Omega_\alpha\Omega_\alpha^*\rho(t)$ tends to 0 in the trace norm as $t\to\infty$, for every fixed α. Since $J^{1/2}$ commutes with $\Omega_\alpha\Omega_\alpha^*$, it follows with Eq. (5.5) that

$$\begin{aligned}J\rho(t)J\Omega_\alpha\Omega_\alpha^*\rho(t) &= J\rho(t)J^{1/2}\Omega_\alpha\Omega_\alpha^*J^{1/2}\rho(t) \\ &= \exp(iHt)W(t)J\rho\Omega_\alpha J_\alpha^{1/2}\exp(-2k_\alpha^2 t)J_\alpha^{1/2}\Omega_\alpha^*\rho\exp(iHt) \\ &= \exp(iHt)W(t)J\rho J^{1/2}\Omega_\alpha\exp(-2k_\alpha^2 t)\Omega_\alpha^*J^{1/2}\rho\exp(iHt).\end{aligned} \tag{13.5}$$

The operator $\exp(-2k_\alpha^2 t)$ tends strongly to 0 as $t\to\infty$. Since $\Omega_\alpha^*J^{1/2}\rho$ belongs to the trace class and $J\rho J^{1/2}\Omega_\alpha$ is bounded, the expression on the right in Eq. (13.5) tends to 0 in the trace norm, as we wanted to show.

The proof of Eq. (13.4) rests on a fundamental concept of physics. To explain this, we have to go back to the dilation operator D_ν of Sec. IV. Let $P_{\nu+}$ and $P_{\nu-}$ be the spectral projections onto the subspaces of $L^2(\mathbb{R}^\nu)$ in which D_ν is positive and negative, respectively. The important equations are[69]

$$\begin{aligned}\lim_{t\to\infty}\|P_{\nu-}\exp(-ik^2t)f\| &= 0, \\ \lim_{t\to-\infty}\|P_{\nu+}\exp(-ik^2t)f\| &= 0\end{aligned} \tag{13.6}$$

for every $f(\mathbf{k})\in L^2(\mathbb{R}^\nu)$. If $f\in K_\nu^2$, it follows with Eq. (4.5) that

$$\lim_{t\to\infty}\|P_{\nu+}J_\nu\exp(-ik^2t)f\| = 0.$$

Hence $\exp(-ik^2t)f$ and $J_\nu\exp(-ik^2t)f$ become mutually orthogonal as $t\to\infty$.

The dilation operator is the quantum analog of $\mathbf{x}\cdot\mathbf{k}$, where $\mathbf{x}$ represents the position relative to the center of mass and $\mathbf{k}$ is proportional to the momentum of a multiparticle system. One expects that $\mathbf{x}\cdot\mathbf{k}$ was negative in the distant past and will be positive in the remote future. This is confirmed by Eq. (13.6). It is the irreversible aspect of the time evolution that causes $S[\sigma(t)]$ to tend to its least upper bound.

The generalization to a scattering system goes as follows. Depending on the channel being considered, D_ν is denoted by D_α, giving rise to the generalized dilation operator

$$D := \sum_\alpha \Omega_\alpha D_\alpha \Omega_\alpha^*.$$

For any $f\in K^2$, it is easy to show that $Jf = \exp(-\pi D/2)f$. The projection operators $P_{\nu\pm}$ are denoted by $P_{\alpha\pm}$. They determine orthogonal projections

$$P_{\pm} := \sum_{\alpha} \Omega_{\alpha} P_{\alpha\pm} \Omega_{\alpha}^{*}$$

satisfying $P_{+} + P_{-} = \Sigma_{\alpha} \Omega_{\alpha} \Omega_{\alpha}^{*} = \Pi$. By Eq. (5.1) and the intertwining relation (3.5), any $f \in \Pi L^2$ satisfies

$$\lim_{t\to\infty} \| P_{-} \exp(-iHt) f \| = 0,$$
$$\lim_{t\to-\infty} \| P_{+} \exp(-iHt) f \| = 0. \tag{13.7}$$

If $f \in K^2$, if follows from Eq. (5.4) that

$$\lim_{t\to\infty} \| P_{+} J \exp(-iHt) f \| = 0. \tag{13.8}$$

Given the interpretation of the dilation operators D_{α}, Eq. (13.7) expresses the fact that clusters in a scattering experiment moved in the direction of the center of mass in the distant past and will move away from the center of mass in the remote future.

The above-mentioned relations are the key ingredients in proving Eq. (13.4). Since the proof is the same as in Ref. 1, we sketch the general idea, referring to Ref. 1 for details.

The first step defines

$$\pi_{+}(t) := P_{+} \rho(t) P_{+}, \quad \pi_{-}(t) := P_{-} J \rho(t) J P_{-}$$

and shows that

$$\lim_{t\to\infty} \| \pi_{+}(t) + \pi_{-}(t) - \sigma(t) \|_1 = 0.$$

It follows that

$$\lim_{t\to\infty} \gamma_k[\pi_{+}(t) + \pi_{-}(t)] = \lim_{t\to\infty} \gamma_k[\sigma(t)].$$

By a separate argument

$$\lim_{t\to\infty} \gamma_k[\pi_{+}(t) + \pi_{-}(t)] = \lambda_k,$$

where λ_k ($k = 1,2,...$) is the kth largest number, counting multiplicity, in the set consisting of all nonvanishing eigenvalues $\gamma_n(\rho)$ and $\gamma_m(J\rho J)$ ($m,n = 1,2,...$).

We want to compare the entropies

$$S(\rho) + S(J\rho J) = \sum_{k} s(\lambda_k) = \sum_{k} \lim_{t\to\infty} s\{\gamma_k[\sigma(t)]\} \tag{13.9}$$

and

$$\lim_{t\to\infty} S[\sigma(t)] = \lim_{t\to\infty} \sum_{k} s\{\gamma_k[\sigma(t)]\}. \tag{13.10}$$

To prove that $S[\sigma(t)]$ tends to $S(\rho) + S(J\rho J)$, it is sufficient to show that the limit and the summation in Eq. (13.10) may be interchanged. In this context, it can be shown that

$$0 \leqslant s\{\gamma_{k+1}[\sigma(t)]\} \leqslant s(2\lambda_k)$$

whenever $2\lambda_k \leqslant 1/e$. Since $\Sigma_k s(2\lambda_k)$ converges absolutely by Eqs. (13.1) and (13.2), the right-hand sides of Eqs. (13.9) and (13.10) are equal by the dominated convergence theorem. This completes the proof of Eq. (13.4). The result is summarized in the following theorem.

Theorem E: (Entropy increase) If ρ is of the form (11.4), $\sigma(t)$ and $S[\sigma(t)]$ are defined by Eqs. (1.5) and (1.2), and Eq. (13.2) is satisfied, the entropy $S[\sigma(t)]$ tends to its maximum possible value $S(\rho)+S(J\rho J)$ as $t \to \infty$.

XIV. RECONSTRUCTING THE DENSITY OPERATOR ρ

With the help of the Mellin transform, it is possible to recover ρ when σ is known. For the reconstruction procedure to be meaningful, σ has to be of the form $\rho + J\rho J$ with a positive trace-class operator ρ satisfying Eq. (11.4). It was shown in Ref. 1 that not all positive operators in the trace class satisfy the conditions on σ. In particular, there are examples of positive τ in the trace class that would yield nonpositive ρ. This paper is not meant for such operators τ. They cannot occur as operators σ.

Given ρ, let us first examine $\Omega_\alpha^* \rho \Omega_\beta$. Since ρ belongs to the trace class on ΠL^2, both ρ and $\Omega_\alpha^* \rho \Omega_\beta$ are integral operators. In the notation of Eq. (5.1), the integral kernel of $\Omega_\alpha^* \rho \Omega_\beta$ is of the form

$$\psi_\alpha(\mathbf{k}'_\alpha)\rho_{\alpha\beta}(\mathbf{k}_\alpha;\mathbf{l}_\beta)\overline{\psi}_\beta(\mathbf{l}'_\beta).$$

It is convenient to write $\Omega_\alpha^* \rho \Omega_\beta = \psi_\alpha \rho_{\alpha\beta} \overline{\psi}_\beta$. Expressing $\mathbf{k}_\alpha, \mathbf{l}_\beta$ in terms of spherical polar coordinates replaces $\rho_{\alpha\beta}(\mathbf{k}_\alpha;\mathbf{l}_\beta)$ by $\rho_{\alpha\beta}(k_\alpha,\omega_\alpha;l_\beta,\omega'_\beta)$. The Mellin transform M_α acting on k_α commutes with $\psi_\alpha(\mathbf{k}'_\alpha)$. Henceforth we omit the variable $\mathbf{k}'_\alpha$. Thus

$$M_\alpha \Omega_\alpha^* \rho \Omega_\beta M_\beta^{-1} = \psi_\alpha M_\alpha \rho_{\alpha\beta} M_\beta^{-1} \overline{\psi}_\beta = \psi_\alpha \rho^\#_{\alpha\beta} \overline{\psi}_\beta$$

has integral kernel

$$\psi_\alpha \rho^\#_{\alpha\beta}(u,\omega_\alpha;v,\omega^*_\beta)\overline{\psi}_\beta. \tag{14.1}$$

By Eq. (4.2) $M_\alpha J_\alpha M_\alpha^{-1}$ acts as multiplication by $\exp(-\pi u/2)$. Hence $M_\alpha J_\alpha \Omega_\alpha^* \rho \Omega_\beta J_\beta M_\beta^{-1}$ has integral kernel

$$\psi_\alpha \exp(-\pi u/2)\rho^\#_{\alpha\beta}(u,\omega_\alpha;v,\omega'_\beta)\exp(-\pi v/2)\overline{\psi}_\beta. \tag{14.2}$$

Adding expressions (14.1) and (14.2) shows that $M_\alpha \Omega_\alpha^* \sigma \Omega_\beta M_\beta^{-1}$ has integral kernel

$$\psi_\alpha\{1+\exp[-\pi(u+v)/2]\}\rho^\#_{\alpha\beta}(u,\omega_\alpha;v,\omega'_\beta)\overline{\psi}_\beta. \tag{14.3}$$

Conversely, suppose σ is known. Construct the integral operator $M_\alpha \Omega_\alpha^* \sigma \Omega_\beta M_\beta^{-1}$. By the reasoning for ρ, the integral kernel is of the form

$$\psi_\alpha \sigma^\#_{\alpha\beta}(u,\omega_\alpha;v,\omega'_\beta)\overline{\psi}_\beta.$$

This quantity must be equal to expression (14.3). Hence

$$\rho^\#_{\alpha\beta}(u,\omega_\alpha;v,\omega'_\beta) = \{1+\exp[-\pi(u+v)/2]\}^{-1}\sigma^\#_{\alpha\beta}(u,\omega_\alpha;v,\omega'_\beta), \tag{14.4}$$

showing that there is a bounded transformation taking $\sigma^\#_{\alpha\beta}$ into $\rho^\#_{\alpha\beta}$.

Once $\rho^{\#}_{\alpha\beta}$ is known, the inverse Mellin transform determines $M_\alpha^{-1}\rho^{\#}_{\alpha\beta}M_\beta=\rho_{\alpha\beta}$, hence $\Omega^*_\alpha\rho\Omega_\beta$. Denoting $\Sigma_{\alpha\leqslant n}\,\Omega_\alpha\Omega^*_\alpha$ by Π_n as in Eq. (12.4), we can find $\Pi_n\rho\Pi_n$. This quantity tends to ρ in the trace norm as $n\to\infty$ (Ref. 65, Chap. III, Theorem 6.3). Hence, even if the number of channels is infinite, σ completely determines ρ.

If ρ is of the form (11.4) then $\rho(t)$ is of this form for all $t\geqslant 0$. Since neither the transformation taking ρ into σ, nor the Mellin transform depends on t, the reasoning that proved Eq. (14.4) can be repeated for every $t>0$. Summarizing, we have a linear transformation $L:\sigma(t)=L\rho(t)$ whose domain consists of all operators ρ of the form (11.4). This operator is invertible. Defined on the range of L, the inverse is a linear operator $L^{-1}:\rho(t)=L^{-1}\sigma(t)$.

XV. OBSERVABLES IN THE σ REPRESENTATION

If T is a bounded self-adjoint operator, its expectation value is $\mathrm{Tr}\,T\rho(t)$. In this section we construct a set of operators $(TL^{-1})_{\beta\alpha}$ with the property that

$$\lim_{n\to\infty}\sum_{\alpha,\beta\leqslant n}\mathrm{Tr}\,\Omega_\beta(TL^{-1})_{\beta\alpha}\Omega^*_\alpha\sigma(t)=\mathrm{Tr}\,T\rho(t), \tag{15.1}$$

provided $\sigma(t)$ is of the form (1.5). This result means that $\sigma(t)$ can be used as a density operator to calculate expectation values of bounded observables.

We first consider

$$\begin{aligned}&(M_\beta\Omega^*_\beta T\Omega_\alpha M_\alpha^{-1})(M_\alpha\Omega^*_\alpha\rho\Omega_\beta M_\beta^{-1})\\&\quad=(M_\beta\Omega^*_\beta T\Omega_\alpha M_\alpha^{-1})(\psi_\alpha\rho^{\#}_{\alpha\beta}\overline{\psi}_\beta)\\&\quad=(M_\beta\Omega^*_\beta T\Omega_\alpha M_\alpha^{-1})\{1+\exp[-\pi(u+v)/2]\}^{-1}\psi_\alpha\sigma^{\#}_{\alpha\beta}\overline{gw_\beta},\end{aligned} \tag{15.2}$$

where u and v are variables in the integral kernel of $\sigma^{\#}_{\alpha\beta}$, as in Eq. (14.4). Now we define

$$(TL^{-1})^{\#}_{\beta\alpha}:=(M_\beta\Omega^*_\beta T\Omega_\alpha M_\alpha^{-1})\{1+\exp[-\pi(u+v)/2]\}^{-1}. \tag{15.3}$$

This is an operator that acts on trace-class operators with kernels $\psi_\alpha\sigma^{\#}_{\alpha\beta}(u,\omega_\alpha;v,\omega'_\beta)\overline{\psi}_\beta$. It cannot act on elements of ΠL^2. We can define

$$(TL^{-1})_{\beta\alpha}:=M_\beta^{-1}(TL^{-1})^{\#}_{\beta\alpha}M_\alpha. \tag{15.4}$$

This operator acts on trace-class operators

$$M_\alpha^{-1}\psi_\alpha\sigma^{\#}_{\alpha\beta}\overline{\psi}_\beta M_\beta=\psi_\alpha\sigma_{\alpha\beta}\overline{\psi}_\beta=\Omega^*_\alpha\sigma\Omega_\beta.$$

Due to Eqs. (15.2)–(15.4)

$$(TL^{-1})_{\beta\alpha}\Omega^*_\alpha\sigma\Omega_\beta=\Omega^*_\beta T\Omega_\alpha\Omega^*_\alpha\rho\Omega_\beta.$$

Hence

$$\mathrm{Tr}\,\Omega_\beta(TL^{-1})_{\beta\alpha}\Omega^*_\alpha\sigma=\mathrm{Tr}\,\Omega_\beta\Omega^*_\beta T\Omega_\alpha\Omega^*_\alpha\rho.$$

Summing over $\alpha,\beta\leqslant n$ on the right gives $\mathrm{Tr}\,\Pi_nT\Pi_n\rho$. In terms of the trace norm

$$\|\Pi_nT\Pi_n\rho-T\rho\|_1=\|\Pi_nT\Pi_n\rho-\Pi_nT\rho+\Pi_nT\rho-T\rho\|_1\leqslant\|T\|\|\Pi_n\rho-\rho\|_1+\|\Pi_nT\rho-T\rho\|_1.$$

Since Π_n tends strongly to the identity on ΠL^2 as $n\to\infty$, each term on the right-hand side tends to 0 as $n\to\infty$. Hence

$$\lim_{n\to\infty}|\mathrm{Tr}\,\Pi_n T\Pi_n\rho-\mathrm{Tr}\,T\rho|\leqslant\lim_{n\to\infty}\|\Pi_n T\Pi_n\rho-T\rho\|_1=0.$$

This proves Eq. (15.1) at time $t=0$. The proof can be repeated at all later times.

The foregoing can be generalized to unbounded operators $A\in\Gamma$ by taking advantage of the fact that $A^{1/2}(1+J^2)^{-1/2}$ is bounded. Instead of $\mathrm{Tr}\,T\rho$ we consider $\mathrm{Tr}(A^{1/2}\rho A^{1/2})$. If ρ is of the form (11.4) it is not difficult to prove that

$$\sum_{\alpha,\beta\leqslant n}\mathrm{Tr}\,A^{1/2}(1+J^2)^{-1/2}\Omega_\alpha\Omega_\alpha^*R\Omega_\beta\Omega_\beta^*[A^{1/2}(1+J^2)^{-1/2}]^* \tag{15.5}$$

tends to $\mathrm{Tr}(A^{1/2}\rho A^{1/2})$ as $n\to\infty$. We want to express this quantity in terms of σ instead of R or ρ.

It is easy to see that

$$(1+J^2)^{-1/2}\Omega_\alpha\Omega_\alpha^*=\Omega_\alpha\Omega_\alpha^*(1+J^2)^{-1/2}=\Omega_\alpha(1+J_\alpha^2)^{-1/2}\Omega_\alpha^*.$$

Hence define

$$(AL^{-1})_\alpha^{1/2}:=A^{1/2}\Omega_\alpha M_\alpha^{-1}\{1+\exp[-\pi(u+v)/2]\}^{-1/2}M_\alpha.$$

This operator is not bounded, but the range of $\Omega_\alpha^*\sigma\Omega_\beta$ is in its domain. The closure of

$$(AL^{-1})_\alpha^{1/2}\Omega_\alpha^*\sigma\Omega_\beta[(AL^{-1})_\beta^{1/2}]^*$$

is equal to the operator in expression (15.5). Taking the trace and summing over α, β gives $\mathrm{Tr}(A^{1/2}\rho A^{1/2})$ as desired.

XVI. THE PRIGOGINE PROGRAM

It has long been advocated by Prigogine and co-workers[6,7] that irreversible behavior originates at the microscopic level. Their strategy for proving this calls for a transformation Λ that breaks the time-reversal symmetry in the sense that $\Lambda\rho(t)$ is defined only for $t\geqslant 0$ and evolves in time according to a semigroup. In quantum mechanics the quantity

$$\Omega(t):=\mathrm{Tr}\,\rho^*(t)\Lambda^*\Lambda\rho(t)\quad(t\geqslant 0) \tag{16.1}$$

should be a decreasing function of t. The classical counterpart of $\Omega(t)$ is obtained if the trace in Eq. (16.1) is replaced by integration over the phase space.

It was predicted early on that any Λ-operator in quantum mechanics would have to act on operators and could not act on the elements of the Hilbert space on which ρ operates.[70] The authors referred to a superoperator. They also observed that one would have to introduce a time evolution that is not generated by the Hamiltonian.[70] Our transformation $\rho(t)\to L\rho(t)=\sigma(t)$ agrees with the above-mentioned requirements. The operator $\sigma(t)$ is defined for $t\geqslant 0$ only. Due to Eq. (1.1) for $\rho(t)$ and Eq. (12.1) for $J\rho(t)J$, the time evolution of $\sigma(t)$ is described by a semigroup. To define σ, we have to start from an operator ρ on ΠL^2, an element $f\in\Pi L^2$ will not do. This is the superoperator aspect. According to Eq. (12.2) $\mathrm{Tr}\,\sigma^2(t)$ is a monotone decreasing function of t, as is $\Omega(t)$ in Eq. (16.1). Since $\mathrm{Tr}\,\sigma(t)$ is the same as $\langle\mathrm{Tr}\,\tilde{\rho}(t)\rangle$, the Prigogine observation about the time evolution agrees with the discussion in Sec. IX, which shows that the time evolution of $\tilde{\rho}(t)$ on K^2 is not generated by the Hamiltonian $\tilde{H}$ on K^2.

In the early years of the Prigogine program, Λ-operators were constructed explicitly for several classical dynamical systems, including the baker map[71] and other Bernoulli systems,[72] as well as K-flows.[73] The focus has since shifted to large nonintegrable Hamiltonian systems with many resonances. Since this part of the program is not directly related to the present paper, we

merely refer to recent papers on classical[74] and quantum systems.[75] A brief overview of earlier work by Prigogine and co-workers can be found in Ref. 1. There are no previous results on Λ-operators for N-particle quantum systems.

The classical dynamical systems for which Λ-operators were constructed have a compact phase space and a uniform equilibrium density $\rho_0=1$. The norm $\|\Lambda\rho(t)-1\|$ is a monotone decreasing function of t which tends to 0 as $t\to\infty$, for all initial densities $\rho(0)\neq 1$. This is necessary and sufficient in order that the entropy associated with $\Lambda\rho(t)$ is a nondecreasing function of t that tends to its maximal value of 0 as $t\to\infty$ (Ref. 4, Ref. 5, Corollary 7.8).

If a classical dynamical system allows an invertible Λ-operator, it has to be mixing.[76] If Λ is a projection and $\|\Lambda\rho(t)-1\|$ is monotone decreasing to 0, it is necessary[77,78] and sufficient[79] that the underlying invertible system is a K-system.

The inverse problem of finding the K-system when $\Lambda\rho(t)$ is known was investigated in recent papers.[80–82] With a slight change of notation, the authors considered measure preserving Markov semigroups $\{M_t|0\leqslant t<\infty\}$ satisfying $\|M_t\rho-1\|\to 0$ as $t\to\infty$, with the understanding that $M_t\Lambda\rho=\Lambda\rho(t)$ in our earlier notation. Their question was whether the semigroup $\{M_t\}$ can be lifted to an invertible time evolution. Assuming that Λ was a projection[80] they showed that the semigroup $\{M_t\}$ is the Frobenius–Perron semigroup of an exact dynamical system. Let this be $\{S_t\}$ with phase space Y. By a result due to Rohlin[83] the system $\{S_t\}$ is a factor of a K-system $\{K_t\}$ with phase space X. This means that there is a transformation $F:X\to Y$ such that $S_t\circ F=F\circ K_t$. The Rohlin theory provides a natural extension mechanism by which the K-system $\{K_t\}$ was constructed explicitly.[80]

Since the Λ-operators referred to previously[71–73] are invertible, the assumption that Λ is a projection does not cover all possibilities. With more general methods than used in Ref. 80 it was shown[81,82] that any measure preserving Markov semigroup can arise as a projection of a K-system, be it that the projection is not necessarily the Λ-operator that was used to find the Markov semigroup in the first place.

The prevalence of K-systems in the foregoing suggest that a Λ-operator for a classical dynamical system is most likely to exist when the time evolution can be represented by a group of shift operators $\{V(t)|-\infty<t<\infty\}$ as in Eq. (9.1). In quantum mechanics the semigroup $\{U(t)|0\leqslant t<\infty\}$ is our best analog of $\{V(t)\}$. Although the Rohlin theory does not apply to this situation, it suggests the follow point of view.

Given ρ and $\tilde{\rho}$ satisfying Eqs. (11.3) and (11.1), and $f,g\in K^2$,

$$\langle\tilde{\rho}f,g\rangle=(\rho f,g)+(\rho J^2 f,g)+(J\rho f,Jg)+(J\rho J^2 f,Jg).$$

To express this equation in a different form, we define the two-component vector $\tilde{f}$ with components $\tilde{f}_0:=f$, $\tilde{f}_1:=Jf$, and inner product

$$\sum_{i=0,1}(\tilde{f}_i,\tilde{g}_i)=\langle f,g\rangle.$$

Next, we define the 2×2 matrix $\tilde{\rho}$ with elements

$$\tilde{\rho}_{00}:=\rho,\quad \tilde{\rho}_{01}:=\rho J,$$

$$\tilde{\rho}_{10}:=J\rho,\quad \tilde{\rho}_{11}:=J\rho J.$$

It follows that

$$\sum_{i,j}(\tilde{\rho}_{ij}\tilde{f}_j,\tilde{g}_i)=\langle\tilde{\rho}f,g\rangle.$$

Now we take the trace of the 2×2 matrix $\tilde{\rho}$ and let this operation be the transformation F,

$$F\rho := \sum_{i=0,1} \tilde{\rho}_{ii} = \sigma.$$

Hence F is the operator that was denoted by L before. The time evolution takes ρ into $\rho(t)$ and $\tilde{\rho}$ into $\tilde{\rho}(t)$. This replaces the Rohlin transformation K_t. Instead of $F \circ K_t$ we consider $\rho \to \rho(t) \to \sigma(t)$. Alternatively, we first take the step $\rho \to \sigma$. The time evolution $\sigma \to \sigma(t)$ replaces S_t. Instead of $S_t \circ F$ we find $\rho \to \sigma \to \sigma(t)$, producing the same net result as $\rho \to \rho(t) \to \sigma(t)$. In this sense, replacing $\rho \to \rho(t)$ by $\sigma \to \sigma(t)$ is like taking a factor of a classical dynamical system.

The idea to introduce $\sigma(t)$ came from publications by Mackey (Ref. 4, Ref. 5, Chap. 9) in which he pointed out that taking a factor of a classical dynamical system with constant entropy may give rise to an entropy that increases. Quoting the Rohlin theorem,[83] Mackey referred to papers on Λ-operators[71,79] as an illustration. If Λ is a projection, it is an example of a transformation F that yields a factor with increasing entropy. In Mackey's terminology, a factor is a specific type of trace. This suggested taking the sum of the diagonal elements of the matrix $\tilde{\rho}$. Since the transformation $\rho(t) \to \sigma(t)$ is invertible, it is not a projection, yet it does have the property of leading to an increasing entropy $S[\sigma(t)]$.

(Received 1 July 1999; accepted for publication 22 November 1999)

We decompose the Hilbert space of wave functions into two subspaces, and assign to a given observable two effective representatives that act in the model space. The first serves to determine some of the eigenvalues of the full observable, while the second serves to determine its matrix elements, in any basis in one of the subspaces, in terms of quantities pertaining to the model space. We also show that if the Hamiltonian of a physical system possesses symmetries then these symmetries continue to hold for its effective representatives of the first type. Maximum information about the system can be obtained in terms of two sets of effective representatives. The first set of representatives is complete. Other observables that do not commute with all members of the complete set have only one type of representative. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1286034]

I. INTRODUCTION

Effective operators are often used in nuclear, atomic, and molecular physics. The general scheme aims to construct from the Hamiltonian of the system, acting on the Hilbert space of wave functions, an operator that acts on a low-dimensional space, so that the eigenvalues of the latter operator are also eigenvalues of the full Hamiltonian of the given system.[1–9] The low-dimensional space we have mentioned is called a model space and the operator acting on it to produce some of the eigenvalues of the full Hamiltonian is called an effective Hamiltonian, or an effective representative of the Hamiltonian. The latter requirement does not determine an effective representative uniquely. A general class of effective representatives was obtained by Suzuki[10] who also delineated forms according to the role of an arbitrary parameter, the starting energy, in the iterative method of solution,[4] or according to their Hermiticity. Hermitian forms have been introduced or adopted by many researchers.[10–17] A standard non-Hermitian form[2,18,19] is relatively simple, and is commonly used for implementing the scheme of effective representatives.

Our present work, which is concerned with the effective representation of any observable in the standard non-Hermitian scheme, has the following objectives:

(1) To establish the equivalence between the decoupling condition on the transformed observable and a corresponding condition on its transformed eigenfunctions.
(2) To show that the decoupling equation always has solutions and to specify the maximum number of inequivalent solutions.
(3) Starting from a complete set of observables associated with the physical system, we construct a complete set of effective representatives, and prove accordingly that the symmetries of the Hamiltonian are carried over to the effective representatives.
(4) Two effective representatives can be constructed associated with every observable. The first representative corresponds to the standard non-Hermitian form and gives some of the eigenvalues of the original observable. The second representative is Hermitian and has the property that the matrix elements of the original observable, in any basis of the subspace that is mapped onto the model space, can be calculated in terms of this representative and the projected basis in the model space.

II. THE MODEL SPACE

The truncated Hilbert space of square integrable functions associated with the system, denoted by H_N, consists of all N-columns with complex entries. H_N is just the unitary space of complex numbers C^N through the isomorphism $\psi \in H_N \leftrightarrow \psi^t \in C^N$, where (t) denotes the transpose. The standard basis in H_N will be denoted by $e_i (i=1,...,N)$, so that

$$e_1=(1,0,....,0)^t, e_2=(0,1,....,0)^t, \ldots\ldots\ldots, e_N=(0,....,0,1)^t. \tag{1}$$

Let K be a distinct subset of d elements of the set $\{1,2,...,N\}$. The subspace generated by the subset of basis elements $\{e_k : k \in K\}$ will be denoted by Π_K, and will be called a model space. The projection on Π_K will be denoted by P_K, whereas Q_K will denote the projection on the orthogonal complement $\Pi_K^{\perp} = H_N \ominus \Pi_K$. It follows that $P_K + Q_K = I$, $P_K Q_K = Q_K P_K = 0$. If it is desired, one may rearrange the order of the basis elements (1) so that the vectors $e_i (i \in K)$ are placed first. We shall assume that such reordering is done whenever it is necessary, and drop the index K, if no ambiguity arises. The symbol P accordingly, will denote a projection on some model space Π. The reordering operation is particularly useful when we have to represent vectors and operators in matrix form.

Let S be an operator in H_N such that

$$S = QSP. \tag{2}$$

It follows that $S^2 = 0$, and hence $e^{\pm S} = 1 \pm S$. Equation (2) implies also that

$$S = \begin{pmatrix} 0_d & 0 \\ s & 0 \end{pmatrix}, \tag{3}$$

where 0_d is the nil $d \times d$ matrix. Consider the transformation

$$e^{-S} : H_N \to H_N, \quad \psi \to \tilde{\psi} = (1-S)\psi. \tag{4}$$

Setting $\psi = \binom{\alpha}{\beta}$ where $\alpha^t \in C^d$, we write

$$\tilde{\psi} \equiv \begin{pmatrix} \tilde{\alpha} \\ \tilde{\beta} \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ -s & 1 \end{pmatrix} \begin{pmatrix} \alpha \\ \beta \end{pmatrix} = \begin{pmatrix} \alpha \\ \beta - s\alpha \end{pmatrix}. \tag{5}$$

It is apparent that the mapping e^{-S} is determined by S given by (3), which in turn is determined by $s : \Pi \to \Pi^{\perp}$.

Through an obvious isomorphism we may overlook Π as being a subspace of H_N and consider it as a space on its own right. Hence, and whenever it is convenient, we may set $P\psi = \alpha$, $P\tilde{\psi} = \tilde{\alpha}$, and thus consider $P\psi, P\tilde{\psi}$ as d-vectors instead of being N-vectors with vanishing components in $\Pi^{\perp}$. A similar statement is applicable to $\Pi^{\perp}$ and to the vectors $Q\psi, Q\tilde{\psi}$, and hence we may set $Q\psi = \beta$, $Q\tilde{\psi} = \tilde{\beta}$. It is evident from (5) that if $\alpha = 0$ then $\psi = \tilde{\psi}$, and hence every point in the invariant subspace $\{\binom{0}{\beta} : \beta^t \in C^{N-d}\}$ is a fixed point of the transformation e^{-S}.

Let $\Psi = \{\psi_i \in H_N : i = 1,...,d\}$ be a linearly independent set of vectors. Hence there exists at least one subspace Π_K in which the set of projections of these vectors is linearly independent. This last statement is equivalent to say that the rank of the matrix $[\langle e_j | \psi_i \rangle]$, $(i=1,...,d; j=1,...,N)$ is d. The symbol $\langle | \rangle$ designates the inner product.

We shall choose the matrix S such that

(i) $Q\tilde{\psi}_i = 0, \quad (i=1,...,d)$;

(ii) The set of vectors $P\Psi = \{P\psi_i : i=1,...,d\}$, where P is the projection corresponding to $\{1,2,...,d\}$, is linearly independent.

Requirement (ii) can always be satisfied through reordering the basis if necessary. By (5), requirement (i) implies $s\alpha_i-\beta_i=0 (i=1,...,d)$, or

$$sP\psi_i-Q\psi_i=0 \quad (i=1,...,d). \tag{6}$$

We write (6) collectively as a matrix equation $s[P\Psi]-[Q\Psi]=0$, in which $[P\Psi]=[P\psi_1 \vdots ..... \vdots P\psi_d]$, $[Q\Psi]=[Q\psi_1 \vdots ..... \vdots Q\psi_d]$. As its columns are linearly independent the matrix $[P\Psi]$ is invertible, and hence

$$s=[Q\psi][P\Psi]^{-1}. \tag{7}$$

Therefore requirements (i) and (ii) yield Eq. (7). It is easy to see that Eq. (7), which embodies in it that the matrix $[P\Psi]$ is invertible, is in fact equivalent to conditions (i) and (ii).

With s so-chosen, the matrix S given by (3) has the property: e^{-S} projects every vector of the d-dimensional space $\mathrm{Lin}\,\Psi$, generated by the set of vectors $\Psi=\{\psi_1,\ldots,\psi_d\}$, onto the model space $\mathrm{Lin}\{\alpha_1,\ldots,\alpha_d\}\equiv\Pi$. This follows immediately from requirement (i) and linearity of e^{-S}. In other words, an arbitrary vector

$$\begin{pmatrix} \alpha \\ s\alpha \end{pmatrix} \in \mathrm{Lin}\,\psi$$

is mapped by e^{-S} to

$$\begin{pmatrix} \alpha \\ 0 \end{pmatrix} \in \Pi.$$

The operator e^{-S} is not a projection operator as implied by the mathematical definition of a projection operator. The word ''project'' however is used here in a geometrical sense to describe an operation in which every vector of a certain subspace (visualized as hyperplane) is mapped to a vector that has the same first d-components, whereas its remaining components are zeros (visualized as a vector in a coordinate hyperplane). Also if $\phi\notin\mathrm{Lin}\,\Psi$, then its image $\tilde{\phi}$ is not in the model space. The proof of the last fact relies on the regularity of e^{-S}, which implies that the image of the independent set $\{\psi_1,.....,\psi_d,\phi\}$ namely $\{\alpha_1,.....,\alpha_d,\tilde{\phi}\}$ is linearly independent, and hence $\phi\notin\mathrm{Lin}\{\alpha_1,.....,\alpha_d\}=\Pi$. The vector $\tilde{\phi}$ therefore has at least one nonvanishing component outside the space Π.

The operator e^{-S}, with s given by (7), as projects the subspace $\mathrm{Lin}\,\Psi$ orthogonally on Π, is thus determined solely by $\mathrm{Lin}\,\Psi$ and Π, and is independent of the particular choice of a set of d-independent vectors in $\mathrm{Lin}\,\Psi$. Indeed if $\Psi'=\{\psi_1',...,\psi_d'\}$ is another set of independent vectors in $\mathrm{Lin}\,\Psi$, then

$$\psi_i'=\sum_{j=1}^{d} c_{ji}\psi_j \quad (i=1,...,d), \tag{8}$$

where c_{ji} are constants. Denoting the matrix whose elements are c_{ji} $(i,j=1,...,d)$ by C, and the matrices whose columns are ψ_i and ψ_i' by $[\Psi]$ and $[\Psi']$, respectively, we write the last relation as $[\Psi']=[\Psi]C$. Equivalently we have $[P\Psi']=[P\Psi]C$ and $[Q\Psi']=[Q\Psi]C$. Substituting from these equations for $[P\Psi]$ and $[Q\Psi]$ in (7) we get $s=[Q\Psi'][P\Psi']^{-1}$, which proves our assertion.

We finally note that as e^{-S} is invertible, the inverse image of every vector $\alpha\in\Pi$, which also is identifiable with $\binom{\alpha}{0}$, is retrievable as $\binom{\alpha}{s\alpha}$.

III. LEE AND SUZUKI TRANSFORMATION

Let O be a Hermitian $N\times N$ matrix, with an independent set of eigenvectors $\{\psi_i : i=1,....,N\}$, and consider the eigenequation

$$O\psi_i = E_i\psi_i \quad (i=1,...,N). \tag{9}$$

Applying the Lee and Suzuki similarity transformation[5] to the matrix O and to the truncated space H_N, we obtain

$$\tilde{O}\tilde{\psi}_i = E_i\tilde{\psi}_i \quad (i=1,...,N), \tag{10}$$

where we have used tilde to designate transformed quantities so that

$$\tilde{O} = e^{-S}Oe^{S}, \quad \tilde{\psi} = e^{-S}\psi. \tag{11}$$

Our work will be distinguished from that of Lee and Suzuki through our identification of additional freedom in the choice of S. Multiplying both sides of (10) by P and injecting $I=P+Q$ conveniently in the right-hand side we get

$$P\tilde{O}P\tilde{\psi}_i + P\tilde{O}Q\tilde{\psi}_i = E_iP\tilde{\psi}_i \quad (i=1,...,N). \tag{12}$$

In a similar way we get

$$Q\tilde{O}P\tilde{\psi}_i + Q\tilde{O}Q\tilde{\psi}_i = E_iQ\tilde{\psi}_i \quad (i=1,...,N). \tag{13}$$

We shall choose the transformation (11) such that there exists a subset $J\subset\{1,...,N\}$ with *card* $J=d$, for which (i) the set of vectors $\{P\tilde{\psi}_i : i\in J\}$ is linearly independent, and (ii) $Q\tilde{\psi}_i = 0 (i\in J)$. Such a choice, as we have seen in the previous section, is certainly possible.

Proposition 1: Let $J\subset\{1,...,N\}$ be such that the set $\{P\psi_i : i\in J\}$ is linearly independent. The following assertions concerning the Lee and Suzuki transformation are equivalent:

A1. $Q\tilde{\psi}_i = 0\ (i\in J)$

A2. $s_J = [Q\Psi_J][P\Psi_J]^{-1}$

A3. (i) the decoupling equation $Q\tilde{O}P=0$ holds, and

(ii) $P\psi_i (i\in J)$ are eigenvectors of $P\tilde{O}P$.

Proof: We have seen in Sec. II that the assertions A1 and A2 are equivalent (this expression of s_J was first given by Navratil and Barrett).[17] To prove that assertion A1 implies A3, we set $Q\tilde{\psi}_i = 0 (i\in J)$ in (12) and (13) to find that $P\tilde{\psi}_i (i\in J)$ are eigenvectors of $P\tilde{O}P$, and $Q\tilde{O}P\tilde{\psi}_i = 0\ (i\in J)$. Due to the linear independence of $P\psi_i (i\in J)$, the later d-equations imply that $Q\tilde{O}P=0$. Conversely, if $\alpha_k\,(i=1,...,d)$ are linearly independent eigenvectors of $P\tilde{O}P$ then the N-vectors $\binom{\alpha_k}{0}$ $(k=1,...,d)$ are eigenvectors of $\tilde{O}$. It follows that the inverse image of these vectors $\{e^S\binom{\alpha_k}{0} : k=1,...,d\}$ coincides with a subset $\Psi_J=\{\psi_i : i\in J\}$ of eigenvectors of O. The subset Ψ_J clearly fulfills assertion 1. Hence A1 is equivalent to A3.

IV. THE EFFECTIVE FORM

When the transformed operator $\tilde{O}$ is such that $Q_K\tilde{O}P_K=0$, for some subset $K\subset\{1,...,N\}$, with *card* $K=d$, we refer to the operator $O_{\text{eff}}\equiv P_K\tilde{O}P_K$ as an effective representative of the operator O corresponding to the model space Π_K, and to the form taken by $\tilde{O}$ as an effective form. When $\tilde{O}$ is in an effective form corresponding to the model space Π, the matrix elements $(O_{\text{eff}})_{ij}$ are all zero except those for which $i,j\leqslant d$, and consequently we make the identification $O_{\text{eff}}:\Pi\to\Pi$, in which O_{eff} is considered a $d\times d$ matrix. In a similar way we treat $Q\tilde{O}Q$ as an $(N-d)\times(N-d)$ matrix.

We elaborate here on the effective form and develop a more explicit framework. We write the eigenequation (9) as

$$\begin{pmatrix} a & b \\ b^+ & f \end{pmatrix}\begin{pmatrix} \alpha_i \\ \beta_i \end{pmatrix} = E_i \begin{pmatrix} \alpha_i \\ \beta_i \end{pmatrix} \quad (i=1,.....,N), \tag{14}$$

where the matrix O has been partitioned to submatrices corresponding to Π and $\Pi^{\perp}$, with a is a $d\times d$ matrix. By (11) the last equation is transformed to

$$\begin{pmatrix} a+bs & b \\ -s(a+bs)+b^+ +fs & f-sb \end{pmatrix}\begin{pmatrix} \alpha_i \\ \beta_i - s\alpha_i \end{pmatrix} = E_i \begin{pmatrix} \alpha_i \\ \beta_i - s\alpha_i \end{pmatrix}. \tag{15}$$

The later equation is equivalent to (12) and (13) together. It is easy to check that every s_J, given as in proposition 1, puts $\tilde{O}$ into an effective form corresponding to some model space Π. In other words, every s_J is a solution to the decoupling equation

$$Q\tilde{O}P \equiv -s(a+bs)+b^+ +fs=0. \tag{16}$$

To demonstrate the converse we assume that the later equation is satisfied by some s, and hence the action of $Q\tilde{O}P$ on any vector in Π is zero. In particular this action is zero for all vectors α_i such that $\psi_i=\binom{\alpha_i}{\beta_i}$, $(i=1,....,N)$ are eigenvectors of O, and hence

$$-s(a+bs)\alpha_i + b^+\alpha_i + fs\alpha_i = 0 \quad (i=1,....,N). \tag{17}$$

Making use of (14) we reduce the last equation to the eigenequation

$$(f-sb)(s\alpha_i-\beta_i) = E_i(s\alpha_i-\beta_i) \quad (i=1,....,N), \tag{18}$$

which is the same as embodied in Eq. (15) but now extended to all i. However, not all vectors $s\alpha_i-\beta_i$ can be eigenvectors of $(f-sb)$ because the later operator has only $N-d$ eigenvectors. It follows that there exists a subset J consisting of d elements of $\{1,....,N\}$ such that $s\alpha_i-\beta_i=0$ $(i\in J)$, which implies that $s=s_J$, as given in proposition 1.

We list here the following comments on the effective form assuming from now on that $\tilde{O}$ is in such a form, i.e., the transformation (10) is such that $Q\tilde{O}P=0$.

(1) If $\tilde{O}$ is the effective form corresponding to the model space Π then the right-hand side of the secular (characteristic) equation $\det(O-EI_N)=0$ can be factorized to a product of two polynomials; one of which is of degree d in E

$$\det(O_{\text{eff}}-EI_d)\cdot\det(Q\tilde{O}Q-EI_{N-d})=0. \tag{19}$$

The eigenvalues of O is the set of zeros of these two polynomials. In practical problems the secular equation of O_{eff} can be solved numerically as it is of low degree in E, whereas that of $Q\tilde{O}Q$ is of high degree in E and it is often hopeless to approach it for direct solution. One may apply the method of effective form described in the previous section afresh to the operator $Q\tilde{O}Q$. Or alternatively one may pick up a new set of eigenvectors, say $\Psi_{J'}$, determine $s_{J'}$, and consequently a new effective form. Alternatively the matrix s could be determined by iterative methods.[4,12,7]

(2) If $P\psi_i$ is an eigenvector of O_{eff} corresponding to E_i then by (12) $P\tilde{O}Q\tilde{\psi}_i=0$ which implies that the $(N-d)$-vector $Q\tilde{\psi}_i$ is complex orthogonal to the rows of $d\times(N-d)$ matrix $P\tilde{O}Q$, and the vector $Q\tilde{\psi}_i$ is not necessarily zero. Therefore, if α is an eigenvector of O_{eff} then, though $\binom{\alpha}{0}$ is an eigenvector of $\tilde{O}$ belonging to the eigenvalue E_i, there may exist another

eigenvector $\binom{\alpha}{\gamma}$ of $\tilde{O}$ that belongs to the same eigenvalue E_i. In the latter case $b\gamma=0$ and γ is an eigenvector of $Q\tilde{O}Q$ belonging to the eigenvalue E_i. It is clear that $\binom{0}{\gamma}$ is an eigenvector of $\tilde{O}$ that belongs to the eigenvalue E_i. We summarize the latter observations by the following proposition

Proposition 2: Let ϕ be an eigenvector of $\tilde{O}$ belonging to the eigenvalue E.
(i) If $Q\phi=0$ then E is an eigenvalue of O_{eff} to which the eigenvector $P\phi$ belongs.
(ii) if $Q\phi\neq 0$ then $Q\phi$ is an eigenvector of $Q\tilde{O}Q$ belonging to the eigenvalue E. If in addition, $P\phi\neq 0$, then $P\phi$ is not an eigenvector of O_{eff} unless $bQ\phi=0$. In the latter case E is a common eigenvalue of O_{eff} and $Q\tilde{O}Q$ to which the independent eigenvectors $\binom{P\phi}{0}$ and $\binom{0}{Q\phi}$ belong. In the latter case the spectra of O_{eff} and $Q\tilde{O}Q$ intersect.
(iii) $P\phi$ is an eigenvector of O_{eff} does not necessitate that $Q\phi=0$. However if the spectra of O_{eff} and $Q\tilde{O}Q$ do not intersect in E, then $Q\phi=0\Leftrightarrow P\phi$ is an eigenvector of O_{eff} belonging to the eigenvalue E.

(3) If the matrix $[P\Psi_J]$ is singular for some choice of model space, say Π, then we have to replace it by another Π' such that the matrix $[P'\Psi_J]$ is invertible. There certainly exists such a new choice of model space, otherwise the set Ψ_J would be linearly dependent.

We demonstrate here that for a given set of eigenvectors Ψ_J, two legitimate choices of model spaces lead to two effective representatives which are related by a similarity transformation. Let Π and Π' be two legitimate choices and denote the projections on the corresponding model spaces by P and P', respectively. This leads to two distinct s, say s and s', and hence to two distinct effective representatives $O_{\text{eff}}=P\tilde{O}P$ and $O'_{\text{eff}}=P'\tilde{O}'P'$. If $\{E_i:i\in J\}$ is the set of eigenvalues to which Ψ_J belong, then

$$O_{\text{eff}}[P\Psi_J]=[P\Psi_J]\Lambda_J, \quad O'_{\text{eff}}[P'\Psi_J]=[P'\Psi_j]\Lambda_J, \tag{20}$$

where Λ_J is a diagonal matrix with diagonal elements $(E_i:i\in J)$. From (20) we deduce that

$$O_{\text{eff}}=[P\Psi_J][P'\Psi_J]^{-1}O'_{\text{eff}}[P'\Psi_J][P\Psi_J]^{-1}, \tag{21}$$

which proves our claim.

Each independent set of eigenvectors Ψ_J provide at least one model space Π_K. The number of possible choices of Π_K is not less than one and not greater than $\binom{N}{d}$, which is of course the number of independent sets of projections $\{P_K\Psi_J:card\ K=d,\ K\subset\{1,....,N\}\}$. All such choices lead of course to the same set of eigenvalues Λ_J.

If the eigenvalues of O are nondegenerate then different choices of Ψ_J out of the set of N-independent eigenvectors Ψ, result in effective representatives with different spectra. The total choices of inequivalent effective representatives corresponding to O is $\binom{N}{d}$; and within each of these there are a maximum number of $\binom{N}{d}$ equivalent representatives.

The above-identified freedoms are new and extend the work of Lee and Suzuki.

V. SPECTRAL REPRESENTATION OF O_{eff}

Let O_{eff} be an effective representative of the operator O in the model space Π, and let $\{E_i:i\in J\}$ be the spectrum of O_{eff}, to which the vectors $P\Psi_i(i\in J)$ belong, so that $O_{\text{eff}}P\psi_i=E_iP\psi_i(i\in J)$. Since each $P\psi_i$ lies in the model space we have

$$P\psi_i=\sum_{\mu=1}^{d} c_{i\mu}e_\mu \quad (i\in J), \tag{22}$$

$$\langle P\psi_i|P\psi_j\rangle=\sum_{\mu=1}^{d} c^*_{i\mu}c_{j\mu}\equiv\gamma_{ij} \quad (i,j\in J). \tag{23}$$

The matrix γ is clearly Hermitian, and determines the overlap the eigenvector of O_{eff} one with respect to another. Let

$$\chi=\sum_{j\in J} b_j P\psi_j \tag{24}$$

be an arbitrary vector in the model space, then

$$\langle P\psi_i|\chi\rangle=\sum_{j\in J} \gamma_{ij}b_j \quad (i\in J). \tag{25}$$

Hence

$$\sum_{i\in J} \gamma_{ki}^{-1}\langle P\psi_i|\chi\rangle=b_k \quad (k\in J), \tag{26}$$

where γ^{-1} is the inverse of the matrix γ. It is clear that γ^{-1} always exists since $P\psi_i\,(i\in J)$ are linearly independent. Applying O_{eff} to χ where b_k are given by (26) we get

$$O_{\text{eff}}|\chi\rangle=\sum_{i,k\in J} \gamma_{ki}^{-1}\langle P\psi_i|\chi\rangle E_k P\psi_k\,. \tag{27}$$

This yields

$$O_{\text{eff}}=\sum_{i,k\in J} E_i\gamma_{ik}^{-1}|P\psi_i\rangle\langle P\psi_k|,$$

which expresses O_{eff} in terms of quantities pertaining to the model space.

VI. A COMPLETE SET OF EFFECTIVE REPRESENTATIVES

Let $O_1\equiv H$ be the Hamiltonian of a physical system and $O^2,\ldots\ldots,O^c$ be a set of observables pertaining to the system so that the set of observables $\Gamma=\{O^1,O^2,\ldots,O^c\}$ is complete. It follows from the latter assumption that

$$[O^\rho,O^\sigma]=0 \quad (\rho,\sigma=1,....,c). \tag{28}$$

The energy eigenvectors $\{e_i:i=1,2,...\}$ of a suitably chosen Hamiltonian could be taken as a basis for the Hilbert space of wave functions of the physical system. For example, these could be the energy eigenstates of the simple harmonic oscillator, when one considers the bound states of the nucleus. Observables pertaining to the system are represented by Hermitian matrices in terms of this basis. Unless the matrices representing observables are given by recurrence formulas, we have to be content with finite matrix approximations, which imply truncating the infinite basis $\{e_i\}_1^\infty$ at some sufficiently large term N. The space generated by the truncated basis $[e_1,\ldots,e_N]\equiv H_N$ will hopefully contain good approximations of all states of interest to the problem we consider.

It must be noted that, whenever the eigenvalue problem is to be solved numerically, which is usually the case in physically interesting problems, truncation is an inevitable task. It is true that if $\{e_i\}_1^\infty$ is a basis of the Hilbert space of square integrable functions H_∞, the sequence (e_N) tends weakly to zero as N tends to infinity.[20,21] This means that for every $\psi\in H_\infty$ the sequence of numbers $(\langle e_N|\psi\rangle)$ tends to zero as N tends to infinity. However one cannot be confident that the space H_N resulting from a specific choice of N will contain, to a good approximation, the physical states of interest unless a skillful choice of basis is made. Only in the latter case an upper cutoff can be safely applied without seriously changing the low-lying properties.

It is noted that all the algebra carried out in the previous sections, or to be carried out in the forthcoming discussion, is valid for infinite matrices as much as it is valid for finite ones, and hence we may replace N by ∞ without affecting the validity of these results.

The Hermitian commuting set of matrices Γ is complete, and there exists accordingly a complete set of simultaneous eigenfunctions ψ_i of the observables O^σ such that

$$O^\sigma \psi_i = E_i^\sigma \psi_i \quad (i=1,...,N;\sigma=1,....,c), \tag{29}$$

where E_i^σ are the eigenvalues of the observable O^σ to which the eigenvector ψ_i belongs. The eigenvectors given by (29) are preserved when the similarity transformation (11) is applied to the Hilbert space of wave functions H_N and to the operators acting on H_N, and hence

$$\tilde{O}^\sigma \tilde{\psi}_i = E_i^\sigma \tilde{\psi}_i \quad (i=1,...,N;\sigma=1,...,c). \tag{30}$$

Assume that the eigenvectors $\tilde{\psi}_1,....,\tilde{\psi}_d$ are such that the set $\{P\tilde{\psi}_1,.....,P\tilde{\psi}_d\}$ is linearly independent, and take

$$s=[Q\tilde{\psi}_1.....Q\tilde{\psi}_d][P\tilde{\psi}_1.....P\tilde{\psi}_d]^{-1}. \tag{31}$$

The matrix s is the same for observables forming the complete set Γ, for it is constructed of the same subset of the simultaneous eigenvectors of $\tilde{O}^\sigma(\sigma=1,...,c)$. The resulting transformed observables $\tilde{O}^\sigma$, have the same effective form, and hence have $P\tilde{\psi}_i(i=1,...,d)$ as a common subset of eigenvectors $\{\tilde{\psi}_i : i=1,...,N\}$. Define a set of effective representatives

$$\sigma_{\text{eff}}^\sigma = P\tilde{O}^\sigma P \quad (\sigma=1,....,c), \tag{32}$$

and hence

$$O_{\text{eff}}^\sigma P\tilde{\psi}_i = E_i^\sigma P\tilde{\psi}_i \quad (i=1,....,d;\sigma=1,....,c). \tag{33}$$

It follows, and since the set $\{P\psi_i : i=1,...,d\}$ is complete in the model space Π, that

$$[O_{\text{eff}}^\rho, O_{\text{eff}}^\sigma]=0 \quad (\sigma,\rho=1,...,c). \tag{34}$$

The effective Hamiltonian $H_{\text{eff}} \equiv O_{\text{eff}}^1$ and the effective representatives $O_{\text{eff}}^\sigma(\sigma=2,...,c)$ we have constructed have the virtue that the symmetries exhibited by the original Hamiltonian H are carried over to H_{eff} with the effective representatives $O_{\text{eff}}^\sigma(\sigma=2,...,c)$ playing the role of generators of symmetry for H_{eff}.

The matrices (32) are obviously non-Hermitian and, consequently, the expectation value of an effective representative in a state $P\psi$ in the model space is generally a complex number. An exception to this fact is that when $P\psi$ is an eigenvector $P\psi_i$ of O_{eff}. In this case

$$\langle O_{\text{eff}} \rangle_{P\psi_i} = \langle P\psi_i | O_{\text{eff}} | P\psi_i \rangle / \|P\psi_i\|^2 = E_i. \tag{35}$$

VII. A SECOND TYPE OF EFFECTIVE REPRESENTATIVE

The role of an effective operator seems limited to producing some of the eigenvalues of the original observable. However, we may enhance the scheme of ''effectiveness'' and make a further step as follows: The matrix S which is determined by iterative methods[4,7,18] and utilized to construct the effective representative O_{eff} can also be utilized to construct an effective representative of a second type $\overline{O}_{\text{eff}}$ that satisfy the property

$$\langle \psi | O | \phi \rangle = \langle P\psi | \overline{O}_{\text{eff}} | P\phi \rangle, \tag{36}$$

for all $\psi,\phi\in \mathrm{Lin}\{\psi_1,\ldots,\psi_d\}$. Using (11) and the definition of the adjoint operator, we have

$$\begin{aligned}\langle\psi|O|\phi\rangle&=\langle e^{-S}\tilde{\psi}|O|e^{-S}\tilde{\phi}\rangle\\&=\langle\tilde{\psi}|e^{-S^+}Oe^{-S}|\tilde{\phi}\rangle\\&=\langle P\tilde{\psi}|e^{-S^+}Oe^{-S}|P\tilde{\phi}\rangle\\&=\langle P\psi|Pe^{-S^+}Oe^{-S}P|P\phi\rangle.\end{aligned}\tag{37}$$

The requirement (36) is fulfilled on taking

$$\tilde{O}_{\mathrm{eff}}=Pe^{-S^+}Oe^{-S}P.\tag{38}$$

In particular $\langle\psi_i|O|\psi_j\rangle=\langle\alpha_i|\overline{O}_{\mathrm{eff}}|\alpha_j\rangle$.

We therefore associate with every observable $O^\sigma\in\Gamma$ two effective representatives. The first, O_{eff}, serves to determine some of the eigenvalues of O^σ and the projection of the corresponding eigenvectors on the model space; the second $\overline{O}^\sigma_{\mathrm{eff}}$ has the important property: the matrix elements of the original operator O^σ with respect to any basis in the space $\mathrm{Lin}\{\psi_1,\ldots,\psi_d\}$ is given in terms of $\overline{O}^\sigma_{\mathrm{eff}}$ and the projected basis in the model space. It is evident that the last matrix can be calculated easily since $\overline{O}^\sigma_{\mathrm{eff}}$ is known whenever S is known, and since the basis elements of the model space have finite components. We mention that the matrix $\langle P\psi_i|\overline{O}_{\mathrm{eff}}|P\psi_j\rangle$ is not the matrix of $\overline{O}_{\mathrm{eff}}$ since $\{P\psi_i\}_{i=1}^d$ is not orthogonal. In particular, and if $\psi\in\mathrm{Lin}\,\Psi$ then

$$\langle O\rangle_\psi=\langle P\psi|\overline{O}_{\mathrm{eff}}|P\psi\rangle=\|P\psi\|^2\langle\overline{O}_{\mathrm{eff}}\rangle_{P\psi}.$$

Expressed in words, the expectation value of the observable O in the state $\psi\in\mathrm{Lin}\,\Psi$ is equal to the expectation value of its representative of the second type in the projection of the given state on the model space times the square norm of this projection.

For observables O that do not commute with all elements of the complete set Γ we can define only one effective representative, that is the effective representative of the second type $\overline{O}_{\mathrm{eff}}$. This serves to give a portion of the transition matrix of O, namely that which corresponds to a basis of $\mathrm{Lin}\,\Psi$.

A systematic study of the system is achieved by decomposing the space H_N into linear subspaces $\mathrm{Lin}\,\Psi_{J_r}$ $(r=1,2,\ldots,a)$, with $J_r\cap J_s=\varnothing$ if $(r\neq s)$, so that

$$H_N=\mathrm{Lin}\,\Psi_{J_1}\oplus\ldots\oplus\mathrm{Lin}\,\Psi_{J_a}.\tag{39}$$

Now in each subspace $\mathrm{Lin}\,\Psi_{J_r}$ we assign to every observable O in a complete set of observables an effective representative of the first type $O_{r\,\mathrm{eff}}$ and an effective observable of the second type $\overline{O}_{r\,\mathrm{eff}}$. These effective representatives, of first or second type, differ from one subspace to another as does s_J. If representatives of the first type are all obtained, all eigenvalues of the full observable O become known. Also if $\chi,\chi'\in\mathrm{Lin}\,\Psi_{J_r}$ then we have $\langle\chi|O|\chi'\rangle=\langle P_r\chi|\overline{O}_{r\,\mathrm{eff}}|P_r\chi'\rangle$ where P_r denotes the projection on the model space corresponding to the subspace $\mathrm{Lin}\,\Psi_{J_r}$. Although similar relations are valid for every two vectors in the same subspace, one cannot express $\langle\chi|O|\chi'\rangle$ in terms of representatives of second type when χ and χ' belong to different subspaces, and consequently when they are arbitrary vectors in H_N.

VIII. TOWARDS PRACTICAL APPLICATIONS

Following the traditional lines of thinking for many-body problems, we suggest that S is developed for small subsystems and used as an approximation for the full S. For example two- and three-body problems may be solved with high precision using current numerical techniques.[17,18] A

set of solutions $P\psi_i\ (i=1,...,d)$ is selected, S is evaluated, and the resulting H_{eff} is then used in many-body problems within the appropriately restricted model space. Detailed tests will be needed for specific Hamiltonians to determine the efficacy of this approach and the utility of the various freedoms we have identified within the present work.

Variable separation for natural Hamiltonians with scalar and vector potentials on Riemannian manifolds

S. Benenti,[a] C. Chanu, and G. Rastelli
Department of Mathematics, University of Turin, 10123 Torino, Italy

(Received 9 October 2000; accepted for publication 6 November 2000)

The additive variable separation in the Hamilton–Jacobi equation is studied for a natural Hamiltonian with scalar and vector potentials on a Riemannian manifold with positive–definite metric. The separation of this Hamiltonian is related to the separation of a suitable geodesic Hamiltonian over an extended Riemannian manifold. Thus the geometrical theory of the geodesic separation is applied and the geometrical characterization of the separation is given in terms of Killing webs, Killing tensors, and Killing vectors. The results are applicable to the case of a nondegenarate separation on a manifold with indefinite metric, where no null essential separable coordinates occur. © *2001 American Institute of Physics.*

I. INTRODUCTION

A smooth real function V and a smooth vector field $\mathbf{A}$ on a Riemannian n-manifold $(Q,\mathbf{g})$ define a Hamiltonian function on the cotangent bundle T^*Q,

$$H=\tfrac{1}{2}g^{ij}(p_i+A_i)(p_j+A_j)+V=\tfrac{1}{2}g^{ij}p_ip_j+A^ip_i+U, \tag{1.1}$$

where the function on Q

$$U=V+\tfrac{1}{2}A^iA_i=V+\tfrac{1}{2}\mathbf{A}\cdot\mathbf{A} \tag{1.2}$$

is extended to T^*Q as a function constant on the fibers. Hamiltonians of this kind appear in many classical problems of analytical mechanics and physics, and for this reason they are called *natural*. The Hamiltonian (1.1) corresponds to a Lagrangian $L:TQ\to\mathbb{R}$ of the form

$$L=\tfrac{1}{2}g_{ij}\dot{q}^i\dot{q}^j-A_i\dot{q}^i-V, \tag{1.3}$$

where $\frac{1}{2}g_{ij}\dot{q}^i\dot{q}^j$ is the *kinetic energy* and V and $\mathbf{A}$ play the role of *scalar* and *vector potentials*, respectively, generating Lagrangian forces

$$F_i=(\partial_jA_i-\partial_iA_j)\dot{q}^j-\partial_iV. \tag{1.4}$$

Here we denote by $(\underline{q},\underline{p})=(q^i,p_i)$ and by $(\underline{q},\underline{\dot{q}})=(q^i,\dot{q}^i)$ the coordinate systems on T^*Q and TQ, associated with a coordinate system $\underline{q}=(q^i)$ on Q. We denote by ∂_i the partial derivative with respect to the variable q^i. In the following we shall use the symbol ∂^i for the partial derivative with respect to p_i.

A natural Hamiltonian is called separable if there are coordinates $\underline{q}$ on Q such that the Hamilton–Jacobi equation

$$H(\underline{q},\underline{p})=h, \quad p_i=\partial_iW \tag{1.5}$$

[a]Electronic mail: benenti@dm.unito.it

admits a *separated complete solution* of the form

$$W(\underline{q},\underline{c})=W_1(q^1,\underline{c})+\cdots W_n(q^n,\underline{c}), \tag{1.6}$$

where $\underline{c}=(c_i)$ is a set of n constants satisfying the *completeness condition*

$$\det\left[\frac{\partial^2 W}{\partial q^i \partial c_j}\right]\neq 0. \tag{1.7}$$

The interest of separable Hamiltonians lies essentially on two facts: (1) in separable coordinates $\underline{q}$ the integration of the Hamilton–Jacobi equation is reduced to (at most n) simple integrals (i.e., involving single variables); (2) the separation of variables is characterized by the existence of n first integrals in involution, quadratic or linear in the conjugate momenta $\underline{p}$. Hence, separable Hamiltonians give rise to a particular but wide class of completely integrable Hamiltonian systems. In the theory of separation of variables a basic role is played by the geodesic Hamiltonian

$$G=\tfrac{1}{2}g^{ij}p_i p_j\,. \tag{1.8}$$

Indeed, as pointed out by Levi-Civita,[1] a necessary condition for the separability of a natural Hamiltonian (1.1) is the separability of the corresponding geodesic Hamiltonian (1.8). Moreover, it is known that the separability of G is characterized by the existence of Killing vectors and Killing 2-tensors on the Riemannian manifold Q (which generate quadratic and linear first integrals in involution) satisfying suitable properties.[2–9] This shows that the separability is not simply a local property concerning with coordinates but it is in fact related to the existence of intrinsic objects satisfying coordinate-independent properties. As a consequence, the intrinsic characterization of the separability (by means of algebraic objects like Killing vectors and tensors[4–8] and geometrical objects like ''Killing webs''[9,10]) provide a useful and effective tool for finding and constructing separable Hamiltonian systems. While the theory of the geodesic separability can be easily extended to natural Hamiltonians of the kind

$$G=\tfrac{1}{2}g^{ij}p_i p_j+V, \tag{1.9}$$

involving a scalar potential only, the extension to the general Hamiltonian (1.1) with a vector potential meets some difficulties, as explained below. However, several important results are already present in the literature, but all concerning the general form of the functions (g^{ij},A^i,V) in separable coordinates[11–14] (also in the time-dependent case). The aim of the present paper is to revisit all this matter at the light of the more recent progress in the geometrical characterization of the separation.[10] As it has been done for a pure geodesic Hamiltonian G, for investigating on the intrinsic properties of the objects $(\mathbf{g},\mathbf{A},V)$ underlying the separation, a starting point could be the fundamental *Levi-Civita separability conditions*[1]

$$\partial^i\partial^j H\partial_i H\partial_j H+\partial_i\partial_j H\partial^i H\partial^j H-\partial^i\partial_j H\partial_i H\partial^j H-\partial_i\partial^j H\partial^i H\partial_j H=0 \tag{1.10}$$

(no sum over the indices $i\neq j$) which yield second-order differential equations on the functions (g^{ij},A^i,V). But these equations turn out to be of such a complexity that this way seems to be hopeless. An alternative method could be the analysis of the known expressions[11,12] of the functions (g^{ij},A^i,V) in separable coordinates (as done for instance in Ref. 15, for the orthogonal separation, on the basis of previous results by Steigeberger[13]). But also this method appears to be rather difficult and, moreover, it does not provide a good and complete understanding of the intrinsic meaning of the separation, where a basic and simplifying role is played by particular classes of coordinates, called *normal separable coordinates*.[7–10] Instead, we propose here a direct and geometrical method which makes the problem clear and easily solvable from the very beginning. The basic (and very simple) idea of this method is the following: we replace the original Hamiltonian (1.1) by an ''equivalent'' geodesic Hamiltonian on the ''extended manifold'' Q

$\times\mathbb{R}$ endowed with a suitable ''extended metric'' (Sec. IV); then, we apply to this new Hamiltonian the well-known methods of the theory of the geodesic separability.[7,8,10]

In the present paper we consider, for simplicity, only the case of a positive–definite metric. This makes the discussion considerably easier, since we avoid the cases of degenerate separation where the so-called second-class null coordinates occur. However, all results hold for the nondegenerate separation in a metric of any signature. The case of a Lorentzian metric will be considered in detail in a further paper.

II. NOTATION

We denote by $\langle \mathbf{X}, \varphi \rangle = X^i \varphi_i$ the evaluation between a vector field $\mathbf{X}$ and a 1-form φ. In particular, $\langle \mathbf{X}, dV \rangle = X^i \partial_i V$ is the derivative of the function V with respect to the vector $\mathbf{X}$. We denote by $\mathbf{u} \cdot \mathbf{v}$ the scalar product of two vectors, $\mathbf{u} \cdot \mathbf{v} = \mathbf{g}(\mathbf{u}, \mathbf{v}) = g_{ij} u^i v^j$. The canonical Poisson–Lie brackets of functions over a cotangent bundle are defined by

$$\{f, g\} = \partial^i f \partial_i g - \partial^i g \partial_i f. \tag{2.1}$$

We consider the natural identification between contravariant symmetric tensors $\mathbf{K} = (K^{i_1 \cdots i_k})$ on Q and the homogeneous polynomial functions on the cotangent bundle T^*Q, defined by

$$P(\mathbf{K}) = P_{\mathbf{K}} = K^{i_1 \cdots i_k} p_{i_1} \cdots p_{i_k}. \tag{2.2}$$

For a function f on Q (tensor of order 0) P_f is its natural extension to T^*Q constant on the fibers. Then the Poisson brackets induce Nijenhuis–Lie brackets between contravariant symmetric tensors on Q by setting

$$\{P_{\mathbf{K}}, P_{\mathbf{L}}\} = P_{[\mathbf{K}, \mathbf{L}]}. \tag{2.3}$$

If $\mathbf{K}$ and $\mathbf{L}$ are of order k and l, respectively, then $[\mathbf{K}, \mathbf{L}]$ is of order $k + l - 1$. In particular, for two vector fields, $[\mathbf{X}, \mathbf{Y}]$ are the ordinary Lie brackets, and $[\mathbf{X}, \mathbf{K}]$ is the Lie derivative of the tensor field $\mathbf{K}$ with respect to the vector field $\mathbf{X}$. We say that two (symmetric) tensors are *in involution* (or that they *commute*) if $[\mathbf{K}, \mathbf{L}] = 0$. This means that the corresponding polynomial functions are in involution: $\{P_{\mathbf{K}}, P_{\mathbf{L}}\} = 0$. Killing vectors and Killing tensors are defined by the *Killing equations*

$$[\mathbf{X}, \mathbf{G}] = 0, \quad [\mathbf{K}, \mathbf{G}] = 0, \tag{2.4}$$

where

$$\mathbf{G} = (g^{ij})$$

is the contravariant metric tensor. This means that the corresponding functions $P_{\mathbf{X}}$ and $P_{\mathbf{K}}$ are first integrals of the geodesic flow. As for any symmetric 2-tensor on a Riemannian manifold, a Killing tensor $\mathbf{K}$ can be interpreted as a linear operator over 1-forms or vector fields; we shall denote by $\mathbf{K}\varphi$ and by $\mathbf{K}\mathbf{X}$, respectively, the images by $\mathbf{K}$ of a 1-form φ and of a vector $\mathbf{X}$, whose local representations, in any coordinate system $\underline{q}$, are

$$\mathbf{K}\varphi = g_{ij} K^{jh} \varphi_h \, dq^i, \quad \mathbf{K}\mathbf{X} = K^{ih} g_{hj} X^j \partial_i. \tag{2.5}$$

The contravariant metric tensor $\mathbf{G}$ corresponds to the identity mapping,

$$\mathbf{G}\varphi = \varphi, \quad \mathbf{G}\mathbf{X} = \mathbf{X}.$$

We denote by $\flat$ the bijective mapping from vector fields to 1-forms on Q, defined by the equivalent equations

$$\langle \mathbf{Y}, \mathbf{X}^\flat \rangle = \mathbf{Y} \cdot \mathbf{X}, \quad \mathbf{G}(\mathbf{X}^\flat, \varphi) = \langle \mathbf{X}, \varphi \rangle. \tag{2.6}$$

III. AN OUTLINE ON THE GEODESIC SEPARATION

In order to make this paper self-contained we recall in this section, with suitable adaptations, the basic definitions and results of the geometrical theory of the separation of the geodesic Hamilton–Jacobi equation.

(A) An *orthogonal web* on a Riemannian manifold Q_n is a set $(\mathcal{S}^a)$ $(a=1,...,m)$ of $m \leqslant n$ pairwise transversal and orthogonal foliations of leaves of codimension 1. In a positive–definite metric the orthogonality implies the transversality, and moreover, the intersections of all the leaves of $(\mathcal{S}^a)$ form a foliation $\mathcal{O}$ of submanifolds of dimension $r=n-m$. If these submanifolds are the orbits of a r-dimensional space D of commuting Killing vectors, then we say that the set

$$(\mathcal{S}^a, D) = (\mathcal{S}^1, \ldots, \mathcal{S}^m, D) \tag{3.1}$$

is a *Killing web*. The orbits of D are locally flat submanifolds.

(B) If the foliations $(\mathcal{S}^a)$ are, respectively, orthogonal to m eigenvectors $(\mathbf{X}_a)$ of a Killing 2-tensor $\mathbf{K}$ associated with m pointwise distinct eigenvalues (λ^a), and if $\mathbf{K}$ is D-invariant $([\mathbf{X}, \mathbf{K}]=0, \forall \mathbf{X} \in D)$ then we say that the set

$$(\mathcal{S}^1, \ldots, \mathcal{S}^m, D, \mathbf{K}) \tag{3.2}$$

is a *separable Killing web* and that $\mathbf{K}$ is a *characteristic Killing tensor* of the web. Since only the eigenvectors (or eigenforms) orthogonal to the foliations $(\mathcal{S}^a)$ are relevant for the separation, we call them *main eigenvectors* (or *main eigenforms*) of $\mathbf{K}$. Points of Q where these objects are not defined or do not satisfy the above requirements are called *singular points* of the web. They form the *singular set* of the web.

(C) From a purely algebraic point of view a separable Killing web is then completely determined by a pair

$$(D, \mathbf{K}) \tag{3.3}$$

which we call *characteristic Killing pair*, made of a r-dimensional linear space $(r \leqslant n)$ D of commuting Killing vectors and of a Killing 2-tensor $\mathbf{K}$ satisfying the following requirements: (i) the vectors of D span a regular distribution Δ of rank r (i.e., a subbundle $\Delta \subseteq TQ$ such that $\dim(\Delta)=n+r$); (ii) $\mathbf{K}$ is D-invariant; (iii) $\mathbf{K}$ has $m=n-r$ *normal* (i.e., orthogonally integrable) eigenvectors $(\mathbf{X}_a)$ $(a=1,...,m)$ (the *main eigenvectors*) orthogonal to D and associated with m pointwise distinct eigenvalues (λ^a).

(D) In a neighborhood of a nonsingular point a Killing web $(\mathcal{S}^a, D)$ generates coordinate systems (q^a, q^α) $(a=1,...,m;\ \alpha=m+1,...,n)$ such that each dq^a is a characteristic 1-form of the corresponding foliation $\mathcal{S}^a$ (q^a is constant on the leaves of $\mathcal{S}^a$) and (q^α) are the affine parameters of the integral curves of r vector fields $(\mathbf{X}_\alpha)$ forming a basis of D, with zero values on a chosen submanifold $\mathcal{Z}$ of codimension r, transversal to the orbits of D. It follows that the coordinates (q^a) are orthogonal, $g^{ab}=\mathbf{G}(dq^a, dq^b)=0$ for $a \neq b$, and their coordinate hypersurfaces are open submanifolds of the leaves of the web. Moreover, the coordinates (q^α) are ignorable, $\partial_\alpha g^{ij}=0$, since they are generated by Killing vectors. We say that such a coordinate system is *adapted* to or *generated* by the Killing web, and *based on the section* $\mathcal{Z}$ (Fig. 1).

(E) It can be shown that[10] the coordinates adapted to a Killing web are separable for the geodesic Hamiltonian G if and only if there exists a Killing 2-tensor $\mathbf{K}$ satisfying conditions of item (B), i.e., if and only if $(\mathcal{S}^a, D, \mathbf{K})$ is a separable Killing web. This is equivalent to say that the geodesic Hamiltonian G is separable if and only if there exists a characteristic Killing pair $(D, \mathbf{K})$ [see item (C)].

(F) It can be proved that[9,10] in a separable Killing web the distribution $\Delta^\perp$ orthogonal to D is completely integrable, so that there exists a foliation of m-dimensional manifolds orthogonal to the

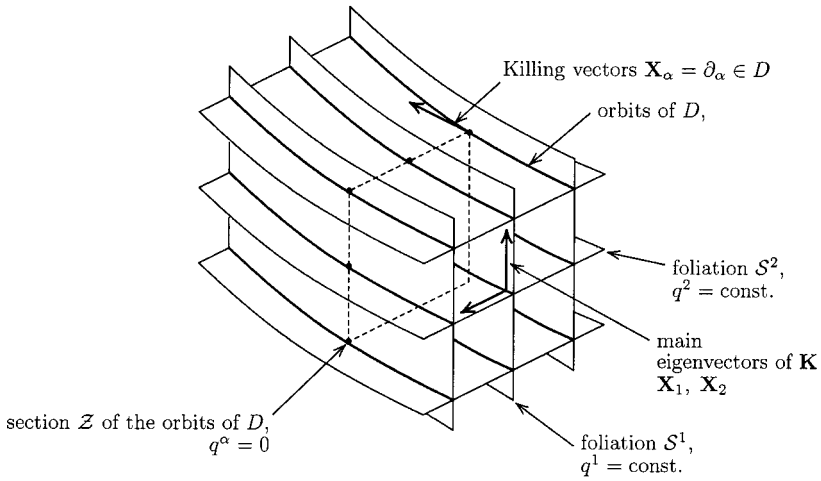

FIG. 1. Illustration of the elements of a separable Killing web $(\mathcal{S}^a, D, \mathbf{K})$ (for $a=1,2$).

orbits of D. The separable coordinates adapted to a separable Killing web and based on a section $\mathcal{Z}$ orthogonal to D are called *normal separable coordinates*. In these coordinates the contravariant metric assumes the semidiagonal *standard form*

$$[g^{ij}] = \left[\begin{array}{ccc|c} g^{11} & & & \\ & \ddots & 0 & \\ & g^{aa} & & 0 \\ & 0 & \ddots & \\ & & g^{mm} & \\ \hline & 0 & & g^{\alpha\beta} \end{array}\right]. \tag{3.4}$$

(G) There are two extreme cases of the above description: (i) $m=n$, $r=0$; in this case the space of Killing vectors D vanishes, the Killing web is simply an orthogonal web of n foliations of codimension 1; (ii) $m=0$, $r=n$; in this case the foliations $\mathcal{S}^a$ disappear, and only the n-dimensional space D of commuting K-vectors is present; such a K-web is always separable, with $\mathbf{K}=0$. There is a further particular case: (iii) $m=1$, $r=n-1$; in this case we have a single foliation of codimension 1 made of the orbits of $n-1$ commuting K-vectors; such a K-web is always separable, with $\mathbf{K}=\mathbf{G}$.

(H) Separable coordinate systems occur in equivalence classes: two separable systems are equivalent if the corresponding complete integrals generate the same Lagrangian foliation in T^*Q. A separable Killing web is the geometrical counterpart of an equivalence class of separable coordinates for the geodesic Hamiltonian. According to Levi-Civita,[1] the coordinates (q^i) of a separable system are divided into two classes: a coordinate q^i is of *first class* if the fraction $\partial_i H/\partial^i H$ is linear (homogeneous) in the momenta (p_j). Otherwise, it is of *second class*. Second-class coordinates are also called *essential separable coordinates*. They are usually labeled by indices $a,b,\ldots$ running from 1 to $m \leqslant n$. The first-class coordinates are labeled by indices $\alpha, \beta, \ldots$ running from $m+1$ to n. The numbers (r, m) of coordinates of first and second class, respectively, are the same for two equivalent separable systems and moreover, a separable systems is always equivalent to a normal separable system, see item (F), in which the first-class coordinates are ignorable and the metric tensor has the standard form (2.1).[7,8] In the transformation from a generic separable coordinate system to a normal one, the second-class coordinates remain essentially unchanged (they are related by a separated transformation, whose Jacobian is diagonal) so that their coordinate surfaces are invariant; these surfaces span the foliations $\mathcal{S}^a$ of the underlying

separable Killing web. Moreover, the partial derivatives (∂_α) with respect to the first-class coordinates (ignorable or not), interpreted as vector fields, span the space D of the underlying separable Killing web.

(I) The nonvanishing metric components (3.4) in normal separable coordinates have the form

$$g^{aa}=\varphi^a_{(m)}, \quad g^{\alpha\beta}=g^{aa}\phi_a^{\alpha\beta}, \tag{3.5}$$

where $\phi_a^{\alpha\beta}$ are functions of q^a only and $\varphi^a_{(m)}$ is the mth row of the inverse of a $m\times m$ *Stäckel matrix* $[\varphi_a^{(b)}]$: this is a matrix of functions depending only on the coordinate q^a corresponding to the lower index.

(J) A characteristic Killing pair $(D,\mathbf{K})$ generates an m-dimensional space $\mathcal{K}$ of Killing 2-tensors which are (i) D-invariant, (ii) in involution, and (iii) with m eigenvectors in common orthogonal to D (the main eigenvectors of the characteristic tensor $\mathbf{K}$). The components of an element of $\mathcal{K}$ in normal separable coordinates form a matrix similar to that of the metric (3.4). By formulas similar to (3.5), the rows of the inverse Stäckel matrix generate the components of a basis $(\mathbf{K}_b)$ of $\mathcal{K}$, $b=1,...,m$, with $\mathbf{K}_m=\mathbf{G}$,

$$K_b^{aa}=\varphi^a_{(b)}, \quad K_b^{\alpha\beta}=\varphi^a_{(b)}\phi_a^{\alpha\beta}. \tag{3.6}$$

This space includes $\mathbf{K}$ and the contravariant metric tensor $\mathbf{G}$. We call $\mathcal{K}$ the separable Killing algebra generated by $(D,\mathbf{K})$. If $\mathbf{K}^0$ is an element of $\mathcal{K}$ with distinct eigenvalues corresponding to the main eigenvectors, then the pairs $(D,\mathbf{K}^0)$ and $(D,\mathbf{K})$ are said to be equivalent (the define the same $\mathcal{K}$). The m quadratic functions

$$G_b=\tfrac{1}{2}P(\mathbf{K}_b)=\tfrac{1}{2}K_b^{ij}p_ip_j=\tfrac{1}{2}\varphi^a_{(b)}(p_a^2+\phi_a^{\alpha\beta}p_\alpha p_\beta) \tag{3.7}$$

together with the r linear functions

$$G_\alpha=P(\mathbf{X}_\alpha)=p_\alpha$$

associated with a basis $(\mathbf{X}_\alpha)$ of D, form a system of n independent first integrals in involution of the geodesic flow. Moreover, from the eigenform equations

$$\mathbf{K}_b\,dq^a=\lambda_b^a\,dq^a, \tag{3.8}$$

we derive the following relation between the main eigenvalues of $\mathbf{K}_b$ (corresponding to the main eigenvectors of the characteristic tensor $\mathbf{K}$) and the inverse Stäckel matrix,

$$\lambda_b^a=\frac{\varphi^a_{(b)}}{\varphi^a_{(m)}}, \tag{3.9}$$

so that

$$G_b=\tfrac{1}{2}\lambda_b^a g^{aa}(p_a^2+\phi_a^{\alpha\beta}p_\alpha p_\beta). \tag{3.10}$$

In this last formula, the quadratic first integrals in involution are expressed in terms of the main eigenvalues of the Killing tensors forming a basis of $\mathcal{K}$, without any reference to the Stäckel matrix.

(K) It can be shown that[10] a natural Hamiltonian $H=G+V$ is separable if and only if there exists a characteristic Killing pair $(D,\mathbf{K})$ such that

$$D(V)=0, \quad d(\mathbf{K}\,dV)=0. \tag{3.11}$$

The first of these two conditions means that V is D-invariant, $\langle \mathbf{X}, dV\rangle = 0$, $\forall \mathbf{X} \in D$, the second one that the 1-form $\mathbf{K}\,dV$ (image of dV by $\mathbf{K}$) is closed, hence locally exact. We call the second equation (3.11) the *characteristic equation of a separable potential*. Moreover,[7,8] a function V satisfies conditions (3.11) if and only if in a normal separable coordinate system is of the form

$$V = g^{aa}\phi_a = \varphi^a_{(m)}\phi_a\,, \tag{3.12}$$

where each ϕ_a is a function of q^a only. Functions of this kind are called *Stäckel multipliers*.[6] We observe that the first-class metric components $g^{\alpha\beta}$ (3.5) are Stäckel multipliers. It is remarkable that if V satisfies equations (3.11) then the characteristic equation holds for all elements of the algebra $\mathcal{K}$ generated by the characteristic Killing pair $(D,\mathbf{K})$. Hence, with a basis $(\mathbf{K}_b)$ of $\mathcal{K}$, we can associate (at least locally) m D-invariant functions (V_b) such that

$$\mathbf{K}_b\, dV = dV_b\,. \tag{3.13}$$

These *associated potentials* have a form similar to (3.12),

$$V_b = K_b^{aa}\phi_a = \varphi^a_{(b)}\phi_a\,. \tag{3.14}$$

The n functions

$$\begin{gathered} H_b = G_b + V_b = \tfrac{1}{2}\varphi^a_{(b)}(p_a^2 + \phi_a^{\alpha\beta}p_\alpha p_\beta + 2\phi_a) = \tfrac{1}{2}\lambda^a_b g^{aa}(p_a^2 + \phi_a^{\alpha\beta}p_\alpha p_\beta + 2\phi_a), \\ H_\alpha = P(\mathbf{X}_\alpha) = p_\alpha \end{gathered} \tag{3.15}$$

are independent first integrals in involution.

(L) It is useful to remark that, from an intrinsic point of view, a Stäckel multiplier is always the sum of scalar products of gradients of functions constant on the leaves of the web.

IV. THE EXTENDED METRIC

Let Q be a differentiable manifold with local coordinates (q^i) and let $\hat{Q} = Q \times \mathbb{R}$ be the *extended manifold* with local coordinates $(q^A) = (q^i, q^0)$ (q^0 is the natural coordinate over the real line). Let us consider on Q a positive–definite contravariant metric tensor $\mathbf{G} = (g^{ij})$, a vector field $\mathbf{A} = (A^i)$, and a function U. The triple

$$\hat{\mathbf{G}} = (\mathbf{G}, \mathbf{A}, U)$$

generates a contravariant symmetric 2-tensor $\hat{\mathbf{G}}$ on $\hat{Q}$ by setting

$$\hat{G}^{AB} = \begin{bmatrix} \hat{G}^{ij} & \hat{G}^{i0} \\ \hat{G}^{0j} & \hat{G}^{00} \end{bmatrix} = \begin{bmatrix} g^{ij} & A^i \\ A^j & 2U \end{bmatrix}. \tag{4.1}$$

In matrix notation,

$$\hat{\mathbf{G}} = \begin{bmatrix} \mathbf{G} & \mathbf{A} \\ \mathbf{A}^\tau & 2U \end{bmatrix}. \tag{4.2}$$

If $\det \hat{\mathbf{G}} > 0$, then $\hat{\mathbf{G}}$ is a positive–definite metric tensor, which we call *extended metric tensor*. Since $\det \mathbf{G} > 0$ and the determinant of the matrix (4.2) is a sum containing the term $2U \cdot \det \mathbf{G}$, the regularity condition $\det \hat{\mathbf{G}} > 0$ can be locally satisfied by adding to the function U a suitable positive constant. Because of the physical meaning of the function U (1.2) any additional constant

is inessential. If the function U has a lower bound, then this process of regularization is global. However, the local definition of the extended metric when U has no lower bound is not an obstruction to our purposes, since we shall use it as a local device.

Remark 4.1: In order to get a globally regular metric we could extend the manifold Q by two real axes, $\hat{Q}=Q\times\mathbb{R}\times\mathbb{R}$, and consider the contravariant metric

$$\hat{\mathbf{G}}=\begin{bmatrix}\mathbf{G} & \mathbf{A} & 0\\ \mathbf{A}^{\intercal} & 2U & 1\\ 0 & 1 & 0\end{bmatrix} \tag{4.3}$$

for which $\det\hat{\mathbf{G}}=-\det\mathbf{G}$. However, this metric is Lorentzian. Both the extensions (4.2) and (4.3) are contravariant. The metric (4.2) is a sort of Kaluza–Klein metric. Metrics similar to (4.2) and (4.3), with $\mathbf{A}=0$, have been considered by Eisenhart[16] in his interpretation of the dynamical trajectories of a holonomic system, with time-dependent constraints and potentials, as geodesics on a Riemannian manifold.

Remark 4.2: Any real function f on Q has a natural extension to $\hat{Q}=Q\times\mathbb{R}$ (constant along the fiber $\mathbb{R}$). For the sake of simplicity we denote this extension by the same symbol f. From the definition (4.2) it follows that the extended metric is characterized by the following equations, where (f, g) are arbitrary functions on Q:

$$\begin{aligned}\hat{\mathbf{G}}(df,dg)&=\mathbf{G}(df,dg),\\ \hat{\mathbf{G}}(df,dq^0)&=\langle\mathbf{A},df\rangle,\\ \hat{\mathbf{G}}(dq^0,dq^0)&=2U.\end{aligned} \tag{4.4}$$

Remark 4.3: The extended geodesic Hamiltonian is

$$\hat{G}=\tfrac{1}{2}P(\hat{\mathbf{G}})=\tfrac{1}{2}\hat{G}^{AB}p_Ap_B=\tfrac{1}{2}g^{ij}p_ip_j+A^ip_ip_0+Up_0^2 \tag{4.5}$$

(with indices $A=0,1,...,n$; $i, j=1,...,n$). Since q^0 is ignorable, the corresponding momentum p_0 is a first integral. As a consequence, the integral curves with $p_0=1$ of the Hamilton equations of $\hat{G}$ reduce to the integral curves of the Hamilton equations of H (1.1). In other words, the geodesic flow of the extended metric is projectable onto the Hamiltonian flow of H.

Remark 4.4: Let $W(\underline{q},\underline{c})$ be a complete solution of the Hamilton–Jacobi equation (1.5). Then the function

$$\hat{W}(\underline{q},q^0,\underline{c},c_0)=c_0(W(\underline{q},\underline{c})+q^0) \tag{4.6}$$

is a complete solution of the Hamilton–Jacobi equation associated with $\hat{G}$:

$$\tfrac{1}{2}g^{ij}\partial_i\hat{W}\partial_j\hat{W}+A^i\partial_i\hat{W}\partial_0\hat{W}+U(\partial_0\hat{W})^2=k.$$

Indeed, this equation reduces to

$$c_0^2(\tfrac{1}{2}g^{ij}\partial_iW\partial_jW+A^i\partial_iW+U)=k,$$

i.e., to Eq. (1.5) with $h=k/c_0^2$. Furthermore,

$$\begin{bmatrix} \dfrac{\partial^2 \hat{W}}{\partial q^i \partial c_j} & \dfrac{\partial^2 \hat{W}}{\partial q^i \partial c_0} \\ \dfrac{\partial^2 \hat{W}}{\partial q^0 \partial c_j} & \dfrac{\partial^2 \hat{W}}{\partial q^0 \partial c_0} \end{bmatrix} = \begin{bmatrix} c_0 \dfrac{\partial^2 W}{\partial q^i \partial c_j} & \dfrac{\partial W}{\partial q^i} \\ 0 & 1 \end{bmatrix}$$

and the completeness condition, i.e., the regularity of this matrix, is satisfied for $c_0 \neq 0$. By (4.6) we observe that if W is a separated complete solution of the form (1.6), then also $\hat{W}$ is separated. In other words, if (q^i) are separable coordinates for the Hamiltonian H, then (q^i, q^0) are also separable for the geodesic extended Hamiltonian $\hat{G}$. This shows that the separation of $\hat{G}$ is a necessary condition for the separation of H, and this is the reason why we shall analyze the separation in the extended space (Sec. V). However, as we shall see, the converse is not always true: the separation of $\hat{G}$ does not imply the separation of H, unless we consider a more general kind of separation, the *gauge separation* (see Definition 5.9 below).

Let us look at some properties of the fundamental objects defined on the extended manifold: vectors, 1-forms and 2-tensors. A vector field on $\hat{Q}$ is represented by a pair

$$\hat{\mathbf{X}} = (\mathbf{X}, \xi), \tag{4.7}$$

where $\mathbf{X}$ is a q^0-dependent vector field on Q and ξ a function on $\hat{Q}$. Its components are

$$(\hat{X}^A) = (X^i, \xi), \quad \hat{X}^i = X^i, \quad \hat{X}^0 = \xi,$$

so that, as a derivation,

$$\hat{\mathbf{X}} = X^i \frac{\partial}{\partial q^i} + \xi \frac{\partial}{\partial q^0} = X^i \partial_i + \xi \partial_0 .$$

A vector field $\hat{\mathbf{X}}$ is *horizontal* if $\xi = 0$, *vertical* if $\mathbf{X} = 0$. If we introduce the *fundamental vertical* vector field

$$\hat{\mathbf{X}}_0 = (0,1) = \partial_0 \tag{4.8}$$

then the expression (4.7) can be replaced with

$$\hat{\mathbf{X}} = \mathbf{X} + \xi \hat{\mathbf{X}}_0 . \tag{4.9}$$

We say that a vector field $\hat{\mathbf{X}}$ on $\hat{Q}$ is *vertically invariant* if $[\hat{\mathbf{X}}, \hat{\mathbf{X}}_0] = 0$. A vector field is vertically invariant iff both components $(\mathbf{X}, \xi)$ are q^0-independent. In this case, $\mathbf{X}$ is a vector field on Q and ξ is a function on Q. We call $\mathbf{X}$ the *basic component* of $\hat{\mathbf{X}}$ and ξ the *vertical component*.

Proposition 4.5: Two vertically invariant vector fields $\hat{\mathbf{X}} = (\mathbf{X}, \xi)$ and $\hat{\mathbf{Y}} = (\mathbf{Y}, \eta)$ commute, $[\hat{\mathbf{X}}, \hat{\mathbf{Y}}] = 0$, iff

$$\begin{gathered} \langle \mathbf{X}, d\eta \rangle = \langle \mathbf{Y}, d\xi \rangle, \\ [\mathbf{X}, \mathbf{Y}] = 0. \end{gathered} \tag{4.10}$$

Proof: Since all components do not depend on q^0, we have

$$[\hat{\mathbf{X}}, \hat{\mathbf{Y}}]^i = \hat{X}^A \partial_A Y^i - \hat{Y}^A \partial_A X^i = \hat{X}^j \partial_j Y^i - \hat{Y}^j \partial_j X^i = [\mathbf{X}, \mathbf{Y}]^i .$$

$$[\hat{\mathbf{X}}, \hat{\mathbf{Y}}]^0 = \hat{X}^A \partial_A \hat{Y}^0 - \hat{Y}^A \partial_A \hat{X}^0 = X^j \partial_j \hat{Y}^0 - Y^j \partial_j \hat{X}^0 = \langle \mathbf{X}, d\eta \rangle - \langle \mathbf{Y}, d\xi \rangle .$$

■

Proposition 4.6: A vertically invariant vector field $\hat{\mathbf{X}}=(\mathbf{X},\xi)$ is a Killing vector iff

$$\langle \mathbf{A}, d\xi\rangle = \langle \mathbf{X}, dU\rangle,$$

$$[\mathbf{X},\mathbf{A}] = \nabla\xi, \tag{4.11}$$

$$[\mathbf{X},\mathbf{G}] = 0.$$

Proof: The Killing equation $[\hat{\mathbf{X}},\hat{\mathbf{G}}]=0$ is equivalent to

$$\{\xi p_0 + X^i p_i, \tfrac{1}{2} g^{ij} p_i p_j + A^i p_i p_0 + U p_0^2\} = 0,$$

that is to

$$X^i(\tfrac{1}{2}\partial_i g^{hk} p_h p_k + \partial_i A^h p_h p_0 + \partial_i U p_0^2) - (\partial_i \xi p_0 + \partial_i X^h p_h)(g^{ik} p_k + A^i p_0) = 0.$$

The coefficients of p_0^2, $p_0 p_k$, and $p_h p_k$ generate equations

$$X^i \partial_i U - A^i \partial_i \xi = 0,$$

$$X^i \partial_i A^k - g^{ik}\partial_i \xi - A^i \partial_i X^k = 0,$$

$$(\tfrac{1}{2} X^i \partial_i g^{hk} - g^{ik}\partial_i X^h) p_h p_k = 0,$$

which are the coordinate representations of Eqs. (4.11).

■

The last equation (4.11) means that the basic component $\mathbf{X}$ of $\hat{\mathbf{X}}$ is a Killing vector. We notice that the fundamental vertical vector $\hat{\mathbf{X}}_0$ is a Killing vector. As for the contravariant metric, a contravariant symmetric 2-tensor on $\hat{Q}$ is represented by a triple

$$\hat{\mathbf{K}} = (\mathbf{K},\mathbf{C},F), \tag{4.12}$$

where $\mathbf{K}=(K^{ij})$ is a contravariant symmetric 2-tensor, $\mathbf{C}=(C^i)$ is a vector field, and F is a function on Q (all these objects may be q^0-dependent). In components,

$$\hat{K}^{AB} = \begin{bmatrix} K^{ij} & K^{i0} \\ K^{0j} & K^{00} \end{bmatrix} = \begin{bmatrix} K^{ij} & C^i \\ C^j & 2F \end{bmatrix}. \tag{4.13}$$

In matrix notation,

$$\hat{\mathbf{K}} = \begin{bmatrix} \mathbf{K} & \mathbf{C} \\ \mathbf{C}^{\intercal} & 2F \end{bmatrix}. \tag{4.14}$$

With this tensor we associate the Hamiltonian

$$\tfrac{1}{2} P(\hat{\mathbf{K}}) = \tfrac{1}{2}\hat{K}^{AB} p_A p_B = \tfrac{1}{2} K^{ij} p_i p_j + C^i p_i p_0 + F p_0^2. \tag{4.15}$$

This tensor is vertically invariant, $[\hat{\mathbf{X}}_0,\hat{\mathbf{K}}]=0$, iff all components are q^0-independent. In this case $\mathbf{K}$, $\mathbf{C}$, and F are objects on Q.

Proposition 4.7: A vertically invariant 2-tensor $\hat{\mathbf{K}}=(\mathbf{K},\mathbf{C},F)$ is a Killing tensor iff

$$
\begin{gathered}
[\mathbf{G},\mathbf{K}]=0,\\
[\mathbf{C},\mathbf{G}]=[\mathbf{A},\mathbf{K}],\\
[\mathbf{C},\mathbf{A}]=\nabla F-\mathbf{K}\nabla U,\\
\langle\mathbf{C},dU\rangle=\langle\mathbf{A},dF\rangle.
\end{gathered}
\tag{4.16}
$$

Proof: The Killing equation $[\hat{\mathbf{K}},\hat{\mathbf{G}}]=0$ is equivalent to $\{P_{\hat{\mathbf{G}}},P_{\hat{\mathbf{K}}}\}=0$,

$$
\begin{aligned}
&(g^{il}p_l+A^i p_0)(\tfrac{1}{2}\partial_i K^{hk}p_h p_k+\partial_i C^k p_k p_0+\partial_i F p_0^2)\\
&\quad-(K^{il}p_l+C^i p_0)(\tfrac{1}{2}\partial_i g^{hk}p_h p_k+\partial_i A^k p_k p_0+\partial_i U p_0^2)=0.
\end{aligned}
$$

The first equation (4.16) is determined by the coefficient of $(p_h p_k p_l)$. The coefficients of $p_0 p_h p_k$, $p_k p_0^2$, and p_0^3 give rise, respectively, to equations

$$
\begin{gathered}
(g^{ih}\partial_i C^k+\tfrac{1}{2}A^i\partial_i K^{hk}-K^{ih}\partial_i A^k-\tfrac{1}{2}C^i\partial_i g^{hk})p_h p_k=0,\\
g^{ik}\partial_i F+A^i\partial_i C^k-K^{ik}\partial_i U-C^i\partial_i A^k=0,\\
A^i\partial_i F-C^i\partial_i U=0,
\end{gathered}
$$

which are the coordinate representations of the last three equations (4.16). ■

We notice that the first equation (4.16) means that the basic component $\mathbf{K}$ is a Killing tensor.

Remark 4.8: As for any Riemannian manifold, the bijective mapping $\flat$ from 1-forms to vector fields on $\hat{Q}$ is defined by, see (2.6),

$$
\langle\hat{\mathbf{X}},df\rangle=\hat{\mathbf{G}}(df,\hat{\mathbf{X}}^{\flat}),
\tag{4.17}
$$

where f is a function on $\hat{Q}$. Since

$$
df=\frac{\partial f}{\partial q^i}dq^i+\frac{\partial f}{\partial q^0}dq^0,
$$

it follows that

$$
\hat{\mathbf{G}}(df,dq^0)=\frac{\partial f}{\partial q^i}\hat{G}^{i0}+\frac{\partial f}{\partial q^0}\hat{G}^{00}=A^i\frac{\partial f}{\partial q^i}+2U\frac{\partial f}{\partial q^0}.
$$

This shows that

$$
dq^0=(\mathbf{A},2U)^{\flat}.
\tag{4.18}
$$

Remark 4.9: A 1-form $\hat{\varphi}$ on $\hat{Q}$ is represented by a pair (φ,φ_0), where φ is a q^0-dependent 1-form on Q and φ_0 is a function on $\hat{Q}$. In local coordinates (q^i,q^0) we have $\hat{\varphi}=\hat{\varphi}_A\,dq^A=\varphi_i\,dq^i+\varphi_0\,dq^0$, where $\varphi=\varphi_i\,dq^i$. For any vector field $\hat{\mathbf{X}}=(\mathbf{X},\xi)$,

$$
\langle\hat{\mathbf{X}},\hat{\varphi}\rangle=\langle\mathbf{X},\varphi\rangle+\xi\varphi_0.
\tag{4.19}
$$

We say that $\hat{\varphi}$ is a *basic 1-form* if

$$
\varphi_0=\langle\hat{\mathbf{X}}_0,\hat{\varphi}\rangle=0.
\tag{4.20}
$$

The contravariant components of the image of a 1-form $\hat{\varphi}$ by a symmetric 2-tensor $\hat{\mathbf{K}}$ are

$$\begin{aligned}\hat{K}^{AB}\hat{\varphi}_B &= (\hat{K}^{ij}\varphi_j + \hat{K}^{i0}\varphi_0, \hat{K}^{0i}\varphi_i + \hat{K}^{00}\varphi_0)\\ &= (\hat{K}^{ij}\varphi_j + C^i\varphi_0, C^i\varphi_i + 2F\varphi_0).\end{aligned} \tag{4.21}$$

This shows that the eigenform equation $\hat{\mathbf{K}}\hat{\varphi} = \lambda\hat{\varphi}$ is equivalent to equations

$$\begin{aligned}&\mathbf{K}\varphi + \varphi_0\mathbf{C}^\flat = \lambda(\varphi + \varphi_0\mathbf{A}^\flat),\\ &\langle \mathbf{C}, \varphi\rangle + 2F\varphi_0 = \lambda(\langle \mathbf{A}, \varphi\rangle + 2U\varphi_0).\end{aligned} \tag{4.22}$$

For a basic eigenform these equations become

$$\begin{aligned}&\mathbf{K}\varphi = \lambda\varphi,\\ &\langle \mathbf{C}, \varphi\rangle = \lambda\langle \mathbf{A}, \varphi\rangle.\end{aligned} \tag{4.23}$$

V. SEPARABLE KILLING WEBS IN THE EXTENDED METRIC

Assume that the extended geodesic Hamiltonian $\hat{G}$ is separable. According to the general theory of the geodesic separability, this fact is characterized by the existence of a separable Killing web,

$$(\hat{\mathcal{S}}^a, \hat{D}, \hat{\mathbf{K}}), \tag{5.1}$$

where (I) $\hat{\mathcal{S}}^a$ is a set of m orthogonal foliations of submanifolds of codimension 1 ($a = 1,...,m$); (II) $\hat{D}$ is a $r+1$-dimensional linear space of commuting Killing vectors ($m + r = n$). These Killing vectors are tangent to the orbits of $\hat{D}$, and these orbits coincide with the complete intersections of the leaves of the foliations $\hat{\mathcal{S}}^a$; (III) $\hat{\mathbf{K}}$ is a Killing tensor of order 2. (III.a) $\hat{\mathbf{K}}$ is $\hat{D}$-invariant (it commutes with all elements of $\hat{D}$); (III.b) $\hat{\mathbf{K}}$ has m main eigenvectors orthogonal to the leaves of $\hat{\mathcal{S}}^a$, corresponding to distinct eigenvalues. It follows that locally on $\hat{Q}$ there are m independent functions $(\hat{q}^a)$ such that $(d\hat{q}^a)$ are characteristic 1-forms of the web, so that

$$\hat{\mathbf{K}}\, dq^a = \lambda^a\, dq^a, \quad \langle \hat{\mathbf{X}}, d\hat{q}^a\rangle = 0, \quad \forall \hat{\mathbf{X}} \in \hat{D}, \tag{5.2}$$

and

$$\hat{\mathbf{G}}(d\hat{q}^a, d\hat{q}^b) = 0, \quad a \neq b. \tag{5.3}$$

As it will be justified below, it is interesting to consider the particular case in which the fundamental vertical vector field $\hat{\mathbf{X}}_0$ is an element of $\hat{D}$.

Proposition 5.1: A separable Killing web $(\hat{\mathcal{S}}^a, \hat{D}, \hat{\mathbf{K}})$ on the extended manifold $\hat{Q}$, such that $\hat{\mathbf{X}}_0 \in \hat{D}$, is reducible to a separable Killing web on Q,

$$(\mathcal{S}^a, D, \mathbf{K}). \tag{5.4}$$

The meaning of the term ''reducible'' is explained in the following proof.

Proof: Since the second equation (5.2) implies in particular

$$\langle \hat{\mathbf{X}}_0, d\hat{q}^a\rangle = 0, \tag{5.5}$$

the functions $(\hat{q}^a)$ are vertically invariant and reduce to functions (q^a) on Q, so that, according to Remark 4.2, we can use the simplified notation $\hat{q}^a = q^a$. As a consequence, the web $(\hat{\mathcal{S}}^a)$ reduces to a web $(\mathcal{S}^a)$ with characteristic 1-forms (dq^a). Because of (4.4) and (5.3),

$$\mathbf{G}(dq^a, dq^b) = \hat{\mathbf{G}}(dq^a, dq^b) = 0 \quad (a \neq b) \tag{5.6}$$

and the reduced web is orthogonal. According to Propositions 4.5 and 4.6, the Killing vectors $\hat{\mathbf{X}} = (\mathbf{X}, \xi) \in \hat{D}$ reduce to commuting Killing vectors $\mathbf{X}$ on Q and form a space D of dimension $r = n - m$ (one dimension is lost by the vertical vector $\hat{\mathbf{X}}_0 \in \hat{D}$, which projects onto the zero vector field of Q). Since (dq^a) are basic 1-forms, from (4.19) it follows that

$$\langle \mathbf{X}, dq^a \rangle = \langle \hat{\mathbf{X}}, dq^a \rangle = 0. \tag{5.7}$$

Thus, the reduced Killing vectors are tangent to the leaves of the reduced web. The Killing tensor $\hat{\mathbf{K}}$ reduces to a Killing tensor $\mathbf{K}$ on Q (Proposition 4.7). The reduced Killing tensor commutes with all the reduced Killing vectors of D; the proof that $[\hat{\mathbf{X}}, \hat{\mathbf{K}}] = 0$ implies $[\mathbf{X}, \mathbf{K}] = 0$ is similar to that in the proof of Proposition 4.6. Finally, because of (4.23), the eigenform equation (5.2) reduces to equation

$$\mathbf{K}\, dq^a = \lambda^a\, dq^a,$$

and this shows that the reduced characteristic 1-forms (dq^a) are eigenforms of $\mathbf{K}$ corresponding to the distinct eigenvalues (λ^a). Since these eigenvalues are vertically invariant, they reduce to functions on Q.

■

Remark 5.2: If we choose a local basis $(\hat{\mathbf{X}}_\alpha, \hat{\mathbf{X}}_0)$ of $\hat{D}$ including the fundamental vertical vector field and a local section $\hat{\mathcal{Z}}$ orthogonal to the orbits of $\hat{D}$, then normal separable coordinates $(\hat{q}^A) = (\hat{q}^a, \hat{q}^\alpha, \hat{q}^0)$ are defined on $\hat{Q}$ such that $\hat{q}^a = q^a$,

$$\frac{\partial}{\partial \hat{q}^\alpha} = \hat{\mathbf{X}}_\alpha, \quad \frac{\partial}{\partial \hat{q}^0} = \hat{\mathbf{X}}_0, \tag{5.8}$$

and

$$\langle \hat{\mathbf{X}}_0, d\hat{q}^0 \rangle = 1, \quad \langle \hat{\mathbf{X}}_0, d\hat{q}^\alpha \rangle = 0, \quad \langle \hat{\mathbf{X}}_\alpha, d\hat{q}^0 \rangle = 0, \quad \langle \hat{\mathbf{X}}_\alpha, d\hat{q}^\beta \rangle = \delta^\beta_\alpha. \tag{5.9}$$

According to the general theory of the geodesic separation, the m separable coordinates (q^a) are essential, the $r+1$ coordinates $(\hat{q}^\alpha, \hat{q}^0)$ are ignorable, and the contravariant components of the extended metric

$$\hat{G}^{AB} = \hat{\mathbf{G}}(d\hat{q}^A, d\hat{q}^B), \tag{5.10}$$

have a form similar to (3.4) and (3.5), with one additional line and row with index 0 (index of first-class),

$$\begin{gathered} \hat{G}^{ab} = 0 \quad (a \neq b), \quad \hat{G}^{a\alpha} = 0, \quad \hat{G}^{a0} = 0, \\ \hat{G}^{aa} = \varphi^a_{(m)}, \quad \hat{G}^{00} = \phi_a \hat{G}^{aa}, \quad \hat{G}^{\alpha 0} = \phi^\alpha_a \hat{G}^{aa}, \quad \hat{G}^{\alpha\beta} = \phi^{\alpha\beta}_a \hat{G}^{aa}, \end{gathered} \tag{5.11}$$

where ϕ_a, ϕ^α_a, $\phi^{\alpha\beta}_a$ are functions of the coordinate corresponding to the lower index only. Furthermore, since all the elements of $\hat{D}$ commute, we have in particular $[\hat{\mathbf{X}}_0, \hat{\mathbf{X}}_\alpha] = 0$, and, due to (5.9), also the coordinates $(\hat{q}^\alpha)$ reduce to coordinates (q^α) on Q, so that we can use the simpler notation q^α instead of $\hat{q}^\alpha$. It follows that (q^a, q^α) is a normal separable coordinate system asso-

ciated with the reduced separable Killing web (5.4). However, as we shall see below, these coordinates are not separable with respect to the complete Hamiltonian H (1.1). For the separability of H further conditions are required. From the first characteristic equation of the extended metric (4.4) it follows that

$$\begin{aligned}\hat{G}^{ab}&=\hat{\mathbf{G}}(dq^a,dq^b)=\mathbf{G}(dq^a,dq^b)=g^{ab},\\ \hat{G}^{a\alpha}&=\hat{\mathbf{G}}(dq^a,dq^\alpha)=\mathbf{G}(dq^a,dq^\alpha)=g^{a\alpha},\\ \hat{G}^{\alpha\beta}&=\hat{\mathbf{G}}(dq^\alpha,dq^\beta)=\mathbf{G}(dq^\alpha,dq^\beta)=g^{\alpha\beta}.\end{aligned} \tag{5.12}$$

Hence, the comparison with (5.11) shows that the metric components (g^{ij}) maintain the same expressions (3.4) and (3.5),

$$\begin{aligned}&g^{ab}=0 \quad (a\neq b), \quad g^{aa}=\varphi^a_{(m)},\\ &g^{a\alpha}=0, \quad g^{\alpha\beta}=g^{aa}\phi_a^{\alpha\beta}=\varphi^a_{(m)}\phi_a^{\alpha\beta}.\end{aligned} \tag{5.13}$$

Remark 5.3: The natural coordinate q^0 of $\hat{Q}$ does not coincide with the separable coordinate $\hat{q}^0$ determined by $\hat{\mathbf{X}}_0$ in the basis of $\hat{D}$. As for any function of $\hat{Q}$, we can consider the differential of q^0 in the coordinates $(\hat{q}^A)=(q^a,q^\alpha,\hat{q}^0)$, written in the form

$$dq^0=f\,d\hat{q}^0+f_\alpha\,dq^\alpha+\xi_a\,dq^a.$$

Since we have $\langle\hat{\mathbf{X}}_0,dq^0\rangle=1$ because of the definition of $\hat{\mathbf{X}}_0$, from (5.9) and (5.5) (where $\hat{q}^\alpha=q^\alpha$, $\hat{q}^a=q^a$) it follows that $f=1$. Moreover, by applying to both sides of this equation the Killing vector $\hat{\mathbf{X}}_\alpha=(\mathbf{X}_\alpha,\xi_\alpha)$, due again to (5.9) and to (5.2) we get

$$\langle\hat{\mathbf{X}}_\alpha,d\hat{q}^0+f_\alpha\,dq^\alpha+\xi_a\,dq^a\rangle=f_\alpha, \quad \langle\hat{\mathbf{X}}_\alpha,dq^0\rangle=\langle\mathbf{X}_\alpha+\xi_\alpha\hat{\mathbf{X}}_0,dq^0\rangle=\xi_\alpha,$$

so that $f_\alpha=\xi_\alpha$. Hence,

$$dq^0=d\hat{q}^0+\xi_\alpha\,dq^\alpha+\xi_a\,dq^a, \tag{5.14}$$

where (ξ_α) are just the vertical components of the Killing vectors $(\hat{\mathbf{X}}_\alpha)$. Since the Killing vectors commute with $\hat{\mathbf{X}}_0$, these components reduce to functions on Q. By developing the commutation relations

$$\begin{aligned}0&=\left[\frac{\partial}{\partial\hat{q}^a},\frac{\partial}{\partial\hat{q}^\alpha}\right]=\left[\frac{\partial}{\partial\hat{q}^a},\hat{\mathbf{X}}_\alpha\right]\\ &=\left[\frac{\partial}{\partial\hat{q}^a},\mathbf{X}_\alpha+\xi_\alpha\hat{\mathbf{X}}_0\right]=\left[\frac{\partial}{\partial q^a},\mathbf{X}_\alpha\right]+\frac{\partial\xi_\alpha}{\partial q^a}\hat{\mathbf{X}}_0\\ &=\partial_a\xi_\alpha\hat{\mathbf{X}}_0,\end{aligned}$$

we find that

$$\partial_a\xi_\alpha=0. \tag{5.15}$$

By differentiating Eq. (5.14), we find equation

$$d\xi_\alpha\wedge dq^\alpha+d\xi_a\wedge dq^a=0.$$

Due to (5.15) and the q^0-independence of ξ_α, we obtain

$$\partial_\beta \xi_\alpha \, dq^\beta \wedge dq^\alpha + \partial_\alpha \xi_a \, dq^\alpha \wedge dq^a + \partial_b \xi_a \, dq^b \wedge dq^a + \partial_0 \xi_a \, dq^0 \wedge dq^a = 0.$$

It follows that

$$\partial_\alpha \xi_\beta = \partial_\beta \xi_\alpha, \quad \partial_\alpha \xi_a = 0, \quad \partial_a \xi_b = \partial_b \xi_a, \quad \partial_0 \xi_a = 0. \tag{5.16}$$

The last equation (5.16) shows that also the functions (ξ_a) appearing in (5.14) are q^0-independent. The remaining equations show that on Q there exist local functions $S_1(q^a)$ and $S_2(q^\alpha)$ depending on the essential coordinates (q^a) and on the ignorable coordinates (q^α), respectively, such that

$$\xi_a = \partial_a S_1, \quad \xi_\alpha = \partial_\alpha S_2. \tag{5.17}$$

Thus, the link (5.14) between q^0 and $\hat{q}^0$ takes the form

$$d\hat{q}^0 = dq^0 - d(S_1 + S_2), \quad S_1 = S_1(q^a), \quad S_2 = S_2(q^\alpha). \tag{5.18}$$

Remark 5.4: From Eqs. (4.4) it follows that

$$\begin{gathered}\hat{\mathbf{G}}(dq^a, dq^0) = \langle \mathbf{A}, dq^a \rangle = A^a, \\ \hat{\mathbf{G}}(dq^\alpha, dq^0) = \langle \mathbf{A}, dq^\alpha \rangle = A^\alpha, \\ \hat{\mathbf{G}}(dq^0, dq^0) = 2U.\end{gathered} \tag{5.19}$$

On the other hand, from (5.14), using (5.11) and (5.12), and recalling that $\hat{q}^a = q^a$, $\hat{q}^\alpha = q^\alpha$, we derive

$$\begin{aligned}\hat{\mathbf{G}}(dq^a, dq^0) &= \hat{\mathbf{G}}(dq^a, d\hat{q}^0) + \hat{\mathbf{G}}(dq^a, dq^\alpha)\xi_\alpha + \hat{\mathbf{G}}(dq^a, dq^b)\xi_b \\ &= \hat{G}^{a0} + \hat{G}^{a\alpha}\xi_\alpha + \hat{G}^{ab}\xi_b = \hat{G}^{aa}\xi_a = g^{aa}\xi_a, \\ \hat{\mathbf{G}}(dq^\alpha, dq^0) &= \hat{\mathbf{G}}(dq^\alpha, d\hat{q}^0) + \hat{\mathbf{G}}(dq^\alpha, dq^\beta)\xi_\beta + \hat{\mathbf{G}}(dq^\alpha, dq^b)\xi_b \\ &= \hat{G}^{\alpha 0} + \hat{G}^{\alpha\beta}\xi_\beta + \hat{G}^{ab}\xi_b = \hat{G}^{aa}\phi_a^\alpha + \hat{G}^{\alpha\beta}\xi_\beta = g^{aa}\phi_a^\alpha + g^{\alpha\beta}\xi_\beta, \\ \hat{\mathbf{G}}(dq^0, dq^0) &= \hat{\mathbf{G}}(d\hat{q}^0, d\hat{q}^0) + \hat{\mathbf{G}}(dq^\alpha, dq^\beta)\xi_\alpha\xi_\beta + \hat{\mathbf{G}}(dq^a, dq^b)\xi_a\xi_b \\ &\quad + 2\hat{G}(d\hat{q}^0, dq^\alpha)\xi_\alpha + 2\hat{\mathbf{G}}(d\hat{q}^0, dq^a)\xi_a + 2\hat{\mathbf{G}}(dq^\alpha, dq^a)\xi_\alpha\xi_a \\ &= \hat{G}^{00} + \hat{G}^{\alpha\beta}\xi_\alpha\xi_\beta + \hat{G}^{ab}\xi_a\xi_b + 2\hat{G}^{\alpha 0}\xi_\alpha = g^{aa}(\phi_a + \phi_a^{\alpha\beta}\xi_\alpha\xi_\beta + \xi_a^2 + 2\phi_a^\alpha\xi_\alpha).\end{aligned} \tag{5.20}$$

The comparison of Eqs. (5.19) and (5.20) shows that

$$\begin{gathered}A^a = g^{aa}\xi_a, \\ A^\alpha = g^{aa}\phi_a^\alpha + g^{\alpha\beta}\xi_\beta = g^{aa}(\phi_a^\alpha + \phi_a^{\alpha\beta}\xi_\beta), \\ 2U = g^{aa}(\phi_a + \phi_a^{\alpha\beta}\xi_\alpha\xi_\beta + \xi_a^2 + 2\phi_a^\alpha\xi_\alpha).\end{gathered} \tag{5.21}$$

We can summarize the preceding remarks in the following.

Proposition 5.5: If the extended metric admits a separable Killing web $(\hat{\mathcal{S}}^a, \hat{D}, \hat{\mathbf{K}})$ with $\hat{\mathbf{X}}_0 \in \hat{D}$, then on Q there exists a coordinate system (q^a, q^α) such that the components of $\mathbf{G}$ and $\mathbf{A}$ and the function U assume the form (5.13), (5.21), with $(\phi_a^\alpha, \phi_a^{\alpha\beta}, \phi_a)$ functions of the coordinate corresponding to the lower index only, and $\xi_i = \partial_i(S_1 + S_2)$, with $S_1(q^a)$ and $S_2(q^\alpha)$ functions of the essential coordinates (q^a) and of the ignorable coordinates (q^α), respectively.

Remark 5.6: From Eqs. (5.21) we observe that the vector field $\mathbf{A}$ is a sum of three vectors:

$$\mathbf{A}=\mathbf{A}_{(1)}+\mathbf{A}_{(2)}+\mathbf{A}_{(3)},$$

$$\mathbf{A}_{(1)}=g^{aa}\xi_a\mathbf{X}_a=\nabla S_1, \qquad \mathbf{A}_{(2)}=g^{\alpha\beta}\xi_\beta\mathbf{X}_\alpha=\nabla S_2=g^{aa}\phi_a^{\alpha\beta}\xi_\beta\mathbf{X}_\alpha, \tag{5.22}$$

$$\mathbf{A}_{(3)}=g^{aa}\phi_a^\alpha\mathbf{X}_\alpha,$$

where

$$\mathbf{X}_a=\partial_a=\frac{\partial}{\partial q^a}, \quad \mathbf{X}_\alpha=\partial_\alpha=\frac{\partial}{\partial q^\alpha}. \tag{5.23}$$

Since $\mathbf{X}_a\cdot\mathbf{X}_\alpha=0$, both vectors $\mathbf{A}_{(2)}$ and $\mathbf{A}_{(3)}$ are orthogonal to $\mathbf{A}_{(1)}$:

$$\mathbf{A}_{(1)}\cdot\mathbf{A}_{(2)}=0, \quad \mathbf{A}_{(1)}\cdot\mathbf{A}_{(3)}=0. \tag{5.24}$$

From the last equation (5.21) we get the following decomposition for the function U:

$$U=\tfrac{1}{2}\mathbf{A}_{(1)}\cdot\mathbf{A}_{(1)}+\tfrac{1}{2}\mathbf{A}_{(2)}\cdot\mathbf{A}_{(2)}+\mathbf{A}_{(2)}\cdot\mathbf{A}_{(3)}+V^0, \tag{5.25}$$

where

$$V^0=g^{aa}\phi_a \tag{5.26}$$

is a Stäckel multiplier. From (1.2), (5.22), (5.24), and (5.25) we derive the following expression for the (physical) scalar potential:

$$V=U-\tfrac{1}{2}\mathbf{A}\cdot\mathbf{A}=V^0-\tfrac{1}{2}\mathbf{A}_{(3)}\cdot\mathbf{A}_{(3)}. \tag{5.27}$$

Remark 5.7: Let us consider the reduced separable Killing web $(\mathcal{S}^a,D,\mathbf{K})$ of Proposition 5.1. Each foliation $\mathcal{S}^a$ is locally represented by equation $q^a=\text{const}$, the vectors $\mathbf{X}_\alpha=\partial_\alpha$ form a local basis of D, and the vectors $\mathbf{X}_a=\partial_a$ are eigenvectors of $\mathbf{K}$ orthogonal to D. Then the function S_1 is constant on the orbits of D, since it depends on the coordinates (q^a) only, while the function S_2 is constant on the submanifolds orthogonal to the orbits of D, since $\langle\mathbf{X}_a,dS_2\rangle=\partial_aS_2=0$. Hence, the vectors of the decomposition (5.22) are completely characterized by the following properties:

$$\begin{gathered}\mathbf{A}_{(1)} \text{ is a gradient of the orbits of } D,\\ \mathbf{A}_{(2)} \text{ is a gradient of the foliation orthogonal to the orbits of } D,\\ \mathbf{A}_{(3)} \text{ is tangent to the orbits of } D \text{ and its components in any}\\ \text{basis of } D \text{ are Stäckel multipliers.}\end{gathered} \tag{5.28}$$

Here, by *gradient of a foliation* we mean a vector field which is the gradient of a function constant on the leaves of the foliation (i.e., the corresponding 1-form is the differential of a function constant on the leaves). It follows in particular that $\mathbf{A}_{(1)}$ and $\mathbf{A}_{(3)}$ are D-invariant.

Remark 5.8: As a consequence of the expressions (5.13) and (5.21), the Hamilton–Jacobi equation (1.5) can be written in the form

$$\tfrac{1}{2}\varphi^a_{(m)}(\overline{p}_a^2+\phi_a^{\alpha\beta}\overline{p}_\alpha\overline{p}_\beta+2\phi_a^\alpha\overline{p}_\alpha+\phi_a)=h, \tag{5.29}$$

by setting

$$\overline{p_i}=p_i+\xi_i=p_i+\partial_i(S_1+S_2)\Leftrightarrow\begin{cases}\overline{p_a}=p_a+\xi_a=p_a+\partial_a S_1,\\ \overline{p_\alpha}=p_\alpha+\xi_\alpha=p_\alpha+\partial_\alpha S_2.\end{cases}\tag{5.30}$$

We can consider this equation as the last one of the following system of m equations:

$$\varphi^a_{(b)}(\overline{p}^2_a+\phi^{\alpha\beta}_a\overline{p}_\alpha\overline{p}_\beta+2\phi^\alpha_a\overline{p}_\alpha+\phi_a)=c_b,\tag{5.31}$$

where (c_b) are m arbitrary constants, and $c_m=2h$. By applying the Stäckel matrix $[\varphi^{(b)}_a]$ we get the equivalent system

$$\overline{p}^2_a+\phi^{\alpha\beta}_a\overline{p}_\alpha\overline{p}_\beta+2\phi^\alpha_a\overline{p}_\alpha+\phi_a=\varphi^{(b)}_a c_b.\tag{5.32}$$

By setting $\overline{p}_\alpha=c_\alpha=\text{const}$, this system splits into m separated equations:

$$(p_a+\partial_a S_1)^2=\Phi_a(q^a,\underline{c}),\quad p_\alpha=c_\alpha-\partial_\alpha S_2,\tag{5.33}$$

where

$$\Phi_a(q^a,\underline{c})=\varphi^{(b)}_a c_b-\phi^{\alpha\beta}_a c_\alpha c_\beta-2\phi^\alpha_a c_\alpha-\phi_a\tag{5.34}$$

are functions of the coordinate corresponding to the index only, and (in general) of all the n constants $\underline{c}=(c_b,c_\alpha)$. If we consider the integrals (with any choice of the signs)

$$W_a(q^a,\underline{c})=\pm\int\sqrt{\Phi_a(q^a,\underline{c})}dq^a,\tag{5.35}$$

then we build a complete solution of the Hamilton–Jacobi equation of the form

$$W=c_\alpha q^\alpha+\sum_a W_a-S,\quad S=S_1+S_2.\tag{5.36}$$

We observe that this is not a separated complete solution, due to the presence of the function S, which is not in general a sum of functions of single coordinates. However, this function does not contain the constants $\underline{c}$.

Hence, we are led to consider a more general kind of separation.

Definition 5.9: A Hamiltonian is *gauge-separable* if the corresponding Hamilton–Jacobi equation admits a complete solution of the form

$$W(\underline{q},\underline{c})=\sum_{i=1}^n W_i(q^i,\underline{c})-S(\underline{q}).\tag{5.37}$$

The gauge-separation is also called *R-separation* in connection with the multiplicative separation of the Helmholtz equation.[17]

Thus, we have proved

Proposition 5.10: If the extended metric admits a separable Killing web with $\hat{\mathbf{X}}_0\in\hat{D}$, then the Hamiltonian H (1.1) is gauge separable.

Remark 5.11: We have the ordinary separation of the Hamiltonian H if and only if (ξ_a) and (ξ_α) are functions of the coordinate corresponding to the index only, i.e.,

$$\partial_b\xi_a=0\quad(a\neq b),\quad\partial_\beta\xi_\alpha=0\quad(\alpha\neq\beta).\tag{5.38}$$

Since these functions are the covariant components of the vectors $\mathbf{A}_{(1)}$ and $\mathbf{A}_{(2)}$, it follows that the first equation (5.38) and the second equation (5.38) are, respectively, equivalent to the following two conditions:

$$\begin{aligned}&(1)\ \mathbf{A}_{(1)}\ \text{is the sum of gradients of the foliations } S^a,\\ &(2)\ \text{there is a basis } (\mathbf{X}_\alpha)\ \text{of } D\ \text{such that } \langle \mathbf{X}_\alpha, d(\mathbf{A}_{(2)}\cdot\mathbf{X}_\beta)\rangle = 0\ \text{ for }\ \alpha\neq\beta.\end{aligned} \tag{5.39}$$

Furthermore, going back to (5.14), we remark that conditions (5.38) are necessary and sufficient for the separability of the coordinate system (q^a,q^α,q^0), which in this case is equivalent to the coordinate system $(q^a,q^\alpha,\hat{q}^0)$ associated with the separable Killing web on the extended manifold.

VI. FINAL STATEMENTS AND REMARKS

From the discussion in the preceding section we can derive the following theorem on the intrinsic characterization of the separation of a natural Hamiltonian with scalar and vector potential.

Theorem 6.1: The Hamiltonian (1.1) is separable if and only if (i) on Q there exists a separable Killing web $(\mathcal{S}^a,D,\mathbf{K})$; (ii) the vector field $\mathbf{A}$ is a sum of three vectors,

$$\mathbf{A}=\mathbf{A}_{(1)}+\mathbf{A}_{(2)}+\mathbf{A}_{(3)},$$

where (ii.1) $\mathbf{A}_{(1)}$ is locally the sum of gradients of the foliations $\mathcal{S}^a$, (ii.2) $\mathbf{A}_{(2)}$ is locally a gradient of the foliation orthogonal to the orbits of D, and there exists a basis $(\mathbf{X}_\alpha)$ of D $(\alpha=m+1,\ldots,n)$ such that

$$\langle \mathbf{X}_\alpha, d(\mathbf{A}_{(2)}\cdot\mathbf{X}_\beta)\rangle = 0 \quad \text{for}\ \ \alpha\neq\beta;$$

(ii.3) $\mathbf{A}_{(3)}$ is tangent to the orbits of D and its components $A^\alpha_{(3)}$ with respect to any basis $(\mathbf{X}_\alpha)$ of D are Stäckel multipliers,

$$\langle \mathbf{X}, dA^\alpha_{(3)}\rangle = 0,\ \ \forall \mathbf{X}\in D, \quad d(\mathbf{K}\,dA^\alpha_{(3)})=0;$$

(iii) the function V is a sum

$$V=V^0-\tfrac{1}{2}\mathbf{A}_{(3)}\cdot\mathbf{A}_{(3)},$$

where V^0 is a Stäckel multiplier,

$$\langle \mathbf{X}, dV^0\rangle = 0, \quad \forall \mathbf{X}\in D, \quad d(\mathbf{K}\,dV^0)=0.$$

Proof: Assume that the Hamiltonian (1.1) is separable in a coordinate system (q^i). Then (Remark 4.4) the extended metric is separable in the coordinate system (q^i,q^0), with q^0 ignorable. As a consequence, on $\hat{Q}$ there exists a separable Killing web (5.1). Since q^0 is ignorable, the vector field ∂_0 belongs to $\hat{D}$. But this vector coincides with the fundamental vector field $\hat{\mathbf{X}}_0$. Thus, we are in the situation considered in Sec. V, and because of Proposition 5.5, Remarks 5.6–5.7, Proposition 5.10, and Remark 5.11, the conditions (i)–(iii) are fulfilled. Conversely, assume that these conditions are satisfied. Then, because of Remarks 5.7, 5.8, and 5.11, the Hamilton–Jacobi equation admits a separated solution.

■

Remark 6.2: The separable coordinates (q^α) are ignorable (hence, of first class) with respect to both the geodesic Hamiltonians $\hat{G}$ and G but in general they could be nonignorable and of second class for the Hamiltonian H, due to the presence of the functions ξ_α in the components of the vector potential. More precisely, an ignorable coordinate q^α is also of first class and ignorable in the whole Hamiltonian H if and only if the corresponding function ξ_α is constant. To see this, we consider the Hamiltonian written in the form

$$H=\tfrac{1}{2}g^{\alpha\beta}(p_\alpha+A_\alpha)(p_\beta+A_\beta)+\tfrac{1}{2}g^{aa}(p_a+A_a)^2+V.$$

The coordinates (q^α) appear only in the components (A_α). Because of (5.21),

$$A_\alpha = \xi_\alpha + g^{aa} g_{\alpha\beta} \phi_a^\beta,$$

so that $\partial_\alpha A_\beta = \partial_\alpha \xi_\beta = \delta_{\alpha\beta} \xi_\alpha^0$, where $\xi_\alpha^0 = \partial_\alpha \xi_\alpha$. Thus,

$$\frac{\partial_\alpha H}{\partial^\alpha H} = \frac{g^{\beta\gamma}(p_\beta + A_\beta)\partial_\alpha \xi_\gamma}{g^{\alpha\beta}(p_\beta + A_\beta)} = \xi_\alpha^0,$$

and this fraction becomes a linear (homogeneous) function in the momenta if and only if $\xi_\alpha^0 = 0$; in this case, $\partial_\alpha H = 0$.

Remark 6.3: The only physically interesting component of the vector potential $\mathbf{A}$ is $\mathbf{A}_{(3)}$, since the other two components are gradients and do not influence the motion of the system in the configuration space. Since the orbits in the configuration space are determined, via the Jacobi method, by the partial derivatives of W with respect to the constants $\underline{c}$, the independence of the motions from the gradient components can also be observed by the expressions of the separated solution (5.34)–(5.36), where the covariant components (ξ_a) and (ξ_α) of $\mathbf{A}_{(1)}$ and $\mathbf{A}_{(2)}$ do not appear explicitly. It follows, in particular, that there are no physically interesting separable systems with a vector potential $\mathbf{A}$, without the occurrence of symmetries (Killing vectors), since in this case $\mathbf{A}_{(3)}$ vanishes.

After this last remark we can confine our interest to the case $\mathbf{A}_{(1)} = \mathbf{A}_{(2)} = 0$, that is $\mathbf{A} = \mathbf{A}_{(3)}$, and consider the following simplified version of Theorem 6.1.

Theorem 6.4: The Hamiltonian (1.1) is separable if and only if (i) on Q there exists a characteristic Killing pair $(D, \mathbf{K})$, (ii) up to a gauge transformation the vector potential $\mathbf{A}$ is D-invariant, tangent to the orbits of D and its components (A^α) with respect to any basis $(\mathbf{X}_\alpha)$ of D are Stäckel multipliers,

$$\langle \mathbf{X}, dA^\alpha \rangle = 0, \quad \forall \mathbf{X} \in D, \quad d(\mathbf{K}\, dA^\alpha) = 0; \tag{6.1}$$

(iii) the scalar potential V is a sum

$$V = U - \tfrac{1}{2}\mathbf{A}\cdot\mathbf{A} \tag{6.2}$$

where U is a Stäckel multiplier,

$$\langle \mathbf{X}, dU \rangle = 0, \quad \forall \mathbf{X} \in D, \quad d(\mathbf{K}\, dU) = 0. \tag{6.3}$$

Remark 6.5: In (ii) the condition that $\mathbf{A}$ is D-invariant is redundant, since it follows from the other requirements. However, in view of the applications, it is convenient to mention it explicitly in the statement. We also observe that the Stäckel multiplier U in (6.2) is just the scalar part of the Hamiltonian (1.1). The expression (6.2) exhibits a relation of the ''physical'' potential energy V with the vector potential $\mathbf{A}$. This represents a very strong restriction for the separability of a physical system with $\mathbf{A} \neq 0$.

Remark 6.6: According to Theorem 6.4, the separation of a Hamilton–Jacobi equation always occurs in coordinates (q^a, q^α) for which (i) the metric tensor components assume the form (3.4)–(3.5); (ii) up to a gauge transformation the components of the vector potential have the form

$$A^a = 0, \quad A^\alpha = g^{aa} \phi_a^\alpha; \tag{6.4}$$

(iii) the scalar potentials have the form

$$U = g^{aa} \phi_a, \quad V = U - \tfrac{1}{2} g^{aa} g^{bb} \phi_a^\alpha \phi_b^\beta g_{\alpha\beta}, \tag{6.5}$$

where ϕ_a^α and ϕ_a are functions depending on the coordinate corresponding to the lower index only. All these expressions are derived from (5.21), with $\xi_a = 0$ and $\xi_\alpha = 0$. From (1.4) it follows that the Lagrangian forces are

$$F_a = -\partial_a V - \partial_a A_\alpha \dot{q}^\alpha, \quad F_\alpha = \partial_a A_\alpha \dot{q}^a. \tag{6.6}$$

In the case of a vanishing scalar potential, $V=0$, also the scalar product

$$\mathbf{A}\cdot\mathbf{A} = g^{aa} g^{bb} \phi_a^\alpha \phi_b^\beta g_{\alpha\beta} \tag{6.7}$$

must be a Stäckel multiplier. This is a further very strong restriction for the separability, which, however, disappears in the case $m=1$.

Remark 6.7: Theorem 6.4 has another interesting consequence. Let $(\mathbf{K}_b)$ $(b=1,...,m)$ be a basis of the Killing algebra $\mathcal{K}$ generated by the characteristic Killing pair $(D,\mathbf{K})$, with $\mathbf{K}_1=\mathbf{K}$ and $\mathbf{K}_m=\mathbf{G}$ [see item (J) of Sec. III]. Then, besides the $r=n-m$ linear first integrals $H_\alpha = P(\mathbf{X}_\alpha)$ associated with a basis of D, we have m independent quadratic (nonhomogeneous) first integrals in involution of the form

$$H_b = \tfrac{1}{2} P_{\mathbf{K}_b} + P_{\mathbf{A}_b} + U_b, \tag{6.8}$$

where $\mathbf{A}_b = A_b^\alpha \mathbf{X}_\alpha$ are m vector fields and U_b are m functions such that

$$\mathbf{K}_b\, dA^\alpha = dA_b^\alpha, \quad \mathbf{K}_b\, dU = dU_b. \tag{6.9}$$

Note that $\mathbf{A}_m=\mathbf{A}$ and $U_m=U$. In the separable coordinates (q^a,q^α), these objects have the following expressions, involving the inverse Stäckel matrix $[\varphi^a_{(b)}]$:

$$A_b^\alpha = \varphi^a_{(b)} \phi_a^\alpha, \quad U_b = \varphi^a_{(b)} \phi_a, \tag{6.10}$$

so that the final coordinate expressions of the first integrals are

$$\begin{aligned} H_\alpha &= p_\alpha, \\ H_b &= \tfrac{1}{2}\varphi^a_{(b)}(p_a^2 + \phi_a^{\alpha\beta} p_\alpha p_\beta + 2\phi_a^\alpha p_\alpha + 2\phi_a) \\ &= \tfrac{1}{2}\lambda^a_{(b)} g^{aa}(p_a^2 + \phi_a^{\alpha\beta} p_\alpha p_\beta + 2\phi_a^\alpha p_\alpha + 2\phi_a), \end{aligned} \tag{6.11}$$

where λ_b^a are the eigenvalues of the Killing tensors [see (3.9)]. For the case $\mathbf{A}=0$ they reduce to the expressions (3.15). These first integrals correspond to the constants of integration (c_b,c_α) of the separated Hamilton–Jacobi equations of the kind (5.31) (in the present case $\overline{p_\alpha}=p_\alpha=c_\alpha$). Thus, due to the Jacobi theorem, they are certainly first integrals in involution. However, it is interesting to prove that functions (6.8) are first integrals in involution, in a direct and intrinsic way, from their defining equations (6.8) and (6.9) and from the D-invariance, by analyzing their Poisson brackets with the Hamiltonian

$$H = H_m = \tfrac{1}{2} P_{\mathbf{G}} + P_{\mathbf{A}} + U.$$

We get

$$\begin{aligned} \{H_b,H\} = {} & \tfrac{1}{4}\{P_{\mathbf{K}_b}, P_{\mathbf{G}}\} + \tfrac{1}{2}\{P_{\mathbf{K}_b}, P_{\mathbf{A}}\} + \tfrac{1}{2}\{P_{\mathbf{A}_b}, P_{\mathbf{G}}\} + \tfrac{1}{2}\{P_{\mathbf{K}_b}, U\} \\ & + \{P_{\mathbf{A}_b}, P_{\mathbf{A}}\} + \tfrac{1}{2}\{U_b, P_{\mathbf{G}}\} + \{P_{\mathbf{A}_b}, U\} + \{U_b, P_{\mathbf{A}}\}. \end{aligned} \tag{6.12}$$

The terms in (6.12) are, in the order, polynomials of third, second, first, and 0th degree in the momenta. Thus, the Poisson brackets vanish iff these polynomials vanish separately. This gives rise to equations similar to (4.16),

$$
\begin{aligned}
&[\mathbf{G},\mathbf{K}_b]=0,\\
&[\mathbf{A}_b,\mathbf{G}]=[\mathbf{A},\mathbf{K}_b],\\
&[\mathbf{A}_b,\mathbf{A}]=\nabla U_b-\mathbf{K}_b\nabla U,\\
&\langle \mathbf{A}_b, dU\rangle=\langle \mathbf{A}, dU_b\rangle.
\end{aligned}
\tag{6.13}
$$

This shows, in other words, that the fact that (H_b) are first integrals in involution is equivalent to the fact that the 2-tensors $\hat{\mathbf{K}}_b=(\mathbf{K}_b,\mathbf{A}_b,U_b)$ in the extended manifold are Killing tensors in involution and form the Killing algebra $\hat{\mathcal{K}}$ associated with the characteristic Killing pair $(\hat{D},\hat{\mathbf{K}})$, where $\hat{D}$ is spanned by the vectors $\hat{\mathbf{X}}_\alpha=(\mathbf{X}_\alpha,0)$ and by $\hat{\mathbf{X}}_0$. The first equation (6.13) is just the Killing equation for $\mathbf{K}_b$. If we assume that all these objects, in particular the functions U_b (including $U_m=U$), are D-invariant (which is equivalent to assume that H_b and H_α are in involution) and that the vector fields $\mathbf{A}_b$ are tangent to D, then both terms on the right-hand side of the third equation (6.13) are orthogonal to D, while the Lie bracket at the left one is tangent to D. Hence, both sides vanish identically and we get the second equation (6.9) together with $[\mathbf{A}_b,\mathbf{A}]=0$. Under the same assumptions, both sides of the fourth equation (6.13) vanish identically. The second remaining equation (6.13) is equivalent to the first equation (6.9). The fact that all (H_b) are in involution can be proved in a similar way. We remark that all the vector potentials commute, $[\mathbf{A}_b,\mathbf{A}_a]=0$.

VII. ILLUSTRATIVE EXAMPLES

Let us apply the above results to the Euclidean three-space $Q=\mathbb{E}_3$. In the following examples we give only the expressions of separable scalar and vectors potentials, without entering in the details of the integration of the corresponding Hamilton–Jacobi equations. In $\mathbb{E}_3$ the Lagrangian forces (1.4) are the components of the Lorentz force

$$\mathbf{F}=\mathbf{B}\times\mathbf{v}-\nabla V,\quad \mathbf{B}=\nabla\times\mathbf{A},$$

where $\mathbf{v}$ is the velocity of the particle, ∇ is the gradient operator, $\nabla\times$ is the curl operator, and $\times$ is the cross product of vectors. We shall use the well-known formula

$$\nabla\times(f\mathbf{V})=\nabla f\times\mathbf{V}+f\nabla\times\mathbf{V},$$

for any smooth function f and vector field $\mathbf{V}$. We consider on $\mathbb{E}_3$ Cartesian rectangular coordinates (x, y, z) with origin at a point O and denote by $(\mathbf{X}, \mathbf{Y}, \mathbf{Z})$ the corresponding unit vectors. Due to Remark 6.3, only the cases of separable webs with symmetries (rotational or translational) are interesting for the separation of a vector potential. We consider for brevity and simplicity the cylindrical and the spherical web only (although the remaining two rotational webs, the prolate and oblate spheroidal ones, could be of some interest for the applications).

Example 1. The cylindrical web. In this first example we consider the cylindrical web around the z axis, made of cylinders around the axis, half-planes issued from the axis (the *meridian planes*) and planes orthogonal to the axis (the *equatorial planes*). These surfaces are, respectively, orthogonal to the vectors

$$(\mathbf{u}_z,\mathbf{R}_z,\mathbf{Z}),$$

where

$$\mathbf{u}_z=\frac{\mathbf{r}_z}{|\mathbf{r}_z|}$$

is the unit vector determined by the radius vector orthogonal to the z axis,

$$\mathbf{r}_z=\mathbf{r}-z\mathbf{Z}, \quad \mathbf{r}=x\mathbf{X}+y\mathbf{Y}+z\mathbf{Z}=r\mathbf{u},$$

and

$$\mathbf{R}_z=\mathbf{Z}\times\mathbf{r}$$

is the rotational vector around the z axis. The standard cylindrical coordinates are (ρ, θ, z), where ρ is the distance from the z axis, $\rho=|\mathbf{r}_z|$, and θ is the rotation angle around it, oriented as $\mathbf{R}_z$ and starting (for instance) from the (x, z) plane. Thus we have

$$\nabla\rho=\mathbf{u}_z, \quad |\mathbf{u}_z|=1,$$

$$\nabla\theta=\rho^{-2}\mathbf{R}_z, \quad |\mathbf{R}_z|=\rho=|\mathbf{r}_z|,$$

$$\nabla z=\mathbf{Z}, \quad |\mathbf{Z}|=1,$$

and from

$$\mathbf{p}=\mathbf{v}=p_\rho\nabla\rho+p_\theta\nabla\theta+p_z\nabla z=p_\rho\mathbf{u}_z+p_\theta\rho^{-2}\mathbf{R}_z+p_z\mathbf{Z},$$

we get the well-known expression of the geodesic Hamiltonian

$$G=\tfrac{1}{2}\mathbf{p}\cdot\mathbf{p}=\tfrac{1}{2}(p_\rho^2+\rho^{-2}p_\theta^2+p_z^2).$$

The curls of all vectors above are zero, with the exception of

$$\nabla\times\mathbf{R}_z=2\mathbf{Z}.$$

We have three inequivalent characteristic Killing pairs $(D,\mathbf{K})$ associated with this web.

Case 1. $r=\dim(D)=2$:

$$D=\mathrm{span}(\mathbf{Z},\mathbf{R}_z), \quad \mathbf{K}=\mathbf{G}.$$

With respect to this Killing pair, (θ, z) are first-class (ignorable), and ρ is the essential (second-class) coordinate, so that a Stäckel multiplier is any function $U(\rho)$. Thus in this case the most general separable vector potential has the form

$$\mathbf{A}=\phi(\rho)\mathbf{Z}+\psi(\rho)\mathbf{R}_z.$$

It follows that

$$\begin{aligned}\mathbf{B}=\nabla\times(\phi\mathbf{Z}+\psi\mathbf{R}_z)&=\nabla\phi\times\mathbf{Z}+\nabla\psi\times\mathbf{R}_z+2\psi\mathbf{Z}\\&=\phi'\mathbf{u}_z\times\mathbf{Z}+\psi'\mathbf{u}_z\times\mathbf{R}_z+2\psi\mathbf{Z}\\&=\phi'\rho^{-1}\mathbf{r}\times\mathbf{Z}+\psi'\rho\mathbf{Z}+2\psi\mathbf{Z},\end{aligned}$$

that is

$$\mathbf{B}=-\rho^{-1}\phi'\mathbf{R}_z+(\rho\psi'+2\psi)\mathbf{Z}=f(\rho)\mathbf{R}_z+h(\rho)\mathbf{Z},$$

where $f=-\rho^{-1}\phi'$, $h=\rho\psi'+2\psi$ are two independent functions. Since

$$\mathbf{A}\cdot\mathbf{A}=\phi^2(\rho)+\rho^2\psi(\rho)$$

is a function of ρ only, the most general separable scalar potential (6.2) is any function $V(\rho)$. Thus the Hamiltonian is

$$H=\tfrac{1}{2}\mathbf{p}^2+\mathbf{A}\cdot\mathbf{p}+U=\tfrac{1}{2}(p_\rho^2+\rho^{-2}p_\theta^2+p_z^2)+\phi(\rho)p_z+\rho^{-2}\psi(\rho)p_\theta+U(\rho).$$

Note that the Coriolis and centrifugal forces, appearing in a frame rotating around the z axis with constant angular velocity $\boldsymbol{\omega}=\omega\mathbf{Z}$ with respect to an inertial one, fits with this scheme, being

$$V=\tfrac{1}{2}\omega^2\rho^2,\quad \mathbf{A}=-\omega\mathbf{R}_z,\quad \omega\in\mathbb{R},$$

so that

$$\mathbf{F}=-2\omega\mathbf{Z}\times\mathbf{v}+\omega^2\rho\mathbf{u}_z.$$

Case 2. $r=1$:

$$D=\mathrm{span}(\mathbf{Z}),\quad \mathbf{K}=\mathbf{R}_z\otimes\mathbf{R}_z.$$

Note that $\mathbf{K}$ has eigenvectors $(\mathbf{u}_z,\mathbf{R}_z)$ orthogonal to D, with distinct eigenvalues $(0,\rho^2)$ (they coincide on the z axis, which is the singular set of the web). In this case only z is ignorable, while (ρ,θ) are essential coordinates, so that any Stäckel multiplier is of the kind

$$U=f(\rho)+\rho^{-2}h(\theta),$$

where $f(\rho)$ is any smooth function and $h(\theta)$ is any periodic smooth function (the same is understood for any function of θ considered below). Thus, a separable vector potential has the form

$$\mathbf{A}=(\phi(\rho)+\rho^{-2}\psi(\theta))\mathbf{Z},$$

and consequently

$$\mathbf{B}=\rho^{-1}(2\psi(\theta)\rho^{-3}-\phi'(\rho))\mathbf{R}_z+\psi'(\theta)\rho^{-3}\mathbf{u}_z.$$

The corresponding Hamiltonian is

$$H=\tfrac{1}{2}\mathbf{p}^2+\mathbf{A}\cdot\mathbf{p}+U=\tfrac{1}{2}(p_\rho^2+\rho^{-2}p_\theta^2+p_z^2)+(\phi(\rho)+\rho^{-2}\psi(\theta))p_z+f(\rho)+\rho^{-2}\psi(\theta).$$

Since

$$\mathbf{A}\cdot\mathbf{A}=\phi^2(\rho)+\rho^{-4}\psi^2(\theta)-2\rho^{-2}\psi(\rho)\psi(\theta),$$

the separable scalar potential (6.2) has the form

$$V=f(\rho)+\rho^{-2}h(\theta)-\tfrac{1}{2}\phi^2(\rho)-\tfrac{1}{2}\rho^{-4}\psi^2(\theta)-\rho^{-2}\phi(\rho)\psi(\theta),$$

i.e.,

$$V=f(\rho)+\rho^{-2}(h(\theta)-\phi(\rho)\psi(\theta))-\tfrac{1}{2}\rho^{-4}\psi^2(\theta),$$

where $f(\rho)$ and $h(\theta)$ are arbitrary functions, while $\phi(\rho)$ and $\psi(\theta)$ are the functions entering in the expressions of $\mathbf{A}$ and $\mathbf{B}$. In this case we have a quadratic first integral

$$H_1=\tfrac{1}{2}P_{\mathbf{K}_1}+P_{\mathbf{A}_1}+U_1,\quad \mathbf{K}_1=\mathbf{K}.$$

We compute its elements U_1 and $\mathbf{A}_1$ as follows: for any Stäckel multiplier U

$$\nabla U=(f'(\rho)-2\rho^{-3}h(\theta))\mathbf{u}_z+\rho^{-4}h'(\theta)\mathbf{R}_z$$

and

$$\mathbf{K}\nabla U=\rho^{-2}h'(\theta)\mathbf{R}_z,$$

since $\mathbf{R}_z \cdot \mathbf{u}_z = 0$ and $\mathbf{R}_z^2 = \rho^2$. It follows that

$$U_1 = h(\theta),$$

since $\nabla U_1 = h'(\theta)\nabla\theta = h'(\theta)\rho^{-2}\mathbf{R}_z$. By applying the same method to the component of $\mathbf{A}$ (which is a Stäckel multiplier) we find

$$\mathbf{A}_1 = \psi(\theta)\mathbf{Z}.$$

Thus the quadratic first integral is

$$H_1 = \tfrac{1}{2}(\mathbf{R}_z \cdot \mathbf{p})^2 + \mathbf{A}_1 \cdot \mathbf{p} + U_1 = \tfrac{1}{2}p_\theta^2 + \psi(\theta)p_z + h(\theta).$$

Case 3. $r = 1$:

$$D = \mathrm{span}(\mathbf{R}_z), \quad \mathbf{K} = \mathbf{Z} \otimes \mathbf{Z}.$$

The Killing tensor $\mathbf{K} = \mathbf{Z} \otimes \mathbf{Z}$ has eigenvectors $(\mathbf{Z}, \mathbf{u_z})$ orthogonal to D, with distinct eigenvalues (1, 0). In this case θ is ignorable, while (ρ, z) are essential coordinates. Thus any Stäckel multiplier has the form

$$U = f(\rho) + h(z),$$

and the most general separable vector potential is

$$\mathbf{A} = (\phi(\rho) + \psi(z))\mathbf{R}_z.$$

As a consequence,

$$\mathbf{B} = (\rho\phi'(\rho) + 2\phi(\rho) + 2\psi(z))\mathbf{Z} - \psi'(z)\rho\mathbf{u}_z.$$

The corresponding Hamiltonian is

$$H = \tfrac{1}{2}\mathbf{p}^2 + \mathbf{A} \cdot \mathbf{p} + U = \tfrac{1}{2}(p_\rho^2 + \rho^{-2}p_\theta^2 + p_z^2) + (\phi(\rho) + \psi(z))p_\theta + f(\rho) + h(z).$$

Since

$$\mathbf{A} \cdot \mathbf{A} = \rho^2(\phi^2(\rho) + \psi^2(z) + 2\phi(\rho)\psi(z)),$$

the separable scalar potential (6.2) has the form

$$V = f(\rho) + h(z) - \tfrac{1}{2}\rho^2(\phi^2(\rho) + \psi^2(z) + 2\phi(\rho)\psi(z)),$$

i.e.,

$$V = f(\rho) + h(z) - \rho^2(\tfrac{1}{2}\psi^2(z) + \phi(\rho)\psi(z)),$$

where $f(\rho)$, $h(z)$ are arbitrary functions, while $\psi(z)$, $\phi(\rho)$ are the functions entering in the expressions of $\mathbf{A}$ and $\mathbf{B}$. Also in this case we have a quadratic first integral H_1. Since

$$\nabla U = f'(\rho)\mathbf{u}_z + h'(z)\mathbf{Z}, \quad \mathbf{K}\nabla U = h'(z)\mathbf{Z},$$

we find $U_1 = h(z)$, and in a similar way, $\mathbf{A}_1 = \psi(z)\mathbf{R}_z$. Thus the quadratic first integral is

$$H_1 = \tfrac{1}{2}(\mathbf{Z} \cdot \mathbf{p})^2 + \mathbf{A}_1 \cdot \mathbf{p} + U_1 = \tfrac{1}{2}p_z^2 + \psi(z)p_\theta + h(z).$$

Example 2. The spherical web. This web is made of spheres around the origin, meridian half-planes (issued from the z axis), and circular cones around the axis with vertex at the origin. These surfaces are, respectively, orthogonal to the vectors

$$(\mathbf{r},\mathbf{R}_z,\mathbf{l}),$$

where $\mathbf{l}$ is the unit vector

$$\mathbf{l}=\frac{\mathbf{r}\times\mathbf{R}_z}{|\mathbf{r}\times\mathbf{R}_z|}=\frac{\mathbf{r}\times\mathbf{R}_z}{r\rho}$$

tangent to the meridian planes and to the spheres. The standard spherical coordinates are (r,θ,ϕ), where ϕ is the latitude, so that

$$\nabla r=\mathbf{u},\quad \nabla\theta=\rho^{-2}\mathbf{R}_z,\quad \mathbf{p}=p_r\mathbf{u}+p_\theta\rho^{-2}\mathbf{R}_z+r^{-1}p_\phi\mathbf{l},\quad \nabla\phi=r^{-1}\mathbf{l},$$

with $\rho=r\cos\phi$, and the geodesic Hamiltonian assumes the standard form

$$G=\tfrac{1}{2}(p_r^2+\rho^{-2}p_\theta^2+r^{-2}p_\phi^2).$$

Up to equivalences, there is only one characteristic Killing pair characterizing this web, with $r=1$:

$$D=\mathrm{span}(\mathbf{R}_z),\quad \mathbf{K}=r^2\mathbf{G}-\mathbf{r}\otimes\mathbf{r}.$$

The vectors $(\mathbf{r},\mathbf{l})$ are eigenvectors of $\mathbf{K}$ orthogonal to $\mathbf{R}_z$, with distinct eigenvalues $(0,r^2)$. The coordinates (r,ψ) are essential, θ is ignorable, and a Stäckel multiplier is a function

$$U=f(r)+r^{-2}h(\phi).$$

Thus the separable vector potential is

$$\mathbf{A}=(\alpha(r)+r^{-2}\beta(\phi))\mathbf{R}_z,$$

and

$$\mathbf{B}=(\alpha'-2\beta r^{-3})\rho\mathbf{l}-\beta' r^{-3}\rho\mathbf{u}+2(\alpha+\beta r^{-2})\mathbf{Z}.$$

The Hamiltonian is

$$H=\tfrac{1}{2}(p_r^2+\rho^{-2}p_\phi^2)+(\alpha(r)+r^{-2}\beta(\phi))p_\theta+f(r)+r^{-2}h(\phi).$$

Since

$$\nabla U=(f'-2r^{-3}h)\mathbf{u}+r^{-3}h'\mathbf{l},\quad \mathbf{K}\nabla U=h'(\phi)\nabla\phi=\nabla h,$$

we find $U_1=h(\phi)$ and, in a similar way, $\mathbf{A}_1=\beta(\phi)\mathbf{R}_z$. It follows that the associated quadratic first integral is

$$H_1=r^2G-\tfrac{1}{2}(\mathbf{p}\cdot\mathbf{r})^2+\mathbf{A}_1\cdot\mathbf{p}+U_1=\tfrac{1}{2}r^2(\rho^{-2}p_\theta^2+r^{-2}p_\phi^2)+\beta(\phi)p_\theta+h(\phi).$$

Example 3. Rotational surfaces in $\mathbb{E}_3$. For a particle moving on a regular surface S in $\mathbb{E}_3$ only the restriction of the scalar potential V to S and the tangent component of the vector potential $\mathbf{A}$ have influence on the motion, as well as the orthogonal part of $\mathbf{B}$. Only the case of a surface with symmetry (translational or rotational) is relevant for the separation of a vector potential. Let us consider the case of a rotational surface around the z axis. Then the dynamics of the point on this

surface is separable for any scalar and vector potential in $\mathbb{E}_3$ invariant under the rotation $\mathbf{R}_z$. Indeed, let us consider the cylindrical web of Example 1 and the cylindrical coordinates (ρ,θ,z). Let us consider the decomposition of the vector potential,

$$\mathbf{A}=\alpha\mathbf{u}_z+\beta\mathbf{R}_z+\gamma\mathbf{Z},$$

where, due to the rotational invariance, the functions (α,β,γ) do not depend on the rotation angle θ. It follows that

$$\mathbf{B}=\nabla\alpha\times\mathbf{u}_z+\nabla\beta\times\mathbf{R}_z+2\beta\mathbf{Z}+\nabla\gamma\times\mathbf{Z}.$$

But the first and the last terms are vectors parallel to $\mathbf{R}_z$, since the gradients of θ-invariant functions are tangent to the meridian half-planes, thus they are tangent to the surface and can be disregarded. The relevant potential is then

$$\mathbf{A}=\beta(\rho,z)\mathbf{R}_z,$$

which is tangent to the surface and orthogonal to the meridian planes. On the surface (ρ,z) can be represented as functions of a parameter u, so that the scalar and vector potentials are

$$V=f(u),\quad \mathbf{A}=\phi(u)\mathbf{R}_z.$$

The coordinates on the surfaces are then (θ,u), with θ ignorable and u essential coordinate.

Example 4. The Euclidean plane $\mathbb{E}_2$. We consider $\mathbb{E}_2$ as the (x,y) plane in the three-dimensional Euclidean space $\mathbb{E}_3$. In the rectangular Cartesian web the only interesting case is $m=1$, $D=\mathrm{span}(\mathbf{X})$, $\mathbf{K}=\mathbf{G}$, so that

$$\mathbf{A}=A(y)\mathbf{X},\quad V=V(y).$$

It follows that

$$\mathbf{B}=A'(y)\mathbf{Y}\times\mathbf{X}=-A'(y)\mathbf{Z},\quad \mathbf{F}=-A'(y)\mathbf{Z}\times\mathbf{v}-V'(y)\mathbf{Y}.$$

For the polar web we have $r=1$, $D=\mathrm{span}(\mathbf{R}_z)$, $\mathbf{K}=\mathbf{G}$, and

$$\mathbf{A}=A(r)\mathbf{R}_z,\quad V=V(r).$$

It follows that

$$\begin{aligned}\mathbf{B}=\nabla\times(A\mathbf{R}_z)&=\nabla A\times\mathbf{R}+2A\mathbf{Z}\\&=A'(r)\nabla r\times\mathbf{R}+2A\mathbf{Z}\\&=A'(r)r^{-1}\mathbf{r}\times(\mathbf{Z}\times\mathbf{r})+2A\mathbf{Z}\\&=(rA'+2A)\mathbf{Z},\end{aligned}$$

and the corresponding separable force is

$$\mathbf{F}=B(r)\mathbf{Z}\times\mathbf{v}-V'(r)\mathbf{u},\quad B(r)=rA'+2A,\quad \mathbf{r}=r\mathbf{u}.$$

A geometrical description of classical field theories of first order is given. The underlying k-cosymplectic structure permits to derive the corresponding field equations. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1360997]

I. INTRODUCTION

As is well-known, the natural arena to study mechanics is symplectic geometry. One interesting problem is to extend this geometric framework for the case of classical field theories. Several different approaches were developed in the past forty years, and according to them, the field equations are presented in different geometric formats: jet fields, Ehresmann connections, or multivector fields (we refer the reader to Refs. 1–5 and the references therein; see also Refs. 6–21 for recent developments).

In a recent paper[22] we have constructed a geometric description of classical field theories in terms of k-cosymplectic manifolds. A k-cosymplectic manifold is a natural generalization of a cosymplectic manifold, which is the geometrical setting for nonautonomous mechanical systems (see Refs. 23–25).

In the present paper, which can be viewed as a natural extension of Ref. 22, we consider the Lagrangian description of first order classical field theories. The field equations are then derived by using the canonical almost stable k-tangent structure on the stable k-tangent bundle $\mathbf{R}^k \times T^1_k Q$ of a manifold Q. From the Lagrangian function L, we construct in an intrinsical way the Poincaré–Cartan forms $(\omega_L)_A$, $1 \leqslant A \leqslant k$, which determine a k-cosymplectic structure if L is regular. The k-cosymplectic structure provides us a k-vector field whose integral sections are the solutions of the field equations. The integrability is not assured, but it can be checked in terms of an arbitrary solution.

If the Lagrangian is not regular, then we develop a constraint algorithm which, if the field equations are compatible, yields a final constraint submanifold where a solution exists. This algorithm is very similar to that constructed in Ref. 25.

This Lagrangian description is of course completely equivalent to the Hamiltonian one developed in our precedent paper by means of a convenient Legendre transformation.

II. *k*-VECTOR FIELDS

Let M be a differentiable manifold of dimension m and $\mathbf{R^k}$ the k-dimensional Euclidean space with coordinates $t=(t^A)=(t^1,\ldots,t^k)$. Let $J^1_0(\mathbf{R^k},M)$ be the $(k+1)m$-dimensional manifold of one jet of mappings from $\mathbf{R^k}$ to M at the origin of $\mathbf{R^k}$ with elements denoted by $j^1_0\sigma$. $J^1_0(\mathbf{R^k},M)$ is called the tangent bundle of k^1-velocities in Ref. 26.

Let $\{\mathbf{r_1},\ldots,\mathbf{r_k}\}$ be the canonical basis of $\mathbf{R^k}$. The manifold $J^1_0(\mathbf{R^k},M)$ can be canonically identified with the Whitney sum $T^1_k M = TM \oplus \cdots \oplus TM$ of k copies of TM via the diffeomorphism,

$$J^1_0(\mathbf{R^k},M) \to T^1_k M = TM \oplus \cdots \oplus TM$$

[b]Electronic mail: uxiomer@eps.cdf.udc.es
[c]Electronic mail: modesto@zmat.usc.es

$$j_0^1\sigma \to (v_1,\ldots,v_k)$$

defined by

$$v_A = \left.\frac{d\sigma_A}{ds}\right|_{s=0}, \quad s\in\mathbf{R}, \quad 1\leqslant A\leqslant k,$$

where $\sigma_A(s)=\sigma(s\mathbf{r_A})$.

Let $\tau_M : T_k^1M \to M$ be the canonical projection. If (x^i) are local coordinates on $U\subseteq M$ then the induced local coordinates (x^i,x_A^i), $1\leqslant i\leqslant m$, $1\leqslant A\leqslant k$, on $\tau_M^{-1}(U)\equiv T_k^1U$ are given by

$$x^i(j_0^1\sigma)=x^i(\sigma(0)), \quad x_A^i(j_0^1\sigma)=\frac{d}{ds}(x^i\circ\sigma^A)_{|s=0}=v_A(x^i). \tag{1}$$

Definition II.1: A section $\mathbf{X}:M\to T_k^1M$ *of the projection* $\tau_M:T_k^1M\to M$ *will be called a k-vector field on M.*

Since T_k^1M is the Whitney sum of k copies of TM we deduce that a k-vector field $\mathbf{X}$ defines k vector fields $\{X_1,\ldots,X_k\}$ on M by projecting $\mathbf{X}$ onto every factor. We shall identify $\mathbf{X}$ with the k-tuple $(X_1,\ldots,X_k)$.

Definition II.2: An integral section of the k-vector field $(X_1,\ldots,X_k)$ *passing through a point* $x\in M$ *is a map* $\sigma:U_0\subset\mathbf{R}^k\to M$, *defined on some neighborhood* U_0 *of* $0\in\mathbf{R^k}$, *and satisfying*

$$\sigma(0)=x, \quad d\sigma(t)\left(\left.\frac{\partial}{\partial t^A}\right|_t\right)=X_A(\sigma(t)), \quad 1\leqslant A\leqslant k, \quad \text{for all} \quad t\in U_0.$$

We say that a k-vector field $(X_1,\ldots,X_k)$ *on M is integrable if there is an integral section passing through each point of M.*

Remark II.3: Let us consider the trivial bundle $\pi:E=R^k\times M\to R^k$. A jet field γ on π (see Ref. 5) is a section of the projection $\pi_{1,0}:J^1\pi\equiv\mathbf{R}^k\times T_k^1M\to E\equiv\mathbf{R}^k\times M$. We identify each k-vector field $\mathbf{X}$ on M with the jet field $\gamma=(id_{\mathbf{R}^k},\mathbf{X})$, that is $\gamma(t,x)=(t,X_1(x),\ldots,X_k(x))$. The integral sections of the jet field γ (see Ref. 5) correspond to the solutions of the k-vector field $\mathbf{X}$ (see Ref. 27). For this reason the *solutions* of $\mathbf{X}$ are called its *integral sections*.

Let us remark that if σ is an *integral section* of a k-vector field $(X_1,\ldots,X_k)$ then each curve on M defined by $\sigma_A=\sigma(s\,\mathbf{r_A})$ is an integral curve of the vector field X_A on M.

Howewer, given k integral curves of $X_1,\ldots,X_k$, respectively, it is not possible in general to reconstruct an integral section of $(X_1,\ldots,X_k)$.

Proposition II.4: Assume that the vector fields $\{X_1,\ldots,X_k\}$ *on M are linearly independent. Then, the k-vector field* $(X_1,\ldots,X_k)$ *is integrable if and only if the distribution generated by* $\{X_1,\ldots,X_k\}$ *is integrable.*

III. THE CANONICAL STABLE *k*-TANGENT STRUCTURE

Let Q be a manifold of dimension n with local coordinates (q^i) and let (q^i,v_A^i) be the induced coordinates on T_k^1Q. Let F be a tensor field of type (1,1) on Q such that $F=\Sigma_{i,j}F_j^i(\partial/\partial q^i)\otimes dq^j$. Then the A-lift F^A of F to T_k^1Q is the (1,1)-tensor field with local expression:

$$F^A=\sum_{i,j} F_j^i\left(\frac{\partial}{\partial v_A^i}\right)\otimes dq^j$$

(see Ref. 26 for further details about the intrinsic construction). If $I_M=\Sigma_i(\partial/\partial q^i)\otimes dq^i$ is the identity tensor field on M then for each $A\in\{1,2,\ldots k\}$, its A-lifting defines the tensor field $\tilde{J}_A=I^A$ locally given by

$$\tilde{J}_A = \sum_i \frac{\partial}{\partial v_A^i} \otimes dq^i. \tag{2}$$

The family $(\tilde{J}_1,\ldots,\tilde{J}_k)$ is called the *canonical k-tangent structure* of $T_k^1 M$ (see Ref. 28).

Let $J^1(\mathbf{R^k},Q)$ be the $k+(k+1)n$-dimensional manifold of one jets from $\mathbf{R^k}$ to Q, with elements denoted by $j_t^1\phi$. This manifold can be identified with the manifold $J^1\pi$ of one jets of sections of the trivial bundle $\pi:\mathbf{R^k}\times Q\to\mathbf{R^k}$.

$J^1\pi$ is diffeomorphic to $\mathbf{R^k}\times T_k^1 Q$ by composing the following diffeomorphisms:

$$J^1\pi \to \mathbf{R^k}\times J_0^1(\mathbf{R^k},Q)\to \mathbf{R^k}\times T_k^1 Q,$$

$$j_t^1\phi \to (t, j_0^1\phi_t)\to (t,v_1,\ldots,v_k),$$

where

$$\phi_t(t')=\phi(t+t'),\quad t'\in\mathbf{R^k},\quad v_A=\frac{d}{ds}(\phi_t^A)_{|s=0},\quad s\in\mathbf{R},\quad 1\leqslant A\leqslant k,$$

and $\phi_t^A(s)=\phi_t(s\,\mathbf{r_A})$.

Let $\tau:\mathbf{R^k}\times T_k^1 Q\to Q$ be the canonical projection. If (q^i) are local coordinates on $U\subseteq Q$ then the induced local coordinates (t^A,q^i,v_A^i), $1\leqslant i\leqslant n$, $1\leqslant A\leqslant k$, on $\tau^{-1}(U)\equiv\mathbf{R^k}\times T_k^1 U$ are given by

$$t^A(j_t^1\phi)=t^A,\quad q^i(j_t^1\sigma)=q^i(\phi_t(0)),\quad v_A^i(j_t^1\phi)=\frac{d}{ds}(q^i\circ\phi_t^A)_{|s=0}=v_A(q^i).$$

Therefore we obtain $\tau(t^A,q^i,v_A^i)=(q^i)$.

On $\mathbf{R^k}\times T_k^1 Q$ there exist a family of k tensor fields J_A of type (1,1) defined by

$$J_A=\frac{\partial}{\partial t^A}\otimes dt^A+\tilde{J}_A=\frac{\partial}{\partial t^A}\otimes dt^A+\sum_{i=1}^n \frac{\partial}{\partial v_A^i}\otimes dq^i,\quad 1\leqslant A\leqslant k,$$

where we have transported the canonical k-tangent structure $(\tilde{J}_1,\ldots,\tilde{J}_k)$ of $T_k^1 Q$ to $\mathbf{R^k}\times T_k^1 Q$.

If we set $\overline{\eta}_A=dt^A$ and $\xi_A=\partial/\partial t^A$, then the family $(J_A,\overline{\eta}_A,\xi_A;1\leqslant A\leqslant k)$ is called the *canonical stable k-tangent structure* on $\mathbf{R^k}\times T_k^1 Q$, and $\mathbf{R^k}\times T_k^1 Q$ is the *stable k-tangent bundle of Q*.

IV. SECOND ORDER PARTIAL DIFFERENTIAL EQUATIONS

In this section we characterize the k-vector fields on $\mathbf{R}^k\times T_k^1 Q$ such that their integral sections are canonical prolongations of maps from $\mathbf{R}^k$ to Q.

Let C be the *canonical vector field* of the vector bundle $\pi_{1,0}:\mathbf{R}^k\times T_k^1 Q\to\mathbf{R^k}\times Q$. This vector field C is the infinitesimal generator of the following flow:

$$\mathbf{R}\times(\mathbf{R}^k\times T_k^1 Q)\to\mathbf{R}^k\times T_k^1 Q$$

$$(s,(t,q^i,v_A^i))\to(t,q^i,e^s v_A^i),$$

and in local coordinates it has the form

$$C=\sum_{i,A} v_A^i\frac{\partial}{\partial v_A^i}. \tag{3}$$

C is a sum of vector fields,

$$C=\sum_{A=1}^{k} C_A,$$

where each C_A is the infinitesimal generator of the following flow:

$$\mathbf{R}\times(\mathbf{R}^k\times T_k^1Q)\to\mathbf{R}^k\times T_k^1Q$$

$$(s,(t,q^i,v_A^i))\to(t,q^i,v_1^i,\ldots,v_{A-1}^i,e^s v_A^i,v_{A+1}^i,\ldots,v_k^i).$$

In local coordinates they have the form

$$C_A=\sum_{i=1}^{n} v_A^i\frac{\partial}{\partial v_A^i},\quad 1\leqslant A\leqslant k. \tag{4}$$

Let us consider on $\mathbf{R}^k\times T_k^1Q$ the tensor fields $\hat{J}_1,\ldots,\hat{J}_k$ of type (1,1), defined as follows:

$$\hat{J}_A=\tilde{J}_A-C_A\otimes dt^A,\quad 1\leqslant A\leqslant k.$$

Definition IV.1: A k-vector field $\zeta=(\zeta_1,\ldots,\zeta_k)$ on $\mathbf{R}^k\times T_k^1Q$ is said to be a second order partial differential equation (SOPDE for short) if

$$\hat{J}_A(\zeta_A)=0,\quad \overline{\eta}_A(\zeta_B)=\delta_{AB},$$

for all $1\leqslant A,B\leqslant k$.

From a direct computation in local coordinates we obtain that the local expression of a SOPDE $\zeta=(\zeta_1,\ldots,\zeta_k)$ on $\mathbf{R}^k\times T_k^1Q$ is

$$\zeta_A=\frac{\partial}{\partial t^A}+v_A^i\frac{\partial}{\partial q^i}+(\zeta_A)_B^i\frac{\partial}{\partial v_B^i},\quad 1\leqslant A\leqslant k, \tag{5}$$

where $(\zeta_A)_B^i$ are functions on $\mathbf{R}^k\times T_k^1Q$.

As a direct consequence of the above local expressions, we deduce that the familiy of vector fields $\{\zeta_1,\ldots,\zeta_k\}$ are linearly independent.

Definition IV.2: Let $\phi:\mathbf{R}^k\to Q$ be a map, we define the first prolongation $\phi^{(1)}$ of ϕ as the map

$$\phi^{(1)}:\mathbf{R}^k\to J^1\pi\equiv\mathbf{R}^k\times T_k^1Q,$$

$$t\to j_t^1\phi\equiv(t,j_0^1\phi_t).$$

In local coordinates:

$$\phi^{(1)}(t^1,\ldots,t^k)=\left(t^1,\ldots,t^k,\phi^i(t^1,\ldots,t^k),\frac{\partial\phi^i}{\partial t^A}(t^1,\ldots,t^k)\right),\quad 1\leqslant A\leqslant k,1\leqslant i\leqslant n. \tag{6}$$

From (5) it follows that an integral section σ of a SOPDE ζ is the first prolongation $\phi^{(1)}$ of a map ϕ from $\mathbf{R}^k$ to Q.

Definition IV.3: $\phi:\mathbf{R}^k\to Q$ is called a solution of the SOPDE ζ on $\mathbf{R}^k\times T_k^1Q$ if the first prolongation $\phi^{(1)}$ of ϕ is an integral section of ζ.

From (5) and (6) we have the following.

Proposition IV.4: $\phi:\mathbf{R}^k\to Q$ is a solution of the SOPDE $\zeta=(\zeta_1,\ldots,\zeta_k)$, locally given by (5), if and only if

$$\frac{\partial\phi^i}{\partial t^A}=v_A^i,\quad \frac{\partial^2\phi^i}{\partial t^A\,\partial t^B}=(\zeta_A)_B^i.$$

Remark IV.5: Let us consider the trivial bundles $\pi: E = R^k \times Q \to R^k$ and $\pi_1: \mathbf{R^k} \times T^1_k Q \to \mathbf{R^k}$. We identify each SOPDE $(\zeta_1, \ldots, \zeta_k)$ with the following *semi-holonomic second order jet field:*

$$J^1\pi \equiv \mathbf{R^k} \times T^1_k Q \to J^1\pi_1 \equiv \mathbf{R^k} \times T^1_k (T^1_k Q),$$

$$(t^A, q^i, v^i_A) \to (t^A, q^i, v^i_A, v^i_A, (\zeta_A)^i_B).$$

If the SOPDE ζ on $\mathbf{R}^k \times T^1_k Q$ is integrable, then its integral sections are canonical prolongations of maps from $\mathbf{R^k}$ to Q and then ζ defines a second order jet field Γ on π whose coordinate representation of the corresponding connection $\tilde{\Gamma}$ is

$$\tilde{\Gamma} = dt^A \otimes \left(\frac{\partial}{\partial t^A} + v^i_A \frac{\partial}{\partial q^i} + (\zeta_A)^i_B \frac{\partial}{\partial v^i_B} \right),$$

since $(\zeta_A)^i_B = (\zeta_B)^i_A$ (see Ref. 5).

The integrability of the SOPDE is equivalent to the condition given by $\mathcal{R} = 0$, where $\mathcal{R}$ is the curvature tensor of the above connection (see Ref. 13 and 5).

V. *k*-COSYMPLECTIC STRUCTURES

The keystone of the nonautonomous Lagrangian formalism of classical mechanics is the cosymplectic structure on the phase space $\mathbf{R} \times TQ$. For field theory we shall show that this statement remains true, provided the two- forms that define the cosymplectic structure are replaced by two vector valued forms.

Let $J^1(Q, \mathbf{R^k})_0$ be the manifold of one jets of maps from Q to $\mathbf{R^k}$ with target at $0 \in \mathbf{R^k}$.

The manifold $J^1(Q, \mathbf{R^k})_0$ can be canonically identified with the Whitney sum $(T^1_k)^* Q$ of k copies of T^*Q, that is

$$J^1(Q, \mathbf{R^k})_0 \to (T^1_k)^* Q = T^*Q \oplus \cdots \oplus T^*Q,$$

$$j^1_{q,0}\sigma \equiv (p^1_q, \ldots, p^k_q),$$

where $p^A_q = d(\pi_A \circ \sigma)(q)$ being $\pi_A: \mathbf{R^k} \to \mathbf{R}$ the canonical projection.

Let $J^1(Q, \mathbf{R^k})$ be the $k + (k+1)n$-dimensional manifold of one jets from Q to $\mathbf{R^k}$, with elements denoted by $j^1_{q,t}\sigma$. We recall that one jets of mappings from Q to $\mathbf{R^k}$ can be identified with the manifold $J^1\rho$ of one jets of sections of the trivial bundle $\rho: \mathbf{R^k} \times Q \to Q$.

$J^1\rho$ is diffeomorphic to $\mathbf{R^k} \times (T^1_k)^* Q$, via the diffeomorphism given by

$$j^1_q \alpha \in J^1\rho \to (\sigma(q), j^1_{q,0}\sigma_q) \in \mathbf{R^k} \times (T^1_k)^* Q,$$

where $\sigma_q(\tilde{q}) = \sigma(\tilde{q}) - \sigma(q)$ and $\tilde{q}$ denotes an arbitrary point in Q.

Let us denote by $\tau^*: \mathbf{R^k} \times (T^1_k)^* Q \to Q$ the canonical projection. If (q^i) are local coordinates on $U \subseteq Q$ then the induced local coordinates $(t^A, q^i, p^A_i), 1 \leq i \leq n, 1 \leq A \leq k$, on $(\tau^*)^{-1}(U) \equiv \mathbf{R^k} \times (T^1_k)^* U$ are given by

$$t^A(j^1_q\sigma) = t^A(\sigma(q)), \quad q^i(j^1_q\sigma) = q^i(q), \quad p^A_i(j^1_q\sigma) = d(\sigma^A_q)(q)\left(\frac{\partial}{\partial q^i}_{|q} \right),$$

where $\sigma^A_q = \pi_A \circ \sigma_q$.

An $\mathbf{R^k}$-valued one-form η_0 and a $\mathbf{R^k}$-valued two-form ω_0 on $\mathbf{R^k} \times (T^1_k)^* Q$ are defined by

$$\eta_0 = \sum_{A=1}^{m} (\eta_0)_A \, \mathbf{r_A} = \sum_{A=1}^{k} ((\pi^1_A)^* dt) \mathbf{r_A}, \quad \omega_0 = \sum_{A=1}^{k} (\omega_0)_A \, \mathbf{r_A} = \sum_{A=1}^{m} (\pi^2_A)^* (\omega_Q) \, \mathbf{r_A}, \tag{7}$$

where $\pi_A^1:\mathbf{R^k}\times(T_k^1)^*Q\to\mathbf{R}$ and $\pi_A^2:\mathbf{R^k}\times(T_k^1)^*Q\to T^*Q$ are the projections defined by

$$\pi_A^1((t^B),(p^B))=t^A,\quad \pi_A^2((t^B),(p^B))=p^A,$$

and ω_Q is the canonical symplectic form on T^*Q.

In local coordinates we have

$$(\eta_0)_A=dt^A,\quad (\omega_0)_A=\sum_{i=1}^{n} dq^i\wedge dp_i^A\quad 1\leqslant A\leqslant k. \tag{8}$$

Moreover, let be $V=\ker T\mu^*$, where $\mu^*:\mathbf{R^k}\times(T_k^1)^*Q\to\mathbf{R^k}\times Q$. A simple inspection in local coordinates shows that the forms $(\eta_0)_A$ and $(\omega_0)_A$ are closed and the following relations hold:

(i) $(\eta_0)_1\wedge\cdots\wedge(\eta_0)_k\neq 0$, $(\eta_0)_{A_{|V}}=0$, $\omega_{A_{|V\times V}}=0$,

(ii) $(\cap_{A=1}^n\ker(\eta_0)_A)\cap(\cap_{A=1}^n\ker(\omega_0)_A)=\{0\}$, $\dim(\cap_{A=1}^n\ker(\omega_0)_A)=k$.

Inspired in the above geometrical model we have introduced in Ref. 22 the following definition.

Definition V.1: Let M be a differentiable manifold of dimension $(k+1)n+k$. A family $(\eta_A,\omega_A,V;1\leqslant A\leqslant k)$, where each η_A is a closed 1-form, each ω_A is a closed 2-form and V is an nk-dimensional integrable distribution on M, such that

(i) $\eta_1\wedge\cdots\wedge\eta_k\neq 0$, $\eta_{A_{|V}}=0$, $\omega_{A_{|V\times V}}=0$,

(ii) $(\cap_{A=1}^k\ker\eta_A)\cap(\cap_{A=1}^k\ker\omega_A)=\{0\}$, $\dim(\cap_{A=1}^k\ker\omega_A)=k$,

is called a k-cosymplectic structure, and the manifold M a k-cosymplectic manifold.

The canonical model for these geometrical structures is $(\mathbf{R^k}\times(T_k^1)^*Q,\eta_0,\omega_0,V)$.

For any k-cosymplectic structure (η_A,ω_A,V) on M, there exists a family of k vector fields $(\xi_1,\ldots,\xi_k)$ characterized by the conditions

$$\eta_A(\xi_B)=\delta_{AB},\quad \iota_{\xi_B}\omega_A=0,$$

for all $1\leqslant A,B\leqslant k$. These vector fields are called the Reeb vector fields associated to the k-cosymplectic structure.

If (M,η,ω,V) is a k-cosymplectic manifold we can define the vector bundle morphism,

$$\begin{gathered}\Omega^\sharp:T_k^1M\to T^*M\\ (X_1,\ldots,X_k)\to\Omega^\sharp(X_1,\ldots,X_k)=\sum_{A=1}^{k}\iota_{X_A}\omega_A+\eta_A(X_A)\,\eta_A.\end{gathered} \tag{9}$$

Remark V.2: If $k=1$ then $\Omega^\sharp$ is defined from TM onto T^*M and it is in fact the isomorphism $\chi_{\eta,\omega}$ defined on the cosymplectic manifold (M,η,ω) by (see Ref. 23, 24)

$$\chi_{\eta,\omega}(X)=\iota_X\omega+\eta(X)\,\eta.$$

Let (M,η_A,ω_A,V) be a k-cosymplectic manifold, $H:M\to\mathbf{R}$ a Hamiltonian function and ξ_A are the Reeb vector fields determined by (η_A,ω_A,V). In Ref. 22 we have proved that if an integrable k-vector field $\mathbf{X}=(X_1,\ldots,X_k)$ satisfies the equations

$$\begin{gathered}\eta_A(X_B)=\delta_{AB},\quad \forall A,B,\\ \Omega^\sharp(X_1,\ldots,X_k)=dH+\sum_{A=1}^{k}(1-\xi_A(H))\,\eta_A,\end{gathered} \tag{10}$$

then its integral sections ϕ are solutions of the Hamiltonian field equations corresponding to H:

$$\frac{\partial H}{\partial x^i}=-\sum_{A=1}^{k}\frac{\partial \phi_i^A}{\partial s^A},\quad \frac{\partial H}{\partial x_i^A}=\frac{\partial \phi^i}{\partial s^A}.$$

The existence of canonical coordinates (s^A,x^i,x_i^A) is ensured by the corresponding Darboux theorem (see Ref. 22).

VI. THE LAGRANGIAN FORMALISM

Given a Lagrangian function of the form $L=L(t^A,q^i,v_A^i)$ one obtains, by using a variational principle, the *Euler–Lagrange equations* for L:

$$\sum_{A=1}^{k}\frac{d}{dt^A}\left(\frac{\partial L}{\partial v_A^i}\right)-\frac{\partial L}{\partial q^i}=0,\quad v_A^i=\frac{\partial q^i}{\partial t^A}. \tag{11}$$

First of all, one realizes that such a L can be considered as a function $L:\mathbf{R^k}\times T_k^1Q\to\mathbf{R}$.

In this section we shall give a geometrical description of the above equations (11) using a k-cosymplectic structure on $\mathbf{R^k}\times T_k^1Q$ associated to the regular Lagrangian L. This k-cosymplectic structure shall be constructed using the canonical stable k-tangent structure of $\mathbf{R^k}\times T_k^1Q$.

For each $1\leqslant A\leqslant k$, we define the following.

• The vertical derivation ι_{J_A} of forms on $\mathbf{R^k}\times T_k^1Q$ by

$$\iota_{J_A}f=0,\ (\iota_{J_A}\alpha)(X_1,\ldots,X_p)=\sum_{j=1}^{p}\alpha(X_1,\ldots,J_AX_j,\ldots,X_p),$$

for any function f and any p-form α on $\mathbf{R^k}\times T_k^1Q$;

• the vertical differentation d_{J_A} of forms on $\mathbf{R^k}\times T_k^1Q$ by

$$d_{J_A}=[\iota_{J_A},d]=\iota_{J_A}\circ d-d\circ\iota_{J_A},$$

where d denotes the usual exterior differentation.

Let us consider the 1-forms,

$$(\beta_L)_A=d_{J_A}L-\xi_A(L)\,\overline{\eta}_A,\ 1\leqslant A\leqslant k.$$

In bundle coordinates (t^A,q^i,v_A^i) we have

$$(\beta_L)_A=\sum_{i=1}^{n}\frac{\partial L}{\partial v_A^i}dq^i,\ 1\leqslant i\leqslant k. \tag{12}$$

Definition VI.1: A Lagrangian L is called regular if and only if the Hessian matrix,

$$\left(\frac{\partial^2 L}{\partial v_A^i\,\partial v_B^j}\right), \tag{13}$$

is nonsingular.

Now, we introduce the following 2-forms:

$$(\omega_L)_A=-d(\beta_L)_A,\ 1\leqslant A\leqslant k.$$

Proposition VI.2: Let $L:\mathbf{R^k}\times T_k^1Q\to\mathbf{R}$ be a regular Lagrangian, and V_0 the vertical distribution of the bundle $\pi_{1,0}:\mathbf{R^k}\times T_k^1Q\to\mathbf{R^k}\times Q$. Then, L is regular if and only if $(\mathbf{R^k}\times T_k^1Q,\overline{\eta}_A,(\omega_L)_A,V_0)$ is a k-cosymplectic manifold.

Proof: Assume that L is a regular Lagrangian. We shall prove that $(\mathbf{R}^k \times T^1_k Q, \overline{\eta}_A, (\omega_L)_A, V_0)$ is a k-cosymplectic manifold.

Conditions (i) are rather obvious. Now, we shall prove condition (ii) in Definition V.1. Let X be a vector field with the local expression

$$X = X^A \frac{\partial}{\partial t^A} + X^i \frac{\partial}{\partial q^i} + X^i_A \frac{\partial}{\partial v^i_A},$$

such that

$$\imath_X (\omega_L)_A = 0, \text{ and } \overline{\eta}_A(X) = 0, \quad \text{for all } 1 \leqslant A \leqslant k.$$

The second condition implies that $X^A = 0$, for all A, and then the first condition yields

$$X^i \frac{\partial^2 L}{\partial v^i_A \partial v^j_B} = 0, \tag{14}$$

and

$$X^i \frac{\partial^2 L}{\partial v^i_A \partial q^j} - X^i \frac{\partial^2 L}{\partial v^j_A \partial q^i} - X^i_B \frac{\partial^2 L}{\partial v^j_A \partial v^i_B} = 0. \tag{15}$$

Since L is regular, from (14) we deduce that $X^i = 0$, for all i, so that (15) implies $X^i_A = 0$, for all i and A. Therefore, we conclude that $X = 0$.

Next, we shall prove the second part of condition (ii) in Definition V.1. Let Y be a vector field with the local expression

$$Y = Y^A \frac{\partial}{\partial t^A} + Y^i \frac{\partial}{\partial q^i} + Y^i_A \frac{\partial}{\partial v^i_A},$$

such that

$$\imath_X (\omega_L)_A = 0, \quad \text{for all } 1 \leqslant A \leqslant k.$$

We then have

$$Y^j \frac{\partial^2 L}{\partial v^i_A \partial v^j_B} = 0, \tag{16}$$

and

$$- Y^B \frac{\partial^2 L}{\partial v^i_A \partial t^B} + Y^j \frac{\partial^2 L}{\partial v^j_A \partial q^i} - Y^j \frac{\partial^2 L}{\partial v^i_A \partial q^j} - Y^j_B \frac{\partial^2 L}{\partial v^i_A \partial v^j_B} = 0. \tag{17}$$

From (16) and the regularity of L we deduce that $Y^j = 0$, for all j, so that (17) reduces to

$$- Y^B \frac{\partial^2 L}{\partial v^i_A \partial t^B} - Y^j_B \frac{\partial^2 L}{\partial v^i_A \partial v^j_B} = 0. \tag{18}$$

Since the matrix $(\partial^2 L / \partial v^i_A \partial v^j_B)$ is regular, (18) implies that

$$Y^j_B = \mathcal{A}^j_{BD} Y^D,$$

for some matrix $\mathcal{A}^j_{BD}$. Therefore, we get

$$Y = Y^B\left(\frac{\partial}{\partial t^B} + \mathcal{A}^j_{CB}\frac{\partial}{\partial v^j_C}\right).$$

Thus, $\cap_{A=1}^n \ker(\omega_L)_A$ is locally spanned by the family of k independente local vector fields $\{\partial/\partial t^B + \mathcal{A}^j_{CB}(\partial/\partial v^j_C)\}$.

Then we have proved that $(\mathbf{R^k}\times T^1_kQ, (\eta_0)_A, (\omega_L)_A, V_0)$ is a k-cosymplectic manifold.

The converse is proved by reversing the above arguments. ■

Let $L:\mathbf{R^k}\times T^1_kQ\to\mathbf{R}$ be a regular Lagrangian and $(\overline{\eta}_A, (\omega_L)_A, V_0)$ the associated k-cosymplectic structure on $\mathbf{R^k}\times T^1_kQ$.

The equations,

$$\overline{\eta}_A((\xi_L)_B) = \delta^A_B, \quad \iota_{(\xi_L)_A}(\omega_L)_B = 0, \quad 1\leqslant A,B\leqslant k, \tag{19}$$

define the Reeb vector fields $\{(\xi_L)_1,\ldots,(\xi_L)_k\}$ on $\mathbf{R^k}\times T^1_kQ$ which are locally given by

$$(\xi_L)_A = \frac{\partial}{\partial t^A} + ((\xi_L)_A)^i_B\frac{\partial}{\partial v^i_B}, \tag{20}$$

where the functions $((\xi_L)_A)^i_B$ satisfy

$$\frac{\partial^2 L}{\partial t^A\,\partial v^j_C} + \frac{\partial^2 L}{\partial v^i_B\,\partial v^j_C}((\xi_L)_A)^i_B = 0, \tag{21}$$

for all $1\leqslant A,B,C\leqslant k$ and $1\leqslant i,j\leqslant n$.

Since L is regular, from the local conditions (21) we can define, in a neighborhood of each point of $\mathbf{R^k}\times T^1_kQ$, a k-vector field that satisfies (19). Next, one can construct a global k-vector field ξ_L, which is a solution of (19), by using a partition of unity.

Let L be a regular Lagrangian and let $\Omega^\sharp_L$ be the $\sharp$-morphism defined by the k-cosymplectic structure $(\overline{\eta}_A, (\omega_L)_A, V_0)$, as in (9):

$$\begin{gathered}\Omega^\sharp_L : T^1_k(\mathbf{R^k}\times T^1_kQ)\to T^*(\mathbf{R^k}\times T^1_kQ)\\ (X_1,\ldots,X_k)\to\Omega^\sharp_L(X_1,\ldots,X_k) = \sum_{A=1}^k \iota_{X_A}(\omega_L)_A + \overline{\eta}_A(X_A)\,\overline{\eta}_A.\end{gathered} \tag{22}$$

Theorem VI.3: *Let L be a regular Lagrangian and let $\mathbf{X}=(X_1,\ldots,X_k)$ be a k-vector field such that*

$$\begin{gathered}\overline{\eta}_A(X_B) = \delta_{AB}, \quad 1\leqslant A,B\leqslant k,\\ \Omega^\sharp_L(X_1,\ldots,X_k) = dE_L + \sum_{A=1}^k (1-(\xi_L)_A(E_L))\,\overline{\eta}_A,\end{gathered} \tag{23}$$

where $E_L = C(L) - L$. Then $\mathbf{X}=(X_1,\ldots,X_k)$ is a SOPDE. In addition, if $\mathbf{X}=(X_1,\ldots,X_k)$ is integrable then its solutions satisfy the Euler–Lagrange equations (11).

Proof: It should be noticed that in general Eqs. (23) have not a unique solution. In fact, the solutions of (23) are given by $(X_1,\ldots,X_k) + (\ker\Omega^\sharp)$, where $(X_1,\ldots,X_k)$ is a particular solution. Nevertheless, we shall show now that there exist always solutions of equations (23) when L is assumed to be regular. In this case, from (3) and (20) we obtain

$$(\xi_L)_A(E_L) = -\frac{\partial L}{\partial t^A}. \tag{24}$$

Let $(X_1,\ldots,X_k)$ be a solution of (23) locally given by

$$X_A(t,q^i,v_A^i)=\frac{\partial}{\partial t^A}+(X_A)^i\frac{\partial}{\partial q^i}+(X_A)_B^j\frac{\partial}{\partial v_B^j}.$$

Then, from (24) we obtain

$$\sum_{A,B,j}\left(-\frac{\partial^2 L}{\partial t^A\partial v_A^i}+(X_A)^j\left(\frac{\partial^2 L}{\partial q^i\partial v_A^j}-\frac{\partial^2 L}{\partial q^j\partial v_A^i}\right)-(X_A)_B^j\frac{\partial^2 L}{\partial v_B^j\partial v_A^i}\right)=\sum_{A,j}\left(v_A^j\frac{\partial^2 L}{\partial q^i\partial v_A^j}-\frac{\partial L}{\partial q^i}\right), \tag{25}$$

$$\sum_{A,i}(X_A)^i\frac{\partial^2 L}{\partial v_B^j\,\partial v_A^i}=\sum_{A,i}v_A^i\frac{\partial^2 L}{\partial v_B^j\,\partial v_A^i}, \tag{26}$$

and since L is regular, from (26) we deduce that the solutions of Eqs. (23) are SOPDE's, that is, each X_A has the form

$$X_A(t,q^i,v_A^i)=\frac{\partial}{\partial t^A}+v_A^i\frac{\partial}{\partial q^i}+(X_A)_B^j\frac{\partial}{\partial v_B^j}. \tag{27}$$

From (25) we deduce that the functions $(X_A)_B^j$ satisfy the equations

$$\sum_A\frac{\partial^2 L}{\partial t^A\,\partial v_A^i}+\sum_{j,B}\left(v_B^j\frac{\partial^2 L}{\partial q^j\,\partial v_B^i}+\sum_A(X_A)_B^j\frac{\partial^2 L}{\partial v_B^j\,\partial v_A^i}\right)=\frac{\partial L}{\partial q^i},\quad 1\leqslant i\leqslant n. \tag{28}$$

Since L is regular, (28) leads us to define local solutions of (23) in a neigborhood of each point of $\mathbf{R^k}\times T_k^1Q$. Using a partition of unity one can easily obtain a global solution of (23).

Now, let

$$\phi:\mathbf{R^k}\to Q,$$

$$(t^B)\to(\phi^i(t^1,\ldots,t^k)),$$

be a solution of $(X_1,\ldots,X_k)$. From Proposition IV.4 and Eq. (27) we deduce that

$$\frac{\partial\phi^i}{\partial t^A}=v_A^i,\quad \frac{\partial^2\phi_A^i}{\partial t^A\,\partial t^B}=(X_A)_B^i.$$

Replacing in (28) we get

$$\sum_A\frac{\partial^2 L}{\partial t^A\,\partial v_A^i}+\sum_{j,B}\left(\frac{\partial\phi^j}{\partial t^B}\frac{\partial^2 L}{\partial q^j\,\partial v_B^i}+\sum_A\frac{\partial^2\phi^j}{\partial t^A\,\partial t^B}\frac{\partial^2 L}{\partial v_B^j\,\partial v_A^i}\right)=\frac{\partial L}{\partial q^i},\quad 1\leqslant i\leqslant n, \tag{29}$$

which shows that ϕ is a solution of the Euler–Lagrange equations (11). ■

In conclussion, we can consider Eqs. (23) as a *geometric version* of the Euler–Lagrange field equations.

Remark VI.4: We have given a geometric version of the Euler–Lagrange equations for a nonautonomous Lagrangian constructing a k-cosymplectic structure on $\mathbf{R^k}\times T_k^1Q$ defined from the Lagrangian and the canonical stable k-tangent structure on $\mathbf{R^k}\times T_k^1Q$. We can also construct this k-cosymplectic structure using the *Legendre tranformation* $\mathcal{F}L$ of L which is the map

$$\mathcal{F}L:\mathbf{R^k}\times T_k^1Q\to\mathbf{R^k}\times(T_k^1)^*Q,$$

defined as follows: if $(t,\mathbf{v})=(t^1,\ldots,t^k,v_1,\ldots,v_k)\in\mathbf{R^k}\times(T_k^1Q)_q$ with $q\in Q$ and $v_A\in T_qQ$, then

$$\mathcal{FL}(t,y)=(t^1,\ldots,t^k,p^1,\ldots p^k)\in \mathbf{R^k}\times(T^1_kQ)^*_q,\quad p^A\in T^*_qQ$$

is given by

$$p^A(v_q)=(\beta_L)_A(\overline{v_q}),\quad 1\leqslant A\leqslant k,$$

for any $v_q\in T_qQ$, where $\overline{v_q}\in T_v(T^1_kQ)$ is any tangent vector such that $d\tau_Q(v)(\overline{v_q})=v_q$, with $\tau_Q:T^1_kQ\to Q$ the canonical projection. In induced coordinates we have

$$\mathcal{FL}:(t^A,q^i,v^i_A)\to\left(t^A,q^i,\frac{\partial L}{\partial v^i_A}\right). \tag{30}$$

The Jacobian matrix of $\mathcal{FL}$ is

$$\begin{pmatrix} I_k & & 0 & 0 & \ldots & 0\\ 0 & & I_n & 0 & \ldots & 0\\ & \mathcal{B} & & & \mathcal{C} & \end{pmatrix}, \tag{31}$$

where I_k e I_n are the identity matrices of order k and n, respectively, $\mathcal{B}$ is a matrix $nk\times(k+n)$ and $\mathcal{C}$ is the matrix

$$\left(\frac{\partial^2 L}{\partial v^i_A\,\partial v^j_B}\right).$$

Now, from (12) and (30) we deduce the following.

Lemma VI.5: We have

$$(\omega_L)_A=\mathcal{FL}^*((\omega_0)_A),\quad \overline{\eta}_A=\mathcal{FL}^*((\eta_0)_A),$$

for all A.

Next, from (31) we obtain the following proposition.

Proposition VI.6: The following conditions are equivalent:

(1) L is regular.

(2) $\mathcal{FL}$ is a local diffeomorphism.

(3) $(\overline{\eta}_1,\ldots,\overline{\eta}_k,(\omega_L)_1,\ldots,(\omega_L)_k,V_0)$ is a k-cosymplectic structure on $\mathbf{R}^k\times T^1_kQ$.

VII. SINGULAR CASE

When the Lagrangian function L is not regular, the family $(\overline{\eta}_A,(\omega_L)_A,V_0,1\leqslant A\leqslant k)$ is no longer a k-cosymplectic structure. Even in this case, from (24), we deduce that if $\mathbf{X}=(X_1,\ldots,X_k)$ is an integrable SOPDE such that

$$\begin{aligned}&\overline{\eta}_A(X_B)=\delta_{AB},\\ &\Omega^\sharp_L(X_1,\ldots,X_k)=dE_L+\sum_{A=1}^{k}\left(1+\frac{\partial}{\partial t^A}(L)\right)\overline{\eta}_A,\end{aligned} \tag{32}$$

then its solutions satisfy the Euler–Lagrange equations.

But we cannot assure that such a solution exists. Therefore we shall develop a constraint algorithm inspired in the well-known one for singular Lagrangians in mechanics in order to obtain a final constraint submanifold where such a solution exists.

We put $P_1=\mathbf{R}^k\times T^1_kQ$. Next, let P_2 be the subset of P_1 which consists of those points where there exists solution of (32), that is,

$$P_2=\{z\in P_1/\exists \mathbf{X}\in (T^1_k(\mathbf{R}^k\times(T^1_k)^*Q))_z \text{ satisfying the SOPDE condition and being a solution of (32)}\}.$$

If P_2 is a submanifold of P_1, then there exists a section of $\tau_{\mathbf{R}^k\times T^1_kQ}$ over P_2. This section is not in general a k-vector field on P_2. To find solutions taking values into $T^1_kP_2$ we construct a new subset P_3 of P_2 as follows:

$$P_3=\{z\in P_2/\exists \mathbf{X}\in (T^1_kP_2)_z \text{satisfying the SOPDE condition and being a solution of (32)}\}.$$

If P_3 is a submanifold of P_2, there exists a section of τ_{P_2} over P_3 which is solution of (23), but that not defines, in general, a k-vector field on P_3.

Proceeding further, we get a family of constraint manifolds,

$$\cdots\to P_3\to P_2\to P_1=\mathbf{R}^k\times T^1_kQ.$$

In the most favorable case, this constraint algorithm stabilizes at some step, say $P_{h+1}=P_h$ and $\dim P_h>0$. In this case, we call $P_f=P_h$ the final constraint manifold. On P_f there exists a SOPDE solution of (32).

Of course, this solution would not be unique as in the regular case. It should be noticed that, in addition, the solutions on P_f shall not be in principle integrable. To guarantee the existence of an integrable solution one has to develop an additional constraint algorithm taking the brackets of the vector fields which compose a SOPDE solution. Doing that we shall obtain an integrable SOPDE solution on a (smaller, in general) submanifold S of P_f; its solutions shall satisfy the Euler–Lagrange equations (11) (see Ref. 13).

(Received 8 November 1999; accepted for publication 30 January 2001)

We consider the Miura map between the lattice Kadomtsev–Petviashvili hierarchy and the lattice modified KP hierarchy and prove that the map is canonical not only between the first Hamiltonian structures, but also between the second Hamiltonian structures. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1359416]

I. INTRODUCTION

It is well known that the Miura map, a transformation between the Korteweg–de Vries (KdV) equation and modified KdV (MKdV) equation, plays a central role in the development of soliton theory. Indeed, the celebrated inverse scattering method for solving nonlinear equations starts with the Miura map.[1] This type of transformation turns out to exist in the context of other integrable equations (see Refs. 2–13, and references therein).

Kupershmidt, in a recent paper,[9] considered the canonical properties of Miura maps between Kadomtsev–Petviashvili and MKP hierarchies. He shows that, both in continuous and discrete cases, Miura transformations are canonical between the first Hamiltonian structures. For the ordinary or continuous KP and its modification, Shaw and Tu[12] generalized the results of Kupershmidt and proved that the very Miura map is also canonical between the second Hamiltonian structures.

We will consider the canonical property of the Miura map between the lattice MKP (LMKP) and the lattice KP (LKP) hierarchies. The LKP hierarchy is a bi-Hamiltonian system and two Hamiltonian structures were constructed by using the residue calculus in Ref. 8. For the LMKP hierarchy, the first Hamiltonian structure was also found in Ref. 9. A slightly different version of the LMKP hierarchy was proposed by Oevel and he further obtained the bi-Hamiltonian description for this hierarchy by means of an *r*-matrix approach.[14] By introducing a parameter, we unify Kupershmidt's version of the LMKP hierarchy and Oevel's version into a single system. Our main purpose of the paper is to prove that Kupershmidt's Miura map is a canonical map not only between the first Hamiltonian structures of LKP and LMKP, but also between the second Hamiltonian structures.

The paper is organized as follows. In Sec. II, we introduce notations and recall the relevant formulas such as bi-Hamiltonian structures of the LKP and LMKP hierarchies. In Secs. III and IV, we show that Kupershmidt's Miura map is a canonical transformation for the first Hamiltonian structures and the second Hamiltonian structures, respectively. Section V is intended for a summary and discussions.

II. BACKGROUND AND NOTATIONS

To introduce the LKP and LMKP hierarchies, we consider the algebra of shift operators

$$g=\{u_N(n)T^N+u_{N-1}(n)T^{N-1}+\cdots+u_0(n)+u_{-1}(n)T^{-1}+\cdots\},$$

a)Electronic mail: qpl@mail.cumtb.edu.cn

where u_j are scalar functions of integer n. The shift operator T is given by

$$(Tf)(n)=f^{(1)}(n):=f(n+1),$$

and for arbitrary integer k, $(T^k f)(n)=f^{(k)}(n)=f(n+k)$.

For any operator $\xi=\Sigma_j u_j T^j \in g$, the projections to various shift orders are denoted by

$$\xi_j=u_j T^j, \quad \xi_{\geqslant k}=\sum_{j\geqslant k} u_j T^j, \quad \xi_{<k}=\sum_{j<k} u_j T^j,$$

$$\xi_{>k}=\sum_{j>k} u_j T^j, \quad \xi_{\leqslant k}=\sum_{j\leqslant k} u_j T^j.$$

From the shift operator T, we also have the difference operator

$$\Delta=T-1,$$

and its formal inverse

$$\Delta^{-1}=\sum_{j\geqslant 1} T^{-j}.$$

Another important notation is the so-called trace, which is defined as

$$\mathrm{tr}\left(\sum_i u_i T^i\right)=\sum_n u_0(n),$$

this permits us to identify g and its dual by the metric $g^*:\langle u^*,u\rangle=\mathrm{tr}(u^*u)$. It can be shown that the metric is bi-invariant.

The LKP hierarchy is defined by the following Lax operator:

$$L=T+\sum_{i=0}^{\infty} A_i T^{-i}, \tag{1}$$

and the flow equations are constructed as

$$L_{t_n}=[(L^n)_{\geqslant 0},L]. \tag{2}$$

The LKP hierarchy (2) is a bi-Hamiltonian system. Its two Hamiltonian structures are constructed by means of the residue calculus in Ref. 8. Recently, Oevel proposed an r-matrix setting for these Hamiltonian structures. The two Hamiltonian structures are given by the following Poisson tensors:

$$P_1(\nabla H)=[\nabla H,L]_{\leqslant 0}, \tag{3}$$

$$P_2(\nabla H)=(L\nabla H)_{\geqslant 1}L-L(\nabla HL)_{\geqslant 1}+\tfrac{1}{2}[(L\nabla H+\nabla HL)_0,L]+\tfrac{1}{2}[\rho([\nabla H,L]_0),L], \tag{4}$$

where ρ is a skew-symmetric linear map on the algebra g_0 given explicitly by

$$\rho=\frac{T+1}{T-1}, \tag{5}$$

and

$$\nabla H = \frac{\delta H}{\delta A_0} + T\frac{\delta H}{\delta A_1} + \cdots . \tag{6}$$

As for the LMKP hierarchy, we consider the following Lax operator:

$$\mathcal{L} = qT + \sum_{i=0}^{\infty} a_i T^{-i}, \tag{7}$$

and the flow equations are represented by

$$\mathcal{L}_{t_n} = [(\mathcal{L}^n)_{\geqslant 1} + \alpha(\mathcal{L}^n\Delta^{-1})_0, \mathcal{L}], \tag{8}$$

where α is a constant.

The case $\alpha=0$ and the case $\alpha=1$ were considered by Kupershmidt and Oevel, respectively. In these two cases, the MLKP hierarchy (8) is a bi-Hamiltonian system. When $\alpha=0$, the first Hamiltonian structure of (8) is found by Kupershmidt in the context of the residue calculus, it is not clear how to construct the second one this way. Oevel, in the case $\alpha=1$, gives the bi-Hamiltonian structures by means of an *r*-matrix approach.

Consider the linear operator on g,

$$r(\xi) = \xi_{\geqslant 1} - \xi_{<1} - 2\alpha(\xi\Delta^{-1})_0,$$

by direct calculations it is found that the above-mentioned r solves the modified Yang–Baxter equation only and only if $\alpha=0$ or $\alpha=1$. As we mentioned previously, these are exactly the two cases studied by Kupershmidt and by Oevel. In the following, our parameter α will take the value either one or zero. The above-mentioned *r*-matrix leads to the first Hamiltonian structure for the LMKP hierarchy.

To get the second Poisson tensor, one may use Suris's construction[15] by considering the following linear operators:

$$\mathcal{A}_1(\xi) = \xi_{\geqslant 1} - \xi_{<0} - 2\alpha(\xi\Delta^{-1})_0 - \rho(\xi_0) + 2\alpha\Delta^{-1}\xi_0,$$

$$\mathcal{A}_2(\xi) = \xi_{\geqslant 1} - \xi_{<0} + \rho(\xi_0),$$

$$\mathcal{S}(\xi) = \rho(\xi_0) - \xi_0 - 2\alpha\Delta^{-1}\xi_0,$$

$$\mathcal{S}^{\dagger}(\xi) = -\rho(\xi_0) - \xi_0 - 2\alpha(\xi\Delta^{-1})_0.$$

When $\alpha=1$, the above-mentioned operators are those presented by Oevel and lead to the second Poisson tensor for this case. It can be proved that in the case $\alpha=0$, these operators satisfy the conditions of Suris's theorem (or the theorem 1 of Oevel[14]), therefore they also lead to a Poisson tensor, this time for Kupershmidt's case. Unifying both Kupershmidt's case and Oevel's case, we have the following two Poisson tensors:

$$\widetilde{\mathcal{P}}_1(\nabla H) = [(\nabla H)_{\geqslant 1}, \mathcal{L}] - [\nabla H, \mathcal{L}]_{\geqslant 0} - \alpha[(\nabla H\Delta^{-1})_0, \mathcal{L}] - \alpha\Delta^{-1}[\nabla H, \mathcal{L}]_0, \tag{9}$$

$$\begin{aligned}\widetilde{\mathcal{P}}_2(\nabla H) = {} & (\mathcal{L}\nabla H)_{\geqslant 1}\mathcal{L} - \mathcal{L}(\nabla H\mathcal{L})_{\geqslant 1} + \tfrac{1}{2}[\mathcal{L}, \nabla H]_0\mathcal{L} + \tfrac{1}{2}\mathcal{L}[\mathcal{L}, \nabla H]_0 + \alpha\Delta^{-1}[\mathcal{L}, \nabla H]_0\mathcal{L} \\ & + \alpha[\mathcal{L}, (\mathcal{L}\nabla H\Delta^{-1})_0] + \tfrac{1}{2}[\rho([\nabla H, \mathcal{L}]_0), \mathcal{L}],\end{aligned} \tag{10}$$

where ρ is the one defined by (5) and ∇H is parametrized as

$$\nabla H = T^{-1}\frac{\delta H}{\delta q} + \frac{\delta H}{\delta a_0} + T\frac{\delta H}{\delta a_1} + \cdots . \tag{11}$$

In the remaining part of this section, we introduce the Miura map between LKP hierarchy and LMKP hierarchy following Kupershmidt. With the aid of a new field w, we introduce a map between LKP and MLKP hierarchies via the conjugacy

$$L=e^{w}\mathcal{L}e^{-w}=e^{w}qTe^{-w}+\sum_{i=0}^{\infty}e^{w}a_{i}T^{-i}e^{-w},$$

comparing the coefficients of different power of the shift operator of two sides leads to a transformation

$$q=e^{w^{(1)}-w},\quad A_{i}=a_{i}e^{w-w^{(-i)}}\quad (i\geqslant 0).$$

Let us introduce the new notations

$$R_{i}=R_{i}(q):=\prod_{s=0}^{i}q^{(-s)}/q\quad (i\geqslant 0).$$

By eliminating the intermediate variable w, we reach the Miura map between the two sets of variables

$$M:\quad A_{0}=a_{0},\quad A_{i}=R_{i}a_{i}\quad (i>0). \tag{12}$$

This is the Miura map constructed in Ref. 9.

Now we prove that if $\mathcal{L}$ solves the MLKP hierarchy, $L=e^{w}\mathcal{L}e^{-w}$ solves the LKP hierarchy. From $q=e^{w^{(1)}-w}$, we obtain $q_{t}=q(T-1)w_{t}$. On the other hand, the time evolution of q can be read from the MLKP hierarchy, that is $q_{t}=q(T-1)((\mathcal{L}^{n})_{0}+\alpha(\mathcal{L}^{n}\Delta^{-1})_{0})$, so $w_{t}=(\mathcal{L}^{n})_{0}+\alpha(\mathcal{L}^{n}\Delta^{-1})_{0}$. Now

$$\begin{aligned}L_{t}&=[w_{t},L]+e^{w}[(\mathcal{L}^{n})_{\geqslant 1}-\alpha(\mathcal{L}^{n}\Delta^{-1})_{0},\mathcal{L}]e^{-w}\\&=[w_{t},L]+[e^{w}(\mathcal{L}^{n})_{\geqslant 1}e^{-w},L]-\alpha[(\mathcal{L}^{n}\Delta^{-1})_{0},L]=[(L^{n})_{\geqslant 0},L],\end{aligned}$$

where we used $(\mathcal{L}^{n})_{0}=(L^{n})_{0}$ and $e^{w}(\mathcal{L}^{n})_{\geqslant 1}=(L^{n})_{\geqslant 1}e^{w}$. Thus the Miura map (12) indeed converts the LMKP hierarchy into the LKP hierarchy.

III. CANONICAL PROPERTIES FOR FIRST HAMILTONIAN STRUCTURES

In this section, we prove that the Miura map is canonical between the first Hamiltonian structures. First we calculate the Hamiltonian matrices from the Poisson tensors (3) and (9). By substituting (6) into P_{1} and (11) into P_{2}, it is straightforward to get

$$B_{1}^{\mathrm{LKP}}=(B_{ij}),B_{ij}=T^{j}A_{i+j}-A_{i+j}T^{-i}\quad (i,j\geqslant 0), \tag{13}$$

and

$$B_{1}^{\mathrm{LMKP}}=\begin{array}{c}\\ q\\ a_{0}\\ a_{i>0}\end{array}\begin{array}{c}\begin{array}{ccc}q & a_{0} & a_{j>0}\end{array}\\ \begin{pmatrix}0 & q(T-1) & \alpha q(T-1)T^{j}\\ (1-T^{-1})q & 0 & 0\\ \alpha T^{-i}(1-T^{-1})q & 0 & B_{ij}^{(\mathrm{LMKP})}\end{pmatrix}\end{array}, \tag{14}$$

where

$$B_{ij}^{(\mathrm{LMKP})}=T^{j}a_{i+j}-a_{i+j}T^{-i}+\alpha(a_{i}T^{j-i}-T^{j-i}a_{j}+T^{-i}a_{j}-a_{i}T^{j}), \tag{15}$$

The Jacobian matrix of the Miura map (12) is easily calculated as

$$q \qquad a_0 \qquad a_{i>0}$$

$$J = A_n(a_n D_n \quad R_n\delta_n^0 \quad R_n\delta_n^i), \tag{16}$$

where δ_j^i is the standard Kronecker symbol and D_n is the abbreviated notation for the Fréchet derivative given by

$$D_n := D(R_n) = R_n \frac{1-T^{-n}}{T-1} q^{-1}, \quad D_n^\dagger = q^{-1}\frac{1-T^n}{T^{-1}-1} R_n . \tag{17}$$

We need to calculate the matrix operator $JB_1^{\mathrm{LMKP}}J^\dagger$, but first it is easy to find that

$$q \qquad\qquad a_0 \qquad\qquad a_{j>0}$$

$$JB_1^{\mathrm{LMKP}} = \begin{matrix} A_0 \\ A_{i>0} \end{matrix}\begin{pmatrix} (1-T^{-1})q & 0 & 0 \\ \alpha R_i T^{-i}(1-T^{-1})q & a_i D_i q(T-1) & \alpha a_i D_i q(T-1)T^j + R_i B_{ij}^{(\mathrm{LMKP})} \end{pmatrix},$$

now the entries of the first row of the $JB_1^{\mathrm{LMKP}}J^\dagger$ are seen as

$$(JB_1^{\mathrm{LMKP}}J^\dagger)_{0,m} = (1-T^{-1})qD_m^\dagger a_m = -(1-T^m)R_m a_m = (T^m-1)A_m ,$$

which coincide with the $(B_1^{\mathrm{LKP}})_{0,m}$. It is noticed that we have used the second formula of (17). Therefore, for the first row and the first column, two matrix operators B_1^{LKP} and $JB_1^{\mathrm{LMKP}}J^\dagger$ are just the same as expected. We turn our attention to other entries of matrices. We find that

$$\begin{aligned}(JB_1^{\mathrm{LMKP}}J^\dagger)_{mn} &= \alpha R_m T^{-m}(1-T^{-1})qD_n^\dagger a_n + \alpha a_m D_m q(T-1)T^n R_n + \alpha R_m(a_m T^{n-m} - T^{n-m}a_n \\ &\quad + T^{-m}a_n - a_m T^n)R_n + R_m(T^n a_{m+n} - a_{n+m}T^{-m})R_n \\ &= \alpha R_m T^{-m}(T^n-1)R_n a_n + \alpha a_m R_m(1-T^{-m})T^n R_n + \alpha R_m(a_m T^{n-m} - T^{n-m}a_n \\ &\quad + T^{-m}a_n - a_m T^n)R_n + R_m(T^n a_{m+n} - a_{n+m}T^{-m})R_n \\ &= R_m(T^n a_{m+n} - a_{n+m}T^{-m})R_n .\end{aligned}$$

Now we use the formula in Ref. 9,

$$R_n T^m R_m = T_m R_{n+m} ,$$

and obtain the desired the results $(JB_1^{\mathrm{LMKP}}J^\dagger)_{mn} = (B_1^{\mathrm{LKP}})_{mn}$. Thus, the Miura map is indeed canonical.

IV. CANONICAL PROPERTY FOR SECOND HAMILTONIAN STRUCTURES

We now show that the Miura map (12) is also canonical between the second Hamiltonian structure of the LKP hierarchy and the second Hamiltonian structure of the LMKP hierarchy. As in Sec. III, we first calculate the Hamiltonian matrix operators from the Poisson tensors (4) and (10). The calculation in the present case is a bit cumbersome although it is straightforward. For the LKP hierarchy we have

$$A_{k,t} = \sum_{\ell=0}^{\infty} (B_2^{\mathrm{LKP}})_{k\ell}\frac{\delta H}{\delta A_\ell}, \quad k \geqslant 0, \quad t \equiv t_n, \quad H \equiv H_n = \frac{1}{n}\mathrm{tr}(L^n),$$

where

$$(B_2^{\mathrm{LKP}})_{k\ell} = \sum_{j=1}^{\ell+1}(A_{\ell-j}T^j A_{k+j} - A_{k+j}T^{\ell-k-j}A_{\ell-j}) + A_k(1-T^{-k})(1+T+\cdots+T^\ell)A_\ell ,$$

$$A_{-1}\equiv 1,\quad k\geqslant 0,\quad \ell\geqslant 0.$$

For the MLKP hierarchy, we have

$$B_2^{\mathrm{LMKP}} \begin{matrix} q \\ a_{k\geqslant 0} \end{matrix} = \begin{matrix} q & a_{m\geqslant 0} \end{matrix} \begin{pmatrix} q(T-T^{-1})q & \alpha q(T-1)\sum_{i=1}^{m+1} a_{m-i}T^i + q(T-T^m)a_m \\ \alpha\sum_{j=1}^{k+1} T^{-j}a_{k-j}(1-T^{-1})q + a_k(T^{-k}-T^{-1})q & B_{km}^{\mathrm{LMKP}} \end{pmatrix}$$

with

$$B_{km}^{\mathrm{LMKP}} = \sum_{i=1}^{m+1}(a_{m-i}T^i a_{k+i} - a_{k+i}T^{m-k-i}a_{m-i}) + a_k\frac{(1-T^{-k+1})(1-T^m)}{1-T}a_m + \alpha a_k(T^{-k}-1)\sum_{i=1}^{m+1} a_{m-i}T^i + \alpha\sum_{j=1}^{k+1} T^{-j}a_{k-j}(1-T^m)a_m,$$

$$a_{-1}\equiv q.$$

Thus, the matrix operator JB_2^{LMKP} reads as

$$JB_2^{\mathrm{LMKP}} = \begin{matrix} A_0 \\ A_{k\geqslant 0} \end{matrix} \begin{matrix} q & a_{m\geqslant 0} \end{matrix} \begin{pmatrix} (a_0+\alpha T^{-1}q)(1-T^{-1})q & qT^{m+1}a_{m+1} - a_{m+1}T^{-1}q + \alpha T^{-1}q(1-T^m)a_m \\ a_kD_kq(T-T^{-1})q + a_kR_k(T^{-k}-T^{-1})q + \alpha R_k\sum_{j=1}^{k+1} T^{-j}a_{k-j} \times (1-T^{-1})q & a_kD_k(q(T-T^{-m})a_m + \alpha R_kq(T-1) \times \sum_{i=1}^{m+1} a_{m-i}T^i) + R_kB_{km}^{\mathrm{LMKP}} \end{pmatrix}.$$

With all these formulas in hand, we find that the entries of the first row of $JB_2^{\mathrm{LMKP}}J^\dagger$ are

$$\begin{aligned}(JB_2^{\mathrm{LMKP}}J^\dagger)_{0,n} &= (a_0+\alpha T^{-1}q)(1-T^{-1})qD_n^\dagger a_n \\ &\quad + (qT^{n+1}a_{n+1} - a_{n+1}T^{-1}q + \alpha T^{-1}q(1-T^n)a_n)R_n \\ &= -(a_0+\alpha T^{-1}q)(1-T^n)A_n + qT^{n+1}a_{n+1}R_n - a_{n+1}T^{-1}qR_n + \alpha T^{-1}q(1-T_n)A_n \\ &= -a_0(1-T^n)A_n + qT^{n+1}a_{n+1}R_n - a_{n+1}T^{-1}qR_n \\ &= A_0(T^n-1)A_n + T^{n+1}A_{n+1} - A_{n+1}T^{-1} = (B_2^{\mathrm{LKP}})_{0,n},\end{aligned}$$

where we used

$$q^{(-n-1)}R_n = R_{n+1},\quad q^{-1}R_n^{(-1)} = R_{n+1},$$

which hold identically. For the remaining entries, we have

$$(JB_2^{\mathrm{LMKP}}J^{\dagger})_{mn}=a_mD_mq(T-T^{-1})qD_n^{\dagger}a_n+R_ma_m(T^{-m}-T^{-1})qD_n^{\dagger}a_n \tag{18}$$

$$+a_mD_mq(T-T^n)a_n+R_ma_m\frac{(1-T^{-m+1})(1-T^n)}{1-T}a_nR_n \tag{19}$$

$$+\alpha R_m\sum_{j=1}^{m+1}T^{-j}a_{m-j}((1-T^{-1})qD_n^{\dagger}a_n+(1-T^n)a_nR_n) \tag{20}$$

$$+\alpha(a_mD_mq(T-1)+R_ma_m(T^{-m}-1))\sum_{j=1}^{n+1}a_{n-j}T^jR_n \tag{21}$$

$$+R_m\left(\sum_{l=1}^{n+1}(a_{n-l}T^la_{m+l}-a_{m+l}T^{n-m-l}a_{n-l})\right)R_n, \tag{22}$$

so we need to prove that the above-mentioned expression is $(B_2^{\mathrm{LKP}})_{mn}$.

It is easy to see that $(20)=(21)=0$ in terms of D_m.

Since $T-T^{-1}=-(1+T)(T^{-1}-1)$, we obtain

$$(18)+(19)=-A_m\frac{1-T^{-m}}{T-1}(1+T)(1-T^n)A_n+A_m(T^{-m}-T^{-1})\frac{1-T^n}{T^{-1}-1}A_n$$

$$+A_m\frac{1-T^{-m}}{T-1}(T-T^n)A_n+A_m\frac{(1-T^{-m+1})(1-T^n)}{1-T}A_n$$

$$=A_m\frac{1-T^{-m}-T^{n+1}+T^{n-m+1}}{1-T}A_n=A_m\frac{(1-T^{-m})(1-T^{n+1})}{1-T}A_n.$$

Thus to complete the proof, we need to show that

$$R_m\left(\sum_{i=1}^{n+1}a_{n-i}T^ia_{m+i}-a_{m+i}T^{n-m-i}a_{n-i}\right)R_n=\sum_{j=1}^{n+1}(A_{n-j}T^jA_{m+j}-A_{m+j}T^{n-m-j}A_{n-j}),$$

this amounts to the identity

$$R_mT^jR_n=R_{n-j}T^jR_{m+j},\quad 1\leqslant j\leqslant n+1,$$

which can be seen as follows:

$$\begin{aligned}R_mT^jR_n&=q^{(-1)}\cdots q^{(-m)}q^{(-1+j)}\cdots q^{(-n+j)}\\&=q^{(-1)}\cdots q^{(-m)}q^{(-1+j)}\cdots qq^{(-1)}\cdots q^{(-n+j)}\\&=q^{(-1)}\cdots q^{(-n+j)}q^{(-1+j)}\cdots qa^{(-1)}\cdots q^{(-m)}\\&=R_{n-j}T^jR_{m+j}.\end{aligned}$$

Thus, we conclude that the Miura map is canonical in the sense of the second Hamiltonian structures.

V. CONCLUSIONS AND DISCUSSIONS

We have proved that the canonical property of the Miura map holds between the LKP hierarchy and the LMKP hierarchy, that is, it maps the bi-Hamiltonian structures of the LMKP hierarchy to those of the LKP hierarchy. In Ref. 9, the lattice KP hierarchy is extended and it turns

out that the extended lattice KP hierarchy is isomorphic to the lattice MKP hierarchy. Since we are dealing with a slightly generalized version of the LMKP hierarchy here (8), we have a different extended LKP hierarchy.

Introducing a new field u and defining the following invertible transformation

$$u=q, \quad A_0=a_0, \quad A_i=R_i a_i,$$

it is easy to see that the first Hamiltonian matrix operator for our extended LKP hierarchy reads

$$B_1^{\mathrm{ELKP}}=\begin{array}{c} \\ u \\ A_0 \\ A_{n>0} \end{array}\begin{array}{c} \begin{array}{ccc} u & A_0 & A_{m>0} \end{array} \\ \begin{pmatrix} 0 & u(T-1) & \alpha u(T-1)T^m R_m \\ (1-T^{-1})u & 0 & (T^m-1)A_m \\ \alpha R_n T^{-n}(1-T^{-1})u & A_n(1-T^{-n}) & T^m A_{n+m}-A_{n+m}T^{-n} \end{pmatrix} \end{array}, \tag{23}$$

and the flow equations are given

$$u_t=u(T-1)\frac{\delta H}{\delta A_0}+\alpha\sum_{m=1}^{\infty} u(T-1)T^m\frac{\delta H}{\delta A_m},$$

$$A_{i,t}=\alpha R_n T^{-n}(1-T^{-1})u\frac{\delta H}{\delta u}+\sum_{j=0}^{\infty}(B_1^{\mathrm{ELKP}})_{ij}\frac{\delta H}{\delta A_j}, \quad H\equiv H_{n+1}=\frac{1}{n+1}\mathrm{tr}(L^{n+1}),$$

where the Hamiltonian H is the seam as in the LKP case. We could have a second Hamiltonian structure for the extended LKP hierarchy, but it is in a rather complicated form. So we omit it.

To conclude the paper, we point out that it seems interesting to prove the canonical property of the Miura map on the level of the Poisson tensors since that will hopefully make the proof more concise. For the Gelfand–Dickey hierarchy, such proof was given by Dickey[4] and for the continuous KP hierarchy and the constrained KP hierarchy, it is provided in Ref. 12 and in Refs. 11, 13, respectively.

(Received 16 August 2000; accepted for publication 19 January 2001)

Two binary (integral type) Darboux transformations for the KdV hierarchy with self-consistent sources are proposed. In contrast with the Darboux transformation for the KdV hierarchy, one of the two binary Darboux transformations provides non-auto-Bäcklund transformation between two nth KdV equations with self-consistent sources with different degrees. The formula for the m-times repeated binary Darboux transformations are presented. This enables us to construct the N-soliton solution for the KdV hierarchy with self-consistent sources. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1357826]

I. INTRODUCTION

The soliton equations with self-consistent sources have important physical applications (see Refs. 1–11), for example, the KdV equation with self-consistent source describes the interaction of long and short capillary-gravity waves.[5] There are some ways to derive the integrable nonlinear evolution equations with self-consistent sources.[1–3,12,13] In recent years soliton equations with self-consistent sources (SESCS) were studied based on the constrained flows of soliton equations which are just the stationary equations of SESCSs.[14–19] Since the Lax representations for the constrained flows of soliton equations can always be deduced from the adjoint representations of the Lax representations for soliton equations, this approach provides a simple and natural way to derive both the SESCSs and their Lax representations.[15–17] The SESCS is an infinite-dimensional integrable Hamiltonian system possessing t-type Hamiltonian or bi-Hamiltonian formulation[20] and can be solved by the inverse scattering method.[1–3,21–23]

The Darboux transformation is a power tool for solving soliton equations (see Ref. 24 for a review). The Darboux transformation for KdV hierarchy was widely studied (see, for example, Refs. 24–27). In the present paper we will generalize these results to the KdV hierarchy with self-consistent sources. We construct one Darboux transformation and two binary (integral type) Darboux transformations for the KdV hierarchy with self-consistent sources. The Darboux transformations usually present auto-Bäcklund transformations for soliton equations. In contrast with the case of soliton equations, one binary Darboux transformation in our case is proved to be a non-auto-Bäcklund transformation between two nth KdV equations with self-consistent sources with different degrees. This provides an interesting example for constructing non-auto-Bäcklund transformations by means of Darboux transformations. Furthermore we present the formula for the m-times repeated binary Darboux transformations and construct the N-soliton solution for the KdV hierarchy with self-consistent sources.

The paper is organized as follows. In the next section we recall the KdV hierarchy with self-consistent sources and briefly describe how to derive their Lax representation from the adjoint

representation of the Lax representation for the KdV hierarchy. In Sec. III, we briefly review Darboux transformations for the KdV hierarchy and present two binary Darboux transformations. Based on these results, in Sec. IV, we propose one Darboux transformation and two binary Darboux transformations for the KdV hierarchy with self-consistent sources and show that the first binary Darboux transformation gives the auto-Bäcklund transformation for the KdV hierarchy with self-consistent sources, and the second binary Darboux transformation leads to a non-auto-Bäcklund transformation relating two nth KdV equations with self-consistent sources with different degrees. Finally in the last section we present the m-times repeated binary Darboux transformations and construct the N-soliton solution for the nth KdV equation with self-consistent sources.

II. THE KdV HIERARCHY WITH SELF-CONSISTENT SOURCES

To make the paper self-contained, we first recall the high-order constrained flows of the KdV hierarchy and briefly describe how to derive the Lax representation for the KdV hierarchy with self-consistent sources.

Consider the Schrödinger equation

$$\phi_{xx}+(\lambda+u)\phi=0. \tag{2.1}$$

In order to derive the Lax representation for the KdV hierarchy with self-consistent sources, we rewrite Eq. (2.1) in the matrix form

$$\begin{pmatrix}\phi\\ \phi_x\end{pmatrix}_x=U\begin{pmatrix}\phi\\ \phi_x\end{pmatrix},\quad U=\begin{pmatrix}0 & 1\\ -\lambda-u & 0\end{pmatrix}. \tag{2.2}$$

The adjoint representation of (2.2) reads[28]

$$V_x=[U,V]\equiv UV-VU. \tag{2.3}$$

Set

$$V=\sum_{i=0}^{\infty}\begin{pmatrix}a_i & b_i\\ c_i & -a_i\end{pmatrix}\lambda^{-i}. \tag{2.4}$$

Equation (2.3) yields

$$a_0=b_0=0,\quad c_0=-1,\quad a_1=0,\quad b_1=1,\quad c_1=-\tfrac{1}{2}u,$$

$$a_2=\tfrac{1}{4}u_x,\quad b_2=-\tfrac{1}{2}u,\quad c_2=\tfrac{1}{8}(u_{xx}+u^2),\ldots,$$

and in general for $k=1,2,\ldots,$

$$a_k=-\tfrac{1}{2}b_{k,x},\quad b_{k+1}=Lb_k=-\tfrac{1}{2}L^{k-1}u,\quad c_k=-\tfrac{1}{2}b_{k,xx}-b_{k+1}-b_ku, \tag{2.5}$$

where

$$L=-\tfrac{1}{4}\partial^2-u+\tfrac{1}{2}\partial^{-1}u_x,\quad \partial=\frac{\partial}{\partial x},\quad \partial\partial^{-1}=\partial^{-1}\partial=1.$$

Set

$$V^{(n)}=\sum_{i=0}^{n+1}\begin{pmatrix}a_i & b_i\\ c_i & -a_i\end{pmatrix}\lambda^{n+1-i}+\begin{pmatrix}0 & 0\\ b_{n+2} & 0\end{pmatrix}, \tag{2.6}$$

and take

$$\begin{pmatrix} \phi \\ \phi_x \end{pmatrix}_{t_n} = V^{(n)}(u,\lambda)\begin{pmatrix} \phi \\ \phi_x \end{pmatrix}, \tag{2.7}$$

or equivalently

$$\phi_{t_n} = A^{(n)}(u,\lambda)\phi, \quad A^{(n)}(u,\lambda) \equiv \sum_{i=0}^{n+1} (a_i + b_i\partial)\lambda^{n+1-i}. \tag{2.8}$$

Then the compatibility condition of Eqs. (2.1) and (2.8) or (2.2) and (2.7) gives rise to the KdV hierarchy

$$u_{t_n} = K_n[u] \equiv \partial \frac{\delta H_n}{\delta u} \equiv -2b_{n+2,x}, \quad n = 0,1,\ldots, \tag{2.9}$$

where $H_n = 4b_{n+3}/2n+3$. We have

$$\frac{\delta\lambda}{\delta u} = \phi^2, \quad L\phi^2 = \lambda\phi^2. \tag{2.10}$$

The high-order constrained flows of the KdV hierarchy consist of the equations obtained from the spectral problem (2.1) for N distinct λ_j and the restriction of the variational derivatives for the conserved quantities H_n and λ_j,[29]

$$D\left[\frac{\delta H_n}{\delta u} - 2\alpha\sum_{j=1}^{N}\frac{\delta\lambda_j}{\delta u}\right] \equiv D\left[-2b_{n+2} - 2\alpha\sum_{j=1}^{N}\phi_j^2\right] = 0, \tag{2.11a}$$

$$\phi_{j,xx} + (\lambda_j + u)\phi_j = 0, \quad j = 1,\ldots,N, \tag{2.11b}$$

where $n = 0,1,\ldots$. According to Eqs. (2.5), (2.10), and (2.11), we may define

$$\tilde{a}_i = a_i, \quad \tilde{b}_i = b_i, \quad \tilde{c}_i = c_i, \quad i = 0,1,\ldots,n+1,$$

$$\tilde{b}_{n+2+i} = -\alpha\sum_{j=1}^{N}\lambda_j^i\phi_j^2, \quad \tilde{a}_{n+2+i} = -\tfrac{1}{2}\tilde{b}_{n+2+i,x} = \alpha\sum_{j=1}^{N}\lambda_j^i\phi_j\phi_{j,x}, \quad i = 0,1,2,\ldots,$$

$$\tilde{c}_{n+2+i} = -\frac{1}{2}\tilde{b}_{n+2+i,xx} - \tilde{b}_{n+3+i} - \tilde{b}_{n+2+i}u = \alpha\sum_{j=1}^{N}\lambda_j^i\phi_{j,x}^2.$$

Then the construction of $\tilde{a}_i, \tilde{b}_i, \tilde{c}_i$ ensures that

$$\begin{aligned} N^{(n)} &= \lambda^{n+1}\sum_{k=0}^{\infty}\begin{pmatrix} \tilde{a}_k & \tilde{b}_k \\ \tilde{c}_k & -\tilde{a}_k \end{pmatrix}\lambda^{-k} + \begin{pmatrix} \eta & 0 \\ 0 & \eta \end{pmatrix} \\ &= \sum_{k=0}^{n+1}\begin{pmatrix} a_k & b_k \\ c_k & -a_k \end{pmatrix}\lambda^{n+1-k} + \begin{pmatrix} \eta & 0 \\ 0 & \eta \end{pmatrix} + \alpha\sum_{j=1}^{N}\frac{1}{\lambda-\lambda_j}\begin{pmatrix} \phi_j\phi_{j,x} & -\phi_j^2 \\ \phi_{j,x}^2 & -\phi_j\phi_{j,x} \end{pmatrix}, \end{aligned}$$

where η is a constant, also satisfies the adjoint representation (2.3), i.e.,

$$N_x^{(n)} = [U, N^{(n)}], \tag{2.12}$$

which gives rise to the Lax representation of the constrained flow (2.11).

The KdV hierarchy with self-consistent sources is given by[16,17]

$$u_{t_n}=D\left[\frac{\delta H_n}{\delta u}-2\alpha\sum_{j=1}^{N}\frac{\delta\lambda_j}{\delta u}\right]\equiv D\left[-2b_{n+2}-2\alpha\sum_{j=1}^{N}\phi_j^2\right], \tag{2.13a}$$

$$\phi_{j,xx}+(\lambda_j+u)\phi_j=0,\quad j=1,\ldots,N. \tag{2.13b}$$

Since the high-order constrained flows (2.11) are just the stationary equations of the KdV hierarchy with self-consistent sources (2.13), it is obvious that the zero-curvature representation for the KdV hierarchy with self-consistent sources (2.13) is given by

$$U_{t_n}-N_x^{(n)}+[U,N^{(n)}]=0, \tag{2.14}$$

with the auxiliary linear problems

$$\begin{pmatrix}\psi\\ \psi_x\end{pmatrix}_x=U\begin{pmatrix}\psi\\ \psi_x\end{pmatrix},\quad \begin{pmatrix}\psi\\ \psi_x\end{pmatrix}_{t_n}=N^{(n)}\begin{pmatrix}\psi\\ \psi_x\end{pmatrix}, \tag{2.15}$$

or equivalently

$$\psi_{xx}+(\lambda+u)\psi=0, \tag{2.16a}$$

$$\psi_{t_n}=A^{(n)}\psi+\eta\psi+\alpha\sum_{j=1}^{N}\frac{1}{\lambda-\lambda_j}\phi_j(\phi_{j,x}\psi-\phi_j\psi_x). \tag{2.16b}$$

Let's assume that all products $\phi_j\psi$ decay at $x=-\infty$ and that $\partial^{-1}=\int_{-\infty}^{x}dx$. It is easy to find from (2.13b) and (2.16a) that

$$\frac{1}{\lambda-\lambda_j}(\phi_{j,x}\psi-\phi_j\psi_x)=\partial^{-1}\phi_j\psi. \tag{2.17}$$

Let's denote

$$B_N=\alpha\sum_{j=1}^{N}\phi_j\partial^{-1}\phi_j.$$

Then Eq. (2.16b) can be rewritten as

$$\psi_{t_n}=Q^{(n,N)}\psi\equiv A^{(n)}\psi+\eta\psi+B_N\psi. \tag{2.18}$$

When $n=1$, the Eq. (2.13) gives the KdV equation with self-consistent sources

$$u_{t_1}=-\frac{1}{4}(6uu_x+u_{xxx})-2\alpha D\sum_{j=1}^{N}\phi_j^2, \tag{2.19a}$$

$$\phi_{j,xx}+(\lambda_j+u)\phi_j=0,\quad j=1,\ldots,N, \tag{2.19b}$$

and the auxiliary linear problem reads

$$\psi_{xx}+(\lambda+u)\psi=0, \tag{2.20a}$$

$$\psi_{t_1}=\left(\frac{1}{4}u_x+\eta\right)\psi+\left(\lambda-\frac{1}{2}u\right)\psi_x+\alpha\sum_{j=1}^{N}B_j\psi. \tag{2.20b}$$

III. THE DARBOUX TRANSFORMATION FOR THE KdV HIERARCHY

In this section we recall the Darboux transformation for the KdV hierarchy (see Ref. 24 for a review[25–27]).

(1) The Darboux transformation for the KdV hierarchy.

Assume that u be the solution of the nth KdV equation (2.9) and denote the fixed solution of (2.1) and (2.8) with $\lambda=\xi$ by $f=f(x,t,\xi)$. The Darboux transformation (DT) is defined by

$$\tilde{\phi}=\phi_x-\frac{f_x}{f}\phi, \tag{3.1a}$$

$$\tilde{u}=u+2\partial^2\ln f. \tag{3.1b}$$

It is known that the Schrödinger equations (2.1) and (2.8) are covariant with respect to the action of the Darboux transformation (3.1), namely $\tilde{\phi},\tilde{u}$ satisfy

$$\tilde{\phi}_{xx}+(\lambda+\tilde{u})\tilde{\phi}=0, \tag{3.2}$$

$$\tilde{\phi}_{t_n}=\tilde{A}^{(n)}\tilde{\phi}\equiv A^{(n)}(\tilde{u},\lambda)\tilde{\phi}, \tag{3.3}$$

and $\tilde{u}$ satisfies the nth KdV equation (2.9). Equations (2.8), (3.1), and (3.3) imply that

$$\tilde{\phi}_{t_n}=\left[\phi_x-\frac{f_x}{f}\phi\right]_{t_n}=(A^{(n)}\phi)_x-\left(\frac{A^{(n)}f}{f}\right)_x\phi-\frac{f_x}{f}A^{(n)}\phi=\tilde{A}^{(n)}\tilde{\phi}. \tag{3.4}$$

So the covariance of (2.1) and (2.8) with respect to the action of DT (3.1) leads to the following lemma.

Lemma 3.1: If u is the solution of the nth KdV equation (2.9) and f is a solution of (2.1) and (2.8) with $\lambda=\xi$ and the Darboux transformation is given by (3.1), then formula (3.4) holds.

We now construct the binary Darboux transformation.

(2) The first binary Darboux transformation.

Also, it is known that the linearly independent solution of (2.1) and (2.8) with $\lambda=\xi$ is given by the Liouville formula

$$g=f\partial^{-1}\frac{1}{f^2}. \tag{3.5}$$

The DT (3.1) implies that

$$\tilde{g}=g_x-\frac{f_x}{f}g=\frac{1}{f} \tag{3.6}$$

is one of the solutions of (3.2) and (3.3) with $\lambda=\xi$ and $\tilde{u}$ given by (3.1b). The linearly independent solution $\tilde{g}_1$ of (3.2) and (3.3) with $\lambda=\xi$ is once more given by the Liouville formula

$$\tilde{g}_1=\tilde{g}\partial^{-1}\frac{1}{\tilde{g}^2}=\frac{1}{f}\partial^{-1}f^2. \tag{3.7}$$

By using f and $\tilde{g}_1$, performing two-times repeated DT of (3.1) [notice that the right-hand side of (3.1a) can be added to a constant factor] and using (2.17) gives rise to the binary Darboux transformation

$$\overline{\phi}=\frac{1}{\xi-\lambda}\left[\tilde{\phi}_x-\frac{\tilde{g}_{1x}}{\tilde{g}_1}\tilde{\phi}\right]=\frac{1}{\xi-\lambda}\left[\xi\phi-\lambda\phi+\frac{f}{\partial^{-1}f^2}(f_x\phi-f\phi_x)\right]=\phi-\frac{f}{\partial^{-1}f^2}\partial^{-1}(f\phi), \tag{3.8a}$$

$$\overline{u}=\tilde{u}+2\partial^2\ln\tilde{g}_1=u+2\partial^2\ln(\partial^{-1}f^2). \tag{3.8b}$$

Obviously, the equations (2.1) and (2.8) are covariant with respect to the action of the binary DT (3.8), namely $\overline{\phi},\overline{u}$ satisfy

$$\overline{\phi}_{xx}+(\lambda+\overline{u})\overline{\phi}=0, \tag{3.9}$$

$$\overline{\phi}_{t_n}=\overline{A^{(n)}}\overline{\phi}\equiv A^{(n)}(\overline{u},\lambda)\overline{\phi}, \tag{3.10}$$

and this $\overline{u}$ satisfies the nth KdV equation (2.9). It is found from (3.8), (2.8), and (3.10) that

$$\overline{\phi}_{t_n}=\overline{A^{(n)}}\overline{\phi}=\left[\phi-\frac{f}{\partial^{-1}f^2}\partial^{-1}(f\phi)\right]_{t_n}=A^{(n)}\phi-\frac{1}{\partial^{-1}f^2}\left\{\left[A^{(n)}f-\frac{2f}{\partial^{-1}f^2}\partial^{-1}(fA^{(n)}f)\right]\partial^{-1}(f\phi)\right.$$
$$\left.+f\partial^{-1}[fA^{(n)}\phi+\phi A^{(n)}f]\right\}. \tag{3.11}$$

So the covariance of (2.1) and (2.8) with respect to the action of binary DT (3.8) leads to the following lemma.

Lemma 3.2: If u is the solution of the nth KdV equation (2.9) and f is a solution of (2.1) and (2.8) with $\lambda=\xi$ the binary DT is given by (3.8), then formula (3.11) holds.

(3) The second binary Darboux transformation.

Also the combination of $\tilde{g}$ and $\tilde{g}_1$ gives a solution of (3.2) and (3.3) with $\lambda=\xi$

$$\tilde{g}_2=\tilde{g}+\tilde{g}_1=\frac{1}{f}(1+\partial^{-1}f^2). \tag{3.12}$$

By using f and $\tilde{g}_2$, performing two-times repeated DT (3.1) leads to second binary Darboux transformation

$$\overline{\phi}=\frac{1}{\xi-\lambda}\left[\tilde{\phi}_x-\frac{\tilde{g}_{2x}}{\tilde{g}_2}\tilde{\phi}\right]=\frac{1}{\xi-\lambda}\left[\xi\phi-\lambda\phi+\frac{f}{1+\partial^{-1}f^2}(f_x\phi-f\phi_x)\right]=\phi-\frac{f}{1+\partial^{-1}f^2}\partial^{-1}(f\phi), \tag{3.13a}$$

$$\overline{u}=\tilde{u}+2\partial^2\ln\tilde{g}_2=u+2\partial^2\ln(1+\partial^{-1}f^2). \tag{3.13b}$$

Also the equation (2.1) and (2.8) are covariant with respect to the action of the binary DT (3.13), namely $\overline{\phi},\overline{u}$ satisfy (3.9) and (3.10), $\overline{u}$ satisfies the nth KdV equation (2.9). Similarly, the covariance of (2.1) and (2.8) with respect to the action of binary DT (3.13) leads to the following lemma.

Lemma 3.3: If u is a solution of the nth KdV equation (2.9) and f is a solution of (2.1) and (2.8) with $\lambda=\xi$ and the binary DT is given by (3.13), then the following formula holds:

$$\overline{\phi}_{t_n}=\overline{A^{(n)}}\overline{\phi}=\left[\phi-\frac{f}{1+\partial^{-1}f^2}\partial^{-1}(f\phi)\right]_{t_n}=A^{(n)}\phi-\frac{1}{1+\partial^{-1}f^2}\left\{\left[A^{(n)}f\right.\right.$$
$$\left.\left.-\frac{2f}{1+\partial^{-1}f^2}\partial^{-1}(fA^{(n)}f)\right]\partial^{-1}(f\phi)+f\partial^{-1}[fA^{(n)}\phi+\phi A^{(n)}f]\right\}. \tag{3.14}$$

IV. THE DARBOUX TRANSFORMATION FOR THE KdV HIERARCHY WITH SELF-CONSISTENT SOURCES

Based on the Darboux transformation for the KdV hierarchy, we now construct Darboux transformation and two binary Darboux transformations for the KdV hierarchy with self-consistent sources. The first binary Darboux transformation is an auto-Bäcklund transformation for the nth KdV equation with self-consistent sources (2.13). The second one is a Bäcklund transformation relating two nth KdV equations with self-consistent sources (2.13) with degree N and $N+1$, respectively.

(1) Darboux transformation for the KdV hierarchy with sources.

Theorem 4.1: *Assume that $u,\phi_1,\ldots,\phi_N$ be the solution of the nth KdV equation with self-consistent sources (2.13) and f_1 satisfies (2.16a) and (2.18) with $\lambda=\xi_1$, then the Darboux transformation is defined by*

$$\overline{\psi}=\psi_x-\frac{f_{1,x}}{f_1}\psi, \tag{4.1a}$$

$$\overline{u}=u+2\partial^2\ln f_1, \tag{4.1b}$$

$$\overline{\phi}_j=\frac{1}{\sqrt{\lambda_j-\xi_1}}\left[\phi_{j,x}-\frac{f_{1,x}}{f_1}\phi_j\right],\quad j=1,\ldots,N, \tag{4.1c}$$

the Lax representation (2.16a) and (2.18) are covariant with respect to the Darboux transformation (4.1). Namely $\overline{u},\overline{\psi},\overline{\phi}_j, j=1,\ldots,N$, satisfy

$$\overline{\psi}_{xx}+(\lambda+\overline{u})\overline{\psi}=0, \tag{4.2}$$

$$\overline{\psi}_{t_n}=\overline{Q}^{(n,N)}\overline{\psi}=\overline{A}^{(n)}\overline{\psi}+\eta\overline{\psi}+\overline{B}_N\overline{\psi}\equiv A^{(n)}(\overline{u},\lambda)\overline{\psi}+\eta\overline{\psi}+\alpha\sum_{j=1}^{N}\overline{\phi}_j\partial^{-1}(\overline{\phi}_j\overline{\psi}), \tag{4.3}$$

and $\overline{u},\overline{\phi}_1,\ldots,\overline{\phi}_N$ satisfy the nth KdV equation with self-consistent sources (2.13),

$$\overline{u}_{t_n}=D\left[-2\overline{b}_{n+2}-2\alpha\sum_{j=1}^{N}\overline{\phi}_j^2\right], \tag{4.4a}$$

$$\overline{\phi}_{j,xx}+(\lambda_j+\overline{u})\overline{\phi}_j=0,\quad j=1,\ldots,N. \tag{4.4b}$$

Proof: Based on the results in the previous section, it is obvious that (4.2) and (4.4b) hold. In order to prove (4.3) we need to show the following equality:

$$\tilde{\psi}_{t_n}=\left[\psi_x-\frac{f_{1,x}}{f_1}\psi\right]_{t_n}=(Q^{(n,N)}\psi)_x-\left(\frac{Q^{(n,N)}f_1}{f_1}\right)_x\psi-\frac{f_{1,x}}{f_1}Q^{(n,N)}\psi=\tilde{Q}^{(n,N)}\tilde{\psi}. \tag{4.5}$$

The Lemma 3.1 implies that equality (3.4) with ϕ replaced by ψ holds. So we only need to check the terms containing $\phi_1,\ldots,\phi_N$ in the equality (4.5), i.e., to show the following equality:

$$(B_N\psi)_x-\left(\frac{B_Nf_1}{f_1}\right)_x\psi-\frac{f_{1,x}}{f_1}B_N\psi=\overline{B}_N\overline{\psi}. \tag{4.6}$$

Using (4.1) and (2.17), we have

$$\begin{aligned}\overline{B}_N\overline{\psi}&=\alpha\sum_{j=1}^{N}\overline{\phi}_j\partial^{-1}\left[\frac{1}{\sqrt{\lambda_j-\xi_1}}\left(\phi_{j,x}-\frac{f_{1,x}}{f_1}\phi_j\right)\left(\psi_x-\frac{f_{1,x}}{f_1}\psi\right)\right]\\&=\alpha\sum_{j=1}^{N}\frac{1}{\sqrt{\lambda_j-\xi_1}}\overline{\phi}_j\left[\phi_{j,x}\psi-\partial^{-1}(\phi_{j,xx}\psi)-\frac{f_{1,x}}{f_1}\phi_j\psi+\partial^{-1}\left(\frac{f_{1,xx}}{f_1}\phi_j\psi\right)\right]\\&=\alpha\sum_{j=1}^{N}\frac{1}{\sqrt{\lambda_j-\xi_1}}\overline{\phi}_j\left[\phi_{j,x}\psi-\frac{f_{1,x}}{f_1}\phi_j\psi+(\lambda_j-\xi_1)\partial^{-1}(\phi_j\psi)\right]\end{aligned}\tag{4.7}$$

and

$$\begin{aligned}\text{the left terms in (4.6)}=\alpha\sum_{j=1}^{N}&\left[\phi_{j,x}\partial^{-1}(\phi_j\psi)-\frac{1}{f_1}\psi\phi_{j,x}\partial^{-1}(f_1\phi_j)\right.\\&\left.+\frac{f_{1,x}}{f_1^2}\psi\phi_j\partial^{-1}(f_1\phi_j)-\frac{f_{1,x}}{f_1}\phi_j\partial^{-1}(\phi_j\psi)\right]\\=\alpha\sum_{j=1}^{N}&\sqrt{\lambda_j-\xi_1}\overline{\phi}_j\left[\partial^{-1}(\phi_j\psi)-\frac{1}{f_1}\psi\partial^{-1}(f_1\phi_j)\right]\\=\alpha\sum_{j=1}^{N}&\sqrt{\lambda_j-\xi_1}\overline{\phi}_j\left[\partial^{-1}(\phi_j\psi)+\frac{1}{f_1(\lambda_j-\xi_1)}\psi(f_1\phi_{j,x}-f_{1,x}\phi_j)\right].\end{aligned}\tag{4.8}$$

Comparing (4.7) with (4.8), it is immediately found that equality (4.6) holds. The equations (4.2) and (4.3) lead to (4.4a). This completes the proof.

(2) The first binary Darboux transformation for the KdV hierarchy with sources.

Theorem 4.2: *Assume that $u,\phi_1,\ldots,\phi_N$ be the solution of the n*th *KdV equation with self-consistent sources (2.13) and f_1 satisfies (2.16a) and (2.18) with $\lambda=\xi_1$, then the first binary Darboux transformation is defined by*

$$\overline{\psi}=\psi-\frac{f_1}{\partial^{-1}f_1^2}\partial^{-1}(f_1\psi),\tag{4.9a}$$

$$\overline{u}=u+2\partial^2\ln(\partial^{-1}f_1^2),\tag{4.9b}$$

$$\overline{\phi}_j=\phi_j-\frac{f_1}{\partial^{-1}f_1^2}\partial^{-1}(f_1\phi_j),\quad j=1,\ldots,N,\tag{4.9c}$$

*the Lax representation (2.16a) and (2.18) are covariant with respect to the binary Darboux transformation (4.9). Namely $\overline{u},\overline{\psi},\overline{\phi}_j, j=1,\ldots,N$, satisfy (4.2), (4.3) and the n*th *KdV equation with self-consistent sources (4.4).*

Proof: It is obvious that (4.2) and (4.4b) hold. Similarly, in order to prove (4.3) we need to show the equality (3.11) with $\phi,A^{(n)}$ replaced by $\psi,Q^{(n,N)}$. In fact, using Lemma 3.2, we only need to check the terms containing $\phi_1,\ldots,\phi_N$ in the equality, i.e., to show the following equality:

$$B_N\psi-\frac{1}{\partial^{-1}f_1^2}\left[B_Nf_1-2\frac{1}{\partial^{-1}f_1^2}f_1\partial^{-1}(f_1B_Nf_1)\right]\partial^{-1}(f_1\psi)-\frac{f_1}{\partial^{-1}f_1^2}\partial^{-1}[f_1B_N\psi+\psi B_Nf_1]=\overline{B}_N\overline{\psi}.\tag{4.10}$$

Notice that

$$\partial^{-1}\left[\frac{f_1^2}{(\partial^{-1}f_1^2)^2}(\partial^{-1}(f_1\phi_j))(\partial^{-1}(f_1\psi))\right]=-\frac{1}{\partial^{-1}f_1^2}(\partial^{-1}(f_1\phi_j))(\partial^{-1}(f_1\psi))$$
$$+\partial^{-1}\left[\frac{f_1\phi_j}{\partial^{-1}f_1^2}\partial^{-1}(f_1\psi)+\frac{f_1\psi}{\partial^{-1}f_1^2}\partial^{-1}(f_1\phi_j)\right]. \tag{4.11}$$

Using (4.9) and (4.11), we have

$$\begin{aligned}\overline{B_N}\overline{\psi}&=\alpha\sum_{j=1}^{N}\overline{\phi}_j\partial^{-1}(\overline{\phi}_j\overline{\psi})\\&=\alpha\sum_{j=1}^{N}\overline{\phi}_j\partial^{-1}\left[\left(\phi_j-\frac{f_1}{\partial^{-1}f_1^2}\partial^{-1}(f_1\phi_j)\right)\left(\psi-\frac{f_1}{\partial^{-1}f_1^2}\partial^{-1}(f_1\psi)\right)\right]\\&=\alpha\sum_{j=1}^{N}\overline{\phi}_j\left[\partial^{-1}(\phi_j\psi)-\frac{1}{\partial^{-1}f_1^2}(\partial^{-1}(f_1\phi_j))(\partial^{-1}(f_1\psi))\right],\end{aligned} \tag{4.12}$$

and

$$\begin{aligned}\text{the left terms in (4.10)}=\alpha\sum_{j=1}^{N}\Bigg\{&\phi_j\partial^{-1}(\phi_j\psi)-\frac{1}{\partial^{-1}f_1^2}\Bigg[\phi_j(\partial^{-1}(f_1\phi_j))(\partial^{-1}(f_1\psi))\\&-2\frac{f_1}{\partial^{-1}f_1^2}\partial^{-1}(f_1\phi_j\partial^{-1}(f_1\phi_j))(\partial^{-1}(f_1\psi))+f_1\partial^{-1}(f_1\phi_j\partial^{-1}(\phi_j\psi))\\&+f_1\partial^{-1}(\phi_j\psi\partial^{-1}(\phi_jf_1))\Bigg]\Bigg\}\\=\alpha\sum_{j=1}^{N}\Bigg[&\phi_j\partial^{-1}(\phi_j\psi)-\frac{\phi_j}{\partial^{-1}f_1^2}(\partial^{-1}(f_1\phi_j))(\partial^{-1}(f_1\psi))\\&+\frac{f_1}{(\partial^{-1}f_1^2)^2}(\partial^{-1}(f_1\phi_j))^2(\partial^{-1}(f_1\psi))-\frac{f_1}{\partial^{-1}f_1^2}(\partial^{-1}(f_1\phi_j))\\&\times(\partial^{-1}(\phi_j\psi))\Bigg].\end{aligned} \tag{4.13}$$

By substituting (4.9c) into (4.12) and comparing it with (4.13), it is immediately found that equality (4.10) holds. The equations (4.2) and (4.3) lead to (4.4a). This completes the proof.

(3) The second binary Darboux transformation for the KdV hierarchy with sources.

Theorem 4.3: *Assume that $u,\phi_1,\ldots,\phi_N$ is the solution of the n*th *KdV equation with self-consistent sources (2.13), $f_1\equiv\phi_{N+1}$ satisfies (2.16a) and (2.18) with $\lambda=\lambda_{N+1}$ and $\eta=-\frac{1}{2}\alpha$, then the second binary Darboux transformation is defined by*

$$\overline{\psi}=\psi-\frac{f_1}{1+\partial^{-1}f_1^2}\partial^{-1}(f_1\psi)=\psi-\overline{\phi}_{N+1}\partial^{-1}(f_1\psi), \tag{4.14a}$$

$$\overline{u}=u+2\partial^2\ln(1+\partial^{-1}f_1^2), \tag{4.14b}$$

$$\overline{\phi}_j=\phi_j-\frac{f_1}{1+\partial^{-1}f_1^2}\partial^{-1}(f_1\phi_j)=\phi_j-\overline{\phi}_{N+1}\partial^{-1}(f_1\phi_j),\quad j=1,\ldots,N, \tag{4.14c}$$

where

$$\overline{\phi}_{N+1}=\frac{f_1}{1+\partial^{-1}f_1^2},\quad f_1=\phi_{N+1}, \tag{4.14d}$$

and the binary Darboux transformation (4.14) transforms the Lax representation (2.16a) and (2.18) with $\eta=-\frac{1}{2}\alpha$ *into the following Lax representation:*

$$\overline{\psi}_{xx}+(\lambda+\overline{u})\overline{\psi}=0, \tag{4.15}$$

$$\overline{\psi}_{t_n}=\overline{Q}^{(n,N+1)}\overline{\psi}=\overline{A}^{(n)}\overline{\psi}-\frac{1}{2}\alpha\overline{\psi}+\overline{B}_{N+1}\overline{\psi}\equiv A^{(n)}(\overline{u},\lambda)\overline{\psi}-\frac{1}{2}\alpha\overline{\psi}+\alpha\sum_{j=1}^{N+1}\overline{\phi}_j\partial^{-1}(\overline{\phi}_j\overline{\psi}), \tag{4.16}$$

and $\overline{u},\overline{\phi}_1,\ldots,\overline{\phi}_{N+1}$ *satisfies the n*th *KdV equation with self-consistent sources (2.13) with degree* $N+1$

$$\overline{u}_{t_n}=D\left[-2\overline{b}_{n+2}-2\alpha\sum_{j=1}^{N+1}\overline{\phi}_j^2\right], \tag{4.17a}$$

$$\overline{\phi}_{j,xx}+(\lambda_j+\overline{u})\overline{\phi}_j=0,\quad j=1,\ldots,N+1. \tag{4.17b}$$

Proof: It is easy to see that (4.14c) holds for $j=N+1$. So, based on the results in the previous section, it is obvious that (4.15) and (4.17b) hold. Similarly, in order to prove (4.16), by using Lemma 3.3 one only needs to check the terms containing $\phi_1,\ldots,\phi_N,\overline{\phi}_{N+1}$ in the equality (3.14) with $\phi,A^{(n)}$ replaced by $\psi,Q^{(n,N)}$, i.e., to show the following equality:

$$\begin{aligned}&B_N\psi-\frac{1}{1+\partial^{-1}f_1^2}\left[B_Nf_1-\frac{1}{2}\alpha\overline{\phi}_{N+1}(1-\partial^{-1}f_1^2)-2\overline{\phi}_{N+1}\partial^{-1}(f_1B_Nf_1)\right]\partial^{-1}(f_1\psi)\\&\quad-\overline{\phi}_{N+1}\partial^{-1}\left[\psi B_Nf_1-\frac{1}{2}\alpha f_1\psi+f_1B_N\psi\right]=\overline{B}_{N+1}\overline{\psi}.\end{aligned} \tag{4.18}$$

Notice that

$$\partial^{-1}(\overline{\phi}_{N+1}\overline{\psi})=\partial^{-1}\left[\frac{f_1}{1+\partial^{-1}f_1^2}\psi-\left(\frac{f_1}{1+\partial^{-1}f_1^2}\right)^2\partial^{-1}(f_1\psi)\right]=\frac{1}{1+\partial^{-1}f_1^2}\partial^{-1}(f_1\psi). \tag{4.19}$$

By means of (4.11) and (4.12) with $\partial^{-1}f_1^2$ replaced by $(1+\partial^{-1}f_1^2)$ one gets

$$\begin{aligned}\overline{B}_{N+1}\overline{\psi}&=\alpha\sum_{j=1}^{N+1}\overline{\phi}_j\partial^{-1}(\overline{\phi}_j\overline{\psi})\\&=\alpha\sum_{j=1}^{N}\overline{\phi}_j\left[\partial^{-1}(\phi_j\psi)-\frac{1}{1+\partial^{-1}f_1^2}(\partial^{-1}(f_1\phi_j))\partial^{-1}(f_1\psi)\right]+\frac{\alpha\overline{\phi}_{N+1}}{1+\partial^{-1}f_1^2}\partial^{-1}(f_1\psi).\end{aligned} \tag{4.20}$$

Using (4.13) with $\partial^{-1}f_1^2$ replaced by $(1+\partial^{-1}f_1^2)$ it is found that

$$\text{the left terms in (4.18)} = \alpha \sum_{j=1}^{N} \left\{ \phi_j \partial^{-1}(\phi_j \psi) - \frac{1}{1+\partial^{-1} f_1^2} [\phi_j (\partial^{-1}(f_1 \phi_j)) \partial^{-1}(f_1 \psi) - \overline{\phi}_{N+1} (\partial^{-1}(f_1 \phi_j))^2 \partial^{-1}(f_1 \psi)] - \overline{\phi}_{N+1} (\partial^{-1}(f_1 \phi_j)) \partial^{-1}(\phi_j \psi) \right\} + \frac{\alpha \overline{\phi}_{N+1}}{1+\partial^{-1} f_1^2} \partial^{-1}(f_1 \psi). \tag{4.21}$$

By substituting (4.14c) into (4.20) and comparing it with (4.21), it is easy to see that equality (4.18) holds. The equations (4.15) and (4.16) yield (4.17). This completes the proof.

Remark: The binary Darboux transformation defined by (4.14) is a non-auto-Bäcklund transformation relating the two nth KdV equations with self-consistent sources (2.13) and (4.17). This Darboux transformation can be used to construct the soliton solution for (2.13).

For example, in order to find one soliton solution for the KdV equation with self-consistent sources (2.19) with $N=1$, we start from the solution $u=0$ for the KdV equation with self-consistent sources (2.19) with $N=0$. The solution for (2.20) with $N=0, u=0, \lambda=-k^2, k>0$, $\eta=-\frac{1}{2}\alpha$ reads

$$\phi_1 = c e^{kx-k^3 t-1/2\,\alpha t}.$$

Then one finds from (4.14) that

$$\overline{u} = 2k^2 \operatorname{sech}^2(kx-k^3 t-\tfrac{1}{2}\alpha t + x_0),$$

$$\phi_1 = \frac{1}{2}\sqrt{2k}\operatorname{sech}\left(kx-k^3 t-\frac{1}{2}\alpha t + x_0\right),$$

which is the one soliton solution for the KdV equation with self-consistent sources (2.19) with $N=1$.

V. THE *m*-TIMES REPEATED BINARY DARBOUX TRANSFORMATION FOR THE KdV HIERARCHY WITH SELF-CONSISTENT SOURCES

It is evident that the Darboux transformation can be applied to (4.2), (4.3), and (4.15), (4.16) once more to produce some new solutions for the KdV hierarchy with self-consistent sources.

(1) The m-times repeated second binary Darboux transformation.

Assume that $f_1, \ldots, f_m$ be solution of (2.16a) and (2.18) with $\lambda = \lambda_{N+1}, \ldots, \lambda_{N+m}$, respectively. We use $u[i], \psi[i], f_j[i], \phi_j[i]$ to denote the action of i-times repeated binary Darboux transformation of (4.14) on the initial solution u, ψ, f_j, ϕ_j. We have

$$f_j[i]_{xx} + (\lambda_j + u[i]) f_j[i] = 0, \tag{5.1}$$

$$f_{j,t_n}[i] = Q^{(n,N+i)}[i] f_j[i]. \tag{5.2}$$

We define two integral types of the Wronskian determinant of k functions $g_1, \ldots, g_k$ in a similar way as in Ref. 27 by

$$W_1(g_1, \ldots, g_k) = \det F, \quad W_2(g_1, \ldots, g_k) = \det G,$$

where

$$F_{ij} = \delta_{ij} + \partial^{-1}(g_i g_j), \quad i,j = 1, \ldots, k,$$

$$G_{ij}=\delta_{ij}+\partial^{-1}(g_ig_j),\quad i=1,\ldots,k-1,\quad j=1,\ldots,k,\quad G_{kj}=g_j,\quad j=1,\ldots,k.$$

Lemma 5.1: For arbitrary integers $l,k(1\leqslant l\leqslant m-1,1\leqslant k\leqslant m-l)$, we have

$$W_1(f_{l+1}[l],\ldots,f_{l+k}[l])=\frac{W_1(f_l[l-1],f_{l+1}[l-1],\ldots,f_{l+k}[l-1])}{1+\partial^{-1}f_l^2[l-1]},\tag{5.3}$$

$$W_2(f_{l+1}[l],\ldots,f_{l+k}[l],\psi[l])=\frac{W_1(f_l[l-1],f_{l+1}[l-1],\ldots,f_{l+k}[l-1],\psi[l-1])}{1+\partial^{-1}f_l^2[l-1]}.\tag{5.4}$$

Proof: According to (4.14), we have

$$f_{l+j}[l]=f_{l+j}[l-1]-\frac{f_l[l-1]}{1+\partial^{-1}f_l^2[l-1]}\partial^{-1}(f_l[l-1]f_{l+j}[l-1]),\tag{5.5}$$

so using (4.11)

$$\begin{aligned}F_{ij}&=\delta_{ij}+\partial^{-1}(f_{l+i}[l]f_{l+j}[l])\\&=\delta_{ij}+\partial^{-1}(f_{l+i}[l-1]f_{l+j}[l-1])\\&\quad-\frac{1}{1+\partial^{-1}f_l^2[l-1]}(\partial^{-1}f_{l+i}[l-1]f_l[l-1])(\partial^{-1}f_l[l-1]f_{l+j}[l-1])\\&\equiv\delta_{ij}+a_{ij}-ba_{i0}a_{0j},\end{aligned}\tag{5.6}$$

where

$$a_{ij}=\partial^{-1}(f_{l+i}[l-1]f_{l+j}[l-1]),\quad b=\frac{1}{1+\partial^{-1}f_l^2[l-1]}.$$

Then

$$\begin{aligned}&W_1(f_{l+1}[l],\ldots,f_{l+k}[l])\\&\quad=\det(F_{ij})\\&\quad=\begin{pmatrix}1+a_{11}-ba_{10}a_{01}&a_{12}-ba_{10}a_{02}&a_{13}-ba_{10}a_{03}&\cdots&a_{1k}-ba_{10}a_{0k}\\a_{21}-ba_{20}a_{01}&1+a_{22}-ba_{20}a_{02}&a_{23}-ba_{20}a_{03}&\cdots&a_{2k}-ba_{20}a_{0k}\\\vdots&\vdots&\vdots&\ddots&\vdots\\a_{k1}-ba_{k0}a_{01}&a_{k2}-ba_{k0}a_{02}&a_{k3}-ba_{k0}a_{03}&\cdots&1+a_{kk}-ba_{k0}a_{0k}\end{pmatrix}\\&\quad=\begin{pmatrix}1+a_{11}&a_{12}&\cdots&a_{1k}\\a_{21}&1+a_{22}&\cdots&a_{2k}\\\vdots&\vdots&\ddots&\vdots\\a_{k1}&a_{k2}&\cdots&1+a_{kk}\end{pmatrix}-ba_{01}\begin{pmatrix}a_{10}&a_{12}&a_{13}&\cdots&a_{1k}\\a_{20}&1+a_{22}&a_{23}&\cdots&a_{2k}\\\vdots&\vdots&\vdots&\ddots&\vdots\\a_{k0}&a_{k2}&a_{k3}&\cdots&1+a_{kk}\end{pmatrix}\end{aligned}$$

$$-ba_{02}\begin{pmatrix} 1+a_{11} & a_{10} & a_{13} & \cdots & a_{1k} \\ a_{21} & a_{20} & a_{23} & \cdots & a_{2k} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{k1} & a_{k0} & a_{k3} & \cdots & 1+a_{kk} \end{pmatrix}-\cdots$$

$$-ba_{0k}\begin{pmatrix} 1+a_{11} & a_{12} & \cdots & a_{1(k-1)} & a_{10} \\ a_{21} & 1+a_{22} & \cdots & a_{2(k-1)} & a_{20} \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ a_{k1} & a_{k2} & \cdots & a_{k(k-1)} & a_{k0} \end{pmatrix}$$

$$=\frac{1}{1+a_{00}}\begin{pmatrix} 1+a_{00} & a_{01} & a_{02} & \cdots & a_{0k} \\ a_{10} & 1+a_{11} & a_{12} & \cdots & a_{1k} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{k0} & a_{k1} & a_{k2} & \cdots & 1+a_{kk} \end{pmatrix}$$

$$=\frac{W_1(f_l[l-1],\ldots,f_{l+k}[l-1])}{1+\partial^{-1}f_l^2[l-1]}.$$

In the similar way the formula (5.4) can be proved. This completes the proof.

Theorem 5.1: *Assume that $u,\phi_1,\ldots,\phi_N$ is the solution of the n*th *KdV equation with self-consistent sources (2.13), $f_1,\ldots,f_m$ is the solution of (2.16a) and (2.18) with $\lambda=\lambda_{N+1},\ldots,\lambda_{N+m}$, respectively, and $\eta=-\frac{1}{2}\alpha$. Then the m-times repeated binary Darboux transformation of (4.14) is given by*

$$\psi[m]=\frac{W_2(f_1,\ldots,f_m,\psi)}{W_1(f_1,\ldots,f_m)}, \tag{5.7a}$$

$$u[m]=u+2\partial^2\ln W_1(f_1,\ldots,f_m), \tag{5.7b}$$

$$\phi_j[m]=\frac{W_2(f_1,\ldots,f_m,\phi_j)}{W_1(f_1,\ldots,f_m)},\quad j=1,\ldots,N, \tag{5.7c}$$

$$\phi_{N+j}[m]=\frac{W_2(f_1,\ldots,f_m,f_j)}{W_1(f_1,\ldots,f_m)}=\frac{W_2(f_1,\ldots,f_{j-1},f_{j+1},\ldots,f_m,f_j)}{W_1(f_1,\ldots,f_m)},\quad j=1,\ldots,m, \tag{5.7d}$$

and $u[m],\psi[m],\phi_1[m],\ldots,\phi_{N+m}[m]$ satisfy

$$\psi_{xx}[m]+(\lambda+u[m])\psi[m]=0, \tag{5.8}$$

$$\psi_{t_n}[m]=Q^{(n,N+m)}[m]\psi[m]=A^{(n)}(u[m],\lambda)\psi[m]-\frac{1}{2}\alpha\psi[m]+\alpha\sum_{j=1}^{N+m}\phi_j[m]\partial^{-1}(\phi_j[m]\psi[m]), \tag{5.9}$$

and

$$u_{t_n}[m]=D\left[-2b_{n+2}(u[m])-2\alpha\sum_{j=1}^{N+m}\phi_j^2[m]\right], \tag{5.10a}$$

$$\phi_{j,xx}[m]+(\lambda_j+u[m])\phi_j[m]=0, \quad j=1,\ldots,N+m. \tag{5.10b}$$

Proof: Using (4.14), (5.3), and (5.4), one obtains

$$\begin{aligned}
\psi[m]&=\psi[m-1]-\frac{f_m[m-1]}{1+\partial^{-1}f_m^2[m-1]}\partial^{-1}(f_m[m-1]\psi[m-1])\\
&=\frac{1}{1+\partial^{-1}f_m^2[m-1]}W_2(f_m[m-1],\psi[m-1])\\
&=\frac{W_2(f_m[m-1],\psi[m-1])}{W_1(f_m[m-1])}\\
&=\frac{W_2(f_{m-1}[m-2],f_m[m-2],\psi[m-2])}{1+\partial^{-1}f_{m-1}^2[m-2]}\frac{1+\partial^{-1}f_{m-1}^2[m-2]}{W_1(f_{m-1}[m-2],f_m[m-2])}\\
&=\cdots=\frac{W_2(f_1,\ldots,f_m,\psi)}{W_1(f_1,\ldots,f_m)},
\end{aligned} \tag{5.11}$$

$$\begin{aligned}
u[m]&=u[m-1]+2\partial^2\ln(1+\partial^{-1}f_m^2[m-1])\\
&=u[m-1]+2\partial^2\ln W_1(f_m[m-1])\\
&=u[m-2]+2\partial^2\ln(1+\partial^{-1}f_{m-1}^2[m-2])+2\partial^2\ln\frac{W_1(f_{m-1}[m-2],f_m[m-2])}{1+\partial^{-1}f_{m-1}^2[m-2]}\\
&=u[m-2]+2\partial^2\ln W_1(f_{m-1}[m-2],f_m[m-2])\\
&=\cdots=u+2\partial^2\ln W_1(f_1,\ldots,f_m).
\end{aligned} \tag{5.12}$$

Similarly we can prove the (5.7c) and (5.7d). It is easy to find (5.8), (5.9), and (5.10) from the Proposition 4.3.

The m-times repeated binary Darboux transformation (5.8) provides a Bäcklund transformation relating two nth KdV equations with self-consistent sources (2.13) with degree N and $N+m$, respectively. We now use the N-times repeated binary Darboux transformation (5.6) to construct the N-soliton solution for the nth KdV equation with self-consistent sources (2.13) with $\lambda_j=-k_j^2<0,k_j>0,j=1,\ldots,N$. We start from (2.13) with $N=0$. Taking $N=0,u=0,\lambda=-k_j^2,\eta=-\frac{1}{2}\alpha$, then (2.16a) and (2.18) reduce to

$$\psi_{xx}-k_j^2\psi=0,$$

$$\psi_{t_n}=(-1)^n k_j^{2n}\psi_x-\tfrac{1}{2}\alpha\psi,$$

which solution is given by

$$f_j=e^{k_jx+(-1)^n k_j^{2n+1}t_n-\frac{1}{2}\alpha t_n+x_{0,j}}, \quad j=1,\ldots,N. \tag{5.13}$$

Then according to Proposition 5.1, the N-soliton solution for the nth KdV equation with self-consistent sources (2.13) with $\lambda_j=-k_j^2<0,k_j>0,j=1,\ldots,N$, is given by

$$u=2\partial^2\ln W_1(f_1,\ldots,f_N), \tag{5.14}$$

$$\phi_j=\frac{W_2(f_1,\ldots,f_N,f_j)}{W_1(f_1,\ldots,f_N)}=\frac{W_2(f_1,\ldots,f_{j-1},f_{j+1},\ldots,f_N,f_j)}{W_1(f_1,\ldots,f_N)},\quad j=1,\ldots,N, \tag{5.15}$$

where f_j is given by (5.13).

(2) The m-times repeated first binary Darboux transformation.

We define

$$W_1(g_1,\ldots,g_k)=\det F,\qquad W_2(g_1,\ldots,g_k)=\det G, \tag{5.16}$$

where

$$F_{ij}=\partial^{-1}(g_ig_j),\quad i,j=1,\ldots,k,$$

$$G_{ij}=\partial^{-1}(g_ig_j),\quad i=1,\ldots,k-1,\quad j=1,\ldots,k,\quad G_{kj}=g_j,\quad j=1,\ldots,k.$$

In exactly the same way we can prove the following theorem.

Theorem 5.2: *Assume that $u,\phi_1,\ldots,\phi_N$ is the solution of the n*th *KdV equation with self-consistent sources (2.13), $f_1,\ldots,f_m$ is the solution of (2.16a) and (2.18) with $\lambda=\xi_1,\ldots,\xi_m$, respectively. Then the m-times repeated binary Darboux transformation of (4.9) is given by*

$$\psi[m]=\frac{W_2(f_1,\ldots,f_m,\psi)}{W_1(f_1,\ldots,f_m)}, \tag{5.17a}$$

$$u[m]=u+2\partial^2\ln W_1(f_1,\ldots,f_m), \tag{5.17b}$$

$$\phi_j[m]=\frac{W_2(f_1,\ldots,f_m,\phi_j)}{W_1(f_1,\ldots,f_m)},\quad j=1,\ldots,N, \tag{5.17c}$$

and $u[m],\psi[m],\phi_1[m],\ldots,\phi_N[m]$ satisfy

$$\psi_{xx}[m]+(\lambda+u[m])\psi[m]=0, \tag{5.18}$$

$$\psi_{t_n}[m]=Q^{(n,N)}[m]\psi[m], \tag{5.19}$$

and

$$u_{t_n}[m]=D\left[-2b_{n+2}(u[m])-2\alpha\sum_{j=1}^{N}\phi_j^2[m]\right], \tag{5.20a}$$

$$\phi_{j,xx}[m]+(\lambda_j+u[m])\phi_j[m]=0,\quad j=1,\ldots,N. \tag{5.20b}$$

(3) The m-times repeated Darboux transformation of (4.1).

We define the Wronskian determinant W by

$$W_1(g_1,\ldots,g_k)=\det F,\quad F_{ij}=\frac{\partial^{i-1}g_j}{\partial x^{i-1}},\quad i,j=1,\ldots,k. \tag{5.21}$$

In exactly the same way we can prove the following theorem.

Theorem 5.3: *Assume that $u,\phi_1,\ldots,\phi_N$ is the solution of the n*th *KdV equation with self-consistent sources (2.13), $f_1,\ldots,f_m$ is the solution of (2.16a) and (2.18) with $\lambda=\xi_1,\ldots,\xi_m$, respectively. Then the m-times repeated Darboux transformation of (4.1) is given by*

$$\psi[m]=\frac{W(f_1,\ldots,f_m,\psi)}{W(f_1,\ldots,f_m)}, \tag{5.22a}$$

$$u[m]=u+2\partial^2 \ln W(f_1,\ldots,f_m), \tag{5.22b}$$

$$\phi_j[m]=\frac{W(f_1,\ldots,f_m,\phi_j)}{W(f_1,\ldots,f_m)}, \quad j=1,\ldots,N, \tag{5.22c}$$

and $u[m],\psi[m],\phi_1[m],\ldots,\phi_N[m]$ *satisfy (5.18), (5.19), and (5.20).*

(Received 20 November 2000; accepted for publication 12 February 2001)

The condition for the vanishing of the Weyl tensor is integrated in the spherically symmetric case. Then, the resulting expression is used to find new, conformally flat, interior solutions to Einstein equations for locally anisotropic fluids. The slow evolution of these models is contrasted with the evolution of models with similar energy density or radial pressure distribution but nonvanishing Weyl tensor, thereby bringing out the different role played by the Weyl tensor, the local anisotropy of pressure, and the inhomogeneity of the energy density in the collapse of relativistic spheres. © *2001 American Institute of Physics.*
[DOI: 10.1063/1.1364503]

I. INTRODUCTION

In the study of self-gravitating systems there are three factors whose relevance has been recurrently and separately stressed in the literature. These are, the Weyl tensor, the local anisotropy of pressure, and the inhomogeneity of energy density distribution (density contrast).

The Weyl tensor[1] or some functions of it,[2] have been proposed to provide a gravitational arrow of time. The rationale behind this idea being that tidal forces tend to make the gravitating fluid more inhomogeneous as the evolution proceeds, thereby indicating the sense of time. However, some works have thrown doubts on this proposal.[3] Also, as it will be seen below, it is worth noticing that the relation between the Weyl tensor and the density contrast is affected by the presence of local anisotropy of pressure.

The role of density inhomogeneities in the collapse of dust[4] and in particular in the formation of naked singularities,[5] has been extensively discussed in the literature.

Finally, the assumption of local anisotropy of pressure, has proved to be very useful in the study of relativistic compact objects (see Ref. 6, and references therein).

A hint pointing to the relevance of the above mentioned three factors in the fate of spherical collapse is also provided by the expression of the active gravitational mass in terms of those factors.[7,8]

These three factors are usually considered separately, their relationship being omitted from discussion, even though they are related by a simple expression, which we shall present below.[7,8]

The purpose of this work is twofold. On the one hand we shall integrate the vanishing Weyl tensor condition, which will allow us to construct conformally flat models (with anisotropic pressure). The obtained solutions represent static or slowly evolving (in the quasistatic approximation) spheres, which could serve for the modeling of compact self-gravitating objects. On the other hand, we want to study, comparatively, the effects of the above mentioned parameters on the (slow) evolution of relativistic spheres. For doing this we shall contrast the evolution of the conformally flat models with the evolution of models with the same energy density or radial

[b]On leave from Universidad Central de Venezuela, Caracas, Venezuela.

pressure distribution, but nonvanishing Weyl tensor. With this purpose it will be useful to calculate the active gravitational mass and the fluid velocity for each model.

The paper is organized as follows: In the next section all relevant equations and conventions are given. The condition for the vanishing of the Weyl tensor is integrated in Sec. III and the models are described in Sec. IV. Finally a discussion of results is presented in the last section.

II. RELEVANT EQUATIONS AND CONVENTIONS

A. The field equations

We consider a spherically symmetric distribution of collapsing fluid, which we assume to be locally anisotropic and bounded by a spherical surface Σ. The line element is given in Schwarzschild-type coordinates by

$$ds^2=e^{\nu}dt^2-e^{\lambda}dr^2-r^2(d\theta^2+\sin^2\theta d\phi^2), \tag{1}$$

where ν and λ are functions of t and r. The coordinates are $x^0=t$; $x^1=r$; $x^2=\theta$; $x^3=\phi$.

The metric (1) has to satisfy Einstein field equations

$$G^{\mu}_{\nu}=-8\pi T^{\mu}_{\nu}, \tag{2}$$

which in our case read[9]

$$-8\pi T^0_0=-\frac{1}{r^2}+e^{-\lambda}\left(\frac{1}{r^2}-\frac{\lambda'}{r}\right), \tag{3}$$

$$-8\pi T^1_1=-\frac{1}{r^2}+e^{-\lambda}\left(\frac{1}{r^2}+\frac{\nu'}{r}\right), \tag{4}$$

$$-8\pi T^2_2=-8\pi T^3_3=-\frac{e^{-\nu}}{4}(2\ddot{\lambda}+\dot{\lambda}(\dot{\lambda}-\dot{\nu}))+\frac{e^{-\lambda}}{4}\left(2\nu''+\nu'^2-\lambda'\nu'+2\frac{\nu'-\lambda'}{r}\right), \tag{5}$$

$$-8\pi T_{01}=-\frac{\dot{\lambda}}{r}, \tag{6}$$

where dots and primes stand for partial differentiation with respect to t and r, respectively.

In order to give physical significance to the T^{μ}_{ν} components we apply the Bondi approach,[9] i.e., we introduce local Minkowski coordinates (τ,x,y,z), defined by

$$d\tau=e^{\nu/2}dt, \quad dx=e^{\lambda/2}dr, \quad dy=rd\theta, \quad dz=r\sin\theta d\phi.$$

Then, denoting the Minkowski components of the energy tensor by a bar, we have

$$\overline{T^0_0}=T^0_0, \quad \overline{T^1_1}=T^1_1, \quad \overline{T^2_2}=T^2_2, \quad \overline{T^3_3}=T^3_3, \quad \overline{T_{01}}=e^{-(\nu+\lambda)/2}T_{01}.$$

Next we suppose that, when viewed by an observer moving relative to these coordinates with velocity ω in the radial direction, the physical content of space consists of an anisotropic fluid of energy density ρ, radial pressure P_r, and tangential pressure $P_{\perp}$. Thus, when viewed by this moving observer, the covariant energy-momentum tensor in Minkowski coordinates is

$$\begin{pmatrix} \rho & 0 & 0 & 0 \\ 0 & P_r & 0 & 0 \\ 0 & 0 & P_{\perp} & 0 \\ 0 & 0 & 0 & P_{\perp} \end{pmatrix}.$$

Then a Lorentz transformation readily shows that

$$T_0^0=\overline{T}_0^0=\frac{\rho+P_r\omega^2}{1-\omega^2}, \tag{7}$$

$$T_1^1=\overline{T}_1^1=-\frac{P_r+\rho\omega^2}{1-\omega^2}, \tag{8}$$

$$T_2^2=T_3^3=\overline{T}_2^2=\overline{T}_3^3=-P_\perp, \tag{9}$$

$$T_{01}=e^{(\nu+\lambda)/2}\overline{T}_{01}=-\frac{(\rho+P_r)\omega e^{(\nu+\lambda)/2}}{1-\omega^2}. \tag{10}$$

Note that the velocity in the (t,r,θ,ϕ) system, dr/dt, is related to ω by

$$\omega=\frac{dr}{dt}e^{(\lambda-\nu)/2}. \tag{11}$$

Outside of the fluid, the spacetime is Schwarzschild,

$$ds^2=\left(1-\frac{2M}{r}\right)dt^2-\left(1-\frac{2M}{r}\right)^{-1}dr^2-r^2(d\theta^2+\sin^2\theta d\phi^2). \tag{12}$$

In order to match the two metrics smoothly on the boundary surface $r=r_\Sigma(t)$, we require continuity of the first and second fundamental forms across that surface. As a result of this matching we obtain the well known result

$$[P_r]_\Sigma=0. \tag{13}$$

Next, the radial component of the conservation law,

$$T^\mu_{\nu;\mu}=0 \tag{14}$$

gives

$$(-8\pi T_1^1)'=\frac{16\pi}{r}(T_1^1-T_2^2)+4\pi\nu'(T_1^1-T_0^0)+\frac{e^{-\nu}}{r}\left(\ddot{\lambda}+\frac{\dot{\lambda}^2}{2}-\frac{\dot{\lambda}\dot{\nu}}{2}\right), \tag{15}$$

which in the static case becomes

$$P_r'=-\frac{\nu'}{2}(\rho+P_r)+\frac{2(P_\perp-P_r)}{r}, \tag{16}$$

representing the generalization of the Tolman–Oppenheimer–Volkof equation for anisotropic fluids.[6]

In this work we shall consider exclusively static or slowly evolving (quasistatic) systems. By this we mean that our sphere either does not change or changes slowly on a time scale that is very long compared to the typical time in which the sphere reacts to a slight perturbation of hydrostatic equilibrium (this typical time scale is called hydrostatic time scale). Thus our system is always very close to or in hydrostatic equilibrium and its evolution may be regarded as a sequence of static models linked by (6). This assumption is very sensible because the hydrostatic time scale is very small for almost any phase of the life of the star. It is of the order of 27 min for the Sun, 4.5 s for a white dwarf, and 10^{-4} s for a neutron star of one solar mass, and 10 km radius. It is well

known that any of the stellar configurations mentioned above, change on a time scale that is very long compared to their respective hydrostatic time scales. Let us now translate this assumption in conditions to ω and metric functions.

First of all, slow contraction means that the radial velocity ω as measured by the Minkowski observer is always much smaller than the velocity of light ($\omega \ll 1$). Therefore we shall neglect terms of the order $O(\omega^2)$.

Then (15) yields

$$\ddot{\lambda} + \frac{\dot{\lambda}^2}{2} - \frac{\dot{\nu}\dot{\lambda}}{2} = 8\pi r e^{\nu}\left[P_r' + (\rho + P_r)\frac{\nu'}{2} - 2\frac{P_\perp - P_r}{r}\right]. \tag{17}$$

Since, by assumption, our system is always (not only at a given time t) in equilibrium (or very close to), (16) and (17) imply then, for an arbitrary slowly evolving configuration,

$$\ddot{\lambda} \approx \dot{\nu}\dot{\lambda} \approx \dot{\lambda}^2 \approx 0, \tag{18}$$

and of course, time derivatives of any order of the left-hand side of the hydrostatic equilibrium equation must also vanish, for otherwise the system will deviate from equilibrium. This condition implies, in particular, that we must demand

$$\ddot{\nu} \approx 0.$$

Finally, from the time derivative of (6), and using (10), it follows that

$$\dot{\omega} \approx O(\ddot{\lambda}, \dot{\lambda}\omega, \dot{\nu}\omega), \tag{19}$$

which implies that we shall also neglect terms linear in the acceleration. On purely physical considerations, it is obvious that the vanishing of $\dot{\omega}$ is required to keep the system always in equilibrium.

Thus, from now on, we shall always assume

$$O(\omega^2) = \dot{\lambda}^2 = \dot{\nu}^2 = \dot{\lambda}\dot{\nu} = \ddot{\lambda} = \ddot{\nu} = 0, \tag{20}$$

implying that the system remains in (or very close to) equilibrium.

B. The Weyl tensor

We can now calculate the components of the Weyl tensor. Neglecting terms of order $\dot{\lambda}\dot{\nu}, \dot{\lambda}^2, \dot{\nu}^2, \ddot{\lambda}$, and $\ddot{\nu}$, we find that all nonvanishing components can be expressed through C^3_{232}. Thus,

$$W \equiv \frac{r}{2}C^3_{232} = \frac{r^3 e^{-\lambda}}{6}\left(\frac{e^{\lambda}}{r^2} + \frac{\nu'\lambda'}{4} - \frac{1}{r^2} - \frac{\nu'^2}{4} - \frac{\nu''}{2} - \frac{\lambda' - \nu'}{2r}\right). \tag{21}$$

Next, defining the mass function as usual

$$m(r,t) = 4\pi \int_0^r T^0_0 r^2 dr, \tag{22}$$

the following relations may be established:[7,8]

$$W = -\frac{4}{3}\pi \int_0^r r^3 (T^0_0)' dr + \frac{4}{3}\pi r^3 (T^2_2 - T^1_1), \tag{23}$$

$$m(r,t)=\frac{4}{3}\pi r^3 T_0^0-\frac{4}{3}\pi\int_0^r r^3(T_0^0)'dr. \tag{24}$$

Both, (23) and (24) are valid in the general (dynamic) case. However only in the static or the quasistatic case T_0^0 and T_1^1 denote the proper energy density and the radial pressure, respectively.

C. The Tolman–Whittaker mass

The Tolman–Whittaker mass[10] within a sphere of radius r inside Σ, is defined as[8]

$$m_{\mathrm{TW}}(r,t)=4\pi\int_0^r r^2 e^{(\nu+\lambda)/2}(T_0^0-T_1^1-2T_2^2)dr. \tag{25}$$

Two alternative expressions, easily obtained from the field equations (see Ref. 8 for details) are

$$m_{\mathrm{TW}}=e^{(\nu+\lambda)/2}(m+4\pi P_r r^3) \tag{26}$$

and

$$m_{\mathrm{TW}}=\tfrac{1}{2}e^{(\nu-\lambda)/2}\nu' r^2. \tag{27}$$

The interpretation of m_{TW} as the active gravitational mass follows at once from (27) and (16). Indeed, the first term on the right-hand side of (16) (the ''gravitational force'' term) is the product of the passive gravitational mass density $(\rho+P_r)$ and a term proportional to m_{TW}/r^2. A similar conclusion can be obtained if we recall that the gravitational acceleration of a test particle, instantaneously at rest in a static gravitational field, as measured with standard rods and coordinate clocks is given by[11]

$$a=-\frac{e^{(\nu-\lambda)/2}\nu'}{2}=-\frac{m_{\mathrm{TW}}}{r^2}. \tag{28}$$

D. The velocity of a fluid element

For the comparative study of the (slow) evolution of different solutions, it will be useful to plot the velocity (ω) profiles for different pieces of material. A simple expression for ω, may be obtained as follows: from (3) and (22), it results

$$e^{-\lambda}=1-\frac{2m}{r}, \tag{29}$$

and from (29),

$$\dot{m}=\frac{\dot{\lambda}re^{-\lambda}}{2}, \tag{30}$$

then using (6),

$$\omega=-\frac{\dot{m}e^{(\lambda-\nu)/2}}{4\pi r^2(\rho+P_r)}. \tag{31}$$

III. THE VANISHING WEYL CONDITION

We shall now proceed to integrate the condition,

$$W=0, \tag{32}$$

which, using (21), may be written as

$$\left(\frac{e^{-\lambda}\nu'}{2r}\right)'+e^{-(\nu+\lambda)}\left(\frac{e^{\nu}\nu'}{2r}\right)'-\left(\frac{e^{-\lambda}-1}{r^2}\right)'=0. \tag{33}$$

Introducing new variables,

$$y=e^{-\lambda}; \quad \frac{\nu'}{2}=\frac{u'}{u}, \tag{34}$$

Eq. (33) is cast into

$$y'+\frac{2y[u''-u'/r+u/r^2]}{[u'-u/r]}-\frac{2u}{r^2[u'-u/r]}=0, \tag{35}$$

whose formal solution is

$$y=e^{-\int k(r)dr}\left[\int e^{\int k(r)dr}f(r)dr+C_1\right], \tag{36}$$

where C_1 is a constant of integration, and

$$k(r)=2\frac{d}{dr}\left[\ln\left(u'-\frac{u}{r}\right)\right], \tag{37}$$

$$f(r)=\frac{2u}{r^2(u'-u/r)}, \tag{38}$$

changing back to the original variables, Eq. (36) becomes

$$\frac{\nu'}{2}-\frac{1}{r}=\frac{e^{\lambda/2}}{r}\sqrt{1-c^2r^2e^{-\nu}} \tag{39}$$

with $c^2\equiv -C_1$.

Next, (39) may be formally integrated, to obtain

$$e^{\nu}=c^2r^2\cosh^2\left[\int\frac{e^{\lambda/2}}{r}dr+\tilde{C}\right], \tag{40}$$

where $\tilde{C}$ is a constant of integration (a function of t, in the slowly evolving case). The reader may check that (40) satisfies (39) and (32) [or (33)].

In the next section we shall present some models satisfying (39) [or (40)].

IV. THE MODELS

A simple counting of Eqs. (3)–(6) and unknowns $(\nu,\lambda,\rho,P_r,P_\perp,\omega)$ indicates that we have to provide two additional relations (in the form of equations of state and/or restrictions on metric variables), in order to integrate the system (3)–(6).

If one assumes that the fluid is locally isotropic ($P_r=P_\perp$) then, demanding $W=0$, we are driven to a unique solution (the Schwarzschild interior solution), a fact also obvious from (23). However, if $P_r\neq P_\perp$, then the condition $W=0$, does not single out a unique model.

In what follows we shall construct two models with $W=0$. One of them characterized by $P_r=0$, and for the other we prescribe a given energy density distribution which is similar to the one proposed by Gokhroo and Mehra.[12] Additionally, we present two other models with $W\neq 0$. One is characterized by $P_r=0$ and $\rho=\rho(t)$, (Refs. 8, 13) and the other has the same energy density distribution as one of the conformally flat solutions.

A. Model I

Our first model is characterized by

$$W=0 \tag{41}$$

and

$$P_r=0. \tag{42}$$

Then, from (4) and (39), it follows

$$e^{-\nu}=\frac{g}{c^2r^2}\frac{(4-9g)}{(1-2g)} \tag{43}$$

with

$$g\equiv\frac{m(r,t)}{r}, \tag{44}$$

and where (29) has been used.

Next, taking r-derivative of (43), and using

$$\nu'=\frac{2m}{r^2(1-2m/r)}\equiv\frac{2g}{r(1-2g)}, \tag{45}$$

easily derived from (4), we obtain

$$g'=\frac{54g^3-42g^2+8g}{r(18g^2-18g+4)}, \tag{46}$$

which after integration yields

$$Dr=\frac{g^{1/2}}{(4-9g)^{1/6}}, \tag{47}$$

where D is a constant (a function of t in the slowly evolving case) of integration. Solving (47) for g, one obtains

$$g=a^{1/3}\{[2+(27a+4)^{1/2}]^{1/3}+[2-(27a+4)^{1/2}]^{1/3}\} \tag{48}$$

with

$$(Dr)^6=a\equiv\left(\frac{r}{r_\Sigma}\right)^6\frac{g_\Sigma^3}{4-9g_\Sigma}, \tag{49}$$

where subscript Σ indicates that the quantity is evaluated at the boundary surface $r=r_\Sigma$.

The remaining variables are now easily obtained from the field equations and (43), (48). Thus,

$$\rho=\frac{3g}{2\pi r^2}\frac{(1-2g)}{(2-3g)}, \tag{50}$$

$$P_\perp=\frac{3g^2}{4\pi r^2}\frac{1}{(2-3g)}, \tag{51}$$

$$e^{-\lambda}=1-2g. \tag{52}$$

For the Tolman–Whittaker mass we obtain, using either (26) or (27),

$$m_{\mathrm{TW}}=g\left(\frac{r}{r_\Sigma}\right)r\left[\frac{g_\Sigma\left(1-\frac{9}{4}g_\Sigma\right)}{g\left(1-\frac{9}{4}g\right)}\right]^{1/2}, \tag{53}$$

or, using the dimensionless varibles,

$$x\equiv\frac{r}{r_\Sigma};\quad n=\frac{m_\Sigma}{r_\Sigma}\equiv\frac{M}{r_\Sigma}=g_\Sigma, \tag{54}$$

$$m_{\mathrm{TW}}=\frac{Mx^3(Z_1+Z_2)^{1/2}(4-9n)^{1/2}}{[4(4-9n)^{1/2}-9nx^2(Z_1+Z_2)]^{1/2}}, \tag{55}$$

with

$$Z_{1,2}=[2(4-9n)^{1/2}\pm(27x^6n^3+16-36n)^{1/2}]^{1/3}. \tag{56}$$

It is worth noticing that from the requirement $\rho\geqslant 0$, it follows, using (50),

$$g<\tfrac{1}{2}, \tag{57}$$

a stronger restriction appears from the condition

$$\rho\geqslant P_\perp \tag{58}$$

which requires

$$g<\tfrac{2}{5}. \tag{59}$$

Finally, the velocity ω of any fluid element is given by

$$\omega=\frac{\omega_\Sigma n^{1/2}x^2(2-3g)(4-9g)^{1/2}(1-2n)}{g^{1/2}(4-9n)^2(1-2g)^2}\times\left\{2(Z_1+Z_2)+\frac{3nx^2(Z_2^2-Z_1^2)}{(27x^6n^3+16-36n)^{1/2}}\right\}, \tag{60}$$

where (11), (31), (48)–(50), (54), and (56) have been used.

B. Model II

The second model we shall consider, is well known. It is characterized by

$$P_r=0, \tag{61}$$

$$\rho=\rho(t), \tag{62}$$

and is not conformally flat.

A static version of this model was studied by Florides.[13] Models with vanishing radial pressure have been discussed in the past,[14] and more recently in relation with the formation of naked singularities.[15]

The corresponding variables are (see Ref. 8 for details),

$$\rho=\rho(t); \quad P_r=0, \tag{63}$$

$$P_\perp=\frac{2\pi r^2\rho^2}{3\left(1-\frac{8\pi}{3}r^2\rho\right)}, \tag{64}$$

$$e^{\nu}=\frac{\left(1-\frac{8\pi}{3}r_\Sigma^2\rho\right)^{3/2}}{\left(1-\frac{8\pi}{3}r^2\rho\right)^{1/2}}, \tag{65}$$

$$e^{-\lambda}=1-\frac{8\pi}{3}r^2\rho, \tag{66}$$

$$W=-\frac{8\pi^2r^5\rho^2}{9\left(1-\frac{8\pi}{3}r^2\rho\right)}, \tag{67}$$

$$m_{\mathrm{TW}}=\frac{4\pi}{3}r^3\rho\left(\frac{1-\frac{8\pi}{3}r_\Sigma^2\rho}{1-\frac{8\pi}{3}r^2\rho}\right)^{3/4}, \tag{68}$$

$$\omega=\omega_\Sigma\left(\frac{r}{r_\Sigma}\right)\left(\frac{1-\frac{8\pi}{3}r_\Sigma^2\rho}{1-\frac{8\pi}{3}r^2\rho}\right)^{1/4}. \tag{69}$$

C. Model III

This model is conformally flat and is further characterized by

$$e^{-\lambda}=\left(1-\frac{r^2}{b^2}\right)^2, \tag{70}$$

where b is a constant (a function of t in the slowly evolving case).

Then, from (40) one obtains

$$e^{\nu}=\frac{c^2}{4B^2}\,\frac{[B^2r^2+b^2-r^2]^2}{(b^2-r^2)} \tag{71}$$

with

$$\tilde{C}=\ln B. \tag{72}$$

From the field equations, (70) and (71), we can now obtain the expressions for ρ, P_r, and $P_\perp$,

$$\rho=\frac{3}{4\pi b^2}\left(1-\frac{5r^2}{6b^2}\right), \tag{73}$$

$$8\pi P_r=-\frac{1}{r^2}+\frac{(b^2-r^2)^2}{b^4}\left[\frac{1}{r^2}+\frac{4B^2b^2-2[B^2r^2+b^2-r^2]}{(b^2-r^2)[B^2r^2+b^2-r^2]}\right], \tag{74}$$

$$8\pi(P_r-P_\perp)=-\frac{2r^2}{b^4}. \tag{75}$$

b, c, and B are related to the total mass and the radius of the sphere through the boundary conditions

$$e^{-\lambda_\Sigma}=1-\frac{2M}{r_\Sigma}, \tag{76}$$

$$e^{\nu_\Sigma}=1-\frac{2M}{r_\Sigma}, \tag{77}$$

$$P_{r_\Sigma}=0, \tag{78}$$

the corresponding expressions are

$$b=\frac{r_\Sigma}{\left[1-\left(1-\frac{2M}{r_\Sigma}\right)^{1/2}\right]^{1/2}}, \tag{79}$$

$$c=\frac{1}{r_\Sigma}\left[\frac{4M}{r_\Sigma}-\frac{9M^2}{r_\Sigma^2}\right]^{1/2}, \tag{80}$$

$$B=\frac{(1-2M/r_\Sigma)^{1/4}[(1-2M/r_\Sigma)^{1/2}+(3M/r_\Sigma-1)]}{[1-(1-2M/r_\Sigma)^{1/2}]^{1/2}[4M/r_\Sigma-9M^2/r_\Sigma^2]^{1/2}}. \tag{81}$$

For the Tolman–Whittaker mass the obtained expression is

$$m_{\mathrm{TW}}=\frac{cr^3}{2Bb^2(b^2-r^2)^{1/2}}[2B^2b^2-B^2r^2-b^2+r^2], \tag{82}$$

or, using (79)–(81) and (54),

$$m_{\mathrm{TW}}=\frac{Mx^3(1-2n)^{1/4}}{[1-x^2+x^2(1-2n)^{1/2}]^{1/2}}\left\{3-2x^2-\frac{(1-x^2)}{n}[1-(1-2n)^{1/2}]\right.$$
$$\left.\times\left[1+\frac{4n-9n^2}{2(1-2n)^{1/2}[(1-2n)^{1/2}+3n-1]}\right]\right\}, \tag{83}$$

and the expression for ω in this model, results in

$$\omega=\frac{4\dot{b}Bx[1-(1-2n)^{1/2}]}{(4n-9n^2)^{1/2}(1-x^2[1-(1-2n)^{1/2}])^{1/2}}$$
$$\times\frac{1}{[2B^2+B^2x^2[1-(1-2n)^{1/2}]+1-x^2[1-(1-2n)^{1/2}]]}, \tag{84}$$

where $\dot{b}$ is easily obtained from (79),

$$\dot{b}=\frac{\omega_\Sigma n(1-2n)^{1/2}\left(5-\frac{2}{n}[1-(1-2n)^{1/2}]\right)}{2[1-(1-2n)^{1/2}]^{3/2}}. \tag{85}$$

D. Model IV

This model has the same energy density distribution as the previous one (same λ), but is not conformally flat ($W\neq 0$). Instead, the model is further characterized by

$$P_r=0. \tag{86}$$

Then, from (70), (86) and field equations, we obtain

$$\rho=\frac{3}{4\pi b^2}\left(1-\frac{5r^2}{6b^2}\right), \tag{87}$$

$$e^{\nu}=\frac{\beta}{(b^2-r^2)^{1/2}}e^{b^2/2(b^2-r^2)}, \tag{88}$$

$$P_\perp=\frac{(2b^2r^2-r^4)(6b^2-5r^2)}{32\pi b^4(b^2-r^2)^2}, \tag{89}$$

with

$$\beta\equiv b\left(1-\frac{2M}{r_\Sigma}\right)^{5/4}e^{-[1/2(1-2M/r_\Sigma)^{1/2}]}, \tag{90}$$

and b is given by (79).

For the active gravitational mass, we obtain, after some lengthy calculations,

$$m_{\mathrm{TW}}=M(1-2n)^{5/8}x^3(1-(1-2n)^{1/2})\frac{\left[1-\frac{x^2}{2}(1-(1-2n)^{1/2})\right]}{n(1-x^2[1-(1-2n)^{1/2}])^{5/4}}$$
$$\times\exp\frac{1}{4}\left[\frac{(x^2-1)(1-(1-2n)^{1/2})}{(1-2n)^{1/2}[1-x^2(1-(1-2n)^{1/2})]}\right], \tag{91}$$

where n and x are defined by Eq. (54). Observe that condition $\rho\geqslant 0$ is satisfied for all n, however if we demand $\rho\geqslant P_\perp$, then

$$n\leqslant 0.4. \tag{92}$$

Finally, the expression for the velocity takes the form

$$\omega=\frac{2\omega_\Sigma x[1-x^2+x^2(1-2n)^{1/2}]^{1/4}[5n-2+2(1-2n)^{1/2}]}{(1-2n)^{1/8}[6-5x^2+5x^2(1-2n)^{1/2}][1-(1-2n)^{1/2}]}$$
$$\times\exp\tfrac{1}{4}\left[\frac{(1-x^2)[1-(1-2n)^{1/2}]}{(1-2n)^{1/2}[1-x^2+x^2(1-2n)^{1/2}]}\right]. \tag{93}$$

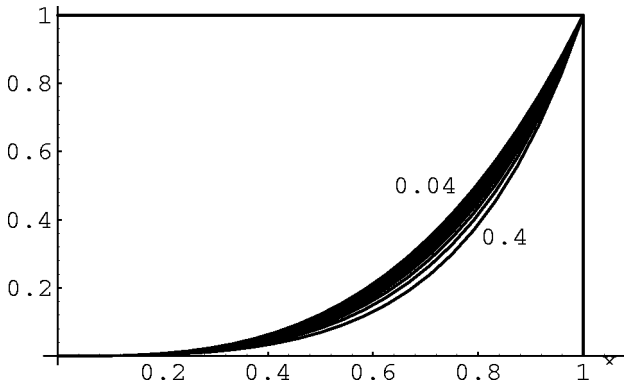

FIG. 1. m_{TW}/M as function of x for the model I, and ten values of n, from 0.04 to 0.4.

V. DISCUSSION

We have integrated the vanishing Weyl condition. The resulting expression (39) [and (40)] allows us to find conformally flat models in a very simple way, once an additional condition on physical or metric variables is imposed. Specifically we have found two conformally flat models (I, III). In order to bring out the role of Weyl tensor in its slow evolution, we have also presented two other models (II, IV) with the nonvanishing Weyl tensor. Model II, as model I has vanishing radial pressure, whereas model IV has the same energy density distribution as model III. This will allow us to see the effect of the three abovementioned factors (local anisotropy, Weyl tensor, density contrast) on the Tolman–Whittaker mass distribution within the sphere, and on the velocity profile of different pieces of matter. With this purpose, all models are considered with the same total mass M and surface velocity ω_{Σ}.

Figure 1 exhibits the evolution of m_{TW}/M as function of x, in the process of slow contraction (increasing n), for model I. For all other models the behavior is qualitatively the same, i.e., as the contraction proceeds, the active gravitational mass within the sphere decreases. However, the absolute value of m_{TW} is different for different models (for same n and x) as can be seen from Figs. 2–4, which display the ratio $m_{\mathrm{TW}}/m_{\mathrm{TW}}(\mathrm{II})$ for the three models (I, III, IV).

As it can be seen, for any $r<r_{\Sigma}$ (for the same total mass M), we have

$$m_{\mathrm{TW}}(\mathrm{III})>m_{\mathrm{TW}}(\mathrm{I})>m_{\mathrm{TW}}(\mathrm{IV})>m_{\mathrm{TW}}(\mathrm{II}),$$

the differences being larger for more compact (larger n) configurations. Parenthetically, the two conformally flat models present the largest TW masses.

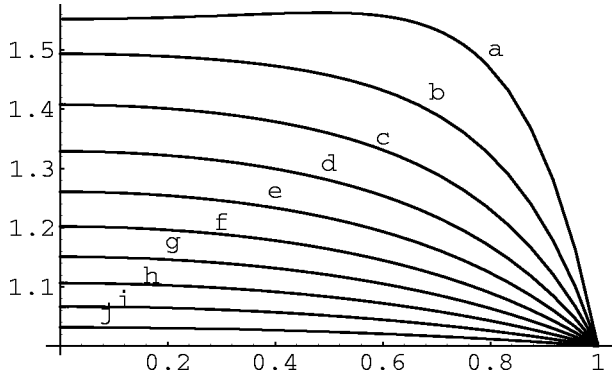

FIG. 2. $m_{\mathrm{TW}}(\mathrm{I})/m_{\mathrm{TW}}(\mathrm{II})$ as function of x, curves a–j correspond to $n=0.4$, 0.36, 0.32, 0.28, 0.24, 0.20, 0.16, 0.12, 0.08, 0.04.

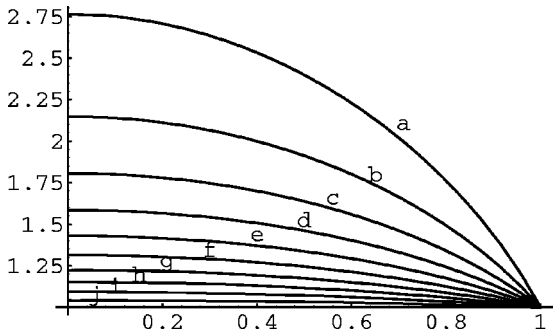

FIG. 3. $m_{TW}(III)/m_{TW}(II)$ as a function of x, for the same values of n as in Fig. 2.

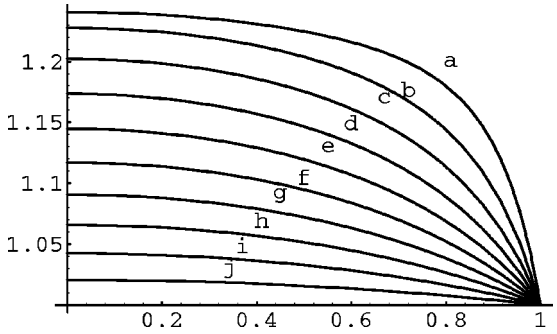

FIG. 4. $m_{TW}(IV)/m_{TW}(II)$ as function of x, for the same values of n as in Fig. 2.

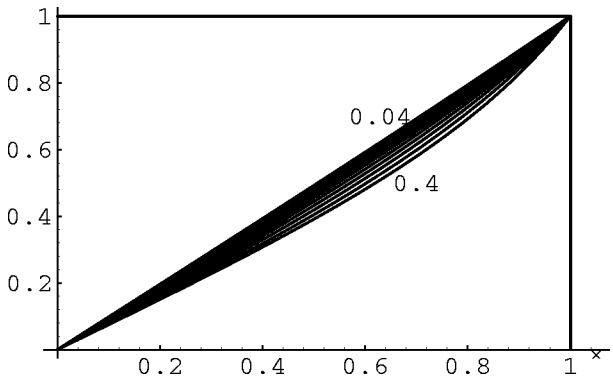

FIG. 5. ω/ω_Σ as function of x for model III, and ten values of n, from 0.04 to 0.4.

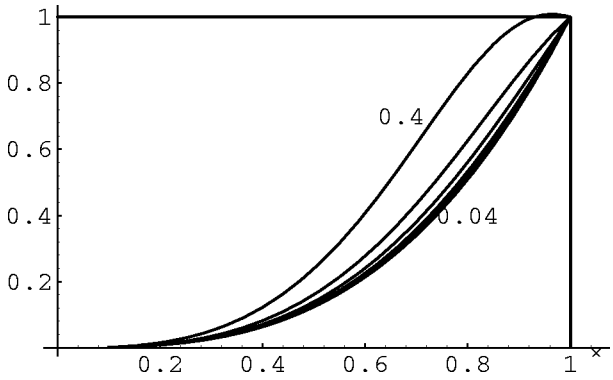

FIG. 6. Same as Fig. 5 for model I.

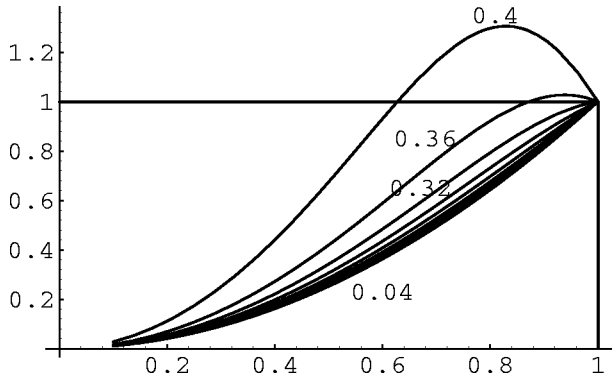

FIG. 7. The ratio $\omega(\mathrm{I})/\omega(\mathrm{II})$ as function of x, for ten values of n from 0.04 to 0.4.

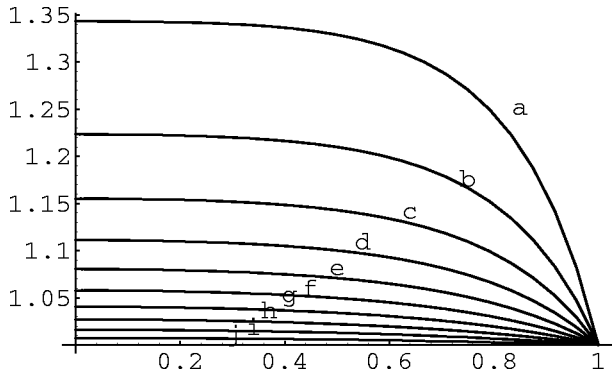

FIG. 8. The ratio $\omega(\mathrm{IV})/\omega(\mathrm{II})$ as function of x, curves a–j correspond to $n=0.4$, 0.36, 0.32, 0.28, 0.24, 0.20, 0.16, 0.12, 0.08, 0.04.

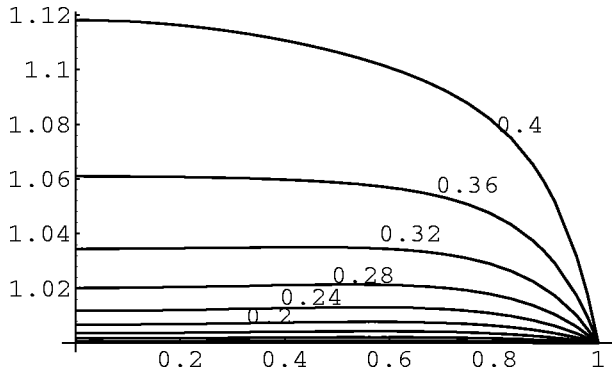

FIG. 9. The ratio $\omega(\mathrm{III})/\omega(\mathrm{II})$ as function of x, for ten values of n from 0.04 to 0.4.

For models II, III, and IV the collapse proceeds in a quasihomologous (quasilinear) regime as indicated in Fig. 5 for model III (for models II and IV the figures are similar), deviating from that regime as n increases.

However for model I, the contraction is not homologous even for small n as indicated in Fig. 6.

Figures 7–9 display the ratio $\omega/\omega(\mathrm{II})$ for the three models (I, III, IV).

Except for extremely high fields in model I, we see that

$$\omega(\mathrm{IV})>\omega(\mathrm{III})>\omega(\mathrm{II})>\omega(\mathrm{I}),$$

which indicate that for the same energy density distribution (III, IV) or radial pressure distribution (I, II), the slow contraction of interior shells proceeds slower in the conformally flat case.

(Received 5 June 2000; accepted for publication 7 July 2000)

In this paper we study systems with a closed algebra of second class constraints. We describe a construction of the reduced theory that resembles the conventional treatment of first class constraints. It suggests, in particular, to compute the symplectic form on the reduced space by a fiber integral of the symplectic form on the original space. This approach is then applied to a class of systems with loop group symmetry. The chiral anomaly of the loop group action spoils the first class character of the constraints but not their closure. Proceeding along the general lines described above, we obtain a 2-form from a fiber (path) integral. This form is not closed as a relict of the anomaly. Examples of such reduced spaces are provided by *D*-branes on group manifolds with WZW action. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1330730]

I. INTRODUCTION

According to Dirac's classification, constraints in Hamiltonian mechanics split into first-class and second-class. The theory of the first-class constraints is well developed because it is a major tool in gauge theories. Second-class constraints naturally arise in gauge theories with anomalies: quantum corrections may cause first-class constraints of the classical system to become second-class.[1,2]

We reconsider Dirac's approach to second-class constraints and provide a new realization of the reduced phase space which is more in line with the reduction procedure for the first-class constraints (see also Ref. 1). In this framework the Liouville form (the exponential of the symplectic form) on the reduced phase space can be obtained by fiber integration from the Liouville form on the original phase space of the system. The procedure can suffer from possible global difficulties similar to the Gribov problems one often encounters in the context of ordinary (anomaly-free) gauge theories.

Our main interest is to apply this formalism to loop group actions on symplectic manifolds. If the Poisson bracket of the symmetry generators contains a Schwinger term (for instance, this is the case in the WZW model), the constraints become second-class. Such a situation was considered in the mathematical literature.[3,4] We use a fiber integration procedure to derive the Liouville form on the reduced phase space. As a new manifestation of the anomaly it turns out that this form is not closed (see also Ref. 4)!

''Anomalous'' reduced spaces of this type naturally arise in the theory of D-branes on group manifolds.[5] It is an interesting problem to develop a consistent quantization theory for such

spaces. Because of the connection between deformation quantization and open strings (see, e.g., Refs. 6–8) one expects valuable insights from open string theory. For the case of D-branes on group manifolds this was analyzed in Ref. 9.

II. DIRAC BRACKETS FROM FIBER INTEGRATION

Our aim in the present section is to reformulate the symplectic reduction for a system of constraints which form a closed algebra. To begin with we shall briefly recall the standard theory of reduction. This is used as a starting point for presenting an alternative formulation, applicable to closed constraint algebras under certain additional conditions. For the case of a purely second-class constraint system the approach suggests we construct the symplectic two-form and its associated Liouville form through a fiber integral. The material within this section serves as a toy model for the discussion of infinite dimensional phase spaces with an anomalous loop group action in Secs. 3 and 4.

Let us denote the original, unconstrained phase space by N and let x^i, $i=1,\ldots,2n$, be local coordinates. Their Poisson bracket is denoted by $P^{ij}=\{x^i,x^j\}$ and its associated symplectic form by

$$\Omega=\tfrac{1}{2}\Omega_{ij}dx^i\,dx^j.$$

$\Phi^\alpha=\Phi^\alpha(x)$, $\alpha=1,\ldots,2m$, are constraints in this phase space. According to our assumptions they form a closed algebra, i.e.,

$$\{\Phi_\alpha,\Phi_\beta\}=\Pi_{\alpha\beta}(\Phi), \tag{1}$$

with a matrix Π that is a function of the constraints Φ_α only. For simplicity we also assume that the constraints are independent from one another (*irreducible* constraints) and that they are all *regular* so that they may be used as local coordinates in phase space, at least in a neighborhood of the constraint surface $\Phi(x)=0$. Details and further results used in the text below can be found, e.g., in Ref. 10.

The standard procedure of symplectic reduction proceeds as follows: First the symplectic form Ω is pulled back to the constraint surface, which we denote by N_0. The resulting two-form Ω_0 on N_0 is degenerate in general. Its kernel is surface-forming, however, and the quotient of N_0 with respect to the orbits (''gauge orbits'') is the reduced phase space M. By construction, the induced two-form ω on M is nondegenerate.

In the case of mere second-class constraints, i.e., $\det\Pi\neq 0$ on N_0 in our context, the last step does not arise, since Ω_0 is nondegenerate already. The Poisson bracket associated with Ω_0 may be obtained directly from the Poisson bracket on N by the following prescription:

$$\{f,g\}_D:=\{f,g\}-\{f,\Phi^\alpha\}(\Pi^{-1})_{\alpha\beta}\{\Phi^\beta,g\},$$

which is defined at least in some neighborhood of the constraint surface $N_0\subset N$. As a bivector-field this bracket, known as the Dirac bracket, is *tangential* to the constraint surface $\Phi(x)=0$ (in contrast to the original Poisson bracket). Hence, it has a push-forward to N_0, and this coincides with the inverse of Ω_0.

Due to the closedness of our constraint algebra (1), the Hamiltonian vector fields,

$$v^\alpha:=\{\Phi^\alpha,\cdot\}\equiv P^{ij}\frac{\partial\Phi^\alpha}{\partial x_i}\frac{\partial}{\partial x_j},$$

are surface-forming everywhere in N. In fact, one can easily show that

$$[v^\alpha,v^\beta]=\frac{\partial\Pi^{\alpha\beta}}{\partial\Phi^\gamma}v^\gamma.$$

Thus the v^α's generate orbits in *all* of N and this is true even if the set (Φ^α) contains second-class constraints.

The last observation opens new possibilities for performing the symplectic reduction, viewing the reduced phase space M as an appropriate orbit space. The difference to the standard Dirac procedure outlined above lies primarily in the treatment of the second-class constraints, which are dealt with very analogously to first-class constraints in their standard reduction. Consequently, our main focus in the remainder of this section will be on second-class constraints. We will briefly comment on the extension to more general cases with the simultaneous presence of first- and second-class constraints towards the end of the section.

For the case of pure second-class constraints, the matrix (1) is nondegenerate on the constraint surface, i.e., at $\Phi=0$. In what follows we will strengthen this requirement by assuming that $\det\Pi(\Phi)\neq 0$ not only at the value zero, but for all values of Φ adopted. This permits us to regard the image C of the constraint map $\phi: N\to C\subset\mathbb{R}^{2m}$, $x\mapsto\Phi^\alpha(x)$, as a symplectic manifold; indeed $C\equiv \mathrm{Im}\,\phi$ is endowed naturally with the symplectic form

$$\varpi=\tfrac{1}{2}(\Pi^{-1})_{\alpha\beta}d\Phi^\alpha\, d\Phi^\beta. \tag{2}$$

By construction, the map ϕ is Poisson.

In contrast to the standard approaches in which the reduced phase space M is regarded as a restriction of the original phase space N to the constraint surface $\Phi(x)=0$, we propose to view M as the *space of orbits* generated by the second-class constraints Φ^α. Since the constraints are second-class, their Hamiltonian vector fields v^α are nowhere tangential to the constraint surface. Thus, at least locally, any point of the constraint surface, i.e., of the reduced phase space M, corresponds to an orbit (namely the one that is generated by the v^αs through the point in question).

Before we follow this general idea, we shall pause for a moment and comment on the possible global difficulties. The full equivalence between the reduced phase space M and the orbit space requires any orbit to intersect the constraint surface once and once only. Despite the fact that we required Π to be nondegenerate everywhere, the orbits do not necessarily have this property in general. The situation we meet here is similar to the one of choosing gauge conditions for a set of first-class constraints, with $\det\Pi$ playing the role of the Faddeev–Popov determinant. Note that the combined system of first-class constraints and gauge-conditions forms a set of second-class constraints. It is known that even for a nonvanishing Faddeev–Popov determinant (along the intersection of the constraint surface with the gauge conditions) the chosen gauge conditions may show global deficiencies, in which case they are referred to as having a Gribov problem.[11]

By analogy, we call the orbits generated by the v^α's to have a *Gribov problem*, if they do not intersect the constraint surface precisely once. To conclude these remarks, let us illustrate such problems through the following simple example where we take $N=T^*\mathbb{R}\backslash(0,0)$ with standard symplectic form $\Omega=dq\wedge dp$. Now let us choose the constraints,

$$\Phi^1:=\frac{(q^2-p^2)}{2\sqrt{q^2+p^2}}-\frac{1}{2}\quad\text{and}\quad\Phi^2:=\frac{qp}{2\sqrt{q^2+p^2}}.$$

Their Poisson bracket is given by $\Pi^{12}=1$ and one can easily establish that there is just *one* orbit in $T^*\mathbb{R}\backslash(0,0)$. On the other hand, $T^*\mathbb{R}\backslash(0,0)$ contains *two* points of the reduced phase space: $(q,p)=(\pm 1,0)$. In fact, the map from $N=T^*\mathbb{R}\backslash(0,0)$ to $C=\mathbb{R}^2\backslash(-\frac{1}{2},0)$ defines a two-fold covering (as one may see most easily in polar coordinates). These constructions are easily extended to obtain examples with an arbitrary number of Gribov copies.

In the absence of a Gribov problem,[12] however, the reduced phase space M may be fully identified with the space of orbits. Let π denote the projection from N to M along the orbits. In its spirit related to Ref. 1, we make the following proposition: The symplectic two-form ω on M satisfies

$$\pi^*\omega=\Omega-\phi^*\varpi. \tag{3}$$

The proof proceeds in several steps. First, we show that the form $(\Omega-\phi^*\varpi)$ descends to the space of leaves of the foliation. Indeed, it is horizontal,

$$\Omega(v^\alpha,\cdot)-\phi^*\varpi(u^\alpha,\cdot)=d\Phi_\alpha(x)-\phi^*d\Phi_\alpha=0. \tag{4}$$

Here u^α denotes the projection of the vector fields v^α to C (which is well-defined since the v^α's are tangential to the orbits): $u^\alpha=\{\Phi^\alpha,\cdot\}_C$, the index C being used to make clear that the bracket corresponds to (2). For later use we remark here that by assumption on the determinant of Π, the vector fields u^α—and thus also the vector fields v^α—are nonzero everywhere; correspondingly, the action generated by the constraints is free.

Equation (4) implies that, since the form in question is closed, it is also invariant with respect to the flows generated by the constraints. Hence, it is a pullback of some two-form on M, which we denote by ω.

Next, we show that ω coincides with the inverse of Dirac's bracket. For this purpose we consider two functions f and g on N which are constant on the leaves of the foliation. This implies that their Poisson brackets with the constraints vanish, yielding $\{f,g\}_D=\{f,g\}$. Denote the corresponding Hamiltonian vector fields by v_f and v_g. Note that one can use either the original Poisson bracket or the Dirac bracket to define them. We would like to show that

$$\omega(\pi_*v_f,\pi_*v_g)=\{f,g\}_D.$$

Indeed,

$$\{f,g\}_D=\{f,g\}=\Omega(v_f,v_g)=\omega(\pi_*v_f,\pi_*v_g).$$

Here we have used that the vector fields v_f and v_g project to zero by ϕ. Thus we have fully established our formula (3) above.

In the presence of a Gribov problem with nonvanishing number of Gribov copies the map ϕ restricted to an orbit is not injective. For the following constructions we shall assume that the restriction of ϕ is a bijection. Note that this property is not guaranteed by the absence of a Gribov problem, since ϕ may still fail to be surjective after restriction to an orbit. As an example we take N to be $T^*\mathbb{R}^2$ with the standard symplectic form and choose the constraints $\Phi^1:=\exp(q^2)[\exp(q^1)-1]$, $\Phi^2:=\exp(-q^1-q^2)p_1$, which again leads to $\Pi^{12}=1$. Now, $C\equiv\mathrm{Im}\,\phi=T^*\mathbb{R}$, but an orbit characterized by a fixed value of q^2 maps only to the parts of C with $\Phi^1>-\exp(q^2)$.

If the map ϕ restricted to any orbit is surjective and there is no Gribov problem, the original phase space is a fiber bundle with typical fiber C and base manifold M. In this case there is an alternative way to express the relation between the form Ω on N and ω on M: Let us consider the Liouville forms of mixed degree $L:=\exp(\Omega)$ on N and $l:=\exp(\omega)$ on M. The top degree components of L and l are the Liouville volume forms on N and M, respectively. We define the normalized fiber integral (or push forward map) π_* over the leaves of our foliation by the formula

$$\pi_*\alpha:=\frac{1}{\mathrm{Vol}\,C}\int_{\mathrm{fiber}}\alpha. \tag{5}$$

Here α is a differential form on N and Vol C is a (possibly infinite) symplectic volume of the constraint space C. If C is compact, π_* is just the ordinary push-forward map to M. Otherwise, the normalization factor $(\mathrm{Vol}\,C)^{-1}$ is reminiscent of the infinite normalization constants in the definitions of path integrals. By applying the fiber integral (5) to the Liouville form L, we obtain

$$\pi_* L = \frac{1}{\mathrm{Vol}\, C} \int_{\mathrm{fiber}} \exp(\Omega) = \frac{1}{\mathrm{Vol}\, C} \exp(\omega) \int_{\mathrm{fiber}} \exp(\Phi^* \varpi)$$

$$= \frac{\int_C \exp(\varpi)}{\mathrm{Vol}\, C} \exp(\omega) = l. \tag{6}$$

In the next section we shall generalize Eq. (3) to an infinite dimensional context where Ω is given by a symplectic form on some space of fields. There will be one major difference in comparison to the considerations in the present section: the forms ω and ϖ will no longer be closed! The fiber integral (5) (which becomes a path integral) will then provide a prescription of how to define the Liouville form l for a nonclosed form ω.

Before turning to this, however, we briefly extend the above considerations to the general setting of a closed algebra of constraints, where there are both first- and second-class constraints. Note in this context that although one may always replace a set of constraints by an equivalent set of constraints where first- and second-class constraints are split,[10] this splitting is achieved only on-shell (i.e., in a ''weak sense''). On the full phase space of the original theory, however, it may be impossible to find a splitting for which the second-class constraints do not generate first-class constraints upon Poisson commutation.

In the case of a closed constraint algebra containing first-class constraints, the matrix $\Pi(\Phi)$ is degenerate. Consequently, the manifold $C = \mathrm{Im}\, \phi$ is no longer symplectic but only a Poisson manifold. Hence, C foliates into symplectic leaves. Let C_0 denote the symplectic leaf containing the origin $\Phi = 0$ and $\tilde{N}_0$ be the pre-image of C_0, i.e., $\tilde{N}_0 = \phi^{-1}(C_0)$. ($\tilde{N}_0$ may be obtained equivalently through the action on N_0 of the flow generated by the constraints.) The reduced phase space may now be regarded as the space of orbits in $\tilde{N}_0$, at least in the absence of a Gribov problem. A formula of the type (3) is true, if in the right-hand side Ω is the restriction of the symplectic form on the original space N to $\tilde{N}_0$ and ϖ is the symplectic form on C_0. By means of such a formula one may, however, no more relate the Liouville forms on N and M such as in (6). The reason is that the fiber integration over Ω restricted to $\tilde{N}_0$ yields zero, since in the presence of first-class constraints this differential form has a kernel along the fibers.

III. HAMILTONIAN SYSTEMS WITH LOOP GROUP SYMMETRY

Now we turn to the infinite dimensional situation of interest. Our phase space N is a field space with symplectic form Ω. By assumption, it has a Hamiltonian action of the loop group LG of some Lie group G, which we take to be compact, simple, and simply connected for simplicity. To an algebra element $\varepsilon(s) \in L\mathcal{G}$ we associate a Hamiltonian vector field,

$$v_\varepsilon = \{J_\varepsilon, \cdot\}, \tag{7}$$

on N, where

$$J_\varepsilon = \mathrm{tr} \int_0^1 \varepsilon(s) J(s) ds, \tag{8}$$

and $J(s)$ is a field giving rise to the moment map for the loop group action.

Using an orthonormal basis t^a in the Lie algebra $\mathcal{G}$, we can write the Poisson brackets of the components of $J(s)$ in the form

$$\{J^a(s), J^b(s')\} = k \delta^{ab} \delta'(s - s') + f_c^{ab} \delta(s - s') J^c(s). \tag{9}$$

Here k is a coefficient in front of the anomalous term in the bracket. We would like to use the currents $J^a(s)$ as constraints in our Hamiltonian system. If k vanishes, they are first-class constraints and can be treated by the standard procedure. Our main interest is to deal with the case of nonvanishing k. To simplify notations we will set $k = 1$ for the rest of the paper.

According to Eq. (9), the currents $J(s)$ form a closed algebra of both first- and second-class constraints. The zero modes of the currents $J_0^a := \int J^a(s)ds$ are first-class. All the remaining modes in a Fourier decomposition of $J(s)$ are second-class. The latter do not close among themselves since Poisson brackets of J_n with J_{-n} have J_0-contributions. Hence, the Fourier modes J_n do not allow us to split off a closed algebra of pure second-class constraints. As we remarked above, such a splitting into closed first-class and closed second-class constraints need not even exist.

In the present case, however, we can split the constraints into first- and second-class. To see this, we return to the loop group LG, whose Lie algebra elements enter the Hamiltonians (8). LG may be written as a semidirect product of the group of based loops ΩG, formed by the loops with property $g(0)=e$, and the group G: Any $g(s)\in LG$ can be written uniquely as $g(s)=\tilde{g}(s)\hat{g}$ with $\tilde{g}(s)\in\Omega G$ and $\hat{g}\in G$. On the Lie algebra level this corresponds to the unique splitting of any $\varepsilon(s)\in L\mathcal{G}$ into the sum of a constant Lie algebra element $\varepsilon(0)$ and an $\tilde{\varepsilon}(s)\in\Omega\mathcal{G}$: $\varepsilon(s)=\varepsilon(0)+\tilde{\varepsilon}(s)$ with $\tilde{\varepsilon}(0)=0$. Re-expressing the relations (9) in terms of the Hamiltonians (8), one finds

$$\{J_\varepsilon, J_\eta\} = \mathrm{tr}\int_0^1 \varepsilon(s)\,\eta'(s)ds + J_{[\varepsilon,\eta]}. \tag{10}$$

Since $\delta'(s-s')$ is an invertible operator on test-functions vanishing on the end-points of the interval, these relations become second-class upon restriction to $\Omega\mathcal{G}$. Moreover, the algebra of this subclass of Hamiltonians is obviously closed now.

So, following the ideas of Sec. II, we should now be able to forget the first-class constraints and just restrict our attention to the subclass of second-class constraints so as to perform the pushforward integral (6) we are after. However, at this point we have to fight with the infinite dimensionality of the space of constraints and with the properties of an (appropriately defined) dual for the Lie algebra of the group ΩG. [Recall that the moment(um) map yields elements in the *dual* space of the Lie algebra of the group action in question; cf., e.g., Ref. 13 for details.]

In this paper, we do not intend to go into the functional analytical details that would be necessary to fully and rigoroulsy *extend* the approach of the previous section to the present infinite dimensional case (although this might yield interesting insights). Instead we will make use of a (mathematically rigorous) formula which is of the *form* of Eq. (3) with a (weakly) nondegenerate ϖ, which, however, is not closed and thus not symplectic.

For this purpose we return to the action of the group ΩG. As follows from Eq. (9), this group (or also LG) acts on the space of currents by standard gauge transformation,

$$J^g(s) = g^{-1}Jg + g^{-1}\partial_s g.$$

This action has no fixed points (here the restriction to ΩG becomes relevant!), similar to the flows of the vector fields u_α on C in Sec. II. Hence, the action of ΩG on N is also free. Then, one can form the space of orbits, $M := N/\Omega G$ which replaces the space of leaves of the foliation of Sec. II. The projection from N to M is denoted by π.

Similar to Eq. (3) we may decompose the symplectic form Ω on the original phase space according to (cf. Theorem 8.3 in Ref. 3)

$$\Omega = \pi^*\omega + J^*\varpi, \tag{11}$$

where ω is a two-form on M and ϖ lives on the space of currents (for a more precise definition of this space cf. Ref. 3). The explicit formula for ϖ looks as follows. Denote by Ψ the solution of the equation

$$\partial_s\Psi\Psi^{-1} = J(s),$$

with the boundary condition $\Psi(0)=e$. In other words, $\Psi(s)$ is a path ordered exponential of $J(s)$ and $\Psi(1)$ is the holonomy map, which takes values in the group G. Obviously, the holonomy map descends to M and we shall denote the induced map by $\psi: M\to G$.

The form ϖ is given by

$$\varpi := \frac{1}{2}\mathrm{tr}\int_0^1 (\Psi^{-1}d\Psi\,\partial_s(\Psi^{-1}d\Psi))ds. \tag{12}$$

As remarked above, it is not closed,

$$d\varpi = \tfrac{1}{6}\mathrm{tr}(\Psi^{-1}(1)d\Psi(1))^3.$$

As a consequence of formula (11), the form ω is also not closed,

$$d\omega = -\tfrac{1}{6}\mathrm{tr}(\psi^{-1}d\psi)^3.$$

Note, however, that the right-hand side of the last two formulas is proportional to the coefficient k in (9), which we have set to one thereafter. Thus, these forms become closed in the absence of the anomalous term in the current algebra. This observation will become relevant when interpreting the final result of the calculation in Sec. 4.

Although ϖ is not symplectic, it comes very close to an inverse of the Poisson brackets (10) between the second-class constraints. By straightforward calculation one verifies the two relations:

$$\iota(v_{\tilde{\varepsilon}})\varpi \equiv \varpi(v_{\tilde{\varepsilon}},\cdot) = -dJ_{\tilde{\varepsilon}}, \quad \varpi(v_{\tilde{\varepsilon}},v_{\tilde{\eta}}) = \{J_{\tilde{\varepsilon}},J_{\tilde{\eta}}\}. \tag{13}$$

For these relations to hold it is essential that one restricts the Lie algebra elements to $\Omega\mathcal{G}$ (for the corrections appearing otherwise cf. Proposition 8.1 in Ref. 3). In the finite dimensional setting, equations of the form (13) for a complete set of Hamiltonian vector fields are already sufficient to ensure that ϖ is the sought-for symplectic form; the closedness would then follow automatically by validity of the Jacobi identity for the Poisson bracket.

In the present infinite dimensional setting, the form ϖ yielding relations of the form (13) is even not unique. Indeed, one can change the splitting (11) by an arbitrary 2-form β on the group G,

$$\tilde{\omega} = \omega + \psi^*\beta, \quad \tilde{\varpi} = \varpi - \Psi^*\beta,$$

without affecting the relations (13) where ϖ is replaced by $\tilde{\varpi}$. Note that because the 3-form $\mathrm{tr}(\psi^{-1}\,d\psi)^3$ belongs to a nontrivial cohomology class on G, also the 2-form $\tilde{\omega}$ is not closed,

$$d\tilde{\omega} = d\omega + \psi^*\,d\beta \neq 0.$$

The phase space N is symplectic and carries the Liouville form $L = \exp(\Omega)$. The (formal) top degree part of L gives the measure of the Hamiltonian path integral. Inspired by Eq. (6), we would like to (formally) *define* the Liouville form l on M by the formula

$$l := \pi_* L = \frac{1}{\mathrm{Vol}\,\Omega G}\int_{\Omega G}\exp\Omega \equiv \frac{\int_{\Omega G}\exp(\varpi)}{\mathrm{Vol}\,\Omega G}\exp(\omega), \tag{14}$$

where we made use of the definition (5) as well as of the relation (11). In the next section we compute the path integral,

$$I(\psi) := \frac{1}{\mathrm{Vol}\,\Omega G}\int_{\Omega G}\exp(\varpi),$$

where $\psi = \Psi(1)$ is an element of G. Note that the resulting integral will be a differential form of mixed degree rather than a function on G (or its pullback to M).

IV. EVALUATION OF THE PATH INTEGRAL

We want to integrate $\exp(\varpi)$ over the group of based loops ΩG. Therefore we split the field $\Psi(s)$ in formula (12) into a product of an element $h \in \Omega G$ and an extra factor $\exp(\alpha s)$, i.e.,

$$\Psi(s) = h(s)\exp(\alpha s),$$

where $h(s) \in G$ is a periodic G-valued function and $\alpha \in \mathcal{G}$ is sent to the group element $\Psi(1) = \exp(\alpha) \in G$ by the exponential mapping.

A short and elementary computation allows us to reexpress the form ϖ in terms of the variables $h(s)$ and α. The result is

$$\varpi = \frac{1}{2}\mathrm{tr}\int_0^1 ds((h^{-1}dh)D_\alpha(h^{-1}\,dh) + 2h^{-1}dh\,d\alpha + d(e^{\alpha s})e^{-\alpha s}\,d\alpha).$$

D_α denotes the covariant derivative $D_\alpha = \partial_s - \mathrm{ad}_\alpha$ where $\mathrm{ad}_\alpha(\cdot) = [\alpha, \cdot]$. The last term in ϖ can be evaluated with the help of the following formula:

$$\theta(s) := d(e^{\alpha s})e^{-\alpha s} = \frac{1}{\mathrm{ad}_\alpha}(e^{s\mathrm{ad}_\alpha} - 1)d\alpha. \tag{15}$$

Here, $1/\mathrm{ad}_\alpha = (\mathrm{ad}_\alpha)^{-1}$ is the inverse of the adjoint action ad_α with α. Note that the function $(1/x)(1-e^{sx}) = \Sigma_{n\geqslant 1} s^n x^{n-1}/n!$ is regular even at $x=0$ so that the right-hand side of formula (15) is well-defined. To establish Eq. (15) we differentiate the function $\theta(s)$ with respect to s to find

$$\partial_s\theta(s) = d\alpha + [\alpha, \theta(s)].$$

If the ansatz $\theta(s) = \exp(s\,\mathrm{ad}_\alpha)\,\vartheta(s)$ is inserted into the expression for $\partial_s\theta(s)$, we deduce

$$\partial_s\vartheta(s) = e^{-s\ \mathrm{ad}_\alpha}d\alpha.$$

This equation can easily be integrated to give the claimed formula for $\theta(s)$.

Formula (15) actually allows us to perform the integral over s for the third term in ϖ. This results in

$$\varpi = \frac{1}{2}\mathrm{tr}\int_0^1 ds(\phi D_\alpha\phi + 2\phi\,d\alpha) - \frac{1}{2}\mathrm{tr}\left(d\alpha\frac{1}{(\mathrm{ad}_\alpha)^2}(e^{\mathrm{ad}_\alpha} - 1 - \mathrm{ad}_\alpha)d\alpha\right). \tag{16}$$

Again, the argument of the second trace is well-defined on the kernel of ad_α. In this expression for the form ϖ we also introduced the field $\phi(s) = h^{-1}(s)dh(s)$. By construction, $\phi(s)$ is a fermionic field subject to the constraint $\phi(0) = 0 = \phi(1)$. The integral over the exponential of the two-form ϖ is now reinterpreted as a fermionic ''path integral'' $\int \mathcal{D}\phi\exp(\varpi)$.

From the proof of Eq. (15) above it is obvious that $D_\alpha\theta(s) = d\alpha$. Therefore one can rewrite the form ϖ also as

$$\varpi = \frac{1}{2}\mathrm{tr}\int_0^1 ds(\phi + \theta)D_\alpha(\phi + \theta).$$

This may lead one to conclude that the integration of $\exp\varpi$ over ϕ merely results in the Pfaffian of D_α. However, $(\phi+\theta)(s)$ does not vanish at $s=1$ and a change of variables to $\phi+\theta$ is illegitimate.

We therefore proceed with integrating $\exp(\varpi)$ in the form of Eq. (16). As the last term does not depend on ϕ (resp. h) and as, being a two-form, it commutes with the first two terms, we can split the exponential into two parts, the second one of which we may pull out of the integral, i.e., we shall write $\varpi = \varpi_1 - \varpi_2$ with

$$\varpi_1=\frac{1}{2}\mathrm{tr}\int_0^1 ds(\phi D_\alpha\phi+2\phi\, d\alpha), \tag{17}$$

$$\varpi_2=\frac{1}{2}\mathrm{tr}\left(d\alpha\frac{1}{(\mathrm{ad}_\alpha)^2}(e^{\mathrm{ad}_\alpha}-1-\mathrm{ad}_\alpha)d\alpha\right), \tag{18}$$

and compute the Integral $I=\int\mathcal{D}\phi\exp(\varpi_1)$, leaving out the extra factor $\exp(-\varpi_2)$ for the moment.

The field $\phi(s)$ is a periodic fermionic field which admits a Fourier decomposition: $\phi(s)=\Sigma_n\phi_n\exp(2\pi ins)$. In terms of the Fourier modes ϕ_n, the constraint $\phi(0)=0$ becomes $\Sigma_n\phi_n=0$. To turn the integral into a Gaussian one over *unrestricted* variables, we introduce a Lagrange multiplier λ. This leaves us with the computation of the following integral:

$$I=\int\prod_n d\phi_n\, d\lambda\,\exp\mathrm{tr}\left(\frac{1}{2}\sum_m\ \phi_{-m}D_m\phi_m+\phi_0\, d\alpha+\lambda\sum_m\ \phi_m\right),$$

where $D_n\equiv 2\pi in-\mathrm{ad}_\alpha$ and λ is again a fermionic variable. A product over the Lie algebra indices of ϕ_n and λ in the integration measure is understood, furthermore. Defining $J_n=\lambda+\delta_{n,0}\,d\alpha$, the second and third terms in the exponent may be combined into $\Sigma_m\phi_{-m}J_m$.

We would like to remark that the last reformulation of our integral involves the choice of some particular (anti)self-adjoint extension for the operator D_α: on its original domain of definition which consists of sections vanishing at both ends of the interval $[0,1]$, iD_α is symmetric only, while on sections satisfying periodic boundary conditions it becomes self-adjoint.

The operator D_α is not invertible in the space of periodic sections. Its kernel is the ''diagonal part'' of the constant section. By ''diagonal'' we mean the subspace of the Lie algebra that commutes with α, thus being in the kernel of ad_α. We therefore integrate over ϕ_0^{diag} first. This produces a delta function $\delta(J_0^{\mathrm{diag}})\equiv\delta(\lambda^{\mathrm{diag}}+(d\alpha)^{\mathrm{diag}})$, which fixes the diagonal part of λ. On the remaining space the operator is invertible and we can perform the fermionic Gaussian integration, using

$$\int\ \mathcal{D}\psi\exp\left(\frac{1}{2}\psi_i\mathcal{O}_{ij}\psi_j+\psi_iJ_i\right)=\mathrm{Pf}(\mathcal{O})\exp\left(\frac{1}{2}J_i\mathcal{O}^{-1}_{ij}J_j\right). \tag{19}$$

Here, ψ and J have been taken fermionic, the operator $\mathcal{O}$ was assumed to satisfy $\psi\mathcal{O}\psi=-(\mathcal{O}\psi)\psi$, and $Pf(\mathcal{O})$ denotes the Pfaffian of $\mathcal{O}$. We get

$$I=\mathrm{Pf}(D_\alpha)\int d\tilde{\lambda}\,\exp\mathrm{tr}\left(\frac{1}{2}\sum_n\ J_{-n}D_n^{-1}J_n\right), \tag{20}$$

where the Pfaffian is taken over the space of periodic sections without a kernel and $\tilde{\lambda}$ denotes the nondiagonal part of λ. Note that $J_0^{\mathrm{diag}}\equiv 0$ so that the expression in the exponent is well-defined. Actually, since D_n becomes merely the number $2\pi in$ on diagonal elements, all of the diagonal parts of J_n drop out due to $J_{-n}=J_n$ and the fermionic character of J_n. We indicate this again by means of tildes. Inserting the definition of J_n, Eq. (20) becomes

$$I=\mathrm{Pf}(D_\alpha)\int d\tilde{\lambda}\,\exp\mathrm{tr}\left[\frac{1}{2}\tilde{\lambda}\left(\sum_n\ D_n^{-1}\right)\tilde{\lambda}+\tilde{\lambda}(\mathrm{ad}_\alpha)^{-1}\widetilde{d\alpha}+\frac{1}{2}\widetilde{d\alpha}(\mathrm{ad}_\alpha)^{-1}\widetilde{d\alpha}\right].$$

This is again a Gaussian integral for the variable $\tilde{\lambda}$ and we assume that α is sufficiently ''generic'' for $\Sigma_nD_n^{-1}$ to possess an inverse. We may again apply Eq. (19) to obtain

$$I=\mathrm{Pf}(D_\alpha)\mathrm{Pf}\left(\sum_n\ D_n^{-1}\right)\exp\mathrm{tr}\left[-\frac{1}{2}\widetilde{d\alpha}\frac{(\Sigma_nD_n^{-1})^{-1}}{ad_\alpha^2}\widetilde{d\alpha}+\frac{1}{2}\widetilde{d\alpha}(ad_\alpha)^{-1}\widetilde{d\alpha}\right],$$

where use of the ad-invariance of the trace (Killing metric) has been made.

This result for $I=\int \mathcal{D}\exp(\varpi_1)$ may now be combined with the expression for ϖ_2 in Eq. (18) to yield

$$\int \mathcal{D}\phi \exp(\varpi)=\mathrm{Pf}(D_\alpha)\mathrm{Pf}\left(\sum_n D_n^{-1}\right)\exp\left[-\frac{1}{2}\mathrm{tr}\,\widetilde{d\alpha}\frac{(\Sigma_n D_n^{-1})^{-1}+e^{\mathrm{ad}_\alpha}}{\mathrm{ad}_\alpha^2}\widetilde{d\alpha}\right].$$

Here we made use of the fact that the diagonal parts of $d\alpha$ drop out in (18) and that $\mathrm{tr}(\widetilde{d\alpha}f(\mathrm{ad}_\alpha)\widetilde{d\alpha})$ vanishes for any function f with $f(x)=f(-x)$. We are left with the computation of the operator $\Sigma_n D_n^{-1}$ and the two Pfaffians.

We start with $\mathrm{Pf}(D_\alpha)$. Denote by $i\alpha_r$ the nonvanishing eigenvalues of ad_α, which are purely imaginary as G is taken compact. The index r runs over all roots in the Lie algebra of G; with $r>0$ $(r<0)$ labeling the positive (negative) roots, one has $\alpha_r=-\alpha_{-r}$, furthermore. In this notation one finds the following formal expression for the Pfaffian:

$$\mathrm{Pf}(D_\alpha)=\left(\prod_{r>0} i\alpha_r\right)\prod_{n>0}\left((2\pi i\, n)^{\mathrm{rank}G}\prod_{r'}(2\pi i\, n+i\alpha_{r'})\right).$$

Clearly this is not well-defined. However, integrating $\exp\varpi$ over all of ΩG we cannot expect to obtain a finite result as the volume of the ''gauge group'' ΩG is infinite. So we should divide (again formally) by this volume. The group of (based) loops is a group of even cohomology, $H^{2k+1}(\Omega G)=0$, $\varepsilon=\int_0^1 ds\,\mathrm{tr}(h^{-1}dh\partial_s h^{-1}dh)$ being the generator of $H^2(\Omega G)$. So, formally the Haar measure of ΩG is given by the infinite product of ε's multiplied by the Haar measure on G (since the zero mode drops out from ε). Using our previous notation and Fourier decomposition, ε may be rewritten as $\mathrm{tr}\Sigma_{n\neq 0}(2\pi i\, n)d\phi_{-n}\,d\phi_n$. Thus we are led to *define*

$$\mathrm{Pf}(D_\alpha)/\mathrm{Vol}\,\Omega G:=\left(\prod_{r>0}\alpha_r\right)\prod_{n>0}\prod_{r'}\left(1+\frac{\alpha_{r'}}{2\pi n}\right).$$

By means of $\sin x=x\Pi_{n=1}^{\infty}(1-x^2/n^2\pi^2)$ we then obtain

$$\mathrm{Pf}(D_\alpha)/\mathrm{Vol}\,\Omega G=\prod_{r>0}\left(\sin\left(\frac{\alpha_r}{2}\right)\right). \tag{21}$$

We remark that the square of this result agrees with the expression obtained for $\det D_\alpha$ obtained in Ref. 14 by means of zeta function regularization.

We now come to the operator $\Sigma_n D_n^{-1}$, $D_n\equiv 2\pi i\, n-\mathrm{ad}_\alpha$, acting in that part of the Lie algebra that does not commute with α. Here we may use the simple formula,

$$\sum_n \frac{1}{2\pi i n-x}=\frac{1}{2}\coth\left(\frac{x}{2}\right),$$

to conclude that

$$\sum_n D_n^{-1}=\frac{1}{2}\coth(\mathrm{ad}_\alpha/2)\quad\text{and thus}\quad\left(\sum_n D_n^{-1}\right)^{-1}=2\tanh(\mathrm{ad}_\alpha/2).$$

Putting all this together, we arrive at the following result:

$$\frac{\int\mathcal{D}\phi\exp(\varpi)}{\mathrm{Vol}\,\Omega G}=\prod_{r>0}\cos\left(\frac{\alpha_r}{2}\right)\exp\left[-\mathrm{tr}\,d\alpha\frac{\sinh^3(\mathrm{ad}_\alpha/2)}{ad_\alpha^2\cosh(\mathrm{ad}_\alpha/2)}d\alpha\right].$$

Again, we have replaced $\widetilde{d\alpha}$ by $d\alpha$ as the extra contributions involving $(d\alpha)^{\mathrm{diag}}$ cancel anyway. We can finally rewrite the two-form in the exponent in terms of the group element $\psi=\exp(\alpha)$. First, we remark that

$$\prod_{r>0}\cos\left(\frac{\alpha_r}{2}\right)=\det{}^{1/2}\left(\frac{1+\mathrm{Ad}_\psi}{2}\right),$$

where $\det^{1/2}$ denotes the unique positive square root of the matrix $(1+\mathrm{Ad}_\psi)/2$. Next, formula (15) can be evaluated at $s=1$ to give $d\psi\,\psi^{-1}=\mathrm{ad}_\alpha^{-1}(1-e^{\mathrm{ad}_\alpha})d\alpha$. This may be inserted into our previous result for the integral and leads to

$$I(\psi)=\frac{\int\mathcal{D}\phi\exp(\varpi)}{\mathrm{Vol}\,\Omega G}=\det{}^{1/2}\left(\frac{1+\mathrm{Ad}_\psi}{2}\right)\exp\frac{1}{4}\left(\mathrm{tr}\,d\psi\,\psi^{-1}\frac{\mathrm{Ad}_\psi-1}{\mathrm{Ad}_\psi+1}\,d\psi\,\psi^{-1}\right).\tag{22}$$

V. RESULTS AND DISCUSSION

Combining Eqs. (14) and (22), we obtain the expression

$$l=\det{}^{1/2}\left(\frac{1+\mathrm{Ad}_\psi}{2}\right)\exp\left(\omega+\frac{1}{4}\,\mathrm{tr}\,d\psi\,\psi^{-1}\frac{\mathrm{Ad}_\psi-1}{\mathrm{Ad}_\psi+1}\,d\psi\,\psi^{-1}\right),\tag{23}$$

for the Liouville form l on the orbit space M. The same expression was previously used in Ref. 4 [formula (21)]. Our path integral consideration gives a natural derivation of Eq. (23), and shows its relation to the Liouville form L on the field space N.

Let us recall on this occasion that there was some freedom in our computation associated with the choice of an anti-self-adjoint extension for D_α. Instead of the periodic boundary conditions we introduced in the paragraph below Eq. (18), we could have extended the antisymmetric operator D_α also to sections with different (only quasi-periodic) behavior at the boundary. The final formula for $I(\psi)$ does depend on this choice of boundary conditions. It is expected, however, that the top degree part of the Liouville form l is insensitive to this freedom in the computation.

The space M arises as a result of reduction from the field space N with respect to second-class constraints. The residual first-class constraints J_0^a generate vector fields v_a on N which descend to M. According to Ref. 4, Proposition 4.1, the Liouville form l satisfies the following interesting equation:

$$(d+\tfrac{1}{24}f_{abc}\iota(v_a)\iota(v_b)\iota(v_c))l=0.\tag{24}$$

Note that in the finite dimensional case of Sec. II, $l=\exp(\omega)$ is a closed form. In the infinite dimensional situation we obtain an extra term $(1/24)f_{abc}\iota(v_a)\iota(v_b)\iota(v_c)$ on the left-hand side of Eq. (24), which modifies the exterior differential and should be interpreted as yet another manifestation of the chiral anomaly. It is a very interesting open question to trace the nature of this anomaly back to properties of the path integral in Sec. IV.

Simple examples of spaces M are given by D-branes in the WZW model.[5] There, the reduced spaces are conjugacy classes in a group manifold, and the form ω is given by the formula [see Eq. (7) in Ref. 5),

$$\omega=-\frac{1}{4}\mathrm{tr}\left(d\psi\,\psi^{-1}\frac{\mathrm{Ad}_\psi+1}{\mathrm{Ad}_\psi-1}\,d\psi\,\psi^{-1}\right).$$

Formula (23) shows that the form ω should be corrected by the extra term arising from the path integral to yield

$$\tilde{\omega}=-\mathrm{tr}\left(d\psi\,\psi^{-1}\frac{1}{\mathrm{Ad}_\psi-\mathrm{Ad}_\psi^{-1}}\,d\psi\,\psi^{-1}\right).$$

Note that in this case, the linear map $(\mathrm{Ad}_\psi - 1)(\mathrm{Ad}_\psi + 1)^{-1}$ representing the correction term in Eq. (23) is inverse to the element $B = (\mathrm{Ad}_\psi + 1)(\mathrm{Ad}_\psi - 1)^{-1}$ that appears in ω. Hence, their difference $\tilde{\omega}$ is represented by $B - B^{-1}$. Surprisingly, the same combination shows up in the expression for the effective B-field derived in Ref. 8 in the analysis of D-branes on the flat background. It is another challenging question to understand why the formula of Ref. 8 applies to group manifolds and to establish the relation with the path integral of Sec. III.

In this paper we did not touch the issue of quantization of the spaces N and M. While one can attempt to quantize N using the symplectic form Ω, it is not clear what it means to quantize M because the form ω is not closed. In the case of the D-branes in the WZW model one can use the link between string theory and noncommutative geometry to obtain an answer to this question.[9] The general case, however, remains an open problem.

The braiding for representations of q-deformed affine sl_2

E. J. Beggs[a] and P. R. Johnson
Department of Mathematics, University of Wales, Swansea, Wales SA2 8PP, United Kingdom

(Received 14 August 2000; accepted for publication 18 January 2001)

We compute the braiding for the ''principal gradation'' of $U_q(\widehat{sl_2})$ for $|q|=1$ from first principles, starting from the idea of a rigid braided tensor category. It is not necessary to assume either the crossing or the unitarity condition from S-matrix theory. We demonstrate the uniqueness of the normalization of the braiding under certain analyticity assumptions, and show that its convergence is critically dependent on the number theoretic properties of the number τ in the deformation parameter $q=e^{2\pi i\tau}$. We also examine the convergence using probability, assuming a uniform distribution for q on the unit circle. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1357197]

I. INTRODUCTION

The sine-Gordon S-matrix for the quantum scattering of solitons was solved initially in the literature in Ref. 1, by imposing conditions on the S-matrix called crossing and unitarity. These conditions were previously observed in other S-matrices found using perturbative techniques in quantum field theory,[2] and were subsequently taken to be axioms for the nonperturbative result.

The bootstrap methods use the $U_q(\widehat{sl_2})$ Hopf algebra,[3] and its spin half representation W, which is a space of functions taking values in $\mathbb{C}^2$, where the first component corresponds to ''solitons'' and the second to ''anti-solitons.'' Then $W\otimes W$ corresponds to a two soliton system, which can interact by collision. There is an initial two soliton quantum state in $W\otimes W$, and after the collision process we have a final quantum state in $W\otimes W$. The scattering matrix gives a map $W\otimes W\to W\otimes W$, which sends the initial to the final state. In terms of the Hopf algebra, this map is a braiding.[4]

This scattering matrix is fairly easy to find up to a multiplication by a scalar function, but the scalar function itself is more difficult. We denote this scalar function by $a(z)$ where $z\in\mathbb{C}$. The crossing condition in terms of this function becomes

$$a(z)=a\left(-\frac{q}{z}\right)\frac{(z-z^{-1})}{(zq^{-1}-z^{-1}q)}, \tag{1}$$

and the unitarity condition is $a(z)a(z^{-1})=1$.

The crossing condition arises from physics by equating a scattering process with the same scattering process after rotating the space–time diagram of the collision by a right-angle. This rotation involves a time reversal of one of the incoming and one of the outgoing solitons, which implies that these are turned into anti-solitons. The rotation of the diagram also implies that z, which corresponds roughly to the relative momentum of the colliding solitons (conserved in the collision), is transformed to $-z^{-1}q$. The interested reader can refer to the comprehensive book[2] for a complete discussion. The article[1] is also an excellent review.

Zamolodchikov–Zamolodchikov[1] solved these equations (1) to get a formula for $a(z)$ in terms of a double infinite product of gamma functions. It was thought that this product probably

[a]Electronic mail: e.j.beggs@swansea.ac.uk

converged for all physical values of z, and all values of q where $|q|=1$. However no proof of this was provided. The convergence of this function has also not been treated in subsequent papers in the literature.

Here, in this paper, we find an alternative formula which is more amenable to a convergence analysis. We find that the convergence is highly delicate, and the function converges with probability one, for q on the unit circle, i.e., $q=e^{2\pi i\tau}$, including convergence for all irrational algebraic values of τ, and diverges for certain transcendental values of τ.

Another alternative formula for $a(z)$ was found in Johnson,[5] as an integral, or as a combination of ''regularized'' quantum dilogarithms. This was done to make contact with semiclassical results for the scattering which involve integrating classical time delays. However, the convergence of this formula, or of the individual quantum dilogarithms, was also difficult to analyze because the contour integrals which one has to do are difficult to perform, involving sums over an infinite double set of poles.

In this paper we shall consider the problem purely in terms of braidings of the representations of a Hopf algebra, rather than invoking the crossing and unitarity conditions of S-matrix theory. We begin with the loop group of analytic functions used in the classical inverse scattering procedure for sine-Gordon,[6] and deform this by inclusion of a parameter q.[7]

II. THE UNIVERSAL ENVELOPING ALGEBRA $\mathcal{H}$

We begin with the loop group of analytic functions from $\mathbb{C}^*$ to $SL_2(\mathbb{C})$ which obey the symmetry condition $U\phi(-z)U^{-1}=\phi(z)$, where

$$U=\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}.$$

The Lie algebra for this group has generators $X_{\pm 1}$, $X_{\pm 2}$, and H, given by

$$X_{+1}(z)=\begin{pmatrix}0 & 0\\ z & 0\end{pmatrix},\quad X_{-1}(z)=\begin{pmatrix}0 & 1/z\\ 0 & 0\end{pmatrix},\quad H(z)=\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix},$$

$$X_{+2}(z)=\begin{pmatrix}0 & z\\ 0 & 0\end{pmatrix},\quad X_{-2}(z)=\begin{pmatrix}0 & 0\\ 1/z & 0\end{pmatrix}. \tag{2}$$

These generators obey the usual coproduct rule for the universal enveloping algebra of a Lie algebra, namely $\Delta(X_{\pm 1})=X_{\pm 1}\otimes 1+1\otimes X_{\pm 1}$, etc. This rule can be deformed by the inclusion of a parameter $q\in\mathbb{C}$ to give

$$\Delta H=1\otimes H+H\otimes 1,\quad \Delta X_{\pm 1}=X_{\pm 1}\otimes q^{-H/2}+q^{H/2}\otimes X_{\pm 1},$$

$$\Delta X_{\pm 2}=X_{\pm 2}\otimes q^{H/2}+q^{-H/2}\otimes X_{\pm 2}. \tag{3}$$

The Lie algebra structure remains the same, with the exception of an alteration in the Serre relation.[3,4] If in addition we define a counit ϵ (which kills all the generators) and an antipode S [which has $S(H)=-H$ and $S(X_{\pm n})=-q^{\pm 1}X_{\pm n}$] we can make the universal enveloping algebra into a Hopf algebra, which we denote $\mathcal{H}$. This is the so-called ''principal gradation'' of $U_q(\widehat{sl_2})$, which is actually a subalgebra of $U_q(\widehat{sl_2})$. We use the convention that $r=\sqrt{q}$ in the terms $q^{\pm H/2}$.

III. RIGID BRAIDED TENSOR CATEGORIES

Here we shall give a highly abbreveiated, specialized, and incomplete account of rigid braided tensor categories, for a full account see Ref. 4.

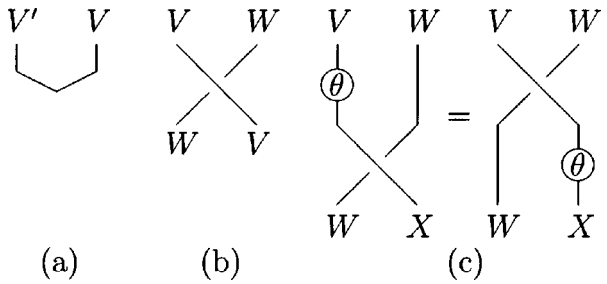

FIG. 1. Diagrams for braided categories.

The representations of a Hopf algebra $\mathcal{H}$ form a category, with objects the representations, and the morphisms $\rho: V \to W$ are intertwining maps for the representations V and W. This means that ρ is linear and that $\rho(h(v)) = h(\rho(v))$ for all $h \in \mathcal{H}$.

The tensor product of two representations is also a representation. The action on $V \otimes W$ is given by the coproduct $\Delta: \mathcal{H} \to \mathcal{H} \otimes \mathcal{H}$. If we write $\Delta h = \Sigma h_{(1)} \otimes h_{(2)}$, then $h(v \otimes w) = \Sigma h_{(1)}(v) \otimes h_{(2)}(w)$. The category contains an ''identity object,'' the representation $\mathbb{C}$ with all generators having zero action. This means that category of representations forms a tensor or monoidal category. (Technically we should also say that the associator is trivial.)

If the category is *rigid*, for an object V there is a dual object V', and an ''evaluation'' morphism $\mathrm{eval}: V' \otimes V \to \mathbb{C}$ given by $\mathrm{eval}(\alpha, v) = \alpha(v)$.

If the category is *braided*, for two objects V and W there is a morphism $\Psi_{VW}: V \otimes W \to W \otimes V$. The braiding is functorial, which means that if there is a morphism $\theta: V \to X$, then the maps $(I \otimes \theta)\Psi_{VW}: V \otimes W \to W \otimes X$ and $\Psi_{XW}(\theta \otimes I): V \otimes W \to W \otimes X$ are the same.

Figure 1 shows the standard diagramatic notation used for braided categories. Elements of representations are denoted by vertical lines. For Fig. 1(a), note that $\mathbb{C}$ is traditionally denoted by an invisible line. The braiding $\Psi_{VW}: V \otimes W \to W \otimes V$ is shown in Fig. 1(b), and the rule for the functoriality of the braiding in Fig. 1(c).

The finite dimensional representations of a quasitriangular Hopf algebra form a rigid braided tensor category. We shall assume that the representations of our Hopf algebra $\mathcal{H}$ also form a rigid braided tensor category, and this will allow us to explicitly calculate the braiding.

IV. THE ''STANDARD'' REPRESENTATION OF $\mathcal{H}$

Take W to be a vector space of analytic functions: $\mathbb{C}^* \to \mathbb{C}^2$ (or at least analytic in a neighborhood of zero and a neighborhood of infinity), which obeys the condition $Uw(-z) = w(z)$ for all $w \in W$. The algebra $\mathcal{H}$ acts on W using matrix multiplication, $(hw)(z) = h(z)w(z)$, for the five generators listed in (2).

We can consider a dual space W' to W, which shall consist of analytic functions: $\mathbb{C}^* \to \mathbb{C}^2$ which are defined for $|z|$ sufficiently small and sufficiently large. Now define an evaluation map $\mathrm{eval}: W' \otimes W \to \mathbb{C}$ by

$$\mathrm{eval}\left(\begin{pmatrix} f \\ g \end{pmatrix} \otimes \begin{pmatrix} u \\ v \end{pmatrix}\right) = \frac{1}{4\pi i} \oint_\gamma (f(z)\, u(z) + g(z)\, v(z)) \frac{dz}{z}, \tag{4}$$

where γ consists of two anticlockwise circular contours about 0, one of large radius, and one of small radius. To find the action of $\mathcal{H}$ on W' we use the fact that the action commutes with $\mathrm{eval}: W' \otimes W \to \mathbb{C}$, and that the action of the generators is zero on $\mathbb{C}$. This means that

$$0=H\left(\operatorname{eval}\left(\begin{pmatrix}f\\g\end{pmatrix}\otimes\begin{pmatrix}u\\v\end{pmatrix}\right)\right)$$
$$=\operatorname{eval}\left(H\left(\begin{pmatrix}f\\g\end{pmatrix}\otimes\begin{pmatrix}u\\v\end{pmatrix}\right)\right)$$
$$=\operatorname{eval}\left(H\begin{pmatrix}f\\g\end{pmatrix}\otimes\begin{pmatrix}u\\v\end{pmatrix}+\begin{pmatrix}f\\g\end{pmatrix}\otimes H\begin{pmatrix}u\\v\end{pmatrix}\right),$$

so we get

$$\operatorname{eval}\left(H\begin{pmatrix}f\\g\end{pmatrix}\otimes\begin{pmatrix}u\\v\end{pmatrix}\right)=-\operatorname{eval}\left(\begin{pmatrix}f\\g\end{pmatrix}\otimes\begin{pmatrix}u\\-v\end{pmatrix}\right)$$
$$=-\frac{1}{4\pi i}\oint\left(f(z)\,u(z)-g(z)\,v(z)\right)\frac{dz}{z},$$

so we deduce that

$$H\begin{pmatrix}f\\g\end{pmatrix}(z)=\begin{pmatrix}-1&0\\0&1\end{pmatrix}\begin{pmatrix}f(z)\\g(z)\end{pmatrix}.$$

Now we continue with the generator X_{+1}

$$0=\operatorname{eval}\left(X_{+1}\left(\begin{pmatrix}f\\g\end{pmatrix}\otimes\begin{pmatrix}u\\v\end{pmatrix}\right)\right)$$
$$=\operatorname{eval}\left(X_{+1}\begin{pmatrix}f\\g\end{pmatrix}\otimes\begin{pmatrix}u/r\\vr\end{pmatrix}+\begin{pmatrix}f/r\\gr\end{pmatrix}\otimes X_{+1}\begin{pmatrix}u\\v\end{pmatrix}\right),$$

from which we get

$$\operatorname{eval}\left(X_{+1}\begin{pmatrix}f\\g\end{pmatrix}\otimes\begin{pmatrix}u/r\\vr\end{pmatrix}\right)=-\operatorname{eval}\left(\begin{pmatrix}f/r\\gr\end{pmatrix}\otimes\begin{pmatrix}0\\zu\end{pmatrix}\right)=-\frac{r}{4\pi i}\oint z\,g(z)\,u(z)\frac{dz}{z}.$$

From this, and the corresponding calculations for the other generators, we see that the action on W' is given by the matrix multiplication

$$\left(h\begin{pmatrix}f\\g\end{pmatrix}\right)(z)=\tilde{h}(z)\begin{pmatrix}f(z)\\g(z)\end{pmatrix},\tag{5}$$

where the matrices $\tilde{h}(z)$ are given by

$$\tilde{X}_{+1}(z)=-q\begin{pmatrix}0&z\\0&0\end{pmatrix},\quad \tilde{X}_{-1}(z)=-q^{-1}\begin{pmatrix}0&0\\1/z&0\end{pmatrix},\quad \tilde{H}(z)=-\begin{pmatrix}1&0\\0&-1\end{pmatrix},$$

$$\tilde{X}_{+2}(z)=-q\begin{pmatrix}0&0\\z&0\end{pmatrix},\quad \tilde{X}_{-2}(z)=-q^{-1}\begin{pmatrix}0&1/z\\0&0\end{pmatrix}.\tag{6}$$

There is a morphism $\theta: W\to W'$ given by

$$\theta(k)(z)=\begin{pmatrix}0&1\\1&0\end{pmatrix}k(-zq).\tag{7}$$

To verify this we check that it commutes with the actions of the generators, for example;

$$\left(X_{+1}\theta\left(\begin{pmatrix}u\\v\end{pmatrix}\right)\right)(z)=-\begin{pmatrix}0&qz\\0&0\end{pmatrix}\theta\left(\begin{pmatrix}u\\v\end{pmatrix}\right)(z)=-\begin{pmatrix}0&qz\\0&0\end{pmatrix}\begin{pmatrix}v(-zq)\\u(-zq)\end{pmatrix},$$

$$\theta\left(X_{+1}\begin{pmatrix}u\\v\end{pmatrix}\right)(z)=\begin{pmatrix}0&1\\1&0\end{pmatrix}\left(X_{+1}\begin{pmatrix}u\\v\end{pmatrix}\right)(-zq)=\begin{pmatrix}0&1\\1&0\end{pmatrix}\begin{pmatrix}0&0\\-qz&0\end{pmatrix}\begin{pmatrix}u(-zq)\\v(-zq)\end{pmatrix},$$

which are equal as required.

V. THE BRAIDINGS

We use the convention for tensor products that $\mathbb{C}^2\otimes\mathbb{C}^2\cong\mathbb{C}^4$ and $M_2\otimes M_2\cong M_4$, where

$$\begin{pmatrix}u\\v\end{pmatrix}\otimes\begin{pmatrix}u'\\v'\end{pmatrix}\cong\begin{pmatrix}uu'\\uv'\\vu'\\vv'\end{pmatrix},\quad\begin{pmatrix}a&b\\c&d\end{pmatrix}\otimes\begin{pmatrix}a'&b'\\c'&d'\end{pmatrix}\cong\begin{pmatrix}aa'&ab'&ba'&bb'\\ac'&ad'&bc'&bd'\\ca'&cb'&da'&db'\\cc'&cd'&dc'&dd'\end{pmatrix}. \tag{8}$$

Then we can consider $W\otimes W$ or $W'\otimes W$ as a space of analytic maps from a subset of $\mathbb{C}^*\times\mathbb{C}^*$ to $\mathbb{C}^4$. Now if $k\in W'\otimes W$ we have

$$\mathrm{eval}(k)=\frac{1}{4\pi i}\oint(1\ \ 0\ \ 0\ \ 1)\,k(x,x)\,\frac{dx}{x}.$$

By the coproduct rule H and (for example) X_{+1} act on $W\otimes W$ by matrix multiplication

$$(Hk)(x,y)=(H(x)\otimes I_2+I_2\otimes H(y))k(x,y),$$

$$(X_{+1}k)(x,y)=(X_{+1}(x)\otimes q^{-H(y)/2}+q^{H(x)/2}\otimes X_{+1}(y))\,k(x,y),$$

and they act on $W'\otimes W$ by

$$(Hk)(x,y)=(\tilde{H}(x)\otimes I_2+I_2\otimes H(y))k(x,y),$$

$$(X_{+1}k)(x,y)=(\tilde{X}_{+1}(x)\otimes q^{-H(y)/2}+q^{\tilde{H}(x)/2}\otimes X_{+1}(y))\,k(x,y).$$

The braiding $\Psi_{WW}:W\otimes W\to W\otimes W$ will be assumed to have the form $(\Psi_{WW}k)(x,y)=M(x,y)k(y,x)$, where $M(x,y)$ is a 4×4 matrix. Since the braiding is a morphism we must have $\Psi_{WW}(hk)=h(\Psi_{WW}k)$ for the five generators h and all $k\in W\otimes W$. The cases for $h=H$ and X_{+1} are given below:

$$M(x,y)(H(y)\otimes I_2+I_2\otimes H(x))=(H(x)\otimes I_2+I_2\otimes H(y))\,M(x,y),$$

$$M(x,y)\,(X_{+1}(y)\otimes q^{-H(x)/2}+q^{H(y)/2}\otimes X_{+1}(x))=(X_{+1}(x)\otimes q^{-H(y)/2}+q^{H(x)/2}\otimes X_{+1}(y))\,M(x,y).$$

A simple calculation will show that these five conditions determine the matrix $M(x,y)$ up to a complex multiple, and we find

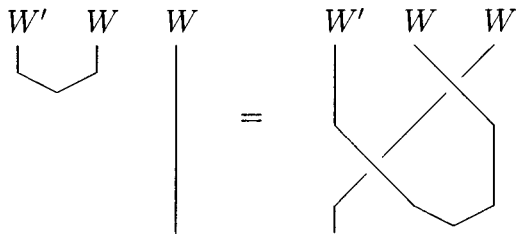

FIG. 2. Moving the evaluation map.

$$(\Psi_{WW}k)(x,y)=a(x,y)\begin{pmatrix}1 & 0 & 0 & 0\\ 0 & \dfrac{xy(q^2-1)}{q^2x^2-y^2} & \dfrac{q(x^2-y^2)}{q^2x^2-y^2} & 0\\ 0 & \dfrac{q(x^2-y^2)}{q^2x^2-y^2} & \dfrac{xy(q^2-1)}{q^2x^2-y^2} & 0\\ 0 & 0 & 0 & 1\end{pmatrix}k(y,x),$$

where $a(x,y)$ is complex valued. Note that $(\Psi_{WW}^2k)(x,y)=a(x,y)a(y,x)k(x,y)$. In the same manner we can determine the braiding $\Psi_{W'W}:W'\otimes W\to W\otimes W'$ to be $(\Psi_{W'W}k)(x,y)=N(x,y)k(y,x)$, where the matrix $N(x,y)$ is given by

$$(\Psi_{W'W}k)(x,y)=\frac{c(x,y)}{q^2y^2-x^2}\begin{pmatrix}q^2y^2-x^2 & 0 & 0 & (q^2-1)xy\\ 0 & 0 & q(y^2-x^2) & 0\\ 0 & q(y^2-x^2) & 0 & 0\\ (q^2-1)xy & 0 & 0 & q^2y^2-x^2\end{pmatrix}k(y,x),$$

where $c(x,y)$ is another complex valued function.

Now we use the fact that as the braiding is functorial, it must commute with the evaluation morphism. We see that the maps $(I\otimes\mathrm{eval})(\Psi_{W'W}\otimes I)(I\otimes\Psi_{WW})$ and $\mathrm{eval}\otimes I:W'\otimes W\otimes W\to W$ are the same. In terms of the standard pictures, this is Fig. 2.

Now, identifying $W'\otimes W\otimes W$ with maps from subsets of $(\mathbb{C}^*)^3$ to $\mathbb{C}^2\otimes\mathbb{C}^2\otimes\mathbb{C}^2$, we get

$$\begin{aligned}((\Psi_{W'W}\otimes I)(I\otimes\Psi_{WW})k)(x,y,z)&=(N(x,y)\otimes I_2)((I\otimes\Psi_{WW})k)(y,x,z)\\&=(N(x,y)\otimes I_2)\,(I_2\otimes M(x,z))\,k(y,z,x),\end{aligned}\tag{9}$$

and applying $I\otimes\mathrm{eval}$ to this gives

$$\frac{1}{4\pi i}\oint(I_2\otimes(1\,0\,0\,1))\,(N(x,z)\otimes I_2)\,(I_2\otimes M(x,z))\,k(z,z,x)\,\frac{dz}{z},$$

and some matrix multiplication shows that this is

$$\frac{1}{4\pi i}\oint a(x,z)\,c(x,z)\,((1\,0\,0\,1)\otimes I_2)\,k(z,z,x)\,\frac{dz}{z}.$$

Just applying $\mathrm{eval}\otimes I$ to k gives

$$\frac{1}{4\pi i}\oint((1\,0\,0\,1)\otimes I_2)\,k(z,z,x)\,\frac{dz}{z},$$

and since these must be the same for all choices of k we deduce that $c(x,z)=1/a(x,z)$.

Now use the fact that the braiding commutes with the morphism $\theta: W \to W'$ in (7), so $(I \otimes \theta)\Psi_{WW}$ and $\Psi_{W'W}(\theta \otimes I): W \otimes W \to W \otimes W'$ are the same. Then

$$((I \otimes \theta)\Psi_{WW}k)(x,y) = \left(I_2 \otimes \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}\right)(\Psi_{WW}k)(x,-qy)$$

$$= \left(I_2 \otimes \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}\right) M(x,-qy)\, k(-qy,x),$$

$$(\Psi_{W'W}(\theta \otimes I)k)(x,y) = N(x,y)\,((\theta \otimes I)k)(y,x),$$

$$= N(x,y) \left(\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \otimes I_2\right) k(-qy,x). \tag{10}$$

From some more matrix multiplication, this is true if

$$\frac{1}{a(x,y)} = a(x,-qy)\,\frac{x^2 - q^2y^2}{q(x^2-y^2)}. \tag{11}$$

VI. THE NORMALIZATION OF THE BRAIDING, $|q|=1$

In this section we find the normalization $a(x,y)$. For the moment we shall suppose that the value of x is fixed. Suppose that a solution $a(x,y)$ of (11) is an analytic function of y (except for isolated singularities) in some annulus centered on zero contained in the region $|y|>|x|$. We can narrow the annulus down until it no longer contains any isolated singularities or zeros. For convenience we set $z=x/y$ (so $|z|<1$), and $f(z)=a(x,x/z)$. Then $f(z)$ satisfies the equation

$$f(z)f(-z/q) = q\,\frac{z^2-1}{z^2-q^2}. \tag{12}$$

Now $f(z)$ will have a winding number $\omega \in \mathbb{Z}$ around zero as z winds once around zero. The function $c(z)=z^{-\omega}f(z)$ will have zero winding number, so its log, $b(z)=\log(c(z))$, will be analytic (and single valued) in the annulus. Now $c(z)$ obeys the equation $c(z)c(-z/q)=q(-z^2/q)^{-\omega}(z^2-1)/(z^2-q^2)$, so we must have

$$b(z)+b(-z/q) = \log(1-z^2) - \log(1-z^2/q^2) - \log(q) - \omega \log(-z^2/q),$$

as $-z/q$ is in the annulus if z is, because $|q|=1$. Since all the other functions are single valued in the annulus, we must have $\omega=0$. Now we can take the Laurent expansion of both sides in the annulus, and compare coefficients, to get the *unique* solution (up to the addition of a multiple of πi)

$$b(z) = -\tfrac{1}{2}\log(q) + \sum_{n>0} \frac{1}{n}\,\frac{1-q^{2n}}{1+q^{2n}} z^{2n}, \quad |z|<1, \quad z \in \text{annulus}. \tag{13}$$

By the uniqueness of analytic continuation, the exponential of this formula must coincide with $f(z)$ in a disk from zero up to the radius of convergence of the series. We also conclude that $f(z)$ did in fact not have any zeros or isolated singularities in this disk.

In the same manner, if $f(z)$ were analytic (except for isolated singularities) in some annulus centered on zero outside the unit disk, we could conclude that on that annulus (again up to the addition of a multiple of πi)

$$b(z) = \tfrac{1}{2}\log(q) - \sum_{n>0} \frac{1}{n}\,\frac{1-q^{2n}}{1+q^{2n}} z^{-2n}, \quad |z|>1. \tag{14}$$

We can now see explicitly from the series (on the assumption that the series converge anywhere) that $b(z)=-b(1/z)$ plus a multiple of πi, i.e., that $1/f(z)=\pm f(1/z)$.

Now we can look at different values of x. As a consequence of the analyticity condition we assumed for $a(x,y)$, it can be seen that $a(x,y)$ in fact only depends on $z=x/y$. We shall abuse our previous notation by referring to $a(z)$.

VII. THE CONVERGENCE OF THE SERIES BY NUMBER THEORY, $|q|=1$

The radius of convergence R of the series (13) is given by

$$R^{-1}=\limsup_{n\to+\infty}\left|\frac{1}{n}\cdot\frac{1-q^{2n}}{1+q^{2n}}\right|^{1/(2n)}=\limsup_{n\to+\infty}\left|\frac{1-q^{2n}}{1+q^{2n}}\right|^{1/(2n)}. \tag{15}$$

We see that the series is not even defined if q is an even root of -1. For any other root of unity the series has radius of convergence 1, except for $q=\pm 1$, when the series terminates. Now consider the case $q=e^{2\pi i\tau}$, where τ is irrational.

Call $n\in\mathbb{N}$ type 1 if $|1-q^{2n}|<1$, which implies that $|1+q^{2n}|\geqslant 1$. Then

$$\limsup_{n\to+\infty,\ \text{type 1}}\left|\frac{1-q^{2n}}{1+q^{2n}}\right|^{1/(2n)}\leqslant\limsup_{n\to+\infty,\ \text{type 1}}1=1.$$

Call $n\in\mathbb{N}$ type 2 if $|1-q^{2n}|\geqslant 1$, in which case

$$\limsup_{n\to+\infty,\ \text{type 2}}\left|\frac{1-q^{2n}}{1+q^{2n}}\right|^{1/(2n)}\geqslant\limsup_{n\to+\infty,\ \text{type 2}}\left|\frac{1}{1+q^{2n}}\right|^{1/(2n)}\geqslant 1,$$

and we deduce that

$$R^{-1}=\limsup_{n\to+\infty,\ \text{type 2}}\left|\frac{1-q^{2n}}{1+q^{2n}}\right|^{1/(2n)}.$$

Then we find

$$\limsup_{n\to+\infty,\ \text{type 2}}\left|\frac{1}{1+q^{2n}}\right|^{1/(2n)}\leqslant R^{-1}\leqslant\limsup_{n\to+\infty,\ \text{type 2}}\left|\frac{2}{1+q^{2n}}\right|^{1/(2n)},$$

which implies

$$R^{-1}=\limsup_{n\to+\infty,\ \text{type 2}}\left|\frac{1}{1+q^{2n}}\right|^{1/(2n)}=\limsup_{n\to+\infty}\left|\frac{1}{1+q^{2n}}\right|^{1/(2n)}. \tag{16}$$

If we let $d(\tau,n)$ be the minimum distance from $4\pi in\tau$ to an odd multiple of πi, then $d(\tau,n)\geqslant|1+q^{2n}|\geqslant(2/\pi)\,d(\tau,n)$, so

$$R=\liminf_{n\to+\infty}\left(\min_{p\ \text{odd}}|4\pi in\tau-p\pi i|\right)^{1/(2n)}=\liminf_{n\to+\infty}\left(\min_{p\ \text{odd}}\left|\tau-\frac{p}{4n}\right|\right)^{1/(2n)}\leqslant 1. \tag{17}$$

We see that the radius of convergence of the power series is dependent on how well τ can be approximated by rational numbers. Fortunately many results are known in this area,[8] and we shall use one of these now.

Suppose that the irrational number $\tau\in\mathbb{R}$ is *algebraic* of degree $k>1$ (this means that it is a root of a polynomial of degree k with integer coefficients). Then there is a constant $K>0$ so that for all n and all $p\in\mathbb{Z}$

$$\left|\tau-\frac{p}{4n}\right|\geqslant\frac{K}{(4n)^k}.$$

From the formula for R above (17)

$$R\geqslant\liminf_{n\to+\infty}\left(\frac{K}{2^k(2n)^k}\right)^{1/(2n)}=1,$$

so we conclude that for any irrational algebraic number τ, the radius of convergence is 1.

To get a radius of convergence less than 1, we shall have to create an irrational number with very good rational approximations. Let

$$\tau=\sum_{s\geqslant 1}\frac{1}{4m_s}, \tag{18}$$

where the strictly positive integers m_s have the property that $4m_s$ divides m_{s+1} for all $s\geqslant 1$. If we set $n=m_t$, then

$$\frac{n}{m_{t+1}}\leqslant|l-4n\tau|\leqslant\frac{2n}{m_{t+1}},$$

for $l=\Sigma_{t\geqslant s\geqslant 1}m_t/m_s$ an odd integer, so

$$\frac{1}{4m_{t+1}}\leqslant\min_{p\ \text{odd}}\left|\tau-\frac{p}{4n}\right|\leqslant\frac{1}{2m_{t+1}}.$$

Then by (17)

$$R\leqslant\liminf_{t\to+\infty}\left(\frac{1}{m_{t+1}}\right)^{1/(2m_t)}.$$

If we set $m_1=1$ and $m_{s+1}=2^{2sm_s}$ for all $s\geqslant 1$, then the radius of convergence of the series (13) for τ given by (18) is zero. Also τ is too closely approximated by nonequal rational numbers to be rational itself.

VIII. THE CONVERGENCE OF THE SERIES BY PROBABILITY, $|q|=1$

We consider the probability that the radius of convergence R of the series (13) is 1, given that q has a uniform distribution on the circle (equivalently, τ has a uniform distribution on [0,1]). From (17), for $0<s<1$

$$P[R>s]=P\left[\liminf_{n\to+\infty}\min_{p\ \text{odd}}\left|\tau-\frac{p}{4n}\right|^{1/(2n)}>s\right]=\lim_{m\to\infty}P\left[\inf_{n\geqslant m}\min_{p\ \text{odd}}\left|\tau-\frac{p}{4n}\right|^{1/(2n)}>s\right]. \tag{19}$$

For any random variable X_n and $s<t<1$,

$$(\forall n\geqslant m\ \ X_n>t)\Rightarrow\inf_{n\geqslant m}X_n>s,$$

or alternatively

$$P[X_n>t\ \ \forall n\geqslant m]\leqslant P[\inf_{n\geqslant m}X_n>s].$$

Then from (19),

$$P[R>s]\geqslant \lim_{m\to\infty} P\left[\min_{p\ \text{odd}}\left|\tau-\frac{p}{4n}\right|^{1/(2n)}>t \quad \forall n\geqslant m\right].$$

If we define

$$A_n(x)=\left\{\tau\in[0,1]:\min_{p\ \text{odd}}\left|\tau-\frac{p}{4n}\right|\leqslant x\right\},$$

then (with superscript c denoting complement)

$$P[R>s]\geqslant \lim_{m\to\infty} P[\cap_{n\geqslant m}A_n(t^{2n})^c].$$

Then by taking complements

$$P[R\leqslant s]\leqslant \lim_{m\to\infty} P[\cup_{n\geqslant m}A_n(t^{2n})]\leqslant \lim_{m\to\infty}\sum_{n\geqslant m} P[A_n(t^{2n})],$$

so if the series

$$\sum_{n\geqslant 1} P[A_n(t^{2n})], \tag{20}$$

converges, then $R>s$ with probability one. If we write

$$A_n(x)=\{\tau\in[0,1]:\min_{p\ \text{odd}}|4n\tau-p|\leqslant 4nx\},$$

then, if $4nx\leqslant 1$, in the interval $[0,4n]$ there are $2n$ odd integers p, and each has a disjoint interval of length $8nx$ about it satisfying the inequality above. From this we find $P[A_n(x)]=4nx$, so the sum (20) becomes (with the exception of a finite number of terms at the beginning),

$$\sum_{n\geqslant 1} 4n\,t^{2n},$$

which converges since $|t|<1$. We conclude that $P[R>s]=1$, and so $R=1$ with probability one. Since the algebraic numbers have measure zero, the series must have $R=1$ for many transcendental (nonalgebraic) τ.

IX. THE CASE $|q|\neq 1$

In this case we would get the same unique series *if* the annulus in which $a(z)$ was analytic and free of zeros or singularities was sufficiently wide. We would need to have both z and $-z/q$ in the same annulus, so the ratio of the outer and inner radii of the annulus would have to be greater than the larger of $|q|$ and $1/|q|$. If this condition was satisfied, we would have the solutions (13) or (14). However there may be other solutions to the normalization which would always have zeros or singularities in such wide annuli.

Let us examine the series (13) for $|q|\neq 1$. Here $\lim_{n\to+\infty}|(1-q^{2n})/(1+q^{2n})|=1$, so the series has radius of convergence 1. However, now we can make an analytic continuation of the series. In the case $|q|<1$ we write, for any integer $k\geqslant 1$

$$\frac{1-q^{2n}}{1+q^{2n}}=1+2\sum_{m=1}^{k}(-1)^m q^{2mn}-\frac{2(-1)^k q^{2(k+1)n}}{1+q^{2n}}, \tag{21}$$

and substituting this into (13) gives

$$b(z)=-\frac{1}{2}\log(q)-\log(1-z^2)-2\sum_{m=1}^{k}(-1)^m\log(1-z^2q^{2m})-\sum_{n\geqslant 1}\frac{2(-1)^k q^{2(k+1)n}z^{2n}}{n(1+q^{2n})}.$$

The last term in the formula tends to zero uniformly on any bounded set as $k\to\infty$, allowing us to take the limit as $k\to\infty$ of the other terms. We then get the infinite product expansion, valid everywhere in $\mathbb{C}^*$,

$$a_+(z)=\frac{1}{r}\cdot\frac{1}{(1-z^2)}\cdot\prod_{\text{odd } m\geqslant 1}\frac{(1-z^2q^{2m})^2}{(1-z^2q^{2(m+1)})^2},\quad |q|<1. \tag{22}$$

A similar rearrangement to (21) for $|q|>1$ would give

$$a_+(z)=\frac{(1-z^2)}{r}\cdot\prod_{\text{odd } m\geqslant 1}\frac{(1-z^2q^{-2(m+1)})^2}{(1-z^2q^{-2m})^2},\quad |q|>1. \tag{23}$$

These are the *unique* (up to a sign) solutions of (12) which are analytic for z in a neighborhood of zero in $\mathbb{C}^*$. In the same way we can analytically extend the series (14) to obtain $a_-(z)=\pm 1/a_+(1/z)$, the *unique* solutions of (11) which are analytic for z in a neighborhood of infinity in $\mathbb{C}^*$.

(Received 11 October 2000; accepted for publication 15 February 2001)

Recently, several studies of non-Hermitian Hamiltonians having $\mathcal{PT}$ symmetry have been conducted. Most striking about these complex Hamiltonians is how closely their properties resemble those of conventional Hermitian Hamiltonians. This paper presents further evidence of the similarity of these Hamiltonians to Hermitian Hamiltonians by examining the summation of the divergent weak-coupling perturbation series for the ground-state energy of the $\mathcal{PT}$-symmetric Hamiltonian $H=p^2+\frac{1}{4}x^2+i\lambda x^3$ recently studied by Bender and Dunne. For this purpose the first 193 (nonzero) coefficients of the Rayleigh–Schrödinger perturbation series in powers of λ^2 for the ground-state energy were calculated. Padé-summation and Padé-prediction techniques recently described by Weniger are applied to this perturbation series. The qualitative features of the results obtained in this way are indistinguishable from those obtained in the case of the perturbation series for the quartic anharmonic oscillator, which is known to be a Stieltjes series.

I. INTRODUCTION

Hamiltonians describing fundamental interactions traditionally possess two symmetries, the continuous symmetry of the proper Lorentz group and the discrete symmetry of Hermiticity. Lorentz invariance is a physical requirement. Hermiticity is a useful mathematical constraint that guarantees that the spectrum is real, although recent work shows that Hermiticity is only a sufficient condition and is not necessary for the reality of eigenvalues. From the assumptions of Lorentz invariance and positivity of the spectrum of the Hamiltonian one can prove the $\mathcal{PCT}$ theorem and thereby establish the physical symmetry of $\mathcal{PCT}$ invariance.

What happens if we impose only the more physical symmetries of Lorentz invariance and $\mathcal{PCT}$ invariance when we construct a Hamiltonian? The constraint of $\mathcal{PCT}$ invariance is weaker than Hermiticity, so Hamiltonians having this property need not be Hermitian. While it has not been proved, there is compelling analytical and numerical evidence supporting the conjecture that, except when $\mathcal{PCT}$ symmetry is spontaneously broken, the energy levels of such Hamiltonians are all real and positive.[1,2] The reality and positivity of the spectrum is apparently a consequence of the $\mathcal{PCT}$ symmetry of H.

Many examples of $\mathcal{PCT}$-symmetric Hamiltonians in quantum field theory have been studied.[3–8] In quantum mechanics, where the $\mathcal{C}$ operator is unity, many examples of $\mathcal{PT}$-symmetric Hamiltonians have also been studied.[9–19] A simple example of such a quantum-mechanical Hamiltonian is $H=p^2+ix^3$. Hamiltonians such as this may be regarded as *complex deformations* of conventional Hermitian Hamiltonians. To understand this deformation we consider the Hamiltonian

a)Electronic mail: cmb@howdy.wustl.edu
b)Electronic mail: joachim.weniger@chemie.uni-regensburg.de

$$H = p^2 - (ix)^{2+\epsilon},$$

where $\epsilon \geqslant 0$. When $\epsilon = 0$, we have the conventional harmonic oscillator Hamiltonian, whose spectrum is real and positive. As ϵ increases from 0, the entire spectrum of the Hamiltonian smoothly deforms as a function of ϵ and remains real and positive for all positive values of ϵ. Thus, these theories are in effect the analytic continuation of conventional quantum mechanics into the complex plane.

These non-Hermitian theories exhibit some remarkable properties. Most interesting is that the expectation value of the operator x in quantum mechanics (and of the field ϕ in quantum field theory) is *nonzero* when $\epsilon > 0$. This is true even for the $p^2 - x^4$ Hamiltonian that one obtains at $\epsilon = 2$ and it is also true for the $-g\phi^4$ scalar quantum field theory. The $-g\phi^4$ quantum field theory is particularly surprising because it has a positive real spectrum and exhibits a nonzero value of $\langle \phi \rangle$. In four-dimensional space–time it has a dimensionless coupling constant, is renormalizable, and is asymptotically free (and thus nontrivial). It may thus provide a useful setting to describe the Higgs particle.[7]

We are struck by the close similarity between the properties of non-Hermitian $\mathcal{PT}$-symmetric quantum-mechanical Hamiltonians and conventional Hermitian Hamiltonians. Moreover, in mathematical terms, we are struck by the strong resemblance between self-adjoint Sturm–Liouville problems and these new complex Sturm–Liouville problems. The purpose of this paper is to present further evidence of this strong similarity by investigating various aspects of Padé summation and Padé prediction of the Rayleigh–Schrödinger perturbation series for the ground-state energy of the complex $\mathcal{PT}$-symmetric Hamiltonian

$$H(\lambda) = p^2 + \tfrac{1}{4}x^2 + i\lambda x^3. \tag{1}$$

Note that this Hamiltonian is $\mathcal{PT}$ symmetric because under parity reflection $\mathcal{P}: p \to -p$ and $\mathcal{P}: x \to -x$ and under time reversal, which is an antiunitary operation, $\mathcal{T}: p \to -p$, $\mathcal{T}: x \to x$, and $\mathcal{T}: i \to -i$.

The Schrödinger equation for the Hamiltonian in (1) reads

$$-\psi''(x) + (\tfrac{1}{4}x^2 + i\lambda x^3)\psi(x) = E\psi(x),$$

where the wave function obeys the boundary conditions $\lim_{|x|\to\infty} \psi(x) = 0$. Note that this Schrödinger equation is obeyed on the *real axis* in the complex-x plane. The wave function vanishes exponentially as $\exp(-2\sqrt{\lambda}|x|^{5/2}/5)$ as $x \to \pm\infty$ on the real axis.

The large-order behavior of the divergent Rayleigh–Schrödinger perturbation series,

$$E_0(\lambda) \sim \frac{1}{2} + \sum_{n=1}^{\infty} b_n \lambda^{2n} \quad (\lambda \to 0^+), \tag{2}$$

for the ground-state energy eigenvalue of the Hamiltonian in (1) has already been examined in Ref. 20, where the first 46 terms of the perturbation expansion had been generated using recursion formulas. It was observed there that the coefficients b_n are all integers, that they alternate in sign, and that their magnitude grows rapidly with n. The first 10 coefficients are listed in Table I.

To calculate the coefficients b_n we make the *ansatz* that the wave function is a formal series in powers of the coupling constant λ and that the coefficient of λ^n has the form of a Gaussian $\exp(-x^2/4)$ times a polynomial of degree $3n$ in the variable x. The eigenvalue $E_0(\lambda)$ automatically appears as a series in powers of λ^2. Thus, for each additional coefficient in the series for E_0 it is necessary to calculate *two* orders in powers of λ for the wave function.

In Ref. 20 it was pointed out that the Hamiltonian (1) describes a $0+1$ dimensional ϕ^3 field theory and that ϕ^3 theories were the first quantum field theories in which the divergences of

perturbation theory were studied.[21] Using the standard methods for determining the large-order behavior of perturbation theory[22,23] it can be shown that the leading large-n behavior of the coefficients b_n is given by

$$b_n=(-1)^{n+1}60^{n+1/2}(2\pi)^{-3/2}\Gamma(n+1/2)[1+O(1/n)] \quad (n\to\infty). \tag{3}$$

This asymptotic behavior was verified numerically in Ref. 20. There, it was also shown that the first correction term to this leading asymptotic behavior, which is proportional to $1/n$, is negative. Although divergent, the series in (2) is Borel summable.[24–27] If the factor of i were absent from the Hamiltonian (1), then the perturbation coefficients b_n would not alternate in sign and the perturbation series would not be Borel summable.

It is interesting that to derive the asymptotic formula in (3) one must use dispersion-relation techniques that rely on crucial assumptions about the analyticity of the function $E_0(\lambda)$. These assumptions are justified for the Hermitian Hamiltonian of the anharmonic oscillator,[28,29]

$$\mathcal{H}(\beta)=p^2+x^2+\beta x^4. \tag{4}$$

However, the validity of these assumptions is unproved for the non-$\mathcal{PT}$-symmetric λx^3 oscillator.

The eigenvalues $\mathcal{E}(\beta)$ of the quartic anharmonic oscillator possess several other properties which closely resemble those of the eigenvalues $E(\lambda)$ of the $\mathcal{PT}$-symmetric Hamiltonian (1). For example, the ground-state energy eigenvalue $\mathcal{E}_0(\beta)$ of the quartic anharmonic oscillator possesses a divergent weak-coupling perturbation expansion, which also diverges factorially:[22,30]

$$\mathcal{E}_0(\beta)\sim 1+\sum_{n=1}^{\infty}\mathcal{B}_n\beta^n \quad (\beta\to 0^+), \tag{5}$$

$$\mathcal{B}_n=(-1)^{n+1}\frac{4}{\pi^{3/2}}\left(\frac{3}{2}\right)^{n+1/2}\Gamma(n+1/2)[1+O(1/n)] \quad (n\to\infty). \tag{6}$$

A comparison of the large-order asymptotics (3) and (6) shows that the two perturbation expansions (2) and (5) possess the same rate of divergence if we choose

$$\beta=40\lambda^2. \tag{7}$$

In view of these striking similarities between the ground-state eigenvalues $E_0(\lambda)$ and $\mathcal{E}_0(\beta)$ it should be interesting to investigate what other similarities do exist. In particular, we are interested in similarities that could provide evidence that the Padé summation of the divergent perturbation series (2) for the ground-state energy of the $\mathcal{PT}$-symmetric Hamiltonian (1) converges.

In the case of the ground-state energy shift $\Delta\mathcal{E}_0(\beta)$ of the quartic anharmonic oscillator, which is defined by

$$\mathcal{E}_0(\beta) = 1 + \beta\Delta\mathcal{E}_0(\beta), \tag{8}$$

it was shown rigorously by Simon (Theorem IV.2.1 of Ref. 28) that the corresponding perturbation series is a Stieltjes series. This has some far-reaching consequences. In the case of the Stieltjes series, Padé approximants possess a highly developed convergence theory, as we discuss in detail in Sec. II. In particular, the Stieltjes nature of the perturbation series (5) guarantees that certain subsequences of the Padé table converge to a uniquely determined Stieltjes function.

Although we cannot prove it rigorously, we believe that for the $\mathcal{PT}$-symmetric Hamiltonian (1) the ground-state energy shift $\Delta E_0(\lambda^2)$ defined by

$$E_0(\lambda) = \tfrac{1}{2} + \lambda^2\Delta E_0(\lambda^2), \tag{9}$$

in which E_0 is considered as a function of λ^2, is also a Stieltjes function. This implies that the corresponding perturbation series is a Stieltjes series.

It is the intention of this paper to provide numerical evidence supporting this conjecture. We do this by comparing Padé summations and Padé predictions (see Ref. 31, and references therein) of the perturbation expansions for the ground-state energy shift $\Delta E_0(\lambda^2)$ and for the analogous ground-state energy shift $\Delta\mathcal{E}_0(\beta)$ of the quartic anharmonic oscillator.

Here, one might argue that one should also investigate the summation of the perturbation expansion for the ground-state energy shift $\Delta E_0(\lambda^2)$ with the help of the sequence transformations that were described in Secs. 7 and 8 of Ref. 32 and which produced very good results in the case of the anharmonic oscillators.[30,33,34] However, the convergence theory of these sequence transformations, which in the case of power series also produce rational approximants, is still very much in its infancy and no theoretical results concerning the transformation of the Stieltjes series are known so far. Consequently, we would only produce numbers without gaining any further mathematical insight.

In Sec. II, we present the relevant details of Padé approximants, the computation of Padé approximants by means of Wynn's recursive epsilon algorithm,[35] and we discuss the Stieltjes series and their associated Stieltjes functions. In Sec. III, we show that the Padé summation of the perturbation expansions for $\Delta E_0(\lambda^2)$ and $\Delta\mathcal{E}_0(\beta)$, respectively, produces results of identical quality if the two coupling constants λ and β satisfy (7). In Sec. IV, we discuss the prediction of unknown perturbation coefficients with the help of Wynn's epsilon algorithm, and we show that the coefficients of the perturbation expansions for either $\Delta E_0(\lambda^2)$ or $\Delta\mathcal{E}_0(\beta)$ can be predicted equally well. Finally, in Sec. V we give a brief summary.

Here, we would like to emphasize that we are fully aware that our approach, which uses only a *finite* number of perturbation series coefficients, has obvious limitations. While it is in this way possible to disprove the Stieltjes nature of a given series, it is not possible to prove rigorously its Stieltjes nature. Nevertheless, we believe that our numerical results are interesting and provide some insight into the nature of the $\mathcal{PT}$-symmetric Hamiltonian (1) and of its associated divergent Rayleigh–Schrödinger perturbation series (2).

II. PADÉ APPROXIMANTS, WYNN'S EPSILON ALGORITHM, AND STIELTJES SERIES

In recent years, Padé approximants have become the standard tool in theoretical physics to overcome problems with slowly convergent or divergent power series. Accordingly, there is a vast literature on the mathematical properties of Padé approximants as well as on their applications in theoretical physics. Any attempt to provide a reasonably complete bibliography would be beyond the scope of this paper (see, e.g., the extensive bibliography compiled by Brezinski[36]). We just mention that the popularity of Padé approximants in theoretical physics can be traced back to a review by Baker,[37] that the first specialized monograph on Padé approximants is due to Baker,[38] and that currently the most complete source of information is the second edition of the monograph

by Baker and Graves-Morris.[39] In addition to treatments in more mathematically oriented books on continued fractions and related topics,[40–43] Padé approximants are also discussed in books on mathematical and theoretical physics, e.g., in Sec. 8 of the book by Bender and Orszag,[26] or in Part III of a book by Baker on critical phenomena.[44] Then, there is a book by Pozzi[45] on the use of Padé approximants in fluid dynamics. Finally, there is even a monograph[46] and two articles[47,48] on the history of Padé approximants and related topics.

A Padé approximant $P_m^l(z)$ to a function f possessing a (formal) power series expansion

$$f(z)=\sum_{\nu=0}^{\infty}\gamma_\nu z^\nu, \tag{10}$$

which may converge or diverge, is the ratio of two polynomials $A_l(z)$ and $B_m(z)$ of degrees l and m in z (p. 383 of Ref. 26):

$$P_m^l(z)=\frac{A_l(z)}{B_m(z)}=\frac{a_0+a_1z+a_2z^2+\cdots a_lz^l}{1+b_1z+b_2z^2+\cdots b_mz^m}. \tag{11}$$

An alternative notation for Padé approximants, which is used in the books by Baker and Graves-Morris,[38,39] is $P_m^l(z)=[l/m]_f(z)$. This notation is usually simplified further to $P_m^l(z)=[l/m]$ if explicit references to f and z are not necessary.

The coefficients a_λ and b_μ of the polynomials $A_l(z)$ and $B_m(z)$ in (11) are chosen in such a way that the Taylor expansion of $f(z)$ and of its Padé approximant agree as far as possible:

$$f(z)-P_m^l(z)=O(z^{l+m+1})\quad(z\to 0). \tag{12}$$

This asymptotic error estimate leads to a system of linear equations by means of which the coefficients $a_0,\ a_1,\ldots,\ a_l$ and $b_1,\ b_2,\ldots,\ b_m$ in (11) can be computed.[38,39] Moreover, several algorithms are known which permit a recursive computation of Padé approximants. A discussion of the merits and weaknesses of the various computational schemes can for instance be found in Sec. II.3 of the book by Cuyt and Wuytack.[49]

Probably, the best known recursive algorithm for Padé approximants is Wynn's epsilon algorithm:[35]

$$\varepsilon_{-1}^{(n)}=0,\quad \varepsilon_0^{(n)}=s_n\quad(n\in\mathbb{N}_0), \tag{13a}$$

$$\varepsilon_{k+1}^{(n)}=\varepsilon_{k-1}^{(n+1)}+1/[\varepsilon_k^{(n+1)}-\varepsilon_k^{(n)}]\quad(k,n\in\mathbb{N}_0). \tag{13b}$$

A compact FORTRAN program for the epsilon algorithm as well as the underlying computational algorithm is described in Sec. 4.3 of Ref. 32.

If the input data $\varepsilon_0^{(n)}=s_n$ of Wynn's epsilon algorithm are the partial sums

$$f_n(z)=\sum_{\nu=0}^{n}\gamma_\nu z^\nu \tag{14}$$

of the formal power series (10) according to $\varepsilon_0^{(n)}=f_n(z)$, then the elements $\varepsilon_{2k}^{(n)}$ with *even* subscripts are Padé approximants to $f(z)$ according to[35]

$$\varepsilon_{2k}^{(n)}=P_k^{k+n}(z). \tag{15}$$

The elements $\varepsilon_{2k+1}^{(n)}$ with *odd* subscripts are only auxiliary quantities, which diverge if the whole transformation process converges.

The epsilon algorithm is a useful numerical algorithm that is applied successfully in a large variety of different fields. Accordingly, there is an extensive literature dealing with it. A fairly complete coverage of the older literature can be found in a book by Brezinski.[50] It may be

interesting to note that the epsilon algorithm is not restricted to scalar sequences but can be generalized to cover vector sequences. A recent review of these developments can be found in Ref. 51.

If one tries to sum a divergent power series by converting its partial sums (14) to Padé approximants, it is usually a good idea to use *diagonal* Padé approximants, whose numerator and denominator polynomials have equal degrees. If this is not possible one should use Padé approximants with numerator and denominator polynomials whose degrees differ as little as possible. If we use the epsilon algorithm for the computation of the Padé approximants, then (15) implies that we should use the elements of the following staircase sequence in the Padé table as approximations to $f(z)$ [see Eq. (4.3-7) of Ref. 32]:

$$P_0^0(z),P_0^1(z),P_1^1(z),\ldots,P_\nu^\nu(z),P_\nu^{\nu+1}(z),P_{\nu+1}^{\nu+1}(z),\ldots. \tag{16}$$

This staircase sequence exploits the available information optimally if the partial sums $f_n(z)$ with $n\geqslant 0$ are computed successively and if, after the computation of each new partial sum, the element of the epsilon table with the highest possible *even* subscript is computed. With the help of the notation $[\![x]\!]$ for the integral part of x, this staircase sequence can be written compactly as follows:

$$\varepsilon_{2[\![n/2]\!]}^{(n-2[\![n/2]\!])}=P_{[\![n/2]\!]}^{n-[\![n/2]\!]}(z) \quad (n=0,1,2,\ldots). \tag{17}$$

As remarked previously, Padé approximants are now used almost routinely to overcome problems with slowly convergent or divergent power series. Hence, their practical usefulness is beyond question. However, from a theoretical point of view, the situation is not so good. So far, a completely satisfactory *general* convergence theory of Padé approximants for essentially arbitrary power series does not exist.

Nevertheless, there is a special class of series, the so-called *Stieltjes* series, which possess a highly developed and elegant convergence theory. In this section we will only discuss those properties of Stieltjes series and Stieltjes functions that are needed to provide numerical evidence that the perturbation expansion for the ground-state energy shift $\Delta E_0(\lambda^2)$ of the complex $\mathcal{PT}$-symmetric Hamiltonian (1), considered as a function of λ^2, is a Stieltjes series. Detailed discussions of the properties of Stieltjes series and their special role in the theory of Padé approximants can be found in Sec. 8.6 of Ref. 26 or in Sec. 5 of Ref. 39.

A function $F(z)$ with $z\in\mathbb{C}$ is called a *Stieltjes* function if it can be expressed as a Stieltjes integral according to

$$F(z)=\int_0^\infty \frac{d\Phi(t)}{1+zt} \quad (|\arg(z)|<\pi). \tag{18}$$

Here, $\Phi(t)$ is a bounded, nondecreasing function taking infinitely many different values on $0\leqslant t<\infty$. Moreover, the moment integrals

$$\mu_n=\int_0^\infty t^n\, d\Phi(t) \quad (n\in\mathbb{N}_0) \tag{19}$$

must be real and finite for all finite values of n. A Stieltjes function can be expressed by its corresponding *Stieltjes* series:

$$F(z)=\sum_{\nu=0}^{\infty} (-1)^\nu \mu_\nu z^\nu. \tag{20}$$

Whether this series converges or diverges depends on the behavior of the Stieltjes moments μ_n as $n\to\infty$.

In a typical Stieltjes summation problem, as it occurs in the context of divergent perturbation expansion, only the numerical values of a finite number of Stieltjes moments μ_n are known. Thus, one has to find a way of constructing an approximation to the unknown Stieltjes function $F(z)$ from a finite string of moments.

Of course, one would also like to have some theoretical evidence that $F(z)$ exists and is uniquely determined by the Stieltjes moments $\{\mu_n\}_{n=0}^{\infty}$. Many necessary and sufficient conditions that guarantee this are known in literature.

Unfortunately, it is normally by no means easy to apply them. For example, a necessary condition that the series (20) is indeed a Stieltjes series is that the Hankel determinants

$$D(m,n)=\begin{vmatrix} \mu_m & \mu_{m+1} & \cdots & \mu_{m+n} \\ \mu_{m+1} & \mu_{m+2} & \cdots & \mu_{m+n+1} \\ \vdots & \vdots & \ddots & \vdots \\ \mu_{m+n} & \mu_{m+n+1} & \cdots & \mu_{m+2n} \end{vmatrix} \tag{21}$$

are positive for all $m,n\geqslant 0$ (see Theorem 5.1.2 on p. 197 of Ref. 39). A straightforward evaluation of such a Hankel determinant is in particular for larger values of n computationally very unattractive. However, these determinants can be evaluated recursively with the help of the Frobenius formula [see Eq. (4.10) on p. 23 of Ref. 39].

Then, there is a sufficient criterion, the so-called Carleman condition (see p. 410 of Ref. 26 or pp. 239 and 240 of Ref. 39), which requires that the series $\Sigma_{j=1}^{\infty}(\mu_j)^{-1/(2j)}$ diverges and thus limits the admissible growth of the moments μ_n as $n\to\infty$.[52] If the condition $D(m,n)>0$ on the determinants as well as the Carleman condition are both satisfied, then the Padé approximants $P_m^{m+j}(z)$ constructed from the partial sums of the moment expansion (20) converge for every $j\geqslant -1$ to the corresponding Stieltjes function $F(z)$ as $m\to\infty$ [see for example Theorem 5.5.1 on p. 240 of Ref. 39].

If only a finite number of moments are known, it is impossible to prove that $D(m,n)>0$ holds for all $m,n\geqslant 0$, and it is also not possible to prove rigorously that the Carleman condition is satisfied, although we would like to emphasize that the large-order formula (3), which was verified numerically in Ref. 20, is in agreement with the Carleman condition.

In this paper, we prefer to use an indirect approach in order to provide evidence that the perturbation series for the energy shift $\Delta E_0(\lambda^2)$ of the $\mathcal{PT}$-symmetric Hamiltonian (1) is indeed a Stieltjes series. For that purpose, let us assume that the moment expansion (20), whose Stieltjes nature we want to establish, is a Stieltjes series. Padé approximants to Stieltjes series possess a highly developed convergence theory, and many conditions and inequalities are known that Padé approximants to a Stieltjes series must satisfy. For example, Padé approximants constructed from the partial sums

$$F_n(z)=\sum_{\nu=0}^{n}(-1)^{\nu}\mu_{\nu}z^{\nu} \tag{22}$$

of the moment expansion (20) for a Stieltjes function $F(z)$ satisfy for $z>0$ the following inequalities (Theorem 15.2 on p. 215 of Ref. 38):

$$(-1)^{j+1}\{P_{m+1}^{m+j+1}(z)-P_m^{m+j}(z)\}\geqslant 0, \tag{23}$$

$$(-1)^{j+1}\{P_m^{m+j}(z)-P_{m-1}^{m+j+1}(z)\}\geqslant 0, \tag{24}$$

$$P_m^m(z)\geqslant F(z)\geqslant P_m^{m-1}(z). \tag{25}$$

It follows from inequality (23) that the Padé sequence $\{P_m^{m+j}(z)\}_{m=0}^{\infty}$ is *increasing* for $z>0$ if j is *odd*, and it is *decreasing* if j is *even*. Moreover, if we set $j=-1$ in (24) and replace m by $m+1$, we obtain the inequality

$$P_{m+1}^{m}(z)\geqslant P_m^{m+1}(z) \quad (m\in\mathbb{N}_0). \tag{26}$$

Thus, if we use Wynn's epsilon algorithm (13) to convert the partial sums (22) to Padé approximants and choose the approximants to $F(z)$ according to (17), then it follows from inequalities (25) and (26) that these Padé approximants satisfy the following inequality if the moment expansion (20) for $F(z)$ is a Stieltjes series:

$$P_m^{m+1}(z)\leqslant F(z)\leqslant P_{m+1}^{m+1}(z) \quad (z>0,\ m\in\mathbb{N}_0). \tag{27}$$

Thus, the approximants (17) produced by Wynn's epsilon algorithm yield for $z>0$ two nesting sequences $P_m^{m+1}(z)=\varepsilon_{2m}^{(1)}$ and $P_{m+1}^{m+1}(z)=\varepsilon_{2m+2}^{(0)}$ of lower and upper bounds to $F(z)$ if the moment expansion (20) is a Stieltjes series.

If only the numerical values of a finite number of Stieltjes moments are available, then it is of course not possible to prove rigorously that the series under consideration is a Stieltjes series. Nevertheless, we can provide considerable evidence that this hypothesis is true if inequality (27) is valid in all cases that can be checked.

III. SUMMATION RESULTS

In this section we want to show that the Padé summation of the perturbation expansion

$$\Delta E_0(\lambda^2)=\sum_{\nu=0}^{\infty} b_{\nu+1}\lambda^{2\nu} \tag{28}$$

for the ground-state energy shift of the $\mathcal{PT}$-symmetric Hamiltonian (1) and of the perturbation expansion

$$\Delta \mathcal{E}_0(\beta)=\sum_{\nu=0}^{\infty} \mathcal{B}_{\nu+1}\beta^{\nu} \tag{29}$$

for the ground-state energy shift of the quartic anharmonic oscillator yield results of virtually identical quality if the two coupling constants λ and β satisfy (7). Moreover, we want to demonstrate numerically that inequality (27), which is satisfied in the case of the Padé summation of a Stieltjes series, is apparently also satisfied. In our summation calculations, we used all coefficients b_ν and $\mathcal{B}_\nu$ with $0\leqslant\nu\leqslant 193$ which had been computed recursively.

In this paper, we compute all Padé approximants with the help of Wynn's epsilon algorithm (13). Thus, the partial sums

$$s_n(\lambda^2)=\sum_{\nu=0}^{n} b_{\nu+1}\lambda^{2\nu} \tag{30}$$

and

$$\sigma_n(\beta)=\sum_{\nu=0}^{n} \mathcal{B}_{\nu+1}\beta^{\nu} \tag{31}$$

are used as input data for Wynn's epsilon algorithm according to $\varepsilon_0^{(n)}=s_n(\lambda^2)$ or $\varepsilon_0^{(n)}=\sigma_n(\beta)$, respectively, and the approximations to the energy shifts are chosen according to (17).

In Table II we present illustrative results of the Padé summation of the perturbation expansion (28) for the ground-state energy shift $\Delta E_0(\lambda^2)$ with $\lambda=1/7$ and of the perturbation expansion (29)

TABLE II. Padé summation of the perturbation expansions (28) and (29) for the ground-state energy shifts $\Delta E_0(\lambda^2)$ and $\Delta\mathcal{E}_0(\beta)$ with $\lambda=1/7$ and $\beta=40/49$, respectively.

for the ground-state energy shift $\Delta\mathcal{E}_0(\beta)$ with $\beta=40/49$. Thus, the two coupling constants λ and β satisfy (7). This implies that the two perturbation expansions, whose partial sums are displayed in columns 2 and 3, should show the same rate of divergence.

Here, we must remember that the larger-order estimates (3) and (6), respectively, imply that the partial sums (30) for the ground-state energy shift $\Delta E_0(\lambda^2)$ of the $\mathcal{PT}$-symmetric Hamiltonian (1) are for all $n\geqslant 0$ at least one order of magnitude greater than the partial sums (31) for the ground-state energy shift $\Delta\mathcal{E}_0(\beta)$ of the quartic anharmonic oscillator. Otherwise, the observed rates of divergence in columns 2 and 3 are virtually identical.

Moreover, the Padé approximants in columns 4 and 5 apparently satisfy inequality (27), which holds if the series to be transformed is a Stieltjes series. If the index n in column 1 is even ($n=2m$), then the diagonal Padé approximants $P^m_m(\lambda^2)$ and $P^m_m(\beta)$ provide upper bounds that strictly decrease with increasing m and, if n is odd ($n=2m+1$), then the Padé approximants $P^{m+1}_m(\lambda^2)$ and $P^{m+1}_m(\beta)$ provide lower bounds that strictly increase with increasing m.

We have done analogous summation calculations also for many other values of the coupling constants λ and β. Of course, the performance of the Padé summations depend very much on the size of the coupling constants. For smaller values of λ and the corresponding β, convergence is better than in Table II, whereas for $\lambda=1$ and $\beta=40$ only the first digit of the summation results stabilize. For larger values of λ and β, Padé summation produces only relatively crude upper and lower bounds. However, we emphasize that the typical qualitative features of the summation results in Table II—the same rate of divergence of two perturbation series and the occurrence of strictly decreasing upper bounds P^m_m and strictly increasing lower bounds P^{m+1}_m—were consistently observed in all cases considered.

Thus, Wynn's epsilon algorithm is apparently unable to detect any substantial difference

between the perturbation series (29) for $\Delta\mathcal{E}_0(\beta)$, whose Stieltjes nature was established rigorously by Simon (Theorem IV.2.1 of Ref. 28), and the perturbation series (28) for $\Delta E_0(\lambda^2)$, whose Stieltjes nature we conjecture.

IV. PADÉ PREDICTIONS

As shown by countless articles from all branches of physics, Padé approximants have become the standard tool to overcome problems with slowly convergent or divergent power series. However, Padé approximants have other useful features that are not as well known yet. For example, Padé approximants can be used to make predictions for higher-order series coefficients that were not used for the construction of the approximant.

On a heuristic level the prediction capability of Padé approximants, which was apparently first noted and used by Gilewicz,[53] can be explained quite easily. Let us assume that the partial sums (14) of the power series for some function $f(z)$ are to be converted to Padé approximants. Then, the *accuracy-through-order* relationship (12) implies that a Padé approximant $P_m^l(z)$ to $f(z)$ can be expressed as the partial sum $f_{l+m}(z)$ from which it was constructed plus a term $z^{l+m+1}\mathcal{R}_m^l(z)$, which was generated by the transformation of the partial sum to the rational approximant:

$$P_m^l(z)=\sum_{\nu=0}^{l+m}\gamma_\nu z^\nu+z^{l+m+1}\mathcal{R}_m^l(z)=f_{l+m}(z)+z^{l+m+1}\mathcal{R}_m^l(z). \tag{32}$$

Similarly, the power series (10) can be expressed as follows:

$$f(z)=\sum_{\nu=0}^{l+m}\gamma_\nu z^\nu+z^{l+m+1}\sum_{\nu=0}^{\infty}\gamma_{l+m+\nu+1}z^\nu=f_{l+m}(z)+z^{l+m+1}\mathcal{F}_{l+m+1}(z). \tag{33}$$

Let us now assume that the indices l and m are so large that the Padé approximant $P_m^l(z)$ provides a sufficiently accurate approximation to $f(z)$. Then, the Padé transformation term $\mathcal{R}_m^l(z)$ must also provide a sufficiently accurate approximation to the truncation error $\mathcal{F}_{l+m+1}(z)$ of the power series. In general, we have no reason to assume that

$$\mathcal{R}_m^l(z)=\mathcal{F}_{l+m+1}(z) \tag{34}$$

might hold *exactly* for finite values of l and m. Consequently, Taylor expansions of $\mathcal{R}_m^l(z)$ and $\mathcal{F}_{l+m+1}(z)$, respectively, will in general produce different results. Nevertheless, the *leading* coefficients of the Taylor expansion for $\mathcal{R}_m^l(z)$ should in such a case provide sufficiently accurate approximations to the corresponding coefficients of the Taylor series for $\mathcal{F}_{l+m+1}(z)$.

It is important to note that this prediction capability of Padé approximants does not depend on the convergence of the power series expansions for $\mathcal{R}_m^l(z)$ and $\mathcal{F}_{l+m+1}(z)$, respectively, which was used implicitly in our heuristic reasoning given previously. Padé approximants are able to make predictions about series coefficients even if the power series (10) for f as well as the power series expansions for $\mathcal{R}_l^m$ and $\mathcal{F}_{l+m+1}(z)$ are only asymptotic as $z\to 0$. This fact explains why the prediction capability of Padé approximants can be so very useful in the case of violently divergent perturbation expansions (see Refs. 31, 54–72, and references therein).

Theoretically, very little is known about the prediction of series coefficients that were not used for the construction of the Padé approximant. A notable exception are again Stieltjes series for which inequalities are known.

Let us assume that the partial sums (22) of the moment expansion for some Stieltjes function $F(z)$ are to be converted to Padé approximants. Such a Padé approximant $P_m^l(z)$ possesses the following power series expansion:

$$P_m^l(z)=\sum_{\nu=0}^{\infty}(-1)^\nu\mu_\nu^{[l/m]}z^\nu. \tag{35}$$

In Theorem 5.2.7 on p. 220 of Ref. 39 it was shown that for all $n \in \mathbb{N}_0$ and for all $l \geqslant m-1$ the coefficients $\mu_n^{[l/m]}$ in (35) are bounded in magnitude by the Stieltjes moments μ_n in (20) according to

$$0 \leqslant \mu_n^{[l/m]} \leqslant \mu_n . \tag{36}$$

This inequality can be used to analyze the Stieltjes nature of a moment expansion of the type of (20). With the help of computer algebra systems like MAPLE or MATHEMATICA it is possible to construct Padé approximants $P_m^l(z)$ in an unspecified symbolic variable z, and this can even be done free of rounding errors if the coefficients of the series to be transformed are exact integers like the coefficients b_n in (2) or exact rational numbers like the coefficients $\mathcal{B}_n$ in (5). In the next step, a leading part of a power series expansion of the Padé approximant must be constructed. The resulting series coefficients can then be compared with the corresponding coefficients of the moment expansion.

Again, this poses no principal problems for computer algebra systems like MAPLE and MATHEMATICA. However, the accuracy-through-order relationship (12) implies that inequality (36), which is to be checked, is by default satisfied for all indices $n \leqslant l+m$, and only for $n \geqslant l+m+1$ we obtain useful information about the Stieltjes nature of the moment expansion, from which the Padé approximant was constructed. Thus, if $l+m$ becomes large, the brute-force approach based on computer algebra systems becomes very demanding both with respect to computer time and memory because it requires both the symbolic construction of complicated Padé approximants and also symbolic differentiations of very high orders.

These computational problems can be simplified considerably with the help of a recently derived recursive scheme (Sec. 3 of Ref. 31) that permits a direct calculation of the transformation term $\mathcal{R}_m^l(z)$ in (32) if the corresponding Padé approximant $P_m^l(z)$ can be computed with the help of Wynn's epsilon algorithm according to (15); that is, for Padé approximants of the type $P_k^{k+n}(z)$ with $k, n \in \mathbb{N}_0$.

It follows from the accuracy-through-order relationship (12) in combination with (15) that $\varepsilon_{2k}^{(n)}$ can be expressed as follows if the partial sums (14) of the power series for some function $f(z)$ are used as input data for Wynn's epsilon algorithm (13):

$$\varepsilon_{2k}^{(n)} = f_{n+2k}(z) + z^{n+2k+1} \varphi_{2k}^{(n)}(z). \tag{37}$$

The quantities $\varphi_{2k}^{(n)}(z)$ can be computed with the help of the recursive scheme in Eq. (3.15) of Ref. 31, which uses the coefficients γ_n of the power series (10) for $f(z)$ as input data, as follows:

$$\varphi_0^{(n)}(z) = 0, \quad n \in \mathbb{N}_0, \tag{38a}$$

$$\varphi_2^{(n)}(z) = \frac{[\gamma_{n+2}]^2}{\gamma_{n+1} - \gamma_{n+2} z}, \quad n \in \mathbb{N}_0, \tag{38b}$$

$$\varphi_{2k+2}^{(n)}(z) = \varphi_{2k}^{(n+2)}(z) + \frac{\alpha_{2k+2}^{(n)}(z)}{\beta_{2k+2}^{(n)}(z)}, \quad k \in \mathbb{N}, \quad n \in \mathbb{N}_0, \tag{38c}$$

$$\alpha_{2k+2}^{(n)}(z) = \frac{\gamma_{n+2k+2} + \delta\varphi_{2k}^{(n+1)}(z)}{\gamma_{n+2k+1} + \delta\varphi_{2k}^{(n)}(z)} - \frac{\gamma_{n+2k+2} + \delta\varphi_{2k}^{(n+1)}(z)}{\gamma_{n+2k+1} + z\varphi_{2k}^{(n+1)}(z) - \varphi_{2k-2}^{(n+2)}(z)}, \tag{38d}$$

$$\beta_{2k+2}^{(n)}(z) = \frac{1}{\gamma_{n+2k+2} + \delta\varphi_{2k}^{(n+1)}(z)} - \frac{z}{\gamma_{n+2k+1} + \delta\varphi_{2k}^{(n)}(z)} + \frac{z}{\gamma_{n+2k+1} + z\varphi_{2k}^{(n+1)}(z) - \varphi_{2k-2}^{(n+2)}(z)}, \tag{38e}$$

where

15	$0.806\,654\,532\,549\,091\,198\,441\times 10^{271}$	$0.806\,654\,545\,029\,445\,531\,410\times 10^{271}$

$$\delta\varphi_{2k}^{(n)}(z) = z\varphi_{2k}^{(n+1)}(z) - \varphi_{2k}^{(n)}(z). \tag{39}$$

The rational function $\varphi_{2k}^{(n)}(z)$ can be expressed as a power series in z according to

$$\varphi_{2k}^{(n)}(z) = g_0^{(n,2k)} + g_1^{(n,2k)}z + g_2^{(n,2k)}z^2 + \cdots + g_\nu^{(n,2k)}z^\nu + \cdots. \tag{40}$$

The coefficients $g_\nu^{(n,2k)}$ of this series expansion can be used to predict the coefficients $\gamma_{n+2k+\nu+1}$ with $\nu \geqslant 0$ of the power series expansion (10) for $f(z)$ that were not used for the construction of either $\varepsilon_{2k}^{(n)}$ or $\varphi_{2k}^{(n)}(z)$.

Thus, we can compute the rational function $\varphi_{2k}^{(n)}$ with the help of the recursive scheme (38) in the case of the perturbation series (28) for $\Delta E_0(\lambda^2)$ and (29) for $\Delta\mathcal{E}_0(\beta)$. In the case of the $\mathcal{PT}$-symmetric perturbation series we obtain the expansion

$$\varphi_{2k}^{(n)}(\lambda^2) = b_0^{(n,2k)} + b_1^{(n,2k)}\lambda^2 + b_2^{(n,2k)}\lambda^4 + \cdots + b_\nu^{(n,2k)}\lambda^{2\nu} + \cdots, \tag{41}$$

and in the case of the perturbation series for the quartic anharmonic oscillator we obtain

$$\varphi_{2k}^{(n)}(\beta) = \mathcal{B}_0^{(n,2k)} + \mathcal{B}_1^{(n,2k)}\beta + \mathcal{B}_2^{(n,2k)}\beta^2 + \ldots + \mathcal{B}_\nu^{(n,2k)}\beta^\nu + \cdots. \tag{42}$$

The coefficients $b_\nu^{(n,2k)}$ and $\mathcal{B}_\nu^{(n,2k)}$ with $\nu \geqslant 0$ can be used to obtain predictions for the coefficients $b_{n+2k+\nu+2}$ and $\mathcal{B}_{n+2k+\nu+2}$, respectively, that were not used for the construction of the Padé approximants $\varepsilon_{2k}^{(n)} = P_k^{k+n}$ or the transformation terms $\varphi_{2k}^{(n)}$.

In Table III we compute the rational function $\varphi_{66}^{(0)}(\lambda^2)$ corresponding to the diagonal Padé approximant $\varepsilon_{66}^{(n)} = P_{33}^{33}(\lambda^2)$ with the help of the recursive scheme (38) from the coefficients b_ν with $1 \leqslant \nu \leqslant 67$. The resulting expansion coefficients $b_\nu^{(0,66)}$ defined in (41) with $\nu \geqslant 0$ provide predictions to the coefficients $b_{\nu+68}$ of the perturbation series (28). All calculations for Table III were done free of rounding errors using the exact rational arithmetics of MAPLE. Only in the final step the coefficients were converted to floating point numbers for the sake of readability.

The results in Table III show that the expansion coefficients $b_\nu^{(0,66)}$ with $\nu \geqslant 0$ provide already remarkably accurate predictions to the corresponding coefficients $b_{\nu+68}$. Moreover, the Stieltjes inequality (36) is satisfied in all cases.

In Table IV we do the same calculations as in Table III, but this time for the ground-state energy shift $\Delta\mathcal{E}_0(\beta)$ of the quartic anharmonic oscillator. Thus, the expansion of the rational function $\varphi_{66}^{(0)}(\beta)$, which is computed from the coefficients $\mathcal{B}_\nu$ with $1 \leqslant \nu \leqslant 67$ of the perturbation series (29), provides predictions $\mathcal{B}_\nu^{(0,66)}$ to the coefficients $\mathcal{B}_{\nu+68}$.

A comparison of Tables III and IV shows that their qualitative features are identical. In this context it is quite remarkable that although the coefficients b_n grow significantly more rapidly in magnitude than the coefficients $\mathcal{B}_n$, which follows from the large-order estimates (3) and (6), Padé prediction nevertheless yields results of virtually identical quality.

The Padé prediction of unknown series coefficients based on the recursive scheme (38) is certainly computationally simpler than the straightforward symbolic computation and expansion of Padé approximants. The rational function $\varphi_{2k}^{(n)}(z)$ has a simpler structure than $\varepsilon_{2k}^{(n)} = P_k^{k+n}(z)$, and the first $n+2k$ symbolic differentiations can be avoided. Nevertheless, the recursive symbolic computation of the rational function $\varphi_{2k}^{(n)}(z)$ from the coefficients $\gamma_0, \gamma_1, \ldots, \gamma_{n+2k}$ of the power series (10) can become quite demanding, in particular if k becomes large.

The problems connected with the computation of $\varphi_{2k}^{(n)}(z)$ can largely be avoided if one only tries to compute a prediction

$$g_{2k}^{(n)} = g_0^{(n,2k)} \tag{43}$$

for the *first* term γ_{n+2k+1} not used for the construction of either $\varepsilon_{2k}^{(n)}$ or $\varphi_{2k}^{(n)}(z)$. For that purpose, we have only to set $z=0$ in (38). This yields the following recursive scheme [Eq. (3.17) of Ref. 31]:

$$g_0^{(n)} = 0, \quad n \in \mathbb{N}_0, \tag{44a}$$

$$g_2^{(n)} = \frac{[\gamma_{n+2}]^2}{\gamma_{n+1}}, \quad \in \mathbb{N}_0, \tag{44b}$$

$$g_{2k+2}^{(n)} = g_{2k}^{(n+2)} + \frac{[\gamma_{n+2k+2} - g_{2k}^{(n+1)}]^2}{\gamma_{n+2k+1} - g_{2k}^{(n)}} - \frac{[\gamma_{n+2k+2} - g_{2k}^{(n+1)}]^2}{\gamma_{n+2k+1} - g_{2k-2}^{(n+2)}}, \quad k \in \mathbb{N}, \quad n \in \mathbb{N}_0. \tag{44c}$$

The main advantage of this recursive scheme over the recursive scheme (38), from which it was derived, is that it only involves numbers but no symbolic expressions.

In Table V we present selected results for the Padé predictions of the *first* coefficients of the perturbation expansion (28) for $\Delta E_0(\lambda^2)$ and (29) for $\Delta \mathcal{E}_0(\beta)$, which were not used in the Padé approximants $\varepsilon_{2[\![n/2]\!]}^{(n-2[\![n/2]\!])} = P_{[\![n/2]\!]}^{n-[\![n/2]\!]}$ for $2 \leqslant n \leqslant 191$. The first predictions $b_0^{(n-2[\![n/2]\!],2[\![n/2]\!])}$ to b_{n+2} and $\mathcal{B}_0^{(n-2[\![n/2]\!],2[\![n/2]\!])}$ to $\mathcal{B}_{n+2}$ were computed with the help of the recursive scheme (44). For the sake of readability, we present in Table V only the relative errors

TABLE V. Relative errors R_n and $\mathcal{R}_n$ defined in (45) and (46) of the Padé predictions for the first coefficients of the perturbation series (28) and (29) not used for the construction of the rational approximants.

$$R_n=\frac{b_0^{(n-2\llbracket n/2\rrbracket,2\llbracket n/2\rrbracket)}-b_{n+2}}{b_{n+2}} \tag{45}$$

and

$$\mathcal{R}_n=\frac{\mathcal{B}_0^{(n-2\llbracket n/2\rrbracket,2\llbracket n/2\rrbracket)}-\mathcal{B}_{n+2}}{\mathcal{B}_{n+2}}. \tag{46}$$

If the input data of the recursive scheme (44) are exact rational numbers as the coefficients b_n or $\mathcal{B}_n$, then the predictions can be computed free of rounding errors. However, it turned out that the predictions computed in this way were *huge* rational numbers which slowed down computation considerably. Therefore, we used the floating-point arithmetics of MAPLE with an accuracy of 600 decimal digits for the computation of results presented in Table V.

The results in Table V show that the first coefficients not used for the construction of the Padé approximants $\varepsilon_{2\llbracket n/2\rrbracket}^{(n-2\llbracket n/2\rrbracket)}=P_{\llbracket n/2\rrbracket}^{n-\llbracket n/2\rrbracket}$ can be predicted with remarkable accuracy by the recursive scheme (44) if n is sufficiently large. Moreover, the agreement of the relative errors R_n and $\mathcal{R}_n$ is stunning. However, for our purposes most important is the observation that all relative errors in Table V are negative which is in agreement with the Stieltjes inequality (36).

Thus, the prediction results of this section show that there is no significant difference between the prediction of coefficients b_n of the perturbation series (28), whose Stieltjes nature we want to establish, and the prediction of the coefficients $\mathcal{B}_n$ of the analogous quartic anharmonic oscillator perturbation series (29), whose Stieltjes nature was established rigorously by Simon (Theorem

IV.2.1 of Ref. 28). Accordingly, these results provide further numerical evidence that the perturbation series (28) for the ground-state energy shift $\Delta E_0(\lambda^2)$ is indeed a Stieltjes series.

V. SUMMARY AND CONCLUSIONS

As shown by countless monographs or articles, the mathematical theory of the conventional Hermitian Hamiltonians of quantum mechanics is well established and has reached a high degree of sophistication. Moreover, the divergence and the summation of the perturbation expansions resulting from these Hamiltonians is also comparatively well understood, in particular in the case of the Padé summation of Stieltjes series. In contrast, the rigorous mathematical theory of non-Hermitian, $\mathcal{PT}$-symmetric Hamiltonians is virtually nonexistent. It is not known whether divergent perturbation expansions resulting from such Hamiltonians can be summed to yield a uniquely determined result. Consequently, the best we can do for the moment is to perform numerical studies from which we can try to draw general qualitative conclusions.

The main intention of this paper is to provide numerical evidence that the perturbation series (28) for the ground-state energy shift $\Delta E_0(\lambda^2)$ is a Stieltjes series, because this would guarantee that certain subsequences of the Padé table constructed from the partial sums of this perturbation series converge to a uniquely determined summation result, as discussed in Sec. II.

If the Padé approximants are computed with the help of Wynn's recursive algorithm (13) according to (15) and (17)—as it is done in this paper—and if the series to be transformed is the moment expansion of a Stieltjes function, then the Padé approximants must satisfy inequality (27). As shown in Table II, the Padé summation results for the perturbation series (28) for the ground-state energy shift $\Delta E_0(\lambda^2)$ as well as for the analogous perturbation series (29) for the ground-state energy shift $\Delta \mathcal{E}_0(\beta)$ of the quartic anharmonic oscillator, which is known to be a Stieltjes series, satisfy this inequality. Moreover, the divergence of the two perturbation expansions (28) and (29) as well as as the convergence of their Padé summation results is virtually indistinguishable if the two coupling constants λ and β satisfy (7).

If a Padé approximant $P_m^l(z)$ constructed from the partial sums (22) of the moment expansion for a Stieltjes function $F(z)$ is expanded in power series around $z=0$ according to (35), then this series must be strictly alternating for $z>0$ just like the Stieltjes series for $F(z)$. Moreover, the coefficients $\mu_n^{[l/m]}$ of this expansion are bounded in magnitude by the Stieltjes moments μ_n according to inequality (36).

Thus, via inequality (36) it can be checked whether a moment expansion of the type of (20) is a Stieltjes series. However, the accuracy-through-order relationship (12) implies that this inequality is by default satisfied for all indices $n \leqslant l+m$, and only for $n \geqslant l+m+1$ do we obtain useful information. In particular for large values of l and m, the symbolic construction of Padé approximants and their subsequent expansion may become quite demanding both with respect to time and memory.

These computational problems can to some extent be overcome by expressing the Padé approximants $P_k^{k+n}(z)$, that can be computed with the help of Wynn's epsilon algorithm, according to (37) by the partial sum from which it was constructed plus the transformation term $z^{n+2k+1}\varphi_{2k}^{(n)}(z)$. The quantities $\varphi_{2k}^{(n)}(z)$ can be computed recursively with the help of (38), and their computation is less demanding than the recursive computation of the corresponding Padé approximants $P_k^{k+n}(z)$. Moreover, the Taylor expansion of $\varphi_{2k}^{(n)}(z)$ according to (40) yields the desired coefficients $\mu_{n+2k+\nu+1}^{[k+n/k]}$ with $\nu \geqslant 0$.

In Tables III and IV, we proceed as described previously and confirm the validity of the Stieltjes inequality (36) in the case of the first 15 coefficients of the quantities $\varphi_{66}^{(0)}(\lambda^2)$ and $\varphi_{66}^{(0)}(\beta)$ corresponding to the Padé approximants $P_{33}^{33}(\lambda^2)$ and $P_{33}^{33}(\beta)$, respectively. In this context, it is remarkable that the quality of the predictions is virtually indistinguishable although the coefficients b_n of the $\mathcal{PT}$-symmetric perturbation series grow much more rapidly than the coefficients $\mathcal{B}_n$ for the quartic anharmonic oscillator.

For larger values of n and k the symbolic computation of the quantities $\varphi_{2k}^{(n)}(z)$ via the recursive scheme (38) becomes quite demanding. In such a case, it is much simpler to compute

only the prediction for the first series coefficient not used for the computation of $\varphi_{2k}^{(n)}(z)$. This can be done with the help of the recursive scheme (44). In Table V we show that all first predictions, which we can compute from the coefficients b_ν and $\mathcal{B}_\nu$ with $1 \leqslant \nu \leqslant 192$, satisfy the Stieltjes inequality (36). Moreover, the quality of the prediction results is again virtually identical.

We are of course aware that numerical results cannot replace rigorous mathematical proofs. Nevertheless, we believe that our numerical experiments are both interesting and useful, and that they provide considerable evidence that the perturbation series (28) for the ground-state energy shift $\Delta E_0(\lambda^2)$ of the $\mathcal{PT}$-symmetric Hamiltonian (1) is indeed a Stieltjes series, which would imply that the Padé summation of this divergent perturbation series converges.

Given the abstract wave equation $\ddot{\phi}-\Delta_\alpha\phi=0$, where Δ_α is the Laplace operator with a point interaction of strength α, we define and study $\overline{W}_\alpha$, the associated wave generator in the phase space of finite energy states. We prove the existence of the phase flow generated by $\overline{W}_\alpha$, and describe its most relevant properties with a particular emphasis on the associated symplectic structure and scattering theory.
 [DOI: 10.1063/1.1360194]

I. INTRODUCTION

To introduce the problem we begin with a well known example. Given the free scalar, *zero mass*, wave equation,

$$\ddot{\phi}-\Delta\phi=0, \tag{1}$$

the usual attitude in the literature is to search the solutions in the real Sobolev–Hilbert space $H^2(\mathsf{R}^3)$; in order to fix the notations we recall that $H^s(\mathsf{R}^3)$, $s\in\mathsf{R}$, is defined as the set of tempered distributions with a Fourier transform which is square integrable w.r.t. the measure with density $(1+|k|^2)^s$. This is a standard mathematical choice but not the more natural one. In fact, Eq. (1) can be written in the first order form

$$\dot{\psi}=W\psi, \tag{2}$$

where the linear operator,

$$W:H^2(\mathsf{R}^3)\oplus H^1(\mathsf{R}^3)\to H^1(\mathsf{R}^3)\oplus L^2(\mathsf{R}^3),$$

is defined as

$$W\begin{pmatrix}\phi\\ \dot{\phi}\end{pmatrix}=\begin{pmatrix}0 & 1\\ \Delta & 0\end{pmatrix}\begin{pmatrix}\phi\\ \dot{\phi}\end{pmatrix}. \tag{3}$$

Here Δ is the usual Laplace operator viewed as a self-adjoint operator on $L^2(\mathsf{R}^3)$. It is well known that Eq. (2) generates a strongly continuous one parameter group of evolution,

$$U^t:H^1(\mathsf{R}^3)\oplus L^2(\mathsf{R}^3)\to H^1(\mathsf{R}^3)\oplus L^2(\mathsf{R}^3).$$

This group is energy preserving, i.e., there exists an energy form

a)Electronic mail: posilicano@mat.unimi.it

$$\mathcal{E}(\phi,\dot{\phi})=\tfrac{1}{2}(\|\dot{\phi}\|_2^2+\|\sqrt{-\Delta}\,\phi\|_2^2),$$

coinciding with the Hamiltonian of the system, preserved by the flow. Moreover U^t constitutes a group of canonical transformations w.r.t. the symplectic form

$$\omega((\phi,\dot{\phi}),(\varphi,\dot{\varphi})):=\langle\phi,\dot{\varphi}\rangle-\langle\varphi,\dot{\phi}\rangle$$

[$\langle\cdot,\cdot\rangle$ denoting the usual scalar product on $L^2(\mathsf{R}^3)$] and W is nothing but the Hamiltonian vector field corresponding, via ω, to $\mathcal{E}$.

As the form of Hamiltonian $\mathcal{E}$ suggests, a more natural domain for the study of the system described by (3) is the space of the finite energy states, which is larger than the original one, because the first component ϕ of such a state is not necessarily square integrable, as instead is implicit in the standard Sobolev environment recalled above. This more suitable description goes as follows.

Let us define (general and more complete definitions will be given in the following section) $\overline{H}^1(\mathsf{R}^3)$ as the completion of the space $C_0^\infty(\mathsf{R}^3)$ in the norm $\|\sqrt{-\Delta}\,\phi\|_2$. Now it is possible to define the new operator $\overline{W}$ on $\overline{H}^1(\mathsf{R}^3)\oplus L^2(\mathsf{R}^3)$, the Hilbert space of finite energy states, by

$$\overline{W}:\overline{H}^2(\mathsf{R}^3)\oplus H^1(\mathsf{R}^3)\to\overline{H}^1(\mathsf{R}^3)\oplus L^2(\mathsf{R}^3),\quad \overline{W}(\phi,\dot{\phi}):=(\dot{\phi},\mathbf{\Delta}\phi),\tag{4}$$

where

$$\overline{H}^2(\mathsf{R}^3):=\{\phi\in\overline{H}^1(\mathsf{R}^3):\mathbf{\Delta}\phi\in L^2(\mathsf{R}^3)\}.$$

It is an easy matter to verify that $\overline{W}$ is a skew-adjoint operator (see, e.g., Ref. 1, Thm. 2.1.2, Ref. 2, Sec. XI.10) so that due to the Stone theorem it defines a strongly continuous one parameter group of evolution,

$$\overline{U}^t:\overline{H}^1(\mathsf{R}^3)\oplus L^2(\mathsf{R}^3)\to\overline{H}^1(\mathsf{R}^3)\oplus L^2(\mathsf{R}^3),$$

which is trivially energy preserving, just because the energy coincides with the norm of the Hilbert space, and the flow is given by a group of isometric operators. This procedure generalizes to the case in which one considers an abstract wave equation with a positive self-adjoint operator in the place of $-\Delta$ (see Ref. 3 and Ref. 4, Sec. 8).

Here we consider and study in detail the case in which $-\Delta$ is replaced by $-\Delta_\alpha$, the Laplace operator with a point interaction of strength α (see Sec. II for its precise definition), and construct the corresponding wave generator $\overline{W}_\alpha$; since $-\Delta_\alpha$ is not positive when $\alpha<0$ one cannot directly use the results appearing in Refs. 3 and 4.

The abstract wave equation corresponding to Δ_α, i.e.,

$$\ddot{\phi}-\Delta_\alpha\phi=0,\tag{5}$$

was introduced for the first time in Ref. 5. There, when ϕ is vector-valued and when $\alpha=-mc/e$ (m the phenomenological mass, c the velocity of light, e the electric charge), it is shown that (5) describes the evolution of the electromagnetic field self-interacting with a point particle in the dipole approximation (the so called linearized Pauli–Fierz model). Another model connected with the wave equation (5), often studied in the 1950s and 1960s literature on exact models in quantum field theory, is the so called ''pair theory'' (see Refs. 6–8 and references therein). The classical version of this model is the regularized version of the one we study here, and many at the time unanswered questions about its behavior in the ultraviolet limit find their rigorous collocation in the present work.

In Refs. 5, 9, and 10 it is also shown that the Cauchy problem is well posed on the phase space $D^1(\mathsf{R}^3)\oplus L^2(\mathsf{R}^3)$, $D^1(\mathsf{R}^3)\simeq H^1(\mathsf{R}^3)\oplus\mathsf{R}$, [refer to Sec. II for the definition of $D^1(\mathsf{R}^3)$] and that the corresponding strongly continuous one parameter group of evolution,

$$U_\alpha^t : D^1(\mathsf{R}^3)\oplus L^2(\mathsf{R}^3)\to D^1(\mathsf{R}^3)\oplus L^2(\mathsf{R}^3),$$

preserves the energy,

$$\mathcal{E}_\alpha(\phi,\dot\phi) := \tfrac{1}{2}(\|\dot\phi\|_2^2 + F_\alpha(\phi,\phi)),$$

where F_α denotes the bilinear form corresponding to the self-adjoint operator $-\Delta_\alpha$. Therefore, analogously to the case of the free wave equation, the problem of defining (5) on the larger space of finite energy states naturally arises. The theory of delta point interactions was originally developed in the context of nonrelativistic quantum mechanics (see Ref. 11 and references therein); this made it natural to use $L^2(\mathsf{R}^3)$ as the underlying Hilbert space and so, in order to define the dynamics on the space of finite energy states, one has to modify the original definition of $-\Delta_\alpha$, to allow the elements of its domain being not square integrable. This is done in Sec. III where we also show (Thm. 3.1) that the operators $\overline{W}_\alpha$ here constructed generate an evolution group $\overline{U}_\alpha^t$, a fact that, in the case $\alpha\leqslant 0$, is not immediately evident. So, as an aside result, a conserved energy form exists; this form however is not positive when $\alpha<0$, and therefore it is not suitable to define the norm of the appropriate phase space.

In Sec. IV we treat the Hamiltonian formulation of the wave equations with delta interactions. Here we solve the problem by giving a complex structure $\mathcal{J}_\alpha$ commuting with the operator $\overline{W}_\alpha$. This leads to an equivalent Schrödinger-like first order formulation which, also in view of a future quantization of the dynamical system under study, plays a key role. The complex structure before mentioned is obtained considering separately the case $\alpha\leqslant 0$ from the other case: in the strictly negative case we obtain an invariant splitting of the phase space and the complex structure in such a way that the Hamiltonian vector field appears separately as a Schrödinger equation both on the stable and unstable part of the phase space; in particular, on the unstable subspace, which is finite dimensional, the Hamiltonian is that of a harmonic repulsor, and the Schrödinger equation is the corresponding ordinary differential equation, as expected.

The last topic treated (see Sec. V) is the scattering theory for the pair of operators $(\overline{W}_\alpha,\overline{W})$. The Hilbert phase spaces for $\overline{W}_\alpha$ and $\overline{W}$ being different, a resort has to be made to the two Hilbert space scattering theory introduced by Kato in Ref. 4. Using the Birman invariance principle and the trace condition of the Birman–Kuroda theorem, we are able to prove the existence of the Möller wave operators and their completeness (Thms. 5.1 and 5.2). As a consequence of the machinery needed for the definition of wave operators, one obtains a relation [see (12)–(14)] between the evolution group (acting on the real Hilbert space of states with finite energy) generated by $\overline{W}_\alpha$ and the unitary group [acting on the complex Hilbert space $L^2_{\mathsf{C}}(\mathsf{R}^3)$, the complexification of $L^2(\mathsf{R}^3)$] generated by $\sqrt{-\Delta_\alpha}$ (in the case $\alpha<0$ one considers only the positive part of the operator). This can be seen as a variation of the procedure applied in Sec. III in case one uses the standard complex structure on $L^2_{\mathsf{C}}(\mathsf{R}^3)$: indeed the two structures are related in a simple way [see (10) and (11)]. The relations (12)–(14) could also be used to define the group $\overline{U}_\alpha^t$, the generator of which is easily seen to be $\overline{W}_\alpha$, providing an alternative proof of the existence of the dynamics.

II. PRELIMINARIES

We start by giving definitions and main properties of the Sobolev type spaces needed in the sequel, and to which we made reference in the Introduction. We define the family of pre-Hilbert spaces $\tilde H^s(\mathsf{R}^3)$, $s\in\mathsf{R}$, as the set of tempered distributions with a Fourier transform (denoted by $\hat{}$ or by $\mathcal{F}$) which is square integrable w.r.t. the measure with density $|k|^{2s}$. The scalar product is defined as

$$\langle \phi_1, \phi_2 \rangle_s := \int_{\mathbb{R}^3} dk\, |k|^{2s} \hat{\phi}_1(k)\, \hat{\phi}_2(k).$$

Note that, when $s>0$, $H^s(\mathbb{R}^3) \subset \tilde{H}^s(\mathbb{R}^3)$ and $\tilde{H}^{-s}(\mathbb{R}^3) \subset H^{-s}(\mathbb{R}^3)$, the embeddings being continuous. Since $|k|^{-2s}$ is locally integrable for any $s<3/2$,

$$\forall s < \tfrac{3}{2}, \quad L^2(\mathbb{R}^3, |x|^{2s}\, dx) \subset \mathcal{S}'(\mathbb{R}^3), \quad \tilde{H}^s(\mathbb{R}^3) \equiv \mathcal{F}^{-1}(L^2(\mathbb{R}^3, |k|^{2s}\, dk)),$$

and thus $\tilde{H}^s(\mathbb{R}^3)$ is complete for any $s<3/2$ and coincides with the usual Riesz potential spaces (see, e.g., Ref. 12, Sec. 7.1.2).

We can then define the isomorphism $(r-s<3/2)$,

$$(-\overline{\Delta})^{s/2}: \tilde{H}^r(\mathbb{R}^3) \to \tilde{H}^{r-s}(\mathbb{R}^3), \quad \mathcal{F}((-\overline{\Delta})^{s/2}\phi)(k) := |k|^s \hat{\phi}(k).$$

Our notation is justified by observing that, in the case $0<r=s<3/2$, $(-\overline{\Delta})^{s/2}$ coincides with the closure of $(-\Delta)^{s/2}: H^s(\mathbb{R}^3) \to L^2(\mathbb{R}^3)$.

Since, contrary to what happens for the usual Sobolev chain $H^s(\mathbb{R}^3)$, $\tilde{H}^r(\mathbb{R}^3)$ is not included in $\tilde{H}^s(\mathbb{R}^3)$ when $r>s$, we also define the sequence of spaces,

$$\overline{H}^n(\mathbb{R}^3) := \bigcap_{k=1}^{n} \tilde{H}^k(\mathbb{R}^3) \equiv \mathcal{F}^{-1}\Big(\bigcap_{k=1}^{n} L^2(\mathbb{R}^3, |x|^{2k}\, dx)\Big).$$

Obvioulsy $\overline{H}^n(\mathbb{R}^3)$ is a Hilbert space with norm

$$\|\phi\|_{\overline{H}^n} := \left(\sum_{k=1}^{n} \|(-\overline{\Delta})^{k/2}\phi\|_2^2 \right)^{1/2}.$$

We come now to point interactions; for their general theory of we refer to Ref. 11; here we confine ourselves to the essential definitions and results. The operator $-\Delta_\alpha$ describing a standard point interaction at the origin with strength α is defined as follows. Let us introduce the dense linear subspace of $L^2(\mathbb{R}^3)$,

$$D^2_\alpha(\mathbb{R}^3) := \left\{ \phi \in L^2(\mathbb{R}^3) : \phi = \phi_\lambda + Q_\phi G_\lambda, \ \ \phi_\lambda \in H^2(\mathbb{R}^3), \left(\alpha + \frac{\sqrt{\lambda}}{4\pi} \right) Q_\phi = \phi_\lambda(\mathbf{0}) \right\},$$

where $0<\lambda \neq -\mathrm{sign}(\alpha)\ (4\pi\alpha)^2$ and

$$G_\lambda(x) = \frac{e^{-\sqrt{\lambda}|x|}}{4\pi|x|}.$$

The Laplacian with a point interaction with strength α is the operator,

$$-\Delta_\alpha : D^2_\alpha(\mathbb{R}^3) \to L^2(\mathbb{R}^3), \quad -\mathbf{\Delta}_\alpha \phi := -\mathbf{\Delta}\phi_\lambda - \lambda Q_\phi G_\lambda .$$

Its resolvent is given by

$$(-\Delta_\alpha + \lambda)^{-1} = (-\Delta + \lambda)^{-1} + \left(\alpha + \frac{\sqrt{\lambda}}{4\pi} \right)^{-1} G_\lambda \otimes G_\lambda ,$$

where $G_\lambda \otimes G_\lambda(\phi) := \langle G_\lambda, \phi \rangle\, G_\lambda$.

The bilinear form corresponding to $-\Delta_\alpha$ has domain $D^1(\mathbb{R}^3) \times D^1(\mathbb{R}^3)$,

$$D^1(\mathbb{R}^3) := \{ \phi \in L^2(\mathbb{R}^3) : \phi = \phi_\lambda + Q_\phi G_\lambda, \phi_\lambda \in H^1(\mathbb{R}^3), \ \ Q_\phi \in \mathbb{R} \},$$

and is defined by

$$F_\alpha(\phi,\varphi) := \langle (-\Delta+\lambda)^{1/2}\phi_\lambda, (-\Delta+\lambda)^{1/2}\varphi_\lambda\rangle - \lambda\langle \phi,\varphi\rangle + \left(\alpha + \frac{\sqrt{\lambda}}{4\pi}\right) Q_\phi Q_\varphi$$

(see Ref. 13). Both the expressions for F_α and $-\Delta_\alpha$ contain the arbitrary parameter λ, but contrary to the appearance, they do not depend on it. Indeed (following Ref. 14, Sec. 2) the operator and form domain can be defined in the following alternative, and more useful, way. Note that, since for any $\lambda>0$,

$$G_\lambda \in L^2(\mathbb{R}^3), \quad G-G_\lambda \in \overline{H}^2(\mathbb{R}^3), \quad (G-G_\lambda)(\mathbf{0}) = \frac{\sqrt{\lambda}}{4\pi},$$

where

$$G(x) = \frac{1}{4\pi|x|},$$

defining

$$\phi_{\mathrm{reg}} := \phi_\lambda + Q_\phi(G_\lambda - G) \in \overline{H}^2(\mathbb{R}^3),$$

we have equivalently,

$$D^2_\alpha(\mathbb{R}^3) = \{\phi \in L^2(\mathbb{R}^3) : \phi = \phi_{\mathrm{reg}} + Q_\phi G, \phi_{\mathrm{reg}} \in \overline{H}^2(\mathbb{R}^3), \quad Q_\phi \in \mathbb{R}, \alpha\, Q_\phi = \phi_{\mathrm{reg}}(\mathbf{0})\}.$$

Correspondingly, the form domain is

$$D^1(\mathbb{R}^3) = \{\phi \in L^2(\mathbb{R}^3) : \phi = \phi_{\mathrm{reg}} + Q_\phi G, \phi_{\mathrm{reg}} \in \overline{H}^1(\mathbb{R}^3), Q_\phi \in \mathbb{R}\},$$

so that, with this definition, the singular part of the field is exactly Coulombian. However such a singular field G *is not in the configuration space* $D^1(\mathbb{R}^3)$. The removal of this incongruence will lead, in the following section, to the introduction of the operator $\overline{W}_\alpha$.

With the domains so given we can redefine the operator and the form as

$$-\Delta_\alpha \phi = -\overline{\Delta}\phi_{\mathrm{reg}}$$

and

$$F_\alpha(\phi,\varphi) = \langle (-\overline{\Delta})^{1/2}\phi_{\mathrm{reg}}, (-\overline{\Delta})^{1/2}\varphi_{\mathrm{reg}}\rangle + \alpha\, Q_\phi Q_\varphi .$$

Now it is well known (see Ref. 11, Chap. I.1) that $-\Delta_\alpha$ is a self-adjoint operator in $L^2(\mathbb{R}^3)$. An important property is that $-\Delta_\alpha$ is positive only for $\alpha \geqslant 0$, whereas for $\alpha<0$ it is only bounded from below; more precisely if $\alpha \geqslant 0$ (*repulsive* delta interactions) the spectrum of the operator is absolutely continuous and coinciding with $[0,+\infty)$; if $\alpha<0$ (*attractive* delta interactions) the spectrum is given by $\{-\lambda_0\}\cup[0,+\infty)$, where $-\lambda_0 = -(4\pi\alpha)^2$ is an isolated negative eigenvalue, and the remaining part of the spectrum is absolutely continuous. In the Schrödinger case this eigenvalue corresponds to a bound state, while in the wave case where one has a second order equation in time, it leads to unstable solutions exponentially running away in the past or in the future (see Refs. 5, 9, 10 and reference therein for the meaning of these well known runaway solutions in classical electrodynamics).

We now come to the wave generator associated to the standard delta operator. Its domain and action are given by

$$W_\alpha : D^2_\alpha(\mathbb{R}^3) \oplus D^1(\mathbb{R}^3) \to D^1(\mathbb{R}^3) \oplus L^2(\mathbb{R}^3),$$

$$W_\alpha \begin{pmatrix} \phi \\ \dot{\phi} \end{pmatrix} = \begin{pmatrix} 0 & \mathbf{1} \\ \Delta_\alpha & 0 \end{pmatrix} \begin{pmatrix} \phi \\ \dot{\phi} \end{pmatrix}. \tag{6}$$

By considering the Hilbert space structure given by $D^1(\mathbb{R}^3) \oplus L^2(\mathbb{R}^3) \simeq H^1(\mathbb{R}^3) \oplus \mathbb{R} \oplus L^2(\mathbb{R}^3)$ this operator is the generator of a strongly continuous group of operators,

$$U^t_\alpha : D^1(\mathbb{R}^3) \oplus L^2(\mathbb{R}^3) \to D^1(\mathbb{R}^3) \oplus L^2(\mathbb{R}^3).$$

In the case $\alpha \geqslant 0$ this is an immediate consequence of the skew-adjointness of W_α with respect to the positive energy scalar product on the phase space given by

$$\langle\langle (\phi, \dot{\phi}), (\varphi, \dot{\varphi}) \rangle\rangle_\alpha := \langle \dot{\phi}, \dot{\varphi} \rangle + F_\alpha(\phi, \varphi). \tag{7}$$

More precisely one has the following result (the proof being a straighforward calculation).

Theorem 2.1: *For any $\alpha \in \mathbb{R}$, with respect to the scalar product $\langle\langle \cdot, \cdot \rangle\rangle_\beta$, $\beta \geqslant 0$, one has*

$$D(W^*_\alpha) = D(W_\beta)$$

and

$$W^*_\alpha(\phi, \dot{\phi}) = -\left(\dot{\phi}_{\mathrm{reg}} + \frac{\alpha}{\beta} Q_{\dot{\phi}} G, \overline{\Delta} \phi_{\mathrm{reg}} \right), \quad \beta > 0,$$

$$W^*_\alpha(\phi, \dot{\phi}) = -(\dot{\phi}_{\mathrm{reg}} + Q_{\dot{\phi}} G, \overline{\Delta} \phi_{\mathrm{reg}}) \equiv W_\beta(\phi, \dot{\phi}), \quad \beta = 0 = \alpha.$$

In the case $\alpha < 0$ the operator W_α is readily proven to be a generator by considering the operator

$$W_{\alpha,\lambda}(\phi, \dot{\phi}) := (\dot{\phi}, (\Delta_\alpha - \lambda)\phi_{\mathrm{reg}}),$$

where $\lambda > \lambda_0$. This, being now $-\Delta_\alpha + \lambda$ positive, is skew-adjoint with respect to the scalar product,

$$\langle\langle (\phi, \dot{\phi}), (\varphi, \dot{\varphi}) \rangle\rangle_{\alpha,\lambda} := \langle \dot{\phi}, \dot{\varphi} \rangle + F_\alpha(\phi, \varphi) + \lambda \langle \phi, \varphi \rangle, \tag{8}$$

and so it generates a group of isometries [w.r.t. the Hilbert structure given by (8)]. The original operator W_α, being a perturbation of the previous one by a bounded operator, also generates a strongly continuous group of operators on the phase space (which however are no longer isometries).

We now describe an alternative way to prove that W_α, $\alpha < 0$, is a generator. Such a different method will play a key role in the next sections. As we already said before in the case $\alpha < 0$ the self-adjoint operator $-\Delta_\alpha$ has a negative eigenvalue $-\lambda_0$ (with corresponding normalized eigenvector $4\pi\sqrt{-2\alpha}\, G_{\lambda_0}$) which gives rise to the runaway solutions of the wave equation associated to W_α. Proceeding as in Ref. 10, Sec. 4 (note that there we worked with the different decomposition $\phi = \phi_{\lambda_0} + Q_\phi G_{\lambda_0}$) we consider the linear operator

$$W^{\mathrm{nr}}_\alpha : [D^2_\alpha(\mathbb{R}^3)]_{\mathrm{nr}} \oplus [D^1(\mathbb{R}^3)]_{\mathrm{nr}} \to [D^1(\mathbb{R}^3)]_{\mathrm{nr}} \oplus [L^2(\mathbb{R}^3)]_{\mathrm{nr}},$$

$$W_\alpha \begin{pmatrix} \phi \\ \dot{\phi} \end{pmatrix} = \begin{pmatrix} 0 & 1 \\ \Delta^{\mathrm{nr}}_\alpha & 0 \end{pmatrix} \begin{pmatrix} \phi \\ \dot{\phi} \end{pmatrix},$$

where, given any vector subspace $\mathcal{V} \subseteq L^2(\mathbb{R}^3)$, we have defined the corresponding ''nonrunaway'' subspace $[\mathcal{V}]_{\mathrm{nr}}$ by

$$[\mathcal{V}]_{\mathrm{nr}} := \{\phi \in \mathcal{V} : \langle \phi, G_{\lambda_0} \rangle = 0\},$$

and

$$\Delta_\alpha^{\mathrm{nr}} := (\Delta_\alpha)_{|[D^2_\alpha(\mathsf{R}^3)]_{\mathrm{nr}}} \equiv P_{\mathrm{nr}} \cdot (\Delta_\alpha)_{|[D^2_\alpha(\mathsf{R}^3)]_{\mathrm{nr}}},$$

P_{nr} being the orthogonal projector onto $[L^2(\mathsf{R}^3)]_{\mathrm{nr}}$. By simple calculations one has (see Ref. 10, Sec. 4])

$$[D^1(\mathsf{R}^3)]_{\mathrm{nr}} = \{\phi \in D^1(\mathsf{R}^3) : Q_\phi = -4\pi\sqrt{\lambda_0}\,\langle \phi_{\mathrm{reg}}, G_{\lambda_0} \rangle\},$$

$$[D^2_\alpha(\mathsf{R}^3)]_{\mathrm{nr}} = \{\phi \in D^2_\alpha(\mathsf{R}^3) : \phi_{\mathrm{reg}}(0) = \lambda_0\,\langle \phi_{\mathrm{reg}}, G_{\lambda_0} \rangle\},$$

and

$$\begin{aligned}
\Delta_\alpha^{\mathrm{nr}}\phi &= \overline{\Delta}\phi_{\mathrm{reg}} - 8\pi\sqrt{\lambda_0}\,\langle \overline{\Delta}\phi_{\mathrm{reg}}, G_{\lambda_0} \rangle G_{\lambda_0} \\
&= \overline{\Delta}\phi_{\mathrm{reg}} + 8\pi\sqrt{\lambda_0}\,\langle (-\overline{\Delta} + \lambda_0)\phi_{\mathrm{reg}}, G_{\lambda_0} \rangle G_{\lambda_0} - 8\pi\sqrt{\lambda_0}\,\lambda_0\,\langle \phi_{\mathrm{reg}}, G_{\lambda_0} \rangle G_{\lambda_0} \\
&= \overline{\Delta}\phi_{\mathrm{reg}}.
\end{aligned}$$

The *non-negative* bilinear form associated to $-\Delta_\alpha^{\mathrm{nr}}$ is then

$$F_\alpha^{\mathrm{nr}}(\phi, \varphi) = \langle (-\overline{\Delta})^{1/2}\phi_{\mathrm{reg}}, (-\overline{\Delta})^{1/2}\varphi_{\mathrm{reg}} \rangle - 4\pi\,\lambda_0^{3/2}\langle \phi_{\mathrm{reg}}, G_{\lambda_0} \rangle \langle \varphi_{\mathrm{reg}}, G_{\lambda_0} \rangle$$

and W_α^{nr} is skew-adjoint w.r.t. the scalar product

$$\langle\langle (\phi, \dot{\phi}), (\varphi, \dot{\varphi}) \rangle\rangle_\alpha^{\mathrm{nr}} := \langle \dot{\phi}, \dot{\varphi} \rangle + F_\alpha^{\mathrm{nr}}(\phi, \varphi).$$

The strongly continuous one parameter group of evolution generated by W_α^{nr} preserves the *non-negative* energy,

$$\mathcal{E}_\alpha^{\mathrm{nr}}(\phi, \dot{\phi}) := \tfrac{1}{2}(\langle \dot{\phi}, \dot{\phi} \rangle + F_\alpha^{\mathrm{nr}}(\phi, \phi)),$$

which coincides with the Hamiltonian of the system w.r.t. the symplectic form ω (see Ref. 10, Thm. 4.2] for an alternative Hamiltonian picture).

Since $\Delta_\alpha G_{\lambda_0} = \lambda_0 G_{\lambda_0}$, and

$$D^2_\alpha(\mathsf{R}^3) \simeq [D^2_\alpha(\mathsf{R}^3)]_{\mathrm{nr}} \oplus \mathsf{R},$$

$$D^1(\mathsf{R}^3) \simeq [D^1(\mathsf{R}^3)]_{\mathrm{nr}} \oplus \mathsf{R},$$

$$L^2(\mathsf{R}^3) \simeq [L^2(\mathsf{R}^3)]_{\mathrm{nr}} \oplus \mathsf{R},$$

we can write

$$W_\alpha = W_\alpha^{\mathrm{nr}} \times \Lambda_0,$$

where

$$\Lambda_0 : \mathsf{R}^2 \to \mathsf{R}^2, \quad \mathbf{\Lambda}_0(x, \dot{x}) := (\dot{x}, \lambda_0 x).$$

Therefore W_α, $\alpha < 0$, is a generator and

$$U_\alpha^t \equiv e^{tW_\alpha} = e^{tW_\alpha^{\mathrm{nr}}} \times e^{t\Lambda_0}.$$

Here and below, given two linear operators $A_1 : D(A_1) \to H_1$ and $A_2 : D(A_2) \to H_2$, $A_1 \times A_2 : D(A_1) \times D(A_2) \to H_1 \oplus H_2$ denotes the linear operator defined by

$$A_1 \times A_2 (\phi_1, \phi_2) := (A_1 \phi_1, A_2 \phi_2).$$

In conclusion, for any $\alpha \in \mathsf{R}$, U_α^t is a group of canonical transformation w.r.t. the symplectic form ω, and W_α is the Hamiltonian vector field corresponding to the energy

$$\mathcal{E}_\alpha(\phi, \dot{\phi}) = \frac{1}{2}\left(\|\dot{\phi}\|_2^2 + F_\alpha(\phi, \phi) \right) \equiv \mathcal{E}(\phi_{\mathrm{reg}}, \dot{\phi}) + \frac{\alpha}{2} Q_\phi^2.$$

Let us remark that the flow U_α^t can be explicitly calculated (see Ref. 5, Thm. 3.1).

III. THE OPERATOR $\overline{W}_\alpha$

Now we would like to mimic the construction of the energy space for the usual wave generator and the extension of the operator itself, to the case of delta point interactions. To this end, let us define the linear operator,

$$\overline{W}_\alpha : \overline{D}_\alpha^2(\mathsf{R}^3) \oplus D^1(\mathsf{R}^3) \to \overline{D}^1(\mathsf{R}^3) \oplus L^2(\mathsf{R}^3), \quad \overline{W}_\alpha(\phi, \dot{\phi}) := (\dot{\phi}, \overline{\mathbf{\Delta}} \phi_{\mathrm{reg}}),$$

where

$$\overline{D}_\alpha^2(\mathsf{R}^3) := \{ \phi = \phi_{\mathrm{reg}} + Q_\phi G, \phi_{\mathrm{reg}} \in \overline{H}^2(\mathsf{R}^3), Q_\phi \in \mathsf{R}, \alpha\, Q_\phi = \phi_{\mathrm{reg}}(0) \},$$

$$\overline{D}^1(\mathsf{R}^3) := \{ \phi = \phi_{\mathrm{reg}} + Q_\phi G, \phi_{\mathrm{reg}} \in \overline{H}^1(\mathsf{R}^3), Q_\phi \in \mathsf{R} \}.$$

Analogously to the free case, $\overline{D}^1(\mathsf{R}^3) \oplus L^2(\mathsf{R}^3)$ describes now the space of finite energy states. Moreover the Coulombian singularity G *is now in the configuration space* $\overline{D}^1(\mathsf{R}^3)$.

Introducing the Hilbert space structure given by $\overline{D}^1(\mathsf{R}^3) \oplus L^2(\mathsf{R}^3) \simeq \overline{H}^1(\mathsf{R}^3) \oplus \mathsf{R} \oplus L^2(\mathsf{R}^3)$ we want now to show that also in this case $\overline{W}_\alpha$ generates a strongly continuous one parameter group of evolution. When $\alpha > 0$, considering, similarly to the case of W_α, the scalar product,

$$\langle\langle (\phi, \dot{\phi}), (\varphi, \dot{\varphi}) \rangle\rangle_\alpha := \langle \dot{\phi}, \dot{\varphi} \rangle + \langle (-\overline{\Delta})^{1/2} \phi_{\mathrm{reg}}, (-\overline{\Delta})^{1/2} \varphi_{\mathrm{reg}} \rangle + \alpha\, Q_\phi Q_\varphi,$$

one can prove that $\overline{W}_\alpha$ is skew-adjoint and so it is a generator. Note that when $\alpha = 0$, contrary to the situation discussed in the previous section, $\langle\langle \cdot, \cdot \rangle\rangle_\alpha$ is no more a scalar product, being annihilated by the zero energy eigenvector $(G, 0)$ (this fact has to be compared with the presence of a zero energy resonance for $-\Delta_0$). In order to show that also in the case $\alpha \leqslant 0$ $\overline{W}_\alpha$ is a generator one cannot use the same strategy as before consisting in a translation, since the scalar product (8) is now ill-defined, $\overline{D}^1(\mathsf{R}^3)$ being not a subset of $L^2(\mathsf{R}^3)$. So the perturbation argument fails and we are forced to proceed in an alternative way. The decomposition of W_α, $\alpha < 0$, introduced at the end of the previous section is our starting point: we simply extend it to the case of $\overline{W}_\alpha$. Therefore we define, when $\alpha < 0$,

$$[\overline{D}_\alpha^2(\mathsf{R}^3)]_{\mathrm{nr}} = \{ \phi \in \overline{D}_\alpha^2(\mathsf{R}^3) : \phi_{\mathrm{reg}}(\mathbf{0}) = \lambda_0 \langle \phi_{\mathrm{reg}}, G_{\lambda_0} \rangle \}$$

$$[\overline{D}^1(\mathsf{R}^3)]_{\mathrm{nr}} = \{ \phi \in \overline{D}^1(\mathsf{R}^3) : Q_\phi = -4\pi \sqrt{\lambda_0} \langle \phi_{\mathrm{reg}}, G_{\lambda_0} \rangle \},$$

and

$$\overline{W}_\alpha^{\mathrm{nr}}:[\overline{D}_\alpha^2(\mathsf{R}^3)]_{\mathrm{nr}}\oplus[D^1(\mathsf{R}^3)]_{\mathrm{nr}}\to[\overline{D}^1(\mathsf{R}^3)]_{\mathrm{nr}}\oplus[L^2(\mathsf{R}^3)]_{\mathrm{nr}},$$

$$\overline{W}_\alpha^{\mathrm{nr}}(\phi,\dot\phi):=(\dot\phi,\overline{\Delta}_\alpha^{\mathrm{nr}}\phi),$$

where

$$\overline{\Delta}_\alpha^{\mathrm{nr}}:[\overline{D}_\alpha^2(\mathsf{R}^3)]_{\mathrm{nr}}\to[L^2(\mathsf{R}^3)]_{\mathrm{nr}},$$

$$\overline{\Delta}_\alpha^{\mathrm{nr}}\phi:=\overline{\Delta}\phi_{\mathrm{reg}}.$$

With such definitions $\overline{W}_\alpha^{\mathrm{nr}}$ results skew-adjoint with respect to the scalar product on $[\overline{D}^1(\mathsf{R}^3)]_{\mathrm{nr}}\oplus[L^2(\mathsf{R}^3)]_{\mathrm{nr}}$ given by

$$\langle\langle(\phi,\dot\phi),(\varphi,\dot\varphi)\rangle\rangle_\alpha^{\mathrm{nr}}:=\langle\dot\phi,\dot\varphi\rangle+\langle(-\overline{\Delta})^{1/2}\phi_{\mathrm{reg}},(-\overline{\Delta})^{1/2}\varphi_{\mathrm{reg}}\rangle-4\pi\lambda_0^{3/2}\langle\phi_{\mathrm{reg}},G_{\lambda_0}\rangle\langle\varphi_{\mathrm{reg}},G_{\lambda_0}\rangle.$$

Moreover, since

$$\overline{D}_\alpha^2(\mathsf{R}^3)\simeq[\overline{D}_\alpha^2(\mathsf{R}^3)]_{\mathrm{nr}}\oplus\mathsf{R},\quad \overline{D}^1(\mathsf{R}^3)\simeq[D^1(\mathsf{R}^3)]_{\mathrm{nr}}\oplus\mathsf{R},$$

similarly to the case of W_α, we have

$$\overline{W}_\alpha=\overline{W}_\alpha^{\mathrm{nr}}\times\Lambda_0.$$

For the case $\alpha=0$ a similar decomposition is possible by using the projection onto the subspace orthogonal to the eigenvector $(G,0)$. Indeed, defining

$$\overline{W}_{(0)}:\overline{H}_0^2(\mathsf{R}^3)\oplus D^1(\mathsf{R}^3)\to\overline{H}^1(\mathsf{R}^3)\oplus L^2(\mathsf{R}^3),\quad \overline{W}_{(0)}(\phi,\dot\phi):=(\dot\phi_{\mathrm{reg}},\overline{\boldsymbol{\Delta}}\phi),$$

where $\overline{H}_0^2(\mathsf{R}^3):=\{\phi\in\overline{H}^2(\mathsf{R}^3):\phi(\mathbf{0})=\mathbf{0}\}$, the operator $\overline{W}_{(0)}$ is skew-adjoint with respect to the scalar product

$$\langle\langle(\phi,\dot\phi),(\varphi,\dot\varphi)\rangle\rangle_{(0)}:=\langle\dot\varphi,\dot\varphi\rangle+\langle(-\overline{\Delta})^{1/2}\phi,(-\overline{\Delta})^{1/2}\varphi\rangle$$

and, since $\overline{D}^1(\mathsf{R}^3)\simeq\overline{H}^1(\mathsf{R}^3)\oplus\mathsf{R}$, the following decomposition holds:

$$\overline{W}_0=\overline{W}_{(0)}\times 0.$$

We can now state our result regarding the existence of dynamics.

Theorem 3.1: *$\overline{W}_\alpha$ is a closed operator coinciding with the closure of W_α. It generates a strongly continuous group of evolution,*

$$\overline{U}_\alpha^t:\overline{D}^1(\mathsf{R}^3)\oplus L^2(\mathsf{R}^3)\to\overline{D}^1(\mathsf{R}^3)\oplus L^2(\mathsf{R}^3),$$

which can be defined as

$$\overline{U}_\alpha^t(\phi,\dot\phi)=\lim_{n\uparrow\infty}U_\alpha^t(\phi_n,\dot\phi),$$

where $\{\phi_n\}_1^\infty\subset D^1(\mathsf{R}^3)$ is any sequence such that $\phi_n\to\phi$ in $\overline{D}^1(\mathsf{R}^3)$.

Proof: $\overline{W}_\alpha$ is a generator since it is skew-adjoint when $\alpha>0$ and $\overline{W}_0=\overline{W}_{(0)}\times 0$, $\overline{W}_\alpha=\overline{W}_\alpha^{\mathrm{nr}}\times\Lambda_0$, $\alpha<0$, where both $\overline{W}_{(0)}$ and $\overline{W}_\alpha^{\mathrm{nr}}$ are skew-adjoint. Therefore $\overline{W}_\alpha$ is closed. By its definition $\overline{W}_\alpha$ is equal to W_α on $D_\alpha^2(\mathsf{R}^3)\oplus D^1(\mathsf{R}^3)$ and so it coincides with the closure of W_α if $D_\alpha^2(\mathsf{R}^3)\oplus D^1(\mathsf{R}^3)$ is a core. This is proven as follows:

analogously to the case of W_α, any $\phi \in \overline{D^2_\alpha}(\mathsf{R}^3)$ admits the representation

$$\phi = \phi_\lambda + Q_\phi G_\lambda ,$$

where

$$\phi_\lambda = \phi_{\mathrm{reg}} - Q_\phi (G_\lambda - G) \in \overline{H^2}(\mathsf{R}^3)$$

and

$$\left(\alpha + \frac{\sqrt{\lambda}}{4\pi} \right) Q_\phi = \phi_\lambda(0).$$

Consider then a sequence ϕ^n_λ in $H^2(\mathsf{R}^3)$ and define

$$\phi_n := \phi^n_\lambda + Q_n G_\lambda \in D^2_\alpha(\mathsf{R}^3),$$

where

$$Q_n := \left(\alpha + \frac{\sqrt{\lambda}}{4\pi} \right)^{-1} \phi^n_\lambda(0).$$

Now if ϕ^n_λ converges in $\overline{H^2}(\mathsf{R}^3)$ to ϕ_λ, we have that Q_n converges to Q_ϕ, thanks to the continuous embedding of $\overline{H^2}(\mathsf{R}^3)$ in $C^0_b(\mathsf{R}^3)$ (see, e.g., Ref. 12, Sec. 5.6.2).

$\overline{W}_\alpha$ being equal to W_α on $D^2_\alpha(\mathsf{R}^3) \oplus D^1(\mathsf{R}^3)$, the same is true for the corresponding groups of evolution. Since $D^2_\alpha(\mathsf{R}^3) \oplus D^1(\mathsf{R}^3)$ is dense in $D^1(\mathsf{R}^3) \oplus L^2(\mathsf{R}^3)$ which is continuously embedded in $\overline{D^1}(\mathsf{R}^3) \oplus L^2(\mathsf{R}^3)$, one has the equality $\overline{U^t_\alpha}(\phi, \dot\phi) = U^t_\alpha(\phi, \dot\phi)$ for any $\phi \in D^1(\mathsf{R}^3)$. The proof is then concluded by the denseness of $D^1(\mathsf{R}^3)$ in $\overline{D^1}(\mathsf{R}^3)$. □

Let us remark, that since $\overline{W}_\alpha$ is the closure of W_α, our construction coincides, in the case $\alpha \geqslant 0$, with the abstract one given in Ref. 3 (see also Ref. 4, Sec. 8 for a similar construction). Moreover, since $W_\alpha = W^{\mathrm{nr}}_\alpha \times \Lambda_0$ when $\alpha < 0$, one has that $\overline{W}^{\mathrm{nr}}_\alpha$ is the closure of W^{nr}_α.

IV. THE SYMPLECTIC STRUCTURE

The standard symplectic structure recalled in the Introduction,

$$\omega((\phi, \dot\phi), (\varphi, \dot\varphi)) := \langle \phi, \dot\varphi \rangle - \langle \varphi, \dot\phi \rangle,$$

it is not well defined on the phase space of finite energy states, i.e., $\overline{D^1}(\mathsf{R}^3) \oplus L^2(\mathsf{R}^3)$. This requires a different approach to the Hamiltonian description of the dynamical system described in the previous paragraph. The problem shows up already in the case of the free wave equation, with the phase space $\overline{H^1}(\mathsf{R}^3) \oplus L^2(\mathsf{R}^3)$; usually in the standard literature on infinite dimensional Hamiltonian systems (see, e.g., Ref. 15) only the easier case of the free field with strictly positive mass is explicitly discussed.

We recall that (see Refs. 16, 15) when the Hilbert space carries a complex structure $\mathcal{J}$, it is possible to complexify the space in such a way that the imaginary part of the complex scalar product turns out to be a symplectic form, while the real part is the old (real) scalar product, coinciding with the energy. Any skew-adjoint operator A *commuting* with $\mathcal{J}$ remains skew-adjoint within the complex Hilbert space, so that $iA := \mathcal{J} \cdot A$ is self-adjoint. Therefore, since $e^{tA} \equiv e^{-it(iA)}$, A generates a strongly continuous group of unitary (hence symplectic) transformations. More precisely, collecting the known results on the subject (see, e.g., Ref. 15, Sec. 2.6, Sec. 2.7, Ref. 16, Chap. II), we state the following.

Theorem 4.1: *Let A be an injective skew-adjoint operator on the real Hilbert space H with inner product $\langle\cdot,\cdot\rangle$. Then the closure of the densely defined linear operator,*

$$A\cdot(-A^2)^{-1/2}:\mathrm{Range}\,(A)\to H,$$

defines a complex structure $\mathcal{J}$ commuting with A. Defining, for any $\psi\in H$, the multiplication by the complex number i as

$$i\,\psi:=\mathcal{J}\psi,$$

H becomes a complex Hilbert space with a Hermitian inner product,

$$[\psi_1,\psi_2]:=\langle\psi_1,\psi_2\rangle+i\,\langle\psi_1,\mathcal{J}\psi_2\rangle.$$

The strongly continuous one parameter group $U^t:=e^{tA}$ is a group of symplectic transformations relative to the symplectic form

$$\Omega(\psi_1,\psi_2):=\mathrm{Im}\,[\psi_1,\psi_2],$$

and the linear vector field,

$$A:D(A)\to H$$

is Hamiltonian with an associated densely defined Hamiltonian function

$$\mathcal{H}:D(\mathcal{Q})\to\mathsf{R},\quad \mathcal{H}(\psi):=\tfrac{1}{2}\,\mathcal{Q}(\psi),$$

where $\mathcal{Q}$ denotes the quadratic form associated to the self-adjoint operator $\mathcal{J}\cdot A$.

A wide class of examples is obtained by the following construction, which is a simple consequence of the above theorem. Let us consider an injective non-negative self-adjoint operator,

$$B:D(B)\to K$$

on the Hilbert space K and let us consider the closure of

$$\begin{pmatrix} 0 & 1 \\ -B^2 & 0 \end{pmatrix}$$

on the Hilbert space $H=\overline{D}(B)\oplus K$, where $\overline{D}(B)$ is the completion of $D(B)$ with respect to the norm $\|u\|_B:=\|Bu\|_K$. In the case in which this closure is injective, the complex structure $\mathcal{J}$ given by the previous theorem is

$$\mathcal{J}_B:\overline{D}(B)\oplus K\to\overline{D}(B)\oplus K,\quad \mathcal{J}_B(u,v)=(\overline{B}^{-1}v,\overline{B}u),$$

where $\overline{B}$ and $\overline{B}^{-1}$ are the closures, respectively, of B and its inverse $B^{-1}:\mathrm{Range}\,(B)\to\overline{D}(B)$. This allows us to endow H with the structure of a complex Hilbert space, which we continue to call H; precisely, defined a generic element as $w:=(u,v)\in\overline{D}(B)\oplus K$, the Hermitian scalar product in H is

$$[w_1,w_2]_B:=\langle\langle w_1,w_2\rangle\rangle_B+i\,\langle\langle w_1,\mathcal{J}_B w_2\rangle\rangle_B,$$

where

$$\langle\langle w_1,w_2\rangle\rangle_B:=\langle\overline{B}u_1,\overline{B}u_2\rangle+\langle v_1,v_2\rangle.$$

On the product $H\times H$ we have the symplectic form

$$\Omega_B : \overline{D}(B) \oplus K \times \overline{D}(B) \oplus K \to \mathsf{R}, \quad \mathbf{\Omega}_B(w_1, w_2) = \langle\langle w_1, \mathcal{J}_B w_2 \rangle\rangle.$$

With respect to the complex variable w, the wave equation,

$$\ddot{u} = -\overline{B^2} u, \tag{9}$$

assumes the Schrödinger-like form,

$$-i\,\dot{w} = \overline{B} w.$$

Moreover such an equation is Hamiltonian w.r.t. the symplectic form Ω_B and the densely defined Hamiltonian function,

$$\mathcal{H}_B : D(\overline{B}^{3/2}) \times D(\overline{B}^{1/2}) \to \mathsf{R}, \quad \mathcal{H}_B(w) = \tfrac{1}{2}(\|\overline{B}^{1/2} v\|^2 + \|\overline{B}^{3/2} u\|^2),$$

where the operator $\overline{B^s}$ is defined as the closure of B^s.

The strongly continuous symplectic group of operators obtained by solving Eq. (9) preserves the energy $\mathcal{E}_B(u,v) := \frac{1}{2}[w,w]_B$.

An immediate example is given by the choice $B = \sqrt{-\Delta} : H^1(\mathsf{R}^3) \to L^2(\mathsf{R}^3)$, corresponding to the standard wave equation and leading to the complex structure

$$\mathcal{J} : \overline{H}^1(\mathsf{R}^3) \oplus L^2(\mathsf{R}^3) \to \overline{H}^1(\mathsf{R}^3) \oplus L^2(\mathsf{R}^3),$$

$$\mathcal{J}(\phi, \dot{\phi}) := ((-\overline{\Delta})^{-1/2} \dot{\phi}, -(-\overline{\Delta})^{1/2} \phi).$$

Other concrete examples are obtained when the operator B^2 is a point interaction, more precisely $B = \sqrt{-\Delta_\alpha} : D^1(\mathsf{R}^3) \to L^2(\mathsf{R}^3)$ with $\alpha > 0$. In this case the corresponding complex structure is given by

$$\mathcal{J}_\alpha : \overline{D}^1(\mathsf{R}^3) \oplus L^2(\mathsf{R}^3) \to \overline{D}^1(\mathsf{R}^3) \oplus L^2(\mathsf{R}^3),$$

$$\mathcal{J}_\alpha(\phi, \dot{\phi}) := ((-\overline{\Delta}_\alpha)^{-1/2} \dot{\phi}, -(-\overline{\Delta}_\alpha)^{1/2} \phi).$$

The same procedure is not directly applicable to the cases $\alpha \leqslant 0$, due to the lack of skew-adjointness and injectivity for the operator $\overline{W}_\alpha$. A natural way out is to project the operator on the subspace of absolute continuity and to apply the abstract scheme to this projection. This works well for the case $\alpha < 0$, whereas the case $\alpha = 0$ deserves a different treatment. Here are the details of the two constructions.

In the case $\alpha < 0$ we have seen in Sec. III that $\overline{W}_\alpha^{\mathrm{nr}}$ is skew-adjoint, w.r.t. the scalar product $\langle\langle \cdot, \cdot \rangle\rangle_\alpha^{\mathrm{nr}}$, and one-to-one. Therefore we can apply to it Thm. 4.1 (or better the successive example with $B = \sqrt{-\Delta_\alpha^{\mathrm{nr}}}$) obtaining the complex structure $\mathcal{J}_\alpha$ commuting with W_α, $\alpha < 0$, defined as

$$\mathcal{J}_\alpha := \mathcal{J}_\alpha^{\mathrm{nr}} \times j,$$

where

$$\mathcal{J}_\alpha^{\mathrm{nr}} : [\overline{D}^1(\mathsf{R}^3)]_{\mathrm{nr}} \oplus [L^2(\mathsf{R}^3)]_{\mathrm{nr}} \to [\overline{D}^1(\mathsf{R}^3)]_{\mathrm{nr}} \oplus [L^2(\mathsf{R}^3)]_{\mathrm{nr}},$$

$$\mathcal{J}_\alpha^{\mathrm{nr}}(\phi, \dot{\phi}) = ((-\overline{\Delta}_\alpha^{\mathrm{nr}})^{-1/2} \dot{\phi}, -(-\overline{\Delta}_\alpha^{\mathrm{nr}})^{1/2} \phi)$$

and

$$j : \mathsf{R}^2 \to \mathsf{R}^2, \quad \mathrm{j}(x, \dot{x}) := (\dot{x}, -x).$$

Here, analogously to the case $\alpha>0$, the linear operators,

$$(-\overline{\Delta}_\alpha^{\mathrm{nr}})^{1/2}:[\overline{D^1}(\mathsf{R}^3)]_{\mathrm{nr}}\to[L^2(\mathsf{R}^3)]_{\mathrm{nr}},$$

and

$$(-\overline{\Delta}_\alpha^{\mathrm{nr}})^{-1/2}:[L^2(\mathsf{R}^3)]_{\mathrm{nr}}\to[\overline{D^1}(\mathsf{R}^3)]_{\mathrm{nr}},$$

are defined as the closures of

$$(-\Delta_\alpha^{\mathrm{nr}})^{1/2}:[D^1(\mathsf{R}^3)]_{\mathrm{nr}}\subset[\overline{D^1}(\mathsf{R}^3)]_{\mathrm{nr}}\to[L^2(\mathsf{R}^3)]_{\mathrm{nr}}$$

and

$$(-\Delta_\alpha^{\mathrm{nr}})^{-1/2}:\mathrm{Range}\,((-\Delta_\alpha^{\mathrm{nr}})^{1/2})\subset[L^2(\mathsf{R}^3)]_{\mathrm{nr}}\to[\overline{D^1}(\mathsf{R}^3)]_{\mathrm{nr}},$$

respectively.

We have then the complex Hilbert space of the couples,

$$(\psi,z):=((\phi,\dot\phi),(x,\dot x))\in[\overline{D^1}(\mathsf{R}^3)]_{\mathrm{nr}}\oplus[L^2(\mathsf{R}^3)]_{\mathrm{nr}}\oplus\mathsf{R}^2,$$

with the Hermitian scalar product

$$[(\psi_1,z_1),(\psi_2,z_2)]_\alpha:=[\psi_1,\psi_2]_\alpha^{\mathrm{nr}}+[z_1,z_2],$$

where

$$[\psi_1,\psi_2]_\alpha^{\mathrm{nr}}:=\langle\langle\psi_1,\psi_2\rangle\rangle_\alpha^{\mathrm{nr}}+i\,\langle\langle\psi_1,\mathcal{J}_\alpha^{\mathrm{nr}}\psi_2\rangle\rangle_\alpha^{\mathrm{nr}},$$

and

$$[z_1,z_2]:=(z_1,z_2)+i\,(z_1,jz_2),\quad (z_1,z_2):=\dot x_1\dot x_2+x_1x_2.$$

The associated symplectic form is

$$\Omega_\alpha:[\overline{D^1}(\mathsf{R}^3)]_{\mathrm{nr}}\oplus[L^2(\mathsf{R}^3)]_{\mathrm{nr}}\oplus\mathsf{R}^2\to\mathsf{R},$$

$$\Omega_\alpha((\psi_1,z_1),(\psi_2,z_2))=\langle\langle\psi_1,\mathcal{J}_\alpha^{\mathrm{nr}}\psi_2\rangle\rangle_\alpha^{\mathrm{nr}}+(z_1,jz_2).$$

With respect to the complex variables (ψ,z) the wave equation corresponding to W_α takes the Schrödinger-like form

$$\begin{cases}-i\,\dot\psi=(-\overline{\Delta}_\alpha^{\mathrm{nr}})^{1/2}\psi,\\ -i\,\dot z=L_0z,\end{cases}\qquad L_0:=\begin{pmatrix}-\lambda_0 & 0\\ 0 & 1\end{pmatrix},$$

and such an equation is Hamiltonian w.r.t. the symplectic form Ω_α and the densely defined Hamiltonian function

$$\mathcal{H}_\alpha:D(\mathcal{Q}_\alpha^{\mathrm{nr}})\oplus\mathsf{R}^2\to\mathsf{R},\quad \mathcal{H}_\alpha(\psi,z)=\tfrac12\,\mathcal{Q}_\alpha^{\mathrm{nr}}(\psi)+\tfrac12\,(L_0z,z),$$

where

$$\mathcal{Q}_\alpha^{\mathrm{nr}}(\phi,\dot\phi)=\tfrac12\,(\|(-\overline{\Delta}_\alpha^{\mathrm{nr}})^{1/4}\dot\phi\|_2^2+\|(-\overline{\Delta}_\alpha^{\mathrm{nr}})^{3/4}\phi\|_2^2)$$

is the quadratic form associated to the self-adjoint operator $\mathcal{J}_\alpha^{\mathrm{nr}}\cdot W_\alpha^{\mathrm{nr}}$.

If $(\phi,\dot{\phi})\in \overline{D}^1(\mathsf{R}^3)\oplus L^2(\mathsf{R}^3)$ has the orthogonal decomposition $(\phi,\dot{\phi})\equiv\psi+z\tilde{G}$, where $\tilde{G}$ denotes the normalized eigenvector corresponding to λ_0, then

$$\mathcal{E}_\alpha(\phi,\dot{\phi})=\tfrac{1}{2}[\psi,\psi]^{\mathrm{nr}}_\alpha+\tfrac{1}{2}(L_0 z,z).$$

Therefore, being

$$\overline{U}^t_\alpha=e^{t\overline{W}^{\mathrm{nr}}_\alpha}\times e^{t\Lambda_0},$$

a strongly continuous group of unitary and symplectic transformations, the energy is conserved by the flow.

We come now to the case $\alpha=0$. In this case, in order to apply Thm. 4.1, which requires injectivity, it is necessary to project onto the subspace orthogonal to the eigenvector $(G,0)$. Being $\overline{W}_{(0)}$ one-to-one and skew-adjoint w.r.t. the scalar product $\langle\langle\cdot,\cdot\rangle\rangle_{(0)}$, one can then apply Thm. 4.1 thus obtaining a one parameter group $\overline{U}^t_{(0)}$ of symplectic transformations such that

$$\overline{U}^t_0=\overline{U}^t_{(0)}\times 1,$$

and so $\overline{U}^t_0$ preserves the energy $\mathcal{E}_0(\phi,\dot{\phi})=\mathcal{E}(\phi_{\mathrm{reg},},\dot{\phi})$.

Since $(-\Delta_0)^{1/2}\phi=(-\overline{\Delta})^{1/2}\phi_{\mathrm{reg}}$ (note that this equality holds true only in the case $\alpha=0$) one has

$$\phi_{\mathrm{reg}}=(-\overline{\Delta})^{-1/2}\cdot(-\Delta_0)^{1/2}\phi,$$

and so, when $(\phi,\dot{\phi})\in\overline{H}^2_0(\mathsf{R}^3)\oplus D^1(\mathsf{R}^3)$,

$$\mathcal{J}\cdot\overline{W}_{(0)}(\phi,\dot{\phi})=((-\overline{\Delta})^{1/2}\phi,(-\Delta_0)^{1/2}\dot{\phi})\equiv((-\overline{\Delta}_0)^{1/2}\phi,(-\Delta_0)^{1/2}\dot{\phi}).$$

Moreover, $\mathcal{J}$ commutes with $\overline{W}_{(0)}$ [see (15) in the next section] and so $\mathcal{J}$ coincides with the complex structure associated to $\overline{W}_{(0)}$ by Thm. 4.1. With respect to the complex variable $\psi=(\phi,\dot{\phi})$ the wave equation corresponding to $\overline{W}_{(0)}$ assumes the Schrödinger-like form

$$-i\dot{\psi}=(-\overline{\Delta}_0)^{1/2}\psi.$$

We summarize the results obtained in the following.

Theorem 4.2: *For every $\alpha\in\mathsf{R}\backslash\{\mathbf{0}\}$ there exists a symplectic form,*

$$\Omega_\alpha:\overline{D}^1(\mathsf{R}^3)\oplus L^2(\mathsf{R}^3)\times\overline{D}^1(\mathsf{R}^3)\oplus L^2(\mathsf{R}^3)\to\mathsf{R},$$

with respect to which the vector field

$$\overline{W}_\alpha:\overline{D}^2_\alpha(\mathsf{R}^3)\times D^1(\mathsf{R}^3)\to\overline{D}^1(\mathsf{R}^3)\oplus L^2(\mathsf{R}^3)$$

is Hamiltonian. Moreover for $\alpha\leqslant 0$ the analogous result occurs for the reduced vector fields,

$$\overline{W}^{\mathrm{nr}}_\alpha:[\overline{D}^2_\alpha(\mathsf{R}^3)]_{\mathrm{nr}}\times[\overline{D}^1(\mathsf{R}^3)]_{\mathrm{nr}}\to[\overline{D}^1(\mathsf{R}^3)]_{\mathrm{nr}}\oplus[L^2(\mathsf{R}^3)]_{\mathrm{nr}}$$

and

$$\overline{W}_{(0)}:\overline{H}^2_0(\mathsf{R}^3)\oplus D^1(\mathsf{R}^3)\to\overline{H}^1(\mathsf{R}^3)\oplus L^2(\mathsf{R}^3).$$

For every $\alpha\in\mathsf{R}$ the evolution group $\overline{U}^t_\alpha$ preserves the energy,

$$\mathcal{E}_\alpha(\phi,\dot\phi)=\tfrac{1}{2}(\|\dot\phi\|_2^2+F_\alpha(\phi,\phi)).$$

V. SCATTERING THEORY

The Hilbert spaces where the operators $\overline{W}_\alpha$ and $\overline{W}$ act on, respectively, $\overline{D^1}(\mathsf{R}^3)\oplus L^2(\mathsf{R}^3)$ and $\overline{H^1}(\mathsf{R}^3)\oplus L^2(\mathsf{R}^3)$, are different (also as sets), and so one is forced to use a two Hilbert space formulation to treat scattering theory for the pair $(\overline{W}_\alpha,\overline{W})$. We refer to the seminal paper by Kato[4] for the relevant constructions and results in scattering theory with two Hilbert spaces. Our approach will follow the lines of the construction given in Ref. 4, Secs. 8–9 (also see Ref. 17, Sec. 3.5).

From now on, given the real vector space $L^2(\mathsf{R}^3)$, we will denote by $L^2_{\mathsf{C}}(\mathsf{R}^3)$ the complex vector space,

$$L^2_{\mathsf{C}}(\mathsf{R}^3):=\{\phi_1+i\phi_2,\phi_1,\phi_2\in L^2(\mathsf{R}^3)\}.$$

We begin introducing the isometries

$$C:\overline{H^1}(\mathsf{R}^3)\oplus L^2(\mathsf{R}^3)\to L^2_{\mathsf{C}}(\mathsf{R}^3),$$

$$C(\phi,\dot\phi)\equiv C_0(\phi,\dot\phi):=(-\overline{\Delta})^{1/2}\phi-i\dot\phi,$$

$$C_\alpha:\overline{D^1}(\mathsf{R}^3)\oplus L^2(\mathsf{R}^3)\to L^2_{\mathsf{C}}(\mathsf{R}^3),\quad \alpha>0,$$

$$C_\alpha(\phi,\dot\phi):=(-\overline{\Delta}_\alpha)^{1/2}\phi-i\dot\phi,$$

$$C_\alpha:[\overline{D^1}(\mathsf{R}^3)]_{\mathrm{nr}}\oplus[L^2(\mathsf{R}^3)]_{\mathrm{nr}}\to[L^2_{\mathsf{C}}(\mathsf{R}^3)]_{\mathrm{nr}},\quad \alpha<0,$$

$$C_\alpha((\phi,\dot\phi)):=(-\overline{\Delta}^{\mathrm{nr}}_\alpha)^{1/2}\phi-i\dot\phi.$$

These isometries lead to the following relations:

$$\mathcal{J}=C^{-1}\cdot iC, \tag{10}$$

$$\mathcal{J}_\alpha=C_\alpha^{-1}\cdot i\,C_\alpha,\quad \alpha>0,\quad \mathcal{J}^{\mathrm{nr}}_\alpha=C_\alpha^{-1}\cdot i\,C_\alpha,\quad \alpha<0, \tag{11}$$

$$\overline{U}^t=C^{-1}\cdot e^{it\sqrt{-\Delta}}\cdot C,$$

$$\overline{U}^t_0=C^{-1}\cdot e^{it\sqrt{-\Delta_0}}\cdot C\times 1, \tag{12}$$

$$\overline{U}^t_\alpha=C_\alpha^{-1}\cdot e^{it\sqrt{-\Delta_\alpha}}\cdot C_\alpha,\quad \alpha>0, \tag{13}$$

$$\overline{U}^t_\alpha=C_\alpha^{-1}\cdot e^{it\sqrt{-\Delta^{\mathrm{nr}}_\alpha}}\cdot C_\alpha\times e^{t\Lambda_0},\quad \alpha<0. \tag{14}$$

Note that the two equalities,

$$\mathcal{J}=C^{-1}\cdot i\,C,\quad \overline{U}^t_{(0)}=C^{-1}\cdot e^{it\sqrt{-\Delta_0}}\cdot C, \tag{15}$$

imply, as we stated in the previous section, that $\mathcal{J}$ commutes with $\overline{W}_{(0)}$.

Moreover the relations (12)–(14) provide an alternative construction of the dynamics generated by $\overline{W}_\alpha$. In fact one could use such relations as definitions of $\overline{U}^t_\alpha$ and then check by differentiating with respect to the time parameter that this evolution group is generated by the operator $\overline{W}_\alpha$.

We introduce now the identification operators,

$$J_\alpha : \overline{D}^1(\mathbf{R}^3) \oplus L^2(\mathbf{R}^3) \to \overline{H}^1(\mathbf{R}^3) \oplus L^2(\mathbf{R}^3),$$

$$J_\alpha(\phi, \dot{\phi}) := \begin{cases} ((-\overline{\Delta})^{-1/2} \cdot (-\overline{\Delta}_\alpha)^{1/2} \phi, \dot{\phi}), & \text{for } \alpha > 0, \\ (\phi_{\mathrm{reg}}, \dot{\phi}) \equiv ((-\overline{\Delta})^{-1/2} \cdot (-\overline{\Delta}_0)^{1/2} \phi, \dot{\phi}), & \text{for } \alpha = 0, \\ ((-\overline{\Delta})^{-1/2} \cdot (-\overline{\Delta}_\alpha^{\mathrm{nr}})^{1/2} \cdot \Pi_{\mathrm{nr}} \phi, \dot{\phi}), & \text{for } \alpha < 0, \end{cases}$$

where Π_{nr} denotes the projection

$$\Pi_{\mathrm{nr}} : \overline{D}^1(\mathbf{R}^3) \to [\overline{D}^1(\mathbf{R}^3)]_{\mathrm{nr}},$$

and

$$J'_\alpha : \overline{H}^1(\mathbf{R}^3) \oplus L^2(\mathbf{R}^3) \to \overline{D}^1(\mathbf{R}^3) \oplus L^2(\mathbf{R}^3),$$

$$J'_\alpha(\phi, \dot{\phi}) := \begin{cases} ((-\overline{\Delta}_\alpha)^{-1/2} \cdot (-\overline{\Delta})^{1/2} \phi, \dot{\phi}), & \text{for } \alpha > 0 \\ (\phi, \dot{\phi}), & \text{for } \alpha = 0 \\ ((-\overline{\Delta}_\alpha^{\mathrm{nr}})^{-1/2} \cdot P_{\mathrm{nr}} \cdot (-\overline{\Delta})^{1/2} \phi, \dot{\phi}), & \text{for } \alpha < 0. \end{cases}$$

We can then define the Möller wave operators,

$$\Omega_\pm(\overline{W}, \overline{W}_\alpha; J_\alpha) := \text{s-} \lim_{t \to \pm\infty} \overline{U}^{-t} \cdot J_\alpha \cdot \overline{U}_\alpha^t \cdot P_{\mathrm{ac}}(\overline{W}_\alpha),$$

$$\Omega_\pm(\overline{W}_\alpha, \overline{W}; J'_\alpha) := \text{s-} \lim_{t \to \pm\infty} \overline{U}_\alpha^{-t} \cdot J'_\alpha \cdot \overline{U}^t,$$

where

$$P_{\mathrm{ac}}(\overline{W}_\alpha) : \overline{D}^1(\mathbf{R}^3) \oplus L^2(\mathbf{R}^3) \to \overline{D}^1(\mathbf{R}^3) \oplus L^2(\mathbf{R}^3),$$

$$P_{\mathrm{ac}}(\overline{W}_\alpha)(\phi, \dot{\phi}) := \begin{cases} (\phi, \dot{\phi}), & \text{for } \alpha > 0, \\ (\phi_{\mathrm{reg}}, \dot{\phi}), & \text{for } \alpha = 0, \\ (\Pi_{\mathrm{nr}} \phi, P_{\mathrm{nr}} \dot{\phi}), & \text{for } \alpha < 0. \end{cases}$$

Concerning the existence of such wave operators, we have the following

Theorem 5.1: *The Möller wave operators,*

$$\Omega_\pm(\overline{W}, \overline{W}_\alpha; J_\alpha) := \text{s-} \lim_{t \to \pm\infty} \overline{U}^{-t} \cdot J_\alpha \cdot \overline{U}_\alpha^t \cdot P_{\mathrm{ac}}(\overline{W}_\alpha),$$

$$\Omega_\pm(\overline{W}_\alpha, \overline{W}; J'_\alpha) := \text{s-} \lim_{t \to \pm\infty} \overline{U}_\alpha^{-t} \cdot J'_\alpha \cdot \overline{U}^t,$$

exist, are complete and are mutually adjoint isometries, i.e.,

$$\mathrm{Range}\, \Omega_+(\overline{W}, \overline{W}_\alpha; J_\alpha) = \mathrm{Range}\, \Omega_-(\overline{W}, \overline{W}_\alpha; J_\alpha) = \overline{H}^1(\mathbf{R}^3) \oplus L^2(\mathbf{R}^3),$$

$$\mathrm{Range}\, \Omega_+(\overline{W}_\alpha, \overline{W}; J'_\alpha) = \mathrm{Range}\, \Omega_-(\overline{W}_\alpha, \overline{W}; J'_\alpha) = \mathrm{Range}\, P_{\mathrm{ac}}(\overline{W}_\alpha),$$

$$\Omega_{\pm}(\overline{W},\overline{W}_{\alpha};J_{\alpha})^{*}\cdot\Omega_{\pm}(\overline{W},\overline{W}_{\alpha};J_{\alpha})=P_{\mathrm{ac}}(\overline{W}_{\alpha}),$$

$$\Omega_{\pm}(\overline{W}_{\alpha},\overline{W};J'_{\alpha})^{*}\cdot\Omega_{\pm}(\overline{W}_{\alpha},\overline{W};J'_{\alpha})=1_{\overline{H^{1}}(\mathbb{R}^{3})\oplus L^{2}(\mathbb{R}^{3})},$$

$$\Omega_{\pm}(\overline{W},\overline{W}_{\alpha};J_{\alpha})^{*}=\Omega_{\pm}(\overline{W}_{\alpha},\overline{W};J'_{\alpha}).$$

Proof: With the above definitions one has

$$\Omega_{\pm}(\overline{W},\overline{W}_{\alpha};J_{\alpha})=C^{-1}\cdot\Omega_{\pm}(\sqrt{-\Delta},\sqrt{H_{\alpha}};I_{\alpha})\cdot C_{\alpha}\cdot P_{\mathrm{ac}}(\overline{W}_{\alpha}),$$

$$\Omega_{\pm}(\overline{W}_{\alpha},\overline{W};J'_{\alpha})=C_{\alpha}^{-1}\cdot\Omega_{\pm}(\sqrt{H_{\alpha}},\sqrt{-\Delta};I'_{\alpha})\cdot C,$$

where

$$\Omega_{\pm}(\sqrt{-\Delta},\sqrt{H_{\alpha}};I_{\alpha}):=\text{s-}\lim_{t\to\pm\infty}e^{-it\sqrt{-\Delta}}\cdot I_{\alpha}\cdot e^{it\sqrt{H_{\alpha}}},$$

$$\Omega_{\pm}(\sqrt{H_{\alpha}},\sqrt{-\Delta};I'_{\alpha}):=\text{s-}\lim_{t\to\pm\infty}e^{-it\sqrt{H_{\alpha}}}\cdot I'_{\alpha}\cdot e^{it\sqrt{-\Delta}}.$$

Here $I'_{\alpha}:=P_{\mathrm{ac}}(-\Delta_{\alpha})$, I_{α} is its left inverse, and

$$H_{\alpha}:=\begin{cases}-\Delta_{\alpha}, & \text{for } \alpha\geqslant 0\\ -\Delta_{\alpha}^{\mathrm{nr}}, & \text{for } \alpha<0.\end{cases}$$

By Birman invariance principle one has

$$\Omega_{\pm}(\sqrt{-\Delta},\sqrt{H_{\alpha}};I_{\alpha})=\Omega_{\pm}(-\Delta,H_{\alpha};I_{\alpha})$$

and

$$\Omega_{\pm}(\sqrt{H_{\alpha}},\sqrt{-\Delta};I'_{\alpha})=\Omega_{\pm}(H_{\alpha},-\Delta;I'_{\alpha}).$$

Therefore one has the identities

$$\Omega_{\pm}(\sqrt{-\Delta},\sqrt{H_{\alpha}};I_{\alpha})=\text{s-}\lim_{t\to\pm\infty}e^{it\Delta}\cdot I_{\alpha}\cdot e^{itH_{\alpha}}=\text{s-}\lim_{t\to\pm\infty}e^{it\Delta}\cdot e^{-it\Delta_{\alpha}}\cdot P_{\mathrm{ac}}(-\Delta_{\alpha})=\Omega_{\pm}(-\Delta,-\Delta_{\alpha})$$

and

$$\begin{aligned}\Omega_{\pm}(\sqrt{H_{\alpha}},\sqrt{-\Delta};I'_{\alpha})&=\text{s-}\lim_{t\to\pm\infty}e^{-itH_{\alpha}}\cdot I'_{\alpha}\cdot e^{-it\Delta}\\&=\text{s-}\lim_{t\to\pm\infty}P_{\mathrm{ac}}(-\Delta_{\alpha})\cdot e^{it\Delta_{\alpha}}\cdot e^{-it\Delta}\\&=P_{\mathrm{ac}}(-\Delta_{\alpha})\cdot\Omega_{\pm}(-\Delta_{\alpha},-\Delta)=\Omega_{\pm}(-\Delta_{\alpha},-\Delta).\end{aligned}$$

In conclusion one obtains the equalities

$$\Omega_{\pm}(\overline{W},\overline{W}_{\alpha};J_{\alpha})=C^{-1}\cdot\Omega_{\pm}(-\Delta,-\Delta_{\alpha})\cdot C_{\alpha}\cdot P_{\mathrm{ac}}(\overline{W}_{\alpha}),$$

$$\Omega_{\pm}(\overline{W}_{\alpha},\overline{W};J'_{\alpha})=C_{\alpha}^{-1}\cdot\Omega_{\pm}(-\Delta_{\alpha},-\Delta;)\cdot C,$$

and the proof is concluded since the wave operators $\Omega_{\pm}(-\Delta,-\Delta_\alpha)$, and $\Omega_{\pm}(-\Delta_\alpha,-\Delta)$ exist, are complete and are mutually adjoint isometries. This is proven (see Ref. 11, Appendix E) by the Birman–Kuroda theorem being the resolvent difference,

$$(-\Delta_\alpha+z)^{-1}-(-\Delta+z)^{-1},$$

a rank one (hence trace class) operator. □

The previous theorem holds true also with the different (α-independent and much simpler and natural) couple of identification operators defined by

$$J:\overline{D^1}(\mathsf{R}^3)\oplus L^2(\mathsf{R}^3)\to\overline{H^1}(\mathsf{R}^3)\oplus L^2(\mathsf{R}^3),\quad J(\phi,\dot\phi):=(\phi_{\mathrm{reg}},\dot\phi),$$

$$J':\overline{H^1}(\mathsf{R}^3)\oplus L^2(\mathsf{R}^3)\to\overline{D^1}(\mathsf{R}^3)\oplus L^2(\mathsf{R}^3),\quad J'(\phi,\dot\phi):=(\phi,\dot\phi).$$

This is true by Ref. 4, Thms. 10.3 and 10.5 since the condition 10.1 in Ref. 4 is verified with $m=M=1$. In our situation such a condition simply reads as

$$\forall\,\phi\in H^1(\mathsf{R}^3)\cap\mathrm{Range}\,P_{\mathrm{ac}}(-\mathbf{\Delta}_\alpha),\quad \|\sqrt{H_\alpha}\,\phi\|_{L^2}=\|\sqrt{-\mathbf{\Delta}}\,\phi\|_{L^2}.$$

In more detail one has the following.

Theorem 5.2: *J is $(\overline{U}^t_\alpha,\pm)$-equivalent to J_α, i.e.,*

$$\text{s-}\lim_{t\to\pm\infty}(J_\alpha-J)\cdot\overline{U}^t_\alpha\cdot P_{\mathrm{ac}}(\overline{W}_\alpha)=0.$$

Therefore

$$\Omega_{\pm}(\overline{W},\overline{W}_\alpha;J):=\text{s-}\lim_{t\to\pm\infty}\overline{U}^{-t}\cdot J\cdot\overline{U}^t_\alpha\cdot P_{\mathrm{ac}}(\overline{W}_\alpha)$$

exist and are equal to $\Omega_{\pm}(\overline{W},\overline{W}_\alpha;J_\alpha)$.

J' is a $(\overline{U}^t_\alpha,\pm)$-asymptotic left-inverse to J, i.e.,

$$\text{s-}\lim_{t\to\pm\infty}(J'\cdot J-1)\cdot\overline{U}^t_\alpha\cdot P_{\mathrm{ac}}(\overline{W}_\alpha)=0,$$

thus

$$\Omega_{\pm}(\overline{W}_\alpha,\overline{W};J'):=\text{s-}\lim_{t\to\pm\infty}\overline{U}^{-t}_\alpha\cdot J'\cdot\overline{U}^t$$

exist and are equal to $\Omega_{\pm}(\overline{W},\overline{W}_\alpha;J)^*\equiv\Omega_{\pm}(\overline{W}_\alpha,\overline{W};J'_\alpha)$.

Fractional differential forms

Kathleen Cottrill-Shepherd[a] and Mark Naber[b]
Department of Mathematics, Monroe County Community College, Monroe, Michigan 48161-9746

(Received 15 November 2000; accepted for publication 16 February 2001)

A generalization of exterior calculus is considered by allowing the partial derivatives in the exterior derivative to assume fractional orders. That is, a fractional exterior derivative is defined. This is found to generate new vector spaces of finite and infinite dimension, fractional differential form spaces. The definitions of closed and exact forms are extended to the new fractional form spaces with closure and integrability conditions worked out for a special case. Coordinate transformation rules are also computed. The transformation rules are different from those of the standard exterior calculus due to the properties of the fractional derivative. The metric for the fractional form spaces is given, based on the coordinate transformation rules. All results are found to reduce to those of standard exterior calculus when the order of the coordinate differentials is set to one. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1364688]

I. INTRODUCTION

In recent years exterior calculus has been generalized by basing it on various graded algebras, see, e.g., Refs. 1 and 2. Other attempts at generalization are based on nonassociative geometries, see, e.g., Refs. 3 and 4. In this paper another attempt at generalization is made using fractional derivatives in the definition of the exterior derivative. That is, a fractional exterior derivative is defined. Having a fractional exterior derivative gives rise to the notion of coordinate differentials of fractional order. These in turn can be used to define vector spaces of fractional differential forms. This formalism is found to produce an infinite number of finite and infinite dimensional vector spaces associated with each point $P \in E^n$ (n dimensional Euclidean space).

In Secs. II and III a brief review of exterior calculus and fractional calculus will be given to fix notation and provide a convenient reference. They are by no means complete, but are sufficient for the purposes of this paper. Section IV defines fractional form spaces based on the fractional exterior derivative. Basis sets are given for the new vector spaces and notation is fixed. In Sec. V the definitions of closed and exact are expanded to include the fractional form case. Once defined, the notions of closed and exact forms are examined for these new vector spaces. In both cases the results reduce to those found in standard exterior calculus when the order of the coordinate differentials is set equal to one. Coordinate transformations are worked out for the fractional form spaces in Sec. VI. The transformation rules are somewhat more complicated than for standard exterior calculus. They do, however, reduce to the usual transformation rules when the order or the coordinate differentials is set to one. Having found the coordinate transformation rule, a metric for the fractional form spaces is constructed. Metrical properties of these new vector spaces will be investigated in a later paper.

The convention in the literature is that the coordinate index is a superscript. For the topics presented in this paper it is more convenient for the coordinate index to be a subscript rather than the traditional superscript. To avoid confusion with this, the summation convention will not be used in this paper.

II. BRIEF REVIEW OF DIFFERENTIAL FORMS

The calculus of differential forms is an elegant branch of pure mathematics and a powerful tool in applied mathematics. A clear introduction to the field, with emphasis on applications, is given in Flanders.[5] Vector spaces at a point $P \in E^n$ (n dimensional Euclidean space) can be constructed out of expressions of the following type:

$$\text{one forms,} \quad \alpha = \sum_{i=1}^{n} a_i \, dx_i , \tag{1}$$

$$\text{two forms,} \quad \beta = \sum_{i,j=1}^{n} b_{ij} \, dx_i \wedge dx_j , \tag{2}$$

$$\vdots$$

$$\text{``}n\text{''} \text{ forms,} \quad \omega = w \, dx_1 \wedge dx_2 \wedge \cdots \wedge dx_n , \tag{3}$$

where the $\{x_i\}$ are the Cartesian coordinates of E^n. The above sums are taken over all possible values of the indices with the constraint that

$$dx_i \wedge dx_j = - dx_j \wedge dx_i . \tag{4}$$

The functions a_i , b_{ij}, etc., depend only on P and may be real or complex depending on the application. If a k form, γ, is multiplying an m form, μ, the following would be true:

$$\gamma \wedge \mu = (-1)^{km} \mu \wedge \gamma. \tag{5}$$

The result would be zero if $k+m>n$. The exterior product, $\wedge$, is distributive, associative, and antisymmetric. The dimension of the vector space of k forms over $P \in E^n$ is

$$\binom{n}{k} = \frac{n!}{k!(n-k)!},$$

which is zero if $k>n$. For the purposes of this paper let $F(k,k,n)$ denote the vector space of k forms over $P \in E^n$. The apparently redundant ''k'' in the above notation will be needed later for the fractional form case, as there is some additional freedom.

The exterior derivative is defined as

$$d = \sum_{i=1}^{n} dx_i \frac{\partial}{\partial x_i}. \tag{6}$$

The exterior derivative maps k forms into $k+1$ forms and has the following algebraic properties. Let γ and λ be k forms, and μ be an m form, then

$$d(\gamma + \lambda) = d\gamma + d\lambda, \tag{7}$$

$$d(\gamma \wedge \mu) = (d\gamma) \wedge \mu + (-1)^k \gamma \wedge d\mu, \tag{8}$$

$$d(d\gamma) = 0. \tag{9}$$

The last identity is called the Poincaré lemma. A form, γ, is called closed if $d\gamma = 0$. A form, γ, is called exact if there exists a form, μ, such that $d\mu = \gamma$. The order of μ is one less than the order of γ. Exact forms are always closed. Closed forms are not always exact. The interested reader should consult Flanders[5] or Lovelock and Rund[6] for further details.

III. BRIEF OVERVIEW OF FRACTIONAL CALCULUS

There are many books that develop fractional calculus and the various definitions of fractional integration and differentiation. The reader should consult Refs. 7–9 for further details and applications. For the purposes of this paper the Riemann–Liouville definition of fractional integration and differentiation will be used. $\Gamma(q)$ is the gamma function (generalized factorial) of the parameter ''q'' [i.e., $\Gamma(n+1)=n!$ for all whole numbers, ''n''],

$$\frac{\partial^q f(x)}{(\partial(x-a))^q}=\frac{1}{\Gamma(-q)}\int_a^x \frac{f(\xi)\mathrm{d}\xi}{(x-\xi)^{q+1}}, \quad \mathrm{Re}(q)<0, \tag{10}$$

$$\frac{\partial^q f(x)}{(\partial(x-a))^q}=\frac{\partial^n}{\partial x^n}\left[\frac{1}{\Gamma(n-q)}\int_a^x \frac{f(\xi)\mathrm{d}\xi}{(x-\xi)^{q-n+1}}\right], \quad \frac{\mathrm{Re}(q)\geqslant 0}{n>q(n \text{ is whole})}. \tag{11}$$

The parameter q is the order of the integral or derivative and is allowed to be complex. Positive real values of q represent derivatives and negative real values represent integrals.

Equation (10) is a fractional integral and Eq. (11) is a fractional derivative. In this paper only real and positive values of q will be considered. Notice that the derivative written in this form becomes a nonlocal object. Fractional derivatives have many interesting properties. For example the derivative of a constant need not be zero (the initial point a in the above-given definition is set to zero in the following),

$$\frac{\partial^q 1}{(\partial x)^q}=\frac{x^{-q}}{\Gamma(1-q)}. \tag{12}$$

The derivative of powers of x is

$$\frac{\partial^q x^p}{(\partial x)^q}=\frac{\Gamma(p+1)}{\Gamma(p-q+1)}x^{p-q}, \quad \frac{p>-1}{q\geqslant 0}. \tag{13}$$

Composition and product rules for fractional derivatives are given in the following. In the following, n is a whole number and q is a complex number whose real part is greater than zero,

$$\frac{\partial^n}{\partial x^n}\frac{\partial^q}{(\partial(x-a))^q}f(x)=\frac{\partial^{n+q}}{(\partial(x-a))^{n+q}}f(x), \tag{14}$$

$$\frac{\partial^q}{(\partial(x-a))^q}\frac{\partial^{-q}}{(\partial(x-a))^{-q}}f(x)=f(x), \tag{15}$$

$$\frac{\partial^{-q}}{(\partial(x-a))^{-q}}\frac{\partial^q}{(\partial(x-a))^q}f(x)\neq f(x). \tag{16}$$

Composing derivatives where both have fractional order is given by the following formula:

$$\frac{\partial^p}{(\partial(x-a))^p}\frac{\partial^q}{(\partial(x-a))^q}f(x)=\frac{\partial^{p+q}}{(\partial(x-a))^{p+q}}f(x)-\sum_{j=1}^{k}\frac{\partial^{q-j}}{(\partial(x-a))^{q-j}}f(x)\bigg|_{x=a}\frac{(x-a)^{-p-j}}{\Gamma(1-p-j)}, \tag{17}$$

where $0\leqslant k-1\leqslant q\leqslant k$, $p\geqslant 0$, and k is a whole number. The product rule is

$$\frac{\partial^q}{(\partial x)^q}(fg)=\sum_{j=0}^{\infty}\binom{q}{j}\left(\frac{\partial^{q-j}f}{(\partial x)^{q-j}}\right)\left(\frac{\partial^j g}{\partial x^j}\right). \tag{18}$$

The above-mentioned formula and definitions can be found in Refs. 7–9.

IV. FRACTIONAL FORM SPACES

If the partial derivatives in the definition of the exterior derivative are allowed to assume fractional orders, a fractional exterior derivative can be defined

$$\mathrm{d}^{\nu}=\sum_{i=1}^{n}\mathrm{d}x_i^{\nu}\frac{\partial^{\nu}}{(\partial(x_i-a_i))^{\nu}}. \tag{19}$$

Note that the subscript i denotes the coordinate number, the superscript ν denotes the order of the fractional coordinate differential, and a_i is the initial point of the derivative.

Sometimes the notation ∂_i^{ν} will be used to denote

$$\frac{\partial^{\nu}}{(\partial(x_i-a_i))^{\nu}}.$$

In two dimensions (x,y), the fractional exterior derivative of order ν of x^p, with the initial point taken to be the origin, is given by

$$\mathrm{d}^{\nu}x^p=\mathrm{d}x^{\nu}\frac{\Gamma(p+1)}{\Gamma(p-\nu+1)}x^{p-\nu}+\mathrm{d}y^{\nu}\frac{x^p}{y^{\nu}\Gamma(1-\nu)}. \tag{20}$$

For specific values of the derivative parameter the following results are obtained:

$$\nu=0,\quad \mathrm{d}^0x^p=2x^p, \tag{21}$$

$$\nu=1,\quad \mathrm{d}^1x^p=\mathrm{d}x^1px^{p-1}, \tag{22}$$

$$\nu=2,\quad \mathrm{d}^2x^p=\mathrm{d}x^2\,p(p-1)x^{p-2}. \tag{23}$$

By analogy with standard exterior calculus, vector spaces can be constructed using the $\mathrm{d}x_i^{\nu}$. Let $\mathrm{F}(\nu,m,n)$ be a vector space at $P\in E^n$. ν denotes the sum of the fractional differential orders of the basis elements, m denotes the number of coordinate differentials appearing in the basis elements, n the number of coordinates, and $\{x_i\}$ are the Cartesian coordinates for E^n. For example, a basis set for $\mathrm{F}(\nu,1,n)$ would be $\{\mathrm{d}x_1^{\nu},\mathrm{d}x_2^{\nu},\ldots,\mathrm{d}x_n^{\nu}\}$ and arbitrary element of $F(\nu,1,n)$ would be expressed as

$$\alpha=\sum_{i=1}^{n}\alpha_i\,\mathrm{d}x_i^{\nu}. \tag{24}$$

For a fixed ν this is an n dimensional vector space. Also note that there is a different vector space for each value of ν. For $\nu=1$ the one forms from exterior calculus are recovered. Now suppose that the basis elements are made up of two coordinate differentials, $F(\nu,2,n)$. In this case the basis set is more complicated,

$$\{\mathrm{d}x_1^{\mu_{11}}\wedge\mathrm{d}x_1^{\mu_{21}},\mathrm{d}x_1^{\mu_{11}}\wedge\mathrm{d}x_2^{\mu_{31}},\ldots,\mathrm{d}x_n^{\mu_{n-1m}}\wedge\mathrm{d}x_n^{\mu_{\mathrm{nm}}}|\,\mu_{ij}+\mu_{kj}=\nu\}. \tag{25}$$

Note that $\mathrm{d}x_1^{\mu_{11}}\wedge\mathrm{d}x_1^{\mu_{21}}$ would be zero if and only if $\mu_{11}=\mu_{21}$, etc. An arbitrary element of $F(\nu,2,n)$ would be expressed as a sum of the form

$$\beta=\sum_{i=1}^{n}\sum_{j=1}^{n}\int_0^{\nu}(\beta_{ij}(\nu_1,\nu-\nu_1)\mathrm{d}x_i^{\nu_1}\wedge\mathrm{d}x_j^{\nu-\nu_1})\mathrm{d}\nu_1, \tag{26}$$

where $\beta_{ii}(\mu,\mu)=0$. Unlike the previous vector space, $F(\nu,1,n)$, this is clearly infinite dimensional for any value of ν. Not only is it infinite but it is uncountably infinite. An arbitrary element of $F(\nu,3,n)$ would be expressed as an integral of the form

$$\beta=\sum_{i=1}^{n}\sum_{j=1}^{n}\sum_{k=1}^{n}\int_0^{\nu}\int_0^{\nu-\nu_1}(\beta_{ijk}(\nu_1,\nu-\nu_2,\nu-\nu_1-\nu_2)\mathrm{d}x_i^{\nu_1}\wedge\mathrm{d}x_j^{\nu_2}\wedge\mathrm{d}x_k^{\nu-\nu_1-\nu_2})\mathrm{d}\nu_2\,\mathrm{d}\nu. \tag{27}$$

With each step up on the middle index of $F(\nu,m,n)$ another integral and summation is included. A basis set for this vector space would be

$$F(\nu,m,n)=\left\{\mathrm{d}x_{\nu_1}^{\mu_{i_k i}}\wedge\mathrm{d}x_{\mu_2}^{\mu_{2}1}\wedge\ldots\wedge\mathrm{d}x_{i_m}^{\mu_{m^i}},\cdots\middle|\sum_{k=1}^{m}\mu_{i_k j}=\nu\right\}. \tag{28}$$

The basis elements range over all possible combinations of the fractional coordinate differentials and all possible choices for the μ's. Note that m need not be less than or equal to n.

Let $P\in E^n$, and let $A\in F(\nu,m,n)$ and $B\in F(\mu,k,n)$ at the point P. Then the exterior product of A and B maintains the antisymmetry property of Eq. (5),

$$A\wedge B=(-1)^{km}B\wedge A\in F(\mu+\nu,k+m,n). \tag{29}$$

If $k+m>n$, $A\wedge B$ need not be zero. Equation (7) is also maintained due to the linearity of the fractional derivative. Equation (8) is not maintained due to the product rule for the fractional derivative [see Eq. (18)]. Note also that d^{ν} maps $F(\mu,k,n)$ into $F(\mu+\nu,k+1,n)$.

V. CLOSED AND EXACT FRACTIONAL FORMS

By analogy with exterior calculus the notions of closed and exact can be extended to fractional forms.

Let $g\in F(\mu,k,n)$ then g is ν-exact if $\exists$ and $f\in F(\mu-\nu,k-1,n)$ such that $\mathrm{d}^{\nu}f=g$.

Let $g\in F(\nu,k,n)$ then g is μ closed if $\mathrm{d}^{\mu}g=0$.

To examine the notion of exactness (integrability conditions) in the fractional form case the kernel is needed for the fractional derivative operator. This will be denoted by $\mathrm{Ker}(\partial_i^{\nu})$. In the following the initial point of the derivative will be taken to be the origin. Solve

$$\partial_i^{\nu}(h)=0. \tag{30}$$

Equation (30) is solved using Eq. (11). Let m be the first whole number greater than or equal to ν then

$$h=(x_i)^{\nu-m}\sum_{k=0}^{m-1}c_k(x_i)^k. \tag{31}$$

This is basically the result from Oldham (Ref. 7, p. 155). The c_k's can be functions of the other coordinates. The kernel for the operator, d^{ν} (when restricted to act only on scalar functions), is similarly constructed, $\mathrm{Ker}(\mathrm{d}^{\nu})$.

$$\mathrm{d}^{\nu} f = \sum_{i=1}^{m} \mathrm{d}x_i^{\nu} \frac{\partial^{\nu} f}{(\partial x_i)^{\nu}} = 0 \tag{32}$$

$$\Rightarrow f = \left(\prod_{i=1}^{n} x_i \right)^{\nu - m} \left(\sum_{k_1=0}^{m-1} \cdots \sum_{k_n=0}^{m-1} C_{k_1 \cdots k_n} (x_1)^{k_1} \cdots (x_n)^{k_n} \right). \tag{33}$$

The $C_{k_1,\ldots k_n}$ are now constants and m is once again the first whole number greater than or equal to ν.

The fractional integrability conditions can now be constructed for the following restricted case. Let g be a ν form in $F(\nu,1,\mathrm{n})$,

$$g = \sum_{i=1}^{n} \alpha_i \, \mathrm{d}x_i^{\nu}. \tag{34}$$

When can a 0 form, f, be found such that $\mathrm{d}^{\nu} f = g$? If such an f exists it will be contained in the family of functions given by

$$f = \partial_i^{-\nu}(\alpha_i) + (x_i)^{\nu - m} \sum_{k=0}^{m-1} c_k (x_i)^k. \tag{35}$$

Recall that there is no sum over the repeated indices, except where a summation symbol is encountered. This solution must satisfy, $\partial_j^{\nu} f = \alpha_j$,

$$\partial_j^{\nu} \left(\partial_i^{-\nu}(\alpha_i) + (x_i)^{\nu - m} \sum_{k=0}^{m-1} c_k (x_i)^k \right) = \alpha_j. \tag{36}$$

Equation (36) is to be solved to determine the unknown functions c_k, and must be true for all values of i. Equation (36) can be rearranged to give

$$\sum_{k=0}^{m-1} (\partial_j^{\nu} c_k)(x_i)^k = \frac{\alpha_j - \partial_j^{\nu}(\partial_i^{-\nu} \alpha_i)}{(x_i)^{\nu - m}}. \tag{37}$$

The left-hand side of (37) is a polynomial of order $m-1$ in the variable x_i, hence it can only be solved for the c_k if the following is true:

$$\frac{\partial^m}{\partial x_i^m} \left(\frac{\alpha_j - \partial_j^{\nu}(\partial_i^{-\nu} \alpha_i)}{(x_i)^{\nu - m}} \right) = 0. \tag{38}$$

Equation (38) is the integrability condition for fractional forms of type $F(\nu,1,n)$. Note that if $\nu = m = 1$ the usual integrability conditions from exterior calculus are recovered.

Consider the second definition and examine what it takes to be closed for fractional forms. Let

$$\alpha = \sum_{i=1}^{n} \alpha_i \, \mathrm{d}x_i^{\nu} \in F(\nu,1,n)$$

and consider its fractional exterior derivative,

$$\mathrm{d}^{\mu} \alpha = \sum_{i=1}^{n} \mathrm{d}^{\mu}(\alpha_i \, \mathrm{d}x_i^{\nu}), \tag{39}$$

$$d^{\mu}\alpha=\sum_{i=1}^{n}\sum_{j=1}^{n} dx_j^{\mu}\wedge\sum_{k=0}^{\infty}\binom{\mu}{k}\left(\frac{\partial^{\mu-k}}{(\partial x_j)^{\mu-k}}\alpha_j\right)\left(\frac{\partial^k}{\partial x_j^k}dx_i^{\nu}\right). \tag{40}$$

In the last sum of Eq. (40) k takes on only whole number values hence

$$\frac{\partial^k}{\partial x_j^k}(dx_i^{\nu})=0 \quad \forall \quad k\geqslant 1. \tag{41}$$

This reduces Eq. (40) to the following:

$$d^{\mu}\alpha=\sum_{i=1}^{n}\sum_{j=1}^{n} dx_j^{\mu}\wedge dx_i^{\nu}\binom{\mu}{0}\left(\frac{\partial^{\mu}}{(\partial x_j)^{\mu}}\alpha_i\right). \tag{42}$$

Since dx_j^{μ} and dx_i^{ν} are linearly independent, provided $\mu\neq\nu$ or $i\neq j$, $d^{\mu}\alpha=0$ if and only if

$$\frac{\partial^{\mu}}{(\partial x_j)^{\mu}}\alpha_i=0. \tag{43}$$

In other words $\alpha_i\in\mathrm{Ker}(\partial_j^{\mu})$. For the special case of $\mu=\nu$ the symmetry from Eq. (29) can be used to obtain

$$\frac{\partial^{\nu}}{(\partial x_i)^{\nu}}\alpha_j+(-1)\frac{\partial^{\nu}}{(\partial x_j)^{\nu}}\alpha_i=0. \tag{44}$$

For $\nu=1$ the usual result from exterior calculus is recovered,

$$\frac{\partial}{\partial x_i}\alpha_j-\frac{\partial}{\partial x_j}\alpha_i=0. \tag{45}$$

VI. TRANSITION TO CURVILINEAR COORDINATES

When coordinate transformation rules are worked out for exterior or tensor calculus (see Refs. 5 and 6) the following construction can be used. Let $\{x_i\}$ and $\{y_i\}$ be two coordinate systems with a one to one mapping between them in some neighborhood of $P\in E^n$. Take $\{x_i\}$ to again be Cartesian coordinates and $\{y_i\}$ to be curvilinear coordinates. Assume the $\{x_i\}$ can be written smoothly in terms of the $\{y_i\}$,

$$x_i=x_i(y). \tag{46}$$

The exterior derivative is then applied to the Eq. (46) giving the following:

$$dx_i=dx_i(y), \tag{47}$$

$$\sum_{k=1}^{n} dx_k\frac{\partial x_i}{\partial x_k}=\sum_{l=1}^{n} dy_l\frac{\partial x_i}{\partial y_l}, \tag{48}$$

$$\sum_{k=1}^{n} dx_k\,\delta_i^k=\sum_{l=1}^{n} dy_l\frac{\partial x_i}{\partial y_l}, \tag{49}$$

$$dx_i=\sum_{l=1}^{n} dy_l\frac{\partial x_i}{\partial y_l}. \tag{50}$$

This is very straightforward and can be adapted to the fractional from case. In the two coordinate systems the fractional exterior derivative d^ν takes the following forms:

$$\mathrm{d}^\nu = \sum_{i=1}^{n} \mathrm{d}x_i^\nu \frac{\partial^\nu}{(\partial(x_i - a_i))^\nu}, \tag{51}$$

and

$$\mathrm{d}^\nu = \sum_{i=1}^{n} \mathrm{d}y_i^\nu \frac{\partial^\nu}{(\partial(y_i - \tilde{a}_i))^\nu}, \tag{52}$$

where a_i is the initial point of the derivative in the Cartesian system and $\tilde{a}_i$ is the same point but in the curvilinear coordinates. Recall that x_i is in the kernel for the operator $\partial/\partial x_k$ for $k \neq i$, and when $k = i$ the result is one. For the fractional case the same type of object is needed. Consider a function α_k that maps points in E^n into the complex numbers

$$\alpha_k = \frac{\Gamma(1)}{\Gamma(\nu+1)} \left(\prod_{i=1/i\neq k}^{n} (x_i - a_i) \right)^{\nu-m} (x_k - a_k)^\nu, \tag{53}$$

where a_i is the initial point for the fractional derivative. The function α_k was chosen so that it would be in the kernel of

$$\frac{\partial^\nu}{(\partial(x_i - a_i))^\nu}$$

for $i \neq k$, and for $i = k$,

$$\frac{\partial^\nu \alpha_k}{(\partial(x_k - a_k))^\nu} = 1. \tag{54}$$

If the fractional exterior derivative is applied to α_k in the two different coordinate systems the following coordinate transformation rule can be obtained [where all quantities on the right-hand side of (55) must be expressed in terms of the $\{y_i\}$ coordinates]:

$$\mathrm{d}x_k^\nu = \sum_{i=1}^{n} \frac{\mathrm{d}y_i^\nu}{\Gamma(\nu+1)} \frac{\partial^\nu}{(\partial(y_i - \tilde{a}_i))^\nu} \left(\left(\prod_{j=1/j\neq k}^{n} (x_j - a_j) \right)^{\nu-m} (x_k - a_k)^\nu \right). \tag{55}$$

Note that for $\nu = m = 1$ the usual coordinate transformation rule is recovered. The coordinate transformation matrix for the fractional forms will be denoted by

$$J_i^k(x,y,\nu) = \frac{1}{\Gamma(\nu+1)} \frac{\partial^\nu}{(\partial(y_i - \tilde{a}_i))^\nu} \left(\left(\prod_{j=1/j\neq k}^{n} (x_j - a_j) \right)^{\nu-m} (x_k - a_k)^\nu \right), \tag{56}$$

$$\mathrm{d}x_k^\nu = \sum_{i=1}^{n} \mathrm{d}y_i^\nu \, J_i^k(x,y,\nu). \tag{57}$$

A fractional form,

$$A = \sum_{k=1}^{n} A_k(x) \mathrm{d}x_k^\nu, \tag{58}$$

written in the $\{x_i\}$ coordinates would be transformed into the $\{y_i\}$ coordinates according to

$$A=\sum_{k=1}^{n}\sum_{i=1}^{n}A_k(x(y))J_i^k(x,y,\nu)\mathrm{d}y_i^{\nu}. \tag{59}$$

Reversing the coordinate transformation yields

$$A=\sum_{k=1}^{n}\sum_{i=1}^{n}\sum_{j=1}^{n}A_k(x)J_i^k(x,y,\nu)J_j^i(y,x,\nu)\mathrm{d}x_j^{\nu} \tag{60}$$

$$\Rightarrow\delta_j^k=\sum_{i=1}^{n}J_j^i(y,x,\nu)J_i^k(x,y,\nu). \tag{61}$$

As an example consider the coordinate transformation for two-dimensional Cartesian coordinates to polar coordinates. The initial point for the fractional derivatives is taken to be the origin

$$x_1=r\cos(\theta),\quad x_2=r\sin(\theta). \tag{62}$$

The coordinate transformations for the fractional differentials are then

$$\mathrm{d}x_1^{\nu}=\frac{\Gamma(2\nu-m+1)}{\Gamma(\nu+1)\Gamma(\nu-m+1)}\frac{\cos^{\nu}(\theta)}{\sin^{m-\nu}(\theta)}r^{\nu-m}\,\mathrm{d}r^{\nu}+\frac{r^{2\nu-m}}{\Gamma(\nu+1)}\frac{\partial^{\nu}}{(\partial\theta)^{\nu}}\left(\frac{\cos^{\nu}(\theta)}{\sin^{m-\nu}(\theta)}\right)\mathrm{d}\theta^{\nu}, \tag{63}$$

$$\mathrm{d}x_2^{\nu}=\frac{\Gamma(2\nu-m+1)}{\Gamma(\nu+1)\Gamma(\nu-m+1)}\frac{\sin^{\nu}(\theta)}{\cos^{m-\nu}(\theta)}r^{\nu-m}\,\mathrm{d}r^{\nu}+\frac{r^{2\nu-m}}{\Gamma(\nu+1)}\frac{\partial^{\nu}}{(\partial\theta)^{\nu}}\left(\frac{\sin^{\nu}(\theta)}{\cos^{m-\nu}(\theta)}\right)\mathrm{d}\theta^{\nu}. \tag{64}$$

For $\nu=m=1$ the transformation equations from exterior calculus are recovered,

$$\mathrm{d}x_1=\cos(\theta)\mathrm{d}r-r\sin(\theta)\mathrm{d}\theta, \tag{65}$$

$$\mathrm{d}x_2=\sin(\theta)\mathrm{d}r+r\cos(\theta)\mathrm{d}\theta. \tag{66}$$

Having found the coordinate transformation rule a metric for $F(\nu,1,n)$ can be constructed just as is done in exterior calculus (see Ref. 6, p. 46)

$$g_{ij}(y,\nu)=\sum_{k=1}^{n}J_i^k(x,y,\nu)J_j^k(x,y,\nu), \tag{67}$$

which can be used to give a fractional line element

$$\mathrm{d}s^{2\nu}=\sum_{i,j=1}^{n}g_{ij}(y,\nu)\mathrm{d}y_i^{\nu}\otimes\mathrm{d}y_j^{\nu} \tag{68}$$

or

$$\mathrm{d}s^{\nu}=\sqrt{\sum_{i,j=1}^{n}g_{ij}(y,\nu)\mathrm{d}y_i^{\nu}\otimes\mathrm{d}y_j^{\nu}}, \tag{69}$$

where $\otimes$ is the symmetric product for coordinate differentials.

VII. CONCLUSION

In this paper a natural extension of the exterior derivative to a fractional exterior derivative was considered. It was found to generate some new vector spaces, both finite and infinite in dimension. Of particular interest is the observation that at each point $P\in E^n$ there is an infinite

number of n dimensional vector spaces. Due to their similarity with tangent spaces, perhaps an appropriate name for these new vector spaces should be fractional tangent spaces. Notions of closed and exact were also defined for these fractional form spaces. Integrability and closure conditions were investigated for the special case of $F(\nu,1,n)$. The results produced were found to reduce to the standard results from exterior calculus when the order of the fractional exterior derivative was set equal to one. Coordinate transformation rules were also worked out for $F(\nu,1,n)$. The transformation rules are somewhat more complicated than for traditional exterior calculus. They do, however, reduce to the usual formula when the order of the coordinate differentials is set equal to one. Coordinate transformation rules give rise to a metric for $F(\nu,1,n)$. Properties of the metric, such as its associated covariant derivative, will be investigated in a later paper.

Structure and representation theory for the double group of the four-dimensional cubic group

Jian Dai[a] and Xing-Chang Song[b]
Theory Group, Department of Physics, Peking University, Beijing, 100871, People's Republic of China

(Received 17 October 2000; accepted for publication 2 February 2001)

Hypercubic groups in any dimension are defined and their conjugate classifications and representation theories are derived. Double group and spinor representation are introduced. A detailed calculation is carried out on the structures of four-dimensional cubic group O_4 and its double group, as well as all inequivalent single-valued representations and spinor representations of O_4. All representations are derived adopting Clifford theory of decomposition of induced representations. Based on these results, single-valued and spinor representations of the orientation-preserved subgroup of O_4 are calculated. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1358880]

I. INTRODUCTION

It is well known that electrons stay in spinor representations of the symmetry group of a given lattice in condensed matter physics; it is reasonable to assume that quarks, leptons, as well as baryons, should reside in *spinor representations* of the symmetry group of a four-dimensional lattice in lattice field theory (the concept of ''spinor representation'' will be clarified in Sec. II). Accordingly, to explore the structure and representations (spinor representations especially) of such groups has important significance in high energy physics.

In this paper, we concentrate on the case of hypercubic lattices, though they are not the maximum symmetric lattices in four dimension.[1] In history, the first representation-theoretical consideration of a symmetry group of such lattices was given by Young.[2] Then mathematicians worked in this field due to interest in the wreath product[3,4] to which Kerber gave a thorough review in his book.[5] Physicists became involved after Wilson introduced lattice gauge theory.[6] Baake *et al.* first gave an explicit description of characters of the four-dimensional cubic group;[7] Mandula *et al.* derived the same results using a different method.[8] As for spinor representations, Mandula *et al.* resolved this problem for what we call the *orientation-preserved* four-dimensional cubic-group in Ref. 9.

In this paper, the power of Clifford theory on decomposition of induced representations (Sec. II A) is fully applied. A systematic and schematic description of conjugate classification and representation theory of the generalized cubic group O_n, as well as the concept of the orientation-preserved subgroup of them SO_n, is given in Sec. II B. The double group is introduced in Sec. II C to clarify the terms ''single-valued representation'' and ''two-valued representation (spinor representation).'' Then specifying these general results to four dimension, we give a detailed description of structure and conjugate classification of O_4 (Sec. III A), its double $\overline{O_4}$ (Sec. III B), and those of SO_4, $\overline{SO_4}$ (Sec. V). We derive all inequivalent single-valued representations as well as spinor representations of O_4, adopting Clifford theory (Sec. IV). Based on these results, we reproduce representation theory of $\overline{SO_4}$ in Sec. VI.

It should be pointed out that the ''spinor'' part for O_4 of our work is completely new and that although other results are well known, our method to derive them is much more tidy and system-

[b]Electronic mail: songxc@ibm320h.phy.pku.edu.cn

atic than that used by other authors who gave the same results, thanks to the power of Clifford theory.

II. CONCEPTUAL FOUNDATIONS

A. Clifford theory on decomposition of induced representations

Two results of Clifford theory, a powerful method for decomposing induced representations of a given group E with a normal subgroup N,[10–13] will be applied in this paper. We will use $\mathcal{C}[E]$ for the group algebra of E in complex field and G for E/N in the following. The first result is

Theorem 1: *(Clifford—Refs. 14 and 10.) Let M be a simple $\mathcal{C}[E]$-module, and L a simple $\mathcal{C}[N]$-submodule of M_N s.t. L is stable relative to E, i.e., L is isomorphic to all of its conjugates. Then*

$$M \cong L \otimes_{\mathcal{C}} I$$

for a left ideal I in $End_{\mathcal{C}[E]} L^E$. The E-action on $L \otimes_{\mathcal{C}} I$ is given by

$$x \mapsto U(x) \otimes V(x), x \in E,$$

where $U: E \to GL(L)$ is a projective representation of E on L, and $V: E \to GL(I)$ is a projective representation of G, that is, $V(x)$ depends only on the coset xN of x in G, for each $x \in E$. The factor sets associated with U and V are inverse of each other.

The second result can be regarded as a special case of Theorem 1. Let $E = N \rtimes G, |E| < \infty$ and N be Abelian, then adjoint action of G upon N makes N a G-module. This G-action can be extended naturally to a G-action upon $\mathcal{C}[N]$ by linearity. Define $\Pi(N) := \{\pi_\mu\} \subset \mathcal{C}[N]$,

$$\pi_\mu := \sum_{a \in N} \chi_\mu(a^{-1}) a, \tag{1}$$

where χ_μ are all irreducible representations of N. The G-action on $\Pi(N)$ is closed and thus $\Pi(N)$ is separated into orbits $\Pi(N) = \amalg_{o \in \mathcal{I}} \Pi_o$ where $\mathcal{I}$ is an index set to label different orbits. For each Π_o, choose one of its elements and denote it as $\pi_{o,e}$. The stabilizer of each $\pi_{o,e}$ in G (*little group*) is denoted as S_o. There is a bijection from $G/S_o = \{hS_o\}$ to Π_o defined by

$$\mathrm{Ad}_h(\pi_{o,e}) = h \pi_{o,e} h^{-1} =: \pi_{o,h}, \tag{2}$$

where $\{h\}$ is a system of representatives of left cosets G/S_o. Define

$$\Pi_{o,h;\eta,i} \equiv \pi_{o,h} h \otimes_{S_o} e^o_{\eta,i} \tag{3}$$

in which $\{e^o_{\eta,i} | i = 1,2,\ldots,d^o_\eta\}$ with fixed o, η, and η is the ηth irreducible representation of S_o whose dimension is d^o_η, then

Proposition 1 (Little group method—Refs. 11–13):

(1) For each fixed (o,η), $\{\Pi_{o,h;\eta,i}\}$ induces an irreducible representation of E, denoted as $D_{o,\eta}$.
(2) If $(o,\eta) \neq (o',\eta')$, then $D_{o,\eta}$ and $D_{o',\eta'}$ are inequivalent.
(3) $\{D_{o,\eta}\}$ gives all inequivalent irreducible representations of E.

B. Cubic group in any dimension

The symmetry group of a cube including inversions in three-dimensional Euclidean space, which is denoted as O_h in the theory of point groups,[15] can be generalized into any n-dimensional Euclidean space E^n, along two different approaches whose results are equivalent. The first approach of generalization, which is very natural and straightforward, is geometrical. An *n-cube* (or *hypercube in E^n*) C_n is defined to be a subset of E^n, $C_n = \{p | x^i(p) = \pm 1\}$, where $x^i: E^n \to \mathcal{R}, i = 1,2,\ldots,n$ are coordinate functions of E^n, together with the distance inherited from E^n. *n-cubic*

group (*hypercubic group of degree n*) O_n consists of all isometries of E^n which stabilize C_n. While the second approach of generalization is algebraic. O_h has a semidirect product structure as $Z_2^3 \rtimes S_3$;[11] we generalize this to $Z_2^n \rtimes S_n$, which is just a *wreath product* $Z_2 \wr S_n$ of Z_2 with S_n. We point out that these two generalizations are identical. Let $\{e_i\}$ be a standard orthogonal basis of E^n, namely $x^j(e_i)=\delta_i^j$. Define $n+1$ points in C_n to be $p_0=(-1,-1,\ldots,-1), p_i=p_0+2e_i$.

Lemma 1: $\forall \epsilon \in O_n$, ϵ *is entirely determined by images* $\epsilon(p_i), i=0,1,2,\ldots,n$.

Proof: The fact that ϵ is an isometry of E^n ensures the equality of Euclidean distances $d(p,p_i)=d(\epsilon(p),\epsilon(p_i))$, $i=0,1,\ldots,n$ for any other p in C_n. If all $\epsilon(p_i)$ are given, $\epsilon(p)$ will be fixed for any other p accordingly due to the fundamental lemma of Euclidean geometry (lemma A1 in the Appendix). In fact, the existence of solution in lemma A1 is guaranteed by the fact that ϵ stablizes C_n and lemma A1 itself ensures the uniqueness. □

To fix $\epsilon(p_0)$, there are 2^n ways; while for a fixed $\epsilon(p_0)$, there are $n!$ possibilities to fix $\epsilon(p_i), i=1,2,\ldots,n$. Therefore, $|O_n|=2^n \cdot n!$.

Proposition 2 (*Structure of* O_n)*:*

$$O_n \cong Z_2^n \rtimes S_n. \tag{4}$$

Proof: Introduce a class of isometries in E^n:

$$\sigma(e_i)=e_{\sigma(i)}, \quad I_i(e_j)=(1-2\delta_{ij})e_j, \quad i=1,2,\ldots,n, \tag{5}$$

where $\sigma \in S_n$ permutes the axes and I_i inverts the ith axis. Subjected to the relations

$$I_i^2=e, \quad I_iI_j=I_jI_i, \quad i,j=1,2,\ldots,n, \quad \sigma I_i=I_{\sigma(i)}\sigma, \sigma \in S_n \tag{6}$$

these isometries generate a subgroup of C_n isomorphic to $Z_2^n \rtimes S_n$ whose order is $2^n n! = |O_n|$. So Eq. (4) follows. □

Kerber gave a detailed introduction on the conjugate classification and representation theory of a general wreath product $N \wr G$ in Ref. 5. We specify his general results to our case $Z_2^n \rtimes S_n \cong Z_2 \wr S_n$.

Some fundamental facts about symmetrical groups S_n should be recalled.[15] Each element $\sigma \in S_n$ has a cycle decomposition

$$\sigma=\begin{pmatrix} 1 & 2 & \ldots & n \\ \sigma(1) & \sigma(2) & \ldots & \sigma(n) \end{pmatrix}=\prod_{k=1}^{n}\prod_{\alpha=1}^{\nu_k}\tau_{k\alpha}, \tag{7}$$

where $\tau_{k\alpha}$ are independent k cycles, which can be expressed as $(a_1a_2\ldots a_k)$, and write $n(k,\alpha)=\{a_1,a_2,\ldots,a_n\}$. The cycle structure of σ can be represented formally as

$$(\nu)=\prod_{k=1}^{n}(k^{\nu_k}), \tag{8}$$

where $\{\nu_k\}$ satisfies $\Sigma_{k=1}^n k\cdot\nu_k=n$. Two elements in S_n are conjugate equivalent, iff they have the same cycle structure. The number of elements in class (ν) is equal to $N_{(\nu)}=n!/\Pi_{k=1}^n(k^{\nu_k}\nu_k!)$. Each cycle structure (ν) can be visualized by one unique Young diagram which is denoted also by (ν). There is a one-to-one correspondence between all inequivalent irreducible representations of S_n and all Young diagrams, which enable us to represent each irreducible representation by the corresponding Young diagram (ν). We write the basis of one of these representations (ν) in $d_{(\nu)}$ dimension as $e_{(\nu)i}, i=1,2,\ldots,d_{(\nu)}$.

We point out that the conjugate classification of O_n has a deep relation to that of S_n. A generic element in $Z_2 \wr S_n$ can be written as

$$\sigma\cdot\prod_i I_i^{s_i}=\begin{pmatrix} 1 & 2 & \ldots & n \\ (-)^{s_1}\sigma(1) & (-)^{s_2}\sigma(2) & \ldots & (-)^{s_n}\sigma(n) \end{pmatrix} \tag{9}$$

in which $s_i \in \mathcal{Z}/2\mathcal{Z}$. We call the right-hand side of Eq. (9) by *permutation with signature*. $\sigma\Pi_i I_i^{s_i}$ can be decomposed according to Eq. (7), i.e.,

$$\prod_i I_i^{s_i} = \prod_{k=1}^{n} \prod_{\alpha=1}^{\nu_i} \prod_{a \in n(k,\alpha)} I_a^{s_a}$$

and

$$\sigma \prod_i I_i^{s_i} = \prod_{k=1}^{n} \prod_{\alpha=1}^{\nu_i} \left(\tau_{k\alpha} \prod_{a \in n(k,\alpha)} I_a^{s_a} \right). \tag{10}$$

The *cycle with signature* is defined to be

$$\tau_{k\alpha} \prod_{a \in n(k,\alpha)} I_a^{s_a} = \begin{pmatrix} a_1 & a_2 & \dots & a_k \\ (-)^{s_{a_1}} a_2 & (-)^{s_{a_2}} a_3 & \dots & (-)^{s_{a_k}} a_1 \end{pmatrix}.$$

For two independent $(k,\alpha),(k',\alpha')$, it is easy to verify that

$$\tau_{k\alpha}\tau_{k'\alpha'} = \tau_{k'\alpha'}\tau_{k\alpha}, \quad \prod_{a \in n(k,\alpha)} I_a^{s_a} \tau_{k'\alpha'} = \tau_{k'\alpha'} \prod_{a \in n(k,\alpha)} I_a^{s_a}, \quad \prod_{a \in n(k',\alpha')} I_a^{s_a} \tau_{k\alpha} = \tau_{k\alpha} \prod_{a \in n(k',\alpha')} I_a^{s_a}.$$

Proposition 3 (Refs. 3–5): We use $\sim$ to denote conjugate equivalent.
(1) Descent rule:

$$\sigma \prod_i I_i^{s_i} \sim \sigma' \prod_i I_i^{s_i'} \Rightarrow \sigma \sim \sigma'. \tag{11}$$

(2) Permutation rule: Let

$$\tilde{\sigma} = \begin{pmatrix} 1 & 2 & \dots & n \\ \tilde{\sigma}(1) & \tilde{\sigma}(2) & \dots & \tilde{\sigma}(n) \end{pmatrix} = \begin{pmatrix} \sigma(1) & \sigma(2) & \dots & \sigma(n) \\ \sigma'(1) & \sigma'(2) & \dots & \sigma'(n) \end{pmatrix}$$

then

$$\tilde{\sigma} \left(\sigma \prod_i I_i^{s_i} \right) \tilde{\sigma}^{-1} = \begin{pmatrix} \tilde{\sigma}(1) & \tilde{\sigma}(2) & \dots & \tilde{\sigma}(n) \\ (-)^{s_1}\sigma'(1) & (-)^{s_2}\sigma'(2) & \dots & (-)^{s_n}\sigma'(n) \end{pmatrix}. \tag{12}$$

(3) Signature rule within one cycle: Let $\tau_{k\alpha}$ be a k-cycle and a_0 be a given number in $n(k,\alpha)$, then

$$\tau_{k\alpha} \prod_{a \in n(k,\alpha)} I_a^{s_a} \sim \tau_{k\alpha} \prod_{a \in n(k,\alpha)} I_a^{s_a + \delta_{aa_0} + \delta_{a,\tau_{k\alpha}(a_0)}}. \tag{13}$$

Note that $\tau_{k\alpha}(a_0)$ is calculated modulo k (the subscripts of I_a are always understood in this way).

(4) Signature rule between two cycles: Let $\tau_{k\alpha}, \tau_{k\beta}$ be two independent k-cycles and we define a bijection $\theta: n(k,\alpha) \to n(k,\beta), a_i \mapsto b_i$. Then

$$\tau_{k\alpha} \prod_{a \in n(k,\alpha)} I_a^{s_a} \cdot \tau_{k\beta} \prod_{b \in n(k,\beta)} I_b^{s_b} \sim \tau_{k\alpha} \prod_{a \in n(k,\alpha)} I_a^{s_{\theta(a)}} \cdot \tau_{k\beta} \prod_{b \in n(k,\beta)} I_b^{s_{\theta^{-1}(b)}}. \tag{14}$$

This theorem ensures conjugate classification of $Z_2 \wr S_n$ is totally determined by the structure of cycles with signature. We verify this statement by generalizing Young diagram technology. First, draw a *Young diagram with numbers and signatures* for each element

$$\sigma \Pi_i I_i^{s_i} \in Z_2 \wr S_n$$

according to the decomposition Eq. (10) by the following rules:

(1) Plot Young diagram of the class in S_n to which σ belongs and fill each column of this Young diagram with numbers in corresponding cycle by cyclic ordering from the upmost box to the downmost box.
(2) Draw a *slash* in the Young box if the number in this box is mapped to a minus-signed number.

Secondly, partition elements in $Z_2 \wr S_n$ by their cycle structure in S_n and Eq. (11) guarantees that elements belonging to different partitions cannot be conjugate equivalent. Equation (12) implies that all the numbers that we filled by rule (1) are unnecessary, so smear them out and leave boxes and *slash*es only. Within each column, Eq. (13) says that the positions of *slash*es make no difference. What's more, only the fact that the total number of *slash*es is even or odd distinguishes different classes. Therefore we regulate each column to contain zero or one *slash* at the bottom box. Equation (14) shows that we cannot distinguish the case where one column without any *slash* (Mr. Zero) is put to the left of another column with one *slash* (Mr. One) from that Mr. Zero is to the right of Mr. One, if they have same cyclic length; thus we regulate that Mr. Zero shall always stand left to Mr. One. Therefore, conjugate classes of $Z_2 \wr S_n$ can be uniquely characterized by generalizing Young diagrams containing *slash*es. Following Eq. (8), we represent conjugate classes by

$$(\nu^+, \nu^-) = \prod_{k=1}^{n} (k^{\nu_k^+ + \nu_k^-}), \tag{15}$$

where ν_k^+ is the number of Mr. Zero-type k-cycles and ν_k^- is that of Mr. One-type k-cycles, which satisfy $\nu_k^+ + \nu_k^- = \nu_k$. It is not difficult to check some numerical properties of conjugate classes of $Z_2 \wr S_n$.

Corollary 1: (1) Given a class (ν) *in* S_n, *there are*

$$\prod_{k=1}^{n} (1 + \nu_k) \tag{16}$$

classes in $Z_2 \wr S_n$ *which descend to* (ν).
(2) The number of elements in a class (ν^+, ν^-) *is*

$$N_{(\nu^+,\nu^-)} = N_{(\nu)} \prod_{k=1}^{n} \left(C_{\nu_k}^{\nu_k^+} \left(\sum_{i=0}^{[k/2]} C_k^{2i} \right)^{\nu_k^+} \left(\sum_{j=1}^{[(k+1)/2]} C_k^{2j-1} \right)^{\nu_k^-} \right), \tag{17}$$

where C_m^n *is combinatorial number defined to be* $m!/(n!(m-n)!)$.
(3) The order of a class (ν^+, ν^-) *is*

$$lcm(\{k \cdot 2^{\delta(\nu_k^-)} | \nu_k \neq 0\}), \tag{18}$$

where $\delta(\nu_k^-) = 0$, *if* $\nu_k^- = 0$; $\delta(\nu_k^-) = 1$, *if* $\nu_k^- > 0$.
(4) Determinant (signature, parity) of a class

$$\det((\nu^+, \nu^-)) = (-1)^{\sum_{k=1}^{n} \nu_k^-} \cdot \det((\nu)), \tag{19}$$

where $\det((\nu))$ *is the determinant of* (ν) *in* S_n.
All inequivalent irreducible representations of Z_2^n can be expressed as

$$\chi_{(s)} := \bigotimes_{p=1}^{n} \chi_{(-)^{s_p}} \tag{20}$$

in which $s_p \in \mathcal{Z}/2\mathcal{Z}, p=1,2,\ldots,n$ and $\chi_{(-)}, \chi_{(+)}$ are two irreducible representations of Z_2 with $\chi_{(+)}$ being the unit representation. Thus $\pi_{(s)}$ can be defined by Eq. (1) and $\Pi(Z_2^n)=\{\pi_{(s)}\}$. Note that $\pi_{(s)}$ satisfy $\pi_{(s)}\pi_{(s')}=\pi_{(s\cdot s')}$ where $(s\cdot s')(p)=s(p)s'(p)$. $\Pi(Z_2^n)$ is divided into $n+1$ orbits under the S_n-action, namely $\Pi(Z_2^n)=\amalg_{p=0}^{n}\Pi_p$. For a given p, Π_p consists of those $\pi_{(s)}$ that have p components in (s) equal to 1, other $n-p$ components equal to 0; hence $|\Pi_p|=C_n^p$. Each $\pi_{p,e}$ is specified to a $\pi_{(s)}$ with $s_p=0, p=1,2,\ldots,n-p; s_p=1, p=n-p+1,\ldots,n$, whose stationary subgroup is just $S_{(n-p)}\otimes S_p$, denoted as F_p. Representatives of left-cosets in S_n/F_p are written as σ_r, then according to Eqs. (2) and (3) and Theorem 1,

Proposition 4 (*Representation theory of $Z_2 \wr S_n$*)*:*

$$\Pi_{p,\sigma_r;(\mu)i,(\nu)j} = \pi_{p,\sigma_r}\sigma_r \otimes_{F_p} (e_{(\mu)i}\otimes e_{(\nu)j})$$

give all inequivalent irreducible representations of $Z_2 \wr S_n$ when $(p,(\mu),(\nu))$ runs over its domain. where $\pi_{p,\sigma_r}=Ad_{\sigma_r}(\pi_{p,e})$ whose (s) will be denoted as $(s^{(p\sigma_r)})$.

Corollary 2: (1) Burside formula. $\Sigma_{(p,(\mu),(\nu))}(C_n^p d_{(\mu)} d_{(\nu)})^2 = 2^n n!$

(2) The number of conjugate classes is $\Sigma_{(p,(\mu),(\nu))} 1$.

(3) Representation matrix element. Given $\sigma \Pi_q I_q^{t_q} \in Z_2 \wr S_n$,

$$D_{(p,(\mu),(\nu))}\left(\sigma \prod_q I_q^{t_q}\right)_{\sigma_r ij}^{\sigma_r' i' j'} = \delta^{\sigma'}_{\tilde{\sigma}_r(\sigma\sigma_r)} D_{(\mu)}(\sigma_{(n-p)}(\sigma\sigma_r))_i^{i'} D_{(\nu)}(\sigma_p(\sigma\sigma_r))_j^{j'} \prod_q (-)^{s_q^{(p\sigma_r)} t_q}.$$

(4) Character:

$$\chi_{(p,(\mu),(\nu))}\left(\sigma \prod_q I_q^{t_q}\right) = \delta^{\sigma'}_{\tilde{\sigma}_r(\sigma\sigma_r)} \chi_{(\mu)}(\sigma_{(n-p)}(\sigma\sigma_r)) \chi_{(\nu)}(\sigma_p(\sigma\sigma_r)) \prod_q (-)^{s_q^{(p\sigma_r)} t_q},$$

where $\tilde{\sigma}_r, \sigma_{(n-p)}, \sigma_p$ map an element in S_n to its decompositions according to S_n/F_p, S_{n-p}, and S_p, respectively.

At the end of this section, we introduce the *orientation-preserved* n-cubic group SO_n which is a normal subgroup of O_n,

$$SO_n := (O_n \cap SO(n)) \lhd O_n. \tag{21}$$

Define $Z_2^n|_e$ as a subgroup of Z_2^n generated by $I_i I_j, i \neq j$ and $Z_2^n|_o := Z_2^n \setminus Z_2^n|_e$. Then

$$SO_n = (Z_2^n|_e \cdot A_n) \sqcup (Z_2^n|_o \cdot (S_n \setminus A_n)) \tag{22}$$

in which $\cdot$ is the product of two subsets in a group, A_n stands for the alternative subgroup in S_n. Thus, $|SO_n| = (2^n \cdot (n)!)/2$.

C. Double group and spinor representation

Some fundamental facts of Clifford algebra are necessary for giving the definition and properties of double groups. Denote the Clifford algebra upon Euclidean space V as $\mathrm{Cl}(V)$; the isometry $x \mapsto -x$ on V extends to an automorphism of $\mathrm{Cl}(V)$ denoted by $x \mapsto \tilde{x}$ and referred to as the canonical automorphism of $\mathrm{Cl}(V)$. We use $\mathrm{Cl}^*(V)$ to denote the multiplicative group of invertible elements in $\mathrm{Cl}(V)$ and the Pin group is the subgroup of $\mathrm{Cl}^*(V)$ generated by unit vectors in V, i.e.,

$$\mathrm{Pin}(V) := \{a \in \mathrm{Cl}^*(V) : a = u_1 \cdots u_r, u_j \in V, \|u_j\| = 1\}.$$

Proofs of the following four statements can be found in Ref. 16.

Lemma 2: If $u \in V$ is non-null, then R_u, reflection along u, is given in terms of Clifford multiplication by

$$R_u x = -uxu^{-1}, \quad \forall x \in V.$$

Theorem 2: *The sequence*

$$0 \to Z_2 \to \mathrm{Pin}(V) \xrightarrow{\widetilde{Ad}} O(V) \to 1$$

is exact, in which

$$\widetilde{\mathrm{Ad}}_a(x) := \tilde{a}xa^{-1}, \quad \forall x \in \mathrm{Cl}(V), \quad a \in \mathrm{Pin}(V).$$

We will usually write $\widetilde{\mathrm{Ad}}$ just by π as a surjective homomorphism.

Proposition 5: $\mathrm{Cl}(E^4)$, *as an associative algebra with unit, is isomorphic to* $M_2(\mathbf{H})$ *where* $\mathbf{H}$ *denotes quaternions.*

Lemma 3: Under the above-given algebra isomorphism, the image of $\mathrm{Pin}(E^4)$ *is a subset of* $SU(4)$.

Now we give the main definition of this paper.

Definition 1: Let ϵ be an injective homomorphism from a group G to $O(n)$, then the double group or the spin-extension of G with respect to ϵ is defined to be $D_n(G,\epsilon) := \pi^{-1}(\epsilon(G))$.

An introduction to double groups in three dimension can be found in Ref. 17. Following elementary facts in the theory of group extension,[18] this diagram

$$\begin{array}{ccccccccc} 0 & \to & Z_2 & \to & \mathrm{Pin}(E^n) & \xrightarrow{\pi} & O(n) & \to & 1 \\ & & \| & & \uparrow & & \uparrow \epsilon & & \\ 0 & \to & Z_2 & \to & \pi^{-1}(\epsilon(G)) & \to & G & \to & 1 \end{array}$$

is commutative. If $\epsilon_1(G) \sim \epsilon_2(G)$, there is

$$\begin{array}{ccccccccc} 0 & \to & Z_2 & \xrightarrow{i} & \pi^{-1}(\epsilon_1(G)) & \xrightarrow{\pi} & \epsilon_1(G) & \to & 1 \\ & & \| & & \downarrow & & \downarrow & & \\ 0 & \to & Z_2 & \xrightarrow{i'} & \pi^{-1}(\epsilon_2(G)) & \xrightarrow{\pi'} & \epsilon_2(G) & \to & 1. \end{array}$$

Note that the double group is not a universal object for a given abstract group G but a special type of Z_2-central extension of G subjected to the embedding ϵ. For example, the results of doubling two Z_2 subgroups in $O(2)$, $I := \{1,\sigma\}, R := \{1, R(\pi)\}$, where σ denotes reflection along y axis and $R(\pi)$ is the rotation over π, are $\pi^{-1}(I) \cong Z_2 \otimes Z_2$ while $\pi^{-1}(R) \cong Z_4$. Nevertheless, we will use the symbol $\overline{G}$ to denote the double group at most cases where n and ϵ are fixed, and will not distinguish G from $\epsilon(G)$. Meanwhile, the symbol $\overline{e}$ is adopted to refer -1 in Clifford algebra and is called *central element.*

Let $s: G \to \overline{G}, s.t. \pi s = Id_G$, namely s is a cross section of π. There is a property of the conjugate classes of $\overline{G}$ which is easy to verify.

Lemma 4: Let C be a conjugate class in G, then either $\pi^{-1}(C)$ will be one conjugate class in $\overline{G}$ satisfying $\forall g \in C, s(g) \sim -s(g)$; or it will split into two conjugate classes C_1, C_2 in $\overline{G}$ s.t. $\forall g \in C, s(g) \in C_1 \Leftrightarrow -s(g) \in C_2$.

We will give a more in-depth result on the splitting of conjugate classes when doubling G to $\overline{G}$ in another paper.

Let r be an irreducible representation of $\overline{G}$ on L, then $r(-1) = \pm \mathbf{1}$.

Definition 2: An irreducible representation of $\overline{G}$ *with* $r(-1)=\mathbf{1}$ *is called a single-valued representation of* G *while an irreducible representation with* $r(-1)=-\mathbf{1}$ *is called a spinor representation or two-valued representation of* G.

Proposition 6: Let $\mathrm{IRR}_{\mathcal{C}}(G)$ *be the class of all inequivalent irreducible representations of* G *and* $\mathrm{IRR}_{\mathcal{C}}(G)^s$ *be the class of all inequivalent single-valued representations of* G, *define* $\phi:\mathrm{IRR}_{\mathcal{C}}(G)\to\mathrm{IRR}_{\mathcal{C}}(G)^s, r\mapsto r\circ\pi$. *Then* ϕ *is a bijection.*

Proof: One can check: $r\circ\pi$ is a representation of $\overline{G}$; if $r\cong r'$, then $r\circ\pi\cong r'\circ\pi$; that r is irreducible implies that $r\circ\pi$ is irreducible and $r\circ\pi$ is single valued. Therefore, ϕ is well defined. If r and r' are inequivalent, then $r\circ\pi$ and $r'\circ\pi$ are two elements in $\mathrm{IRR}_{\mathcal{C}}(G)^s$, namely ϕ is injective. To prove that ϕ is a surjection, consider any $\tilde{r}\in\mathrm{IRR}_{\mathcal{C}}(G)^s:\overline{G}\to L$. Define $r:G\to L, g\mapsto\tilde{r}(s(g))$ where $s(g)$ is any element in $\pi^{-1}(g)$. One can check: r is a well-defined map since $\tilde{r}$ is single valued; r is an irreducible representation of G on L, accordingly $r\in\mathrm{IRR}_{\mathcal{C}}(G)$ and lastly, $\phi(r)=\tilde{r}$. So the result follows. □

This proposition says that all single-valued representations of G which are part of inequivalent irreducible representations of $\overline{G}$ are completely determined by the representation theory of G.

III. STRUCTURE OF $\overline{O_4}$

A. Structure of O_4

It follows Proposition 2, that $O_4\cong Z_2^4\rtimes S_4$; hence $|O_4|=384$. In point group theory, the rotation subgroup of O_h is denoted as O; on the other hand, $S_4\cong Z_2^2\rtimes S_3\cong O$.[11] We write the isomorphism explicitly. The structure of $Z_2^2\rtimes S_3$ is given by four generators α,β,η,t and the relations

$$\alpha^2=e,\quad \beta^2=e,\quad \alpha\beta=\beta\alpha, \tag{23}$$

$$t^3=e,\quad \eta^2=e,\quad \eta t=t^2\eta, \tag{24}$$

$$t\alpha=\alpha\beta t,\quad t\beta=\alpha t,\quad \eta\alpha=\beta\eta, \tag{25}$$

and the isomorphisms are defined to be

$$(12)(34)\leftrightarrow\alpha\leftrightarrow\mathrm{diag}(-1,-1,1),(13)(24)\leftrightarrow\beta\leftrightarrow\mathrm{diag}(1,-1,-1)$$

$$(234)\leftrightarrow t\leftrightarrow\begin{pmatrix}0&1&0\\0&0&1\\1&0&0\end{pmatrix},(23)\leftrightarrow\eta\leftrightarrow\begin{pmatrix}0&0&-1\\0&-1&0\\-1&0&0\end{pmatrix}.$$

The structure of $Z_2^4\rtimes S_4$ is given by Eqs. (23)–(25) together with [see Eq. (6)]

$$I_i^2=e,\quad I_iI_j=I_jI_i,\quad i,j=1..4,\quad i\neq j, \tag{26}$$

$$\begin{gathered}\alpha I_1=I_2\alpha,\quad \alpha I_3=I_4\alpha,\\ \beta I_1=I_3\beta,\quad \beta I_2=I_4\beta,\\ tI_1=I_1t,\quad tI_2=I_4t,\quad tI_3=I_2t,\quad tI_4=I_3t,\\ \eta I_1=I_1\eta,\quad \eta I_2=I_3\eta,\quad \eta I_4=I_4\eta.\end{gathered} \tag{27}$$

The matrix representations of above generators are given by [see Eq. (5)]

$$(I_i)^j_k=\delta^j_k(1-2\delta^j_i),\quad i,j,k=1,2,3,4, \tag{28}$$

TABLE I. Conjugate classes of $Z_2^4 \rtimes S_4$. ''SplitNo'' reflects the relation between the classes of $Z_2 \wr S_4$ and those of S_4. ''Ord'' means order of each class. ''Num'' is the number of elements in each class. ''Det'' is the signature of each class. See. Eqs. (16)–(19).

No	SplitNo	YoungDiagram	ord	num	det	No	SplitNo	YoungDiagram	ord	num	det
1	1-1		1	1	1	2	1-2		2	4	-1
3	1-3		2	6	1	4	1-4		2	4	-1
5	1-5		2	1	1						
6	2-1		2	12	-1	7	2-2		2	24	1
8	2-3		4	12	1	9	2-4		2	12	-1
10	2-5		4	24	-1	11	2-6		4	12	1
12	3-1		2	12	1	13	3-2		4	24	-1
14	3-3		4	12	1						
15	4-1		3	32	1	16	4-2		6	32	-1
17	4-3		6	32	-1	18	4-4		6	32	1
19	5-1		4	48	-1	20	5-2		8	48	1

$$\alpha \mapsto \begin{pmatrix} 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{pmatrix}, \quad \beta \mapsto \begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{pmatrix}, \quad t \mapsto \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 \end{pmatrix}, \quad \eta \mapsto \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}. \tag{29}$$

In fact, if we introduce

$$\gamma \mapsto \begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

then the generators of O_4 can be reduced to a smaller set $\{I_i, \gamma, t | i = 1,2,3,4\}$ whose generating relations are Eqs. (26) and (27) together with

$$\gamma^2 = e, \quad t^3 = e, \quad (t\gamma)^4 = e, \tag{30}$$

$$\gamma I_1 = I_3 \gamma, \quad \gamma I_2 = I_2 \gamma, \quad \gamma I_4 = I_4 \gamma, \tag{31}$$

while $\alpha = (t^2\gamma)^2, \beta = t\gamma t^2 \gamma t, \eta = \gamma t \gamma t^2 \gamma$.

Applying the general results on conjugate classification of O_n Eqs. (15)–(19), we give the table of conjugate classes of O_4 (see Table I).

B. Construction of $\overline{O_4}$

We will denote $s(g)$ still as g for all $g \in G$. $\overline{O_4}$ is generated by the following equations.

Proposition 7:

$$I_i^2 = -1, \quad I_i I_j = -I_j I_i, \quad i,j = 1..4, \quad i \neq j, \tag{32}$$

$$\gamma^2 = -1, \quad t^3 = -1, \quad (t\gamma)^4 = -1, \tag{33}$$

$$\underline{\gamma I_1 = -I_3 \gamma}, \quad \gamma I_2 = -I_2 \gamma, \gamma I_4 = -I_4 \gamma, \tag{34}$$

$$tI_1 = I_1 t, \quad \underline{tI_2 = I_4 t}, \quad \underline{tI_3 = I_2 t}, \quad \underline{tI_4 = I_3 t}. \tag{35}$$

Proof: First, Eqs. (32)–(35) are valid. In fact, the standard orthogonal bases in E^4 satisfy Clifford relations $e_i e_j + e_j e_i = -2\delta_{ij}$, which is equivalent to Eq. (32); therefore, one can take $I_i = e_i$. Following lemma 2, we set

$$\gamma = \frac{1}{\sqrt{2}}(e_3 - e_1)$$

and check that Eq. (34) is satisfied. Let $t = 1/2\,(1 - e_2 e_3 + e_2 e_4 - e_3 e_4)$, which is the product of

$$\frac{1}{\sqrt{2}}(e_2 - e_3) \text{ and } \frac{1}{\sqrt{2}}(e_4 - e_2),$$

and Eq. (35) can be verified. Finally, one can check that Eq. (33) is also satisfied.

Second, notice that the above-mentioned equations are just Eqs. (26), (27), (30), and (31), which generate $\underline{O_4}$, twisted by a Z_2 factor set. So due to the validity of the above-mentioned equations, $\forall g \in \overline{O_4}$, either g or $-g$ will be generated. But -1 can be generated. Therefore, the above-mentioned equation set generations $\overline{O_4}$. □

We can give another proof of this result by proposition 5. In fact, we introduce γ-matrices in E^4 as

$$\gamma_i = \begin{pmatrix} \mathbf{0}_{2\times 2} & i\sigma_i \\ i\sigma_i & \mathbf{0}_{2\times 2} \end{pmatrix}, \quad i = 1,2,3; \quad \gamma_4 = \begin{pmatrix} \mathbf{0}_{2\times 2} & -\mathbf{1}_{2\times 2} \\ \mathbf{1}_{2\times 2} & \mathbf{0}_{2\times 2} \end{pmatrix}$$

in which σ_i stand for three Pauli matrices

$$\sigma_1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \sigma_2 = \begin{pmatrix} 0 & i \\ -i & 0 \end{pmatrix}, \quad \sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}.$$

Note that σ_2 in our convention is different from the usual definition in physics. $\gamma_i (i = 1..4)$ satisfy Clifford relations $\gamma_i \gamma_j + \gamma_j \gamma_i = -2\delta_{ij}\mathbf{1}_{4\times 4}$ and $\gamma_i^\dagger = -\gamma_i, \gamma_i \gamma_i^\dagger = \mathbf{1}_{4\times 4}, \det(\gamma_i) = 1$.

We use $S(g)$ as the image of $s(g)$ in $M_2(\mathbf{H})$. Let

$$S(I_i) = \gamma_i, \quad S(\gamma) = \frac{i}{\sqrt{2}} \cdot \begin{pmatrix} 0 & 0 & 1 & -1 \\ 0 & 0 & -1 & -1 \\ 1 & -1 & 0 & 0 \\ -1 & -1 & 0 & 0 \end{pmatrix}, \quad S(t) = \frac{e^{i(7\pi/4)}}{\sqrt{2}} \cdot \begin{pmatrix} 1 & -i & 0 & 0 \\ 1 & i & 0 & 0 \\ 0 & 0 & i & 1 \\ 0 & 0 & -i & 1 \end{pmatrix}, \tag{36}$$

then one can check that these matrices give correct images under $\widetilde{\mathrm{Ad}}$ and satisfy the corresponding relations in Eqs. (32)–(35). It should be noticed that the $\widetilde{\mathrm{Ad}}$-map condition can fix these matrices

TABLE II. Conjugate classes of $\overline{O_4}$. The labels of classes are descended from those of O_4 with the ($'$) for those classes split when lifted into $\overline{O_4}$.

No.	1	1′	2	3	4	5	6	7	8	8′	9	10	11	12	13	14	14′	15	15′	16	17	18	19	20	20′
Num.	1	1	8	12	8	2	24	48	12	12	24	48	24	24	48	12	12	32	32	64	64	64	96	48	48

up to a nonvanishing scalar and that by using lemma 3, the scalar can be fixed up to a Z_4 uncertainty, namely if one searches out an $S(g)$ then $iS(g), -S(g), -iS(g)$ will also work. One can figure out two of them by calculating the projections on the basis of $\mathrm{Cl}(E^4)$ and ruling out those whose projections are purely imaginary.

We point out that the generating relations in proposition 7 are not unique, due to the canonical automorphism of $\mathrm{Cl}(E^4)$. In fact from the second proof of this proposition, we have noticed that at last there is still a Z_2 uncertainty. Consequently, we can change the cross section s to another one s' by a ''local'' Z_2 transformation and the underlined equations in Eqs. (32)–(35) may gain or lose some (-1)-factors accordingly. Anyway, they are equivalent to the former ones.

To classify the elements in $\overline{O_4}$, Lemma 4 will enable us to use the same symbols for the conjugate classes of O_4 and to use a ($'$) for those splitting classes. Except for classes 1,8,14,15,20, which split into two classes for each, any other class in O_4 is lifted to one class. Therefore, there are totally 25 classes in $\overline{O_4}$ (see Table II).

IV. REPRESENTATIONS OF $\overline{O_4}$

A. Single-valued representations of O_4

Due to Theorem 6, there are totally 20 inequivalent single-valued representations of O_4 corresponding to the 20 inequivalent irreducible representations of O_4; the representation theory of O_4 can be systematically solved by applying little group method (Proposition 1).

All inequivalent irreducible characters of Z_2^4 are listed in Table III. Following Theorem 4, $\Pi(Z_2^4)$ are partitioned into orbits with index set defined in a physical convention $\mathcal{I} := \{S,P,V,A,T\}$.

$$\Pi_S = \{\pi_{0000}\}, \quad F_S \cong S_4; \quad \Pi_P = \{\pi_{1111}\}, \quad F_P \cong S_4,$$

TABLE III. Character table of Z_2^4. $I_{i_1 i_2 \ldots I_a} := I_{i_1} \cdot I_{i_2} \cdot \ldots \cdot I_{i_a}$. Irreducible characters are labeled as $\chi_{s_1 s_2 s_3 s_4}, s_i \in \mathcal{Z}/2\mathcal{Z}$ [see Eq. (20)].

$$\Pi_V=\{\pi_{0001},\pi_{0010},\pi_{0100},\pi_{1000}\},\quad F_V\cong S_3,$$

$$\Pi_A=\{\pi_{1110},\pi_{1101},\pi_{1011},\pi_{0111}\},\quad F_A\cong S_3,$$

$$\Pi_T=\{\pi_{0011},\pi_{0101},\pi_{1001},\pi_{0110},\pi_{1010},\pi_{1100}\},\quad F_T\cong Z_2^2.$$

We will use $[\lambda]$ instead of (ν) to denote Young diagrams where $[\lambda]=[\lambda_1\lambda_2\ldots\lambda_n],\lambda_k=\sum_{i=k}^{n}\nu_i$.

1. Orbit S

All inequivalent irreducible representations of S_4 are labeled by $[4],[31],[2^2],[21^2],[1^4]$; accordingly,

$$\Pi_S\cdot([4],[31],[2^2],[21^2],[1^4])$$

provide two one-dimensional, one two-dimensional, and two three-dimensional representations. As for representation matrices, all $I_i,i=1,..,4$ are mapped to identity, while α,β,t,η take the same matrix form as they have in S_4, i.e., $\Pi_S\cdot[4]:I_i,\alpha,\beta,t,\eta\to 1$; $\Pi_S\cdot[1^4]:I_i,\alpha,\beta,t\to 1$, $\eta\to -1$;

$$\Pi_S\cdot[2^2]:I_i,\alpha,\beta\to\mathbf{1}_{2\times 2},t\to\begin{pmatrix} e^{i\frac{2\pi}{3}} & 0\\ 0 & e^{i\frac{4\pi}{3}}\end{pmatrix},\quad \eta\to\begin{pmatrix}0&1\\1&0\end{pmatrix},$$

$$\Pi_S\cdot[31]:I_i\to\mathbf{1}_{3\times 3},\alpha\to\begin{pmatrix}-1&0&0\\0&1&0\\0&0&-1\end{pmatrix},\quad \beta\to\begin{pmatrix}-1&0&0\\0&-1&0\\0&0&1\end{pmatrix},\quad t\to\begin{pmatrix}0&0&1\\1&0&0\\0&1&0\end{pmatrix},$$

$$\eta\to\begin{pmatrix}1&0&0\\0&0&1\\0&1&0\end{pmatrix};$$

$\Pi_S\cdot[21^2]$: I_i,α,β,t take the same form of $\Pi_S\cdot[31]$ and η gains a minus sign compared to $\Pi_S\cdot[31]$.

2. Orbit P

$$\Pi_P\cdot([4],[31],[2^2],[21^2],[1^4]).$$

The only difference from *orbit S* is that I_i are mapped to $-\mathbf{1}$.

3. Orbit V

All inequivalent irreducible representations of S_3 can be written as $[3],[21],[1^3]$ and it has no difficulty, using our generating relations, to check

$$\alpha\pi_{1000}\alpha^{-1}=\pi_{0100},\quad \eta\pi_{0100}\eta^{-1}=\pi_{0010},\quad \alpha\pi_{0010}\alpha^{-1}=\pi_{0001}.$$

Hence, this orbit gives two four-dimensional representations and one eight-dimensional representation,

$$\Pi_V\cdot([3],[21],[1^3])=(e,\alpha,\beta\eta,\alpha\beta\eta)\cdot\pi_{1000}\cdot([3],[21],[1^3]).$$

The representation matrices of $\Pi_V\cdot[3]$ are coincident with those in Eqs. (28) and (29). Representation matrices of $\Pi_V\cdot[1^3]$ are the same as those in $\Pi_V\cdot[3]$, except that η picking on a minus sign. $\Pi_V\cdot[21]$:

$$e_i\rightarrow\begin{pmatrix}\Pi_V\cdot[3](e_i) & \mathbf{0}_{4\times4}\\ \mathbf{0}_{4\times4} & \Pi_V\cdot[3](e_i)\end{pmatrix},$$

$$\alpha\rightarrow\begin{pmatrix}\Pi_V\cdot[3](\alpha) & \mathbf{0}_{4\times4}\\ \mathbf{0}_{4\times4} & \Pi_V\cdot[3](\alpha)\end{pmatrix},\quad \beta\rightarrow\begin{pmatrix}\mathbf{0}_{4\times4} & \Pi_V\cdot[3](\beta)\\ \Pi_V\cdot[3](\beta) & \mathbf{0}_{4\times4}\end{pmatrix},$$

$$t\rightarrow\begin{pmatrix}e^{i\frac{2\pi}{3}}\cdot\Pi_V\cdot[3](t) & \mathbf{0}_{4\times4}\\ \mathbf{0}_{4\times4} & e^{i\frac{4\pi}{3}}\cdot\Pi_V\cdot[3](t)\end{pmatrix},\quad \eta\rightarrow\begin{pmatrix}\mathbf{0}_{4\times4} & \Pi_V\cdot[3](\eta)\\ \Pi_V\cdot[3](\eta) & \mathbf{0}_{4\times4}\end{pmatrix}.$$

4. Orbit A

Similar to *orbit V*, there are two four-dimensional representations and one eight-dimensional representation,

$$\Pi_A\cdot([3],[21],[1^3])=(e,\alpha,\beta\eta,\alpha\beta\eta)\cdot\pi_{0111}\cdot([3],[21],[1^3])$$

while the representation matrices for I_i pick on a minus sign, without changing the others.

5. Orbit T

The stationary subgroup F_T leaving π_{0110} invariant is $\{e,\eta,\alpha\beta,\alpha\beta\eta\}$ with four one-dimensional irreducible representations, denoted by $\pi_{(a,b)},a,b=0,1$. Therefore, there are four six-dimensional representations given by this orbit. Notice that

$$\alpha\pi_{0110}\alpha^{-1}=\pi_{1001},\quad t\pi_{1001}t^{-1}=\pi_{1010},\quad t\pi_{1010}t^{-1}=\pi_{1100},$$

$$\alpha\pi_{1010}\alpha^{-1}=\pi_{0101},\quad \beta\pi_{1100}\beta^{-1}=\pi_{0011},$$

the four representations can be labeled as

$$\Pi_T\cdot(\pi_{00},\pi_{01},\pi_{10},\pi_{11})=(e,\alpha,\alpha\beta t,\beta t^2,\beta t,t^2)\cdot\pi_{0110}\cdot(\pi_{00}+\pi_{01}+\pi_{10}+\pi_{11}).$$

Then we enumerate the matrices for the four representations,

$$\Pi_T\cdot\pi_{00}:I_1\rightarrow\mathrm{diag}(1,-1,-1,-1,1,1),\quad I_2\rightarrow\mathrm{diag}(-1,1,1,-1,-1,1),$$

$$I_3\rightarrow\mathrm{diag}(-1,1,-1,1,1,-1),\quad I_4\rightarrow\mathrm{diag}(1,-1,1,1,-1,-1),$$

$$\alpha\rightarrow\begin{pmatrix}0&1&0&0&0&0\\1&0&0&0&0&0\\0&0&0&0&1&0\\0&0&0&1&0&0\\0&0&1&0&0&0\\0&0&0&0&0&1\end{pmatrix},\quad \beta\rightarrow\begin{pmatrix}0&1&0&0&0&0\\1&0&0&0&0&0\\0&0&1&0&0&0\\0&0&0&0&0&1\\0&0&0&0&1&0\\0&0&0&1&0&0\end{pmatrix},$$

$$t\to\begin{pmatrix}0&0&0&0&0&1\\0&0&0&1&0&0\\0&1&0&0&0&0\\0&0&1&0&0&0\\1&0&0&0&0&0\\0&0&0&0&1&0\end{pmatrix},\quad \eta\to\begin{pmatrix}1&0&0&0&0&0\\0&1&0&0&0&0\\0&0&0&1&0&0\\0&0&1&0&0&0\\0&0&0&0&0&1\\0&0&0&0&1&0\end{pmatrix},$$

$$\Pi_T\cdot\pi_{01}: I_1\to\Pi_2\cdot\pi_{00}(I_1),\quad I_2\to\Pi_T\cdot\pi_{00}(I_2),\quad I_3\to\Pi_T\cdot\pi_{00}(I_3),\quad I_4\to\Pi_T\cdot\pi_{00}(I_4),$$

$$\alpha\to\begin{pmatrix}0&1&0&0&0&0\\1&0&0&0&0&0\\0&0&0&0&1&0\\0&0&0&-1&0&0\\0&0&1&0&0&0\\0&0&0&0&0&-1\end{pmatrix},\quad \beta\to\begin{pmatrix}0&-1&0&0&0&0\\-1&0&0&0&0&0\\0&0&-1&0&0&0\\0&0&0&0&0&1\\0&0&0&0&-1&0\\0&0&0&1&0&0\end{pmatrix},$$

$$t\to\begin{pmatrix}0&0&0&0&0&1\\0&0&0&1&0&0\\0&1&0&0&0&0\\0&0&1&0&0&0\\-1&0&0&0&0&0\\0&0&0&0&-1&0\end{pmatrix},\quad \eta\to\begin{pmatrix}1&0&0&0&0&0\\0&-1&0&0&0&0\\0&0&0&-1&0&0\\0&0&-1&0&0&0\\0&0&0&0&0&-1\\0&0&0&0&-1&0\end{pmatrix},$$

$$\Pi_T\cdot\pi_{10}: I_1\to\Pi_T\cdot\pi_{00}(I_1),\quad I_2\to\Pi_T\cdot\pi_{00}(I_2),\quad I_3\to\Pi_T\cdot\pi_{00}(I_3),\quad I_4\to\Pi_T\cdot\pi_{00}(I_4),$$

$$\alpha\to\Pi_T\cdot\pi_{00}(\alpha),\quad \beta\to\Pi_T\cdot\pi_{00}(\beta),\quad t\to\Pi_T\cdot\pi_{00}(t),\quad \eta\to(-1)\cdot\Pi_T\cdot\pi_{00}(\eta),$$

$$\Pi_T\cdot\pi_{11}: I_1\to\Pi_T\cdot\pi_{01}(I_1),\quad I_2\to\Pi_T\cdot\pi_{01}(I_2),\quad I_3\to\Pi_T\cdot\pi_{01}(I_3),\quad I_4\to\Pi_T\cdot\pi_{01}(I_4),$$

$$\alpha\to\Pi_T\cdot\pi_{01}(\alpha),\quad \beta\to\Pi_T\cdot\pi_{01}(\beta),\quad t\to\Pi_T\cdot\pi_{01}(t),\quad \eta\to(-1)\cdot\Pi_T\cdot\pi_{01}(\eta).$$

Here we find all 20 inequivalent irreducible representations corresponding to the 20 conjugate classes of O_4, which satisfy Burside formula

$$2\times(1^2+1^2+2^2+3^2+3^2)+2\times(4^2+4^2+8^2)+4\times6^2=384.$$

Following Proposition 6, we have found all of the single-valued representations of O_4.

B. Spinor representations of O_4

Notice the following facts that $\overline{Z_2^4}\lhd\overline{O_4}$, $\overline{O_4}/\overline{Z_2^4}\cong S_4$ and Eq. (36) generates a spinor representation of O_4 which is still denoted as S; what's more, its restriction to $\overline{Z_2^4}$ is also a two-valued representation of Z_2^4. These facts ensure two conditions in Theorem 1. To apply Theorem 1 to deduce spinor representations of O_4, we develop a calculation method. The matrices of a spinor representation of O_4 for I_i,γ,t, denoted as $\tilde{S}(I_i),\tilde{S}(\gamma),\tilde{S}(t)$, can be decomposed as

$$\tilde{S}(I_i)=S(I_i)\otimes\mathbf{1},\quad i=1,3,4,\quad \tilde{S}(I_2)=-S(I_2)\otimes\mathbf{1};$$

$$\tilde{S}(\gamma)=\Gamma\otimes\tilde{\gamma};\quad \tilde{S}(t)=T\otimes\tilde{t},$$

where Γ, T and $S(I_i)$ act on the same module, $\tilde{\gamma}, \tilde{t}$ have *the same texture (zero matrix elements) of the representation matrices of five inequivalent irreducible representations of* S_4 [the minus added before $S(I_2)$ is for a physical convention]. There are five spinor representations of dimension 4,4,8,12, and 12, respectively, and the second half of Burside formula is satisfied

$$4^2+4^2+8^2+12^2+12^2=384.$$

Corresponding to the generating equations (32)–(35), there are a system of matrix equations

$$\tilde{S}(\gamma)^2=\tilde{S}(t)^3=-\mathbf{1}, \quad (\tilde{S}(\gamma)\tilde{S}(t))^4=-\mathbf{1}, \tag{37}$$

$$\tilde{S}(\gamma)\tilde{S}(I_2)=-\tilde{S}(I_2)\tilde{S}(\gamma), \quad \tilde{S}(\gamma)\tilde{S}(I_4)=-\tilde{S}(I_4)\tilde{S}(\gamma), \quad \tilde{S}(\gamma)\tilde{S}(I_1)=-\tilde{S}(I_3)\tilde{S}(\gamma), \tag{38}$$

$$\tilde{S}(t)\tilde{S}(I_1)=\tilde{S}(I_1)\tilde{S}(t), \quad \tilde{S}(t)\tilde{S}(I_2)=-\tilde{S}(I_4)\tilde{S}(t), \quad \tilde{S}(t)\tilde{S}(I_3)=-\tilde{S}(I_2)\tilde{S}(t),$$

$$\tilde{S}(t)\tilde{S}(I_4)=\tilde{S}(I_3)\tilde{S}(t), \tag{39}$$

plus a unitary condition

$$\tilde{S}(\gamma)^{\dagger}\tilde{S}(\gamma)=\mathbf{1}, \quad \tilde{S}(t)^{\dagger}\tilde{S}(t)=\mathbf{1}. \tag{40}$$

Note that we add a minus sign to the second and the third equations in Eq. (39) compared with Eq. (35) according to the same physics convention, though they are completely equivalent.

Solving Eqs. (37)–(40) for the four-dimensional case gives two solutions:

$$\underline{4}_+ : \tilde{S}(\gamma)=\Gamma\cdot\tilde{\gamma}_+, \quad \Gamma=\frac{1}{\sqrt{2}}\cdot\begin{pmatrix} 0 & 0 & 1 & -1 \\ 0 & 0 & -1 & -1 \\ 1 & -1 & 0 & 0 \\ -1 & -1 & 0 & 0 \end{pmatrix}, \quad \tilde{\gamma}_+=i,$$

$$\tilde{S}(t)=T\cdot\tilde{t}, \quad T=\frac{1}{\sqrt{2}}\cdot\begin{pmatrix} 1 & -i & 0 & 0 \\ 1 & i & 0 & 0 \\ 0 & 0 & i & 1 \\ 0 & 0 & -i & 1 \end{pmatrix}, \quad \tilde{t}=e^{i(7\pi/4)},$$

$$\underline{4}_- : \tilde{S}(\gamma)=\Gamma\cdot\tilde{\gamma}_-, \quad \tilde{\gamma}_-=-i, \quad \tilde{S}(t)=T\cdot\tilde{t}.$$

Note that $\underline{4}_+$ is just the representation S with $\tilde{S}(I_2)=-S(I_2)$.

As for the eight-dimensional case we can suppose

$$\tilde{\gamma}=\begin{pmatrix} 0 & \tilde{c} \\ \tilde{d} & 0 \end{pmatrix}, \quad \tilde{t}=\begin{pmatrix} \tilde{a} & 0 \\ 0 & \tilde{d} \end{pmatrix}.$$

The solution $\underline{8}$ is given by

$$\tilde{c}=e^{i(\pi/3)}, \quad \tilde{d}=e^{i(2\pi/3)}, \quad \tilde{a}=e^{i(5\pi/12)}, \quad \tilde{d}=e^{i(13\pi/12)}.$$

Finally, we set for the twelve-dimensional case

$$\tilde{\gamma}=\begin{pmatrix} 0 & 0 & \tilde{z} \\ 0 & \tilde{y} & 0 \\ \tilde{x} & 0 & 0 \end{pmatrix}, \quad \tilde{t}=\begin{pmatrix} 0 & 0 & \tilde{n} \\ \tilde{l} & 0 & 0 \\ 0 & \tilde{m} & 0 \end{pmatrix},$$

such that

$$\underline{12}_+ : \tilde{x}=1, \quad \tilde{y}=i, \quad \tilde{z}=-1, \quad \tilde{l}=1, \quad \tilde{m}=1, \quad \tilde{n}=e^{i(5\pi/4)},$$

$$\underline{12}_- : \tilde{x}=1, \quad \tilde{y}=-i, \quad \tilde{z}=-1, \quad \tilde{l}=1, \quad \tilde{m}=-1, \quad \tilde{n}=e^{i(\pi/4)}.$$

So far, we obtain all inequivalent irreducible representations of $\overline{O_4}$ and we summarize our results in Table IV.

V. STRUCTURE OF $\overline{SO_4}$

Specify $n=4$ in Eq. (21). Then we know immediately that $|SO_4|=192$. Introduce

$$\eta=\gamma t\gamma t^2\gamma, \tag{41}$$

$$\alpha=(t^2\gamma)^2, \quad \beta=t\gamma t^2\gamma t, \tag{42}$$

$$x=e_1\eta, \quad y=e_4\eta, \quad q=e_2\eta. \tag{43}$$

Then the structure of SO_4 can be summarized as

$$x^2=y^2=q^4=e, \quad yx=xy, \quad qx=xq^3, \quad qy=yq^3, \tag{44}$$

$$\alpha^2=\beta^2=t^3=e, \quad \beta\alpha=\alpha\beta, \quad t\alpha=\alpha\beta t, \quad t\beta=\alpha t, \tag{45}$$

$$\alpha x=q\beta, \quad \alpha y=q^3\beta, \quad \alpha q=x\beta, \tag{46}$$

$$\beta x=q^3\alpha, \quad \beta y=q\alpha, \quad \beta q=y\alpha, \tag{47}$$

$$tx=xt^2, \quad ty=q^3t^2, \quad tq=yt^2, \tag{48}$$

together with

$$x\alpha=\beta q^3, \quad xt=t^2x, \quad y\beta=\alpha q^3, \quad yt=t^2q^3, \quad qt=t^2y. \tag{49}$$

Accordingly, each group element can be expressed as a ''normal ordering'' product of $x,y\rightarrow q\rightarrow\alpha,\beta\rightarrow t$ and their powers from left to right. Throwing away all classes which belong to O_4 but not to SO_4, there are 11 left which are 1,3,5,7,8,11,12,14,15,18,20 in Table I. The 14th and the 20th will part into two classes with equal numbers of elements each under adjoint action of SO_4 which are denoted as $14,\underline{14'},20,\underline{20'}$. Therefore, there are 13 conjugate classes in SO_4.

Due to the fact that $\overline{SO_4}\lhd\overline{O_4}$, the diagram

$$\begin{array}{ccccccccc} 0 & \rightarrow & Z_2 & \rightarrow & \overline{O_4} & \overset{\pi}{\rightarrow} & O_4 & \rightarrow & 1 \\ & & \| & & \uparrow & & \uparrow & & \\ 0 & \rightarrow & Z_2 & \rightarrow & \overline{SO_4} & \rightarrow & SO_4 & \rightarrow & 1 \end{array}$$

is commutative. We can lift generating relations (44), (45)–(49) to

$$x^2=y^2=q^4=-1, \quad yx=-xy, \quad qx=-xq^3, \quad qy=-yq^3,$$

TABLE IV. Character table of $\overline{O_4}$. Character is labeled by a superscript showing its dimension where an underline shows a spinor representation and a subscript distinguishing different representations with same dimension.

by definitions (41)–(43). As to the conjugate classification, 1,5,8,11,14,15,18,20,$14'$,$20'$ violate relation $-g\sim g$, so that $\overline{SO_4}$ is partitioned into 23 classes, suggesting that there are altogether 23 inequivalent irreducible representations in which 13 representations are single valued to SO_4. We summarize the conjugate classes of $\overline{SO_4}$ in Table V.

VI. REPRESENTATION THEORY OF $\overline{SO_4}$

All inequivalent irreducible representations of $\overline{SO_4}$ can be reduced from those of $\overline{O_4}$. Table VI gives the characters of all inequivalent irreducible representations of $\overline{O_4}$, with respect to the classes of $\overline{SO_4}$. A brief observation gives some important information. First, $1_1\cong 1_4, 1_2\cong 1_3, 2_1\cong 2_2, 3_1\cong 3_4, 3_2\cong 3_3, 4_1\cong 4_4, 4_2\cong 4_3, 8_1\cong 8_2, 6_1\cong 6_3$. Second, omitting equivalence, 1_1, 1_2, 2_1, 3_1, 3_1, 4_1, 4_2, 8_1, 6_1, remain irreducible within $\overline{SO_4}$, while other seven become reducible. Third, as for each of these reducible ones, the inner product of the character with itself equals 2, implying that it can be reduced to two inequivalent irreducible representations; thus there are 13 single-valued and 10 spinor representations as we expected. Finally, it is one possible solution to the Burside theorem that each of these seven reducible representations splits into two inequivalent irreducible representations with equal dimensions. We conjecture that it is the solution to our representation theory of $\overline{SO_4}$ and try to verify it in the following.

Summarily speaking, there are nine single-valued inequivalent irreducible representations inherited from $\overline{O_4}$,

$$1_1, 1_2, 2\equiv 2_1, 3_1, 3_2, 4_1, 4_2, 8\equiv 8_1, 6\equiv 6_1$$

and we conjecture the splitting relations

$$6_2, 6_4 \to 3_\alpha, 3_\beta, 3_\gamma, 3_\delta,$$

$$\underline{4}_1, \underline{4}_2 \to 2_\alpha, 2_\beta, 2_\gamma, 2_\delta,$$

$$\underline{8} \to 4_\alpha, 4_\beta,$$

$$\underline{12}_1, \underline{12}_2 \to 6_\alpha, 6_\beta, 6_\gamma, 6_\delta.$$

A. Hidden single-valued representations

The representation matrices of x, y, q in 6_2 are written as

$$x\mapsto\begin{pmatrix}1&0&0&0&0&0\\0&1&0&0&0&0\\0&0&0&1&0&0\\0&0&1&0&0&0\\0&0&0&0&0&-1\\0&0&0&0&-1&0\end{pmatrix},\quad y\mapsto\begin{pmatrix}1&0&0&0&0&0\\0&1&0&0&0&0\\0&0&0&-1&0&0\\0&0&-1&0&0&0\\0&0&0&0&0&1\\0&0&0&0&1&0\end{pmatrix},$$

$$q\mapsto\begin{pmatrix}-1&0&0&0&0&0\\0&-1&0&0&0&0\\0&0&0&-1&0&0\\0&0&1&0&0&0\\0&0&0&0&0&1\\0&0&0&0&-1&0\end{pmatrix}.$$

The textures of these matrices inspire us to such hypotheses that in $3_{\alpha,\beta,\gamma,\delta}$, x,y,q take on a form like

$$x,y\mapsto\begin{pmatrix}\pm1&\\&\pm H\end{pmatrix},\quad q\mapsto\begin{pmatrix}\pm1&\\&\pm Q\end{pmatrix},$$

where

$$H\equiv\begin{pmatrix}0&1\\1&0\end{pmatrix},\quad Q\equiv\begin{pmatrix}0&-1\\1&0\end{pmatrix}.$$

After taking account of the conjugate equivalence, only four possibilities survive from the totally 64, i.e.,

$$\text{I:}x\to\begin{pmatrix}1&\\&H\end{pmatrix},\quad y\to\begin{pmatrix}1&\\&-H\end{pmatrix},\quad q\to\begin{pmatrix}-1&\\&Q\end{pmatrix},\tag{50}$$

$$\text{II:}x\to\begin{pmatrix}-1&\\&H\end{pmatrix},\quad y\to\begin{pmatrix}-1&\\&-H\end{pmatrix},\quad q\to\begin{pmatrix}1&\\&Q\end{pmatrix},\tag{51}$$

$$\text{III:}x\to\begin{pmatrix}1&\\&-H\end{pmatrix},\quad y\to\begin{pmatrix}1&\\&H\end{pmatrix},\quad q\to\begin{pmatrix}-1&\\&Q\end{pmatrix},\tag{52}$$

$$\text{IV:}x\to\begin{pmatrix}-1&\\&-H\end{pmatrix},\quad y\to\begin{pmatrix}-1&\\&H\end{pmatrix},\quad q\to\begin{pmatrix}1&\\&Q\end{pmatrix},\tag{53}$$

which also satisfy Eq. (44). Then we regard α,β,t as unknowns, Eqs. (45)–(49) as constraints, and solve these matrix equations. Modulo similarity, each of Eqs. (50)–(53) gives two solutions, labeled as I, I′, II, II′, III, III′, IV, IV′; however, there is no difficulty to find out that I≅III, I′≅III′, II≅IV, II′≅IV′. Thus I, I′, II, II′ are what we need:

$$3_\alpha \equiv \mathrm{I}{:}\alpha \to \mathrm{diag}(-1,1,-1),\quad \beta \to \mathrm{diag}(1,-1,-1),\quad t \to \begin{pmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix},$$

$$3_\beta \equiv \mathrm{I}'{:}\alpha \to \mathrm{diag}(1,-1,-1),\quad \beta \to \mathrm{diag}(-1,-1,1),\quad t \to \begin{pmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix},$$

$$3_\gamma \equiv \mathrm{II}{:}\alpha \to \mathrm{diag}(-1,1,-1),\quad \beta \to \mathrm{diag}(1,-1,-1),\quad t \to \begin{pmatrix} 0 & 0 & 1 \\ -1 & 0 & 0 \\ 0 & -1 & 0 \end{pmatrix},$$

$$3_\delta \equiv \mathrm{II}'{:}\alpha \to \mathrm{diag}(1,-1,-1),\quad \beta \to \mathrm{diag}(-1,-1,1),\quad t \to \begin{pmatrix} 0 & 0 & 1 \\ -1 & 0 & 0 \\ 0 & -1 & 0 \end{pmatrix}.$$

B. Spinor representations

It is more straightforward to reduce out the spinor representations. We recall that the spinor representation matrices of O_4 are of the form of tensor product

$$S_i(g) = S(g) \otimes s_i(g),\quad \forall g \in \overline{O_4}, i = \underline{4}_1, \underline{4}_2, \underline{8}, \underline{12}_1, \underline{12}_2,$$

where S is given by the algebraic isomorphism from $\mathrm{Cl}(E^4)$ to $M_2(\mathbf{H})$ and s_i has the same texture (zero matrix element positions) of irreducible representation i of S_4. Additionally, for g in $\overline{SO_4}$, $S(g)$ takes on a 2-by-2 block diagonal form

$$S(g) = \begin{pmatrix} S_{\mathrm{up}}(g) & 0 \\ 0 & S_{\mathrm{down}}(g) \end{pmatrix}. \tag{54}$$

So it is just what we want

$$S_{\mathrm{up}}(x) = \frac{1}{\sqrt{2}} \cdot \begin{pmatrix} e^{i(3/4)\pi} & e^{i(-3/4)\pi} \\ e^{i(1/4)\pi} & e^{i(-1/4)\pi} \end{pmatrix},\quad S_{\mathrm{up}}(y) = \frac{1}{\sqrt{2}} \cdot \begin{pmatrix} e^{i(3/4)\pi} & e^{i(1/4)\pi} \\ e^{i(-3/4)\pi} & e^{i(-1/4)\pi} \end{pmatrix}, \tag{55}$$

$$S_{\mathrm{up}}(q) = \frac{1}{\sqrt{2}} \cdot \begin{pmatrix} e^{i(1/4)\pi} & e^{i(3/4)\pi} \\ e^{i(3/4)\pi} & e^{i(1/4)\pi} \end{pmatrix},\quad S_{\mathrm{up}}(t) = \frac{1}{\sqrt{2}} \cdot \begin{pmatrix} 1 & -i \\ 1 & i \end{pmatrix}, \tag{56}$$

$$S_{\mathrm{up}}(\alpha) = \begin{pmatrix} 0 & -i \\ -i & 0 \end{pmatrix},\quad S_{\mathrm{up}}(\beta) = \begin{pmatrix} -i & 0 \\ 0 & i \end{pmatrix}, \tag{57}$$

$$S_{\mathrm{down}}(x) = \frac{1}{\sqrt{2}} \cdot \begin{pmatrix} e^{i(3/4)\pi} & e^{i(-3/4)\pi} \\ e^{i(1/4)\pi} & e^{i(-1/4)\pi} \end{pmatrix},\quad S_{\mathrm{down}}(y) \to \frac{1}{\sqrt{2}} \cdot \begin{pmatrix} e^{i(-1/4)\pi} & e^{i(-3/4)\pi} \\ e^{i(1/4)\pi} & e^{i(3/4)\pi} \end{pmatrix}, \tag{58}$$

$$S_{\mathrm{down}}(q) = \frac{1}{\sqrt{2}} \cdot \begin{pmatrix} e^{i(1/4)\pi} & e^{i(3/4)\pi} \\ e^{i(3/4)\pi} & e^{i(1/4)\pi} \end{pmatrix},\quad S_{\mathrm{down}}(t) = \frac{1}{\sqrt{2}} \cdot \begin{pmatrix} i & 1 \\ -i & 1 \end{pmatrix}, \tag{59}$$

$$S_{\mathrm{down}}(\alpha) = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix},\quad S_{\mathrm{down}}(\beta) = \begin{pmatrix} 0 & -i \\ -i & 0 \end{pmatrix}. \tag{60}$$

Keeping the second factor unchanged, each spinor representation in $\overline{O_4}$ splits into two spinor representations in $\overline{SO_4}$, denoted as 2_α, 2_β, 2_γ, 2_δ, 4_α, 4_β, 6_α, 6_β, 6_γ, 6_δ.

In fact, $S(g)$ falls in the so-called ''chiral''-representation of $\mathrm{Cl}(E^4)$ in physical language. Due to $\mathrm{Cl}(V)=\mathrm{Cl}(V)_e\oplus\mathrm{Cl}(V)_o$, and the choice of chiral-representation, there are

$$\mathrm{Cl}(E^4)_e\cong\begin{pmatrix}\mathbf{H} & O\\ 0 & \mathbf{H}\end{pmatrix},\quad \mathrm{Cl}(E^4)_o\cong\begin{pmatrix}0 & \mathbf{H}\\ \mathbf{H} & 0\end{pmatrix}.$$

Notice that $\overline{SO_4}<\mathrm{Spin}(4)\subset\mathrm{Cl}(E^4)_e$, so our reducing process for spinor representations roots in the structure of Clifford algebra.

Conclusively, our conjecture gives all inequivalent irreducible representations of $\overline{SO_4}$ whose characters are summarized in Table VII.

APPENDIX: FUNDAMENTAL LEMMA OF *n*-DIMENSIONAL EUCLIDEAN GEOMETRY

Lemma A1 (Weak form): Let $p_i, i=0,1,2,\ldots,n$ be $n+1$ *points in n-dimensional Euclidean space* E^n *which are noncollinear and give* $n+1$ *non-negative real numbers* $d_i, i=0,1,2,\ldots,n$, *then there exists at most one point* $p\in E^n$ *s.t.* $d(p,p_i)=d_i$.

Proof: Without losing generality, set $p_0=(0,0,\ldots,0)$ and understand $p,p_i, i=1,2,\ldots,n$ as vectors in E^n. Consider equation set

$$(p-p_i,p-p_i)=d_i^2,\quad i=1,2,\ldots,n, \tag{A1}$$

$$(p,p)=d_0^2, \tag{A2}$$

where $(,)$ is the standard inner product of E^n.

Substitute Eq. (A2) into Eq. (A1)

$$(p_i,p)=\tfrac{1}{2}(d_0^2-d_i^2+(p_i,p_i)),\quad i=1,2,\ldots,n. \tag{A3}$$

The noncollinearity implies that Eq. (A3) has a solution p. The weak form of *fundamental lemma of Euclidean geometry* follows. □

(Received 9 October 2000; accepted for publication 6 February 2001)

Motivated by a quaternionic formulation of quantum mechanics, we discuss quaternionic and complex linear differential equations. We touch only a few aspects of the mathematical theory, namely the resolution of the second order differential equations with constant coefficients. We overcome the problems coming out from the loss of the fundamental theorem of the algebra for quaternions and propose a practical method to solve quaternionic and complex linear second order differential equations with constant coefficients. The resolution of the complex linear Schrödinger equation, in the presence of quaternionic potentials, represents an interesting application of the mathematical material discussed in this paper. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1360195]

I. INTRODUCTION

There is substantial literature analyzing the possibility to discuss quantum systems by adopting quaternionic wave functions.[1–14] This research field has been attacked by a number of people leading to substantial progress. In the last years, many articles,[15–31] review papers[32–34] and books[35–37] provided a detailed investigation of group theory, eigenvalue problem, scattering theory, relativistic wave equations, Lagrangian formalism and variational calculus within a quaternionic formulation of quantum mechanics and field theory. In this context, by observing that the formulation of physical problems in mathematical terms often requires the study of partial differential equations, we develop the necessary theory to solve quaternionic and complex linear differential equations. The main difficulty in carrying out the solution of quaternionic differential equations is obviously represented by the noncommutative nature of the quaternionic field. The standard methods of resolution break down and, consequently, we need to modify the classical approach. It is not our purpose to develop a complete quaternionic theory of differential equations. This exceeds the scope of this paper. The main objective is to include what seemed to be most important for an introduction to this subject. In particular, we restrict ourselves to second order differential equations and give a practical method to solve such equations when quaternionic constant coefficients appear.

Some of the results given in this paper can be obtained by translation into a complex formalism.[15,16,31] Nevertheless, many subtleties of quaternionic calculus are often lost by using the translation trick. See, for example, the difference between quaternionic and complex geometry in quantum mechanics,[32,34] generalization of variational calculus,[9,10] the choice of a one-dimensional quaternionic Lorentz group for special relativity,[21] the new definitions of transpose and determinant for quaternionic matrices.[29] A wholly quaternionic derivation of the general solution of second order differential equations requires a detailed discussion of the fundamental theorem of algebra for quaternions, a revision of the resolution methods and a quaternionic generalization of the complex results.

[b)]Electronic mail: ducati@mat.ufpr.br

The study of quaternionic linear second order differential equations with constant coefficients is based on the explicit resolution of the characteristic quadratic equation.[38–41] We shall show that the loss of fundamental theorem of the algebra for quaternions does not represent a problem in solving quaternionic linear second order differential equations with constant coefficients. From there, we introduce more advanced concepts, like diagonalization and Jordan form for quaternionic and complex linear matrix operators, which are developed in detail in the recent literature[22–31] and we apply them to solve quaternionic and complex linear second order differential equations with constant coefficients.

As an application of the mathematical material presented in this paper, we discuss the complex linear Schrödinger equation in the presence of quaternionic potentials and solve such an equation for stationary states and constant potentials. We also calculate the relation between the reflection and transmition coefficients for the step and square potential and give the quaternionic solution for bound states.

This work was intended as an attempt at motivating the study of quaternionic and complex linear differential equations in view of their future applications within a quaternionic formulation of quantum mechanics. In particular, our future objective is to understand the role that such equations could play in developing nonrelativistic quaternionic quantum dynamics[4] and the meaning that quaternionic potentials[15,16] could play in discussing CP violation in the kaon system.[36]

In order to give a clear exposition and to facilitate access to the individual topics, the sections are rendered as self-contained as possible. In Sec. II, we review some of the standard concepts used in quaternionic quantum mechanics, i.e., state vector, probability interpretation, scalar product and left/right quaternionic operators.[29,35,42–45] Section III contains a brief discussion of the momentum operator. In Sec. IV, we summarize without proofs the relevant material on quaternionic eigenvalue equations from Ref. 31. Section V is devoted to the study of the one-dimensional Schrödinger equation in quaternionic quantum mechanics. Sections VI and VII provide a detailed exposition of quaternionic and complex linear differential equations. In Sec. VIII, we apply the results of previous sections to the one-dimensional Schrödinger equation with quaternionic constant potentials. Our conclusions are drawn in the final section.

II. STATES AND OPERATORS IN QUATERNIONIC QUANTUM MECHANICS

In this section, we give a brief survey of the basic mathematical tools used in quaternionic quantum mechanics.[32–37] The quantum state of a particle is defined, at a given instant, by a quaternionic wave function interpreted as a probability amplitude given by

$$\Psi(\mathbf{r})=[f_0+\mathbf{h}\cdot\mathbf{f}](\mathbf{r}), \tag{1}$$

where $\mathbf{h}=(i,j,k)$, $\mathbf{f}=(f_1,f_2,f_3)$ and $f_m:\mathbb{R}^3\to\mathbb{R}$, $m=0,1,2,3$. The probabilistic interpretation of this wave function requires that it belong to the Hilbert vector space of square-integrable functions. We shall denote by $\mathcal{F}$ the set of wave functions composed of sufficiently regular functions of this vector space. The same function $\Psi(\mathbf{r})$ can be represented by several distinct sets of components, each one corresponding to the choice of a particular basis. With each pair of elements of $\mathcal{F}$, $\Psi(\mathbf{r})$, and $\Phi(\mathbf{r})$, we associate the quaternionic scalar product,

$$(\Psi,\Phi)=\int d^3r\overline{\Psi}(\mathbf{r})\Phi(\mathbf{r}), \tag{2}$$

where

$$\overline{\Psi}(\mathbf{r})=[f_0-\mathbf{h}\cdot\mathbf{f}](\mathbf{r}) \tag{3}$$

represents the quaternionic conjugate of $\boldsymbol{\Psi}(\mathbf{r})$.

A quaternionic linear operator, $\mathcal{O}_{\mathbb{H}}$, associates with every wave function $\Psi(\mathbf{r})\in\mathcal{F}$ another wave function $\mathcal{O}_{\mathbb{H}}\Psi(\mathbf{r})\in\mathcal{F}$, the correspondence being linear from the right on $\mathbb{H}$,

$$\mathcal{O}_{\mathbb{H}}[\Psi_1(\mathbf{r})q_1+\Psi_2(\mathbf{r})q_2]=[\mathcal{O}_{\mathbb{H}}\Psi_1(\mathbf{r})]q_1+[\mathcal{O}_{\mathbb{H}}\Psi_2(\mathbf{r})]q_2,$$

$q_{1,2}\in\mathbb{H}$. Due to the noncommutative nature of the quaternionic field we need to introduce complex and real linear quaternionic operators, respectively, denoted by $\mathcal{O}_{\mathbb{C}}$ and $\mathcal{O}_{\mathbb{R}}$, the correspondence being linear from the right on $\mathbb{C}$ and $\mathbb{R}$

$$\mathcal{O}_{\mathbb{C}}[\Psi_1(\mathbf{r})z_1+\Psi_2(\mathbf{r})z_2]=[\mathcal{O}_{\mathbb{C}}\Psi_1(\mathbf{r})]z_1+[\mathcal{O}_{\mathbb{C}}\Psi_2(\mathbf{r})]z_2,$$

$$\mathcal{O}_{\mathbb{R}}[\Psi_1(\mathbf{r})\lambda_1+\Psi_2(\mathbf{r})\lambda_2]=[\mathcal{O}_{\mathbb{H}}\Psi_1(\mathbf{r})]\lambda_1+[\mathcal{O}_{\mathbb{H}}\Psi_2(\mathbf{r})]\lambda_2,$$

$z_{1,2}\in\mathbb{C}$ and $\lambda_{1,2}\in\mathbb{R}$.

As a concrete illustration of these operators let us consider the case of a finite, say n-dimensional, quaternionic Hilbert space. The wave function $\Psi(\mathbf{r})$ will then be a column vector,

$$\Psi=\begin{pmatrix}\Psi_1\\ \Psi_2\\ \vdots\\ \Psi_n\end{pmatrix},\quad \Psi_{1,2,\ldots,n}\in\mathcal{F}.$$

Quaternionic, complex and real linear operators will be represented by $n\times n$ quaternionic matrices $M_n[\mathcal{A}\otimes\mathcal{O}]$, where $\mathcal{O}$ represents the space of real operators acting on the components of Ψ and $\boldsymbol{\mathcal{A}}=(\mathcal{A}_{\mathbb{H}},\mathcal{A}_{\mathbb{C}},\mathcal{A}_{\mathbb{R}})$ denote the real algebras,

$$\mathcal{A}_{\mathcal{H}}\ :\ \{\mathbf{1},\ \mathbf{L},\ \mathbf{R},\ \mathbf{L}*\mathbf{R}\}_{16},$$

$$\mathcal{A}_{\mathbb{C}}\ :\ \{\mathbf{1},\ \mathbf{L},\ R_i,\ \mathbf{L}R_i\}_8,$$

$$\mathcal{A}_{\mathbb{R}}\ :\ \{\mathbf{1},\ \mathbf{L}\}_4,$$

generated by the left and right operators,

$$\mathbf{L}:=(L_i,L_j,L_k),\quad \mathbf{R}:=(R_i,R_j,R_k),\tag{4}$$

and by the mixed operators,

$$\mathbf{L}*\mathbf{R}:=\{L_pR_q\},\quad p,q=i,j,k.\tag{5}$$

The action of these operators on the quaternionic wave function Ψ is given by

$$\mathbf{L}\Psi\equiv\mathbf{h}\Psi,\quad \mathbf{R}\Psi\equiv\Psi\mathbf{h}.$$

The operators $\mathbf{L}$ and $\mathbf{R}$ satisfy the left/right quaternionic algebra,

$$L_i^2=L_j^2=L_k^2=L_iL_jL_k=R_i^2=R_j^2=R_k^2=R_kR_jR_i=-\mathbf{1},$$

and the following commutation relations:

$$[L_p,R_q]=0.$$

III. SPACE TRANSLATIONS AND QUATERNIONIC MOMENTUM OPERATOR

Space translation operators in quaternionic quantum mechanics are defined in the coordinate representation by the real linear anti-Hermitian operator,[36]

$$\boldsymbol{\partial}\equiv(\partial_x,\partial_y,\partial_z).\tag{6}$$

To construct an observable momentum operator we must look for a Hermitian operator that has all the properties of the momentum expected by analogy with the momentum operator in complex quantum mechanics. The choice of the quaternionic linear operator,

$$\boldsymbol{\mathcal{P}}_L = -L_i \hbar \boldsymbol{\partial}, \tag{7}$$

as a Hermitian momentum operator, would appear completely satisfactory, until we consider the translation invariance for quaternionic Hamiltonians, $\mathcal{H}_q$. In fact, due to the presence of the left acting imaginary unit i, the momentum operator (7) does not commute with the j/k-part of $\mathcal{H}_q$. Thus, although this definition of the momentum operator gives a Hermitian operator, we must return to the anti-Hermitian operator $\boldsymbol{\partial}$ to get a translation generator, $[\boldsymbol{\partial}, \mathcal{H}_q] = 0$. A second possibility to be considered is represented by the complex linear momentum operator, introduced by Rotelli in Ref. 44,

$$\boldsymbol{\mathcal{P}}_R = -R_i \hbar \boldsymbol{\partial}. \tag{8}$$

The commutator of $\boldsymbol{\mathcal{P}}_R$ with a quaternionic linear operator $\mathcal{O}_{\mathbb{H}}$ gives

$$[\boldsymbol{\mathcal{P}}_R, \mathcal{O}]\Psi = \hbar[\mathcal{O}, \boldsymbol{\partial}]\Psi i.$$

Taking $\mathcal{O}_{\mathbb{H}}$ to be a translation invariant quaternionic Hamiltonian $\mathcal{H}_q$, we have

$$[\boldsymbol{\mathcal{P}}_R, \mathcal{H}_q] = 0.$$

However, this second definition of the momentum operator has the following problem: the complex linear momentum operator $\boldsymbol{\mathcal{P}}_R$ does not represent a quaternionic Hermitian operator. In fact, by computing the difference

$$(\Psi, \boldsymbol{\mathcal{P}}_R \Phi) - \overline{(\Phi, \boldsymbol{\mathcal{P}}_R \Psi)},$$

which should vanish for a Hermitian operator $\boldsymbol{\mathcal{P}}_R$, we find

$$(\Psi, \boldsymbol{\mathcal{P}}_R \Phi) - (\boldsymbol{\mathcal{P}}_R \Psi, \Phi) = \hbar[i, (\Psi, \boldsymbol{\partial}\Phi)], \tag{9}$$

which is in general nonvanishing. There is one important case in which the right-hand side of Eq. (9) does vanish. The operator $\boldsymbol{\mathcal{P}}_R$ gives a satisfactory definition of the Hermitian momentum operator when restricted to a *complex geometry*,[45] that is a *complex projection* of the quaternionic scalar product, $(\Psi, \boldsymbol{\mathcal{P}}_R \Phi)_{\mathbb{C}}$. Note that the assumption of a complex projection of the quaternionic scalar product does not imply complex wave functions. The state of quaternionic quantum mechanics with complex geometry will be again described by vectors of a quaternionic Hilbert space. In quaternionic quantum mechanics with complex geometry observables can be represented by the quaternionic Hermitian operator, H, obtained taking the *spectral decomposition*[31] of the corresponding anti-Hermitian operator, A, or simply by the complex linear operator, $-AR_i$, obtained by multiplying A by the operator representing the right action of the imaginary unit i. These two possibilities represent equivalent choices in describing quaternionic observables within a quaternionic formulation of quantum mechanics based on complex geometry. In this scenario, the complex linear operator $\boldsymbol{\mathcal{P}}_R$ has all the expected properties of the momentum operator. It satisfies the standard commutation relations with the coordinates. It is a translation generator. Finally, it represents a *quaternionic observable*. A review of quaternionic and complexified quaternionic quantum mechanics by adopting a complex geometry is found in Ref. 34.

IV. OBSERVABLES IN QUATERNIONIC QUANTUM MECHANICS

In a recent paper,[31] we find a detailed discussion of eigenvalue equations within a quaternionic formulation of quantum mechanics with quaternionic and complex geometry. Quaternionic eigen-

value equations for quaternionic and complex linear operators require eigenvalues from the right. In particular, without loss of generality, we can reduce the eigenvalue problem for quaternionic and complex linear anti-Hermitian operators $A \in M_n[\mathcal{A}_{\mathrm{H}} \otimes \mathcal{C}]$ to

$$A\Psi_m = \Psi_m \lambda_m i, \quad m = 1,2,\ldots,n, \tag{10}$$

where λ_m are real eigenvalues.

There is an important difference between the structure of Hermitian operators in complex and quaternionic quantum mechanics. In complex quantum mechanics we can always trivially relate an anti-Hermitian operator, A, to a Hermitian operator, H, by removing a factor i, i.e., $A = iH$. In general, due to the noncommutative nature of the quaternionic field, this does not apply to quaternionic quantum mechanics.

Let $\{\Psi_m\}$ be a set of normalized eigenvectors of A with complex imaginary eigenvalues $\{i\lambda_m\}$. The anti-Hermitian operator A is then represented by

$$A = \sum_{r=1}^{n} \Psi_r \lambda_r i \Psi_r^{\dagger}, \tag{11}$$

where $\Psi^{\dagger} := \overline{\Psi^t}$. It is easy to verify that

$$A\Psi_m = \sum_{r=1}^{n} \Psi_r \lambda_r i \Psi_r^{\dagger} \Psi_m = \sum_{r=1}^{n} \Psi_r \lambda_r i \delta_{rm} = \Psi_m \lambda_m i.$$

In quaternionic quantum mechanics with quaternionic geometry,[36] the observable corresponding to the anti-Hermitian operator A is represented by the following Hermitian quaternionic linear operator:

$$H = \sum_{r=1}^{n} \Psi_r \lambda_r \Psi_r^{\dagger}. \tag{12}$$

The action of these operators on the eigenvectors Ψ_m gives

$$H\Psi_m = \Psi_m \lambda_m.$$

The eigenvalues of the operator H are real and eigenvectors corresponding to different eigenvalues are orthogonal.

How to relate the Hermitian operator H to the anti-Hermitian operator A? A simple calculation shows that the operators $L_i H$ and HL_i does not satisfy the same eigenvalue equation of A. In fact,

$$L_i H \Psi_m = \left[L_i \left(\sum_{r=1}^{n} \Psi_r \lambda_r \Psi_r^{\dagger} \right) \right] \Psi_m = i \sum_{r=1}^{n} \Psi_r \lambda_r \Psi_r^{\dagger} \Psi_m = i \Psi_m \lambda_m$$

and

$$HL_i \Psi_m = \left[\left(\sum_{r=1}^{n} \Psi_r \lambda_r \Psi_r^{\dagger} \right) L_i \right] \Psi_m = \sum_{r=1}^{n} \Psi_r \lambda_r \Psi_r^{\dagger} i \Psi_m.$$

These problems can be avoided by using the right operator R_i instead of the left operator L_i. In fact, the operator HR_i satisfies the same eigenvalue equation of A,

$$HR_i \Psi_m = \left[\left(\sum_{r=1}^{n} \Psi_r \lambda_r \Psi_r^{\dagger} \right) R_i \right] \Psi_m = \sum_{r=1}^{n} \Psi_r \lambda_r \Psi_r^{\dagger} \Psi_m i = \Psi_m \lambda_m i.$$

The eigenvalues of the operator $-AR_i$ are real and eigenvectors corresponding to different eigenvalues are orthogonal. The right hermiticity of this operator is recovered within a quaternionic formulation of quantum mechanics based on complex geometry.[34]

When the space state is finite-dimensional, it is always possible to form a basis with the eigenvectors of the operators H and $-AR_i$. When the space state is infinite-dimensional, this is no longer necessarily the case. So, it is useful to introduce a new concept, that of an observable. By definition, the Hermitian operators H or $-AR_i$ are observables if the orthonormal system of vectors forms a basis in the state space.

In quaternionic quantum mechanics with quaternionic geometry, the Hermitian operator corresponding to the anti-Hermitian operator A of Eq. (11) is thus given by the operator H of Eq. (12). By adopting a complex geometry, observables can also be represented by complex linear Hermitian operators obtained by multiplying the corresponding anti-Hermitian operator A by $-R_i$. We remark that for complex eigenvectors, the operators L_iH, HL_i, HR_i and A reduce to the same complex operator,

$$iH = i\sum_{r=1}^{n} \lambda_r \Psi_r \Psi_r^{\dagger}.$$

We conclude this section by giving an explicit example of quaternionic Hermitian operators in a finite two-dimensional space state. Let

$$A = \begin{pmatrix} -i & 3j \\ 3j & i \end{pmatrix} \tag{13}$$

be an anti-Hermitian operator. An easy computation shows that the eigenvalues and the eigenvectors of this operator are given by

$$\{2i,4i\} \quad \text{and} \quad \left\{ \frac{1}{\sqrt{2}} \begin{pmatrix} i \\ j \end{pmatrix}, \frac{1}{\sqrt{2}} \begin{pmatrix} k \\ 1 \end{pmatrix} \right\}.$$

It is immediate to verify that iA and Ai are characterized by complex eigenvalues and so cannot represent quaternionic observables. In quaternionic quantum mechanics with quaternionic geometry, the quaternionic observable corresponding to the anti-Hermitian operator of Eq. (13) is given by the Hermitian operator,

$$H = \Psi_1 2 \Psi_1^{\dagger} + \Psi_2 4 \Psi_2^{\dagger} = \begin{pmatrix} 3 & k \\ -k & 3 \end{pmatrix}. \tag{14}$$

Within a quaternionic quantum mechanics with complex geometry, a second equivalent definition of the quaternionic observable corresponding to the anti-Hermitian operator of Eq. (13) is given by the complex linear Hermitian operator,

$$\tilde{H} = \begin{pmatrix} -i & 3j \\ 3j & i \end{pmatrix} R_i. \tag{15}$$

V. THE QUATERNIONIC SCHRÖDINGER EQUATION

For simplicity, we shall assume a one-dimensional description. In the standard formulation of quantum mechanics, the wave function of a particle whose potential energy is $V(x,t)$ must satisfy the Schrödinger equation,

$$i\hbar\, \partial_t \Phi(x,t) = \mathcal{H}\, \Phi(x,t) = \left(-\frac{\hbar^2}{2m} \partial_{xx} + V(x,t) \right) \Phi(x,t). \tag{16}$$

Let us modify the previous equation by introducing the quaternionic potential,

$$[V+\mathbf{h}\cdot\mathbf{V}](x,t).$$

The i-part of this quaternionic potential violates the norm conservation. In fact,

$$\partial_t \int_{-\infty}^{+\infty} dx\, \overline{\Phi}\,\Phi = \int_{-\infty}^{+\infty} dx \left[\frac{\hbar}{2m}\overline{\Phi}\, i\, \partial_{xx}\Phi - \frac{\hbar}{2m}(\partial_{xx}\overline{\Phi}) i\,\Phi - \frac{1}{\hbar}\overline{\Phi}\{i,\mathbf{h}\}\cdot\mathbf{V}\Phi \right]$$

$$= \frac{2}{\hbar}\int_{-\infty}^{+\infty} dx\, \overline{\Phi}\, V_1 \Phi.$$

The j/k-part of $\mathbf{h}\cdot\mathbf{V}$ is responsible for T-violation.[4] To show that, we briefly discuss the time reversal invariance in quaternionic quantum mechanics. The quaternionic Schrödinger equation in the presence of a quaternionic potential which preserves norm conservation, is given by[4,15,16,36]

$$i\,\hbar\,\partial_t \Phi(x,t) = [\mathcal{H} - j\,W]\Phi(x,t), \tag{17}$$

where $W \in \mathbb{C}$. Evidently, quaternionic conjugation,

$$-\hbar\,\partial_t \overline{\Phi}(x,t) i = \mathcal{H}\,\overline{\Phi}(x,t) + \overline{\Phi}(x,t) j\, W,$$

does not yield a time-reversed version of the original Schrödinger equation

$$-i\,\hbar\,\partial_t \Phi_{\mathrm{T}}(x,-t) = [\mathcal{H} - j\,W]\Phi_{\mathrm{T}}(x,-t). \tag{18}$$

To understand why the T-violation is proportional to the j/k-part of the quaternionic potential, let us consider a real potential W. Then, the Schrödinger equation has a T-invariance. By multiplying Eq. (17) by j from the left, we have

$$-i\,\hbar\,\partial_t\, j\,\Phi(x,t) = [\mathcal{H} - j\,W] j\,\Phi(x,t), \quad W \in \mathbb{R},$$

which has the same form of Eq. (18). Thus,

$$\Phi_{\mathrm{T}}(x,-t) = j\,\Phi(x,t).$$

A similar discussion applies for imaginary complex potential $W \in i\,\mathbb{R}$. In this case, we find

$$\Phi_{\mathrm{T}}(x,-t) = k\,\Phi(x,t).$$

However, when both V_2 and V_3 are nonzero, i.e., $W \in \mathbb{C}$, this construction does not work, and the quaternionic physics is T-violating. The system of neutral kaons is the natural candidate to study the presence of *effective* quaternionic potentials, $V+\mathbf{h}\cdot\mathbf{V}$. In studying such a system, we need of V_1 and $V_{2,3}$ in order to include the decay rates of $K_{\mathrm{S}}/K_{\mathrm{L}}$ and CP-violation effects.

A. Quaternionic stationary states

For stationary states,

$$V(x,t) = V(x) \quad \text{and} \quad W(x,t) = W(x),$$

we look for solutions of the Schrödinger equation of the form

$$\Phi(x,t) = \Psi(x)\zeta(t). \tag{19}$$

Substituting (19) in the quaternionic Schrödinger equation, we obtain

$$i\,\hbar\,\Psi(x)\dot{\zeta}(t) = [\mathcal{H} - j\,W(x)]\Psi(x)\zeta(t). \tag{20}$$

Multiplying by $-\overline{\Psi}(x)i$ from the left and by $\overline{\zeta}(t)$ from the right, we find

$$\hbar\,\dot{\zeta}(t)\overline{\zeta}(t)/|\zeta(t)|^2=\overline{\Psi}(x)[-i\,\mathcal{H}+k\,W(x)]\Psi(x)/|\Psi(x)|^2. \tag{21}$$

In this equation we have a function of t on the left-hand side and a function of x on the right-hand side. The previous equality is only possible if

$$\hbar\,\dot{\zeta}(t)\overline{\zeta}(t)/\,|\zeta(t)|^2=\overline{\Psi}(x)[-i\,\mathcal{H}+k\,W(x)]\Psi(x)/|\Psi(x)|^2=q, \tag{22}$$

where q is a quaternionic constant. The energy operator $-i\,\mathcal{H}+k\,W(x)$ represents an anti-Hermitian operator. Consequently, its eigenvalues are purely imaginary quaternions, $q=\mathbf{h}\cdot\mathbf{E}$. By applying the unitary transformation u,

$$\overline{u}\,\mathbf{h}\cdot\mathbf{E}\,u=-\,i\,E,\quad E=\sqrt{E_1^2+E_2^2+E_3^2},$$

Eq. (22) becomes

$$\hbar\,\overline{u}\,\dot{\zeta}(t)\overline{\zeta}(t)u/|\zeta(t)|^2=\overline{u}\,\overline{\Psi}(x)[-i\,H+k\,W(x)]\Psi(x)u/|\Psi(x)|^2=-i\,E. \tag{23}$$

The solution $\Phi(x,t)$ of the Schrödinger equation is not modified by this similarity transformation. In fact,

$$\Phi(x,t)\rightarrow\Psi(x)u\,\overline{u}\,\zeta(t)=\Psi(x)\zeta(t).$$

By observing that $|\Phi(x,t)|^2=|\Psi(x)|^2|\zeta(t)|^2$, the norm conservation implies $|\zeta(t)|^2$ constant. Without loss of generality, we can choose $|\zeta(t)|^2=1$. Consequently, by equating the first and the third term in Eq. (23) and solving the corresponding equation, we find

$$\zeta(t)=\exp[-iEt/\hbar]\zeta(0), \tag{24}$$

with $\zeta(0)$ unitary quaternion. Note that the position of $\zeta(0)$ in Eq. (24) is very important. In fact, it can be shown that $\zeta(0)\exp[-iEt/\hbar]$ is not solution of Eq. (23). Finally, to complete the solution of the quaternionic Schrödinger equation, we must determine $\Psi(x)$ by solving the following second order (right complex linear) differential equation,

$$\left[i\,\frac{\hbar^2}{2m}\,\partial_{xx}-i\,V(x)+k\,W(x)\right]\Psi(x)=-\Psi(x)i\,E. \tag{25}$$

B. Real potential

For $W(x)=0$, Eq. (25) becomes

$$\left[\frac{\hbar^2}{2m}\,\partial_{xx}-V(x)\right]\{[\Psi(x)]_{\mathrm{C}}-j[j\Psi(x)]_{\mathrm{C}}\}=i\,\{[\Psi(x)]_{\mathrm{C}}-j[j\Psi(x)]_{\mathrm{C}}\}i\,E. \tag{26}$$

Consequently,

$$\left[\frac{\hbar^2}{2m}\,\partial_{xx}-V(x)\right][\Psi(x)]_{\mathrm{C}}=-[\Psi(x)]_{\mathrm{C}}E,$$

and

$$\left[\frac{\hbar^2}{2m}\,\partial_{xx}-V(x)\right][j\Psi(x)]_{\mathrm{C}}=[j\Psi(x)]_{\mathrm{C}}E.$$

By solving these complex equations, we find

$$\Psi(x)=\exp\left[\sqrt{\frac{2m}{\hbar^2}(V-E)}\,x\right]k_1+\exp\left[-\sqrt{\frac{2m}{\hbar^2}(V-E)}\,x\right]k_2+j$$
$$\times\left\{\exp\left[\sqrt{\frac{2m}{\hbar^2}(V+E)}\,x\right]k_3+\exp\left[-\sqrt{\frac{2m}{\hbar^2}(V+E)}\,x\right]k_4\right\},$$

where k_n, $n=1,\ldots,4$, are complex coefficients determined by the initial conditions.

C. Free particles

For free particles, $V(x)=W(x)=0$, the previous solution reduces to

$$\Psi(x)=\exp\left[i\frac{p}{\hbar}x\right]k_1+\exp\left[-i\frac{p}{\hbar}x\right]k_2+j\left\{\exp\left[\frac{p}{\hbar}x\right]k_3+\exp\left[-\frac{p}{\hbar}x\right]k_4\right\},$$

where $p=\sqrt{2mE}$. For scattering problems with a wave function incident from the left on quaternionic potentials, we have

$$\Psi(x)=\exp\left[i\frac{p}{\hbar}x\right]+r\exp\left[-i\frac{p}{\hbar}x\right]+j\,\tilde{r}\exp\left[\frac{p}{\hbar}x\right], \tag{27}$$

where $|r|^2$ is the standard coefficient of reflection and $|\tilde{r}\exp[(p/\hbar)x]|^2$ represents an additional evanescent probability of reflection. In our study of quaternionic potentials, we shall deal with the rectangular potential barrier of width a. In this case, the particle is free for $x<0$, where the solution is given by (27), and $x>a$, where the solution is

$$\Psi(x)=t\exp\left[i\frac{p}{\hbar}x\right]+j\,\tilde{t}\exp\left[-\frac{p}{\hbar}x\right]. \tag{28}$$

Note that, in Eqs. (27) and (28), we have, respectively, omitted the complex exponential solution $\exp[-(p/\hbar)x]$ and $\exp[(p/\hbar)x]$ which are in conflict with the boundary condition that $\Psi(x)$ remain finite as $x\to-\infty$ and $x\to\infty$. In Eq. (28), we have also omitted the complex exponential solution $\exp[-i(p/\hbar)x]$ because we are considering a wave incident from the left.

VI. QUATERNIONIC LINEAR DIFFERENTIAL EQUATION

Consider the second order quaternionic linear differential operator,

$$\mathcal{D}_{\mathbb{H}}=\partial_{xx}+(a_0+\mathbf{L}\cdot\mathbf{a})\partial_x+b_0+\mathbf{L}\cdot\mathbf{b}\in\mathcal{A}_{\mathbb{H}}\otimes\mathcal{O}.$$

We are interested in finding the solution of the quaternionic linear differential equation,

$$\mathcal{D}_{\mathbb{H}}\,\varphi(x)=0. \tag{29}$$

In analogy to the complex case, we look for solutions of exponential form

$$\varphi(x)=\exp[qx],$$

where $q\in\mathbb{H}$ and $x\in\mathbb{R}$. To satisfy Eq. (29), the constant q has to be a solution of the quaternionic quadratic equation,[38–41]

$$q^2+(a_0+\mathbf{h}\cdot\mathbf{a})q+b_0+\mathbf{h}\cdot\mathbf{b}=0. \tag{30}$$

A. Quaternionic quadratic equation

To simplify our discussion, it is convenient to modify Eq. (30) by removing the real constant a_0. To do this, we introduce a new quaternionic constant p defined by $p=q+a_0/2$. The quadratic equation (30) then becomes

$$p^2+\mathbf{h}\cdot\mathbf{a}\,p+c_0+\mathbf{h}\cdot\mathbf{c}=0, \tag{31}$$

where $c_0=b_0-a_0^2/4$ and $\mathbf{c}=\mathbf{b}-(a_0/2)\mathbf{a}$. We shall give the solution of Eq. (31) in terms of real constant c_0 and of the real vectors $\mathbf{a}$ and $\mathbf{c}$. Let us analyze the following cases:

- $\mathbf{a}\neq 0$, $\mathbf{c}\neq 0$:
  - **(i)** $\mathbf{a}\times\mathbf{c}=0$,
  - **(ii)** $\mathbf{a}\cdot\mathbf{c}=0$,
  - **(iii)** $\mathbf{a}\times\mathbf{c}\neq 0\neq\mathbf{a}\cdot\mathbf{c}$;
- $\mathbf{a}=0$, $\mathbf{c}\neq 0$;
- $\mathbf{a}\neq 0$, $\mathbf{c}=0$;
- $\mathbf{a}=\mathbf{c}=0$.

• **(i)** $\mathbf{a}\times\mathbf{c}=0$. In this case $\mathbf{a}$ and $\mathbf{c}$ are parallel vectors, so Eq. (31) can be easily reduced to a complex equation. In fact, by introducing the imaginary unit $\mathcal{I}=\mathbf{h}\cdot\mathbf{a}/|\mathbf{a}|$ and observing that $\mathbf{h}\cdot\mathbf{c}=\mathcal{I}\alpha$, with $\alpha\in\mathbb{R}$, we find

$$p^2+\mathcal{I}|\mathbf{a}|p+c_0+\mathcal{I}\alpha=0,$$

whose *complex* solutions are immediately found.

• **(ii)** $\mathbf{a}\cdot\mathbf{c}=0$. By observing that $\mathbf{a}$, $\mathbf{c}$ and $\mathbf{a}\times\mathbf{c}$ are orthogonal vectors, we can rearrange the imaginary part of p, $\mathbf{h}\cdot\mathbf{p}$, in terms of the new basis $(\mathbf{a},\mathbf{c},\mathbf{a}\times\mathbf{c})$, i.e.,

$$p=p_0+\mathbf{h}\cdot(x\,\mathbf{a}+y\,\mathbf{c}+z\,\mathbf{a}\times\mathbf{c}). \tag{32}$$

Substituting (32) in Eq. (31), we obtain the following system of equations for the real variables p_0, x, y and z:

$$\begin{aligned}
&\mathbb{R}: && p_0^2-(x^2+x)|\mathbf{a}|^2-y^2|\mathbf{c}|^2-z^2|\mathbf{a}|^2|\mathbf{c}|^2+c_0=0,\\
&\mathbf{h}\cdot\mathbf{a}: && p_0(1+2x)=0,\\
&\mathbf{h}\cdot\mathbf{c}: && 1+2p_0y-z|\mathbf{a}|^2=0,\\
&\mathbf{h}\cdot\mathbf{a}\times\mathbf{c}: && y+2p_0z=0.
\end{aligned}$$

The second equation, $p_0(1+2x)=0$, implies $p_0=0$ and/or $x=-\frac{1}{2}$. For $p_0=0$, it can be shown that the solution of Eq. (31), in terms of p_0, x, y and z, is given by

$$p_0=0,\quad x=-\frac{1}{2}\pm\sqrt{\Delta},\quad y=0,\quad z=\frac{1}{|\mathbf{a}|^2}, \tag{33}$$

where

$$\Delta=\frac{1}{4}+\frac{1}{|\mathbf{a}|^2}\left(c_0-\frac{|\mathbf{c}|^2}{|\mathbf{a}|^2}\right)\geqslant 0.$$

For $x=-\frac{1}{2}$, we find

$$y=-\frac{2p_0}{4p_0^2+|\mathbf{a}|^2},\quad z=\frac{1}{4p_0^2+|\mathbf{a}|^2}, \tag{34}$$

and

$$p_0^2=\tfrac{1}{4}[\pm 2\sqrt{c_0^2+|\mathbf{c}|^2}-2c_0-|\mathbf{a}|^2].$$

It is easily verified that

$$\Delta\leqslant 0\Rightarrow\sqrt{c_0^2+|\mathbf{c}|^2}-c_0\geqslant\frac{|\mathbf{a}|^2}{2};$$

thus

$$p_0=\pm\tfrac{1}{2}\sqrt{2(\sqrt{c_0^2+|\mathbf{c}|^2}-c_0)-|\mathbf{a}|^2}. \tag{35}$$

Summarizing, for $\Delta\neq 0$, we have two quaternionic solutions, $p_1\neq p_2$,

$$\Delta>0\ :\quad p_0=0,$$

$$x=-\tfrac{1}{2}\pm\sqrt{\Delta},$$

$$y=0,$$

$$z=\frac{1}{|\mathbf{a}|^2}; \tag{36}$$

$$\Delta<0\ :\quad p_0=\pm\tfrac{1}{2}\sqrt{2(\sqrt{c_0^2+|\mathbf{c}|^2}-c_0)-|\mathbf{a}|^2},$$

$$x=-\tfrac{1}{2},$$

$$y=-\frac{2p_0}{4p_0^2+|\mathbf{a}|^2},$$

$$z=\frac{1}{4p_0^2+|\mathbf{a}|^2}. \tag{37}$$

For $\Delta=0$, these solutions tend to the same solution $p_1=p_2$ given by

$$\Delta=0\ :\quad p_0=0,\quad x=-\frac{1}{2},\quad y=0,\quad z=\frac{1}{|\mathbf{a}|^2}. \tag{38}$$

• **(iii)** $\mathbf{a}\times\mathbf{c}\neq 0\neq\mathbf{a}\cdot\mathbf{c}$. In discussing this case, we introduce the vector $\mathbf{d}=\mathbf{c}-d_0\,\mathbf{a}$, $d_0=\mathbf{a}\cdot\mathbf{c}/|\mathbf{a}|^2$ and the imaginary part of p in terms of the orthogonal vectors $\mathbf{a}$, $\mathbf{d}$ and $\mathbf{a}\times\mathbf{d}$,

$$p=p_0+\mathbf{h}\cdot(x\,\mathbf{a}+y\,\mathbf{d}+z\,\mathbf{a}\times\mathbf{d}). \tag{39}$$

By using this decomposition, from Eq. (31) we obtain the following system of real equations:

$$\begin{array}{ll}\mathbb{R}: & p_0^2-(x^2+x)|\mathbf{a}|^2-y^2|\mathbf{d}|^2-z^2|\mathbf{a}|^2|\mathbf{d}|^2+c_0=0,\\ \mathbf{h}\cdot\mathbf{a}: & p_0(1+2x)+d_0=0,\\ \mathbf{h}\cdot\mathbf{d}; & 1+2p_0y-z|\mathbf{a}|^2=0,\\ \mathbf{h}\cdot\mathbf{a}\times\mathbf{d}: & y+2p_0z=0.\end{array}$$

The second equation of this system, $p_0(1+2x)+d_0=0$, implies $p_0\neq 0$ since $d_0\neq 0$. Therefore, we have

$$x=-\frac{p_0+d_0}{2p_0},\quad y=-\frac{2p_0}{4p_0^2+|\mathbf{a}|^2},\quad z=\frac{1}{4p_0^2+|\mathbf{a}|^2},\tag{40}$$

and

$$16\,w^3+8[|\mathbf{a}|^2+2c_0]w^2+4\left[|\mathbf{a}|^2(c_0-d_0^2)+\frac{|\mathbf{a}|^4}{4}-|\mathbf{d}|^2\right]w-d_0^2|\mathbf{a}|^4=0,\tag{41}$$

where $w=p_0^2$. By using the Descartes rule of signs it can be proved that Eq. (41) has only one real positive solution,[38] $w=\alpha^2$, $\alpha\in\mathbb{R}$. This implies $p_0=\pm\,\alpha$. Thus, we also find two quaternionic solutions.

• $\mathbf{a}=0$ and $\mathbf{c}\neq 0$. By introducing the imaginary *complex* unit $\mathcal{I}=\mathbf{h}\cdot\mathbf{c}/|\mathbf{c}|$, we can reduce Eq. (31) to the following *complex* equation:

$$p^2+c_0+\mathcal{I}|\mathbf{c}|=0.$$

• $\mathbf{a}\neq 0$ and $\mathbf{c}=0$. This case is similar to the previous one. We introduce the imaginary *complex* unit $\mathcal{I}=\mathbf{h}\cdot\mathbf{a}/|\mathbf{a}|$ and reduce Eq. (31) to the *complex* equation,

$$p^2+\mathcal{I}\,|\mathbf{a}|p+c_0=0.$$

• $\mathbf{a}=\mathbf{c}=0$. Equation (31) becomes

$$p^2+c_0=0.$$

For $c_0=-\alpha^2$, $\alpha\in\mathbb{R}$, we find two real solutions. For $c_0=\alpha^2$, we obtain an *infinite* number of quaternionic solutions, i.e., $p=\mathbf{h}\cdot\mathbf{p}$, where $|\mathbf{p}|=|\alpha|$.

Let us resume our discussion on a quaternionic linear quadratic equation. For $\mathbf{a}=0$ and/or $\mathbf{c}=0$ and for $\mathbf{a}\times\mathbf{c}=0$ we can reduce quaternionic linear quadratic equations to *complex* equations. For non null vectors satisfying $\mathbf{a}\cdot\mathbf{c}=0$ or $\mathbf{a}\times\mathbf{c}\neq 0\neq\mathbf{a}\cdot\mathbf{c}$, we have *effective* quaternionic equations. In these cases, we always find two quaternionic solutions (36), (37) and (40)–(41). For $\mathbf{a}\cdot\mathbf{c}=0$ and $\Delta=0$, these solutions tend to the same solution (38). Finally, the fundamental theorem of algebra is lost for a *restricted* class of quaternionic quadratic linear equations, namely

$$q^2+\alpha^2=0,\quad \alpha\in\mathbb{R}.$$

B. Second order quaternionic differential equations with constant coefficients

Due to the quaternionic linearity from the right of Eq. (29), we look for general solutions which are of the form

$$\varphi(x)=\varphi_1(x)c_1+\varphi_2(x)c_2,$$

where $\varphi_1(x)$ and $\varphi_2(x)$ represent two linear independent solutions of Eq. (29) and c_1 and c_2 are quaternionic constants fixed by the initial conditions. In analogy to the complex case, we can distinguish between quaternionic linear dependent and independent solutions by constructing a Wronskian functional. To do this, we need to define a quaternionic determinant. Due to the noncommutative nature of quaternions, the standard definition of the determinant must be revised. The study of quaternionic, complex and real functionals, extending the complex determinant to quaternionic matrices, has been extensively developed in quaternionic linear algebra.[46–49] In a recent paper,[50] we find an interesting discussion on the impossibility to obtain a quaternionic functional with the main properties of the complex determinant. For quaternionic matrices, M, a *real positive* functional, $|\det M|=\sqrt{\det[MM^{\dagger}]}$, which reduces to the absolute value of the standard

determinant for complex matrices, was introduced by Study[51] and its properties axiomatized by Dieudonné.[52] The details can be found in the excellent survey paper of Aslaksen.[53] This functional allows us to construct a real positive Wronskian,[31]

$$\begin{aligned}\mathcal{W}(x) &= \left| \det\begin{pmatrix} \varphi_1(x) & \varphi_2(x) \\ \dot{\varphi}_1(x) & \dot{\varphi}_2(x) \end{pmatrix} \right| \\ &= |\varphi_1(x)\| \dot{\varphi}_2(x) - \dot{\varphi}_1(x)\varphi_1^{-1}(x)\varphi_2(x)| \\ &= |\varphi_2(x)\| \dot{\varphi}_1(x) - \dot{\varphi}_2(x)\varphi_2^{-1}(x)\varphi_1(x)| \\ &= |\dot{\varphi}_1(x)\| \varphi_2(x) - \varphi_1(x)\dot{\varphi}_1^{-1}(x)\dot{\varphi}_2(x)| \\ &= |\dot{\varphi}_2(x)\| \varphi_1(x) - \varphi_2(x)\dot{\varphi}_2^{-1}(x)\dot{\varphi}_1(x)|.\end{aligned}$$

Solutions of Eq. (29),

$$\varphi_{1,2}(x) = \exp[q_{1,2}\, x] = \exp\left[\left(p_{1,2} - \frac{a_0}{2}\right)x\right],$$

are given in terms of the solutions of the quadratic equation (31), $p_{1,2}$, and of the real variable x. In this case, the Wronskian becomes

$$\mathcal{W}(x) = |p_1 - p_2\| \exp[q_1 x]\| \exp[q_2 x]|.$$

This functional allows us to distinguish between quaternionic linear dependent ($\mathcal{W}=0$) and independent ($\mathcal{W}\neq 0$) solutions. A generalization for quaternionic second order differential equations with nonconstant coefficients should be investigated.

For $p_1 \neq p_2$, the solution of Eq. (29) is then given by

$$\varphi(x) = \exp\left[-\frac{a_0}{2}x\right]\{\exp[p_1\, x]c_1 + \exp[p_2\, x]c_2\}. \tag{42}$$

As observed at the end of the previous subsection, the fundamental theorem of algebra is lost for a *restricted* class of quaternionic quadratic equation, i.e., $p^2 + \alpha^2 = 0$ where $\alpha \in \mathbb{R}$. For these equations we find an infinite number of solutions, $p = \mathbf{h}\cdot\boldsymbol{\alpha}$ with $|\boldsymbol{\alpha}|^2 = \alpha^2$. Nevertheless, the general solution of the second order differential equation,

$$\ddot{\varphi}(x) + \alpha^2\, \varphi(x) = 0, \tag{43}$$

is also expressed in terms of *two* linearly independent exponential solutions,

$$\varphi(x) = \exp[i\, \alpha\, x]c_1 + \exp[-i\, \alpha\, x]c_2. \tag{44}$$

Note that any other exponential solution, $\exp[\mathbf{h}\cdot\boldsymbol{\alpha}\, x]$, can be written as a linear combination of $\exp[i\,\alpha\, x]$ and $\exp[-i\,\alpha\, x]$,

$$\exp[\mathbf{h}\cdot\boldsymbol{\alpha}\, x] = \frac{1}{2\alpha}\{\exp[i\, \alpha\, x](\alpha - i\, \mathbf{h}\cdot\boldsymbol{\alpha}) + \exp[-i\, \alpha\, x](\alpha + i\, \mathbf{h}\cdot\boldsymbol{\alpha})\}.$$

As a consequence, the loss of the fundamental theorem of algebra for quaternions does *not*

represent an obstacle in solving second order quaternionic linear differential equations with constant coefficients. To complete our discussion, we have to examine the case $p_1=p_2$. From Eq. (38) we find

$$p_1=p_2=-\frac{\mathbf{h}\times\mathbf{a}}{2}+\frac{1}{|\mathbf{a}|^2}\mathbf{h}\cdot\mathbf{a}\times\left(\mathbf{b}-\frac{a_0}{2}\mathbf{a}\right),$$

Thus, a first solution of the differential equation (29) is

$$\xi(x)=\exp\left\{\left[\mathbf{h}\cdot\left(\frac{\mathbf{a}\times\mathbf{b}}{|\mathbf{a}|^2}-\frac{\mathbf{a}}{2}\right)-\frac{a_0}{2}\right]x\right\}.$$

For $\mathbf{a}\times\mathbf{b}=0$, we can immediately obtain a second linearly independent solution by multiplying $\exp[-(a/2)x]$ by x, $\eta(x)=x\,\xi(x)$. For $\mathbf{a}\times\mathbf{b}\neq 0$, the second linearly independent solution takes a more complicated form, i.e.,

$$\eta(x)=\left(x+\frac{\mathbf{h}\cdot\mathbf{a}}{|\mathbf{a}|^2}\right)\xi(x). \tag{45}$$

It can easily be shown that $\eta(x)$ is a solution of the differential equation (29),

$$\begin{aligned}
&\ddot{\eta}(x)+a\,\dot{\eta}(x)+b\,\eta(x)\\
&\quad=\left[x(q^2+a\,q+b)+2\,q+a+\frac{\mathbf{h}\cdot\mathbf{a}}{|\mathbf{a}|^2}(q^2+a\,q)+b\,\frac{\mathbf{h}\cdot\mathbf{a}}{|\mathbf{a}|^2}\right]\xi(x)\\
&\quad=\left(2\,q+a+\left[b,\frac{\mathbf{h}\cdot\mathbf{a}}{|\mathbf{a}|^2}\right]\right)\xi(x)\\
&\quad=\left(2\,\mathbf{h}\cdot\frac{\mathbf{a}\times\mathbf{b}}{|\mathbf{a}|^2}+\left[\mathbf{h}\cdot\mathbf{b},\frac{\mathbf{h}\cdot\mathbf{a}}{|\mathbf{a}|^2}\right]\right)\xi(x)=0.
\end{aligned}$$

Thus, for $p_1=p_2=p=\mathbf{h}\cdot((\mathbf{a}\times\mathbf{b})/|\mathbf{a}|^2-\mathbf{a}/2$, the general solution of the differential equation (29) is given by

$$\varphi(x)=\exp\left[-\frac{a_0}{2}x\right]\left\{\exp[p\,x]c_1+\left(x+\frac{\mathbf{h}\cdot\mathbf{a}}{|\mathbf{a}|^2}\right)\exp[p\,x]c_2\right\}. \tag{46}$$

C. Diagonalization and Jordan form

To find the general solution of linear differential equations, we can also use quaternionic formulations of eigenvalue equations, matrix diagonalization and Jordan form. The quaternionic linear differential equation (29) can be written in matrix form as follows:

$$\dot{\Phi}(x)=M\,\Phi(x), \tag{47}$$

where

$$M=\begin{pmatrix}0 & 1\\ -b & -a\end{pmatrix}\quad\text{and}\quad\Phi(x)=\begin{bmatrix}\varphi(x)\\ \dot{\varphi}(x)\end{bmatrix}.$$

By observing that x is real, the formal solution of the matrix equation (47) is given by

$$\Phi(x)=\exp[M\,x]\Phi(0), \tag{48}$$

where $\Phi(0)$ represents a constant quaternionic column vector determined by the initial conditions $\varphi(0)$, $\dot{\varphi}(0)$ and $\exp[Mx]=\Sigma_{n=0}^{\infty}[(Mx)^n/n!]$. In the sequel, we shall use right eigenvalue equations for quaternionic linear matrix operators equations,

$$M\,\Phi=\Phi\,q. \tag{49}$$

Without loss of generality, we can work with *complex* eigenvalue equations. By setting $\Psi=\Phi u$, from the previous equation, we have

$$M\,\Psi=M\,\Phi u=\Phi\,q\,u=\Phi u\,\bar{u}qu=\Psi\,z, \tag{50}$$

where $z\in\mathbb{C}$ and u is a unitary quaternion. In a recent paper,[31] we find a complete discussion of the eigenvalue equation for quaternionic matrix operators. In such a paper was shown that the complex counterpart of the matrix M has an eigenvalue spectrum characterized by eigenvalues which appear in conjugate pairs $\{z_1,\bar{z}_1,z_2,\bar{z}_2\}$. Let Ψ_1 and Ψ_2 be the quaternionic eigenvectors corresponding to the complex eigenvalues z_1 and z_2,

$$M\,\Psi_1=\Psi_1\,z_1 \quad \text{and} \quad M\,\Psi_2=\Psi_2\,z_2.$$

It can be shown that for $|z_1|\neq|z_2|$, the eigenvectors Ψ_1 and Ψ_2 are linearly independent on $\mathbb{H}$ and consequently there exists a 2×2 quaternionic matrix $S=[\Psi_1\,\Psi_2]$ which diagonalizes M,

$$\exp[M\,x]=S\exp\left[\begin{pmatrix} z_1 & 0\\ 0 & z_2\end{pmatrix}x\right]S^{-1}=S\begin{pmatrix}\exp[z_1x] & 0\\ 0 & \exp[z_2x]\end{pmatrix}S^{-1}.$$

In this case, the general solution of the quaternionic differential equation can be written in terms of the elements of the matrices S and S^{-1} and of the complex eigenvalues z_1 and z_2,

$$\begin{bmatrix}\varphi(x)\\ \dot{\varphi}(x)\end{bmatrix}=\begin{pmatrix}S_{11}\exp[z_1x] & S_{12}\exp[z_2x]\\ S_{21}\exp[z_1x] & S_{22}\exp[z_2x]\end{pmatrix}\begin{bmatrix}S_{11}^{-1}\,\varphi(0)+S_{12}^{-1}\,\dot{\varphi}(0)\\ S_{21}^{-1}\,\varphi(0)+S_{22}^{-1}\,\dot{\varphi}(0)\end{bmatrix}.$$

Hence,

$$\begin{aligned}\varphi(x)&=S_{11}\exp[z_1\,x][S_{11}^{-1}\,\varphi(0)+S_{12}^{-1}\,\dot{\varphi}(0)]\\ &\quad+S_{12}\exp[z_2\,x][S_{21}^{-1}\,\varphi(0)+S_{22}^{-1}\,\dot{\varphi}(0)]\\ &=\exp[S_{11}\,z_1(S_{11})^{-1}\,x]S_{11}[S_{11}^{-1}\,\varphi(0)+S_{12}^{-1}\,\dot{\varphi}(0)]\\ &\quad+\exp[S_{12}\,z_2(S_{12})^{-1}\,x]S_{12}[S_{21}^{-1}\,\varphi(0)+S_{22}^{-1}\,\dot{\varphi}(0)]\\ &=\exp[S_{21}(S_{11})^{-1}\,x]S_{11}[S_{11}^{-1}\,\varphi(0)+S_{12}^{-1}\,\dot{\varphi}(0)]\\ &\quad+\exp[S_{22}(S_{12})^{-1}\,x]S_{12}[S_{21}^{-1}\,\varphi(0)+S_{22}^{-1}\,\dot{\varphi}(0)].\end{aligned} \tag{51}$$

We remark that a different choice of the eigenvalue spectrum does *not* modify the solution (51). In fact, by taking the following quaternionic eigenvalue spectrum:

$$\{q_1,q_2\}=\{\bar{u}_1z_1u_1,\bar{u}_2z_2u_2\},\quad |q_1|\neq|q_2|, \tag{52}$$

and observing that the corresponding linearly independent eigenvectors are given by

$$\{\,\Phi_1=\Psi_1u_1,\Phi_2=\Psi_2u_2\}, \tag{53}$$

we obtain

$$
\begin{aligned}
M &= [\Phi_1\, \Phi_2]\mathrm{diag}\{q_1, q_2\}[\Phi_1\, \Phi_2]^{-1} \\
&= [\Psi_1 u_1\, \Psi_2 u_2]\mathrm{diag}\{\overline{u_1} z_1 u_1, \overline{u_2} z_2 u_2\}[\Psi_1 u_1\, \Psi_2 u_2]^{-1} \\
&= [\Psi_1\, \Psi_2]\mathrm{diag}\{z_1, z_2\}[\Psi_1\, \Psi_2]^{-1}.
\end{aligned}
$$

Let us now discuss the case $|z_1| = |z_2|$. If the eigenvectors $\{\Psi_a, \Psi_b\}$, corresponding to the eigenvalue spectrum $\{z, z\}$, are linearly independent on $\mathbb{H}$, we can obviously repeat the previous discussion and diagonalize the matrix operator M by the 2×2 quaternionic matrix $U = [\Psi_1\, \Psi_2]$. Then, we find

$$
\begin{aligned}
\varphi(x) &= \exp[U_{11} z (U_{11})^{-1} x] U_{11} [U_{11}^{-1} \varphi(0) + U_{12}^{-1} \dot{\varphi}(0)] \\
&\quad + \exp[U_{12} z (U_{12})^{-1} x] U_{12} [U_{21}^{-1} \varphi(0) + U_{22}^{-1} \dot{\varphi}(0)] \\
&= \exp[U_{21} (U_{11})^{-1} x] U_{11} [{}_{11}^{-1} \varphi(0) + U_{12}^{-1} \dot{\varphi}(0)] \\
&\quad + \exp[U_{22} (U_{12})^{-1} x] U_{12} [U_{21}^{-1} \varphi(0) + U_{22}^{-1} \dot{\varphi}(0)].
\end{aligned} \tag{54}
$$

For linearly dependent eigenvectors, we cannot construct a matrix which diagonalizes the matrix operator M. Nevertheless, we can transform the matrix operator M to Jordan form,

$$
M = J \begin{pmatrix} z & 1 \\ 0 & z \end{pmatrix} J^{-1}. \tag{55}
$$

It follows that the solution of our quaternionic differential equation can be written as

$$
\Phi(x) = J \exp\left[\begin{pmatrix} z & 1 \\ 0 & z \end{pmatrix} x\right] J^{-1} \Phi(0) = \begin{pmatrix} J_{11} & x J_{11} + J_{12} \\ J_{21} & x J_{21} + J_{22} \end{pmatrix} \exp[zx] \begin{bmatrix} J_{11}^{-1} \varphi(0) + J_{12}^{-1} \dot{\varphi}(0) \\ J_{21}^{-1} \varphi(0) + J_{22}^{-1} \dot{\varphi}(0) \end{bmatrix}.
$$

Thus,

$$
\begin{aligned}
\varphi(x) &= J_{11} \exp[z\, x][J_{11}^{-1} \varphi(0) + J_{12}^{-1} \dot{\varphi}(0)] \\
&\quad + (x J_{11} + J_{12}) \exp[z\, x][J_{21}^{-1} \varphi(0) + J_{22}^{-1} \dot{\varphi}(0)] \\
&= \exp[J_{11} z (J_{11})^{-1} x] J_{11} [J_{11}^{-1} \varphi(0) + J_{12}^{-1} \dot{\varphi}(0)] \\
&\quad + [x + J_{12} (J_{11})^{-1}] \exp[J_{11} z (J_{11})^{-1} x] \\
&\quad \times J_{11} [J_{21}^{-1} \varphi(0) + J_{22}^{-1} \dot{\varphi}(0)] \\
&= \exp[J_{21} (J_{11})^{-1} x] J_{11} [J_{11}^{-1} \varphi(0) + J_{12}^{-1} \dot{\varphi}(0)] \\
&\quad + [x + J_{12} (J_{11})^{-1}] \exp[J_{21} (J_{11})^{-1} x] \\
&\quad \times J_{11} [J_{21}^{-1} \varphi(0) + J_{22}^{-1} \dot{\varphi}(0)].
\end{aligned} \tag{56}
$$

The last equality in the previous equation follows from the use of Eq. (55) and the definition of M.

Finally, the general solution of the quaternionic differential equation (29) can be given by solving the corresponding eigenvalue problem. We conclude this section by observing that the quaternionic exponential solution, $\exp[q\, x]$, can also be written in terms of complex exponential solutions, $u \exp[z\, x] u^{-1}$, where $q = u\, z\, u^{-1}$. The elements of the similarity transformations S, U or J and the complex eigenvalue spectrum of M determine the quaternion u and the complex number z. This form for exponential solutions will be very useful in solving complex linear differential equations with constant coefficients. In fact, due to the presence of the right acting operator R_i, we cannot use quaternionic exponential solutions for complex linear differential equations.

VII. COMPLEX LINEAR QUATERNIONIC DIFFERENTIAL EQUATIONS

Consider now the second order complex linear quaternionic differential operator,

$$\begin{aligned}\mathcal{D}_{\mathbb{C}}=&[a_{02}+\mathbf{L}\cdot\mathbf{a}_2+(b_{02}+\mathbf{L}\cdot\mathbf{b}_2)R_i]\partial_{xx}\\&+[a_{01}+\mathbf{L}\cdot\mathbf{a}_1+(b_{01}+\mathbf{L}\cdot\mathbf{b}_1)R_i]\partial_x\\&+a_{00}+\mathbf{L}\cdot\mathbf{a}_0+(b_{00}+\mathbf{L}\cdot\mathbf{b}_0)R_i\\&\in\mathcal{A}_{\mathbb{C}}\otimes\mathcal{O},\end{aligned}$$

and look for solutions of the complex linear quaternionic differential equation,

$$\mathcal{D}_{\mathbb{C}}\,\varphi(x)=0. \tag{57}$$

Due to the presence of R_i in (57), the general solution of the complex linear quaternionic differential equation cannot be given in terms of quaternionic exponentials. In matrix form, Eq. (57) reads as

$$\dot{\Phi}(x)=M_{\mathbb{C}}\Phi(x), \tag{58}$$

where

$$M_{\mathbb{C}}=\begin{pmatrix}0 & 1\\ -b_{\mathbb{C}} & -a_{\mathbb{C}}\end{pmatrix}\quad\text{and}\quad\Phi(x)=\begin{bmatrix}\varphi(x)\\ \dot{\varphi}(x)\end{bmatrix}.$$

The complex counterpart of complex linear quaternionic matrix operator $M_{\mathbb{C}}$ has an eigenvalue spectrum characterized by four complex eigenvalues $\{z_1,z_2,z_3,z_4\}$. It can be shown that $M_{\mathbb{C}}$ is diagonalizable if and only if its complex counterpart is diagonalizable. For diagonalizable matrix operator $M_{\mathbb{C}}$, we can find a complex linear quaternionic linear similarity transformation $S_{\mathbb{C}}$ which reduces the matrix operator $M_{\mathbb{C}}$ to diagonal form,[31]

$$M_{\mathbb{C}}=S_{\mathbb{C}}\begin{pmatrix}\dfrac{z_1+\overline{z_2}}{2}+\dfrac{z_1-\overline{z_2}}{2i}R_i & 0\\ 0 & \dfrac{z_3+\overline{z_4}}{2}+\dfrac{z_3-\overline{z_4}}{2i}R_i\end{pmatrix}S_{\mathbb{C}}^{-1}.$$

It is immediate to verify that

$$\left\{\begin{pmatrix}1\\0\end{pmatrix},\ \begin{pmatrix}j\\0\end{pmatrix},\ \begin{pmatrix}0\\1\end{pmatrix},\ \begin{pmatrix}0\\j\end{pmatrix}\right\}$$

are eigenvectors of the diagonal matrix operator,

$$\begin{pmatrix}\dfrac{z_1+\overline{z_2}}{2}+\dfrac{z_1-\overline{z_2}}{2i}R_i & 0\\ 0 & \dfrac{z_3+\overline{z_4}}{2}+\dfrac{z_3-\overline{z_4}}{2i}R_i\end{pmatrix},$$

with right complex eigenvalues z_1, z_2, z_3 and z_4. The general solution of the differential equation (57) can be given in terms of these complex eigenvalues,

$$\varphi(x)=S_{\mathrm{C}\,11}\exp\left[\left(\frac{z_1+\overline{z_2}}{2}+\frac{z_1-\overline{z_2}}{2i}R_i\right)x\right][S_{\mathrm{C}\,11}^{-1}\varphi(0)+S_{\mathrm{C}\,12}^{-1}\dot{\varphi}(0)]$$
$$+S_{\mathrm{C}\,12}\exp\left[\left(\frac{z_3+\overline{z_4}}{2}+\frac{z_3-\overline{z_4}}{2i}R_i\right)x\right][S_{\mathrm{C}\,21}^{-1}\varphi(0)+S_{\mathrm{C}\,22}^{-1}\dot{\varphi}(0)]$$
$$=u_1\exp[z_1x]k_1+u_2\exp[z_2x]k_2$$
$$+u_3\exp[z_3x]k_3+u_4\exp[z_4x]k_4, \tag{59}$$

where k_n are complex coefficients determined by the initial conditions. This solution holds for diagonalizable matrix operator M_{C}. For nondiagonalizable matrix operators we need to find the similarity transformation J_{C} which reduces M_{C} to the Jordan form. For instance, it can be shown that for equal eigenvalues, $z_1=z_2$, the general solution of the differential equation (57) is

$$\varphi(x)=u\exp[zx]k_1+(ux+\tilde{u})\exp[zx]k_2+u_3\exp[z_3x]k_3+u_4\exp[z_4x]k_4. \tag{60}$$

A. Schrödinger equation

Let us now examine the complex linear Schrödinger equation in the presence of a constant quaternionic potential,

$$\left[\frac{\hbar^2}{2m}\partial_{xx}-V+jW\right]\Psi(x)=i\Psi(x)iE. \tag{61}$$

In this case, the complex linear matrix operator,

$$M_{\mathrm{C}}=\begin{pmatrix}0 & 1\\ -b_{\mathrm{C}} & 0\end{pmatrix},\quad b_{\mathrm{C}}=V-jW+iER_i,$$

represents a diagonalizable operator. Consequently, the general solution of the Schrödinger equation is given by

$$\varphi(x)=u_1\exp[z_1x]k_1+u_2\exp[z_2x]k_2+u_3\exp[z_3x]k_3+u_4\exp[z_4x]k_4. \tag{62}$$

The quaternions u_n and the complex eigenvalues z_n are obtained by solving the eigenvalue equation for the complex linear operator M_{C}. We can also obtain the general solution of Eq. (61) by substituting $u\exp[\sqrt{2m/\hbar^2}\,zx]$ in the Schrödinger equation. We find the following quaternionic equation:

$$uz^2-(V-jW)u-iEui=0,$$

where $u=z_u+j\tilde{z}_u$. This equation can be written as two complex equations:

$$[z^2-(V-E)]z_u-\overline{W}\tilde{z}_u=[z^2-(V+E)]\tilde{z}_u+Wz_u=0.$$

An easy calculation shows that z satisfies the complex equation,

$$z^4-2Vz^2+V^2+|W|^2-E^2=0, \tag{63}$$

whose roots are

$$z_{1,2}=\pm\sqrt{V-\sqrt{E^2-|W|^2}}=\pm z_-\quad\text{and}\quad z_{3,4}=\pm\sqrt{V+\sqrt{E^2-|W|^2}}=\pm z_+. \tag{64}$$

By setting $(u_{1,2})_{\mathrm{C}}=(-ju_{3,4})_{\mathrm{C}}=1$, we find

$$u_- = \left(1 + j\frac{W}{E+\sqrt{E^2-|W|^2}}\right) \quad \text{and} \quad u_+ = \left(\frac{\overline{W}}{E+\sqrt{E^2-|W|^2}} + j\right). \tag{65}$$

The solution of the complex linear quaternionic Schrödinger equation is then given by

$$\Psi(x) = u_- \left\{ \exp\left[\sqrt{\frac{2m}{\hbar^2}} z_- x \right] k_1 + \exp\left[-\sqrt{\frac{2m}{\hbar^2}} z_- x \right] k_2 \right\} + u_+ \left\{ \exp\left[\sqrt{\frac{2m}{\hbar^2}} z_+ x \right] k_3 + \exp\left[-\sqrt{\frac{2m}{\hbar^2}} z_+ x \right] k_4 \right\}. \tag{66}$$

Equation (63) can also be obtained by multiplying the complex linear Schrödinger equation (61) from the left by the operator,

$$\frac{\hbar^2}{2m}\partial_{xx} - V - j\,W.$$

This gives

$$\left[\left(\frac{\hbar^2}{2m}\right)^2 \partial_{xxxx} - 2\frac{\hbar^2}{2m} V \partial_{xx} + V^2 + |W|^2\right]\Psi(x) = i\left[\frac{\hbar^2}{2m}\partial_{xx} - V + j\,W\right]\Psi(x) i\,E = E^2\,\Psi(x).$$

By substituting the exponential solution $u \exp[\sqrt{2m/\hbar^2}\, z\, x]$ in the previous equation, we immediately re-obtain Eq. (63).

VIII. QUATERNIONIC CONSTANT POTENTIALS

Of all Schrödinger equations the one for a constant potential is mathematically the simplest. The reason for resuming the study of the Schrödinger equation with such a potential is that the qualitative features of a physical potential can often be approximated reasonably well by a potential which is pieced together from a number of constant portions.

A. The potential step

Let us consider the quaternionic potential step,

$$V(x) - j\,W(x) = \begin{cases} 0, & x<0, \\ V - j\,W, & x>0, \end{cases}$$

where V and W represent constant potentials. For scattering problems with a wave function incident from the left on the quaternionic potential step, the complex linear quaternionic Schrödinger equation has the solution

$$\Psi(x) = \begin{cases} x<0: \quad \exp\left[i\frac{p}{\hbar}x \right] + r\exp\left[-i\frac{p}{\hbar}x \right] + j\,\tilde{r}\exp\left[\frac{p}{\hbar}x \right]; & \\ x>0: \quad u_- t \exp\left[\sqrt{\frac{2m}{\hbar^2}} z_- x \right] + u_+ \tilde{t} \exp\left[-\sqrt{\frac{2m}{\hbar^2}} z_+ x \right] & [E > \sqrt{V^2+|W|^2}], \\ u_- t \exp\left[-\sqrt{\frac{2m}{\hbar^2}} z_- x \right] + u_+ \tilde{t} \exp\left[-\sqrt{\frac{2m}{\hbar^2}} z_+ x \right] & [E < \sqrt{V^2+|W|^2}], \end{cases} \tag{67}$$

where r, $\tilde{r}$, t and $\tilde{t}$ are complex coefficients to be determined by matching the wave function $\Psi(x)$ and its slope at the discontinuity of the potential $x=0$.

For $E>\sqrt{V^2+|W|^2}$, the complex exponential solutions of the quaternionic Schrödinger equation are characterized by

$$z_-=i\sqrt{\sqrt{E^2-|W|^2}-V}\in i\,\mathbb{R} \quad \text{and} \quad z_+=\sqrt{\sqrt{E^2-|W|^2}+V}\in\mathbb{R}.$$

The complex linearly independent solutions,

$$u_-\exp\left[-\sqrt{\frac{2m}{\hbar^2}}z_-x\right] \quad \text{and} \quad u_+\exp\left[\sqrt{\frac{2m}{\hbar^2}}z_+x\right],$$

have been omitted, $k_2=k_3=0$ in (66), because we are considering a wave incident from the left and because the second complex exponential solution, $\exp[\sqrt{2m/\hbar^2}\,z_+x]$, is in conflict with the boundary condition that $\Psi(x)$ remain finite as $x\to\infty$. The standard result of complex quantum mechanics are immediately recovered by considering $W=0$ and taking the complex part of the quaternionic solution.

For $E<\sqrt{V^2+|W|^2}$, the complex exponential solutions of the quaternionic Schrödinger equation are characterized by

$$z_-=\sqrt{V-\sqrt{E^2-|W|^2}}, \quad z_+=\sqrt{V+\sqrt{E^2-|W|^2}} \quad \in\mathbb{R} \quad [E>|W|],$$

$$z_\pm=(V^2+|W|^2-E^2)^{1/4}\exp\left[\pm\,i\frac{\theta}{2}\right], \quad \tan\theta=\frac{\sqrt{|W|^2-E^2}}{V} \quad \in\mathbb{C} \quad [E<|W|].$$

The complex linearly independent solutions,

$$u_-\exp\left[\sqrt{\frac{2m}{\hbar^2}}z_-x\right] \quad \text{and} \quad u_+\exp\left[\sqrt{\frac{2m}{\hbar^2}}z_+x\right],$$

have been omitted, $k_1=k_3=0$ in (66), because they are in conflict with the boundary condition that $\Psi(x)$ remain finite as $x\to\infty$.

A relation between the complex coefficients of reflection and transmission can immediately be obtained by the continuity equation,

$$\partial_t\rho(x,t)+\partial_xJ(x,t)=0, \tag{68}$$

where

$$\rho(x,t)=\overline{\Phi}(x,t)\Phi(x,t),$$

and

$$J(x,t)=\frac{\hbar}{2m}\{[\partial_x\overline{\Phi}(x,t)]i\,\Phi(x,t)-\overline{\Phi}(x,t)i\,\partial_x\Phi(x,t)\}.$$

Note that, due to the noncommutative nature of the quaternionic wave functions, the position of the imaginary unit i in the probability current density $J(x,t)$ is important to recover a continuity equation in quaternionic quantum mechanics. For stationary states, $\Phi(x,t)=\Psi(x)\exp[-i\,(E/\hbar)t]\zeta(0)$, it can easily be shown that the probability current density,

$$J(x,t)=\frac{\hbar}{2m}\overline{\zeta}(0)\exp\left[\,i\frac{E}{\hbar}t\,\right]\{[\partial_x\overline{\Psi}(x)]i\,\Psi(x)-\overline{\Psi}(x)i\,\partial_x\Psi(x)\}\exp\left[-i\frac{E}{\hbar}t\,\right]\zeta(0),$$

must be independent of x, $J(x,t)=f(t)$. Hence,

$$\frac{\hbar}{2m}\{[\partial_x\overline{\Psi}(x)]i\,\Psi(x)-\overline{\Psi}(x)i\,\partial_x\Psi(x)\}=\exp\left[-i\frac{E}{\hbar}t\right]\zeta(0)f(t)\overline{\zeta}(0)\exp\left[i\frac{E}{\hbar}t\right]=\alpha,$$

where α is a real constant. This implies that the quantity

$$\mathcal{J}=\frac{p}{2m}\{[\partial_x\overline{\Psi}(x)]i\,\Psi(x)-\overline{\Psi}(x)i\,\partial_x\Psi(x)\},$$

has the same value at all points x. In the free potential region, $x<0$, we find

$$\mathcal{J}_-=\frac{p}{m}(1-|r|^2).$$

In the potential region, $x>0$, we obtain

$$\mathcal{J}_+=\begin{cases}\sqrt{\dfrac{2}{m}(\sqrt{E^2-|W|^2}-V)}\left[1-\left(\dfrac{|W|}{E+\sqrt{E^2-|W|^2}}\right)^2\right]|t|^2 & [E>\sqrt{V^2+|W|^2}],\\ 0 \quad [E<\sqrt{V^2+|W|^2}].\end{cases}$$

Finally, for stationary states, the continuity equation leads to

$$\begin{gathered}|r|^2+\frac{\sqrt{E^2-|W|^2}-V}{E}\left[1-\left(\frac{|W|}{E+\sqrt{E^2-|W|^2}}\right)^2\right]|t|^2=1 \quad [E>\sqrt{V^2+|W|^2}],\\ |r|^2=1 \quad [E<\sqrt{V^2+|W|^2}].\end{gathered} \tag{69}$$

Thus, by using the concept of a probability current, we can define the following coefficients of transmission and reflection:

$$R=|r|^2,\quad T=\frac{\sqrt{E^2-|W|^2}-V}{E}\left[1-\left(\frac{|W|}{E+\sqrt{E^2-|W|^2}}\right)^2\right]|t|^2 \quad [E>\sqrt{V^2+|W|^2}],$$

$$R=|r|^2,\quad T=0 \quad [E<\sqrt{V^2+|W|^2}].$$

These coefficients give the probability for the particle, arriving from $x=-\infty$, to pass the potential step at $x=0$ or to turn back. The coefficients R and T depend only on the ratios E/V and $|W|/V$. The predictions of complex quantum mechanics are recovered by setting $W=0$.

B. The rectangular potential barrier

In our study of quaternionic potentials, we now reach the rectangular potential barrier,

$$V(x)-j\,W(x)=\begin{cases}0, & x<0,\\ V-j\,W, & 0<x<a,\\ 0, & x>a.\end{cases}$$

For scattering problems with a wave function incident from the left on the quaternionic potential barrier, the complex linear quaternionic Schrödinger equation has the solution

$$\Psi(x)=\begin{cases} x<0: \quad \exp\left[i\frac{p}{\hbar}x \right]+r\exp\left[-i\frac{p}{\hbar}x \right]+j\,\tilde{r}\exp\left[\frac{p}{\hbar}x \right]; \\ 0<x<a: \quad u_-\left\{ \exp\left[\sqrt{\frac{2m}{\hbar^2}}z_- x \right] k_1+\exp\left[-\sqrt{\frac{2m}{\hbar^2}}z_- x \right] k_2 \right\} \\ \qquad\qquad +u_+\left\{ \exp\left[\sqrt{\frac{2m}{\hbar^2}}z_+ x \right] k_3+\exp\left[-\sqrt{\frac{2m}{\hbar^2}}z_+ x \right] k_4 \right\}; \\ x>a: \quad t\exp\left[i\frac{p}{\hbar}x \right]+j\,\tilde{t}\exp\left[-\frac{p}{\hbar}x \right]. \end{cases} \tag{70}$$

The complex coefficients r, $\tilde{r}$, t and $\tilde{t}$ are determined by matching the wave function $\Psi(x)$ and its slope at the discontinuity of the potential $x=0$ and will depend on $|W|$.

By using the continuity equation, we immediately find the following relation between the transmission, $T=|t|^2$, and reflection, $R=|r|^2$, coefficients

$$R+T=1. \tag{71}$$

C. The rectangular potential well

Finally, we briefly discuss the quaternionic rectangular potential well,

$$V(x)-j\,W(x)=\begin{cases} 0, & x<0, \\ -V+j\,W, & 0<x<a, \\ 0, & x>a. \end{cases}$$

In the potential region, the solution of the complex linear quaternionic Schrödinger equation is then given by

$$\begin{aligned} \Psi(x)=&u_-\left\{ \exp\left[\sqrt{\frac{2m}{\hbar^2}}z_- x \right] k_1+\exp\left[-\sqrt{\frac{2m}{\hbar^2}}z_- x \right] k_2 \right\} \\ &+u_+\left\{ \exp\left[\sqrt{\frac{2m}{\hbar^2}}z_+ x \right] k_3+\exp\left[-\sqrt{\frac{2m}{\hbar^2}}z_+ x \right] k_4 \right\}, \end{aligned} \tag{72}$$

where

$$u_-=\left(1-j\frac{W}{E+\sqrt{E^2-|W|^2}} \right), \quad u_+=\left(j-\frac{\overline{W}}{E+\sqrt{E^2-|W|^2}} \right),$$

and

$$z_-=i\sqrt{\sqrt{E^2-|W|^2}+V}, \quad z_+=\sqrt{\sqrt{E^2-|W|^2}-V}.$$

Depending on whether the energy is positive or negative, we distinguish two separate cases. If $E>0$, the particle is unconfined and is scattered by the potential; if $E<0$, it is confined and in a bound state. We limit ourselves to discussing the case $E<0$. For $|W|<|E|<\sqrt{V^2+|W|^2}$, solution (72) becomes

$$u_-\left\{\exp\left[i\sqrt{\frac{2m}{\hbar^2}}\sqrt{\sqrt{E^2-|W|^2}+V}\,x\right]k_1+\exp\left[-i\sqrt{\frac{2m}{\hbar^2}}\sqrt{\sqrt{E^2-|W|^2}+V}\,x\right]k_2\right\}$$
$$+u_+\left\{\exp\left[i\sqrt{\frac{2m}{\hbar^2}}\sqrt{V-\sqrt{E^2-|W|^2}}\,x\right]k_3+\exp\left[-i\sqrt{\frac{2m}{\hbar^2}}\sqrt{V-\sqrt{E^2-|W|^2}}\,x\right]k_4\right\}. \tag{73}$$

For $|E|<|W|$, the solution is given by

$$u_-\left\{\exp\left[\sqrt{\frac{2m}{\hbar^2}}\rho\exp\left[i\frac{\theta+\pi}{2}x\right]\right]k_1+\exp\left[-\sqrt{\frac{2m}{\hbar^2}}\rho\exp\left[i\frac{\theta-\pi}{2}x\right]\right]k_2\right\}$$
$$+u_+\left\{\exp\left[\sqrt{\frac{2m}{\hbar^2}}\rho\exp\left[i\frac{\pi-\theta}{2}\right]x\right]k_3+\exp\left[-\sqrt{\frac{2m}{\hbar^2}}\rho\exp\left[-i\frac{\theta+\pi}{2}x\right]\right]k_4\right\}, \tag{74}$$

where $\rho=\sqrt{V^2+|W|^2-E^2}$ and $\tan\theta=\sqrt{|W|^2-E^2}/V$. In the region of zero potential, by using the boundary conditions at large distances, we find

$$\Psi(x)=\begin{cases}x<0: & \exp\left[\sqrt{\frac{2m}{\hbar^2}|E|}\,x\right]c_1+j\exp\left[-i\sqrt{\frac{2m}{\hbar^2}|E|}\,x\right]c_4;\\ x>a: & \exp\left[-\sqrt{\frac{2m}{\hbar^2}|E|}\,x\right]d_2+j\exp\left[i\sqrt{\frac{2m}{\hbar^2}|E|}\,x\right]d_3.\end{cases} \tag{75}$$

The matching conditions at the discontinuities of the potential yield the energy eigenvalues.

IX. CONCLUSIONS

In this paper, we have discussed the resolution of quaternionic, $\mathcal{D}_{\mathbb{H}}\varphi(x)=0$, and complex, $\mathcal{D}_{\mathbb{C}}\varphi(x)=0$, linear differential equations with constant coefficients within a quaternionic formulation of quantum mechanics. We emphasize that the only *quaternionic quadratic* equation involved in the study of second order linear differential equations with constant coefficients is given by Eq. (30) following from $\mathcal{D}_{\mathbb{H}}\varphi(x)=0$. Due to the right action of the factor i in complex linear differential equations, we cannot factorize a quaternionic exponential and consequently we are not able to obtain a *quaternionic quadratic* equation from $\mathcal{D}_{\mathbb{C}}\varphi(x)=0$. Complex linear differential equations can be solved by searching for quaternionic solutions of the form $q\exp[zx]$, where $q\in\mathbb{H}$ and $z\in\mathbb{C}$. The complex exponential factorization gives a *complex quartic* equation. A similar discussion can be extended to real linear differential equations, $\mathcal{D}_{\mathbb{R}}\varphi(x)=0$. In this case, the presence of left/right operators **L** and **R** in $\mathcal{D}_{\mathbb{R}}$ requires quaternionic solutions of the form $q\exp[\lambda x]$, where $q\in\mathbb{H}$ and $\lambda\in\mathbb{R}$. A detailed discussion of real linear differential equations deserves a further investigation.

The use of quaternionic mathematical structures in solving the complex linear Schrödinger equation could represent an important direction for the search of new physics. The open question of whether quaternions could play a significant role in quantum mechanics is strictly related to the whole understanding of resolutions of quaternionic differential equations and eigenvalue problems. The investigation presented in this work is only a first step towards a whole theory of quaternionic differential, integral and functional equations. Obviously, due to the great variety of problems in using a noncommutative field, it is very difficult to define the precise limit of the subject.

APPENDIX A: QUATERNIONIC LINEAR QUADRATIC EQUATIONS

In this appendix, we give some examples of quaternionic linear quadratic equations; see cases (i)–(iii) and find their solutions.

• **(i):** $p^2+\sqrt{2}(i+j)p-1-2\sqrt{2}(i+j)=0$.

In solving such an equation we observe that $\mathbf{a}=(\sqrt{2},\sqrt{2},0)$ and $\mathbf{c}=-(2\sqrt{2},2\sqrt{2},0)$ are parallel vectors, $\mathbf{c}=-2\,\mathbf{a}$. Consequently, by introducing the *complex* imaginary unit $\mathcal{I}=(i+j)/\sqrt{2}$, we can reduce the quadratic quaternionic equation to the following *complex* equation:

$$p^2+2\,\mathcal{I}\,p-1-4\,\mathcal{I}=0,$$

whose solutions are $p_{1,2}=-\mathcal{I}\pm 2\,\sqrt{\mathcal{I}}$. It follows that the quaternionic solutions are

$$p_{1,2}=\pm\sqrt{2}-(1\mp\sqrt{2})\,\frac{i+j}{\sqrt{2}}.$$

• **(ii):** $p^2+i\,p+\frac{1}{2}k=0, \quad \Delta=0$.

We note that $\mathbf{a}=(1,0,0)$ and $\mathbf{c}=(0,0,\frac{1}{2})$ are orthogonal vectors and $\mathbf{\Delta}=0$. So, we find two coincident quaternionic solutions given by

$$p=-\frac{1}{2}\mathbf{h}\cdot\mathbf{a}+\mathbf{h}\cdot\mathbf{a}\times\mathbf{c}=-\frac{i+j}{2}.$$

• **(ii):** $p^2+j\,p+1-k=0, \quad \Delta>0$.

In this case, $\mathbf{a}=(0,1,0)$ and $\mathbf{c}=(0,0,-1)$ are orthogonal vectors, $c_0=1$ and $\Delta=1/4$. So,

$$p_0=0, \quad x=-\tfrac{1}{2}\pm\tfrac{1}{2}, \quad y=0, \quad z=1.$$

By observing that

$$\mathbf{h}\cdot\mathbf{a}=j, \quad \mathbf{h}\cdot\mathbf{c}=-k, \quad \mathbf{h}\cdot\mathbf{a}\times\mathbf{c}=-i,$$

we find the following quaternionic solutions:

$$p_1=-i \quad \text{and} \quad p_2=-(i+j).$$

• **(ii):** $p^2+k\,p+j=0, \quad \mathbf{\Delta}<0$.

We have $\mathbf{a}=(0,0,1)$, $\mathbf{c}=(0,1,0)$ and $c_0=0$. Then $\mathbf{a}\cdot\mathbf{c}=0$ and $\Delta=-3/4$. So,

$$p_0=\pm\tfrac{1}{2}, \quad x=-\tfrac{1}{2}, \quad y=\mp\tfrac{1}{2}, \quad z=\tfrac{1}{2}.$$

In this case,

$$\mathbf{h}\cdot\mathbf{a}=k, \quad \mathbf{h}\cdot\mathbf{c}=j, \quad \mathbf{h}\cdot\mathbf{a}\times\mathbf{c}=-i;$$

thus, the solutions are given by

$$p_{1,2}=\tfrac{1}{2}(\pm 1-i\mp j-k).$$

• **(iii):** $p^2+i\,p+1+i+k=0$.

We have $\mathbf{a}=(1,0,0)$, $\mathbf{c}=(1,0,1)$ and $c_0=1$. In this case $\mathbf{a}\cdot\mathbf{c}\neq 0$, so we introduce the quaternion $d_0+\mathbf{h}\cdot\mathbf{d}=1+k$, whose vectorial part $\mathbf{d}=\mathbf{c}-d_0\mathbf{a}=(0,0,1)$ is orthogonal to $\mathbf{a}$. The imaginary part of our solution will be given in terms of the imaginary quaternions,

$$\mathbf{h}\cdot\mathbf{a}=i, \quad \mathbf{h}\cdot\mathbf{d}=k, \quad \mathbf{h}\cdot\mathbf{a}\times\mathbf{d}=-j.$$

The real part of p is determined by solving the equation

$$16\,p_0^6+24\,p_0^4-3\,p_0^2-1=0.$$

The real positive solution is given by $p_0^2=\frac{1}{4}$. Consequently,

$$p_0=\pm\tfrac{1}{2}, \quad x=-\tfrac{1}{2}\mp 1, \quad y=\mp\tfrac{1}{2}, \quad z=\tfrac{1}{2}.$$

The quaternionic solutions are

$$p_1=\tfrac{1}{2}(1-3i-j-k) \quad \text{and} \quad p_2=-\tfrac{1}{2}(1-i+j-k).$$

APPENDIX B: QUATERNIONIC LINEAR DIFFERENTIAL EQUATIONS

We solve quaternionic linear differential equations whose characteristic equations are given by examples **(i)**–**(iii)** in Appendix A.

• **(i):** $\ddot{\varphi}(x)+\sqrt{2}(i+j)\dot{\varphi}(x)-[1+2\sqrt{2}(i+j)]\varphi(x)=0, \quad \varphi(0)=i, \quad \dot{\varphi}(0)=\dfrac{1+k}{\sqrt{2}}.$

The exponential $\exp[p\,x]$ is solution of the previous differential equation if and only if the quaternion p satisfies the following quadratic equation:

$$p^2+\sqrt{2}(i+j)p-1-2\sqrt{2}(i+j)=0,$$

whose solutions are given by

$$p_{1,2}=\pm\sqrt{2}-(1\mp\sqrt{2})\frac{i+j}{\sqrt{2}}.$$

Consequently,

$$\varphi(x)=\exp\left\{\left[\sqrt{2}-(1-\sqrt{2})\frac{i+j}{\sqrt{2}}\right]x\right\}c_1+\exp\left\{\left[-\sqrt{2}-(1+\sqrt{2})\frac{i+j}{\sqrt{2}}\right]x\right\}c_2.$$

By using the initial conditions, we find

$$\varphi(x)=\exp\left[-\frac{i+j}{\sqrt{2}}x\right]\cosh\left[\left(\sqrt{2}+\frac{i+j}{\sqrt{2}}\right)x\right]i.$$

• **(ii):** $\ddot{\varphi}(x)+(1+i)\dot{\varphi}(x)+\dfrac{2+i+k}{4}\varphi(x)=0, \quad \varphi(0)=0, \quad \dot{\varphi}(0)=-\dfrac{1+i+j}{2}.$

We look for exponential solutions of the form $\varphi(x)=\exp[q\,x]=\exp[(p-\frac{1}{2})x]$. The quaternion p must satisfy the quadratic equation,

$$p^2+i\,p+\tfrac{1}{2}k=0.$$

This equation implies

$$p_1 = p_2 = -\frac{i+j}{2}.$$

Thus,

$$\varphi_1(x) = \exp\left[-\frac{1+i+j}{2}x\right].$$

The second linearly independent solution is given by

$$\varphi_2(x) = (x+i)\exp\left[-\frac{1+i+j}{2}x\right].$$

By using the initial conditions, we find

$$\varphi(x) = \{\exp[q\,x] + (x+i)\exp[\,qx]i\}[1+q^{-1}(1+i\,q)i]^{-1},$$

where $q = -(1+i+j)/2$.

- **(ii):** $\ddot{\varphi}(x) + (2+j)\dot{\varphi}(x) + (2+j-k)\varphi(x) = 0,\ \varphi(0) = \dfrac{1-i}{2},\ \dot{\varphi}(0) = j.$

  The exponential solution $\varphi(x) = \exp[q\,x] = \exp[(p-1)x]$ leads to

$$p^2 + j\,p + 1 - k = 0,$$

whose solutions are

$$p_1 = -i \quad \text{and} \quad p_2 = -(i+j).$$

Consequently,

$$\varphi(x) = \exp[-x]\{\exp[-i\,x]c_1 + \exp[-(i+j)x]c_2\}.$$

The initial conditions yield

$$\varphi(x) = \exp[-x]\left\{\exp[-i\,x]\frac{3-i-2j}{2} + \exp[-(i+j)x](j-1)\right\}.$$

- **(ii):** $\ddot{\varphi}(x) + k\,\dot{\varphi}(x) + j\,\varphi(x) = 0,\ \varphi(0) = i+k,\ \dot{\varphi}(0) = 1.$

  The characteristic equation is

$$p^2 + k\,p + j = 0,$$

whose solutions are

$$p_{1,2} = \tfrac{1}{2}(\pm 1 - i \mp j - k).$$

Thus, the general solution of our differential equation reads as

$$\varphi(x) = \exp\left[\frac{1-i-j-k}{2}x\right]c_1 + \exp\left[-\frac{1+i-j+k}{2}x\right]c_2.$$

By using the initial conditions, we obtain

$$\varphi(x)=\left\{ \exp\left[\frac{1-i-j-k}{2}x\right]+\exp\left[-\frac{1+i-j+k}{2}x\right]\right\}\frac{i+k}{2}.$$

• **(iii):** $\ddot{\varphi}(x)+(i-2)\dot{\varphi}(x)+(2+k)\varphi(x)=0$, $\varphi(0)=0$, $\dot{\varphi}(0)=j$.
By substituting $\varphi(x)=\exp[q\,x]=\exp[(p+1)x]$ in the previous differential equation, we find

$$p^2+i\,p+1+i+k=0.$$

The solutions of this quadratic quaternionic equation are

$$p_1=\tfrac{1}{2}(1-3i-j-k) \quad \text{and} \quad p_2=-\tfrac{1}{2}(1-i+j-k).$$

So, the general solution of the differential equation is

$$\varphi(x)=\exp\left[\frac{1-3i-j-k}{2}x\right]c_1+\exp\left[-\frac{1-i+j-k}{2}x\right]c_2.$$

By using the initial conditions, we obtain

$$\varphi(x)=\left\{\exp\left[\frac{1-3i-j-k}{2}x\right]-\exp\left[-\frac{1-i+j-k}{2}x\right]\right\}\frac{j-i+2k}{6}.$$

APPENDIX C: DIAGONALIZATION AND JORDAN FORM

In this appendix, we find the solution of quaternionic and complex linear differential equations by using diagonalization and Jordan form.

1. Quaternionic linear differential equation

By using the discussion about quaternionic quadratic equation, it can immediately be shown that the solution of the following second order equation:

$$\ddot{\varphi}(x)+(k-i)\dot{\varphi}(x)-j\,\varphi(x)=0,$$

with initial conditions

$$\varphi(0)=\frac{k}{2}, \quad \dot{\varphi}(0)=1+\frac{j}{2},$$

is given by

$$\varphi(x)=\left(x+\frac{k}{2}\right)\exp[i\,x].$$

Let us solve this differential equation by using its matrix form (47), with

$$M=\begin{pmatrix}0 & 1\\ j & i-k\end{pmatrix}.$$

This quaternionic matrix can be reduced to its Jordan form,

$$M=J\begin{pmatrix}i & 1\\ 0 & i\end{pmatrix}J^{-1},$$

by the matrix transformation

$$J=\begin{pmatrix} 1 & \dfrac{k}{2} \\ i & 1+\dfrac{j}{2} \end{pmatrix}, \quad J^{-1}=\begin{pmatrix} \dfrac{3+j}{4} & -\dfrac{i+k}{4} \\ -\dfrac{i+k}{2} & \dfrac{1-j}{2} \end{pmatrix}.$$

The solution of the quaternionic linear quaternionic differential equation is then given by

$$\begin{aligned}\varphi(x)&=J_{11}\exp[i\,x][J_{11}^{-1}\,\varphi(0)+J_{12}^{-1}\,\dot{\varphi}(0)]\\&\quad+(x\,J_{11}+J_{12})\exp[i\,x][J_{21}^{-1}\,\varphi(0)+J_{22}^{-1}\,\dot{\varphi}(0)]\\&=(x\,J_{11}+J_{12})\exp[i\,x]\\&=\left(x+\frac{k}{2}\right)\exp[i\,x].\end{aligned}$$

2. Complex linear differential equations

Let us now consider the complex linear quaternionic differential equation,

$$\ddot{\varphi}(x)-j\,\varphi(x)i=0,$$

with initial conditions

$$\varphi(0)=j, \quad \dot{\varphi}(0)=k.$$

To find particular solutions, we set $\varphi(x)=q\exp[z\,x]$. Consequently,

$$q\,z^2-j\,q\,i=0.$$

The solution of the complex linear second order differential equation is

$$\varphi(x)=\tfrac{1}{2}[(i+j)\exp[-ix]+(j-i)\cosh x+(k-1)\sinh x].$$

This solution can also be obtained by using the matrix

$$M_{\mathrm{C}}=\begin{pmatrix} 0 & 1 \\ j\,R_i & 0 \end{pmatrix},$$

and its diagonal form

$$M_{\mathrm{C}}=S_{\mathrm{C}}\begin{pmatrix} -i\,R_i & 0 \\ 0 & i \end{pmatrix}S_{\mathrm{C}}^{-1},$$

where

$$S_{\mathrm{C}}=\begin{pmatrix} \dfrac{1-i-j-k}{2}+\dfrac{1-i+j+k}{2}R_i & \dfrac{1+i-j+k}{2}-\dfrac{1+i+j-k}{2}R_i \\ \dfrac{1+i+j-k}{2}-\dfrac{1+i-j+k}{2}R_i & -\dfrac{1-i-j-k}{2}+\dfrac{1-i+j+k}{2}R_i \end{pmatrix}$$

and

$$S_{\mathrm{C}}^{-1}=\frac{1}{4}\begin{pmatrix} \dfrac{1+i+j+k}{2}-\dfrac{1+i-j-k}{2}R_i & \dfrac{1-i-j+k}{2}+\dfrac{1-i+j-k}{2}R_i \\ \dfrac{1-i+j-k}{2}+\dfrac{1-i-j+k}{2}R_i & -\dfrac{1+i+j+k}{2}-\dfrac{1+i-j-k}{2}R_i \end{pmatrix}.$$

The solution of the complex linear quaternionic differential equation is then given by

$$\begin{aligned}\varphi(x)&=S_{\mathrm{C}\,11}\exp[-iR_ix][S_{\mathrm{C}\,11}^{-1}\varphi(0)+S_{\mathrm{C}\,12}^{-1}\dot{\varphi}(0)]\\&\quad+S_{\mathrm{C}\,12}\exp[ix][S_{\mathrm{C}\,21}^{-1}\varphi(0)+S_{\mathrm{C}\,22}^{-1}\dot{\varphi}(0)]\\&=\frac{1}{4}\{(1-i+j-k)\exp[-x]-(1+i-j-k)\exp[x]\}\\&\quad+\frac{i+j}{2}\exp[-ix].\end{aligned}$$

The holonomy Lie algebras of neutral metrics in dimension four

Ryad Ghanam

(Received 7 December 1999; accepted for publication 13 February 2001)

The Lie algebra isomorphism between $su(1,1)\times su(1,1)$ and $o(2,2)$ is used to obtain a list of subalgebras of the latter. The resulting list of 32 subalgebras is then examined on a case by case basis to see if each can be the Lie algebra of the holonomy group of a neutral metric in four dimensions. The conclusions, taken in conjunction with previously known results, furnish a classification of such Lie subalgebras of $o(2,2)$, with only one case remaining unresolved. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1362284]

I. INTRODUCTION

In this article we shall study and indeed classify the subalgebras of $o(2,2)$ that can occur as holonomy Lie algebras of a neutral metric in dimension four. By a *neutral* metric we mean one that has signature (2,2). The notion of holonomy is due to E. Cartan. In two encyclopaedic articles Berger[1,2] in the 1950s succeeded in classifying the holonomy groups of irreducible Riemannian spaces apart from a few exceptional cases which were resolved later. See Ref. 3 for a discussion of the most difficult cases G_2 and Spin(7). Actually Berger's work even extends to the case of indefinite metrics and symmetric linear connections but all the time under the assumption that the holonomy representation is irreducible.

Let us turn our attention now to the case of indefinite metrics. In the book by Besse[4] the reader can see a discussion of the possible holonomy groups that can occur for Lorentz metrics in dimensions two through four and the corresponding geometric interpretation. We should mention here that Besse considers exclusively the local solution so that one may as well work at the Lie algebra rather than the Lie group level. Likewise in this article all considerations will be local. Another treatment of four-dimensional Lorentzian manifolds and the significance of holonomy in general relativity may be found in a series of papers by Hall and co-workers.[5–9] It is important to appreciate that our classification pertains to subalgebras of $o(2,2)$ under the adjoint representation. For a classification of low-dimensional abstract Lie algebras we refer to the work of Patera *et al.*[10] Finally we should mention the work of Berard-Bergery and Ikemakhen[11] who considered the possible holonomy groups of neutral metrics in dimension four. Their work may be seen as complementary to ours: putting the results together gives almost a complete classification of which Lie algebras can occur as holonomy Lie algebras of a neutral metric in dimension four.

We begin in Sec. II by obtaining a classification of all possible Lie subalgebras of $o(2,2)$ exploiting the fact that $o(2,2)$ is isomorphic to $su(1,1)\times su(1,1)$ and give the isomorphisim explicitly. We obtain a list of 32 classes of Lie subalgebras and they are displayed in Table I. Remarkably all but 2 of these 32 subalgebras are reducible.

The principal concern of our article has been throughout to decide whether there exists at least one metric that gives rise to a particular subalgebra in our list of 32. For certain subalgebras we are able to write down a metric directly in which case we move on to the next subalgebra. In the more difficult cases we actually construct metrics by integrating the conditions imposed upon them by the curvature and its covariant derivatives. We do not claim to have described the most general

32	$\begin{bmatrix}-J & 0\\ 0 & J\end{bmatrix}, \begin{bmatrix}J & 0\\ 0 & J\end{bmatrix}, \begin{bmatrix}0 & I\\ I & 0\end{bmatrix}, \begin{bmatrix}0 & K\\ K & 0\end{bmatrix}, \begin{bmatrix}0 & J\\ -J & 0\end{bmatrix}, \begin{bmatrix}0 & L\\ L & 0\end{bmatrix}$	6

metric corresponding to every subalgebra. We shall come back to this question in a future project.

The are two main differential geometric tools that we shall use in our analysis, of which the first is the Ambrose–Singer[12] theorem, which says that the holonomy algebra can be computed from successive derivatives of the curvature tensor.[4,7,12,13] The second tool is a coordinate normal form due to A. G. Walker[14] for a metric that leaves invariant a null distribution. As a result of this normal form, in trying to construct metrics of this type, instead of dealing potenially with ten unknown functions, we only have three unknowns. Walker's normal form is all the more impor-

tant because of the following easily proved fact about the holonomy representation of neutral geometries, again to be understood in a purely local sense: whenever a null line is left invariant so is a null plane containing the line. Thus Walker's theorem is applicable to 27 of the subalgebras that appear in Table I.

In Sec. IV we turn our attention to one-dimensional algebras which forms a self-contained story. In Sec. V we give a second table which displays the geometric properties that a metric would have to have if its holonomy is to correspond to one of the algebras in our list of 32. Actually we exclude the first nine algebras in Table I, because they are accounted for already in Sec. IV, as well the two irreducible cases.

In Sec. VI we eliminate several easy cases by elementary arguments. In the remaining sections we consider in turn various classes of subalgebras within which the geometric properties of the putative metrics are similar. In every case but one the existence question is answered definitively.

We shall use a minimum of notation. The curvature tensor of a connection will be thought of as type (1,3) tensor field with components R^i_{jkl} in some coordinate system. The components of the covariant derivative of R^i_{jkl} will be similarly denoted by $R^i_{jkl;m}$. The summation convention on repeated indices applies unless the contrary is specified.

II. CLASSIFICATION OF THE LIE SUBALGEBRAS OF o(2,2)

In this section we shall obtain a classification of the Lie subalgebras of o(2,2). We exploit the fact that o(2,2) is isomorphic to $\mathrm{su}(1,1)\oplus\mathrm{su}(1,1)$. Such an isomorphism is mentioned by Helgason[15] but he does not give details. In fact at the group level we have an epimorphism f of $\mathrm{SU}(1,1)\times\mathrm{SU}(1,1)$ onto $\mathrm{SO}_\circ(2,2)$ whose kernel is isomorphic to $\mathbb{Z}_2$. Since the formulas are rather complicated and will not be needed later we refrain from giving them and refer the reader to Ref. 16.

In order to describe the isomorphism f_* at the Lie algebra level we shall introduce the following notation for certain 2×2 real matrices:

$$J=\begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}, \quad K=\begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}, \quad L=\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}. \tag{2.1}$$

The matrices iK, iJ and L then constitute a basis for su(1,1) and under the adjoint representation every element of su(1,1) is conjugate to one of $\alpha iJ, \beta iK$ or $iK+L$ where $\alpha,\beta\in\mathbb{R}$ and the latter $iK+L$ is nilpotent.

An explicit form of f_* mapping generators to generators is as follows:

$$f_*\begin{bmatrix} iK & 0 \\ 0 & 0 \end{bmatrix}=\begin{bmatrix} -J & 0 \\ 0 & J \end{bmatrix}, \quad f_*\begin{bmatrix} 0 & 0 \\ 0 & iK \end{bmatrix}=\begin{bmatrix} J & 0 \\ 0 & J \end{bmatrix},$$

$$f_*\begin{bmatrix} iJ & 0 \\ 0 & 0 \end{bmatrix}=\begin{bmatrix} 0 & I \\ I & 0 \end{bmatrix}, \quad f_*\begin{bmatrix} 0 & 0 \\ 0 & iJ \end{bmatrix}=\begin{bmatrix} 0 & K \\ K & 0 \end{bmatrix},$$

$$f_*\begin{bmatrix} L & 0 \\ 0 & 0 \end{bmatrix}=\begin{bmatrix} 0 & J \\ -J & 0 \end{bmatrix}, \quad f_*\begin{bmatrix} 0 & 0 \\ 0 & L \end{bmatrix}=\begin{bmatrix} 0 & L \\ L & 0 \end{bmatrix}.$$

At this stage we consider $\mathbb{R}^4$ to be equipped with the neutral inner product $\left[\begin{smallmatrix} I & 0 \\ 0 & -I \end{smallmatrix}\right]$. Subsequently we shall find it convenient to change this representation.

To obtain the classification of the subalgebras of o(2,2) we now have the apparently simple task of finding subalgebras in $\mathrm{su}(1,1)\oplus\mathrm{su}(1,1)$ and pushing forward with f_*. The following elementary fact should be noted:

Lemma 2.1: There is a two-dimensional Lie subalgebra of su(1,1) *with generators* iJ *and* $iK+L$ *and this subalgebra is unique up to isomorphism.*

We obtained the classification by considering elements of $\mathrm{su}(1,1)\oplus\mathrm{su}(1,1)$ as 2×2 block diagonal matrices and letting the restriction of a subalgebra to each block have dimensions m and n, respectively. Of course the primary invariant of a subalgebra is its dimension which can vary

from zero to six. We note also that the matrix $\left[\begin{smallmatrix} K & 0 \\ 0 & I \end{smallmatrix}\right]$ defines an automorphism of o(2,2) which maps $\left[\begin{smallmatrix} -J & 0 \\ 0 & J \end{smallmatrix}\right]$ to $\left[\begin{smallmatrix} J & 0 \\ 0 & J \end{smallmatrix}\right]$, $\left[\begin{smallmatrix} 0 & I \\ I & 0 \end{smallmatrix}\right]$ to $\left[\begin{smallmatrix} 0 & K \\ K & 0 \end{smallmatrix}\right]$ and $\left[\begin{smallmatrix} 0 & J \\ -J & 0 \end{smallmatrix}\right]$ to $\left[\begin{smallmatrix} 0 & L \\ L & 0 \end{smallmatrix}\right]$, respectively. It follows that the cases (m,n) and (n,m) give rise to isomorphic subalgebras in o(2,2).

The classification for one-dimensional algebras is obtained immediately and, allowing for change of basis, agrees with results obtained previously in Ref. 17. For the remaining algebras, one simply checks for a given dimension d, with $2 \leqslant d \leqslant 5$, all the possible subalgebras of $\mathrm{su}(1,1) \oplus \mathrm{su}(1,1)$ that can arise for particular values of m and n such that $m \geqslant n$ and $2 \leqslant m+n \leqslant 5$ and one realizes the corresponding subalgebra of o(2,2) by applying f_*.

Let us outline the method for three-dimensional sualgebras. First of all (3,0) corresponds to $\mathrm{su}(1,1) \oplus \{0\}$ and the algebra in o(2,2) has generators $\left[\begin{smallmatrix} 0 & I \\ I & 0 \end{smallmatrix}\right]$, $\left[\begin{smallmatrix} -J & 0 \\ 0 & J \end{smallmatrix}\right]$, $\left[\begin{smallmatrix} -J & 0 \\ 0 & J \end{smallmatrix}\right]$. For the case (3,1) we may assume that our generators are of the form $\left[\begin{smallmatrix} iJ & 0 \\ 0 & aN \end{smallmatrix}\right]$, $\left[\begin{smallmatrix} iK & 0 \\ 0 & bN \end{smallmatrix}\right]$ and $\left[\begin{smallmatrix} L & 0 \\ 0 & cN \end{smallmatrix}\right]$ where $a,b,c \in \mathbb{R}$ and the precise form of N is unknown. The Lie bracket of the first two must be twice the third, which implies that $c=0$. Likewise from the brackets of the first and third and second and third, respectively, we deduce that $a=b=0$, and hence no such algebra of this kind is possible.

Similarly one may argue that the case (3,2) is impossible and that (3,3) corresponds precisely to the diagonal subalgebra in $\mathrm{su}(1,1) \oplus \mathrm{su}(1,1)$. For the case (2,1) we may assume that the generators have the form $\left[\begin{smallmatrix} iJ & 0 \\ 0 & aM \end{smallmatrix}\right]$, $\left[\begin{smallmatrix} iK+L & 0 \\ 0 & bM \end{smallmatrix}\right]$ and $\left[\begin{smallmatrix} 0 & 0 \\ 0 & M \end{smallmatrix}\right]$ where $a,b \in \mathbb{R}$. We can now put M into canonical form and we obtain three classes of algebras in o(2,2) depending on a parameter α. Similarly for the case (2,2) we obtain a single class of Lie algebras in o(2,2) that depends on a parameter α. Table I gives our list of the subalgebras of o(2,2) in terms of a basis for each subalgebra. We state the dimension of the subalgebra and have numbered the subalgebras from 1 to 32 for future reference, though certain of these numbers pertain to classes of subalgebras depending on parameters α and β.

III. DIFFERENTIAL GEOMETRIC PRELIMINARIES

For the moment M will denote a C^∞ manifold of dimension n. Also ∇ will denote a C^∞ symmetric linear connection on M. A tensor field T on M is said to be *parallel* if $\nabla_X T = 0$ for all vector fields X on M. On the other hand T is said to be *recurrent* if $\nabla_X T = \theta(X)T$ for some one-form θ on M or equivalently $\nabla T = \theta \otimes T$. An r-dimensional distribution D on M will be said to be parallel if for all Y in D and all vector fields X on M, the vector field $\nabla_X Y$ also belongs to D. If ∇ is a symmetric connection, then D is necessarily integrable. Even if D is parallel it may contain no parallel or recurrent vector fields itself.

We will assume that the reader is familiar with the basic idea of holonomy and refer to Refs. 4 and 13. A good reference also is Ref. 7 which is concerned with four-dimensional Lorentzian manifolds as opposed to the neutral metrics which is the subject of the present article. There are a number of technical difficulties associated with holonomy which we shall ignore. Specifically we shall have occasion to solve linear systems of equations and we shall need to assume that the rank of these systems is constant. We also need to know that the Lie algebra of the holonomy group can be computed pointwise from the curvature R of ∇ and the covariant derivatives of R. Therefore, we shall make the assumption that the manifolds, metrics and connections concerned are real analytic. We shall be working infinitesimally at the Lie algebra rather that the group level throughout.

From now on ∇ will be the Levi-Civita connection of a metric g on M and the holonomy group of g will be denoted by $\mathrm{Hol}(g)$ and its Lie algebra by $\mathrm{hol}(g)$. We say that $\mathrm{Hol}(g)$ is *nondegenerately reducible* if on each tangent space $T_x M$ to M the group $\mathrm{Hol}(g)$ leaves invariant a proper *nondegenerate* subspace. The local de Rham theorem asserts that if $\mathrm{Hol}(g)$ [or even $\mathrm{hol}(g)$] acts nondegenerately reducibly, then M and g split locally as a product manifold and product metric.

We turn now to a theorem of A. G. Walker[14] that will be fundamental to much of our analysis.

Theorem 3.1:[14] Let (M,g) *be a pseudo-Riemannian manifold of class* C^∞. *If* g *admits a parallel, null* r*-distribution, then there is a system of coordinates* (x^i) *relative to which* g *assumes the following form,*

$$g_{ij}=\begin{bmatrix} 0 & 0 & I \\ 0 & A & H \\ I & H^t & B \end{bmatrix},$$

where I is the $r\times r$ identity matrix and A,B,H and H^t are matrix functions of the same class as M, satisfying the following conditions but otherwise arbitrary:

(i) *A and B are symmetric, A is of order $(n-2r)\times(n-2r)$ and nonsingular, B is of order $r\times r$, H is of order $(n-2r)\times r$ and H^t is the transpose of H.*

(ii) *A and H are independent of the coordinates $x^1,x^2,\ldots,x^r$.* □

As a footnote to Theorem 3.1 we note that if in addition B is independent of, say, x^k, for a fixed k with $1\leqslant k\leqslant r$, then $\partial/\partial x^k$ is a parallel vector field for g.

The special case of Walker's theorem that we shall need is when $n=4$ and $r=2$. In that case A and H are zero and we denote the 2×2 matrix B by $\left[\begin{smallmatrix} a & c \\ c & b \end{smallmatrix}\right]$. We shall also use (x,y,z,w) for the coordinate system rather than (x^1,x^2,x^3,x^4). We record next the geodesic equations as an efficient means of the encoding the components Γ^i_{jk} of the Levi-Civita connection of g:

$$\ddot{x}+a_x\dot{x}\dot{z}+c_x\dot{x}\dot{w}+a_y\dot{y}\dot{z}+c_y\dot{y}\dot{w}+\tfrac{1}{2}(aa_x+ca_y+a_z)(\dot{z})^2$$

$$+(ac_x+cc_y+a_w)\dot{z}\dot{w}+\tfrac{1}{2}(ab_x+cb_y+2c_w-b_z)(\dot{w})^2=0,$$

$$\ddot{y}+c_x\dot{x}\dot{z}+b_x\dot{x}\dot{w}+c_y\dot{y}\dot{z}+b_y\dot{y}\dot{w}+\tfrac{1}{2}(ca_x+ba_y+2c_z-a_w)(\dot{z})^2$$

$$+(cc_x+bc_y+b_z)\dot{z}\dot{w}+\tfrac{1}{2}(cb_x+bb_y+b_w)(\dot{w})^2=0,$$

$$\ddot{z}-\tfrac{1}{2}a_x(\dot{z})^2-c_x\dot{z}\dot{w}-\tfrac{1}{2}b_x(\dot{w})^2=0,$$

$$\ddot{w}-\tfrac{1}{2}a_y(\dot{z})^2-c_y\dot{z}\dot{w}-\tfrac{1}{2}b_y(\dot{w})^2=0.$$

One finds also that the nonzero components (allowing for symmetry) of the totally covariant curvature tensor are given by

$$R_{1313}=-\tfrac{1}{2}a_{xx},$$

$$R_{1314}=-\tfrac{1}{2}c_{xx},$$

$$R_{1323}=-\tfrac{1}{2}a_{xy},$$

$$R_{1324}=-\tfrac{1}{2}c_{xy},$$

$$R_{1334}=\tfrac{1}{2}a_{xw}-\tfrac{1}{2}c_{xz}-\tfrac{1}{4}b_xa_y+\tfrac{1}{4}c_xc_y,$$

$$R_{1414}=-\tfrac{1}{2}b_{xx},$$

$$R_{1423}=-\tfrac{1}{2}c_{xy},$$

$$R_{1424}=-\tfrac{1}{2}b_{xy},$$

$$R_{1434}=\tfrac{1}{2}c_{xw}-\tfrac{1}{2}b_{xz}-\tfrac{1}{4}(c_x)^2+\tfrac{1}{4}b_xa_x-\tfrac{1}{4}b_xc_y+\tfrac{1}{4}c_xb_y,$$

$$R_{2323}=-\tfrac{1}{2}a_{yy},$$

$$R_{2324}=-\tfrac{1}{2}c_{yy},$$

$$R_{2334}=\tfrac{1}{2}a_{yw}-\tfrac{1}{2}c_{yz}+\tfrac{1}{4}c_xa_y-\tfrac{1}{4}a_xc_y-\tfrac{1}{4}c_ya_y+\tfrac{1}{4}(c_y)^2,$$

$$R_{2424}=-\tfrac{1}{2}b_{yy},$$

$$R_{2434}=\tfrac{1}{2}c_{yw}-\tfrac{1}{2}b_{yz}+\tfrac{1}{4}b_xa_y-\tfrac{1}{4}c_xc_y,$$

$$\begin{aligned}R_{3434}=&c_{zw}-\tfrac{1}{2}a_{ww}-\tfrac{1}{2}b_{zz}+\tfrac{1}{4}ab_xa_x-\tfrac{1}{4}a(c_x)^2-\tfrac{1}{2}cc_xc_y\\&+\tfrac{1}{4}ca_xb_y-\tfrac{1}{2}c_xa_w+\tfrac{1}{2}a_xc_w-\tfrac{1}{4}a_xb_z+\tfrac{1}{4}cb_xa_y+\tfrac{1}{4}bb_ya_y\\&-\tfrac{1}{4}b(c_y)^2-\tfrac{1}{2}c_yb_z+\tfrac{1}{4}a_yb_w+\tfrac{1}{4}b_xa_z+\tfrac{1}{2}b_yc_z-\tfrac{1}{4}b_ya_w.\end{aligned}$$

From the formulas for the geodesic equations we obtain the following facts.

Corollary 3.2: Suppose the neutral metric g on $\mathbb{R}^4$ admits a parallel null two-distribution. Then g has the following extra properties:

(1) *g possesses a parallel null vector field iff there exists a coordinate system (x,y,z,w) in which a, b and c are independent of x.*
(2) *g possesses a null recurrent vector field iff there exists a coordinate system (x,y,z,w) in which b and c are independent of x.*
(3) *g possesses two parallel orthogonal null vector fields iff there exists a coordinate system (x,y,z,w) in which a, b and c are independent of x and y.*
(4) *g possesses orthogonal null recurrent and null parallel vector fields iff there exists a coordinate system (x,y,z,w) in which a, b and c are independent of y and b and c are independent of x.*
(5) *g possesses two orthogonal null recurrent vector fields iff there exists a coordinate system (x,y,z,w) in which b and c are independent of x and a and b are independent of y.*

We record another useful result in this section.

Proposition 3.3: Suppose on the n-dimensional manifold M with symmetric connection ∇ there exists a vector field Δ that is recurrent, nowhere vanishing, and satisfies

$$R(X,Y)\Delta=0$$

for all vector fields X and Y on M and R is the type (1,3) *Riemann tensor. Then Δ may be rescaled locally so as to give a parallel vector field.*

Proof: Since Δ is recurrent we find by calculation that

$$R(X,Y)\Delta=d\theta(X,Y)\Delta.$$

It follows that θ is closed. Write locally $\theta=df$ for some function on M and define

$$\overline{\Delta}=e^{-f}\Delta.$$

Then $\overline{\Delta}$ is parallel. □

We finish up this section with two results that will be used several times in the analysis of the more difficult cases. As before g denotes a neutral metric on the four-dimensional space M and g has a parallel and of course integrable distribution D. The quotient space M/D assumed to be a smooth manifold will be denoted by Q.

Lemma 3.4: If the Levi-Civita connection of g is projectable to the quotient space Q, then the Ricci tensor of the projected connection is symmetric.

Proof: Assuming that the connection of g projects to Q to show that induced connection of Q has symmetric Ricci tensor, it is sufficient to show that

$$R^1_{341}+R^2_{342}+R^3_{343}-R^1_{431}-R^2_{432}-R^4_{434}=0. \tag{3.1}$$

We replace the third term in (3.1) by R^1_{134}, the sixth term by R^2_{234} and apply the Bianchi identity to the fourth term. Thus the left hand side of (3.1) becomes

$$R^1_{341}+R^2_{342}+R^1_{134}-R^1_{143}+R^1_{314}-R^2_{432}+R^2_{234}=R^2_{342}+R^2_{234}+R^2_{423}=0$$

by the Bianchi identity. □

Proposition 3.5: If the Levi-Civita connection of g is projectable to Q and the connection on Q has one-dimensional holonomy group, then either it is a Levi-Civita connection or else g has a parallel vector field.

Proof: By Lemma 3.4 the connection on Q is symmetric. Furthermore, since the holonomy group is one-dimensional, the Ricci tensor, which embodies the entire curvature tensor, is recurrent. There are now two possibilities according as the Ricci tensor on Q is nondegenerate or degenerate. In the former case Ricci may be scaled so as to produce a metric on Q for which the induced connection on Q is its Levi-Civita connection.[18] In the latter case the connection on Q possesses a parallel one-form.[19] It follows by pullback that g on M possesses a parallel one-form and hence, by duality, a parallel vector field. □

We remark that in Theorem 3.1, in the case where the projected connection is Levi-Civita, g is not necessarily of the form of a complete lift of a metric on Q but differs from it by the pullback of a quadratic form on Q. This point is fully discussed in Ref. 19 where it is explained how M may be identified locally as the tangent bundle of Q.

IV. ONE-DIMENSIONAL HOLONOMY ALGEBRAS

The case of the Lie algebras that are one-dimensional will be discussed in this section. The argument in this case is self-contained and closely resembles the the Lorentzian situation. The following results are based on lemmas of Hall and McIntosh[8] in the Lorentzian case.

Lemma 4.1: If G and F are a pair of two forms on a finite dimensional vector space V such that

$$F(X,Y)G(Z,W)=F(Z,W)G(X,Y)$$

for all $X,Y,Z,W, \in V$ and F is nonzero, then there exists $\lambda \in \mathbb{R}$ such that $G=\lambda F$.

Proof: If we assume $F_{12}\neq 0$, then in some basis of V we have $G_{ij}F_{12}=G_{12}F_{ij}$ and therefore $G_{ij}=(G_{12}/F_{12})F_{ij}$. Take $\lambda=(G_{12}/F_{12})$ then $G_{ij}=\lambda F_{ij}$ for all i and j. □

Proposition 4.2: Suppose that the dimension of the ambient manifold M is at least four. The curvature tensor cannot be spanned by a single nondegenerate form, in the sense that if $R=\theta \otimes F$ where θ is an endomorphism field and F is a two-form, then F cannot be of maximal rank.

Proof: Relative to a not necessarily coordinate frame field we have in components that

$$R_{ijkl}=g_{in}\theta^n_j F_{kl}=G_{ij}F_{kl},$$

where $G_{ij}=g_{in}\theta^n_j$. Since $R_{ijkl}=R_{klij}$ then we find that

$$G_{ij}F_{kl}=G_{kl}F_{ij},$$

and by Lemma 4.1 we conclude that for some function λ

$$G_{ij}=\lambda F_{ij}.$$

Thus

$$R_{ijkl}=\lambda F_{ij}F_{kl}.$$

Since $R^{i}_{[jkl]}=0$ the above condition gives $F_{i[j}F_{kl]}=0$ which implies that F is decomposable hence singular. □

Corollary 4.3: None of $A_1(\alpha\beta\neq 0), A_2(\alpha\beta\neq 0), A_4, A_5(\alpha\neq 0), A_6, A_7, A_8(\alpha\neq 0)$ *are holonomy Lie algebras.*

Note also that the cases $A_1(\alpha=0)$ and $A_2(\alpha=0)$ are obviously holonomy algebras: take respectively the product of flat and nonflat two-dimensional Riemannian spaces (with signs adjusted to obtain neutral signature) and, after effecting the permutation switching the second and third basis vectors, the product of flat and nonflat two-dimensional Lorentzian spaces. □

Proposition 4.4: A_3 *is a holonomy algebra*

Proof: We take the metric to be the product of a special three-dimensional Lorentzian metric $2dxdz+dy^2+b(y,z)dz^2$ where b_{zz} in nonzero and $-dw^2$. The three-dimensional Lorentzian metric has a one-dimensional algebra[4] and ∂_x is a parallel null vector field. Thus the metric $-dw^2+2dxdz+dy^2+b(y,z)dz^2$ has one-dimensional holonomy with the algebraic type of A_3. □

Finally, note that the cases $A_5(\alpha=0)$ and $A_8(\alpha=0)$ are identical. Furthermore, this case is equivalent to A_9 by means of making the transformation on $\mathbb{R}^4$ that has matrix $\left[\begin{smallmatrix} I & 0 \\ 0 & K \end{smallmatrix}\right]$.

Proposition 4.5: A_9 *is a holonomy algebra.*

Proof: In this case there must be two orthogonal null parallel vector fields. We apply Corollary 3.2 (5) and deduce that the Riemann curvature [as a type (1,3) tensor] components R^{i}_{jkl} for fixed k and l are multiples of $\left[\begin{smallmatrix} 0 & J \\ 0 & 0 \end{smallmatrix}\right]$. Note that because $\partial/\partial x$ and $\partial/\partial x$ are parallel we have that

$$\nabla_W R(X,Y)\frac{\partial}{\partial x}=0$$

and

$$\nabla_W R(X,Y)\frac{\partial}{\partial y}=0$$

for arbitrary W,X and Y, which proves that the holonomy algebra is indeed one-dimensional. To obtain the generator in the form given in A_9 it is necessary to apply the transformation with matrix $1/\sqrt{2}\left[\begin{smallmatrix} I & I \\ I & -I \end{smallmatrix}\right]$ to $\mathbb{R}^4$. □

The entire situation for one-dimensional holonomy can be summarized very neatly by means of the following theorem.

Theorem 4.6: *The holonomy Lie algebra is one-dimensional if and only if the metric possesses two parallel vector fields.*

V. GEOMETRIC STRUCTURE OF THE SUBALGEBRAS

Of the algebras listed in Table I only A_{28} and A_{32} act irreducibly. Berger[1] classified the irreducible holonomy groups of pseudo-Riemannian manifolds. Actually there are a number of exceptions to Berger's list, but the dimensions of these groups are too high to concern us here. Furthermore, Berger assumes that the spaces concerned are not pseudo-Riemannian symmetric spaces which he discussed separately in Ref. 2. In a recent paper Berard-Bergery and Ikemakhen[11] listed all symmetric spaces for neutral metrics in dimension four. Of these spaces, $SO_{\circ}(2,3)/SO_{\circ}(2,2)$ gives an example where the holonomy algebra is A_{32}. Likewise $SU(1,1)/U(1,1)$ being irreducible must correspond to A_{28}.

TABLE II. The geometric structure of the subalgebras.

Geometric structure	Lie subalgebras
A null two-dimensional distribution D	$A_{12}, A_{19}, A_{24}, A_{29}, A_{31}$
Two null two-dimensional complementary distributions D_1, D_2	A_{15}, A_{21}, A_{27}
Two nondegenerate two-dimensional orthogonal distributions D_1, D_2	A_{14}, A_{16}
Two null two-dimensional distributions D_1, D_2 D_1 containing a parallel vector field and D_2 a recurrent vector field	A_{11}(with $\alpha=\pm 1$)
Two null two-dimensional distributions D_1 and D_2 each containing a recurrent vector field	$A_{10}, A_{11}(\alpha=\pm 1), A_{18}, A_{23}$
A null two-dimensional distribution D containing a recurrent vector field	$A_{13}, A_{25}, A_{26}, A_{30}$
A null two-dimensional distribution D containing one parallel vector field	A_{17}, A_{26}(with $\alpha=-1$)
One-dimensional and three-dimensional nondegenerate distributions D_1, D_2, with D_2 containing a null recurrent vector field.	$A_{20}(\beta=\pm 1)$

Since all the algebras except A_{28} and A_{32} in Table I are reducible the existence of such an algebra as a holonomy algebra implies that the associated metric will preserve various geometric structures. Since we have already considered A_1-A_9 we list below in Table II the geometric properties that a metric with a reducible holonomy algebra must have in the remaining cases, *provided it exists*.

VI. ELIMINATION OF SOME EASY CASES

In this section we shall discuss some of the cases in Table I where we can decide easily whether or not the algebra comes from a metric.

Proposition 6.1: $A_{14}, A_{16}, A_{20}(\beta=\pm 1)$ *and* A_{22} *are holonomy algebras.*

Proof: For A_{16} an equivalent pair of generators is $\left[\begin{smallmatrix} J & 0 \\ 0 & 0 \end{smallmatrix}\right]$ and $\left[\begin{smallmatrix} 0 & 0 \\ 0 & J \end{smallmatrix}\right]$. The existence of a metric follows from the local de Rham theorem: use a pair of nonflat two-dimensional Riemannian metrics with the signs adjusted so as to produce a neutral four-dimensional metric.

For A_{14} apply the permutation $e_2 \leftrightarrow e_3$ on $\mathbb{R}^4$. We then obtain the generators $\left[\begin{smallmatrix} L & 0 \\ 0 & 0 \end{smallmatrix}\right]$ and $\left[\begin{smallmatrix} 0 & 0 \\ 0 & L \end{smallmatrix}\right]$ for A_{14} and the inner product is $\left[\begin{smallmatrix} K & 0 \\ 0 & K \end{smallmatrix}\right]$. This time the de Rham theorem implies that we have a product of nonflat two-dimensional Lorentzian manifolds. Similarly A_{22} corresponds to the product of an irreducible three-dimensional Lorentzian metric and a one-dimensional flat factor adjusted so as to obtain a neutral signature.

In the case of $A_{20}(\beta=1)$ we have the product of a three-dimensional Lorentzian manifold, which has a recurrent null vector field that cannot be scaled so as to give a parallel field, and a one-dimensional factor with negative squared length. Similarly for $A_{20}(\beta=-1)$ we have the product of such a Lorentzian manifold and a one-dimensional factor with positive squared length. □

Proposition 6.2: A_{18}, A_{19} *are holonomy algebras.*

Proof: Consider the following metric on $\mathbb{R}^2$,

$$g = a dx^2 + 2c dx dy + b dy^2,$$

where a, b and c are functions of x and y. Now define

$$\overline{g} = 2a dx dz + 2c dz dy + 2b dw dy + (z a_x + w a_y) dx^2 + (z b_x + w b_y) dy^2 + 2(z c_x + w c_y) dx dy$$

on $\mathbb{R}^4 = T\mathbb{R}^2$ where (x,y,z,w) is the induced coordinate system. Then $\overline{g}$ is the complete lift of g.[20] It turns out that the curvature $\overline{R}$ of $\overline{g}$ is the complete lift of the curvature R of g. Furthermore, because g is two-dimensional, R is recurrent and hence so is $\overline{R}$. Assuming that g is not flat its

holonomy group is one-dimensional and the holonomy group of $\bar{g}$ is two-dimensional being in fact the tangent group of the group of g. For details see Ref. 20. It follows immediately that if g is Riemannian the holonomy algebra type of $\bar{g}$ is A_{19}.

If, however, g is Lorentzian and we assume that g is represented in some frame by the matrix L, then $\bar{g}$ is represented by $\left[\begin{smallmatrix}0 & L\\ L & 0\end{smallmatrix}\right]$ and the holonomy algebra has a basis consisting of $\left[\begin{smallmatrix}K & 0\\ 0 & K\end{smallmatrix}\right]$ and $\left[\begin{smallmatrix}0 & K\\ 0 & 0\end{smallmatrix}\right]$. The latter algebra is equivalent to A_{18} by means of the transformation of $\mathbb{R}^4$ whose matrix is $1/\sqrt{2}\left[\begin{smallmatrix}L & L\\ I & -I\end{smallmatrix}\right]$. □

We now consider the algebras $A_{10}, A_{11}, A_{15}, A_{21}, A_{23}$ and A_{27}. In each of these algebras there are two 'null, complementary invariant subspaces. This situation has been studied in Ref. 11. The authors use a normal form for such a metric, which was actually obtained by one of the present authors in Ref. 21. The normal form is valid in $2n$ dimensions for a metric with two null, complementary invariant distributions and comes down to the fact that the components of the metric are the second order derivatives of a single function. Berard-Bergery and Ikhemaken exhibit metrics for cases which correspond in our classification to $A_{10}, A_{11}, A_{12}, A_{15}, A_{18}, A_{23}$ and A_{27}. They also mention that the existence of a metric in case A_{21} follows from general results of Bryant.[3]

We conclude this section with examples for A_{30} and A_{31}. These examples are actually easy to find because they are generic cases within the class of metrics possessing the corressponding geometric structure. Furthermore, in both cases the curvature by itself generates the full holonomy algebra, the dimension of which is maximal given that the metrics in question possess that particular geometric structure.

Proposition 6.3: $A_{26}(\alpha=-1)$, A_{30} *and* A_{31} *are holonomy algebras.*

Proof: The algebra A_{31} can be obtained by a generic metric that satisfies the condition of Theorem 3.1 with $n=4$ and $r=2$. As a specific example take

$$g = dxdz + dydw + e^{2x}(dz^2 + dw^2).$$

It is easy to check that the five curvature matrices derived from g are linearly independent. Similarly generic metrics that satisfy the conditions of Corollary 3.2 (1) and (2) provide examples of the algebras $A_{26}(\alpha=-1)$ and A_{30}, respectively. □

Proposition 6.4: A_{17} *is a holonomy algebra.*

Proof: In this case we have an invariant null distribution containing a parallel null vector field and so we are in the situation of part 1 of Corollary 3.2. The corresponding nonzero curvature matrices are

$$R^i_{j24} = \begin{bmatrix} 0 & C_{yy} & 2CC_{yy} & R_{3424}+2CB_{yy} \\ 0 & B_{yy} & 2BC_{yy}-R_{3424} & 2BB_{yy} \\ 0 & 0 & 0 & 0 \\ 0 & 0 & -C_{yy} & -B_{yy} \end{bmatrix},$$

$$R^i_{j23} = \begin{bmatrix} 0 & A_{yy} & 2CA_{yy} & 2CC_{yy}+R_{3423} \\ 0 & C_{yy} & 2BA_{yy}-R_{3423} & 2BC_{yy} \\ 0 & 0 & 0 & 0 \\ 0 & 0 & -A_{yy} & -C_{yy} \end{bmatrix},$$

$$R^i_{j34} = \begin{bmatrix} 0 & -R_{2334} & -2CR_{2334} & -2CR_{2434}+R_{3434} \\ 0 & -R_{2434} & -2BR_{2334}-R_{3434} & -2BR_{2434} \\ 0 & 0 & 0 & 0 \\ 0 & 0 & R_{2334} & R_{2434} \end{bmatrix},$$

where $A=\frac{1}{2}a, B=\frac{1}{2}b$ and $C=\frac{1}{2}c$.

All the matrices in A_{17} are nilpotent and so we must have that $B_{yy}=C_{yy}=C_{yw}-B_{yz}=0$, as a result of which R^i_{j24} becomes zero. In order to realize A_{17} as a holonomy algebra all that is needed now is that the covariant derivatives $R^i_{jkl;m}$ should bring in no new holonomy generators; and in order for that situation to occur all that is needed is for the components $R^2_{2kl;m}$ to vanish. One can easily check that in view of all the preceding hypotheses these conditions are satisfied identically. To summarize: A_{17} will be produced by generic metrics of the form given by part (1) of Corollary 3.2 for which in addition

$$b_{yy}=c_{yy}=c_{yw}-b_{yz}=0.$$

□

VII. THE ALGEBRAS A_{12} AND A_{24}

Proposition 7.1: Neither A_{12} nor A_{24} is a holonomy algebra.

Proof: In both cases we change the inner product to $\left[\begin{smallmatrix}0 & I\\ I & 0\end{smallmatrix}\right]$. The generators for A_{12} become $\left[\begin{smallmatrix}\alpha J+I & 0\\ 0 & \alpha J-I\end{smallmatrix}\right]$ and $\left[\begin{smallmatrix}0 & J\\ 0 & 0\end{smallmatrix}\right]$ and for A_{24} $\left[\begin{smallmatrix}J & 0\\ 0 & J\end{smallmatrix}\right]$, $\left[\begin{smallmatrix}I & 0\\ 0 & -I\end{smallmatrix}\right]$ and $\left[\begin{smallmatrix}0 & J\\ 0 & 0\end{smallmatrix}\right]$, respectively. In both cases $\left[\begin{smallmatrix}J & 0\\ 0 & J\end{smallmatrix}\right]$ commutes with each generator. It follows that we must in each case be looking at a pseudo-Kähler metric that keeps a null two-dimensional distribution D invariant.

We apply Walker's normal form to the five nonzero generators of the curvature. It is then easy to see that we can obtain A_{12} only in the case where all the second order derivatives of A, B and C with respect to x and y vanish and that we can never obtain A_{24}. Indeed each upper left hand 2×2 block in the generators must be a linear combination of I and J. In the case of A_{12} there are at least two dependence relations among the generators $R^i_{i13}, R^i_{j24}, R^i_{j23}$ and R^i_{j34} which implies that all the stated second order derivatives are zero. In the case of A_{24} it is easy to see that if any of the 2×2 blocks is zero, so are all the above-mentioned second derivatives. Hence there are again at least two dependence relations among the 2×2 blocks which again implies the vanishing of $A_{xx}, A_{xy}, A_{yy}, B_{xx}, B_{xy}, B_{yy}, C_{xx}$, C_{xy} and C_{yy}. Thus the curvature matrices span at most a two-dimensional subspace.

Given that the stated second order derivatives of A, B and C are zero we see that the connection of g is projectable via the submersion $(x,y,z,w)\mapsto(z,w)$. We can now apply Proposition 3.5 to conclude that both A_{12} and A_{24} are excluded as holonomy algebras. In the former case the generator $\alpha J-I$ on Q does not correspond to the holonomy of a two-dimensional metric. In the latter case we would have a two-dimensional holonomy algebra on Q isomorphic to $\mathrm{gl}(1,\mathbb{C})$. Thus the connection would correspond to the real and imaginary parts of a scalar holomorphic connection. Such a connection has Ricci symmetric only when it reduces to a metric connection and thus its holonomy algebra cannot be two-dimensional. □

VIII. THE ALGEBRAS $A_{13}, A_{25}, A_{26}(\alpha\neq -1)$

In this section we investigate the case where we have a single recurrent vector field that cannot be scaled so as to give a parallel field. We are thus looking at A_{13}, A_{25} and $A_{26}(\alpha\neq -1)$, the case A_{30} already having been dealt with.

Proposition 8.1: A_{13} is not a holonomy algebra in the cases where (i) $a_{xx}=a_{yy}=0$ or (ii) $b=a_{xw}=0$. (The generic case as explained below remains undecided.)

Proof: In this case following the notation of Corollary 3.2 we have that $b_x=c_x=0$. We now record the form of the curvature matrices that are possibly nonzero and write $\frac{1}{2}a, \frac{1}{2}b$ and $\frac{1}{2}c$ as A, B and C, respectively. Thus

$$R^i_{j13}=\begin{bmatrix} A_{xx} & A_{xy} & 2(AA_{xx}+CA_{xy}) & A_{xw}\\ 0 & 0 & 2CA_{xx}+2BA_{xy}-A_{xw} & 0\\ 0 & 0 & -A_{xx} & 0\\ 0 & 0 & -A_{xy} & 0\end{bmatrix}, \tag{8.1}$$

$$R^i_{j24}=\begin{bmatrix} 0 & C_{yy} & 2CC_{yy} & 2CB_{yy}+C_{yw}-B_{yz} \\ 0 & B_{yy} & 2BC_{yy}-C_{yw}+B_{yz} & 2BB_{yy} \\ 0 & 0 & 0 & 0 \\ 0 & 0 & -C_{yy} & -B_{yy} \end{bmatrix}, \tag{8.2}$$

$$R^i_{j23}=\begin{bmatrix} A_{xy} & A_{yy} & 2(AA_{xy}+CA_{yy}) & 2CC_{yy}+R_{3423} \\ 0 & C_{yy} & 2(CA_{xy}+BA_{yy})-R_{3423} & 2BC_{yy} \\ 0 & 0 & -A_{xy} & 0 \\ 0 & 0 & -A_{yy} & -C_{yy} \end{bmatrix}, \tag{8.3}$$

$$R^i_{j34}=\begin{bmatrix} -A_{xw} & -R_{2334} & -2(AA_{xw}+CR_{2334}) & 2C(B_{yz}-C_{yw})+R_{3434} \\ 0 & B_{yz}-C_{yw} & -2(CA_{xw}+BR_{2334})-R_{3434} & 2B(B_{yz}-C_{yw}) \\ 0 & 0 & A_{xw} & 0 \\ 0 & 0 & R_{2334} & C_{yw}-B_{yz} \end{bmatrix}. \tag{8.4}$$

The algebra A_{13} has a generator, unique up to scaling, that is singular and in fact nilpotent. It follows that

$$A_{xx}=B_{yy}=0. \tag{8.5}$$

Furthermore, any nonsingular generator in A_{13} has doubly degenerate eigenvalues which implies

$$A_{xy}=\pm C_{yy}, \tag{8.6}$$

$$A_{xw}=\pm(C_{yw}-B_{yz}). \tag{8.7}$$

It follows that R^i_{j13} and R^i_{j24} are proportional. Since the order of nilpotence of the singular generator is 2 we can distinguish two subcases

$$A_{xy}=0 \tag{8.8}$$

or

$$BA_{xy}-A_{xw}=0. \tag{8.9}$$

Note both A_{xy} and A_{xw} can be zero or else $\partial/\partial x$ would be parallel. If (8.9) holds, then to obtain A_{13} we must also have that

$$B^2A_{yy}-2BR_{2334}-R_{3434}=0, \tag{8.10}$$

whereas if (8.8) holds, then we must have that

$$A_{yy}=0. \tag{8.11}$$

Let us assume now that (8.9) holds and we use R^i_{j13} and R^i_{j34} as generators of A_{13}. Now one may check that $R^1_{113;m}$ vanishes in view of the given hypotheses. In order to obtain A_{13} we can therefore posit the existence of one-forms λ, μ and ν such that

$$R^i_{j13m}=\nu_m R^i_{j13} \tag{8.12}$$

and

$$R^i_{j34m}=\lambda_m R^i_{j13}+\mu_m R^i_{j34}. \tag{8.13}$$

In fact, by applying the second (differential) Bianchi identity to (8.12) and using (8.9) we can deduce that

$$\nu_m = \mu_m \tag{8.14}$$

and also that μ_1 is zero.

It turns out that (8.12) is satisfied identically and that (8.13) holds for $m=1$. The remaining conditions in (8.13) give three third order partial differential equation (PDE) conditions which have to be adjoined to (8.5)–(8.7), (8.9) and (8.10) as well as the vanishing of B_x and C_x. Analyzing this PDE system presents a considerable challenge and is probably best formulated as an exterior differential system. We hope to return to this problem at a later stage.

We now take up the case given by (8.8). We find now that the Levi-Civita connection projects via the submersion $(x,y,z,w)\mapsto(z,w)$. The curvature will also project to and so too will the Ricci tensor. The holonomy group of the projected connection must be one-dimensional since one of the generators for A_{13} is annihilated in the projection and so the projected Ricci tensor is recurrent and symmetric. Now according to Proposition 3.5 the two-dimensional connection is either a Levi-Civita connection or has a parallel vector field. However, the generator of the holonomy algebra on the quotient space is not semi-simple, and so the connection is not Levi-Civita and also A_{13} corresponds to the situation where g has no parallel vector field.

To finish Proposition 3.5 it remains to take care of the case where B and A_{xw} vanish. This situation is similar to the preceding paragraph but this time the connection projects via $(x,y,z,w)\mapsto(y,z)$. Again the connection on the quotient space cannot be Levi-Civita because it leaves a direction invariant. □

Proposition 8.2: A_{26} is a holonomy algebra.

Proof: Again A_{26} corresponds to the case where $\partial/\partial x$, say, is a recurrent vector field and we select our generators for A_{26} as combinations of $R^i_{j13}, R^i_{j23}, R^i_{j24}$ and R^i_{j34} given in (8.1)–(8.4). Now A_{26} has a semi-simple generator and two nilpotent ones. Furthermore, we cannot have all of A_{xx}, A_{xy}, and A_{xw} zero or else $\partial/\partial x$ will be parallel. Likewise if all of B_{yy}, C_{yy} and $C_{yw}-B_{yz}$ are zero, every generator will be singular and we must be in the case $\alpha=\pm 1$. Now the case $\alpha=-1$ has been discussed in Proposition 6.3. The case $\alpha=1$ will be discussed later. To obtain the algebra A_{26} we can assume then that

$$A_{xx}=B_{yy}=A_{xy}(C_{yz}-B_{yy})+A_{xw}C_{yy}=0. \tag{8.15}$$

Notice that R^i_{j24} is proportional to R^i_{j13} so our assumptions imply that the curvature spans A_{26}. We have to ensure now that the covariant derivatives $R^i_{jkl;m}$ produce no new generators and it is sufficient to show that no new generators with *semi-simple* parts occur. However, an easy calculation shows that any covariant derivative of the form $R^i_{ikl;m}$ (i fixed and no sum) is simply the ordinary derivative $R^i_{ikl,m}$. It follows that in considering the introduction of new generators from the derivatives $R^i_{jkl;m}$ we need only take into account $R^i_{j23;m}$ and $R^i_{j34;m}$. Thus the following conditions, in addition to the ones previously imposed, are necessary and sufficient to obtain the algebra A_{26}:

$$R^1_{123}R^2_{223;m}-R^2_{223}R^1_{123;m}=0, \tag{8.16}$$

$$R^1_{123}R^2_{234;m}-R^2_{223}R^1_{134;m}=0. \tag{8.17}$$

However, we can be even more explicit in this case. In fact, (8.17) can be written compactly as

$$\left(\frac{A_{xy}}{C_{yy}}\right),m=0, \tag{8.18}$$

where m denotes derivative with respect to each if the four coordinates x,y,z,w. Thus

$$A_x = kC_y + F(x,z,w), \tag{8.19}$$

where $k \in \mathbb{R}$ and F is a smooth function of its three arguments.

Turning next to (8.16) the first two conditions corresponding to $m=1$ and $m=2$ are already satisfied so that (8.16) gives in addition only

$$A_{xy}(C_{yw} - B_{yz})_z - C_{yy}A_{xzw} = 0, \tag{8.20}$$

$$A_{xy}(C_{yw} - B_{yz})_w - C_{yy}A_{xww} = 0. \tag{8.21}$$

However, note that in view of (8.15) and (8.19) both (8.20) and (8.21) will be satisfied identically. Note that if $A_{xy}=0$, then since A_{xw} cannot also vanish we must have that $C_{yy}=0$. Clearly all the conditions in (8.16) and (8.17) are satisfied in this case. We shall summarize all of these possibilities below.

We now come back to the other possibility at the beginning of the proof, namely, that all of B_{yy}, C_{yy} and $C_{yw} - B_{yz}$ are zero. If now the matrix M where

$$M = \begin{bmatrix} A_{xx} & A_{xy} & -A_{xw} \\ A_{xy} & A_{yy} & R_{2334} \\ -A_{xw} & R_{2334} & R_{3434} \end{bmatrix} \tag{8.22}$$

is nonsingular, then the curvature will determine the algebra A_{26}. But the same argument about the covariant derivatives of diagonal elements $R^i_{ikl;m}$ holds equally as above and so no additional semi-simple generator can be produced by the covariant derivatives $R^i_{jkl;m}$. Thus without any further conditions we can be sure that we will have A_{26} as the holonomy algebra.

The possibilities for obtaining the algebra A_{26} can be summarized by the following formulas: either

$$A = xH_y(y,z,w) + K(y,z,w), \tag{8.23}$$

$$kB = yN_w(x,z,w) + L(x,z,w), \tag{8.24}$$

$$kC = yN_z(x,z,w) + G(x,z,w) + H(y,z,w), \tag{8.25}$$

or

$$A = A(x,y,z,w) \tag{8.26}$$

with $\det(M) \neq 0$, where M is given by (8.22),

$$B = yN_w(x,z,w) + L(x,z,w), \tag{8.27}$$

$$kC = yN_z(x,z,w) + G(x,z,w), \tag{8.28}$$

where $k \in \mathbb{R}$ and the notion indicates the functions concerned are arbitrary smooth functions of the arguments indicated. □

Proposition 8.3: A_{25} is a holonomy algebra.

Proof: This case is very similar to A_{26}. Again starting from (8.1)–(8.4) to obtain A_{25} we shall need the following conditions to be satisfied:

$$A_{xx} = 0, \tag{8.29}$$

$$B_{yy} = 0, \tag{8.30}$$

$$A_{xy} - C_{yy} = 0, \tag{8.31}$$

$$A_{xw}-C_{yw}+B_{yz}=0. \tag{8.32}$$

Again when covariant derivatives of R^i_{jkl} are considered no new generators with a semi-simple part independent of the one already obtained can be produced and so the stated conditions are sufficient to obtain A_{25}. The conditions we have found to obtain A_{25} have the following solution in terms of arbitrary smooth functions:

$$A=xg_y(y,z,w)+h(y,z,w), \tag{8.33}$$

$$B=yf(w)-yk_w(z,w)+l(x,z,w), \tag{8.34}$$

$$C=g(y,z,w)-yk_z(z,w). \tag{8.35}$$

□

IX. THE ALGEBRAS A_{21} AND A_{29}

In this section we consider the algebras A_{29} and A_{21}

Proposition 9.1: A_{29} is not a holonomy algebra.

Proof: A metric g that has A_{29} as its holonomy algebra is characterized by the property that it keeps invariant a two-dimensional null distribution and that the upper left hand block 2×2 in the algebra is trace-free. We shall argue first of all that these conditions force the Levi-Civita connection to project via the submersion $(x,y,z,w)\mapsto(z,w)$ referring to Theorem 3.1. Recalling A, B and C stand for $\frac{1}{2}a$, $\frac{1}{2}b$ and $\frac{1}{2}c$, respectively, these conditions on the curvature matrices may be written as

$$A_{xx}+C_{xy}=0, \tag{9.1}$$

$$A_{xy}+C_{yy}=0, \tag{9.2}$$

$$C_{xy}+B_{yy}=0, \tag{9.3}$$

$$C_{xx}+B_{xy}=0, \tag{9.4}$$

$$R_{1334}+R_{2434}=0. \tag{9.5}$$

Now the covariant derivatives of the curvature $R^i_{jkl;m}$ must have the same trace-free property. We thus obtain precisely the following conditions:

$$C_yC_{xx}-B_xA_{xy}=0, \tag{9.6}$$

$$C_yB_{xy}-C_{yy}B_x=0, \tag{9.7}$$

$$C_yC_{xy}-A_{yy}B_x=0, \tag{9.8}$$

$$C_yB_{xx}-C_{xy}B_x=0, \tag{9.9}$$

$$C_yR_{1434}-B_xR_{2334}=0, \tag{9.10}$$

$$A_yC_{xx}-A_{xy}C_x=0, \tag{9.11}$$

$$A_xB_{xy}-C_{yy}C_x=0, \tag{9.12}$$

$$A_yC_{xy}-A_{yy}C_x=0, \tag{9.13}$$

$$A_yB_{xx}-C_{xy}C_x=0, \tag{9.14}$$

$$A_y R_{1434} - C_x R_{2334} = 0. \tag{9.15}$$

The argument now depends on whether the quantity $C_x C_y - A_y B_x$ is zero or nonzero. In the latter case it is easy to see from (9.1)–(9.4), (9.6)–(9.9) and (9.11)–(9.14) that all second order derivatives of A, B and C, respectively, vanish and hence the connection of g is projectable.

Now suppose that $C_x C_y - A_y B_x$ is zero. Then using the condition itself and (9.7), (9.9), (9.11) and (9.13) we deduce that

$$B_x = \theta(z,w) C_y, \tag{9.16}$$

$$A_y = \theta(z,w) C_x \tag{9.17}$$

for some smooth function θ of z and w. Again because $C_x C_y - A_y B_x$ is zero we find from (9.16) and (9.17) that

$$\theta = \pm 1. \tag{9.18}$$

In what follows we shall take the positive value in (9.18). We shall come back to the negative value later.

From (9.16) and (9.17) with θ having the value unity we can assert the existence of a function ρ such that

$$A = \rho_{xx}, \tag{9.19}$$

$$B = \rho_{yy}, \tag{9.20}$$

$$C = \rho_{xy}. \tag{9.21}$$

One can now see that (9.6)–(9.9) and (9.11)–(9.14) are satisfied identically and that (9.1)–(9.4) imply precisely that ρ satisfies

$$\Delta \rho = \theta(z,w) x + \varphi(z,w) y + \psi(z,w) \tag{9.22}$$

for some functions θ, φ and ψ of z and w where Δ denotes the Laplacian operator with respect to the x,y variables. It remains to satisfy (9.5), (9.10) and (9.15). Condition (9.5) implies that there exists a function σ such that

$$\theta = \sigma_z,$$

$$\varphi = \sigma_w.$$

Equation (9.22) may be integrated twice to give

$$8\rho = (\theta(z,w) x + \varphi(z,w) y)(x^2 + y^2) + p(x,y), \tag{9.23}$$

where $p(x,y)$ is a a quadratic polynomial in x and y. Finally we come to (9.10), (9.15) being essentially the same as (9.10). In terms of ρ (9.10) reads

$$(\rho_{xxy})^2 - \rho_{xxx}\rho_{xyy} + (\rho_{xyy})^2 - \rho_{xxy}\rho_{yyy} = 0. \tag{9.24}$$

When (9.23) is substituted into (9.24) we find finally that

$$\theta^2 + \varphi^2 = 0, \tag{9.25}$$

and hence both θ and φ vanish. Thus ρ is quadratic in x and y and A, B and C are independent of x and y. It follows that the Levi-Civita connection of g projects via the submersion $(x,y,z,w)\mapsto(z,w)$ to a flat connection, there are two parallel one-forms associated to g and we certainly do not obtain algebra A_{29}.

We return now to (9.18) and take θ to be -1. The analysis is very similar to the case where θ is 1 so we shall proceed quickly using similar notation. Thus we now have

$$A=\rho_{xx}, \tag{9.26}$$

$$B=\rho_{yy}, \tag{9.27}$$

$$C=-\rho_{xy}. \tag{9.28}$$

The analog of (9.23) now is

$$\rho=\tfrac{1}{2}(x\sigma_w+y\sigma_z)xy+q(x,y), \tag{9.29}$$

where $q(x,y)$ is a quadratic polynomial in x and y. The analog of (9.24) reads

$$\rho_{xxx}\rho_{xyy}-\rho_{yyy}\rho_{xxy}+(\rho_{xyy})^2-(\rho_{xxy})^2=0. \tag{9.30}$$

When (9.29) is substituted in (9.30) we find in contradiction to (9.25) that

$$\sigma_z^2=\sigma_w^2, \tag{9.31}$$

so the solution for A, B and C is given by

$$A=y\tau, \tag{9.32}$$

$$B=x\tau, \tag{9.33}$$

$$C=-(x+y)\tau, \tag{9.34}$$

where $\tau=\sigma'$ is a function of $z+w$. Now the connection corresponding to (9.32)–(9.34) is clearly projectable via the submersion $(x,y,z,w)\mapsto(z,w)$ and the projected connection is given by

$$\ddot{z}=\tau(\dot{w}^2-2\dot{z}\dot{w}), \tag{9.35}$$

$$\ddot{w}=\tau(\dot{z}^2-2\dot{z}\dot{w}). \tag{9.36}$$

The Ricci tensor of the connection corresponding to (9.35) and (9.36) is symmetric only in the case where τ is a function of $z+w$. However, in that case the connection is Levi-Civita with metric given by

$$\overline{g}=e^{\tau}(dz^2-dzdw+dw^2). \tag{9.37}$$

It follows that the holonomy algebra of g is two-dimensional and so A_{29} cannot occur as a holonomy algebra. □

Corollary 9.2: A_{21} cannot occur as a holonomy algebra.

Proof: We note that A_{21} is a three-dimensional subalgebra of A_{29} and so has the same characteristic trace-free property. Thus the argument is the same as in Proposition 9.1. □

Quantization of a loop extended Lie algebra of a diffeomorphism group of a torus with a central extension is considered. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1357825]

I. INTRODUCTION

Recently, Lie algebras of an area preserving diffeomorphism group of two-dimensional regions received a lot of attention.

Algebras of an area preserving diffeomorphisms play an important role in the theory of a classical and quantum W-gravity,[1] W-string theory.[2]

In Ref. 3 based on a special deformation method applied to an area preserving diffeomorphism algebra of a two dimensional region it was obtained a centralles realization of W_∞ algebra.

In Ref. 4 Arnold studied a model of ideal liquid on a two dimensional region D. The area preserving diffeomorphism group of the region D is a configuration space for the model. In Ref. 4 it was given a detailed analysis of an algebraic structure of the Lie algebra of an area preserving diffeomorphism group of a torus $\mathrm{diff}(T^2)$.

In this paper we construct a Yangian algebra of a centrally extended Lie algebra of an area preserving diffeomorphism group of a two dimensional torus $Y(\mathrm{diff}(T^2)_c)$.

Yangian algebra is example of noncommutative, noncocommutative Hopf algebra (quantum group) and was introduced by Drinfeld in Ref. 5 as a deformation of a universal enveloping algebra $U(g[\lambda])$ of a loop extended simple Lie algebra g.

Yangian algebras are related to a rational solution of a classical Yang–Baxter equation. Each solution of a classical Yang–Baxter equation on a given Lie algebra g determines a Lie bialgebra structure on g. Lie bialgebras may be thought of as a classical limit for quantum groups. A general method of quantization of Lie bialgebras was given in Ref. 5.

In this paper we will follow Drinfeld's method of quantization of Lie bialgebras and apply it to the construction of a Yangian algebra for the $\mathrm{diff}(T^2)_c$ algebra. Yangian algebra $Y(\mathrm{diff}(T^2)_c)$ is a deformation of loop extended $\mathrm{diff}(T^2)_c$ algebra, i.e., a set of all polynomial mappings

$$g: S^1 \to \mathrm{diff}(T^2)_c,$$

where S^1 is a unit circle.

A Lie bialgebra structure on $\mathrm{diff}(T^2)_c[\lambda]$ is determined by a cocommutator mapping ϕ

$$\phi: \mathrm{diff}(T^2)_c[\lambda] \to \mathrm{diff}(T^2)_c[\lambda] \otimes \mathrm{diff}(T^2)_c[\lambda],$$

satisfying a 1-cocycle condition

$$ad_x \phi(y) - ad_y \phi(x) = \phi([x,y]), \tag{1}$$

for $x,y,z \in \mathrm{diff}(T^2)_c[\lambda]$, $ad_x(y \otimes z) = [x \otimes 1 + 1 \otimes x, y \otimes z]$.

In Sec. II we construct a cocommutator mapping ϕ with the help of a new solution of classical Yang–Baxter equation on $\mathrm{diff}(T^2)_c[\lambda]$.

In Sec. III we quantize constructed Lie bialgebra. As a result, we obtain a Yangian algebra $Y(\mathrm{diff}(T^2)_c[\lambda])$ and its quantum double $DY(\mathrm{diff}(T^2)_c[\lambda])$. We give also an asymptotic form of a quantum R-matrix for $DY(\mathrm{diff}(T^2)_c[\lambda])$.

II. LIE BIALGEBRA STRUCTURE ON $\mathrm{diff}(T^2)_c[\lambda]$

Let us denote by $\mathrm{diff}(T^2)'_c[\lambda]$ an algebra generated by $g_{\bar{m}}\lambda^M$, $c\lambda^M$, $\bar{m}\in Z\times Z$, $M\in Z$ satisfying the following commutation relations:

$$[q_{\bar{m}}\lambda^M, q_{\bar{n}}\lambda^N] = \omega(\bar{m},\bar{n}) q_{\bar{m}+\bar{n}}\lambda^{M+N} + |\bar{m}|\,\delta_{\bar{m}+\bar{n},0} c\lambda^{M+N}, \tag{2}$$

$$[c\lambda^M, q_{\bar{m}}\lambda^N] = 0, \tag{3}$$

where $\omega(\bar{m},\bar{n}) := m_1 n_2 - n_1 m_2$, $|\bar{m}| := m_1 + m_2$, and $\delta_{\bar{m}+\bar{n},0} := \delta_{m_1+n_1,0}\,\delta_{m_2+n_2,0}$. To the algebra $\mathrm{diff}(T^2)'_c[\lambda]$ we add a set of new generators $d\lambda^M$, $M\in Z$ satisfying

$$[d\lambda^M, q_{\bar{m}}\lambda^N] = |\bar{m}| q_{\bar{m}}\lambda^{M+N} \quad [c\lambda^M, d\lambda^N] = 0. \tag{4}$$

The algebra defined by (2), (3), and (4) is a centrally extended Lie algebra of a diffeomorphism group of a torus. We denote it by $\mathrm{diff}(T^2)_c[\lambda]$.

We define an operator $r(\lambda,\mu)\in \mathrm{diff}(T^2)_c[\lambda]\otimes\mathrm{diff}(T^2)_c[\lambda] \equiv \mathrm{diff}(T^2)_c\otimes\mathrm{diff}(T^2)_c[\lambda,\mu]$ in the following way:

$$r(\lambda,\mu) = \frac{1}{\lambda-\mu}\left(\sum_{\bar{m}\in Z\times Z} q_{-\bar{m}}\otimes q_{\bar{m}} + d\otimes c + c\otimes d\right).$$

It is easy to check that $r(\lambda,\mu)$ satisfies a classical Yang–Baxter equation

$$[r_{12}(\lambda,\mu), r_{13}(\lambda,\nu)] + [r_{12}(\lambda,\mu), r_{23}(\mu,\nu)] + [r_{13}(\lambda,\nu), r_{23}(\nu,\mu)] = 0,$$

where $r_{12}(\lambda,\mu) = r(\lambda,\mu)\otimes 1$, $r_{23}(\mu,\nu) = 1\otimes r(\mu,\nu)$ $r_{13}(\lambda,\nu) = 1/\lambda-\nu\,(\Sigma_{\bar{m}\in Z\times Z} q_{-\bar{m}}\otimes 1\otimes q_{\bar{m}} + d\otimes 1\otimes c + c\otimes 1\otimes d)$.

The cocommutator mapping ϕ determined by $r(\lambda,\mu)$ has the form

$$\phi(q_{\bar{m}}\lambda^M) = [r(\lambda,\mu), q_{\bar{m}}\lambda^M\otimes 1 + 1\otimes q_{\bar{m}}\mu^M],$$

$$\phi(d\lambda^M) = [r(\lambda,\mu), d\lambda^M\otimes 1 + 1\otimes d\mu^M],$$

$$\phi(c\lambda^M) = 0.$$

It is straightforward to verify that ϕ satisfies a 1-cocycle condition (1). This means that a pair $(\mathrm{diff}(T^2)_c[\lambda],\phi)$ is a Lie bialgebra.

Quantization of the $(\mathrm{diff}(T^2)_c[\lambda],\phi)$ Lie bialgebra we perform in three steps.

First, we quantize the $(\mathrm{diff}(T^2)'_c[\lambda]_+,\phi)$ Lie bialgebra, generated by $g_{\bar{m}}\lambda^M$, $c\lambda^M$, $\bar{m}\in Z\times Z$, $M\geqslant 0$. As a result we obtain a Yangian algebra $Y(\mathrm{diff}(T^2)'_c[\lambda])$.

In the second step we quantize the $(\mathrm{diff}(T^2)'_c[\lambda]_-,\phi)$ Lie bialgebra generated by $g_{\bar{m}}\lambda^M$, $c\lambda^M$, $\bar{m}\in Z\times Z$, $M<0$. Quantization of this Lie bialgebra we denote by $Y^*(\mathrm{diff}(T^2)'_c[\lambda])$.

Separately we will discuss quantization of the $d\lambda^M$, $\in Z$ generators.

III. YANGIAN ALGEBRA $Y(\mathrm{diff}(T^2)'_c)$

The algebra $Y(\mathrm{diff}(T^2)'_c)$ is generated by $Q_{\bar{m},}$ M, c_M, $\bar{m}\in Z\times Z$, $M\geqslant 0$ which depend on a quantum parameter h such that

$$\lim_{h\to 0}(Q_{\bar{m},M}, c_M) = (q_{\bar{m}}\lambda^M, c\lambda^M).$$

The algebra $Y(\mathrm{diff}(T^2)'_c)$ is endowed with a counit $\varepsilon(Q_{\bar{m},M})=0$, $\varepsilon(c_M)=0$, and a coassociative comultiplication Δ which in classical limit gives the cocommutator ϕ

$$\lim_{h\to 0}\frac{1}{h}(\Delta-\Delta')=\phi,$$

where Δ' denotes the transposed comultiplication, i.e., for $\Delta(a)=b\otimes c$, $\Delta'(a)=c\otimes b$. Unfortunately an antipodal mapping S does not exist for the $Y(\mathrm{diff}(T^2)'_c[\lambda])$ algebra. It means that quantization of the $(\mathrm{diff}(T^2)'_c[\lambda]_+,\phi)$ Lie bialgebra leads to a noncommutative, noncocommutative bialgebra.

The classical algebra $\mathrm{diff}(T^2)'_c[\lambda]_+$ can be generated by $q_{\bar{m}}$, c, $q_{\bar{m}}\lambda$, $c\lambda$, $\bar{m}\in Z\times Z$. We describe quantization of the $(\mathrm{diff}(T^2)'_c[\lambda]_+,\phi)$ Lie bialgebra in terms of quantum generators $Q_{\bar{m},0}=g_{\bar{m}}$, $c_0=c$, $Q_{\bar{m},1}$, c_1.

Lemma: An algebra $Y(\mathrm{diff}(T^2)'_c)$ generated by $q_{\bar{m}},Q_{\bar{m},1}$ having the following properties:

$$[q_{\bar{m}},q_{\bar{n}}]=\omega(\bar{m},\bar{n})q_{\bar{m}+\bar{n}}+|\bar{m}|\,\delta_{\bar{m}+\bar{n},0}c, \tag{5}$$

$$[q_{\bar{m}},Q_{\bar{n},1}]=\omega(\bar{m},\bar{n})Q_{\bar{m}+\bar{n},1}+|\bar{m}|\,\delta_{\bar{m}+\bar{n},0}c_1, \tag{6}$$

$$[Q_{\bar{m},1},[Q_{\bar{n},1},q_{\bar{k}}]]-[q_{\bar{m}},[Q_{\bar{n},1},Q_{\bar{k},1}]$$

$$=\frac{1}{12}h^2\sum_{\bar{l},\bar{f}\in Z\times Z}\alpha^{\bar{f},\bar{l}}_{\bar{m},\bar{n},\bar{k}}\{q_{\bar{m}+\bar{n}+\bar{k}-\bar{l}-\bar{f}},q_{\bar{f}},q_{\bar{l}}\}_+ +\frac{1}{16}h^2\sum_{\bar{l}\in Z\times Z}\tilde{\alpha}^{\bar{l}}_{\bar{m},\bar{n},\bar{k}}\{q_{\bar{m}+\bar{n}+\bar{k}-\bar{l}},q_{\bar{l}}\}_+c$$
$$+\frac{1}{4}h^2\tilde{\alpha}_{\bar{m},\bar{n},\bar{k}}q_{\bar{m}+\bar{n}+\bar{k}}c^2+\frac{1}{12}h^2|\bar{m}||\bar{n}||\bar{k}|(\omega(\bar{m},\bar{n})+\omega(\bar{n},\bar{k})+\omega(\bar{k},\bar{m}))\,\delta_{\bar{m}+\bar{n}+\bar{k},0}c^3, \tag{7}$$

with a comultiplication

$$\Delta(q_{\bar{m}})=q_{\bar{m}}\otimes 1+1\otimes q_{\bar{m}},$$

$$\Delta(c)=c\otimes 1+1\otimes c,\quad \Delta(c_1)=c_1\otimes 1+1\otimes c_1,$$

$$\Delta(Q_{\bar{m},1})=Q_{\bar{m},1}\otimes 1+1\otimes Q_{\bar{m},1}+\frac{1}{2}h\sum_{\bar{k}\in Z\times Z}\omega(\bar{m},\bar{k})q_{\bar{m}-\bar{k}}\otimes q_{\bar{k}}+\frac{1}{2}h|\bar{m}|(q_{\bar{m}}\otimes c-c\otimes q_{\bar{m}})$$

and a counit

$$\varepsilon(q_{\bar{m}})=0,\quad \varepsilon(Q_{\bar{m},1})=0,\quad \varepsilon(c)=0,\quad \varepsilon(c_1)=0$$

is a bialgebra.

In (7), $\{q_{\bar{m}_1},\ldots,q_{\bar{m}_n}\}_+=1/n!\,\Sigma_{\sigma\in S_n}q_{\sigma(\bar{m}_1)},\ldots,q_{\sigma(\bar{m}_n)}$, where S_n is a permutation group of n elements $(\bar{m}_1,\ldots,\bar{m}_n)$. Exact form of the coefficients $\alpha^{\bar{f},\bar{l}}_{\bar{m},\bar{n},\bar{k}}$, $\tilde{\alpha}^{\bar{l}}_{\bar{m},\bar{n},\bar{k}}$, $\tilde{\alpha}_{\bar{m},\bar{n},\bar{k}}$ is given in the appendix.

The formula (7) can be obtained from (5), and (6), Jacobi identity and the relation

$$[Q_{\bar{m},1},Q_{\bar{n},1}]=\omega(\bar{m},\bar{n})Q_{\bar{m}+\bar{n},2}+|\bar{m}|\,\delta_{\bar{m}+\bar{n},0}c_2+\frac{1}{12}h^2\underline{\sum_{k,l\in Z\times Z}}\beta^{\bar{k},\bar{l}}_{\bar{m},\bar{n}}\{q_{\bar{m}+\bar{n}-\bar{k}-\bar{l}},q_{\bar{k}},q_{\bar{l}}\}_+$$
$$-\frac{1}{8}h^2(|\bar{m}|-|\bar{n}|)\underline{\sum_{k\in Z\times Z}}\omega(\bar{m},\bar{k})\omega(\bar{n},\bar{k})\{q_{\bar{m}+\bar{n}-\bar{k}},q_{\bar{k}}\}_+c$$
$$-\frac{1}{8}h^2\omega(\bar{m},\bar{n})\underline{\sum_{k\in Z\times Z}}(\omega(\bar{m},\bar{k})|\bar{m}|+\omega(\bar{n},\bar{k})|\bar{n}|)\{q_{\bar{m}+\bar{n}-\bar{k}},q_{\bar{k}}\}_+c$$
$$-\frac{1}{4}h^2\omega(\bar{m},\bar{n})|\bar{m}||\bar{n}|q_{\bar{m}+\bar{n}}c^2-\frac{1}{12}h^2|\bar{m}|^3\delta_{\bar{m}+\bar{n},0}c^3. \tag{8}$$

Another way to obtain (7) is to use (5), and (6) and

$$[q_{\bar{m}},Q_{\bar{n},2}]=\omega(\bar{m},\bar{n})Q_{\bar{m}+\bar{n},2}+|\bar{m}|\,\delta_{\bar{m}+\bar{n},0}c_2+\frac{1}{12}h^2\underline{\sum_{k,l\in Z\times Z}}\tilde{\beta}^{\bar{k},\bar{l}}_{\bar{m},\bar{n}}\{q_{\bar{m}+\bar{n}-\bar{k}-\bar{l}},q_{\bar{k}},q_{\bar{l}}\}_+$$
$$+\frac{1}{8}h^2\underline{\sum_{k\in Z\times Z}}\tilde{\tilde{\beta}}_{\bar{m},\bar{n},\bar{k}}\{q_{\bar{m}+\bar{n}-\bar{k}},q_{\bar{k}}\}_+c$$
$$+\frac{1}{8}h^2\omega(\bar{m},\bar{n})|\bar{m}||\bar{n}|q_{\bar{m}+\bar{n}}c^2-\frac{1}{12}h^2|\bar{m}|^3\delta_{\bar{m}+\bar{n},0}c^3. \tag{9}$$

Explicit form of the coefficients $\beta^{\bar{k},\bar{l}}_{\bar{m},\bar{n}}$, $\tilde{\beta}^{\bar{k},\bar{l}}_{\bar{m},\bar{n}}$, $\tilde{\tilde{\beta}}_{\bar{m},\bar{n},\bar{k}}$ is given in the appendix.

The comultiplication for the elements $Q_{\bar{m},2}$ has the following form:

$$\Delta(Q_{\bar{m},2})=Q_{\bar{m},2}\otimes 1+1\otimes Q_{\bar{m},2}+\frac{1}{2}h\underline{\sum_{k\in Z\times Z}}\omega(\bar{m},\bar{k})(Q_{\bar{m}-\bar{k},1}\otimes q_{\bar{k}}-q_{\bar{k}}\otimes Q_{\bar{m}-\bar{k},1})$$
$$+\frac{1}{2}h|\bar{m}|(Q_{\bar{m},1}\otimes c-c\otimes Q_{\bar{m},1}+q_{\bar{m}}\otimes c_1-c_1\otimes q_{\bar{m}})$$
$$-h^2\frac{1}{8}\underline{\sum_{k,l\in Z\times Z}}\gamma^{\bar{k},\bar{l}}_{\bar{m}}(\{q_{\bar{k}},q_{\bar{l}}\}_+\otimes q_{\bar{m}-\bar{k}-\bar{l}}+q_{\bar{m}-\bar{k}-\bar{l}}\otimes\{q_{\bar{k}},q_{\bar{l}}\}_+)$$
$$+\frac{1}{8}h^2|\bar{m}|\underline{\sum_{k\in Z\times Z}}\omega(\bar{m},\bar{k})(q_{\bar{m}-\bar{k}}\otimes cq_{\bar{k}}+q_{\bar{k}}c\otimes q_{\bar{m}-\bar{k}})$$
$$+\frac{1}{16}h^2\underline{\sum_{k\in Z\times Z}}\omega(\bar{m},\bar{k})(2|\bar{k}|-|\bar{m}|)(\{q_{\bar{m}-\bar{k}},q_{\bar{k}}\}_+\otimes c+c\otimes\{q_{\bar{m}-\bar{k}},q_{\bar{k}}\}_+)$$
$$-\frac{1}{4}h^2|\bar{m}|^2(c\otimes cq_{\bar{m}}+q_{\bar{m}}c\otimes c), \tag{10}$$

where $\gamma^{\bar{k},\bar{l}}_{\bar{m}}$ is given in the appendix.

Relations (5), (6), and (7) uniquely determine commutation relations and comultiplication for all $Q_{\bar{m},M}$, $\bar{m}\in Z\times Z$, $M\geqslant 0$.

Quantization of the $(\mathrm{diff}(T^2)'_c[\lambda]_-,\phi)$ Lie bialgebra is much more complicated. We denote the algebra generated by $Q_{\bar{m},-M}$, c_{-M}, $\bar{m}\in Z\times Z$, $M>0$ by $Y^*(\mathrm{diff}(T^2)'_c)$. The comultiplication $\Delta(Q_{\bar{m},-M})$, $\bar{m}\in Z\times Z, M>0$, and commutation relations for $Q_{\bar{m},-M}$ are an infinite power series in quantum parameter h and defining relations for $Y^*(\mathrm{diff}(T^2)'_c)$, similar to (7) cannot be given. All formulas, i.e., comultiplication and commutation relations can be given only asymptotically.

Up to second order terms in h the algebra $Y^*(\mathrm{diff}(T^2)'_c)$ is defined by the following commutation relations:

$$[Q_{\overline{m},-M},Q_{\overline{n},-N}]=\omega(\overline{m},\overline{n})Q_{\overline{m}+\overline{n},-M-N}+|\overline{m}|\,\delta_{\overline{m}+\overline{n},0}c_{-M-N}+O(h^2),$$

$\overline{m},\ \overline{n}\in Z\times Z,\ M,\ N>0$. The bialgebra structure on $Y^*(\mathrm{diff}(T^2)'_c)$ is given by the counit

$$\varepsilon(Q_{\overline{m},-M})=0,\quad \varepsilon(c_{-M})=0$$

and the comultiplication $\Delta(Q_{\overline{m},-M})$, $\overline{m}\in Z\times Z,\ M>0$,

$$\Delta(Q_{\overline{m},-M})=Q_{\overline{m},-M}\otimes 1+1\otimes Q_{\overline{m},-M}-\frac{1}{2}h\sum_{i=0}^{M-1}\sum_{\overline{k}\in Z\times Z}\omega(\overline{m},\overline{k})Q_{\overline{m}-\overline{k},-i-1}\otimes Q_{\overline{k},i-M}$$
$$-\frac{1}{2}h|\overline{m}|\sum_{i=0}^{M-1}(Q_{\overline{m},-i-1}\otimes c_{i-M}-c_{-i-1}\otimes Q_{\overline{m},i-M})+O(h^2).$$

It is possible to determine commutation relations between elements of $Y(\mathrm{diff}(T^2)'_c)$ and $Y^*(\mathrm{diff}(T^2)'_c)$. The simplest formulas read

$$[q_{\overline{m}},Q_{\overline{n},-1}]=\omega(\overline{m},\overline{n})Q_{\overline{m}+\overline{n},-1}+|\overline{m}|\,\delta_{\overline{m}+\overline{n},0}c_{-1}+O(h^3)$$

or

$$Q_{\overline{m},1},Q_{\overline{n},-1}]=\omega(\overline{m},\overline{n})q_{\overline{m}+\overline{n}}+|\overline{m}|\,\delta_{\overline{m}+\overline{n},0}c+O(h^2).$$

Quantum generators d_M, $M\in Z$, which in classical limit are equal to $d\lambda^M$ cannot be written as a commutator of elements of $Y(\mathrm{diff}(T^2)_c)$ or $Y^*(\mathrm{diff}(T^2)_c)$. This implies that there is no general formula for comultiplication and commutation relations for quantum generators d_M, $M\in Z$. From $\phi(d)=0$ follows that the comultiplication $\Delta(d)$ is undeformed,

$$\Delta(d)=d\otimes 1+1\otimes d,$$

where $d=d_0$. The comultiplication $\Delta(d_M)$ $M>0$ up to linear terms in the quantum parameter h has the form

$$\Delta(d_M)=d_M\otimes 1+1\otimes d_M+\frac{1}{2}h\sum_{i=0}^{M-1}\sum_{\overline{k}\in Z\times Z}|\overline{k}|Q_{-\overline{k},M-i-1}\otimes Q_{\overline{k},i}+O(h^2),\tag{11}$$

and is a finite power series in h. For example, for $M=1$ formula (11) is exact

$$\Delta(d_1)=d_1\otimes 1+1\otimes d_1+\frac{1}{2}h\sum_{\overline{k}\in Z\times Z}|\overline{k}|q_{-\overline{k}}\otimes q_{\overline{k}}.$$

The comultiplication $\Delta(d_M)$, $M<0$ is an infinite power series in the quantum parameter h. Up to the linear terms it has the following form:

$$\Delta(d_{-M})=d_{-M}\otimes 1+1\otimes d_{-M}-\frac{1}{2}h\sum_{i=0}^{M-1}\sum_{\overline{k}\in Z\times Z}|\overline{k}|Q_{-\overline{k},-i-1}\otimes Q_{\overline{k},i-M}+O(h^2).$$

The commutation relations for d_M, $M\in Z$ asymptoticaly can be written as

$$[d_M,d_N]=0+O(h^2)$$

and

$$[d_M, Q_{\bar{m},N}] = |\bar{m}| Q_{\bar{m},M+N} + O(h^2).$$

Quantization of the $(\mathrm{diff}(T^2)'_c[\lambda]_-, \phi)$ Lie bialgebra is equivalent to a construction of an algebra called a quantum double for $Y(\mathrm{diff}(T^2)_c)$. If we introduce in the quantum space spanned by $Q_{\bar{m},M}, c_M, d_M$, $\bar{m} \in Z \times Z, M \in Z$ the following scalar product

$$< Q_{\bar{m},M}, Q_{\bar{n},N} > = \delta_{\bar{m},\bar{n}} \delta_{M+N+1,0},$$

$$< d_M, c_N > = \delta_{M+N+1,0},$$

then with respect to this scalar product the algebras $Y(\mathrm{diff}(T^2)_c)$ and $Y^*(\mathrm{diff}(T^2)_c)$ are dual. The pair $(Y(\mathrm{diff}(T^2)_c), Y^*(\mathrm{diff}(T^2)_c))$ is called a quantum double $DY(\mathrm{diff}(T^2)_c)$.

Having defined the Yangian algebra $Y(\mathrm{diff}(T^2)_c)$ and its quantum double $DY(\mathrm{diff}(T^2)_c)$ we would like to discuss existence of a quantum R-matrix for $DY(\mathrm{diff}(T^2)_c)$. A comultiplication defined on the quantum algebra $DY(\mathrm{diff}(T^2)_c)$ can be replaced by a transposed comultiplication Δ'. In this way we obtain another bialgebra structure on $DY(\mathrm{diff}(T^2)_c)$. These two structures are connected by a transformation called quantum R-matrix,

$$R\Delta = \Delta' R.$$

It has an asymptotic form

$$R = 1 \otimes 1 - h \sum_{M=0}^{\infty} \left(\sum_{\bar{k} \in Z \times Z} Q_{-\bar{k},-M-1} \otimes Q^{\bar{}}_{\bar{k},M} + d_{-M-1} \otimes c_M + c_{-M-1} \otimes d_M \right) + O(h^2).$$

IV. CONCLUDING REMARKS

In this paper we discussed a quantization of a loop extended Lie algebra of a diffeomorphism group of a two dimensional torus with a central extension. We found a new solution of a classical Yang–Baxter equation $r(\lambda, \mu)$ on the $\mathrm{diff}(T^2)_c[\lambda]$ Lie algebra. Using this solution we constructed a Lie bialgebra structure on $\mathrm{diff}(T^2)_c[\lambda]$ and quantized it by applying Drinfeld's method of quantization of Lie bialgebras. As a result, we obtained a Yangian algebra $Y(\mathrm{diff}(T^2)_c)$ and its dual $Y^*(\mathrm{diff}(T^2)_c)$.

The main result of this paper is formulated in the lemma, Sec. III. According to this lemma $Y(\mathrm{diff}(T^2)'_c)$ is a bialgebra. It means that on $Y(\mathrm{diff}(T^2)'_c)$ is defined a coassociative comultiplication Δ and a counit ε. Unfortunately the antipodal mapping S, defined by the formula

$$m(S \otimes 1)\Delta = \varepsilon \tag{12}$$

does not exist, i.e., there is no Hopf algebra structure on the $Y(\mathrm{diff}(T^2)'_c)$ algebra. In (12) m denotes a multiplication in the algebra $Y(\mathrm{diff}(T^2)'_c)$, i.e., for $a, b \in Y(\mathrm{diff}(T^2)'_c)$, $m(a \otimes b) = ab$. By applying the formula (12) to the generator $Q_{\bar{m},2}$ it is easy to see that the expression $S(Q_{\bar{m},2})$ is divergent.

There are some interesting, unsolved problems connected with the quantum algebra $DY(\mathrm{diff}(T^2)_c)$. The main unsolved problem is to construct a representation theory for $DY(\mathrm{diff}(T^2)_c)$. It is also important to find the full expression for a quantum R-matrix. We would like to discuss these problems in future publications.

ACKNOWLEDGMENT

This paper is dedicated to Professor B. Mróz.

APPENDIX

In this appendix we give explicit expressions of the coefficients $\alpha^{\overline{f,l}}_{\overline{m,n,k}}$, $\tilde{\alpha}^{\overline{l}}_{\overline{m,n,k}}$, $\tilde{\tilde{\alpha}}_{\overline{m,n,k}}$, $\beta^{\overline{k,l}}_{\overline{m,n}}$, $\tilde{\beta}^{\overline{k,l}}_{\overline{m,n}}$, $\tilde{\tilde{\beta}}_{\overline{m,n,k}}$, and $\gamma^{\overline{k,l}}_{\overline{m}}$ from Eqs. (7), (8), (9), and (10).

Coefficients from Eq. (7) have the following form:

$$
\begin{aligned}
\alpha^{\overline{f,l}}_{\overline{m,n,k}} = {} & \tfrac{1}{4}\omega(\overline{n},\overline{k})(2\omega(\overline{m},\overline{n})+2\omega(\overline{m},\overline{k})-\omega(\overline{m},\overline{f})-\omega(\overline{m},\overline{l})+\omega(\overline{n},\overline{f})+\omega(\overline{n},\overline{l})+\omega(\overline{k},\overline{f})\\
& +\omega(\overline{k},\overline{l}))[(|\overline{m}||\overline{f}|-g(\overline{m},\overline{f}))(|\overline{n}||\overline{l}|+|\overline{k}||\overline{l}|-g(\overline{n},\overline{l})-g(\overline{k},\overline{l}))\\
& +\omega(\overline{m},\overline{f})\omega(\overline{n},\overline{l})+\omega(\overline{m},\overline{f})\omega(\overline{k},\overline{l})]+\tfrac{1}{4}\omega(\overline{k},\overline{m})(2\omega(\overline{n},\overline{m})+2\omega(\overline{n},\overline{k})\\
& -\omega(\overline{n},\overline{f})-\omega(\overline{n},\overline{l})+\omega(\overline{m},\overline{f})+\omega(\overline{m},\overline{l})+\omega(\overline{k},\overline{f})+\omega(\overline{k},\overline{l}))[(|\overline{n}||\overline{f}|\\
& -g(\overline{n},\overline{f}))(|\overline{m}||\overline{l}|+|\overline{k}||\overline{l}|-g(\overline{m},\overline{l})-g(\overline{k},\overline{l}))+\omega(\overline{n},\overline{f})\omega(\overline{m},\overline{l})\\
& +\omega(\overline{n},\overline{f})\omega(\overline{k},\overline{l})]+\tfrac{1}{4}\omega(\overline{m},\overline{n})(2\omega(\overline{k},\overline{m})+2\omega(\overline{k},\overline{n})-\omega(\overline{k},\overline{f})-\omega(\overline{k},\overline{l})\\
& +\omega(\overline{m},\overline{f})+\omega(\overline{n},\overline{f})+\omega(\overline{m},\overline{l})+\omega(\overline{n},\overline{l}))[(|\overline{k}||\overline{f}|-g(\overline{k},\overline{f}))(|\overline{m}||\overline{l}|+|\overline{n}||\overline{l}|\\
& -g(\overline{m},\overline{l})-g(\overline{n},\overline{l}))+\omega(\overline{k},\overline{f})\omega(\overline{m},\overline{l})+\omega(\overline{k},\overline{f})\omega(\overline{n},\overline{l})]+\tfrac{1}{4}(|\overline{f}||\overline{l}|\\
& -g(\overline{f},\overline{l}))[(|\overline{m}|^2-g(\overline{m},\overline{m}))\{\omega(\overline{n},\overline{k})(\omega(\overline{n}+\overline{k},\overline{f})+\omega(\overline{n}+\overline{k},\overline{l}))\\
& -\omega(\overline{k},\overline{m})\omega(\overline{n},\overline{f}+\overline{l})-\omega(\overline{m},\overline{n})\omega(\overline{k},\overline{f}+\overline{l})\}+(|\overline{n}|^2-g(\overline{n},\overline{n}))\{\omega(\overline{k},\overline{m})\\
& \times(\omega(\overline{m}+\overline{k},\overline{f})+\omega(\overline{m}+\overline{k},\overline{l}))-\omega(\overline{n},\overline{k})\omega(\overline{m},\overline{f}+\overline{l})-\omega(\overline{m},\overline{n})\omega(\overline{k},\overline{f}+\overline{l})\}\\
& +(|\overline{k}|^2-g(\overline{k},\overline{k}))\{\omega(\overline{m},\overline{n})(\omega(\overline{m}+\overline{n},\overline{f})+\omega(\overline{m}+\overline{n},\overline{l}))\\

Quantum toroidal algebra $U_q(sl_{2,\mathrm{tor}})$ and R matrices

Kei Miki
Department of Mathematics, Graduate School of Science,
Osaka University Toyonaka 560, Japan

(Received 11 August 2000; accepted for publication 31 January 2001)

We show the existence of R matrices acting on the tensor product of a certain class of representations of the quantum toroidal algebra $U_q(sl_{2,\mathrm{tor}})$. In particular, the explicit expressions of R matrices acting on the tensor product of level 1 integrable highest weight representations of $U_q(\widehat{sl_2})$ are obtained. Our approach is based on the work of Chari and Pressley. © *2001 American Institute of Physics.*
[DOI: 10.1063/1.1357198]

I. INTRODUCTION

In Ref. 1, based on the work of Chari and Pressley,[2,3] we studied representations of the quantum toroidal algebra $U_q(sl_{n+1,\mathrm{tor}})$ and proved the existence of R matrices acting on the tensor product of a certain class of representations. In this analysis, we used an isomorphism of $U_q'(sl_{n+1,\mathrm{tor}})$ obtained in Ref. 4. Since this result had been proved only for the case $n \geqslant 2$, the analysis in Ref. 4 was restricted to this case.

In this paper, for the algebra $U_q(sl_{2,\mathrm{tor}})$ we prove the existence of a similar isomorphism and show that R matrices exist if we consider tensor product representations via similar comultiplications used in Ref. 1. This part is essentially the same as the results in Refs. 1 and 4. Moreover we show that R matrices exist for other comultiplications of $U_q(sl_{2,\mathrm{tor}})$. (This result is not restricted to the case $n=1$.) In particular, we obtain the explicit expressions of the latter R matrices acting on the tensor product of level 1 integrable highest weight representations of $U_q(\widehat{sl_2})$ as trigonometric R matrices were obtained as intertwiners of the tensor products of finite dimensional representations of the quantum affine algebras in Ref. 5.

II. MAIN RESULTS

A. Definition of algebras

Throughout this paper, we fix a complex number q which is transcendental over $\mathbf{Q}$. Let $(a_{ij})_{0\leqslant i,j\leqslant 1}$ be the Cartan matrix of type $A_1^{(1)}$. Set $\mathfrak{h}=\mathbf{C}h_0\oplus\mathbf{C}h_1\oplus\mathbf{C}d$, and let α_i and $\Lambda_i (i=0,1)$ be the elements of $\mathfrak{h}^*$ determined by

$$\langle h_i,\alpha_j\rangle = a_{ij}, \quad \langle d,\alpha_j\rangle = 1, \quad \langle h_i,\Lambda_j\rangle = \delta_{ij}, \quad \langle d,\Lambda_j\rangle = 0. \tag{2.1}$$

We set $Q^+=\mathbf{Z}_{\geqslant 0}\alpha_0\oplus\mathbf{Z}_{\geqslant 0}\alpha_1$ and define a partial order $\leqslant$ on $\mathfrak{h}^*$ by $\mu\leqslant\lambda$ if and only if $\lambda-\mu\in Q^+$.

Following Refs. 7 and 8, we define $U_q(sl_{2,\mathrm{tor}})$ to be the $\mathbf{C}$ algebra with generators $x_{i,k}^{\pm}$, $h_{i,r}$, $k_i^{\pm 1}$, $C^{\pm 1}$ and $\tilde{D}^{\pm 1} (i=0,1, k\in\mathbf{Z}, r\in\mathbf{Z}\backslash\{0\})$ and relations

$$\tilde{D}^{\pm 1}\tilde{D}^{\mp 1}=1, \quad \tilde{D}k_i=k_i\tilde{D}, \tag{2.2}$$

$$\tilde{D}x_{i,k\pm\delta_{i0}}^{\pm}\tilde{D}^{-1}=q^{2k\pm 1}x_{i,k\pm\delta_{i0}}^{\pm}, \quad \tilde{D}h_{i,r}\tilde{D}^{-1}=q^{2r}h_{i,r}, \tag{2.3}$$

$$C^{\pm 1} \text{ central}, \quad k_i^{\pm 1} k_i^{\mp 1} = C^{\pm 1} C^{\mp 1} = 1, \tag{2.4}$$

$$[k_i, k_j] = [k_i, h_{j,r}] = 0, \tag{2.5}$$

$$[h_{i,r}, h_{j,s}] = \delta_{r+s,0} \frac{[ra_{ij}]}{r} \frac{C^r - C^{-r}}{q - q^{-1}}, \tag{2.6}$$

$$k_i x_{j,k}^{\pm} k_i^{-1} = q^{\pm a_{ij}} x_{j,k}^{\pm}, \tag{2.7}$$

$$[h_{i,r}, x_{j,k}^{\pm}] = \pm \frac{[ra_{ij}]}{r} C^{(r \mp |r|)/2} x_{j,r+k}^{\pm}, \tag{2.8}$$

$$[x_{i,k}^{+}, x_{j,l}^{-}] = \frac{\delta_{ij}}{q - q^{-1}} (C^{-l} \phi_{i,k+l}^{(-)} - C^{-k} \phi_{i,k+l}^{(+)}), \tag{2.9}$$

$$[x_{i,k+1}^{\pm}, x_{i,l}^{\pm}]_{q^{\pm 2}} + [x_{i,l+1}^{\pm}, x_{i,k}^{\pm}]_{q^{\pm 2}} = 0, \tag{2.10}$$

$$[x_{i,0}^{\pm}, [x_{i,0}^{\pm}, [x_{i,0}^{\pm}, x_{j,0}^{\pm}]_{q^2}]]_{q^{-2}} = 0 \quad (i \neq j). \tag{2.11}$$

Here $[m] = (q^m - q^{-m})/(q - q^{-1})$, $[x,y]_p = xy - pyx$, and $\phi_{i,\mp r}^{(\pm)} (r \geqslant 0)$ is expressed in terms of $k_i^{\pm 1}$ and $h_{i,r}$'s by

$$\sum_{r \geqslant 0} \phi_{i,\mp r}^{(\pm)} z^{\pm r} = k_i^{\mp 1} \exp\left(\mp (q - q^{-1}) \sum_{r > 0} h_{i,\mp r} z^{\pm r} \right). \tag{2.12}$$

For later purpose, we introduce generating series $x_i^{\pm}(z)$ and $\phi_i^{(\pm)}(z)$ by

$$x_i^{\pm}(z) = \sum x_{i,k}^{\pm} z^{-k},$$

and the left hand side of (2.12), respectively.

Let $U_q(\widehat{sl}_2)$[6] be the **C** algebra defined by generators $x_k^{\pm}, h_r, k^{\pm 1}, C^{\pm 1}, \tilde{D}^{\pm 1} (k \in \mathbf{Z}, r \in \mathbf{Z} \backslash \{0\})$ and relations (2.2)–(2.10) with $i = j = 1$ and $x_{1,k}^{\pm}, h_{1,r}, k_1$ replaced by $x_k^{\pm}, h_r, k$, respectively.

We shall denote $U_q(sl_{2,\mathrm{tor}})$ and $U_q(\widehat{sl}_2)$ by $\tilde{\mathcal{U}}$ and U, respectively. Let $\tilde{v}$ be the homomorphism $U \to \tilde{\mathcal{U}}$ such that

$$x_k^{\pm} \mapsto x_{1,k}^{\pm}, \quad h_r \mapsto h_{1,r}, \quad k \mapsto k_1, \quad C \mapsto C, \quad \tilde{D} \mapsto \tilde{D}. \tag{2.13}$$

B. $\tilde{\mathcal{U}}$ modules and their tensor products

In this paper, we shall consider only irreducible $\tilde{\mathcal{U}}$ modules satisfying the following condition (*) and their tensor products.

(*) The element $k_0 k_1$ acts as 1 on a $\tilde{\mathcal{U}}$ module V, and if regarded as a U module via the map $\tilde{v}$, the $\tilde{\mathcal{U}}$ module V satisfies the following three conditions:

(i) V is a direct sum of integrable highest weight modules of type **1**;
(ii) each weight space of V is finite dimensional;
(iii) the set of weights of V has a maximal element.

Let V be an irreducible $\tilde{\mathcal{U}}$ module satisfying the above condition (*) and λ a maximal element of the set of weights of V. Then by Theorem 2 in the next section and the remark after it, we can

see that V_λ, the weight space of V of weight λ, is one dimensional. Since V is irreducible, V is generated as a $\tilde{\mathcal{U}}$ module by a nonzero vector in this space. We shall call such a vector a highest weight vector of V.

For $a\in\mathbf{C}^\times$, let γ_a be the automorphism of $\tilde{\mathcal{U}}$ such that

$$x_{i,k}^{\pm}\mapsto a^{\pm\delta_{i0}}x_{i,k}^{\pm},\quad h_{i,r}\mapsto h_{i,r},\quad k_i\mapsto k_i,\quad C\mapsto C,\quad \tilde{D}\mapsto\tilde{D}. \tag{2.14}$$

For a representation (ρ,V) of $\tilde{\mathcal{U}}$, we denote the representation $(\rho\circ\gamma_a,V)$ by $V(a)$.

Let $\tilde{\Delta}_1$ and $\tilde{\Delta}_2$ be the comultiplications $\tilde{\mathcal{U}}\to\tilde{\mathcal{U}}\otimes\tilde{\mathcal{U}}$ such that

$$\begin{aligned}
&\tilde{\Delta}_1(C)=\tilde{\Delta}_2(C)=C\otimes C,\quad \tilde{\Delta}_1(D)=\tilde{D}_2(D)=D\otimes D,\\
&\tilde{\Delta}_1(\phi_i^{(+)}(z))=\tilde{\Delta}_2(\phi_i^{(+)}(z))=\phi_i^{(+)}(z/C_2)\otimes\phi_i^{(+)}(z),\\
&\tilde{\Delta}_1(\phi_i^{(-)}(z))=\tilde{\Delta}_2(\phi_i^{(-)}(z))=\phi_i^{(-)}(z)\otimes\phi_i^{(-)}(z/C_1),\\
&\tilde{\Delta}_1(x_i^{+}(z))=x_i^{+}(z)\otimes 1+\phi_i^{(-)}(z)\otimes x_i^{+}(z/C_1),\\
&\tilde{\Delta}_1(x_i^{-}(z))=1\otimes x_i^{-}(z)+x_i^{-}(z/C_2)\otimes\phi_i^{(+)}(z),\\
&\tilde{\Delta}_2(x_i^{+}(z))=x_i^{+}(z)\otimes 1+\phi_i^{(+)}(C_1z)\otimes x_i^{+}(C_1z),\\
&\tilde{\Delta}_2(x_i^{-}(z))=1\otimes x_i^{-}(z)+x_i^{-}(C_2z)\otimes\phi_i^{(-)}(C_2z),
\end{aligned} \tag{2.15}$$

where $C_1=C\otimes 1$ and $C_2=1\otimes C$. [These comultiplications are similar to those by Drinfeld for the quantum affine algebras. To check relations (2.11) (or (4.17) below), we need Lemma 4 and its corollary in Sec. IV.] For $\tilde{\mathcal{U}}$ modules V_1 and V_2 satisfying condition (*), we regard the tensor product $V_1\otimes V_2$ as a $\tilde{\mathcal{U}}$ module via the comultiplication $\tilde{\Delta}_j$ and denote it by $V_1\tilde{\otimes}_jV_2$ $(j=1,2)$.

C. Main results

Our main results in this paper are Theorem 1 and Proposition 2 below.

Theorem 1: *Let $V_\alpha(\alpha=1,2,3)$ be an irreducible $\tilde{\mathcal{U}}$ module satisfying condition (*) and v_α its highest weight vector. Then for each $i=0,1$, the following hold.*

(1) There exists a unique $\mathrm{Hom}_{\mathbf{C}}(V_\alpha\otimes V_\beta,V_\beta\otimes V_\alpha)$ *valued rational function $R^{(\alpha\beta)}(x)$ such that $R^{(\alpha\beta)}(a/b):V_\alpha(a)\tilde{\otimes}_iV_\beta(b)\to V_\beta(b)\tilde{\otimes}_iV_\alpha(a)$ is a homomorphism sending $v_\alpha\otimes v_\beta$ to $v_\beta\otimes v_\alpha$.*

(2) *The $R^{(\alpha\beta)}(x)$ satisfy the Yang–Baxter equation*

$$\begin{aligned}
&(I^{(3)}\otimes R^{(12)}(a))(R^{(13)}(ab)\otimes I^{(2)})(I^{(1)}\otimes R^{(23)}(b))\\
&\quad=(R^{(23)}(b)\otimes I^{(1)})(I^{(2)}\otimes R^{(13)}(ab))(R^{(12)}(a)\otimes I^{(3)}),
\end{aligned} \tag{2.16}$$

where $I^{(\alpha)}=id_{V_\alpha}$.

Remark: A similar result holds also for $U_q(sl_{n+1,\mathrm{tor}})$ with $n\geqslant 2$.

Leaving the proof of this theorem to the next section, we give some result on the explicit expression of the R matrix.

For $j=0,1$, set $V_j=W_j\otimes\mathcal{H}$ where $W_0=\mathbf{C}[e^{\pm\alpha}]$, $W_1=e^{\alpha/2}\mathbf{C}[e^{\pm\alpha}]$ and $\mathcal{H}=\mathbf{C}[a_{-1},a_{-2},\ldots]$. Define $\partial_\alpha,a_r(r\in\mathbf{Z}_{>0}),\bar{D}\in\mathrm{End}\ V_j$ by

$$\partial_\alpha(e^{m\alpha}\otimes x)=2me^{m\alpha}\otimes x,\quad a_r(e^{m\alpha}\otimes x)=\frac{[r][2r]}{r}e^{m\alpha}\otimes\frac{\partial x}{\partial a_{-r}}, \tag{2.17}$$

$$\overline{D}(e^{m\alpha}\otimes x)=q^{-(2m^2-m)-2\Sigma m_r r}e^{m\alpha}\otimes x\left(x=\prod_{r>0}a_{-r}^{m_r}\right).$$

Proposition 1: (Ref. 9) *For each* $j=0,1$, *the assignment*

$$x_i^+(z)\mapsto ze^{s_i\alpha}z^{s_i\partial_\alpha}\exp\left(s_i\sum_{r>0}\frac{a_{-r}}{[r]}z^r\right)\exp\left(-s_i\sum_{r>0}\frac{a_r}{[r]}(qz)^{-r}\right),$$

$$x_i^-(z)\mapsto ze^{-s_i\alpha}z^{-s_i\partial_\alpha}\exp\left(-s_i\sum_{r>0}\frac{a_{-r}}{[r]}(qz)^r\right)\exp\left(s_i\sum_{r>0}\frac{a_r}{[r]}z^{-r}\right),$$

$$\phi_i^{(\pm)}(z)\mapsto q^{\mp s_i\partial_\alpha}\exp\left(\mp s_i(q-q^{-1})\sum_{r>0}a_{\mp r}z^{\pm r}\right),$$

$$C\mapsto q,\quad \tilde{D}\mapsto\overline{D},$$

with $s_1=1$ *and* $s_0=-1$ *defines a* $\tilde{\mathcal{U}}$ *action on* V_j. *This is the irreducible highest weight module with highest weight* Λ_j *if regarded as a* $U_q(\widehat{sl}_2)$ *module via the map* $\tilde{v}$.

Remark: This proposition was proved in Ref. 9. But contrary to the claim there, the $x_{i,k}^{\pm}$ do not satisfy the relation

$$[x_{1,k+1}^{\pm},x_{0,l}^{\pm}]_{q^{\mp 2}}+[x_{0,l+1}^{\pm},x_{1,k}^{\pm}]_{q^{\mp 2}}=0.$$

We do not include the above among the relations of the algebra. This is consistent with the $q=1$ case.[10]

Set

$$\psi^{(\pm)}(w)=w(e^{\pm\alpha/2}\otimes e^{\mp\alpha/2})w^{\pm\partial_\alpha\otimes 1\mp|\otimes\partial_\alpha}\exp\left(\pm\sum_{r>0}\frac{b_{-r}}{[2r]}w^{2r}\right)\exp\left(\mp\sum_{r>0}\frac{b_r}{[2r]}w^{-2r}\right),\tag{2.18}$$

where

$$b_r=a_r^{(1)}-q^{-r}a_r^{(2)},\quad b_{-r}=q^r a_{-r}^{(1)}-a_{-r}^{(2)},$$

$$(r>0,\quad a_s^{(1)}=a_s\otimes 1,\quad a_s^{(2)}=1\otimes a_s).$$

Define $c_r^{\pm}\in\oplus_j\mathrm{Hom}_{\mathbf{C}}(V_j\otimes V_j,V_{1-j}\otimes V_{1-j})(r\in\mathbf{Z}+\frac{1}{2})$ and $c_r^{\pm}\in\oplus_j\mathrm{Hom}_{\mathbf{C}}(V_j\otimes V_{1-j},V_{1-j}\otimes V_j)$ $(r\in\mathbf{Z})$ by

$$\sum_r c_r^{\pm}/w^{2r}=\psi^{(+)}(w)\pm\psi^{(-)}(q^{\mp 1}w).\tag{2.19}$$

The $c_r^{\pm}$ satisfy

$$\{c_r^{\pm},c_s^{\pm}\}=\pm\delta_{r+s,0}(q^{2r}+q^{-2r}),\quad \{c_r^+,c_s^-\}=0,$$
$$(\overline{D}\otimes\overline{D})c_r^{\pm}(\overline{D}\otimes\overline{D})^{-1}=q^{2r}c_r^{\pm}.\tag{2.20}$$

where $\{x,y\}=xy+yx$.

Proposition 2: For the $\tilde{\mathcal{U}}$ *modules* V_j *in Proposition 1, the explicit expression of the intertwiner* $R(a/b):V_j(a)\tilde{\otimes}_1V_k(b)\to V_k(b)\tilde{\otimes}_1V_j(a)$ *is given by*

$$R(x)=\prod_{\substack{r>0\\ r\in\mathbf{Z}+1/2}}\left(1+\frac{x-1}{q^{2r}x-q^{-2r}}c_{-r}^{-}c_{r}^{-}\right)\quad\text{if}\quad j=k,$$

$$R(x)=(-1)^{(\partial_\alpha\otimes 1-1\otimes\partial_\alpha-1)/2}c_0^{-}\prod_{\substack{r>0\\ r\in\mathbf{Z}}}\left(1+\frac{x-1}{q^{2r}x-q^{-2r}}c_{-r}^{-}c_{r}^{-}\right)\quad\text{if}\quad j\neq k.$$

Proof: First note that the vectors $v_0=1\otimes 1$ and $v_1=e^{\alpha/2}\otimes 1$ are higheset weight vectors of V_0 and V_1, respectively, and that on the tensor product $V_j(a)\widetilde{\otimes}_1V_k(b)$, $\widetilde{\mathcal{U}}$ acts as follows:

$$\phi_i^{(\pm)}(z)=q^{\mp s_i\partial_+}\exp\left(\mp s_i(q-q^{-1})\sum_{r>0}h_{\mp r}z^{\pm r}\right),$$

$$\begin{aligned}x_i^{+}(w^2)&=we^{s_i\alpha_+}w^{s_i\partial_+}\exp\left(s_i\sum_{r>0}\frac{h_{-r}}{[2r]}w^{2r}\right)\exp\left(-s_i\sum_{r>0}\frac{q^{-2r}h_r}{[2r]}w^{-2r}\right)\\&\quad\times(a^{\delta_{i0}}\psi^{(s_i)}(w)+b^{\delta_{i0}}\psi^{(-s_i)}(w/q)),\\x_i^{-}(w^2)&=we^{-s_i\alpha_+}w^{-s_i\partial_+}\exp\left(-s_i\sum_{r>0}\frac{q^{2r}h_{-r}}{[2r]}w^{2r}\right)\exp\left(s_i\sum_{r>0}\frac{h_r}{[2r]}w^{-2r}\right)\\&\quad\times(b^{-\delta_{i0}}\psi^{(s_i)}(w)+a^{-\delta_{i0}}\psi^{(-s_i)}(w/q)),\\\widetilde{D}&=\overline{D}\otimes\overline{D},\quad C=q^2\end{aligned}\tag{2.21}$$

where

$$h_r=a_r^{(1)}+q^ra_r^{(2)},\quad h_{-r}=q^{-r}a_{-r}^{(1)}+a_{-r}^{(2)}\ (r>0),$$

$$e^{\pm\alpha_+}=e^{\pm\alpha/2}\otimes e^{\pm\alpha/2},\quad \partial_+=\partial_\alpha\otimes 1+1\otimes\partial_\alpha.$$

Since

$$\begin{aligned}&c_r^{-}v_j\otimes v_k=0\quad\text{for}\quad r>0,\quad r\in\mathbf{Z}+\delta_{j,k}/2,\\&c_0^{-}v_j\otimes v_k=(-1)^jv_k\otimes v_j\quad\text{for}\quad j\neq k,\end{aligned}\tag{2.22}$$

the expression for $R(x)$ maps $v_j\otimes v_k$ to $v_k\otimes v_j$. So it is sufficient to prove that the expression is an intertwiner. Noting $[h_r,b_s]=0$, it is easy to show that the $c_r^{\pm}$ commute with h_r, ∂_+ and $e^{\pm\alpha_+}$, so the expression commutes with h_r, ∂_+, $e^{\pm\alpha_+}$ and $\overline{D}\otimes\overline{D}$. Therefore we only have to show that

$$\begin{aligned}&[R(x),\psi^{(+)}(w)+\psi^{(-)}(w/q)]=0,\\&R(x)(x\psi^{(-)}(w)+\psi^{(+)}(w/q))=(\psi^{(-)}(w)+x\psi^{(+)}(w/q))R(x).\end{aligned}\tag{2.23}$$

This is equivalent to

$$[R(x),c_r^{+}]=0,\quad R(x)(q^{2r}-q^{-2r}x)c_r^{-}=(q^{2r}x-q^{-2r})c_r^{-}R(x)\tag{2.24}$$

and easily checked, using (2.20). □

Remark: The expression of the intertwiner $R(a/b):V_j(a)\widetilde{\otimes}_2V_k(b)\to V_k(b)\widetilde{\otimes}_2V_j(a)$ is also similarly obtained.

III. PROOF OF THEOREM 1

A. Notations

First we introduce more notations.

1. Algebra U

The algebra U is well known to be described by generators e_i, f_i, $t_i^{\pm 1}$, $D^{\pm 1}$ $(i=0,1)$ and relations

$$D^{\pm 1}D^{\mp 1}=1, \quad Dt_i=t_iD, \tag{3.1}$$

$$De_iD^{-1}=qe_i, \quad Df_iD^{-1}=q^{-1}f_i, \tag{3.2}$$

$$t_i^{\pm 1}t_i^{\mp 1}=1, \quad t_it_j=t_jt_i, \tag{3.3}$$

$$t_ie_jt_i^{-1}=q^{a_{ij}}e_j, \quad t_if_jt_i^{-1}=q^{-a_{ij}}f_j, \tag{3.4}$$

$$[e_i,f_j]=\frac{\delta_{ij}}{q-q^{-1}}(t_i-t_i^{-1}), \tag{3.5}$$

$$[e_i,[e_i,[e_i,e_j]_{q^2},],]_{q^{-2}}=0 \quad (i\neq j), \tag{3.6}$$

$$[f_i,[f_i,[f_i,f_j]_{q^2},],]_{q^{-2}}=0 \quad (i\neq j). \tag{3.7}$$

We take the following correspondence of the generators:[11]

$$\begin{aligned} &e_1=x_0^+, \quad f_1=x_0^-, \quad t_1=k, \quad D=\tilde{D}, \\ &e_0=Ck^{-1}x_1^-, \quad f_0=x_{-1}^+kC^{-1}, \quad t_0=Ck^{-1}. \end{aligned} \tag{3.8}$$

We let U' denote the subalgebra of U generated by e_i, f_i and $t_i^{\pm 1}$ $(i=0,1)$. The defining relations of this subalgebra are (3.3)–(3.7). Let σ be the anti-automorphism of U determined by

$$e_i\mapsto e_i, \quad f_i\mapsto f_i, \quad t_i\mapsto t_i^{-1}, \quad D\mapsto D^{-1}. \tag{3.9}$$

Since σ preserves the subalgebra U', it defines an anti-automorphism of U', which we denote by the same letter σ.

2. Algebras $\mathcal{U}$ and $\tilde{\mathcal{U}}$

We need the $\mathbf{C}$ algebra defined by the same generators as those of $U_q(sl_{2,\mathrm{tor}})$ ($\tilde{D}^{\pm 1}$ replaced by $D^{\pm 1}$) and relations (2.4)–(2.11) and

$$D^{\pm 1}D^{\mp 1}=1, \quad Dk_i=k_iD, \tag{3.10}$$

$$Dx_{i,k}^{\pm}D^{-1}=q^{\pm 1}x_{i,k}^{\pm}, \quad Dh_{i,r}D^{-1}=h_{i,r}. \tag{3.11}$$

We shall denote this algebra by $\mathcal{U}$.

We let $\mathcal{U}'$ (resp. $\tilde{\mathcal{U}}'$) signify the subalgebra of $\mathcal{U}$ (resp. $\tilde{\mathcal{U}}$) generated by $x_{i,k}^{\pm}$, $h_{i,r}$, $k_i^{\pm 1}$ and $C^{\pm 1}$ $(i=0,\ 1,\ k\in\mathbf{Z},\ r\in\mathbf{Z}\backslash\{0\})$. As easily shown, these two subalgebras are isomorphic and their defining relations are (2.4)–(2.11). We shall identify these two subalgebras.

Let $\mathcal{X}_j$ $(j=0,1)$, δ_a $(a\in\mathbf{C}^{\times})$ and ζ be the automorphisms of $\mathcal{U}$ determined by

$$\mathcal{X}_j \ : \ x_{i,k}^{\pm}\mapsto(-1)^{j\delta_{ij}}x_{i,k\mp\delta_{ij}}^{\pm}, \quad h_{i,r}\mapsto h_{i,r}, \quad k_i\mapsto C^{-\delta_{ij}}k_i, \tag{3.12}$$

$$C\mapsto C,\quad D\mapsto D,$$

$$\delta_a\ :\ x^{\pm}_{i,k}\mapsto a^k x^{\pm}_{i,k},\quad h_{i,r}\mapsto a^r h_{i,r},\quad k_i\mapsto k_i, \tag{3.13}$$

$$C\mapsto C,\quad D\mapsto D,$$

$$\zeta\ :\ x^{\pm}_{i,k}\mapsto q^{\pm 2\delta_{i0}}x^{\mp}_{i,-k},\quad h_{i,r}\mapsto -h_{i,-r},\quad k_i\mapsto k_i^{-1}, \tag{3.14}$$

$$C\to C^{-1},\quad D\to D^{-1}.$$

(The existence of $\mathcal{X}_j$ is guaranteed by Lemma 3 in Sec. IV.) We also need the anti-automorphism η of $\mathcal{U}$ such that

$$x^{\pm}_{i,k}\mapsto x^{\pm}_{i,-k},\quad h_{i,r}\mapsto -C^r h_{i,-r},\quad k_i\mapsto k_i^{-1}, \tag{3.15}$$

$$C\mapsto C,\quad D\mapsto D^{-1}.$$

Since these (anti-)automorphisms preserve the subalgebra $\mathcal{U}'$, they define (anti)-automorphisms of $\mathcal{U}'$, which we denote by the same letters.

We define an automorphism $\tilde{\zeta}$ and an anti-automorphism $\tilde{\eta}$ of $\tilde{\mathcal{U}}$ so that they map the generators other than $\tilde{D}^{\pm 1}$ as ζ and η do, and send $\tilde{D}$ to $\tilde{D}^{-1}$ and $\tilde{D}k_1^{-1}$, respectively.

3. $\mathcal{U}$ modules

Let λ be a dominant integral weight of $\widehat{sl}_2$ and $\mathbf{P}=(P_0,P_1)$ a pair of polynomials with constant term 1 and $\deg P_i=\langle h_i,\lambda\rangle$. By $V(\lambda,\mathbf{P})$, we denote an irreducible $\mathcal{U}$ module genenated by a simultaneous eigenvector v_+ annihilated by the $x^+_{i,k}$ of C, D, and the $\phi^{(\pm)}_{i,\mp r}$ such that

$$Cv_+=v_+,\quad Dv_+=q^{\langle d,\lambda\rangle}v_+,$$

$$\sum_{r\geqslant 0}\phi^{(\pm)}_{i,\mp r}u^{\mp r}v_+=q^{\deg P_i}P_i(q^{-2}u)/P_i(u)v_+, \tag{3.16}$$

where the right-hand side of the last equality should be understood as a Laurent expansion around $u=\infty$ (resp. 0) for the $\phi^{(+)}_{i,-r}$ (resp. the $\phi^{(-)}_{i,r}$). The existence and uniqueness of $V(\lambda,\mathbf{P})$ are proven in the standard manner. (See Refs. 1–3). We call v_+ a highest weight vector of $V(\lambda,\mathbf{P})$.

For a representation (ρ,V) of $\mathcal{U}$, we let V_a signify the representation $(\rho\circ\delta_a,V)$.

B. Results in Refs. 1 and 4 for $U_q(sl_{2,\mathrm{tor}})$

Most of the results in Refs. 1 and 4 hold also for $U_q(sl_{2,\mathrm{tor}})$. We state them in this section. We will give the proof of Proposition 3 and Lemma 1 in the next section. The remaining claims are proven as in Ref. 1, using Lemmas 3 and 4 in the next section.

1. Isomorphisms ψ and π

Let $h:U\to\mathcal{U}$, $v:U'\to\mathcal{U}$ and $\tilde{h}:U'\to\tilde{\mathcal{U}}$ be the homomorphisms determined by

$$h\ :\ e_i\mapsto x^+_{i,0},\quad f_i\mapsto x^-_{i,0},\quad t_i\mapsto k_i,\quad D\mapsto D, \tag{3.17}$$

$$v\ :\ x^{\pm}_k\mapsto x^{\pm}_{1,k},\quad h_r\mapsto h_{1,r},\quad k\mapsto k_1,\quad C\mapsto C, \tag{3.18}$$

$$\tilde{h}\ :\ e_i\mapsto x^+_{i,0},\quad f_i\mapsto x^-_{i,0},\quad t_i\mapsto k_i. \tag{3.19}$$

Proposition 3: There exist isomorphisms $\psi:\mathcal{U}\to\tilde{\mathcal{U}}$ and $\pi:\mathcal{U}\to\tilde{\mathcal{U}}$ determined by

$$\psi v=\tilde{h},\quad \psi h=\tilde{\eta}\tilde{v}\sigma \text{ and } \pi h=\tilde{v},\quad \pi\eta v\sigma=\tilde{h},$$

respectively.

Lemma 1: The isomorphisms ψ and π satisfy the following identities:

(1) $\pi=\tilde{\eta}\psi\eta$,
(2) $\tilde{\zeta}\psi=\psi\zeta$,
(3) $\gamma_{a^{-1}}\pi=\pi\delta_a$.

2. $\mathcal{U}$ modules and $\tilde{\mathcal{U}}$ modules

We shall regard a $\tilde{\mathcal{U}}$ module as a $\mathcal{U}$ module via the map π. Then thanks to Lemma 1 (3) we can see that

$$V(a^{-1})\simeq V_a, \tag{3.20}$$

as a $\mathcal{U}$ module. Moreover condition (*) for an irreducible $\tilde{\mathcal{U}}$ module can be rewritten as a condition for an irreducible $\mathcal{U}$ module as follows.

Theorem 2: *An irreducible $\tilde{\mathcal{U}}$ module satisfies condition (*) if and only if it is isomorphic to one of the $V(\lambda,\mathbf{P})$ as a $\mathcal{U}$ module.*

Noting $\pi(D)=\tilde{v}(D)$, $\pi(k_i)=\tilde{v}(t_i)$ $(i=0,1)$, and the fact that $V(\lambda,\mathbf{P})$ is spanned by the vectors $x^{-}_{i_1,k_1}\cdots x^{-}_{i_m,k_m}v_+$, we find from this theorem that the notions of highest weight vectors for both modules coincide.

3. Tensor product of $\mathcal{U}$ modules and R matrices

Letting $\psi'=\psi\mathcal{X}_0^{-1}$, set

$$\Delta_i=(\psi'\otimes\psi')^{-1}\circ\tilde{\Delta}_i\circ\psi',\quad \Delta_i'=(\pi\otimes\pi)^{-1}\circ\tilde{\Delta}_i\circ\pi\ \ (i=1,2). \tag{3.21}$$

For $\mathcal{U}$ modules $V_\alpha=V(\lambda_\alpha,\mathbf{P}_\alpha)$ $(\alpha=1,2)$, we regard the tensor product $V_1\otimes V_2$ as a $\mathcal{U}$ module via the comultiplication Δ_i (resp. Δ_i') and denote it by $V_1\otimes_i V_2$ (resp. $V_1\otimes_i' V_2$) $(i=1,2)$.

Theorem 3: *Set $V_\alpha=V(\lambda_\alpha,\mathbf{P}_\alpha)$ $(\alpha=1,2,3)$ and let v_α's be their highest weight vectors. Then for each $i=0,1$, the following hold.*

(1) There exists a unique $\mathrm{Hom}_{\mathbf{C}}(V_\alpha\otimes V_\beta,V_\beta\otimes V_\alpha)$ *valued rational function $\mathcal{R}^{(\alpha\beta)}(x)$ such that $\mathcal{R}^{(\alpha\beta)}(a/b):V_{\alpha,b}\otimes_i V_{\beta,a}\to V_{\beta,a}\otimes_i V_{\alpha,b}$ is a homomorphism sending $v_\alpha\otimes v_\beta$ to $v_\beta\otimes v_\alpha$;*

(2) the $\mathcal{R}^{(\alpha\beta)}(x)$ satisfy the Yang–Baxter equation (2.16).

C. Proof of Theorem 1

Now we turn to the proof of Theorem 1.

Lemma 2: Set $\phi=\mathcal{X}_0\zeta\eta$. Then the following hold:

$$(\Delta_i^{\phi})^{\mathrm{op}}=\Delta_j' \ \text{ for } \ (i,j)=(1,2),(2,1).$$

Proof: For a comultiplication Δ and (anti-)automorphism p, set $\Delta^p=(p\otimes p)^{-1}\circ\Delta\circ p$. Since $\tilde{\Delta}_i^{\tilde{\zeta}}=\tilde{\Delta}_i^{\mathrm{op}}$ and $\tilde{\Delta}_i^{\tilde{\eta}}=\tilde{\Delta}_j$, it is sufficient to show that $\tilde{\zeta}\psi'\phi=\tilde{\eta}\pi$. Thanks to Lemma 1 (1) and $\tilde{\eta}^2=1=\zeta^2$, this is equivalent to Lemma 1 (2). □

Proposition 4: Set $V=V(\lambda,\mathbf{P})$ and let v_+ be its highest weight vector. There exists a bilinear form $(\cdot,\cdot)$ on V uniquely determined by

$$(v_+,v_+)=1,\quad (xv,v')=(v,\phi(x)v')\ \ (v,v'\in V,x\in\mathcal{U}). \tag{3.22}$$

This bilinear form is nondegenerate and symmetric.

Proof: First we show the existence. For $V=\oplus_{\mu\in Q^+}V_{\lambda-\mu}$, set $V^{\mathrm{res}*}=\oplus_{\mu\in Q^+}V^*_{\lambda-\mu}$ and regard this space as a $\mathcal{U}$ module by

$$\langle xf,v\rangle=\langle f,\phi(x)v\rangle \quad (f\in V^{\mathrm{res}*},v\in V,x\in\mathcal{U}). \tag{3.23}$$

Then since

$$\begin{aligned}&\phi(x^{\pm}_{i,k})=q^{\pm 2\delta_{i0}}x^{\mp}_{i,k\pm\delta_{i0}},\quad \phi(h_{i,r})=C^{-r}h_{i,r},\\ &\phi(k_i)=C^{-\delta_{i0}}k_i,\quad \phi(D)=D,\quad \phi(C)=C^{-1},\end{aligned} \tag{3.24}$$

there exists an isomorphism $g:V\tilde{\to}V^{\mathrm{res}*}$. A scalar multiple of the bilinear form determined by

$$(v,v')=\langle g(v),v'\rangle \quad (v,v'\in V), \tag{3.25}$$

satisfies conditions (3.22).

The uniqueness follows from (3.22) and (3.24). Since V is irreducible and $\phi^2=1$, the form is nondegenerate and symmetric. □

Now we are in a position to give the following proof.

Proof of Theorem 1.

In this proof, we let $i\neq j\in\{1,2\}$. Set $V_\alpha=V(\lambda_\alpha,\mathbf{P}_\alpha)$ $(\alpha=1,2,3)$ and $E_{\alpha\beta}=\Pi_\mu\mathrm{Hom}_{\mathbf{C}}((V_\alpha\otimes V_\beta)_{\lambda_\alpha+\lambda_{\beta-\mu}},(V_\beta\otimes V_\alpha)_{\lambda_\alpha+\lambda_{\beta-\mu}})$. For $f\in E_{\alpha\beta}$, define $\overline{f}\in E_{\alpha\beta}$ by

$$(f(u_\alpha\otimes u_\beta),u'_\beta\otimes u'_\alpha)=(u_\beta\otimes u_\alpha,\overline{f}(u'_\alpha\otimes u'_\beta)) \quad (u_\gamma,u'_\gamma\in V_r). \tag{3.26}$$

Let $\mathcal{R}^{(\alpha\beta)}(a/b)$ signify the intertwiner $V_{\alpha,b}\otimes_i V_{\beta,a}\to V_{\beta,a}\otimes_i V_{\alpha,b}$ in Theorem 3. Proposition 4 gives

$$(\Delta_i(x)u_\alpha\otimes u_\beta,u'_\alpha\otimes u'_\beta)=(u_\alpha\otimes u_\beta,\Delta_i^{\phi}(\phi(x))u'_\alpha\otimes u'_\beta) \quad (x\in\mathcal{U},u_\gamma,u'_\gamma\in V_\gamma). \tag{3.27}$$

This fact and Lemma 2 show that $\overline{\mathcal{R}}^{(\alpha\beta)}(a/b)$ is an intertwiner $V_{\alpha,b}\otimes'_j V_{\beta,a}\to V_{\beta,a}\otimes'_j V_{\alpha,b}$. Thanks to Eq. (3.20) and the definition of Δ'_j, this implies that $\overline{\mathcal{R}}^{(\alpha\beta)}(a/b)$ is an intertwiner $V_\alpha(a)\tilde{\otimes}'_j V_\beta(b)\to V_\beta(b)\tilde{\otimes}'_j V_\alpha(a)$. Clearly the $\overline{\mathcal{R}}^{(\alpha,\beta)}(x)$ send $v_\alpha\otimes v_\beta$ to $v_\beta\otimes v_\alpha$ and satisfy the Yang–Baxter equation. Therefore the theorem follows from Theorem 2. □

IV. PROOF OF PROPOSITION 3 AND LEMMA 1

Proposition 3 follows from Proposition 7 below as in Ref. 1. Lemma 1 follows from Proposition 7 (1) and its corollary since $\psi|_{\mathcal{U}'}=f$ and $\pi|_{\mathcal{U}'}=f^{-1}$. Therefore, in this section we shall prove Proposition 7.

A. Presentations of $\mathcal{U}'$

First we prove the following proposition.

Proposition 5: (1) The algebra $\mathcal{U}'$ admits a presentation in terms of generators $x^{\pm}_{i,0},x^{\pm}_{i,1},x^{\pm}_{i,-1},k_i^{\pm1}$ $(i=0,1)$, $C^{\pm1}$ and relations

$$k_i^{\pm1}k_i^{\mp1}=C^{\pm1}C^{\mp1}=1, \tag{4.1}$$

$$C \text{ central},\quad k_ik_j=k_jk_i, \tag{4.2}$$

$$k_ix^{\pm}_{j,k}k_i^{-1}=q^{\pm a_{ij}}x^{\pm}_{j,k}, \tag{4.3}$$

$$[x^+_{i,k},x^-_{i,-k}]=\frac{C^k k_i-C^{-k}k_i^{-1}}{q-q^{-1}}, \tag{4.4}$$

$$[x^+_{i,\pm 1},x^-_{i,0}]=C[x^+_{i,0},x^-_{i,\pm 1}], \tag{4.5}$$

$$[x^\pm_{i,0},x^\pm_{i,-1}]_{q^{\pm 2}}=[x^\pm_{i,1},x^\pm_{i,0}]_{q^{\pm 2}}=0, \tag{4.6}$$

$$[x^+_{i,-1},X^+_{i-2}]_{q^2}=[X^-_{i,2},x^-_{i,1}]_{q^{-2}}=0, \tag{4.7}$$

$$[x^+_{i,k},x^-_{j,l}]=0 \quad (i\neq j), \tag{4.8}$$

$$[x^\pm_{i,0},[x^\pm_{i,0},[x^\pm_{i,0},x^\pm_{j,0}]_{q^2}]]_{q^{-2}}=0 \quad (i\neq j). \tag{4.9}$$

For $i\neq j$ the following elements are central

$$[x^\pm_{i,0},x^\pm_{j,-1}]_{q^{\mp 2}}+[x^\pm_{j,0},x^\pm_{i,-1}]_{q^{\mp 2}}, \tag{4.10}$$

$$[x^\pm_{i,1},x^\pm_{j,0}]_{q^{\mp 2}}+[x^\pm_{j,1},x^\pm_{i,0}]_{q^{\mp 2}}, \tag{4.11}$$

$$[x^+_{i,-1},x^+_{j,-1}]_{q^{-2}}+[x^+_{j,0},X^+_{i,-2}]_{q^{-2}}, \tag{4.12}$$

$$[x^-_{i,1},x^-_{j,1}]_{q^2}+[X^-_{j,2},x^-_{i,0}]_{q^2}, \tag{4.13}$$

where

$$X^\pm_{i,\mp 2}=\pm\frac{C^{\pm 1}}{[2]}[H_{i,\mp 1},x^\pm_{i\mp 1}],$$

with

$$H_{i,1}=Ck_i^{-1}[x^+_{i,0},x^-_{i,1}](=k_i^{-1}[x^+_{i,1},x^-_{i,0}]),$$

$$H_{i,-1}=C^{-1}k_i[x^+_{i,-1},x^-_{i,0}](=k_i[x^+_{i,0},x^-_{i,-1}]).$$

(2) Relations (4.7), (4.12), and (4.13) can be replaced by

$$[X^+_{i,2},x^+_{i,1}]_{q^2}=[x^-_{i,-1},X^-_{i,-2}]_{q^{-2}}=0, \tag{4.14}$$

$$[x^+_{i,1},x^+_{j,1}]_{q^{-2}}+[X^+_{j,2},x^+_{i,0}]_{q^{-2}}, \tag{4.15}$$

$$[x^-_{i,-1},x^-_{j,-1}]_{q^2}+[x^-_{j,0},X^-_{i,-2}]_{q^2}. \tag{4.16}$$

where

$$X^\pm_{i,\pm 2}=\pm\frac{1}{[2]}[H_{i,\pm 1},x^\pm_{i,\pm 1}].$$

Hereafter we shall denote the algebra defined by the generators and relations in the proposition (1) [resp. (2)] by A [resp. B].

First we prove the following two lemmas.

Lemma 3: In $\mathcal{U}'$, the following equalities hold:

$$\mathrm{Sym}_{m_1,m_2,m_3}[x^\pm_{i,m_1},[x^\pm_{i,m_2},[x^\pm_{i,m_3},x^\pm_{j,n}]_{q^2}]]_{q^{-2}}=0 \quad (i\neq j). \tag{4.17}$$

Proof: Set

$$I_{ij}^{\pm}(n)=[x_{i,0}^{\pm},[x_{i,0}^{\pm},[x_{i,0}^{\pm},x_{j,n}^{\pm}]_{q^2}]]_{q^{-2}} \quad (i\neq j). \tag{4.18}$$

Then, as easily checked, the following equalities hold:

$$[3]q^2[x_{i,0}^{+},[x_{i,0}^{+},[x_{i,1}^{+},x_{j,m}^{+}]_{q^{-2}}]]_{q^{-2}}-I_{ij}^{+}(m+1)=\frac{1}{[2]}[h_{i,1},I_{ij}^{+}(m)], \tag{4.19}$$

$$[x_{i,0}^{+},[x_{i,1}^{+},x_{j,m}^{+}]_{q^{-2}}]-q^{-2}[x_{i,0}^{+},[x_{i,0}^{+},x_{j,m+1}^{+}]_{q^2}]=\frac{C}{[3][2]}[I_{ij}^{+}(m),x_{i,1}^{-}]. \tag{4.20}$$

Since $I_{ij}^{+}(0)=0$, we can see that $I_{ij}^{+}(m)=0$ for $m\geqslant 0$ by combining (4.19) and (4.20) with $m\geqslant 0$. Applying η and ζ to this result, we get $I_{ij}^{\pm}(m)=0$ for any m.

From $[h_{i,m_1},I_{ij}^{\pm}(n)]=0$, relations (4.17) with $m_2=m_3=0$ follow. Considering the commutator of these relations with h_{i,m_2}, we find that relations (4.17) with $m_3=0$ hold. From the commutator of these relations with h_{i,m_3}, the assertion follows. □

Lemma 4: We have

$$[x_{1,k+1}^{\pm},x_{0,l}^{\pm}]_{q^{\mp 2}}+[x_{0,l+1}^{\pm},x_{1,k}^{\pm}]_{q^{\mp 2}}\in Z(\mathcal{U}').$$

Proof: Set $X=[x_{1,1}^{+},x_{0,0}^{+}]_{q^{-2}}+[x_{0,1}^{+},x_{1,0}^{+}]_{q^{-2}}$. It is straightforward to show that X commutes with $x_{i,m}^{-}$, k_i and C $(i=0,1,\ m=0,\pm 1)$. From (4.20) with $m=0$, it follows that X also commutes with $x_{i,0}^{+}$ $(i=0,1)$. From these we find $X\in Z(\mathcal{U}')$. Applying $\mathcal{X}_i^{\pm 1}$ $(i=0,1)$ repeatedly to X, we get the claim for the $x_{i,k}^{+}$. The claim for the $x_{i,k}^{-}$ can be proven by the use of the automorphism ζ. □

By considering the commutator of the central elements in the lemma with $h_{1,1}$, we obtain

Corollary 1: In $\mathcal{U}'$, the following equalities hold:

$$(z-w)((z-q^{\mp 2}w)x_1^{\pm}(z)x_0^{\pm}(w)+(w-q^{\mp 2}z)x_0^{\pm}(w)x_1^{\pm}(z))=0.$$

Next assuming Lemma 5 below for a while, we give the following proof.

Proof of Proposition 5

(1) By Lemma 4, we can see that there exists a homomorphism $A\to\mathcal{U}'$ determined by

$$x_{i,k}^{\pm}\mapsto x_{i,k}^{\pm} \quad (k=0,\pm 1), \quad k_i\mapsto k_i, \quad C\mapsto C. \tag{4.21}$$

We shall show the existence of the inverse mapping of this homomorphism.

First we note that for each $i=0$, 1, there exists a homomorphism $\rho_i:U'\to A$ determined by

$$\begin{gathered} e_1\mapsto x_{i,0}^{+}, \quad f_1\mapsto x_{i,0}^{-}, \quad t_1\mapsto k_i, \\ e_0\mapsto Ck_i^{-1}x_{i,1}^{-}, \quad f_0\mapsto x_{i,-1}^{+}k_iC^{-1}, \quad t_0\mapsto Ck_i^{-1}. \end{gathered} \tag{4.22}$$

For example, since $[e_0,e_1]_{q^{-2}}\mapsto k_i^{-1}[x_{i,0}^{-},x_{i,1}^{+}]$, we get $[[e_0,e_1]_{q^{-2}},e_1]\mapsto -[2]x_{i,1}^{+}$. Therefore relation (3.6) with $i=1$ and $j=0$ is preserved. Set

$$X_{i,k}^{\pm}=\rho_i(x_k^{\pm}) \ \text{ and } \ H_{i,r}=\rho_i(h_r). \tag{4.23}$$

Then by the definition of ρ_i we have $X_{i,0}^{\pm}=x_{i,0}^{\pm}$ and $X_{i,\mp 1}^{\pm}=x_{i,\mp 1}^{\pm}$. This implies that $H_{i,\pm 1}$ and $X_{i,\mp 2}^{\pm}$ defined above coincide with those in the proposition. Moreover we have $X_{i,\pm 1}^{\pm}=x_{i,\pm 1}^{\pm}$ since the following equalities hold:

$$[H_{i,r},x_{i,0}^{\pm}]=\pm[2]C^{(r\mp|r|)/2}x_{i,r}^{\pm} \ \text{ for } \ r=\pm 1. \tag{4.24}$$

Next we prove that the assignment

$$x_{i,k}^{\pm}\mapsto X_{i,k}^{\pm},\quad h_{i,r}\mapsto H_{i,r},\quad k_i\mapsto k_i,\quad C\mapsto C, \tag{4.25}$$

defines the desired homomorphism $\mathcal{U}'\to A$. Since the ρ_i's are homomorphisms, the relations of $\mathcal{U}'$ among the generators with the same subscript $i=j$ are clearly preserved. Relations (2.5) and (2.7) with $i\neq j$ are checked by using the fact $k_0k_1\in Z(A)$. Relation (2.11) is clearly preserved. Relations (2.6) and (2.8) [resp. (2.9)] with $i\neq j$ are checked, using Lemma 5 (1) [resp. (2)] below. This completes the proof of the existence of the map. Since $X_{i,k}^{\pm}=x_{i,k}^{\pm}$ for $k=0,\pm1$, this map is the inverse mapping of the one in the first paragraph.

(2) Since $A\simeq\mathcal{U}'$, relations (4.14) hold and the elements (4.15) and (4.16) are central in A. So we can see the existence of a homomorphism $B\to A$.

Clearly there exists an anti-homomorphism $A\to B$ such that

$$x_{i,k}^{\pm}\mapsto x_{i,-k}^{\pm},\quad k_i\mapsto k_i^{-1},\quad C\mapsto C. \tag{4.26}$$

The composition of this map and the anti-automorphism η of $A(\simeq\mathcal{U}')$ gives the inverse mapping of the preceding homomorphism. □

Finally, to complete the proof of Proposition 5, we prove the following lemma.

Lemma 5: In A, the following hold:

(1) $H_{0,r}+H_{1,r}\in Z(A)$ *for any* $r(\neq0)$.

(2) $[X_{i,k}^{+},X_{j,l}^{-}]=0$ *for* $i\neq j$ *and any k,l.*

Proof: Throughout this proof let $i\neq j\in\{0,1\}$. We prove in three steps.

(i) Proof of (1) with $|r|=1,2$. First we consider the case $|r|=1$. It is easy to check the equalities $[x_{i,0}^{\pm},X_{j,\pm2}^{\mp}]=0(i\neq j)$. Using these, we can show that $H_{0,r}+H_{1,r}$ commutes with the elements $x_{i,0}^{\pm}$, $x_{i,\mp1}^{\pm}$, $k_i(i=0,1)$ and C. Recalling the definition of $H_{i,\pm1}$ and using (4.24), we find from the above that $H_{0,r}+H_{1,r}$ also commutes with $H_{i,\pm1}$ and $x_{i,\pm1}^{\pm}$. This completes the proof. Clearly $H_{0,r}+H_{1,r}$ commutes with k_i and C. The fact $H_{0,\pm1}+H_{1,\pm1}\in Z(A)$ implies

$$[H_{0,r}+H_{1,r},H_{i,\pm1}]=[H_{i,r},H_{i,\pm1}]-[H_{j,r},H_{j,\pm1}]=0.$$

Therefore, noting (4.24), we can see that to prove (1) for $|r|>1$ it is sufficient to show that $H_{0,r}+H_{1,r}$ commutes with $x_{i,0}^{\pm}(i=0,1)$. Noting this remark and using

$$H_{i,\pm2}=C^{\pm1}k_i^{\mp1}[x_{i,\pm1}^{+},x_{i,\pm1}^{-}]\mp\frac{q-q^{-1}}{2}H_{i,\pm1}^{2},$$

it is easy to prove the case $|r|=2$.

(ii) Proof of (2). Comparing

$$[H_{i,\pm1},[H_{i,\pm1},[X_{i,k}^{+},X_{j,l}^{-}]]]\ \text{ and }\ [H_{i,\pm2},[X_{i,k}^{+},X_{j,l}^{-}]],$$

we find that $[X_{i,k\pm1}^{+},X_{j,l\pm1}^{-}]=0$ follows from $[X_{i,k}^{+},X_{j,l}^{-}]=0$ (†). So it is sufficient to prove the assertion with $l=0$. We show that $[X_{i,k}^{+},X_{j,0}^{-}]=0$ for $0\leqslant|k|\leqslant m$ by induction on m. The case $m=1$ holds thanks to (4.8) and the fact $X_{i,k}^{\pm}=x_{i,k}^{\pm}$ $(k=0,\pm1)$. Suppose that the case $m(\geqslant1)$ holds. Then

$$0=\frac{C^{(1\mp1)/2}}{[2]}[H_{i,\pm1},[X_{i,\pm m}^{+},X_{j,0}^{-}]]=[X_{i,\pm(m+1)}^{+},X_{j,0}^{-}]+C[X_{i,\pm m}^{+},X_{j,\pm1}^{-}]$$

and the second term on the right-most side vanishes thanks to the induction assumption and (†). So we get the case $m+1$.

(iii) Proof of (1) with $|r|\geqslant3$. We prove the case $r\geqslant3$. The proof of the case $r\leqslant-3$ is similar. Set

$$P_{i,0}=1,\quad P_{i,k}=(q-q^{-1})C^l k_i^{-1}[X^+_{i,k-l},X^-_{i,l}]\ \text{ for }\ k>0,$$
$$Q_{ij,m}=\sum_{\substack{s+t=m\\ s,t\geqslant 0}} P_{i,s}P_{j,t}\ \text{ for }\ m\geqslant 0, \tag{4.27}$$

where l is any integer. Using (4.6) and (4.11), calculate the commutator of $P_{i,k+1}$ (with $l=k$) with $x^+_{m,0}$ and that of $P_{i,k+1}$ (with $l=1$) with $x^-_{m,0}$ $(m=0,1)$. Then we get

$$[P_{i,k+1},x^\pm_{j,0}]=C^{(1\mp 1)/2}(q^{\mp 2}P_{i,k}x^\pm_{j,1}-q^{\pm 2}x^\pm_{j,1}P_{i,k}),$$
$$[P_{i,k+1},x^\pm_{i,0}]=C^{(1\mp 1)/2}(q^{\pm 2}P_{i,k}x^\pm_{i,1}-q^{\mp 2}x^\pm_{i,1}P_{i,k}), \tag{4.28}$$

for $k\geqslant 0$. From this we obtain

$$[Q_{ij,m+1},x^\pm_{i,0}]=q^{\mp 2}C^{(1\mp 1)/2}[Q_{ij,m},x^\pm_{i,1}], \tag{4.29}$$

for $m\geqslant 0$.

Now we prove that $H_{0,r}+H_{1,r}\in Z(A)$ for $0<r\leqslant m$ by induction on m. We have already proved this for $m=2$. Suppose that the case $m(\geqslant 2)$ holds. Then

$$[H_{i,r},H_{j,s}]=-[H_{i,r},H_{i,s}]=0\ \text{ for }\ 0<r,s\leqslant m.$$

Noting this and

$$P_i(u):=\sum_{k\geqslant 0} P_{i,k}u^k=\exp\left((q-q^{-1})\sum_{l>0} H_{i,l}u^l\right), \tag{4.30}$$

we find that

$$\sum_{k\geqslant 0} Q_{ij,k}u^k(=P_i(u)P_j(u))\ \text{ and }\ \exp\left((q-q^{-1})\sum_{l>0}(H_{0,l}+H_{1,l})u^l\right)$$

coincide mod $O(u^{m+2})$, so

$$Q_{ij,k}\in Z(A)\ \text{ for }\ 0\leqslant k\leqslant m,$$
$$Q_{ij,m+1}-(q-q^{-1})(H_{0,m+1}+H_{1,m+1})\in Z(A). \tag{4.31}$$

Using this and (4.29), we find that $H_{0,m+1}+H_{1,m+1}$ commutes with $x^\pm_{i,0}$ $(i=0,1)$. Thanks to the remark in (i), this proves the case $m+1$. □

B. Braid group action on $\mathcal{U}'$

Next we show the existence of a braid group action on $\mathcal{U}'$.

Define an automorphism $T_1{}^{12}$ of U' by

$$T_1:\ e_1\mapsto -f_1t_1,\quad f_1\mapsto -t_1^{-1}e_1,\quad t_1\mapsto t_1^{-1},\quad t_0\mapsto t_0t_1^2,$$
$$e_0\mapsto\frac{1}{[2]}[e_1,[e_1,e_0]_{q^{-2}}],\quad f_0\mapsto\frac{1}{[2]}[[f_0,f_1]_{q^2},f_1]. \tag{4.32}$$

Let S denote the automorphism of $\mathcal{U}'$ determined by

$$x^\pm_{i,k}\mapsto(-1)^k x^\pm_{1-i,k},\quad h_{i,r}\mapsto(-1)^r h_{1-i,r},\quad k_i\mapsto k_{1-i},\quad C\mapsto C. \tag{4.33}$$

Let $\mathcal{B}$ be the group defined by generators $\mathcal{T}$, $\mathcal{Y}$, Q and relations

$$\mathcal{T}^{-1}\mathcal{Y}\mathcal{T}^{-1}=\mathcal{Y}^{-1},\quad Q\mathcal{Y}Q^{-1}=\mathcal{Y}^{-1},\quad Q^2=1. \tag{4.34}$$

Let $^-$ denote the automorphism of $\mathcal{B}$ such that

$$\overline{\mathcal{T}}=\mathcal{T},\quad \overline{\mathcal{Y}}=Q\mathcal{T},\quad \overline{Q}=\mathcal{Y}^{-1}\mathcal{T}. \tag{4.35}$$

Proposition 6: (1) There exist automorphisms $\mathcal{T}_0$ and $\mathcal{T}_1$ of $\mathcal{U}'$ determined by

$$\mathcal{T}_1 v=vT_1,\quad \mathcal{T}_1 h=hT_1,\quad \mathcal{T}_0=S\mathcal{T}_1S^{-1}.$$

The inverse $\mathcal{T}_i^{-1}$ is given by $\eta\mathcal{T}_i\eta$.

(2) The automorphisms $\mathcal{T}_i$, $\mathcal{X}_i$ $(i=0,1)$ and S satisfy

$$\mathcal{X}_0\mathcal{X}_1=\mathcal{X}_1\mathcal{X}_0,$$

$$\mathcal{T}_i\mathcal{X}_{1-i}=\mathcal{X}_{1-i}\mathcal{T}_i,$$

$$\mathcal{T}_i^{-1}\mathcal{X}_i\mathcal{T}_i^{-1}=\mathcal{X}_{1-i}^2\mathcal{X}_i^{-1},$$

$$S\mathcal{T}_iS^{-1}=\mathcal{T}_{1-i},\quad S\mathcal{X}_iS^{-1}=\mathcal{X}_{1-i}.$$

Corollary 2: The mapping $\mathcal{T}\mapsto\mathcal{T}_1$, $\mathcal{Y}\mapsto\mathcal{X}_1\mathcal{X}_0^{-1}$, $Q\mapsto S$ defines a $\mathcal{B}$ action on $\mathcal{U}'$.

Proof: We show only the existence of the homomorphism $\mathcal{T}_1$. The remaining claims are proven as in Ref. 4.

Since

$$x_1^+=-T_1^{-1}e_0,\quad x_{-1}^-=-T_1^{-1}f_0,$$

it is easy to show that the automorphism T_1 maps as follows:

$$\begin{gathered}x_0^+\mapsto -x_0^-k,\quad x_0^-\mapsto -k^{-1}x_0^+,\quad k\mapsto k^{-1},\\ x_1^+\mapsto -Ck^{-1}x_1^-,\quad x_{-1}^-\mapsto -x_{-1}^+kC^{-1},\quad C\mapsto C,\\ x_{-1}^+\mapsto\frac{k^2}{[2]}[[x_{-1}^+,x_0^-]_{q^4},x_0^-]_{q^2},\quad x_1^-\mapsto[x_0^+,[x_0^+,x_1^-]_{q^{-4}}]_{q^{-2}}\frac{k^{-2}}{[2]}.\end{gathered} \tag{4.36}$$

Thanks to this, (4.32) and Proposition 5 (2), it is sufficient to show that the assignment

$$\begin{gathered}x_{1,0}^+\mapsto -x_{1,0}^-k_1,\quad x_{1,0}^-\mapsto -k_1^{-1}x_{1,0}^+,\quad k_1\mapsto k_1^{-1},\\ x_{1,1}^+\mapsto -Ck_1^{-1}x_{1,1}^-,\quad x_{1,-1}^-\mapsto -x_{1,-1}^+k_1C^{-1},\quad C\mapsto C,\\ x_{1,-1}^+\mapsto\frac{k_1^2}{[2]}[[x_{1,-1}^+,x_{1,0}^-]_{q^4},x_{1,0}^-]_{q^2},\quad x_{1,1}^-\mapsto[x_{1,0}^+,[x_{1,0}^+,x_{1,1}^-]_{q^{-4}}]_{q^{-2}}\frac{k_1^{-2}}{[2]},\\ x_{0,k}^+\mapsto\frac{1}{[2]}[x_{1,0}^+,[x_{1,0}^+,x_{0,k}^+]_{q^{-2}}],\quad x_{0,k}^-\mapsto\frac{1}{[2]}[[x_{0,k}^-,x_{1,0}^-]_{q^2},x_{1,0}^-]\ \ (k=0,\pm1),\\ k_0\mapsto k_0k_1^2\end{gathered} \tag{4.37}$$

defines a homomorphism $B\to\mathcal{U}'$.

Nearly half of the relations of B are easily shown to be preserved by noting that vT_1 and hT_1 are homomorphisms. For example, $[x^+_{1,0},x^+_{1,-1}]_{q^2}$ is mapped to $vT_1([x^+_0,x^+_{-1}]_{q^2})=0$. The rest of the relations are checked by tedious but straightforward calculations. Here we only note the following two facts:

(i) The above assignment sends $X^{\pm}_{0,\pm 2}$ as

$$X^+_{0,2}\mapsto\frac{1}{[2]}[x^+_{1,0},[x^+_{1,0},x^+_{0,2}]_{q^{-2}}],\quad X^-_{0,-2}\mapsto\frac{1}{[2]}[[x^-_{0,-2},x^-_{1,0}]_{q^2},x^-_{1,0}],$$

and maps the elements (4.10), (4.11), (4.15), and (4.16) to their counterparts in $\mathcal{U}'$.

(ii) To check (4.6) and (4.14) with $i=0$, and (4.8), we need the following simple fact. If X, Y, and Z are elements of an algebra such that

$$[X,[X,[X,Y]_{q^2}]]_{q^{-2}}=0,\quad [X,[X,[X,Z]_{q^2}]]_{q^{-2}}=0,\quad [Y,Z]_{q^2}=0$$

then they satisfy

$$[[X,[X,Y]_{q^{-2}}],[X,[X,Z]_{q^{-2}}]]_{q^2}=0.$$

□

C. Isomorphism *f*

Now we can prove the following proposition:

Proposition 7: (1) There exists an automorphism f of $\mathcal{U}'$ determined by

$$f\upsilon=\tilde{h},\quad f\tilde{h}=\eta\upsilon\sigma.$$

The inverse f^{-1} is given by $\eta f\eta$.

(2) The automorphism f and the $\mathcal{B}$ action in Corollary 2 satisfy

$$f(x\cdot u)=\overline{x}\cdot f(u)\quad (x\in\mathcal{B},u\in\mathcal{U}').$$

Proof: Define elements $\mathbf{x}^{\pm}_{i,k}$ and $\mathbf{k}_i$ $(i=0,1,\ k=0,\pm 1)$ of $\mathcal{U}'$ by

$$\begin{aligned}&\mathbf{x}^{\pm}_{1,k}=(-1)^k\overline{\mathcal{Y}^{\mp k}}x^{\pm}_{1,0},\quad \mathbf{k}_1=k_1,\\ &\mathbf{x}^{\pm}_{0,k}=(-1)^k\overline{Q}\mathbf{x}^{\pm}_{1,k},\quad \mathbf{k}_0=\overline{Q}\mathbf{k}_1.\end{aligned}\tag{4.38}$$

The explicit expressions are

$$\begin{aligned}&\mathbf{x}^{\pm}_{1,0}=x^{\pm}_{1,0},\quad \mathbf{k}_1=k_1,\\ &\mathbf{x}^+_{1,-1}=x^-_{0,0}k_0,\quad \mathbf{x}^+_{1,1}=-\frac{1}{[2]}[[x^+_{0,0},x^+_{1,0}]_{q^{-2}},x^+_{1,0}],\\ &\mathbf{x}^+_{0,0}=x^-_{1,-1}k_1C,\quad \mathbf{k}_0=C^{-1}k_1^{-1},\\ &\mathbf{x}^+_{0,1}=x^+_{0,-1},\quad \mathbf{x}^+_{0,-1}=-\frac{1}{[2]}[x^-_{1,0},[x^-_{1,0},x^-_{0,-1}]_{q^2}]k_0k_1^2C,\\ &\mathbf{x}^{\mp}_{i,k}=q^{\mp 2\delta_{i0}}\zeta\mathbf{x}^{\pm}_{i,-k}.\end{aligned}\tag{4.39}$$

and it is easy to show that they satisfy

$$\mathbf{x}^{\pm}_{1,k}=h(x^{\pm}_k),\quad \mathbf{k}_1=h(k).\tag{4.40}$$

Using the above, we can show that the mapping

$$x_{i,k}^{\pm} \mapsto \mathbf{x}_{i,k}^{\pm}, \quad k_i \mapsto \mathbf{k}_i, \quad C \mapsto k_0 k_1 (= h(C)), \tag{4.41}$$

defines a homomorphism $f : B \to \mathcal{U}'$. We omit the details. The remaining claims of (1) and (2) are proven as in Ref. 4. □

From Eqs. (4.39) and (4.41), we can easily obtain the following corollary.

Corollary 3: (*of the proof*)

The automorphism f satisfies the following identities:

(1) $f\zeta = \zeta f$;
(2) $f\gamma_{a^{-1}} = \delta_a f$.

The Hausdorff entropic moment problem

E. Romera,[a] J. C. Angulo, and J. S. Dehesa
Departamento de Física Moderna and Instituto ''Carlos I'' de Física Teórica y Computacional, Universidad de Granada, E-18071, Granada, Spain

(Received 2 January 2001; accepted for publication 5 February 2001)

Our aim in this paper is twofold. First, to find the necessary and sufficient conditions to be satisfied by a given sequence of real numbers $\{\omega_n\}_{n=0}^{\infty}$ to represent the ''entropic moments'' $\int_{[0,a]}[\rho(x)]^n dx$ of an unknown non-negative, decreasing and differentiable (*a.e.*) density function $\rho(x)$ with a finite interval support. These moments are called entropic moments because they are closely connected with various information entropies (Renyi, Tsallis, ...). Second, we outline an efficient method for the reconstruction of the density function from the knowledge of its first N entropic moments. © *2001 American Institute of Physics.*
[DOI: 10.1063/1.1360711]

I. INTRODUCTION

The problem of moments[1,2] asks when a given sequence of complex numbers may be represented as the moments around the origin of a non-negative measure, defined on the line (Hamburger), on a half-line (Stieltjes), on a finite interval (Hausdorff) or on the unit circumference (the trigonometric moment problem).

This is a classical topic in analysis which has illuminated an extraordinary number of scientific subjects from both standpoints, theoretical and applied. Indeed, it has facilitated many developments[3] in function theory, in functional analysis, in spectral representations of operators, in Fourier analysis as well as in probability and statistics. Also, it has numerous applications not only in approximation theory, in numerical mathematics and for the prediction of stochastic processes, but also in linear prediction, in inverse scattering, in digital filtering and for the determination of rigorous relationships among physical quantities of many-particle systems within the framework of the density functional theory as well as in the design of algorithms for simulating physical systems. The latter should not surprise anybody since the own terminology ''problem of moments'' was taken by Stieltjes from Mechanics. Moreover, he used very often physical concepts (mass, stability, electrostatic properties, ...) in solving analytical problems.[1,4]

In this paper, we shall focus our attention on the problem of entropic moments, which differs from the ordinary moment problem above mentioned in that it does not consider the moments-around-the-origin of a density function $\rho(x)$ defined by

$$\mu_n = \int_K x^n \rho(x) dx, \tag{1}$$

but the quantities

$$\omega_n = \int_K [\rho(x)]^n dx, \tag{2}$$

which are called frequency moments of $\rho(x)$, $x \in K$, in probability and statistics.[5–9] The study of these quantities was initiated by Yule following a suggestion of Pearson. Then Sichel[6,7] usefully employed them for the fitting of certain frequency curves. It happens that estimators based on

[a]Electronic mail: eromera@ugr.es

frequency moments are, at times, much better than the ordinary moment estimates. Moreover, the frequency moments are fairly efficient in the range where the ordinary moments are very inefficient.[10] This is so in some cases where the range K is unlimited and the density is poorly known.[8]

It is interesting to remark that the frequency moments ω_n are location independent when $K=\mathbb{R}$ (Hamburger case); that is, two densities differing only in location have identical frequency moments. In these cases, the location parameter can be provided by the mode, the median or any other appropriate quantity.[9]

We shall call the quantities ω_n the ''entropic'' moments of the density function $\rho(x)$, because they are closely connected to the so-called Renyi and Tsallis entropies of $\rho(x)$ defined[11,12] by

$$S_q^R := \frac{1}{1-q}\ln\int_K [\rho(x)]^q\,dx; \quad q>0, \quad q\neq 1, \quad \int_K \rho(x)dx=1, \tag{3}$$

and

$$S_q^T := \frac{1}{q-1}\left[1-\int_K [\rho(x)]^q\,dx\right]; \quad q>0, \quad q\neq 1, \quad \int_K \rho(x)dx=1, \tag{4}$$

respectively. The entropic adjective allows us to identify more appropriately the moments ω_n from the other type of moments[8] (moments around the origin, central moments, factorial moments, absolute moments, ...) of a frequency distribution.

In addition, the entropic moments ω_α have various physical meanings depending on the nature of the associated density function ρ (charge density, momentum density, ...). Indeed, they characterize some density functionals which describe certain physical quantities of fundamental and/or experimentally accessible character such as, up to a constant factor, the Thomas–Fermi kinetic energy ($\omega_{5/3}$), the Dirac exchange energy ($\omega_{4/3}$) and the electron average density (ω_2) of the many-electron systems; see, e.g., Ref. 24.

This paper has a twofold aim. First we solve the Hausdorff entropic moment problem in Sec. II, which allows us to characterize a density function by means of its entropic moments. Then, in Sec. III, we describe a practical procedure to reconstruct the density from its entropic moments.

II. THE HAUSDORFF ENTROPIC MOMENT PROBLEM

Let $K=[0,a]$ with $a>0$, and $\mathcal{M}(K)$ the set of real density functions $f(x)$ bounded on K and such that $f(0)=1$ and $f(a)=0$. We have obtained the following result for this set of functions.

Theorem 1: *The necessary and sufficient conditions which the given sequence of positive numbers $\omega_0,\omega_1,\ldots,\omega_n,\ldots$, must satisfy in order that a positive, decreasing and differentiable (a.e.) density function $f(x), x\in K$, having these entropic moments (2) may exist, are given by*

$$\Sigma^k \frac{\omega_{m+1}}{m+1}\geqslant 0 \quad \text{and} \quad \Sigma^k\omega_m\geqslant 0, \tag{5}$$

for $k,m=0,1,2,\ldots$, and being

$$\Sigma^k\omega_m=\omega_m-\binom{k}{1}\omega_{m+1}+\ldots+(-1)^k\omega_{m+k}.$$

Proof: Let us first prove the sufficiency condition. For convenience we adopt the notations

$$\mu_m\equiv\frac{\omega_{m+1}}{m+1}, \quad \nu_m\equiv\omega_m; \quad m=0,1,2,\ldots,$$

so that $\nu_m = m\mu_{m-1}$ for $m=1,2,\ldots$, and $\mu_{-1}\equiv a$. If conditions (5) are fulfilled, the Hausdorff theorem for the ordinary moment problem on the interval $[0,1]$ allows us to state[1] that

$$\exists! z(t)\geqslant 0 \quad \text{on } [0,1], \quad \text{such that } \int_0^1 t^m z(t)\,dt = \nu_m$$

and

$$\exists! g(t)\geqslant 0 \quad \text{on } [0,1], \quad \text{such that } \int_0^1 t^m g(t)\,dt = \mu_m .$$

On the other hand, let us define

$$h(t) = \int_t^1 z(s)\,ds, \quad t\in[0,1].$$

So, $h'(t) = -z(t)$. Moreover, $h(t)$ has the same ordinary moments as $g(t)$; then, they are equal. Thus $g(t)$ is a decreasing function since $g'(t) = -z(t)$. We can define $f(x)$ as its inverse with $x\in[g(1)=0, g(0)=a]$, which will be positive, decreasing and differentiable (*a.e.*). One should realize that in case that $g(t)$ is a constant $c>0$ on some subintervals, this would provoke a jump discontinuity for $f(x)$ in $x=c$ and *vice versa*. Then, it is straightforward to obtain that

$$\int_0^a [f(x)]^m\,dx = \nu_m = \omega_m; \quad m=0,1,2,\ldots \quad .$$

To prove necessity, we define the inverse of $f(x)$ as $h(t)$, $t\in[0,1]$, which is decreasing and differentiable (*a.e.*). A simple change of variable $t=f(x)$ allows us to find the following relationship between the entropic moments of $f(x)$ and the ordinary moments of $h(t)$:

$$m\int_0^a t^m h(t)\,dt = \frac{\omega_{m+1}}{m+1}, \quad m=0,1,2,\ldots \quad .$$

Now we consider the function $z(t) = -h'(t)$, $t\in[0,1]$, and we realize that its ordinary moments are given by ω_m. Then, the direct application of the classical Hausdorff moment above mentioned leads us to the relations (5). □

III. DENSITY RECONSTRUCTION

Associated to any moment problem there exists an inverse problem, namely that of the reconstruction of the corresponding density function. Moreover, in practical purposes we have at our disposal only a finite number of moments. The inverse Hausdorff (ordinary) moment problem (1), that is the determination of the density $\rho(x)$ from the moments around the origin $\{\mu_n\}_{n=0}^{\infty}$, was first proposed by Pafnuty Chebyshev.[13] It is a severely ill-conditioned problem because of the lack of *a priori* information and the large involved numerical instabilities.[14–19] To avoid these instabilities, various regularization methods (Tikhonov, maximum-entropy methods, orthogonal-polynomials based methods,...) have been proposed; see Ref. 16 for a brief survey. The maximum-entropy method has been widely and efficiently used for scientific applications.[16,20–22] It consists in maximizing an entropic functional, and it allows us to find a density estimate which converges to the solution of the problem when the number of the involved moments increases.

Here we shall use a maximum entropy method to solve the inverse Hausdorff entropic moment problem discussed in the previous section when the number of known entropic moments is finite. Based on the proof of Theorem 1, this method first computes the maximum-entropy estimate to the solution $z(t)$ of the inverse Hausdorff problem related to the sequence $\{\mu_n\}_{n=0}^{\infty}$ with $\mu_n \equiv \omega_{n+1}/n+1$. Then, the inverse of the estimated $z(t)$ is the desired approximated solution of

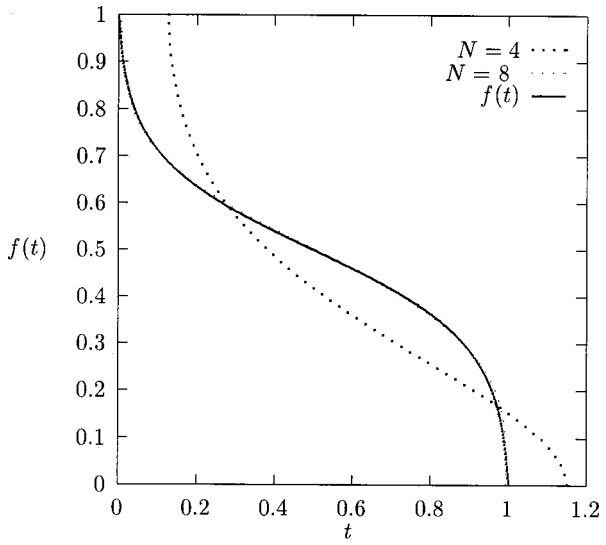

FIG. 1. Graphical representation of the function $f(t)=\frac{1}{2}+\frac{1}{10}\ln[1/(At+B)-1]$ and its estimates from the entropic moments ω_n, $n=0,1,\ldots,N$ with $N=4$ and $N=8$.

our problem. Let us notice that, although we know that the asymptotic ($N\to\infty$) approach to $z(t)$ is inversible, the different Nth estimates to $z(t)$ may not have this property. In the case that there is not any inversible approach, our method is not applicable.

Although we may use any entropic functional to be maximized, we have chosen the Fisher information measure defined by

$$E_f \equiv \int_{[0,a]} \frac{[f'(x)]^2}{f(x)}\,dx,$$

if $f(x)>0$, and $E_f=0$ if $f(x)\equiv 0$. Contrary to other entropic functionals (e.g., Boltzmann–Shannon information entropy, Burg entropy, positive L^2 entropy), this choice has the advantage of taking into account information from the derivative of the function, what is expected to have a strong smoothing effect on the estimate. In doing so we follow the operation lines of Borwein, Limber, and Noll[23] to which we refer for further details.

To illustrate the method and the rate of convergence of the Fisher-information estimates for a function $f(t)$ from its first $N+1$ entropic moments $\omega_n=\int_0^1[f(t)]^n dt$, $n=0,1,\ldots,N$, we have represented in Fig. 1 the exact values and the Fisher estimates for the cases $N=4$ and $N=8$ of a specific function, namely,

$$f(t)=\frac{1}{2}+\frac{1}{10}\ln\left(\frac{1}{At+B}-1\right),\quad \text{with}\quad A=\frac{1}{1+e^5}\quad \text{and}\quad B=\frac{1}{1+e^{-5}}-\frac{1}{1+e^5}. \tag{6}$$

We visually notice in the figure the fast convergence of the method for this function as well as the good precision reached with nine entropic moments.

Finally we show in Fig. 2 the reconstruction of the function $f(t)$ given by (6) from the first $N+1$ moments around the origin $\mu_n=\int_0^1 f(t)t^n\,dt$ in the cases $N=4$ and 8. The comparison of the two figures for the two corresponding Nth cases illustrates that there are functions that may be better estimated or reconstructed from the entropic moments (2) that from the ordinary moments (1). Needless to say that there exist other functions where the reciprocal situation occurs; consider, for example, the inverse of the function $f(t)$ given by Eq. (6).

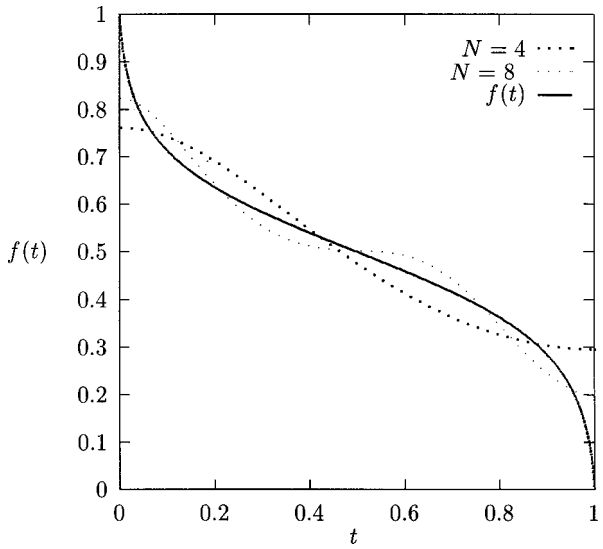

FIG. 2. Graphical representation of the function $f(t)=\frac{1}{2}+\frac{1}{10}\ln[1/(At+B)-1]$ and its estimates from the moments μ_n, $n=0,1,\ldots,N$ with $N=4$ and $N=8$.

IV. CONCLUSIONS

In this paper we have posed the entropic moment problem, whose elements are information measures of an unknown density function. Physically, the entropic moments may also describe some fundamental and/or experimentally accessible quantities of quantum-mechanical systems as already pointed out. Then, we have solved the Hausdorff entropic moment problem by use of some specific properties of the inverse function of the density according to the lines of a recent work of the authors.[24] Moreover, our strategy has let us outline a maximum-entropy method based on an algorithm of minimization of the Fisher information measure[23] which allows one to solve the inverse finite Hausdorff entropic moment problem; that is, to determine the density function from its first few entropic moments. We realize that other density reconstruction procedures which do not include the previous determination of the inverse density function (which would avoid the requirement of decreasing behavior for the density) would be desirable.

(Received 21 July 2000; accepted for publication 23 January 2001)

Asymptotic limits are given for the SU(2) Wigner $\mathcal{D}^j_{mn}$ functions as $j\to\infty$ for three domains of m and n. Similar asymptotic limits are given for the SU(3) Wigner functions of an irrep with highest weight $(\lambda,0)$ as $\lambda\to\infty$. The results are shown to be relevant to the analysis of experiments with quantum interferometers. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1358305]

I. INTRODUCTION

The asymptotic properties of Wigner functions provide a classical interpretation of these functions. This is of interest, for example, for the design and interpretation of quantum interferometer experiments. It is known that a passive optical element which linearly transforms two input modes (beams) into two output modes, is represented by a U(2) transformation.[1–4] Similarly, a three-mode passive element is represented by a U(3) transformation.[5,6] Typically, the input modes in multimode interferometry are minimal uncertainty wave packets containing large photon numbers;[7] as a result, the relevant U(2) and U(3) transformations are close to corresponding classical limits.

We show that different asymptotic limits correspond to different classical situations and/or to group (and Lie algebra) contractions. For example, in one limit, the group SU(2) contracts to the Euclidean group E(2) and, in another, it contracts to the Heisenberg–Weyl group HW(2) of the two-dimensional harmonic oscillator. Thus, the SU(2) Wigner functions, in the corresponding limits, approach those of E(2) and HW(2), respectively. Similar contractions apply to SU(3).

Some asymptotic limits of the SU(2) Wigner functions are known.[8–14] Others can be inferred from known limits of the Jacobi polynomials $\{P_n^{(\alpha,\beta)}\}$ to which the reduced SU(2) Wigner d functions are related.[15] In particular, the following limits can be found in Szegö's book[8] and elsewhere:

$$H_n(x)=n!\lim_{\lambda\to\infty}\lambda^{-n/2}P_n^{(\lambda)}(x/\lambda), \tag{1}$$

$$L_n^{(\alpha)}(x)=\lim_{\beta\to\infty}P_n^{(\alpha,\beta)}(1-2x/\beta), \tag{2}$$

$$J_\alpha(x)=\lim_{n\to\infty}\left(\frac{x}{2n}\right)^\alpha P_n^{(\alpha,\beta)}(\cos(x/n)), \tag{3}$$

where $P_n^{(\lambda)}$ is an ultraspherical polynomial, H_n is a Hermite polynomial, $L_n^{(\alpha)}$ is a Laguerre polynomial, and J_α is a Bessel function. These classical limits hold for any finite value of the variable x. Hence, they give the asymptotic limits of the SU(2) d functions for values of their

[a)]Current address: Faculté Saint-Jean, University of Alberta, 8406 rue Marie-Anne Gaboury, Edmonton, AB T6C 4G9, Canada.

arguments close to 0 or $\pi/2$. For the applications we have in mind, the asymptotic behavior of d functions is required over most of the range of its argument. This is not given by the classical limits of Eqs. (1)–(3). For example, it would be wrong to conclude from Eq. (1) that the value of $P_n^{(\lambda)}(x)$ approaches the value $\lambda^{n/2}H_n(\lambda x)/n!$ as $\lambda\to\infty$.

An example of the kind of classical limit we seek has been derived by Arecchi *et al.*[11] who show that, for finite $l+m$, the values $d^l_{0m}(\beta)$ of the d functions that are proportional to spherical harmonics become proportional to $u_{l+m}(\sqrt{l}(\beta-\pi/2))$ as $l\to\infty$, where u_n is a harmonic oscillator wave function. It is shown in this paper, that asymptotic expressions of this kind can be extended to arbitrary $d^j_{m,\pm(j-\nu)}$ for finite m and ν. We also give asymptotic expressions for d^j_{mn} that apply when m and n are both finite and other expressions that apply when $j\pm m$ and $j\pm n$ are both finite. We also show by numerical examples that the limits are approached rapidly with increasing j and that, between them, the three sets of expressions given cover the range of possible m and n values for a given set of d^j_{mn} functions.

The asymptotic expressions derived for SU(2) in Sec. II are applied, in Sec. III, to give corresponding limits for the SU(3) Wigner functions for an irrep of highest weight $(\lambda,0)$.

Applications to quantum interferometers are considered briefly in the concluding section.

II. LIMITS OF SU(2) WIGNER FUNCTIONS

The complex extension of the SU(2) Lie algebra is spanned by 2×2 complex matrices $\{J_0,J_+,J_-\}$ which satisfy the commutation relations

$$[J_0,J_\pm]=\pm J_\pm,\quad [J_+,J_-]=2J_0. \tag{4}$$

We consider an irrep in which these elements are represented by operators $\{\hat J_0,\hat J_+,\hat J_-\}$ which act, in the usual way, on a $(2j+1)$-dimensional Hilbert space spanned by vectors $\{|jm\rangle; m=-j,\ldots,+j\}$:

$$\begin{aligned}\hat J_0|jm\rangle&=m|jm\rangle,\\ \hat J_\pm|jm\rangle&=\sqrt{(j\mp m)(j\pm m+1)}\ \ |jm\pm1\rangle.\end{aligned} \tag{5}$$

Wigner functions for SU(2) are defined by

$$\mathcal{D}^j_{mn}(\alpha,\beta,\gamma)=e^{-im\alpha}d^j_{mn}(\beta)e^{-in\gamma}, \tag{6}$$

where

$$d^j_{mn}(\beta)=\langle jm|e^{-i\beta\hat J_y}|jn\rangle, \tag{7}$$

with $\hat J_y=-\frac{1}{2}i(\hat J_+-\hat J_-)$, is the so-called reduced Wigner function. We consider asymptotic expressions for $d^j_{mn}(\beta)$ as $j\to\infty$, in three situations: (i) when $n\approx j$ and $m^2\ll j^2$, (ii) when $m\approx n$ and $m^2\approx j^2$, and (iii) when $m\approx n$ and $m^2\ll j^2$.

A. Harmonic oscillator limits

For $n=j$, the reduced Wigner function, d^j_{mn}, is given by

$$d^j_{mj}(\beta)=\sqrt{\frac{(2j)!}{(j+m)!(j-m)!}}(\cos\beta/2)^{j+m}(\sin\beta/2)^{j-m}. \tag{8}$$

The derivative of this function vanishes when $\beta=\beta_m$, where β_m is the semiclassical angle for which $\cos\beta_m=m/j$. For this angle

$$\cos(\beta_m/2)=\sqrt{\frac{j+m}{2j}},\quad \sin(\beta_m/2)=\sqrt{\frac{j-m}{2j}}, \tag{9}$$

and the substitutions

$$\beta-\beta_m=2\phi,\quad j+m=s,\quad j-m=d, \tag{10}$$

give

$$\begin{aligned}(\cos\beta/2)^{j+m}&=(s/2j)^{s/2}[\cos\phi-\sqrt{d/s}\sin\phi]^s,\\ (\sin\beta/2)^{j+m}&=(d/2j)^{d/2}[\cos\phi+\sqrt{s/d}\sin\phi]^d.\end{aligned} \tag{11}$$

Defining the two functions

$$X(\phi)=\cos\phi-\sqrt{\frac{d}{s}}\sin\phi,\quad Y(\phi)=\cos\phi+\sqrt{\frac{s}{d}}\sin\phi, \tag{12}$$

then gives

$$d^j_{mj}(\beta)=\sqrt{\frac{(2j)!}{s!d!}\frac{s^s d^d}{(2j)^{2j}}}X(\phi)^s\,Y(\phi)^d. \tag{13}$$

The functions $X(\phi)$ and $Y(\phi)$ satisfy

$$\frac{dX(\phi)}{d\phi}=-\sqrt{\frac{d}{s}}Y(\phi),\quad \frac{dY(\phi)}{d\phi}=\sqrt{\frac{s}{d}}X(\phi), \tag{14}$$

so that

$$f(\phi)=X(\phi)^sY(\phi)^d \tag{15}$$

satisfies the equation

$$\frac{df}{d\phi}=\sqrt{sd}\frac{X^2-Y^2}{XY}f. \tag{16}$$

For small values of ϕ,

$$\sqrt{sd}\,(X^2-Y^2)\approx-4j\sin\phi\cos\phi,\quad XY\approx\cos^2\phi. \tag{17}$$

Thus

$$\frac{df}{d\phi}\approx-4j\frac{\sin\phi}{\cos\phi}f(\phi), \tag{18}$$

with solution

$$X(\phi)^s\,Y(\phi)^d=f(\phi)\approx(\cos\phi)^{4j}. \tag{19}$$

When $s=j+m$ and $d=j-m$ are both large, the asymptotic expression for the factorials[16]

$$z!\to\sqrt{\frac{2\pi}{z}}e^{-z}z^{z+1}, \tag{20}$$

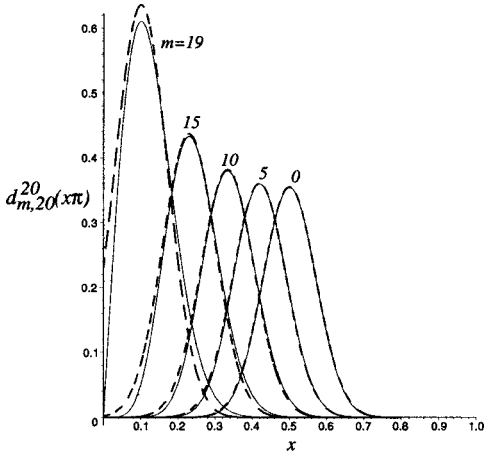

FIG. 1. The reduced Wigner function $d^j_{mj}(x\pi)$ for $j=20$ and various values of m. Exact values are shown as thin continuous lines and asymptotic values, given by Eq. (22), as broken heavy lines.

gives

$$\sqrt{\frac{(2j)!}{s!d!}\frac{s^s d^d}{(2j)^{2j}}} \to \left(\frac{j}{\pi s d}\right)^{1/4}. \tag{21}$$

Combining this expression with Eq. (19) gives the asymptotic expression, for large values of $j+m$ and $j-m$

$$\begin{aligned} d^j_{mj}(\beta) = (-1)^{j-m} d^j_{jm}(\beta) &\to \left(\frac{1}{\sqrt{j\,\pi}\sin\beta_m}\right)^{1/2} [\cos((\beta-\beta_m)/2)]^{4j} \\ &\to \left(\frac{1}{\sqrt{j\,\pi}\sin\beta_m}\right)^{1/2} \exp[-j(\beta-\beta_m)^2/2]. \end{aligned} \tag{22}$$

This asymptotic expression is compared with the exact result for a range of values of m for $j=20$ in Fig. 1. It is seen to be remarkably accurate even for m close to j. It breaks down for $m=\pm j$ but then we have

$$\begin{aligned} d^j_{jj}(\beta) &= [\cos(\beta/2)]^{2j} \to \exp[-j\beta^2/4], \\ d^j_{-jj}(\beta) &= [\sin(\beta/2)]^{2j} \to \exp[-j(\beta-\pi)^2/4]. \end{aligned} \tag{23}$$

These results have a simple classical interpretation. A state with angular momentum j and z component $m=j$ is a minimal uncertainty state. It has a density function $|\psi_{jj}(\theta,\varphi)|^2$ that is independent of φ and concentrated about the $\theta=0$ direction (the z axis). The rate of falloff of the density with increasing angle is indicated by

$$\langle jj|e^{-i\beta\hat{J}_y}|jj\rangle = d^j_{jj}(\beta), \tag{24}$$

which, as seen from Eq. (23), decreases rapidly with increasing β, for large values of j. This is what one would expect from classical mechanics where the angular momentum vector is directed along the z axis when $m=j$. By the same token, a classical angular-momentum vector with z-component m makes an angle β_m with the z axis with $\cos\beta_m = m/j$. Thus, the rotated state $e^{-i\beta_m\hat{J}_y}|jj\rangle$ is expected to have maximum overlap with the state $|jm\rangle$ and conversely the overlap

$$\langle jm|e^{-i\beta\hat{J}_y}|jj\rangle = d^j_{mj}(\beta) \tag{25}$$

is expected to peak at a value of β equal to β_m, as indeed it does.

A significant property of the above asymptotic limits are that they are all simple harmonic oscillator coherent states; i.e., harmonic oscillator ground-state wave functions centered about β_m. We now show that, in the $j\to\infty$ limit, the other d^j_{mn} functions, for m small and $n\approx j$, approach excited harmonic oscillator coherent states.

Consider first the d^l_{0n} function, which for integer values of l, is proportional to a spherical harmonic

$$d^l_{0n}(\theta) = (-1)^n \sqrt{\frac{4\pi}{2l+1}}\, Y_{ln}(\theta,0). \tag{26}$$

For $l\to\infty$, we have, from Eq. (22), the limit

$$d^l_{0l}(\theta)\to\left(\frac{1}{\sqrt{l\pi}}\right)^{1/2} \exp[-l(\theta-\pi/2)^2/2]; \tag{27}$$

which is a harmonic oscillator ground-state wave function centered about $\theta=\pi/2$. Let $n=l-\nu$, so that $\nu\ll l$ when $n\approx l$. Thus, if $\psi_{l\nu}$ denotes the function

$$\psi_{l\nu}(\theta) = (-1)^\nu d^l_{0,l-\nu}(\theta+\pi/2) = (-1)^l \sqrt{\frac{4\pi}{2l+1}}\, Y_{l,l-\nu}(\theta+\pi/2,0), \tag{28}$$

then, in the $l\to\infty$ limit,

$$\psi_{l0}(\theta)\to\left(\frac{1}{\sqrt{l\pi}}\right)^{1/2} e^{-l\theta^2/2} = l^{-1/4} u_0(\sqrt{l}\,\theta), \tag{29}$$

where u_0 is the harmonic oscillator ground-state wave function.

For $l\gg\nu$ and $l\to\infty$, the limits

$$\begin{aligned} \hat{J}_+ Y_{l,l-\nu} &= \sqrt{\nu(2l-\nu+1)}\, Y_{l,l-\nu+1} \to \sqrt{2l\nu}\, Y_{l,l-\nu+1}, \\ \hat{J}_- Y_{l,l-\nu} &= \sqrt{(2l-\nu)(\nu+1)}\, Y_{l,l-\nu-1} \to \sqrt{2l(\nu+1)}\, Y_{l,l-\nu-1}, \end{aligned} \tag{30}$$

imply that the angular momentum raising and lowering operators contract to harmonic oscillator lowering and raising operators, respectively. From the explicit expression for the actions of the $\hat{J}_\pm$ operators on spherical harmonic oscillators, we also have

$$[\hat{J}_\pm Y_{l,l-\nu}](\theta+\pi/2,0) = \left[(l-\nu)\tan\theta \pm \frac{d}{d\theta}\right] Y_{l,l-\nu}(\theta+\pi/2,0) \tag{31}$$

so that, for small θ and $l\gg\nu$,

$$[\hat{J}_\pm Y_{l,l-\nu}](\theta+\pi/2,0) \to \left(l\theta \pm \frac{d}{d\theta}\right) Y_{l,l-\nu}(\theta+\pi/2,0). \tag{32}$$

It follows that, in the $l\to\infty$ limit,

$$\psi_{l,\nu+1}(\theta) = \frac{1}{\sqrt{2l(\nu+1)}}\left(l\theta - \frac{d}{d\theta}\right)\psi_{l\nu}(\theta) = \frac{1}{\sqrt{(\nu+1)}}\,\frac{1}{\sqrt{2}}\left(\sqrt{l}\,\theta - \frac{1}{\sqrt{l}}\,\frac{d}{d\theta}\right)\psi_{l\nu}(\theta), \tag{33}$$

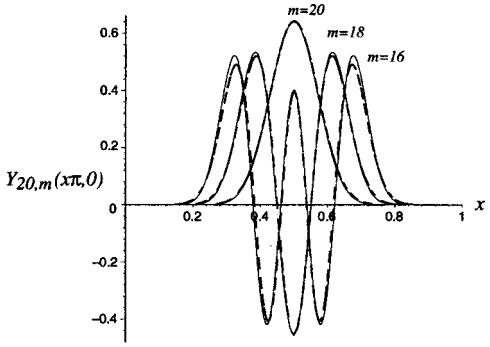

FIG. 2. Spherical harmonics $Y_{20,m}(\theta,\varphi)$ for $m=20$, 18, and 16 plotted as a function of θ for $\varphi=0$. Exact values are shown as fine continuous lines and asymptotic values, given by Eq. (37), as heavy dashed lines.

thereby providing a recursion relation for the $\psi_{l\nu}$ functions. Since ψ_{l0} is a harmonic oscillator ground-state wave function, the recursion relation is easily solved to give

$$\psi_{l\nu}(\theta)\rightarrow l^{-1/4}u_{\nu}(\sqrt{l}\,\theta), \tag{34}$$

where u_{ν} is the harmonic oscillator wave function

$$u_{\nu}(x)=\left(\frac{1}{\sqrt{\pi}2^{\nu}\nu!}\right)^{1/2}H_{\nu}(x)\,e^{-x^2/2} \tag{35}$$

with H_{ν} a Hermite polynomial. Thus, we obtain the asymptotic limit of the Wigner function for $\nu\ll l$ and $l\rightarrow\infty$,

$$d^{l}_{0,l-\nu}(\beta)\rightarrow(-1)^{\nu}l^{-1/4}u_{\nu}(\sqrt{l}\,(\beta-\pi/2)), \tag{36}$$

and the corresponding asymptotic expression for a spherical harmonic

$$Y_{l,m}(\theta,0)=(-1)^{m}\sqrt{\frac{2l+1}{4\pi}}\,d^{l}_{0,m}(\theta)\rightarrow(-1)^{l}\sqrt{\frac{2l+1}{4\pi}}\,l^{-1/4}u_{l-m}(\sqrt{l}(\theta-\pi/2)), \tag{37}$$

when $m\approx l$. The latter expression accords with the result obtained by Arecchi *et al.*[11] after correction for what are presumed to be typographical errors.

The asymptotic expression for Y_{lm} is compared with exactly computed spherical harmonics for $l=20$ and $m=20$, 18, and 16, in Fig. 2. Comparisons for $l=20$ and $m=19$, 17, and 15 are

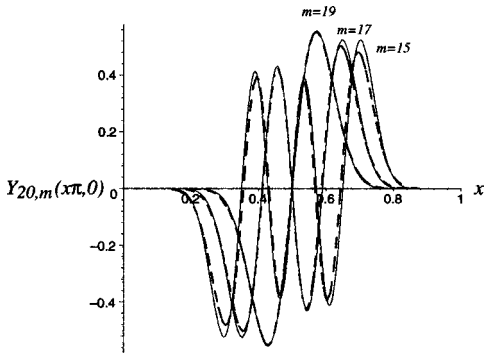

FIG. 3. Spherical harmonics $Y_{20,m}(\theta,\varphi)$ for $m=19$, 17, and 15 plotted as a function of θ for $\varphi=0$. Exact values are shown as fine continuous lines and asymptotic values, given by Eq. (37), as heavy dashed lines.

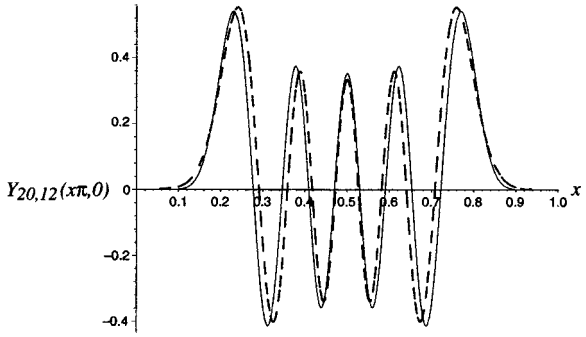

FIG. 4. The spherical harmonic $Y_{20,12}(\theta,\varphi)$. Exact values are shown as a fine continuous line and asymptotic values, given by Eq. (37) multiplied by a factor $1/\sqrt{\sin\theta}$, are shown as a heavy dashed line.

shown in Fig. 3. Even for finite values of l the agreement is excellent for θ near $\pi/2$. It deteriorates as θ approaches 0 or π. This can be attributed in part to the fact that the volume element for the spherical harmonics is $\sin\theta d\theta$ whereas the corresponding harmonic oscillator wave functions are normalized without the factor $\sin\theta$. Thus, one expects better agreement if the asymptotic expressions are renormalized by a factor $1/\sqrt{\sin\theta}$. This indeed turns out to be the case. Figure 4 shows that, with this adjustment, quite good agreement can be obtained even for $m=12$.

A similar analysis can be applied to other d functions. For $l\gg\nu$ and $j\to\infty$, the equations

$$\begin{aligned}\hat{J}_+ d^j_{m,j-\nu} &= \sqrt{\nu(2j-\nu+1)}\, d^j_{m,j-\nu+1} \to \sqrt{2j\nu}\, d^j_{m,j-\nu+1},\\ \hat{J}_- d^j_{m,j-\nu} &= \sqrt{(2j-\nu)(\nu+1)}\, d^j_{m,j-\nu-1} \to \sqrt{2j(\nu+1)}\, d^j_{m,j-\nu-1}\end{aligned} \tag{38}$$

imply that $\hat{J}_\pm$ can again be interpreted as harmonic oscillator raising and lowering operators. Starting with the shifted harmonic oscillator wave functions

$$d^j_{mj}(\beta) \to \left(\frac{1}{\sqrt{j\pi}\sin\beta_m}\right)^{1/2} e^{-j(\beta-\beta_m)^2/2} = \left(\frac{1}{\sqrt{j}\sin\beta_m}\right)^{1/2} u_0(\sqrt{j}\,(\beta-\beta_m)), \tag{39}$$

we find, for small values of ν that

$$d^j_{m,j-\nu}(\beta) \to (-1)^\nu \left(\frac{1}{\sqrt{j}\sin\beta_m}\right)^{1/2} u_\nu(\sqrt{j}(\beta-\beta_m)) \tag{40}$$

as $j\to\infty$, and

$$d^j_{j-\nu,m}(\beta) \to (-1)^{j-m} \left(\frac{1}{\sqrt{j}\sin\beta_m}\right)^{1/2} u_\nu(\sqrt{j}(\beta-\beta_m)). \tag{41}$$

Similarly, from the symmetry properties of the d-functions,

$$d^j_{m,\nu-j}(\beta) \to (-1)^{j+m} \left(\frac{1}{\sqrt{j}\sin\beta_m}\right)^{1/2} u_\nu(\sqrt{j}\,(\beta-\beta_m)) \tag{42}$$

and

$$d^j_{\nu-j,m}(\beta) \to (-1)^\nu \left(\frac{1}{\sqrt{j}\sin\beta_m}\right)^{1/2} u_\nu(\sqrt{j}(\beta-\beta_m)). \tag{43}$$

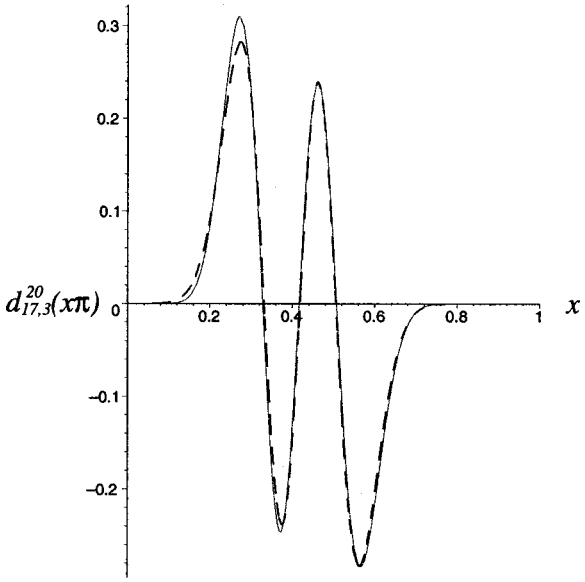

FIG. 5. The Wigner function $d^{20}_{17,3}$ compared to its asymptotic harmonic oscillator limit. Exact values are shown as a fine continuous line and asymptotic values, given by Eq. (41), as a dashed line.

Figure 5 shows the function $d^{20}_{17,3}$ compared to its asymptotic harmonic oscillator limit. Again further improvement in the limit can be obtained by dividing the asymptotic expression by $\sqrt{\sin\beta}$.

B. The SU(2)→HW(2) contraction

The above harmonic oscillator limits for d^j_{mn} apply when m is small and n is close to $\pm j$ (or vice versa). They are at their best, for finite values of j, when β is close to the appropriate semiclassical angle and deteriorate as β approaches 0 or π. When $m\approx n$, there are other asymptotic limits which derive from contractions of the SU(2) Lie algebra.

We consider here a HW(2) contraction of SU(2) which follows from the Holstein–Primakoff[17] representation in which the angular momenta are realized as the operators

$$\hat{J}_0=j-\hat{n},\quad \hat{J}_+=\sqrt{2j-\hat{n}}\,a,\quad \hat{J}_-=a^\dagger\sqrt{2j-\hat{n}}; \tag{44}$$

$a^\dagger$ and a are the raising and lowering operators of a simple harmonic oscillator with commutation relation

$$[a,a^\dagger]=I, \tag{45}$$

and $\hat{n}=a^\dagger a$ is the number operator. In this representation, a state $|jm\rangle$ becomes a simple harmonic oscillator state $|\mu\rangle$ having $\mu=j-m$ quanta, for which $\hat{n}|\mu\rangle=\mu|\mu\rangle$. It follows that, when acting on states for which m is close to some value $\bar{m}\gg -j$, the angular momentum operators approach the asymptotic forms

$$\hat{J}_0\to jI-a^\dagger a,\quad \hat{J}_+\to\sqrt{j+\bar{m}}\,a,\quad \hat{J}_-\to\sqrt{j+\bar{m}}\,a^\dagger. \tag{46}$$

Likewise $\hat{J}_y\to\frac{1}{2}i\sqrt{j+\bar{m}}(a^\dagger-a)$ and, for m and n both close to $\bar{m}=\frac{1}{2}(m+n)$,

$$d^j_{mn}(\beta)\to\langle j-m|e^{(1/2)\,\beta\sqrt{j+\bar{m}}\,(a^\dagger-a)}|j-n\rangle. \tag{47}$$

The last expression, derived from a contraction limit of the SU(2) Lie algebra, is at its best for small values of β and for m and n far from $-j$. A similar expression holds for m and n far from $+j$.

From the identity

$$e^{\alpha(a^\dagger - a)} = e^{\alpha a^\dagger} e^{-\alpha^2/2} e^{-\alpha a}, \tag{48}$$

it follows that

$$\begin{aligned}\langle \mu | e^{\alpha(a^\dagger - a)} | \nu \rangle &= \frac{1}{\sqrt{\mu!\,\nu!}} \langle 0 | a^\mu e^{\alpha a^\dagger} e^{-\alpha a} (a^\dagger)^\nu | 0 \rangle e^{-\alpha^2/2} \\ &= \frac{1}{\sqrt{\mu!\,\nu!}} \langle 0 | (a+\alpha)^\mu (a^\dagger - \alpha)^\nu | 0 \rangle e^{-\alpha^2/2} \\ &= \sqrt{\frac{\nu!}{\mu!}} \sum_p \binom{\mu}{p} \frac{(-\alpha^2)^{\nu-p}}{(\nu-p)!} \alpha^{\mu-\nu} e^{-\alpha^2/2}.\end{aligned} \tag{49}$$

Now recall[16] that, for $\mu - \nu > -1$,

$$\sum_p \binom{\mu}{p} \frac{(-\alpha^2)^{\nu-p}}{(\nu-p)!} = L_\nu^{(\mu-\nu)}(\alpha^2), \tag{50}$$

where $L_\nu^{(\mu-\nu)}$ is a generalized Laguerre polynomial. Thus, for $\mu - \nu > -1$, we obtain the identity

$$\langle \mu | e^{\alpha(a^\dagger - a)} | \nu \rangle = \sqrt{\frac{\nu!}{\mu!}}\, \alpha^{\mu-\nu} L_\nu^{(\mu-\nu)}(\alpha^2)\, e^{-\alpha^2/2} \tag{51}$$

and, with $\alpha = \frac{1}{2}\beta\sqrt{j+(m+n)/2}$, we obtain the asymptotic expression

$$d^j_{mn}(\beta) \to \sqrt{\frac{(j-n)!}{(j-m)!}} (a_{jmn}\beta)^{n-m} L_{j-n}^{(n-m)}(a_{jmn}^2\beta^2)\, e^{-a_{jmn}^2\beta^2/2}, \quad \text{for } m \leqslant n, \tag{52}$$

where $a_{jmn} = \frac{1}{2}\sqrt{(2j+m+n)/2}$. This expression is valid for small values of β and $j+\overline{m} \gg n-m$. For $m \geqslant n$ and $j+\overline{m} \gg m-n$, the identity $d^j_{mn}(\beta) = d^j_{nm}(-\beta)$ gives

$$d^j_{mn}(\beta) \to \sqrt{\frac{(j-m)!}{(j-n)!}} (-a_{jmn}\beta)^{m-n} L_{j-m}^{(m-n)}(a_{jmn}^2\beta^2)\, e^{-a_{jmn}^2\beta^2/2}, \quad \text{for } m \geqslant n. \tag{53}$$

The asymptotic expression (53) for $d^{20}_{18,15}$ is compared with the exactly computed function in Fig. 6.

Other expressions are obtained from the symmetry properties of the d^j_{mn} functions. For example, an asymptotic expression for m close to $-j$ and n close to $+j$ is obtained from the identity

$$d^j_{mn}(\beta) = (-1)^{j-m} d^j_{-mn}(\beta + \pi). \tag{54}$$

These limits are approached for the largest range of β when m and n are similar and close to $\pm j$. This is because the SU(2)$\to$HW(2) contraction is valid to within some specified accuracy over the largest span of $\{|jm\rangle\}$ states when $|m|$ is close to j.

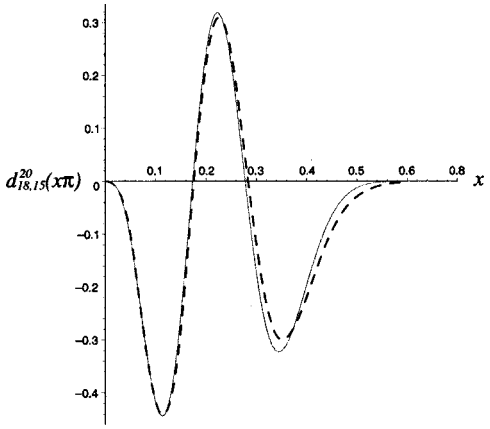

FIG. 6. The reduced Wigner function $d^{20}_{18,15}(x\pi)$. Exact values are shown as a fine continuous line and asymptotic values, given by Eq. (53), as a dashed line.

C. The SU(2)→E(2) contraction limit

For m close to n and both far from $\pm j$, a more appropriate contraction is the one in which SU(2)→E(2), where E(2) is the Euclidean group of transformations of the two-dimensional plane. This limit is obtained from the observation that, as $j^2-m^2\to\infty$, the right-hand sides of Eq. (5) approach values given by

$$\hat{J}_0|jm\rangle = m\,|jm\rangle,$$
$$\hat{J}_\pm|jm\rangle \to \sqrt{j^2-m^2}\,|jm\pm1\rangle = j\sin\beta_m\,|jm\pm1\rangle. \tag{55}$$

With $\cos\beta_{\overline{m}}=\overline{m}/j$, $\sqrt{j^2-\overline{m}^2}=j\sin\beta_{\overline{m}}$, and, for values of m close to $\overline{m}$, the SU(2) states are represented, in the $j^2-\overline{m}^2\to\infty$ limit, as functions on the circle, i.e., $|jm\rangle\to\psi_m$ with

$$\psi_m(\theta) = \frac{e^{im\theta}}{\sqrt{2\pi}}, \tag{56}$$

and the angular momentum operators are represented

$$\hat{J}_0 \to -i\frac{d}{d\theta}, \quad \hat{J}_\pm \to j\sin\beta_{\overline{m}} e^{\pm i\theta}. \tag{57}$$

It follows that $\hat{J}_y\to j\sin\beta_{\overline{m}}\sin\theta$ and, for m and n both close to $\overline{m}=\frac{1}{2}(m+n)$,

$$d^j_{mn}(\beta)\to\frac{1}{2\pi}\int_0^{2\pi} e^{-i(m-n)\theta}\,e^{-i\beta j\sin\beta_{\overline{m}}\sin\theta}\,d\theta = (-1)^{m-n}J_{m-n}(j\beta\sin\beta_{\overline{m}}), \tag{58}$$

where J_m is a Bessel function and we have used a known[16,10] integral expression for J_m. This expression is a generalization to finite values of the d-function's argument of the known asymptotic limit, for infinitesimal β/j,[12,13]

$$\lim_{j\to\infty} d^j_{mn}(\beta/j) = (-1)^{m-n}J_{m-n}(\beta). \tag{59}$$

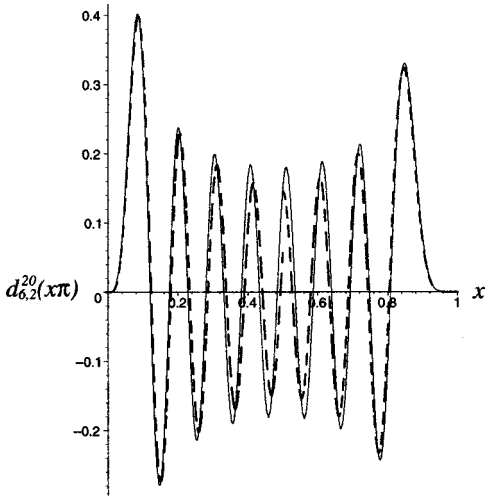

FIG. 7. The reduced Wigner function $d^{20}_{6,2}(x\pi)$. Exact values are shown as a fine continuous line and asymptotic values as a dashed heavy line. For $0<x<0.5$ the asymptotic values are given by Eq. (58) and for $0.5<x<1$ they are given by Eq. (61).

The expressions given by Eq. (57) are the limits of a general coherent state representation of the SU(2) algebra carried by functions on the circle. Note, however, that since it is derived from a contraction of the Lie algebra, it is only valid locally. Thus, the asymptotic limit of Eq. (58) is only expected to be good for relatively small values of β and $m-n$.

The asymptotic expression (58) for the reduced Wigner function $d^{20}_{6,2}$ is compared, for $0\leqslant\beta\leqslant\pi/2$, with the exact function in Fig. 7. It is seen to be an excellent approximation for small values of its argument. It is appropriate to restrict the use of Eq. (58) to $0\leqslant\beta\leqslant\pi/2$ because, for β in the range $\pi/2\leqslant\beta\leqslant\pi$, a better limit is obtained by use of the identity

$$d^j_{mn}(\beta)=(-1)^{j+m}d^j_{m,-n}(\pi-\beta), \tag{60}$$

which, for $\pi/2\leqslant\beta\leqslant\pi$, leads to the asymptotic expression

$$d^j_{mn}(\beta)\rightarrow(-1)^{j+m}J_{m+n}(j(\beta-\pi)\sin\beta_{(m-n)/2}). \tag{61}$$

Comparison of the exact expression with Eq. (58) for β in the range $0\leqslant\beta\leqslant\pi/2$ and with (61) for $\pi/2\leqslant\beta\leqslant\pi$ is shown in Fig. 7.

For small values of β it turns out that a remarkable improvement in accuracy is obtained by the *ad hoc* replacement $j\rightarrow j+1/2$ in the argument of the Bessel function of the asymptotic expression. This replacement has also been found by other authors to increase numerical accuracy; to first order, it can be regarded as a substitution of j by $\sqrt{j(j+1)}$, which is the appropriate classical value of the magnitude of the angular momentum. The modified estimate is compared with the exact expression for $d^{20}_{6,2}(x\pi)$ in Fig. 8.

The above results have a natural interpretation in terms of an SU(2)→E(2) contraction. If we define

$$x=\frac{1}{2j\sin\beta_{\bar{m}}}(J_++J_-),\quad y=-\frac{i}{2j\sin\beta_{\bar{m}}}(J_+-J_-),\quad J_z=J_0, \tag{62}$$

we obtain the commutation relations

$$[J_z,x]=\mathrm{i}y,\quad [J_z,y]=-\mathrm{i}x,\quad [x,y]=\frac{i}{j^2\sin^2\beta_{\bar{m}}}J_z\rightarrow 0, \tag{63}$$

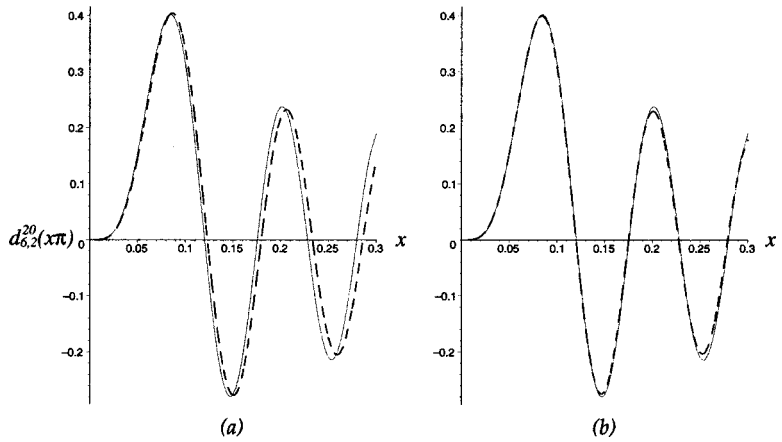

FIG. 8. The reduced Wigner function $d^{20}_{6,2}(x\pi)$. Exact values are shown as a fine continuous line and asymptotic values as a dashed line. The asymptotic expression in (a) is given by Eq. (58) and in (b) it is given by (58) with j replaced by $j+1/2$.

as $j \sin \beta_{\overline{m}} \to \infty$. They are the commutation relations of the infinitesimal generators of the Euclidean group in two dimensions. Moreover, the SU(2) representation with highest weight j contracts to a representation of the Euclidean group E(2) in which

$$x \to \cos\theta, \quad y \to \sin\theta, \quad J_z \to -i\frac{d}{d\theta}. \tag{64}$$

This contraction limit makes sense geometrically if one considers the manifold of SU(2) coherent states in the Hilbert space generated by applying all SU(2) transformations to a fixed state $|jm\rangle$. This manifold has the geometry of a sphere and one knows that small neighborhoods on a sphere look locally like neighborhoods of a two-dimensional Euclidean plane.

D. Summary of SU(2) Wigner function limits in a U(2) basis

In summarizing the limits for d^j_{mn}, it is useful to characterize the value of m as being central if $m \approx 0$ and extremal if $m \approx \pm j$. The various asymptotic limits for d^j_{mn} are then at their best in the following situations: (i) Harmonic oscillator limits; when m is central and n is extremal, (ii) HW(2) contraction limits; when m and n are both extremal, and (iii) E(2) contraction limits; when m and n are both central.

For application of the above results to SU(3), the results are most usefully expressed in a U(2) weight basis in which a state $|jm\rangle$ is identified with the U(2) weight state $|sd\rangle$ with $s=j+m$ and $d=j-m$. A reduced SU(2) Wigner function is then expressed

$$d^j_{mn}(\beta) = \langle s_1 d_1 | \beta | s_2 d_2 \rangle, \tag{65}$$

with $s_1=j+m$, $d_1=j-m$, $s_2=j+n$, and $d_2=j-n$. The above asymptotic limits are summarized as follows.

1. Harmonic oscillator limits

If m is central then $s=j+m \gg 0$ and $d=j-m \gg 0$ in the $j \to \infty$ limit. Equations (40) and (41) are then expressed

$$\langle sd|\beta|2j-n,n\rangle = (-1)^{n-d}\langle 2j-n,n|\beta|sd\rangle \to \delta_{s+d,2j}\,(-1)^n \left(\frac{j}{sd}\right)^{1/4} u_n(\sqrt{j}(\beta-\beta_{sd})), \tag{66}$$

where $j=(s+d)/2$ and

$$\cos\beta_{sd}=\frac{s-d}{s+d} \quad \Rightarrow \quad \sin\beta_{sd}=\sqrt{\frac{sd}{j}}, \tag{67}$$

and u_n is given by Eq. (35). This limit is valid for small values of n.

2. HW(2) contraction limits

If m and n are both close to j, then $s_1 \gg d_1$ and $s_2 \gg d_2$. Substituting the expression

$$a^2_{jmn}=\tfrac{1}{8}(2j+m+n)=\tfrac{1}{8}(s_1+s_2) \tag{68}$$

for a^2_{jmn} into Eqs. (52) and (53) then gives, in this limit,

$$\langle s_1 d_1|\beta|s_2 d_2\rangle \to \delta_{s_1+d_1,s_2+d_2}\sqrt{\frac{d_2!}{d_1!}}\left(\frac{\beta}{2}\sqrt{\frac{s_1+s_2}{2}}\right)^{s_2-s_1} L_{d_2}^{(s_2-s_1)}(\beta^2(s_1+s_2)/8)e^{-\beta^2(s_1+s_2)/16} \tag{69}$$

for $s_1 \leqslant s_2$ and

$$\langle s_1 d_1|\beta|s_2 d_2\rangle \to \delta_{s_1+d_1,s_2+d_2}\sqrt{\frac{d_1!}{d_2!}}\left(-\frac{\beta}{2}\sqrt{\frac{s_1+s_2}{2}}\right)^{s_1-s_2} L_{d_1}^{(s_1-s_2)}(\beta^2(s_1+s_2)/8)e^{-\beta^2(s_1+s_2)/16} \tag{70}$$

for $s_1 \geqslant s_2$.

If m is close to j and n is close to $-j$, so that $s_1 \gg d_1$ and $s_2 \ll d_2$, the identity $d^j_{mn}(\beta)=(-1)^{j-n}d^j_{m,-n}(\beta+\pi)$ interchanges the coefficients s_2 and d_2 to give

$$\langle s_1 d_1|\beta|s_2 d_2\rangle=(-1)^{d_2}\langle s_1 d_1|\beta+\pi|d_2 s_2\rangle \tag{71}$$

for which Eqs. (69) and (70) continue to apply. Similarly, for $s_1 \ll d_1$ and $s_2 \gg d_2$,

$$\langle s_1 d_1|\beta|s_2 d_2\rangle=(-1)^{d_1}\langle d_1 s_1|\beta+\pi|s_2 d_2\rangle, \tag{72}$$

and, for $s_1 \ll d_1$ and $s_2 \ll d_2$, the identity $d^j_{mn}(\beta)=(-1)^{m-n}d^j_{-m,-n}(\beta)$ gives

$$\langle s_1 d_1|\beta|s_2 d_2\rangle=(-1)^{s_1-s_2}\langle d_1 s_1|\beta|d_2 s_2\rangle. \tag{73}$$

3. E(2) contraction limits

When m and n are both small and j is large, $s_1 \gg 0$, $d_1 \gg 0$, $s_2 \gg 0$, and $d_2 \gg 0$. Replacing $2j\sin\beta_{\overline{m}}$ by $\sqrt{(s_1+s_2)(d_1+d_2)}$ in Eq. (58) then gives

$$\langle s_1 d_1|\beta|s_2 d_2\rangle \to \delta_{s_1+d_1,s_2+d_2}(-1)^{s_1-s_2}J_{s_1-s_2}(\sqrt{(s_1+s_2)(d_1+d_2)}\beta/2). \tag{74}$$

III. $(\lambda,0)$ SU(3) WIGNER FUNCTIONS

The complex extension of the U(3) Lie algebra is spanned by 3×3 matrices $\{C_{ij}\}$ which satisfy the commutation relations

$$[C_{ij},C_{kl}]=\delta_{jk}C_{il}-\delta_{il}C_{kj}. \tag{75}$$

The $SU(3)\subset U(3)$ subalgebra is spanned by the subset $\{C_{11}-C_{22},C_{22}-C_{33},C_{ij};i\neq j\}$.

A. Representations of the U(3) Lie algebra

We consider a U(3) irrep of highest weight $(\lambda,0,0)$ in which the $\{C_{ij}\}$ matrices are represented by operators $\{\hat{C}_{ij}\}$ on a Hilbert space spanned by a weight basis $\{|\nu\rangle\}$. The components of a weight $\nu\equiv(\nu_1,\nu_2,\nu_3)$ are the eigenvalues of the $\hat{C}_{ii}$ operators, viz.

$$\hat{C}_{ii}|\nu\rangle=\nu_i|\nu\rangle, \quad i=1,2,3, \tag{76}$$

and sum to give $\nu_1+\nu_2+\nu_3=\lambda$. For a $(\lambda,0,0)$ irrep, the weight basis states are defined uniquely, to within phase factors. Such an irrep restricts to an SU(3) irrep of highest weight $(\lambda,0)$.

The basis states $\{|\nu\rangle\}$ are conveniently realized within the space of a three-dimensional harmonic oscillator. Thus, if $\{c_i^\dagger,c_i;i=1,2,3\}$ denotes a triplet of harmonic oscillator raising and lowering operators, the (orthonormal) weight states are

$$|\nu\rangle=\frac{(c_1^\dagger)^{\nu_1}(c_2^\dagger)^{\nu_2}(c_3^\dagger)^{\nu_3}}{\sqrt{\nu_1!\,\nu_2!\,\nu_3!}}|0\rangle, \quad \nu_1+\nu_2+\nu_3=\lambda, \tag{77}$$

where $|0\rangle$ is the harmonic oscillator lowest-weight (vacuum) state, and the U(3) operators are expressed

$$\hat{C}_{ij}=a_i^\dagger a_j\,. \tag{78}$$

It follows that the $i\neq j$ operators act on the weight states according to the equation

$$\hat{C}_{ij}|\nu_1,\nu_2,\nu_3\rangle=\sqrt{(\nu_i+1)\nu_j}\sum_{\nu'}\delta_{\nu_i',\nu_i+1}\delta_{\nu_j',\nu_j-1}\delta_{\nu_k',\nu_k}|\nu_1',\nu_2',\nu_3'\rangle, \tag{79}$$

for $i\neq k\neq j$.

The above (weight) basis reduces the $SU(2)_{23}\subset SU(3)$ subalgebra spanned by the I-spin operators

$$\hat{I}_+=\hat{C}_{23}, \quad \hat{I}_-=\hat{C}_{32}, \quad \hat{I}_0=\tfrac{1}{2}(\hat{C}_{22}-\hat{C}_{33}). \tag{80}$$

The corresponding I-spin quantum numbers are identified by setting

$$\nu_1=\lambda-2I, \quad \nu_2=I+N, \quad \nu_3=I-N, \tag{81}$$

and writing

$$|\nu\rangle\equiv|IN\rangle=\frac{(c_1^\dagger)^{\lambda-2I}}{\sqrt{(\lambda-2I)!}}\frac{(c_2^\dagger)^{I+N}(c_3^\dagger)^{I-N}}{\sqrt{(I+N)!(I-N)!}}|0\rangle. \tag{82}$$

The action of the $SU(2)_{23}$ operators is then expressed in the usual way by

$$\hat{I}_0|IN\rangle=N|IN\rangle, \quad \hat{I}_\pm|IN\rangle=\sqrt{(I\mp N)(I\pm N+1)}\,|IN\pm1\rangle. \tag{83}$$

Similarly, the $SU(2)_{12}$ and $SU(2)_{13}$ subalgebras are spanned by U-spin and V-spin operators, respectively,

$$\hat{U}_+=\hat{C}_{12}, \quad \hat{U}_-=\hat{C}_{21}, \quad \hat{U}_0=\tfrac{1}{2}(\hat{C}_{11}-\hat{C}_{22}), \tag{84}$$

$$\hat{V}_+=\hat{C}_{13}, \quad \hat{V}_-=\hat{C}_{31}, \quad \hat{V}_0=\tfrac{1}{2}(\hat{C}_{11}-\hat{C}_{33}). \tag{85}$$

Thus, we have the identifications $|\nu\rangle\equiv|IN\rangle\equiv|UM\rangle\equiv|VP\rangle$ with

$$\nu_1=\lambda-2I=U+M=V+P,$$

$$\nu_2=I+N=U-M=\lambda-2V, \tag{86}$$

$$\nu_3=I-N=\lambda-2U=V-P.$$

It is important to note that, for a $(\lambda,0)$ irrep, the above weight basis becomes identical to the basis $\{|jIN\rangle\}$ constructed, for a general $SU(3)\supset SU(2)_{23}$ irrep, by VCS methods[18] and used in the computation of SU(3) Clebsch–Gordan coefficients.[19] [For a $(\lambda,0)$ irrep the extra label j in $\{|jIN\rangle\}$ is redundant and can be dropped.] The bases are identified explicitly as follows. First observe that the highest weight state of the SU(3) $(\lambda,0)$ irrep is the state

$$|\phi\rangle=\frac{(c_1^\dagger)^\lambda}{\sqrt{\lambda!}}|0\rangle. \tag{87}$$

Thus, with the observation that

$$(c_1)^{\lambda-\nu_1}(c_1^\dagger)^\lambda|0\rangle=\frac{\lambda!}{\nu_1!}(c_1^\dagger)^{\nu_1}|0\rangle, \tag{88}$$

we obtain the expression of the $U(3)\supset SU(3)$ basis states

$$|\nu\rangle=\sqrt{\frac{\nu_1!}{\lambda!\,\nu_2!\,\nu_3!}}(\hat{C}_{21})^{\nu_2}(\hat{C}_{31})^{\nu_3}|\phi\rangle. \tag{89}$$

This basis is identical to that of VCS theory,

$$|IN\rangle=\sqrt{\frac{(\lambda-2I)!}{\lambda!}}\frac{(\hat{C}_{21})^{I+N}(\hat{C}_{31})^{I-N}}{\sqrt{(I+N)!(I-N)!}}|\phi\rangle, \tag{90}$$

with the relationship between ν and IN given by Eq. (81). It is also identical to the Gel'fand basis $\{|\nu I\rangle\}$ used for a $(\lambda,0)$ irrep in Ref. 20 with $I=\frac{1}{2}(\nu_2+\nu_3)$ (cf. appendix of Ref. 19).

B. $(\lambda,0)$ Wigner functions for finite λ

As shown recently,[20] an SU(3) element can be expressed as a product of SU(2) subgroup elements in the form

$$g(\alpha_1,\beta_1,\gamma_1,\alpha_2,\beta_2,\alpha_3,\beta_3,\gamma_3)=R_{23}(\alpha_1,\beta_1,\gamma_1)R_{12}(\alpha_2,\beta_2,\alpha_2)R_{23}(\alpha_3,\beta_3,\gamma_3). \tag{91}$$

This is a particularly convenient parametrization because, in the above basis, the matrices of the $SU(2)_{23}$ rotations are given by standard SU(2) Wigner functions; viz.

$$\langle I'N'|\hat{R}_{23}(\alpha,\beta,\gamma)|IN\rangle=\delta_{I'I}\mathcal{D}^I_{N'N}(\alpha,\beta,\gamma) \tag{92}$$

or, in terms of weights,

$$\langle\nu|\hat{R}_{23}(\alpha,\beta,\gamma)|\mu\rangle=\delta_{\nu_1,\mu_1}\mathcal{D}^{(\lambda-\nu_1)/2}_{(\nu_2-\nu_3)/2,(\mu_2-\mu_3)/2}(\alpha,\beta,\gamma). \tag{93}$$

Similarly, for the $SU(2)_{12}$ matrix elements

$$\langle\mu|\hat{R}_{12}(\alpha,\beta,\gamma)|\mu'\rangle=\delta_{\mu_3,\mu_3'}\mathcal{D}^{(\lambda-\mu_3)/2}_{(\mu_1-\mu_2)/2,(\mu_1'-\mu_2')/2}(\alpha,\beta,\gamma). \tag{94}$$

The expressions are simplified by writing the SU(2) Wigner functions in a U(2) basis [cf. Eq. (65)] in which

$$\mathcal{D}^{j}_{mn}(\alpha,\beta,\gamma)=\langle j+m,j-m|\beta|j+n,j-n\rangle e^{-i(m\alpha+n\gamma)}. \tag{95}$$

Then

$$\begin{aligned}\langle \nu|\hat{R}_{23}(\alpha,\beta,\gamma)|\mu\rangle&=\delta_{\nu_1,\mu_1}\langle \nu_2\nu_3|\beta|\mu_2\mu_3\rangle e^{-i[(\nu_2-\nu_3)\alpha+(\mu_2-\mu_3)\gamma]/2},\\ \langle \mu|\hat{R}_{12}(\alpha,\beta,\gamma)|\mu'\rangle&=\delta_{\mu_3,\mu_3'}\langle \mu_1\mu_2|\beta|\mu_1'\mu_2'\rangle e^{-i[(\mu_1-\mu_2)\alpha+(\mu_1'-\mu_2')\gamma]/2},\end{aligned} \tag{96}$$

and

$$\begin{aligned}&D^{(\lambda,0)}_{\nu,\nu'}(\alpha_1,\beta_1,\gamma_1,\alpha_2,\beta_2,\alpha_3,\beta_3,\gamma_3)\\ &\quad=e^{-i[(\nu_2-\nu_3)\alpha_1+(\lambda-\nu_1)\gamma_1+2(\nu_1+\nu_1'-\lambda)\alpha_2+(\lambda-\nu_1')\alpha_3+(\nu_2'-\nu_3')\gamma_3]/2}\\ &\qquad\times\sum_{n=0}^{n_{\max}}e^{in(\gamma_1-\alpha_2+\alpha_3)}\langle \nu_2\nu_3|\beta_1|\lambda-\nu_1-n,n\rangle\\ &\qquad\times\langle \nu_1,\lambda-\nu_1-n|\beta_2|\nu_1',\lambda-\nu_1'-n\rangle\langle \lambda-\nu_1'-n,n|\beta_3|\nu_2'\nu_3'\rangle,\end{aligned} \tag{97}$$

where $n_{\max}=\mathrm{Min}(\lambda-\nu_1,\lambda-\nu_1')$.

Expressions for the SU(3) Wigner functions of other irreps are given in Ref. 20.

IV. $(\lambda,0)$ WIGNER FUNCTIONS FOR $\lambda\to\infty$

Wigner functions for an SU(3) $(\lambda,0)$ irrep have a number of asymptotic expressions which can be obtained by substituting the corresponding limits for the SU(2) Wigner functions into Eq. (97). The appropriate limits depend on the location of the weights ν and ν' in the weight diagram. A weight can be characterized as extremal if it is close to a vertex, or central, if it is far from a vertex.

A. Limits of $(\lambda,0)$ Wigner functions for ν central and ν' close to a highest weight

When ν' is of highest weight, i.e., $\nu'=(\lambda,0,0)$, the expression for the SU(3) Wigner function of Eq. (97) reduces to

$$\begin{aligned}D^{(\lambda)}_{\nu,(\lambda)}(\alpha_1,\beta_1,\gamma_1,\alpha_2,\beta_2,\alpha_3,\beta_3,\gamma_3)&=e^{-i[(\nu_2-\nu_3)\alpha_1+(\lambda-\nu_1)\gamma_1+2\nu_1\alpha_2]/2}\\ &\quad\times\langle \nu_2\nu_3|\beta_1|\lambda-\nu_1,0\rangle\langle \nu_1,\lambda-\nu_1|\beta_2|\lambda 0\rangle,\end{aligned} \tag{98}$$

where, to simplify the notation, we have identified the weights $(\lambda)\equiv(\lambda,0)\equiv(\lambda,0,0)$. The reduced SU(2) Wigner functions in this expression are of the type with asymptotic limits given by Eq. (22). Thus, we obtain

$$\begin{aligned}D^{(\lambda)}_{\nu,(\lambda)}(\alpha_1,\beta_1,\gamma_1,\alpha_2,\beta_2,\alpha_3,\beta_3,\gamma_3)&\to\left(\frac{\lambda}{4\pi^2\nu_1\nu_2\nu_3}\right)^{1/4}e^{-i[(\nu_2-\nu_3)\alpha_1+(\nu_2+\nu_3)\gamma_1+2\nu_1\alpha_2]/2}\\ &\quad\times e^{-[(\nu_2+\nu_3)(\beta_1-\beta_{\nu_2\nu_3})^2+\lambda(\beta_2-\beta_{\nu_1,\nu_2+\nu_3})^2]/4}\end{aligned} \tag{99}$$

with $\beta_{\nu_2\nu_3}$ defined by Eq. (35).

More generally, for ν' close to the highest weight, the use of the harmonic oscillator limits of Eq. (66) give

$$
\begin{aligned}
&D^{(\lambda)}_{\nu,\nu'}(\alpha_1,\beta_1,\gamma_1,\alpha_2,\beta_2,\alpha_3,\beta_3,\gamma_3)\\
&\quad\to e^{-i[(\nu_2-\nu_3)\alpha_1+(\lambda-\nu_1)\gamma_1+2(\nu_1+\nu_1'-\lambda)\alpha_2+(\lambda-\nu_1')\alpha_3+(\nu_2'-\nu_3')\gamma_3]/2}\\
&\qquad\times(-1)^{\lambda-\nu_1'}\left(\frac{\lambda-\nu_1}{4\nu_1\nu_2\nu_3}\right)^{1/4}\sum_{n=0}^{\lambda-\nu_1'}e^{in(\gamma_1-\alpha_2+\alpha_3)}\left(\frac{\lambda-n}{\lambda-\nu_1-n}\right)^{1/4}\\
&\qquad\times u_n\left(\sqrt{\tfrac{1}{2}(\lambda-\nu_1)}\,(\beta_1-\beta_{\nu_2,\nu_3})\right)\\
&\qquad\times u_{2I-n}\left(\sqrt{\tfrac{1}{2}(\lambda-n)}(\beta_2-\beta_{\nu_1,\lambda-\nu_1-n})\right)d^I_{I-n,N}(\beta_3),
\end{aligned}
\tag{100}
$$

where $I=\frac{1}{2}(\nu_2'+\nu_3')$ and $N=\frac{1}{2}(\nu_2'-\nu_3')$. It can be seen that this expression reduces to that of Eq. (99) when $I=0$ and $\nu'=(\lambda,0,0)$.

This limiting expression for the $\lambda=60$ SU(3) Wigner function is compared with the exact expression for a range of values of some of its arguments in Fig. 9.

B. Limits of $(\lambda,0)$ Wigner functions for ν and ν' both close to vertices

If ν and ν' are both close to the highest weight, then the first and last SU(2) Wigner functions in Eq. (97) are those of small-dimensional SU(2) irreps, while, for the middle function, the limit given by Eqs. (69) and (70) applies. Thus, for $\nu_1'\geqslant\nu_1$,

$$
\begin{aligned}
&D^{(\lambda)}_{\nu,\nu'}(\alpha_1,\beta_1,\gamma_1,\alpha_2,\beta_2,\alpha_3,\beta_3,\gamma_3)\\
&\quad\to\sum_{n=0}^{\lambda-\nu_1'}e^{-i(\nu_1+\nu_1'-\lambda+n)\alpha_2}\sqrt{\frac{(\lambda-\nu_1'-n)!}{(\lambda-\nu_1-n)!}}\left(\frac{\beta_2}{2}\sqrt{\frac{\nu_1+\nu_1'}{2}}\right)^{\nu_1'-\nu_1}\\
&\qquad\times\mathcal{D}^{(\lambda-\nu_1)/2}_{(\nu_2-\nu_3)/2,(\lambda-\nu_1-2n)/2}(\alpha_1,\beta_1,\gamma_1)\,\mathcal{D}^{(\lambda-\nu_1')/2}_{(\lambda-\nu_1'-2n)/2,(\nu_2'-\nu_3')/2}(\alpha_3,\beta_3,\gamma_3)\\
&\qquad\times L^{(\nu_1'-\nu_1)}_{\lambda-\nu_1'-n}(\beta_2^2(\nu_1+\nu_1')/8)e^{-\beta_2^2(\nu_1+\nu_1')/16}
\end{aligned}
\tag{101}
$$

and, for $\nu_1'\leqslant\nu_1$,

$$
\begin{aligned}
&D^{(\lambda)}_{\nu,\nu'}(\alpha_1,\beta_1,\gamma_1,\alpha_2,\beta_2,\alpha_3,\beta_3,\gamma_3)\\
&\quad\to\sum_{n=0}^{\lambda-\nu_1}e^{-i(\nu_1+\nu_1'-\lambda+n)\alpha_2}\sqrt{\frac{(\lambda-\nu_1-n)!}{(\lambda-\nu_1'-n)!}}\left(-\frac{\beta_2}{2}\sqrt{\frac{\nu_1+\nu_1'}{2}}\right)^{\nu_1-\nu_1'}\\
&\qquad\times\mathcal{D}^{(\lambda-\nu_1)/2}_{(\nu_2-\nu_3)/2,(\lambda-\nu_1-2n)/2}(\alpha_1,\beta_1,\gamma_1)\,\mathcal{D}^{(\lambda-\nu_1')/2}_{(\lambda-\nu_1'-2n)/2,(\nu_2'-\nu_3')/2}(\alpha_3,\beta_3,\gamma_3)\\
&\qquad\times L^{(\nu_1-\nu_1')}_{\lambda-\nu_1-n}(\beta_2^2(\nu_1+\nu_1')/8)e^{-\beta_2^2(\nu_1+\nu_1')/16}.
\end{aligned}
\tag{102}
$$

This limiting expression for the $\lambda=60$ SU(3) Wigner function is compared with the exact expression for a range of values of some of its arguments in Fig. 10.

If ν is near $(\lambda,0,0)$ and ν' near $(0,\lambda,0)$, then the matrix element $\langle\nu_2\nu_3|\beta_1|\lambda-\nu_1-n,n\rangle$ in Eq. (97) is a reduced Wigner function for a low-dimensional SU(2) irrep. The second matrix element $\langle\nu_1,\lambda-\nu_1-n|\beta_2|\nu_1',\lambda-\nu_1'-n\rangle$ is one for which $\nu_1\gg\lambda-\nu_1-n$ and $\nu_1'\ll\lambda-\nu_1'-n$. Thus, by Eq. (71), it is re-expressed in the form

$$
\langle\nu_1,\lambda-\nu_1-n|\beta_2|\nu_1',\lambda-\nu_1'-n\rangle=(-1)^{\lambda-\nu_1'-n}\langle\nu_1,\lambda-\nu_1-n|\beta_2+\pi|\lambda-\nu_1'-n,\nu_1'\rangle
\tag{103}
$$

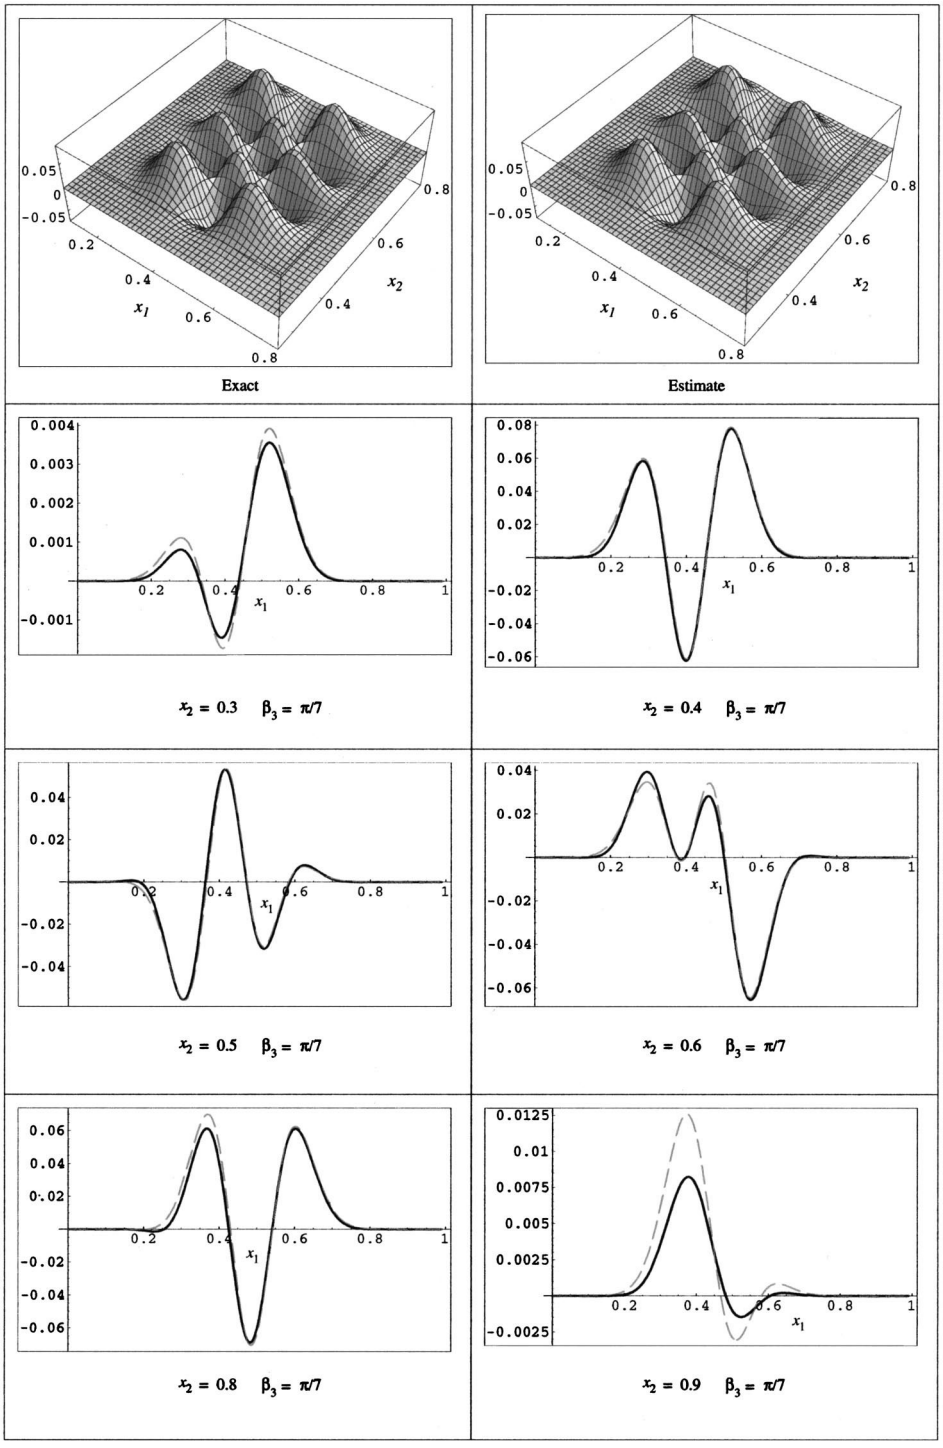

FIG. 9. The SU(3) Wigner function $\mathcal{D}^{(\lambda)}_{\nu,\nu'}(0,\beta_1=x_1\pi,0,0,\beta_2=x_2\pi,0,\beta_3=\pi/7,0)$ for $(\lambda)=(60,0,0)$, $\nu=(24,21,15)$, $\nu'=(54,4,2)$. The top graphs show, respectively, the surfaces for the exact function and its estimate using Eq. (100). The sequence of slices provide a detailed comparison between the exact function (full line) and its estimate (dashed line) for the sequence of values of $\beta_2=0.3\pi,0.4\pi,\ldots,0.8\pi$.

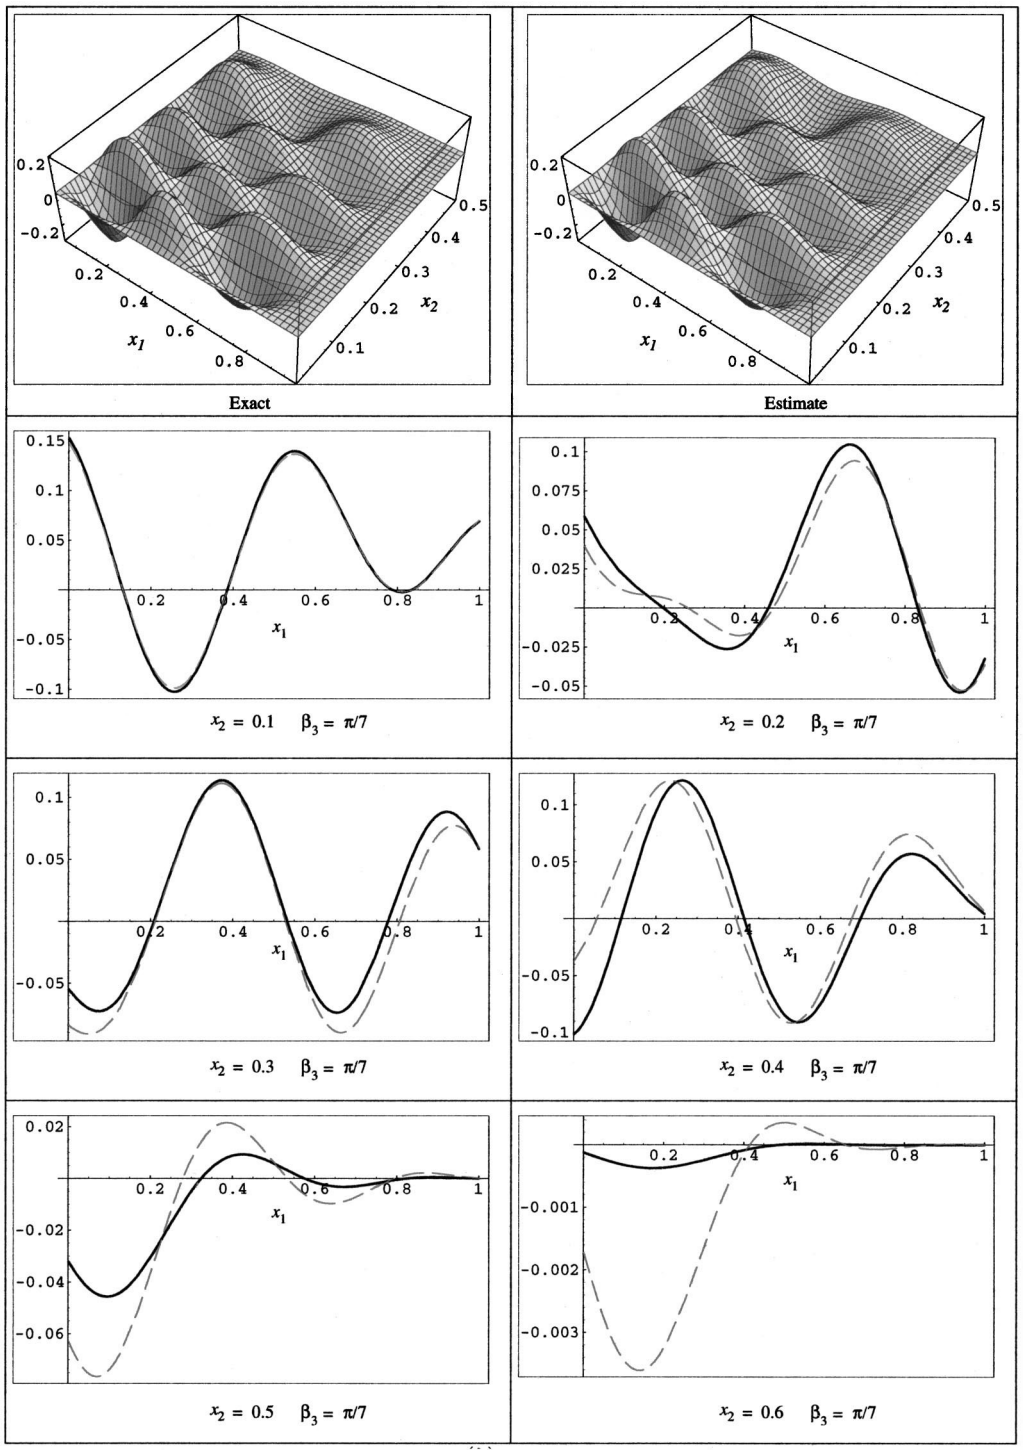

FIG. 10. The SU(3) Wigner function $\mathcal{D}^{(\lambda)}_{\nu,\nu'}(0,\beta_1=x_1\pi,0,0,\beta_2=x_2\pi,0,\beta_3=\pi/7,0)$ for $(\lambda)=(60,0,0)$, $\nu=(52,6,2)$, $\nu'=(50,7,3)$. The top graphs show, respectively, the surfaces for the exact function and its estimate using Eq. (102). The sequences of slices provide a detailed comparison between the exact function (full line) and its estimate (dashed line) for the sequence of values of $\beta_2=0.1\,\pi,0.2\,\pi,\ldots,0.6\,\pi$.

for which Eqs. (69) and (70) apply. The third matrix element, $\langle \lambda-\nu_1'-n,n|\beta_3|\nu_2'\nu_3'\rangle$, is one for which $\lambda-\nu_1'-n \gg n$ and $\nu_2' \gg \nu_3'$ and for which Eqs. (69) and (70) apply directly.

Asymptotic expressions are similarly found for ν and ν' near other vertices. Thus, for instance, if ν and ν' are both close to $(0,\lambda,0)$, then each of the three SU(2) Wigner functions in Eq. (97) will be approximated by the limit given by Eqs. (69) or (70).

C. $(\lambda,0)$ Wigner functions for ν and ν' both central

If ν and ν' are both central weights of a $(\lambda,0)$ irrep and $\lambda\to\infty$, then the E(2) limit of Eq. (74) applies. If we replace the SU(2) matrix elements in Eq. (97) by their E(2) limits, we obtain

$$\begin{aligned} D^{(\lambda)}_{\nu,\nu'}&(\alpha_1,\beta_1,\gamma_1,\alpha_2,\beta_2,\alpha_3,\beta_3,\gamma_3) \\ &\to e^{-i[(\nu_2-\nu_3)\alpha_1+(\lambda-\nu_1)\gamma_1+2(\nu_1+\nu_1'-\lambda)\alpha_2+(\lambda-\nu_1')\alpha_3+(\nu_2'-\nu_3')\gamma_3]/2} \\ &\quad\times\sum_{n=0}^{n_{\max}} e^{in(\gamma_1-\alpha_2+\alpha_3)} J_{\nu_3-n}\left(\sqrt{(2\nu_2+\nu_3-n)(\nu_3+n)}\,\beta_1/2\right) \\ &\quad\times J_{\nu_1'-\nu_1}\left(\sqrt{(\nu_1+\nu_1')(2\lambda-\nu_1-\nu_1'-2n)}\,\beta_2/2\right) \\ &\quad\times J_{n-\nu_3'}\left(\sqrt{(2\nu_2'+\nu_3'-n)(\nu_3'+n)}\,\beta_3/2\right). \end{aligned} \tag{104}$$

It is important to note that this expression presumes the E(2) limit to be applicable for all values of n that occur in the summation. The following considerations show that this presumption is valid for sufficiently small values of β_1 and β_3.

Consider the matrix element

$$\langle \nu_2\nu_3|\beta_1|\lambda-\nu_1-n,n\rangle = d^{(\lambda-\nu_1)/2}_{(\nu_2-\nu_3)/3,(\lambda-\nu_1-2n)/2}(\beta_1). \tag{105}$$

For $\nu_2=\nu_3=\lambda/3$, for example, this matrix element becomes

$$d^{\lambda/3}_{0,\lambda/3-n}(\beta_1) = \sqrt{\frac{12\pi}{2\lambda+3}}\,Y_{\lambda/3,\lambda/3-n}(\beta_1,0). \tag{106}$$

For small β_1, it takes its largest values when $n\approx\lambda/3$. Moreover, Figs. 2 and 3 show that, for $\lambda=60$, the value of this matrix element becomes negligible for $\beta_1<\pi/5$ as n approaches 0. A similar result holds for the matrix element $\langle \lambda-\nu_1'-n,n|\beta_3|\nu_2'\nu_3'\rangle$ for $\nu_2'\approx\nu_3'\approx\lambda/3$.

The limiting expression (104) for the $\lambda=150$ SU(3) Wigner function is compared with the exact expression for a range of values of some of its arguments in Fig. 11.

V. APPLICATIONS TO QUANTUM INTERFEROMETRY

Quantum interferometers are important in quantum information theory and for precision measurements of phases shifts, e.g., for the detection of gravitational waves.[21] The accuracies obtainable with such devices are naturally expressed in terms of Wigner functions—SU(2) Wigner functions for two-channel interferometers and SU(3) Wigner functions for three-channel interferometers.

A. Two-channel interferometry

A two-channel interferometer is an optical device, such as a beam splitter or a Mach–Zehnder interferometer, that transforms a two-channel input state of the electromagnetic field into a two-channel output state. If the device consists of passive optical elements that conserve photon number (i.e., the sum of the photon numbers in the output channels equals the sum in the input channels), then it is characterized by a U(2) transformation.[1]

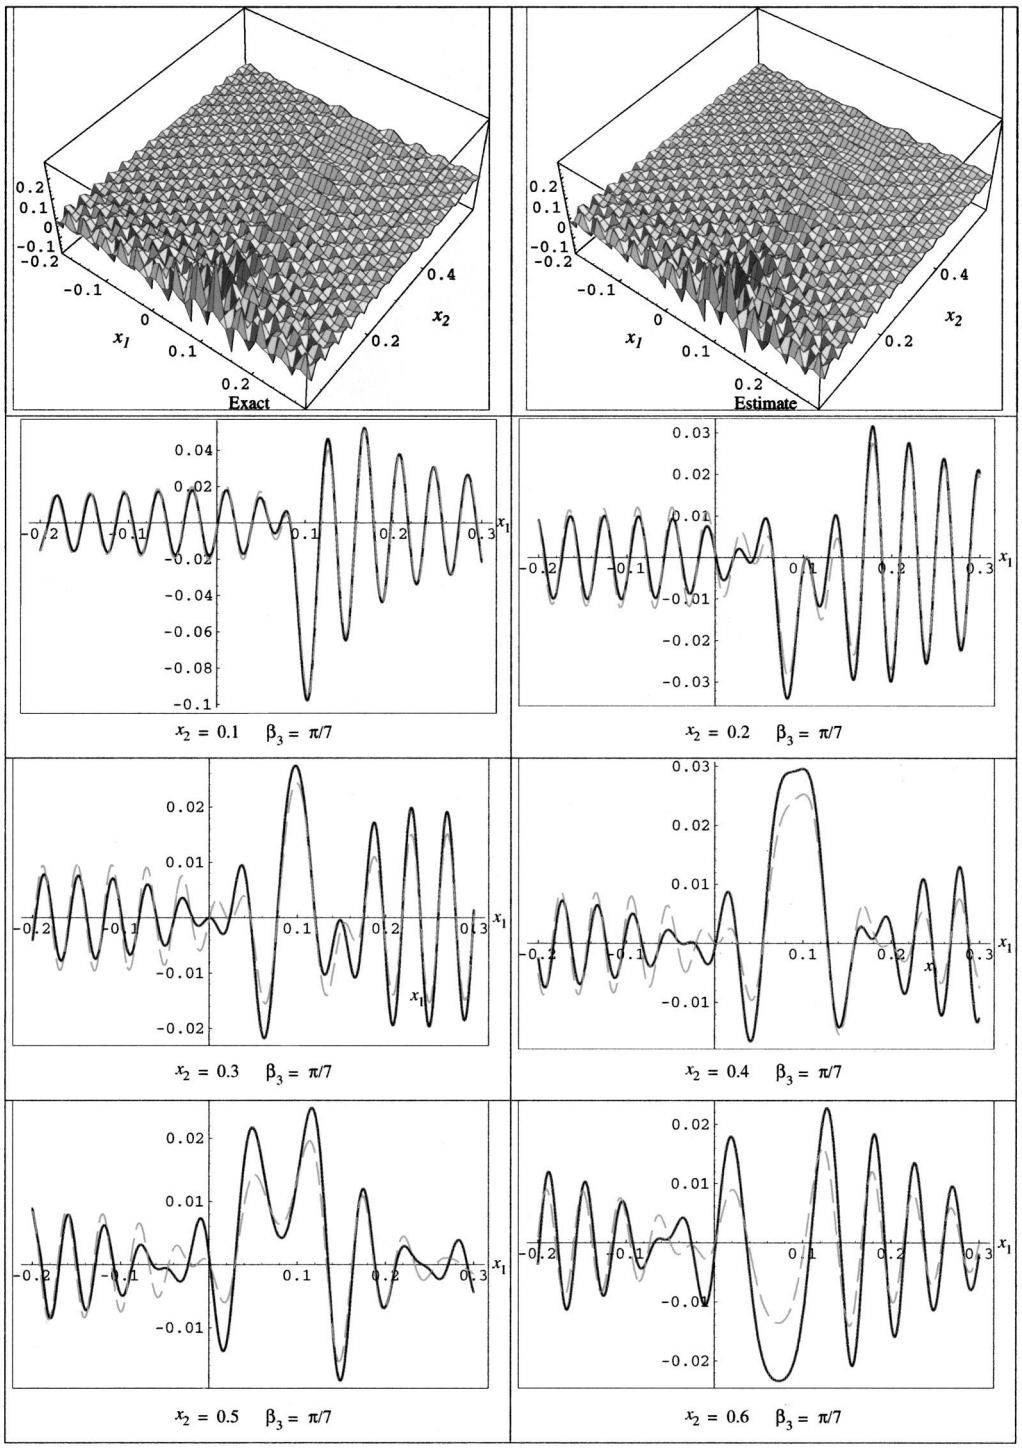

FIG. 11. The SU(3) Wigner function $\mathcal{D}^{(\lambda)}_{\nu,\nu'}(0,\beta_1=x_1\pi,0,0,\beta_2=x_2\pi,0,\beta_3=-\pi/9,0)$ for $(\lambda)=(150,0,0)$, $\nu=(46,44,49)$, $\nu'=(47,52,51)$. The top graphs show, respectively, the surfaces for the exact function and its estimate using Eq. (104). The sequences of slices provide a detailed comparison between the exact function (full line) and its estimate (dashed line) for the sequence of values of $\beta_2=0.1\,\pi,0.2\,\pi,\ldots,0.6\,\pi$.

In a classical description of two-channel interferometry, the electromagnetic field is represented by a two-component complex vector $\alpha=(\alpha_1,\alpha_2)$, where α_1 and α_2 are the amplitudes of the fields in the two channels. The interferometer effects a U(2) transformation

$$\alpha^{\text{in}}\rightarrow\alpha^{\text{out}}=\omega\alpha^{\text{in}}, \tag{107}$$

where

$$\omega=\begin{pmatrix} u & v \\ -v^* & u^* \end{pmatrix}, \quad \text{with } |u|^2+|v|^2=1, \tag{108}$$

is a U(2) matrix. For example, a beam splitter effects a U(2) transformation with $u=e^{i\phi_{\text{tr}}}\cos\theta$ and $v=e^{i\phi_{\text{ref}}}\sin\theta$ where ϕ_{tr} is the phase shift due to transmission, ϕ_{ref} is the phase shift due to reflection, and $\cos\theta$ is the amplitude transmissivity of the beam splitter.[2] A lossless two-path interferometer, such as a Mach–Zehnder interferometer, is also described by a U(2) transformation; in effect a lossless two-path interferometer is equivalent to a number-conserving beam splitter.

In quantum mechanics, a closest-to-classical two-channel field is a two-component coherent state of a two-dimensional harmonic oscillator

$$|\alpha\rangle\equiv|(\alpha_1,\alpha_2)\rangle=e^{\alpha_1 a_1^\dagger-\alpha_1^* a_1}e^{\alpha_2 a_2^\dagger-\alpha_2^* a_2}|0\rangle, \tag{109}$$

where $|0\rangle$ is the harmonic oscillator ground state and $a_1^\dagger$ and $a_2^\dagger$ are harmonic oscillator raising operators. The raising operators transform under $\omega\in$ U(2) according to the equation

$$\begin{aligned} a_1^\dagger&\rightarrow\hat{U}(\omega)a_1^\dagger\hat{U}^\dagger(\omega)=ua_1^\dagger-v^*a_2^\dagger, \\ a_2^\dagger&\rightarrow\hat{U}(\omega)a_2^\dagger\hat{U}^\dagger(\omega)=u^*a_2^\dagger+va_1^\dagger, \end{aligned} \tag{110}$$

from which it follows that $\hat{U}(\omega)|\alpha\rangle=|\omega\alpha\rangle$ and that the transformation of a coherent input is given by

$$|\alpha^{\text{in}}\rangle\rightarrow|\alpha^{\text{out}}\rangle=|\omega\alpha^{\text{in}}\rangle. \tag{111}$$

These relationships express the correspondence between classical and quantal coherent states. More importantly, they show that an interferometer transforms any input state by a map $|\psi\rangle\rightarrow\hat{U}(\omega)|\psi\rangle$. An arbitrary input state $|\psi\rangle$ is a superposition $\Sigma_{jm}c_{jm}|jm\rangle$ of basis states defined in a Schwinger representation by

$$|jm\rangle=\frac{(a_1^\dagger)^{j+m}(a_2^\dagger)^{j-m}}{\sqrt{(j+m)!(j-m)!}}|0\rangle, \quad m=-j,\ldots,+j. \tag{112}$$

Such states are identified with fields having a fixed number, $2j$, of photons; an input state $|jm\rangle$ is one with $j+m$ photons in channel one and $j-m$ in channel two. Thus the transformation of an arbitrary state is expressed in terms of SU(2) Wigner functions

$$\hat{U}(\omega):|\psi\rangle\rightarrow|\psi'\rangle=\hat{U}(\omega)|\psi\rangle=\sum_{jmn}c_{jm}|jn\rangle\,\mathcal{D}^j_{nm}(\omega), \quad \omega\in\text{SU(2)}. \tag{113}$$

It is interesting to note that a minimal uncertainty state entering channel one

$$|(\alpha,0)\rangle=e^{\alpha a_1^\dagger-\alpha^* a_1}|0\rangle, \tag{114}$$

is a coherent state of the Heisenberg–Weyl group, whereas the state

$$\hat{U}(\omega)|jm=j\rangle \tag{115}$$

is a coherent state of the group U(2), according to the generalized definition of coherent states by Perelomov and others.[22] Thus a state emerging from a quantum interferometer when the input is the state $|(\alpha,0)\rangle$ is a combined Heisenberg–Weyl–U(2) coherent state

$$|\omega(\alpha,0)\rangle=\hat{U}(\omega)e^{\alpha a_1^\dagger-\alpha^* a_1}|0\rangle. \tag{116}$$

Some of the interesting questions in quantum interferometry concern the measurement of phase shifts of specially prepared quantum input states. Consider, for example, the phase shift

$$\alpha_1\rightarrow e^{-i\theta}\alpha_1, \quad \alpha_2\rightarrow\alpha_2, \tag{117}$$

of a classical input. With the understanding that only relative phase shifts of the two components (α_1,α_2) are measured, such a phase shift is equivalent to

$$\alpha_1\rightarrow e^{-i\theta/2}\alpha_1, \quad \alpha_2\rightarrow e^{i\theta/2}\alpha_2. \tag{118}$$

Thus the equivalent transformations of quantum mechanical states are generated by

$$a_1^\dagger\rightarrow e^{-i\theta/2}a_1^\dagger, \quad a_2^\dagger\rightarrow e^{i\theta/2}a_2^\dagger. \tag{119}$$

It is then seen that the corresponding transformation $|jm\rangle\rightarrow e^{-im\theta}|jm\rangle$ of an SU(2) weight state is an overall phase change and undetectable. However, the transformation becomes detectable in a symmetric quantum interferometer in which the beams pass through beam splitters immediately before and immediately after they are phase shifted. If the first beam splitter effects an SU(2) transformation $e^{-i\hat{J}_x\pi/2}$ and the second reverses the transformation of the first, then the net result of the quantum interferometer is a detectable transformation in which

$$|jm\rangle\rightarrow e^{i\hat{J}_x\pi/2}e^{-i\theta\hat{J}_z}e^{-i\hat{J}_x\pi/2}|jm\rangle=e^{-i\theta\hat{J}_y}|jm\rangle=\sum_n |jn\rangle\, d^j_{nm}(\theta). \tag{120}$$

In such an interferometer, a minimal uncertainty input $|(\alpha,0)\rangle$ is transformed to an output $|(\alpha\cos(\theta/2),\alpha\sin(\theta/2))\rangle$. Thus, the ratio $\tan(\theta/2)$ of the output amplitudes provides a measure of θ; if only intensities are measured it provides a measure of θ modulo π. Measurements of phase shifts can also be made with other input states and it is of interest to consider choices with the greatest potential for accuracy.

The potential accuracy of a phase shift measurement is given by the width of the distribution function

$$N_\theta(\varphi)=|\langle\psi(\theta)|e^{-i\varphi\hat{J}_y}|\psi\rangle|^2=|\langle\psi|e^{-i(\varphi-\theta)\hat{J}_y}|\psi\rangle|^2. \tag{121}$$

It follows that $N_\theta(\varphi)=P(\varphi-\theta)$ where

$$P(\theta)=|\langle\psi|e^{-\theta\hat{J}_y}|\psi\rangle|^2. \tag{122}$$

For example, if $|\psi\rangle$ is the highest weight state $|jm=j\rangle$ then $P(\theta)$ is given by Eq. (23),

$$P_1(\theta)=|d^j_{jj}(\theta)|^2=\exp[-j\theta^2/2]. \tag{123}$$

On the other hand, if $|\psi\rangle$ is the state $|j\,m=0\rangle$, then $P(\theta)$ has the asymptotic expression given by Eq. (58),

$$P_2(\theta)=|d^j_{00}(\theta)|^2\sim|J_0(j\theta)|^2. \tag{124}$$

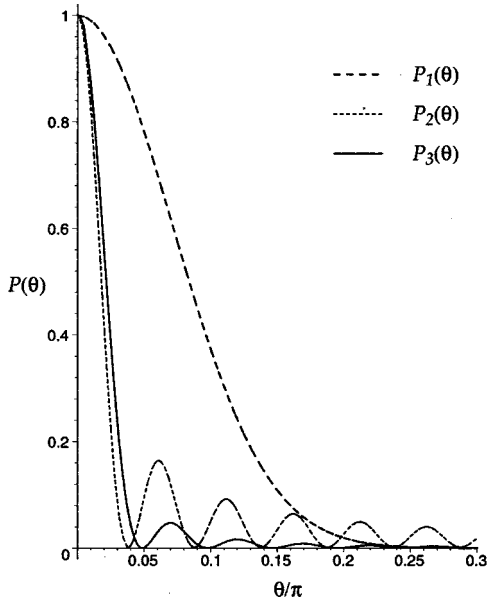

FIG. 12. The distribution functions given by Eqs. (123), (124), and (127) for $j=20$.

Thus, in spite of the fact that the highest weight state $|jj\rangle$ is a minimal uncertainty state, the variance in θ when the input state is $|jj\rangle$ is proportional to $1/\sqrt{j}$, whereas for a $|j\,m=0\rangle$ input state, it is proportional to $1/j$. This can be understood as follows. The density distribution of a spherical harmonic $|Y_{jj}(\theta,\varphi)|^2$ is concentrated about the $\theta=0$ pole whereas the density $|Y_{j0}(\theta,\varphi)|^2$ is spread uniformly about the $\theta=\pi/2$ equatorial circumference. Thus, the variance in θ can be much smaller for the latter distribution without violation of the uncertainty principle. This raises the question as to whether or not there might exist states with even less uncertainty relative to the $\hat{J}_y$ orientation than the state $|j0\rangle$. One candidate is the so-called SU(2) phase states[3,6,23]

$$|j\varphi\rangle=(2j+1)^{-1/2}\sum_{\mu=-j}^{j}e^{i\mu\varphi}|y;j\mu\rangle, \tag{125}$$

where $|y;j\mu\rangle$ is an eigenstate of $\hat{J}_y$ with eigenvalue μ. Putting $|\psi\rangle$ equal to $|j\varphi\rangle$ in Eq. (122) gives

$$P_3(\theta)=|\langle j\varphi|e^{-i\theta\hat{J}_y}|j\varphi\rangle|^2=(2j+1)^{-2}\left|\sum_{\mu}e^{i\mu\theta}\right|^2=(2j+1)^{-2}|\chi_j(\theta)|^2, \tag{126}$$

where χ_j is the well-known character of the SU(2) irrep of angular momentum j. Thus,

$$P_3(\theta)=\frac{\sin^2[(2j+1)\theta/2]}{(2j+1)^2\sin^2[\theta/2]}. \tag{127}$$

The function P_3 is also familiar in diffraction theory. The variance of φ for this function is proportional to $1/(j+0.5)$.

The distribution function $P(\theta)$ is shown in Fig. 12 for each of the three input states $|jj\rangle$, $|j0\rangle$, and $|j\theta\rangle$. The figure shows that the phase state and the $m=0$ state gives much more accurate measurements than the highest weight state. The down side is that these states are much more difficult to prepare and measure than a coherent mixture of $m=j$ minimal uncertainty states. (Another candidate for improving the estimation of phase is the so-called intelligent state,[24] which is also difficult to prepare.)

The advantage of using $|jm=0\rangle$ or SU(2) phase states over $|jm=j\rangle$ states for precision measurements is an example of the greater potential for acquiring or transmitting information by quantal states than is possible with classical states. A highest weight state $|jj\rangle$ is a state with all photons in channel one. A classical-like coherent state

$$|(\alpha,0)\rangle = e^{\alpha a_1^\dagger - \alpha^* a_1}|0\rangle, \tag{128}$$

is a superposition of many highest weight states:

$$|(\alpha,0)\rangle = e^{-|\alpha|^2/2}\sum_j \frac{\alpha^{2j}}{\sqrt{(2j)!}}|jj\rangle. \tag{129}$$

The distribution function for a coherent state is given by

$$|\langle(\alpha,0)|e^{-i\theta\hat{J}_y}|(\alpha,0)\rangle|^2 = |\langle(\alpha,0)|(\alpha\cos(\theta/2),\alpha\sin(\theta/2))\rangle|^2 = e^{-|\alpha|^2(1-\cos(\theta/2))}. \tag{130}$$

Thus, if $|\alpha|^2$ is set equal to the average number of photons, $2j$, then as $j\to\infty$ this distribution function approaches the value $\exp[-j\theta^2/2]$ that it has for the number state $|jj\rangle$ as one would expect.

In contrast, the state $|j\,m=0\rangle$ is unlike any classical state. In quantum mechanics it is a state

$$|j0\rangle = \frac{(a_1^\dagger)^j(a_2^\dagger)^j}{j!}|0\rangle, \tag{131}$$

having an equal number of photons in each channel. Whereas the preparation of such a state has not been performed, a compromise state is the coherent linear superposition of such states given[25] by a two-mode squeezed coherent state

$$e^{\beta(a_1^\dagger a_2^\dagger - a_1 a_2)}|0\rangle = \operatorname{sech}\beta\sum_{j=0}^{\infty}(\tanh\beta)^j\,|j\,m=0\rangle. \tag{132}$$

This state produces the desired $1/\langle j\rangle$ scaling of the phase uncertainty[26] for the appropriately weighted average value of j. However, apart from the problems of producing such a squeezed state, it is also noted that the distribution of j values is heavily weighted in favor of low-j values. Thus, it is doubtful that much could be gained by the use of such squeezed states.[3]

One might suppose that a classical-like input

$$|(\alpha,\alpha)\rangle = e^{\alpha a_1^\dagger - \alpha^* a_1}e^{\alpha a_2^\dagger - \alpha^* a_2}|0\rangle, \tag{133}$$

with equal amplitudes in each of the two ports might have some advantages. Such a state corresponds to an equal distribution of photon numbers in each port with a relatively narrow spread about some mean value. However, it follows from Eq. (111) that

$$|(\alpha,\alpha)\rangle = e^{-i\hat{J}_y\pi/2}\,|(\sqrt{2}\,\alpha,0)\rangle. \tag{134}$$

Hence

$$P(\theta) = |\langle(\alpha,\alpha)|e^{-i\theta\hat{J}_y}|(\alpha,\alpha)\rangle|^2 = |\langle(\sqrt{2}\,\alpha,0)|e^{-i\theta\hat{J}_y}|(\sqrt{2}\,\alpha,0)\rangle|^2, \tag{135}$$

and the variance is precisely the same as for the input state $|(\sqrt{2}\,\alpha,0)\rangle$. It should be noted that, whereas the state $|(\alpha,\alpha)\rangle$ can be obtained by an SU(2) rotation of the state $|(\sqrt{2}\,\alpha,0)\rangle$, it is impossible to rotate a highest weight state $|jj\rangle$ into the state $|jm=0\rangle$.

The optimization of the inputs to an interferometer in order to yield the most precise phase shift information possible with a limited number of photons is important; e.g., for the detection of

gravitational waves.[21] Caves has suggested injecting a standard coherent state into one channel and a squeezed vacuum state into the other. Another suggestion is to put a squeezed input into one channel and an antisqueezed input into the other.[27] Clearly an expansion of such inputs in an SU(2) basis will make it possible to analyze the precisions obtainable with such inputs in the large photon number limit using the asymptotic SU(2) Wigner functions given in this paper.

B. Three-channel interferometry

Similar considerations apply to a three-channel interferometer which transforms input states by a U(3) transformation

$$T(g):|\psi\rangle \rightarrow T(g)|\psi\rangle, \quad g \in \mathrm{U}(3). \tag{136}$$

The transformation is analogous to the U(2) transformation discussed in the preceding section, but with $T(g)$ a unitary representation of a matrix $g \in \mathrm{U}(3)$. The U(3) transformation can be factorized into a sequence of SU(2) transformations and an overall phase factor; physically, this corresponds to a realization of a three-channel interferometer as a combination of two-channel devices (phase shifters, mirrors and beam splitters).

The infinitesimal generators of the unitary transformation $T(g)$ are given in a generalized Schwinger representation in Eq. (78). In such a representation, basis states for an SU(3) irrep of highest weight $(\lambda,0)$ are weight states $|\nu\rangle \equiv |\nu_1 \nu_2 \nu_3\rangle$; they can be regarded as triplet Fock number states with ν_i photons in channel i of the interferometer and fixed total photon number.

Many of the results for two-channel interferometry, discussed in the preceding section, carry forward to the three-channel case in an intuitively clear manner. For instance, the state in which all photons enter through channel one is the minimal uncertainty (highest weight) state $|(\lambda)\rangle \equiv |\lambda,0,0\rangle$. For analysis of experiments with such an input state, the SU(3) Wigner function $D^{(\lambda)}_{\nu,(\lambda)}$ and its asymptotic limit is relevant. On the other hand, the Wigner functions for central weights are relevant for balanced input states.

Whereas the two-channel interferometer is suited to the measurement of phase difference between two channels of propagation, it may be desirable to measure multiple phase shifts simultaneously, e.g., because the phase shifts are transient or the mean particle flux of the source is limited. Moreover, the most efficient use of photons for precision measurement is to divide them up and measure relative phases between multiple paths.[7,6] The SU(N) interferometer is ideally suited for this purpose. The SU(3) interferometer allows the measurement of two phase shifts simultaneously.

D'Ariano and Paris[7] have shown that much improved accuracy is already obtained with an easily produced coherent state input by suitably dividing the input into the many channels of a multichannel interferometer. They show that with a mean number λ of photons, the variance of the phase shift estimation scales as $\Delta\theta^2 \propto 1/N^2\lambda$ for an N-channel interferometer. In contrast, if the fixed input of λ photons were to be split between $N-1$ two-channel interferometers, then the variance of each would be proportional to $(N-1)/\lambda$ and, with the estimate of θ given by the mean of the θ_i obtained in the two-channel interferometers, the variance would be independent of N (assuming the spread of measured phase shifts is small compared to the range 0 to 2π). Thus, nothing is gained by splitting the λ photons over many two-channel interferometers but a huge gain results from appropriate use of a multichannel interferometer.

Still further gains can, in principle, be achieved by use both of exotic inputs and multichannel interferometers. The balanced input state is a preferred input state for phase-shift determination but it is hard to generate. Also, it is just one of many inputs which can, in principle, improve the precision of phase-shift estimation. The generalization to SU(3) of the SU(2) phase state considered in the preceding section,[6] could also yield superior scaling laws for the phase-shift estimation in terms of λ. The precision of two simultaneously measured phase shifts is rigorously expressed in terms of the covariance matrix for the two phases. This 2×2 matrix includes the variance for each phase and the covariance between the two phases. Detailed analyses of the results achievable

with various techniques and three-channel inputs is in principle possible by expanding the inputs in an SU(3) basis and using the asymptotic Wigner functions to infer variances as done for two-channel interferometers in Sec. V A.

VI. CONCLUDING REMARKS

In this paper, we have derived several previously unknown asymptotic limits of SU(2) Wigner d^j_{mn} functions which converge rapidly as $j\to\infty$ and are shown to be accurate over a wide range of their arguments. We have also shown how SU(3) Wigner functions for multiplicity-free irreps of highest weight $(\lambda,0)$ can be factored into products of SU(2) Wigner functions so that their limits can be inferred from those of SU(2). This kind of inference is not limited to SU(3) and can be generalized to SU(N) irreps of highest weight $(\lambda,0,...)$ for $N>3$.

Explicit limiting expressions have been given for some representative classes of SU(3) Wigner functions. In particular, we have considered Wigner functions for states whose weights are either extremal or central in the terminology of Sec. IV. Other expressions can be derived by variations of the methods given. For example, useful asymptotic SU(3) Wigner functions can be determined for which one weight is extremal and the other is close to a side. Depending on the domains of the initial and final states of a Wigner function, it will often happen that the expressions are much simpler in some other set of SU(3) Euler angles than those given. This is a simple reflection of the fact that a given SU(3) transformation may be simple when expressed as one sequence of SU(2) transformations but seemingly complex when expressed in some other way. Thus, by choosing the most appropriate sequence the number of summations over products of SU(2) Wigner functions can be minimized.

Asymptotic limits of Wigner functions are of interest for many reasons. In situations where they are valid, they can facilitate computations and provide quick estimates of the behaviors of quantum systems. In this way they give physical insight into the ways quantal systems approach classical limits. This has been illustrated in this paper by using the limits to estimate variances in phase shift measurements by quantum interferometry and to determine the ways they scale with the number of photons. Asymptotic limits may also be important in quantum information theory for identifying quantum states that behave in very nonclassical and potentially useful ways.

Our initial hope was to derive asymptotic expressions for the Wigner functions of generic SU(3) irreps. However, while we did succeed in deriving some expressions, they proved under numerical investigation to be accurate only over narrow ranges of their arguments. Thus, while of some mathematical interest, they are of limited practical value. Clearly further investigation is needed before any results are presented.

[DOI: 10.1063/1.1360710]

There are two errors in Ref. 1 which we would like to set straight. The first affects some of the equations, but none of the results. The second is more serious, and was noticed in the course of writing the paper.[3]

The first error, which is in some sense a matter of convention, comes in the computation of the boundary operator associated to the Dirac operator, for example, in the second equation of Appendix A. Namely, if X is a manifold with boundary whose metric is a product near the boundary, then near the boundary we write the Dirac operator on X as

$$D_X = J(\partial_\mu + B_{\partial X}),$$

where the boundary is cut out by $\mu = 0$, the coordinate μ is negative on the interior of X, the 1-form $d\mu$ has unit length, and J is Clifford multiplication by $d\mu$. We call $B_{\partial X}$ the boundary operator associated to D_X. In the familiar case where X is even-dimensional, if D_X is the chiral Dirac operator mapping plus spinor fields to minus spinor fields, then the boundary operator $B_{\partial X}$ may be identified with the ordinary Dirac operator on ∂X. (Both the plus spinors and minus spinors restricted to the boundary may be identified with $S_{\partial X}$, and J is an isomorphism between the two restrictions.) However, if X is odd-dimensional, as in the paper, then near the boundary $J = \left(\begin{smallmatrix} -\sqrt{-1} & 0 \\ 0 & \sqrt{-1} \end{smallmatrix}\right)$ relative to the decomposition of spinors on the boundary $S_{\partial X} = S^+_{\partial X} \oplus S^-_{\partial X}$, and we have

$$B_{\partial X} = J^{-1} D_{\partial X}.$$

In the paper we left off the factor J^{-1}, and so factors of $\sqrt{-1}$ are missing in formulas sprinkled throughout the paper, though they do not affect the main results. For example, the basic boundary condition in Eq. (1.2) should read as

$$W_{(a,T)} = \left\{ \langle \phi^+, \phi^- \rangle \in H_{\partial X} : \phi^- - \sqrt{-1}\left(T \oplus \frac{D_{\partial X}(a)}{\sqrt{D_{\partial X}(a)^2}} \right) \phi^+ = 0 \right\}. \tag{1.2$'$}$$

Other affected formulas include (1.5), (2.16), and many formulas in Sec. IV and Appendix A. For example, Eq. (4.8) should be replaced by

$$\tau_C(a,T) = (-\sqrt{-1})^{\dim K^+ + \dim K^-} \det T. \tag{4.8$'$}$$

Although explicit formulas for $\tau_X(a,T)$ are changed, the main conclusions about the invariant τ_X are unchanged by these factors.

a)Electronic mail: dafr@math.utexas.edu

These factors are also important in understanding what happens when we reverse orientation. For any manifold X we identify spinors on the manifold X with spinors on the oppositely oriented manifold $-X$:

$$S_{-X} \cong S_X .$$

[See the text following (2.14) in the paper.] The Dirac operator changes sign under this identification:

$$D_{-X} = -D_X .$$

However, if Y is even-dimensional (for example, the boundary of an odd-dimensional manifold), then $S^{\pm}_{-Y} \cong S^{\mp}_{Y}$ and the boundary operators are identified:

$$B_{-Y} = B_Y .$$

A more substantial correction occurs in the formula after (2.18) for the τ-invariant of the orientation-reversed manifold:

$$\tau_{-X} = (-1)^{\binom{k}{2}} \tau_X^{-1}, \qquad (*)$$

where k is the number of components of ∂X on which the boundary Dirac operator has odd index. (Of course, $k=0$ if ∂X is connected.) This was applied in Ref. 3 to the double X^d of a manifold X to conclude

$$\tau_{X^d} = (-1)^{\binom{k}{2}}. \qquad (**)$$

As a simple example, let X be the closed interval $[0, 1]$. Then the double X^d is the circle with the nonbounding spin structure. In this case $k=2$ and formula $(**)$ is correct.

To understand $(*)$ one should be aware that the pairing in the statement of the gluing formula Theorem 2.20 depends on the gluing map. For example, one can glue together two disjoint closed intervals into a single circle or into two disjoint circles, depending on the choice of gluing map. For circles with the nonbounding spin structure, the τ-invariants differ by a sign in the two cases. The equality in Eq. $(*)$ refers to the identification of the inverse determinant line of $\partial(-X)$ with the dual of the determinant line of ∂X under which boundary components are not permuted; the formula states that τ_X and τ_{-X} pair to $(-1)^{\binom{k}{2}}$. If we choose a boundary condition (a,T) for X, then with the boundary condition $(a,-T^{-1})$ for $-X$ we see easily that $\tau_{-X}(a,-T^{-1}) = \tau_X(a,T)^{-1}$. But if $L_1,\ldots,L_n$ are the inverse determinant lines of the components of ∂X, then to pair $L_1 \otimes \cdots \otimes L_n$ with $L_1^{-1} \otimes \cdots \otimes L_n^{-1}$ we must permute the latter tensor product to $L_n^{-1} \otimes \cdots \otimes L_1^{-1}$, and this accounts for the sign.

Finally, we remark that an improved argument deriving the holonomy theorem for determinant line bundles (see Sec. V of the paper) appears in Ref. 2.

This article is a direct illustration of a construction of coherent states which has been recently proposed by two of us (JPG and JK). We have chosen the example of a particle trapped in an infinite square-well and also in Pöschl–Teller potentials of the trigonometric type. In the construction of the corresponding coherent states, we take advantage of the simplicity of the solutions, which ultimately stems from the fact they share a common SU(1,1) symmetry *à la* Barut-Girardello. Many properties of these states are then studied, both from mathematical and from physical points of view. © *2001 American Institute of Physics*.
[DOI: 10.1063/1.1367328]

I. INTRODUCTION

Despite its relevance for the understanding of the most elementary parts of quantum mechanics, the problem of a particle trapped in an infinite square-well (Fig. 1) usually deserves no more than a few pages in most physics textbooks.[1–3] Solutions are straightforward to derive, energy is nicely quantized and trigonometric wave functions afford an immediate intuition of quantum behavior. The model is widely used to give a fair idea of many body systems in atomic or molecular physics. However, very soon one may become puzzled by less trivial problems pertaining to the mathematics of quantum mechanics: domain of self-adjointness for the operators involved, possible nonuniqueness of self-adjoint extensions (see in particular the very instructive examples in Chapters VIII.I, VIII.2, and X.1 of Ref. 4), explicit kernel of the evolution operator, crucial role played by the boundary conditions, semiclassical behavior and the classical limit, and other limiting situations such as a very large or a vanishingly small width of the well.

Actually all these questions can be considered through a nice analytic regularization of the infinite well potential. Indeed, consider the continuously indexed family of potentials

$$V(x)\equiv V_{\lambda,\kappa}(x)=\frac{1}{2}V_0\left(\frac{\lambda(\lambda-1)}{\cos^2/2a}+\frac{\kappa(\kappa-1)}{\sin^2 x/2a}\right),\quad 0\leqslant x\leqslant \pi a, \tag{1.1}$$

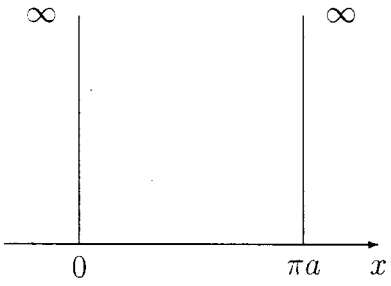

FIG. 1. The infinite square-well potential.

for $\lambda,\kappa>1$ ($V_0>0$ is a coupling constant). Clearly this is a smooth approximation, for $\lambda,\kappa \to 1^+$, of the infinite square-well over the interval $[0,\pi a]$. These potentials, called the Pöschl–Teller (PT) potentials,[3,5] are shown in Fig. 2 for the values $(\lambda,\kappa)=(4,4),(4,8),(4,16)$, respectively. In order to make contact with standard quantum mechanics on the whole line, there are two possibilities. Either one requires that $V(x)=\infty$ outside the interval $[0,\pi a]$, or one periodizes the potential, with period πa, and one imposes periodic boundary conditions at the points $\{n\pi a, n\in\mathbb{Z}\}$. But, since the walls separating the successive cells are impenetrable, one may also simply ignore these extensions and consider only the interval $[0,\pi a]$, which we shall do in the present article.

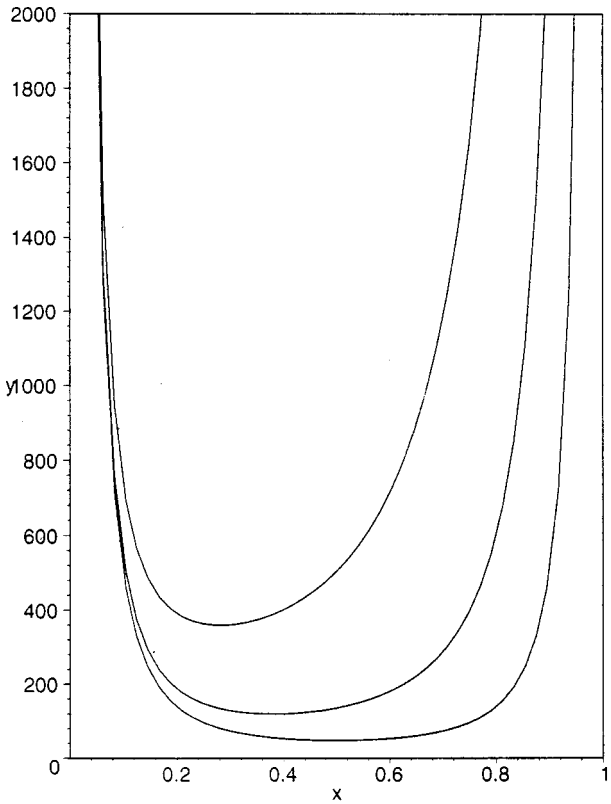

FIG. 2. The Pöschl–Teller potential $V(x)=1/2V_0[\lambda(\lambda-1)\cos^{-2}x/2a+\kappa(\kappa-1)\sin^{-2}x/2a]$, with $a=\pi^{-1}$ and for $(\lambda,\kappa)=(4,4),(4,8),(4,16)$ (from bottom to top).

The Pöschl–Teller potentials share with their infinite well limit the nice property of being analytically integrable. The reason behind this can be understood within a group-theoretical context: The family of potentials (1.1) possesses an underlying dynamical algebra, namely $\mathfrak{su}(1,1)$ and the discrete series representations of the latter. We recall that the discrete series unitary irreducible representations (UIRs) of $\mathfrak{su}(1,1)$ are labeled by a parameter η, which takes its values in $\{1/2,1,3/2,2,...\}$ for the discrete series *stricto sensu*, and in $[1/2,+\infty)$ for the extension to the universal covering of the group SU(1, 1). The relation between the Pöschl–Teller parameters and η is given by

$$2\eta-1=\lambda+\kappa,$$

and the limit case $\lambda,\kappa\rightarrow 1^{+}$ corresponds to $\eta=3/2$.

Other approaches in the past led to the group SU(2) as the dynamical group for the Pöschl–Teller potentials, when $\lambda+\kappa$ is an integer.[6] We emphasize here the fact that the SU(1, 1) approach seems more natural, for it extends easily and naturally to noninteger values of $\lambda+\kappa$.

In fact, the Pöschl–Teller potential (1.1), sometimes called PT of the first type, is closely related to several other potentials, widely used in molecular and solid state physics.

- The symmetric Pöschl–Teller potential well, given by $\lambda=\kappa\geqslant 1$, is

$$V_{\lambda}(x)=2V_0\frac{\lambda(\lambda-1)}{\sin^2 x/a}. \tag{1.2}$$

  This potential may be periodized with period $\pi a/2$, instead of πa.

- The same potential, for $1/2\leqslant\lambda<1$, is known as the Scarf potential.[7] This is no longer a well, but an inverted well, that is, a peak between two infinite negative wells. When periodized over the whole line, this is a good model for a 1-D crystal (as a smooth substitute to the well-known Kronig–Penney model), since the spectrum of the corresponding Hamiltonian has a band structure. The nonsymmetric extension of the Scarf potential has similar properties.[8] Interestingly, both cases admit SU(1, 1) as a dynamical group, although the representations underlying the band part are those of the complementary series.
- There exists also the so-called scattering (or modified) Pöschl–Teller potentials, obtained by replacing the trigonometric functions in (1.1) by their hyperbolic counterparts.[5] A special case is the Rosen-Morse potential,[9] which is simply the symmetric version of the previous one. These potentials are widely used in molecular physics, and they have the same dynamical group SU(1, 1) (but again other representations are involved). For a review of this case and its applications, we refer to Refs. 10–12.

In this article we present and study families of coherent states (CSs) adapted to the infinite well and to the Pöschl–Teller potentials. We call these states *adapted* and *coherent* because they are a direct generalization of the standard ones corresponding to the harmonic oscillator[13] (for an extensive and up-to-date bibliography see, for instance, Ref. 14). We recall that the Schrödinger-Klauder-Glauber CS reads

$$|z\rangle=e^{-|z|^2/2}\sum_{n\geqslant 0}\frac{z^n}{\sqrt{n!}}|n\rangle. \tag{1.3}$$

We extend them in a sense already explained in Refs. 15–17 and briefly sketched in the following. We first consider in (1.3) the kets $|n\rangle$ as the eigenstates of the infinite well (resp. Pöschl–Teller) Hamiltonian H corresponding to the eigenvalue $\hbar\omega e_n$, $n\geqslant 0$, $e_0=0$. Next, analogous to the pioneering work of Jackson,[18] we replace in the square root the factorial $n!$ by the generalized factorial $[e_n]!=e_1\ldots e_n$, to get the so-called action identity[16]

$$\langle z|H|z\rangle=\hbar\omega|z|^2. \tag{1.4}$$

Note that similar factorial ''deformations'' in the construction of coherent states already appear in Refs. 19 and 20. We finally require (temporal) stability for our new family of coherent states under the action of the evolution operator $e^{-iHt/\hbar}$ (see Ref. 16 and Sec. VII of this work for details). Our interest in these infinite well and Pöschl–Teller coherent states lies mostly in the simplicity of the formulas involved. We have here at our disposal a nice tool for examining many quantum features, such as probability densities, autocorrelation, mean values of observables, Heisenberg inequalities, semiclassical limits, and others.

The article is organized as follows. In Sec. II, we describe the classical motion in an infinite square-well potential and in a Pöschl–Teller potential. In our opinion, it is essential to recall this elementary (and pedagogical!) material for the subsequent discussions on a quantum level. Sections III and IV are devoted to the quantum infinite well and Pöschl–Teller potentials, respectively. In particular, we give here an up-to-date survey of the nontrivial questions of self-adjointness for some of the most familiar physical observables. We examine in Sec. V the questions related to various limits: semiclassical $\hbar \to 0$, $n\hbar = \text{const}$, infinite narrowness $a \to 0$, infinite width $a \to \infty$, Pöschl–Teller→infinite well, and others. We describe in Sec. VI the dynamical symmetry algebra $\mathfrak{su}(1,1)$ common to both models and underlying their integrability. In Sec. VII we first review the general construction of ''action-angle'' or rather ''energy-time'' coherent states before giving their explicit form and their most immediate mathematical properties in the infinite well case, and in the Pöschl–Teller case (Sec. VIII). Section IX is devoted to the most interesting physical properties of our states, and in particular to the revival features they present, which are well illustrated by the large number of figures shown there. Finally. Sec. X summarizes the discussion about the role of coherent states when expressed in terms of action-angle variables.

A final lesson of the article is that a comprehensive study of quantum mechanics requires not only algebra, or numerical simulations, but also a precise use of functional analysis. The fine points of the latter are not mathematical pedantry; they express deep physical properties.

II. THE CLASSICAL PROBLEM

A. Classical infinite well

It is worthwhile to start out this article with a short pedagogical review of the classical behavior of a particle of mass m trapped in an infinite well of width πa.

For a nonzero energy

$$E = \tfrac{1}{2} m v^2, \tag{2.1}$$

there corresponds a speed

$$v = \sqrt{\frac{2E}{m}} \tag{2.2}$$

for a position $0 < x < \pi a$. There are perfect reflections at the boundaries of the well. So the motion is periodic with period (the ''round trip time'') T equal to

$$T = \frac{2\pi a}{v} = 2\pi a \sqrt{\frac{m}{2E}}. \tag{2.3}$$

With the initial condition $x(0) = 0$, the time behavior of the position is then given by (see Fig. 3)

$$\begin{aligned} 0 \leqslant t \leqslant \tfrac{1}{2} T: &\quad x = v t, \\ \tfrac{1}{2} T \leqslant t \leqslant T: &\quad x = 2\pi a - v t, \end{aligned} \tag{2.4}$$

and of course

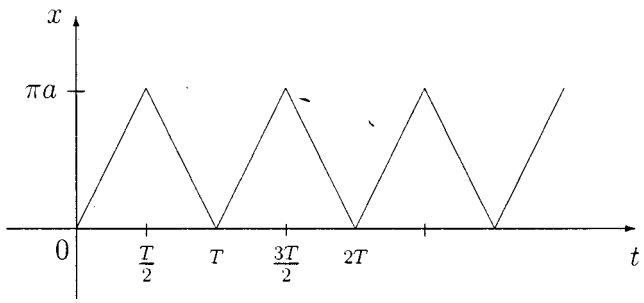

FIG. 3. The position $x(t)$ of the particle trapped in the infinite square-well of width πa, as a function of time.

$$x(t+nT)=x(t). \tag{2.5}$$

Consequently the velocity is a periodized Haar function (Fig. 4):

$$\mathbf{v}=v\sum_{n=0}^{+\infty}[\mathbb{1}_{[nT,(n+1/2)T]}-\mathbb{1}_{[(n+1/2)T,(n+1)T]}] \tag{2.6}$$

(here $\mathbb{1}_B$ denotes the characteristic function of a set $B\in\mathbb{R}$), whereas the acceleration is the superposition of two Dirac combs on the half-line (Fig. 5):

$$\gamma=\sum_{n=0}^{+\infty}[\delta_{nT}-\delta_{(n+1/2)T}]. \tag{2.7}$$

The average position and average velocity of the particle are then

$$\overline{x}=\frac{1}{T}\int_0^T x(t)dt=\frac{\pi a}{2},\quad \overline{v}=0, \tag{2.8}$$

whereas the mean square dispersions are

$$\sqrt{\overline{x^2}-\overline{x}^2}=\frac{\pi a}{2\sqrt{3}},\quad \sqrt{\overline{v^2}-\overline{v}^2}=\sqrt{\frac{2E}{m}}. \tag{2.9}$$

Note the standard Fourier expansion for the position and the velocity, respectively,

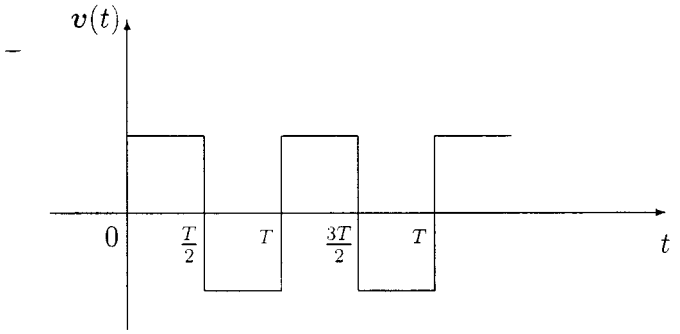

FIG. 4. The velocity $\mathbf{v}(t)$ of the particle in the infinite square-well: periodized Haar function.

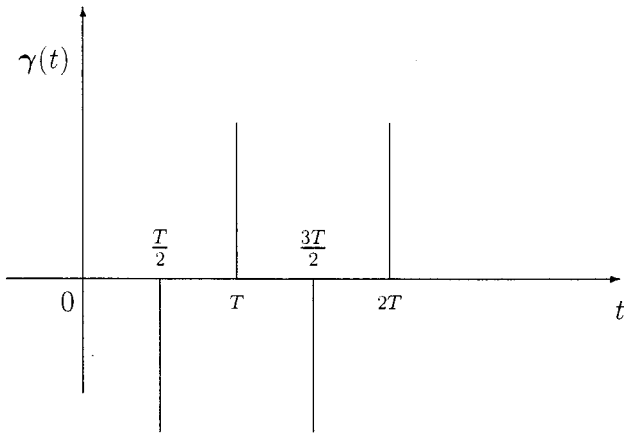

FIG. 5. The acceleration $\gamma(t)$ of the particle of the particle in the infinite square-well.

$$x(t)=\frac{\pi a}{2}-\frac{4a}{\pi}\sum_{n=0}^{\infty}\frac{1}{(2n+1)^2}\cos\frac{2\pi}{T}(2n+1)t, \tag{2.10}$$

$$\mathbf{v}(t)=4\frac{v}{\pi}\sum_{n=0}^{\infty}\frac{1}{2n+1}\sin\frac{2\pi}{T}(2n+1)t. \tag{2.11}$$

Figure 6 shows the phase trajectory of the system. This trajectory encircles a surface of area equal to the action variable

$$A=\frac{1}{2\pi}\oint pdq=mva, \tag{2.12}$$

where $q=x$ and $p=mv$ are canonically conjugate. Note the other expressions for A:

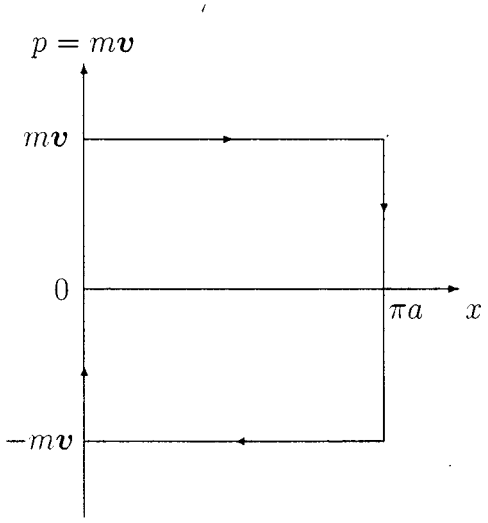

FIG. 6. Phase trajectory of the particle in the infinite square-well.

$$A=\frac{2\pi a^2 m}{T}=\frac{mv^2 T}{2\pi}=a\sqrt{2mE}. \tag{2.13}$$

The action-angle variables (A,φ) are obtained through the canonical transformation (ϑ denotes the step function)

$$\varphi=\mathrm{sgn}(p)\frac{q}{a}+\vartheta(-p)2\pi \pmod{2\pi}, \tag{2.14}$$

$$A=|p|a, \tag{2.15}$$

with generating function equal to the Maupertuis action, as should be expected:

$$\begin{aligned} S_0&=2\pi nA+S_0^{\mathrm{princ}},\\ S_0^{\mathrm{princ}}&=A\varphi=pq+|p|\vartheta(-p)a, \quad \varphi\in(0,2\pi). \end{aligned} \tag{2.16}$$

Finally, note the time evolution of the angle variable:

$$\varphi=\frac{\mathbf{v}}{a}t+\varphi_0\equiv\alpha t+\varphi_0. \tag{2.17}$$

B. Pöschl–Teller potentials

The solution to the equations of motion with the potentials (1.1) is straightforward, in spite of the rather heavy expression of the latter. The turning points $x_\pm$ of the periodic motion at a given energy E are given by

$$x_\pm=a\arccos\left[\frac{\alpha-\beta}{2}\pm\sqrt{\Delta}\right], \tag{2.18}$$

where $\Delta=(1-1/2(\sqrt{\alpha}+\sqrt{\beta})^2)(1-1/2(\sqrt{\alpha}-\sqrt{\beta})^2)$, $\alpha=(V_0/E)\lambda(\lambda-1)$, $\beta=(V_0/E)\kappa(\kappa-1)$.

So, the motion is possible only if

$$E>\frac{V_0}{2}(\sqrt{\lambda(\lambda-1)}+\sqrt{\kappa(\kappa-1)})^2. \tag{2.19}$$

The time evolution of the position is given by

$$\begin{aligned} x(t)&=a\arccos\left[\frac{\alpha-\beta}{2}+\sqrt{\Delta}\cos\left(\sqrt{\frac{2E}{m}}\frac{t}{a}\right)\right],\\ x(0)&=x_-. \end{aligned} \tag{2.20}$$

Hence the period is

$$T=2\pi a\sqrt{\frac{m}{2E}}. \tag{2.21}$$

It is remarkable that the period T does not depend on the strength V_0, nor on λ and κ.

The action variable A satisfies the relation $dA/dE=T/2\pi$, and thus

$$A=\alpha\sqrt{2mE}+\mathrm{const.} \tag{2.22}$$

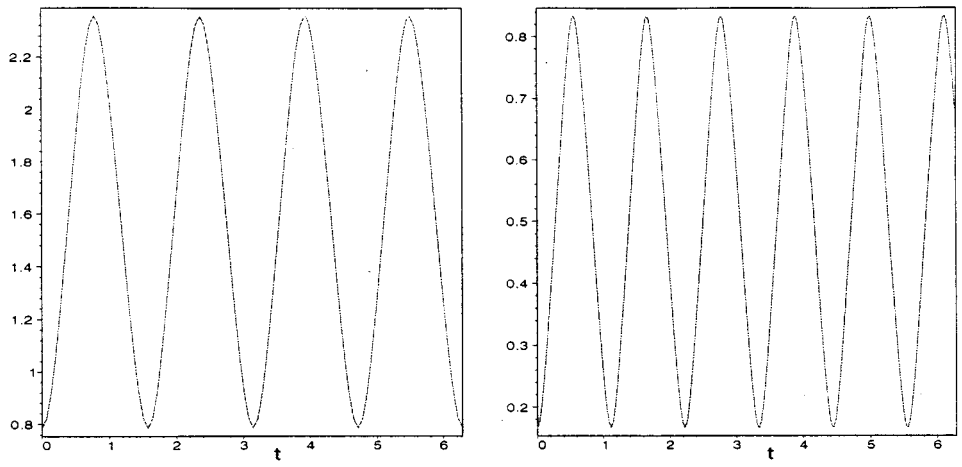

FIG. 7. The position $x(t)$ of the particle in the symmetric Pöschl–Teller potential $\lambda=\kappa=2$: (a) $E=8V_0$, $T=\pi/2$; and (b) $E=16V_0$, $T=\pi/2\sqrt{2}$ (compare Fig. 3).

The constant is determined by the condition that $A=0$ for $E=V_{\min}$, that is, const $=-a\sqrt{2mV_{\min}}$. The Pöschl–Teller potential $V(x)$ reaches its minimum at the location x_0 defined by

$$\tan^2\frac{x_0}{2a}=\sqrt{\frac{\kappa(\kappa-1)}{\lambda(\lambda-1)}}. \tag{2.23}$$

So we have, in agreement with (2.19),

$$V_{\min}=V(x_0)=\frac{V_0}{2}[\sqrt{\lambda(\lambda-1)}+\sqrt{\kappa(\kappa-1)}]^2, \tag{2.24}$$

and, consequently,

$$A=a\sqrt{2mE}-a\sqrt{mV_0}[\sqrt{\lambda(\lambda-1)}+\sqrt{\kappa(\kappa-1)}]. \tag{2.25}$$

It is worthwhile to compare (2.21) and (2.25) with their respective infinite well counterparts (2.3) and (2.13). We should also check that the time behavior (2.20) of $x(t)$ goes into (2.4) at the limits $\alpha,\beta\to 0$. We give in Figures 7–9 the curves for $x(t)$, $\mathbf{v}(t)$ and $\boldsymbol{\gamma}(t)$, respectively, in the particular symmetric case $\lambda=\kappa=2$, for two different values of the energy, namely, $E=8V_0$ and $E=16V_0$. Figure 10 shows the corresponding phase trajectory in the plane $(q=x,\ p=mv)$. Note that, in the general case, the equation for the latter reads (at energy E)

$$p=\pm\frac{\sqrt{2mE}}{\sin q/a}\left[1-(\alpha+\beta)+(\alpha-\beta)\cos\frac{q}{a}-\cos^2\frac{q}{a}\right]^{1/2}. \tag{2.26}$$

Finally, let us give the canonical transformation leading to the action-angle variables

$$\varphi=\arccos\frac{1}{\sqrt{\Delta}}\left[\cos\frac{q}{a}-\frac{\alpha-\beta}{2}\right], \tag{2.27}$$

$$A=a[p^2+2mV(q)]^{1/2}. \tag{2.28}$$

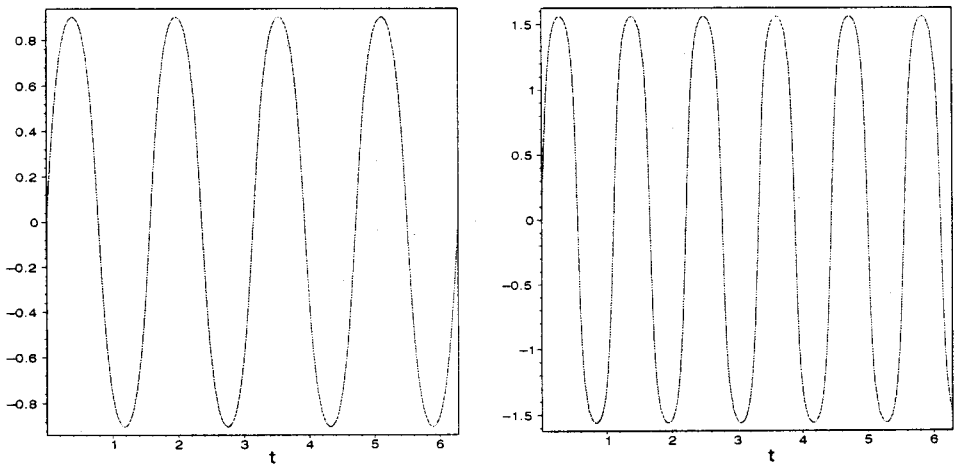

FIG. 8. The velocity $\mathbf{v}(t)$ of the particle in the symmetric (2,2) Pöschl–Teller potential, for the same values of E and T as in Fig. 7 (compare Fig. 4).

The Maupertuis action generating (2.25) is given by

$$S_0(u) = 2\pi nA + S_0^{\text{princ}}(u),$$

$$S_0^{\text{princ}}(u) = -a\sqrt{2mE}\int_{u_-}^{u} [1-(\alpha+\beta)+(\alpha-\beta)s-s^2]^{1/2}\frac{ds}{1-s^2}$$

with $u = \cos x/a$. The last integral may be calculated explicitly, but the result is not illuminating.

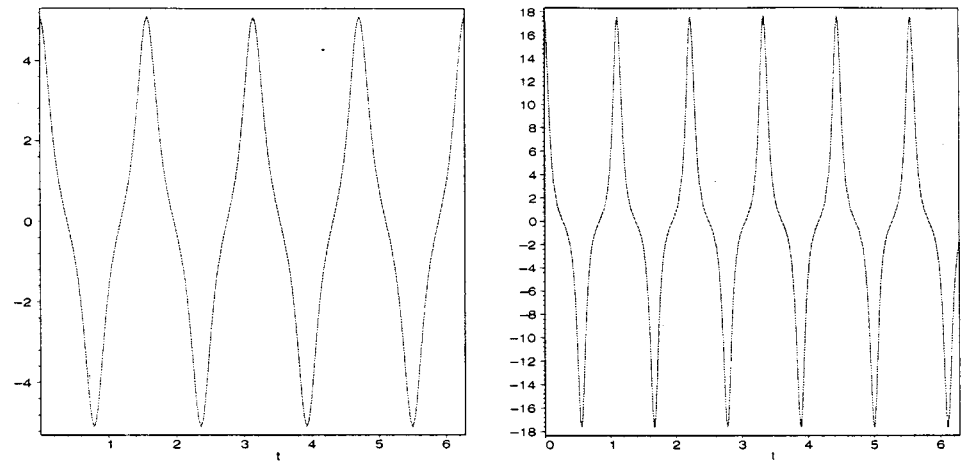

FIG. 9. The acceleration $\gamma(t)$ of the particle in the symmetric (2,2) Pöschl–Teller potential, for the same values of E and T as in Fig. 7 (compare Fig. 5).

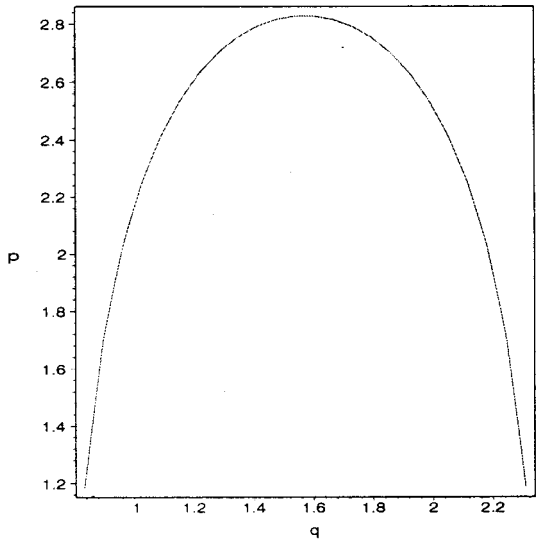

FIG. 10. Upper part of the phase trajectory of the particle the symmetric (2,2) Pöschl–Teller system, for the same values of E and T as in Fig. 7 (compare Fig. 6).

III. THE QUANTUM PROBLEM FOR THE INFINITE WELL

Any quantum system trapped inside the infinite well $0 \leqslant x \leqslant \pi a$ must have its wave function equal to zero outside the well. It is thus natural to impose on the wave functions the boundary conditions

$$\psi(x) = 0, \quad x \geqslant \pi a \quad \text{and} \quad x \leqslant 0. \tag{3.1}$$

Since the movement takes place only inside the interval $[0, \pi a]$, we may as well ignore the rest of the line and replace the conditions (3.1) by the following ones:

$$\psi \in L^2([0, \pi a], dx), \quad \psi(0) = \psi(\pi a) = 0. \tag{3.2}$$

Alternatively, one may consider the periodized well and impose the same periodic boundary conditions, namely, $\psi(n\pi a) = 0$, $\forall n \in \mathbb{Z}$.

In either case, stationary states of the trapped particle of mass m are easily found from the eigenvalue problem for the Schrödinger operator. For reasons to be justified in the sequel, we choose the shifted Hamiltonian:

$$H \equiv H_w = -\frac{\hbar^2}{2m}\frac{d^2}{dx^2} - \frac{\hbar^2}{2ma^2}. \tag{3.3}$$

Then

$$\Psi(x,t) = e^{-iHt/\hbar}\Psi(x,0), \tag{3.4}$$

where $\Psi(x,0) \equiv \psi(x)$ obeys the eigenvalue equation

$$H\psi(x) = E\psi(x), \tag{3.5}$$

together with the boundary conditions (3.1). Normalized eigenstates and corresponding eigenvalues are then given by

$$\psi_n(x)=\sqrt{\frac{2}{\pi a}}\sin(n+1)\frac{x}{a}\equiv\langle x|n\rangle,\quad 0\leqslant x\leqslant \pi a, \tag{3.6}$$

$$H|n\rangle=E_n|n\rangle,\quad n=0,1,..., \tag{3.7}$$

$$E_n=\frac{\hbar^2}{2ma^2}n(n+2)\equiv\hbar\omega e_n, \tag{3.8}$$

with

$$\omega=\frac{\hbar}{2ma^2}\equiv\frac{2\pi}{T_r}\quad\text{and}\quad e_n=n(n+2),\quad n=0,1,...,$$

where T_r is the ''revival'' time to be compared with the purely classical round trip time given in (2.3). Now the Bohr–Sommerfeld quantization rule applied to the classical action gives

$$a\sqrt{2mE}=A=(n+1)\hbar, \tag{3.9}$$

so

$$E=(n+1)^2\frac{\hbar^2}{2ma^2}=E_n+\frac{\hbar^2}{2ma^2},\quad n=0,1,\ldots. \tag{3.10}$$

Thus here the Bohr–Sommerfeld quantization is exact,[2] despite the presence of the extra term $\hbar^2/2ma^2$ which follows from our particular choice of zero in the energy scale [see (3.3)].

After these elementary considerations, let us have a closer look at the functional analysis of our problem, following mostly Refs. 4 and 21. We shall denote by $\mathcal{H}$ the state space of the infinite well, that is, the closure of the linear span of the orthonormal set $\{|n\rangle, n\in\mathbb{N}\}$. In the x-representation, of course, $\mathcal{H}=L^2([0,\pi a],dx)$. We also denote by $AC(0,\pi a)$ the set of absolutely continuous functions on $[0,\pi a]$ whose derivatives belong to $L^2([0,\pi a],dx)$ and by $AC^2(0,\pi a)$ the set of functions in $L^2([0,\pi a],dx)$ whose weak derivatives are in $AC(0,\pi a)$ [we recall that, roughly speaking, a function is absolutely continuous iff it is the indefinite (Lebesgue) integral of an integrable function].

We begin with the Hamiltonian (3.3). More precisely, we define the infinite well Hamiltonian as the unbounded operator $H\equiv H_w$ in $L^2([0,\pi a],dx)$, acting as (3.3), on the dense domain

$$\mathcal{D}(H_w)=\{\psi\in AC^2(0,\pi a)\,|\,\psi(0)=\psi(\pi a)=0\}. \tag{3.11}$$

On this domain, H_w is self-adjoint, with purely discrete, nondegenerate spectrum $\{E_n=\hbar\omega e_n, n=0,1,...\}$, and the corresponding eigenfunctions $\{\psi_n, n=0,1,...\}$ form an orthonormal basis. Furthermore, the resolvent

$$R_w(-\hbar\omega)\equiv(H_w+\hbar\omega)^{-1}=\frac{1}{\hbar\omega}\sum_{n=0}^{\infty}\frac{1}{(n+1)^2}|n\rangle\langle n|$$

is a trace-class operator, with trace norm and Hilbert–Schmidt norm, respectively:

$$\|R_w(-\hbar\omega)\|_1=\frac{1}{\hbar\omega}\sum_{n=0}^{\infty}\frac{1}{(n+1)^2}=\frac{\pi^2}{6}\frac{1}{\hbar\omega},$$

$$\|R_w(-\hbar\omega)\|_2=\frac{1}{\hbar\omega}\left[\sum_{n=0}^{\infty}\frac{1}{(n+1)^4}\right]^{1/2}=\frac{\pi^2}{\sqrt{90}}\frac{1}{\hbar\omega}.$$

At this stage, it is instructive to compare the Hamiltonian of the infinite well with that of a free particle constrained on a circle of radius $a/2$. Here also, the Hilbert space is $L^2([0,\pi a],dx)$. The Hamiltonian H_c has the same expression as $H_w \equiv H$, but on the domain

$$\mathcal{D}(H_c)=\{\psi\in AC^2(0,\pi a)\,|\,\psi(0)=\psi(\pi a),\psi'(0)=\psi'(\pi a)\}, \tag{3.12}$$

and it is also self-adjoint on its domain. The spectrum is again purely discrete, the eigenvalues coincide with half of those of H_w, namely, $E_{2n-1}=\hbar\omega e_{2n-1}$, $n=1,2,...$, but each of them is doubly degenerate, and there is the additional, simple eigenvalue corresponding to $n=0$, namely, $e_{-1}=-1$. The eigenfunctions are

$$\left\{\sqrt{\frac{2}{\pi a}}\sin 2n\frac{x}{a},n=1,2,...;\sqrt{\frac{2}{\pi a}}\cos 2n\frac{x}{a},n=0,1,2,...\right\}, \tag{3.13}$$

and they constitute another orthonormal basis of $L^2([0,\pi a],dx)$. Thus, there exists a unitary correspondence between the two bases (3.6) and (3.13). However, the explicit form of this map rests on the full Hilbert space structure and not only on simple trigonometric identities (see also later in this work).

This is another instance of the well-known fact that the physics is determined by the boundary conditions, not only by the differential expression of the operator.

Now we turn to the canonical position and momentum operators. The position operator is $Q=x$, acting on $L^2([0,\pi a],dx)$. It is bounded and self-adjoint. As for the momentum, the natural choice is the operator $P_0=-id/dx$, acting on the dense domain

$$\mathcal{D}(P_0)=\{\psi\in AC(0,\pi a)\,|\,\psi(0)=\psi(\pi a)=0\}. \tag{3.14}$$

This operator is closed and symmetric, but *not* self-adjoint. Since its defect indices are (1,1), P_0 has self-adjoint extensions, in fact an infinite number of them, indexed by the points of a unit circle, namely $P_\alpha=-i\hbar d/dx$, acting on the dense domain

$$\mathcal{D}(P_\alpha)=\{\psi\in AC(0,\pi a)\,|\,\psi(\pi a)=\alpha\psi(0),\ \ |\alpha|=1\}. \tag{3.15}$$

For simplicity, we choose $\alpha=1$, that is, periodic boundary conditions. Any other choice $P_\alpha,\alpha\neq 1$, is physically acceptable, and yields similar results.

The operator $P\equiv P_1$ is a valid candidate for the momentum observable. Its spectrum is purely discrete and nondegenerate, $\sigma(P)=\{2n\hbar/a,n=0,\pm 1,\pm 2,...\}$, with corresponding eigenfunctions $\chi_n(x)=1/\sqrt{\pi a}\exp(i2nx/a)$. The trouble is that none of these belongs to the domain of the Hamiltonian H_w! And indeed, one has

$$\frac{P^2}{2m}\neq H_w+\frac{\hbar^2}{2ma^2}, \tag{3.16}$$

since

$$\mathcal{D}(P^2)=\{\psi\in AC^2(0,\pi a)\,|\,\psi(0)=\psi(\pi a),\psi'(0)=\psi'(\pi a)\},$$

so that, up to the constant $\hbar^2/2ma^2$, $P^2/2m$ coincides with the Hamiltonian H_c of a particle on a circle, not H_w!

To conclude, we evaluate the canonical commutation relations (CCRs), which take the standard form

$$[Q,P]=i\hbar I, \tag{3.17}$$

on the domain $\mathcal{D}(QP)\cap\mathcal{D}(PQ)=\mathcal{D}(P_0)$, as given in (3.14). Correspondingly, we obtain the uncertainty relations in the eigenstates ψ_n of the Hamiltonian H_w [compare with the classical case, (2.8) and (2.9)]:

$$\begin{aligned}\langle Q\rangle_n&=\frac{\pi a}{2},\\ \langle Q^2\rangle_n&=a^2\left(\frac{\pi^2}{3}-\frac{1}{2(n+1)^2}\right),\\ \langle P\rangle_n&=0,\\ \langle P^2\rangle_n&=\frac{1}{a^2}\hbar^2(n+1)^2,\end{aligned}\tag{3.18}$$

where $\langle\cdot\rangle_n\equiv\langle\psi_n|\cdot|\psi_n\rangle$. Note that, in the last relation, $\psi_n\in\mathcal{D}(P)$, but $\psi_n\notin\mathcal{D}(P^2)$, so that we really mean $\langle P^2\rangle_n\equiv\|P\psi_n\|^2$. Also, according to Ref. 3, the relation $\langle P\rangle_n=0$ expresses the fact that the current associated to the particle vanishes identically.

Taking all these relations together, we obtain the uncertainties

$$\langle\Delta Q\rangle_n^2=\langle Q^2\rangle_n-\langle Q\rangle_n^2=a^2\left(\frac{\pi^2}{12}-\frac{1}{2(n+1)^2}\right)\geqslant a^2\left(\frac{\pi^2}{12}-\frac{1}{2}\right),$$

$$\langle\Delta P\rangle_n^2=\langle P^2\rangle_n-\langle P\rangle_n^2=\frac{1}{a^2}\hbar^2(n+1)^2\geqslant\frac{\hbar^2}{a^2},$$

and the uncertainty relations

$$\langle\Delta Q\rangle_n\langle\Delta P\rangle_n=\hbar\left(\frac{(n+1)^2\pi^2}{12}-\frac{1}{2}\right)^{1/2}\geqslant\hbar\left(\frac{\pi^2}{12}-\frac{1}{2}\right)^{1/2}\simeq 0.57\hbar>\frac{1}{2}\hbar,\tag{3.19}$$

as expected for a quantum state which is *not* of minimal uncertainty. We will make similar considerations in Sec. IX for the case of coherent states.

However, although the CCRs (3.17) look perfectly normal, they still lead to inconsistencies, because of the unbounded character of the operators. The problem arises, for instance, when one tries to prove the absence of condensation in a one-dimensional interacting Bose gas,[22] by first putting the system in a finite box of length Λ with periodic boundary conditions, and then taking the thermodynamic limit $\Lambda\to\infty$. The key ingredient is the Bogoliubov inequality, namely

$$\tfrac{1}{2}\beta\langle AA^*+A^*A\rangle_\beta\langle[[C,H],C^*]\rangle_\beta\geqslant|\langle[C,A]\rangle_\beta|^2,\tag{3.20}$$

where H is the Hamiltonian, and $\langle X\rangle_\beta=\mathrm{Tr}(e^{-\beta H}X)/\mathrm{Tr}(e^{-\beta H})$ denotes the thermal average of the observable X with respect to the temperature $T=(k\beta)^{-1}$ and the Hamiltonian H. In the relation (3.20), A and C are observables of the system which are to be chosen in a convenient way for a specific application. The inequality (3.20) is perfectly valid for bounded operators, but some care must be exercised with domains in the case of unbounded ones, lest absurdities follow!

In the present case, there are two possibilities. The first one[22] consists in keeping the CCR (3.17), introducing a generalized notion of state as a quadratic form and generalizing the Bogoliubov inequality (3.20) in a corresponding way. This indeed allows one to prove the absence of condensation in the Bose gas for a reasonable class of interactions, including of course a gas of free particles.

An alternative[23] consists in keeping (3.20) unchanged, but generalizing the usual algebraic formalism to the quasi-*algebra generated by the operators Q, P. By this we mean the following. Define the dense domain

$$\mathcal{D}=\{\psi\in C^{\infty}(0.\pi a)\,|\,\psi^{(k)}(0)=\psi^{(k)}(\pi a),k=0,1,\ldots\}. \tag{3.21}$$

Then it is easy to see that

$$\mathcal{D}=\bigcap_{k=0}^{\infty}\mathcal{D}(P^k),$$

and this gives to $\mathcal{D}$ a natural structure of Fréchet space. From this one gets a rigged Hilbert space

$$\mathcal{D}\subset L^2([0,\pi a],dx)\subset\mathcal{D}',$$

where $\mathcal{D}'$ denotes the strong dual of $\mathcal{D}$. Define $\mathfrak{A}=\mathcal{L}(\mathcal{D},\mathcal{D}')$ as the space of all continuous linear maps from $\mathcal{D}$ into $\mathcal{D}'$. This space then carries a natural structure of quasi-*algebra in the sense of Ref. 24. Roughly speaking, this means that $\mathfrak{A}$ obeys the usual rules of algebra, except that the product AB of two elements of $\mathfrak{A}$ is well defined iff one of them leaves the domain $\mathcal{D}$ invariant. But then the canonical commutator $[Q,P]$, when viewed as an element of $\mathfrak{A}$, becomes

$$[Q,P]=i\hbar(I-\pi a\,\hat{\delta}(x)), \tag{3.22}$$

where $\hat{\delta}(x)$ denotes the multiplication operator $\mathcal{D}\ni\varphi\mapsto\delta(x)\varphi\in\mathcal{D}'$, an element of $\mathfrak{A}$. Then, with the modified CCR (3.22), the usual Bogoliubov inequality (3.20) holds on $\mathfrak{A}$ and the standard argument for proving the absence of condensation applies. The same reasoning can be made with any other momentum observable P_α $\alpha\neq 1$, only the r.h.s. of (3.22) becomes slightly more complicated.[23]

This somewhat long digression should convince the reader that the infinite well problem is really singular, and therefore formal considerations, in particular with respect to boundary conditions, may be misleading (see, for instance, Ref. 25 or 26)!

In the light of the preceding results, the time evolution (3.4) is trivial. On one hand, we can expand $\Psi(x,0)\equiv\psi(x)$ in terms of the basis of eigenvectors ψ_n given in (3.6):

$$\Psi(x,0)=\sum_{n=0}^{\infty}c_n\psi_n(x),$$

and thus

$$\Psi(x,t)=\sum_{n=0}^{\infty}c_n e^{-iHt/\hbar}\psi_n(x)=\sum_{n=0}^{\infty}c_n e^{-iE_nt/\hbar}\psi_n(x)=\sum_{n=0}^{\infty}c_n\psi_n(x,t).$$

Alternatively, one may obtain the same result[27] with help of the propagator (Green function) $G(x-x_0,t)$:

$$\Psi(x,t)=\int_0^{\pi a}G(x-x_0,t)\Psi(x_0,0)dx_0. \tag{3.23}$$

Since the Green function is the solution with initial condition $\delta(x-x_0)$ at $t=0$ [we must take, of course, $x_0\in(0,\pi a)$], we may write

$$
\begin{aligned}
G(x-x_0,t) &= e^{-iHt/\hbar}\delta(x-x_0) \\
&= e^{-iHt/\hbar}\sum_{n=0}^{\infty}\overline{\psi_n(x_0)}\psi_n(x) \\
&= \sum_{n=0}^{\infty}\overline{\psi_n(x_0)}e^{-iE_nt/\hbar}\psi_n(x) \\
&= \sum_{n=0}^{\infty}\overline{\psi_n(x_0)}\psi_n(x,t).
\end{aligned}
$$

Here we have used the relation

$$
\delta(x-x_0)=\sum_{n=0}^{\infty}\overline{\psi_n(x_0)}\psi_n(x) \Leftrightarrow \langle x_0|x\rangle=\sum_{n=0}^{\infty}\langle x_0|n\rangle\langle n|x\rangle,
$$

which expresses the completeness of the basis $\{|n\rangle\}$.

Inserting the value of $G(x-x_0,t)$ into (3.23), we get indeed

$$
\begin{aligned}
\Psi(x,t) &= \int_0^{\pi a}\sum_{n=0}^{\infty}\overline{\psi_n(x_0)}\psi_n(x,t)\Psi(x_0,0)dx_0 \\
&= \sum_{n=0}^{\infty}\psi_n(x,t)\int_0^{\pi a}\overline{\psi_n(x_0)}\Psi(x_0,0)dx_0 \\
&= \sum_{n=0}^{\infty}c_n\psi_n(x,t).
\end{aligned}
$$

Next we turn to the momentum representation. Since the spectrum of the operator P is discrete, the Hilbert space in the momentum representation reduces to the space l^2 of square summable sequences. This is just a reformulation of the theory of Fourier series, as opposed to the Fourier integral that makes the transition between the position and the momentum representation for quantum mechanics on the full line $\mathbb{R}$. This fact has been overlooked, for instance, in Ref. 26 [nothing, of course, forbids one to take the Fourier integral transform of the infinite well wave function $\Psi(x,t)$, but the result is just a mathematically equivalent version of the same object, *not* the momentum representation wave function]. Thus an arbitrary state $\psi\in\mathcal{H}$ is expressed in terms of the eigenstates χ_n of P,

$$
\psi=\sum_{n=-\infty}^{\infty}a_n\chi_n, \quad a_n=\langle\chi_n|\psi\rangle, \quad \text{thus} \quad \hat{\psi}\equiv\{a_n\}\in l^2.
$$

For instance, we obtain for the energy eigenstates

$$
\psi_{2k+1}(x)=-\frac{i}{\sqrt{2}}[\chi_{k+1}(x)-\chi_{-k-1}(x)], \tag{3.24}
$$

$$
\psi_{2k}(x)=-\frac{4}{\pi}\sum_{n=-\infty}^{\infty}\frac{2k+1}{4n^2-(2k+1)^2}\chi_n(x). \tag{3.25}
$$

These relations constitute in fact the unitary correspondence between two different orthonormal bases, as discussed after (3.13), and the map is indeed nontrivial.

A last topic that would deserve to be discussed is the solution of the infinite well problem in the path integral formalism. However, this is treated in full detail in Ref. 28, so we will refrain from reproducing it here.

IV. THE SAME FOR PÖSCHL–TELLER

Pöschl–Teller potentials were originally introduced in a molecular physics context. The energy eigenvalues and corresponding eigenstates are solutions to the Schrödinger equation

$$\left[-\frac{\hbar^2}{2m}\frac{d^2}{dx^2}+\frac{V_0}{2}\left(\frac{\lambda(\lambda-1)}{\cos^2 x/2a}+\frac{\kappa(\kappa-1)}{\sin^2 x/2a}\right)-\frac{\hbar^2}{8ma^2}(\lambda+\kappa)^2\right]\psi(x)=E\psi(x),\quad 0\leqslant x\leqslant \pi a, \tag{4.1}$$

where we have also shifted the Hamiltonian of the trapped particle of mass m by an amount equal to $-(\hbar^2/8ma^2)(\lambda+\kappa)^2$. Here, too, as for the infinite well, we have the choice of putting the potential equal to infinity outside the interval $[0,\pi a]$, or periodizing the problem, with period $2\pi a$.

Since the potential strength is overdetermined by specifying V_0, λ and κ simultaneously, we can freely put for convenience, as in Refs. 3 and 5,

$$V_0=\frac{\hbar^2}{4ma^2}. \tag{4.2}$$

With this choice, and the boundary conditions (BC) $\psi(0)=\psi(\pi a)=0$, the normalized eigenstates and the corresponding eigenvalues, all of them simple, are given by

$$\Psi_n(x)=[c_n(\kappa,\lambda)]^{-1/2}\left(\cos\frac{x}{2a}\right)^{\lambda}\left(\sin\frac{x}{2a}\right)^{\kappa}{}_2F_1\left(-n,n+\lambda+\kappa;\kappa+\frac{1}{2};\sin^2\frac{x}{2a}\right), \tag{4.3}$$

where $c_n(\kappa,\lambda)$ is a normalization factor that can be given analytically when κ and λ are positive integers, ${}_2F_1$ is a hypergeometric function, and

$$E_n=\frac{\hbar^2}{2ma^2}n(n+\lambda+\kappa)\equiv\hbar\omega e_n,\quad n=0,1,..., \tag{4.4}$$

with

$$\omega=\frac{\hbar}{2ma^2},\quad e_n=n(n+\lambda+\kappa),\quad \lambda,\kappa>1. \tag{4.5}$$

Note that the Bohr–Sommerfeld rule applied to the canonical action (2.25) yields [here we do *not* impose the normalization (4.2)]:

$$a\sqrt{2mE}-a\sqrt{mV_0}[\sqrt{\lambda(\lambda-1)}+\sqrt{\kappa(\kappa-1)}]=\hbar(n+\tfrac{1}{2}),$$

that is,

$$E_n=\frac{\hbar^2}{2ma^2}\left(n+\frac{1}{2}\right)^2+\frac{\hbar}{ma}\sqrt{mV_0}\left(n+\frac{1}{2}\right)[\sqrt{\lambda(\lambda-1)}+\sqrt{\kappa(\kappa-1)}]$$
$$+\frac{V_0}{2}[\sqrt{\lambda(\lambda-1)}+\sqrt{\kappa(\kappa-1)}]^2. \tag{4.6}$$

This formula is interesting on two counts at least.

(a) The first term in (4.6) gives, apart from the term 1/2 in $(n+1/2)$, the exact spectrum of the infinite well. More precisely, these values of the energy may be obtained simply by letting $V_0 \to 0$ in $V(x)$ and keeping in mind that $V=\infty$ outside $[0,\pi a]$.

(b) In the limit $V_0 \to \infty$, the first term in (4.6) can be neglected and one is left, up to a global, V_0 dependent, shift, with the spectrum of a harmonic oscillator with elementary quantum

$$\hbar\omega = \hbar \sqrt{\frac{V_0}{ma^2}} [\sqrt{\lambda(\lambda-1)} + \sqrt{\kappa(\kappa-1)}].$$

Hence, the Pöschl–Teller potential interpolates between the square-well and the harmonic oscillator.

As we did in the case of the infinite well, let us examine now the functional-analytic properties of the Pöschl–Teller Hamiltonian. The Schrödinger equation (4.1) is an eigenvalue equation for an ordinary differential Sturm–Liouville operator, which is singular at both ends of the interval $[0,\pi a]$ (see, for instance, Ref. 29). The situation now depends on the values of λ and κ, as follows from the thorough analysis of Gesztesy *et al.*[30] In particular, there exist critical values λ, $\kappa = \frac{3}{2}$, although one would naively expect the value 1 to play that role.

Let $\dot{T}$ be the minimal differential operator, that is, the operator defined by the differential expression (4.1) on the space $C_0^\infty(0,\pi a)$ of C^∞ functions with (compact) support strictly contained in the open interval $(0,\pi a)$. Then, we have the following.

- If λ, $\kappa \geqslant \frac{3}{2}$, the operator $\dot{T}$ is in the limit point case at both ends $x=0$, πa, thus it is essentially self-adjoint and its closure H_{PT} automatically satisfies Dirichlet BCs at $x=0$ and $x=\pi a$, i.e., $\psi(0)=\psi(\pi a)=0$.
- If $\lambda \geqslant \frac{3}{2} > \kappa$, the operator $\dot{T}$ is in the limit point case at $x=\pi a$, but in the limit circle case at $x=0$; hence the defect indices of its closure are (1,1) and we need a BC at $x=0$ for defining a self-adjoint extension; quite naturally, we choose the Dirichlet BC, the one at $x=\pi a$ being automatic.
- If $\kappa \geqslant \frac{3}{2} > \lambda$, the operator $\dot{T}$ is in the limit point case at $x=0$, but in the limit circle case at $x=\pi a$; again we impose a Dirichlet BC at $x=\pi a$, the one at $x=0$ being automatic.
- If $\frac{1}{2} < \lambda$, $\kappa < \frac{3}{2}$, the operator $\dot{T}$ is in the limit circle case at both ends $x=0$, πa, the defect indices are (2,2), and we have to impose two BCs, again chosen as Dirichlet. Notice that the Dirichlet BC may be written as $\psi(0)=\psi(\pi a)=0$ in the first, regular, case, but it takes a more complicated form in the singular cases.[30] Clearly this choice of boundary conditions is dictated by physics, namely, it is the same as for the infinite well. One may also say that the chosen self-adjoint extension of $\dot{T}$ is obtained by analytic extension from large positive values λ, $\kappa \geqslant \frac{3}{2}$, since, in this context, everything depends analytically on λ, κ.

In all four cases, we define the Pöschl–Teller Hamiltonian as the self-adjoint operator H_{PT} in $L^2([0,\pi a],dx)$, acting as the left-hand side of (4.1), on the dense domain

$$\mathcal{D}(H_{\mathrm{PT}}) = \{\psi \in AC^2(0,\pi a) \,|\, V_{\mathrm{PT}}\psi \in L^2([0,\pi a],dx) \ \text{ and } \ \psi \text{ satisfies a Dirichlet BC at } x=0,\pi a\}, \tag{4.7}$$

where V_{PT} is the Pöschl–Teller potential. The Pöschl–Teller Hamiltonian has pure point spectrum, without multiplicity, and given by $E_n = (\hbar^2/2ma^2)n(n+\lambda+\kappa) \equiv \hbar\omega e_n$, $n=0,1,...$, as given in (4.4), with corresponding eigenvectors (4.3). Notice that these eigenfunctions belong to the domain $\mathcal{D}(H_{\mathrm{PT}})$, since they satisfy the boundary conditions (by assumption[5]).

Several remarks are in order at this point.

(1) First, the case $\frac{1}{2} < \lambda$, $\kappa < 1$ (the mixed cases have no physical relevance) corresponds to the inverted well, yet the spectrum of H_{PT} remains unchanged, that is, pure point and positive.

Although the potential is now attractive, it is too close to the walls to allow negative energy bound states. This counterintuitive situation follows, of course, from the Dirichlet BC that make the walls impenetrable and thus confine the particle inside of the interval. On the other hand, for λ or $\kappa<\frac{1}{2}$, the problem is of a different nature and the analysis of Ref. 30 does not apply any more (presumably, here one faces again the ''fall towards the center'' phenomenon[2]).

(2) Next, one may choose different BCs for defining a self-adjoint extension of $\dot{T}$. An interesting choice is to take the full periodicity interval $[-\pi a,\pi a]$, that is, $(-\pi a,0)\cup(0,\pi a)$, and to impose to both ψ and ψ' continuity conditions at $x=0$ and periodic BCs at $x=\pm\pi a$. The resulting self-adjoint Hamiltonian $H_{\mathrm{PT}}^{\mathrm{per}}$ also has a pure point spectrum, namely $\{n(n+\lambda+\kappa),(n+1)(n+1-\lambda-\kappa),n=0,1,2,...\}$, with all eigenvalues simple. For $\lambda=\kappa=1$, one indeed recovers the doubly degenerate spectrum of the circle Hamiltonian H_c of Sec. III.

(3) Finally, the real difference with respect to the values of λ, κ comes when one periodizes the Pöschl–Teller Hamiltonian over the whole line, that is, on $\mathbb{R}\backslash\pi a\mathbb{Z}$, with continuity BCs at $x\in\pi a\mathbb{Z}$. Then, if $\lambda\geqslant\frac{3}{2}$ or $\kappa\geqslant\frac{3}{2}$, the periodized Hamiltonian $H_{\mathbb{R}}^{\mathrm{per}}$ is self-adjoint, and has a pure point spectrum, with each eigenvalue of infinite multiplicity. On the contrary, if $\frac{1}{2}<\lambda$, $\kappa\leqslant\frac{3}{2}$, then $H_{\mathbb{R}}^{\mathrm{per}}$ really looks as the Hamiltonian of a 1-D crystal, and, indeed, it has no eigenvalue and its spectrum has a band structure, that is, it is purely continuous with infinitely many gaps.[7,8,30]

Coming back to the interval $[0,\pi a]$, the resolvent of the Pöschl–Teller Hamiltonian H_{PT} reads

$$R_{\mathrm{PT}}\left(-\frac{1}{4}\hbar\omega(\lambda+\kappa)^2\right)\equiv\left(H_{\mathrm{PT}}+\frac{1}{4}\hbar\omega(\lambda+\kappa)^2\right)^{-1}=\frac{1}{\hbar\omega}\sum_{n=0}^{\infty}\frac{1}{\left[n+\frac{1}{2}(\lambda+\kappa)\right]^2}|n,\lambda,\kappa\rangle\langle n,\lambda,\kappa|,$$

where $|n,\lambda,\kappa\rangle$ denotes the eigenfunction Ψ_n of (4.3). As before, it is a trace-class operator, with trace norm:

$$\left\|R_{\mathrm{PT}}\left(-\frac{1}{4}\hbar\omega(\lambda+\kappa)^2\right)\right\|_1=\frac{1}{\hbar\omega}\sum_{n=0}^{\infty}\frac{1}{\left[n+\frac{1}{2}(\lambda+\kappa)\right]^2}.$$

Note that the Hilbert space and the momentum observable P remain the same as in the case of the infinite well. Thus, the previous discussion remains valid and the same difficulties are present. For instance, as for (3.16), $P^2/2m$ does *not* coincide with the first term of H_{PT}. Also one can calculate, at least in principle, the analogs of (3.24) and (3.25), which are simply the Fourier series expansion of the Pöschl–Teller energy eigenstates Ψ_n.

V. THE LIMITS

In this section, we shall investigate various limiting cases. Let us begin with the infinite square-well. Since the natural dimensionless variable is $y=x/a$, we may rewrite the Hamiltonian (3.3) in terms of y, and we get the scaling equation

$$H_{\mathrm{W}}\equiv H_{\mathrm{W}}[a]=\frac{1}{a^2}H_{\mathrm{W}}[1]. \tag{5.1}$$

The operator $H_{\mathrm{W}}[1]$ is self-adjoint in $L^2([0,\pi],dy)$, its eigenvalues are $E_n[1]=(\hbar^2/2m)n(n+2)$, and one has the scaling law $E_n[a]=(1/a^2)E_n[1]$. From these relations, the two limits $a\to0$ (infinitely narrow well) and $a\to\infty$ (infinitely large well) are trivial. The spectrum keeps the same shape, only the eigenvalues scale as $1/a^2$.

The same considerations apply to the Pöschl–Teller Schrödinger equation (4.1). If we do not impose the normalization relation (4.2), we get the scaling relation

$$H_{\mathrm{PT}} \equiv H_{\mathrm{PT}}[a, V_0] = \frac{1}{a^2} H_{\mathrm{PT}}[1, a^2 V_0]. \tag{5.2}$$

With (4.2), this becomes, exactly as for the infinite well,

$$H_{\mathrm{PT}}[a] = \frac{1}{a^2} H_{\mathrm{PT}}[1], \tag{5.3}$$

and the same for the eigenvalues. Thus, when the well gets narrower as $a \to 0$, the eigenvalues increase as $1/a^2$, but the spectrum keeps the same shape. Similarly, $a \to \infty$ implies $V_0 \to 0$, and the spacing between successive eigenvalues goes to zero: in the limit, we recover a free particle, with continuous energy spectrum $[0, \infty)$.

Next we analyze the limit $\lambda, \kappa \to 1$, that is, the limit Pöschl–Teller→infinite square-well. For simplicity, we take the symmetric case $\lambda = \kappa$, with Pöschl–Teller potential (1.2). As in the case of the infinite square-well, the symmetric Pöschl–Teller Hamiltonian is self-adjoint and its resolvent

$$R_{\mathrm{PT}}(-\hbar\omega\lambda^2) \equiv (H_{\mathrm{PT}} + \hbar\omega\lambda^2)^{-1} = \frac{1}{\hbar\omega} \sum_{n=0}^{\infty} \frac{1}{(n+\lambda)^2} |n,\lambda\rangle\langle n,\lambda|$$

is a trace-class operator, with trace norm:

$$\| R_{\mathrm{PT}}(-\hbar\omega\lambda^2) \|_1 = \frac{1}{\hbar\omega} \sum_{n=0}^{\infty} \frac{1}{(n+\lambda)^2}.$$

As for the limit Pöschl–Teller→infinite square-well, the exact statement is that $H_{\mathrm{PT}} \to H_{\mathrm{W}}$ in strong resolvent sense as $\lambda \to 1$, that is, $R_{\mathrm{PT}}(z) \to R_{\mathrm{W}}(z)$ strongly, for all nonreal z. This follows from Ref. 4, Theorem VIII.25 (a), as we now prove. The domain $C_0^\infty(0, \pi a)$ is dense in $L^2([0, \pi a], dx)$ and it is a core both for H_{W} and for $H_{\mathrm{PT}}[\lambda]$, for any $\lambda \geqslant \frac{3}{2}$.[21] Then, we obtain a core for $H_{\mathrm{PT}}[\lambda]$, $1 < \lambda < \frac{3}{2}$, by taking the set $\mathcal{D}_{\mathrm{PT}} = \{\psi = \phi + c_1\psi_1 + c_2\psi_2, \phi \in C_0^\infty(0, \pi a)\}$, where ψ_1 and ψ_2 are two solutions of $H_{\mathrm{PT}}\chi = k^2\chi$, $\mathrm{Im}\, k \geqslant 0$, chosen in such a way that ψ obeys the boundary conditions that define H_{PT}. In our case of Dirichlet BC, this implies[30] that $c_1 = 0$ and $\psi_2 = \Psi_n$, the eigenfunction (4.3), taken for $\lambda = \kappa$.

Choose any decreasing sequence $\{\lambda_j, j = 1,2,...; \lambda_j > 1, \lambda_j \to 1 \text{ as } j \to \infty\}$. Then, $H_{\mathrm{PT}}[\lambda_j]\psi \to H_{\mathrm{W}}\psi$, for each $\psi = \phi + c\psi_2 \in \mathcal{D}_{\mathrm{PT}}$. Indeed,

$$\begin{aligned} \| H_{\mathrm{PT}}[\lambda_j]\psi - H_{\mathrm{W}}\psi \| &= \left\| V_{\lambda_j}(x)\psi - \frac{\hbar^2}{2ma^2}(\lambda_j^2 - 1)\psi \right\| \\ &= \frac{\hbar^2}{ma^2} \left\| \lambda_j(\lambda_j - 1) \left[\sin\frac{x}{a} \right]^{-2} \psi - \frac{1}{2}(\lambda_j^2 - 1)\psi \right\| \\ &= (\lambda_j - 1)\frac{\hbar^2}{ma^2} \left(\lambda_j \left\| \left[\sin\frac{x}{a} \right]^{-2} \psi \right\| + \frac{1}{2}(\lambda_j + 1)\|\psi\| \right) \to 0 \quad \text{as} \quad j \to \infty, \end{aligned}$$

since both $\phi \in C_0^\infty(0, \pi a)$ and $\psi_2 = \Psi_n$ belong to the domain of $[\sin x/a]^{-2}$. By the theorem quoted, this implies that $H_{\mathrm{PT}} \to H_{\mathrm{W}}$ in a strong resolvent sense. As a consequence, by Ref. 4, Theorem VIII.24, for each eigenvalue $E_n = \hbar\omega n(n+2)$ of the limiting operator H_{W}, there is, for each j, an eigenvalue $E_n[\lambda_j] = \hbar\omega n(n + 2\lambda_j)$ of $H_{\mathrm{PT}}[\lambda_j]$ such that $E_n[\lambda_j] \to E_n$ as $j \to \infty$. Put in a simpler way, the eigenvalues $E_n[\lambda]$ are continuous in λ and $E_n[\lambda] \to E_n$ as $\lambda \to 1$, for each $n = 0,1,2,....$

Finally, there is the semiclassical limit $\hbar \to 0$, $n\hbar = \text{const}$, but this problem is fully treated in the literature, for instance, in Ref. 2, so we omit it.

VI. THE DYNAMICAL ALGEBRA $\mathfrak{su}(1,1)$

Behind the spectral structure of the infinite well or Pöschl–Teller Hamiltonians, there exists a dynamical algebra generated by lowering and raising operators.[17,31] The latter are defined by

$$a|n\rangle = \sqrt{e_n}|n-1\rangle, \tag{6.1}$$

$$a^\dagger|n\rangle = \sqrt{e_{n+1}}|n+1\rangle, \tag{6.2}$$

with

$$e_n = n(n+2), \text{ for the infinite well,}$$

$$e_n = n(n+\lambda+\kappa), \text{ for the Pöschl-Teller potential, } n = 0,1,2,\ldots.$$

Then we note that the operator

$$X_N = a^\dagger a \tag{6.3}$$

is diagonal with eigenvalues e_n:

$$X_N|n\rangle = e_n|n\rangle. \tag{6.4}$$

Note that the number operator N,

$$N|n\rangle = n|n\rangle, \tag{6.5}$$

is given in terms of X_N by

$$N = -\tfrac{1}{2}(\lambda+\kappa) + (X_N + \tfrac{1}{4}(\lambda+\kappa)^2)^{1/2}. \tag{6.6}$$

For any diagonal operator Δ with eigenvalues δ_n,

$$\Delta|n\rangle = \delta_n|n\rangle, \tag{6.7}$$

we denote its finite difference by Δ'. The latter is defined as the diagonal operator with eigenvalues $\delta'_n \equiv \delta_{n+1} - \delta_n$,

$$\Delta'|n\rangle = \delta'_n|n\rangle. \tag{6.8}$$

More generally, the mth finite difference $\Delta^{(m)}$ will be recursively defined by

$$\Delta^{(m)} = (\Delta^{(m-1)})'. \tag{6.9}$$

Now, from the infinite matrix representation (in the basis $|n\rangle$) of the operators a and $a^\dagger$,

$$a = \begin{pmatrix} 0 & \sqrt{e_1} & 0 & 0 & \ldots \\ 0 & 0 & \sqrt{e_2} & 0 & \ldots \\ 0 & 0 & 0 & \sqrt{e_3} & \ldots \\ \ldots & \ldots & \ldots & \ldots & \ldots \end{pmatrix}, \tag{6.10}$$

$$a^{\dagger}=\begin{pmatrix} 0 & 0 & 0 & 0 & \cdots \\ \sqrt{e_1} & 0 & 0 & 0 & \cdots \\ 0 & \sqrt{e_2} & 0 & 0 & \cdots \\ 0 & 0 & \sqrt{e_3} & 0 & \cdots \\ \cdots & \cdots & \cdots & \cdots & \cdots \end{pmatrix}, \tag{6.11}$$

it is easy to check that

$$[a,a^{\dagger}]=\begin{pmatrix} e_1-e_0 & 0 & 0 & \cdots \\ 0 & e_2-e_1 & 0 & \cdots \\ 0 & 0 & e_3-e_2 & 0 \\ \cdots & \cdots & \cdots & \cdots \end{pmatrix}=X_N', \tag{6.12}$$

$$X_N'|n\rangle=e_n'|n\rangle,\ \ e_n'=e_{n+1}-e_n=2n+3,\ \text{resp. } 2n+1+\lambda+\kappa. \tag{6.13}$$

We also check that, for any diagonal operator Δ, we have

$$\begin{aligned} [a,\Delta]&=\Delta' a, \\ [a^{\dagger},\Delta]&=-a^{\dagger}\Delta'. \end{aligned} \tag{6.14}$$

Therefore,

$$[a,X_N']=X_N''a,$$

with

$$X_N''|n\rangle=e_n''|n\rangle=(e_{n+1}'-e_n')|n\rangle=2|n\rangle. \tag{6.15}$$

So

$$X_N''=2I,\ \ X_N'''=0, \tag{6.16}$$

and

$$[a,X_N']=2a. \tag{6.17}$$

Similarly,

$$[a^{\dagger},X_N']=-2a^{\dagger}. \tag{6.18}$$

In summary, there exists a ''dynamical'' Lie algebra, which is generated by $\{a,a^{\dagger},X_N'\}$. Then the commutation rules

$$[a,a^{\dagger}]=X_N',\ \ [a,X_N']=2a,\ \ [a^{\dagger},X_N']=-2a^{\dagger} \tag{6.19}$$

clearly indicate that it is isomorphic to

$$\mathfrak{su}(1,1)\sim\mathfrak{sl}(2,\mathbb{R})\sim\mathfrak{so}(2,1). \tag{6.20}$$

A more familiar basis for (6.20) is given [in $\mathfrak{so}(2,1)$ notation] by

$$L^{-}=\frac{1}{\sqrt{2}}a,\ \ L^{+}=\frac{1}{\sqrt{2}}a^{\dagger},\ \ L_{12}=\frac{1}{2}X_N', \tag{6.21}$$

where L_{12} is the generator of the compact subgroup SO(2), namely,

$$[L^{\pm},L_{12}]=\mp L^{\pm},\ \ [L^{-},L^{+}]=L_{12}. \tag{6.22}$$

Note that if we add the operator X_N (i.e., the Hamiltonian H) to the set $\{a,a^{\dagger},X_N'\}$, we obtain an infinite-dimensional Lie algebra contained in the enveloping algebra. Indeed

$$\begin{gathered}[a,X_N]=X_N'a,\ \ [a^{\dagger},X_N]=-a^{\dagger}X_N',\\ [a,X_N'a]=2a^2,\ \ [a^{\dagger},X_N'a]=-X_N'^2-2X_N,\end{gathered} \tag{6.23}$$

etc. Note also the relation between X_N and X_N':

$$X_N=\tfrac{1}{4}(X_N'^2-2X_N'-3),\ \ \text{resp.}\ \ \tfrac{1}{4}(X_N'^2-2X_N'-(\lambda+\kappa+1)(\lambda+\kappa)). \tag{6.24}$$

In the same vein, we note that the condition $X_N'''=0$ is necessary for obtaining a genuine Lie algebra (instead of a subset of the enveloping algebra). Therefore, $\mathfrak{su}(1,1)$ is the *only* dynamical Lie algebra that can arise in such a problem.

It follows from the considerations above that the space $\mathcal{H}$ of states $|n\rangle$ carries some representation of $\mathfrak{su}(1,1)$. The latter is found by examining the formulas for the $\mathfrak{su}(1,1)$ discrete series representation.[32–34]

Given $\eta=1/2,1,3/2,...$ the discrete series UIR U_η is realized on the Hilbert space $\mathcal{H}_\eta$ with basis $\{|\eta,n\rangle, n\in\mathbb{N}\}$ through the following actions of the Lie algebra elements:

$$L_{12}|\eta,n\rangle=(\eta+n)|\eta,n\rangle, \tag{6.25}$$

$$L^{-}|\eta,n\rangle=\frac{1}{\sqrt{2}}\sqrt{(2\eta+n-1)n}\,|\eta,n-1\rangle, \tag{6.26}$$

$$L^{+}|\eta,n\rangle=\frac{1}{\sqrt{2}}\sqrt{(2\eta+n)(n+1)}\,|\eta,n+1\rangle. \tag{6.27}$$

The representation U_η fixes the Casimir operator

$$Q=-L_{12}(L_{12}-1)+2L^{+}L^{-} \tag{6.28}$$

to the following value:

$$Q\mathcal{H}_\eta=\eta(\eta-1)\mathcal{H}_\eta. \tag{6.29}$$

Using (6.21) and (6.26), and comparing with (6.1), (6.2), and (6.13), we obtain the specific value of η for the infinite well problem, namely, $\eta=3/2$, so that we can make the identifications $\mathcal{H}_{3/2}\equiv\mathcal{H}$,$|3/2,n\rangle\equiv|n\rangle$. On the other hand, we obtain a continuous range of values for the Pöschl–Teller potentials:

$$\eta=\frac{\lambda+\kappa+1}{2}>\frac{3}{2}, \tag{6.30}$$

and we shall denote the corresponding Hilbert spaces and states (3.6) by $\mathcal{H}_\eta$ and $|\eta,n\rangle$, respectively. The relation (6.30) simply means that we are here in the presence of the (abusively called) discrete series representations of the universal covering of SU(1, 1), except for the interval $\eta\in(1/2,3/2)$.

VII. COHERENT STATES FOR THE INFINITE WELL

In a general setting, consider a strictly increasing sequence of positive numbers

$$0=e_0<e_1<e_2\ldots<e_n<\ldots, \tag{7.1}$$

which are eigenvalues of a self-adjoint positive operator X_N in some Hilbert space $\mathcal{H}$,

$$X_N|n\rangle=e_n|n\rangle, \tag{7.2}$$

where the set $\{|n\rangle, n\in\mathbb{N}\}$ is an orthonormal basis of $\mathcal{H}$.[16,31]

There corresponds to (7.1) a (generically infinite) dynamical Lie algebra with basis $\{a,a^\dagger,X'_N,\ldots\}$, with the notation of the previous section. There also corresponds a continuous family $\{|z\rangle, z\in C(0,R)\subset\mathbb{C}\}$ [$C(0,R)$ is the open disk of center 0 and radius R] of normalized coherent states, eigenvectors of the operator a:

$$a|z\rangle=z|z\rangle. \tag{7.3}$$

The explicit form of those coherent states is

$$|z\rangle=\frac{1}{N(|z|^2)}\sum_{n\geqslant 0}\frac{z^n}{\sqrt{\rho_n}}|n\rangle, \tag{7.4}$$

where

$$\rho_0=1,\ \ \rho_n=e_1e_2\cdots e_n,\ \ n>0. \tag{7.5}$$

$N(|z|^2)$ is a normalization factor:

$$\langle z|z\rangle=1\Leftrightarrow(N(|z|^2))^2=\sum_{n=0}^{+\infty}\frac{|z|^{2n}}{\rho_n}. \tag{7.6}$$

Of course, these coherent states exist only if the radius of convergence

$$R=\limsup_{n\to+\infty}\sqrt[n]{\rho_n} \tag{7.7}$$

is nonzero. In fact, different specific choices of ρ_n give rise to many different families of coherent states, as illustrated in a series of recent works.[35–38]

Now suppose that X_N is (up to a factor) the Hamiltonian for a quantum system,

$$H=\hbar\omega X_N. \tag{7.8}$$

Then the coherent states (7.4) evolve in time as

$$e^{-iHt/\hbar}|z\rangle=\frac{1}{N(|z|^2)}\sum_{n\geqslant 0}\frac{z^n}{\sqrt{\rho_n}}e^{-i\omega e_n t}|n\rangle. \tag{7.9}$$

If $e_n\propto n$, i.e., in the case of the harmonic oscillator, the temporal evolution of the coherent state $|z\rangle$ reduces to a rotation in the complex plane, namely, $e^{-iHt/\hbar}|z\rangle=|ze^{-i\omega t}\rangle$. In general, however, we will lose the temporal stability of our family of coherent states (7.4). Hence, in order to restore it, we must extend our original definitions to the entire orbits

$$\{e^{-iHt/\hbar}|z\rangle,\ \ z\in C(0,R),\ \ t\in I\}. \tag{7.10}$$

The interval I is the whole real line when e_n is generic, whereas it can be restricted to a period, that is, a finite interval $[a, b]$,

$$b-a=\frac{2\pi}{\omega\alpha} \tag{7.11}$$

if $e_n \in \alpha\mathbb{N}$. A straightforward calculation now shows that

$$\langle z|H|z\rangle=\langle z|\hbar\omega X_N|z\rangle=\hbar\omega|z|^2. \tag{7.12}$$

Therefore the quantity $|z|^2$ is the average energy evaluated in the elementary quantum unit $\hbar\omega$. Note that

$$\hbar|z|^2\equiv J \tag{7.13}$$

is simply the action variable in the case where H is the Hamiltonian of the harmonic oscillator and the variable z is given the meaning of a classical state in the phase space $\mathbb{C}$. Indeed, the given choice of ρ_n in (7.5) ensures that $\langle z|H|z\rangle=\omega J$ for a general Hamiltonian.

On the other hand, introducing the dimensionless number

$$\gamma=\omega t, \quad \gamma\in\omega I, \tag{7.14}$$

we are naturally led to study the continuous family of states

$$|z,\gamma\rangle=\frac{1}{N(J)}\sum_{n\geqslant 0}\frac{z^n e^{-i\gamma e_n}}{\sqrt{\rho_n}}|n\rangle. \tag{7.15}$$

These states, parametrized by $(z,\gamma)\in C(0,R)\times I$, may be called ''coherent'' for several reasons. First they are, by construction, eigenvectors of the operator

$$a(\gamma)\equiv e^{-i\gamma H/\hbar\omega}a e^{i\gamma H/\hbar\omega}, \tag{7.16}$$

namely,

$$a(\gamma)|z,\gamma\rangle=z|z,\gamma\rangle. \tag{7.17}$$

They obey the temporal stability condition

$$e^{-iHt/\hbar}|z,\gamma\rangle=|z,\gamma+\omega t\rangle. \tag{7.18}$$

Again, if we consider the harmonic oscillator case, we do not make any distinction between the argument of the complex parameter z and the angle variable γ, since then $e_n=n$ and $z^n e^{-i\gamma n}=(ze^{-i\gamma})^n$, so that the only parameters we need are $J=|z|^{1/2}$ and γ. The latter are easily identified with the classical action-angle variables. We shall stick to the minimal parametrization set in the present generalization and shall denote from now on our coherent states by

$$|J,\gamma\rangle=\frac{1}{N(J)}\sum_{n\geqslant 0}\frac{J^{n/2}e^{-i\gamma e_n}}{\sqrt{\rho_n}}|n\rangle. \tag{7.19}$$

In a suitable way[16] (see also the discussion in Sec. X), it is also acceptable to regard the parametrization (J, γ) as ''action-angle'' variables, and it is convenient to refer to them as such, even when keeping in mind the possibility of extending $\sqrt{J}$ to the complex plane, i.e., replacing $\sqrt{J}$ by z.

Let us now make those things explicit in our problem of the infinite well. In that case,

$$\rho_n = e_1 e_2 \ldots e_n = \frac{n!(n+2)!}{2}, \tag{7.20}$$

$$|J,\gamma\rangle = \frac{1}{N(J)} \sum_{n\geqslant 0} \frac{J^{n/2} e^{-i\gamma n(n+2)}}{\sqrt{n!(n+2)!/2}} |n\rangle. \tag{7.21}$$

The normalization factor is easily calculated in terms of the modified Bessel function I_ν:[39]

$$(N(J))^2 = 2\sum_{n=0}^{+\infty} \frac{J^n}{n!(n+2)!} \tag{7.22}$$

$$= \frac{2}{J} I_2(2\sqrt{J}). \tag{7.23}$$

The radius of convergence $R = \limsup_{n\to+\infty} \sqrt[n]{n!(n+2)!/2}$ is of course infinite. Moreover, since the e_n's here are natural numbers, the interval of variation of the evolution parameter γ can be chosen as $I=[0,2\pi]$.

The positive constants ρ_n arise as moments of a probability distribution $\rho(u)$,

$$\rho_n = \int_0^\infty u^n \rho(u) du. \tag{7.24}$$

Also, $\rho(u)$ is explicitly given in terms of the other modified Bessel function K_ν,[39]

$$\rho(u) = u K_2(2\sqrt{u}). \tag{7.25}$$

It is then immediate to check that the family $\{|J,\gamma\rangle, J\in\mathbb{R}^+, \gamma\in[0,2\pi]\}$ resolves the unit operator, i.e.,

$$I = \int |J,\gamma\rangle\langle J,\gamma| d\mu(J,\gamma), \tag{7.26}$$

with

$$\int (\cdot) d\mu(J,\gamma) = \frac{1}{2\pi} \int_{-\pi}^{\pi} d\gamma \int_0^{+\infty} k(J)(\cdot) dJ, \tag{7.27}$$

where

$$k(J) = N(J)^2 \rho(J) = 2 I_2(2\sqrt{J}) K_2(2\sqrt{J}). \tag{7.28}$$

As it is well known, the overlap of two coherent states does not vanish in general. Explicitly, we have

$$\langle J',\gamma'|J,\gamma\rangle = \frac{2}{N(J)N(J')} \sum_{n\geqslant 0} \frac{(JJ')^{n/2}}{n!(n+2)!} e^{-in(n+2)(\gamma-\gamma')}. \tag{7.29}$$

If $\gamma=\gamma'$, we obtain a Bessel function

$$\langle J',\gamma|J,\gamma\rangle = \frac{2}{(JJ')^{1/2} N(J)N(J')} I_2(2(JJ')^{1/4}). \tag{7.30}$$

If $\gamma\neq\gamma'$, we can give an integral representation of (7.29) in terms of a theta function and Bessel functions:[39]

$$\langle J',\gamma'|J,\gamma\rangle=\frac{e^{i(\gamma-\gamma')/4}}{i\pi N(J)N(J')}\int_0^\pi d\varphi\,\theta_1\left(\frac{\varphi}{\pi},-\frac{\gamma-\gamma'}{\pi}\right)$$
$$\times\left[\frac{-e^{-i(\varphi-\gamma+\gamma')}}{(JJ')^{1/2}}I_2(2(JJ')^{1/4}e^{i(\varphi-(\gamma-\gamma')/2+\pi/2)})\right.$$
$$\left.+\frac{e^{i(\varphi+\gamma-\gamma')}}{(JJ')^{1/2}}I_2(2(JJ')^{1/4}e^{-i(\varphi+(\gamma-\gamma')/2-\pi/2)})\right]. \tag{7.31}$$

VIII. COHERENT STATES FOR THE PÖSCHL–TELLER POTENTIALS

The relations (7.20) and (7.21) of the previous section are easily generalized to the present case. We shall list them without unnecessary comments.

From the energies $E_n=\hbar\omega e_n$ given by (4.4), we get the moments

$$\rho_n=e_1e_2\ldots e_n=n!\,\frac{\Gamma(n+\nu+1)}{\Gamma(\nu+1)} \tag{8.1}$$

with $\nu=\lambda+\kappa>2$.

Thus, the coherent states read

$$|J,\gamma\rangle=\frac{[\Gamma(\nu+1)]^{1/2}}{N(J)}\sum_{n\geqslant 0}\frac{J^{n/2}e^{-i\gamma n(n+\nu)}}{[n!\Gamma(n+\nu+1)]^{1/2}}|n\rangle. \tag{8.2}$$

The normalization is then given by

$$N(J)^2=\Gamma(\nu+1)\sum_{n\geqslant 0}\frac{J^n}{n!\Gamma(n+\nu+1)}=\frac{\Gamma(\nu+1)}{J^{\nu/2}}I_\nu(2\sqrt{J}). \tag{8.3}$$

The radius of convergence R is infinite. The interval of variation of the evolution parameter γ is generically the whole real line, unless the parameter ν is an integer.

The numbers ρ_n are moments of a probability distribution $\rho(u)$ involving the modified Bessel function K_ν:

$$\rho_n=\int_0^\infty u^n\rho(u)du, \tag{8.4}$$

with [compare with (7.25)]

$$\rho(u)=\frac{2}{\Gamma(\nu+1)}u^{\nu/2}K_\nu(2\sqrt{u}). \tag{8.5}$$

It might be useful to recall here the well-known relation between modified Bessel functions,[39]

$$K_\nu(z)=\frac{\pi}{2\sin\pi\nu}[I_{-\nu}(z)-I_\nu(z)],\quad \nu\notin\mathbb{Z}. \tag{8.6}$$

The resolution of the unity is then explicitly given by

$$I=\int|J,\gamma\rangle\langle J,\gamma|d\mu(J,\gamma), \tag{8.7}$$

with

$$\int (\cdot)d\mu(J,\gamma)=\lim_{\Gamma\to\infty}\frac{1}{2\Gamma}\int_{-\Gamma}^{\Gamma}d\gamma\left[\int_{0}^{+\infty}k(J)(\cdot)dJ\right], \tag{8.8}$$

where

$$k(J)=N(J)^2\rho(J)=2I_\nu(2\sqrt{J})K_\nu(2\sqrt{J}).$$

Finally, the overlap between two coherent states is given by the series

$$\langle J',\gamma'|J,\gamma\rangle=\frac{\Gamma(\nu+1)}{N(J)N(J')}\sum_{n\geqslant 0}\frac{(JJ')^{n/2}}{n!\Gamma(n+\nu+1)}e^{-in(n+\nu)(\gamma-\gamma')}, \tag{8.9}$$

which reduces to a Bessel function for $\gamma=\gamma'$:

$$\langle J',\gamma|J,\gamma\rangle=\frac{\Gamma(\nu+1)}{N(J)N(J')}\frac{I_\nu(2(JJ')^{1/4})}{(JJ')^{\nu/4}}. \tag{8.10}$$

At this point, we should emphasize the fact that, when $\gamma=0$ and J is taken as a complex parameter, our temporally stable families of coherent states (7.21) and (8.2) are nothing else but the temporal evolution orbits of the well-known Barut-Girardello coherent states for SU(1, 1).[40] It seems that this connection between infinite square-well/Pöschl–Teller potentials and the latter CS has not been pointed out so far.

In addition, we should also quote Nieto and Simmons,[41] who have considered the infinite square-well and the Pöschl–Teller potentials as examples of their construction of coherent states. The latter are required to minimize an uncertainty relation or, equivalently, to be eigenvectors of some ''lowering operator'' A^- (*à la* Barut-Girardello[40]). However, those states have a totally different meaning and should be considered only in the semiclassical limit.

IX. PHYSICAL FEATURES OF THE COHERENT STATES

In this section, we shall study the spatial and temporal features of the coherent states, treating together the infinite well CS (7.19) and the Pöschl–Teller CS (8.2), the former being obtained from the latter simply by putting $\nu=\lambda+\kappa=2$. As (infinite) superposition of stationary states which are spatially and temporally periodic for integer values of ν, they should display nonambiguous revivals and fractional revivals. Quantum revivals have recently attracted the interest of many authors and some of them have considered the infinite square-well as a toy-model for preparing more realistic studies. But let us first recall the main definitions concerning the notion of revival, as given in Ref. 42. For other related works, see Refs. 43–48; for updated references, see also Ref. 26.

A *revival* of a wave function occurs when a wave function evolves in time to a state closely reproducing its initial form. A *fractional revival* occurs when the wave function evolves in time to a state that can be described as a collection of spatially distributed subwave functions, each of which closely reproduces the shape of the initial wave function. If a revival corresponds to phase alignments of nearest-neighbor energy eigenstates that constitute the wave function, it can be asserted that a fractional revival corresponds to phase alignments of nonadjacent energy eigenstates that constitute this wave function.

For a general wave packet of the form

$$|\psi(t)\rangle=\sum_{n\geqslant 0}c_n e^{-iE_n t/\hbar}|n\rangle, \tag{9.1}$$

with $\Sigma_{n\geqslant 0}|c_n|^2=1$, the concept of revival arises from the weighting probabilities $|c_n|^2$. Suppose that the expansion (9.1) is strongly weighted around a mean value $\langle n\rangle$ for the number operator N, $N|n\rangle=n|n\rangle$:

$$\langle\psi|N|\psi\rangle=\sum_{n\geqslant 0} n|c_n|^2\equiv\langle n\rangle. \tag{9.2}$$

Let $\overline{n}\in\mathbb{N}$ be the closest integer to $\langle n\rangle$. Assuming that the spread $\sigma\approx\Delta n\equiv[\langle n^2\rangle-\langle n\rangle^2]^{1/2}$ is small compared with $\langle n\rangle\approx\overline{n}$, we expand the energy E_n in a Taylor series in n around the centrally excited value $\overline{n}$:

$$E_n\simeq E_{\overline{n}}+E'_{\overline{n}}(n-\overline{n})+\tfrac{1}{2}E''_{\overline{n}}(n-\overline{n})^2+\tfrac{1}{6}E'''_{\overline{n}}(n-\overline{n})^3+\ldots, \tag{9.3}$$

where each prime on $E_{\overline{n}}$ denotes a derivative. These derivatives define distinct time scales,[43] namely the *classical period* $T_{\rm cl}=2\pi\hbar/|E'_{\overline{n}}|$; the *revival time* $t_{\rm rev}=2\pi\hbar/(1/2|E''_{\overline{n}}|)$; the *superrevival time* $t_{\rm sr}=2\pi\hbar/(1/6|E'''_{\overline{n}}|)$; and so on. Inserting this expansion into the evolution factor $e^{-iE_nt/\hbar}$ of (9.1) allows us to understand the possible occurrence of a quasiperiodic revival structure of the wave packet (9.1) *according* to the weighting probability $n\mapsto|c_n|^2$. In the present case, we have

$$E_n=\frac{\hbar}{2ma^2}n(n+\nu)=\frac{\hbar}{2ma^2}[\overline{n}(\overline{n}+\nu)+(2\overline{n}+\nu)(n-\overline{n})+(n-\overline{n})^2]. \tag{9.4}$$

So the first characteristic time is the ''classical'' period

$$T_{\rm cl}=\frac{2\pi\hbar}{2\overline{n}+\nu}\,\frac{2ma^2}{\hbar^2}=\frac{2\pi ma^2}{\hbar(\overline{n}+\nu/2)}, \tag{9.5}$$

which should be compared with the actual classical (Bohr–Sommerfeld) counterpart deduced from (2.21) and (2.25),

$$T=\frac{2\pi ma^2}{A+a\sqrt{mV_0}[\sqrt{\lambda(\lambda-1)}+\sqrt{\kappa(\kappa-1)}]}. \tag{9.6}$$

The second characteristic time is the revival time

$$t_{\rm rev}=\frac{4\pi ma^2}{\hbar}=(2\overline{n}+\nu)T_{\rm cl}. \tag{9.7}$$

There is no superrevival time here, because the energy is a quadratic function of n.

With these definitions, the wave packet (9.1) reads in the present situation (up to a global phase factor):

$$|\psi(t)\rangle=\sum_{n\geqslant 0} c_n e^{-2\pi i[(n-\overline{n})t/T_{\rm cl}+(n-\overline{n})^2t/t_{\rm rev}]}|n\rangle. \tag{9.8}$$

Hence, it will undergo motion with the classical period, modulated by the revival phase.[49] Since $T_{\rm cl}\ll t_{\rm rev}$ for large $\overline{n}$, the classical period dominates for small values of t (mod $t_{\rm rev}$), and the motion is then periodic with period $T_{\rm cl}$. As t increases from 0 and becomes nonnegligible with respect to $t_{\rm rev}$, the revival term $(n-\overline{n})^2t/t_{\rm rev}$ in the phase of (9.8) causes the wave packet to spread and collapse. The latter gathers into a series of subsidiary waves, the fractional revivals, which move periodically with a period equal to a rational fraction of $T_{\rm cl}$. Then, a full revival obviously occurs at each multiple of $t_{\rm rev}$.

In order to put into evidence these revival structures for a given wave packet $\psi(x,t)=\langle x|\psi(t)\rangle$, an efficient method is to calculate its autocorrelation function[49]

$$A(t)=\langle\psi(x,0)|\psi(x,t)\rangle=\sum_{n\geqslant 0}|c_n|^2e^{-iE_nt/\hbar}. \tag{9.9}$$

Numerically, $|A(t)|^2$ varies between 0 and 1. The maximum $|A(t)|^2=1$ is reached when $\psi(x,t)$ exactly matches the initial wave packet $\psi(x,0)$, and the minimum 0 corresponds to nonoverlapping: $\psi(x,t)$ is far from the initial state. On the other hand, fractional revivals and fractional ''superrevivals'' appear (in the general case) as periodic peaks in $|A(t)|^2$ with periods that are rational fractions of the classical round trip time $T_{\rm cl}$ and the revival time $t_{\rm rev}$.

Since the weighting distribution $|c_n|^2$ is crucial for understanding the temporal behavior of the wave packet (9.1), it is worthwhile to give also some general precisions of a statistical nature[20,50,51] before examining the special case of our coherent states. It is clear that the revival features will be more or less apparent, depending on the value of the deviation $(n-\overline{n})$ (relatively to n) that is effectively taken into account in the construction of the wave packet. In this respect, it is interesting to compare $|c_n|^2$ with the Poissonian case $\langle n\rangle^n e^{-\langle n\rangle}/n!$ and with the Gaussian case, $(2\pi(\Delta n)^2)^{-1/2}\exp[-(n-\langle n\rangle)^2/2(\Delta n)^2]$.

A quantitative estimate is given by the so-called Mandel parameter Q[20,50] defined as follows:

$$Q=\frac{(\Delta n)^2}{\langle n\rangle}-1. \tag{9.10}$$

In the Poissonian case, we have $Q=0$, i.e., $\Delta n=\langle n\rangle^{1/2}$. We say that the weighting distribution is sub-Poissonian (resp. super-Poissonian) if $Q<0$ (resp. $Q>0$). In the super-Poissonian case, i.e., $\Delta n>\langle n\rangle^{1/2}$, the set of states $|n\rangle$ which contribute significantly to the wave packet can be rather widely spread around $n\simeq\langle n\rangle$, and this may have important consequences for the properties of localization and temporal stability of the wave packet.

When the wave packets are precisely our coherent states

$$|J,\gamma\rangle=\frac{1}{N(J)}\sum_{n\geqslant 0}\frac{J^{n/2}e^{-ie_n\gamma}}{\sqrt{\rho_n}}|n\rangle, \tag{9.11}$$

the weighting distribution depends on J,

$$|c_n|^2=\frac{J^n}{N(J)^2\rho_n}, \tag{9.12}$$

and we can see the interesting statistical interplay with the probability distribution $\rho(J)$ of which the ρ_n are the moments [see (7.24)].

To simplify, we put

$$E(J)\equiv N(J)^2=\sum_{n\geqslant 0}\frac{J^n}{\rho_n}=\frac{\Gamma(\nu+1)}{J^{\nu/2}}I_\nu(2\sqrt{J}),\quad \nu\geqslant 2. \tag{9.13}$$

The following mean values are easily computed, together with their asymptotic values for large J:[39]

$$\langle n\rangle=\frac{J}{E(J)}\frac{d}{dJ}E(J)=J\frac{d}{dJ}\ln E(J)=\sqrt{J}\frac{I_{\nu+1}(2\sqrt{J})}{I_\nu(2\sqrt{J})}=\sqrt{J}-\frac{\nu}{2}-\frac{1}{4}+O\left(\frac{1}{\sqrt{J}}\right). \tag{9.14}$$

$$\begin{aligned}\langle n^2\rangle &= \frac{J}{E(J)}\frac{d}{dJ}J\frac{d}{dJ}E(J)\\ &= \sqrt{J}\frac{I_{\nu+1}(2\sqrt{J})}{I_\nu(2\sqrt{J})}+J\frac{I_{\nu+2}(2\sqrt{J})}{I_\nu(2\sqrt{J})}\\ &= \langle n\rangle + J\frac{I_{\nu+2}(2\sqrt{J})}{I_\nu(2\sqrt{J})}\\ &\approx \sqrt{J}(\sqrt{J}+1)\quad (J\gg 1).\end{aligned} \tag{9.15}$$

So, the dispersion is

$$\begin{aligned}(\Delta n)^2 &= J\frac{I_{\nu+2}(2\sqrt{J})}{I_\nu(2\sqrt{J})}+\langle n\rangle-\langle n\rangle^2\\ &= \frac{J}{[I_\nu(2\sqrt{J})]^2}(I_{\nu+2}(2\sqrt{J})I_\nu(2\sqrt{J})-[I_{\nu+1}(2\sqrt{J})]^2)+\sqrt{J}\frac{I_{\nu+1}(2\sqrt{J})}{I_\nu(2\sqrt{J})}\\ &\approx \frac{\sqrt{J}}{2},\quad \text{for } J \text{ large.}\end{aligned} \tag{9.16}$$

Finally, the Mandel parameter is given explicitly by

$$Q = J\frac{d}{dJ}\ln\frac{d}{dJ}\ln E(J) = \sqrt{J}\left[\frac{I_{\nu+2}(2\sqrt{J})}{I_{\nu+1}(2\sqrt{J})}-\frac{I_{\nu+1}(2\sqrt{J})}{I_\nu(2\sqrt{J})}\right]. \tag{9.17}$$

It is easily checked that $(I_{\nu+1}(x))^2 \geqslant I_\nu(x)I_{\nu+2}(x)$, for any $x\geqslant 0$, and thus, $Q\leqslant 0$ for any $J\geqslant 0$. Note that $Q\simeq 0$ for large J, while $Q\simeq -J$ for small J. Therefore, $|c_n|^2$ is sub-Poissonian in the case of our coherent states, whereas a quasi-Poissonian behavior is restored at high J. This fact is important for understanding the curves presented in Fig. 11(a), which show the distributions

$$D(n,J,\nu)\equiv|c_n|^2=\frac{1}{n!\Gamma(n+\nu+1)}\frac{J^{n+\nu/2}}{I_\nu(2\sqrt{J})} \tag{9.18}$$

for $\nu=2$ and different values of J. For the sake of comparison, we show in Fig. 11(b) the corresponding distribution $|c_n|^2=(1/n!)|\alpha|^{2n}e^{-|\alpha|^2}$ for the harmonic oscillator. Exactly as in the latter case, it can be shown easily that the distribution $D(n,J,\nu)$ tends for $J\to\infty$ to a Gaussian distribution. This Gaussian is centered at $\sqrt{J}-\nu/2-1/4$ and has a half-width equal to $(1/\sqrt{2})J^{1/4}$:

$$D(n,J,\nu)\approx\frac{1}{\sqrt{\pi\sqrt{J}}}e^{-[n-(\sqrt{J}-\nu/2-1/4)]^2/\sqrt{J}}\quad (n\gg 1). \tag{9.19}$$

We consider now the probability density $|\langle x|J,\gamma\rangle|^2$ as a function of the evolution parameter $\gamma=\omega t$ for increasing values of J. This evolution is shown in Fig. 12 in the case of the infinite square-well, for $J=2$, 10, and 50. We can see here at $\gamma=\pi=1/2t_{\text{rev}}$ a perfect revival of the initial shape at $\gamma=0$. This revival takes place near the opposite wall, as expected from the symmetry with respect to the center of the well. On the other hand, the ruling of the wave packet evolution by the classical period $T_{\text{cl}}=t_{\text{rev}}/(2\bar{n}+\nu)=\pi/(\bar{n}+1)$ becomes more and more apparent as J increases. We also note that, at multiples of the half reversal time $1/2t_{\text{rev}}=\pi$, the probability of localization near the walls increases with the energy J.

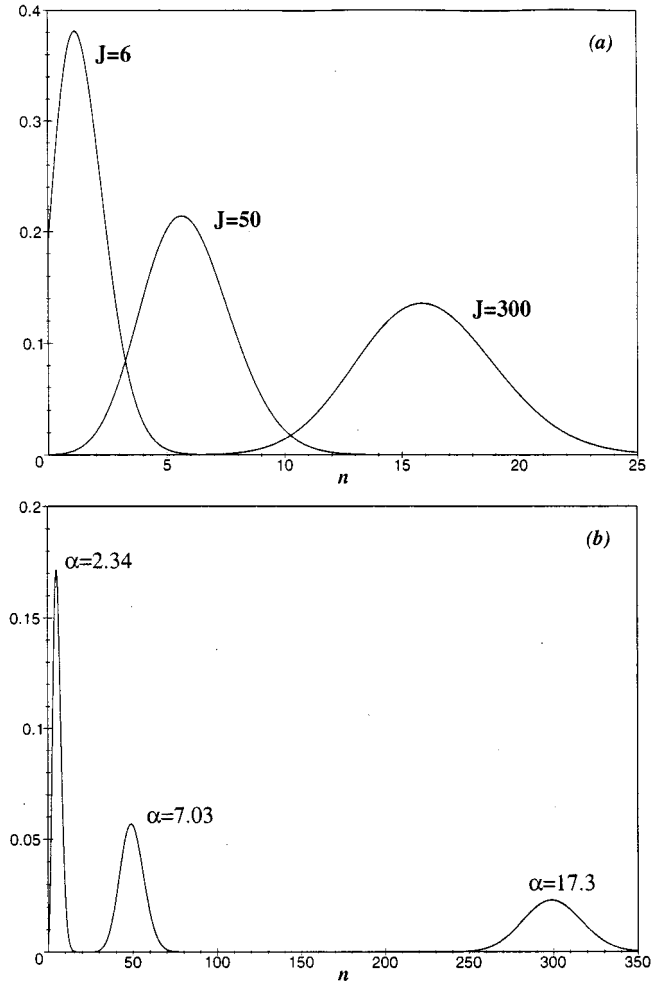

FIG. 11. (a) The weighting distribution $|c_n|^2 \equiv D(n,J,\nu)$ given in (9.18) for the infinite square-well $\nu=2$ and different values of J. Note the almost Gaussian shape at $J=300$, centered at $n=\langle n\rangle=\sqrt{J}-\nu/2-1/4\simeq 16$, with a width equal to $2\Delta n=\sqrt{2}J^{1/4}\simeq 5.9$. (b) The same for for the harmonic oscillator: $|c_n|^2=(1/n!)|\alpha|^{2n}e^{-|\alpha|^2}$. The values of α are chosen so as to get essentially the same mean energy values as in (a): $\alpha=\sqrt{J}$.

In Fig. 13, we show the squared modulus

$$|\langle J,0|e^{-iHt/\hbar}|J,0\rangle|^2=|\langle J,0|J,\omega t\rangle|^2 \tag{9.20}$$

$$=\frac{\Gamma(\nu+1)}{N(J)^2}\left|\sum_{n\geqslant 0}\frac{J^n}{n!\Gamma(n+\nu+1)}e^{-i\omega n(n+\nu)t}\right|^2 \tag{9.21}$$

of the autocorrelation versus $\gamma=\omega t$ for the infinite well, for $J=2$, 10, 50. Like in Fig. 12, we draw the attention on the large J regime. Here fractional revivals occur as intermediate peaks at rational multiples of the classical period $T_{\rm cl}=\pi/(\overline{n}+1)\approx\pi/\sqrt{J}$, $J\gg 1$, and they tend to diminish as J increases, which is clearly the mark of a quasiclassical behavior. The same quantity is shown in Fig. 14 for the Pöschl–Teller potential, for $J=20$ and 40. Note that, in actual calculations like this, one has to choose a finite number of orthonormal eigenstates of the Pöschl–Teller potential, denoted here by $n_{\max}$. Correspondingly, the normalization of the coherent state $|J,\gamma\rangle$ has then to be modified as

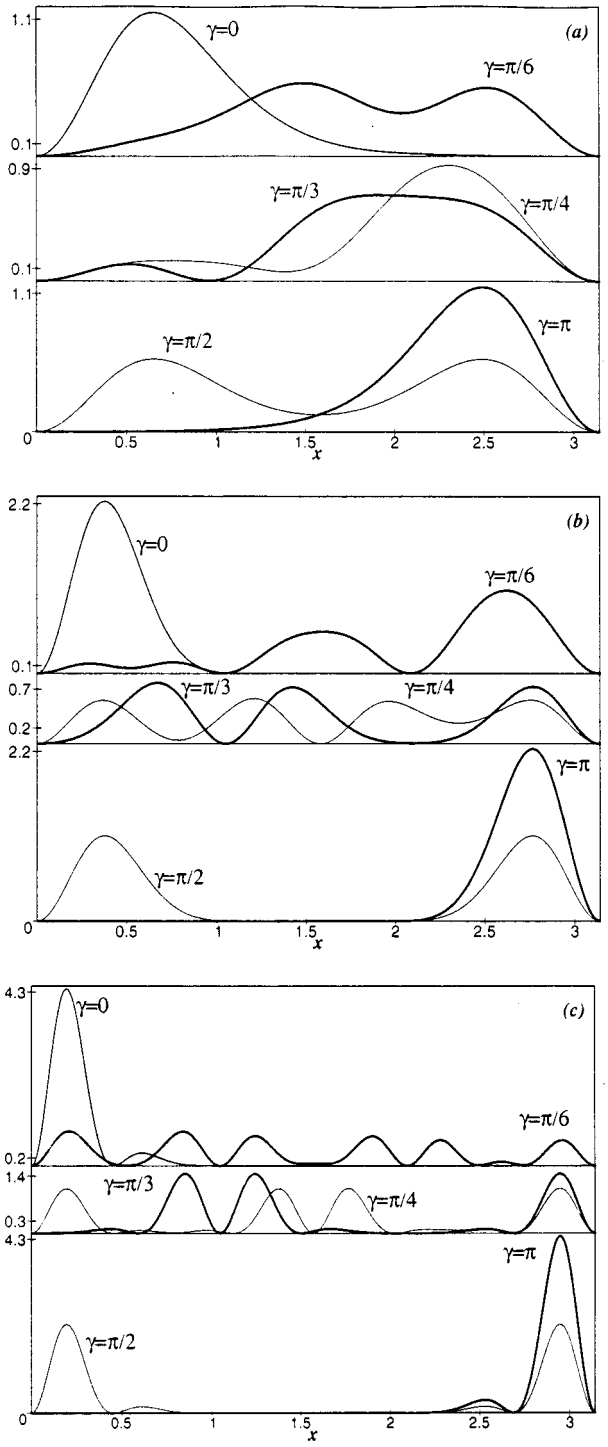

FIG. 12. The evolution (vs γ) of the probability density $|\langle x|J,\gamma\rangle|^2$, in the case of the infinite square-well for (a) $J=2$; (b) $J=10$; and (c) $J=50$. We note the perfect revival at $\gamma=\pi=1/2t_{\text{rev}}$ (in suitable units), symmetric with respect to the center of the well.

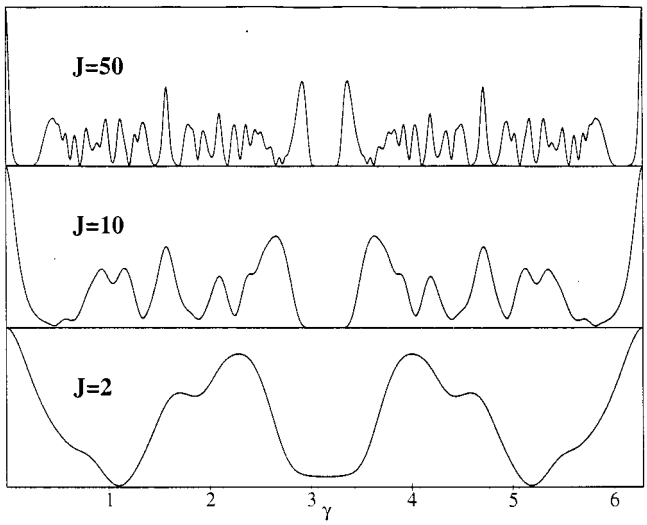

FIG. 13. Squared modulus $|\langle J,0|J,\omega t\rangle|^2$ of the autocorrelation vs $\gamma=\omega t$ for the infinite square-well, for $J=2$, 10, 50. As in Fig. 12, the large J regime is characterized by the occurrence of fractional revivals.

$$\sum_{p=0}^{n_{\max}} \frac{J^p}{p!\Gamma(p+\kappa+\lambda)} = \frac{I_{\kappa+\lambda-1}(2\sqrt{J})}{J^{1/2(\kappa+\lambda-1)}} - \frac{J^{n_{\max}+1}\,{}_1F_2(1;n_{\max}+2,n_{\max}+1+\kappa+\lambda;J)}{(n_{\max}+1)!\Gamma(n_{\max}+1+\kappa+\lambda)}, \quad (9.22)$$

where ${}_1F_2$ is a hypergeometric function.

Most interesting is the temporal behavior of the average position $\langle Q\rangle$ and of the average momentum $\langle P\rangle$ in such coherent states:

$$\langle J,0|A(t)|J,0\rangle = \langle J,0|e^{iHt/\hbar}Ae^{-iHt/\hbar}|J,0\rangle = \langle J,\omega t=\gamma|A|J,\omega t=\gamma\rangle \quad (9.23)$$

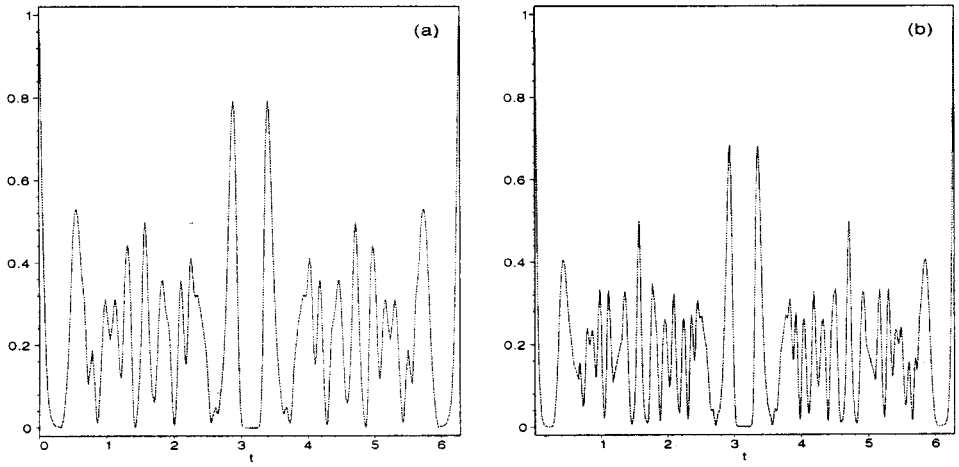

FIG. 14. Squared modulus $|\langle J,0|J,\omega t\rangle|^2$ of the autocorrelation for the Pöschl–Teller potential with $n_{\max=10}$, for (a) $J=20$; (b) $J=40$.

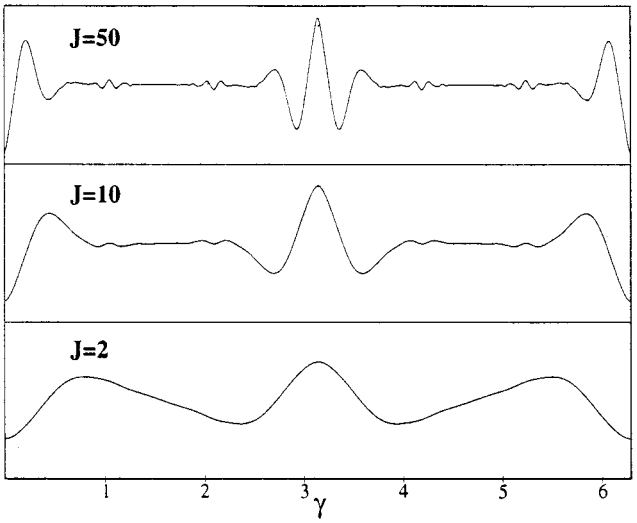

FIG. 15. Temporal behavior of the average position of the particle in the infinite square-well (in the Heisenberg picture), $\langle J,0|Q(t)|J,0\rangle=\langle J,\omega t=\gamma|Q|J,\omega t=\gamma\rangle$, as a function of $\gamma=\omega t$, for $J=2$, 10, 50.

for $A=Q$ or $A=P\equiv P_1$. This temporal behavior is shown in Fig. 15 for the average position in the infinite square-well, for $J=2$, 10, 50. We note the tendency to stability around the classical mean value $1/2\pi a$, except for strong oscillations of ultrashort duration between the walls near $\gamma=n\pi$. The latter increase with J as expected when one approaches the classical regime. For the sake of comparison, we show in Fig. 16 the temporal behavior of the average position in the asymmetric Pöschl–Teller potential $(\kappa,\lambda)=(4,8)$, for $J=20$ and 50.

Figure 17 shows the temporal behavior of the average momentum $\langle J,0|P(t)|J,0\rangle$ in the case of the infinite square-well, for $J=2$, 10, 50. Like in Fig. 15, we note the presence of strong ultrashort oscillations at $\gamma=n\pi$, whereas a tendency to perfect stability (around the classical mean value 0) exists at intermediate values of γ (this tendency is, however, less marked than for the average position).

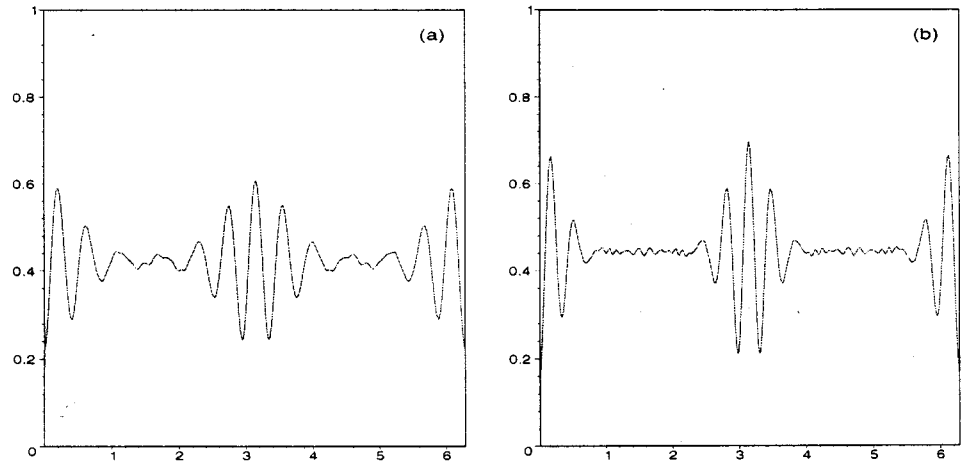

FIG. 16. Temporal behavior of the average position for the asymmetric Pöschl–Teller potential $(\lambda,\kappa)=(4,8)$ with $n_{\max=10}$, for (a) $J=20$ and (b) $J=50$.

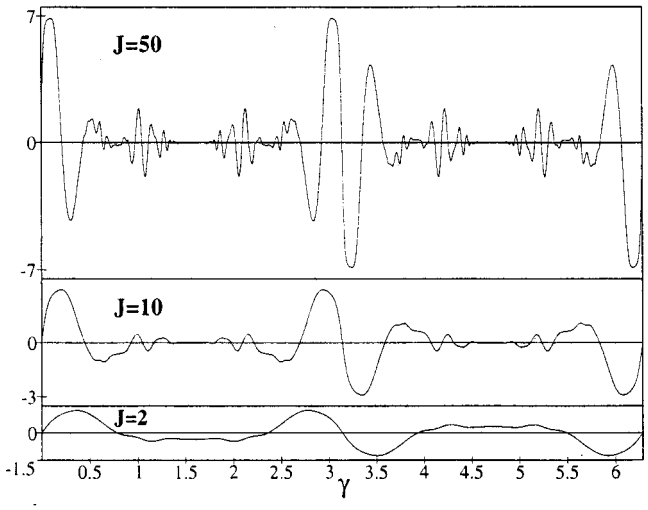

FIG. 17. Temporal behavior of the average momentum $\langle J,0|P(t)|J,0\rangle$ in the case of the infinite square-well, for $J=2$, 10, 50.

Next, we examine the uncertainty in position and momentum, in order to evaluate how close these CS come to saturating the uncertainty relations. Figure 18 shows the temporal behavior of the squared uncertainty in position, $(\Delta Q)^2$, for the infinite square-well, again for $J=2$, 10, 50. Figure 19 does the same for momentum, $(\Delta P)^2$, and Fig. 20 shows the product of the two, $(\Delta Q)^2(\Delta P)^2$. We note here that the product approaches the limit value 1/4 (saturation of the Heisenberg inequality) for a longer time at small J. This is consistent with (3.19), since at small J the wave packet is centered near the ground state, for which we reach the minimal value $(0.57)^2$. On the other hand, we also note the strong oscillations of $(\Delta Q)^2(\Delta P)^2$ at half the revival time, a fact which is consistent with the previous figures, showing the average position and momentum.

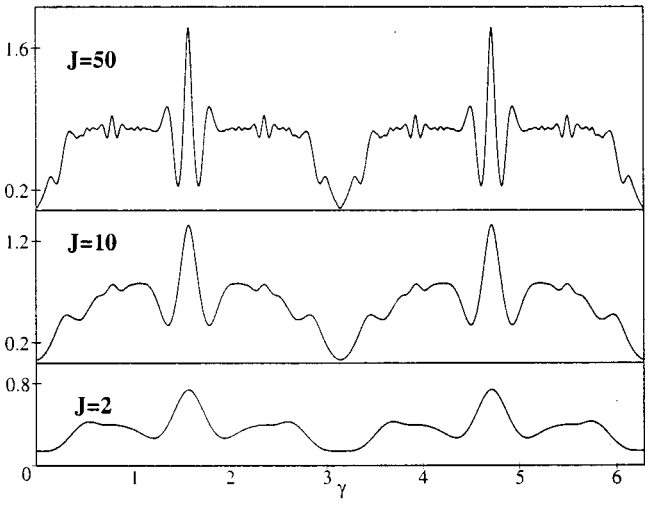

FIG. 18. Temporal behavior of the squared uncertainty in position $(\Delta Q)^2$, in the case of the infinite square-well, for $J=2$, 10, 50.

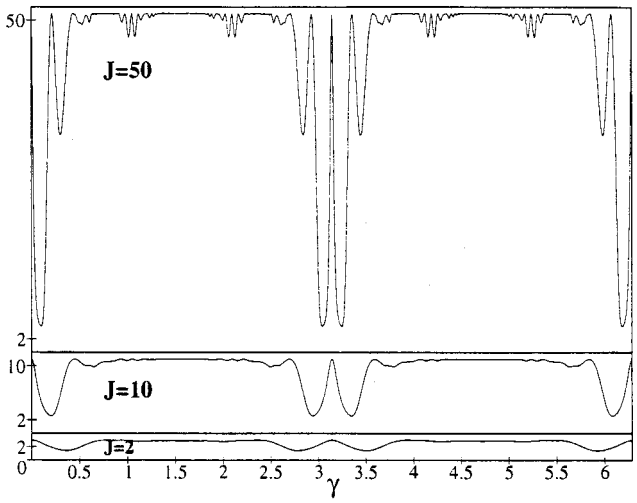

FIG. 19. Temporal behavior of the squared uncertainty in momentum $(\Delta P)^2$, in the case of the infinite square-well, for $J=2$, 10, 50.

At $1/2t_{\mathrm{rev}}$, the quantum interferences are dominant and they enforce the spreading of the wave packet for a relatively long duration.

As a last bit of information (but not the least!), we exhibit in Fig. 21 the temporal behavior of the average position $\langle J,0|Q(t)|J,0\rangle$ for the infinite square-well, for a very high value $J=10^6$, near $\gamma=\omega t=0$. Here the quasiclassical behavior is striking in the range of values considered for γ. These temporal oscillations are clearly governed by $T_{\mathrm{cl}}\simeq\pi/\sqrt{J}=3\times10^{-3}$ and should be compared with their purely classical counterpart of Fig. 3.

X. DISCUSSION

Coherent states have many roles to play in quantum theory. Among those roles is included the Hilbert space representation that coherent states induce, which is largely kinematical in nature, and

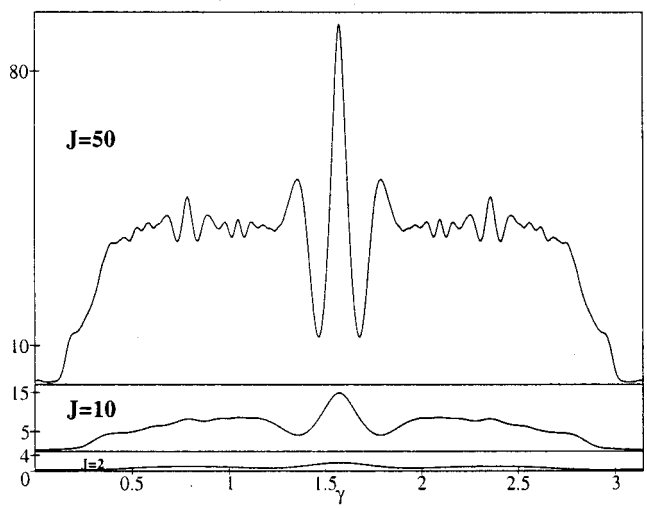

FIG. 20. Temporal behavior of the product of the squared uncertainties $(\Delta Q)^2(\Delta P)^2$, in the case of the infinite square-well, for $J=2$, 10, 50.

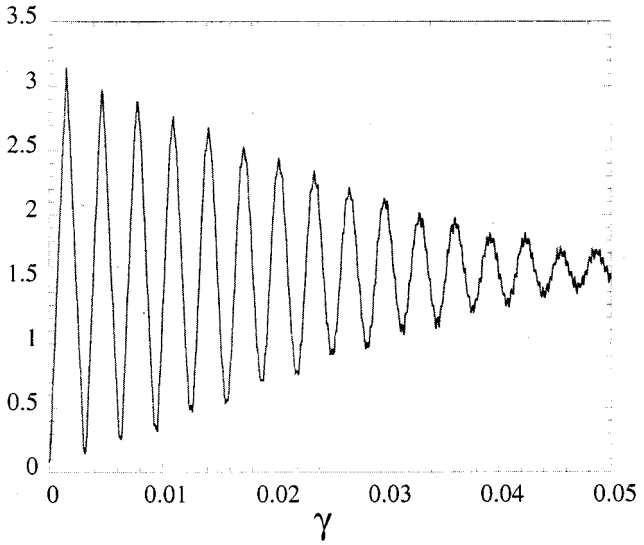

FIG. 21. Temporal behavior of the average position in the case of the infinite square-well, for a very high value $J=10^6$.

the adaption of the coherent states themselves to some particular dynamics and the possible description that ensues. To accommodate these goals, the definition of what constitutes a ''set of coherent states'' has been increasingly broadened over the years. Widening the scope of coherent states also widens the range of potential applications. This basic principle lies behind the developments in this article.

The minimal definition of a set of coherent states involves continuity of labeling and a resolution of unity, and, therefore, holomorphic representations and/or definitions via groups are just a small subset of the possibilities. In the present article, we have exploited this diversity in coherent state definition to study the motion of a particle in Pöschl–Teller potentials as well as in the closely related infinite square-well potential.

The specific choices we have made for the set of coherent states are based on two additional guiding principles besides continuity and resolution of unity.[15,16] The first of these is ''temporal stability,'' which in words asserts that the temporal evolution of any coherent state always remains a coherent state. The second of these, referred to as the ''action identity'' in Ref. 16, chooses variables for the coherent state labels that have as close a connection as possible with classical ''action-angle'' variables. In particular, for a single degree of freedom, the label pair (J,γ) is used to identify the coherent state $|J,\gamma\rangle$. Temporal stability means that, under the chosen dynamics, temporal evolution proceeds according to $|J,\gamma+\omega t\rangle$, for some fixed parameter ω. To ensure that (J,γ) describes action-angle variables, it is sufficient to require that the symplectic potential induced by the coherent states themselves is of Darboux form, or specifically that

$$i\hbar\langle J,\gamma|d|J,\gamma\rangle = J\,d\gamma,$$

where $d|J,\gamma\rangle \equiv |J+dJ,\gamma+d\gamma\rangle - |J,\gamma\rangle$. Temporal stability is what fixes the *phase* behavior of the coherent states, i.e., the factor $e^{-i\gamma e_n}$ [cf. (7.15)], while ensuring that (J,γ) are canonical action-angle variables is what fixes the *amplitude* behavior of the coherent states, i.e., $1/N\sqrt{[e_n]!}$ [cf. (7.19) and (7.20)]. The given amplitude behavior may be arrived at by other means,[20] but requiring that J and γ be canonical classical coordinates is equivalent and tends to stress the physics of the situation.

In order for coherent states to interpolate well between quantum and classical mechanics, it is necessary for values of the action $J \gg \hbar$ that the quantum motion be well approximated by the

classical motion. In particular, for a classical system with closed, localized trajectories, a suitable wave packet should, if possible, remain ''coherent'' for a number of classical periods. For the systems under study in this article, we have demonstrated the tendency for improved packet coherence with increasing J values within the range studied. For significantly larger values of J, we notice that the packet coherence substantially improves. Interesting results have been obtained independently in a related study by Fox and Choi,[52] who found a similar packet coherence for ten or more classical periods for an infinite square-well, even though they used a different amplitude prescription for their coherent states. In both works, however, the probability distribution shows a Gaussian behavior for large values of J, and this explains the similarity of the results.

It would appear that allowing for generalized phase and amplitude behavior in the definition of coherent states has led us closer to the idealized goal of a set of coherent states adapted to a chosen system and having a large number of properties in common with the associated classical system, despite being fully quantum in their characteristics.

Note added. After completion of the present article, an article by Crawford[53] has come to the authors' attention. This paper studies the dependence of various coherent states on the weighting parameters $\{\rho_n\}$ and how they effect various correlation functions of interest regarding general systems, and particularly for the hydrogen atom. The studies reported in Ref. 53 offer a good complement to those of the present article.

Note added in proof. As this article was going to press, an article by Bonneau *et al.*[54] appeared, in which the authors discuss in a pedagogical way some of the functional analysis of the infinite well problem, in the same spirit as in Sec. III and with similar results.

Stereographic variables for multidimensional quantum group covariant *q*-oscillators

M. Arik and A. S. Arikan
Department of Physics, Boğaziçi University, Bebek, Istanbul, Turkey

(Received 3 February 2000; accepted for publication 28 February 2001)

In this paper, we study the unitary matrix representation of quantum group $SU_q(2)$ in terms of stereographic coordinates z and z^* and a central unitary phase u. The fractional linear transformation of z and z^* gives the action of $SU_q(2)$ on the quantum sphere $SU_q(2)/U(1)$ with coordinates z and z^*. We then extend this action to $SU_q(2)$ and derive the transformation law of u. Finally, we construct the two-dimensional covariant q-oscillators in terms of stereographic variables and then we generalize it to d-dimensional case. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1370953]

I. INTRODUCTION

Over the last decade, a great deal of attention has been paid to quantum groups both in the mathematical and the physical literature. An algebraic structure for a quantum group, called the q-deformation algebra, is the generalization of its corresponding Lie algebra. Deformations of Lie algebras were first introduced in the context of group contractions,[1] where a Lie algebra is deformed into another Lie algebra. The q-oscillator which is the simplest deformation of the oscillator algebra was introduced by Coon and collaborators[2] and by Kuryshkin.[3] Quantum groups and quantum algebras entailing a Hopf Algebra structure were formulated by Faddeev,[4] Jimbo,[5] Drinfeld,[6] and Woronowicz.[7] For the quantum algebra $SU_q(2)$, Macfarlane[8] and Biedenharn[9] achieved a new realization where they constructed the quantum enveloping algebra in terms of the two independent new q-deformed harmonic oscillators. They used the Schwinger approach[10] of quantum theory of angular momentum and they also generalized the Schwinger construction used in the quantum theory of $SU(2)$ angular momentum.

As is know from previous studies;[11–13] a 2×2 unitary matrix can be parametrized in terms of a phase and a stereographic complex coordinate z which can be used as the coordinates of $SU(2)/U(1)=CP^1$. We also know that a 2×2 quantum unitary matrix can be parametrized in terms of a central unitary phase u and the operator z such that this z is the stereographic quantum coordinate of the quantum sphere $SU_q(2)/U(1)$. Here the operator z which describes the complex sphere S_q^2 satisfies the following commutation relation:

$$zz^*-q^{-2}z^*z=q^{-2}-1, \quad 0<q<1. \tag{1}$$

The action of $SU_q(2)$ on the quantum sphere is given by a fractional linear transformation on z and z^*.

In this paper, we consider the action of $G=SU_q(2)$ on $M=SU_q(2)$ where we consider M to be given in terms of coordinates z, z^* and a central phase u and we derive the transformation law of u. Moreover, we construct the d-dimensional covariant q-oscillators in terms of stereographic variables. The plan of this paper is as follows: In Sec. II we consider a 2×2 unitary matrix. A coset representation of this matrix in terms of stereographic variables z and z^* is given. This yields an equation which determines the linear fractional transformation of z. In Sec. III we discuss the unitary quantum group $SU_q(2)$. The quantum sphere is described in terms of stereographic variables z and z^*.[14] The coset representation of $SU_q(2)/U(1)=CP_q^1$ is obtained. Then we show that the commutation relation between z and z^* is as in Eq. (1) and we find quantum linear fractional transformation equations for z, z^*z, and u. In Sec. IV by starting with the consideration

of the commutation relation satisfied by a and a^* which are quantum coordinates of $SU_q(2)/U(1)$, we get the covariant q-oscillators in two-dimensions. Then we change the variables into stereographic variables and we generalize this two-dimensional covariant q-oscillators to d-dimensional ones. Finally, in Sec. V we present our conclusion.

II. THE UNITARY GROUP SU(2) AND THE COSET SU(2)/U(1)=CP[1]

We start by writing elements of unitary group SU(2) in terms of 2×2 matrices. If A is a 2×2 unitary matrix, then its elements can be represented as

$$A=\begin{pmatrix} a & -\overline{c} \\ c & \overline{a} \end{pmatrix}, \quad a,c\in C. \tag{2}$$

It is clear that elements of matrix A also satisfies the equality of $a\overline{a}+c\overline{c}=1$.

Since we want to show that this matrix A can be parametrized in terms of a phase and stereographic complex coordinate z first we write A as the product of two matrices,

$$A=ZU=\begin{pmatrix} a' & -r \\ r & \overline{a}' \end{pmatrix}\begin{pmatrix} u & 0 \\ 0 & \overline{u} \end{pmatrix}, \quad a',u\in C; r\geqslant 0; u\overline{u}=1. \tag{3}$$

This representation is well known in the nonlinear realization[15] language. The matrix Z is called an SU(2)/U(1) coset representative, which here is fixed by choosing r real. Z is also a unitary matrix. Therefore, we can easily say that its elements also satisfy the following equality:

$$\overline{a}'a'+r^2=1 \tag{4}$$

which describes the upper half of the sphere. Starting from this point of view, we can write

$$a'=z(1+z\overline{z})^{-1/2}, \tag{5}$$

$$r=(1+z\overline{z})^{-1/2}. \tag{6}$$

If we rewrite the elements of the matrix Z by using equalities (5) and (6); our coset representation of Z becomes

$$Z=(1+z\overline{z})^{-1/2}\begin{pmatrix} z & -1 \\ 1 & \overline{z} \end{pmatrix} \tag{7}$$

such that Z describes an element of S^2.

In order to write a linear fractional transformation for z; we first consider the unitary matrix M which can be written as follows:

$$M=\begin{pmatrix} \alpha & -\overline{\gamma} \\ \gamma & \overline{\alpha} \end{pmatrix}, \quad \alpha,\gamma\in C; \alpha\overline{\alpha}+\gamma\overline{\gamma}=1. \tag{8}$$

Then, by multiplying this matrix M with matrix Z and equating the product to matrix Z', we attain the fractional transformation

$$z'=\frac{\alpha z-\overline{\gamma}}{\gamma z+\overline{\alpha}}. \tag{9}$$

III. THE QUANTUM UNITARY GROUP $SU_q(2)$ AND QUANTUM LINEAR FRACTIONAL TRANSFORMATIONS FOR STEREOGRAPHIC COORDINATES z AND UNITARY PHASE u

In this section we will discuss the unitary quantum group $SU_q(2)$ by using its matrix representation. If $A=\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$ is an element of $SU_q(2)$, then in addition to the $GL_q(2)$ commutation relations, the equalities $d=a^*$, $b=-qc^*$, and $ad-qbc=1$ hold. Therefore, matrix A can be rewritten as

$$A=\begin{pmatrix} a & -qc^* \\ c & a^* \end{pmatrix}. \tag{10}$$

Here elements of matrix A are noncommuting quantities such that they satisfy the following commutation relations:

$$ac=qca, \tag{11}$$

$$c^*a^*=qa^*c^*, \tag{12}$$

$$ac^*=qc^*a, \tag{13}$$

$$ca^*=qa^*c, \tag{14}$$

$$aa^*+q^2c^*c=1, \tag{15}$$

$$a^*a+cc^*=1, \tag{16}$$

$$cc^*=c^*c. \tag{17}$$

By using Eqs. (15), (16), and (17); we can easily attain the commutation relation for a and a^*

$$aa^*-q^2a^*a=1-q^2, \quad 0<q<1. \tag{18}$$

When a is rescaled by $(1-q^2)^{-1/2}$, we get precisely the q^2-oscillator commutation relation[2,3] such that if $a/(1-q^2)^{1/2}$ is defined as b, then

$$bb^*-q^2b^*b=1, \quad 0<q<1. \tag{19}$$

As in Sec. II, if we want to express the $SU_q(2)$ matrices in terms of stereographic coordinates z and z^*, which describe the complex sphere S^2, we should use the following transformations

$$a=z(1+z^*z)^{-1/2}, \tag{20}$$

$$c=u(1+z^*z)^{-1/2}, \tag{21}$$

where u is a central unitary phase such that $u^{-1}=u^*$. Inverse ''coordinate transformation'' equations can also be written as follows:

$$z=a(c^*c)^{-1/2}, \tag{22}$$

$$z^*=(c^*c)^{-1/2}a^*. \tag{23}$$

In the above equalities, we should be careful which variables commute with each other. From relations (11)–(17), it follows[11] that u commutes with z and z^*, which means it commutes with everything, but of course z and z^* do not commute with each other. To find the commutation

relation between z and z^*, we can use the commutation relation between a and a^*. If we write $(1+z^*z)^{-1/2}z^*$ and $z(1+z^*z)^{-1/2}$ instead of a^* and a, respectively, in Eq. (18), then we get

$$zz^*-q^{-2}z^*z=q^{-2}-1. \tag{24}$$

Since $0<q<1$, $q^{-2}-1>0$ and rescaling z by $w=z/(q^{-2}-1)^{1/2}$ gives

$$ww^*-q'w^*w=1, \quad q'=q^{-2}>1 \tag{25}$$

which is again a q-oscillator relation. Thus whereas (19) is a $q<1$ q-oscillator, (25) is a $q'>1$ q-oscillator. Hence, we saw that from the point of view of $SU_q(2)$ the q-oscillator ($q<1$) and the q^{-1}-oscillator ($q^{-1}>1$) are just different ''coordinates'' of the same algebraic structure.

Now let us rewrite the matrix A by using z and z^*,

$$A=ZU=\begin{pmatrix} u^*z(1+z^*z)^{-1/2} & -q(1+z^*z)^{-1/2} \\ (1+z^*z)^{-1/2} & (1+z^*z)^{-1/2}z^*u \end{pmatrix}\begin{pmatrix} u & 0 \\ 0 & u^* \end{pmatrix}. \tag{26}$$

In the above equality, matrix U is an element of U(1) which is a subgroup of $SU_q(2)$ and the matrix Z is the coset representative of $CP_q^1=SU_q(2)/U(1)$.

Let us redefine z and z^* such that $z\to u^*z$ and $z^*\to z^*u$. Notice that this redefinition of z and z^* leaves Eq. (24) invariant. By using this equation we can rearrange Z matrix as follows:

$$Z=\begin{pmatrix} z(1+z^*z)^{-1/2} & -(1+zz^*)^{-1/2} \\ (1+z^*z)^{-1/2} & z^*(1+zz^*)^{-1/2} \end{pmatrix}. \tag{27}$$

Now we can derive the transformation laws for z, z^*z, and u, respectively. By following the steps in Sec. I, we can write the following equality:

$$\begin{pmatrix} \tilde{z}(1+\tilde{z}^*\tilde{z})^{-1/2}\tilde{u} & -(1+\tilde{z}\tilde{z}^*)^{-1/2}\tilde{u}^* \\ (1+\tilde{z}^*\tilde{z})^{-1/2}\tilde{u} & \tilde{z}^*(1+\tilde{z}\tilde{z}^*)^{-1/2}\tilde{u}^* \end{pmatrix}=\begin{pmatrix} a & -qc^* \\ c & a^* \end{pmatrix}\begin{pmatrix} z(1+z^*z)^{-1/2}u & -(1+zz^*)^{-1/2}u^* \\ (1+z^*z)^{-1/2}u & z^*(1+zz^*)^{-1/2}u^* \end{pmatrix} \tag{28}$$

This equality is the key point. Because, only by looking at corresponding elements of the right-hand side and the left-hand side matrices, we can easily find the transformation laws.

For $z \xrightarrow{SU_q(2)} \tilde{z}$; we consider the (1,1) elements and (2,1) elements of the matrices in the RHS and LHS. Equating these elements gives the following equalities:

$$\tilde{z}(1+\tilde{z}^*\tilde{z})^{-1/2}\tilde{u}=(az-qc^*)(1+z^*z)^{-1/2}u, \tag{29}$$

$$(1+\tilde{z}^*\tilde{z})^{-1/2}\tilde{u}=(cz+a^*)(1+z^*z)^{-1/2}u. \tag{30}$$

If Eq. (29) is divided by (30), then we will get the fractional linear transformation equation for z,

$$\tilde{z}=(az-qc^*)(cz+a^*)^{-1}=(qcz+a^*)^{-1}(az-c^*). \tag{31}$$

In order to find the transformation law for z^*z, first we should find the transformation law of z^* by considering (1,2) and (2,2) matrix elements of Eq. (28). Then by multiplying the transformation of z^* with Eq. (31), we get the following one:

$$\tilde{z}^*\tilde{z}=((-c+a^*z^*)(az-q^2c^*))((cz+a^*)(a+q^2c^*z^*))^{-1}. \tag{32}$$

Considering (1,2) and (2,1) elements of RHS and LHS matrices in (28) gives the following equality:

$$\tilde{u}^2=(cz+a^*)(a+qc^*z^*)^{-1}u^2 \tag{33}$$

which is the linear fractional transformation equation for u^2. As a result, since u is central, it is clear that we can write the transformation law of u as

$$\tilde{u}=[(cz+a^*)(a+qc^*z^*)^{-1}]^{1/2}u, \tag{34}$$

$$\tilde{u}=vu, \quad \text{where} \quad v=[(cz+a^*)(a+qc^*z^*)^{-1}]^{1/2}. \tag{35}$$

It can be verified that v is unitary by using the relation

$$(a+qc^*z^*)(cz+a^*)^{-1}=(a^*+qcz)^{-1}(c^*z^*+a) \tag{36}$$

which follows from (11)–(17) and (24). The transformation given by (31) and (34) completely define the action of $\mathrm{SU}_q(2)$ on the ''coordinates'' z and u of $\mathrm{SU}_q(2)$. For $q\to 1$ these transformations reduce to their classical form.

IV. MULTIDIMENSIONAL QUANTUM GROUP COVARIANT *q*-OSCILLATORS WITH STEREOGRAPHIC VARIABLES

In this section, first we will consider the two-dimensional q-oscillators, then we generalize it to the d-dimensional case. For two-dimensional q-oscillators we have two copies of the one-dimensional q-oscillator such that

$$a_i a_i^*-q^2 a_i^* a_i=1-q^2, \tag{37}$$

$$[a_i,a_j]=0, \quad i\neq j$$

$$[a_i,a_j^*]=0, \quad i\neq j \quad \text{where} \quad i,j=1,2. \tag{38}$$

From previous studies, we also know that the basic number[16,17] $[n]$ for this system can be written, respectively, as

$$[n_1]=a_1^* a_1=1-q^{2n_1}, \tag{39}$$

$$[n_2]=a_2^* a_2=1-q^{2n_2}, \tag{40}$$

and the spectrum degeneracy of the basic number operator for two copies of the q-oscillator can be achieved as

$$[n_1+n_2]=1-q^{2(n_1+n_2)}=[n_1]+q^{2n_1}[n_2] \tag{41}$$

which implies that we can redefine our annihilation operators

$$c_1=a_1, \tag{42}$$

$$c_2=q^{n_1}a_2. \tag{43}$$

Thus, (41) becomes

$$H=[n_1+n_2]=a_1^* a_1+q^{2n_1}a_2^* a_2=c_1^* c_1+c_2^* c_2, \tag{44}$$

c_i and c_i^* are quantum group covariant oscillator creation and annihilation operators.[18] H is invariant under the quantum group $\mathrm{U}_q(2)$. Its expression in terms of c_i^* and c_i is the same as the expression of the multidimensional quantum harmonic oscillator in terms of the undeformed creation and annihilation operators. In this sense it can be called a Hamiltonian. By considering the above redefinition, the commutation relations satisfied by these operators c_i's can be written as

$$c_1 c_2 = q c_2 c_1, \tag{45}$$

$$c_1 c_2^* = q c_2^* c_1, \tag{46}$$

$$c_1 c_1^* - q^2 c_1^* c_1 = 1 - q^2, \tag{47}$$

$$c_2 c_2^* - q^2 c_2^* c_2 = c_1 c_1^* - c_1^* c_1. \tag{48}$$

With the consideration of (20), we can also write our new creation and annihilation operators c_i^* and c_i in terms of stereographic variables as

$$c_1 = a_1 = z_1 (1 + z_1^* z_1)^{-1/2}, \tag{49}$$

$$c_2 = q^{n_1} a_2 = q^{n_1} z_2 (1 + z_2^* z_2)^{-1/2}. \tag{50}$$

Thus our H can be rewritten as

$$H = \frac{z_1^* z_1}{1 + z_1^* z_1} + q^{2n_1} \frac{z_2^* z_2}{1 + z_2^* z_2}. \tag{51}$$

In order to find the covariant multidimensional generalization of $H = [z^* z/(1 + z^* z)]$, we try an expression for H which corresponds to the replacement $z^* z \to w_1^* w_1 + w_2^* w_2 + \cdots + w_d^* w_d$. Hence for two dimensions

$$H = \frac{w_1^* w_1 + w_2^* w_2}{1 + w_1^* w_1 + w_2^* w_2} \tag{52}$$

such that for the one-dimensional case $w_1 = z$, $w_2 = 0$.

Then we can write

$$H = \frac{K}{1 + K}, \tag{53}$$

where $K = w_1^* w_1 + w_2^* w_2$, thus operator c_i's can be written as

$$c_i = w_i \sqrt{1 - H}. \tag{54}$$

By considering equations (44) to (48), we can obtain

$$c_1 f(H) = f(1 - q^2 + q^2 H) c_1, \tag{55}$$

$$c_2 f(H) = f(1 - q^2 + q^2 H) c_2. \tag{56}$$

Thus, with the help of Eqs. (45)–(48) and (54)–(56), we can easily find the commutation relations satisfied by w_i's as

$$w_1 w_2 = q w_2 w_1, \tag{57}$$

$$w_1 w_2^* = q^{-1} w_2^* w_1, \tag{58}$$

$$w_1 w_1^* - q^{-2} w_1^* w_1 = w_2 w_2^* - w_2^* w_2, \tag{59}$$

$$w_2 w_2^* - q^{-2} w_2^* w_2 = q^{-2} - 1. \tag{60}$$

Up to now, although we consider the two-dimensional q-oscillator, its generalization to the d-dimensional case is straightforward. In order to see this, let us consider operator a_i's ($i=1,2,\ldots,d$) which satisfy the following commutation relation:

$$a_i a_i^* - q^2 a_i^* a_i = 1 - q^2,$$

$$[a_i, a_j] = 0, \quad i \neq j, \tag{61}$$

$$[a_i, a_j^*] = 0, \quad i \neq j, \quad \text{where } i,j = 1,2,\ldots,d$$

and the basic number operator

$$\begin{aligned}[n] &= [n_1 + n_2 + \cdots + n_d] \\ &= [n_1] + q^{2n_1}[n_2] + q^{2(n_1+n_2)}[n_3] + \cdots + q^{2(n_1+n_2+\cdots+n_{d-1})}[n_d].\end{aligned} \tag{62}$$

Thus, annihilation operator can be redefined

$$c_i = q^{n_1+n_2+\cdots+n_{i-1}} a_i, \quad i = 2,3,\ldots,d, \tag{63}$$

whereas $c_1 = a_1$ and the Hamiltonian becomes

$$H = c_1^* c_1 + c_2^* c_2 + \cdots + c_d^* c_d. \tag{64}$$

Here, unlike operator a_i's which commute operator c_i's satisfy the following commutation relation:

$$c_i c_j = q c_j c_i, \quad i < j \tag{65}$$

$$c_i c_j^* = q c_j^* c_i, \quad i \neq j, \quad \text{where } i,j = 1,2,\ldots,d, \tag{66}$$

$$c_1 c_1^* - q^2 c_1^* c_1 = 1 - q^2, \tag{67}$$

$$c_i c_i^* - q^2 c_i^* c_i = c_{i-1} c_{i-1}^* - c_{i-1}^* c_{i-1}, \quad i = 2,3,\ldots,d. \tag{68}$$

As in the two-dimensional case, operator c_i's can be written in terms of w_i's as in (54). By considering this equation with (55), (56) and (65) to (68), commutation relations which are satisfied by w_i's can be written as

$$w_i w_j = q w_j w_i, \quad i < j, \tag{69}$$

$$w_i w_j^* = q^{-1} w_j^* w_i, \quad i \neq j, \quad \text{where } i,j = 1,2,\ldots,d, \tag{70}$$

$$w_{i-1} w_{i-1}^* - q^{-2} w_{i-1}^* w_{i-1} = w_i w_i^* - w_i^* w_i, \quad i = 2,3,\ldots,d, \tag{71}$$

$$w_d w_d^* - q^{-2} w_d^* w_d = q^{-2} - 1, \tag{72}$$

whereas the Hamiltonian H (64) now becomes

$$H = K(1+K)^{-1}, \tag{73}$$

where $K = w_1^* w_1 + w_2^* w_2 + \cdots + w_d^* w_d$.

V. CONCLUSION

We have shown that there are three most useful oscillator representations of the d-dimensional q-oscillator. One of these is simply given by d commuting copies of the one dimensional

q-oscillator. This set of quantum coordinates for the q-oscillator is simple, though not very useful since the invariance of the d-dimensional q-oscillator under the action of the quantum group $SU_q(d)$ is hidden. To see the action of $SU_q(d)$ one has to make a (nonlinear) transformation from these oscillator creation and annihilation operators into Pusz–Woronowicz creation and annihilation operators on which the quantum group $SU_q(2)$ acts linearly. Similarly the set of stereographic q-oscillators given by (69)–(72) we have constructed in this paper transform linearly under the quantum group $SU_q(d)$. Their commutation relations are remarkably similar to the commutation relations of Pusz–Woronowicz oscillators. The one-dimensional restriction of all three realizations of the d-dimensional q-oscillator are the same.

(Received 15 January 2001; accepted for publication 26 February 2001)

In the context of phase-space quantization, matrix elements and observables result from integration of c-number functions over phase space, with Wigner functions serving as the quasiprobability measure. The complete sets of Wigner functions necessary to expand all phase-space functions include off-diagonal Wigner functions, which may appear technically involved. Nevertheless, it is shown here that suitable generating functions of these complete sets can often be constructed, which are relatively simple, and lead to compact evaluations of matrix elements. New features of such generating functions are detailed and explored for integer-indexed sets, such as for the harmonic oscillator, as well as continuously indexed ones, such as for the linear potential and the Liouville potential. The utility of such generating functions is illustrated in the computation of star functions, spectra, and perturbation theory in phase space. © *2001 American Institute of Physics.*

I. INTRODUCTION

General phase-space functions $f(x,p)$ and $g(x,p)$ compose noncommutatively through Groenewold's $\star$-product,[1] which is the unique associative pseudodifferential deformation[2] of ordinary products:

$$\star \equiv e^{i\hbar(\overleftarrow{\partial}_x\overrightarrow{\partial}_p-\overleftarrow{\partial}_p\overrightarrow{\partial}_x)/2}. \tag{1}$$

This product is the cornerstone of deformation (phase-space) quantization,[2–5] as well as applications of matrix models and noncommutative geometry ideas in M-physics.[6] Its mechanics, however, is not always straightforward.

The practical Fourier representation of this product as an integral kernel has been utilized widely since Baker's[7] early work,

$$f\star g=\frac{1}{\hbar^2\pi^2}\int \mathrm{d}p'\,\mathrm{d}p''\,\mathrm{d}x'\,\mathrm{d}x''\,f(x',p')g(x'',p'')$$
$$\times\exp\left(\frac{-2i}{\hbar}(p(x'-x'')+p'(x''-x)+p''(x-x'))\right). \tag{2}$$

The determinantal nature of the star product controls the properties of the phase-space trace,[8,9]

[c)]Electronic mail: zachos@hep.anl.gov

$$\int \mathrm{d}p\,\mathrm{d}x\, f\star g=\int \mathrm{d}p\,\mathrm{d}x\, fg=\int \mathrm{d}p\,\mathrm{d}x\, g\star f. \tag{3}$$

The above-mentioned $\star$-product and phase-space integrals provide the multiplication law and, respectively, the trace in phase-space quantization,[3] the third autonomous and logically complete formulation of quantum mechanics beyond the conventional formulations based on operators in Hilbert space or path integrals. (This formulation is reviewed in Refs. 2 and 5.) Properly ordered operators (e.g., Weyl-ordered) correspond uniquely to phase-space c-number functions (referred to as ''classical kernels'' of the operators in question); operator products correspond to $\star$-products of their classical kernels; and operator matrix elements, conventionally consisting of traces thereof with the density matrix, correspond to phase-space integrals of the classical kernels with the Wigner function (WF), the Weyl correspondent of the density matrix.[5,10] The celebrated $\star$-genvalue functional equations determining the Wigner functions[8,11] and their spectral properties (e.g., projective orthogonality[12]) are reviewed and illustrated in Ref. 4.

The functions introduced by Wigner[10] and Szilard correspond to diagonal elements of the density matrix, but quantum mechanical applications (such as perturbation theory), as well as applications in noncommutative soliton problems[13] often require the evaluation of off-diagonal matrix elements; they therefore utilize the complete set of diagonal and off-diagonal generalized Wigner functions introduced by Moyal.[3] For instance, in noncommutative soliton theory, the diagonal WFs are only complete for radial phase-space functions (functions $\star$-commuting with the harmonic oscillator Hamiltonian—the radius squared), whereas deviations from radial symmetry necessitate the complete off diagonal set.

As for any representation problem, the particular features of the $\star$-equations under consideration frequently favor an optimal basis of WFs; but, even in the case of the oscillator, the equations are technically demanding. It is pointed out here, however, that suitable generating functions for them, acting as a transform of these basis sets, often result in substantially simpler and more compact objects, which are much easier to use, manipulate, and intuit. In the following, after some elementary overview of the Weyl correspondence formalism (Sec. II), we illustrate such functions for the harmonic oscillator (Sec. III), which serves as the archetype of WF bases indexed discretely; it turns out that these generating functions amount to the phase-space coherent states for WFs, and also the WFs of coherent state wave functions (Appendix A). Direct applications to first-order perturbation theory are illustrated in Appendix B.

For sets indexed continuously, the generating function may range from a mere Fourier transform, illustrated by the linear potential (Sec. IV), to a less trivial continuous transform we provide for the Liouville potential problem (Sec. V), where the advantage of the transform method comes to cogent evidence.

Throughout our discussion, we provide the typical $\star$-composition laws of such generating functions, as well as applications such as the evaluation of $\star$-exponentials of phase-space functions (Appendix C), or $\star$-versions of modified Bessel functions (technical aspects of integral transforms of which are detailed in Appendix D). Appendix E provides the operator (Weyl-) correspondent to the generating function for the Liouville diagonal WF introduced in Sec V.

II. OVERVIEW OF GENERAL RELATIONS IN THE WEYL REPRESENTATION

Without loss of generality, we review basic concepts in two-dimensional phase space, (x,p), as the extension to higher dimensions is straightforward. In addition, we first address discrete spectra, E_n, $n=0,1,2,3,\ldots$, and will only later generalize to continuous spectra.

In the Weyl correspondence,[14] c-number phase-space kernels $a(x,p)$ of suitably ordered operators $\mathcal{A}(\mathcal{X},\mathcal{P})$ are defined by

$$a(x,p)\equiv\frac{1}{2\pi}\int \mathrm{d}y\, e^{-iyp}\left\langle x-\frac{\hbar}{2}y\right|\mathcal{A}(\mathcal{X},\mathcal{P})\left|x+\frac{\hbar}{2}y\right\rangle. \tag{4}$$

Conversely, the ordering of these operators is specified through

$$\mathcal{A}(\mathcal{X},\mathcal{P})=\frac{1}{(2\pi)^2}\int \mathrm{d}\tau\,\mathrm{d}\sigma\,\mathrm{d}x\,\mathrm{d}p\;a(x,p)\exp(i\tau(\mathcal{P}-p)+i\sigma(\mathcal{X}-x)). \tag{5}$$

An operator product then corresponds to a star-composition of these kernels,[1]

$$a(x,p)\star b(x,p)=\frac{1}{2\pi}\int \mathrm{d}y\,e^{-iyp}\left\langle x-\frac{\hbar}{2}y\right|\mathcal{A}(\mathcal{X},\mathcal{P})\mathcal{B}(\mathcal{X},\mathcal{P})\left|x+\frac{\hbar}{2}y\right\rangle. \tag{6}$$

Moyal[3] appreciated that the density matrix in this phase-space representation is a Hermitean generalization of the Wigner function:

$$\begin{aligned} f_{mn}(x,p)&\equiv\frac{1}{2\pi}\int \mathrm{d}y\,e^{-iyp}\left\langle x-\frac{\hbar}{2}y\right|\psi_n\rangle\langle\psi_m\left|x+\frac{\hbar}{2}y\right\rangle \\ &=\frac{1}{2\pi}\int \mathrm{d}y\,e^{-iyp}\psi_m^*\left(x-\frac{\hbar}{2}y\right)\psi_n\left(x+\frac{\hbar}{2}y\right)=f_{nm}^*(x,p), \end{aligned} \tag{7}$$

where the $\psi_m(x)$'s are (ortho-)normalized solutions of a Schrödinger problem. (Wigner[10] mainly considered the diagonal elements of the density matrix (pure states), usually denoted as $f_m \equiv f_{mm}$.) As a consequence, matrix elements of operators are produced by mere phase-space integrals,[3]

$$\langle\psi_m|\mathcal{A}|\psi_n\rangle=\int \mathrm{d}x\,\mathrm{d}p\;a(x,p)f_{mn}(x,p). \tag{8}$$

The standard machinery of density matrices then is readily transcribed in this language, e.g., the trace relation,[3]

$$\int \mathrm{d}x\,\mathrm{d}p\;f_{mn}(x,p)=\int \mathrm{d}x\;\psi_n^*(x)\psi_m(x)=\delta_{mn}; \tag{9}$$

and[8]

$$f_{mn}\star f_{kl}=\frac{1}{2\pi\hbar}\,\delta_{ml}f_{kn}=\frac{1}{h}\,\delta_{ml}f_{kn}. \tag{10}$$

Given (3), it follows from Eqs. (9) and (10) that[3]

$$\int \mathrm{d}x\,\mathrm{d}p\;f_{mn}(x,p)f_{lk}^*(x,p)=\frac{1}{2\pi\hbar}\,\delta_{ml}\delta_{nk}. \tag{11}$$

For complete sets of input wave functions, it also follows that[3]

$$\sum_{m,n} f_{mn}(x,p)f_{mn}^*(x',p')=\frac{1}{2\pi\hbar}\,\delta(x-x')\,\delta(p-p'). \tag{12}$$

An arbitrary phase-space function $\varphi(x,p)$ can thus be expanded as

$$\varphi(x,p)=\sum_{m,n} c_{mn}f_{mn}(x,p), \tag{13}$$

the coefficients being specified through (11),

$$c_{mn}=2\pi\hbar\int \mathrm{d}x\,\mathrm{d}p\;f_{mn}^*(x,p)\varphi(x,p). \tag{14}$$

Further note the resolution of the identity,[3]

$$\sum_n f_{nn}(x,p)=\frac{1}{2\pi\hbar}=\frac{1}{h}. \tag{15}$$

For instance, for eigenfunctions of the Hamiltonian $\mathcal{H}(\mathcal{X},\mathcal{P})$ with eigenvalues E_n, the corresponding WFs satisfy the following star-genvalue equations[8] (also see Refs. 11 and 4), with $H(x,p)$, the phase-space kernel of $\mathcal{H}(\mathcal{X},\mathcal{P})$:

$$H\star f_{mn}=E_n f_{mn}, \quad f_{mn}\star H=E_m f_{mn}. \tag{16}$$

The time dependence of a pure state WF is given by Moyal's dynamical equation:[3]

$$i\hbar\frac{\partial}{\partial t}f(x,p;t)=H\star f(x,p;t)-f(x,p;t)\star H. \tag{17}$$

By virtue of the $\star$-unitary evolution operator (a "$\star$-exponential"[2]),

$$U_\star(x,p;t)=e_\star^{itH/\hbar}\equiv 1+(it/\hbar)H(x,p)+\frac{(it/\hbar)^2}{2!}H\star H+\frac{(it/\hbar)^3}{3!}H\star H\star H+\cdots, \tag{18}$$

the time-evolved WF is obtained formally in terms of the WF at $t=0$,

$$f(x,p;t)=U_\star^{-1}(x,p;t)\star f(x,p;0)\star U_\star(x,p;t). \tag{19}$$

(These associative combinatoric operations completely parallel those of operators in the conventional formulation of quantum mechanics in Hilbert space.[15]) Just like any star-function of H, this $\star$-exponential can be computed,[16]

$$\exp_\star(itH/\hbar)=\exp_\star(itH/\hbar)\star 1=\exp_\star(itH/\hbar)\star 2\pi\hbar\sum_n f_{nn}=2\pi\hbar\sum_n e^{itE_n/\hbar}f_{nn}. \tag{20}$$

(Of course, for $t=0$, the obvious identity resolution is recovered.)

For continuous spectra, the sums in the above-mentioned relations extend to integrals over a continuous parameter (the energy), and the Kronecker δ_{mn}'s into δ-functions (these last ones reflecting the infinite normalizations of unnormalizable states). For example, Eqs. (9) and (11) extend to

$$\int \mathrm{d}x\,\mathrm{d}p\, f_{E_1E_2}(x,p)=\delta(E_1-E_2), \tag{21}$$

$$\int \mathrm{d}x\,\mathrm{d}p\, f_{E_1E_2}(x,p)f^*_{E_1'E_2'}(x,p)=\frac{1}{2\pi\hbar}\,\delta(E_1-E_1')\,\delta(E_2-E_2'). \tag{22}$$

Completeness (12) extends to

$$\int \mathrm{d}E_1\,\mathrm{d}E_2\, f_{E_1E_2}(x,p)f^*_{E_1E_2}(x',p')=\frac{1}{2\pi\hbar}\,\delta(x-x')\,\delta(p-p'). \tag{23}$$

More generally, (10) extends to

$$f_{E_1E_2}\star f_{E_1'E_2'}=\frac{1}{2\pi\hbar}\,\delta(E_1-E_2')f_{E_1'E_2}. \tag{24}$$

Finally, Eq. (15) extends to

$$\frac{1}{2\pi\hbar}=\frac{1}{2\pi}\int \mathrm{d}y\, e^{-ipy}\int \mathrm{d}E\left\langle x-\frac{\hbar y}{2}\middle|E\right\rangle\left\langle E\middle|x+\frac{\hbar y}{2}\right\rangle=\int \mathrm{d}E\, f_{EE}(x,p), \tag{25}$$

and hence (20) extends to

$$\exp_\star(itH/\hbar)=2\pi\hbar\int \mathrm{d}E\, e^{itE/\hbar} f_{EE}(x,p). \tag{26}$$

III. GENERATING FUNCTIONS FOR THE HARMONIC OSCILLATOR

Consider the harmonic oscillator,

$$H(x,p)=\tfrac{1}{2}(p^2+x^2), \tag{27}$$

where, without loss of generality, parameters have been absorbed in the phase space variables: $m=1$, $\omega=1$. Further recall that the normalized eigenfunctions of the corresponding operator Hamiltonian $\mathcal{H}$ are $\psi_n(x)=(\sqrt{\pi}2^n n!)^{-1/2}e^{-(1/2)x^2}H_n(x)$, for the eigenvalues $E_n=\hbar(n+1/2)$. Define a radial and an angular variable,

$$z\equiv 4H=2(x^2+p^2),\quad \tan\theta=\frac{p}{x}, \tag{28}$$

so that

$$a\sqrt{2}\equiv(x+ip)=|x+ip|e^{i\theta}=\left(\frac{z}{2}\right)^{1/2}e^{i\theta}. \tag{29}$$

Groenewold,[1] as well as Bartlett and Moyal,[17] have worked out the complete sets of solutions to Moyal's time-evolution equation (17), which are all linear combinations of terms $\exp(it(m-n))f_{mn}$. They solved that equation indirectly, by evaluating the integrals (7) for time-dependent Hermite wave functions, which yield generalized Laguerre polynomial-based functions. More directly, Fairlie[8] dramatically simplified the derivation of the solution by relying on his fundamental equation (16). He thus confirmed Groenewold's WFs,[1,17]

$$f_{mn}(x,p)=\frac{(-1)^m}{\pi}\sqrt{\frac{m!}{n!}}z^{(n-m)/2}e^{-z/2}e^{i(n-m)\theta}L_m^{n-m}(z). \tag{30}$$

The special case of diagonal elements,

$$f_n\equiv f_{nn}=\frac{(-1)^n}{\pi}e^{-z/2}L_n(z), \tag{31}$$

constitutes the time-independent ''$\star$-genfunctions'' of the oscillator hamiltonian kernel[4] [i.e., the complete set of solutions of the time-independent Moyal equation $H\star f-f\star H=0$, where $H\star f_n=E_n f_n$. Incidentally, (10) restricted to diagonal WFs closes them under $\star$-multiplication,[12] $f_m\star f_n=\delta_{mn}f_m/(2\pi\hbar)$.] That is to say, ''radially symmetric'' phase-space functions, i.e., functions that only depend on z but not θ, can be expanded in terms of merely these diagonal elements—unlike the most general functions in phase space which require the entire set of off-diagonal f_{mn} above for a complete basis. Note, however, that all $\star$-products of such radially symmetric functions are commutative, since, manifestly,

$$\sum_n c_n f_n\star\sum_m d_m f_m=\sum_m d_m f_m\star\sum_n c_n f_n. \tag{32}$$

Moreover, the $\star$-exponential (20) for this set of $\star$-genfunctions is directly seen to amount to

$$\exp_\star(itH/\hbar)=\left(\cos\left(\frac{t}{2}\right)\right)^{-1}\exp\left(\frac{2i}{\hbar}H\tan\left(\frac{t}{2}\right)\right), \tag{33}$$

which is, to say, a Gaussian in phase space.[2] As an application, note that the hyperbolic tangent $\star$-composition law of Gaussians follows trivially, since these amount to $\star$-exponentials with additive time intervals, $\exp_\star(tf)\star\exp_\star(Tf)=\exp_\star((t+T)f)$,[2]

$$\exp\left(-\frac{a}{\hbar}(x^2+p^2)\right)\star\exp\left(-\frac{b}{\hbar}(x^2+p^2)\right)=\frac{1}{1+ab}\exp\left(-\frac{a+b}{\hbar(1+ab)}(x^2+p^2)\right). \tag{34}$$

We now introduce the following generating function for the entire set of generalized Wigner functions:

$$G(\alpha,\beta;x,p)\equiv\sum_{m,n}\frac{\alpha^m}{\sqrt{m!}}\frac{\beta^n}{\sqrt{n!}}f_{mn}=\frac{1}{\pi}\sum_n\ \beta^n\frac{1}{n!}z^{n/2}e^{-z/2}e^{in\theta}\sum_m\ (-z^{-1/2}e^{-i\theta}\alpha)^m L_m^{n-m}(z). \tag{35}$$

Utilizing the identity[18] 8.975.2,

$$\sum_{m=0}^{\infty}L_m^{n-m}(z)k^m=e^{-zk}(1+k)^n, \tag{36}$$

we obtain

$$\begin{aligned}G(\alpha,\beta;x,p)&=\frac{1}{\pi}e^{-z/2}\sum_n\ \frac{1}{n!}(\beta\sqrt{z}e^{i\theta})^n e^{-z(-z^{-1/2}e^{-i\theta}\alpha)}(1-z^{-1/2}e^{-i\theta}\alpha)^n\\&=\frac{1}{\pi}e^{-z/2}\sum_n\ \frac{1}{n!}(\beta\sqrt{z}e^{i\theta}-\alpha\beta)^n e^{\sqrt{z}e^{-i\theta}\alpha}=\frac{1}{\pi}e^{-z/2}e^{\beta\sqrt{z}e^{i\theta}-\alpha\beta}e^{\sqrt{z}e^{-i\theta}\alpha}.\end{aligned} \tag{37}$$

Thus,

$$G(\alpha,\beta;x,p)=\frac{1}{\pi}\exp\left(\sqrt{z}\,(\alpha e^{-i\theta}+\beta e^{i\theta})-\alpha\beta-\frac{z}{2}\right). \tag{38}$$

Since

$$\sqrt{z}\,(\alpha e^{-i\theta}+\beta e^{i\theta})=\sqrt{2}(\alpha+\beta)x-\sqrt{2}ip(\alpha-\beta), \tag{39}$$

one can re-express:

$$G(\alpha,\beta;x,p)=G^*(\beta,\alpha;x,p)=\frac{1}{\pi}\exp\left(\alpha\beta-\left(x-\frac{\alpha+\beta}{\sqrt{2}}\right)^2-\left(p+i\frac{\alpha-\beta}{\sqrt{2}}\right)^2\right). \tag{40}$$

As the name implies, from $G(\alpha,\beta;x,p)$, the f_{mn}'s are generated by

$$f_{mn}(x,p)=\frac{1}{\sqrt{m!n!}}\frac{\partial^m}{\partial\alpha^m}\frac{\partial^n}{\partial\beta^n}G(\alpha,\beta;x,p)\bigg|_{\alpha=\beta=0}. \tag{41}$$

These functions $\star$-compose as

$$G(\alpha,\beta)\star G(\epsilon,\zeta)=\frac{e^{\alpha\zeta}}{2\pi\hbar}G(\epsilon,\beta). \tag{42}$$

The phase-space trace is

$$\int \mathrm{d}x\,\mathrm{d}p\,G(\alpha,\beta)=e^{\alpha\beta}. \tag{43}$$

By (16), the action of the Hamiltonian kernel on this function is

$$H\star G=\hbar\left(\frac{1}{2}+\beta\frac{\partial}{\partial\beta}\right)G=\hbar\left(\frac{1}{2}-\alpha\beta+\beta\sqrt{z}e^{i\theta}\right)G, \tag{44}$$

and

$$G\star H=\hbar\left(\frac{1}{2}+\alpha\frac{\partial}{\partial\alpha}\right)G=\hbar\left(\frac{1}{2}-\alpha\beta+\alpha\sqrt{z}e^{-i\theta}\right)G. \tag{45}$$

Consequently,

$$\int \mathrm{d}x\,\mathrm{d}p\,H\star G(\alpha,\beta)=\hbar\left(\frac{1}{2}+\beta\frac{\partial}{\partial\beta}\right)e^{\alpha\beta}=\hbar\left(\frac{1}{2}+\alpha\beta\right)e^{\alpha\beta}. \tag{46}$$

The spectrum then follows by operating on both sides of this equation,

$$E_n=\frac{1}{n!}\frac{\partial^n}{\partial\alpha^n}\frac{\partial^n}{\partial\beta^n}\int \mathrm{d}x\,\mathrm{d}p\,H\star G(\alpha,\beta)\Big|_{\alpha=\beta=0}=\frac{\hbar}{n!}\frac{\partial^n}{\partial\alpha^n}\frac{\partial^n}{\partial\beta^n}\left(\frac{1}{2}+\alpha\beta\right)e^{\alpha\beta}\Big|_{\alpha=\beta=0}=\hbar\left(\frac{1}{2}+n\right). \tag{47}$$

In general, matrix elements of operators may be summarized compactly through this generating function in phase space.

This generating function could be interpreted as a phase-space coherent state, or the off-diagonal WF of coherent states, as discussed in Appendix A,[19]

$$G(\alpha,\beta;x,p)=\exp_\star(\beta a^\dagger)f_0\exp_\star(\alpha a), \tag{48}$$

$$\begin{aligned} &a\star G(\alpha,\beta)=\hbar\beta G(\alpha,\beta),\quad a^\dagger\star G(\alpha,\beta)=\frac{\partial}{\partial\beta}G(\alpha,\beta),\\ &G(\alpha,\beta)\star a=\frac{\partial}{\partial\alpha}G(\alpha,\beta),\quad G(\alpha,\beta)\star a^\dagger=\hbar\alpha G(\alpha,\beta), \end{aligned} \tag{49}$$

and hence Eqs. (44) and (45) amount to

$$\begin{aligned} H\star G(\alpha,\beta)&=\left(a^\dagger\star a+\frac{\hbar}{2}\right)\star G(\alpha,\beta)=\hbar\left(\beta\frac{\partial}{\partial\beta}+\frac{1}{2}\right)G(\alpha,\beta),\\ G(\alpha,\beta)\star H&=G(\alpha,\beta)\star\left(a^\dagger\star a+\frac{\hbar}{2}\right)=\hbar\left(\alpha\frac{\partial}{\partial\alpha}+\frac{1}{2}\right)G(\alpha,\beta). \end{aligned} \tag{50}$$

This formalism finds application in, e.g., perturbation theory in phase space, cf. Appendix B.

IV. GENERATING FUNCTIONS FOR THE LINEAR POTENTIAL

The linear potential in phase space has been addressed[11] (also see Refs. 19 and 4). We shall adopt the simplified conventions of Ref. 4, i.e., $m=1/2$, $\hbar=1$. The Hamiltonian kernel is then

$$H(x,p)=p^2+x, \tag{51}$$

and the eigenfunctions of $\mathcal{H}$ are Airy functions,

$$\psi_E(x)=\frac{1}{2\pi}\int_{-\infty}^{+\infty}\mathrm{d}X\, e^{iX(E-x-X^2/3)}=\mathrm{Ai}(x-E), \tag{52}$$

indexed by the continuous energy E. The spectrum being continuous, the Airy functions are not square integrable, but have continuum normalization, $\int \mathrm{d}x\, \psi^*_{E_1}(x)\psi_{E_2}(x)=\delta(E_1-E_2)$, instead. Thus, (21) *et seq.* are now operative. The generalized WFs are[11]

$$\begin{aligned} f_{E_1E_2}(x,p)&=\frac{1}{4\pi^2}\int \mathrm{d}z \exp\left(iz\left(\frac{E_1+E_2}{2}-x-p^2-z^2/12\right)\right)\exp(ip(E_1-E_2))\\ &=\exp(ip(E_1-E_2))\frac{2^{2/3}}{2\pi}\mathrm{Ai}\left(2^{2/3}\left(x+p^2-\frac{E_1+E_2}{2}\right)\right). \end{aligned} \tag{53}$$

The $\star$-exponential (26) then is again a plain exponential of the shifted Hamiltonian kernel,

$$\exp_\star(it(x+p^2))=2\pi\int_{-\infty}^{\infty}\mathrm{d}E\, e^{iEt}\frac{2^{2/3}}{2\pi}\mathrm{Ai}\left(2^{2/3}\left(x+p^2-\frac{E_1+E_2}{2}\right)\right)=\exp(it(x+p^2+t^2/12)). \tag{54}$$

(This could also be derived directly, as the CBH expansion simplifies dramatically in this case, cf. Appendix C.) As before, the $\star$-composition law for plain exponentials of the hamiltonian kernel function follows,

$$\exp(a(x+p^2))\star\exp(b(x+p^2))=\exp((a+b)(x+p^2-\tfrac{1}{4}ab)). \tag{55}$$

Since the complete basis Wigner functions are now indexed continuously, a generating function for them must rely on an integral instead of an infinite sum. The simplest transform is possibly a double Fourier transform with respect to the energy indices [but note the transform factors $\exp(iE_1X)$, $\exp(-iE_2Y)$ may also be regarded as plane waves]. Suitably normalized,

$$\begin{aligned} G(X,Y;x,p)&\equiv 2\pi\int_{-\infty}^{+\infty}\mathrm{d}E_1\int_{-\infty}^{+\infty}\mathrm{d}E_2\left(\frac{1}{\sqrt{2\pi}}e^{iE_1X}\right)f_{E_1E_2}(x,p)\left(\frac{1}{\sqrt{2\pi}}e^{-iE_2Y}\right)\\ &=\frac{1}{2\pi}\int_{-\infty}^{+\infty}\mathrm{d}E_1\int_{-\infty}^{+\infty}\mathrm{d}E_2\, e^{i(E_1-E_2)\,p+iE_1X-iE_2Y}2^{2/3}\mathrm{Ai}\left(2^{2/3}\left(x+p^2-\frac{E_1+E_2}{2}\right)\right)\\ &=\frac{1}{2\pi}\int_{-\infty}^{+\infty}\mathrm{d}E\int_{-\infty}^{+\infty}\mathrm{d}\omega\, e^{i\omega\, p+i(E+\omega/2)X-i(E-\omega/2)Y}2^{2/3}\mathrm{Ai}(2^{2/3}(x+p^2-E))\\ &=\delta\left(p+\frac{X+Y}{2}\right)\int_{-\infty}^{+\infty}\mathrm{d}E\, e^{iE(X-Y)}2^{2/3}\mathrm{Ai}(2^{2/3}(x+p^2-E))\\ &=\delta\left(p+\frac{X+Y}{2}\right)\int_{-\infty}^{+\infty}\mathrm{d}E\, e^{iE(X-Y)}\frac{1}{2\pi}\int \mathrm{d}z\, e^{iz(E-x-p^2-z^2/12)} \end{aligned}$$

$$= \delta\left(p + \frac{X+Y}{2}\right) e^{i(X-Y)(x+p^2+(X-Y)^2/12)}. \tag{56}$$

The phase-space trace is

$$\int \mathrm{d}x\, \mathrm{d}p\, G(X,Y;x,p) = 2\pi\delta(X-Y), \tag{57}$$

and, given (24) for these functions, $f_{E_1E_2} \star f_{E_1'E_2'} = (1/2\pi)\,\delta(E_1-E_2')f_{E_1'E_2}$, the $\star$-composition law for these G's is

$$G(X,Y;x,p) \star G(W,Z;x,p) = \delta(X-Z)G(W,Y;x,p). \tag{58}$$

V. GENERATING FUNCTIONS FOR THE LIOUVILLE POTENTIAL

A less trivial system with a continuous spectrum is the Hamiltonian with the Liouville potential.[20,21] In the conventions of Ref. 4 ($\hbar=1$, $m=1/2$), the Hamiltonian kernel is

$$H = p^2 + e^{2x}, \tag{59}$$

and the eigenfunctions of the corresponding $\mathcal{H}$ are

$$\psi_E(x) = \psi_E^*(x) = \frac{1}{\pi}\sqrt{\sinh(\pi\sqrt{E})}K_{i\sqrt{E}}(e^x), \tag{60}$$

with continuum normalizations $\int \mathrm{d}x\, \psi_{E_1}^*(x)\psi_{E_2}(x) = \delta(E_1-E_2)$. The modified Bessel function (Ref. 22, Chap. VI, Sec. 6.22) can be written in the Heine–Schläfli form,

$$K_{ip}(e^x) = \frac{1}{2}\int_{-\infty}^{\infty} \mathrm{d}X\, \exp(-e^x\cosh X + iXp) = K_{-ip}(e^x). \tag{61}$$

The nondiagonal WF is then

$$f_{E_1E_2}(x,p) = \frac{1}{\pi^3}\int \mathrm{d}y\, e^{-2ipy}\sqrt{\sinh(\pi\sqrt{E_1})}K^*_{i\sqrt{E_1}}(e^{x-y})\sqrt{\sinh(\pi\sqrt{E_2})}K_{i\sqrt{E_2}}(e^{x+y}). \tag{62}$$

This Wigner function amounts to Meijer's G function,

$$f_{E_1E_2}(x,p) = \frac{1}{8\pi^3}\sqrt{\sinh(\pi\sqrt{E_1})\sinh(\pi\sqrt{E_2})} \times G^{40}_{04}\left(\frac{e^{4x}}{16}\middle| \frac{ip+i\sqrt{E_1}}{2}, \frac{ip-i\sqrt{E_1}}{2}, \frac{-ip+i\sqrt{E_2}}{2}, \frac{-ip-i\sqrt{E_2}}{2}\right). \tag{63}$$

Alternatively, the WF may be written as a double integral representation,

$$f_{E(k)\,E(q)}(x,p) = \frac{1}{2\pi^3}\sqrt{\sinh(\pi\sqrt{E(k)})\sinh(\pi\sqrt{E(q)})} \times \int \mathrm{d}X\, \mathrm{d}Y\, e^{ikX}\, e^{iqY}\left(\frac{\cosh Y}{\cosh X}\right)^{ip} K_{2ip}(e^x\sqrt{4\cosh X\cosh Y}), \tag{64}$$

where $E(k)\equiv k^2$, $E(q)\equiv q^2$. This is an inverse integral transform, as in Sec. IV, of a generating function

$$G(X,Y;x,p)\equiv\int_{-\infty}^{\infty}\frac{\mathrm{d}k}{\sqrt{\sinh(\pi\sqrt{E(k)})}}\int_{-\infty}^{\infty}\frac{\mathrm{d}q}{\sqrt{\sinh(\pi\sqrt{E(q)})}}e^{-ikX}e^{-iqY}f_{E(k)\,E(q)}(x,p)$$
$$=\frac{2}{\pi}\left(\frac{\cosh Y}{\cosh X}\right)^{ip}K_{2ip}(e^{x}\sqrt{4\cosh X\cosh Y})=G^{*}(Y,X;x,p). \tag{65}$$

The form and construction of this G are consequences of (61), as detailed in Appendix D.

However, the $\star$-composition law of this particular generating function is not so straightforward. It is singular, as a consequence of the general relation (24) and the behavior of the integrand in (65) as $k,q\to 0$.

The singularity may be controlled by regulating the $\star$-product through imaginary shifts in the momenta,

$$G\left(X,Y;x,p-\frac{i\epsilon}{2}\right)\star G\left(W,Z;x,p+\frac{i\epsilon}{2}\right)=\frac{1}{2\pi}G(W,Y;x,p)\Gamma(\epsilon)\left(e^{x}\sqrt{\frac{\cosh Y\cosh W}{\cosh X\cosh Z}}(\cosh X+\cosh Z)\right)^{-\epsilon}.$$

It follows that one derivative with respect to either of X or Z suffices to eliminate the divergence at $\epsilon=0$,

$$\lim_{\epsilon\to 0}\partial_{X}G\left(X,Y;x,p-\frac{i\epsilon}{2}\right)\star G\left(W,Z;x,p+\frac{i\epsilon}{2}\right)$$
$$=\frac{1}{2\pi}G(W,Y;x,p)(-\partial_{X})\ln\left(e^{x}\sqrt{\frac{\cosh Y\cosh W}{\cosh X\cosh Z}}(\cosh X+\cosh Z)\right)$$
$$=\frac{1}{2\pi}G(W,Y;x,p)\left(\frac{1}{2}\tanh X-\frac{\sinh X}{\cosh X+\cosh Z}\right).$$

Unlike the situation in (58), here the right-hand side vanishes at $X=Z$. More symmetrically,

$$\lim_{\epsilon\to 0}\partial_{X}G\left(X,Y;x,p-\frac{i\epsilon}{2}\right)\star\partial_{W}G\left(W,Z;x,p+\frac{i\epsilon}{2}\right)=\frac{1}{2\pi}\partial_{W}G(W,Y;x,p)\left\{\frac{1}{2}\tanh X-\frac{\sinh X}{\cosh X+\cosh Z}\right\}.$$

By some contrast to the above, Eq. (65), an alternate generating function for just the diagonal WFs, $f_{EE}\equiv f_{E}$, could be defined through the spectral resolution of the $\star-K$ function,

$$\mathcal{G}(z;x,p)\equiv K_{\star\, i\sqrt{H(x,p)}}(e^{z})=2\pi\int_{0}^{\infty}\mathrm{d}E\,K_{i\sqrt{E}}(e^{z})\,f_{E}(x,p). \tag{66}$$

This can be evaluated by reliance on Macdonald's trilinear identity,[22,23]

$$\int_{0}^{\infty}\mathrm{d}E\,K_{i\sqrt{E}}(e^{z})\psi_{E}(x)\,\psi_{E}^{*}(y)=\frac{1}{2}\exp\left(-\frac{1}{2}(e^{x+y-z}+e^{x-y+z}+e^{-x+y+z})\right). \tag{67}$$

$\mathcal{G}$ then is obtained by replacing $x\to x+Y$ and $y\to x-Y$, and Fourier transforming by $(1/\pi)\int\mathrm{d}Y\,e^{-2ipY}$,

$$\int_0^\infty \mathrm{d}E\, K_{i\sqrt{E}}(e^z)\, f_E(x,p) = \frac{1}{2\pi}\int \mathrm{d}Y\, e^{-2ipY} \exp\left(-\frac{1}{2}(e^{2x-z}+e^{z+2Y}+e^{z-2Y})\right). \tag{68}$$

Finally, simplifying the right-hand side gives

$$\begin{aligned} 2\pi\int_0^\infty \mathrm{d}E\, K_{i\sqrt{E}}(e^z)\, f_E(x,p) &= \exp\left(-\frac{1}{2}e^{2x-z}\right)\int \mathrm{d}Y\, e^{-2ipY}\exp\left(-\frac{1}{2}e^z(e^{2Y}+e^{-2Y})\right) \\ &= \exp(-\tfrac{1}{2}e^{2x-z})K_{ip}(e^z) = \mathcal{G}(z;x,p). \end{aligned} \tag{69}$$

As a side check of this expression, (69), note that it must satisfy

$$H\star\mathcal{G}(z;x,p) = \mathcal{G}(z;x,p)\star H = (-\partial_z^2+e^{2z})\mathcal{G}(z;x,p), \tag{70}$$

which follows from the spectral resolution evident in (66). Indeed, since $e^{-z}\partial_z K_{ip}(e^z) = ipe^{-z}K_{ip}(e^z) - K_{ip+1}(e^z)$, and $(-\partial_z^2+e^{2z})K_{ip}(e^z) = p^2K_{ip}(e^z)$, these relations are satisfied,

$$\begin{aligned} (p^2+e^{2x})\star(\exp(-\tfrac{1}{2}e^{2x-z})K_{ip}(e^z)) &= (\exp(-\tfrac{1}{2}e^{2x-z})K_{ip}(e^z))\star(p^2+e^{2x}) \\ &= \exp(-\tfrac{1}{2}e^{2x-z})(-e^{2x-z}\,\partial_z K_{ip}(e^z)) \\ &\quad + (p^2+\tfrac{1}{2}e^{2x-z}-\tfrac{1}{4}e^{4x-2z})\exp(-\tfrac{1}{2}e^{2x-z})K_{ip}(e^z) \\ &= (-\partial_z^2+e^{2z})(\exp(-\tfrac{1}{2}e^{2x-z})K_{ip}(e^z)). \end{aligned} \tag{71}$$

Parenthetically, as an alternative to the ordinary product form in (69), the phase-space kernel $\mathcal{G}$ may also be represented as an integral either of a $\star$-exponential or of a single $\star$-product (Note: Do not shift the integration parameter y by the phase-space variable x before the star products are evaluated.),

$$\begin{aligned} \mathcal{G}(z;x,p) &= \frac{1}{2}\int \mathrm{d}y\, \exp_\star\left(-\frac{y}{2\sinh y}e^{2x-z}+iyp-e^z\cosh y\right) \\ &= \frac{1}{2}\int \mathrm{d}y\, \exp\left(-\frac{1}{2}e^{y-z}e^{2x}\right)\star\exp(iyp-e^z\cosh y). \end{aligned} \tag{72}$$

This follows from the identities (cf. Appendix C)

$$\exp_\star\left(-\frac{y}{2\sinh y}e^{2x-z}+iyp\right) = \exp\left(-\frac{1}{2}e^{y-z}e^{2x}\right)\star\exp(iyp) = \exp\left(-\frac{1}{2}e^{2x-z}+iyp\right). \tag{73}$$

The ordinary product form in (69) and the $\star$-exponential form in (72) reveal that $\mathcal{G}(z;x,p) = \mathcal{G}(z;x,-p)$, so one may replace $\exp(iyp)$ by $\cos(yp)$ in the second line of (72). Given these, there are several ways to verify (70). These relations and the star-product expressions for the kernel in (72) are isomorphic to those of the corresponding operators, as discussed in Appendix E.

The $\star$-composition law of these generating functions follows from (24) and Macdonald's identity,

$$\mathcal{G}(u;x,p)\star\mathcal{G}(v;x,p) = \frac{1}{2}\int \mathrm{d}w\, \exp\left(-\frac{1}{2}(e^{u+v-w}+e^{u-v+w}+e^{-u+v+w})\right)\mathcal{G}(w;x,p). \tag{74}$$

This also follows directly from the explicit form (69). Again, this is isomorphic to the corresponding operator composition law given in Appendix E.

From the orthogonality of the ψ_E's, the diagonal WFs may be recovered by inverse transformation,

$$f_E(x,p)=\int \mathrm{d}z\,\frac{\sinh(\pi\sqrt{E})}{2\pi^3}K_{i\sqrt{E}}(e^z)\mathcal{G}(z;x,p). \tag{75}$$

This representation and the specific factorized x,p-dependence of $\mathcal{G}$ can be of considerable use, e.g., in systematically computing diagonal matrix elements in phase space.

In illustration of the general pattern, consider the first-order energy shift effected by a perturbation Hamiltonian kernel H_1. It is, cf. Appendix B, Eq. (B11),

$$\Delta E=\int \mathrm{d}z\,\mathrm{d}x\,\mathrm{d}p\,H_1\frac{\sinh(\pi\sqrt{E})}{2\pi^3}K_{i\sqrt{E}}(e^z)\mathcal{G}(z;x,p). \tag{76}$$

Choosing

$$H_1=e^{2nx}e^{isp/2}, \tag{77}$$

yields

$$\Delta E=\frac{\sinh(\pi\sqrt{E})}{2\pi^3}\int \mathrm{d}z\,K_{i\sqrt{E}}(e^z)\left(\int \mathrm{d}x\,e^{2nx}\exp\left(-\frac{1}{2}e^{2x-z}\right)\right)\left(\int \mathrm{d}p\,K_{ip}(e^z)\,e^{isp/2}\right). \tag{78}$$

Now,

$$\int \mathrm{d}x\,e^{2nx}\exp\left(-\frac{1}{2}e^{2x-z}\right)=2^{n-1}\Gamma(n)\,e^{nz}, \tag{79}$$

and hence (Ref. 18, 6.576.4, $a=b$),

$$\begin{aligned}\int \mathrm{d}z\,K_{i\sqrt{E}}(e^z)\,K_{ip}(e^z)\,e^{nz}=&\frac{2^{n-3}}{\Gamma(n)}\Gamma\left(\frac{n+i\sqrt{E}+ip}{2}\right)\Gamma\left(\frac{n+i\sqrt{E}-ip}{2}\right)\\&\times\Gamma\left(\frac{n-i\sqrt{E}+ip}{2}\right)\Gamma\left(\frac{n-i\sqrt{E}-ip}{2}\right).\end{aligned} \tag{80}$$

Thus,

$$\begin{aligned}\Delta E=&\frac{\sinh(\pi\sqrt{E})}{2\pi^3}4^{n-2}\int \mathrm{d}p\,e^{isp/2}\Gamma\left(\frac{n+i\sqrt{E}+ip}{2}\right)\\&\times\Gamma\left(\frac{n+i\sqrt{E}-ip}{2}\right)\Gamma\left(\frac{n-i\sqrt{E}+ip}{2}\right)\Gamma\left(\frac{n-i\sqrt{E}-ip}{2}\right).\end{aligned} \tag{81}$$

Finally (Ref. 18, 6.422.19),

$$\begin{aligned}&\int \mathrm{d}p\,e^{isp/2}\Gamma\left(\frac{n+i\sqrt{E}+ip}{2}\right)\Gamma\left(\frac{n+i\sqrt{E}-ip}{2}\right)\Gamma\left(\frac{n-i\sqrt{E}+ip}{2}\right)\Gamma\left(\frac{n-i\sqrt{E}-ip}{2}\right)\\&=4\pi\,G^{22}_{22}\left(e^s\left|\begin{matrix}\frac{2-n+i\sqrt{E}}{2},\frac{2-n-i\sqrt{E}}{2}\\ \frac{n+i\sqrt{E}}{2},\frac{n-i\sqrt{E}}{2}\end{matrix}\right.\right).\end{aligned} \tag{82}$$

To sum up, the perturbed energy shift is a Meijer function,

$$\Delta E = \frac{4^n \sinh(\pi\sqrt{E})}{8\pi^2} G^{22}_{22}\left(e^s \left| \begin{matrix} \frac{2-n+i\sqrt{E}}{2}, \frac{2-n-i\sqrt{E}}{2} \\ \frac{n+i\sqrt{E}}{2}, \frac{n-i\sqrt{E}}{2} \end{matrix} \right. \right). \tag{83}$$

In principle, any polynomial perturbation in either x or p can be obtained from this, by differentiation with respect to n and s. (Retaining a bit of exponential in x would be helpful to suppress the region of large negative x).

APPENDIX A: ⋆-FOCK SPACE AND COHERENT STATES

Dirac's Hamiltonian factorization method for algebraic solution of the harmonic oscillator carries through (cf. Ref. 2) intact in ⋆-space. Indeed,

$$H = \frac{1}{2}(x-ip)\star(x+ip) + \frac{\hbar}{2}, \tag{A1}$$

motivating definition of

$$a \equiv \frac{1}{\sqrt{2}}(x+ip), \quad a^\dagger \equiv \frac{1}{\sqrt{2}}(x-ip). \tag{A2}$$

Thus, noting

$$a\star a^\dagger - a^\dagger \star a = \hbar, \tag{A3}$$

and also that, by above,

$$a\star f_0 = \frac{1}{\sqrt{2}}(x+ip)\star e^{-(x^2+p^2)} = 0, \tag{A4}$$

provides a ⋆-Fock vacuum, it is evident that associativity of the ⋆-product permits the entire ladder spectrum generation to go through as usual. The ⋆-genstates of the Hamiltonian, such that $H\star f = f\star H$, are thus

$$f_{nn} = f_n = \frac{1}{n!}(a^\dagger\star)^n f_0 (\star a)^n. \tag{A5}$$

These states are real, like the Gaussian ground state, and are thus left-right symmetric ⋆-genstates. They are also transparently ⋆-orthogonal for different eigenvalues; and they project to themselves, as they should, since the Gaussian ground state does, $f_0\star f_0 = f_0/2\pi\hbar$.

The complete set of generalized WFs can thus be written as

$$f_{mn} = \frac{1}{\sqrt{n!m!}}(a^\dagger\star)^n f_0 (\star a)^m, \quad m,n = 0,1,2,3,\cdots. \tag{A6}$$

The standard combinatoric features of conventional Fock space apply separately to left and right (its adjoint) $\star$-multiplication:

$$a\star f_n \equiv a\star f_{nn} = \hbar\sqrt{n} f_{n,n-1}, \quad a^\dagger\star a\star f_n = \hbar\sqrt{n} a^\dagger\star f_{n,n-1} = \hbar n f_n,$$

$$a^\dagger\star f_n \equiv a^\dagger\star f_{nn} = \sqrt{n+1} f_{n,n+1}, \tag{A7}$$

$$a\star a^\dagger\star f_n = \sqrt{n+1} a\star f_{n,n+1} = \hbar(n+1) f_n,$$

$$f_n\star a = \sqrt{n+1} f_{n+1,n},$$

$$f_n\star a\star a^\dagger = \hbar(n+1) f_n, \tag{A8}$$

$$f_n\star a^\dagger = \hbar\sqrt{n} f_{n-1,n}, \quad f_n\star a^\dagger\star a = \hbar n f_n.$$

Furthermore, a left/right (non-self-adjoint) coherent state is naturally defined[19,24]

$$\Phi(\alpha,\beta) = \exp_\star(\alpha a^\dagger) f_0 \exp_\star(\beta a), \quad a\star\Phi(\alpha,\beta) = \alpha\Phi(\alpha,\beta), \quad \Phi(\alpha,\beta)\star a^\dagger = \beta\Phi(\alpha,\beta). \tag{A9}$$

Up to a factor of $\exp((|\alpha|^2+|\beta|^2)/2)$, this is also the WF of coherent states $|\alpha\rangle$ and $\langle\beta|$.[24] As indicated in the text, this coherent state is identifiable with the generating function G for the harmonic oscillator.

APPENDIX B: STATIONARY PERTURBATION THEORY

Perturbation theory could be carried out in Hilbert space and its resulting wave functions utilized to evaluate the corresponding WF integrals. However, in the spirit of logical autonomy of Moyal's formulation of quantum mechanics in phase space, the perturbed Wigner functions may also be computed *ab initio* in phase space,[17,25] without reference to the conventional Hilbert space formulation. The basics are summarized in the following.

As usual, the Hamiltonian kernel decomposes into free and perturbed parts,

$$H = H_0 + \lambda H_1. \tag{B1}$$

Fairlie's stationary, real, $\star$-genvalue equations[8,4] for the full Hamiltonian,

$$H(x,p)\star f_n(x,p) = f_n(x,p)\star H(x,p) = E_n(\lambda) f_n(x,p), \tag{B2}$$

are solved upon expansion of their components E and f in powers of λ, the perturbation strength,

$$E_n = E_n^0 + \lambda E_n^1 + \lambda^2 E_n^2 + \cdots, \tag{B3}$$

$$f_n = f_n^0 + \lambda f_n^1 + \lambda^2 f_n^2 + \cdots. \tag{B4}$$

Note the superscripts on E and f are order indices and not exponents. Resolution into individual powers of λ yields the real equations:

$$H_0\star f_n^0 = f_n^0\star H_0 = E_n^0 f_n^0, \tag{B5}$$

$$H_0\star f_n^1 + H_1\star f_n^0 = f_n^1\star H_0 + f_n^0\star H_1 = E_n^0 f_n^1 + E_n^1 f_n^0, \tag{B6}$$

$$H_0\star f_n^2 + H_1\star f_n^1 = f_n^2\star H_0 + f_n^1\star H_1 = E_n^0 f_n^2 + E_n^1 f_n^1 + E_n^2 f_n^0. \tag{B7}$$

Left multiplication of (B6) by $f_n^0\star$ yields

$$f_n^0\star H_0\star f_n^1 + f_n^0\star H_1\star f_n^0 = E_n^0 f_n^0\star f_n^1 + E_n^1 f_n^0\star f_n^0, \tag{B8}$$

and, by (B5),

$$f_n^0 \star H_1 \star f_n^0 = E_n^1 f_n^0 \star f_n^0; \tag{B9}$$

by (11), (10), and the cyclicity of the trace (3),

$$\int \mathrm{d}x\, \mathrm{d}p\, E_n^1 f_n^0 \star f_n^0 = \int \mathrm{d}x\, \mathrm{d}p (f_n^0 \star H_1 \star f_n^0) = \int \mathrm{d}x\, \mathrm{d}p (H_1 \star f_n^0 \star f_n^0) = \frac{1}{2\pi\hbar} \int \mathrm{d}x\, \mathrm{d}p H_1 \star f_n^0. \tag{B10}$$

Hence,

$$E_n^1 = \int \mathrm{d}x\, \mathrm{d}p\, H_1 f_n^0, \tag{B11}$$

the diagonal element of the perturbation. For the off-diagonal elements, similarly left-$\star$-multiply (B6) by f_m^0,

$$f_m^0 \star H_0 \star f_n^1 + f_m^0 \star H_1 \star f_n^0 = E_n^0 f_m^0 \star f_n^1 + E_n^1 f_m^0 \star f_n^0. \tag{B12}$$

By completeness, f_n^i, $i \neq 0$, resolves to

$$f_n^i = \sum_{k,l} a_{n,kl}^i f_{kl}^0, \tag{B13}$$

the reality condition dictating

$$a_{n,kl}^i = a_{n,lk}^{*i}. \tag{B14}$$

Consequently, by (10),

$$E_m^0 \sum_{k,l} a_{n,kl}^1 f_m^0 \star f_{kl}^0 + f_m^0 \star H_1 \star f_n^0 = E_n^0 \sum_{k,l} a_{n,kl}^1 f_m^0 \star f_{kl}^0 + E_n^1 \frac{1}{2\pi\hbar} f_n^0 \delta_{mn}, \tag{B15}$$

and hence

$$E_m^0 \sum_{k} a_{n,km}^1 f_{km}^0 + 2\pi\hbar f_m^0 \star H_1 \star f_n^0 = E_n^0 \sum_{k} a_{n,km}^1 f_{km}^0 + E_n^1 f_n^0 \delta_{mn}. \tag{B16}$$

For $m \neq n$,

$$(E_n^0 - E_m^0) \sum_{l} a_{n,lm}^1 f_{lm}^0 = 2\pi\hbar (f_m^0 \star H_1 \star f_n^0), \tag{B17}$$

so that

$$\sum_{l} a_{n,lm}^1 f_{lm}^0 = \frac{2\pi\hbar (f_m^0 \star H_1 \star f_n^0)}{E_n^0 - E_m^0}. \tag{B18}$$

Finally, use of (11), yields

$$a^1_{n,lm}=(2\pi\hbar)^2\int \mathrm{d}x\,\mathrm{d}p\,\frac{f^0_{ml}\star f^0_m\star H_1\star f^0_n}{E^0_n-E^0_m}$$
$$=(2\pi\hbar)^2\int \mathrm{d}x\,\mathrm{d}p\,\frac{1}{2\pi\hbar}\,\frac{f^0_{ml}\star H_1\star f^0_n}{E^0_n-E^0_m}$$
$$=(2\pi\hbar)\int \mathrm{d}x\,\mathrm{d}p\,\frac{H_1\star f^0_n\star f^0_{ml}}{E^0_n-E^0_m}$$
$$=\frac{\delta_{nl}}{E^0_n-E^0_m}\int \mathrm{d}x\,\mathrm{d}p\,H_1 f^0_{mn},\quad (m\neq n). \tag{B19}$$

We also have the similar equation for $l\neq n$. Consequently, $a^1_{n,lm}$ is proportional to the matrix element of the perturbation, and it vanishes unless l or m is equal to n. [Note: This differs from Ref. 25, Eq. (45).] To sum up,

$$f^1_n=\sum_{m\neq n}\frac{1}{E^0_n-E^0_m}\Bigg(f^0_{nm}\Bigg(\int \mathrm{d}x'\,\mathrm{d}p'\,H_1(x',p')f^0_{mn}(x',p')\Bigg)$$
$$+f^0_{mn}\Bigg(\int \mathrm{d}x'\,\mathrm{d}p'\,H_1(x',p')f^0_{nm}(x',p')\Bigg)\Bigg). \tag{B20}$$

By (8), it can be seen that the same result may also follow from evaluation of the WF integrals of perturbed wave functions obtained in standard perturbation theory in Hilbert space.

For example, consider $H_1=\sqrt{2}\,x=a+a^\dagger$. It follows that $E^1_0=0$, and

$$a^1_{n,lm}=\frac{\delta_{n,l}}{(E^0_n-E^0_m)}\int\int \mathrm{d}x\,\mathrm{d}p\,f^0_{mn}\star(a+a^\dagger)$$
$$=\frac{\delta_{n,}}{(E^0_n-E^0_m)}\int\int \mathrm{d}x\,\mathrm{d}p(\sqrt{m+1}\,f^0_{m+1,n}+\sqrt{n+1}\,f^0_{m,n+1})$$
$$=\delta_{n,l}(\sqrt{m+1}\,\delta_{m+1,n}-\sqrt{n+1}\,\delta_{m,n+1}), \tag{B21}$$

for $m\neq n$, and the $(m\leftrightarrow l)$ expression for $l\neq n$. Hence,

$$f^1_n=\sqrt{n}\,(f^0_{n-1,n}+f^0_{n,n-1})-\sqrt{n+1}\,(f^0_{n,n+1}+f^0_{n+1,n}). \tag{B22}$$

APPENDIX C: COMBINATORIC DERIVATION OF IDENTITIES (54) AND (73)

The $\star$-exponential (54) of the Hamiltonian kernel for the linear potential is also easy to work out directly, since the combinatorics in $\star$-space are identical to the combinatorics of any associative algebra. In particular, the Campbell-Baker-Hausdorff expansion also holds for $\star$-exponentials,

$$\exp_\star(A)\star\exp_\star(B)=\exp_\star(A+B+\tfrac{1}{2}[A,B]_\star+\tfrac{1}{12}[A,[A,B]_\star]_\star+\tfrac{1}{12}[[A,B]_\star,B]_\star+C), \tag{C1}$$

where C represents a sum of triple or more nested $\star$-commutators (Moyal Brackets, $[A,B]_\star\equiv A\star B-B\star A$). Now, choosing $A=itx$ and $B=itp^2+it^2p+\frac{1}{3}it^3$, yields $[A,B]_\star=-2it^2p-it^3$, $[A,[A,B]_\star]_\star=2it^3$, $[[A,B]_\star,B]_\star=0$, and hence $C=0$.

Consequently,

$$\exp_\star(itx)\star\exp_\star(itp^2+it^2p+\tfrac{1}{3}it^3)=\exp_\star(itx+itp^2). \tag{C2}$$

But further note $\exp_\star(ax)=\exp(ax)$, and also $\exp_\star(bp^2+cp+d)=\exp(bp^2+cp+d)$. This reduces the $\star$-product to a mere translation,

$$\begin{aligned}\exp_\star(ax)\star\exp_\star(bp^2+cp+d)&=\exp(ax)\star\exp(bp^2+cp+d)\\&=\exp(ax+\tfrac{1}{2}ia\partial_p)\exp(bp^2+cp+d)\\&=\exp(ax+b(p+\tfrac{1}{2}ia)^2+c(p+\tfrac{1}{2}ia)+d)\\&=\exp(ax+bp^2+(c+iab)p+d-\tfrac{1}{4}a^2b+\tfrac{1}{2}iac).\end{aligned}\tag{C3}$$

Consequently,

$$\exp_\star(itx)\star\exp_\star(itp^2+it^2p+\tfrac{1}{3}it^3)=\exp(it(x+p^2+t^2/12)),\tag{C4}$$

and the identity

$$\exp_\star(it(x+p^2))=\exp(it(x+p^2+t^2/12))\tag{54′}$$

follows.

The proof of

$$\exp_\star\left(-\frac{y}{2\sinh y}e^{2x-z}+iyp\right)=\exp\left(-\frac{1}{2}e^{y-z}e^{2x}\right)\star\exp(iyp)=\exp\left(-\frac{1}{2}e^{2x-z}+iyp\right)\tag{73}$$

is similar. Choosing now $A=-\frac{1}{2}e^{y-z}e^{2x}$ and $B=iyp$, it follows that $[A,B]_\star=-2yA$, so that only those multiple Moyal commutators survive which are linear in A. This means, then, that in the Hausdorff expansion[26] for $Z(A,B)\equiv\ln_\star(\exp_\star(A)\star\exp_\star(B))$, only B and terms *linear* in A survive. Hence, Z reduces to merely

$$Z=B+A\left(\frac{B]_\star}{1-e^{-B]_\star}}\right).\tag{C5}$$

The Hadamard expansion in $B]_\star$ means successive right $\star$-commutation with respect to B as many times as the regular power expansion of the function in the parenthesis dictates. Consequently,

$$\exp\left(-\frac{1}{2}e^{y-z}e^{2x}\right)\star\exp(iyp)=\exp_\star\left(-\frac{1}{2}e^{y-z}e^{2x}\right)\star\exp_\star(iyp)=\exp_\star\left(-\frac{y}{2\sinh y}e^{2x-z}+iyp\right).\tag{C6}$$

On the other hand,

$$\exp(-\tfrac{1}{2}e^{y-z}e^{2x})\star\exp(iyp)=\exp(-\tfrac{1}{2}e^{y-z+2x})\exp(iy(p+i\tilde{\partial}_x/2))=\exp(-\tfrac{1}{2}e^{2x-z}+iyp),\tag{C7}$$

and the identity is proven.

APPENDIX D: CONSTRUCTION OF THE GENERATING FUNCTION FOR THE LIOUVILLE WFS

From (60) and (61), it is evident that the Liouville wave functions can be generated by

$$\exp(-e^x\cosh X)=\int_{-\infty}^{\infty}\frac{dk}{\sqrt{\sinh(\pi\sqrt{E(k)})}}e^{-ikX}\,\psi_{E(k)}(x),\tag{D1}$$

where $E(k)\equiv k^2$. Therefore, the usual wave function bilinears appearing in the WFs are generated by (recalling that the ψ's are real)

$$\exp(-e^{x-y}\cosh X)\exp(-e^{x+y}\cosh Y)=\int_{-\infty}^{\infty}\frac{dk}{\sqrt{\sinh(\pi\sqrt{E(k)})}}\int_{-\infty}^{\infty}\frac{dq}{\sqrt{\sinh(\pi\sqrt{E(q)})}}$$
$$\times e^{-ikX-iqY}\psi_{E(k)}(x-y)\psi_{E(q)}(x+y). \tag{D2}$$

Consequently, Fourier transforming this produces a generating function for WFs,

$$\frac{1}{\pi}\int_{-\infty}^{\infty}\mathrm{d}y\, e^{-2ipy}\exp(-e^{x-y}\cosh X)\exp(-e^{x+y}\cosh Y)$$
$$=\int_{-\infty}^{\infty}\frac{\mathrm{d}k}{\sqrt{\sinh(\pi\sqrt{E(k)})}}\int_{-\infty}^{\infty}\frac{\mathrm{d}q}{\sqrt{\sinh(\pi\sqrt{E(q)})}}e^{-ikX-iqY}f_{E(k)\,E(q)}(x,p). \tag{D3}$$

Evaluation of this expression yields just a factor multiplying a modified Bessel function,

$$\int_{-\infty}^{\infty}\mathrm{d}y\, e^{-2ipy}\exp(-e^{x-y}\cosh X-e^{x+y}\cosh Y)$$
$$=\int_{-\infty}^{\infty}\mathrm{d}y\exp\left(-2ip\left(y+\frac{1}{2}\ln(\cosh X/\cosh Y)\right)\right)\exp(-(e^{x}\sqrt{4\cosh X\cosh Y})\cosh y)$$
$$=2\left(\frac{\cosh Y}{\cosh X}\right)^{ip}K_{2ip}(e^{x}\sqrt{4\cosh X\cosh Y}). \tag{D4}$$

Thus, a generating function for the complete set of Liouville Wigner functions is

$$\frac{2}{\pi}\left(\frac{\cosh Y}{\cosh X}\right)^{ip}K_{2ip}(e^{x}\sqrt{4\cosh X\cosh Y})=\int_{-\infty}^{\infty}\frac{\mathrm{d}k}{\sqrt{\sinh(\pi\sqrt{E(k)})}}\int_{-\infty}^{\infty}\frac{\mathrm{d}q}{\sqrt{\sinh(\pi\sqrt{E(q)})}}$$
$$\times e^{-ikX-iqY}f_{E(k)\,E(q)}(x,p), \tag{65$'$}$$

as in the text.

APPENDIX E: OPERATOR ORDERING AND EQ. (69)

Given the factorized phase-space generating function

$$\mathcal{G}(z;x,p)=\exp(-\tfrac{1}{2}e^{2x-z})K_{ip}(e^{z}), \tag{69$'$}$$

what is the operator corresponding to it? According to Weyl's prescription, Eq. (5), the associated operator is

$$\mathfrak{G}(z;\mathcal{X},\mathcal{P})=\frac{1}{(2\pi)^2}\int \mathrm{d}\tau\,\mathrm{d}\sigma\,\mathrm{d}x\,\mathrm{d}p\,\mathcal{G}(z;x,p)\exp(i\tau(\mathcal{P}-p)+i\sigma(\mathcal{X}-x))$$
$$=\frac{1}{(2\pi)^2}\int \mathrm{d}\tau\,\mathrm{d}\sigma\,\mathrm{d}x\,\mathrm{d}p\exp(i\tau\mathcal{P}+i\sigma\mathcal{X})\exp\left(-\frac{1}{2}e^{2x-z}-i\sigma x\right)K_{ip}(e^{z})\exp(-i\tau p). \tag{E1}$$

The integrals over x and p may be evaluated separately, if the σ contour is first shifted slightly above the real axis, $\sigma\to\sigma+i\epsilon$, thereby suppressing contributions to the x-integral as $x\to-\infty$. Now $s\equiv\frac{1}{2}e^{2x-z}$ gives

$$\int_{-\infty}^{+\infty} dx \exp\left(-\frac{1}{2} e^{2x-z} - i(\sigma + i\epsilon)x \right) = \int_0^\infty \frac{ds}{2s} (2se^z)^{-i(\sigma+i\epsilon)/2} \exp(-s)$$
$$= \tfrac{1}{2} e^{-i(z+\ln 2)\sigma/2} \Gamma(-i(\sigma+i\epsilon)/2). \tag{E2}$$

By (61),

$$\int dp\, K_{ip}(e^z) \exp(-i\tau p) = \frac{1}{2} \int_{-\infty}^{\infty} dX\, e^{-e^z \cosh X}\, 2\pi \delta(X-\tau) = \pi\, e^{-e^z \cosh \tau}. \tag{E3}$$

So

$$\mathfrak{G}(z;\mathcal{X},\mathcal{P}) = \frac{1}{8\pi} \int d\tau\, d\sigma\, e^{-i(z+\ln 2)\sigma/2} \Gamma(-i(\sigma+i\epsilon)/2)\, e^{-e^z \cosh \tau} \exp(i\tau\mathcal{P} + i\sigma\mathcal{X}). \tag{E4}$$

The shifted σ contour avoids the pole in Γ at the origin.

Ordering with all $\mathcal{P}$'s to the right, thereby departing from Weyl ordering, yields $\exp(i\tau\mathcal{P} + i\sigma\mathcal{X}) = \exp(i\sigma\mathcal{X})\exp(i\sigma\pi/2)\exp(i\tau\mathcal{P})$. Performing the σ integration before the τ integration, permits taking the limit $\epsilon \to 0$ to obtain

$$\mathfrak{G}(z;\mathcal{X},\mathcal{P}) = \frac{1}{8\pi} \int d\tau \left(\int d\sigma \Gamma(-i(\sigma+i\epsilon)/2) \exp(i\sigma\mathcal{X} + i\sigma\tau/2 - i\sigma(z+\ln 2)/2) \right)$$
$$\times e^{-e^z \cosh \tau} \exp(i\tau\mathcal{P})$$
$$= \frac{1}{8\pi} \int d\tau (4\pi \exp(-e^{2\mathcal{X}+\tau-(z+\ln 2)})) e^{-e^z \cosh \tau} \exp(i\tau\mathcal{P})$$
$$= \frac{1}{2} \int d\tau \exp\left(-\frac{1}{2} e^{2\mathcal{X}+\tau-z} - \frac{1}{2} e^{z+\tau} - \frac{1}{2} e^{z-\tau} \right) \exp(i\tau\mathcal{P}). \tag{E5}$$

This is the operator correspondent to (72); it reflects the Weyl correspondence through which it was originally defined (although, technically, it was taken out of Weyl ordering above, merely as a matter of convenience, not a bona-fide change of representation).

This form leads to a more intuitive Hilbert space representation. Acting to the right of a position eigen-bra, $\langle x|\mathcal{X} = \langle x|x$, while the subsequent exponential of the momentum operator just translates, $\langle x|\exp(i\tau\mathcal{P}) = \langle x+\tau|$. So the full right-operation of $\mathfrak{G}$ is

$$\langle x|\mathfrak{G}(z;\mathcal{X},\mathcal{P}) = \frac{1}{2} \int d\tau \langle x+\tau| \exp\left(-\frac{1}{2} e^{2x+\tau-z} - \frac{1}{2} e^{z+\tau} - \frac{1}{2} e^{z-\tau} \right)$$
$$= \frac{1}{2} \int dy \langle y| \exp\left(-\frac{1}{2} e^{x+y-z} - \frac{1}{2} e^{z+y-x} - \frac{1}{2} e^{z-y+x} \right). \tag{E6}$$

Inserting $1 = \int dx\, |x\rangle\langle x|$ gives $\mathfrak{G}(z;\mathcal{X},\mathcal{P}) = \int dx\, |x\rangle\langle x|\mathfrak{G}(z;\mathcal{X},\mathcal{P})$, and leads to a coordinate space realization of the operator involving an x,y-symmetric kernel,

$$\mathfrak{G}(z;\mathcal{X},\mathcal{P}) = \frac{1}{2} \int dx\, dy\, |x\rangle\langle y| \exp\left(-\frac{1}{2} e^{x+y-z} - \frac{1}{2} e^{x-y+z} - \frac{1}{2} e^{-x+y+z} \right). \tag{E7}$$

This operator is diagonal on energy states: by Macdonald's identity (67), and the reality and orthogonality of the wave functions,

$$\langle E_1|\mathfrak{G}(z;\mathcal{X},\mathcal{P})|E_2\rangle = \frac{1}{2}\int \mathrm{d}x\,\mathrm{d}y\;\psi^*_{E_1}(x)\;\psi_{E_2}(y)\exp\left(-\frac{1}{2}e^{x+y-z}-\frac{1}{2}e^{z+y-x}-\frac{1}{2}e^{z-y+x}\right)$$
$$= \delta(E_1-E_2)\,K_{i\sqrt{E_1}}(e^z). \tag{E8}$$

This is in agreement with the corresponding phase-space expression, (66).

The composition law of this operator also parallels its phase-space isomorph, (74),

$$\mathfrak{G}(u)\mathfrak{G}(v) = \frac{1}{2}\int \mathrm{d}w\exp\left(-\frac{1}{2}(e^{u+v-w}+e^{u-v+w}+e^{-u+v+w})\right)\mathfrak{G}(w). \tag{E9}$$

(Received 19 October 2000; accepted for publication 12 December 2000)

It is shown that two types of shape invariance with respect to quantum numbers n and m lead us to solve Dirac equation for a spin-$\frac{1}{2}$ charged particle in two-dimensional and three-dimensional Euclidean spaces in the presence of magnetic fields. Also, we introduce supersymmetry algebra and shape invariance symmetry represented by two bunches of spinors obtained from the above solutions. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1350635]

I. INTRODUCTION

The study of supersymmetry in quantum mechanics was first done by Nicolai,[1] then, a few years later, Witten introduced the concept of supersymmetry breaking in quantum field models.[2] Over the last few years it has been shown that supersymmetry in quantum mechanics plays an important role in deriving exact solutions of quantum mechanical problems.[3–6] A certain class of exactly solvable potentials is characterized by a property known as shape invariance.[7–12] It has been shown that the Schrödinger equation with shape invariant potentials[4,5,9–12] can be exactly solved by an algebraic procedure or elementary calculation. Also, there have been some attempts to solve the Schrödinger equation for 2-dimensional potentials from the shape invariance approach.[13,14]

In Ref. 15, with the help of the master function together with the corresponding weight function, and using from the solvable quantum models, obtained from shape invariance on secondary quantum number m, we derived solutions of the Dirac equation on the real forms of homogeneous manifold $SL(2,c)/GL(1,c)$ in the presence of a magnetic monopole field. Now, in the present paper our aim is to use the formalism of supersymmetric quantum mechanics and shape invariance symmetry to study the motion of a spin-$\frac{1}{2}$ charged particle in the presence of different magnetic fields in two-dimensional (2D) and three-dimensional (3D) Euclidean spaces. Therefore, it seems appropriate to mention first some of the results obtained so far.

In our previous works[11,16] we introduced the master function $A(x)$ as a polynomial of at most degree two, and also, the non-negative weight function $W(x)$ depending on the master function in the interval (a,b). For a given master function $A(x)$, the weight function $W(x)$ is chosen so that $(1/W(x))(d/dx)(A(x)W(x))$ is at most a first order polynomial, and also, the interval (a,b) is fixed by letting $A(x)W(x)$ and its derivatives vanish at both ends. It is shown that polynomials $\Phi_n(x)$ of order n with the Rodrigues representation,

a)Electronic mail: hfakhri@ark.tabrizu.ac.ir

$$\Phi_n(x)=\frac{a_n}{W(x)}\left(\frac{d}{dx}\right)^n(A^n(x)W(x)), \tag{1}$$

are orthogonal with respect to the defined scalar product by weight function $W(x)$ in the interval (a,b), where constants a_n depend on the selection of normalization; n is a natural number. These orthogonal polynomials which are the special functions used in mathematical physics, such as Jacobi functions, hypergeometric functions, satisfy the second order differential equation,

$$A(x)\Phi_n''(x)+\frac{(A(x)W(x))'}{W(x)}\Phi_n'(x)-\left[n\left(\frac{A(x)W'(x)}{W(x)}\right)'+\frac{n(n+1)}{2}A''(x)\right]\Phi_n(x)=0,\quad n=0,1,2,\ldots, \tag{2}$$

where the prime means a derivative with respect to x. Also, a new second order differential equation has been associated to the differential equation corresponding to classical orthogonal functions $\Phi_n(x)$ just by differentiating the differential equation (2) m times then multiplying it by $(-1)^m A^{m/2}(x)$:

$$A(x)\Phi_{n,m}''(x)+\frac{(A(x)W(x))'}{W(x)}\Phi_{n,m}'(x)+\left[-\frac{1}{2}(n^2+n-m^2)A''(x)+(m-n)\left(\frac{A(x)W'(x)}{W(x)}\right)'-\frac{m^2}{4}\frac{A'^2(x)}{A(x)}-\frac{m}{2}\frac{A'(x)W'(x)}{W(x)}\right]\Phi_{n,m}(x)=0,\quad m=0,1,2,\ldots,n. \tag{3}$$

Equation (3) has the following solution as the Rodrigues formula, and the so-called associated special function related to the master function $A(x)$ and weight function $W(x)$:

$$\Phi_{n,m}(x)=\frac{a_n(-1)^m}{A^{m/2}(x)W(x)}\left(\frac{d}{dx}\right)^{n-m}(A^n(x)W(x)). \tag{4}$$

In Ref. 12 using a differential equation (2) and the procedure of factorization introduced in Ref. 16 with respect to the parameter n, we have obtained the following shape invariance equations:

$$B(n)A(n)\psi_n(x)=E(n)\psi_n(x),$$
$$A(n)B(n)\psi_{n-1}(x)=E(n)\psi_{n-1}(x), \tag{5}$$

with

$$E(n)=\frac{n}{4\left[\left(\frac{A(x)W'(x)}{W(x)}\right)'+nA''(x)\right]^2}\left\{4\left(\frac{A(x)W'(x)}{W(x)}\right)'^2\left(nA'^2(0)-A(0)\left(\frac{A(x)W'(x)}{W(x)}\right)'\right)-\left(\frac{AW'}{W}\right)(0)\left(A''(x)\left(\frac{AW'}{W}\right)(0)-2A'(0)\left(\frac{A(x)W'(x)}{W(x)}\right)'\right)\times\left(2\left(\frac{A(x)W'(x)}{W(x)}\right)'+nA''(x)\right)+n^2A''(0)(A'^2(0)-2A''(0)A(0))\times\left(nA''(0)+4\left(\frac{A(x)W'(x)}{W(x)}\right)'\right)-10nA(0)A''(x)\left(\frac{A(x)W'(x)}{W(x)}\right)'^2\right\}. \tag{6}$$

The 1-dimensional wavefunctions $\psi_n(x)$ are expressed in terms of a multiple of orthogonal polynomials $\Phi_n(x)$ as

$$\psi_n(x)=W^{1/2}(x)\Phi_n(x), \tag{7}$$

where n is named the main quantum number. The raising and the lowering operators of the main quantum number n, i.e., $B(n)$ and $A(n)$ that are adjoint of each other, have the following explicit form:

$$B(n)=A(x)\frac{d}{dx}+\frac{1}{2}\left[nA'(x)+\frac{A(x)W'(x)}{W(x)}+n\frac{A'(0)\left(\frac{A(x)W'(x)}{W(x)}\right)'-A''(x)\left(\frac{AW'}{W}\right)(0)}{\left(\frac{A(x)W'(x)}{W(x)}\right)'+nA''(x)}\right], \tag{8}$$

$$A(n)=-A(x)\frac{d}{dx}+\frac{1}{2}\left[nA'(x)+\frac{A(x)W'(x)}{W(x)}+n\frac{A'(0)\left(\frac{A(x)W'(x)}{W(x)}\right)'-A''(x)\left(\frac{AW'}{W}\right)(0)}{\left(\frac{A(x)W'(x)}{W(x)}\right)'+nA''(x)}\right].$$

One can easily show that the shape invariance relations (5) are written as follows:

$$\begin{aligned} B(n)\psi_{n-1}(x)&=E_n\psi_n(x),\\ A(n)\psi_n(x)&=E_n\psi_{n-1}(x), \end{aligned} \tag{9}$$

in which we have defined

$$E_n:=\sqrt{E(n)}. \tag{10}$$

Also, we are reminded that in Ref. 11 the differential equation (3) was factorized with respect to parameter m, and that we obtained the shape invariant equations with respect to secondary quantum number m as

$$\begin{aligned} B(m)A(m)\psi_{n,m}(x)&=E(n,m)\psi_{n,m}(x),\\ A(m)B(m)\psi_{n,m-1}(x)&=E(n,m)\psi_{n,m-1}(x), \end{aligned} \tag{11}$$

with

$$E(n,m)=-(n-m+1)\left[\left(\frac{A(x)W'(x)}{W(x)}\right)'+\frac{1}{2}(n+m)A''(x)\right]. \tag{12}$$

Thus, the 1-dimensional wavefunctions $\psi_{n,m}(x)$ were expressed in terms of a multiple of associated special functions as

$$\psi_{n,m}(x)=A^{1/4}(x)W^{1/2}(x)\Phi_{n,m}(x). \tag{13}$$

The raising and the lowering operators of the secondary quantum number m, i.e., $B(m)$ and its adjoint $A(m)$ are

$$B(m)=\sqrt{A(x)}\frac{d}{dx}-\frac{\frac{A(x)W'(x)}{2W(x)}+\frac{2m-1}{4}A'(x)}{\sqrt{A(x)}},$$
$$A(m)=-\sqrt{A(x)}\frac{d}{dx}-\frac{\frac{A(x)W'(x)}{2W(x)}+\frac{2m-1}{4}A'(x)}{\sqrt{A(x)}}. \tag{14}$$

The shape invariance relations (11) can be written as relations of raising and lowering of the wavefunctions $\psi_{n,m}(x)$ with respect to the secondary quantum number m,

$$B(m)\psi_{n,m-1}(x)=E_{n,m}\psi_{n,m}(x),$$
$$A(m)\psi_{n,m}(x)=E_{n,m}\psi_{n,m-1}(x), \tag{15}$$

with

$$E_{n,m}:=\sqrt{E(n,m)}. \tag{16}$$

II. SOLUTION OF THE DIRAC EQUATION IN 1+2 SPACE–TIME WITH THE EUCLIDEAN SPATIAL PART

Now, we use the usual polar coordinates for the flat spatial part of the 1+2 space–time, i.e., $0\leqslant r<+\infty$ and $0\leqslant\theta<2\pi$. Thus the Minkowskian space–time metric can be written as

$$g_{\mu\nu}=\begin{pmatrix}1&0&0\\0&-1&0\\0&0&-r^2\end{pmatrix}, \tag{17}$$

where μ and ν denote rows and columns by t, r and θ. Naturally, the 3-bein $E_a{}^\mu$ and its inverse, i.e., $e_\mu{}^a$, establish a connection between the Minkowskian diagonal metric $\eta^{ab}:=(1,-1,-1)$ with the space–time metric $g_{\mu\nu}$:

$$E_a{}^\mu\eta^{ab}E_b{}^\nu=g^{\mu\nu},$$
$$E_a{}^\mu g_{\mu\nu}E_b{}^\nu=\eta_{ab}, \tag{18a}$$
$$e_\mu{}^a g^{\mu\nu}e_\nu{}^b=\eta^{ab},$$
$$e_\mu{}^a\eta_{ab}e_\nu{}^b=g_{\mu\nu}. \tag{18b}$$

Indices a and b take the values 0, 1 and 2 due to the generators of Clifford algebra, and $g^{\mu\nu}$ and η^{ab} are inverse of metrics $g_{\mu\nu}$ and η_{ab}, respectively. Using Eqs. (18) we obtain the following 3-beins for the metric (17):

$$E_a{}^\mu=(e_\mu{}^a)^{-1}=\begin{pmatrix}1&0&0\\0&1&0\\0&0&\frac{1}{r}\end{pmatrix}. \tag{19}$$

The nonvanishing components of Christoffel symbols $\Gamma^\lambda_{\mu\nu}$ for the space–time metric (17) are calculated as

$$\Gamma^{r}_{\theta\theta}=-r, \quad \Gamma^{\theta}_{r\theta}=\frac{1}{r}. \tag{20}$$

Of course, it is evident that just for the spatial part of the 1+2 space–time the nonvanishing Christoffel symbols are calculated the same as (20), thus describing a 2-dimensional space with zero Ricci scalar curvature, i.e., $R=0$.

The Dirac equation for the space–time corresponding to the metric (17) is

$$D\Psi(t;r,\theta)=0, \tag{21}$$

in which the Dirac operator D is defined as[17]

$$D=-i\gamma^{a}E_{a}{}^{\mu}(\partial_{\mu}-iA_{\mu}+\tfrac{1}{8}\omega_{\mu ab}[\gamma^{a},\gamma^{b}]). \tag{22}$$

Here, A_t is a scalar potential corresponding to an electric field, and A_r and A_θ are components of a gauge potential corresponding to a magnetic field. The generators of Clifford algebra, i.e., the matrices γ^a are

$$\gamma^{0}=\sigma^{3}, \quad \gamma^{1}=i\sigma^{2}, \quad \gamma^{2}=-i\sigma^{1}, \tag{23}$$

where σ^1, σ^2 and σ^3 are the known Pauli matrices. The generators of Clifford algebra generate the Minkowskian diagonal metric η^{ab} by the following equation:

$$\gamma^{a}\gamma^{b}=\eta^{ab}I_{2\times 2}-i\epsilon^{abc}\gamma_{c}. \tag{24}$$

The components of the spin connection $\omega_{\mu}{}^{a}{}_{b}$ satisfy

$$\partial_{\mu}e_{\nu}{}^{a}-\Gamma^{\lambda}_{\mu\nu}e_{\lambda}{}^{a}+\omega_{\mu}{}^{a}{}_{b}e_{\nu}{}^{b}=0. \tag{25}$$

Then, with the help of Eqs. (19) and (20) we calculate the nonvanishing components of the spin connection as

$$\omega_{\theta\ 12}=-\omega_{\theta\ 21}=1. \tag{26}$$

Using the relation (24), for the space–time 1+2 with the flat spatial part with spin connections given in Eqs. (26), evidently we can calculate contribution of the last term in the Dirac operator D is zero. Substituting Eqs. (19) and (23) in Eq. (21), we obtain the Dirac matrix equation (21) as follows:

$$\begin{pmatrix} \partial_t-iA_t & \partial_r-\dfrac{i}{r}\partial_\theta-iA_r+\dfrac{1}{2r}-\dfrac{1}{r}A_\theta \\ -\partial_r-\dfrac{i}{r}\partial_\theta+iA_r-\dfrac{1}{2r}-\dfrac{1}{r}A_\theta & -\partial_t+iA_t \end{pmatrix}\Psi(t;r,\theta)=0. \tag{27}$$

In this paper we assume that the electric field does not exist, i.e., $A_t=0$, and that the magnetic field is static, i.e., $\partial_t A_\mu=0$, with radial symmetry $A_\mu=A_\mu(r)$ for $\mu=r$ and θ. There are two approaches to solve Eq. (27).

A. The first approach for solving the Dirac equation in 2D Euclidean space

The first approach uses the shape invariance with respect to the main quantum number n, where we assume time evolution spinors as e^{-iE_nt}, in which the spectrum E_n is defined as in Eq. (10). Then, for

$$\Psi(t;r,\theta)=e^{-iE_nt}\Psi(r,\theta)=e^{-iE_nt}\begin{pmatrix}\psi_1(r,\theta)\\ i\psi_2(r,\theta)\end{pmatrix}, \tag{28}$$

from the Dirac equation (27) we obtain the following two equations:

$$\left(\frac{\partial}{\partial r}-\frac{i}{r}\frac{\partial}{\partial\theta}-iA_r+\frac{1}{2r}-\frac{1}{r}A_\theta\right)\psi_2(r,\theta)=E_n\psi_1(r,\theta),$$
$$\left(-\frac{\partial}{\partial r}-\frac{i}{r}\frac{\partial}{\partial\theta}+iA_r-\frac{1}{2r}-\frac{1}{r}A_\theta\right)\psi_1(r,\theta)=E_n\psi_2(r,\theta). \tag{29}$$

We assume angular functionality as phase factor for functions $\psi_1(r,\theta)$ and $\psi_2(r,\theta)$, and it is easy to conclude that existence of the difference of phase between functions $\psi_1(r,\theta)$ and $\psi_2(r,\theta)$ has no effect on the determination of the magnetic field. Thus, we choose the same phase factor as follows:

$$\psi_a(r,\theta)=e^{ik\theta}\psi_a(r),\quad a=1,2. \tag{30}$$

We establish the relation between variable x and radial coordinate r as

$$\frac{dx}{A(x)}=dr. \tag{31}$$

Also we substitute Eqs. (30) into Eqs. (29) and then we reduce the equations with respect to θ in order to compare the obtained results with Eqs. (9). Then, we find that

$$B(n)=\frac{d}{dr}+\frac{k}{r}-iA_r(n)+\frac{1}{2r}-\frac{1}{r}A_\theta(n),$$
$$A(n)=-\frac{d}{dr}+\frac{k}{r}+iA_r(n)-\frac{1}{2r}-\frac{1}{r}A_\theta(n), \tag{32}$$

with

$$A_r(n)=\frac{-i}{2r},$$
$$A_\theta(n)=k-\frac{r}{2}\left[nA'(x)+\frac{A(x)W'(x)}{W(x)}+n\frac{A'(0)\left(\frac{A(x)W'(x)}{W(x)}\right)'-A''(x)\left(\frac{AW'}{W}\right)(0)}{\left(\frac{A(x)W'(x)}{W(x)}\right)'+nA''(x)}\right]_{x=x(r)}, \tag{33}$$

where $x=x(r)$ is obtained from Eq. (31). It is necessary to limit the variable x such that one can restrict the interval of r to $0\leqslant r<+\infty$. The 2-form of the magnetic field is calculated as

$$B_n(r)=-\frac{1}{2}\left[\left(nA''(x)+\left(\frac{A(x)W'(x)}{W(x)}\right)'\right)rA(x)+nA'(x)+\frac{A(x)W'(x)}{W(x)}\right.$$
$$\left.+n\frac{A'(0)\left(\frac{A(x)W'(x)}{W(x)}\right)'-A''(x)\left(\frac{AW'}{W}\right)(0)}{\left(\frac{A(x)W'(x)}{W(x)}\right)'+nA''(x)}\right]_{x=x(r)}dr\wedge d\theta. \tag{34}$$

In general, magnetic fields described by Eq. (34) are quantized by the main quantum number n, except for $A(x)=1$ (see Appendix A). Also, from the above comparison, it obviously becomes clear that the first bunch spinors describing a spin-$\frac{1}{2}$ charged particle in the presence of magnetic field (34) on the flat surface, labeled by n, are

$$\Psi_n(t;r,\theta)=e^{-iE_nt}\begin{pmatrix}\psi_n(r,\theta)\\ i\psi_{n-1}(r,\theta)\end{pmatrix}=e^{-iE_nt}\Psi_n(r,\theta), \tag{35}$$

where we have used the following notation:

$$\psi_n(r,\theta)=e^{ik\theta}\psi_n(x(r))=:e^{ik\theta}\psi_n(r). \tag{36}$$

In this approach, by accepting the results (33) and (35), the equations

$$\begin{aligned} b(n)\psi_{n-1}(r,\theta)&=E_n\psi_n(r,\theta),\\ a(n)\psi_n(r,\theta)&=E_n\psi_{n-1}(r,\theta),\end{aligned} \tag{37}$$

with

$$\begin{aligned} b(n)&=\frac{\partial}{\partial r}-\frac{i}{r}\frac{\partial}{\partial\theta}-\frac{1}{r}A_\theta(n),\\ a(n)&=-\frac{\partial}{\partial r}-\frac{i}{r}\frac{\partial}{\partial\theta}-\frac{1}{r}A_\theta(n),\end{aligned} \tag{38}$$

describe the matrix components of the Dirac equation (27). However, Eqs. (37) together with the change of variable (31) represent a 2-dimensional shape invariance equations on the flat space (r,θ), where the shape invariance parameter is the main quantum number n. In Appendix A for different choices of the master function $A(x)$, we have introduced the solvable Dirac equations on the flat surface in the presence of the related magnetic fields (quantized by n) with the spinors expressed in terms of the special orthogonal polynomials. An example is the case in which $A(x)=1$ together with $\beta=0$, where the magnetic field has a constant value along the z-axis perpendicular to the flat surface. In Appendix A for the sake of brevity, we have not introduced the explicit form of the raising and the lowering operators $b(n)$ and $a(n)$, and also, have written the components of the spinors in terms of the special functions without phase factor $e^{ik\theta}$.

Now, we show that the first bunch of the spinors, i.e., Eq. (35), represents a supersymmetry algebra and also a shape invariance symmetry in terms of the quantum number n. With attention to Eqs. (36), one can easily rewrite the Dirac equation for the spinors $\Psi_n(r,\theta)$ as the following by using Eqs. (37):

$$D_2(n)\Psi_n(r,\theta)=E_n\Psi_n(r,\theta), \tag{39}$$

where time-independent Dirac operator $D_2(n)$ is defined as

$$D_2(n):=\begin{pmatrix}0 & -ib(n)\\ ia(n) & 0\end{pmatrix}. \tag{40}$$

It is obvious that the square of the Dirac operator $D_2(n)$ becomes

$$D_2^2(n)=\begin{pmatrix}b(n)a(n) & 0\\ 0 & a(n)b(n)\end{pmatrix}=:H(n), \tag{41}$$

which leads to the Schrödinger equations in the flat surface. Let us define the chiral fermionic creation and annihilation operators as[18]

$$Q_+(n)=Q_+b(n), \tag{42a}$$

$$Q_-(n)=Q_-a(n), \tag{42b}$$

with $Q_\pm=\mp(i/2(\sigma_1\pm i\sigma_2)$, where $D_2(n)=Q_+(n)+Q_-(n)$. It is clear that these operators are nilpotent, i.e., $Q_\pm^2(n)=0$. Also, we have

$$H(n)=\{Q_+(n),Q_-(n)\},\quad [Q_\pm(n),H(n)]=0, \tag{43}$$

therefore, two fermionic operators $Q_+(n)$ and $Q_-(n)$ together with the square of the time-independent Dirac operator, i.e., the bosonic generator $H(n)$ satisfy the supersymmetry algebra. The representation of the supersymmetry algebra by the spinors $\Psi_n(r,\theta)$ is

$$\begin{aligned} Q_+(n)\Psi_n(r,\theta)&=E_n\begin{pmatrix}\psi_n(r,\theta)\\0\end{pmatrix},\\ Q_-(n)\Psi_n(r,\theta)&=E_n\begin{pmatrix}0\\ i\psi_{n-1}(r,\theta)\end{pmatrix},\\ H(n)\Psi_n(r,\theta)&=E(n)\Psi_n(r,\theta).\end{aligned} \tag{44}$$

The appropriate operators for representing the shape invariance symmetry by the spinors $\Psi_n(r,\theta)$ are

$$\mathcal{B}(n):=\begin{pmatrix} b(n) & 0\\ 0 & \dfrac{E_n}{E_{n-1}}b(n-1)\end{pmatrix}, \tag{45a}$$

$$\mathcal{A}(n):=\begin{pmatrix} a(n) & 0\\ 0 & \dfrac{E_n}{E_{n-1}}a(n-1)\end{pmatrix}. \tag{45b}$$

One can readily conclude the raising and the lowering relations of the spinors $\Psi_n(r,\theta)$ as

$$\begin{aligned}\mathcal{B}(n)\Psi_{n-1}(r,\theta)&=E_n\Psi_n(r,\theta),\\ \mathcal{A}(n)\Psi_n(r,\theta)&=E_n\Psi_{n-1}(r,\theta).\end{aligned} \tag{46}$$

Also, with the help of Eqs. (46) one can obtain the shape invariant equations on the flat surface for the spinors $\Psi_n(r,\theta)$ as

$$\begin{aligned}\mathcal{B}(n)\mathcal{A}(n)\Psi_n(r,\theta)&=E(n)\Psi_n(r,\theta),\\ \mathcal{A}(n)\mathcal{B}(n)\Psi_{n-1}(r,\theta)&=E(n)\Psi_{n-1}(r,\theta).\end{aligned} \tag{47}$$

In this discussion of supersymmetry algebra and shape invariance symmetry, angular functionality of the spinors $\Psi_n(r,\theta)$ does not play any essential role, and in fact, the solvable models related to the first approach represent supersymmetry and shape invariance properties just by restricting on the radial part.

B. The second approach for solving the Dirac equation in 2D Euclidean space

The second approach uses the shape invariance symmetry with respect to the secondary quantum number m. Thus, in order to solve the Dirac equation (27), we take time evolution

spinors as $e^{-iE_{n,m}t}$; then instead of E_n, $A_r(n)$ and $A_\theta(n)$ we arrive at Eqs. (29) with $E_{n,m}$ given in Eq. (16), $A_r(m)$ and $A_\theta(m)$, respectively. After reducing $e^{ik\theta}$, by comparing components of the obtained Dirac equation with Eqs. (15), we get

$$\begin{aligned} B(m)&=\frac{d}{dr}+\frac{k}{r}-iA_r(m)+\frac{1}{2r}-\frac{1}{r}A_\theta(m),\\ A(m)&=-\frac{d}{dr}+\frac{k}{r}+iA_r(m)-\frac{1}{2r}-\frac{1}{r}A_\theta(m). \end{aligned} \tag{48}$$

This time the radial coordinate r is related to variable x by the following relation:

$$\frac{dx}{\sqrt{A(x)}}=dr, \tag{49}$$

and also, the scalar potential and components of the gauge potential become

$$\begin{aligned} A_r(m)&=\frac{-i}{2r},\\ A_\theta(m)&=k+\frac{r}{2}\left[\frac{\dfrac{A(x)W'(x)}{W(x)}+\dfrac{2m-1}{2}A'(x)}{\sqrt{A(x)}}\right]_{x=x(r)}. \end{aligned} \tag{50}$$

The end points of the interval (a,b) for variable x must be chosen such that the interval of radial coordinate r can be restricted to $0\leqslant r<+\infty$. In order to define the radial coordinate as in Eq. (49), we must clearly choose the master function $A(x)$ positive in the interval (a,b). The 2-form magnetic field, in this approach, is quantized by the secondary quantum number m as

$$\begin{aligned} B_m(r)=\frac{1}{2}\Bigg[&\frac{1}{\sqrt{A(x)}}\frac{A(x)W'(x)}{W(x)}+\frac{2m-1}{2}\frac{A'(x)}{\sqrt{A(x)}}+\left(\left(\frac{A(x)W'(x)}{W(x)}\right)'+\frac{2m-1}{2}A''(x)\right)r\\ &-\frac{1}{4}\left(2\frac{A'(x)W'(x)}{W(x)}+(2m-1)\frac{A'^2(x)}{A(x)}\right)r\Bigg]_{x=x(r)} dr\wedge d\theta, \end{aligned} \tag{51}$$

where, we have used relation (49) to express the relations (50) and (51). The second bunch spinors describing the states of a spin-$\frac{1}{2}$ charged particle in the presence of the magnetic field (51), labeled by two quantum numbers n and m, are

$$\Psi_{n,m}(t;r,\theta)=e^{-iE_{n,m}t}\begin{pmatrix}\psi_{n,m}(r,\theta)\\ i\psi_{n,m-1}(r,\theta)\end{pmatrix}=e^{-iE_{n,m}t}\Psi_{n,m}(r,\theta), \tag{52}$$

in which we have used the following notation using the change of variable (49):

$$\psi_{n,m}(r,\theta)=e^{ik\theta}\psi_{n,m}(x(r))=e^{ik\theta}\psi_{n,m}(r). \tag{53}$$

In the second approach, while admitting the gauge potentials and the spinors as in Eqs. (50) and (52), respectively, the following equations:

$$\begin{aligned} b(m)\psi_{n,m-1}(r,\theta)&=E_{n,m}\psi_{n,m}(r,\theta),\\ a(m)\psi_{n,m}(r,\theta)&=E_{n,m}\psi_{n,m-1}(r,\theta), \end{aligned} \tag{54}$$

with

$$b(m)=\frac{\partial}{\partial r}-\frac{i}{r}\frac{\partial}{\partial_\theta}-\frac{1}{r}A_\theta(m),$$
$$a(m)=-\frac{\partial}{\partial r}-\frac{i}{r}\frac{\partial}{\partial_\theta}-\frac{1}{r}A_\theta(m), \tag{55}$$

express the matrix components of the Dirac equation (27). In this case, Eqs. (54) describe shape invariance symmetry on the flat surface (r,θ), such that the shape invariance parameter is the secondary quantum number m. Possible different choices for the master function $A(x)$, some of the solvable Dirac equations on the flat surface in the presence of corresponding magnetic fields (quantized by m) with the spinors that are described in terms of associated special functions are included in Appendix B, where we have not added the explicit form of the raising and the lowering operators $b(m)$ and $a(m)$ for the sake of brevity.

Now we show the second bunch of the spinors, i.e. (52), representing a supersymmetry algebra and a shape invariance symmetry. Using Eqs. (54) and omitting time-dependence, we can rewrite the Dirac equation (27) as

$$D_2(m)\Psi_{n,m}(r,\theta)=E_{n,m}\Psi_{n,m}(r,\theta), \tag{56}$$

with time-independent Dirac operator $D_2(m)$ as

$$D_2(m):=\begin{pmatrix}0 & -ib(m)\\ ia(m) & 0\end{pmatrix}. \tag{57}$$

The square of the Dirac operator $D_2(m)$ leads to the Schrödinger Hamiltonians on the flat surface with a shape invariant parameter of secondary quantum number m,

$$D_2^2(m)=\begin{pmatrix}b(m)a(m) & 0\\ 0 & a(m)b(m)\end{pmatrix}=:H(m). \tag{58}$$

Choosing the chiral fermionic creation and annihilation operators as

$$Q_+(m)=Q_+b(m), \tag{59a}$$
$$Q_-(m)=Q_-a(m), \tag{59b}$$

one evidently gets for the nilpotent operators $Q_\pm(m)$ of order two and the bosonic operator $H(m)$ the supersymmetry algebra (43) but with m instead of n. The spinors $\Psi_{n,m}(r,\theta)$ on the flat surface represent supersymmetry algebra as

$$Q_+(m)\Psi_{n,m}(r,\theta)=E_{n,m}\begin{pmatrix}\psi_{n,m}(r,\theta)\\ 0\end{pmatrix},$$
$$Q_-(m)\Psi_{n,m}(r,\theta)=E_{n,m}\begin{pmatrix}0\\ i\psi_{n,m-1}(r,\theta)\end{pmatrix}, \tag{60}$$
$$H(m)\Psi_{n,m}(r,\theta)=E(n,m)\Psi_{n,m}(r,\theta).$$

The matrix and differential operators for describing the shape invariance symmetry by the second bunch of spinors, i.e., $\Psi_{n,m}(r,\theta)$ on the flat surface are

$$\mathcal{B}(m):=\begin{pmatrix}b(m) & 0\\ 0 & \dfrac{E_{n,m}}{E_{n,m-1}}b(m-1)\end{pmatrix}, \tag{61a}$$

$$\mathcal{A}(m) := \begin{pmatrix} a(m) & 0 \\ 0 & \dfrac{E_{n,m}}{E_{n,m-1}} a(m-1) \end{pmatrix}. \tag{61b}$$

The raising and the lowering relations and the shape invariant equations of the spinors $\Psi_{n,m}(r,\theta)$ are obtained as

$$\begin{aligned} \mathcal{B}(m)\Psi_{n,m-1}(r,\theta) &= E_{n,m}\Psi_{n,m}(r,\theta), \\ \mathcal{A}(m)\Psi_{n,m}(r,\theta) &= E_{n,m}\Psi_{n,m-1}(r,\theta), \end{aligned} \tag{62}$$

$$\begin{aligned} \mathcal{B}(m)\mathcal{A}(m)\Psi_{n,m}(r,\theta) &= E(n,m)\Psi_{n,m}(r,\theta), \\ \mathcal{A}(m)\mathcal{B}(m)\Psi_{n,m-1}(r,\theta) &= E(n,m)\Psi_{n,m-1}(r,\theta). \end{aligned} \tag{63}$$

Once again we see that in the properties of supersymmetry algebra and the shape invariance described by the spinors $\Psi_{n,m}(r,\theta)$, the angular functionality of the spinors do not have any important role.

III. SOLUTION OF THE DIRAC EQUATION IN 1+3 SPACE–TIME WITH THE EUCLIDEAN SPATIAL PART

The metric that describes 1+3 space–time with the flat spatial part is

$$g_{\mu\nu} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & -r^2 & 0 \\ 0 & 0 & 0 & -r^2 \sin^2\theta \end{pmatrix}, \tag{64}$$

here, μ and ν take symbols t, r, θ and ϕ with intervals $0 \leqslant r < +\infty$, $0 \leqslant \theta \leqslant \pi$ and $0 \leqslant \phi < 2\pi$. The variables r, θ and ϕ are the usual global spherical coordinates. We also emphasize that in this section the spherical radial coordinate r is different from the polar coordinate r in the previous section. The nonvanishing components of the Christoffel symbols $\Gamma^{\lambda}_{\mu\nu}$ corresponding to the space–time metric (64) are

$$\Gamma^{r}_{\theta\theta} = -r, \quad \Gamma^{\theta}_{r\theta} = \Gamma^{\phi}_{r\phi} = \frac{1}{r}, \quad \Gamma^{r}_{\phi\phi} = -r\sin^2\theta, \quad \Gamma^{\phi}_{\theta\phi} = \cot\theta, \quad \Gamma^{\theta}_{\phi\phi} = -\frac{1}{2}\sin 2\theta. \tag{65}$$

Also, the generators γ^a of the Clifford algebra,

$$\{\gamma^a, \gamma^b\} = 2I_{4\times 4}\eta^{ab}, \tag{66}$$

are chosen as

$$\gamma^0 = \begin{pmatrix} I_{2\times 2} & 0 \\ 0 & -I_{2\times 2} \end{pmatrix}, \quad \gamma^1 = i\begin{pmatrix} 0 & \sigma^2 \\ \sigma^2 & 0 \end{pmatrix}, \quad \gamma^2 = -i\begin{pmatrix} 0 & \sigma^1 \\ \sigma^1 & 0 \end{pmatrix}, \quad \gamma^3 = -i\begin{pmatrix} 0 & \sigma^3 \\ \sigma^3 & 0 \end{pmatrix}, \tag{67}$$

where η^{ab} are components of the 1+3 diagonal Minkowskian space–time metric, i.e., $\eta^{ab} = (1, -1, -1, -1)$. The 4-beins for the Minkowskian space–time metric (64) are calculated as

$$E_a{}^{\mu}=(e_{\mu}{}^{a})^{-1}=\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & \frac{1}{r} & 0 \\ 0 & 0 & 0 & \frac{1}{r\sin\theta} \end{pmatrix}. \tag{68}$$

Using Eqs. (25), (65) and (68) we derive the nonvanishing components of the spin connection $\omega_{\theta ab}$ as

$$\omega_{\theta\ 12}=-\omega_{\theta\ 21}=1, \quad \omega_{\phi\ 13}=-\omega_{\phi\ 31}=\sin\theta, \quad \omega_{\phi\ 23}=-\omega_{\phi\ 32}=\cos\theta. \tag{69}$$

Now, we use the Dirac operator introduced in Eq. (22) in the following equation:

$$D\Psi(t;r,\theta,\phi)=0, \tag{70}$$

for the 1+3 space–time. Substituting the results obtained in Eqs. (67)–(69), for the Dirac equation (70) we obtain the following explicit form:

$$\begin{pmatrix} I_{2\times2}(\partial_t-iA_t) & i\sigma^2\left(\partial_r-iA_r+\frac{1}{r}\right)-\frac{i}{r}\sigma^1(\partial_\theta-iA_\theta \\ & +\frac{1}{2}\cot\theta)-\frac{i}{r\sin\theta}\sigma^3(\partial_\phi-iA_\phi) \\ i\sigma^2\left(\partial_r-iA_r+\frac{1}{r}\right)-\frac{i}{r}\sigma^1(\partial_\theta-iA_\theta & \\ +\frac{1}{2}\cot\theta)-\frac{i}{r\sin\theta}\sigma^3(\partial_\phi-iA_\phi) & -I_{2\times2}(\partial_t-iA_t) \end{pmatrix}\Psi(t;r,\theta,\phi)=0. \tag{71}$$

There exist two approaches for solving the Dirac matrix equation (71) by using shape invariance symmetry with respect to the main and secondary quantum numbers n and m, respectively, as of the previous section. For this purpose, we take the scalar potential equal to zero, i.e. $A_t=0$, and also, we assume that 2-form of the static magnetic field has the spherical radial symmetry.

A. The first approach for solving the Dirac equation in 3D Euclidean space

In the first approach due to the shape invariance symmetry with respect to the main quantum number n, we introduce the spinors $\Psi(t;r,\theta,\phi)$ as

$$\Psi(t;r,\theta,\phi)=e^{-iE_nt}\Psi(r,\theta,\phi)=e^{-iE_nt}\begin{pmatrix} \psi_1(r,\theta,\phi) \\ \psi_2(r,\theta,\phi) \\ i\psi_1(r,\theta,\phi) \\ i\psi_2(r,\theta,\phi) \end{pmatrix}. \tag{72}$$

If we choose the functionality of the spinors from the angular variables θ and ϕ as phase factors in the following form:

$$\psi_a(r,\theta,\phi)=e^{ik_\theta\theta+ik_\phi\phi}\psi_a(r), \quad a=1,2; \tag{73}$$

then, by choosing $A_\phi=k_\phi$ in the Dirac equation (71), one can obtain the following equations:

$$\left(\frac{\partial}{\partial r}-\frac{i}{r}\frac{\partial}{\partial\theta}-\frac{i}{r\sin\theta}\frac{\partial}{\partial\phi}-iA_r-\frac{A_\theta-1}{r}-\frac{A_\phi}{r\sin\theta}-\frac{i}{2r}\cot\theta\right)\psi_2(r,\theta,\phi)=E_n\psi_1(r,\theta,\phi),$$
$$\left(-\frac{\partial}{\partial r}-\frac{i}{r}\frac{\partial}{\partial\theta}-\frac{i}{r\sin\theta}\frac{\partial}{\partial\phi}+iA_r-\frac{A_\theta+1}{r}-\frac{A_\phi}{r\sin\theta}-\frac{i}{2r}\cot\theta\right)\psi_1(r,\theta,\phi)=E_n\psi_2(r,\theta,\phi). \tag{74}$$

Reducing the equations (74) with respect to the variables θ and ϕ and by changing the variable as given in (31), we can compare the derived results with Eqs. (9), to get the spinors (72) as

$$\Psi_n(t;r,\theta,\phi)=e^{-iE_nt}\begin{pmatrix}\psi_n(r,\theta,\phi)\\ \psi_{n-1}(r,\theta,\phi)\\ i\psi_n(r,\theta,\phi)\\ i\psi_{n-1}(r,\theta,\phi)\end{pmatrix}=e^{-iE_nt}\Psi_n(r,\theta,\phi), \tag{75}$$

with the following convention:

$$\psi_n(r,\theta,\phi)=e^{ik_\theta\theta+ik_\phi\phi}\psi_n(x(r))$$
$$=:e^{ik_\theta\theta+ik_\phi\phi}\psi_n(r). \tag{76}$$

Also, from the latter comparison we lead to the following values for the components of the gauge potential:

$$A_r(n)=-\frac{i}{r},$$

$$A_\theta(n)=k_\theta-\frac{i}{2}\cot\theta-\frac{r}{2}$$
$$\times\left[nA'(x)+\frac{A(x)W'(x)}{W(x)}+n\frac{A'(0)\left(\frac{A(x)W'(x)}{W(x)}\right)'-A''(x)\left(\frac{AW'}{W}\right)(0)}{\left(\frac{A(x)W'(x)}{W(x)}\right)'+nA''(x)}\right]_{x=x(r)},$$

$$A_\phi(n)=k_\phi, \tag{77}$$

where $x=x(r)$ is the solution of Eq. (31). It is obvious that the 2-form of the magnetic field is calculated as Eq. (34). Thus the operators that describe shape invariance symmetry on components of the spinors are

$$b(n)=\frac{\partial}{\partial r}-\frac{i}{r}\frac{\partial}{\partial\theta}-\frac{i}{r\sin\theta}\frac{\partial}{\partial\phi}-iA_r(n)-\frac{A_\theta(n)-1}{r}-\frac{A_\phi(n)}{r\sin\theta}-\frac{i}{2r}\cot\theta,$$
$$a(n)=-\frac{\partial}{\partial r}-\frac{i}{r}\frac{\partial}{\partial\theta}-\frac{i}{r\sin\theta}\frac{\partial}{\partial\phi}+iA_r(n)-\frac{A_\theta(n)+1}{r}-\frac{A_\phi(n)}{r\sin\theta}-\frac{i}{2r}\cot\theta, \tag{78}$$

with the relations of raising and lowering of the spinors components $\psi_n(r,\theta,\phi)$ as

$$b(n)\psi_{n-1}(r,\theta,\phi)=E_n\psi_n(r,\theta,\phi),$$
$$a(n)\psi_n(r,\theta,\phi)=E_n\psi_{n-1}(r,\theta,\phi). \tag{79}$$

The information given in Appendix A includes the solutions of this subsection, too. It must be noted that the raising and the lowering operators $b(n)$ and $a(n)$ act in 3D Euclidean space with coordinates (r,θ,ϕ), and the functionality of the spinors to angles of θ and ϕ have no role in expressing shape invariance symmetry.

The spinors obtained in this subsection represent the supersymmetry algebra and the shape invariance symmetry with respect to the main quantum number n. From the results of the Dirac equation as Eqs. (78) we can define time-independent Dirac operator $D_3(n)$ in the following form:

$$D_3(n) := \begin{pmatrix} 0 & Q_+ b(n) - Q_- a(n) \\ Q_- a(n) - Q_+ b(n) & 0 \end{pmatrix}, \tag{80}$$

where it has the following eigenvalue equation:

$$D_3(n)\Psi_n(r,\theta,\phi) = E_n \Psi_n(r,\theta,\phi). \tag{81}$$

Now, one can check that the chiral fermionic creation and annihilation operators defined as

$$\begin{aligned} Q_+(n) &:= \begin{pmatrix} 0 & Q_+ b(n) - Q_- a(n) \\ 0 & 0 \end{pmatrix}, \\ Q_-(n) &:= \begin{pmatrix} 0 & 0 \\ Q_- a(n) - Q_+ b(n) & 0 \end{pmatrix}, \end{aligned} \tag{82}$$

together with the square of the time-independent Dirac operator, i.e. bosonic operator $H(n) = D_3^2(n)$, satisfy the supersymmetry algebra (43). The supersymmetry algebra (43) is represented by the chiral fermionic creation and annihilation operators, together with the square of the time-independent Dirac operator in 3D Euclidean space as

$$\begin{aligned} Q_+(n)\Psi_n(r,\theta,\phi) &= E_n \begin{pmatrix} \psi_n(r,\theta,\phi) \\ \psi_{n-1}(r,\theta,\phi) \\ 0 \\ 0 \end{pmatrix}, \\ Q_-(n)\Psi_n(r,\theta,\phi) &= E_n \begin{pmatrix} 0 \\ 0 \\ i\psi_{n-1}(r,\theta,\phi) \\ i\psi_{n-1}(r,\theta,\phi) \end{pmatrix}, \\ H(n)\Psi_n(r,\theta,\phi) &= E(n)\Psi_n(r,\theta,\phi). \end{aligned} \tag{83}$$

The spinors themselves $\Psi_n(r,\theta,\phi)$ in 3D Euclidean space represent a shape invariance symmetry as

$$\begin{aligned} \mathcal{B}(n)\Psi_{n-1}(r,\theta,\phi) &= E_n \Psi_n(r,\theta,\phi), \\ \mathcal{A}(n)\Psi_n(r,\theta,\phi) &= E_n \Psi_{n-1}(r,\theta,\phi), \end{aligned} \tag{84}$$

or

$$\begin{aligned} \mathcal{B}(n)\mathcal{A}(n)\Psi_n(r,\theta,\phi) &= E(n)\Psi_n(r,\theta,\phi), \\ \mathcal{A}(n)\mathcal{B}(n)\Psi_{n-1}(r,\theta,\phi) &= E(n)\Psi_{n-1}(r,\theta,\phi), \end{aligned} \tag{85}$$

in which the operators $\mathcal{B}(n)$ and $\mathcal{A}(n)$ are the raising and the lowering operators, respectively:

$$\mathcal{B}(n) := \frac{1}{2}\left((I_{2\times 2}+\sigma^3)b(n) + \frac{E_n}{E_{n-1}}(I_{2\times 2}-\sigma^3)b(n-1)\right)\otimes I_{2\times 2},$$
$$\mathcal{A}(n) := \frac{1}{2}\left((I_{2\times 2}+\sigma^3)a(n) + \frac{E_n}{E_{n-1}}(I_{2\times 2}-\sigma^3)a(n-1)\right)\otimes I_{2\times 2}. \tag{86}$$

B. The second approach for solving the Dirac equation in 3D Euclidean space

The second approach is obtained by using the shape invariance symmetry with respect to the secondary quantum number m, again. For this purpose one can take the spinors $\Psi(t;r,\theta,\phi)$ as in Eqs. (72), but with $E_{n,m}$ instead of E_n. Choosing the time-independent components of spinors as Eqs. (73), the Dirac equation (71) is transformed to two equations given in (74), but with $E_{n,m}$ instead of E_n. Thus, by comparing the derived results with those of Eqs. (15), the solution of the Dirac equation (70) is obtained as the following spinors:

$$\Psi_{n,m}(t;r,\theta,\phi) = e^{-iE_{n,m}t}\begin{pmatrix} \psi_{n,m}(r,\theta,\phi) \\ \psi_{n,m-1}(r,\theta,\phi) \\ i\psi_{n,m}(r,\theta,\phi) \\ i\psi_{n,m-1}(r,\theta,\phi)\end{pmatrix} = e^{-iE_{n,m}t}\Psi_{n,m}(r,\theta,\phi), \tag{87}$$

in which the components $\psi_{n,m}(r,\theta,\phi)$ are

$$\psi_{n,m}(r,\theta,\phi) = e^{ik_\theta\theta+ik_\phi\phi}\psi_{n,m}(x(r)) =: e^{ik_\theta\theta+ik_\phi\phi}\psi_{n,m}(r). \tag{88}$$

Here, $x=x(r)$ is the solution of differential equation related to the change of variable (49). Also, in this approach, the components of the gauge potential are

$$A_r(m) = -\frac{i}{r},$$
$$A_\theta(m) = k_\theta - \frac{i}{2}\cot\theta + \frac{r}{2}\left[\frac{\frac{A(x)W'(x)}{W(x)} + \frac{2m-1}{2}A'(x)}{\sqrt{A(x)}}\right]_{x=x(r)}, \tag{89}$$
$$A_\phi(m) = k_\phi.$$

One can conclude the 2-form of the magnetic field as Eq. (51). Consequently, information obtained in Appendix B describes solvability of the Dirac equation in the 3D Euclidean space due to the shape invariance symmetry with respect to the secondary quantum number m.

It is easy to show that with definitions of the time-independent Dirac operator $D_3(m)$, the fermionic creation $Q_+(m)$, and the annihilation $Q_-(m)$ operators as

$$D_3(m) := \begin{pmatrix} 0 & Q_+b(m)-Q_-a(m) \\ Q_-a(m)-Q_+b(m) & 0\end{pmatrix}, \tag{90}$$

$$Q_+(m) := \begin{pmatrix} 0 & Q_+b(m)-Q_-a(m) \\ 0 & 0\end{pmatrix},$$
$$Q_-(m) := \begin{pmatrix} 0 & 0 \\ Q_-a(m)-Q_+b(m) & 0\end{pmatrix}, \tag{91}$$

the bosonic operator $H(m) \coloneqq D_3^2(m)$ and the fermionic operators $Q_{\pm}(m)$ satisfy the supersymmetry algebra (43). One can consider that the spinors $\Psi_{n,m}(r,\theta,\phi)$ represent shape invariance symmetry by the raising and the lowering operators $\mathcal{B}(m)$ and $\mathcal{A}(m)$ as

$$\begin{aligned}\mathcal{B}(m) &\coloneqq \frac{1}{2}\left((I_{2\times 2}+\sigma^3)b(m)+\frac{E_{n,m}}{E_{n,m-1}}(I_{2\times 2}-\sigma^3)b(m-1)\right)\otimes I_{2\times 2},\\ \mathcal{A}(m) &\coloneqq \frac{1}{2}\left((I_{2\times 2}+\sigma^3)a(m)+\frac{E_{n,m}}{E_{n,m-1}}(I_{2\times 2}-\sigma^3)a(m-1)\right)\otimes I_{2\times 2}.\end{aligned} \tag{92}$$

IV. CONCLUSION

Using the master function $A(x)$ we have obtained two bunches of solutions for the Dirac equation of a spin-$\frac{1}{2}$ charged particle in 2D and 3D Euclidean spaces in the presence of the magnetic fields (34) and (51), where they are quantized by the main quantum number n and the secondary quantum number m, respectively. The first bunch spinors, i.e. $\Psi_n(r,\theta)$ and $\Psi_n(r,\theta,\phi)$, are expressed in terms of orthogonal polynomials $\Phi_n(x(r))$ via the change of variable (31) and the second bunch spinors, i.e. $\Psi_{n,m}(r,\theta)$ and $\Psi_{n,m}(r,\theta,\phi)$, are expressed in terms of the associated special functions $\Phi_{n,m}(x(r))$ via the change of variable (49). Both of these spinors represent supersymmetry algebra and shape invariance symmetry.

ACKNOWLEDGMENTS

We wish to thank Dr. S. K. A. Seyed Yagoobi for carefully reading the article and for his constructive comments.

APPENDIX B: SHAPE INVARIANCE APPROACH OF THE SECONDARY QUANTUM NUMBER *m* TO THE SOLUTION OF DIRAC EQUATION IN 2D AND 3D EUCLIDEAN SPACES

Noncommutative Bloch theory

Michael J. Gruber[a)]
MSRI, 1000 Centennial Drive, Berkeley, California 94720-5070

(Received 27 October 2000; accepted for publication 5 March 2001)

For differential operators which are invariant under the action of an Abelian group Bloch theory is the preferred tool to analyze spectral properties. By shedding some new noncommutative light on this we motivate the introduction of a noncommutative Bloch theory for elliptic operators on Hilbert C*-modules. It relates properties of C*-algebras to spectral properties of module operators such as band structure, weak genericity of cantor spectra, and absence of discrete spectrum. It applies, e.g., to differential operators invariant under a projective group action, such as Schrödinger, Dirac, and Pauli operators with periodic magnetic field, as well as to discrete models, such as the almost Matthieu equation and the quantum pendulum.
 [DOI: 10.1063/1.1369122]

I. INTRODUCTION

Bloch (or Floquet) theory in its usual form has a long history already. Basically it starts from the fact that partial differential equations with constant coefficients are mapped into algebraic equations by means of the Fourier or Laplace transform. Now, if the coefficients are not constant but just periodic under an Abelian (locally compact topological) group one still has the Fourier transform on such groups, mapping functions on the group Γ into functions on the dual group $\hat{\Gamma}$; the original spectral problem on a noncompact manifold is mapped into a (continuous) sum of spectral problems on a compact manifold (see Sec. II).

This is what makes Bloch theory an indispensable tool especially for solid state physics, where one describes the motion of noninteracting electrons in a periodic solid crystal by a Schrödinger operator $-\Delta+V$ on $L^2(\mathbb{R}^d)$. The potential function V is the gross electric potential generated by all the crystal ions and thus is periodic under the lattice given by the crystal symmetry. Bloch theory shows that the spectrum of the periodic Schrödinger operator has band structure in the following sense:

Definition 1 (band structure): A subset of the real line has band structure if it is a locally finite union of closed intervals.

Band structure is an essential ingredient of electronic transport in metals and semi-conductors. By exploiting Bloch theory and the structure of the Schrödinger operator further one can see that the spectrum is purely absolutely continuous, which is sometimes included in the definition of band structure.

Measurements of crystals often require magnetic fields b (2-form). In quantum mechanics, they are described by a vector potential (1-form) a such that $b=da$ ($B=\operatorname{curl} A$ for the corresponding vector fields). The magnetic Schrödinger operator then reads

$$H=-(\nabla-ia)^2+V.$$

But, although b is periodic or even constant, a need not be so, and H will not be periodic. It is therefore necessary to use magnetic translations under which H still is invariant.[1] But now, these translations do not commute with each other in general. Therefore ordinary (commutative) Bloch theory does not apply.

[a)]Electronic mail: mjg@msri.org

Basically, the reason for this failure is that a non-Abelian group has no ''good'' group dual: the set of (equivalence classes of) irreducible representations has no natural group structure whereas the set of one-dimensional representations is too small to describe the group—otherwise it would be Abelian.

But although $\hat{\Gamma}$ does not exist anymore, the algebra $C(\hat{\Gamma})$ of continuous functions continues to exist in some sense: It is given by the reduced group C^*-algebra of Γ which is just the C^*-algebra generated by Γ in its regular representation on itself [on $l^2(\Gamma)$].

Section III shows how one can reformulate ordinary Bloch theory in a way which refrains from using the points of $\hat{\Gamma}$ and relies just on the role of $C(\hat{\Gamma})$. From a technical point of view this requires switching from measurable fields of Hilbert spaces to continuous fields which then can be described as Hilbert C^*-modules over the commutative C^*-algebra $C(\hat{\Gamma})$.

Having done this one can retain the setup but omit the condition of commutativity for the C^*-algebra $C(\hat{\Gamma})$. Thus one is lead to noncommutative Bloch theory (Sec. IV) dealing with elliptic operators on Hilbert C^*-modules over noncommutative C^*-algebras. The basic task is now to relate properties of the C^*-algebra to spectral properties of ''periodic'' operators. Thus one generalizes spectral results for elliptic operators on compact manifolds as well as results of ordinary Bloch theory:

Theorem 1: *Isolated eigenvalues of $\mathcal{A}$-elliptic operators have $\mathcal{A}$-finite eigenprojections, their eigenspaces have finite τ-dimension.*

Under certain assumptions they have essential spectrum only (isolated eigenvalues have infinite multiplicity).

See Theorem 6 for exact assumptions (they are fulfilled by Schrödinger operators with periodic magnetic field).

Noncommutative Bloch theory allows to treat continuous and discrete models, i.e., differential and difference operators, on equal footing. It opens the way to apply a result of Choi and Elliott[2] on weak genericity of Cantor spectra in discrete models to the continuous models also, i.e., to the phenomenon opposite to the band structure:

Definition 2 (Cantor set): A Cantor set is a subset of a topological space which is nowhere dense (the closure has empty interior) and has no isolated points.

Now the C^*-algebras of symmetries determines which of the two opposite spectral types is present:

Definition 3 (Kadison property): The Kadison constant K of a C^*-algebra $\mathcal{A}$ together with a trace τ is defined by

$$K = \inf\{\tau(P) \,|\, 0 \neq P \in \mathcal{A} \text{ projection}\}. \tag{1}$$

We say the pair $(\mathcal{A}, \tau)$ has the Kadison property if $K > 0$.

Theorem 2 (band structure): *If $(\mathcal{A}, \tau)$ has the Kadison property, then the spectrum of every symmetric $\mathcal{A}$-elliptic operator has a band structure.*

(See Theorem 7.) This applies, e.g., to magnetic Schrödinger operators in the case of rational magnetic flux.

Opposite to the Kadison property is the property RRI_0 (see Definition 4), and it is a criterion for the opposite spectral type:

Theorem 3 (Cantor spectrum): *If $(\mathcal{A}, \tau)$ has the property RRI_0, then every $\mathcal{A}$-elliptic operator can be approximated arbitrarily well (in norm resolvent sense) by one which has Cantor spectrum.*

(See Theorem 8.) The important issue here is that the approximation takes place within a natural C^*-algebra generated by symmetries connected to the operator. Approximation within a von Neumann algebra would be pointless, of course. This theorem applies, e.g., to magnetic Schrödinger operators on $\mathbb{R}^2$ in the case of irrational flux.

In Sec. V we list examples where noncommutative Bloch theory applies: gauge-periodic

elliptic differential operators (Schrödinger, Pauli, Dirac with periodic magnetic field) and difference operators (almost Matthieu, quantum pendulum).

For the convenience of the reader we add an appendix on continuous fields of Hilbert spaces and on Hilbert C^*-modules and their GNS representation.

A short overview of this paper appeared in Ref. 3.

II. COMMUTATIVE BLOCH THEORY

In this section we recall the basic elements of Bloch theory for periodic operators in the geometric context of vector bundles, since even in the scalar case of a magnetic Schrödinger operator one is lead to consider possibly nontrivial complex line bundles.[4] The standard reference for the theory of direct integrals is Ref. 5, Chap. II; for the Bloch theory in Euclidean space see Ref. 6, Chap. XIII.16.

Our general assumptions are: X is an oriented smooth Riemannian manifold without boundary, Γ a discrete abelian group acting on X freely, isometrically, and properly discontinuously. Furthermore, we assume the action to be cocompact in the sense that the quotient $M:=X/\Gamma$ is compact.

Next, let E be a smooth Hermitian vector bundle over X.

Example 1 (solid crystals): The main motivating example for our setting comes from solid state physics. Here, $X=\mathbb{R}^n$ is the configuration space of a single electron $(n=2,3)$. It is supposed to move in a crystal whose translational symmetries are described by a lattice $\mathbb{Z}^n\simeq\Gamma\subset\mathbb{R}^n$, which acts on X by translations, of course. Note that this does not take into account the point symmetries. Γ could be extended by them but the action would not be free any more. Considering just the translations is enough to achieve the compactness of the quotient $M\simeq T^n$.

Wave functions of electrons are just complex-valued functions on $\mathbb{R}^n$, so we can set $E=\mathbb{R}^n\times\mathbb{C}$. One may also include the spin of the electrons into the picture by choosing the appropriate trivial spinor bundle $E=\mathbb{R}^n\times\mathbb{C}^k$.

Definition 4 (periodic operator): Assume there is an isometric lift γ_* of the action of γ from X to E in the following sense:

$$\gamma_*:E_x\to E_{\gamma x} \quad \text{for} \quad x\in X,\gamma\in\Gamma. \tag{2}$$

This defines an action T_γ on the sections: For $s\in C_c^\infty(E)$ we define

$$(T_\gamma s)(x):=\gamma_* s(\gamma^{-1}x) \quad \text{for} \quad x\in X,\gamma\in\Gamma. \tag{3}$$

$(T_\gamma)_{\gamma\in\Gamma}$ induces a unitary representation of Γ in $L^2(E)$ since γ_* acts isometrically and $T_\gamma^*=(T_\gamma)^{-1}$.

A differential operator D on $\mathcal{D}(D):=C_c^\infty(E)$ is called periodic if, on $\mathcal{D}(D)$, we have

$$\forall\,\gamma\in\Gamma:[T_\gamma,D]=0. \tag{4}$$

Example 2 (periodic Schrödinger operator): Given a manifold as described above, we may lift the action to any trivial vector bundle $E:=X\times\mathbb{C}^k$ canonically. If D is a periodic operator on X (for example any geometric operator, i.e., defined by the metric on X) and $V\in C^\infty(X,M(k,\mathbb{C}))$ a periodic field of endomorphisms, then $D+V$ is a periodic operator on E.

In the case of a crystal, we choose the Laplacian (which describes the kinetic energy quantum mechanically) and a periodic potential $V\in C^\infty(\mathbb{R}^n,\mathbb{R})$ (which describes the electric field of the ions at the lattice sites) to get the periodic Schrödinger operator $\Delta+V$.

Example 3 (Schrödinger operator with exact periodic magnetic field): Let $b\in\Omega^2(X)$ be a magnetic field 2-form. In dimension 3 this corresponds (by the Hodge star) to a vector field B, in dimension 2 to a scalar function which may be thought of as the length and orientation of a normal vector B. From physical reasons one has $\operatorname{div}B=0$, *i.e., $db=0$. For simplicity we assume that b is not only closed but exact, so there is $a\in\Omega^1(X)$ with $b=da$ ($B=\operatorname{curl}A$ for the corresponding vector fields). This defines a magnetic Hamiltonian operator*

$$\Delta^a := (d-\imath a)^*(d-\imath a) \tag{5}$$

(the minimally coupled Hamiltonian), where d is the ordinary differential (corresponding to the gradient) and $*$ the adjoint of an operator between the Hilbert spaces of L^2-functions $L^2(X)$ and of L^2-1-forms $L^2(X,\Lambda T^*X)$.

For later convenience we set, for $\gamma\in\Gamma$ and $\omega\in\Omega(X)$, $\gamma^*\omega := (\gamma^{-1})^*\omega$, considering γ^{-1} as a map $X\to X$ and using the usual pullback of forms. This puts the action on forms in a notation compatible with the action in sections (3) from the preceding definition.

Now, if b is periodic, a does not need to be so: If $b\in\Omega^2(\mathbb{R}^n)$ is constant then a is affine linear. So the translations are no symmetries for the magnetic Hamiltonian. Reference 1 was the first to define the so-called magnetic translations: Since $d(a-\gamma^*a)=da-\gamma^*da=b-\gamma^*b=0$, one can [at least if $H^1(X)=0$] find a function χ_γ with $d\chi_\gamma=a-\gamma^*a$. One may define such a function explicitly by

$$\chi_\gamma(x) := \int_{x_0}^{x}(a-\gamma^*a)$$

which is well-defined if $H_1(X)=0$. If we now define a gauge function $s_\gamma := e^{\imath\chi_\gamma}$ then

$$\begin{aligned}(d-\imath a)(s_\gamma\gamma^*f) &= s_\gamma\gamma^*df+\imath(a-\gamma^*a)s_\gamma\gamma^*f-\imath a s_\gamma\gamma^*f\\ &= s_\gamma\gamma^*df-\imath\gamma^*a\gamma^*f\\ &= s_\gamma\gamma^*df-\imath s_\gamma\gamma^*(af)\\ &= s_\gamma\gamma^*((d-\imath a)f).\end{aligned}$$

So we have found symmetries of the magnetic Hamiltonian operator, the gauged translations

$$T_\gamma : C^\infty(X)\to C^\infty(X),\quad (T_\gamma s)(x)=s_\gamma(x)(\gamma^*s)(x)$$

coming from the lifted action,

$$\gamma_* : X\times\mathbb{C}\to X\times\mathbb{C},\quad \gamma_*(x,c)=(\gamma x, s_\gamma(x)c).$$

The commutation relation for the magnetic translations is

$$\begin{aligned}(T_{\gamma_1}T_{\gamma_2}s)(x) &= s_{\gamma_1}(x)s_{\gamma_2}(\gamma_1^{-1}x)s(\gamma_2^{-1}\gamma_1^{-1}x)\\ &= \exp\left(\imath\left(\int_{x_0}^{x}a-\gamma_1^*a+\int_{x_0}^{\gamma_1^{-1}x}a-\gamma_2^*a\right)\right)s(\gamma_2^{-1}\gamma_1^{-1}x)\\ &= \exp\left(\imath\left(\int_{x_0}^{x}a-\gamma_1^*a+\int_{\gamma_1x_0}^{x}\gamma_1^*a-(\gamma_1\gamma_2)^*a\right)\right)s(\gamma_2^{-1}\gamma_1^{-1}x)\\ &= \exp\left(\imath\left(\int_{x_0}^{\gamma_1x_0}(\gamma_1\gamma_2)^*a-\gamma_1^*a+\int_{x_0}^{x}a-(\gamma_1\gamma_2)^*a\right)\right)s(\gamma_2^{-1}\gamma_1^{-1}x)\\ &= \exp\left(\imath\left(\int_{x_0}^{\gamma_1x_0}(\gamma_1\gamma_2)^*a-\gamma_1^*a\right)\right)s_{\gamma_1\gamma_2}(x)s(\gamma_2^{-1}\gamma_1^{-1}x)\\ &= \Theta(\gamma_1,\gamma_2)s_{\gamma_1\gamma_2}(x)s(\gamma_2^{-1}\gamma_1^{-1}x)\\ &= \Theta(\gamma_1,\gamma_2)(T_{\gamma_1\gamma_2}s)(x)\end{aligned} \tag{6}$$

with $\Theta(\gamma_1,\gamma_2)\in S^1$. In general this is just a projective representation of Γ. If a itself is periodic, then $\chi_\gamma=0$ for $\gamma\in\Gamma$, i.e., there is no gauge, and we have just ordinary translations forming a proper representation.

But even if a is not periodic it can happen that the magnetic translations commute with each other. This is called the case of integral flux since the term occurring in the exponential in line (6) is just the magnetic flux through one lattice face. A periodic a obviously gives rise to zero magnetic flux.

Furthermore, if $V\in C^\infty(X,\mathbb{R})$ is Γ-periodic it commutes with the magnetic translations as well, so Δ^a+V is a (symmetric elliptic) periodic operator.

Finally, the very same magnetic translations can be used for the Pauli Hamiltonian and the magnetic Dirac operator.

Remark 1 (integral flux): In the case of the integral flux mentioned above quite the opposite spectral phenomena can occur: Periodic Schrödinger operators have an absolutely continuous band spectrum, whereas the Landau Hamiltonian on $\mathbb{R}^2$ (constant magnetic field, no electric potential) exhibits a pure point spectrum of infinite degeneracy. In Ref. 7 we show that these are indeed the only phenomena that can occur (although possibly combined) in the case of integral flux.

Remark 2 (nonintegral flux): If the magnetic flux is rational one can find a superlattice of Γ, i.e., a subgroup of finite index, such that the flux is integral. The quotient will still be compact, of course, so that the rational case can be completely reduced to the integral.

If the magnetic flux is irrational there is no such superlattice. Still, one may try to make use of the projective representation defined above. There are several approaches, similar in the objects which are used, different in the objectives that are aimed at and accordingly in the results. Our approach will mimic Bloch theory noncommutatively, see Sec. III.

Remark 3 (nonexact magnetic field): If b is closed but not exact one first has to agree upon the quantization procedure used. (5) may be identified as a Bochner Laplacian for a connection with curvature b, and such a connection exists if and only if b defines an integral cohomology class, i.e., $[b]\in H^2(X,\mathbb{Z})$. There may exist different quantizations for the same magnetic field. This is connected to the Bloch decomposition again. For this and the construction of the magnetic translations in this case, see Ref. 8.

Lemma 1 (associated bundle): E is the lift π^*E' of a Hermitian vector bundle E' over M by the projection $\pi:X\to M$. E and X are Γ-principal fiber bundles over E' resp. M.

To every Γ-principal fiber bundle and every character $\chi\in\hat{\Gamma}$ we associate a line bundle. This gives the relations depicted in the following diagram ("$\rightsquigarrow$" denotes association of line bundles.),

$$\begin{array}{ccccccc}
 & \mathbb{C}^N & & \mathbb{C}^N & & \mathbb{C}^N & & \mathbb{C}^N \\
 & \downarrow & & \downarrow & & \downarrow & & \downarrow \\
\Gamma & \hookrightarrow & E & \longrightarrow & E' & \rightsquigarrow & \mathbb{C} \hookrightarrow E_\chi & \longrightarrow & E' \\
 & \downarrow{\scriptstyle \pi^E} & & \downarrow{\scriptstyle \pi^{E'}} & & & \downarrow & & \downarrow \\
\Gamma & \hookrightarrow & X & \xrightarrow{\pi} & M & \rightsquigarrow & \mathbb{C} \hookrightarrow F_\chi & \longrightarrow & M
\end{array}$$

principal fiber bundles and associated line bundles.

In this situation we have $E_\chi\simeq E'\otimes F_\chi$.

For proofs of this and the following, basically well-known material in this section: see e.g., Ref. 8.

Example 4 (magnetic bundles): Consider again the case of the magnetic translations for a periodic magnetic 2-form $b \in \Omega^2(X)$, E being a complex line bundle with curvature b ($b \in H^2(X,\mathbb{Z})$). Hence we have $c_1(E)=[b]$ for the Chern class (up to factors of 2π, depending on the convention). Since b is periodic we may restrict it to a form $b_M \in \Omega^2(M)$ on the quotient. The existence of the lifted action, i.e., the fact that E can be written as a pull-back $E=\pi^*E'$, corresponds to the integrality of b_M from $c_1(E')=[b_M] \in H^2(M,\mathbb{Z})$. Tensoring E' with the flat line bundle F_χ does not change the Chern class (up to torsion). In particular, in dimension 2 the integrality of b_M is equivalent to the integrality of the flux, and E' is trivial only for zero flux.

Next we want to decompose the Hilbert space $L^2(E)$ of square-integrable sections of E into a direct integral over the character space $\hat{\Gamma}$. On $\hat{\Gamma}$ we use the Haar measure. From the theory of representations of locally compact groups we need the following character relations for abelian discrete Γ, i.e., for Abelian, compact $\hat{\Gamma}$ (see Ref. 9, Sec. I E):

Lemma 2 (character relations): For $\gamma \in \Gamma$,

$$\int_{\hat{\Gamma}} \chi(\gamma)\, d\chi = \begin{cases} 1, & \gamma = e, \\ 0, & \gamma \neq e. \end{cases} \tag{7}$$

For $\chi, \chi' \in \hat{\Gamma}$,

$$\sum_{\gamma \in \Gamma} \overline{\chi}(\gamma)\chi'(\gamma) = \delta(\chi - \chi') \tag{8}$$

in the distributional sense, i.e., for $f \in C(\hat{\Gamma})$,

$$\sum_{\gamma \in \Gamma} \int_{\hat{\Gamma}} \overline{\chi}(\gamma)\chi'(\gamma) f(\chi)\, d\chi = f(\chi').$$

We define for every character $\chi \in \hat{\Gamma}$ a mapping $\Phi_\chi : C_c^\infty(E) \ni s \mapsto \tilde{s}_\chi \in C^\infty(E)$ by

$$\tilde{s}_\chi(x) := \sum_{\gamma \in \Gamma} \chi(\gamma)\, \gamma_* s(\gamma^{-1}x). \tag{9}$$

Since

$$\begin{aligned} \tilde{s}_\chi(\gamma' x) &= \sum_{\gamma \in \Gamma} \chi(\gamma)\, \gamma s(\gamma^{-1}\gamma' x) \\ &= \sum_{\gamma \in \Gamma} \chi(\gamma' \gamma'^{-1}\gamma)(\gamma' \gamma'^{-1}\gamma)_* s((\gamma'^{-1}\gamma)^{-1}x) \\ &= \chi(\gamma')\, \gamma'_* \tilde{s}_\chi(x), \end{aligned}$$

we have

$$\tilde{s}_\chi \in C^\infty(E)^{\Gamma,\chi} = \{ r \in C^\infty(E) \mid \forall_{\gamma \in \Gamma} T_\gamma r = \chi(\gamma) r \}$$

which defines a section $s_\chi \in C^\infty(E_\chi)$.

Let $\mathcal{D}$ be a fundamental domain for the Γ-action, i.e., an open subset of X such that $\cup_{\gamma \in \Gamma} \gamma \mathcal{D} = X$ up to a set of measure 0 and $\gamma \mathcal{D} \cap \mathcal{D} = \varnothing$ for $\gamma \neq e$. Then,

$$\int_{\hat{\Gamma}} \|s_\chi\|^2_{L^2(E_\chi)} d\chi = \int_{\hat{\Gamma}} \int_{\mathcal{D}} |\tilde{s}_\chi(x)|^2 dx\, d\chi$$

$$= \int_{\mathcal{D}} \int_{\hat{\Gamma}} \sum_{\gamma_1, \gamma_2 \in \Gamma} \chi(\gamma_1^{-1}\gamma_2) \langle \gamma_{1*} s(\gamma_1^{-1}x) | \gamma_{2*} s(\gamma_2^{-1}x) \rangle_E d\chi\, dx$$

$$= \int_{\mathcal{D}} \sum_{\gamma \in \Gamma} |s(\gamma^{-1}x)|^2 dx$$

$$= \|s\|^2_{L^2(E)}.$$

On the one hand, this shows that we can define a measurable structure on $\Pi_{\chi \in \hat{\Gamma}} L^2(E_\chi)$ by choosing a sequence in $C_c^\infty(E)$ which is the total in $L^2(E)$. On the other hand, we can see that the direct integral $\int_{\hat{\Gamma}}^{\oplus} L^2(E_\chi)\, d\chi$ is isomorphic to $L^2(E)$ via the isometry Φ, whose inverse is given by

$$\Phi^*: (s_\chi)_{\chi \in \hat{\Gamma}} \mapsto \int_{\hat{\Gamma}} \tilde{s}_\chi(x)\, d\chi,$$

as is easily seen from the character relations (7) and (8).

This shows

Lemma 3 (direct integral): The mapping defined by (9) can be extended continuously to a unitary,

$$\Phi: L^2(E) \to \int_{\hat{\Gamma}}^{\oplus} L^2(E_\chi)\, d\chi. \tag{10}$$

For the direct integral of Hilbert spaces $H = \int_{\hat{\Gamma}}^{\oplus} H_\chi d\chi$ the set of decomposable bounded operators $L^\infty(\hat{\Gamma}, \mathcal{L}(H))$ is given by the commutant $(L^\infty(\hat{\Gamma}, \mathbb{C}))'$ in $\mathcal{L}(H)$. Since commutants are weakly closed and $C(\hat{\Gamma}, \mathbb{C})$ is weakly dense in $L^\infty(\hat{\Gamma}, \mathbb{C})$ one has $(L^\infty(\hat{\Gamma}, \mathbb{C}))' = (C(\hat{\Gamma}, \mathbb{C}))'$. Therefore, in order to determine the decomposable operators one has to determine the action of $C(\hat{\Gamma})$ on $L^2(E)$. This is easily done using the explicit form of Φ:

Proposition 1 $[C(\hat{\Gamma})\text{-}action]$: *$f \in C(\hat{\Gamma})$ acts on $s \in C_c^\infty(E)$ by*

$$M_f s := \Phi^* f \Phi s, \tag{11}$$

and one has

$$(M_f s)(x) = \sum_{\gamma \in \Gamma} \hat{f}(\gamma^{-1}) T_\gamma s(x), \tag{12}$$

where

$$\hat{f}(\gamma) := \int_{\hat{\Gamma}} f(\chi) \overline{\chi}(\gamma)\, d\chi \tag{13}$$

is the Fourier transform of f. M_f is a bounded operator with norm $\|f\|_\infty$.

Corollary 1 (decomposable operators): Conjugation by Φ defines an isomorphism between decomposable bounded operators on $\int_{\hat{\Gamma}}^{\oplus} L^2(E_\chi)\, d\chi$ and Γ-periodic bounded operators on $L^2(E)$.

An unbounded operator is decomposable if and only if its (bounded) resolvent is decomposable. For a periodic symmetric elliptic operator D we have a domain of definition $\mathcal{D}(D)$

$=C_c^\infty(X)$ on which D is essentially self-adjoint. This domain is invariant for D as well as for the Γ-action, and one has $[D,\gamma]=0$ for all $\gamma\in\Gamma$. Thus all bounded functions of D commute with the Γ-action, and one has

Theorem 4 (decomposition of periodic operators): *The closure $\overline{D}$ of every periodic symmetric elliptic operator D is decomposable with respect to the direct integral of Hilbert spaces $\int_{\hat\Gamma}^{\oplus} L^2(E_\chi)\,d\chi$. A core for the domain of $\overline{D}_\chi$ is given by $C^\infty(E_\chi)$, and the action of D_χ on $C^\infty(E_\chi)\simeq C^\infty(E)^{\Gamma,\chi}$ is just the action of D as differential operator on $C^\infty(E)^{\Gamma,\chi}$. We have $\overline{D}_\chi=\overline{D_\chi}$, where*

$$D_\chi := D|_{C^\infty(E)^{\Gamma,\chi}} \tag{14}$$

and the closures are to be taken as operators in $L^2(E_\chi)$.

Proof: Given the remark above we have shown the decomposability already.

$C_c^\infty(X)$ is a core for $\overline{D}$, its image under Φ_χ is contained in $C^\infty(E)^{\Gamma,\chi}$ and is a core for $\overline{D}_\chi$, since Φ is an isometry. On this domain (9) gives the action of $\overline{D}_\chi$ as asserted in the theorem. Since D_χ is a symmetric elliptic operator on the compact manifold M it is essentially self-adjoint. $\overline{D}_\chi$ is a fiber of $\overline{D}$ (which is self-adjoint by, e.g., Ref. 10) and therefore self-adjoint, thus both define the same unique self-adjoint extension $\overline{D_\chi}$ of D_χ. □

In passing we harvest a corollary which we will not use in the sequel, but which is well known in the Euclidean setting:

Corollary 2 (reverse Bloch property): Every symmetric elliptic Abelian periodic operator has the reverse Bloch property, i.e., to every $\lambda\in\operatorname{spec}\overline{D}$ there is a bounded generalized eigensection $s\in C^\infty(E)$ with $Ds=\lambda s$.

Proof: If $\lambda\in\operatorname{spec}\overline{D}$ then, by the general theory for direct integrals,

$$\{\chi\in\hat\Gamma\,|\,(\lambda-\varepsilon,\lambda+\varepsilon)\cap\operatorname{spec}\overline{D}_\chi\neq\varnothing\}$$

has positive measure for every $\varepsilon>0$. The fibers $\overline{D}_\chi$ are elliptic operators on a compact manifold and thus have discrete spectrum; the eigenvalues depend continuously on χ (even piecewise real-analytically; see below). We choose a sequence $(\chi_n)_{n\in\mathbb{N}}$ with $(\lambda-1/n,\lambda+1/n)\cap\operatorname{spec}\overline{D}_{\chi_n}\neq\varnothing$, so that there is an accumulation point χ_∞ ($\hat\Gamma$ is compact), and $\lambda\in\operatorname{spec}\overline{D}_{\chi_\infty}$ due to continuity.

Since $\operatorname{spec}\overline{D}_{\chi_\infty}$ is discrete λ is an eigenvalue of $\overline{D}_{\chi_\infty}$. The lift of an eigensection (which is smooth due to ellipticity) lies in $C^\infty(E)^{\Gamma,\chi}$ and therefore is bounded. Furthermore the lift satisfies the same eigenvalue equation because of (14). □

III. COMMUTATIVE BLOCH THEORY FROM A NONCOMMUTATIVE POINT OF VIEW

By Gelfand's representation theorem every commutative C^*-algebra $\mathcal{A}$ is isomorphic to $C_\infty(X)$, the continuous functions vanishing at infinity of a topological Hausdorff space X, where X is the spectrum $\hat{\mathcal{A}}$ of $\mathcal{A}$, i.e., the set of equivalence classes of irreducible unitary representations;[11] C^*-norm is given by the supremum norm, the involution by pointwise complex conjugation. Hilbert $\mathcal{A}$-modules are given by the sections $C_\infty(\mathcal{H})$ of a continuous field of Hilbert spaces over X, finitely generated projective $\mathcal{A}$-modules are given by the sections $C_\infty(E)$ of a vector bundle E over X.[12] In this section we describe the corresponding structures in the case of periodic elliptic differential operators, so that we can find a formulation of Bloch theory that avoids using the points of the space $\hat\Gamma$ and relies solely on the algebraic structures with respect to $C(\hat\Gamma)$.

In Proposition 1 we already determined the action of $C(\hat{\Gamma})$ on $L^2(E)$. Now we use the scalar product that is given in each fiber by the direct integral to define a $C(\hat{\Gamma})$-values scalar product:

Definition and proposition 1 [pre-Hilbert $C(\hat{\Gamma})$-module]: For $s_1, s_2 \in C_c^\infty(E)$ we define by

$$\langle s_1 | s_2 \rangle(\chi) := \langle (\Phi s_1)_\chi | (\Phi s_2)_\chi \rangle_{L^2(E_\chi)}, \tag{15}$$

a $C(\hat{\Gamma})$-valued scalar product that makes $C_c(E)$ into a pre-Hilbert C^*-module over $C(\hat{\Gamma})$; it is a submodule of the $C(\hat{\Gamma})$-module $L^2(E)$.

Proof: $C_c(E)$ is obviously a $C(\hat{\Gamma})$-submodule of $L^2(E)$. Furthermore, by definition the scalar product is

$$\begin{aligned}
\langle s_1 | s_2 \rangle(\chi) &= \langle (\Phi s_1)_\chi | (\Phi s_2)_\chi \rangle_{L^2(E_\chi)} \\
&= \sum_{\gamma, \gamma' \in \Gamma} \overline{\chi}(\gamma) \chi(\gamma') \int_{\mathcal{D}} \langle \gamma_* s_1(\gamma^{-1} x) | \gamma'_* s_2(\gamma'^{-1} x) \rangle_{E_x} \, dx \\
&= \sum_{\gamma, \gamma'' \in \Gamma} \chi(\gamma'') \int_{\gamma^{-1}\mathcal{D}} \langle s_1(y) | \gamma''_* s_2(\gamma''^{-1} y) \rangle_{E_y} \, dy \\
&= \sum_{\gamma'' \in \Gamma} \chi(\gamma'') \langle s_1 T_{\gamma''} s_2 \rangle_{L^2(E)}, \qquad (16)
\end{aligned}$$

and therefore continuous in χ, since the last sum in (16) is finite. The $*$-property is immediately clear, and the $C(\hat{\Gamma})$-linearity of the scalar product follows from

$$\begin{aligned}
\langle s_1 | M_f s_2 \rangle(\chi) &= \langle (\Phi s_1)_\chi | (f \Phi s_2)_\chi \rangle_{L^2(E_\chi)} \\
&= \langle (\Phi s_1)_\chi | f(\chi) (\Phi s_2)_\chi \rangle_{L^2(E_\chi)} \\
&= \langle (\Phi s_1)_\chi | (\Phi s_2)_\chi \rangle_{L^2(E_\chi)} f(\chi).
\end{aligned}$$

□

(16) is the Fourier transform of the map $\gamma \mapsto \langle s_1 T_\gamma s_2 \rangle$ and will lead us on the right track for the construction of a suitable Hilbert C^*-module in the noncommutative example of gauge-periodic elliptic operators (see Lemma 8).

In Appendix B we describe how—for arbitrary (i.e., noncommutative) C^*-algebras—a C^*-valued scalar product on an $\mathcal{A}$-module together with the C^*-norm on $\mathcal{A}$ defines a Banach norm on the $\mathcal{A}$-module. The C^*-norm on $C(\hat{\Gamma})$ is the supremum norm, so that in this case the Banach norm $\|\cdot\|'_{\mathcal{E}}$ on $\mathcal{E}' := C_c(E) \ni s$ is given by

$$\|s\|_{\mathcal{E}'} := \sup_{\chi \in \hat{\Gamma}} \langle s | s \rangle(\chi).$$

We can take the closure $\mathcal{E}'$ with respect to this norm, and hence make $\mathcal{E}'$ into a C^*-module over $\hat{\Gamma}$:

Definition and proposition 2 [Hilbert $C(\hat{\Gamma})$-module and GNS representation]: We denote the closure of $C_c(E)$ as Hilbert $C(\hat{\Gamma})$- module by $\mathcal{E}$. $\mathcal{E}$ is a submodule of the $C(\hat{\Gamma})$-module $L^2(E)$. The Haar measure on $\hat{\Gamma}$ defines a faithful trace τ on $C(\hat{\Gamma})$, and the corresponding GNS representation π_τ (see appendix B) of $\mathcal{E}$ is just the original $C(\hat{\Gamma})$-action on $L^2(E)$.

Proof: Since

$$\|\langle s_1|s_2\rangle_{\mathcal{E}}\|_{L^\infty(\hat{\Gamma})} \geqslant \|\langle s_1|s_2\rangle_{\mathcal{E}}\|_{L^1(\hat{\Gamma})} \geqslant |\langle s_1|s_2\rangle_{L^2(E)}|,$$

the closure of $C_c(E)$ in the $\mathcal{E}$-norm is a subspace of $L^2(E)$, and by definition a $C(\hat{\Gamma})$-module.

The integral with respect to a measure defines a trace. Since $\hat{\Gamma}$ is compact (Γ is discrete) it has finite volume with respect to Haar measure, so that the trace is finite, and all $f \in C(\hat{\Gamma}) \subset L^1(\hat{\Gamma})$ are trace class. Since $\hat{\Gamma}$ has no open subsets of Haar measure zero the trace is faithful. We can compute the scalar product that is defined by τ for $s_1, s_2 \in \mathcal{E}$ as follows:

$$\begin{aligned}\langle s_1|s_2\rangle_\tau &\overset{\text{defi}}{=} \tau\langle s_1|s_2\rangle_{\mathcal{E}} \\ &\overset{(17)}{=} \int_{\hat{\Gamma}} \sum_{\gamma\in\Gamma} \chi(\gamma)\langle s_1 T_\gamma s_2\rangle_{L^2(E)}\, d\chi \\ &\overset{(7)}{=} \langle s_1|s_2\rangle_{L^2(E)}.\end{aligned}$$

Since $\mathcal{E} \supset C_c(E)$ is dense in $L^2(E)$ with respect to the L^2-norm and therefore with respect to the norm generated by τ, the GNS representation space for τ is $L^2(E)$. Hence, the module structures coincide. □

Proposition 2 (continuous field of Hilbert spaces over $\hat{\Gamma}$): The continuous field of Hilbert spaces over $\hat{\Gamma}$ that corresponds to $\mathcal{E}$ (see Appendix A) has the fiber $L^2(E_\chi)$ over χ, the continuity structure is defined by $\mathcal{E}$.

Proof: We get the fiber at χ as GNS representation space of the state $\pi_\chi : C(\hat{\Gamma}) \ni f \mapsto f(\chi)$. For the continuity structure, see Appendix A. □

To sum up: We have replaced the decomposition of $L^2(E)$ into a direct integral of Hilbert spaces over the space $\hat{\Gamma}$ by a Hilbert C^*-module over the C^*-algebra $C(\hat{\Gamma})$, endowed with a faithful trace whose GNS representation gives us back the original Hilbert space $L^2(E)$. In Proposition 1 we determined the $C(\hat{\Gamma})$-action and noticed that decomposable bounded operators with respect to the direct integral are just the ones commuting with this action (the periodic operators). Thus, decomposable operators are just the module maps on the $C(\hat{\Gamma})$-module $L^2(E)$. This includes especially the images (under the GNS representation) of module maps on $\mathcal{E}$. To conclude this section we cite a special case of Theorem 11 from Sec. V that shows that periodic elliptic differential operators define indeed regular unbounded module maps (see, e.g., Ref. 13, Chap. 9 for these notions) on $\mathcal{E}$, so that the resolvent of such operators belongs to the image of the GNS representation.

Theorem 5 (decomposition of periodic operators): *Let D be a periodic symmetric elliptic differential operator. Then D defines a regular operator $D_{\mathcal{E}}$ with domain of definition $\mathcal{D}(D_{\mathcal{E}}) = C_c^\infty(E)$ in $\mathcal{E}$. For $\lambda \in \mathbb{R}$ we have*

$$\pi_\tau((\lambda \mathbb{1}_{\mathcal{E}} + \overline{D_{\mathcal{E}}})^{-1}) = (\lambda \mathbb{1}_{L^2(E)} + \overline{D})^{-1}. \tag{17}$$

IV. NONCOMMUTATIVE BLOCH THEORY

Motivated by the noncommutative insight gained in the previous section, we will now define a general class of abstract elliptic operators that allows for a noncommutative version of Bloch theory. This will let us read off spectral properties from properties of the C^*-algebras that are involved.

Definition 5 ($\mathcal{A}$-elliptic operator): Let $\mathcal{A}$ be a unital C^*-algebra, $\mathcal{E}$ a Hilbert C^*-module over $\mathcal{A}$. An unbounded operator D on $\mathcal{E}$ is called $\mathcal{A}$-elliptic if

(1) D is densely defined;
(2) D is regular in the sense that D has a densely defined adjoint D^* with range $\mathrm{ran}(1+D^*D) \overset{\text{dense}}{\subset} \mathcal{E}$*; and*
(3) D has $\mathcal{A}$-compact resolvent, i.e., $(1+D^*D)^{-1} \in \mathcal{K}_{\mathcal{A}}(\mathcal{E})$.

We will explain the name $\mathcal{A}$-compact resolvent in the proof of Lemma 7. Hilbert modules are understood to be Hilbert right modules, as described in Appendix B. Hilbert spaces are Hilbert $\mathbb{C}$-modules, therefore our scalar products are complex linear in the second entry and complex antilinear in the first entry, corresponding to the convention in Mathematical Physics.

Remark 4 (module and Hilbert space operators): Given a normalized faithful trace τ on $\mathcal{A}$ we can define, as described in Appendix B, a Hilbert space scalar product on $\mathcal{E}$ by

$$\langle e_1|e_2\rangle_\tau := \tau(\langle e_1|e_2\rangle_{\mathcal{E}})$$

for $e_1, e_2 \in \mathcal{E}$. Let H_τ be the completion of $\mathcal{E}$ with respect to $\langle\cdot|\cdot\rangle_\tau$, i.e., the corresponding GNS representation space. We write $\langle\cdot|\cdot\rangle_{H_\tau}$ for $\langle\cdot|\cdot\rangle_\tau$. $\mathcal{L}_{\mathcal{A}}(\mathcal{E})$ is represented faithfully on H_τ. Thus the spectrum of an element a of the C^*-algebra $\mathcal{L}_{\mathcal{A}}(\mathcal{E})$ coincides (as a set) with the spectrum of the operator $\pi_\tau(a)$ on the Hilbert space H_τ:

Lemma 4 (spectrum of module and Hilbert space operators): If $a \in \mathcal{L}_{\mathcal{A}}(\mathcal{E})$, then

$$\mathrm{spec}\, a = \mathrm{spec}\, \pi_\tau(a).$$

In the sequel we will identify $\mathcal{E}$ resp. $\mathcal{L}_{\mathcal{A}}(\mathcal{E})$ with the images in H_τ resp. $\mathcal{L}(H_\tau)$.

Definition and proposition 3 (tr_τ-trace): The $\mathcal{A}$-finite operators $\mathcal{F}_{\mathcal{A}}$ are defined by

$$\mathcal{F}_{\mathcal{A}}(\mathcal{E}) = \mathrm{span}\{\pi^{\mathcal{E}}_{x,y} | x,y \in \mathcal{E}\}$$

with

$$\pi^{\mathcal{E}}_{x,y}(z) = x\langle y|z\rangle_{\mathcal{E}} \quad \text{for} \quad z \in \mathcal{E},$$

so that $\mathcal{K}_{\mathcal{A}}(\mathcal{E}) = \overline{\mathcal{F}_{\mathcal{A}}(\mathcal{E})}$. On $\mathcal{F}_{\mathcal{A}}(\mathcal{E})$ we define a faithful trace by

$$\mathrm{tr}_\tau(\pi^{\mathcal{E}}_{x,y}) = \tau(\langle y|x\rangle_{\mathcal{E}}), \tag{18}$$

the trace associated to τ in the GNS representation. We denote the corresponding trace class ideal in $\mathcal{L}_{\mathcal{A}}(\mathcal{E})$ by $\mathcal{L}^1_{\mathcal{A}}(\mathcal{E}, \mathrm{tr}_\tau)$.

Proof: For the generators of $\mathcal{F}_{\mathcal{A}}(\mathcal{E})$ one can easily show the relations,

$$(\pi^{\mathcal{E}}_{x,y})^* = \pi^{\mathcal{E}}_{y,x}, \pi^{\mathcal{E}}_{xa,y} = \pi^{\mathcal{E}}_{x,ya^*},$$

$$T\pi^{\mathcal{E}}_{x,y} = \pi^{\mathcal{E}}_{Tx,y}, \pi^{\mathcal{E}}_{x,y}T = \pi^{\mathcal{E}}_{x,T^*y}$$

for $x,y \in \mathcal{E}, a \in \mathcal{A}, T \in \mathcal{L}_{\mathcal{A}}(\mathcal{E})$. Thus, from the trace property of τ we have

$$\mathrm{tr}_\tau((\pi^{\mathcal{E}}_{x,y})^*) = \tau(\langle x|y\rangle_{\mathcal{E}}) = (\mathrm{tr}_\tau \pi^{\mathcal{E}}_{x,y})^*,$$

$$\mathrm{tr}_\tau(T\pi^{\mathcal{E}}_{x,y}) = \tau(\langle y|Tx\rangle_{\mathcal{E}}) = \tau(\langle T^*y|x\rangle_{\mathcal{E}}) = \mathrm{tr}_\tau(\pi^{\mathcal{E}}_{x,y}T).$$

For all $z,t \in \mathcal{E}$ we have

$$\begin{aligned}\mathrm{tr}_\tau(\pi^{\mathcal{E}}_{x,y}\pi^{\mathcal{E}}_{z,t}) &= \mathrm{tr}_\tau(\pi^{\mathcal{E}}_{x\langle y|z\rangle_{\mathcal{E}},t}) \\ &= \tau(\langle t|x\langle y|z\rangle_{\mathcal{E}}\rangle_{\mathcal{E}}) \\ &= \tau(\langle t|\pi^{\mathcal{E}}_{x,y}(z)\rangle_{\mathcal{E}})\end{aligned}$$

so that $\mathrm{tr}_{\mathcal{E}}$ is faithful: Set $t=\pi^{\mathcal{E}}_{x,y}(z)$, and note that τ is a faithful trace on $\mathcal{A}$. □

Remark 5 ($\mathrm{tr}\,\pi^{H_\tau}_{x,y}$ *vs* $\mathrm{tr}_\tau\,\pi^{\mathcal{E}}_{x,y}$)*: By Definition 3, we have*

$$\mathrm{tr}_\tau\,\pi^{\mathcal{E}}_{x,y}=\tau(\langle y|x\rangle_{\mathcal{E}})=\langle y|x\rangle_{H_\tau}=\mathrm{tr}\,\pi^{H_\tau}_{x,y}$$

with the usual canonical Hilbert space trace tr *and the usual rank 1 operators,*

$$\pi^{H_\tau}_{x,y}:H_\tau\ni z\mapsto x\langle y|z\rangle_{H_\tau}\in H_\tau$$

on the Hilbert space H_τ*. However,* $\pi^{\mathcal{E}}_{x,y}$ *and* $\pi^{H_\tau}_{x,y}$ *are different operators,*

$$\pi^{\mathcal{E}}_{x,y}(z)=x\langle y|z\rangle_{\mathcal{E}},$$

whereas

$$\pi^{H_\tau}_{x,y}(z)=x\langle y|z\rangle_{H_\tau}=x\,\tau(\langle y|z\rangle_{\mathcal{E}}).$$

Thus, in general tr_τ *and* tr *are indeed different traces.*

Remark 6 ($\mathrm{tr}\,\pi^{\mathcal{E}}_{x,y}$ *vs* $\mathrm{tr}_\tau\,\pi^{\mathcal{E}}_{x,y}$)*: Let* $(e_n)_{n\in\mathbb{N}}$ *be an orthonormal base of* H_τ*. To simplify matters we assume* $e_n\in\mathcal{E}$ *for all* $n\in\mathbb{N}$*. Since* $\mathcal{E}$ *is dense in* H_τ *this can always be achieved. Then,*

$$\begin{aligned}\mathrm{tr}_\tau\,\pi^{\mathcal{E}}_{x,y}=\mathrm{tr}\,\pi^{H_\tau}_{x,y} &= \sum_{n\in\mathbb{N}}\langle e_n|\pi^{H_\tau}_{x,y}(e_n)\rangle_{H_\tau} \\ &= \sum_{n\in\mathbb{N}}\langle e_n x\langle y|e_n\rangle_{H_\tau}\rangle_{H_\tau} \\ &= \sum_{n\in\mathbb{N}}\langle e_n|x\rangle_{H_\tau}\langle y|e_n\rangle_{H_\tau} \\ &= \sum_{n\in\mathbb{N}}\tau(\langle e_n|x\rangle_{\mathcal{E}})\,\tau(\langle y|e_n\rangle_{\mathcal{E}}),\end{aligned}$$

$$\begin{aligned}\mathrm{tr}\,\pi^{\mathcal{E}}_{x,y}=\sum_{n\in\mathbb{N}}\langle e_n\rangle|\pi^{\mathcal{E}}_{x,y}(e_n)\rangle_{H_\tau} &= \sum_{n\in\mathbb{N}}\langle e_n|x\langle y|e_n\rangle_{\mathcal{E}}\rangle_{H_\tau} \\ &= \sum_{n\in\mathbb{N}}\tau(\langle e_n|x\langle y|e_n\rangle_{\mathcal{E}}\rangle_{\mathcal{E}}) \\ &= \sum_{n\in\mathbb{N}}\tau(\langle e_n|x\rangle_{\mathcal{E}}\langle y|e_n\rangle_{\mathcal{E}}).\end{aligned}$$

So, $\mathrm{tr}\,\pi^{H_\tau}_{x,y}$ *and* $\mathrm{tr}\,\pi^{\mathcal{E}}_{x,y}$ *coincide if* τ *is multiplicative. But in this case* τ*, being a multiplicative faithful trace, is a* $*$*- isomorphism* $\mathcal{A}\to\mathbb{C}$ *already, so that we just reproduce the Hilbert space trace.*

In general tr *will be larger than* tr_τ *because*

$$\begin{aligned}\operatorname{tr}\pi^{\mathcal{E}}_{e_m,e_m}&=\sum_{n\in\mathbb{N}}\tau(\langle e_n|e_m\rangle_{\mathcal{E}}\langle e_m|e_n\rangle_{\mathcal{E}})=\sum_{n\in\mathbb{N}}\tau(\langle e_m|e_n\rangle^*_{\mathcal{E}}\langle e_m|e_n\rangle_{\mathcal{E}})\\&\geqslant\tau(\langle e_m|e_m\rangle^*_{\mathcal{E}}\langle e_m|e_m\rangle_{\mathcal{E}})\\&\geqslant(\tau(\langle e_m|e_m\rangle_{\mathcal{E}}))^2\\&=\|e_m\|^2_{H_\tau}\\&=1\\&=\operatorname{tr}\pi^{H_\tau}_{e_m,e_m}\\&=\operatorname{tr}_\tau\pi^{\mathcal{E}}_{e_m,e_m}.\end{aligned}$$

Here we used the Cauchy–Schwarz inequality $\tau(a^*b)\leqslant\sqrt{\tau(a^*a)\tau(b^*b)}$ *and the fact that the trace is normalized.*

To sum up: The tr_τ*-trace is defined only on the image of the adjointable module operators in the GNS representation, and on these it is in general smaller than the Hilbert space trace, so that the corresponding trace class ideal is larger,*

$$\pi_\tau(\mathcal{L}^1_{\mathcal{A}}(\mathcal{E},\operatorname{tr}_\tau))\supset\pi_\tau(\mathcal{L}_{\mathcal{A}}(\mathcal{E}))\cap\mathcal{L}^1(H_\tau,\operatorname{tr}).$$

Remark 7 (tr_τ *for standard Hilbert modules): If* $\mathcal{E}$ *is a standard* $\mathcal{A}$*-module* $H\otimes\mathcal{A}$ *(tensor product of Hilbert modules) with a Hilbert space* H*, then the GNS representation space* H_τ *of* $\mathcal{E}$ *is given by* $H_\tau=H\hat{\otimes}Xh_\tau$ *(tensor product of Hilbert spaces), where* h_τ *is the GNS representation space of* $\mathcal{A}$*. Therefore we have for the elementary tensors* $x\otimes a,y\otimes b\in\mathcal{E}$*,*

$$\langle y\otimes b|x\otimes a\rangle_{\mathcal{E}}=\langle y|x\rangle_H\,b^*a,$$

$$\pi^{H_\tau}_{x\otimes a,y\otimes b}=\pi^H_{x,y}\otimes\pi^{h_\tau}_{a,b},$$

$$\pi^{\mathcal{E}}_{x\otimes a,y\otimes b}=\pi^H_{x,y}\otimes\pi^{\mathcal{A}}_{a,b}=\pi^H_{x,y}\otimes ab^*.$$

With the standard traces $\operatorname{tr}_H,\operatorname{tr}_{h_\tau}$ *on the Hilbert spaces* H,h_τ *we get*

$$\operatorname{tr}\pi^{H_\tau}_{x\otimes a,y\otimes b}=\operatorname{tr}_\tau\pi^{\mathcal{E}}_{x\otimes a,y\otimes b}=\langle y|x\rangle_H\,\tau(b^*a)=\operatorname{tr}_H(\pi^H_{x,y})\operatorname{tr}_{h_\tau}(\pi^{h_\tau}_{a,b}).$$

Thus we arrive at

$$\operatorname{tr}=\operatorname{tr}_H\otimes\operatorname{tr}_{h_\tau},\quad \operatorname{tr}_\tau=\operatorname{tr}_H\otimes\tau.$$

Lemma 5 (tr *for* tr_τ*-trace class): Let* $\mathcal{E}=H\otimes\mathcal{A}$ *be as above. If* $\mathcal{A}$ *is infinite dimensional with a unitary orthonormal basis for* h_τ*, then* 0 *is the only* tr_τ*-trace class operator with finite standard trace. In particular, all Hilbert* $\mathcal{A}$*-submodules are infinite dimensional vector spaces.*

Proof: Let $(x_n)_{n\in\mathbb{N}}$ be an orthonormal basis of h_τ, consisting of unitary elements of $\mathcal{A}$. Then,

$$\operatorname{tr}_{h_\tau}\pi^{\mathcal{A}}_{a,b}=\sum_{n\in\mathbb{N}}\langle x_nab^*x_n|ab^*x_n\rangle_{h_\tau}=\sum_{n\in\mathbb{N}}\tau(x_n^*ab^*x_n)=\sum_{n\in\mathbb{N}}\tau(ab^*).$$

□

Lemma 6 (nonexistence of finite dimensional modules): If $\mathcal{A}$ *is infinite dimensional with a unitary orthonormal basis for* h_τ*, then every projective* $\mathcal{A}$*-module is an infinite dimensional vector space.*

Proof: If $\mathcal{E}$ is a projective Hilbert $\mathcal{A}$-module, then $\mathcal{E}$ is a direct summand of a free module $H\otimes\mathcal{A}$ for a suitable Hilbert space H, and we can apply Lemma 5. □

Lemma 7 (spectral projections): Let D be a self-adjoint $\mathcal{A}$-elliptic operator and let $\lambda_1,\lambda_2 \in \mathbb{R}\backslash\operatorname{spec} D$, $\lambda_1 \leqslant \lambda_2$. Then the corresponding spectral projection $P_{[\lambda_1,\lambda_2]}$ on the interval $[\lambda_1,\lambda_2]$ is $\mathcal{A}$-compact. If $e^{-tD^2} \in \mathcal{L}^1_{\mathcal{A}}(\mathcal{E},\mathrm{tr}_\tau)$ for $t>0$ then the spectral projections are tr_τ-trace class.

Proof: Reduction to $D \geqslant 0$: If $\operatorname{spec} D = \mathbb{R}$ there is nothing to prove. So, let $\lambda_0 \in \mathbb{R}\backslash\operatorname{spec} D$. We show that we can assume $D \geqslant 0$ for the proof of $\mathcal{A}$-compactness, Let,

$$D' := f(D)$$

with

$$f(x) := x - \lambda_0 \quad \text{for} \quad x \in \mathbb{R}.$$

Then $0 \notin \operatorname{spec} D'$. We set $g(x) := (1+x^2)^{-1}$ so that

$$(1+D'^2)^{-1} = g \circ f(D) = g(D)b(D)$$

with

$$b(x) = \frac{g \circ f(x)}{g(x)} = \frac{1+(x-\lambda_0)^2}{1+x^2}.$$

Since b is continuous and bounded $b(D) \in \mathcal{L}_{\mathcal{A}}(\mathcal{E})$. If D is $\mathcal{A}$-elliptic, i.e., $g(D) \in \mathcal{K}_{\mathcal{A}}(\mathcal{E})$, then we get $g(D)b(D) \in \mathcal{K}_{\mathcal{A}}(\mathcal{E})$, i.e., D' is $\mathcal{A}$-elliptic. Denote the spectral projections of D' with P'. Then obviously $P'(\lambda) = P(\lambda+\lambda_0)$, so that it suffices to test P' for $\mathcal{A}$-compactness.

Finally, we set $D'' := |D'|$. Then D'' is $\mathcal{A}$-elliptic by definition, positive by construction, and strictly positive because $0 \notin \operatorname{spec} D'$. If we denote the spectral projections of D'' by P'', then

$$P''(\lambda) = 1_{(-\infty,\lambda]}(D'') = (1_{(-\infty,\lambda]^\circ}|\cdot|)(D') = 1_{[-\lambda,\lambda]}(D') = P'_{[-\lambda,\lambda]}.$$

Therefore we get for $0 \leqslant \lambda_1 \leqslant \lambda_2$,

$$P''_{(\lambda_1,\lambda_2]} = P''(\lambda_2) - P''(\lambda_1) = P'_{[-\lambda_2,\lambda_2]} - P'_{[-\lambda_1,\lambda_1]} = P'_{[-\lambda_2,-\lambda_1)\cup(\lambda_1,\lambda_2]}.$$

By assumption $0 \notin \operatorname{spec} D'$ and therefore $P'_{[0,\infty)}, P'_{(-\infty,0]} \in \mathcal{L}_{\mathcal{A}}(\mathcal{E})$, so that

$$P'_{(\lambda_1,\lambda_2]} = P''_{(\lambda_1,\lambda_2]} P'_{[0,\infty)} \in \mathcal{K}_{\mathcal{A}}(\mathcal{E}) \tag{19}$$

and

$$P'_{[-\lambda_2,-\lambda_1)} = P''_{(\lambda_1,\lambda_2]} P'_{(-\infty,0]} \in \mathcal{K}_{\mathcal{A}}(\mathcal{E}), \tag{20}$$

if $P''_{(\lambda_1,\lambda_2]} \in \mathcal{K}_{\mathcal{A}}(\mathcal{E})$. If $\lambda_1 \leqslant 0 \leqslant \lambda_2$ we write

$$P'_{[\lambda_1,\lambda_2]} = P'_{[\lambda_1,0)} + P'_{(0,\lambda_2]}$$

and apply Eqs. (19) and (20). Hence it suffices to test P'' for $\mathcal{A}$-compactness.

$\mathcal{A}$-compactness: We show that every spectral projection $P_{[\lambda_1,\lambda_2]}$ for $\lambda_1,\lambda_2 \in \mathbb{R}\backslash\operatorname{spec} D$ can be produced by continuous functional calculus from $S := (1+D^2)^{-1}$, so that it belongs to $\mathcal{K}_{\mathcal{A}}(\mathcal{E})$. For this we note that $S^{-1} = D^2+1$ is densely defined (D is regular), self-adjoint and bounded below by 1. Thus $\sqrt{S^{-1}-1}$ exists, is positive and self-adjoint. By the spectral mapping theorem we have

$$z \in \operatorname{spec}\sqrt{S^{-1}-1} \Leftrightarrow (z^2+1)^{-1} \in \operatorname{spec} S \Leftrightarrow z \in \operatorname{spec} D.$$

Therefore, the operator

$$R_z := (z - \sqrt{S^{-1} - 1})^{-1}$$

exists for all z in the resolvent set of D. Since the function

$$\lambda \mapsto (z - \sqrt{\lambda^{-1} - 1})^{-1}$$

is continuous and bounded on every closed set not containing $(z^2+1)^{-1}$, R_z belongs to the C^*-algebra generated by S for every $z \in \mathbb{C} \backslash \operatorname{spec} D$ and therefore belongs to $\mathcal{K}_{\mathcal{A}}(\mathcal{E})$, i.e., it is $\mathcal{A}$-compact. Since

$$P_{[\lambda_1,\lambda_2]} = \frac{1}{2\pi\imath} \oint_c R_z \, dz$$

for a suitable closed path c in $\mathbb{C} \backslash \operatorname{spec} D$ with winding number 1 fulfilling $c \cap \mathbb{R} = \{\lambda_1, \lambda_2\}$, $P_{[\lambda_1,\lambda_2]}$ belongs to the C^*-algebra generated by all R_z.

Trace class property: Let e^{-tD^2} be tr_τ-trace class. (We do not assume positivity of D any more.) Since

$$\begin{aligned} P_{[\lambda_1,\lambda_2]} = \int_{\lambda_1}^{\lambda_2} dP(\lambda) &\leqslant e^{t(\lambda_2-\lambda_1)^2} \int_{\lambda_1}^{\lambda_2} e^{-t(\lambda-\lambda_1)^2} dP(\lambda) \\ &\leqslant e^{t(\lambda_2-\lambda_1)^2} \int_{\mathbb{R}} e^{-t(\lambda-\lambda_1)^2} dP(\lambda) \\ &= e^{t(\lambda_2-\lambda_1)^2} e^{-tD^2}, \end{aligned}$$

the spectral projections inherit the trace class property from e^{-tD^2}. □

If λ is an isolated eigenvalue then for sufficiently small $\varepsilon > 0$ $P_\lambda := P_{[\lambda-\varepsilon,\lambda+\varepsilon]}$ is the projection on the eigenspace of λ, independent of ε. So P_λ fulfills the hypotheses of Lemma 7, and we can determine the dimension of the eigenspace.

Theorem 6 (isolated eigenvalue): *If λ is an isolated eigenvalue of a self-adjoint $\mathcal{A}$-elliptic operator D, then the corresponding eigenspace E_λ is an (algebraically) finitely generated projective Hilbert $\mathcal{A}$-module, and the projection P_λ is $\mathcal{A}$-finite. If e^{-tD^2} is tr_τ-trace class then so is P_λ, i.e., E_λ has finite τ-dimension $\mathrm{tr}_\tau P_\lambda$.*

If $\mathcal{E}, \mathcal{A}$ fulfill the hypotheses of Lemma 6, then E_λ has infinite Hilbert dimension $\mathrm{tr}\, P_\lambda$ for every isolated eigenvalue λ of D. In particular, D has essential spectrum only.

Proof: P_λ is the spectral projection of a self-adjoint operator and therefore self-adjoint, and $\mathcal{A}$-compact by Lemma 7. Thus the eigenspace E_λ is the image of a closed adjointable projection P_λ and therefore a closed complementable $\mathcal{A}$-module. Since the projection $P_\lambda|_{E_\lambda} = \mathbb{1}$ is $\mathcal{A}$-compact E_λ is algebraically finitely generated and projective, because algebraically finitely generated $\mathcal{A}$-modules E are just the ones with unital $\mathcal{K}_{\mathcal{A}}(E)$ and automatically projective (see Ref. 14, Theorem 15.4.2 and Corollary 15.4.8).

If $e^{-tD^2} \in \mathcal{L}_{\mathcal{A}}{}^1(\mathcal{E}, \mathrm{tr}_\tau)$ then so is P_λ by Lemma 7, and under the same hypotheses we can apply Lemma 6. □

The main idea of the following proof goes back to Ref. 15:

Theorem 7 (band structure): *Assume that $\mathcal{K}_{\mathcal{A}}(\mathcal{E})$ has the Kadison property with respect to tr_τ (see Definition 3). Then the spectrum of every self-adjoint $\mathcal{A}$-elliptic operator D with $e^{-tD^2} \in \mathcal{L}^1_{\mathcal{A}}(\mathcal{E}, \mathrm{tr}_\tau)$ has band structure.*

Proof: Let $a = \lambda_0 < \cdots < \lambda_n = b \in \mathbb{R} \backslash \operatorname{spec} D$, so that $P_{[\lambda_i,\lambda_{i+1}]} \neq 0$ for $0 \leqslant i \leqslant n-1$, i.e., $\operatorname{spec} D$ has at least n components in $[a,b]$. Then,

$$P_{[a,b]}=\sum_{i=0}^{n-1} P_{[\lambda_i,\lambda_{i+1}]}$$

and therefore

$$\mathrm{tr}_\tau P_{[a,b]}=\sum_{i=0}^{n-1} \mathrm{tr}_\tau P_{[\lambda_i,\lambda_{i+1}]}\geqslant nc_K$$

$$\Leftrightarrow n\leqslant \frac{1}{c_K}\mathrm{tr}_\tau P_{[a,b]},$$

since all projections occurring in this sum are tr_τ-trace class by Lemma 7. □

If $c_K=0$ then we cannot apply Theorem 7. Instead, spectra with the structure of a Cantor set seem possible. Examples show that the opening of gaps which are allowed depends heavily on the specific structure of the operator and cannot easily be controlled globally. To get generic results we therefore have to make sure that not only $c_K=0$, but also that the trace can be arbitrarily small on ''many'' projections. This is accomplished by the following theorem by Choi and Elliott:[2]

Theorem 8 (Cantor spectrum): *Let $\mathcal{A}$ be a C*-algebra with a faithful state Φ. Assume that every self-adjoint element can be approximated arbitrarily well by an element with finite spectrum on whose minimal spectral projections Φ is arbitrarily small. Then the self-adjoint elements with Cantor spectrum are dense in all self-adjoint elements.*

In particular, the algebras in Theorem 8 have real rank zero, i.e., the invertible self-adjoint elements are dense in all self-adjoint ones:

Definition and proposition 4 (real rank): Let $\mathcal{A}$ be a unital C-algebra. The real rank of $\mathcal{A}$ is defined by*

$$\mathrm{RR}(\mathcal{A})=\min\{m\in\mathbb{N}_0|\forall n\geqslant m+1:\mathrm{RR}_n(\mathcal{A})\},\tag{21}$$

where

$$\mathrm{RR}_n(\mathcal{A})=\left\langle \forall x\in\mathcal{A}_{sa}^n:\forall\varepsilon>0:\exists y\in\mathcal{A}_{sa}^n:\sum_{k=1}^n y_k^2\in\mathcal{A}^\times\wedge\left\|\sum_{k=1}^n (y_k-x_k)^2\right\|<\varepsilon\right\rangle.\tag{22}$$

For all $n\in\mathbb{N}_0$ we have $\mathrm{RR}_n(\mathcal{A})\Rightarrow\mathrm{RR}_{n+1}(\mathcal{A})$. The following conditions are equivalent:

(1) $\mathrm{RR}(\mathcal{A})=0$;
(2) $\mathcal{A}_{sa}^\times\subset\mathcal{A}_{sa}$ dense;
(3) The self-adjoint elements with finite spectrum are dense in $\mathcal{A}_{sa}$.

We say $\mathcal{A}$ has real rank 0 with infinitesimal state (RRI_0) if $\mathcal{A}$ fulfills the assumptions of Theorem 8.

For the convenience of the reader we include a proof of these equivalences which are well known in the C^*-community.

Proof: This well-known result can be proven as an exercise in continuous functional calculus. □

Remark 8 (Kadison property and RRI_0):

(1) Kadison property and property RRI_0 are mutually exclusive since the first forbids existence of projections with arbitrarily small trace whereas the latter requires this.
(2) C-algebras $\mathcal{A}$ with RRI_0 can contain operators with band structure: If $\mathcal{A}$ is the irrational rotation algebra (see below) then $\mathcal{A}$ has RRI_0 by Theorem 9. But $\mathcal{A}$ contains a subalgebra isomorphic to $C(S^1)$, consisting of operators with band spectrum only.*
(3) On the other hand, a C-algebra $\mathcal{A}$ with the Kadison property cannot contain self-adjoint elements with Cantor spectrum: If $x\in\mathcal{A}_{sa}$ has Cantor spectrum, then every point in* spec x *is*

an accumulation point of $\operatorname{spec} x$ *and* $\mathbb{R}\backslash\operatorname{spec} x$, *so that* x *has no band spectrum in contradiction to Theorem 7.*

(4) If $\mathcal{A}_1$ *has the Kadison property and* $\mathcal{A}_2$ *has property* RRI_0, *then* $\mathcal{A}:=\mathcal{A}_1\oplus\mathcal{A}_2$ *has neither of these properties.*

Remark 9 (real rank and dimension):

(1) If $\mathcal{A}$ *is commutative so that* $\mathcal{A}=C(X)$ *for a topological space* X *then* $\mathrm{RR}(\mathcal{A})=\dim X$ *with the usual definition of dimension.*

(2) Therefore, C-algebras with real rank 0 are (noncommutative) zero-dimensional spaces. This includes finite discrete spaces. However, the additional trace condition in Theorem 8 excludes finite spaces: By the Riesz–Kakutani theorem every state on* $C(X)$ *is given by an integral with respect to a normalized measure* μ, *i.e.,* $\Phi(f)=\int f\,d\mu$ *and* $\mu(X)=1$. *Such states are faithful if and only if every open set has strictly positive measure. The trace condition requires that* X *has connected components with arbitrary small measure.*

(3) Every W-algebra has real rank 0, since the measurable functional calculus (as opposed to the continuous one) allows us to ''cut out'' points from the spectrum arbitrarily close.*

(4) Property RR_0 *is preserved under inductive limits, in particular* $\mathcal{A}\otimes\mathcal{K}$ *has real rank 0 if* $RR(\mathcal{A})=0$.

Example 5 (rotation algebra): The rotation algebra $\mathcal{A}_\theta$ *is the C*-algebra generated by two unitaries* U,V *and the relation*

$$VU=e^{2\pi\imath\theta}UV$$

for a given $\theta\in\mathbb{R}$. *It also arises as a reduced twisted group C*-algebra* $C_r^*(\mathbb{Z}_2,\Theta)$ *for the cocycle* Θ *given by* $e^{2\pi\imath\theta}$ *since* $H^2(\mathbb{Z}^2,S^1)\simeq S^1$. *It carries a canonical trace defined by*

$$\tau(1)=1,\tau(U)=\tau(V)=0.$$

The properties of this algebra depend strongly on the nature of θ:

Theorem 9 (properties of the rotation algebra):

(1) If $\theta=p/q$ *with* $p\in\mathbb{Z},q\in\mathbb{N}$ *co-prime then the Kadison constant of* $\mathcal{A}_\theta$ *and of* $\mathcal{A}_\theta\otimes\mathcal{K}$ *is* $1/q$.

(2) If θ *is irrational then* $\mathcal{A}_\theta$ *and* $\mathcal{A}_\theta\otimes\mathcal{K}$ *(together with the canonical trace) have real rank 0 with infinitesimal state.*

Proof:

(1) As is well known, the spectrum of $\mathcal{A}_\theta$ *is* T^2, *and all irreducible representations* π_z *have dimension* q. *The canonical trace of* $a\in\mathcal{A}_\theta$ *is*

$$\tau(a)=\frac{1}{q}\int_{T^2}\mathrm{tr}\,\pi_z(a)\,dz$$

with the canonical trace tr *on* $M(q,\mathbb{C})$. *Minimal projections have rank 1 in the fiber, and so the Kadison constant is* $1/q$.

(2) $\mathcal{A}_\theta$ *has real rank zero.*[16] *Since* $\mathcal{A}_\theta$ *is simple and nonelementary we also get* RRI_0 (Ref. 2, Corollary 8).

□

Theorem 10 (Cantor spectrum): *Assume the C*-algebra* $\mathcal{K}_{\mathcal{A}}(\mathcal{E})$ *has real rank 0 with an infinitesimal state. Then every self-adjoint* $\mathcal{A}$*-elliptic operator can be approximated arbitrarily close in norm resolvent sense by a self-adjoint operator with Cantor spectrum.*

Proof: Lemma 7 and Theorem 8. □

V. APPLICATIONS

A. Discrete models

Example 6 (generalized Harper operators): Sunada[17] *defines magnetic Schrödinger Operators on graphs: Let X be a connected locally finite graph, χ a $\mathbb{C}^\times$-valued (i.e., nonvanishing complex-valued) map (a weight) on the oriented edges $E(X)$, $o,t:E(X)\to X$ the origin and termination point mappings. We define a symmetric operator on $l^2(X)$ by*

$$(H_\chi f)(x)=\sum_{\substack{e\in E(X)\\ o(e)=x}}\chi(e)f(t(e))$$

for $f\in l^2(X)$. Two weights χ_1,χ_2 are called cohomologous if there is a function $s:X\to S^1$ with

$$\chi_1(e)=\chi_2(e)\frac{s(o(e))}{s(t(e))}$$

for $e\in E(X)$.

Furthermore, let Γ be a group with a properly discontinuous free action on X and such that the quotient graph is finite (say n points). A weight χ is called gauge-invariant if $\gamma^*\chi$ is cohomologous to χ for all $\gamma\in\Gamma$. Then χ defines a cocycle $\Theta\in Z^2(\Gamma,S^1)$ such that H_χ commutes with the corresponding twisted right translations $[R^\Theta_\gamma f(\gamma')=\Theta(\gamma',\gamma)f(\gamma'\gamma)]$. Referemce 17 constructs an injective $*$-homomorphismus,

$$C_r^*(\Gamma,\Theta)\otimes M(n,\mathbb{C})\to\mathrm{End}(l^2(X)),$$

whose image contains H_χ. On the other hand,

$$\mathcal{A}\otimes M(n,\mathbb{C})=\mathcal{K}_\mathcal{A}(\mathcal{A}\otimes\mathbb{C}^n)$$

for the Hilbert $\mathcal{A}$-module $\mathcal{A}\otimes\mathbb{C}^n$ which is the tensor product of the canonical module $\mathcal{A}=C_r^*(\Gamma,\Theta)$ and the Hilbert $\mathbb{C}$-module $\mathbb{C}^n$. As in Theorem 7, Ref. 17 proves band structure.

All spectral characterizations of this section apply as soon as the corresponding C-algebra $C_r^*(\Gamma,\Theta)\otimes M(n,\mathbb{C})$ fulfills the corresponding assumptions.*

We get the ordinary Harper operator for $E(X)=\Gamma=\mathbb{Z}^2$ and a suitable graph X with coordination number 4 (square lattice), the hexagonal Harper operator and the quantum pendulum for graphs with coordination numbers 6 resp. 8. The corresponding C-algebras are rotation algebras, so that we have band structure for rational flux, and weak genericity of Cantor spectrum for irrational flux.*

For another approach to the Harper operator, properties of the density of states, and for necessary (though yet unverified) conditions for Cantor spectrum see the beautiful paper by Shubin on discrete magnetic Laplacians.[18]

B. Continuous models

Example 7 (gauge-periodic elliptic operators): In this case $\mathcal{A}$ will be a twisted group C-algebra (left translations), and the Hilbert module will be a tensor product $\mathcal{E}=\mathcal{A}\otimes\mathcal{H}$ with a Hilbert space $\mathcal{H}$ such that $\mathcal{K}_\mathcal{A}(\mathcal{E})\simeq\mathcal{A}\otimes\mathcal{K}(\mathcal{H})$. The operator D will be a differential operator which is invariant under a projective representation of a group, such as Schrödinger, Dirac, and Pauli operators with periodic magnetic and electric fields.*

The geometric situation we consider is similar to the case of Abelian periodic operators (see Definition 4) from the Introduction. Now we allow the group to be noncommutative, and we allow the action to be represented projectively only on the bundle.

Definition and proposition 5 (gauge-periodic operator): Let X be a smooth oriented Riemannian manifold without boundary, Γ a discrete group acting on X from the left freely, isometrically,

and properly discontinuously. Furthermore, we assume the action to be cocompact in the sense that the quotient $M:=X/\Gamma$ *is compact. This defines, as in the Abelian case, a left action of* $\gamma \in \Gamma$ *on smooth functions* $f \in C^\infty(X)$ *by*

$$\gamma^* f(x) := f(\gamma^{-1}x) \tag{23}$$

for $x \in X$. *As before, this extends to a unitary action on* $L^2(X)$.

Next, let E be a smooth Hermitian vector bundle over X. Let U be a projective representation of Γ *in the unitary operators* $\mathcal{U}(L^2(E))$ *in the following sense:*

$$\forall \gamma_1, \gamma_2 \in \Gamma: \exists \Theta(\gamma_1, \gamma_2) \in C(X, S^1): U_{\gamma_1} U_{\gamma_2} = \Theta(\gamma_1, \gamma_2) U_{\gamma_1 \gamma_2}. \tag{24}$$

Assume that U is a (projective) lift of the Γ*-action on* $C^\infty(X)$, i.e.,

$$\forall \varphi \in C_c^\infty(X): \forall s \in L^2(E): \forall \gamma \in \Gamma: U_\gamma(\varphi s) = (\gamma^* \varphi) U_\gamma(s). \tag{25}$$

Assume that U is smooth, i.e., $\forall \gamma \in \Gamma: U_\gamma(C^\infty(E) \cap L^2(E)) \subset C^\infty(E)$. *Then* U_γ *is* γ*-local, i.e.,*

$$\forall s \in C^\infty(E): \operatorname{supp}(U_\gamma s) \subset \gamma \operatorname{supp} s, \tag{26}$$

and it leaves the domain $\mathcal{D}(D) = C_c^\infty(E)$ *of any differential operator D on E invariant. We call D* **gauge-periodic** *if, on* $\mathcal{D}(D)$, *one has*

$$\forall \gamma \in \Gamma: [U_\gamma, D] = 0. \tag{27}$$

Proof: Let $x \in X \backslash \operatorname{supp} s$. Since $\operatorname{supp} s$ is closed there is a neigborhood $O \subset X$ of x and $\varphi \in C_c^\infty(X)$ with $\varphi|O = 1$, $\varphi|_{\operatorname{supp} s} = 0$. Then $(1-\varphi)s = s$ and therefore

$$U_\gamma s = U_\gamma((1-\varphi)s) = (1 - \gamma^* \varphi) U_\gamma s = 0 \text{ on } \gamma O.$$

Since U is smooth also, it leaves $C_c^\infty(E)$ invariant. □

Proposition 3 (cocycle property): Θ *fulfills the cocycle property,*

$$\forall \gamma_1, \gamma_2, \gamma_3 \in \Gamma: \Theta(\gamma_1, \gamma_2)\Theta(\gamma_1\gamma_2, \gamma_3) = \Theta(\gamma_1, \gamma_2\gamma_3)\gamma_1^*[\Theta(\gamma_2, \gamma_3)]. \tag{28}$$

Proof: This follows from associativity $U_{\gamma_1}(U_{\gamma_2}U_{\gamma_3}) = (U_{\gamma_1}U_{\gamma_2})U_{\gamma_3}$ and the projectivity condition (24),

$$\begin{aligned} U_{\gamma_1}(U_{\gamma_2}U_{\gamma_3}) = U_{\gamma_1}\Theta(\gamma_2, \gamma_3)U_{\gamma_2\gamma_3} &= \gamma_1^*[\Theta(\gamma_2, \gamma_3)]U_{\gamma_1}U_{\gamma_2\gamma_3} \\ &= \Theta(\gamma_1, \gamma_2\gamma_3)\gamma_1^*[\Theta(\gamma_2, \gamma_3)]U_{\gamma_1\gamma_2\gamma_3}, \end{aligned}$$

$$\begin{aligned} (U_{\gamma_1}U_{\gamma_2})U_{\gamma_3} &= \Theta(\gamma_1, \gamma_2)U_{\gamma_1\gamma_2}U_{\gamma_3} \\ &= \Theta(\gamma_1, \gamma_2)\Theta(\gamma_1\gamma_2, \gamma_3)U_{\gamma_1\gamma_2\gamma_3}. \end{aligned}$$

□

Remark 10 (exact cocycle and representation): Θ *therefore defines a class in the group cohomology* $H^2(\Gamma, C(X, S^1))$.[19] *Exact 2-cocycles have the form,*

$$\Theta(\gamma, \gamma') = \sigma(\gamma)\gamma^*[\sigma(\gamma')]\sigma(\gamma\gamma')^{-1} \tag{29}$$

with a 1-cocycle σ, *so they define a proper representation of* Γ *by*

$$\tilde{U}_\gamma := \sigma(\gamma)^{-1} U_\gamma, \tag{30}$$

which also commutes with D if the cocycle is constant in $x \in X$. Without loss of generality we assume that Θ is normalized, i.e., $\Theta(e,e)=1$.

Proposition 4 (bundle morphisms): U defines a family u of vector bundle morphisms on E, $u_\gamma : E_x \to E_{\gamma x}$. u is a projective lift of the Γ-action from X to E, i.e.,

$$\forall \gamma_1 \gamma_2 \in \Gamma : u_{\gamma_1} u_{\gamma_2} = \Theta(\gamma_1, \gamma_2) u_{\gamma_1 \gamma_2} \tag{31}$$

with the same cocycle Θ as for U. u induces U via

$$(U_\gamma s)(x) := u_\gamma s(\gamma^{-1} x). \tag{32}$$

If t is a (proper) lift of the Γ-action from X to E and T the induced action

$$(T_\gamma s)(x) := t_\gamma s(\gamma^{-1} x) \tag{33}$$

on $C^\infty(X)$, then u and U can be expressed as $u=mt$ and $U=MT$, where m is a family of (strict) vector bundle isomorphisms.

Proof: Let $v \in E_x$. We choose $s \in C^\infty(E)$ with $s(x)=v$ and set—*a priori* depending on s $-u^s_\gamma(v) := (U_\gamma(s))(\gamma x) \in E_{\gamma x}$. If $\varphi \in C^\infty(x)$, $\varphi(x)=1$, we get

$$u^{\varphi s}_\gamma(v) = (\gamma^* \varphi)(\gamma x)(U_\gamma(s))(\gamma x) = u^s_\gamma(v),$$

i.e., $u^s_\gamma(v)$ depends on the value of s at the point x only; hence we omit s in the notation. The morphism property follows from the corresponding property of U_γ, and from $(u_\gamma)^{-1} = u_{\gamma^{-1}}$.

u induces U by construction.

If there is a proper lift t then $m := u t^{-1}$ defines the strict morphism we look for

$$\begin{array}{ccccc} E & \xrightarrow{t_\gamma^{-1}} & E & \xrightarrow{u_\gamma} & E \\ \downarrow & & \downarrow & & \downarrow \\ X & \xrightarrow{\gamma^{-1}} & X & \xrightarrow{\gamma} & X \end{array}$$

□

Remark 11 (lift of the action): If Θ is exact and $\tilde{u}$ the family of vector bundle isomorphisms belonging to $\tilde{U}$ by remark 10 then $\tilde{u}$ is a proper lift of the Γ-action from X to E.

Proposition 5 (properties of the cocycle): (1) $\forall \gamma \in \Gamma : \Theta(\gamma, e) = \Theta(e, \gamma) = 1$; (2) $\forall \gamma \in \Gamma : \Theta(\gamma, \gamma^{-1}) = \Theta(\gamma^{-1}, \gamma)$.

Proof: Easy consequences of the cocycle property. □

For the case of a bicharacter Θ Brüning and Sunada[20,21] describe how to construct a parametrix for elliptic gauge-periodic differential operator by lifting and translating a parametrix for a fundamental domain. The same construction works for the slightly more general case of a 2-cocycle.

From this one concludes as in the cited work:

Theorem 11 (self-adjointness): *Every symmetric elliptic gauge-periodic differential operator is essentially self-adjoint on $C^\infty_c(E)$.*

Similarly, a trivial extension of Refs. 20 and 21 shows how to construct the heat kernel:

Theorem 12 (heat kernel): *Let D be a symmetric elliptic gauge-periodic differential operator, bounded below, of order $p > d = \dim X$. Then $e^{-t\overline{D}}$ has, for $t>0$, a smooth integral kernel $K_t(x,y) \in E_x \otimes E_y^*$ such that*

$$|K_t(x,y)| \leq C_1 t^{-d/p} \exp(-C_2 \operatorname{dist}(x,y)^{p/(p-1)} t^{-1/(p-1)}) \tag{34}$$

with $C_1, C_2 > 0$, *uniformly on* $(0,T] \times X \times X$.

Again following 20 we construct a suitable decomposition of $L^2(E)$. For that we choose a fundamental domain $\mathcal{D}$ for the Γ-action, set $\mathcal{H} = L^2(E|_{\mathcal{D}})$ and define a unitary map by

$$\Phi: L^2(E) \to l^2(\Gamma, \mathcal{H}) \simeq l^2(\Gamma) \otimes \mathcal{H}, \quad \Phi(s)(\gamma) = (U_\gamma(s))|_{\mathcal{D}}.$$

Then we have for $f \in l^2(\Gamma) \otimes \mathcal{H}$,

$$\begin{aligned}(\Phi U_\gamma \Phi^* f)(\gamma') &= (U_{\gamma'} U_\gamma \Phi^* f)|_{\mathcal{D}} = \Theta(\gamma', \gamma)(U_{\gamma' \gamma} \Phi^* f)|_{\mathcal{D}} \\ &= \Theta(\gamma', \gamma)(\Phi \Phi^* f)(\gamma' \gamma) = \Theta(\gamma', \gamma) f(\gamma' \gamma) \\ &=: \Theta(\gamma', \gamma) R_\gamma f(\gamma') = R^\Theta_\gamma f(\gamma')\end{aligned}$$

with the right translation R_γ and twisted right translation $R^\Theta_\gamma f(\gamma')$.

So it is natural to try and define a $C^*_r(\Gamma, \Theta)$-action on $L^2(E)$ by

$$R^\Theta_\gamma(s) = U_\gamma(s)$$

for $s \in L^2(E)$. Here, the cocycle Θ can in general depend on $x \in X$ so that we have to find the gauge-translations in $C(X, S^1) \times_{\alpha, \theta} \Gamma$. This C^*-algebra has interesting structural properties but is not suitable for the applications on spectral theory developed in the previous section.

If Θ is periodic in $x \in X$ then we get a field of twisted reduced group C^*-algebras $C^*_r(\Gamma, \Theta_x), x \in M$ over M. In general this field is still too ''large.''

Therefore we require the cocycle to be constant in $x \in X$, so that we have to deal with the reduced twisted group C^*-algebra $C^*_r(\Gamma, \Theta)$ only. This is still general enough for the applications we are interested in: magnetic Schrödinger operators (and their Pauli and Dirac analogs).

Now note that $l^2(\Gamma)$ is the GNS representation space of $\mathcal{A} := C^*_r(\Gamma, \Theta)$ with respect to the canonical trace given by

$$\tau(R^\Theta_\gamma) = \begin{cases} 1, & \gamma = e, \\ 0, & \text{else}, \end{cases}$$

and that $l^1(\Gamma) \subset C^*_r(\Gamma, \Theta) \subset l^2(\Gamma)$. The action is naturally a left action since it is given by endomorphisms on a vector space. Therefore it's natural to view the left Hilbert-$\mathcal{A}$ module as $\mathcal{E} := \mathcal{H} \otimes \mathcal{A}$ so that $L^2(E)$ is the Hilbert-GNS representation space of $\mathcal{E}$. To define the scalar product we use the observations made in the commutative case (see Definition and Proposition 1),

$$\langle s_1 | s_2 \rangle_{\mathcal{E}} = \sum_{\gamma \in \Gamma} \langle U_\gamma s_2 | s_1 \rangle_{L^2(E)} R^\Theta_\gamma. \tag{35}$$

Lemma 8 (left pre-Hilbert $\mathcal{A}$-module): for $s_1, s_2 \in C_c(E)$ *defines the structure of a left pre-Hilbert $\mathcal{A}$-module on* $C_c(E)$*; under the isomorphism* Φ *it coincides with the left tensor Hilbert $\mathcal{A}$-module structure of* $\mathcal{H} \otimes \mathcal{A}$.

Proof: For $f_1, f_2 \in \mathcal{H}, a_1, a_2 \in \mathcal{A}$ we have by definition

$$\langle a_1 \otimes f_1 | a_2 \otimes f_2 \rangle_{\mathcal{A} \otimes \mathcal{H}} = \langle f_2 | f_1 \rangle_{\mathcal{H}} a_1 a_2^*,$$

since a left Hilbert-$\mathbb{C}$-module is a Hilbert space with conjugated scalar product (complex linear in the first argument, antilinear in the second). For $s_1, s_2 \in C_c(E)$ we get after identifying $\delta_{\gamma^{-1}}$ with $\overline{\Theta}(\gamma, \gamma^{-1}) R^\Theta_\gamma$,

$$\langle \Phi(s_1)|\Phi(s_2)\rangle_{\mathcal{A}\otimes\mathcal{H}} = \sum_{\gamma,\gamma'\in\Gamma} \langle \delta_\gamma \otimes \Phi(s_1)(\gamma)|\delta_{\gamma'}\otimes\Phi(s_2)(\gamma')\rangle_{\mathcal{A}\otimes\mathcal{H}}$$

$$= \sum_{\gamma,\gamma'\in\Gamma} \langle \Phi(s_2)(\gamma')\Phi(s_1)(\gamma)\rangle_{\mathcal{H}} \overline{\Theta}(\gamma^{-1},\gamma)\Theta(\gamma'^{-1},\gamma') R^{\Theta}_{\gamma^{-1}}(R^{\Theta}_{\gamma'^{-1}})^*$$

$$= \sum_{\gamma,\gamma'\in\Gamma} \langle \Phi(s_2)(\gamma')|\Phi\Phi(s_1)(\gamma)\rangle_{\mathcal{H}} \overline{\Theta}(\gamma^{-1},\gamma) R^{\Theta}_{\gamma^{-1}} R^{\Theta}_{\gamma'}$$

$$= \sum_{\gamma,\gamma'\in\Gamma} \langle (U_{\gamma'}s_2)|_{\mathcal{D}}(U_\gamma s_1)|_{\mathcal{D}}\rangle_{\mathcal{H}} \overline{\Theta}(\gamma^{-1},\gamma)\Theta(\gamma^{-1},\gamma') R^{\Theta}_{\gamma^{-1}\gamma'}$$

$$= \sum_{\gamma,\gamma'\in\Gamma} \langle (U_{\gamma\gamma'}s_2)|_{\mathcal{D}}|(U_\gamma s_1)|_{\mathcal{D}}\rangle_{\mathcal{H}} \overline{\Theta}(\gamma^{-1},\gamma)\Theta(\gamma^{-1},\gamma\gamma') R^{\Theta}_{\gamma'}$$

$$= \sum_{\gamma,\gamma'\in\Gamma} \langle (U_\gamma U_{\gamma'}s_2)|_{\mathcal{D}}|(U_\gamma s_1)|_{\mathcal{D}}\rangle_{\mathcal{H}} \Theta(\gamma,\gamma')\overline{\Theta}(\gamma^{-1},\gamma)\Theta(\gamma^{-1},\gamma\gamma') R^{\Theta}_{\gamma'}$$

$$= \sum_{\gamma,\gamma'\in\Gamma} \langle (U_\gamma U_{\gamma'}s_2)|_{\mathcal{D}}|(U_\gamma s_1)|_{\mathcal{D}}\rangle_{\mathcal{H}} R^{\Theta}_{\gamma'}$$

$$= \sum_{\gamma'\in\Gamma} \langle U_{\gamma'}s_2|s_1\rangle_{L^2(E)} R^{\Theta}_{\gamma'}.$$

This shows that the structures coincide. □

Lemma 9 (left Hilbert $\mathcal{A}$-module): The completion of the left pre-Hilbert $\mathcal{A}$ -module $C_c(E)$ is isomorphic to $\mathcal{E}=\mathcal{H}\otimes\mathcal{A}$. The GNS representation of $\mathcal{E}$ with respect to the canonical trace τ on $\mathcal{A}$ is isomorphic to $L^2(E)$.

Proof: By Eq. (35) we have for $s\in C_c(E)$,

$$\|s\|^2_{\mathcal{E}} = \|\langle s|s\rangle_{\mathcal{E}}\|_{\mathcal{A}} \geqslant \langle s|s\rangle_{L^2(E)}.$$

Therefore, the completion of $C_c(E)$ with respect to $\|\cdot\|_{\mathcal{E}}$ is contained in the one with respect to $\|\cdot\|_{L^2(E)}$, i.e. in $L^2(E)$. But $C_c(E)$ is dense in $\mathcal{E}$.

We get the scalar product of the GNS representation with respect to τ for $s_1, s_2\in C_c(E)$ from

$$\langle s_1|s_2\rangle_\tau = \tau(\langle s_2|s_1\rangle_{\mathcal{E}}) = \tau\left(\sum_{\gamma\in\Gamma}\langle U_\gamma s_1|s_2\rangle_{L^2(E)} R^{\Theta}_{\gamma}\right),$$

$$= \sum_{\gamma\in\Gamma}\langle U_\gamma s_1|s_2\rangle_{L^2(E)}\tau(\tilde{\rho}(\delta_\gamma))$$

$$= \langle s_1|s_2\rangle_{L^2(E)}.$$

Since $C_c(E)\subset\mathcal{E}\subset L^2(E)$ is dense the GNS representation space is exactly $L^2(E)$. □

Lemma 10 ($\mathcal{A}$-compact operators): The $\mathcal{A}$-compact operators on $\mathcal{E}$ are given by

$$\mathcal{K}_{\mathcal{A}}(\mathcal{E}) \simeq \mathcal{A}^{op}\otimes\mathcal{K}. \tag{36}$$

Here $\mathcal{K}$ denotes the compact operators on $\mathcal{H}=L^2(E|_{\mathcal{D}})$, and $\mathcal{A}^{op}$ is the C-algebra $C^*_r(\Gamma,\theta)^L$ generated by the left translations twisted with θ.*

Proof: For tensor products of left Hilbert modules we have in general,

$$\mathcal{K}_{\mathcal{A}}(\mathcal{A}\otimes\mathcal{H})\simeq\mathcal{K}_{\mathcal{A}}(\mathcal{A})\otimes\mathcal{K}_{\mathbb{C}}(\mathcal{H}) \quad \simeq\mathcal{A}^{\mathrm{op}}\otimes\mathcal{K}.$$

The statement about $\mathcal{A}^{\mathrm{op}}$ is well known in the untwisted case since the opposite of left multiplication is right multiplication. It is easy to check that this holds in the twisted case also. □

Following our rationale from Sec. IV we define a trace tr_τ and identify bounded module operators in $\mathcal{L}_{\mathcal{A}}(\mathcal{E})$ with their images in $\mathcal{L}(L^2(E))$ under the faithful representation with respect to τ.

As in Refs. 22 and 21, one shows, using Theorem 12:

Theorem 13 (gauge-periodic operators): *Let D be a symmetric gauge-periodic differential operator. Then the resolvent of $\overline{D}$ is $\mathcal{A}$-compact, and $e^{-t\overline{D}^2}$ is tr_τ-trace class.*

Theorem 14 (gauge-periodic module operators): *Let D be a symmetric gauge-periodic differential operator. Then D defines an $\mathcal{A}$-elliptic operator T such that the resolvents of $\overline{D}$ and $\overline{T}$ coincide (under the GNS representation).*

Proof: Set $\mathcal{D}(T):=\mathcal{D}(D)=C_c^\infty(E)$. Then $\mathcal{D}(T)\subset\mathcal{E}$ dense, we set $T:=D$ as operators on vector spaces.

T is adjointable since D is symmetric and gauge-periodic: For $s_1,s_2\in C_c^\infty(E)$ we have

$$\begin{aligned}\langle s_1|Ds_2\rangle_{\mathcal{E}}&=\sum_{\gamma\in\Gamma}\langle U_\gamma s_1|Ds_2\rangle_{L^2(E)}R_\gamma^\theta\\&=\sum_{\gamma\in\Gamma}\langle DU_\gamma s_1|s_2\rangle_{L^2(E)}R_\gamma^\theta\\&=\sum_{\gamma\in\Gamma}\langle U_\gamma Ds_1|s_2\rangle_{L^2(E)}R_\gamma^\theta\\&=\langle Ds_1|s_2\rangle_{\mathcal{E}}.\end{aligned}$$

Finally, $\mathrm{ran}(1+D^*D)$ is dense in $L^2(E)$ because D is essentially self-adjoint; therefore, T is regular. □

This allows us to apply all of the spectral characterizations from the previous section.

Example 8 (periodic elliptic operator): A gauge-periodic operator is called periodic if the corresponding cocycle fulfills $\Theta\equiv 1$. If the group Γ is Abelian then we are back in the commutative case (see Definition 4) where ordinary Bloch theory applies. If Γ is not Abelian then it does not apply, although the cocycle is trivial. But it is still covered by noncommutative Bloch theory, of course.

Example 9 (magnetic Schrödinger operator): In example 3 and Remark 3 we saw that the magnetic Schrödinger operator with a magnetic field $b\in\Omega^2(X), db=0, [(1/2\pi)\,b]\in H^2(X,\mathbb{Z})$ is given by a (symmetric elliptic) Bochner–Laplace operator on a Hermitian line bundle L over X with curvature b. It is gauge-periodic with possibly nonconstant cocycle if $H^1(X,S^1)=0$ (see Remark 3 and the work cited there in). If b is exact then the cocycle can be chosen to be constant. If the magnetic flux is integral $[b_M\in H^2(M,\mathbb{Z})$, see Example 3], then the operator is periodic. If there is a periodic magnetic potential a for $b=da$ (i.e., if the magnetic flux is 0) then the operator is strictly periodic in the usual sense of ordinary Bloch theory, i.e., it is a periodic operator on $L^2(X)$ (no magnetic translations, no bundles).

Example 10 (magnetic Schrödinger operator on $\mathbb{R}^2$): In the Euclidean case, if $\Gamma=\mathbb{Z}^2$ we end up with a rotation algebra $\mathcal{A}_\theta$, where θ is given by the magnetic flux. So, from Theorem 9 we get band structure in the case of rational flux and weak genericity of Cantor spectra in the case of irrational flux. Since it is a criterion inside the algebra of symmetries it applies to the corresponding Pauli and Dirac operators as well.

Example 11 (magnetic Schrödinger operator on $\mathbb{H}^2$): To investigate the importance of the geometry it is interesting to study the hyperbolic analog, since the corresponding cocompact

groups (Fuchsian groups) are nonamenable and therefore ''opposite'' to the amenable groups in the Euclidean case. The analog of a constant magnetic field is a constant multiple of the volume form. References 23, 24 compute K-groups and Kadison constants for twisted Fuchsian groups: Again, one has Kadison property if and only if the magnetic flux is rational.

References 25 and 26 study similar questions for good orbifolds.

Example 12 (gauge-periodic point perturbations): In Euclidean space, point perturbations provide explicitly solvable models for periodic Schrödinger operators. References 27 and 28 show how to define these types of operators more generally in our given geometric context (manifold with cocompact group action). If the point perturbation is gauge-periodic, then the perturbed operator is gauge-periodic in our sense, so that noncommutative Bloch theory applies. In particular, periodic point perturbations of the magnetic Schrödinger operator with rational flux have band structure.

C. Elliptic operators on Hilbert module bundles

Example 13: Ref. 29 extended the usual notion of an index of an operator by replacing Hilbert spaces by Hilbert modules: Let $\mathcal{A}$ be a C^*-algebra, M a compact Riemannian manifold and E a bundle over M of Hilbert $\mathcal{A}$-modules (a Hilbert module bundle). On can define Sobolev norms as usual, now coming from an $\mathcal{A}$-scalar product. Thus one gets a scale of Sobolev–Hilbert $\mathcal{A}$-modules for which the Sobolev lemma holds. Instead of the usual pseudo-differential operators whose coefficients are vector space endomorphisms one has $\mathcal{A}$-pseudo-differential operators with coefficients in the bundle $\mathcal{L}_{\mathcal{A}}(E)\cup_{x\in M}\mathcal{L}_{\mathcal{A}}(E_x)$. They act in the usual way on the Sobolev–Hilbert modules. Symbols of $\mathcal{A}$-pseudo-differential operators are represented by section of $\mathcal{L}_{\mathcal{A}}(E)$. As in the scalar case, an elliptic operator has an $\mathcal{A}$-compact resolvent, hence it is $\mathcal{A}$-elliptic in the sense of Definition 5. Furthermore, elliptic operators are $\mathcal{A}$-Fredholm and therefore have an index in $K_0(\mathcal{A})$.

A special case are the periodic elliptic operators: Let X be a Riemannian manifold with properly discontinuous, isometric, cocompact action of a group Γ, and D a Γ-periodic operator as in Example 8, $M:=\Gamma\backslash X$. Let ρ be the right regular representation of Γ on $\mathcal{A}:=C_r^*(\Gamma)$. [Usually one studies the right regular representation on the vector space $\mathbb{C}\Gamma\subset C_r^*(\Gamma)$ or on the Hilbert space $l^2(\Gamma)\supset C_r^*(\Gamma)$; but $C_r^*(\Gamma)$ is a Γ-invariant subspace of $l^2(\Gamma)$.] Then $X\times_\rho\mathcal{A}$ is an $\mathcal{A}$-bundle over M on which D acts. Besides, $\mathcal{A}$ carries the structure of a standard Hilbert-$\mathcal{A}$ module. If D is elliptic then D determines an elliptic operator on $X\times_\rho\mathcal{A}$.

APPENDIX A: CONTINUOUS FIELDS OF HILBERT SPACES

We follow the classic Ref. 30.

Definition 6 (continuous fields of Banach and Hilbert spaces): Let B be a topological space, $(E(z))_{z\in B}$ a family of Banach spaces. The linear space $\Pi:=\Pi_{z\in B}E(z)$ is called space of all vector fields. A continuity structure on Π is defined by a subspace $\Lambda\subset\Pi$ such that:

(1) Λ is a $C_\infty(B)$-submodule of Π;
(2) $\forall z\in B:\forall\xi\in E(z):\exists x\in\Lambda:x(z)=\xi$;
(3) $\forall x\in\Lambda:(z\mapsto\|x(z)\|)\in C_\infty(B)$;
(4) $\forall x\in\Pi:\langle\forall\varepsilon>0:\forall z\in B:\exists x'\in\Lambda,$ neighborhood $U\ni z:\ \forall z'\in U:\|x(z')-x'(z')\|<\varepsilon\rangle\Rightarrow x\in\Lambda\rangle$;

$\mathcal{E}:=((E(z))_{z\in B},\Lambda)$ *is called continuous field of Banach spaces. If the fibers* $E(z)$ *are Hilbert spaces we have a continuous field of Hilbert spaces. The scalar product is automatically continuous.*

Condition 4 is a completeness condition: If a vector field $x\in\Pi$ can be locally approximated arbitrarily well by continuous vector fields then it is continuous.

Proposition 6 (defining submodule): Let B,Π *be as above and* $\Lambda\subset\Pi$ *a subspace with*

(1) $\forall z\in B:\{x(z)|x\in\Lambda\}=:\Lambda(z)$ *dense in* $E(z)$*; and*
(2) $\forall x\in\Lambda:(z\mapsto\|x\|)\in C_\infty(B)$.

Then there is a unique continuity structure $\tilde{\Lambda}$ *on* Π *with* $\tilde{\Lambda}\supset\Lambda$. $\tilde{\Lambda}$ *is given by*

$$\tilde{\Lambda}=\{x\in\Pi|\forall z\in B:\varepsilon>0\,\exists\ neighborhood\ U\ni z,x'\in\bar{\Lambda}:\forall z'\in U:\|x(z')-x'(z')\|<\varepsilon\}.$$

Lemma 11 (continuous fields and Banach space bundles): A continuous field of Banach spaces $\mathcal{E}$ *defines a Banach space bundle* E *over* B *so that the continuous sections* $C(E)$ *are the continuous vector fields of* $\mathcal{E}$.

Proof: As a set $E:=\Pi_{z\in B}E(z)$. We choose the topology so that the natural projection $\pi:E\to B$ is continuous and open: The topology is generated by the tubular neighborhoods

$$T(U,x,\varepsilon):=\{\xi\in E|\pi(\xi)\in U\wedge\|\xi-x(\pi(\xi))\|<\varepsilon\}$$

for open sets $U\subset B$, continuous fields $x\in\mathcal{E}$ and $\varepsilon>0$. It is easy to check that the tubular neighborhoods generate a topology on E with the desired properties. On the fibers $E(z)$ it induces the strong topology since the intersections $E(z)\cap T(U,x,\varepsilon)$ of the fibers with the tubular neighborhoods are just norm balls in the fiber. □

Remark 12 (local triviality): A bundle has a continuous open surjection onto the base, but is not necessarily locally trivial. However, for a locally compact base and finite dimensional fibers this follows from the existence of the projection.

Lemma 12 (continuous field as the Hilbert C-module): A continuous field of Hilbert spaces* $\mathcal{E}=((E(z))_{z\in B},\Lambda)$ *over* B *defines a Hilbert* $C_\infty(B)$*-module structure on* Λ. *Vice versa: A Hilbert* $C_\infty(B)$*-module defines a continuous field of Hilbert spaces, and this correspondence is one-to-one.*

APPENDIX B: HILBERT *C**-MODULES

Usually Hilbert C^*-modules are defined to be right modules. We define these and the left modules and list basic properties and objects connected to them.

Definition 7 [(right) Hilbert module]: Let $\mathcal{A}$ *be a* C^**-algebra. A right* $\mathcal{A}$*-module* $\mathcal{E}$ *is called (right) pre-Hilbert* $\mathcal{A}$*-module if it is endowed with a map* $\langle\cdot|\cdot\rangle:\mathcal{E}\times\mathcal{E}\to\mathcal{A}$ *with the following properties:*

(1) $\langle e|f+g\rangle=\langle e|f\rangle+\langle e|g\rangle$ *for* $e,f,g\in\mathcal{E}$;
(2) $\langle e|f\lambda\rangle=\langle e|f\rangle\lambda$ *for* $e,f\in\mathcal{E},\lambda\in\mathbb{C}$;
(3) $\langle e|fa\rangle=\langle e|f\rangle a$ *for* $e,f\in\mathcal{E},a\in\mathcal{A}$;
(4) $\langle f|e\rangle=\langle e|f\rangle^*$ *for* $e,f\in\mathcal{E}$;
(5) $\langle e|e\rangle\geqslant 0$ *in* $\mathcal{A}$ *for* $e\in\mathcal{E}$, *and* $\langle e|e\rangle=0\Leftrightarrow e=0$.

Then the map $\mathcal{E}\ni e\mapsto\sqrt{\|\langle e|e\rangle\|_{\mathcal{A}}}$ *defines a norm on* $\mathcal{E}$. *The closure of* $\mathcal{E}$ *is defined as the completion of* $\mathcal{E}$ *as Banach space with this norm.*

$\mathcal{E}$ *is called (right) Hilbert* $\mathcal{A}$*-module if* $\mathcal{E}$ *is complete in this norm.*

An operator $T\in\mathcal{L}(\mathcal{E})$ *is called adjointable if there is* $T^*\in\mathcal{L}(\mathcal{E})$ *such that for all* $e,f\in\mathcal{E}$: $\langle e|Tf\rangle=\langle T^*e|f\rangle$. *The set of adjointable operators is denoted by* $\mathcal{L}_{\mathcal{A}}(\mathcal{E})$.

For $e,f\in\mathcal{E}$ *we define an operator* $\pi_{e,f}$ *by*

$$\pi_{e,f}:\mathcal{E}\ni x\mapsto e\langle f|x\rangle\in\mathcal{E}.$$

We set $\mathcal{F}_{\mathcal{A}}(\mathcal{E}):=\mathrm{span}\{\pi_{e,f}|e,f\in\mathcal{E}\}$ *and call this the set of* $\mathcal{A}$*-finite operators. The set* $\mathcal{K}_{\mathcal{A}}(\mathcal{E})$ *of* $\mathcal{A}$*-compact operators is the closure of* $\mathcal{F}_{\mathcal{A}}(\mathcal{E})$ *in* $\mathcal{L}_{\mathcal{A}}(\mathcal{E})$.

The brackets indicate that by Hilbert module we mean a right Hilbert module.

Definition 8 (left Hilbert module): Let $\mathcal{A}$ *be a C*-algebra. A left* $\mathcal{A}$*-module* $\mathcal{E}$ *is called left pre-Hilbert* $\mathcal{A}$*-module if it is endowed with a map* $\langle\cdot|\cdot\rangle:\mathcal{E}\times\mathcal{E}\to\mathcal{A}$ *with the following properties:*

(1) $\langle e+f|g\rangle=\langle e|g\rangle+\langle f|g\rangle$ *for* $e,f,g\in\mathcal{E}$;
(2) $\langle\lambda e|f\rangle=\lambda\langle e|f\rangle$ *for* $e,f\in\mathcal{E},\lambda\in\mathbb{C}$;
(3) $\langle ae|f\rangle=a\langle e|f\rangle$ *for* $e,f\in\mathcal{E},a\in\mathcal{A}$;
(4) $\langle f|e\rangle=\langle e|f\rangle^*$ *for* $e,f\in\mathcal{E}$;
(5) $\langle e|e\rangle\geqslant 0$ *in* $\mathcal{A}$ *for* $e\in\mathcal{E}$, *and* $\langle e|e\rangle=0\Leftrightarrow e=0$.

Then the map $\mathcal{E}\ni e\mapsto\sqrt{\|\langle e|e\rangle\|_{\mathcal{A}}}$ *defines a norm on* $\mathcal{E}$. *The closure of* $\mathcal{E}$ *is defined as the completion of* $\mathcal{E}$ *as Banach space with this norm.*

$\mathcal{E}$ *is called left Hilbert* $\mathcal{A}$*-module if* $\mathcal{E}$ *is complete in this norm.*

An operator $T\in\mathcal{L}(\mathcal{E})$ *is called adjointable if there is* $T^*\in\mathcal{L}(\mathcal{E})$ *such that for all* $e,f\in\mathcal{E}$: $\langle e|Tf\rangle=\langle T^*e|f\rangle$. *The set of adjointable operators is denoted by* $\mathcal{L}_{\mathcal{A}}(\mathcal{E})$.

For $e,f\in\mathcal{E}$ *we define an operator* $\pi^L_{e,f}$ *by*

$$\pi^L_{e,f}:\mathcal{E}\ni x\mapsto\langle x|e\rangle f\in\mathcal{E}.$$

We set $\mathcal{F}_{\mathcal{A}}(\mathcal{E}):=\mathrm{span}\{\pi^L_{e,f}|e,f\in\mathcal{E}\}$ *and call this the set of* $\mathcal{A}$*-finite operators. The set* $\mathcal{K}_{\mathcal{A}}(\mathcal{E})$ *of* $\mathcal{A}$*-compact operators is the closure of* $\mathcal{F}_{\mathcal{A}}(\mathcal{E})$ *in* $\mathcal{L}_{\mathcal{A}}(\mathcal{E})$.

Remark 13 (basic properties):

(1) If $\mathcal{E}$ *is a pre-Hilbert* $\mathcal{A}$*-module,* $e\in\mathcal{E}$, *then Definition 7.4 implies* $\langle e|e\rangle\in\mathcal{A}_{sa}$ *so that the condition* $\langle e|e\rangle\geqslant 0$ *in 7.5 makes sense indeed;*
(2) If $\mathcal{E}$ *is a pre-Hilbert* $\mathcal{A}$*-module,* $e,f\in\mathcal{E},a\in\mathcal{A}$ *then we have*

$$\langle ea|f\rangle=\langle f|ea\rangle^*=(\langle f|e\rangle a)^*=a^*\langle f|e\rangle^*=a^*\langle e|f\rangle,$$

i.e., we have $\mathbb{C}$*- and* $\mathcal{A}$*-sesqui-linearity;*
(3) The $\mathbb{C}$*-sesqui-linearity follows for unital* $\mathcal{A}$ *from the* $\mathcal{A}$*-sesqui-linearity.*
(4) For $e,f\in\mathcal{E}$ *we have* $\pi^*_{e,f}=\pi_{f,e}$ *so that indeed* $\mathcal{F}_{\mathcal{A}}(\mathcal{E})\subset\mathcal{L}_{\mathcal{A}}(\mathcal{E})$;
(5) $\mathcal{L}_{\mathcal{A}}(\mathcal{E})$ *and* $\mathcal{K}_{\mathcal{A}}(\mathcal{E})$ *are C*-algebras, the former is the multiplier algebra of the latter (Ref. 14, Chap. 15);*
(6) Everything analogous for left Hilbert modules;
(7) $\mathcal{A}\times\mathcal{A}\ni(a,b)\mapsto a^*b\in\mathcal{A}$ *together with multiplication of* $\mathcal{A}$ *on* $\mathcal{A}$ *on the right gives the standard Hilbert* $\mathcal{A}$*-module structure on* $\mathcal{A}$;
(8) $\mathcal{A}\times\mathcal{A}\ni(a,b)\mapsto ab^*\in\mathcal{A}$ *together with multiplication of* $\mathcal{A}$ *on* $\mathcal{A}$ *on the left gives the standard left Hilbert* $\mathcal{A}$*-module structure on* $\mathcal{A}$;

Definition 9 (free and projective Hilbert modules): A Hilbert $\mathcal{A}$*-module is called free if it is a free module over* $\mathcal{A}$. *It is called projective if it is a direct summand of a free module.*

Lemma 13 (left and right Hilbert modules): Let $\mathcal{A}$ *be a C*-*algebra *and* $(\mathcal{E},\langle\cdot|\cdot\rangle)$ *a left pre-Hilbert* $\mathcal{A}$*-module over* $\mathcal{A}$. *Then,*

$$\langle\cdot|\cdot\rangle^{\mathcal{E}^{\mathrm{op}}}:\mathcal{E}^{\mathrm{op}}\times\mathcal{E}^{\mathrm{op}}\to\mathcal{A}^{\mathrm{op}},\quad(e^{\mathrm{op}},f^{\mathrm{op}})\mapsto(\langle f|e\rangle)^{\mathrm{op}}\tag{B1}$$

defines on $\mathcal{E}=\mathcal{E}^{\mathrm{op}}$ *(equality as vector spaces) the structure of a pre-Hilbert* $\mathcal{A}^{\mathrm{op}}$*-module.*

Furthermore, for a left Hilbert $\mathcal{A}$*-module* $(\mathcal{E},\langle\cdot|\cdot\rangle)$ *we have* $\mathcal{F}_{\mathcal{A}}(\mathcal{E})\simeq\mathcal{F}_{\mathcal{A}^{\mathrm{op}}}(\mathcal{E}^{\mathrm{op}})$ *and therefore* $\mathcal{K}_{\mathcal{A}}(\mathcal{E})\simeq\mathcal{K}_{\mathcal{A}^{\mathrm{op}}}(\mathcal{E}^{\mathrm{op}})$ *and* $\mathcal{L}_{\mathcal{A}}(\mathcal{E})\simeq\mathcal{L}_{\mathcal{A}^{\mathrm{op}}}(\mathcal{E}^{\mathrm{op}})$.

Proof: It is well known that right $\mathcal{A}$-modules $\mathcal{E}$ and left $\mathcal{A}^{\mathrm{op}}$-modules $\mathcal{E}^{\mathrm{op}}$ are in one-to-one correspondence. So we just have to verify the corresponding Hilbert module structures: Let e^{op}, $f^{\mathrm{op}} \in \mathcal{E}^{\mathrm{op}}$, $a^{\mathrm{op}} \in \mathcal{A}^{\mathrm{op}}$. We denote by a^{op} and a corresponding elements in $\mathcal{A}^{\mathrm{op}}$ resp. $\mathcal{A}$. ($\mathcal{A}^{\mathrm{op}}$ and $\mathcal{A}$ are identical as Banach spaces, and in this sense $a^{\mathrm{op}}=a$.) Then,

$$\langle e^{\mathrm{op}}|f^{\mathrm{op}}a^{\mathrm{op}}\rangle^{\mathcal{E}^{\mathrm{op}}}=(\langle e^{\mathrm{op}}|(af)^{\mathrm{op}}\rangle)^{\mathrm{op}}=\langle af|e\rangle=a\langle f|e\rangle=(\langle f|e\rangle)^{\mathrm{op}}a^{\mathrm{op}}=\langle e^{\mathrm{op}}|f^{\mathrm{op}}\rangle^{\mathcal{E}^{\mathrm{op}}}a^{\mathrm{op}}.$$

Since $\mathcal{E}=\mathcal{E}^{\mathrm{op}}$ as Banach space we have $\mathcal{L}(\mathcal{E})\simeq\mathcal{L}(\mathcal{E}^{\mathrm{op}})$. Furthermore, for $e,f,x\in\mathcal{E}$,

$$\pi_{e,f}(x)=e\langle f|x\rangle=(\langle f|x\rangle)^{\mathrm{op}}e^{\mathrm{op}}=\langle x^{\mathrm{op}}|f^{\mathrm{op}}\rangle^{\mathcal{E}^{\mathrm{op}}}e^{\mathrm{op}}=\pi^{L}_{f^{\mathrm{op}},e^{\mathrm{op}}},$$

so that $\mathcal{F}_{\mathcal{A}}(\mathcal{E})$ and $\mathcal{F}_{\mathcal{A}^{\mathrm{op}}}(\mathcal{E}^{\mathrm{op}})$ are isomorphic, and so are the corresponding closures and multiplier algebras. □

Remark 14 (standard module): For the standard Hilbert $\mathcal{A}$-module structure on $\mathcal{A}$ it is well known that $\mathcal{F}_{\mathcal{A}}(\mathcal{A})=\mathcal{A}$, $\mathcal{K}_{\mathcal{A}}(\mathcal{A})=\mathcal{A}$ and $\mathcal{L}_{\mathcal{A}}(\mathcal{A})=\mathcal{M}(\mathcal{A})$. If we denote by $\mathcal{A}^{L}$ the standard left Hilbert $\mathcal{A}$-module then Lemma 13 shows: $\mathcal{F}_{\mathcal{A}}(\mathcal{A}^{L})\simeq\mathcal{F}_{\mathcal{A}^{\mathrm{op}}}(\mathcal{A}^{\mathrm{op}})=\mathcal{A}^{\mathrm{op}}$.

APPENDIX C: GNS REPRESENTATION FOR HILBERT *C**-MODULES

Let $\mathcal{A}$ be a C^*-algebra, τ a state on $\mathcal{A}$ and $\mathcal{E}$ a Hilbert $\mathcal{A}$-module. Analogously to the well know GNS representation of Banach $*$-algebras we define a scalar product on $\mathcal{E}$ by

$$\langle x|y\rangle_{\tau}:=\tau(\langle x|y\rangle_{\mathcal{E}}) \quad \text{for} \quad x,y\in\mathcal{E}. \tag{C1}$$

$N_{\tau}:=\{x\in\mathcal{E}|\langle x|x\rangle_{\tau}=0\}$ is the corresponding null space. Then the GNS representation space $\mathcal{E}_{\tau}$ is given by the completion of $\mathcal{E}/N_{\tau}$ with respect to $\langle\cdot|\cdot\rangle_{\tau}$. $L\in\mathcal{L}_{\mathcal{A}}(\mathcal{E})$ acts continuously on $x\in\mathcal{E}_{\tau}$ because

$$\begin{aligned}\|Lx\|_{\tau}^2=\langle Lx|Lx\rangle_{\tau}&=\tau(\langle Lx|Lx\rangle_{\mathcal{E}})\\&=\tau(\langle x|L^*Lx\rangle_{\mathcal{E}})\\&\leqslant\tau(\langle x|x\rangle_{\mathcal{E}})\|L^*L\|\\&=\|x\|_{\tau}^2\|L\|^2.\end{aligned}$$

Thus we have a $*$-representation of $\mathcal{L}_{\mathcal{A}}(\mathcal{E})$ in $\mathcal{L}(\mathcal{E}_{\tau})$.

If τ is faithful then $N_{\tau}=0$ so that the representation is faithful.

If $\mathcal{E}=\mathcal{A}$ with $\langle a|b\rangle_{\mathcal{E}}=a^*b$ is the standard Hilbert $\mathcal{A}$-module then we get back the usual GNS representation of the multiplier algebra $\mathcal{L}_{\mathcal{A}}(\mathcal{A})=\mathcal{M}(\mathcal{A})$ and, by restriction, the GNS representation of $\mathcal{K}_{\mathcal{A}}(\mathcal{A})=\mathcal{A}$.

For left Hilbert modules the scalar product must be reversed so that one gets complex linearity on the correct entry.

(Received 22 November 2000; accepted for publication 19 February 2001)

The one-dimensional (1D) SU(n) Hubbard model with open boundary condition is solved by using the coordinate Bethe ansatz method. The energy and integrable boundary conditions are obtained. At the same time, the corresponding Bethe ansatz equations are achieved by diagonalizing the inhomogeneous transfer matrix of the open SU($2n-2$) XXX vertex model. When $n=2$, our result comes back to that of the 1D Hubbard model given by Deguchi and Yue (con-mat/9704138). © *2001 American Institute of Physics.* [DOI: 10.1063/1.1368368]

I. INTRODUCTION

In the integrable models to describe the strongly correlated electron system, the one-dimensional (1D) Hubbard model is one of the well studied models. It was proposed in Refs. 1 and 2 in order to describe electrons hopping on a D-dimension lattice while experiencing an on-site interaction. Although much work has been done on the Hubbard model since Lieb-Wu's work,[3] the integrability was not shown until 1986 by Shastry,[4] Olmedilla and Wadati.[5] Moreover, the eigenvalue of the transfer matrix related to the Hubbard model was suggested in Ref. 4 and proved through different methods.[6,7] Based on the Lie algebra knowledge, Maassarani succeeded in generalizing Shastry's method to construct an SU(n) Hubbard model[8] by considering two coupled SU(n) XX models.[9] Furthermore, he found the related R-matrix which ensures the integrability of the one-dimensional SU(n) Hubbard model.[10] (It was also proved by Martins for $n=3,4$,[11] and by Yue and Sasaki for general n in terms of Lax-pair formalism.[12]) The exact solution for the SU(3) and SU(n) Hubbard model with period boundary condition was also given in Refs. 13 and 14, respectively.

Recently, the integrable models with open boundary and impurities boundary have attracted a lot of interest.[15–30] On the 1D Hubbard model with open boundary conditions, the integrability and the exact solution have been investigated by several authors.[22–24] However, for the SU(n) Hubbard model, due to the noninvertibility of the partial transposition of the R matrix, the generalized algebraic method[15] does not work on the model with open boundary conditions. At the same time, the exact solution for the model with open boundary conditions has not been obtained yet. In this paper, we will apply the coordinate Bethe ansatz method to solve the SU(n) Hubbard model with open boundary conditions.

This paper is organized as following. In Sec. II, we will describe the open boundary SU(n) Hubbard model and present the integrable boundary conditions. In Sec. III, we will diagonalize the transfer matrix of open boundary SU($2n-2$) XXX vertex model by using the nested Bethe ansatz method to obtain the Bethe ansatz equations for the open boundary SU(n) Hubbard model. Some discussions are included in Sec. IV.

II. COORDINATE BETHE ANSATZ FOR SU(n) HUBBARD

The Hamiltonian of the open SU(n) Hubbard model is

$$H=\sum_{k=1}^{\tilde{L}-1}\sum_{\alpha=1}^{n-1}\left(E_{\sigma,k}^{n\alpha}E_{\sigma,k+1}^{\alpha n}+E_{\sigma,k}^{\alpha n}E_{\sigma,k+1}^{n\alpha}+E_{\tau,k}^{n\alpha}E_{\tau,k+1}^{\alpha n}+E_{\tau,k}^{\alpha n}E_{\tau,k+1}^{n\alpha}\right)$$
$$+\frac{n^2U}{4}\sum_{k=1}^{\tilde{L}}C_{\sigma,k}C_{\tau,k}+\sum_{\alpha=1}^{n}\left(p_{\sigma\alpha}E_{\sigma,\tilde{L}}^{\alpha\alpha}+p_{\tau\alpha}E_{\tau,\tilde{L}}^{\alpha\alpha}+q_{\sigma\alpha}E_{\sigma,1}^{\alpha\alpha}+q_{\tau\alpha}E_{\tau,1}^{\alpha\alpha}\right), \tag{1}$$

where U is the Coulomb coupling constant and $E_{\rho,k}^{\alpha\beta}(\rho=\sigma,\tau)$ is a matrix with zeros everywhere except for a one at the intersection of row α and column β. The subscripts ρ and k stand for two different E operators at site $k(k=1,2,...,\tilde{L})$. The $(2n-2)\times(2n-2)$ diagonal matrix C is defined by $C=\Sigma_{\alpha=1}^{n-1}E^{\alpha\alpha}-E^{nn}$.

As in Ref. 13, we introduce the following particle state $|1\rangle_j,\cdots,|n-1\rangle_j$ and vacuum state $|0\rangle_j$ of the jth site:

$$|1\rangle_j=\begin{Bmatrix}1\\0\\\vdots\\0\\0\end{Bmatrix}_j,\quad |2\rangle_j=\begin{Bmatrix}0\\1\\\vdots\\0\\0\end{Bmatrix}_j,\quad\cdots,\quad |n-1\rangle_j=\begin{Bmatrix}0\\0\\\vdots\\1\\0\end{Bmatrix}_j,\quad |0\rangle_j=|n\rangle_j=\begin{Bmatrix}0\\0\\\vdots\\0\\1\end{Bmatrix}_j. \tag{2}$$

One can prove that $E_j^{\alpha n}$ and $E_j^{n\alpha}$ act as a creating and destroying operators of $|\alpha\rangle_j$, respectively.

In the coordinate Bethe ansatz method, the N particle eigenstates of the Hamiltonian can be assumed as

$$|\psi\rangle=\sum_{x_1\leqslant x_2\leqslant\cdots\leqslant x_N}f_{\rho_1\rho_2\cdots\rho_N}^{\alpha_1\alpha_2\cdots\alpha_N}E_{\rho_1x_1}^{\alpha_1n}E_{\rho_2x_2}^{\alpha_2n}\cdots E_{\rho_Nx_N}^{\alpha_Nn}|0\rangle. \tag{3}$$

Here $|0\rangle$ is the vacuum state of the total chain defined by $|0\rangle=\Pi_{j=1}^{\tilde{L}}\otimes|0\rangle_j$ and

$$f_{\rho_1\rho_2\cdots\rho_N}^{\alpha_1\alpha_2\cdots\alpha_N}=\sum_{Q,P}\epsilon_P\epsilon_QA_{\rho_{Q_1}\rho_{Q_2}\cdots\rho_{Q_N}}^{\alpha_{Q_1}\alpha_{Q_2}\cdots\alpha_{Q_N}}(k_{P_1},k_{P_2},\cdots,k_{P_N})\exp\left\{i\sum_{j=1}^{N}k_{P_j}x_{Q_j}\right\}\times\theta(x_{Q_1}\leqslant x_{Q_2}\leqslant\cdots\leqslant x_{Q_N}) \tag{4}$$

with

$$\theta(x_1\leqslant x_2\leqslant\cdots\leqslant x_N)=\begin{cases}1, & x_1<x_2<\cdots<x_N\\ \frac{1}{2}, & x_i=x_j(i\neq j,i,j=1,2,\cdots,N)\\ 0, & \text{others,}\end{cases} \tag{5}$$

where $\alpha_i\in[1,n-1](i\in[1,N])$ stands for different particle states, x_i the position of the particle, and $\rho_i=\sigma,\tau$ the type of the ith particle. The Q runs over S_N, the permutation group of N coordinates x_j, and P over all the permutations and the ways of negations of N momenta k_j. There are $N!\times2^N$ possibilities for P, while $N!$ for Q. ϵ_Q, ϵ_P denotes the sign of Q and P, respectively. For the permutation of P, if the permutation is even, P makes $\epsilon_P=-1$ for odd number of k's negative and $\epsilon_P=1$ for even number of k's negative. Substituting the wave function into the Schrödinger equation

$$H|\psi_N\rangle=E|\psi_N\rangle, \tag{6}$$

we have the following results:

$$A^{\cdots\alpha_i,\alpha_j,\cdots}_{\cdots\rho_i,\rho_j,\cdots}(\cdots,k_i,k_j,\cdots)=S^{\alpha_i\rho_i\ \ \alpha_j\rho_j}_{\alpha_i'\rho_i'\ \ \alpha_j'\rho_j'}(\sin k_i,\sin k_j)A^{\cdots\alpha_j',\alpha_i',\cdots}_{\cdots\rho_j',\rho_i'\cdots}(\cdots,k_j,k_i,\cdots), \tag{7}$$

$$A^{\alpha_1,\cdots}_{\rho_1,\cdots}(k_{P_1},\cdots)=M^{\alpha_1}_{\rho_1}(k_{P_1})A^{\alpha_1,\cdots}_{\rho_1,\cdots}(-k_{P_1},\cdots), \tag{8}$$

$$A^{\cdots,\alpha_N}_{\cdots,\rho_N}(\cdots,k_{P_N})=V^{\alpha_N}_{\rho_N}(-k_{P_N})A^{\cdots,\alpha_N}_{\cdots,\rho_N}(\cdots,-k_{P_N}) \tag{9}$$

with $S_{ij}(\sin k_i,\sin k_j)$ being the two-particle scattering matrix

$$S_{ij}(\sin k_i,\sin k_j)=\frac{(\sin k_i-\sin k_j)\tilde{I}+i\gamma\tilde{P}_{ij}}{\sin k_i-\sin k_j+i\gamma}, \tag{10}$$

where $\gamma=n^2U$, $\tilde{I}_{ij}=I^{\rho}_{ij}\otimes I^{\alpha}_{ij}$, $\tilde{P}_{ij}=P^{\rho}_{ij}\otimes P^{\alpha}_{ij}$ is the direct product of two kinds of permutation operators and permutes the particle styles and particle states simultaneously,

$$M^{\alpha_i}_{\rho_i}(k)=\frac{1+q^{\alpha_i}_{\rho_i}e^{-ik}}{1+q^{\alpha_i}_{\rho_i}e^{ik}}, \tag{11}$$

$$V^{\alpha_i}_{\rho_i}(k)=\frac{1+p^{\alpha_i}_{\rho_i}e^{-ik}}{1+p^{\alpha_i}_{\rho_i}e^{ik}}e^{2i(\tilde{L}+1)k} \tag{12}$$

with $q^{\alpha_i}_{\rho_i}=q_{\rho_i,n}-q_{\rho_i,\alpha_i}$, $p^{\alpha_i}_{\rho_i}=p_{\rho_i,n}-p_{\rho_i,\alpha_i}$. The energy of the Hamiltonian is

$$E=2\sum_{i=1}^{N}\cos k_i+\frac{\gamma}{2}(\tilde{L}-2N)+p_{\sigma n}+p_{\tau n}+q_{\sigma n}+q_{\tau n}. \tag{13}$$

From Eqs. (7)–(9), we can find that the amplitudes A satisfy

$$A^{\alpha_1,\cdots,\alpha_N}_{\rho_1,\cdots,\rho_N}(k_{P_1},\cdots k_{P_N})=\sum_{\{\rho_i',\alpha_i'\}}\{M(k_{P_1})X_{\hat{1}2}X_{\hat{1}3}\cdots X_{\hat{1}N}V(k_{P_1})\times X_{N1}X_{N-11}\cdots X_{21}\}^{\alpha_1\rho_1\cdots\alpha_N\rho_N}_{\alpha_1'\rho_1'\cdots\alpha_N'\rho_N'}A^{\alpha_1',\cdots,\alpha_N'}_{\rho_1',\cdots,\rho_N'}(k_{P_1},\cdots k_{P_N}), \tag{14}$$

where $X_{\hat{ij}}=S_{ij}(-\sin k_i,\sin k_j)$, $X_{ij}=S_{ij}(\sin k_i,\sin k_j)$,

$$M(k)=\mathrm{diag}(M^1_{\sigma}(k),\cdots,M^{n-1}_{\sigma}(k),M^1_{\tau}(k),\cdots,M^{n-1}_{\tau}(k)), \tag{15}$$

$$V(k)=\mathrm{diag}(V^1_{\sigma}(k),\cdots,V^{n-1}_{\sigma}(k),V^1_{\tau}(k),\cdots,V^{n-1}_{\tau}(k)). \tag{16}$$

From the point of the vertex model's view, the scattering matrix S_{ij} can be viewed as a SU($2n-2$) vertex model R_{ij}, which are defined by

$$R_{ij}(\sin k_i,-\sin k_j)=\frac{(\sin k_i-\sin k_j)I+\eta P_{ij}}{\sin k_i-\sin k_j+\eta}, \tag{17}$$

where $\eta=i\gamma$, I and P_{ij} are $(2n-2)^2\times(2n-2)^2$ identy matrix and permutation matrix, respectively. The notations $R_{ij}(u)=R_{ij}(u,0)$, $R_{ij}(u+v)=R_{ij}(u,v)$ will be used later. The R-matrix defined by (17) satisfies the Yang–Baxter equation

$$R_{12}(u-v)R_{13}(u)R_{23}(v)=R_{23}(v)R_{13}(u)R_{12}(u-v), \tag{18}$$

it also fulfills the following properties

$$P\text{-}T \text{ invariance:} \quad P_{12}R_{12}(u)P_{12}=R_{12}^{t_1t_2}(u), \tag{19}$$

$$\text{unitarity:} \quad R_{12}(u)R_{21}(-u)=1\cdot \mathrm{id}, \tag{20}$$

$$\text{crossing symmetry:} \quad R_{12}^{t_1}(u)R_{12}^{t_2}(-u-2(n-1)\eta)=\frac{u(u+2(n-1)\eta)}{(u+\eta)(u+(2n-3)\eta)}\cdot \mathrm{id}. \tag{21}$$

In order to diagonalize Eq. (14), we introduce the following operator $t(u)$:

$$t(u)=\mathrm{tr}_0\, K_0^+(u)T(u,\{-\sin k_i\})K_0^-(u)T(-u,\{-\sin k_i\})^{-1}, \tag{22}$$

where

$$T(u,\{-\sin k_i\})=L_{01}(u,-\sin k_1)L_{02}(u,-\sin k_2)\cdots L_{0N}(u,-\sin k_N) \tag{23}$$

with $L_{0j}(u,v)=R_{0j}(u,v)$. $K_0^+(u)$ and $K_0^-(u)$ are all $2(n-1)\times 2(n-1)$ diagonal matrices. If we choose

$$K_0^-(-\sin k)=\mathrm{diag}(V_\sigma^1(k),\cdots,V_\sigma^{n-1}(k),V_\tau^1(k),\cdots,V_\tau^{n-1}(k)), \tag{24}$$

$$K_0^+(-\sin k)=\mathrm{diag}(M_1^1(k),\cdots,M_1^{n-1}(k),M_2^1(k),\cdots,M_2^{n-1}(k)), \tag{25}$$

where

$$\begin{aligned} M_1^i(k)&=[-2\sin k+2(n-1)i\gamma]M_\sigma^i(k)-i\gamma\sum_{j=1}^{n-1}(M_\sigma^j(k)+M_\tau^j(k)),\\ M_2^i(k)&=[-2\sin k+2(n-1)i\gamma]M_\tau^i(k)-i\gamma\sum_{j=1}^{n-1}(M_\sigma^j(k)+M_\tau^j(k)), \end{aligned} \tag{26}$$

in terms of the operator $t(u)$ (22), Eq. (14) is given by the form

$$t(-\sin k_{P_1})\vec{A}(k_{P_1},\cdots,k_{P_N})=\frac{-2\sin k_{P_1}(-2\sin k_{P_1}+2(n-1)i\gamma)}{-2\sin k_{P_1}+i\gamma}\vec{A}(k_{P_1},\cdots,k_{P_N}), \tag{27}$$

where the eigenvalue is given by $-2\sin k_{P_1}(-2\sin k_{P_1}+2(n-1)i\gamma)/(-2\sin k_{P_1}+i\gamma)$. Now our attention is paid to the diagonalizing operator $t(u)$ (22), which is similar to the transfer matrix in the vertex model with open boundary conditions. If we know the eigenvalue $\Lambda(u)$ of $t(u)$, we will obtain the Bethe equations for the energy (13), which is

$$\Lambda(-\sin k_{P_1})=\frac{-2\sin k_{P_1}(-2\sin k_{P_1}+2(n-1)i\gamma)}{-2\sin k_{P_1}+i\gamma}. \tag{28}$$

The diagonalization of the $t(u)$ requires that $[t(u),t(v)]=0$ for arbitrary u, v, which means that the model is integrable. One can prove that only R matrix satisfy the unitary, crossing unitary properties, and $K^-(u)$,$K^+(u)$, respectively, satisfy the following reflection equations:[17]

$$R_{12}(u-v)K_1^-(u)R_{21}(u+v)K_2^-(v)=K_2^-(v)R_{12}(u+v)K_1^-(u)R_{21}(u-v), \tag{29}$$

$$R_{12}(-u+v)K_1^+(u)^{t_1}R_{21}(-u-v-2(n-1)\eta)K_2^+(v)^{t_2}$$
$$=K_2^+(v)^{t_2}R_{12}(-u-v-2(n-1)\eta)K_1^+(u)^{t_1}R_{21}(-u+v), \tag{30}$$

where $t(u)$ can be diagonalized. Solving the reflection equations (29) and (30), we have the following diagonal solution:

$$K^-(u,\xi)=\mathrm{diag}(P_1^A,P_2^A,\cdots,P_{2n-2}^A), \tag{31}$$

where

$$P_a^A(u,\xi)=\begin{cases}\xi+u, & 1\leqslant a\leqslant A\\ \xi-u, & A<a\leqslant 2n-2\end{cases} \tag{32}$$

and

$$K^+(u,\tilde{\xi})=\mathrm{diag}(P_1^B,P_2^B,\cdots,P_{2n-2}^B) \tag{33}$$

with

$$P_a^B(u,\tilde{\xi})=\begin{cases}\tilde{\xi}-u-(n-1)\eta, & 1\leqslant a\leqslant B\\ \tilde{\xi}+u+(n-1)\eta, & B<a\leqslant 2n-2.\end{cases} \tag{34}$$

In Eqs. (32) and (34), ξ and $\tilde{\xi}$ both are free parameters. The integer numbers A and B are also free parameters which take values from 1 to $2n-2$. Comparing Eq. (24) with Eq. (31), and Eq. (25) with Eq. (32), we can get the constraint relation between ξ, $\tilde{\xi}$ and $p_{\rho,\alpha}$, $q_{\rho,\alpha}$. The relations are given as follows:

$$\begin{gathered}p_\sigma^1=\cdots=p_\sigma^A=p,\\ p_\sigma^{A+1}=\cdots=p_\sigma^{n-1}=p_\tau^1=\cdots=p_\tau^{n-1}=-p,\quad A\in[1,n-1],\\ p_\sigma^1=\cdots=p_\sigma^{n-1}=p_\tau^1=\cdots=p_\tau^{A-n+1}=p,\\ p_\tau^{A-n+2}=\cdots=p_\tau^{n-1}=-p,\quad A\in[n,2n-2],\end{gathered} \tag{35}$$

$$\begin{gathered}q_\sigma^1=\cdots=q_\sigma^B=q,\\ q_\sigma^{B+1}=\cdots=q_\sigma^{n-1}=q_\tau^1=\cdots=q_\tau^{n-1}=-q,\quad B\in[1,n-1]\\ q_\sigma^1=\cdots=q_\sigma^{n-1}=q_\tau^1=\cdots=q_\tau^{B-n+1}=q,\\ q_\tau^{B-n+2}=\cdots=q_\tau^{n-1}=-q,\quad B\in[n,2n-2]\end{gathered} \tag{36}$$

with

$$\xi=\begin{cases}\infty & \text{for } A=2n-2\\ \dfrac{1-p^2}{2ip} & \text{for } A\in[1,2n-3],\end{cases}\qquad \tilde{\xi}=\begin{cases}\infty & \text{for } B=2n-2\\ -\dfrac{1-q^2}{2iq}-i(n-1-B)\gamma & \text{for } B\in[1,2n-3].\end{cases} \tag{37}$$

In Sec. III we will diagonalize Eq. (22) with K^- and K^+ taking the form of Eqs. (31) and (33), respectively.

III. NESTED BETHE ANSATZ

Let

$$U(u)=T(u)K^{-}(u)T^{-1}(u), \tag{38}$$

one can prove that double-row monodromy matrix $U(u)$ satisfies the reflection equation

$$R_{12}(u-v)U_1(u)R_{21}(u+v)U_2(v)=U_2(v)R_{12}(u+v)U_1(u)R_{21}(u-v). \tag{39}$$

Rewriting Eq. (39) in the component form

$$R_{12}(u_-)^{a_1a_2}_{c_1c_2}U(u)_{c_1d_1}R_{21}(u_+)^{d_1c_2}_{b_1d_2}U(v)_{d_2b_2}=U(v)_{a_2c_2}R_{12}(u_+)^{a_1c_2}_{c_1d_2}U(u)_{c_1d_1}R_{21}(u_-)^{d_1d_2}_{b_1b_2}, \tag{40}$$

where the repeated indices sum over 1 to $2n-2$, $u_-=u-v$, $u_+=u+v$ and introducing a set of notations for convenience:

$$\begin{gathered}A(v)=U(v)_{11},\quad B_a(v)=U(v)_{1a},\quad C_a(v)=U(v)_{a1},\\ D_{ab}(v)=U(v)_{ab},2\leqslant a,b\leqslant 2n-2\end{gathered} \tag{41}$$

we have the commutation relations from Eq. (40)

$$B_{b_1}(u_1)B_{b_2}(u_2)=R_{12}(u_1-u_2)^{d_2d_1}_{b_2b_1}B_{d_2}(u_2)B_{d_1}(u_1), \tag{42}$$

$$\begin{aligned}A(v)B_b(u)=&\frac{a(u-v)b(u+v)}{a(u+v)b(u-v)}B_b(u)A(v)-\frac{b(2u)c(u-v)}{a(2u)b(u-v)}B_b(v)A(u)\\&-\frac{c(u+v)}{a(u+v)}B_c(v)\tilde{D}_{cb}(u),\end{aligned} \tag{43}$$

$$\begin{aligned}\tilde{D}_{a_1b_1}(u)B_{b_2}(v)=&\frac{a(u-v)a(u+v+\eta)}{b(u-v)b(u+v+\eta)}R_{12}(u+v+\eta)^{a_1c_2}_{c_1d_2}R_{21}(u-v)^{d_1d_2}_{b_1b_2}B_{c_2}(v)\tilde{D}_{c_1d_1}(u)\\&-\frac{a(2u+\eta)c(u-v)}{b(2u+\eta)b(u-v)}R_{12}(2u+\eta)^{a_1d_1}_{d_2b_1}B_{d_1}(u)\tilde{D}_{d_2b_2}(v)\\&+\frac{a(2u+\eta)}{b(2u+\eta)}\frac{c(u+v)b(2v)}{a(u+v)a(2v)}R_{12}(2u+\eta)^{a_1d_2}_{b_2b_1}B_{d_2}(u)A(v),\end{aligned} \tag{44}$$

where all indices take values from 2 to $2n-2$, and the repeated indices sum over 2 to $2n-2$. The notations $a(u)=u+\eta$, $b(u)=u$, $c(u)=\eta$ are used. The new operators $\tilde{D}$ are defined by

$$\tilde{D}_{ab}(v)=D_{ab}(v)-\delta_{ab}\frac{R_{12}(2v)^{a1}_{1a}}{R_{12}(2v)^{11}_{11}}A(v). \tag{45}$$

Introducing the vacuum state,

$$|\mathrm{vac}\rangle=\prod^{\otimes N}(1,0,...,0)^t, \tag{46}$$

where t denotes the transposition and $(1,0,\cdots,0)$ is a $1\times 2(n-1)$ matrix. The action of the double-row monodromy matrix on the vacuum state is

$$A(u)|\mathrm{vac}\rangle = K_1^-(u)|\mathrm{vac}\rangle = \alpha^{(1)}(u)|\mathrm{vac}\rangle,$$

$$\tilde{D}_{ab}(u)|\mathrm{vac}\rangle = \delta_{ab}\left(K_a^-(u) - \frac{c(2u)}{a(2u)}K_1^-(u)\right)\frac{a(2u)}{b(2u)}\beta^{(1)}(u)|\mathrm{vac}\rangle,$$

$$C_a(u)|\mathrm{vac}\rangle = 0, \quad B_a(u)|\mathrm{vac}\rangle \neq 0, \tag{47}$$

where $\alpha^{(1)}(u)$ and $\beta^{(1)}(u)$ are defined by Eqs. (58) and (59), respectively. Note that the action of $B_a(u)$ on the vacuum state is not proportional to the vacuum state. Now we construct the eigenvectors of transfer matrix $t(u)$. It takes the form

$$\Psi(v_1,\cdots,v_L) = B_{b_1}(v_1)\cdots B_{b_L}(v_L)|\mathrm{vac}\rangle F^{b_1\cdots b_L}. \tag{48}$$

Using Eq. (22), we then obtain the action of $t(u)$ on Ψ,

$$\begin{aligned}
t(u)\Psi = {} & \alpha^{(1)}(u)S_1(u)\prod_{j=1}^{L}\frac{a(v_j-u)b(v_j+u)}{b(v_j-u)a(v_j+u)}\times F^{b_1\cdots b_L}B_{b_1}(v_1)\cdots B_{b_L}(v_L)|\mathrm{vac}\rangle \\
& + \prod_{j=1}^{L}\frac{a(u-v_j)a(u+v_j+\eta)}{b(u-v_j)b(v_j+u+\eta)}\beta^{(1)}(u)\tau^{(2)}(\tilde{u},\{\tilde{v}_i\})_{b_1\cdots b_L}^{d_1\cdots d_L} \\
& \times F^{b_1\cdots b_L}B_{d_1}(v_1)\cdots B_{d_L}(v_L)|\mathrm{vac}\rangle \\
& + \sum_{k=1}^{L}\left(\frac{-c(v_k-u)}{b(v_k-u)}S_1(u) + \frac{c(v_k+u)a(2u+\eta)}{a(v_k+u)b(2u+\eta)}T_1(u)\right)\frac{b(2v_k)}{a(2v_k)} \\
& \cdot \prod_{j=1,\neq k}^{L}\frac{a(v_j-v_k)b(v_j+v_k)}{b(v_j-v_k)a(v_j+v_k)}\alpha^{(1)}(v_k)S(v_k,\{v_i\})_{b_1\cdots b_L}^{d_1\cdots d_L}F^{b_1\cdots b_L} \\
& \cdot B_{d_1}(u)b_{d_2}(v_1)\cdots B_{d_k}(v_{k-1})B_{d_{k+1}}(v_{k+1})\cdots B_{d_L}(v_L)|\mathrm{vac}\rangle \\
& - \sum_{k=1}^{L}\left(\frac{c(u+v_k)}{a(u+v_k)}S_1(u) + \frac{c(u-v_k)a(2u+\eta)}{b(u-v_k)b(2u+\eta)}T_1(u)\right) \\
& \times \frac{\beta^{(1)}(v_k)}{T_1(v_k)}\prod_{j=1,\neq k}^{L}\frac{a(v_k-v_j)a(v_j+v_k+\eta)}{b(v_k-v_j)b(v_j+v_k+\eta)}\times S(v_k,\{v_i\})_{c_1\cdots c_L}^{d_1\cdots d_L}\tau^{(2)} \\
& \times(\tilde{v}_k,\{\tilde{v}_i\})_{b_1\cdots b_L}^{c_1\cdots c_L}F^{b_1\cdots b_L}\times B_{d_1}(u)b_{d_2}(v_1)\cdots B_{d_k}(v_{k-1})B_{d_{k+1}}(v_{k+1})\cdots B_{d_L}(v_L)|\mathrm{vac}\rangle,
\end{aligned} \tag{49}$$

where

$$\begin{aligned}
\tau^{(2)}(\tilde{u},\{\tilde{v}_i\})_{b_1\cdots b_L}^{c_1\cdots c_L} &= \sum_{a=2}^{m+n}K_a^+(u)\{(L^{(1)}(\tilde{u},\tilde{v}_1)\cdots L^{(1)}(\tilde{u},\tilde{v}_L)K^-(\tilde{u},\xi^{(1)}) \\
&\quad \cdot L^{(1)}(-\tilde{u},\tilde{v}_L)^{-1}\cdots L^{(1)}(-\tilde{u},\tilde{v}_1)^{-1})_{b_1\cdots b_L}^{c_1\cdots c_L}\}_{aa} \\
&= \sum_{a=2}^{m+n}K_a^+(u)\{(T^{(1)}(\tilde{u},\{\tilde{v}_i\})K^-(\tilde{u},\xi^{(1)})T^{(1)}(-\tilde{u},\{\tilde{v}_i\})^{-1})_{b_1\cdots b_L}^{c_1\cdots c_L}\}_{aa}
\end{aligned} \tag{50}$$

with $\tilde{u}=u+\eta/2$, $\xi^{(1)}=\xi-\eta/2$, $\tilde{v}_i=v_i+\eta/2$. $S_1(u)$ is defined by Eq. (56), $T_1(u)$ is defined by Eq. (57) and

$$S(v_k,\{v_i\})^{d_1\cdot d_L}_{b_1\cdots b_L}=\prod_{j=1+k}^{L}\delta_{b_jd_j}R_{12}(v_1-v_k)^{d_1d_2}_{c_2b_1}R_{12}(v_2-v_k)^{c_2d_3}_{c_3b_2}\times\cdots R_{12}(v_{k-1}-v_k)^{c_{k-1}d_k}_{b_kb_{k-1}}. \tag{51}$$

From Eq. (49), one can see that the function Ψ is not the eigenstate of $t(u)$ unless F's are the eigenstates of $\tau^{(2)}$ and the sum of the third and the fourth term in Eq. (49) is zero, which will give a restriction on the L spectrum parameters $\{v_i\}$. So, we arrive at the following results.

If F is the eigenstate of $\tau^{(2)}$ with the eigenvalue $\Lambda^{(2)}$ satisfying Eq. (53), then Ψ is the eigenstate of $t(u)$ with the eigenvalue $\Lambda^{(1)}$,

$$\begin{aligned}\Lambda^{(1)}(u)=&\alpha^{(1)}(u)S_1(u)\prod_{j=1}^{L}\frac{a(v_j-u)b(v_j+u)}{b(v_j-u)a(v_j+u)}\\&+\beta^{(1)}(u)\prod_{j=1}^{L}\frac{a(u-v_j)a(u+v_j+\eta)}{b(u-v_j)b(v_j+u+\eta)}\Lambda^{(2)}(u,\{v_i\}),\end{aligned} \tag{52}$$

where

$$\begin{aligned}&\tau^{(2)}(u,\{v_i\})F=\Lambda^{(2)}(u,\{v_i\})F,\\&\Lambda^{(2)}(v_k,\{v_i\})=\frac{\alpha^{(1)}(v_k)b(2v_k)T_1(v_k)}{\beta^{(1)}(v_k)a(2v_k)}\prod_{j=1,\neq k}^{L}\frac{b(v_j+v_k)a(v_j-v_k)}{-a(v_k-v_j)a(v_k+v_j+\eta)}.\end{aligned} \tag{53}$$

Therefore, the diagonalization of $t(u)$ is reduced to finding the eigenvalue of $\tau^{(2)}$. The explicit expression of $\tau^{(2)}$ [see Eq. (49)] implies that $\tau^{(2)}$ can be considered as the transfer matrix of an L-sites quantum chain, in which every spin takes $2n-3$ values. The related Yang–Baxter equation is the same as the one of $t(u)$, except R being an $(2n-3)^2\times(2n-3)^2$ matrix. Hence, we can use the same method to find the eigenvalue of $\tau^{(2)}$. Repeating the procedure $2n-4$ times again, we have the following result:

$$\begin{aligned}\Lambda^{(k)}(u,\{v_i^{(k-1)}\},\{v_i^{(k)}\})=&S_k(u)\alpha^{(k)}(u,\{v_i^{(k-1)}\})\cdot\prod_{j=1}^{L_k}\frac{a(v_j^{(k)}-u)b(u+v_j^{(k)}+(k-1)\eta)}{b(v_j^{(k)}-u)a(u+v_j^{(k)}+(k-1)\eta)}\\&+\beta^{(k)}(u,\{v_i^{(k-1)}\})\prod_{j=1}^{L_k}\frac{a(u-v_j^{(k)})a(u+v_j^{(k)}+k\eta)}{b(u-v_j^{(k)})b(u+v_j^{(k)}+k\eta)}\\&\cdot\Lambda^{(k+1)}(u,\{v_i^{(k)}\},\{v_i^{(k+1)}\})\quad(1\leqslant k\leqslant 2n-3)\end{aligned} \tag{54}$$

and

$$\begin{aligned}\Lambda^{(k+1)}(v_l^{(k)},\{v_i^{(k)}\},\{v_i^{(k+1)}\})=&\frac{\alpha^{(k)}(v_l^{(k)},\{v_i^{(k-1)}\})2v_l^{(k)}+(k-1)\eta}{\beta^{(k)}(v_l^{(k)},\{v_i^{(k-1)}\})}\frac{2v_l^{(k)}+(k-1)\eta}{2v_l^{(k)}+k\eta}T_k(v_l^{(k)})\\&\cdot\prod_{j=1,\neq l}^{L_k}\frac{(v_l^{(k)}+v_j^{(k)}+(k-1)\eta)(v_l^{(k)}-v_j^{(k)}-\eta)}{(v_l^{(k)}+v_j^{(k)}+(k+1)\eta)(v_l^{(k)}-v_j^{(k)}+\eta)},(1\leqslant k\leqslant 2n-3)\end{aligned} \tag{55}$$

where

$$S_k(u)=\begin{cases}(\tilde{\xi}+(n-1)\eta-B\eta-u)\dfrac{2u+2(n-1)\eta}{2u+k\eta}, & 1\leqslant k\leqslant B\\ (\tilde{\xi}+(n-1)\eta+u)\dfrac{2u+2(n-1)\eta}{2u+k\eta}, & B<k\leqslant 2n-2\end{cases} \tag{56}$$

and

$$T_k(u)=\begin{cases}(\tilde{\xi}+(n-1)\eta-B\eta-u)\dfrac{2u+2(n-1)\eta}{2u+(k+1)\eta}, & 1\leqslant k\leqslant B\\ (\tilde{\xi}+(n-1)\eta+u)\dfrac{2u+2(n-1)\eta}{2u+(k+1)\eta}, & B<k\leqslant 2n-3,\end{cases} \tag{57}$$

$$\alpha^{(k)}(u,\{v_i^{(k-1)}\})=\begin{cases}\xi+u, & 1\leqslant k\leqslant A\\ \xi-A\eta-u, & A<k\leqslant 2n-2,\end{cases} \tag{58}$$

$$\beta^{(k)}(u,\{v_i^{(k-1)}\})=\prod_{j=1}^{L_{k-1}}\frac{(u+v_j^{(k-1)}+(k-1)\eta)(u-v_j^{(k-1)})}{(u+v_j^{(k-1)}+k\eta)(u-v_j^{(k-1)}+\eta)}\frac{2u+(k-1))\eta}{2u+k\eta}. \tag{59}$$

In the above-mentioned representation, $v_j^{(1)}=v_j$, $v_j^{(0)}=-\sin k_{P_j}$, $L_0=N$, $L_1=L$, $L_{2n-2}=0$, and $\Lambda^{(2n-1)}=0$, $\Pi^0=1$ are assumed. Notice that $\beta^{(k)}(u,\{v_i^{k-1}\})$ vanishes at the special points $v_i^{(k-1)}$ due to the factor $u-v_i^{(k-1)}$ appearing in $\beta^{(k)}$. Taking $u=v_i^{(k-1)}$ in formula (54), we can get another kind of constraints on $\Lambda^{(k)}$,

$$\begin{aligned}\Lambda^{(k)}(v_l^{(k-1)},\{v_i^{(k-1)}\},\{v_i^{(k)}\})=&\alpha^{(k)}(v_l^{(k-1)},(v_i^{(k-1)}\})S_k(v_l^{k-1})\\ &\cdot\prod_{j=1}^{L_k}\frac{(v_j^{(k)}-v_l^{(k-1)}+\eta)(v_j^{(k)}+v_l^{(k-1)}+(k-1)\eta)}{(v_j^{(k)}-v_l^{(k-1)})(v_j^{(k)}+v_l^{(k-1)}+k\eta)},\\ &1\leqslant k\leqslant 2n-3.\end{aligned} \tag{60}$$

Now, changing the index k into $k+1$ in the above formula (60), we can obtain constrains on $\Lambda^{(k+1)}$. Comparing these with Eq. (55), one can derive out the following Bethe ansatz equations

$$\begin{aligned}&\prod_{j=1}^{L_{k-1}}\frac{(v_l^{(k)}-v_j^{(k-1)}+\eta)(v_l^{(k)}+v_j^{(k-1)}+k\eta)}{(v_l^{(k)}-v_j^{(k-1)})(v_l^{(k)}+v_j^{(k-1)}+(k-1)\eta)}\cdot\prod_{j=1}^{L_{k+1}}\frac{(v_l^{(k)}-v_j^{(k+1)})(v_l^{(k)}+v_j^{(k+1)}+(k+1)\eta)}{(v_l^{(k)}-v_j^{(k+1)}-\eta)(v_l^{(k)}+v_j^{(k+1)}+(k\eta)}\\ &\cdot\prod_{j=1,\neq l}^{L_k}\frac{(v_l^{(k)}-v_j^{(k)}-\eta)(v_l^{(k)}+v_j^{(k)}+(k-1)\eta)}{(v_l^{(k)}-v_j^{(k)}+\eta)(v_l^{(k)}+v_j^{(k)}+(k+1)\eta)}=\frac{S_{k+1}(v_l^{(k)})\alpha^{(k+1)}(v_l^{(k)})}{T_k(v_l^{(k)})\alpha^{(k)}(v_l^{(k)})},\quad 1\leqslant k\leqslant 2n-3.\end{aligned} \tag{61}$$

The function $\Lambda^{(1)}(u,\ldots)$ must not be singular at $u=v_j^{(k)}$ $(1\leqslant j\leqslant L_k,\ 1\leqslant k\leqslant 2n-3)$ since the transfer matrix $t(u)$ is an analytic function of u. In fact, Eq. (53) comes from the condition under which the unwanted term vanishes. One can understand this constraint from another point of view: From Eq. (52), we know that $u=v_j=v_j^{(1)}$ is a pole of $\Lambda^{(1)}(u)$. In order to keep the analyticity of $\Lambda^{(1)}(u)$, one should need the residue of $\Lambda^{(1)}(u)$ at v_j vanishing, which also gives the constraint (53). So, $\Lambda^{(1)}(u)$ is analytic at v_j. Similarly, Eq. (64) ensures the anlayticity of $\Lambda^{(1)}(u)$ at all $v_j^{(k)}$. Therefore, the eigenvalues of the transfer matrix are analytic functions if the previous Bethe ansatz equations are satisfied. Substituting

$$\Lambda(-\sin k)=\frac{-2\sin kM_\sigma^1(k)V_\sigma^1(k)}{(\tilde{\xi}+\sin k+(n-1-B)i\gamma)(\xi-\sin k)}\Lambda^{(1)}(-\sin k) \tag{62}$$

into Eq. (28), we then obtain all the Bethe ansatz equations for the SU(n) Hubbard model with open boundary conditions which take the following forms:

$$\frac{(1+qe^{ik_{P_1}})(p+e^{-ik_{P_1}})}{(1+qe^{-ik_{P_1}})(p+e^{ik_{P_1}})}e^{-2i\tilde{L}k_{P_1}}=\prod_{j=1}^{L_1}\frac{(w_j^{(1)}+\sin k_{P_1}+\eta/2)(w_j^{(1)}-\sin k_{P_1}-\eta/2)}{(w_j^{(1)}+\sin k_{P_1}-\eta/2)(w_j^{(1)}-\sin k_{P_1}+\eta/2)}, \tag{63}$$

$$\prod_{j=1}^{L_{k-1}}\frac{(w_l^{(k)}-w_j^{(k-1)}-\eta/2)(w_l^{(k)}+w_j^{(k-1)}-\eta/2)}{(w_l^{(k)}-w_j^{(k-1)}+\eta/2)(w_l^{(k)}+w_j^{(k-1)}+\eta/2)}\cdot\prod_{j=1}^{L_{k+1}}\frac{(w_l^{(k)}-w_j^{(k+1)}-\eta/2)(w_l^{(k)}+w_j^{(k+1)}-\eta/2)}{(w_l^{(k)}-w_j^{(k+1)}+\eta/2)(w_l^{(k)}+w_j^{(k+1)}+\eta/2)}$$
$$\times\prod_{j=1,\neq l}^{L_k}\frac{(w_l^{(k)}-w_j^{(k)}+\eta)(w_l^{(k)}+w_j^{(k)}+\eta)}{(w_l^{(k)}-w_j^{(k)}-\eta)(w_l^{(k)}+w_j^{(k)}-\eta)}=\frac{T_k(w_l^{(k)}-k\eta/2)\alpha^{(k)}(w_l^{(k)}-k\eta/2)}{S_{k+1}(w_l^{(k)}-k\eta/2)\alpha^{(k+1)}(w_l^{(k)}-k\eta/2)},$$
$$(1\leqslant k\leqslant 2n-3). \tag{64}$$

In the above representations Eqs. (63) and (64), $v_j^{(k)}=w_j^{(k)}-k\eta/2$, $v_j^{(0)}=-\sin k_{P_j}$.

IV. SUMMARY

We obtain the energy and the integrable open boundary conditions for the open boundary SU(n) Hubbard model by using the coordinate Bethe ansatz method. The Bethe ansatz equations are achieved by diagonalizing the inhomogeneous transfer matrix of the open SU($2n-2$) XXX vertex model. Using these Bethe ansatz equations one can study the boundary contributions to the thermodynamical quantities such as special heat and magnetic susceptibility. When $n=2$, our result coincides with that obtained by Deguchi and Yue.[23]

However, there is a shortage in our results. We only get the eigenvalue of the Hamiltonian instead of all the conserved quantities. There may be other alternative ways to deal with this problem.

On the observables describing a quantum reference frame

S. Mazzucchi[a)]
Department of Mathematics of the University, I-38050 Trento, Italy

(Received 22 September 2000; accepted for publication 13 March 2001)

A reference frame F is described by the element g of the Poincaré group $\mathcal{P}$ which connects F with a given fixed frame F_0. If F is a quantum frame, defined by a physical object following the laws of quantum physics, the parameters of g have to be considered as quantum observables. However, these observables are not compatible and some of them, namely the coordinates of the origin of F, cannot be represented by self-adjoint operators. Both these difficulties can be overcome by considering a positive-operator-valued measure on $\mathcal{P}$, covariant with respect to the left translations of the group, namely a covariance system. We develop a construction procedure for this kind of mathematical structure. The formalism is also used to discuss the quantum observables measured with respect to a quantum reference frame. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1370395]

I. INTRODUCTION

As Mach remarked at the end of the nineteenth century,[1] from the physical point of view a frame of reference is defined by a material object of the same nature as the objects that form the system under investigation and the measuring instruments. Such an idea does not conflict with classical mechanics: for example a rigid body can define a spatial origin and an orientation. The situation becomes more complicated in quantum mechanics: Heisenberg's uncertanty relations forbid the exact determination of the position and the velocity of a frame. As noted by some authors,[2] such an analysis not only contributes to remove a classical concept from quantum mechanics, but also reveals some surprising physical consequences, such as the ''paradox of the quantum frames.'' That is, if we have three frames of reference, F_1,F_2 and F_3, the observables that describe the relation between F_1 and F_2 may not be compatible with the observables that describe the relation between F_2 and F_3, even if the systems do not interact.

We follow an operational approach: the mathematical structures involved should have a direct physical meaning. From this point of view, a frame is determined by the procedures that transform an initial frame into the chosen one. The set of the transformations allowed by a relativistic theory is represented by the proper orthochronous Poincaré group $\mathcal{P}$. Each element of $\mathcal{P}$ can be identified by means of ten indipendent parameters, indicating the coordinates of the new origin in the Minkowsky space–time, the three components of the velocity and three angles of orientation. From a physical point of view these ten variables can be determined by their measurement performed on the physical object defining the frame: They have to be considered observables. Unfortunately spectral measures, the mathematical structures traditionally associated to the physical concept of observables in quantum mechanics, cannot describe either simultaneous measurements of position and velocity or measurements of time (Pauli's theorem). According to Gleason's theorem, the natural generalization of spectral measures, compatible with the ''Copenhagen interpretation,'' is given by the so-called *positive operator value measures* (POVMs).[3–5]

An observable is often characterized by its transformation properties under a particular symmetry group. We can define a *system of covariance* as a POVM endowed with its covariance properties under some symmetry group.[6–8] If a POVM reduces to a spectral measure, the structure so defined is called a system of imprimitivity.[9]

a)Electronic mail: mazzucch@science.unitn.it

Following some hints that can be found in Ref. 8, in Sec. II we illustrate a general construction procedure for covariant observables, which allows one to assign the statistical distribution of the outcomes to the state vector of the system on which the measurement is performed. The cornerstones of our procedure are three theorems. The first one (covariant dilatation) asserts that any system of covariance can be derived from a suitable system of imprimitivity to which it is linked by means of a suitable ''intertwining operator.'' The second theorem is Mackey's imprimitivity theorem, which allows us to find the most general form of a system of imprimitivity. The third one is the ''intertwining operator theorem,'' which we derived in order to find the most general intertwining operator connecting the systems of imprimitivity to the unknown system of covariance. Its application is possible when the unitary representations of the symmetry group acting on the involved Hilbert spaces are decomposed into irreducible unitary representations.

We stress that our results are very general and allow one to describe all the possible measurements of a given observable, defined by its spectrum and its transformation properties under a relevant symmetry group, performed on a physical system which is identified by its covariance properties under the same group. We do not introduce any model, but use general symmetry properties of the measurement, to get all the POVMs describing a chosen observable.

In Sec. III, the developed procedure is used for a new derivation of the most general POVM on Minkowsky space–time which is covariant with respect to the Poincaré group, found in Ref. 10 by means of a different method.

Coming back to quantum frames in Sec. IV, their description can be given by a system of covariance on the proper orthochronous Poincaré group, which is in this case both the parameter space and the symmetry group. Harmonic analysis on $\mathrm{SL}(2C)$ and on the group of translations of $\mathbf{R}^4$ allows the decomposition of the most general unitary representation of $\mathcal{P}$ into irreducible unitary representations. In this way, the intertwining operator theorem can be applied and the most general probability distribution can be found.

A comparison with the Poincaré covariant POVM on Minkowsky space–time indicates the existence of some constraints. In particular the so-called baricentric measures cannot be obtained: In other words one cannot require that the coordinates of the origin coincide with the coordinates of the center of mass of the physical system defining the frame. Moreover through an analysis of our results, one realizes that, for a complete description of a quantum reference frame, kinematical variables are not sufficient and internal degrees of freedom of the system have to be involved.

Finally, the formalism we adopted also allows an alternative derivation of the paradox of the quantum frames. Indeed, in Sec. V, we derive the form of the POVMs describing the relative observables between a generical quantum object and a quantum reference frame. The observables describing the relations between noninteracting quantum frames are just a particular case.

We hope that an analysis of the variances of the probability distributions we have found will give a new class of indeterminacy relations.

II. MATHEMATICAL TOOLS

In the traditional framework of quantum mechanics, the states of a system are described by rays in a complex separable Hilbert space, or by normalized positive trace class operators, while observables are described by self-adjoint operators or, equivalentely, by spectral measures. It is well known that the last ones cannot describe either joint measurements of incompatible observables, or measurements of time, indeed Pauli's theorem[11,12] forbids the description by means of a self-adjoint operator of an observable canonically conjugate to a Hamiltonian with a semibounded spectrum. Nevertheless, as noted by some authors,[8,13,14] the description of some measuring instruments requires a different mathematical structure, which can be recognized as a generalization of spectral measures: the so-called POVMs. Gleason's theorem assures us that they are the most general mathematical structures describing observables compatible with the probabilistic interpretation of quantum mechanics.

The analysis of the proof of Pauli's theorem, shows that it is based on the covariance of time measurements with respect to time translations. This is not accidental, but shows the importance of

symmetry in our discussion. Indeed, the requirement of precise covariance properties of the quantum measurement under some symmetry group $\mathcal{G}$ leads to the following definition of covariance systems.[6]

Notation: From now on:

(1) S will indicate a topological space that is locally compact and has a countable base of its topology. S is called the ''space of the possible results of the measurement.''
(2) $\mathcal{H}$ will indicate a complex separable Hilbert space. $\mathcal{H}$ is called ''the space of states (of the quantum system).''
(3) $\mathcal{G}$ will indicate a locally compact topological group which has a countable base of its topology. $\mathcal{G}$ is called the ''symmetry group of the theory.''

Definition 1: Let $\mathcal{H}$ be a space of states and S be a space of possible results. A POVM on S is a class $\tau := \{\tau(I)\}_{I\in\mathcal{B}(S)}$, where $\mathcal{B}$ is the σ-algebra of Borel sets of S and each $\tau(I):\mathcal{H}\to\mathcal{H}$ is a positive bounded operator such that:
(1) $\tau(I)\geqslant\tau(\varnothing)=0 \quad \forall I\in\mathcal{B}$,
(2) $\tau(\cup I_i)=\Sigma\tau(I_i)$,
(3) $\tau(S)=1$,

where $\{I_i\}$ is a countable collection of disjoint elements of $\mathcal{B}$ and the convergence is in the weak topology.

Given a space of states $\mathcal{H}$, a space of possible results S and a POVM $\{\tau(I)\}_{I\in\mathcal{B}(S)}$, for any pure state of the system determined by a normalized vector $\phi\in\mathcal{H}$, the probability that the outcome of the measurement of the observable described by $\{\tau(I)\}_{I\in\mathcal{B}(S)}$ belongs to the Borel set I is

$$P(\phi,I)=\langle\phi,\tau(I)\phi\rangle. \tag{1}$$

More generally, for any mixed state of the system determined by a normalized positive trace class operator ρ on $\mathcal{H}$, the probability above is given by

$$P(\rho,I)=\mathrm{Tr}[\rho\tau(I)]. \tag{2}$$

Note: If $\tau(I_1\cap I_2)=\tau(I_1)\cdot\tau(I_2)$ for all $I_1,I_2\in\mathcal{B}$, then τ is a spectral measure.

The physical requirement that two observers, related by a transformation of the symmetry group $\mathcal{G}$ and performing the same experiment, get the same statistical distribution of the outcomes of the measurement, leads to a natural covariance condition and, eventually, to the following definition:

Definition 2: Let *$\mathcal{H}$ be a space of states, S be a space of possible results and $\mathcal{G}$ a symmetry group of the theory. Suppose that $\mathcal{G}$ acts on S by means of a representation $\Lambda:g\to\Lambda(g),g\in\mathcal{G}$, where $\Lambda(g):S\to S$ are Borel mappings. Suppose $\mathcal{G}$ acts on $\mathcal{H}$ by means of a strongly continuous unitary representation $U:g\to U(g)$. Let $\{\tau(I)\}_{I\in\mathcal{B}(S)}$ a POVM on S, with the property.*

$$U(g)\tau(I)U(g)^{\dagger}=\tau(\Lambda(g)I) \tag{3}$$

for any $I\in\mathcal{B}(S),g\in\mathcal{G}$. In this case the structure $(\mathcal{H},S,\mathcal{G},\Lambda,U,\tau)$ so defined is called the system of covariance. Furthermore, if τ is a spectral measure, it is called the system of imprimitivity.[6–9,15]

While spectral measures represent a ''property'' of the system on which the measurement is performed, generic POVMs can't describe ''definite observables,'' but we have to prefer them because they are able to describe simultaneous measurements of incompatible observables and measurements of time.

While there is a unified treatment of imprimitivity systems, mainly due to Mackey, we cannot say the same for covariance systems. Anyway we can overcome this difficulty by means of the following theorem, which may be recognized as a covariant version of Naimark's dilatation theorem.[7,8]

Proposition 1: Let $(\mathcal{H},S,\mathcal{G},\Lambda,U,\tau)$ *be a system of covariance. Then there is an imprimitivity system* $(\mathcal{H}',S,\mathcal{G},\Lambda,V,E)$*, where* $\mathcal{H}'$ *is a Hilbert space,* V *a strongly continuous unitary representation of the symmetry group* $\mathcal{G}$ *acting on* $\mathcal{H}'$*,* E *is a spectral measure on the Borel* σ *algebra* $\mathcal{B}$ *of* S*, and there is an ''intertwining operator'' A*:$\mathcal{H}\to\mathcal{H}'$*, with the property* $AU(g)=V(g)A$*, for any* $g\in\mathcal{G}$*, so that the following relation connects the spectral measure* E *to the POVM* τ*:*

$$\tau(I)=A^{+}E(I)A. \tag{4}$$

Moreover, τ *is normalized* (i.e., $\tau(S)=1$) *if and only if* $A^{+}A=1$*, namely if* A *is isometric.*

Finally Mackey's imprimitivity theorem allows one to find the most general form of a system of imprimitivity.

Proposition 2: Let $(\mathcal{H}',S,\mathcal{G},\Lambda,V,E)$ *be a transitive system of imprimitivity. Let* $q\in S$ *be a generical element of* S*, for any* $x\in S$ *let* $g_x\in\mathcal{G}$ *be an element of* $\mathcal{G}$ *with the property* $x=\Lambda(g_x)q$*. Let* H_q *be ''the little group,'' namely the closed subgroup of* $\mathcal{G}$ *defined by*

$$g\in H_q\Leftrightarrow\Lambda(g)q=q. \tag{5}$$

Then one can represent $\mathcal{H}'$ *as direct integral of Hilbert spaces on* S

$$\mathcal{H}'=\int_S^{\oplus}\mathcal{H}'(x)d\mu(x), \tag{6}$$

where $d\mu(x)$ *is a measure on* $\mathcal{B}(S)$ *having the same null sets as the spectral measure* E*. The vectors* $\phi\in\mathcal{H}'$ *can be represented by ''wave functions''* $\psi(x)$ *and the projectors* $E(I)$ *as diagonal operators*:

$$(E(I)\psi)(x)=f_I(x)\psi(x), \tag{7}$$

where $f_I(x)$ *is the characteristic function of the Borel set* $I\in\mathcal{B}$*. Moreover the unitary representation* V *of* $\mathcal{G}$ *takes the form of an ''induced representation:''*

$$[V(g)\psi](x)=\left[\frac{d\mu(x')}{d\mu(x)}\right]^{1/2}R(g_x^{-1}gg_{x'})\psi(x'),\quad x'=\Lambda(g^{-1})x, \tag{8}$$

where $g_x^{-1}gg_{x'}\in H_q$ *and* R *is a unitary representation of* H_q*.*

The introduction of a system of imprimitivity is very advantageous: in this way the probability that the result of the measurement, performed on the state ϕ, belongs to the Borel set $I\in S$ takes the following simple form:

$$\begin{aligned}P(\phi,I)&=\langle\phi,\tau(I)\phi\rangle\\&=\langle A\phi,E(I)A\phi\rangle\\&=\int_S f_I(x)\|\psi(x)\|^2d\mu(x),\quad \psi=A\phi.\end{aligned} \tag{9}$$

In other words the usual concept of *probability density*, which can be found in the traditional formulation of quantum mechanics, can be reestablished even if spectral measures are replaced by generic POVMs.

The last step of our construction procedure is the description of the most general intertwining operator joining the imprimitivity system found by means of Mackey's theorem to the unknown covariance system. The following theorem allows one to know when such an operator exists and what its general form is. It is based on a generalization of an argument given in Ref. 16 and on Schur's lemma.

Proposition 3: Let $\mathcal{G}$ be a locally compact topological group with a countable base of open sets and of type I. Let $\hat{\mathcal{G}}$ be its dual space, namely the space of equivalence classes of its irriducible representations. Let U and V be two unitary representations of its, defined by their central decompositions:

$$U(g)=\int_{\hat{\mathcal{G}}}^{\oplus}(U_\lambda(g)\otimes 1_\lambda)d\mu(\lambda),\quad V(g)=\int_{\hat{\mathcal{G}}}^{\oplus}(U_\lambda(g)\otimes 1'_\lambda)d\mu'(\lambda), \tag{10}$$

acting, respectively, on Hilbert spaces

$$\mathcal{H}=\int_{\hat{\mathcal{G}}}^{\oplus}\mathcal{H}_\lambda\otimes\mathcal{K}_\lambda d\mu(\lambda),\quad \mathcal{H}'=\int_{\hat{\mathcal{G}}}^{\oplus}\mathcal{H}_\lambda\otimes\mathcal{K}'_\lambda d\mu'(\lambda), \tag{11}$$

where U_λ are irreducible representation and 1_λ and $1'_\lambda$ are the unity operators acting on the Hilbert spaces $\mathcal{K}_\lambda$ or $\mathcal{K}'_\lambda$.

An isometric intertwining operator $A:\mathcal{H}\to\mathcal{H}'$

$$AU(g)=V(g)A,\quad \forall g\in\mathcal{G},\quad A^+A=1 \tag{12}$$

exists if and only if μ is absolutely continuous with respect to μ' and

$$\dim(\mathcal{K}'_\lambda)\geqslant\dim(\mathcal{K}_\lambda) \tag{13}$$

almost everywhere with respect to μ. In this case it will assume the following form:

$$[A\phi]_\lambda=\left(\frac{d\mu}{d\mu'}\right)^{1/2}(1_\lambda\otimes A_\lambda)\phi_\lambda,\quad A_\lambda^+A_\lambda=1, \tag{14}$$

where 1_λ is the unity operator in $\mathcal{H}_\lambda$ and $A_\lambda:\mathcal{K}_\lambda\to\mathcal{K}'_\lambda$ is an isometry defined almost everywhere with respect to μ.

The theorem reduces all our efforts, once we have the imprimitivity system, to the decomposition of *V* into irreducible unitary representations of the symmetry group *G*, that, from now on, will be denoted by I.U.R.s. The conditions for the applicability of the theorem are not too restrictive, since most of the groups of physical interest have the required properties, namely they are locally compact with a countable base of open sets and of type I. However we shall see that the absolute continuity of the measure μ on $\hat{\mathcal{G}}$ with respect to μ' leads to interesting physical consequences, namely to a series of constraints on the realizability of some measurements on particular physical systems.

III. LOCALIZATION OF EVENTS IN SPACE–TIME

The first step necessary for the description of a realistic quantum reference frame is the definition of its origin. From an operational point of view this is the description of the way in which a microscopical object can localize a point of the Minkowsky space–time manifold, namely an instant indicating the beginning of the time scale and a point in space with respect to which position measurements are referred. In other words, how a quantum system can point at a particular event, in a relativistic covariant way. This kind of measurement can be described by a POVM on the Minkowsky space–time $\mathcal{M}$ covariant with respect to the universal covering of the proper orthochronous Poincaré group, which will be indicated by $\mathcal{P}$. The problem has already been studied in Ref. 10 with a different method. We are going to rederive those results by means of the above developed construction procedure.

The first step is the construction of the most general imprimitivity system on $\mathcal{M}$ covariant with respect to $\mathcal{P}$, whose action $\tilde{\Lambda}$ on $\mathcal{M}$ is given by

$$\tilde{\Lambda}(y,a)(x)=y+\Lambda(a)x,\quad (y,a)\in\mathcal{P},\quad y\in\mathcal{T}_4,\quad a\in \mathrm{SL}(2C), \tag{15}$$

where $\Lambda: a \to \Lambda(a)$ is the representation of SL$(2C)$ acting on $\mathcal{M}$ by means of the Lorentz matrices.

The system of imprimitivity is transitive. If we choose as a representative point of the only orbit in $\mathcal{M}$ under the action of $\mathcal{P}$ the origin $O=(0,0,0,0)$, we can recognize the little group in the Lorentz group, or more precisely in SL$(2C)$, its universal covering. According to the imprimitivity theorem the unitary representation V has the form of an induced representation

$$[V(y,a)\psi](x) = D(a)\psi(x'), \quad x,x' \in \mathcal{M}, \tag{16}$$

where ψ takes its values in a Hilbert space $\tilde{\mathcal{H}}$, $D(a)$ is a unitary representation (not necessarily irreducible) of SL$(2C)$ and

$$x' = \Lambda(a^{-1})(x-y). \tag{17}$$

The projection-valued measure E on the homogeneous space $\mathcal{M}$ allows one to represent the vectors ψ belonging to the Hilbert space $\mathcal{H}'$ as square-integrable vector-value function defined on $\mathcal{M}$. The Lebesgue measure d^4x on $\mathcal{M}$, canonically associated to Minkowsky coordinates, is invariant under the action of $\mathcal{P}$ and the norm of ψ assumes the simple form:

$$\|\psi\|^2 = \int_{\mathcal{M}} \|\psi(x)\|^2 d^4x, \tag{18}$$

while the spectral measure E on the Borel σ algebra B of $\mathcal{M}$ assumes the diagonal form:

$$[E(I)\psi](x) = f_I(x)\psi(x), \quad I \in \mathcal{B}. \tag{19}$$

The second step is the decomposition of V into I.U.R.s of the Poincaré group $\mathcal{P}$. We perform a Fourier transform on $\mathcal{M}$ and pass from the coordinate representation to the momentum representation:

$$\tilde{\psi}(k) = (2\pi)^{-2} \int_{\mathcal{M}} \exp(ik\cdot x)\psi(x) d^4x, \quad k\cdot x = x^\alpha k_\alpha, \tag{20}$$

$$\|\psi\|^2 = \int \|\tilde{\psi}(k)\|^2 d^4k. \tag{21}$$

V takes the following form:

$$[V(y,a)\tilde{\psi}](k) = \exp(ik\cdot y) D(a)\tilde{\psi}(k'), \quad k' = \Lambda(a^{-1})k. \tag{22}$$

The physical states of $\mathcal{H}$ contain only non-negative energy representations, it follows that if A is an intertwining operator between U and V, then $A\mathcal{H} \subseteq \mathcal{H}'' \subseteq \mathcal{H}'$, where $\mathcal{H}''$ is the invariant subspace of $\mathcal{H}'$ which contains the vectors with non-negative energy, namely the wave functions $\tilde{\psi}(k)$ with support in the future cone V_+. We may disregard the values taken by $\tilde{\psi}(k)$ on the boundary of the cone, which has vanishing Lebesgue measure. In what follows we consider the subrepresentation V'' of V acting on $\mathcal{H}''$.

Now we introduce for any k in the open future cone an element $a_k \in$ SL$(2C)$ defined by

$$k = \Lambda(a_k)(M,0,0,0), \quad k^{02} - \mathbf{k}^2 = M^2, \tag{23}$$

and the new wave function ψ', defined by

$$\tilde{\psi}(k) = D(a_k)\psi'(k). \tag{24}$$

The representation V'' takes the following form:

$$[V''(y,a)\psi'](k)=\exp(ik\cdot y)D(a_k^{-1}aa_{k'})\psi'(k'), \tag{25}$$

where $a_k^{-1}aa_{k'}=u\in \mathrm{SU}(2)$. We can now consider the decomposition of D into I.U.R.s of $\mathrm{SL}(2C)$, whose matrix elements we indicate with $D^{\rho n}_{jmj'm'}(a)$. They are identified by two parameters: $\chi=(\rho,n)$. Two different I.U.R.s identified by (ρ,n) and $=(\rho',n')$ are equivalent if and only if either $(\rho,n)=(\rho',n')$, or $(\rho,n)=(-\rho',-n')$. There are two series of I.U.R.s: the principal series with ρ real and n integer, and the supplementary series with ρ imaginary and $n=0$.[17–20] Moreover one should not forget the trivial one-dimensional representation. The restriction of these representations to the subgroup SU(2) is given by

$$D^{\chi}_{jmj'm'}(u)=\delta_{jj'}R^{j}_{mm'}(u), \tag{26}$$

where $R^{j}_{mm'}(u)$ stands for the matrix elements of the I.U.R. of SU(2), labeled by the integer or half-integer index j, with

$$j=\left|\frac{n}{2}\right|,\left|\frac{n}{2}\right|+1,\ldots \quad m=-j,-j+1,\ldots,j-1,j. \tag{27}$$

Every unitary representation of SL(2C) can be decomposed uniquely into primary representations, which are direct sums of I.U.R.s, as SL(2C) is a type I group. We consider the direct integral decomposition of the Hilbert space $\tilde{\mathcal{H}}$ into irreducible spaces labeled by the variable $\chi=(\rho,n)$, and introduce an index α, which distinguishes the spaces where equivalent I.U.R.s operate:

$$\tilde{\mathcal{H}}=\int_{\widehat{\mathrm{SL}(2C)}}^{\oplus}\bigoplus_{\alpha}\tilde{\mathcal{H}}^{\chi}_{\alpha}d\omega(\chi), \tag{28}$$

$$\|\psi\|^2=\int_{\widehat{\mathrm{SL}(2C)}\times V_+}\sum_{\alpha}\|\psi_{\alpha}(k,\chi)\|^2 d\omega(\chi)d^4k, \tag{29}$$

where ω is a generic measure on $\widehat{\mathrm{SL}(2C)}$.

For fixed values of α,M,χ the Poincaré group $\mathcal{P}$ acts in the way described by Wigner[21]

$$[V''(y,a)\psi']_{\alpha,jm}(k,\chi)=\exp(ik\cdot y)\sum_{m'}R^{j}_{mm'}(a_k^{-1}aa_{k'})\psi'_{\alpha,jm'}(k',\chi), \tag{30}$$

as

$$a_k^{-1}aa_{k'}=u\in \mathrm{SU}(2). \tag{31}$$

Every I.U.R. of $\mathcal{P}$ with positive mass, identified by the variables (M,j), appears in the direct integral decomposition of V'' with a given multiplicity (defined almost everywhere on the positive real axis, i.e., on the M axis). The multiplicity of a particular representation (M,j) is strictly positive if the subset of $\widehat{\mathrm{SL}(2C)}$, whose elements are the I.U.R.s $\chi=(\rho,n)$ of $\mathrm{SL}(2C)$ with $n\leqslant 2j$, has nonvanishing measure ω. Then one can always assume that the multiplicity is as large as one needs, allowing the index α to take a sufficient number of different values.

As we have seen in Sec. II the intertwining operator theorem can be applied once U, the unitary representation of $\mathcal{P}$ acting on the Hilbert space $\mathcal{H}$, is decomposed into direct integral of spaces where I.U.R.s of $\mathcal{P}$ operate:

$$[U(y,a)\phi]_{\alpha jm}(k)=\exp(ik\cdot y)\sum_{m'}R^{j}_{mm'}(u)\phi_{\alpha jm'}(k'), \tag{32}$$

with

$$\|\phi\|^2 = \int \sum_{\alpha,j} \|\phi_\alpha(k,j)\|^2 d\mu(k). \tag{33}$$

The discrete index α distinguishes the spaces where equivalent I.U.R.s operate. Note that the range of the sum on the indices α and j may depend on M. The measure $d\mu(k)$ gives some information about the mass spectrum of the system on which the measurement is performed. According to our third theorem, an isometric intertwining operator A between U and V'' exists only if $\mu(k)$ (and therefore the corresponding measure on the range of M) is absolutely continuous with respect to the Lebesgue measure d^4k. This is possible if and only if the physical system on which the measurement is performed has a continuous mass spectrum, so we have to disregard the vacuum state and the one-particle states, whose mass spectrum has a vanishing Lebesgue measure. Moreover, if a value j appears in the decomposition, the measure ω of the set $I \in \mathcal{B}(\widehat{\mathrm{SL}(2C)})$ with $I = (\{\chi = (\rho,n) \in \widehat{\mathrm{SL}(2C)}, n \leqslant 2j\})$ has to be strictly positive. Eventually, if these conditions are satisfied the most general intertwining operator takes the following form:

$$\psi'_{\alpha jm}(k,\chi) = \sum_{\alpha'} A^j_{\alpha\alpha'}(M,\chi)\phi_{\alpha' jm}(k), \tag{34}$$

assuming that $d\mu(k)/d^4k = 1$ when M belongs to the mass spectrum, with

$$\int \sum_{\alpha} \overline{A^j_{\alpha\alpha'}(M,\chi)} A^j_{\alpha\alpha''}(M,\chi) d\omega(\chi) = \delta_{\alpha'\alpha''}. \tag{35}$$

Finally the most general density of probability on the Minkowsky space–time, describing the measurement of the coordinates of an event individuated by a quantum state described by a vector $\phi \in \mathcal{H}$ takes the following form:

$$\rho(x) = \sum_{\alpha} \int_{\widehat{\mathrm{SL}(2C)}} \|\psi_\alpha(x,\chi)\|^2 d\omega(\chi), \tag{36}$$

where

$$\psi_{\alpha pl}(x,\chi) = (2\pi)^{-2} \int \exp(-ik\cdot x) \sum_{\alpha',jm} D^\chi_{pljm}(a_k) A^j_{\alpha\alpha'}(M,\chi)\phi_{\alpha' jm}(k) d^4k. \tag{37}$$

This is the main result of Ref. 10.

IV. QUANTUM FRAMES OF REFERENCE

From an operational point of view a reference frame F can be defined by the operations which allow one to connect it to an initially fixed frame F_0. In a relativistic theory the set of the allowed transformation is represented by the Poincaré group $\mathcal{P}$. Every element of $\mathcal{P}$ individuates the translation in the Minkowsky space–time and the Lorentz transformation which cause the origin and the axes of the two frames coincide. We can also recognize in the four-vector individuating the translation the coordinates of the new origin with respect to the old one, while in the columns of the Lorentz matrix one finds the components of the new four orthogonal axes, relative to the old orthogonal basis. The ten indipendent parameters individuating the Poincaré transformation can also be recognized as relative observables of the two frames, namely relative position, time, velocity and spatial orientation. Their description can be given by a POVM on $\mathcal{P}$, covariant with respect to $\mathcal{P}$ itself. In other words the Poincaré group is in this case both the symmetry group and the measured space, endowed with the invariant Haar measure ν. The description is simplified by the assumption of the classical nature of the frame F_0, in other words it will be considered an

abstract mathematical tetrad with well-defined position, velocity and orientation. In this case the Poincaré group acts just on the system F by means of left translation and the covariance condition assumes the following form:

$$U(g)\tau(I)U(g)^{-1}=\tau(gI), \quad g\in\mathcal{P}, I\subseteq\mathcal{P}. \tag{38}$$

As shown in the previous sections, the starting point is the application of Mackey's imprimitivity theorem. In this case it is particulary simple: there is only one orbit and, if we choose, for example, as a representative point the identity $e\in\mathcal{P}$, the little group is reduced to the identity and the induced representation is simply the left regular representation or the direct sum of several representations equivalent to the left regular one and distinguished by the index α:

$$[V(g')\psi]_\alpha(g)=\psi_\alpha(g'^{-1}g), \tag{39}$$

$$[V(y,a)\psi]_\alpha(x,b)=\psi_\alpha(\Lambda(a^{-1})(x-y),a^{-1}b). \tag{40}$$

It can be decomposed into I.U.R.s of $\mathcal{P}$ by means of the harmonic analysis on $\mathcal{P}$, defined by

$$\tilde{\psi}(\gamma)=\int \psi(g)D^\gamma(g)d\nu(g), \tag{41}$$

where γ stands for (M,j). The inversion formula is given by

$$\psi(g)=\int_{\hat{\mathcal{P}}}\mathrm{Tr}[\tilde{\psi}(\gamma)D^\gamma(g^{-1})]d\hat{\nu}(\gamma), \tag{42}$$

where $d\hat{\nu}(\gamma)$ is the Plancherel measure on $\hat{\mathcal{P}}$. On the new ''wave function,'' defined on $\hat{\mathcal{P}}$, the space of equivalence classes of I.U.R.s of $\mathcal{P}$, the group action assumes the following form:

$$[V(g)\tilde{\psi}]_\alpha(\gamma)=D^\gamma(g)\tilde{\psi}_\alpha(\gamma). \tag{43}$$

This procedure can be repeated whenever the action of the symmetry group $\mathcal{G}$ on the measure space S is free and transitive, namely if for all $x,y\in S$ exists one and only one $g\in\mathcal{G}$ so that $y=\Lambda(g)x$. In this way, for example, we can construct time measurements covariant with respect to time translations and position measurements covariant with respect to space displacements.

In our case we just have to combine the usual Fourier transform on R^4 and the harmonis analysis on $\mathrm{SL}(2C)$, which give

$$\tilde{\psi}_{\alpha,jmj'm'}(k,\rho,n)=(2\pi)^{-2}\int \exp(ikx)D^{\rho n}_{jmj'm'}(a)\psi_\alpha(x,a)d\mu(a)d^4x, \tag{44}$$

and

$$\|\psi\|^2=\int_{\hat{T}\times\widehat{\mathrm{SL}(2C)}}\sum_\alpha \mathrm{Tr}[\psi^+_\alpha(k,\chi)\psi_\alpha(k,\chi)]d^4k\,d\hat{\mu}(\chi), \tag{45}$$

where $d\hat{\mu}(\chi)$ is the Plancherel measure on $\widehat{\mathrm{SL}(2C)}$, which is concentrated on the principal series only.

As in Sec. III we consider only $\mathcal{H}''$, the invariant subspace of $\mathcal{H}'$ which contains only the vectors with non-negative energy, and the subrepresentation V'' acting on $\mathcal{H}''$. For every k belonging to the open future cone V_+ we introduce an element $a_k\in\mathrm{SL}(2C)$ defined by Eq. (23) and the new wave function ψ', given by

$$\tilde{\psi}_{\alpha,plj'm'}(k,\chi)=\sum_{qs} D^\chi_{plqs}(a_k)\psi'_{\alpha,qsj'm'}(k,\chi). \tag{46}$$

In this way the action of $\mathcal{P}$ on $\mathcal{H}''$ for fixed values of α, M, χ, j', m' assumes the form introduced by Wigner[21]

$$[V''(y,a)\psi']_{\alpha,jmj'm'}(k,\chi) = \exp(ik\cdot y)\sum_{m'} R^{j}_{mn}(a_k^{-1}aa_{k'})\psi'_{\alpha,jnj'm'}(k',\chi), \tag{47}$$

because of Eqs. (31) and (26) Once we have introduced the primary decomposition of U shown in Eq. (32), the most general intertwining operator can be found if and only if the measure $d\mu(k)$, defining the mass spectrum of the physical system on which the measurement is performed, is absolutely continuous with respect to d^4k. In this case, redefining if necessary the normalization of the wave function $\phi \in \mathcal{H}$ so that $d\mu(k)/d^4k = 1$ when M belongs to the mass spectrum, we can write:

$$\psi'_{\alpha jmqs}(k,\chi) = \sum_{\alpha'} A^{j}_{qs,\alpha\alpha'}(M,\chi)\phi_{\alpha' jm}(k), \tag{48}$$

with

$$\int \sum_{\alpha} \sum_{q=|n/2|}^{\infty} \sum_{s=-q}^{q} \overline{A^{j}(M,\chi)_{\alpha\alpha' qs}} A^{j}(M,\chi)_{\alpha\alpha'' qs} d\hat{\mu}(\chi) = \delta_{\alpha'\alpha''}. \tag{49}$$

Finally the density of probability assumes the following form:

$$\rho(x,b) = \sum_{\alpha} |\psi_{\alpha}(x,b)|^2, \tag{50}$$

where

$$\begin{aligned}\psi_{\alpha}(x,b) &= (2\pi)^{-2}\int \exp(-ik\cdot x)\mathrm{Tr}[D^{\chi}(b^{-1}a_k)\psi'_{\alpha}(k,\chi)]d^4k\,d\hat{\mu}(\chi)\\ &= (2\pi)^{-6}\int d^4k \exp(-ik\cdot x)\int_0^{+\infty} d\rho \sum_{n=-\infty}^{+\infty}(n^2+\rho^2)\\ &\quad\times \sum_{j,q=|n/2|}^{\infty}\sum_{m=-j}^{j}\sum_{s=-q}^{q} D^{(\rho,n)}_{qsjm}(b^{-1}a_k)\psi'_{\alpha jmqs}(k,\chi).\end{aligned} \tag{51}$$

It is quite interesting to compare the density of probability on the Minkowsky space–time, which is described by equations (36) and (37), which was found indpendently in Sec. III, and the density of probability which can be found from Eqs. (50) and (51) by integration on $\mathrm{SL}(2C)$:

$$\rho(x) = \int_{\mathrm{SL}(2C)} \rho(x,a)d\mu(a), \tag{52}$$

which after some calculations assumes the following form:

$$\rho(x) = \sum_{\alpha} \int \mathrm{Tr}[\psi'_{\alpha}(x,\chi)^{+}\psi'_{\alpha}(x,\chi)]d\hat{\mu}(\chi), \tag{53}$$

with

$$\hat{\psi}_{\alpha}(x,\chi) = (2\pi)^{-2}\int \exp(-ik\cdot x)\tilde{\psi}_{\alpha}(k,\chi)d^4k, \tag{54}$$

where $d\hat{\mu}(\chi)$ is the Plancherel measure on the principal series of the I.U.R.s of SL$(2C)$.

As Eqs. (36) and (37) show, the most general density of probability on the Minkowsky space–time admits a generic measure $d\omega(\chi)$ on the space of I.U.R.s of SL$(2C)$. From these considerations one can guess there are some constraints on the realizability of some measurement, whose properties can be found through an analysis of the physical meaning of the parameters $\chi=(\rho,n)$ in this context. For example, as shown in Ref. 10 one can recognize as ''baricentric'' a measurement of events such that the measure ω on $\mathcal{B}(\widehat{\mathrm{SL}(2C)})$ appearing in Eq. (36) is concentrated on the trivial representation $D(a)=1$. Our results show that such a requirement cannot be compatible with the measurement of the further parameters fully describing a reference frame. In other words the origin of the quantum reference frame can never be localized on the world line of the center of mass of the microscopical system defining it. Moreover, as the same author suggested in a previous paper,[22] for a complete description of a quantum reference frame kinematical variables are not sufficient, but internal degree of freedom must be involved. We can see, for example, that neither the invariant mass of the system nor its spatial distribution, namely the center of mass position, can be arbitrarily fixed and disregarded, but have a fundamental role in the whole description.

V. THE OBSERVABLES RELATIVE TO A QUANTUM REFERENCE FRAME

The quantum picture is complete if every classical element is disregarded and every kinematical variable of a quantum system F_j is referred to a quantum reference frame F_i, namely a microscopical system with continuous mass spectrum. This can be simply obtained in two steps if the quantum systems F_i and F_j do not mutually interact.

First of all let us introduce as a preliminary tool a classical frame F_0, with respect to which the parameters of the Poincaré tranformation connecting it to the quantum frame F_i and a cinematical variable of the system F_j are referred. The first ones are described by a POVM τ_i on the universal covering of the Poincaré group $\mathcal{P}$, acting on the Hilbert space $\mathcal{H}_i$, while the second ones are described by a POVM τ_j on a measure space S acting on the Hilbert space $\mathcal{H}_j$. If there is no interaction the POVMs τ_i and τ_j and the unitary representation of $\mathcal{P}$ can be extended to the whole Hilbert space $\mathcal{H}=\mathcal{H}_j\otimes\mathcal{H}_i$ by the relations:

$$U(g)=U_j(g)\otimes U_i(g), \quad g\in\mathcal{P}, \tag{55}$$

$$\hat{\tau}_i(I)=I\otimes\tau_i(I) \quad \hat{\tau}_j(J)=\tau_j(J)\otimes I, \tag{56}$$

for all Borel subsets $I\subseteq\mathcal{P}$ and $J\subseteq S$. One can easily see that $\hat{\tau}_i$ and $\hat{\tau}_j$ are endowed with the right covariance properties with respect to Poincaré transformations

$$U(g)\hat{\tau}_i(I)U(g^{-1})=\hat{\tau}_i(gI) \quad U(g)\hat{\tau}_j(J)U(g^{-1})=\hat{\tau}_j(\Lambda(g)J) \quad \forall g\in\mathcal{P}. \tag{57}$$

Moreover the operators in their ranges are mutually commuting

$$[\hat{\tau}_i(I),\hat{\tau}_j(J)]=0, \quad I\subseteq\mathcal{P}, \quad J\subseteq S. \tag{58}$$

If these condition are satisfied the *convolution*[23,24] τ_{ij} of the two POVMs $\hat{\tau}_i$ and $\hat{\tau}_j$ can be defined by the relation

$$\tau_{ij}(J)=\int f_J(\Lambda(g^{-1})x)d\hat{\tau}_i(g)d\hat{\tau}_j(x), \quad g\in\mathcal{P}, \quad x\in S, \quad J\subseteq S. \tag{59}$$

It is suitable for the description of the relative observables of the system F_j with respect to the quantum frame F_i. Indeed τ_{ij} is endowed with the properties of a POVM acting on the Hilbert space $\mathcal{H}$, namely positivity, σ additivity and normalization. Moreover, as we expected, it is invariant under the action of the Poincaré group $\mathcal{P}$:

$$U(\tilde{g})\tau_{ij}(J)U(\tilde{g}^{-1})=\int f_J(\Lambda(g^{-1}\tilde{g})\Lambda(\tilde{g}^{-1})x)d\hat{\tau}_i(g)d\hat{\tau}_j(x)=\tau_{ij}(J), \tag{60}$$

in fact a Poincaré transformation will act on both F_i and F_j, changing the ''absolute'' cinematical variables of the two systems but leaving invariant the relative ones.

The mathematical description of the relations connecting two noninteracting quantum frames F_i and F_j can be obtained as a special case of this formalism. If in the previous discussion the quantum system F_j has a continuous mass spectum, while the measure space S coincides with the Poincaré group again, τ_{ij} describes the measurement of the ten parameters of the transformation connecting the two frames. It assumes the following form:

$$\tau_{ij}(I)=\int f_I(g^{-1}g')d\hat{\tau}_i(g)d\hat{\tau}_j(g'), \quad J\subseteq\mathcal{P}. \tag{61}$$

The intuition can be helped by a calculation of the density of probability describing the statistics of the measurement, defined by

$$\langle\phi_i\otimes\phi_j,\tau_{ij}(I)\phi_i\otimes\phi_j\rangle=\int_{\mathcal{P}}f_I(g)\rho_{ij}(g)d\mu(g), \tag{62}$$

which assumes the following form:

$$\rho_{ij}(g)=\int_{\mathcal{P}}\rho_i(\phi_i,g')\rho_j(\phi_j,g'g)d\mu(g'), \tag{63}$$

where $\rho_i(\phi_i,g')$ and $\rho_j(\phi_j,g'g)$ are the densities of probability describing a measurement of the ''absolute'' parameters g' and $g'g$, namely relative to a classical reference frame F_0, which were calculated in Sec. IV. In other words if the Poincaré transformations identified by the elements g' and $g'g$ connect the classical frame to the quantum frames F_i and F_j, respectively, then the transformation from F_i to F_j will be individuated by the element $g\in\mathcal{P}$, whatever g' may be.

The introduction of a third quantum frame F_k in the description leads to some surprising consequences, which are commonly called ''the paradox of quantum frames.'' While the relative observables of F_i and F_j, or of F_i and F_k, can be described, respectively, by $\tau_{ij}=\tilde{\tau}_i*\tau_j$ or by $\tau_{ik}=\tau_i*\tau_k$, the relative observables of F_j and F_k cannot be obtained by the convolution $\widetilde{\tau_{ik}}*\tau_{ij}$ as it does not own the necessary properties. The operators in its range could be positive if and only if the POVMs τ_{ik} and τ_{ij} commute, but it cannot be required and it is not generally true. One can easily see that the commutativity of the POVM $\{\tau_i(I)\}_{I\in\mathcal{B}(\mathcal{P})}$ is a sufficient condition for the commutativity of τ_{ik} and τ_{ij}:

$$[\hat{\tau}_i(I),\hat{\tau}_i(I')]=0\Rightarrow[\tau_{ik}(I),\tau_{ij}(I')]=0, \quad I,I'\subseteq\mathcal{P}, \tag{64}$$

however the first condition cannot be required. Note that the commutativity of the projectors in the range of the spectral measure $\{E_i(I)\}_{I\in\mathcal{B}(\mathcal{P})}$ does not involve the commutativity of the POVM $\tau_i(I)=A^+E_i(I)A$, unless the range of the intertwining operator $\mathcal{H}''=A\mathcal{H}$ is an invariant subspace under the action of the projectors $E_i(I)$. One can easily see that in this case the positive operators in the range of the POVM τ_i would be projectors too, but this is forbidden by Pauli's theorem and by the noncompatibility of the observables describing a reference frame. In other words sequential measurement of the relative parameters of two quantum frames F_j and F_k with respect to a third quantum frame F_i are not compatible, even if they do not mutually interact.[2,22]

(Received 2 June 2000; accepted for publication 19 March 2001)

A soluble model of weakly coupled ''molecular'' and ''nuclear'' Hamiltonians is studied in order to exhibit explicitly the mechanism leading to the enhancement of fusion probability in case of a narrow near-threshold nuclear resonance. We, further, consider molecular cells of this type being arranged in lattice structures. It is shown that if the real part of the narrow nuclear resonance lies within the molecular band generated by the intercellular interaction, an enhancement, proportional to the inverse width of the nuclear resonance, is to be expected. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1371264]

I. INTRODUCTION

Molecules are usually treated as purely Coulombic systems, while the strong interaction between their nuclear constituents is assumed to play a negligible role. However, at least in principle, any Coulombic molecular level lying above the lower threshold of the nuclear subsystem, is embedded in the continuous spectrum of the nuclear sub-Hamiltonian. The coupling between the molecular and nuclear channels, hence, turns this level into a resonance (see, e. g., Refs. 1–5 and references cited therein). Of course, due to the wide Coulombic barrier between the nuclei and the short-range character of the nuclear interaction, this coupling, and thus the width of the resonance, which determines the fusion probability of the nuclear constituents of the molecule, is in general extremely small.

However, as pointed out in Refs. 6 and 7 the situation is rather different if the nuclear subsystem of a molecule has a sufficiently narrow near-threshold resonance. Examples of such nuclear systems may be read off from the data presented in Ref. 8. Among them are even customary systems like $p\,p\,{}^{16}\mathrm{O}$ and $p\,{}^{17}\mathrm{O}$,[9,10] i.e., the nuclear constituents of the water molecule H_2O or the hydroxyl ion OH^- with O being the isotope ^{17}O. For LiD and H_2O the influence of near-threshold nuclear resonances on the molecular properties has been studied in Refs. 11–13 by estimating the overlap integrals between the corresponding molecular and nuclear wave functions. The best known example of such phenomena is the muon catalyzed fusion of deuteron and triton in the $dt\,\mu$ molecule, where the near-threshold nuclear resonance $^5\mathrm{He}(3/2^+)$ plays a decisive role.[14]

Being motivated by the above special cases, we deal in this paper with a rather general model Hamiltonian related to the ones considered by Friedrichs in Ref. 15. This Hamiltonian consists of a ''nuclear'' part, a ''molecular'' part with eigenvalues embedded in the continuous spectrum of the nuclear part, and a weak coupling term which turns these unperturbed eigenvalues into ''molecular'' resonances. Since the model is explicitly solvable, the mechanism of formation of the resonances becomes clearly visible.

The following property pointed out in Refs. 6 and 7 appears, in particular, as a general feature: if the ''nuclear'' channel itself has a narrow resonance with a position close to the ''molecular''

[a]On leave of absence from the Bogoliubov Laboratory of Theoretical Physics, Joint Institute for Nuclear Research, 141980 Dubna, Russia.

energy, then the width (the imaginary part) of the resulting ''molecular'' resonance is found to be inversely proportional to the ''nuclear'' width. In other words, a large increase of the decay rate of the ''molecular'' state, i.e., of the fusion probability, is observed in this case. Such a coincidence of nuclear and molecular energies is, of course, a rather rare phenomenon in nature.

A further goal of the present work is to show that the decay rate may be considerably enhanced when arranging molecular clusters of this type within a crystalline structure. The reason is that in such a configuration the original discrete molecular energy turns into a band, i.e., into a whole interval of the continuous spectrum. (Note that in the models under consideration, the spectral band generated by the ''molecular'' level is shifted finally, after switching on the coupling between the ''nuclear'' and ''molecular'' channels, into the unphysical sheet.) That is, even if the position of the ''nuclear'' resonance differs from the original ''molecular'' level, it can get into this band. This allows for a fine tuning by exciting the crystalline structure to energies as close as possible to the energy of the ''nuclear'' resonance. We show that the lattice states, which correspond to such an initial choice of their quasimomentum distribution, decay exponentially with a rate which is again inversely proportional to the width of the ''nuclear'' resonance.

Concluding this introduction, we would like to mention the papers Refs. 16 and 17 which develop approaches of the direct spectral modelling resembling the one employed in the present work. Reference 16 is devoted, in particular, to the study of a one-electron model of a solid having a cubic crystalline lattice (see Sec. 3.2 in Ref. 16). This model exibits a mechanism of the formation of gaps in the absolutely continuous spectrum of the total Hamiltonian due to the resonance coupling between the electron and lattice sub-Hamiltonians, while the absolutely continuous spectra of the sub-Hamiltonians do not have the corresponding gaps. Reference 17 discusses a similar effect of formation of gaps in the absolutely continuous spectrum of a self-adjoint operator defined in a Hilbert space associated with a periodically ''decorated'' periodic graph. The gaps are produced by the resonance interaction between the basic graph and the attached (''decorating'') graphs.

Notice that the phenomena we discuss in the present paper also arise partly due to the resonance coupling between the sub-Hamiltonians. In particular, some resonances and resonance bands are formed of an eigenvalue or spectral band of one of the sub-Hamiltonians embedded into the absolutely continuous spectrum of another sub-Hamiltonian. We refer, however, not to details of the structure of the resulting (real) spectrum of the total Hamiltonian like the spectral gaps of Refs. 16 and 17 but study an interplay between the arising resonances (or resonance bands) and the resonances which occurred before coupling.

The paper is organized as follows.

In Sec. II we introduce the explicitly soluble model designed to demonstrate the interplay of the molecular and nuclear resonance widths. It is also shown that in a wide time interval the decay of the ''molecular'' state is indeed of the standard exponential character.[19] This transition will take place primarily into the open nuclear channels and its rate is determined by the inverse width of the nuclear resonance. In Sec. III we consider the case where molecular Hamiltonians of the type considered in Sec. II are arranged in form of an infinite one-dimensional lattice. Section IV is devoted to the generalization to multi-dimensional lattices. In both these sections, the time evolution of originally pure molecular states, extended to a spectral band within a lattice, is studied. It is shown that if the real part of the ''nuclear'' resonance lies within such a spectral band, then there exist molecular states which decay exponentially, with a rate inversely proportional to the ''nuclear'' width.

II. TWO-CHANNEL MOLECULAR RESONANCE MODEL

A. Description of the model Hamiltonian

Let us consider a two-channel Hilbert space $\mathcal{H}=\mathcal{H}_1\oplus\mathcal{H}_2$ consisting of a ''nuclear'' Hilbert space $\mathcal{H}_1$ (channel 1) and a one-dimensional ''molecular'' space $\mathcal{H}_2=\mathbb{C}$ (channel 2). The elements

of $\mathcal{H}$ are represented as vectors $u=\binom{u_1}{u_2}$ where $u_1\in\mathcal{H}_1$ and $u_2\in\mathcal{H}_2$, with u_2 being a complex number. The inner product $\langle u,v\rangle_{\mathcal{H}}=\langle u_1,v_1\rangle+u_2\overline{v_2}$ in $\mathcal{H}$ is naturally defined via the inner products $\langle u_1,v_1\rangle$ in $\mathcal{H}_1$ and $u_2\overline{v_2}$ in $\mathcal{H}_2$.

As a Hamiltonian in $\mathcal{H}$ we consider the 2×2 operator matrix

$$A=\begin{pmatrix} h_1 & b \\ \langle\,\cdot\,,b\rangle & \lambda_2 \end{pmatrix}, \tag{2.1}$$

where h_1 is the (self-adjoint) ''nuclear Hamiltonian'' in $\mathcal{H}_1$, and $\lambda_2\in\mathbb{R}$ a trial ''molecular'' energy. A vector $b\in\mathcal{H}_1$ provides the coupling between the channels. It should be mentioned that the Hamiltonian (2.1) resembles one of the well-known Friedrichs models[15] (for a discussion of the other Friedrichs-type models see, e.g., Ref. 18 and the references cited therein).

If there is no coupling between the channels, i.e., for $b=0$, the spectrum of A consists of the spectrum of h_1 and the additional discrete eigenvalue λ_2. We assume that the continuous spectrum $\sigma_c(h_1)$ of the Hamiltonian h_1 is not empty and that the eigenvalue λ_2 is embedded in $\sigma_c(h_1)$. It is also assumed that λ_2 is not a threshold point of $\sigma_c(h_1)$, and that this spectrum is absolutely continuous in a sufficiently wide neighborhood of λ_2.

A nontrivial coupling ($b\neq 0$) between the channels will, in general, shift the eigenvalue λ_2 into an unphysical sheet of the energy plane. The resulting perturbed energy appears as a resonance, i.e., as a pole of the analytic (or, more precisely, meromorphic) continuation of the resolvent $r(z)=(A-z)^{-1}$ taken between suitable states (see, e.g., Ref. 5). In the present paper we assume that such a continuation through the absolutely continuous spectrum of h_1 in some neighborhood of λ_2 is possible at least for the matrix element $\langle r_1(z)b,b\rangle$ of the resolvent $r_1(z)=(h_1-z)^{-1}$. Then one infers a meromorphic continuability at least for the compressed resolvent $P_2(A-z)^{-1}|_{\mathcal{H}_2}$ where P_2 denotes the orthogonal projection onto the space $\mathcal{H}_2$. Indeed, the explicit representation for the resolvent $r(z)$ is easily seen to be

$$r(z)=\begin{pmatrix} r_1(z)+\dfrac{r_1(z)b\langle\,\cdot\,,b\rangle r_1(z)}{M_2(z)} & -\dfrac{r_1(z)b}{M_2(z)} \\ -\dfrac{\langle\,\cdot\,,b\rangle r_1(z)}{M_2(z)} & \dfrac{1}{M_2(z)} \end{pmatrix}, \tag{2.2}$$

where the transfer function $M_2(z)$ reads $M_2(z)=\lambda_2-z-\beta(z)$ with $\beta(z)=\langle r_1(z)b,b\rangle$. Thus, if $\beta(z)$ admits a meromorphic continuation through an interval of the absolutely continuous spectrum of the ''nuclear'' Hamiltonian h_1, then the function $P_2(A-z)^{-1}|_{\mathcal{H}_2}=M_2^{-1}(z)$ admits such a continuation, too.

Evidently the poles of $r(z)$ on the physical sheet are either due to zeros of the function $M_2(z)$ or due to poles of the resolvent $r_1(z)$. The latter correspond to the discrete spectrum of the operator h_1 which may determine part of the point spectrum of A. This is true, in particular, for the multiple eigenvalues of h_1. In any case it is obvious that the perturbation of the eigenvalue λ_2 only corresponds to solutions of the equation $M_2(z)=0$, i.e., of

$$z=\lambda_2-\beta(z). \tag{2.3}$$

This equation has no roots z with $\operatorname{Im} z\neq 0$ on the physical sheet. For, being eigenvalues of the selfadjoint operator A, they have, of course, to be real. Thus, Eq. (2.3) may have solutions only on the real axis and in the unphysical sheet(s) of the Riemann surface of the resolvent $r_1(z)$.

We start with a brief discussion of the case where the ''nuclear'' channel Hamiltonian h_1 generates no resonances close to λ_2 in a domain $\mathcal{D}$ of the unphysical sheet which adjoins the physical sheet from below the cut. This assumption implies that for a wide set of unit vectors $\hat{b}$

$=b/\|b\|$ the quadratic form $\beta(z)=\|b\|^2\langle r_1(z)\hat{b},\hat{b}\rangle$ can be analytically continued in $\mathcal{D}$. Moreover, under certain smallness conditions for $\|b\|$, Eq. (2.3) is uniquely solvable[22] in $\mathcal{D}$ providing in first order perturbation theory (see, e.g., Refs. 20 and 21)

$$z_2 =_{\|b\|\to 0} \lambda_2 - \langle r_1(\lambda_2+\mathrm{i}0)b,b\rangle + o(\|b\|^2). \tag{2.4}$$

The real and imaginary parts of the resonance $z_2=E_R^{(2)}-\mathrm{i}(\Gamma_R^{(2)}/2)$, thus, are given by

$$\begin{aligned} E_R^{(2)} &= \lambda_2 - \mathrm{Re}\langle r_1(\lambda_2+\mathrm{i}0)b,b\rangle + o(\|b\|^2), \\ \Gamma_R^{(2)} &= 2\,\mathrm{Im}\langle r_1(\lambda_2+\mathrm{i}0)b,b\rangle + o(\|b\|^2). \end{aligned} \tag{2.5}$$

B. Perturbation of the ''molecular'' resonance by a nearby ''nuclear'' resonance

Our main interest concerns the opposite case of a ''nuclear'' resonance $z_1=E_R^{(1)}-\mathrm{i}(\Gamma_R^{(1)}/2)$, $\Gamma_R^{(1)}>0$, with a real part $E_R^{(1)}$ close to λ_2. For the sake of simplicity we assume the corresponding pole of $r_1(z)$ to be of first order. Let the element $b\in\mathcal{H}_1$ be such that the function $\beta(z)$ admits an analytic continuation into a domain $\mathcal{D}$ which contains both points λ_2 and z_1. This domain, moreover, is assumed to belong to the unphysical sheet which adjoins the physical sheet along the upper rim of the cut. In $\mathcal{D}$ the function $\beta(z)$, thus, can be written as

$$\beta(z)=\frac{a}{z_1-z}+\beta^{\mathrm{reg}}(z) \tag{2.6}$$

with $\beta^{\mathrm{reg}}(z)$ being a holomorphic function. For a fixed ''structure function'' $\hat{b}=b/\|b\|$ we have $|a|=C_a\|b\|^2$ with a constant C_a determined by the residue of $r_1(z)$ at $z=z_1$. Note that this residue is usually expressed in terms of resonance (Gamow) functions (see, for example, Ref. 23). In fact, we assume that the resonance corresponds to an ''almost eigenstate'' of h_1. That is, in principle a limiting procedure $\Gamma_R^{(1)}\to 0$ is possible so that the resonance turns into a usual eigenvalue with an eigenvector $\psi_1\in\mathcal{H}_1$. More precisely, we assume

$$C_a=C_a^{(0)}+o(1) \quad \text{as} \quad \Gamma_R^{(1)}\to 0 \tag{2.7}$$

with $C_a^{(0)}\equiv\langle\hat{b},\psi_1\rangle\langle\psi_1,\hat{b}\rangle\neq 0$. This can be achieved, e.g., if the Hamiltonian h_1 itself has a matrix representation of the form (2.1) and the resonance z_1 is generated by a separated one-dimensional channel. In such a case, according to (2.2) and (2.4), we would have $C_a^{(0)}=1$ (for details see Ref. 7, Sec. II).

Let

$$\mathrm{Re}\,a>0 \quad \text{and} \quad \mathrm{Im}\,a\ll\mathrm{Re}\,a \tag{2.8}$$

and, for $z\in\mathcal{D}$,

$$|\mathrm{Im}\,\beta^{\mathrm{reg}}(z)|\geqslant c_{\mathcal{D}}\|b\|^2 \quad \text{and} \quad |\beta^{\mathrm{reg}}(z)|\leqslant C_{\mathcal{D}}\|b\|^2$$

with constants $c_{\mathcal{D}}>0$ and $C_{\mathcal{D}}>0$. Furthermore, the coupling between the channels in the Hamiltonian (2.1) is assumed to be so weak that

$$|\beta^{\mathrm{reg}}(z)|\leqslant C_{\mathcal{D}}\|b\|^2\ll\Gamma_R^{(1)} \quad \text{while} \quad |a|=C_a\|b\|^2\ll(\Gamma_R^{(1)})^2. \tag{2.9}$$

It can be expected that these conditions are fulfilled in specific molecular systems even under the supposition that the ''nuclear'' width $\Gamma_R^{(1)}$ itself is very small.

After inserting (2.6) for $\beta(z)$, Eq. (2.3) turns into the ''quadratic'' equation

$$(\lambda_2-z)(z_1-z)-a+(z_1-z)\beta^{\mathrm{reg}}(z)=0$$

which can be ''solved,'' i.e., can be rewritten in form of two equations:

$$z=\frac{\lambda_2+z_1-\beta^{\rm reg}(z)}{2}\pm\sqrt{\left(\frac{\lambda_2-z_1-\beta^{\rm reg}(z)}{2}\right)^2+a}. \tag{2.10}$$

Under conditions (2.9) the existence of solutions of (2.10), and thus of Eq. (2.3), is guaranteed, analogously to the proof in Ref. 22, by Banach's fixed point theorem. Each of the equations (2.10) has only one solution in the domain $\mathcal{D}$. In case of the sign ''$-$'' we denote the root of (2.10) by $z_{\rm nucl}$, in case of the sign ''$+$'' by $z_{\rm mol}$.

The inequalities (2.9) imply

$$\frac{|a|}{|\lambda_2-z_1-\beta^{\rm reg}(z)|_{z\in\mathcal{D}}|^2}\approx\frac{|a|}{|\lambda_2-E_R^{(1)}|^2+\left(\frac{\Gamma_R^{(1)}}{2}\right)^2}\leqslant\frac{4C_a\|b\|^2}{(\Gamma_R^{(1)})^2}\ll 1. \tag{2.11}$$

For $z\in\mathcal{D}$ the value of

$$\varepsilon(z)=\frac{4a}{[\lambda_2-z_1-\beta^{\rm reg}(z)]^2} \tag{2.12}$$

is very small, $|\varepsilon(z)|\ll 1$. Thus, to separate the main terms of the solutions of Eqs. (2.10), one can apply the asymptotic relation $\sqrt{1+\varepsilon}=1+\varepsilon/2+O(\varepsilon^2)$. As a result we find

$$z=\frac{\lambda_2+z_1-\beta^{\rm reg}(z)}{2}\pm\frac{\lambda_2-z_1-\beta^{\rm reg}(z)}{2}\left(1+\frac{2a}{(\lambda_2-z_1-\beta^{\rm reg}(z))^2}+O(\varepsilon^2)\right). \tag{2.13}$$

In other words, the roots $z_{\rm nucl}$ and $z_{\rm mol}$ of (2.10) are essentially given by

$$z_{\rm nucl}\cong z_1-\frac{a}{\lambda_2-z_1-\beta^{\rm reg}(z_1)}\cong z_1-\frac{a}{\lambda_2-z_1}, \tag{2.14}$$

$$z_{\rm mol}\cong\lambda_2-\beta^{\rm reg}(\lambda_2+{\rm i}0)+\frac{a}{\lambda_2-z_1-\beta^{\rm reg}(\lambda_2+{\rm i}0)}\cong\lambda_2+\frac{a}{\lambda_2-z_1}. \tag{2.15}$$

From the second condition (2.9) follows $|a/(\lambda_2-z_1)|\ll\Gamma_R^{(1)}$. Consequently, this term provides in $z_{\rm nucl}$ a very small perturbation of the initial ''nuclear'' resonance z_1. As compared to $\Gamma_R^{(1)}$ it represents also in $z_{\rm mol}$ a very weak perturbation of the ''molecular'' energy λ_2. However, as compared to the result (2.4), valid in case of a missing nearby ''nuclear'' resonance, it can be rather large. In particular, if the ''molecular'' energy λ_2 coincides with the real part $E_R^{(1)}$ of the ''nuclear'' resonance z_1, then $z_{\rm mol}=E_R^{(m)}-i\,(\Gamma_R^{(m)}/2)$ with

$$E_R^{(m)}\cong\lambda_2-2\,\frac{{\rm Im}\,a}{\Gamma_R^{(1)}}\quad\text{and}\quad\Gamma_R^{(m)}\cong 4\,\frac{{\rm Re}\,a}{\Gamma_R^{(1)}}. \tag{2.16}$$

The width of the ''molecular'' resonance $z_{\rm mol}$ in the presence of a nearby ''nuclear'' resonance z_1, thus, turns out to be inversely proportional to the ''nuclear'' width $\Gamma_R^{(1)}$.

Let us contrast the results (2.4) and (2.16) in some more detail. Since such a comparison is necessarily of a qualitative character, we simulate the situation of a missing nearby nuclear resonance simply by dropping the pole term in the representation (2.6) of $\beta(z)$. After this removal we get $\beta(z)\equiv\beta^{\rm reg}(z)$ and for ${\rm Im}\,z\leqslant 0$ the eigenvalue λ_2 generates the resonance (2.4) having the width $\Gamma_R^{(2)}\approx 2\,{\rm Im}\,\beta^{\rm reg}(\lambda_2+{\rm i}0)$. The latter satisfies the inequalities $c_{\mathcal{D}}\|b\|^2\leqslant\Gamma_R^{(2)}/2\leqslant C_{\mathcal{D}}\|b\|^2$. Substituting $|{\rm Re}\,a|\sim C_a\|b\|^2\sim(C_a/c_{\mathcal{D}})\,\Gamma_R^{(2)}$ in (2.16) we find the following approximate estimate of $\Gamma_R^{(m)}$ relative to $\Gamma_R^{(2)}$:

$$\Gamma_R^{(m)} \sim \Gamma_R^{(2)} \cdot \frac{C_a / c_{\mathcal{D}}}{\Gamma_R^{(1)}}. \tag{2.17}$$

The second inequality (2.9), chosen as a condition for $\|b\|$ reflects the fact that the ''usual'' molecular width $\Gamma_R^{(2)}$ is much smaller than the width of a usual ''nuclear'' resonance $\Gamma_R^{(1)}$,

$$C_a \Gamma_R^{(2)} \ll c_{\mathcal{D}} (\Gamma_R^{(1)})^2. \tag{2.18}$$

This can practically always be assumed for concrete molecules.

Under condition (2.7) the value of $C_a = |a|/\|b\|^2$ differs from zero, $C_a \geqslant C > 0$, as $\Gamma_R^{(1)} \to 0$. Therefore the estimates (2.16) and (2.17) imply that in the presence of a narrow ($\Gamma_R^{(1)} \ll C_a / c_{\mathcal{D}}$) ''nuclear'' resonance close to λ_2 the ''molecular'' width $\Gamma_R^{(m)}$ is much larger than the ''molecular'' width $\Gamma_R^{(2)}$ observed in absence of such a resonance. In fact, according to (2.17) this ratio is determined by the large quotient $(C_a / c_{\mathcal{D}} / \Gamma_R^{(1)})$.

Finally we note that if the conditions (2.9), and hence the condition (2.18) are not fulfilled, i.e., if the coupling between the channels in the Hamiltonian (2.1) is not small compared with the ''nuclear'' width, then it follows from (2.10) that the molecular width $\Gamma_R^{(m)}$ achieves itself an order of $\Gamma_R^{(1)}$. We do not discuss this case since such a situation can hardly be assumed to exist.

C. Exponential decay of the ''molecular'' state

Let us suppose that an initial state of the system described by the Hamiltonian A corresponds exactly to the pure ''molecular'' wave function $\varphi = \binom{1}{0}$. Then, the time evolution of the system is described by the solution $\psi(t)$ of the Cauchy problem

$$i \frac{d\psi}{dt} = A\psi, \quad \psi|_{t=0} = \varphi. \tag{2.19}$$

The probability of finding the system at the time t still in the molecular state φ is given by

$$P_{\mathrm{mol}}(t) = |\langle \psi(t), \varphi \rangle|^2.$$

The remainder $1 - P_{\mathrm{mol}}(t)$, hence, determines the probability for the state φ to decay into open channels of the continuous spectrum of the ''nuclear'' sub-Hamiltonian h_1.

To estimate the probability $P_{\mathrm{mol}}(t)$, we use the standard integral representation of a function of an operator via its resolvent. In the case considered this means

$$\exp\{-\mathrm{i}At\} = -\frac{1}{2\pi \mathrm{i}} \oint_\gamma dz\, \mathrm{e}^{-\mathrm{i}zt} (A - z)^{-1}. \tag{2.20}$$

The integration in (2.20) is performed in the physical sheet along a contour γ going counterclockwise around the spectrum of the matrix A. Recall that, due to the self-adjointness of the operator A, this spectrum is real. Taking into account the representations (2.2) and (2.20) one finds

$$\langle \psi(t), \varphi \rangle = -\frac{1}{2\pi \mathrm{i}} \oint_\gamma dz\, \frac{\exp(-\mathrm{i}zt)}{\lambda_2 - z - \beta(z)}. \tag{2.21}$$

This leads to the following important result. Under the conditions of Sec. II B the behavior of the integral (2.21) for $t > 0$ is described by the formula

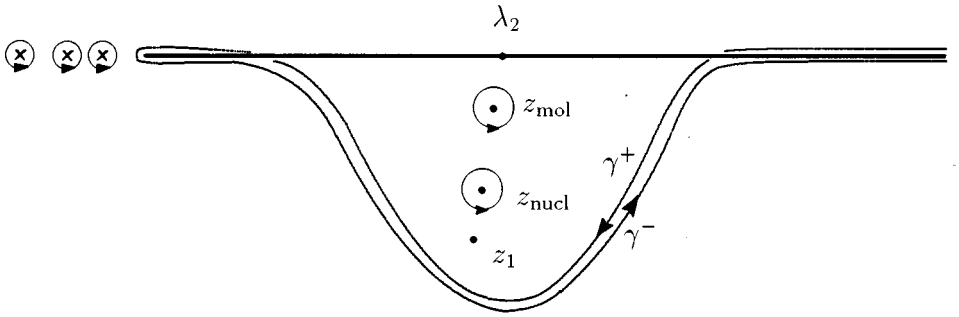

FIG. 1. A scheme showing the deformation of the integration path γ. The part γ^+ of the resulting contour belongs to the unphysical sheet, part γ^- to the physical sheet. The crosses ''×'' denote the discrete eigenvalues of the Hamiltonian A while the solid line corresponds to the continuous spectrum.

$$\langle \psi(t),\varphi\rangle = \exp\{-\mathrm{i}z_{\rm mol}t\}\left[1-\frac{a}{(\lambda_2-z_1-\beta^{\rm reg}(\lambda_2+\mathrm{i}0))^2}+O(\varepsilon^4(\lambda_2+\mathrm{i}0))\right] + \exp\{-\mathrm{i}z_{\rm nucl}t\}\left[\frac{a}{(\lambda_2-z_1-\beta^{\rm reg}(z_1))^2}+O(\varepsilon^4(z_1))\right]+\tilde{\varepsilon}(t), \tag{2.22}$$

where the value of $\varepsilon(z)$ is given by Eq. (2.12). The background term $\tilde{\varepsilon}(t)=O(\|b\|^2)$ is small, $|\tilde{\varepsilon}(t)|\ll 1$, for all $t>0$. In particular, if $E_R^{(1)}=\lambda_2$ we have

$$\langle \psi(t),\varphi\rangle \approx \exp\{-\mathrm{i}z_{\rm mol}t\}\left[1+\frac{4a}{(\Gamma_R^{(1)})^2}+\cdots\right]+\exp\{-\mathrm{i}z_{\rm nucl}t\}\left[-\frac{4a}{(\Gamma_R^{(1)})^2}+\cdots\right]. \tag{2.23}$$

The proof of the asymptotic relation (2.22) is carried out by estimating the contribution of the resonance poles $z_{\rm mol}$ and $z_{\rm nucl}$ to the integral (2.21). This is done by deforming parts of the contour γ situated in a neighborhood of the molecular energy λ_2 (see Fig. 1). A part γ^+ of γ, situated initially on the upper rim of the cut, is shifted into the neighboring unphysical sheet. Having done such a deformation one finds explicitly the residues of the integrand in (2.21) at $z=z_{\rm mol}$ and $z=z_{\rm nucl}$. An analogous deformation of a part γ^- of γ, situated initially on the lower rim, is performed in a domain $\mathrm{Im}\,z<0$ of the physical sheet. It is assumed that, though the parts γ^+ and γ^- belong to different energy sheets, their positions on these sheets coincide. It is also assumed that for any $z\in\gamma^\pm$ the estimate $|\beta^\pm(z)|\ll|\lambda_2-z|$ holds. Thus, the integration in (2.21) around the continuous spectrum of A, except the residues at $z=z_{\rm mol}$ and $z=z_{\rm nucl}$, gives

$$-\frac{1}{2\pi\mathrm{i}}\int_{\gamma^+}dz\,\exp(-\mathrm{i}zt)\left(\frac{1}{\lambda_2-z-\beta^+(z)}-\frac{1}{\lambda_2-z-\beta^-(z)}\right) = -\frac{1}{2\pi\mathrm{i}}\int_{\gamma^+}dz\,\exp(-\mathrm{i}zt)\,\frac{\beta^+(z)-\beta^-(z)}{[\lambda_2-z-\beta^+(z)][\lambda_2-z-\beta^-(z)]}. \tag{2.24}$$

Here we have used the specific notation $\beta^+(z)$ for the values of the function $\beta(z)$ at points z belonging to the curve γ^+ (i.e., lying in the unphysical sheet), and $\beta^-(z)$ for the values of $\beta(z)$ at the same points of the curve γ^- (i.e., lying in the physical sheet). Both $\beta^-(z)$ and $\beta^+(z)$ are of the order of $O(\|b\|^2)$, and $|\beta^\pm(z)|\ll|\lambda_2-z|$, while the exponential $\exp(-\mathrm{i}zt)$ at $\mathrm{Im}\,z<0$ is decreasing for $t>0$. The value of the function (2.24), thus, is always small, having an order of $O(\|b\|^2)$, and is even decreasing (in general nonexponentially) with increasing t. We include the contribution of this function in the background term $\tilde{\varepsilon}(t)$. The summand $\tilde{\varepsilon}(t)$ also includes a

contribution to (2.21) from the residues at the discrete eigenvalues of A. Apart from factors oscillating when t changes, the value of this contribution remains practically the same for all $t \geqslant 0$.

The formulas (2.22) and (2.23) show explicitly that in a large time interval $0 \leqslant t < T$, $T \sim (2/\Gamma_R^{(m)})\,|\ln \max|\tilde{\varepsilon}(t)||$, the decay of a ''molecular'' state φ in the presence of a narrow ''nuclear'' resonance is indeed of exponential character. The rate of this decay is determined mainly by the width $\Gamma_R^{(m)}$ of the ''molecular'' resonance z_{mol}, i.e., by the ratio $|\mathrm{Re}\, a|/\Gamma_R^{(1)}$,

$$P_{\mathrm{mol}}(t) \cong \exp\{-\Gamma_R^{(m)} t\} \cong \exp\left\{-\frac{4|\mathrm{Re}\, a|}{\Gamma_R^{(1)}} t\right\}. \tag{2.25}$$

III. ''MOLECULAR'' RESONANCES IN A ONE-DIMENSIONAL LATTICE

Let us assume that the ''molecules'' described by the Hamiltonian (2.1) are arranged in form of an infinite one-dimensional (linear) crystalline structure. To describe such a crystal we introduce the lattice Hilbert space

$$\mathcal{G} = \bigoplus_{i=-\infty}^{+\infty} \mathcal{H}^{(i)}$$

representing an orthogonal sum of the Hilbert spaces associated with the individual cells

$$\mathcal{H}^{(i)} = \mathcal{H}_1^{(i)} \oplus \mathcal{H}_2^{(i)}. \tag{3.1}$$

Here the subspaces $\mathcal{H}_1^{(i)} \equiv \mathcal{H}_1$ and $\mathcal{H}_2^{(i)} \equiv \mathcal{H}_2 \equiv \mathbb{C}$ are exactly the same ones as in Sec. II and, thus, $\mathcal{H}^{(i)} \equiv \mathcal{H}$. The elements of the total Hilbert space $\mathcal{G}$ are represented by the sequences $u = (\ldots, u^{(-2)}, u^{(-1)}, u^{(0)}, u^{(1)}, u^{(2)}, \ldots)$ with components $u^{(i)} = \binom{u_1^{(i)}}{u_2^{(i)}}$ where $u_1^{(i)} \in \mathcal{H}_1$ and $u_2^{(i)} \in \mathcal{H}_2 = \mathbb{C}$. The inner product in $\mathcal{H}$ is defined by $\langle u, v \rangle_{\mathcal{H}} = \Sigma_{i=-\infty}^{+\infty} \langle u^{(i)}, v^{(i)} \rangle_{\mathcal{H}(i)}$. The subspaces $\mathcal{G}_1 = \oplus_{i=-\infty}^{+\infty} \mathcal{H}_1^{(i)}$ and $\mathcal{G}_2 = \oplus_{i=-\infty}^{+\infty} \mathcal{H}_2^{(i)}$, with $\mathcal{G} = \mathcal{G}_1 \oplus \mathcal{G}_2$, are called pure nuclear and pure molecular channels, respectively.

In the present section we deal with the Hamiltonian H acting in $\mathcal{H}$ according to

$$(Hu)^{(i)} = W u^{(i-1)} + A u^{(i)} + W u^{(i+1)}, \tag{3.2}$$

where only the interaction between neighboring cells is taken into account and the interaction operator W is chosen in the simplest form

$$W = \begin{pmatrix} 0 & 0 \\ 0 & w \end{pmatrix} \tag{3.3}$$

with w being a positive number. Such a choice of the interaction corresponds to the natural assumption that the cells interact between each other via the molecular states, while the direct interaction between nuclear constituents belonging to different cells is negligible. We assume that the closed interval $[\lambda_2 - 2w, \lambda_2 + 2w]$ is totally embedded in the continuous spectrum $\sigma_c(h_0)$ of h_0 and, moreover, that no thresholds of $\sigma_c(h_0)$ belong to this interval. For the sake of simplicity we also assume that the interval belongs to the domain $\mathcal{D}$ introduced in Sec. II and that for any $\mu \in [\lambda_2 - 2w, \lambda_2 + 2w]$

$$\mathrm{Im}\langle r_0(\mu \pm \mathrm{i}0)\hat{b}, \hat{b} \rangle \neq 0. \tag{3.4}$$

Obviously, the Hamiltonian (3.2) represents a special case of the infinite Jacobi operator matrix (regarding the properties of some infinite scalar Jacobi matrices see, e.g., Refs. 24 and 25 and references cited therein). It is a self-adjoint operator on the domain $\mathcal{D}(H)=\oplus_{i=-\infty}^{+\infty}\mathcal{D}^{(i)}$ with $\mathcal{D}^{(i)}=\mathcal{D}(h_1)\oplus\mathbb{C}$.

The resolvent $R(z)=(H-z)^{-1}$ of H possesses a natural block structure, $R(z)=\{R(j,k;z)\}$, $j,k=0,\pm1,\pm2,\ldots,\pm\infty$. The blocks $R(j,k;z)$, providing the mapping $\mathcal{H}^{(k)}\to\mathcal{H}^{(j)}$, satisfy the equations

$$WR(j-1,k;z)+(A-z)R(j,k;z)+WR(j+1,k;z)=\delta_{jk}I, \tag{3.5}$$

where δ_{jk} stands for the Kronecker delta and I for the identity operator in the Hilbert space $\mathcal{H}$ of cells. Hereafter we assume $\operatorname{Im} z\neq0$ so that the value of z automatically belongs to the resolvent set of the operator H. The blocks $R(j,k;z)$ themselves possess a 2×2 matrix structure, $R(j,k;z)=\{R_{mn}(j,k;z)\}$, $m,n=1,2$, corresponding to the decomposition $\mathcal{H}=\mathcal{H}_1\oplus\mathcal{H}_2$.

The Fourier transform

$$(Fu)(p)=\frac{1}{\sqrt{2\pi}}\sum_{j=-\infty}^{+\infty}u^{(j)}\exp(\mathrm{i}pj) \tag{3.6}$$

in $\mathcal{G}$ reduces Eq. (3.5) to

$$(A-z)R(p,p';z)+2\cos p\,WR(p,p';z)=\delta(p-p')I, \tag{3.7}$$

where the quasimomentum p runs through the interval $[-\pi,\pi]$ and the function $R(p,p';z)$ represents the kernel of the resolvent $R(z)$ in this representation. From (3.7) follows immediately

$$R(p,p';z)=G(p;z)\,\delta(p-p'), \tag{3.8}$$

where

$$G(p;z)=\begin{pmatrix} r_1(z)+\dfrac{r_1(z)b\langle\cdot,b\rangle r_1(z)}{\widetilde{M}_2(p;z)} & -\dfrac{r_1(z)b}{\widetilde{M}_2(p;z)} \\ -\dfrac{\langle\cdot,b\rangle r_1(z)}{\widetilde{M}_2(p;z)} & \dfrac{1}{\widetilde{M}_2(p;z)} \end{pmatrix}. \tag{3.9}$$

This corresponds to the representation (2.2) of the resolvent of the cell Hamiltonian A, the only difference being that the transfer function $M_2(z)$ is replaced by the expression

$$\widetilde{M}_2(p;z)=\lambda_2-z+2w\cos p-\beta(z). \tag{3.10}$$

The factorization (3.8) implies

$$R(j,k;z)=\frac{1}{2\pi}\int_{-\pi}^{\pi}dp\,\mathrm{e}^{-\mathrm{i}p(j-k)}G(p;z)$$

and with the representation (3.9) we, thus, obtain

$$R(j,k;z)=\begin{pmatrix} \delta_{jk}r_1(z)+r_1(z)b\,R_{22}(j,k;z)\langle\cdot,b\rangle r_1(z) & -r_1(z)b\,R_{22}(j,k;z) \\ -R_{22}(j,k;z)\langle\cdot,b\rangle r_1(z) & R_{22}(j,k;z) \end{pmatrix}, \tag{3.11}$$

where

$$R_{22}(j,k;z)=\frac{1}{2\pi}\int_{-\pi}^{\pi}dp\,\frac{e^{-ip(j-k)}}{\lambda_2-z+2w\cos p-\beta(z)}. \tag{3.12}$$

Introducing the new variable $\zeta=e^{-ip}$, this integral is reduced to

$$R_{22}(j,k;z)=\frac{1}{2\pi i}\oint_{\gamma}d\zeta\,\frac{\zeta^{j-k}}{w\zeta^2+M_2(z)\zeta+w}.$$

Here, γ stands for the unit circle centered at the origin, the integration over γ being performed in the counterclockwise sense. Further, applying the residue theorem and taking into account the sign of the difference $j-k$ one finds

$$R_{22}(j,k;z)=\frac{\left\{\frac{1}{2w}[\sqrt{[M_2(z)-2w][M_2(z)+2w]}-M_2(z)]\right\}^{|j-k|}}{\sqrt{[M_2(z)-2w][M_2(z)+2w]}}. \tag{3.13}$$

It is assumed here that the branch $\sqrt{(\xi-2w)(\xi+2w)}$ of the function $((\xi-2w)(\xi+2w))^{1/2}$ is defined in the plane of the complex parameter ξ, cut along the interval $[-2w,2w]$, and that $\mathrm{Im}\,\xi>0$ implies $\mathrm{Im}\sqrt{(\xi-2w)(\xi+2w)}>0$, while $\mathrm{Im}\,\xi<0$ implies $\mathrm{Im}\sqrt{(\xi-2w)(\xi+2w)}<0$.

From Eqs. (3.11) and (3.13) it follows that all the nontrivial singularities of the resolvent $R(z)$, differing from those of the cell ''nuclear'' channel resolvent $r_1(z)$, are determined by the properties of the function

$$D(z)=\sqrt{[M_2(z)-2w][M_2(z)+2w]}.$$

First, we note that if $\|b\|=0$, and thus $M_2(z)=\lambda_2-z$, then the ''molecular'' and ''nuclear'' channels in the Hamiltonian H decouple. In this case the eigenvalue λ_2 generates for H an additional branch of the absolutely continuous spectrum which occupies the interval $[\lambda_2-2w,\lambda_2+2w]$. Second, even if $\|b\|\neq 0$ then the function $D(z)$ cannot have roots z with $\mathrm{Im}\,z\neq 0$ in the physical sheet. Otherwise such roots would generate for H a complex spectrum. But this is impossible because of the selfadjointness of H. Also, under the condition (3.4) this function cannot have real roots within the interval $[\lambda_2-2w,\lambda_2+2w]$ since for $\lambda_2-2w\leqslant\mu\leqslant\lambda_2+2w$ the imaginary part

$$\mathrm{Im}[M_2(\mu\pm i0)-2w]=\mathrm{Im}[M_2(\mu\pm i0)+2w]=-\|b\|^2\,\mathrm{Im}\langle r_1(\mu\pm i0)\hat{b},\hat{b}\rangle$$

is nonzero by the assumption (3.4). Thus, in a close neighborhood of the interval $[\lambda_2-2w,\lambda_2+2w]$ the equation $D(z)=0$ may only have roots in the unphysical sheet. In fact, assuming the conditions (2.9) and repeating literally the considerations which led to (2.13), one can rewrite this relation in form of the four equations,

$$z=\frac{\lambda_2-2w+z_1-\beta^{\mathrm{reg}}(z)}{2}\pm\frac{\lambda_2-2w-z_1-\beta^{\mathrm{reg}}(z)}{2}\left[1+\frac{2a}{(\lambda_2-2w-z_1-\beta^{\mathrm{reg}}(z))^2}+O(\varepsilon_-^2)\right], \tag{3.14}$$

$$z=\frac{\lambda_2+2w+z_1-\beta^{\mathrm{reg}}(z)}{2}\pm\frac{\lambda_2+2w-z_1-\beta^{\mathrm{reg}}(z)}{2}\left[1+\frac{2a}{(\lambda_2+2w-z_1-\beta^{\mathrm{reg}}(z))^2}+O(\varepsilon_+^2)\right], \tag{3.15}$$

where $\varepsilon_\pm=4a/(\lambda_2\pm 2w-z_1-\beta^{\mathrm{reg}}(z))$. In that part of the domain $\mathcal{D}$ which belongs to the unphysical sheet, equation $D(z)=0$ has four solutions being given essentially by

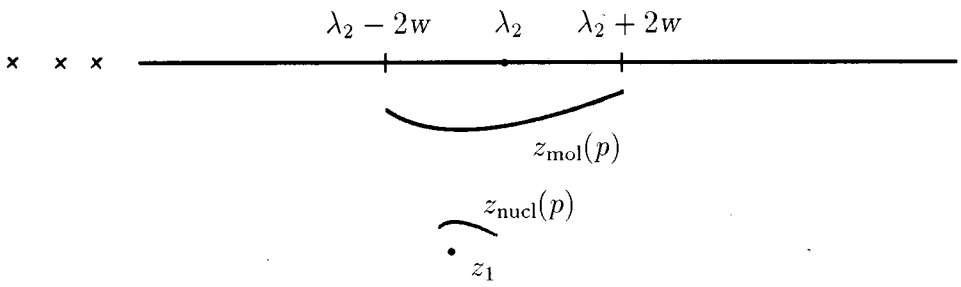

FIG. 2. A scheme showing the position of the resonance bands generated in the unphysical sheet by the ''molecular'' eigenvalue λ_2 and the ''nuclear'' resonance z_1. These bands are generated, respectively, by the points $z_{\rm mol}(p)$ and $z_{\rm nucl}(p)$ with the quasimomentum p running through the interval $[-\pi,\pi]$.

$$z_{\rm nucl}^{(\pm)} \cong z_1 - \frac{a}{\lambda_2 \pm 2w - z_1 - \beta^{\rm reg}(z_1)} \cong z_1 - \frac{a}{\lambda_2 \pm 2w - z_1}, \tag{3.16}$$

$$z_{\rm mol}^{(\pm)} \cong \lambda_2 \pm 2w - \beta^{\rm reg}(\lambda_2 \pm 2w + {\rm i}0) + \frac{a}{\lambda_2 \pm 2w - z_1 - \beta^{\rm reg}(\lambda_2 \pm 2w + {\rm i}0)}$$

$$\cong \lambda_2 \pm 2w + \frac{a}{\lambda_2 \pm 2w - z_1}. \tag{3.17}$$

Obviously, each of the roots $z_{\rm nucl}^{(\pm)}$ and $z_{\rm mol}^{(\pm)}$ represents an additional square-root branching point of the Riemann surface of the functions $R_{22}(j,k;z)$. Consequently, these roots are also the branching points of the Riemann surface of the total resolvent $R(z)$. Thus, one has to introduce the ''resonance'' cuts in the unphysical sheet considered. The cuts can be made, say, between $z_{\rm nucl}^{(-)}$ to $z_{\rm nucl}^{(+)}$ and between $z_{\rm mol}^{(-)}$ and $z_{\rm mol}^{(+)}$. Evidently, these cuts are to be interpreted as the resonance spectral bands generated by the initial ''molecular'' level λ_2 and the ''nuclear'' resonance z_1 (see Fig. 2).

Consider now the time evolution of the system described by the Hamiltonian H starting from a pure molecular state $\varphi = \varphi_1 \oplus \varphi_2$, $\|\varphi_n\| \in \mathcal{G}_n$, $n=1,2$, with $\varphi_1 = 0$ and $\|\varphi\| = \|\varphi_2\| = 1$. The probability to find the system at a time $t \geqslant 0$ in the molecular channel is given by

$$P_{\rm mol}(\varphi,t) = \|\mathsf{P}_2 {\rm e}^{-{\rm i}Ht}\varphi\|^2, \tag{3.18}$$

where P_2 is the orthogonal projection in $\mathcal{G}$ on the pure molecular subspace $\mathcal{G}_2$.

As in (2.20) we represent the time evolution operator $\exp(-{\rm i}Ht)$ in terms of the resolvent $R(z) = (H-z)^{-1}$,

$$\exp\{-{\rm i}Ht\} = -\frac{1}{2\pi{\rm i}} \oint_\gamma dz\, e^{-{\rm i}zt}(H-z)^{-1}, \tag{3.19}$$

where the integration is performed along a counterclockwise contour γ in the physical sheet encircling the spectrum of the Hamiltonian H. Recall that this spectrum is real since H is a self-adjoint operator.

According to Eqs. (3.8) and (3.10) the operator $\mathsf{P}_2 R(z)|_{\mathcal{G}_2}$ acts in quasimomentum representation as the multiplication operator

$$G_{22}(p,z) = [\tilde{M}_2(p;z)]^{-1} \tag{3.20}$$

and, thus,

$$(\mathsf{P}_2 R(z)\varphi)(p) = \frac{1}{\tilde{M}_2(p;z)}\,\varphi_2(p), \quad p \in [-\pi,\pi].$$

Here $\varphi_2(p)$ stands for the values of the Fourier transform (3.6) of the vector $\varphi_2 = (\ldots,\varphi_2^{(-2)},\varphi_2^{(-1)},\varphi_2^{(0)},\varphi_2^{(1)},\varphi_2^{(2)},\ldots)$, which means

$$(\mathsf{P}_2 \mathrm{e}^{-\mathrm{i}Ht}\varphi)(p) = -\frac{1}{2\pi\mathrm{i}}\,\varphi_2(p)\,J(p,t) \tag{3.21}$$

with

$$J(p,t) = \oint_\gamma dz\,\frac{\exp(-\mathrm{i}zt)}{\tilde{\lambda}_2(p) - z - \beta(z)}. \tag{3.22}$$

This expression has exactly the same form as the integral (2.21). The only difference consists in the replacement of λ_2 by the sum

$$\tilde{\lambda}_2(p) = \lambda_2 + 2w\cos p. \tag{3.23}$$

Thus, to estimate the function $J(p,t)$ one can immediately use the relation (2.22) in order to find

$$\begin{aligned} J(p,t) = {} & \exp\{-\mathrm{i}z_{\mathrm{mol}}(p)t\}\left[1 - \frac{a}{(\tilde{\lambda}_2(p) - z_1 - \beta^{\mathrm{reg}}(\tilde{\lambda}_2(p)+\mathrm{i}0))^2} + O(\varepsilon^4(p,\tilde{\lambda}_2(p)+\mathrm{i}0))\right] \\ & + \exp\{-\mathrm{i}z_{\mathrm{nucl}}(p)t\}\left[\frac{a}{(\tilde{\lambda}_2(p) - z_1 - \beta^{\mathrm{reg}}(z_1))^2} + O(\varepsilon^4(p,z_1))\right] + \tilde{\varepsilon}(p,t), \end{aligned} \tag{3.24}$$

where

$$\varepsilon(p,z) = \frac{a}{[\tilde{\lambda}_2(p) - z_1 - \beta^{\mathrm{reg}}(z)]^2}. \tag{3.25}$$

The function $\tilde{\varepsilon}(p,t) = O(\|b\|^2)$ is always small, $|\tilde{\varepsilon}(p,t)| \ll 1$. In accordance with Eqs. (2.14) and (2.15) we, hence, obtain for the positions of the poles

$$z_{\mathrm{nucl}}(p) \cong z_1 - \frac{a}{\lambda_2 + 2w\cos p - z_1}, \tag{3.26}$$

$$z_{\mathrm{mol}}(p) \cong \lambda_2 + 2w\cos p + \frac{a}{\lambda_2 + 2w\cos p - z_1}. \tag{3.27}$$

The resonance bands representing the ranges of the functions $z_{\mathrm{nucl}}(p)$ and $z_{\mathrm{mol}}(p)$, with p running through the interval $[-\pi,\pi]$, are schematically depicted in Fig. 2.

The asymptotics (3.24) implies

$$P_{\mathrm{mol}}(\varphi,t) = \int_{-\pi}^{\pi} dp\,|J(p,t)|^2\,|\varphi_2(p)|^2 = \int_{-\pi}^{\pi} dp\,\exp\{-\Gamma_R^{(m)}(p)\,t\}\,|\varphi_2(p)|^2 + \tilde{\varepsilon}(t), \tag{3.28}$$

where

$$\Gamma_R^{(m)}(p) = -2\,\mathrm{Im}\,z_{\mathrm{mol}}(p) \cong -2\,\mathrm{Im}\,\frac{a}{\lambda_2 + 2w\cos p - z_1}. \tag{3.29}$$

The background term $\tilde{\varepsilon}(t)$ in (3.28) is small for any $t\geqslant 0$, $\tilde{\varepsilon}(t)=O(\|b\|^2)$ and $|\tilde{\varepsilon}(t)|\ll 1$.

Further, let us assume that the real part $E_R^{(1)}$ of the ''nuclear'' resonance z_1 belongs to the interval $[\lambda_2-2w,\lambda_2+2w]$, that is $|E_R^{(1)}-\lambda_2|\leqslant 2w$. Then, one can always prepare an initial ''molecular'' state φ which decays via the ''nuclear'' channel with a rate as close as possible to the desired maximal value. Under the assumption (2.8), this maximum is given by

$$\max_{-\pi\leqslant p\leqslant\pi}\Gamma_R^{(m)}(p)\cong 4\frac{\operatorname{Re} a}{\Gamma_R^{(1)}}$$

[cf. formula (2.16)]. The correspondingly prepared ''molecular'' state φ has an almost monochromatic component $\varphi_2(p)$ being localized in a close neighborhood of the quasimomenta

$$p=\pm\arccos\frac{E_R^{(1)}-\lambda_2}{2w}.$$

For example, if the function $\varphi_2(p)$ is nonzero only for quasimomenta p restricted by $|\cos p-(E_R^{(1)}-\lambda_2)/2w|\leqslant\delta\Gamma_R^{(1)}/(4w)$ with some small $\delta>0$, then the width $\Gamma_R^{(m)}$ given by the relation (3.29) varies in an interval lying approximately between $[1/(1+\delta^2)]4\operatorname{Re} a/\Gamma_R^{(1)}$ and $4\operatorname{Re} a/\Gamma_R^{(1)}$.

IV. ''MOLECULAR'' RESONANCES IN A MULTIDIMENSIONAL LATTICE

In this section we consider the case where the ''molecules'' described by the Hamiltonians (2.1) form an infinite N-dimensional crystalline structure. To label the cells of the respective lattice we use the multi-index $i\in\mathbb{Z}^N$, i.e., $i=(i_1,i_2,\ldots,i_N)$ with $i_k=\ldots,-2,-1,0,1,2,\ldots$, $k=1,2,\ldots,N$. The Hilbert space of the system considered is in this case $\mathcal{G}=\oplus_{i\in\mathbb{Z}^N}\mathcal{H}^{(i)}$, where the individual cell spaces are given by (3.1), with $\mathcal{H}_1^{(i)}\equiv\mathcal{H}_1$ and $\mathcal{H}_2^{(i)}\equiv\mathcal{H}_2\equiv\mathbb{C}$ being the spaces introduced in Sec. II. For the components $u^{(i)}\in\mathcal{H}^{(i)}$ of the elements u of the total Hilbert space $\mathcal{G}$ we again use the column representation $u^{(i)}=\binom{u_1^{(i)}}{u_2^{(i)}}$ with $u_1^{(i)}\in\mathcal{H}_1$ and $u_2^{(i)}\in\mathcal{H}_2=\mathbb{C}$. The inner product in $\mathcal{H}$ is defined as $\langle u,v\rangle_{\mathcal{H}}=\Sigma_{i\in\mathbb{Z}^N}\langle u^{(i)},v^{(i)}\rangle_{\mathcal{H}^{(i)}}$. The subspaces $\mathcal{G}_1=\oplus_{i\in\mathbb{Z}^N}\mathcal{H}_1^{(i)}$ and $\mathcal{G}_2=\oplus_{i\in\mathbb{Z}^N}\mathcal{H}_2^{(i)}$, with $\mathcal{G}_1\oplus\mathcal{G}_2=\mathcal{G}$, represent pure nuclear and pure molecular channels, respectively.

The Hamiltonian is defined in $\mathcal{G}$ by the expression

$$(Hu)^{(i)}=Au^{(i)}+\sum_{j\in\mathbb{Z}^n,j\neq i}W(i,j)u^{(j)},\tag{4.1}$$

where the interaction matrices

$$W(i,j)=\begin{pmatrix}w_{11}(i,j) & w_{12}(i,j)\\ w_{21}(i,j) & w_{22}(i,j)\end{pmatrix}$$

consist of the block components $w_{mn}(i,j)$ providing the mappings $\mathcal{H}_n\to\mathcal{H}_m$, $m,n=1,2$. These components describe the direct interaction between the mth and nth channels of the different cells i and j, respectively. The matrices $W(i,j)$ are assumed to be bounded operators in $\mathcal{H}$ which depend only on the difference $i-j=(i_1-j_1,i_2-j_2,\ldots,i_N-j_N)$, i.e., $W(i,j)=W(i-j)$ and, thus, the same holds for the block components, $w_{mn}(i,j)=w_{mn}(i-j)$. Moreover, the series of $W(j)$ is assumed to be convergent with respect to the operator norm topology, i.e.,

$$\sum_{j\in\mathbb{Z}_N,j\neq 0}\|W(j)\|<+\infty\tag{4.2}$$

and the property

$$W(j-i)=[W(i-j)]^*\tag{4.3}$$

is assumed. With such $W(i,j)$ the Hamiltonian (4.1) is a self-adjoint operator on the domain $\mathcal{D}(H)=\oplus_{i\in\mathbb{Z}^N}\mathcal{D}^{(i)}$ with $\mathcal{D}^{(i)}=\mathcal{D}(h_1)\oplus\mathbb{C}$. Note that, since $\mathcal{H}_2=\mathbb{C}$, the quantities $w_{22}(i-j)$ are complex numbers. The $w_{12}(i-j)$ are vectors in $\mathcal{H}_1$, the $w_{21}(i-j)$ are continuous linear forms on $\mathcal{H}_1$, and the $w_{11}(i-j)$ are bounded operators in $\mathcal{H}_1$.

Let us denote by $\mathbb{T}^N$ the Cartesian product $\mathbb{T}^N=\underbrace{\mathbb{T}\times\mathbb{T}\times\ldots\times\mathbb{T}}_{N}$ of the N intervals $\mathbb{T}=[-\pi,\pi]$ and by p the points of $\mathbb{T}^N$, $p=(p_1,p_2,\ldots,p_N)$, $p_k\in\mathbb{T}$. The assumption (4.2) implies that the operator-valued function

$$\Omega(p)=\sum_{j\in\mathbb{Z}_n,j\neq 0} W(j)\exp(\mathrm{i}\langle p,j\rangle),\quad \Omega(p):\mathcal{H}\to\mathcal{H},\quad p\in\mathbb{T}^N, \tag{4.4}$$

where $\langle p,j\rangle=\Sigma_{k=1}^{N}p_kj_k$ is continuous and bounded on $\mathbb{T}^N$. Due to Eq. (4.3), the values

$$\Omega(p)=\begin{pmatrix}\omega_{11}(p) & \omega_{12}(p)\\ \omega_{21}(p) & \omega_{22}(p)\end{pmatrix}$$

of this function represent selfadjoint operators in $\mathcal{H}$ for any $p\in\mathbb{T}^N$, with

$$\omega_{mn}(p):\mathcal{H}_n\to\mathcal{H}_m;\quad [\omega_{11}(p)]^*=\omega_{11}(p),\quad \omega_{22}(p)\in\mathbb{R},\quad \text{and}\quad [\omega_{21}(p)]^*=\omega_{12}(p).$$

The quantity $\tilde{b}(p)=\omega_{12}(p)$ can be considered as a vector of $\mathcal{H}_1$ while $\omega_{21}(p)=\langle\cdot,\tilde{b}(p)\rangle$ [cf. definition (2.1) of the Hamiltonian A].

The blocks $R(j,k;z)$, $R(j,k;z):\mathcal{H}^{(k)}\to\mathcal{H}^{(j)}$, $j,k\in\mathbb{Z}^N$, of the resolvent $R(z)=(H-z)^{-1}$ satisfy the equation

$$(A-z)R(j,k;z)+\sum_{j'\in\mathbb{Z}_N,j'\neq j} W(j-j')R(j',k;z)=\delta_{jk}I. \tag{4.5}$$

After Fourier transformation in $\mathcal{G}$,

$$(Fu)(p)=\frac{1}{(2\pi)^{N/2}}\sum_{j\in\mathbb{Z}^N} u^{(j)}\exp(\mathrm{i}\langle p,j\rangle),\quad p\in\mathbb{T}^N,$$

the system (4.5) takes the form

$$(A-z)R(p,p';z)+\Omega(p)\,R(p,p';z)=\delta(p-p')I, \tag{4.6}$$

where the quasimomenta p,p' run through the set $\mathbb{T}^N$ and $R(p,p';z)$ stands for the transformed resolvent $R(z)$. Thus, the factorization (3.8) holds with

$$G(p;z)=[A+\Omega(p)-z]^{-1}. \tag{4.7}$$

First, let us consider the specific case where intercellular interactions $W(i-j)$ in the Hamiltonian (4.1) have the simple form

$$W(i-j)=\begin{pmatrix}0 & 0\\ 0 & w_{22}(i-j)\end{pmatrix}, \tag{4.8}$$

i.e., where the cells interact with each other only via the molecular channels. Obviously, in this case the factor $G(p;z)$ is still given by (3.9). As compared to this expression the only difference is that now $p\in\mathbb{T}^N$ and

$$\widetilde{M}_2(p;z)=\lambda_2-z+\omega_{22}(p)-\beta(z). \tag{4.9}$$

Let $\omega_{22}^{\min}=\min_{p\in\mathbb{T}^N}\omega_{22}(p)$ and $\omega_{22}^{\max}=\max_{p\in\mathbb{T}^N}\omega_{22}(p)$. Similarly to the analogous assumption in Sec. III we assume that the closed interval $[\lambda_2+\omega_{22}^{\min},\lambda_2+\omega_{22}^{\max}]$ is totally embedded in the absolutely continuous spectrum $\sigma_c(h_1)$ of h_1, and no thresholds of this spectrum belong to $[\lambda_2+\omega_{22}^{\min},\lambda_2+\omega_{22}^{\max}]$. We also assume that this interval belongs to the holomorphy domain $\mathcal{D}$ of the function $\beta(z)$, and that for $\mu\in[\lambda_2+\omega_{22}^{\min},\lambda_2+\omega_{22}^{\max}]$ the inequality (3.4) holds.

Let us consider the time evolution of the system described by the Hamiltonian (4.1) with the simple intercellular interactions (4.8) subject to the above conditions. We start again from a pure molecular state $\varphi=\varphi_1\oplus\varphi_2$, $\|\varphi_n\|\in\mathcal{G}_n$, $n=1,2$, with $\varphi_1=0$ and $\|\varphi\|=\|\varphi_2\|=1$. The probability $P_{\mathrm{mol}}(\varphi,t)$ to find the system at a time $t\geqslant 0$ in the molecular channel is given by the analog of (3.18). As in Sec. III one finds the quasimomentum representation

$$(\mathsf{P}_2R(z)\varphi)(p)=G_{22}(p;z)\varphi_2(p)=\frac{1}{\widetilde{M}_2(p;z)}\,\varphi_2(p),\quad p\in\mathbb{T}^N,$$

and relations (3.21), (3.22) and (3.24) are still valid with the only difference that instead of (3.23) $\widetilde{\lambda}_2(p)$ is now of the form

$$\widetilde{\lambda}_2(p)=\lambda_2+\omega_{22}(p),\quad p\in\mathbb{T}^N.$$

According to Eqs. (2.14) and (2.15) the main terms of the roots $z_{\mathrm{nucl}}(p)$ and $z_{\mathrm{mol}}(p)$ of the function (4.9) in the unphysical sheet read

$$z_{\mathrm{nucl}}(p)\cong z_1-\frac{a}{\lambda_2+\omega_{22}(p)-z_1}, \tag{4.10}$$

$$z_{\mathrm{mol}}(p)\cong\lambda_2+\omega_{22}(p)+\frac{a}{\lambda_2+\omega_{22}(p)-z_1}. \tag{4.11}$$

The asymptotic equation (3.24) now implies

$$P_{\mathrm{mol}}(\varphi,t)=\int_{\mathbb{T}^N}dp\,|J(p,t)|^2\,|\varphi_2(p)|^2=\int_{\mathbb{T}^N}dp\,\exp\{-\Gamma_R^{(m)}(p)t\}|\varphi_2(p)|^2+\widetilde{\varepsilon}(t) \tag{4.12}$$

with

$$\Gamma_R^{(m)}(p)=-2\,\mathrm{Im}\,z_{\mathrm{mol}}(p)\cong-2\,\mathrm{Im}\frac{a}{\lambda_2+\omega_{22}(p)-z_1}.$$

As in Sec. III the background term $\widetilde{\varepsilon}(t)$ is small for any $t\geqslant 0$, $\widetilde{\varepsilon}(t)=O(\|b\|^2)$ and $|\widetilde{\varepsilon}(t)|\ll 1$.

Thus, if the real part $E_R^{(1)}$ of the ''nuclear'' resonance z_1 belongs to the interval $[\lambda_2+\omega_{22}^{\min},\lambda_2+\omega_{22}^{\max}]$ then there are ''molecular'' states φ which decay via the ''nuclear'' channel with a rate as close as possible to the maximal value (2.16). In this case the components $\varphi_2(p)$ are localized in a close neighborhood of the manifold

$$\lambda_2+\omega_{22}(p)=E_R^{(1)} \tag{4.13}$$

in the quasimomentum space $\mathbb{T}^N$. In particular, if the initial state φ is prepared such that the component $\varphi_2(p)$ is nonzero only for the quasimomenta p lying in the domain $|\lambda_2+\omega_{22}(p)-E_R^{(1)}|\leqslant\delta\Gamma_R^{(1)}/2$ with some small $\delta>0$, then one should only integrate over this domain in the

integral (4.12). In such a case, under the condition (2.8), a lower estimate for the decay rate $\Gamma_R^{(m)}$ is given, as in Sec. III, by $[1/(1+\delta^2)]4\,\mathrm{Re}\,a/\Gamma_R^{(1)}$. Thus, by varying δ one can get a rate as close as possible to the maximum (2.16).

Now, let us consider briefly the case of more general intercellular interactions $W(i-j)$ where all the components $\omega_{mn}(p)$, $m,n=1,2$, of the matrix $\Omega(p)$, $p\in\mathbb{T}^N$, can be nontrivial. In this case the component $G_{22}(p;z)$ of the factor (4.7) is given again by Eqs. (3.20) and (4.9). However, the function $\beta(z)$ in (4.9) is to be replaced by the modified function

$$\tilde{\beta}(p;z)=\langle[h_1+\omega_{11}(p)-z]^{-1}[b+\tilde{b}(p)],[b+\tilde{b}(p)]\rangle,$$

where $\tilde{b}(p)=\omega_{12}(p)$. We make the natural assumption that the direct intercellular interactions in nuclear channels $w_{11}(i-j)$ are so weak that the term $\omega_{11}(p)$ produces only a very small perturbation of the initial ''nuclear'' resonance z_1 generated by the Hamiltonian h_1. More precisely, we assume that the resonance $\tilde{z}_1(p)$ generated by the perturbed Hamiltonian $h_1+\omega_{11}(p)$ has the property

$$|\tilde{z}_1(p)-z_1|\ll\Gamma_R^{(1)}\quad\text{for any}\quad p\in\mathbb{T}^N \tag{4.14}$$

and that no other resonances arise in the domain $\mathcal{D}$. Another natural assumption is that the strength of the interactions $w_{12}(i-j)$ and $w_{21}(i-j)$, $i\neq j$, between ''nuclear'' and ''molecular'' channels of different cells is much weaker than the one of a single cell. This is why we can assume $\|\tilde{b}(p)\|/\|b\|\lesssim 1$ and the following features. The elements $\tilde{b}(p)\in\mathcal{H}_1$ are such that for any $p\in\mathbb{T}^n$ the function $\tilde{\beta}(p;z)$ admits an analytic continuation into the domain $\mathcal{D}$ of the unphysical sheet and in $\mathcal{D}$ a representation of the type (2.6) holds for $\tilde{\beta}(p;z)$,

$$\tilde{\beta}(p;z)=\frac{\tilde{a}(p)}{\tilde{z}_1(p)-z}+\tilde{\beta}^{\mathrm{reg}}(p;z), \tag{4.15}$$

with an explicitly separated pole term $\tilde{a}(p)/(\tilde{z}_1(p)-z)$ and a holomorphic remainder $\tilde{\beta}^{\mathrm{reg}}(p;z)$. As in Sec. II B we assume that $|\tilde{a}(p)|=C_a(p)\|b\|^2$, and that for any $p\in\mathbb{T}^N$ the limiting procedure (2.7) is possible for $C_a(p)$ while $\mathrm{Im}\,\tilde{a}(p)\ll\mathrm{Re}\,\tilde{a}(p)$. For the remainder $\tilde{\beta}^{\mathrm{reg}}(p;z)$, $p\in\mathbb{T}^N$, $z\in\mathcal{D}$, the same statements are assumed to be valid as for the function $\beta^{\mathrm{reg}}(z)$. Under these assumptions one can repeat almost literally the study of the probability $P_{\mathrm{mol}}(\varphi,t)$ as performed above in case of the interactions (4.8). We find again that the asymptotics of $P_{\mathrm{mol}}(\varphi,t)$ is given by (4.12) with

$$\Gamma_R^{(m)}(p)\cong -2\,\mathrm{Im}\frac{\tilde{a}(p)}{\lambda_2+\omega_{22}(p)-\tilde{z}_1(p)}.$$

Let us denote by $(\mathrm{Re}\,\tilde{a})_{\max}$ the maximal value of the function $\mathrm{Re}\,\tilde{a}(p)$ on the manifold (4.13). It is obvious that if one prepares the initial pure ''molecular'' state φ such that its component $\varphi_2(p)$ is localized in a close neighborhood of the subset of the manifold (4.13), where $\mathrm{Re}\,\tilde{a}(p)=(\mathrm{Re}\,\tilde{a})_{\max}$, then for the probability $P_{\mathrm{mol}}(\varphi,t)$ the main qualitative result remains practically the same as in case of the interactions (4.8). Namely, varying the support of the component $\varphi_2(p)$ in $\mathbb{T}^N$ one can achieve a decay rate of the state φ as close as possible to the maximal value of the width $\Gamma_R^{(m)}(p)$ in (4.13). The main term $4(\mathrm{Re}\,\tilde{a})_{\max}/\Gamma_R^{(1)}$ of this value is again inversely proportional to the ''nuclear'' width $\Gamma_R^{(1)}$.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 42, NUMBER 6 JUNE 2001

A uniqueness theorem for entanglement measures

Oliver Rudolph[a)]
Physics Division, Starlab nv/sa, Engelandstraat 555, B-1180 Brussels, Belgium

(Received 31 January 2000; accepted for publication 14 March 2001)

We obtain a mathematically simple characterization of all functionals coinciding with the von Neumann reduced entropy on pure states based on the Khinchin–Faddeev axiomatization of Shannon entropy and give a physical interpretation of the axioms in terms of entanglement. © *2001 American Institute of Physics.*
[DOI: 10.1063/1.1370954]

I. INTRODUCTION

The characterization and classification of entanglement in quantum mechanics is one of the cornerstones of the emerging field of quantum information theory. This note is devoted to the study of entanglement measures. Entanglement measures are positive real-valued functionals defined on the joint state space of two or more quantum systems (subject to further requirements). A number of entanglement measures have been discussed in the literature, such as the von Neumann reduced entropy, the relative entropy of entanglement,[1] the so-called entanglement of distillation and the entanglement of formation.[2] Several authors proposed physically motivated postulates to characterize entanglement measures (see, e.g., Refs. 1, 3, and 4). These postulates (although they vary from author to author in the details) have in common that they are based on the concepts of the operational formulation of quantum mechanics.[5] Mathematically, the list of postulates for entanglement measures serves as the definition of the notion of entanglement measure. Many authors agree that the only physically reasonable entanglement measure on pure states is given by the von Neumann reduced entropy. Indeed, it is a known fact that there are important entanglement measures which do coincide with the von Neumann reduced entropy on pure states, for instance the relative entropy of entanglement.[1] Accordingly, it is generally seen as a desirable property of the axiomatic characterization of entanglement measures that it allows only for entanglement measures which coincide with the von Neumann reduced entropy on pure states. This point of view is supported by an argument by Popescu and Rohrlich[6] who claimed to have identified a list of physically reasonable axioms which ensure the uniqueness of entanglement measures on pure states. A mathematically exact statement and proof of this *operational* uniqueness theorem remained so far elusive but will be given in a forthcoming paper.[7]

In this paper we present an alternative list of physically reasonable and mathematically simple postulates for entanglement measures such that all entanglement measures satisfying these postulates coincide with the von Neumann reduced entropy on pure states. Mathematically our postulates are just an adaptation of the Khinchin–Faddeev characterization of Shannon entropy[8] and all proofs in this paper are elementary. The main purpose of this paper is not to communicate new mathematical methods but rather that physically the Khinchin-Faddeev postulates admit a natural interpretation in terms of entanglement rather than information or lack of information. What is also interesting about the present result is first that our axiomatization can be formulated without resorting to the mathematical apparatus and the physical concepts of the theory of local quantum operations and second that the technical asymptotic requirements which are so central to the Popescu–Rohrlich argument (see Refs. 6 and 7) can be eliminated as well. It turns out that they can be replaced basically by a single intuitive and comparably weak requirement which fixes the value of entanglement measures on pure states.

II. PRELIMINARIES

In this section we collect some basic definitions and results which are used in the course of this paper.

In the present paper we restrict ourselves mainly to the situation of a composite quantum system consisting of two subsystems with Hilbert space $\mathcal{H}_1\otimes\mathcal{H}_2$ where $\mathcal{H}_1$ and $\mathcal{H}_2$ denote the Hilbert spaces of the subsystems. The states of the system are identified with the density operators on $\mathcal{H}_1\otimes\mathcal{H}_2$. A density operator is a positive trace class operator with trace one.

Definition 1: Let $\mathcal{H}_1$ and $\mathcal{H}_2$ be two Hilbert spaces of arbitrary dimension. A density operator ρ on the tensor product $\mathcal{H}_1\otimes\mathcal{H}_2$ is called separable *or* disentangled *if there exist a family $\{\omega_i\}$ of positive real numbers, a family $\{\rho_i^{(1)}\}$ of density operators on $\mathcal{H}_1$ and a family $\{\rho_i^{(2)}\}$ of density operators on $\mathcal{H}_2$ such that*

$$\rho=\sum_i \omega_i\rho_i^{(1)}\otimes\rho_i^{(2)}, \tag{1}$$

where the sum converges in trace class norm.

The set of states is a convex set and its extreme points, which are also called *pure states*, are the projection operators. Every pure state obviously corresponds to a unit vector ψ in $\mathcal{H}_1\otimes\mathcal{H}_2$. We denote the projection operator onto the subspace spanned by the unit vector ψ by P_ψ.

The Schmidt decomposition (see also Ref. 9) is of central importance in the characterization and quantification of entanglement associated with pure states.

Lemma 2: Let $\mathcal{H}_1$ and $\mathcal{H}_2$ be Hilbert spaces of arbitrary dimension and let $\psi\in\mathcal{H}_1\otimes\mathcal{H}_2$. Then there exist a family of non-negative real numbers $\{p_i\}_i$ and orthonormal bases $\{a_i\}_i$ and $\{b_i\}_i$ of $\mathcal{H}_1$ and $\mathcal{H}_2$, respectively, such that

$$\psi=\sum_i \sqrt{p_i}a_i\otimes b_i.$$

The family of positive numbers $\{p_i\}_i$ is called the family of *Schmidt coefficients* of ψ. For pure states the family of Schmidt coefficients of a state completely characterizes the amount of entanglement of that state. A pure state ψ is separable if and only if $\psi=a\otimes b$ for some $a\in\mathcal{H}_1$ and $b\in\mathcal{H}_2$. With every vector ψ in $\mathcal{H}_1\otimes\mathcal{H}_2$ we associate a closed subspace $M(\psi)$ of $\mathcal{H}_1\otimes\mathcal{H}_2$: let $\psi=\Sigma_i\sqrt{p_i}a_i\otimes b_i$ be the Schmidt decomposition of ψ as in Lemma 2, then $M(\psi)$ is defined as the subspace of $\mathcal{H}_1\otimes\mathcal{H}_2$ spanned by all simple product states $a_i\otimes b_i$ with nonzero Schmidt coefficient in the Schmidt decomposition of ψ. We call $M(\psi)$ the *Schmidt subspace* associated with ψ. The dimension of $M(\psi)$ is called the *Schmidt rank* of ψ. Moreover, we call two states ψ and ϕ *Schmidt orthogonal* if $M(\psi)$ and $M(\phi)$ are orthogonal.

The *von Neumann reduced entropy* for density operators σ on a tensor product Hilbert space $\mathcal{H}_1\otimes\mathcal{H}_2$ is defined as

$$S_{\mathrm{vN}}(\sigma):=-\mathrm{Tr}_{\mathcal{H}_1}(\mathrm{Tr}_{\mathcal{H}_2}\sigma\ln(\mathrm{Tr}_{\mathcal{H}_2}\sigma)), \tag{2}$$

where $\mathrm{Tr}_{\mathcal{H}_1}$ and $\mathrm{Tr}_{\mathcal{H}_2}$ denote the partial traces over $\mathcal{H}_1$ and $\mathcal{H}_2$, respectively. In the case of pure states $\sigma=P_\psi$, it can be shown that $-\mathrm{Tr}_{\mathcal{H}_1}(\mathrm{Tr}_{\mathcal{H}_2}P_\psi\ln(\mathrm{Tr}_{\mathcal{H}_2}P_\psi))=-\mathrm{Tr}_{\mathcal{H}_2}(\mathrm{Tr}_{\mathcal{H}_1}P_\psi\ln(\mathrm{Tr}_{\mathcal{H}_1}P_\psi))$ $=-\Sigma_i p_i\ln p_i$ where $\{p_i\}_i$ denotes the family of Schmidt coefficients of ψ. However, for a general mixed state σ we have $\mathrm{Tr}_{\mathcal{H}_1}(\mathrm{Tr}_{\mathcal{H}_2}\sigma\ln(\mathrm{Tr}_{\mathcal{H}_2}\sigma))\neq\mathrm{Tr}_{\mathcal{H}_2}(\mathrm{Tr}_{\mathcal{H}_1}\sigma\ln(\mathrm{Tr}_{\mathcal{H}_1}\sigma))$.

The Khinchin–Faddeev axiomatization of Shannon entropy can be formulated as follows (taken from Ref. 10)

Lemma 3: Let Π denote the set of all probability distributions $(p_1,\ldots,p_n)$ $(p_i\geqslant 0,\Sigma_i p_i=1)$. Let $S:\Pi\to\mathbb{R}$ be a function satisfying

Continuity: $p\mapsto S(p,1-p)$ is continuous on $[0,1]$.

Normalization: $S(1/2,1/2)=\log 2$.

Symmetry: $S(p_{\kappa(1)},\ldots,p_{\kappa(n)})=S(p_1,\ldots,p_n)$ *for all permutations* κ *of* $\{1,\ldots,n\}$.

Recursion: For every $0\leqslant\eta\leqslant 1$ *we have* $S(p_1,\ldots,p_{n-1},\eta p_n,(1-\eta)p_n)=S(p_1,\ldots,p_n)+p_n S(\eta,1-\eta)$.

Then S is equal to the Shannon entropy, i.e., $S(p_1,\ldots,p_n)=-\Sigma_{i=1}^n p_i\log p_i$.

III. KHINCHIN–FADDEEV-TYPE POSTULATES FOR ENTANGLEMENT MEASURES

A. Entanglement measures on pure states

Let $\mathcal{H}_1$ and $\mathcal{H}_2$ be Hilbert spaces. For the moment we restrict ourselves to the problem of characterizing entanglement measures defined on pure states, i.e., functionals $E:\mathcal{H}_1\otimes\mathcal{H}_2\to\mathbb{R}^+$. The discussion in this section starts from the question: what are the minimal conditions we want to impose on a mathematically satisfactory measure of entanglement? It is reasonable to require that E is defined and continuous on the tensor product of the Hilbert spaces of any given two systems. Moreover, we have argued above that the sequence of Schmidt coefficients fully characterizes the entanglement of a pure state. Therefore we expect $E(\psi)$ to depend only on the Schmidt coefficients of ψ. Equivalently, we require that for any given system $\mathcal{H}_1\otimes\mathcal{H}_2$ the entanglement measure $E:\mathcal{H}_1\otimes\mathcal{H}_2\to\mathbb{R}^+$ is invariant under unitary operations of the form $U\otimes V$, where U and V are unitaries on $\mathcal{H}_1$ and on $\mathcal{H}_2$, respectively. We also require that E is invariant under embeddings into larger Hilbert spaces.

(P1) An entanglement measure is a positive real-valued functional E which for any given two systems is well defined on the tensor product of the Hilbert spaces of the two systems. For any given two systems corresponding to Hilbert spaces $\mathcal{H}_1$ and $\mathcal{H}_2$ the function $\mathcal{H}_1\otimes\mathcal{H}_2\ni\psi\mapsto E(\psi)$ is continuous in the norm topology.

(P2) For any given two systems with Hilbert spaces $\mathcal{H}_1$ and $\mathcal{H}_2$ the function $E:\mathcal{H}_1\otimes\mathcal{H}_2\to\mathbb{R}^+$ satisfies

$$E(U\otimes V\psi)=E(\psi)$$

for all $\psi\in\mathcal{H}_1\otimes\mathcal{H}_2$ and all unitaries U,V acting on $\mathcal{H}_1$ and $\mathcal{H}_2$, respectively.

(P3) Whenever $\psi\in\mathcal{H}_1\otimes\mathcal{H}_2\subset\mathsf{H}_1\otimes\mathsf{H}_2$ with embeddings $\mathcal{H}_1\hookrightarrow\mathsf{H}_1$ and $\mathcal{H}_2\hookrightarrow\mathsf{H}_2$ of $\mathcal{H}_1$ and $\mathcal{H}_2$ into larger Hilbert spaces H_1 and H_2, respectively, then $E|_{\mathcal{H}_1\otimes\mathcal{H}_2}(\psi)=E|_{\mathsf{H}_1\otimes\mathsf{H}_2}(\psi)$.

We exclude the identically vanishing functional $E\equiv 0$. It is an immediate consequence of (P2) and (P3), that for every pure state ψ the value $E(\psi)$ does only depend on the nonzero Schmidt coefficients of ψ. We will therefore also write $E(\lambda_1,\ldots,\lambda_n)$ for $E(\psi)$ where $\{\lambda_1,\ldots,\lambda_n\}$ denotes the family of (nonvanishing) Schmidt coefficients of ψ.

Hilbert spaces are linear spaces, and therefore, trivially, all normalized linear combinations of pure states are pure states themselves. Consider for instance $\phi=\Sigma_m\sqrt{p_m}\psi_m$ where $\{p_m\}$ is a probability distribution and where $\psi_m\in\mathcal{H}_1\otimes\mathcal{H}_2$. Naively one might hope that the entanglement $E(\phi)$ of ϕ is a weighted sum of the entanglement of the ψ_m plus the entanglement associated with the superposition $E(p_1,\ldots,p_m)$. It is easy to see that this is not true in general, and that on the contrary superpositions of maximally entangled states can even be unentangled. Mathematically this can be traced back to the fact that the Schmidt spaces of the superimposed states are not orthogonal. Generally, superposing a family $\psi_1,\ldots,\psi_m$ of pure states whose Schmidt spaces are not mutually orthogonal may increase as well as decrease entanglement. However, in the case of superpositions of mutually Schmidt orthogonal pure states no term in the Schmidt decomposition of one state can cancel terms in the Schmidt decomposition of another state. Therefore for the special case of a superposition $\phi=\Sigma_m\sqrt{p_m}\psi_m$ of a family $\{\psi_1,\ldots,\psi_m\}$ of mutually Schmidt orthogonal pure states (where $\{p_1,\ldots,p_m\}$ is a probability distribution), what we expect physically is that the entanglement of the superposed state equals the averaged entanglement of the $\{\psi_i\}$ plus the entanglement $E(p_1,\ldots,p_n)$ associated with the superposition. More formally we require

(P4) Let $\{\psi_1,\ldots,\psi_m\}$ be a family of mutually Schmidt orthogonal pure states and $\{\lambda_1,\ldots,\lambda_m\}$ be a distribution of probability amplitudes, i.e., a sequence of complex numbers with $\Sigma_{i=1}^m|\lambda_i|^2=1$, then

$$E(\lambda_1\psi_1+\cdots+\lambda_m\psi_m)=E(|\lambda_1|^2,\ldots,|\lambda_m|^2)+\sum_{i=1}^{m}|\lambda_i|^2E(\psi_i).$$

We note the following:

Lemma 4: Let E be an entanglement measure on pure states satisfying (P1), (P2), (P3), and (P4). Then $E(\psi)=0$ *for all separable pure states.*

Proof: Let ψ_1,ψ_2 be two separable orthogonal pure states. Then by (P4) $E(1\psi_1+0\psi_2)=E(1,0)=1E(\psi_1)+0E(\psi_2)+E(1,0)$. Thus $E(\psi_1)=0$. □

Lemma 5: The von Neumann reduced entropy S_{vN} *satisfies (P1), (P2), (P3), and (P4).*

Proof: Straightforward. □

We show that the requirements (P1)–(P4) already fix the von Neumann reduced entropy up to a multiplicative constant.

Proposition 6: Let E be an entanglement measure on pure states satisfying the postulates (P1), (P2), (P3), and (P4). Then there exist a positive real constant c such that $E=cS_{\mathrm{vN}}$.

Proof: Let $\psi_1,\ldots,\psi_{n+1}$ be a collection of mutually orthogonal separable pure states and $\{\lambda_1,\ldots,\lambda_n\}$ be a distribution of complex probability amplitudes and $\eta\in[0,1]$. Then

$$\begin{aligned}E(\lambda_1\psi_1+\ldots+\lambda_{n-1}\psi_{n-1}+\sqrt{\eta}\lambda_n\psi_n+\sqrt{1-\eta}\lambda_n\psi_{n+1})\\ =|\lambda_n|^2E(\sqrt{\eta}\psi_n+\sqrt{1-\eta}\psi_{n+1})+(1-|\lambda_n|^2)E\left(\frac{1}{1-|\lambda_n|^2}(\lambda_1\psi_1+\cdots+\lambda_{n-1}\psi_{n-1})\right)\\ +E(|\lambda_n|^2,1-|\lambda_n|^2).\end{aligned}$$

Moreover,

$$\begin{aligned}E(\lambda_1\psi_1+\cdots+\lambda_n\psi_n)=|\lambda_n|^2E(\psi_n)+(1-|\lambda_n|^2)E\left(\frac{1}{1-|\lambda_n|^2}(\lambda_1\psi_1+\cdots+\lambda_{n-1}\psi_{n-1})\right)\\ +E(|\lambda_n|^2,1-|\lambda_n|^2).\end{aligned}$$

Thus

$$E(|\lambda_1|^2,\ldots,|\lambda_{n-1}|^2,\eta|\lambda_n|^2,(1-\eta)|\lambda_n|^2)=E(|\lambda_1|^2,\ldots,|\lambda_n|^2)+|\lambda_n|^2E(\eta,1-\eta).$$

Therefore E considered as a function of the Schmidt coefficients satisfies all conditions of the Khinchin–Faddeev characterization of Shannon's entropy. Therefore $E(p_1,\ldots,p_n)=-c\Sigma_{i=1}^{n}p_i\ln p_i$ for some positive real constant c. □

B. Entanglement measures for mixed states

An entanglement measure on mixed states is a functional defined on the state space of any given two quantum systems. If the Hilbert spaces of the two systems are $\mathcal{H}_1$ and $\mathcal{H}_2$, then the state space is the set of density operators on $\mathcal{H}_1\otimes\mathcal{H}_2$, denoted by $\mathcal{D}(\mathcal{H}_1\otimes\mathcal{H}_2)$. An entanglement measure is then a functional satisfying the obvious generalizations of (P1)–(P3).

(M1) An entanglement measure is a positive real-valued functional E which for any given two systems is well defined on the set of density operators on the tensor product of the Hilbert spaces of the two systems. For any given two systems corresponding to Hilbert spaces $\mathcal{H}_1$ and $\mathcal{H}_2$ the function $\mathcal{D}(\mathcal{H}_1\otimes\mathcal{H}_2)\ni\rho\mapsto E(\rho)$ is continuous with respect to the trace class norm.

(M2) For any given two systems with Hilbert spaces $\mathcal{H}_1$ and $\mathcal{H}_2$ the function $E:\mathcal{D}(\mathcal{H}_1\otimes\mathcal{H}_2)\to\mathbb{R}^+$ satisfies

$$E(U\otimes V\rho U^\dagger\otimes V^\dagger)=E(\rho)$$

for all $\rho\in\mathcal{D}(\mathcal{H}_1\otimes\mathcal{H}_2)$ and all unitaries U,V acting on $\mathcal{H}_1$ and $\mathcal{H}_2$, respectively.

(M3) whenever $\rho \in \mathcal{D}(\mathcal{H}_1 \otimes \mathcal{H}_2) \subset \mathcal{D}(\mathsf{H}_1 \otimes \mathsf{H}_2)$ with embeddings $\mathcal{H}_1 \hookrightarrow \mathsf{H}_1$ and $\mathcal{H}_2 \hookrightarrow \mathsf{H}_2$ of $\mathcal{H}_1$ and $\mathcal{H}_2$ into larger Hilbert spaces H_1 and H_2 respectively, then $E|_{\mathcal{H}_1 \otimes \mathcal{H}_2}(\rho) = E|_{\mathsf{H}_1 \otimes \mathsf{H}_2}(\rho)$.
Moreover we require that (P4) is satisfied without change and that mixing of states does not increase entanglement.

(M4) Let $\{\psi_1, \ldots, \psi_m\}$ be a family of mutually Schmidt orthogonal pure states and $\{\lambda_1, \ldots, \lambda_m\}$ be a distribution of probability amplitudes, then

$$E(P_\psi) = E(|\lambda_1|^2, \ldots, |\lambda_m|^2) + \sum_{i=1}^{m} |\lambda_i|^2 E(P_{\psi_i}),$$

where $\psi \equiv \lambda_1 \psi_1 + \cdots + \lambda_m \psi_m$ and where P_ψ and P_{ψ_i} denote the projection operators onto the subspace spanned by ψ and ψ_i, respectively.

(M5) Mixing of states does not increase entanglement, i.e., E is convex

$$E(\eta\sigma + (1-\eta)\tau) \leqslant \eta E(\sigma) + (1-\eta) E(\tau)$$

for all $0 \leqslant \eta \leqslant 1$ and all $\sigma, \tau \in \mathcal{D}(\mathcal{H}_1 \otimes \mathcal{H}_2)$.

Lemma 7: Let E be an entanglement measure on mixed states satisfying (M1), (M2), (M3), (M4), and (M5). Then $E(\rho) = 0$ for all separable states ρ.

Proof: By Lemma 4 E vanishes for all separable pure states. Every separable state ρ is a statistical mixture $\rho = \Sigma_{i=1}^{n} p_i P_{\psi_i}$ where $\{\psi_i\}_{i=1}^{n}$ is a family of separable pure states and where $(p_1, \ldots, p_n)$ is a probability distribution with n possibly infinite. Thus, by (M5) and (M1)

$$E(\rho) \leqslant \sum_{i=1}^{n} p_i E(P_{\psi_i}) = 0.$$

Hence $E(\rho) = 0$ for all separable states ρ. □

Example 8: Let H and K be finite dimensional Hilbert spaces. The greatest cross norm on the space of trace class operators $T(\mathsf{H} \otimes \mathsf{K})$ on $\mathsf{H} \otimes \mathsf{K}$ is defined by

$$\|\sigma\|_\gamma := \inf\left\{ \sum_{i=1}^{n} \|x_i\|_1 \|y_i\|_1 \;\middle|\; \sigma = \sum_{i=1}^{n} x_i \otimes y_i \right\}, \tag{3}$$

where $\sigma \in T(\mathsf{H} \otimes \mathsf{K})$, where the infimum runs over all finite decompositions of σ into elementary tensors and where $\|\cdot\|_1$ denotes the trace class norm. For projection operators P_ψ the value of $\|\cdot\|_\gamma$ has been computed in Ref. 11: *$\|P_\psi\|_\gamma = (\Sigma_i \sqrt{p_i})^2$ where $\{p_i\}$ denotes the family of Schmidt coefficients of the unit vector ψ. The entanglement measure introduced in Ref. 11,*

$$E(\sigma) \equiv \|\sigma\|_\gamma \ln \|\sigma\|_\gamma,$$

does not satisfy (P4).

IV. DISCUSSION

In this work we gave a mathematical characterization of all functionals defined on the state space of composite quantum systems which coincide with von Neumann reduced entropy on pure states: a functional on pure states coincides with the von Neumann reduced entropy if and only if it satisfies the conditions (P1)–(P4). Mathematically the axioms (P1)–(P4) are just a version of the Khinchin–Faddeev characterization of Shannon entropy but physically we have seen that they admit an interpretation in terms of entanglement.

On the eigenproblems of $\mathcal{PT}$-symmetric oscillators

K. C. Shin[a)]
Department of Mathematics, University of Illinois, Urbana, Illinois 61801

(Received 22 September 2000; accepted for publication 26 February 2001)

We consider the non-Hermitian Hamiltonian $H=-d^2/dx^2+P(x^2)-(ix)^{2n+1}$ on the real line, where $P(x)$ is a polynomial of degree at most $n\geqslant 1$ with all non-negative real coefficients (possibly $P\equiv 0$). It is proved that the eigenvalues λ must be in the sector $|\arg\lambda|\leqslant \pi/(2n+3)$. Also for the cubic case $H=-d^2/dx^2-(ix)^3$, we establish a zero-free region of the eigenfunction u and its derivative u' and we find some other interesting properties of eigenfunctions. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1366328]

I. INTRODUCTION

We are considering the eigenproblem

$$-u''(x)+[P(x^2)-(ix)^{2n+1}]u(x)=\lambda u(x), \quad \text{for } -\infty<x<\infty, \tag{1}$$

with $u(\pm\infty)=0$, where $P(x)$ is a polynomial of degree at most $n\geqslant 1$ with all non-negative real coefficients (possibly $P\equiv 0$).

This is an example of a class of problems, the so-called $\mathcal{PT}$-symmetric non-Hermitian Hamiltonian problems, which have arisen in recent years in a number of physical contexts.[1–3] Bessis conjectured the following in 1995.

Conjecture: *Eigenvalues of $H=-d^2/dx^2-(ix)^3$ are all real and positive.*

Many numerical and asymptotic results[4–7] support this conjecture. And later for $n>1$ it was conjectured that the equation (1) also has positive real eigenvalues, under different boundary conditions.[8] However, there is no rigorous proof of this to date.

This paper is organized as follows: In Sec. II, we prove that eigenvalues of the equation (1) lie in the sector

$$|\arg\lambda|\leqslant\frac{\pi}{2n+3}.$$

This goes part way to proving that the eigenvalues are real and positive. We generalize this result to $H=-d^2/dx^2+[P(x^2)+ixQ(x^2)]$ for some real polynomials P and Q. In particular, for the potentials $-(ix)^3$ and x^2+igx^3 with any real g, we have that $|\arg\lambda|\leqslant\pi/5$. Then next in Sec. III, for the case $H=-d^2/dx^2-(ix)^3$, we fairly precisely locate the zeros of the eigenfunctions and their first derivatives in the complex plane. Conversely we find a large zero-free region. In Sec. IV, still with $H=-d^2/dx^2-(ix)^3$, we find a large class of polynomials that are orthogonal to $|u|^2$ on each horizontal line. And finally in the last section, we discuss related open problems.

For the rest of the Introduction, we provide some more background information on (1). First, a $\mathcal{PT}$-symmetric Hamiltonian is a Hamiltonian which is invariant under the product of the parity operation $\mathcal{P}(:x\mapsto -x)$ and the time reversal operation $\mathcal{T}(:i\mapsto -i)$. Certainly (1) is $\mathcal{PT}$-symmetric while, for example, $-d^2/dx^2+x-(ix)^3$ is not $\mathcal{PT}$-symmetric. If $H=-d^2/dx^2+V(x)$ is $\mathcal{PT}$-symmetric, then $\overline{V(-x)}=V(x)$ (an overbar denotes the complex conjugate) and so $\mathrm{Re}\,V(x)$ is an even function and $\mathrm{Im}\,V(x)$ is an odd function. Hence if $V(x)$ is a polynomial, then $V(x)=P(x^2)+ixQ(x^2)$ for some real polynomials P and Q.

a)Electronic mail: kcshin@math.uiuc.edu

Next by the work of Caliceti *et al.*,[9,10] it is known that the $\mathcal{PT}$-symmetric Hamiltonian $H=-d^2/dx^2+x^2-g(ix)^3$ has a discrete spectrum, for g real, and these eigenvalues are positive real if g is small enough. However, there are some $\mathcal{PT}$-symmetric Hamiltonians that have no eigenvalues,[11] or nonreal eigenvalues.[12]

Last, for any $\lambda\in\mathbb{C}$ there are two linearly independent solutions of (1), if the boundary conditions are not imposed. In generic cases, the solutions blow up at both $+\infty$ and $-\infty$, while in exceptional cases, the solutions decay to zero as x approaches $+\infty$ or $-\infty$. Only in very exceptional cases (when λ is an eigenvalue!) one does find a solution that decays to zero at both $+\infty$ and $-\infty$ (see Lemma 1 for details).

II. THE EIGENVALUES LIE IN A SECTOR

In this section, we prove that the eigenvalues λ of (1) lie in the sector $|\arg\lambda|\leqslant\pi/2n+3$ and we extend this result for more general cases. To do this we will use results in Sec. 7.4 of Hille.[13]

A. Definitions and set-up

For any $\lambda\in\mathbb{C}$ Eq. (1) without the boundary conditions allows two linearly independent solutions. Also if $u(x)$ solves the ODE (1), then since $P(z^2)-(iz)^{2n+1}$ is an entire function (analytic in the whole complex plane), there exists an entire function $u(z)$ which agrees with $u(x)$ on the real line and satisfies $-u''(z)+[P(z^2)-(iz)^{2n+1}]u(z)=\lambda u(z)$. Now we begin by describing the asymptotic behavior of u near infinity. Recall that deg $P\leqslant n$.

Definition: Let

$$\theta_j=2\pi\frac{j}{2n+3}-\frac{\arg(i^{2n+1})}{2n+3}=\begin{cases}\dfrac{2\pi j-\dfrac{\pi}{2}}{2n+3}, & \text{if } n \text{ is even;}\\[2ex] \dfrac{2\pi j+\dfrac{\pi}{2}}{2n+3}, & \text{if } n \text{ is odd.}\end{cases}$$

We define *Stokes regions*,

$$S_j=\{z\in\mathbb{C}:\theta_j<\arg z<\theta_{j+1}\},$$

for $j=0,1,2,\ldots,2n+2$. And for notational convenience, we define $S_{j+2n+3}=S_j$ for all j. Also we denote

$$S_{j,\epsilon}=\{z\in\mathbb{C}:\theta_j+\epsilon<\arg z<\theta_{j+1}-\epsilon\},$$

for $0<\epsilon<\pi/(2n+3)$.

Notice θ_j is neither 0 nor π. Thus the negative and the positive real axes lie within two of the Stokes regions (see Fig. 1). We call these the *left-* and the *right-hand* Stokes regions, respectively. Also we call the rays $\{\arg z=\theta_j\}$ ''critical rays.''

Lemma 1: Every solution of $-u''(z)+[P(z^2)-(iz)^{2n+1}]u(z)=\lambda u(z)$ *is asymptotic to*

$$(\text{const})z^{-(2n+1)/4}\exp\left[\pm\frac{2}{2n+3}(iz)^{(2n+3)/2}(1+o(1))\right], \tag{2}$$

as $z\to\infty$ *in* $S_{j,\epsilon}$, *for each* $0<\epsilon<\pi/(2n+3)$. *The error* $o(1)$ *is uniform in* $\arg z$ *in the sense that* $\lim_{r\to\infty}\sup\{|o(1)|:z\in S_{j,\epsilon},|z|=r\}=0$.

Also u *has infinitely many zeros in* $\mathbb{C}$ *but only finitely many in* $\cup_j S_{j,\epsilon}$, *for each* $0<\epsilon<\pi/(2n+3)$.

The asymptotic expressions imply in particular that in each Stokes region, $u(z)$ either decays to 0 or blows up, as z approaches infinity in $S_{j,\epsilon}$.

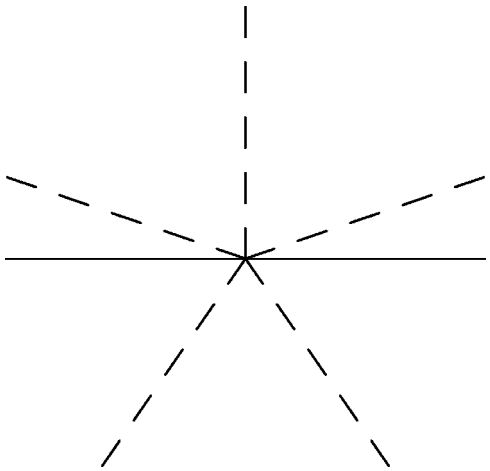

FIG. 1. For $n=1$; the solid line is the real axis and the dotted rays are the critical rays, $\arg z=\theta_j=\pi/10$, $\pi/2$, $9\pi/10$, $13\pi/10$ and $17\pi/10$.

Proof: See Sec. 7.4 of Hille[13] for a proof of a more general result. An outline of the proof is as follows: Hille first transforms the equation into another complex Z-plane by using the Liouville transform. And then he compares u with the solutions of the sine equation $w''(Z)+w(Z)=0$ and finally transforms back to the original complex z-plane. The above asymptotic expressions are the asymptotic expressions for solutions of the sine equation (in the Z-variable) expressed in terms of the original z-variable. The Stokes regions are determined by the Liouville transformation.

Also one can deduce the last assertion of this lemma from Sec. 7.4 of Hille.[13] This is proved in Theorem 5 of Gundersen[14] for more general equations. □

Remark 1: Under the Liouville transformation, a neighborhood of infinity in each Stokes region in the complex z-plane maps to a neighborhood of infinity in either the upper or lower half Z-plane. Thus if u decays in a Stokes region S_j for some j, then u must blow up in the Stokes regions S_{j+1} and S_{j-1}. Otherwise, there would be a solution of the sine equation in the Z-plane which decays to zero in all directions. This is a contradiction. However, u might blow up in many consecutive Stokes regions (even in all Stokes regions) (see Sec. 7.4 of Hille[13]).

Definition: Let $\lambda \in \mathbb{C}$ and let $u(z)\not\equiv 0$ be an analytic function on $\mathbb{C}$ that satisfies (1). We say u is an *eigenfunction* and λ is an *eigenvalue*, for (1), if $u(z)$ decays to zero along rays to infinity in the left- and right-hand Stokes regions [that is, if u has decaying asymptotics in (2), in these two regions].

Remark 2: Given a Stokes region S_j, there always exists a solution of $-u''(z)+[P(z^2)-(iz)^{2n+1}]u(z)=\lambda u(z)$ that blows up in S_j by Sec. 7.4 of Hille.[13] If there were two linearly independent eigenfunctions with the same eigenvalue, then all the solutions of $-u''(z)+[P(z^2)-(iz)^{2n+1}]u(z)=\lambda u(z)$ would satisfy $u(\pm\infty+0i)=0$ and there would be no solutions that blow up in the left- and right-hand Stokes regions. Thus there are no repeated eigenvalues, and all eigenvalues are simple.

Remark 3: Note that if $u(z)$ is an eigenfunction with eigenvalue λ, then $\overline{u}(-\overline{z})$ is an eigenfunction with eigenvalue $\overline{\lambda}$. If an eigenvalue is real then $u(z)=c\overline{u}(-\overline{z})$ by Remark 2, and clearly $|c|=1$. Writing $c=e^{-2i\phi}$ and replacing u by $e^{i\phi}u$, we get that eigenfunctions with real eigenvalues are symmetric with respect to the imaginary axis.

B. The main results

The main result of this paper is the following.

Theorem 2: *If λ is an eigenvalue of (1), then, $\lambda\neq 0$ and $|\arg\lambda|\leqslant \pi/(2n+3)$.*

According to Mezincescu,[11] that the eigenvalues have a positive real part was known already;[15] our proof below includes a very simple argument for this fact. In the proof and elsewhere, we will use the following.

Since $u(z)$ decays exponentially along rays to infinity in the left- and right-hand Stokes regions, so does u' by the Cauchy integral formula. Therefore $p(r)|u(re^{i\theta})|^2$ and $p(r)|u'(re^{i\theta})|^2$ are integrable along the line $\{re^{i\theta}: -\infty<r<\infty\}$ for any polynomial $p(r)$, provided $|\theta|<\pi/2(2n+3)$ (if $|\theta|$ is larger than this, then one end of the line will be outside the decaying Stokes regions).

Proof of Theorem 2: Let u be an eigenfunction with eigenvalue λ, so that

$$u''(z)+[-P(z^2)+(iz)^{2n+1}]u(z)=-\lambda u(z),$$

where $P(z)=\Sigma_{k=0}^{n}a_k z^k$ for some $a_k\geqslant 0$, $k=0,1,2,\ldots,n$.

Write

$$\lambda=\alpha+i\beta, \quad \alpha,\beta\in\mathbb{R}.$$

Fix θ with $|\theta|<\pi/2(2n+3)$ and let $v(r)=u(re^{i\theta})$. Then $v'(r)=u'(re^{i\theta})e^{i\theta}$ and $v''(r)=u''(re^{i\theta})e^{2i\theta}$. Thus our ODE becomes

$$v''(r)+\{[\alpha+i\beta-P(r^2e^{2i\theta})]e^{2i\theta}+i^{2n+1}r^{2n+1}e^{i(2n+3)\theta}\}v(r)=0.$$

Then we multiply this by $e^{-i(2n+3)\theta}\overline{v(r)}$, integrate and use integration by parts to obtain

$$e^{-i(2n+3)\theta}\int_{-\infty}^{\infty}|v'|^2\,dr=(\alpha+i\beta)e^{-i(2n+1)\theta}\int_{-\infty}^{\infty}|v|^2\,dr-\int_{-\infty}^{\infty}e^{-i(2n+1)\theta}P(r^2e^{2i\theta})|v|^2\,dr$$

$$+i^{2n+1}\int_{-\infty}^{\infty}r^{2n+1}|v|^2\,dr, \tag{3}$$

for all $|\theta|<\pi/2(2n+3)$. We note that for these θ the line $re^{i\theta}$ stays in the left- and right-hand Stokes regions where u (and hence u') decays exponentially to zero as r approaches $\pm\infty$.

Taking the real part of (3) yields [since $|\theta|<\pi/2(2n+3)$]

$$0<\cos(2n+3)\theta\int_{-\infty}^{\infty}|v'|^2\,dr$$

$$=\{\alpha\cos(2n+1)\theta+\beta\sin(2n+1)\theta\}\int_{-\infty}^{\infty}|v|^2\,dr-\int_{-\infty}^{\infty}\mathrm{Re}[e^{-i(2n+1)\theta}P(r^2e^{2i\theta})]|v|^2\,dr. \tag{4}$$

But $\mathrm{Re}[e^{-i(2n+1)\theta}P(r^2e^{2i\theta})]=\Sigma_{k=0}^{n}a_k r^{2k}\cos(2n-2k+1)\theta\geqslant 0$ if $a_k\geqslant 0$ and $|\theta|<\pi/2(2n+1)$ [certainly true if $|\theta|<\pi/2(2n+3)$]. Thus it follows from (4) that

$$\alpha\cos(2n+1)\theta+\beta\sin(2n+1)\theta>0,$$

for all $|\theta|<\pi/2(2n+3)$. That is,

$$\alpha>|\beta|\tan(2n+1)\theta,$$

for all $0\leqslant\theta<\pi/2(2n+3)$.

Then with $\theta=0$ we have $\alpha>0$, in particular $\lambda\neq 0$ and by letting $\theta\to\pi/2(2n+3)$ we get

$$\alpha\geqslant|\beta|\tan\frac{(2n+1)\pi}{2(2n+3)}.$$

Finally using $\tan\phi=\cot(\pi/2-\phi)$, we conclude that

$$\tan\frac{\pi}{2n+3}\geqslant\frac{|\beta|}{\alpha}.$$

That is, $|\arg\lambda|\leqslant\pi/(2n+3)$. □

Remark 4: We can extend Theorem 2 by allowing P to have some negative coefficients as long as P satisfies $\mathrm{Re}[e^{-i(2n+1)\theta}P(r^2e^{2i\theta})]\geqslant 0$ for $|\theta|<\pi/2(2n+3)$. For example, with $n=3$ and $c\in\mathbb{R}$, let $P(z)=z^3+cz^2+z$; then $\mathrm{Re}[e^{-7i\theta}P(r^2e^{2i\theta})]=r^2[r^4\cos\theta+cr^2\cos(3\theta)+\cos(5\theta)]$. Thus if $c^2\cos^2(3\theta)-4\cos\theta\cos(5\theta)\leqslant 0$ for $|\theta|<\pi/18$, i.e., $|c|\leqslant\sqrt{\frac{16}{3}}\cos(\pi/18)\cos(5\pi/18)\approx 1.837$, then $\mathrm{Re}[e^{-7i\theta}P(r^2e^{2i\theta})]\geqslant 0$. Therefore, the theorem holds for this P provided $c\geqslant-\sqrt{\frac{16}{3}}\cos(\pi/18)\cos(5\pi/18)$.

Also by a simple change of variables, we get the same result for $H=-d^2/dz^2+[P(z^2)-g(iz)^{2n+1}]$ for any nonzero real g.

Moreover, by translations in $\mathbb{C}$, we have the same result for $H=-d^2/dz^2+P((z-\xi)^2)-gi^{2n+1}(z-\xi)^{2n+1}$ for any $\xi\in\mathbb{C}$. For instance, if u solves $u''(z)-iz^3u(z)=-\lambda u(z)$, then $v(z)=u(z+ai)$ solves $v''(z)+[(3az^2-a^3)-iz(z^2-3a^2)]v(z)=-\lambda v(z)$ for any real number a. Observe that v still satisfies the boundary conditions $v(\pm\infty+0i)=u(\pm\infty+ai)=0$.

Remark 5: The readers should notice that our boundary conditions are different, for $n\geqslant 2$, from those Bender *et al.*[8] take. Bender *et al.*[8] impose the zero boundary conditions of the problems $-u''-(iz)^Nu=\lambda u$ for $N\geqslant 4$ not on Stokes regions containing the real axis but instead on Stokes regions which are near the negative imaginary axis for large N.

The next theorem extends Theorem 2.

Theorem 3: *Let $\lambda\in\mathbb{C}$ and $n\geqslant 1$. Suppose that u solves the ODE,*

$$u''-[P(z^2)+izQ(z^2)]u=-\lambda u,\quad u(\pm\infty+0i)=0, \tag{5}$$

for some real polynomials $P(z)=\Sigma_{k=0}^{n}a_kz^k$ and $Q(z)=\Sigma_{k=0}^{n}b_kz^k$ with all non-negative a_k and with $b_n\in\mathbb{R}-\{0\}$. If for all $k<n$ the coefficients a_k,b_k satisfy

$$\frac{\sin^2(2n-2k)\theta}{\cos(2n-2k+1)\theta\cos(2n-2k-1)\theta}b_k^2\leqslant\begin{cases}4a_ka_{k+1}, & \text{if } n=1 \text{ and } k=0;\\ 2a_ka_{k+1}, & \text{if } n>1 \text{ and } k=0,\ n-1;\\ a_ka_{k+1}, & \text{if } n>1 \text{ and } 1\leqslant k\leqslant n-2;\end{cases} \tag{6}$$

at $\theta=\pi/2(2n+3)$, then $|\arg\lambda|\leqslant\pi/(2n+3)$.

For $n=3$, the coefficients of b_k^2 in (6) are approximately 3.41,0.74 and 0.14 for $k=0,1,2$, respectively.

Theorem 3 contains Theorem 2, just by taking $b_k=0$ for $k=0,1,\ldots,n-1$ [in which case (6) is trivially satisfied].

Proof: The main idea of the proof is the same as that of the proof of Theorem 2. Even if the equation (5) is little different from the equation for (2), Stokes regions for (5) are the same as for (2) [if b_n has the same sign as $(-1)^{n+1}$] or else are rotated by 180° (if b_n has the opposite sign). See Sec. 7.4 of Hille[13] for details. Thus in either case, the lines $r\mapsto re^{i\theta}$ with $|\theta|<\pi/2(2n+3)$ lie within the left- and right-hand Stokes regions, where we impose the zero boundary conditions. And this gives the integrabilities in the proof.

Let $v(r)=u(re^{i\theta})$. Then like we derived (4) in the proof of Theorem 2 we have

$$\{\alpha\cos(2n+1)\theta+\beta\sin(2n+1)\theta\}\int_{-\infty}^{\infty}|v|^2\,dr$$

$$=\int_{-\infty}^{\infty}\{\cos[(2n+3)\theta]|v'|^2+\Sigma_{k=0}^{n}a_k\cos[(2n-2k+1)\theta]r^{2k}|v|^2$$

$$+\Sigma_{k=0}^{n-1}b_k\sin[(2n-2k)\theta]r^{2k+1}|v|^2\}dr,\quad \text{for } |\theta|<\frac{\pi}{2(2n+3)}. \tag{7}$$

Since $a_k\geqslant 0$ for all k, we get $\alpha>0$ by letting $\theta=0$ in (7). (This is true for any Q with real coefficients and deg $Q=n$.)

If we find conditions on a_k and b_k such that

$$\Sigma_{k=0}^{n}a_k\cos[(2n-2k+1)\theta]r^{2k}+\Sigma_{k=0}^{n-1}b_k\sin[(2n-2k)\theta]r^{2k+1}\geqslant 0, \tag{8}$$

for every $r\in\mathbb{R}$ and $|\theta|<\pi/2(2n+3)$, then it follows from (7) with $\theta\to\pm\pi/2(2n+3)$, that

$$\alpha\cos\frac{(2n+1)\pi}{2(2n+3)}\pm\beta\sin\frac{(2n+1)\pi}{2(2n+3)}\geqslant 0.$$

Therefore, $|\arg\lambda|\leqslant\pi/(2n+3)$ as desired, like in the proof of Theorem 2.

When $n\geqslant 3$, we can rewrite the expression in (8) as

$$\left\{a_0\cos(2n+1)\theta+rb_0\sin 2n\theta+r^2\frac{a_1}{2}\cos(2n-1)\theta\right\}$$

$$+\Sigma_{k=1}^{n-2}\left\{\frac{a_k}{2}\cos(2n-2k+1)\theta+rb_k\sin(2n-2k)\theta+r^2\frac{a_{k+1}}{2}\cos(2n-2k-1)\theta\right\}r^{2k}$$

$$+\left\{\frac{a_{n-1}}{2}\cos 3\theta+rb_{n-1}\sin 2\theta+r^2a_n\cos\theta\right\}r^{2n-2}. \tag{9}$$

Now (9) is non-negative if each quadratic in r has a nonpositive discriminant:

$$b_0^2\sin^2 2n\theta-2a_0a_1\cos(2n+1)\theta\cos(2n-1)\theta\leqslant 0,$$

$$b_k^2\sin^2(2n-2k)\theta-a_ka_{k+1}\cos(2n-2k+1)\theta\cos(2n-2k-1)\theta\leqslant 0,\quad \text{for } 1\leqslant k\leqslant n-2,$$

$$b_{n-1}^2\sin^2 2\theta-2a_{n-1}a_n\cos 3\theta\cos\theta\leqslant 0,$$

which is (6). The coefficients of b_k^2 in (6) are all increasing functions of $0\leqslant\theta<\pi/2(2n+3)$, and so it suffices that (6) hold at $\theta=\pi/2(2n+3)$.

Now when $n=1,2$, it is easy to see similarly that the theorem holds. This completes the proof. □

Remark 6: In (7), the sign of $\int_{-\infty}^{\infty}r^{2k+1}|v|^2\,dr$ is difficult to determine because r can be negative as well as positive. However, we were able to estimate the right-hand side of (7) by using properties of quadratic functions. Certainly, as it is clear from the proof, the conditions in Theorem 3 are sufficient but not necessary. For example, in the proof of Theorem 2 we used $a_k=a_k/2+a_k/2$ to get (9) from (7). If we use $a_k=\delta_ka_k+(1-\delta_k)a_k$ for some $0<\delta_k<1$, we will obtain new sufficient conditions for the theorem.

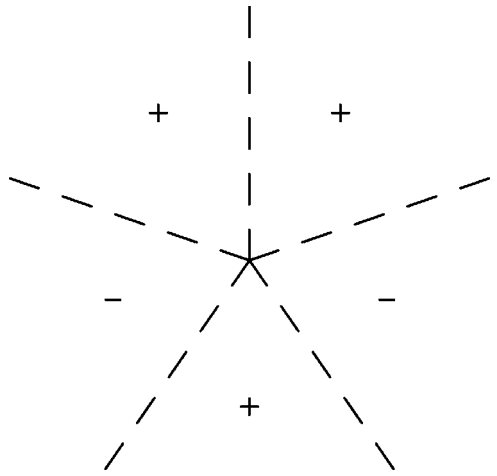

FIG. 2. In this figure, rays are $\arg z = \pi/10,\ \pi/2,\ 9\pi/10,\ 13\pi/10$ and $17\pi/10$. A ''+'' indicates that the eigenfunction is blowing up while a ''−'' indicates that the eigenfunction is decaying to zero as z approaches infinity.

III. THE ZERO-FREE REGION FOR u AND u', FOR THE CUBIC POTENTIAL

The results in the previous section are based on the eigenfunction u decaying to zero as z approaches infinity on the left- and the right-hand Stokes regions. Hence consideration of the *finite* zeros of u may be useful for further results on our eigenproblem.

For the next two sections, we will suppose $H = -d^2/dz^2 - (iz)^3$. See Fig. 2 for the asymptotic behavior of the eigenfunction u. In this section, we provide a zero-free region for the eigenfunction u of

$$u'' - iz^3 u = -\lambda u, \quad \text{with } u(\pm\infty + 0i) = 0, \tag{10}$$

and for its derivative u'. And we give some answers on how zeros of the eigenfunction should be arranged in $\mathbb{C}$.

It is obvious that u and u' do not share a common zero. Otherwise, by (10), all the derivatives of u and u itself would vanish at zero, and so $u \equiv 0$.

The following lemma is needed for our argument. Recall $\lambda = \alpha + i\beta$.

Lemma 4: Let $z:[c,d] \to \mathbb{C}$ be a smooth curve with $z'(t) \neq 0$ for $t \in [c,d]$. If u solves (10), then writing $z(t) = x(t) + iy(t)$,

$$\operatorname{Re}(u'\overline{u})\big|_{z(c)}^{z(d)} = \int_c^d x' |u_x(z(t))|^2\, dt + \int_c^d [x' \operatorname{Re}(iz^3(t) - \lambda) - y' \operatorname{Im}(iz^3(t) - \lambda)] |u(z(t))|^2\, dt, \tag{11}$$

and

$$\operatorname{Im}(u'\overline{u})\big|_{z(c)}^{z(d)} = -\int_c^d y' |u_x(z(t))|^2\, dt + \int_c^d [y' \operatorname{Re}(iz^3(t) - \lambda) + x' \operatorname{Im}(iz^3(t) - \lambda)] |u(z(t))|^2\, dt. \tag{12}$$

Hille calls this lemma the Green's transform,[13] and he uses it to get information on zero-free regions of solutions of linear second order equations (mainly with coefficient functions that are real on the real line).

Proof: Let $f(t) = u(z(t))$ for $t \in [c,d]$. Then $f'(t) = z'(t)u'(z(t))$ and

$$\left(\frac{f'(t)}{z'(t)}\right)' = z'(t)u''(z(t)) = z'(t)[iz^3(t) - \lambda] f(t).$$

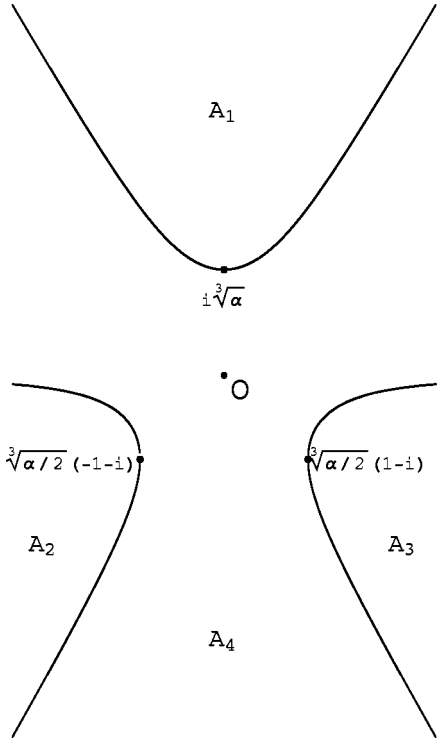

FIG. 3. The level curves $\mathrm{Re}(iz^3-\lambda)=0$. Here $\mathrm{Re}(iz^3-\lambda)$ is negative in A_4 since $\alpha>0$, while it is positive in A_1, A_2 and A_3.

Hence by integration by parts,

$$\left(\frac{f'(t)}{z'(t)}\right)\overline{f}(t)\Big|_c^d=\int_c^d\frac{|f'|^2}{z'}dt+\int_c^d z'[iz^3-\lambda]|f|^2\,dt. \tag{13}$$

Now by the formula $f'(t)=z'(t)u'(z(t))$ and splitting real and imaginary parts of the above, we get the lemma. □

Now we examine the consequences of this lemma. First, if $\mathrm{Re}(u'\overline{u})$ were not one-to-one on the imaginary axis, that would imply that the eigenvalue would be real by (11) with $z(t)=it$.

Remark 7: Second, another immediate consequence of Lemma 4 is that on any vertical line segments on which $\mathrm{Im}(iz^3-\lambda)$ does not change its sign, $\mathrm{Re}(u_x\overline{u})$ as a function of y is one-to-one. On horizontal line segments on which $\mathrm{Im}(iz^3-\lambda)$ does not change its sign, $\mathrm{Im}(u_x\overline{u})$ as a function of x is one-to-one (Mezincescu[11] observed this last fact on the real axis, where $y\equiv 0$). These observations are special cases of Theorem 11.3.3 of Hille.[13]

A. Case of nonreal eigenvalues

Next, let us define open regions A_j and B_j, $j=1,2,3,4$ as in Figs. 3 and 4. The following two theorems provide a large zero-free region for an eigenfunction u of (10) and its derivative u', assuming λ is nonreal. Perhaps these theorems might help show that λ must actually be real. The underlying ideas of the proofs are taken from Sec. 11.3 of Hille's book.[13]

Theorem 5: *If* $\beta:=\mathrm{Im}\,\lambda>0$ *then* $\mathrm{Im}(u'\overline{u})<0$ *on*

$$B_1\cup\{z\in B_4:\mathrm{Re}\,z\leqslant-\sqrt[3]{\beta/2}\}\cup\{z\notin A_1:\mathrm{Im}\,z\geqslant-\sqrt[3]{\beta/2}\};\quad \text{see Fig. 5.}$$

Mezincescu[11] has previously observed that the eigenfunction has no zeros on the real axis, which obviously lies in the shaded region of Fig. 5. Moreover, we see that all the zeros of u and u' in $\mathrm{Im}\,z\geqslant 0$ must be in A_1.

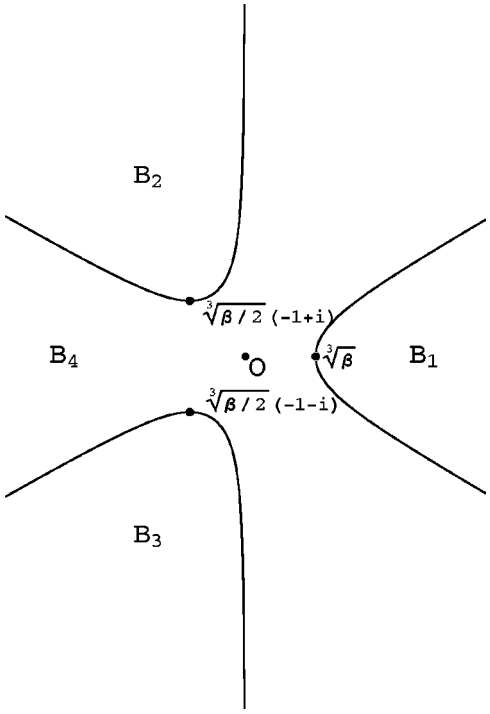

FIG. 4. The level curves $\mathrm{Im}(iz^3-\lambda)=0$ with $\beta>0$ fixed. Here $\mathrm{Im}(iz^3-\lambda)$ is negative in B_4 while it is positive in B_1, B_2 and B_3.

Note that the lowest point in the closure $cl(B_2)$ of B_2 is $-\sqrt[3]{\beta/2}+i\sqrt[3]{\beta/2}$.

Proof of Theorem 5: For any fixed $y_0\in\mathbb{R}$, by (12) with $z(t)=t+iy_0$ and by $u(\pm\infty+iy_0)=0=u'(\pm\infty+iy_0)$, it follows that

$$\mathrm{Im}[u'(x+iy_0)\overline{u}(x+iy_0)]=\int_{-\infty}^{x}\mathrm{Im}(iz(t)^3-\lambda)|u|^2\,dt,$$

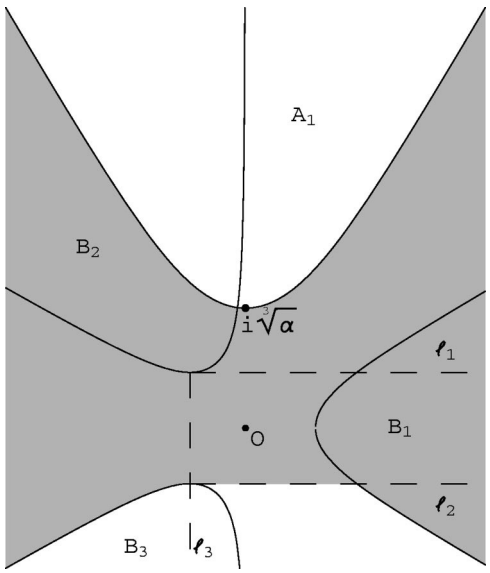

FIG. 5. $\mathrm{Im}(u'\overline{u})<0$ in the shaded area. The lines l_1,l_2,l_3 are $l_1:\mathrm{Im}\,z=\sqrt[3]{\beta/2}$, $l_2:\mathrm{Im}\,z=-\sqrt[3]{\beta/2}$ and $l_3:\mathrm{Re}\,z=-\sqrt[3]{\beta/2}$.

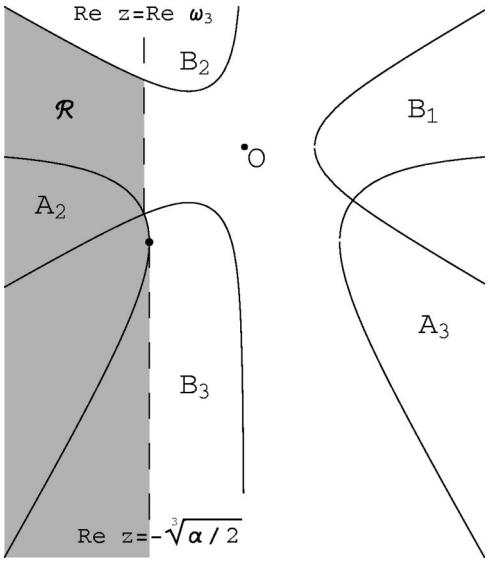

FIG. 6. $\mathrm{Re}(u'\overline{u})>0$ in the shaded area.

and this is negative for $x+iy_0\in B_4$ with $|y_0|\leqslant\sqrt[3]{\beta/2}$, because then $z(t)=t+iy_0\in B_4$ for all $-\infty<t<x$ and so $\mathrm{Im}(iz(t)^3-\lambda)<0$.

This argument also implies that $\mathrm{Im}(u'\overline{u})<0$ in $\{z\in B_4:\mathrm{Re}\,z\leqslant-\sqrt[3]{\beta/2}\}$; see Fig. 5.

Similarly in B_1, for all y_0 we have that $\mathrm{Im}(u'\overline{u})=-\int_x^\infty\mathrm{Im}(iz(t)^3-\lambda)|u(t+iy_0)|^2\,dt<0$.

For $z\notin A_1$ with $\mathrm{Im}\,z\geqslant\sqrt[3]{\beta/2}$ (so that $z\in A_4$), we use (12) along vertical line segments starting from points on the line $\mathrm{Im}\,z=\sqrt[3]{\beta/2}$ to conclude that $\mathrm{Im}(u'\overline{u})<0$ in this region. □

Note that $\mathrm{Im}(u'\overline{u})=-\frac{1}{2}(\partial/\partial y)|u(x+iy)|^2$. Hence in the region in Theorem 5, $|u(x+iy)|$ is an increasing function of y.

Theorem 6: *Assume* $\beta>0$. *Then*

(i) $\mathrm{Re}(u'\overline{u})>0$ *on the union of the regions* A_2, *the region below* A_2 *and the region* $\mathcal{R}\subset B_4$ *between* A_2 *and* B_2 *with the real part less than or equal to that of the zero* ω_3 *of* $iz^3-\lambda$ *in the third quadrant. See Fig. 6.*

(ii) $\mathrm{Re}(u'\overline{u})<0$ *on the union of the regions* A_3, *the region below* A_3 *and the region in* B_1 *with the real part greater than or equal to that of the zero* ω_4 *of* $iz^3-\lambda$ *in the fourth quadrant. See Fig. 7.*

Obviously $iz^3-\lambda$ has three zeros. When $\beta>0$, one of the zeros is in the second quadrant, one ω_3 in the third and one ω_4 in the fourth quadrant. Certainly these are the three points at which the boundaries of the A_i and B_i intersect.

Theorem 2 with $n=1$ shows that $|\beta|/\alpha\leqslant\tan(\pi/5)\approx0.73$. And it is easy to see that the rightmost point of $cl(A_2)$ is $\sqrt[3]{\alpha/2}\,(-1-i)$, at which $\mathrm{Im}(iz^3-\lambda)=x^3-3xy^2-\beta>0$ by $0<\beta<\alpha$. Thus the rightmost point of $cl(A_2)$ lies inside B_3 as shown in Fig. 6. Similarly, the leftmost point of $cl(A_3)$ is $\sqrt[3]{\alpha/2}\,(1-i)$, at which $\mathrm{Im}(iz^3-\lambda)=x^3-3xy^2-\beta<0$. Hence the leftmost point of $cl(A_3)$ lies outside B_1 as shown in Fig. 7.

Proof of Theorem 6: In regions A_2 and A_3, we use (11) with horizontal lines to infinity to get the statements in parts (i) and (ii) of this theorem. In the region $\mathcal{R}$ between A_2 and B_2 with the real part less than or equal to that of the zero ω_3 of $iz^3-\lambda$ in the third quadrant (see Fig. 6), we use (11) with vertical lines $z(t)=x_0+it$ to show that $\mathrm{Re}(u'\overline{u})>0$. That is, we use $\mathrm{Re}(u'\overline{u})|_{x_0+ic}^{x_0+id}$ $=-\int_c^d\mathrm{Im}(iz(t)^3-\lambda)|u(x_0+it)|^2\,dt$. If $x_0+id\in\mathcal{R}$, we can find $x_0+ic\in cl(A_2\cap B_3^c)$, so that $\mathrm{Re}\,[u'(x_0+ic)\overline{u}(x_0+ic)]>0$, and $-\mathrm{Im}(iz(t)^3-\lambda)>0$. Hence, the above integral is an increasing function of d. Therefore we have the desired result in this region $\mathcal{R}$.

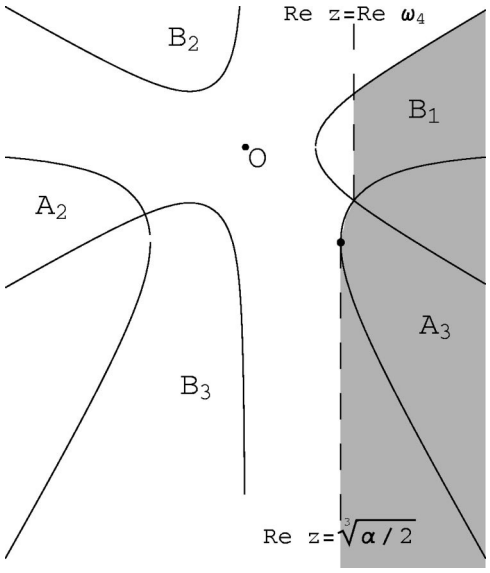

FIG. 7. $\mathrm{Re}(u'\overline{u})<0$ in the shaded area.

The region below A_2 is contained in B_3 since the rightmost point of $cl(A_2)$ lies in B_3 (see Fig. 6). Thus a similar argument implies that $\mathrm{Re}(u'\overline{u})>0$ in the region below A_2. Also, the region below A_3 is contained in B_4 (see Fig. 7) and so modified arguments show that the other statements of this theorem in part (ii) hold. □

Corollary 7: When $\mathrm{Im}\,\lambda=\beta>0$, *the zero-free region of u and u′ contains the union of the three shaded regions in Figs. 5, 6 and 7.*

Note that in case $\mathrm{Im}\,\lambda=\beta<0$ we can get similar theorems corresponding to the above two, since $\overline{u}(-\overline{z})$ is an eigenfunction with eigenvalue $\overline{\lambda}$. The regions involved are simply the reflections of the above with respect to the imaginary axis.

B. Case of real eigenvalues

In case $\beta=0$, so that λ is real and $\lambda=\alpha>0$, the regions B_1,B_2,B_3 degenerate to the sectors $\{-\pi/6<\arg z<\pi/6\},\{\pi/2<\arg z<5\pi/6\},\{-5\pi/6<\arg z<-\pi/2\}$, respectively, and we obtain the following theorem on zero-free regions.

Theorem 8: *Suppose* λ *is real. Then* $\mathrm{Im}(u'\overline{u})<0$ *on* $\{-\pi/6\leqslant\arg z\leqslant 7\pi/6\}-A_1$ (*which is a degenerate case of Fig. 5), while* $\mathrm{Re}(u'\overline{u})$ *behaves as in Figs. 6 and 7 with* B_1,B_2,B_3 *being sectors as above*.

Also $\mathrm{Re}(u'\overline{u})<0$ *in* $cl(A_1)\cap\{\mathrm{Re}\,z<0\}$ *and* $\mathrm{Re}(u'\overline{u})>0$ *in* $cl(A_1)\cap\{\mathrm{Re}\,z>0\}$.

Corollary 9: When λ *is real, the zero-free region of u and u′ contains the union of all regions in Theorem 8; see Fig. 8. That is, u and u′ can only have zeros in* $\{iy:y>\sqrt[3]{\lambda}\}$

$$\cup\left\{z\in A_4:-\frac{5\pi}{6}<\arg z<-\frac{\pi}{6},\mathrm{Im}\,z>-\sqrt[3]{\lambda/2}\right\}\cup\{z:|\mathrm{Re}\,z|<\sqrt[3]{\lambda/2},\mathrm{Im}\,z\leqslant-\sqrt[3]{\lambda/2}\}.$$

Remark 8: Bender *et al.*[16] find numerically that u has some zeros along an ''arch'' within the unshaded region in Fig. 8, when λ is real.

In proving Theorem 8, we will use the following lemma.

Lemma 10: Suppose $\zeta\in A_1$, $\mathrm{Re}(u'\overline{u})=0$ at ζ. *Then* $\mathrm{Re}(u'\overline{u})<0$ *at all* $\zeta-t\in A_1,t>0$ *and* $\mathrm{Re}(u'\overline{u})>0$ *at all* $\zeta+t\in A_1,t>0$.

Note that there is no restriction on the sign of $\mathrm{Im}\,\lambda$, in this lemma.

Proof: On horizontal line segments $z(t)=t+iy_0$ in A_1, (11) becomes

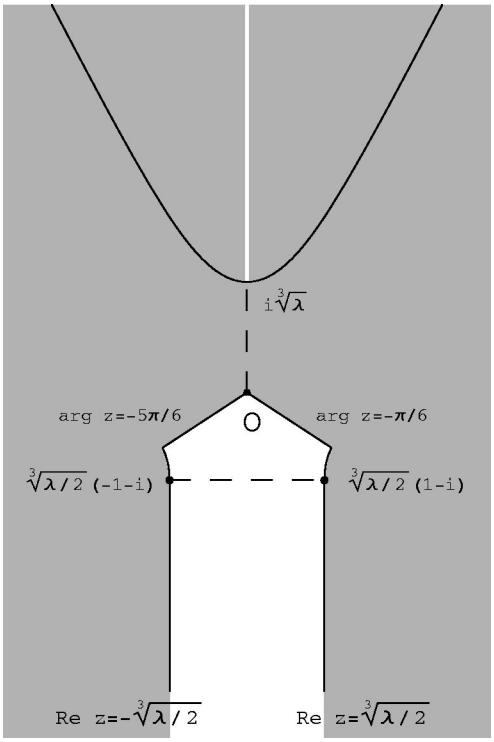

FIG. 8. When λ is real, the shaded area is the zero-free region of u and u'.

$$\mathrm{Re}(u'\overline{u})\Big|_{c+iy_0}^{d+iy_0}=\int_c^d |u_x(z(t))|^2\,dt+\int_c^d \mathrm{Re}(iz^3(t)-\lambda)|u(z(t))|^2\,dt.$$

Since $\mathrm{Re}(iz^3(t)-\lambda)>0$ in A_1, $\mathrm{Re}(u'\overline{u})$ is a strictly increasing function of x on each horizontal line segment in A_1. □

Proof of Theorem 8: The proofs of Theorems 5 and 6 give everything except the last statement of the theorem. For that, recall that we can take $u(z)=\overline{u}(-\overline{z})$ by Remark 3; this implies that $\mathrm{Re}(u'\overline{u})$ is an odd function with respect to reflection in the imaginary axis, and so $\mathrm{Re}(u'\overline{u})=0$ on the whole imaginary axis. Now we use Lemma 10 to complete the proof. □

C. Arrangement of the zeros

In the previous two subsections, we find zero-free regions of eigenfunctions and their first derivatives. We now examine the locations of zeros of such functions. For this purpose, mainly we will use Lemma 4 and make use of Fig. 2.

By the last statement of Lemma 1, in the sector $S_{-1,\pi/20}$ that contains the negative imaginary axis, the eigenfunction u has only finitely many zeros. Now with the zero-free region in Corollaries 7 and 9, we see that u has only finitely many zeros in $\mathrm{Im}\,z<0$. Since u has infinitely many zeros, u has infinitely many zeros in $\mathrm{Im}\,z\geqslant 0$. When $\beta>0$ (hence when $\beta<0$ as well), by Theorem 5, u must have infinitely many zeros in A_1. Also when $\beta=0$, by Theorem 8, u has infinitely many zeros on the positive imaginary axis.

The next theorem gives some information on how zeros of u and u' in A_1 should be arranged, when $\beta>0$. Note that all the zeros of u and u' in $\mathrm{Im}\,z\geqslant 0$ lie in A_1 by Theorem 5.

Theorem 11: *Suppose $u(z)$ is an eigenfunction of (10) with eigenvalue $\lambda\in\mathbb{C}$, with $\mathrm{Im}\,\lambda=\beta>0$. Then*

(i) $\mathrm{Re}(u'\overline{u})\geqslant 0$ *for some point on the imaginary axis if and only if* uu' *has infinitely many zeros in* $A_1\cap B_2$ *and at most finitely many zeros in* $A_1\cap B_2^c$; *and*

(ii) $\mathrm{Re}(u'\overline{u})<0$ *for every point on the imaginary axis if and only if* uu' *has no zeros in* $\{z\in A_1:\mathrm{Re}\,z\leqslant 0\}$ *and infinitely many in* $\{z\in A_1:\mathrm{Re}\,z>0\}$.

We will use the following lemma along with Lemma 10.

Lemma 12: Assume $\mathrm{Im}\,\lambda=\beta>0$. *Suppose* $\mathrm{Re}\,\zeta_1\leqslant\mathrm{Re}\,\zeta_2$ *and* $\mathrm{Re}(u'\overline{u})=0$ *at* ζ_1, ζ_2 (*where* $\zeta_1\neq\zeta_2$). *Then*

(i) $\zeta_1,\zeta_2\in cl(A_1\cap B_2)\Rightarrow \mathrm{Re}\,\zeta_1<\mathrm{Re}\,\zeta_2$ *and* $\mathrm{Im}\,\zeta_1<\mathrm{Im}\,\zeta_2$, *and*

(ii) $\zeta_1,\zeta_2\in cl(A_1\cap B_2^c)\Rightarrow \mathrm{Re}\,\zeta_1<\mathrm{Re}\,\zeta_2$ *and* $\mathrm{Im}\,\zeta_1>\mathrm{Im}\,\zeta_2$.

Proof of part (i): We will first prove this for $\zeta_1,\zeta_2\in A_1\cap B_2$. Suppose that $\mathrm{Re}\,\zeta_1=\mathrm{Re}\,\zeta_2$. Then we could find a vertical line segment $z(t)$ in $A_1\cap B_2$ whose end points are ζ_1 and ζ_2. We now apply (11) to this line segment to get

$$0=-\int_c^d \mathrm{Im}(iz^3(t)-\lambda)|u(z(t))|^2\,dt.$$

This would imply $u\equiv 0$ on the curve $z(t)$ since $\mathrm{Im}(iz^3(t)-\lambda)>0$ in B_2. Then since u is analytic, $u\equiv 0$ in $\mathbb{C}$. This is a contradiction. Hence $\mathrm{Re}\,\zeta_1<\mathrm{Re}\,\zeta_2$.

Similarly, suppose that $\mathrm{Im}\,\zeta_1\geqslant\mathrm{Im}\,\zeta_2$. Then we could find a smooth curve $z(t)=x(t)+iy(t)$ in $A_1\cap B_2$ such that $z(c)=\zeta_1$, $z(d)=\zeta_2$, $x'(t)>0$ and $y'(t)\leqslant 0$. Note that $\mathrm{Im}(iz^3(t)-\lambda)>0$ and $\mathrm{Re}(iz^3(t)-\lambda)>0$ in $A_1\cap B_2$. This contradicts (11) like for the case of $\mathrm{Re}\,\zeta_1=\mathrm{Re}\,\zeta_2$. We now see that the above argument still holds for $\zeta_1,\zeta_2\in cl(A_1\cap B_2)$.

Proof of part (ii): We use (11) again and a similar argument like in the proof of part (i). □

Proof of Theorem 11: Suppose $u(z)$ is an eigenfunction of (10) with eigenvalue $\lambda\in\mathbb{C}$, with $\mathrm{Im}\,\lambda=\beta>0$. Since u has infinitely many zeros in A_1 (by the paragraph shortly before Theorem 11), certainly uu' also has infinitely many zeros in A_1.

Proof of part (i): Suppose that $\mathrm{Re}(u'\overline{u})\geqslant 0$ for some point iy_0 on the imaginary axis. From (11) with $z(t)=it$, it follows that

$$\mathrm{Re}(u'\overline{u})|_{ic}^{id}=\beta\int_c^d |u(it)|^2\,dt. \tag{14}$$

Since $\beta>0$, $\mathrm{Re}(u'\overline{u})>0$ at every point iy for $y>y_0$. Now by Lemma 10, we obtain that $\mathrm{Re}(u'\overline{u})>0$ at every $x+iy\in A_1$ for $y>y_0$ and $x\geqslant 0$. Thus uu' does not have any zeros in $\{z\in A_1\cap B_2^c:\mathrm{Re}\,z\geqslant 0,\mathrm{Im}\,z>y_0\}$.

The entire function uu' does not have infinitely many zeros in any bounded region. If uu' had infinitely many zeros in $A_1\cap B_2^c$, then uu' would have infinitely many zeros in $\{z\in A_1\cap B_2^c:\mathrm{Re}\,z<0\}$ (see Fig. 9). But if uu' has a zero z_1 in $\{z\in A_1\cap B_2^c:\mathrm{Re}\,z<0\}$, then by Lemma 12 (ii), uu' has no zeros in $\{z\in A_1\cap B_2^c:\mathrm{Re}\,z_1\leqslant\mathrm{Re}\,z<0\}$. This requires that uu' would have infinitely many zeros in a bounded region. This is a contradiction. Thus uu' has infinitely many zeros in $A_1\cap B_2$ and at most finitely many zeros in $A_1\cap B_2^c$.

Conversely, suppose that uu' has infinitely many zeros in $A_1\cap B_2$ and at most finitely many zeros in $A_1\cap B_2^c$. Choose a zero z_0 in $A_1\cap B_2$. Then it follows from Lemma 10 that $\mathrm{Re}(u'\overline{u})>0$ at $i\,\mathrm{Im}\,z_0$ since $\mathrm{Re}\,z_0<0$.

Proof of part (ii): Suppose that $\mathrm{Re}(u'\overline{u})<0$ for every point on the imaginary axis. Then by Lemma 10, $\mathrm{Re}(u'\overline{u})<0$ for every point in $\{z\in A_1:\mathrm{Re}\,z\leqslant 0\}$. This implies that uu' has no zeros in $\{z\in A_1:\mathrm{Re}\,z\leqslant 0\}$. Now since we know that uu' has infinitely many zeros in A_1, uu' must have infinitely many zeros in $\{z\in A_1:\mathrm{Re}\,z>0\}$.

Conversely, suppose that $\mathrm{Re}(u'\overline{u})\geqslant 0$ for some point on the imaginary axis. Then uu' would have at most finitely many zeros in $\{z\in A_1:\mathrm{Re}\,z>0\}$ by the argument as in the proof of part (i). This completes the proof. □

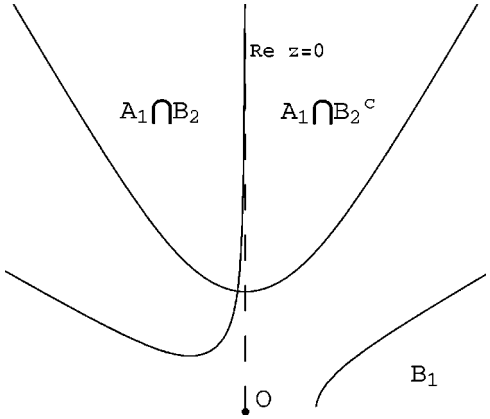

FIG. 9. The relative positions of $A_1 \cap B_2$, $A_1 \cap B_2^c$ and the imaginary axis with $\beta > 0$.

Remark 9: Since the negative imaginary axis is in the middle of a blowing-up Stokes region (see Fig. 2), $u(iy)$ blows up as y tends to $-\infty$. On the other hand, the positive imaginary axis is a critical ray. We can show that $|u(iy)|^2 \leqslant (\text{const}) y^{-3/2}$ for all y near positive infinity, by Theorem 7.4.4 of Hille.[13]

Since the right-hand side of (14) approaches $+\infty$ as c tends to $-\infty$ (while d is fixed), we see that $\mathrm{Re}[u'(ic)\overline{u}(ic)] < 0$ for all c near negative infinity. However, the right-hand side of (14) is convergent as d tends to $+\infty$ (while c is fixed). Thus $\mathrm{Re}(u'\overline{u})$ may or may not become positive near infinity along the positive imaginary axis.

The next lemma gives some information on the locations of zeros of u and u' in $\mathrm{Im}\, z < 0$, if any exist. There can only be finitely many such zeros of u, by the paragraph shortly before Theorem 11. One can show that u' also has at most finitely many zeros in $\mathrm{Im}\, z < 0$. Indeed, using (12) along each vertical half-line in the Stokes region containing the negative imaginary axis, one can show that $\mathrm{Im}(u'\overline{u}) = 0$ at some point z_0 on each vertical half-line in $\mathrm{Im}\, z < 0$ by an argument similar to that in Remark 9. This with the next lemma implies that uu' has at most finitely many zeros in $\mathrm{Im}\, z < 0$.

Lemma 13: Assume $\mathrm{Im}\,\lambda = \beta \geqslant 0$. *Suppose* $\mathrm{Im}\,\zeta_1 \leqslant \mathrm{Im}\,\zeta_2$ *and* $\mathrm{Im}(u'\overline{u}) = 0$ *at* ζ_1, ζ_2 *(where* $\zeta_1 \neq \zeta_2$*). Then*

(i) $\zeta_1, \zeta_2 \in cl(A_4 \cap B_3) \Rightarrow \mathrm{Im}\,\zeta_1 < \mathrm{Im}\,\zeta_2$ *and* $\mathrm{Re}\,\zeta_1 < \mathrm{Re}\,\zeta_2$, *and*

(ii) $\zeta_1, \zeta_2 \in cl(A_4 \cap B_4) \Rightarrow \mathrm{Im}\,\zeta_1 < \mathrm{Im}\,\zeta_2$ *and* $\mathrm{Re}\,\zeta_1 > \mathrm{Re}\,\zeta_2$.

Proof: We omit the proof because it is very similar to the proof of Lemma 12. We use (12) instead of (11), and also make use of Figs. 6 and 7. □

Roughly speaking, then, the zeros move up and to the right in the third quadrant, and down and to the right in the fourth quadrant. This observation supports that when λ is real, zeros of u in $\mathrm{Im}\, z < 0$ lie on an arch-shaped curve as in Figs. 5 and 6 of the paper by Bender *et al.*[16]

IV. OTHER PROPERTIES OF EIGENFUNCTIONS

In this section, we present a possible way of proving the conjecture that the eigenvalues λ of $H = -d^2/dz^2 - (iz)^3$ are positive real. Given an eigenfunction u with eigenvalue λ, Theorem 14 below gives a class $\mathcal{O}$ of polynomials $p(x,y)$ which are orthogonal to $|u|^2$ in the sense that $\int_{-\infty}^{\infty} p(x,y)|u(x+iy)|^2\, dx = 0$ for all y. One can perhaps prove the conjecture as follows. Suppose $\mathrm{Im}\,\lambda \neq 0$; if $\mathcal{O}$ is large enough then $|u|^2 \equiv 0$, giving a contradiction, so that $\mathrm{Im}\,\lambda = 0$.

Let u be an eigenfunction of $H = -d^2/dz^2 - (iz)^3$ with eigenvalue $\lambda = \alpha + i\beta$.

Theorem 14: *Let* $\mathcal{O} = \{\text{polynomials } p(\cdot,\cdot) : \int_{-\infty}^{\infty} p(x,y)|u(x+iy)|^2\, dx = 0 \text{ for all } y\}$. *Then:*

(i) $x^3 - 3xy^2 - \beta \in \mathcal{O}$,

(ii) for all $m \geqslant 0$,

$$\tilde{p}(x,y) := \frac{4}{m+1}\left(\frac{x^{m+5}}{m+5} - 3y^2\frac{x^{m+3}}{m+3} - \beta\frac{x^{m+2}}{m+2}\right)(x^3 - 3y^2x - \beta) - m(m-1)x^{m-2}$$
$$-4x^m(3x^2y - y^3 + \alpha) - \frac{12}{m+1}yx^{m+2} \in \mathcal{O},$$

(iii) if $p \in \mathcal{O}$ *then* $p_y + 2(x^3 - 3xy^2 - \beta)\int_0^x p(t,y)\,dt \in \mathcal{O}$, *and*
(iv) if $p \in \mathcal{O}$ *then* $p_{xx} + p_{yy} + 12x^2yp + 4(x^3 - 3xy^2 - \beta)\int_0^x p_y(t,y)\,dt \in \mathcal{O}$.

For example the following polynomials are in $\mathcal{O}$:

$$p_3(x,y) = x^3 - 3xy^2 - \beta, \text{ by } (i),$$

$$p_7(x,y) = x^7 - 9x^5y^2 - 5x^4\beta + 18x^3y^4 + 18x^2y^2\beta + 4x(\beta^2 - 3y),$$

by applying (iii) to p_3 and multiplying by 2,

$$p_8(x,y) = 2x^8 - 16x^6y^2 - 7x^5\beta + 30x^4y^4 + 25x^3y^2\beta + 5x^2(\beta^2 - 12y) + 10y^3 - 10\alpha,$$

by applying (ii) with $m = 0$ and multiplying by $\frac{5}{2}$,

$$p_9(x,y) = 2x^9 - 15x^7y^2 - 6x^6\beta + 27x^5y^4 + 4x^3(\beta^2 - 27y) + 24xy^3 + 21x^4y^2\beta - 24x\alpha,$$

by applying (ii) with $m = 1$ and multiplying by 6, and

$$p_{10}(x,y) = 20x^{10}y - 144x^8y^3 - 55x^7y\beta + 252x^6y^5 + 189x^5y^3\beta + x^4(-1680y^2 + 35y\beta^2)$$
$$-35x^3\beta + x^2(420y^4 - 420y\alpha) + 105xy^2\beta + 35\beta^2 - 210y,$$

by applying (iv) to p_8 and multiplying by $\frac{7}{2}$.

We do not know whether Theorem 14 generates all the polynomials in $\mathcal{O}$.

Proof of Theorem 14: It is useful to have the following two formulas, which follow from multiplying (10) by $\overline{u}$ and separating real and imaginary parts:

$$\mathrm{Im}[u_x(x+iy)\overline{u}(x+iy)]_x = (x^3 - 3xy^2 - \beta)|u(x+iy)|^2 \tag{15}$$

and

$$\mathrm{Re}[u_x(x+iy)\overline{u}(x+iy)]_x = |u_x|^2 + (-3x^2y + y^3 - \alpha)|u|^2. \tag{16}$$

Also, it can be shown that the exponential decay of u and its derivatives at $\pm\infty + iy$ allows us to differentiate through the integrals that follow.

Proof of part (i): This is clear by integrating (15), using the zero boundary conditions in the left- and right-hand Stokes regions.

Proof of part (ii): Suppose m is a non-negative integer. Then

$$\frac{d^2}{dy^2}\int_{-\infty}^{\infty} x^m|u|^2\,dx = \frac{d}{dy}\int_{-\infty}^{\infty} x^m\frac{\partial}{\partial y}|u|^2\,dx$$

$$= -2\frac{d}{dy}\int_{-\infty}^{\infty} x^m\,\mathrm{Im}(u_x\overline{u})dx$$

$$= \frac{2}{m+1}\frac{d}{dy}\int_{-\infty}^{\infty} x^{m+1}\,\mathrm{Im}(u_x\overline{u})_x dx \quad \text{by integration by parts,} \tag{17}$$

$$= \frac{2}{m+1}\frac{d}{dy}\int_{-\infty}^{\infty} x^{m+1}(x^3-3xy^2-\beta)|u|^2\,dx, \quad \text{by (15)}$$

$$= \frac{2}{m+1}\int_{-\infty}^{\infty}[-2(x^{m+4}-3x^{m+2}y^2-\beta x^{m+1})\mathrm{Im}(u_x\overline{u})-6x^{m+2}y|u|^2]dx$$

$$= \frac{2}{m+1}\int_{-\infty}^{\infty} 2\left(\frac{x^{m+5}}{m+5}-3y^2\frac{x^{m+3}}{m+3}-\beta\frac{x^{m+2}}{m+2}\right)(x^3-3xy^2-\beta)|u|^2\,dx$$

$$-\frac{12}{m+1}\int_{-\infty}^{\infty} x^{m+2}y|u|^2\,dx, \tag{18}$$

where the last step is by integration by parts and (15).

Also we have

$$\frac{d^2}{dy^2}\int_{-\infty}^{\infty} x^m|u|^2\,dx = -2\int_{-\infty}^{\infty} x^m[\mathrm{Re}(u_x\overline{u})_x-2|u_x|^2]dx, \quad \text{by differentiating through (17);} \tag{19}$$

$$= -2\int_{-\infty}^{\infty} x^m[(-3x^2y+y^3-\alpha)|u|^2-|u_x|^2]dx, \quad \text{by (16);} \tag{20}$$

$$= -m(m-1)\int_{-\infty}^{\infty} x^{m-2}|u|^2\,dx+4\int_{-\infty}^{\infty} x^m|u_x|^2\,dx, \tag{21}$$

where the last step is from (19) with integration by parts.

Now use (21) to eliminate $\int_{-\infty}^{\infty} x^m|u_x|^2\,dx$ from (20), and then equate the resulting expression to (18). This yields $\int_{-\infty}^{\infty}\tilde{p}(x,y)|u|^2\,dx=0$, which is (ii).

Proof of part (iii): Suppose that $\int_{-\infty}^{\infty} p(x,y)|u|^2\,dx=0$ for all y. Then

$$0 = \frac{d}{dy}\int_{-\infty}^{\infty} p(x,y)|u|^2\,dx$$

$$= \int_{-\infty}^{\infty}[p_y(x,y)|u|^2-2p(x,y)\mathrm{Im}(u_x\overline{u})]dx$$

$$= \int_{-\infty}^{\infty}\left[p_y(x,y)|u|^2+2\left\{\int_0^x p(t,y)dt\right\}\mathrm{Im}(u_x\overline{u})_x\right]dx, \tag{22}$$

by integration by parts. This with (15) gives (iii).

Proof of part (iv): Suppose $\int_{-\infty}^{\infty} p(x,y)|u|^2\,dx=0$ for all y. Then we differentiate through (22) with respect to y again to get

$$
\begin{aligned}
0 &= \int_{-\infty}^{\infty} [p_{yy}(x,y)|u|^2 - 4p_y(x,y)\mathrm{Im}(u_x\overline{u}) - 2p(x,y)\mathrm{Im}(iu_{xx}\overline{u} - i|u_x|^2)]dx \\
&= \int_{-\infty}^{\infty} \left[p_{yy}(x,y)|u|^2 + 4\left\{ \int_0^x p_y(t,y)dt \right\} \mathrm{Im}(u_x\overline{u})_x - 2p(x,y)(\mathrm{Re}(u_x\overline{u})_x - 2|u_x|^2) \right] dx \\
&= \int_{-\infty}^{\infty} \left[p_{yy}(x,y) + 4\left\{ \int_0^x p_y(t,y)dt \right\} (x^3 - 3xy^2 - \beta) \right] |u|^2\, dx - 2\int_{-\infty}^{\infty} p(x,y)[-\mathrm{Re}(u_x\overline{u})_x \\
&\quad + 2(-3x^2y + y^3 - \alpha)|u|^2]dx, \quad \text{by (15) and (16);} \\
&= \int_{-\infty}^{\infty} \left[p_{yy}(x,y) + 4\left\{ \int_0^x p_y(t,y)dt \right\} (x^3 - 3xy^2 - \beta) - 4p(x,y)(-3x^2y + y^3 - \alpha) \right] |u|^2\, dx \\
&\quad - \int_{-\infty}^{\infty} p_x(x,y) 2\,\mathrm{Re}(u_x\overline{u})dx.
\end{aligned}
$$

But $(y^3-\alpha)\int_{-\infty}^{\infty} p|u|^2\,dx = 0$, and so applying integration by parts again to the last term gives (iv). □

Corollary 15: Let $u(z)$ be an eigenfunction of (2). Then $\int_{-\infty}^{\infty}|u(x+iy)|^2\,dx$ is a convex function.

Proof: This is a consequence of (21) with $m=0$, or it can be proved using the subharmonicity of $|u|^2$. □

V. CONCLUSIONS

Using path integrations, we were able to prove that eigenvalues of (1) lie in the sector $|\arg\lambda| \leqslant \pi/(2n+3)$ and we extended the result for some more general Hamiltonians. Also we provided zero-free regions of eigenfunctions and their first derivatives, for the potential $-(ix)^3$. Then finally we had the set $\mathcal{O}$ of polynomials $p(x,y)$ which are orthogonal to $|u|^2$ in the sense that $\int_{-\infty}^{\infty} p(x,y)|u|^2\,dx = 0$ for all y.

In a recent communication with Mezincescu, he pointed out that for the potential $-(ix)^3$, the formula (13) with $z(t) = y_0 + (t - y_0\cos\theta)e^{i\theta}$ together with the harmonic oscillator inequality implies $\alpha \geqslant \max_{0<\theta<\pi/10}\{|\beta|\sin 3\theta + 5(\cos 5\theta/12)^{3/5}\}/\cos 3\theta$. This is a slight improvement over our estimate $|\arg\lambda| \leqslant \pi/5$, and gives an almost sharp lower bound of 1.1258 on the real part of the first eigenvalue for the potential $-(ix)^3$ (numerically $\lambda_1 \approx 1.1562$ by Bender *et al.*[8]).

In this paper we consider only polynomial potentials with odd degrees. However, a number of other authors have worked on even degree potentials, particularly quartic[17,18] and sextic[19,20] polynomial potentials. Our techniques in proving Theorems 2 and 3 can be used to obtain information on eigenvalues for even degree potentials if both ends of a line passing through the origin stay in decaying Stokes regions.

Obvious open problems are to narrow the eigenvalue sectors closer to the positive real axis, and finally to prove that the eigenvalues are real. Since some $\mathcal{PT}$-symmetric non-Hermitian Hamiltonians do not have all real eigenvalues, one might further want to classify $\mathcal{PT}$-symmetric non-Hermitian Hamiltonians which do have positive real eigenvalues.

(Received 3 November 2000; accepted for publication 14 February 2001)

In this paper we consider symmetry transformations that preserve the first law and the second law of thermodynamics, as well as the pseudo-Riemannian structure of the Legendre manifold defined in terms of the second derivative matrix of the entropy function in extended irreversible thermodynamics. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1368844]

I. INTRODUCTION

In 1973 Hermann[1] suggested that equilibrium thermodynamics (ET) might be formulated in terms of a contact manifold M with coordinate cover (x,u,y), $x=(x^1,\ldots,x^n)$, $y=(y_1,\ldots,y_n)$. This contact manifold M is equipped with a contact one-form $w=\mathrm{d}u-\Sigma_{i=1}^{n} y_i\,\mathrm{d}x^i=\mathrm{d}u-y_i\,\mathrm{d}x^i$ (summation over repeated indices), where the fundamental equation of states in ET is a Legendre submanifold $\mathcal{L}$ of M. Later, Weinhold[2] suggested that the second derivative matrix elements of the total internal energy might be used to define a metric structure on the set of thermodynamic states. In 1983 Salamon *et al.*[3] constructed a group of coordinate transformations that preserve the structure of w and the metric structure of Weinhold. In this paper we further generalize and clarify the work of Salamon *et al.* to extended irreversible thermodynamics (EIT). First we consider symmetry transformations that preserve the first law and the second law in $\mathcal{L}$. We then generalize these results to the contact manifold M such that the contact structure of M as well as the pseudometric structure of $\mathcal{L}$ are preserved. Finally as an illustration of our results, we consider the transformations that carry the entropy surface to the energy surface, the coordinate transformations of Salamon *et al.*, and the partial Legendre involutions.

Consider a system of molecules in r components contained in a volume V, where no chemical reactions take place. Let E be the total internal energy of the system, N_i the number of particles of species i, Φ_i^α the generalized fluxes such as the mass flux, heat flux, etc.,[4] P the hydrostatic pressure, μ_i the chemical potential conjugate to N_i, and X_i^α the generalized potential conjugate to Φ_i^α.[4] Here $i=1,2,\ldots,r$, and $\alpha=1,2,\ldots,k$, represent the order of the tensor variables Φ_i^α. For simplicity we denote the set of extensive thermodynamic variables $\{E,V,N_i,\Phi_i^\alpha : i=1,2,\ldots,r;\alpha=1,2,\ldots,k\}$ by $x=(x^1,\ldots,x^N)$, where the x^i's are the global thermodynamic variables. Thus x^i's are differentiable functions of time t. Depending on the nonequilibrium system under consideration we can take k as large as necessary so that a sufficient number of the generalized fluxes are included in the system. To this end we consider an irreversible path γ in the thermodynamic base space B_N with coordinate cover $x=(x^1,\ldots,x^N)$. Assume that P, μ_i, and X_i^α are C^1 functions defined on an open subset of B_N with compact support. Consider an infinitesimal portion of the irreversible process along γ. Let $\Delta W=-P\Delta V+\mu_i\Delta N_i-X_i^\alpha\Delta\Phi_i^\alpha$ be the infinitesimal change of work, ΔQ the net amount of heat exchanged between the system and its surroundings, and ΔQ_d the change of dissipative energy (loss of available energy). Define the work one form

$$\xi=-P\,\mathrm{d}V+\mu_i\mathrm{d}N_i-X_i^\alpha\mathrm{d}\Phi_i^\alpha, \tag{1}$$

a)Electronic mail: masaoca@yahoo.com

and the heat one-form $\Omega = dE - \xi$. The first law and the second law of thermodynamics can be formulated as[5]

$$\Delta E = \Delta W + \Delta Q + \Delta Q_d, \tag{2a}$$

and

$$\Omega \wedge d\Omega = 0, \quad \Delta Q_d \geqslant 0, \tag{2b}$$

where we have assumed that ΔQ_d is semipositive definite and vanishes only at thermodynamic equilibrium. Notice that the second law formulated in (2b) is equivalent to the Clausius principle[5] as well as the Kelvin's principle.[6]

By solving the Pfaffian equation $\Omega = 0$ under the Frobenius integrability condition $\Omega \wedge d\Omega = 0$[7] (or Caratheodory's inaccessibility condition[8]) we can obtain the generalized Gibbs relation:[5]

$$\Omega = T\,dS = dE + P\,dV - \mu_i\,dN_i + X_i^\alpha\,d\Phi_i^\alpha, \tag{3}$$

where T is the thermodynamic temperature and S is the entropy function of the system. Let $u = S = f(x)$ be the integral surface of the Pfaffian equation $\Omega = 0$ under the integrability condition (2b). Denote $y = (T^{-1}, PT^{-1}, -\mu_i T^{-1}, X_i^\alpha T^{-1}) = (y_1, \ldots, y_N)$. As a consequence of the Gibbs relation we have $y_i = \partial_i f$. Thus the entropy surface $u = f(x)$ can be used to define the one graph space

$$\mathcal{L} = \left\{ (x,u,y) \,\middle|\, u = f(x), y_i = \frac{\partial f}{\partial x^i} = \partial_i f \right\}. \tag{4}$$

In Sec. II we consider symmetry transformations that preserve the Pfaffian equation together with the integrability condition (2b).

II. SYMMETRY TRANSFORMATIONS PRESERVING THE FIRST LAW AND THE SECOND LAW

The change of dissipative energy ΔQ_d depends on the irreversible process under consideration. Based on the expression of Q_d in local theory of EIT, Q_d cannot be expressed as a function of x alone in B_N.[5] From a physical point of view the semipositive definite property of ΔQ_d must be invariant under symmetry transformations that preserve the Pfaffian equation $\Omega = 0$ together with the integrability condition (2b). Otherwise it leads to violation of the second law. On the other hand, symmetry transformations preserving the structure of the Pfaffian equation together with condition (2b) are equivalent to the invariance of the integral surface $u = S = f(x)$ with the contact condition $du = y_i\,dx^i$. Therefore the invariance of the first law and the second law is equivalent to the invariance of the integral surface $u = f(x)$ together with the contact condition $du = y_i\,dx^i$.

Let B_N^* be a replica of B_N with coordinate cover x^*. Let U and U^* be open subsets of $B_N \times R$ and $B_N^* \times R$, respectively. Consider the transformations $\varphi: (x,u) \in U \to (x^*, u^*) \in U^*$ given by

$$\begin{gathered} x^* = F(x,u), \quad F = (F^1, \ldots, F^N) \\ u^* = G(x,u), \end{gathered} \tag{5}$$

where φ is a one-to-one (1–1) and onto mapping from U onto U^*, and F, G are C^1 functions defined on U. Further, we assume that the matrix A with matrix elements $D_j F^i = \partial_j F^i + y_j \partial_u F^i$ is nonsingular. Now

$$du^* - y_i^* d(x^*)^i = (\partial_u G - y_i^* \partial_u F^i)[du - y_i\,dx^i] + [D_j G - y_i^* D_j F^i]dx^j, \tag{6}$$

it is evident that $du^*=y_i^*\mathrm{d}(x^*)^i$, if and only if,

$$D_jG=y_i^*(D_jF^i),\ \text{ or }\ y^*=A^{-1}\cdot DG\ \text{ with }\ DG=\begin{bmatrix}D_1G\\ \vdots\\ D_NG\end{bmatrix}. \tag{7}$$

Since φ is 1–1 onto, thus $u^*=g(x^*)$ and

$$y_i^*=\partial_i^*g=\frac{\partial}{\partial(x^*)^i}g.$$

Let

$$\mathcal{L}^*=\{(x^*,u^*,y^*)|u^*=g(x^*),y_i^*=\partial_i^*g\}.$$

Then $\varphi\mathcal{L}=\mathcal{L}^*$. Hence the first law and the second law are invariant under the transformations (5) if and only if (7) is satisfied. So far F and G are arbitrary differentiable functions defined on U. The transformations (5) can be reformulated as

$$x^*=F(x,u),\quad u^*=G(x,y), \tag{8}$$

$$y^*=H(x,u,y)=A^{-1}DG.$$

The second derivative matrix D^2u of the entropy function $u=f(x)$ is symmetric and nondegenerate. However, it is not positive definite. Thus D^2u can be considered as a nondegenerate tensor field of type (0, 2). Following Ruppeiner[9] we define a pseudometric d^2s on $\mathcal{L}$ by $d^2s=(\partial_i\partial_ju)\mathrm{d}x^i\,\mathrm{d}x^j=g_{ij}\mathrm{d}x^i\,\mathrm{d}x^j=\mathrm{d}x^i\,\mathrm{d}y_i=\langle\mathrm{d}x,\mathrm{d}y\rangle$, where $\langle,\rangle$ denotes scalar product of vectors in R^N. The entropy surface $u=f(x)$ becomes a pseudo-Riemannian manifold when it is endowed with the pseudometric d^2s. The physical significance of d^2s has been investigated by Salamon and Berry.[10] They showed that d^2s was related to the dissipative availability of energy. On the other hand, Casas-Vazquez and Jou[11] have computed the Gaussian curvature of the thermodynamic metric for a nonequilibrium system. They found that the presence of heat flux increased the thermodynamic curvature. In this paper we only concentrate on the geometric aspect of the pseudometric d^2s.

By (8) we can obtain

$$\begin{aligned}\langle\mathrm{d}x^*,\mathrm{d}y^*\rangle=&\{\langle\partial_jF,\partial_kH\rangle+\langle\partial_jF,\partial_uH\rangle y_k+\langle\partial_uF,\partial_jH\rangle y_k+\langle\partial_uF,\partial_uH\rangle y_jy_k\}\mathrm{d}x^j\,\mathrm{d}x^k\\&+\langle D_kF,\partial^jH\rangle\mathrm{d}x^k\,\mathrm{d}y_j\,.\end{aligned} \tag{9}$$

Hence $\langle\mathrm{d}x^*,\mathrm{d}y^*\rangle=B(x,u,y)\langle\mathrm{d}x,\mathrm{d}y\rangle$ provided the following conditions are satisfied:

$$\langle\partial_jF,\partial_kH\rangle=0,\quad\langle\partial_jF,\partial_uH\rangle=0,\quad j,k=1,2,...,N. \tag{9a}$$

$$\langle\partial_uF,\partial_kH\rangle=0,\quad\langle\partial_uF,\partial_uH\rangle=0,\quad k=1,2,...,N. \tag{9b}$$

$$B(x,u,y)=\delta_{jk}\langle D_jF,\partial^kH\rangle. \tag{9c}$$

As an example we consider the following transformations:

$$x^*=F(x,u)=(u,x^2,\ldots,x^N),\quad u^*=G(x,u)=x^1. \tag{10}$$

Then $du^*=y_i^*\mathrm{d}(x^*)^i$ if and only if $y^*=H(x,u,y)=A^{-1}DG=(y_1^{-1},-y_1^{-1}y_2,\ldots,-y_1^{-1},y_N)$. We can easily check that (9a) and (9b) are satisfied, while (9c) yields $B(x,u,y)=-y_1^{-1}=-T$. Furthermore we have $\partial_uG-y_i^*(\partial_uF^i)=-y_1^{-1}=\lambda$. Therefore $\mathrm{d}u^*-y_i^*\mathrm{d}(x^*)^i=\lambda(\mathrm{d}u-y_i\,\mathrm{d}x^i)$ and $\langle\mathrm{d}x^*,\mathrm{d}y^*\rangle=\lambda\langle\mathrm{d}x,\mathrm{d}y\rangle$.

We notice that (8) is the transformation from the entropy surface $u=\mathcal{S}=f(x)$ to the energy surface $u^*=E=g(x^*)$. Except for the negative sign, the pseudo-Riemannian structures of $\mathcal{L}$ and $\mathcal{L}^*$ are (conformal) equivalent.[12] This example cannot be obtained from the work of Salamon *et al.*

III. CONTACT TRANSFORMATIONS

In this section we generalize the transformations defined on $B_N\times R$ to the $(2N+1)$-dimensional contact manifold M with coordinate cover (x,u,y), where x, u, y are independent variables. Define the one-form $\omega=\mathrm{d}u-y_i\,\mathrm{d}x^i$ in M. For every $x\in B_N$, the vector space

$$\Delta_x=\{v\in T_xM\,|\langle\omega(x),v(x)\rangle=\omega_i v^i=0;\omega(x)=\omega_i(x)\mathrm{d}x^i,v(x)=v^i(x)\partial_i\}$$

is called the contact hyperplane to M at x, where T_xM is the tangent bundle to M at x. Since $\omega\wedge(\mathrm{d}\omega)^N\neq 0$ and $\omega\wedge(\mathrm{d}\omega)^{N+1}=0$, the one-form ω defines a nondegenerate hyperplane distribution $x\to\Delta_x$ with Δ_x as the kernel of ω. This distribution of hyperplanes is called the contact structure of M. If λ is a function defined on M which does not vanish at any point of M, then $\lambda\omega$ defines the same contact structure of M. The differentiable manifold M equipped with such a one-form (contact one-form) ω is called a contact manifold.[13] Notice that M can be identified with $T^*(B_N)\times R$, where $T^*(B_N)$ is the cotangent bundle of B_N. On the other hand, M can also be identified with the one-jet space $J^1(B_N,R)$ from B_N into R, which is a vector bundle with base B_N. The fiber at $x\in B_N$ is $R\times T^*(B_N)$. The jet j^1_xf is the pair $(f(x),\mathrm{d}f(x))$, and the canonical projection $\pi:M\to B_N$ is the mapping $j^1_xf\to x$. A section of M is a mapping $\sigma:B_N\to M$ such that $\pi\circ\sigma(x)=x$ for every $x\in B_N$. Hence the mapping $j^1f:x\to j^1_xf$ defines a section of M such that $(j^1f)^*\omega=0$, where $(j^1f)^*$ is the pull-back of j^1f. The image of B_N under j^1f is the one-graph space

$$\mathcal{L}=\{(x,u,y)\,|u=f(x),y_i=\partial_i f\},$$

which is the N-dimensional Legendre submanifold of M.

We now consider the 1–1 onto mapping $\varphi:M\to M^*$ given by

$$\begin{aligned} x^*&=F(x,u),\quad u^*=G(x,u),\\ y^*&=H(x,u,y), \end{aligned}\tag{11}$$

where F, G are arbitrary functions of class C^1 defined at every $(x,u)\in U$, U an open subset of $B_N\times R$. Let $\omega^*=\mathrm{d}u^*-y_i^*\,\mathrm{d}(x^*)^i$. By (10) we have

$$\omega^*=[\partial_uG-(\partial_uF^i)y_i^*]\omega+[D_jG-(D_jF^i)y_i^*]\mathrm{d}x^j.$$

Set $\lambda=\partial_uG-(\partial_uF^i)y_i^*$. Since F and G are arbitrary functions of (x,u), without loss of generality, we can assume that λ is nowhere vanishing in M. Hence $\omega^*=\lambda\omega$ if and only if

$$D_jG=(D_jF^i)y_i^*,\quad \text{or}\quad H(x,u,y)=A^{-1}\cdot DG.\tag{12}$$

As $\mathrm{d}\omega=\mathrm{d}\lambda\wedge\omega+\lambda\,\mathrm{d}\omega$, the contact ideal[14] generated by $(\omega,\mathrm{d}\omega)$ is invariant under φ. By examining (5), (8), and (11), we notice that (11) is the lift of (5) from $\mathcal{L}$ into M, while (5) is the projection of (11) onto $\mathcal{L}$. Hence

$$\mathcal{L}^*=\{(x^*,u^*,y^*)\,|u^*=g(x^*),y_i^*=\partial_i^*g\}$$

is the image of $\mathcal{L}$ under φ, where $\omega|_{\mathcal{L}}=\omega^*|_{\mathcal{L}^*}=0$. The first law and the second law are therefore invariant under φ if and only if (12) is satisfied. Next we calculate $\langle\mathrm{d}x^*,\mathrm{d}y^*\rangle$. By (11) we obtain

$$\langle dx^*, dy^* \rangle = \{\langle \partial_j F, \partial_k H \rangle dx^j\, dx^k + \langle \partial_j F, \partial_u H \rangle dx^j\, du + \langle \partial_u F, \partial_k H \rangle du\, dx^k\}$$
$$+ \langle \partial_u F, \partial_u H \rangle du\, du + \langle \partial_u F, \partial^k H \rangle du\, dy_k\} + \langle \partial_j F, \partial^k H \rangle dx^j dy_k . \tag{13}$$

Since dx^i, du, and dy_k are independent, $\langle dx^*, dy^* \rangle = B(x,u,y)\langle dx, dy \rangle$ if and only if the following conditions are satisfied:

$$\langle \partial_j F, \partial_k H \rangle = 0, \quad \langle \partial_i F, \partial_u H \rangle = 0, \tag{14a}$$

$$\langle \partial_u F, \partial_k H \rangle = 0, \quad \langle \partial_u F, \partial_u H \rangle = 0, \quad \langle \partial_u F, \partial^k H \rangle = 0, \tag{14b}$$

$$B(x,u,y) = \delta_{jk} \langle \partial_j F, \partial^k H \rangle \tag{14c}$$

for $j,k = 1,2,...,N$.

Suppose $\langle dx^*, dy^* \rangle = B(x,u,y)\langle dx, dy \rangle$. Then $\langle dx^*, dy^* \rangle|_{\mathcal{L}^*}$ and $\langle dx, dy \rangle|_{\mathcal{L}}$ are conformal equivalent pseudometrices on $\mathcal{L}$ and $\mathcal{L}^*$, respectively. However, the converse is not necessarily true. Comparing (9) and (13) we observe that (9) is the projection of (13) on $\mathcal{L}^*$. Consequently (14a)–(14c) become (9a)–(9c), respectively, if we impose the condition

$$\langle dx^*, dy^* \rangle|_{\mathcal{L}^*} = B(x,u,y)|_{\mathcal{L}} \langle dx, dy \rangle|_{\mathcal{L}} . \tag{15}$$

Therefore the transformations in (11) preserve the contact structure of M and the pseudometric structure on $\mathcal{L}$ if conditions (12), (14a), (9b), and (9c) are satisfied.

Suppose the transformations in (11) define a one-parameter Lie group of transformations,

$$x^* = F(x,u,\epsilon), \quad u^* = G(x,u,\epsilon), \quad y^* = H(x,u,y,\epsilon). \tag{16a}$$

Consider the infinitesimal transformations of (16a):

$$(x^*)^i = x^i + \xi^i(x,u)\epsilon + 0(\epsilon^2),$$
$$u^* = u + \eta(x,u)\epsilon + 0(\epsilon^2), \tag{16b}$$
$$y_i^* = y_i + \eta_i(x,u,y)\epsilon + 0(\epsilon^2).$$

To the first order of ϵ we have the following results:

$$\omega^* = \{1 + \epsilon \partial_u(\eta - y_i \xi^i)\}\omega + \epsilon[D_j(\eta - y_i \xi^i) - \eta_j] dx^j, \tag{17a}$$

$$\langle dx^*, dy^* \rangle|_{\mathcal{L}^*} = \langle dx, dy \rangle|_{\mathcal{L}} + \epsilon[D_j \eta_i\, dx^i\, dx^j + (D_j \xi^i + \partial^i \eta_j) dx^j\, dy_i]|_{\mathcal{L}} . \tag{17b}$$

Let $\alpha = \partial_u(\eta - y_i \xi^i)$. Then $\omega^* = (1 + \epsilon\alpha)\omega$ if and only if

$$\eta_j = D_j(\eta - y_i \xi^i). \tag{18}$$

On the other hand, $\langle dx^*, dy^* \rangle|_{\mathcal{L}^*}$ and $\langle dx, dy \rangle|_{\mathcal{L}}$ are conformal equivalent pseudometrices if

$$D_j \eta_i|_{\mathcal{L}} = 0 \quad B(x,u,y)|_{\mathcal{L}} = \delta_{ij}(D_j \xi^i + \partial^i \eta_j)|_{\mathcal{L}} . \tag{19}$$

Therefore the infinitesimal transformations in (16b) with generator

$$X = \xi^i(x,u)\partial_i + \eta(x,u)\partial_u + \eta_i(x,u,y)\partial^i$$

preserve the contact structure as well as the pseudometric structure if conditions (18) and (19) are satisfied.

Next we consider the coordinate transformations that satisfy (12), (14a), (9b), and (9c). For simplicity we set $\partial_j G = b_j(x,u)$, $\partial_u G = b(x,u)$, $\partial_j F^i = a_{ij}(x,u)$, $\partial_u F^i = a^i(x,u)$, where we have abused the notation for a_{ij}. Then (12) can be rewritten as

$$b_j(x,u) + b(x,u)y_j = y_i^*[a_{ij}(x,u) + a^i(x,u)y_j]. \tag{20a}$$

Assume that matrix A with elements $(A)_{ij} = a_{ij}$ is nonsingular. Since F and G are arbitrary C^1 functions, we can choose b_j, b, a_{ij} and a^i in (20a) such that (14a) and (9b) are satisfied. To this end we set $a_{ij}(x,u) = a_{ij} = \text{const}$, $a^i(x,u) = a^i = \text{const}$. In order to satisfy (14a) we must have $b_j(x,u) = b_j = \text{const}$, and $b(x,u) = b = \text{const}$. Thus (20a) becomes

$$(a_{ij} + a^i y_j)y_i^* = b_j + by_j. \tag{20b}$$

This equation can be solved for y_i^* such that $y_i^* = H_i(x,u,y) = H_i(y)$. Thus, by assumption we have

$$\begin{aligned} (x^*)^i &= F^i(x,u) = a^i u + a_{ij}x^j + \alpha^i, \alpha^i \in R, \\ u^* &= G(x,u) = bu + b_j x^j + c, c \in R, \\ y_i^* &= H_i(y). \end{aligned} \tag{21}$$

In the following discussions we consider two special solutions of (21).

(i) Without loss of generality we set $a^i = a$ for $i = 1$ and $a^i = 0$ for $i \geqslant 2$. Then (20b) becomes

$$a_{ij}y_i^* + ay_j y_1^* = b_j + by_j. \tag{22}$$

Since a, b, b_j, and a_{ij} are arbitrary, we can solve this equation in many different ways, where the simplest solution can be obtained by setting $b = 0$, $a = 1$, $b_1 = 1$, $b_j = 0$ for $j \geqslant 2$, $a_{1j} = 0$ for all j and $a_{ij} = \delta_{ij}$ for $i,j \geqslant 2$. Then $y^* = (y_1^{-1}, -y_1^{-1}y_2, \ldots, -y_1^{-1}y_N)$. This is exactly what we have in example 1.

(ii) We set $a^i = 0$ for all i. Then

$$F^i(x,u) = a_{ij}x^j + \alpha^i, \quad G(x,u) = bu + b_j x^j + c.$$

Equation (20b) becomes $a_{ij}y_i^* = b_j + by_j$, which has the solution

$$y_i^* = [(A^T)^{-1}]_{ij}(b_j + by_j). \tag{23}$$

Notice that

$$\begin{aligned} F(x,u) &= A(x+\alpha), \quad \alpha = (\alpha^1, \ldots, \alpha^N), \\ G(x,u) &= bu + b_j x^j + c, \\ H(x,u,y) &= (A^T)^{-1}(by + r), \quad r = (b_1, \ldots b_N) \end{aligned}$$

are the coordinate transformations considered by Salamon *et al.*

IV. FURTHER GENERALIZATIONS

In order to consider partial Legendre involutions[15] we generalize (11) as follows:

$$x^* = F(x,u,y), \quad u^* = G(x,u,y), \quad y^* = H(x,u,y), \tag{24}$$

where F, G, H are functions of class C^1 defined in M. Thus

$$\omega^*=[\partial_u G-(\partial_u F^i)y_i^*]\omega+[D_j G-(D_j F^i)y_i^*]\mathrm{d}x^j+[\partial^j G-(\partial^j F^i)y_i^*]\mathrm{d}y_j. \tag{25}$$

Let $\lambda=\partial_u G-(\partial_u F^i)y_i^*$. Then $\omega^*=\lambda\omega$ if and only if

$$D_j G=(D_j F^i)y_i^*, \tag{26a}$$

$$\partial^i G=(\partial^j F^i)y_i^*. \tag{26b}$$

Furthermore, as an extension of (14a)–(14c) we obtain $\langle \mathrm{d}x^*,\mathrm{d}y^*\rangle=B(x,u,y)\langle \mathrm{d}x,\mathrm{d}y\rangle$ if and only if the following conditions are satisfied:

$$\langle \partial_j F,\partial_k H\rangle=0,\quad \langle \partial_j F,\partial_u H\rangle=0, \tag{27a}$$

$$\langle \partial_u F,\partial_k H\rangle=0,\quad \langle \partial_u F,\partial_u H\rangle=0,\quad \langle \partial_u F,\partial^k H\rangle=0, \tag{27b}$$

$$\langle \partial^j F,\partial^k H\rangle=0,\quad \langle \partial^j F,\partial_u H\rangle=0 \tag{27c}$$

and

$$B(x,u,y)=\delta_{jk}[\langle \partial_j F,\partial^k H\rangle+\langle \partial^j F,\partial_k H\rangle]. \tag{27d}$$

It should be noted that (26a) and (26b) are complementary conditions. By examining (27a)–(27c) we conclude that both F^i and H_i are independent of u. For simplicity we assume

$$F^i(x,u)=\sum_{j=1}^{N}(a_{ij}x^j+b_{ij}y_j)+\alpha^i. \tag{28a}$$

This implies that G can be written as

$$G=au+c\sum_{i=1}^{N}x^i y_i+d. \tag{28b}$$

By (26a) and (26b) we obtain

$$cx^j=\sum_{i=1}^{N}b_{ij}y_i^*, \tag{29a}$$

$$(a+c)y_j=\sum_{i=1}^{N}a_{ij}y_i^*. \tag{29b}$$

We now solve (29a) and (29b) for y_i^*. Since $\langle \partial_j F,\partial_k H\rangle=\langle \partial^j F,\partial^k H\rangle=0$, without loss of generality we choose b_{ij} and a_{ij} such that

$$\sum_{i=1}^{N}b_{ij}y_i^*=\begin{cases}cx^j, & j\leqslant m\\ 0, & i,j\geqslant m+1,\end{cases} \tag{30a}$$

$$\sum_{i=1}^{N}a_{ij}y_i^*=\begin{cases}0, & i,j\leqslant m\\ (a+c)y_j, & i,j\geqslant m+1.\end{cases} \tag{30b}$$

In order to obtain a unique solution for y_i^*, both matrices A and B must be nonsingular with matrix elements $(A)_{ij}=a_{ij}$ and $(B)_{ij}=b_{ij}$. Thus A is $(N-m)$ by $(N-m)$ and B is m by m. Furthermore, $a=-c$ so that the sum in (28b) is restricted to $i\leqslant m$. Consequently (30a) and (30b) yield the following solution for y_i^*:

$$y_i^* = \begin{cases} -a[(B^T)^{-1}]_{ij}x^j, & i,j \leqslant m \\ a^{-1}[(A^T)^{-1}]_{ij}y_j, & i,j \geqslant m+1. \end{cases} \tag{31}$$

By (28a) and (31) we finally obtain

$$\langle dx^*, dy^* \rangle = -a\left\{ \sum_{i=1}^{m} dx^i\, dy_i - a^{-2} \sum_{i=m+1}^{N} dx^i\, dy_i \right\}. \tag{32}$$

Hence $\langle dx^*, dy^* \rangle|_{\mathcal{L}^*}$ is a pseudo-Riemannian metric with signature $(m, N-m)$ if $a=-1$. To summarize, the following transformations

$$(x^*)^i = F^i(x,u) = \begin{cases} \sum_{j=1}^{m} b_{ij}y_j + \alpha^i, & i \leqslant m \\ \sum_{j=m+1}^{N} a_{ij}x^j + \alpha^i, & i \geqslant m+1, \end{cases} \tag{33a}$$

$$u^* = G(x,u,y) = -u + \sum_{i=1}^{m} x^i y_i + d, \tag{33b}$$

$$y_i^* = H_i(x,y) = \begin{cases} \sum_{j=1}^{m} [(B^T)^{-1}]_{ij}x^j, & i \leqslant m \\ -\sum_{j=m+1}^{N} [(A^T)^{-1}]_{ij}y_j, & i \geqslant m+1 \end{cases} \tag{33c}$$

preserve the contact structure in M and the pseudometric structure in $\mathcal{L}$. It is interesting to note that the Legendre involution

$$x^* = (y_1, \ldots, y_m, x^{m+1}, \ldots, x^N),$$

$$u^* = -u + \sum_{i=1}^{m} x^i y_i,$$

$$y^* = (x^1, \ldots, x^m, -y_{m+1}, \ldots, -y_N)$$

is a special example of (33a)–(33c).

V. CONCLUSION

In this paper we consider symmetry transformations that preserve the first law and the second law of thermodynamics. These symmetry transformations form a group of contact transformations on a contact manifold M, where the entropy surface (or energy surface) is a Legendre submanifold $\mathcal{L}$ of the contact manifold M. These contact transformations depend on $N+1$ arbitrary differentiable functions $F=(F^1,\ldots,F^N)$ and G [or $\xi=(\xi^1,\ldots,\xi^N)$ and η]. Under some specific conditions on F and G (ξ and η) we show that these contact transformations preserve the contact structure of M as well as the pseudometric structure of $\mathcal{L}$ defined by the second derivative matrix of the entropy function (or the energy function). Finally, as an illustration of our results, we consider three examples, the transformations between the entropy surface and the energy surface, the group of coordinate transformations by Salamon *et al.*, and the partial Legendre involutions.

Free energies based on generalized entropies and H-theorems for nonlinear Fokker–Planck equations

Masatoshi Shiino
Department of Applied Physics, Faculty of Science, Tokyo Institute of Technology, 2-12-1 Ohokayama Meguro-ku Tokyo, Japan

(Received 27 September 2000; accepted for publication 29 January 2001)

The relationship between H-theorems and free energies is studied on the basis of generalized entropies. Two kinds of nonlinear Fokker–Planck equations with different nonlinear diffusion terms that exhibit the power-law-type equilibrium distributions of Tsallis thermostatistics are investigated from the viewpoint of nonequilibrium free energies and stability analysis of their solutions. Using the generalized entropies Liapunov functions are constructed to show H-theorems, which ensure uniqueness of and convergence to the equilibrium distributions of the nonlinear Fokker–Planck equations. © *2001 American Institute of Physics.*

I. INTRODUCTION

Recently Tsallis proposed use of a nonextensive entropy that is obtained by generalizing the Boltzmann entropy and developed generalized thermostatistics.[1–3] Tsallis' thermostatistics, which is characterized by power-law-type equilibrium probability distributions[1–3] unlike Boltzmann statistics with exponential type distributions and also is closely related with fractal-inspired statistics based on Renyi entropy,[4] has aroused great interest in various research areas because of its potential applicability in a variety of physical systems. Among them are systems exhibiting Levy-type anomalous diffusion[5] and self-gravitating systems.[6] Tsallis' equilibrium probability distributions are obtained by maximizing, with respect to probabilities $\{p_i\}$, the generalized entropies S_q with a real parameter q representing nonextensivity:[1–3,7]

$$S_q=\frac{k(1-\Sigma_i p_i^q)}{q-1} \tag{1}$$

(k stands for a constant corresponding to the Boltzmann constant k_B in the limit $q\to 1$) under the constraints of normalization of a probability distribution $\Sigma_{i=1} p_i=1$ and conservation of internal energy.[1–3]

According to averaging procedures for the energy constraint, Tsallis' thermostatistics has been so far classified into three versions or choices.[3]

In the so-called first choice,[1] the energy constraint takes the standard form

$$\sum_{i=1} p_i \epsilon_i=\langle \epsilon\rangle^{(1)} \tag{2}$$

with ϵ_i representing the energy of ith state of a system and $\langle \epsilon\rangle^{(1)}$ a given constant. Solving the variational problem for the well known MaxEnt principle $\delta(S_q-\lambda_1\Sigma_{i=1} p_i-\lambda_2\Sigma_{i=1} p_i\epsilon_i)=0$ (λ_1 and λ_2 represent Lagrange multipliers) yields the equilibrium distribution of the form

$$p_i^{(1)}=\frac{1}{Z_q^{(1)}}[1-\beta^{(1)}(q-1)\epsilon_i]^{1/(q-1)}, \tag{3}$$

where $Z_q^{(1)}$ stands for the normalization constant (i.e., partition function) and $\beta^{(1)}$ the Lagrange multiplier related constant.

In the second choice,[1,2] the energy constraint is given by

$$\sum_{i=1} p_i^q \epsilon_i = \langle \epsilon \rangle^{(2)} \tag{4}$$

and the corresponding MaxEnt principle yields the equilibrium distribution

$$p_i^{(2)} = \frac{1}{Z_q^{(2)}} [1 - \beta^{(2)}(1-q)\epsilon_i]^{1/(1-q)}, \tag{5}$$

where $\beta^{(2)}$ represents a constant that is proportional to the Lagrange multiplier associated to the energy constraint (4) and $Z_q^{(2)}$ normalization constant.

In the third choice,[3] one adopts

$$\frac{\Sigma_{i=1} p_i^q \epsilon_i}{\Sigma_{i=1} p_i^q} = \langle \epsilon \rangle_q \tag{6}$$

as an energy constraint to have the equilibrium distribution

$$p_i = \frac{1}{Z_q} \left[1 - \frac{\beta(1-q)}{C(q)} (\epsilon_i - \langle \epsilon \rangle_q) \right]^{1/(1-q)} \tag{7}$$

with

$$C(q) = \sum_{i=1} p_i^q, \tag{8}$$

$$Z_q = \sum_{i=1} \left[1 - \frac{\beta(1-q)}{C(q)} (\epsilon_i - \langle \epsilon \rangle_q) \right]^{1/(1-q)}, \tag{9}$$

$$\langle \epsilon \rangle_q = \sum_{i=1} \frac{p_i^q}{C(q)} \epsilon_i, \tag{10}$$

where β represents a constant that is proportional to the Lagrange multiplier associated to the energy constraint (6) and Z_q normalization constant.

Most of the papers published so far have concerned formal arguments on equilibrium properties of the novel statistics. The nature and physical implications of the nonextensive generalized entropies of Tsallis (hereafter referred to as Tsallis entropy) are still far less understood. The study of dynamical aspects of the Tsallis entropies is considered to be useful to get deeper insights into its physical meaning.

The Tsallis entropies themselves are known to play a Liapunov function of a certain type of nonlinear diffusion equations[8] that exhibit super or subdiffusion phenomena.[9–12] Recently a nonlinear Fokker–Planck equation (NFPE) that is obtained by adding a linear streaming term based on the introduction of a quadratic potential to the above mentioned nonlinear diffusion equations has been proposed by Plastino and Plastino[13] to investigate dynamical behaviors of the temporal solutions. They showed that the equilibrium probability distributions of Tsallis can be given as a fixed-point-type solution of the nonlinear Fokker–Planck equation and that a special version of H-theorem holds with the entropy chosen as an H-functional: the Tsallis entropy itself becomes a Liapunov functional of the NFPE. A microscopic derivation of the NFPE was studied by Borland[14] and also by Kaniadakis and Lapenta,[15] who investigated the relationships between the

linear Fokker–Planck equation, the NFPE with a quadratic potential, and the nonlinear porous media equation exhibiting the same equilibrium probability distribution of Tsallis' thermostatistics to show their equivalence.

An H-theorem is well known to be quite useful to ensure convergence to equilibrium probability distribution(s) of any temporal solution of a master equation.[16–23] The H-function (functional) associated with an H-theorem usually takes the form of difference of nonequilibrium free energies between two states of a system[23] as in the case of the Kullback Leibler divergence[24] or relative entropy for standard linear Markovian master equations.

Previously I proposed, within the framework of Markovian stochastic processes, generalized relative entropies,[23] which are a natural extension of the relative entropy of Boltzmann statistics, together with generalized nonequilibrium free energies based on the Tsallis entropies. The generalized relative entropies $H_q(\{p_i\},\{g_i\})$ defined as a function of two arbitrary probabilities $\{p_i\}$ and $\{g_i\}$ $(p_i>0, g_i>0)$, which were also proposed independently by Tsallis,[25] are given by

$$H_q(\{p_i\},\{g_i\})=\frac{1}{(q-1)}\left[\sum_{i=1} p_i\left(\frac{p_i}{g_i}\right)^{q-1}-1\right]. \tag{11}$$

I showed that an H-theorem holds for an arbitrary linear master equation, when the generalized relative entropies are chosen as its H-function (see also Ref. 26):

$$\begin{aligned}&\frac{d}{dt}H_q(\{p_i(t)\},\{g_i(t)\})\leq 0 \quad \text{for} \quad q>0,\ q\neq 1\\ &\frac{d}{dt}H_q(\{p_i(t)\},\{g_i(t)\})\geq 0 \quad \text{for} \quad q<0,\end{aligned} \tag{12}$$

where the two probabilities $\{p_i(t)\}$ and $\{g_i(t)\}$ are assumed to obey a given linear master equation of a Markovian dynamics.

The generalized nonequilibrium free energies that were studied in Ref. 23 in connection with the above mentioned generalized relative entropies, however, have a drawback that they do not physically make sense, since the construction of them is based on the second choice of Tsallis statistics, where the average of unity differs from unity.[2,3] I also note here that in the generalized relative entropy (11) as an H-function of the H-theorem of Ref. 23, the equilibrium probability distribution (when dealing with the case of $\{g_i\}=\{g_i^{\rm eq}\}$) exhibited by a given linear master equation need not be the Tsallis distribution. Although such an H-theorem with an H-function that makes sense for an arbitrarily given linear master equation will be useful in some engineering problems where the generalized relative entropies, if chosen as a target function of a certain computational task, may improve efficiencies of computations involved, it will not be helpful for understanding underlying concepts or physical meaning of the Tsallis entropies as well as Tsallis statistics.

I would like to be concerned with finding free energies appropriately defined based on the Tsallis entropies that play the role of a Liapunov function exclusively for such a master equation as exhibiting equilibrium probability distributions of Tsallis' thermostatistics (3), (5), or (7). I consider the NFPE of Plastino and Plastino[13] to be a nice candidate for dealing with dynamical behaviors of its solution in terms of an H-theorem. An example of free energy as a Liapunov functional of a nonlinear master equation was studied previously by the author[27] for a different type of NFPE, which exhibits mean field-type phase transitions.[27,28]

The aims of this article are twofold. First, I want to show that NFPE studied in Ref. 13, which exhibits the Tsallis distribution of the first choice as a fixed point solution, has a Liapunov functional taking the form of free energy involving the Tsallis entropies and an H-theorem holds. Second, I want to extend the above-mentioned H-theorem so as to adapt to the case with the third choice of Tsallis statistics,[3] where the escort probability[3,29] manifests itself and the generalized entropies expressed in terms of the escort probability take a modified form.

In the following section I define a free energy based on the Tsallis entropy for the system described by the NFPE of Ref. 13 to show that the free energy functional is bounded from below and it decreases monotonically with time (H-theorem), provided that $0<q<1$ with the natural boundary condition imposed. In Sec. III, I propose another kind of NFPE that has a fixed-point-type solution associated with the Tsallis equilibrium distribution of the third choice and construct a free energy using a modified Tsallis entropy that is expressed in terms of the escort probability. With this free energy functional being chosen as a Liapunov functional I show an H-theorem to hold, provided that $0<1/q<1$ with the natural boundary condition imposed. A brief summary and discussion is given in Sec. IV. A preliminary result of the present work was reported in the workshop proceedings of the 5th International Workshop on Similarity and Diversity.

II. H-THEOREM FOR A NONLINEAR FOKKER-PLANCK EQUATION AND THE GENERALIZED ENTROPY

The nonlinear Fokker-Planck equation (NFPE) we deal with in this section reads

$$\frac{\partial p}{\partial t}=-\frac{\partial}{\partial x}(A(x)p)+D\frac{\partial^2}{\partial x^2}p^q, \tag{13}$$

where q is a real number, D a positive constant, and $A(x)$ an arbitrary function. This equation was studied previously for the temporal behavior of its time dependent solution $p(t,x)$ (Refs. 13, 30, and 31) and for a microscopic derivation of the NFPE itself.[14,15] Introducing the probability current j,

$$j=A(x)p-D\frac{\partial}{\partial x}p^q, \tag{14}$$

one can transform the NFPE into the equation describing the conservation law of probability:

$$\frac{\partial p}{\partial t}+\frac{\partial j}{\partial x}=0. \tag{15}$$

Indeed, with the natural boundary condition of the present system,

$$p(t,\pm\infty)=0, \quad \frac{\partial p^q}{\partial x}(t,\pm\infty)=0, \tag{16}$$

it follows

$$\frac{d}{dt}\int_{-\infty}^{\infty}p\,dx=j(t,-\infty)-j(t,\infty)=0. \tag{17}$$

Since $\partial p/\partial t=0$ implies $j=0$, the equilibrium distribution $P_{\mathrm{eq}}(x)$ satisfies

$$A(x)=qDp^{q-2}\frac{\partial p}{\partial x}. \tag{18}$$

Integrating this equation yields

$$p^{q-1}=\frac{-(q-1)\phi(x)}{Dq}+(Dq\beta)^{-1} \tag{19}$$

with

$$\phi(x)=-\int^{x}A(x)dx, \tag{20}$$

where the integration constant is set to be $(Dq\beta)^{-1}$.

When $\phi(x)\to\infty$ as $|x|\to\infty$, Eq. (19) implies $0<q<1$, because $P_{\rm eq}^{q-1}>0$. Then it follows that $P_{\rm eq}\to 0(|x|\to\infty)$. Assuming that $0<q<1$ and $\phi(x)\approx|x|^m$ with $m>0(|x|\to\infty)$, one also has $\partial P_{\rm eq}^q/\partial x\approx|x|^{mq/(q-1)-1}\to 0(|x|\to\infty)$. In what follows we deal with the relevant case with $0<q<1$, where the natural boundary condition (16) makes sense.

We now see that the equilibrium distribution takes the form that appears in Tsallis statistics as a result of optimizing the generalized entropy under the constraints called the first choice:[1,13]

$$P_{\rm eq}(x)=[(Dq\beta)^{-1}(1-\beta(q-1)\phi(x))]^{1/(q-1)}, \tag{21}$$

where β is determined by normalization of $P_{\rm eq}(x)$. We note that β uniquely exists with $\beta>0$ when the potential is bounded from below: $\phi(x)>^{\exists}d$. Defining the partition function $Z^{(1)}$ as

$$Z^{(1)}=\int_{-\infty}^{\infty}(1-\beta(q-1)\phi(x))^{1/(q-1)}dx, \tag{22}$$

one has

$$\beta=\frac{Z^{(1)q-1}}{Dq} \tag{23}$$

with the above equilibrium distribution being rewritten as

$$P_{\rm eq}(x)=\frac{1}{Z^{(1)}}\left[1-\frac{Z^{(1)q-1}(q-1)\phi(x)}{Dq}\right]^{1/(q-1)}. \tag{24}$$

We proceed to define a Liapunov functional taking the form of a free energy based on Tsallis entropy as

$$F\equiv U-\frac{D}{k}S \tag{25}$$

with

$$U\equiv\int\phi p\,dx,\quad S\equiv\frac{k}{q-1}\left[1-\int p^q dx\right], \tag{26}$$

where integrability for each quantity is assumed. When $P=P_{\rm eq}$ and $\phi(x)\approx|x|^m$ (for large $|x|$), the condition of integrability becomes $1/(m+1)<q<1$.

A. Boundedness from below

The Liapunov functional F satisfies the following inequality:

$$F(p(\cdot))\geqslant F(P_{\rm eq}(\cdot)),\quad 0<q<1. \tag{27}$$

Proof: First we note that $\phi(x)$ can be expressed in terms of $P_{\rm eq}(x)$ as

$$\phi(x)=\frac{Dq\beta P_{\rm eq}^{q-1}-1}{(1-q)\beta}, \tag{28}$$

which follows from Eq. (21). Then F is rewritten as

$$F(p(\cdot))=\int\phi p\,dx-\frac{D}{q-1}\left[1-\int p^q dx\right]=\frac{D}{q-1}\int(p^q-qpP_{\rm eq}^{q-1})dx+\frac{1}{q-1}\left(\frac{1}{\beta}-D\right) \tag{29}$$

with

$$F(P_{\rm eq}(\cdot))=-D\int P_{\rm eq}^{q}dx+\frac{1}{q-1}\left(\frac{1}{\beta}-D\right). \tag{30}$$

Then one has

$$F(p(\cdot))-F(P_{\rm eq}(\cdot))=\frac{D}{q-1}\int (p^{q}-qpP_{\rm eq}^{q-1}+(q-1)P_{\rm eq}^{q})dx. \tag{31}$$

Since

$$\begin{aligned} P^{q}-qpP_{\rm eq}^{q-1}+(q-1)P_{\rm eq}^{q}&=P_{\rm eq}^{q}(y^{q}-qy+q-1)\geqslant 0, \quad q>1,\ q<0,\\ &\leqslant 0, \quad 0<q<1, \end{aligned} \tag{32}$$

with $y\equiv p/P_{\rm eq}$, it follows that for $0<q<1$ one has $F(p(\cdot))\geqslant F(P_{\rm eq}(\cdot))$.

B. H-theorem

An H-theorem with the Liapunov functional (i.e., H-functional) defined earlier holds for $0<q<1$:

$$\frac{dF}{dt}\leqslant 0. \tag{33}$$

Proof: Differentiating F with respect to t one obtains

$$\begin{aligned} \frac{dF}{dt}&=\int\left(\phi+\frac{Dq}{q-1}p^{q-1}\right)\left[-\frac{\partial}{\partial x}(-\phi_{x}(x)p)+D\frac{\partial^{2}}{\partial x^{2}}p^{q}\right]dx\\ &=-\int\phi_{x}^{2}pdx+2D\int\phi_{xx}p^{q}dx-D^{2}q^{2}\int p^{2q-3}\left(\frac{\partial p}{\partial x}\right)^{2}dx, \end{aligned} \tag{34}$$

where integration by parts was used. We assume the existence of each integral on the rhs of Eq. (34):

$$\int p^{2q-3}\left(\frac{\partial p}{\partial x}\right)^{2}dx<\infty, \qquad \int pP_{\rm eq}^{2q-4}\left(\frac{\partial P_{\rm eq}}{\partial x}\right)^{2}dx<\infty. \tag{35}$$

Using (28), dF/dt is further rewritten as

$$\frac{dF}{dt}=\int\left[B_{1}\left(\frac{\partial p}{\partial x}\right)^{2}+B_{2}\frac{\partial p}{\partial x}\frac{\partial P_{\rm eq}}{\partial x}+B_{3}\left(\frac{\partial P_{\rm eq}}{\partial x}\right)^{2}\right]dx, \tag{36}$$

where

$$\begin{aligned} B_{1}&=-D^{2}q^{2}p^{2q-3}, \quad B_{2}=2D^{2}q^{2}p^{q-1}P_{\rm eq}^{q-2},\\ B_{3}&=-D^{2}q^{2}pP_{\rm eq}^{2q-4}. \end{aligned} \tag{37}$$

Then it follows that

$$\frac{dF}{dt}=-D^{2}q^{2}\int p\left(p^{q-2}\frac{\partial p}{\partial x}-P_{\rm eq}^{q-2}\frac{\partial P_{\rm eq}}{\partial x}\right)^{2}dx=-\frac{D^{2}q^{2}}{(q-1)^{2}}\int p\left[\frac{\partial}{\partial x}(p^{q-1}-P_{\rm eq}^{q-1})\right]^{2}dx\leqslant 0. \tag{38}$$

We see that equality is implied by $p^{q-1}-P_{\mathrm{eq}}^{q-1}=c(\mathrm{const})$. It can easily be shown that $dF/dt=0$ is attained, if and only if $p=P_{\mathrm{eq}}(c=0)$: noting that, with $\tilde{c}$ representing some constant,

$$p^{q-1}=P_{\mathrm{eq}}^{q-1}+c=(Dq\beta)^{-1}(\tilde{c}-\beta(q-1)\phi(x)) \tag{39}$$

and $\beta>0$, $q<1$, and $\phi(x)>^{\exists}d(\mathrm{const})$, we see that $p(x;\tilde{c})$ is a monotonically decreasing function of $\tilde{c}$. With the normalization condition $\int p(x;\tilde{c})dx=1$, it follows $p=P_{\mathrm{eq}}$. When $0<q<1$, inequality (33) together with (27) implies that the equilibrium distribution (21) is the unique equilibrium solution of the NFPE (13) and that the free energy (25) continues to decrease until it approaches $F(P_{\mathrm{eq}}(\cdot))$.

III. ANOTHER H-THEOREM BASED ON THE MODIFIED GENERALIZED ENTROPIES

In this section I propose another kind of NFPE to study an H-theorem based on the modified generalized entropies that arise within the framework of Tsallis statistics of the third choice.

A. Escort probability and modified generalized entropy in Tsallis statistics of third choice

Since it follows from the equilibrium probability distribution in Tsallis statistics of the third choice (7) that

$$\sum_{i=1}\frac{p_i^q}{C(q)}p_i^{1-q}Z_q^{1-q}=\sum_{i=1}\frac{p_i^q}{C(q)}\left[1-\frac{\beta(1-q)}{C(q)}(\epsilon_i-\langle\epsilon\rangle_q)\right]=1, \tag{40}$$

one has

$$C(q)=Z_q^{1-q}. \tag{41}$$

We note that the β used in this section should be independent of the β used in Sec. II. Then the equilibrium distribution (7) can be rewritten as

$$p_i=C(q)^{1/(q-1)}\left[1-\frac{\beta(1-q)}{C(q)}(\epsilon_i-\langle\epsilon\rangle_q)\right]^{1/(1-q)}, \tag{42}$$

where the parameters $C(q)$ and $\langle\epsilon\rangle_q$ are determined by (8) and (10).

In general, the escort probability[3,29] is defined as

$$\tilde{p}_i=\frac{p_i^q}{C(q)}. \tag{43}$$

Then the equilibrium distribution (42) can be rewritten as

$$\tilde{p}_i=C(q)^{1/(q-1)}\left[1-\frac{\beta(1-q)}{C(q)}(\epsilon_i-\langle\epsilon\rangle_q)\right]^{q/(1-q)}. \tag{44}$$

Introducing

$$Q=\frac{1}{q} \tag{45}$$

and noting

$$C(q)=\sum_{i=1}p_i^q=\sum_{i=1}\left(\frac{\tilde{p}_i^{1/q}}{\Sigma_{i=1}\tilde{p}_i^{1/q}}\right)^q=\frac{1}{(\Sigma_{i=1}\tilde{p}_i^{1/q})^q}\sum_{i=1}\tilde{p}_i=\left(\sum_{i=1}\tilde{p}_i^{1/q}\right)^{-q}, \tag{46}$$

we define

$$\tilde{C}(Q)=\left(\sum_{i=1}\tilde{p}_i^{Q}\right)^{-1/Q}, \tag{47}$$

to have

$$\tilde{C}(Q)=C(q). \tag{48}$$

Then the escort probability (43) can be rewritten as

$$\tilde{p}_i=\tilde{C}(Q)^{Q/(1-Q)}\left[1-\frac{\beta(Q-1)}{\tilde{C}(Q)Q}(\epsilon_i-\langle\epsilon\rangle)\right]^{1/(Q-1)} \tag{49}$$

with $\langle\epsilon\rangle=\Sigma_{i=1}\tilde{p}_i\epsilon_i$. The introduction of Q (45) together with considering the escort probability (49) make the theoretical treatment presented below quite smart.

Note that Tsallis entropy S_q can be rewritten in terms of $\{\tilde{p}_i\}$ as

$$S_q=\frac{1-\Sigma_i p_i^q}{q-1}=\frac{1-C(q)}{q-1}=\frac{1-\tilde{C}(Q)}{q-1}=\frac{1-(\Sigma_{i=1}\tilde{p}_i^{Q})^{-1/Q}}{(1/Q)-1}=\tilde{S}_Q, \tag{50}$$

where we have defined the transformed entropy $\tilde{S}_Q$ that takes a modified form of generalized entropy as a function of $\{\tilde{p}_i\}$.

B. Nonlinear Fokker–Planck equation with nonlocal diffusion coefficient

We propose a nonlinear Fokker–Planck equation that will turn out to be closely related to Tsallis statistics of the third choice:[3]

$$\frac{\partial p}{\partial t}=-\frac{\partial}{\partial x}(A(x)p)+\frac{1}{\beta}\left(\int p^Q\,dx\right)^{-(Q+1)/Q}\frac{\partial^2}{\partial x^2}p^Q, \tag{51}$$

where β is a positive constant and the coefficient of the diffusion term is a time varying nonlocal quantity instead of a constant D of the NFPE of Sec. II. Introducing the probability current j,

$$j=A(x)p-D_p(Q)\frac{\partial}{\partial x}p^Q \tag{52}$$

with

$$D_p(Q)=\frac{1}{\beta}\tilde{C}(Q)^{Q+1}, \tag{53}$$

$$\tilde{C}(Q)=\left(\int p^Q dx\right)^{-1/Q}, \tag{54}$$

one can transform the NFPE (51) into the equation describing the conservation law of probability:

$$\frac{\partial p}{\partial t}+\frac{\partial j}{\partial x}=0,$$

which implies, as in the previous section, $(d/dt)\int_{-\infty}^{\infty}p\,dx=j(t,-\infty)-j(t,\infty)=0$ when the natural boundary condition $p(t,\pm\infty)=0$, $(\partial p^Q/\partial x)(t,\pm\infty)=0$ is imposed.

Since $\partial p/\partial t=0$ implies $j=0$, one has

$$A(x)=QD_{p_{\rm eq}}(Q)P_{\rm eq}^{Q-2}\frac{\partial P_{\rm eq}}{\partial x}. \tag{55}$$

Integrating this equation yields

$$P_{\rm eq}^{Q-1}=\frac{-(Q-1)(\phi(x)-\langle\phi(x)\rangle)}{D_{p_{\rm eq}}(Q)Q}+\theta \tag{56}$$

with $\phi(x)=-\int^x A(x)dx$,

$$\langle\phi(x)\rangle=\int \phi(x)p_{\rm eq}dx, \tag{57}$$

where the integration constant is set to be $(Q-1)\langle\phi(x)\rangle/D_{p_{\rm eq}}(Q)Q+\theta$.

The θ is a constant which will be identified later. Since it follows from Eq. (56) that

$$\int P_{\rm eq}^{Q}dx=\theta, \tag{58}$$

one has

$$\theta=\tilde{C}_0(Q)^{-Q} \tag{59}$$

with

$$\tilde{C}_0(Q)=\left(\int P_{\rm eq}^{Q}dx\right)^{-1/Q}. \tag{60}$$

We now see that the equilibrium distribution takes the form of the escort probability that appears in Tsallis statistics of the third choice Eq. (49):

$$P_{\rm eq}(x)=\tilde{C}_0(Q)^{-Q/(Q-1)}\left[1-\frac{\beta(Q-1)}{\tilde{C}_0(Q)Q}(\phi(x)-\langle\phi\rangle)\right]^{1/(Q-1)}, \tag{61}$$

where $\langle\phi(x)\rangle$ and $\tilde{C}_0(Q)$ are determined by Eq. (57) and normalization of $P_{\rm eq}(x)$. The existence of the equilibrium probability distribution $P_{\rm eq}(x)$ with the self-consistently determined $\langle\phi\rangle$ and $\tilde{C}_0$ can be confirmed in the course of our analysis. Defining the partition function $\tilde{Z}_Q$ as

$$\tilde{Z}_Q=\int_{-\infty}^{\infty}\left[1-\frac{\beta(Q-1)}{\tilde{C}_0(Q)Q}(\phi(x)-\langle\phi\rangle)\right]^{1/(Q-1)}dx, \tag{62}$$

one can rewrite the above equilibrium distribution as

$$P_{\rm eq}(x)=\frac{1}{\tilde{Z}_Q}\left[1-\frac{\tilde{Z}_Q^{Q-1}(Q-1)}{\tilde{C}_0(Q)^{Q+1}Q1/\beta}(\phi(x)-\langle\phi\rangle)\right]^{1(Q-1)}. \tag{63}$$

Note that as far as equilibrium distributions are concerned, $(1/\beta)\tilde{C}_0(Q)^{Q+1}$ corresponds to D of the NFPE (13). We then find that the above expression of the equilibrium distribution (63) takes a form similar to the Tsallis equilibrium distribution of the first choice (24) exhibited by the NFPE of Sec. II except for the appearance of $\langle\phi\rangle$.

C. Free energy and H-theorem

We define a Liapunov functional taking the form of a free energy based on the modified Tsalliis entropy (50) as

$$F \equiv U - \frac{1}{\beta}\tilde{S} \tag{64}$$

with

$$U \equiv \int \phi p dx, \quad \tilde{S} \equiv \frac{1}{1/Q-1}\left[1-\left(\int p^Q dx\right)^{-1/Q}\right]. \tag{65}$$

Assuming the existence of the equilibrium distribution $P_{\mathrm{eq}}(x)$ for the sake of simplicity, we show that the Liapunov functional F satisfies the following inequality:

$$F(p(\cdot)) \geqslant F(P_{\mathrm{eq}}(\cdot)) \quad (0<Q<1). \tag{66}$$

Proof: First we note that ϕ can be expressed in terms of P_{eq} as

$$\phi = \langle \phi \rangle + \frac{\tilde{C}_0(Q) Q (1-\tilde{C}_0(Q)^Q P_{\mathrm{eq}}^{Q-1})}{(Q-1)\beta}, \tag{67}$$

which follows from Eq. (56). Then $F(p(\cdot))$ is rewritten as

$$\begin{aligned} F(p(\cdot)) &= \int \phi p dx - \frac{1}{\beta(1/Q-1)}\left[1-\left(\int p^Q dx\right)^{-1/Q}\right] \\ &= \langle \phi \rangle - \frac{\tilde{C}_0(Q)^{Q+1} Q}{\beta(Q-1)} \int p P_{\mathrm{eq}}^{Q-1} dx - \frac{Q}{\beta(Q-1)}\left(\int p^Q dx\right)^{-1/Q} + \frac{Q(\tilde{C}_0(Q)+1)}{\beta(Q-1)} \end{aligned} \tag{68}$$

with

$$F(P_{\mathrm{eq}}(\cdot)) = \langle \phi \rangle + \frac{Q(1-\tilde{C}_0(Q))}{\beta(Q-1)}. \tag{69}$$

Then one has

$$F(p(\cdot)) - F(P_{\mathrm{eq}}(\cdot)) = \frac{Q}{\beta(Q-1)}\left[2\tilde{C}_0(Q) - \tilde{C}(Q) - \tilde{C}_0(Q)^{Q+1}\int p P_{\mathrm{eq}}^{Q-1} dx\right]. \tag{70}$$

Using a Hölder inequality one has

$$\left[\int (P_{\mathrm{eq}}^{(Q-1)/b} p^{1/b})^b dx\right]^{1/b}\left[\int (P_{\mathrm{eq}}^{Q/b'})^{b'} dx\right]^{1/b'} \geqslant \int p^{1/b} dx \tag{71}$$

with $b = 1/Q$, $b' = 1/(1-Q)$ $(1/b + 1/b' = 1)$.

Accordingly it follows that

$$\int P_{\mathrm{eq}}^{Q-1} p dx \left[\int P_{\mathrm{eq}}^Q dx\right]^{(1-Q)/Q} \geqslant \left(\int p^Q dx\right)^{1/Q}. \tag{72}$$

Substituting this into Eq. (70) one obtains inequality (66) implying that $F(p(\cdot))$ is bounded from below:

$$F(p(\cdot))-F(P_{\rm eq}(\cdot))\geqslant \frac{Q}{\beta(1-Q)}[-2\tilde{C}_0(Q)+\tilde{C}(Q)+\tilde{C}_0(Q)^2\tilde{C}(Q)^{-1}]$$
$$=\frac{Q}{\beta(1-Q)}(\tilde{C}_0(Q)-\tilde{C}(Q))^2\tilde{C}(Q)^{-1}\geqslant 0. \tag{73}$$

It is worth noting that the result that $F(p(\cdot))$ is bounded from below can be obtained without assuming the existence of the equilibrium probability distribution $P_{\rm eq}(x)$, which requires the self-consistent determining of $\langle\phi\rangle$ and $\tilde{C}_0$ in Eq. (61). In the above proof we have essentially used Eq. (67) to represent $\phi(x)$ in terms of a function that suffices to satisfy $\partial p/\partial t=0$ in Eq. (51) alone. Then also note that time independent terms in $F(p(\cdot))$ has no contribution to the boundedness of the $F(p(\cdot))$.

Assuming again the existence of the equilibrium distribution $P_{\rm eq}(x)$ for the sake of simplicity, we can show that an H-theorem with the H-functional given by the Liapunov functional (64) holds for $0<Q<1$:

H-Theorem:

$$\frac{dF}{dt}\leqslant 0. \tag{74}$$

Proof: Differentiating F with respect to t one obtains

$$\frac{dF}{dt}=\int\left(\phi-\frac{\tilde{C}(Q)^{Q+1}}{\beta(1/Q-1)}p^{Q-1}\right)\frac{\partial p}{\partial t}dx$$
$$=\int\left(\phi-\frac{\tilde{C}(Q)^{Q+1}}{\beta(1/Q-1)}p^{Q-1}\right)\left[-\frac{\partial}{\partial x}(-\phi_x(x)p)+\frac{1}{\beta}\tilde{C}(Q)^{Q+1}\frac{\partial^2}{\partial x^2}p^Q\right]dx$$
$$=-\int\phi_x^2 p\,dx-\frac{2}{\beta}Q\tilde{C}(Q)^{Q+1}\int\phi_x p^{Q-1}\frac{\partial p}{\partial x}dx-\frac{Q^2}{\beta^2}\tilde{C}(Q)^{2Q+2}\int p^{2Q-3}\left(\frac{\partial p}{\partial x}\right)^2 dx, \tag{75}$$

where integration by parts was used. Noting

$$\phi_x=-\frac{Q}{\beta}\tilde{C}_0(Q)^{Q+1}P_{\rm eq}^{Q-2}\frac{\partial p_{\rm eq}}{\partial x}, \tag{76}$$

dF/dt is further rewritten as

$$\frac{dF}{dt}=-\frac{Q^2}{\beta^2}\int p\left[\tilde{C}_0(Q)^{2(Q+1)}P_{\rm eq}^{2(Q-2)}\left(\frac{\partial P_{\rm eq}}{\partial x}\right)^2-2\tilde{C}_0(Q)^{Q+1}\tilde{C}(Q)^{Q+1}P_{\rm eq}^{Q-2}p^{Q-2}\frac{\partial p}{\partial x}\frac{\partial P_{\rm eq}}{\partial x}\right]dx$$
$$-\frac{Q^2}{\beta^2}\int p\tilde{C}(Q)^{2(Q+1)}p^{2(Q-2)}\left(\frac{\partial p}{\partial x}\right)^2 dx$$
$$=-\frac{Q^2}{\beta^2}\int p\left[\tilde{C}_0(Q)^{Q+1}P_{\rm eq}^{Q-2}\frac{\partial P_{\rm eq}}{\partial x}-\tilde{C}(Q)^{Q+1}p^{Q-2}\frac{\partial p}{\partial x}\right]^2 dx. \tag{77}$$

Then it follows that

$$\frac{dF}{dt}=-\frac{Q^2}{\beta^2(Q-1)^2}\int p\left[\frac{\partial}{\partial x}(\tilde{C}(Q)^{Q+1}p^{Q-1}-\tilde{C}_0(Q)^{Q+1}P_{\rm eq}^{Q-1})\right]^2 dx\leqslant 0. \tag{78}$$

We see that equality is implied by

$$\tilde{C}(Q)^{Q+1}p^{Q-1}-\tilde{C}_0(Q)^{Q+1}P_{\rm eq}^{Q-1}=c(\text{const}). \tag{79}$$

We can prove that $dF/dt=0$ is attained, if and only if $p=P_{\rm eq}$ $(c=0)$ as follows. Multiplying both hands of Eq. (79) by p and performing integration, one obtains

$$\tilde{C}(Q)-\tilde{C}_0(Q)^{Q+1}\int pP_{\rm eq}^{Q-1}dx=c. \tag{80}$$

Using inequality (72) one has

$$\int P_{\rm eq}^{Q-1}pdx\geqslant\left(\int p^Q dx\right)^{1/Q}\left[\int P_{\rm eq}^Q dx\right]^{-(1-Q)/Q}=\tilde{C}(Q)^{-1}\tilde{C}_0(Q)^{1-Q}. \tag{81}$$

Hence it follows from (80) and (81) that

$$c\tilde{C}(Q)\leqslant\tilde{C}(Q)^2-\tilde{C}_0(Q)^2. \tag{82}$$

On the other hand, one also obtains, by multiplying both hands of Eq. (79) by $P_{\rm eq}$ and by performing integration,

$$\tilde{C}(Q)^{Q+1}\int P_{\rm eq}p^{Q-1}dx-\tilde{C}_0(Q)=c. \tag{83}$$

Noting inequality similar to (72),

$$\int P_{\rm eq}p^{Q-1}dx\geqslant\tilde{C}_0(Q)^{-1}\tilde{C}(Q)^{1-Q}. \tag{84}$$

It follows from (83) that

$$c\tilde{C}_0(Q)\geqslant\tilde{C}(Q)^2-\tilde{C}_0(Q)^2. \tag{85}$$

Accordingly one has from (82) and (85)

$$c\tilde{C}_0(Q)\geqslant\tilde{C}(Q)^2-\tilde{C}_0(Q)^2\geqslant c\tilde{C}(Q). \tag{86}$$

Now we can see that assuming $c\neq 0$ leads to contradiction. Let $c>0$. One immediately obtains from the above inequality

$$\tilde{C}_0(Q)\geqslant\tilde{C}(Q)>0 \tag{87}$$

as well as

$$\tilde{C}(Q)^2-\tilde{C}_0(Q)^2>0 \tag{88}$$

which are in contradiction.

Assuming $c<0$ also leads to contradiction.

Accordingly one has

$$c=0, \tag{89}$$

which implies

$$p=\left[\frac{\tilde{C}_0(Q)}{\tilde{C}(Q)}\right]^{(Q+1)/(Q-1)}P_{\rm eq}. \tag{90}$$

Since both p and $P_{\rm eq}$ satisfy the normalization condition, it follows $p=P_{\rm eq}$. This concludes the proof of the H-theorem.

When $0<Q<1$, inequality (74) together with (66) implies that the equilibrium distribution (61) is the unique equilibrium solution of the NFPE (51), which is approached for long times from any initial condition, and that the free energy (64) continues to decrease until it approaches $F(P_{\rm eq}(\cdot))$.

We here note that inequality (78) together with the equality condition given by Eq. (79) would hold without the assumption for the existence of the equilibrium distribution $P_{\rm eq}(x)$ that satisfies the normalization condition: With regard to $P_{\rm eq}$ appearing in Eqs. (78) and (79) it suffices to use Eq. (56) or Eq. (76), which is obtained from the equilibrium condition $\partial p/\partial t=0$ of Eq. (51) alone. Given a function $P_{\rm eq}(x)$ satisfying Eq. (56), the equality condition (79) of the H-theorem (74) implies

$$p^{Q-1}=\frac{-(Q-1)\phi(x)}{(Q/\beta)\tilde{C}(Q)^{Q+1}}+\omega', \tag{91}$$

where ω' is some constant. Then, noting Eq. (56) the p given by (91) is seen to satisfy the equilibrium condition $\partial p/\partial t=0$ of Eq. (51). Since $\int p(t,x)dx=1$ holds for any $t>0$ for some initial condition $\int p(0,x)dx=1$, there must exist ω' such that the p given by Eq. (91) satisfy $\int p dx=1$. This implies the existence of the legitimate equilibrium distribution $P_{\rm eq}(x)$ given by Eq. (61) for the NFPE (51).

Finally, it is noted that whereas the correspondence between D and $(1/\beta)\tilde{C}_0(Q)^{Q+1}$ in the diffusion terms of the two NFPEs (13) and (51) under the equilibrium conditions turns out to hold with respect to the equilibrium distributions (24) and (63), it should not be the case dynamically. Comparing between the expressions of the nonequilibrium free energies (25) and (64), we see that $1/\beta$ in the NFPE (51) simply corresponds to D in the NFPE (13) putting aside the difference of the definitions of the entropies S and $\tilde{S}$.

IV. SUMMARY AND DISCUSSION

We have studied two different types of nonlinear master equations (13) and (51) taking the form of nonlinear Fokker–Planck equations exhibiting equilibrium distributions of Tsallis statistics respectively with the first and third choices. We have proven H-theorems by constructing Liapunov functions that take the form of free energy based on Tsallis entropies. The H-theorems in this case ensure uniqueness of as well as convergence to the equilibrium distribution. It is important to note that although the equilibrium distributions of Tsallis statistics of the third choice take a form with a self-reference style that must be determined in a self-consistent manner from Eqs. (7)–(10), no multiple distributions are possible with a single equilibrium distribution being uniquely determined for a given set of parameters q and β.

When defining the free energy, we incorporated the ordinarily used average of the internal energy exhibiting extensivity instead of q-averaged internal energy exhibiting nonextensivity, which was used in Tsallis statistics of the second choice[2,3] and was also incorporated to construct a free energy associated with the H-function (11) of the H-theorem (12) for a linear master equation.[23] It is worth noting that when the q-averaged internal energy is used, we can no longer prove H-theorems for our NFPEs.

In proving the H-theorems of the present systems I have assumed that the support of the equilibrium distribution extends to infinity for the sake of simplicity. It is straightforward to prove that our H-theorems also hold true in the case where the equilibrium distribution has a compact support and a boundary condition analogous to the natural boundary condition (16) is imposed. For instance, in the case of the NFPE (13) of Sec. II the restriction $0<q<1$ can be lifted and the H-theorem (33) together with inequality (27) can be extended to the case with $q>1$ where the equilibrium distribution (21) must be subjected to a high-energy cutoff [the Tsallis cutoff, i.e., $P_{\rm eq}(x)=0$ for x satisfying $1-\beta(q-1)\phi(x)<0$].

The present study reveals that understanding physical meaning of Tsallis entropies may be reduced to that of the nonlinear Fokker–Planck equations investigated. Our results have clarified the relationship between Tsallis' thermostatistics of the first and third choices from the view point of dynamical processes. The two choices of Tsallis' thermostatistics yield similar equilibrium distributions similar to each other, when the escort probabilities are considered instead of the original probabilities. The dynamics underlying the equilibrium distributions, however, are governed by different nonlinear evolution equations associated with different entropies. In this regard, it might well be understood that Tsallis statistics of the third choice follows from the modified form of the generalized entropy (50) rather than from using such an unfamiliar averaging procedure for the energy constraint as (6) for optimizing the original form of Tsallis entropy (1). Parameters D and $1/\beta$, characterizing, respectively, the equilibrium distributions of the first (24) and third (63) choices, are given a meaning within the dynamics level, that is, the constant coefficients of the nonlinear diffusion terms of the NFPEs. Furthermore, those parameters play the role of ''temperature'' in each expression of the free energies.

For more detailed knowledge about the physical meaning of Tsallis entropies, research of microscopic mechanisms underlying the appearance of the nonlinear diffusion terms of the NFPEs will be required, without introducing phenomenology.

A simple treatment of the sine-Gordon equation

Shi-Rong Chen[a] and Nian-Ning Huang
Department of Physics, Wuhan University, Wuhan 430072, People's Republic of China

(Received 2 February 2000; accepted for publication 4 October 2000)

To avoid difficulties due to the complexity of the Lax pair of the sine-Gordon equation, the orthogonality relations of the squared Jost solutions is derived simply using the $1+1$ dimensional Green's theorem. The direct perturbation theory for sine-Gordon in the laboratory reference is re-developed, correcting some numerical coefficients in published orthogonality relationships. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1329342]

I. INTRODUCTION

The pioneering work on direct theory for the perturbed sine-Gordon equation by McLaughlin and Scott[1] has deep meaning not only in physical applications but also in mathematical substance. It is the first example of the perturbed nonlinear equation of second derivative in time that is essentially different from that for the perturbed equations involving only first derivative in time. They transformed the linearized equation of second derivative in time to an equivalent equation just containing the first derivative in time. Then they treated the equation with the idea of the usual Green's function theory for the linear partial differential equations. Since the linearized equation is very complicated and its potential is often defined by some of its functional properties rather than given explicitly, development of the theory is very laborious.

At that time the perturbation theory based on the inverse scattering transform(IST) was generally accepted. In order to emphasize the special meaning of the direct perturbation theory, the authors[1] inclined to avoid using the results of the inverse scattering transform and developed the direct theory based on a particular method of variation with respect to the potential. However, avoiding results of IST is obviously unnecessary. A recent work[2,3] on direct perturbation theory for dark solitons do use the results of IST to construct a rigorous complete set of squared Jost solutions, overcoming the long frustrating difficulty caused by the nonvanishing boundary conditions.

In Ref. 1, although the authors inclined to avoid using results of IST, a set of squared Jost solutions was still given in the appendix in which we find one biorthogonality relationship contains an incorrect numerical coefficient because they can not be verified via explicit expressions of Jost solutions of the one-kink case. Since a complete set of solutions for the linearized equation is fundamental to the direct perturbation theory, it is reasonable to develop a direct theory for perturbed sine-Gordon equation along a similar procedure for the perturbed NLS equation,[2–4] that is, first, to construct a rigorous complete set of solutions for the linearized equation via results of the IST.

In this paper work all of these difficulties are overcome by using $1+1$ dimensional Green's theorem and the direct theory for the perturbed sine-Gordon equation is exactly developed. For simplicity and to emphasize essential points, we are restricted mainly to a single soliton (kink) case, however, almost all of the formulas can be extended to the multisoliton case.

II. THE PERTURBED EQUATION

For physical applications it is necessary to develop a direct approach to the perturbed sine-Gordon equation in the laboratory reference in which it takes the form

[a]Electronic mail: shrchen@mail.ccnu.edu.cn

$$\alpha_{xx}-\alpha_{tt}-\sin\alpha=\epsilon r[\alpha], \tag{1}$$

where x, t are the space–time, ϵ is a small parameter, and $r[\alpha]$ is a functional of α. When ϵ vanishes, (1) tends to the unperturbed sine-Gordon equation. Since (1) has a second-order derivative in t, the initial condition also is included $\alpha_t(x,0)$, in addition to $\alpha(x,0)$. For example, we assume

$$\alpha(x,0)=\theta(x,0), \quad \alpha_t(x,0)=\theta_t(x,0), \tag{2}$$

where $\theta(x,t)$ is usually a soliton solution of the unperturbed sine-Gordon equation.

Soliton solutions of the unperturbed sine-Gordon equation are easily found in the light-cone coordinates where its Lax pair takes a standard Zakharov–Shabat form. Soliton solutions in the laboratory reference can then be obtained by a simple coordinate transformation.[5] However, the initial condition (2) can not be expressed in the light-cone coordinates, hence the direct approach to the perturbed sine-Gordon was developed in the laboratory reference in the pioneering work of McLaughlin and Scott.[1]

Suppose

$$\alpha=\theta^a+\epsilon q, \tag{3}$$

where θ^a is the adiabatic solution in the usual sense[1,4,6–8] and ϵq is the remaining term of the order of ϵ. Substitution of it into (1) yields

$$\{\partial_{xx}-\partial_{tt}-\cos\theta\}q=R, \tag{4}$$

where the operator on the left hand side is called the linearized operator and

$$R=r[\theta]-s[\theta], \quad s[\theta]=\frac{1}{\epsilon}\{\theta_{xx}-\theta_{tt}-\sin\theta\}. \tag{5}$$

(4) is of the order of ϵ, the θ in the left hand side and in the term $r[\theta]$ is the exact soliton solution while θ in the term $s[\theta]$ is the adiabatic solution. The initial condition (2) turns to

$$q(x,0)=0, \quad q_t(x,0)=0. \tag{6}$$

To solve (4) with the initial condition (6) by the Green's function method, we must first find solutions of the homogeneous version of (4), i.e., (4) with a vanishing right hand side.

III. A SINGLE SOLITON CASE

To explain the essential points of the direct perturbation theory, we take the simplest case, i.e., a single soliton (kink) case as an example. The kink solution of the unperturbed sine-Gordon equation is known as[1,5]

$$\theta=4\arctan e^X, \tag{7}$$

where

$$X=-i[\kappa_1(x-x_1)+\lambda_1 t], \tag{8}$$

x_1 is a real constant

$$\kappa=\tfrac{1}{2}(\zeta-\zeta^{-1}), \quad \lambda=\tfrac{1}{2}(\zeta+\zeta^{-1}), \quad \lambda^2-\kappa^2=1, \tag{9}$$

ζ is a spectral parameter[2] and ζ_1 lies on the upper imaginary axis of the complex ζ-plane, $\zeta_1=i|\zeta_1|$. Substituting the expression of $\cos\theta=1-2\,\mathrm{sech}^2 X$ obtained from (8) into (4) we have

$$\{\partial_{xx}-\partial_{tt}-(1-2\,\mathrm{sech}^2 X)\}q=R. \tag{10}$$

To construct the Green's function theory for (10), we must find all eigenfunctions of the linearized operator with zero eigenvalue in advance. Suppose $\Psi(x,t,\zeta)$ is one of such solutions, then

$$\{\partial_{xx}-\partial_{tt}-(1-2\,\mathrm{sech}^2 X)\}\Psi(x,t,\zeta)=0. \tag{11}$$

Setting

$$\Psi(x,t,\zeta)=\theta(x,t,\zeta)e^{i(\kappa x+\lambda t)}, \tag{12}$$

where the form of the exponential is chosen to ensure the $1+1$ dimensional Lorentz invariance, (11) becomes

$$\{i2\lambda\partial_t-i2\kappa\partial_x+\partial_{tt}-\partial_{xx}-2\,\mathrm{sech}^2 X\}\theta(x,t,\zeta)=0, \tag{13}$$

here we have used (9). We may assume $\theta(x,t,\zeta)$ depends on t and x via X, then

$$\partial_{tt}-\partial_{xx}=-\partial_{XX},\quad i2\lambda\partial_t-i2\kappa\partial_x=(\zeta\zeta_0^{-1}+\zeta^{-1}\zeta_0)\partial_X. \tag{14}$$

Hence (13) becomes

$$\{\xi^2\partial_X+\xi L+\partial_X\}\theta=0, \tag{15}$$

where

$$\xi=\frac{\zeta}{\zeta_0},\quad L=\partial_{XX}+2(1-\tanh^2 X). \tag{16}$$

Expanding $\theta(X,\zeta)$ into a power series of ξ whose coefficients $\theta_n(X)$ are functions of X only, $\theta=\theta_0+\xi\theta_1+\xi^2\theta_2+\cdots$, then equating the coefficients of each power of ξ, from (15) we obtain recursion equations:

$$\theta_{0X}=0,\quad \theta_{1X}=L\theta_0,\quad \theta_{2X}=L\theta_1,\quad \theta_{3X}=L\theta_2-\theta_{1X},\ldots. \tag{17}$$

It is easy to solve (17) successively, we finally obtain an eigenfunction of (11)

$$\Psi(x,t,\zeta)=\frac{e^{i(\kappa x+\lambda t)}}{(\zeta-\overline{\zeta_1})^2}(\zeta^2-2\zeta\overline{\zeta_1}\tanh X+\overline{\zeta_1^2}), \tag{18}$$

where the constant factor $(\zeta-\overline{\zeta_1})^{-2}$ is introduced for later convenience. Similarly, another eigenfunction of (11) is

$$\Phi(x,t,\zeta)=\frac{e^{-i(\kappa x+\lambda t)}}{(\zeta-\overline{\zeta_1})^2}(\zeta^2+2\zeta\overline{\zeta_1}\tanh X+\overline{\zeta_1^2}). \tag{19}$$

$\Psi(x,t,\zeta)$ and $\Phi(x,t,\zeta)$ are analytic in the upper half plane, but have different asymptotic behaviors

$$\begin{aligned}&\Psi(x,t,\zeta)\to e^{i(\kappa x+\lambda t)},\\ &\Phi(x,t,\zeta)\to a(\zeta)^2 e^{-i(\kappa x+\lambda t)},\end{aligned}\quad \text{as } x\to\infty \tag{20}$$

and

$$\begin{aligned}\Psi(x,t,\zeta)&\to e^{i(\kappa x+\lambda t)},\\ \Phi(x,t,\zeta)&\to a(\zeta)^2 e^{-i(\kappa x+\lambda t)},\end{aligned}\quad \text{as } x\to-\infty, \tag{21}$$

where

$$a(\zeta)=\frac{\zeta-\zeta_1}{\zeta-\bar{\zeta}_1}. \tag{22}$$

Different asymptotic behaviors of $\Psi(x,t,\zeta)$ and $\Phi(x,t,\zeta)$ show the linear independence between them.

IV. GREEN'S THEOREM

The next step of development is to choose an adequate adjoint function for the eigenfunction of (11) and to define the corresponding inner product. We now derive a general integral relation by using the $1+1$ dimensional Green's theorem. Because both $\Psi(x,t,\zeta)$ and $\Phi(x,t,\zeta)$ are eigenfunctions of (11), we have

$$\begin{aligned}&i\partial_t\{\Phi(x,t,\zeta')\Psi(x,t,\zeta)_t-\Phi(x,t,\zeta')_t\Psi(x,t,\zeta)\}\\ &\quad=i\partial_x\{\Phi(x,t,\zeta')\Psi(x,t,\zeta)_x-\Phi(x,t,\zeta')_x\Psi(x,t,\zeta)\}.\end{aligned} \tag{23}$$

Integration upon each side with respect to t and x in a domain of Ω where x runs from $-\infty$ to ∞ and t from 0 to t, by Green's theorem,[9] we obtain

$$\begin{aligned}&i\int_{-\infty}^{\infty}dx\{\Phi(x,t,\zeta')\Psi(x,t,\zeta)_t-\Phi(x,t,\zeta')_t\Psi(x,t,\zeta)\}\Big|_{t=0}^{t=t}\\ &\quad=i\int_0^t dt\{\Phi(x,t,\zeta')\Psi(x,t,\zeta)_x-\Phi(x,t,\zeta')_x\Psi(x,t,\zeta)\}\Big|_{x=-\infty}^{x=\infty}.\end{aligned} \tag{24}$$

The integrand of the right hand side, $A(x,t,\zeta',\zeta)$, tends to

$$\begin{aligned}A(L,t,\zeta',\zeta)&=-a(\zeta')^2(\kappa'+\kappa)e^{-i(\kappa'-\kappa)L}e^{-i(\lambda'-\lambda)t},\\ A(-L,t,\zeta',\zeta)&=a(\zeta)^2(\kappa'+\kappa)e^{i(\kappa'-\kappa)L}e^{-i(\lambda'-\lambda)t},\end{aligned} \tag{25}$$

in the limit of $L\to\infty$. In (25), only the factors $e^{-i(\lambda'-\lambda)t}$ is dependent of t. The integration on the right hand side of (25) is equal to the integrand divided by $i(\lambda-\lambda')$, hence we obtain

$$i\int_{-\infty}^{\infty}dx\{\Phi(x,t,\zeta')\Psi(x,t,\zeta)_t-\Phi(x,t,\zeta')_t\Psi(x,t,\zeta)\}=\lim_{L\to\infty}\frac{1}{-i(\lambda'-\lambda)}B(L.t,\zeta',\zeta), \tag{26}$$

where

$$B(L,t,\zeta',\zeta)=A(L,t,\zeta',\zeta)-A(-L,t,\zeta',\zeta). \tag{27}$$

Noticing

$$\begin{aligned}\lambda-\lambda'&=\tfrac{1}{2}(\zeta-\zeta')(1-\zeta^{-1}\zeta'^{-1}),\\ \kappa-\kappa'&=\tfrac{1}{2}(\zeta-\zeta')(1+\zeta^{-1}\zeta'^{-1}),\end{aligned} \tag{28}$$

and ζ and ζ' should be considered as $\zeta+i0$ and $\zeta'+i0$, we have

$$\lim_{L\to\infty} P\frac{1}{-i(\lambda'-\lambda)}e^{-i(\kappa'-\kappa)L}=\frac{2}{(1-\zeta^{-2})}\pi\delta(\zeta-\zeta')=\frac{\zeta}{\kappa}\pi\delta(\zeta-\zeta'). \tag{29}$$

Finally, (26) becomes

$$i\int_{-\infty}^{\infty}dx\{\Phi(x,t,\zeta')\Psi(x,t,\zeta)_t-\Phi(x,t,\zeta')_t\Psi(x,t,\zeta)\}=-4\pi\zeta a(\zeta)^2\delta(\zeta-\zeta'). \tag{30}$$

V. THE LINEARIZED OPERATOR WITH THE FIRST DERIVATIVE IN *t*

Since (4) has a second-order derivative in t, in the direct approach it is necessary to transform it into an equivalent equation having first-order derivatives in t only.[1] (4) is obviously equivalent to

$$\begin{pmatrix} i\partial_t & -1 \\ \partial_{xx}-\cos\theta & i\partial_t \end{pmatrix}\begin{pmatrix} q \\ iq_t \end{pmatrix}=\begin{pmatrix} 0 \\ R \end{pmatrix}. \tag{31}$$

We can simply write it as

$$\{i\partial_t-\mathbf{L}\}\mathbf{q}=\mathbf{R}, \tag{32}$$

where

$$\mathbf{L}=-\begin{pmatrix} 0 & -1 \\ \partial_{xx}-(1-2\,\mathrm{sech}^2\,X) & 0 \end{pmatrix}, \tag{33}$$

$$\mathbf{q}=\begin{pmatrix} q \\ iq_t \end{pmatrix},\quad \mathbf{R}=\begin{pmatrix} 0 \\ R \end{pmatrix}. \tag{34}$$

Now we write (11) as

$$\{i\partial_t-\mathbf{L}\}\mathbf{\Psi}(x,t,\zeta)=\mathbf{0}, \tag{35}$$

where $\mathbf{0}=(0,0)^T$ and

$$\mathbf{\Psi}(x,t,\zeta)=\begin{pmatrix} \Psi(x,t,\zeta) \\ i\Psi(x,t,\zeta)_t \end{pmatrix}. \tag{36}$$

Taking (30) into account, we define the adjoint function for $\mathbf{\Psi}(x,t,\zeta)$ by

$$\mathbf{\Psi}(x,t,\zeta)^A=\mathbf{\Phi}(x,t,\zeta)^T(-i\sigma_2)=(-i\Phi(x,t,\zeta)_t\ \ \Phi(x,t,\zeta)), \tag{37}$$

and the inner product by

$$\langle\mathbf{\Psi}(t,\zeta')|\mathbf{\Psi}(t,\zeta)\rangle=\int_{-\infty}^{\infty}dx\mathbf{\Psi}(x,t,\zeta')^A\mathbf{\Psi}(x,t,\zeta). \tag{38}$$

(26) and (30) turn to

$$\langle\mathbf{\Psi}(t,\zeta')|\mathbf{\Psi}(t,\zeta)\rangle=\lim_{L\to\infty}\frac{1}{-i(\lambda'-\lambda)}B(L,t,\zeta',\zeta)=-4\pi\zeta a(\zeta)^2\delta(\zeta-\zeta'). \tag{39}$$

Noticing time-independence of the right hand side of (39), it is convenient to introduce

$$\Psi(x,\zeta)=e^{-i\lambda t}\Psi(x,t,\zeta),\quad \Psi'(x,\zeta)=e^{-i\lambda t}i\Psi(x,t,\zeta)_t, \tag{40}$$

namely

$$\Psi(x,\zeta)=\frac{e^{i\kappa x}}{(\zeta-\bar{\zeta}_1)^2}(\zeta^2-2\zeta\zeta_1\tanh X+\zeta_1^2), \tag{41}$$

and

$$\Psi'(x,\zeta)=-\lambda\Psi(x,\zeta)+\lambda_1\frac{e^{i\kappa x}}{(\zeta-\bar{\zeta}_1)^2}2\zeta\zeta_1(1-\tanh^2 X). \tag{42}$$

From (35) we obtain

$$\{i\partial_t-\mathbf{L}\}\mathbf{\Psi}(x,\zeta)=\lambda\mathbf{\Psi}(x,\zeta), \tag{43}$$

where

$$\mathbf{\Psi}(x,\zeta)=\begin{pmatrix}\Psi(x,\zeta)\\ \Psi'(x,\zeta)\end{pmatrix}. \tag{44}$$

Since the right hand side of (39) is independent of t, and involves $\delta(\zeta-\zeta')$, we define the inner product of $\mathbf{\Psi}(x,\zeta)$ with its adjoint such that

$$\langle\mathbf{\Psi}(\zeta')|\mathbf{\Psi}(\zeta)\rangle=\int_{-\infty}^{\infty}dx\mathbf{\Psi}(x,\zeta')^A\mathbf{\Psi}(x,\zeta), \tag{45}$$

where the adjoint is

$$\mathbf{\Psi}(x,\zeta)^A=\mathbf{\Phi}(x,\zeta)^T(-i\sigma_2)=(-\Phi'(x,\zeta),\ \Phi(x,\zeta)). \tag{46}$$

We then obtain

$$\langle\mathbf{\Psi}(\zeta')|\mathbf{\Psi}(\zeta)\rangle=\lim_{L\to\infty}\frac{1}{-i(\lambda'-\lambda)}B(L,0,\zeta',\zeta)=-4\pi\zeta a(\zeta)^2\delta(\zeta-\zeta'). \tag{47}$$

For $\zeta=\zeta_1$, from (43) we have

$$\{i\partial_t-\mathbf{L}\}\mathbf{\Psi}(x,\zeta_1)=\lambda_1\mathbf{\Psi}(x,\zeta_1) \tag{48}$$

and

$$\{i\partial_t-\mathbf{L}\}\dot{\mathbf{\Psi}}(x,\zeta_1)=\lambda_1\dot{\mathbf{\Psi}}(x,\zeta_1)+\zeta_1^{-1}\kappa_1\mathbf{\Psi}(x,\lambda_1), \tag{49}$$

where

$$\dot{\Psi}(x,\zeta_1)=\frac{d}{d\zeta}\Psi(x,\zeta)|_{\zeta=\zeta_1}. \tag{50}$$

But for $\zeta=\zeta_1$, which is a double zero of $a(\zeta)^2$, we have

$$\langle\mathbf{\Psi}(\zeta_1)|\mathbf{\Psi}(\zeta_1)\rangle=0. \tag{51}$$

From (47) we have

$$-i(\lambda'-\lambda)\langle\mathbf{\Psi}(\zeta')|\mathbf{\Psi}(\zeta)\rangle=B(\infty,0,\zeta',\zeta). \tag{52}$$

Applying an operator $d/d\zeta^2$ to (52), then setting $\zeta=\zeta'=\zeta_1$, we obtain

$$\langle \mathbf{\Psi}(\zeta_1)|\dot{\mathbf{\Psi}}(\zeta_1)\rangle = -i2\zeta_1\dot{a}(\zeta_1)^2. \tag{53}$$

Applying an operator $\{d^3/d\zeta^3+3(d/d\zeta' d^2/d\zeta^2\}$ to (52), setting $\zeta=\zeta'=\zeta_1$, we obtain

$$\langle \dot{\mathbf{\Psi}}(\zeta_1)|\dot{\mathbf{\Psi}}(\zeta_1)\rangle = -i2\zeta_1\dot{a}(\zeta_1)\ddot{a}(\zeta_1) - i2\dot{a}(\zeta_1)^2. \tag{54}$$

(47), (53), and (54) are desired orthogonality relations. These agree with the orthogonality relations published in Ref. 1 (after proper normalization of the eigenfunctions), except for Eq. (54) for which an incorrect numerical coefficient appears in Ref. 1.

VI. THE EXPANSION OF THE UNITY

Assume $\mathbf{q}(x)$ in (32) be expanded as

$$\mathbf{q}(x) = \frac{1}{2\pi}\int_{-\infty}^{\infty} d\zeta f(\zeta)\mathbf{\Psi}(x,\zeta) + f_1\mathbf{\Psi}(x,\zeta_1) + g_1\dot{\mathbf{\Psi}}(x,\zeta_1). \tag{55}$$

By using the orthogonality relations, we obtain

$$f(\zeta) = -\frac{1}{2\zeta a(\zeta)^2}\langle \mathbf{\Psi}(\zeta)|\mathbf{f}\rangle, \quad g_1 = i\frac{1}{2\zeta_1\dot{a}(\zeta_1)^2}\langle \mathbf{\Psi}(\zeta_1)|\mathbf{f}\rangle, \tag{56}$$

and

$$f_1 = i\frac{1}{2\zeta_1\dot{a}(\zeta_1)^2}\langle \dot{\mathbf{\Psi}}(\zeta_1)|\mathbf{f}\rangle - i\frac{1}{2\zeta_1\dot{a}(\zeta_1)^2}\left\{\frac{1}{\zeta_1}+\frac{\ddot{a}(\zeta_1)}{\dot{a}(\zeta_1)}\right\}\langle \mathbf{\Psi}(\zeta_1)|\mathbf{f}\rangle. \tag{57}$$

Substituting them back to (55) yields

$$\begin{aligned}\delta(x-y) = &-\frac{1}{2\pi}\int_\Gamma d\zeta \frac{1}{2\zeta a(\zeta)^2}\mathbf{\Psi}(x,\zeta)\mathbf{\Psi}(y,\zeta)^A \\ &+ i\frac{1}{2\zeta_1\dot{a}(\zeta_1)^2}\{\dot{\mathbf{\Psi}}(x,\zeta_1)\mathbf{\Psi}(y,\zeta_1)^A + \mathbf{\Psi}(x,\zeta_1)\dot{\mathbf{\Psi}}(y,\zeta_1)^A\} \\ &- i\frac{1}{2\zeta_1\dot{a}(\zeta_1)^2}\left\{\frac{1}{\zeta_1}+\frac{\ddot{a}(\zeta_1)}{\dot{a}(\zeta_1)}\right\}\mathbf{\Psi}(x,\zeta_1)\mathbf{\Psi}(y,\zeta_1)^A.\end{aligned} \tag{58}$$

Here, as noted, real ζ should be considered as $\zeta+i0$, the factor ζ^{-1} in the integrand is replaced by $(\zeta+i0)^{-1}$, its pole $\zeta=0-i0$ is in the lower half plane. Hence, the integral path Γ is along the real axis from $-\infty$ to ∞ and runs above the origin when approaches it. This integral path is denoted by Γ. (59) is the expansion of the unity.

VII. PROOF OF COMPLETENESS RELATION

To prove (58), it is necessary to show that the right hand side is equal to $\delta(x-y)$ by using an independent approach. $\mathbf{\Psi}(x,\zeta)$ and $\mathbf{\Phi}(x,\zeta)$ are analytical on the upper half-plane of complex ζ, as seen from their explicit expressions (18) and (19). It can be shown[5] that

$$-\frac{1}{2\pi}\int_\Gamma d\zeta\frac{1}{2\zeta}B(x,y,\zeta) = \delta(x-y), \tag{59}$$

where

$$B(x,y,\zeta)=\begin{pmatrix}1\\-\lambda\end{pmatrix}(-\lambda\,1)e^{i\kappa(x-y)}. \tag{60}$$

In the case of $x>y$, the first term in the right hand side of (58) minus the left hand side of (59) is

$$-\frac{1}{2\pi}\int_\Gamma d\zeta\frac{1}{2\zeta}\left\{\frac{1}{a(\zeta)^2}\mathbf{\Psi}(x,\zeta)\mathbf{\Psi}(y,\zeta)^A-B(x,y,\zeta)\right\}. \tag{61}$$

In the limit of $|\zeta|\to\infty$, the integrand of (61) approaches $O(|\zeta|^{-1})e^{i\kappa(x-y)}$.

As $x>y$, a vanishing integral on an upper semicircle with an extremely large radius can be added to the integral in (61). Thus the integral in (61) becomes a clockwise contour integral. The pole $\zeta=-i0$, locating on the lower half-plane, lies out of the contour.

Near ζ_1, we have

$$\frac{1}{a(\zeta)^2}=\frac{1}{\dot a(\zeta_1)^2(\zeta-\zeta_1)^2}-\frac{\ddot a(\zeta_1)}{\dot a(\zeta_1)^3(\zeta-\zeta_1)}+\cdots. \tag{62}$$

Evaluating the contour integral, the contribution due to ζ_1 just cancels the second in the right hand side of (58). Hence the right hand side of (58) is indeed equal to $\delta(x-y)$ when $x\geqslant y$.

As $x\leqslant y$, we can show

$$\begin{aligned}\delta(x-y)=&-\frac{1}{2\pi}\int_\Gamma d\zeta\frac{1}{2\zeta\tilde a(\zeta)^2}\tilde{\mathbf{\Phi}}(x,\zeta)\tilde{\mathbf{\Phi}}(y,\zeta)^A\\&-i\frac{1}{2\overline{\zeta_1}\dot{\tilde a}(\overline{\zeta_1})^2}\{\dot{\tilde{\mathbf{\Phi}}}(x,\overline{\zeta_1})\tilde{\mathbf{\Phi}}(y,\overline{\zeta_1})^A+\tilde{\mathbf{\Phi}}(x,\overline{\zeta_1})\dot{\tilde{\mathbf{\Phi}}}(y,\overline{\zeta_1})^A\}\\&+i\frac{1}{2\overline{\zeta_1}\dot{\tilde a}(\overline{\zeta_1})^2}\left\{\frac{1}{\overline{\zeta_1}}+\frac{\ddot{\tilde a}(\overline{\zeta_1})}{\dot{\tilde a}(\overline{\zeta_1})}\right\}\mathbf{\Psi}(x,\overline{\zeta_1})\mathbf{\Psi}(y,\overline{\zeta_1})^A.\end{aligned} \tag{63}$$

Here

$$\tilde a(\zeta)=a(\zeta)^{-1}=\frac{\zeta-\overline{\zeta_1}}{\zeta-\zeta_1}, \tag{64}$$

and

$$\tilde{\mathbf{\Phi}}(x,\zeta)=\tilde a(\zeta)^2\mathbf{\Psi}(x,\zeta),\quad \tilde{\mathbf{\Psi}}(x,\zeta)=\tilde a(\zeta)^2\mathbf{\Phi}(x,\zeta) \tag{65}$$

are analytical on the lower half-plane of complex ζ.

Noting (64) and (65), we can transform (61) into

$$-\frac{1}{2\pi}\int_\Gamma d\zeta\frac{1}{2\zeta}\left\{\frac{1}{\tilde a(\zeta)^2}\tilde{\mathbf{\Phi}}(x,\zeta)\tilde{\mathbf{\Phi}}(y,\zeta)^A-B(x,y,\zeta)\right\}. \tag{66}$$

When $x<y$, in the limit of $|\zeta|\to\infty$, the integrand of (66) approaches $O(|\zeta|^{-1})e^{i\kappa(x-y)}$. A vanishing integral on a lower semicircle with an extremely large radius can be added to the integral in (66). Thus the integral in (66) becomes an anti-clockwise contour integral. The pole $\zeta=-i0$, locating on the lower half plane, lies inside of the contour.

As $\zeta\to-i0$, we have $i\kappa\to\infty$ and $e^{i\kappa(x-y)}\to0$, that is, the contribution of this pole vanishes.

Near $\overline{\zeta_1}$, we have

$$\frac{1}{\tilde{a}(\zeta)^2}=\frac{1}{\dot{\tilde{a}}(\bar{\zeta}_1)^2(\zeta-\bar{\zeta}_1)^2}-\frac{\ddot{\tilde{a}}(\bar{\zeta}_1)}{\dot{\tilde{a}}(\bar{\zeta}_1)^3(\zeta-\bar{\zeta}_1)}+\cdots. \tag{67}$$

Evaluating the contour integral, the contribution due to $\bar{\zeta}_1$ just cancels the second in the right hand side of (63). Hence the right hand side of (63) is indeed equal to $\delta(x-y)$ when $x\geqslant y$.

VIII. VERIFICATION IN A SINGLE SOLITON CASE

We have shown (58) for $x\geqslant y$ and (63) for $x\leqslant y$. If we can show that the right hand sides of these two equations are equal to each other for arbitrary x and y, then the right hand side of (58) and that of (63) are equal to $\delta(x-y)$ in general. From (22), we have

$$\zeta_1\ddot{a}(\zeta_1)+\dot{a}(\zeta_1)=0,\quad \bar{\zeta}_1\ddot{\tilde{a}}(\bar{\zeta}_1)+\dot{\tilde{a}}(\bar{\zeta}_1)=0 \tag{68}$$

and

$$i\zeta_1\dot{a}(\zeta_1)^2=-i\bar{\zeta}_1\dot{\tilde{a}}(\bar{\zeta}_1)=\frac{1}{4|\zeta_1|}. \tag{69}$$

Hence, comparing (58) with (63), it is necessary to show the following equation for arbitrary x and y:

$$\dot{\mathbf{\Psi}}(x,\zeta_1)\mathbf{\Psi}(y,\zeta_1)^A+\mathbf{\Psi}(x,\zeta_1)\dot{\mathbf{\Psi}}(y,\zeta_1)^A=\dot{\tilde{\mathbf{\Phi}}}(x,\bar{\zeta}_1)\tilde{\mathbf{\Phi}}(y,\bar{\zeta}_1)^A+\tilde{\mathbf{\Phi}}(x,\bar{\zeta}_1)\dot{\tilde{\mathbf{\Phi}}}(y,\bar{\zeta}_1)^A. \tag{70}$$

From (41), we have

$$\mathbf{\Psi}(x,\zeta_1)=\tilde{\mathbf{\Phi}}(x,\bar{\zeta}_1)=h_1\frac{1}{2}\operatorname{sech}X\begin{pmatrix}1\\ \lambda_1\tanh X\end{pmatrix}, \tag{71}$$

where $h_1=e^{i\kappa_1x_1-\lambda_1t}$. Similarly, we have

$$\mathbf{\Phi}(x,\zeta_1)=\tilde{\mathbf{\Psi}}(x,\bar{\zeta}_1)=h_1^{-1}\frac{1}{2}\operatorname{sech}X\begin{pmatrix}1\\ -\lambda_1\tanh X\end{pmatrix}. \tag{72}$$

From (42), we have

$$\dot{\mathbf{\Psi}}(x,\zeta_1)=\dot{\tilde{\mathbf{\Phi}}}(x,\bar{\zeta}_1)=-h_1\zeta_1\kappa_1\frac{1}{2}\operatorname{sech}X\begin{pmatrix}0\\ 1\end{pmatrix}+h_1i\zeta_1\lambda_1x\frac{1}{2}\operatorname{sech}X\begin{pmatrix}1\\ \lambda_1\tanh X\end{pmatrix}. \tag{73}$$

Similarly, we have

$$\dot{\mathbf{\Phi}}(x,\zeta_1)=\dot{\tilde{\mathbf{\Psi}}}(x,\bar{\zeta}_1)=h_1^{-1}\zeta_1\kappa_1\frac{1}{2}\operatorname{sech}X\begin{pmatrix}0\\ 1\end{pmatrix}-h_1^{-1}i\zeta_1\lambda_1x\frac{1}{2}\operatorname{sech}X\begin{pmatrix}1\\ -\lambda_1\tanh X\end{pmatrix}. \tag{74}$$

Substituting these formula into (70), we can see the validity of (70). Therefore, (68) is correct, and the completeness relation is proved.

IX. SECULARITY CONDITIONS

Substituting the expansion (55) into (32), and evaluating the inner products of $\mathbf{\Psi}(x,\zeta)^A$, $\mathbf{\Psi}(x,\zeta_1)^A$ and $\dot{\mathbf{\Psi}}(x,\zeta_1)^A$ with the resulted equation, respectively, we obtain

$$-4\pi\zeta a(\zeta)^2\{ig_t(\zeta)+\lambda f(\zeta)\}=\langle\mathbf{\Psi}(\zeta)|\mathbf{R}\rangle, \tag{75}$$

$$-i2\zeta_1\dot{a}(\zeta_1)^2\{ig_{1t}+\lambda_1 g_1\}=\langle\mathbf{\Psi}(\zeta_1)|\mathbf{R}\rangle, \tag{76}$$

and

$$-i2\zeta_1\dot{a}(\zeta_1)^2\{if_{1t}+\lambda_1 f_1+\zeta_1\kappa_1 g_1\}-i2\dot{a}(\zeta_1)\{\zeta_1\ddot{a}(\zeta_1)+\dot{a}(\zeta_1)\}\{ig_{1t}+\lambda_1 g_1\}=\langle\dot{\mathbf{\Psi}}(\zeta_1)|\mathbf{R}\rangle. \tag{77}$$

Although the initial value of $g_1(0)$ and $f_1(0)$ vanishes, the values of $g_1(t)$ and $f_1(t)$ will grow in time unless we impose the secularity condition[4,6,7,10–12]

$$\langle\mathbf{\Psi}(\zeta_1)|\mathbf{R}\rangle=0, \quad \langle\dot{\mathbf{\Psi}}(\zeta_1)|\mathbf{R}\rangle=0. \tag{78}$$

By means of these secularity conditions the adiabatic solution can be determined. That is, the time dependence of the parameters characterizing soliton solution of order of ϵ can be determined. Then from (75) one can determine the time dependence of $f(\zeta)$, because the right hand side has been found.

X. ADIABATIC TERMS

In the case of a single soliton (kink), the solution is characterized by two parameters $\zeta_1=i|\zeta_1|$ and the center position x_1, it is necessary to determine their time dependence of order of ϵ. We write

$$X=-i\kappa_1 z, \quad z=x-\hat{x}, \quad \hat{x}=x_1-\frac{\lambda_1}{\kappa_1}t, \quad \frac{d}{dt}\hat{x}=-\frac{\lambda_1}{\kappa_1}. \tag{79}$$

We then have

$$s[\theta]=-i2\lambda_{1\tau}\operatorname{sech}X+4\lambda_1\{\kappa_{1\tau}z-\kappa_1\hat{x}_\tau\}\operatorname{sech}X\tanh X, \tag{80}$$

where $\tau=\epsilon t$.

Because of the vanishing of the first component of $\mathbf{R}$, and the integrands depend on x via z, the secularity conditions reduce to

$$\int_{-\infty}^{\infty}dz\Phi(z,\zeta_1)s[\theta]=\int_{-\infty}^{\infty}dz\Phi(z,\zeta_1)r[\theta] \tag{81}$$

and

$$\int_{-\infty}^{\infty}dz\dot{\Phi}(z,\zeta_1)s[\theta]=\int_{-\infty}^{\infty}dz\dot{\Phi}(z,\zeta_1)r[\theta]. \tag{82}$$

Substituting (80), we obtain

$$\int_{-\infty}^{\infty}dz\Phi(z,\zeta_1)s[\theta]=2\frac{1}{\kappa_1}\lambda_{1\tau}-2\frac{\lambda_1}{\kappa_1^2}\kappa_{1\tau}=2\left(\frac{\lambda_1}{\kappa_1}\right)_\tau \tag{83}$$

and

$$\int_{-\infty}^{\infty}dz\dot{\Phi}(z,\zeta_1)s[\theta]=-i\zeta_1^{-1}\lambda_1\frac{\lambda_1}{\kappa_1}\hat{x}_\tau. \tag{84}$$

XI. VISCOSITY, AN EXAMPLE

Considering a kink under viscosity, the perturbation term is expressed as $-\eta\alpha_t$, where η is the coefficient of viscosity. In this case, η is our small parameter ϵ and

$$r[\theta]=\theta_t=-i2\lambda_1 \operatorname{sech} X. \tag{85}$$

We then obtain

$$\int_{-\infty}^{\infty} dz\Phi(z,\zeta_1)r[\theta]=-2\frac{\lambda_1}{\kappa_1} \tag{86}$$

and

$$\int_{-\infty}^{\infty} dz\dot{\Phi}(z,\zeta_1)r[\theta]=0. \tag{87}$$

The secularity conditions up to the order of ϵ are

$$2\left(\frac{\lambda_1}{\kappa_1}\right)_t=-2\eta\frac{\lambda_1}{\kappa_1}, \quad \hat{x}_t=-\frac{\lambda_1}{\kappa_1}. \tag{88}$$

From (88) we have

$$\ln\left(\frac{\lambda_1}{\kappa_1}\right)\Big|_0^t=-\eta t, \quad \frac{\lambda_1(t)}{\kappa_1(t)}=\frac{\lambda_1(0)}{\kappa_1(0)}e^{-\eta t}, \tag{89}$$

and

$$\frac{d}{dt}\hat{x}=-\frac{\lambda_1(0)}{\kappa_1(0)}e^{-\eta t}, \quad \hat{x}(t)=-\frac{\lambda_1(0)}{\kappa_1(0)}\frac{1}{\eta}(1-e^{-\eta t})+x_0. \tag{90}$$

When $\eta\to 0$, (90) tends to the last formula of (79).

XII. EXTENSION TO MULTISOLITON CASE

Now we discuss the problem of how to extend the above theory to the multisoliton case. In the multisoliton case, we must use the inverse scattering transform. The corresponding Lax equations of the unperturbed sine-Gordon equation are

$$\partial_x w(x,t,\zeta)=L(x,t,\zeta)w(x,t,\zeta), \quad \partial_t w(x,t,\zeta)=M(x,t,\zeta)w(x,t,\zeta), \tag{91}$$

with

$$L(x,t,\zeta)=\frac{1}{4}\begin{pmatrix} -i\zeta+i\frac{1}{\zeta}\cos\theta & -\{\theta_x-\theta_t\}+i\frac{1}{\zeta}\sin\theta \\ \{\theta_x-\theta_t\}+i\frac{1}{\zeta}\sin\theta & i\zeta-i\frac{1}{\zeta}\cos\theta \end{pmatrix} \tag{92}$$

and

$$M(x,t,\zeta)=\frac{1}{4}\begin{pmatrix} i\zeta+i\frac{1}{\zeta}\cos\theta & \{\theta_x-\theta_t\}+i\frac{1}{\zeta}\sin\theta \\ -\{\theta_x-\theta_t\}+i\frac{1}{\zeta}\sin\theta & -i\zeta-i\frac{1}{\zeta}\cos\theta \end{pmatrix}. \tag{93}$$

The function satisfying two Lax equations is called the full Jost solution.

Under boundary condition

$$\cos\theta\to 1, \quad \text{as}|x|\to\infty. \tag{94}$$

As $|x|\to\infty$,

$$L(x,t,\zeta)\to -i\,\tfrac{1}{2}\kappa\sigma_3, \quad M(x,t,\zeta)\to i\,\tfrac{1}{2}\lambda\sigma_3. \tag{95}$$

In the inverse scattering transform, the Jost solutions $\psi(x,\zeta)$ and $\varphi(x,\zeta)$ are defined only by the first Lax equation and by the asymptotic behaviors

$$\psi(x,\zeta)\to\begin{pmatrix}0\\1\end{pmatrix}e^{i1/2\,\kappa x}, \quad \text{as } x\to\infty,$$

$$\varphi(x,\zeta)\to\begin{pmatrix}1\\0\end{pmatrix}e^{-i\,1/2\,\kappa x}, \quad \text{as } x\to-\infty. \tag{96}$$

By introducing a t-dependent factor $h(t,\zeta)=e^{-i(1/2)\lambda t}$ which is determined by the second Lax equation, we obtain the full Jost solutions

$$\psi(x,t,\zeta)=h(t,\zeta)^{-1}\psi(x,t), \quad \varphi(x,t,\zeta)=h(t,\zeta)\varphi(x,t), \tag{97}$$

for example.

From Lax equations it can be shown that

$$\{\partial_{xx}-\partial_{tt}-\cos\theta\}W(x,t,\zeta)=0, \tag{98}$$

which corresponds to (11) for a single soliton case, where $W=w_1^2+w_2^2$, and $w=(w_1\ w_2)^T$ is a full Jost solution. We write

$$\Psi(x,t,\zeta)=\psi_1(x,t,\zeta)^2+\psi_2(x,t,\zeta)^2, \quad \Psi(x,\zeta)=\psi_1(x,\zeta)^2+\psi_2(x,\zeta)^2, \tag{99}$$

and similar expressions for $\Phi(x,t,\zeta)$ and $\Phi(x,\zeta)$. It is obvious that

$$\Psi(x,t,\zeta)=h(t,\zeta)^{-2}\Psi(x,t), \quad \Phi(x,t,\zeta)=h(t,\zeta)^2\Phi(x,t). \tag{100}$$

With these squared Jost solutions as solutions of the linearized equation, our previous derivations can be easily extended to multisoliton case, except those in Sec. VIII. It is obvious that the verification of the completeness in multisoliton case can not be based on the explicit expressions of the squared Jost solutions. It may be shown by using Marchenko equation for the sine-Gordon equation in the laboratory Ref. 5 which will be discussed elsewhere.

XIII. DISCUSSION

As we have seen, owing to the complexity of the Lax pair of the sine-Gordon equation, the orthogonality relations of the squared Jost solutions is not easy to derive. Moreover, derivation of the orthogonality relation by using the $1+1$ dimensional Green's theorem is suitable for perturbed

nonlinear equations whose unperturbed counterparts are not completely integrable, such as the perturbed φ^4 equation, the perturbed driven sine-Gordon equation,[13] and other perturbed relativistic nonlinear Klein–Gordon equations.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 42, NUMBER 6 JUNE 2001

On bidirectional fifth-order nonlinear evolution equations, Lax pairs, and directionally dependent solitary waves

J. M. Dye and A. Parker[a)]
Department of Engineering Mathematics, University of Newcastle upon Tyne, NE1 7RU, United Kingdom

(Received 5 September 2000; accepted for publication 8 January 2001)

In this paper, Lax pairs are constructed for two fifth-order nonlinear evolution equations of ''Boussinesq''-type which govern wave propagation in two opposite directions. One of the equations is related to the well-known Sawada–Kotera (SK) equation and, through its bilinear form, is identified with the Ramani equation. The second equation—about which very little seems to be known—may be considered a *bidirectional* version of the Kaup–Kupershmidt (KK) equation and is the main focus of this study. The ''anomalous'' solitary wave of this latter equation is derived and is found to possess the remarkable property that *its profile depends on the direction of propagation*. This type of directional dependence would appear to be quite unusual and, to our knowledge, has not been reported in the literature before now. By taking an appropriate undirectional (long wave) limit, it is shown that neither the Ramani, nor the bidirectional Kaup–Kupershmidt (bKK) equation can be classified as truly ''Boussinesq'' in character (a distinction that is made precise in the study). Recursion formulas are given for generating an infinity of conserved densities for both equations. These are used to obtain the first few conservation laws of the bKK and Ramani equations explicitly; not surprisingly, they exhibit the same lacunary behavior as their unidirectional counterparts. In conclusion, a canonical interpretation of the *N*-soliton solution of the bKK equation is proposed which provides a basis for constructing these anomalous solitons in a future work. [DOI: 10.1063/1.1354642]

I. INTRODUCTION

Nonlinear partial differential equations (PDEs) that describe wave propagation (in both one and two spatial dimensions) have been studied extensively since Korteweg and de Vries[1] first proposed their celebrated equation,

$$u_t - 6uu_x + u_{3x} = 0 \tag{1}$$

(the subscripts denote partial derivatives), as a model for small-amplitude gravity waves on shallow water. The continued interest in the Kortewg–de Vries (KdV) equation (1) stems, in large measure, from its exact solvability (for suitably restricted initial data) by the inverse scattering transform (IST).[2,3] The equation is now considered generic among completely integrable equations that govern the propagation of *unidirectional* weakly nonlinear, weakly dispersive waves (both because of its simple structure and the important rôle it plays in many different areas of mathematical physics).[4–9] By virtue of their derivation (from the ''full'' governing physical equations), the plethora of nonlinear PDEs that have been reported over the last thirty years or so describe, in the main, wave propagation in a *single* spatial direction. Additionally—and quite astonishingly—a significant number of these equations have turned out to be *completely integrable*[10] and, consequently, possess all the remarkable properties that characterize this very special class of evolution equations.[11,12] Chief among these distinguishing properties is the existence of multisoliton solu-

a)Author to whom correspondence should be addressed. Electronic mail: allen.parker@newcastle.ac.uk

tions which describe the ''elastic'' collisions of mutually interacting solitary waves. Yet—by their very construction—the KdV and other unidirectional nonlinear evolution equations (NEEs) are relevant to waves that progress in only one direction, and *de facto* permit only *overtaking* solitons.

However, in many physical situations, it is often preferable (and more satisfactory) to have an equation which allows us to model waves that propagate in *opposite* directions. In the context of soliton theory, the NEE would then admit solutions which represent the *head-on* collisions between solitary waves, as well as overtaking ones. For modeling small-amplitude shallow water waves, the relevant equation (in $1+1$ dimensions) is the well-known Boussinesq equation[13] which, in its familiar normalized form, may be written

$$u_{tt}-u_{xx}+3(u^2)_{xx}-u_{4x}=0. \tag{2}$$

We note that u_{xx} term in Eq. (2) can be removed by a simple translation of u, though we shall not do so here. Boussinesq's equation (*singular*) should not be confused with the classical Boussinesq equations (*plural*), a pair of coupled shallow water equations that were first reported by Boussinesq in Ref. 13, though they too describe both left- and right-traveling waves. Although Boussinesq was able to obtain Eq. (2) by simplifying the coupled equations, his derivation is in fact contradictory and strictly incorrect. A discussion of this paradox and an appreciation of the historical importance of Boussinesq's somewhat neglected contribution to shallow water wave theory can be found in Refs. 14–17. Equation (2) can be derived directly from the underlying Euler equations using precisely the same asymptotic assumptions that lead to the KdV Eq. (1), except that one allows for propagation in both the positive and negative x directions (see, e.g., Ref. 18). Remarkably, it turns out that the Boussinesq Eq. (2) is also completely integrable[19,20] just like its unidirectional cousin the KdV Eq. (1). [Lest this outcome be thought less than remarkable, it is as well to recall that the exactly comparable asymptotic derivation of the Boussinesq version of the two-dimensional KdV or Kadomtsev–Petviashvili (KP) equation yields a bidirectional nonlinear wave equation that is *not* completely integrable![21]] Thus, the Boussinesq equation (2) has all the special properties that we normally attribute to integrable equations. In particular, its left- and right-running soliton solutions have profiles that are identical to their unidirectional KdV counterparts[22] and so—and this is the important point—these profiles are the *same* regardless of the direction of propagation [a property that is implicit in Eq. (2)]. In other words, the Boussinesq equation *is* the bidirectional equivalent of the KdV equation: Put more precisely, Eq. (2) subsumes the KdV equation in the sense that we can recover Eq. (1) and its solutions by restricting to waves traveling in only one direction (either to the left or right; see Sec. V).

Bearing in mind the preceding remarks, we now wish to be more precise in our use of terminology. Though we intend the descriptive term Boussinesq to imply that an equation is *bidirectional* (i.e., supports wave propagation in two opposite directions), the converse may not be the case. A NEE may be bidirectional and yet not be strictly Boussinesq in character because the equation cannot be reduced to a corresponding *uni*directional integrable equation (in some suitably chosen approximation). In this study, a bidirectional NEE will be deemed to be of *Boussinesq* form if it possesses the following properties: (1) The equation reduces to a completely integrable unidirectional equation when propagation is restricted to one direction; (2) The *two* reduced equations—and hence their solutions—that are obtained in the left- and rightward running limits are essentially the same. Where (1) and (2) are not satisfied, then we will use the looser designation ''bidirectional'' to describe the equation. Until now, this subtle but important distinction seems to have attracted little or no attention; yet, as we shall see, it is of some relevance to the fifth-order equations that concern us here.

Before proceeding, a further comment on our use of terminology and notation is necessary. In the context of this study, we will use the order of the *uni*directional equation to fix the ''order'' of its bidirectional counterpart. Thus, the Boussinesq equation is taken to be *third*-order—the order of the KdV equation—rather than the fourth-order implied by Eq. (2). The reason for doing so becomes clearer when we rewrite Eq. (2) in its nonlocal form

$$\partial_x^{-1}u_{tt}-u_x+6uu_x-u_{3x}=0,$$

which reduces the order by one and makes transparent its connection with the KdV Eq. (1). Similarly, the ''fifth-order'' of the title is intended to preserve the genealogy of the bidirectional equations with the more familiar fifth-order unidirectional NEEs that form the starting point for this study. [Here, and in general, $\partial_x^{-1}f=\int^x f(x',t)\mathrm{d}x'$ denotes the indefinite integral of $f(x,t)$ with respect to x (and contains an arbitrary function of t). However, if $f\to 0$ sufficiently rapidly as $x\to-\infty$ or $+\infty$ (as, for example, when ''soliton'' boundary conditions are imposed), then we intend $\partial_x^{-1}f=\int_{-\infty}^x f(x',t)\mathrm{d}x'$ or $-\int_x^{\infty}f(x',t)\mathrm{d}x'$, respectively.]

The foregoing considerations lead us to suspect that we should be able to find a bidirectional counterpart of a given unidirectional nonlinear evolution equation, which may or may not be of Boussinesq form. (Under our strict definition, Johnson's 2D bidirectional equation[21] would not be classified as Boussinesq since it is not completely integrable). One obvious place to look for such equations is the classification of integrable equations based on Sato theory and the τ-function that was developed by the Kyoto school.[23] Yet it is often far from apparent—particularly from the standpoint of wave propagation—which, if any, of the equations in an integrable hierarchy would be the appropriate choice of bidirectional equation (much less identify *the* Boussinesq generalization). This lack of transparency stems from the fact that the equations in Ref. 23 are, for the most part, expressed in Hirota's bilinear formalism.[24] Other than the more easily recognizable equations of lower-order, the bilinear equations in Ref. 23 are far removed from any obvious physical interpretation (which, at the very least, would require knowledge of the ''correct'' transformation from the τ-function to the dependent physical variable). A further complication may arise where the equation being sought happens to be a reduction of one of the bilinear forms listed. Nevertheless, the Jimbo–Miwa[23] scheme is thought to provide a broad classification of integrable systems and, as we shall see, can be helpful in identifying a NEE that has been obtained by other means.

Now, two important unidirectional NEEs that have been studied extensively over the last two decades are the Sawada–Kotera (SK) (or Caudrey–Dodd–Gibbon) equation[25,26]

$$u_t+45u^2u_x-15u_xu_{xx}-15uu_{3x}+u_{5x}=0, \tag{3}$$

and the Kaup–Kupershmidt (KK) equation[27,28]

$$u_t+45u^2u_x-\tfrac{75}{2}u_xu_{xx}-15uu_{3x}+u_{5x}=0. \tag{4}$$

The close connection between these two completely integrable fifth-order equations is well-documented;[27,29–33] nevertheless, despite their evident duality, Eqs. (3) and (4) are fundamentally different.[29] One might anticipate that both equations will have bidirectional (possibly Boussinesq) counterparts; yet, as far as we can tell, these have not been ''identified'' specifically.

In this paper, we present a procedure for constructing bidirectional generalizations of known unidirectional NEEs. The method proceeds by generating a Lax pair for the putative bidirectional equation from the Lax pair of its unidirectional cousin, and does so by exploiting the connection between the prototype KdV and Boussinesq equations. Aside from its intuitive appeal, the other advantages of this approach are that it is equation specific and, by construction, provides us with a Lax pair which ensures the complete integrability of the resulting bidirectional equation. We shall describe the procedure in the next section, and then use it to construct bidirectional versions of the SK Eq. (3) and the KK Eq. (4), together with their Lax pairs. As both these NEEs are associated with fifth-order scattering problems, solving them by the IST method[2,3] will, we suspect, prove extremely difficult. Rather, we shall make use of Hirota's bilinear transform method[24,34] which is an effective tool for obtaining exact solutions of NEEs using only ''elementary'' means. In Sec. III, we construct two quite distinct bilinear forms for the bidirectional SK equation; one of them comprises a *single* bilinear equation which identifies it with the well-known Ramani[35] equation. The second bilinear form is a coupled system that is given in Ref. 23, where

it appears as a special reduction of the KP hierarchy of the *B*-type (BKP) (though no mention is made there of its connection with Ramani's equation). On the other hand, the bidirectional counterpart of the KK equation constructed here has two bilinear representations which appear to be equally complicated coupled systems. It is this completely integrable equation—which we designate the bidirectional Kaup–Kupershmidt (bKK) equation—that is the main focus of this study. Not surprisingly, the bKK equation is also listed in Ref. 23 (as a special reduction in the KP hierarchy of *C*-type (CKP)), though there is no intimation of its specific relation to the KK equation. Nevertheless, as far as we can tell, very little is known about this equation and the Lax pair constructed here would, therefore, appear to be a new result.

In Sec. IV, we derive the solitary wave of the bKK equation by exploiting the duality between the bilinear forms of the Ramani and bKK equations [in much the same way that one of us (A.P.) has done for the SK and KK equations (3) and (4)[32]]. Remarkably, the profile of this solitary wave *depends on its direction of propagation*, a property that we have not encountered before now. According to the definition formulated earlier, this would imply that the bKK equation is not the Boussinesq form of the KK equation. This is indeed the case; in Sec. V we show that the bKK equation cannot be reduced to the KK equation by restricting wave propagation to only one direction. [Incidentally, this result justifies the designation bKK (*small* b) for the equation.] In the same way, we demonstrate that the Ramani equation is not truly Boussinesq since it cannot be reduced to the Sawada–Kotera equation in a unidirectional approximation.

It is well-known that the sequence of conservation laws for both the SK and KK equations exhibit the unusual behavior whereby every third conserved density is absent.[26,27,36] In Sec. VI, we show that, not unexpectedly, this same lacunary pattern is shared by both the Ramani and bKK equations. We formulate their first few conservation laws explicitly, and give recursion formulas for generating an infinity of conserved densities for each equation. (Although Hu[37] has previously investigated the conservation laws of Ramani's equation, there would appear to be a small but significant error in this work.) Finally, just like its unidirectional cousin the KK Eq. (4),[32,33] we show how the anomalous character of the multisoliton solutions of the bKK equation arises quite naturally within the bilinear formalism. This leads us to a canonical interpretation of its *N*-soliton that paves the way for constructing these somewhat complicated solutions explicitly in a future study. Some bilinear identities that facilitate the analysis are given in Appendix A.

II. LAX PAIRS AND BIDIRECTIONAL EVOLUTION EQUATIONS

We recall that the Lax operators[38] for the KdV Eq. (1) may be written

$$L^{\mathrm{KdV}}=\partial_x^2-u,$$
$$M^{\mathrm{KdV}}=-4\partial_x^3+6u\partial_x+3u_x \tag{5}$$

(where ∂_x^n denotes the nth partial derivative with respect to x). Then the Lax equation $L_t^{\mathrm{KdV}}+[L^{\mathrm{KdV}},M^{\mathrm{KdV}}]=0$ leads to Eq. (1), while $L^{\mathrm{KdV}}\psi=\lambda\psi$, $\psi_t=M^{\mathrm{KdV}}\psi$ constitute the classical IST scheme for the KdV equation. On the other hand, Eq. (2) has the Lax pair[19]

$$L^{\mathrm{B}}=-4\partial_x^3-\partial_x+6u\partial_x+3u_x+i\sqrt{3}\partial_x^{-1}u_t,$$
$$M^{\mathrm{B}}=\partial_x^2-u, \tag{6}$$

so that the IST for the Boussinesq equation comprises the third-order scattering problem $L^{\mathrm{B}}\psi=\lambda\psi$. (This inverse spectral problem was solved by Deift *et al.*[20]) Now, if we compare Eqs. (5) and (6), we observe that the Lax pair of the Boussinesq equation can be recast in terms of the KdV operators as

$$L^{\mathrm{B}}=M^{\mathrm{KdV}}-\partial_x+i\sqrt{3}\partial_x^{-1}u_t,\quad M^{\mathrm{B}}=L^{\mathrm{KdV}}. \tag{7}$$

Written in this way, the Lax pair (7) mirrors the intimate connection between the KdV and Boussinesq equations that is apparent at the physical level where the equations describe equivalent models for shallow water waves that propagate in one and two opposite directions, respectively. In effect, Eq. (7) uses the Lax pair of the *uni*directional KdV Eq. (1) to generate the Lax pair of its *bi*directional cousin, Eq. (2), by exchanging the rôles of the KdV scattering and time evolution operators L^{KdV} and M^{KdV}. The first of the two extra terms in L^{B} is simply required to give the u_{xx} term of the Boussinesq Eq. (2) (but note our earlier comment regarding the elimination of this term), whereas the second term ensures that its Lax equation $(i/\sqrt{3})L^{\mathrm{B}}_t+[L^{\mathrm{B}},M^{\mathrm{B}}]=0$ is purely multiplicative. This exchange mechanism suggests a general procedure for constructing bidirectional versions of unidirectional NEEs which we will now exploit to obtain bidirectional counterparts of the SK and KK equations.

A. A bidirectional Sawada–Kotera equation

We start with the Lax pair of the SK Eq. (3)[36]

$$\begin{aligned} L^{\mathrm{SK}}&=\partial_x^3-3u\partial_x,\\ M^{\mathrm{SK}}&=9\partial_x^5-45u\partial_x^3-45u_x\partial_x^2+(45u^2-30u_{xx})\partial_x. \end{aligned} \tag{8}$$

Following the exchange procedure outlined above, we define new operators

$$L^{\mathrm{bSK}}=M^{\mathrm{SK}}+K,\quad M^{\mathrm{bSK}}=L^{\mathrm{SK}}, \tag{9}$$

which give the putative Lax pair for our *bi*directional Sawada–Kotera (bSK) equation. The unknown differential operator K must be chosen so as to eliminate any unwanted terms from the compatibility condition on L^{bSK} and M^{bSK}: One easily shows that K must have the form

$$K=a(x,t)\partial_x+b(x,t), \tag{10}$$

where $a(x,t)$, $b(x,t)$ are functions to be found. Direct substitution of Eqs. (9) and (10) into the Lax equation $L^{\mathrm{bSK}}_t+[L^{\mathrm{bSK}},M^{\mathrm{bSK}}]=0$ yields the defining equations

$$15u_t+a_x=0,\quad 15u_{xt}+a_{xx}+b_x=0,\quad b_t=0,$$

from which we obtain $a=-15\partial_x^{-1}u_t$ and $b=$constant (which may be set to zero without loss of generality). The Lax operators (9) now read

$$\begin{aligned} L^{\mathrm{bSK}}&=9\partial_x^5-45u\partial_x^3-45u_x\partial_x^2+(45u^2-30u_{xx}-15\partial_x^{-1}u_t)\partial_x\\ M^{\mathrm{bSK}}&=\partial_x^3-3u\partial_x, \end{aligned} \tag{11}$$

and their compatibility leads to the completely integrable equation

$$5\partial_x^{-1}u_{tt}+5u_{xxt}-15uu_t-15u_x\partial_x^{-1}u_t-45u^2u_x+15u_xu_{xx}+15uu_{3x}-u_{5x}=0. \tag{12}$$

Though we have been able to construct a bidirectional version of the SK Eq. (3), the NEE (12), in its present form at least, is not readily identifiable. Moreover, if we were to use the IST method to obtain its soliton solutions, we must solve the *fifth*-order inverse spectral problem, $L^{\mathrm{bSK}}\psi=\lambda\psi$, which, we suspect, will be considerably more difficult than the corresponding third-order scattering problem for the SK equation.[27] Rather, we shall make use of Hirota's direct method[24] which, additionally, will allow us to recognize Eq. (12) by its bilinear form. Now that we have shown that the exchange method works for the SK equation, we turn to our main purpose: To find a bidirectional counterpart of the Kaup–Kupershmidt equation (4).

B. A bidirectional Kaup–Kupershmidt equation

Repeating the procedure of Sec. II A for the KK Eq. (4), its Lax representation[27]

$$L^{\mathrm{KK}}=\partial_x^3-3u\partial_x-\tfrac{3}{2}u_x,$$
$$M^{\mathrm{KK}}=9\partial_x^5-45u\partial_x^3-\tfrac{135}{2}u_x\partial_x^2+(45u^2-\tfrac{105}{2}u_{xx})\partial_x+45uu_x-15u_{3x}, \tag{13}$$

is replaced by

$$L^{\mathrm{bKK}}=M^{\mathrm{KK}}+A(x,t)\partial_x+B(x,t),\quad M^{\mathrm{bKK}}=L^{\mathrm{KK}}, \tag{14}$$

which gives a putative Lax pair for the *bi*directional Kaup–Kupershmidt (bKK) equation. The unknown functions $A(x,t)$, $B(x,t)$ are determined by requiring that the operators (14) constitute a legitimate Lax pair: Proceeding on this basis, we get

$$15u_t+A_x=0,\quad \tfrac{45}{2}u_{xt}+A_{xx}+B_x=0.$$

Integrating these equations once, we find that $A=-15\partial_x^{-1}u_t$ and $B=-\frac{15}{2}u_t$ (where the arbitrary function of integration in the last expression has been set to zero, with no loss in generality). Combining these results with Eqs. (13) and (14), we finally obtain the Lax pair

$$L^{\mathrm{bKK}}=9\partial_x^5-45u\partial_x^3-\tfrac{135}{2}u_x\partial_x^2+(45u^2-\tfrac{105}{2}u_{xx}-15\partial_x^{-1}u_t)\partial_x+45uu_x-15u_{3x}-\tfrac{15}{2}u_t,$$
$$M^{\mathrm{bKK}}=\partial_x^3-3u\partial_x-\tfrac{3}{2}u_x, \tag{15}$$

whose compatibility yields the integrable bKK equation

$$5\partial_x^{-1}u_{tt}+5u_{xxt}-15uu_t-15u\partial_x^{-1}u_t-45u^2u_x+\tfrac{75}{2}u_xu_{xx}+15uu_{3x}-u_{5x}=0. \tag{16}$$

Although we have succeeded in constructing a bidirectional version of the KK Eq. (4) by using the exchange procedure, the resulting fifth-order NEE (16) is not new. As we anticipated, the bKK equation can be found in the Jimbo–Miwa classification as a special reduction of the CKP hierarchy of integrable equations (see Ref. 23, p. 969). Yet no mention is made there of its connection with the KK equation or of its bidirectional character; furthermore, the Lax pair (15) is not given in Ref. 23 and would appear to be new. Even so, to the best of our knowledge, Eq. (16) has not been studied in any detail and is the main interest of the remainder of this paper. In the next section, we shall obtain the bilinear form of the bKK equation with a view to finding its soliton solutions. (This avoids solving the associated *fifth*-order inverse spectral problem which lies outside the scope of the present study).

One further comment is warranted before we proceed. The bidirectional NEEs (12) and (16) differ only in the coefficients of the nonlinear term u_xu_{xx} [cf. Eqs. (3) and (4)]. Yet, just like their unidirectional cousins, the bSK and bKK equations are fundamentally different: There is no scaling that transforms one equation into the other. We shall say more about this distinction later.

III. BILINEAR FORMS

As an alternative to the IST[2,3]—which, in this instance, would mean solving a fifth-order inverse spectral problem—Hirota's bilinear transform method[24,34] is arguably the most straightforward technique for finding exact solutions of NEEs. In this section, we construct bilinear forms of both the bSK and bKK equations, Eqs. (12) and (16), primarily with a view to obtaining multisoliton solutions. Yet, here, the bilinear formalism confers further advantages. Thus, the bSK Eq. (12) has a bilinear form that allows us to identify it with a well-known integrable equation and which, by virtue of its simple structure, is easily solved for soliton solutions. Additionally, we can

exploit the duality between the bSK and bKK equations to develop a strategy for solving the more complicated bilinear form of the latter equation (in much the same way as has been done for the SK and KK equations[32,33]).

A. Bilinearization of the bidirectional Sawada–Kotera equation

Following Hirota's method,[24,34] we make a change of dependent variable

$$u(x,t)=\alpha\partial_x^2 \ln f(x,t), \tag{17}$$

where α is a constant. Integrating the bSK Eq. (12) with respect to x, we obtain

$$5\alpha(\ln f)_{tt}+5u_{xt}-15\alpha u(\ln f)_{xt}-G(u)=0, \tag{18}$$

where we have used (17) and put

$$G(u)=15u^3-15uu_{xx}+u_{4x}. \tag{19}$$

The arbitrary function of integration in (18) has been set to zero by imposing soliton (i.e., rapidly decaying) boundary conditions as $x\to\pm\infty$.

The first term of (18) can be cast into bilinear form by using the identity

$$(\ln f)_{tt}=(\mathrm{D}_t^2 f\cdot f)/2f^2, \tag{20}$$

where the Hirota derivatives D_x, D_t are defined by[34]

$$\mathrm{D}_x\mathrm{D}_t a(x,t)\cdot b(x,t)=(\partial_x-\partial_{x'})(\partial_t-\partial_{t'})a(x,t)b(x',t')\big|_{x'=x,\ t'=t}.$$

We can bilinearize the next pair of terms in (18) by first noting the identity (A3) (with $u\to u/\alpha$)

$$u_{xt}+6u(\ln f)_{xt}=\alpha(\mathrm{D}_x^3\mathrm{D}_t f\cdot f)/2f^2. \tag{21}$$

Combining the identities (A1) and (A6), we also deduce the relation

$$[\partial_{xt}^2+2(\ln f)_{xt}](g/f)=(\mathrm{D}_x\mathrm{D}_t f\cdot g)/f^2,$$

where $g(x,t)$ is an arbitrary function. But if we define g by

$$g/f=u, \tag{22}$$

then the last result yields the identity

$$u_{xt}+2u(\ln f)_{xt}=(\mathrm{D}_x\mathrm{D}_t f\cdot g)/f^2. \tag{23}$$

Using Eqs. (21) and (23), we can now bilinearize the next two terms of Eq. (18) through the linear combination

$$5u_{xt}-15\alpha u(\ln f)_{xt}=\lambda\frac{\mathrm{D}_x\mathrm{D}_t f\cdot g}{f^2}+\alpha\mu\frac{\mathrm{D}_x^3\mathrm{D}_t f\cdot f}{2f^2}, \tag{24}$$

provided that λ and μ satisfy $\lambda+\mu=5$, $2\lambda+6\mu=-15\alpha$, in which case

$$\lambda=\tfrac{15}{4}(\alpha+2),\quad \mu=-\tfrac{5}{4}(3\alpha+2). \tag{25}$$

It only remains to bilinearize the expression $G(u)$. We first make use of (A5) (with $u\to u/\alpha$), which gives

$$120u^3+60\alpha uu_{xx}+2\alpha^2u_{4x}=\alpha^3(\mathrm{D}_x^6f\cdot f)/f^2. \tag{26}$$

By combining the identities (A7) and (A8), and substituting (A2), (A4), and (22), we get the further relation between the three terms of G

$$12u^3+14\alpha uu_{xx}+\alpha^2u_{4x}=\alpha^2(\mathrm{D}_x^4f\cdot g)/f^2. \tag{27}$$

The bilinearization of $G(u)$ follows from (26) and (27) if we can find constants γ and ν such that

$$G(u)=\gamma(12u^3+14\alpha uu_{xx}+\alpha^2u_{4x})+\nu(120u^3+60\alpha uu_{xx}+2\alpha^2u_{4x}). \tag{28}$$

Comparing (19) with (28), we require

$$12\gamma+120\nu=15,\quad \alpha(14\gamma+60\nu)=-15,\quad \alpha^2(\gamma+2\nu)=1,$$

which are compatible if $\alpha^2+3\alpha+2=0$, i.e., $\alpha=-1$ or $\alpha=-2$.

Solving for γ and ν, and substituting from Eqs. (20), (24)–(28) into Eq. (18), we finally obtain the bilinear form of the bSK Eq. (12)

$$[80\alpha\mathrm{D}_t^2-20\alpha(3\alpha+2)\mathrm{D}_x^3\mathrm{D}_t-\alpha^2(7\alpha+6)\mathrm{D}_x^6]f\cdot f+(\alpha+2)[120\mathrm{D}_x\mathrm{D}_t+30\alpha\mathrm{D}_x^4]f\cdot g=0, \tag{29a}$$

$$\alpha\mathrm{D}_x^2f\cdot f-2\,f\cdot g=0, \tag{29b}$$

where the last equation is just a restatement of Eq. (22) [using the bilinear identity (A2)]. There are two cases to consider: (i) $\alpha=-1$. The bilinear form (29) reads

$$(80\mathrm{D}_t^2+20\mathrm{D}_x^3\mathrm{D}_t-\mathrm{D}_x^6)f\cdot f-(120\mathrm{D}_x\mathrm{D}_t-30\mathrm{D}_x^4)f\cdot g=0, \tag{30a}$$

$$\mathrm{D}_x^2f\cdot f+2\,f\cdot g=0. \tag{30b}$$

(ii) $\alpha=-2$. In this case Eqs. (29a) and (29b) decouple, thus making the auxiliary function g redundant and reducing the bilinear form to the single equation

$$(5\mathrm{D}_t^2+5\mathrm{D}_x^3\mathrm{D}_t-\mathrm{D}_x^6)f\cdot f=0. \tag{31}$$

Using the transformation (17), we have shown that it is possible to construct *two* bilinear forms of the bidirectional Sawada–Kotera equation (12). The first of these, Eq. (30), has u and f related by $u=-\partial_x^2\ln f$, and is a coupled bilinear system that is given in Ref. 23. This shows that the bSK Eq. (12) is, in fact, a reduction of the BKP hierarchy of integrable equations. The alternative bilinear representation, Eq. (31), with $u=-2\partial_x^2\ln f$, identifies the bSK Eq. (12) with the well-known Ramani equation.[35] The latter equation has attracted considerable attention in the literature and is widely held to be completely integrable.[23,35,37,39,40] In particular, the Lax representation (11) that has been obtained here through the exchange procedure, agrees with the Lax pair of the Ramani equation that was found previously by other means.[39] Hitherto, the designation ''Ramani equation'' appears to have been used only in connection with the bilinear form (31). However, we shall also use it to refer to the bidirectional Sawada–Kotera Eq. (12) and invoke the alternative description ''bSK equation'' whenever we wish to emphasize its bidirectional character and genealogy with the Sawada–Kotera equation, Eq. (3).

B. Bilinearization of the bidirectional Kaup–Kupershmidt equation

Proceeding as above, we obtain the integrated form of the bKK Eq. (16)

$$5\alpha(\ln f)_{tt}+5u_{xt}-15\alpha u(\ln f)_{xt}-H(u)=0, \tag{32}$$

where u and f are related by Eq. (17) and

$$H(u)=15u^3-\tfrac{45}{4}u_x^2-15uu_{xx}+u_{4x}. \tag{33}$$

Since the first three terms in Eq. (32) are identical to those of Eq. (18), they can be bilinearized exactly as in Sec. III A [using an auxiliary function g, Eq. (22)]. Moreover, the expression $H(u)$ differs from $G(u)$, Eq. (19), by just a single term. Thus, to complete the bilinearization of the bKK equation, we need only find a further bilinear relation between the terms of $H(u)$ in addition to (26) and (27) (and containing the extra u_x^2 term).

To this end, we first make use of (A4) (with $u\to u/\alpha$) to deduce the two identities

$$\alpha^2 u\left(\frac{\mathrm{D}_x^4 f\cdot f}{f^2}\right)=12u^3+2\alpha uu_{xx},\quad \alpha^2\frac{\partial^2}{\partial x^2}\left(\frac{\mathrm{D}_x^4 f\cdot f}{f^2}\right)=24(uu_{xx}+u_x^2)+2\alpha u_{4x}, \tag{34}$$

which taken together involve all four terms of $H(u)$. We also have

$$2u\left(\frac{h}{f}\right)+\alpha\frac{\partial^2}{\partial x^2}\left(\frac{h}{f}\right)=\alpha\frac{\mathrm{D}_x^2 f\cdot h}{f^2}, \tag{35}$$

which follows directly from (A2), (A7), and (17), for any ancillary function $h(x,t)$. But if we define h by [cf. (29b)]

$$\frac{h}{f}=\alpha\frac{\mathrm{D}_x^4 f\cdot f}{2f^2}, \tag{36}$$

and use (34), then Eq. (35) yields the additional bilinear relation

$$12u^3+14\alpha uu_{xx}+12\alpha u_x^2+\alpha^2 u_{4x}=\alpha^2(\mathrm{D}_x^2 f\cdot h)/f^2. \tag{37}$$

The bilinearization of H now follows from Eqs. (26), (27), and (37) provided we can find constants σ, γ, and ν such that

$$\begin{aligned}H(u)=&\sigma(12u^3+14\alpha uu_{xx}+12\alpha u_x^2+\alpha^2u_{4x})+\gamma(12u^3+14\alpha uu_{xx}+\alpha^2u_{4x})\\&+\nu(120u^3+60\alpha uu_{xx}+2\alpha^2u_{4x}).\end{aligned} \tag{38}$$

As before, this is possible only if $\alpha=-1$ or $\alpha=-2$, and then

$$\sigma=-\frac{15}{16\alpha},\quad \gamma=-\frac{15(\alpha+1)}{16\alpha},\quad \nu=\frac{7\alpha+6}{32\alpha}. \tag{39}$$

Every term in Eq. (32) has now been bilinearized: The resulting bilinear form of the bKK Eq. (16) is

$$\begin{gathered}\alpha(5\mathrm{D}_t^2+\mu\mathrm{D}_x^3\mathrm{D}_t-2\alpha^2\nu\mathrm{D}_x^6)f\cdot f+2(\lambda\mathrm{D}_x\mathrm{D}_t-\alpha^2\gamma\mathrm{D}_x^4)f\cdot g-2\alpha^2\sigma\mathrm{D}_x^2 f\cdot h=0,\\ \alpha\mathrm{D}_x^2 f\cdot f-2f\cdot g=0,\\ \alpha\mathrm{D}_x^4 f\cdot f-2f\cdot h=0,\end{gathered} \tag{40}$$

where λ, μ, σ, γ, and ν are given by Eqs. (25) and (39) [and the last equation is simply a restatement of Eq. (36)]. Once again, there are two possibilities: (i) $\alpha=-1$. The bilinear form (40) becomes

$$(80D_t^2+20D_x^3D_t-D_x^6)f\cdot f-120D_xD_tf\cdot g+30D_x^2f\cdot h=0, \tag{41a}$$

$$D_x^2f\cdot f+2\,f\cdot g=0, \tag{41b}$$

$$D_x^4f\cdot f+2\,f\cdot h=0, \tag{41c}$$

with $u=-\partial_x^2\ln f$. (ii) $\alpha=-2$. In this case, we have $u=-2\partial_x^2\ln f$ and the bilinear form (40) reads

$$16(5D_t^2+5D_x^3D_t-D_x^6)f\cdot f-30D_x^4f\cdot g+30D_x^2f\cdot h=0,$$

$$D_x^2f\cdot f+f\cdot g=0, \tag{42}$$

$$D_x^4f\cdot f+f\cdot h=0.$$

Although the bKK equation appears in Ref. 23 in its normal form (16), the bilinear forms (41) and (42) are not listed there and, as far as we can tell, are new results.

For our part, the crucial observation is the following one: Although we have been able to construct two bilinear forms for the bKK equation [under the transformation (17)], neither of these systems can be reduced to a *single* bilinear equation [comparable to Eq. (31) for the Ramani equation]. As we shall see, this distinguishing feature of the bKK Eq. (16) has consequences for obtaining its soliton solutions. Indeed, both the bilinear forms (41) and (42) involve three field variables [cf. Eq. (30)]; thus, in spite of their duality, the bKK equation would seem to be a more complicated system than Ramani's equation.

Not surprisingly, the results that we have obtained here for the Ramani and bKK equations mirror those given in Ref. 32 for their unidirectional cousins, the SK Eq. (3) and KK Eq. (4), with one notable exception. The assertion in Ref. 32 that the KK equation possesses a *single* bilinear form [under (17)] is incorrect. There, the author did not take account of the relation (27) when constructing its bilinear form, and so missed a second bilinear representation [akin to (42) for the bKK equation]. However, as there is no simple way of solving this alternative bilinear form of the KK equation for soliton solutions [the same comment applies to Eq. (42) incidentally; see Sec. IV], the results and conclusions of Ref. 32 remain valid.

IV. SOLITARY WAVES

Now that we have found bilinear forms of the bidirectional NEEs (12) and (16), we would like to be able to solve them for exact solutions. For the Ramani equation this is comparatively straightforward since we can employ the simpler bilinear form (31) as opposed to the coupled equations (30a) and (30b). More particularly, we can make use of Hirota's celebrated formula[24] to obtain the explicit N-soliton solution of Eq. (31). Hereafter, we shall dub this generic form the ''*regular*'' N-soliton solution. Understandably, the alternate and more complicated bilinear form of Ramani's equation, Eq. (30), has largely been ignored for analytic purposes. Yet its multisoliton solutions are easily inferred from the corresponding solutions of Eq. (31) and this provides the key to solving the bilinear form of the bKK equation, Eq. (41), for which there is no obvious ansatz. In this section, we shall pursue this line of reasoning with a view to deriving the solitary wave of the bKK equation.

The ''regular'' solitary wave has the form[24]

$$f(x,t)=1+e^{\theta},\quad \theta=px+\omega t+\eta, \tag{43}$$

which solves the Ramani bilinear form (31) if $\omega(p)$ satisfies the dispersion relation

$$5\omega^2+5\omega p^3-p^6=0. \tag{44}$$

Transforming to the ''physical'' variable u, we get

$$u(x,t) = -2\partial_x^2 \ln f = -\tfrac{1}{2}p^2 \operatorname{sech}^2 \tfrac{1}{2}(px+\omega t+\eta), \tag{45}$$

where p, η are arbitrary (real) parameters and ω is given by Eq. (44). This is the familiar sech^2 solitary wave of the Ramani Eq. (12) which propagates to the left or right depending on the sign of ω. However, it is important to emphasize that the left- and right-going solitary waves have *identical* bell-shaped profiles (for a given wave number p) but travel with different speeds.

Evidently, the bilinear forms (30) and (31) are equivalent under the transformation $f \leftrightarrow f^2$ (we omit the formal demonstration here which makes use of various bilinear identities; but see Ref. 32 for a similar argument). It follows that the corresponding solitary-wave solution of the alternative bilinear form (30) is given by squaring Eq. (43); i.e.,

$$f(x,t) = 1 + 2e^{\theta} + e^{2\theta}, \tag{46}$$

which is a solution of Eqs. (30a) and (30b) provided that ω satisfies the dispersion law (44) (and $g = -2p^2 e^{\theta}$).

The situation for the bKK equation is not quite so simple: At first glance, there seems little to choose between the bilinear forms (41) and (42). However, on closer scrutiny, we see that (modulo the ancillary equations) the bilinear forms of the Ramani Eq. (30) and bKK Eq. (41)—corresponding to $\alpha = -1$—bear a marked resemblance to one another: Ditto the bilinear forms (31) and (42) for which $\alpha = -2$. This is hardly surprising: These bilinear forms echo the intimate connection between the Ramani and bKK equations that is evident from their normalized forms, Eqs. (12) and (16). We can expect this duality to be manifested in their analytic properties and, importantly, in the structure of their soliton solutions. In particular, we anticipate that the solitary wave of the bilinearized bKK Eq. (41) will mimic the corresponding solution of the Ramani Eq. (30). This suggests that we seek a solitary-wave solution of Eqs. (41a)–(41c) in the form [cf. Eq. (46)]

$$f(x,t) = 1 + e^{\theta} + be^{2\theta}, \quad \theta = px + \omega t + \eta, \tag{47}$$

where b is a constant (and the coefficient of e^{θ} has been set to unity without loss of generality). We will take this as a working hypothesis, choosing to work with the bilinear form (41) rather than (42).

For a general bilinear operator $F(\mathrm{D}_x, \mathrm{D}_t)$, we have the fundamental result[34]

$$F(\mathrm{D}_x, \mathrm{D}_t) e^{\theta_1} \cdot e^{\theta_2} = F(\mathbf{p}_1 - \mathbf{p}_2) e^{\theta_1 + \theta_2}, \quad \theta_i = p_i x + \omega_i t + \eta_i, \quad i = 1,2, \tag{48}$$

where for brevity we write $F(\mathbf{p}) = F(p,\omega)$. Then, with f given by Eq. (47), we obtain

$$F(\mathrm{D}_x, \mathrm{D}_t) f \cdot f = 2e^{\theta}[F(\mathbf{p}) + bF(2\mathbf{p})e^{\theta} + bF(\mathbf{p})e^{2\theta}], \tag{49}$$

whenever F is even and $F(\mathbf{0}) = 0$.

We first solve the ancillary equations (41b) and (41c) for g and h, respectively. Setting $F = \mathrm{D}_x^2$ in Eq. (49), and substituting into Eq. (41b), we deduce

$$g = -p^2 e^{\theta}\left[1 + (4b-1)\frac{e^{\theta}}{f}\right]. \tag{50}$$

Similarly, we solve Eq. (41c) to obtain

$$h = -p^4 e^{\theta}\left[1 + (16b-1)\frac{e^{\theta}}{f}\right]. \tag{51}$$

There is good reason to write the auxiliary functions in this way. First and foremost, they will simplify the computations needed to solve the third bilinear equation (41a). But they also identify two special values of b. When $b = 1/4$, Eq. (50) simplifies to $g = -p^2 e^{\theta}$ and (47) becomes f

$=(1+\frac{1}{2}e^{\theta})^2$; in the absence of h, this would recover the solitary-wave solution of the Ramani bilinear form (30) noted above [a similar result holds for the SK Eq. (3)[32]]. On the other hand, if $b=1/16$, then Eq. (51) reduces to $h=-p^4e^{\theta}$ and $f=(1+e^{\theta}+\frac{1}{16}e^{\theta})$ which is just the anomalous solitary wave of the KK Eq. (4) (with g now absent).[32]

For the bKK equation, however, we cannot simplify *both* Eqs. (50) and (51) simultaneously, and this complicates matters. It is clear that direct substitution of g and h into Eq. (41a) may present difficulties since the last two bilinear terms would then involve quotients. However, we can avoid these by making use of the identities (A9) and (A10) which, together with Eqs. (48) and (49), give

$$\mathrm{D}_x\mathrm{D}_t f\cdot g=-\omega p^3e^{\theta}\left[(1+be^{2\theta})+\frac{4(4b-1)}{f^2}e^{\theta}(1-be^{2\theta})^2\right]$$

and

$$\mathrm{D}_x^2 f\cdot h=-p^6e^{\theta}\left[(1+be^{2\theta})+\frac{4(16b-1)}{f^2}e^{\theta}(1-be^{2\theta})^2\right].$$

Then, using Eq. (49) once more with $F=80\mathrm{D}_t^2+20\mathrm{D}_x^3\mathrm{D}_t-\mathrm{D}_x^6$, Eq. (41a) becomes

$$\{[F(\mathbf{p})+15(4\omega p^3-p^6)](1+be^{2\theta})+bF(2\mathbf{p})e^{\theta}\}f^2$$
$$+60p^3[4(4b-1)\omega-(16b-1)p^3]e^{\theta}(1-be^{2\theta})^2=0.$$

But, bearing in mind the form of f, Eq. (47), we must have

$$F(\mathbf{p})+15(4\omega p^3-p^6)=0,\quad F(2\mathbf{p})=0,\quad 4(4b-1)\omega-(16b-1)p^3=0.$$

Substituting the expression for F, the first and second equations both yield the dispersion relation (44). The last equation determines the constant b as

$$b=\frac{1}{16}\left(\frac{4\omega-p^3}{\omega-p^3}\right), \tag{52}$$

and completes the derivation of the solitary-wave solution of the bKK Eq. (16). And now we have a surprise: The parameter b depends on the dispersion relation ω and, therefore, on the direction of travel! This is quite different from the result for the bidirectional SK Eq. (12), which has $b=1/4$ independent of the direction of propagation. Before we go on to consider the consequences for the solitary wave itself, it will pay us to take a closer look at the expression (52).

Now, using the dispersion relation (44), one easily shows that $b>0$ for all real $p\neq 0$. To emphasize this, we write $b=\frac{1}{16}a^2$ where

$$a^2=\frac{4\omega-p^3}{\omega-p^3},\quad a>0. \tag{53}$$

The solitary wave of the bKK Eq. (16) that is generated by f, Eq. (47), is therefore,

$$u(x,t)=-\partial_x^2\ln f(x,t)=-\partial_x^2\ln(1+e^{\theta}+\tfrac{1}{16}a^2e^{2\theta}),$$

which may be written

$$u(x,t)=-\partial_x^2\ln(a\cosh\theta+2)=-ap^2\frac{a+2\cosh\theta}{(a\cosh\theta+2)^2}. \tag{54}$$

As far as we are aware, this solution was not previously known (although it bears comparison with the anomalous solitary wave of its unidirectional cousin, the KK Eq. (4)[27,32]). To pin down the directional dependence of the solitary wave (54), we first solve the dispersion equation (44); this has the two real roots

$$\omega = -\Omega_{\pm} p^3, \quad \Omega_{\pm} = \frac{1}{2}\left(1 \pm \frac{3}{\sqrt{5}}\right). \tag{55}$$

Substituting for ω in (53) and simplifying, we get

$$a(\Omega_+) = \tfrac{1}{2}(\sqrt{5}+1), \quad a(\Omega_-) = \tfrac{1}{2}(\sqrt{5}-1). \tag{56}$$

The parameter a plays a crucial rôle in distinguishing the left- and right-running solitary waves; before we examine this in greater detail, we wish to make one or two more general observations. Evidently, the bKK solitary wave (54) has a symmetrical profile that decays rapidly to zero, but not as fast as the sech^2 solitary wave (45) of the companion Ramani Eq. (12). Further, it is clear that $u(x,t)$ is invariant under the parity transformation $p \to -p$ and we may, therefore, take $p > 0$ in what follows, without loss of generality.

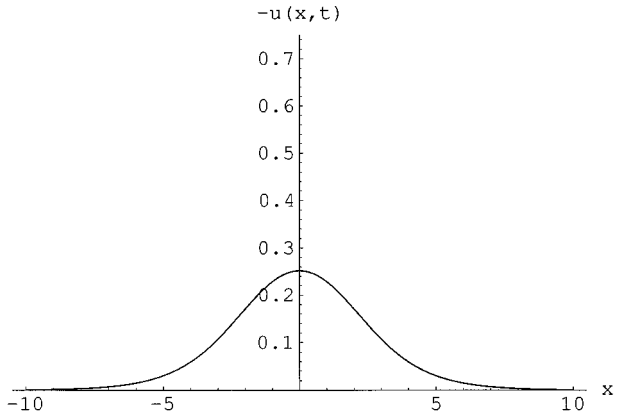
Yet the most striking feature of the bKK solitary wave is that *its shape depends on the direction of propagation*, a property that we have not come across before. The rightward travelling wave is parameterized by Ω_+ in Eqs. (55) and (56). In this case, the solitary wave (54) is a single bell-shaped hump which propagates in the positive x direction with speed $c = \Omega_+ p^2$ and amplitude $A_+ = 1/\sqrt{5}\, p^2$. Figure 1 shows three typical solitary waves with wave numbers $p = 0.75$, 1, 1.25 [where in all figures we plot the physical wave $-u(x,t)$ in its rest frame]. They exhibit the characteristic soliton properties whereby taller waves are narrower and travel faster than short, fat waves.

The left-going solitary wave is given by taking the negative parameter Ω_- in Eq. (55). And now we have another surprise: Its wave profile is strikingly different to that of the right-going solitary wave, it being comprised of two symmetrically positioned peaks! Figure 2 shows three of these double-humped solitary waves which, typically, increase in amplitude as the wavelength shortens and speed $c = |\Omega_-| p^2$ increases. The shape of this twin-peaked solitary wave merits further scrutiny. Its amplitude

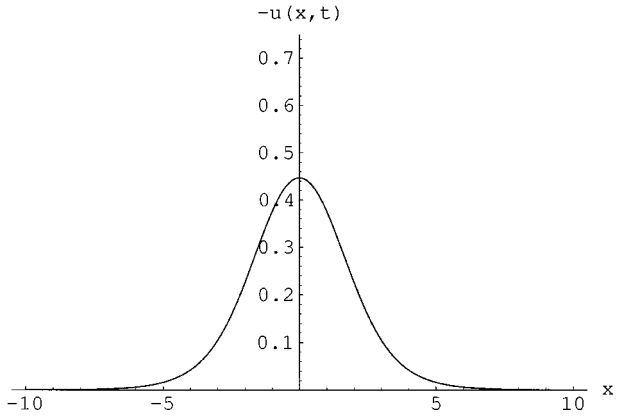
$$A_- = \left(\frac{5-\sqrt{5}}{10}\right) p^2 = a(\Omega_-) A_+ ,$$

is significantly smaller than the amplitude of its right-moving counterpart. This is clearly illustrated in Figs. 1 and 2 where, for the purpose of comparison, we have chosen the same wave numbers for left- and right-going waves. More precisely, for any prescribed wave number p, the amplitude A_- is a *fixed* fraction $a(\Omega_-) \approx 0.618$ of the amplitude A_+. This should not surprise us: both solitary waves transport the same ''mass'' $(= 2p)$, but for the left-traveling wave it is distributed equally over the two humps. Also, the trough that is formed by the two peaks is relatively shallow and, significantly, *never vanishes* even in the long wavelength limit $(p \to 0)$. In fact, one can easily show that the depth of the trough is a constant proportion (≈ 0.146) of the wave amplitude A_- for all wave numbers p.

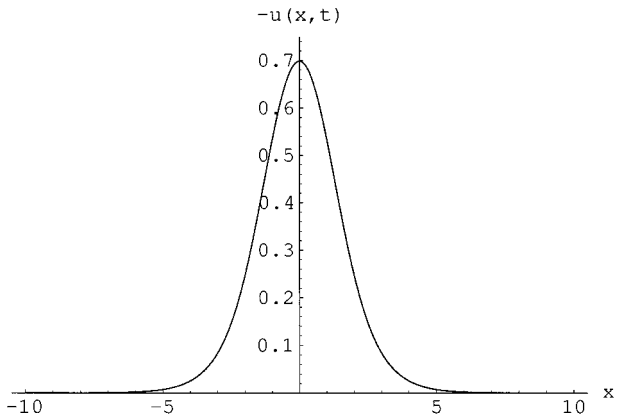
We mention that a solitary wave with a similar double-hump profile has been reported by Sasa and Satsuma[41] for a higher-order nonlinear Schrödinger equation. However, this NEE describes *uni*directional propagation, and its solitary wave possesses quite different properties; most notably, this twin-peaked wave can be reduced to a single-hump (sech) profile in a suitable limit. Contrast this with the bKK solitary wave (54) whose profile changes from a double to a single hump simply by switching direction from left to right (and vice versa). This type of *directionally dependent solitary wave* is quite unusual and, as far as we know, has not been reported before now. Moreover, this remarkable property has an important consequence: According to our strict



(a)



(b)



(c)

FIG. 1. The right-traveling single-humped solitary wave of the bKK equation: (a) $p=0.75$, (b) $p=1$, and (c) $p=1.25$.

definition, the bidirectional Kaup–Kupershmidt Eq. (16) cannot be *the* Boussinesq version of the Kaup–Kupershmidt Eq. (4). Similarly, Ramani's equation (12) is not the Boussinesq counterpart of the SK Eq. (3), even though the solitary wave in this case has the same profile irrespective of its direction of propagation. Before we proceed to verify these assertions in the next section, a last remark is in order. The reason for solving the bilinear form (41) instead of (42) is, with hindsight, now clear. To generate the solitary wave of Eq. (42) would require the ansatz

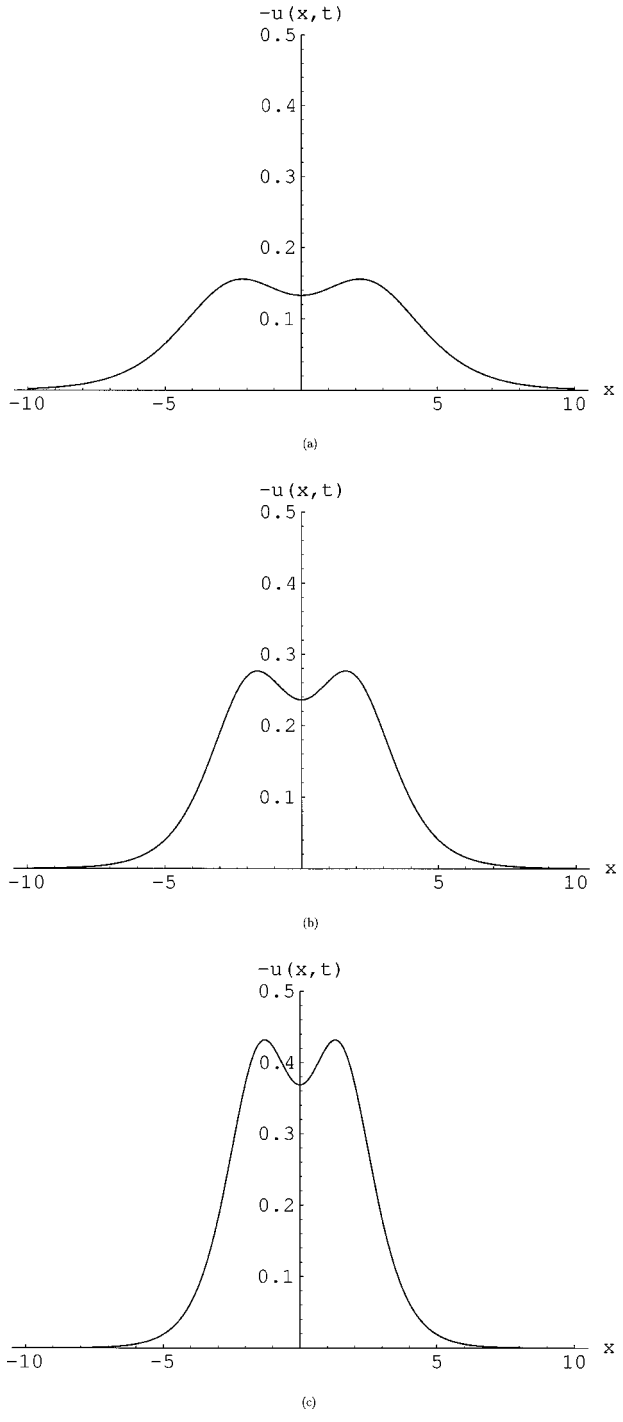


FIG. 2. The left-traveling double-humped solitary wave of the bKK equation: (a) $p=0.75$, (b) $p=1$, and (c) $p=1.25$.

$f=(1+e^{\theta}+be^{2\theta})^{1/2}$; but this form of f cannot be easily handled within the bilinear formalism, whether expressed in this way or otherwise formulated as an *infinite* series in e^{θ}.

V. UNIDIRECTIONAL APPROXIMATIONS

We stated earlier that the Boussinesq Eq. (2) may considered the bidirectional equivalent of the KdV Eq. (1): We shall now make this equivalence more precise. Let us introduce new far-field variables

$$\xi=\epsilon(x\pm t),\quad \tau=\tfrac{1}{2}\epsilon^3 t,\quad u=\epsilon^2 U(\xi,\tau),$$

where $\epsilon>0$ is a constant parameter. The choice of the characteristic variable ξ restricts wave propagation to one direction only: To the left $(+)$ or right $(-)$. Then, to leading order as $\epsilon\to 0$ with $U=O(1)$, the Boussinesq Eq. (2) transforms to the KdV equation

$$\pm U_\tau+3(U^2)_\xi-U_{3\xi}=0,$$

in *both* the left- and right-running limits. Thus, the Boussinesq equation subsumes the KdV equation in the unidirectional (long wave) approximation. Similarly, one easily shows that the solitary wave and multisoliton solutions of the Boussinesq equation transform to their KdV counterparts travelling to the left $(+)$ or right $(-)$. Hence, and not unexpectedly, Eq. (2) does satisfy the two requirements that characterize this equation as the *Boussinesq* form of the KdV Eq. (1).

We repeat this procedure with a view to deriving unidirectional approximations for both Ramani and bKK equations. By writing Eqs. (12) and (16) in the form

$$5\partial_x^{-1}u_{tt}+5u_{xxt}-15uu_t-15u_x\partial_x^{-1}u_t-45u^2u_x+15\rho u_x u_{xx}+15uu_{3x}-u_{5x}=0, \tag{57}$$

we can deal with both equations simultaneously. With $\rho=1$ we obtain Ramani's Eq. (12), while $\rho=5/2$ yields the bKK Eq. (16). Incidentally, written in this way, Eq. (57) also serves to emphasize the close connection between these two bidirectional equations. As before, we introduce a unidirectional transformation

$$\xi=\epsilon x+\kappa t,\quad \tau=\delta t,\quad u=\beta U(\xi,\tau),\quad (\delta,\epsilon>0), \tag{58}$$

that allows us to track left- or right-running waves according to the sign of κ. After transforming the variables in Eq. (57), and simplifying, we get

$$\begin{aligned}5\kappa^2U_\xi+10\kappa\delta U_\tau+5\delta^2\partial_\xi^{-1}U_{\tau\tau}+\epsilon\kappa(5\epsilon^2U_{3\xi}-30\beta UU_\xi)+\epsilon\delta(5\epsilon^2U_{\xi\xi\tau}-15\beta UU_\tau\\ -15\beta U_\xi\partial_\xi^{-1}U_\tau)-\epsilon^2(45\beta^2U^2U_\xi-15\beta\epsilon^2\rho U_\xi U_{\xi\xi}-15\beta\epsilon^2UU_{3\xi}+\epsilon^4U_{5\xi})=0.\end{aligned}$$

But if we are to obtain the SK Eq. (3) and KK Eq. (4) as the unidirectional approximations for the Ramani and bKK equations, respectively, then we must take $\beta=\epsilon^2$ and $\kappa\delta=O(\epsilon^6)$. We now have

$$\begin{aligned}\epsilon^6(\zeta U_\tau-45U^2U_\xi+15\rho U_\xi U_{\xi\xi}+15UU_{4\xi}-U_{5\xi})+5\kappa^2U_\xi+5\delta^2\partial_\xi^{-1}U_{\tau\tau}\\ +\epsilon^3\kappa(5U_{3\xi}-30UU_\xi)+\epsilon^3\delta(5U_{\xi\xi\tau}-15UU_\tau-15U_\xi\partial_\xi^{-1}U_\tau)=0,\end{aligned}$$

where the constant ζ has the sign of κ. Evidently, we will obtain the SK and KK equations to leading order as $\epsilon\to 0$ only if the remaining terms have order greater than ϵ^6. But this would require the order of both κ and δ to exceed ϵ^3 which contradicts the requirement that $\kappa\delta=O(\epsilon^6)$.

In other words, we have shown that neither the SK nor KK equation can be recovered from their bidirectional cousins in a suitable unidirectional approximation. This justifies our contention that, contrary to appearances, the Ramani Eq. (12) and bKK Eq. (16) are not *the* Boussinesq forms of the SK Eq. (3) and KK Eq. (4), respectively. This conclusion is borne out when we attempt to retrieve the solitary waves of the SK and KK equations from their bidirectional counterparts Eqs. (45) and (54), respectively. For, under the transformation (58), there is no way of deriving the correct dispersion relation $(\omega=-p^5)$ from the bidirectional counterpart (44) in the unidirectional limit $(\epsilon\to 0)$.

VI. CONSERVATION LAWS

One of the many remarkable properties that are deemed to characterize soliton equations is the existence of an infinite sequence of conservation laws. These are of the form

$$\frac{\partial T_n}{\partial t}+\frac{\partial X_n}{\partial x}=0, \quad n=1,2,..., \tag{59}$$

where T_n denotes the nth conserved density and X_n is the corresponding flux. Then, with suitable boundary conditions, Eq. (59) yields a corresponding sequence of integrals of motion $\int T_n dx$. Conservation laws play an important rôle in soliton theory. It is often the case that the first few conservation laws of a NEE have a physical interpretation. They can also be used to investigate both quantative and qualitative aspects of solutions, particularly soliton solutions.[5,18,22,38,42–44] Not least, the possession of infinitely many conserved densities may predict, or at least confirm, the integrability of an equation.

The conservation laws of the SK Eq. (3) have been obtained in one way or another by a number of authors,[26,27,36,37,45] while those of the KK Eq. (4) were reported in Refs. 27 and 45. Both sequences have the unusual property whereby every third conserved density is missing; specifically T_2, T_5, T_8,... are absent. In this section, we show that, not surprisingly, this same lacunary pattern is shared by their bidirectional cousins the Ramani Eq. (12) and bKK Eq. (16). We present recursion formulas for generating an infinite sequence of conservation laws for each equation, and formulate the first few conserved densities and associated flux explicitly. We should add that Hu[37] has investigated the conservation laws of Ramani's equation, but his results contain a slight error. The author gives only the first two nontrivial conserved densities [Eqs. (61) and (62) below] and no recursion formula, and so missed the lacunary behavior. On the other hand, the results given here for the bKK equation are, we believe, entirely new.

We begin by adopting an elementary approach; i.e., we search for conservation laws of the Ramani equation by just manipulating Eq. (12). This has the advantage of identifying the appropriate variables in which to express the conserved densities, and highlights the more complicated scenario that obtains for bidirectional NEEs over unidirectional equations. To this end, we rewrite Eq. (12) as the system [cf. the Boussinesq Eq. (2)[19,22]]

$$u_t+v_x=0, \tag{60a}$$

$$v_t+(3u^3-3uv-3uu_{xx}+v_{xx}+\tfrac{1}{5}u_{4x})_x=0, \tag{60b}$$

where the auxiliary field variable $v(x,t)$ is effectively defined by Eq. (60a) as $v=-\partial_x^{-1}u_t$. Both these equations are in the conservation form (59) and so, by inspection, we deduce the first two conserved densities and associated flux of Ramani's equation

$$T_1=u, \quad X_1=v, \tag{61}$$

$$T_2=v, \quad X_2=3u^3-3uv-3uu_{xx}+v_{xx}+\tfrac{1}{5}u_{4x}. \tag{62}$$

They have ranks $R(T_1)=1$ and $R(T_2)=2$, and may be identified with the conservation of mass and momentum, respectively. [Note that the corresponding flux has rank $R(X_n)=n+1$]. Clearly, little further progress is possible using this direct approach: Indeed, we anticipate that T_3 will be missing and there is no obvious way to formulate T_4.

Various techniques are available for obtaining an infinity of conservation laws for completely integrable equations. We shall employ the systematic method that was developed by Satsuma[46,47] to derive the conserved densities of a NEE from its Bäcklund transformation (BT). This procedure was used by Hu[37] and we shall broadly follow his development for the Ramani equation.

Following the standard procedure,[36] we introduce the potential $w(x,t)$ defined by

$$u=-2w_x, \tag{63}$$

and consider the BT equation for the Ramani Eq. (12)

$$(w'-w)_t-[(w'-w)_{xx}+3(w'-w)(w'+w)_x+(w'-w)^3]_x=0, \tag{64}$$

where w' is a second solution. This is the corrected version of the BT that was reported by Hu.[37] The lengthy derivation of Eq. (64), along with the more complex second half of the BT (which we will not need), can be found in Ref. 37. It is a complicating feature of bidirectional NEEs that the BT does not separate neatly into spatial and temporal equations (unlike their unidirectional counterparts): Both parts of the BT contain time derivatives. Nonetheless, it is worth noting that Eq. (64) has the form of a conservation law in which the flux is precisely the *spatial* part of the BT of its unidirectional cousin, the SK Eq. (3). In this sense, we may regard Eq. (64) as the ''spatial'' half of the BT of Ramani's equation. We shall find that the BT for the bKK Eq. (16) has exactly the same type of structure.

To proceed, we introduce the expansion[36]

$$w'-w=k+\sum_{n=1}^{\infty}\frac{J^{(n)}}{k^n}, \quad (k>0), \tag{65}$$

where $J^{(n)}(n=1,2,...)$ is the sequence of ''generalized'' conserved densities (that also includes any trivial ones). We now substitute Eq. (65) into Eq. (64) and equate coefficients of powers k^{-n} to zero. Then, using Eqs. (60a) and (63), we get for the first four $J^{(n)}$'s

$$\begin{aligned} J^{(1)}&=u,\\ J^{(2)}&=-J_x^{(1)}=-u_x,\\ J^{(3)}&=\tfrac{1}{3}\partial_x^{-1}J_t^{(1)}+\tfrac{2}{3}u_{xx}=-\tfrac{1}{3}(v-2u_{xx}),\\ J^{(4)}&=\tfrac{1}{3}\partial_x^{-1}J_t^{(2)}+\tfrac{1}{3}v_x-\tfrac{1}{3}u_{3x}=\tfrac{1}{3}(2v-u_{xx})_x, \end{aligned} \tag{66}$$

and the general recursion relation

$$\begin{aligned} J^{(n+2)}=&\tfrac{1}{3}\partial_x^{-1}J_t^{(n)}-\tfrac{1}{3}J_{xx}^{(n)}-J_x^{(n+1)}+uJ^{(n)}-\sum_{m=1}^{n-1}J^{(n-m)}J_x^{(m)}\\ &-\sum_{m=1}^{n}J^{(n-m+1)}J^{(m)}-\tfrac{1}{3}\sum_{m=1}^{n-2}\sum_{p=1}^{n-m-1}j^{(n-m-p)}J^{(m)}J^{(p)}, \end{aligned} \tag{67}$$

for $n\geqslant 3$.

Now, $J^{(n)}$ has rank $R(J^{(n)})=\frac{1}{2}(n+1)$. When n is even, the generalized density $J^{(n)}$ has fractional rank and is trivial (i.e., it can be expressed as an x-derivative). The conserved densities $T_n(n=1,2,...)$ are generated by the odd $J^{(2n-1)}$ and have integer rank $R(T_n)=n$. Thus, from Eq. (66) we see that $J^{(1)}$, $J^{(3)}$ reproduce the first two conserved densities T_1, T_2, Eqs. (61)–(62), whereas $J^{(2)}$, $J^{(4)}$ give trivial results. To obtain T_3 we set $n=3$ in the recursion formula (67): This yields

$$J^{(5)}=-\tfrac{2}{3}(v-\tfrac{1}{5}u_{xx})_{xx},$$

which shows that T_3 is trivial. Proceeding in the same way, we deduce the conserved densities of ranks 4–6

$$T_4=v^2-3u^2v-3uu_x^2-2u_xv_x-\tfrac{4}{5}u_{xx}^2, \tag{68}$$

$$T_5=9u^5+10uv^2+90u^2u_x^2-5vu_x^2+10uu_xv_x+25uu_{xx}^2+5v_x^2+2u_{xx}v_{xx}+2u_{3x}^2, \tag{69}$$

$$T_6=0. \tag{70}$$

As expected, the sequence of conservation laws of Ramani's equation exhibits the same lacunary behavior as the SK equation, with every third one missing. However, we note that the SK Eq. (3) has its densities of ranks 2, 5, 8,... absent, whereas the bSK Eq. (12) has those of ranks 3, 6, 9,... missing! Hu[37] only reported $J^{(1)}$, $J^{(2)}$, $J^{(3)}$, so was unable to spot this lacunary pattern.

The recursion relation (67) for Ramani's equation was not previously known and merits further scrutiny. In order to compute the next generalized density $J^{(n+2)}$ one certainly needs to know all $n+1$ densities of lower rank. But there is a further consideration: Unfortunately, the first term on the right-hand side of (67) involves $\partial_x^{-1}J_t^{(n)}$ which can only be integrated *directly* for those $J^{(n)}$ which are trivial. For any $J^{(n)}$ which corresponds to a nontrivial conserved density, T_m say, one is faced with evaluating $\partial_x^{-1}(T_m)_t$ and this evidently requires knowledge of the associated flux X_m. This underlines the extra complexity that is involved in deriving the conservation laws of a bidirectional equation as compared with its unidirectional counterpart (where knowledge of the flux is not required; cf. the SK equation[36]). The expressions for the flux become increasingly intricate and unwieldy, and we have, therefore, chosen to omit X_4 and X_5 here; they are listed in Appendix B, Eqs. (B1) and (B2).

We can repeat the entire procedure to obtain the sequence of conservation laws of the bidirectional KK equation. The ''spatial'' part of the BT for the bKK Eq. (16) is

$$(w'-w)_t-[(w'-w)_{xx}+3(w'-w)(w'+w)_x+(w'-w)^3+3w_{xx}]_x=0. \tag{71}$$

Notice that this is again in conservation form with the flux now given by the spatial half of the BT for the KK Eq. (4).[48] Substituting the series (65) into (71), and collecting powers of k, we deduce

$$J^{(1)}=u, \quad J^{(2)}=-\tfrac{1}{2}u_x,$$

$$J^{(3)}=-\tfrac{1}{3}(v-\tfrac{1}{2}u_{xx}), \quad J^{(4)}=\tfrac{1}{2}(v-\tfrac{1}{2}u^2)_x,$$

where $v=-\partial_x^{-1}u_t$, as before. The BT (71) differs from Eq. (64) by the single extra term $3w_{xx}=-\frac{3}{2}u_x$ which contributes to the term of $O(k^0)$. It follows that the recursion relation for the bKK Eq. (16) is identical to the recursion formula (67) obtained above for Ramani's Eq. (12). The additional term kicks in at $J^{(2)}$ and we get the first six conservation laws for the bKK equation

$$\begin{gathered}
T_1=u, \quad X_1=v,\\
T_2=v, \quad X_2=3u^3-3uv-\tfrac{9}{4}u_x^2-3uu_{xx}+v_{xx}+\tfrac{1}{5}u_{4x},\\
T_3=0, \quad X_3=0,\\
T_4=v^2-3u^2v-\tfrac{3}{4}uu_x^2-\tfrac{1}{2}u_xv_x-\tfrac{1}{20}u_{xx}^2,\\
T_5=36u^5+40uv^2+180u^2u_x^2+10vu_x^2-20uu_xv_x+25uu_{xx}^2+10v_x^2-2u_{xx}v_{xx}+u_{3x}^2,\\
T_6=0, \quad X_6=0.
\end{gathered} \tag{72}$$

The flux X_4 and X_5 are given in Appendix C, Eqs. (C1) and (C2). The lacunary pattern is again evident with every third conserved density absent: Those of ranks 3, 6, 9,... are missing whereas its undirectional cousin the KK Eq. (4) has ranks 2, 5, 8,... missing.

VII. SUMMARY AND PROSPECTUS

A method has been described for finding bidirectional versions of unidirectional nonlinear evolution equations. Specifically, we are able to construct a Lax pair for the bidirectional NEE from the Lax pair of its unidirectional cousin by using a novel exchange procedure (Sec. II). This

has the advantage of assuring that the ''new'' equation is completely integrable. In this study, the method was used to obtain bidirectional versions of the well-known Sawada–Kotera equation (3) and Kaup–Kupershmidt equation (4). We make no claim to originality of these fifth-order Bousinesq-type NEEs. Indeed, we identified the bidirectional counterpart of the SK equation, Eq. (12), with the familiar Ramani equation through its bilinear form (31). Similarly, the bidirectional KK equation (16) that is constructed here appears in the Jimbo–Miwa classification[23] as a reduction of the CKP hierarchy.[49] Yet very little is known about the bKK equation; to the best of our knowledge, its Lax pair (15) and bilinear forms (41) and (42) are reported here for the first time.

The close resemblance between the bSK-Ramani Eq. (12) and the bKK Eq. (16) belies the fact that they are fundamentally different integrable equations. Nevertheless, we were able to take advantage of their duality to derive the anomalous solitary wave of the bKK equation. This solitary wave, Eq. (54), has the remarkable property that its shape depends on the direction of propagation. This type of *directionally dependent solitary wave* is quite unusual in soliton theory and, as far as we know, has not been observed till now. Moreover, this special feature of the bKK equation distinguishes it from the bSK–Ramani equation whose solitary wave, Eq. (45), has the *same* classical bell-shaped profile whether traveling to the left or right.

Though they admit solutions that can propagate in two opposite directions, the bSK–Ramani and bKK equations are *not* the bidirectional equivalents of the SK and KK equations, respectively. We found that neither the bSK–Ramani nor bKK equation could be reduced to its unidirectional counterpart in a suitable unidirectional (far-field) approximation. In other words, we can assert that the bidirectional NEEs (12) and (16) constructed here are not of truly Boussinesq form (a distinguishing feature that was made precise in Sec. I). This justified our usage of the *small* ''b'' in the designations bSK and bKK for these bidirectional NEEs.

Finally, we presented Bäcklund transformations for the bSK–Ramani and bKK equations [the first of these, Eq. (64), being a corrected version of the BT given by Hu[37]]. Using these BTs we were able to obtain recursion formulas for generating an infinite sequence of conservation laws for both equations. The first six conserved densities of each equation—and their associated flux—were formulated explicitly and found to possess the same lacunary pattern as their unidirectional cousins; namely, that every third conservation law in the sequence is missing.

Naturally, our study raises further questions which deserve investigation. We shall consider these briefly, and offer some thoughts on future work. The most obvious unanswered question concerns the derivation of the multisoliton solutions of the bKK Eq. (16). Of course, for the related bSK–Ramani Eq. (12) we are free to solve the simpler bilinear form (31)—rather than the coupled system (30a) and (30b)—for which the N-soliton solution is given by Hirota's celebrated generic formula.[24] For the bKK equation, however, no reduction to a single bilinear equation is possible and we must, therefore, solve one or other of the two coupled bilinear forms (41) or (42). This is an altogether more difficult problem: Both bilinear forms involve three field variables and, more to the point, there is no prescribed ansatz akin to Hirota's regular N-soliton for solving Eqs. (41) or (42).

Nevertheless, let us consider this problem in the light of our successful derivation of the bKK solitary wave (in Sec. IV). To generate the regular two-soliton of the bSK–Ramani equation, we take[24]

$$f(x,t)=1+e^{\theta_1}+e^{\theta_2}+A_{12}e^{\theta_1+\theta_2},\quad \theta_i=p_ix+\omega_it+\eta_i,\quad i=1,2, \tag{73}$$

and solve the Ramani bilinear form (31) for the dispersion relations $\omega_i(p_i)$ [cf. Eq. (44)] and the interaction coefficient A_{12}. [The calculations, which make use of Eq. (48), are quite routine and we omit the details here.] Now, the analysis in Sec. IV shows that the equivalent two-soliton solution of the alternative coupled bilinear form (30a) and (30b) is given by squaring (73); i.e., we set

$$\begin{aligned} f(x,t)=1&+2e^{\theta_1}+2e^{\theta_2}+e^{2\theta_1}+e^{2\theta_2}+2(A_{12}+1)e^{\theta_1+\theta_2}\\ &+2A_{12}(e^{2\theta_1+\theta_2}+e^{\theta_1+2\theta_2})+A_{12}^2e^{2(\theta_1+\theta_2)}. \end{aligned} \tag{74}$$

But, if we exploit the duality between the bSK–Ramani and bKK equations through their bilinear forms (30) and (41) (just as we did for the solitary wave), then we can conjecture that the structure of the two-soliton solution of the bKK equation (41) will mimic (74). Clearly, we can apply this same reasoning to the *N*-soliton solution: This suggests a possible strategy for deriving the *N*-soliton by the bilinear transform method. As a first step, and to confirm the efficacy of this strategy, we were able to deduce the directionally dependent solitary wave of the bKK equation. Furthermore, we would expect the multisoliton solutions to have this same directional dependence: This holds out the prospect of studying multiple head-on collisions between single- and double-humped solitary waves.

A last remark on the soliton solutions is germane. We notice that, on setting $\theta_1=\theta_2$ in Eq. (73), we get the correct form of the anomalous solitary wave (47) of the bKK equation (modulo a phase shift $\eta\rightarrow\eta-\ln 2$). Similarly, if we were to put $\theta_1=\theta_3$ and $\theta_2=\theta_4$ in the regular four-soliton solution,[24] the resulting expression would give the form of the putative two-soliton solution of the bKK equation [cf. Eq. (74)]. Put another way, we may consider the *two*-soliton solution of the bKK equation to be a degenerate regular *four*-soliton solution. By the same token, the *N*-soliton would be a degenerate regular $2N$-soliton (obtained by setting the phase variables equal in pairs). This interpretation accords with that given by Date *et al.*[49] who described the *N*-soliton of those equations in the CKP hierarchy in a similar manner (albeit *implicitly* and from an entirely different perspective). For our own part, the anomalous character of the bKK solitons (like those of its close relative the KK equation[32,33]) arises quite naturally within the bilinear formalism as a *squared* regular *N*-soliton. This canonical interpretation of the *N*-soliton provides a basis on which one might construct these somewhat complicated solutions explicitly and work on this is currently in progress.

In Ref. 29, Fordy and Gibbons (and, independently, Hirota and Ramani[50]) established the deep relation between the SK Eq. (3) and KK Eq. (4) by obtaining Miura-type transformations linking them to an ''intermediate'' fifth-order NEE (the Fordy–Gibbons equation). The question then arises as to whether there exist similar transformations connecting their bidirectional cousins the bSK–Ramani Eq. (12) and bKK Eq. (16). We have attempted but failed to find Miura transformations relating these equations; but this should not be taken to imply that no comparable link exists. Indeed, we have already exploited their close relation in deriving the bKK solitary wave. This strongly suggests that it should be possible to construct a Bäcklund transformation between Eqs. (12) and (16), either linking the equations directly or via some intermediary NEE (which, presumably, would be a bidirectional counterpart to the unidirectional Fordy–Gibbons equation). These are open questions worthy of attention.

Lastly, but certainly not least, we have concluded that the bSK–Ramani Eq. (12) and bKK Eq. (16), are not truly *Boussinesq* in character. This begs the obvious question: What, then, are the Boussinesq versions of the SK Eq. (3) and KK Eq. (4)? We can be quite confident that they will belong to the generic BKP and CKP hierarchies of NEEs,[23,49] respectively. But is it possible to construct these Boussinesq equations specifically, along with their Lax pairs, by means of the exchange procedure described here? These, and other questions concerning their properties, merit investigation.

APPENDIX A: BILINEAR FORMULAS

If $u=\partial_x^2\ln f$ and $u_{nx}=\partial^n u/\partial_x^n$, then

$$\mathrm{D}_x\mathrm{D}_t f\cdot f/f^2=2(\ln f)_{xt}, \tag{A1}$$

$$\mathrm{D}_x^2 f\cdot f/f^2=2u, \tag{A2}$$

$$\mathrm{D}_x^3\mathrm{D}_t f\cdot f/f^2 = 2u_{xt} + 12u(\ln f)_{xt}, \tag{A3}$$

$$\mathrm{D}_x^4 f\cdot f/f^2 = 12u^2 + 2u_{xx}, \tag{A4}$$

$$\mathrm{D}_x^6 f\cdot f/f^2 = 120u^3 + 60uu_{xx} + 2u_{4x}. \tag{A5}$$

For arbitrary functions f and g

$$\frac{\mathrm{D}_x\mathrm{D}_t f\cdot g}{f^2} = \frac{g}{f}\left(\frac{\mathrm{D}_x\mathrm{D}_t f\cdot f}{f^2}\right) + \frac{\partial^2}{\partial x\partial t}\left(\frac{g}{f}\right), \tag{A6}$$

$$\frac{\mathrm{D}_x^2 f\cdot g}{f^2} = \frac{g}{f}\left(\frac{\mathrm{D}_x^2 f\cdot f}{f^2}\right) + \frac{\partial^2}{\partial x^2}\left(\frac{g}{f}\right), \tag{A7}$$

$$\frac{\mathrm{D}_x^4 f\cdot g}{f^2} = \frac{g}{f}\left(\frac{\mathrm{D}_x^4 f\cdot f}{f^2}\right) + 6\left(\frac{\mathrm{D}_x^2 f\cdot f}{f^2}\right)\left(\frac{\mathrm{D}_x^2 f\cdot g}{f^2}\right) - 6\frac{g}{f}\left(\frac{\mathrm{D}_x^2 f\cdot f}{f^2}\right)^2 + \frac{\partial^4}{\partial x^4}\left(\frac{g}{f}\right), \tag{A8}$$

$$\mathrm{D}_x\mathrm{D}_t\left(f\cdot\frac{g}{f}\right) = \frac{1}{f^2}(\mathrm{D}_x\mathrm{D}_t f^2\cdot g - g\mathrm{D}_x\mathrm{D}_t f\cdot f), \tag{A9}$$

$$\mathrm{D}_x^2\left(f\cdot\frac{g}{f}\right) = \frac{1}{f^2}(\mathrm{D}_x^2 f^2\cdot g - g\mathrm{D}_x^2 f\cdot f). \tag{A10}$$

APPENDIX B: THE RAMANI EQUATION: THE FLUX X_4 AND X_5

$$\begin{aligned}X_4 = &-\tfrac{27}{5}u^5 + 9u^3v - 6uv^2 - 18u^2u_x^2 + 3vu_x^2 + 6uu_xv_x - 2v_x^2 + 9u^3u_{xx} - 6uvu_{xx} + \tfrac{24}{5}u_x^2u_{xx}\\ &- \tfrac{18}{5}uu_{xx}^2 - 3u^2v_{xx} + 2vv_{xx} + \tfrac{2}{5}u_{xx}v_{xx} + \tfrac{36}{5}uu_xu_{3x} - \tfrac{2}{5}v_xu_{3x} - \tfrac{1}{5}u_{3x}^2 - 2u_xv_{3x}\\ &- \tfrac{3}{5}u^2u_{4x} + \tfrac{2}{5}vu_{4x} + \tfrac{2}{5}u_{xx}u_{4x} - \tfrac{2}{5}u_xu_{5x},\end{aligned} \tag{B1}$$

$$\begin{aligned}X_5 = &\,45u^4v - 30u^2v^2 + \tfrac{10}{3}v^3 + 45u^3u_x^2 + 15uvu_x^2 + 9u_x^4 + 150u^2u_xv_x - 30vu_xv_x - 20uv_x^2\\ &- 60u^2vu_{xx} + 15uu_x^2u_{xx} - 22u_xv_xu_{xx} + 24u^2u_{xx}^2 - vu_{xx}^2 - \tfrac{20}{3}u_{xx}^3 + 20uvv_{xx} - 15u_x^2v_{xx}\\ &+ 34uu_{xx}v_{xx} - 4v_{xx}^2 - 30u^2u_xu_{3x} - 4vu_xu_{3x} - 34uv_xu_{3x} - 4u_xu_{xx}u_{3x} + 4uu_{3x}^2 + 10uu_xv_{3x}\\ &+ 10v_xv_{3x} + 2u_{3x}v_{3x} + 4uvu_{4x} - 3u_x^2u_{4x} - 8uu_{xx}u_{4x} - 2v_{xx}u_{4x} + \tfrac{1}{5}u_{4x}^2 + 2u_{xx}v_{4x}\\ &+ 2uu_xu_{5x} + 2v_xu_{5x} - \tfrac{2}{5}u_{3x}u_{5x} + \tfrac{2}{5}u_{xx}u_{6x}.\end{aligned} \tag{B2}$$

APPENDIX C: THE bKK EQUATION: THE FLUX X_4 AND X_5

$$\begin{aligned}X_4 = &-\tfrac{27}{5}u^5 + 9u^3v - 6uv^2 - \tfrac{9}{2}u^2u_x^2 - \tfrac{15}{4}vu_x^2 + 6uu_xv_x - \tfrac{5}{4}v_x^2 + 9u^3u_{xx} - 6uvu_{xx} + \tfrac{51}{20}u_x^2u_{xx}\\ &- \tfrac{27}{20}uu_{xx}^2 - 3u^2v_{xx} + 2vv_{xx} + \tfrac{2}{5}u_{xx}v_{xx} + \tfrac{27}{10}uu_xu_{3x} - \tfrac{2}{5}v_xu_{3x} - \tfrac{1}{20}u_{3x}^2 - \tfrac{1}{2}u_xv_{3x}\\ &- \tfrac{3}{5}u^2u_{4x} + \tfrac{2}{5}vu_{4x} + \tfrac{1}{10}u_{xx}u_{4x} - \tfrac{1}{10}u_xu_{5x},\end{aligned} \tag{C1}$$

$$\begin{aligned}X_5 = &\,180u^4v - 120u^2v^2 + \tfrac{40}{3}v^3 - 90u^3u_x^2 - 30uvu_x^2 - \tfrac{171}{4}u_x^4 + 420u^2u_xv_x - 60vu_xv_x - 80uv_x^2\\ &- 240u^2vu_{xx} + 60uu_x^2u_{xx} - 118u_xv_xu_{xx} - 39u^2u_{xx}^2 + 11vu_{xx}^2 + \tfrac{46}{3}u_{xx}^3 + 80uvv_{xx} + 30u_x^2v_{xx}\\ &+ 76uu_{xx}v_{xx} - 11v_{xx}^2 + 60u^2u_xu_{3x} - 16vu_xu_{3x} - 76uv_xu_{3x} + 5u_xu_{xx}u_{3x} - 5uu_{3x}^2 - 20uu_xv_{3x}\end{aligned}$$

$$+20v_xv_{3x}+4u_{3x}v_{3x}+16uvu_{4x}+6u_x^2u_{4x}+10uu_{xx}u_{4x}-4v_{xx}u_{4x}-\tfrac{1}{5}u_{4x}^2-2u_{xx}v_{4x}$$
$$-4uu_xu_{5x}+4v_xu_{5x}+\tfrac{2}{5}u_{3x}u_{5x}-\tfrac{2}{5}u_{xx}u_{6x}. \quad \text{(C2)}$$

(Received 14 November 2000; accepted for publication 18 January 2001)

The variational principle for a thin dust shell in General Relativity is constructed. The principle is compatible with the boundary-value problem of the corresponding Euler–Lagrange equations, and leads to ''natural boundary conditions'' on the shell. These conditions and the gravitational field equations which follow from an initial variational principle, are used for elimination of the gravitational degrees of freedom. The transformation of the variational formula for spherically-symmetric systems leads to two natural variants of the effective action. One of these variants describes the shell from a stationary interior observer's point of view, another from the exterior one. The conditions of isometry of the exterior and interior faces of the shell lead to the momentum and Hamiltonian constraints. The canonical equivalence of the mentioned systems is shown in the extended phase space. Some particular cases are considered. © *2001 American Institute of Physics.*

I. INTRODUCTION

A thin spherically-symmetric dust shell is among the simplest popular models of collapsing gravitating configurations. The equations of motion of these objects are obtained in Refs. 1 and 2. The construction of a variational principle for such systems was discussed from different points of view in Refs. 3–7. There are a number of problems here, most basic of which is the dependence on the choice of the evolution parameter (internal, external, proper). The choice of time coordinate, in turn, affects the choice of a particular quantization scheme, leading, in general, to quantum theories which are not unitarily equivalent.

In most of these papers the variational principle for shells is usually constructed in a comoving frame of reference, or in one of variants of freely falling frames of reference. However, use of such frames of reference frequently leads to effects unrelated to the object under consideration. The essential physics involves a picture of a gravitational collapse from the point of view of an infinitely remote stationary observer. In quantum theory this point of view enables us to treat bound states in terms of asymptotic quantities and to build the relevant scattering theory correctly. On the other hand, to treat primordial black holes in the theory of self-gravitating shells it is convenient to take the viewpoint of a central stationary observer. In the approach related to proper time of the shell reduction of the system leads to complicated Lagrangians and Hamiltonians which creates difficulties on quantization. In particular it leads to theories with higher derivatives or to finite difference equations.

In our opinion, the choice of the exterior or interior stationary observers is most natural and corresponds to the real physics. To provide the necessary properties of invariance, specification of the canonical transformations in an extended phase space which translate the corresponding dynamical systems into one another enough. In addition the action for a shell should satisfy some natural requirements. In the absence of self-forces it should pass into the action for a geodesic motion. Further, according to the correspondence principle, at small velocities and masses of the

[a)]Electronic mail: gladush@ff.dsu.dp.ua

shell, and also in the absence of other sources of the gravitational field, we should obtain the action for a self-gravitating Newtonian shell (see Appendix C).

The natural Hamiltonian formulation of a self-gravitating shell was considered in works.[8,9] However, this formulation was not obtained by a variational procedure from some initial action containing the standard Einstein–Hilbert term. The action for such a self-gravitating spherical shell of mass m can be introduced with the help of a naive ''relativization'' of the Newtonian action. It is carried out by simple replacement of the kinetic energy $mv^2/2$ by the relativistic expression $-mc\sqrt{(1-v^2/c^2)}$ [see below Lagrangians (C17) and (4.3)]. If there is an exterior gravitational field then the kinetic and potential energy of the shell have as their general relativistic analog the geodesic Lagrangian $-mc\,{}^{(2)}ds_{\pm}/dt_{\pm}$. The subsigns ''$_{\pm}$'' correspond to exterior and interior observers. The gravitational self-action of the shell is the same for all cases, and its sign depends on whether stationary observer can exist inside and outside the shell.

The above Hamiltonian formulation for the shell, as well as the procedure of ''relativization'' follows from the Lagrange formalism of dust shells constructed in the present paper. We view the system as a compound configuration consisting of two vacuum regions with a spatially-closed boundary surface formed by the shell. The initial action we take as the sum of actions of York type for either region and the action for dust matter. For the complete action introduced in this way the variational principle is compatible with the boundary-value problem of the corresponding Euler–Lagrange equations for either region of the configuration, and leads to ''natural boundary conditions'' on the shell. The missing boundary conditions are obtained by consideration of the variations with respect to normal displacements of the shell. The obtained conditions coincide with the known Israel matching conditions at singular hypersurfaces and are considered as constraints. Together with the equations of the gravitational field they are used to eliminate of the gravitational degrees of freedom. The tangential variations of thus-obtained action with constraints lead to the known equations of motion of the Israel.[1]

The problem of the complete reduction of the action is solved for spherically-symmetric systems. By transforming the variational formula and using the constraints the obtained action is reduced to two variants of the effective action. One of these variants describes the shell from an interior stationary observer's point of view, and the other from the exterior one. Then we go over from the Lagrangian to the Hamiltonian description. The conditions of isometry of the exterior and interior sides of the shell lead to the momentum and Hamiltonian constraints. The canonical equivalence of these two variants of the description of the shells in the extended phase space indicates the existence of a ''discrete gauge'' transformation associated with the transition from the interior observer to the exterior one.

The paper is organized as follows: In Sec. II the full action is constructed for a compound, piecewise smooth Lorentz manifold with a four-dimensional spatially-closed boundary surface between two vacuum regions, corresponding to the world sheet of the shell. From here the Einstein equations for regions outside the shell and surface equations follow. Further, the action for the shell and the equations of motion are constructed.

In Sec. III spherically-symmetric relativistic dust shells are considered. The Lagrangians and Hamiltonians describing the shell from the point of view of the interior or exterior observer are obtained. Then momentum and Hamiltonian constraints are found. They emerge from independent consideration of the interior and exterior faces of the shell using the conditions of isometry of its two faces. In Sec. IV special cases of dust shells and configurations of several shells are briefly considered.

In Appendix A it is shown that the surface equations, obtained in Sec. II, reduce to the known equations for jumps of the extrinsic curvature tensor of the shell. In Appendix B we show the canonical equivalence of the actions for the dust spherically-symmetric shell written relative to the interior and exterior observers. This equivalence is thought of as operating in the extended phase space of the corresponding dynamical system. In Appendix C the action for an arbitrary nonrelativistic gravitating dust shell is constructed. The Lagrangian for the spherical gravitating nonrelativistic dust shell is found. It was deemed worthwhile to consider the nonrelativistic case because

it clarifies the interpretation of the results and allows comparisons with the general relativistic approach.

In this work we consider both relativistic and nonrelativistic systems. In this connection, we shall keep all the dimensional constants. Here c is the velocity of light, γ is the gravitational constant, $\chi=8\pi\gamma/c^2$, $\hbar$ is Planck's constant. The metric tensor $g_{\mu\nu}$ ($\mu,\nu=0, 1, 2, 3$) has the signature $(+\,-\,-\,-)$.

II. THE VARIATIONAL PRINCIPLE AND EQUATIONS OF MOTION FOR RELATIVISTIC DUST SHELLS

Consider a timelike spatially-closed hypersurface $\Sigma_t^{(3)}$ into some region $D^{(4)}$ of the space–time $V^{(4)}$. Let it be the world sheet of the infinitely thin dust shell with the surface density of dust σ. This shell divides the region $D^{(4)}$ into the interior and exterior ones, $D_-^{(4)}$ and $D_+^{(4)}$. Introduce the general coordinate map x^μ on our compound manifold $D^{(4)}=D_-^{(4)}\cup\Sigma_t^{(3)}\cup D_+^{(4)}$ and the metrics $g_{\mu\nu}^{\pm}$ on $D_\pm^{(4)}$, so that $g_{\mu\nu}^-|_{\Sigma_t^{(3)}}=g_{\mu\nu}^+|_{\Sigma_t^{(3)}}$.

One defines the elements of the four-volume $d^4\Omega$ on $D_\pm^{(4)}$ and three-volume $d^3\Omega$ on $\Sigma_t^{(3)}$ according to the formulas,

$$d^4\Omega=\sqrt{-g}d^4x=\sqrt{-g}dx^0\wedge dx^1\wedge dx^2\wedge dx^3, \tag{2.1}$$

$$d^3\Omega=-\sqrt{-g}n^\mu d\Sigma_\mu=\sqrt{-g}d\Sigma, \tag{2.2}$$

where n^μ is the unit normal to $\Sigma_t^{(3)}$, directed from $D_-^{(4)}$ to $D_+^{(4)}$ ($n_\mu n^\mu=-1, u_\mu n^\mu=0$), $g=\det|g_{\mu\nu}|$. Three-forms $d\Sigma_\mu$ and $d\Sigma$ are determined by the relations,

$$dx^\mu\wedge d\Sigma_\nu=\delta^\mu_\nu d^4x,\quad \eta\wedge d\Sigma=d^4x\quad (d\Sigma_\mu=n_\mu d\Sigma), \tag{2.3}$$

where "$\wedge$" denotes the exterior product, and $\eta=n_\mu dx^\mu$ is a normal covector.

Now let us fix coordinate system x^μ so that the coordinates $x^a(a=2, 3)$ be Lagrange coordinates of particles on the shell $\Sigma_t^{(3)}$. Then $u^\mu x^a{}_{,\mu}=n^\mu x^a{}_{,\mu}=0$, where "$,\mu$" is derivative with respect to the coordinate x^μ. Hence it follows $u^a=n^a=0$. The equations $x^a=\text{const}$ determine the world line γ of some particle of dust on $\Sigma_t^{(3)}$. The set $\{\gamma\}=\{x^a, x^a+dx^a\}$ of the world lines forms the elementary stream tube of dust. On the shell $\Sigma_t^{(3)}$ we shall introduce the basis of one-forms,

$$\{e^0\equiv\omega=u_\mu dx^\mu,\quad e^a=dx^a\}\quad (a,b=2,3) \tag{2.4}$$

and the dual vector basis,

$$\{e_0\equiv u=u^\mu\partial_\mu,\quad e_a\},\quad e^i(e_k)=\delta^i_k\quad (i,k=0,2,3). \tag{2.5}$$

In the basis $\{e^i\}=\{\omega, dx^a\}$ the metric tensor and three-form of volume on $\Sigma_t^{(3)}$ are

$${}^{(3)}g=\omega\otimes\omega-q_{ab}dx^a\otimes dx^b, \tag{2.6}$$

$$d^3\Omega=-\omega\wedge d^2\Omega,\quad d^2\Omega=\sqrt{q}dx^2\wedge dx^3. \tag{2.7}$$

Here "$\otimes$" is the sign of a tensor product, $d^2\Omega$ is the surface element of the area for the section which is orthogonal to the elementary stream tube of dust, q_{ab} is the metric on these sections, $q=\det|q_{ab}|$. In the neighborhood of the hypersurface $\Sigma_t^{(3)}$ the metric tensor ${}^{(4)}g$ and four-form of volume $d^4\Omega$ can be expressed in the form

$${}^{(4)}g={}^{(3)}g-\eta\otimes\eta, \tag{2.8}$$

$$d^4\Omega=\eta\wedge d^3\Omega=\omega\wedge\eta\wedge d^2\Omega. \tag{2.9}$$

We introduce the two-form of mass on $\Sigma_t^{(3)}$ by the formula $d^2m=\sigma d^2\Omega$, then $\sigma d^3\Omega=\omega \wedge d^2m$.

Now we take the full action of the compound configuration in the form,

$$I_{\rm tot}^{(g)}=I_{\rm EH}-c\int_{\Sigma_t^{(3)}}\left(\sigma n^\mu+\frac{1}{2\chi}[\omega^\mu]\right)\sqrt{-g}d\Sigma_\mu+I_{\partial D^{(4)}}+I_0. \tag{2.10}$$

It is the functional of the metric $g_{\mu\nu}$, density of the dust σ and hypersurface $\Sigma_t^{(3)}$: $I_{\rm tot}^{(g)}\equiv I_{\rm tot}^{(g)}(g_{\mu\nu},\sigma,\Sigma_t^{(3)})$. The first term in the right-hand side of (2.10),

$$I_{\rm EH}=-\frac{c}{2\chi}\int_{D_-^{(4)}\cup D_+^{(4)}}{}^{(4)}R d^4\Omega \tag{2.11}$$

is the Einstein–Hilbert action for the regions $D_\pm^{(4)}$, where ${}^{(4)}R$ is the curvature scalar.

The second term in the right-hand side (2.10) contains the matter term $c\sigma d^3\Omega$ and matching term. The symbol $[\omega^\mu]=\omega^\mu|_+-\omega^\mu|_-$ denotes the jump of the quantity,

$$\omega^\mu=g^{\sigma\rho}\Gamma^\mu_{\sigma\rho}-g^{\mu\rho}\Gamma^\sigma_{\sigma\rho}, \tag{2.12}$$

$$\Gamma^\mu_{\sigma\rho}=\tfrac{1}{2}g^{\mu\nu}(g_{\nu\rho,\sigma}+g_{\nu\sigma,\rho}-g_{\rho\sigma,\nu}), \tag{2.13}$$

on Σ_t. The sign ''$|_+$'' or ''$|_-$'' indicates the marked values to be calculated as a limiting magnitude when approaching the boundary Σ_t from outside or inside, respectively. In Appendix A it will be shown, that the relation

$$[\omega^\mu]n_\mu=2[K] \tag{2.14}$$

takes place. Here $K=g^{\mu\nu}K_{\mu\nu}$ is the trace of the extrinsic curvature tensor

$$K_{\mu\nu}=-n_{\mu;\rho}h^\rho_\nu \quad (h^\rho_\nu=\delta^\rho_\nu+n^\rho n_\nu), \tag{2.15}$$

where $_{;\rho}$ is covariant derivative with respect to the coordinate x^μ. The third term

$$I_{\partial D^{(4)}}=\frac{c}{2\chi}\int_{\partial D^{(4)}}\omega^\mu\sqrt{-g}d\Sigma_\mu \tag{2.16}$$

contains the surface terms which are introduced to fix the metric on the boundary $\partial D^{(4)}$ of the region $D^{(4)}$. Note, that the boundary $\partial D^{(4)}$ consists of the pieces of timelike as well as spacelike hypersurfaces. The last term I_0 in (2.10) contains the boundary terms on the timelike infinitely remote hypersurfaces, necessary for normalization of the action.

The relation

$$\sqrt{-g}\,{}^{(4)}R=\sqrt{-g}G+(\sqrt{-g}\omega^\mu)_{,\mu} \tag{2.17}$$

takes place, where

$$G=g^{\mu\nu}(\Gamma^\rho_{\mu\sigma}\Gamma^\sigma_{\nu\rho}-\Gamma^\sigma_{\mu\nu}\Gamma^\rho_{\rho\sigma}) \tag{2.18}$$

contains only the first derivatives of the metric. Therefore the action (2.10) can be rewritten in a more compact form

$$I_{\rm tot}^{(g)}=I_g+I_m+I_0, \tag{2.19}$$

where

$$I_g=-\frac{c}{2\chi}\int_{D_-^{(4)}\cup D_+^{(4)}}\sqrt{-g}G d^4x=\int_{D_-^{(4)}\cup D_+^{(4)}}L_g d^4x \tag{2.20}$$

is the gravitational action of the first order, and

$$I_m=c\int_{\Sigma_t^{(3)}}\sigma d^3\Omega=-c\int_{S_t^{(2)}}d^2m\int_\gamma\omega \tag{2.21}$$

is the action for the dust.

The first and the penultimate terms in (2.10) form the action which can be ascribed to that of the York's type $I_Y=I_{\mathrm{EH}}+I_{\partial D^{(4)}}$.[10] It is used in variational problems with the fixed metric on the boundary $\partial D^{(4)}$ of the region $D^{(4)}$. It can also be used in variational problems with the general relativistic version of ''natural boundary conditions'' for ''free edge.''[11] In this case the metric on the boundary is arbitrary and the corresponding momenta vanishes. Together with I_0 it forms the York–Gibbons–Hawking action $I_{\mathrm{YGH}}=I_Y+I_0$ for a free gravitational field.

In our case of the compound configuration we also fix the metric on boundary $\partial D^{(4)}$, as it was done in variational problem for action I_Y. In addition, inside the system there is the boundary surface $\Sigma_t^{(3)}$, with singular distribution of matter on it. One can interpret this configuration as the two vacuum regions $D_\pm^{(4)}$ with a common ''loaded edge'' (or with a ''massive edge''). The sum of the actions of type I_Y for these regions and of the action for matter I_m and normalizing term I_0 do leads to the action $I_{\mathrm{tot}}^{(g)}$.

If there is no dust, $\sigma=0$, the common boundary is not ''loaded.'' Then, the requirement $\delta I_{\mathrm{tot}}^{(g)}=0$, at arbitrary, everywhere continuous variations of the metric, gives generalization of the above ''natural boundary conditions'' for free hypersurface $\Sigma_t^{(3)}$. They coincide with the condition of continuity for the extrinsic curvature on $\Sigma_t^{(3)}$, i.e., with ordinary matching conditions. If the edge, being matched, is ''loaded'' by some surface distribution of matter, then we obtain the corresponding surface equation or the boundary conditions for $D_\pm^{(4)}$. They are the analog of the generalized ''natural boundary conditions'' for ''loaded edges.'' The initial action is chosen so, that the surface equations on $\Sigma_t^{(3)}$ following from the requirement $\delta I_{\mathrm{tot}}^{(g)}=0$, coincide with the matching conditions on singular hypersurfaces.[1] In this case, the variational principle for the action $I_{\mathrm{tot}}^{(g)}$ will be compatible with the boundary-value problem of the corresponding Euler–Lagrange equations.[12,13]

Note, that, as a rule, the boundary terms are formulated in terms of the extrinsic curvature of the corresponding hypersurfaces. For the configuration which contains the boundary hypersurface dividing the domain $D^{(4)}$ into parts and the whole boundary consisting of several pieces of edge, initial, and eventual hypersurfaces, it is more convenient to use the covariant approach. In order to calculate $\delta I_{\mathrm{tot}}^{(g)}$ we use the complete action in the form (2.10). According to Ref. 14 we have

$$\delta(\sqrt{-g}\,{}^{(4)}R)=-\sqrt{-g}\,{}^{(4)}G^{\mu\nu}\delta g_{\mu\nu}+(\sqrt{-g}\Omega^\mu)_{,\,\mu}, \tag{2.22}$$

where

$$\Omega^\mu=g^{\sigma\rho}\delta\Gamma^\mu_{\sigma\rho}-g^{\mu\rho}\delta\Gamma^\sigma_{\sigma\rho}, \tag{2.23}$$

and ${}^{(4)}G^{\mu\nu}={}^{(4)}R^{\mu\nu}-\frac{1}{2}{}^{(4)}Rg^{\mu\nu}$ is the Einstein tensor. In addition, we shall use the following conditions: the boundary of the configuration $\partial D^{(4)}$, the metric on it, and the normal vector are fixed. Then $\delta d\Sigma_\mu|_{\partial D^{(4)}}=0$, $\delta g_{\mu\nu}|_{\partial D^{(4)}}=0$, $\delta n_\mu|_{\partial D^{(4)}}=0$. The hypersurface $\Sigma_t^{(3)}$ is fixed, and the metric and its variations are continuous on $\Sigma_t^{(3)}$: $[g_{\mu\nu}]_{\Sigma_t^{(3)}}=0$, $[\delta g_{\mu\nu}]_{\Sigma_t^{(3)}}=0$, $[n_\mu]_{\Sigma_t^{(3)}}=0$, $[\delta n_\mu]_{\Sigma_t^{(3)}}=0$.

For the variation δI_m according to the formula (2.21) we have $\delta I_m=-c\int d^2m\int\delta\omega=-c\int d^2m\int\delta\omega_\gamma$. Here, the quantity d^2m is considered as a stationary value at variations of the metric.[15] The sign ''$|_\gamma$'' designates restriction of the one-forms on the world line γ so, that

$$\delta\omega_{|\gamma}=\delta ds=\tfrac{1}{2}u^{\mu}u^{\nu}ds\ \delta g_{\mu\nu}=-\tfrac{1}{2}u_{\mu}u_{\nu}\omega_{|\gamma}\delta g^{\mu\nu}. \tag{2.24}$$

If all these conditions are satisfied, then from the requirement $\delta I^{(g)}_{\rm tot}=0$ one obtains the vacuum Einstein equations

$$^{(4)}G^{\mu\nu}=0,\quad \forall D^{(4)}_{\pm} \tag{2.25}$$

and the surface equations on $\Sigma^{(3)}_t$,

$$Q_{\mu\nu}-\tfrac{1}{2}Qg_{\mu\nu}=-\chi\sigma u_{\mu}u_{\nu}, \tag{2.26}$$

where $Q=g^{\mu\nu}Q_{\mu\nu}$, and

$$Q_{\sigma\rho}=n_{\mu}[\Gamma^{\mu}_{\sigma\rho}]-\tfrac{1}{2}(n_{\sigma}[\Gamma^{\mu}_{\mu\rho}]+n_{\rho}[\Gamma^{\mu}_{\mu\sigma}]). \tag{2.27}$$

It is shown in Appendix A that the surface equations (2.26) reduce to the known equations for the jump discontinuity of the extrinsic curvature tensor of the hypersurface $\Sigma^{(3)}_t$,[1]

$$[K_{\mu\nu}]-[K]h_{\mu\nu}=-\chi\sigma u_{\mu}u_{\nu}, \tag{2.28}$$

where $h_{\mu\nu}=g_{\mu\nu}+n_{\mu}n_{\nu}$ is the metric on $\Sigma^{(3)}_t$. From the relations (2.28) it follows

$$[K_{\mu\nu}]u^{\mu}u^{\nu}=-\frac{\chi}{2}\sigma, \tag{2.29}$$

The missing equation for the average tensor of the extrinsic curvature

$$\overline{K^{\mu}_{\nu}}=\tfrac{1}{2}(K^{\mu}_{\nu|_+}+K^{\mu}_{\nu|_-}) \tag{2.30}$$

can be obtained by considering the variations of $I^{(g)}_{\rm tot}$ with respect to normal displacements of the hypersurface $\Sigma^{(3)}_t$. For this purpose we define some one-parameter family of timelike hypersurfaces in a neighborhood of $\Sigma^{(3)}_t$ so that $\Sigma^{(3)}_t$ is included in this family. The family induces $(3+1)$-decomposition of the objects in the neighborhood of $\Sigma^{(3)}_t$. Thus for the four-curvature scalar one has

$$^{(4)}R=\,^{(3)}R+K^{\mu}_{\nu}K^{\nu}_{\mu}-K^2+\frac{2}{\sqrt{-g}}\{\sqrt{-g}(Kn^{\mu}-a^{\mu})\}_{,\mu}, \tag{2.31}$$

where $a^{\mu}=n^{\mu}_{;\nu}n^{\nu}$ and $^{(3)}R$ is the curvature scalar of hypersurfaces of the family. Substituting (2.31) into (2.11) and taking into account the relations $a^{\mu}n_{\mu}=0$ and (2.14), one obtains the action (2.10) in the form

$$I^{(g)}_{\rm tot}=\hat{I}_g+I_m+\hat{I}_{\partial D^{(4)}}+I_0, \tag{2.32}$$

where

$$\hat{I}_g=\int_{D^{(4)}_-\cup D^{(4)}_+}\hat{L}_g d^4x=-\frac{c}{2\chi}\int_{D^{(4)}_-\cup D^{(4)}_+}(^{(3)}R+K^{\mu}_{\nu}K^{\nu}_{\mu}-K^2)\sqrt{-g}d^4x \tag{2.33}$$

is the gravitational action, containing normal derivatives up to the first order, and $\hat{I}_{\partial D^{(4)}}$ and I_0 contain the boundary terms, which are unessential here.

Now let every point $p\in\Sigma^{(3)}_t$ be translated at a coordinate distance $\delta x^{\mu}(p)=n^{\mu}\delta\lambda(p)$ in the normal direction. As a result of the displacement one gets a new hypersurface $\tilde{\Sigma}^{(3)}_t$. The initial

and eventual positions of a shell are fixed, therefore $\delta\lambda(p)=0$, $\forall p\in\Sigma_t^{(3)}\cap\partial D^{(4)}=\tilde{\Sigma}_t^{(3)}\cap\partial D^{(4)}$. In addition, we fix the metric $g_{\mu\nu}$ and all the quantities on $\Sigma_t^{(3)}$, so that $\delta I_m=0$.

As a result of the displacement of the hypersurface $\Sigma_t^{(3)}$, the initial regions $D_+^{(4)}$ and $D_-^{(4)}$ are transformed into new ones $\tilde{D}_+^{(4)}$ and $\tilde{D}_-^{(4)}$, so that, $\tilde{D}_-^{(4)}\cup\tilde{\Sigma}_t^{(3)}\cup\tilde{D}_+^{(4)}=D_-^{(4)}\cup\Sigma_t^{(3)}\cup D_+^{(4)}=D^{(4)}$. Then, for example, the variation of the region $D_-^{(4)}$ can be expressed in the form $\delta D_-^{(4)}=\tilde{D}_-^{(4)}\setminus D_-^{(4)}=D_+^{(4)}\setminus\tilde{D}_+^{(4)}$. The variation of the action (2.33), under the above conditions, proves to be equal,

$$\delta I_{\rm tot}^{(g)}=\delta\hat{I}_g=\int_{\tilde{D}_-^{(4)}\cup\tilde{D}_+^{(4)}}\hat{L}_g d^4x-\int_{D_-^{(4)}\cup D_+^{(4)}}\hat{L}_g\,d^4x\cong-\int_{\delta D_-^{(4)}}(\hat{L}_g^+-\hat{L}_g^-)d^4x. \tag{2.34}$$

Here $\hat{L}_g^+$ and $\hat{L}_g^-$ are Lagrangians defined by the relation (2.33) and calculated as a limiting magnitude when approaching the hypersurface $\Sigma_t^{(3)}$ from outside or inside, respectively. Under the infinitesimal normal displacement of the hypersurface $\Sigma_t^{(3)}$, the full action is variated by the formula,

$$\delta I_{\rm tot}^{(g)}=-\int_{\Sigma_t^{(3)}}(\hat{L}_g^+-\hat{L}_g^-)\,\delta x^\mu d\Sigma_\mu=\int_{\Sigma_t^{(3)}}[\hat{L}_g]\delta\lambda\,d\Sigma. \tag{2.35}$$

Hence, from arbitrariness of $\delta\lambda(p)$ and the requirement $\delta I_{\rm tot}^{(g)}=0$, one finds

$$[\hat{L}_g]=\hat{L}_g^+-\hat{L}_g^-=[K_\nu^\mu K_\mu^\nu-K^2]=2\overline{K}_\nu^\mu([K_\mu^\nu]-[K]\delta_\mu^\nu)=0. \tag{2.36}$$

Here we considered that $[{}^{(3)}R]=0$ on $\Sigma_t^{(3)}$. Then, using (2.28), from (2.36) we obtain

$$\overline{K}_{\mu\nu}u^\mu u^\nu=0. \tag{2.37}$$

The relations (2.28) and (2.37) form the necessary complete set of algebraic conditions or constraints for the extrinsic curvature tensor $K_{\nu|_\pm}^\mu$ of the hypersurface $\Sigma_t^{(3)}$.

Now we can eliminate gravitational degrees of freedom in the action $I_{\rm tot}^{(g)}$ and construct the action for the shell. For this purpose it is necessary to calculate $I_{\rm tot}^{(g)}$ on the solutions of the vacuum Einstein equations (2.25) taking into account the constraints (2.28) and (2.37). Note, first, that on this stage we use explicitly only the following results of these equations:

$${}^{(4)}R=0,\quad [\omega^\mu]n_\mu=2[K]=\chi\sigma. \tag{2.38}$$

Substituting these relations for the corresponding terms in (2.10) one finds

$$I_{\rm tot}^{(g)}{}_{|\{\text{Eqs. (2.38)}\}}=I_{\rm sh}+I_{\partial D^{(4)}}+I_0, \tag{2.39}$$

where

$$I_{\rm sh}=\frac{1}{2}\int_{\Sigma_t^{(3)}}c\sigma d^3\Omega=-\frac{c}{2}\int_{S_t^{(2)}}d^2m\int_\gamma\omega \tag{2.40}$$

is the reduced action for the dust shell. This action must be considered together with constraints (2.28) and (2.37). The action $I_{\rm sh}^{(g)}$ is quite certain if the gravitational fields in the neighborhood of $\Sigma_t^{(3)}$ are determined as the solutions of the vacuum Einstein equations (2.25) which satisfy the boundary conditions (2.28) and (2.37). That is the finding of these fields that completes the construction of the action for the shell. At this stage all the equations (2.25) and constraints (2.28), (2.37) are already used.

Note, that one usually comes to the action for the shell in the other form. In our approach the action can be obtained at the partial reduction of initial action $I^{(g)}_{\rm tot}$, when the constraint in (2.38) is not taken into account. As a result we come to the action of the type,

$$\tilde{I}_{\rm sh}=-c\int_{\Sigma^{(3)}_t}\left(\sigma-\frac{1}{\chi}[K]\right)\omega\wedge d^2\Omega, \tag{2.41}$$

or to some its modification. In the spherically-symmetric case from here follows the Lagrangian of the shell in a frame of reference of the comoving observer. However, quantity $[K]$ contains second derivatives with respect to proper time of the shell. When eliminating them, through the integration by parts, one comes to rather complicated Lagrangians and Hamiltonians.

To find the equations of motion for particles of the shell from action $I_{\rm sh}$ (2.40) one should introduce the independent coordinates $x^\mu_\pm$ in each of the regions $D^{(4)}_\pm$, and the interior coordinates $y^i\,(i,k=0,2,3)$ on $\Sigma^{(3)}_t$. Let the equations of embedding of $\Sigma^{(3)}_t$ into $D^{(4)}_\pm$ have the form $x^\mu_\pm=x^\mu_\pm(y^i)$. Then we can write the relations,

$$^{(4)}ds^2_\pm=g^\pm_{\mu\nu}dx^\mu_\pm dx^\nu_\pm,\quad {}^{(3)}ds^2=g^\pm_{\mu\nu}x^\mu_{\pm,i}x^\mu_{\pm,k}dy^i dy^k=h_{ik}dy^i dy^k, \tag{2.42}$$

$$\omega=\omega^\pm=u^\pm_\mu dx^\mu_\pm,\quad \omega^\pm_{|\gamma}=ds_\pm,\quad u^\mu_\pm=dx^\mu_\pm/ds_\pm, \tag{2.43}$$

$$^{(3)}\omega=u^\pm_\mu x^\mu_{\pm,i}dy^i=u_i dy^i,\quad {}^{(3)}\omega_{|\gamma}={}^{(3)}ds,\quad u^i=dy^i/{}^{(3)}ds. \tag{2.44}$$

Nongravitational interaction between particles of the dust is absent. Therefore we consider quantity d^2m to be unchanged when a flow line is varied.

First, consider variations $I_{\rm sh}$ with respect to the internal coordinates y^i. In this case $\int_\gamma\omega=\int_\gamma{}^{(3)}\omega_{|\gamma}=\int_\gamma{}^{(3)}ds$. Then the metric $h_{ik}(y^i)$ is given on $\Sigma^{(3)}_t$ and the variation of $I_{\rm sh}$ leads to the equations of three-dimensional geodesic on the hypersurface $\Sigma^{(3)}_t$,

$$u^i_{;k}u^k=0. \tag{2.45}$$

Here ''$_{;k}$'' denotes the covariant derivative with respect to the coordinate y^k calculated with the help of the metric h_{ik}.

The consideration of the variational principle $\delta I^{(g)}_{\rm sh}=0$ with respect to the exterior coordinates $x^\mu_\pm$ is more interesting treatment. In this case $\int_\gamma\omega=\int_\gamma\omega^\pm_{|\gamma}=\int^{(4)}_\gamma ds_\pm$. Then the metrics $g^\pm_{\mu\nu}(x^\rho)$ are given in a neighborhood of the shell. Since the normal variations of the shell are already used, it is possible to consider the variations of dynamical quantities, generated only by the tangential to $\Sigma^{(3)}_t$ variations of the coordinates x^μ. These variations of the values will be denoted by the sign $\tilde{\delta}$. Thus, omitting for simplicity signs ''$\pm$,'' we have

$$\tilde{\delta}x^\mu=\delta x^\mu+n^\mu n_\nu\delta x^\nu\equiv h^\mu_\nu\delta x^\nu\quad (n_\mu\tilde{\delta}x^\mu=0,\quad h^\mu_\nu=\delta^\mu_\nu+n^\mu n_\nu), \tag{2.46}$$

where δx^μ are arbitrary values. Then we find

$$\tilde{\delta}\omega_{|\gamma}=\tilde{\delta}\,{}^{(4)}ds=\tilde{\delta}\sqrt{g_{\mu\nu}dx^\mu dx^\nu}=-u_{\mu;\nu}u^\nu h^\mu_\rho\delta x^\rho\,{}^{(4)}ds+d(u_\mu\delta x^\mu). \tag{2.47}$$

Supposing that $\delta x^\mu=0$ on $\Sigma^{(3)}_t\cap\partial D^{(4)}$, from the requirement $\tilde{\delta}I^{(g)}_{\rm sh}=0$ we obtain the three-dimensional geodesic equations on $\Sigma^{(3)}_t$, but, here, in the four-dimensional form,

$$u_{\mu;\nu}u^\nu h^\mu_\rho=0. \tag{2.48}$$

This equation can be rewritten as

$$u_{\rho;\nu}u^\nu=-u_{\mu;\nu}u^\nu n^\mu n_\rho. \tag{2.49}$$

Hence, using the definition of $K_{\mu\nu}$ (2.15) one obtains

$$u_{\rho;\nu}u^{\nu}=n_{\rho}n_{\mu;\nu}u^{\mu}u^{\nu}=-n_{\rho}K_{\mu\nu}u^{\mu}u^{\nu}. \tag{2.50}$$

Here we again introduce signs ''$\pm$'' and use the relations $K_{\mu\nu|_{\pm}}=\overline{K}_{\mu\nu}\pm\frac{1}{2}[K_{\mu\nu}]$. Then, taking into account constraints (2.29) and (2.37), we come to the equations of motion for the shell's particles with respect to the exterior coordinates,

$$(u_{\mu;\nu}u^{\nu})_{|\pm}=\pm\frac{\chi}{4}\sigma n_{\mu}. \tag{2.51}$$

For completeness one should add the unused constraints,

$$[K_{\mu\nu}]u^{\mu}e_{i}^{\nu}=0, \quad [K_{\mu\nu}]e_{a}^{\mu}e_{b}^{\nu}=\frac{\chi\sigma}{2}h_{ab}, \tag{2.52}$$

where $e_{a}^{\mu}=\partial x^{\mu}/\partial y^{a}$.

From (2.51) it follows the well-known Israel equations,[1]

$$n^{\mu}\frac{Du_{\mu}}{ds}\bigg|_{+}+n^{\mu}\frac{Du_{\mu}}{ds}\bigg|_{-}=0, \quad e_{i}^{\mu}\frac{Du_{\mu}}{ds}\bigg|_{\pm}=0, \tag{2.53}$$

$$n^{\mu}\frac{Du_{\mu}}{ds}\bigg|_{+}-n^{\mu}\frac{Du_{\mu}}{ds}\bigg|_{-}=-\frac{\chi\sigma}{2}, \tag{2.54}$$

where $Du_{\mu}=u_{\mu;\nu}dx^{\nu}$ is the covariant differential.

The equations of motion of the dust shell (2.51) can immediately be found from the action I_{sh}. Indeed, acting in the same manner as when deducing the equations of motion (2.51), the variational formula (2.47) can be transformed to the form,

$$\tilde{\delta}^{(4)}ds_{|_{\pm}}=-u_{\mu;\nu}u^{\nu}\delta x^{\mu}_{|_{\pm}}{}^{(4)}ds_{|_{\pm}}\mp\tfrac{1}{2}[K_{\mu\nu}]u^{\mu}u^{\nu}n_{\rho}\delta x^{\rho}ds_{|_{\pm}}+d(u_{\mu}\delta x^{\mu})_{|_{\pm}} \tag{2.55}$$

or

$$\tilde{\delta}\omega_{|\gamma}^{\pm}=\tilde{\delta}^{(4)}ds_{|_{\pm}}=\left\{\left(-u_{\mu;\nu}u^{\nu}\pm\frac{\chi\sigma}{4}n_{\mu}\right)\delta x^{\mu}{}^{(4)}ds+d(u_{\mu}\delta x^{\mu})\right\}_{|\pm}. \tag{2.56}$$

From here, under the above conditions, the equations of motion follow.

The proposed variational deducing of the equations of motion makes the problem of construction of the effective action for the dust shell free from constrains (2.28) and (2.37). It turns out that it is possible for some special class of the configurations. To show it, we shall choose such interior coordinates y^{i}, which at $i=a=2,3$ are the Lagrange coordinates of particles on the shell $\Sigma_{t}^{(3)}$. In addition, we introduce the coordinates $x^{\mu}_{|\pm}$ in the regions $D_{\pm}^{(4)}$ so that, when $\mu=a=2,3$ the equalities $x_{+}^{a}|_{\Sigma_{t}^{(3)}}=x_{-}^{a}|_{\Sigma_{t}^{(3)}}=y^{a}$ are satisfied. These coordinates are arbitrary in any other respect. Then the formulas of embedding of $\Sigma_{t}^{(3)}$ into $D_{\pm}^{(4)}$ have the form $x_{\pm}^{n}=x_{\pm}^{n}(y^{0})$ $(n=0,1)$ or $f_{\pm}(x^{0},x^{1})=0$. Therefore we have $u_{\pm}^{\mu}=\{u_{\pm}^{0},u_{\pm}^{1},0,0\}$ and $n_{\mu}^{\pm}=\{n_{0}^{\pm},n_{1}^{\pm},0,0\}$. Using the conditions $(u_{\mu}u^{\mu})_{|\pm}=-(n_{\mu}n^{\mu})_{|\pm}=1$ and $(u_{\mu}n^{\mu})_{|\pm}=0$ one finds $n_{0}^{\pm}=u_{\pm}^{1}$, $n_{1}^{\pm}=-u_{\pm}^{0}$. Hence it follows

$$n_{\mu}\delta x^{\mu}ds_{|_{\pm}}=(u^{1}\delta x^{0}-u^{0}\delta x^{1})ds_{|_{\pm}}=(dx^{1}\delta x^{0}-dx^{0}\delta x^{1})_{|_{\pm}}. \tag{2.57}$$

Therefore the variational formula (2.56) has the form

$$\tilde{\delta}\omega^{\pm}_{|\gamma}=\tilde{\delta}^{(4)}ds_{|_{\pm}}=\left\{\delta^{(4)}ds\pm\tfrac{1}{4}\chi\sigma(dx^1\delta x^0-dx^0\delta x^1)+d(u_\mu\delta x^\mu)\right\}_{|\pm}. \tag{2.58}$$

Now we introduce the vector potential $U_n=U_n(x^0,x^1)$ by the relation

$$d\wedge(U_n dx^n)\equiv G_{01}dx^0\wedge dx^1=-\tfrac{1}{4}\chi\sigma dx^0\wedge dx^1, \tag{2.59}$$

where $G_{nm}\equiv U_{m,n}-U_{n,m}(n,m=0,1)$. Hence it follows that the configurations, being considered, admit such motions of matter for which $\sigma=\sigma(x^0,x^1)$.

Using the definition (2.59) and the relation

$$\delta(U_n dx^n)-d(U_n\delta x^n)=G_{10}(dx^0\delta x^1-dx^1\delta x^0), \tag{2.60}$$

the variational formula (2.58) can be rewritten in the following form:

$$\tilde{\delta}\omega^{\pm}_{|\gamma}=\tilde{\delta}^{(4)}ds_{|_{\pm}}=\{\delta(ds\mp U_n dx^n)+d[(u_n\pm U_n)\delta x^n+u_a\delta y^a]\}_{|\pm}. \tag{2.61}$$

Returning to action for the shell (2.40), we conclude, that in the case under consideration we have

$$\delta I_{\rm sh}=\delta I^{\pm}_{\rm sh}-\frac{c}{2}\int_{S^{(2)}_t}d^2m\{(u_n\pm U_n)x^n{}_{,0}\delta y^0+u_a\delta y^a\}_{\pm}|^B_A, \tag{2.62}$$

where

$$I^{\pm}_{\rm sh}=-\frac{c}{2}\int_{S^{(2)}_t}d^2m\int_\gamma(ds\mp U_n dx^n)_{|\pm}, \quad (n=0,1) \tag{2.63}$$

is the effective action for the shell written in terms of the exterior coordinates. Indices A and B indicate that the corresponding quantities are taken in initial and final positions of the shell. Since at fixed initial and final positions of particles $\delta y^i|_{A,B}=0$, then it follows $\delta I_{\rm sh}=\delta I^{\pm}_{\rm sh}$.

In such away, under the above conditions, the action of the shell (2.40) with the constraints (2.28), (2.37) and the action (2.62) without these constraints are equivalent. The actions $I^{+}_{\rm sh}$ and $I^{-}_{\rm sh}$ are equivalent in the same sense. Let us note, that in the considered above independent treatment of the interior and exterior faces of the shell there are new constraints following from isometry conditions of these faces.

III. EFFECTIVE ACTION FOR THE SPHERICAL DUST SHELL

Let us consider spherically-symmetric compound region $D^{(4)}=D^{(4)}_{-}\cup\Sigma^{(3)}_t\cup D^{(4)}_{+}\subset V^{(4)}$ into the spherically-symmetric space–time $V^{(4)}$, where $D^{(4)}_{\mp}$ are exterior and interior regions separated from each other by spherically-symmetric timelike hypersurface $\Sigma^{(3)}_t$. By using the curvature coordinates we can choose common in $D^{(4)}_{\pm}$, spatial, spherical coordinates $\{r,\theta,\alpha\}$, and individual time coordinates $t_{\pm}$ for $D^{(4)}_{\pm}$, respectively. Then the world sheet for the shell $\Sigma^{(3)}_t$, respectively, the interior and exterior coordinates is determined by the equations $r=R_{-}(t_{-})$ and $r=R_{+}(t_{+})$. Under appropriate choice of $t_{\pm}$ we have $R_{-}(t_{-})=R_{+}(t_{+})$. Thus, the interior and exterior regions are determined by the relations

$$D^{(4)}_{-}=\{t_{-},r,\theta,\alpha: r_0<r<R_{-}(t_{-})\},\quad D^{(4)}_{+}=\{t_{+},r,\theta,\alpha: R_{+}(t_{+})<r<\infty\}$$

for all $\{\theta,\alpha\}\in\{0\leqslant\theta\leqslant\pi, 0\leqslant\alpha<2\pi,\}$ and for all admissible $t_{\pm}$. The particles of the shell are described by one collective dynamical coordinate $R=R_{\pm}(t_{\pm})$ and by the two fixed individual (Lagrange) angular coordinates θ and α. The minimal value of r_0 is limited by the domain of definition of the curvature coordinates.

The gravitational fields into the regions $D^{(4)}_{\pm}$ are given by the metrics

$$^{(4)}ds_{\pm}^2 = f_{\pm}c^2dt_{\pm}^2 - f_{\pm}^{-1}dr^2 - r^2(d\theta^2 + \sin^2\theta d\alpha^2), \tag{3.1}$$

where

$$f_{\pm} = 1 - \frac{2\gamma M_{\pm}}{c^2 r}, \tag{3.2}$$

and $M_{\pm}$ are the Schwarzschild masses ($M_+ > M_-$).

Owing to the spherical symmetry $\sigma = \sigma(t_{\pm}, R)$. Therefore the conditions of applicability of the modified action (2.62) are satisfied. In this case we have

$$d^2m = \sigma d^2\Omega = \sigma R^2 \sin\theta d\theta d\alpha, \tag{3.3}$$

$$U_n dx^n = c\varphi(t_{\pm}, R)dt_{\pm} + U_R(t_{\pm}, R)dR. \tag{3.4}$$

Using the gauge condition $U_R(t_{\pm}, r) = 0$, the action (2.62) can be written in the form

$$I_{\rm sh}^{\pm} = -\frac{c}{2}\int_{S_t^{(2)}} \sigma R^2 \sin\theta d\theta d\alpha \int_{\gamma_{\pm}} (^{(2)}ds \mp c\varphi dt)_{|\pm}. \tag{3.5}$$

Since the particles move only radially ($\theta = \text{const}$, $\varphi = \text{const}$) we shall use the truncate interval

$$^{(2)}ds_{\pm}^2 = f_{\pm}c^2dt_{\pm}^2 - f_{\pm}^{-1}dR^2. \tag{3.6}$$

Further, from the formula (2.59) it follows

$$\frac{1}{4}\chi\sigma = \frac{\gamma m}{2c^2R^2} = \frac{\partial\varphi}{\partial R}, \tag{3.7}$$

where $m = 4\pi\sigma R^2$ is the rest mass of the shell. Hence, up to an additive constant, one finds

$$\varphi = -\frac{\gamma m}{2c^2 R}. \tag{3.8}$$

Finally, integrating in (3.5) over the angles θ and α and making use of (3.6) and (3.8), the effective action of the shell can be expressed in the form,

$$I_{\rm sh}^{\pm} = \frac{1}{2}\int_{\gamma_{\pm}} L_{\rm sh}^{\pm} dt_{|\pm} = -\frac{1}{2}\int_{\gamma_{\pm}} \left(mc^{(2)}ds \pm \frac{\gamma m^2}{2R}dt \right)_{|\pm}, \tag{3.9}$$

where

$$L_{\rm sh}^{\pm} = -mc^2\sqrt{f_{\pm} - f_{\pm}^{-1}R_{t\pm}^2/c^2} \pm U \tag{3.10}$$

are the Lagrangians of the dust shell with respect stationary observes into the regions $D_{\pm}^{(4)}$, ($R_{t\pm} = dR/dt_{\pm}$), and

$$U^{(G)} = -\frac{\gamma m^2}{2R} \tag{3.11}$$

is the effective potential energy of the gravitational self-action of the shell. It is important that the self-action (3.11) has the same form as that in the Newtonian theory [formula (C12) in Appendix C]. The Lagrangians (3.10) themselves can be obtained from the corresponding Newtonian analogs [see Appendix C, formulas (C13) and (C14)] by the formal replacement of the first and second terms describing the kinetic and potential energies of the shell into the external field by

their general relativistic analog, the geodesic Lagrangian $-mc^{(2)}ds_{\pm}/dt_{\pm}$. It is natural that the Lagrangians (C13), (C14), up to an additive constant, are the Newtonian limits of the relativistic Lagrangians (3.10).

It is easy to see that the actions (3.9) transform each into other under the discrete gauge transformation,

$$M_{\pm}\to M_{\mp}\quad (f_{\pm}\to f_{\mp}),\quad U^{(G)}\to -U^{(G)},\quad t_{\pm}\to t_{\mp}.$$

This transformation generalizes the corresponding transformation of the Newtonian theory of shells (see Appendix C) and reduce to the transformation from the interior observer to the exterior one and otherwise.

Note, that despite the equivalence of the actions $I^{\pm}_{\rm sh}$, similar to Newtonian case (C13), (C14), they can be considered quite independently. We also can consider the regions $D^{(4)}_{\pm}$ together with the corresponding gravitational fields (3.1) separately and independently, as manifolds with the edge $\Sigma^{(3)}_{t\pm}$. The edges $\Sigma^{(3)}_{t\pm}$ acquire the physical meaning of different faces of the shell with the world sheet $\Sigma^{(3)}_{t}$, provided the regions $D^{(4)}_{\pm}$ are joined along these edges $\Sigma^{(3)}_{t\pm}$. This can be performed only if the conditions of isometry of the edges $\Sigma^{(3)}_{t\pm}$ are satisfied

$$f_+c^2dt_+^2-f_+^{-1}dR^2=f_-c^2dt_-^2-f_-^{-1}dR^2=c^2d\tau^2, \tag{3.12}$$

where τ is the proper time of the shell. In addition we have $\Sigma^{(3)}_{t+}=\Sigma^{(3)}_{t-}=\Sigma^{(3)}_{t}$, $\gamma_+(t_+)=\gamma_-(t_-)=\gamma$.

Now we study some results following from the isometry conditions of the edges. First, we obtain the relations between the velocities,

$$c^2\frac{f_+}{R^2_{t+}}-\frac{1}{f_+}=c^2\frac{f_-}{R^2_{t-}}-\frac{1}{f_-}, \tag{3.13}$$

$$R^2_{\tau}\equiv\left(\frac{dR}{d\tau}\right)^2=\frac{c^2R^2_{t\pm}}{c^2f_{\pm}-f_{\pm}^{-1}R^2_{t\pm}},\quad R^2_{t\pm}\equiv\left(\frac{dR}{dt_{\pm}}\right)^2=\frac{c^2f^2_{\pm}R^2_{\tau}}{c^2f_{\pm}+R^2_{\tau}}. \tag{3.14}$$

Then from the Lagrangians $L^{\pm}_{\rm sh}$ (3.10) one finds the momenta and Hamiltonians of the shell,

$$P_{\pm}=\frac{\partial L^{\pm}_{\rm sh}}{\partial R_{t\pm}}=\frac{mR_{t\pm}}{f_{\pm}\sqrt{f_{\pm}-f_{\pm}^{-1}R^2_{t\pm}/c^2}}=\frac{m}{f_{\pm}}R_{\tau}, \tag{3.15}$$

$$H^{\pm}_{\rm sh}=\frac{mc^2f_{\pm}}{\sqrt{f_{\pm}-f_{\pm}^{-1}R^2_{t\pm}/c^2}}\mp U=mc^2f_{\pm}\frac{dt_{\pm}}{d\tau}\mp U \tag{3.16}$$

or

$$H^{\pm}_{\rm sh}=c\sqrt{f_{\pm}(m^2c^2+f_{\pm}P^2_{\pm})}\mp U=mc^2\sqrt{f_{\pm}+R^2_{\tau}/c^2}\mp U=E_{\pm}, \tag{3.17}$$

where $E_{\pm}$ are the energies of the shell which are conjugated to the time $t_{\pm}$, respectively, and conserve with respect to the corresponding interior or exterior stationary observers' point of view. After elimination of velocity R_{τ} from (3.15) and (3.17), the isometry conditions of the edges can be expressed in the form

$$f_+P_+=f_-P_-, \tag{3.18}$$

$$(E_--U)^2-m^2c^4f_-=(E_++U)^2-m^2c^4f_+. \tag{3.19}$$

Substituting U and $f_{\pm}$ from (3.2) and (3.11) for those in the last relation and equating the coefficients at the same power of R we obtain the relations between the Hamiltonian $H_{\rm sh}^{\pm}$ and the Schwarzschild masses $M_{\pm}$,

$$H_{\rm sh}^{+}=H_{\rm sh}^{-}=(M_{+}-M_{-})c^2=E. \tag{3.20}$$

Here $E=E_{\pm}$ is the full energy of the shell. This energy is conjugated to the coordinate time t_{+} and t_{-} as well, and does not depend on the position of the stationary observer (inside or outside the shell). We shall interpret the relations (3.18) and (3.20) following from the above independent consideration of the shell faces, as momentum and Hamiltonian constraints.

The Lagrangians $L_{\rm sh}^{\pm}$ (3.10), as well as the relations (3.13)–(3.20), are valid only in a limited domain, since the used curvature coordinates are valid outside the event horizon only. Therefore, $L_{\rm sh}^{-}$ can be used when $R>2\gamma M_{-}/c^2$, and $L_{\rm sh}^{+}$ when $R>2\gamma M_{+}/c^2 (M_{+}>M_{-})$.

As is known, the complete description of the shells can be performed in the Kruskal–Szekeres coordinates. With respect to these coordinates the full Schwarzschild geometry consists of the four regions R^{+}, T^{-}, R^{-}, T^{+}, detached by the event horizons. Our above consideration concerned with the R^{+} region only.

Supposing r to be a time coordinate, we can formally use the action in the form (3.9) under the horizon. However, here we encounter the ambiguity when choosing the sign before ${}^{(2)}ds$. It is usually ascribed to ambiguity of the radial component direction of the unit normal to $\Sigma_t^{(3)}$. The point is that in the curvature coordinates the regions T^{-} and T^{+} coincide. Hence the time singularity $r=0$ contains the two singularities: past singularity and future singularity. Therefore, for instance, the movement of a test particle with the energy $E=0$ consists of the two stages. At the first stage the particle begins to move into the expanding region T^{+} from the past singularity $r=0$ and reaches the horizon at a moment when r reaches $2\gamma M/c^2$. Then it goes over into the contracting T^{-} region and moves from the horizon to the future singularity $r=0$. In the coordinates $\{r,t\}$, where r is the time coordinate, the latter stage looks like the movement directed backwards in time.

Similarly, in the curvature coordinates the regions R^{-} and R^{+} of the Kruskal–Szekeres diagram coincide and ordinary movement of particles into the future of the R^{-}-region looks as the movement directed backwards in time which corresponds to the change $ds\to -ds$. It means that ordinary particles moving into the R^{-}-region are mapped into the R^{+}-region as antiparticles (remember the Feynman's interpretation of antiparticles as ordinary particles moving backwards in time). Such trajectories can be taken into account by the change of the sign before $mc\,{}^{(2)}ds_{\pm}$ in the expression for the action (3.9) of the shell.

In order to use simplicity and convenience of the curvature coordinates and, at the same time, to keep information about shells into the R^{-}-region we introduce an auxiliary discrete variable $\varepsilon=\pm 1$ and make a change ${}^{(2)}ds_{\pm}\to\varepsilon_{\pm}\,{}^{(2)}ds_{\pm}$ in $I_{sh}^{\pm}$ (3.9). Herewith $\varepsilon_{\pm}=1$ correspond to the shell into the R^{+}-region, and $\varepsilon_{\pm}=-1$ to the shell into the R^{-}-region. Then, we introduce the quantities $\mu_{\pm}=\varepsilon_{\pm}m$. As a result the extended action has the form

$$I_{\rm sh}^{\pm}(\mu_{\pm})=\frac{1}{2}\int_{\gamma_{\pm}} L_{\rm sh}^{\pm}(\mu_{\pm})dt_{|\pm}=-\frac{1}{2}\int_{\gamma_{\pm}}(\mu c\,{}^{(2)}ds\mp U^{G}dt)_{|\pm}, \tag{3.21}$$

where

$$L_{\rm sh}^{\pm}(\mu_{\pm})=-\mu_{\pm}c^2\sqrt{f_{\pm}-f_{\pm}^{-1}R_{t\pm}^2/c^2}\pm U \tag{3.22}$$

are the generalized Lagrangians describing the shell inside any of the $R^{\pm}$-regions with respect to the curvature coordinates of the interior $\{t_{-},R\}$ or exterior $\{t_{+},R\}$ regions. The event horizons $R_g=2\gamma M_{\pm}/c^2$ are, still, singular points of the dynamical systems (3.21) and must be excluded from consideration.

For the extended system (3.21) the Hamiltonian has the form

$$H^{\pm}_{\rm sh}(\mu_{\pm})=c\varepsilon_{\pm}\sqrt{f_{\pm}(m^2c^2+f_{\pm}P^2_{\pm})}\mp U=\mu_{\pm}c^2\sqrt{f_{\pm}+R^2_{\tau}/c^2}\mp U. \tag{3.23}$$

Hence, taking into account the Hamiltonian constraints (3.20) one finds the standard relations of the theory of dust spherical shells.[1] We shall rewrite them in terms of new designations,

$$\mu_{-}\sqrt{f_{-}+R^2_{\tau}/c^2}-\mu_{+}\sqrt{f_{+}+R^2_{\tau}/c^2}=\frac{\gamma\mu^2}{Rc^2}, \tag{3.24}$$

$$\mu_{-}\sqrt{f_{-}+R^2_{\tau}/c^2}+\mu_{+}\sqrt{f_{+}+R^2_{\tau}/c^2}=2(M_{+}-M_{-}). \tag{3.25}$$

In the end of the section we write out the Hamilton–Jacobi equations corresponding to the Hamiltonians (3.23) and to the constraints (3.18), (3.20) for truncated actions $S^{\pm}_0=S^{\pm}_0(R)$,

$$\frac{1}{f_{\pm}}\left(M_{+}-M_{-}\mp\frac{U}{c^2}\right)^2-\frac{f_{\pm}}{c^2}\left(\frac{dS^{\pm}_0}{dR}\right)^2=m^2, \tag{3.26}$$

$$f_{+}\,dS^{+}_0=f_{-}\,dS^{-}_0\,. \tag{3.27}$$

Then, the complete actions are determined by the formula $S^{\pm}=-c^2(M_{+}-M_{-})t_{\pm}+S^{\pm}_0$.

IV. PARTICULAR CASES OF SPHERICAL DUST CONFIGURATIONS

A. Self-gravitating dust shell

In this case $M_{-}=0$. Denote $M_{+}=M$ and consider the shell moving into the R_{+}-region. Then with respect to the exterior coordinates, the Lagrangian and the Hamiltonian of the shell have the form,

$$L^{+}_{\rm sh}=-mc^2\sqrt{1-\frac{2\gamma M}{c^2R}-\left(1-\frac{2\gamma M}{c^2R}\right)^{-1}\frac{R^2_{t+}}{c^2}}-\frac{\gamma m^2}{2R}, \tag{4.1}$$

$$H^{+}_{\rm sh}=c\sqrt{1-\frac{2\gamma M}{c^2R}}\sqrt{m^2c^2+\left(1-\frac{2\gamma M}{c^2R}\right)P^2_{+}}+\frac{\gamma m^2}{2R}. \tag{4.2}$$

The same shell with respect to the interior coordinates is described by the Lagrangian and the Hamiltonian,

$$L^{-}_{\rm sh}=-mc^2\sqrt{1-R^2_{t-}/c^2}+\frac{\gamma m^2}{2R}, \tag{4.3}$$

$$H^{-}_{\rm sh}=c\sqrt{m^2c^2+P^2_{-}}-\frac{\gamma m^2}{2R}. \tag{4.4}$$

This Hamiltonian was considered in the works.[8,9] The dynamical systems with $L^{\pm}_{\rm sh}$ obey momentum and Hamiltonian constraints $P_{-}=f_{+}P_{+}$, $H^{+}_{\rm sh}=H^{-}_{\rm sh}=Mc^2$ and they are canonically equivalent (see Appendix B).

B. The dust shell with vanishing full energy

Now we consider the shell for which the binding energy $E_b=(m+M_{-}-M_{+})c^2$ coincides with the rest energy mc^2. Denote $M_{+}=M_{-}\equiv M$, $f_{+}=f_{-}\equiv f=1-2\gamma M/c^2R$, $t_{+}=t_{-}\equiv t$. Then for the full energy we have $E=0$. This is possible, as it follows from (3.24), (3.25), only when $\mu_{+}=-\mu_{-}<0$, i.e., for the wormhole. Such a shell can be considered as a classical model for ''zeroth oscillations'' of dust matter with bare mass m under the gravitational field with $f=1-2\gamma M/c^2R$.

In terms $\{t, R\}$ the trajectories of ''zeroth oscillations'' are determined by the equation

$$\frac{dR}{dt}=\frac{2c^3}{\gamma m}\left(1-\frac{2\gamma M}{c^2R}\right)\sqrt{\frac{\gamma^2m^2}{4c^4}+\frac{2\gamma M}{c^2}R-R^2}. \tag{4.5}$$

Hence for the turning radius we have

$$R_m=\frac{\gamma}{c^2}\left(M+\sqrt{M+\frac{m^2}{4}}\right). \tag{4.6}$$

In the case of the flat space when $M=0$, from (4.5)and (4.6) we find

$$\frac{dR}{dt}=c\sqrt{1-\frac{R^2}{R_{m0}^2}},\quad R_{m0}=\frac{\gamma m}{2c^2}. \tag{4.7}$$

The equations of motion of such ''zeroth'' shells coincide with those for the oscillator,

$$\frac{d^2R}{dt^2}+\omega^2R=0. \tag{4.8}$$

Its oscillations $R(t)=R_{m0}\cos\omega(t-t_0)$ occur with the amplitude R_{m0} and frequency $\omega=c/R_{m0}=2c^3/\gamma m$. Hence we find the time of life of these shells into the flat space–time as a half-period of the oscillation,

$$T=\frac{\pi}{\omega}=\frac{\pi\gamma m}{2c^3}=\frac{\pi}{c}R_{m0}. \tag{4.9}$$

For the shell with mass equal to the mass of the Earth we have $R_g=2\gamma M/c^2\simeq 4cm$, $R_{m0}=R_g/4\simeq 1cm$, $T\simeq 10^{-10}c$. For the shells with Planck's mass $m=m_{\rm pl}=\sqrt{\hbar c/\gamma}$ the time of life equals $T=\pi T_{\rm pl}/2$, where $T_{\rm pl}=\sqrt{\hbar\gamma/c^5}$ is Planck's time. We underline, that the ''zero'' shells are characterized by that their gravitational binding energy completely compensate proper energy, leaving their total energy to be equal to zero. These shells can be thought of as a classical prototype of the Wheeler's space–time foam.[16]

C. The set of concentric dust shells

Now, consider briefly configurations consisting from the set of N concentric dust shells. Let R_a, m_a, τ_a be the radius, bare mass, and proper time of an ath shell, respectively ($a=1,2,\ldots,N$). For simplicity we suppose that $R_a>R_b$ if $a>b$. Then let M_a be the Schwarzschild mass determining the gravitational field $f_a=1-2\gamma M_a/c^2r$ on the right-hand side of an ath shell, into the region $R_a<r<R_{a+1}$. Suppose $f_a^-=1-2\gamma M_{a-1}/c^2R_a$ and $f_a^+=1-2\gamma M_a/c^2R_a$. Let $P_a^\pm=m_adR_a/f_a^\pm d\tau_a$ be the momenta of the ath shell, and $U_a^{(G)}=-\gamma m_a^2/2R_a$ be its potential energy of the self-action. Then,

$$H_a^\pm=c\varepsilon_a^\pm\sqrt{f_a^\pm(m_a^2c^2+f_a^\pm(P_a^\pm)^2)}\mp U_a \tag{4.10}$$

is the Hamiltonians of an ath shell. They, similarly to momenta $P_a^\pm$, are considered from the stationary observers' points of view, into the interior $R_{a-1}<r<R_a$ and exterior $R_a<r<R_{a+1}$, regions respectively. They satisfy the momentum and Hamiltonian constraints,

$$f_a^+P_a^+=f_a^-P_a^-,\quad H_a^+=H_a^-=(M_a-M_{a-1})c^2. \tag{4.11}$$

Now we are ready to determine the full Hamiltonian of this configuration,

$$H_N=\sum_{a=1}^{N} H_a^{\pm}. \tag{4.12}$$

For the self-gravitating configuration $M_0=0$. Then $H_1^{\pm}=M_1c^2$ and the full Hamiltonian of the configuration satisfies the constrain

$$H_N=Mc^2. \tag{4.13}$$

Here $M=M_N$ is the Schwarzschild mass of the configuration. The system admits the discrete gauge transformations,

$$M_a\leftrightarrow M_{a-1},\quad U_a\leftrightarrow -U_a,\quad t_a\leftrightarrow t_{a-1}\quad (a=1,2,\ldots,N),$$

where t_a is coordinate time determined on the right from an ath shell. The choice of sides (left or right) of the shells is not fixed beforehand and can be made by the reason of convenience.

ACKNOWLEDGMENTS

I would like to acknowledge M. Korkina and S. Stepanov for helpful discussions of problems, touched in this paper.

APPENDIX A: TRANSFORMATIONS OF THE SURFACE EQUATIONS

We show that the surface equations (2.26) reduce to the known equations for the jumps of the extrinsic curvature tensor on the shell.[1] First, we shall calculate $n_\mu[\omega^\mu]$.

We suppose that the following conditions are satisfied on the hypersurface $\Sigma_t^{(3)}$:

$$[n_\mu]=0,\quad [n_{\mu,\nu}]h_\sigma^\nu=0,\quad [n^\mu_{,\nu}]h_\sigma^\nu=0,\quad [g_{\mu\nu,\rho}]h_\sigma^\rho=0. \tag{A1}$$

Hence it follows

$$[\Gamma^\mu_{\rho\sigma}]h_\mu^\nu h_\beta^\rho h_\alpha^\sigma=0. \tag{A2}$$

Then from the definition (2.15) one finds

$$[\Gamma^\sigma_{\alpha\nu}]n_\sigma h_\beta^\nu=[K_{\alpha\beta}],\quad [\Gamma^\sigma_{\alpha\nu}]n_\sigma h^{\alpha\nu}=[K], \tag{A3}$$

$$[\Gamma^\sigma_{\alpha\nu}]n^\alpha h_\beta^\nu=-[K^\sigma_\beta]\quad ,[\Gamma^\sigma_{\alpha\nu}]n^\alpha h_\sigma^\nu=-[K], \tag{A4}$$

$$[\Gamma^\sigma_{\alpha\nu}]n_\sigma n^\alpha h_\beta^\nu=0. \tag{A5}$$

According to (2.12) we find

$$n_\mu\omega^\mu=n_\mu g^{\sigma\rho}\Gamma^\mu_{\sigma\rho}-n^\rho\Gamma^\sigma_{\rho\sigma}=n_\mu h^{\sigma\rho}\Gamma^\mu_{\rho\sigma}-n^\mu h^\sigma_\rho\Gamma^\rho_{\mu\sigma}.$$

Therefore, making use of Eqs. (A4) and (A5) we obtain the sought result (2.14).

Then, projecting the equation (2.26) into the hypersurface $\Sigma_t^{(3)}$ and into the normal n^ρ one finds

$$Q_{\sigma\rho}n^\rho-\tfrac{1}{2}Qn_\sigma=0, \tag{A6}$$

$$Q_{\sigma\rho}h^\sigma_\alpha h^\rho_\beta-\tfrac{1}{2}Qh_{\alpha\beta}=-\chi\sigma u_\alpha u_\beta. \tag{A7}$$

Using the definitions (2.27) and Eqs. (A2)–(A5) we obtain

$$Q=g_{\mu\nu}Q^{\mu\nu}=n_\mu[\omega^\mu]=2[K], \tag{A8}$$

$$
\begin{aligned}
Q_{\sigma\rho}n^{\rho} &= n_{\mu}n^{\rho}[\Gamma^{\mu}_{\rho\sigma}] - \tfrac{1}{2}n_{\sigma}n^{\rho}[\Gamma^{\mu}_{\rho\mu}] + \frac{1}{2}[\Gamma^{\mu}_{\sigma\mu}] \\
&= -n_{\sigma}(n_{\mu}[\Gamma^{\mu}_{\alpha\beta}]n^{\alpha}n^{\beta} + [\Gamma^{\mu}_{\mu\alpha}]n^{\alpha}) \\
&= -n_{\sigma}n^{\rho}[\Gamma^{\mu}_{\rho\nu}]h^{\nu}_{\mu} \\
&= [K]n_{\sigma}, \qquad \text{(A9)}
\end{aligned}
$$

$$
Q_{\sigma\rho}h^{\sigma}_{\alpha}h^{\rho}_{\beta} = n_{\mu}[\Gamma^{\mu}_{\sigma\rho}]h^{\sigma}_{\alpha}h^{\rho}_{\beta} = [K_{\alpha\beta}]. \qquad \text{(A10)}
$$

Thus Eqs. (A6) is satisfied identically, and Eq. (A7) yields the sought relations (2.28).

APPENDIX B: ON THE CANONICAL EQUIVALENCE OF THE ACTIONS $I^{\pm}_{\mathrm{sh}}$ FOR THE DUST SPHERICAL SHELL

In order to show the canonical equivalence of the actions $I^{\pm}_{\mathrm{sh}}$ in the extended phase space we write the variational principle (3.9) in the form

$$
\delta I^{\pm}_{\mathrm{sh}} = \delta \int (P_{\pm}dR - H_{\pm}dt_{\pm}) = 0, \qquad \text{(B1)}
$$

where

$$
P_{\pm} = \frac{1}{cf_{\pm}}\sqrt{(H_{\pm} \pm U)^2 - m^2c^4 f_{\pm}}\,. \qquad \text{(B2)}
$$

The dynamical systems with the actions $I^{\pm}_{\mathrm{sh}}$ are restricted by momentum and Hamiltonian constraints (3.18) and (3.20), which follow from the independent consideration of the faces of the shell.

The systems $I^{\pm}_{\mathrm{sh}}$ will be canonically equivalent in the extended phase space of variables $\{P_{\pm}, H_{\pm}, R, t_{\pm}\}$, if

$$
dI^{+}_{\mathrm{sh}} = dI^{-}_{\mathrm{sh}} + dF, \qquad \text{(B3)}
$$

or

$$
P_{+}dR - H_{+}dt_{+} = P_{-}dR - H_{-}dt_{-} + dF, \qquad \text{(B4)}
$$

where $F = F(R, t_{+}, t_{-})$ is the generating function of the canonical transformation $\{P_{+} = P_{+}(P_{-}, t_{-}, R),\ t_{+} = t_{+}(P_{-}, t_{-}, R)\}$. From (B4) we find

$$
H_{+} = -\frac{\partial F}{\partial t_{+}}, \quad H_{-} = \frac{\partial F}{\partial t_{-}}, \quad P_{+} = P_{-} - \frac{\partial F}{\partial R}. \qquad \text{(B5)}
$$

Using these relations the constraints (3.18) and (3.20) can be rewritten in the following way:

$$
-\frac{\partial F}{\partial t_{+}} = \frac{\partial F}{\partial t_{-}} = E\,, \quad \frac{\partial F}{\partial R} = P_{-}\left(1 - \frac{f_{-}}{f_{+}}\right). \qquad \text{(B6)}
$$

From here we find

$$
F = E(t_{-} - t_{+}) + \sigma(R, E), \qquad \text{(B7)}
$$

where

$$\sigma(R,E)=\frac{1}{c}\int\left(\frac{1}{f_-}-\frac{1}{f_+}\right)\sqrt{(E\pm U)^2-m^2c^4f_\pm}\,dR\,. \tag{B8}$$

The expression under the radical is invariant with respect to the replacement $f_\pm\to f_\mp$, $U\to -U$.

Then differentiating the expression (B7) over E one finds the relation between t_+ and t_-,

$$\frac{\partial F}{\partial E}=t_--t_++\frac{\partial\sigma}{\partial E}=\alpha, \tag{B9}$$

where the constant α cab be omitted. Thus, the transformations

$$\begin{cases} t_+=t_-+\dfrac{\partial\sigma(R,E)}{\partial E}, \\ P_+=P_-+\dfrac{\partial\sigma(R,E)}{\partial R}, \end{cases} \tag{B10}$$

are the sought canonical transformations of the extended phase space $\{P_\pm,H_\pm,R,t_\pm\}$ of the system. Herewith, the corresponding presymplectic form

$$dP_+\wedge dR-dE\wedge dt_+=dP_-\wedge dR-dE\wedge dt_- \tag{B11}$$

is invariant under these transformations.

The difference of the shell actions, which are considered from the point of view of the exterior and interior observers, up to an additive constant is $I^+_{\rm sh}(R,t_+)-I^-_{\rm sh}(R,t_-)=F(R,t_+,t_-)$, where $F=F(R,t_+,t_-)$ is the generating function, is calculated by the elimination of the energy E from the relations (B7) and (B9).

APPENDIX C: NONRELATIVISTIC DUST SHELL

Let us consider an infinitely thin dust layer in the Euclidean space $R^{(3)}$ in the form of the closed surface Σ_t moving in its own Newtonian gravitational field $\varphi=\varphi(\mathbf{r})$. The full action for this configuration has the form,

$$I^{(N)}_{\rm tot}=\int_{t_1}^{t_2}dt\left\{\int_{\Sigma_t}\left(\frac{1}{2}\sigma\mathbf{v}^2-\sigma\varphi\right)d^2f-\frac{1}{8\pi\gamma}\int_{D_-\cup D_+}(\nabla\varphi)^2\,dV\right\}. \tag{C1}$$

Here $\Sigma_t\,(t_1\leqslant t\leqslant t_2)$ is a one-parameter family of the closed surfaces, D_- and D_+ are interior and exterior regions of the shell Σ_t at a moment t, d^2f is the surface element on Σ_t, dV is the volume element in R^3, $\mathbf{v}$ is the velocity of particles of the shell, ∇ is the nabla operator, σ is surface mass density of dust on Σ_t. By virtue of the mass conservation law the value $dm\equiv\sigma d^2f$ conserves along the stream tube and in case of dust can be considered as a stationary value under arbitrary variations. Note also, that, we require that the potential φ be continuous, and, together with all its derivatives, vanish at infinity.

The requirement of extremity of the action $\delta I^{(N)}_{\rm tot}=0$ with respect to everywhere continuous variations $\delta\varphi$, vanishing on infinity, leads to the Laplace equation,

$$\Delta\varphi(\mathbf{r})=0,\quad \mathbf{r}\in D_-\cup D_+\,, \tag{C2}$$

with the boundary conditions for normal derivatives of φ on Σ_t. The latter, for completeness, will be written out together with the continuity conditions for φ on Σ_t,

$$[\varphi]\equiv\varphi_{|_+}-\varphi_{|_-}=0,\quad \left[\frac{\partial\varphi}{\partial\eta}\right]\equiv\left.\frac{\partial\varphi}{\partial\eta}\right|_+-\left.\frac{\partial\varphi}{\partial\eta}\right|_-=4\pi\gamma\sigma,\quad \mathbf{r}\in\Sigma_t\,(t=\text{const}). \tag{C3}$$

Here $\partial/\partial\eta=(\mathbf{n}\cdot\nabla)$ is the derivative with respect to the exterior normal $\mathbf{n}$ to Σ_t, vector $\mathbf{n}$ ($\mathbf{n}^2=1$) is directed from D_- to D_+. The solution of Eqs. (C2) and (C3) is the potential of a ''simple layer,''

$$\varphi_\sigma(\mathbf{r})=-\gamma\int_{\Sigma_t}\frac{\sigma(\mathbf{r}')d^2f'}{|\mathbf{r}-\mathbf{r}'|}. \tag{C4}$$

Now we can calculate $I^{(N)}_{\text{tot}}$ on the solutions of Eqs. (C2) and (C3). Thereby, the potential φ is excluded from the full action (C1). Note that owing to (C2) we have $(\nabla\varphi)^2=\nabla(\varphi\nabla\varphi)$. This allows to transform the volume integral of (C1) into the surface one on the boundaries of the regions $D_\pm$. Taking into account the boundary conditions (C3) and an asymptotic behavior of φ, we find the reduced action $I^{(N)}_{\text{tot}}$, as the value of the initial action on the solution (C4) of Eqs. (C2) and (C3),

$$I^{(N)}_{\text{tot}}|_{\{\text{solutions Eqs. (C2), (C3)}\}}=I^{(N)}_{\text{sh}}+I^{(N)}_0. \tag{C5}$$

Here $I^{(N)}_0$ contains the surface term, which is unessential for further consideration, and

$$I^{(N)}_{\text{sh}}=\int_{t_1}^{t_2}L^{(N)}_{\text{sh}}\,dt \tag{C6}$$

is the effective action for the shell with the Lagrangian,

$$L^{(N)}_{\text{sh}}=\frac{1}{2}\int_{\Sigma_t}\sigma\mathbf{v}^2df-U, \tag{C7}$$

where

$$U=\frac{1}{2}\int_{\Sigma_t}\sigma\varphi_\sigma\,df=-\frac{\gamma}{2}\int_{\Sigma_t}\int_{\Sigma_t}\frac{\sigma(\mathbf{r})\sigma(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}dfdf' \tag{C8}$$

is the functional of the potential energy of the gravitational self-action of the shell.

The Lagrangian of the shell in an external gravitational field $\varphi_0=\varphi_0(\mathbf{r})$ has the form,

$$L^{(N)}_{\text{sh}}=\int_{\Sigma_t}\left(\frac{1}{2}\sigma\mathbf{v}^2-\sigma\varphi_0\right)df-U. \tag{C9}$$

Now consider the spherical nonrelativistic dust shell. Let $R=R(t)$ be the radius of the spherical shell at a moment t. With respect to the spherical coordinates $\{r,\theta,\alpha\}$, we have $\sigma=\sigma(r)$, $d^2f=R(t)\sin\theta d\theta d\alpha$, $\mathbf{v}^2=\dot{R}^2=(dR/dt)^2$. The mass of the shell is $m=4\pi\sigma R^2=\text{const}$. The potential of the external field φ_0 on the shell has the value

$$\varphi_0\equiv\varphi_-=-\frac{\gamma m_-}{R(t)}, \tag{C10}$$

where m_- is the total mass of the interior source. The potential φ_σ and the self-action energy for the shell U prove to be equal

$$\varphi_\sigma(r)=\begin{cases}-\gamma m/r, & r\geqslant R(t)\\ -\gamma m/R(t), & r<R(t)\end{cases}, \tag{C11}$$

$$U=\frac{1}{2}m\varphi_\sigma=-\frac{\gamma m^2}{2R(t)}. \tag{C12}$$

Replacing the corresponding terms in (C9) by those of (C10)–(C12), we obtain the Lagrangian of the spherically-symmetric dust shell in Newtonian theory of gravity,

$$L^{(N)}_{\mathrm{sh}-}=\frac{1}{2}m\dot{R}^2+\frac{\gamma m m_-}{R}-U. \tag{C13}$$

A distinctive feature of spherical shell is that the two-valued description of the shell dynamic becomes possible with respect to the observer's position. From an interior observer's point of view, except for the force of self-action $-\partial U/\partial R$, the shell is effected by the external force $F_-=-md\varphi_-/dr$, which determines an interior gravitational field. This situation corresponds to the Lagrangian $L^{(N)}_{\mathrm{sh}-}$, therefore the latter can be interpreted as the Lagrangian describing the nonrelativistic shell from an interior observer's point of view.

An exterior observer $[r>R(t)]$ determines the field, judging by the force $F_+=-md\varphi_+/dr$ acting on the shell in the field $\varphi_+=\varphi_-+\varphi_\sigma=-\gamma m_+/R(t)$. This field is generated by the total mass of the system $m_+=m_-+m$. If, by making use of this relation, we eliminate m_- from $L^{(N)}_{\mathrm{sh}-}$ we obtain the following Lagrangian:

$$L^{(N)}_{\mathrm{sh}+}=\frac{1}{2}m\dot{R}^2+\frac{\gamma m m_+}{R}+U. \tag{C14}$$

It can be interpreted as the Lagrangian describing the Newtonian shell from an exterior observer's point of view.

In such a way, transformation from an exterior observer to an interior one stipulates the discrete transformation $m_\pm\to m_\mp=m_\pm\mp m$. Its can be interpreted as both the gravitational potential transformation $\varphi_\pm\to\varphi_\mp=\varphi_\pm\pm\gamma m/R$ and the change of sign of the self-action potential $U^{(N)}\to-U^{(N)}$. The above two-valued description of spherical shell in the Newtonian theory has a formal character. This ambiguity, arising when describing spherically-symmetric shell, is a matter of principle in General Relativity.

Note other feature of the shell, which has nontrivial meaning in General Relativity. The Lagrangians $L^{(N)}_{\mathrm{sh}\pm}$ completely and closely determine the motion of boundaries of regions $D_\pm$. That is why they can be thought of as independent systems with their momenta and Hamiltonians,

$$P_\pm=m\dot{R}_\pm,\quad H_\pm=\frac{P_\pm^2}{2m}-\frac{\gamma m m_\pm}{R_\pm}\mp U_\pm=E_\pm. \tag{C15}$$

Here $E_\pm$ are the total energies of these boundaries, $U^{(N)}_\pm=-\gamma m^2/2R_\pm$ are their potential energies of self-action, and $R_\pm=R_\pm(t)$ are the radiuses of the regions' boundary $D_\pm$. The systems (C15) describe the same shell provided the regions $D_\pm$ have a common boundary $R_+(t)=R_-(t)\equiv R(t)$ for all moments t. In this case, eliminating the momentum $P\equiv P_+=P_-$ from the equations $H_\pm=E_\pm$ one has

$$E_+-E_-=\frac{\gamma m}{R}(m_+-m-m_-). \tag{C16}$$

Hence it follows an ordinary equality of energies and the additivity of masses $E_+=E_-$, $m_+=m-m_-$. In General Relativity, a similar but not trivial procedure follows from the isometry conditions for the boundaries of the corresponding four-dimensional regions.

Finally we shall write the corresponding relations for a self-gravitating shell, when $m_-=0$,

$$L^{(N)}_{\mathrm{sh}-}=\frac{1}{2}m\dot{R}^2+\frac{\gamma m^2}{2R}, \tag{C17}$$

$$P = m\dot{R}, \quad H = \frac{P^2}{2m} - \frac{\gamma m^2}{2R} = E. \tag{C18}$$

[15] In the four-dimensional case, for configurations with the dust density ρ, we have $\rho d^4\Omega = \omega \wedge d^3m$, where $d^3m = \rho\sqrt{-g}u^\mu d\Sigma_\mu$ is the 3-form of the element of the mass for some hypersurface. The requirement of the closure $d \wedge d^3m = 0$ gives a conservation law $(\sqrt{-g}\,\rho u^\mu)_{,\mu} = 0$. Therefore, in the Lagrange formulation of an perfect fluid, quantity $\sqrt{-g}\,\rho u^\mu$ does not vary when varying of the metric [see, S. W. Hawking and G. F. R. Ellis, *The Large Scale Structure of Space–Time* (Cambridge University Press, Cambridge, 1973)]. Therefore, the 3-form d^3m does not vary too. Similarly to this, in a three-dimensional case the 2-form d^2m is closed on $\Sigma_t^{(3)}$ and, by virtue of a conservation law, does not vary when varying the metric.

The trace formula for Sturm–Liouville operator with operator coefficient

Ehliman Adigüzelov, Hamit Avci,[a] and Erdal Gül
Yildiz Technical University, Faculty of Science and Art, Department of Mathematics, Davutpasa Campus, Istanbul, Turkey

(Received 4 December 2000; accepted for publication 28 February 2001)

We will obtain a formula for the trace of the Sturm–Liouville operator with operator coefficient. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1367866]

I. INTRODUCTION

Let H be a separable Hilbert space. Let us consider the operators L_0 and L in the space $H_1 = L_2(H;[0,\pi])$ which are formed by the following differential expression:

$$l_0(y) = -y''(x), \quad l(y) = -y''(x) + Q(x)y(x),$$

with the same boundary condition $y(0) = y(\pi) = 0$, respectively. Suppose that the operator function $Q(x)$ in the expression $l(y)$ satisfies the following conditions:

(1) For $\forall x \in [0,\pi]$, $Q(x)$: $H \to H$ is a self-adjoint kernel operator. Moreover, $Q(x)$ has continuous derivative of second order with respect to the norm in space $\sigma_1(H)$ in the interval $[0, \pi]$ and for $x \in [0,\pi]$, $Q^{(i)}(x)$: $H \to H$ are self-adjoint operators $(i = 1,2)$.

(2) $\mathrm{Sup}_{[0,\pi]} \|Q(x)\|_H < \frac{3}{2}$.

(3) There is an orthonormal basis $\{\varphi_n\}_{n=1}^{\infty}$ of the space H such that

$$\sum_{n=1}^{\infty} \|Q(x)\varphi_n\| < \infty.$$

Here $\sigma_1(H)$ is the space of kernel operators from H to H as in Ref. 1. Moreover $\|.\|_H$ and $\|.\|$ denote the norms in H and H_1, respectively, and $\mathrm{tr}\, A = \mathrm{trace}\, A$ denotes the sum of eigenvalues of a kernel operator A.

In Ref. 2, it is proved that the spectrum of the operator L is a subset of the union of the intervals $[m^2 - \frac{3}{2}, m^2 + \frac{3}{2}]$ $(m = 1,2,...)$ and that spectrum is a disjoint eigenvalue whose points, not belonging to the set $\{m^2\}_{m=1}^{\infty}$, have finite multiplicity. Again in Ref. 2, it is proved that m^2 $(m = 1,2,...)$ is a eigenvalue of L which has finite or infinite multiplicity and that

$$\lim_{n \to \infty} \lambda_{mn} = m^2$$

such that $\{\lambda_{mn}\}_{n=1}^{\infty}$ are eigenvalues which belong to the interval $[m^2 - \frac{3}{2}, m^2 + \frac{3}{2}]$. Moreover, the trace formula in the form

$$\sum_{m=1}^{\infty} \left[\sum_{n=1}^{\infty} (\lambda_{mn} - m^2) - \frac{1}{\pi} \int_0^{\pi} \mathrm{tr}\, Q(x)\, dx \right] = -\frac{\mathrm{tr}\, Q(0) + \mathrm{tr}\, Q(\pi)}{4} + \frac{1}{2\pi} \int_0^{\pi} \mathrm{tr}\, Q(x)\, dx$$

has been found for the self-adjoint operator L in Ref. 2.

In this work, we will find a formula for the sum of series

[a]Electronic mail: avci@yildiz.edu.tr

$$\sum_{m=1}^{\infty}\left\{\sum_{n=1}^{\infty}(\lambda_{mn}^2-m^4)-\frac{2m^2}{\pi}\int_0^{\pi}\operatorname{tr}Q(x)\,dx-\frac{1}{2\pi}[\operatorname{tr}Q'(0)-\operatorname{tr}Q'(\pi)]\right.$$
$$\left.-\frac{1}{2\pi}\int_0^{\pi}\operatorname{tr}Q^2(x)\,dx-\frac{1}{2\pi^2}\operatorname{tr}\left(\int_0^{\pi}Q(x)\,dx\right)^2\right\}.$$

The trace formulas for the scalar differential operators have been found by Gelfand and Levitan,[3] Dikiy,[4] Halberg and Kramer[5] and many other works. The list of the works on this subject is given in Levitan and Sargsyan[6] and Fulton and Pruess.[7] Note that we have only a few works on the trace of differential operators with operator coefficient. In Ref. 8, the trace of the Sturm–Liouville operator with unbounded operator coefficient has been investigated.

Let R_λ^0 and R_λ be the resolvents of the operators L_0 and L, respectively. The spectrum of the operator L_0 is the set $\{m^2\}_{m=1}^{\infty}$ and every point of this set is the eigenvalue of L_0 which has infinite multiplicity. The eigenvectors corresponding to eigenvalue m^2 are given by the form

$$\psi_{mn}=\sqrt{\frac{2}{\pi}}\operatorname{Sin}mx\cdot\varphi_n,\quad n=1,2,\ldots. \tag{1.1}$$

II. SOME FORMULAS ABOUT EIGENVALUES AND THE OPERATOR QR_λ^0

Since the operator Q satisfies the condition (3) and the system (1,1) of eigenvectors of operator L_0 is a orthonormal basis of the space H_1, it can be seen that QR_λ^0: $H_1\to H_1$ is a kernel operator for every $\lambda\notin\{m^2\}_{m=1}^{\infty}$. Then, from the relation

$$R_\lambda-R_\lambda^0=-R_\lambda QR_\lambda^0 \tag{2.1}$$

we see that $R_\lambda-R_\lambda^0\in\sigma_1(H)$ for each λ which belongs to the resolvent set of L. In this case, from Ref. 2, since

$$\operatorname{tr}(R_\lambda-R_\lambda^0)=\sum_{m=1}^{\infty}\sum_{n=1}^{\infty}\left(\frac{1}{\lambda_{mn}-\lambda}-\frac{1}{m^2-\lambda}\right)$$

we obtain

$$\frac{1}{2\pi i}\int_{|\lambda|=b_p}\lambda^2\operatorname{tr}(R_\lambda-R_\lambda^0)\,d\lambda=\sum_{m=1}^{p}\sum_{n=1}^{\infty}(m^4-\lambda_{mn}^2),$$

where $b_p=p^2+p$. From (2.1) and this last relation, we write

$$\sum_{m=1}^{p}\sum_{n=1}^{\infty}(\lambda_{mn}^2-m^4)=\sum_{j=1}^{N}M_{pj}+M_p^{(N)}. \tag{2.2}$$

Here N is a integer,

$$M_{pj}=\frac{(-1)^{j+1}}{2\pi i}\int_{|\lambda|=b_p}\lambda^2\operatorname{tr}[R_\lambda^0(QR_\lambda^0)^j]\,d\lambda$$

and

$$M_p^{(N)}=\frac{(-1)^N}{2\pi i}\int_{|\lambda|=b_p}\lambda^2\operatorname{tr}[R_\lambda(QR_\lambda^0)^{N+1}]d\lambda. \tag{2.3}$$

Since the operator function QR_λ^0 in the domain $\mathbb{C}\backslash\{m^2\}_{m=1}^{\infty}$ is analytic with respect to the norm in $\sigma_1(H_1)$, we can show that

$$M_{pj}=\frac{(-1)^j}{\pi i j}\int_{|\lambda|=b_p}\lambda\,\mathrm{tr}\,(QR_\lambda^0)^j\,d\lambda. \tag{2.4}$$

From relations (1.1) and (2.4), we write

$$\begin{aligned}M_{p1}&=-\frac{1}{\pi i}\int_{|\lambda|=b_p}\lambda\sum_{m=1}^{\infty}\sum_{n=1}^{\infty}(QR_\lambda^0\psi_{mn},\psi_{mn})\,d\lambda\\&=2\sum_{m=1}^{\infty}\sum_{n=1}^{\infty}(Q\psi_{mn},\psi_{mn})\frac{1}{2\pi i}\int_{|\lambda|=b_p}\frac{\lambda}{\lambda-m^2}\,d\lambda\\&=2\sum_{m=1}^{p}\sum_{n=1}^{\infty}m^2(Q\psi_{mn},\psi_{mn})\\&=\frac{2}{\pi}\sum_{m=1}^{p}m^2\int_0^{\pi}\mathrm{tr}\,Q(x)\,dx-\frac{2}{\pi}\sum_{m=1}^{p}m^2\int_0^{\pi}\mathrm{tr}\,Q(x)\,\mathrm{Cos}\,2mx\,dx.\end{aligned}$$

On the other hand, since

$$\int_0^{\pi}\mathrm{tr}\,Q(x)\,\mathrm{Cos}\,2mx\,dx=\frac{\mathrm{tr}\,Q'(\pi)-\mathrm{tr}\,Q'(0)}{4m^2}-\frac{1}{4m^2}\int_0^{\pi}\mathrm{tr}\,Q''(x)\,\mathrm{Cos}\,2mx\,dx,$$

we have

$$M_{p1}=\frac{2}{\pi}\sum_{m=1}^{p}m^2\int_0^{\pi}\mathrm{tr}\,Q(x)\,dx+\frac{p}{2\pi}[\mathrm{tr}\,Q'(0)-\mathrm{tr}\,Q'(\pi)]+\frac{1}{2\pi}\sum_{m=1}^{p}\int_0^{\pi}\mathrm{tr}\,Q''(x)\,\mathrm{Cos}\,2mx\,dx. \tag{2.5}$$

Now, let us compute M_{p2}: From (2.4) we write

$$M_{p2}=\frac{1}{2\pi i}\int_{|\lambda|=b_p}\lambda\,\mathrm{tr}\,(QR_\lambda^0)^2\,d\lambda=\frac{1}{2\pi i}\int_{|\lambda|=b_p}\lambda\sum_{m=1}^{\infty}\sum_{n=1}^{\infty}((QR_\lambda^0)^2\psi_{mn},\psi_{mn})\,d\lambda. \tag{2.6}$$

Moreover, we know that

$$QR_\lambda^0\psi_{mn}=\frac{Q\psi_{mn}}{m^2-\lambda}$$

and

$$\begin{aligned}(QR_\lambda^0)^2\psi_{mn}&=(m^2-\lambda)^{-1}QR_\lambda^0(Q\psi_{mn})\\&=(m^2-\lambda)^{-1}QR_\lambda^0\left\{\sum_{r=1}^{\infty}\sum_{q=1}^{\infty}(Q\psi_{mn},\psi_{rq})\psi_{rq}\right\}\\&=(m^2-\lambda)^{-1}\sum_{r=1}^{\infty}\sum_{q=1}^{\infty}(r^2-\lambda)^{-1}(Q\psi_{mn},\psi_{rq})Q\psi_{rq}.\end{aligned}$$

If we write this last expression, in (2.6), we find

$$M_{p2}=\frac{1}{2\pi i}\int_{|\lambda|=b_p}\lambda\left[\sum_{m=1}^{\infty}\sum_{n=1}^{\infty}\sum_{r=1}^{\infty}\sum_{q=1}^{\infty}\frac{(Q\psi_{mn},\psi_{rq})(Q\psi_{rq},\psi_{mn})}{(\lambda-m^2)(\lambda-r^2)}\right]d\lambda$$

$$=\sum_{m=1}^{\infty}\sum_{n=1}^{\infty}\sum_{r=1}^{\infty}\sum_{q=1}^{\infty}|(Q\psi_{mn},\psi_{rq})|^2\frac{1}{2\pi i}\int_{|\lambda|=b_p}\frac{\lambda}{(\lambda-m^2)(\lambda-r^2)}d\lambda$$

$$=\sum_{m=1}^{p}\sum_{n=1}^{\infty}\sum_{r=1}^{p}\sum_{q=1}^{\infty}|(Q\psi_{mn},\psi_{rq})|^2\frac{1}{2\pi i}\int_{|\lambda|=b_p}\frac{\lambda}{(\lambda-m^2)(\lambda-r^2)}d\lambda$$

$$+\sum_{m=1}^{p}\sum_{n=1}^{\infty}\sum_{r=p+1}^{\infty}\sum_{q=1}^{\infty}|(Q\psi_{mn},\psi_{rq})|^2\frac{1}{2\pi i}\int_{|\lambda|=b_p}\frac{\lambda}{(\lambda-m^2)(\lambda-r^2)}d\lambda$$

$$+\sum_{m=p+1}^{\infty}\sum_{n=1}^{\infty}\sum_{r=1}^{p}\sum_{q=1}^{\infty}|(Q\psi_{mn},\psi_{rq})|^2\frac{1}{2\pi i}\int_{|\lambda|=b_p}\frac{\lambda}{(\lambda-m^2)(\lambda-r^2)}d\lambda$$

$$+\sum_{m=p+1}^{\infty}\sum_{n=1}^{\infty}\sum_{r=p+1}^{\infty}\sum_{q=1}^{\infty}|(Q\psi_{mn},\psi_{rq})|^2\frac{1}{2\pi i}\int_{|\lambda|=b_p}\frac{\lambda}{(\lambda-m^2)(\lambda-r^2)}d\lambda$$

$$=\sum_{m=1}^{p}\sum_{n=1}^{\infty}\sum_{r=1}^{p}\sum_{q=1}^{\infty}|(Q\psi_{mn},\psi_{rq})|^2+2\sum_{m=1}^{p}\sum_{n=1}^{\infty}\sum_{r=p+1}^{\infty}\sum_{q=1}^{\infty}|(Q\psi_{mn},\psi_{rq})|^2\frac{m^2}{m^2-r^2}$$

$$=\sum_{m=1}^{p}\sum_{n=1}^{\infty}\sum_{r=1}^{\infty}\sum_{q=1}^{\infty}|(Q\psi_{mn},\psi_{rq})|^2-\sum_{m=1}^{p}\sum_{n=1}^{\infty}\sum_{r=p+1}^{\infty}\sum_{q=1}^{\infty}\left(1+\frac{2m^2}{r^2-m^2}\right)|(Q\psi_{mn},\psi_{rq})|^2$$

$$=\sum_{m=1}^{p}\sum_{n=1}^{\infty}\|Q\psi_{mn}\|^2-\sum_{m=1}^{p}\sum_{n=1}^{\infty}\sum_{r=p+1}^{\infty}\sum_{q=1}^{\infty}\frac{r^2+m^2}{r^2-m^2}|(Q\psi_{mn},\psi_{rq})|^2.$$

Here if we take

$$\alpha_p=\alpha_p(n,q)=\sum_{m=1}^{p}\sum_{r=p+1}^{\infty}\frac{r^2+m^2}{r^2-m^2}|(Q\psi_{mn},\psi_{rq})|^2,$$

then we write

$$M_{p2}=\sum_{m=1}^{p}\sum_{n=1}^{\infty}\|Q\psi_{mn}\|^2-\sum_{n=1}^{\infty}\sum_{q=1}^{\infty}\alpha_p. \tag{2.7}$$

From Eq. (1.1) we have

$$\alpha_p=\alpha_{p1}-\alpha_{p2}+\alpha_{p3}, \tag{2.8}$$

where

$$\alpha_{p1}=\pi^{-2}\sum_{m=1}^{p}\sum_{r=p+1}^{\infty}\frac{r^2+m^2}{r^2-m^2}\left|\int_0^{\pi}(Q(x)\varphi_n,\varphi_q)_H\operatorname{Cos}(m-r)x\,dx\right|^2,$$

$$\alpha_{p2}=2\pi^{-2}\sum_{m=1}^{p}\sum_{r=p+1}^{\infty}\frac{r^2+m^2}{r^2-m^2}\operatorname{Re}\left[\int_0^{\pi}(Q(x)\varphi_n,\varphi_q)_H\cdot\operatorname{Cos}(m-r)x\,dx\right.$$

$$\left.\times\int_0^{\pi}\overline{(Q(x)\varphi_n,\varphi_q)_H}\operatorname{Cos}(m+r)x\,dx\right], \tag{2.9}$$

$$\alpha_{p3}=\pi^{-2}\sum_{m=1}^{p}\sum_{r=p+1}^{\infty}\frac{r^2+m^2}{r^2-m^2}\left|\int_0^{\pi}(Q(x)\varphi_n,\varphi_q)_H\operatorname{Cos}(m+r)x\,dx\right|^2. \tag{2.10}$$

For any integers p and i, we let

$$E=\{(r,m):r,m\in N;r-m=i;m\leqslant p;r>p\}.$$

Then, for the expression α_{p1}, we can write

$$\alpha_{p1}=\pi^{-2}\sum_{i=1}^{\infty}\left(\sum_{m,r\in E}\frac{r^2+m^2}{r^2-m^2}\right)\left|\int_0^{\pi}(Q(x)\varphi_n,\varphi_q)_H\operatorname{Cos}(ix)\,dx\right|^2. \tag{2.11}$$

The equalities

$$\sum_{m,r\in E}\frac{r^2+m^2}{r^2-m^2}=p+\frac{1}{2}+i^2O(p^{-1})\quad\text{for}\quad i\leqslant p \tag{2.12}$$

and

$$\sum_{m,r\in E}\frac{r^2+m^2}{r^2-m^2}=O(p)\quad\text{for}\quad i\geqslant p \tag{2.13}$$

can be proved easily. Here $O(p^{-1})$ and $O(p)$ depend on p and i and they satisfy the inequalities

$$|O(p^{-1})|<\operatorname{const}p^{-1},\quad |O(p)|<\operatorname{const}p.$$

From (2.11)–(2.13), we obtain

$$\begin{aligned}\alpha_{p1}&=\pi^{-2}\left(p+\frac{1}{2}\right)\sum_{i=1}^{\infty}\left|\int_0^{\pi}(Q(x)\varphi_n,\varphi_q)_H\operatorname{Cos}ix\,dx\right|^2\\&\quad+\sum_{i=1}^{\infty}i^2O(p^{-1})\left|\int_0^{\pi}(Q(x)\varphi_n,\varphi_q)_H\operatorname{Cos}ix\,dx\right|^2\\&\quad+\sum_{i=p+1}^{\infty}O(p)\left|\int_0^{\pi}(Q(x)\varphi_n,\varphi_q)_H\operatorname{Cos}ix\,dx\right|^2\\&=\alpha_{p1}^{(1)}+\alpha_{p1}^{(2)}+\alpha_{p1}^{(3)}.\end{aligned}$$

Here,

$$\begin{aligned}\alpha_{p1}^{(1)}&=\pi^{-2}\left(p+\frac{1}{2}\right)\sum_{i=1}^{\infty}\left|\int_0^{\pi}(Q(x)\varphi_n,\varphi_q)_H\operatorname{Cos}ix\,dx\right|^2\\&=\frac{2p+1}{4\pi}\int_0^{\pi}|(Q(x)\varphi_n,\varphi_q)_H|^2dx-\frac{2p+1}{4\pi^2}\int_0^{\pi}|(Q(x)\varphi_n,\varphi_q)_H\,dx|^2,\end{aligned}$$

$$|\alpha_{p1}^{(2)}|=\left|\sum_{i=1}^{p}i^2O(p^{-1})\left|\int_0^{\pi}(Q(x)\varphi_n,\varphi_q)_H\operatorname{Cos}ix\,dx\right|^2\right|\leqslant\operatorname{const}p^{-1}\int_0^{\pi}|(Q'(x)\varphi_n,\varphi_q)_H|^2\,dx,$$

and

$$|\alpha_{p1}^{(3)}|=\left|\sum_{i=p+1}^{\infty} O(p)\left|\int_0^{\pi}(Q(x)\varphi_n,\varphi_q)_H \operatorname{Cos} ix\,dx\right|^2\right|\leqslant \text{const} p^{-1}\int_0^{\pi}|(Q'(x)\varphi_n,\varphi_q)_H|^2\,dx.$$

From (2.8) and these last relations, we find

$$\sum_{n=1}^{\infty}\sum_{q=1}^{\infty}\alpha_{p1}=\frac{2p+1}{4\pi}\int_0^{\pi}\operatorname{tr}Q^2(x)\,dx-\frac{2p+1}{4\pi^2}\operatorname{tr}\left(\int_0^{\pi}Q(x)\,dx\right)^2+O(p^{-1}). \tag{2.14}$$

Since $Q(x)$ satisfies the condition (1), it can be shown that

$$\left|\sum_{n=1}^{\infty}\sum_{q=1}^{\infty}\alpha_{pj}\right|<\text{const}\,p^{-1}\quad (j=2,3). \tag{2.15}$$

By using (2.7), (2.8), (2.14) and (2.15), we find

$$M_{p2}=\sum_{m=1}^{p}\sum_{n=1}^{\infty}\|Q\psi_{mn}\|^2-\frac{2p+1}{4\pi}\int_0^{\pi}\operatorname{tr}Q^2(x)\,dx+\frac{2p+1}{4\pi^2}\operatorname{tr}\left(\int_0^{\pi}Q^2(x)\,dx\right)^2+O(p^{-1}), \tag{2.16}$$

where $O(p^{-1})$ depends on p and satisfies the inequality

$$|O(p^{-1})|<\text{const}\,p^{-1}.$$

Now, let us compute the sum $\Sigma_{m=1}^{p}\Sigma_{n=1}^{\infty}\|Q\psi_{mn}\|^2$:

$$\begin{aligned}\sum_{m=1}^{p}\sum_{n=1}^{\infty}\|Q\psi_{mn}\|^2&=\frac{2}{\pi}\sum_{m=1}^{p}\sum_{n=1}^{\infty}\int_0^{\pi}\operatorname{Sin}^2 mx(Q^2(x)\varphi_n,\varphi_n)_H\,dx\\&=\frac{p}{\pi}\int_0^{\pi}\sum_{n=1}^{\infty}(Q^2(x)\varphi_n,\varphi_n)\,dx-\frac{1}{\pi}\sum_{m=1}^{p}\int_0^{\pi}\sum_{n=1}^{\infty}(Q^2(x)\varphi_n,\varphi_n)_H\operatorname{Cos}2mx\,dx\\&=\frac{p}{\pi}\int_0^{\pi}\operatorname{tr}Q^2(x)\,dx-\frac{1}{\pi}\sum_{m=1}^{p}\int_0^{\pi}\operatorname{tr}Q^2(x)\operatorname{Cos}2mx\,dx.\end{aligned}$$

If we put this expression into (2.16), we have

$$\begin{aligned}M_{p2}=&\frac{2p-1}{4\pi}\int_0^{\pi}\operatorname{tr}Q^2(x)+\frac{2p+1}{4\pi^2}\operatorname{tr}\left(\int_0^{\pi}Q(x)\,dx\right)^2\\&-\frac{1}{\pi}\sum_{m=1}^{p}\int_0^{\pi}\operatorname{tr}Q^2(x)\operatorname{Cos}2mx\,dx+O(p^{-1}).\end{aligned} \tag{2.17}$$

III. A FORMULA FOR THE TRACE OF THE OPERATOR *L*

In this section, we will find a formula for the sum

$$\sum_{m=1}^{\infty}\left[\sum_{n=1}^{\infty}(\lambda_{mn}^2-m^4)-\frac{2m^2}{\pi}\int_0^{\pi}\operatorname{tr}Q(x)\,dx-C\right],$$

where

$$C=\frac{1}{2\pi}[\operatorname{tr}Q'(0)-\operatorname{tr}Q'(\pi)]+\frac{1}{2\pi}\int_0^{\pi}\operatorname{tr}Q^2(x)\,dx+\frac{1}{2\pi^2}\operatorname{tr}\left(\int_0^{\pi}Q(x)\,dx\right)^2.$$

For this, we will first show that the formulas

$$\lim_{p\to\infty} M_{pj}=0, \quad j\geqslant 3, \tag{3.1}$$

$$\lim_{p\to\infty} M_p^N=0, \quad N\geqslant 6, \tag{3.2}$$

are satisfied. It is not difficult to see that the inequalities

$$\|QR_\lambda^0\|_{\sigma_1(H_1)}<C_1 \quad (|\lambda|=b_p), \tag{3.3}$$

$$\|R_\lambda^0\|<C_1p^{-1} \quad \|R_\lambda\|<C_1p^{-1} \quad (|\lambda|=b_p), \tag{3.4}$$

are true. Here $C_1>0$ is a constant. From (2.4), (3.3), and (3.4) and since $Q(x)$ satisfies the condition (2), we have

$$\begin{aligned}
|M_{pj}| &= \frac{1}{\pi j}\left|\int_{|\lambda|=b_\rho} \lambda \operatorname{tr}(QR_\lambda^0)^j\, d\lambda\right| \\
&\leqslant \frac{b_p}{\pi j}\int_{|\lambda|=b_p} \|(QR_\lambda^0)^j\|_{\sigma_1(H_1)}|\, d\lambda| \\
&\leqslant \frac{b_p}{\pi j}\int_{|\lambda|=b_p} \|(QR_\lambda^0)\|_{\sigma_1(H_1)}\|(QR_\lambda^0)^{j-1}\||d\lambda| \\
&\leqslant \frac{C_1b_p}{\pi j}\int_{|\lambda|=b_p} \|Q\|^{j-1}\|R_\lambda^0\|^{j-1}|d\lambda| \\
&\leqslant \frac{C_1^jb_p}{\pi j}\int_{|\lambda|=b_p}\left(\frac{3}{2}\right)^{j-1} p^{1-j}|d\lambda| \\
&< C_2p^{5-j} \quad (C_2>0).
\end{aligned}$$

And so, we find

$$\lim_{p\to\infty} = M_{pj}=0 \quad (j\geqslant 6),$$

but we claim that this is true also for $j=3,4,5$. Let us try this for $j=3$. It can be seen that

$$M_{pj}=\frac{(-1)^j}{\pi ij}\sum_{m_1=1}^{\infty}\sum_{n_1=1}^{\infty}\cdots\sum_{m_j=1}^{\infty}\sum_{n_j=1}^{\infty}{}^{*}\left[\int_{|\lambda|=b_p}\lambda\prod_{l=1}^{j}(m_l^2-\lambda)^{-1}\,d\lambda\right]\cdot\prod_{l=1}^{j}(Q\psi_{m_ln_l},\psi_{m_{g(l)}n_{g(l)}}). \tag{3.5}$$

Here the symbol ''*'' denotes that there are numbers, between $m_1^4, m_2^4, \ldots, m_j^4$, less than or greater than b_p and

$$g(l)=\begin{cases} l+1, & l<j, \\ 1, & l=j. \end{cases}$$

For $j=3$, we write

$$M_{p3}=-\frac{1}{3\pi i}\sum_{m=1}^{\infty}\sum_{n=1}^{\infty}\sum_{r=1}^{\infty}\sum_{q=1}^{\infty}\sum_{R=1}^{\infty}\sum_{N=1}^{\infty}*\int_{|\lambda|=b_p}\frac{\lambda\,d\lambda}{(m^2-\lambda)(r^2-\lambda)(R^2-\lambda)}$$
$$\cdot(Q\psi_{mn},\psi_{rq})(Q\psi_{rq},\psi_{RN})(Q\psi_{RN},\psi_{mn}). \tag{3.6}$$

Let us take

$$F(m,r,R)=\sum_{n=1}^{\infty}\sum_{q=1}^{\infty}\sum_{N=1}^{\infty}(Q\psi_{mn},\psi_{rq})(Q\psi_{rq},\psi_{rN})(Q\psi_{rN},\psi_{mn}).$$

Since $F(m,r,R)=F(r,m,R)=F(R,m,r)=F(R,r,m)=F(m,R,r)=F(r,R,m)$ and from (3.6), we obtain

$$\begin{aligned}M_{p3}=&\frac{1}{\pi i}\sum_{m=1}^{p}\sum_{r=p+1}^{\infty}\sum_{R=p+1}^{\infty}\int_{|\lambda|=b_p}\frac{\lambda\,d\lambda}{(\lambda-m^2)(\lambda-r^2)(\lambda-R^2)}F(m,r,R)\\&+\frac{1}{\pi i}\sum_{m=1}^{p}\sum_{\substack{r=1\\m\neq r}}^{p}\sum_{R=p+1}^{\infty}\int_{|\lambda|=b_p}\frac{\lambda\,d\lambda}{(\lambda-m^2)(\lambda-r^2)(\lambda-R^2)}F(m,r,R)\\&+\frac{1}{\pi i}\sum_{m=1}^{p}\sum_{R=p+1}^{\infty}\int_{|\lambda|=b_p}\frac{\lambda\,d\lambda}{(\lambda-m^2)^2(\lambda-R^2)}F(m,m,R)\\=&2\sum_{m=1}^{p}\sum_{r=p+1}^{\infty}\sum_{R=p+1}^{\infty}\frac{m^2}{(r^2-m^2)(R^2-m^2)}F(m,r,R)\\&+4\sum_{m=1}^{p}\sum_{\substack{r=1\\m\neq r}}^{p}\sum_{R=p+1}^{\infty}\frac{m^2}{(m^2-r^2)(m^2-R^2)}F(m,r,R)\\&-2\sum_{m=1}^{p}\sum_{R=p+1}^{\infty}\frac{R^2}{(R^2-m^2)^2}(F(m,m,R)).\end{aligned}\tag{3.7}$$

Let

$$F_1(m,r,R)=\pi^{-3}\sum_{n=1}^{\infty}\sum_{q=1}^{\infty}\sum_{N=1}^{\infty}\int_0^{\pi}(Q(x)\varphi_n,\varphi_q)_H\operatorname{Cos}(m-r)x\,dx\cdot\int_0^{\pi}(Q(x)\varphi_q,\varphi_N)_H$$
$$\times\operatorname{Cos}(r-R)x\,dx\int_0^{\pi}(Q(x)\varphi_N,\varphi_n)_H\operatorname{Cos}(R-m)x\,dx, \tag{3.8}$$

$$F_2(m,r,R)=F(m,r,R)-F_1(m,r,R),$$

$$A_{pi}=\sum_{m=1}^{p}\sum_{r=p+1}^{\infty}\sum_{R=p+1}^{\infty}\frac{m^2}{(r^2-m^2)(R^2-m^2)}F_i(m,r,R),$$

$$B_{pi}=\sum_{m=1}^{p}\sum_{\substack{r=1\\m\neq r}}^{p}\sum_{R=p+1}^{\infty}\frac{m^2}{(m^2-r^2)(m^2-R^2)}F_i(m,r,R),$$

$$C_{pi}=\sum_{m=1}^{p}\sum_{R=p+1}^{\infty}\frac{R^2}{(R^2-m^2)^2}F_i(m,m,R).$$

It can be shown that

$$A_{p1}=2\sum_{m=1}^{p}\sum_{\substack{r=p+1\\ r>R}}^{\infty}\sum_{R=p+1}^{\infty}\frac{m^2}{(r^2-m^2)(R^2-m^2)}F_1(m,r,R)+\sum_{m=1}^{p}\sum_{R=p+1}^{\infty}\frac{m^2}{(R^2-m^2)^2}F_1(m,m,R),$$

$$B_{p1}=-\sum_{m=1}^{p}\sum_{\substack{r=1\\ m<r}}^{p}\sum_{R=p+1}^{\infty}\frac{R^2}{(R^2-m^2)(R^2-r^2)}F_1(m,r,R). \tag{3.9}$$

Hence, we write M_{p3} as in the form

$$M_{p3}=4A_p^1-4B_p^1-2C_p^1+2A_{p2}+4B_{p2}-2C_{p2} \tag{3.10}$$

such that

$$A_p^1=\sum_{m=1}^{p}\sum_{\substack{r=p+1\\ r>R}}^{\infty}\sum_{R=p+1}^{\infty}\frac{m^2}{(r^2-m^2)(R^2-m^2)}F_1(m,r,R),$$

$$B_p^1=-B_{p1}, \tag{3.11}$$

$$C_p^1=\sum_{m=1}^{p}\sum_{R=p+1}^{\infty}\frac{1}{R^2-m^2}F_1(m,m,R).$$

Let $E_1=\{(m,r,R):m,r,R\in N;r-m=i;R-m=j;m\leqslant p;r,R>p\}$, where p, i and j are integers such that $p\geqslant j$, $i\geqslant j$ Then

$$\begin{aligned}A_p^1=&\sum_{m=1}^{p}\sum_{\substack{r=p+1\\ r>R,R-m\leqslant p}}^{\infty}\sum_{R=p+1}^{2p}\frac{m^2}{(r^2-m^2)(R^2-m^2)}F_1(m,r,R)\\&+\sum_{m=1}^{p}\sum_{\substack{r=p+1\\ r>R,R-m>p}}^{\infty}\sum_{R=p+1}^{\infty}\frac{m^2}{(r^2-m^2)(R^2-m^2)}F_1(m,r,R)\\&=\pi^{-3}\sum_{\substack{i=2\\ i>j}}^{\infty}\sum_{j=1}^{p}\left[\left(\sum_{m,r,R\in E_1}\frac{m^2}{(r^2-m^2)(R^2-m^2)}\right)\sum_{n=1}^{\infty}\sum_{q=1}^{\infty}\sum_{N=1}^{\infty}\int_0^{\pi}(Q(x)\varphi_n,\varphi_q)\right]_H\\&\times\operatorname{Cos}ix\cdot\int_0^{\pi}(Q(x)\varphi_q,\varphi_N)_H\operatorname{Cos}(i-j)x\,dx\int_0^{\pi}(Q(x)\varphi_N,\varphi_n)_H\operatorname{Cos}ix\,dx\\&+\sum_{m=1}^{p}\sum_{\substack{r=p+1\\ r>R,R-m>p}}^{\infty}\sum_{R=p+1}^{\infty}\frac{m^2}{(r^2-m^2)(R^2-m^2)}F_1(m,r,R).\end{aligned} \tag{3.12}$$

If we let

$$\beta_{ij}=\pi^{-3}\sum_{n=1}^{\infty}\sum_{q=1}^{\infty}\sum_{N=1}^{\infty}\int_0^{\pi}(Q(x)\varphi_n,\varphi_q)_H\,\mathrm{Cos}\,ix\,dx\int_0^{\pi}(Q(x)\varphi_q,\varphi_N)_H$$

$$\times\mathrm{Cos}\,(i-j)x\,dx\cdot\int_0^{\pi}(Q(x)\varphi_N,\varphi_n)_H\,\mathrm{Cos}\,ix\,dx, \tag{3.13}$$

$$A_p^{11}=\sum_{\substack{i=2\\ i>j}}^{\infty}\sum_{j=1}^{p}\left[\left(\sum_{m,r,R\in E_1}\frac{m^2}{(r^2-m^2)(R^2-m^2)}\right)\beta_{ij}\right],$$

$$A_p^{12}=\sum_{\substack{m=1\\ r>R,R-m>p}}^{p}\sum_{r=p+1}^{\infty}\sum_{R=p+1}^{\infty}\frac{m^2}{(r^2-m^2)(R^2-m^2)}F_1(m,r,R),$$

then we write

$$A_p^1=A_p^{11}+A_p^{12}. \tag{3.14}$$

On the other hand, it can be shown that

$$\sum_{m,r,R\in E_1}\frac{m^2}{(r^2-m^2)(R^2-m^2)}=\frac{1}{4i}+\frac{j}{p}O(1),$$

where $O(1)$ satisfies the condition

$$|O(1)|<\mathrm{const}$$

and it depends on p, i and j. Moreover, if $Q(x)$ has a continuous derivative of second order at $[0,\ \pi]$ with respect to the norm in $\sigma_1(H)$, then we can show that

$$|\beta_{ij}|<\frac{\mathrm{const}}{i^2j^2}. \tag{3.15}$$

Hence, we have

$$A_p^{11}=\sum_{\substack{i=2\\ i>j}}^{\infty}\sum_{j=1}^{p}\left[\frac{\beta_{ij}}{4i}+\frac{O(1)}{pi^2j}\right]. \tag{3.16}$$

Since

$$\left|\sum_{i=2}^{\infty}\sum_{j=1}^{p}\frac{O(1)}{pi^2j}\right|\leqslant\mathrm{const}\left(\sum_{i=1}^{\infty}i^{-2}\right)\sum_{j=1}^{p}j^{-1}<\mathrm{const}\;p^{-1}\ln p,$$

we find

$$A_p^{11}=\sum_{\substack{i=2\\ i>j}}^{\infty}\sum_{j=1}^{p}\frac{\beta_{ij}}{4i}+o(1). \tag{3.17}$$

Here $o(1)$ is an expression which satisfies the condition

$$\lim_{p\to\infty} o(1)=0,$$

and it depends on p. From (3.14) and (3.17) we obtain

$$A_p^1=\sum_{i=2}^{\infty}\sum_{\substack{j=1\\ i>j}}^{p}\frac{\beta_{ij}}{4i}+A_p^{12}+o(1). \tag{3.18}$$

Now, let us find a formula for the B_p^1:

Let

$$B_p^{11}=\sum_{m=1}^{p}\sum_{\substack{r=1\\ m<r,R-m\leqslant p}}^{p}\sum_{R=p+1}^{2p}\frac{R^2}{(R^2-m^2)(R^2-r^2)}F_1(m,r,R)$$

and

$$B_p^{12}=\sum_{m=1}^{p}\sum_{\substack{r=1\\ m<r,R-m>p}}^{p}\sum_{R=p+1}^{\infty}\frac{R^2}{(R^2-m^2)(R^2-r^2)}F_1(m,r,R).$$

Then, from (3.9) and (3.11), we have

$$B_p^1=B_p^{11}+B_p^{12}. \tag{3.19}$$

By using (3.8) and (3.13), we write B_p^{11} as in the form

$$B_p^{11}=\sum_{j=2}^{p}\sum_{\substack{i=1\\ j>i}}^{p-1}\left(\sum_{m,r,R\in E_2}\frac{R^2}{(R^2-m^2)(R^2-r^2)}\right)\beta_{ij}, \tag{3.20}$$

where E_2 is a set defined by

$$E_2=\{(m,r,R):m,r,R\in N;r-m=i;R-m=j;m,r\leqslant p;R>p\}$$

such that $i<j\leqslant p$. Moreover, we can show that

$$\sum_{m,r,R\in E_2}\frac{R^2}{(R^2-m^2)(R^2-r^2)}=\frac{1}{4j}+\frac{i}{p}O(1). \tag{3.21}$$

From (3.15), (3.20) and (3.21) we obtain

$$B_p^{11}=\sum_{j=2}^{p}\sum_{\substack{i=1\\ j>i}}^{p-1}\left[\frac{\beta_{ij}}{4j}+\frac{O(1)}{pj^2i}\right]$$

and, since $\beta_{ij}=\beta_{ji}$, we write

$$B_p^{11}=\sum_{j=2}^{p}\sum_{\substack{i=1\\ i<j}}^{p-1}\frac{\beta_{ji}}{4j}+o(1).$$

By using (3.19) and this last equation, we find

$$B_p^1=\sum_{\substack{i=2\\ i>j}}^{p}\sum_{j=1}^{p-1}\frac{\beta_{ij}}{4i}+B_p^{12}+o(1).$$

On the other hand, by using (3.15), it can be shown that

$$\sum_{i=2}^{p}\sum_{j=1}^{p-1}\frac{\beta_{ij}}{i}=\sum_{\substack{i=2\\ i>j}}^{\infty}\sum_{j=1}^{p}\frac{\beta_{ij}}{4i}+o(1).$$

Thus, we have

$$B_p^1=\sum_{\substack{i=2\\ i>j}}^{\infty}\sum_{j=1}^{p}\frac{\beta_{ij}}{4i}+B_p^{12}+o(1). \tag{3.22}$$

From (3.10), (3.18) and (3.22) we obtain

$$M_{p3}=4A_p^{12}-4B_p^{12}-2C_p^1+2A_{p2}+4B_{p2}-2C_{p2}+o(1).$$

Here, it can be seen that

$$\lim_{p\to\infty}A_p^{12}=\lim_{p\to\infty}B_p^{12}=\lim_{p\to\infty}C_p^1=\lim_{p\to\infty}A_{p2}=\lim_{p\to\infty}B_{p2}=\lim_{p\to\infty}C_{p2}=0.$$

For this reason, it follows that

$$\lim_{p\to\infty}M_{p3}=0.$$

In a similar form, it is proved that

$$\lim_{p\to\infty}M_{p4}=\lim_{p\to\infty}M_{p5}=0.$$

Now let us prove the formula (3.2): By employing (2.3), (3.3) and (3.4), we obtain

$$\begin{aligned}
|M_p^{(N)}|&=\frac{1}{2\pi}\left|\int_{|\lambda|=b_p}\lambda^2\,\mathrm{tr}\,[R_\lambda(QR_\lambda^0)^{N+1}]\,d\lambda\right|\\
&\leqslant\frac{b_p^2}{2\pi}\int_{|\lambda|=b_p}\|R_\lambda(QR_\lambda^0)^{N+1}\|_{\sigma_1(H_1)}|d\lambda|\\
&\leqslant b_p^2\int_{|\lambda|=b_p}\|R_\lambda\|\|(QR_\lambda^0)^{N+1}\|_{\sigma_1(H_1)}|d\lambda|\\
&\leqslant C_1b_p^2p^{-1}\int_{|\lambda|=b_p}\|QR_\lambda^0\|^N\|QR_\lambda^0\|_{\sigma_1H_1}|d\lambda|\\
&\leqslant\mathrm{const}\,p^{5-N}.
\end{aligned}$$

This shows that

$$\lim_{p\to\infty} M_p^{(N)}=0; \quad N\geqslant 6.$$

The main result of this article is given by the following theorem.

Theorem 3.1: If the operator function $Q(x)$ satisfies the conditions (1)–(3), then

$$\sum_{m=1}^{\infty}\left[\sum_{n=1}^{\infty}(\lambda_{mn}^2-m^4)-\frac{2m^2}{\pi}\int_0^{\pi}\operatorname{tr}Q(x)\,dx-C\right]$$
$$=\frac{C}{2}+\frac{1}{8}[\operatorname{tr}Q''(0)+\operatorname{tr}Q''(\pi)]-\frac{1}{4}[\operatorname{tr}Q^2(0)+\operatorname{tr}Q^2(\pi)],$$

where

$$C=\frac{1}{2\pi}[\operatorname{tr}Q'(0)-\operatorname{tr}Q'(\pi)]+\frac{1}{2\pi}\int_0^{\pi}\operatorname{tr}Q^2(x)\,dx+\frac{1}{2\pi^2}\operatorname{tr}\left(\int_0^{\pi}Q(x)\,dx\right)^2.$$

Proof: By using the relations (2.2), (2.5), (2.17), (3.1) and (3.2), we find

$$\sum_{m=1}^{p}\sum_{n=1}^{\infty}(\lambda_{mn}^2-m^4)=\frac{2}{\pi}\int_0^{\pi}\operatorname{tr}Q(x)\,dx\sum_{m=1}^{p}m^2+\frac{p}{2\pi}[\operatorname{tr}Q'(0)-\operatorname{tr}Q'(\pi)]$$
$$+\frac{1}{2\pi}\sum_{m=1}^{p}\int_0^{\pi}\operatorname{tr}Q''(x)\operatorname{Cos}2mx\,dx+\frac{2p-1}{4\pi}\int_0^{\pi}\operatorname{tr}Q^2(x)\,dx$$
$$+\frac{2p+1}{4\pi^2}\operatorname{tr}\left(\int_0^{\pi}Q(x)\,dx\right)^2-\frac{1}{\pi}\sum_{m=1}^{p}\int_0^{\pi}\operatorname{tr}Q^2(x)\operatorname{Cos}2mx\,dx+o(1).$$

Or, by taking

$$g(x)=\operatorname{tr}Q''(x)-2\operatorname{tr}Q^2(x),$$

we get

$$\sum_{m=1}^{\infty}\left[\sum_{n=1}^{\infty}(\lambda_{mn}^2-m^4)-\frac{2m^2}{\pi}\int_0^{\pi}\operatorname{tr}Q(x)\,dx-C\right]$$
$$=\frac{1}{4\pi^2}\operatorname{tr}\left(\int_0^{\pi}Q(x)\,dx\right)^2-\frac{1}{4\pi}\int_0^{\pi}\operatorname{tr}Q^2(x)\,dx+\frac{1}{2\pi}\sum_{m=1}^{\infty}\int_0^{\pi}g(x)\operatorname{Cos}2mx\,dx. \tag{3.23}$$

Here, we note that

$$\frac{1}{2\pi}\sum_{m=1}^{\infty}\int_0^{\pi}g(x)\operatorname{Cos}mx\,dx=\frac{1}{4\pi}\sum_{m=1}^{\infty}\left[\int_0^{\pi}g(x)\operatorname{Cos}mx\,dx+(-1)^m\int_0^{\pi}g(x)\operatorname{Cos}mx\,dx\right]$$
$$=\frac{1}{8}\left\{\sum_{m=1}^{\infty}\left[\frac{2}{\pi}\int_0^{\pi}g(x)\operatorname{Cos}mx\,dx\right]\operatorname{Cos}m0+\frac{1}{\pi}\int_0^{\pi}g(x)dx\operatorname{Cos}0\right\}$$
$$+\frac{1}{8}\left\{\sum_{m=1}^{\infty}\left[\frac{2}{\pi}\int_0^{\pi}g(x)\operatorname{Cos}mx\,dx\right]\operatorname{Cos}m\pi\right.$$
$$\left.+\frac{1}{\pi}\int_0^{\pi}g(x)\,dx\operatorname{Cos}0\pi\right\}-\frac{1}{4\pi}\int_0^{\pi}g(x)\,dx$$
$$=\frac{1}{8}[g(0)+g(\pi)]-\frac{1}{4\pi}\int_0^{\pi}g(x)\,dx.$$

By considering this in (3.23), we obtain

$$\sum_{m=1}^{\infty}\left[\sum_{n=1}^{\infty}(\lambda_{mn}^2-m^4)-\frac{2m^2}{\pi}\int_0^{\pi}\operatorname{tr}Q(x)\,dx-C\right]$$

$$=\frac{1}{4\pi^2}\operatorname{tr}\left(\int_0^{\pi}Q(x)dx\right)^2-\frac{1}{4\pi}\int_0^{\pi}\operatorname{tr}Q^2(x)\,dx+\frac{1}{8}[\operatorname{tr}Q''(0)-2\operatorname{tr}Q^2(0)+\operatorname{tr}Q''(\pi)$$

$$-2\operatorname{tr}Q^2(\pi)]-\frac{1}{4\pi}\int_0^{\pi}\operatorname{tr}Q''(x)\,dx+\frac{1}{2\pi}\int_0^{\pi}\operatorname{tr}Q^2(x)\,dx$$

$$=\frac{1}{4\pi^2}\operatorname{tr}\left(\int_0^{\pi}Q(x)\,dx\right)^2+\frac{1}{4\pi}\int_0^{\pi}\operatorname{tr}Q^2(x)\,dx+\frac{1}{4\pi}[\operatorname{tr}Q'(0)-\operatorname{tr}Q'(\pi)]$$

$$+\tfrac{1}{8}[\operatorname{tr}Q''(0)+\operatorname{tr}Q''(\pi)]-\tfrac{1}{4}[\operatorname{tr}Q^2(0)+\operatorname{tr}Q^2(\pi)]$$

or

$$\sum_{m=1}^{\infty}\left[\sum_{n=1}^{\infty}(\lambda_{mn}^2-m^4)-\frac{2m^2}{\pi}\int_0^{\pi}\operatorname{tr}Q(x)\,dx-C\right]$$

$$=\frac{C}{2}+\frac{1}{8}[\operatorname{tr}Q''(0)+\operatorname{tr}Q''(\pi)]-\frac{1}{4}[\operatorname{tr}Q^2(0)+\operatorname{tr}Q^2(\pi)].$$

This proves the theorem.

(Received 13 November 2000; accepted for publication 26 January 2001)

An extension of the super Korteweg–de Vries (KdV) integrable system in terms of operator valued functions is obtained. Following the ideas of Gardner, a general algebraic approach for finding the infinitely many conserved quantities of integrable systems is presented. The approach is applied to the above described system and infinitely many conserved quantities are constructed. In a particular case they reduce to the corresponding conserved quantities of super KdV. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1368139]

I. INTRODUCTION

It was shown in Ref. 1 that among the one parameter supersymmetric extensions of the Korteweg–de Vries (KdV) equation there is a special system that has an infinite number of conservation laws. This system is equivalent to the super KdV equations obtained in Ref. 2 by reduction from the super-Kadomtsev–Petviashvili hierarchy. $N=2$ supersymmetric extension of the KdV equations have also been obtained in Refs. 3–5.

The supersymmetric extension of the KdV equation is a system of coupled equations for a commuting and an anticommuting field. The commuting field $u(x,t)$ takes values in the even part of a Grassmann algebra $\mathcal{G}$ while the anticommuting field $\xi(x,t)$ takes values on the odd part of $\mathcal{G}$. The explicit form of the supersymmetric extension with an infinite number of conservation laws is[1]

$$u_t = -u''' + 6uu' - 3\xi\xi'', \tag{1}$$

$$\xi_t = -\xi''' + 3(\xi u)'. \tag{2}$$

If we use, as a particular case, the four dimensional Grassman algebra with generators e_1 and e_2, and express

$$u(x,t) = u_0(x,t) + u_{12}(x,t)e_1e_2, \tag{3}$$

$$\xi(x,t) = \xi_1(x,t)e_1 + \xi_2(x,t)e_2, \tag{4}$$

the system (1) and (2) may be reformulated as a coupled system in terms of real or complex fields $u_0, u_{12}, \xi_1\xi_2$ in the following way:

[a)]Electronic mail: sandrea@usb.ve
[b)]Electronic mail: arestu@usb.ve
[c)]Electronic mail: sotomayo@.fis.usb.ve

$$u_{0t} = -u_0''' + 6u_0u_0', \tag{5}$$

$$\xi_{1t} = -\xi_1''' + 3(\xi_1 u_0)', \tag{6}$$

$$\xi_{2t} = -\xi_2''' + 3(\xi_2 u_0)', \tag{7}$$

$$u_{12t} = -u_{12}''' + 6(u_0u_{12})' - 3(\xi_1\xi_2'' - \xi_2\xi_1''). \tag{8}$$

Equation (5) is exactly the KdV equation. Equations (6) and (7) are linear homogeneous in ξ_1 and ξ_2, respectively. Equation (8) is also linear in u_{12} but contains a source in terms of ξ_1 and ξ_2. The super KdV system (1) is not the only integrable extension of the KdV equation constructed using a single anticommuting field. Another such system is the one proposed in Ref. 6:

$$u_t = -u''' + 6uu' - 3\xi\xi'', \tag{9}$$

$$\xi_t = -4\xi''' + 6\xi' u + 3\xi u'. \tag{10}$$

This system also has an infinite number of conservation laws. Its expansion in the particular Grassmann algebra generated by e_1 and e_2 gives again for the u_0 the KdV equation. In the case of $N=2$ supersymmetric systems, the equation for u_0 is modified by nonlinear terms coming from the other even field of the $N=2$ superfield. But again, there is no contribution to this equation from the odd fields. In this work we present an extension of the super KdV system in terms of coupled system of partial differential equations which yields a nonlinear modification for the KdV equation with an interacting term constructed from complex spinors. Our formulation will be in terms of operator valued functions which for a particular case reduce to the supersymmetric algebra. The final form of the nonlinear system will be in terms of commuting real or complex functions in contrast with (1) and (2). There is also a physical motivation for our program. The classical formulation of supersymmetric field theory is always in terms of commuting and anticommuting fields which, after quantization, yield a field theory in terms of bosonic and fermionic operators. However, once we have the quantum field theory we may consider the mean values of the bosonic and fermionic operators. We then obtain real scalar or vector fields from the bosonic sector, while complex spinors come from the fermionic sector. That is, for many applications the quantum theory may be analyzed in terms of real fields and complex spinors, without introducing the commuting and anticommuting fields of the classical formulation. For example, all the analysis of the spontaneous breaking of supersymmetry is formulated in those terms. It is then natural to ask if there is an extension of the KdV equation in terms of a real field $u(x,t)$ and a complex spinor $\xi(x,t)$. One particular case of the general approach we will discuss is the following system:

$$\begin{aligned} u_t &= -u''' + 6uu' - 3(\varphi_1\varphi_2'' - \varphi_1''\varphi_2), \\ \varphi_{1t} &= -\varphi_1''' + 3(\varphi_1 u)', \\ \varphi_2 t &= -\varphi_2''' + 3(\varphi_2 u)', \end{aligned} \tag{11}$$

where we consider only one complex field $\Psi(x,t) = \varphi_1(x,t) + i\varphi_2(x,t)$. System (11) should be compared with (5)–(8) where the anticommuting fields in (1) and (2) have been explicitly expanded in terms of a basis of a Grassmann algebra with real or complex coefficients.

There is also another general, but maybe indirect, motivation to our program. It has been recently recognized in the formulation of M-theory as a matrix model (IKKT)[7] that the construction of the theory in terms of elements of a complex Lie algebra equipped with an invariant bilinear inner product is not only directly related to superstring theory but also contains Yang–Mills theory, for a suitable election of the Lie algebra. The relation between self-dual Yang–Mills equations and integrable systems is well known, in particular to the KdV hierarchy. It is then natural to ask for an integrable generalization of the self-dual Yang–Mills equations in terms of

operator valued geometrical objects related to the IKKT formulation of M-theory and its relation to KdV hierarchy. Our contribution in this article may be a first step in this construction.

In Sec. II we present, following the ideas of Gardner,[8] a general algebraic approach for obtaining the infinitely many conserved quantities of certain integrable systems. We consider as a particular case of our analysis the conserved quantities associated with the system (11). In Sec. IV we present a generalization of the super KdV system in terms of operator valued functions. We apply the general approach developed in Sec. III to prove the existence of the infinitely many operator valued, conserved quantities of the integrable system.

In Sec. V we discuss our conclusions.

II. AN ALGEBRAIC APPROACH TO NONLINEAR SYSTEMS AND THEIR CONSERVATION LAWS

In order to study nonlinear equations and their conservation laws, one can start by choosing a ring V of infinitely differentiable functions $\mathbb{R}\to\mathbb{R}$ which satisfies $(d/dx)V\subset V$. A system of equations gives a flow in the manifold $\mathcal{M}=V\times V\times\cdots\times V$, whose general element is written $u(x)=(u_1(x),u_2(x),\ldots,u_n(x))$. The general model for formulas involving sums of products of derivatives of the $u_p(x)$ is a polynomial

$$f(a_{10},a_{11},a_{20},\ldots)$$

in a finite number of the commuting symbols a_{pm} with $1\leqslant p\leqslant n$, $\leqslant 0\leqslant m<\infty$. Then, replacing a_{pm} by $(d/dx)^m(u_p(x)$, an element u of the manifold $\mathcal{M}$ is taken to

$$f(u)=f(u_1(x),x_1'(x),u_2(x),\ldots),$$

an element of V whose derivative is given by

$$\frac{d}{dx}f(u)=(Df)(u),$$

$$D=\sum_{p=1}^{n}\sum_{m=0}^{\infty}a_{p,m+1}\frac{\partial}{\partial a_{pm}}.$$

The commutative ring $\mathcal{A}$ consisting of all such polynomials f, together with the derivation $D:\mathcal{A}\to\mathcal{A}$, may be called the free derivation ring on n generators.

The algebra $Op\mathcal{A}$, on the other hand, consists of the linear operators $L:\mathcal{A}\to\mathcal{A}$ which have the form $L=\Sigma_{m=0}^{N}l_mD^m$ with $l_m\in\mathcal{A}$. The standard operator transpose anti-involution $Op\mathcal{A}\to Op\mathcal{A}$ sends L to L^*, where $L^*f=\Sigma_{m=0}^{N}(-l)^mD^m(l_mf)$. Then fLg and gL^*f differ by an element of $\mathcal{D}\mathcal{A}$ for all $f,g\in\mathcal{A}$.

Given $u\in\mathcal{M}$ and $L\in Op\mathcal{A}$, the function substitution operation replaces

$$L(a,D)=\sum l_m(a_{10},a_{11},a_{20},\ldots)D^m$$

by

$$L\left(u,\frac{d}{dx}\right)=\sum l_m(u_1(x),u_1'(x),u_2(x)\ldots)\left(\frac{d}{dx}\right)^m,$$

a variable coefficient differential operator

$$L\left(u,\frac{d}{dx}\right):V\to V.$$

In order to see how ordinary differential equation (ODE) systems are related by internal substitutions, the following constructions are performed in $\mathcal{A}$ and in $Op\mathcal{A}$.

(1) A ring homomorphism $S:\mathcal{A}\to\mathcal{A}$ which commutes with $D:\mathcal{A}\to\mathcal{A}$ is completely determined by its values on the generators a_{p0}, $1\leqslant p\leqslant n$. Conversely, if $b=(b_1,\ldots,b_n)$ is any n-tuple of elements of $\mathcal{A}$, there is a unique ring homomorphism $\mathcal{S}_b:\mathcal{A}\to\mathcal{A}$ which commutes with D and satisfies $\mathcal{S}_b(a_{p0})=b_p$, $1\leqslant p\leqslant n$. The effect of $\mathcal{S}_b$ on $f(a_{10},a_{11},a_{20},\ldots)$ is to replace a_{pm} by $(D^m b_p)(a_{10},a_{11},a_{20},\ldots)$.

The transformation $\mathcal{S}_b$ also sends $Op\mathcal{A}\to Op\mathcal{A}$. If $L=\Sigma l_m D^m$, then $\mathcal{S}_b L=\Sigma(\mathcal{S}_b l_m)D^m$. Again, as in $\mathcal{A}$, $\mathcal{S}_b$ preserves sums and products.

(2) In the special case $b_p=a_p+te_p(a_{10},a_{11},a_{20},\ldots)$ with $t\in\mathbb{R}$ and arbitrary $e_p\in\mathcal{A}$, one can take the derivative at $t=0$ of $\mathcal{S}_b f$. The result is

$$\sum_{p=1}^{n}\sum_{m=0}^{\infty}\frac{\partial f}{\partial a_{pm}}D^m e_p=\sum_{p=1}^{n}\partial_p f(a,D)e_p,$$

where, for $1\leqslant p\leqslant n$, the Fréchet derivative operator $\partial_p f\in\mathcal{O}p\mathcal{A}$ is defined to be

$$\partial_p f(a,D)=\sum_{m=0}^{\infty}\frac{\partial f}{\partial a_{pm}}D^m.$$

Taking the derivative of the equation $\mathcal{S}_b Df=D\mathcal{S}_b f$, one sees that the Fréchet derivative operators of Df are given by

$$\partial_p(Df)=D(\partial_p f).$$

When $\partial_p f$ is applied to $a_{p1}=Da_{p0}\in\mathcal{A}$, one gets

$$\sum_{p=1}^{n}(\partial_p f)a_{p1}=Df.$$

(3) Returning to the case of general b one can verify the chain rule

$$\partial_p S_b f=\sum_{q=1}^{n}(\mathcal{S}_b\partial_q f)(\partial_p b_q).$$

The first step is to apply the usual chain rule, obtaining

$$\frac{\partial}{\partial a_{pm}}\mathcal{S}_b f=\sum_{q=1}^{n}\sum_{r=0}^{\infty}\left(\frac{\partial f}{\partial a_{qr}}\bigg|^{a_{qr}=D^r b_q}\right)\frac{\partial}{\partial a_{pm}}(D^r b_q).$$

Multiplying on the right by D^m and summing over $0\leqslant m<\infty$ one gets

$$\partial_p\mathcal{S}_b f=\sum_{q=1}^{n}\sum_{r=0}^{\infty}\left(\frac{\partial f}{\partial a_{pr}}\bigg|^{a_{qr}=D^r b_q}\right)(\partial_p D^r b_q)=\sum_{q=1}^{n}(\mathcal{S}_b\partial_q f)(\partial_p b_p).$$

This completes the proof.

(4) Nonlinear ODE systems are given by n-tuples $g=(g_1,\ldots,g_n)$ of elements of $\mathcal{A}$. The unknown functions $v_p(x,t)$ are required to satisfy

$$\frac{\partial}{\partial t}v_p(x,t)=g_p\left(v_1(x,t),\frac{\partial}{\partial x}v_1(x,t),v_2(x,t),\ldots\right).$$

It then follows that

$$\frac{\partial}{\partial t}\left(\frac{\partial}{\partial x}\right)^m v_p(x,t)=(D^m g_p)(v_1(x,t),\ldots).$$

(5) Given $h\in\mathcal{A}$, the formula

$$H(v)=\int h(v)dx$$

defines a (nonlinear) functional $H:\mathcal{M}\to\mathbb{R}$ when, for example, v is the space of infinitely differentiable 2π-periodic functions and the integral is taken from 0 to 2π.

If $v(x,t)$ satisfies $(\partial/\partial t)v=g(v)$, then the derivative of H along the solution is given by

$$\frac{d}{dt}H=\int\sum_{p=1}^{\infty}\sum_{m=0}^{\infty}\frac{\partial h}{\partial a_{pm}}(v)\left(\frac{d}{dt}\left(\frac{\partial}{\partial x}\right)^m v_p(x,t)\right)dx=\int\sum_{p=1}^{m}\partial_p h\left(v,\frac{d}{dx}\right)g_p(v)dx.$$

For H to be a conservation law for $\dot v=g(v)$ it suffices that

$$\sum_{p=1}^{m}(\partial_p h)g_p\in\mathcal{DA}.$$

(6) Given $b=(b_1,\ldots,b_n)$, there arises the transformation $v=b(u)$ of $\mathcal{M}$ into itself, where

$$v_p(x)=b_p(u_1(x),u_1'(x),u_2(x),\ldots).$$

If $u=u(x,t)$ satisfies the ODE system $\dot u=f(u)$, then $v=b(u)$ satisfies

$$\frac{\partial}{\partial t}v_p(x,t)=\sum_{q=1}^{n}\sum_{m=0}^{\infty}\frac{\partial b_p}{\partial a_{qm}}(u)\left(\frac{\partial}{\partial t}\left(\frac{\partial}{\partial x}\right)^m u_q(x,t)\right)=\sum_{q=1}^{n}\partial_q b_p\left(u,\frac{\partial}{\partial x}\right)f_q(u).$$

On the other hand,

$$g_p(v)=g_p(b(u))=(\mathcal{S}_b g_p)(u).$$

Therefore, in order for $v=b(u)$ to be a ''Miura transformation'' taking solutions of $\dot u=f(u)$ to solutions of $\dot v=g(v)$, the equations

$$\sum_{q=1}^{n}(\partial_q b_p)f_q=\mathcal{S}_b g_p$$

should hold in $\mathcal{A}$.

(7) We should expect the pullback of a conserved quantity to be a conserved quantity. Suppose that $h\in\mathcal{A}$ gives a conserved quantity for $\dot v=g(v)$, and that $v=b(u)$ is a Miura transformation to $\dot v=g(v)$ from $\dot u=f(u)$.

Then the b-pullback of h, that is to say $\mathcal{S}_b h$, has Fréchet derivative operators given by

$$\partial_p\mathcal{S}_p h=\sum_{q=1}^{n}(\mathcal{S}_b\partial_q h)(\partial_p b_q).$$

After applying this equation to $f_p\in\mathcal{A}$ we get

$$\sum_p(\partial_p\mathcal{S}_b h)f_p=\sum_{p,q}(\mathcal{S}_b\partial_q h)(\partial_p b_q)f_p=\sum_q(\mathcal{S}_b\partial_q h)(\mathcal{S}_b g_q)$$

because $v=g(u)$ is a Miura transformation. Then, $\mathcal{S}_b$ being a ring homomorphism,

$$\sum_p (\partial_p \mathcal{S}_b h) f_p = \mathcal{S}_b \left(\sum_q (\partial_q h) g_q \right) = \mathcal{S}_b \mathcal{D} e$$

for some $e \in \mathcal{A}$, because h gives a conserved quantity for $\dot{v} = g(v)$. Since $\mathcal{S}_b$ commutes with $\mathcal{D}$, we may conclude that $\mathcal{S}_b h$ gives a conserved quantity for $\dot{u} = f(u)$.

III. CONSERVATION LAWS FOR A KdV SYSTEM

This theory will now be applied to a generalization of the KdV equation. The usual version corresponds to the element $-a_1''' + 6a_1 a_1'$ in the free derivation ring on one generator, where the double suffix notation is shortened to $a_p = a_{p0}$, $a_p' = a_{p1}$, $a_p'' = a_{p2}$, etc., for small values of m in a_{pm}.

For the extended KdV we go from $n=1$ to $n=3$ and set

$$g_1 = (-a_1'' + 3a_1^2 + 3[a_2, a_3])', \quad g_2 = (-a_2'' + 3a_1 a_2)', \quad g_3 = (-a_3'' + 3a_1 a_3)',$$

in which $[a_p, a_q] = a_p' a_q - a_p a_q'$ in general.

This system, to be called $\dot{v} = g(v)$, is subjected to the transformation $\mathcal{S}_b : \mathcal{A} \to \mathcal{A}$ where

$$\begin{pmatrix} b_1 \\ b_2 \\ b_3 \end{pmatrix} = \begin{pmatrix} a_1 \\ a_2 \\ a_3 \end{pmatrix} + \varepsilon \begin{pmatrix} a_1' \\ a_2' \\ a_3' \end{pmatrix} + \varepsilon^2 \begin{pmatrix} a_1^2 + [a_2, a_3] \\ a_1 a_2 \\ a_1 a_3 \end{pmatrix}$$

and ε is any real number. When $\varepsilon = 0$, $\mathcal{S}_b$ reduces to the identity map. Since the g_p are quadratic one gets

$$\mathcal{S}_b g = \sum_{i=0}^{4} \varepsilon^i \mathcal{C}_i$$

in which g is the column vector $(g_1, g_2, g_3)^T$. Evidently $\mathcal{C}_0 = g$ and $\mathcal{C}_1 = \mathcal{D}_g$, the latter because $d/d\varepsilon|^{\varepsilon=0} \mathcal{S}_b f = \Sigma_p (\partial_p f) a_p' = \mathcal{D} f$ for any $f \in \mathcal{A}$.

The last two columns are

$$\mathcal{C}_3 = \begin{pmatrix} (2a_1^3 + 3a_1[a_2, a_3])' \\ 3a_1(a_1 a_2)' + 3a_2'[a_2, a_3] \\ 3a_1(a_1 a_3)' + 3a_3'^I[a_2, a_3] \end{pmatrix}'$$

and

$$\mathcal{C}_4 = \begin{pmatrix} 3a_1^4 + 9a_1^2[a_2, a_3] + 3[a_2, a_3]^2 \\ 3a_1^3 a_2 + 3a_1 a_2[a_2, a_3] \\ 3a_1^3 a_3 + 3a_1 a_3[a_2, a_3] \end{pmatrix}'.$$

Turning now to the Fréchet derivative operators of the three components of b, we find the 3×3 matrix of elements of $\mathcal{O}_p \mathcal{A}$ which is given by

$$\partial_q b_p = I + \varepsilon \mathcal{D} + \varepsilon^2 B_2$$

in which

$$B_2 = \begin{pmatrix} 2a_1 & [*, a_3] & [a_2, *] \\ a_2 & a_1 & 0 \\ a_3 & 0 & a_1 \end{pmatrix}.$$

In order for a system $\dot{u}=f(u)$ to be sent to $\dot{v}=g(v)$ by $v=b(u)$, the coefficients f_p must satisfy

$$\mathcal{S}_b g_p=\sum_{q=1}^{3}(\partial_q b_p)f_q.$$

The corresponding equation of column vectors, expanded in powers of ε, is

$$\sum_{i=0}^{4}\varepsilon^i\mathcal{C}_i=(I+\varepsilon\mathcal{D}+\varepsilon^2 B_2)\sum_{j=0}^{\infty}\varepsilon^j F_j.$$

All the column vectors F_j are determined recursively; in particular $F_0=\mathcal{C}_0=g$, $F_1=0$, and

$$F_2=\begin{pmatrix}(2a_1^3+3a_1[a_2,a_3])'\\ 3a_1(a_1a_2)'+3a_2'[a_2,a_3]\\ 3a_1(a_1a_3)'+3a_3'[a_2,a_3]\end{pmatrix}.$$

It now turns out that $F_j=0$ for $j\geqslant 3$, permitting the fourth degree polynomial $\mathcal{S}_b g_p$ to be written as the product of $(\partial_q b_p)$ by f_q with $f=(f_1,f_2,f_3)^T$, $f=g+\varepsilon^2 F_2$, that is, as a product of two quadratic polynomials in ε. This completes the construction of $\dot{u}=f(u)$, a system sent to $\dot{v}=g(v)$ by $v=b(u)$.

Conservation laws for $\dot{u}=f(u)$ are given by $h\in\mathcal{A}$ satisfying $\Sigma_{p=1}(\partial_p h)f_p\in\mathcal{D}\mathcal{A}$. Since $\partial_p a_q=\delta(p,q)$ in general, the choice $h=a_1$ gives just f_1, which by the construction of f is always in $\mathcal{D}\mathcal{A}$. Therefore $h=a_1$ is indeed a conserved quantity for $\dot{u}=f(u)$.

If the ring homomorphism $\mathcal{S}_b:\mathcal{A}\to\mathcal{A}$ could be inverted, the pullback of a_1 would give a conservation law for $\dot{v}=g(v)$, for all ε. But it can indeed be inverted if we embed $\mathcal{A}$ within $\mathcal{A}[[\varepsilon]]=B$, whose elements are the formal power series in ε with coefficients in $\mathcal{A}$. The given elements $b_p\in B$, $1\leqslant p\leqslant 3$, define a unique ring homomorphism $\mathcal{S}_b:\mathcal{A}\to B$ which sends a_{p0} to b_p and commutes with $\mathcal{D}$. Obviously it extends to $\mathcal{S}_b:B\to B$.

But when $\varepsilon=0$ the element $b_p\in B$ reduces to the element $a_p\in\mathcal{A}$. Therefore, for any $h(a_{10},a_{11},a_{20},\ldots)\in\mathcal{A}$, $\mathcal{S}_b h$ will have the form

$$\mathcal{S}_b h=h+\varepsilon h_1+\varepsilon^2 h_2+\cdots$$

for some $h_1,h_2,\ldots,\varepsilon\mathcal{A}$.

Within B one has the ideals $\mathcal{B}_k=\varepsilon^k\mathcal{B}$ and the filtration $B\supset B_1\supset B_2\supset\cdots$. The preceding observation shows that $\mathcal{S}_b$ sends each B_k into itself, and reduces to the identity map in each quotient space B_k/B_{k+1}. This shows that, given any $f_0,f_1,\ldots$ in $\mathcal{A}$, the equation

$$\mathcal{S}_b\left(\sum_{k=0}^{\infty}\varepsilon^k g_k\right)=\sum_{k=0}^{\infty}\varepsilon^k f_k$$

can be solved recursively for $g_0,g_1,\ldots,\varepsilon\mathcal{A}$. Therefore $\mathcal{S}_b:B\to B$ is an isomorphism.

In order to see the recursion algorithm more clearly we work in the space $\mathcal{A}\oplus\mathcal{A}\oplus\mathcal{A}$ of column vectors $e=(e_1,e_2,e_3)^T$. Then

$$b=a+\varepsilon a'+\varepsilon^2\langle a,a\rangle,$$

where in general

$$\langle f,g\rangle=(f_1g_1+[f_2,g_3],f_1g_2,f_1g_3)^T,$$

a bilinear map of $\mathcal{A}\oplus\mathcal{A}\oplus\mathcal{A}$ into itself. We ask that column vectors $\mathcal{C}_0,\mathcal{C}_1,\mathcal{C}_2,\ldots$ be determined in such a way that

$$\mathcal{C}=\mathcal{C}_0+\varepsilon\mathcal{C}_1+\varepsilon^2\mathcal{C}_2+\cdots$$

satisfies

$$a=\mathcal{C}+\varepsilon\mathcal{C}'+\varepsilon^2\langle\mathcal{C},\mathcal{C}\rangle.$$

That is, the ring homomorphism $\mathcal{S}_{\mathcal{C}}:B\to B$ should send b_p to a_p for $1\leqslant p\leqslant 3$.

After equating the coefficients of corresponding powers of ε one finds the recursion relation

$$0=\mathcal{C}_{m+2}+\mathcal{C}'_{m+1}+\langle\mathcal{C}_m,\mathcal{C}_0\rangle+\langle\mathcal{C}_{m-1},\mathcal{C}_1\rangle+\cdots+\langle\mathcal{C}_0,\mathcal{C}_m\rangle.$$

The values for $0\leqslant m\leqslant 4$ are

$$\mathcal{C}_0=a,$$

$$\mathcal{C}_1=-a',$$

$$\mathcal{C}_2=a''-\langle a,a\rangle,$$

$$\mathcal{C}_3=-a'''+2\langle a,a\rangle',$$

$$\mathcal{C}_4=a''''-2\langle a,a\rangle''+\langle a',a'\rangle+\langle\langle a,a\rangle,a\rangle+\langle a\langle a,a\rangle\rangle.$$

By construction, the transformation $\mathcal{S}_{\mathcal{C}}$ takes $\dot{v}=g(v)$ to $\dot{u}=f(u)$. The latter equation has a_1 as a conserved quantity. Its pullback is the top entry in the column $\mathcal{C}=\mathcal{C}(\varepsilon)$.

As this is true for all ε, we conclude that the top entries of all the columns $\mathcal{C}_m$ give conserved quantities for the extended KdV equation $\dot{v}=g(v)$.

Simplifying where possible by subtracting elements of $\mathcal{DA}$ or by changing signs, the first three nontrivial functionals $\mathcal{M}\to R$ are

$$H_m(v)=\int h_m(v_1(x),v_1'(x),v_2(x),\ldots)dx$$

with

$$h_0=a_1,$$

$$h_2=(a_1)^2+a_2'a_3-a_2a_3',$$

$$h_4=2(a_1)^3+(a_1')^2+a_2''a_3'-a_2'a_3''+4a_1(a_2'a_3-a_2a_3').$$

Evidently, the extended KdV equation has infinitely many conservation laws.

IV. EXTENSION OF THE KdV EQUATION TO OPERATOR-VALUED FUNCTIONS

This extension, which also has infinitely many conservation laws, includes the supersymmetric KdV as a special case, as well as the extension seen in the preceding section.

That extension is a system of equations in the three real-valued functions $v_p(x,t)$, $1\leqslant p\leqslant 3$. It is recast in operator form by writing

$$\mathcal{P}=v_1(x,t)I,$$

$$\mathcal{Q}=v_2(x,t)E_2+v_3(x,t)E_3,$$

where E_2 and E_3 are linear operators in some space which satisfy $[E_2,E_3]=E_2E_3-E_3E_2=I$. The quantity $v_2'v_3-v_2v_3'$, which was denoted before by $[v_2,v_3]$, will now appear as the coefficient of I in the usual commutator $[\mathcal{Q}',\mathcal{Q}]$. Thus we have the equivalent system of operator differential equations

$$\mathcal{P}_t = -\mathcal{P}''' + 6\mathcal{P}\mathcal{P}' + 3[\mathcal{Q}'', \mathcal{Q}],$$
$$\mathcal{Q}_t = -\mathcal{Q}''' + 3(\mathcal{P}\mathcal{Q})'. \tag{12}$$

Further, setting $p = u_1(x,t)I$ and $q = u_2(x,t)E_2 + u_3(x,t)E_3$, the Gardner transformation takes the form

$$\mathcal{P} = p + \epsilon p' + \epsilon^2(p^2 + [q', q]),$$
$$\mathcal{Q} = q + \epsilon q' + \epsilon^2 pq, \tag{13}$$

and the modified KdV equation $\dot{u} = f(u)$ takes the form

$$p_t = (-p'' + 3p^2 + 3[q', q])' + \epsilon^2(2p^3 + 3p[q', q])',$$
$$q_t = (-q'' + 3pq)' + \epsilon^2 3(p^2 q' + pp'q + q'[q', q]). \tag{14}$$

It was shown in the preceding section that the Gardner transformation takes a solution p,q of the latter system to a solution $\mathcal{P}$, $\mathcal{Q}$ of the former.

But more generally one can suppose that P and p have values in $\mathcal{P}$, a commutative algebra with unit, of operators acting in some vector space. Then, if $\mathcal{Q}$ is a linear space of operators satisfying

$$[\mathcal{Q}, \mathcal{P}] = 0,$$
$$\mathcal{Q}\mathcal{P} \subset \mathcal{Q}, \tag{15}$$
$$[\mathcal{Q}, \mathcal{Q}] \subset \mathcal{P},$$

then $\mathcal{Q}$ and q can take their values in $\mathcal{Q}$.

For the specific choice $\mathcal{P} = \{\alpha I\}$, $\mathcal{Q} = \{\beta_2 E_2 + \beta_3 E_3\}$ just considered, we have observed that the Gardner transformation (13) takes solutions of (14) to solutions of (12), this being no more than a restatement of the results of the preceding section.

However, upon reexamining the calculations in that section, one sees that they remain valid not just for the $\mathcal{P}$, $\mathcal{Q}$ just considered but for any $\mathcal{P}$ and $\mathcal{Q}$ satisfying (15).

Therefore the conservation laws of (12) and of (14) are interrelated by the Gardner transformation (13) and its inverse, just as before; in particular (12) has infinitely many conservation laws.

After simplifying by crossing out derivatives in x, the first four nontrivial conserved quantities for the operator-extended KdV system are

$$H_0 = \int \mathcal{P}\, dx,$$
$$H_2 = \int (\mathcal{P}^2 + [\mathcal{Q}', \mathcal{Q}])\, dx,$$
$$H_4 = \int (2\mathcal{P}^3 + (\mathcal{P}')^2 + 4\mathcal{P}[\mathcal{Q}', \mathcal{Q}] + [\mathcal{Q}'', \mathcal{Q}'])\, dx, \tag{16}$$
$$H_6 = \int (5\mathcal{P}^4 + 10\mathcal{P}(\mathcal{P}')^2 + (\mathcal{P}'')^2 + 15\mathcal{P}^2[\mathcal{Q}', \mathcal{Q}] - 2\mathcal{P}[\mathcal{Q}'', \mathcal{Q}']$$
$$-8\mathcal{P}[\mathcal{Q}''', \mathcal{Q}] + 3[\mathcal{Q}', \mathcal{Q}]^2 + [\mathcal{Q}''', \mathcal{Q}''])\, dx.$$

In each case, the conserved quantity has its values in the operator algebra $\mathcal{P}$.

The foregoing theory applies to any operator spaces $\mathcal{P}$, $\mathcal{Q}$ having the stipulated properties. For example, the $\mathcal{Q}$ seen before can be enlarged to $\mathcal{Q}=\{\Sigma_{k=1}^{m}(\mu_k E_k+\nu_k F_k)\}$ where $\mu_k,\nu_k \epsilon \mathbb{R}$ while $E_1,\ldots,E_m$, $F_1,\ldots,F_m$ are linearly independent operators in some vector space, satisfying $[E_k,F_k]=I$ but with all other commutator brackets zero. Then, with $\mathcal{P}=\{\alpha I\}$ as before, the operator-extended KdV system becomes a system of nonlinear differential equations for $2m+1$ functions $\alpha(x,t),\mu_k(x,t),\nu_k(x,t)$, specifically

$$\frac{\partial}{\partial t}\alpha=-\alpha'''+6\alpha\alpha'+3\sum_{k=1}^{m}(\mu_k''\nu_k-\mu_k\nu_k''),$$

$$\frac{d}{dt}\mu_k=-\mu_k'''+3(\alpha\mu_k)', \tag{17}$$

$$\frac{d}{dt}\nu_k=-\nu_k'''+3(\alpha\nu_k)'.$$

Another choice of $\mathcal{P}$ and $\mathcal{Q}$ leads to the supersymmetric extension of KdV. An exterior algebra Λ on a finite set of generators is the direct sum $\Lambda=\Lambda_0\oplus\Lambda_1$, where Λ_0 and Λ_1 consist of the linear combinations of even products, respectively odd products, of the generators. Then $\mathcal{P}$ and $\mathcal{Q}$ are, respectively, the operators of left multiplication in Λ by elements of Λ_0 and of Λ_1. In this example some of the equations in the general theory are to be simplified, for example $[\mathcal{Q}'',\mathcal{Q}]=2\mathcal{Q}''\mathcal{Q}$. The change of variables $\mathcal{P}=u$, $\mathcal{Q}=2^{-1/2}\xi$ converts the operator-extended KdV into

$$u_t=-u'''+6uu'-3\xi\xi'',$$

$$\xi_t=-\xi'''+3(\xi u)',$$

which is the supersymmetric extension of KdV given by Mathieu in Ref. 1. Moreover, the modified system (12) and the conserved quantity H_6 are simplified a bit by $q'[q',q]=0$ and $[\mathcal{Q}',\mathcal{Q}]^2=0$ in the supersymmetric case.

V. CONCLUSION

In this article an operator valued extension of the KdV equation was constructed. In a particular case the super KdV equations were recovered. A general algebraic method was developed and applied to show that there are infinitely many conserved quantities for certain integrable systems. When the method was applied to the operator extension of the KdV equation, the first few conserved quantities were computed explicitly. The conserved quantities H_0, H_2, and H_4 of the super KdV equation can be seen to correspond term by term with the corresponding quantities of the operator extension. However, the quantities $H_6,H_8,\ldots$ contain extra terms in the operator case which reduce to zero for the super KdV equation.

(Received 19 January 2001; accepted for publication 10 February 2001)

The multiscale method has been applied in J. Math. Phys. **41**, 6399 (2000) to evolution PDEs to obtain various nonlinear Schrödinger-type equations. Here these results are exploited to derive necessary conditions of integrability for nonlinear, real, evolution PDEs in $1+1$ dimensions. These conditions are given by explicit formulas, and several examples are detailed. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1366296]

I. INTRODUCTION

In the first paper of this series[1] we began a systematic exploration of results obtainable by applying ''multiscale expansions'' techniques to nonlinear evolution PDEs. In particular we exhibited a set of *universal nonlinear evolution equations of nonlinear Schrödinger type* obtained via such technique.[1] The qualifying adjective ''universal'' refers to the fact that, to each of these model equations, an entire *large* class of nonlinear evolution PDEs can be associated, via an appropriate *reduction* technique (involving a small parameter ϵ) which is asymptotically *exact* (in the $\epsilon \to 0$ limit).

An important by-product of this technique emerges from the observation[2] that the ''universal'' model equation obtainable from an entire class of nonlinear evolution PDEs via such an *asymptotically exact* technique cannot be ''less solvable'' than any one of the (many) equations contained in that class, since the solution of the model equation can indeed be obtained by making an appropriate asymptotic expansion of an appropriately chosen solution of any evolution equation in that class. The way is thereby opened to establish *necessary conditions of integrability* for nonlinear evolution PDEs: if a given nonlinear evolution PDE yields by reduction a *nonintegrable* model equation, then it cannot be itself *integrable*. This technique to obtain necessary conditions for the integrability of nonlinear PDEs was introduced by Wiktor Eckhaus and by one of us (F.C.) a dozen years ago[2,3] (for analogous approaches see Refs. 4 and 5); the present paper is devoted to a systematic presentation of such results, based on the findings reported in paper I. For simplicity we restrict attention in this paper to *real* nonlinear evolution PDEs of the kind treated in paper I, namely to real evolution PDEs featuring a *linear part* which is *dispersive* and a *nonlinear part* which is *analytic* but otherwise *largely arbitrary*. Hence the nonlinear evolution PDEs on which we hereafter focus read as follows:

$$Du = (\partial/\partial x)^h F, \tag{1.1}$$

where we have separated the linear part of the equation on the left-hand side from the nonlinear part on the right-hand side, according to the following specifications.

[c)]Electronic mail: antonio.degasperis@roma1.infn.it
[d)]Electronic mail: jxd@ustc.edu.cn

The dependent variable $u \equiv u(x,t)$ is a *real* function of the two (real) independent variables x (''space'') and t (''time''). The (real) *linear* differential operator D,

$$D = \partial/\partial t + \sum_{m=0}^{M} (-1)^m \ a_{2m+1} \ (\partial/\partial x)^{2m+1}, \tag{1.2}$$

is characterized by the *real* coefficients a_{2m+1} (with M an arbitrary positive integer, $M \geqslant 1$, and of course $a_{2M+1} \neq 0$). The *nonlinear* function $F \equiv F(u,u_x,u_{xx},\ldots)$ is defined as follows:

$$F(u,u_x,u_{xx},\ldots) = \sum_{m=2}^{\infty} F^{(m)}(u,u_x,u_{xx},\ldots), \tag{1.3a}$$

where $F^{(m)}(u,u_x,u_{xx},\ldots)$ is a *homogeneous* polynomial of degree m in u and its x-derivatives $u_x,u_{xx},\ldots$:

$$F^{(m)}(u,u_x,u_{xx},\ldots) = \sum_{j_1=0}^{\infty} \sum_{j_2=j_1}^{\infty} \cdots \sum_{j_m=j_{m-1}}^{\infty} c^{(m)}_{j_1 j_2 \ldots j_m} u^{(j_1)} u^{(j_2)} \cdots u^{(j_m)}. \tag{1.3b}$$

Here and throughout $u^{(1)} \equiv u_x \equiv \partial u/\partial x$, $u^{(2)} \equiv u_{xx} \equiv \partial^2 u/\partial x^2$, and so on; and the (constant) coefficients $c^{(m)}_{j_1 j_2 \ldots j_m}$ are of course *real*. For instance, if the coefficients $c^{(2)}_{j_1 j_2}$ vanish for $j_2 > 2$,

$$F^{(2)} = c^{(2)}_{00} u^2 + c^{(2)}_{01} u u_x + c^{(2)}_{02} u u_{xx} + c^{(2)}_{11} u_x^2 + c^{(2)}_{12} u_x u_{xx} + c^{(2)}_{22} u_{xx}^2, \tag{1.4}$$

and likewise, if the coefficients $c^{(3)}_{j_1 j_2 j_3}$ vanish for $j_3 > 2$,

$$\begin{aligned} F^{(3)} = {} & c^{(3)}_{000} u^3 + c^{(3)}_{001} u^2 u_x + c^{(3)}_{002} u^2 u_{xx} + c^{(3)}_{011} u u_x^2 + c^{(3)}_{012} u u_x u_{xx} + c^{(3)}_{022} u u_{xx}^2 + c^{(3)}_{111} u_x^3 \\ & + c^{(3)}_{112} u_x^2 u_{xx} + c^{(3)}_{122} u_x u_{xx}^2 + c^{(3)}_{222} u_{xx}^3 . \end{aligned} \tag{1.5}$$

Finally, the derivative operator $(\partial/\partial x)^h$, with h a non-negative integer, is introduced in the right-hand side of (1.1) to take account of the possibility that the nonlinear part of the evolution equation under consideration be a perfect differential of order h, see (1.1). Such recognition is generally helpful to obtain more effective integrability conditions (see below), but it is of course not required for the validity of the results obtained below.

According to the notation we just detailed every nonlinear evolution PDE of the class under consideration in this paper is identified by assigning all the (nonvanishing) *real* coefficients a_{2m+1} and $c^{(m)}_{j_1 j_2 \ldots j_m}$, as well as the non-negative integer h; as for the latter, let us re-emphasize that any equation of type (1.1) with $h > 0$ can be equivalently rewritten with a smaller value of h, say by replacing h with $\tilde{h}$ where $0 \leqslant \tilde{h} < h$, and by correspondingly replacing, in an appropriate manner, the coefficients $c^{(m)}_{j_1 j_2 \ldots j_m}$ with $\tilde{c}^{(m)}_{j_1 j_2 \ldots j_m}$; this ambiguity does not affect the validity of the following findings; but it is generally advisable, to get more cogent results, to choose for h the largest non-negative integer value consistent with the nonlinear evolution equation under consideration. The user-friendly character of the results reported in this paper is evidenced by the possibility they provide to get information on the integrability of any equation of type (1.1)–(1.3), in the guise of conditions formulated directly in terms of these constants ($a_{2m+1}, c^{(m)}_{j_1 j_2 \ldots j_m}$ and h): conditions which, whenever they are *not* satisfied, guarantee that the nonlinear evolution PDE under consideration is *not integrable*.

In Sec. II we review some results of paper I, to the extent necessary and sufficient to render the present paper self-contained. In the subsequent Sec. III the notion of *integrability* is reviewed, with particular reference to certain model equations that provide the basic tools to derive those *necessary conditions of integrability* that constitute the core of this paper. These results, which are of course applicable to nonlinear evolution PDEs of type (1.1)–(1.3), are detailed in Sec. IV; readers more interested in using these findings than in understanding their origin are advised to

proceed immediately to that section, and as well to Sec. V, where some examples are exhibited which demonstrate the ease of applicability, and the efficacy, of these tools to test the possible integrability of nonlinear evolution PDE of type (1.1)–(1.3). Finally, let us emphasize that, while in this paper we have for simplicity restricted attention to *real scalar* nonlinear PDEs in *one* space variable only and only of *first-order* in time, clearly the approach used herein is applicable more generally.

II. REVIEW OF PREVIOUS RESULTS

In this section we review previous findings,[1] to the extent needed to derive, in Sec. 4, the main results of the present paper. Our presentation is notationally self-consistent, but of course for the justification of the assertions made herein the interested reader is referred to paper I.

Let k be a *real* and *nonvanishing* parameter, and define the following five (real) quantities in terms of this parameter and of the coefficients a_{2m+1} that characterize the linear differential operator (1.2):

$$A_0^{(1)}(k) = -\sum_{m=1}^{M} (2m+1)\, a_{2m+1}\, k^{2m}, \tag{2.1a}$$

$$A_1^{(2)}(k) = \sum_{m=1}^{M} m(2m+1)\, a_{2m+1}\, k^{2m-1}, \tag{2.1b}$$

$$A_2^{(0)}(k) = 2\sum_{m=1}^{M} (2^{2m}-1)\, a_{2m+1}\, k^{2m+1}, \tag{2.1c}$$

$$A_2^{(1)}(k) = \sum_{m=1}^{M} (2m+1)(2^{2m}-1)\, a_{2m+1}\, k^{2m}, \tag{2.1d}$$

$$A_2^{(2)}(k) = \frac{1}{2}\sum_{m=1}^{M} m(2m+1)\, 2^{2m}\, a_{2m+1}\, k^{2m-1}. \tag{2.1e}$$

Next define the following eight quantities in terms of the (real) parameter k and of the coefficients $c^{(m)}_{j_1 j_2 \cdots j_m}$ that characterize the nonlinear part of the evolution PDE (1.1) [see (1.3b)]:

$$g_{01}(k) = 2c_{00}^{(2)} + \sum_{j=1}^{\infty} (-1)^j k^{2j} c_{0,2j}^{(2)} + i\sum_{j=0}^{\infty} (-1)^j k^{2j+1} c_{0,2j+1}^{(2)}, \tag{2.2a}$$

$$g_{11}(k) = \sum_{j=0}^{\infty} (-1)^j k^{2j} \sum_{j'=0}^{j} c_{j',2j-j'}^{(2)} + i\sum_{j=0}^{\infty} (-1)^j k^{2j+1} \sum_{j'=0}^{j} c_{j',2j+1-j'}^{(2)}, \tag{2.2b}$$

$$g_{-1,1}(k) = 2\sum_{j=0}^{\infty} (-1)^j k^{2j} \sum_{j'=0}^{j} (-1)^{j'} c_{j',2j-j'}^{(2)}, \tag{2.2c}$$

$$\begin{aligned} g_{-1,2}(k) = {} & \sum_{j=0}^{\infty} (-1)^j k^{2j} \sum_{j'=0}^{j} (-1)^{j'} (2^{2j-j'} + 2^{j'})\, c_{j',2j-j'}^{(2)} \\ & + i\sum_{j=0}^{\infty} (-1)^j k^{2j+1} \sum_{j'=0}^{j} (-1)^{j'} (2^{2j+1-j'} - 2^{j'})\, c_{j',2j+1-j'}^{(2)}, \end{aligned} \tag{2.2d}$$

$$g_{-n,n,n}(k)=\sum_{l=0}^{\infty}(-1)^l(nk)^{2l}\sum_{j=0}^{[4l/3]}\sum_{j'=\mathrm{Max}[0,2j-2l]}^{[j/2]}[(-1)^{j'}+(-1)^j+(-1)^{j+j'}]$$
$$\times c^{(3)}_{j',j-j',2l-j}+i\sum_{l=0}^{\infty}(-1)^l(nk)^{2l+1}$$
$$\times\sum_{j=0}^{[4l+2/3]}\sum_{j'=\mathrm{Max}[0,2j-2l-1]}^{[j/2]}[(-1)^{j'}-(-1)^j+(-1)^{j+j'}]$$
$$\times c^{(3)}_{j',\,j-j',\,2l+1-j},\quad n=1,2, \tag{2.2e}$$

$$g_{-n,1,2}(k)=\sum_{0\leqslant j_1\leqslant j_2\leqslant j_3<\infty}(ik)^{j_1+j_2+j_3}[(-n)^{j_1}(2^{j_2}+2^{j_3})$$
$$+(-n)^{j_2}(2^{j_1}+2^{j_3})+(-n)^{j_3}(2^{j_1}+2^{j_2})]c^{(3)}_{j_1j_2j_3},\quad n=1,2. \tag{2.2 f}$$

The first four of these quantities, $g_{01}(k),g_{11}(k),g_{-1,1}(k),g_{-1,2}(k)$, are defined in terms of the coefficients $c^{(2)}_{j_1j_2}$ of the *quadratic* term $F^{(2)}$ [see (1.3)], on the right-hand side of (1.1); the last four of these quantities, $g_{-1,1,1}$, $g_{-2,2,2}$, $g_{-1,1,2}$, $g_{-2,1,2}$, are instead defined in terms of the coefficients $c^{(3)}_{j_1j_2j_3}$ of the *cubic* term, $F^{(3)}$ [see (1.3)], on the right-hand side of (1.1). Note that, of these eight quantities, only one, $g_{-1,1}(k)$ [see (2.2c)], is always real. The notation used here is closely analogous, if not identical, to the notation of Ref. 1 (note that the commas introduced occasionally to separate subscripts have no significance other than for typographical neatness).

Lemma 2.1. If $h\geqslant 1$ and

$$A^{(1)}_0(k)\neq 0,\quad A^{(2)}_1(k)\neq 0,\quad A^{(0)}_2(k)\neq 0, \tag{2.3}$$

an asymptotically exact reduction of (1.1)–(1.3) reads

$$i\psi_\tau+\alpha\psi_{\xi\xi}=\lambda|\psi|^2\psi, \tag{2.4a}$$

with $\psi\equiv\psi(\xi,\tau)$ and

$$\alpha\equiv\alpha(k)=A^{(2)}_1(k), \tag{2.4b}$$

$$\lambda\equiv\lambda(k)=-\delta_{h1}[A^{(1)}_0(k)]^{-1}kg_{01}(k)g_{-11}(k)+[A^{(0)}_2(k)]^{-1}(-2k^2)^hg_{-1,2}(k)g_{1,1}(k)$$
$$+i^{h+1}k^hg_{-1,1,1}(k). \tag{2.4c}$$

□

Remark 2.1. The model equation (2.4) is of course the standard NLS (nonlinear Schrödinger) equation. The validity of this *Lemma 2.1* is entailed by Eq. (C10) of paper I.

□

Lemma 2.2. If $h=0$ and

$$A^{(1)}_0(k)\neq 0,\quad A^{(2)}_1(k)\neq 0, \tag{2.5}$$

an asymptotically exact reduction of (1.1)–(1.3) reads

$$i\psi_\tau+\alpha\psi_{\xi\xi}=\lambda_1\varphi\psi, \tag{2.6a}$$

$$\varphi_\xi=\lambda_2|\psi|^2, \tag{2.6b}$$

with $\psi\equiv\psi(\xi,\tau)$, $\varphi\equiv\varphi(\xi,\tau)$, α given by (2.4b) and

$$\lambda_1 \equiv \lambda_1(k) = g_{01}(k), \tag{2.6c}$$

$$\lambda_2 \equiv \lambda_2(k) = [A_0^{(1)}(k)]^{-1} g_{-1,1}(k). \tag{2.6d}$$

□

Remark 2.2. Note that the model evolution equation takes now the form of a system of two coupled equations, see (2.6a) (2.6b). The validity of this *Lemma 2.2* is entailed by Eq. (C.11) of paper I.

□

Lemma 2.3. If, for some *real nonvanishing* value $k=\tilde{k}$, $A_2^{(0)}$ vanishes,

$$A_2^{(0)}(\tilde{k}) = 0, \tag{2.7}$$

and in addition there hold the relations

$$h \geqslant 1, \tag{2.8a}$$

$$A_1^{(2)}(\tilde{k}) \neq 0, \quad A_2^{(1)}(\tilde{k}) \neq 0, \tag{2.8b}$$

then an asymptotically exact reduction of (1.1)–(1.3) reads

$$i\psi_\tau + \alpha \psi_{\xi\xi} = \mu_1 \chi \psi^*, \tag{2.9a}$$

$$\chi_\xi = \mu_2 \psi^2 \tag{2.9b}$$

with $\psi \equiv \psi(\xi,\tau)$, $\chi \equiv \chi(\xi,\tau)$, and

$$\alpha = A_1^{(2)}(\tilde{k}), \tag{2.9c}$$

$$\mu_1 = i^{h+1} \tilde{k}^h g_{-1,2}(\tilde{k}), \tag{2.9d}$$

$$\mu_2 = (2i\tilde{k})^h [A_2^{(1)}(\tilde{k})]^{-1} g_{11}(\tilde{k}); \tag{2.9e}$$

while if (2.8a) does not hold, namely if

$$h = 0, \tag{2.10a}$$

but (2.7) continues to hold (for some real nonvanishing $\tilde{k}$) and (2.8b) is augmented to read

$$A_0^{(1)}(\tilde{k}) \neq 0, \quad A_1^{(2)}(\tilde{k}) \neq 0, \quad A_2^{(1)}(\tilde{k}) \neq 0, \tag{2.10b}$$

then an asymptotically exact reduction of (1.1)–(1.3) reads

$$i\psi_\tau + \alpha \psi_{\xi\xi} = i g_{0,1}(\tilde{k}) \varphi \psi + i g_{-1,2}(\tilde{k}) \chi \psi^*, \tag{2.11a}$$

$$\varphi_\xi = \nu_1 |\psi|^2, \tag{2.11b}$$

$$\chi_\xi = \nu_2 \psi^2, \tag{2.11c}$$

with $\psi \equiv \psi(\xi,\tau)$, $\varphi \equiv \varphi(\xi,\tau)$, $\chi \equiv \chi(\xi,\tau)$, α given by (2.9c), and

$$\nu_1 = [A_0^{(1)}(\tilde{k})]^{-1} g_{-1,1}(\tilde{k}), \tag{2.11d}$$

$$\nu_2 = [A_2^{(1)}(\tilde{k})]^{-1} g_{11}(\tilde{k}). \tag{2.11e}$$

□

Remark 2.3. This *Lemma 2.3*, in contrast to the previous two *Lemmata 2.1* and *2.2*, requires that k have a special value, see (2.7): note that this polynomial equation in k, (2.7) with (2.1c), has at most $2M$ *real nonvanishing* solutions (it might of course have none). Depending on the value of h, $h \geqslant 1$, respectively, $h=0$, the model equation is now a system of two, respectively, three coupled equations, see (2.9a) and (2.9b), respectively (2.11a), (2.11b), and (2.11c). The validity of *Lemma 2.3* is entailed by Eqs. (C.12) respectively (C.13) of paper I.

□

Lemma 2.4. If $h=1$ and for some *real nonvanishing* value $k=\tilde{k}$, $A_0^{(1)}$ vanishes and $A_1^{(2)}$ does not,

$$A_0^{(1)}(\tilde{k})=0, \tag{2.12a}$$

$$A_1^{(2)}(\tilde{k})\neq 0, \tag{2.12b}$$

then an asymptotically exact reduction of (1.1)–(1.3) reads

$$i\psi_\tau+\alpha\psi_{\xi\xi}=i\tilde{k}g_{01}(\tilde{k})\varphi\psi, \tag{2.13a}$$

$$\varphi_\tau=g_{-1,1}(\tilde{k})(|\psi|^2)_\xi, \tag{2.13b}$$

with α given by (2.9c).

□

Remark 2.4. In analogy to *Lemma 2.3*, and in contrast to *Lemmata 2.1* and *2.2*, this *Lemma 2.4* requires that k have a special value, see (2.12a): note that this polynomial equation in k, (2.12a) with (2.1a), has again at most $2M$ *real nonvanishing* solutions (it might of course have none). The model equation is now a system of two coupled equations, see (2.13a) and (2.13b). The validity of *Lemma 2.4* is entailed by Eq. (C15) of paper I.

□

The last result we report here is only applicable to evolution equations of type (1.1)–(1.3) which feature nonlinearities of *cubic*, or higher, degree. Hence we now assume

$$F^{(2)}(u,u_x,u_{xx},\ldots)=0 \tag{2.14}$$

[see (1.3)]. For the subclass of evolution PDEs of type (1.1)–(1.3) satisfying this restriction there then holds

Lemma 2.5. If, for some *real nonvanishing* value $k=\tilde{k}$, both $A_2^{(0)}$ and $A_2^{(1)}$ vanish,

$$A_2^{(0)}(\tilde{k})=A_2^{(1)}(\tilde{k})=0, \tag{2.15a}$$

and moreover

$$A_1^{(2)}(\tilde{k})\neq 0,\ A_2^{(2)}(\tilde{k})\neq 0, \tag{2.15b}$$

then an asymptotically exact reduction of (1.1)–(1.3) reads

$$i\psi_{1,\tau}+\alpha_1\psi_{1,\xi\xi}=(\lambda_{11}|\psi_1|^2+\lambda_{12}|\psi_2|^2)\psi_1, \tag{2.16a}$$

$$i\psi_{2,\tau}+\alpha_2\psi_{2,\xi\xi}=(\lambda_{21}|\psi_1|^2+\lambda_{22}|\psi_2|^2)\psi_2, \tag{2.16b}$$

with

$$\alpha_1 = A_1^{(2)}(\tilde{k}), \quad \alpha_2 = A_2^{(2)}(\tilde{k}), \tag{2.16c}$$

$$\begin{aligned} \lambda_{11} &= i^{h+1}\tilde{k}^h g_{-1,1,1}(\tilde{k}), \quad \lambda_{12} = i^{h+1}\tilde{k}^h g_{-2,1,2}(\tilde{k}), \\ \lambda_{21} &= i^{h+1}(2\tilde{k})^h g_{-1,1,2}(\tilde{k}), \quad \lambda_{22} = i^{h+1}(2\tilde{k})^h g_{-2,2,2}(\tilde{k}). \end{aligned} \tag{2.16d}$$

□

Remark 2.5. The applicability of this *Lemma 2.5* is restricted by the condition (2.14), and in addition by the requirement that *both equalities* (2.15a) hold [as well as the *inequalities* (2.15b)]: this generally entails that the coefficients a_{2m+1} satisfy one equation, see (2.15a) with (2.1c) and (2.1d). The model equation takes now the form of a coupled system of two NLS equations, see (2.16a) and (2.16b). The validity of this *Lemma 2.5* is entailed by Eq. (E3) of paper I.

□

This concludes our presentation of the results of paper I that are instrumental to derive useful necessary conditions for integrability. A crucial issue in this respect is the *integrable* (or rather the *nonintegrable*) character of the five model equations yielded by the five Lemmata we just reported. This is discussed in Sec. III.

III. INTEGRABILITY

In this section we discuss the all-important issue of *integrability*. As it is well known, although this notion is now well understood by practitioners, there does not yet exist a precise, universally accepted definition of integrability for (nonlinear evolution) PDEs. Hence we cannot formulate *necessary conditions for integrability* as *Theorems* backed by rigorous *Proofs*. Nevertheless we believe the results of this kind presented below are both cogent and useful.

The point of departure of our treatment is the following:

Axiom. Every nonlinear evolution PDE that yields via an *asymptotically exact* reduction process a nonlinear evolution PDE known *not* to be *integrable*, should itself be pronounced *nonintegrable*.

□

We use the term ''Axiom'' to denote this statement, because the lack of a precise, universally accepted definition of *integrability* precludes any hope to ''prove'' it. On the other hand, its validity is plain, being predicated, as we already noted, on the fact that the task of solving a model equation derived via an *asymptotically exact reduction* from a given equation, cannot be ''more difficult'' than that of solving the original equation; since the solution of the model equation can indeed be obtained by applying the asymptotic expansion process to an appropriately chosen solution of the original equation. Hence no model equation derived via an asymptotically exact reduction from a given equation can be ''less integrable'' than the original equation. Hence a nonlinear evolution PDE that yields via an asymptotically exact reduction process a model equation known *not* to be *integrable*, is necessarily itself *nonintegrable*.

This line of argumentation can be made more specific by introducing the heuristic (i.e., not quite precise but very useful) distinction[3] among *S-integrable* nonlinear evolution PDEs (i.e., those solvable via the spectral transform technique, or some variant of it; see, for instance, Ref. 6), and *C-integrable* nonlinear evolution PDEs (i.e., those solvable via some appropriate change of variables; see, for instance, Refs. 3 and 7). This *Axiom* is indeed equally applicable if the terms ''integrable'' respectively ''nonintegrable'' are systematically replaced by ''*C*-integrable'' respectively ''not *C*-integrable'' or, as the case may be, ''*S*-integrable'' respectively ''not *S*-integrable.'' In the following we use the terms ''integrable'' and ''integrability'' (as well as their negatives) whenever we do not wish to introduce the (fine!?) distinction among *S*-integrability and *C*-integrability; when we do instead specify the kind of integrability we refer to, it is useful that the reader be aware of the hierarchical character of this distinction, according to which *C-integrable* equations are ''more integrable'' than *S-integrable* ones: namely, every

C-integrable equation is automatically considered to also belong to the *S-integrable* class, while there are (many) examples of *S-integrable* equations which are *not C-integrable*.[3]

In the light of the results reported in the preceding section it is now clear that the next step of our treatment is to assess the integrable character of the five model equations detailed there. Before delving into this discussion we like to reiterate the word of caution already voiced above, related to the *lack* of a precise and universally accepted *definition of integrability* for nonlinear evolution PDEs. Thus our assertions in the remainder of this section must rely on what we consider *common knowledge*—or, equivalently, *universal lore*.

Statement 3.1. The NLS equation (2.4a), with α *real* and *nonvanishing*, is *not S-integrable* unless λ is real,

$$\mathrm{Im}(\lambda)=0, \tag{3.1a}$$

and it is *not C-integrable* unless λ vanishes,

$$\lambda=0. \tag{3.1b}$$

□

Statement 3.2. The model equation (2.6) with α *real* and *nonvanishing* is *not integrable* unless it effectively linearizes, namely unless at least one of the two constants λ_1,λ_2 vanishes, entailing

$$\lambda_1\lambda_2=0. \tag{3.2}$$

□

Statement 3.3. The model equation (2.9a) and (2.9b) with α *real* and *nonvanishing* is *not integrable* unless it effectively linearizes, namely unless at least one of the two constants μ_1,μ_2 vanishes, entailing

$$\mu_1\mu_2=0. \tag{3.3}$$

□

Statement 3.4. The model equation (2.11a), (2.11b), and (2.11c) with α *real* and *nonvanishing* is *not integrable* unless it effectively linearizes, namely unless at least one of the following four conditions holds:

$$g_{01}(\tilde{k})=\nu_2=0, \tag{3.4a}$$

or

$$g_{-1,2}(\tilde{k})=\nu_1=0, \tag{3.4b}$$

or

$$g_{01}(\tilde{k})=g_{-1,2}(\tilde{k})=0, \tag{3.4c}$$

or

$$\nu_1=\nu_2=0. \tag{3.4d}$$

□

Statement 3.5. The LW–SW (''long wave–short wave'') model equation (2.13a) and (2.13b) with α *real* and nonvanishing, is *not S-integrable* unless $g_{01}(\tilde{k})$ is *imaginary* and $g_{-1,1}(\tilde{k})$ is *real*,

$$\mathrm{Re}[g_{0,1}(\tilde{k})]=0, \quad \mathrm{Im}[g_{-1,1}(\tilde{k})]=0, \tag{3.5a}$$

and it is *not C-integrable* unless it effectively linearizes,

$$g_{0,1}(\tilde{k})\, g_{-1,1}(\tilde{k}) = 0. \tag{3.5b}$$

Statement 3.6. The system of two coupled NLS equations (2.16a) and (2.16b), is *not S-integrable* unless: either (i) it is *C-integrable*, see below; or (ii) the two *real nonvanishing quantities* α_1, α_2 are equal,

$$\alpha_1 = \alpha_2, \tag{3.6a}$$

and moreover the four quantities λ_{11}, λ_{12}, λ_{21}, λ_{22} are all *real* and are (appropriately) *pairwise equal*, namely

$$\mathrm{Im}(\lambda_{jk}) = 0, \quad j,k = 1,2, \tag{3.6b}$$

$$\lambda_{11} = \lambda_{21}, \quad \lambda_{12} = \lambda_{22}; \tag{3.6c}$$

and this system, (2.16a) and (2.16b), is *not C-integrable* unless it linearizes, namely unless the ''diagonal coupling constants'' $\lambda_{11}, \lambda_{22}$ both vanish,

$$\lambda_{11} = \lambda_{22} = 0, \tag{3.6d}$$

and moreover at least one of the two ''off-diagonal coupling constants'' λ_{12}, λ_{21} also vanishes, namely

$$\lambda_{12} = 0, \tag{3.6e}$$

or

$$\lambda_{21} = 0. \tag{3.6f}$$

□

Before ending this section, let us add a few more words to provide an appropriate context for the six statements proffered above.

Statement 3.1 is, we submit, so firmly embedded in universally accepted lore not to require any elaboration.

Statement 3.2 points out that the nonlinear evolution equation (2.6a) and (2.6b) is generally not integrable. It only becomes integrable if it effectively linearizes, due to the vanishing of λ_1 or λ_2: in the former case, the NLS-type equation (2.6a) becomes indeed linear, and once this has been solved, (2.6b) can be integrated by a quadrature; in the latter case, (2.6b) entails that φ is ξ independent, $\varphi(\xi,\tau) = \varphi(\tau)$, and under this condition (2.6a) becomes essentially the *linear* Schrödinger equation, indeed the term in the right-hand side can then be gotten rid of by introducing the new dependent variable $\tilde{\psi}(\xi,\tau) = \exp[i\lambda_1 \int^{\tau} d\tau'\, \varphi(\tau')]\psi(\xi,\tau)$. Arguments to support this *Statement 3.2* are given in paper I.

Analogous considerations apply to *Statement 3.3*, except for the impossibility, in the case $\mu_2 = 0$ entailing [see (2.9b)] $\chi(\xi,\tau) = \chi(\tau)$, to eliminate altogether the term on the right-hand side of (2.9a) via an appropriate change of dependent variable [but the essentially linear character, in this case, of (2.9a) remains]. Arguments to support this *Statement 3.3* are also given in paper I.

As for *Statement 3.4*, it can be seen as a combination of the two *Statements, 3.2* and *3.3*, that precede it; hence the elaborations given above with respect to those two *Statements, 3.2* and *3.3*, apply as well, to a large extent, to this *Statement 3.4*.

On the other hand, *Statement 3.5* is rather analogous to *Statement 3.1*: the *S-integrability* (provided the relevant coupling constants satisfy appropriate reality conditions) of the LW–SW (long wave–short wave) evolution equation (2.13) is a well-known fact [we believe, but we cannot prove, this was first noted in Ref. 8; see also Ref. 3, where it is shown how this nonlinear evolution equation, (2.13), can be obtained from the *S-integrable, second-order*, Boussinesq equation via a multiscale reduction process altogether analogous to that of paper I]. The fact that

S-integrability evaporates if the coupling constants *fail* to satisfy the relevant reality conditions is, as in the case of the NLS equation, universally accepted lore. Likewise for the *C-integrability* properties, as detailed in *Statement 3.5*.

Finally, some comments on *Statement 3.6*. For the *S-integrability* part we refer, as we did in paper I, to Ref. 9; and for the *C-integrability* part, to the universally accepted notion that, for coupled NLS equations, as indeed for a single NLS equation, *C-integrability* only holds if the equations become essentially *linear* [of course in this case—namely, when (3.6d) holds, as well as either (3.6e) or (3.6f)—the condition (3.6a) is no more necessary].

IV. NECESSARY CONDITIONS OF INTEGRABILITY

In this section we finally attain the core of our paper, namely the presentation of *necessary conditions of integrability* for nonlinear evolution PDEs of type (1.1)–(1.3). The strategy to obtain such results, and their import, have been adequately elaborated in the preceding sections. Hence here we proceed directly to their formulation. The user-friendly character of our presentation is augmented below by a step-by-step guide to the utilization of these findings in order to test whether any given nonlinear evolution PDE, belonging to the class (1.1)–(1.3), might be *integrable*: equations that do *not* pass the test are then guaranteed *not* to be *integrable* (and, more specifically, *not S-integrable* or *not C-integrable*, as the case may be).

But first let us formulate, and justify, these *necessary conditions for integrability*.

Proposition 4.1. *A necessary condition* for the *S-integrability*, respectively, for the *C-integrability*, of a nonlinear evolution PDE of type (1.1)–(1.3) with $h \geqslant 1$ is that, for *all* real values of k such that (2.3) hold, the quantity $\lambda(k)$, see (2.4c), be *real*, see (3.1a), respectively, that it *vanish*, see (3.1b).

□

This *Proposition 4.1* (which is not new[2,3]) follows from *Lemma 2.1* and *Statement 3.1*. The requirement (3.1b) that $\lambda(k)$ vanish for *all* values k entails a very stringent *necessary condition* for *C-integrability* (see examples and corollaries in the following section). The necessary condition (3.1a) for *S-integrability* involves both quantities related to the *linear* and *nonlinear* parts of the original equation (1.1)–(1.3), but in many cases [as can be easily checked; see (2.4c)] it amounts to the requirements that (i) the quantity $g_{01}(k)$ be *real* [note that $g_{-1,1}(k)$ is always *real*, see (2.2c)], if $h=1$; (ii) the quantities $g_{-1,2}(k)$ and $g_{11}(k)$ be *both real* or *both imaginary*; (iii) the quantity $g_{-1,11}(k)$ be *real* if h is *odd*, *imaginary* if h is *even*. Given the arbitrariness of k, the first of these three conditions clearly entails [see (2.2a)] the vanishing of all the coefficients $c^{(2)}_{0n}$ with n odd; the second, either it entails the vanishing of $c^{(2)}_{01}$ and $c^{(2)}_{03}$ (already implied by the first condition), of $c^{(2)}_{12}$, of $c^{(2)}_{14}$ and $c^{(2)}_{23}$ (if one assumes that $c^{(2)}_{05}$ vanishes, as entailed by the first condition) and many other relations for the coefficients $c^{(2)}_{nm}$ with $n+m$ odd, or it entails the vanishing of $c^{(2)}_{00}$, $c^{(2)}_{02}$, $c^{(2)}_{11}$ and many other relations for the coefficients $c^{(2)}_{nm}$ with $n+m$ even (see the Appendix); the third condition, either it entails the vanishing of $c^{(3)}_{001}$ and many other relations for the coefficients $c^{(3)}_{nml}$ with $n+m+l$ odd, or it entails the vanishing of $c^{(3)}_{000}$ and many other relations for the coefficients $c^{(3)}_{nml}$ with $n+m+l$ even. These are very stringent, and quite explicit, conditions on the nonlinear part of (1.1)–(1.3).

Proposition 4.2. *A necessary condition of integrability* for nonlinear evolution PDEs of type (1.1)–(1.3) with $h=0$ is the requirement that, for *all* real values of k such that (2.5) hold, at least one of the two quantities $g_{01}(k)$, $g_{-1,1}(k)$ [see (2.2a) and (2.2c)] vanish [see (3.2) with (2.6c) and (2.6d)].

□

This *Proposition 4.2* follows from *Lemma 2.2* and *Statement 3.2*. It complements the preceding *Proposition 4.1*, since that applies if $h \geqslant 1$, while this *Proposition 4.2* applies if $h=0$. The requirement that $g_{01}(k)$ or $g_{-1,1}(k)$ vanish for *all* (real) values of k entails, via (2.2a) and (2.2c), quite explicit restrictions (only) on the nonlinear part of (1.1)–(1.3). This is made explicit by the following:

Corollary 4.2.1. A *necessary* condition for the *integrability* of a nonlinear evolution PDE of type (1.1)–(1.3) with $h=0$ is that either

$$c_{0,n}^{(2)}=0, \quad n=0,1,2,\ldots, \tag{4.1}$$

or

$$\sum_{j=0}^{n}(-1)^j c_{j,2n-j}^{(2)}=0, \quad n=0,1,2,\ldots, \tag{4.2a}$$

namely

$$c_{0,0}^{(2)}=0, \tag{4.2b}$$

$$c_{0,2}^{(2)}-c_{1,1}^{(2)}=0, \tag{4.2c}$$

$$c_{0,4}^{(2)}-c_{1,3}^{(2)}+c_{2,2}^{(2)}=0, \tag{4.2d}$$

and so on.

□

Clearly the condition (4.1) comes from the requirement that $g_{01}(k)$ vanish, see (2.2a), while (4.2a) comes from the requirement that $g_{-1,1}(k)$ vanish, see (2.2c). Since they concur in the requirement that $c_{0,0}^{(2)}$ vanish, see (4.1) and (4.2b), we obtain the following remarkably neat result:

Corollary 4.2.2. Every nonlinear evolution PDE of type (1.1)–(1.3) (with $h=0$) featuring in its nonlinear part (right-hand side) a term $c_{00}^{(2)}u^2$ is *not integrable*.

□

Let us emphasize the remarkable nature of this finding, that holds irrespective of the specific form of the linear part of the nonlinear (real) PDE (1.1) [provided it is dispersive, see (1.2)] and, even more strikingly, quite independently of the specifics of the nonlinear part [provided it has the form (1.3), with the single requirement that $c_{00}^{(2)}$ not vanish, $c_{00}^{(2)}\neq 0$].

Proposition 4.3. A *necessary condition* for the *integrability* of a nonlinear evolution PDE of type (1.1)–(1.3) with $h\geqslant 1$ is that, for all the real values $\tilde{k}$ (if any) of the parameter k such that (2.7) and (2.8b) hold, at least one of the two quantitities $g_{-1,2}(\tilde{k})$, $g_{11}(\tilde{k})$ [namely, the values that the functions $g_{-1,2}(k)$, $g_{11}(k)$, see (2.2d) and (2.2b), take at $k=\tilde{k}$] vanish:

$$g_{-1,2}(\tilde{k})\,g_{11}(\tilde{k})=0. \tag{4.3}$$

□

This *Proposition 4.3* follows from the first part of *Lemma 2.3* and *Statement 3.3*. Its applicability and potency is of course somewhat reduced relative to *Proposition 4.1* (also applicable for $h\geqslant 1$), due to the requirement to restrict consideration to only those (real) values $\tilde{k}$ of k (if any) which satisfy the *equality* (2.7) [as well as the *inequalities* (2.8b)]. Yet there clearly is a large class of nonlinear evolution PDEs to which this *Proposition 4.3* is applicable (see examples in Sec. V).

Proposition 4.4. A *necessary condition* for the *integrability* of a nonlinear evolution PDE of type (1.1)–(1.3) with $h=0$ is that, for all the real values $\tilde{k}$ (if any) of the parameter k such that (2.7) and (2.10b) hold, at least one of the following four equalities holds [see (2.2a), (2.2b), (2.2d), (2.2c)]:

$$g_{01}(\tilde{k})=g_{11}(\tilde{k})=0, \tag{4.4a}$$

or

$$g_{-1,2}(\tilde{k})=g_{-1,1}(\tilde{k})=0, \tag{4.4b}$$

or

$$g_{01}(\tilde{k})=g_{-1,2}(\tilde{k})=0, \tag{4.4c}$$

or

$$g_{-1,1}(\tilde{k})=g_{11}(\tilde{k})=0. \tag{4.4d}$$

□

This *Proposition 4.4* follows from the second part of *Lemma 2.3* and *Statement 3.4*. It complements the preceding *Proposition 4.3*, since that applies if $h\geqslant 1$, while this *Proposition 4.4* applies if $h=0$. In this case, as well as in the preceding one, the applicability and potency of this *Proposition 4.4* is somewhat reduced relative to *Proposition 4.2* (also applicable for $h=0$), due to the requirement to restrict consideration to only those (real) values $\tilde{k}$ of k (if any) which satisfy the equality (2.7) [as well as the *inequalities* (2.10b)]. Yet in this case as well there is a large class of nonlinear evolution PDEs to which this *Proposition 4.4* is applicable (see examples in the next section).

Proposition 4.5. A necessary condition for the *S-integrability*, respectively, the *C-integrability*, of a nonlinear evolution PDE of type (1.1)–(1.3) with $h=1$ is that, for all the real values $\tilde{k}$ (if any) of the parameter k such that (2.12a) and (2.12b) hold, the quantity $g_{01}(\tilde{k})$ be *imaginary* (or vanish),

$$\mathrm{Re}[g_{01}(\tilde{k})]=0, \tag{4.5a}$$

respectively, at least one of the two quantities $g_{01}(\tilde{k}),g_{-1,1}(\tilde{k})$ vanish,

$$g_{0,1}(\tilde{k})g_{-1,1}(\tilde{k})=0. \tag{4.5b}$$

Here of course $g_{01}(\tilde{k})$, $g_{-1,1}(\tilde{k})$ are the values that $g_{01}(k)$, $g_{-1,1}(k)$ [see (2.2a) and (2.2c)] take at $k=\tilde{k}$.

□

This *Proposition 4.5* follows from *Lemma 2.4* and *Statement 3.5* [note that $g_{-1,1}(\tilde{k})$, as given by (2.2c), is always *real*]. Of course if the nonlinear evolution PDE under consideration passes the test to be *C-integrable* [namely if (4.5b) holds], it automatically also passes the test to be *S-integrable* [even if (4.5a) were not to hold]. This *Proposition 4.5* is analogous to *Propositions 4.3* and *4.4*, and different from *Propositions 4.1* and *4.2*, inasmuch as it requires focussing on special values $\tilde{k}$ of k, identified by the *equality* (2.12a); hence analogous remarks to those made in this respect after *Propositions 4.3* and *4.4* are relevant here (but they will not be repeated).

Proposition 4.6. A necessary condition for the *S-integrability*, respectively, the *C-integrability*, of a nonlinear evolution PDE of type (1.1)–(1.3) with only *cubic*, or higher, nonlinearities [see (2.14)] is that, for all the *real* values $\tilde{k}$ (if any) of the parameter k such that *both equalities* (2.15a), as well as the *inequalities* (2.15b), hold, the conditions (3.6a), (3.6b), and (3.6c) with (2.16c) and (2.16d) be satisfied, respectively the conditions (3.6d) with (2.16d), and at least one of the conditions (3.6e), (3.6f) with (2.16d), be satisfied. Of course the value(s) $\tilde{k}$ of k in the definitions (2.16d) [with (2.2)] must be the same one(s) (if any) that satisfy (2.15a) and (2.15b).

□

This *Proposition 4.6* follows from *Lemma 2.5* and *Statement 3.6*; it holds for *all* (non-negative integer) values of h [see (1.1)]. The applicability of this *Proposition 4.6* is however severely restricted by the requirement that the parameter k satisfy *both equalities* (2.15a); hence this necessary condition of integrability is only applicable to a subclass of nonlinear evolution PDEs of type (1.1)–(1.3), whose linear part, see (1.2), must satisfy a restriction that negates its genericity.

Let us now outline how these findings can be used, providing thereby a friendly guide for customers who are confronted with some given nonlinear evolution PDE of type (1.1)–(1.3) (possibly of applicative origin) and who are interested to find out whether *it might be integrable*. The first step is to write the nonlinear evolution PDE in question in the form (1.1), fixing thereby the value of the non-negative integer h. As noted in the Introduction, it is generally advisable to settle for the largest value of h compatible with the nonlinear evolution PDE under consideration; a clear advantage of this approach is to simplify the set of (nonvanishing) coefficients $c^{(m)}_{j_1 j_2 \cdots j_m}$ that characterize the nonlinear part of the equation, see (1.3). However, the possibility to get additional information by also considering other (smaller) values $\tilde{h}$ of h (with correspondingly redefined coefficients $\tilde{c}^{(m)}_{j_1 j_2 \cdots j_m}$) cannot be altogether excluded.

If $h=0$, the first *necessary condition of integrability* to be tested is provided by *Propositions 4.2* (but see also its two *Corollaries 4.2.1* and *4.2.2*), which can be synthesized by the formula

$$g_{01}(k)\, g_{-1,1}(k) = 0, \tag{4.6}$$

with $g_{01}(k)$, $g_{-1,1}(k)$ defined by (2.2a) and (2.2c) and where k is an *arbitrary (real)* parameter [only restricted by the *inequalities* (2.5) with (2.1a) (2.1b)]. If this test is passed, the next *necessary condition of integrability* comes from *Proposition 4.4*, and it consists of the requirement that (4.4a) or (4.4b) be satisfied, for those real values $\tilde{k}$ of k (if any) for which the *equality* (2.7) [with (2.1c)], as well as the *inequalities* (2.10b) [with (2.1a), (2.1b), (2.1d)] hold. Note that, in spite of the fact that the previous test, (4.6), is required to hold for *all* (real) values of k, this second test associated with *Proposition 4.4*, apparently much less potent because it is required to hold for only a finite set of values $\tilde{k}$ of k, is nevertheless not altogether redundant: there indeed are nonlinear evolution equations which pass the first test but fail the second (see examples in Sec. V).

Finally, if the nonlinear evolution PDE (with $h=0$) under scrutinity has passed both these tests, the last resort is to apply *Proposition 4.6*, which is however only applicable if (2.14) holds. An example in the following section shows that this third test is not redundant, although its applicability and potency are clearly quite limited.

Let us now outline the analogous procedure to test a nonlinear evolution PDE of type (1.1)–(1.3) with $h \geqslant 1$ (rather than $h=0$). In this case the first *necessary condition of integrability* to be tested is provided by *Proposition 4.1*; the second is provided by *Proposition 4.3*; the third (applicable however only if $h=1$) is provided by *Proposition 4.5*; and the fourth by *Proposition 4.6* [applicable only if (2.14) holds]. Note that in this case, $h \geqslant 1$, the possibility is provided from the very beginning to test separately for *S-integrability* and for *C-integrability* (see *Propositions 4.1*, *4.5* and *4.6*).

Two final obvious remarks conclude this section.

Remark 4.1. Let us reemphasize that, as soon as any given nonlinear evolution PDE *fails* to comply with a *necessary condition for integrability*, it can be pronounced *nonintegrable* (or, more specifically, *not S-integrable*, respectively, *not C-integrable*, as the case may be).

□

This information is often quite useful, for instance to terminate the search for integrability techniques applicable to the nonlinear evolution PDE under scrutinity. Of course, if a given nonlinear evolution PDE does comply with a *necessary condition of integrability*, no information is, strictly speaking, gained; although the hunch that it indeed be *integrable* becomes sometimes justified (see examples in Sec. V).

Remark 4.2. All the *necessary conditions of integrability* obtained in this paper only entail the *quadratic* and *cubic* nonlinear terms; in fact *Propositions 4.2, 4.3, 4.4*, and *4.5* refer only to the *quadratic* terms; but their applicability extends to nonlinear evolution PDEs featuring much more general nonlinearities, see (1.1) with (1.3).

□

V. EXAMPLES

In this section we display various examples; some of the results written below in fact qualify as *Corollaries* of the *Propositions* of the preceding section, although we do not denote them as such.

Example 5.1. Consider the class of nonlinear evolution PDEs (1.1)–(1.3) with $h=0$ and with $F^{(2)}$ given by (1.4) (no limitation on $F^{(m)}$ with $m>2$). Then *Proposition 4.2* (or, more directly, *Corollaries 4.2.2* and *4.2.1*) yield the following *necessary conditions of S-integrability*:

$$c_{00}^{(2)}=0, \tag{5.1a}$$

and in addition at least one of the following two couples of equalities:

$$c_{01}^{(2)}=0,\ c_{02}^{(2)}=0, \tag{5.1b}$$

or

$$c_{22}^{(2)}=0,\ \ c_{02}^{(2)}=c_{11}^{(2)}\,. \tag{5.1c}$$

If moreover $M=2$ [see (1.2)] and the two coefficients a_3 and a_5 do not vanish and have different signs,

$$a_3\,a_5<0, \tag{5.2}$$

Proposition 4.4, together with *Proposition 4.2*, yield the following (of course more stringent) *necessary conditions of integrability*:

$$c_{00}^{(2)}=0,\quad c_{01}^{(2)}=0,\quad c_{02}^{(2)}=0,\quad c_{12}^{(2)}=0, \tag{5.3a}$$

and in addition at least one of the following three equalities:

$$c_{11}^{(2)}=0,\ \ c_{22}^{(2)}=0, \tag{5.3b}$$

or

$$5a_5c_{11}^{(2)}+a_3c_{22}^{(2)}=0, \tag{5.3c}$$

or

$$5a_5c_{11}^{(2)}-2a_3c_{22}^{(2)}=0; \tag{5.3d}$$

or, in alternative to (5.3a),

$$c_{00}^{(2)}=0,\quad c_{02}^{(2)}=0,\quad c_{11}^{(2)}=0,\quad c_{22}^{(2)}=0, \tag{5.4a}$$

and in addition at least one of the following three equalities:

$$c_{01}^{(2)}=0,\quad c_{12}^{(2)}=0, \tag{5.4b}$$

or

$$5a_5c_{01}^{(2)}-2a_3c_{12}^{(2)}=0, \tag{5.4c}$$

or

$$5a_5c_{01}^{(2)}+a_3c_{12}^{(2)}=0. \tag{5.4d}$$

□

The derivation of these results [via (A11)] is straightforward if tedious; they illustrate the explicit potency of (some of) the *necessary conditions of integrability* given in Sec. IV.

Example 5.2. Consider the class of nonlinear evolution PDEs (1.1)–(1.3) with $M=1$ [and of course $a_3 \neq 0$, see (1.2)], $h=1$, $F^{(2)}$ given by (1.4), and $F^{(3)}=0$ (no limitation on $F^{(m)}$ with $m>3$). Then *Proposition 4.1* entails the following *necessary conditions of S-integrability*:

$$c_{01}^{(2)}=0, \quad c_{12}^{(2)}=0, \tag{5.5a}$$

or

$$c_{01}^{(2)}=0, \quad c_{22}^{(2)}=0, \quad c_{02}^{(2)}=2c_{11}^{(2)}, \tag{5.5b}$$

or

$$c_{00}^{(2)}=0, \quad c_{12}^{(2)}=0, \quad c_{22}^{(2)}=0, \quad c_{11}^{(2)}=4c_{02}^{(2)}, \tag{5.5c}$$

or

$$c_{00}^{(2)}=0, \quad c_{02}^{(2)}=0, \quad c_{11}^{(2)}=0, \quad c_{22}^{(2)}=0, \tag{5.5d}$$

as well as the following (of course more stringent) *necessary conditions of C-integrability*:

$$c_{00}^{(2)}=0, \quad c_{01}^{(2)}=0, \quad c_{12}^{(2)}=0, \tag{5.6a}$$

and in addition

$$c_{02}^{(2)}=0, \quad c_{11}^{(2)}=0, \tag{5.6b}$$

or

$$c_{22}^{(2)}=0, \quad 3[c_{02}^{(2)}]^2+3c_{02}^{(2)}c_{11}^{(2)}-4[c_{11}^{(2)}]^2=0. \tag{5.6c}$$

□

The derivation of these results via (A11) is again both straightforward and tedious: note that they only involve, in a quite simple and explicit manner, the coefficients $c_{j_1 j_2}^{(2)}$ of the *quadratic* term (1.4). This is a consequence of the, quite simple, assumed nature ($M=1$!) of the linear operator D, see (1.2). For this same reason the results of no *Proposition* of Sec. IV (other than *Proposition 4.1*) are applicable to this class of nonlinear evolution PDE.

Example 5.3. Consider the class of nonlinear evolution PDEs (1.1)–(1.3) with $h \geqslant 1$, $F^{(2)}=0, F^{(3)}$ given by (1.5) (no limitation on $F^{(m)}$ with $m>3$). Then *Proposition 4.1* yields the following *necessary conditions of S-integrability*: if h is *even*,

$$c_{000}^{(3)}=0, \quad c_{011}^{(3)}=3c_{002}^{(3)}, \quad c_{112}^{(3)}=3c_{022}^{(3)}; \tag{5.7a}$$

if h is *odd*,

$$c_{001}^{(3)}=0, \quad c_{012}^{(3)}=3c_{111}^{(3)}, \quad c_{122}^{(3)}=0. \tag{5.7b}$$

Likewise, the *necessary conditions of C-integrability* yielded by *Proposition 4.1* require the simultaneous validity of (5.7a) and (5.7b) (irrespective of the parity of h).

□

These results follow straightforwardly from (2.4c) via (A12). Let us again emphasize the simple and explicit nature of these conditions, (5.7a) and (5.7b), as well as their independence from the *linear part* of (1.1)–(1.3), see (1.2) (the assumption $M \geqslant 1$, with $a_{2M+1} \neq 0$, is of course essential). Note that the well-known *S-integrable* modified KdV equation (characterized by M

$=1, h=1, c^{(3)}_{000}\neq 0$ and all other coefficients $c^{m}_{j_1 j_2 \ldots j_m}$ vanishing) passes the test of *S-integrability* [see (5.7b)], but not that of *C-integrability* [see (5.7a)]; while the *C-integrable* nonlinear PDE[10]

$$u_t - u_{xxx} = 3u^2 u_{xx} + 9u u_x^2 + 3u^4 u_x, \tag{5.7c}$$

with $c^{(3)}_{002}=3, c^{(3)}_{011}=9$ and all other coefficients $c^{(3)}_{j_1 j_2 j_3}$ vanishing, does indeed pass the *C-integrability* test, namely it complies with *both* (5.7a) and (5.7b).

ACKNOWLEDGMENTS

One of us (J.X.) would like to acknowledge partial financial support by the Chinese Natural Sciences Fund, and to thank the University of Rome ''La Sapienza'' and INFN for supporting a two month visit to Rome in 1999. Two of us (F.C. and A.D.) would like to thank ICTP in Trieste for travel support in connection to one visit made by each of us to the USTC in Hefei, PRC, as well as our colleagues at the Mathematics Department there for their kind hospitality.

APPENDIX

In this Appendix we discuss some points whose detailed treatment in the body of the paper would have been too distracting.

Let us first detail the implication of the condition that, for *all* real values of k, $g_{-1,2}(k)$ and $g_{11}(k)$ be (i) both real or (ii) both immaginary. In case (i) we get from (2.2d) and (2.2b) the conditions

$$\sum_{j=0}^{n} (-1)^j (2^{2n+1-j} - 2^j)\, c^{(2)}_{j,\,2n+1-j} = 0, \tag{A1a}$$

$$\sum_{j=0}^{n} c^{(2)}_{j,\,2n+1-j} = 0, \tag{A1b}$$

which are required to hold for all non-negative integer values of n. Hence by setting $n=0,1,2,\ldots$, we get

$$c^{(2)}_{0,1} = 0, \tag{A2a}$$

$$7c^{(2)}_{0,3} - 2c^{(2)}_{1,2} = c^{(2)}_{0,3} + c^{(2)}_{1,2} = 0, \tag{A2b}$$

$$31c^{(2)}_{0,5} - 14c^{(2)}_{1,4} + 4c^{(2)}_{2,3} = c^{(2)}_{0,5} + c^{(2)}_{1,4} + c^{(2)}_{2,3} = 0, \tag{A2c}$$

and so on. Clearly (A2b) entails

$$c^{(2)}_{0,3} = c^{(2)}_{1,2} = 0, \tag{A3}$$

and (A2c) entails

$$c^{(2)}_{1,4} = \tfrac{3}{2} c^{(2)}_{0,5}, \quad c^{(2)}_{2,3} = -\tfrac{5}{2} c^{(2)}_{0,5}. \tag{A4}$$

In case (ii) (2.2d) and (2.2b) yield the conditions

$$\sum_{j=0}^{n} (-1)^j (2^{2n-j} + 2^j) c^{(2)}_{j,2n-j} = 0, \tag{A5a}$$

$$\sum_{j=0}^{n} c^{(2)}_{j,2n-j}=0, \tag{A5b}$$

which are again required to hold for all non-negative integer values of n. Hence by setting $n=0,1,2,\ldots$, we get

$$c^{(2)}_{00}=0, \tag{A6a}$$

$$5c^{(2)}_{02}-4c^{(2)}_{11}=c^{(2)}_{02}+c^{(2)}_{11}=0, \tag{A6b}$$

$$17c^{(2)}_{04}-10c^{(2)}_{13}+8c^{(2)}_{22}=c^{(2)}_{04}+c^{(2)}_{13}+c^{(2)}_{22}=0, \tag{A6c}$$

and so on. Clearly (A6b) entail $c^{(2)}_{02}=c^{(2)}_{11}=0$.

Next let us detail the implication of the condition that $g_{-1,1,1}(k)$ be, for all (real) values of k, either *real* or *imaginary*. The first condition entails [see (2.2e)] the relations

$$\sum_{j=0}^{[(4n+2)/3]} \sum_{j'=\mathrm{Max}[0,2j-2n-1]}^{[j/2]} [(-1)^{j'}-(-1)^{j}+(-1)^{j+j'}]\, c^{(3)}_{j',j-j',2n+1-j}=0, \tag{A7}$$

which are again required to hold for all non-negative integer values of n. Hence

$$c^{(3)}_{001}=0, \tag{A8a}$$

$$c^{(3)}_{003}+c^{(3)}_{012}-3c^{(3)}_{111}=0, \tag{A8b}$$

and so on. Likewise the second condition entails [see (2.2e)]

$$\sum_{j=0}^{[4n/3]} \sum_{j'=0}^{[j/2]} [(-1)^{j'}+(-1)^{j}+(-1)^{j+j'}]\, c^{(3)}_{j',j-j',2n-j}=0, \tag{A9}$$

again for all non-negative integer values of n. Hence

$$c^{(3)}_{000}=0, \tag{A10a}$$

$$3c^{(3)}_{002}-c^{(3)}_{011}=0, \tag{A10b}$$

and so on.

We end this Appendix by displaying the explicit form taken by the four quantities $g_{01}(k)$, $g_{11}(k)$, $g_{-1,1}(k)$, $g_{-1,2}(k)$ if $c^{(2)}_{j_1j_2}$ vanishes for $j_2>2$, namely if $F^{(2)}$ has the form (1.4):

$$g_{01}(k)=2c^{(2)}_{00}-k^2c^{(2)}_{02}+ikc^{(2)}_{01}, \tag{A11a}$$

$$g_{11}(k)=c^{(2)}_{00}-k^2(c^{(2)}_{02}+c^{(2)}_{11})+k^4c^{(2)}_{22}+ik(c^{(2)}_{01}-k^2c^{(2)}_{12}), \tag{A11b}$$

$$g_{-1,1}(k)=2[c^{(2)}_{00}-k^2(c^{(2)}_{02}-c^{(2)}_{11})+k^4c^{(2)}_{22}], \tag{A11c}$$

$$g_{-1,2}(k)=2c^{(2)}_{00}-k^2(5c^{(2)}_{02}-4c^{(2)}_{11})+8k^4c^{(2)}_{22}+ik(c^{(2)}_{01}+2k^2c^{(2)}_{12}); \tag{A11d}$$

and the explicit form taken by the quantity $g_{-n,n,n}(k)$ if $c^{(3)}_{j_1j_2j_3}$ vanishes for $j_3>2$, namely if $F^{(3)}$ has the form (1.5):

$$\begin{aligned} g_{-n,n,n}(k)=&\,3c^{(3)}_{000}-(nk)^2(3c^{(3)}_{002}-c^{(3)}_{011})+(nk)^4(3c^{(3)}_{022}-c^{(3)}_{112}) \\ &+ink[c^{(3)}_{001}-(nk)^2(c^{(3)}_{012}-3c^{(3)}_{111})+(nk)^4c^{(3)}_{122}]. \end{aligned} \tag{A12}$$

RTT relations, a modified braid equation and noncommutative planes

A. Chakrabarti[a)]
Centre de Physique Théorique,[b)] Ecole Polytechnique, 91128 Palaiseau Cedex, France

(Received 27 September 2000; accepted for publication 20 February 2001)

With the known group relations for the elements (a,b,c,d) of a quantum matrix T as input a general solution of the RTT relations is sought without imposing the Yang–Baxter (YB) constraint for R or the braid equation for $\hat{R}=PR$. For three biparametric deformatios, $\mathrm{GL}_{(p,q)}(2)$, $\mathrm{GL}_{(g,h)}(2)$, and $\mathrm{GL}_{(q,h)}(1/1)$, the standard, the nonstandard, and the hybrid one, respectively, R or $\hat{R}$ is found to depend, apart from the two parameters defining the deformation in question, on an extra free parameter K, such that $\hat{R}_{(12)}\hat{R}_{(23)}\hat{R}_{(12)}-\hat{R}_{(23)}\hat{R}_{(12)}\hat{R}_{(23)}=[(K/K_1)-1][(K/K_2)-1](\hat{R}_{(23)}-\hat{R}_{(12)})$ with $(K_1,K_2)=(1,p/q),(1,1)$, and $(1,1/q)$, respectively. Only for $K=K_1$ or $K=K_2$ one has the braid equation. Arbitray K corresponds to a class (conserving the group relations independent of K) of the MQYBE or modified quantum YB equations studied by Gerstenhaber, Giaquinto, and Schack. Various properties of the triparametric $\hat{R}(K;p,q)$, $\hat{R}(K;g,h)$, and $\hat{R}(K;q,h)$ are studied. In the larger space of the modified braid equation (MBE) even $\hat{R}(K;p,q)$ can satisfy $\hat{R}^2=1$ outside the braid equation (BE) subspace. A generalized, K-dependent, Hecke condition is satisfied by each three-parameter $\hat{R}$. The role of K in noncommutative geometries of the $(K;p,q)$, $(K;g,h)$, and $(K;q,h)$ deformed planes is studied. K is found to introduce a ''soft symmetry breaking,'' preserving most interesting properties and leading to new interesting ones. Further aspects to be explored are indicated. © *2001 American Institute of Physics.*

I. INTRODUCTION

Our starting point will be the group relations of the elements of the quantum matrix

$$T=\begin{pmatrix} a & b \\ c & d \end{pmatrix}. \tag{1.1}$$

Three known cases will be considered.

(1) The biparametric (p,q) or standard deformation of GL(2).
(2) The biparametric (g,h) or nonstandard deformation of Gl(2).
(3) The (q,h) or ''hybrid'' deformation of GL(1/1).

Each set will be presented explicitly below. These three have been studied in Ref. 1 where many original sources can be found. We start directly with the biparametric cases since the one-parameter deformations can then be systematically obtained through suitable constraints ($p=q^{-1}, g=h$ and so on).

[a)]Electronic mail: chakra@cpht.polytechnique.fr
[b)]Laboratoire Propre du CNRS UPR A.0014.

For the given group relations we construct for each case the matrix R satisfying

$$RT_1T_2=T_2T_1R, \tag{1.2}$$

where

$$T_1=T\otimes I_2, \quad T_2=I_2\otimes T.$$

To start with, we do not require R to satisfy the Yang–Baxter (YB) equation. It will be found that, apart from the parameters concerned $[(p,q),\ (g,h)$ or $(q,h)]$ the solution for R satisfying (2) contains a supplementary arbitrary parameter K. Two particular values of K (say K_1 and K_2) will give the two solutions of YB related through

$$((21)R(K_1))^{-1}=R(K_2) \tag{1.3}$$

both satisfying

$$R_{12}R_{13}R_{23}-R_{23}R_{13}R_{12}=0.$$

The existence of such a pair of solutions is assured by the fact that (1.2) can be written as

$$T_1T_2R^{-1}=R^{-1}T_2T_1.$$

The germ of our paper is in the question: what structure is obtained when K is not restricted to the values K_1 and K_2.

For arbitrary K the situation is best expressed in terms of

$$\hat{R}=PR,$$

where P is the permutation matrix and for our 4×4 case it permutes the second and third rows.

One obtains, for the normalizations we will choose,

$$\hat{R}_{(12)}\hat{R}_{(23)}\hat{R}_{(12)}-\hat{R}_{(23)}\hat{R}_{(12)}\hat{R}_{(23)}=\left(\frac{K}{K_1}-1\right)\left(\frac{K}{K_2}-1\right)(\hat{R}_{(23)}-\hat{R}_{(12)}). \tag{1.4}$$

This is our modified braid equation (MBE). (See Discussion for further comments.)

In terms of R one obtains

$$R_{12}R_{13}R_{23}-R_{23}R_{13}R_{12}=\left(\frac{K}{K_1}-1\right)\left(\frac{K}{K_2}-1\right)((123)R_{(12)}-(213)R_{(23)}), \tag{1.5}$$

where (123) and (213) denote corresponding permutations of the tensor factors of $V^{\otimes}3$ (R acting on $V\otimes V$). [Having pointed out the structure (1.5) we will use throughout (1.4) as our fundamental relation.]

Thus (1.2) by itself is seen to lead to a particular class of solutions of the ''modified quantum Yang–Baxter equations'' (MQYBE) introduced by Gerstenhaber *et al.*[2] Our (1.4) has the same structure as Eq. (2.4) of Ref. 3 for ''quantum transpositions'' $(\sigma_{12},\sigma_{23})$ defined by the authors, though we do not impose in general their ''unitarity'' leading to

$$\hat{R}^2=I.$$

An example of a solution of (1.2) with an arbitrary K can be found in Ref. 1.

We present below some particularly interesting explicit examples. Their properties will reveal that the existence of such a class of more general solutions of MBE is more than an accident and can play a significant role in various domains, such as noncommutative geometry.

II. EXPLICIT SOLUTIONS

A. Standard (p,q) deformation of GL(2)

The elements (a,b,c,d) of T satisfy

$$\begin{gathered} ab=qba, \quad pac=ca, \\ ad=da+(q-p)bc, \quad pqbc=cb, \\ pbd=db, \quad cd=qdc. \end{gathered} \tag{2.1}$$

Apart from a possible normalizing factor, the solution of (1.2) turns out to be (writing directly $\hat{R}=PR$ and assuming p to be nonzero)

$$\hat{R}(K;p,q)=\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & (1-K) & \dfrac{K}{p} & 0 \\ 0 & Kq & \left(1-\dfrac{Kq}{p}\right) & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}. \tag{2.2}$$

This is found to satisfy

$$\hat{R}_{(12)}\hat{R}_{(23)}\hat{R}_{(12)}-\hat{R}_{(23)}\hat{R}_{(12)}\hat{R}_{(23)}=(K-1)\left(\frac{Kq}{p}-1\right)(\hat{R}_{(23)}-\hat{R}_{(12)}) \tag{2.3}$$

with

$$K_1=1, \quad K_2=\frac{p}{q}.$$

B. Nonstandard (g,h) deformation of GL(2)

The group relations are

$$\begin{gathered} ca=ac-gc^2, \quad cb=bc-gdc-hac+ghc^2, \\ cd=dc-hc^2, \quad da=ad-gdc+hac, \\ db=bd+g(ad-bc+hac-d^2), \\ ba=ab-h(ad-bc+hac-a^2). \end{gathered} \tag{2.4}$$

From (1.2) one obtains

$$\hat{R}(K;g,h)=\begin{pmatrix} 1 & -hK & hK & ghK \\ 0 & (1-K) & K & gK \\ 0 & K & (1-K) & -gK \\ 0 & 0 & 0 & 1 \end{pmatrix}. \tag{2.5}$$

This is found to satisfy

$$\hat{R}_{(12)}\hat{R}_{(23)}\hat{R}_{(12)}-\hat{R}_{(23)}\hat{R}_{(12)}\hat{R}_{(23)}=(K-1)^2(\hat{R}_{(23)}-\hat{R}_{(12)}) \tag{2.6}$$

with, independently of (g,h),

$$K_1=K_2=1.$$

C. Hybrid (q,h) deformation of G(1/1)

The group relations are

$$\begin{gathered} ba=ab+hcd, \quad ac=qca, \quad bc=qcb, \\ dc+qcd=0, \quad ad-da+(1-q)cb=0, \\ bd+db=hca, \quad ha^2=hd^2+(q+1)b^2, \quad c^2=0. \end{gathered} \tag{2.7}$$

One obtains from (1.2)

$$\hat{R}(K;q,h)=\begin{pmatrix} 1 & 0 & O & Kh \\ 0 & (1-K) & Kq & 0 \\ 0 & K & (1-Kq) & 0 \\ 0 & 0 & 0 & (1-K(q+1)) \end{pmatrix}. \tag{2.8}$$

This satisfies

$$\hat{R}_{(12)}\hat{R}_{(23)}\hat{R}_{(12)}-\hat{R}_{(23)}\hat{R}_{(12)}\hat{R}_{(23)}=(K-1)(Kq-1)(\hat{R}_{(23)}-\hat{R}_{(12)}). \tag{2.9}$$

Here $K_1=1, K_2=q^{-1}$, both being independent of h.

III. PROPERTIES

A. K and triangularity

The matrix R is called ''triangular'' if

$$(21)R=R^{-1}$$

when

$$\hat{R}^2=(PR)^2=I.$$

In Ref. 2 the term ''unitary'' is used in this context. For an R matrix satisfying the Yang–Baxter constraint, the following features are well known.

(1) For standard [q or (p,q)] deformations the R satisfying YB is ''quasitriangular'' and

$$\hat{R}^2\neq I.$$

(2) For nonstandard [h or (g,h)] deformations for R satisfying YB one has ''triangularity'' or

$$\hat{R}^2=I.$$

(It is in this sense that we use the term triangular, without R being necessarily strictly upper or lower triangular.)

In the presence of an arbitrary K the modified braid equation (MBE) breaks this dichotomy. Specifically in the preceding three cases one has the following situation:

$$(21)R(K;p,q)=(R(K';p,q))^{-1}, \tag{3.1}$$

where

$$K'=K(K(1+qp^{-1})-1)^{-1},$$
$$(21)R(K;g,h)=(R(K';g,h))^{-1}, \tag{3.2}$$

where

$$K'=K(2K-1)^{-1},$$
$$(21)R(K;q,h)=(R(K';q,h))^{-1}, \tag{3.3}$$

where

$$K'=K(K(1+q)-1)^{-1}.$$

Thus in each case one obtains

$$K'=K\left(\frac{K}{K_1}+\frac{K}{K_2}-1\right)^{-1}. \tag{3.4}$$

In general none is triangular (or unitary). On the other hand, in each case one can have triangularity by choosing

$$K'=K$$

or

$$K=2K_1K_2(K_1+K_2)^{-1}. \tag{3.5}$$

For the three previous cases this gives, respectively,

$$K=2p(p+q)^{-1}, \quad 1, \quad 2(1+q)^{-1}. \tag{3.6}$$

Thus for the nonstandard case triangularity coincides with the YB property. In contrast, for the other two cases triangularity implies a nonzero right-hand side in (1.4). In particular for the (p,q) case one obtains (permuting the second and the third rows of $\hat{R}$) for

$$K=2p(p+q)^{-1},$$
$$R=\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & \frac{2pq}{p+q} & \frac{p-q}{p+q} & 0 \\ 0 & \frac{q-p}{p+q} & \frac{2}{p+q} & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}. \tag{3.7}$$

Now one has

$$R(K;p,q)=((21)M)^{-1}M,$$

where one can set, choosing an upper triangular form,

$$M=\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & (2pq/p+q)^{1/2} & \dfrac{p-q}{(2pq(p+q))^{1/2}} & 0 \\ 0 & 0 & (p+q/2pq)^{1/2} & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}. \tag{3.8}$$

R is invariant under

$$M\rightarrow VM,$$

where

$$(21)V=V.$$

B. Projectors

For each case $((K;p,q),(K;g,h),(K;q,h))$ one obtains, I being the 4×4 unit matrix,

$$\hat{R}^2=X\hat{R}+(1-X)I, \quad X=2-\left(\frac{K}{K_1}+\frac{K}{K_2}\right). \tag{3.9}$$

Thus for the three cases $((p,q),(g,h),(q,h))$ one has, respectively,

$$X=2-K(1+qp^{-1}), \quad X=2(1-K), \quad X=2-K(1+q). \tag{3.10}$$

Two special cases are

$$X=0, \quad (\hat{R})^2=I$$

and

$$X=2, \quad (\hat{R}-I)^2=0.$$

For $X\neq 2$ one obtains for each deformation considered two projectors $(P^2=P)$ as follows:

$$P_1=\frac{(\hat{R}-I)}{(X-2)}, \tag{3.11}$$

$$P_2=\frac{(\hat{R}-(X-1)I)}{(2-X)}. \tag{3.12}$$

Finally one has

$$\hat{R}=(X-1)P_1+P_2 \tag{3.13}$$

with

$$P_1+P_2=I, \quad P_1P_2=0.$$

Note that one obtains a canonical formalism valid for all the deformations considered.

It follows from the preceding results that if C is a column vector (with 4 rows) a constraint (n being a constant)

$$C=n\hat{R}C$$

is only consistent for

$$n=1 \quad (P_1C=0,\ C=P_2C)$$

or

$$n=(X-1)^{-1} \quad (P_2C=0,\ C=P_1C).$$

This fact should be kept in mind for what follows.

IV. *K* AND NONCOMMUTATIVE PLANES

Detailed study of noncommutativity implemented via $\hat{R}$ in the plane and higher dimensional spaces can be found in Refs. 4, 5, and 6 where numerous sources are cited. Here we limit our considerations to the two dimensional plane. But we let our $\hat{R}$ be more general by letting it depend on an extra arbitrary parameter K permitted by our MBE. Our $\hat{R}$ will depend on three parameters. The biparametric nonstandard deformation with differential calculus was first presented (for $K=1, g=h, h=h'$) in Ref. 7. The original formalism is due to Wess and Zumino.[8]

We use the following notations:

$$x^i=(x^1,x^2)=(x,y),$$

$$dx^i=\xi^i=(\xi^1,\xi^2)=(\xi,\eta),$$

$$(\alpha,\beta)=(p,q),(g,h),(q,h).$$

We postulate

$$x^ix^j=(\hat{R}(K;\alpha,\beta))^{ij}_{i'j'}x^{i'}x^{j'}, \tag{4.1}$$

i.e.,

$$(P_1)^{(ij)}_{i'j'}x^{i'}x^{j'}=0,$$

$$\xi^i\xi^j=-\frac{1}{(1-X)}(\hat{R}(K;\alpha,\beta))^{(ij)}_{i',j'}\xi^{i'}\xi^{j'}, \tag{4.2}$$

i.e.,

$$(P_2)^{(ij)}_{i',j'}\xi^{i'}\xi^{j'}=0,$$

$$x^i\xi^j=\frac{1}{(1-X)}(\hat{R}(K;\alpha,\beta))^{(ij)}_{i',j'}\xi^{i'}x^{j'}, \tag{4.3}$$

where

$$(1-X)=\left(\frac{K}{K_1}+\frac{K}{K_2}-1\right).$$

The bilinear constraints (4.1), (4.2), (4.3), related through derivations, are required to satisfy suitable consistency relations. (See, for example, Sec. 4 of Ref. 4 and Ref. 7.) Following the usual procedure the required consistency for our case can be shown to be assured precisely by our generalized Hecke condition, namely,

$$(\hat{R}(K;\alpha,\beta)-I)\left(\frac{\hat{R}(K;\alpha,\beta)}{(1-X)}+I\right)=0 \tag{4.4}$$

or

$$P_1P_2=0.$$

This generalizes some well-known results. Thus, for example, setting

$$p=q^{-1},\quad K_1=1,\quad K=K_2=q^{-2}$$

and changing the normalization of R by a factor q one obtains the result (4.4.15) of Ref. 4. One obtains analogous generalizations for the other cases. Note that the consistency is obtained for our case by by implementing K nontrivially through the factor $(1-X)$ for the (ξ,η) constraints. But once this is done the final consequences of (4.1) and (4.2) turn out to be systematically independent of K. [Those of (4.3) do involve K but, as will be shown below, in a particularly simple fashion.] We recapitulate for completeness the first two sets of results which are the same as one would obtain with $K=(K_1,K_2)$.

One obtains for $(\alpha,\beta)=(p,q)$

$$pxy=yx, \tag{4.5}$$

$$\xi^2=0,\quad \eta^2=0,\quad \eta\xi+q\xi\eta=0. \tag{4.6}$$

For $(\alpha,\beta)=(g,h)$

$$xy-yx=gy^2, \tag{4.7}$$

$$\xi^2=h\xi\eta,\quad \eta^2=0,\quad \eta\xi+\xi\eta=0. \tag{4.8}$$

The results above are for GL(2). For GL(1/1), namely for

$$(\alpha,\beta)=(q,h)$$

one obtains

$$xy=qyx,\quad y^2=0, \tag{4.9}$$

$$(1+q)\xi^2+h\eta^2=0,\quad \eta\xi+\xi\eta=0. \tag{4.10}$$

For the deformed GL(1/1) y becomes fermionic. [After exhibiting as above how the three cases can be treated uniformly in our formalism, in what follows we will consider only the deformations $(K;p,q)$ and $(K;g,h)$ of GL(2). Those for GL(1/1) can easily be added.]

In contrast to the foregoing results, the consequences of (4.3) involve K nontrivially. For $\hat{R}(K;p,q)$ one obtains

$$x\xi=\frac{1}{(1-X)}\xi x,\quad x\eta=\frac{1}{(1-X)}\left(\xi y+\frac{K}{p}\Phi_1\right),$$

$$y\xi=\frac{1}{(1-X)}\left(\eta x-\frac{Kq}{p}\Phi_1\right),\quad y\eta=\frac{1}{(1-X)}\eta y \tag{4.11}$$

with

$$\Phi_1=(\eta x-p\xi y). \tag{4.12}$$

For $p=q^{-1}$, $K=q^{-2}$ and again suitably choosing the normalization of $\hat{R}$ these results reduce to (4.1.8) of Ref. 4. In order to compare with κ of (4.1.10) of Ref. 4 one can show by reordering terms

$$\Phi_1^2=\frac{1}{(1-X)}(-qp+Kqp+p^2-Kqp+pq-p^2)(\xi\eta xy)=0. \tag{4.13}$$

Note that K reappears on reordering but the coefficient of K in the numerator vanishes separately. Thus, apart from the overall factor, K appears as a factor of the nilpotent Φ_1. Moreover one can show that

$$\begin{gathered} px\Phi_1=\frac{1}{(1-X)}K\Phi_1 x, \quad y\Phi_1=\frac{1}{(1-X)}Kq\Phi_1 y, \\ \frac{1}{(1-X)}(p+q-Kq)\xi\Phi_1=-\Phi_1\xi, \quad \frac{1}{(1-X)}(p+q-Kq)\eta\Phi_1=-pq\Phi_1\eta. \end{gathered} \tag{4.14}$$

For the prescriptions indicated before ($K=q^{-2}$ and so on) one finds back the corresponding results of Sec. 4.1.13 and Sec. 4.1.17 of Ref. 4.

For $\hat{R}(K;g,h)$ one obtains [compare (3.1.6) of Ref. 5 where $K=1$ and $g=h$]

$$\begin{gathered} x\xi=\frac{1}{(1-X)}(\xi x+Kh\Phi_2), \quad x\eta=\frac{1}{(1-X)}(\xi y+K\Phi_2), \\ y\xi=\frac{1}{(1-X)}(\eta x-K\Phi_2), \quad y\eta=\frac{1}{(1-X)}\eta y \end{gathered} \tag{4.15}$$

with

$$\Phi_2=(\eta x-\xi y+g\eta y) \tag{4.16}$$

and

$$\Phi_2^2=0. \tag{4.17}$$

Moreover,

$$\begin{gathered} x\Phi_2=\frac{1}{(1-X)}(K\Phi_2 x+K(g-h)\Phi_2 y), \quad y\Phi_2=\frac{1}{(1-X)}Kq\Phi_2 y, \\ \frac{1}{(1-X)}(2-K)\xi\Phi_2=-(\Phi_2\xi+(h-g)\Phi_2\eta), \quad \frac{1}{(1-X)}(2-K)\eta\Phi_2=-\Phi_2\eta. \end{gathered} \tag{4.18}$$

The results for the (g,h) case can of course be obtained independently. But they are obtained more efficiently and with a deeper understanding by starting from the corresponding ones for (p,q) and using the ''contraction'' studied in the following section. It is instructive to see, in particular, how the $(g-h)$ factors in the results above arise (end of the next section). These terms are present even for the YB subspace ($K=1$) unless $g=h$. Finally, for $K=1$ and $g=h$ one obtains the simple results of Sec. 4.1.17 of Ref. 4.

V. $((K;p,q)\rightarrow(K;g,h))$: SINGULAR LIMIT OF A TRANSFORMATION

In Sec. 4 of Ref. 1 such a passage was presented for the case where $R(p,q)$ and $R(g,h)$ both satisfied YBE. Here we generalize it to include an arbitrary K. In fact the same transformation will

work again, leading to a well defined $R(K;g,h)$. We want to emphasize this fact. It underlines again the ''soft symmetry breaking'' role of K. Moreover we will display here how the corresponding features of the two noncommutative plains are related systematically through this ''contraction''procedure. The $(K;g,h)$-deformed plane emerges in full detail from the $(K;p,q)$ deformed one. Some previous sources are cited in Ref. 1, which in turn lead to some original ones.

Setting

$$G=\begin{pmatrix} 1 & \omega \\ 0 & 1 \end{pmatrix} \tag{5.1}$$

and with $R=P\hat{R}$ one obtains

$$(G^{-1}\otimes G^{-1})R(K;p,q)(G\otimes G)=\begin{pmatrix} 1 & -K(q-1)\omega & \frac{K}{p}(q-1)\omega & -\frac{K}{p}(p-1)(q-1)\omega^2 \\ 0 & Kq & \left(1-K\frac{q}{p}\right) & K\frac{q}{p}(p-1)\omega \\ 0 & (1-K) & \frac{K}{p} & \frac{K}{p}(p-1)\omega \\ 0 & 0 & 0 & 1 \end{pmatrix}. \tag{5.2}$$

Now, as in Ref. 1, let $p\to 1, q\to 1$ in such a way that $(p-1)(q-1)^{-1}$ remains constant. And ω_0 being a constant, define

$$\omega=\omega_0((p-1)(q-1))^{-1/2}.$$

Now one can define finite constants (g,h) such that as $p\to 1$ and $q\to 1$

$$((1-p)\omega)\to g, \quad ((q-1)\omega)\to h. \tag{5.3}$$

Now from (2.5) and (5.2) (with $R=P\hat{R}$), one obtains

$$(G^{-1}\otimes G^{-1})R(K;p,q)(G\otimes G)\to R(K;g,h). \tag{5.4}$$

The same procedure works for (a,b,c,d), (x,y), and (ξ,η). In this section, to distinguish the cases (p,q) and (g,h), we will use for the latter the notations

$$(\tilde{a},\tilde{b},\tilde{c},\tilde{d});(\tilde{x},\tilde{y});(\tilde{\xi},\tilde{\eta}).$$

Consistently with transformation of R one defines (with the previous definitions of G and T)

$$G^{-1}TG=\begin{pmatrix} \tilde{a} & \tilde{b} \\ \tilde{c} & \tilde{d} \end{pmatrix}, \quad G^{-1}\begin{pmatrix} x \\ y \end{pmatrix}=\begin{pmatrix} \tilde{x} \\ \tilde{y} \end{pmatrix}, \quad G^{-1}\begin{pmatrix} \xi \\ \eta \end{pmatrix}=\begin{pmatrix} \tilde{\xi} \\ \tilde{\eta} \end{pmatrix}.$$

Let us now consider some examples to appreciate how the technique works. From the preceding definitions one obtains

$$\tilde{a}=a-\omega c, \quad \tilde{b}=(b-\omega d)+\omega(a-\omega c), \quad \tilde{c}=c, \quad \tilde{d}=d+\omega c. \tag{5.5}$$

The inverse relations are easily obtained. Using them and the group relations for (a,b,c,d) one obtains

$$\tilde{c}\tilde{a}=c(a-\omega c)=pac-\omega c^2=p(\tilde{a}+\omega\tilde{c})\tilde{c}-\omega\tilde{c}^2=p\tilde{a}\tilde{c}-(1-p)\omega\tilde{c}^2.$$

Using the definition of g now one obtains, in the limit,

$$\tilde{c}\tilde{a}=\tilde{a}\tilde{c}-g\tilde{c}^2. \tag{5.6}$$

Again,

$$\begin{aligned}\tilde{c}\tilde{b}&=c(\omega a+b-\omega^2 c-\omega d)\\&=pqbc-\omega qdc+p\omega ac-\omega^2c^2\\&=pq\tilde{b}\tilde{c}+q(p-1)\omega\tilde{d}\tilde{c}-p(q-1)\omega\tilde{a}\tilde{c}+(1-p)(q-1)\omega^2\tilde{c}^2\end{aligned}$$

giving in the limit

$$\tilde{c}\tilde{b}=\tilde{b}\tilde{c}-g\tilde{d}\tilde{c}-h\tilde{a}\tilde{c}+gh\tilde{c}^2. \tag{5.7}$$

We have thus obtained the first two group relations (with tildes added to avoid confusion) for the nonstandard case (2.4). The others can be obtained analogously. Let us now look at the $(K;g,h)$-deformed plane. One obtains from the definitions introduced

$$\tilde{x}=x-\omega y,\quad \tilde{y}=y. \tag{5.8}$$

Hence, using the constraints for (x,y),

$$\tilde{x}\tilde{y}-\tilde{y}\tilde{x}=(x-\omega y)y-y(x-\omega y)=xy-yx=(1-p)xy=(1-p)(\tilde{x}\tilde{y}+\omega\tilde{y}^2).$$

Now taking limit and using the definition of g,

$$\tilde{x}\tilde{y}-\tilde{y}\tilde{x}=g\tilde{y}^2. \tag{5.9}$$

This is the nonstandard version (with tildes added).

Similarly starting with

$$\tilde{\xi}=\xi-\omega\eta,\quad \tilde{\eta}=\eta \tag{5.10}$$

and using

$$\xi^2=0,\quad \eta^2=0,\quad (\xi\eta+q\eta\xi)=0$$

one obtains in the limit the expected results

$$\tilde{\xi}^2=h\tilde{\xi}\tilde{\eta},\quad \tilde{\eta}^2=0,\quad (\tilde{\xi}\tilde{\eta}+\tilde{\eta}\tilde{\xi})=0.$$

These simple cases have been presented to give a feeling for the limiting process at work. But they have further usefulness. For the important nilpotent operators of the preceding section one easily obtains, taking our limits,

$$\Phi_1=(\eta x-p\xi y)\rightarrow(\tilde{\eta}\tilde{x}-\tilde{\xi}\tilde{y}+g\tilde{\eta}\tilde{y})=\Phi_2.$$

Hence avoiding a lengthy reordering process one obtains directly from

$$\Phi_1^2=0,$$

$$(\Phi_1^2)\rightarrow\Phi_2^2=0.$$

The commutators of Φ_2 can again be derived simply from those of Φ_1. The terms involving $(g-h)$ in the latter set can be seen to emerge as follows:

$$(p^{-1}-q)\omega=(p^{-1}(1-p)\omega-(q-1)\omega)\rightarrow(g-h),$$

$$(pq-1)\omega=(p(q-1)\omega-(1-p)\omega)\rightarrow(h-g).$$

VI. DISCUSSION

The following points are worth noting.

(1) If $\hat{R}(K;\alpha,\beta)$ depend linearly on K and satisfy the braid equation for $K=(K_1,K_2)$, then the right-hand side of (1.4) becomes almost evident as follows. One can set

$$\hat{R}_{(12)}\hat{R}_{(23)}\hat{R}_{(12)}-\hat{R}_{(23)}\hat{R}_{(12)}\hat{R}_{(23)}=\left(\frac{K}{K_1}-1\right)\left(\frac{K}{K_2}-1\right)Z. \tag{6.1}$$

The first two factors on the right-hand side assure the braid property for $K=(K_1,K_2)$. Next one notes the following points.

The left-hand side is trilinear in K. Hence Z, coming after the first two factors, should be linear in K.

The left-hand side is antisymmetric under the exchange

$$\hat{R}_{(12)}\leftrightarrow\hat{R}_{(23)}.$$

Hence Z should have the same property. Thus the evident ansatz is

$$Z=(\hat{R}_{(23)}-\hat{R}_{(12)}). \tag{6.2}$$

This is indeed found to be correct. A possible K-independent constant factor can be normalized to unity, as we have done.

(The following two properties have been pointed out to the author by Daniel Arnaudon.)

(2) For the (p,q) and the (q,h) cases one can write

$$\hat{R}(K;\alpha,\beta)=c_1\hat{R}(K_1;\alpha,\beta)+c_2\hat{R}(K_2;\alpha,\beta), \tag{6.3}$$

where

$$c_1+c_2=1, \quad c_1K_1+c_2K_2=K.$$

However, for the (g,h) case (since $K_1=K_2=1$) such a relation does not hold for $K\neq 1$.

(3) For

$$\hat{R}_{(12)}\hat{R}_{(23)}\hat{R}_{(12)}-\hat{R}_{(23)}\hat{R}_{(12)}\hat{R}_{(23)}=\lambda(\hat{R}_{(23)}-\hat{R}_{(12)}) \tag{6.4}$$

and

$$\hat{R}^2=X\hat{R}+(1-X)I \tag{6.5}$$

(λ and X not being necessarily restricted to the values considered previously) defining

$$\hat{S}=(\hat{R}-\mu I) \tag{6.6}$$

one can verify that

$$\hat{S}_{(12)}\hat{S}_{(23)}\hat{S}_{(12)}-\hat{S}_{(23)}\hat{S}_{(12)}\hat{S}_{(23)}=(\lambda+X\mu-\mu^2)(\hat{S}_{(23)}-\hat{S}_{(12)}). \tag{6.7}$$

This generalizes an analogous result of Ref. 2 since we do not restrict R to be ''unitary.'' One can choose μ so that $\hat{S}$ satisfies the braid equation. Directly connected with the last two equations is the following canonical relation valid for all the cases considered before,

$$\hat{R}(K;\alpha,\beta)=\left(\frac{K}{K_i}\right)\hat{R}(K_i;\alpha,\beta)-\left(\frac{K}{K_i}-1\right)I. \tag{6.8}$$

Here K_i denotes either one of the ''braid'' (or YB) values of K. This is of basic importance. The parameter $K/(K_i-K)$ can be shown to provide the prescription for Baxterization. In fact, (6.8) can be recognized to correspond to the usual ansatz for Baxterization.[9]

(4) The works of Gerstenhaber, Giaquinto, and Schak[2,3] assure that our MBE encodes deformations satisfying basic criteria but removing certain restrictive features of the standard (BE) (or (YB)). For our class the factor λ on the right-hand side in (6.4) is neither zero nor entirely arbitrary. It has the specific form given by (1.4) arising out of our basic condition: K-independence of the group relations. Our parametrization of of this factor carries information. The YB or the braid solutions are obtained effortlessly as byproducts. This leads also to agreeable properties designated here as ''soft symmetry breaking'' role of K in the noncommutative geometries studied. For all K (and all the cases studied) one obtains the crucial, canonical Hecke condition we have emphasized. It permits us to introduce consistently and uniformly the noncommutativity constraints. Let us recapitulate the remarkable consequences.

(a) The bilinear constraints for the coordinates and those for the differentials remain independent of K.

(b) In the constraints involving both coordinates and differentials K does appear, but in a ''minimal'' fashion. Apart from a simple overall factor, in the linear combinations on the right-hand side, K appears as a factor of a nilpotent combination (Φ_1 or Φ_2). Along with the commutation relations satisfied by these nilpotents, this has the consequence that reordering any higher order product one obtains, apart from an overall factor, finally linearity in K. The operator Φ, crucial for constructing covariant derivatives,[4] remains nilpotent for arbitrary K [see (4.13)]. The main point is that conserving the (x,y) and the (ξ,η) commutators and without violating the constraints imposed by the postulated actions of exterior derivations one can implement the parameter K in the mixed commutators [(x,ξ), etc.], even there conserving good properties.

(c) The ''contraction'' procedure leading from standard (p,q) to nonstandard (g,h) deformations is not perturbed by K. Even the titles of previous papers[10,11] give an idea of the scope of this approach. It is reassuring to note that one can continue to implement it in presence of K.

Having noted some interesting features of the results obtained let us now look at further developments they suggest. One naturally thinks of the following aspects.

(1) Extension of our results to higher dimensional MBE. First by going beyond the 4×4 cases for deformations of GL(2). Second by starting from group relations for deformed SL(N) and SO(N). Higher dimensional cases have already been studied in Refs. 2 and 3. Our aim would be to obtain explicit structures correponding to conserved group relations for such cases. Then one can see if our soft symmetry breaking still gets implemented and in what fashion.

(2) For $K=(K_1,K_2)$ the R matrix flips the tensor components of co-products. Having obtained more general modified R matrices it would be important to examine the consequences for co-products as K moves away from the YB values.

(3) A more complete study of the role of K in noncommutative geometries induced by three-parameter deformations $(K;\alpha,\beta)$. Even for the two-plane we have stopped at a certain point leaving much to be done. After constructing higher dimensional matrices $\hat{R}(K;\alpha,\beta)$ one can implement them in higher dimensional spaces.

(4) Study of twists in the context of ''modified'' R matrices. In particular, the fact that one can implement triangularity for all types of deformations by suitably choosing K suggests intriguing possibilities. Various aspects studied in Refs. 12, 13, and 14 can be re-examined in this broader context.

(5) Our MBE (or MYBQE of Gerstenhaber *et al.*) and Baxterization can be seen to be [see (6.8)] two facets of the same underlying construction, namely the general solution of the RTT relations. In the first case the parameter K is kept fixed in each term and the right-hand side of the braid equation is allowed to be nonzero. In the second one, the right-hand side is held fixed at zero and to permit this the parameter is suitably varied from term to term. The two procedures are complementary.

(6) What are the consequences for knot invariants associated to an $\hat{R}$ as K moves away from the ''braid values''? Can a conceptually consistent generalization (parametrized third Reidemeister move) be implemented fruitfully?

Presumably this list is not exhaustive. Some of these objectives should be directly accessible. Elsewhere one may encounter obstructions. We hope to explore different directions in future studies.

This work owes much to sustained and reassuring help from Daniel Arnaudon. It goes beyond results explicitly attributed to him. Our treatment of noncommutative planes took shape from succesive discussions with John Madore.

Department of Mathematics, Ritsumeikan University, Kusatsu, Shiga 525–8577, Japan

(Received 2 January 2001; accepted for publication 8 February 2001)

We give some results about the essential self-adjointness of the Dirac operator $H=\Sigma_{j=1}^{n}\alpha_j p_j+m(x)\,\alpha_{n+1}+V(x)\,I_N$ $(N=2^{[(n+1)/2]})$, on $[C_0^\infty(\mathbf{R}^n\backslash\{0\})]^N$, where the α_j $(j=1,2,\ldots,n)$ are Dirac matrices and $m(x)$ and $V(x)$ are real-valued functions. We are mainly interested in a singularity of $V(x)$ and $m(x)$ near the origin which preserves the essential self-adjointness of H. As a result, if $m=m(r)$ is spherically symmetric or $m(x)\equiv V(x)$, then we can permit a singularity of m and V which is stronger than that of the Coulomb potential. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1367331]

I. INTRODUCTION

In this article we consider the essential self-adjointness of the Dirac operator

$$H:=\sum_{j=1}^{n}\alpha_j p_j+m(x)\,\alpha_{n+1}+V(x)\,I_N$$

$$\left(x\in\mathbf{R}^n,\quad n\geqslant 2,\quad p_j=-i\frac{\partial}{\partial x_j},\quad N=N(n):=2^{[(n+1)/2]}\right)$$

in the Hilbert space $\mathbf{H}:=L^2(\mathbf{R}^n)^N$. Here I_N is the $N\times N$ unit matrix, and the α_j are $N\times N$ Dirac matrices, i.e., Hermitian matrices satisfying

$$\alpha_j\,\alpha_k+\alpha_k\,\alpha_j=2\,\delta_{jk}\,I_N\quad(j,k=1,2,\ldots,n+1);\tag{1}$$

$m(x)$ and $V(x)$ are real-valued functions.

In contrast to the Schrödinger case, the essential self-adjointness of H cannot be destroyed by the behavior of m and V at infinity (Ref. 1), but only by local singularities of these functions. For example, if m is constant and $V(r)=e/r$, H is essentially self-adjoint if and only if $|e|\leqslant\sqrt{3}/2$. Extending a seminal paper by Schmincke,[2] very general self-adjointness criteria were given by, e.g., Levitan and Otelbaev,[3] Arai,[4] Yamada,[5] Vogelsang[6] and Kalf[7] for the situation that m is a constant and V is a strongly singular potential that is not necessarily spherically symmetric.

The principal interest of Dirac operators with a variable mass term lies in the fact that they can have a purely discrete spectrum. That was why they were proposed in the 1960s as simple quark models. Brief historical remarks can be found in Vasconcelos[8] and Eich, Rein, and Rodenberg.[9] Vasconcelos[8] explicitly solves the bound-state problem $V(r)=e/r$, $m(r)=e'/r$; other specific cases were treated by Critchfield and Rein (see the references in Ref. 9).

In the article in hand we present three self-adjointness criteria for Dirac operators with a variable mass term, concentrating on the case that m and V have a singularity at the origin. We generalize the results given in Ref. 10 and show the complete proofs, which are not given in

[a)]Dedicated to Professor Joachim Weidmann on the occasion of his sixtieth birthday.

Ref. 10. Theorem 1 assumes that m is spherically symmetric and involves a pointwise bound on $V(x)$ and $m(r)$, $m'(r)$ which admits, in the presence of m, a singularity of V that is stronger than the Coulomb singularity. Theorem 1 reduces to Schmincke's result when $m=0$. In Theorem 2 an integral condition is imposed on V and m, neither of which necessarily rotationally symmetric. When $m=0$, this theorem reduces to the criterion of Levitan and Otelbaev.[3] Our last theorem concerns the special situation that $m\equiv V$. In this case it turns out that the condition which is necessary to define the canonical minimal operator is already sufficient to establish its essential self-adjointness. Since $(I_N\pm\alpha_{n+1})/2$ is a projection operator, it is possible to bring in the Laplace operator and use Kato's inequality.

In this article we employ the following abbreviations:

$$\alpha:=(\alpha_1,\alpha_2,\ldots,\alpha_n),\quad p:=(p_1,p_2,\ldots,p_n),\quad \alpha\cdot p:=\sum_{j=1}^{n}\alpha_j p_j,$$

$$\Omega:=\mathbf{R}^n\backslash\{0\},\quad \mathbf{R}_+:=(0,+\infty),\quad \mathbf{D}:=C_0^\infty(\Omega)^N.$$

Theorem 1: *Let $m=m(r)$ be spherically symmetric and absolutely continuous in $\mathbf{R}_+$ with the derivative $m'(r)\in L^2_{\mathrm{loc}}(\mathbf{R}_+)$. Assume that $\alpha\cdot p+m\,\alpha_{n+1}$ on $\mathbf{D}$ is essentially self-adjoint, and $V(x)\in L^2_{\mathrm{loc}}(\Omega)$ satisfies*

$$(1+\varepsilon)^2\left[V^2(x)+\frac{1}{4\,r^2}\right]+\left|m'(r)+\frac{m(r)}{r}\right|\leqslant m^2(r)+\left(\frac{n-1}{2r}\right)^2\quad(x\in\Omega)\tag{2}$$

for some $\varepsilon>0$. Then H is essentially self-adjoint. If $n\geqslant 3$ and $r\,m(r)$ is bounded, then the domain $D(\overline{H})$ of the closure $\overline{H}$ coincides with the Sobolev space $W^{1,2}(\mathbf{R}^n)^N$.

The next result does not require m to be spherically symmetric and extends a theorem of Levitan and Otelbaev.[3]

Theorem 2: *Let $n\geqslant 3$ and $m,V\in L^2_{\mathrm{loc}}(\Omega)$ be real-valued,*

$$q(r):=\sup_{|x|=r}\left[V^2(x)+m^2(x)+2\,|m(x)|\,\sqrt{V^2(x)+\frac{1}{4\,r^2}}\right]^{1/2}$$

and

$$a:=\sup_{r>0}\left(\frac{1}{r^{n-2}}\int_0^r t^{n-1}q^2(t)\,dt\right)^{1/2}<\sqrt{\frac{n}{2}}.\tag{3}$$

Then H is essentially self-adjoint with $D(\overline{H})=W^{1,2}(\mathbf{R}^n)^N$.

The Dirac operator is in general not essentially self-adjoint on $C_0^\infty(\mathbf{R}^n)^N$ if m, V are merely in $L^2_{\mathrm{loc}}(\mathbf{R}^n)$. By dint of a theorem of Kato[11] we do, however, have the following result.

Theorem 3: *Assume that $m(x)$ and $V(x)$ are $L^2_{\mathrm{loc}}(\mathbf{R}^n)$ functions satisfying $m(x)\equiv V(x)$ or $m(x)\equiv -V(x)$. Then $H=(\alpha\cdot p)+m\,\alpha_{n+1}+V$ on $C_0^\infty(\mathbf{R}^n)^N$ is essentially self-adjoint.*

II. PRELIMINARIES AND PROOF OF THEOREM 1

The existence of Dirac matrices satisfying (1) is well known. In the Appendix we sketch an inductive method of constructing Dirac matrices such that

$$\alpha_j:=\begin{pmatrix}\mathbf{0} & a_j\\ a_j^* & \mathbf{0}\end{pmatrix}\quad(j=1,2,\ldots,n),\quad \alpha_{n+1}:=\begin{pmatrix}I_{N/2} & \mathbf{0}\\ \mathbf{0} & -I_{N/2}\end{pmatrix},\tag{4}$$

where the a_j are $N/2\times N/2$ matrices (which are Hermitian if n is odd) with the property

$$a_j a_k^* + a_k a_j^* = 2\delta_{jk} I_{N/2}, \quad a_j^* a_k + a_k^* a_j = 2\delta_{jk} I_{N/2} \ \ (j,k=1,2,\ldots,n). \tag{5}$$

If $\{\alpha_1,\alpha_2,\ldots,\alpha_{n+1}\}$ and $\{\alpha_1',\alpha_2',\ldots,\alpha_{n+1}'\}$ are two sets of Dirac matrices, then there is a unitary matrix U such that $\alpha_j' = U\alpha_j U^{-1}$ $(j=1,2,\ldots,n+1)$ or $\alpha_j' = U[-\alpha_j]U^{-1}$ $(j=1,2,\ldots,n+1)$, and, if n is odd, we always have the former case (see, e.g., Ref. 12, p. 267). If n is even and $\alpha_j' = U[-\alpha_j]U^{-1}$ $(j=1,2,\ldots,n+1)$, we have

$$\begin{aligned} H' &:= \sum_{j=1}^{n} \alpha_j' p_j + m(x)\alpha_{n+1}' + V(x) I_N \\ &= (U\alpha_1\alpha_2\cdots\alpha_n)\left[\sum_{j=1}^{n} \alpha_j p_j - m(x)\alpha_{n+1} + V(x) I_N\right](U\alpha_1\alpha_2\cdots\alpha_n)^{-1}. \end{aligned}$$

Therefore, H' is unitarily equivalent to H or to

$$\sum_{j=1}^{n} \alpha_j p_j - m(x)\alpha_{n+1} + V(x) I_N .$$

It should be remarked that the condition (2) remains invariant under replacing $m(x)$ by $-m(x)$.

In order to explain the separation of variables of Dirac operators the spin-orbit coupling operator,

$$S := \frac{n-1}{2} - \sum_{1\leqslant j<k\leqslant n} i\alpha_j\alpha_k(x_j p_k - x_k p_j),$$

is needed, with the help of which we have

$$\alpha\cdot p = \alpha_r\left(p_r + \frac{i}{r}S\right),$$

where the α_j are given in (4) with (5) and

$$\alpha_r := \sum_{j=1}^{n} \frac{x_j}{r}\alpha_j, \quad p_r := -ir^{(1-n)/2}\frac{\partial}{\partial r}r^{(n-1)/2} = -i\left(\frac{\partial}{\partial r} + \frac{n-1}{2r}\right).$$

It is well known that the self-adjoint extension of S in $L^2(S^{n-1})^N$ has only discrete eigenvalues k with finite multiplicity such that

$$k \in -\left(\mathbf{N}_0 + \frac{n-1}{2}\right) \cup \left(\mathbf{N}_0 + \frac{n-1}{2}\right), \tag{6}$$

where $\mathbf{N}_0 := \{0,1,2,\cdots\}$ (see, e.g., Ref. 13, p. 161). Let

$$U := \begin{pmatrix} I_{N/2} & \mathbf{0} \\ \mathbf{0} & -ia_r^* \end{pmatrix}, \quad a_r := \sum_{j=1}^{n} \frac{x_j}{r} a_j ,$$

where

$$\alpha_j := \begin{pmatrix} \mathbf{0} & a_j \\ a_j^* & \mathbf{0} \end{pmatrix} \quad (j=1,2,\ldots,n), \quad \alpha_{n+1} := \begin{pmatrix} I_{N/2} & \mathbf{0} \\ \mathbf{0} & -I_{N/2} \end{pmatrix}.$$

Then U is a unitary matrix which commutes with α_{n+1} and satisfies

$$U^{-1}\alpha_r U=\begin{pmatrix} \mathbf{0} & -iI_{N/2} \\ iI_{N/2} & \mathbf{0} \end{pmatrix}.$$

Thus, if $V=V(r)$ and $m=m(r)$ are spherically symmetric, the Dirac operator on the eigenspace of S with respect to the eigenvalue k is unitarily equivalent to

$$\begin{pmatrix} \mathbf{0} & -I_{N/2} \\ I_{N/2} & \mathbf{0} \end{pmatrix}\frac{d}{dr}+\begin{pmatrix} [m(r)+V(r)]I_{N/2} & (-k/r)I_{N/2} \\ (-k/r)I_{N/2} & [-m(r)+V(r)]I_{N/2} \end{pmatrix}$$

in $L^2(\mathbf{R}_+)^N$. Therefore, the question if such Dirac operators are essentially self-adjoint reduces to the problem whether every one-dimensional Dirac operator in $L^2(\mathbf{R}_+)^2$,

$$L_k:=\begin{pmatrix} m(r)+V(r) & -(d/dr)+(k/r) \\ (d/dr)+(k/r) & -m(r)+V(r) \end{pmatrix},$$

is of limit point type at the origin for every k satisfying (6) (see, e.g., Ref. 14, Theorem 5.4).

We remark that, if $V(r)\equiv 0$, then any L_k is of limit point type at 0 for a relatively large class of $m(r)$. For example, the following proposition can be shown by Arnold, Kalf, and Schneider in Ref. 15, where more general theorems are given.

Proposition 2.1: Let $m=m(r)$ be a real-valued function and belong to $L^1_{\mathrm{loc}}(\mathbf{R}_+)$. Then the one-dimensional Dirac operator L_k with *$V=0$ is of limit point type at* 0, *if $m(r)$ satisfies one of the following conditions:*

(i) $\lim_{r\to 0} r\, m(r)$ *exists and is finite, or*
(ii) $\lim_{r\to 0} r\,|m(r)|=\infty$, *and* $\operatorname{sgn} m$ *is constant near the origin.*

The proof of Theorems 1 and 2 will rest upon the following well-known abstract result about the closure and bounded invertibility of the sum of two operators (for a proof see, e.g., Ref. 16, pp. 190 and 196).

Proposition 2.2: Let A, B be closable linear operators in a Hilbert space **H** *with $D(A)\subset D(B)$. Suppose that the closure $\overline{A}$ has a bounded inverse defined on* **H** *and that for some $\varepsilon>0$*

$$(1+\varepsilon)\|Bu\|\leqslant\|Au\| \quad [u\in D(A)].$$

Then $A+B$ is closable and $\overline{A+B}=\overline{A}+\overline{B}$ with domain $D(\overline{A})$. Moreover, $\overline{A+B}$ has a bounded inverse on **H**.

Let $W^{1,2}_{\mathrm{loc}}(\Omega)$ be the Sobolev space of all functions $u\in L^2_{\mathrm{loc}}(\Omega)$ with generalized first-order derivatives in $L^2_{\mathrm{loc}}(\Omega)$, and D_1 be the space of $u\in W^{1,2}_{\mathrm{loc}}(\Omega)^N$ with compact support in Ω. Note that $C_0^\infty(\Omega)^N\subset D_1$. If $g\in L^2_{\mathrm{loc}}(\Omega)$ has first-order derivatives in $L^2_{\mathrm{loc}}(\Omega)$, then we consider a multiplication operator

$$u\mapsto g\,u$$

for $u\in D_1$. It should be noted that $g\,v\in D_1$ for $v\in D_1$. The subsequent operator calculations will be valid on the domain D_1.

Lemma 2.3: Let s be a real number, $m(r)$ a real-valued function which is absolutely continuous in $\mathbf{R}_+$ with $m'\in L^2_{\mathrm{loc}}(\mathbf{R}_+)$ and

$$A_1:=\alpha\cdot p+m(r)\alpha_{n+1}+\frac{i}{2r}\alpha_r+is.$$

Then we have

$$A_1^* A_1 \geqslant m^2(r) + \left(\frac{n-1}{2r}\right)^2 - \left| m'(r) + \frac{m(r)}{r} \right|.$$

Proof: Since S anticommutes with α_r, a direct calculation gives us

$$A_1^* A_1 = p_r^2 + \frac{(n-1)(n-3)}{4r^2} + \frac{1}{r^2}\left[S^2 - \left(\frac{n-1}{2}\right)^2 \right] + \frac{2n-3}{4r^2} + s^2 + \frac{s}{r}\alpha_r + m^2 - i\alpha_r \alpha_{n+1}\left(m' + \frac{m}{r} \right)$$

$$\geqslant p_r^2 + \frac{(n-1)(n-3)}{4r^2} + \frac{1}{r^2}\left[S^2 - \left(\frac{n-1}{2}\right)^2 \right] + \frac{2n-3}{4r^2} + s^2 - \frac{|s|}{r} + m^2 - \left| m' + \frac{m}{r} \right|,$$

where the inequality stems from the observation that α_r and $i\alpha_r\alpha_{n+1}$ are Hermitian matrices with square I_N. The assertion now follows from the Hardy-type inequality

$$p_r^2 \geqslant \frac{1}{4r^2} + \frac{d}{r} - d^2 \quad (d \geqslant 0)$$

[see, e.g., Ref. 4, (3.15)] and

$$S^2 \geqslant \left(\frac{n-1}{2}\right)^2$$

[see (6)].

Proof of Theorem 1: Let

$$A_t := \alpha \cdot p + m(r)\alpha_{n+1} + \frac{it}{2r}\alpha_r + is \quad (0 \leqslant t \leqslant 1),$$

where $s = 1$ or -1 and

$$B := V(x) - \frac{i}{2r}\alpha_r .$$

Lemma 2.3 and assumption (2) imply

$$A_1^* A_1 \geqslant (1+\varepsilon)^2 \left(V^2 + \frac{1}{4r^2} \right) = (1+\varepsilon)^2 B^* B, \tag{7}$$

so that the range of $H \pm i = A_1 + B$ is dense in $\mathbf{H}$, once we know that $\overline{A_1}$ has a bounded inverse which is defined on the whole Hilbert space $\mathbf{H}$. For $0 \leqslant t \leqslant 1$ we conclude from (7)

$$\|A_t u\| = \left\| \left(A_1 - (1-t)\frac{i}{2r}\alpha_r \right) u \right\| \geqslant (\varepsilon + t) \left\| \frac{i}{2r}\alpha_r u \right\| \quad (u \in \mathbf{D}). \tag{8}$$

Since $\overline{A_0}^{-1}$ is bounded on $\mathbf{H}$ owing to our hypothesis, the same applies to the inverse of the closure of $A_0 + (it/2r)\alpha_r = A_t$ for $t < \varepsilon =: t_1$ by (8) and Propositon 2.2, and we are finished if $t_1 > 1$. Otherwise, this information, jointly with (8), shows that $\overline{A_t}^{-1}$ is bounded on $\mathbf{H}$ for $t < t_1 + \varepsilon + t_1 =: t_2$. For some $l \in \mathbf{N}$ we eventually arrive at some number $t_l = (2^l - 1)\varepsilon > 1$.

Finally we prove $D(\overline{H}) = W^{1,2}(\mathbf{R})^N$ if $rm(r)$ is bounded and $n \geqslant 3$. The inequality (7) implies that $D(\overline{H}) = D(\overline{A_1})$ is contained in $D(1/r)$. Let $u \in D(\overline{H})$. Since $V(x) = O(1/r)$ by means of (2), we conclude $(\alpha \cdot p)u \in \mathbf{H}$, which gives $u \in W^{1,2}(\mathbf{R})^N$. On the other hand, if we write $H_0 = \alpha \cdot p$ on $\mathbf{D}$, the inclusion

$$D(\overline{H_0}) = W^{1,2}(\mathbf{R}^n)^N \subset D(1/r)$$

is clear from Hardy's inequality

$$p^2 \geqslant \left(\frac{n-2}{2}\right)^2 \frac{1}{r^2}. \tag{9}$$

□

Remark: In Theorem 1 we can adopt a stronger singularity of m and V at the origin than the one of Coulomb potentials. For example, H is essentially self-adjoint if we assume

$$m(r) = \frac{C_1}{r^\mu}, \quad |V(x)| \leqslant \frac{C_2}{r^\mu}, \quad C_1 > C_2 > 0 \tag{10}$$

and $\mu > 1$, Indeed, if we set

$$\tilde{m} = \frac{C_1}{r^\mu} + C$$

for $C > 0$, then V and $\tilde{m}$ satisfy condition (2) if $\varepsilon > 0$ is sufficiently small and $C > 0$ is sufficiently large. Thus the essential self-adjointness is valid for $\alpha \cdot P + m\,\beta + VI_4 + C\,\beta$, and, therefore, for $\alpha \cdot D + m\,\beta + VI_4$.

In the special case $m(r) = C_1/r^\mu$ and $V(r) = C_2/r^\mu$ $(C_1 > C_2 > 0, \mu > 1)$ it follows from Theorem 3 in Ref. 15 that the equation $L_k v = 0$ has, for any $k \in \mathbf{Z}\backslash\{0\}$, a fundamental system of solutions $v_\pm$ with

$$|v_\pm(r)| = \exp\{[\pm\sqrt{C_1^2 - C_2^2}/(\mu-1) + o(1)]\, r^{1-\mu}\} \quad \text{as} \quad r \to 0.$$

This singularity of m therefore has the same effect on the solutions as an anomalous magnetic moment (Ref. 17).

If $\mu = 1$ in (9), then the condition (2) is satisfied provided $C_2^2 < C_1^2 + \frac{3}{4}$. This result corresponds to the case $b_1 = 0$ and $s = \frac{1}{2}$ in Theorem 3.1 by Arai.[4] In this case the essential self-adjointness still holds when $C_2^2 = C_1^2 + (\frac{3}{4})$, if we ignore the domain property of the closure (Ref. 5).

In the plane, $H = \sigma_1 P_1 + \sigma_2 P_2 + m\,\sigma_3 + VI_2$ with $m(r) = C_1/r$ and $V(r) = C_2/r$ is essentially self-adjoint if and only if $|C_2| \leqslant |C_1|$. Indeed, L_k $[k \in \mathbf{Z} + \frac{1}{2}$ if $n = 2]$ is of limit point type at 0 if and only if $C_2^2 - C_1^2 \leqslant k^2 - \frac{1}{4}$.

III. PROOF OF THEOREM 2

The proof is given along the line of Ref. 7.

Lemma 3.1: Let $q(r):(0,\infty) \to \mathbf{R}$ *satisfy*

$$\frac{1}{r^{n-2}} \int_0^r t^{n-1} q^2(t)\, dt \leqslant a^2$$

for some $a > 0$. *Then*

$$p_r^2 + \frac{(n-1)(n-3)}{4r^2} \geqslant \frac{n-2}{4a^2} q^2 + \frac{d}{r} - d^2$$

for any $d \geqslant 0$.

Proof: The Lemma is an n-dimensional version of (Ref. 7, Lemma 2). Let $b \geqslant 0$, $0 \leqslant c \leqslant (n-1)/2$ and

$$g(r):=\frac{b}{r^{n-1}}\int_0^r t^{n-1}q^2(t)dt-\frac{c}{r}+d.$$

Then we have

$$p_r^2+\frac{(n-1)(n-3)}{4r^2}\geqslant g'(r)-g^2+\frac{(n-1)(n-3)}{4r^2}\geqslant \phi(c)\frac{1}{r^2}-d^2+(c-a^2b)\frac{2d}{r}+bq^2,$$

where

$$\phi(c):=c(1-c+2a^2b)+\tfrac{1}{4}(n-1)(n-3)-(n-1)a^2b-a^4b^2.$$

This function has its maximum at $c=a^2b+\frac{1}{2}$, so that

$$\geqslant\left[\left(\frac{n-2}{2}\right)^2-(n-2)a^2b\right]\frac{1}{r^2}-d^2+\frac{d}{r}+bq^2.$$

Choose

$$b=\frac{n-2}{4a^2},\quad c=\frac{n}{4}\leqslant\frac{n-1}{2}$$

and we have the assertion. □

Proof of Theorem 2: Let $\varepsilon>0$, $s\in\mathbf{R}\backslash\{0\}$ and

$$f(r):=\frac{1-\varepsilon}{2\,a^2r^{n-1}}\int_0^r t^{n-1}\,q^2(t)\,dt+\frac{\varepsilon}{4\,r},\quad A:=\alpha\cdot p+i\,f(r)\,\alpha_r+is,$$

$$B:=m\,\alpha_{n+1}+V-i\,f(r)\,\alpha_r,\quad A_1:=\alpha\cdot p+is,\quad B_1:=-if(r)\alpha_r,$$

that is, $H=A+B$ and $A_1=A+B_1$. The definition of a in (3) gives

$$0\leqslant f(r)\leqslant\frac{1-\varepsilon}{2r}+\frac{\varepsilon}{4r}=\frac{1-(\varepsilon/2)}{2r}\leqslant\frac{1}{2r}.\tag{11}$$

It is well known that $\overline{A_1}$ has a bounded inverse defined on $\mathbf{H}$. In view of (11) and Hardy's inequality (9) we have

$$A_1^*A_1=p^2+s^2\geqslant\left(\frac{n-2}{2}\right)^2\frac{1}{r^2}\geqslant\left(\frac{n-2}{1-(\varepsilon/2)}\right)^2f^2=\left(\frac{n-2}{1-(\varepsilon/2)}\right)^2B_1^*B_1,$$

so that $\overline{A}^{-1}$ is bounded on $\mathbf{H}$ as well with $D(\overline{A})=D(\overline{A_1-B_1})=D(\overline{A_1})=W^{1,2}(\mathbf{R}^n)^N$.

Since $V\,\alpha_{n+1}+f\,(i\alpha_r\alpha_{n+1})$ is Hermitian with square V^2+f^2 we have

$$\begin{aligned}B^*\,B&=f^2+m^2+V^2+2\,m\,[V\,\alpha_{n+1}+f\,(i\alpha_r\alpha_{n+1})]\\&\leqslant f^2+m^2+V^2+2\,|m|\,\sqrt{V^2(x)+\frac{1}{4\,r^2}}=f^2+q^2.\end{aligned}\tag{12}$$

On the other hand,

$$
\begin{aligned}
A^*A &= p_r^2 + \frac{(n-1)(n-3)}{4r^2} + \frac{1}{r^2}\left[S^2 - S - \frac{(n-1)(n-3)}{4}\right] + \frac{2f}{r}\left(S - \frac{n-1}{2}\right) \\
&\quad + f' + \frac{n-1}{r}f + f^2 + s^2 + 2sf\alpha_r \\
&= p_r^2 + \frac{(n-1)(n-3)}{4r^2} + \left[S^2 - S - \frac{(n-1)(n-3)}{4}\right](1-2rf)\frac{1}{r^2} \\
&\quad + \left[S^2 - \left(\frac{n-1}{2}\right)^2\right]\frac{2f}{r} + f' + \frac{n-1}{r}f + f^2 + s^2 + 2sf\alpha_r \\
&\geqslant p_r^2 + \frac{(n-1)(n-3)}{4r^2} + f' + \frac{n-1}{r}f + f^2 + s^2 + 2sf\alpha_r
\end{aligned}
$$

on account of (6), (10) and

$$
S^2 - S - \frac{(n-1)(n-3)}{4} = \left(S - \frac{n-1}{2}\right)\left(S + \frac{n-3}{2}\right) \geqslant 0.
$$

Therefore, we have

$$
A^*A \geqslant p_r^2 + \frac{(n-1)(n-3)}{4r^2} + f' + \frac{n-1}{r}f + f^2 + s^2 - 2|s|f.
$$

Owing to Lemma 3.1 and

$$
f'(r) + \frac{n-1}{r}f = \frac{1-\varepsilon}{2a^2}q^2(r) + \frac{\varepsilon(n-2)}{4r^2}
$$

we find

$$
A^*A \geqslant \frac{n-2\varepsilon}{4a^2}q^2 + \frac{d}{r} - d^2 + \frac{\varepsilon(n-2)}{4r^2} + f^2 + s^2 - 2|s|f. \tag{13}
$$

Equations (12) and (13) imply

$$
\begin{aligned}
A^*A - (1+\varepsilon)B^*B &\geqslant \frac{n-2\varepsilon}{4a^2}q^2 + \frac{d}{r} - d^2 + \frac{\varepsilon(n-2)}{4r^2} + s^2 - 2|s|f - (1+\varepsilon)q^2 - \varepsilon f^2 \\
&\geqslant \left[\frac{n-2\varepsilon}{4a^2} - (1+\varepsilon)\right]q^2 + s^2 - d^2 + \left[d - \left(1 - \frac{\varepsilon}{2}\right)|s|\right]\frac{1}{r} \\
&\quad + \left[n - 2 - \left(1 - \frac{\varepsilon}{2}\right)^2\right]\frac{\varepsilon}{4r^2}.
\end{aligned}
$$

Since $n/4a^2 > 1$ in view of (3), an appropriate choice of $\varepsilon > 0$ yields

$$
A^*A - (1+\varepsilon)B^*B \geqslant 0.
$$

Since $\overline{A}$ has a bounded inverse on $\mathbf{H}$ with $D(\overline{A}) = W^{1,2}(\mathbf{R})^N$, H is essentially self-adjoint with $D(\overline{H}) = D(\overline{A+B}) = D(\overline{A}) = W^{1,2}(\mathbf{R})^N$. □

IV. PROOF OF THEOREM 3

We have only to see that the ranges of $(H\pm i)$ are dense in $\mathbf{H}$. We note that $u\in\mathbf{H}$ belongs to $D(H^*)$ if and only if $(\alpha\cdot p)\,u$ exists in the weak sense on $C_0^\infty(\mathbf{R}^n)^N$, and

$$(\alpha\cdot p)\,u+m\,\alpha_{n+1}\,u+V\,u\in\mathbf{H},$$

since $V\in L^2_{\mathrm{loc}}(\mathbf{R}^n)$. Let $u\in R(H+i)^\perp=\ker(H^*-i)$. Then we have

$$(\alpha\cdot p)\,u+m\,\alpha_{n+1}\,u+V\,u=iu.$$

As remarked at the beginning of Sec. II, every Dirac operator is unitarily equivalent to the Dirac operator defined by Dirac matrices in (4) with (5), replacing $m(x)$ by $-m(x)$ if necessary. Therefore, with suitable vectors

$$v:={}^t(v_1,v_2,\ldots,v_{N/2}),\quad w:={}^t(w_1,w_2,\ldots,w_{N/2})\in L^2(\mathbf{R}^n)^{N/2}$$

we have

$$u=\begin{pmatrix} v\\ w\end{pmatrix}$$

and

$$\sum_{j=1}^n a_j\,p_j\,w+(m+V)v=iv, \tag{14a}$$

$$\sum_{j=1}^n a_j^*\,p_j\,v+(-m+V)w=iw, \tag{14b}$$

or

$$\sum_{j=1}^n a_j\,p_j\,w+(-m+V)v=-iv,\quad \sum_{j=1}^n a_j^*\,p_j\,v+(m+V)w=-iw. \tag{15}$$

Let us consider the earlier case (14) and assume $m(x)\equiv V(x)$. By virtue of (14a) we can apply $\Sigma_{j=1}^n a_jp_j$ to (14b), and using (5) together with $Vv\in L^1_{\mathrm{loc}}(\mathbf{R}^n)^N$ we see that $\Delta v\in L^1_{\mathrm{loc}}(\mathbf{R}^n)^N$, and so

$$-\Delta\,v+2\,i\,V\,v=-v \tag{16}$$

in the weak sense. From (16) and Kato's inequality we have for $j=1,2,\ldots,N/2$,

$$(-\Delta+1)|v_j|\leqslant\mathrm{Re}[(\mathrm{sgn}\,\overline{v_j})(-\Delta+1)v_j]=0,$$

and so $v_j=0$ (see Ref. 11 or Ref. 18, p. 184). By (14b) we then have $w=0$, i.e., $u=0$. The proofs for (15), $m\equiv -V$, and $u\in R(H-i)^\perp$ are similarly obtained. □

APPENDIX

Finally we show that Dirac matrices of the special form (4) and (5) exist. $n+1$ $N(n)\times N(n)$ Dirac matrices with a simple block structure can be constructed inductively by starting with the Pauli matrices $(n=2)$

$$\alpha_1^{(2)}:=\sigma_1=\begin{pmatrix}0&1\\1&0\end{pmatrix},\quad \alpha_2^{(2)}:=\sigma_2=\begin{pmatrix}0&-i\\i&0\end{pmatrix},\quad \alpha_3^{(2)}:=\sigma_3=\begin{pmatrix}1&0\\0&-1\end{pmatrix}.$$

If n is odd and we know the $N(n-1)\times N(n-1)$ matrices $\alpha_1^{(n-1)},\alpha_2^{(n-1)},\ldots,\alpha_n^{(n-1)}$, we define $N(n)\times N(n)$ matrices $[N(n)=2N(n-1)]$

$$\alpha_j^{(n)}:=\begin{pmatrix}\mathbf{0} & \alpha_j^{(n-1)}\\ \alpha_j^{(n-1)} & \mathbf{0}\end{pmatrix}\quad (j=1,2,\ldots,n),\quad \alpha_{n+1}^{(n)}:=\begin{pmatrix}I_{N(n-1)} & \mathbf{0}\\ \mathbf{0} & -I_{N(n-1)}\end{pmatrix}.$$

If n is even, we define $N(n)\times N(n)$ matrices $(N(n)=N(n-1)=2N(n-2))$

$$\alpha_1^{(n)}:=\begin{pmatrix}\mathbf{0} & I_{N(n-2)}\\ I_{N(n-2)} & \mathbf{0}\end{pmatrix},\quad \alpha_{j+1}^{(n)}:=\begin{pmatrix}\mathbf{0} & -i\alpha_j^{(n-2)}\\ i\alpha_j^{(n-2)} & \mathbf{0}\end{pmatrix}\quad (j=1,2,\ldots,n-1),$$

$$\alpha_{n+1}^{(n)}:=\begin{pmatrix}I_{N(n-2)} & \mathbf{0}\\ \mathbf{0} & -I_{N(n-2)}\end{pmatrix},$$

which are Hermitian matrices satisfying (1). Therefore, in any dimension n we can find $N\times N$ Dirac matrices $\alpha_1,\ldots,\alpha_{n+1}$ of the form

$$\alpha_j:=\begin{pmatrix}\mathbf{0} & a_j\\ a_j^* & \mathbf{0}\end{pmatrix}\quad (j=1,2,\ldots,n),\quad \alpha_{n+1}:=\begin{pmatrix}I_{N/2} & \mathbf{0}\\ \mathbf{0} & -I_{N/2}\end{pmatrix},$$

where the a_j are $N/2\times N/2$ matrices (which are Hermitian if n is odd) such that

$$a_j a_k^*+a_k a_j^*=2\delta_{jk}I_{N/2},\quad a_j^* a_k+a_k^* a_j=2\delta_{jk}I_{N/2}.$$

(Received 6 September 2000; accepted for publication 19 March 2001)

In this article, we construct gauge bundles on a noncommutative toroidal orbifold $\mathbb{T}^4_\theta/\mathbb{Z}_2$. First, we explicitly construct a bundle with constant curvature connections on a noncommutative $\mathbb{T}^4_\theta$ following Rieffel's method. Then, applying the appropriate quotient conditions for its $\mathbb{Z}_2$ orbifold, we find a Connes–Douglas–Schwarz type solution of matrix theory compactified on $\mathbb{T}^4_\theta/\mathbb{Z}_2$. When we consider two copies of a bundle on $\mathbb{T}^4_\theta$ invariant under the $\mathbb{Z}_2$ action, the resulting Higgs branch moduli space of equivariant constant curvature connections becomes an ordinary toroidal orbifold $\mathbb{T}^4/\mathbb{Z}_2$. © *2001 American Institute of Physics.*

I. INTRODUCTION

The pioneering work of Connes, Douglas, and Schwarz (CDS)[1] revealing the equivalence between noncommutative Yang–Mills theory living on the noncommutative torus and toroidally compactified IKKT (and also BFSS) M(atrix) theory[2,3] with the constant three-form background field has spurred various works[4] on noncommutative geometry and M/string theory since then. It has soon been known that the T-duality of M(atrix) theory can be understood in terms of Morita equivalence of the vector bundles over noncommutative tori.[5,6]

Many of these works have been related to the torus compactification and not much has been addressed to the noncommutative orbifold case. Recently, Konechny and Schwarz[7] worked out the compactification of M(atrix) theory on the $\mathbb{Z}_2$ orbifold of the noncommutative two-torus. However, physically more relevant compactification on the $\mathbb{Z}_2$ orbifold of noncommutative four-torus, a singular $K3$ surface, has not been worked out so far. In the commutative case, systems of D0-branes on the commutative orbifold $\mathbb{T}^4/\mathbb{Z}_2$ were studied in Refs. 8 and 9, and it is our main objective to extend the result of Ref. 8 to the noncommutative case.

We consider the compactification in the context of IKKT M(atrix) model[2] on the orbifold $\mathbb{T}^4/\mathbb{Z}_2$ where $\mathbb{Z}_2$ acts as a central symmetry $x \mapsto -x$. Thus, we need to find a Hilbert space $\mathcal{H}$ and unitary representations of $\mathbb{T}^4$ and $\mathbb{Z}_2$ on $\mathcal{H}$ and Hermitian operators X such that

$$U_i X_j U_i^{-1} = X_j + 2\pi\delta_i^j R_i, \quad i,j = 1, \ldots, 4, \tag{1}$$

$$U_i X_\nu U_i^{-1} = X_\nu, \tag{2}$$

$$\Omega X_i \Omega = -X_i, \tag{3}$$

$$\Omega X_\nu \Omega = X_\nu, \quad \nu = 0,5,\ldots,9. \tag{4}$$

Following the description of Refs. 10 and 7 we can find operator relations compatible with the quotient conditions (1)–(4):

$$U_i U_j = e^{2\pi i \theta_{ij}} U_j U_i, \tag{5}$$

$$\Omega U_i \Omega = U_i^{-1}, \quad \Omega^2 = 1. \tag{6}$$

When $\theta = 0$, the relations (5) and (6) describe a $\mathbb{Z}_2$ equivariant vector bundle on the $\mathbb{Z}_2$ space $\mathbb{T}^4$ and X_i specify an equivariant connection on the bundle. Now the equivariant version of the Serre–Swan theorem indicates that there is a one-to-one correspondence between $\mathbb{Z}_2$ equivariant vector bundles on the $\mathbb{Z}_2$ space $\mathbb{T}^4$ and finitely generated projective modules over the crossed product C^*-algebra $C(\mathbb{T}^4) \rtimes_\alpha \mathbb{Z}_2$. As a noncommutative analog we see that the relations (5) and (6) imply that the Hilbert space $\mathcal{H}$ is simply a module over the crossed product algebra $C(\mathbb{T}^4_\theta) \rtimes_\alpha \mathbb{Z}_2$ or $\mathcal{A}_\theta \rtimes_\alpha \mathbb{Z}_2$, where α denotes the action of $\mathbb{Z}_2$ on $\mathcal{A}_\theta$ by involution. The crossed product $\mathcal{A}_\theta \rtimes_\alpha \mathbb{Z}_2$ is the C^*-completion of the linear space of $\mathcal{A}_\theta$-valued functions on $\mathbb{Z}_2$. Thus a general element of $\mathcal{A}_\theta \rtimes_\alpha \mathbb{Z}_2$ is a formal linear combination of elements of the form $\Pi_i U_i^{n_i} \Omega^{\epsilon_i}$, where $\epsilon_i \in \{0,1\}$. As noted in Ref. 7, an $\mathcal{A}_\theta$-module is a finitely generated projective module if and only if its corresponding module over $\mathcal{A}_\theta \rtimes_\alpha \mathbb{Z}_2$ is finitely generated projective. Thus, bundles on a noncommutative (NC) torus $\mathbb{T}^4_\theta$ are closely related with bundles on the noncommutative torodial orbifold $\mathbb{T}^4_\theta / \mathbb{Z}_2$.

In this article we find a projective module solution to the quotient conditions (1)–(4). First we calculate a CDS type solution of M(atrix) theory compactified on the noncommutative four-torus. There, we also show explicitly that the dual tori are actually related to each other through SO(4,4|$\mathbb{Z}$) transformations. From this solution we discuss that the moduli space of constant curvature connections can be identified with ordinary four-torus. Based on such an explicit CDS type solution on noncommutative $\mathbb{T}^4$, we find its $\mathbb{Z}_2$ orbifold solutions extending the result of Ref. 8 to the noncommutative torodial orbifold $\mathbb{T}^4_\theta / \mathbb{Z}_2$.

In Sec. II, we review the projective modules over noncommutative torus. In Sec. III, we construct a projective module on noncommutative four-torus *a la* Rieffel[11] explicitly, and find a CDS type solution of M(atrix) theory compactified on the noncommutative four-torus. It is also shown that the dual torus is actually related via SO(4,4|$\mathbb{Z}$) transformation. In Sec. IV, we find a solution for the noncommutative toroidal orbifold. From this solution we study the moduli space of equivariant constant curvature connections. We conclude in Sec. V.

II. NONCOMMUTATIVE VECTOR BUNDLES OVER NONCOMMUTATIVE TORUS

In this section we review noncommutative vector bundles over NC d-torus $\mathbb{T}^d_\theta$, following the lines of Refs. 12, 11, 5, and 6. Recall that $\mathbb{T}^d_\theta$ is the deformed algebra of the algebra of smooth functions on the torus $\mathbb{T}^d$ with the deformation parameter θ, which is a real $d \times d$ anti-symmetric matrix. This algebra is generated by operators $U_1, \ldots, U_d$ obeying the following relations:

$$U_i U_j = e^{2\pi i \theta_{ij}} U_j U_i \quad \text{and} \quad U_i^* U_i = U_i U_i^* = 1, \quad i,j = 1,\ldots,d.$$

The above relations define the presentation of the involutive algebra

$$\mathcal{A}^d_\theta = \left\{ \sum a_{i_1 \cdots i_d} U_1^{i_1} \cdots U_d^{i_d} \,\middle|\, a = (a_{i_1 \cdots i_d}) \in \mathcal{S}(\mathbb{Z}^d) \right\},$$

where $\mathcal{S}(\mathbb{Z}^d)$ is the Schwartz space of sequences with rapid decay. According to the dictionary in Ref. 13, the construction of a noncommutative vector bundle over $\mathbb{T}^d_\theta$ corresponds to the construc-

tion of finitely generated projective modules over $\mathcal{A}_\theta^d$. It was proved in Ref. 11 that when θ is not rational, every projective module over a smooth Algebra $\mathcal{A}_\theta^d$ can be represented by a direct sum of modules of the form $\mathcal{S}(\mathbb{R}^p\times\mathbb{Z}^q\times F)$, the linear space of Schwartz functions on $\mathbb{R}^p\times\mathbb{Z}^q\times F$, where $2p+q=d$ and F is a finite Abelian group. The module action is specified by operators on $\mathcal{S}(\mathbb{R}^p\times\mathbb{Z}^q\times F)$ and the commutation relation of these operators should be matched with that of elements in $\mathcal{A}_\theta^d$.

On such bundles or modules there are notions of connections and the Chern character.[1,5,6,14] Recall that there is the dual action of the torus group $\mathbb{T}^d$ on $\mathcal{A}_\theta^d$ which gives a Lie group homomorphism of $\mathbb{T}^d$ into the group of automorphisms of $\mathcal{A}_\theta^d$. Its infinitesimal form generates a homomorphism of Lie algebra L of $\mathbb{T}^d$ into Lie algebra of derivations of $\mathcal{A}_\theta^d$. Note that the Lie algebra L is Abelian and is isomorphic to $\mathbb{R}^d$. Let $\delta: L\to \mathrm{Der}(\mathcal{A}_\theta^d)$ be the homomorphism. For each $X\in L$, $\delta(X):=\delta_X$ is a derivation, i.e., for $u,v\in\mathcal{A}_\theta^d$,

$$\delta_X(uv)=\delta_X(u)v+u\,\delta_X(v).$$

Derivations corresponding to the generators $\{e_1,\ldots,e_d\}$ of L will be denoted by $\delta_1,\ldots,\delta_d$. For the generators U_i's of $\mathbb{T}_\theta^d$, it has the following property:

$$\delta_i(U_j)=2\pi i\,\delta_{ij}\cdot U_j.$$

If E is a projective $\mathcal{A}_\theta^d$-module, a connection ∇ on E is a linear map from E to $E\otimes L^*$ such that for all $X\in L$,

$$\nabla_X(\xi u)=(\nabla_X\xi)u+\xi\delta_X(u),\quad \xi\in E, u\in\mathcal{A}_\theta^d.$$

It is easy to see that

$$[\nabla_i,U_j]=2\pi i\,\delta_{ij}\cdot U_j.$$

Furthermore, for an $\mathcal{A}_\theta^d$-valued inner product $\langle\cdot,\cdot\rangle$ on E, if ∇ has the property that

$$\langle\nabla_X\xi,\eta\rangle+\langle\xi,\nabla_X\eta\rangle=\delta_X(\langle\xi,\eta\rangle),$$

then it is called a Hermitian connection. The curvature $\mathcal{F}_\nabla$ of a connection ∇ is a two-form on L with values in the algebra of endomorphisms of E. That is, for $X,Y\in L$,

$$\mathcal{F}_\nabla(X,Y):=[\nabla_X,\nabla_Y]-\nabla_{[X,Y]}.$$

Since L is Abelian, we simply have $\mathcal{F}_\nabla(X,Y)=[\nabla_X,\nabla_Y]$. Denote by $\mathcal{E}=\mathrm{End}_{\mathcal{A}_\theta}(E)$ the algebra of endomorphisms of E. Note that if ∇ and ∇' are two connections, then $\nabla_X-\nabla'_X$ belongs to the algebra $\mathcal{E}$. Thus once we have fixed a connection ∇, then every other connection is of the form $\nabla+A$ (here A is a linear map L into $\mathcal{E}$). Moreover, the space of Hermitian connections is an affine space with vector space consisting of the linear maps from L into the skew-adjoint part of $\mathcal{E}$ and also the algebra is related with a moduli space of a certain connections.

We now consider the endomorphisms algebra of a module over $\mathcal{A}_\theta^d$. Let Λ be a lattice in $H=M\times\hat{M}$, where $M=\mathbb{R}^p\times\mathbb{Z}^q\times F$ and $\hat{M}$ is its dual. Let T be the corresponding embedding map in the sense of Ref. 11. Thus Λ is the image of $\mathbb{Z}^d$ under the map T and this determines a projective module which will be denoted by E_Λ. Consider the lattice

$$\Lambda^\perp:=\{(m,\hat{s})\in M\times\hat{M}\,|\,\theta((m,\hat{s}),(n,\hat{t}))=\hat{t}(m)-\hat{s}(n)\in\mathbb{Z},\quad \text{for all}\quad (n,\hat{t})\in\Lambda\}.$$

From the definition, it is easy to see that every operator of the form

$$\mathcal{U}_{(m,\hat{s})}f(n)=e^{2\pi i\hat{s}(n)}f(n+m)$$

for $(m,\hat{s}) \in \Lambda^{\perp}$ commutes with all operators $\mathcal{U}_{(n,\hat{t})}$, $(n,\hat{t}) \in \Lambda$. In fact, one can show that the algebra of endomorphisms on E_{Λ}, denoted by $\mathrm{End}_{\mathcal{A}_\theta}(E_{\Lambda})$, is a C^*-algebra which is obtained by C^*-completion of the space spanned by operators $\mathcal{U}_{(m,\hat{s})}$, $(m,\hat{s}) \in \Lambda^{\perp}$. As shown in Ref. 11, the algebra $\mathrm{End}_{\mathcal{A}_\theta}(E_{\Lambda})$ can be identified with a noncommutative torus $\mathcal{A}_{\hat{\theta}}$ (here $\hat{\theta}$ is a bilinear form on $\Lambda^{\perp}$), i.e., $\mathcal{A}_{\hat{\theta}}$ is Morita equivalent to $\mathcal{A}_\theta$. Recall that a C^*-algebra A is said to be (strongly) Morita equivalent to A' if $A' \cong \mathrm{End}_A(E)$ for some finite projective module E. In general, as was proved in Ref. 6, a NC torus $\mathcal{A}_{\tilde{\theta}}$ is Morita equivalent to $\mathcal{A}_\theta$ if θ and $\tilde{\theta}$ are related by $\tilde{\theta} = (A\theta + B)(C\theta + D)^{-1}$, where $\left(\begin{smallmatrix} A & B \\ C & D \end{smallmatrix}\right) \in \mathrm{SO}(d,d|\mathbb{Z})$.

We shall now turn to the description of the Chern character. In general $K_0(\mathcal{A}_\theta^d)$ classifies projective modules over $\mathcal{A}_\theta^d$. In fact, the positive cone $K_0^+(\mathcal{A}_\theta^d)$ corresponds to genuine projective modules and, if θ is not rational, $K_0^+(\mathcal{A}_\theta^d)$ consists exactly of its elements of strictly positive trace. The Chern character of a gauge bundle, which corresponds to a projective module, on a noncommutative torus is an element in the Grassmann algebra $\wedge^{\cdot}(L^*)$, where L denotes the Lie algebra of $\mathbb{T}^d$ and L^* is the dual vector space of L. Since there is a lattice D in L, we see that there are elements of $\wedge^{\cdot} D^*$ which are integral. Now the Chern character is the map $\mathrm{Ch}: K_0(\mathcal{A}_\theta^d) \to \wedge^{\mathrm{ev}}(L^*)$ defined by

$$\mathrm{Ch}(E) := \hat{\tau}(e^{\mathcal{F}/2\pi i}) = \sum_{k=0} \frac{1}{(2\pi i)^k} \frac{\hat{\tau}(\mathcal{F}^k)}{k!},$$

where E is any gauge bundle and $\mathcal{F}$ is a curvature of an arbitrary connection on E and $\hat{\tau}$ is a trace on the algebra of endomorphisms. In general the Chern character is integral in the commutative case. This is no longer true for the noncommutative case. However, in the case of noncommutative torus, there is an integral element related to the Chern character by the formula

$$\mathrm{Ch}(E) = e^{i(\theta)} \mu(E). \tag{7}$$

Here $i(\theta)$ denotes the contraction with the deform parameter θ regarded as an element of $\wedge^2 L$. The formula (7) can be realized as a noncommutative generalization of Mukai vector.[15,16] In particular, $\mu(E) = e^{-i(\theta)}\mathrm{Ch}(E)$ is an integral element of $\wedge^{\cdot}(L^*)$ which is related with the Chern character on the classical torus. Also once we fix the deformation parameter, then the Chern character $\mathrm{Ch}(E)$ is completely determined by its integral part $\mu(E)$. Note that if, for θ not rational, the zeroth component of the Chern character or the trace is strictly positive, then the gauge bundle E belongs to the positive cone of $K_0(\mathcal{A}_\theta^d)$ and hence it can be written as a direct sum of the form $\mathcal{S}(\mathbb{R}^p \times \mathbb{Z}^q \times F)$.[11]

III. COMPACTIFICATION ON NONCOMMUTATIVE $\mathbb{T}^4$

In this section we study the compactification solutions on a noncommutative four-torus $\mathbb{T}_\theta^4$ for the case $e^{2\pi i \theta_{ij}} \neq 1$, following the guide line in Ref. 1. After we fix U_1, U_2, U_3 and U_4, or a projective module, the general solution has the form of $X_i = \overline{X_i} + A_i$, where $\overline{X_i}$ are particular solutions and A_i are operators commuting with U_i. Here we consider a projective module of the form $\mathcal{S}(\mathbb{R}^p \times \mathbb{Z}^q) \otimes \mathcal{S}(F)$, where $2p+q=4$. Thus there are three types of modules over $\mathcal{A}_\theta$ according to $p=0,1,2$. When $p=0$, it is a free module. The other two types are of the form $\mathcal{S}(\mathbb{R} \times \mathbb{Z}^2) \otimes \mathcal{S}(F)$ and $\mathcal{S}(\mathbb{R}^2) \otimes \mathcal{S}(F)$. As is discussed in Sec. II, a gauge bundle on $\mathbb{T}_\theta^4$ corresponds to an element of positive trace which is the zeroth component of the Chern character and the Chern character is determined by its integral part μ. Thus it is natural to start with the construction on $\mathcal{S}(F)$ to describe projective modules. Here we will only consider the case when $p=2$, which is related with (4220)-systems with a constant curvature considered in Ref. 17 and 18. Let $F = \mathbb{Z}_{M_1} \times \mathbb{Z}_{M_2}$, where $\mathbb{Z}_{M_i} = \mathbb{Z}/M_i\mathbb{Z}$, $(i=1,2)$ and consider the space $\mathbb{C}^{M_1} \otimes \mathbb{C}^{M_2}$ as the space of functions on $C(\mathbb{Z}_{M_1} \times \mathbb{Z}_{M_2})$. For all $M_i \in \mathbb{Z}$ and $N_i \in \mathbb{Z}/M_i\mathbb{Z}$ such that M_i and N_i are relatively prime, define operators W_i on $C(\mathbb{Z}_{M_1} \times \mathbb{Z}_{M_2})$ by

$$(W_1 f)(k_1,k_2)=f(k_1-N_1,k_2), \quad (W_2 f)(k_1,k_2)=\exp\left(-\frac{2\pi i k_1}{M_1}\right) f(k_1,k_2),$$

$$(W_3 f)(k_1,k_2)=f(k_1,k_2-N_2), \quad (W_4 f)(k_1,k_2)=\exp\left(-\frac{2\pi i k_2}{M_2}\right) f(k_1,k_2).$$

The operators satisfy the commutation relation

$$W_1 W_2=\exp\left(2\pi i \frac{N_1}{M_1}\right) W_2 W_1, \quad W_3 W_4=\exp\left(2\pi i \frac{N_2}{M_2}\right) W_4 W_3,$$

otherwise commuting. If we write $W_i W_j=\exp(2\pi i \psi_{ij}) W_j W_i$, then the antisymmetric 4×4 matrix $\psi=(\psi_{ij})$ is of the form

$$\psi=\begin{pmatrix} 0 & \frac{N_1}{M_1} & 0 & 0 \\ -\frac{N_1}{M_1} & 0 & 0 & 0 \\ 0 & 0 & 0 & \frac{N_2}{M_2} \\ 0 & 0 & -\frac{N_2}{M_2} & 0 \end{pmatrix}. \tag{8}$$

Let $T:\mathbb{Z}^4\to\mathbb{R}^2\times\mathbb{R}^{2*}$ be an embedding map. Thus its matrix representation $T=(x_{ij})$, $i,j=1,\ldots,4$, has nonzero determinant and satisfies $(\wedge^2 T^*)(\omega)=-\gamma$ where $\omega=e_3\wedge e_1+e_4\wedge e_2 \in\wedge^2(\mathbb{Z}^4)$ and e_i are standard basis for $\mathbb{Z}^4$. Equivalently, if we consider the Heisenberg representation of $\mathbb{Z}^4$ in a Hilbert space, the desired operators acting on the space of smooth functions on $\mathbb{R}^2$ are defined by the following form:

$$(V_i f)(s_1,s_2)=(V_{e_i} f)(s_1,s_2) := \exp(2\pi i(s_1 x_{3i}+s_2 x_{4i})) f(s_1+x_{1i},s_2+x_{2i}).$$

These operators obey the commutation relation

$$V_i V_j=e^{-2\pi i \gamma_{ij}} V_j V_i,$$

where

$$\gamma_{ij}=\begin{vmatrix} x_{1i} & x_{1j} \\ x_{3i} & x_{3j} \end{vmatrix}+\begin{vmatrix} x_{2i} & x_{2j} \\ x_{4i} & x_{4j} \end{vmatrix}.$$

Since γ is a real matrix, the operators V_i act on the Schwartz space $\mathcal{S}(\mathbb{R}^2)$. Now we define operators $U_i=V_i\otimes W_i$ acting on the space $E_T:=\mathcal{S}(\mathbb{R}^2)\otimes\mathbb{C}^{M_1}\otimes\mathbb{C}^{M_2}$ as follows:

$$(U_1 f)(s_1,s_2,k_1,k_2)=e^{2\pi i(s_1 x_{31}+s_2 x_{41})} f(s_1+x_{11},s_2+x_{21},k_1-N_1,k_2),$$

$$(U_2 f)(s_1,s_2,k_1,k_2)=e^{2\pi i(s_1 x_{32}+s_2 x_{42})}\cdot e^{-2\pi i k_1/M_1} f(s_1+x_{12},s_2+x_{22},k_1,k_2),$$

$$(U_3 f)(s_1,s_2,k_1,k_2)=e^{2\pi i(s_1 x_{33}+s_2 x_{43})} f(s_1+x_{13},s_2+x_{23},k_1,k_2-N_2),$$

$$(U_4 f)(s_1,s_2,k_1,k_2)=e^{2\pi i(s_1 x_{34}+s_2 x_{44})}\cdot e^{-2\pi i k_2/M_2} f(s_1+x_{14},s_2+x_{24},k_1,k_2).$$

Then it is easy to see that they satisfy

$$U_iU_j=\exp(-2\pi i\gamma_{ij}+2\pi i\psi_{ij})U_jU_i.$$

Thus we have solution of (5) if $\gamma=\psi-\theta$.

Consider operators $\overline{X_i}$ acting on $E_T=\mathcal{S}(\mathbb{R}^2)\otimes\mathbb{C}^{M_1}\otimes\mathbb{C}^{M_2}$ given by

$$(\overline{X_i}f)(s_1,s_2,k_1,k_2)=2\pi iA_i^1s_1f(s_1,s_2,k_1,k_2)+2\pi iA_i^2s_2f(s_1,s_2,k_1,k_2)$$
$$-A_i^3\frac{\partial f(s_1,s_2,k_1,k_2)}{\partial s_1}-A_i^4\frac{\partial f(s_1,s_2,k_1,k_2)}{\partial s_2}, \tag{9}$$

where A_i^k are any real numbers yet to be determined. From the definition of U_i and $\overline{X_i}$, it is easy to see that the operators W_i commute with $\overline{X_i}$. Suppose that the operators $\overline{X_i}$ satisfy the equation (1), i.e.,

$$U_i\overline{X_j}U_i^{-1}=\overline{X_j}+2\pi\delta_i^jR_i.$$

By a straightforward calculation, the constant matrix (A_i^j) in (9) can be obtained as in the following form:

$$(R_iA_i^j)T=-i\,\mathrm{Id}.$$

Since the inverse matrix of T can be written as

$$T^{-1}=\frac{1}{\det T}((-1)^{i+j}B_{ji}),$$

where B_{ij} is the (ij)-minor of the matrix T, we see that

$$A_i^k=(-1)^{i+k}\cdot\frac{R_i}{i}\cdot\frac{1}{\det T}\cdot B_{ki}, \tag{10}$$

and this gives a particular solution to the equations (2) and (3). It is easy to check that the commutator is of the form

$$[\overline{X_i},\overline{X_j}]=2\pi i\left(\begin{vmatrix}A_i^1 & A_i^3\\ A_j^1 & A_j^3\end{vmatrix}+\begin{vmatrix}A_i^2 & A_i^4\\ A_j^2 & A_j^4\end{vmatrix}\right).$$

By (10), we have

$$[\overline{X_i},\overline{X_j}]=-2\pi i\cdot\frac{R_iR_j}{(\det T)^2}\left\{(-1)^{i+1}(-1)^{j+1}\begin{vmatrix}B_{1i} & B_{3i}\\ B_{1j} & B_{3j}\end{vmatrix}+(-1)^i(-1)^j\begin{vmatrix}B_{2i} & B_{4i}\\ B_{2j} & B_{4j}\end{vmatrix}\right\}$$
$$=2\pi i(-1)^{i+j+1}\cdot\frac{R_iR_j}{(\det T)^2}\left\{\begin{vmatrix}B_{1i} & B_{3i}\\ B_{1j} & B_{3j}\end{vmatrix}+\begin{vmatrix}B_{2i} & B_{4i}\\ B_{2j} & B_{4j}\end{vmatrix}\right\}$$
$$=2\pi i(-1)^{i+j+1}\cdot\frac{R_iR_j}{\det T}\cdot*\gamma_{ij}.$$

Now we should find generators of the set of operators which commute with U_i's. To find such operators we need to describe an embedding map which corresponds to the dual lattice of the lattice defined by the embedding map T as discussed in Sec. II. For such a map, let

$$S=\begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \end{pmatrix}\cdot (T^t)^{-1}=\frac{1}{\det T}\begin{pmatrix} B_{31} & -B_{32} & B_{33} & -B_{34} \\ -B_{41} & B_{42} & -B_{43} & B_{44} \\ -B_{11} & B_{12} & -B_{13} & B_{14} \\ B_{21} & -B_{22} & B_{23} & -B_{24} \end{pmatrix}. \tag{11}$$

Using the matrix (11), we define operators acting on E_T by

$$(Z_1 f)(s_1,s_2,k_1,k_2)=e^{2\pi i(-s_1B_{11}+s_2B_{21})/M_1|T|}\cdot e^{2\pi i b_1 k_1/M_1} f\left(s_1+\frac{B_{31}}{M_1|T|},s_2-\frac{B_{41}}{M_1|T|},k_1,k_2\right),$$

$$(Z_2 f)(s_1,s_2,k_1,k_2)=e^{2\pi i(s_1B_{12}-s_2B_{22})/M_1|T|} f\left(s_1-\frac{B_{32}}{M_1|T|},s_2+\frac{B_{42}}{M_1|T|},k_1-1,k_2\right),$$

$$(Z_3 f)(s_1,s_2,k_1,k_2)=e^{2\pi i(-s_1B_{13}+s_2B_{23})/M_2|T|}\cdot e^{2\pi i b_2 k_1/M_2} f\left(s_1+\frac{B_{33}}{M_2|T|},s_2-\frac{B_{43}}{M_2|T|},k_1,k_2\right),$$

$$(Z_4 f)(s_1,s_2,k_1,k_2)=e^{2\pi i(s_1B_{14}-s_2B_{24})/M_2|T|} f\left(s_1-\frac{B_{34}}{M_2|T|},s_2+\frac{B_{44}}{M_2|T|},k_1,k_2-1\right),$$

where $|T|=\mathrm{Pf}(\psi-\theta)$ denotes the determinant of T and b_1, b_2 are integers such that $a_iM_i+b_iN_i=1$, and a_i are also integers. To check the operators Z_i commute with all U_j's, let $Z_iU_j=e^{2\pi i\lambda_{ij}}U_jZ_i$. Then it is easy to see that

$$\lambda_{ij}=\frac{1}{M_k|T|}\left\{\begin{vmatrix} x_{1i} & x_{3i} \\ (-1)^{3+j}B_{3j} & (-1)^{1+j}B_{1j}\end{vmatrix}+\begin{vmatrix} x_{2i} & x_{4i} \\ (-1)^{4+j}B_{4j} & (-1)^{2+j}B_{2j}\end{vmatrix}\right\}-\delta_{ij}\frac{b_kN_k}{M_k}, \tag{12}$$

where $k=1,2$ depending on ij. From the relation (12),

$$\lambda_{ij}=0 \quad \text{when } i\neq j,$$

$$\lambda_{ii}=\frac{1}{M_k}-\frac{b_kN_k}{M_k}=\frac{-a_kM_k}{M_k}=-a_k\in\mathbb{Z}.$$

Thus Z_i commute with all U_j's.

Furthermore the operators satisfy

$$Z_iZ_j=e^{2\pi i\hat{\theta}}Z_jZ_i. \tag{13}$$

Now $\hat{\theta}$ can be calculated directly and it is given by

$$\hat{\theta}_{12}=\frac{a_1N_2+b_1N_2\theta_{12}+a_1M_2\theta_{34}-b_1M_2\mathrm{Pf}(\theta)}{M_1M_2\mathrm{Pf}(\psi-\theta)},\quad \hat{\theta}_{13}=\frac{\theta_{13}}{M_1M_2\mathrm{Pf}(\psi-\theta)},$$

$$\hat{\theta}_{14}=\frac{\theta_{14}}{M_1M_2\mathrm{Pf}(\psi-\theta)},\quad \hat{\theta}_{23}=\frac{\theta_{23}}{M_1M_2\mathrm{Pf}(\psi-\theta)},$$

$$\hat{\theta}_{24}=\frac{\theta_{24}}{M_1M_2\mathrm{Pf}(\psi-\theta)},\quad \hat{\theta}_{34}=\frac{a_2N_1+b_2N_1\theta_{34}+a_2M_1\theta_{12}-b_2M_1\mathrm{Pf}(\theta)}{M_1M_2\mathrm{Pf}(\psi-\theta)}.$$

Also we have

$$\hat{\theta}=(A\theta+B)(N-M\theta)^{-1}, \tag{14}$$

where

$$A=\begin{pmatrix} 0 & -a_1 & 0 & 0 \\ a_1 & 0 & 0 & 0 \\ 0 & 0 & 0 & -a_2 \\ 0 & 0 & a_2 & 0 \end{pmatrix}, \quad B=\begin{pmatrix} b_1 & 0 & 0 & 0 \\ 0 & b_1 & 0 & 0 \\ 0 & 0 & b_2 & 0 \\ 0 & 0 & 0 & b_2 \end{pmatrix}$$

and

$$N=\begin{pmatrix} N_1 & 0 & 0 & 0 \\ 0 & N_1 & 0 & 0 \\ 0 & 0 & N_2 & 0 \\ 0 & 0 & 0 & N_2 \end{pmatrix}, \quad M=\begin{pmatrix} 0 & M_1 & 0 & 0 \\ -M_1 & 0 & 0 & 0 \\ 0 & 0 & 0 & M_2 \\ 0 & 0 & -M_2 & 0 \end{pmatrix}.$$

From the equation (14), we see that $-\theta$ and $\hat{\theta}$ are related by SO(4,4$|\mathbb{Z}$) transformation.

Note that U(n) theory on $\mathcal{A}_{-\theta}$ is equivalent to U(1) theory on $\mathcal{A}_{\hat{\theta}}$. For U(1) theory the generators Z_i can be identified with functions on the dual torus:

$$Z_j \to e^{i\sigma_j},$$

where σ_j are coordinates of the dual torus such that

$$[\sigma_i,\sigma_j]=-2\pi i\hat{\theta}_{ij}.$$

Now the general solution of the compactification is given by

$$X_i=\overline{X_i}+\sum_{i_1,\ldots,i_4\in\mathbb{Z}}\Psi_{i_1i_2i_3i_4}Z_1^{i_1}Z_2^{i_2}Z_3^{i_3}Z_4^{i_4},$$

where the coefficients $\Psi_{i_1i_2i_3i_4}$ are c-numbers.

Recall that a connection in a module E_T is determined by a set of operators $\nabla_1,\ldots,\nabla_4$ in E_T such that

$$[\nabla_i,U_j]=2\pi i\delta_{ij}U_j.$$

From the definition of $\overline{X_i}$ given in (9) we have

$$[\overline{X_i},U_j]=-2\pi\delta_{ij}R_jU_j.$$

Thus we see that the special solution $\overline{X_i}$ is related with connections by $\overline{X_i}=(R_i/i)\nabla_i$ and for such connection ∇, the constant curvature $\mathcal{F}=(\mathcal{F}_{ij})$ is given by

$$\mathcal{F}=\gamma^{-1}\cdot \mathrm{Id}_N, \quad \text{where } N=N_1N_2. \tag{15}$$

Now the general solution should be identified as

$$X_i=\frac{R_i}{i}\nabla_i+A_i(\sigma_1,\sigma_2,\sigma_3,\sigma_4), \tag{16}$$

where A_i are gauge fields defined on a noncommutative torus.

Note that from the curvature form (15), it corresponds to the $U(N)$ gauge theory with vanishing su(N) curvature. This type of solution has been studied in Ref. 19 for noncommutative $\mathbb{T}^2$ and in Ref. 20 for the higher torus case. This was generalized to a nonvanishing su(N) curvature case in Ref. 17 and it has been noted that the analysis for noncommutative tori is the same as that of Ref. 18 for commutative tori. In fact the above solution has been described by (4220) system with trivial SU(N) gauge fields in Ref. 18 and its moduli space can be identified with $\mathbb{T}^4$. So we may expect that the moduli space of constant curvature connections in noncommutative torus is of the same form as in the ordinary torus.

The operators

$$\tilde{\nabla}_j=\frac{i}{R_j}\overline{X}_j+\alpha_j, \quad j=1,\ldots,4, \tag{17}$$

where α_j is any real number, determine a Hermitian connection with constant curvature in E_T. Furthermore, connections of the form (16) define a representation on $L^2(\mathbb{R}^2,\mathbb{C}^{M_1}\otimes\mathbb{C}^{M_2})$ of the Heisenberg commutation relations and from this one can follow the same steps in Ref. 12 to show that connections of the form (17) can be found in each gauge orbit and two such connections $(i/R_j)\overline{X}_j+\alpha_j$ and $(i/R_j)\overline{X}_j+\mu_j$ are gauge equivalent if and only if $\alpha_j-\mu_j\in\mathbb{Z}$. Thus the moduli space of constant curvature connections can be identified with $(\mathbb{R}/\mathbb{Z})^4\cong(S^1)^4\cong\mathbb{T}^4$. In general, if we consider a projective module consisting of n copies of such modules, such as $E_{T_1}\oplus\cdots\oplus E_{T_n}$, where T_i is an embedding, then there is a constant curvature connection on each summand such that the overall curvature is given by $\mathcal{F}=\oplus\mathcal{F}_k$, where $\mathcal{F}_k$ is given as in (15) with the same γ. Thus for a constant curvature connection on E which breaks a projective module E into $\oplus_k E_{T_i}$, block diagonal construction gives the moduli space of the form $(\mathbb{T}^4)^n/S_n$, where S_n is the symmetric group.

IV. COMPACTIFICATION ON NONCOMMUTATIVE TOROIDAL ORBIFOLD $\mathbb{T}_\theta/\mathbb{Z}_2$

In this section we find solutions for the quotient conditions (1)–(4) along with the projective module actions (5) and (6) via the compactification solutions on a noncommutative torus $\mathbb{T}^4_\theta$ obtained in Sec. III. From this we find the moduli space of equivariant constant curvature connections on noncommutative toroidal orbifold $\mathbb{T}^4_\theta/\mathbb{Z}_2$.

Consider the module $E_T:=\mathcal{S}(\mathbb{R}^2)\otimes C(\mathbb{Z}_{M_1})\otimes C(\mathbb{Z}_{M_2})$ together with U_i's as operators acting on it. The general solution for the quotient conditions has been identified as

$$X_j=\frac{R_j}{i}\nabla_j+A_j(\sigma_1,\sigma_2,\sigma_3,\sigma_4), \quad 1\leqslant j\leqslant 4. \tag{18}$$

To find solutions for the quotient conditions on the compactified part we need to solve for Ω which satisfies $\Omega U_i\Omega=U_i^{-1}$ and $\Omega^2=1$. Consider an operator Ω_0 on E_T defined by

$$(\Omega_0 f)(s_1,s_2,k_1,k_2)=f(-s_1,-s_2,-k_1,-k_2).$$

It is easy to see that $\Omega_0U_i\Omega_0U_i=e^{2\pi i(x_{1i}x_{3i}+x_{2i}x_{4i})}$. By redefining $U_i\mapsto e^{-\pi i(x_{1i}x_{3i}+x_{2i}x_{4i})}U_i$, we get $\Omega_0U_i\Omega_0=U_i^{-1}$ and $\Omega_0^2=1$. Thus we have a solution for (6), i.e., Ω_0 together with U_i's define a projective module over $\mathcal{A}_\theta\rtimes\mathbb{Z}_2$. As was indicated in Ref. 7, there might be other $\mathbb{Z}_2$ actions on the module. To get other actions on the module, consider the operators Z_i defined in Sec. III. As for the U_i's, rescale Z_i by $e^{-\pi i(B_{1i}B_{3i}+B_{2i}B_{4i})}Z_i$ and we get the relation

$$\Omega_0Z_i\Omega_0=Z_i^{-1}. \tag{19}$$

Since Z_i commute with all U_j's, the operators $\Omega_{n_1\cdots n_4}=e^{i\phi}\Omega_0Z_1^{n_1}Z_2^{n_2}Z_3^{n_3}Z_4^{n_4}$ ($n_i\in\mathbb{Z}$) satisfy the equation (6), where ϕ is a phase which is chosen to get the relation $\Omega^2=1$ and it can be calculated explicitly by using the commutation relations given in (13). Now consider the general solution

(18) satisfying (1) and (2). Recall $\nabla_i=(i/R_i)\overline{X_i}$. For $\overline{X_i}$, which was defined in (9), it is easy to verify that $\Omega_0\overline{X_i}\Omega_0=-\overline{X_i}$. But since $\overline{X_i}$ do not commute with Z_i's, we see that Ω_0 is the unique solution for the equation $\Omega\overline{X_i}\Omega=-\overline{X_i}$. By definition of the functions A_i on the dual torus and by the relation (19), we have $\Omega_0 A_i(\sigma_1,\sigma_2,\sigma_3,\sigma_4)\Omega_0=A_i(-\sigma_1,-\sigma_2,-\sigma_3,-\sigma_4)$. Applying Ω_0 to the both sides of the equation (18) we see that

$$A_i(-\sigma_1,-\sigma_2,-\sigma_3,-\sigma_4)=-A_i(\sigma_1,\sigma_2,\sigma_3,\sigma_4), \tag{20}$$

which implies that the functions A_i are odd functions. If we consider a constant curvature connection ∇ on E_T, the functions A_i in (20) can be represented by a real constant and hence it vanishes. In other words the moduli space has no Higgs branch. Note that this type of solution has been studied in Ref. 8 for the ordinary torodial orbifold $\mathbb{T}^4/\mathbb{Z}_2$ under the name of Rep. II.

In the above representation, the moduli space of constant curvature connections on E_T over $\mathbb{T}^4_\theta$ is not preserved by the $\mathbb{Z}_2$ action on E_T. So it may be more natural to consider two copies of E_T which respect the $\mathbb{Z}_2$ action and this corresponds to Rep. I of Ref. 8. Consider the bundle of the form $E_T^2=E_T\oplus E_T$ and define operators acting on E_T^2 by

$$\Omega=\begin{pmatrix}\Omega_0 & 0\\ 0 & -\Omega_0\end{pmatrix} \quad \text{and} \quad \mathbf{U}_i=\begin{pmatrix}U_i & 0\\ 0 & U_i\end{pmatrix},$$

where Ω_0 and U_i's are operators on E_T given as above and in Sec. III. Then it is easy to check that

$$\begin{aligned}\mathbf{U}_i\mathbf{U}_j&=e^{2\pi i\theta_{ij}}\mathbf{U}_j\mathbf{U}_i,\\ \Omega\mathbf{U}_i\Omega&=\mathbf{U}_i^{-1} \quad \text{and} \quad \Omega^2=1.\end{aligned} \tag{21}$$

Thus the relations (21) defines a projective module over $\mathcal{A}_\theta\rtimes\mathbb{Z}_2$. Since $\overline{X_i}$ defines a particular solution, we may write the general solution on the torus as follows:

$$X_i=\overline{X_i}+\begin{pmatrix}A_i^{11} & A_i^{12}\\ A_i^{21} & A_i^{22}\end{pmatrix}.$$

Since the matrix $\left(\begin{smallmatrix}A_i^{11} & A_i^{12}\\ A_i^{21} & A_i^{22}\end{smallmatrix}\right)$ should commute with all the $\mathbf{U}_i$'s, each entry A_i^{jk} commutes with U_i's. In other words, the operators A_i^{jk} are generated by Z_i's. Thus they can be identified with functions on the dual torus. Now the general solutions should be identified as

$$X_i=\frac{R_i}{i}\nabla_i+\begin{pmatrix}A_i^{11}(\sigma_j) & A_i^{12}(\sigma_j)\\ A_i^{21}(\sigma_j) & A_i^{22}(\sigma_j)\end{pmatrix}. \tag{22}$$

By applying Ω we find

$$\begin{pmatrix}A_i^{11}(-\sigma_j) & A_i^{12}(-\sigma_j)\\ A_i^{21}(-\sigma_j) & A_i^{22}(-\sigma_j)\end{pmatrix}=\begin{pmatrix}-A_i^{11}(\sigma_j) & A_i^{12}(\sigma_j)\\ A_i^{21}(\sigma_j) & -A_i^{22}(\sigma_j)\end{pmatrix}.$$

Note that the diagonal entries of the matrix in (22) are odd functions on the dual torus, and this fact will be used in finding the moduli space below. Meanwhile, the off-diagonal entries are even fuctions of σ. Here, the gauge transformation should be invariant under Ω implementing the $\mathbb{Z}_2$ quotient condition. This implies that the gauge parameter in general should be given by $\Lambda=\left(\begin{smallmatrix}\lambda_{ev}^{11} & \lambda_{od}^{12}\\ \lambda_{od}^{21} & \lambda_{ev}^{22}\end{smallmatrix}\right)$, where the subscript ev or od indicates an even or odd function of σ. This indicates to us that not all the $U(2)$ group acts. We now consider the constant curvature connection ∇ on E_T considered in Sec. III. In this case, as discussed in Rep. II, we have constant gauge field in (22).

Thus the diagonal entries vanish and the bundle becomes singular at the fixed points. For the ordinary case this has been related to the existence of two-brane charge at the collapsing two-cycle of the blown-up space.[21–23]

Now the solutions of the constant curvature connection in this case are given by

$$X_i=\overline{X_i}+\begin{pmatrix} 0 & A_i^{12}(\sigma_j) \\ A_i^{12\dagger}(\sigma_j) & 0 \end{pmatrix}.$$

One of the A_i components can be gauged away by constant gauge transformation of the type $\left(\begin{smallmatrix}\lambda & 0\\ 0 & \lambda\end{smallmatrix}\right)$ which can be decomposed into two parts, one proportional to the identity and the other proportional to $\sigma_3=\left(\begin{smallmatrix}1 & 0\\ 0 & -1\end{smallmatrix}\right)$. Since we are only considering constant gauge transformations in dealing with the moduli space, the noncommutativity does not affect the result as in Sec. III. The remaining component of A_i has translational symmetry of the commutative four-torus. This fact together with a residual guage symmetry σ_3 now yields a Higgs branch moduli space of constant curvature connections to be an ordinary torodial orbifold $\mathbb{T}^4/\mathbb{Z}_2$.

For the uncompactified X_ν sector, the solution is the same as in the commutative case;[8] the moduli becomes $\mathbb{R}^5\times\mathbb{R}^5$ when $A_i=0$, and when $A_i\neq 0$ the transverse moduli becomes $\mathbb{R}^5$ for generic points in $\mathbb{T}^4/\mathbb{Z}_2$, and $\mathbb{R}^5\times\mathbb{R}^5$ at the fixed points in $\mathbb{T}^4/\mathbb{Z}_2$. Thus this can be viewed as a fibration over the Higgs branch of $\mathbb{T}^4/\mathbb{Z}_2$, with the fiber $\mathbb{R}^5$ at a generic point and with the fiber $\mathbb{R}^5\times\mathbb{R}^5$ at the orbifold fixed points as suggested in the commutative case.[8]

For the ordinary $\mathbb{T}^4$, the discussion above corresponds to the construction of the theory of zero branes on $\mathbb{T}^4/\mathbb{Z}_2$. We first considered a T-duality on the covering torus $\mathbb{T}^4$ to a dual torus $\hat{\mathbb{T}}^4$ and then project to $\hat{\mathbb{T}}^4/\mathbb{Z}_2$. So, for N identical D0-branes on $\mathbb{T}^4/\mathbb{Z}_2$ we need $2N$ zero branes on $\mathbb{T}^4$. This is described by $U(2N)$ gauge theory and the gauge group is broken down to $U(N)\times U(N)$. In Ref. 8, it has been shown that the moduli space of the flat connections is identified with $\mathbb{T}^4/\mathbb{Z}_2$. In fact our earlier analysis on the moduli space of constant curvature connections is exactly the same as the one in Ref. 8.

V. CONCLUSION AND PROSPECT

In this article, we construct a bundle on noncommutative toroidal orbifold $\mathbb{T}^4_\theta/\mathbb{Z}_2$. We start with the construction of a bundle on noncommutative $\mathbb{T}^4$ *a la* Rieffel[11] and find a CDS type solution of M(atrix) theory compactified on the noncommutative four-torus. There, we also show explicitly that the dual tori are actually related to each other through SO(4,4$|\mathbb{Z}$) transformations. Based on our explicit CDS type solution on noncommutative $\mathbb{T}^4$, we find its $\mathbb{Z}_2$ orbifold solutions, Rep. I and Rep. II, by looking into the systems of D0-branes on the covering space projected onto their invariant parts under the discrete symmetry group. From the solutions obtained, we study the moduli space of equivariant constant curvature connections. The Higgs branch moduli space has been identified with the ordinary toroidal orbifold in the Rep. I case where we consider two copies of a bundle over $\mathbb{T}_\theta$ which are invariant under the $\mathbb{Z}_2$ action on $\mathbb{T}_\theta$. In the Rep. II case, the moduli space has no Higgs branch. In conclusion, in the noncommutative $\mathbb{T}^4/\mathbb{Z}_2$ case the moduli space has the same form as its commutative counterpart.

In Ref. 18, the moduli space of D0-branes on commutative $\mathbb{T}^4$ with torons of $U(N)$ Yang–Mills theory was given as $(\mathbb{T}^4)^{p_1}/S_{p_1}\times(\mathbb{T}^4)^{p_2}/S_{p_2}$ where the $U(N)$ gauge group is broken down into $U(k_1)\times U(k_2)$ satisfying $k_1+k_2=N$, and $p_i=gcd(k_i,m_i)$, $i=1,2$ with fluxes m_i of $U(k_i)$. Its extension to the noncommutative case has been recently studied in Ref. 17 using 't Hooft's SU(N) solution of nontrivial twists,[24] and the resulting moduli space of connections turned out to be of the same form, $(\mathbb{T}^4)^{p_1}/S_{p_1}\times(\mathbb{T}^4)^{p_2}/S_{p_2}$. We expect that the same holds for the noncommutative toroidal $\mathbb{Z}_2$ orbifold case.

Note added: After completion of our article, a related paper[25] has appeared which has some overlap with our paper. Their methodology to get the relevant moduli spaces is to use the theory of representation of Heisenberg algebra defined by the commutation relations of a fixed connec-

tion. On the other hand, our approach is the usual one in that we construct a module on $\mathbb{T}^4_\theta$ with explicit computation, and then consider the $\mathbb{Z}_2$ orbifold condition on this module finding the moduli space in the specific cases.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 42, NUMBER 6 JUNE 2001

A class of integrable Davey–Stewartson type systems

Attilio Maccari[a)]
Technical Institute ''G. Cardano,'' Piazza della Resistenza 1, 00015 Monterotondo, Rome, Italy

(Received 16 January 2001; accepted for publication 5 March 2001)

A new integrable Davey–Stewartson type class of systems of partial differential equations in $2+1$ dimensions is derived from a previously known integrable equation by means of an asymptotically exact nonlinear reduction method based on Fourier expansion and spatio–temporal rescaling. The integrability by the inverse scattering method is explicitly demonstrated, because the reduction technique is applied to the Lax pair of the starting equation and the corresponding Lax pair of the class of systems of equations is found. The particular characteristics of the reduction method imply that the new systems are likely to be of applicative relevance. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1370396]

I. INTRODUCTION

Many nonlinear evolution partial differential equations (PDEs), for instance the nonlinear Schrodinger and the Davey–Stewartson equations, are both of wide applicative relevance and integrable, i.e., characterized by a very simple mathematical structure and solvable or via the inverse scattering method (*S*-integrable) or via an appropriate change of variables (*C*-integrable).

A simple explanation of this fact is based on the observation that very large classes of nonlinear evolution PDEs in $1+1$ and $2+1$ dimensions with a dispersive linear part can be reduced, by a limiting procedure involving the wave modulation induced by weak nonlinear effects, to a very limited number of ''universal'' nonlinear evolution PDEs. Moreover, the same model equations obtained in this way appear in many applicative situations (for instance in plasma physics, nonlinear optics, hydrodynamics, etc.), where weakly nonlinear effects are important.[1–4]

The reduction method preserves integrability and then the model equations are likely to be integrable; it is sufficient that the very large class of equations from which they are obtainable contains just one integrable equation, provided the limiting procedure preserves integrability and then the property of integrability is inherited through this limiting technique. Obviously, the last statement about the integrability is based on heuristic considerations and could not be characterized as a rigorous theorem, because no precise definition of integrability is available for nonlinear evolution PDEs.

Thus this approach, besides explaining why certain model equations are integrable and applicable, provides a powerful tool to investigate the relation among different integrable equations, to test the integrability of nonlinear evolution PDEs, and, most importantly, to identify integrable evolution equations that are likely to be of applicative relevance.

In preceding papers, this method has been applied to certain integrable equations in $2+1$ dimensions. The most interesting results are that the Davey–Stewarston equation[5,6] is the typical model equation in $2+1$ dimensions, while new integrable nonlinear PDEs can be obtained together with their Lax pair.[7–10] Moreover, the reduction method has been used to derive two equations of applicative relevance in plasma physics.[11,12]

The basic idea of the reduction method is to consider a nonlinear evolution PDE whose linear part is dispersive; as it is well known that the linear evolution is most appropriately described in terms of Fourier modes and each Fourier mode evolves with constant amplitude and an associated group velocity, which represents the speed with which a wave packet peaked at that Fourier mode

a)Electronic mail: solitone@yahoo.it

would move in configuration space. To evaluate the weak nonlinear effects it is convenient to consider a specific Fourier mode and follow it by going over to a frame of reference that moves with its group velocity. The weak nonlinear effects may involve a non-negligible contribution, because they give rise to a modulation of the amplitude of that Fourier mode (that would remain constant in the absence of nonlinear effects). The modulation is best described in terms of rescaled ''coarse grained'' and ''slow'' variables, which permit us to consider the weak nonlinear effects on larger space and time scales. Indeed, the first step of the reduction method is to use a moving frame of reference with the introduction of the slow variables

$$\xi=\varepsilon^p(x-V_1t),\ \eta=\varepsilon^p(y-V_2t),\ \tau=\varepsilon^q t,$$
$$p>0,q>0, \tag{1.1}$$

where $V_1=V_1(K_1,K_2), V_2=V_2(K_1,K_2)$ are the components of the group velocity $\mathbf{V}(\mathbf{K}) \equiv (V_1(K_1,K_2),V_2(K_1,K_2))$ of the linearized equation, i.e., of the equation obtained after neglecting all the nonlinear terms, and ε is the expansion parameter, supposed to be sufficiently small. Therefore it is demonstrated that the function which represents the amplitude modulation satisfies, in terms of the rescaled, slow variables, evolution equations having a universal character; since the coarse-grained nature of the new variables implies that only certain general features of the nonlinear interaction are important.

In this paper we expose an interesting extension of this approach. If the original nonlinear evolution PDE, which is the starting point for the reduction method, has a linear part characterized by the fact that two (or more) Fourier modes have the same group velocity, then we consider a solution that in the linear limit is a superposition (of course with constant coefficients) of these modes. As a consequence the nonlinear effects induce a modulation of the amplitudes of these modes, which also accounts for their interaction. In particular we consider the equation[13,14] integrable by means of the spectral transform.[15,16]

$$U_t-U_{xxxxx}-5U_{xxy}+5W_y-5U_xU_{xx}-5UU_{xxx}-5U^2U_x-5UU_y-5U_xW=0$$
$$W_x=U_y, \tag{1.2}$$

where $U=U(x,y,t)$, $W=W(x,y,t)$ and the subscripts denote partial differentiation. Applying the reduction method, a new class of integrable systems of nonlinear evolution PDEs depending on two real parameters (a,b) can be derived

$$i\Psi_\tau+L_1\Psi+\delta_1\alpha\Psi+\delta_2\beta\Psi+\delta_3|\Psi|^2\Psi+\delta_4|\Phi|^2\Psi=0, \tag{1.3a}$$

$$i\Phi_\tau+L_2\Phi+\delta_5\alpha\Phi+\delta_6\beta\Phi-\delta_3|\Phi|^2\Phi+\delta_7|\Psi|^2\Phi=0, \tag{1.3b}$$

$$\alpha_\xi+\alpha_\eta+\beta_\eta+(|\Psi|^2)_\xi-(|\Phi|^2)_\xi=0,\quad \beta_\xi=\delta_8\alpha_\eta, \tag{1.3c}$$

where the linear differential operators L_1 and L_2 are given by

$$L_1=\frac{(a+2b)^2(b^2-2a^2+ab)}{(a-b)^4}\frac{\partial^2}{\partial\xi^2}+\frac{2(a+2b)}{b-a}\frac{\partial^2}{\partial\xi\partial\eta}+\frac{\partial^2}{\partial\eta^2}, \tag{1.4a}$$

$$L_2=\frac{9bc(a+2b)^2}{(a-b)^3(4b-a)}\frac{\partial^2}{\partial\xi^2}+\frac{2a(a+2b)}{c(b-a)}\frac{\partial^2}{\partial\xi\partial\eta}+\frac{a}{c}\frac{\partial^2}{\partial\eta^2}, \tag{1.4b}$$

and

$$\delta_1=-10a,\quad \delta_2=\frac{10a(a+2b)}{(b-a)},\delta_3=\frac{10}{3}(b-a), \tag{1.4c}$$

$$\delta_4 = 10a + \frac{50(ab+2a^2+9bc)(4ab-a^2+ac+2bc)}{(a(61a-13a^2-305b)+b(161a^2-48b^2-504ab)+c(61a-305b-127ab-216b^2-61a^2))} + \frac{50a(ab+2a^2-9bc)(4ab-a^2-ac-2bc)}{(a(61a-13a^2-305b)+b(161a^2-48b^2-504ab)-c(61a-305b-127ab-216b^2-61a^2))}, \tag{1.4d}$$

$$\delta_5 = 10c, \quad \delta_6 = \frac{10c(a+2b)}{(b-a)}, \quad \delta_8 = -\frac{(a+2b)}{a(a-b)^2}, \tag{1.4e}$$

$$\delta_7 = 10c + \frac{50(2c^2+9ba+cb)(4ab-a^2+ac+2ba)}{(a(61a-305b-127ab-216b^2-61a^2)+b(161a^2-48b^2-504ab)+c(61a-13a^2-305b))} + \frac{50(2c^2+9ba-cb)(4ab-a^2-ac+2ba)}{(a(61a-305b-127ab-216b^2-61a^2)+b(161a^2-48b^2-504ab)-c(61a-13a^2-305b))}, \tag{1.4f}$$

where

$$c = \sqrt{\frac{a(4b-a)}{3}}. \tag{1.4g}$$

In the system of equations (1.3), $\Psi = \Psi(\xi,\eta,\tau)$ and $\Phi = \Phi(\xi,\eta,\tau)$ are complex, while $\alpha = \alpha(\xi,\eta,\tau)$ and $\beta = \beta(\xi,\eta,\tau)$ are real.

The paper is organized as follows. In Sec. II we apply the reduction method to the starting equation (1.2) and obtain the new system of equations (1.3). Reductions to known integrable equations are discussed. In Sec. III we discuss in some detail how the reduction method can be applied to the Lax pair of Eq. (1.2) and derive the Lax pair of the system of equations (1.3). Finally in Sec. IV we recapitulate the most important results and indicate some possible extensions.

II. A NEW INTEGRABLE SYSTEM IN 2+1 DIMENSIONS

In this section we derive a *S*-integrable system of nonlinear equations, by means of an extension of the reduction method, which is possible if the group velocity, relative to the linearized starting equation, is equal for two Fourier modes with different wave vector $\mathbf{K} = (K_1, K_2)$.

We can consider that particular solution which in the linear approximation is a superposition of these modes. The nonlinear term induces a modulation of their amplitudes, which is due to their interaction. The validity of the method is easily understood, because the variable transformation (1.1) operates in the same way upon the two Fourier modes which move with the same velocity and then can interfere.

The final system of nonlinear PDEs is relative to the modulation of the amplitudes of the two Fourier modes and inherits the integrability property of the starting equation, as it will be demonstrated in Sec. III, applying the reduction method to the Lax pair. The linear dispersive part of the starting equation (1.2) admits as a solution a Fourier mode, with a group velocity $\mathbf{V}(\mathbf{K}) = (V_1(K_1,K_2), V_2(K_1,K_2))$,

$$V_1(K_1,K_2) = -5\left(K_1^2 - \frac{K_2}{K_1}\right)^2, \quad V_2(K_1,K_2) = 5\left(K_1^2 + 2\frac{K_2}{K_1}\right), \tag{2.1}$$

where

$$\mathbf{V}(\mathbf{K}) = \frac{\partial \omega}{\partial \mathbf{K}} \tag{2.2}$$

and $\omega = \omega(K_1,K_2)$ is the dispersion relation.

Two Fourier modes $\mathbf{K}_A = (K_1,K_2)$, $\mathbf{K}_B = (K_3,K_4)$ possess equal group velocity, when

$$K_3=\sqrt{\frac{4K_2-K_1^3}{3K_1}},\quad K_4=\sqrt{\frac{(4K_2-K_1^3)}{3K_1}}\,\frac{K_2+2K_1^3}{3K_1}. \tag{2.3}$$

We can use the transformation (1.1) which is identical for the two Fourier modes and introduce the following formal asymptotic Fourier expansion:

$$U(x,y,t)=\sum_{n_1,n_2=-\infty}^{+\infty}\varepsilon^{\gamma_{n_1n_2}}\psi_{n_1n_2}(\xi,\eta,\tau;\varepsilon)\exp\{i(n_1z_1+n_2z_2)\}, \tag{2.4}$$

where $z_1=K_1x+K_2y-\omega t$, $z_2=K_3x+K_4y-\omega t$, $\gamma_{n_1n_2}=|n_1|+|n_2|$ for $n_1,n_2\neq 0$, $\gamma_{00}=r$, a nonnegative rational number which will be fixed afterward and $\psi_{n_1n_2}(\xi,\eta,\tau;\varepsilon)=\psi^*_{-n_1-n_2}(\xi,\eta,\tau;\varepsilon)$ (recall that $U(x,y,t)$ is real). The unknown functions $\psi_{n_1n_2}$s depend on ε and it is supposed that their limit for $\varepsilon\to 0$ exists and is finite. In the following this limit will be denoted by $\psi_{n_1n_2}(\xi,\eta,\tau)$. Moreover we suppose that they can be expanded in power series of ε, i.e.,

$$\psi_{n_1n_2}(\xi,\eta,\tau;\varepsilon)=\sum_{i=0}^{\infty}\varepsilon^i\psi^{(i)}_{n_1n_2}(\xi,\eta,\tau),\quad \psi_{n_1n_2}(\xi,\eta,\tau)=\psi^{(0)}_{n_1n_2}(\xi,\eta,\tau). \tag{2.5}$$

We now introduce an analog Fourier expansion

$$w(x,y,t)=\sum_{n_1,n_2=-\infty}^{+\infty}\varepsilon^{\tilde{\gamma}_{n_1n_2}}\varphi_{n_1n_2}(\xi,\eta,\tau;\varepsilon)\exp\{i(n_1z_1+n_2z_2)\} \tag{2.6}$$

and obtain

$$\varphi_{n_1n_2}=(n_1K_2+n_2K_4)(n_1K_1+n_2K_3)^{-1}\psi_{n_1n_2}+O(\varepsilon^{p_1},\varepsilon^{p_2}). \tag{2.7}$$

In the following for simplicity we use the abbreviations $\psi^{(0)}_{01}=\Psi$, $\psi^{(0)}_{01}=\Phi$, $\psi^{(0)}_{00}=\alpha$ (and $\phi^{(0)}_{n_1n_2}=\phi_{n_1n_2}$, $\phi^{(0)}_{00}=\beta$).

The final goal is to obtain the evolution equation for the modulation amplitudes $\Psi=\Psi(\xi,\eta,\tau)$ and $\Phi(\xi,\eta,\tau)$ and to understand how it is modified by choosing different wave numbers. We insert the expansions (2.4) and (2.6) into Eq. (1.3) and consider the different equations obtained considering the coefficients of the Fourier modes. From Eq. (1.3b) we get

$$\phi_{10}=\frac{K_2}{K_1}\Psi,\quad \phi^{(p)}_{10}=\frac{i}{K_1}\left(\frac{K_2}{K_1}\Psi_\xi-\Psi_\eta\right),\quad \phi^{(2p)}_{10}=\frac{1}{K_1^2}\left(\Psi_{\xi\eta}-\frac{K_2}{K_1}\Psi_{\xi\xi}\right), \tag{2.8a}$$

$$\phi_{01}=\frac{K_4}{K_3}\Phi,\quad \phi^{(p)}_{01}=\frac{i}{K_3}\left(\frac{K_4}{K_3}\Phi_\xi-\Phi_\eta\right),\quad \phi^{(2p)}_{01}=\frac{1}{K_3^2}\left(\Phi_{\xi\eta}-\frac{K_4}{K_3}\Phi_{\xi\xi}\right), \tag{2.8b}$$

$$\beta_\xi=\alpha_\eta. \tag{2.8c}$$

It is more convenient to separate the contributions of the linear and nonlinear parts

$$\varepsilon^{\gamma_{n_1n_2}}D_{n_1n_2}\psi_{n_1n_2}=\varepsilon^2F_{n_1n_2}, \tag{2.9}$$

where $D_{n_1n_2}$ is a linear differential operator acting on $\psi_{n_1n_2}(\xi,\eta,\tau)$ and $F_{n_1n_2}$ is the contribution of the nonlinear part. The operator $D_{n_1n_2}$ is

$$D_{n_1n_2}=(-in_1\omega-in_2\omega+\varepsilon^q\partial_\tau-V_1\varepsilon^p\partial_\xi-V_2\varepsilon^p\partial_\eta)-(in_1K_1+in_2K_3+\varepsilon^p\partial_\xi)^5$$
$$-5(in_1K_2+in_2K_4+\varepsilon^p\partial_\eta)(in_1K_1+in_2K_3+\varepsilon^p\partial_\xi)^2$$
$$+5\left(\frac{K_2}{K_1}-\frac{i}{K_1}\varepsilon^p\partial_\eta+\frac{iK_2}{K_1^2}\varepsilon^p\partial_\xi+\frac{1}{K_1^2}\varepsilon^{2p}\partial_{\xi\eta}-\frac{K_2}{K_1^3}\varepsilon^{2p}\partial_{\xi\xi}\right)+O(\varepsilon^{3p}). \tag{2.10}$$

$F_{n_1n_2}$ can be derived, evaluating the importance of the different terms, which originate from the interference of the Fourier amplitudes $\psi_{n_1n_2}(\xi,\eta,\tau)$ and $\varphi_{n_1n_2}(\xi,\eta,\tau)$:

$$F_{00}=10\left(\frac{K_2}{K_1}-K_1^2\right)(|\Psi|^2)_\xi\varepsilon^p-10\left(\frac{K_2}{K_1}-K_1^2\right)(|\Phi|^2)_\xi\varepsilon^p+O(\varepsilon^{p+2},\varepsilon^{p+2r}), \tag{2.11a}$$

$$F_{10}=(10iK_2-25iK_1^3)\psi_2\psi^*+(5iK_2-5iK_1^3)\psi\alpha+5iK_1\beta\psi+5iK_1|\psi|^2\psi$$
$$+5\left(K_2+K_4-K_1K_3^2+\frac{K_1K_4}{K_3}-K_1(K_1+K_3)^2-K_3\frac{K_2+K_4}{K_1+K_3}\right)\psi_{11}\psi^*$$
$$+5\left(K_2-K_4-K_1K_3^2+\frac{K_1K_4}{K_3}-K_1(K_1-K_3)^2+K_3\frac{K_2-K_4}{K_1-K_3}\right)\psi_{1-1}\psi^*+O(\varepsilon^{p+r-1},\varepsilon^{2p}) \tag{2.11b}$$

$$F_{20}=10(K_2-K_1^3)\Psi^2+O(\varepsilon^p), \tag{2.11c}$$

and so on.

After taking $q=2, p_1=p_2=1$, and $r=2$ for the proper balance of terms, the equations for the Fourier modes can be obtained at the lowest order for $n_1=0$, $n_2=0$, $n_1=1$, $n_2=\pm1$ and $n_1=2$, $n_2=0$, $n_1=0$, $n_2=2$ (with $\psi_{00}=\alpha$, $\varphi_{00}=\beta$, $\psi_{10}=\Psi$, $\psi_{01}=\Phi$),

$$V_1\alpha_\xi+V_2\alpha_\eta-5\beta_\eta+10\left(\frac{K_2}{K_1}-K_1^2\right)(|\Psi|^2)_\xi-10\left(\frac{K_2}{K_1}-K_1^2\right)(|\Phi|^2)_\xi=0, \tag{2.12a}$$

$$\psi_{1\pm1}=\frac{5\left[(K_2\pm K_4)-(K_1\pm K_3)(K_1^2+K_3^2)-\frac{K_1K_4}{K_3}\mp\frac{K_3K_2}{K_1}\right]}{(-\omega_1\pm\omega_2)-(K_1\pm K_3)^5+5(K_1\pm K_3)^2(K_2\pm K_4)+5\frac{(K_2\pm K_4)^2}{K_1\pm K_3}}\Psi\Phi_\pm, \tag{2.12b}$$

$$\psi_{20}=\frac{1}{3K_1^2}\Psi^2,\quad \psi_{02}=\frac{1}{3K_3^2}\Phi^2, \tag{2.12c}$$

where $\Phi_+=\Phi$, $\Phi_-=\Phi^*$, and for $n_1=1$, $n_2=0$, using (2.12c), we arrive at the nonlinear evolution equation

$$i\Psi_\tau+5\left(K_2-2K_1^3+\frac{K_2^2}{K_1^3}\right)\Psi_{\xi\xi}+10\left(K_1-\frac{K_2}{K_1^2}\right)\Psi_{\xi\eta}+\frac{5}{K_1}\Psi_{\eta\eta}+5(K_2-K_1^3)\alpha\Psi+5K_1\beta\Psi$$
$$+\frac{10}{3}\left(\frac{K_2}{K_1^2}-K_1\right)|\Psi|^2\Psi-5\left(K_2+K_4-K_1K_3^2+\frac{K_1K_4}{K_3}-K_1(K_1+K_3)^2-K_3\frac{K_2+K_4}{K_1+K_3}\right)\psi_{11}\Phi^*$$
$$-5\left(K_2-K_4-K_1K_3^2+\frac{K_1K_4}{K_3}-K_1(K_1-K_3)^2+K_3\frac{K_2-K_4}{K_1-K_3}\right)\psi_{1-1}\Phi=0. \tag{2.13}$$

In a similar way for $n_1=0$, $n_2=1$, we obtain

$$i\Psi_\tau+5\left(K_2-2K_1^3+\frac{K_2^2}{K_1^3}\right)\Psi_{\xi\xi}+10\left(K_1-\frac{K_2}{K_1^2}\right)\Psi_{\xi\eta}+\frac{5}{K_1}\Psi_{\eta\eta}+5(K_2-K_1^3)\alpha\Psi+5K_1\beta\Psi$$

$$+\frac{10}{3}\left(\frac{K_2}{K_1^2}-K_=\right)|\Psi|^2\Psi+10K|\Phi|^2\Psi-5\left(K_2+K_4-K_1K_3^2+\frac{K_1K_4}{K_3}-K_1(K_1+K_3)^2\right.$$

$$\left.-K_3\frac{K_2+K_4}{K_1+K_3}\right)\psi_{11}\Psi^*-5\left(K_4-K_2+K_1K_3^2-\frac{K_1K_4}{K_3}+K_1(K_1-K_3)^2-K_3\frac{K_2-K_4}{K_1-K_3}\right)\psi_{-11}\Psi=0. \tag{2.14}$$

This system must be integrable by the spectral transform, because it has been derived from an *S*-integrable equation, and that will be explicitly demonstrated in Sec. III.

If $K_2\neq K_1^3$, using (2.12b) and after the cosmetic rescaling

$$\xi'=\frac{V_2}{V_1}\sqrt{\frac{K_1}{5}}\,\xi,\quad \eta'=\sqrt{\frac{K_1}{5}}\,\eta, \tag{2.15a}$$

$$\chi'=\frac{V_1}{10\left(\frac{K_2}{K_1}-K_1^2\right)}\chi,\quad \Phi'=\frac{V_1}{2V_2\left(K_1^2-\frac{K_2}{K_1}\right)}\Phi, \tag{2.15b}$$

and with the introduction of two real parameters

$$a=K_1,\quad b=\frac{K_2}{K_1^2}, \tag{2.16a}$$

we arrive at the model equation of Davey–Stewartson type (1.3), where [see (2.3)]

$$c=K_3=\sqrt{\frac{a(4b-a)}{3}}. \tag{2.16b}$$

Integrable Davey–Stewartson type equations and system of equations have been extensively investigated by many authors.[17–21] A very detailed list of Davey–Stewartson systems and equations integrable by the inverse scattering method has been recently given.[22] The system of equations (1.3) does not appear in these papers. We expect that this new system be integrable by the inverse scattering method, because it has been obtained from an integrable equation and the property of integrability is supposed to keep through the application of the reduction method. The integrability of the system of equations (1.3) will be explicitly demonstrated in Sec. III.

Let us now consider the implications of these results in the context of the nonlinear evolution PDEs in $2+1$ dimensions. If we take $\Phi=0$, we obtain the equation

$$i\Psi_\tau+L_1\Psi+\delta_1\alpha\Psi+\delta_2\beta\Psi+\delta_3|\Psi|^2\Psi=0, \tag{2.17a}$$

$$\alpha_\xi+\alpha_\eta+\beta_\eta+(|\Psi|^2)_\xi=0,\quad \beta_\xi=\delta_8\alpha_\eta, \tag{2.17b}$$

where L_1, δ_1, δ_2, δ_3, δ_8 are given by (1.4a) and (1.4c). The nonlinear PDE (2.17), with trivial rescalings, coincides with the integrable equation found in a previous paper.[10]

III. THE LAX PAIR FOR THE INTEGRABLE SYSTEM OF EQUATIONS

We can also apply the reduction method to the Lax pair of the starting equation, to demonstrate explicitly the integrability by the spectral transform of the system (1.3), because in this way we identify the Lax pair that permits us to obtain a compatibility condition which reproduces the system of Eqs. (1.3).

We apply the reduction method to the Lax pair of Eq. (1.2). The Lax operators are

$$L=\frac{\partial}{\partial y}+\frac{\partial^3}{\partial x^3}+U(x,y,t)\frac{\partial}{\partial x},\quad L\phi(x,y,t)=0, \tag{3.1}$$

$$A=9\frac{\partial^5}{\partial x^5}+15U(x,y,t)\frac{\partial^3}{\partial x^3}+15U_x(x,y,t)\frac{\partial^2}{\partial x^2}$$
$$+5(2U_{xx}(x,y,t)+U^2(x,y,t)-W(x,y,t))\frac{\partial}{\partial x}, \tag{3.2}$$

with

$$\phi_t(x,y,t)+A\phi(x,y,t)=0. \tag{3.3}$$

It can be verified by direct substitution that the operator relation

$$L_T=i[L,A]=i(LA-AL) \tag{3.4}$$

reproduces Eq. (1.2).

The function $\phi(x,y,t)$ can be expanded in Fourier modes in the form

$$\phi(x,y,t)=\sum_{n_1,n_2=-\infty[n_1\text{odd},n_2\text{even}]}^{+\infty}\varepsilon^{\gamma_{n_1n_2}}\phi_{n_1n_2}(\xi,\eta,\tau;\varepsilon)\exp\left[i\left(\frac{n_1}{|n_1|}(\lambda_1x+\lambda_2y+\lambda_3t)+\frac{n_1}{2}z_1\right.\right.$$
$$\left.\left.+\frac{n_2}{2}z_2\right)\right]+\sum_{n_1,n_2=-\infty[n_1\text{even},n_2\text{odd}]}^{+\infty}\varepsilon^{\gamma_{n_1n_2}}\phi_{n_1n_2}(\xi,\eta,\tau;\varepsilon)\exp\left[i\left(\frac{n_2}{|n_2|}(\lambda_4x+\lambda_5y+\lambda_6t)\right.\right.$$
$$\left.\left.+\frac{n_1}{2}z_1+\frac{n_2}{2}z_2\right)\right], \tag{3.5}$$

with $z_1=K_1x+K_2y-\omega_1t$, $z_2=K_3x+K_4y-\omega_2t$, $\phi_{n_1n_2}(\xi,\eta,\tau;\varepsilon)$'s which parametrically depend on ε and remain finite when $\varepsilon\to0$, and finally $\gamma_{n_1n_2}$ non-negative rational numbers and $\lambda_j, j=1,...6$, real constants to be determined later on.

Inserting now the expression for $\phi(x,y,t)$ in (3.1), we derive a series of relations which are generated by the coefficients of the Fourier modes. Each relation must be valid for a given order of approximation in ε.

In particular, for the fundamental harmonics $n_1=\pm1,n_2=\pm1$, and $n_1=1,n_2=-2$, or $n_1=-2,n_2=1$, considering terms $O(\varepsilon^0)$ in (3.1) and (3.3), we obtain

$$\left(\pm\frac{iK_1}{2}\pm i\lambda_1\right)^3+\left(\pm\frac{iK_2}{2}\pm i\lambda_2\right)=0, \tag{3.6a}$$

$$\left(\mp\frac{i\omega}{2}\pm i\lambda_3\right)+9\left(\pm\frac{iK_1}{2}\pm i\lambda_1\right)^5=0, \tag{3.6b}$$

and then

$$\lambda_1=\frac{K_3}{2},\quad \lambda_2=\frac{K_4}{2},\quad \lambda_3=-\frac{K_3}{2}\left(K_1^4+\frac{K_2^2}{K_1^2}+7K_1K_2\right). \tag{3.7}$$

As a consequence, we understand that the harmonics

$$\phi_{10},\phi_{-10},\phi_{01},\phi_{0-1},\phi_{-21},\phi_{1-2} \tag{3.8}$$

are fundamental, i.e., for them $\gamma_{n_1n_2}$ assumes the smallest value, i.e., $\gamma_{n_1n_2}=0$. In particular the harmonics $\phi_{10},\phi_{-10},\phi_{1-2},\phi_{-12}$ are decoupled with respect to the other harmonics $\phi_{01},\phi_{0-1},\phi_{-21},\phi_{2-1}$ and we get two separate but identical spectral problems.

The successive order ε for Eq. (3.1) allow us to obtain the new spectral problem, because all the $\phi_{n_1n_2}$s may be expressed by means of the fundamental harmonics (3.8), which are connected through the relations

$$\frac{3}{4}(K_1+K_3)^2\phi_{\pm10,\xi}-\phi_{\pm10,\eta}\pm\frac{i}{2}(K_1+K_3)\Psi_\pm\phi_{\mp10}\mp\frac{i}{2}(K_1-K_3)\Phi_\pm\phi_{\pm1\mp2}=0, \tag{3.9}$$

$$\frac{3}{4}(K_1-K_3)^2\phi_{\pm1\mp2,\xi}-\phi_{\pm1\mp2,\eta}\mp\frac{i}{2}(K_1+K_3)\Phi_\mp\phi_{\pm10}=0. \tag{3.10}$$

By means of the variable rescaling (2.15), and introducing the 4×4 matrix operator L, we arrive at the final form

$$L\hat{\varphi}=0, \tag{3.11}$$

where

$$L=\begin{pmatrix}L_{11}&L_{12}\\L_{21}&L_{22}\end{pmatrix}, \tag{3.12a}$$

$$L_{11}=\begin{pmatrix}\partial_\eta+\dfrac{3(a+c)^2(a+2b)}{4a(a-b)^2}\partial_\xi & -i\sqrt{\dfrac{5}{a}}\dfrac{(a+c)}{2}\Psi\\ i\sqrt{\dfrac{5}{a}}\dfrac{(a+c)}{2}\Psi^* & \partial_\eta+\dfrac{3(a+c)^2(a+2b)}{4a(a-b)^2}\partial_\xi\end{pmatrix}, \tag{3.12b}$$

$$L_{12}=\begin{pmatrix}i\sqrt{\dfrac{5}{a}}\dfrac{(a-c)}{2}\Phi & 0\\ 0 & -i\sqrt{\dfrac{5}{a}}\dfrac{(a-c)}{2}\Phi^*\end{pmatrix}, \tag{3.12c}$$

$$L_{21}=\begin{pmatrix}i\sqrt{\dfrac{5}{a}}\dfrac{(a+c)}{2}\Phi^* & 0\\ 0 & -i\sqrt{\dfrac{5}{a}}\dfrac{(a-c)}{2}\Phi\end{pmatrix}, \tag{3.12d}$$

$$L_{22}=\begin{pmatrix}\partial_\eta+\dfrac{3(a-c)^2(a+2b)}{4a(a-b)^2}\partial_\xi & 0\\ 0 & \partial_\eta+\dfrac{3(a-c)^2(a+2b)}{4a(a-b)^2}\partial_\xi\end{pmatrix}, \tag{3.12e}$$

$$\hat{\varphi}=\begin{pmatrix}\varphi_{10}\\ \varphi_{-10}\\ \varphi_{1-2}\\ \varphi_{-1+2}\end{pmatrix}. \tag{3.12 f}$$

To calculate the temporal evolution, we must insert the expression (3.5) in (3.3) and consider the relation obtained for the different harmonics n_1, n_2 and for a given order of approximation in ε. If we consider the first order in ε, we newly obtain the spectral problem (3.11)–(3.12). Only if we take into account the next orders of approximation of Eq. (3.3), i.e., the order ε^2, can the temporal evolution be determined. However, new quantities, the corrections $\tilde{\phi}_{\pm 10}(\xi,\eta,\tau)$, $\tilde{\phi}_{\pm 1\mp 2}(\xi,\eta,\tau)$ of order ε, to the fundamental harmonics $\phi_{\pm 10}(\xi,\eta,\tau)$, $\phi_{\pm 1\mp 2}(\xi,\eta,\tau)$ appear. These unknown quantities can be eliminated in Eq. (3.3) taking advantage of the relation obtained from Eq. (3.1), considering terms of order ε^2. This elimination is possible only because Eqs. (3.1) and (3.3) are identical at the order ε. In particular, if we consider (3.1) calculated for the order ε^2 for $n_1=\pm 1, n_2=0$, $n_1=\pm 1, n_2=\mp 2$, we get

$$\begin{aligned}\tilde{\phi}_{\pm 10,\xi}&-\frac{4}{3(K_1+K_3)^2}\tilde{\phi}_{\pm 10,\eta}\pm\frac{2i}{3(K_1+K_3)}\Psi_{\pm}\tilde{\phi}_{\mp 10}\mp\frac{2i(K_1-K_3)}{3(K_1+K_3)^2}\Phi_{\pm}\tilde{\phi}_{\pm 1\mp 2}\\ &-\frac{4}{3(K_1+K_3)^2}\Big[\Psi_{\pm}\phi_{\mp 10,\xi}+\Phi_{\pm}\phi_{\pm 1\mp 2,\xi}\pm\frac{3i}{2}(K_1+K_3)\phi_{\pm 10,\xi\xi}\pm\frac{i}{2}(3K_1-K_3)\Psi_{\mp}\phi_{\pm 30}\\ &\pm\frac{i}{2}(K_1+K_3)\alpha\phi_{\pm 10}\pm\frac{i}{2}(K_1+3K_3)\Phi_{\mp}\phi_{\pm 1\pm 2}\mp\frac{i}{2}(3K_1+K_3)\Psi_{\pm 20}\phi_{\mp 30}\mp\frac{i}{2}(K_1\\ &-K_3)\psi_{\pm 1\mp 1}\phi_{\mp 1\pm 2}\Big]=0,\end{aligned} \tag{3.13a}$$

$$\begin{aligned}\tilde{\phi}_{\pm 1\mp 2,\xi}&-\frac{4}{3(K_1-K_3)^2}\tilde{\phi}_{\pm 1\mp 2,\eta}\mp\frac{2i(K_1+K_3)}{3(K_1-K_3)^2}\Phi_{\mp}\tilde{\phi}_{\pm 10}-\frac{4}{3(K_1-K_3)^2}\Big[\Phi_{\mp}\phi_{\pm 10,\xi}\pm\frac{3i}{2}(K_1\\ &-K_3)\phi_{\pm 1\mp 2,\xi\xi}\pm\frac{i}{2}(K_1-3K_3)\Phi_{\pm}\phi_{\pm 1\mp 4}\mp\frac{i}{2}(K_1+K_3)\Psi_{\pm}\phi_{\mp 1\mp 2}\pm\frac{i}{2}(3K_1\\ &-K_3)\Psi_{\mp}\phi_{\pm 3\mp 2}\pm\frac{i}{2}(K_1-K_3)\alpha\phi_{\pm 1\mp 2}\mp\frac{i}{2}(K_1+K_3)\psi_{\pm 1\mp 1}\phi_{\mp 10}\mp\frac{i}{2}(3K_1\\ &-K_3)\Psi_{\pm 20}\phi_{\mp 3\pm 2}\Big]=0.\end{aligned} \tag{3.13b}$$

To evaluate this expression we consider that $\phi_{\pm 30}, \phi_{\pm 1\pm 2}$ are connected with the fundamental harmonics [we must calculate (3.3) for $n_1=\pm 3, n_2=0$, $n_1=\pm 1, n_2=\pm 2$ at the lower order in ε]

$$\phi_{\pm 30}=\left(\frac{4(K_1+K_3)}{(3K_1+K_3)^3-4(3K_2+K_4)}\right)\Psi_{\pm}\phi_{\pm 10}, \tag{3.14a}$$

$$\phi_{\pm 1\pm 2}=\left(\frac{4(K_1+K_3)}{(K_1+3K_3)^2-4(K_2+3K_4)}\right)\Phi_{\pm}\phi_{\pm 10}. \tag{3.14b}$$

We now consider (3.3) at the order ε^2 for $n_1=\pm 1, n_2=0$, $n_1=\pm 1, n_2=\mp 2$, which furnishes the temporal evolution of the harmonics $\phi_{10}, \phi_{-10}, \phi_{1-2}$. Via the transformation (2.15) and after a lengthy calculation we arrive at the final form for the 4×4 matrix operator A which satisfies the equation

$$\hat{\phi}_t(x,y,t)+A\hat{\phi}(x,y,t)=0 \tag{3.15}$$

and is given by

$$A=\begin{pmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{pmatrix}, \tag{3.16a}$$

where

$$A_{11}=\begin{pmatrix} a_{+1}\partial_\xi^2+a_{+4}|\Psi|^2+a_{+5}|\Phi|^2+a_{+6}\beta+a_{+7}\alpha & a_{+2}\Psi_\xi+a_{+3}\Psi_\eta+a_{+8}\Psi\partial_\xi \\ a_{-2}\Psi_\xi^*+a_{-3}\Psi_\eta^*+a_{-8}\Psi^*\partial_\xi & a_{-1}\partial_\xi^2+a_{-4}|\Psi|^2+a_{-5}|\Phi|^2+a_{-6}\beta+a_{-7}\alpha \end{pmatrix}, \tag{3.16b}$$

$$A_{12}=\begin{pmatrix} a_{+9}\Phi_\xi+a_{+10}\Phi\partial_\xi+a_{+11}\Phi_\eta & a_{+12}\Psi\Phi^* \\ a_{-12}\Psi^*\Phi & a_{-9}\Phi_\xi^*+a_{-10}\Phi^*\partial_\xi+a_{-11}\Phi_\eta^* \end{pmatrix}, \tag{3.16c}$$

$$A_{21}=\begin{pmatrix} b_{+2}\Phi^*\partial_\xi+b_{+3}\Phi_\xi^*+b_{+4}\Phi_\eta^* & b_{+9}\Psi\Phi^* \\ b_{-9}\Psi^*\Phi & b_{-2}\Phi\partial_\xi+b_{-3}\Phi_\xi+b_{-4}\Phi_\eta \end{pmatrix}, \tag{3.16d}$$

$$A_{22}=\begin{pmatrix} b_{+1}\partial_\xi^2+b_{+5}|\Psi|^2+b_{+6}|\Phi|^2+b_{+7}\beta+b_{+8}\alpha & 0 \\ 0 & b_{-1}\partial_\xi^2+b_{-5}|\Psi|^2+b_{-6}|\Phi|^2+b_{-7}\beta+b_{-8}\alpha \end{pmatrix}, \tag{3.16e}$$

and

$$a_{\pm1}=\pm\frac{3i(a+2b)^2(a+c)(a+2b+9c)}{4(a-b)^4}, \tag{3.17a}$$

$$a_{\pm2}=-\frac{\sqrt{5}(a+2b)(a+c)(3a+3c-8+2b)}{4\sqrt{a}(a-b)^2}, \quad a_{\pm3}=-\frac{\sqrt{5a}}{4}(a+c), \tag{3.17b}$$

$$a_{\pm4}=\mp\frac{5}{8}(a+c)^2, \quad a_{\pm5}=\frac{5(a-c)}{2c}, \quad a_{\pm6}=\mp5i(a+2b)(a+c), \tag{3.17c}$$

$$a_{\pm8}=\frac{(a+2b)}{\sqrt{5a}(a-b)^2}\left[\frac{20a^2(a-b)^2}{3(a+c)^2}-\frac{45}{4}(a+c)^2+15a(a+c)-10a^2-5ab\right], \tag{3.17d}$$

$$a_{\pm7}=\pm i\frac{15(a+c)c}{(a-b)}, \quad a_{\pm9}=\frac{\sqrt{5}(a+2b)(c-a)}{2\sqrt{a}(a-b)^2}\left[\frac{3(a-c)}{2}+4c-\frac{a(2a+b)}{3c}\right], \tag{3.17e}$$

$$a_{\pm10}=\frac{(a+2b)}{\sqrt{5a}(a-b)^2}\left[\frac{20a^2(a-b)^2}{3(a+c)^2}-\frac{45}{4}(a-c)^2-15c(a-c)+\frac{5a}{3}(7b-4a)\right], \tag{3.17f}$$

$$a_{\pm11}=\frac{\sqrt{5a}(a-c)}{2c}, \quad a_{\pm12}=\mp\frac{5}{4}(a+c)^2, \tag{3.17g}$$

and

$$b_{\pm1}=\mp i\frac{3(a+2b)^2(a-c)(a+2b+3c)}{2(a-b)^2}, \quad b_{\pm2}=\frac{5\sqrt{a}(a+2b)(4b-a+9c)}{2\sqrt{5}(a-b)^2}, \tag{3.18a}$$

$$b_{\pm 3}=\frac{\sqrt{5}(a+2b)(a+c)(5c-3a)}{3\sqrt{a(a-b)^2}}, \quad b_{\pm 4}=\pm i\frac{\sqrt{5a}}{c}, \tag{3.18b}$$

$$b_{\pm 5}=\frac{\sqrt{5}(a-2b)(a-c)(5c-3a)}{3\sqrt{a(a-b)^2}}, \quad b_{\pm 6}=\frac{\sqrt{5}(a+2b)(a+c)(5c+3a)}{3\sqrt{a(a-b)^2}}, \tag{3.18c}$$

$$b_{\pm 7}=\pm i\frac{5(a+2b)(a-c)}{(b-a)}, \quad b_{\pm 8}=\pm i\frac{15[(a-c)^3-4(a+c)^3]}{4a(a-b)}, \tag{3.18d}$$

$$b_{\pm 9}=\pm i\frac{5(a+2b)(a+c)}{(b-a)}. \tag{3.18e}$$

The determination of the Lax pair (3.12) and (3.16)–(3.18), which satisfies Eqs. (3.11) and (3.15), resolves the problem of S-integrability of the system (1.3).

IV. CONCLUSION

We have derived a new integrable and presumably of applicative interest nonlinear evolution Davey–Stewartson type system of equations from the integrable equation (1.2), by means of an extension of a reduction method based on Fourier expansion and space–time rescalings. It reduces to a known integrable equation in the single mode case. The application of this method is restricted to the case of same group velocities for different wave numbers. Moreover, we have applied the reduction method to the Lax pair (3.1)–(3.3) of the original equation and have demonstrated the integrability property of the new system of equations, by exhibiting the corresponding Lax pair (3.11)–(3.12) and (3.15)–(3.18).

We have outlined the approach that permits us to obtain such a system of equations and the next steps will be the explicit resolution of the spectral problem and the possible identification of localized or asymptotically finite solutions.

It is also convenient to push the approach beyond its ''leading order'' application by or considering different rescalings in the two spatial variables ($p_1 \neq p_2$) or looking at special cases when some key parameters vanish, on the analogy of the case of the model equations.[7,8]

(Received 21 November 2000; accepted for publication 12 March 2001)

We give a new derivation of the Manakov and the product case integrability conditions of the Euler equations on Lie algebra so(4). Fourth first integral functionally independent of the three already known integrals is obtained explicitly for *all values* of the parameters by an algorithmic approach. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1370550]

I. INTRODUCTION

Given a system of ordinary differential equations depending on parameters, the following question arises: How does one recognize the values of the parameters for which the equations have first integrals? Except for some simple cases, this problem is very hard and no satisfying methods to solve it are known. Up to now, the most successful approach has been offered by the so-called Painlevé analysis (see Refs. 1–4), the roots of which can be found in the seminal work of Kovalevskaya on the rigid body problem.[5,6] Unfortunately, this method of high practical value, is not based on a firmly established mathematical ground. The Painlevé analysis method puts emphasis on properties of solutions as functions of complex time.

Even for Hamiltonian systems with two degrees of freedom the problem of recognizing the values of parameters for which the equations are completely integrable is largely unsolved (see Ref. 7).

The same question is also relevant for the so-called *Euler equations on Lie algebras*.[8–26] For these equations also the problem is largely open.

In this paper we study one of the simplest examples of this kind—the Euler equations on Lie algebra so(4) corresponding to a ''diagonal quadratic Hamiltonian.'' Because these equations are used here exclusively as an interesting and nontrivial example of a multiparameter family of ordinary differential equations, we write them down without any explanations of their Lie algebraic origin, which can be found for example in Refs. 8, 11, 12, 18–25. We do not discuss their physical origin—relevant information can be found in the cited papers.

Let us take $\lambda := (\lambda_1, \ldots, \lambda_6) \in \mathbb{R}^6$, and let us consider the following system:

[b)]Electronic mail: s.popov@ims.bas.bg
[c)]Electronic mail: Jean-Marie.Strelcyn@univ-rouen.fr, strelcyn@math.univ-paris13.fr

$$\frac{dx_1}{dt}=(\lambda_3-\lambda_2)x_2x_3+(\lambda_6-\lambda_5)x_5x_6,$$

$$\frac{dx_2}{dt}=(\lambda_1-\lambda_3)x_1x_3+(\lambda_4-\lambda_6)x_4x_6,$$

$$\frac{dx_3}{dt}=(\lambda_2-\lambda_1)x_1x_2+(\lambda_5-\lambda_4)x_4x_5, \tag{I.1}$$

$$\frac{dx_4}{dt}=(\lambda_3-\lambda_5)x_3x_5+(\lambda_6-\lambda_2)x_2x_6,$$

$$\frac{dx_5}{dt}=(\lambda_4-\lambda_3)x_3x_4+(\lambda_1-\lambda_6)x_1x_6,$$

$$\frac{dx_6}{dt}=(\lambda_2-\lambda_4)x_2x_4+(\lambda_5-\lambda_1)x_1x_5.$$

The above-mentioned equations form the system of Euler equations on Lie algebra so(4) corresponding to the diagonal quadratic ''Hamiltonian'' $\frac{1}{2}\Sigma_{i=1}^{6}\lambda_i x_i^2$. It always has three first integrals:

$$H_1=x_1x_4+x_2x_5+x_3x_6, \quad H_2=\sum_{i=1}^{6}x_i^2, \quad H_3=\sum_{i=1}^{6}\lambda_i x_i^2. \tag{I.2}$$

Unless all the $(\lambda_i)_{1\leqslant i\leqslant 6}$ are equal, in which case system (I.1) is trivial, these three integrals are functionally independent. Thus from now on we assume that at least two $(\lambda_i)_{1\leqslant i\leqslant 6}$ are distinct.

The first integrals H_1 and H_2 are intimately related to the Lie algebra so(4). They represent its ''Casimir functions'' (see, e.g., Refs. 11 and 18).

To be integrable (Ref. 9, Sec. 28), system (I.1) needs a supplementary fourth first integral H_4, functionally independent of H_1, H_2, H_3, referred to here as a *fourth integral*. The only known cases when such fourth integral exists are the so-called *Manakov case*, defined by the *Manakov condition*

$$M\overset{\text{def}}{=}\lambda_1\lambda_4(\lambda_2+\lambda_5-\lambda_3-\lambda_6)+\lambda_2\lambda_5(\lambda_3+\lambda_6-\lambda_1-\lambda_4)+\lambda_3\lambda_6(\lambda_1+\lambda_4-\lambda_2-\lambda_5)=0, \tag{I.3}$$

and the *product case*, defined by the conditions

$$\lambda_4=\lambda_1, \quad \lambda_5=\lambda_2, \quad \lambda_6=\lambda_3. \tag{I.4}$$

We denote sets of λ satisfying the Manakov and the product case by $\mathcal{M}$ and $\mathcal{P}$, respectively.

One can prove that except for the above-mentioned two cases, system (I.1) is never algebraically completely integrable; see Refs. 8, 13, and 14, where also the precise definition of an algebraically completely integrable system can be found. Although we do not repeat this definition here, let us remark that it is based on the properties of the system when complex time is considered and goes back to Kovalevskaya's ideas.[5,6]

In the present paper we derive the Manakov and the product case conditions applying the following method. We search for the cases when the fourth integral does not depend on all variables. In fact, in the Manakov case, the existence of such fourth integral follows from the form of the fourth integral reported, e.g., in Refs. 8, 13, 14, and 22; in Ref. 10 one can find a fourth integral depending only on three variables (see also Ref. 22). In the product case, one can take as a fourth integral $H_4=\lambda_1x_1x_4+\lambda_2x_2x_5+\lambda_3x_3x_6$, which, when $(\lambda_1,\lambda_2,\lambda_3)\neq(c,c,c)$ for some c

$\in \mathbb{R}$, is always functionally independent of H_1, H_2, and H_3. Thus the fourth integral $\tilde{H}_4 = \lambda_1 H_1 - H_4 = (\lambda_1 - \lambda_2) x_2 x_5 + (\lambda_1 - \lambda_3) x_3 x_6$ does not depend on all variables.

Let us stress that we require only C^1 differentiability of the fourth integral. Moreover, all the considerations are *local*. We never use the fact that such fourth integral is globally defined.

The main tools used are the simplest facts from linear algebra and the following well-known fact. If F is a first integral common for two vector fields X and Y, then F is also a first integral of their Lie bracket $[X,Y]$. Indeed, if $X(F)=Y(F)=0$, then evidently $[X,Y](F)=X[Y(F)] - Y[X(F)]=0$. In Secs. V and VII we use the Frobenius integrability theorem. To study the functional independence of the first integrals we use the method from Ref. 27.

For the Euler equations (I.1) this program can be completely fulfilled and we arrive either at the Manakov (I.3) or the product case conditions (I.4). In this way we also obtain a nice expression for the fourth integral in the generic Manakov case, much more direct and simple than those reported in Refs. 8, 10–14, 22. In the Manakov case this leads also to a coherent, structured algorithmic approach and to an explicit description of the fourth integral for all values of $\lambda \in \mathcal{M}$ and not only for a generic one as in the above-cited papers.

In fact this method is not new. It was already applied in Ref. 28 to the successful study of integrable cases of the Euler–Poisson equations describing the motion of a heavy rigid body with a fixed point. The second author (S.I.P.) applied it in Refs. 29–31 to complete the results from Ref. 28.

Although to the best of our knowledge this method has not been applied to a system other than the one mentioned, its scope is undoubtedly substantially larger.

It is really astonishing that this method provides all known integrable cases of the Euler–Poisson system (for an overview of integrable cases see Ref. 16) as well as of the Euler equations on so(4).[8,13] We are convinced that this reflects a general fact, not yet understood.

To successfully complete this work, we used MAPLE. To avoid errors, all statements were verified using it.

The paper is sharply divided into two almost independent parts. The first one contains Secs. II and III. In Sec. II we study some symmetries of system (I.1) and their relation to the existence of first integrals. In Sec. III we arrive at the Manakov and the product case conditions assuming only the existence of a fourth integral which does not depend on all variables $(x_i)_{1\leqslant i\leqslant 6}$. In the second part we present an algorithm for finding a fourth integral for all $\lambda \in \mathcal{M}$. In Sec. IV we explain the choice of subsets of three variables among the variables $(x_i)_{1\leqslant i\leqslant 6}$, which are used later to find the fourth integral in the Manakov case. Sections V–VII are devoted to the explicit description of the fourth integral for all $\lambda \in \mathcal{M}$. After some preliminary considerations in Sec. V, the case of generic values of $\lambda \in \mathcal{M}$ is considered in Sec. VI. In Sec. VII the case of the remaining values of λ is considered. Our results are summarized in Table I at the end of Sec. VII.

A very preliminary account concerning this work was published in Ref. 32.

II. PERMUTATIONAL SYMMETRIES

The Euler equations (I.1) possess invariant property which we called *permutational symmetry*. The permutational symmetries can be described in a general framework as follows. Let $x = (x_1,\ldots,x_n) \in \mathbb{R}^n$, $\lambda = (\lambda_1,\ldots,\lambda_n) \in \mathbb{R}^n$, and let $V(x,\lambda) = (V_1(x,\lambda),\ldots,V_n(x,\lambda))$ depend smoothly on $(x,\lambda) \in \mathbb{R}^{2n}$. Let us consider the following system:

$$\frac{dx}{dt} = V(x,\lambda). \tag{II.1}$$

Let σ be an element of the symmetric group S_n, i.e., the group of all permutations of $\{1,\ldots,n\}$. For $a = (a_1,\ldots,a_n) \in \mathbb{R}^n$ we will note $\sigma(a) = (a_{\sigma(1)},\ldots,a_{\sigma(n)})$.

The permutation $\sigma \in \mathrm{S}_n$ will be called a *permutational symmetry* of system (II.1) if for all $(x,\lambda) \in \mathbb{R}^{2n}$, one has

$$V_k(\sigma(x),\sigma(\lambda)) = \varepsilon V_{\sigma(k)}(x,\lambda), \quad 1\leqslant k\leqslant n, \tag{II.2}$$

where $\varepsilon = \pm 1$ is a constant independent of k. It is obvious that all permutational symmetries of given equation form a group.

Before studying permutational symmetries of the Euler equations (I.1) let us prove the following.

Theorem II.1: *Let $F=F(x)$ be a first integral of system (II.1) and σ its permutational symmetry. Then function $G=F\circ\sigma^{-1}$,* i.e., *$G(x)=F(\sigma^{-1}(x))$ is a first integral of the system*

$$\frac{\mathrm{d}x}{\mathrm{d}t} = V(x,\sigma(\lambda)). \tag{II.3}$$

Proof: As F is a first integral of system (II.1), then

$$\sum_{k=1}^{n} V_k(x,\lambda)\left(\frac{\partial F}{\partial x_k}\right)(x)=0.$$

As σ is a permutation of $\{1,\ldots,n\}$, the last equality is equivalent to

$$\sum_{k=1}^{n} V_{\sigma(k)}(x,\lambda)\left(\frac{\partial F}{\partial x_{\sigma(k)}}\right)(x)=0.$$

Taking into account (II.2), we can write this as

$$\sum_{k=1}^{n} V_k(\sigma(x),\sigma(\lambda))\left(\frac{\partial F}{\partial x_{\sigma(k)}}\right)(x)=0.$$

The last equality is satisfied for every $x\in\mathbb{R}^n$. Then putting instead of x, $\sigma^{-1}(x)$ we obtain that for every $x\in\mathbb{R}^n$,

$$\sum_{k=1}^{n} V_k(x,\sigma(\lambda))\left(\frac{\partial F}{\partial x_{\sigma(k)}}\right)(\sigma^{-1}(x))=0.$$

On the other hand a function $G=G(x)$ is a first integral of system (II.3) if

$$\sum_{k=1}^{n} V_k(x,\sigma(\lambda))\left(\frac{\partial G}{\partial x_k}\right)(x)=0.$$

Thus to finish the proof it remains to prove that for $G=F\circ\sigma^{-1}$ and $1\leqslant k\leqslant n$ one has

$$\left(\frac{\partial F}{\partial x_{\sigma(k)}}\right)(\sigma^{-1}(x))=\left(\frac{\partial G}{\partial x_k}\right)(x),$$

but this is obvious. □

We denote by **P** the group of permutational symmetries of the Euler equations (I.1). The simplest permutational symmetry of (I.1) can be described as follows. Let σ_0 be a permutation of $\{1,2,3\}$. Let us extend σ_0 to the permutation σ of $\{1,2,3,4,5,6\}$ by the formula $\sigma(i)=\sigma_0(i-3)+3$, $4\leqslant i\leqslant 6$, then $\sigma\in\mathbf{P}$. The just described six permutations are the following:

$$\begin{aligned}
&\sigma_e:\ (1,2,3,4,5,6)\to(1,2,3,4,5,6),\\
&\sigma_1:\ (1,2,3,4,5,6)\to(2,1,3,5,4,6),\\
&\sigma_2:\ (1,2,3,4,5,6)\to(1,3,2,4,6,5),
\end{aligned} \tag{II.4}$$

$$\sigma_3:\ (1,2,3,4,5,6)\to(3,2,1,6,5,4),$$

$$\sigma_4:\ (1,2,3,4,5,6)\to(2,3,1,5,6,4),$$

$$\sigma_5:\ (1,2,3,4,5,6)\to(3,1,2,6,4,5).$$

They form a subgroup of **P**. We also consider the following three additional permutational symmetries of system (I.1):

$$\sigma_6:\ (1,2,3,4,5,6)\to(1,5,6,4,2,3),$$

$$\sigma_7:\ (1,2,3,4,5,6)\to(4,2,6,1,5,3), \tag{II.5}$$

$$\sigma_8:\ (1,2,3,4,5,6)\to(4,5,3,1,2,6).$$

Let us also consider the following products of permutations:

$$\sigma_{ij}=\sigma_i\circ\sigma_j,$$

where

$$i\in\{6,7,8\},\quad j\in\{1,2,3,4,5\}. \tag{II.6}$$

Then using MAPLE it is easy to check that among all $6!=720$ elements of group S_6, 24 permutations (II.4)–(II.6) exhaust group **P**.

It is interesting to observe that if $\lambda\in\mathcal{M}$ then for every permutation $\sigma\in\mathbf{P}$, $\sigma(\lambda)\in\mathcal{M}$. The same is true for the product case (I.4) too, i.e., if $\lambda\in\mathcal{P}$ then $\sigma(\lambda)\in\mathcal{P}$. In what concerns the Manakov case, this can be easily verified directly. In fact it suffices to verify that this is so only for permutations σ_i, $1\leqslant i\leqslant 8$. Another way to see it is to notice that the Manakov condition (I.3) can be also written in four equivalent different ways:

$$\begin{aligned}
M&=\lambda_{43}\lambda_{51}\lambda_{62}+\lambda_{16}\lambda_{24}\lambda_{35}=0,\\
M&=\lambda_{46}\lambda_{21}\lambda_{35}+\lambda_{13}\lambda_{54}\lambda_{62}=0,\\
M&=\lambda_{16}\lambda_{54}\lambda_{32}+\lambda_{43}\lambda_{21}\lambda_{65}=0,\\
M&=\lambda_{13}\lambda_{24}\lambda_{65}+\lambda_{46}\lambda_{51}\lambda_{32}=0,
\end{aligned} \tag{II.7}$$

where to simplify notation we will denote from now on $\lambda_{ij}=\lambda_i-\lambda_j$, $1\leqslant i,j\leqslant 6$. Now it is very easy to see that permutations σ_i, $1\leqslant i\leqslant 8$ always transform one of these four equivalent conditions to another. For the product case this verification is completely evident.

III. MANAKOV AND PRODUCT CASE CONDITIONS

In this section we come to the Manakov condition (I.3) and to the product case (I.4) by an approach which differs from already know derivations of these cases.[8,11–14,17]

In what follows we will always suppose that the considered first integrals are not constant on any open subset of their domain of definition.

Theorem III.1: *If system (I.1) admits, even only locally, a fourth integral which does not depend on all the variables, then* $\lambda\in\mathcal{M}\cup\mathcal{P}$.

Proof: The plan of the proof is as follows. First we show that our theorem is true if we assume that the fourth integral does not depend on x_6. Then, using permutational symmetries, we easily show that our theorem is valid in all remaining cases.

Thus let us suppose first that the function

$$F=F(x_1,x_2,x_3,x_4,x_5)$$

is such first integral of (I.1). This obviously means that

$$\frac{\mathrm{d}F}{\mathrm{d}t}=Y_\lambda(F)=(\lambda_{32}x_2x_3+\lambda_{65}x_5x_6)\partial_1F+(\lambda_{13}x_1x_3+\lambda_{46}x_4x_6)\partial_2F+(\lambda_{21}x_1x_2+\lambda_{54}x_4x_5)\partial_3F$$
$$+(\lambda_{35}x_3x_5+\lambda_{62}x_2x_6)\partial_4F+(\lambda_{43}x_3x_4+\lambda_{16}x_1x_6)\partial_5F=0,$$

or equivalently

$$\frac{\mathrm{d}F}{\mathrm{d}t}=Y_\lambda(F)=x_6Y_1(F)+Y_2(F)=0, \tag{III.1}$$

where Y_λ is the vector field defined by the Euler system (I.1) and Y_1 and Y_2 are the following vector fields defined in $\mathbb{R}^5=\mathbb{R}^5(x_1,x_2,x_3,x_4,x_5)$:

$$Y_1=\lambda_{65}x_5\partial_1+\lambda_{46}x_4\partial_2+\lambda_{62}x_2\partial_4+\lambda_{16}x_1\partial_5,$$

$$Y_2=\lambda_{32}x_2x_3\partial_1+\lambda_{13}x_1x_3\partial_2+(\lambda_{21}x_1x_2+\lambda_{54}x_4x_5)\partial_3+\lambda_{35}x_3x_5\partial_4+\lambda_{43}x_3x_4\partial_5.$$

Hereafter by ∂_i we denote the partial derivative with respect to x_i, for $1\leqslant i\leqslant 6$. Since (III.1) is an identity with respect to all the variables we have

$$Y_1(F)=Y_2(F)=0. \tag{III.2}$$

Let us compute the Lie brackets $Y_3=[Y_1,Y_2]$ and $Y_4=[Y_1,Y_3]$. We obtain

$$Y_3=x_3x_4(\lambda_{32}\lambda_{46}-\lambda_{43}\lambda_{65})\partial_1+x_3x_5(\lambda_{13}\lambda_{65}-\lambda_{35}\lambda_{46})\partial_2+[x_1x_4(\lambda_{16}\lambda_{54}+\lambda_{21}\lambda_{46})+x_2x_5(\lambda_{21}\lambda_{65}$$
$$+\lambda_{54}\lambda_{62})]\partial_3+x_1x_3(\lambda_{16}\lambda_{35}-\lambda_{13}\lambda_{62})\partial_4+x_2x_3(\lambda_{43}\lambda_{62}-\lambda_{16}\lambda_{32})\partial_5,$$

$$Y_4=x_2x_3(\lambda_{16}\lambda_{32}\lambda_{65}+\lambda_{32}\lambda_{46}\lambda_{62}-2\lambda_{43}\lambda_{62}\lambda_{65})\partial_1+x_1x_3(\lambda_{13}\lambda_{16}\lambda_{65}+\lambda_{13}\lambda_{46}\lambda_{62}-2\lambda_{16}\lambda_{35}\lambda_{46})\partial_2$$
$$+[x_1x_2(\lambda_{16}\lambda_{21}\lambda_{65}+\lambda_{21}\lambda_{46}\lambda_{62}+2\lambda_{16}\lambda_{54}\lambda_{62})+x_4x_5(\lambda_{16}\lambda_{54}\lambda_{65}+\lambda_{46}\lambda_{54}\lambda_{62}$$
$$+2\lambda_{21}\lambda_{46}\lambda_{65})]\partial_3+x_3x_5(\lambda_{16}\lambda_{35}\lambda_{65}+\lambda_{35}\lambda_{46}\lambda_{62}-2\lambda_{13}\lambda_{62}\lambda_{65})\partial_4+x_3x_4(\lambda_{16}\lambda_{43}\lambda_{65}$$
$$+\lambda_{43}\lambda_{46}\lambda_{62}-2\lambda_{16}\lambda_{32}\lambda_{46})\partial_5.$$

Equations (III.2) imply that

$$Y_3(F)=Y_4(F)=0. \tag{III.3}$$

Equations (III.2) and (III.3) can be considered as a system of four homogeneous linear algebraic equations with unknowns

$$F=(\partial_1F,\partial_2F,\partial_3F,\partial_4F,\partial_5F),$$

which do not vanish identically.

This system has a solution H with $H=H_3-\lambda_6H_2$. However, H is obviously dependent on the known first integrals. Thus, if a fourth integral F exists, system (III.2)–(III.3) has at least two linearly independent solutions. We will now try to *find the conditions under which system (III.2)–(III.3) has at least two linearly independent solutions*.

Let us consider the 4×5 matrix A of the coefficients of this system. It is clear that our problem has a solution if and only if

$$\operatorname{rank}A\leqslant 3. \tag{III.4}$$

Now we are going to study when (III.4) is fulfilled. For this purpose we calculate all possible determinants of order four which can be obtained from the matrix A. For $1\leqslant i\leqslant 5$, by D_i, we denote the determinant obtained from matrix A by scratching its ith column. We have

$$\begin{aligned} D_1&=-2\lambda_{16}x_1x_3^2MD,\\ D_2&=-2\lambda_{62}x_2x_3^2MD,\\ D_3&=-2\lambda_{36}x_3^3MD,\\ D_4&=2\lambda_{46}x_3^2x_4MD,\\ D_5&=2\lambda_{65}x_3^2x_5MD, \end{aligned} \tag{III.5}$$

where M is defined by (I.3), and

$$\begin{aligned} D=&x_1^3x_2\lambda_{16}(\lambda_{13}\lambda_{62}-\lambda_{16}\lambda_{35})+x_1^2x_4x_5\lambda_{16}(\lambda_{35}\lambda_{46}-\lambda_{13}\lambda_{65})+x_1x_2^3\lambda_{62}(\lambda_{43}\lambda_{62}-\lambda_{16}\lambda_{32})\\ &+x_1x_2x_4^2\lambda_{46}(\lambda_{16}\lambda_{32}-\lambda_{43}\lambda_{62})+x_1x_2x_5^2\lambda_{65}(\lambda_{16}\lambda_{35}-\lambda_{13}\lambda_{62})+x_2^2x_4x_5\lambda_{62}(\lambda_{32}\lambda_{46}-\lambda_{43}\lambda_{65})\\ &+x_4^3x_5\lambda_{46}(\lambda_{43}\lambda_{65}-\lambda_{32}\lambda_{46})+x_4x_5^3\lambda_{65}(\lambda_{13}\lambda_{65}-\lambda_{35}\lambda_{46}). \end{aligned}$$

Condition (III.4) is equivalent to five equations $D_i=0$ for $1\leqslant i\leqslant 5$. Now, let us assume that $\lambda\notin\mathcal{M}\cup\mathcal{P}$. Then, we have two cases when all the above-mentioned determinants vanish: either $D\neq 0$ or $D=0$.

In the first case when $D\neq 0$ and $M\neq 0$ (III.5) imply immediately that all components of λ are equal but it is in contradiction with our assumption that $M\neq 0$.

Now we prove that $D=0$ implies that $\lambda\in\mathcal{M}\cup\mathcal{P}$, i.e., it also implies a contradiction with our assumption. Indeed, let us write down the coefficients of D,

$$\lambda_{13}\lambda_{62}-\lambda_{16}\lambda_{35}=0, \tag{III.6}$$

$$\lambda_{32}\lambda_{46}-\lambda_{43}\lambda_{65}=0, \tag{III.7}$$

$$\lambda_{43}\lambda_{62}-\lambda_{16}\lambda_{32}=0, \tag{III.8}$$

$$\lambda_{35}\lambda_{46}-\lambda_{13}\lambda_{65}=0. \tag{III.9}$$

We can always suppose that all λ_{ij} which appear in the above-mentioned equations are different from zero. Let us prove this, e.g., for λ_{13}. If $\lambda_{13}=0$ then from (III.9) we have that either $\lambda_{35}=0$ or $\lambda_{46}=0$. But each of these possibilities leads to the Manakov case.

Consider now Eqs. (III.6) and (III.7). They represent a linear system in unknowns λ_2 and λ_5,

$$-\lambda_{13}\lambda_2+\lambda_{16}\lambda_5=\lambda_1\lambda_{36},\quad -\lambda_{46}\lambda_2+\lambda_{43}\lambda_5=-\lambda_4\lambda_{36}. \tag{III.10}$$

We denote by Δ_0 the determinant of (III.10) and consider two possible cases.

(1) $\Delta_0\neq 0$. Solving (III.10) we obtain

$$\lambda_2=\frac{\lambda_1\lambda_{43}+\lambda_4\lambda_{16}}{\lambda_{16}+\lambda_{43}},\quad \lambda_5=\frac{\lambda_1\lambda_{46}+\lambda_4\lambda_{13}}{\lambda_{16}+\lambda_{43}},$$

but, for these values of λ_2 and λ_5, we have $M=0$.

(2) $\Delta_0=0$. In this case, (III.10) have to be dependent because if not they have no solution. This is equivalent to requiring that all order two minors of the corresponding 2×3 matrix vanish, which means

$$\Delta_0=\lambda_{36}(\lambda_{13}+\lambda_{46})=0, \tag{III.11}$$

$$\Delta_1=\lambda_{36}(\lambda_1\lambda_{43}+\lambda_4\lambda_{16})=0, \tag{III.12}$$

$$\Delta_2=\lambda_{36}(\lambda_1\lambda_{46}+\lambda_4\lambda_{13})=0. \tag{III.13}$$

From (III.12) and (III.13) we have

$$\Delta_2-\Delta_1=\lambda_{36}^2\lambda_{14}=0.$$

The last equation shows that if $\lambda_{36}\neq 0$ then $\lambda_{14}=0$, and (III.11) leads to

$$\lambda_3=2\lambda_1-\lambda_6.$$

Now (III.8) and (III.9) write

$$2\lambda_{21}\lambda_{16}=0, \quad -2\lambda_{51}\lambda_{16}=0.$$

Since $\lambda_{16}\neq 0$ we have $\lambda_{51}=\lambda_{21}=0$, which together with $\lambda_{14}=0$ leads to $M=0$.

It remains only to study the possibility $\lambda_{36}=0$, i.e., $\lambda_3=\lambda_6$. From (III.6) and (III.8) we obtain

$$-\lambda_{13}\lambda_{25}=0, \quad \lambda_{32}\lambda_{14}=0.$$

But $\lambda_{13}\neq 0$ and $\lambda_{32}\neq 0$ and therefore

$$\lambda_5=\lambda_2, \quad \lambda_4=\lambda_1,$$

i.e., we come to the product case.

All the above considerations lead to the conclusion that the Euler equations (I.1) can admit a fourth integral which does not depend on the variable x_6 only when $\lambda\in\mathcal{M}\cup\mathcal{P}$.

Let us suppose now that the fourth integral does not depend on x_1. Let us consider the permutational symmetry σ_{63} [see (II.6)]. From Theorem II.1 we know that if for some $\lambda\in\mathbb{R}^6$, system (I.1), i.e., vector field Y_λ, admits a first integral F not depending on x_1, then function $F\circ\sigma_{63}^{-1}$ will be a first integral of $Y_{\sigma(\lambda)}$. But function $F\circ\sigma_{63}^{-1}$ does not depend of x_6. Thus, from what we proved previously it follows that $\sigma_{63}(\lambda)\in\mathcal{M}\cup\mathcal{P}$. However, as we have already noticed, both sets $\mathcal{M}$ and $\mathcal{P}$ are invariant with respect to the permutational symmetries. Thus $\lambda\in\mathcal{M}\cup\mathcal{P}$.

Exactly in the same way, using permutational symmetries σ_{62}, σ_6, σ_3, and σ_2, we prove the nonexistence of a fourth integral that does not depend on x_2, x_3, x_4, or x_5, respectively.□

Further we study only the Manakov case because in the product case we have already known the fourth integral. Thus, to the end of this paper we always assume that $\lambda\in\mathcal{M}$ although we do not write it explicitly all the time.

The main problem related to the present work that remains open is the following. Let us suppose that system (I.1) possesses a rational fourth integral G depending on all the variables $(x_i)_{1\leqslant i\leqslant 6}$. Deduce in this case the existence of a local C^1 smooth fourth integral that does not depend on all the variables. Taking into account Theorem III.1, this will imply that the rational fourth integral can exist only in the Manakov or product case. To the best of our knowledge, the last assertion has not yet been proved in its full generality.

IV. CHOICE OF GOOD VARIABLES

Our first aim is to find an explicit formula for the fourth integral which does not depend on all variables $(x_i)_{1\leqslant i\leqslant 6}$ for the *generic*, i.e., an open and dense subset of $\mathcal{M}$.

The purpose of this section is to select all triples of variables x_k, x_l, x_m, $1\leqslant k<l<m\leqslant 6$, such that the fourth integral depends only on these variables.

We say that a differentiable function $F=F(x_1,\ldots,x_n)$ depends *essentially* on variables $x_1,\ldots,x_n$ if partial derivatives $\partial_i F,\ 1\leqslant i\leqslant n$, do not vanish identically on any open subset of the domain of definition of F.

First let us note that the subset of parameters $\lambda\in\mathcal{M}$ for which there exists a first integral of the system (I.1) depending essentially only on one variable, is never generic. The same is true also for first integrals depending essentially only on two variables x_k and $x_l,\ 1\leqslant k<l\leqslant 6$. Indeed, let us suppose for example that a function $F=F(x_1,x_2)$ which depends essentially on variables x_1 and x_2 is a first integral of system (I.1). Then

$$\frac{\mathrm{d}F}{\mathrm{d}t}=(\lambda_{32}x_2x_3+\lambda_{65}x_5x_6)\partial_1F+(\lambda_{13}x_1x_3+\lambda_{46}x_4x_6)\partial_2F=0.$$

Thus $\lambda_{65}x_5x_6\partial_1F$ and $\lambda_{46}x_4x_6\partial_2F$ vanish identically. As ∂_1F and ∂_2F do not vanish identically on any open set, then $\lambda_{65}=\lambda_{46}=0$. But the subset of $\mathcal{M}$ defined by $\lambda_{65}=\lambda_{46}=0$ is not dense, and thus is not generic in $\mathcal{M}$. The same arguments cover also the case of first integral $F=F(x_1,x_4)$. Now using the permutational symmetries, like at the end of Sec. III we cover the remaining 13 cases of variables x_k and $x_l,\ 1\leqslant k<l\leqslant 6$.

Thus, to find fourth integrals corresponding to a generic subset of $\mathcal{M}$ we are obliged to consider the functions of at least three variables $x_k,\ x_l,\ x_m,\ 1\leqslant k<l<m\leqslant 6$. As we will prove, we can always find such fourth integrals depending on three properly chosen variables.

Let us consider now all possible 20 sets of three variables $x_k,\ x_l,\ x_m,\ 1\leqslant k<l<m\leqslant 6$. We will say that the set (x_k,x_l,x_m) is a *good set* of variables if there exists a generic set $\mathcal{G}_{k,l,m}\subset\mathcal{M}$ such that for any $\lambda\in\mathcal{G}_{k,l,m}$, the Euler equations (I.1) admit a fourth integral depending essentially only on variables $x_k,\ x_l$, and x_m.

Let us consider the four sets

$$(x_4,x_5,x_6), \tag{IV.1}$$

$$(x_2,x_3,x_4), \tag{IV.2}$$

$$(x_1,x_3,x_5), \tag{IV.3}$$

$$(x_1,x_2,x_6). \tag{IV.4}$$

Now we prove the following fact.

Theorem IV.1: *All 16 remaining cases of sets of variables* $(x_k,x_l,x_m),\ 1\leqslant k<l<m\leqslant 6$ *are never good.*

Proof: Let function F be a first integral of (I.1) functionally independent of integrals (I.2). First we prove that $(x_1,x_2,x_3)\notin\mathbf{G}$ (case 1) and $(x_1,x_2,x_4)\notin\mathbf{G}$ (case 2).

Case 1. To prove that $(x_1,x_2,x_3)\notin\mathbf{G}$ let us suppose that $(x_1,x_2,x_3)\in\mathbf{G}$ and let $F(x_1,x_2,x_3)$ be the corresponding first integral depending essentially on (x_1,x_2,x_3). Then

$$\frac{\mathrm{d}F}{\mathrm{d}t}=(\lambda_{32}x_2x_3+\lambda_{65}x_5x_6)\partial_1F+(\lambda_{13}x_1x_3+\lambda_{46}x_4x_6)\partial_2F+(\lambda_{21}x_1x_2+\lambda_{54}x_4x_5)\partial_3F=0. \tag{IV.5}$$

Equation (IV.5) is an identity with respect to all the variables $x_1,\ldots,x_6$. Since F depends essentially on (x_1,x_2,x_3), then from (IV.5) it follows that

$$\lambda_{65}=\lambda_{46}=\lambda_{54}=0.$$

So we are out of the generic case and consequently $(x_1,x_2,x_3)\notin\mathbf{G}$.

From this case and the permutational symmetry arguments like at the end of the proof of Theorem III.1 we also cover the three other cases:

(156)	(246)	(345)
σ_6	σ_7	σ_8

where we denote for brevity (klm) instead of (x_k, x_l, x_m).

Case 2. To prove that $(x_1, x_2, x_4) \notin \mathbf{G}$, let us suppose that $(x_1, x_2, x_4) \in \mathbf{G}$ and $F(x_1, x_2, x_4)$ is the corresponding first integral depending essentially on (x_1, x_2, x_4). Then

$$\frac{\mathrm{d}F}{\mathrm{d}t} = (\lambda_{32}x_2x_3 + \lambda_{65}x_5x_6)\partial_1 F + (\lambda_{13}x_1x_3 + \lambda_{46}x_4x_6)\partial_2 F + (\lambda_{35}x_3x_5 + \lambda_{62}x_2x_6)\partial_4 F = 0. \tag{IV.6}$$

Like in Case 1, one deduces from (IV.6) that $\lambda_{65} = \lambda_{35} = 0$ but this is not the generic case. Thus $(x_1, x_2, x_4) \notin \mathbf{G}$. By the permutational symmetry argument the same applies also to the remaining 11 cases:

(125)	(134)	(136)	(145)	(146)	(235)	(236)	(245)	(256)	(346)	(356)
σ_1	σ_2	σ_5	σ_6	σ_{62}	σ_4	σ_3	σ_{61}	σ_{64}	σ_{65}	σ_{63}

Thus in all 16 cases it turns out that $(x_k, x_l, x_m) \notin \mathbf{G}$. □

What concerns four cases (IV.1)–(IV.4), we have not proved yet that they belong to **G**. Let us note one characteristic feature of the four cases of (IV.1)–(IV.4). Looking at (I.1) one notices that the right-hand sides of equations corresponding to x_k, x_l, and x_m are linear homogeneous functions of the remaining variables. This is never the case for the 16 cases which do not belong to **G**.

In fact cases (IV.2)–(IV.4) are obtained from case (IV.1) by the permutational symmetry argument that can be seen from the table:

(234)	(135)	(126)
σ_6	σ_7	σ_8

In Secs. V and VI we investigate set (IV.1) and prove that it [and therefore (IV.2)–(IV.4) too] indeed belong to **G**.

V. TOWARD THE FIRST INTEGRALS

Let us consider case (IV.1) when the fourth integral of system (I.1) we look for has the form

$$F = F(x_4, x_5, x_6), \tag{V.1}$$

and depends essentially on x_4, x_5, and x_6. Thus we have

$$\begin{aligned}\frac{\mathrm{d}F}{\mathrm{d}t} &= x_1(\lambda_{16}x_6\partial_5 F + \lambda_{51}x_5\partial_6 F) + x_2(\lambda_{62}x_6\partial_4 F + \lambda_{24}x_4\partial_6 F) + x_3(\lambda_{35}x_5\partial_4 F + \lambda_{43}x_4\partial_5 F)\\ &= x_1\tilde{Y}_1(F) + x_2\tilde{Y}_2(F) + x_3\tilde{Y}_3(F) = 0,\end{aligned} \tag{V.2}$$

where the definition of vector fields $\tilde{Y}_i$ for $1 \leqslant i \leqslant 3$, is obvious. Since $\tilde{Y}_1(F)$, $\tilde{Y}_2(F)$, and $\tilde{Y}_3(F)$ do not depend on x_1, x_2, and x_3, and since (V.2) is an identity with respect to all the variables, then

$$\tilde{Y}_1(F) = \tilde{Y}_2(F) = \tilde{Y}_3(F) = 0. \tag{V.3}$$

Equations (V.3) give a system of three first-order linear homogeneous partial differential equations for determining the function F. This function depends essentially on x_4, x_5, and x_6. Therefore the determinant of linear system (V.3) with respect to the unknowns $\partial_i F$, $4 \leqslant i \leqslant 6$, has to vanish identically. We prove that it really vanishes. Indeed, we have

$$\det\begin{pmatrix} 0 & \lambda_{16}x_6 & \lambda_{51}x_5 \\ \lambda_{62}x_6 & 0 & \lambda_{24}x_4 \\ \lambda_{35}x_5 & \lambda_{43}x_4 & 0 \end{pmatrix} = (\lambda_{43}\lambda_{51}\lambda_{62}+\lambda_{16}\lambda_{24}\lambda_{35})x_4x_5x_6.$$

However

$$\lambda_{43}\lambda_{51}\lambda_{62}+\lambda_{16}\lambda_{24}\lambda_{35}=0,$$

because this coincides with the first form of the Manakov condition (II.7). Thus, in a way completely independent of Sec. III, we proved that the Manakov condition is necessary for the existence of a nontrivial first integral $F=F(x_4,x_5,x_6)$. Let us stress the great simplicity of this derivation.

In Sec. VI in an elementary way we prove that generically the Manakov condition is also sufficient for the existence of such fourth integral.

When the vector fields $\tilde{Y}_1$ and $\tilde{Y}_2$ are independent, equation $\tilde{Y}_3(F)=0$ follows from $\tilde{Y}_1(F)=\tilde{Y}_2(F)=0$ and it suffices to consider only these two equations, i.e.,

$$\begin{aligned} &\tilde{Y}_1(F)=\lambda_{16}x_6\partial_5F+\lambda_{51}x_5\partial_6F=0, \\ &\tilde{Y}_2(F)=\lambda_{62}x_6\partial_4F+\lambda_{24}x_4\partial_6F=0. \end{aligned} \tag{V.4}$$

As it is easy to see these two linear equations with unknowns ∂_4F, ∂_5F and ∂_6F are dependent if and only if the matrix of this system is of rank 0 or 1, or equivalently if at least one of the following conditions is satisfied:

$$\begin{aligned} &\text{case I:} \quad \lambda_{16}=\lambda_{62}=0, \\ &\text{case II:} \quad \lambda_{16}=\lambda_{51}=0, \\ &\text{case III:} \quad \lambda_{24}=\lambda_{62}=0. \end{aligned} \tag{V.5}$$

These singular cases will be investigated in Sec. VII.

We note here that the local solvability of system (V.4) around any point $(x_4,x_5,x_6) \neq (0,0,0)$ follows from the Frobenius integrability Theorem (see Ref. 33). Indeed, the Lie bracket $[\tilde{Y}_1,\tilde{Y}_2]$ of vector fields

$$\tilde{Y}_1=\lambda_{16}x_6\partial_5+\lambda_{51}x_5\partial_6=0, \quad \tilde{Y}_2=\lambda_{62}x_6\partial_4+\lambda_{24}x_4\partial_6=0,$$

is equal to

$$[\tilde{Y}_1,\tilde{Y}_2]=\lambda_{51}\lambda_{62}x_5\partial_4-\lambda_{16}\lambda_{24}x_4\partial_5.$$

The determinant formed by the coefficients of vector fields $\tilde{Y}_1$, $\tilde{Y}_2$ and $[\tilde{Y}_1,\tilde{Y}_2]$ is

$$\det\begin{pmatrix} 0 & \lambda_{16}x_6 & \lambda_{51}x_5 \\ \lambda_{62}x_6 & 0 & \lambda_{24}x_4 \\ \lambda_{51}\lambda_{62}x_5 & -\lambda_{16}\lambda_{24}x_4 & 0 \end{pmatrix} = 0.$$

Hence Eqs. (V.4) have, at least locally, a nontrivial solution. In fact one can find a global solution as shown in Sec. VI.

VI. FIRST INTEGRALS IN GENERIC CASE

We start this section with formulation of a useful criterion for the functional independence which we will use later in this section and Sec. VII.

Let $U\subset\mathbb{R}^n$ be an open set. Let us suppose that $F_1,\ldots,F_q\in C^1(U)$, $1\leqslant q<n$, are functionally independent functions at point $x\in U$, i.e.,

$$\operatorname{rank}\frac{\partial(F_1,\ldots,F_q)}{\partial(x_1,\ldots,x_n)}(x)=q. \tag{VI.1}$$

Let us define the following matrix:

$$S(x)=\begin{pmatrix} \partial_1F_1 & \ldots & \partial_1F_q & 0 & \ldots & 0 \\ \vdots & & & & & \\ \partial_qF_1 & \ldots & \partial_qF_q & 0 & \ldots & 0 \\ \partial_{q+1}F_1 & \ldots & \partial_{q+1}F_q & 1 & \ldots & 0 \\ \vdots & & & & \ddots & \\ \partial_nF_1 & \ldots & \partial_nF_q & 0 & \ldots & 1 \end{pmatrix},$$

and let

$$\Delta=\det\frac{\partial(F_1,\ldots,F_q)}{\partial(x_1,\ldots,x_q)}(x).$$

Matrix $S(x)$ is invertible if and only if $\Delta\neq 0$. Let $F\in C^1(U)$ be a function. When there exists $S(x)^{-1}$ we define vector $Z(x)=(Z_1(x),\ldots,Z_n(x))=S^{-1}(x)(\operatorname{grad}F)$.

Condition (VI.1) allows us to assume without any loss of generality that $\Delta\neq 0$ and we can now formulate a simple but very useful fact that goes back to Ref. 27.

Theorem VI.1: *Functions $F_1,\ldots,F_q$ and F are functionally independent at point x if and only if functions $Z_j(x)$, $q+1\leqslant j\leqslant n$, do not vanish simultaneously.*

The proof of this theorem is immediate if we note that $S^{-1}(x)(\operatorname{grad}F_k(x))$ is the kth vector of the standard basis of $\mathbb{R}^n$.

Now, we obtain first integral (V.1) in an explicit form. In order to find it we suppose that it is a homogeneous function of some degree $p\neq 0$. By the Euler theorem on homogeneous functions this is equivalent to

$$\sum_{i=4}^{6}x_i\partial_iF=pF. \tag{VI.2}$$

Let us note, that at least locally, as system (I.1) is homogeneous, then the existence of homogeneous of degree $p\neq 0$ first integrals follows from Ref. 34. We can suppose that $p=2$. This assumption is not restrictive because the power of a homogeneous function is homogeneous.

The searched first integral satisfies equations (V.4) and (VI.2). We solve this system of three equations with respect to the partial derivatives of F and obtain

$$\partial_4F=\frac{2\lambda_{16}\lambda_{24}x_4F}{\lambda_{16}\lambda_{24}x_4^2+\lambda_{51}\lambda_{62}x_5^2-\lambda_{16}\lambda_{62}x_6^2},$$

$$\partial_5 F = \frac{2\lambda_{62}\lambda_{51}x_5 F}{\lambda_{16}\lambda_{24}x_4^2+\lambda_{51}\lambda_{62}x_5^2-\lambda_{16}\lambda_{62}x_6^2},$$

$$\partial_6 F = \frac{-2\lambda_{16}\lambda_{62}x_6 F}{\lambda_{16}\lambda_{24}x_4^2+\lambda_{51}\lambda_{62}x_5^2-\lambda_{16}\lambda_{62}x_6^2}.$$

By inspection one immediately sees that

$$F=\lambda_{16}\lambda_{24}x_4^2+\lambda_{51}\lambda_{62}x_5^2-\lambda_{16}\lambda_{62}x_6^2 \tag{VI.3}$$

is a solution.

Let us notice that first integral F depends on first integrals (I.2) when $\lambda_{13}=\lambda_{32}=0$. Indeed in this case we can write F in the form

$$F=\lambda_{16}(\lambda_1 H_2 - H_3).$$

This is why we have to add to the three singular cases (V.5) another one

$$\text{case IV:} \quad \lambda_{13}=\lambda_{32}=0. \tag{VI.4}$$

Now we prove the following

Theorem VI.2: *For $\lambda \in \mathcal{M}$ first integrals H_1, H_2, H_3, and F are functionally independent except in cases* (V.5) *and* (VI.4).

Proof: We showed already that F depends on H_1, H_2, H_3 in case IV. Let us suppose now that we are out of case IV then, as it is easy to see, determinant

$$\Delta = \det\frac{\partial(H_1,H_2,H_3)}{\partial(x_1,x_2,x_3)} = 4(\lambda_{13}x_1x_3x_5+\lambda_{21}x_1x_2x_6+\lambda_{32}x_2x_3x_4), \tag{VI.5}$$

does not vanish. Thus matrix $S(x)$ is invertible and we can compute vector $Z(x)$. By virtue of Theorem VI.1 the first integral F of the Euler equations (I.1) is functionally independent of first integrals (I.2) if and only if the last three components of vector Z do not vanish simultaneously. Direct computations for the first integral F given by (VI.3) show that

$$Z_4=2\lambda_{16}\lambda_{24}x_4, \quad Z_5=2\lambda_{62}\lambda_{51}x_5, \quad Z_6=-2\lambda_{62}\lambda_{16}x_6.$$

One can easily see that $Z_4=Z_5=Z_6=0$ only in the following cases [see (V.5]:

- $\lambda_{16}=\lambda_{62}=0$ which coincides with case I,
- $\lambda_{16}=\lambda_{51}=0$ which coincides with case II,
- $\lambda_{24}=\lambda_{62}=0$ which coincides with case III. □

For our further considerations it is important to notice that determinant (VI.5) vanishes identically only when case IV is fulfilled.

VII. INVESTIGATION OF SINGULAR CASES

In this section we examine all values of parameters $(\lambda_i)_{1\leqslant i\leqslant 6}$ which satisfy one of conditions (V.5) or (VI.4). All these cases satisfy the Manakov condition.

First let us note that it suffices to examine only cases I and II. Indeed, by the permutational symmetry arguments we recover the fourth integral for case III [see (V.5) and case IV (see (VI.4)] from the fourth integral of case II by the permutations σ_1 and σ_6, respectively.

Let us consider case I when $\lambda_{16}=\lambda_{62}=0$. From (V.3) we have

$$\tilde{Y}_1(F)=\lambda_{56}x_5\partial_6 F=0, \quad \tilde{Y}_2(F)=\lambda_{64}x_4\partial_6 F=0,$$

$$\widetilde{Y}_3(F)=\lambda_{35}x_5\partial_4F+\lambda_{43}x_4\partial_5F=0.$$

We can immediately find a function satisfying these equations, i.e., a first integral of (I.1) depending only on variables x_4, x_5, and x_6. This is function $F=\lambda_{43}x_4^2-\lambda_{35}x_5^2$. However, instead of F, we prefer to use the first integral $G=x_3^2+x_4^2+x_5^2$ because, as we will see, in contrast to F, it remains functionally independent of first integrals (I.2) in some particular cases when F is functionally dependent. To verify the independence of integrals (I.2) and G we apply Theorem VI.1. Let us suppose that conditions $\lambda_{13}=\lambda_{32}=0$ are not fulfilled, i.e., we are in case I and out of case IV. Noticing that under this assumption $\lambda_{63}\neq 0$, let us compute the expressions Z_j, $4\leqslant j\leqslant 6$, for function G,

$$Z_4=\frac{2\lambda_{43}x_4}{\lambda_{63}},\quad Z_5=\frac{2\lambda_{53}x_5}{\lambda_{63}},\quad Z_6=0.$$

We have $Z_4=Z_5=Z_6=0$ only when $\lambda_{43}=\lambda_{53}=0$. However in this last case x_3, x_4, and x_5 are first integrals of (I.1). We compute

$$\det\frac{\partial(H_1,x_3,x_4,x_5)}{\partial(x_1,x_3,x_4,x_5)}=x_4,$$

so that H_1, x_3, x_4, and x_5 are functionally independent.

Now, let us assume that cases I and IV are fulfilled simultaneously. Function $G=x_3^2+x_4^2+x_5^2$ is still a first integral but instead of using Theorem VI.1 we can compute directly that

$$\det\frac{\partial(H_1,H_2,H_3,G)}{\partial(x_2,x_3,x_4,x_5)}=8x_2(\lambda_{65}x_1x_3x_5+\lambda_{54}x_4x_5x_6+\lambda_{46}x_2x_3x_4).$$

This expression vanishes identically only when $\lambda_{54}=\lambda_{64}=0$, and this, together with conditions of cases I and IV leads to the trivial case when all components of λ are equal. Hence the first integral G is functionally independent of (I.2) even when conditions of cases I and IV are fulfilled simultaneously and this does not happen when instead of G we take F.

In case II listed in (V.5) we have $\lambda_{16}=\lambda_{51}=0$. In this case from (V.3) we obtain that $\widetilde{Y}_1\equiv 0$. Now

$$\widetilde{Y}_2=\lambda_{62}x_6\partial_4+\lambda_{24}x_4\partial_6,\quad \widetilde{Y}_3=\lambda_{36}x_5\partial_4+\lambda_{43}x_4\partial_5.$$

We compute the Lie bracket $\widetilde{Y}_4=[\widetilde{Y}_2,\widetilde{Y}_3]$ and obtain

$$\widetilde{Y}_4=\lambda_{62}\lambda_{43}x_6\partial_5+\lambda_{24}\lambda_{63}x_5\partial_6.$$

One can easily see that $x_4\widetilde{Y}_4=\lambda_{63}x_5\widetilde{Y}_2+\lambda_{62}x_6\widetilde{Y}_3$. Thus, according to the Frobenius integrability theorem, the system $\widetilde{Y}_2(G)=0$, $\widetilde{Y}_3(G)=0$ admits at least locally a solution. To find it we apply the already used approach supposing that G is a homogeneous function of degree 2. Solving the system

$$\widetilde{Y}_2(G)=0,\quad \widetilde{Y}_3(G)=0,\quad x_4\partial_4G+x_5\partial_5G+x_6\partial_6G=2G,$$

with respect to the partial derivatives of G we obtain

$$\partial_4G=\frac{2\lambda_{24}\lambda_{43}x_4G}{\lambda_{24}\lambda_{43}x_4^2+\lambda_{24}\lambda_{63}x_5^2-\lambda_{43}\lambda_{62}x_6^2},$$

$$\partial_5 G = \frac{2\lambda_{63}\lambda_{24}x_5 G}{\lambda_{24}\lambda_{43}x_4^2+\lambda_{24}\lambda_{63}x_5^2-\lambda_{43}\lambda_{62}x_6^2},$$

$$\partial_6 G = \frac{-2\lambda_{43}\lambda_{62}x_6 F}{\lambda_{24}\lambda_{43}x_4^2+\lambda_{24}\lambda_{63}x_5^2-\lambda_{43}\lambda_{62}x_6^2}.$$

One can see that

$$G=\lambda_{24}\lambda_{43}x_4^2+\lambda_{24}\lambda_{63}x_5^2-\lambda_{43}\lambda_{62}x_6^2,$$

is a solution. Let us notice that in case IV this function is functionally dependent on first integrals (I.2).

Now, let us assume that we are out of case IV. Then determinant (VI.5) does not vanish identically and let us apply Theorem VI.1. We obtain

$$Z_4=2\lambda_{24}\lambda_{43}x_4, \quad Z_5=2\lambda_{24}\lambda_{63}x_5, \quad Z_6=-2\lambda_{43}\lambda_{62}x_6.$$

Thus $Z_4=Z_5=Z_6=0$ only in the following three subcases:

(1) $\lambda_{43}=\lambda_{63}=0$,
(2) $\lambda_{43}=\lambda_{24}=0$,
(3) $\lambda_{24}=\lambda_{62}=0$.

In subcase (1) x_5 is a first integral of (I.1). As we are still out of case IV determinant (VI.5) does not vanish and we can calculate Z_j for $4\leqslant j\leqslant 6$ for integrals (I.2) and x_5. We obtain $Z_5=1$ and therefore the first integrals (I.2) and x_5 are functionally independent. In subcase (2) again x_5 is a first integral and we again have $Z_5=1$. In subcase (3) x_6 is a first integral and we have $Z_6=1$.

Now let us assume that the conditions of cases II and IV are fulfilled simultaneously. Then, as it is easy to check, x_1 is a first integral and we have

$$\det\frac{\partial(H_1,H_2,H_3,x_1)}{\partial(x_1,x_2,x_3,x_4)}=4\lambda_{46}x_4(x_2x_6-x_3x_5),$$

i.e., if $\lambda_{46}\neq 0$ then x_1 is a functionally independent of (I.2) first integral. If $\lambda_{46}=0$ then we come to the trivial case when all components of λ are equal.

The results obtained in this and previous sections are summarized in Table I, which covers all the space of parameters $(\lambda_i)_{1\leqslant i\leqslant 6}$ satisfying the Manakov condition. In Table I all cases are explicitly written down, unless they can be deduced one from another by the permutational symmetry argument. The last column contains necessary and sufficient conditions for functional independence of the integrals. The generic case in Table I is defined explicitly by the conditions of functional independence of the first integrals H_1, H_2, H_3, and F given in the last column. For the last four rows the listed first integrals are functionally independent for $\lambda\in\mathcal{M}$ except for the trivial case when all components of λ are equal. The results given in Table I remain valid also when $\lambda\in\mathbb{C}^6$. Indeed, we can directly check that functions listed in the second column remain first integrals of (I.1) when $\lambda\in\mathbb{C}^6$. They are also functionally independent. This is so because our proof of independence also works in the complex case.

Let us note that if, for example, $\lambda_1\neq\lambda_6$ and $\lambda_1=\lambda_3=\lambda_4$ the fourth integral written in Refs. 8, 11, 13, 14, and 22 is not defined while our fourth integral (VI.3) remains valid.

Finally let us note that the starting point to produce Table I was the particular place that we attributed to integral F. If instead of it we chose the integrals coming from (IV.2), (IV.3), or (IV.4) the corresponding table would be different.

TABLE I. Functionally independent first integrals for the Manakov case.

Case	First integrals	Conditions
Generic	$H_1,\ H_2,\ H_3,$	$\lvert\lambda_{16}\rvert+\lvert\lambda_{62}\rvert>0$ and
	$F=\lambda_{16}\lambda_{24}x_4^2$	$\lvert\lambda_{16}\rvert+\lvert\lambda_{51}\rvert>0$ and

$\lambda_{24}=\lambda_{62}=0$	$H_1,\ H_2,\ H_3,\ x_6$	No conditions
$\lambda_{13}=\lambda_{32}=0$	$H_1,\ H_2,\ H_3,\ x_1$	No conditions

ACKNOWLEDGMENTS

Elie Youndje and Stephane Legros from the Department of Mathematics of the University of Rouen helped us in some formal algebra manipulations. Alfred Ramani from the Center of Theoretical Physics of the Ecole Polytechnique (Palaiseau, France) suggested the permutational symmetry of system (I.1) and this greatly simplified the first version of the present paper. Jean Moulin-Ollagnier from Laboratoire GAGE UMS CNRS 658 MEDICIS, Ecole Polytechnique (Palaiseau, France) greatly helped us by discussions on permutational symmetries. We sincerely thank them all.

A.J.M. and S.I.P. acknowledge the Department of Mathematics of the University of Rouen as well as the UMR-CNRS 6085 for their hospitality and excellent working conditions. In particular they sincerely thank Gerard Grancher for continuous help and attention during their stay in Rouen. S.I.P. was supported by a NATO 1999 fellowship for Science Research and Technics.

(Received 31 January 2000; accepted for publication 9 March 2001)

The inhomogeneous multiboson and multivariable differential realizations of the polynomial angular momentum algebra of quadratic type, $\mathcal{L}_2$, which may be seen as the nonlinear extension of an ordinary angular momentum algebra su(2) or its noncompact form su(1,1), are obtained from Fock representations of $\mathcal{L}_2$, which are related to master representation of $\mathcal{L}_2$ on the space of its universal enveloping algebra $U(\mathcal{L}_2)$ or to induced representations on their respective quotient spaces $U(\mathcal{L}_2)/I_i$ with different left ideals I_i. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1369656]

I. INTRODUCTION

Lie groups and Lie algebras, associated tightly with symmetries, have played an important role in quantum physics. In recent years, many works[1–15] have been devoted to investigating various nonlinear Lie algebras, which correspondingly describe nonlinear symmetries, and their applications in some quantum problems. The nonlinear Lie algebra to be discussed in this article in fact is a so-called polynomial angular momentum algebra, denoted by $\mathcal{L}_n$ (the suffix n is referred to as the highest degree of polynomial).[12–15] Similar to an ordinary angular momentum algebra su(2) [or its noncompact form su(1,1)],[16,17] $\mathcal{L}_n$ is generated by three elements $\{J_3, J_+, J_-\}$, and however, they satisfy the following commutation relations:

$$[J_3, J_\pm] = \pm J_m, \quad [J_+, J_-] = P(J_3), \tag{1}$$

where $P(J_3)$ is a polynomial function of J_3 with a finite degree n, i.e., $P(J_3) = \Sigma_{i=0}^{n} C_i J_3^i$ (C_i are arbitrary real numbers). When $C_0 = 0, C_1 = 1$ (or -1), $C_j = 0$ ($j > 1$), the polynomial angular momentum algebra $\mathcal{L}_n$ defined by Eq. (1) goes back to the ordinary angular momentum algebra su(2) [or su(1,1)]. Therefore, $\mathcal{L}_n$ may be seen as nonlinear extension of su(2) [or su(1,1)]. More recently, Beckers *et al.*[14] studied the *single-variable* differential realizations of the polynomial angular momentum algebras of quadratic ($n = 2$) and cubic ($n = 3$) types, respectively, by suggesting the generators $\{J_3, J_+, J_-\}$ be functions of the real variable x and the corresponding differential operator d/dx, whose concrete forms are determined by Eq. (1).

In this paper, we shall discuss the various inhomogeneous boson realizations (IHBRs) and the corresponding inhomogeneous differential realizations (IHDRs) of $\mathcal{L}_n$ by a purely algebraic approach similar to one proposed by Gruber and his co-workers.[18,19] This approach is based upon the master representation[21,22] of $\mathcal{L}_n$ on its universal enveloping algebra $U(\mathcal{L}_n)$ or the induced repre-

[a)]Electronic mail: dongruan@tsinghua.edu.cn

sentations on the quotient spaces $U(\mathcal{L}_n)/I_i$, where I_i are left ideals with respect to $U(\mathcal{L}_n)$. From these representations, we may define the corresponding Fock representations of $\mathcal{L}_n$ on the Fock spaces, and then obtain the IHBRs of $\mathcal{L}_n$. Moreover, by means of the corresponding relations between the boson creation and annihilation operators and the differential operators, we may obtain directly the IHDRs of $\mathcal{L}_n$. In the present paper, we restrict ourselves to the polynomial angular momentum algebra of quadratic type, $\mathcal{L}_2$.

This paper is arranged as follows: In Sec. II, the general approach of obtaining the IHBR and IHDR from the master representation or from the induced representation is reviewed, which is adapted to any Lie algebra or nonlinear Lie algebra. Then, in Sec. III, we will apply this approach to the polynomial angular momentum algebra $\mathcal{L}_2$, and discuss its various IHBRs and IHDRs in detail. A simple discussion is given in the final section.

The symbol $\mathcal{N}$ denotes the set of non-negative integers and the symbol $\mathcal{C}$ denotes the complex number field.

II. GENERAL APPROACH

Let the generators of (nonlinear) Lie algebra $\mathcal{G}$ be T_a $(a=1,2,...,M)$. In terms of the Poincaré–Birkhoff–Witt theorem,[17,21,22] a basis for its universal enveloping algebra $U(\mathcal{G})$ can be chosen as the following set of ordered elements:

$$\{X(i_1,i_2,\ldots,i_M)=T_1^{i_1}T_2^{i_2}\cdots T_M^{i_M}|i_1,i_2,\ldots,i_M\in\mathcal{N}\}. \tag{2}$$

Then, by acting with the generators of $\mathcal{G}$ from the left upon the basis (2), i.e.,

$$\rho(T_a)X(i_1,i_2,\ldots,i_M)=T_aT_1^{i_1}T_2^{i_2}\cdots T_M^{i_M}=\sum_{i_1',\ldots,i_M'}\rho(T_a)_{i_1,i_2,\ldots,i_M}^{i_1',i_2',\ldots,i_M'}X(i_1',i_2',\ldots,i_M'), \tag{3}$$

we can obtain a so-called master representation ρ of $\mathcal{G}$ on $U(\mathcal{G})$.[20,21] On the quotient space $U(\mathcal{G})/I$, where I is a left ideal of $U(\mathcal{G})$, ρ may induce a representation. The different choice of I enables us to obtain various representations of $\mathcal{G}$.

Now let us construct the IHBR of $\mathcal{G}$ from the master representation ρ on $U(\mathcal{G})$ or from the induced representation on $U(\mathcal{G})/I$. It is obvious from Eq. (3) that the matrix elements $\rho(T_a)_{i_1,i_2,\ldots,i_M}^{i_1',i_2',\ldots,i_M'}$, determined by the commutation relations of $\mathcal{G}$, are related to M independent parameters $i_1,i_2,\ldots,i_M$ (non-negative integers), so we need M sets of independent boson pairs $\{a_i^+,a_i\}$ $(i=1,2,...,M)$ to define a Fock space $\mathcal{F}$ in the following way:

$$\{|i_1,i_2,\ldots,i_M\rangle=(a_1^+)^{i_1}(a_2^+)^{i_2}\cdots(a_M^+)^{i_M}|0\rangle|i_1,i_2,\ldots,i_M\in\mathcal{N}\}, \tag{4}$$

where $|0\rangle$ stands for a ''vacuum state,'' and $a_i|0\rangle=0$. Then consider a mapping Φ: $U(\mathcal{G})\to\mathcal{F}$ defined by

$$\Phi(X(i_1,i_2,\ldots,i_M))=|i_1,i_2,\ldots,i_M\rangle, \tag{5}$$

which is automorphic to $U(\mathcal{G})$, and let

$$F(T_a)=\Phi\rho(T_a)\Phi^{-1}, \tag{6}$$

it follows from Eqs. (3), (5), and (6) that Eq. (6) defines a Fock representation of $\mathcal{G}$ on $\mathcal{F}$,

$$F(T_a)|i_1,i_2,\ldots,i_M\rangle=\sum_{i_i',\ldots,i_M'}\rho(T_a)_{i_1,i_2,\ldots,i_M}^{i_1',i_2',\ldots,i_M'}|i_1',i_2',\ldots,i_M'\rangle, \tag{7}$$

since $F(T_a)$ satisfies the same commutation relations as the generators T_a of $\mathcal{G}$, i.e.,

$$[F(T_a),F(T_b)]=F([T_a,T_b]). \tag{8}$$

Thus, by solving Eq. (7), we can obtain the IHBR of $\mathcal{G}$ provided that we know the explicit forms of $\rho(T_a)^{i_1',i_2',\ldots,i_M'}_{i_1,i_2,\ldots,i_M}$. In order to obtain the IHBRs for the various representations, the following formulas will be needed:

$$\begin{aligned}
&a_k^+|i_1,i_2,\ldots,i_M\rangle=|i_1,i_2,\ldots,i_k+1,\ldots,i_M\rangle,\\
&a_k|i_1,i_2,\ldots,i_M\rangle=i_k|i_1,i_2,\ldots,i_k-1,\ldots,i_M\rangle,\\
&a_k^+a_k|i_1,i_2,\ldots,i_M\rangle=i_k|i_1,i_2,\ldots,i_k,\ldots,i_M\rangle,\\
&e^{a_k}|i_1,i_2,\ldots,i_M\rangle=\sum_{j=0}^{i_k}\frac{i_k!}{j!(i_k-j)!}|i_1,i_2,\ldots,j,\ldots,i_M\rangle.
\end{aligned} \tag{9}$$

In this paper, the following corresponding relations between the boson creation and annihilation operators and the differential operators will be adopted for simplicity,

$$a_i^+\Leftrightarrow\xi_i,\quad a_i\Leftrightarrow\frac{\partial}{\partial\xi_i},\quad i=1,2,\ldots,M, \tag{10}$$

they satisfy, respectively,

$$\begin{aligned}
&[a_i,a_j^+]=\delta_{ij},\quad [a_i,a_j]=[a_i^+,a_j^+]=0;\\
&\left[\frac{\partial}{\partial\xi_i},\xi_j\right]=\delta_{ij},\quad \left[\frac{\partial}{\partial\xi_i},\frac{\partial}{\partial\xi_j}\right]=[\xi_i,\xi_j]=0.
\end{aligned} \tag{11}$$

Thus, by making use of Eq. (10), we can immediately obtain the IHDR of $\mathcal{G}$ from the IHBR of $\mathcal{G}$.

III. IHBRs AND IHDRs OF $\mathcal{L}_2$

According to the definition (1), the polynomial angular momentum algebra $\mathcal{L}_2$ is spanned by three elements $\{J_3,J_\pm\}$, which satisfy the commutation relations,

$$[J_3,J_\pm]=\pm J_\pm,\quad [J_+,J_-]=C_0+C_1J_3+C_2J_3^2, \tag{12}$$

where C_i $(i=0,1,2)$ are real numbers. The basis for its universal enveloping algebra $U(\mathcal{L}_2)$ can be written as

$$\{X(n,m,r)=J_+^nJ_-^mJ_3^r|n,m,r\in\mathcal{N}\}, \tag{13}$$

and $X(0,0,0)=1$ denotes the identity operator. It follows that we have

$$\begin{aligned}
\rho(J_3)X(n,m,r)&=X(n,m,r+1)+(n-m)X(n,m,r),\\
\rho(J_+)X(n,m,r)&=X(n+1,m,r),\\
\rho(J_-)X(n,m,r)&=X(n,m+1,r)-C_2nX(n-1,m,r+2)-[C_1n+C_2n(n-1-2m)]\\
&\quad\times X(n-1,m,r+1)-\{C_0n+\tfrac{1}{2}C_1n(n-1-2m)+\tfrac{1}{6}C_2n[(n-1)(2n-1)\\
&\quad-6m(n-1-m)]\}X(n-1,m,r).
\end{aligned} \tag{14}$$

Here we have used the following equations with respect to Eq. (12):

$$
\begin{aligned}
&[J_3, J_\pm^n] = \pm n J_\pm^n, \\
&[J_-, J_+^n] = -n J_+^{n-1}\{C_2 J_3^2 + [C_1 + C_2(n-1)]J_3 \\
&\qquad + [C_0 + \tfrac{1}{2}C_1(n-1) + \tfrac{1}{6}C_2(n-1)(2n-1)]\}.
\end{aligned} \tag{15}
$$

It is easy to prove that the map ρ forms a master representation of $\mathcal{L}_2$ on $U(\mathcal{L}_2)$, i.e., that

$$
[\rho(J_3), \rho(J_\pm)] = \pm \rho(J_\pm), \quad [\rho(J_+), \rho(J_-)] = C_0 + C_1\rho(J_3) + C_2\rho(J_3^2). \tag{16}
$$

The corresponding Fock representation may be obtained by the approach discussed in the preceding Sec. II as

$$
\begin{aligned}
&F(J_3)|n,m,r\rangle = |n,m,r+1\rangle + (n-m)|n,m,r\rangle, \\
&F(J_+)|n,m,r\rangle = |n+1,m,r\rangle, \\
&F(J_-)|n,m,r\rangle = |n,m+1,r\rangle - C_2 n|n-1,m,r+2\rangle - [C_1 n + C_2 n(n-1-2m)]|n-1,m,r+1\rangle \\
&\qquad - \{C_0 n + \tfrac{1}{2}C_1 n(n-1-2m) + \tfrac{1}{6}C_2 n[(n-1)(2n-1) \\
&\qquad - 6m(n-1-m)]\}|n-1,m,r\rangle.
\end{aligned} \tag{17}
$$

By making use of Eq. (9), we can immediately obtain from Eq. (17) the IHBR of $\mathcal{L}_2$,

$$
\begin{aligned}
&B(J_3) = a_3^+ + a_1^+ a_1 - a_2^+ a_2, \quad B(J_+) = a_1^+, \\
&B(J_-) = a_2^+ - (C_0 + C_1 a_3^+ + C_2 (a_3^+)^2)a_1 + (C_1 - C_2 + 2C_2 a_3^+)a_2^+ a_2 a_1 \\
&\qquad - \tfrac{1}{2}(C_1 + C_2 + 2C_2 a_3^+)a_1^+ a_1^2 - C_2 (a_2^+)^2 a_2^2 a_1 + C_2 a_2^+ a_1^+ a_2 a_1^2 - \tfrac{1}{3}C_2 (a_1^+)^2 a_1^3.
\end{aligned} \tag{18}
$$

The corresponding IHDR may be obtained directly in terms of the relation (10) as

$$
\begin{aligned}
&D(J_3) = \xi_3 + \xi_1 \frac{\partial}{\partial \xi_1} - \xi_2 \frac{\partial}{\partial \xi_2}, \quad D(J_+) = \xi_1, \\
&D(J_-) = \xi_2 - (C_0 + C_1 \xi_3 + C_2 \xi_3^2)\frac{\partial}{\partial \xi_1} + (C_1 - C_2 + 2C_2 \xi_3)\xi_2 \frac{\partial^2}{\partial \xi_1 \partial \xi_2} \\
&\qquad - \frac{1}{2}(C_1 + C_2 + 2C_2 \xi_3)\xi_1 \frac{\partial^2}{\partial \xi_1^2} - C_2 \xi_2^2 \frac{\partial^3}{\partial \xi_1 \partial \xi_2^2} + C_2 \xi_1 \xi_2 \frac{\partial^3}{\partial \xi_1^2 \partial \xi_2} - \frac{1}{3} C_2 \xi_1^2 \frac{\partial^3}{\partial \xi_1^3}.
\end{aligned} \tag{19}
$$

Equations (18) and (19) are the *three-boson* realization and the *three-variable* differential realization of $\mathcal{L}_2$, respectively. When $C_0 = 0$, $C_1 = 1$, and $C_2 = 0$, Eqs. (18) and (19) become the results of the ordinary angular momentum algebra su(2).[19,20]

In the following, we shall further consider several quotient spaces $U(\mathcal{L}_2)/I_i$, where I_i are the left ideals with respect to $U(\mathcal{L}_2)$, and discuss, by the same approach, the IHBRs and IHDRs of $\mathcal{L}_2$ from its induced representations on $U(\mathcal{L}_2)/I_i$.

(1) On the quotient space $U(\mathcal{L}_2)/I_1$, where the left ideal I_1 is generated by one element $J_3 - \Lambda 1 (\Lambda \in \mathcal{C})$, with the basis,

$$
\{X(n,m) \equiv X(n,m,0) \bmod I_1 | n,m \in \mathcal{N}\} \tag{20}
$$

the master representation ρ, given by Eq. (14), induces a representation

$$\rho_1(J_3)X(n,m)=(\Lambda+n-m)X(n,m),$$

$$\rho_1(J_+)X(n,m)=X(n+1,m), \tag{21}$$

$$\rho_1(J_-)X(n,m)=X(n,m+1)-\{C_2n\Lambda^2+[C_1n+C_2n(n-1-2m)]\Lambda+C_0n+\tfrac{1}{2}C_1n(n-1-2m)+\tfrac{1}{6}C_2n[(n-1)(2n-1)-6m(n-1-m)]\}X(n-1,m).$$

In the process of calculating Eq. (21), the property $\rho_1(J_3)1=\Lambda 1$ has been utilized. It is obvious that the operator $\rho_1(J_3)$ on $U(\mathcal{L}_2)/I_1$ has the eigenvector $X(n,m)$ corresponding to the eigenvalue $\Lambda+n-m$. Thus, by making use of Eq. (9), we may obtain from the Fock representation that corresponds to Eq. (21) the IHBR of $\mathcal{L}_2$,

$$B_1(J_3)=\Lambda+a_1^+a_1-a_2^+a_2,\quad B_1(J_+)=a_1^+,$$
$$B_1(J_-)=a_2^+-(C_0+C_1\Lambda+C_2\Lambda^2)a_1+(C_1-C_2+2C_2\Lambda)a_2^+a_2a_1-\tfrac{1}{2}(C_1+C_2+2C_2\Lambda)a_1^+a_1^2-C_2(a_2^+)^2a_2^2a_1+C_2a_2^+a_1^+a_2a_1^2-\tfrac{1}{3}C_2(a_1^+)^2a_1^3. \tag{22}$$

The corresponding IHDR reads

$$D_1(J_3)=\Lambda+\xi_1\frac{\partial}{\partial\xi_1}-\xi_2\frac{\partial}{\partial\xi_2},\quad D_1(J_+)=\xi_1,$$
$$D_1(J_-)=\xi_2-(C_0+C_1\Lambda+C_2\Lambda^2)\frac{\partial}{\partial\xi_1}+(C_1-C_2+2C_2\Lambda)\xi_2\frac{\partial}{\partial\xi_1\partial\xi_2}-\frac{1}{2}(C_1+C_2+2C_2\Lambda)\xi_1\frac{\partial^2}{\partial\xi_1^2}-C_2\xi_2^2\frac{\partial^3}{\partial\xi_1\partial\xi_2^2}+C_2\xi_1\xi_2\frac{\partial^3}{\partial\xi_1^2\partial\xi_2}-\frac{1}{3}C_2\xi_1^2\frac{\partial^3}{\partial\xi_1^3}. \tag{23}$$

Equations (22) and (23) are the *two-boson* realizations and the *two-variable* differential realizations of $\mathcal{L}_2$, respectively.

(2) Consider a left ideal I_2 generated by the one element $J_-\lambda 1(\lambda\in\mathcal{C})$. Then, on the quotient space $U(\mathcal{L}_2)/I_2$ with the basis

$$\{X(nr)\equiv X(n0r)\bmod I_2|n,r,\in\mathcal{N}\} \tag{24}$$

the master representation ρ, Eq. (14), induces a representation,

$$\rho_2(J_3)X(n,r)=X(n,r+1)+nX(n,r),$$

$$\rho_2(J_+)X(n,r)=X(n+1,r), \tag{25}$$

$$\rho_2(J_-)X(n,r)=\lambda\sum_{k=0}^{r}C_r^kX(n,k)-C_2nX(n-1,r+2)-[C_1n+C_2n(n-1)]X(n-1,r+1)-[C_0n+\tfrac{1}{2}C_1n(n-1)+\tfrac{1}{6}C_2n(n-1)(2n-1)]X(n-1,r),$$

where the symbol C_r^k is the usual binomial coefficient $C_r^k=r!/k!(r-k!,)$ and the property $\rho_2(J_-)1=\lambda 1$ has been used. From the Fock representation that corresponds to Eq. (25), we may obtain with the help of Eq. (9) the IHBR of $\mathcal{L}_2$,

$$B_2(J_3)=a_2^++a_1^+a_1,\quad B_2(J_+)=a_1^+,$$
$$B_2(J_-)=\lambda e^{a_2}-(C_0+C_1a_2^++C_2(a_2^+)^2)a_1-\tfrac{1}{2}(C_1+C_2+2C_2a_2^+)a_1^+a_1^2-\tfrac{1}{3}C_2(a_1^+)^2a_1^3. \tag{26}$$

The corresponding IHDR is obtained directly as

$$D_2(J_3)=\xi_2+\xi_1\frac{\partial}{\partial\xi_1},\quad D_2(J_+)=\xi_1,$$
$$D_2(J_-)=\lambda e^{\partial/\partial\xi_2}-(C_0+C_1\xi_2+C_2\xi_2^2)\frac{\partial}{\partial\xi_1}-\frac{1}{2}(C_1+C_2+2C_2\xi_2)\xi_1\frac{\partial^2}{\partial\xi_1^2}-\frac{1}{3}C_2\xi_1^2\frac{\partial^2}{\partial\xi_1^3}. \tag{27}$$

Compared to Eqs. (22) and (23), clearly, Eqs. (26) and (27) are another kind of *two-boson* realization and the *two-variable* differential realization of $\mathcal{L}_2$, respectively.

(3) On the quotient space $U(\mathcal{L}_2)/I_3$, where the left ideal I_3 is generated by two elements $\{J_-, J_3-\kappa 1\}(\kappa\in C)$, with the basis

$$\{X(n)\equiv X(n00)\bmod I_3 | n\in\mathcal{N}\}, \tag{28}$$

the master representation ρ, Eq. (14), induces a representation,

$$\rho_3(J_3)X(n)=(\kappa+n)X(n),$$
$$\rho_3(J_+)X(n)=X(n+1), \tag{29}$$
$$\rho_3(J_-)X(n)=-\{(C_0+C_1\kappa+C_2\kappa^2)n+(C_2\kappa+\tfrac{1}{2}C_1)n(n-1)+\tfrac{1}{6}C_2n(n-1)(2n-1)\}X(n-1),$$

by virtue of the property $\rho_3(J_3)1=\kappa 1$. The operator $\rho(J_3)$ on $U(\mathcal{L}_2)/I_3$ has the eigenvector $X(n)$ with $\kappa+n$ as the eigenvalue. From the Fock representation that corresponds to (29), we may obtain by making use of Eq. (9) the IHBR of $\mathcal{L}_2$,

$$B_3(J_3)=\kappa+a_1^+a_1,\quad B_3(J_+)=a_1^+, \tag{30}$$
$$B_3(J_-)=-(C_0+C_1\kappa+C_2\kappa^2)a_1-\tfrac{1}{2}(C_1+C_2+2C_2\kappa)a_1^+a_1^2-\tfrac{1}{3}C_2(a_1^+)^2a_1^3.$$

The corresponding IHDR reads

$$D_3(J_3)=\kappa+\xi_1\frac{d}{d\xi_1},\quad D_3(J_+)=\xi_1, \tag{31}$$
$$D_3(J_-)=-(C_0+C_1\kappa+C_2\kappa^2)\frac{d}{d\xi_1}-\frac{1}{2}(C_1+C_2+2C_2\kappa)\xi_1\frac{d^2}{d\xi_1^2}-\frac{1}{3}C_2\xi_1^2\frac{d^3}{d\xi_1^3}.$$

Equations (30) and (31) are the *single-boson* realization and the *single-variable* differential realization of $\mathcal{L}_2$, respectively. When $C_0=0$, $C_1=1$, and $C_2=0$, combined with $\kappa=-j$, Eq. (30) becomes the so-called Gel'fand–Dyson representation of the ordinary angular momentum algebra su(2).[23] The single-variable differential realization (31) is not any of the three kinds of single-variable differential realizations obtained by Beckers *et al.*[14]

IV. DISCUSSIONS

In this paper the single-, two-, and three-boson realizations and the corresponding single-, two-, and three-variable differential realizations of the polynomial angular momentum algebra of quadratic type, $\mathcal{L}_2$, are obtained, respectively, from the master representation of $\mathcal{L}_2$ on the space of its universal enveloping algebra and the induced representations on the quotient spaces. It is easy to check that all these realizations satisfy the commutation relations (12) of $\mathcal{L}_2$. It is worthy of noting that (a) these boson realizations, given by Eqs. (22), (26), and (30), are merely the basic forms since from them we may construct the more complex forms of boson realizations. For example, replacing the arbitrary constant numbers, Λ in Eq. (22), λ in Eq. (26), and κ in Eq. (30),

by $\Lambda a_3^+ a_3$, $\lambda a_3^+ a_3$, and $\kappa a_2^+ a_2$, respectively, will lead to the extended boson realizations of $\mathcal{L}_2$, which satisfy the commutation relations (12) of $\mathcal{L}_2$ as well. The similar property is held for the corresponding differential realizations. (b) For the universal enveloping algebra $U(\mathcal{L}_2)$, we can further choose the other bases by ordering three generators J_+, J_-, J_3 in different sequences such as $J_-^n J_+^m J_3^r$, $(n,m,r \in \mathcal{N})$, $J_3^n J_+^m J_-^r$ and so on, then the corresponding inhomogeneous boson and differential realizations of $\mathcal{L}_2$ may be obtained easily by the approach used above. In fact, the realizations based upon the base $\{J_-^n J_+^m J_3^r\}$ and upon the base $\{J_+^n J_-^m J_3^r\}$ adopted in this paper may be related by simple symmetry considerations. We see that the approach we employed is straightforward and simpler than the other methods, and may be applied to the polynomial angular momentum algebra of an higher degree, $\mathcal{L}_n (n>2)$, and the other nonlinear Lie (super)algebras associated with ordinary Lie (super)algebras.[24] This work is now underway.

Classification of *R*-operators[a]

Youichi Shibukawa
Department of Mathematics, Faculty of Science, Hokkaido University, Sapporo 060-0810, Japan

(Received 24 August 2000; accepted for publication 6 February 2001)

We classified the *R*-operators which satisfy the quantum Yang–Baxter equation on a function space. In this study, we gave all the meromorphic solutions of the system of the functional equations which is a necessary and sufficient condition for the *R*-operator to satisfy the Yang–Baxter equation. Most of the solutions were expressed in terms of the elliptic, trigonometric and rational functions. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1367326]

I. INTRODUCTION

During the last 8 years, significant advances have been made in our understanding of the solutions of the (quantum) Yang–Baxter equation on a function space, which we call the *R*-operators.[1–3]

Definition 1 (R-operator[1]): For $x_1,x_2,\ldots,x_n\in\mathbb{C}$ and $r>0$, define the sets $C(x_1,r)$ and $C((x_1,x_2,\ldots,x_n),r)$ by $C(x_1,r)=\{x\in\mathbb{C};|x-x_1|<r\}$ and $C((x_1,x_2,\ldots,x_n),r)=C(x_1,r)\times C(x_2,r)\times\ldots\times C(x_n,r)$. Let functions $A(x)$ and $B(u,x)$ be meromorphic on $C(0,r)$ and $C((0,0),r)$, respectively. For a function f meromorphic on $C((0,0),r/2)$, we define the function $(R(u)f)(z_1,z_2)$ meromorphic on $C(0,r)\times C((0,0),r/2)(\ni(u,z_1,z_2))$ as

$$(R(u)f)(z_1,z_2)=A(z_1-z_2)f(z_1,z_2)-B(u,z_1-z_2)f(z_2,z_1).$$

We call this operator $R(u)$ the *R*-operator.

There are three kinds of the *R*-operators expressed in terms of the elliptic, trigonometric, and rational functions, respectively. The elliptic *R*-operator has been investigated in particular. We found it by taking the limit $n\to\infty$ of Belavin's *R*-matrix.[1] Belavin's *R*-matrix is conversely obtained through restricting the domain of a modified version of the elliptic *R*-operator to a suitable finite-dimensional subspace.[4] This suggests that the properties of Belavin's *R*-matrix are generalized to those of the elliptic *R*-operator. Actually the author constructed the incoming and outgoing intertwining vectors for the elliptic *R*-operator, and proved the vertex-IRF correspondence.[5] The boundary *K*-operators,[6,7] which satisfy the boundary Yang–Baxter equation for the elliptic *R*-operator, are also obtained. We essentially use the elliptic *R*-operator and boundary *K*-operators to construct the (generalized) Ruijsenaars operators,[8–10] the commuting difference operators. Therefore, it is very important to find out new solutions of the Yang–Baxter equation in order to investigate the integrable models. What remains a question is the classification of the *R*-operators.

The aim of this article is to classify the *R*-operators.

Proposition I.1: For any function f meromorphic on $C((0,0,0),r/2)$, a necessary and sufficient condition for the functions $R_{12}(u)R_{13}(u+v)R_{23}(v)f$ and $R_{23}(v)R_{13}(u+v)R_{12}(u)f$ meromorphic on $C((0,0,0,0,0),r/2)$ to satisfy the Yang–Baxter equation

$$R_{12}(u)R_{13}(u+v)R_{23}(v)f=R_{23}(v)R_{13}(u+v)R_{12}(u)f$$

is that the meromorphic functions A and B satisfy the following equations on $C((0,0,0,0),r/2)$:

[a]Dedicated to Professor Yoshiyuki Shimizu on the occasion of his sixtieth birthday.

$$B(u+v,x+y)(A(x)A(-x)-A(y)A(-y))$$
$$=B(v,y)B(u+v,x)B(u,y)-B(u,x)B(u+v,y)B(v,x), \tag{1}$$

$$A(y)B(u,x)B(v,x+y)=A(y)(B(u+v,x+y)B(u,-y)+B(v,y)B(u+v,x)). \tag{2}$$

Therefore, in order to classify the *R*-operators, we gave the complete classification of the meromorphic solutions A and B of the functional equations (1) and (2).

Theorem I.2: *The meromorphic solutions $A(x)$ and $B(u,x)$ of Eqs. (1) and (2) defined on the polydiscs $C(0,r)$ and $C((0,0),r)$, respectively, are one of the following*:
0. *Trivial case:*

$$A(x) \text{ is arbitrary}, \quad B(u,x)\equiv 0.$$

$$A(x)\equiv 0,$$

$$B(u,x)=\exp(F(x)u)G(u) \text{ on } C(0,r)\times C(0,r_1)$$

$$(0<r_1\leqslant r).$$

1. *Generic case:*
1-1. *Elliptic:*

$$A(x)=c\cdot h(x)\frac{\sigma(x+s;\tau_1,\tau_2)}{\sigma(x;\tau_1,\tau_2)\sigma(s;\tau_1,\tau_2)},$$

$$B(u,x)=c\exp(\rho u x)\frac{\sigma(x+au;\tau_1,\tau_2)}{\sigma(x;\tau_1,\tau_2)\sigma(au;\tau_1,\tau_2)}$$

$$(a,c,\tau_1,\tau_2\in\mathbb{C}\setminus\{0\},\operatorname{Im}\tau_2/\tau_1>0,s\in\mathbb{C}\setminus(\mathbb{Z}\tau_1+\mathbb{Z}\tau_2),\rho\in\mathbb{C}).$$

1-2. *Trigonometric:*

$$A(x)=\begin{cases} c\cdot h(x)\dfrac{\sinh(x+s)/\lambda}{\sinh(x/\lambda)\sinh(s/\lambda)}, \\ c\cdot h(x)\dfrac{1}{\sinh(x/\lambda)}, \end{cases}$$

$$B(u,x)=\begin{cases} c\exp(\rho u x)\dfrac{\sinh(x+au)/\lambda}{\sinh(x/\lambda)\sinh(au/\lambda)}, \\ c\exp(\rho u x)\dfrac{\exp(\pm x/\lambda)}{\sinh x/\lambda} \end{cases}$$

$$(a,c,\lambda\in\mathbb{C}\setminus\{0\},s\in\mathbb{C}\setminus\mathbb{Z}\pi\sqrt{-1}\lambda,\rho\in\mathbb{C}).$$

1-3. *Rational:*

$$A(x)=\begin{cases} c\cdot h(x)\dfrac{x+s}{xs}, \\ c\cdot h(x)\dfrac{1}{x}, \end{cases} \qquad B(u,x)=\begin{cases} c\exp(\rho u x)\dfrac{x+au}{axu}, \\ c\exp(\rho u x)\dfrac{1}{x} \end{cases}$$

$$(a,c,s\in\mathbb{C}\setminus\{0\},\rho\in\mathbb{C}).$$

2. *Singular case:*

$$A(x)=c_1h(x),\quad B(u,x)=c_2\exp(\rho ux)\frac{1}{u}$$

$$(c_1,\rho\in\mathbb{C},c_2\in\mathbb{C}\setminus\{0\}).$$

Here the function F is holomorphic on $C(0,r_1)$, the function $G(\not\equiv 0)$ is meromorphic on $C(0,r)$, the function h is meromorphic on $C(0,r)$ satisfying the relation $h(x)h(-x)=1$ and the function $\sigma(x)=\sigma(x;\tau_1,\tau_2)$ is the Weierstrass sigma function,

$$\sigma(x;\tau_1,\tau_2)=x\prod_{\omega=m_1\tau_1+m_2\tau_2}\left\{\left(1-\frac{x}{\omega}\right)\exp\left(\frac{x}{\omega}+\frac{1}{2}\left(\frac{x}{\omega}\right)^2\right)\right\},$$

where (m_1,m_2) in the product above runs over all the elements in $\mathbb{Z}^2$ except (0, 0).

We can show the following theorem easily.

Theorem I.3: *The functions A and B in Theorem I.2 satisfy Eqs. (1) and (2).*

Our strategy to solve the functional equations (1) and (2) is as follows. We reduced Eqs. (1) and (2) to the functional equation introduced by Braden and Buchstaber:[11]

$$\phi_1(x+y)(\phi_4(x)\phi_5(y)-\phi_4(y)\phi_5(x))=\phi_2(x)\phi_3(y)-\phi_2(y)\phi_3(x). \tag{3}$$

They have proved that the solutions of this functional equation above were characterized by those of the functional equation discussed by Bruschi and Calogero:[12,13]

$$\alpha(x+y)-\alpha(x)\alpha(y)=\varphi(x)\varphi(y)\psi(x+y). \tag{4}$$

Since Kawazumi and the author[14] have given the complete classification of the meromorphic solutions near the origin of Eq. (4), we obtained all the meromorphic solutions of Eqs. (1) and (2) near the origin.

Let us now explain how this article is organized. Section II gives a brief summary of the functional equations above. In Sec. III, we solve the functional equations (1) and (2) on the assumptions that $B\not\equiv 0$ and that $A(x)A(-x)$ is not identically constant. There are three kinds of meromorphic solutions of Eqs. (1) and (2) expressed in terms of the elliptic, trigonometric and rational functions. We discuss the elliptic case in Sec. IV, the trigonometric case in Sec. V and the rational case in Sec. VI, respectively. Section VII presents the classification of the meromorphic solutions of the functional equations (1) and (2) on the assumptions that $B\not\equiv 0$ and that $A(x)A(-x)(\not\equiv 0)$ is identically constant. In the final section, Sec. VIII, we classify the meromorphic solutions of the functional equations (1) and (2) with $A\equiv 0$ or $B\equiv 0$.

After finishing this article, the author found the thesis[15] in which Komori investigated the *R*-operators associated with root algebras. We note that the definition of the *R*-operators in his thesis was slightly different from that in this article.

II. REVIEWS OF CERTAIN FUNCTIONAL EQUATIONS OF ADDITION TYPE

In this section, we review the solutions of the functional equations (3) and (4) of addition type.

A. Solutions of Eq. (4)

Bruschi and Calogero have investigated the general analytic solution of Eq. (4).[12,13] They have obtained the elliptic solution in the most general case and some trigonometric and rational solutions by degenerating the periods of the elliptic functions.

Kawazumi and the author classified the meromorphic solutions near the origin of Eq. (4).

Theorem II.1 (Kawazumi-Shibukawa[14]): *Let α, φ and ψ be holomorphic functions defined on a punctured disk $\{x\in\mathbb{C};0<|x|<r'\}$ for some $r'>0$. If they satisfy the functional equation (4), then they are equal to one of the following functions.*

$$\text{(0-i)}\quad \alpha(x)=0 \ \ or \ \ \exp(\rho x)\ \ (\rho\in\mathbb{C}),$$

$$\varphi\equiv 0 \ \ and \ \ \psi\text{: arbitrary, } or \ \ \varphi\text{: arbitrary and } \psi\equiv 0.$$

$$\text{(0-ii)}\quad \alpha(x)=C\exp(\rho x),\quad \varphi(x)=C_1\exp(C_2x),$$

$$\psi(x)=C(1-C)C_1^{-2}\exp((\rho-C_2)x)$$

$$(C,\rho,C_1,C_2\in\mathbb{C}, C\neq 0,1, C_1\neq 0).$$

$$\text{(I)}\quad \alpha(x)=\exp(\rho x)\frac{\sigma(\nu;\tau_1,\tau_2)\sigma(x+\mu;\tau_1,\tau_2)}{\sigma(\mu;\tau_1,\tau_2)\sigma(x+\nu;\tau_1,\tau_2)},$$

$$\varphi(x)=\exp(C_1x+C_2)\frac{\sigma(x)}{\sigma(x+\nu)},$$

$$\psi(x)=\exp((\rho-C_1)x-2C_2)\frac{\sigma(\nu)\sigma(\mu-\nu)\sigma(x+\mu+\nu)}{\sigma^2(\mu)\sigma(x+\nu)},$$

$$(\rho,\mu,\nu,C_1,C_2\in\mathbb{C},\ \ \tau_1,\tau_2\in\mathbb{C}\setminus\{0\},\ \ \mathrm{Im}\,\tau_2/\tau_1>0\quad \mu,\nu\notin\mathbb{Z}\tau_1+\mathbb{Z}\tau_2,\quad \mu-\nu\notin\mathbb{Z}\tau_1+\mathbb{Z}\tau_2).$$

$$\text{(II)}\quad \alpha(x)=\exp(\rho x)\frac{a(\exp(2x/\lambda)-1)+b}{c(\exp(2x/\lambda)-1)+b},$$

$$\varphi(x)=\exp(C_1x+C_2)\frac{\exp(2x/\lambda)-1}{c(\exp(2x/\lambda)-1)+b},$$

$$\psi(x)=\exp(-C_1x-2C_2)\frac{(a-c)\{-ac(\exp(2x/\lambda)-1)+b^2-b(a+c)\}}{c(\exp(2x/\lambda)-1)+b}$$

$$(\lambda,\rho,a,b,c,C_1,C_2\in\mathbb{C},\ \ \lambda\neq 0,\ \ b(a-c)\neq 0).$$

$$\text{(III)}\quad \alpha(x)=\exp(\rho x)\frac{ax+b}{cx+b},\ \ \varphi(x)=\exp(C_1x+C_2)\frac{x}{cx+b},$$

$$\psi(x)=\exp((\rho-C_1)x-2C_2)\frac{(c-a)\{acx+b(a+c)\}}{cx+b}$$

$$(\rho,a,b,c,C_1,C_2\in\mathbb{C},\ \ b(a-c)\neq 0).$$

All the solutions except for the case (0-i) *extend themselves to meromorphic functions defined on the whole plane* $\mathbb{C}$.

Remark: In Theorem II.1 (I), we use τ_1, τ_2, μ and ν instead of τ_1/λ, τ_2/λ, μ/λ and ν/λ in Ref. 14. Moreover, we note that the condition $\mu-\nu\notin\mathbb{Z}\tau_1+\mathbb{Z}\tau_2$ in Theorem II.1 (I) was dropped in Ref. 14.

B. Solutions of Eq. (3)

Braden and Buchstaber[11] have investigated Eq. (3). They have shown that the solutions of Eq. (3) were characterized by the solutions of Eq. (4). We review their results briefly.

Let ϕ_1 be a holomorphic function on $C(2x_0,2r_0)$ and ϕ_2, ϕ_3, ϕ_4 and ϕ_5 be holomorphic functions on $C(x_0,r_0)$ for some $x_0\in\mathbb{C}$ and $r_0>0$. We assume that they satisfy the following conditions:

(a) Eq. (3) for all $x,y\in C(x_0,r_0)$,
(b) $\phi_2(x_0)\phi_3'(x_0)-\phi_2'(x_0)\phi_3(x_0)\neq 0$,
(c) $\phi_4(x_0)\phi_5'(x_0)-\phi_4'(x_0)\phi_5(x_0)\neq 0$.

Lemma II.2: We define the function $\tilde{\phi}_1$ *holomorphic on* $C(0,2r_0)$ *and the functions* $\tilde{\phi}_2,\ldots,\tilde{\phi}_5$ *holomorphic on* $C(0,r_0)$ *as follows*:

$$\tilde{\phi}_1(x)=c\,\phi_1(x+2x_0),$$

$$\begin{pmatrix}\tilde{\phi}_{2k}(x)\\ \tilde{\phi}_{2k+1}(x)\end{pmatrix}=\begin{pmatrix}\phi_{2k}'(x_0) & \phi_{2k}(x_0)\\ \phi_{2k+1}'(x_0) & \phi_{2k+1}(x_0)\end{pmatrix}^{-1}\begin{pmatrix}\phi_{2k}(x+x_0)\\ \phi_{2k+1}(x+x_0)\end{pmatrix}\quad(k=1,2),$$

where

$$c=\det\begin{pmatrix}\phi_4'(x_0) & \phi_4(x_0)\\ \phi_5'(x_0) & \phi_5(x_0)\end{pmatrix}\Big/\det\begin{pmatrix}\phi_2'(x_0) & \phi_2(x_0)\\ \phi_3'(x_0) & \phi_3(x_0)\end{pmatrix}.$$

Then they satisfy

$$\tilde{\phi}_1(x+y)(\tilde{\phi}_4(x)\tilde{\phi}_5(y)-\tilde{\phi}_4(y)\tilde{\phi}_5(x))=\tilde{\phi}_2(x)\tilde{\phi}_3(y)-\tilde{\phi}_2(y)\tilde{\phi}_3(x)$$

for all $x,\ y\in C(0,r_0)$.

By straightforward computation, we deduce $\tilde{\phi}_{2k}(0)=\tilde{\phi}_{2k+1}'(0)=0$ and $\tilde{\phi}_{2k}'(0)=\tilde{\phi}_{2k+1}(0)=1$ for $k=1,2$.

Lemma II.3: There exist $(0<)r_2\leqslant r_1$, *the functions* γ_k *and* ξ_k $(k=1,2)$ *holomorphic on* $C(0,r_2)$ *such that* $\gamma_k(x)\neq 0$ *for all* $x\in C(0,r_2)$,

$$\begin{pmatrix}\tilde{\phi}_{2k}(x)\\ \tilde{\phi}_{2k+1}(x)\end{pmatrix}=\frac{1}{\gamma_k(x)}\begin{pmatrix}\xi_k(x)\\ \xi_k'(x)\end{pmatrix}$$

for all $x\in C(0,r_2)$, $\xi_k(0)=0$, *and* $\xi_k'(0)=\gamma_k(0)=1$.

For $k=1,2$, define $\tilde{\xi}_k(x)=\exp(-\lambda_k x)\xi_k(x)$, where $\lambda_k=-\tilde{\phi}_{2k}''(0)/2$. Then the functions $\tilde{\xi}_k(x)$ are holomorphic on $C(0,r_2)$ and satisfy $\tilde{\xi}_k(0)=\tilde{\xi}_k''(0)=0$ and $\tilde{\xi}_k'(0)=1$. We define the functions $\tilde{\xi}_0$ on $x\in C(0,2r_2)$ and γ on $x\in C(0,r_2)$ by $\tilde{\xi}_0(x)=\exp((\lambda_1-\lambda_2)x)\tilde{\phi}_1(x)$ and $\gamma(x)=\exp(2(\lambda_1-\lambda_2)x)\gamma_2(x)/\gamma_1(x)$.

Lemma II.4: (1) *The function* $\tilde{\xi}_1(x)/\tilde{\xi}_2(x)$ *is holomorphic on* $C(0,r_2)$.
(2) *For all* $x,y\in C(0,r_2)$

$$\tilde{\xi}_0(x+y)(\tilde{\xi}_2(x)\tilde{\xi}_2'(y)-\tilde{\xi}_2(y)\tilde{\xi}_2'(x))=\gamma(x)\gamma(y)(\tilde{\xi}_1(x)\tilde{\xi}_1'(y)-\tilde{\xi}_1(y)\tilde{\xi}_1'(x)).$$

Since there exists $(0<)r_3\leqslant r_2$ such that $\tilde{\xi}_1(x)\neq 0$ and $\tilde{\xi}_2(x)\neq 0$ for all $x\in C(0,r_3)\backslash\{0\}$, we are led to the following.

Theorem II.5 (Braden–Buchstaber[11]):

(1) $\gamma(x)=(\tilde{\xi}_2(x)/\tilde{\xi}_1(x))^2$ *and* $\tilde{\xi}_0(x)=\tilde{\xi}_2(x)/\tilde{\xi}_1(x)$ *for all* $x\in C(0,r_3)$.
(2) *Define the functions* α *and* φ *holomorphic on* $C(0,r_3)$ *by* $\alpha(x)=\tilde{\xi}_2(x)/\tilde{\xi}_1(x)$ *and* $\varphi(x)=\tilde{\xi}_2(x)$. *Then they satisfy Eq. (4) for all* $x,\ y\in C(0,r_3/2)\backslash\{0\}$.

It is to be mentioned that the function ψ is determined by the functions α and φ. We can reconstruct the solutions $\phi_1,\ldots,\phi_5$ of Eq. (3) from the functions α and φ in the theorem above.

III. GENERIC CASE

In this section, we solve Eqs. (1) and (2) on the assumption below.

Assumption 1: (1) The meromorphic function $A(x)A(-x)$ is not identically constant on $C(0,r)$.

(2) The meromorphic function B is not identically zero on $C((0,0),r)$.

The purpose of this section is to prove the following theorem.

Theorem III.1: (1) *The function $A(x)A(-x)$ meromorphic on the disk $C(0,r)$ is one of the following:*

$$\textit{elliptic:}\quad A(x)A(-x)=\frac{a_1\wp(x;\tau_1,\tau_2)+a_2}{a_3\wp(x;\tau_1,\tau_2)+a_4}, \tag{5}$$

$$\textit{trigonometric:}\quad A(x)A(-x)=\frac{a_1\sinh^{-2}(x/\lambda)+a_2}{a_3\sinh^{-2}(x/\lambda)+a_4},$$

$$\textit{rational:}\quad A(x)A(-x)=\frac{a_1x^{-2}+a_2}{a_3x^{-2}+a_4},$$

where $\wp(x)=\wp(x;\tau_1,\tau_2)$ is the Weierstrass pe function

$$\wp(x;\tau_1,\tau_2)=-\frac{d}{dx}\left(\frac{\sigma'(x;\tau_1,\tau_2)}{\sigma(x;\tau_1,\tau_2)}\right),$$

and the constants $\tau_1,\ \tau_2,\ \lambda\in\mathbb{C}\backslash\{0\}$ and $a_1,\ a_2,\ a_3,\ a_4\in\mathbb{C}$ satisfy the relations $\mathrm{Im}\,\tau_2/\tau_1>0$ *and* $a_1a_4-a_2a_3\neq 0$.

(2) *There exists $C(u_1,r_1)\subset C(0,r/4)$ such that the function $B(u,x)$ is one of the following:*

$$\textit{elliptic:}\quad B(u,x)=\exp(\rho(u)x)b(u)\frac{\sigma(x+a(u);\tau_1,\tau_2)}{\sigma(x;\tau_1,\tau_2)}, \tag{6}$$

$$\forall(u,x)\in D_1\cap D^e\cap(C(u_1,r_1)\times C(0,r)),$$

$$\textit{trigonometric:}\quad B(u,x)=\exp(\tilde{\rho}(u)x)\tilde{b}(u)\times\frac{c(u)(\exp((x+2\tilde{a}(u))/\lambda)-\exp(-x/\lambda))+\exp(-x/\lambda)}{\sinh(x/\lambda)}, \tag{7}$$

$$\forall(u,x)\in D_1\cap D^t\cap(C(u_1,r_1)\times C(0,r)),$$

$$\textit{rational:}\quad B(u,x)=\exp(\rho(u)x)\frac{b(u)+a(u)x}{x},$$

$$\forall(u,x)\in D_1\cap D^r\cap(C(u_1,r_1)\times C(0,r)),$$

where $\rho(u),\ a(u),\ b(u)\in\mathbb{C}$ for all $u\in C(u_1,r_1)$. Here $D_1(\subset C((0,0),r))$ is the domain of the meromorphic function $B(u,x)$ and

$$D^e=C(0,r)\times(C(0,r)\backslash(\mathbb{Z}\tau_1+\mathbb{Z}\tau_2)),$$

$$D^t=C(0,r)\times(C(0,r)\backslash\mathbb{Z}\pi\sqrt{-1}\lambda),$$

$$D^r=C(0,r)\times(C(0,r)\backslash\{0\}).$$

Assumption 1 implies the following lemma. (For part (2), see Lemma 5 in Ref. 11.)

Lemma III.2: (1) *Equations (1) and (2) on* $C((0,0,0,0),r/2)$ *are equivalent to the following equations:*

$$A(x)A(-x)-A(y)A(-y)=B(u,x)B(u,-x)-B(u,y)B(u,-y), \tag{8}$$

$$B(u,x)B(v,x+y)=B(u+v,x+y)B(u,-y)+B(v,y)B(u+v,x) \tag{9}$$

on $C((0,0,0),r)$ *and* $C((0,0,0,0),r/2)$, *respectively.*

(2) *The meromorphic solutions* $A(x)$ *and* $B(u,x)$ *of the previous equations satisfy the equation*

$$\begin{aligned} &B(v,x+y)(A(x)A(-x)-A(y)A(-y)) \\ &\quad =B(u,-x)B(u+v,x)B(v,y)-B(u,-y)B(u+v,y)B(v,x) \end{aligned} \tag{10}$$

as meromorphic functions on $C((0,0,0,0),r/2)$.

Now we intend to apply Sec. II B to Eq. (10).

Lemma III.3: For any $C((u_0',x_0'),r_0')\subset C((0,0),r/2)$, *there exist* $(u_1,x_1)\in C((u_0',x_0'),r_0')$ *and* $r_1(>0)$ *such that*

(0) $C((u_1,x_1),r_1)\subset C((u_0',x_0'),r_0')$,

(1) $B(u,x)$ *is holomorphic on* $C((u_1,x_1),r_1)$, $C(u_1,r_1)\times C(2x_1,2r_1)$ *and* $C(2u_1,2r_1)\times C(x_1,r_1)$,

(2) $B(u,-x)$ *is holomorphic on* $C((u_1,x_1),r_1)$ *and* $C(u_1,r_1)\times C(2x_1,2r_1)$,

(3) $A(x)$ *is holomorphic on* $C(x_1,r_1)$ *and* $C(2x_1,2r_1)$,

(4) $A(-x)$ *is holomorphic on* $C(x_1,r_1)$ *and* $C(2x_1,2r_1)$,

(5) $B(u,x)\neq 0$ *for all* $(u,x)\in C((u_1,x_1),r_1)$.

By $C((u_0',x_0'),r_0')\coloneqq C((0,0),r/4)$ in Lemma III.3, there exist $(u_1,x_1)\in C((0,0),r/4)$ and r_1 (>0) satisfying the conditions in Lemma III.3.

Lemma III.4: (1) $(d/dx)(A(x)A(-x))\not\equiv 0$ *on* $C(x_1,r_1)$.

(2) *For all* u, $v\in C(u_1,r_1)$,

$$\begin{vmatrix} B(u,-x)B(u+v,x) & \dfrac{\partial}{\partial x}(B(u,-x)B(u+v,x)) \\ B(v,x) & \dfrac{\partial B}{\partial x}(v,x) \end{vmatrix} \not\equiv 0$$

on $C(x_1,r_1)$.

Proof: We prove part (2) only. The proof is by contradiction. Assume the assertion were false. Then there would exist u_0, $v_0\in C(u_1,r_1)$ such that

$$\begin{vmatrix} B(u_0,-x)B(u_0+v_0,x) & \dfrac{d}{dx}(B(u_0,-x)B(u_0+v_0,x)) \\ B(v_0,x) & \dfrac{\partial B}{\partial x}(v_0,x) \end{vmatrix} \equiv 0$$

on $C(x_1,r_1)$. Thus there exists $c\in\mathbb{C}$ such that

$$\frac{B(u_0,-x)B(u_0+v_0,x)}{B(v_0,x)}\equiv c \quad \text{on} \quad C(x_1,r_1).$$

By Eq. (10) and Assumption 1 (1), we have $B(v_0,x)\equiv 0$ on $C(2x_1,2r_1)$. From Lemma III.5, we get $B(v_0,x)\equiv 0$ on $C(0,r)$, which implies a contradiction of Assumption 1 (1) because of Eq. (8). □
