The following calculations provide expressions for the drift velocity and the average diffusion coefficient, applying to diffusion in configuration space of a nonrelativistic charged particle interacting with the zero-point field of stochastic electrodynamics. The particle is assumed to evolve according to a widely popular reduced form of the Braffort–Marshall equation, which is free from runaway solutions, and supposed to be found in stationary conditions, with regard to the average values of physical quantities. The results show an interesting similarity with the equations of quantum mechanics. © *2001 American Institute of Physics.*

I. INTRODUCTION

This work attempts to find a general expression for the diffusion coefficient of a particle interacting with a zero-point field (ZPF), following a procedure, which has been applied previously to a quasi-free particle in a ZPF.[1] It has been found that the results can be easily extended to cover more general cases of a particle acted upon by a static potential field, if one only wants to calculate the averaged diffusion coefficient in steady conditions. This modified procedure makes use of a representation of the response functions involved by a Fourier integral.

The position of the problem will be recalled very briefly in the following, since it has been displayed more extensively elsewhere.[1–5]

A charged particle in an electromagnetic (em) ZPF is considered, although a ZPF of different nature could also be taken into consideration,[6] embedded in a three-dimensional configuration space. The particle has mass m, electromagnetic charge e (or $-e$), and coordinate $\vec{x}$. Canonical coordinates and conjugated momenta are denoted by q_i, p_i $(i=1,2,3)$, and, since the static potential field $\nu(q_1,q_2,q_3)$ is assumed separable, the subscripts will be omitted throughout, thus reducing the problem to a one-dimensional one.

The full relativistic problem has been treated by Dirac, and Abraham and Lorentz (see Ref. 7 for a review). Here a nonrelativistic limit is taken, so that the following equation of motion results in each coordinate (the dots denoting time derivatives, and the prime derivatives with respect to the spatial coordinate in the argument)

$$-\tau_c\ddot{p}+\dot{p}+\nu'(q)=k(t) \tag{1.1}$$

with $p=m\dot{q}$, τ_c the interaction time related to the classical radius of the particle through the velocity of light c in vacuo,

$$\tau_c=\frac{2}{3}\frac{e^2}{mc^3}=\frac{2}{3}\left(\frac{1}{137}\right)^3 \quad \text{in a.u.,} \tag{1.2}$$

the numbers referring to the electron, $k(t)$ is the electric component of the force from ZPF. Equation (1.1) has often been called the Braffort–Marshall equation.

The stochastic properties of the random electric force $\vec{k}(t)=-e\vec{E}(t)$ have been analyzed in detail by numerous authors.[8–12] The spectrum is given by

$$\phi_{ij}(\omega)=m\hbar\,\tau_c|\omega|^3\delta_{ij}\,, \tag{1.3}$$

where $\hbar$ is Planck constant divided by 2π, ω the frequency, and δ_{ij} denoting the Kronecker symbols. Then the autocorrelation function of the electric force results

$$\phi_{ij}(t-s)=\frac{1}{2\pi}\int_{-\infty}^{+\infty}\mathrm{d}\omega\;\phi_{ij}(\omega)e^{-i\omega(t-s)-\varepsilon|t-s|} \tag{1.4}$$

with $\varepsilon>0$ arbitrarily small.

The next step consists of splitting the velocity into a Eulerian plus a Lagrangian component, in the following manner:[3]

$$p(q,t)=p(q)+\tilde{p}(t) \tag{1.5}$$

with $p(q)$ verifying a differential equation

$$-\frac{\tau_c}{m^2}[p(q)^2p''(q)+p(q)p'(q)^2]+\frac{1}{m}p(q)p'(q)+\nu'(q)=g(q), \tag{1.6}$$

$g(q)$ being an arbitrary smooth function, and $\tilde{p}(t)$ verifying the following system of first-order ordinary differential equations, valid to $O(\tau_c^2)$,

$$\left.\begin{aligned}\dot{q}&=\frac{1}{m}[p(q)+\tilde{p}(t)],\\ \dot{\tilde{p}}&=-\left[\frac{1}{m}p'(q)+\beta(q)+\frac{\tau_c^2}{m}\frac{\mathrm{d}}{\mathrm{d}t}\nu''(q)\right]\tilde{p}(t)\\ &\quad-\overline{g}(q)+\left[1-\frac{\tau_c^2}{m}\nu''(q)\right]mb(t).\end{aligned}\right\} \tag{1.7}$$

The symbols are explained in the following equations:

$$\beta(q)=\frac{\tau_c}{m}\nu''(q)+\frac{\tau_c^2}{m^2}p(q)\nu'''(q), \tag{1.8}$$

$$\overline{g}(q)=g(q)+\frac{\tau_c}{m}p(q)g'(q)+O(\tau_c^2), \tag{1.8$'$}$$

$$b(t)=\frac{1}{m\tau_c}\int_t^{+\infty}k(\alpha)\exp\left\{\frac{t-\alpha}{\tau_c}\right\}\mathrm{d}\alpha, \tag{1.8$''$}$$

Now, the splitting (1.5) without further specification is quite arbitrary and meaningless, because both terms on the right-hand side depend, besides their arguments, also upon initial conditions, as pointed out in Refs. 3, 5, and 13–15. However, the explicitation of the dependence upon q and t, respectively, allows to compute their averages by different means, as a function of coordinate q times the average density or as a function of the derivatives of the average density at the point q. This was shown in the quoted references (see especially Ref. 15), where the nonuniqueness of the diffusion operator for a given set of initial conditions was pointed out. It was shown moreover in a specific example that for a given $p(q)$ a precise relation among initial conditions is required in order that the diffusion equation may be attributed with a physical significance, as an equation for the two-time transition probabilities, at arbitrary times.

By substitution of Eq. (1.5) into Eq. (1.1) and considering that $q(t)$ is a function of initial conditions and time, it is possible to obtain a closed equation for $p(q)$, not involving the time nor the random force explicity, by introducing an appropriate separating function $g(q)$ (see Ref. 3 for details).

Then, after an integration with respect to time, the original equation (1.1) has been transformed into the system of coupled first-order differential equations (1.7) for the variables $q(t)$ and $\tilde{p}(t)$. Equations (1.7) look like characteristic equations, and actually they may be reobtained up to $O(\tau_c)$ as characteristic equations from the dissipative Hamilton–Jacobi equation relative to Eq. (1.13) below, which consequently might as well be considered the starting point of this paper, in the place of (1.1).

It will be found convenient to use Refs. 3 and 5, in order to cancel out the memory term in the averaged equation of continuity for the density of particles in configuration space

$$\overline{g}(q) = -mD_0\left[\frac{1}{m}p''(q)+\beta'(q)\right]+O(\tau_c^2), \tag{1.8'''}$$

where D_0 is the averaged diffusion coefficient. More generally, an operator $\hat{D}_q^{\mathrm{tr}}$ acting upon the variable q may be substituted for D_0. System (1.7) can be solved in terms of the function[1,4]

$$\begin{aligned} g(t,s) &= \exp\left\{-\frac{1}{m}\int_s^t p'(q(\alpha))\mathrm{d}\alpha - \int_s^t \beta(q(\alpha))\mathrm{d}\alpha\right\} \\ &\cong \exp\left\{-\frac{1}{m}\int_s^t p'(q(\alpha))\mathrm{d}\alpha - \overline{\beta}(t-s)\right\} \end{aligned} \tag{1.9}$$

the approximate expression being sufficiently accurate for the purposes of this work. The existence of $\overline{\beta}$ is guaranteed under the hypothesis of Birkhoff theorem for the extended system, particle plus ZPF. Thus $\overline{\beta}$ is given by the phase average over the metrically indecomposable invariant set in which the trajectory evolves.[16] For a mixing system, in which correlations vanish for sufficiently large time, $\overline{\beta}$ can be given by Kubo's[17] cumulant expansion in this limit $|t-s|\to\infty$. To $O(\tau_c)$,

$$\overline{\beta} = \frac{\tau_c}{m}\langle \nu''(q)\rangle + O(\tau_c^2). \tag{1.10}$$

From (1.6) and (1.8‴) follows

$$\frac{1}{2m}p(q)^2+\nu(q)+D_0p'(q) = E - \int p(q)\beta(q)\mathrm{d}q - mD_0\beta(q) \tag{1.11}$$

and, therefore, upon differentiating, averaging, and making use of stationarity there follows[1,5]

$$\frac{1}{m}\langle p'(q)^2\rangle + \langle \nu''(q)\rangle = O(\tau_c), \tag{1.12}$$

where $O(\tau_c)$ consists of the smaller terms in (1.11) and of the corrections to the leading constant term D_0—the averaged diffusion coefficient.[1] This assumption will be proved to be self-consistent [see Eqs. (2.8″) and (2.9)]. From (1.12) follows that the system has positive dissipation and therefore is stable given that $\langle[\Re\mathrm{e}p'(q)]^2\rangle < \langle[\Im\mathrm{m}p'(q)]^2\rangle$, and, in particular, for purely imaginary $p(q)$, which entails that the right-hand side (rhs) of (1.10) be real and positive.

Equations (1.7) do not constitute a complete solution for the third-order differential equation (1.1). By computing the derivative of the first equation (1.7), substituting from the second-one and from (1.8″), (1.11) there follows

$$\mathring{\mathring{q}}+\beta(q)\mathring{q}+\frac{1}{m}\nu'(q)=b(t)+O(\tau_c^2) \tag{1.13}$$

which shows that the solutions which are being considered satisfy simultaneously Eqs. (1.1) and (1.13). They also satisfy a fourth order equation proposed by Caldirola [see Ref. 2 Eqs. (1.11a) and (1.11b)], and are exempt from runaway effects, because of the particular choice of boundary conditions.

Equation (1.11) above can be interpreted as the Hamilton–Jacobi equation satisfied by the average motion, augmented with the term [see Ref. 4 Eq. (2.7)], which is proportional to the average density of that part of kinetic energy which depends bilinearly on both components of velocity

$$\int_{-\infty}^{\infty} D_0 p'(q)\langle\delta(q(t)-q)\rangle \mathrm{d}q \approx \int_{-\infty}^{+\infty}\frac{1}{m}\langle p(q(t))\tilde{p}(t)\delta(q(t)-q)\rangle \mathrm{d}q. \tag{1.14}$$

The dissipative terms also can be interpreted as the potential of the average density of dissipative forces, since

$$\int_{-\infty}^{+\infty} m D_0\beta'(q)\langle\delta(q(t)-q)\rangle \mathrm{d}q \approx \int_{-\infty}^{\infty}\langle\beta(q(t))\tilde{p}(t)\delta(q(t)-q)\rangle \mathrm{d}q. \tag{1.15}$$

In the above expressions and in the following the Heaviside function $h(\alpha)$ and the Dirac $\delta(\alpha)$ function of argument α are used.

II. THE DIFFUSION COEFFICIENT

The diffusion coefficient can thus be obtained from the expression in terms of functional integrals over the realizations of the stochastic electric field $\{E(s);-\infty<s\leqslant t\}$.[1–3]

The boundary conditions for the driven process $q(t)$ have been adjusted in such a way that the particle has a fixed coordinate q_0 at the time t_0, while the velocity is supposed to be equilibrated with the stochastic random field.[1–4] There follows the general expression for the diffusion coefficient in the frozen-trajectory approximation (FTA), see Ref. 1,

$$\hat{D}_q(t,t_0)^{\mathrm{FTA}}\langle\delta(q(t)-q)\rangle=\int_0^t \mathrm{d}\tau\left\langle \delta(q(t)-q)e^{-\bar{\beta}(t-\tau)}\int_{-\infty}^{\tau}\mathrm{d}\sigma\int_{-\infty}^{t}\mathrm{d}s\, g(\tau,\sigma)g(\tau,s)\right\rangle \phi_b(s-\sigma), \tag{2.1}$$

the brackets denoting stochastic averages taken over the realizations of the random process $\{k(t');-\infty<t'\leqslant t\}$, and ϕ_b the autocorrelation function of the renormalized random force $b(t)$. The hat stands for an operator notation over the variable q. Averaging both sides of Eq. (2.1) by integration over $\mathrm{d}q$, there results

$$D_0(t,t_0)^{\mathrm{FTA}}=\int_{t_0}^{t}\mathrm{d}\tau\, e^{-\bar{\beta}(t-\tau)}\int_{-\infty}^{\tau}\mathrm{d}\sigma\int_{-\infty}^{t}\mathrm{d}s\langle g(\tau,\sigma)g(\tau,s)\rangle\phi_b(s-\sigma). \tag{2.2}$$

Higher-order terms containing higher derivatives of $\langle\delta(q(t)-q)\rangle$ could be added to this expression, which represents the first term of an expansion of the rhs of (2.1) in powers of the autocorrelation function ϕ_b.[18] In the following the averaged expression (2.2) will be analyzed, although the similar methods could equally be applied to the more refined expression (2.1), as shown in Ref. 1.

To this end it is convenient to represent the function

$$\Phi\langle\tau-\sigma,\tau-s\rangle=\left\langle \exp\left\{-\frac{1}{m}\int_{\sigma}^{\tau}p'(q(\alpha))\mathrm{d}\alpha-\frac{1}{m}\int_{s}^{\tau}p'(q(\alpha))\mathrm{d}\alpha\right\}\right\rangle e^{-\overline{\beta}(\tau-\sigma)h(\tau-\sigma)-\overline{\beta}(\tau-s)h(\tau-s)} \tag{2.3}$$

as a double Fourier integral in the variables $\tau-\sigma$, $\tau-s$. Having assumed stationarity of the physical state of the system, it is defined

$$\begin{aligned}
\Phi(\omega,\tau-s)=&\int_{-\infty}^{0}\mathrm{d}(\tau-\sigma)\left\langle \exp\left\{-\frac{1}{m}\int_{\sigma}^{\tau}p'(q(\alpha))\mathrm{d}\alpha-\frac{1}{m}\int_{s}^{\tau}p'(q(\alpha))\mathrm{d}\alpha\right\}\right\rangle\\
&\times e^{-\overline{\beta}(\tau-s)h(\tau-s)+\iota\omega(\tau-\sigma)}+\int_{0}^{+\infty}\mathrm{d}(\tau-\sigma)\left\langle \exp\left\{-\frac{1}{m}\int_{\sigma}^{\tau}p'(q(\alpha))\mathrm{d}\alpha\right.\right.\\
&\left.\left.-\frac{1}{m}\int_{s}^{\tau}p'(q(\alpha))\mathrm{d}\alpha\right\}\right\rangle e^{-\overline{\beta}(\tau-\sigma)-\overline{\beta}(\tau-s)h((\tau-s)+i\omega(\tau-\sigma)}\\
=&\int_{-\infty}^{0}\mathrm{d}(\tau-\sigma)\left\langle m\frac{\delta q(\sigma)}{\delta\tilde{p}(\tau)}\exp\left\{-\frac{1}{m}\int_{s}^{\tau}p'(q(\alpha))\mathrm{d}\alpha\right\}\right\rangle e^{-\overline{\beta}(\tau-s)h(\tau-s)+\iota\omega(\tau-\sigma)}\\
&+\int_{0}^{+\infty}\mathrm{d}(\tau-\sigma)\left\langle\left(\frac{\delta\tilde{p}(\tau)}{\delta k(\sigma)}\right)^{\mathrm{FTA}}\exp\left\{-\frac{1}{m}\int_{s}^{\tau}p'(q(\alpha))\mathrm{d}\alpha\right\}\right\rangle e^{-\overline{\beta}(\tau-s)h(\tau-s)+\iota\omega(\tau-\sigma)}\\
=&\left\langle m\left(\frac{\delta q}{\delta\tilde{p}}\right)_{-\omega}\exp\left\{-\frac{1}{m}\int_{s}^{\tau}p'(q(\alpha))\mathrm{d}\alpha\right\}\right\rangle e^{-\overline{\beta}(\tau-s)h(\tau-s)}\\
&+\left\langle\left(\frac{\delta\tilde{p}}{\delta k}\right)_{\omega}^{\mathrm{FTA}}\exp\left\{-\frac{1}{m}\int_{s}^{\tau}p'(q(\alpha))\mathrm{d}\alpha\right\}\right\rangle e^{-\overline{\beta}(\tau-s)h(\tau-s)}\\
=&\left\langle m\frac{(\delta q/\delta k)_{-\omega}^{\mathrm{FTA}}}{(\delta\tilde{p}/\delta k)_{-\omega}^{\mathrm{FTA}}}\exp\left\{-\frac{1}{m}\int_{s}^{\tau}p'(q(\alpha))\mathrm{d}\alpha\right\}\right\rangle e^{-\overline{\beta}(\tau-s)h(\tau-s)}\\
&+\left\langle\left(\frac{\delta\tilde{p}}{\delta k}\right)_{\omega}^{\mathrm{FTA}}\exp\left\{-\frac{1}{m}\int_{s}^{\tau}p'(q(\alpha))\mathrm{d}\alpha\right\}\right\rangle e^{-\overline{\beta}(\tau-s)h(\tau-s)}.
\end{aligned} \tag{2.4}$$

Consequently, the Fourier transform $\Phi(\omega,\omega')$ exists if the Fourier transform of the response functions in the FTA exists for position and velocity. $\Phi(\omega,\omega')$ is of course a symmetric function of ω and ω'. The results of the explicit calculations are

$$\begin{aligned}
&\int_{-\infty}^{\tau}\mathrm{d}\sigma\int_{-\infty}^{t}\mathrm{d}s\langle g(\tau,\sigma)g(\tau,s)\rangle\phi_b(s-\sigma)\\
&=-\frac{\hbar\tau_c}{8\pi^3 m}\int_{-\infty}^{+\infty}\mathrm{d}\omega\int_{-\infty}^{+\infty}\mathrm{d}\omega'\int_{0}^{+\infty}\mathrm{d}u\,\frac{u^3}{1+\tau_c^2u^2}\Phi(\omega,\omega')\left\{\frac{1}{\omega+\omega'-\iota\varepsilon}\right.\\
&\times\left(\frac{1}{\omega'-u-\iota\varepsilon}+\frac{1}{\omega'+u-\iota\varepsilon}\right)-\frac{1}{\omega+\omega'-\iota\overline{\beta}}\left(\frac{1}{\omega'-u-\iota\overline{\beta}}+\frac{1}{\omega'+u-\iota\overline{\beta}}\right)\\
&+\frac{1}{\omega+\omega'-\iota\varepsilon}\left(\frac{1}{\omega+u-\iota\varepsilon}+\frac{1}{\omega-u-\iota\varepsilon}\right)-\frac{1}{\omega+\omega'-\iota\overline{\beta}}\left(\frac{1}{\omega+u-\iota\varepsilon}+\frac{1}{\omega-u-\iota\varepsilon}\right)
\end{aligned}$$

$$+\frac{e^{(\iota\omega'-\iota u+\overline{\beta})(t-\tau)}}{\omega+\omega'-\iota\overline{\beta}}\left(\frac{1}{\omega'-u-\iota\overline{\beta}}+\frac{1}{\omega+u-\iota\varepsilon}\right)$$
$$+\frac{e^{(\iota\omega'+\iota u+\overline{\beta})(t-\tau)}}{\omega+\omega'-\iota\overline{\beta}}\left(\frac{1}{\omega'+u-\iota\overline{\beta}}+\frac{1}{\omega-u-\iota\varepsilon}\right)\Bigg\}. \tag{2.5}$$

Since the integral over du in this expression is (for $\varepsilon\to 0$) convergent, using (2.2), there follows, by shifting the path of integration over du from the real to the imaginary axis

$$D_0(t,t_0)^{\mathrm{FTA}}=-\frac{\iota\hbar\tau_c}{4\pi^3 m}\int_{-\infty}^{0}\mathrm{d}\eta\,\frac{\eta^3}{1-\tau_c^2\eta^2}\int_{-\infty}^{+\infty}\mathrm{d}\omega\int_{-\infty}^{+\infty}\mathrm{d}\omega'\,\frac{\Phi(\omega,\omega')}{\omega+\omega'-\iota\overline{\beta}}\,\frac{1-e^{(\iota\omega'+\eta)(t-t_0)}}{\iota\omega'+\eta}$$
$$\times\left(\frac{1}{\iota\omega'+\eta+\overline{\beta}}+\frac{1}{\iota\omega-\eta}\right)-(1-e^{-\overline{\beta}(t-t_0)})\,\frac{\iota\hbar\tau_c}{4\pi^2 m}$$
$$\times\int_{-\infty}^{+\infty}\mathrm{d}\omega\int_{-\infty}^{+\infty}\mathrm{d}\omega'\frac{\Phi(\omega,\omega')|\omega'|^3}{\overline{\beta}(1+\tau_c^2\omega'^2)(\omega+\omega'-\iota\varepsilon)}+O(\overline{\beta}\tau_c). \tag{2.6}$$

Now, the first term is easily proved to be equivalent to that which has been calculated in Ref. 3, Eq. (20). It yields corrections to the diffusion coefficient which produce, by first-order perturbation theory applied to the Hamilton–Jacobi–Yasue–Riccati (HJYR) Eq. (1.11), energy shifts which are the same functional form as the Lamb shifts.[1,3,5]

Using the symmetry properties of the function $\Phi(\omega,\omega')$, the pole term can be rewritten in the following manner, so as to recast the whole expression for $D_0(t,t_0)^{\mathrm{FTA}}$ into the form (see Ref. 1)

$$D_0(t,t_0)^{\mathrm{FTA}}\cong-\langle\Re(t,t_0)\rangle+(1-e^{-\overline{\beta}(t-t_0)})\,\frac{\hbar\tau_c\iota}{8\pi^2 m}\Bigg\{\int_{-\infty}^{+\infty}\mathrm{d}\omega\int_{-\infty}^{+\infty}\mathrm{d}\omega'\frac{\Phi(\omega,\omega')}{\overline{\beta}(\omega+\omega'-\iota\varepsilon)}$$
$$\times\left(\frac{\omega^3}{1+\tau_c^2\omega^2}+\frac{\omega'^3}{1+\tau_c^2\omega'^2}\right)-2\int_{-\infty}^{+\infty}\mathrm{d}\omega\int_{0}^{+\infty}\mathrm{d}\omega'\frac{\Phi(\omega,\omega')}{\overline{\beta}(\omega+\omega'-\iota\varepsilon)}\,\frac{2\omega'^3}{1+\tau_c^2\omega'^2}\Bigg\}$$
$$=-\langle\Re(t,t_0)\rangle+(1-e^{-\overline{\beta}(t-t_0)})\,\frac{\hbar\tau_c\iota}{8\pi^2 m}\Bigg\{\int_{-\infty}^{+\infty}\mathrm{d}\omega\int_{-\infty}^{+\infty}\mathrm{d}\omega'\frac{\Phi(\omega,\omega')}{\overline{\beta}(1-\tau_c^2\omega\omega')}$$
$$\times\left(\frac{\omega^2}{1+\tau_c^2\omega^2}+\frac{\omega'^2}{1+\tau_c^2\omega'^2}-\omega\omega'\right)$$
$$-2\int_{-\infty}^{+\infty}\mathrm{d}\omega\int_{0}^{+\infty}\mathrm{d}\omega'\frac{2\Phi(\omega,\omega')\omega'^3}{\overline{\beta}(\omega+\omega')(1+\tau_c^2\omega'^2)}-2\iota\pi\int_{0}^{+\infty}\mathrm{d}\omega\,\frac{2\Phi(-\omega,\omega)\omega^3}{\overline{\beta}(1+\tau_c^2\omega^2)}\Bigg\}. \tag{2.7}$$

Now, using stationarity, Eqs. (1.10), (1.12), and (2.3), there follows:

$$D_0(t,t_0)^{\mathrm{FTA}} \cong -\langle \Re(t,t_0)\rangle + (1-e^{-\overline{\beta}(t-t_0)})\frac{\hbar\tau_c\iota}{2m}\left\{ -\frac{\frac{1}{m^2}\langle p'(q)^2\rangle}{\frac{\tau_c}{m}\langle \nu''(q)\rangle} - \frac{1}{2\pi^2}\int_{-\infty}^{+\infty} d\omega \right.$$

$$\left. \times 2\int_0^{+\infty} d\omega' \frac{\Phi(\omega,\omega')\omega'^3}{\overline{\beta}(\omega+\omega')(1+\tau_c^2\omega'^2)} - \frac{1}{2\pi} 2\int_0^{+\infty} d\omega \frac{\Phi(-\omega,\omega)\omega^3}{\overline{\beta}(1+\tau_c^2\omega^2)} \right\}$$

$$= -\langle \Re(t,t_0)\rangle + (1-e^{-\overline{\beta}(t-t_0)})\frac{\iota\hbar}{2m} - (1-e^{-\overline{\beta}(t-t_0)})\frac{\iota\hbar}{2\pi^2\langle \nu''(q)\rangle}$$

$$\times \left\{ \int_{-\infty}^{+\infty} d\omega \int_0^{+\infty} d\omega' \, \frac{\Phi(\omega,\omega')\omega'^3}{(\omega+\omega')(1+\tau_c^2\omega'^2)} + \iota\pi \int_0^{+\infty} d\omega \frac{\Phi(-\omega,\omega)\omega^3}{(1+\tau_c^2\omega^2)} \right\}. \tag{2.8}$$

The justification for the substitution

$$\frac{1}{4\pi^2}\int_{-\infty}^{+\infty} d\omega \int_{-\infty}^{+\infty} d\omega' \frac{\Phi(\omega,\omega')}{(1-\tau_c^2\omega\omega')}\left(\frac{\omega^2}{1+\tau_c^2\omega^2} + \frac{\omega'^2}{1+\tau_c^2\omega'^2} - \omega\omega' \right) \to -\frac{1}{m^2}\langle p'(q)^2\rangle \tag{2.8'}$$

is obvious in the limit $\tau_c \to 0$, hence $\overline{\beta}\to 0$. It is only necessary to prove that the left-hand side (lhs) is continuous for $\tau_c \to 0$, so that the limiting value equals the second derivative in the origin of the function (2.3), multiplied by (-1). For $\overline{\beta}$ finite, the second derivative diverges, but nevertheless (2.8′) is valid because the lhs is a continuous function of τ_c. Equation (2.8) has been obtained by dropping all the terms originating from the step function in the definition (2.3).

Thus, two different procedures may be followed.

(a) If $\Phi(\omega,\omega')$ exists in the limit $\tau_c \to 0$, then it is allowed to put $\overline{\beta}=0$ in Eqs. (2.3) and (2.4), thus making $\Phi(\tau-\sigma,\tau-s)$ a smooth function of the arguments. This leads to (2.7) and (2.8) whose range of validity is, strictly speaking

$$\overline{\beta}\tau_\Phi \ll 1 \ll \overline{\beta}(t-t_0),$$

where τ_Φ is the correlation time of $\Phi(\tau-\sigma,\tau-s)$.

Equation (2.8) has been proved under the assumption $\tau_c \to 0$. Therefore, in this limit, three terms survive in the expression for the diffusion coefficient, which are written extensively in the rhs of (2.8).

(b) The discontinuity of the derivatives of $\Phi(\tau-\sigma,\tau-s)$ introduced by (2.3) can be handled by making use of the theory of distributions, thus yielding an equivalent result, as shown below through Eqs. (3.2)–(3.4).

If the support of the spectral function $\Phi(\omega,\omega')$ is entirely contained in the region comprised between the negative semiaxes, then D_0 is purely imaginary positive, because[1,5]

$$D_0(t,t_0)^{\mathrm{FTA}} = -\langle \Re(t,t_0)\rangle + (1-e^{-\overline{\beta}(t-t_0)})\frac{\iota\hbar}{2m} + O(\tau_c). \tag{2.8''}$$

Then every stationary probability distribution can be chosen as a real function of coordinate $P_{\rm st}(q)$. Consequently, $p(q)$ results to be purely imaginary for real q. The average of $(1/m)p'(q)$ then is given by

$$\left\langle \frac{1}{m}p'(q)\right\rangle = D_0\left\langle \frac{\mathrm{d}^2}{\mathrm{d}q^2}\ln P_{\rm st}(q)\right\rangle$$
$$= D_0\int_{-\infty}^{+\infty}\mathrm{d}q\left(\frac{P''_{\rm st}(q)}{P_{\rm st}(q)}-\frac{P'_{\rm st}(q)^2}{P_{\rm st}(q)^2}\right)P_{\rm st}(q)$$
$$= D_0P'_{\rm st}(q)\big|_{-\infty}^{+\infty}-D_0\int_{-\infty}^{+\infty}\mathrm{d}q\,\frac{P'_{\rm st}(q)^2}{P_{\rm st}(q)}. \tag{2.9}$$

Since $P'_{\rm st}(q)$ must vanish in both limits, there follows that $\langle(1/m)p'(q)\rangle$ is purely imaginary with the sign opposite to that of D_0.

Consequently, $\Phi(\omega,\omega')$ is centered inside the region comprised between the negative semiaxes ω, ω', and if it is assumed Gaussian sharply peaked around its center, it can be inferred that with high accuracy

$$\Phi(\omega,\omega')=0 \quad \text{for } \omega \text{ or } \omega'>0. \tag{2.10}$$

Thus, loosely speaking, the remaining terms in Eq. (2.8) can only produce small corrections to the main value represented by (2.8″), since they remain bounded in the limit $\tau_c\to 0$, being proportional to $\hbar/m$.

III. COMMENTS

The averaged diffusion coefficient for a classical Newtonian particle interacting with a ZPF through the Braffort–Marshall equation,[11] which is the nonrelativistic limit of the Dirac equation for a point particle,[7] has been calculated under the assumption of stationarity of the system, making use of a Fourier representation of the response functions involved. These are evaluated in the frozen-trajectory approximation. The present approach, although restricted by the stationarity assumption, is however in some respect more general than the developments followed in Refs. 1 and 5, because the asymptotic expansion of the ZPF correlation function has been avoided, consequently, the results do not suffer from the restriction that the particle oscillation frequencies should be smaller than $1/\tau_c$. Of course, this does not allow to extend the present treatment to the higher frequencies, although the equations that are used are, like Newton's equations, still meaningful beyond that frequency. In fact, the contribution of the pole term to the diffusion coefficient is here evaluated exactly and is given by the second term in the rhs of (2.6), by summing over the whole spectrum of the response functions of the particle.

The main result which has been obtained by the present developments is that, for systems whose response functions have only a narrow frequency band centered around the main frequency, the diffusion coefficient, averaged in configuration space over a stationary state probability density distribution, has the same value independently of the system, *viz.* $i\hbar/2m$ (see Ref. 2). The leading corrections for a small interaction constant τ_c produce corrections to the ''energy'' of the stationary states of the same functional form as the Lamb shifts of quantum electrodynamics.[1,19]

If the wings of the frequency spectrum include the region of positive frequencies ω, ω', they produce small corrections to the main value, which remain bounded and small in the limit $\tau_c\to 0$. This follows readily if the wings have a Lorentzian shape for τ_c and $\overline{\beta}\neq 0$, but they have finite right and left second moments as $\tau_c\to 0$, hence $\overline{\beta}\to 0$.

We proceed now to examine the conditions under which the main term on the rhs of (2.6) is bounded.

(a) Generally speaking, $\Phi(\omega,\omega')$ is the Fourier transform of a linear combination of products of response functions or FTA response functions, therefore it is licit to assume that it is a meromorphic function of both arguments, falling off to zero at infinity. Divergences might occur in the limits $\omega'\to\pm\infty$, because

$$\lim_{\omega'\to\pm\infty}\frac{\Phi(\omega,\omega')|\omega'|^3}{(1+\tau_c^2\omega'^2)(\omega+\omega'-\iota\varepsilon)}=\pm\frac{\Phi(\omega,\omega')}{\tau_c^2}, \tag{3.1}$$

$$\lim_{\omega'\to\pm\infty}\frac{\Phi(\omega,\omega')|\omega'|^3}{\omega+\omega'-\iota\varepsilon}=\pm\Phi(\omega,\omega')\omega'^2. \tag{3.1'}$$

Now, if ω is not a pole

$$\left|\frac{1}{2\pi}\int_{-\infty}^{+\infty}\Phi(\omega,\omega')\mathrm{d}\omega'\right|=|\Phi(\omega,\tau=s)|<+\infty. \tag{3.2}$$

Putting

$$\Phi(\omega,\omega')=\frac{c(\omega)}{\omega'}+\Phi^R(\omega,\omega') \tag{3.3}$$

results in

$$\begin{aligned}\Phi(\omega,t)&=\frac{c(\omega)}{2\pi}\int_{-\infty}^{+\infty}\mathrm{d}\omega'\frac{e^{-i\omega' t}}{\omega'}+\frac{1}{2\pi}\int_{-\infty}^{+\infty}\mathrm{d}\omega'\,\Phi^R(\omega,\omega')e^{-i\omega' t}\\&=-\frac{c(\omega)}{2\pi}\int_{0}^{+\infty}\mathrm{d}\omega'\frac{2\iota\sin\omega' t}{\omega'}+\frac{1}{2\pi}\int_{-\infty}^{+\infty}\mathrm{d}\omega'\,e^{-i\omega' t}\Phi^R(\omega,\omega')\end{aligned} \tag{3.4}$$

with

$$\Phi^R(\omega,\omega')=O\left(\frac{1}{\omega'^2}\right) \tag{3.5}$$

for $\omega'\to\infty$.

Since the first term is discontinuous for $t=0$, while $\Phi(\omega,t)$ is continuous, there follows

$$c(\omega)=0 \tag{3.6}$$

and consequently the integral of (3.1) converges absolutely in both limits $\omega'\to\pm\infty$. However, there appears a proportionality coefficient $(1/\tau_c)^2$ which would allow the integral, though bounded for every τ_c, to diverge as $\tau_c\to 0$.

Now the same argument shows that for $\tau_c=0$, $\omega'\to\pm\infty$,

$$\Phi_0(\omega,\omega')=O\left(\frac{1}{\omega'^4}\right), \tag{3.7}$$

where $\Phi_0(\omega,\omega')$ is the limit of $\Phi(\omega,\omega')$ as $\tau_c\to 0$, hence $\overline{\beta}\to 0$ everywhere in (2.3). There follows that the expression on the rhs of (3.1′) which contains $\Phi_0(\omega,\omega')$ in the place of $\Phi(\omega,\omega')$ converges absolutely in both limits $\omega'\to\pm\infty$, when integrated over $\mathrm{d}\omega'$. There follows that the main integral in the rhs of (2.6) converges absolutely $\forall\tau_c$ in a suitable closed interval $0\leqslant\tau_c\leqslant a$ of the real axis.

Now, if the function $\Phi(\omega,\omega')\to\Phi_0(\omega,\omega')$ uniformly with respect to ω, ω', the integral in question results to be a continuous function of τ_c in the closed interval, and therefore is bounded inside that interval by a quantity independent of τ_c. The continuity is certainly uniform if the support of $\Phi(\omega,\omega';\tau_c)$ is a compact subset of the plane ω, ω'. This compactification can be obtained by introducing a large cutoff maximum frequency, the limiting results for $\tau_c\to 0$ being however independent of that value. For $\tau_c\neq 0$, however, the cutoff dependence may become effective, in the form of a logarithmic divergence (see below).

(b) The introduction of a cutoff maximum frequency can be avoided by defining as before $\Phi_0(\omega,\tau-s)$ as the limiting value of the function $\Phi(\omega,\tau-s,\tau_c)$ as $\beta(q)\to 0$ in Eqs. (1.9) and (1.11) and consequently in (2.3). Then, by assuming $\Phi_0(\omega,\tau-s)$ to be a smooth function of the arguments, it is convenient to evidence the singularity in the second derivative introduced by definition (2.3), by the following ansatz, where the equality must be intended in the sense of distribution theory:[20]

$$\frac{\partial^2}{\partial s^2}\Phi(\omega,\tau-s;\tau_c)=\frac{\partial^2}{\partial s^2}\Phi_0(\omega,\tau-s)+\overline{\beta}\delta(\tau-s)\int_{-\infty}^{+\infty}\Phi_0(\omega,\omega')\frac{\mathrm{d}\omega'}{2\pi} \tag{3.8}$$

which implies

$$\Phi(\omega,\omega';\tau_c)=\Phi_0(\omega,\omega')-\frac{\overline{\beta}}{\omega'^2}\int_{-\infty}^{+\infty}\Phi_0(\omega,\omega'')\frac{\mathrm{d}\omega''}{2\pi}. \tag{3.9}$$

This accounts for terms which are not absolutely integrable at infinity in $-\omega'^2\Phi(\omega,\omega';\tau_c)$, which is the Fourier transform of the second derivative with respect to t of (3.4). By this substitution into Eq. (2.6), taking into account the term denoted by $O(\overline{\beta}\tau_c)$ on the rhs of this equation, there follows:

$$\begin{aligned}D_0(t,t_0)^{\mathrm{FTA}}=(1-e^{-\overline{\beta}(t-t_0)})&\left(\frac{\iota\hbar}{2m}-\frac{\iota\hbar}{2\pi^2\langle\nu''(q)\rangle}\int_{-\infty}^{+\infty}\mathrm{d}\omega\int_0^{+\infty}\mathrm{d}\omega'\frac{\Phi_0(\omega,\omega')\omega'^3}{(1+\tau_c^2\omega'^2)(\omega+\omega'-\iota\varepsilon)}\right.\\&\left.+\frac{\iota\hbar\tau_c}{4\pi^3 m}\int_{-\infty}^{+\infty}\mathrm{d}\omega\int_{-\infty}^{+\infty}\mathrm{d}\omega'\,\Phi_0(\omega,\omega')\frac{\omega\ln|\tau_c\omega|+\frac{\iota\pi}{2}|\omega|}{1+\tau_c^2\omega^2}\right)+\frac{\hbar\tau_c}{4\pi^3 m}\\&\times\int_{-\infty}^{0}\mathrm{d}\eta\frac{\eta^3}{1-\tau_c^2\eta^2}\int_{-\infty}^{+\infty}\mathrm{d}\omega\int_{-\infty}^{+\infty}\mathrm{d}\omega'\,\Phi_0(\omega,\omega')\frac{e^{(i\omega'+\eta)(t-t_0)}-e^{-\overline{\beta}(t-t_0)}}{(\eta+\iota\omega')(\eta+\iota\omega'+\overline{\beta})(\eta-\iota\omega)},\end{aligned} \tag{3.10}$$

which is the same as Eq. (2.8) to $O(\tau_c\ln\tau_c)$ (see Ref. 1), higher order terms having not been thoroughly considered here. The notation $O(\overline{\beta}\tau_c)$ results from taking the limit $\overline{\beta}\to 0$ everywhere in the last term of (2.6): this is appropriate because this term must exactly cancel the equivalent term of the main integral [see Eq. (3.8)], which has therefore consistently been neglected in (2.8). If a cutoff frequency $\omega_m\ll 1/\tau_c$ were introduced as explained in (a), then $\ln 1/\omega_m$ would appear in Eq. (3.10) in the place of $\ln\tau_c$.

The present developments strongly suggest that wavelike properties could be attributed to material particles interacting with a ZPF, beyond the special case of a harmonic oscillator in the ground state (see Ref. 2 and references therein), inasmuch as the diffusing behavior of these particles could be satisfactorily described by equations surprisingly similar to the equations describing quantum mechanical particles in stationary states, provided the detailed spatial dependence of the diffusion coefficient would be neglected.[21] Notice that this dependence can be handled by the same methods, by redefining the various averaged quantities according to Ref. 1

[see Eq. (3.10) therein]. In this paper the basic formulas for the diffusion coefficient have been evaluated using the Fourier transforms of the response functions, thereby taking advantage of their well-known analytical properties.[20]

It may be recalled that similar results were obtained in Refs. 22 and 23 by considering a stochastic process in which the coordinate is driven by a Wiener process through a complex coupling constant, whose value is adjusted ''*ad hoc*.'' The equations of motion are thus obtained from a stationary principle for expectation values of appropriate functionals. The interest in the present developments results from the fact that the equations of motion can be deduced from the Newtonian equation (1.13), which after all, is not in contradiction with electrodynamics.[7,10,11,24–39]

Computation of Lie transfer maps for perturbed Hamiltonian systems

Liam M. Healy[a)]

(Received 16 May 2000; accepted for publication 19 October 2000)

Time evolution of a Hamiltonian system can be viewed as a canonical transformation; therefore perturbations, giving rise to near-identity deviations from an unperturbed solution, can be represented by products of Lie transformations, or, together with the unperturbed solution, *Lie transfer maps*. In this paper I broaden the applicability to all perturbed Hamiltonian systems the method of Dragt and Finn and subsequent co-workers, who developed a representation using a product of Lie transformations factored by phase space variable order. In the present paper, perturbation parameters are no longer necessarily associated with the phase space variables; this method treats both ''internal'' and ''external'' perturbations on an equal footing, and a *rank* is assigned to each variable to reflect the degree of perturbation it represents. With the companion program PGLT, analytic development of the Lie transfer maps is relatively easy for many systems.
[DOI: 10.1063/1.1331563]

I. INTRODUCTION

From a perturbation Hamiltonian, a known unperturbed solution, and a sequence of Lie transformations factored by rank, it is possible to compute a *transfer map* through a particular order in perturbation parameters. This can be viewed as a function giving positions and momenta (generalized coordinates) at the final time as a function of those at the initial time. Upon combining the unperturbed solutions with the Lie transformations, one may call this a *Lie transfer map*. From the map, this function can then be evaluated numerically to propagate the system. Propagation in this way is unlike the two prevalent methods: numerical integration and normal form. Numerical integration requires iterative computation of the right-hand sides of a differential equation over a number of short time steps. Normal form propagation, common in celestial mechanics, requires the derivation of an analytic Hamiltonian that is in some sense close to the original, that is purely secular (independent of coordinates) and thereby represents an averaged motion. Then propagation involves multiplying the time rate of change of the coordinates by the time interval. In contrast to the normal form method, the transfer map method uses the actual Hamiltonian, and does not compute an averaged Hamiltonian. It should be noted that Deprit's[1] application of Lie transformations, widely used in celestial mechanics, was in the context of the computation of the normal form. Although some of his general mathematical results—properties of Lie transformations—are applicable here, our use of these transformations is different.

Dragt and Finn[2] showed that an analytic symplectic map can be written as a product of Lie transformations. Later, Steinberg[3] showed that one need not assume a Hamiltonian system; the solution of any system of ordinary differential equations may be given as a factored product expansion of partial differential operators. A method for computing the transfer maps using Lie transformations for some kinds of perturbations was described by Dragt and Forest.[4] This was expanded to treat Hamiltonian terms linear in the phase space variables by the author.[5,6] The present paper continues in this tradition; like the foregoing papers, it is an example of a *regular perturbation* theory (Ref. 7 Chap. 132; Ref. 8). (This class of methods is called ''naive perturba-

a)Electronic mail: liam.healy@nrl.navy.mil

tion theory'' in Ref. 9, but ''regular perturbation'' is more common, and less pejorative.) It describes a method for computing perturbations of any system for which the unperturbed solution is known, not just linear.

Anticipating the developments of this paper, it is worthwhile to jump to the end and see what results we can expect for a simple problem, that of the perturbed simple harmonic oscillator in one degree of freedom. The Hamiltonian will be

$$\mathcal{H}=(\tfrac{1}{2}\omega_0^2x^2+\tfrac{1}{2}X^2)-\tfrac{1}{4}x^4\mu, \tag{1}$$

with x the coordinate and X its conjugate momentum. The quantity $0<\mu\ll 1$ is the perturbation parameter. In action-angle variables,

$$J=\frac{1}{2\omega_0}(\omega_0^2x^2+X^2), \quad \theta=\arctan\left(\frac{\omega_0 x}{X}\right), \tag{2}$$

$$x=\sqrt{\frac{2J}{\omega_0}}\sin\theta, \quad X=\sqrt{2\omega_0 J}\cos\theta, \tag{3}$$

so that the Hamiltonian is

$$\mathcal{H}=\omega_0 J+\mu J^2\frac{1}{\omega_0^2}\left(\frac{3}{8}-\frac{1}{2}\cos 2\theta+\frac{1}{8}\cos 4\theta\right). \tag{4}$$

For a particle evolving under this Hamiltonian, the position and momentum after some time t may be computed,

$$\begin{aligned}\theta\leftarrow\theta+\phi_0+\mu J\left(\frac{3}{4}\frac{t}{\omega_0^2}+\frac{1}{\omega_0^3}\left(\frac{1}{2}\sin 2\theta-\frac{1}{2}\sin(2\theta+2\phi_0)-\frac{1}{16}\sin 4\theta+\frac{1}{16}\sin(4\theta+4\phi_0)\right)\right),\\ J\leftarrow J+\mu J^2\frac{1}{\omega_0^3}\left(-\frac{1}{2}\cos 2\theta+\frac{1}{2}\cos(2\theta+2\phi_0)+\frac{1}{8}\cos 4\theta-\frac{1}{8}\cos(4\theta+4\phi_0)\right),\end{aligned} \tag{5}$$

with $\phi_0=\omega_0 t$, to first order in the perturbation μ. The details of computing with the Lie transfer maps are addressed in another paper.[10]

Clearly, the quartic harmonic oscillator is not our ultimate goal. More realistic, and complicated problems, such as a satellite orbit, pendulum motion, charged-particle motion through a magnet in a particle accelerator, ray paths of light through a lens in light optics, or a satellite orbit are solvable by this method.

II. LIE TRANSFORMATIONS

With f and g functions on phase space, let the *Lie operator* $:f:$ be defined by the Poisson bracket $:f:g=[f,g]$. A *Lie transformation* is defined as the exponential of a Lie operator:

$$e^{:f:}=\sum_{i=0}^{\infty}\frac{:f:^i}{i!}, \tag{6}$$

and thus

$$e^{:f:}g=g+[f,g]+\tfrac{1}{2}[f,[f,g]]+\cdots. \tag{7}$$

Lie transformations have several interesting properties. For ease of reference, some are repeated here; for details, proofs and other theorems, consult Dragt[11] or Steinberg,[12] which both provide a comprehensive overview of the field. First, each of the Lie transformations is *symplectic*:

if M is the Jacobian matrix of the transformation, $M_{ij}=\partial e^{:f:}\zeta_i/\partial\zeta_j$ in phase space ζ, then $M^TJM=J$, with $J_{ij}=[\zeta_i,\zeta_j]$, a matrix of ones and zeros. When considering numeric calculations, however, the truncation of the Taylor series in (6) or (7) will produce a nonsymplectic transformation. Second, a similarity transformation on a Lie transformation has the effect of transforming the argument of the function,

$$e^{:f:}e^{:g:}e^{:-f:}=e^{:e^{:f:}g:}. \tag{8}$$

The goal of this paper is to show that any perturbed symplectic map can be represented as a factored product of Lie transformations. Dragt[11] showed a similar fact for arbitrary symplectic maps factored by order of phase space variables, and later with Forest[4] how to construct the Lie expressions. In the present paper, the factorization is by order of perturbation; the exact meaning of this will be provided. I will show that the full map of a perturbed system can be written in terms of Lie expressions f and the solution to the unperturbed problem $\mathcal{U}$,

$$\mathcal{M}=\ldots e^{:f_{\Delta+2}:}e^{:f_{\Delta+1}:}e^{:f_{\Delta}:}\mathcal{U}, \tag{9}$$

and describe a method for computing the f_i from the unperturbed $\mathcal{U}$ and Hamiltonian $\mathcal{H}$.

Once the Lie expressions f_i are known, computation of the map for a fixed time interval, including perturbations, is straightforward. One may extend this calculation to any order for which the map has been computed.

III. GRADING: COUNTING PERTURBATIONS

A. Rank

Traditionally, in a perturbation of Taylor series analysis, we use a small quantity, say ϵ, to regulate the consistent computation of terms. By expanding each computation in ϵ properly, we may cutoff the series at a particular order. In this section, we shall make this more rigorous. In particular, we need to generalize to multiple perturbations of different order, and to phase space variables that are themselves perturbations.

Any variable may be assigned a non-negative integer *rank* based on the exponent of the perturbation parameter. This parameter δ accompanies all perturbation quantities; these quantities have a defined rank, a non-negative integer that represents the exponent of the parameter associated with the variable. For example, suppose the variables x and y exist in a system, and have ranks 1 and 3, respectively. Then every instance of x may be viewed as being δx and every instance of y may be viewed as being $\delta^3 y$. This rank will follow the algebra of exponents, e.g., if x is rank 1, then x^2 is rank 2. The rank of a term (product of a constant and variables) is the sum of the individual ranks of the variables.

It needs to be emphasized that, subject to the constraints outlined above, the grading is arbitrary—a given physical system could have several different gradings. However, one would typically give a grade of one to each power of the most significant perturbation(s), two to terms that were approximately their square, etc.

B. Bracket grade

A polynomial that is the sum of terms of different rank does not have a defined rank. However, the space of polynomials may be divided into subspaces according to the the minimum of the ranks of their terms. By this definition, the rank *grades* the space of polynomials, that is, divides it into subspaces S_m for m a non-negative integer, such that $[S_m,S_n]\subseteq S_{m+n}$ for m, $n\geqslant 0$ (see Healy and Dragt,[13] Sec. 4.2.1) provided a particular condition is met: If f and g have defined ranks, then the rank of their Poisson bracket $r([f,g])$ is

$$r([f,g])=r(f)+r(g)-\Delta. \tag{10}$$

The quantity Δ will be called the *bracket grade*; it is a constant non-negative integer, characteristic of the algebra. The bracket grade constraint (10) is equivalent to the statement that the sum of the ranks of the two conjugate phase space variables x_i, X_i are equal for all degrees of freedom i:

$$r(x_i)+r(X_i)=\Delta. \tag{11}$$

To see this, note that $[x_i,X_i]=1$ which has a rank of zero (being a constant), $0=r([x_i,X_i])=r(x_i)+r(X_i)-\Delta$, so $r(x_i)+r(X_i)=\Delta$.

The grading function $\mathcal{G}(f)$ gives the maximum i for which the function f is a member of S_i. It is equal to the rank r for functions in which r has a value (i.e., individual terms). Without ambiguity, one may speak of the rank of a polynomial or function, meaning this grading function. For analytic functions other than polynomials, we can assign a subspace on the basis of the Taylor series approximation to it. In general though, the functions we shall use will be polynomials in the perturbation quantities; any other functions (like sine and cosine) will have nonperturbation variables as arguments. Thus the Lie expressions discussed in Sec. II can be thought of as polynomials representing the perturbation.

We shall need to be able to select terms of a certain rank; let the symbol P_k denote the *projection operator* at rank k; that is, $P_k(x)$ consists of all terms of x at rank k.

A *grading* implies a *percolation* that forms an ideal structure for the Lie algebra which allows us to do perturbation theory; see Ref. 13 for more details. There it is shown that one need not have a grading in order to do perturbation, just a percolation. In fact, the method described there for dealing with inhomogeneous terms in particle accelerator beamline elements is a percolation with no grading. However, with a grading, the symbolic computations are a great deal simpler. The method described in this paper can be used to solve these types of problems (as well as perturbations for many other physical systems) in an easier way.

C. Perturbation operators and Lie transformations

In order to compute the result of a Lie transformation, the Taylor series for the exponential must be stopped at some order. Stopping is permissible if the perturbations become too insignificant to worry about, or the series is finite. Thus we may make the following definition: A Lie operator $\mathcal{O}$ is a *perturbation operator* if for all phase space functions g,

$$\mathcal{G}(\mathcal{O}g)>\mathcal{G}(g), \tag{12}$$

or there is an integer n such that

$$\mathcal{O}^n g=0. \tag{13}$$

The only terms that satisfy the latter condition are those that are linear in the phase space variables. Closely related, a *perturbation transformation* is a Lie transformation that is the exponential of a perturbation operator. These will be used to define perturbations.

Define the *rank raising* of a function, Lie operator or transformation as the amount by which the corresponding Lie operator $:f:$, when applied to another function g, raises the rank, i.e., $\mathcal{G}(\{f,g\})-\mathcal{G}(g)$. According to (10), this means that the rank raising for f is $\mathcal{G}(f)-\Delta$.

The conditions above state that a perturbation transformation $e^{:f:}$ has either positive rank raising or terminates. In the former and more common case, each term in the Taylor series of the exponential (6) becomes less significant or ''higher order,'' and can be safely neglected at some rank. In formal language, we pick an integer n, do our computations in a subspace S_n, and drop terms that are not in S_n, but rather in S_m for $m>n$. In the latter case the Taylor series of the exponential actually terminates; there is some n for which $:f:^n=0$. It has special applications; for example, handling placement errors in a particle accelerator. This requirement means that one of the Poisson brackets in the Taylor series is known to be zero for all arguments to the Lie transformation. There is one way that this can happen: if the function f is linear in the phase-space variables, the series for $e^{:f:}$ will terminate at the second term:

$$e^{:f:} = I + :f: , \tag{14}$$

because a Poisson bracket's action on first-order polynomials is to produce a constant.

In the terminating series case, if the grade of the function is less than the bracket grade $\mathcal{G}(f) < \Delta$, the second term in the Taylor series of the exponential would produce terms of lower rank than the first. While this is mathematically sensible, it corresponds to no physically realistic system and makes computer implementation harder, so it is excluded. Similarly, f could have no perturbations, $\mathcal{G}(f) = 0$ if $\Delta = 0$ and it was linear in the phase space variables. As we are after a perturbation development, however, we shall insist that the grade of f is positive, $\mathcal{G}(f) > 0$.

Thus Lie transformations $e^{:f:}$ acceptable to perturbation theory may be easily summarized. One of these conditions must hold:

(i) The rank raising of f is positive, $\mathcal{G}(f) > \Delta$,
(ii) f is first order in the phase space variables, and $\mathcal{G}(f) \geqslant \Delta > 0$.

D. Internal and external perturbations

For some applications, it is possible to view the perturbations as *internal*, that is, the generalized coordinates themselves represent the perturbation: the deviation of a particle in a magnet from a reference trajectory subjects it to forces unaccounted for in that trajectory (the unperturbed solution); these forces are small if the deviation is. For some applications, such as celestial mechanics, it is possible to view the perturbations as *external*, that is, some parameter(s) (not a generalized coordinate) represent the perturbation: a satellite's orbit around the earth deviates from the Keplerian ellipse (the unperturbed solution) due to the earth's deviation from perfectly spherical mass distribution, a fixed property of the earth. The perturbed harmonic Hamiltonian (1), has an external perturbation, μ, but may also be written with an internal perturbation.

A more precise definition of internal and external perturbation is that if one or more phase space variables have positive rank, then the system has an internal perturbation. If one or more nonphase space variables have positive rank, then it has an external perturbation. A perturbed system may have internal perturbations, external perturbations, or both. A phase space variable with a positive rank represents an internal perturbation; a nonphase space variable with a positive rank represents an external perturbation.

If the perturbation is purely internal and the rank is a count of the phase space variables, that is, each phase space variable has a rank of one, then the rank is merely the *order* of the phase space variables. This is the perturbation counting used in the program MARYLIE.[14]

IV. REPRESENTATIONS OF TRANSFORMATIONS

A. Perturbation transformations

There are a number of representations of a map $\mathcal{M}$ possible. First, any map, not necessarily symplectic, may be described as an explicit list of the transformations of each of the phase space variables. Second, as a Lie transformation $e^{:f:}$; it will always be symplectic. A subclass of this is the *homogeneous Lie transformation*, represented by $e^{:f_n:}$, where n indicates a polynomial homogeneous in rank n.

We now broaden the concept of perturbation transformation in Sec. III C to any representation. Let a map $\mathcal{M}$ be a function of external perturbation(s) $\epsilon_1, \ldots, \epsilon_n$, and acting on phase space, $\mathcal{M}(\epsilon_1, \ldots, \epsilon_n)\zeta$. This map is a perturbation transformation if it is the displaced identity at the rank of each phase space variable with no external perturbations,

$$c_i + \zeta_i = P_{r_i}\mathcal{M}(0,0,\ldots)\zeta_i , \tag{15}$$

where P_n is projection of terms of rank n, for all phase space variables z_i, and c_i is a constant independent of the phase space variables and perturbations.

A Lie transformation that is a perturbation transformation by the definition of Sec. III C is one under this definition as well. If the rank raising of f is positive, the projection of $e^{:f:}$ is the identity. If the rank raising is zero, and f is first order in the phase space variables, this produces the displacement term c_i. Normally, we would only consider a perturbation-dependent displacement, so c_i would be zero.

B. Map factorization

It is possible to represent the perturbations of any analytic symplectic perturbation transformation as the product of homogeneous Lie transformations:

Theorem 1 (Map factorization): Let $\mathcal{M}$ be a perturbation transformation that is analytic and symplectic. Then it may be represented by successive homogeneous Lie transformations

$$\mathcal{M}\zeta=\cdots e^{:f_{\Delta+1}:}e^{:f_{\Delta}:}\zeta \tag{16}$$

or

$$\mathcal{M}\zeta=e^{:g_{\Delta}:}e^{:g_{\Delta+1}:}\cdots\zeta, \tag{17}$$

where Δ is the bracket grade.

Proof: The proof will be for ascending factorization (17); the proof of the descending factorization (16) is similar. Because $\mathcal{M}$ is analytic, it has an explicit representation, a Taylor series in the perturbation parameter(s):

$$\mathcal{M}\zeta_i=P_r(\mathcal{M}\zeta_i)+P_{r_i+1}(\mathcal{M}\zeta_i)+\cdots. \tag{18}$$

The first term on the right-hand side may be removed with the appropriate g_{Δ}. We require

$$e^{:g_{\Delta}:}\zeta_i=P_{r_i}(\mathcal{M}\zeta_i); \tag{19}$$

this is easily solved for g_{Δ} because it is linear in phase space, so $e^{:g_{\Delta}:}\zeta_i=c_i+\zeta_i$ for some constant c_i. With this quantity, we can say

$$e^{:-g_{\Delta}:}\mathcal{M}\zeta_i=c_i+\zeta_i+P_{r_i+1}(\mathcal{M}'\zeta_i)+P_{r_i+2}(\mathcal{M}'\zeta_i)+\cdots, \tag{20}$$

with $\mathcal{M}'=e^{:-g_{\Delta}:}\mathcal{M}$. Call this $\overline{\zeta_i}$, the transformed phase space variable. The Poisson bracket is

$$[\overline{\zeta_i},\overline{\zeta_j}]=[\zeta_i,\zeta_j]+[\zeta_i,P_{r_j+1}(\mathcal{M}'\zeta_j)]+[P_{r_i+1}(\mathcal{M}'\zeta_i),\zeta_j]+\mathcal{O}(\delta^{r_i+r_j-\Delta+2}). \tag{21}$$

By virtue of $\mathcal{M}$ and $e^{:g_{\Delta}:}$ being symplectic, the two Poisson brackets $[\overline{\zeta_i},\overline{\zeta_j}]=[\zeta_i,\zeta_j]=J_{ij}$ are the same. The two remaining Poisson brackets are of equal rank, $r_i+r_j-\Delta+1$. Thus at rank $r_i+r_j-\Delta+1$, $[\zeta_i,P_{r_j+1}(\mathcal{M}'\zeta_j)]=[\zeta_j,P_{r_i+1}(\mathcal{M}'\zeta_i)]$ for all i, j. The individual coefficients $\{M_k^1,\ldots,M_k^{2d}\}$, where d is the number of degrees of freedom, must be related in order that the map be symplectic. By Lemma 1 of Dragt and Finn[2] there is a function g such that

$$P_{r_i+1}(\mathcal{M}'\zeta_i)=[g,\zeta_i]. \tag{22}$$

Applying this transformation, we eliminate the terms of (20) at rank r_i+1,

$$e^{:-g_{\Delta+1}:}e^{:-g_{\Delta}:}\mathcal{M}\zeta_i=c_i+\zeta_i+P_{r_i+2}(\mathcal{M}''\zeta_i)+\cdots, \tag{23}$$

with $\mathcal{M}''=e^{:-g_{\Delta+1}:}\mathcal{M}'\zeta_i=e^{:-g_{\Delta+1}:}e^{:-g_{\Delta}:}\mathcal{M}\zeta_i$.

The process described can continue at successively higher ranks, so that continuing to rank k gives

$$\mathcal{M}\zeta_i = e^{:g_\Delta:} e^{:g_{\Delta+1}:} \cdots e^{:g_k:} \zeta_i + \mathcal{O}(\delta^{r_i+k-\Delta+1}). \tag{24}$$

Since this is true for all i and k was arbitrary, we have (17). □

While this proof is not constructive, there is an algorithm described in Ref. 15 that shows how to compute the homogeneous polynomials f and g. In general terms, the function g_n is computed by integrating the M^i_{n-1} with respect to the conjugate variable, but any given i will produce only ζ_i-dependent terms, and any terms dependent on more than one phase space variable will show up in more than one integration. Thus the algorithm must be careful to get all terms and not duplicate.

In an ascending series, the highest rank is applied first and then successively lower ones, whereas in a descending series the lowest rank is applied first and then successively higher ones. The names, while they appear reversed, are a reference to how the ranks read left-to-right, rather than how they are applied mathematically. It is possible to represent any symplectic map either way, but of course the polynomials are different. It turns out that for some contexts, one form is ''natural,'' while for others, the other one is. In particular, the Hamiltonian factorization algorithm (Sec. V) produces descending factorizations, while in numerical application of maps for propagation, the ascending form is more convenient. It is thus useful to be able to transform between the two, along with transformation to and from explicit maps; both these topics are covered in Ref. 15.

The concept of rank introduced above provides a convenient method of factorization, but factorization may also be done by order, the total exponent of phase space variables. If there is an external perturbation, one must then keep an entirely separate expansion. This is less convenient because expression of a full perturbed transformation can be more complicated, but it has been done in the context of accelerator physics problems.[6] The two forms may be converted by concatenating the factored transformations together, and then map factoring by order or rank as appropriate. Two Lie transformations can be *concatenated*, that is, combined into a single Lie transformation, by means of the Baker–Campbell–Hausdorff formula. More details on this and related manipulations are given in Ref. 15.

We shall call the sequence of maps (16) or (17) a *factored Lie product*. When combined with the unperturbed solution, we have the complete Lie transfer map.

V. HAMILTONIAN FACTORIZATION

The map factorization theorem, while useful for calculating the polynomials if the map is given, is not helpful in a constructive sense when we seek to solve a Hamiltonian problem. This section shows a method for computing the factored Lie product for time evolution of a perturbed Hamiltonian, knowing

(i) the full Hamiltonian,
(ii) the solution for the unperturbed Hamiltonian,
(iii) how to do Poisson brackets,
(iv) how to do time integration.

The method presented in this section will produce a factored Lie product of the descending form (16). In Sec. V E an example worked step-by-step is given.

The method of Hamiltonian factorization was developed in the context of what we are calling here internal perturbations by Dragt and Forest.[4] The method described here is a generalization, primarily in the following ways: the map under the unperturbed Hamiltonian is arbitrarily labeled $\mathcal{U}$ instead of presuming that it will be a linear function of the generalized coordinates, and the bracket grade is an arbitrary non-negative integer (Δ) instead of two. These result in a subtle difference in the development of the solution; here we need to include ''at bracket grade'' terms not present in the previous analysis. Nevertheless, where the details are unclear here, the reader should consult their paper.

In this method, there is a constraint which has no meaningful implication to real physics problems, and that is the assumption that time (the independent variable) must be rank zero, so that differentiation and integration with respect to time will not change rank.

A. Hamiltonian evolution

Using properties of Lie transformations, it can be shown that evolution of a map $\mathcal{M}$ on phase space under a Hamiltonian satisfies Hamilton's equations,

$$\dot{\mathcal{M}} = \mathcal{M} : -\mathcal{H}(\zeta^{\text{in}}, t) : , \tag{25}$$

with initial generalized coordinates ζ^{in}, which means that for an arbitrary function on phase space $g(\zeta)$, for ζ at an arbitrary time,

$$\dot{\mathcal{M}}(g(\zeta^{\text{in}})) = \mathcal{M} : -\mathcal{H}(\zeta^{\text{in}}, t) : (g(\zeta^{\text{in}})). \tag{26}$$

B. The interaction picture

We say that evolution under a Hamiltonian $\mathcal{H}$ gives rise to a map $\mathcal{M}$ over some time period if $\mathcal{M}$ is the function that gives the generalized coordinates at the final time ζ^f after evolving under $\mathcal{H}$ from the generalized coordinates at the initial time ζ^i,

$$\zeta^f = \mathcal{M}\zeta^i. \tag{27}$$

Let the $\mathcal{M}$ be defined as the composition of two other maps, called the unperturbed map $\mathcal{U}$ and the perturbation $\mathcal{P}$:

$$\mathcal{M} = \mathcal{P}\mathcal{U}. \tag{28}$$

The terminology will be justified shortly. Differentiating the map product

$$\dot{\mathcal{M}} = \dot{\mathcal{P}}\mathcal{U} + \mathcal{P}\dot{\mathcal{U}} \tag{29}$$

and substituting the map evolution equation (25) gives

$$\mathcal{P}\mathcal{U} : -\mathcal{H} := \dot{\mathcal{P}}\mathcal{U} + \mathcal{P}\dot{\mathcal{U}}. \tag{30}$$

The Hamiltonian may be expanded by rank,

$$\mathcal{H} = \mathcal{H}^u_\Delta + \mathcal{H}^p_\Delta + \mathcal{H}_{\Delta+1} + \mathcal{H}_{\Delta+2} + \cdots . \tag{31}$$

The Hamiltonian is free of phase-space dependent terms of rank lower than Δ. The terms of the Hamiltonian at rank Δ are split into two, $\mathcal{H}^u_\Delta$ and $\mathcal{H}^p_\Delta$. $\mathcal{H}^u_\Delta$ is meant to be the unperturbed part, and $\mathcal{H}^p_\Delta$, together with $\mathcal{H}_i$ $(i > \Delta)$ is meant to capture the perturbations. According to the definitions of Sec. III C, if $\Delta = 0$, there are no perturbation terms at bracket grade, i.e., $\mathcal{H}^p_\Delta = 0$. If $\Delta > 0$, however, then $\mathcal{H}^p_\Delta$ consists of those terms at bracket grade that are linear in phase space. $\mathcal{H}_n = P_n(\mathcal{H})$ for $n > 0$ are terms of the Hamiltonian with rank n, which are all perturbations.

There is a known solution $\mathcal{U}$ to the equation of motion for the Hamiltonian $\mathcal{H}^u_\Delta$,

$$\dot{\mathcal{U}} = \mathcal{U} : -\mathcal{H}^u_\Delta :, \tag{32}$$

which may be substituted in (30) to obtain an equation of motion for $\mathcal{P}$:

$$\dot{\mathcal{P}}\mathcal{U} = \mathcal{P}\mathcal{U} : -\mathcal{H}_R : \quad \text{with} \quad \mathcal{H}_R = \mathcal{H} - \mathcal{H}^u_\Delta \tag{33}$$

or

$$\dot{\mathcal{P}}=\mathcal{P}\mathcal{U}:-\mathcal{H}_R:\mathcal{U}^{-1}=\mathcal{P}:-\mathcal{H}_R^{\text{int}}:, \tag{34}$$

where $\mathcal{H}_R^{\text{int}}(\zeta)=\mathcal{H}_R(\mathcal{U}\zeta)$ is the perturbed interaction Hamiltonian.

The known solution to the unperturbed problem $\mathcal{U}$, though denoted analogously to the perturbation map $\mathcal{P}$ being solved, will not usually be represented the same way. The solution $\mathcal{U}$ will usually be written as an explicit transformation, that is, as expressions for the final phase space variables as function(s) of the initial phase space variables. For example, if the unperturbed problem is a linear system, $\mathcal{U}$ may be written as a matrix. On the other hand, the perturbation map $\mathcal{P}$ is being developed as a sequence of Lie transformations.

The goal of the next two sections is to derive an algorithm for computing $\mathcal{P}$ using factored Lie products (16).

C. The map in the interaction picture

Since $\mathcal{P}$ is a perturbation transformation, it can be factored (Sec. IV B); for convenience let the homogeneous Lie transformations be designated $\mathcal{M}_\Delta^p=e^{:f_\Delta:}$ and $\mathcal{M}_n=e^{:f_n:}$ for $n>\Delta$; the perturbation map is

$$\mathcal{P}=\cdots\mathcal{M}_{\Delta+2}\mathcal{M}_{\Delta+1}\mathcal{M}_\Delta^p. \tag{35}$$

The time derivative of this map may be computed using (34)

$$\begin{aligned}\dot{\mathcal{P}}&=\cdots+\cdots\dot{\mathcal{M}}_{\Delta+2}\mathcal{M}_{\Delta+1}\mathcal{M}_\Delta^p+\cdots\mathcal{M}_{\Delta+2}\dot{\mathcal{M}}_{\Delta+1}\mathcal{M}_\Delta^p+\cdots\mathcal{M}_{\Delta+2}\mathcal{M}_{\Delta+1}\dot{\mathcal{M}}_\Delta^p\\&=\cdots\mathcal{M}_{\Delta+2}\mathcal{M}_{\Delta+1}\mathcal{M}_\Delta^p:-\mathcal{H}_R^{\text{int}}:.\end{aligned} \tag{36}$$

We may apply $\mathcal{P}^{-1}$ on the left to obtain a relation between the interaction Hamiltonian and the perturbation transformations,

$$\begin{aligned}&\cdots+\cdots\mathcal{M}_\Delta^{p-1}\mathcal{M}_{\Delta+1}^{-1}\mathcal{M}_{\Delta+2}^{-1}\dot{\mathcal{M}}_{\Delta+2}\mathcal{M}_{\Delta+1}\mathcal{M}_\Delta^p+\cdots\mathcal{M}_\Delta^{p-1}\mathcal{M}_{\Delta+1}^{-1}\dot{\mathcal{M}}_{\Delta+1}\mathcal{M}_\Delta^p\\&\quad+\cdots\mathcal{M}_\Delta^{p-1}\dot{\mathcal{M}}_\Delta^p=:-\mathcal{H}_R^{\text{int}}:.\end{aligned} \tag{37}$$

This may look complicated, but we can reduce it to something usable by taking the ''adjoint of the adjoint;'' we define the operator # # by analogy to : :, so that $\#f\#:g:=\{:f:,:g:\}$, where the braces indicate the commutator. The exponential of this operator is defined with the customary Taylor series, and, as a Lie transformation, possesses all the identities such as the similarity relationship (8). We may take each term in (37) and rewrite the similarity transformation using this adjoint, for example,

$$\mathcal{M}_\Delta^{p-1}\mathcal{M}_{\Delta+1}^{-1}\mathcal{M}_{\Delta+2}^{-1}\dot{\mathcal{M}}_{\Delta+2}\mathcal{M}_{\Delta+1}\mathcal{M}_\Delta^p=e^{\#-f_\Delta\#}e^{\#-f_{\Delta+1}\#}\mathcal{M}_{\Delta+2}^{-1}\dot{\mathcal{M}}_{\Delta+2}. \tag{38}$$

With the integrated exponential function iex defined as

$$\text{iex}(w)=\int_0^1 e^{tw}\,dt=\sum_{m=0}^{\infty}\frac{w^m}{(m+1)!}, \tag{39}$$

then

$$\mathcal{M}_n^{-1}\dot{\mathcal{M}}_n=\text{iex}(-\#f_n\#):\dot{f}_n: \tag{40}$$

(see Ref. 4); we find that we have labored fruitfully to simplify (37)

$$\cdots e^{\#-f_\Delta\#}e^{\#-f_{\Delta+1}\#}\,\mathrm{iex}(-\#f_{\Delta+2}\#):\dot{f}_{\Delta+2}:+e^{\#-f_\Delta\#}\,\mathrm{iex}(-\#f_{\Delta+1}\#):\dot{f}_{\Delta+1}:$$
$$+\mathrm{iex}(-\#f_\Delta\#):\dot{f}_\Delta:=:-\mathcal{H}_R^{\mathrm{int}}:. \tag{41}$$

Using the technique of ''decolonizing,'' [4] we may demote each expression on the adjoint scale $-\#\ \#$ to : : and : : to simple phase space expressions:

$$\cdots e^{:-f_\Delta:}e^{:-f_{\Delta+1}:}\,\mathrm{iex}(-:f_{\Delta+2}:)\dot{f}_{\Delta+2}+e^{:-f_\Delta:}\,\mathrm{iex}(-:f_{\Delta+1}:)\dot{f}_{\Delta+1}$$
$$+\mathrm{iex}(-:f_\Delta:)\dot{f}_\Delta=-\mathcal{H}_R^{\mathrm{int}}, \tag{42}$$

which may be rewritten more compactly in terms of summation and products:

$$\sum_{i=\Delta}^{\infty}\left(\prod_{j=\Delta}^{i-1}e^{:-f_j:}\right)\mathrm{iex}(-:f_i:)\dot{f}_i=-\mathcal{H}_R^{\mathrm{int}}. \tag{43}$$

We may now begin to see our destination: from this formula, we can compute each of the polynomials f_n. We can compute $-\mathcal{H}_R^{\mathrm{int}}$ from the original Hamiltonian and the solution to the unperturbed problem. Then rank by rank, we can compute each of the polynomials in order $f_\Delta,\ldots,f_{n-1}$ to get f_n.

D. Sequential computation of polynomials

Explicitly, this procedure is as follows. Let the ''rest map'' C_k be defined as the difference of the two sides of (43) with the summation truncated

$$C_k(t)=-\mathcal{H}_R^{\mathrm{int}}(t)-\sum_{i=\Delta}^{k}\left(\prod_{j=\Delta}^{i-1}e^{:-f_j:}\right)\mathrm{iex}(-:f_i:)\dot{f}_i. \tag{44}$$

If the upper limit is lower than the lower limit for the summation or product, the term is to be ignored, i.e., $\Sigma_A^B=0$ and $\Pi_A^B=1$ if $B<A$. We can express (44) inductively:

$$C_{\Delta-1}=-\mathcal{H}_R^{\mathrm{int}} \tag{45a}$$

and

$$C_k=C_{k-1}-\left(\prod_{j=\Delta}^{k-1}e^{:-f_j:}\right)\mathrm{iex}(-:f_k:)\dot{f}_k \tag{45b}$$

for $k\geqslant\Delta$.

Note that the rest map is seen to be zero at a rank below the step k, $P_l(C_k)=0$ for $l\leqslant k$, because the Lie operator $:f_k:$ raises the rank for $k>\Delta$. Thus we apply the projection P_k to both sides of (45b) to find

$$P_k(C_{k-1})=e^{:-f_\Delta:}\dot{f}_k; \tag{46}$$

the right-hand side is purely rank k. The product of Lie transformations reduces to just the Lie transformation in f_Δ because all other transformation are the identity at rank-raise zero. Similarly, $\mathrm{iex}(-:f_k:)$ is the identity at rank-raise zero. Since $\dot{f}_k$ is rank k, we care only about rank-raise zero in the transformations.

Solving for f_Δ, Eq. (46) with $k=\Delta$ becomes

$$P_\Delta(-\mathcal{H}_R^{\mathrm{int}})=e^{:-f_\Delta:}\dot{f}_\Delta. \tag{47}$$

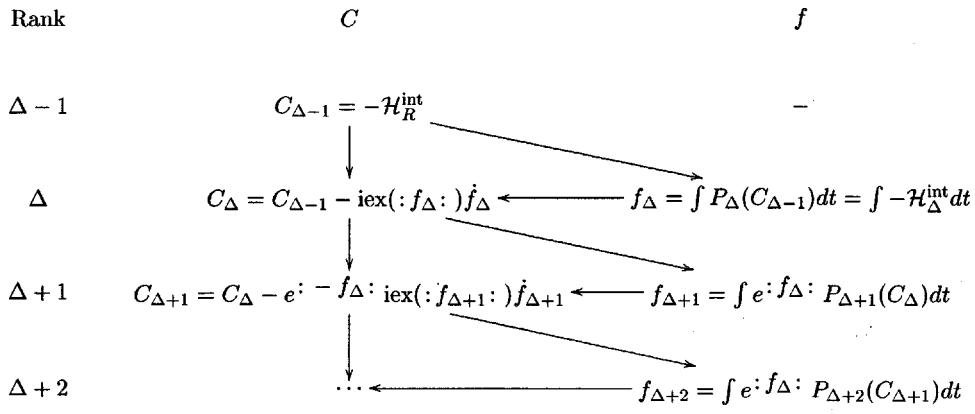

FIG. 1. Factoring the Hamiltonian rank by rank. Each f_n is computed using prior values of C; each C_n is computed using current and prior values of f.

As stated in Sec. III B, f_Δ must be first order in the phase space variables. Therefore, $:f_\Delta:\dot{f}_\Delta$ is a constant, and there are no subsequent terms. We can thus truncate the series at the first term

$$P_\Delta(-\mathcal{H}_R^{\text{int}}) = \dot{f}_\Delta, \tag{48}$$

which is easily solved,

$$f_\Delta = \int P_\Delta(C_{\Delta-1})dt = \int -\mathcal{H}_\Delta^{\text{int}}dt, \tag{49}$$

where $\mathcal{H}_\Delta^{\text{int}}$ is the rank-Δ term of $\mathcal{H}_R^{\text{int}}$. For $k>\Delta$ the solution is straightforward. Solving for $\dot{f}_k$ in (46),

$$\dot{f}_k = e^{:f_\Delta:}P_k(C_{k-1}) \tag{50}$$

or

$$f_k = \int e^{:f_\Delta:}P_k(C_{k-1})dt. \tag{51}$$

The factorization (35) that this algorithm produces is the descending form (16).

E. Summary and example of the computation

The Lie polynomials and transfer map are computed with the following steps: compute

(1) the interaction Hamiltonian according to $\mathcal{H}_R^{\text{int}}(\zeta) = -\mathcal{H}_R(\mathcal{U}\zeta)$, and $C_{\Delta-1}$ by (45a),
(2) f_Δ from $C_{\Delta-1}$ according to (49),
(3) for $k \geqslant \Delta$, C_k from C_{k-1} and $f_\Delta, \ldots, f_{k-1}$, according to (45b),
(4) f_k from C_{k-1} for $k>\Delta$ according to (51),
(5) repeat at step 3 as desired.

This procedure is diagrammed in Fig. 1. With it, we may iteratively find all the polynomials up to the rank we desire.

We may now use these steps to compute the Lie transfer map for the quartic harmonic oscillator introduced in Sec. I, with action-angle Hamiltonian (4). First, assume that the unperturbed solution,

$$\mathcal{U}=\begin{cases}\theta\leftarrow\theta+\omega_0 t,\\ J\leftarrow J,\end{cases} \tag{52}$$

is known. In this formulation, the bracket grade is zero, $\Delta=0$. As before, we will use ϕ for $\omega_0 t$; then the transformed Hamiltonian is obtained by substituting $\theta+\phi$ for θ in the action-angle Hamiltonian (4),

$$\mathcal{H}^{\text{int}}=\omega_0 J+\delta\mu J^2\frac{1}{\omega_0^2}\left(\frac{3}{8}-\frac{1}{2}\cos(2\theta+2\phi_0)+\frac{1}{8}\cos(4\theta+4\phi_0)\right). \tag{53}$$

We can split this into the unperturbed part, $\omega_0 J$, and the perturbation part,

$$\mathcal{H}_R^{\text{int}}=\delta\mu J^2\frac{1}{\omega_0^2}\left(\frac{3}{8}-\frac{1}{2}\cos(2\theta+2\phi)+\frac{1}{8}\cos(4\theta+4\phi)\right). \tag{54}$$

The first rest-map is, according to (45a), just the negative of the interaction Hamiltonian

$$C_{-1}=-\mathcal{H}_R^{\text{int}}=-\delta\mu J^2\frac{1}{\omega_0^2}\left(\frac{3}{8}-\frac{1}{2}\cos(2\theta+2\phi)+\frac{1}{8}\cos(4\theta+4\phi)\right). \tag{55}$$

Thus, the first polynomial, at the bracket grade $\Delta=0$, is zero, $f_0=\int P_0(C_{-1})dt=0$. Using (45b) and this fact, we find $C_0=C_{-1}$.

So far, this is not really interesting. At $k=1$ though, we start getting nonzero results; using (51),

$$\begin{aligned}f_1&=\int e^{:f_0:}P_1(C_0)dt\\&=\int-\delta\mu J^2\frac{1}{\omega_0^2}\left(\frac{3}{8}-\frac{1}{2}\cos(2\theta+2\phi)+\frac{1}{8}\cos(4\theta+4\phi)\right)dt\\&=\delta\mu J^2\left(-\frac{3}{8}\frac{t}{\omega_0^2}+\frac{1}{\omega_0^3}\left(-\frac{1}{4}\sin 2\theta+\frac{1}{4}\sin(2\theta+2\phi_0)+\frac{1}{32}\sin 4\theta-\frac{1}{32}\sin(4\theta+4\phi_0)\right)\right).\end{aligned} \tag{56}$$

At the next rank, the rest map is more complicated, because we now must apply f_1 as a transformation:

$$\begin{aligned}C_1=\exp:\delta\mu J^2\frac{1}{\omega_0^2}&\left(-\frac{3}{8}+\frac{1}{2}\cos(2\theta+2\phi_0)-\frac{1}{8}\cos(4\theta+4\phi_0)\right)+\delta^2\mu^2J^3\left(\frac{t}{\omega_0^4}\left(-\frac{3}{8}\sin(2\theta\right.\right.\\&+2\phi_0)+\frac{3}{16}\sin(4\theta+4\phi_0)\Big)+\frac{1}{\omega_0^5}\left(\frac{17}{64}-\frac{1}{4}\cos 2\phi_0-\frac{1}{64}\cos 4\phi_0+\frac{3}{64}\cos(2\theta-2\phi_0)\right.\\&+\frac{3}{16}\cos 2\theta-\frac{21}{64}\cos(2\theta+2\phi_0)+\frac{3}{32}\cos(2\theta+4\phi_0)-\frac{3}{64}\cos 4\theta+\frac{3}{64}\cos(4\theta+4\phi_0)\\&\left.\left.+\frac{1}{64}\cos(6\theta+2\phi_0)-\frac{1}{32}\cos(6\theta+4\phi_0)+\frac{1}{64}\cos(6\theta+6\phi_0)\right)\right)+\mathcal{O}(\delta^3):.\end{aligned} \tag{57}$$

Note that the rest map is now an infinite series in δ; we must cut it off at order 2, because that is all that is necessary for calculating the next polynomial:

$$f_2=\exp:\delta^2\mu^2J^2\Bigg(\frac{t}{\omega_0^5}\Bigg(\frac{17}{64}+\frac{3}{16}\cos 2\theta+\frac{3}{16}\cos(2\theta+2\phi_0)-\frac{3}{64}\cos 4\theta-\frac{3}{64}\cos(4\theta+4\phi_0)\Bigg)$$
$$+\frac{1}{\omega_0^6}\Bigg(-\frac{1}{8}\sin 2\phi_0-\frac{1}{256}\sin 4\phi_0-\frac{3}{128}\sin(2\theta-2\phi_0)+\frac{33}{128}\sin 2\theta-\frac{33}{128}\sin(2\theta+2\phi_0)$$
$$+\frac{3}{128}\sin(2\theta+4\phi_0)-\frac{3}{128}\sin 4\theta+\frac{3}{128}\sin(4\theta+4\phi_0)-\frac{1}{384}\sin 6\theta+\frac{1}{128}\sin(6\theta+2\phi_0)$$
$$-\frac{1}{128}\sin(6\theta+4\phi_0)+\frac{1}{384}\sin(6\theta+6\phi_0)\Bigg)\Bigg):. \tag{58}$$

When applied to the phase space variables θ and J, the factored Lie product to this rank $e^{:f_2:}e^{:f_1:}$ will give us the explicit map (5); this is done in Ref. 10.

The above example has no f_Δ term. Consider then another example, with $\Delta=2$ and a nonzero f_Δ term. It is a simple harmonic oscillator in Cartesian coordinates with a quartic perturbation as above, but in addition it has a bracket-grade perturbation $X\nu$,

$$\mathcal{H}=\delta^2(\tfrac{1}{2}X\nu+\tfrac{1}{2}\omega_0^2x^2+\tfrac{1}{2}X^2)-\tfrac{1}{4}\delta^4x^4\mu. \tag{59}$$

Here, the Cartesian phase space variable x and its conjugate momentum X each have rank one, as does the external perturbation ν. The unperturbed solution is simply the harmonic oscillator solution,

$$\mathcal{U}=\begin{cases} x\leftarrow & x\cos\phi_0+X\dfrac{1}{\omega_0}\sin\phi_0 \\ X\leftarrow & -x\omega_0\sin\phi_0+X\cos\phi_0 \end{cases}. \tag{60}$$

The interaction Hamiltonian is

$$\mathcal{H}_R^{\text{int}}=\delta^2\Bigg(\nu\Bigg(-\frac{1}{2}x\omega_0\sin\phi_0+\frac{1}{2}X\cos\phi_0\Bigg)+\frac{1}{2}\omega_0^2x^2+\frac{1}{2}X^2\Bigg)+\delta^4\mu\Bigg(x^4\Bigg(-\frac{3}{32}-\frac{1}{8}\cos 2\phi_0$$
$$-\frac{1}{32}\cos 4\phi_0\Bigg)+x^3X\frac{1}{\omega_0}\Bigg(-\frac{1}{4}\sin 2\phi_0-\frac{1}{8}\sin 4\phi_0\Bigg)+x^2X^2\frac{1}{\omega_0^2}\Bigg(-\frac{3}{16}+\frac{3}{16}\cos 4\phi_0\Bigg)$$
$$+xX^3\frac{1}{\omega_0^3}\Bigg(-\frac{1}{4}\sin 2\phi_0+\frac{1}{8}\sin 4\phi_0\Bigg)+X^4\frac{1}{\omega_0^4}\Bigg(-\frac{3}{32}+\frac{1}{8}\cos 2\phi_0-\frac{1}{32}\cos 4\phi_0\Bigg)\Bigg)+\mathcal{O}(\delta^5). \tag{61}$$

Because $\Delta=2$, the first rest map computed is C_1,

$$C_1=\exp:\delta^2\nu(\tfrac{1}{2}x\omega_0\sin\phi_0-\tfrac{1}{2}X\cos\phi_0)+\mathcal{O}(\delta^3):\ . \tag{62}$$

In contrast to the previous example, at the bracket grade two, this is nonzero, so that the first Lie polynomial f_2 is nonzero,

$$f_2=\exp:\mathcal{O}(\delta^3):\exp:\delta^2\nu\Bigg(x\Bigg(\frac{1}{2}-\frac{1}{2}\cos\phi_0\Bigg)-\frac{1}{2}X\frac{1}{\omega_0}\sin\phi_0\Bigg):\ . \tag{63}$$

The next rest map C_3 is the same as the last one (62); however, at rank 4,

$$C_4=\exp{:}\,\delta^2\nu\left(\frac{1}{2}x\omega_0\sin\phi_0-\frac{1}{2}X\cos\phi_0\right)+\delta^4\mu\left(x^4\left(\frac{3}{32}+\frac{1}{8}\cos 2\phi_0+\frac{1}{32}\cos 4\phi_0\right)\right.$$
$$+x^3X\frac{1}{\omega_0}\left(\frac{1}{4}\sin 2\phi_0+\frac{1}{8}\sin 4\phi_0\right)+x^2X^2\frac{1}{\omega_0^2}\left(\frac{3}{16}-\frac{3}{16}\cos 4\phi_0\right)+xX^3\frac{1}{\omega_0^3}\left(\frac{1}{4}\sin 2\phi_0\right.$$
$$\left.\left.-\frac{1}{8}\sin 4\phi_0\right)+X^4\frac{1}{\omega_0^4}\left(\frac{3}{32}-\frac{1}{8}\cos 2\phi_0+\frac{1}{32}\cos 4\phi_0\right)\right)+\mathcal{O}(\delta^5){:}\ \ , \tag{64}$$

and the corresponding Lie polynomial is

$$f_4=\exp{:}\,\mathcal{O}(\delta^5){:}\exp{:}\,\delta^4\left(\mu\nu^{24}\left(\frac{3}{512}\frac{t}{\omega_0^4}+\frac{1}{\omega_0^5}\left(-\frac{1}{256}\sin 2\phi_0+\frac{1}{2048}4\phi_0\right)\right)+\mu\nu^3\left(x\frac{1}{\omega_0^4}\left(\frac{3}{256}\right.\right.\right.$$
$$\left.-\frac{1}{64}\cos 2\phi_0+\frac{1}{256}\cos 4\phi_0\right)+X\left(\frac{3}{64}\frac{t}{\omega_0^4}+\frac{1}{\omega_0^5}\left(-\frac{1}{32}\sin 2\phi_0+\frac{1}{256}\sin 4\phi_0\right)\right)\Big)$$
$$+\mu\nu^2\left(x^2\left(\frac{3}{64}\frac{t}{\omega_0^2}-\frac{3}{256}\frac{1}{\omega_0^3}\sin 4\phi_0\right)+xX\frac{1}{\omega_0^4}\left(\frac{9}{128}-\frac{3}{32}\cos 2\phi_0+\frac{3}{128}\cos 4\phi_0\right)\right.$$
$$\left.+X^2\left(\frac{9}{64}\frac{t}{\omega_0^4}+\frac{1}{\omega_0^5}\left(-\frac{3}{32}\sin 2\phi_0+\frac{3}{256}\sin 4\phi_0\right)\right)\right)+\mu\nu\left(x^3\frac{1}{\omega_0^2}\left(\frac{5}{64}-\frac{1}{16}\cos 2\phi_0\right.\right.$$
$$\left.-\frac{1}{64}\cos 4\phi_0\right)+x^2X\left(\frac{3}{16}\frac{t}{\omega_0^2}-\frac{3}{64}\frac{1}{\omega_0^3}\sin 4\phi_0\right)+xX^2\frac{1}{\omega_0^4}\left(\frac{9}{64}-\frac{3}{16}\cos 2\phi_0+\frac{3}{64}\cos 4\phi_0\right)$$
$$\left.+X^3\left(\frac{3}{16}\frac{t}{\omega_0^4}+\frac{1}{\omega_0^5}\left(-\frac{1}{8}\sin 2\phi_0+\frac{1}{64}\sin 4\phi_0\right)\right)\right)+\mu\left(x^4\left(\frac{3}{32}t+\frac{1}{\omega_0}\left(\frac{1}{16}\sin 2\phi_0\right.\right.\right.$$
$$\left.\left.+\frac{1}{128}\sin 4\phi_0\right)\right)+x^3X\frac{1}{\omega_0^2}\left(\frac{5}{32}-\frac{1}{8}\cos 2\phi_0-\frac{1}{32}\cos 4\phi_0\right)+x^2X^2\left(\frac{3}{16}\frac{t}{\omega_0^2}-\frac{3}{64}\frac{1}{\omega_0^3}\sin 4\phi_0\right)$$
$$+xX^3\frac{1}{\omega_0^4}\left(\frac{3}{32}-\frac{1}{8}\cos 2\phi_0+\frac{1}{32}\cos 4\phi_0\right)+X^4\left(\frac{3}{32}\frac{t}{\omega_0^4}+\frac{1}{\omega_0^5}\left(-\frac{1}{16}\sin 2\phi_0\right.\right.$$
$$\left.\left.\left.\left.+\frac{1}{128}\sin 4\phi_0\right)\right)\right)\right){:}\exp{:}\,\delta^2\nu\left(x\left(\frac{1}{2}-\frac{1}{2}\cos\phi_0\right)-\frac{1}{2}X\frac{1}{\omega_0}\sin\phi_0\right){:}\,. \tag{65}$$

VI. CONCLUSION

For a particular perturbation problem where each perturbation has a positive integer rank, knowledge of its Hamiltonian, a map for the unperturbed solution, and a method for doing time integrals and Poisson brackets is sufficient to calculate a transfer map represented in Lie polynomials to a desired rank of perturbation. Such a map is a regular perturbation solution to the problem.

For propagation of a given system once the map has been computed, it is necessary to turn the Lie transfer map into an explicit function of the coordinates and time (and parameters, of course). Once such an explicit map is obtained, it is possible to check its validity by seeing that it satisfies the map form of Hamilton's equations. In some cases the difficulty in computing the map of a full Hamiltonian dictates the combination of this method with numerical integration. A paper is in preparation by the author addressing these topics.

The perturbed harmonic oscillator in one degree of freedom used to illustrate the method has pedagogical value but limited practical value. Real applications can be as diverse as celestial mechanics and accelerator physics. Applications to celestial mechanics and astrodynamics are

worthy of separate papers in themselves; a paper is in preparation by the author on the application of this technique to the perturbed Kepler problem of a satellite orbiting a body with zonal perturbations. In this case, the perturbation is external, the phase space variables are not perturbation variables.

Potential application to accelerator beam dynamics problems might take the form of phase space as deviations from a *design trajectory* through a beamline element as in Dragt's formulation. One expects that the deviations are small, thus, there is an internal perturbation, with each phase space variable having rank one. External perturbations may arise from lattice parameter errors, such as powering or placement errors. It is possible to handle these problems by keeping two separate hierarchies of perturbations,[5] but the unified approach described here greatly simplifies the management of the computation.

Readers interested in results from computing maps for these or other nontrivial physical systems should contact the author.

For any application, the computation and manipulation of maps and associated expressions can become cumbersome quite quickly. For this reason, the author has developed a computer algebra program PGLT (perturbations with graded lie transformations) to automate the algebra involved in using Lie expressions, transformations and related objects. It is described in more detail in another paper.[15] All of the Lie algebraic calculations described in this paper (as well as a good deal more) become a matter of calling a single function, once an appropriate algebra hierarchy and integration rules have been defined.

Exactly calculable field components of electric dipoles in planar boundary

Dionisios Margetis[a] and Tai Tsun Wu
Gordon McKay Laboratory, Harvard University, Cambridge, Massachusetts 02138-2901

(Received 19 January 2000; accepted for publication 13 October 2000)

The Sommerfeld integrals for the electromagnetic fields in the planar boundary between air and a homogeneous, isotropic medium, due to a horizontal and a vertical electric dipole each lying along the interface, are examined in detail. In the case of the horizontal dipole, the tangential electric field is given in terms of series that involve confluent hypergeometric functions, namely, the Fresnel and exponential integrals. A similar exposition is presented for the magnetic and vertical electric fields of the vertical dipole. When the index of refraction of the adjacent space is of a sufficiently large magnitude, the derived series converge rapidly and uniformly with the distance from the source. Specifically, their rates of convergence are shown to be independent of distance. It is pointed out that the corresponding formulas of King *et al.* are valid down to any distance close to the source, where they smoothly connect to known ''quasi-static'' approximations. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1330731]

I. INTRODUCTION

Almost a century ago, Sommerfeld[1] first formulated the problem of the radiating vertical electric dipole located in the planar boundary between two homogeneous and isotropic half spaces by invoking the Hertz vector $\mathbf{\Pi}$ rather than the electromagnetic fields $\mathbf{E}$ and $\mathbf{B}$. With the use of the Fourier–Bessel representations in cylindrical coordinates, Sommerfeld proposed approximate formulas for $\mathbf{\Pi}$ for distances of many wavelengths in air away from the source. Soon after, his student Hörschelman[2] applied the same method to the case of the horizontal electric dipole in air. Other authors revisited these problems aiming at alternative representations for $\mathbf{\Pi}$ that could be amenable to asymptotic evaluations for sufficiently large distances. A historical account and extensive list of references can be found in the monograph by Baños.[3]

Serious efforts to derive accurate expressions for the $\mathbf{\Pi}$ of electric or magnetic dipoles were often made under the simplifying yet practically significant assumption that both the source and the observation point lie at the interface.[3–10] Some of the components of $\mathbf{\Pi}$ then involve the Fourier–Bessel integrals,[3]

$$U(\rho)=\int_0^\infty d\lambda\lambda\,\frac{1}{\sqrt{\lambda^2-k_1^2}+\sqrt{\lambda^2-k_2^2}}J_0(\lambda\rho), \tag{1.1}$$

$$V(\rho)=\int_0^\infty d\lambda\lambda\,\frac{1}{k_2^2\sqrt{\lambda^2-k_1^2}+k_1^2\sqrt{\lambda^2-k_2^2}}J_0(\lambda\rho), \tag{1.2}$$

where k_j $(j=1,2)$ is the complex wave number in medium j, ρ is the polar distance from the source, and J_0 is the Bessel function of order 0. Van der Pol[6] showed that $U(\rho)$ is given in terms of elementary functions, while $V(\rho)$ can be converted to a finite, one-dimensional integral of an elementary function that readily yields Sommerfeld's approximate result. On the basis of Van der

[a]Electronic mail: dmarget@fas.harvard.edu

Pol's formula for $V(\rho)$, Rice[10] derived exact series expansions that, although credited as being ''uniform'' in the distance ρ,[11] become impractical when $|k_j\rho| \gg 1$. He also proposed disparate asymptotic expansions for these distances when the refraction index k_1/k_2 is close to 1, k_2 being the wave number in air. Along the same lines is the exposition by Wise.[7] Noteworthy is Fock's[9] expansion for $V(\rho)$ in terms of products of Bessel functions with half-integer indices, where the expansion parameter $(k_1^2-k_2^2)/(k_1^2+k_2^2)$ is assumed to be of magnitude less than 1. Baños[3] re-derived the Sommerfeld–Van der Pol formula by applying a version of the steepest descent method, where a simple pole is extracted from the vicinity of a saddle point, and neglecting high orders in k_2/k_1. However, the issue of connecting this formula, which is valid in the range $k_2^3\rho/|k_1^2| \geqslant O(1)$, to the respective approximation for $|k_1\rho| \ll 1$ was not essentially addressed.

In a series of works,[12] Wait gave asymptotic formulas for the Sommerfeld integrals in different ranges of polar distances and source heights. Consider, for example, the ranges $k_2\rho \ll 1$, $k_2\rho = O(1)$, and $k_2\rho \gg 1$ when the dipole and the observation point both lie in the boundary;[13] even in this simplest nontrivial case, Wait's approximations seem to be based on intuitive arguments. In particular, in the ''quasi-static approach,''[13] the fields in air are regarded as solutions of Laplace's or Poisson's equation with no practical restriction on $k_1\rho$, but there is no clear indication, for instance, about the convergence or the magnitude of the remainder of the underlying expansion when $k_1 = O(k_2)$ with $k_2 < |k_1|$. In the spirit of the quasi-static approach, the computation of the Hertz vector is carried out in Refs. 14–16 for low frequencies via a convenient resummation of the λ-Maclaurin expansion for the radical under the integral sign. The ensuing simple expressions are interpreted as superpositions of primary and reflected fields, where the earth is replaced by a perfectly conducting medium with the boundary being shifted by the distance $1/k_1$.[16] Notably, the electric and magnetic fields are obtained through direct differentiations of the approximate formulas for $\mathbf{\Pi}$.

Recently, integrated formulas were derived by King *et al.*[17] for the electromagnetic field in air over an imperfectly conducting or dielectric earth when the source is a horizontal or vertical electric dipole. Their major simplifying conditions are $k_2^2 \ll |k_1^2|$ and $k_2 r > O(1)$, r being the radial distance from the source. Some of the novelties of their approach can be outlined as follows. First, these authors deal directly and systematically with the field itself and not the Hertz vector; their set of formulas satisfy Maxwell's equations and the required boundary conditions consistently to the desired order in k_2^2/k_1^2. Second, in their sequence of approximation steps, the direct and the ideal-image fields are singled out, some of the remaining integrals are computed exactly by analytical means, and large-argument approximations for the Bessel functions are only applied to the remainders that involve the Sommerfeld pole. The results advance the works of Baños[3] and others both quantitatively, with the retainment of a larger number of terms, and qualitatively, with the notions of the surface and lateral waves being dissociated in the mathematical treatment from that of a saddle-point in the vicinity of a pole.

In a recent paper,[18] King and Wu make use of the approximate formulas of Ref. 17 for the horizontal dipole to calculate the electromagnetic field in air of infinitely long transmission lines above the earth. However, as pointed out in Ref. 18, the violation of the condition $|k_1 r| > 1$ at extremely low frequencies introduces an inaccuracy for the axial component of the electric field. A formula for this component that is uniform in distance was later derived in a more elaborate analysis by Margetis.[19] The inaccuracy mentioned above signifies one of the instances where approximate formulas that are known to hold sufficiently far from the source are forced to be extended to distances too close to the source. An interesting question is whether it is possible, and if so in what sense, to connect the lateral-wave formulas of King *et al.*[17] to known near-field expressions, such as those given by Wait for $k_2\rho \ll 1$,[13] so that the final formulas adequately describe the field for all reasonable distances when $k_2^2 \ll |k_1^2|$.[20] Various interesting references and formulas for the evaluation of Sommerfeld-type integrals are provided in Ref. 21. Noteworthy among these formulas are the representations in terms of incomplete cylindrical functions.

The purpose of this paper is twofold. The first is to evaluate exactly, in terms of series that are uniform in ρ, those Sommerfeld integrals that are given by integrals of elementary functions, by relaxing the condition $k_2^2 \ll |k_1^2|$. This task is carried out in Secs. III and IV for the electromagnetic

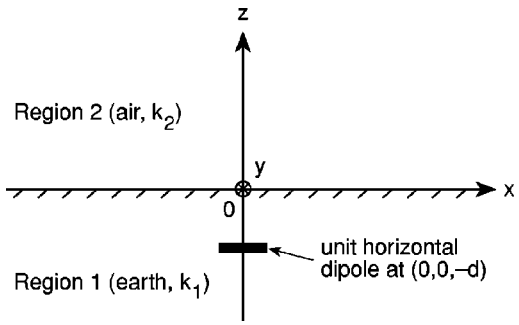

FIG. 1. The geometry and Cartesian coordinate system for a unit horizontal dipole in the earth. The height d is allowed to approach zero ($d\to 0^+$).

field of electric dipoles lying in the planar interface; the use of the Hertz vector is entirely avoided, in the spirit of Ref. 17. The expansion parameter is the inverse of the refraction index, k_2/k_1, which is assumed to be of magnitude less than 1, and the coefficients are known transcendental functions, namely, the exponential and Fresnel integrals. These series are believed to be new. In particular, the rates of convergence of the derived series are shown to depend only on the ratio k_2^2/k_1^2.[11] Emphasis is also placed on obtaining bounds and estimates for the remainders when a finite number of terms are summed. As a consequence, stringent conditions for the validity of simplifications under $k_2^2 \ll |k_1^2|$ can follow. All derivations are subject to routine mathematical rigor, and comparisons with numerical computations are beyond the scope of this paper.[22] A discussion on the merits of the present analysis for numerical evaluations is provided in Sec. VI.

The second purpose is to demonstrate that the corresponding lateral-wave formulas in Ref. 17 may indeed be extended to distances from the source that are short compared to the wavelength in air. In Sec. V we deal precisely with this task via the step-by-step approximations of the exact series. Finally, in Appendix A we calculate analytically a class of integrals involving Bessel functions through a generalized Schwinger–Feynman representation; Van der Pol's formula[6] essentially follows as a special case. The nature of the field asymptotic expansions for $k_2\rho \gg 1$ is analyzed in Appendix B on the basis of the derived series, while in Appendix C we revisit the simplifications of the original integrals in the limiting cases $k_2\rho \ll 1$ and $k_2\rho \gg 1$. The time dependence $e^{-i\omega t}$ is suppressed throughout the analysis.

II. FORMAL REPRESENTATIONS

A. Horizontal electric dipole

The geometry and Cartesian coordinate system are shown in Fig. 1. As the source and the observation point approach the boundary from below ($d\to 0^+$) and from above ($z\to 0^+$), respectively, the Fourier–Bessel representation for the electromagnetic field in the cylindrical coordinates (ρ,ϕ,z) with $x=\rho\cos\phi$ and $y=\rho\sin\phi$ $(0\leqslant\phi<2\pi)$ is[17]

$$E_{2z}=\frac{k_1^2}{k_2^2}E_{1z}=\frac{i\omega\mu_0}{4\pi k_2^2}\int_0^\infty d\lambda\lambda^2\frac{k_2^2\sqrt{k_1^2-\lambda^2}-k_1^2\sqrt{k_2^2-\lambda^2}}{k_2^2\sqrt{k_1^2-\lambda^2}+k_1^2\sqrt{k_2^2-\lambda^2}}J_1(\lambda\rho)\cos\phi, \tag{2.1}$$

$$E_{2\phi}=E_{1\phi}=\frac{\omega\mu_0}{4\pi}\int_0^\infty d\lambda\,\lambda\left\{\frac{\sqrt{k_1^2-\lambda^2}\,\sqrt{k_2^2-\lambda^2}}{k_1^2\sqrt{k_2^2-\lambda^2}+k_2^2\sqrt{k_1^2-\lambda^2}}[J_0(\lambda\rho)+J_2(\lambda\rho)]\right.$$
$$\left.+\frac{1}{\sqrt{k_1^2-\lambda^2}+\sqrt{k_2^2-\lambda^2}}[J_0(\lambda\rho)-J_2(\lambda\rho)]\right\}\sin\phi, \tag{2.2}$$

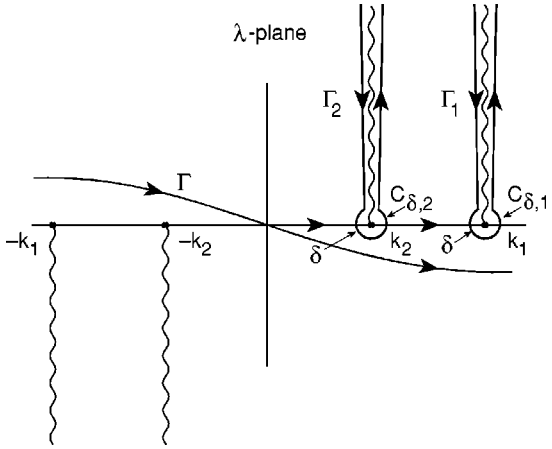

FIG. 2. Branch-cut configuration and integration paths pertaining to the Sommerfeld integrals (2.1)–(2.6) for the horizontal electric dipole and (2.10)–(2.12) for the vertical electric dipole. The original integration path is shown with arrows in the positive real axis. The contours Γ and Γ_j $(j=1,2)$ serve the asymptotic evaluations for $k_2\rho \gg 1$ carried out in Appendix C.

$$E_{2\rho}=E_{1\rho}=-\frac{\omega\mu_0}{4\pi}\int_0^\infty d\lambda\lambda\left\{\frac{\sqrt{k_1^2-\lambda^2}\sqrt{k_2^2-\lambda^2}}{k_1^2\sqrt{k_2^2-\lambda^2}+k_2^2\sqrt{k_1^2-\lambda^2}}[J_0(\lambda\rho)-J_2(\lambda\rho)]\right.$$
$$\left.+\frac{1}{\sqrt{k_1^2-\lambda^2}+\sqrt{k_2^2-\lambda^2}}[J_0(\lambda\rho)+J_2(\lambda\rho)]\right\}\cos\phi, \tag{2.3}$$

$$B_{2z}=B_{1z}=i\frac{\mu_0}{2\pi}\int_0^\infty d\lambda\lambda^2\frac{1}{\sqrt{k_1^2-\lambda^2}+\sqrt{k_2^2-\lambda^2}}J_1(\lambda\rho)\sin\phi, \tag{2.4}$$

$$B_{2\phi}=B_{1\phi}=-\frac{\mu_0}{8\pi}\int_0^\infty d\lambda\lambda\left\{\frac{\sqrt{k_2^2-\lambda^2}-\sqrt{k_1^2-\lambda^2}}{\sqrt{k_2^2-\lambda^2}+\sqrt{k_1^2-\lambda^2}}[J_0(\lambda\rho)+J_2(\lambda\rho)]\right.$$
$$\left.+\frac{k_2^2\sqrt{k_1^2-\lambda^2}-k_1^2\sqrt{k_2^2-\lambda^2}}{k_2^2\sqrt{k_1^2-\lambda^2}+k_1^2\sqrt{k_2^2-\lambda^2}}[J_0(\lambda\rho)-J_2(\lambda\rho)]\right\}\cos\phi, \tag{2.5}$$

$$B_{2\rho}=B_{1\rho}=-\frac{\mu_0}{8\pi}\int_0^\infty d\lambda\lambda\left\{\frac{\sqrt{k_2^2-\lambda^2}-\sqrt{k_1^2-\lambda^2}}{\sqrt{k_2^2-\lambda^2}+\sqrt{k_1^2-\lambda^2}}[J_0(\lambda\rho)-J_2(\lambda\rho)]\right.$$
$$\left.+\frac{k_2^2\sqrt{k_1^2-\lambda^2}-k_1^2\sqrt{k_2^2-\lambda^2}}{k_2^2\sqrt{k_1^2-\lambda^2}+k_1^2\sqrt{k_2^2-\lambda^2}}[J_0(\lambda\rho)+J_2(\lambda\rho)]\right\}\sin\phi, \tag{2.6}$$

the first subscript in each component referring to the region (1 for $z<0$ and 2 for $z>0$).

These integrals are divergent in the conventional sense. The procedure implied by allowing $d\to 0^+$ and $z\to 0^+$ in Fig. 1 dictates that they be interpreted in the sense of Abel.[23] The first Riemann sheet is such that $(j=1,2)$

$$\mathrm{Im}\,\sqrt{k_j^2-\lambda^2}\geqslant 0,\quad \lambda>0, \tag{2.7}$$

with the branch-cut configuration of Fig. 2 where k_1 is taken to be real and $k_2<k_1$. Note that each $\sqrt{k_j^2-\lambda^2}$ is even in λ and the denominator,

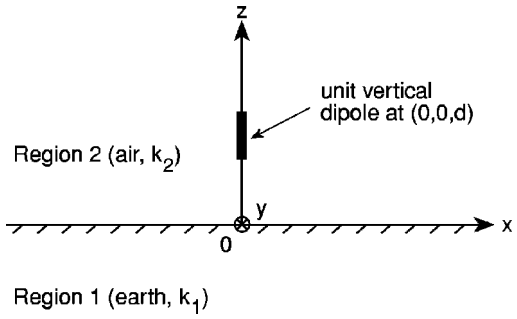

FIG. 3. The geometry and Cartesian coordinate system for a unit vertical dipole in air. The height d is allowed to approach zero ($d\to 0^+$).

$$D(\lambda)=k_1^2\sqrt{k_2^2-\lambda^2}+k_2^2\sqrt{k_1^2-\lambda^2}, \tag{2.8}$$

has four simple zeros in the Riemann surface. These are located at

$$\lambda=\pm k_S=\pm\frac{k_1k_2}{\sqrt{k_1^2+k_2^2}}, \tag{2.9}$$

and are not present in the first Riemann sheet.

B. Vertical electric dipole

The $\hat{\mathbf{z}}$-directed unit dipole is immersed in air (region 2, $z>0$), as depicted in Fig. 3. In the limit $d\to 0^+$ and $z\to 0^+$ the field is[17]

$$B_{2\phi}=B_{1\phi}=i\frac{\mu_0k_1^2}{2\pi}\int_0^\infty d\lambda\lambda^2\frac{1}{k_2^2\sqrt{k_1^2-\lambda^2}+k_1^2\sqrt{k_2^2-\lambda^2}}J_1(\lambda\rho), \tag{2.10}$$

$$E_{2z}=\frac{k_1^2}{k_2^2}E_{1z}=-\frac{\omega\mu_0k_1^2}{2\pi k_2^2}\int_0^\infty d\lambda\lambda^3\frac{1}{k_2^2\sqrt{k_1^2-\lambda^2}+k_1^2\sqrt{k_2^2-\lambda^2}}J_0(\lambda\rho)=\frac{i\omega}{k_2^2}\frac{1}{\rho}\frac{d}{d\rho}\rho B_{2\phi}, \tag{2.11}$$

$$E_{2\rho}=E_{1\rho}=-\frac{i\omega\mu_0}{4\pi k_2^2}\int_0^\infty d\lambda\lambda^2\frac{k_2^2\sqrt{k_1^2-\lambda^2}-k_1^2\sqrt{k_2^2-\lambda^2}}{k_2^2\sqrt{k_1^2-\lambda^2}+k_1^2\sqrt{k_2^2-\lambda^2}}J_1(\lambda\rho). \tag{2.12}$$

The first Riemann sheet along with the branch-cut configuration, and the integration path are chosen as described in Sec. II A and shown in Fig. 2. Throughout the following analysis, it is assumed that

$$0<k_2<|k_1|,\quad 0\leqslant \mathrm{Arg}\ k_1<\pi/4. \tag{2.13}$$

III. EXACT B_{2z}, $E_{2\phi}$, AND $E_{2\rho}$ OF HORIZONTAL ELECTRIC DIPOLE

For mathematical convenience, consider the replacements

$$k_j=iq_j,\quad \sqrt{k_j^2-\lambda^2}=i\sqrt{\lambda^2+q_j^2}\quad (j=1,2). \tag{3.1}$$

The Sommerfeld pole corresponds to $q_S=-ik_S$. For the purpose of carrying out the requisite integrations, q_1 and q_2 are thought of as positive with $q_2<q_1$, unless it is stated or implied otherwise. The final formulas are continued analytically to complex $q_j=-ik_j$ $(j=1,2)$ in view of restrictions (2.13).

A. The *z*-component of the magnetic field

It is verified that B_{2z} is expressed in terms of elementary functions.[13] The requisite integral equals

$$B_{2z}=\frac{\mu_0}{2\pi}\frac{1}{q_1^2-q_2^2}\frac{1}{\rho^4}[\mathcal{I}_m(q_1\rho)-\mathcal{I}_m(q_2\rho)]\sin\phi, \tag{3.2}$$

where

$$\mathcal{I}_m(\alpha)=\int_0^\infty dx\, x^2\sqrt{x^2+\alpha^2}J_1(x)=\frac{\alpha^{5/2}}{2^{-3/2}\Gamma\left(-\frac{1}{2}\right)}K_{5/2}(\alpha), \tag{3.3}$$

via the analytic continuation to $\mu=-3/2$ of the right-hand side of the equation,[24]

$$\int_0^\infty dx\frac{x^2J_1(x)}{(x^2+\alpha^2)^{\mu+1}}=\frac{\alpha^{1-\mu}}{2^\mu\Gamma(\mu+1)}K_{1-\mu}(\alpha).$$

$K_\nu(\alpha)$ is the modified Bessel function of the third kind.[25] Hence,

$$\mathcal{I}_m(\alpha)=-\alpha^2\left(1+\frac{3}{\alpha}+\frac{3}{\alpha^2}\right)e^{-\alpha}. \tag{3.4}$$

It follows that

$$B_{2z}=-\frac{\mu_0}{2\pi}\frac{1}{(k_1^2-k_2^2)\rho^2}\left[e^{ik_1\rho}k_1^2\left(1+\frac{3i}{k_1\rho}-\frac{3}{k_1^2\rho^2}\right)-e^{ik_2\rho}k_2^2\left(1+\frac{3i}{k_2\rho}-\frac{3}{k_2^2\rho^2}\right)\right]\sin\phi. \tag{3.5}$$

This result is also derived by Wait through differentiation of the Hertz vector.[13] Discussions on a similar integral appearing in the problem of the radiating vertical magnetic dipole can be found in the books by Baños[3] and Kong.[26]

B. The ϕ-component of the electric field

With the definition $q_S=-ik_S$, consider the decomposition

$$\frac{\sqrt{\lambda^2+q_1^2}\sqrt{\lambda^2+q_2^2}}{q_1^2\sqrt{\lambda^2+q_2^2}+q_2^2\sqrt{\lambda^2+q_1^2}}=\frac{1}{q_1^4-q_2^4}[q_1^2\sqrt{\lambda^2+q_1^2}-q_2^2\sqrt{\lambda^2+q_2^2}]+\frac{q_1^3q_2^3}{q_1^4-q_2^4}\times\frac{1}{q_1^2+q_2^2}\left[\frac{q_2}{q_1}\frac{\sqrt{\lambda^2+q_1^2}}{\lambda^2+q_S^2}-\frac{q_1}{q_2}\frac{\sqrt{\lambda^2+q_2^2}}{\lambda^2+q_S^2}\right]. \tag{3.6}$$

Accordingly, Eq. (2.2) reads as

$$E_{2\phi}=-\frac{i\omega\mu_0}{2\pi}\frac{1}{q_1^2-q_2^2}\left\{\frac{d}{d\rho}\left[\frac{\mathcal{I}_e(q_1\rho)-\mathcal{I}_e(q_2\rho)}{\rho^2}\right]+\frac{1}{q_1^2+q_2^2}\frac{1}{\rho}\left[\frac{q_1^2\mathcal{I}_e(q_1\rho)-q_2^2\mathcal{I}_e(q_2\rho)}{\rho^2}\right]\right.$$
$$\left.+\frac{q_1^3q_2^3}{(q_1^2+q_2^2)^2}\frac{1}{\rho}\mathcal{W}(\rho)\right\}\sin\phi, \tag{3.7}$$

where

$$\mathcal{I}_e(\alpha)=\int_0^\infty dx\sqrt{x^2+\alpha^2}J_1(x)=\alpha+e^{-\alpha}, \tag{3.8}$$

with recourse to Ref. 24, and

$$\mathcal{W}(\rho)=\int_0^\infty d\lambda\left[\frac{q_2}{q_1}\frac{\sqrt{\lambda^2+q_1^2}}{\lambda^2+q_S^2}-\frac{q_1}{q_2}\frac{\sqrt{\lambda^2+q_2^2}}{\lambda^2+q_S^2}\right]J_1(\lambda\rho). \tag{3.9}$$

The task is to express $\mathcal{W}(\rho)$ in terms of known transcendental functions.

Following Van der Pol,[6] a first step is to convert the representation (3.9) into an integral of elementary functions. The radical in the integrand reads as follows:

$$\frac{q_2}{q_1}\frac{\sqrt{\lambda^2+q_1^2}}{\lambda^2+q_S^2}-\frac{q_1}{q_2}\frac{\sqrt{\lambda^2+q_2^2}}{\lambda^2+q_S^2}=\frac{1}{\lambda^2+q_S^2}\frac{\sqrt{\lambda^2+q_s^2x^2}}{\sqrt{x^2-1}}\Bigg|_{x=q_2/q_S}^{q_1/q_S}$$
$$=\int_{q_2/q_S}^{q_1/q_S}d[(x^2-1)^{-1/2}]\frac{1}{\sqrt{\lambda^2+q_S^2x^2}}. \tag{3.10}$$

The interchange of the order of integration yields

$$\mathcal{W}(\rho)=\int_{q_2/q_S}^{q_1/q_S}d\left(\frac{1}{\sqrt{x^2-1}}\right)\int_0^\infty d\lambda\frac{J_1(\lambda\rho)}{\sqrt{\lambda^2+q_S^2x^2}}, \tag{3.11}$$

where, from Ref. 24 or Eq. (A6) of Appendix A,

$$\int_0^\infty d\lambda\frac{J_1(\lambda\rho)}{\sqrt{\lambda^2+q_S^2x^2}}=\frac{1}{q_S\rho x}(1-e^{-q_S\rho x}). \tag{3.12}$$

Therefore, through integration by parts,

$$\mathcal{W}(\rho)=-\frac{1}{q_S\rho}\left[\frac{q_1-q_2}{q_S}-\frac{q_1e^{-q_2\rho}-q_2e^{-q_1\rho}}{q_S}+\rho W(\rho)\right], \tag{3.13}$$

where

$$W(\rho)=W(\rho;q_1,q_2,q_S),\quad W(\rho;\xi_1,\xi_2,\xi_3)=\int_{\xi_2}^{\xi_1}d\upsilon\frac{\upsilon}{\sqrt{\upsilon^2-\xi_3^2}}e^{-\upsilon\rho},\quad \xi_3\leqslant\xi_2<\xi_1. \tag{3.14}$$

The procedure described hitherto is not different from the one in Ref. 27 for the Hertz vector of a vertical dipole. An alternative derivation of the last equation, that is amenable to generalizations, is provided in Appendix A. It is noted that $W(\rho)$ can be expressed in terms of incomplete cylindrical functions as further discussed in Sec. VI. Despite this fact, it is more advantageous to rewrite $W(\rho)$ as

$$W(\rho)=W(\rho;\infty,q_S,q_S)-W(\rho;\infty,q_1,q_S)-W(\rho;q_2,q_S,q_S). \tag{3.15}$$

The first term is calculated explicitly:[25]

$$W(\rho;\infty,q_S,q_S)=q_S\int_0^\infty dy\,\cosh y e^{-q_S\rho\cosh y}=q_S K_1(q_S\rho). \tag{3.16}$$

1. Integral $W(\rho;\infty,q_1,q_S)$

By invoking the identity

$$(1-u)^{-1/2}=\sum_{m=0}^{M-1}\frac{(\frac{1}{2})_m}{m!}u^m+\frac{(\frac{1}{2})_M}{(M-1)!}u^M\int_0^1 dt(1-t)^{M-1}(1-ut)^{-M-1/2}, \tag{3.17}$$

with $u=q_S^2\nu^{-2}$ and a positive integer M, the second term in Eq. (3.15) reads as

$$W(\rho;\infty,q_1,q_S)=\frac{e^{-q_1\rho}}{\rho}\left[\sum_{m=0}^{M-1}U_m(\rho)+R_{1M}(\rho)\right], \tag{3.18}$$

where

$$U_m(\rho)=\frac{(\frac{1}{2})_m}{m!}(q_S\rho)^{2m}g_{2m}(q_1\rho), \tag{3.19}$$

$$g_n(z)=\int_z^\infty d\tau\tau^{-n}e^{-\tau+z}, \tag{3.20}$$

$$R_{1M}(\rho)=q_1\rho\frac{(\frac{1}{2})_M}{(M-1)!}\left(\frac{q_S}{q_1}\right)^{2M}\int_1^\infty d\eta\eta^{-2M}e^{-q_1\rho(\eta-1)}$$

$$\times\int_0^1 dt(1-t)^{M-1}(1-q_S^2q_1^{-2}\eta^{-2}t)^{-M-1/2} \tag{3.21a}$$

$$=q_1\rho\frac{(\frac{1}{2})_M}{M!}\left(\frac{q_S}{q_1}\right)^{2M}\int_1^\infty d\eta\eta^{-2M}{}_2F_1(M+\tfrac{1}{2},1;M+1;q_S^2q_1^{-2}\eta^{-2})e^{-q_1\rho(\eta-1)}. \tag{3.21b}$$

In the above, ${}_2F_1$ is the hypergeometric function[28] and $(a)_m$ is Pochhammer's symbol.[28]

By bearing in mind that $1-t\leqslant|1-wt|$ for $0\leqslant t\leqslant 1$ and $|w|\leqslant 1$, it is inferred that for admissible complex q_1 and q_2 ($\mathrm{Re}\,q_1\geqslant 0$),

$$|R_{1M}(\rho)|<|q_1\rho|(1-|q_S^2|/|q_1^2|)^{-3/2}\frac{(\frac{1}{2})_M}{M!}\left|\frac{q_S^2}{q_1^2}\right|^M,\quad M=1,2,\ldots, \tag{3.22a}$$

which can be used to prove the convergence of the corresponding series as $M\to\infty$. This relation must be supplemented with the formula

$$R_{1M}(\rho)\sim\frac{(\frac{1}{2})_M}{M!}{}_2F_1(M+\tfrac{1}{2},1;M+1;q_S^2/q_1^2)\frac{q_1\rho}{2M+q_1\rho}\left(\frac{q_S}{q_1}\right)^{2M},\quad |q_1\rho|\gg 1, \tag{3.22b}$$

in order to show that $|R_{1M}(\rho)|$ remains bounded as $|q_1\rho|\to\infty$. It is noted in passing that for $m=0,1,2,\ldots,$

$$ {}_2F_1(m+\tfrac{3}{2},1;m+2;z)=(-1)^m\frac{m+1}{(\tfrac{1}{2})_{m+1}}(1-z)^{-1/2}\frac{d^m}{dz^m}\left[\frac{(1-z)^m}{1+\sqrt{1-z}}\right]. $$

Use of the asymptotic formula ($\eta\gg 1$),

$$ \int_0^1 dt(1-t)^{M-1}(1-q_S^2q_1^{-2}\eta^{-2}t)^{-M-1/2} $$

$$ \sim\frac{1}{M-1-(M+1/2)q_S^2q_1^{-2}\eta^{-2}},\quad M\gg 1, \tag{3.23} $$

in Eq. (3.21a) leads to

$$ R_{1M}(\rho)\sim\frac{(\tfrac{1}{2})_M}{M!}\left(\frac{q_S^2}{q_1^2}\right)^M(1-q_S^2/q_1^2)^{-1}\frac{q_1\rho}{2M+q_1\rho},\quad M\gg 1. \tag{3.24} $$

By inspection of Eq. (3.14), the rate of convergence of the series from Eq. (3.18) is essentially independent of ρ. In particular, $U_m(\rho)$ is approximated by

$$ U_m(\rho)\sim\frac{q_1\rho}{2m+q_1\rho}\frac{(\tfrac{1}{2})_m}{m!}\left(\frac{q_S^2}{q_1^2}\right)^m,\quad m\gg 1. \tag{3.25} $$

This formula also holds when $m=O(1)$ and $|q_1\rho|\gg 1$ with $\mathrm{Re}\,q_1\geqslant 0$, and becomes exact when $m=0$ for any $q_1\rho$. Hence,

$$ \frac{U_{m+1}(\rho)}{U_m(\rho)}\sim\frac{m+1/2}{m+1}\frac{2m+q_1\rho}{2m+2+q_1\rho}\frac{q_S^2}{q_1^2},\quad |2m+q_1\rho|\gg 1. \tag{3.26} $$

In the sense of Cauchy for convergence,

$$ W(\rho;\infty,q_1,q_S)=\frac{e^{-q_1\rho}}{\rho}\sum_{m=0}^{\infty}\frac{(\tfrac{1}{2})_m}{m!}(q_S\rho)^{2m}g_{2m}(q_1\rho). \tag{3.27} $$

The coefficients $g_n(q_1\rho)$ are partial derivatives in x of the generating function,

$$ \sum_{n=1}^{\infty}g_n(z)x^{n-1}=-e^{z-x}\,\mathrm{Ei}(x-z), \tag{3.28} $$

where $\mathrm{Ei}(-z)$ is the exponential integral.[28] Finally,

$$ g_n(z)=\begin{cases}1, & n=0,\\ \dfrac{(-1)^n}{(n-1)!}\dfrac{d^{n-1}}{dz^{n-1}}[e^z\mathrm{Ei}(-z)], & n=1,2,\ldots.\end{cases} \tag{3.29} $$

An asymptotic expansion for $W(\rho;\infty,q_1,q_S)$ when $|q_1\rho|\gg 1$ is derived in Appendix B.

2. Integral $W(\rho;q_2,q_S,q_S)$

With the change of variable $\xi=v-q_S$ in the original integral from Eqs. (3.14) and use of the identity

$$(1+2u)(1+u)^{-1/2}=\sum_{m=0}^{M-1}(-1)^{m+1}\frac{(\frac{1}{2})_m}{m!}\frac{m+1/2}{m-1/2}u^m+(-1)^{M-1}\frac{(\frac{1}{2})_{M-1}}{(M-1)!}u^M$$
$$\times\int_0^1 dt(1-t)^{M-1}(M+1/2+ut)(1+ut)^{-M-1/2}, \tag{3.30}$$

where now $u=(2q_S)^{-1}\xi$, it is straightforward to get

$$W(\rho;q_2,q_S,q_S)=\frac{e^{-q_S\rho}}{\sqrt{2q_S}}\int_0^{q_2-q_S}\frac{d\xi}{\sqrt{\xi}}(\xi+q_S)\left(1+\frac{\xi}{2q_S}\right)^{-1/2}e^{-\xi\rho}, \tag{3.31a}$$

$$=-q_Se^{-q_2\rho}\left[\sum_{m=0}^{M-1}V_m(\rho)+R_{2M}(\rho)\right]. \tag{3.31b}$$

In the above,

$$V_m(\rho)=-e^{i\pi/4}i^{m+1}\frac{(\frac{1}{2})_m}{m!}\frac{m+1/2}{m-1/2}(2q_S\rho)^{-m-1/2}f_m(i(q_2-q_S)\rho), \tag{3.32}$$

$$f_m(z)=\int_0^z d\tau\tau^{m-1/2}e^{-i(z-\tau)}, \tag{3.33}$$

$$R_{2M}(\rho)=(-1)^M\frac{(\frac{1}{2})_{M-1}}{(M-1)!}\left(\frac{q_2-q_S}{2q_S}\right)^{M+1/2}\int_0^1 d\eta\eta^{M-1/2}e^{(q_2-q_S)\rho(1-\eta)}$$
$$\times\int_0^1 dt(1-t)^{M-1}\left(M+\frac{1}{2}+\frac{q_2-q_S}{2q_S}\eta t\right)\left(1+\frac{q_2-q_S}{2q_S}\eta t\right)^{-M-1/2}. \tag{3.34}$$

Because

$$\mathrm{Re}\frac{q_2-q_S}{2q_S}=\mathrm{Re}\frac{k_2-k_S}{2k_S}>0, \tag{3.35}$$

one may employ the inequality $|1+wt|\geqslant 1$ for $t\geqslant 0$ and $\mathrm{Re}\,w>0$, to show that for complex q_1 and q_2 with $\mathrm{Re}\,(q_2-q_S)\leqslant 0$,

$$|R_{2M}(\rho)|<\frac{(\frac{1}{2})_M}{M!}\frac{M+1}{M^2-1/4}\left|\frac{q_2-q_S}{2q_S}\right|^{M+1/2}, \quad M=1,2,\ldots. \tag{3.36a}$$

The convergence of the right-hand side of Eq. (3.31b) as $M\to\infty$ follows. Furthermore,

$$R_{2M}(\rho)\sim(-1)^M\frac{(\frac{1}{2})_M}{M!}\Bigg[{}_2F_1(M+\tfrac{1}{2},1;M+1;-w)$$
$$+\frac{1}{M-1/2}{}_2F_1(M-\tfrac{1}{2},1;M+1;-w)\Bigg]_{w=(q_2-q_S)/(2q_S)}$$
$$\times\frac{1}{M-1/2-(q_2-q_S)\rho}\left(\frac{q_2-q_S}{2q_S}\right)^{M+1/2}, \quad |(q_2-q_S)\rho|\gg 1. \tag{3.36b}$$

M is any positive integer. In the above, the hypergeometric functions reduce to elementary functions. For instance, by setting $M=1$ in the second line,

$$ {}_2F_1(\tfrac{1}{2},1;2;z)=\frac{2}{1+\sqrt{1-z}}. $$

On the other hand, by virtue of formula (3.23),

$$ R_{2M}(\rho)\sim(-1)^M\frac{(\frac{1}{2})_{M-1}}{M!}\left(\frac{q_2-q_S}{2q_S}\right)^{M+1/2}\int_0^1 d\eta\,\frac{M+1/2}{1+\dfrac{q_2-q_S}{2q_S}\,\eta}\,e^{(M-1/2)\ln\,\eta+(q_2-q_S)\rho(1-\eta)} $$

$$ \sim\frac{2q_S}{q_2+q_S}(-1)^M\frac{(\frac{1}{2})_M}{M!}\,\frac{M+1/2}{M-1/2}\,\frac{1}{M-1/2-(q_2-q_S)\rho}\left(\frac{q_2-q_S}{2q_S}\right)^{M+1/2},\quad M\gg 1. \tag{3.37} $$

When $|q_2\rho|\gg 1$, the corresponding sum needs to be combined with the asymptotic expansion for the modified Hankel function of Eq. (3.16), as discussed in Appendix B. In some analogy with expressions (3.25) and (3.26),

$$ V_m(\rho)\sim\frac{(-1)^m}{m-1/2-(q_2-q_S)\rho}\,\frac{(\frac{1}{2})_m}{m!}\,\frac{m+1/2}{m-1/2}\left(\frac{q_2-q_S}{2q_S}\right)^{m+1/2}, \tag{3.38} $$

which in turn leads to

$$ \frac{V_{m+1}(\rho)}{V_m(\rho)}\sim-\frac{m-\frac{1}{2}}{m+\frac{1}{2}}\,\frac{m+\frac{3}{2}}{m+1}\,\frac{m-\frac{1}{2}-(q_2-q_S)\rho}{m+\frac{1}{2}-(q_2-q_S)\rho}\,\frac{q_2-q_S}{2q_S},\quad |m-(q_2-q_S)\rho|\gg 1, \tag{3.39} $$

provided that m is a positive integer.

The aforementioned considerations indicate some rather attractive convergence properties of the series expansions when $|q_2^2|\ll|q_1^2|$. Their termwise differentiation with respect to ρ is legitimate and preserves the uniform-in-ρ convergence. The series from Eq. (3.31b) is

$$ W(\rho;q_2,q_S,q_S)=e^{i\pi/4}\frac{q_S e^{-q_2\rho}}{\sqrt{2q_S\rho}}\sum_{m=0}^{\infty}\,i^{m+1}\frac{(\frac{1}{2})_m}{m!}\,\frac{m+1/2}{m-1/2}(2q_S\rho)^{-m}f_m(i(q_2-q_S)\rho). \tag{3.40} $$

The generating function for $f_m(z)$ is

$$ \sum_{m=0}^{\infty}\frac{f_m(z)}{m!}(ix)^m=\sqrt{2\pi}e^{-iz}(1+x)^{-1/2}F_0((1+x)z), \tag{3.41} $$

where

$$ F_0(z)=\int_0^z dt\,\frac{e^{it}}{\sqrt{2\pi t}}=C(z)+iS(z), \tag{3.42} $$

and $C(z)$ and $S(z)$ are the Fresnel integrals,[28]

$$ C(z)=\int_0^z dx\,\frac{\cos x}{\sqrt{2\pi x}},\quad S(z)=\int_0^z dx\,\frac{\sin x}{\sqrt{2\pi x}}. \tag{3.43} $$

Hence,

$$f_m(z)=\sqrt{2\pi}(-i)^m e^{-iz} z^{1/2+m}\frac{d^m}{dz^m}[z^{-1/2}F_0(z)]. \tag{3.44}$$

3. Exact formula for $E_{2\phi}$

The combination of Eqs. (3.15), (3.16), (3.27), and (3.40), with Eqs. (3.19) and (3.32), furnishes the desired expression for $W(\rho)$, viz.,

$$W(\rho)=q_S K_1(q_S\rho)+q_S e^{-q_2\rho}\sum_{m=0}^{\infty} V_m(\rho)-\frac{e^{-q_1\rho}}{\rho}\sum_{m=0}^{\infty} U_m(\rho). \tag{3.45}$$

From Eq. (3.13),

$$\mathcal{W}(\rho)=-i\frac{k_1-k_2}{k_S^2\rho}+i\frac{k_1 e^{ik_2\rho}-k_2 e^{ik_1\rho}}{k_S^2\rho}+\frac{\pi}{2}H_1^{(1)}(k_S\rho)-e^{ik_2\rho}\sum_{m=0}^{\infty} V_m(\rho)-\frac{e^{ik_1\rho}}{ik_S\rho}\sum_{m=0}^{\infty} U_m(\rho), \tag{3.46}$$

where

$$U_m(\rho)=\begin{cases} 1, & m=0,\\ \dfrac{(\frac{1}{2})_m}{m!(2m-1)!}(-k_S^2\rho^2)^m\dfrac{d^{2m-1}}{dz^{2m-1}}[e^z\ \mathrm{Ei}(-z)]_{z=-ik_1\rho}, & m=1,2,\ldots, \end{cases} \tag{3.47}$$

$$V_m(\rho)=\sqrt{2\pi}i^m\frac{(\frac{1}{2})_m}{m!}\frac{m+1/2}{m-1/2}\left(\frac{k_2-k_S}{2k_S}\right)^{m+1/2}\left\{e^{-iz}\frac{d^m}{dz^m}[z^{-1/2}F_0(z)]\right\}_{z=(k_2-k_S)\rho}. \tag{3.48}$$

The substitution of Eqs. (3.8) and (3.46) into (3.7) gives

$$\begin{aligned} E_{2\phi}=-\frac{i\omega\mu_0}{2\pi}\frac{k_2^2}{k_1^4-k_2^4}\Bigg\{ & -ie^{ik_1\rho}k_1\left[\frac{k_1^2+k_2^2(2-k_S/k_2)}{k_2^2\rho^2}+i\frac{k_1^2+2k_2^2}{k_1k_2^2\rho^3}\right]\\ & +ie^{ik_2\rho}\frac{2k_1^2+k_2^2}{k_2\rho^2}\left(1+\frac{i}{k_2\rho}\right)-i\frac{k_1k_S^2}{k_2\rho}\Bigg[\frac{i\pi}{2}H_1^{(1)}(k_S\rho)-ie^{ik_2\rho}\sum_{m=0}^{\infty} V_m(\rho)\\ & -\frac{e^{ik_1\rho}}{k_S\rho}\sum_{m=0}^{\infty} U_{m+1}(\rho)\Bigg]\Bigg\}\sin\phi. \end{aligned} \tag{3.49}$$

Note that when $k_2^2\ll|k_1^2|$, the argument of each Fresnel integral becomes

$$(k_2-k_S)\rho=k_2\left[1-\left(1+\frac{k_2^2}{k_1^2}\right)^{-1/2}\right]\rho\sim\frac{k_2^3\rho}{2k_1^2}=\wp, \tag{3.50}$$

where $|(k_2-k_S)\rho|$ is the Sommerfeld ''numerical distance.''[29]

For $k_2\rho\gg 1$, the Hankel function in Eq. (3.49) is approximated by an expansion with the phase factor $e^{ik_S\rho}$. This expansion exactly cancels terms produced by the Fresnel integrals, so that the final expression describes only waves traveling with the phase velocity of medium 1 or 2 (terms $\propto e^{ik_j\rho}$, $j=1,2$), as shown in Appendix B.

C. The ρ-component of the electric field

The integral for $E_{2\rho}$ is evaluated via the interchange of $1/\rho$ and the operator $(d/d\rho)$ in Eq. (3.7). The series that result through the term-by-term differentiation of expansions (3.27) and (3.40) also exhibit rapid convergence for $k_2^2 \ll |k_1^2|$, with a rate which is essentially independent of the distance ρ. Without further ado,

$$E_{2\rho}=\frac{i\omega\mu_0}{2\pi}\frac{k_2^2}{k_1^4-k_2^4}\left\{e^{ik_1\rho}\left(\frac{k_1^2-k_2^2}{k_2^2\rho^3}-ik_1\frac{k_1^2-k_2^2}{k_2^2\rho^2}+\frac{k_1^2}{\rho}\right)\right.$$
$$\left.+e^{ik_2\rho}\left(\frac{k_1^2-k_2^2}{k_2^2\rho^3}-i\frac{k_1^2-k_2^2}{k_2\rho^2}-\frac{k_1^2}{\rho}\right)-i\frac{k_1}{k_2}k_S W'(\rho)\right\}\cos\phi, \tag{3.51a}$$

$$=\frac{i\omega\mu_0}{2\pi}\frac{k_2^2}{k_1^4-k_2^4}\left\{e^{ik_1\rho}\left(\frac{k_1^2-k_2^2}{k_2^2\rho^3}-ik_1\frac{k_1^2-k_2^2}{k_2^2\rho^2}+\frac{k_1^2}{\rho}\right)\right.$$
$$+e^{ik_2\rho}\left(\frac{k_1^2-k_2^2}{k_2^2\rho^3}-i\frac{k_1^2-k_2^2}{k_2\rho^2}-\frac{k_1^2}{\rho}\right)+\frac{\pi}{2}\frac{k_1}{k_2}k_S^3 H_1^{(1)'}(k_S\rho)$$
$$\left.-\frac{k_1}{k_2}k_S^2\frac{d}{d\rho}\left[\frac{e^{ik_1\rho}}{ik_S\rho}\sum_{m=0}^{\infty}U_m(\rho)+e^{ik_2\rho}\sum_{m=0}^{\infty}V_m(\rho)\right]\right\}\cos\phi, \tag{3.51b}$$

where $W(\rho)$ is defined by Eq. (3.14) and the prime here denotes differentiation with respect to the argument.

It is desirable to further manipulate this formula. Decomposition (3.15) entails

$$W'(\rho)=ik_S^2\frac{\pi}{2}H_1^{(1)'}(k_S\rho)+\tilde{W}(\rho;\infty,-ik_1,-ik_S)+\tilde{W}(\rho;-ik_2,-ik_S,-ik_S), \tag{3.52a}$$

where

$$\tilde{W}(\rho;\xi_1,\xi_2,\xi_3)=\int_{\xi_2}^{\xi_1}d\nu\frac{\nu^2}{\sqrt{\nu^2-\xi_3^2}}e^{-\nu\rho},\quad \xi_3\leqslant\xi_2<\xi_1. \tag{3.52b}$$

1. Integral $\tilde{W}(\rho;\infty,q_1,q_S)$

With the steps of Sec. III B and for $M=1,2,\ldots,$

$$\tilde{W}(\rho;\infty,q_1,q_S)=\frac{e^{-q_1\rho}}{\rho^2}(1+q_1\rho)-q_S^2e^{-q_1\rho}\left[\sum_{m=0}^{M-1}\tilde{U}_m(\rho)+\tilde{R}_{1M}(\rho)\right], \tag{3.53}$$

where

$$\tilde{U}_m(\rho)=-\frac{(\frac{1}{2})_{m+1}}{(m+1)!}(q_S\rho)^{2m}g_{2m+1}(q_1\rho),\quad m=0,1,2,\ldots, \tag{3.54}$$

with $g_n(z)$ defined by Eq. (3.20), and

$$\tilde{R}_{1M}(\rho)=-\frac{(\frac{1}{2})_{M+1}}{M!}\left(\frac{q_S}{q_1}\right)^{2M}\int_1^{\infty}d\eta\,\eta^{-2M-1}e^{-q_1\rho(\eta-1)}$$
$$\times\int_0^1 dt(1-t)^M(1-q_S^2q_1^{-2}\eta^{-2}t)^{-M-3/2}. \tag{3.55}$$

It is easily verified that

$$|\tilde{R}_{1M}(\rho)|<(1-|k_S^2|/|k_1^2|)^{-3/2}\frac{(\frac{1}{2})_{M+1}}{(M+1)!}\left|\frac{k_S^2}{k_1^2}\right|^M, \quad M=1,2,\ldots, \tag{3.56a}$$

$$\tilde{R}_{1M}(\rho)\sim-\frac{(\frac{1}{2})_{M+1}}{(M+1)!}{}_2F_1(M+\tfrac{3}{2},1;M+2;k_S^2/k_1^2)\frac{1}{2M+1-ik_1\rho}\left(\frac{k_S^2}{k_1^2}\right)^M, \quad |k_1\rho|\gg 1, \tag{3.56b}$$

$$\tilde{R}_{1M}(\rho)\sim-(1-k_S^2/k_1^2)^{-1}\frac{(\frac{1}{2})_{M+1}}{(M+1)!}\frac{1}{2M+1-ik_1\rho}\left(\frac{k_S^2}{k_1^2}\right)^M, \quad M\gg 1, \tag{3.56c}$$

while, for $|2m+1-ik_1\rho|\gg 1$,

$$\tilde{U}_m(\rho)\sim-\frac{(\frac{1}{2})_{m+1}}{(m+1)!}\frac{1}{2m+1-ik_1\rho}\left(\frac{k_S^2}{k_1^2}\right)^m, \tag{3.57a}$$

$$\frac{\tilde{U}_{m+1}(\rho)}{\tilde{U}_m(\rho)}\sim\frac{m+3/2}{m+2}\frac{2m+1-ik_1\rho}{2m+3-ik_1\rho}\frac{k_S^2}{k_1^2}. \tag{3.57b}$$

2. Integral $\tilde{W}(\rho;q_2,q_S,q_S)$

Likewise,

$$\tilde{W}(\rho;q_2,q_S,q_S)=q_S^2e^{-q_2\rho}\left[\sum_{m=0}^{M-1}\tilde{V}_m(\rho)+\tilde{R}_{2M}(\rho)\right], \tag{3.58}$$

where, for $m=0,1,2,\ldots,$

$$\tilde{V}_m(\rho)=-e^{i\pi/4}i^{m+1}\frac{(\frac{1}{2})_m}{m!}\frac{m^2+3/4}{(m-1/2)(m-3/2)}(2q_S\rho)^{-m-1/2}f_m(i(q_2-q_S)\rho), \tag{3.59}$$

with $f_m(z)$ defined by Eq. (3.44), and

$$\begin{aligned}\tilde{R}_{2M}(\rho)=(-1)^M&\frac{(\frac{1}{2})_{M-1}}{(M-1)!}\frac{1}{M-3/2}\left(\frac{q_2-q_S}{2q_S}\right)^{M+1/2}\int_0^1 d\eta\,\eta^{M-1/2}e^{(q_2-q_S)\rho(1-\eta)}\\&\times\int_0^1 dt(1-t)^{M-1}\left[M^2+\frac{3}{4}+\left(2M+3+3\frac{q_2-q_S}{2q_S}\eta t\right)\frac{q_2-q_S}{2q_S}\eta t\right]\\&\times\left(1+\frac{q_2-q_S}{2q_S}\eta t\right)^{-M-1/2}.\end{aligned} \tag{3.60}$$

It is of interest to note the relations

$$|\tilde{R}_{2M}(\rho)|<\frac{(\frac{1}{2})_M}{M!}\frac{M^2+M+3}{|M-3/2|(M^2-1/4)}\left|\frac{k_2-k_S}{2k_S}\right|^{M+1/2}, \quad M=1,2,\ldots, \tag{3.61a}$$

$$\tilde{R}_{2M}(\rho)\sim(-1)^M\frac{(\frac{1}{2})_M}{M!}\Bigg[{}_2F_1(M+\tfrac{1}{2},1;M+1;-w)+\frac{2}{M-1/2}\,{}_2F_1(M-\tfrac{1}{2},1;M+1;-w)$$
$$+\frac{3}{(M-1/2)(M-3/2)}\,{}_2F_1(M-\tfrac{3}{2},1;M+1;-w)\Bigg]_{w=(k_2-k_S)/(2k_S)}$$
$$\times\frac{1}{M-1/2+i(k_2-k_S)\rho}\left(\frac{k_2-k_S}{2k_S}\right)^{M+1/2},\quad |(k_2-k_S)\rho|\gg 1, \tag{3.61b}$$

$$\tilde{R}_{2M}(\rho)\sim\frac{2k_S}{k_2+k_S}(-1)^M\frac{(\frac{1}{2})_M}{M!}\,\frac{M^2+3/4}{(M-1/2)(M-3/2)}\,\frac{1}{M-1/2+i(k_2-k_S)\rho}$$
$$\times\left(\frac{k_2-k_S}{2k_S}\right)^{M+1/2},\quad M\gg 1. \tag{3.61c}$$

Again, the hypergeometric functions here are calculable in terms of elementary functions. For $m\gg 1$ and $|m+i(k_2-k_S)\rho|\gg 1$,

$$\tilde{V}_m(\rho)\sim(-1)^m\frac{(\frac{1}{2})_m}{m!}\,\frac{m^2+3/4}{(m-1/2)(m-3/2)}\,\frac{1}{m-1/2+i(k_2-k_S)\rho}\left(\frac{k_2-k_S}{2k_S}\right)^{m+1/2}, \tag{3.62a}$$

$$\frac{\tilde{V}_{m+1}(\rho)}{\tilde{V}_m(\rho)}\sim-\frac{m+1/2}{m+1}\,\frac{m-3/2}{m+1/2}\,\frac{(m+1)^2+3/4}{m^2+3/4}\,\frac{m-1/2+i(k_2-k_S)\rho}{m+1/2+i(k_2-k_S)\rho}\,\frac{k_2-k_S}{2k_S}. \tag{3.62b}$$

3. Exact formula for $E_{2\rho}$

It follows that in the limit $M\to\infty$ all series converge uniformly in ρ. $W'(\rho)$ from Eq. (3.52) reads as

$$W'(\rho)=e^{ik_1\rho}\left(\frac{1}{\rho^2}-\frac{ik_1}{\rho}\right)+k_S^2\left[\frac{i\pi}{2}H_1^{(1)'}(k_S\rho)-e^{ik_2\rho}\sum_{m=0}^{\infty}\tilde{V}_m(\rho)+e^{ik_1\rho}\sum_{m=0}^{\infty}\tilde{U}_m(\rho)\right]. \tag{3.63}$$

Finally, substituting $W'(\rho)$ in Eq. (3.51a) yields

$$E_{2\rho}=\frac{i\omega\mu_0}{2\pi}\,\frac{k_2^2}{k_1^4-k_2^4}\Bigg\{e^{ik_1\rho}\left[\frac{k_1^2-k_2^2}{k_2^2\rho^3}-ik_1\frac{k_1^2-k_2^2(1-k_S/k_2)}{k_2^2\rho^2}+\frac{k_1^2(1-k_S/k_2)}{\rho}\right]$$
$$+e^{ik_2\rho}\left(\frac{k_1^2-k_2^2}{k_2^2\rho^3}-i\,\frac{k_1^2-k_2^2}{k_2\rho^2}-\frac{k_1^2}{\rho}\right)$$
$$-i\,\frac{k_1}{k_2}k_S^3\left[\frac{i\pi}{2}H_1^{(1)'}(k_S\rho)-e^{ik_2\rho}\sum_{m=0}^{\infty}\tilde{V}_m(\rho)+e^{ik_1\rho}\sum_{m=0}^{\infty}\tilde{U}_m(\rho)\right]\Bigg\}\cos\phi, \tag{3.64}$$

where $\tilde{U}_m(\rho)$ and $\tilde{V}_m(\rho)$ are given by Eqs. (3.54) and (3.59). An asymptotic formula for $k_2\rho\gg 1$ can be derived along the lines of Appendix B.

IV. EXACT $B_{2\phi}$ AND E_{2z} OF VERTICAL ELECTRIC DIPOLE

A. Magnetic field

In consideration of Eq. (3.1) with $q_S=-ik_S$ and the decomposition,

$$\frac{1}{q_1^2\sqrt{\lambda^2+q_2^2}+q_2^2\sqrt{\lambda^2+q_1^2}}=\frac{q_1q_2}{q_1^4-q_2^4}\left[\frac{q_1}{q_2}\frac{\sqrt{\lambda^2+q_2^2}}{\lambda^2+q_S^2}-\frac{q_2}{q_1}\frac{\sqrt{\lambda^2+q_1^2}}{\lambda^2+q_S^2}\right], \tag{4.1}$$

Eq. (2.10) becomes

$$B_{2\phi}=-\frac{\mu_0}{2\pi}\frac{q_1^3q_2}{q_1^4-q_2^4}\int_0^\infty d\lambda\lambda^2\left[\frac{q_2}{q_1}\frac{\sqrt{\lambda^2+q_1^2}}{\lambda^2+q_S^2}-\frac{q_1}{q_2}\frac{\sqrt{\lambda^2+q_2^2}}{\lambda^2+q_S^2}\right]J_1(\lambda\rho). \tag{4.2}$$

From Eq. (3.10), one gets

$$B_{2\phi}=-\frac{\mu_0}{2\pi}\frac{q_1^3q_2}{q_1^4-q_2^4}\int_{q_2/q_S}^{q_1/q_S}d[(x^2-1)^{-1/2}]\int_0^\infty d\lambda\lambda^2\frac{J_1(\lambda\rho)}{\sqrt{\lambda^2+q_S^2x^2}}, \tag{4.3}$$

where

$$\int_0^\infty d\lambda\lambda^2\frac{J_1(\lambda\rho)}{\sqrt{\lambda^2+q_S^2x^2}}=\sqrt{\frac{2}{\pi\rho}}(q_Sx)^{3/2}K_{3/2}(q_S\rho x)=\frac{1}{\rho^2}(1+q_S\rho x)e^{-q_S\rho x}, \tag{4.4}$$

via the analytic continuation to $\nu=1$ of the right-hand side of the formula[24]

$$\int_0^\infty dx\frac{x^{\nu+1}J_\nu(ax)}{\sqrt{x^2+k^2}}=\frac{a^{-1/2}k^{\nu+1/2}}{2^{-1/2}\sqrt{\pi}}K_{\nu+1/2}(ka).$$

Alternatively,

$$B_{2\phi}=-\frac{\mu_0}{2\pi}\frac{q_1^3q_2}{q_1^4-q_2^4}\left\{\frac{1}{\rho^2}\left[\frac{q_2}{q_1}\mathcal{I}_e(q_1\rho)-\frac{q_1}{q_2}\mathcal{I}_e(q_2\rho)\right]-q_S^2\mathcal{W}(\rho)\right\}, \tag{4.5}$$

where $\mathcal{I}_e(\alpha)$ is given by Eq. (3.8) and $\mathcal{W}(\rho)$ is defined by Eq. (3.9). $B_{2\phi}$ can be expressed in terms of incomplete cylindrical functions.[27]

With the $W(\rho)$ introduced in Eq. (3.13), the exact $B_{2\phi}$ from Eq. (4.3) reads as

$$\begin{aligned}B_{2\phi}&=-\frac{\mu_0}{2\pi}\frac{q_1^3q_2}{q_1^4-q_2^4}\left\{\frac{1}{\rho^2}\left[e^{-q_1\rho}\frac{q_2}{q_1}(1+q_1\rho)-e^{-q_2\rho}\frac{q_1}{q_2}(1+q_2\rho)\right]+q_SW(\rho)\right\}\\&=-\frac{\mu_0}{2\pi}\frac{k_1^3k_2}{k_1^4-k_2^4}\left\{e^{ik_1\rho}\frac{k_2}{k_1}\left[-\frac{ik_1(1-k_S/k_2)}{\rho}+\frac{1}{\rho^2}\right]-e^{ik_2\rho}\frac{k_1}{k_2}\left(-\frac{ik_2}{\rho}+\frac{1}{\rho^2}\right)\right.\\&\quad\left.-ik_S^2\left[\frac{i\pi}{2}H_1^{(1)}(k_S\rho)-ie^{ik_2\rho}\sum_{m=0}^\infty V_m(\rho)-\frac{e^{ik_1\rho}}{k_S\rho}\sum_{m=0}^\infty U_{m+1}(\rho)\right]\right\}.\end{aligned} \tag{4.6}$$

U_m and V_m $(m=0,1,2,\ldots)$ are given by Eqs. (3.47) and (3.48). For obtaining an asymptotic formula for $B_{2\phi}$ when $k_2\rho\gg1$, one may follow the steps of Appendix B.

B. The *z*-component of the electric field

By use of Eqs. (4.1) and (3.10), Eq. (2.11) becomes

$$E_{2z}=\frac{i\omega\mu_0 q_1^3}{2\pi q_2}\frac{1}{q_1^4-q_2^4}\int_{q_2/q_S}^{q_1/q_S} d[(x^2-1)^{-1/2}]$$
$$\times\left[\int_0^\infty d\lambda\lambda\sqrt{\lambda^2+q_S^2x^2}J_0(\lambda\rho)-q_S^2x^2\int_0^\infty d\lambda\frac{\lambda J_0(\lambda\rho)}{\sqrt{\lambda^2+q_S^2x^2}}\right]. \tag{4.7}$$

After some straightforward algebra,[24]

$$E_{2z}=-\frac{i\omega\mu_0 k_1^3}{2\pi k_2}\frac{1}{k_1^4-k_2^4}\left\{e^{ik_1\rho}k_2\left[\frac{k_1(1-k_S^2/k_2^2)}{\rho}+\frac{i}{\rho^2}-\frac{1}{k_1\rho^3}\right]\right.$$
$$\left.-e^{ik_2\rho}k_1\left[\frac{k_2(1-k_S^2/k_1^2)}{\rho}+\frac{i}{\rho^2}-\frac{1}{k_2\rho^3}\right]-ik_S^3\check{W}(\rho)\right\}, \tag{4.8}$$

where

$$\check{W}(\rho)=\check{W}(\rho;-ik_1,-ik_2,-ik_S),\quad \check{W}(\rho;\xi_1,\xi_2,\xi_3)=\int_{\xi_2}^{\xi_1}\frac{d\upsilon}{\sqrt{\upsilon^2-\xi_3^2}}e^{-\upsilon\rho},\quad \xi_3\leqslant\xi_2<\xi_1. \tag{4.9}$$

Similar to Eq. (3.15),

$$\check{W}(\rho;q_1,q_2,q_S)=\check{W}(\rho;\infty,q_S,q_S)-\check{W}(\rho;\infty,q_1,q_S)-\check{W}(\rho;q_2,q_S,q_S), \tag{4.10}$$

the first term of which is calculated as[25]

$$\check{W}(\rho;\infty,q_S,q_S)=\int_0^\infty dt e^{-q_S\rho\cosh t}=K_0(q_S\rho). \tag{4.11}$$

1. Integral $\check{W}(\rho;\infty,q_1,q_S)$

On the basis of a term-by-term integration of Eq. (3.17),

$$\check{W}(\rho;\infty,q_1,q_S)=e^{-q_1\rho}\left[\sum_{m=0}^{M-1}\check{U}_m(\rho)+\check{R}_{1M}(\rho)\right],\quad M=1,2,\ldots, \tag{4.12}$$

where

$$\check{U}_m(\rho)=\frac{(\frac{1}{2})_m}{m!}(q_S\rho)^{2m}g_{2m+1}(q_1\rho)=-\frac{(\frac{1}{2})_m}{m!(2m)!}(-k_S^2\rho^2)^m\frac{d^{2m}}{dz^{2m}}[e^z\,\mathrm{Ei}(-z)]_{z=-ik_1\rho}, \tag{4.13}$$

$$\check{R}_{1M}(\rho)=\frac{(\frac{1}{2})_M}{(M-1)!}\left(\frac{q_S}{q_1}\right)^{2M}\int_1^\infty d\eta\,\eta^{-2M-1}e^{-q_1\rho(\eta-1)}$$
$$\times\int_0^1 dt(1-t)^{M-1}(1-q_S^2q_1^{-2}\eta^{-2}t)^{-M-1/2}$$
$$=\frac{(\frac{1}{2})_M}{M!}\left(\frac{q_S}{q_1}\right)^{2M}\int_1^\infty d\eta\,\eta^{-2M-1}{}_2F_1(M+\tfrac{1}{2},1;M+1;q_S^2q_1^{-2}\eta^{-2})e^{-q_1\rho(\eta-1)}. \tag{4.14}$$

Appealing properties of the series expansion ensue from the relations

$$|\check{R}_{1M}(\rho)|<\frac{1}{2}(1-|k_S^2|/|k_1^2|)^{-3/2}\frac{(\frac{1}{2})_M}{M!}\left|\frac{k_S^2}{k_1^2}\right|^M, \quad M=1,2,\ldots, \tag{4.15a}$$

$$\check{R}_{1M}(\rho)\sim\frac{(\frac{1}{2})_M}{M!}{}_2F_1(M+\tfrac{1}{2},1;M+1;k_S^2/k_1^2)\,\frac{1}{2M+1-ik_1\rho}\left(\frac{k_S^2}{k_1^2}\right)^M, \quad |k_1\rho|\gg 1, \tag{4.15b}$$

$$\check{R}_{1M}(\rho)\sim(1-k_S^2/k_1^2)^{-1}\frac{(\frac{1}{2})_M}{M!}\,\frac{1}{2M+1-ik_1\rho}\left(\frac{k_S^2}{k_1^2}\right)^M, \quad M\gg 1, \tag{4.15c}$$

and, with $|2m+1-ik_1\rho|\gg 1$,

$$\check{U}_m(\rho)\sim\frac{(\frac{1}{2})_m}{m!}\,\frac{1}{2m+1-ik_1\rho}\left(\frac{k_S^2}{k_1^2}\right)^m, \tag{4.16a}$$

$$\frac{\check{U}_{m+1}(\rho)}{\check{U}_m(\rho)}\sim\frac{m+1/2}{m+1}\,\frac{2m+1-ik_1\rho}{2m+3-ik_1\rho}\,\frac{k_S^2}{k_1^2}. \tag{4.16b}$$

As $M\to\infty$, the remainder $\check{R}_{1M}(\rho)$ approaches zero while being bounded uniformly in distance. The rate of convergence of the exact series is independent of ρ.

2. Integral $\check{W}(\rho;q_2,q_S,q_S)$

By use of Eq. (3.17),

$$\check{W}(\rho;q_2,q_S,q_S)=e^{-q_2\rho}\left[\sum_{m=0}^{M-1}\check{V}_m(\rho)+\check{R}_{2M}(\rho)\right], \tag{4.17}$$

where

$$\begin{aligned}\check{V}_m(\rho)&=-e^{i\pi/4}i^{m+1}\frac{(\frac{1}{2})_m}{m!}(2q_S\rho)^{-m-1/2}f_m(i(q_2-q_S)\rho)\\&=\sqrt{2\pi}i^m\frac{(\frac{1}{2})_m}{m!}\left(\frac{k_2-k_S}{2k_S}\right)^{m+1/2}\left\{e^{-iz}\frac{d^m}{dz^m}[z^{-1/2}F_0(z)]\right\}_{z=(k_2-k_S)\rho},\end{aligned} \tag{4.18}$$

$$\begin{aligned}\check{R}_{2M}(\rho)&=(-1)^M\frac{(\frac{1}{2})_M}{(M-1)!}\left(\frac{q_2-q_S}{2q_S}\right)^{M+1/2}\int_0^1 d\eta\,\eta^{M-1/2}e^{(q_2-q_S)\rho(1-\eta)}\\&\quad\times\int_0^1 dt(1-t)^{M-1}\left(1+\frac{q_2-q_S}{2q_S}\,\eta t\right)^{-M-1/2}\\&=(-1)^M\frac{(\frac{1}{2})_M}{M!}\left(\frac{q_2-q_S}{2q_S}\right)^{M+1/2}\\&\quad\times\int_1^\infty d\eta\,\eta^{M-1/2}{}_2F_1\left(M+\tfrac{1}{2},1;M+1;-\frac{q_2-q_S}{2q_S}\,\eta\right)e^{(q_2-q_S)\rho(1-\eta)}.\end{aligned} \tag{4.19}$$

$F_0(z)$ is defined by Eq. (3.42).

In analogy with expressions (4.15) and (4.16),

$$|\check{R}_{2M}(\rho)|<\frac{(\frac{1}{2})_M}{M!}\frac{1}{M+1/2}\left|\frac{k_2-k_S}{2k_S}\right|^{M+1/2}, \quad M=1,2,\ldots, \tag{4.20a}$$

$$\check{R}_{2M}(\rho)\sim(-1)^M\frac{(\frac{1}{2})_M}{M!}{}_2F_1\left(M+\tfrac{1}{2},1;M+1;-\frac{k_2-k_S}{2k_S}\right)$$
$$\times\frac{1}{M-1/2+i(k_2-k_S)\rho}\left(\frac{k_2-k_S}{2k_S}\right)^{M+1/2}, \quad |(k_2-k_S)\rho|\gg 1, \tag{4.20b}$$

$$\check{R}_{2M}(\rho)\sim\frac{2k_S}{k_2+k_S}(-1)^M\frac{(\frac{1}{2})_M}{M!}\frac{1}{M-1/2+i(k_2-k_S)\rho}\left(\frac{k_2-k_S}{2k_S}\right)^{M+1/2}, \quad M\gg 1, \tag{4.20c}$$

while for $|m+i(k_2-k_S)\rho|\gg 1$ and $m=1,2,\ldots,$

$$\check{V}_m(\rho)\sim(-1)^m\frac{(\frac{1}{2})_m}{m!}\frac{1}{m-1/2+i(k_2-k_S)\rho}\left(\frac{k_2-k_S}{2k_S}\right)^{m+1/2}, \tag{4.21a}$$

$$\frac{\check{V}_{m+1}(\rho)}{\check{V}_m(\rho)}\sim-\frac{m+1/2}{m+1}\frac{m-1/2+i(k_2-k_S)\rho}{m+1/2+i(k_2-k_S)\rho}\frac{k_2-k_S}{2k_S}. \tag{4.21b}$$

3. Exact formula for E_{2z}

By virtue of Eqs. (4.8)–(4.10),

$$E_{2z}=-\frac{i\omega\mu_0k_1^3}{2\pi k_2}\frac{1}{k_1^4-k_2^4}\left\{e^{ik_1\rho}k_2\left[\frac{k_1(1-k_S^2/k_2^2)}{\rho}+\frac{i}{\rho^2}-\frac{1}{k_1\rho^3}\right]\right.$$
$$-e^{ik_2\rho}k_1\left[\frac{k_2(1-k_S^2/k_1^2)}{\rho}+\frac{i}{\rho^2}-\frac{1}{k_2\rho^3}\right]$$
$$\left.-ik_S^3\left[\frac{i\pi}{2}H_0^{(1)}(k_S\rho)-e^{ik_2\rho}\sum_{m=0}^{\infty}\check{V}_m(\rho)-e^{ik_1\rho}\sum_{m=0}^{\infty}\check{U}_m(\rho)\right]\right\}. \tag{4.22}$$

$\check{U}_m(\rho)$ and $\check{V}_m(\rho)$ are defined by Eqs. (4.13) and (4.18).

V. SIMPLIFIED FORMULAS FOR $k_2\ll|k_1|$

The exact results of Secs. III and IV are simplified considerably under the condition

$$k_2\ll|k_1|, \tag{5.1}$$

which holds in many cases of practical interest. In this section, connection formulas for the approximations of Appendix C are recovered to the leading order in k_2/k_1.

A. Horizontal electric dipole

1. The z-component of the magnetic field

Equation (3.5) for B_{2z} becomes

$$B_{2z}\sim\frac{\mu_0}{2\pi k_1^2}\left[e^{ik_2\rho}\left(\frac{k_2^2}{\rho^2}+\frac{3ik_2}{\rho^3}-\frac{3}{\rho^4}\right)-e^{ik_1\rho}\left(\frac{k_1^2}{\rho^2}+\frac{3ik_1}{\rho^3}-\frac{3}{\rho^4}\right)\right]\sin\phi, \tag{5.2}$$

which is identical to the result given in Ref. 17 and agrees with formulas (C4), (C20), and (C21) of Appendix C. Note that condition (5.1) is redundant for establishing a smooth connection to formula (C4).

2. Tangential electric field

With

$$U_1(\rho)=-\frac{k_S^2\rho^2}{2}\left[e^{-ik_1\rho}\,\mathrm{Ei}(ik_1\rho)-\frac{1}{ik_1\rho}\right], \tag{5.3}$$

$$V_0(\rho)=-e^{i\pi/4}e^{-i(k_2-k_S)\rho}\sqrt{\frac{\pi}{2k_S\rho}}+\sqrt{\frac{\pi}{k_S\rho}}F((k_2-k_S)\rho), \tag{5.4}$$

$E_{2\phi}$ of Eq. (3.49) becomes

$$\begin{aligned}E_{2\phi}\sim-\frac{i\omega\mu_0}{2\pi k_1^2}\Bigg\{&e^{ik_2\rho}k_2\left[\frac{2i}{\rho^2}\left(1+\frac{k_2^2}{2k_1^2}\right)-\frac{2}{k_2\rho^3}\left(1+\frac{k_2^2}{2k_1^2}\right)-\frac{k_S^2}{k_1\rho}\sqrt{\frac{\pi}{k_S\rho}}F((k_2-k_S)\rho)\right.\\&+\frac{\pi k_S^2}{2k_1\rho}e^{-i(k_2-k_S)\rho}\left(e^{-ik_S\rho}H_1^{(1)}(k_S\rho)+e^{i\pi/4}\sqrt{\frac{2}{\pi k_S\rho}}\right)\Bigg]-e^{ik_1\rho}k_1\Bigg[\frac{i}{\rho^2}\left(1+\frac{k_2^2}{k_1^2}\right)\\&\left.-\frac{1}{k_1\rho^3}\left(1+\frac{2k_2^2}{k_1^2}\right)+\frac{ik_2^4}{2k_1^2}\left(e^{-ik_1\rho}\,\mathrm{Ei}(ik_1\rho)-\frac{1}{ik_1\rho}\right)\Bigg]\Bigg\}\sin\phi.\end{aligned} \tag{5.5}$$

A close inspection of the terms inside the parentheses containing the exponential integral Ei shows that these contribute to higher orders in k_2^2/k_1^2. On the other hand, the Hankel function and its accompanying term are negligible for $k_2\rho\leqslant O(1)$ under condition (5.1), while they are cancelled by the V_m's when $k_2\rho\gg 1$, as outlined in Appendix B. A moment's reflection leads to the uniform formula

$$E_{2\phi}\sim-\frac{i\omega\mu_0}{2\pi k_1^2}\left\{e^{ik_2\rho}\left[\frac{2ik_2}{\rho^2}-\frac{2}{\rho^3}-\frac{k_S^2k_2}{k_1\rho}\sqrt{\frac{\pi}{k_S\rho}}F((k_2-k_S)\rho)\right]-e^{ik_1\rho}\left(\frac{ik_1}{\rho^2}-\frac{1}{\rho^3}\right)\right\}\sin\phi, \tag{5.6}$$

valid for all distances that are consistent with the planar-earth model. This formula yields approximation (C6) as well as (C24) and (C25) of Appendix C when $k_2\rho\ll 1$ and $k_2\rho\gg 1$, respectively.

Similar steps can be taken for $E_{2\rho}$ of Eq. (3.64), to obtain

$$\begin{aligned}E_{2\rho}\sim-\frac{i\omega\mu_0}{2\pi}\frac{k_2^2}{k_1^2}\Bigg\{&e^{ik_2\rho}\left[-\frac{1-k_2^2/k_1^2}{k_2^2\rho^3}+i\frac{1-k_2^2/k_1^2}{k_2\rho^2}+\frac{1}{\rho}+\frac{ik_S^3}{k_1k_2}\sqrt{\frac{\pi}{k_S\rho}}F((k_2-k_S)\rho)\right.\\&\left.-\frac{\pi k_S^3}{2k_1k_2}e^{-i(k_2-k_S)\rho}\left(e^{-ik_S\rho}H_1^{(1)\prime}(k_S\rho)-e^{-i\pi/4}\sqrt{\frac{2}{\pi k_S\rho}}\right)\right]\\&-e^{ik_1\rho}\left[\frac{1-k_2^2/k_1^2}{k_2^2\rho^3}-\frac{ik_1}{k_2^2\rho^2}-\frac{ik_S^3}{2k_1k_2}\left(e^{-ik_1\rho}\,\mathrm{Ei}(ik_1\rho)-\frac{k_2^3}{k_S^3}\frac{1}{ik_1\rho}\right)\right]\Bigg\}\cos\phi.\end{aligned} \tag{5.7}$$

In consideration of the asymptotic expansion (B18) of Appendix B, it is inferred that

$$E_{2\rho}\sim-\frac{i\omega\mu_0}{2\pi k_1^2}\left\{e^{ik_2\rho}k_2\left[\frac{k_2}{\rho}+\frac{i}{\rho^2}-\frac{1}{k_2\rho^3}+\frac{ik_S^3}{k_1k_2}\sqrt{\frac{\pi}{k_S\rho}}F((k_2-k_S)\rho)\right]\right.$$
$$\left.-e^{ik_1\rho}k_1\left(\frac{1}{k_1\rho^3}-\frac{i}{\rho^2}\right)\right\}\cos\phi. \tag{5.8}$$

This formula is useful for all reasonable purposes yet it assumes that

$$k_2\rho\ll|k_1^5/k_2^5|, \tag{5.9}$$

which poses no practical restriction. The formula agrees with approximations (C5), (C22), and (C23) of Appendix C.

B. Vertical electric dipole

1. Magnetic field

Equation (4.6) for $B_{2\phi}$ furnishes

$$B_{2\phi}\sim-\frac{\mu_0}{2\pi}\left\{e^{ik_2\rho}\left[\frac{ik_2}{\rho}-\frac{1}{\rho^2}-\frac{k_2k_S^2}{k_1}\sqrt{\frac{\pi}{k_S\rho}}F((k_2-k_S)\rho)\right.\right.$$
$$\left.+\frac{\pi k_S^2k_2}{2k_1}e^{-i(k_2-k_S)\rho}\left(e^{-ik_S\rho}H_1^{(1)}(k_S\rho)+e^{i\pi/4}\sqrt{\frac{2}{\pi k_S\rho}}\right)\right]+e^{ik_1\rho}\frac{k_2^2}{k_1^2}$$
$$\left.\times\left[-\frac{ik_2^2}{2k_1\rho}\left(1-\frac{3}{4}\frac{k_2^2}{k_1^2}\right)+\frac{1}{\rho^2}-\frac{ik_1k_S^3\rho}{2k_2}\left(e^{-ik_1\rho}\,\mathrm{Ei}(ik_1\rho)-\frac{1}{ik_1\rho}\right)\right]\right\}. \tag{5.10}$$

Under the sensible condition

$$k_2\rho\ll|k_1^3/k_2^3|, \tag{5.11}$$

the exponential integral and its accompanying term can be neglected. Consequently,

$$B_{2\phi}\sim-\frac{\mu_0}{2\pi}\left\{e^{ik_2\rho}\left[\frac{ik_2}{\rho}-\frac{1}{\rho^2}-\frac{k_2k_S^2}{k_1}\sqrt{\frac{\pi}{k_S\rho}}F((k_2-k_S)\rho)\right]+e^{ik_1\rho}\frac{k_2^2}{k_1^2}\frac{1}{\rho^2}\right\}, \tag{5.12}$$

which connects smoothly to expressions (C10), and (C32) and (C33) of Appendix C.

2. The z-component of the electric field

The retainment of the first term in each series of Eq. (4.22) for E_{2z} yields

$$E_{2z}\sim-\frac{i\omega\mu_0}{2\pi k_2}\left\{-e^{ik_2\rho}\left[\frac{k_2(1-k_2^2/k_1^2)}{\rho}+\frac{i}{\rho^2}-\frac{1}{k_2\rho^3}+\frac{ik_S^3}{k_1}\sqrt{\frac{\pi}{k_S\rho}}F((k_2-k_S)\rho)\right.\right.$$
$$\left.-\frac{\pi k_S^3}{2k_1}e^{-i(k_2-k_S)\rho}\left(e^{-ik_S\rho}H_0^{(1)}(k_S\rho)-e^{-i\pi/4}\sqrt{\frac{2}{\pi k_S\rho}}\right)\right]$$
$$\left.+e^{ik_1\rho}\frac{k_2}{k_1}\left[-\frac{k_1}{\rho}\frac{k_2^4}{k_1^4}+\frac{i}{\rho^2}-\frac{1}{k_1\rho^3}-\frac{ik_S^3}{k_2}\left(e^{-ik_1\rho}\,\mathrm{Ei}(ik_1\rho)-\frac{k_2^3}{k_S^3}\frac{1}{ik_1\rho}\right)\right]\right\}. \tag{5.13}$$

With condition (5.11), the preceding expression becomes

$$E_{2z}\sim -\frac{i\omega\mu_0}{2\pi k_2}\left\{-e^{ik_2\rho}\left[\frac{k_2}{\rho}+\frac{i}{\rho^2}-\frac{1}{k_2\rho^3}+\frac{ik_S^3}{k_1}\sqrt{\frac{\pi}{k_S\rho}}F((k_2-k_S)\rho)\right]\right.$$
$$\left.+e^{ik_1\rho}\frac{k_2}{k_1}\left(\frac{i}{\rho^2}-\frac{1}{k_1\rho^3}\right)\right\}, \tag{5.14}$$

in agreement with approximations (C11), and (C34) and (C35) of Appendix C.

Approximations (5.6), (5.8), (5.12), and (5.14) are in full agreement with the formulas of King *et al.*,[17] provided that the replacement of $(k_2-k_S)\rho$ by $\wp$ is made according to (3.50).

VI. CONCLUSIONS AND DISCUSSION

We start this paper with the Fourier–Bessel integral representations for the fields in the planar boundary between air and a homogeneous half space of infinitesimal electric dipoles lying in the interface. The focus is on the components E_ρ and E_ϕ of the horizontal dipole and B_ϕ and E_z of the vertical dipole in the cylindrical coordinates of Figs. 1 and 3. These components can be given by one-dimensional integrals of elementary functions, as is known from previous works on the Hertz vector.[4–10] The present analysis is believed to go a step further by relaxing the condition $k_2^2 \ll |k_1^2|$ and replacing the integrals by simple, exact integrated series which are usable for any distance from the source. It is verified that the B_z component of a horizontal dipole is described by simple elementary functions.

The exposition bears two appealing features. The first feature is that the ratio of any successive terms in each series is shown to be proportional to k_2^2/k_1^2, i.e., the inverse of the diffraction index squared, while it remains bounded uniformly in ρ. The relative errors due to the retainment of a finite number of terms in the series, say M, are essentially of the order of $(k_2^2/k_1^2)^M$ regardless of $k_2\rho$ and $k_1\rho$. In most cases of practical interest where $|k_1|\geqslant 3k_2$, at most three or four terms of each expansion suffice for reasonable accuracy.

The second feature is that the summands are expressed in simple closed form as the well-known exponential and Fresnel integrals. These functions explicitly reveal the dependence on the physical parameters such as the $k_1\rho$ and the Sommerfeld numerical distance. They also provide a natural connection to the recently obtained, approximate formulas of King *et al.* that distinguish between the direct and ideal-image fields and the lateral-wave or surface-wave contributions when $k_2^2 \ll |k_1^2|$.[17] The present treatment not only verifies the results of these authors by different, exact means, but also extends their validity to distances close to the source.

The two features mentioned above illustrate the advantages of the proposed formulas over representations of the incomplete Hankel function used for the same purpose.[27] The price that one seems to pay for this simplicity, however, is the limitation in the choice of possible configurations or field components that can be treated exactly in a similar fashion.[21] Obtaining integrated series of analogous properties for the remaining components of Eqs. (2.1)–(2.6) and (2.10)–(2.12) is an open problem for future work.

Higher-order terms of the derived series may become of importance for radiowave propagation over a very dry earth; another example of applications could perhaps be related to the so-called ''low-k'' dielectric insulators.[30] As in Ref. 19, the present model is restricted in its applicability due to the assumption of a planar boundary. Lowest-order correction formulas to take into account the effect of a finite yet sufficiently large radius of curvature are given elsewhere.[31–34]

ACKNOWLEDGMENTS

The authors are grateful to Professor Ronold W. P. King for numerous discussions. Special thanks are due to Margaret Owens for preparing the manuscript for publication.

APPENDIX A: GENERALIZED FORMULA FOR INTEGRAL $\mathcal{W}(\boldsymbol{\rho})$

In this appendix, a generalized integration procedure is described which leads to Eq. (3.13) as a special case. More precisely, with the decomposition

$$\mathcal{W}(\rho)=\frac{q_2}{q_1}I(q_1\rho,q_S\rho;-1/2)-\frac{q_1}{q_2}I(q_2\rho,q_S\rho;-1/2), \tag{A1}$$

attention is focused on the integral

$$I(\alpha,\beta;\zeta)=\int_0^\infty dx\,\frac{(x^2+\alpha^2)^{-\zeta}}{x^2+\beta^2}J_1(x),\quad \alpha\geqslant\beta>0. \tag{A2}$$

Of course, I is understood as Abel summable in $x\to\infty$. Without loss of generality, α and β are assumed to be positive. The inequality $\alpha\geqslant\beta$ is imposed for definiteness.

1. Case $\alpha=\beta$

With $\alpha=\beta$,

$$I(\alpha,\alpha;\zeta)=\int_0^\infty dx(x^2+\alpha^2)^{-\zeta-1}J_1(x). \tag{A3}$$

The starting point is the known formula[24]

$$\int_0^\infty dx\,x^{\nu+1}\frac{J_\nu(x)}{(x^2+\alpha^2)^{1+\zeta}}=\frac{2^{-\zeta}\alpha^{\nu-\zeta}}{\Gamma(1+\zeta)}K_{\nu-\zeta}(\alpha),\quad -1<\mathrm{Re}\,\nu<2\,\mathrm{Re}\,\zeta+3/2, \tag{A4}$$

where $K_{\nu-\zeta}$ is the modified Bessel function of the third kind. Note that one may not set $\nu=-1$ on both sides of this equation simultaneously. Caution needs to be exercised because allowing $\nu\to-1^+$ in

$$x^{\nu+1}J_\nu(x)=O(x^{2\nu+1})\ \text{ as }\ x\to0^+,$$

results in a nonintegrable singularity at $x=0$ with a vanishing numerical coefficient.

A remedy is to employ the integral

$$\int_0^\infty dx\,x^{\nu+1}J_\nu(x)=0,\ \ \mathrm{Re}\,\nu>-1, \tag{A5}$$

and rewrite $I(\alpha,\alpha;\zeta)$ as

$$\begin{aligned}I(\alpha,\alpha;\zeta)=&-\lim_{\nu\to-1^+}\left\{\int_0^\infty dx\,x^{\nu+1}[(x^2+\alpha^2)^{-1-\zeta}-\alpha^{-2(1+\zeta)}]J_\nu(x)\right\}\\&+\alpha^{-2(1+\zeta)}\int_0^\infty dx\,J_1(x)\\=&-\frac{2^{-\zeta}\alpha^{-(1+\zeta)}}{\Gamma(1+\zeta)}K_{1+\zeta}(\alpha)+\alpha^{-2(1+\zeta)}.\end{aligned} \tag{A6}$$

Because $K_{n+1/2}(\alpha)$ is elementary if n is any integer, the conclusion is reached that $I(\alpha,\alpha;\zeta)$ is an elementary function if $\zeta=n-1/2$. Explicitly, one gets[25]

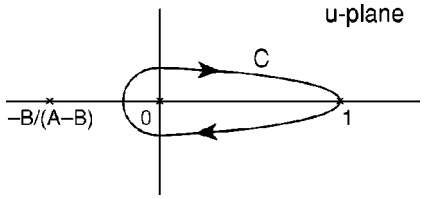

FIG. 4. Contour of integration C for the integral of Eq. (A11).

$$I(\alpha,\alpha;n-1/2)=\begin{cases}\alpha^{-2n-1}+\dfrac{(-1)^{n+1}}{(2n-1)!!}\left(\dfrac{d}{\alpha\,d\alpha}\right)^{n}\dfrac{e^{-\alpha}}{\alpha}, & n=1,2,\ldots,\\ \alpha^{-1}(1-e^{-\alpha}), & n=0,\\ \alpha^{-2n-1}\left[1+\{(2|n|-1)!!\}\left(\dfrac{d}{\alpha\,d\alpha}\right)^{|n|-1}\dfrac{e^{-\alpha}}{\alpha}\right], & -n=1,2,\ldots,\end{cases} \tag{A7}$$

where, in the usual notation, $(2m-1)!!=1\cdot 3\cdots(2m-1)$ for positive integer m.

2. Case $\alpha>\beta$

Let

$$A=x^2+\alpha^2, \quad B=x^2+\beta^2, \tag{A8}$$

and consider the integral representations

$$A^{-\zeta}=\frac{1}{\Gamma(\zeta)}\int_0^\infty d\xi\,\xi^{-1+\zeta}e^{-A\xi}, \quad \mathrm{Re}\,\zeta>0,$$

$$B^{-1}=\int_0^\infty d\eta\,e^{-B\eta}. \tag{A9}$$

The radical in Eq. (A2) is recast in the form

$$A^{-\zeta}B^{-1}=\frac{1}{\Gamma(\zeta)}\int_0^\infty\int_0^\infty d\xi\,d\eta\,\xi^{-1+\zeta}e^{-(A\xi+B\eta)} \quad [\xi=uv,\eta=(1-u)v]$$

$$=\zeta\int_0^1 du\,u^{-1+\zeta}[Au+B(1-u)]^{-1-\zeta}, \quad \mathrm{Re}\,\zeta>0. \tag{A10}$$

Analytic continuation to complex ζ with $\mathrm{Re}\,\zeta<0$ is brought about via the integral

$$A^{-\zeta}B^{-1}=\frac{\zeta}{1-e^{i2\pi\zeta}}\int_C du\,u^{-1+\zeta}[Au+B(1-u)]^{-1-\zeta}, \tag{A11}$$

where C is a closed contour in the u-plane. C originates from $u=1$ in the first Riemann sheet and encircles the origin in the clockwise sense, as shown in Fig. 4. The first Riemann sheet is defined so that

$$u^{-1+\zeta}>0 \quad \text{and} \quad [Au+B(1-u)]^{-1-\zeta}>0, \ 0<u<1, \tag{A12}$$

with the associated branch cuts lying along the positive and negative real axis. Note that in addition to the branch point at $u=0$ another branch point exists in the negative axis at $u=-B/(A-B)$.

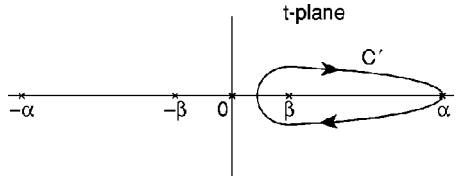

FIG. 5. Map of C of Fig. 4 in the t-plane via $t^2=\alpha^2u+\beta^2(1-u)$.

With Eq. (A6), it follows that

$$I(\alpha,\beta;\zeta)=\frac{\zeta}{1-e^{i2\pi\zeta}}\int_C du\,u^{-1+\zeta}\int_0^\infty dx\{x^2+[\alpha^2u+\beta^2(1-u)]\}^{-1-\zeta}J_1(x)$$

$$=-\frac{\zeta e^{-i\pi\zeta}}{2i\sin\pi\zeta}\int_C du\,u^{-1+\zeta}[\alpha^2u+\beta^2(1-u)]^{-(1+\zeta)}$$

$$\times\left\{1-\frac{2^{-\zeta}}{\Gamma(1+\zeta)}[\alpha^2u+\beta^2(1-u)]^{(1+\zeta)/2}K_{1+\zeta}(\sqrt{\alpha^2u+\beta^2(1-u)})\right\}. \quad \text{(A13)}$$

Hence, $I(\alpha,\beta;\zeta)$ is an integral of an elementary function if $\zeta=n-1/2$, n: integer.

Let

$$t=t(u)=\sqrt{\alpha^2u+\beta^2(1-u)}, \quad t(1)=\alpha, \ \ t(0)=\beta. \quad \text{(A14)}$$

This transformation maps C onto C' (Fig. 5):

$$I(\alpha,\beta;\zeta)=-\frac{\zeta e^{-i\pi\zeta}}{i\sin\pi\zeta}\frac{1}{(\alpha^2-\beta^2)^\zeta}\int_{C'}dt\,t^{-1-2\zeta}(t^2-\beta^2)^{-1+\zeta}$$

$$\times\left\{1-\frac{2^{-\zeta}}{\Gamma(1+\zeta)}t^{1+\zeta}K_{1+\zeta}(t)\right\}. \quad \text{(A15)}$$

By virtue of the identity

$$\frac{d}{dt}[t^{-2\zeta}(t^2-\beta^2)^\zeta]=2\beta^2\zeta t^{-1-2\zeta}(t^2-\beta^2)^{-1+\zeta}, \quad \text{(A16)}$$

application of integration by parts to Eq. (A15) furnishes

$$I(\alpha,\beta;\zeta)=\alpha^{-2\zeta}\beta^{-2}\left[1-\frac{2^{-\zeta}\alpha^{1+\zeta}}{\Gamma(1+\zeta)}K_{1+\zeta}(\alpha)\right]$$

$$-\frac{e^{-i\pi\zeta}}{2i\sin\pi\zeta}\frac{2^{-\zeta}}{\Gamma(1+\zeta)}\frac{1}{\beta^2(\alpha^2-\beta^2)^\zeta}\int_{C'}dt\,t^{-2\zeta}(t^2-\beta^2)^\zeta\frac{d}{dt}[t^{1+\zeta}K_{1+\zeta}(t)]. \quad \text{(A17)}$$

It is of some interest to write down recursive formulas that are particularly useful for $\zeta=n-1/2$, where n is any integer. Clearly, from Eq. (A2),

$$I(\alpha,\beta;\zeta+1)=-\frac{1}{2\alpha}\frac{1}{\zeta}\frac{\partial}{\partial\alpha}I(\alpha,\beta;\zeta), \quad \text{(A18)}$$

while

$$I(\alpha,\beta;\zeta-1)=(\alpha^2-\beta^2)I(\alpha,\beta;\zeta)+I(\alpha,\alpha;\zeta-1)$$
$$=(\alpha^2-\beta^2)I(\alpha,\beta;\zeta)+\alpha^{-2\zeta}-\frac{2^{-\zeta+1}\alpha^{-\zeta}}{\Gamma(\zeta)}K_{-\zeta}(\alpha). \tag{A19}$$

Therefore, it suffices to evaluate $I(\alpha,\beta;\zeta)$ for $\zeta=-1/2$. Equation (A18) can be employed for $\zeta=-1/2, 1/2, 3/2, \ldots$, and Eq. (A19) is adequate for $\zeta=-1/2, -3/2, -5/2, \ldots$.

The substitution $\zeta=-1/2$ in Eq. (A17) gives

$$I(\alpha,\beta;-1/2)=\frac{\alpha}{\beta^2}(1-e^{-\alpha})-\frac{\sqrt{\alpha^2-\beta^2}}{2\beta^2}\int_{C'}dt\,\frac{t}{\sqrt{t^2-\beta^2}}e^{-t}. \tag{A20}$$

Since the integrand has now an integrable singularity at $t=\beta$, the path can be indented back to the positive real axis:

$$I(\alpha,\beta;-1/2)=\frac{\alpha}{\beta^2}(1-e^{-\alpha})-\frac{\sqrt{\alpha^2-\beta^2}}{\beta^2}\int_{\beta}^{\alpha}dt\,\frac{t}{\sqrt{t^2-\beta^2}}e^{-t}. \tag{A21}$$

This result agrees with Eqs. (3.13) and (3.14). Evidently, applying Eq. (A18) does not produce any new integrals of elementary functions.

APPENDIX B: AN ASYMPTOTIC EXPANSION FOR $E_{2\phi}$

In this appendix, an asymptotic formula is derived for the $E_{2\phi}$ of Sec. III when $k_2\rho\gg 1$ and $k_2<|k_1|$ on the basis of its exact series expansion. Consider the $W(\rho)$ of Eq. (3.14). The combination of the first and third terms in Eq. (3.15) yields

$$W(\rho)=W(\rho;\infty,-ik_2,-ik_S)-W(\rho;\infty,-ik_1,-ik_S), \tag{B1}$$

where the second term here is given by Eq. (3.27) and

$$W(\rho;\infty,q_2,q_S)=e^{-q_S\rho}q_S\int_{(q_2-q_S)/q_S}^{\infty}\frac{d\eta}{\sqrt{\eta}}(1+\eta)(2+\eta)^{-1/2}e^{-q_S\rho\eta}. \tag{B2}$$

1. Wave through region 2

When $|q_S\rho|\gg 1$, the major contribution to integral (B2) arises from the vicinity of the lower endpoint of width $O[(q_S\rho)^{-1}]$. If in addition $|(q_2-q_S)\rho|\leqslant O(1)$, $\eta=0$ falls inside the critical region and the radical can be replaced by a Maclaurin expansion. Accordingly,

$$W(\rho;\infty,q_2,q_S)=-e^{-q_2\rho}q_S\left[\sum_{m=0}^{M-1}\mathcal{V}_m(\rho)-e^{(q_2-q_S)\rho}\Upsilon_M(\rho)-R_{2M}(\rho)\right],\quad M\geqslant 1, \tag{B3}$$

where

$$\mathcal{V}_m(\rho)=-e^{i\pi/4}i^{m+1}\frac{(\frac{1}{2})_m}{m!}\frac{m+1/2}{m-1/2}(2q_S\rho)^{-m-1/2}\varphi_m(i(q_2-q_S)\rho), \tag{B4}$$

$$\varphi_m(z)=\sqrt{2\pi}(-i)^m e^{-iz}z^{1/2+m}\frac{d^m}{dz^m}[z^{-1/2}e^{iz}F(z)], \tag{B5}$$

$$F(z)=e^{-iz}\int_z^{\infty}dx\,\frac{e^{ix}}{\sqrt{2\pi x}}=e^{-iz}\left[\frac{1}{2}(1+i)-F_0(z)\right]. \tag{B6}$$

$F_0(z)$ is introduced in Eqs. (3.41) and (3.42), $R_{2M}(\rho)$ is given by Eq. (3.34), and $\Upsilon_M(\rho)$ is the remainder in the sense of Poincaré[35] of an asymptotic expansion for $e^{q_S\rho}K_1(q_S\rho)$ when M terms are summed,[25] i.e., $\Upsilon_M(\rho)=O[(k_S\rho)^{-M-1/2}]$ as $|k_S\rho|\to\infty$ for $M=O(1)$, uniformly in $\mathrm{Arg}(k_S\rho)$. Compare with Eqs. (3.31).

For $1\leqslant M=O(1)$ and $|(k_2-k_S)/(2k_S)|\ll 1$,

$$R_{2M}(\rho)=O\left[\left(\frac{k_2-k_S}{2k_S}\right)^{M+1/2}\right],\quad |(k_2-k_S)\rho|\leqslant O(1), \tag{B7}$$

leading to

$$\frac{e^{-i(k_2-k_S)\rho}\Upsilon_M(\rho)+R_{2M}(\rho)}{\mathcal{V}_{M-1}(\rho)}=O\left(\frac{1}{k_2\rho}\right). \tag{B8}$$

When $|(k_2-k_S)\rho|\gg 1$, the remainder $R_{2M}(\rho)$ dominates over the $\Upsilon_M(\rho)$ in Eq. (B3). It follows that

$$R_{2M}(\rho)=O\left[\left(\frac{k_2-k_S}{2k_S}\right)^{M+1/2}\frac{1}{(k_2-k_S)\rho}\right],\quad |(k_2-k_S)\rho|\gg 1,\ M=O(1), \tag{B9}$$

by inspection of Eq. (3.36b), and

$$\frac{e^{-i(k_2-k_S)\rho}\Upsilon_M(\rho)+R_{2M}(\rho)}{-\mathcal{V}_{M-1}(\rho)}=O\left(\frac{k_2-k_S}{2k_S}\right). \tag{B10}$$

Of course, in the limit $M\to\infty$ the remainder $\Upsilon_M(\rho)$ is unbounded and the series from Eq. (B3) diverges. In the sense implied by Eq. (B3),

$$W(\rho;\infty,q_2,q_S)\sim -e^{-q_2\rho}q_S\sum_{m=0}^{\infty}\mathcal{V}_m(\rho). \tag{B11}$$

This asymptotic expansion can be attained somewhat heuristically from the exact series (3.40) combined with the asymptotic expansion for $H_1^{(1)}(k_S\rho)$. Notice that

$$\frac{d^m}{dz^m}[z^{-1/2}F_0(z)]=\frac{e^{i\pi/4}}{\sqrt{2}}(-1)^m\left(\frac{1}{2}\right)_m z^{-1/2-m}-\frac{d^m}{dz^m}[z^{-1/2}e^{iz}F(z)]. \tag{B12}$$

2. Wave through region 1

From Eq. (B1), consider the integral

$$W(\rho;\infty,q_1,q_S)=q_1\int_1^{\infty}d\eta\,\frac{\eta}{\sqrt{\eta^2-\overline{q}}}e^{-q_1\rho\eta},\quad \overline{q}=q_S^2/q_1^2,\ |\overline{q}|<1. \tag{B13}$$

When $|q_1\rho|\gg 1$, the principal contribution to integration comes from the vicinity of $\eta=1$. Accordingly, expand the radical as

$$\frac{\eta}{\sqrt{\eta^2-\overline{q}}}-1=\sum_{n=0}^{N-1}\frac{(-1)^n}{n!}\mathcal{A}_n(\overline{q})(\eta-1)^n+O[(\eta-1)^N],\quad N\geqslant 1, \tag{B14}$$

where

$$\mathcal{A}_0(\overline{q})=\frac{\overline{q}}{\sqrt{1-\overline{q}}(1+\sqrt{1-\overline{q}})}, \tag{B15}$$

and, for $n=1,2,\ldots,$[28]

$$\begin{aligned}\mathcal{A}_n(\overline{q})&=(-1)^n\frac{d^n}{d\eta^n}\frac{\eta}{\sqrt{\eta^2-\overline{q}}}\bigg|_{\eta=1}\\&=\overline{q}\frac{2^n}{\sqrt{\pi}}\Gamma\left(\frac{n+3}{2}\right)\Gamma\left(1+\frac{n}{2}\right){}_2F_1\left(\frac{n+3}{2},\frac{n}{2}+1;2;\overline{q}\right)\\&=2^{[(n-1)/2]}\{(2[n/2]+1)!!\}\frac{d^{[(n-1)/2]}}{d\overline{q}^{[(n-1)/2]}}\{\overline{q}^{[(n-1)/2]+1}(1-\overline{q})^{-(2[n/2]+3)/2}\}.\end{aligned} \tag{B16}$$

$[x]$ denotes the integral part of x. Note that the second line of Eq. (B16) holds even for $n=0$.

It follows that

$$W(\rho;\infty,q_1,q_S)=\frac{e^{-q_1\rho}}{\rho}\left\{1+\sum_{n=0}^{N-1}\frac{\mathcal{A}_n(\overline{q})}{(-q_1\rho)^n}+O[(q_1\rho)^{-N}]\right\},\quad N\geqslant 1. \tag{B17}$$

The first term inside the braces is the $U_0(\rho)$ from Eq. (3.19). This expansion can be verified directly from Eq. (3.18) by invoking the formula[28]

$$e^z\mathrm{Ei}(-z)=\sum_{n=0}^{N-1}(-1)^{n+1}n!\,z^{-1-n}+O(|z|^{-N-1})\ \text{ as }\ z\to\infty,\quad \begin{cases}N=1,2,\ldots,\\ |\mathrm{Arg}\ z|<3\pi/2,\end{cases} \tag{B18}$$

which holds uniformly in Arg z, interchanging the order of summation and subsequently allowing $M\to\infty$.

3. Asymptotic formula for $E_{2\phi}$

The resulting asymptotic expansion for $E_{2\phi}$ reads as

$$\begin{aligned}E_{2\phi}\sim&-\frac{i\omega\mu_0}{2\pi}\frac{k_2^2}{k_1^4-k_2^4}\left\{-ie^{ik_1\rho}k_1\left[\frac{k_1^2+k_2^2(2-k_S/k_2)}{k_2^2\rho^2}+i\frac{k_1^2+2k_2^2}{k_1k_2^2\rho^3}\right]\right.\\&\left.+ie^{ik_2\rho}\frac{2k_1^2+k_2^2}{k_2\rho^2}\left(1+\frac{i}{k_2\rho}\right)-\frac{k_1k_S^2}{k_2\rho}\left[\frac{e^{ik_1\rho}}{ik_S\rho}\sum_{n=0}^{\infty}\frac{\mathcal{A}_n(k_S^2/k_1^2)}{(ik_1\rho)^n}-e^{ik_2\rho}\sum_{m=0}^{\infty}\mathcal{V}_m(\rho)\right]\right\}\sin\phi.\end{aligned} \tag{B19}$$

Similar expressions can be written down by inspection for the other components of Secs. III and IV.

APPENDIX C: ASYMPTOTIC FORMULAS FOR $k_2\rho\ll 1$ AND $k_2\rho\gg 1$

In this appendix, simple approximations are applied directly to the integrals (2.1)–(2.6) and (2.10)–(2.12) when $k_2^2\ll|k_1^2|$ under the conditions $k_1\rho=O(1)$ and $k_2\rho\gg 1$.

1. Case $k_2^2\ll|k_1^2|$, $k_1\rho=O(1)$

In terms of the q_j $(j=1,2)$ of Eqs. (3.1), $|q_2\rho|\ll 1$ while $q_1\rho$ is kept fixed and $|q_2^2|\ll|q_1^2|$. Then the principal contribution to integration arises from a range where $\lambda=O(1/\rho)\gg|q_2|$. Accordingly, the following approximation becomes effective:

$$\sqrt{k_2^2-\lambda^2}\sim i\lambda$$

A. Horizontal electric dipole

With these approximations, B_{2z} becomes

$$B_{2z}\sim \frac{\mu_0}{2\pi}\int_0^\infty d\lambda\ \lambda^2\frac{J_1(\lambda\rho)}{\sqrt{\lambda^2+q_1^2}+\lambda}\sin\phi=\frac{\mu_0}{2\pi q_1^2}\left\{\frac{1}{\rho^4}\mathcal{I}_m(q_1\rho)-\int_0^\infty d\lambda\ \lambda^3 J_1(\lambda\rho)\right\}\sin\phi, \tag{C2}$$

where

$$\int_0^\infty d\lambda\ \lambda^3 J_1(\lambda\rho)=-\frac{3}{\rho^4}, \tag{C3}$$

while the integral $\mathcal{I}_m$ is given by Eq. (3.4). Hence,

$$B_{2z}\sim \frac{\mu_0 k_1^2}{2\pi}\left[e^{ik_1\rho}\left(\frac{3}{k_1^4\rho^4}-\frac{3i}{k_1^3\rho^3}-\frac{1}{k_1^2\rho^2}\right)-\frac{3}{k_1^4\rho^4}\right]\sin\phi. \tag{C4}$$

In the same vein, by virtue of Eq. (3.8) for $\mathcal{I}_e$,

$$\begin{aligned}E_{2\rho}&\sim \frac{i\omega\mu_0}{2\pi q_1^2}\left\{\left(\frac{1}{\rho}+\frac{d}{d\rho}\right)\left[\frac{1}{\rho^2}\mathcal{I}_e(q_1\rho)\right]-\frac{1}{\rho}\int_0^\infty d\lambda\ \lambda J_1(\lambda\rho)\right\}\cos\phi\\&=\frac{i\omega\mu_0 k_1}{2\pi}\left\{e^{ik_1\rho}\left(\frac{1}{k_1^3\rho^3}-\frac{i}{k_1^2\rho^2}\right)+\frac{1}{k_1^3\rho^3}\right\}\cos\phi,\end{aligned} \tag{C5}$$

$$\begin{aligned}E_{2\phi}&\sim -\frac{i\omega\mu_0}{2\pi q_1^2}\left\{\left(\frac{1}{\rho}+\frac{d}{d\rho}\right)\left[\frac{1}{\rho^2}\mathcal{I}_e(q_1\rho)\right]-\frac{d}{d\rho}\int_0^\infty d\lambda\ \lambda J_1(\lambda\rho)\right\}\sin\phi\\&=\frac{i\omega\mu_0 k_1}{2\pi}\left\{e^{ik_1\rho}\left(-\frac{1}{k_1^3\rho^3}+\frac{i}{k_1^2\rho^2}\right)+\frac{2}{k_1^3\rho^3}\right\}\sin\phi.\end{aligned} \tag{C6}$$

The computation of the limiting forms of E_{2z}, $B_{2\rho}$ and $B_{2\phi}$ is more involved:

$$\begin{aligned}E_{2z}&\sim \frac{i\omega\mu_0}{2\pi q_1^2}\lim_{\epsilon\to 0^+}\frac{\partial}{\partial\rho}\int_0^\infty d\lambda\ \sqrt{\lambda^2+q_1^2}e^{-\epsilon\sqrt{\lambda^2+q_1^2}}J_0(\lambda\rho)\cos\phi\\&=\frac{i\omega\mu_0}{2\pi q_1^2}\lim_{\epsilon\to 0^+}\frac{\partial}{\partial\rho}\frac{\partial^2}{\partial\epsilon^2}\left\{I_0\left[\frac{q_1}{2}(\sqrt{\epsilon^2+\rho^2}-\epsilon)\right]K_0\left[\frac{q_1}{2}(\sqrt{\epsilon^2+\rho^2}+\epsilon)\right]\right\}\cos\phi\\&=\frac{\omega\mu_0}{4\rho}J_1(k_1\rho/2)H_1^{(1)}(k_1\rho/2)\cos\phi,\end{aligned} \tag{C7}$$

$$B_{2\rho}\sim -\frac{i\mu_0}{4}\frac{d}{d\rho}\left[\frac{1}{\rho}J_1(k_1\rho/2)H_1^{(1)}(k_1\rho/2)\right]\sin\phi, \tag{C8}$$

where use is made of Ref. 36, and

$$B_{2\phi}\sim -\frac{i\mu_0}{4\rho^2}\frac{k_1}{k_2}J_1(k_1\rho/2)H_1^{(1)}(k_1\rho/2)\cos\phi. \tag{C9}$$

Compare with the exposition in Ref. 13. In principle, the behavior of the z-component of the electric field depends on the limit path. For instance, if the observation point is forced to approach the source along a straight line from region 1 ($z<0$), this component behaves as $\sim 1/\rho^3$. [The divergence can ensue from taking $\epsilon=\rho$ in the second line of Eq. (C7).]

B. Vertical electric dipole

From the Fourier–Bessel integral (2.10),

$$B_{2\phi}\sim \frac{\mu_0}{2\pi q_1^2}\left[q_1^2\int_0^\infty d\lambda\,\lambda J_1(\lambda\rho)-\frac{q_2^2}{\rho^2}\mathcal{I}_e(q_1\rho)\right]$$
$$=-\frac{\mu_0}{2\pi\rho^2}\left[e^{ik_1\rho}\frac{k_2^2}{k_1^2}-\left(1+\frac{k_2}{k_1}ik_2\rho\right)\right]\sim-\frac{\mu_0}{2\pi\rho^2}\left(e^{ik_1\rho}\frac{k_2^2}{k_1^2}-1\right). \tag{C10}$$

Likewise, starting with Eq. (2.11) gives

$$E_{2z}\sim\frac{i\omega\mu_0}{2\pi\rho}\left[e^{ik_1\rho}\left(\frac{1}{k_1^2\rho^2}-\frac{i}{k_1\rho}\right)-\frac{1}{k_2^2\rho^2}\right]. \tag{C11}$$

The formula for $E_{2\rho}$ is more involved, in analogy with Eqs. (C7)–(C9). It is

$$E_{2\rho}\sim\frac{i\omega\mu_0}{2\pi\rho}\left[\frac{i\pi}{2}J_1(k_1\rho/2)H_1^{(1)}(k_1\rho/2)-\frac{k_2^2}{k_1^2}\right]. \tag{C12}$$

2. Case $k_2^2\ll|k_1^2|$, $k_2\rho\gg 1$

When $|k_j\rho|\gg 1$ $(j=1,2)$, the oscillations of the Bessel functions in Eqs. (2.1)–(2.6) and (2.10)–(2.12) force the major contributions to integration to arise from the vicinities of the branch points at $\lambda=k_j$ with widths $O(1/\rho)$. The condition $k_2^2\ll|k_1^2|$ permits considerable simplification because, heuristically speaking, the two contributing regions separate.

Following Sommerfeld,[29] one may replace each J_n $(n=0,1,2)$ by $(1/2)[H_n^{(1)}+H_n^{(2)}]$. The contour Γ can be chosen symmetric under inversion through the origin, as shown in Fig. 2. Use is made of the analytic continuation formula

$$H_n^{(2)}(ze^{-i\pi})=(-1)^{n+1}H_n^{(1)}(z),\quad n:\ \text{integer}. \tag{C13}$$

For notational convenience, let $\mathcal{F}_{2\kappa,j}$ ($\mathcal{F}=E,\ B;\ \kappa=\rho,\ \phi,\ z;\ j=1,2$) denote the part of the field component that corresponds to the contour integral along Γ_j. Each $\mathcal{F}_{2\kappa,j}$ follows upon the replacements

$$\mathcal{F}_{2\kappa}\to\mathcal{F}_{2\kappa,j}\ \text{ under }\ \int_0^\infty d\lambda(\cdots)J_n(\lambda\rho)\to\frac{1}{2}\int_{\Gamma_j}d\lambda(\cdots)H_n^{(1)}(\lambda\rho). \tag{C14}$$

Each $\mathcal{F}_{2\kappa,j}$ amounts to a wave traveling with the phase velocity of medium j.

With

$$H_0^{(1)}(\lambda\rho)+H_2^{(1)}(\lambda\rho)=\frac{2}{\lambda\rho}H_1^{(1)}(\lambda\rho), \tag{C15}$$

the Hankel functions in each $\mathcal{F}_{2\kappa,j}$ are approximated according to

$$H_n^{(1)}(k_j\rho(1+it))\sim e^{ik_j\rho-in\pi/2-i\pi/4}\sqrt{\frac{2}{\pi k_j\rho}}e^{-k_j\rho t},\quad |k_j\rho|\gg 1,\ t\to 0^+. \tag{C16}$$

Due to the rapid exponential decrease here, the major contribution to integration on each side of the branch cut (positive t-axis) originates from the corresponding branch point ($t=0$).[37]

Upon the change of variable $\lambda=k_j(1+it)$, it is recognized that for $\lambda\sim k_j$,

$$\sqrt{1-(\lambda/k_j)^2}=\pm e^{-i\pi/4}\sqrt{2t}\sqrt{1+it/2}\sim\pm e^{-i\pi/4}\sqrt{2t},\quad t\to 0^+,\quad \sqrt{t}\geqslant 0, \tag{C17}$$

where the upper sign holds along the left-hand side and the lower sign along the right-hand side of each branch cut. For instance, $D(\lambda)$ of Eq. (2.8) becomes

$$D(\lambda)\sim\pm e^{-i\pi/4}\sqrt{2t}+k_2/k_1,\quad \lambda\sim k_2, \tag{C18}$$

$$D(\lambda)\sim ik_1/k_2\pm(k_2/k_1)e^{-i\pi/4}\sqrt{2t}\sim ik_1/k_2,\quad \lambda\sim k_1. \tag{C19}$$

In each $\mathcal{F}_{2\kappa,j}$, the contribution from the circle $C_{\delta,j}$ of radius δ vanishes in the limit $\delta\to 0^+$.

A. Horizontal electric dipole

The integrals for the z-component of the magnetic field are

$$B_{2z,2}\sim e^{ik_2\rho}\frac{\mu_0}{2\pi}\frac{k_2^4}{k_1^2}\sqrt{\frac{2}{\pi k_2\rho}}\int_0^\infty dt\sqrt{2t}e^{-k_2\rho t}\sin\phi=e^{ik_2\rho}\frac{\mu_0}{2\pi}\frac{k_2^2}{k_1^2\rho^2}\sin\phi, \tag{C20}$$

$$B_{2z,1}\sim -e^{ik_1\rho}\frac{\mu_0}{2\pi}\frac{1}{\rho^2}\sin\phi. \tag{C21}$$

The integrals pertaining to the ρ-component of the electric field become

$$\begin{aligned}E_{2\rho,2}&\sim\frac{\omega\mu_0k_2^3}{2\pi k_1^2}\frac{e^{ik_2\rho}}{\sqrt{\pi k_2\rho}}\left[\int_0^\infty dt\frac{\sqrt{t}}{it+(1/2)k_2^2/k_1^2}e^{-k_2\rho t}+\frac{2i}{k_2\rho}\int_0^\infty dt\sqrt{t}e^{-k_2\rho t}\right]\cos\phi\\&\sim e^{ik_2\rho}\frac{\omega\mu_0k_2^4}{2\pi k_1^3}\sqrt{\frac{\pi}{k_2\rho}}[F(\wp)-i(2\pi\wp)^{-1/2}]\cos\phi,\end{aligned} \tag{C22}$$

$$E_{2\rho,1}\sim e^{ik_1\rho}\frac{\omega\mu_0}{2\pi k_1\rho^2}\cos\phi. \tag{C23}$$

$\wp$ and $F(z)$ are defined by Eqs. (3.50) and (B6), respectively.

By a comparison of Eqs. (2.2) and (2.3), no further calculations need to be done for $E_{2\phi,j}$.

$$\begin{aligned}E_{2\phi,2}&\sim-\frac{\omega\mu_0k_2^3}{2\pi k_1^2}\frac{e^{ik_2\rho}}{\sqrt{\pi k_2\rho}}\left\{\frac{1}{ik_2\rho}\left(\frac{\pi k_2}{k_1}[F(\wp)-i(2\pi\wp)^{-1/2}]\right)+ik_2\rho\left(\frac{i}{k_2^2\rho^2}\sqrt{\frac{\pi}{k_2\rho}}\right)\right\}\sin\phi\\&=e^{ik_2\rho}\frac{i\omega\mu_0k_2^3}{2\pi k_1^3\rho}\sqrt{\frac{\pi}{k_2\rho}}[F(\wp)-2i(2\pi\wp)^{-1/2}]\sin\phi,\end{aligned} \tag{C24}$$

$$E_{2\phi,1}\sim -e^{ik_1\rho}\frac{\omega\mu_0}{2\pi k_1\rho^2}\sin\phi. \tag{C25}$$

The rest of the components are calculated under similar approximations as follows:

$$E_{2z,2}\sim e^{ik_2\rho}\frac{\omega\mu_0 k_2^2}{2\pi k_1}\frac{1}{\sqrt{\pi k_2\rho}}\int_0^\infty dt\,\frac{\sqrt{t}}{it+(1/2)k_2^2/k_1^2}e^{-k_2\rho t}\cos\phi$$

$$=e^{ik_2\rho}\frac{\omega\mu_0 k_2^3}{2\pi k_1^2}\sqrt{\frac{\pi}{k_2\rho}}[F(\wp)-i(2\pi\wp)^{-1/2}]\cos\phi, \tag{C26}$$

$$E_{2z,1}\sim e^{ik_1\rho}\frac{i\omega\mu_0}{2\pi k_1\rho^2}\cos\phi, \tag{C27}$$

$$B_{2\rho,2}\sim e^{ik_2\rho}\frac{i\mu_0 k_2^3}{2\pi k_1^2\rho}\sqrt{\frac{\pi}{k_2\rho}}[F(\wp)-2i(2\pi\wp)^{-1/2}]\sin\phi, \tag{C28}$$

$$B_{2\rho,1}\sim e^{ik_1\rho}\frac{i\mu_0}{2\pi\rho^2}\sin\phi, \tag{C29}$$

and, in analogy with formulas (C24) and (C25),

$$B_{2\phi,2}\sim -e^{ik_2\rho}\frac{\mu_0 k_2^4}{2\pi k_1^2}\sqrt{\frac{\pi}{k_2\rho}}[F(\wp)-i(2\pi\wp)^{-1/2}]\cos\phi, \tag{C30}$$

$$B_{2\phi,1}\sim -e^{ik_1\rho}\frac{\mu_0 k_2}{2\pi k_1\rho^2}\left(i\frac{k_2}{k_1}-\frac{1}{k_2\rho}\right)\cos\phi. \tag{C31}$$

Compare with Ref. 17.

B. Vertical electric dipole

In the same vein, the field of a vertical electric dipole can be calculated with recourse to Eqs. (2.10)–(2.12). See also Ref. 32. Without further ado,

$$B_{2\phi,2}\sim e^{ik_2\rho}\frac{\mu_0 k_2^3}{2\pi k_1}\sqrt{\frac{\pi}{k_2\rho}}[F(\wp)-i(2\pi\wp)^{-1/2}], \tag{C32}$$

$$B_{2\phi,1}\sim -e^{ik_1\rho}\frac{\mu_0}{2\pi}\frac{k_2^2}{k_1^2\rho^2}, \tag{C33}$$

$$E_{2z,2}\sim -e^{ik_2\rho}\frac{\omega\mu_0 k_2^2}{2\pi k_1}\sqrt{\frac{\pi}{k_2\rho}}[F(\wp)-i(2\pi\wp)^{-1/2}], \tag{C34}$$

$$E_{2z,1}\sim e^{ik_1\rho}\frac{\omega\mu_0}{2\pi k_1\rho^2}, \tag{C35}$$

$$E_{2\rho,2}\sim -e^{ik_2\rho}\frac{\omega\mu_0 k_2^3}{2\pi k_1^2}\sqrt{\frac{\pi}{k_2\rho}}[F(\wp)-i(2\pi\wp)^{-1/2}], \tag{C36}$$

$$E_{2\rho,1}\sim -e^{ik_1\rho}\frac{i\omega\mu_0}{2\pi k_1\rho^2}. \tag{C37}$$

(Received 19 September 2000; accepted for publication 6 November 2000)

The technique of reduction of order developed by Nucci [J. Math. Phys. **37**, 1772–1775 (1996)] is used to produce nonlocal symmetries in addition to those reported by Krause [J. Math. Phys. **35**, 5734–5748 (1994)] in his study of the complete symmetry group of the Kepler problem. The technique is shown to be applicable to related problems containing a drag term which have been used to model the motion of low altitude satellites in the Earth's atmosphere and further generalizations. A consequence of the application of this technique is the demonstration of the group theoretical relationship between the simple harmonic oscillator and the Kepler and related problems. © *2001 American Institute of Physics.*

I. INTRODUCTION

In a paper of a few years ago Krause[1] introduced a new concept into the study of the symmetries of ordinary differential equations. He called this a complete symmetry group and defined it by adding two properties to the definition of a Lie symmetry group. These were that the manifold of solutions is an homogeneous space of the group and the group is specific to the system, i.e., no other system admits it. This definition required the introduction of a new type of symmetry defined by

$$Y=\left[\int \xi(t,x_1,\ldots,x_N)\mathrm{d}t\right]\partial_t+\sum_{i=1}^{N}\eta_i(t,x_1,\ldots,x_N)\partial_{x_i}. \tag{1.1}$$

This definition of a symmetry differs from that of a Lie point symmetry due to the presence of the integral as the coefficient function of ∂_t.

As an illustration of the concept of a complete symmetry group Krause used the Kepler problem and obtained three symmetries of the type of (1.1). He claimed that these three symmetries could not be obtained by means of the standard Lie point symmetry analysis. Naturally it was not long before this claim was shown by Nucci[2] to be incorrect in the case of an autonomous system. In the case of the Kepler problem, an autonomous system, one of the dependent variables can be taken to be the new independent variable and the order of the system be reduced by one. An analysis of the reduced system for Lie point symmetries leads to results different from the analysis of the original system. In particular the three additional nonlocal symmetries obtained by Krause followed from point symmetries of the reduced system.

One of the fundamental problems of mechanics is that of the Kepler problem which describes the interaction of two point particles with an inverse square law of attraction. It is well known that this problem possesses the first integrals of the conservation of the scalar energy, the vector of angular momentum and vectors in the plane of the orbit known as Hamilton's vector[3] and the

[a)]Permanent address: School of Mathematical and Statistical Sciences, University of Natal, Durban 4041, Republic of South Africa.

Laplace–Runge–Lenz vector.[4–9] The invariance Lie algebra of the first integrals under the operation of taking the Poisson bracket is so(4) (in the case of negative energy) and the Lie algebra of the five Lie point symmetries of the equation of motion $A_2 \oplus \mathrm{so}(3)$. The algebra of the complete symmetry group has not been given. The elements of the five-dimensional algebra are

$$X_1 = \partial_t, \quad X_3 = x_2 \partial_{x_3} - x_3 \partial_{x_2},$$

$$X_2 = t\partial_t + \tfrac{2}{3} r \partial_r, \quad X_4 = x_3 \partial_{x_1} - x_1 \partial_{x_3}, \tag{1.2}$$

$$X_5 = x_1 \partial_{x_2} - x_2 \partial_{x_1}.$$

The additional three nonlocal symmetries provided by Krause are

$$Y_1 = 2\left(\int x_1 \, \mathrm{d}t \right) \partial_t + x_1 r \partial_r,$$

$$Y_2 = 2\left(\int x_2 \, \mathrm{d}t \right) \partial_t + x_2 r \partial_r, \tag{1.3}$$

$$Y_1 = 2\left(\int x_3 \, \mathrm{d}t \right) \partial_t + x_3 r \partial_r$$

in which $r^2 = x_1^2 + x_2^2 + x_3^2$.

There have been several other systems, generalizations of the Kepler problem, which have been shown to have a similar set of conserved quantities.[10–13] Just as the Laplace–Runge–Lenz vector provides a direct route to the equation of the orbit of the classical Kepler problem, the corresponding vectors of the generalized Kepler problems provide the same direct route to the equations of their orbits. The Lie point symmetry associated with the Laplace–Runge–Lenz vector of the classical Kepler problem is the rescaling symmetry, X_2. The generalizations of the Laplace–Runge–Lenz vector do not always have such an associated Lie point symmetry. In the case of the equation of motion

$$\ddot{\mathbf{r}} - \left(\frac{\dot{g}}{2g} + \frac{3\dot{r}}{2r} \right) \dot{\mathbf{r}} + \mu g \mathbf{r} = 0, \tag{1.4}$$

which is a variation of the model proposed by Danby[14–17] for the motion of a satellite in a low altitude orbit subject to atmospheric drag, *viz*.

$$\ddot{\mathbf{r}} + \frac{\alpha \dot{\mathbf{r}}}{r^2} + \frac{\mu \mathbf{r}}{r^3} = 0, \tag{1.5}$$

and for which the generalization of the Laplace–Runge–Lenz vector is

$$\mathbf{J} = \frac{\dot{\mathbf{r}} \times \hat{\mathbf{L}}}{L} + \frac{\mu}{A^2} \hat{\mathbf{r}}, \tag{1.6}$$

where L is the magnitude of the angular momentum, $\mathbf{L}$, and A is a constant of the motion defined through

$$L = A(gr^3)^{1/2}, \tag{1.7}$$

Pillay *et al.*[18] showed that, instead of the Lie point symmetry for the classical Kepler problem, X_2, the nonlocal symmetry

$$G=-\frac{1}{2}\left[\int \frac{g'r}{g}\mathrm{d}t\right]\partial_t+r\partial_r \tag{1.8}$$

was the corresponding associated Lie symmetry.

In this paper we intend to demonstrate the existence of far more nonlocal symmetries for the classical Kepler problem than were reported by Krause. We derive them as Lie point symmetries of a reduced system using the method of Nucci.[19] By deriving these additional nonlocal symmetries in this way we are able to say something definite about the expanded symmetry group. The essence of the method of Nucci is to reduce the order of the system by using the symmetry, X_1, which is a statement of the autonomy of the system. We recall that in a reduction of order the symmetry Z which does not have the property $[X_1,Z]=\lambda X_1$ becomes an exponential nonlocal symmetry.[20] By an exponential nonlocal symmetry we mean one of the form

$$G=\exp\left[\int f\,\mathrm{d}t\right](\tau\partial_t+\eta_i\partial_{x_i}) \tag{1.9}$$

in which without a knowledge of the solution of the differential equation f is not an exact derivative and τ and the η_i are functions only of t, the x_i and their derivatives. In this case we have nonlocal symmetries becoming local on the reduction of order. Consequently we know that the symmetries of the reduced equation quite possibly have zero Lie bracket with X_1 and this will enable us to construct the algebra. Further we shall show that these considerations which are applicable to the classical Kepler problem can be extended to the generalizations such as the one in (1.4).

In the next section we review the reduction procedure of Nucci[2] and in Sec. III we apply it to the classical Kepler problem and see that there is a certain delicacy in the choice of the new independent variable. For the sake of simplicity we work in two dimensions. In Sec. IV we make some observations about these symmetries, the route to further simplification and the algebra. In Sec. V we obtain the results for Danby problem,[14] in Sec. VI those for the generalized problem represented by (1.4), in Sec. VII the symmetries for another generalization in which the force is not only not central but is also angle dependent and in Sec. VIII we present our conclusions and make some pertinent observations about going to the full three dimensions.

II. THE METHOD OF REDUCTION OF ORDER

Consider the system of N second order ordinary differential equations given by

$$\ddot{x}_i=f_i(x,\dot{x}),\quad i=1,N \tag{2.1}$$

in which t is the independent variable and $x_i, i=1,N$ the N dependent variables. These equations may be considered as equations from Newtonian mechanics, which was Krause's approach, but there is no necessity for that to be the case. There is also no necessity for the dependent variables to represent Cartesian coordinates. Indeed there is no need for the system to be of the second order. It just so happens that many of the equations which arise in practice have their origins in Newton's second law and so are second order equations. There is no requirement that the system be autonomous. In the case of a nonautonomous system we can apply the standard procedure of introducing a new variable $x_{N+1}=t$ and an additional first order equation $\dot{x}_{N+1}=1$ so that the system becomes formally autonomous. In our discussion we confine our attention to autonomous systems. We reduce the system (2.1) to a $2N$-dimensional first order system by means of the change of variables

$$\begin{aligned} w_1 &= x_1 & w_{N+1} &= \dot{x}_1 \\ w_2 &= x_2 & w_{N+2} &= \dot{x}_2 \\ &\vdots & &\vdots \\ w_{N-1} &= x_{N-1} & w_{2N-1} &= \dot{x}_{N-1} \\ w_N &= x_N & w_{2N} &= \dot{x}_N \end{aligned} \tag{2.2}$$

so that the system (2.1) becomes

$$\dot{w}_i = g_i(x,w), \quad i = 1,2N, \tag{2.3}$$

where $g_i = w_{N+i}$ for $i = 1,N$ and $g_i = f_i$ for $i = N+1,2N$.

In the first step of the reduction of the original system (2.1) we simply follow the conventional method used to reduce a higher order system to a first order system. Any optimization is performed in the further selection of the final variables. This selection may be motivated by the existence of a known first integral, such as angular momentum, or some specific symmetry in the original system (2.1).

We choose one of the variables w_i to be the new independent variable y. For the purpose of the development here we can make the identification $w_N = y$. By taking the quotients of the first order equations of the remaining members of the set (2.2) with (2.3N) we obtain the $(2N-1)$-dimensional system

$$\frac{\mathrm{d}w_i}{\mathrm{d}w_N} = \frac{g_i}{g_N} = \frac{g_i}{w_{2N}}, \quad i = 1,\ldots,N-1,N+1,\ldots,2N. \tag{2.4}$$

We do not attempt to calculate the Lie point symmetries of the system (2.4) because the Lie point symmetries of a first order system are generalized symmetries and one has to impose some *Ansatz* on the form of the symmetry. Rather we select $n \leqslant N-1$ of the variables to be the new dependent variables and rewrite the system (2.4) as a system of n second order equations plus $2(N-n) - 1$ first order equations. The selection of the new dependent variables is dictated by a number of considerations. The first and foremost is that we must be able to eliminate the unwanted variables from the system (2.4). After this condition has been satisfied we may look to seek variables which reflect some symmetry of the system, for example, an ignorable coordinate such as the azimuthal angle in a central force problem.

After the symmetries have been calculated, they can now be translated back to symmetries of the original system as follows. Suppose that the symmetry in the original variables is given by

$$G = \tau\partial_t + \eta_i\partial_{x_i}. \tag{2.5}$$

The symmetry G is first extended and then rewritten in terms of the new coordinates as follows:

$$G^{[1]} = \tau\partial_t + \eta_i\partial_{x_i} + (\dot{\eta}_i - \dot{x}_i\dot{\tau})\partial_{\dot{x}_i} = \tau\partial_t + \zeta_i\partial_{w_i} = \sigma\partial_y + \xi_i\partial_{u_i}, \tag{2.6}$$

where in the first line the summation is from 1 to N, in the second from 1 to $N-1$ and $N+1$ to $2N$, and in the third over the number of dependent variables u_i (the number cannot be fixed in advance without a knowledge of the specific system); $\zeta_i = \eta_i$ for $i = 1,N-1$ and $\zeta_i = \dot{\eta}_i - \dot{g}_i\dot{\tau}$ for $i = N+1,2N$; $\sigma = \eta_N$; $\xi_i = \zeta_j \partial u_i / \partial w_j$. The only way that τ appears in the symmetries of the reduced system is through its derivative with respect to time. If the nonlocality in the original system occurs as a simple integral in τ of a function of the original dependent variables, x_i, this will be passed to the reduced system as a function of the new variables. When the point symmetries of the reduced system are computed, the form which the symmetries take in the original system can be determined from (2.6). Since τ is determined as its derivative with respect to time, the symmetry of the original system must necessarily be nonlocal unless the derivative is an exact differential. We note in passing that there is no inherent restriction on the nature of the symme-

tries. They could equally be contact or generalized symmetries and the same considerations would apply. The only requirement is that τ be a simple integral, not that the integrand be a point function. However, for the purposes of this paper we confine our attention to point symmetries and the integrand in τ to a point function.

In addition to the nonlocal symmetries which may be collected by this procedure the reduced system will have as point symmetries those symmetries of the original system which have the correct Lie bracket with the symmetry ∂_t which is at the basis of the reduction of order outlined above. Thus, if G is a symmetry of the original system and

$$[G,\partial_t]=\lambda\partial_t, \tag{2.7}$$

G will, when expressed in the appropriate coordinates, be a point symmetry of the reduced system whereas, if

$$[G,\partial_t]\neq\lambda\partial_t, \tag{2.8}$$

G will not be a point symmetry of the original system but an exponential nonlocal symmetry.[20] Consequently there is the potential for a loss of symmetry in the reduction process just as there is the hope of an increase in the total number of symmetries, both point and nonlocal, known for the original system.

III. LIE POINT SYMMETRIES OF THE REDUCED KEPLER PROBLEM

The Lagrangian for the two-dimensional Kepler problem is

$$L=\frac{1}{2}(\dot r^2+r^2\dot\theta^2)+\frac{\mu}{r} \tag{3.1}$$

in plane polar coordinates, and the two equations of motion are

$$\ddot r-r\dot\theta^2=-\frac{\mu}{r^2}, \tag{3.2}$$

$$r\ddot\theta+2\dot r\dot\theta=0. \tag{3.3}$$

We introduce the new variables and their time derivatives

$$w_1=r,\quad \dot w_1=w_3,$$

$$w_2=\theta,\quad \dot w_2=w_4,$$

$$w_3=\dot r,\quad \dot w_3=w_1w_4^2-\frac{\mu}{w_1^2}, \tag{3.4}$$

$$w_4=\dot\theta,\quad \dot w_4=-\frac{2w_3w_4}{w_1}.$$

In accordance with the development in the preceding section we select w_2 to be the new independent variable y. The left-hand side of (3.4) leads to the reduced system

$$\frac{\mathrm{d}w_1}{\mathrm{d}y}=\frac{w_3}{w_4}, \tag{3.5}$$

$$\frac{dw_3}{dy} = w_1 w_4 - \frac{\mu}{w_1^2 w_4} \tag{3.6}$$

$$\frac{dw_4}{dy} = -\frac{2w_3}{w_1}. \tag{3.7}$$

From (3.5) we have $w_3 = w_4 w_1'$, where the prime denotes differentiation with respect to the new independent variable, y, and we replace (3.7) by

$$\frac{dw_4}{dy} = -\frac{2w_4 w_1'}{w_1}. \tag{3.8}$$

In (3.6) we replace w_3 by $w_4 w_1'$ to obtain

$$w_4 w_1'' - \frac{w_4 w_1'^2}{w_1} = w_1 w_4 - \frac{\mu}{w_1^2 w_4}. \tag{3.9}$$

By our replacement of w_3 we have not precisely decided that the variables u_1 and u_2 are to be w_1 and w_4. If we do make this identification, we obtain a system of two equations, one of the second order and one of the first order, *viz*.

$$u_1'' = 2\frac{u_1'^2}{u_1} + u_1 - \frac{\mu}{u_1^2 u_2^2}, \tag{3.10}$$

$$u_2' = -2\frac{u_1' u_2}{u_1}. \tag{3.11}$$

We observe that (3.11) is trivially integrated to give $u_1^2 u_2$ as a constant. [This is a consequence, naturally, of the symmetry ∂_θ of the original system (3.2) and (3.3) which is a reflection of the fact that θ is an ignorable coordinate.] Consequently we may just as well define our new variables to be

$$u_1 = w_1 \quad \text{and} \quad \tilde{u}_2 = u_1^2 u_2 \tag{3.12}$$

so that the system of equations we are to consider is

$$\begin{aligned} u_1'' &= 2\frac{u_1'^2}{u_1} + u_1 - \frac{\mu u_1^2}{\tilde{u}_2^2}, \\ \tilde{u}_2' &= 0. \end{aligned} \tag{3.13}$$

Hereafter we drop the tilde.

We calculate the Lie point symmetries of the system (3.13) using the well-known interactive program developed by Nucci[19] and obtain the symmetries

$$
\begin{aligned}
X_1 &= \partial_y, \\
X_2 &= 2u_1\partial_{u_1} + u_2\partial_{u_2}, \\
X_3 &= u_1(\mu u_1 - u_2^2)\partial_{u_1}, \\
X_4 &= u_1^2 \cos y\, \partial_{u_1}, \\
X_5 &= -u_1^2 \sin y\, \partial_{u_1}, \\
X_6 &= (\mu u_1 - u_2^2)\cos y\, \partial_y + u_1(2\mu u_1 - u_2^2)\sin y\, \partial_{u_1}, \\
X_7 &= -(\mu u_1 - u_2^2)\sin y\, \partial_y + u_1(2\mu u_1 - u_2^2)\cos y\, \partial_{u_1}, \\
X_8 &= u_2^2 \cos 2y\, \partial_y - u_1(\mu u_1 - u_2^2)\sin 2y\, \partial_{u_1}, \\
X_9 &= u_2^2 \sin 2y\, \partial_y + u_1(\mu u_1 - u_2^2)\cos 2y\, \partial_{u_1}.
\end{aligned}
\tag{3.14}
$$

Some of these symmetries are readily identified, but not many of them. Clearly X_1 represents the rotational invariance of the system and constitutes the subalgebra, so(2), of the original system of equations. In X_2 we recognize the rescaling symmetry closely associated with the Laplace–Runge–Lenz vector.

The other symmetries are not so easy to identify without making some calculation. To obtain the form of the symmetries in the original coordinates we must make use of (2.6). If we write the symmetry in the original coordinates as

$$
G = \tau\partial_t + \eta\partial_r + \zeta\partial_\theta, \tag{3.15}
$$

in terms of the new variables, the symmetry has the form

$$
\tilde{G} = \zeta\partial_y + \eta\partial_{u_1} + \left[\dot{\zeta} + \left(\frac{2\eta}{r} - \dot{\tau}\right)\dot{\theta}\right] r^2\partial_{u_2}, \tag{3.16}
$$

where the coefficient functions are all expressed in terms of the original variables. The calculations are not particularly interesting and we simply list the symmetries. They are

$$X_1=\partial_\theta,$$

$$X_2=3t\partial_t+2r\partial_r,$$

$$X_3=2\left[\mu\int r^2\,\mathrm{d}t-L^2t\right]\partial_t+\mu r(r^2-L^2)\partial_r,$$

$$X_4=2\int r\cos\theta\,\mathrm{d}t\partial_t+r^2\cos\theta\partial_r,$$

$$X_5=2\int r\sin\theta\,\mathrm{d}t\partial_t+r^2\sin\theta\partial_r, \tag{3.17}$$

$$X_6=\int\left[(3\mu r-L^2)\sin\theta+\mu\frac{\dot r}{\dot\theta}\cos\theta\right]\mathrm{d}t\,\partial_t+r\sin\theta(2\mu r-L^2)\partial_r+\cos\theta(\mu r-L^2)\partial_\theta,$$

$$X_7=\int\left[(3\mu r-L^2)\cos\theta-\mu\frac{\dot r}{\dot\theta}\sin\theta\right]\mathrm{d}t\,\partial_t+r\cos\theta(2\mu r-L^2)\partial_r-\sin\theta(\mu r-L^2)\partial_\theta,$$

$$X_8=2\mu\int r\sin 2\theta\,\mathrm{d}t\partial_t+r(\mu r-L^2)\sin 2\theta\partial_r-L^2\cos 2\theta\partial_\theta,$$

$$X_9=2\mu\int r\cos 2\theta\,\mathrm{d}t\,\partial_t+r(\mu r-L^2)\cos 2\theta\partial_r+L^2\sin 2\theta\partial_\theta,$$

so that we see that we lost only the time translation symmetry in the reduction of order and therefore gained six additional symmetries.

IV. THE LIE POINT SYMMETRIES OF THE REDUCED KEPLER PROBLEM: FURTHER CONSIDERATIONS

Further interpretation of the Lie point symmetries of the reduced generalized Kepler problem is facilitated by the redefinition of the symmetries given in (3.14). We do not alter the definitions of the first three symmetries, but we shall include them in this new listing for the sake of completeness. We now have the set of symmetries

$$\begin{aligned}
X_1&=\partial_y,\\
X_2&=2u_1\partial_{u_1}+u_2\partial_{u_2},\\
X_3&=u_1(\mu u_1-u_2^2)\partial_{u_1},\\
X_{4\pm}&=X_4\pm iX_5=e^{\pm iy}u_1^2\partial_{u_1},\\
X_{5\pm}&=X_6\mp iX_7=e^{\pm iy}[(\mu u_1-u_2^2)\partial_y\mp u_1(2\mu u_1-u_2^2)\partial_{u_1}],\\
X_{6\pm}&=X_8\pm iX_9=e^{\pm 2iy}[u_2^2\partial_y\pm u_1(\mu u_1-u_2^2)\partial_{u_1}].
\end{aligned} \tag{4.1}$$

We may search for the first integrals/invariants associated with each of these symmetries in the usual way. By way of concrete example we take X_{4+}. The invariants of the first extension of X_{4+}, *viz.*

$$X_{4+}^{[1]}=e^{iy}[u_1^2\partial_{u_1}+(2u_1u_1'+iu_1^2)\partial_{u_1'}], \tag{4.2}$$

are found from the associated Lagrange's system

$$\frac{\mathrm{d}y}{0}=\frac{\mathrm{d}u_1}{u_1^2}=\frac{\mathrm{d}u_2}{0}=\frac{\mathrm{d}u_1'}{2u_1u_1'+iu_1^2} \tag{4.3}$$

and are

$$\alpha=y,\quad \beta=u_2,\quad \text{and}\quad \gamma=\frac{u_1'+iu_1}{u_1^2}, \tag{4.4}$$

where the first two are by inspection and the third comes from the solution of the second and fourth of (4.3). The integral/invariant is a function of these three arguments and is found by demanding that the total derivative with respect to y be zero when the differential equations (3.13) are taken into account. We obtain the associated Lagrange system

$$\frac{\mathrm{d}\alpha}{1}=\frac{\mathrm{d}\beta}{0}=\frac{\mathrm{d}\gamma}{-i\gamma-\mu/\beta^2} \tag{4.5}$$

which gives β as one of the characteristics and

$$\omega_+=e^{iy}\left(\frac{u_1'+iu_1}{u_1^2}-\frac{i\mu}{u_2^2}\right) \tag{4.6}$$

as the second characteristic. Both β and ω are first integrals/invariants of the system (3.13). Naturally we recognize the former as the angular momentum.

If we perform the same calculation with X_{4-}, we obtain a similar result, *viz.*

$$\omega_-=e^{-iy}\left(\frac{u_1'-iu_1}{u_1^2}+\frac{i\mu}{u_2^2}\right). \tag{4.7}$$

The two can be combined into one convenient expression given by

$$J_\pm=e^{\pm iy}(v'\mp iv),\quad v=\mu-\frac{u_2^2}{u_1}, \tag{4.8}$$

where we have made use of the constancy of u_2 to write $J_\pm=u_2^2\omega_\pm$. For the system (3.13) $J_\pm$ are two invariants and for the original system (3.1) and (3.2), the two components of the first integral known as the Laplace–Runge–Lenz vector, written in complex form.

In (4.8) we introduced a new variable v. If we use this variable instead of u_1 in the system (3.13), we obtain the system

$$\begin{aligned} v''+v&=0,\\ u_2'&=0 \end{aligned} \tag{4.9}$$

so that the natural variable which arises from the invariants of $X_{4\pm}$ is a variable which further simplifies the reduced system. This is an interesting phenomenon for we are obtaining natural variables as we progress through the process of determining the symmetries of the reduced equation. It behooves us to rewrite the symmetries in terms of this new variable. We find that

$$
\begin{aligned}
X_1 &= \partial_{u_2}, \\
X_2 &= \partial_y, \\
X_3 &= v\,\partial_v \bmod(u_2^2), \\
X_{4\pm} &= e^{\pm iy}\partial_v \bmod(u_2^2), \\
X_{6\pm} &= e^{\pm 2iy}[\partial_y \pm iv\,\partial_v] \bmod(u_2^2), \\
X_{8\pm} &= e^{\pm iy}[v\,\partial_y \pm iv^2\partial_v] \bmod(u_2^2)
\end{aligned}
\tag{4.10}
$$

which is certainly a simpler appearance.

In the simpler form presented in (4.10) we see that the calculation of the integrals/invariants is simpler. For example, if we take $X_{6\pm}$, the first set of characteristics comes from the solutions of the associated Lagrange system

$$
\frac{dy}{1} = \frac{dv}{iv} = \frac{dv'}{-iv' - 2v}. \tag{4.11}
$$

The characteristics are

$$
\alpha = ve^{\mp iy} \quad \text{and} \quad \beta = vv' \mp iv^2. \tag{4.12}
$$

The condition for the function to be an invariant (in this case not a first integral of the reduced system since the independent variable is explicitly present) is that these two characteristics satisfy the first order equation

$$
\frac{d\alpha}{\alpha} = \frac{d\beta}{\beta}, \tag{4.13}
$$

whence the invariants are given by

$$
I_\pm = \frac{\beta}{\alpha} = (v' \mp iv)e^{\pm iy} \tag{4.14}
$$

which are, of course, the two components of the Laplace–Runge–Lenz vector. We note that there is also a first integral associated with each of $X_{6\pm}$ and this is the angular momentum which, in these coordinates, is an ignorable coordinate.

For the sake of completeness we list the first integrals/invariants associated with the symmetries listed in (4.10). They are given in the same order and with the same subscripts as the symmetries are listed:

$$
\begin{aligned}
&G_1 \quad I_1 = L, \quad I_2 = J_+J_- = 2L^2E + \mu^2, \\
&G_2 \quad I_1 = L, \quad I_2 = \frac{J_+}{J_-}, \\
&G_3 \quad I_1 = L, \quad I_2 = \frac{J_+}{J_-}, \\
&G_{4\pm} \quad I_1 = L, \quad I_{2\pm} = J_\pm, \\
&G_{5\pm} \quad I_1 = L, \quad I_{2\pm} = \frac{J_\pm}{J_\mp}, \\
&G_{6\pm} \quad I_1 = L, \quad I_{2\pm} = J_\pm.
\end{aligned}
\tag{4.15}
$$

We note that in the second integral associated with G_1 we have expanded the product into the standard expression relating the square of the magnitude of the Laplace–Runge–Lenz vector with the energy and the angular momentum. For the second integral of $G_{5\pm}$ we could have equally written $I_2=J_+/J_-$, but we chose to maintain the pattern of $\pm$.

V. THE KEPLER PROBLEM WITH DRAG

In the introduction we referred to the model proposed by Danby[14] for the motion of a low altitude satellite subjected to a resistive force due to the Earth's atmosphere described by the equation of motion

$$\ddot{\mathbf{r}}+\frac{\alpha\dot{\mathbf{r}}}{r^2}+\frac{\mu\mathbf{r}}{r^3}=0, \tag{5.1}$$

where α and μ are constants. Since the direction of the angular momentum is a constant, we may analyze the problem in two dimensions using plane polar coordinates (r,θ). The two equations of motion are

$$\ddot{r}-r\dot{\theta}^2+\frac{\alpha\dot{r}}{r^2}+\frac{\mu}{r^2}=0, \tag{5.2}$$

$$r\ddot{\theta}+2\dot{r}\dot{\theta}+\frac{\alpha\dot{\theta}}{r}=0. \tag{5.3}$$

We introduce the new variables and their time derivatives

$$\begin{gathered} w_1=r, \quad \dot{w}_1=w_3, \\ w_2=\theta, \quad \dot{w}_2=w_4, \\ w_3=\dot{r}, \quad \dot{w}_3=w_1w_4^2-\frac{\alpha w_3}{w_1^2}-\frac{\mu}{w_1^2}, \\ w_4=\dot{\theta}, \quad \dot{w}_4=-\frac{2w_3w_4}{w_1}-\frac{\alpha w_4}{w_1^2}. \end{gathered} \tag{5.4}$$

We again select w_2 to be the new independent variable y. The right-hand side of (5.4) becomes

$$\frac{\mathrm{d}w_1}{\mathrm{d}y}=\frac{w_3}{w_4}, \tag{5.5}$$

$$\frac{\mathrm{d}w_3}{\mathrm{d}y}=w_1w_4-\frac{\alpha w_3}{w_1^2w_4}-\frac{\mu}{w_1^2w_4}, \tag{5.6}$$

$$\frac{\mathrm{d}w_4}{\mathrm{d}y}=-\frac{2w_3}{w_1}-\frac{\alpha w_4}{w_1^2}. \tag{5.7}$$

In this case the choice of (5.5) to eliminate w_3 is obvious and we obtain the two-dimensional system

$$w_1''w_4+w_1'w_4'=w_1w_4-\frac{\alpha w_1'}{w_1^2}-\frac{\mu}{w_1^2w_4}, \tag{5.8}$$

$$w_4' = -\frac{2w_1' w_4}{w_1} - \frac{\alpha}{w_1^2}. \tag{5.9}$$

In the case of (5.9) we can easily manipulate it to obtain

$$(w_1^2 w_4)' = \alpha \Leftrightarrow w_1^2 w_4 = -\alpha y + \beta, \tag{5.10}$$

where β is a constant of integration, which indicates that the angular momentum is not conserved. We have a choice of defining the new variable u_2 as either $w_1^2 w_4$, which is not conserved but is a convenient variable for manipulations, or $w_1^2 w_4 + \alpha y$, which is conserved but is not a convenient variable for manipulation. For the present we make the former choice. In Eq. (5.8) we make use of (5.10) to eliminate w_4 and w_4' to obtain

$$\left(-\frac{1}{w_1}\right)''(\alpha y+\beta)^2 + 2\alpha\left(-\frac{1}{w_1}\right)'(\alpha y+\beta) + \left(-\frac{1}{w_1}\right)(\alpha y+\beta)^2 + \mu = 0. \tag{5.11}$$

We introduce the second new variable as

$$u_1 = -\frac{\alpha y+\beta}{w_1} \tag{5.12}$$

so that (5.11) becomes

$$u_1'' + u_1 = -\frac{\mu}{\alpha y+\beta}. \tag{5.13}$$

Clearly we could regain the equation of a simple harmonic oscillator by means of the further change of variable $v = u_1 - u_{1ps}$, where u_{1ps} is a particular solution of (5.13). Consequently the Kepler problem with drag differs from the standard Kepler problem in that the second equation of the reduced system, *viz.*

$$u_2' = -\alpha, \tag{5.14}$$

has a nonzero right-hand side. This could be eliminated by now making the second choice mentioned above. Consequently we make a final change of variables

$$\begin{aligned} v_1 &= u_1 - \int \frac{\mu \sin(y-s)\,ds}{\alpha s - \beta}, \\ v_2 &= u_2 + \alpha \end{aligned} \tag{5.15}$$

to obtain the same reduced system (4.9), as we had for the Kepler problem when we introduced the sensible coordinates. Naturally we obtain the same set of symmetries as given in (4.10).

The Lie point symmetries of the reduced system translate into the symmetries

$$\Gamma_1=\left(\int\frac{\mathrm{d}t}{r^2\dot\theta}\right)\partial_t,$$

$$\Gamma_2=2\left[\int\frac{(\alpha r+I')\mathrm{d}t}{r(\alpha\theta-\beta)}\right]\partial_t+\left[\frac{\alpha r+I'}{\alpha\theta-\beta}\right]\partial_r-\partial_\theta,$$

$$\Gamma_3=\left[2t+\int\frac{I\,\mathrm{d}t}{r(\alpha\theta-\beta)}\right]\partial_t+\left(r+\frac{I}{\alpha\theta-\beta}\right)\partial_r,$$

$$\Gamma_{4\pm}=2\left[\int\frac{e^{\pm i\theta}\,\mathrm{d}t}{r(\alpha\theta-\beta)}\right]\partial_t+\left[\frac{e^{\pm i\theta}}{\alpha\theta-\beta}\right]\partial_r, \tag{5.16}$$

$$\Gamma_{5\pm}=2\left\{\int e^{\pm i\theta}\left[\frac{\alpha r+I}{r(\alpha\theta-\beta)}\mp\left(2+\frac{I}{r(\alpha\theta-\beta)}\right)\right]\mathrm{d}t\right\}\partial_t+e^{\pm 2i\theta}\left[\frac{\alpha r+I'}{\alpha\theta-\beta}\mp i\left(r+\frac{I}{\alpha\theta-\beta}\right)\right]\partial_r$$
$$-e^{\pm 2i\theta}\partial_\theta,$$

$$\Gamma_{6\pm}=\left\{\int e^{\pm i\theta}\left[(r(\alpha\theta-\beta)+I)\left(\frac{\alpha r+I'}{r(\alpha\theta-\beta)}\mp i\left(3+\frac{2I}{r(\alpha\theta-\beta)}\right)\right)+\alpha r+I'+\frac{\dot r}{\dot\theta}(\alpha\theta-\beta)\right]\mathrm{d}t\right\}\partial_t$$
$$+e^{\pm i\theta}(r(\alpha\theta-\beta)+I)\left[\frac{\alpha r+I'}{\alpha\beta-\beta}\mp i\left(r+\frac{I}{\alpha\theta-\beta}\right)\right]\partial_r-e^{\pm i\theta}[r(\alpha\theta-\beta)+I]\partial_\theta,$$

where I stands for the integral introduced in (5.15a) and I' its derivative with respect to θ, for the original system (5.1).

In addition to the symmetries listed in (5.16) Eq. (5.1) has the point symmetry ∂_t which was the symmetry used for the reduction of order. Consequently we can conclude that algebraically the Kepler problem and the Kepler problem with drag are identical.

In the above derivation we have followed a line of development in which observation and experience play major roles in reducing the system (5.4) to the simplest possible form. The need for both are considerably obviated when the interactive Lie symmetry solver devised by Nucci[19] is used. The equations to be solved suggest the appropriate variables since they are the characteristics of the partial differential equations to be solved. We illustrate this in the case of the variable related to angular momentum with the following tableau:

$$w_2=y,$$

$$w_3=\frac{\mathrm{d}w_1}{\mathrm{d}y}w_4,$$

$w_4=u_1,\quad w_1=u_2,$

$$\dot u_1=-2\frac{\dot u_2u_1}{u_2}-\frac{\alpha}{u_2^2},$$

$$\ddot u_2=\frac{(u_2^2+2\dot u_2^2)u_1^2u_2-\mu}{u_1^2u_2^2},$$

$$w_4=\frac{w_5}{w_1^2},$$

$w_5=u_1, \quad w_1=u_2,$

$$\dot{u}_1=-\alpha,$$

$$\ddot{u}_2=\frac{-\mu u_2^3+u_1^2u_2^2+2u_1^2\dot{u}_2^2}{u_1^2u_2},$$

$$w_5=w_6-\alpha y,$$

$w_6=u_1, \quad w_1=u_2,$

$$\dot{u}_1=0,$$

$$\ddot{u}_2=\frac{(\alpha y-u_1)^2(u_2^2+2\dot{u}_2^2)-\mu u_2^3}{(\alpha y-u_1)^2u_2}.$$

(We have used w_4, w_5, and w_6 to successively define a new variable which is a candidate for selection as u_1. We are not introducing additional variables.)

VI. THE GENERALIZATION OF THE KEPLER PROBLEM WITH DRAG

Equation (1.4) has, in two dimensions, the two components of the equation of motion

$$\begin{aligned}\ddot{r}&=r\dot{\theta}^2+\frac{1}{2}\left(\frac{g'}{g}+\frac{3}{r}\right)\dot{r}^2-\mu g r,\\ \ddot{\theta}&=\frac{\dot{r}\dot{\theta}}{2r}\left(\frac{g'}{g}-\frac{1}{r}\right).\end{aligned} \tag{6.1}$$

We introduce the variables w_i, $i=1,4$ as above. Now the system of first order equations in these variables is

$$\begin{aligned}\dot{w}_1&=w_3,\\ \dot{w}_2&=w_4,\\ \dot{w}_3&=w_1w_4^2+\frac{1}{2}\left(\frac{g'}{g}+\frac{3}{r}\right)w_3^2-\mu g w_1,\\ \dot{w}_4&=\frac{w_3w_4}{2w_1}\left(\frac{g'}{g}-\frac{1}{w_1}\right).\end{aligned} \tag{6.2}$$

As the new independent variable we take again $y=w_2$. The system (6.2) becomes

$$\begin{aligned}\frac{dw_1}{dy}&=\frac{w_3}{w_4}\Leftrightarrow w_3=w_4w_1',\\ \frac{dw_3}{dy}&=w_1w_4+\frac{1}{2}\left(\frac{g'}{g}+\frac{3}{r}\right)w_4w'^2_1-\mu g\frac{w_1}{w_4},\\ \frac{dw_4}{dy}&=\frac{w_3}{2w_1}\left(\frac{g'}{g}w_1-1\right).\end{aligned} \tag{6.3}$$

When we substitute for w_3, the third of (6.3) is easily integrated to give

$$A=\left(\frac{w_1}{g}\right)^{1/2} w_4, \tag{6.4}$$

where A is an arbitrary constant of integration. The right-hand side is the same function as the characteristic of the parabolic partial differential equation produced when the system (6.3) is analyzed using the code developed by Nucci[19] and this is an appropriate choice for one of the variables. We take $u_1=w_1=r$ and $u_2=\dot{\theta}(r/g)^{1/2}$ so that with the elimination of w_3 from (6.3) we have, after a certain amount of simplification, the system of two equations

$$\begin{gathered} u_2u_1''=u_1u_2+2\frac{u_2u_1'^2}{u_1}-\frac{\mu u_1^2}{u_2}, \\ u_2'=0. \end{gathered} \tag{6.5}$$

We observe that (6.5) is precisely the system (3.13) and so we immediately introduce the new variable $v=\mu-u_2^2/u_1$ to obtain the simpler system (4.9) which has the symmetries listed in (4.10). In terms of the original variables these symmetries are

$$\begin{gathered} X_1=\partial_\theta, \\ X_2=-\left(\int \frac{g'r}{g}\,\mathrm{d}t\right)\partial_t+2r\partial_r, \\ X_3=\frac{1}{2}\left[\int (\mu rg-r\dot{\theta}^2)\left(\frac{1}{r}-\frac{g'}{g}\right)\mathrm{d}t\right]\partial_t+(\mu rg-r\dot{\theta}^2)\partial_r, \\ X_{4\pm}=\frac{1}{2}\left[\int e^{\pm i\theta}(g-rg')\mathrm{d}t\right]\partial_t+[e^{\pm i\theta}rg]\partial_r, \\ X_{5\pm}=\frac{1}{2}\left\{\int e^{\pm i\theta}\left[\frac{gr}{\dot{\theta}^2}\left(\mu-\frac{\dot{\theta}^2}{g}\right)^2\left(\frac{1}{r}-\frac{g'}{g}\right)\pm 2i\left(\mu-\frac{\dot{\theta}^2}{g}\right)+\frac{2\dot{r}\dot{\theta}}{gr}\right]\mathrm{d}t\right\}\partial_t \\ +\left\{e^{\pm i\theta}\frac{gr}{\dot{\theta}^2}\left(\mu-\frac{\dot{\theta}^2}{g}\right)^2\right\}\partial_r+\left\{e^{\pm i\theta}\left(\mu-\frac{\dot{\theta}^2}{g}\right)\right\}\partial_\theta, \\ X_{6\pm}=\pm\frac{1}{2}i\left\{\int e^{\pm 2i\theta}\left(3+\frac{rg'}{g}+\frac{\mu(g-rg')}{\dot{\theta}^2}\right)\mathrm{d}t\right\}\partial_t\pm i\left\{e^{\pm 2i\theta}r\left(\frac{\mu g}{\dot{\theta}^2}-1\right)\right\}\partial_r+e^{\pm 2i\theta}\partial_\theta. \end{gathered} \tag{6.6}$$

VII. AN EXAMPLE WITH AN ANGLE-DEPENDENT FORCE

Sen[21] obtained conserved quantities similar to those of the Kepler problem for the Hamiltonian

$$H=\frac{1}{2}\left(p_r^2+\frac{p_\theta}{r^2}\right)-\frac{\mu}{r}-\frac{\alpha\sin[\frac{1}{2}(\theta-\beta)]}{r^{1/2}} \tag{7.1}$$

in which the potential depends upon the azimuthal angle and μ, α, and β are constants. Subsequently Gorringe and Leach[22] showed that the equation of motion

$$\ddot{\mathbf{r}}+g\hat{\mathbf{r}}+h\hat{\boldsymbol{\theta}}=0, \tag{7.2}$$

where

$$g=\frac{U''(\theta)+U(\theta)}{r^2}+2\frac{V'(\theta)}{r^{3/2}} \quad \text{and} \quad h=\frac{V(\theta)}{r^{3/2}}, \tag{7.3}$$

or

$$\ddot{r}-r\dot{\theta}^2+g=0, \tag{7.4}$$

$$r\ddot{\theta}+2\dot{r}\dot{\theta}+h=0 \tag{7.5}$$

in plane polar coordinates, could be solved for the orbit equation in a manner similar to that of the Kepler problem since it also possessed a Laplace–Runge–Lenz vector. The only restrictions on the functions $U(\theta)$ and $V(\theta)$ are that they be differentiable.

We make the same reduction as in the previous cases to arrive at the two- dimensional system

$$w_1w_1''w_4^2-2w_1'^2w_4^2-w_1^2w_4^2=w_1'h-gw_1, \tag{7.6}$$

$$w_1w_4w_4'+2w_1'w_4^2=-h, \tag{7.7}$$

where $w_1=r$ and $w_4=\dot{\theta}$ as before.

The Laplace–Runge–Lenz vector for Eq. (7.2) is[22]

$$\mathbf{J}=\dot{\mathbf{r}}\times\mathbf{L}-U\hat{\mathbf{r}}-[U'+2r^{1/2}V]\hat{\boldsymbol{\theta}}, \tag{7.8}$$

where $\mathbf{L}:=\mathbf{r}\times\dot{\mathbf{r}}$ is the angular momentum. If we take the two Cartesian components of $\mathbf{J}$, *viz*, J_x and J_y, and combine them, we obtain

$$\begin{aligned}J_\pm&=-J_x\pm iJ_y=[(r^3\dot{\theta}^2-U)\pm i(-r^2\dot{r}\dot{\theta}-U'-2r^{1/2}V)]e^{\pm i\theta}\\&=[(w_1^3w_4^2-U)\pm i(-w_1^2w_4w_3-U'-2w_1^{1/2}V)]e^{\pm iy}\\&=\left[\left(\frac{L^2}{w_1}-U\right)\pm i\left(\frac{L^2}{w_1}-U\right)'\right]e^{\pm iy}.\end{aligned} \tag{7.9}$$

We see that, when we write the components of the Laplace–Runge–Lenz vector in this form, we have the same structure as for the standard Kepler problem. (One could call the components the Ermanno–Bernoulli constants in honor of the original discoverers of these conserved quantities.) Immediately we have the clue to the identification of one of the new variables and we let

$$u_1=w_1^3w_4^2-U=\frac{L^2}{w_1}-U, \tag{7.10}$$

so that the Ermanno–Bernoulli constants for (7.2) are

$$J_\pm=(u_1\pm iu_1')e^{\pm iy}. \tag{7.11}$$

The identification of the second variable is more delicate. Equation (7.7) can be written in terms of the magnitude of the angular momentum, L, as

$$LL'=-w_1^{3/2}V(y) \tag{7.12}$$

and, when (7.10) is taken into account, this becomes

$$0=\frac{L'}{L^2}+\frac{V(y)}{(u_1+U(y))^{3/2}}. \tag{7.13}$$

From (7.11) we have

$$u_1=\tfrac{1}{2}(J_+e^{-iy}+J_-e^{+iy})=J\cos y, \tag{7.14}$$

since $J_-=J_+^*$ and we have written $J=|J_+|=|J_-|$. Then we can use (7.13) to define a new variable

$$u_2=\frac{1}{L}-\int\frac{V(y)\mathrm{d}y}{(J\cos y+U(y))^{3/2}}. \tag{7.15}$$

The reduced system of equations is

$$\begin{aligned} &u_1''+u_1=0,\\ &u_2'=0 \end{aligned} \tag{7.16}$$

which is just the reduced system we obtained for the standard Kepler problem and so it has the symmetries given in (7.10). These translate to

$$\begin{aligned}
\Gamma_1&=3\left(\int r^2\dot\theta\,\mathrm{d}t\right)\partial_t+2r^3\dot\theta\partial_r,\\
\Gamma_2&=\left[\int\left(\frac{2U'}{r^2\dot\theta^2}+\frac{3Vr^2\dot\theta}{U+J\cos\theta}\right)\mathrm{d}t\right]\partial_t+\left[\frac{U'}{r^2\dot\theta^2}+\frac{2Vr^3\dot\theta}{U+J\cos\theta}\right]\partial_r-\partial_\theta,\\
\Gamma_3&=2\left[t-\int\frac{U\mathrm{d}t}{r^3\dot\theta^2}\right]\partial_t+\left[r-\frac{U}{r^2\dot\theta^2}\right]\partial_r,\\
\Gamma_{4\pm}&=2\left(\int\frac{e^{\pm i\theta}}{r^3\dot\theta^2}\mathrm{d}t\right)\partial_t+\frac{e^{\pm i\theta}}{r^2\dot\theta^2}\partial_r,\\
\Gamma_{5\pm}&=\left\{\int e^{\pm 2i\theta}\left[\frac{3Vr^2\dot\theta}{U+J\cos\theta}+\frac{2(U'\mp iU)}{r^3\dot\theta^2}\right]\mathrm{d}t\right\}\partial_t\\
&\quad-e^{\pm 2i\theta}\left[\frac{2Vr^3\dot\theta}{U+J\cos\theta}\pm ir+\frac{U'\mp iU}{r^2\dot\theta}\right]\partial_r+e^{\pm 2i\theta}\partial_\theta,\\
\Gamma_{6\pm}&=\left\{\int e^{\pm i\theta}\left[2U'\left(1-\frac{U}{r^3\dot\theta^2}\right)-3(r^2\dot r\dot\theta\pm ir^3\dot\theta^2-2r^{1/2}V\mp iU)\right]\mathrm{d}t\right\}\partial_t\\
&\quad-e^{\pm i\theta}\left[\frac{2Vr^2\dot\theta}{U+J\cos\theta}(U'\pm i(r^3\dot\theta^2-U))\left(1-\frac{U}{r^3\dot\theta^2}\right)\right]\partial_r+e^{\pm i\theta}[r^3\dot\theta^2-U]\partial_\theta,
\end{aligned} \tag{7.17}$$

for the original system (7.2). In addition there is the symmetry, ∂_t, which was used for the reduction of order.

Again we see the very close connection between the structure of the Ermanno–Bernoulli constants and the appropriate variables for the reduction of order.

VIII. CONCLUSIONS AND OBSERVATIONS

For the Kepler problem in three dimensions we obtain the same symmetries as in (3.14) with the addition of

$$X_{10}=\partial_{u_3}, \tag{8.1}$$

where u_3 is the azimuthal angle, ϕ. Consequently our analysis in the lower dimensional configurational space is justified by the result that the additional dimension simply adds another ignorable coordinate to the original system and so a trivial first order ordinary differential equation to the reduced system.

In this paper we have examined the process of reduction of order introduced by Nucci[2] to derive the additional nonlocal symmetries required for the complete specification of the Kepler problem in the context not only of the Kepler problem but also in some generalizations which have appeared in the literature and which possess certain characteristics in common with the Kepler problem. In particular we have found that the possession of a conserved vector similar to that of the Laplace–Runge–Lenz vector, whether or not the magnitude of the angular momentum is conserved, leads in all cases to a reduced system consisting of the simple harmonic oscillator and a trivial first order ordinary differential equation. In the reduced system the Lie point symmetries can be written in a fairly simple fashion. When translated to the original system, they are not so simple in appearance. However, one can determine the algebraic properties of the several systems studied from those of the reduced system provided one adds the Lie point symmetry used in the reduction of order, *viz.* ∂_t. The Lie algebra of Lie point symmetries of the reduced system is $A_1 \oplus \mathrm{sl}(3,R)$ and consequently the original systems each have the algebra $2A_1 \oplus \mathrm{sl}(3,R)$ since the symmetry used in the reduction of order has a zero Lie bracket with the other symmetries.

Considering the results obtained in this paper we can envisage a reversal of the procedure. Instead of taking a system which has a vector of the type of a Laplace–Runge–Lenz vector we could simply commence with the reduced system and introduce some transformation of the two ''reduced'' variables and an *Ansatz* on the relationship defining the variable we have been denoting by w_3. One could expect to obtain many ''lame ducks.'' However, there is one aspect which has the potential for some application. Many of the systems for which Laplace–Runge–Lenz vectors have been obtained do not have a known Hamiltonian representation. By the procedures of transformations treated in this paper one could seek to commence with the Hamiltonian of the Kepler problem and find Hamiltonians for the other systems. In the case of the system (7.3) the existence of a Hamiltonian has been shown only in the restricted case treated by Sen. The attractions for the applications in quantum mechanics are obvious.

In the reduced system the components of the Laplace–Runge–Lenz vector, the Ermanno–Bernoulli constants, are simply the two linearly independent first order invariants of the simple harmonic oscillator. In fact, in the reduced system we have a separation in the new variables of the Ermanno–Bernoulli constants in the second order equation and the conservation of a generalized angular momentum in the first order equation. We recall that for higher dimensional oscillators there exist the conserved components of the Jauch–Hill–Fradkin tensor[23,24] which play an important role in the description of the orbit and their time-dependent counterparts which give the actual trajectory of the particle.[25–27] Naturally these tensors have no role to play in the type of problem considered in this paper. However, it is intriguing to ponder the identity that the corresponding problem of Kepler type would have. (For a recent contribution to this more general problem see Ref. 28.)

(Received 9 August 2000; accepted for publication 26 September 2000)

On the basis of Bethe ansatz solution of bosons with δ-function interaction in a one-dimensional potential well, the thermodynamics equilibrium of the system in finite temperature is studied by using the strategy of Yang and Yang. The thermodynamics quantities, such as specific heat, etc., are obtained for the cases of the strong coupling and weak coupling limits respectively. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1331562]

I. INTRODUCTION

There has been much interest recently in the study of strongly correlated electronic systems in one dimension. This is because not only various nonperturbative methods[1–10] are applicable to models in one dimension but also several photoemission experiments for one-dimensional compounds of alkali-metal copper oxides[11–13] are carried out. Bosons with δ-function interaction in one dimension is a simple but interesting model. It was solved in Ref. 14 under the periodic boundary condition, in Refs. 15 and 16 under the boundary condition of potential well of infinite depth, and in Ref. 17 under that of potential well of finite depth. A strategy for studying the thermodynamics of exactly solvable models was proposed in Ref. 18 when discussing the solution of Ref. 14. In the present paper, using the strategy of Ref. 18 we study the thermodynamics on the basis of the Bethe-ansatz solution of Ref. 17. After we recall the model Hamiltonian and the Bethe-ansatz equation we study the thermal equilibrium in Sec. II. The formal expressions of free energy and pressure are obtained. In Sec. III we consider the strong coupling limit and obtain the quasimomentum distribution and specific heat explicitly. In Sec. IV the case of weak coupling limit is discussed extensively.

II. THERMAL EQUILIBRIUM AT FINITE TEMPERATURE

The Hamiltonian of bosons in a one-dimensional potential well of finite depth with δ interaction reads

$$H=-\sum_{i=1}^{N}\frac{\partial^2}{\partial x_i^2}+\sum_{i=1}^{N}V(x_i)+2c\sum_{i>j=1}^{N}\delta(x_i-x_j), \tag{1}$$

where

$$V(x_i)=\begin{cases}0 & |x|<L/2,\\ V_0^2 & |x|>L/2.\end{cases} \tag{2}$$

Eq. (1) is the first quantization version of the Gross–Pitaevski[19] equation, which was widely used to study the Bose–Einstein condensation[20] in recent years. The model Hamiltonian (1) was solved by means of Bethe-ansatz method.[17] The logarithm of the Bethe-ansatz equation reads

$$\frac{2\pi}{L}I_j = k_j + \frac{2}{L}\sin^{-1}\left(\frac{k_j}{V_0}\right) + \frac{1}{L}\sum_{l\neq j}\left[\tan^{-1}\left(\frac{k_j+k_l}{c}\right)+\tan^{-1}\left(\frac{k_j-k_l}{c}\right)\right], \tag{3}$$

where the integers I_j play the role of the quantum numbers. Equation (3) is the secular equation to determine the spectrum. Moreover the transcendental equation (3) is difficult to solve directly. Now, we consider the problem in the thermodynamic limit: $N\gg 1$ and $L\gg 1$ with a fixed concentration $D=N/L$ by introducing a ''smooth'' positive-defined density $\overline{\rho}(k)$ describing the distribution of roots and holes[21]

$$\overline{\rho}(k)=\frac{1}{L}\frac{dI(k)}{dk}.$$

Treating k_j as a continuous variable k and differentiating Eq. (3) with respect to k, we get an integral equation

$$2\pi\overline{\rho}(k)=1+\frac{1}{L}\frac{2}{\sqrt{V_0^2-k^2}}+\int dk'\,\overline{\rho}(k')\left[\frac{c}{c^2+(k-k')^2}+\frac{c}{c^2+(k+k')^2}\right]$$
$$-\frac{1}{L}\sum_m\left[\frac{c}{c^2+(k-h_m)^2}+\frac{c}{c^2+(k+h_m)^2}\right], \tag{4}$$

where we have used the replacement

$$\lim_{N,L\to\infty}\frac{1}{L}\sum_{l\neq j}f(k_l)=\int\overline{\rho}(k)f(k)dk-\frac{1}{L}\sum_m f(h_m),$$

in the thermodynamics limit. The summation in the right-hand side runs over ''holes'' (including k_j) which can be written formally as an integral $\int\rho_h(k)f(k)dk$ with $\rho_h(k)=(1/L)\Sigma_m\delta(k-h_m)$. Furthermore, Eq. (4) is written as an integral equation for the density of holes $\rho_h(k)$ and the density of roots $\rho(k)=\overline{\rho}(k)-\rho_h(k)$,

$$2\pi(\rho+\rho_h)=1+\frac{1}{L}\frac{2}{\sqrt{V_0^2-k^2}}+\int dk'\,\rho(k')\left[\frac{c}{c^2+(k-k')^2}+\frac{c}{c^2+(k+k')^2}\right]. \tag{5}$$

The Bethe-ansatz solution is obtained for the case of bounded states (i.e., $\mathrm{Im}\,k_j=0$), so the range of the integration is $[-V_0,V_0]$. In terms of the distribution function of roots, we can write out the energy per particle

$$E/N=D^{-1}\int\rho(k)k^2\,dk, \tag{6}$$

where

$$D=N/L=\int\rho(k)dk. \tag{7}$$

On the basis of the strategy of Ref. 18, the total entropy of the system is obtained

$$S/N=D^{-1}\int[(\rho+\rho_h)\ln(\rho+\rho_h)-\rho\ln\rho-\rho_h\ln\rho_h]dk, \tag{8}$$

where the Boltzmann constant is set to unit.

In the thermal equilibrium, the free energy $\Omega=(E-TS-\mu N)$ should be in minimum. Writing

$$\frac{\rho_h(k)}{\rho(k)}=\exp[\epsilon(k)/T], \tag{9}$$

we obtain from the minimizing requirements, $\delta\Omega=0$, the following equations:

$$\epsilon(k)=-\mu+k^2-\frac{T}{2\pi}\int\left[\frac{c}{c^2+(k-k')^2}+\frac{c}{c^2+(k+k')^2}\right]\ln(1+e^{-\epsilon(k')/T})dk'. \tag{10}$$

Equation (5) is readily written as

$$2\pi(1+e^{\epsilon/T})\rho(k)=1+\frac{1}{L}\frac{2}{\sqrt{V_0^2-k^2}}+\int dk'\,\rho(k')\left[\frac{c}{c^2+(k-k')^2}+\frac{c}{c^2+(k+k')^2}\right]. \tag{11}$$

Principally, Eq. (10) can be solved by iteration and then Eq. (5) can be a Fredholm-type equation for $\rho(k)$.

We would like to mention some points about the parameter μ. If minimizing the Helmholtz free energy $F=E-TS$ under the condition that the concentration D in (7) is a constant, one will have a Lagrangian multiplier. The multiplier function is just the same as the chemical potential μ when considering a grand assemble. So both procedures are equivalent.

Multiplying Eq. (10) with ρD^{-1} and integrating over k, we obtain

$$\mu=D^{-1}\int(k^2-\epsilon)\rho\,dk-\frac{T}{2\pi D}\int\left[2\pi(\rho+\rho_h)-1-\frac{1}{L}\frac{2}{\sqrt{V_0^2-k^2}}\right]\ln(1+e^{-\epsilon/T})dk. \tag{12}$$

The argument k of ρ and ϵ are always omitted in our notions as long as it does not bring about confusion. With the help of Eq. (9), the entropy (8) is rewritten as

$$\frac{S}{N}=D^{-1}\int[(\rho+\rho_h)\ln(1+e^{-\epsilon/T})+\rho\epsilon/T]dk. \tag{13}$$

The Helmholtz free energy per particle is

$$\frac{F}{N}=\frac{1}{D}\int(k^2-\epsilon)\rho\,dk-\frac{T}{D}\int[(\rho+\rho_h)\ln(1+e^{-\epsilon/T})]dk. \tag{14}$$

Comparison of Eq. (12) and Eq. (14) gives rise to

$$F=\mu N-\frac{TL}{2\pi}\int\left[1+\frac{1}{L}\frac{2}{\sqrt{V_0^2-k^2}}\right]\ln(1+e^{-\epsilon/T})dk. \tag{15}$$

Thus the free energy will be obtained once the $\epsilon(k)$ is solved from Eq. (10). As in thermodynamics $F=-PL+\mu N$, the pressure is $P=-(\partial F/\partial L)_T$. It was shown[22] that if ϵ, μ are implicit functions of some thermodynamic quantities x (such as T, L), the derivative of Eq. (15) with respect to x is the same as the partial derivative of Eq. (15) with respect to the explicit variable x. Then it is easy to calculate the pressure in terms of the ϵ, namely,

$$P=\frac{T}{2\pi}\int\left[1+\frac{1}{L}\frac{2}{\sqrt{V_0^2-k^2}}\right]\ln(1+e^{-\epsilon/T})dk. \tag{16}$$

It is formally similar to the results of Ref. 18 except that one more term arising from the boundary condition is involved. Likewise, the entropy is

$$S=\frac{L}{2\pi}\int\left[1+\frac{1}{L}\frac{2}{\sqrt{V_0^2-k^2}}\right]\left[\ln(1+e^{-\epsilon/T})+\frac{\epsilon/T}{1+e^{\epsilon/T}}\right]dk. \tag{17}$$

The other thermal quantities such as specific heat, etc., are also obtainable if one is able to solve $\epsilon(k)$ from Eq. (10). We will calculate them in some special cases in the following sections.

III. STRONG COUPLING LIMIT

It is difficult to obtain an explicit expression of $\epsilon(k)$ from Eq. (10). However, in some special cases, we are able to obtain some plausible results. In the strong coupling limit $c\gg V_0$, Eq. (10) becomes

$$\epsilon(k)=-\mu+k^2-\frac{T}{2\pi}\int\ln[1+e^{(\mu-k'^2)/T}]\frac{d}{dk'}\left[\tan^{-1}\left(\frac{k'-k}{c}\right)+\tan^{-1}\left(\frac{k'+k}{c}\right)\right]dk'. \tag{18}$$

Integrating by part under the consideration of the approximation that $\tan^{-1}(k/c)\simeq k/c$ for $c\gg V_0$, we have

$$\epsilon=-\mu'+k^2, \tag{19}$$

where

$$\mu'=\mu+\frac{2}{\pi c}\int\frac{k'^2}{1+e^{(-\mu+k'^2)/T}}dk'. \tag{20}$$

Because of $(2/L)\sqrt{V_0^2-k^2}\ll 1$ and $c\gg V_0$, we obtain up to the first order that

$$2\pi(\rho+\rho_h)=1+\frac{1}{L}\frac{2}{\sqrt{V_0^2-k^2}}+\frac{4V_0}{c}. \tag{21}$$

From Eqs. (9), (19), and (21), we obtain an analytic expression of $\rho(k)$:

$$2\pi\rho(k)=\left[1+\frac{1}{L}\frac{2}{\sqrt{V_0^2-k^2}}+\frac{4V_0}{c}\right][1+e^{(-\mu'+k^2)/T}]^{-1}. \tag{22}$$

Obviously, the $\rho(k)$ is a Fermi-type distribution. When c, $L\to\infty$,

$$2\pi\rho(k)=\frac{1}{1+e^{(-\mu+k^2)/T}}, \tag{23}$$

which is just the distribution of free Fermi gas. The chemical potential μ should be positive–definite for the positive–definite density of roots.

As all particles are bounded in the potential well, i.e., $\mathrm{Max}(k)\sim V_\theta$, $\rho(k)$ should vanish almost for $k>V_0^{1/2}$. This requirement together with Eq. (22) gives

$$(V_0^2-\mu')/T\gg 1.$$

The system being thermal equilibrium exhibits a simple dependence on the large momentum cutoff $T_0(T_0=V_0^2-\mu')$, due to boundary effects. Therefore, the system can be in a state of

thermal equilibrium only when $T \ll T_0$. Otherwise some particles may overcome the potential energy at the boundary and escape out of the well. Substituting the obtained ϵ into Eq. (15), we obtain

$$F = \mu N - \frac{TL}{2\pi} \int \ln[1 + e^{(\mu' - k^2)/T}] \frac{d}{dk} \left[k + \frac{2}{L} \sin^{-1}\left(\frac{k}{V_0} \right) \right] dk. \tag{24}$$

As $k \ll V_0$, we can replace $\sin^{-1}(k/V_0)$ by k/V_0, then

$$F = \mu N - \frac{2L}{\pi} \left(1 + \frac{2}{LV_0} \right) \int_0^{V_0} \frac{k^2}{1 + e^{(-\mu' + k^2)/T}} dk. \tag{25}$$

In the low-temperature condition, the free energy becomes

$$F = \mu N - \frac{2L}{\pi} \left(1 + \frac{2}{LV_0} \right) \left(\frac{1}{3} \mu'^{3/2} + \frac{T^2 \pi^2}{24 \mu'^{1/2}} \right), \tag{26}$$

where

$$\mu' = \mu + \frac{1}{c} \left(\frac{4}{3\pi} \mu^{3/2} + \frac{T^2 \pi}{6 \mu^{1/2}} \right). \tag{27}$$

The μ' is regarded as a mandation of chemical potential according to Eq. (22). However, we are not able to get an explicit result for the specific heat by partial derivative of Eq. (26), because the chemical potential μ might be temperature dependent. In order to observe some properties of specific heat at low temperature, we let $c \to \infty$ and let μ_0 denote chemical potential at zero temperature. The μ_0 is determined by

$$D = \frac{1}{2\pi} \int_{-\sqrt{\mu_0}}^{\sqrt{\mu_0}} \left(1 + \frac{1}{L} \frac{2}{\sqrt{V_0^2 - k^2}} \right) dk. \tag{28}$$

Considering $\lim_{T \to 0} \mu(T)/\mu_0 = 1$, we have

$$F = \mu_0 N - \frac{2L}{\pi} \left(1 + \frac{2}{LV_0} \right) \left(\frac{1}{3} \mu_0^{3/2} + \frac{T^2 \pi^2}{24 \mu_0^{1/2}} \right). \tag{29}$$

We find that the specific heat at low temperature is Fermi-liquid-like,

$$C_V = \frac{\pi L}{6 \mu_0^{1/2}} \left(1 + \frac{2}{LV_0} \right) T. \tag{30}$$

Thus the interaction between the particles plays an important role to their statistical properties though the system we considered is a boson system. This is a model belonging to the class of Haldane's exclusion statistics.[23]

IV. WEAK COUPLING LIMIT

Obviously, Eq. (10) can be written as

$$\epsilon = -\mu + k^2 - \frac{T}{2\pi} \int e^{-c|\omega|} e^{ik\omega} \cos(k'\omega) \ln(1 + e^{-\epsilon/T}) dk'\, d\omega. \tag{31}$$

Because in the weak coupling limit $c \ll 1$, we have

$$\epsilon(k) = -\mu + k^2 - T \ln(1 + e^{-\epsilon/T}) - f(k,c), \tag{32}$$

where

$$f(k,c)=\frac{T}{2\pi}\sum_{n=1}^{\infty}\int\frac{(-1)^n c^n|\omega|^n}{n!}e^{ik\omega}\cos(k'\omega)\ln(1+e^{(\mu-k^2)/T})dk'\,d\omega.$$

This leads to

$$e^{-\epsilon/T}=[e^{(-\mu+k^2-f(k,c))/T}-1]^{-1}. \tag{33}$$

Likewise, Eq. (5) gives rise to

$$2\pi\rho_h(k)=1+\frac{1}{L}\frac{2}{\sqrt{V_0^2-k^2}}+g(k,c), \tag{34}$$

where

$$g(k,c)=\sum_{n=1}^{\infty}\int\frac{(-1)^n c^n|\omega|^n}{n!}e^{ik\omega}\cos(k'\omega)dk'\,d\omega.$$

With the help of (33), we obtain the distribution function of roots

$$2\pi\rho(k)=\left[1+\frac{1}{L}\frac{2}{\sqrt{V_0^2-k^2}}+g(k,c)\right]\frac{1}{e^{[-\mu+k^2-f(k,c)]/T}-1}. \tag{35}$$

Physically, it represents the distribution of quasimomenta of the system as a collection. Because the density of root should be positive–definite, $\mu+f(k,c)$ must be always smaller than the corresponding k^2, particularly, $\mu+f(0,c)\leqslant 0$. So Eq. (35) is a bosonlike distribution. If considering the boundary effects so that $\rho(V_0)\simeq 0$ we have $V_0^2-\mu-f(V_0,c)\gg T$. There is a large-momentum cutoff $T_0=V_0^2-f(V_0,c)-\mu$ such that the system can be in a thermal equilibrium only when $T\ll T_0$.

Now we consider the free energy, and only take account of the leading terms for $c\ll 1$,

$$2\pi\rho(k)=\left[1+\frac{1}{L}\frac{2}{\sqrt{V_0^2-k^2}}\right]\frac{1}{e^{(k^2-\mu)/T}-1}. \tag{36}$$

The free energy (15) becomes

$$F=\mu N+T\frac{L}{2\pi}\int\left[1+\frac{1}{L}\frac{2}{\sqrt{V_0^2-k^2}}\right]\ln[1-e^{(\mu-k^2)/T}]dk. \tag{37}$$

Since $k\ll V_0$, $\sin^{-1}(k/V_0)\simeq k/V_0$, we have

$$F=\mu N-\frac{L}{\pi}\left(1+\frac{2}{LV_0}\right)\int\frac{k^2}{e^{(k^2-\mu)/T}-1}dk. \tag{38}$$

As for free bosons (i.e., $c=0$), the chemical potential should be nonpositive–definite and smaller than the energy of any particles. Moreover, for a fixed concentration ($D=N/L$), it is a function of temperature decreasing as the temperature increases according to Eq. (36). Hence when temperature goes to zero, the chemical potential will approach to zero from a negative value.

At low temperature, Eq. (38) becomes

$$F=\mu N-\frac{LT^{3/2}}{2\sqrt{\pi}}\left(1+\frac{2}{LV_0}\right)Li_{3/2}(e^{\mu/T}), \tag{39}$$

where $Li_n(z)$ is polylogarithm function with $Li_{3/2}(1)=\zeta(3/2)$ and $\zeta(x)$ is Riemann's Zeta function. Since $Li_n(z)$ can be expanded into series of z and the chemical potential μ should be zero at zero temperature, we neglect the $Li_{3/2}(e^{\mu/T})$'s dependence on T. Then the entropy has the form

$$S=\frac{3LT^{1/2}}{4\sqrt{\pi}}\left(1+\frac{2}{LV_0}\right)Li_{3/2}(e^{\mu/T}), \tag{40}$$

and the specific heat

$$C_V=\frac{3LT^{1/2}}{8\sqrt{\pi}}\left(1+\frac{2}{LV_0}\right)Li_{3/2}(e^{\mu/T}), \tag{41}$$

which has boson-gas-like behaviors.

V. CONCLUSIONS AND REMARKS

In the above, we discussed the thermodynamics of bosons in a one-dimensional potential well on the basis of the exact solution of the model. Using the strategy of Yang and Yang,[18] we studied the general thermodynamic properties of the system. We considered the problem in the strong coupling limit and found that the behavior of the system at low temperature is Fermi liquidlike even though it is a boson system. Therefore, the interaction plays an important role. Meanwhile we obtained the specific heat which is linearly dependent on the temperature T. For the weak coupling limit, we found that the system behaves like boson gas at low temperature.

I. INTRODUCTION

Convection refers to fluid motion that is induced by buoyancy. In thermal convection buoyancy is due to temperature differences and one of the interesting questions is how much of the total heat transfer is due to convection. The natural measure of this quantity is the Nusselt number, N, and many experiments and numerical simulations have been performed to discern the relationship between N and the various parameters which describe the system. Much of this research has focused on the forcing parameter,[1–6] although it has been observed that rotation plays a nontrivial role as well.[7]

The standard mathematical description of a convective system in a rotating frame of reference is based on the rotating Boussinesq equations for Rayleigh–Bénard convection (see, for example, Chandrasekhar[8]). This is a system of equations coupling the three dimensional Navier–Stokes equations to a heat advection-diffusion equation. The parameters in this system are the Rayleigh number R which captures the forcing, and the Ekman number E which is inversly proportional to the rate of rotation. The only known rigorous upper bound for N at large values of the Rayleigh number is of the order $R^{1/2}$. This bound was first derived by Howard using variational methods.[9] More recently, a background method[10] has been used to obtain this bound as well.[11] This bound is also valid in the presence of rotation.[12] Experimental and numerical findings, however, indicate a bound of the form

$$N \sim R^q,$$

where the reported values for q belong approximately to the interval $[2/7,1/3]$ for large R. The exponents 2/7 and 1/3 have been discussed by several authors.[13–21]

A third parameter in the system is the Prandtl number, a parameter determined by the physical characteristics of the fluid. The Prandtl number is the ratio of the kinematic viscocity to the heat conduction coefficient. A simplified set of equations can be derived by taking the limit as the Prandtl number goes to infinity. These equations are easier to analyze than the Boussinesq equations; in particular one can prove global existence and uniqueness of smooth solutions.[12] The known rigorous bounds for the rotating infinite Prandtl number system are the uniform bound

$$N \leqslant 1 + C_1 R^{2/5},$$

and the rotation dependent bound

a)Electronic mail: const@math.uchicago.edu

$$N \leqslant 1 + C_2 E R^2$$

(with constants independent of E and R). The latter bound is most useful for strong rotation. These upper bounds were both obtained using the background field method.[12,22–24] In the absence of rotation ($E=\infty$) a bound of the form

$$N \leqslant 1 + cR^{1/3}(1+\log_+ R)^{2/3},$$

has been obtained.[25] The 1/3 exponent is physical and close to the experimentally observed exponents. The goal of this paper is to provide a similar bound in the rotating case, allowing for finite values of E. As we shall see the correction due to rotation vanishes as $E \to \infty$, and we recover the above logarithmic bound even for rather strong rotation [$E \geqslant R^{-1/6}(\log R)^{-5/6}$]. However, as rotation is increased even further the logarithmic bound deteriorates, allowing for the observed increase of Nusselt number at intermediate rotation rates.[7] The $R^{2/5}$ bound may take over for a range of E. As $E \to 0$ the ER^2 bound takes over and accounts for the decrease of the Nusselt number due to very strong stratification.

The paper is organized as follows. In the next section we recall the equations, basic facts about the Nusselt number and some uniform estimates that hold for all Ekman numbers. In the third section we describe the method for bounding the heat flux and the results. The fourth section is devoted to proofs of the estimates of the nonrotation terms and the fifth section to the proofs of the estimates due to rotation.

II. INFINITE PRANDTL NUMBER EQUATIONS

We begin with the equations of motion for infinite Prandtl number Rayleigh–Bénard convection in a rotating reference frame, where the Boussinesq approximation is used for the buoyancy force. These form a system of five equations for velocities (u,v,w), pressure p and temperature T in three spatial dimensions. The components of the velocity vector $\mathbf{u}=(u,v,w)$ satisfy the equations

$$-\Delta u - E^{-1} v + p_x = 0, \tag{1}$$

$$-\Delta v + E^{-1} u + p_y = 0, \tag{2}$$

$$-\Delta w + p_z = RT, \tag{3}$$

and the divergence-free condition

$$u_x + v_y + w_z = 0. \tag{4}$$

The temperature, T, is advected according to the active scalar equation

$$(\partial_t + \mathbf{u}\cdot\nabla) T = \Delta T. \tag{5}$$

The two nondimensional parameters are the Rayleigh number, R, which describes the forcing due to the heat difference, and the Ekman number E which is inversely proportional to the rate of rotation.

We will consider a rectangular domain, with the vertical height scaled to 1 and the horizontal lengths scaled to the aspect ratio L. The horizontal independent variables (x,y) belong to a square $Q \subset \mathbf{R}^2$ of side length L. The vertical variable z belongs to the interval $[0,1]$. The non-negative variable t represents time. For boundary conditions we will consider all the functions u, v, w, p, T periodic in x and y with period L. The velocity components u, v, and w vanish for $z=0$ and 1 while the temperature T obeys $T=0$ at $z=1$ and $T=1$ at $z=0$. By taking a function $\tau(z)$ that satisfies $\tau(0)=1$ and $\tau(1)=0$, we will express the temperature as

$$T(x,y,z,t) = \tau(z) + \theta(x,y,z,t). \tag{6}$$

The role of τ is that of a convenient background which carries the inhomogeneous boundary conditions; thus θ obeys the same homogeneous boundary conditions as the velocity. The equation obeyed by θ is

$$(\partial_t + \mathbf{u}\cdot\nabla - \Delta)\,\theta = \tau'' - w\tau', \tag{7}$$

where we have used $\tau' = d\tau/dz$. We will use a normalized L^2 norm

$$\|f\|^2 = \frac{1}{L^2}\int_0^1\int_0^L\int_0^L |f(x,y,z)|^2\,dxdydz.$$

We denote by Δ_D^{-1} the inverse of the Laplacian with periodic-Dirichlet boundary conditions and the Laplacian in the horizontal directions x and y is denoted by Δ_h. We will use $\langle\cdot\rangle$ for the long time average

$$\langle f\rangle = \lim\sup_{t\to\infty}\frac{1}{t}\int_0^t f(s)ds.$$

The total heat transport is quantified by the Nusselt number which is defined in terms of a long time average of the vertical heat flux

$$N = 1 + \left\langle \int_0^1 b(z)dz \right\rangle, \tag{8}$$

where

$$b(z) = \frac{1}{L^2}\int_0^L\int_0^L w(x,y,z)T(x,y,z)dx\,dy. \tag{9}$$

we note that by using (6) the quantity $b(z)$ can be written

$$b(z) = \frac{1}{L^2}\int_0^L\int_0^L w(x,y,z)\,\theta(x,y,z)dx\,dy. \tag{10}$$

One can verify that the Nusselt number is also expressed as

$$N = \langle\|\nabla T\|^2\rangle. \tag{11}$$

From the velocity equations it follows that

$$\|\nabla\mathbf{u}\|^2 = \frac{R}{L^2}\int_0^L\int_0^L\int_0^1 w(x,y,z,t)T(x,y,z,t)dxdydz, \tag{12}$$

holds at each instant of time and thus

$$\langle\|\nabla\mathbf{u}\|^2\rangle = R(N-1). \tag{13}$$

The temperature equation obeys a maximum principle so that

$$0 \leqslant T \leqslant 1,$$

holds pointwise in space and time and consequently from (12) it follows that

$$\|\nabla\mathbf{u}\|^2 \leqslant R^2, \tag{14}$$

at each instance of time. One can easily derive from the rotating infinite Prandtl number system (see, for example, Ref. 23) two coupled equations for the vertical velocity w and the vertical component of vorticity $\zeta = v_x - u_y$

$$\Delta^2 w - E^{-1}\zeta_z = -R\Delta_h T, \tag{15}$$

$$-\Delta\zeta - E^{-1}w_z = 0. \tag{16}$$

Multiplying the first equation by w, the second one by ζ, adding and integrating we deduce that

$$\|\Delta w\|^2 + 2\|\nabla\zeta\|^2 \leqslant R^2, \tag{17}$$

holds pointwise in time. We used the fact, due to incompressibility, that w together with w_z and ζ vanish at the vertical boundaries.

III. BOUNDING THE HEAT FLUX

From the definition of the Nusselt number (11), given in terms of the temperature, we can derive an equivalent expression in terms of the background profile and fluctuations using (6) to replace T with its decomposition into τ and θ in the quantity $|\nabla T|^2$. This gives us the expression

$$N = \langle \|\nabla\theta|^2\rangle + \int_0^1 (\tau')^2\, dz + 2\left\langle \int_0^L\int_0^L\int_0^1 \theta_z \tau'\, dz dy dx \right\rangle.$$

The last term may be replaced by multiplying the evolution equation for θ (7) by θ and integrating. Upon taking a long time average, we have

$$\left\langle \int_0^L\int_0^L\int_0^1 \tau'\,\theta_z dz dy dx \right\rangle = \langle \|\nabla\theta\|^2\rangle - \left\langle \int_0^L\int_0^L\int_0^1 w\tau'\, dz dy dx \right\rangle,$$

where we have made use of the boundary conditions and the incompressibility condition. Combining these, we have the following form for the Nusselt number:

$$N + \langle \|\nabla\theta\|^2\rangle = 2\left\langle -\int_0^1 \tau'(z) b(z) dz \right\rangle + \int_0^1 (\tau'(z))^2 dz. \tag{18}$$

Let us now write

$$b(z,t) = \frac{1}{L^2}\int_0^L\int_0^L\int_0^z\int_0^{z_1} w_{zz}(x,y,z_2,t)\,\theta(x,z) dx\, dy\, dz\, dz_2\, dz_1.$$

It follows that:

$$|b(z,t)| \leqslant \tfrac{1}{2} z^2 (1 + \|\tau\|_{L^\infty}) \|w_{zz}\|_{L^\infty(dz;L^1(dx))}. \tag{19}$$

Restricting ourselves to bounded profiles, $\|\tau\|_{L^\infty} \leqslant 1$, and relaxing the supnorm we have simply

$$|b(z,t)| \leqslant z^2 \|w_{zz}(\cdot,t)\|_{L^\infty}. \tag{20}$$

Consequently we obtain the inequality

$$N \leqslant \int_0^1 (\tau'(z))^2 dz + 2\int_0^1 z^2 |\tau'(z)| \langle \|w_{zz}(\cdot,t)\|_{L^\infty}\rangle dz. \tag{21}$$

Up to this point, the background profile τ has not been specified. We will choose for simplicity a smooth approximation of a profile concentrated in a boundary layer of width δ, for example $\tau(z)=1-z/\delta$ for $0\leqslant z\leqslant\delta$ and 0 for $z>\delta$. We will assume thus that the function $\tau(z)$ obeys

$$|\tau'(z)|\leqslant C\frac{1}{\delta},$$

$$|\tau''(z)|\leqslant C\frac{1}{\delta^2},$$

$|\tau(z)|\leqslant 1$ and $\tau'(z)=0$ for $z>\delta$. We will adjust δ to optimize the bounds but we will require at least

$$\delta\geqslant\frac{C}{R^p}.$$

We will not attempt to optimize prefactors in this paper; we will simply denote Rayleigh and Ekman number independent constants by C. The power p is not specified (this assumption will only be used inside a logarithmic bound). Before optimizing in δ we deduce from (21) the inequality

$$N\leqslant\frac{C}{\delta}+C\delta^2\langle\|w_{zz}(\cdot,t)\|_{L^\infty}\rangle. \tag{22}$$

We will use now the two equations (15) and (16) to derive a single expression for w_{zz}, the quantity relevant to calculations of the heat flux. Noting that ζ vanishes on the vertical boundaries, solving for ζ in the second equation and substituting into the first equation, we obtain

$$\Delta^2 w+E^{-2}(\partial_z\Delta_D^{-1}\partial_z)w=-R\Delta_h T. \tag{23}$$

Moving the rotation term to the right-hand side and applying the inverse bilaplacian, we deduce

$$w=-R(\Delta_{\mathrm{DN}}^2)^{-1}\Delta_h T-E^{-2}(\Delta_{\mathrm{DN}}^2)^{-1}(\partial_z\Delta_D^{-1}\partial_z)w. \tag{24}$$

Here $(\Delta_{\mathrm{DN}}^2)^{-1}$ is the inverse bilaplacian with homogeneous Dirichlet and Neumann (DN) boundary conditions. Notice that $\Delta_h T=\Delta_h\theta$ since the background temperature profile τ depends on z only. Taking two z derivatives then gives

$$w_{zz}=-RB_1\theta-E^{-2}B_2 w, \tag{25}$$

where

$$B_1=\partial_{zz}(\Delta_{\mathrm{DN}}^2)^{-1}\Delta_h \tag{26}$$

and

$$B_2=\partial_{zz}(\Delta_{\mathrm{DN}}^2)^{-1}(\partial_z\Delta_D^{-1}\partial_z). \tag{27}$$

We will estimate the quantity of interest to us $\|w_{zz}\|_{L^\infty}$ using the decomposition above. Obviously

$$\langle\|w_{zz}(\cdot,t)\|_{L^\infty}\rangle\leqslant R\langle\|B_1\theta(\cdot,t)\|_{L^\infty}\rangle+E^{-2}\langle\|B_2 w(\cdot,t)\|_{L^\infty}\rangle, \tag{28}$$

holds.

In the following sections, we prove the two key estimates

$$\langle\|B_1\theta(\cdot,t)\|_{L^\infty}\rangle\leqslant C\{1+C\log_+ R\}^2 \tag{29}$$

and

$$\langle \|B_2 w(\cdot,t)\|_{L^\infty} \rangle \leqslant C\sqrt{R(N-1)}. \tag{30}$$

Using these two inequalities, and the combination of (28) and (22), we can optimize with respect to δ we obtain our main result

Theorem 1: *There exists a constant C such that the Nusselt number for the infinite Prandtl number equation with rotation is bounded by*

$$N \leqslant 1 + CR^{1/3}\{1+\log_+ R\}^{2/3},$$

when

$$E \geqslant R^{-1/6}\{1+\log_+ R\}^{-5/6}.$$

When $E \leqslant R^{-1/6}\{1+\log_+ R\}^{-5/6}$ *then the Nusselt number obeys*

$$N \leqslant CE^{-4/5}R^{1/5}.$$

Indeed, using the bounds (29) and (30) together with (28) in (22) and optimizing with respect to δ we obtain

$$N \leqslant 1 + C\{R(1+\log_+ R)^2\}^{1/3} + CE^{-2/3}R^{1/6}(N-1)^{1/6}, \tag{31}$$

which implies the statement of the theorem. From inequality (31) and the previously obtained bounds

$$N \leqslant 1 + CR^{2/5},$$

$$N \leqslant 1 + CER^2,$$

the following picture emerges. For rotations ranging from very weak to rather strong, ($E \geqslant R^{-1/6}\{1+\log_+ R\}^{-5/6}$), the bound $R^{1/3}\{1+\log_+ R\}^{2/3}$ applies. For stronger rotation, $R^{-1/4} \leqslant E \leqslant R^{-1/6}\{1+\log_+ R\}^{-5/6}$, the bound $N \leqslant 1 + CE^{-4/5}R^{1/5}$ is optimal. For stronger rotation yet, $R^{-2} \leqslant E \leqslant R^{-1/4}$, the bound $N \leqslant 1 + CR^{2/5}$ operates, and finally at exceedingly large rotation $E \leqslant R^{-2}$ the Nusselt number becomes bounded and then identically one. If instead of varying rotation at fixed Rayleigh numbers one varies the Rayleigh numbers and fixes the Ekman number, then the logarithmic one-third power law bound emerges for any fixed rotation, no matter how strong, provided the Rayleigh number is high enough.

IV. SINGULAR INTEGRALS AND THE B_1 TERM

In this section, we outline the estimates and results for the nonrotating case. Consider the operator

$$B_1 = \frac{\partial^2}{\partial z^2}(\Delta_{\mathrm{DN}}^2)^{-1}\Delta_h,$$

where $w = (\Delta_{\mathrm{DN}}^2)^{-1} f$ is the solution of

$$\Delta^2 w = f,$$

with horizontally periodic and vertically Dirichlet and Neumann boundary conditions $w = w' = 0$. Logarithmic L^∞ estimates for B_1 were obtained in Ref. 25). They are recalled in the following:

Theorem 2: *For any* $\alpha \in (0,1)$ *there exists a positive constant* C_α *such that every Hölder continuous function* θ *that is horizontally periodic and vanishes at the vertical boundaries satisfies*

$$\|B_1\theta\|_{L^\infty} \leqslant C_\alpha \|\theta\|_{L^\infty}\{1+\log(1+\|\theta\|_{C^{0,\alpha}})\}^2. \tag{32}$$

The spatial $C^{0,\alpha}$ norm is defined as

$$\|\theta\|_{C^{0,\alpha}} = \sup_{X=(x,y,z)\in Q\times[0,1]} |\theta(X,t)| + \sup_{X\neq Y} \frac{|\theta(X,t)-\theta(Y,t)|}{|X-Y|^\alpha}.$$

The proof decomposes $B_1\theta$ into the sum

$$B_1\theta = (I - B_3 + B_4 + B_5)B_3\theta,$$

where

$$B_3(\theta) = (\Delta_D)^{-1}\Delta_h\theta.$$

B_3 is an integral operator with kernel K given by

$$B_3(\theta)(x,y,z) = L^{-2}\int_0^L\int_0^L\int_0^1 K(x-\xi,y-\eta,z,\zeta)(\theta(\xi,\eta,\zeta)-\theta(x,y,z))d\xi\, d\eta\, d\zeta. \tag{33}$$

B_4 and B_5 are singular layer integral operators with kernels that are singular at the boundary. The operator B_4 can be written as

$$B_4(\theta)(x,y,z) = L^{-2}\int_0^L\int_0^L\int_0^1 J(x-\xi,y-\eta,z,\zeta)(\theta(\xi,\eta,\zeta)-\theta(\xi,\eta,1))d\xi\, d\eta\, d\zeta \tag{34}$$

and

$$B_5(\theta)(x,y,z) = L^{-2}\int_0^L\int_0^L\int_0^1 S(x-\xi,y-\eta,z,\zeta)(\theta(\xi,\eta,\zeta)-\theta(\xi,\eta,0))d\xi\, d\eta\, d\zeta, \tag{35}$$

for any continuous function θ that obeys the homogeneous boundary conditions [so that $\theta(\xi,\eta,0)=\theta(\xi,\eta,1)=0$]. It was shown in Ref. 25 that there exist constants such that

$$|K(x-\xi,y-\eta,z,\zeta)| \leqslant C(|x-\xi|^2+|y-\eta|^2+|z-\zeta|^2)^{-3/2}, \tag{36}$$

$$|J(x-\xi,y-\eta,z,\zeta)| \leqslant C(|x-\xi|^2+|y-\eta|^2+|1-\zeta|^2)^{-3/2}, \tag{37}$$

$$|S(x-\xi,y-\eta,z,\zeta)| \leqslant C(|x-\xi|^2+|y-\eta|^2+|\zeta|^2)^{-3/2}. \tag{38}$$

Once these inequalities are established it is not difficult to derive for all B_j, $j=3,4,5$ the estimates

$$\|B_j\theta\|_{L^\infty} \leqslant C_\alpha \|\theta\|_{L^\infty}[1+\log(1+\|\theta\|_{C^{0,\alpha}})], \tag{39}$$

for which the bound in (32) follows by composition. We will make now contact with the dynamical evolution of θ given by (7) by establishing two inequalities. The first

$$\|\nabla\theta\|_{L^4}^2 \leqslant C\|\theta\|_{L^\infty}\|\Delta\theta\|_{L^2},$$

is obtained by integration by parts and hold for all functions that are smooth enough and obey the homogeneous boundary conditions. The second inequality,

$$\frac{1}{L^2}\int_0^L\int_0^L |w(x,y,z,t)|^2 \leqslant z\|\nabla\mathbf{u}(\cdot,t)\|^2,$$

follows from the boundary conditions, the fundamental theorem of calculus and the Schwartz inequality. Multiplying (7) by $-\Delta\theta$ and integrating one obtains, after using these last two inequalities

$$\frac{1}{2}\frac{d}{dt}\|\nabla\theta\|^2+\|\Delta\theta\|^2\leqslant C\|\nabla\mathbf{u}\|^2\left\{1+\int_0^1[(\tau''(z))^2+z(\tau'(z))^2]dz\right\}. \tag{40}$$

Now using the bound on $\|\nabla\mathbf{u}\|$, (14), and taking a long time average we see that there exists a positive constant C such that

$$\langle\|\Delta\theta\|^2\rangle\leqslant CR^2\left\{1+\int_0^1[(\tau''(z))^2+z(\tau'(z))^2]dz\right\}. \tag{41}$$

By Sobolev embedding it follows that averages of squares of spatial $C^{0,\alpha}$ norms of θ are bounded by the same right-hand side

$$\langle\|\theta\|_{C^{0,\alpha}}^2\rangle\leqslant CR^2\left\{1+\int_0^1[(\tau''(z))^2+z(\tau'(z))^2]dz\right\}. \tag{42}$$

Taking long time averages in the estimate (32) and using the concavity of the logarithm and the bound (42) we deduce the bound

$$\langle\|B_1\theta(\cdot,t)\|_{L^\infty}\rangle\leqslant C\left\{1+\log\left[1+CR^2\left\{1+\int_0^1[(\tau''(z))^2+z(\tau'(z))^2]dz\right\}\right]\right\}^2. \tag{43}$$

Using the general conditions on τ that make the integrals of gradients of τ not larger than powers of R we obtain (29).

V. ESTIMATES FOR THE ROTATION TERM

The goal of this section is to derive inequality (30), the estimate which appears in the rotating term. This is done using the bound on $\|\nabla\mathbf{u}\|$ (13), the lemma below, and taking long time averages.

Lemma: For the operator B_2 defined by (27), there exists a constant C such that

$$\|B_2w\|_{L^\infty}^2\leqslant C\|w_z\|^2. \tag{44}$$

To prove the lemma we will use Sobolev embedding to obtain pointwise bounds from bounds in H^2; in other words we will use

$$\|B_2w\|_{L^\infty}\leqslant C\|(1-\Delta)B_2w\|. \tag{45}$$

By showing that

$$\|B_2w\|\leqslant\tfrac{1}{2}\|w_z\| \tag{46}$$

and that

$$\|\Delta B_2w\|\leqslant\frac{\sqrt{2}+1}{\sqrt{2}}\|w_z\|, \tag{47}$$

the lemma will follow. We derive first the inequality (46). Recalling that B_2 is defined as $[\partial_{zz}(\Delta_{\mathrm{DN}}^2)^{-1}\partial_z\Delta_D^{-1}\partial_z]$, it is clear that the inequality follows from a corresponding bound of the norm of the operator $[\partial_{zz}(\Delta_{\mathrm{DN}}^2)^{-1}\partial_z\Delta_D^{-1}]$ in L^2. We accomplish this by showing that $\partial_{zz}(\Delta_{\mathrm{DN}}^2)^{-1}$

and $\partial_z \Delta_D^{-1}$ are both bounded in L^2. For the first of these, let ϕ be the solution of the bilaplacian equation $\Delta_{\mathrm{DN}}^2 \phi = f$. Multiplying this equation by ϕ and integrating over the whole domain gives

$$(\Delta^2 \phi, \phi) = (f, \phi), \tag{48}$$

where

$$(f,g) = \frac{1}{L^2} \int_0^1 \int_0^L \int_0^L f(x,y,z) g(x,y,z) dx dy dz.$$

Expressing the bilaplacian as

$$\Delta^2 = \partial_{zzzz} + 2\partial_{zz}\Delta_h + \Delta_h^2, \tag{49}$$

it follows after integrating by parts that

$$(\Delta^2 \phi, \phi) = \|\phi_{zz}\|^2 + 2\|\phi_{xz}\|^2 + 2\|\phi_{yz}\|^2 + \|\Delta_h \phi\|^2. \tag{50}$$

The boundary terms obtained by integrating by parts all vanish because of the boundary conditions. Equations (48) and (50) imply that

$$\|\phi_{zz}\|^2 \leqslant \|f\| \|\phi\|. \tag{51}$$

We now note from the fundamental theorem of calculus applied twice and the boundary conditions that

$$\|\phi\| \leqslant \frac{1}{\sqrt{2}} \|\phi_{zz}\|, \tag{52}$$

and therefore, from (51) we have

$$\|\phi_{zz}\| \leqslant \frac{1}{\sqrt{2}} \|f\|.$$

Since ϕ is by definition the solution to the bilaplacian equation, we can rewrite this inequality as

$$\|\partial_{zz} (\Delta_{\mathrm{DN}}^2)^{-1} f\| \leqslant \frac{1}{\sqrt{2}} \|f\|. \tag{53}$$

We bound the operator $\partial_z \Delta^{-1}$ in the same way. Let ψ represent the solution to the Poisson equation $\Delta \psi = f$ with Dirichlet boundary conditions. Multiplying by ψ and integrating over the domain yields

$$\|\partial_z \Delta_D^{-1} f\| \leqslant \frac{1}{\sqrt{2}} \|f\|. \tag{54}$$

Now the L^2 bounds given by Eqs. (53) and (54) can be used to obtain the estimate (46) on the operator B_2.

For (47) we need to show that

$$\|\Delta \partial_{zz} (\Delta_{\mathrm{DN}}^2)^{-1} \partial_z \Delta_D^{-1} \partial_z w\| \leqslant \frac{\sqrt{2}+1}{\sqrt{2}} \|\partial_z w\|. \tag{55}$$

Noticing that $\partial_z \Delta_D^{-1}$ may be written

$$\Delta\Delta(\Delta_{\mathrm{DN}}^2)^{-1}\partial_z\Delta_D^{-1},$$

and by expressing $\Delta=\partial_{zz}+\Delta_h$, we obtain the following form for the operator in (55):

$$\Delta\partial_{zz}(\Delta_{\mathrm{DN}}^2)^{-1}\partial_z\Delta_D^{-1}=[I-\partial_{zz}\Delta_h(\Delta_{\mathrm{DN}}^2)^{-1}-\Delta_h^2(\Delta_{\mathrm{DN}}^2)^{-1}]\partial_z\Delta_D^{-1}. \tag{56}$$

We have already shown that $\partial_z\Delta_D^{-1}$ is bounded in L^2, so we need only concern ourselves with the other two operators. Let φ be the solution to the bilaplacian equation $\Delta^2\varphi=f$ with Dirichlet and Neumann boundary conditions. Multiplying by $\Delta_h^2\varphi$ and integrating over the domain, we obtain

$$(\Delta^2\varphi,\Delta_h^2\varphi)=(f,\Delta_h^2\varphi). \tag{57}$$

Noting that we can separate the bilaplacian into vertical and horizontal derivatives, we have

$$(\Delta^2\varphi,\Delta_h^2\varphi)=(\partial_{zzzz}\varphi,\Delta_h^2\varphi)+2(\Delta_h\partial_{zz}\varphi,\Delta_h^2\varphi)+\|\Delta_h^2\varphi\|^2. \tag{58}$$

Integrating by parts, the first term gives

$$(\partial_{zzzz}\varphi,\Delta_h^2\varphi)=\|\partial_{zz}\Delta_h\varphi\|^2.$$

The boundary terms disappear due to boundary conditions. Similarly, the second term in (58) becomes, after integrating by parts

$$(\Delta_h\partial_{zz}\varphi,\Delta_h^2\varphi)=\|\Delta_h\partial_{xz}\varphi\|^2+\|\Delta_h\partial_{yz}\varphi\|^2.$$

Again, because of the boundary conditions, the boundary terms vanish. Equations (57) and (58) together with the Schwartz inequality, yield

$$\|\partial_{zz}\Delta_h\varphi\|^2+2\|\Delta_h\partial_{xz}\varphi\|^2+2\|\Delta_h\partial_{yz}\varphi\|^2+\tfrac{1}{2}\|\Delta_h^2\varphi\|^2\leqslant\tfrac{1}{2}\|f\|^2.$$

This inequality implies both that

$$\|\partial_{zz}\Delta_h(\Delta_{\mathrm{DN}}^2)^{-1}w\|^2\leqslant\tfrac{1}{2}\|f\|^2$$

and also that

$$\|\Delta_h^2(\Delta_{\mathrm{DN}}^2)^{-1}w\|^2\leqslant\|f\|^2.$$

Now by using (56) we obtain the estimate stated in (55) and proof of the lemma is completed.

VI. DISCUSSION

For infinite Prandtl number convection without rotation, there exists a rigorous upper bound on the heat transfer which is of the order $R^{1/3}(\log R)^{2/3}$. In the presence of rotation, however, a low-order perturbation to the bilaplacian operator is introduced. This has the effect of an additional term in the upper bound for the heat transfer, as seen in (31). As the rotation is increased the bound deteriorates slowly but holds as long as $E\geqslant R^{-1/6}(\log R)^{-5/6}$. For a region $R^{-1/4}\leqslant E\leqslant R^{-1/6}(\log R)^{-5/6}$ a bound of the type $N\leqslant E^{-4/5}R^{1/5}$ is the best known bound, for stronger rotation $R^{-2}\leqslant E\leqslant R^{-1/4}$ the uniform bound $N\leqslant R^{2/5}$ applies and if rotation is increased further the Nusselt number becomes bounded and then equal to one. On the other hand, suppose the rotation is arbitrary but fixed and the Rayleigh number is increased; for sufficiently large Rayleigh numbers the logarithmic $R^{1/3}(\log R)^{2/3}$ bound applies.

(Received 7 April 2000; accepted for publication 2 November 2000)

Bounds for the bulk heat transport in Rayleigh–Benard convection for an infinite Prandtl number fluid are derived from the primitive equations. The enhancement of heat transport beyond the minimal conduction value (the Nusselt number Nu) is bounded in terms of the nondimensional temperature difference across the layer (the Rayleigh number Ra) according to $\mathrm{Nu} \leqslant c\mathrm{Ra}^{2/5}$, where $c<1$ is an absolute constant. This rigorous upper limit is uniform in the rotation rate when a Coriolis force, corresponding to the rotating convection problem, is included. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1336157]

I. INTRODUCTION

Rayleigh–Benard convection, where a fluid layer heated from below produces an instability leading to convective fluid motions, has played a central role in both the experimental and theoretical development of the modern sciences of nonlinear dynamics and physical pattern formation. Driven far beyond the instability, thermal convection becomes turbulent. Heat transport by convective turbulence is an important component of a wide variety of problems in applied physics ranging from stellar structure in astrophysics,[1] to mantle convection and plate tectonics in geophysics,[2] to transport in physical oceanography and atmospheric science.[3] One of the fundamental quantities of interest in these systems is the total heat transport across the layer, usually expressed in terms of the nondimensional Nusselt number Nu, the enhancement of heat flux beyond the minimal conductive value. This flux is a function of the buoyancy force across the layer, usually measured in units set by the layer geometry and material dissipation parameters as the Rayleigh number Ra. There are at least two other parameters in these systems: The Prandtl number Pr, a material parameter, is the ratio of diffusivities of momentum and temperature. And the aspect ratio $\mathcal{A}$, the ratio of the cross-sectional length scale(s) to the layer depth, is a geometric parameter characterizing the convection domain.

A major goal of both theory and experiment is to elucidate the Nu–Ra relationship, which is expected to take the form of a scaling law

$$\mathrm{Nu} \sim \mathrm{Ra}^{\alpha}, \tag{1.1}$$

in the high Rayleigh number limit of fully developed convective turbulence. It is generally assumed that the high Ra scaling law will be independent of the aspect ratio, and independent of the Prandtl number for finite values of Pr. Great interest centers on the asymptotic (as $\mathrm{Ra} \to \infty$) value of the scaling exponent α.

For many applications there is a relatively uncontroversial model of the phenomena, the so-called Boussinesq equations. This model consists of the heat advection-diffusion equation for the local temperature coupled to the incompressible Navier–Stokes equations via a buoyancy force proportional to the local temperature. There have been many theoretical predictions—as well

a)Electronic mail: const@math.uchicago.edu

as more than a few *a posteriori* explanations—for the numerical value of the scaling exponent α based in part on this model.[4] And while a number of laboratory experiments over the last two decades[5–9] have produced data yielding clear scaling over many orders of magnitude variation in Ra, experiments have not yet produced unambiguous measurements of α. (Directly observed values of α have varied between roughly 1/4 and 1/3.)

One of the early high-Rayleigh number theories[10] predicted, for finite Pr, an ''ultimate'' regime as $\mathrm{Ra}\to\infty$ with $\mathrm{Nu}\sim(\mathrm{Pr}\,\mathrm{Ra})^{1/2}$ (modulo logarithmic modifications). This scaling is distinguished in that the physical heat flux is then independent of the material transport coefficients,[1] and additionally in that this Rayleigh number dependence is in accord with the most general rigorous upper bounds on the heat transport derived from the Boussinesq equations[11] with at most mild statistical assumptions.[12] In particular the best high Ra rigorous bounds to date are of the form $\mathrm{Nu}\leqslant c\mathrm{Ra}^{1/2}$ uniform in the Prandtl number for $0<\mathrm{Pr}\leqslant\infty$. Several recent experimental investigations have suggested some indication of the eventual realization of this $\alpha=1/2$ limit,[6,7] but others have concluded that this regime may not be achieved.[8,9]

In this paper we focus on a specific version of the problem modeled by the infinite Prandtl number limit of the Boussinesq equations. Then the inertial terms in the momentum equations are neglected and the velocity vector field is linearly slaved to the temperature field. The infinite Prandtl number limit is the standard model for mantle convection studies[2] in terrestrial geophysics where $\mathrm{Pr}\approx 10^{24}$, and it is often taken as a reasonable description of high Prandtl number convection at moderate Rayleigh numbers. The Reynolds number is always small for infinite Prandtl number, and the expectation for the high Rayleigh number scaling of the Nusselt number is modified accordingly. The scaling $\mathrm{Nu}\sim\mathrm{Ra}^{1/3}$ was predicted on the basis of marginally stable boundary layer arguments,[13,14] and this value of α is distinguished in that it yields a finite heat flux into a semi-infinite layer. This 1/3 scaling is also predicted as an upper limit of the infinite Prandtl number limit of the Boussinesq equations on the basis of an approximate treatment of an upper bound analysis utilizing mild statistical hypothesis.[15] More recently, the suggestive high Rayleigh number bound $\mathrm{Nu}\leqslant c\mathrm{Ra}^{1/3}(\log\mathrm{Ra})^{2/3}$ was proven directly from the equations of motion.[16]

The effect of rotation on convective heat transport is an important issue in astrophysical and geophysical applications, and it has also been the subject of recent laboratory studies.[17] Rotation is modeled by the addition of a Coriolis force to the momentum balance in the Boussinesq model, and introduces another nondimensional variable into the system, the Taylor number Ta, which is proportional to the square of the rotation rate. Rotation modifies the transition from conduction to convection,[18,19] and generally rotation is observed to suppress convective heat transport in accord with the Taylor–Proudman theorem. The mathematical analysis of the effect of rotation in terms of its effect on rigorous bounds for convective heat transport is only partially successful, however, because to a great extent the existing bounding techniques utilize energy balances. The Coriolis force does no work, so it drops out of the analysis. Indeed, the $\mathrm{Nu}\leqslant c\mathrm{Ra}^{1/2}$ bound for arbitrary Prandtl number convection in Refs. 11 and 12 are uniform Ta. To date there are no rigorous estimates of the suppression of convection by rotation for arbitrary Prandtl number fluids.

There has been considerably more success for the analysis of the effect of rotation on infinite Prandtl number convection. When the Coriolis force is introduced directly into the linear slaving of the velocity field to the temperature field, it remains effective when the full momentum equation—and not just the energy balance—is utilized as a constraint in the analysis. A bound on Nu with the proper qualitative dependence on rotation was recently established,[20] $\mathrm{Nu}\leqslant c_1\,\mathrm{Ra}^2/\sqrt{\mathrm{Ta}}$ for no-slip boundaries. The Rayleigh number dependence of this estimate is overly pessimistic for moderate rotations; in Ref. 21 it is shown that for moderate rotations [$\mathrm{Ta}\leqslant c\,\mathrm{Ra}^{1/3}(\log\mathrm{Ra})^{5/3}$] an estimate of the form $\mathrm{Nu}\leqslant c\mathrm{Ra}^{1/3}(\log\mathrm{Ra})^{2/3}$ is valid.

The new results in this paper are to derive another rigorous upper bound for the Nusselt number in the infinite Prandtl number model which is effective for a range of Rayleigh and Taylor numbers. We will prove that

$$\mathrm{Nu}\leqslant c\mathrm{Ra}^{2/5}, \tag{1.2}$$

where the prefactor c is an absolute constant uniform in Ta. This is a qualitative improvement over the only other known uniform bound $\sim \mathrm{Ra}^{1/2}$, and depending on the specific values of Ra and Ta it can be a quantitative improvement of the estimates in Refs. 20 and 21. We will establish (1.2) two ways, one in the absence of rotation with the prefactor $c=0.2545\cdots$, and another in the presence of rotation[22] with a slightly larger prefactor $c=0.6635\cdots$.

The rest of this paper is organized as follows. In the next section we present a full description of the Boussinesq model of fluid convection along with the precise definitions of the dependent and independent variables, some basic identities, and a little preliminary analysis. Section III contains the upper bound computation, all the relevant estimates, and two proofs of the 2/5 bound, without and with rotation.

II. FORMULATION OF THE PROBLEM

We begin with the Boussinesq model of fluid convection in a rotating reference frame. A layer of fluid is confined between horizontal rigid planes separated by vertical distance h. The bottom plate at $z=0$ is held at constant temperature T_{bottom}, and the top one at $z=h$ is held at temperature T_{top}; both plates are no-slip as regards the fluid motion. The z axis is the vertical direction, the direction in which gravity acts and the direction of the axis of rotation. The unit vectors in the x, y, and z directions are, respectively, $\mathbf{i}$, $\mathbf{j}$, $\mathbf{k}$, and the velocity field is $\mathbf{u}(\mathbf{x},t)=\mathbf{i}u+\mathbf{j}v+\mathbf{k}w$. The temperature field is $T(\mathbf{x},t)$. Neglecting compressibility everywhere except in the buoyancy force, and scaling the density to one, the velocity field, the pressure field $p(\mathbf{x},t)$, and temperature field are governed by the Boussinesq equations

$$\frac{\partial \mathbf{u}}{\partial t}+\mathbf{u}\cdot\nabla\mathbf{u}+\nabla p+2\Omega\mathbf{k}\times\mathbf{u}=\nu\Delta\mathbf{u}+g\alpha\mathbf{k}T, \tag{2.1}$$

$$\nabla\cdot\mathbf{u}=0, \tag{2.2}$$

$$\frac{\partial T}{\partial t}+\mathbf{u}\cdot\nabla T=\kappa\Delta T. \tag{2.3}$$

In the above, Ω is the rotation rate, ν is the kinematic viscosity, g is the acceleration of gravity, α is the thermal expansion coefficient, and κ is the thermal diffusion coefficient. Incompressibility together with the no-slip boundary conditions lead to the supplementary boundary condition

$$\frac{\partial w}{\partial z}=0 \quad \text{at } z=0,h. \tag{2.4}$$

In this work we restrict attention to periodic boundary conditions on all dependent variables in the horizontal directions with periods L_x and L_y.

The standard nondimensional formulation of the problem is realized by measuring lengths in units of the layer depth h, time in units of the thermal diffusion time h^2/κ, velocity in terms of κ/h, and temperature on a scale where $T_{\mathrm{top}}=0$ and $T_{\mathrm{bottom}}=1$. The equations of motion are then transformed to

$$\frac{1}{\mathrm{Pr}}\left(\frac{\partial \mathbf{u}}{\partial t}+\mathbf{u}\cdot\nabla\mathbf{u}\right)+\sqrt{\mathrm{Ta}}\,\mathbf{k}\times\mathbf{u}+\nabla p=\Delta\mathbf{u}+\mathrm{Ra}\,\mathbf{k}T, \tag{2.5}$$

$$\nabla\cdot\mathbf{u}=0, \tag{2.6}$$

$$\frac{\partial T}{\partial t}+\mathbf{u}\cdot\nabla T=\Delta T, \tag{2.7}$$

with boundary conditions

$$\mathbf{u}|_{z=0}=0=\mathbf{u}|_{z=1}, \quad T|_{z=0}=1, \quad T|_{z=1}=0. \tag{2.8}$$

All the parameters of the system are thus absorbed into four pure numbers. The natural control parameter is the Rayleigh number

$$\mathrm{Ra}=\frac{g\alpha(T_{\mathrm{bottom}}-T_{\mathrm{top}})h^3}{\upsilon\kappa}, \tag{2.9}$$

a ratio of the overall buoyancy force to the damping coefficients. The rotation is measured by the Taylor number

$$\mathrm{Ta}=\left[\frac{2\Omega h^2}{\upsilon}\right]^2, \tag{2.10}$$

which is sometimes expressed in terms of the Ekman number $\mathrm{Ek}=\mathrm{Ta}^{-1/2}$. The Prandtl number

$$\mathrm{Pr}=\frac{\upsilon}{\kappa}, \tag{2.11}$$

is a material parameter. In the remainder of this paper we shall be concerned with the infinite Prandtl number model where the inertial terms in the momentum equations (2.5) are dropped so that the velocity field is linearly slaved to the temperature field

$$\sqrt{\mathrm{Ta}}\ \mathbf{k}\times\mathbf{u}+\nabla p=\Delta\mathbf{u}+\mathrm{Ra}\ \mathbf{k}T. \tag{2.12}$$

The fourth pure number characterizing the model is the aspect ratio of the system, which we define to be the nondimensional area on the layer

$$\mathcal{A}=\frac{L_xL_y}{h^2}. \tag{2.13}$$

The infinite Prandtl number model leads to direct linear relationships among the temperature, the vertical velocity w, and the vertical vorticity

$$\zeta=\frac{\partial v}{\partial x}-\frac{\partial u}{\partial y}. \tag{2.14}$$

Indeed, eliminating the pressure from (2.12) it is straightforward to see that

$$\Delta^2 w-\sqrt{\mathrm{Ta}}\,\frac{\partial\zeta}{\partial z}=-\mathrm{Ra}\ \Delta_H T, \tag{2.15}$$

where Δ_H denotes the horizontal Laplacian $\partial_x^2+\partial_y^2$, and

$$-\Delta\zeta-\sqrt{\mathrm{Ta}}\,\frac{\partial w}{\partial z}=0. \tag{2.16}$$

In view of the incompressibility and no-slip conditions on $\mathbf{u}$, the boundary conditions accompanying (2.15) and (2.16) are

$$w|_{z=0}=0=w|_{z=1}, \quad \left.\frac{\partial w}{\partial z}\right|_{z=0}=0=\left.\frac{\partial w}{\partial z}\right|_{z=1} \tag{2.17}$$

and

$$\zeta|_{z=0}=0=\zeta|_{z=1}. \tag{2.18}$$

A. Heat transport

The total heat transport is the space–time average of the vertical component of the heat current $\mathbf{k}\cdot\mathbf{J}$, where $\mathbf{J}$ is proportional to $\mathbf{u}T-\nabla T$. The standard nondimensional measure of the convective heat transport is the enhancement of the heat flux due to fluid motion, the Nusselt number Nu. The Nusselt number is defined as the ratio of the total vertical heat flux to the conductive heat flux $\kappa(T_{\text{bottom}}-T_{\text{top}})/h$.

The convection rate is a time averaged bulk property in the turbulent case, so it is helpful in defining it to introduce the notation

$$\int_V dV=\int_0^{L_x/h}dx\int_0^{L_y/h}dy\int_0^1 dz, \tag{2.19}$$

(where x, y, and z are the nondimensional coordinates) for the volume integration

$$\|f\|=\left(\int_V dV|f(x,y,z)|^2\right)^{1/2}, \tag{2.20}$$

for the L_2 norm on the domain, and

$$\langle f\rangle=\lim_{t\to\infty}\frac{1}{t}\int_0^t f(t')dt', \tag{2.21}$$

for the long time average of f. In the event the limit above does not exist (or is not unambiguously unique), we may interpret the definition in terms of the limit supremum as regards the upper bounds to be derived here.

Straightforward manipulation of the equations of motion yield a variety of expressions for the Nusselt number in terms of solutions to (2.7), (2.15), and (2.16)

$$\text{Nu}=1+\frac{1}{\mathcal{A}}\left\langle\int_V dV\,wT\right\rangle \tag{2.22}$$

$$=\frac{1}{\mathcal{A}}\langle\|\nabla T\|^2\rangle \tag{2.23}$$

$$=\frac{1}{\text{Ra}}\frac{1}{\mathcal{A}}\langle\|\nabla\mathbf{u}\|^2\rangle. \tag{2.24}$$

The goal of the analysis is to produce *a priori* bounds for the function $\text{Nu}(\text{Ra},\text{Ta},\mathcal{A})$. We will derive bounds that are uniform in the rotation rate and the aspect ratio, so for convenience we will refer to the Nusselt number as simply Nu(Ra).

B. A useful decomposition

A device that we shall use throughout is the decomposition of the temperature field into a steady ''background profile'' and a time-dependent fluctuation field

$$T(\mathbf{x},t)=\tau(z)+\theta(\mathbf{x},t). \tag{2.25}$$

The background profile $\tau(z)$ is, for the moment, arbitrary except that it satisfies the boundary conditions on $T(\mathbf{x},t)$. That is

$$\tau(0)=1 \quad \text{and} \quad \tau(1)=0. \tag{2.26}$$

Thus the fluctuation θ satisfies homogeneous boundary conditions

$$\theta|_{z=0}=0=\theta|_{z=1}, \tag{2.27}$$

together with periodicity in the horizontal. A particular background profile will be chosen later for convenience in the analysis.

We introduce the decomposition (2.25) into (2.7) to obtain

$$\frac{\partial\theta}{\partial t}+\mathbf{u}\cdot\nabla\theta=\Delta\theta-\tau' w+\tau'', \tag{2.28}$$

where $\tau'(z)$ and $\tau''(z)$ are the first and second derivatives of the $\tau(z)$. The evolution of the L_2 norm (squared) of the fluctuation field is obtained by dotting θ into Eq. (2.28) and integrating over the volume. Then upon performing some integrations by parts and invoking the boundary conditions we obtain

$$\frac{d}{dt}\frac{1}{2}\|\theta\|^2=-\|\nabla\theta\|^2-\int_V dV\,\tau'(z)\,w\,\theta-\int_V dV\,\tau'(z)\frac{\partial\theta}{\partial z}. \tag{2.29}$$

Now consider the L_2 norm (squared) of the decomposition of the gradient of the temperature field

$$\|\nabla T\|^2=\mathcal{A}\int_0^1 dz\,\tau'(z)^2+2\int_V dV\,\tau'(z)\frac{\partial\theta}{\partial z}+\|\nabla\theta\|^2. \tag{2.30}$$

Adding $2\times$(2.29) to (2.30), taking the long time average and recalling (2.23), we find the fundamental (for what follows) relation for the heat transport:

$$\mathrm{Nu}=\int_0^1 dz\,\tau'(z)^2-\frac{1}{\mathcal{A}}\left\langle\int_V dV\,(|\nabla\theta|^2+2\tau'(z)w\theta)\right\rangle. \tag{2.31}$$

III. UPPER BOUNDS

The derivation of upper bounds on the convective heat transport is based on the basic decomposition in (2.31). From this starting point we follow two distinct paths to producing effective rigorous estimates for Nu(Ra). One approach is to choose the background profile $\tau(z)$ to assure non-negativity of the quadratic form

$$Q\{\theta\}=\int_V dV\,(|\nabla\theta|^2+2\tau'(z)w\theta), \tag{3.1}$$

defined for functions $\theta(x,y,z)$ satisfying the fluctuation's boundary conditions with $w(x,y,z)$ given in terms of θ according to (2.15)—noting that $\Delta_H T=\Delta_H\theta$—and (2.16). Then the Nusselt number is bounded explicitly by $\int_0^1 dz\,\tau'(z)^2$. The other approach is to derive an *a priori* upper bound on $|\langle\int_V dV\tau'(z)w\theta\rangle|$ in terms of Ra and the functional form of τ, followed by an appropriate adjustment of τ to balance this estimate with $\int_0^1 dz\,\tau'(z)^2$. We will see that while the first approach can be carried out to derive a bound $\sim\mathrm{Ra}^{2/5}$ in the absence of rotation, i.e., for Ta=0, the second approach produces a similarly scaling bound uniform in Ta for all $-\infty<\mathrm{Ta}<\infty$, albeit with a slightly larger prefactor.

In both approaches the background profile is chosen so that the support of $\tau'(z)$ is concentrated near the boundaries where w and θ are forced to vanish due to the boundary conditions. In particular we take

$$\tau(z)=\begin{cases} 1-\dfrac{z}{2\delta} & \text{for } 0\leqslant z\leqslant\delta \\ \frac{1}{2} & \text{for } \delta\leqslant z\leqslant 1-\delta \\ \dfrac{1-z}{2\delta} & \text{for } 1-\delta\leqslant z\leqslant 1 \end{cases}, \tag{3.2}$$

where the adjustable parameter $\delta\,(0\leqslant\delta\leqslant\frac{1}{2})$ is referred to as the ''boundary layer'' thickness of the profile. Then $\tau'(z)$ vanishes in the bulk, and is the constant $-1/2\delta$ within distance δ of the isothermal boundaries. With this choice of background profile, both approaches rely on detailed local estimates for θ and w in the boundary layers near $z=0$ and $z=1$.

A. The 2/5 bound without rotation

First we treat the case of no rotation, i.e., Ta=0. Then the vertical velocity w satisfies

$$\Delta^2 w=-\mathrm{Ra}\;\Delta_H\theta, \tag{3.3}$$

together with the boundary conditions in (2.17). The procedure is now to show that we may choose the background profile's boundary layer thickness δ small enough (depending on Ra) to ensure that the quadratic form Q in (3.1) is non-negative. Then the bound will be $\mathrm{Nu}\leqslant 1/2\delta$.

We go over to the Fourier series representation to derive sufficient conditions for the non-negativity of Q. Decomposing Q mode by mode in the translation invariant horizontal directions, we observe that it will be non-negative when for each horizontal wave number $\mathbf{k}$

$$Q_{\mathbf{k}}\{\theta_{\mathbf{k}}\}=\int_0^1[|D\theta_{\mathbf{k}}|^2+k^2|\theta_{\mathbf{k}}|^2+\tau'(w_{\mathbf{k}}^*\theta_{\mathbf{k}}+w_{\mathbf{k}}\theta_{\mathbf{k}}^*)]dz, \tag{3.4}$$

is non-negative. In the above, $\theta_{\mathbf{k}}(z)$ is a complex valued function satisfying $\theta_{-\mathbf{k}}(z)=\theta_{\mathbf{k}}(z)^*$ and homogeneous Dirichlet boundary conditions

$$\theta_{\mathbf{k}}(0)=0=\theta_{\mathbf{k}}(1), \tag{3.5}$$

the z derivative is denoted by D, and the complex valued function $w_{\mathbf{k}}(z)$ is the linear functional of $\theta_{\mathbf{k}}$ defined by

$$(-D^2+k^2)^2 w_{\mathbf{k}}=\mathrm{Ra}\;k^2\theta_{\mathbf{k}}, \tag{3.6}$$

with both homogeneous Dirichlet and Neumann boundary conditions:

$$w_{\mathbf{k}}(0)=0=w_{\mathbf{k}}(1)\quad\text{and}\quad Dw_{\mathbf{k}}(0)=0=Dw_{\mathbf{k}}(1). \tag{3.7}$$

Note that $w_{\mathbf{k}}$ also satisfies $w_{-\mathbf{k}}(z)=w_{\mathbf{k}}(z)^*$. In this subsection we will also use $\|\cdot\|$ to denote the L_2 norm and $\|\cdot\|_\infty$ to denote the L_∞ norm [0,1], i.e.,

$$\|f\|=\sqrt{\int_0^1|f(z)|^2dz} \tag{3.8}$$

and

$$\|f\|_\infty=\sup_{0\leqslant z\leqslant 1}|f(z)|. \tag{3.9}$$

Consider first the temperature fluctuation component $\theta_{\mathbf{k}}(z)$. We estimate the growth of $\theta_{\mathbf{k}}(z)$ in the boundary layer according to

$$|\theta_{\mathbf{k}}(z)| = \left| \int_0^z D\theta_{\mathbf{k}}(z')dz' \right| \leq \sqrt{z} \sqrt{\int_0^{1/2} |D\theta_{\mathbf{k}}(z')|^2 dz'}, \tag{3.10}$$

for $0 \leq z \leq \frac{1}{2}$. Of course a similar estimate holds for the growth away from the boundary at $z = 1$.

We may obtain control of higher derivatives of $w_{\mathbf{k}}(z)$ in terms of the L_2 norm of $\theta_{\mathbf{k}}$ which will result in the growth of $w_{\mathbf{k}}(z)$ away from the boundaries being bounded by a higher power of the distance to the wall. Squaring (3.6) and integrating from 0 to 1, and integrating by parts where the boundary conditions permit, we have

$$\begin{aligned} \mathrm{Ra}^2 k^4 \|\theta_{\mathbf{k}}\|^2 = \|D^4 w_{\mathbf{k}}\|^2 - 2k^2 \int_0^1 [D^4 w_{\mathbf{k}}^* D^2 w_{\mathbf{k}} + D^4 w_{\mathbf{k}} D^2 w_{\mathbf{k}}^*] dz \\ + 6k^4 \|D^2 w_{\mathbf{k}}\|^2 + 4k^6 \|D w_{\mathbf{k}}\|^2 + k^8 \|w_{\mathbf{k}}\|^2. \end{aligned} \tag{3.11}$$

The indefinite term above may be estimated by its neighboring terms. For any $a > 0$

$$\left| 2k^2 \int_0^1 [D^4 w_{\mathbf{k}}^* D^2 w_{\mathbf{k}} + D^4 w_{\mathbf{k}} D^2 w_{\mathbf{k}}^*] dz \right| \leq a \|D^4 w_{\mathbf{k}}\|^2 + \frac{4k^4}{a} \|D^2 w_{\mathbf{k}}\|^2. \tag{3.12}$$

Choosing $a = \frac{1}{2}(\sqrt{41} - 5) \approx 0.7016$, then, we see that

$$\mathrm{Ra}^2 k^4 \|\theta_{\mathbf{k}}\|^2 \geq C[\|D^4 w_{\mathbf{k}}\|^2 + k^4 \|D^2 w_{\mathbf{k}}\|^2], \tag{3.13}$$

where $C = \frac{1}{2}(7 - \sqrt{41}) \approx 0.2984$. This will be enough to give us L_∞ control of $D^2 w_{\mathbf{k}}$ in light of the following:

Lemma: Let $f(z)$ be a smooth (say, $D^3 f$ is continuous) real valued function satisfying both homogeneous Dirichlet and Neumann boundary conditions on [0,1]. Then

$$\|D^2 f\|_\infty \leq \sqrt{2 \|D^4 f\| \|D^2 f\|}. \tag{3.14}$$

We note that this lemma is not true unless both sets of boundary conditions are satisfied. Counterexamples are the functions $f(z) = 2z^3 - 3z^2 + z$ and $f(z) = 2z^3 - 3z^2 + 1$ which satisfy, respectively, homogeneous Dirichlet and homogeneous Neumann boundary conditions on [0,1]. Each of these functions has $\|D^2 f\|_\infty = 6$ although $\|D^4 f\| = 0$.

To prove the lemma, first note that because of the homogeneous Dirichlet conditions, $\int_0^1 Df(z)dz = 0$, so Df must have a zero inside the interval (0,1). That is, there exists a point $z_0 \in (0,1)$ so that $Df(z_0) = 0$. Then because of the homogeneous Neumann conditions, $\int_0^{z_0} D^2 f(z)dz = 0$ and $\int_{z_0}^1 D^2 f(z)dz = 0$ so there exist points $z_1 \in (0, z_0)$ and $z_2 \in (z_0, 1)$ so that $D^2 f(z_1) = 0 = D^2 f(z_2)$.

So with $0 < z_1 < z_2 < 1$ being distinct zeros on $D^2 f$, we use the fundamental theorem of calculus to write

$$(D^2 f(z))^2 = 2 \int_{z_1}^z dz' D^2 f(z') D^3 f(z'), \tag{3.15}$$

and, for any point $\tilde{z} \in (0,1)$

$$D^3 f(z') = D^3 f(\tilde{z}) + \int_{\tilde{z}}^{z'} dz'' D^4 f(z''). \tag{3.16}$$

Inserting (3.16) into (3.15) we have

$$(D^2f(z))^2=2D^3f(\tilde z)\int_{z_1}^{z}dz'D^2f(z')+2\int_{z_1}^{z}dz'D^2f(z')\int_{\tilde z}^{z'}dz''D^4f(z''). \tag{3.17}$$

Integrating (3.17) with respect to $\tilde z$ from z_1 to z_2 and noting that the first term on the right hand side vanishes, we deduce

$$(z_2-z_1)(D^2f(z))^2=2\int_{z_1}^{z_2}d\tilde z\int_{z_1}^{z}dz'D^2f(z')\int_{\tilde z}^{z'}dz''D^4f(z''). \tag{3.18}$$

The Schwarz inequality (applied twice) then implies

$$(z_2-z_1)(D^2f(z))^2\leqslant 2(z_2-z_1)\|D^2f\|\,\|D^4f\|, \tag{3.19}$$

which proves the lemma.

Returning attention to $w_{\mathbf{k}}(z)=u(z)+iv(z)$ with u and v real (and each satisfying the boundary conditions in the lemma) and recalling (3.13), we have

$$\begin{aligned}|D^2w_{\mathbf{k}}(z)|^2&=(D^2u(z))^2+(D^2v(z))^2\\&\leqslant 2\|D^2u\|\|D^4u\|+2\|D^2v\|\,\|D^4v\|\\&\leqslant k^2\|D^2u\|^2+\frac{1}{k^2}\|D^4u\|^2+k^2\|D^2v\|^2+\frac{1}{k^2}\|D^4v\|^2\\&=k^2\|D^2w_{\mathbf{k}}\|^2+\frac{1}{k^2}\|D^4w_{\mathbf{k}}\|^2\\&\leqslant\frac{\mathrm{Ra}^2}{C}k^2\|\theta_{\mathbf{k}}\|^2.\end{aligned} \tag{3.20}$$

Hence the growth of $w_{\mathbf{k}}$ from the boundary at $z=0$ is limited by

$$\begin{aligned}|w_{\mathbf{k}}(z)|&=\left|\int_0^z dz'\int_0^{z'}dz''D^2w_{\mathbf{k}}(z'')\right|\\&\leqslant\frac{1}{2}z^2\|D^2w_{\mathbf{k}}\|_\infty\\&\leqslant\frac{1}{2}z^2\frac{\mathrm{Ra}}{\sqrt{C}}k\|\theta_{\mathbf{k}}\|.\end{aligned} \tag{3.21}$$

An analogous pointwise bound holds near the boundary at $z=1$.

The magnitude of the indefinite term in $Q_{\mathbf{k}}$ is then bounded in terms of the positive definite terms:

$$\int_0^1 \tau'(w_{\mathbf{k}}^*\theta_{\mathbf{k}}+w_{\mathbf{k}}\theta_{\mathbf{k}}^*)dz \leqslant \frac{1}{\delta}\int_0^\delta |w_{\mathbf{k}}(z)\|\theta_{\mathbf{k}}(z)|dz+\frac{1}{\delta}\int_{1-\delta}^1 |w_{\mathbf{k}}(z)\|\theta_{\mathbf{k}}(z)|dz$$

$$\leqslant \frac{1}{\delta}\int_0^\delta dz\,\frac{1}{2}z^2\left(\frac{\mathrm{Ra}}{\sqrt{C}}k\|\theta_{\mathbf{k}}\|\right)\sqrt{z}\sqrt{\int_0^{1/2}|D\theta_{\mathbf{k}}(z')|^2dz'}$$

$$+\frac{1}{\delta}\int_{1-\delta}^1 dz\,\frac{1}{2}(1-z)^2\left(\frac{\mathrm{Ra}}{\sqrt{C}}k\|\theta_{\mathbf{k}}\|\right)|\theta_{\mathbf{k}}(z)|\sqrt{1-z}\sqrt{\int_{1/2}^1|D\theta_{\mathbf{k}}(z')|^2dz'}$$

$$\leqslant \frac{1}{7}\delta^{5/2}\frac{\mathrm{Ra}}{\sqrt{C}}k\|\theta_{\mathbf{k}}\|\left(\sqrt{\int_0^{1/2}|D\theta_{\mathbf{k}}(z')|^2dz'}+\sqrt{\int_{1/2}^1|D\theta_{\mathbf{k}}(z')|^2dz'}\right)$$

$$\leqslant \frac{1}{7}\delta^{5/2}\frac{\mathrm{Ra}}{\sqrt{C}}\frac{1}{\sqrt{2}}(k^2\|\theta_{\mathbf{k}}\|^2+\|D\theta_{\mathbf{k}}\|^2). \tag{3.22}$$

Hence $Q_{\mathbf{k}}$ is non-negative for all $\mathbf{k}$ when we choose δ so that

$$1=\frac{1}{7\sqrt{2C}}\delta^{5/2}\mathrm{Ra}. \tag{3.23}$$

The heat transport is then bounded according to

$$\mathrm{Nu}\leqslant\frac{1}{2\delta}=\frac{1}{2(98C)^{1/5}}\mathrm{Ra}^{2/5}=0.2545\cdots\mathrm{Ra}^{2/5}. \tag{3.24}$$

This proof does not go through when $\mathrm{Ta}\neq 0$, however, because we cannot establish the highest derivative control in (3.13).

B. The 2/5 bound with rotation

In the presence of rotation we adopt another strategy to derive the 2/5 scaling bound, albeit with a slightly larger prefactor. When $\mathrm{Ta}\neq 0$ we cannot use the tight z^2 bound on w near the boundary because we cannot produce an effective estimate for the fourth derivative of w in L_2. We can, however, establish a $z^{3/2}$ growth. Then we do not require that the quadratic form Q be non-negative, but rather we find an *a priori* estimate for Q and then adjust the background boundary layer thickness δ to make the best of it.

Consider first the temperature field. Because $T(\mathbf{x},t)$ solves the advection-diffusion equation (2.7), it satisfies a maximum principle. That is, if the initial data $T(\mathbf{x},0)$ is bounded pointwise between the values at the boundaries, i.e., if $0\leqslant T(\mathbf{x},0)\leqslant 1$, then the solution subsequently sustains those limits: $0\leqslant T(\mathbf{x},t)\leqslant 1$. The background profile in (3.2) is also bounded pointwise in magnitude between 0 and 1, so the fluctuation θ also obeys the same limits. Hence

$$\|T\|_\infty=\|\tau\|_\infty=1 \quad \text{and} \quad \|\theta\|_\infty\leqslant 1. \tag{3.25}$$

We now establish growth limits on w near the boundaries as follows: The vertical components of velocity and vorticity are slaved to the temperature fluctuations by

$$\Delta^2 w-\sqrt{\mathrm{Ta}}\,\frac{\partial\zeta}{\partial z}=-\mathrm{Ra}\;\Delta_H\theta \tag{3.26}$$

and

$$-\Delta\zeta-\sqrt{\mathrm{Ta}}\,\frac{\partial w}{\partial z}=0. \tag{3.27}$$

Multiplying (3.26) by w and (3.27) by ζ, integrating over the full domain, and integrating by parts with the help of the boundary conditions (2.17) and (2.18)

$$\left\|\frac{\partial^2 w}{\partial z^2}\right\|^2+2\left\|\nabla_H\frac{\partial w}{\partial z}\right\|^2+\|\Delta_H w\|^2+\|\nabla\zeta\|^2=\mathrm{Ra}\int_V dV\,\theta(-\Delta_H w)\leqslant\frac{\mathrm{Ra}^2}{4}\|\theta\|^2+\|\Delta_H w\|^2, \tag{3.28}$$

where, not unexpectedly, ∇_H denotes the horizontal gradient $\mathbf{i}(\partial/\partial x)+\mathbf{j}(\partial/\partial y)$. Then thanks to (3.25), the second vertical derivative of the vertical velocity is bounded according to

$$\left\|\frac{\partial^2 w}{\partial z^2}\right\|^2\leqslant\frac{\mathrm{Ra}^2}{4}\|\theta\|^2\leqslant\frac{\mathrm{Ra}^2}{4}\mathcal{A}. \tag{3.29}$$

Then in view of w's boundary conditions, for $0\leqslant z\leqslant\frac{1}{2}$

$$|w(x,y,z)|=\left|\int_0^z dz'\int_0^{z'}dz''\frac{\partial^2 w}{\partial z^2}\right|\leqslant\frac{2}{3}z^{3/2}\sqrt{\int_0^{1/2}dz''\left(\frac{\partial^2 w}{\partial z^2}\right)^2}. \tag{3.30}$$

A similar estimate holds near the top boundary at $z=1$.

Combining (3.25), (3.29), and (3.30), the indefinite (last) term on the right-hand side of

$$\mathrm{Nu}=\int_0^1 dz\,\tau'(z)^2-\frac{1}{\mathcal{A}}\langle\|\nabla\theta\|^2\rangle-\frac{2}{\mathcal{A}}\left\langle\int_V dV\tau'(z)w\theta\right\rangle, \tag{3.31}$$

is seen to satisfy

$$\begin{aligned}\int_V dV\tau'(z)w\theta&\leqslant\frac{1}{2\delta}\int_0^{L_x/h}dx\int_0^{L_y/h}dy\int_0^{\delta}dz|w(x,y,z)|\|\theta\|_\infty\\&\quad+\frac{1}{2\delta}\int_0^{L_x/h}dx\int_0^{L_y/h}dy\int_{1-\delta}^{1}dz|w(x,y,z)|\|\theta\|_\infty\\&\leqslant\frac{1}{2\delta}\frac{2}{3}\frac{2}{5}\delta^{5/2}\sqrt{2\mathcal{A}}\left\|\frac{\partial^2 w}{\partial z^2}\right\|\\&\leqslant\frac{\sqrt{2}}{15}\delta^{3/2}\mathrm{Ra}\,\mathcal{A}.\end{aligned} \tag{3.32}$$

Hence

$$\mathrm{Nu}\leqslant\frac{1}{2\delta}+\frac{2\sqrt{2}}{15}\delta^{3/2}\mathrm{Ra}. \tag{3.33}$$

Now we minimize the right-hand side above with respect to δ by choosing

$$\delta=\frac{5^{2/5}}{2^{3/5}}\mathrm{Ra}^{-2/5} \tag{3.34}$$

to conclude that

$$\mathrm{Nu} \leqslant \frac{5^{3/5}}{3\times 2^{2/5}}\,\mathrm{Ra}^{2/5} = 0.6635\cdots\mathrm{Ra}^{2/5}. \tag{3.35}$$

This bound is independent of the rotation, i.e., uniform in Ta for $0 \leqslant \mathrm{Ta} < \infty$, and valid so long as the initial temperature data lie between the temperatures at the boundaries.

(Received 24 August 2000; accepted for publication 23 October 2000)

This paper establishes the precise relationship between the macroscopic class of factorized Rivlin–Sawyers equations and a class of microscopic-based stochastic models. The former is a well-established and popular class of rheological models for polymeric fluids, while the latter is a more recently introduced class of rheological models which combines aspects of network and reptation theory with aspects of continuum mechanic models. It is shown that the two models are equivalent in a defined sense under certain unrestrictive assumptions. The first part of the proof gives the functional relationship between the linear viscoelastic memory function of the Rivlin–Sawyers model and the probability density for creation times of random variables in the stochastic model. The main part of the proof establishes the relationship between the strain descriptions in each model by showing that the difference in corresponding strain expressions can be made arbitrarily small using the appropriate weighted norm from spectral approximation theory. [DOI: 10.1063/1.1332783]

I. INTRODUCTION

One of the main challenges in fields such as materials science, viscoelastic fluid mechanics, and polymer rheology and processing is the development of accurate rheological models to describe the complex stress–strain relationship in polymeric fluids. Many models have been proposed in the literature, each having varying degrees of success when applied to predict polymer flow behavior. In general, rheological models, or viscoelastic constitutive equations, are classified as macroscopic or microscopic.

Macroscopic models are closed-form phenomenological models which are formulated on the level of continuum mechanics. These models most often take the form of a differential equation, such as the Giesekus model or Phan-Thien–Tanner (PTT) model, or a Lagrangian integral of the Rivlin–Sawyers[1] or K-BKZ type.[2,3] Microscopic models are molecular-based or kinetic theory models. In these models, the macromolecules and their dynamics are modeled and the stress tensor is given by an expression which involves the polymer configurations. For dilute polymer solutions, these models include the bead-spring, or elastic dumbbell, models such as the Rouse model, the Hookean dumbbell model and the FENE model. For concentrated polymer solutions and polymer melts, they include the network theory of Lodge[4,5] and the reptation models of Doi and Edwards[6–9] and Curtiss and Bird.[10,11] Macroscopic expressions for many of these models have been formulated after (most often severe) simplifying assumptions have been made to derive the closed form. Furthermore, some of the macroscopic models, such as the PTT model, have been derived from microscopic considerations.

Among the most successful macroscopic models are those from the class of (factorized) Rivlin–Sawyers integral equations. In general, these models have performed reasonably well in describing polymer behavior in complex flow situations. However, the empirical nature of the

constitutive model limits the degree of success for these highly complicated fluids. All relevant polymer physics have not been included in these empirical models, and the lack of an underlying molecular understanding hinders further improvements.

It is widely recognized that advances in viscoelastic fluid mechanics can only come with the development of improved microscopic-based models since, unlike the macroscopic models, they allow for the inclusion of relevant polymer physics. Armed with efficient stochastic simulation methods, a molecular model can be improved on the molecular level by modifying it within the framework of stochastic processes, without sacrificing its tractability. In particular, no simplifying assumptions need to be made in order to derive a closed-form constitutive equation from the microscopic model. Moreover, advances in micro–macro simulations have allowed the coupling of finite element techniques for calculating macroscopic velocity and pressure fields with Brownian dynamics or stochastic simulation techniques for computing polymer stress from simulated molecular dynamics or coarse-grained models.[12–24]

Recently a new class of microscopic-based stochastic models has been introduced[25,26] which combines aspects of microscopic models from network and reptation theory with aspects of macroscopic models such as the Rivlin–Sawyers model. The model has been shown to provide good predictions of polymer melt rheology in shear and elongational flow. The objective of this paper is to establish the precise relationship between this class of microscopic-based models and the class of factorized Rivlin–Sawyers integral equations. In particular, it is shown that, under quite unrestrictive assumptions, the two models are equivalent in a well-defined sense. By establishing this equivalence, we thus give a precise underlying molecular understanding to the class of factorized Rivlin–Sawyers models. In principle, this then allows the Rivlin–Sawyers equation to be improved through the inclusion of physical insight within its stochastic formulation.

The remaining of the paper is organized as follows. The Rivlin–Sawyers model and the related stochastic model are described in Secs. II and III, respectively. The statement of the equivalence of the two models is presented in Sec. IV, while the main part of the equivalence proof is given in Sec. V. The paper concludes with a discussion in Sec. VI.

II. CONTINUUM MECHANICS MODEL

The incompressible flow of a polymeric fluid under isothermal conditions is governed by the usual mass and momentum conservation equations from continuum mechanics,

$$\nabla \cdot \mathbf{u} = 0,$$

$$\rho \frac{D\mathbf{u}}{Dt} = \nabla \cdot \boldsymbol{\sigma},$$

where $\mathbf{u}$ is the velocity field, ρ is the (constant) density, $D/Dt = \partial/\partial t + (\mathbf{u}\cdot\nabla)$ is the material derivative, and $\boldsymbol{\sigma}$ is the (Cauchy) stress tensor given by

$$\boldsymbol{\sigma} = -p\,\boldsymbol{\delta} + \boldsymbol{\tau}$$

in which $\boldsymbol{\delta}$ is the second-order unit tensor. The scalar field p represents an isotropic pressure and $\boldsymbol{\tau}$ is the extra-stress tensor. A constitutive equation for $\boldsymbol{\tau}$, along with appropriate boundary conditions, are needed to close the system. If the fluid is Newtonian, then $\boldsymbol{\tau}$ is the viscous stress tensor given by Newton's law, $\boldsymbol{\tau} = \mu[\nabla\mathbf{u} + (\nabla\mathbf{u})^{\dagger}]$, assuming incompressibility, where μ is the constant viscosity under constant temperature. Substitution of this $\boldsymbol{\tau}$ into the momentum equation yields the well-known Navier–Stokes equations.

For viscoelastic fluids, Newton's law does not hold and we need another constitutive equation for $\boldsymbol{\tau}$ to relate the stress to the strain, or more precisely, strain history. One of the most successful of these equations, to date, is the factorized Rivlin–Sawyers integral constitutive equation[1] whose general form is

$$\boldsymbol{\pi}(t)=\int_{-\infty}^{t}[h_1(I_1,I_2)\{\mathbf{B}(t,t')-\boldsymbol{\delta}\}+h_2(I_1,I_2)\{\mathbf{C}(t,t')-\boldsymbol{\delta}\}]m(t-t')dt'. \tag{1}$$

In this equation, t represents the present, or reference, time, while t' represents some time in the past ($t'\leqslant t$). The tensors $\mathbf{B}$ and $\mathbf{C}=\mathbf{B}^{-1}$ represent the (finite) Finger strain and (finite) Cauchy strain tensors, respectively, and are defined by

$$\mathbf{B}(t,t')=\mathbf{E}(t,t')\cdot\mathbf{E}^{\dagger}(t,t') \quad \text{and} \quad \mathbf{C}(t,t')=\boldsymbol{\Delta}^{\dagger}(t,t')\cdot\boldsymbol{\Delta}(t,t'), \tag{2}$$

where $\mathbf{E}(t,t')$ and $\boldsymbol{\Delta}(t,t')=\mathbf{E}^{-1}(t,t')$ are relative deformation gradient tensors whose components in Cartesian coordinates are

$$E_{ij}(t,t')=\frac{\partial x_i(t)}{\partial x_j(t')} \quad \text{and} \quad \Delta_{ij}(t,t')=\frac{\partial x_i(t')}{\partial x_j(t)}.$$

The tensor $\mathbf{E}(t,t')$ represents the gradient of the deformation of a fluid element at present time t relative to its configuration at time t' in the past, while $\boldsymbol{\Delta}(t,t')$ represents the gradient of the deformation at time t' relative to its configuration at time t.

The invariants of the Finger strain tensor are $I_1=\operatorname{tr}\mathbf{B}$, $I_2=\frac{1}{2}[(\operatorname{tr}\mathbf{B})^2-\operatorname{tr}(\mathbf{B}^2)]$ and $I_3=\det\mathbf{B}$, where tr and det denote the trace and determinant, respectively. Due to incompressibility, $I_3=\det\mathbf{B}=1$ and by the Cayley–Hamilton theorem,

$$\mathbf{B}^2-I_1\mathbf{B}+I_2\boldsymbol{\delta}=\mathbf{B}^{-1}\equiv\mathbf{C}$$

from which it follows that $I_2=\operatorname{tr}\mathbf{C}$. In the limit of small deformations, both I_1 and I_2 approach the value 3.

The functions h_1 and h_2 are strain-dependent functions of $I_1=\operatorname{tr}\mathbf{B}$ and $I_2=\operatorname{tr}\mathbf{C}$. Both h_1 and h_2 are continuous, positive functions with domain $[3,\infty)\times[3,\infty)$ and range $\Omega\subset\Re_+$ where Ω is a bounded set in the nonnegative real numbers $\Re_+=[0,\infty)$. For realistic strain functions (which are not identically zero), $\Omega=(0,1]$ with $h_i(3,3)=1$ and $h_i(I_1,I_2)$ decreasing to zero as $I_1,I_2\to\infty$.

The function $m(t-t')$ is the linear viscoelastic memory function. Related to this function is the relaxation modulus $G(t-t')$ through the definition $m(t-t')=\partial G(t-t')/\partial t'$. Both $m(s)$ and $G(s)$, where $s=t-t'\geqslant 0$, are continuous, positive functions which decrease monotonically to zero at $s=t-t'\to\infty$.

The tensors $\mathbf{B}$ and $\mathbf{C}$ do not depend on the material being modeled; they depend solely on the flow field. The functions h_1 and h_2, on the other hand, are material-dependent. A variety of forms for these functions have been proposed in the literature, whose parameters are determined by fitting rheological data taken from the material under defined, simple flow conditions.

The factorized K-BKZ equation constitutes a subclass of the Rivlin–Sawyers class of equations in which the strain functions h_1 and h_2 are related by

$$h_1=\frac{\partial W}{\partial I_1} \quad \text{and} \quad h_2=-\frac{\partial W}{\partial I_2},$$

for some potential function $W=W(I_1,I_2)$.[2,3]

Equation (1) is said to be *factorized* since the strain and time effects have been separated into two factors as $h_i(I_1,I_2)m(t-t')$, $i=1,2$. This is a standard assumption that is made when using these models. Another standard assumption implicit in Eq. (1) is that there is no interaction between effects at any two past times, t' and t''. Each past time contributes to the stress only through its interaction with the present time t. This assumption allows the more general, but computationally prohibitive, nested integral model to be reduced to the single-integral form of Eq. (1).

III. STOCHASTIC MODEL

In this section, we describe the microscopic-based stochastic model in which we are interested. We begin with a short review of network and reptation models on which the dynamics of the stochastic model are based. We then describe the dynamics of the stochastic model and form an expression for the extra-stress tensor $\boldsymbol{\tau}$ as a function of these dynamics.

A. Network and reptation models

The dynamics of concentrated polymer solutions and polymer melts must take into account the interactions between the macromolecules. One of the first approaches to model the interactions of polymer molecules in undiluted polymers was to modify the classical network theories of rubber elasticity. The basic idea in these theories is that the chemical crosslinks of a macromolecular solid are represented by permanent junction points in a network structure formed by the macromolecules. As the solid is deformed, the network structure is deformed, but the junction points never break and no new junction points are created. This theory has been modified for liquids by assuming that the junction points are temporary and are always being created and destroyed. In this way, the interactions of polymers are described by the temporary unified motion of macromolecular segments which are connected by the junction points.

The most well-known of the original network models for fluids is the Lodge network model for rubberlike liquids.[4,5] The Lodge model assumes that the creation rates are independent of time and the loss rates are constants. The creation and loss rates are related to the relaxation spectrum of the material (that is, the relaxation times and moduli) and can therefore be determined from the linear viscoelastic behavior of the fluid. There have been several modifications to the original Lodge network model.[27–32] The modifications of Phan-Thien and Tanner[27] and Wagner[28] produce models which allow for derivation of a closed-form expression and analytical solutions in some rheometric flows. Both contain a function which must be empirically determined. In more general network models, where the creation and loss rates are configuration dependent, analytical solutions cannot be found and numerical techniques must be utilized. Simulations of polymer network models in defined flow fields have been performed by Petruccione and Biller.[29–32]

Another class of models for undiluted polymers falls in the category of reptation. The first reptation theory to describe the rheology of undiluted polymers was introduced by Doi and Edwards[6–9] who described the motion of a single polymer represented by a Rouse chain. The main assumption behind the Doi–Edwards model is that each polymer in the highly entangled system of macromolecules moves, or reptates, in a tube formed by the other polymers. That is, the surrounding polymers form a topological constraint, represented by a tube, and allow the polymer inside to move only backwards and forwards within this tube in a reptational manner. The conformation of the polymer chain during deformation is determined by the affine deformation of the tube by the imposed flow field, the retraction of the chain within the tube, and the reptation of the chain ends out of the tube. A few years later, Curtiss and Bird[10,11] developed a kinetic theory for undiluted polymers in which the hindrance of sideway motion of polymers (here represented by Kramer chains) in a concentrated system is described by anisotropic friction tensors. These tensors represent the same physics as the constraining tube in the Doi–Edwards model.

The original Doi–Edwards model has undergone many modifications in efforts to improve its predictions.[33–49] Notable here are those related to tube diameter and tube cross section.[43–49] The original Doi–Edwards model assumes that the diameter of a tube (whose cross section is always circular) does not change during deformation or flow. The assumption of constant tube diameter was relaxed by Marrucci and de Cindio,[43] for example, who assumed that the volume of the tube segment remains constant during deformation, so that the tube diameter varies depending on the relative stretching of the tube segment. Assuming the tube segments deform affinely in the flow field, the tube diameter (as well as the force in the polymer chain) varies according to the orientation of the segment. In a further improvement, Wagner and Schaeffer[45] assumed that the tube radius is a function of the average stretch of the tube. More recently, modifications in the shape of the tube cross section have been considered. Ianniruberto and Marrucci[46] and Marrucci and Ianniruberto[47] postulated that during deformation or flow, the tube cross section does not

remain circular, but instead becomes an ellipse, given that the tube segments deform affinely in the flow field. This idea of ''anisotropic tube cross section'' was further explored by Öttinger.[48,49] Unlike the previous authors, Öttinger was able to derive a time evolution equation for the tube cross section as well as to develop a complete, thermodynamically admissible reptation model including anisotropic tube cross sections and other effects.

Unlike the original Doi–Edwards model which was simple enough to allow for analytical tractability, the modified models rely on stochastic simulation techniques for computing stress.

B. Dynamics and stress tensor

Let the 3×1 column vectors $\mathbf{Q}_1(t')$ and $\mathbf{Q}_2(t')$ denote two independent standard Gaussian (vector-valued) random variables (mean $\langle \mathbf{Q}_i(t')\rangle = \mathbf{0}$ and covariance $\langle \mathbf{Q}_i(t')\mathbf{Q}_i(t')\rangle = \boldsymbol{\delta}$, $i=1,2$), and let $\boldsymbol{\kappa}$ be the transpose of the velocity gradient tensor, $\boldsymbol{\kappa}=(\nabla \mathbf{u})^{\dagger}$. During time interval $t'<t<t'+s<\infty (s>0)$, let $\mathbf{Q}_1(t)$ and $\mathbf{Q}_2(t)$, respectively, be governed by the following deterministic equations:

$$\frac{d\mathbf{Q}_1(t)}{dt} = \boldsymbol{\kappa}(t)\cdot \mathbf{Q}_1(t), \tag{3}$$

$$\frac{d\mathbf{Q}_2(t)}{dt} = -\boldsymbol{\kappa}^{\dagger}(t)\cdot \mathbf{Q}_2(t). \tag{4}$$

These equations are based on the assumption that the vectors deform affinely in the flow field represented by $\boldsymbol{\kappa}$. At time $t'+s$, let $\mathbf{Q}_i (i=1,2)$ again be (independently) randomly generated according to the Gaussian distribution function and, using this newly generated vector as an initial condition, let $\mathbf{Q}_i$ again evolve according to Eq. (3) (for $i=1$) or Eq. (4) (for $i=2$) during a second time interval, and so forth over many time intervals. Finally, let $\mathbf{Q}(t)=[\mathbf{Q}_1^{\dagger}(t),\mathbf{Q}_2^{\dagger}(t)]^{\dagger}$. (In the following, we omit the †.)

In the framework of network theory of concentrated polymer solutions and polymer melts, $\mathbf{Q}_1$, with any distribution function ψ_0 (not necessarily Gaussian), describes the configuration of segments, or strands, defining the temporary physical entanglements of the macromolecules. This segment vector points from one junction point in the network to a neighboring junction point. During the lifetime s of the entanglement, or strand, created at time t', the configuration of $\mathbf{Q}_1$ is governed by the deterministic equation of motion, Eq. (3). The destruction of one or more entanglements can lead to new entanglements, whose initial configurations obey the distribution function ψ_0. See Lodge[4,5] for a description of the original network model for fluids, and Phan-Thien and Tanner,[27] Wagner,[28] and Petruccione and Biller[29–32] for modifications to this model.

The vector $\mathbf{Q}_2$ can be interpreted within the framework of (modified) reptation theory as a representation of the tube cross section, or area element of the strand. Hence, $\mathbf{Q}_2$ represents the same idea of anisotropic tube cross section discussed earlier. This vector points from the centerline of the constraining tube to the surface of the tube, where the tube surface represents an obstruction, such as an entanglement, caused by the presence of the surrounding macromolecules. The equation of motion for $\mathbf{Q}_2$, Eq. (4), describes the time evolution of the tube diameter or area element in the flow field during the lifetime of $\mathbf{Q}_2$. See Doi and Edwards[6–9] for a description of the original reptation model and Ianniruberto and Marrucci,[46] Marrucci and Ianniruberto,[47] and Öttinger[48,49] for modifications to this model based on anisotropic tube cross sections. Modifications based on varying tube diameter can be found in Marrucci and de Cindio,[43] Marrucci and Hermans,[44] and Wagner and Schaeffer.[45]

In general, the configuration vectors $\mathbf{Q}_1(t)$ and $\mathbf{Q}_2(t)$ are not orthogonal. However, if the initial vectors, $\mathbf{Q}_1(t')$ and $\mathbf{Q}_2(t')$, are orthogonal, then $\mathbf{Q}_1(t)$ and $\mathbf{Q}_2(t)$ remain orthogonal during their common lifetimes. In this case, $\mathbf{Q}_2(t)$ represents the orthogonal cross-sectional diameter.

The solutions to the two sets of initial-value ordinary differential equations, Eqs. (3) and (4), are

$$\hat{\mathbf{Q}}_1(t,t') = \mathbf{E}(t,t') \cdot \mathbf{Q}_1(t'), \tag{5}$$

$$\hat{\mathbf{Q}}_2(t,t') = \mathbf{\Delta}^{\dagger}(t,t') \cdot \mathbf{Q}_2(t'). \tag{6}$$

We use the notation $\hat{\mathbf{Q}}_1(t,t')$ and $\hat{\mathbf{Q}}_2(t,t')$ to represent the solutions $\mathbf{Q}_1(t)$ and $\mathbf{Q}_2(t)$ of Eqs. (3) and (4), respectively, in order to indicate the initial time t', i.e., creation time of the entanglement, and set $\hat{\mathbf{Q}}(t,t') = [\hat{\mathbf{Q}}_1(t,t'), \hat{\mathbf{Q}}_2(t,t')]$.

Since $\mathbf{Q}_i(t')$, $i=1,2$, are standard Gaussian random variables, it follows from Eqs. (2), (5), and (6) that $\hat{\mathbf{Q}}_i(t,t')$ are also Gaussian random variables with mean $\langle \hat{\mathbf{Q}}_i(t,t') \rangle = \mathbf{0}$ and covariance,

$$\langle \hat{\mathbf{Q}}_1(t,t') \hat{\mathbf{Q}}_1(t,t') \rangle = \mathbf{B}(t,t'), \tag{7}$$

$$\langle \hat{\mathbf{Q}}_2(t,t') \hat{\mathbf{Q}}_2(t,t') \rangle = \mathbf{C}(t,t'), \tag{8}$$

where $\mathbf{B}(t,t')$ and $\mathbf{C}(t,t')$ are the Finger and Cauchy strain tensors of the Rivlin–Sawyers equation. From the above equations it furthermore follows that

$$\langle \hat{Q}_1^2 \rangle = I_1 \quad \text{and} \quad \langle \hat{Q}_2^2 \rangle = I_2, \tag{9}$$

where $Q^2 = \mathbf{Q} \cdot \mathbf{Q} = \operatorname{tr} \mathbf{QQ}$ and where $I_1 = \operatorname{tr} \mathbf{B}$ and $I_2 = \operatorname{tr} \mathbf{C}$ are the invariants of the Finger strain tensor.

Equations (7)–(9) represent the first immediate relationships to the strain tensors of the Rivlin–Sawyers equation [Eq. (1)] on the continuum mechanics level.

Having introduced the model dynamics through the two random vectors $\mathbf{Q}_1$ and $\mathbf{Q}_2$, we now formulate the extra-stress tensor $\boldsymbol{\tau}$ as a function of these dynamics. For any random vector $\mathbf{Q}(t) = [\mathbf{Q}_1(t), \mathbf{Q}_2(t)]$ (not necessarily Gaussian), the expectation of an arbitrary function, $F(\mathbf{Q}(t))$, can be written in terms of conditional expectations of $F(\mathbf{Q}(t))$ as follows:

$$\langle F(\mathbf{Q}(t)) \rangle = \int_{-\infty}^{t} \mathrm{E}(F(\mathbf{Q}(t)) | \mathrm{T}_t = t') \mu^{\mathrm{T}_t}(t') dt' = \int_{-\infty}^{t} \langle F(\hat{\mathbf{Q}}(t,t')) \rangle \mu(t-t') dt', \tag{10}$$

where T_t is a random variable representing the creation time of a strand $\mathbf{Q}$ which lives at time t, and μ^{T_t} is the probability density associated with the probability measure for the random variable T_t. Therefore, $\mu^{\mathrm{T}_t}(t')dt'$ represents the probability that a strand which lives at time t was created in the interval of length dt' around t', for sufficiently small dt'. In replacing μ^{T_t} with $\mu(t-t')$ in the second integral of Eq. (10), we have adopted the assumption used in the factorized Rivlin–Sawyers equation that strain effects and time effects may be separated, or factored. Hence, the probability $\mu^{\mathrm{T}_t}(t')dt'$ depends only on the time difference $t-t'$ and not on specific values of t and t'.

The following general expression for $\mathbf{F}(\mathbf{Q}(t))$ was proposed,[25,26] thus introducing a new class of stochastic models for the extra-stress $\boldsymbol{\tau}$,

$$\boldsymbol{\tau}(t) = \langle \mathbf{F}(\mathbf{Q}(t)) \rangle = G(0) \langle f_1(Q_1^2, Q_2^2) \mathbf{Q}_1(t) \mathbf{Q}_1(t) + f_2(Q_1^2, Q_2^2) \mathbf{Q}_2(t) \mathbf{Q}_2(t) \rangle, \tag{11}$$

where $G(t-t')$ is the relaxation modulus, and f_1 and f_2 are scalar functions of $Q_i^2 = \operatorname{tr} \mathbf{Q}_i \mathbf{Q}_i$, $i=1,2$. In order for the model to predict the correct linear viscoelastic behavior, f_1 and f_2 must satisfy the constraint

$$\tfrac{1}{3} \langle Q_1^{e2} f_1^e - Q_2^{e2} f_2^e \rangle_0 + \tfrac{2}{15} \langle (Q_1^{e2})^2 f_{1,1}^e - (Q_2^{e2})^2 f_{2,2}^e \rangle_0 = 1,$$

which was derived under small deformation conditions.[25] The superscripts e represent equilibrium values and the notation $\langle\cdot\rangle_0$ indicates taking a Gaussian average in six-dimensional space with respect to the Gaussian probability density in six-dimensional space with mean $\mathbf{0}$ and square of the width $\boldsymbol{\delta}$.

The stochastic model, Eq. (11), was shown to predict well some material behavior of different polymeric melts.[25]

IV. EQUIVALENCE OF MODELS

We have described two models: The factorized Rivlin–Sawyers integral equation, which is a phenomenological model on the continuum mechanics level of description, and a class of microscopic-based stochastic models. By choosing the form of the stress tensor in Eq. (11), in particular by the inclusion of the functions f_1 and f_2, the stochastic model offers the ability to blend the physically-based molecular models from network theory and reptation theory, on which the dynamics are based, with continuum mechanics models.

In this section, we state and prove the manner in which, and conditions under which, these two models are equivalent.

The notation used in the theorem is that introduced above.

Theorem 1: Let $m(t-t')$ denote the linear viscoelastic memory function of a given incompressible fluid, where $m(0)<\infty$. Then given any pair of (continuous) functions $h_i:\mathfrak{R}_+^2\rightarrow\mathfrak{R}$, $i=1,2$, such that

$$\int_0^\infty\int_0^\infty h_i(x,y)e^{-(x+y)}dxdy<\infty, \tag{12}$$

there exists functions $f_i:\mathfrak{R}_+^2\rightarrow\mathfrak{R}$, $i=1,2$, such that the factorized Rivlin–Sawyers integral equation given by Eq. (1) can be approximated to arbitrary accuracy by the stochastic model given by Eq. (11). It also follows that the probability density for the creation time of a strand in the stochastic model, $\mu(t-t')$, is such that $\mu(0)<\infty$.

Conversely, let $\mu(t-t')$ denote the probability density for the creation time of a strand, where $\mu(0)<\infty$. Then given any pair of (continuous) functions $f_i:\mathfrak{R}_+^2\rightarrow\mathfrak{R}$, $i=1,2$, such that

$$\int_0^\infty\int_0^\infty f_i(x,y)e^{-(x+y)}dxdy<\infty, \tag{13}$$

there exists functions $h_i:\mathfrak{R}_+^2\rightarrow\mathfrak{R}$, $i=1,2$, such that the stochastic model given by Eq. (11) can be approximated to arbitrary accuracy by a Rivlin–Sawyers equation given by Eq. (1). It follows also that the linear viscoelastic memory function of the Rivlin–Sawyers model, $m(t-t')$, is such that $m(0)<\infty$.

In the manner just described, we say that the class of factorized Rivlin–Sawyers integral constitutive equations for an incompressible fluid, given by Eq. (1), is equivalent to the class of stochastic models given by Eq. (11). □

The expression for the error is a weighted average as described in the proof.

The theorem is proved by showing:

(1) Any linear viscoelastic memory function $m(t-t')$ of the Rivlin–Sawyers equation, Eq. (1), can be related to a probability density function $\mu(t-t')$ of Eq. (10), and vice versa;
(2) The expression for the strain in the Rivlin–Sawyers equation [the expression enclosed by the brackets in Eq. (1)] is equivalent to $\langle F(\hat{\mathbf{Q}}(t,t'))\rangle$ in Eq. (10), that is,

$$\begin{aligned} &h_1(I_1,I_2)[\mathbf{B}(t,t')-\boldsymbol{\delta}]+h_2(I_1,I_2)[\mathbf{C}(t,t')-\boldsymbol{\delta}] \\ &\quad=\langle f_1(\hat{Q}_1^2,\hat{Q}_2^2)\hat{\mathbf{Q}}_1(t,t')\hat{\mathbf{Q}}_1(t,t')+f_2(\hat{Q}_1^2,\hat{Q}_2^2)\hat{\mathbf{Q}}_2(t,t')\hat{\mathbf{Q}}_2(t,t')\rangle, \end{aligned} \tag{14}$$

to within an isotropic tensor. The proof of part 1 is trivial. Any $m(t-t')$ is related to a probability density function $\mu(t-t')$ via $\mu(t-t')=m(t-t')/G(0)$. By the properties of $m(s)$ and $G(s)$ given in Sec. II it can easily be verified that such a defined $\mu(s)$ satisfies the definition of probability density function, namely, $\mu(s)\geqslant 0$ and $\int_0^\infty \mu(s)ds=1$.

Although it is not necessary for the proof, we can show that both $m(s)$ and $\mu(s)$ are related to the probability of $\mathbf{Q}$ having a survival time exceeding $s=t-t'$. This is useful for the actual simulation procedure in the implementation of the stochastic model.[25] We show this in the following: If we let E_1 represent the event that an entanglement is produced in the time interval $[t',t'+dt']$ and let E_2 represent the event that an entanglement lives at time t, then $\mathrm{P}(E_1|E_2)=\mu^{\mathrm{T}_t}(t')dt'\equiv\mu(t-t')dt'$ by the definition of the probability density $\mu^{\mathrm{T}_t}(t')dt'=\mu(t-t')dt'$ in Eq. (10). Furthermore, letting S be a random variable representing the survival time of an entanglement, then $\mathrm{P}(E_2|E_1)=\int_{t-t'}^\infty p(s)ds$, where $p(s)$ is the probability density for the survival time S. Under the assumption that $\mathrm{P}(E_1)$ and $\mathrm{P}(E_2)$ are constant, which is physically reasonable, we find from the basic principle of conditional probability, $\mathrm{P}(E_1|E_2)=\mathrm{P}(E_2|E_1)\mathrm{P}(E_1)/\mathrm{P}(E_2)$, that

$$\mu(t-t')=\frac{1}{\langle S\rangle}\int_{t-t'}^\infty p(s)ds, \tag{15}$$

where $\langle S\rangle=\int_0^\infty sp(s)ds$ is the expected value of S. Equation (15) can easily be derived using the condition that $\int_{-\infty}^t \mu(t-t')dt'=1$.

From Eq. (15) it follows that $\mu(0)=1/\langle S\rangle$, so that

$$\int_{t-t'}^\infty p(s)ds=\frac{\mu(t-t')}{\mu(0)}=\frac{m(t-t')}{m(0)}. \tag{16}$$

V. PROOF OF PART 2

We now prove part 2 of the theorem. It is sufficient to show that given any functions h_1 and h_2 satisfying the conditions of the theorem, there exists functions f_1 and f_2 such that the left hand side of Eq. (14) can be approximated to arbitrary accuracy by the right-hand side of Eq. (14) in some appropriate norm.

We establish part 2 of the theorem in the following three subsections. In Sec. V A, we prove the result for the special case of polynomial strain functions. Some results from spectral approximations (polynomial approximations on unbounded domains) are given in Sec. V B. The results of these two subsections are used to extend the proof to general strain functions in Sec. V C.

A. Equivalence of models: Case of polynomial strain functions

In this subsection, we establish Theorem 1 for the case of polynomial strain functions by proving the following lemma.

Lemma 1: Let N be a finite nonnegative integer and let the strain functions h_1 and h_2 be polynomials of degree N in two variables I_1 and I_2, denoted by $h_{1,N}(I_1,I_2)$ and $h_{2,N}(I_1,I_2)$, respectively, which satisfy the conditions of Theorem 1. Then there exists a unique pair of polynomials $f_{1,N}$ and $f_{1,N}$, each of degree N, in two (random) variables $\hat{Q}_1^2$ and $\hat{Q}_2^2$ such that, to within an isotropic second order tensor,

$$h_{1,N}(I_1,I_2)[\mathbf{B}-\boldsymbol{\delta}]+h_{2,N}(I_1,I_2)[\mathbf{C}-\boldsymbol{\delta}]=\langle f_{1,N}(\hat{Q}_1^2,\hat{Q}_2^2)\hat{\mathbf{Q}}_1\hat{\mathbf{Q}}_1+f_{2,N}(\hat{Q}_1^2,\hat{Q}_2^2)\hat{\mathbf{Q}}_2\hat{\mathbf{Q}}_2\rangle. \tag{17}$$

□

Proof: Expanding the polynomials $h_{1,N}$ and $h_{2,N}$ about equilibrium, $I_1=I_2=3$, we have for the left-hand side of Eq. (17),

$$h_{1,N}(I_1,I_2)[\mathbf{B}-\boldsymbol{\delta}]+h_{2,N}(I_1,I_2)[\mathbf{C}-\boldsymbol{\delta}]$$
$$=\left[\sum_{\substack{i,j=0\\ i+j\leqslant N}}^{N} b_{ij}(I_1-3)^i(I_2-3)^j\right]\mathbf{B}+\left[\sum_{\substack{i,j=0\\ i+j\leqslant N}}^{N} c_{ij}(I_1-3)^i(I_2-3)^j\right]\mathbf{C}+\text{isotropic tensor}, \tag{18}$$

where the b_{ij} and c_{ij} are constants.

Expanding the polynomials $f_{1,N}$ and $f_{2,N}$ about $\hat{Q}_1^2=\hat{Q}_2^2=0$, and taking advantage of the independence of $\hat{\mathbf{Q}}_1$ and $\hat{\mathbf{Q}}_2$ to factor averages, yields the following for the right-hand side of Eq. (17),

$$\langle f_{1,N}(\hat{Q}_1^2,\hat{Q}_2^2)\hat{\mathbf{Q}}_1\hat{\mathbf{Q}}_1+f_{2,N}(\hat{Q}_1^2,\hat{Q}_2^2)\hat{\mathbf{Q}}_2\hat{\mathbf{Q}}_2\rangle$$
$$=\sum_{\substack{i,j=0\\ i+j\leqslant N}}^{N} f_{ij}^1\langle(\hat{Q}_2^2)^j\rangle\langle(\hat{Q}_1^2)^i\hat{\mathbf{Q}}_1\hat{\mathbf{Q}}_1\rangle+\sum_{\substack{i,j=0\\ i+j\leqslant N}}^{N} f_{ij}^2\langle(\hat{Q}_1^2)^i\rangle\langle(\hat{Q}_2^2)^j\hat{\mathbf{Q}}_2\hat{\mathbf{Q}}_2\rangle, \tag{19}$$

where the f_{ij}^1 and f_{ij}^2 are constants.

Since we take the initial values, $\mathbf{Q}_1(t')$ and $\mathbf{Q}_2(t')$, in the equations of motion, Eqs. (3) and (4), to be Gaussian random vectors, then the following relations between factors in the expansions of Eqs. (18) and (19) can be shown.

Claim 1: Let $\hat{\mathbf{Q}}_1\equiv\hat{\mathbf{Q}}_1(t,t')$ be the solution of the equation of motion given in Eq. (3), where the initial condition is set at time $t'\leqslant t$. Then for $n=0,1,2,\ldots$ we have

$$\langle\hat{\mathbf{Q}}_1\hat{\mathbf{Q}}_1(\hat{Q}_1^2)^n\rangle=p_n^0\boldsymbol{\delta}+p_n^1\mathbf{B}(t,t')+p_n^2\mathbf{C}(t,t'), \tag{20}$$

where p_n^0, p_n^1, and p_n^2 are polynomials in I_1-3 and I_2-3 which can be defined recursively by

$$p_n^0=-2n(I_2-3)p_{n-1}^1-6np_{n-1}^1+2np_{n-1}^2,$$

$$p_n^1=(2n+3)p_{n-1}^0+(2n+1)(I_1-3)p_{n-1}^1+3(2n+1)p_{n-1}^1+(I_2-3)p_{n-1}^2+3p_{n-1}^2,$$

$$p_n^2=2np_{n-1}^1,$$

and $p_0^0=0$, $p_0^1=1$, $p_0^2=0$. Furthermore, denoting $\langle(\hat{Q}_1^2)^n\rangle$ by p_n^3, it immediately follows that

$$p_n^3\equiv\langle(\hat{Q}_1^2)^n\rangle=\mathrm{tr}\langle\hat{\mathbf{Q}}_1\hat{\mathbf{Q}}_1(\hat{Q}_1^2)^{n-1}\rangle$$
$$=(I_1-3)p_{n-1}^1+(I_2-3)p_{n-1}^2+3(p_{n-1}^0+p_{n-1}^1+p_{n-1}^2) \tag{21}$$

for $n=1,2,\ldots$ and $p_0^3=1$. Note that p_n^1 and p_n^3 are polynomials of degree n, while p_n^0 and p_n^2 are polynomials of degree $n-1$. □

Claim 2: Let $\hat{\mathbf{Q}}_2\equiv\hat{\mathbf{Q}}_2(t,t')$ be the solution of the equation of motion given in Eq. (4), where the initial condition is set at time $t'\leqslant t$. Then for $n=0,1,2,\ldots$ we have

$$\langle\hat{\mathbf{Q}}_2\hat{\mathbf{Q}}_2(\hat{Q}_2^2)^n\rangle=p_n^{0'}\boldsymbol{\delta}+p_n^{1'}\mathbf{C}(t,t')+p_n^{2'}\mathbf{B}(t,t'), \tag{22}$$

where $p_n^{0'}$, $p_n^{1'}$, and $p_n^{2'}$ are polynomials in I_1-3 and I_2-3 which can be defined recursively by

$$p_n^{0'}=-2n(I_1-3)p_{n-1}^{1'}-6np_{n-1}^{1'}+2np_{n-1}^{2'},$$

$$p_n^{1'}=(2n+3)p_{n-1}^{0'}+(2n+1)(I_2-3)p_{n-1}^{1'}+3(2n+1)p_{n-1}^{1'}+(I_1-3)p_{n-1}^{2'}+3p_{n-1}^{2'},$$

$$p_n^{2'} = 2n p_{n-1}^{1'},$$

and $p_0^{0'} = 0$, $p_0^{1'} = 1$, $p_0^{2'} = 0$. Furthermore, denoting $\langle (\hat{Q}_2^2)^n \rangle$ by $p_n^{3'}$, it immediately follows that

$$\begin{aligned} p_n^{3'} \equiv \langle (\hat{Q}_2^2)^n \rangle &= \mathrm{tr} \langle \hat{\mathbf{Q}}_2 \hat{\mathbf{Q}}_2 (\hat{Q}_2^2)^{n-1} \rangle \\ &= (I_2 - 3) p_{n-1}^{1'} + (I_1 - 3) p_{n-1}^{2'} + 3(p_{n-1}^{0'} + p_{n-1}^{1'} + p_{n-1}^{2'}) \end{aligned} \tag{23}$$

for $n = 1,2,\ldots$ and $p_0^{3'} = 1$. Note that $p_n^{1'}$ and $p_n^{3'}$ are polynomials of degree n, while $p_n^{0'}$ and $p_n^{2'}$ are polynomials of degree $n-1$. □

The proof of these claims can be established solely with induction arguments and using the relations

$$\langle \hat{\mathbf{Q}}_1 \hat{\mathbf{Q}}_1 (\hat{Q}_1^2)^n \rangle = \mathbf{B} \langle (\hat{Q}_1^2)^n \rangle + 2n \mathbf{B} \cdot \langle \hat{\mathbf{Q}}_1 \hat{\mathbf{Q}}_1 (\hat{Q}_1^2)^{n-1} \rangle, \tag{24}$$

$$\langle \hat{\mathbf{Q}}_2 \hat{\mathbf{Q}}_2 (\hat{Q}_2^2)^n \rangle = \mathbf{C} \langle (\hat{Q}_2^2)^n \rangle + 2n \mathbf{C} \cdot \langle \hat{\mathbf{Q}}_2 \hat{\mathbf{Q}}_2 (\hat{Q}_2^2)^{n-1} \rangle, \tag{25}$$

which follow from Wick's theorem (which can be applied since we assume a Gaussian distribution function)[50] and

$$\mathbf{B}^2 = I_1 \mathbf{B} - I_2 \boldsymbol{\delta} + \mathbf{C},$$

which follows from the Cayley–Hamilton theorem.

The following three observations follow from Claims 1 and 2.

Observation 1: p_n^1 and $p_n^{1'}$ are identical if I_1 and I_2 are interchanged in either. More precisely, for $n = 0,1,2,\ldots$,

$$p_n^1 = (2n+1)!!(I_1 - 3)^n + \sum_{\substack{i,j=0 \\ i+j \leqslant n-1}}^{n-1} \beta_{ij}^{(n)} (I_1 - 3)^i (I_2 - 3)^j, \tag{26}$$

$$p_n^{1'} = (2n+1)!!(I_2 - 3)^n + \sum_{\substack{i,j=0 \\ i+j \leqslant n-1}}^{n-1} \beta_{ij}^{(n)} (I_1 - 3)^j (I_2 - 3)^i. \tag{27}$$

The set of coefficients $\{\beta_{ij}^{(n)}\}$ can be defined recursively in terms of the sets of coefficients $\{\beta_{ij}^{(k)}\}$, $k = n-1, n-2, n-3$ as follows:

$$\beta_{ij}^{(n)} = \begin{cases} (2n+1)[\beta_{i-1,j}^{(n-1)} + 3\beta_{ij}^{(n-1)}] \\ \quad -4(n+1)(n-1)\beta_{i,j-1}^{(n-2)}, \quad \text{if } i+j = n-1 \\ (2n+1)[\beta_{i-1,j}^{(n-1)} + 3\beta_{ij}^{(n-1)}] \\ \quad -4(n+1)(n-1)[\beta_{i,j-1}^{(n-2)} + 3\beta_{ij}^{(n-2)}], \quad \text{if } i+j = n-2 \\ (2n+1)[\beta_{i-1,j}^{(n-1)} + 3\beta_{ij}^{(n-1)}] \\ \quad -4(n+1)(n-1)[\beta_{i,j-1}^{(n-2)} + 3\beta_{ij}^{(n-2)}] \\ \quad +4(2n+3)(n-1)(n-2)\beta_{ij}^{(n-3)}, \quad \text{if } i+j \leqslant n-3 \end{cases}$$

for $n = 1,2,\ldots$, and $\beta_{00}^{(0)} = 1$. The only nonzero nth order coefficient in Eqs. (26) and (27) appears outside the summations; namely, $\beta_{n,0}^{(n)} = (2n+1)!!$ and $\beta_{n-k,k}^{(n)} = 0$ for $k = 1,\ldots,n$. [In the recursive formulas we interpret $\beta_{i-1,j}^{(n-1)} = 0$ for $i = 0$ and $\beta_{i,j-1}^{(n-2)} = 0$ for $j = 0$.] □

Observation 2: p_n^2 and $p_n^{2'}$ are identical if I_1 and I_2 are interchanged in either. More precisely, for $n = 1,2,\ldots$,

$$p_n^2 = 2n(2n-1)!!(I_1-3)^{n-1} + \sum_{\substack{i,j=0 \\ i+j\leqslant n-2}}^{n-2} 2n\beta_{ij}^{(n-1)}(I_1-3)^i(I_2-3)^j, \tag{28}$$

$$p_n^{2'} = 2n(2n-1)!!(I_2-3)^{n-1} + \sum_{\substack{i,j=0 \\ i+j\leqslant n-2}}^{n-2} 2n\beta_{ij}^{(n-1)}(I_1-3)^j(I_2-3)^i, \tag{29}$$

and $p_0^2 = p_0^{2'} = 0$. The coefficients $\beta_{ij}^{(n-1)}$ are the same as those corresponding to p_{n-1}^1 and $p_{n-1}^{1'}$ as defined in Observation 1 above. □

Observation 3: p_n^3 and $p_n^{3'}$ are identical if I_1 and I_2 are interchanged in either. More precisely, for $n = 1,2,\ldots,$

$$p_n^3 = (2n-1)!!(I_1-3)^n + \sum_{\substack{i,j=0 \\ i+j\leqslant n-1}}^{n-1} \gamma_{ij}^{(n)}(I_1-3)^i(I_2-3)^j, \tag{30}$$

$$p_n^{3'} = (2n-1)!!(I_2-3)^n + \sum_{\substack{i,j=0 \\ i+j\leqslant n-1}}^{n-1} \gamma_{ij}^{(n)}(I_1-3)^j(I_2-3)^i, \tag{31}$$

and $p_0^3 = p_0^{3'} = 1$. The set of coefficients $\{\gamma_{ij}^{(n)}\}$ can be defined recursively in terms of the sets of coefficients $\{\beta_{ij}^{(k)}\}$, $k = n-1, n-2, n-3$, of Observation 1, as follows:

$$\gamma_{ij}^{(n)} = \begin{cases} \beta_{i-1,j}^{(n-1)} + 3\beta_{ij}^{(n-1)} - 4(n-1)\beta_{i,j-1}^{(n-2)}, & \text{if } i+j = n-1 \\ \beta_{i-1,j}^{(n-1)} + 3\beta_{ij}^{(n-1)} - 4(n-1)[\beta_{i,j-1}^{(n-2)} + 3\beta_{ij}^{(n-2)}], & \text{if } i+j = n-2 \\ \beta_{i-1,j}^{(n-1)} + 3\beta_{ij}^{(n-1)} - 4(n-1)[\beta_{i,j-1}^{(n-2)} + 3\beta_{ij}^{(n-2)}] & \\ \quad + 12(n-1)(n-2)\beta_{ij}^{(n-3)}, & \text{if } i+j \leqslant n-3 \end{cases}$$

or

$$(2n+1)\gamma_{ij}^{(n)} = \begin{cases} \beta_{ij}^{(n)} - 4n(n-1)\beta_{i,j-1}^{(n-2)}, & \text{if } i+j = n-1 \\ \beta_{ij}^{(n)} - 4n(n-1)[\beta_{i,j-1}^{(n-2)} + 3\beta_{ij}^{(n-2)}], & \text{if } i+j = n-2 \\ \beta_{ij}^{(n)} - 4n(n-1)[\beta_{i,j-1}^{(n-2)} + 3\beta_{ij}^{(n-2)}] & \\ \quad + 16n(n-1)(n-2)\beta_{ij}^{(n-3)}, & \text{if } i+j \leqslant n-3 \end{cases}$$

for $n = 1,2,\ldots$ and $\gamma_{00}^{(0)} = \beta_{00}^{(0)} = 1$. The only nonzero nth order coefficient in Eqs. (30) and (31) appears outside the summations; namely, $\gamma_{n,0}^{(n)} = \beta_{n-1,0}^{(n-1)} = (2n-1)!!$ and $\gamma_{n-k,k}^{(n)} = \beta_{n-k-1,k}^{(n-1)} = 0$ for $k = 1,\ldots,n$. [As before, we interpret $\beta_{i-1,j}^{(n-1)} = 0$ for $i = 0$ and $\beta_{i,j-1}^{(n-2)} = 0$ for $j = 0$.]

(Note: $\{\gamma_{ij}^{(n)}\}$ can also be defined recursively in terms of the sets of coefficients $\{\gamma_{ij}^{(k)}\}$, $k = n-1, n-2, n-3$.) □

A similar observation can be stated for the polynomials p_n^0 and $p_n^{0'}$, but it is not needed in the proof and so is omitted.

Substituting Eqs. (20) and (22), along with $p_n^3 \equiv \langle(\hat{Q}_1^2)^n\rangle$, and $p_n^{3'} \equiv \langle(\hat{Q}_2^2)^n\rangle$, into Eq. (19) yields

$$\begin{aligned}
&\langle f_{1,N}(\hat{Q}_1^2,\hat{Q}_2^2)\hat{\mathbf{Q}}_1\hat{\mathbf{Q}}_1+f_{2,N}(\hat{Q}_1^2,\hat{Q}_2^2)\hat{\mathbf{Q}}_2\hat{\mathbf{Q}}_2\rangle\\
&\quad=\sum_{\substack{i,j=0\\ i+j\leqslant N}}^{N} f_{ij}^1[p_j^{3\prime}][p_i^0\boldsymbol{\delta}+p_i^1\mathbf{B}+p_i^2\mathbf{C}]+\sum_{\substack{i,j=0\\ i+j\leqslant N}}^{N} f_{ij}^2[p_i^3][p_j^{0\prime}\boldsymbol{\delta}+p_j^{1\prime}\mathbf{C}+p_j^{2\prime}\mathbf{B}]\\
&\quad=\sum_{\substack{i,j=0\\ i+j\leqslant N}}^{N}\{[f_{ij}^1p_i^1p_j^{3\prime}+f_{ij}^2p_i^3p_j^{2\prime}]\mathbf{B}+[f_{ij}^1p_i^2p_j^{3\prime}+f_{ij}^2p_i^3p_j^{1\prime}]\mathbf{C}+[f_{ij}^1p_j^{3\prime}p_i^0+f_{ij}^2p_i^3p_j^{0\prime}]\boldsymbol{\delta}\}\\
&\quad=F_{1,N}\mathbf{B}+F_{2,N}\mathbf{C}+\text{isotropic tensor.}
\end{aligned}\tag{32}$$

For convenience, we have denoted by $F_{1,N}$ and $F_{2,N}$ the polynomial factors of $\mathbf{B}$ and $\mathbf{C}$, respectively, in the last line of the above equation.

Equation (32) is precisely in the form we want, the terms on the right-hand side in brackets, represented by $F_{1,N}$ and $F_{2,N}$, being polynomials of I_1-3 and I_2-3. Comparing Eqs. (18) and (32), the proof is complete if we can show that for every pair of polynomials $h_{1,N}$ and $h_{2,N}$, there exists a unique pair of polynomials f_1 and f_2 such that

$$\begin{aligned}
h_{1,N}(I_1,I_2)\mathbf{B}+h_{2,N}(I_1,I_2)\mathbf{C}&=\left[\sum_{\substack{i,j=0\\ i+j\leqslant N}}^{N} b_{ij}(I_1-3)^i(I_2-3)^j\right]\mathbf{B}+\left[\sum_{\substack{i,j=0\\ i+j\leqslant N}}^{N} c_{ij}(I_1-3)^i(I_2-3)^j\right]\mathbf{C}\\
&=\sum_{\substack{i,j=0\\ i+j\leqslant N}}^{N}[f_{ij}^1p_i^1p_j^{3\prime}+f_{ij}^2p_i^3p_j^{2\prime}]\mathbf{B}+\sum_{\substack{i,j=0\\ i+j\leqslant N}}^{N}[f_{ij}^1p_i^2p_j^{3\prime}+f_{ij}^2p_i^3p_j^{1\prime}]\mathbf{C}\\
&=F_{1,N}(I_1,I_2)\mathbf{B}+F_{2,N}(I_1,I_2)\mathbf{C}.
\end{aligned}\tag{33}$$

The isotropic terms in Eqs. (18) and (32), can be neglected in the above equation since they can be combined with the other isotropic tensors in the total stress tensor $\boldsymbol{\sigma}=-p\boldsymbol{\delta}+\boldsymbol{\tau}$.

Equating the coefficients of $(I_1-3)^i(I_2-3)^j$, for $i,j=0,\ldots,N; i+j\leqslant N$, in the series expansions multiplying the tensors $\mathbf{B}$ and $\mathbf{C}$ in Eq. (33) leads respectively to the following relations between the coefficients f_{ij}^1, f_{ij}^2 and the coefficients b_{ij}, c_{ij}:

$$\mathbf{A}_{11}\mathbf{f}^1+\mathbf{A}_{12}\mathbf{f}^2=\mathbf{b},\tag{34}$$

$$\mathbf{A}_{21}\mathbf{f}^1+\mathbf{A}_{22}\mathbf{f}^2=\mathbf{c},\tag{35}$$

where $\mathbf{A}_{11}$, $\mathbf{A}_{12}$, $\mathbf{A}_{21}$, and $\mathbf{A}_{22}$ are each $[(N+1)(N+2)/2]\times[(N+1)(N+2)/2]$ matrices. The vectors $\mathbf{f}^1$ and $\mathbf{f}^2$ are $[(N+1)(N+2)/2]\times 1$ column vectors containing the coefficients f_{ij}^1 and f_{ij}^2, respectively. Likewise, $\mathbf{b}$ and $\mathbf{c}$ are $[(N+1)(N+2)/2]\times 1$ column vectors containing the coefficients b_{ij} and c_{ij}, respectively. The order of the coefficients in these four vectors leads to attractive properties of the matrices $\mathbf{A}_{ij}$, which will be exploited later. The ordering in each vector is such that the $(N+1)$ coefficients of order $i+j=N$ appear first, followed by the N coefficients of order $i+j=N-1$, and so on, the last entry in each vector being the coefficient of order $i+j=0$. Within each group of coefficients of a given order $i+j=l$, we adopt the following convention: in vectors $\mathbf{f}^1$ and $\mathbf{b}$, the coefficients appear in increasing order on the second index j ($f_{l,0}^1,f_{l-1,1}^1,\ldots,f_{0,l}^1$ and $b_{l,0}$, $b_{l-1,1},\ldots,b_{0,l}$), while in vectors $\mathbf{f}^2$ and $\mathbf{c}$ the coefficients appear in increasing order on the first index i ($f_{0,l}^2,f_{1,l-1}^2,\ldots,f_{l,0}^2$ and $c_{0,l}$, $c_{1,l-1},\ldots,c_{l,0}$). In other words, if we define $k_{ij}=[(N+1)(N+2)-(i+j+1)(i+j+2)]/2+(j+1)$ then the k_{ij}-entry of $\mathbf{f}^1$ and $\mathbf{b}$ is f_{ij}^1 and b_{ij}, respectively, and the k_{ij}-entry of $\mathbf{f}^2$ and $\mathbf{c}$ is f_{ji}^2 and c_{ji}, respectively. Observe for later use that, by the definition of k_{ij}, $i+j<i'+j'$ implies $k_{ij}>k_{i'j'}$ (although the converse is not true), and $k_{ij}=k_{i',j'}$ if and only if $i=i'$ and $j=j'$.

Claim 3: Letting $\mathbf{f}=(\mathbf{f}^1,\mathbf{f}^2)^\dagger$ and $\mathbf{d}=(\mathbf{b},\mathbf{c})^\dagger$, systems (34) and (35) can be written as

$$\mathbf{Af}=\mathbf{d}, \tag{36}$$

where

$$\mathbf{A}=\begin{pmatrix}\mathbf{L}_1 & \mathbf{L}_2\\ \mathbf{L}_2 & \mathbf{L}_1\end{pmatrix} \tag{37}$$

and $\mathbf{L}_1$ and $\mathbf{L}_2$ are lower triangular matrices. Furthermore, the diagonal entries of $\mathbf{L}_1$ are all nonzero, while the diagonal entries of $\mathbf{L}_2$ are all zero. It follows that $\det(\mathbf{A})\neq 0$ so that $\mathbf{A}:\Re^m \rightarrow \Re^m$ represents an invertible linear (matrix) operator on the space $\Re^m$, where $m=(N+1)(N+2)$. □

The proof of this claim can be found in the Appendix.

The fact that $\mathbf{A}$ is an invertible operator on $\Re^m$ means that for any set of coefficients $\mathbf{f}\in\Re^m$ of the series expansions in Eq. (19) there exists a unique set of coefficients $\mathbf{d}\in\Re^m$ of the series expansions in Eq. (18) given by $\mathbf{d}=\mathbf{Af}$. Likewise, for any $\mathbf{d}\in\Re^m$ there is a unique $\mathbf{f}\in\Re^m$ given by $\mathbf{f}=\mathbf{A}^{-1}\mathbf{d}$. Therefore, if the functions h_1 and h_2 are polynomials of degree N then there are unique polynomials f_1 and f_2 of degree N such that Eq. (17) holds.

With this, the lemma is proved. □

Remark 1: The lemma and proof still hold if h_1 and h_2 are polynomials of different degrees. In this case, N is taken to be the larger of the two degrees.

Remark 2: The proof above also establishes that for any polynomials $f_{1,N}$ and $f_{2,N}$ satisfying the conditions of Theorem 1, there exists a unique pair of polynomials $h_{1,N}$ and $h_{2,N}$ such that Eq. (17) holds to within an isotropic tensor.

We have shown that the equivalence theorem is true when the strain functions are polynomials in two variables. Before extending the proof to general strain functions satisfying the conditions of the theorem, we need some results from spectral approximations.

B. Results from spectral approximations

In this subsection, some mathematical ideas from polynomial approximations on unbounded domains are discussed. Inasmuch as possible, we restrict the discussion to those concepts necessary for our purposes. Details on this subject can be found in the literature.[51–55] Furthermore, we formulate the ideas in one dimension. The concepts and results generalize to tensorized domains.[55]

We begin by defining some weighted Sobolev spaces on the positive real numbers $\Re_+=[0,\infty)$ along with their norms. In each case, the subscript w denotes the weight function, which is $w=e^{-x}$. First we define the weighted Sobolev space,

$$L^2_w(\Re_+)=\left\{ f:\Re_+\rightarrow\Re \,\middle|\, f \text{ is measurable and } \int_0^\infty [f(x)]^2 e^{-x}dx<\infty \right\}$$

which is equipped with the norm

$$\|f\|_{L^2_w(\Re_+)}=\left(\int_0^\infty [f(x)]^2 e^{-x}dx \right)^{1/2}. \tag{38}$$

This is a Hilbert space under the inner product defined by

$$(f,g)_{L^2_w(\Re_+)}=\int_0^\infty f(x)g(x)e^{-x}dx \quad \forall f,g\in L^2_w(\Re_+).$$

Higher order weighted Sobolev spaces, $H^m_w(\Re_+)$, are defined in the usual manner. Specifically, for any non-negative integer m, the space $H^m_w(\Re_+)$ is the space of all functions in $L^2_w(\Re_+)$ whose derivatives up to and including order m are also in $L^2_w(\Re_+)$. This space is provided with the usual norm

$$\|f\|_{H_w^m(\Re_+)}=\left[\sum_{k=0}^{m}\int_0^\infty\left(\frac{d^k f(x)}{dx^k}\right)^2 e^{-x}dx\right]^{1/2},$$

for any $f\in H_w^m(\Re_+)$.

Next we recall some features of Laguerre polynomials. The family of Laguerre polynomials $\{l_n(x):n=0,1,2,\dots\}$ forms an orthonormal set of polynomials on $\Re_+=[0,\infty)$ with respect to the weight function $w(x)=e^{-x}$ and the inner product

$$(f,g)_w=\int_0^\infty f(x)g(x)w(x)dx.$$

That is, for $m, n=0,1,2,\dots,$

$$\int_0^\infty l_m(x)l_n(x)e^{-x}dx=\delta_{mn}.$$

The polynomials are defined recursively as

$$l_0(x)=1,\quad l_1(x)=1-x$$

$$l_n(x)=[(2n-1-x)l_{n-1}(x)-(n-1)l_{n-2}(x)]/n,\quad n\geqslant 2,$$

and for each n, $u=l_n$ satisfies the differential equation

$$xu''+(1-x)u'+nu=0.$$

It is known that a function f satisfying $\int_0^\infty f(x)e^{-x}dx<\infty$ can be expanded in terms of the Laguerre polynomials as follows:[56]

$$f(x)=\sum_{n=0}^{\infty}c_n l_n(x),\quad \text{where } c_n=\int_0^\infty f(x)l_n(x)e^{-x}dx\quad x>0. \tag{39}$$

Let $P_N(\Re_+)$ be the space of polynomials of degree less than or equal to N, restricted to $\Re_+$. A basis for $P_N(\Re_+)$ is the set of the first $N+1$ Laguerre polynomials, $\{l_k:k=0,\dots,N\}$. The orthogonal projection operator $\pi^N:L_w^2(\Re_+)\to P_N(\Re_+)$ from the weighted Sobolev space $L_w^2(\Re_+)$ onto $P_N(\Re_+)$ is defined by

$$\pi^N f=\sum_{n=0}^{N}c_n l_n,\quad \forall f\in L_w^2(\Re_+), \tag{40}$$

where the coefficients c_n are defined as in Eq. (39). From Eqs. (38), (39), and (40), it is easy to show that for any n and any $f\in L_w^2(\Re_+)$,

$$\|f-\pi^N f\|_{L_w^2(\Re_+)}^2=\sum_{n=N+1}^{\infty}c_n^2. \tag{41}$$

Therefore, Eq. (41) represents the error in approximating a function $f\in L_w^2(\Re_+)$ by the polynomial of degree N defined in Eq. (40).

We now state the following error estimate established by Maday, Pernaud-Thomas, and Vandeven,[53] Funaro,[51] and Bernardi and Maday.[54]

Theorem 2: (Theorem 12.6 in Bernardi and Maday[54]): For any positive integer k and any positive real number s, let $H_{wk}^s(\Re_+)$ be the Sobolev space defined by

$$H^s_{wk}(\mathfrak{R}_+)=\{f\in H^s_w(\mathfrak{R}_+)|x^{k/2}f\in H^s_w(\mathfrak{R}_+)\},$$

where $H^s_w(\mathfrak{R}_+)$ is the interpolation space between $H^m_w(\mathfrak{R}_+)$ and $L^2_w(\mathfrak{R}_+)$ with index $1-s/m$ where m is any integer such that $m\geqslant s$. The space $H^s_{wk}(\mathfrak{R}_+)$ is equipped with the norm

$$\|f\|_{H^s_{wk}(\mathfrak{R}_+)}=\|(1+x)^{k/2}f\|_{H^s_w(\mathfrak{R}_+)}$$

for any $f\in H^s_{wk}(\mathfrak{R}_+)$.

Then, for any real number $s\geqslant 0$, there exists a constant $C>0$, depending only on s, such that for any function $f\in H^s_{wk}(\mathfrak{R}_+)$, the following estimate holds:

$$\|f-\pi^N f\|_{L^2_w(\mathfrak{R}_+)}\leqslant CN^{-s/2}\|f\|_{H^s_{wk}(\mathfrak{R}_+)}, \tag{42}$$

where k is the largest integer less than $s+1$. □

Remark 1: This theorem implies that, once s is fixed, then given any $\epsilon>0$, there is an N such that

$$\|f-\pi^N f\|_{L^2_w(\mathfrak{R}_+)}\leqslant CN^{-s/2}\|f\|_{H^s_{wk}(\mathfrak{R}_+)}<\epsilon. \tag{43}$$

Remark 2: The above concepts and theorem generalize to higher dimension tensorized domains.[55] Of interest to us is the generalization to $\mathfrak{R}^2_+=[0,\infty)\times[0,\infty)$, briefly outlined below.

A function $f(x,y)$ satisfying $\int_0^\infty\int_0^\infty f(x,y)e^{-(x+y)}dxdy<\infty$ can be expanded as

$$f(x,y)=\sum_{k,l=0}^{\infty} c_{kl}l_k(x)l_l(y),$$

where

$$c_{kl}=\int_0^\infty\int_0^\infty f(x,y)l_k(x)l_l(y)e^{-(x+y)}dxdy,$$

and where $\{l_k(x)l_l(y):k,l=0,\ldots,N\}$ is a basis for the tensor space $P_N(\mathfrak{R}^2_+)\equiv P_N(\mathfrak{R}_+)\times P_N(\mathfrak{R}_+)=\{p_{ij}(x,y)|p_{ij}(x,y)=p_i(x)p_j(y)$ for $p_i(x),p_j(y)\in P_N(\mathfrak{R}_+)$ and integers $0\leqslant i,j\leqslant N\}$. The orthogonal projection operator $\Pi^N:L^2_w(\mathfrak{R}^2_+)\to P_N(\mathfrak{R}^2_+)$ from the tensor Sobolev space $L^2_w(\mathfrak{R}^2_+)$ onto $P_N(\mathfrak{R}^2_+)$ is defined by

$$\Pi^N f(x,y)=\sum_{k,l=0}^{N} c_{kl}l_k(x)l_l(y),\quad \forall f\in L^2_w(\mathfrak{R}^2_+). \tag{44}$$

It is easily shown that Π^N is the composite of the individual orthogonal projection operators, π^N_x and π^N_y, i.e., $\Pi^N=\pi^N_x\circ\pi^N_y$, where the subscripts x and y indicate the variable with which the operator π^N, defined in Eq. (40), is applied.

The generalization of Theorem 2 then tells us that given any $\epsilon>0$ there is an N such that

$$\|f(x,y)-\Pi^N f(x,y)\|_{L^2_w(\mathfrak{R}^2_+)}<\epsilon. \tag{45}$$

Equation (45) is the result we use in the following subsection to complete the proof.

C. Equivalence of models: General case

The proof of Eq. (14) for the general case of arbitrary strain functions, satisfying the conditions of Theorem 1, can now be given. It follows from the case of polynomial strain functions and the approximation of functions on unbounded domains given in the previous subsections.

Given any $\epsilon>0$, let N of Eq. (45) be fixed. By the hypothesis of Theorem 1, the functions h_1 and h_2 are in the weighted Laguerre space $L^2_w(\Re^2_+)$. Therefore, h_1 and h_2 can be approximated by polynomials $\hat{h}_{1,N}$ and $\hat{h}_{2,N}$ using Laguerre polynomial basis functions. Following the notation of the previous subsection, we have

$$\hat{h}_{1,N}(I_1,I_2)=\Pi^N h_1(I_1,I_2)=\sum_{i,j=0}^{N}\hat{b}_{ij}l_i(I_1)l_j(I_2),$$

$$\hat{h}_{2,N}(I_1,I_2)=\Pi^N h_2(I_1,I_2)=\sum_{i,j=0}^{N}\hat{c}_{ij}l_i(I_1)l_j(I_2),$$

where Π^N is the orthogonal projection operator given in Eq. (44). The approximating polynomials $\hat{h}_{1,N}$ and $\hat{h}_{2,N}$ can be rewritten in terms of the basis $\{(I_1-3)^i(I_2-3)^j\}$ as follows:

$$\hat{h}_{1,N}(I_1,I_2)=\sum_{i,j=0}^{N}b_{ij}(I_1-3)^i(I_2-3)^j=\sum_{\substack{i,j=0\\ i+j\leqslant N'}}^{N'}b_{ij}(I_1-3)^i(I_2-3)^j=h_{1,N'}(I_1,I_2),$$

$$\hat{h}_{2,N}(I_1,I_2)=\sum_{i,j=0}^{N}c_{ij}(I_1-3)^i(I_2-3)^j=\sum_{\substack{i,j=0\\ i+j\leqslant N'}}^{N'}c_{ij}(I_1-3)^i(I_2-3)^j=h_{2,N'}(I_1,I_2),$$

where $N'=2N$.

From the extension of Theorem 2 to $\Re^2_+$, i.e., Eq. (45),

$$\|h_i(I_1,I_2)-h_{i,N'}(I_1,I_2)\|_{L^2_w(\Re^2_+)}<\epsilon \tag{46}$$

for $i=1,2$.

Now, from the result for the special case of polynomial strain functions [Lemma 1, Eq. (33)], we know that for $h_{1,N'}$ and $h_{2,N'}$ there exists polynomials $f_{1,N'}$ and $f_{2,N'}$ such that

$$h_{1,N'}=\sum_{\substack{i,j=0\\ i+j\leqslant N'}}^{N'}(f^1_{ij}p^1_i p^{3\prime}_j+f^2_{ij}p^3_i p^{2\prime}_j)=F_{1,N'},$$

$$h_{2,N'}=\sum_{\substack{i,j=0\\ i+j\leqslant N'}}^{N'}(f^1_{ij}p^2_i p^{3\prime}_j+f^2_{ij}p^3_i p^{1\prime}_j)=F_{2,N'},$$

where f^1_{ij} and f^2_{ij} are the coefficients in the polynomials $f_{1,N'}$ and $f_{2,N'}$. Replacing $h_{i,N'}$ with $F_{i,N'}$ in Eq. (46) gives us the desired error estimate

$$\|h_i(I_1,I_2)-F_{i,N'}(I_1,I_2)\|_{L^2_w(\Re^2_+)}<\epsilon \tag{47}$$

for $i=1,2$.

Thus we have shown that for every $\epsilon>0$, there is an N' and polynomial functions f_1 and f_2 of degree N' such that the weighted error between h_i and the expression $F_{i,N'}$, which is uniquely defined in terms of the coefficients of f_i, is less than ϵ. This completes the proof.

□

VI. DISCUSSION

We conclude by making some additional small remarks about the conditions of Theorem 1, followed by some properties of the transformation in Eqs. (36) and (37), and finally a corollary to the theorem.

First, we remark that the conditions on the functions h_i and f_i in Eqs. (12) and (13) in Theorem 1 pose no serious restriction. In particular, the realistic forms for h_i decrease to zero as $I_1, I_2 \to \infty$, and it is reasonable to assume that realistic forms for f_i do the same.

Second, the condition on the equivalence that $\mu(0) < \infty$, or $m(0) < \infty$, is needed since the probability density $p(s)$ is not integrable when $\mu(s) \to \infty$ as $s \to 0$. Apparently, this excludes the Doi–Edwards reptation model, which can be written as a Rivlin–Sawyers integral, from having an equivalent stochastic form, Eq. (11), since, in the Doi–Edwards model, $\mu(s) \sim 1/\sqrt{s}$, for small s. However, the divergence of $\mu(s)$ in the Doi–Edwards model results from an infinite number of increasingly higher frequency modes, only a finite number of which can be physically meaningful. Therefore, one can safely truncate after a finite number of modes, without changing the essential physics, but removing the singularity.

Third, the system in Eqs. (36) and (37) results only if the degree of the polynomial approximation of all functions, h_1, h_2, f_1, and f_2, is the same. However, this is not a restriction since such a condition can always be met. The proof proceeds even if one of the functions is identically zero. The corresponding coefficient vector, in this case, is the zero vector.

From the properties of the polynomials p_n^m (or equivalently $p_n^{m'}$), $m = 1,2,3$, it can be seen that the matrices $\mathbf{L}_1$ and $\mathbf{L}_2$ have the forms,

$$\mathbf{L}_1 = \begin{pmatrix} \mathbf{D}_{N+1}^{(N)} & & & & & & & \\ \mathbf{M}_{N,N+1}^{(N)} & \mathbf{D}_N^{(N-1)} & & & & & & \\ \mathbf{M}_{N-1,N+1}^{(N)} & \mathbf{M}_{N-1,N}^{(N-1)} & \mathbf{D}_{N-1}^{(N-2)} & & & & & \\ \cdot & \cdot & \cdot & \cdot & & & & \\ \cdot & \cdot & \cdot & & \cdot & & & \\ \cdot & \cdot & \cdot & & & \cdot & & \\ \mathbf{M}_{2,N+1}^{(N)} & \mathbf{M}_{2,N}^{(N-1)} & \mathbf{M}_{2,N-1}^{(N-2)} & \cdot & \cdot & \cdot & \mathbf{D}_2^{(1)} & \\ \mathbf{M}_{1,N+1}^{(N)} & \mathbf{M}_{1,N}^{(N-1)} & \mathbf{M}_{1,N-1}^{(N-2)} & \cdot & \cdot & \cdot & \mathbf{M}_{1,2}^{(1)} & 1 \end{pmatrix}, \tag{48}$$

$$\mathbf{L}_2 = \begin{pmatrix} \mathbf{0}_{N+1,N+1}^{(N)} & & & & & & & & \\ \tilde{\mathbf{D}}_N^{(N)} | \mathbf{0}_{N,1}^{(N)} & \mathbf{0}_{N,N}^{(N-1)} & & & & & & & \\ \tilde{\mathbf{M}}_{N-1,N}^{(N)} | \mathbf{0}_{N-1,1}^{(N)} & \tilde{\mathbf{D}}_{N-1}^{(N-1)} | \mathbf{0}_{N-1,1}^{(N-1)} & \mathbf{0}_{N-1,N-1}^{(N-2)} & & & & & & \\ \tilde{\mathbf{M}}_{N-2,N}^{(N)} | \mathbf{0}_{N-2,1}^{(N)} & \tilde{\mathbf{M}}_{N-2,N-1}^{(N-1)} | \mathbf{0}_{N-2,1}^{(N-1)} & \tilde{\mathbf{D}}_{N-2}^{(N-2)} | \mathbf{0}_{N-2,1}^{(N-2)} & \mathbf{0}_{N-2,N-2}^{(N-3)} & & & & & \\ \cdot & \cdot & \cdot & \cdot & \cdot & & & & \\ \cdot & \cdot & \cdot & \cdot & & \cdot & & & \\ \cdot & \cdot & \cdot & \cdot & & & \cdot & & \\ \tilde{\mathbf{M}}_{2,N}^{(N)} | \mathbf{0}_{2,1}^{N} & \tilde{\mathbf{M}}_{2,N-1}^{(N-1)} | \mathbf{0}_{2,1}^{(N-1)} & \tilde{\mathbf{M}}_{2,N-2}^{(N-2)} | \mathbf{0}_{2,1}^{(N-2)} & \tilde{\mathbf{M}}_{2,N-3}^{(N-3)} | \mathbf{0}_{2,1}^{(N-3)} & \cdot & \cdot & \cdot & \mathbf{0}_{2,2}^{(1)} & \\ \tilde{\mathbf{M}}_{1,N}^{(N)} | 0 & \tilde{\mathbf{M}}_{1,N-1}^{(N-1)} | 0 & \tilde{\mathbf{M}}_{1,N-2}^{(N-2)} | 0 & \tilde{\mathbf{M}}_{2,N-3}^{(N-3)} | 0 & \cdot & \cdot & \cdot & \tilde{\mathbf{D}}_1^{(1)} | 0 & 0 \end{pmatrix}. \tag{49}$$

Each $\mathbf{M}_{lm}^{(n)}$ and $\tilde{\mathbf{M}}_{lm}^{(n)}$ is an $l \times m$ matrix; $\mathbf{D}_m^{(n)}$ is an $m \times m$ diagonal matrix with all nonzero entries along the principal diagonal (i.e., $[\mathbf{D}_m^{(n)}]_{ii} \neq 0$); $\tilde{\mathbf{D}}_m^{(n)}$ is an $m \times m$ matrix which contains all zero entries except for entries along its minor diagonal which are all nonzero ($[\tilde{\mathbf{D}}_m^{(n)}]_{i,n-i+1} \neq 0$); and $\mathbf{0}_{lm}^{(n)}$ is the $l \times m$ zero matrix. In all matrices, the superscript (n) indicates that the matrix entries are coefficients of terms of order n. Columns k_{0j}, $j = 0, \ldots, N$, of $\mathbf{L}_2$ contain only zeros since $p_0^2 = p_0^{2'} = 0$.

Let $\mathbf{L}_1^{(n)}$ and $\mathbf{L}_2^{(n)}$ be the $\mathbf{L}_1$ and $\mathbf{L}_2$ matrices corresponding to polynomial approximations of degree n. We have the following relations between $\mathbf{L}_1^{(n)}$ and $\mathbf{L}_2^{(n)}$ and the matrices corresponding to polynomial approximations of degree $(n-1)$,

$$\mathbf{L}_1^{(n)}=\begin{pmatrix} \mathbf{D}_{n+1}^{(n)} & \\ \mathbf{M}_{n(n+1)/2,n+1}^{(n)} & \mathbf{L}_1^{(n-1)} \end{pmatrix},$$

$$\mathbf{L}_2^{(n)}=\begin{pmatrix} \mathbf{0}_{n+1}^{(n)} & \\ \tilde{\mathbf{M}}_{n(n+1)/2,n+1}^{(n)} & \mathbf{L}_2^{(n-1)} \end{pmatrix}.$$

Note that the addition of higher order terms with zero coefficients does not change the solution due to the form of $\mathbf{L}_1^{(n)}$ and $\mathbf{L}_2^{(n)}$ above.

The forms of $\mathbf{L}_1$ and $\mathbf{L}_2$ allow us to write directly the solution $\mathbf{f}$ of the system in Eqs. (36) and (37) as follows: For $i,j=0,\ldots,N, i+j\leqslant N$, the k_{ij} entry of $\mathbf{f}^1$ and $\mathbf{f}^2$ are

$$f_{ij}^1=\frac{1}{[\mathbf{L}_1]_{k_{ij}k_{ij}}}\left[b_{ij}-\sum_{\substack{l,m=0\\ i+j+1\leqslant l+m\leqslant N}}^{N} ([\mathbf{L}_1]_{k_{ij}k_{lm}} f_{lm}^1+[\mathbf{L}_2]_{k_{ij}k_{lm}} f_{ml}^2)\right], \tag{50}$$

$$f_{ji}^2=\frac{1}{[\mathbf{L}_1]_{k_{ij}k_{ij}}}\left[c_{ji}-\sum_{\substack{l,m=0\\ i+j+1\leqslant l+m\leqslant N}}^{N} ([\mathbf{L}_1]_{k_{ij}k_{lm}} f_{ml}^2+[\mathbf{L}_2]_{k_{ij}k_{lm}} f_{lm}^1)\right]. \tag{51}$$

Note that for each i,j the expressions defining f_{ij}^1 and f_{ji}^2 only involve variables f_{lm}^1 and f_{ml}^2 corresponding to higher-order terms, i.e., $l+m>i+j$.

From Eqs. (50) and (51) and the properties of matrices $\mathbf{L}_1$ and $\mathbf{L}_2$, a corollary to Theorem 1 results concerning the (factorized) K-BKZ class of equations. The K-BKZ constitutive equation forms a subclass of the Rivlin–Sawyers equation, Eq. (1), in which the strain functions h_1 and h_2 are defined in terms of a potential function $W=W(I_1,I_2)$ as $h_1=\partial W/\partial I_1$ and $h_2=-\partial W/\partial I_2$. Therefore, the strain functions in the K-BKZ equation satisfy the condition

$$\frac{\partial h_1(I_1,I_2)}{\partial I_2}=-\frac{\partial h_2(I_1,I_2)}{\partial I_1}. \tag{52}$$

The following corollary can be shown.

Corollary: The factorized K-BKZ subclass of factorized Rivlin–Sawyers constitutive equations, which satisfies the condition in Eq. (52), is equivalent to the subclass of equations for $\langle \mathbf{F}(\mathbf{Q}(t))\rangle$, given by Eq. (11), in which the functions f_1 and f_2 satisfy the condition

$$\frac{\partial f_1(Q_1^2,Q_2^2)}{\partial Q_2^2}=-\frac{\partial f_2(Q_1^2,Q_2^2)}{\partial Q_1^2}. \tag{53}$$

□

In other words, this corollary says that $\partial h_1/\partial I_2=-\partial h_2/\partial I_1$ if and only if $\partial f_1/\partial Q_2^2=-\partial f_2/\partial Q_1^2$.

The proof of this corollary is established as follows. If the functions h_1, h_2, f_1, and f_2 are written as polynomials of degree N as indicated in Eqs. (18) and (19), then Eqs. (52) and (53) are, respectively, equivalent to the following relationships between the polynomial coefficients:

$$c_{ij}=-\left(\frac{j+1}{i}\right) b_{i-1,j+1}, \tag{54}$$

$$f^2_{ij} = -\left(\frac{j+1}{i}\right) f^1_{i-1,j+1} \tag{55}$$

for $i=1,\ldots,N$, $j=0,\ldots,N-1$, and $i+j\leqslant N$. The corollary is proved by showing that condition (54) holds if and only if condition (55) holds. This can be seen to follow directly from Eqs. (50) and (51) and the properties of matrices $\mathbf{L}_1$ and $\mathbf{L}_2$ given above and in the Appendix.

APPENDIX: PROOF OF CLAIM 3

To prove Claim 3 we need to show that $\mathbf{A}_{11}=\mathbf{A}_{22}=\mathbf{L}_1$ and $\mathbf{A}_{12}=\mathbf{A}_{21}=\mathbf{L}_2$ are lower triangular matrices, and $[\mathbf{L}_1]_{kk}\neq 0$ and $[\mathbf{L}_2]_{kk}=0$ for all $k=1,\ldots,(N+1)(N+2)/2$.

(1) Entry $(k_{i'j'},k_{ij})$ of matrix $\mathbf{A}_{11}$ [in Eq. (34)] contains the coefficient of $(I_1-3)^{i'}(I_2-3)^{j'}$ in the series $p^1_i p^{3'}_j$, which by Eqs. (26) and (31) is

$$\begin{aligned} p^1_i p^{3'}_j &= (2i+1)!!(2j-1)!!\,(I_1-3)^i(I_2-3)^j \\ &\quad + (2i+1)!!(I_1-3)^i \sum_{\substack{m,n=0\\ m+n\leqslant j-1}}^{j-1} \gamma^{(j)}_{nm}(I_1-3)^m(I_2-3)^n \\ &\quad + (2j-1)!!(I_2-3)^j \sum_{\substack{m,n=0\\ m+n\leqslant i-1}}^{i-1} \beta^{(i)}_{mn}(I_1-3)^m(I_2-3)^n \\ &\quad + \sum_{\substack{m,n=0\\ m+n\leqslant i-1}}^{i-1} \sum_{\substack{m',n'=0\\ m'+n'\leqslant j-1}}^{j-1} \beta^{(i)}_{mn}\gamma^{(j)}_{n'm'}(I_1-3)^{m+m'}(I_2-3)^{n+n'} \end{aligned} \tag{A1}$$

for $j=1,2,\ldots$ and all i. For $j=0$, $p^1_i p^{3'}_j$ is simply p^1_i [given in Eq. (26)] since $p^{3'}_0=1$. There is only one term of the highest possible order $i+j$, which is seen on the first line of Eq. (A1). The series on the second and third lines are each of order $i+j-1$, while the series on the fourth line is of order $i+j-2$. Since the order of Eq. (A1) is $i+j$ and given the fact that $i'+j'>i+j$ implies $k_{i'j'}<k_{ij}$ (as previously noted by our numbering convention), it follows that $[\mathbf{A}_{11}]_{k_{i'j'}k_{ij}}=0$ for $k_{i'j'}<k_{ij}$. This says that $\mathbf{A}_{11}$ is a lower triangular matrix. The fact that $\mathbf{A}_{11}$ has nonzero diagonal entries follows from the observation that $k_{ij}=k_{i'j'}$ if and only if $i=i'$ and $j=j'$, so that $[\mathbf{A}_{11}]_{k_{ij}k_{ij}}=(2i+1)!!(2j-1)!!\neq 0$ for $j=1,2,\ldots$ and $[\mathbf{A}_{11}]_{k_{ij}k_{ij}}=(2i+1)!!\neq 0$ for $j=0$.

(2) Entry $(k_{i'j'},k_{ij})$ of matrix $\mathbf{A}_{12}$ [in Eq. (34)] contains the coefficient of $(I_1-3)^{i'}(I_2-3)^{j'}$ in the series $p^3_j p^{2'}_i$, which by Eqs. (29) and (30) is

$$\begin{aligned} p^3_j p^{2'}_i &= 2i(2i-1)!!(2j-1)!!(I_1-3)^j(I_2-3)^{i-1} \\ &\quad + 2i(2j-1)!!(I_1-3)^j \sum_{\substack{m,n=0\\ m+n\leqslant i-2}}^{i-2} \beta^{(i-1)}_{nm}(I_1-3)^m(I_2-3)^n \\ &\quad + 2i(2i-1)!!(I_2-3)^{i-1} \sum_{\substack{m,n=0\\ m+n\leqslant j-1}}^{j-1} \gamma^{(j)}_{mn}(I_1-3)^m(I_2-3)^n \end{aligned}$$

$$+2i\sum_{\substack{m,n=0\\ m+n\leqslant j-1}}^{j-1}\ \sum_{\substack{m',n'=0\\ m'+n'\leqslant i-2}}^{i-2}\gamma_{mn}^{(j)}\beta_{n'm'}^{(i-1)}(I_1-3)^{m+m'}(I_2-3)^{n+n'} \tag{A2}$$

for $i,j=1,2,\ldots$. For $j=0$, $p_j^3 p_i^{2'}$ reduces to $p_i^{2'}$ [given in Eq. (29)] since $p_0^3=1$, while the series vanishes whenever $i=0$ since $p_0^{2'}=0$. The order of Eq. (A2) is only $i+j-1$, and the single term of this order appears on the first line. The series on the second and third lines are each of order $i+j-2$, while the series on the fourth line is of order $i+j-3$. The fact that $\mathbf{A}_{12}$ is a lower triangular matrix follows from the same argument given above for $\mathbf{A}_{11}$. Similarly, the diagonal entries of $\mathbf{A}_{12}$ are all zero since $[\mathbf{A}_{12}]_{k_{ij}k_{ij}}$ is the coefficient of $(I_1-3)^i(I_2-3)^j$, but $p_j^3 p_i^{2'}$ is only of order $i+j-1$, for $i\neq 0$ and is zero for $i=0$.

(3) Entry $(k_{i'j'},k_{ij})$ of matrix $\mathbf{A}_{22}$ [in Eq. (35)] contains the coefficient of $(I_1-3)^{j'}(I_2-3)^{i'}$ in the series $p_i^{1'}p_j^3$. The coefficient of $(I_1-3)^{j'}(I_2-3)^{i'}$ in $p_i^{1'}p_j^3$ equals the coefficient of $(I_1-3)^{i'}(I_2-3)^{j'}$ in $p_i^1 p_j^{3'}$, which is the $(k_{i'j'},k_{ij})$ entry of matrix $\mathbf{A}_{11}$.

The fact that $\mathbf{A}_{22}=\mathbf{A}_{11}$ follows from two observations. First, the different ordering of the coefficients in **b** and **c** is such that row k_{ij} of **b** corresponds to the coefficient of $(I_1-3)^i(I_2-3)^j$ (in the series expansion of damping function h_1) iff row k_{ij} of **c** corresponds to the coefficient of $(I_1-3)^j(I_2-3)^i$ (in the series expansion of damping function h_2). Second, $p_j^{1'}p_i^3$ and $p_i^1 p_j^{3'}$ are identical if in either one, i and j are first interchanged and then all I_1 and I_2 are interchanged (since by Observation 1 p_i^1 and $p_i^{1'}$ are identical if I_1 and I_2 are interchanged in either expression, as are p_i^3 and $p_i^{3'}$ by Observation 3).

(4) Entry $(k_{i'j'},k_{ij})$ of matrix $\mathbf{A}_{21}$ [in Eq. (35)] contains the coefficient of $(I_1-3)^{j'}(I_2-3)^{i'}$ in the series $p_i^2 p_j^{3'}$. The coefficient of $(I_1-3)^{j'}(I_2-3)^{i'}$ in $p_i^2 p_j^{3'}$ equals the coefficient of $(I_1-3)^{i'}(I_2-3)^{j'}$ in $p_i^{2'}p_j^3$, which is the $(k_{i'j'},k_{ij})$ entry of matrix $\mathbf{A}_{12}$.

$\mathbf{A}_{21}=\mathbf{A}_{12}$ by arguments similar to those given in part (3). □

(Received 23 May 2000; accepted for publication 11 July 2000)

The photon sphere concept in Schwarzschild space–time is generalized to a definition of a photon surface in an arbitrary space–time. A photon sphere is then defined as an $SO(3)\times\mathbb{R}$-invariant photon surface in a static spherically symmetric space–time. It is proved, subject to an energy condition, that a black hole in any such space–time must be surrounded by a photon sphere. Conversely, subject to an energy condition, any photon sphere must surround a black hole, a naked singularity or more than a certain amount of matter. A second order evolution equation is obtained for the area of an $SO(3)$-invariant photon surface in a general nonstatic spherically symmetric space–time. Many examples are provided. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1308507]

I. INTRODUCTION

The exterior region of the maximally extended Schwarzschild space–time is described by the metric

$$\mathbf{g}=-\left(1-\frac{2m}{r}\right)dt^2+\left(1-\frac{2m}{r}\right)^{-1}dr^2+r^2(d\theta^2+\sin^2\theta\,d\phi^2),\quad r>2m. \tag{1}$$

For any null geodesic in this exterior region the null geodesic equations give

$$\frac{d^2r}{d\lambda^2}=(r-3m)\left\{\left(\frac{d\theta}{d\lambda}\right)^2+\sin^2\theta\left(\frac{d\phi}{d\lambda}\right)^2\right\}, \tag{2}$$

where λ is an affine parameter along the geodesic. The right side here is evidently positive for $r>3m$ and negative for $r:2m<r<3m$. It follows that any future endless null geodesic in the maximally extended Schwarzschild space–time starting at some point with $r>3m$ and initially directed outwards, in the sense that $dr/d\lambda$ is initially positive, will continue outwards and escape to infinity. Any future endless null geodesic in the maximally extended Schwarzschild space–time starting at some point with $r:2m<r<3m$ and initially directed inwards, in the sense that $dr/d\lambda$ is initially negative, will continue inwards and fall into the black hole. The hypersurface $\{r=3m\}$, known as the Schwarzschild photon sphere, thus distinguishes the borderline between these two types of behavior; any null geodesic starting at some point of the photon sphere and initially tangent to the photon sphere will remain in the photon sphere. (See Darwin[1,2] for a detailed analysis of the behavior of null and timelike geodesics in Schwarzschild space–time.)

The Schwarzschild photon sphere also has physical significance for massive bodies. For any timelike geodesic in the exterior region the geodesic equations give

[a)]Deceased.
[b)]Electronic mail: shwetket@maths.uct.ac.za
[c)]Electronic mail: ellis@maths.uct.ac.za

$$\frac{d^2r}{ds^2} = -\frac{m}{r^2} + (r-3m)\left\{\left(\frac{d\theta}{ds}\right)^2 + \sin^2\theta\left(\frac{d\phi}{ds}\right)^2\right\}, \tag{3}$$

where s is the arc length along the geodesic. At any point with $r>3m$ one may arrange for the two terms on the right of (3) to cancel and so obtain a timelike geodesic at constant r. For $r:2m<r<3m$ the right hand side of (3) is evidently negative. Thus any future endless timelike geodesic in the maximally extended Schwarzschild space–time starting at some point between the event horizon at $r=2m$ and the photon sphere at $r=3m$ and initially directed inwards, in the sense that dr/ds is initially negative, will continue inwards and fall into the black hole. Any observer who traverses a Schwarzschild photon sphere must therefore engage some form of propulsion or else be drawn in to the black hole to meet an inevitable fate.

A photon sphere has been defined by Virbhadra and Ellis[3] as a timelike hypersurface of the form $\{r=r_0\}$ where r_0 is the closest distance of approach for which the Einstein bending angle of a light ray is unboundedly large. These authors subsequently[4] considered the Einstein deflection angle for a general static spherically symmetric metric and obtained an equation for a photon sphere. The existence of a photon sphere in a space–time has important implications for gravitational lensing. In any space–time containing a photon sphere, gravitational lensing will give rise to relativistic images.[3,4]

The Schwarzschild photon sphere may be usefully compared with the concept of a closed trapped surface. Any null geodesic originating from any point on a closed trapped surface in Schwarzschild space–time is drawn into the singularity at $r=0$. By contrast, any null geodesic originating from any point on the photon sphere will be drawn into the singularity if and only if it is initially directed inwards.

Our main objectives in the present paper are to give a geometric definition of a photon surface in a general space–time and of a photon sphere in a general static spherically symmetric space–time.

An evolution equation is obtained for the cross-sectional area of a photon surface in a dynamic spherically symmetric space–time. It is shown, subject to suitable energy conditions, that in any static spherically symmetric space–time a black hole must be surrounded by a photon sphere, and a photon sphere must surround either a black hole, a naked singularity or more than a certain amount of matter. Many examples are given of photon spheres in static spherically symmetric space–times. Photon surface evolution is considered for the dynamic space–time example of Vaidya null dust collapse to a naked singularity.

II. PHOTON SURFACES

The hypersurface $S:=\{r=3m\}$ in Schwarzschild space–time has two main properties: first that any null geodesic initially tangent S will remain tangent to S, and second that S does not evolve with time. The following general definition of a photon surface is based on only the first of these properties. A more restrictive class of photon surfaces may be defined when the space–time admits a group of symmetries (see Definition II.2).

Definition II.1: A photon surface of $(M,\mathbf{g})$ is an immersed, nowhere-spacelike hypersurface S of $(M,\mathbf{g})$ such that, for every point $p\in S$ and every null vector $\mathbf{k}\in T_pS$, there exists a null geodesic $\gamma:(-\epsilon,\epsilon)\to M$ of $(M,\mathbf{g})$ such that $\dot\gamma(0)=\mathbf{k}, |\gamma|\subset S$.

Any null hypersurface is trivially a photon surface. Photon surfaces are conformally invariant structures. If S is a photon surface of $(M,\mathbf{g})$ then S is a photon surface of $(M,\Omega^2\mathbf{g})$ for any smooth function $\Omega:M\to(0,\infty)$.

Note that Definition II.1 is entirely local. In particular, a photon surface S need contain no endless null geodesics of $(M,\mathbf{g})$. Moreover, a photon surface need only be immersed, rather than embedded in M, and so may have self-intersections. If $(M,\mathbf{g})$ is of dimension $n+1$ $(n\geqslant 2)$ then, through each point p of a photon surface S in $(M,\mathbf{g})$, there is an $(n-2)$-parameter family of null geodesics of $(M,\mathbf{g})$ that lie entirely in S.

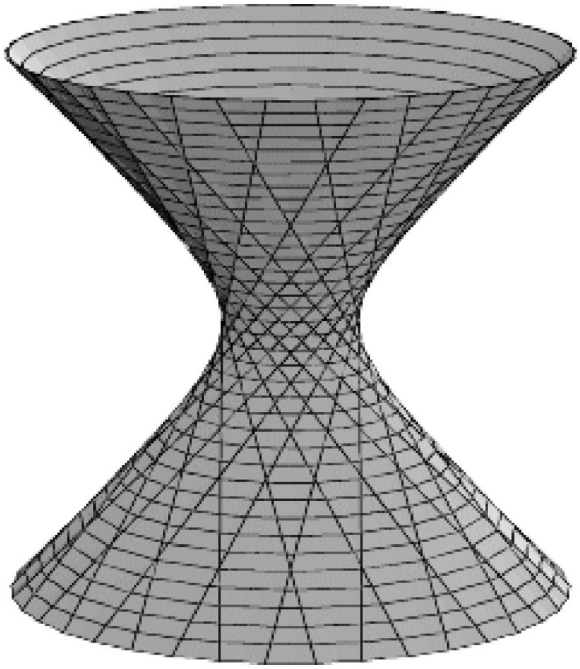

FIG. 1. A photon surface in Minkowski 3-space. The two families of ruling lines are null geodesics with respect to both the Minkowski 3-metric and the induced 2-metric. The lines may be regarded as the space–time paths of pulsed laser beams.

In this paper we will be principally concerned with photon surfaces in space–times of $3+1$ dimensions. The exceptions are Examples 1 and 3 which give photon surfaces in space–times of dimension $2+1$ and $4+1$, respectively.

Example 1 (Minkowski 3-space): In Minkowski 3-space $\mathbb{M}^3$, consider the single-sheeted hyperboloid S given by

$$-t^2+x^2+y^2=a^2, \tag{4}$$

for some constant $a>0$. This surface is doubly ruled, the rulings being given by

$$\gamma_\theta^{\pm}(t) := a(0,\cos\theta,\sin\theta)+at(1,\mp\sin\theta,\pm\cos\theta) \tag{5}$$

$(-\infty<t<\infty, 0\leqslant\theta<2\pi)$, where θ identifies the intersection points with $\{t=0\}$ and t is the parameter along the ruling lines. The tangents $\dot{\gamma}_\theta^{\pm}(t)$ to the ruling lines are null with respect to the $\mathbb{M}^3$ metric. Clearly they are geodesics in $\mathbb{M}^3$. At each point of S there can be just two null directions tangent to S. These must therefore be the directions of the two ruling lines through that point. Hence S is a photon surface in the sense of Definition II.1 (see Fig. 1).

Note that for any circle of the form

$$C=\{t_0,x_0+r\cos\theta,y_0+r\sin\theta\}, \quad r>0, \tag{6}$$

and any future-directed timelike vector field $\mathbf{X}$ along C that respects the symmetry of C, in the sense of

$$\mathbf{X}=(X^t,X^r\cos\theta,X^r\sin\theta), \tag{7}$$

for constant $X^t>0$, X^r such that $(X^t)^2>(X^r)^2$, there is a unique single-sheeted hyperboloid S through C such that $\mathbf{X}$ is tangent to S along C.

In the case $a=0$, Eq. (4) gives the null cone through the origin. The complement of p in this null cone is a null photon surface of $\mathbb{M}^3$.

Example 2 (Minkowski 4-space): One may generalize Example 1 to Minkowski 4-space $\mathbb{M}^4$ as follows. Let S be a timelike hypersurface in $\mathbb{M}^4$ of the form

$$-t^2+x^2+y^2+z^2=a^2, \tag{8}$$

for some constant $a>0$. The two-parameter family of lines,

$$\gamma^{\pm}_{\theta,\phi}(t)=a(0,\cos\theta,\sin\theta\sin\phi,\sin\theta\cos\phi)+at(1,\mp\sin\theta,\pm\cos\theta\sin\phi,\pm\cos\theta\cos\phi), \tag{9}$$

foliate S and are null geodesics with respect to the $\mathbb{M}^4$ metric. For each $p\in S$, the tangents at p to those $\gamma^{\pm}_{\theta,\phi}(t)$ that pass through p can be shown to generate the null cone of T_pS. Hence S is a photon surface in the sense of Definition II.1. In terms of the double null coordinates,

$$u:=t+r, \tag{10}$$

$$v:=t-r, \tag{11}$$

for $r:=(x^2+y^2+z^2)^{1/2}$, Eq. (8) assumes the simple form

$$uv=-a^2. \tag{12}$$

In the future direction S tends asymptotically to the null hypersurface $\{v=0\}$, while in the past direction S tends asymptotically to the null hypersurface $\{u=0\}$.

Example 3 (de Sitter space): de Sitter space–time may be regarded[5] as a single-sheeted hyperboloid in Minkowski 5-space $\mathbb{M}^5$. By analogy with Examples 1 and 2, de Sitter space–time is thus realized as a photon surface in $\mathbb{M}^5$.

Example 4 (The Robertson–Walker models): Every Robertson–Walker model is conformally flat and therefore locally conformally transformable to Minkowski space. The photon surfaces of any Robertson–Walker model may thus be obtained, at least locally, by conformal transformations of Minkowski space.

Theorem II.1: *Let S be a timelike hypersurface of $(M,\mathbf{g})$. Let $\mathbf{n}$ be a unit normal field to S and let h_{ab} be the induced metric on S. Let χ_{ab} be the second fundamental form on S and let σ_{ab} be the trace-free part of χ_{ab}. Then the following are equivalent:*

(i) *S is a photon surface;*
(ii) *$\chi_{ab}k^ak^b=0, \forall$ null $\mathbf{k}\in T_pS, \ \forall p\in S$;*
(iii) *$\sigma_{ab}=0$;*
(iv) *every affine null geodesic of $(S,\mathbf{h})$ is an affine null geodesic of $(M,\mathbf{g})$.*

Proof: (i)⇒(ii). Suppose S is a photon surface. Let $p\in S$ and let $\mathbf{k}\in T_pS$ be null. There exists an affine null geodesic $\gamma:(-\epsilon,\epsilon)\to M$ of $(M,\mathbf{g})$ such that $\dot\gamma(0)=\mathbf{k}, |\gamma|\subset S$. One has

$$\chi_{ab}\dot\gamma^a\dot\gamma^b=n_{a;b}\dot\gamma^a\dot\gamma^b=(n_a\dot\gamma^a)_{;b}\dot\gamma^b=0, \tag{13}$$

along γ. At p this gives $\chi_{ab}k^ak^b=0$.

(ii)⇒(iii). Let $p\in S$. By (ii) one has $\sigma_{ab}k^ak^b=\chi_{ab}k^ak^b=0, \ \forall$ null $\mathbf{k}\in T_pS$. Let $\{\mathbf{e}_{(0)},\mathbf{e}_{(1)},\mathbf{e}_{(2)}\}$ be an orthonormal basis for T_pS with $\mathbf{e}_{(0)}$ timelike and $\mathbf{e}_{(1)}$, $\mathbf{e}_{(2)}$ spacelike. Any null $\mathbf{k}\in T_pS$, normalized such that $g(\mathbf{k},\mathbf{e}_{(0)})=-1$, has components $k^a=(1,\cos\psi,\sin\psi)$ with respect to $\{\mathbf{e}_{(0)},\mathbf{e}_{(1)},\mathbf{e}_{(2)}\}$ for some $\psi\in[0,2\pi)$. A calculation gives

$$\sigma_{ab}k^ak^b=(\sigma_{00}+\tfrac{1}{2}\sigma_{11}+\tfrac{1}{2}\sigma_{22})+2\sigma_{01}\cos\psi+2\sigma_{02}\sin\psi+\tfrac{1}{2}(\sigma_{11}-\sigma_{22})\cos2\psi+\sigma_{12}\sin2\psi. \tag{14}$$

This must vanish for all $\psi \in [0,2\pi)$. One thus has $\sigma_{01}=\sigma_{02}=\sigma_{12}=0$ and $-\sigma_{00}=\sigma_{11}=\sigma_{22}$. Since σ_{ab} is trace-free one must also have $\sigma_{00}=\sigma_{11}+\sigma_{22}$. There follows $\sigma_{ab}=0$.

(iii)⇒(iv). For any curve in S with null tangent $\mathbf{k}$ one has

$$k^a{}_{\|b}k^b = h^a{}_c k^c{}_{;b} k^b = k^a{}_{;b}k^b + (\sigma_{bc}k^b k^c)n^a, \tag{15}$$

where $\|$ denotes covariant differentiation in S with respect to $\mathbf{h}$. The second term on the right of (15) vanishes by hypothesis. If $\mathbf{k}$ is tangent to an affine null geodesic of $(S,\mathbf{h})$ then the term on the left of (15) also vanishes and so $\mathbf{k}$ is tangent to an affine null geodesic of $(M,\mathbf{g})$.

(iv)⇒(i). Let $p \in S$ and let $\mathbf{k} \in T_pS$ be null. Let $\gamma:(-\epsilon,\epsilon)\to S$ be an affine null geodesic of $(S,\mathbf{h})$ such that $\dot\gamma(0)=\mathbf{k}$. Then, by (iv), γ is an affine null geodesic of $(M,\mathbf{g})$ such that $\dot\gamma(0)=\mathbf{k}$, $|\gamma| \subset S$. □

Condition (iii) of Theorem II.1 is equivalent to a requirement that χ_{ab} is pure trace in the sense of

$$\chi_{ab} = \tfrac{1}{3}\Theta h_{ab}, \tag{16}$$

where $\Theta := h^{cd}\chi_{cd}$ is the expansion of the unit normal to S. For Example 1 one has $\Theta = 2/a$; for Example 2 one has $\Theta = 3/a$. [Note that, by a standard abuse of notation, h_{ab} denotes both the induced metric on S and the symmetric tensor field of rank (0,2) along S in M which satisfies $h_{ab}n^b=0$ and pulls back to the induced metric on S.]

It is clear from condition (iii) of Theorem II.1 that a space–time must be specialized in some respect in order to admit any timelike photon surfaces in the sense of Definition II.1. For this reason it is helpful to restrict attention to space–times which admit groups of symmetries.

Definition II.2: Suppose $(M,\mathbf{g})$ admits a group G of isometries. A photon surface S of $(M,\mathbf{g})$ that is invariant under G, in the sense that each $g \in G$ maps S onto itself, will be called a G-invariant photon surface.

Clearly any G-invariant null hypersurface is a G-invariant photon surface. In particular, if $G=\mathbb{R}$ or $G=\mathbb{S}$, then any Killing horizon[6,7] is a G-invariant photon surface.

III. DYNAMIC SPHERICAL SYMMETRY: GENERAL THEORY

By definition, a general spherically symmetric space–time admits an $SO(3)$ isometry group for which the group orbits are spacelike 2-spheres. The following result describes the evolution of the cross-sectional area of an $SO(3)$-invariant photon surface in a spherically symmetric space–time.

Theorem III.1: *Let $(M,\mathbf{g})$ be a spherically symmetric space–time. Let S be an $SO(3)$-invariant timelike hypersurface of $(M,\mathbf{g})$ and let $\mathbf{X}$ be the $SO(3)$-invariant unit future-directed timelike tangent vector field along S orthogonal to the $SO(3)$-invariant 2-spheres in S. Let $\mathcal{T}$ be one such $SO(3)$-invariant 2-sphere in S and let $\mathcal{T}_s$ be the $SO(3)$-invariant 2-sphere in S at arc length s from $\mathcal{T}$ along the integral curves of $\mathbf{X}$. Then S is a photon surface of $(M,\mathbf{g})$ iff the area ${}^{(2)}A_s$ of $\mathcal{T}_s$ satisfies*

$$\frac{d^2}{ds^2}{}^{(2)}A_s = \frac{1}{4\,{}^{(2)}A_s}\left(\frac{d}{ds}{}^{(2)}A_s\right)^2 + {}^{(2)}A_s\left(\frac{1}{3}\Theta^2 - G_{ab}n^a n^b\right) - 4\pi, \tag{17}$$

where n^a is the unit normal to S, Θ is the expansion of n^a and $G_{ab} := R_{ab} - \frac{1}{2}Rg_{ab}$ is the Einstein tensor of $(M,\mathbf{g})$.

Proof: Let h_{ab} be the induced Lorentzian 3-metric on S and, for each s, let ${}^{(2)}h_{ab}$ be the induced Riemannian 2-metric on $\mathcal{T}_s$. The expansion of $\mathbf{X}$ in $(S,\mathbf{h})$ is given by ${}^{(2)}\Theta = {}^{(2)}h^{ab}X_{a;b}$ where the covariant derivative is that of $(M,\mathbf{g})$. Since $\mathbf{X}$ is both shear-free and vorticity-free in $(S,\mathbf{h})$, the Raychaudhuri equation for $\mathbf{X}$ in $(S,\mathbf{h})$ assumes the form

$$\frac{d}{ds}{}^{(2)}\Theta = -\frac{1}{2}({}^{(2)}\Theta)^2 - {}^{(3)}R_{ab}X^aX^b, \tag{18}$$

where ${}^{(3)}R_{ab}$ is the Ricci tensor of $(S,\mathbf{h})$.

From first principles one has

$${}^{(2)}R = {}^{(3)}R + 2\,{}^{(3)}R_{ab}X^aX^b - ({}^{(2)}\chi^a{}_a)^2 + {}^{(2)}\chi^a{}_b\,{}^{(2)}\chi^b{}_a, \tag{19}$$

$${}^{(3)}R = R - 2R_{ab}n^an^b + (\chi^a{}_a)^2 - \chi^a{}_b\chi^b{}_a, \tag{20}$$

where ${}^{(2)}\chi_{ab}$ is the second fundamental form of each $\mathcal{T}_s$ in $(S,\mathbf{h})$. Since X^a is shear-free and vorticity free in $(S,\mathbf{h})$ one has ${}^{(2)}\chi_{ab} = \frac{1}{2}\,{}^{(2)}\Theta\,{}^{(2)}h_{ab}$. The second fundamental form of S admits the canonical decomposition $\chi_{ab} = \frac{1}{3}\Theta h_{ab} + \sigma_{ab}$. Equations (19) and (20) therefore give

$${}^{(2)}R = {}^{(3)}R + 2\,{}^{(3)}R_{ab}X^aX^b - \tfrac{1}{2}{}^{(2)}\Theta^2, \tag{21}$$

$${}^{(3)}R = R - 2R_{ab}n^an^b + \tfrac{2}{3}\Theta^2 - \sigma^a{}_b\sigma^b{}_a, \tag{22}$$

which combine to yield

$$2\,{}^{(3)}R_{ab}X^aX^b = {}^{(2)}R + 2G_{ab}n^an^b - \tfrac{2}{3}\Theta^2 + \tfrac{1}{2}({}^{(2)}\Theta)^2 + \sigma^a{}_b\sigma^b{}_a. \tag{23}$$

One may now substitute for the second term on the right of (18) to obtain

$$\frac{d}{ds}{}^{(2)}\Theta = -\frac{3}{4}({}^{(2)}\Theta)^2 + \frac{1}{3}\Theta^2 - \frac{1}{2}{}^{(2)}R - G_{ab}n^an^b - \frac{1}{2}\sigma^a{}_b\sigma^b{}_a. \tag{24}$$

From first principles one has ${}^{(2)}\Theta = (d/ds)\ln {}^{(2)}A$, and the Gauss–Bonnet theorem gives ${}^{(2)}R\,{}^{(2)}A = 8\pi$. Substituting for ${}^{(2)}\Theta$ and ${}^{(2)}R$ in (24) one obtains

$$\frac{d^2}{ds^2}{}^{(2)}A_s = \frac{1}{4\,{}^{(2)}A_s}\left(\frac{d}{ds}{}^{(2)}A_s\right)^2 + {}^{(2)}A_s\left(\frac{1}{3}\Theta^2 - G_{ab}n^an^b - \frac{1}{2}\sigma^a{}_b\sigma^b{}_a\right) - 4\pi. \tag{25}$$

This agrees with (17) iff $\sigma^a{}_b\sigma^b{}_a = 0$.

Construct, for the tangent bundle TS of S, an orthonormal basis field of the form $\{\mathbf{X},\mathbf{e}_{(1)},\mathbf{e}_{(2)}\}$, with $\mathbf{e}_{(1)}$ and $\mathbf{e}_{(2)}$ unit spacelike. With respect to this basis one has

$$\sigma^a{}_b\sigma^b{}_a = (\sigma^0{}_0)^2 + (\sigma^1{}_1)^2 + (\sigma^2{}_2)^2 + 2(\sigma^1{}_2)^2 - 2(\sigma^1{}_0)^2 - 2(\sigma^2{}_0)^2. \tag{26}$$

By spherical symmetry the vector field $\sigma^a{}_bX^b$ must be proportional to X^a. Hence one has $\sigma^1{}_0 = \sigma^2{}_0 = 0$. The vanishing of $\sigma^a{}_b\sigma^b{}_a$ is thus equivalent to the vanishing of σ_{ab}. One has $\sigma_{ab} = 0$ iff S is a photon surface. □

A spherically symmetric metric is locally expressible in the form

$$g_{ab} = \begin{pmatrix} g_{00} & g_{01} & 0 & 0 \\ g_{10} & g_{11} & 0 & 0 \\ 0 & 0 & g_{\theta\theta} & 0 \\ 0 & 0 & 0 & g_{\theta\theta}\sin^2\theta \end{pmatrix}, \tag{27}$$

with respect to coordinates (x^0,x^1,θ,ϕ) adapted to the spherical symmetry, where g_{00}, $g_{01} = g_{10}$, g_{11} and $g_{\theta\theta} > 0$ depend only on x^0 and x^1. It is often convenient to introduce a radial coordinate r, depending only on x^0 and x^1, such that $g_{\theta\theta}$ is a function of r only. One is free to specify $g_{\theta\theta}$ as a function of r alone since to do so is, in effect, a definition of the coordinate r. This will be assumed to be done throughout this paper.

The following result is useful in the locating of $SO(3)$-invariant photon surfaces in dynamic spherically symmetric space–times.

Lemma III.2: Let $(M,\mathbf{g})$ *be a spherically symmetric space–time. Let S be an* $SO(3)$*-invariant timelike hypersurface of* $(M,\mathbf{g})$ *and let* $\mathbf{X}$ *be the* $SO(3)$*-invariant unit future-directed timelike tangent vector field along S that is orthogonal to the* $SO(3)$*-invariant* 2*-spheres in S. Then S is a photon surface of* $(M,\mathbf{g})$ *iff*

$$X^a{}_{;b}X^b=\tfrac{1}{2}(g^{\theta\theta}n^b\partial_b g_{\theta\theta})n^a, \tag{28}$$

holds along S, where n^a *is the unit normal field to S in* $(M,\mathbf{g})$.

Proof: By spherical symmetry, and since $\mathbf{X}$ is unit timelike, the vector field $\nabla_{\mathbf{X}}\mathbf{X}$ must be proportional to $\mathbf{n}$. Hence it suffices to show that S is a photon surface iff along S one has

$$\mathbf{n}\cdot\nabla_{\mathbf{X}}\mathbf{X}=\tfrac{1}{2}g^{\theta\theta}n^b\partial_b g_{\theta\theta}, \tag{29}$$

or equivalently,

$$\chi_{ab}X^aX^b=-\tfrac{1}{2}g^{\theta\theta}n^a\partial_a g_{\theta\theta}. \tag{30}$$

Construct for TS a local orthonormal basis field of the form $\{\mathbf{X},\mathbf{e}_{(\theta)},\mathbf{e}_{(\phi)}\}$. With respect to this basis field the components of $\chi^a{}_b$ form a diagonal matrix with

$$\chi^\theta{}_\theta=\chi^\phi{}_\phi=n^\theta{}_{;\theta}=\tfrac{1}{2}g^{\theta\theta}n^a\partial_a g_{\theta\theta}. \tag{31}$$

Equation (30) is thus equivalent to $\chi^0{}_0=\chi^\theta{}_\theta=\chi^\phi{}_\phi$ which is in turn equivalent to $\sigma^0{}_0=\sigma^\theta{}_\theta=\sigma^\phi{}_\phi$. In view of the trace-free property of $\sigma^a{}_b$, Eq. (30) is thus equivalent to $\sigma^a{}_b=0$. From Theorem II.1 one has that $\sigma^a{}_b=0$ holds along S iff S is a photon surface. □

Let us continue to work with respect to the coordinate system $\{x^0,x^1,\theta,\phi\}$ employed in (27). Let $x^a(s)$ be an integral curve of the vector field $\mathbf{X}$ in Lemma III.2. One has

$$\frac{dx^a}{ds}=X^a, \tag{32}$$

and Eq. (28) becomes

$$\frac{d^2x^a}{ds^2}+\Gamma^a_{bc}\frac{dx^b}{ds}\frac{dx^c}{ds}=\frac{1}{2}(g^{\theta\theta}n^b\partial_b g_{\theta\theta})n^a. \tag{33}$$

Since $\mathbf{X}=(dx^0/ds)\,(1,dx^1/dx^0,0,0)$ is unit timelike one has

$$\left(\frac{ds}{dx^0}\right)^2=-g_{ab}\frac{dx^a}{dx^0}\frac{dx^b}{dx^0}. \tag{34}$$

The x^0 and x^1 components of Eq. (33) thus combine to give

$$\frac{d^2x^1}{(dx^0)^2}=-\frac{1}{2}g^{\theta\theta}n^a\partial_a g_{\theta\theta}\left(n^1-\frac{dx^1}{dx^0}n^0\right)g_{bc}\frac{dx^b}{dx^0}\frac{dx^c}{dx^0}+\left(\frac{dx^1}{dx^0}\Gamma^0_{ab}-\Gamma^1_{ab}\right)\frac{dx^a}{dx^0}\frac{dx^b}{dx^0}, \tag{35}$$

where the components of $\mathbf{n}$ are given by

$$n^0=\psi g_{1a}\frac{dx^a}{dx^0};\quad n^1=-\psi g_{0a}\frac{dx^a}{dx^0}, \tag{36}$$

for

$$\psi := (-\Delta)^{-1/2}\left(-g_{ab}\frac{dx^a}{dx^0}\frac{dx^b}{dx^0}\right)^{-1/2}, \tag{37}$$

where

$$\Delta := g_{00}g_{11} - (g_{01})^2 \tag{38}$$

is the determinant of the time–space part of g_{ab} in (27). Equation (35) is the coordinate equivalent of (28) and provides for the easy determination of $SO(3)$-invariant photon surfaces (see Example 10).

IV. STATIC SPHERICAL SYMMETRY: GENERAL THEORY

By definition, a spherically symmetric space–time is static if it admits an $SO(3)\times\mathbb{R}$ group of isometries such that the $\mathbb{R}$ orbits are generated by a Killing field **K** which is both hypersurface orthogonal and orthogonal to the $SO(3)$ orbits. In the present section we will be concerned with $SO(3)\times\mathbb{R}$-invariant photon surfaces in static spherically symmetric space–times. Such surfaces may be termed photon spheres because, as will be seen, they are a natural generalization to general static spherically symmetric space–times of the Schwarzschild photon sphere concept. The term ''photon sphere'' will be regarded as applicable only in static spherically symmetric space–times. For clarity, the term ''$SO(3)\times\mathbb{R}$-invariant photon surface'' will usually be employed in preference to ''photon sphere.''

Although the space–times of Examples 1 and 2 are static and spherically symmetric, the photon surfaces in these space–times are not $SO(3)\times\mathbb{R}$-invariant and so are not photon spheres. Of the Robertson–Walker space–times of Example 4, only the Einstein cylinder is both spherically symmetric and static. None of the photon surfaces of the Einstein cylinder are $SO(3)\times\mathbb{R}$-invariant. Thus the Einstein cylinder has no photon spheres.

One may characterize an $SO(3)\times\mathbb{R}$-invariant photon surface, or photon sphere, in a static spherically symmetric space–time by means of the following special case of Theorem III.1.

Theorem IV.1: *Let* $(M,\mathbf{g})$ *be a static spherically symmetric space–time with Killing field* **K** *and let* S *be an* $SO(3)\times\mathbb{R}$*-invariant timelike hypersurface of* $(M,\mathbf{g})$*. Then* S *is an* $SO(3)\times\mathbb{R}$*-invariant photon surface of* $(M,\mathbf{g})$ *if there exists an* $SO(3)$*-invariant* 2*-sphere* $\mathcal{T}\subset S$ *satisfying*

$$A(\Theta^2 - 3G_{ab}n^a n^b) = 12\pi, \tag{39}$$

where A *is the area of* $\mathcal{T}$*,* n^a *is the unit normal to* S *and* Θ *is the trace of the second fundamental form of* S*. Conversely, if* S *is an* $SO(3)\times\mathbb{R}$*-invariant photon surface of* $(M,\mathbf{g})$ *then (39) holds for every* $SO(3)$*-invariant* 2*-sphere* $\mathcal{T}\subset S$*.*

Proof: Note that the unit future-directed timelike tangent field **X** along S in Theorem III.1 is proportional to the restriction to S of the Killing field **K**.

Suppose first that there exists an $SO(3)$-invariant 2-sphere $\mathcal{T}\subset S$ such that (39) holds. The quantities A, Θ and $G_{ab}n^a n^b$ remain constant as $\mathcal{T}$ is mapped along the flow lines of the Killing field **K**. So they also remain constant as they are mapped along the flow lines of **X**. Hence (17) holds with the term on the left and the first term on the right both zero. Thus, by Theorem III.1, S is a photon surface of $(M,\mathbf{g})$. By hypothesis S is $SO(3)\times\mathbb{R}$-invariant.

For the converse, suppose that S is an $SO(3)\times\mathbb{R}$-invariant photon surface of $(M,\mathbf{g})$. Then (17) holds for every $SO(3)$-invariant 2-sphere $\mathcal{T}_s\subset S$. Since **K** induces groups of local isometries, the area A_s of $\mathcal{T}_s$ is independent of the parameter s. Hence the term on the left and the first term on the right of (17) both vanish and one obtains (39). □

Corollary 1: If one has $G_{ab}Y^aY^b \geqslant 0$*,* $\forall$ *vectors* **Y** *and* S *is an* $SO(3)\times\mathbb{R}$*-invariant timelike photon surface of* $(M,\mathbf{g})$*, then for any* $SO(3)$*-invariant* 2*-sphere* $\mathcal{T}\subset S$ *one has*

$$A\Theta^2 \geqslant 12\pi, \tag{40}$$

with equality holding iff $G_{ab}n^a n^b = 0$ *along* S. □

For Schwarzschild space–time where (see Example 5) the only timelike photon sphere is at $r=3m$, one has $A=4\pi(3m)^2$, $\Theta = 1/(\sqrt{3}m)$ and $G_{ab}=0$ which verifies (39) and (40) for this case.

If the Einstein equations hold with a zero cosmological constant then, in the corollary to Theorem IV.1, the hypothesis $G_{ab}Y^aY^b \geqslant 0$ for all vectors $\mathbf{Y}$ is equivalent to $T_{ab}Y^aY^b \geqslant 0$ for all vectors $\mathbf{Y}$. This is a physically reasonable energy condition. In particular, for a perfect fluid with density ρ and pressure p, it is equivalent to a condition that ρ and p are both non-negative. More generally, the condition holds for an energy tensor with a single timelike eigenvector (type I in the classification of Hawking and Ellis[5]) iff each energy tensor eigenvalue is non-negative.

The characterization of timelike photon surfaces provided by Theorem IV.1 involves derivatives of the metric components up to second order. The following result (Theorem IV.2) provides an entirely different characterization of $SO(3)\times\mathbb{R}$-invariant photon surfaces in terms of derivatives of the metric components up to only first order.

Let a general static spherically symmetric metric $\mathbf{g}$ be expressed in the form (27) with $g_{\theta\theta}$ a function of r only. The Killing equation $K_{(a;b)}=0$ and the orthogonality of $\mathbf{K}$ to ∂_θ and ∂_ϕ gives $K^a\partial_a g_{\theta\theta}=0$ and hence $\nabla_{\mathbf{K}} r = 0$ where r is to be regarded as a scalar field on M. Since r is independent of θ and ϕ it follows that any $SO(3)\times\mathbb{R}$-invariant hypersurface S of $(M,\mathbf{g})$ must be of the form $\{r=\text{const}\}$. If S is also a timelike hypersurface then $r^{;a}$ is a spacelike vector field along S and $\mathbf{K}$ is a timelike vector field in a neighborhood of S.

If the coordinates x^0 and x^1 implicit in (27) are chosen such that $\mathbf{K}=\partial_{x^0}$ then the Killing equation gives that all the metric components g_{ab} in (27) are independent of x^0. Since r is constant along the integral curves of $\mathbf{K}$, the coordinate x^1 must be a function of r only. A natural choice is $x^1=r$. One may redefine x^0 according to $x^0 \to x^0 - \int (g_{01}/g_{00})dx^1$. This diagonalizes the time–space part of g_{ab} and leaves the components of g_{ab} independent of x^0. Furthermore the curves $\{x^1,\theta,\phi=\text{const}\}$ are unchanged except that they are re-parametrized. The vector field ∂_{x^0} then becomes a conformal Killing field.

Define the tensor field,

$$\epsilon^{ab} := (-\Delta)^{-1/2}\begin{pmatrix} 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \tag{41}$$

on M, where the components are given with respect to the coordinate basis employed in (27) and Δ is the determinant of the time–space part of $\mathbf{g}$ in (27), as in (38).

Theorem IV.2: *Let* $(M,\mathbf{g})$ *be a static spherically symmetric space–time with* $\mathbf{g}$ *of the form (27), with* $g_{\theta\theta}$ *a function of the coordinate* r *only. Let* S *be an* $SO(3)\times\mathbb{R}$*-invariant timelike hypersurface of* $(M,\mathbf{g})$ *and suppose that* ∇r *is nowhere-zero along* S. *Then* S *is an* $SO(3)\times\mathbb{R}$*-invariant photon surface of* $(M,\mathbf{g})$ *iff*

$$2g_{\theta\theta}\epsilon^{ab}\epsilon^{cd}r_{;ac}r_{;b}r_{;d} + r^{;a}r_{;a}r^{;c}\partial_c g_{\theta\theta} = 0, \tag{42}$$

holds along S.

Proof: Since $(M,\mathbf{g})$ is both spherically symmetric and static, the surface S is of the form $\{r=\text{const}\}$. The unit spacelike normal to S is therefore given by

$$n^a = \eta r^{;a} \tag{43}$$

for

$$\eta := (r^{;a}r_{;a})^{-1/2}. \tag{44}$$

The second fundamental form of S is given by

$$\chi_{ab} := \eta h_a{}^c h_b{}^d r_{;cd}. \tag{45}$$

The vector fields,

$$\mathbf{X}^a := (-\Delta g^{bc} r_{;b} r_{;c})^{-1/2} (r_{;1}, -r_{;0}, 0, 0), \tag{46}$$

$$\mathbf{e}_{(\theta)} := (g_{\theta\theta})^{-1/2} \partial_\theta, \tag{47}$$

$$\mathbf{e}_{(\phi)} := (g_{\theta\theta} \sin^2 \theta)^{-1/2} \partial_\phi, \tag{48}$$

form an orthonormal frame field along S, with $\mathbf{e}_{(\theta)}$ and $\mathbf{e}_{(\phi)}$ unit spacelike and $\mathbf{X}$ unit timelike. One has

$$\chi_{ab} X^a \mathbf{e}^b_{(\theta)} = \chi_{ab} X^a \mathbf{e}^b_{(\phi)} = \chi_{ab} \mathbf{e}^a_{(\theta)} \mathbf{e}^b_{(\phi)} = 0, \tag{49}$$

$$\chi_{ab} \mathbf{e}^a_{(\theta)} \mathbf{e}^b_{(\theta)} = \chi_{ab} \mathbf{e}^a_{(\phi)} \mathbf{e}^b_{(\phi)} = \frac{\eta r^{;a} \partial_a g_{\theta\theta}}{2 g_{\theta\theta}}, \tag{50}$$

$$\chi_{ab} X^a X^b = \eta^3 \epsilon^{ab} \epsilon^{cd} r_{;ac} r_{;b} r_{;d}. \tag{51}$$

Condition (iii) of Theorem II.1 holds iff χ_{ab} is proportional to h_{ab} and hence iff

$$-\chi_{ab} X^a X^b = \chi_{ab} \mathbf{e}^a_{(\theta)} \mathbf{e}^b_{(\theta)} = \chi_{ab} \mathbf{e}^a_{(\phi)} \mathbf{e}^b_{(\phi)}. \tag{52}$$

This is equivalent to

$$-\eta^2 \epsilon^{ab} \epsilon^{cd} r_{;ac} r_{;b} r_{;d} = \frac{r^{;a} \partial_a g_{\theta\theta}}{2 g_{\theta\theta}}, \tag{53}$$

which is in turn equivalent to (42). □

Equation (42) can have solutions such that $\{r = \text{const}\}$ is a spacelike hypersurface and therefore not a photon surface (see, e.g., Example 7). It is therefore always necessary in the use of Theorem IV.2 to check that the hypersurface $\{r = \text{const}\}$ is in fact timelike or null.

Note that in a region of space–time where the Killing field $\mathbf{K}$ is spacelike, for example, behind the event horizon of Schwarzschild space–time, the hypersurfaces $\{r = \text{const}\}$ are necessarily spacelike and so cannot be photon spheres.

Case 1 ($x^1 := r$, components of g_{ab} independent of x^0): As discussed previously, for a static spherically symmetric metric it is possible to choose $x^1 := r$, with $g_{\theta\theta}$ depending only upon r and with all the components of g_{ab} independent of x^0. In this case (42) reduces to

$$g_{00} \partial_r g_{\theta\theta} = g_{\theta\theta} \partial_r g_{00}. \tag{54}$$

This agrees with an equation obtained by Virbhadra and Ellis[4] on the basis of a different definition[3] of a photon sphere. Note that even though the components $g_{rr}, g_{0r} = g_{r0}$ do not appear in (54), they are not assumed to vanish. A particular sub-case of interest is that of time-space coordinates, with $t := x^0$ timelike in the sense of $g^{tt} < 0$. Another sub-case of interest is that of single null (radiation) coordinates, with $u := x^0$ null in the sense of $g^{uu} = 0$.

Case 2 (double null coordinates u, v): Let $x^0 := u$, $x^1 := v$ be double null coordinates in the sense of $g^{uu} = g^{vv} = 0$. The radial coordinate r is to be regarded as a function of u and v. Then (42) assumes the form

$$g_{\theta\theta} \{ r_{;uu} (r_{;v})^2 - 2 r_{;uv} r_{;u} r_{;v} + r_{;vv} (r_{;u})^2 \} + 2 (r_{;u} r_{;v})^2 \partial_r g_{\theta\theta} = 0. \tag{55}$$

The metric components $g_{uv} = g_{vu}$ enter here through the covariant derivatives of r.

Equations (42), (54) and (55) may be referred to as photon sphere equations since they give the location of timelike photon spheres in static spherically symmetric space–times.

In order to facilitate further progress, a general static spherically symmetric metric will be written in such a form as to cast the Einstein tensor in a particularly simple and convenient form.

One has from previous remarks that a general static spherically symmetric metric is locally expressible in the form

$$\mathbf{g}=g_{tt}\,dt^2+g_{rr}\,dr^2+r^2(d\theta^2+\sin^2\theta d\phi^2), \tag{56}$$

where g_{tt} and g_{rr} are functions of r only. Let

$$m(r):=\frac{1}{2}r\left(1-\frac{1}{g_{rr}}\right) \tag{57}$$

$$\mu(r):=\ln(-g_{tt}g_{rr}). \tag{58}$$

Then the metric assumes the form

$$\mathbf{g}=-\left(1-\frac{2m(r)}{r}\right)e^{\mu(r)}\,dt^2+\left(1-\frac{2m(r)}{r}\right)^{-1}dr^2+r^2(d\theta^2+\sin^2\theta d\phi^2), \tag{59}$$

and the Einstein tensor is given by

$$G^a{}_b=8\pi\begin{pmatrix}-\rho(r) & 0 & 0 & 0\\ 0 & p_1(r) & 0 & 0\\ 0 & 0 & p_2(r) & 0\\ 0 & 0 & 0 & p_2(r)\end{pmatrix}, \tag{60}$$

for

$$8\pi\rho(r):=\frac{2m'(r)}{r^2}, \tag{61}$$

$$8\pi p_1(r):=\frac{1}{r^2}\{(r-2m(r))\mu'(r)-2m'(r)\}, \tag{62}$$

$$\begin{aligned}8\pi p_2(r):=\frac{1}{4r^2}\{&(2(r+m(r)-3rm'(r))\mu'(r)+r(r-2m(r))(\mu'(r))^2\\&-4rm''(r)+2r(r-2m(r))\mu''(r)\},\end{aligned} \tag{63}$$

where a prime denotes differentiation with respect to r. For the right sides of (61), (62) and (63) to be defined at some radius $\hat{r}>0$ one evidently needs $m(r)$ and $\mu(r)$ to be twice differentiable at $r=\hat{r}$. Equations (61) and (62) combine to give

$$\mu'(r)=\frac{8\pi r(\rho(r)+p_1(r))}{\left(1-\frac{2m(r)}{r}\right)}, \tag{64}$$

whereby one may rewrite (63) in the more convenient form

$$\frac{2}{r}(p_2(r)-p_1(r))=p_1'(r)+\frac{\left(\frac{m(r)}{r^2}+4\pi r p_1(r)\right)(\rho(r)+p_1(r))}{\left(1-\frac{2m(r)}{r}\right)}. \tag{65}$$

In the perfect fluid case $p_1(r)=p_2(r)=:p(r)$ Eq. (65) reduces to the Tolman–Oppenheimer–Volkoff equation,

$$p'(r)=-\frac{\left(\frac{m(r)}{r^2}+4\pi r p(r)\right)(\rho(r)+p(r))}{\left(1-\frac{2m(r)}{r}\right)}. \tag{66}$$

By means of Eqs. (61) and (64), the photon sphere equation (54) becomes

$$1-\frac{3m(r)}{r}-4\pi r^2 p_1(r)=0. \tag{67}$$

For r such that $2m(r)<r$, and hence such that the hypersurface $\{r=\text{const}\}$ is timelike, Eq. (67) gives the location of the $SO(3)\times\mathbb{R}$-invariant timelike photon surfaces for the metric (59).

Equation (67) is the basis for the following result which shows that, subject to a suitable energy condition, any black hole in a static spherically symmetric space–time must be surrounded by an $SO(3)\times\mathbb{R}$-invariant photon surface. For the purpose of this and subsequent results, a function $f:\mathbb{R}\supset I\to\mathbb{R}$ on an interval I will be said to be piecewise C^r if I is the disjoint union of a locally finite collection of intervals I_i such that $f|I_i$ is C^r. Each interval I_i may be open, closed or half-open.

Theorem IV.3: *Suppose the metric* $\mathbf{g}$ *has the form (59) for* $r_0<r<\infty$, *for some* $r_0>0$, *with* $m(r)$ *and* $\mu(r)$ *both* C^0, *piecewise* C^2 *functions of* $r\in(r_0,\infty)$. *Suppose the following hold:*

(1) $\rho(r)$ *and* $p_1(r)$ *are bounded functions of* $r\in(r_0,\infty)$;
(2) $2m(r)<r$, $\forall r\in(r_0,\infty)$;
(3) $\rho(r)\geqslant 0$, $p_1(r)\geqslant 0$, $\forall r\in(r_0,\infty)$;
(4) $\lim_{r\to\infty}4\pi r^2 p_1(r)=\lim_{r\to\infty}4\pi r^2\rho(r)=0$;
(5) for each value of t *the 2-surfaces* $\mathcal{T}_{t,r}:=\{t=\text{const}\}\cap\{r=\text{const}\}$, $r_0<r<\infty$, *are such that* $\mathcal{T}_t:=\lim_{r\to r_0}\mathcal{T}_{t,r}$ *exists as an embedded spacelike 2-sphere in* $(M,\mathbf{g})$ *and is marginally outer trapped.*

Then $(M,\mathbf{g})$ *admits an* $SO(3)\times\mathbb{R}$*-invariant timelike photon surface of the form* $\{r=r_1\}$ *for some* $r_1\in(r_0,\infty)$.

Proof: Fix t and let $\mathbf{k}$ be the outward future-directed null normal field along each $\mathcal{T}_{t,r}$, $r_0<r<\infty$, normalized such that $\mathbf{g}(\mathbf{k},\mathbf{n})=1$, where $\mathbf{n}=(1-2m(r)/r)^{1/2}\partial_r$ is the outward radial unit tangent to $\{t=\text{const}\}$. Since $\mathbf{k}$ is parallelly propagated along each of the geodesic integral curves of $\mathbf{n}$, one has that $\lim_{r\to r_0}\mathbf{k}$ is a well-defined, nowhere-zero null vector field along $\mathcal{T}_t:=\lim_{r\to r_0}\mathcal{T}_{t,r}$. For $r\in(r_0,\infty)$ the vector field $\mathbf{k}$ has the form $k^a=(k^t,a(r)k^t,0,0)$ for

$$a(r):=(-g_{tt}/g_{rr})^{1/2}=\left(1-\frac{2m(r)}{r}\right)e^{\mu(r)/2}. \tag{68}$$

The expansion of $\mathbf{k}$ is given by

$$\Theta_{\text{out}}={}^{(2)}h^b{}_a k^a{}_{;b}=\frac{2a(r)}{r}k^t. \tag{69}$$

The condition that $\mathcal{T}_t$ is marginally outer trapped therefore implies

$$0=\lim_{r\to r_0} a(r)=\lim_{r\to r_0}\left(1-\frac{2m(r)}{r}\right)e^{\mu(r)/2}. \tag{70}$$

The non-negativity of $\rho(r)$ and $p_1(r)$ gives, by means of (61) and (64), that $m(r)$ and $\mu(r)$ are nondecreasing functions of $r\in(r_0,\infty)$. Thus (70) holds iff at least one of

$$\lim_{r\to r_0}\left(1-\frac{2m(r)}{r}\right)=0; \quad \lim_{r\to r_0}\mu(r)=-\infty \tag{71}$$

holds.

Suppose the first of (71) fails. Then the second must hold and one has

$$\lim_{r\to r_0}\left(1-\frac{2m(r)}{r}\right)^{-1}<\infty. \tag{72}$$

From the boundedness of $\rho(r)$ and $p_1(r)$ on $r\in(0,\infty)$ one has, by means of (64) and (72), that $\limsup_{r\to r_0}\mu'(r)$ is finite. This is incompatible with the second of (71). Hence the first of (71) must hold.

Let $f:(r_0,\infty)\to\mathbb{R}$ be the left side of (67). By the non-negativity of $p_1(r)$ and the first of (71) one has $\lim_{r\to r_0}f(r)\leqslant-\frac{1}{2}$. By condition (4), Eq. (61) and l'Hôpital's rule one has $\lim_{r\to\infty}m(r)/r=\lim_{r\to\infty}r^2p_1(r)=0$ and hence $\lim_{r\to\infty}f(r)=1$. Hence there exists some $r_1\in(r_0,\infty)$ such that $f(r_1)=0$. The hypersurface $\{r=r_1\}$ is an $SO(3)\times\mathbb{R}$-invariant photon surface of $(M,\mathbf{g})$. □

Condition (3) of Theorem IV.3 may be expressed more succinctly as $G_{ab}Y^aY^b\geqslant 0$, $\forall$ vectors $\mathbf{Y}$. With regard to condition (5) of Theorem IV.3, to have required $\mathcal{T}_t$ to be contained in the hypersurface $\{t=\text{const}\}$ would have been too strong since, for Schwarzschild space–time, no spacelike hypersurface of the form $\{t=\text{const}\}$ in the exterior region contains a marginally outer trapped 2-surface.

Theorem IV.3 may be interpreted to the effect that, subject to the energy conditions expressed in condition (3), any static spherically symmetric black hole must be surrounded by an $SO(3)\times\mathbb{R}$-invariant timelike photon surface. The following result may then be regarded as a partial converse in that it shows, subject to a suitable energy condition, that if there exists an $SO(3)\times\mathbb{R}$-invariant timelike photon surface then there must be a naked singularity or a black hole, or more than a certain amount of matter.

Proposition IV.4: *Suppose the metric* $\mathbf{g}$ *has the form (59) for* $0<r<\infty$, *with* $m(r)$ *and* $\mu(r)$ *both* C^0, *piecewise* C^2 *functions of* $r\in(0,\infty)$. *If the following all hold:*

(1) $\rho(r)$ *is a nonincreasing, bounded function of* $r\in(0,\infty)$;
(2) $\lim_{r\to 0}m(r)=0$;
(3) $4m(r)<r$, $\forall r\in(0,\infty)$;
(4) $p_1(r)\leqslant\rho(r)/3$, $\forall r\in(0,\infty)$,

then $(M,\mathbf{g})$ *can contain no* $SO(3)\times\mathbb{R}$*-invariant timelike photon surfaces.*

Proof: By conditions (1) and (2) with Eq. (61) one has $m(r)\geqslant(4\pi/3)r^3\rho(r)$ $\forall r>0$. By condition (4) one therefore has $4\pi r^2p_1(r)\leqslant(4\pi/3)r^2\rho(r)\leqslant m(r)/r$, $\forall r>0$. The left side of (67) is thus bounded from below by $1-4m(r)/r$, $\forall r>0$. This is positive by condition (3). The left side of (67) is therefore nonvanishing for all $r>0$. □

Note that this result is valid even for negative $p_1(r)$ and $\rho(r)$. Condition (2) of Proposition IV.4 prohibits any curvature singularity at $r=0$. Condition (3) may be interpreted as a requirement that there is no black hole and less than a certain amount of matter. The result shows that one of these two conditions must fail if there is an $SO(3)\times\mathbb{R}$-invariant timelike photon surface and conditions (1) and (4) both hold.

When the matter is a perfect fluid it is possible to improve condition (3) of Proposition IV.4 to condition (3) of the following result.

Theorem IV.5: *Suppose the metric* **g** *has the form (59) for* $0<r<\infty$, *with* $m(r)$ *and* $\mu(r)$ *both* C^1, *piecewise* C^2 *functions of* $r\in(0,\infty)$. *If the following all hold:*

(1) *the matter is a perfect fluid with pressure* $p(r)$ *and density* $\rho(r)$;
(2) $\lim_{r\to\infty}4\pi r^2p(r)=\lim_{r\to\infty}4\pi r^2\rho(r)=0$;
(3) $(24/7)m(r)<r$, $\forall r\in(0,\infty)$;
(4) $p(r)\leqslant\rho(r)/3$, $\forall r\in(0,\infty)$,

then $(M,\mathbf{g})$ *can contain no* $SO(3)\times\mathbb{R}$*-invariant timelike photon surfaces.*

Proof: Let $f:(0,\infty)\to\mathbb{R}$ be the left side of Eq. (67). Since $m(r)$ and $\mu(r)$ are C^1, piecewise C^2 functions of $r\in(0,\infty)$, one has by Eq. (62) that $f(r)$ is a C^0, piecewise C^1 function of $r\in(0,\infty)$. The function $f'(r)$ is then a piecewise C^0 function of $r\in(0,\infty)$ which, by means of the Tolman–Oppenheimer–Volkoff Eq. (66), is given by

$$rf'(r)=3\frac{m(r)}{r}-12\pi r^2\rho(r)-8\pi r^2p(r)+\frac{\left(\frac{m(r)}{r}+4\pi r^2p(r)\right)}{\left(1-2\frac{m(r)}{r}\right)}4\pi r^2(\rho(r)+p(r)). \quad (73)$$

For $r=r_1\in(0,\infty)$ such that

$$0=f(r_1)=1-3\frac{m(r_1)}{r_1}-4\pi r_1^2p(r_1), \quad (74)$$

Eq. (73) reduces to

$$r_1f'(r_1)=1-8\pi r_1^2(\rho(r_1)+p(r_1)). \quad (75)$$

From condition (3) and Eq. (74) one has $4\pi r_1^2p(r_1)>1/8$, whence by condition (4) one has $4\pi r_1^2\rho(r_1)>3/8$. Thus (75) gives $f'(r_1)<0$.

By condition (2), Eq. (61) and l'Hôpital's rule one has $\lim_{r\to\infty}m(r)/r=\lim_{r\to\infty}4\pi r^2p(r)=0$ and hence $\lim_{r\to\infty}f(r)=1$. Since it has been established that $f'(r)$ is negative for all $r\in(0,\infty)$ such that $f(r)=0$, one must therefore have $f(r)>0$ for all $r\in(0,\infty)$. Hence the space–time can contain no $SO(3)\times\mathbb{R}$-invariant timelike photon surfaces. □

Note that, as for Proposition IV.4, Theorem IV.5 is valid even for negative pressure and density.

One would like to remove the insufficient matter parts of condition (3) of Proposition IV.4 and condition (3) of Theorem IV.5, in other words to weaken these to a no-black-hole condition $2m(r)<r$, $\forall r>0$. But no result to this effect is forthcoming. On the other hand no counterexample is known.

To conclude this section it will be shown that the physical significance of the photon sphere in Schwarzschild space–time, as discussed in the Introduction, carries over to the general static spherically symmetric case. Suppose the metric has the form (59) for $r_0<r<\infty$ and is asymptotically flat in the limit $r\to\infty$. Assume $p_1(r)\geqslant0$, $m(r)\geqslant0$, $\forall r>r_0$. The matter need not be a perfect fluid. Denote the left side of (67) by $f(r)$. The condition of asymptotic flatness gives $\lim_{r\to\infty}f(r)=1$ so, if there are any $SO(3)\times\mathbb{R}$-invariant timelike photon surfaces, there will be an outermost such surface S. For simplicity assume $f'(r)\neq0$ at S. Let $\mathcal{R}_{\text{ext}}$ be the connected component of $\{q\in M:f(q)>0\}$ that has S as its inner boundary and extends to $r=\infty$. Let $\mathcal{R}_{\text{int}}$ be the connected component of $\{q\in M:f(q)<0\}$ that has S as its outer boundary.

Consider first the case of a future endless affine null geodesic $\gamma(\lambda)$. The null geodesic equations for the metric (59) give

$$\frac{d^2r}{d\lambda^2}=rf(r)\left\{\left(\frac{d\theta}{d\lambda}\right)^2+\sin^2\theta\left(\frac{d\phi}{d\lambda}\right)^2\right\}-\frac{\mu'(r)}{2}\left(\frac{dr}{d\lambda}\right)^2. \tag{76}$$

At any point $p\in|\gamma|\cap\mathcal{R}_{\text{ext}}$ such that $dr/d\lambda=0$ one has $d^2r/d\lambda^2>0$. At any point $p\in|\gamma|\cap\mathcal{R}_{\text{int}}$ such that $dr/d\lambda=0$ one has $d^2r/d\lambda^2<0$. Thus if γ starts outside S (i.e., in $\mathcal{R}_{\text{ext}}$) and is initially directed outwards, in the sense that $dr/d\lambda$ is initially positive, then γ will continue outwards. If γ starts in $\mathcal{R}_{\text{int}}$ and is initially directed inwards, in the sense that $dr/d\lambda$ is initially negative, then γ will continue inwards until it falls either into a singularity or through an $SO(3)\times\mathbb{R}$-invariant photon surface other than S.

Consider now a unit speed timelike geodesic $\xi(s)$. The timelike geodesic equations give

$$\frac{d^2r}{ds^2}=-\frac{m(r)}{r^2}-4\pi rp_1(r)+rf(r)\left\{\left(\frac{d\theta}{ds}\right)^2+\sin^2\theta\left(\frac{d\phi}{ds}\right)^2\right\}-\frac{\mu'(r)}{2}\left(\frac{dr}{ds}\right)^2. \tag{77}$$

For any point $p\in\mathcal{R}_{\text{ext}}$ one can arrange for the first three terms on the right of (77) to cancel and so obtain a unit speed timelike geodesic $\xi(s)$ through $p\in\mathcal{R}_{\text{ext}}$ at constant r. For $p\in\mathcal{R}_{\text{int}}$ the first three terms on the right of (77) are evidently negative. For $p\in|\xi|\cap\mathcal{R}_{\text{int}}$ such that $dr/ds=0$ one has $d^2r/ds^2<0$. Thus if ξ starts in $\mathcal{R}_{\text{int}}$ and is initially directed inwards, in the sense that dr/ds is initially negative, then ξ will continue inwards until it falls either into a singularity or through an $SO(3)\times\mathbb{R}$-invariant photon surface other than S.

V. SPHERICAL SYMMETRY: EXAMPLES

The following are some examples of $SO(3)\times\mathbb{R}$-invariant and $SO(3)$-invariant photon surfaces in familiar space–times.

Example 5 (Schwarzschild space–time): The metric of Schwarzschild space–time in single null (radiation) coordinates has the form

$$\mathbf{g}=-\left(1-\frac{2m}{r}\right)du^2+2\,du\,dr+r^2(d\theta^2+\sin^2\theta d\phi^2). \tag{78}$$

In this case Eq. (54) reduces to $r=3m$. The timelike hypersurface $\{r=3m\}$ is thus an $SO(3)\times\mathbb{R}$-invariant photon surface, or photon sphere, as expected. There are no other $SO(3)\times\mathbb{R}$-invariant timelike photon surfaces.

For a nonzero cosmological constant Λ, the Schwarzschild metric (78) generalizes to the Schwarzschild–de Sitter metric,

$$\mathbf{g}=-\left(1-\frac{2m}{r}+\frac{\Lambda r^2}{3}\right)du^2+2\,du\,dr+r^2(d\theta^2+\sin^2\theta d\phi^2). \tag{79}$$

One finds that Eq. (54) reduces to $r=3m$, independent of the value of Λ. This is surprising since Schwarzschild and Schwarzschild–de Sitter space–times are not conformally related.

Example 6 (Schwarzschild interior solution): The Schwarzschild interior solution describes a spherically symmetric distribution of perfect fluid of radius R, bounded pressure p and constant density $\rho_0>0$. The solution is to have a metric of the form (59) and is to be matched at $r=R$ to a Schwarzschild vacuum solution in such a way that the pressure is a continuous function of r. One thus has $p_1(r)=p_2(r)=:p(r)$ for all $r:0\leqslant r<\infty$, $\rho(r)=\rho_0$ for all $r:0\leqslant r\leqslant R$, $\rho(r)=0$ for all $r:R<r<\infty$ and $p(r)=0$ for all $r:R\leqslant r<\infty$. The pressure $p(r)$ for $r:0\leqslant r\leqslant R$ is to be obtained by an integration of the Tolman–Oppenheimer–Volkoff equation (66) subject to the boundary condition $p(R)=0$. This yields

$$m(r)=\frac{4\pi}{3}\rho_0r^3,\quad 0\leqslant r\leqslant R, \tag{80}$$

$$e^{\mu(r)}=\frac{(3-u(r))^2}{4u^2(r)}, \quad 0\leqslant r\leqslant R, \tag{81}$$

$$p(r)=\frac{u(r)-1}{3-u(r)}\rho_0, \quad 0\leqslant r\leqslant R, \tag{82}$$

for

$$u(r):=\left(\frac{3-8\pi\rho_0 r^2}{3-8\pi\rho_0 R^2}\right)^{1/2}, \quad 0\leqslant r\leqslant R. \tag{83}$$

The spherically symmetric system described by the Schwarzschild interior solution can exist in a state of stable equilibrium iff $m(R)/R<4/9$ (see Stephani[8]). This condition is equivalent to $8\pi\rho_0 R^2<8/3$, which implies $p(r)\geqslant 0$, $\forall r\geqslant 0$, and implies that the absence of a black hole is a general feature of the Schwarzschild interior solution.

The left side of Eq. (67) now assumes the form

$$1-\frac{3m(r)}{r}-4\pi r^2 p(r)=\begin{cases} 1-\dfrac{8\pi\rho_0 r^2}{3-u(r)} & :0<r\leqslant R, \\ 1-\dfrac{3m(R)}{r} & :r\geqslant R. \end{cases} \tag{84}$$

For $m(R)/R<1/3$ one has that (84) is positive for all $r>0$, so there are no timelike photon spheres. For $m(R)/R=1/3$ there is a single timelike photon sphere which lies at the boundary $r=R$ of the matter. For $1/3<m(R)/R<4/9$ there is one timelike photon sphere outside the matter at $r=3m(R)>R$ and one timelike photon sphere inside the matter at

$$r=\left(\frac{1-3\pi\rho_0 R^2}{\pi\rho_0(3-8\pi\rho_0 R^2)}\right)^{1/2}=\frac{2R}{3}\left(\frac{1-\dfrac{9m(R)}{4R}}{\left(1-\dfrac{2m(R)}{R}\right)\dfrac{m(R)}{R}}\right)^{1/2}<R. \tag{85}$$

For fixed R the radius of the outer photon sphere is a strictly increasing function of $m(R)/R$ while the radius of the inner photon sphere is a strictly decreasing function of $m(R)/R$.

Thus a Schwarzschild interior solution matched to a Schwarzschild vacuum exterior solution contains no black hole, and contains one timelike photon sphere iff $1/3=m(R)/R$ and two timelike photon spheres iff $m(R)/R$ lies in the range $1/3<m(R)/R<4/9$. However for such values of $m(R)/R$ the space–time is unphysical in that the pressure at the center is $p(0)\geqslant\rho_0/\sqrt{3}>\rho_0/3$. Therefore under the reasonable energy condition $p(r)\leqslant\rho_0/3$, $\forall r: 0\leqslant r<\infty$ there are no photon spheres in this example.

The energy condition $0\leqslant p(r)\leqslant\rho(r)/3$, $\forall r\in[0,\infty)$ is in fact satisfied iff $m(R)/R$ lies in the range $0\leqslant m(R)/R\leqslant 5/18$. The corresponding space–times (in view of $5/18<7/24$) satisfy all of conditions (1) to (4) of Theorem IV.5, except the smoothness of $\rho(r)$ at $r=R$. Thus considering a smoothed family of solutions approximating the solution above and having it as a strict limit, but each with smooth $\rho(r)$ at $r=R$, we can apply Theorem IV.5 to show no photon spheres exist in all the cases discussed in this section where this energy condition is satisfied. On the other hand Proposition IV.4 is directly applicable without smoothing, but only applies to the subset of these cases with $0\leqslant m(R)/R<1/4$.

Example 7 (Reissner–Nordström space–time): The Reissner–Nordström solution comprises a metric $\mathbf{g}$ and an electromagnetic field F_{ab} given by

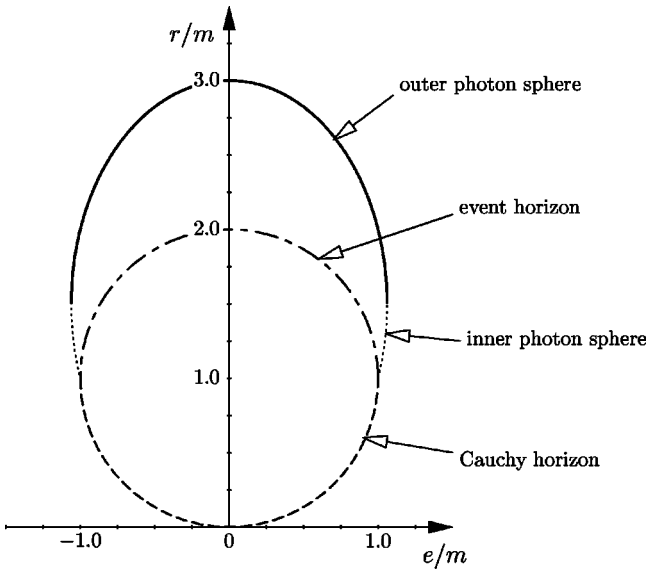

FIG. 2. The radii of the event horizon, Cauchy horizon and photon spheres for Reissner–Nordström space–time.

$$\mathbf{g}=-\left(1-\frac{2m}{r}+\frac{e^2}{r^2}\right)du^2+2\,du\,dr+r^2(d\theta^2+\sin^2\theta d\phi^2), \tag{86}$$

$$F_{tr}=-F_{rt}=\frac{e}{r^2},\ \textit{all other components vanishing,} \tag{87}$$

where m is the ADM mass and e is the electric charge. We assume $m>0$. There is an event horizon at $r=r_+:=m+\sqrt{m^2-e^2}$ and a Cauchy horizon at $r=r_-:=m-\sqrt{m^2-e^2}$. The event horizon exists for $0\leqslant(e/m)^2\leqslant 1$, and the Cauchy horizon exists for $0<(e/m)^2\leqslant 1$. For $(e/m)^2=1$ they both lie at $r=m$. There can be no timelike photon spheres between the event horizon and the Cauchy horizon because the Killing field **K** is spacelike there. Outside the event horizon the Killing field **K** is timelike, so every hypersurface of the form $\{r=\text{const}\}$ which lies outside the event horizon and satisfies the photon sphere equation (54) is necessarily a timelike photon sphere.

Equation (54) assumes the form

$$r^2-3mr+2e^2=0, \tag{88}$$

which has solutions $r_{ps}^{\pm}$ given by

$$r_{ps}^{\pm}/m=\frac{3\pm\sqrt{9-8(e/m)^2}}{2}. \tag{89}$$

The hypersurface $S^+:=\{r=r_{ps}^+\}$ exists for $0\leqslant(e/m)^2\leqslant 9/8$ and lies outside the event horizon and is therefore a timelike photon sphere. The hypersurface $S^-:=\{r=r_{ps}^-\}$ exists for $0<(e/m)^2\leqslant 9/8$ but lies outside the event horizon only for $1<(e/m)^2\leqslant 9/8$, and so is a timelike photon sphere only then. The hypersurfaces S^+ and S^- coincide for $(e/m)^2=9/8$. The Cauchy horizon and event horizon are always null photon spheres.

For $0\leqslant(e/m)^2\leqslant 1$ the curvature singularity at $r=0$ is locally naked but hidden behind an event horizon which lies strictly inside the only timelike photon sphere. For $1<(e/m)^2$ the singularity at $r=0$ is globally naked and is surrounded by two timelike photon spheres in the case $1<(e/m)^2<9/8$, one timelike photon sphere in the case $(e/m)^2=9/8$ and by no photon spheres, either timelike or null, in the case $(e/m)^2>9/8$ (see Fig. 2).

Example 8 (Janis–Newman–Winicour space–time): The most general static spherically symmetric solution to the Einstein massless scalar field equations for a scalar field Φ satisfying $\Box\Phi=0$ was obtained by Janis, Newman and Winicour.[9] The Ricci tensor has the form $R_{ab}=8\pi\Phi_{;a}\Phi_{;b}$. The solution is known[10] to be expressible in the form

$$\mathbf{g}=-\left(1-\frac{b}{r}\right)^{\nu}dt^2+\left(1-\frac{b}{r}\right)^{-\nu}dr^2+\left(1-\frac{b}{r}\right)^{1-\nu}r^2(d\theta^2+\sin^2\theta d\phi^2), \tag{90}$$

$$\Phi=\frac{q}{b\sqrt{4\pi}}\ln\left(1-\frac{b}{r}\right), \tag{91}$$

for $r:b<r<\infty$ where the constants b, ν are related to the ADM mass m and scalar charge q by

$$\nu=\frac{2m}{b},\quad b=2\sqrt{m^2+q^2}. \tag{92}$$

We assume $b>0$. There is a curvature singularity at $r=b$. In order to obtain $m\geqslant 0$ one must assume $0\leqslant\nu\leqslant 1$. For $q=0$ the solution reduces to the Schwarzschild solution.

Since all hypersurfaces of the form $\{r=\text{const}\}$ are timelike, one has from the photon sphere equation (54) that the only timelike photon sphere is at

$$r=\frac{b(2\nu+1)}{2}, \tag{93}$$

which exists only for $\nu:\frac{1}{2}<\nu\leqslant 1$, i.e., for $0\leqslant q^2<3m^2$. For $\frac{1}{2}<\nu\leqslant 1$ it is known[11] that a photon coming from infinity is deflected through an unboundedly large angle, i.e., the photon passes increasingly many times around the singularity as the closest distance of approach tends to the right side of (93).

Example 9 (Charged dilaton space–time): The static spherically symmetric charged dilaton solution[12] comprises a metric $\mathbf{g}$, a dilaton field Φ and an electromagnetic field F_{ab} given by

$$\mathbf{g}=-\left(1-\frac{r_+}{r}\right)\left(1-\frac{r_-}{r}\right)^{\omega}dt^2+\left(1-\frac{r_+}{r}\right)^{-1}\left(1-\frac{r_-}{r}\right)^{-\omega}dr^2+\left(1-\frac{r_-}{r}\right)^{1-\omega}r^2\,d\Omega^2, \tag{94}$$

$$e^{2\Phi}=\left(1-\frac{r_-}{r}\right)^{(1-\omega)/\beta}, \tag{95}$$

$$F_{tr}=-F_{rt}=\frac{e}{r^2},\quad \textit{all other components vanishing}, \tag{96}$$

where r_+ and r_- are related to the ADM mass m and electric charge e by

$$r_++\omega r_-=2m, \tag{97}$$

$$r_+r_-=e^2(1+\beta^2), \tag{98}$$

and β is a free parameter which controls the coupling strength between the dilaton and Maxwell fields, with ω defined in terms of β^2 by

$$\omega:=\frac{1-\beta^2}{1+\beta^2}. \tag{99}$$

We assume $m>0$.

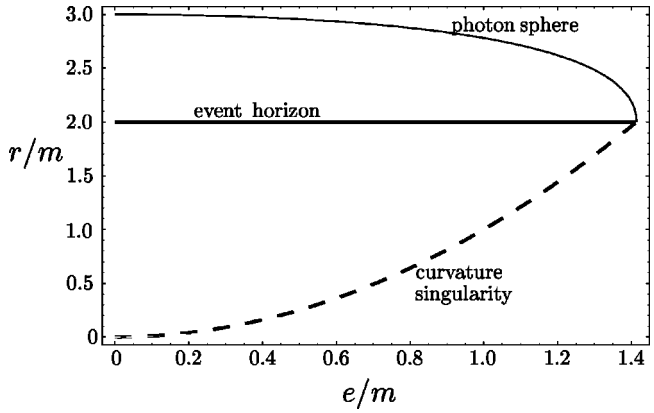

FIG. 3. The radii of the photon sphere, event horizon and curvature singularity are plotted against the electric charge for the charged dilaton solution.

For $\beta=0$ the solution reduces to the Reissner–Nordström solution considered in Example 7. For $\beta=0$ and $e=0$ the solution reduces to the Schwarzschild solution. The solution also reduces to the Schwarzschild solution for $e=r_-=0$ and arbitrary β. Here we shall consider the case $\beta^2=1$. In this case one has $(r_+,r_-)=(2m,e^2/m)$. There is an event horizon at $r=r_+=2m$ and a curvature singularity at $r=r_-=e^2/m$. For $0\leqslant(e/m)^2<2$ the singularity at $r=r_-$ lies inside a black hole while for $(e/m)^2>2$ it is globally naked.

For $\beta^2=1$ the photon sphere equation (54) reduces to

$$r_{ps}^{\pm}/m=\frac{(6+(e/m)^2)\pm\sqrt{36+(e/m)^4-20(e/m)^2}}{4}. \tag{100}$$

For $0\leqslant(e/m)^2<2$ one has $r_{ps}^-\leqslant r_-<r_+<r_{ps}^+$ so there is a single timelike photon sphere. For $(e/m)^2=2$ one has $r_{ps}^-=r_-=r_+=r_{ps}^+$ so there are no timelike photon spheres. For $2<(e/m)^2<18$ both r_{ps}^+ and r_{ps}^- are complex so there are no timelike photon spheres. For $(e/m)^2\geqslant 18$ one has $r_{ps}^-\leqslant r_{ps}^+<r_-$ so there are again no timelike photon spheres. Thus in the black hole case $0\leqslant(e/m)^2<2$ there is a single timelike photon sphere, while in the naked singularity case $(e/m)^2>2$ there are no timelike photon spheres. (See Fig. 3.)

Example 10 (Vaidya null dust collapse): The Vaidya null dust collapse model is a nonstatic, spherically symmetric space–time with a metric which, in terms of single null (radiation) coordinates (u,r,θ,ϕ), assumes the form

$$\mathbf{g}=-\left(1-\frac{2m(u)}{r}\right)du^2+2\,du\,dr+r^2(d\theta^2+\sin^2\theta d\phi^2), \tag{101}$$

where $m(u)$ is a freely specifiable function of u. Setting $x^0:=u$, $x^1:=r$ in (35) one obtains

$$\frac{d^2r}{du^2}=\frac{1}{r}\left(g_{uu}+\frac{dr}{du}\right)\left(g_{uu}+2\frac{dr}{du}\right)-\frac{3}{2}\frac{dr}{du}\partial_r g_{uu}-\frac{1}{2}(g_{uu}\partial_r g_{uu}+\partial_u g_{uu}), \tag{102}$$

$$=\frac{1}{r}\left\{\left(1-\frac{3m(u)}{r}\right)\left(1-\frac{2m(u)}{r}-3\frac{dr}{du}\right)-\frac{dm(u)}{du}+2\left(\frac{dr}{du}\right)^2\right\}. \tag{103}$$

This is the evolution equation for a spherically symmetric photon surface of the Vaidya collapse metric (101).

Consider the special case,

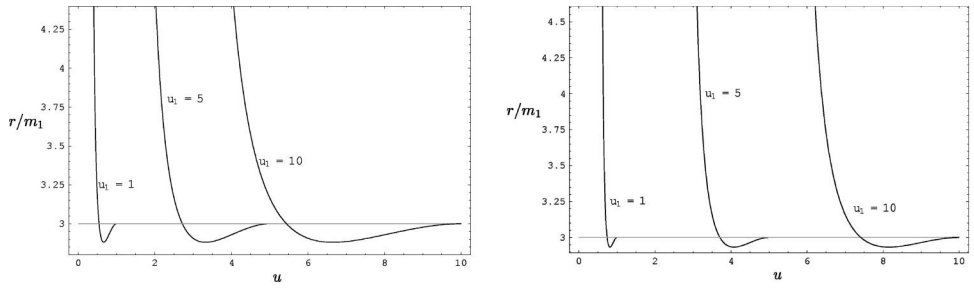

FIG. 4. The backwards evolution of the $r=3m_1$ Schwarzschild photon surface through collapsing Vaidya null dust. The space–time coordinates of the evolved surface are plotted for $m(u)=u/16$ (left) and $m(u)=u/32$ (right) for various values of the null time $u_1>0$ of the junction between the null dust and Schwarzschild regions. In each case the evolved photon surface fails to intersect the Minkowskian region $u<0$.

$$m(u)=\begin{cases} 0 & :-\infty<u<0, \\ \lambda u & :0\leqslant u\leqslant u_1, \\ m_1:=\lambda u_1 & :u_1<u<\infty, \end{cases} \tag{104}$$

for given constants $\lambda>0$, $u_1>0$. For $u<0$ the space–time is locally Minkowskian, for $u:0\leqslant u\leqslant u_1$ there is inward falling null dust, and for $u>u_1$ the space–time is locally isometric to Schwarzschild space–time with ADM mass $m_1>0$. It is well-known there is a curvature singularity at $r=0$ and that for $\lambda:0<\lambda\leqslant\frac{1}{16}$ the part of this singularity at $u=0$ is locally naked.

Fix $\lambda:0<\lambda\leqslant\frac{1}{16}$. For $u>u_1$ Eq. (103) gives, as expected, that there is a photon surface at $r=3m_1$. We seek to evolve this photon surface backwards in time, though the in-falling null dust, to obtain a maximally extended photon surface S. The boundary conditions are

$$\left.\begin{aligned} r&=3m_1 \\ \frac{dr}{du}&=0 \end{aligned}\right\} \quad \text{at } u=u_1. \tag{105}$$

The results are shown in Fig. 4 for $\lambda=1/16$ and $\lambda=1/32$ for selected values of u_1. One sees that in all cases S tends in the past direction to a null hypersurface of the form $\{u=\text{const}\}$. The conformal diagram must therefore be of the form sketched in Fig. 5.

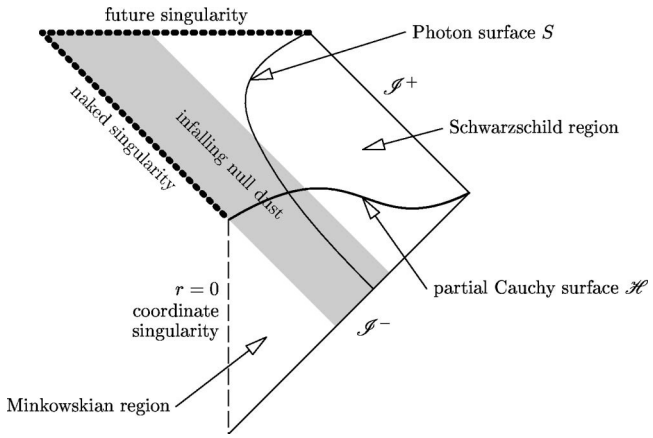

FIG. 5. The conformal diagram of the Vaidya null dust collapse model showing the photon surface S arising from the backwards evolution of the Schwarzschild photon sphere. Any partial Cauchy surface $\mathcal{H}$ which extends to spatial infinity is cut into two components by S.

It is evident from Fig. 5 that the naked central singularity is enclosed within the photon surface S in the sense that any partial Cauchy surface $\mathcal{H}$ extending to spatial infinity must intersect S in a 2-sphere. The physical significance of this may warrant further investigation.

VI. CONCLUDING REMARKS

The definition of a photon surface given in Sec. II is valid in an arbitrary space–time. However the result that a photon surface must have a second fundamental form which is pure trace indicates that a space–time must be specialized in some respect if it is to contain any photon surfaces. For spherically symmetric space–times there are always photon surfaces that respect the spherical symmetry. For space–times that are not spherically symmetric, the definitions of a photon surface and G-invariant photon surface may seem too restrictive. The problem is that, in general, one may not have orbiting null geodesics at a fixed radius. In Kerr space–time, for example, although there are orbiting null geodesics in the equatorial plane, those null geodesics which move in the direction of rotation do so at a different radius than those which move in the opposite direction. But it seems implausible that a concept which is physically important in the case of exact spherical symmetry should become invalid when even a small amount of angular momentum is introduced. A nontrivial generalization of the concepts of photon surface and G-invariant photon surface, at least to axially symmetric space–times, is thus required.

(Received 3 August 2000; accepted for publication 1 November 2000)

The first terms of the general solution for an asymptotically flat stationary axisymmetric vacuum spacetime endowed with an equatorial symmetry plane are calculated from the corresponding Ernst potential up to seventh order in the radial pseudospherical coordinate. The metric is used to determine the influence of high order multipoles in the perihelion precession of an equatorial orbit and in the node line precession of a nonequatorial orbit with respect to a geodesic circle. Both results are written in terms of invariant quantities such as the Geroch–Hansen multipoles and the energy and angular momentum of the orbit. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1335556]

I. INTRODUCTION

The construction of new exact solutions of the Einstein vacuum field equations describing an asymptotically flat stationary axially symmetric spacetime has increased in the last decade due to the several methods of generation of solutions from a given one, such as the Bäcklund transformations, the inverse scattering method and the HKX tranformations (cf., for instance, Ref. 1 and references quoted therein). Nevertheless we are very far from being able to implement the physical behavior of an exact solution at will and in order to obtain results which could be tested experimentally we are led to use approximate expressions for the metrics with the desired physical requirements.

In this paper we study the influence of the first Geroch–Hansen multipole moments[2,3] of order higher than three in some astrophysical situations with stationary and axial symmetry. As it is well known, these moments can be calculated from the coefficients of the power expansion of the Ernst potential on the symmetry axis,[4] being linear the relation between both families of constants until the third moment, that is, the octupole. The subsequent expressions for the multipole moments of order higher than three become considerably more complicated as the order increases and there is not even a closed formula for calculating all of them. Our purpose in this paper is therefore to show to what extent these nonlinearities affect the motion of test particles tracing their orbits around a nonspherical, in principle rotating, compact mass distribution. Of course, these terms are irrelevant for our solar system calculations, but they are meaningful for highly relativistic astrophysical objects, such as pulsars, as stated in Ref. 5.

With this aim in mind we calculate in Sec. II the first seven terms of a power expansion of the Ernst potential with arbitrary values for the multipole moments and construct the corresponding approximate metric. This result is used in Sec. III to obtain an expression for the perihelion precession of an equatorial trajectory and in Sec. IV to produce the corrections to the Newtonian precession of the nodes of a slightly nonequatorial orbit with reference to a close neighboring geodesic circle. There is some previous work on this subject in Refs. 6 and 7, but these references deal only with terms up to the quadrupole moment. The results will be discussed in Sec. V.

II. CALCULATION OF THE METRIC

The metric of a stationary axially symmetric vacuum spacetime can be written in a canonical form in terms of the Weyl coordinates,

$$ds^2=-f(dt-A\,d\phi)^2+\frac{1}{f}\{e^{2\gamma}(d\rho^2+dz^2)+\rho^2 d\phi^2\}, \tag{1}$$

where t and ϕ are the coordinates associated with the commuting Killing vectors ∂_t and ∂_ϕ, and the functions f, A and γ depend only on the coordinates ρ and z.

The whole set of Einstein equations can be shown[8] to be equivalent to the following system of partial differential equations:

$$\varepsilon=f+i\chi, \tag{2}$$

$$\varepsilon_{\rho\rho}+\frac{1}{\rho}\varepsilon_\rho+\varepsilon_{zz}=\frac{2}{\varepsilon+\bar{\varepsilon}}(\varepsilon_\rho^2+\varepsilon_z^2), \tag{3}$$

$$A_\rho=\frac{4\rho}{(\varepsilon+\bar{\varepsilon})^2}\chi_z, \tag{4}$$

$$A_z=-\frac{4\rho}{(\varepsilon+\bar{\varepsilon})^2}\chi_\rho, \tag{5}$$

$$\gamma_\rho=\frac{\rho}{(\varepsilon+\bar{\varepsilon})^2}(\varepsilon_\rho\bar{\varepsilon}_\rho-\varepsilon_z\bar{\varepsilon}_z), \tag{6}$$

$$\gamma_z=\frac{\rho}{(\varepsilon+\bar{\varepsilon})^2}(\varepsilon_\rho\bar{\varepsilon}_z+\varepsilon_z\bar{\varepsilon}_\rho). \tag{7}$$

It can be shown that the integrability of the last four equations is guaranteed if Eq. (3), the Ernst equation, is satisfied. Therefore, in order to obtain a solution of the Einstein equations with two Killing vectors, it suffices to solve the Ernst equation and then calculate the metric functions by quadratures.

It is also usual to write the Ernst equation in terms of another potential, ξ, related to the previous one by the following relation:

$$\xi=\frac{1-\varepsilon}{1+\varepsilon}, \tag{8}$$

which satisfies another partial differential equation,

$$(\xi\bar{\xi}-1)\left(\xi_{\rho\rho}+\frac{1}{\rho}\xi_\rho+\xi_{zz}\right)=2\bar{\xi}(\xi_\rho^2+\xi_z^2), \tag{9}$$

which is also satisfied by ξ^{-1}. This latter form is the one introduced originally in Ref. 8 and allows a simple integration of the Kerr metric.

This form is particularly useful for calculating the multipole moments and it will be the one we shall employ.

In order to calculate the approximate solution, we shall write the Ernst potential ξ as a function of two coordinates r and θ related to the Weyl ones by the following transformation,

$$\rho=r\sin\theta, \quad z=r\cos\theta. \tag{10}$$

We can implement the requirement of asymptotic flatness by writing ξ as a formal inverse power expansion in the pseudospherical radial coordinate r,

$$\xi=\sum_{n=1}^{\infty}\xi_n r^{-n}, \tag{11}$$

where the functions ξ_n depend only on the coordinate θ.

Since we are interested in having a solution which is symmetric with respect to the equatorial plane $\theta=\pi/2$, we shall require that the functions ξ_n of odd order be real whereas those of even order will be taken to be imaginary.

With this information at hand we can now proceed to calculate the metric functions. The function f is just the real part of ε and from our knowledge of ξ we can calculate the first eight terms of its expansion in the radial coordinate,

$$f=1+\sum_{n=1}^{\infty}f_n r^{-n}, \tag{12}$$

$$f_1=-2\,m_0, \tag{13}$$

$$f_2=2\,m_0^2, \tag{14}$$

$$f_3=m_2-\frac{4\,m_0^3}{3}-3\,m_2\cos^2\theta, \tag{15}$$

$$f_4=-2\,m_0\,m_2+\frac{2\,m_0^4}{3}+(6\,m_0 m_2+2\,m_1^2)\cos^2\theta, \tag{16}$$

$$f_5=-\frac{3\,m_4}{4}+2\,m_0^2 m_2+\frac{8\,m_0 m_1^2}{35}-\frac{4\,m_0^5}{15}+\left(\frac{15\,m_4}{2}-6\,m_0^2 m_2-\frac{44\,m_0\,m_1^2}{7}\right)\cos^2\theta-\frac{35\,m_4\cos^4\theta}{4}, \tag{17}$$

$$\begin{aligned} f_6=&\frac{3\,m_0\,m_4}{2}+\frac{m_2^2}{2}-\frac{4\,m_2\,m_0^3}{3}-\frac{16\,m_0^2 m_1^2}{35}+\frac{4\,m_0^6}{45}\\ &+\left(-15\,m_0\,m_4-6\,m_1\,m_3-3\,m_2^2+4\,m_2\,m_0^3+\frac{356\,m_0^2 m_1^2}{35}\right)\cos^2\theta\\ &+\left(\frac{35\,m_0\,m_4}{2}+10\,m_1\,m_3+\frac{9\,m_2^2}{2}\right)\cos^4\theta, \end{aligned} \tag{18}$$

$$\begin{aligned} f_7=&\frac{5\,m_6}{8}-\frac{3\,m_0^2 m_4}{2}-\frac{4\,m_0\,m_1\,m_3}{11}-m_0\,m_2^2-\frac{16\,m_1^2\,m_2}{231}+\frac{2\,m_0^4 m_2}{3}+\frac{32\,m_0^3 m_1^2}{63}-\frac{8\,m_0^7}{315}\\ &+\left(-\frac{105\,m_6}{8}+15\,m_0^2 m_4+\frac{216\,m_0\,m_1\,m_3}{11}+6\,m_0\,m_2^2+\frac{38\,m_1^2\,m_2}{11}-2\,m_0^4 m_2\right.\\ &\left.-\frac{1208\,m_0^3 m_1^2}{105}\right)\cos^2\theta+\left(\frac{315\,m_6}{8}-\frac{35\,m_0^2 m_4}{2}-\frac{340\,m_0\,m_1\,m_3}{11}-\frac{114\,m_1^2\,m_2}{11}-9\,m_0\,m_2^2\right)\cos^4\theta\\ &-\frac{231\,m_6}{8}\cos^6\theta, \end{aligned} \tag{19}$$

where the constants m_n which arise from the integration of the Ernst equation are real if n is even and otherwise imaginary.

The first six terms of the metric function A can be obtained by direct integration of the equations (4) and (5). In spite of the factor i before the expression for A, this function is obviously real since the constants m_n are imaginary for odd n,

$$A=-i\sin^2\theta\sum_{n=1}^{\infty}A_n r^{-n}, \tag{20}$$

$$A_1=-2m_1, \tag{21}$$

$$A_2=-2m_0m_1, \tag{22}$$

$$A_3=m_3-\frac{8m_0^2m_1}{5}-5m_3\cos^2\theta, \tag{23}$$

$$A_4=\frac{3m_0m_3}{2}+\frac{m_1m_2}{2}-\frac{16m_0^3m_1}{15}+\left(-\frac{15m_0m_3}{2}+\frac{3m_1m_2}{2}\right)\cos^2\theta, \tag{24}$$

$$A_5=-\frac{3m_5}{4}+\frac{4m_0^2m_3}{3}+\frac{8m_0m_1m_2}{7}-\frac{64m_0^4m_1}{105}+\left(\frac{21m_5}{2}-\frac{20m_0^2m_3}{3}\right)\cos^2\theta-\frac{63m_5}{4}\cos^4\theta, \tag{25}$$

$$\begin{aligned}A_6=&-\frac{5m_0m_5}{4}-\frac{m_1m_4}{4}-\frac{m_2m_3}{2}+\frac{8m_0^3m_3}{9}+\frac{48m_0^2m_1m_2}{35}+\frac{8m_0m_1^3}{105}-\frac{32m_0^5m_1}{105}\\&+\left(\frac{35m_0m_5}{2}-\frac{5m_1m_4}{2}+m_2m_3-\frac{40m_0^3m_3}{9}-\frac{8m_0^2m_1m_2}{5}+\frac{16m_0m_1^3}{21}\right)\cos^2\theta\\&+\left(-\frac{105m_0m_5}{4}+\frac{35m_1m_4}{4}-\frac{5m_2m_3}{2}\right)\cos^4\theta.\end{aligned} \tag{26}$$

The only function which remains to be calculated is γ and can be obtained as a quadrature from equations (6) and (7),

$$\gamma=\sum_{n=1}^{\infty}\gamma_n r^{-2n}, \tag{27}$$

$$\gamma_1=-\frac{m_0^2\sin^2\theta}{2}, \tag{28}$$

$$\gamma_2=\frac{3m_0m_2}{4}-\frac{m_1^2}{4}+\left(-\frac{9m_0m_2}{2}+\frac{5m_1^2}{2}\right)\cos^2\theta+\left(\frac{15m_0m_2}{4}-\frac{9m_1^2}{4}\right)\cos^4\theta, \tag{29}$$

$$\gamma_3 = -\frac{5\,m_0\,m_4}{8} + \frac{m_1\,m_3}{2} - \frac{3\,m_2^2}{8} + \frac{2\,m_0^2 m_1^2}{35} + \left(\frac{75\,m_0\,m_4}{8} - \frac{21\,m_1\,m_3}{2} + \frac{45\,m_2^2}{8} - \frac{2\,m_0^2 m_1^2}{35}\right)\cos^2\theta + \left(-\frac{175\,m_0\,m_4}{8} + \frac{55\,m_1\,m_3}{2} - \frac{117\,m_2^2}{8}\right)\cos^4\theta + \left(\frac{105\,m_0\,m_4}{8} - \frac{35\,m_1\,m_3}{2} + \frac{75\,m_2^2}{8}\right)\cos^6\theta, \tag{30}$$

$$\gamma_4 = \frac{35\,m_0\,m_6}{64} - \frac{15\,m_1\,m_5}{32} + \frac{45\,m_2\,m_4}{64} - \frac{9\,m_3^2}{32} - \frac{14\,m_0^2 m_1\,m_3}{165} - \frac{2\,m_0\,m_1^2 m_2}{33} + \frac{16\,m_0^4 m_1^2}{1575} + \left(-\frac{245\,m_0\,m_6}{16} + \frac{135\,m_1\,m_5}{8} - \frac{315\,m_2\,m_4}{16} + \frac{81\,m_3^2}{8} + \frac{28\,m_0^2 m_1\,m_3}{55} - \frac{4\,m_0\,m_1^2 m_2}{231} + \frac{16\,m_0^4 m_1^2}{1575}\right)\cos^2\theta + \left(\frac{2205\,m_0\,m_6}{32} - \frac{1365\,m_1\,m_5}{16} + \frac{3075\,m_2\,m_4}{32} - \frac{795\,m_3^2}{16} - \frac{14\,m_0^2 m_1\,m_3}{33} + \frac{6\,m_0\,m_1^2 m_2}{77}\right)\cos^4\theta + \left(-\frac{1617\,m_0\,m_6}{16} + \frac{1071\,m_1\,m_5}{8} - \frac{2415\,m_2\,m_4}{16} + \frac{625\,m_3^2}{8}\right)\cos^6\theta + \left(\frac{3003\,m_0\,m_6}{64} - \frac{2079\,m_1\,m_5}{32} + \frac{4725\,m_2\,m_4}{64} - \frac{1225\,m_3^2}{32}\right)\cos^8\theta. \tag{31}$$

III. PERIHELION PRECESSION OF A CLOSED ORBIT

It is well known from Bertrand's theorem (cf. for instance Ref. 9) that stable bounded orbits of particles moving under the influence of a central force which is neither Newtonian nor harmonic are not closed. Therefore whenever the source of the gravitational field is not exactly monopolar, the bounded trajectories on the equatorial plane will no longer be the elliptic orbits described by Kepler's first law but will take the form of a precessing ellipse if the deviation from spherical symmetry is small.

The situation becomes a bit more complicated in general relativity. Although it has been proven[10] that there are just two asymptotically flat static spherically symmetric spacetimes in which the stable orbits are closed, they are rather different from the classical physical situations. Therefore, when relativistic effects are taken into account, not even the motion around a spherical distribution of mass is closed. This effect has been tested in our solar system and it amounts to a slow precession of the perihelion of the orbit of Mercury. Of course other multipole moments of the mass distribution will also contribute to this effect and, in principle, these moments could be calculated by measuring the precession of a certain number of test particles orbiting at conveniently different distances from the gravitational source.

If the test particles are small enough for the tidal forces to be unimportant within the characteristic length of the particle, we can regard them as point particles. If the effects due to their intrinsic angular momentum can be taken as negligible it can be assumed that they trace out timelike geodesics in the spacetime surrounding the gravitational source. Hence, in order to study the influence of the far field multipole moments of the gravitational field, we shall have to solve the geodesic equations for the previously calculated metric. We shall restrict ourselves to the equatorial plane $\theta = \pi/2$.

Since the timelike and azimuthal coordinates are ignorable, we have two first integrals for the motion corresponding to the conserved quantities E and l, respectively, the total energy per unit of mass and the projection of the angular momentum on the z axis, also per unit of mass, of the test particle. In terms of its 4-velocity $u = (\dot{t}, \dot{r}, \dot{\theta}, \dot{\phi})$ these quantities have the following form:

$$E = -\partial_t \cdot u = f(\dot{t} - A\dot{\phi}) \tag{32}$$

$$l=\partial_\phi\cdot u=f\,A\,(\dot{t}-A\dot{\phi})+\frac{1}{f}r^2\,\dot{\phi}, \tag{33}$$

where the overhead dot stands for the derivative with respect to proper time.

Therefore the equations for t and ϕ can be written as follows:

$$\dot{\phi}=f\,\frac{l-E\,A}{r^2}, \tag{34}$$

$$\dot{t}=\frac{E}{f}+f\,A\,\frac{l-E\,A}{r^2}. \tag{35}$$

Another integral arises from the fact that the trajectory is timelike and therefore $u\cdot u=-1$. For the geodesics under consideration this means

$$-1=-f(\dot{t}-A\dot{\phi})^2+\frac{1}{f}(e^{2\gamma}\dot{r}^2+r^2\,\dot{\phi}^2). \tag{36}$$

From the previous three equations $\dot{r}$ can be obtained as a function of the nonignorable coordinates and the conserved quantities. However, since we are interested in the shape of the orbit rather than in its time evolution, we divide (36) by $\dot{\phi}$ to get the derivative of the radial coordinate with respect to the azimuthal angle,

$$r_\phi^2=e^{-2\gamma}\left\{\frac{r^4\,(E^2-f\,)}{f^2\,(l-E\,A)^2}-r^2\right\}. \tag{37}$$

It will be useful to write this equation in terms of another function $u=1/r$ as it is done in classical mechanics for solving the motion under central forces,

$$u_\phi^2=e^{-2\gamma}\left\{\frac{E^2-f}{f^2\,(l-E\,A)^2}-u^2\right\}=F(u)=\sum_{n=0}^{6}c_n\,u^n+O(u^7). \tag{38}$$

This equation can be turned into a quasilinear one by taking a derivative with respect to ϕ and cancelling the u_ϕ factors, since for the analysis of perihelion precession circular orbits are of no interest,

$$u_{\phi\phi}=\tfrac{1}{2}F'(u). \tag{39}$$

In order to solve these equations perturbatively we need expand them in powers of a small parameter. A good candidate is the inverse of the angular momentum per unit of mass, l, since according to Kepler's 1–2–3 law, which is assumed to be a good approximation at a great distance from the source, it behaves as $l\sim\sqrt{m\,r}$, where m is the mass of the particle. It can be combined with the mass of the source m_0 to yield an acceptable dimensionless small parameter for analyzing the far gravitational field. Hence we shall use $\epsilon=m_0/l$ and expand u in the following way:

$$u=\epsilon^2\sum_{n=0}^{11}u_n\,\epsilon^n+O(\epsilon^{14}). \tag{40}$$

The reason for starting the expansion at this order is that the expression for the Kepler ellipse, which is expected to be the first term, is second order in ϵ.

The energy per unit of mass of the particle is also to be expanded in ϵ. Therefore we write

$$E=1+\epsilon^2\sum_{n=0}^{n=11} E_n\,\epsilon^n+O(\epsilon^{14}). \tag{41}$$

In order to avoid the appearance of secular terms we use a coordinate ψ related to ϕ by

$$\psi=\omega\phi, \quad \omega=\sqrt{1+\sum\ \omega_i\epsilon^i}. \tag{42}$$

The coefficients c_n are all of the order ϵ^2 except c_2 which is clearly of zeroth order in ϵ and therefore Eq. (38) takes the form of a hierarchy of forced harmonic oscillators which can be solved iteratively up to the order of accuracy provided by our knowledge of the metric,

$$u_{n\ \psi\psi}+u_n=f_n(\psi). \tag{43}$$

The first terms of the expansion of the solution to the equations (38) and (39) are

$$u_0=\frac{1}{m_0}(1+\sqrt{1+2\,E_0}\cos\psi), \tag{44}$$

$$u_1=0, \tag{45}$$

$$u_2=\frac{6+4\,E_0}{m_0}, \tag{46}$$

$$u_3=(8+4\,E_0)\,\frac{i\,m_1}{m_0^3}. \tag{47}$$

Of course the term of lowest order is the Kepler ellipse if E_0 is negative.

From the information we have about the metric we can calculate ω up to the eleventh power of ϵ. These terms are just what we need to calculate the expression for the perihelion precession, so we shall focus on them. The expressions of the terms u_n are not needed and therefore we shall not enclose them here.

Instead of writing the results as a function of the integration constants m_i, it will be more useful to write them in terms of the Geroch–Hansen multipole moments, P_i, the physical interpretation of which is more appealing. Bear in mind that the odd multipole moments are imaginary and have to be multiplied by $-i$ to obtain the usual real expressions J_n. To calculate these moments we shall make use of the procedure described in Ref. 4.

If we have an expansion of the Ernst potential ξ on the symmetry axis in terms of the Weyl coordinate z, viz.,

$$\xi(\rho=0)=\sum_{n=0}^{\infty} C_n\,z^{-(n+1)}, \tag{48}$$

then the multipole moments can be calculated as follows:

$$P_n=C_n, \quad n\leqslant 3, \tag{49}$$

$$P_4=C_4+\tfrac{1}{7}\overline{C}_0(C_1^2-C_2C_0), \tag{50}$$

$$P_5=C_5+\tfrac{1}{3}\overline{C}_0(C_2\,C_1-C_3\,C_0)+\tfrac{1}{21}\overline{C}_1\,(C_1^2-C_2\,C_0). \tag{51}$$

As a function of these multipole moments the first coefficients in the expansion of the energy per unit of mass, E, read as

$$E_1=0, \tag{52}$$

$$E_2=-6-10E_0-\frac{E_0^2}{2}, \tag{53}$$

$$E_3=-(8+12E_0)\frac{iP_1}{P_0^2}, \tag{54}$$

$$E_4=-\frac{47}{4}-20E_0-13E_0^2+\frac{E_0^3}{2}+(2+3E_0)\frac{P_2}{P_0^3}, \tag{55}$$

$$E_5=-(56+104E_0+56E_0^2)\frac{iP_1}{P_0^2}, \tag{56}$$

where E_0, the Keplerian energy, is a free parameter which has $-1/2$ as a lower bound, corresponding to a circular orbit.

The frequency ω is different from one and therefore the orbit is not closed. Between two consecutives perihelion approaches the test particle traces an angle $2\pi/\omega$. Hence the perihelion has shifted an angle, $\Delta\phi$ given up to the eleventh power of ϵ by the following expression:

$$\begin{aligned}\Delta\phi&=2\pi(\omega^{-1}-1)\\&=\pi\{\Delta_0+\Delta_1+\Delta_2+\Delta_4+\Delta_8+\Delta_{16}+\Delta_{32}+\Delta_{2\times4}+\Delta_{2\times8}+\Delta_{2\times16}+\Delta_{4\times8}\},\end{aligned} \tag{57}$$

where the shift has been split into different terms according to their origin: The first one, Δ_0, comprises the Newtonian contribution to the precession, that is, the terms which remain after taking the classical limit $c\to\infty$. Of course only the gravitational moments are present since rotation has no influence whatsoever in Newtonian dynamics. Since the speed of light, c, and the gravitational coupling constant, G, have been taken to be one, the terms look rather alike in magnitude. However, if the respective factors are written (a factor G/c for each ϵ, a factor G/c^2 for each P_{2n}, a factor G/c^3 for each P_{2n+1}, a factor c^{-1} for each l and a factor G^{-2} for each E_0), the actual magnitude of every term is recovered. For instance, the first Newtonian term has a factor G^2 and the second a G^4. For oblate gravitational sources the quadrupole moment, P_2 is negative, whence it contributes to a positive shift of the perihelion in the first order. In the next order the shift contribution of the quadrupole is, however, always positive. (*n.b.*: E_0, though negative for bounded orbits, has a lower limit about $-1/2$ which does not allow it to overcome the energy-independent term.) On the other hand the sedecimpole P_4 term bears the opposite sign to the one of the quadrupole,

$$\Delta_0=-\frac{3P_2}{P_0^3}\epsilon^4+\left\{\left(\frac{105}{8}+\frac{45E_0}{4}\right)\frac{P_4}{P_0^5}+\left(\frac{105}{8}+\frac{15E_0}{4}\right)\frac{P_2^2}{P_0^6}\right\}\epsilon^8. \tag{58}$$

The second term, Δ_1, comprises the contribution to the perihelion precession due to a spherically symmetric mass distribution, i.e., the Schwarzschild effect. It can be calculated exactly in terms of elliptic functions and is of the order of G^2/c^2. The contribution of every order is always positive,

$$\begin{aligned}\Delta_1=6\epsilon^2&+\left(\frac{105}{2}+15E_0\right)\epsilon^4+\left(\frac{975}{2}+165E_0\right)\epsilon^6+\left(\frac{159105}{32}+\frac{16725E_0}{8}+\frac{705E_0^2}{8}\right)\epsilon^8\\&+\left(\frac{1701507}{32}+\frac{216375E_0}{8}+\frac{20115E_0^2}{8}\right)\epsilon^{10}.\end{aligned} \tag{59}$$

In the term Δ_2 we have included the influence of a dipole of rotation on the perihelion shift. It is of the order of G^2/c^2. Since its lower terms in ϵ are odd, it is sensitive to whether the probe rotates in the same direction as the source does or not. It is positive if the angular momentum of the source and the orbital angular momentum of the probe are antiparallel and negative otherwise. This has a qualitative explanation in the fact that the perihelion shift due to a mass monopole decreases with the angular momentum of the test particle; if the source happens to be rotating and its angular momentum is J, then l is replaced in the first order by $l+2\,J/r$ as it can be seen in Eq. (38) after substitution of P_1 by $i\,J$, whence the ''effective'' l increases if both momenta are parallel and it would be expected that the perihelion advance diminishes. In contrast, the quadratic terms in P_1 are independent of the direction of rotation and are always positive whence they induce a perihelion advance. The cubic terms in P_1 behave as the linear ones,

$$\begin{aligned}\Delta_2=&\frac{8\,i\,P_1\epsilon^3}{P_0^2}+(168+48\,E_0)\frac{i\,P_1}{P_0^2}\epsilon^5-(120+24\,E_0)\frac{P_1^2}{P_0^4}\epsilon^6+(2562+1020\,E_0+36\,E_0^2)\frac{i\,P_1}{P_0^2}\epsilon^7\\&-\left(\frac{65607}{16}+\frac{44607\,E_0}{28}+\frac{195\,E_0^2}{4}\right)\frac{P_1^2}{P_0^4}\epsilon^8+\left\{(36046+17640\,E_0+1356\,E_0^2-16\,E_0^3)\frac{i\,P_1}{P_0^2}\right.\\&\left.-(2048+672\,E_0)\frac{i\,P_1^3}{P_0^6}\right\}\epsilon^9-\left(\frac{10256685}{112}+\frac{1320387\,E_0}{28}+\frac{118305\,E_0^2}{28}\right)\frac{P_1^2}{P_0^4}\epsilon^{10}\\&+\left\{\left(\frac{3927489}{8}+\frac{569361\,E_0}{2}+\frac{70659\,E_0^2}{2}+174\,E_0^3+15\,E_0^4\right)\frac{i\,P_1}{P_0^2}\right.\\&\left.-\left(\frac{2735961}{28}+\frac{341339\,E_0}{7}+\frac{27429\,E_0^2}{7}\right)\frac{i\,P_1^3}{P_0^6}\right\}\epsilon^{11}.\end{aligned}\tag{60}$$

Under the name Δ_4 the relativistic terms depending only on the quadrupole moment, P_2, and the mass are comprised. The first correction has a factor G^4/c^2 in front of it. As it was to be expected, it does not depend on the direction of rotation and, as its Newtonian counterpart, it is positive for oblate gravitational sources. The quadratic terms as a whole are always positive,

$$\begin{aligned}\Delta_4=&-(90+42\,E_0)\frac{P_2}{P_0^3}\epsilon^6-\left(\frac{25383}{16}+\frac{28305\,E_0}{28}+\frac{375\,E_0^2}{4}\right)\frac{P_2}{P_0^3}\epsilon^8\\&+\left\{-\left(\frac{2686203}{112}+\frac{503379\,E_0}{28}+\frac{80187\,E_0^2}{28}\right)\frac{P_2}{P_0^3}+\left(\frac{12471}{16}+519\,E_0+\frac{165\,E_0^2}{4}\right)\frac{P_2^2}{P_0^6}\right\}\epsilon^{10}.\end{aligned}\tag{61}$$

The symbol Δ_8 stands for the corrections to the perihelion shift due to a rotation octupole moment P_3. The first correction is of the order of G^4/c^2. They bear the same relation to the dipole terms as the quadrupole to the monopole terms: The overall sign changes,

$$\begin{aligned}\Delta_8=&-\left\{(30+24\,E_0)\epsilon^7+(801+825\,E_0+138\,E_0^2)\epsilon^9\right.\\&\left.+\left(\frac{28671}{2}+16475\,E_0+4278\,E_0^2+102\,E_0^3\right)\epsilon^{11}\right\}\frac{i\,P_3}{P_0^4}.\end{aligned}\tag{62}$$

The influence of the sedecimpole gravitational moment, P_4, is included in Δ_{16} and does not show up until the tenth order of the small parameter. In nongeometrized units it is proportional to G^6/c^2,

$$\Delta_{16}=\left(\frac{7425}{16}+570\,E_0+\frac{495\,E_0^2}{4}\right)\frac{P_4}{P_0^5}\epsilon^{10}. \tag{63}$$

The last multipole moment to be considered is the rotational trigintaduopole moment, P_5, and it is comprised in Δ_{32}. It is of the eleventh order in ϵ,

$$\Delta_{32}=\left(\frac{945}{8}+210\,E_0+\frac{135\,E_0^2}{2}\right)\frac{iP_5}{P_0^6}\epsilon^{11}. \tag{64}$$

Now we review the couplings among the different multipole moments other than mass. Up to the order considered there is no coupling between the gravitational moments higher than the mass (except for self-couplings), but there are rotation–rotation couplings and gravitation–rotation couplings. The first one to appear is the dipole–quadrupole coupling, $\Delta_{2\times4}$. It has a factor of G^4/c^2 in the lowest order. If both angular momenta are antiparallel and the source is oblate ($P_2<0$), then the contribution of the bilinear terms is positive. The quadratic terms in the quadrupole P_2 are again positive if J and l are antiparallel. Finally the quadratic terms in the dipole are positive if the body is oblate,

$$\begin{aligned}\Delta_{2\times4}=&-(90+24\,E_0)\frac{iP_1P_2}{P_0^5}\epsilon^7-(3939+2127\,E_0+126\,E_0^2)\frac{iP_1P_2}{P_0^5}\epsilon^9\\&+(2280+900\,E_0)\frac{P_1^2P_2}{P_0^7}\epsilon^{10}+\left\{\left(\frac{1419}{2}+303\,E_0\right)\frac{iP_1P_2^2}{P_0^8}\right.\\&\left.-\left(\frac{2825301}{28}+\frac{507992\,E_0}{7}+\frac{75765\,E_0^2}{7}+90\,E_0^3\right)\frac{iP_1P_2}{P_0^5}\right\}\epsilon^{11}.\end{aligned} \tag{65}$$

The only rotation–rotation coupling up to this order is between the dipole and octupole moments. It comes under the name of $\Delta_{2\times8}$ and it is at least of the order G^6/c^4. Since it is linear on both rotational moments this term is not sensitive to the direction of rotation. It is of the tenth order in ϵ,

$$\Delta_{2\times8}=(1068+972\,E_0+120\,E_0^2)\frac{P_1P_3}{P_0^6}\epsilon^{10}. \tag{66}$$

The higher rotation–gravitation couplings involve the rotational dipole and the gravitational sedecimpole, $\Delta_{2\times16}$, and the rotational octupole and the gravitational quadrupole, $\Delta_{4\times8}$. Both appear first in the eleventh order of perturbation and are at least of the order of ϵ^{11}. The term $\Delta_{2\times16}$ is positive if P_4 is positive and the angular momenta are antiparallel,

$$\Delta_{2\times16}=\left(\frac{4005}{8}+495\,E_0+\frac{135\,E_0^2}{2}\right)\frac{iP_1P_4}{P_0^7}\epsilon^{11}, \tag{67}$$

$$\Delta_{4\times8}=\left(\frac{1383}{4}+348\,E_0+45\,E_0^2\right)\frac{iP_2P_3}{P_0^7}\epsilon^{11}. \tag{68}$$

It would be of great interest to know the range of applicability of this perturbative expansion. In an Appendix at the end of this paper a simpler case is studied: It is shown there for which values of the parameters the expansions are acceptable for the Schwarzschild metric.

IV. PRECESSION OF THE LINE OF NODES OF A NONEQUATORIAL ORBIT

Let us consider now a bounded orbit slightly departing from the equatorial plane. If the mass distribution of the source were spherically symmetric, the equatorial plane would not be at all privileged and the orbit would always intersect it at the same nodes. However, this is no longer the situation when the source is not exactly spherical, since then the nodes precess due to the perturbation generated by higher order multipoles. In classical nonrelativistic mechanics the first contribution to the precession of the nodes arises from the quadrupole moment, as it is shown in an Appendix at the end of this paper, whereas in general relativity it is the rotational dipole moment the first one to contribute.

In the approximation used in this section we consider a geodesic on the equatorial plane and calculate the evolution of small deviations from it. Since the geodesic equation reads as

$$\ddot{x}^{\mu}+\Gamma^{\mu}_{\rho\sigma}\dot{x}^{\rho}\dot{x}^{\sigma}=0, \tag{69}$$

it is straightforward that nearby geodesics which deviate from the original geodesic by a vector δ^{μ} fulfill

$$\ddot{\delta}^{\mu}+2\,\Gamma^{\mu}_{\rho\sigma}\,\dot{\delta}^{\rho}\dot{x}^{\sigma}+\Gamma^{\mu}_{\rho\sigma,\nu}\dot{x}^{\rho}\dot{x}^{\sigma}\,\delta^{\nu}=0. \tag{70}$$

Since we are interested in small deviations from the equatorial plane, we shall focus our attention on the θ coordinate. Taking into account that the reference geodesic lies on the symmetry plane $\theta=\pi/2$ and that the first derivatives of the metric with respect to θ vanish on it, the geodesic deviation equation for δ^{θ} reduces to

$$\ddot{\delta}^{\theta}-\tfrac{1}{2}g^{\theta\theta}g_{\rho\sigma,\theta\theta}\dot{x}^{\rho}\dot{x}^{\sigma}\,\delta^{\theta}=0. \tag{71}$$

Instead of considering an arbitrary bounded reference geodesic on the equatorial plane, we shall restrict ourselves to geodesic circles. Of course many interesting features will be lost, but we deem that this paper would become even longer if we take them into account.

In order to compute the evolution of the nodes with respect to the azimuthal angle on the geodesic, the previous equation needs to be divided by $\dot{\phi}^2$, which is constant on the circle. From now on we shall write δ instead of δ^{θ} to avoid cumbersome notations,

$$\delta_{\phi\phi}+\Omega^2\,\delta=0, \quad \Omega^2=-\frac{1}{2\,\dot{\phi}^2}g^{\theta\theta}g_{\rho\sigma,\theta\theta}\dot{x}^{\rho}\dot{x}^{\sigma}, \tag{72}$$

where every function is to be calculated on $\theta=\pi/2$ and $r=R$, the radius of the geodesic circle.

The previous expression states that the nodes of nearby geodesics are separated by regular intervals of the coordinate ϕ. If Ω is different from one, these nodes will travel around the geodesic circle instead of remaining at constant values of the azimuthal angle. Since it would be of interest to write down the result in a coordinate-independent expression, it will be required to make use of the geodesic equations to remove the dependence on the radius of the circle, R, and also to cast the energy, E, as a function of the angular momentum of the circular orbit, l, so that the final result will be a function of the multipole moments and l only.

As it is well known, the timelike geodesic equations can be obtained from the Lagrange equations applied to a functional $L=g_{\mu\nu}\dot{x}^{\mu}\dot{x}^{\nu}$ and the constraint $L=-1$. Two of these equations, namely (34) and (35), have already been used to remove the dependence on the derivatives of the ignorable coordinates. The equation corresponding to variations of θ is automatically satisfied. We are left just with two equations, corresponding to the constraint and the variations of r, viz.,

$$1=\frac{E^2}{f}-f\frac{(l-E\,A)^2}{r^2}, \tag{73}$$

$$\frac{E^2}{f^2}\partial_r f - 2\,E\,f\frac{l-E\,A}{R^2}\partial_r A - f^2\frac{(l-E\,A)^2}{R^4}\partial_r\left(\frac{r^2}{f}\right)=0, \tag{74}$$

where we have used $\dot{r}=0$ and $\theta=\pi/2$.

From the last equation we get E/l as a function of R,

$$\frac{E}{l}=\frac{-b\pm\sqrt{b^2-4\,a\,c}}{2\,a}, \tag{75}$$

$$\begin{aligned} a&=A^2\,f^2\,R^{-4}\,\partial_r(r^2\,f^{-1})-f^{-2}\,\partial_r f-2\,A\,f\,R^{-2}\partial_r A\\ &=-2\,P_0\,R^{-2}+O(R^{-3}), \end{aligned} \tag{76}$$

$$\begin{aligned} b&=2\,R^{-2}\,f\partial_r A-2\,A\,f^2\,R^{-4}\partial_r(r^2\,f^{-1})\\ &=-12\,i\,P_1\,R^{-4}+O(R^{-5}), \end{aligned} \tag{77}$$

$$c=f^2\,R^{-4}\partial_r(r^2\,f^{-1})=2\,R^{-3}+O(R^{-4}). \tag{78}$$

Since the energy must be positive, the solution with the minus (plus) signus in front of the square root equation corresponds to a positive (negative) l. On the other hand, Eq. (73) furnishes l in terms of E/l which has obviously the same coefficients which were obtained for E in the previous section after substitution of $E_0=-1/2$.

The frequency of the precession of the nodes can be written now independently of the choice of coordinates. As was to be expected, the first term is equal to one, corresponding to the frequency of the nodes when the mass distribution of the gravitational source is perfectly spherical.

The contributions to the precession of the line of nodes of a timelike geodesic which is slightly tilted with respect to a geodesic equatorial circle have been classified in the same way as it was done for the perihelion shift: A classical term plus the relativistic terms, divided according to their multipole content. In order to write down the expressions in nongeometrized units, factors including G and c have to be included as it was done in the previous section. The description which was made there of the necessary factors for each term in $\Delta\phi$ for the perihelion shift also applies. The information that we have of the metric allows us to calculate the coefficients up to l^{-13}.

There is, of course, no contribution from a pure mass monopole. Were the frequency equal to one, then the nodes would remain at constant ϕ. Therefore, $\Delta\phi=2\,\pi\,(\Omega^{-1}-1)$ describes the angle through which the line of nodes has precessed in one revolution of the reference circle,

$$\Delta\phi=\pi\{\Delta_0+\Delta_2+\Delta_4+\Delta_8+\Delta_{16}+\Delta_{32}+\Delta_{2\times4}+\Delta_{2\times8}+\Delta_{2\times16}+\Delta_{4\times8}\}. \tag{79}$$

For oblate objects ($P_2<0$), the influence of the mass quadrupole amounts to a delay in the precession of the line of nodes with respect to the ϕ coordinate on the circle of reference. Therefore the line of nodes does not precess in the same direction as the perihelion. This fact should not be confused with the precession of the angular momentum vector in time, which is of course positive. The contribution from the sedecimpole term is negative for positive P_4 and the one from the sexagintaduopole is positive for positive P_6. There is also a classical coupling between P_4 and P_2. The nonlinear terms in the quadrupole moment bear a positive sign,

$$\Delta_0=\frac{3\,P_0\,P_2}{l^4}+\left(-\frac{15\,P_0^3P_4}{2}+\frac{9\,P_0^2P_2^2}{4}\right)l^{-8}+\left(\frac{105\,P_0^5P_6}{8}+\frac{45\,P_0^4P_2\,P_4}{8}+\frac{81\,P_0^3P_2^3}{8}\right)l^{-12}. \tag{80}$$

Most of the dipole-dependent terms are sensitive to the direction of motion of the test particle relative to the rotation of the source. If the angular momenta are parallel (l has the same sign as

$J=-i\,P_1$), then the linear and cubic terms in P_1 induce an advance of the line of nodes. On the other hand the quadratic and quartic terms in the dipole moment are not sensitive to that relative sign and their influence always amounts to a delay,

$$\Delta_2=-\frac{4\,i\,P_0P_1}{l^3}-\frac{18\,i\,P_0^3P_1}{l^5}+\frac{18\,P_0^2P_1^2}{l^6}-\frac{243\,i\,P_0^5P_1}{2\,l^7}+\frac{4131\,P_0^4P_1^2}{14\,l^8}$$
$$+\left(196\,iP_0^3P_1^3-\frac{3861\,iP_0^7P_1}{4}\right)l^{-9}+\frac{27294\,P_0^6P_1^2}{7}l^{-10}$$
$$+\left(\frac{37983\,iP_0^5P_1^3}{7}-\frac{268515\,iP_0^9P_1}{32}\right)l^{-11}+\left(-2565\,P_0^4P_1^4+\frac{1060043\,P_0^8P_1^2}{22}\right)l^{-12}$$
$$+\left(\frac{734200\,iP_0^7P_1^3}{7}-\frac{4944807\,iP_0{}^{11}P_1}{64}\right)l^{-13}. \tag{81}$$

The relativistic contribution of the linear terms in the quadrupole moment P_2 is again negative for oblate sources. The quadratic terms furnish a negative contribution to the precession shift regardless of whether the source is oblate or prolate, whereas the classical quadratic correction is positive, as it was shown previously,

$$\Delta_4=\frac{24\,P_0^3P_2}{l^6}+\frac{2799\,P_0^5P_2}{14\,l^8}+\left(-24\,P_0^4P_2^2+\frac{12396\,P_0^7P_2}{7}\right)l^{-10}$$
$$+\left(-\frac{327223\,P_0^6P_2^2}{308}+\frac{361993\,P_0^9P_2}{22}\right)l^{-12}. \tag{82}$$

As it happened with the perihelion precession, the rotational octupole term has the opposite sign to the one of the linear dipole term and of course it is dependent on the direction in which the probe orbits,

$$\Delta_8=\frac{12\,iP_0^3P_3}{l^7}+\frac{156\,iP_0^5P_3}{l^9}+\frac{3387\,iP_0^7P_3}{2\,l^{11}}+\frac{17707\,iP_0^9P_3}{l^{13}}. \tag{83}$$

The relativistic sedecimpole term bears the same sign as its classical counterpart, although it is much smaller in magnitude. There is no relativistic term in P_6, just the classical term which has already been described,

$$\Delta_{16}=-\frac{120\,P_0^5P_4}{l^{10}}-\frac{2905\,P_0^7P_4}{2\,l^{12}}, \tag{84}$$

and again we have another permutation of sign; the term in P_5 bears the same sign as the linear dipole term,

$$\Delta_{32}=-\frac{45\,iP_0^5P_5}{2\,l^{11}}-\frac{1905\,iP_0^7P_5}{4\,l^{13}}. \tag{85}$$

Now we discuss the coupling terms between multipole moments other than the mass. The bilinear coupling between the dipole and the quadrupole moment is positive for oblate gravitational sources which rotate in the same direction as the test particle. The quadratic term in P_1 is negative for oblate objects no matter in which direction they rotate. The quadratic term in P_2 is positive when the angular momenta J and l are parallel,

$$\Delta_{2\times 4}=\frac{18\,iP_0^2P_1\,P_2}{l^7}+\frac{441\,iP_0^4P_1\,P_2}{l^9}-\frac{273\,P_0^3P_1^2P_2}{l^{10}}$$
$$+\left(-\frac{81\,iP_0^3P_1\,P_2^2}{2}+\frac{198369\,iP_0^6P_1\,P_2}{28}\right)l^{-11}-\frac{3007003\,P_0^5P_1^2P_2}{308\,l^{12}}$$
$$+\left(-\frac{10899iP_0^5P_1P_2^2}{4}-4482iP_0^4P_1^3P_2+\frac{5509583iP_0^8P_1P_2}{56}\right)l^{-13}. \tag{86}$$

The rotational bilinear coupling between the dipole and the octupole moment is independent of the direction of rotation and it is positive when $J=-i\,P_1$ and $J_3=-i\,P_3$ have the same sign. There is however a higher coupling which is quadratic in the dipole moment and contributes in the same way as does Δ_8

$$\Delta_{2\times 8}=-\frac{186\,P_0^4P_1\,P_3}{l^{10}}-\frac{100201\,P_0^6P_1\,P_3}{22\,l^{12}}-\frac{3168iP_0^5P_1^2P_3}{l^{13}}. \tag{87}$$

The last terms to be considered up to this order are the couplings between P_1 and P_4 and between P_2 and P_3, which are both sensitive to the relative directions of rotation of the source and the probe particle,

$$\Delta_{2\times 16}=-\frac{255\,iP_0^4P_1\,P_4}{2\,l^{11}}-\frac{14193\,iP_0^6P_1\,P_4}{4\,l^{13}}, \tag{88}$$

$$\Delta_{4\times 8}=-\frac{21\,iP_0^4P_2\,P_3}{l^{11}}-\frac{1971\,iP_0^6P_2\,P_3}{2\,l^{13}}. \tag{89}$$

V. CONCLUSIONS

In this paper we have displayed the approximate general asymptotically flat stationary axisymmetric metric for the vacuum spacetime surrounding a compact source possessing a symmetry plane orthogonal to the symmetry axis. The calculations have been carried out for the Ernst potential up to the term in r^{-7} in the pseudospherical radial coordinate. This has been useful to calculate relativistic corrections to the classical orbits around a compact mass distribution. In particular the perihelion precession on the symmetry plane and the precession of the nodes of a slightly tilted circular orbit have been calculated.

Concerning the perihelion shift, it has been shown that the contributions of each gravitational and rotational multipole moment follow a curious pattern of alternation of signs: The term in the mass monopole is always positive, whereas the linear quadrupole term is negative for positive P_2 (the quadratic term in P_2 is always positive) and the sedecimpole term is again positive for positive P_4. The sexagintaquattuorpole P_6 is outside the limits of our perturbative expansion. If we think for instance of an oblate source which is very close to a classical axisymmetric homogeneous ellipsoid, then we would also have alternating signs in the gravitational multipole expansion ($P_{2\,n}=3\,P_0(c^2-a^2)^n/[(2\,n+1)(2\,n+3)]$), c and a being the lengths of the ellipsoid's semiaxis parallel and orthogonal to the symmetry axis, respectively) and every term would have a positive contribution. The linear and cubic rotational dipole term is always positive for counterrotating configurations of the source and the probe (the quadratic contribution is always positive regardless of the relative rotation) whereas the octupole term is positive if $J_3=-i\,P_3$ and l bear the same sign. The trigintaduopole term has the same sign as the dipole term. It should be pointed out that the energy-dependent terms are not strong enough to affect these signs. The coupling between different multipoles preserves the sign of the product of the corresponding linear terms, that is, if there is a P_n-P_m coupling, then its sign is obtained from the product of the -1 factors multiplying the corresponding linear terms in P_n and P_m. No coupling between mass multipole

moments of order higher than the monopole appears to this order except for self-couplings. The sign-independent terms, such as the mass monopole term and the quadratic dipole and quadratic quadrupole terms, always give rise to a perihelion advance.

The influence of the different multipole moments on the precession of the line of nodes of a particle departing by a small amount from the equatorial plane is somewhat different from the behavior which has been shown for the perihelion precession: The alternating pattern of the signs of the linear terms in the multipole moments other than the mass is preserved both for gravitational and rotational moments independently up to the considered perturbation order: If the P_{2n} were all positive, then the contribution of each P_{2n} would be opposite to the one of P_{2n+2} and a similar reasoning is valid for the rotational terms. However the relativistic coupling terms bear the opposite sign to the one which would be expected from the product of the -1 factors before the corresponding linear terms: For instance, if the P_1 and P_2 linear terms are positive then the corresponding bilinear coupling is negative. On the other hand, this rule is not valid for the Newtonian self-couplings. Another difference arises from the fact that the gravitational sexagintaduopole moment P_6 does influence the precession of the line of nodes in this order of perturbation, whereas it does not affect the perihelion precession. Also, there were no couplings between the gravitational moments (self-couplings and mass-couplings excluded) in the perihelion precession, but there is one (the classical P_2-P_4-coupling) in the node precession. It is curious that, while the Newtonian sign-independent terms are always positive, the relativistic ones (the quadratic dipole and the quadratic quadrupole self-couplings) are negative.

Of course most of these corrections are meaningless for astronomical purposes in our solar system, but are very likely to be relevant for highly relativistic astrophysical objects, suchs as pulsars and blackholes, where other post-Newtonian effects[5] have been shown to be present.

APPENDIX A: SCHWARSCHILD SPACE–TIME

In this appendix we shall study the range of applicability of the perturbation expansion for bounded orbits in Schwarschild's space–time. For this metric the geodesic equation (38) can be solved exactly in terms of elliptic functions. Instead of writing it as a differential equation for u as a function of ϕ, we are writing it as a differential equation for ϕ. In this section u is no longer the inverse of the pseudospherical radius but of the usual Boyer–Lindquist radius,

$$\phi_u=\left(2P_0u^3-u^2+\frac{2P_0}{l^2}u+\frac{E^2-1}{l^2}\right)^{-1/2}=g(u)^{-1/2}. \tag{A1}$$

We are considering that $E<1$ and therefore $g(u)$ has at least one zero. For bounded motion we need three zeros so that the orbit ranges between the apsidal points. If we call these zeros $a\geqslant b\geqslant c\geqslant 0$, then Eq. (A1) can be integrated[11] in terms of the elliptic integral of the first kind, $F(\gamma,q)$, in the region $b\geqslant u>c$,

$$(\phi-\phi_0)\sqrt{\frac{P_0(a-c)}{2}}=F(\gamma,q)=\int_0^{\gamma}d\alpha(1-q^2\sin^2\alpha)^{-1/2}, \tag{A2}$$

$$\gamma=\arcsin\sqrt{\frac{u-c}{b-c}},\quad q=\sqrt{\frac{b-c}{a-c}}. \tag{A3}$$

An expression for u in terms of ϕ is easily obtained taking into account that the elliptic sine is the sine of $F(\gamma,q)$,

$$u=c+(b-c)sn^2\left\{\sqrt{\frac{P_0(a-c)}{2}}(\phi-\phi_0)\right\}. \tag{A4}$$

Since the real period of the elliptic sine is $4K(q)=4F(\pi/2,q)$, then our u function is $2K(q)$-periodic. Therefore the exact perihelion precession of the orbit of a test particle around a spherical nonrotating compact object will be

$$\Delta\phi=\frac{2\sqrt{2}K(q)}{\sqrt{P_0(a-c)}}-2\pi, \tag{A5}$$

the perturbation expansion of which in ϵ coincides with the one of Δ_1 in Eq. (59), as it was to be expected,

$$K(q)=\frac{\pi}{2}\left\{1+\sum_{n=1}^{\infty}\left(\frac{(2n-1)!!}{2^n n!}\right)^2 q^{2n}\right\}. \tag{A6}$$

The limits of the range of applicability of the previous expansion are $q=1$ $(a=b)$ and $q=0$ $(b=c)$. For both values, there are two zeros of $g(u)$ which coalesce and the bounded motion is no longer stable. Therefore we are led to study the range of parameters for which $g(u)$ has double roots. This happens when u takes either of the values $u_\pm$ which are solutions of $g'(u)=0$,

$$u_\pm=\frac{1\pm\sqrt{1-12\epsilon^2}}{6P_0}, \tag{A7}$$

and therefore the allowed region is the one enclosed between the curves $g(u_\pm)=0$ in the E^2-q^2 parameter plane. This yields critical values for the energy per unit of mass, $E_c^2=8/9$, and the perturbation parameter, $\epsilon_c^2=1/12$. The perturbative approach is no longer valid beyond this point in the parameter plane since there are no stable bounded orbits. It is remarkable that for $\epsilon^2>1/16$ there is not only a lower limit for the energy of the bounded orbit but also an upper limit.

APPENDIX B: CLASSICAL PRECESSION OF THE LINE OF NODES

In this appendix we shall briefly derive the classical expression for the precession of the line of nodes.

The Lagrangian for the motion of a particle in a gravitational field is

$$L=\tfrac{1}{2}\dot{r}^2+\tfrac{1}{2}r^2\dot{\theta}^2+\tfrac{1}{2}r^2\sin^2\theta\dot{\phi}^2-V(r,\theta), \tag{B1}$$

$$V(r,\theta)=-\sum_{n=0}^{\infty}\frac{P_n p_n(\cos\theta)}{r^{n+1}}. \tag{B2}$$

The equations of motion and conserved quantities which can be obtained from this Lagrangian are

$$E=\tfrac{1}{2}\dot{r}^2+\tfrac{1}{2}r^2\dot{\theta}^2+\tfrac{1}{2}r^2\sin^2\theta\dot{\phi}^2+V(r,\theta), \tag{B3}$$

$$l=r^2\sin^2\theta\dot{\phi}, \tag{B4}$$

$$\ddot{r}=r\dot{\theta}^2+r\sin^2\theta\dot{\phi}^2-\partial_r V(r,\theta), \tag{B5}$$

$$r^2\ddot{\theta}+2r\dot{r}\dot{\theta}=r^2\sin\theta\cos\theta\dot{\phi}^2-\partial_\theta V(r,\theta). \tag{B6}$$

Truncating the Legendre expansion at the sexagintaquattuorpole multipole moment, P_6, we get the following expressions for the energy per unit of mass, E, and the radius, R, of a circular orbit on the plane $\theta=\pi/2$ in the far field region,

$$E=-\frac{P_0^2}{2\,l^2}+\frac{P_0^3\,P_2}{2\,l^6}-\frac{3\,P_0^5\,P_4+9\,P_0^4\,P_2^2}{8\,l^{10}}+O(l^{-14}), \tag{B7}$$

$$R^{-1}=\frac{P_0}{l^2}-\frac{3\,P_0^2\,P_2}{2\,l^6}+\frac{15\,P_0^4\,P_4+36\,P_0^3\,P_2^2}{8\,l^{10}}+O(l^{-14}). \tag{B8}$$

In order to obtain the oscillations about the equatorial plane of a slightly tilted bounded trajectory with respect to the circular orbit, we introduce a small variation in equation (B6). The result will be divided by $\dot{\phi}^2$ to yield the evolution of $\delta\theta$ as a function of ϕ,

$$(\delta\theta)_{\phi\phi}=-\Omega^2\,\delta\theta,\quad \Omega=\sqrt{1+\frac{R^2}{l^2}V_{\theta\theta}(R,\pi/2)}. \tag{B9}$$

From this expression we get the frequency of the oscillations, Ω, which can be written in terms of l and the multipole moments by inserting equation (B8) into it,

$$\Delta\phi=2\,\pi\left(\frac{1}{\Omega}-1\right)=\frac{3\,\pi\,P_0\,P_2}{l^4}+\frac{\pi\,(9\,P_0^2\,P_2^2-30\,P_0^3\,P_4)}{4\,l^8}$$
$$+\frac{\pi\,(105\,P_0^5\,P_6+45\,P_0^4\,P_2\,P_4+81\,P_0^3\,P_2^3)}{8\,l^{12}}+O(l^{-16}), \tag{B10}$$

which obviously coincides with the term Δ_0 which was calculated using the full relativistic theory in Sec. IV.

Acoustics of early universe—Lifshitz versus gauge-invariant theories

Zdzisław A. Golda[a] and Andrzej Woszczyna
Astronomical Observatory, Jagellonian University, ul. Orla 171, 30–244 Kraków, Poland

(Received 26 July 1999; accepted for publication 29 March 2000)

Appealing to classical methods of order reduction, we reduce the Lifshitz system to a second order differential equation. We demonstrate its equivalence to well known gauge-invariant results. For a radiation dominated universe we express the metric and density corrections in their exact forms and discuss their acoustic character. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1335557]

I. INTRODUCTION

The density perturbations affect the microwave background temperature. The theory of gravitational instability describes how these inhomogeneities propagate throughout the radiational era, and foresee the temperature image they ''paint'' on the last scattering surface. Classical perturbation theory formulated half a century ago by Lifshitz and Khalatnikov[1–3] has nowadays been replaced by more appropriate gauge-invariant descriptions.[4–11] These formalisms introduce some new measures of inhomogeneity. They do not appeal to the metric tensor, so they easily avoid spurious perturbations arising from an inappropriate choice of the equal time hypersurfaces. They guarantee that the space structures they describe are real physical objects.

On the other hand, the interpretation of the microwave background temperature fluctuations[12] is based on the Sach–Wolfe effect, where the metric corrections play a key role.[13] Therefore, data obtained from COBE is mostly referred to as the classical concepts of Lifshitz and Khalatnikov, and only in a minor part to gauge-invariant measures, which are more precise but difficult to observe.[14] Both theories in their original formulations differ essentially. Lifshitz theory provides the two parameter family of increasing solutions for the density contrast [Ref. 3, formula (115.19)], while all the gauge-invariant approaches foresee in concert only a single growing density mode. Thus the interpretation of the microwave temperature map as the initial data for cosmic structure formation is fairly ambiguous.

In this paper we attempt to reconcile both types of theories. We appeal to simple and classical methods of order reduction of differential equations.[15] By use of these techniques we remove the pure-gauge perturbations from Lifshitz theory in the radiation dominated universe. In consequence we reduce the Lifshitz system to a second order differential equation, exactly the same as obtained earlier on the ground of gauge-invariant formalisms. Applying well known solutions, we express corrections to the metric tensor, the density contrast and the peculiar velocity in exact form. We show that in the early universe, scalar perturbations of any length-scale form acoustic waves propagating with the velocity $1/\sqrt{3}$.

II. ORDER REDUCTION

[Most of the calculations in this paper have been done by use of MATHEMATICA (Wolfram Research Inc. Version 3.0). Appropriate notebooks are available from the authors (golda@oa.uj.edu.pl) on request.]

Relativistic perturbations of a Friedman universe, described in synchronous coordinates[1–3] form a system of two second order differential equations with variable coefficients. In contrast, the similar Newtonian problem is expressed by only one second order equation.[16–18] Obviously, the

[a]Electronic mail: golda@oa.uj.edu.pl

two additional degrees of freedom appearing in the relativistic case must correspond to pure coordinate transformations (gauge freedom),[2] and should be removed from the theory.

Removing pure-gauge modes we reduce the Lifshitz equations with pressure $p=\rho/3$ to Bessel equation. The procedure is as follows: (1) we raise the equations order to fourth, in order to separate the $\mu_n(\eta)$ and $\lambda_n(\eta)$ coefficients, and then (2) we reduce the order of each of the separated equations back by eliminating gauge degrees of freedom. The resulting equations have exact solutions in the form of Hankel functions $H_{3/2}$ and their integrals.

In the synchronous system of reference, the metric corrections $h_{\mu\nu}$ $(\mu,\nu=1,2,3)$ to the homogeneous and isotropic, spatially flat universe fulfill the partial differential equations[3] $(8\pi G=c=1)$,

$$h_\alpha^{\beta\prime\prime}+2\frac{a'}{a}h_\alpha^{\beta\prime}+(h^{\gamma;\beta}_{\alpha;\gamma}+h^{\beta;\gamma}_{\gamma;\alpha}-h^{;\beta}_{;\alpha}-h^{\beta;\gamma}_{\alpha;\gamma})=0, \tag{2.1}$$

$$2\left[1+3\frac{dp}{d\rho}\right]^{-1}\left(h''+\frac{a'}{a}\left[2+3\frac{dp}{d\rho}\right]h'\right)+(h^{\delta;\gamma}_{\gamma;\delta}-h^{;\gamma}_{;\gamma})=0. \tag{2.2}$$

These equations are usually solved by means of the Fourier transform,

$$h_{\mu\nu}=\int \mathcal{A}(\mathbf{n})\left[\lambda_n(\eta)\left(\frac{\delta_{\mu\nu}}{3}-\frac{n_\mu n_\nu}{n^2}\right)+\frac{1}{3}\mu_n(\eta)\delta_{\mu\nu}\right]e^{i\mathbf{n}\cdot\mathbf{x}}d^3\mathbf{n}+\text{c.c.} \tag{2.3}$$

The Fourier transform (2.3) is defined for absolute integrable functions (the case of least interest for cosmology), for nonintegrable functions in the framework of distribution theory, or can be understood as a stochastic integral if the initial conditions are given at random.[19,20] When the barotropic fluid $(p/\rho=\delta p/\delta\rho=w=\text{const})$ is the matter content of the universe, the functions $\lambda_n(\eta)$ and $\mu_n(\eta)$ obey ordinary, second order equations,

$$-n^2w(\lambda_n(\eta)+\mu_n(\eta))+2\frac{a'(\eta)}{a(\eta)}\lambda_n'(\eta)+\lambda_n''(\eta)=0, \tag{2.4}$$

$$-n^2w(1+3w)(\lambda_n(\eta)+\mu_n(\eta))+(2+3w)\frac{a'(\eta)}{a(\eta)}\mu_n'(\eta)+\mu_n''(\eta)=0, \tag{2.5}$$

where a prime denotes differentiation with respect to the conformal time η and a is the scale factor for the background metric tensor. In order to separate the variable $\lambda_n(\eta)$, we differentiate (2.4) twice and eliminate terms containing $\mu_n(\eta)$ or its derivatives by the help of Eq. (2.5). We obtain the fourth-order differential equation,

$$\begin{aligned}&\left(n^2w\frac{a'(\eta)}{a(\eta)}-6w\left(\frac{a'(\eta)}{a(\eta)}\right)^3+2(-1+3w)\frac{a'(\eta)}{a(\eta)}\frac{a''(\eta)}{a(\eta)}+2\frac{a^{(3)}(\eta)}{a(\eta)}\right)\lambda_n'(\eta)\\&\quad+\left(n^2w+6w\left(\frac{a'(\eta)}{a(\eta)}\right)^2+4\frac{a''(\eta)}{a(\eta)}\right)\lambda_n''(\eta)+(4+3w)\frac{a'(\eta)}{a(\eta)}\lambda_n^{(3)}(\eta)+\lambda_n^{(4)}(\eta)=0.\end{aligned} \tag{2.6}$$

In the same way one can treat (2.5) to find the equation for $\mu_n(\eta)$,

$$\begin{aligned}&\left(n^2w\frac{a'(\eta)}{a(\eta)}-(2+3w)\frac{a'(\eta)}{a(\eta)}\frac{a''(\eta)}{a(\eta)}+(2+3w)\frac{a^{(3)}(\eta)}{a(\eta)}\right)\mu_n(\eta)\\&\quad+\left(n^2w+2(2+3w)\frac{a''(\eta)}{a(\eta)}\right)\mu_n''(\eta)+(4+3w)\frac{a'(\eta)}{a(\eta)}\mu_n^{(3)}(\eta)+\mu_n^{(4)}(\eta)=0.\end{aligned} \tag{2.7}$$

In the following part of this paper we restrict ourselves to a universe filled with relativistic particles, where both $w=p_0/\rho_0=\frac{1}{3}$ and $\mathcal{M}=\rho_0 a^4$ are constants of motion, and the scale factor a is a linear function of the conformal time $a(\eta)=\sqrt{\mathcal{M}/3}\,\eta$. In the flat universe the expansion rate $\theta(\eta)=3a'(\eta)/a(\eta)^2$ and the energy density $\rho_0(\eta)$ relate to each other by $\rho_0(\eta)=\theta(\eta)^2/3$, so the equations for $\lambda_n(\eta)$ and $\mu_n(\eta)$ take fairly legible form, both prior to

$$-\frac{1}{3}n^2(\lambda_n(\eta)+\mu_n(\eta))+\frac{2}{\eta}\lambda_n'(\eta)+\lambda_n''(\eta)=0, \tag{2.8}$$

$$\frac{2}{3}n^2(\lambda_n(\eta)+\mu_n(\eta))+\frac{3}{\eta}\mu_n'(\eta)+\mu_n''(\eta)=0, \tag{2.9}$$

and after separation,

$$\left(\frac{n^2}{3\eta}-\frac{2}{\eta^3}\right)\lambda_n'(\eta)+\left(\frac{n^2}{3}+\frac{2}{\eta^2}\right)\lambda_n(\eta)+\frac{5}{\eta}\lambda_n^{(3)}(\eta)+\lambda_n^{(4)}(\eta)=0, \tag{2.10}$$

$$\frac{n^2}{3\eta}\mu_n'(\eta)+\frac{n^2}{3}\mu_n''(\eta)+\frac{5}{\eta}\mu_n^3(\eta)+\mu_n^{(4)}(\eta)=0. \tag{2.11}$$

We start with Eq. (2.10). The two well known gauge solutions[1] are (with the accuracy to multiplicative constants)

$$f_1(\eta)=1, \tag{2.12}$$

$$f_2(\eta)=-\sqrt{\mathcal{M}/3}\int\frac{1}{a(\eta)}\,d\eta=-\ln(\eta). \tag{2.13}$$

We expect to obtain solutions for (2.10) in the form[15]

$$\lambda_n(\eta)=f_1(\eta)\left(\int A(\eta)\,d\eta\right), \tag{2.14}$$

$$A(\eta)=\frac{d}{d\eta}\left(\frac{f_2(\eta)}{f_1(\eta)}\right)\left(\int\frac{B(\eta)}{\eta}\,d\eta\right), \tag{2.15}$$

where $A(\eta)$ and $B(\eta)$ are some auxiliary functions. Inserting (2.14)–(2.15) into (2.10) we obtain the Bessel equation in its canonical form,

$$\left(\frac{n^2}{3}-\frac{2}{\eta^2}\right)B(\eta)+B''(\eta)=0. \tag{2.16}$$

Equation (2.16) is already free of gauge modes, as one can see from simple heuristic considerations. Let us assume that there exist a third linearly independent solution of Eq. (2.4), which corresponds to a pure coordinate transformation. Then, the linear space of gauge modes would be 3-dimensional, leaving only a single degree of freedom for the real, physical perturbations. Such a theory has no proper Newtonian limit.

Equation (2.16) is identical to the Sakai equation [Ref. 21 formula (5.1)], the equation for density perturbations in an orthogonal gauge [Ref. 5, formula (4.9), Ref. 8, formulas (16)–(17)], the equation for gauge-invariant density gradients [Ref. 9, formula (38)] or Laplacians [Ref. 4, formulas (8)–(9), Ref. 11, formula (22)] after transforming these equations to their canonical form (see Ref. 22). It is interesting to note that Eq. (2.16) is also identical to the propagation equation for gravitational waves[23,24] (except for gravitational waves moving with the speed of light). This means that the solutions to Eq. (2.16) represent waves traveling with the phase velocity $1/\sqrt{3}$ (we

show this explicitly in the next section). This picture also is consistent with the phonon approach,[25] as the transformation $\phi(\eta)=B(\eta)/\eta+B'(\eta)$ to the Field–Shepley variable[26,27] reduces (2.16) to the harmonic oscillator $\phi''(\eta)+(n^2/3)\,\phi(\eta)=0$. (The procedure we present here may also be treated as a method to reconstruct metric corrections and hydrodynamic quantities in their explicit form, out of the Field and Shepley variables.)

III. SOLUTIONS

The general solution for (2.16) is a combination of

$$B(\eta)=e^{-i\omega\eta}\left(1+\frac{1}{i\omega\eta}\right), \tag{3.1}$$

and its complex conjugate, with the frequency $\omega=n/\sqrt{3}$. (For similar solutions in the gravitational waves theory see Ref. 24.) These solutions are proportional to Hankel functions $H_{3/2}$, but more frequently are presented as a combination of Bessel and Neumann functions $B=a_1J+a_2N$.[5] Performing integrations (2.14)–(2.15) we determine the solution for $\lambda_n(\eta)$ and find the correction $\mu_n(\eta)$ by solving Eq. (2.4) algebraically,

$$\lambda(\omega\eta)=-\frac{e^{-i\omega\eta}}{i\omega\eta}-\mathrm{Ei}(-i\omega\eta), \tag{3.2}$$

$$\mu(\omega\eta)=\left(1+\frac{1}{i\omega\eta}\right)\frac{e^{-i\omega\eta}}{i\omega\eta}+\mathrm{Ei}(-i\omega\eta). \tag{3.3}$$

Obviously, Eq. (2.11) is automatically fulfilled. As a result we obtain the metric corrections $h_{\mu\nu}$ expanded into planar waves with the frequency constant in conformal time η and with varying amplitude,

$$\begin{aligned} h_{\mu\nu}=&-\int \mathcal{A}(\mathbf{n})\left(\frac{\delta_{\mu\nu}}{3}-\frac{n_\mu n_\nu}{n^2}\right)\left(\frac{e^{i(\mathbf{n}\cdot\mathbf{x}-\omega\eta)}}{i\omega\eta}+e^{i\mathbf{n}\cdot\mathbf{x}}\,\mathrm{Ei}(-i\omega\eta)\right)d^3\mathbf{n}\\ &+\int \mathcal{A}(\mathbf{n})\frac{\delta_{\mu\nu}}{3}\left(\left(1+\frac{1}{i\omega\eta}\right)\frac{e^{i(\mathbf{n}\cdot\mathbf{x}-\omega\eta)}}{i\omega\eta}+e^{i\mathbf{n}\cdot\mathbf{x}}\,\mathrm{Ei}(-i\omega\eta)\right)d^3\mathbf{n}+\mathrm{c.c.} \end{aligned} \tag{3.4}$$

The density perturbation and peculiar velocity can be inferred from formulas (8.2)–(8.3) of Ref. 2 and expressed as

$$\frac{\delta\rho}{\rho}=\int \mathcal{A}(\mathbf{n})u_\rho(\mathbf{n}\cdot\mathbf{x},\omega\eta)d^3\mathbf{n}+\mathrm{c.c.}, \tag{3.5}$$

$$\delta v=\int \mathcal{A}(\mathbf{n})u_v(\mathbf{n}\cdot\mathbf{x},\omega\eta)d^3\mathbf{n}+\mathrm{c.c.}, \tag{3.6}$$

where the Fourier modes form traveling waves,

$$u_\rho(\mathbf{n}\cdot\mathbf{x},\omega\eta)=\frac{2}{3}\left(1+\frac{1}{i\omega\eta}+\frac{i\omega\eta}{2}\right)\frac{e^{i(\mathbf{n}\cdot\mathbf{x}-\omega\eta)}}{i\omega\eta}, \tag{3.7}$$

$$u_v(\mathbf{n}\cdot\mathbf{x},\omega\eta)=\frac{1}{2\sqrt{3}}\left(1+\frac{i\omega\eta}{2}\right)\frac{e^{i(\mathbf{n}\cdot\mathbf{x}-\omega\eta)}}{i\omega\eta}. \tag{3.8}$$

A generic scalar perturbation in the early universe is a superposition of acoustic waves. Its amplitude decreases to reach a constant and positive value at late times. This decrease is substan-

tial in the low frequency (early times) limit $\omega\eta \ll 1$. Solutions are formally divergent at $\eta=0$, nevertheless evaluating the cosmic structure backward in time beyond its stochastic initiation η_i has no well defined physical sense.

The only perturbations, which are regular at $\eta=0$, and growing near the initial singularity, consist of standing waves $u(\mathbf{n}\cdot\mathbf{x},\omega\eta)+u(-\mathbf{n}\cdot\mathbf{x},\omega\eta)$ (compare Ref. 21, 28, 29 or similar effect in the gravitational waves theory[23]). They form a one-parameter family in the 2-parameter space of all solutions, so they are nongeneric. This property has been confirmed by use of other techniques in the gauge-invariant theories.[30] In the stochastic approach nongeneric solutions are of marginal interest since they contribute with the zero probability measure.

IV. SUMMARY AND CONCLUSIONS

It is a matter of dispute whether cosmic structure was created solely by gravity forces[1] or initiated by other, nongravitational phenomena manifesting themselves as stochastic processes[19,20] in some early epochs. For the first hypothesis regular and growing solutions are indispensable, while in the second one the generic perturbations play a key role. In a radiation dominated universe these properties exclude each other.

Lifshitz theory and the gauge-invariant theories differ less than usually expected. Both types of theories, when properly written, lead to the same perturbation equation of the wave-equation form. Generic scalar perturbations are superpositions of acoustic waves. Solutions depend on the product $n\eta$ (equivalently on $\omega\eta$). Everything which concerns early epochs refers also to long waves, and *vice versa*. (This is a peculiar property of the spatially flat radiation-filled universe.) The perturbation scale does not divide solutions into different classes. Perturbations propagate with the same speed $1/\sqrt{3}$, which does not depend on the wave vector. This confirms the wave nature of scalar perturbations in the radiation dominated universe (an important property already pointed out by Lukash,[25] but hardly discussed elsewhere) and compels one to use the complete metric corrections (3.4) in the Sachs–Wolfe procedure (not only the nongeneric growing solutions) at the end of the radiational era.

The reduction technique we apply in this paper can be used for other equations of state. For $p/\rho=\text{const}\neq 1/3$ solutions can be expressed in terms of hypergeometric functions. In other cases solutions may not reduce to any known elementary or special functions, although the reduced equation (2.16) can be always found.

APPENDIX A: LIFSHITZ ''SYNCHRONOUS'' GAUGE

The original Lifshitz approach[1–3] provides solutions which are different from (3.2)–(3.3), and also inconsistent with the gauge-invariant theories. To explain these differences in detail, we appeal to the complete solution to (2.10)–(2.11) containing both physical and spurious inhomogeneities. All the gauge freedom within the synchronous system is limited to the choice of the integral constants in (2.15). Actually each of these ''constants'' can be defined as an arbitrary function of the wave number $\mathbf{n}$ (equivalently ω). We write them explicitly as $\mathcal{A}(\mathbf{n})$ and $\mathcal{G}(\mathbf{n})$ satisfying

$$\lambda(\omega\eta)=f_1(\eta)\left(\mathcal{A}(\mathbf{n})\int A(\eta)\,d\eta-\mathcal{G}(\mathbf{n})\ln(i\omega)\right), \tag{A1}$$

$$A(\eta)=\frac{d}{d\eta}\left(\frac{f_2(\eta)}{f_1(\eta)}\right)\left(\int\frac{B(\eta)}{\eta}d\eta+\frac{\mathcal{G}(\mathbf{n})}{\mathcal{A}(\mathbf{n})}\right), \tag{A2}$$

so they are equal to the Fourier coefficients in the integral,

$$h_{\mu\nu}=\int \mathcal{A}(\mathbf{n})\left(\frac{n_\mu n_\nu}{n^2}-\frac{\delta_{\mu\nu}}{3}\right)\left(\frac{e^{i(\mathbf{n}\cdot\mathbf{x}-\omega\eta)}}{i\omega\eta}+e^{i\mathbf{n}\cdot\mathbf{x}}\,\mathrm{Ei}(-i\omega\eta)\right)d^3\mathbf{n}$$
$$+\int \mathcal{A}(\mathbf{n})\frac{\delta_{\mu\nu}}{3}\left[\left(1+\frac{1}{i\omega\eta}\right)\frac{e^{i(\mathbf{n}\cdot\mathbf{x}-\omega\eta)}}{i\omega\eta}+e^{i\mathbf{n}\cdot\mathbf{x}}\,\mathrm{Ei}(-i\omega\eta)\right]d^3\mathbf{n}$$
$$+\int \mathcal{G}(\mathbf{n})\left[\left(\frac{n_\mu n_\nu}{n^2}-\frac{\delta_{\mu\nu}}{3}\right)\ln(i\omega\eta)+\frac{\delta_{\mu\nu}}{3}\left(\ln(i\omega\eta)-\frac{1}{\omega^2\eta^2}\right)\right]e^{i\mathbf{n}\cdot\mathbf{x}}\,d^3\mathbf{n}+\text{c.c.} \quad \text{(A3)}$$

Each coefficient $\mathcal{A}(\mathbf{n})$, $\mathcal{G}(\mathbf{n})$, can be defined independently. The gauge freedom is carried by $\mathcal{G}(\mathbf{n})$ which follows directly from (2.13). Also knowing the gauge-invariant methods one can *a posteriori* check that $\mathcal{A}(\mathbf{n})$ affects the gauge-invariant inhomogeneity measures, while $\mathcal{G}(\mathbf{n})$ does not. Now, the density contrast and the peculiar velocity, as inferred from formulas (8.2)–(8.3) of Ref. 2,

$$\frac{\delta\rho}{\rho}=\int\left[\mathcal{A}(\mathbf{n})u_\rho(\mathbf{n}\cdot\mathbf{x},\omega\eta)+\mathcal{G}(\mathbf{n})\tilde{u}_\rho(\mathbf{n}\cdot\mathbf{x},\omega\eta)\right]d^3\mathbf{n}+\text{c.c.}, \quad \text{(A4)}$$

$$\delta v=\int\left[\mathcal{A}(\mathbf{n})u_v(\mathbf{n}\cdot\mathbf{x},\omega\eta)+\mathcal{G}(\mathbf{n})\tilde{u}_v(\mathbf{n}\cdot\mathbf{x},\omega\eta)\right]d^3\mathbf{n}+\text{c.c.}, \quad \text{(A5)}$$

consists of the physical modes u_ρ, u_v already found in (3.7)–(3.8) and the pure-gauge modes equal to

$$\tilde{u}_\rho(\mathbf{n}\cdot\mathbf{x},\omega\eta)=\frac{2}{3}\frac{1}{\omega^2\eta^2}e^{i\mathbf{n}\cdot\mathbf{x}}, \quad \text{(A6)}$$

$$\tilde{u}_v(\mathbf{n}\cdot\mathbf{x},\omega\eta)=\frac{i}{2\sqrt{3}}\frac{1}{\omega\eta}e^{i\mathbf{n}\cdot\mathbf{x}}. \quad \text{(A7)}$$

We expand integrals (A4) and (A5) in the early times limit (with the accuracy to η^2), to obtain

$$\frac{\delta\rho}{\rho}=\int\left[\frac{2}{3}\frac{\mathcal{A}(\mathbf{n})+\mathcal{G}(\mathbf{n})}{\omega^2\eta^2}+\left(\frac{1}{9}i\omega\eta+\frac{1}{12}\omega^2\eta^2\right)\mathcal{A}(\mathbf{n})\right]e^{i\mathbf{n}\cdot\mathbf{x}}d^3\mathbf{n}+\text{c.c.}, \quad \text{(A8)}$$

$$\delta v=\frac{1}{2\sqrt{3}}\int\left[\frac{\mathcal{A}(\mathbf{n})+\mathcal{G}(\mathbf{n})}{i\omega\eta}+\frac{1}{2}\mathcal{A}(\mathbf{n})\left(1+\frac{\omega^2\eta^2}{6}\right)\right]e^{i\mathbf{n}\cdot\mathbf{x}}d^3\mathbf{n}+\text{c.c.} \quad \text{(A9)}$$

Both physical and gauge perturbations manifest identical singular behavior at $\eta=0$. Therefore, one cannot distinguish between them solely on the grounds of their asymptotic forms. On the other hand, one is able to regularize perturbations by the gauge choice $\mathcal{G}(\mathbf{n})=-\mathcal{A}(\mathbf{n})$. Then, the equal time hypersurfaces follow the hypersurfaces of equal density at early epochs. This gauge (commonly known as the synchronous gauge) has been actually employed by Lifshitz and Khalatnikov,[1,2] where divergent terms $1/(\omega\eta)^2$ are cancelled by the exactly opposite pure-gauge corrections. (This does not refer to the metric correction where $1/\eta$-divergence is still present.) In consequence, perturbations described there form a mixture of both the physical and the gauge modes.

In the Lifshitz gauge, the mode amplitude $[u_\rho(\mathbf{n}\cdot\mathbf{x},\omega\eta)\overline{u_\rho(\mathbf{n}\cdot\mathbf{x},\omega\eta)}]^{1/2}$ grow with time, therefore, the two independent solutions for the density contrast increase. The same concerns the

peculiar velocity. In the low $\omega\eta$ limit the density contrast and peculiar velocity form the two-parameter linear spaces of growing solutions. As a consequence, a generic inhomogeneity increases, which is in conflict with the gauge-invariant theories.[4,5,9]

Petrov type *D* Einstein space–times of embedding class two

D. E. Hodgkinson
Department of Mathematical Sciences, The University of Liverpool, Maths and Oceanography Building, Peach Street, Liverpool, L69 7ZL England

(Received 26 June 2000; accepted for publication 18 October 2000)

A space–time is of embedding class 2 if its curvature tensor can be written in terms of two symmetric tensors $a_{\alpha\beta}$ and $b_{\alpha\beta}$ which satisfy the Gauss, Codazzi, and Ricci equations. For an Einstein space–time the Ricci tensor is proportional to the metric tensor. Using the Petrov classification of the curvature tensor and canonical forms of $a_{\alpha\beta}$ and $b_{\alpha\beta}$, this paper produces a list of the embedding class 2 Petrov type *D* Einstein space–times. After a summary of the basic equations and the previous work on embedding class 2 space–times, the field equations for Einstein space–times are expressed in a canonical form and the type *D* Petrov conditions applied. The resulting equations are solved and give two sets of metrics. The first are known metrics which are products of two 2-spaces of constant curvature and the second set is a generalization of the Kottler solution. The form of the second set of solutions depends upon whether the metric depends upon one or two of the four coordinates.
 [DOI: 10.1063/1.1332122]

I. INTRODUCTION

The local isometric embedding of four-dimensional space–times V_4 into a flat pseudo-Euclidean space E_N of $N \leqslant 10$ dimensions has sometimes been used in general relativity as an alternative to the intrinsic curvilinear coordinates of the V_4.

Various attempts have been made to give a physical meaning to the flat embedding space. These issues are discussed in a seminar held in 1965[1] and in the references of the survey article by Goenner.[2]

In this paper the more pragmatic approach adopted by Kramer *et al.*[3] will be used. The invariance of the embedding class gives a classification scheme for all solutions of Einstein's field equations, but is mathematically different from classifications based on groups of motions or Petrov types and can, therefore, act as a refinement of these schemes and can give more information about known solutions or find new solutions.

This paper extends the results of two previous papers Hodgkinson.[4,5] The embedding equations are solved to find two sets of metric tensors. The first set of solutions contains the known metrics which are products of two 2-spaces of constant curvature called decomposable by Kramer,[3] or reducible by Petrov.[6] The second set is related to the known Kottler solution.

The method used is similar to Hodgkinson,[5] the Einstein field equations are written in terms of the first fundamental forms using the Gauss equation and by considering the Codazzi equations simplified forms of $a_{\alpha\beta}$ and $b_{\alpha\beta}$ are obtained. These specialized $a_{\alpha\beta}$ and $b_{\alpha\beta}$ are then used to create differential equations for the components of the metric tensor which are solved to produce the two sets of metric tensors.

II. CODAZZI AND RICCI EQUATIONS

The Gauss, Codazzi, and Ricci equations provide the necessary and sufficient conditions that space–times can be embedded (locally and isometrically) in a pseudo-Euclidean space. For the case of embedding class 2, the conditions are that there exist two symmetric tensors $a_{\alpha\beta}$ and $b_{\alpha\beta}$ and a vector s_α, which satisfy the following equations of Eisenhart.[7]

Gauss equation,

$$R_{\alpha\beta\gamma\delta}=\epsilon_1(a_{\alpha\gamma}a_{\beta\delta}-a_{\alpha\delta}a_{\beta\gamma})+\epsilon_2(b_{\alpha\gamma}b_{\beta\delta}-b_{\alpha\delta}a_{\beta\gamma}), \tag{1}$$

where $\epsilon_1=\pm 1$ and $\epsilon_2=\pm 1$.

Codazzi equations,

$$a_{\alpha\beta;\gamma}-a_{\alpha\gamma;\beta}=\epsilon_2(-s_\gamma b_{\alpha\beta}+s_\beta b_{\alpha\gamma}), \tag{2}$$

$$b_{\alpha\beta;\gamma}-b_{\alpha\gamma;\beta}=-\epsilon_1(-s_\gamma a_{\alpha\beta}+s_\beta a_{\alpha\gamma}). \tag{3}$$

Ricci equation,

$$s_{\alpha;\beta}-s_{\beta;\alpha}=a_{\alpha\gamma}b^{\gamma}_{\beta}-b_{\alpha\gamma}a^{\gamma}_{\beta}. \tag{4}$$

In a previous paper by Hodgkinson[4] it is shown that, for Petrov type D Weyl tensors, the vector s_α is a gradient and therefore from Eq. (4) the matrices a^{α}_{β} and b^{α}_{β} commute. The tensors $a_{\alpha\beta}$, $b_{\alpha\beta}$, and s_α are not uniquely determined, they are subject to rotations (pseudo-rotations) in the 2-space orthogonal to Riemannian V_4 in the pseudo-Euclidean embedding space E_6. The proof that s_α is a gradient depends upon $R_{\alpha\beta}=0$, but for Einstein spaces with $R_{\alpha\beta}=\Lambda g_{\alpha\beta}$ the proof is very similar and the result is the same and this means that it is possible to make the Ricci vector $s_\alpha=0$ and this condition will be used throughout this paper.

The steps followed are as follows: in Sec. III the solution of the Gauss equations for $\epsilon_1=\epsilon_2$ gives two different cases which produce the two different types of metrics. Section IV uses the Codazzi and Ricci equations to find explicit forms for the metrics. Section IV A gives the metrics for the two 2-spaces of constant curvature and Sec. IV B gives the Kottler-type metrics. Section V considers the analysis when $\epsilon_1=-\epsilon_2$ and finally Sec. VI lists the Petrov type D Einstein space–times of embedding class 2.

Throughout the analysis it is assumed that both a^{α}_{β} and b^{α}_{β} were of maximum rank. Kaigorodov and Yakupov[8] have given a list of the degenerate forms of a^{α}_{β} and b^{α}_{β}. Direct substitution of these forms shows that no new solutions are obtained.

III. THE CASE $\epsilon_1=\epsilon_2$ GAUSS AND FIELD EQUATIONS

The field equations for an Einstein space are

$$R^{\gamma}_{\alpha\gamma\beta}=R_{\alpha\beta}=\Lambda g_{\alpha\beta}, \tag{5}$$

where Λ is a constant and $g_{\alpha\beta}$ is the metric tensor. Letting $\epsilon_1=\epsilon_2=\epsilon$ and substituting for the Ricci tensor gives

$$(a^{\alpha}_{\beta}a^{\beta}_{\gamma}-aa^{\alpha}_{\gamma})+(b^{\alpha}_{\beta}b^{\beta}_{\gamma}-bb^{\alpha}_{\gamma})=-\epsilon\Lambda\,\delta^{\alpha}_{\gamma} \tag{6}$$

where $a=a^{\alpha}_{\alpha}$ and $b=b^{\alpha}_{\alpha}$ and the matrices a^{α}_{β} and b^{α}_{β} are both matrices of Segrè-type [1111] (Hodgkinson[4]). Rewriting Eq. (6) in the form

$$A^2+B^2=(\rho^2-\epsilon\Lambda)I, \tag{7}$$

where

$$A\equiv\left(a^{\alpha}_{\beta}-\frac{a}{2}\delta^{\alpha}_{\beta}\right),\quad B\equiv\left(b^{\alpha}_{\beta}-\frac{b}{2}\delta^{\alpha}_{\beta}\right),\quad I=\delta^{\alpha}_{\beta},\ \text{and}\ \rho^2=\frac{a^2+b^2}{4},$$

a^{α}_{β} and b^{α}_{β} are diagonal matrices and have the following forms (no summation on γ):

$$a^{\gamma}_{\gamma}=\rho\cos(\alpha)+r\cos(\theta_\gamma),\quad b^{\gamma}_{\gamma}=\rho\sin(\alpha)+r\sin(\theta_\gamma),$$

where

$$r^2=\rho^2-\epsilon\Lambda$$

and α, θ_γ are five dependent parameters which satisfy the relationship

$$2\epsilon\Lambda=r^2(\cos(\theta_0-\theta_1)+\cos(\theta_0-\theta_2)+\cos(\theta_0-\theta_3)+\cos(\theta_1-\theta_2)+\cos(\theta_1-\theta_3)+\cos(\theta_2-\theta_3)). \tag{8}$$

The nonzero components of the Weyl tensor $C_{\alpha\beta\gamma\delta}\equiv C_{AB}$ in the Petrov notation are

$$C_{11}=\frac{r^2}{2}(\cos(\theta_0-\theta_1)+\cos(\theta_2-\theta_3))-\frac{\epsilon\Lambda}{3}, \tag{9}$$

$$C_{22}=\frac{r^2}{2}(\cos(\theta_0-\theta_2)+\cos(\theta_1-\theta_3))-\frac{\epsilon\Lambda}{3}, \tag{10}$$

$$C_{33}=\frac{r^2}{2}(\cos(\theta_0-\theta_3)+\cos(\theta_1-\theta_2))-\frac{\epsilon\Lambda}{3}. \tag{11}$$

The Petrov classification requires $C_{11}+C_{22}+C_{33}=0$, but for Petrov type D Weyl tensors we need two of the C_{AA} to be equal, without loss of generality we take $C_{11}=C_{22}$. Then using standard trigonometric identities, Eqs. (9) and (10) give

$$\cos\left(\frac{\theta_0-\theta_1-\theta_2+\theta_3}{2}\right)\sin\left(\frac{\theta_1-\theta_2}{2}\right)\sin\left(\frac{\theta_0-\theta_3}{2}\right)=0. \tag{12}$$

Equation (12) will be satisfied if any of the three factors vanish. The consequences of the vanishing of any of the factors will be considered next and in Secs. IV A and IV B.

Considering the case of $\theta_0-\theta_1-\theta_2+\theta_3=\pi$ gives

$$C_{11}=C_{22}=-\frac{\epsilon\Lambda}{3},\quad C_{33}=\frac{2\epsilon\Lambda}{3}.$$

These solutions require

$$2\Lambda=\epsilon r^2(\cos(\theta_0-\theta_3)+\cos(\theta_1-\theta_2)) \tag{13}$$

in agreement with Eq. (8).

Reverting to the matrices $a_{\alpha\beta}$, $b_{\alpha\beta}$ and letting

$$-\lambda_0=a^0_{\ 0},\quad \lambda_1=a^1_{\ 1},\quad \lambda_2=a^2_{\ 2},\quad \lambda_3=a^3_{\ 3},$$

$$-\mu_0=b^0_{\ 0},\quad \mu_1=b^1_{\ 1},\quad \mu_2=b^2_{\ 2},\quad \mu_3=b^3_{\ 3}$$

with the raising and lowering of a zero index on $a^\alpha_{\ \beta}$ or $b^\alpha_{\ \beta}$ changing the sign, the equations for the curvature tensor with $\epsilon_1=\epsilon_2=\epsilon$ are

$$\lambda_1\lambda_3+\mu_1\mu_3=\lambda_2\lambda_3+\mu_2\mu_3=\lambda_0\lambda_1+\mu_0\mu_1=\lambda_0\lambda_2+\mu_0\mu_2=0, \tag{14}$$

$$\lambda_1\lambda_2+\mu_1\mu_2=-\lambda_0\lambda_3-\mu_0\mu_3=\epsilon\Lambda. \tag{15}$$

Using the Grobner basis algorithm to solve this set of six nonlinear equations in eight unknowns gives essentially two solutions in terms of arbitrary unknowns. For the first let λ_2,μ_2, and μ_3 be arbitrary, the remaining five are

$$\lambda_0=\frac{\mu_2\lambda_2\epsilon\Lambda}{\mu_3((\mu_2)^2+(\lambda_2)^2)},\quad \lambda_1=\frac{\lambda_2\epsilon\Lambda}{(\mu_2)^2+(\lambda_2)^2},\quad \lambda_3=-\frac{\mu_2\mu_3}{\lambda_2},\tag{16}$$

$$\mu_0=-\frac{\epsilon\Lambda(\lambda_2)^2}{\mu_3((\mu_2)^2+(\lambda_2)^2)},\quad \mu_1=\frac{\mu_2\epsilon\Lambda}{(\mu_2)^2+(\lambda_2)^2}.\tag{17}$$

The second set is found with λ_0 and μ_1 arbitrary and

$$\lambda_1=\lambda_2=\mu_0=\mu_3=0,\quad \lambda_3=-\frac{\epsilon\Lambda}{\lambda_0},\quad \mu_2=\frac{\epsilon\Lambda}{\mu_1}.\tag{18}$$

Both solutions can be analyzed in a similar manner, although the functional forms are different the same four metrics are produced. So the analysis will only be given for the first solution.

IV. THE CASE $\epsilon_1=\epsilon_2$ CODAZZI AND RICCI EQUATIONS

A. Case 1. The metrics which are products of constant curvature

For further investigation it is necessary to use the Codazzi equations as in Hodgkinson.[5] This involves writing the $a_{\alpha\beta}$ and $b_{\alpha\beta}$ in terms of four basis vectors which can be proved to be hypersurface orthogonal.

The basis vectors satisfy

$$-u_\alpha u^\alpha=v_\alpha v^\alpha=e_\alpha e^\alpha=f_\alpha f^\alpha=1\tag{19}$$

with all other scalar products zero. This gives

$$a_{\alpha\beta}=\lambda_0 u_\alpha u_\beta+\lambda_1 v_\alpha v_\beta+\lambda_2 e_\alpha e_\beta+\lambda_3 f_\alpha f_\beta,\tag{20}$$

$$b_{\alpha\beta}=\mu_0 u_\alpha u_\beta+\mu_1 v_\alpha v_\beta+\mu_2 e_\alpha e_\beta+\mu_3 f_\alpha f_\beta.\tag{21}$$

The derivatives of the tetrad vectors are

$$u_{\alpha;\beta}=v_\alpha A_\beta+e_\alpha B_\beta+f_\alpha C_\beta,\tag{22}$$

$$v_{\alpha;\beta}=u_\alpha A_\beta+e_\alpha D_\beta+f_\alpha E_\beta,\tag{23}$$

$$e_{\alpha;\beta}=u_\alpha B_\beta-v_\alpha D_\beta+f_\alpha G_\beta,\tag{24}$$

$$f_{\alpha;\beta}=u_\alpha C_\beta-v_\alpha E_\beta-e_\alpha G_\beta.\tag{25}$$

Using the Codazzi equations and contracting Eqs. (22)–(25) with the different tetrad vectors gives equations for $A_\alpha, B_\alpha, C_\alpha, D_\alpha, E_\alpha$, and G_α, more details are given in Hodgkinson.[5]

Letting a comma denote partial differentiation, the equations for A_α are

$$(\lambda_0+\lambda_1)A_\alpha=\lambda_{0,\beta}v^\beta u_\alpha-\lambda_{1,\beta}u^\beta v_\alpha+(\lambda_0+\lambda_2)B_\beta v^\beta e_\alpha+(\lambda_0+\lambda_3)C_\beta v^\beta f_\alpha,\tag{26}$$

$$(\lambda_0+\lambda_1)A_\alpha=\lambda_{0,\beta}v^\beta u_\alpha-\lambda_{1,\beta}u^\beta v_\alpha+(\lambda_1-\lambda_2)D_\beta u^\beta e_\alpha+(\lambda_1-\lambda_3)E_\beta u^\beta f_\alpha,\tag{27}$$

$$(\mu_0+\mu_1)A_\alpha=\mu_{0,\beta}v^\beta u_\alpha-\mu_{1,\beta}u^\beta v_\alpha+(\mu_0+\mu_2)B_\beta v^\beta e_\alpha+(\mu_0+\mu_3)C_\beta v^\beta f_\alpha,\tag{28}$$

$$(\mu_0+\mu_1)A_\alpha=\mu_{0,\beta}v^\beta u_\alpha-\mu_{1,\beta}u^\beta v_\alpha+(\mu_1-\mu_2)D_\beta u^\beta e_\alpha+(\mu_1-\mu_3)E_\beta u^\beta f_\alpha,\tag{29}$$

and similar ones exist for $B_\alpha, C_\alpha, D_\alpha, E_\alpha$, and G_α. Using Eqs. (16) and (17) with the linear independence of the basis vectors it is a straightforward substitution task to show that

$$\frac{((\lambda_2)^2+(\mu_2)^2)((\lambda_2)^2+(\mu_2)^2-\epsilon\Lambda)\mu_3}{(\mu_2+\mu_3)(\mu_2\mu_3-(\lambda_2)^2)\epsilon\Lambda}B_\beta v^\beta=0 \tag{30}$$

and

$$\frac{\mu_3((\lambda_2)^2+(\mu_2)^2)((\mu_3)^2((\lambda_2)^2+(\mu_2)^2)-(\lambda_2)^2\epsilon\Lambda)}{(\mu_2+\mu_3)(\mu_2\mu_3-(\lambda_2)^2)\epsilon\Lambda}C_\beta v^\beta=0. \tag{31}$$

We assume, at this stage, that there are no relationships between the arbitrary parameters λ_2,μ_2, and μ_3, which can make the coefficients of $B_\beta v^\beta=C_\beta v^\beta$ zero. The conditions that λ_2,μ_2, and μ_3 are not independent will be considered at the end of this section.

A similar analysis for D_α and E_α gives $B_\beta v^\beta=C_\beta v^\beta=D_\beta u^\beta=E_\beta u^\beta=0$ and the form of the equations for A_α becomes

$$A_\alpha=\frac{1}{\lambda_0+\lambda_1}(\lambda_{0,\beta}v^\beta u_\alpha-\lambda_{1,\beta}u^\beta v_\alpha)=\frac{1}{\mu_0+\mu_1}(\mu_{0,\beta}v^\beta u_\alpha-\mu_{1,\beta}u^\beta v_\alpha). \tag{32}$$

Similar forms for $B_\alpha, C_\alpha, D_\alpha, E_\alpha$, and G_α may be found by an analogous process. Using the fact that $u_\alpha,v_\alpha,e_\alpha$, and f_α are hypersurface orthogonal, conditions for the consistency of Eqs. (32) and those for $B_\alpha, C_\alpha, D_\alpha, E_\alpha$, and G_α can be found. Since this task is repetitive and routine only one example will be given.

Checking for C_α, E_α, and G_α gives

$$\frac{1}{\lambda_0+\lambda_3}(\lambda_{0,\beta}f^\beta)=\frac{1}{\mu_0+\mu_3}(\mu_{0,\beta}f^\beta), \tag{33}$$

$$\frac{1}{\lambda_1-\lambda_3}(\lambda_{1,\beta}f^\beta)=\frac{1}{\mu_1-\mu_3}(\mu_{1,\beta}f^\beta), \tag{34}$$

$$\frac{1}{\lambda_2-\lambda_3}(\lambda_{2,\beta}f^\beta)=\frac{1}{\mu_2-\mu_3}(\mu_{2,\beta}f^\beta). \tag{35}$$

Using the z coordinate adapted to the f_α tetrad gives a set of three partial differential equations. Substituting from Eqs. (16) and (17) gives for Eq. (33)

$$\frac{\partial\mu_2}{\partial z}\lambda_2-\frac{\partial\lambda_2}{\partial z}\mu_2=0, \tag{36}$$

this integrates to give $\mu_2=k\lambda_2$, where k is independent of z. Using this value of μ_2 together with Eqs. (16) and (17) substituted into Eqs. (34) and (35) gives

$$\mu_3(\lambda_2)^3(1+k^2)^2\frac{\partial\lambda_2}{\partial z}=0, \tag{37}$$

$$\mu_3\lambda_2(1+k^2)\frac{\partial\lambda_2}{\partial z}=0. \tag{38}$$

In order to keep the arbitrariness of the parameters these conditions require λ_2 (and μ_2) to be independent of z. Repeating the analysis for the y coordinate adapted to e_α, the x coordinate adapted to v_α gives

$$\mu_2(x,y)=k\lambda_2(x,y), \tag{39}$$

where k is a constant and μ_3 is a function of t and z only. These functional dependencies allow Eqs. (16) and (17) to be simplified to

$$\lambda_0=-\frac{k\epsilon\Lambda}{\mu_3(1+k^2)},\quad \lambda_1=-\frac{\epsilon\Lambda}{\lambda_2(1+k^2)},\quad \lambda_3=k\mu_3, \tag{40}$$

$$\mu_0=\frac{\epsilon\Lambda}{\mu_3(1+k^2)},\quad \mu_1=-\frac{k\epsilon\Lambda}{\lambda_2(1+k^2)},\quad \mu_2=k\lambda_2, \tag{41}$$

where $\lambda_2=\lambda_2(x,y)$ and $\mu_3=\mu_3(t,z)$ are arbitrary functions.

These dependencies between the λ's and the μ's reduce the equations for A_α, B_α, C_α, D_α, E_α, and G_α to

$$A_\alpha=B_\alpha=E_\alpha=G_\alpha=0 \tag{42}$$

and

$$C_\alpha=\frac{1}{\lambda_0+\lambda_3}(\lambda_{0,\beta}f^\beta u_\alpha-\lambda_{3,\beta}u^\beta f_\alpha), \tag{43}$$

$$D_\alpha=\frac{1}{\lambda_1-\lambda_2}(\lambda_{1,\beta}e^\beta v_\alpha+\lambda_{2,\beta}v^\beta e_\alpha). \tag{44}$$

In terms of coordinates adapted to the tetrad, the metric may be written in the form

$$ds^2=-T^2\,dt^2+X^2\,dx^2+Y^2\,dy^2+Z^2\,dz^2, \tag{45}$$

where $u^\alpha=T^{-1}\delta_0^\alpha$, $v^\alpha=X^{-1}\delta_1^\alpha$, $e^\alpha=Y^{-1}\delta_2^\alpha$, and $f^\alpha=Z^{-1}\delta_3^\alpha$ with $x^0=t$, $x^1=x$, $x^2=y$, and $x^3=z$.

Comparing the derivatives of the tetrad vectors obtained from the equation of the metric (45) and those from Eqs. (43) and (44) allows the metric to be written

$$ds^2=-(T(t,z))^2\,dt^2+(X(x,y))^2\,dx^2+(Y(x,y))^2\,dy^2+(Z(t,z))^2\,dz^2. \tag{46}$$

The field equations $R_{\alpha\beta}=\Lambda g_{\alpha\beta}$ give for R_{11},

$$\frac{X_{yy}}{XY^2}+\frac{Y_{xx}}{X^2Y}-\frac{X_xY_x}{X^3Y}-\frac{X_yY_y}{XY^3}=\Lambda, \tag{47}$$

where a suffix denotes partial differentiation, with similar ones for R_{00}, R_{22}, R_{33}.

Since Λ is a constant, the left-hand side of Eq. (47) is a constant, i.e., the xy space is a 2-space of constant curvature K. According to Kramer *et al.*[3] the metrics of 2-spaces of constant curvature have six distinct types

$$d\sigma^2=Q^2((dx^1)^2\pm\Sigma^2(x^1,w)(dx^2)^2),\quad K=wQ^{-2}, \tag{48}$$

where $\Sigma(x^1,w)=\sin(x^1)$ or x^1 or $\sinh(x^1)$ if $w=1$ or $=0$ or $=-1$, respectively. Examination of the values of w and Σ which preserve the signature of ds^2 and satisfy the field equations gives four solutions. When both 2-spaces have positive curvature $K=\Lambda$, the metric is

$$ds^2=-\frac{\sin^2(z)}{\Lambda}dt^2+\frac{dx^2}{\Lambda}+\frac{\sin^2(x)}{\Lambda}dy^2+\frac{dz^2}{\Lambda}. \tag{49}$$

A scaling of the coordinates $x^\alpha\to\sqrt{\Lambda}x^\alpha$ in Eq. (49) reduces it to

$$ds^2 = -\sin^2(z\sqrt{\Lambda})dt^2 + dx^2 + \sin^2(x\sqrt{\Lambda})dy^2 + dz^2.$$

This metric agrees with one of the four classified as reducible and listed by Petrov[6] or called decomposable in the terminology of Kramer *et al.*[3] The other three have similar representations and are listed in Sec. VI.

During the previous analysis any special relationships between the parameters were ignored, so it is necessary, following Eqs. (30) and (31), to consider the implication of λ_2, μ_2, μ_3 being dependent.

From Eqs. (30) and (31) it is possible that

$$(\lambda_2)^2 + (\mu_2)^2 = \epsilon\Lambda \quad \text{and/or} \quad ((\mu_3)^2((\lambda_2)^2 + (\mu_2)^2) - (\lambda_2)^2\epsilon\Lambda) = 0.$$

Using these condition in Eqs. (16) and (17) gives either $\theta_1 = \theta_2$ or $\theta_0 = \theta_1$ and in both cases the analysis would be similar to the $\theta_0 = \theta_3$ case, which follows in Sec. IV B. The denominators of Eqs. (30) and (31) would vanish if $\mu_2 = -\mu_3$ or $\mu_2\mu_3 = (\lambda_2)^2$. The first condition gives $\theta_0 = \theta_1$ considered in Sec. IV B, while the second gives $\lambda_3 = -\lambda_2$ and $\mu_0 = -\mu_1$ which again is essentially analyzed in Sec. IV B.

B. Case 2. The Kottler metrics

For Eq. (12) two other possible solutions are $\theta_0 = \theta_3$ or $\theta_1 = \theta_2$. Without loss of generality we will assume that $\theta_0 = \theta_3$ gives

$$\lambda_0 = \frac{r}{2}(\cos(\theta_1) + \cos(\theta_2)) = -\lambda_3, \tag{50}$$

$$\lambda_1 = \frac{r}{2}(\cos(\theta_1) - \cos(\theta_2) - 2\cos(\theta_0)), \tag{51}$$

$$\lambda_2 = \frac{r}{2}(\cos(\theta_2) - \cos(\theta_1) - 2\cos(\theta_0)), \tag{52}$$

$$\mu_0 = \frac{r}{2}(\sin(\theta_1) + \sin(\theta_2)) = -\mu_3, \tag{53}$$

$$\mu_1 = \frac{r}{2}(\sin(\theta_1) - \sin(\theta_2) - 2\sin(\theta_0)), \tag{54}$$

$$\mu_2 = \frac{r}{2}(\sin(\theta_2) - \sin(\theta_1) - 2\sin(\theta_0)). \tag{55}$$

Again by examining A_α, B_α, C_α, D_α, E_α, and G_α and using linear independence and Eqs. (50) to (55) we obtain

$$A_\alpha = \frac{1}{\lambda_0 + \lambda_1}(\lambda_{0,\beta}v^\beta u_\alpha - \lambda_{1,\beta}u^\beta v_\alpha) = \frac{1}{\mu_0 + \mu_1}(\mu_{0,\beta}v^\beta u_\alpha - \mu_{1,\beta}u^\beta v_\alpha) \tag{56}$$

with similar expressions for B_α, D_α, E_α, and G_α.

Let the t, x, y, and z coordinates be adapted to the tetrad vectors. The fact that C_α is indeterminate makes

$$\frac{\partial\lambda_0}{\partial z} = \frac{\partial\mu_0}{\partial z} = \frac{\partial\lambda_0}{\partial t} = \frac{\partial\mu_0}{\partial t} = 0. \tag{57}$$

Differentiating Eqs. (50) and (53) partially with respect to z gives

$$\frac{\partial r}{\partial z}(\cos(\theta_1)+\cos(\theta_2))-r\left(\sin(\theta_1)\frac{\partial\theta_1}{\partial z}+\sin(\theta_2)\frac{\partial\theta_2}{\partial z}\right)=0, \tag{58}$$

$$\frac{\partial r}{\partial z}(\sin(\theta_1)+\sin(\theta_2))+r\left(\cos(\theta_1)\frac{\partial\theta_1}{\partial z}+\cos(\theta_2)\frac{\partial\theta_2}{\partial z}\right)=0. \tag{59}$$

Eliminating $\partial\theta_2/\partial z$ from Eqs. (58) and (59) gives

$$\frac{\partial r}{\partial z}(1+\cos(\theta_1-\theta_2))-r(\sin(\theta_1-\theta_2))\frac{\partial\theta_1}{\partial z}=0, \tag{60}$$

and similarly eliminating $\partial\theta_1/\partial z$ implies

$$\frac{\partial\theta_1}{\partial z}=-\frac{\partial\theta_2}{\partial z}.$$

To find relationships between $\partial r/\partial z$, $\partial\theta_0/\partial z$, and $\partial\theta_1/\partial z$ use Eqs. (8) with $\theta_0=\theta_3$,

$$2\epsilon\Lambda=r^2(2\cos(\theta_1-\theta_0)+2\cos(\theta_2-\theta_0)+1+\cos(\theta_1-\theta_2)). \tag{61}$$

Differentiating partially with respect to z and substituting for $\partial\theta_2/\partial z$ gives

$$-2r(2\cos(\phi_1)+2\cos(\phi_2)+\cos(\phi_2-\phi_1)+1)\frac{\partial r}{\partial z}-2r^2(\sin(\phi_1)+\sin(\phi_2))\frac{\partial\theta_0}{\partial z}$$
$$+2r^2(\sin(\phi_1)-\sin(\phi_2)-\sin(\phi_2-\phi_1))\frac{\partial\theta_1}{\partial z}=0, \tag{62}$$

where $\phi_1=\theta_1-\theta_0$ and $\phi_2=\theta_2-\theta_0$.

It is possible to find two new equations in $\partial r/\partial z$, $\partial\theta_0/\partial z$, and $\partial\theta_1/\partial z$ in order to examine the z dependency of the r and θ's.

The equations for E_α and G_α require

$$\frac{1}{\lambda_1-\lambda_3}\frac{\partial\lambda_1}{\partial z}=\frac{1}{\mu_1-\mu_3}\frac{\partial\mu_1}{\partial z} \tag{63}$$

and

$$\frac{1}{\lambda_2-\lambda_3}\frac{\partial\lambda_2}{\partial z}=\frac{1}{\mu_2-\mu_3}\frac{\partial\mu_2}{\partial z}. \tag{64}$$

Substituting and simplifying gives

$$1/2r(\sin(\phi_1)+\sin(\phi_2)-\sin(-\phi_1+\phi_2))\frac{\partial r}{\partial z}+r^2(1-\cos(\phi_1))\frac{\partial\theta_0}{\partial z}$$
$$+1/2r^2(-\cos(\phi_1)-\cos(\phi_2)+\cos(-\phi_1+\phi_2)+1)\frac{\partial\theta_1}{\partial z}=0 \tag{65}$$

and

$$1/2r(\sin(\phi_1)+\sin(\phi_2)+\sin(-\phi_1+\phi_2))\frac{\partial r}{\partial z}+r^2(1-\cos(\phi_2))\frac{\partial \theta_0}{\partial z}$$

$$-1/2r^2(-\cos(\phi_1)-\cos(\phi_2)+\cos(-\phi_1+\phi_2)+1)\frac{\partial \theta_1}{\partial z}=0. \tag{66}$$

To examine the dependence of the three equations (62), (65), and (66) they are written in the form $AX=0$, where $X=[\partial r/\partial z, \partial\theta_0/\partial z, \partial\theta_1/\partial z]^T$ and A is the matrix of the coefficients. The determinant of A factors to

$$-4-4\cos(\phi_1+\phi_2)+6\cos(\phi_1)+6\cos(\phi_2)-4\cos(-\phi_1+\phi_2)+\cos(-\phi_1+2\phi_2)$$
$$+\cos(\phi_1+2\phi_2)+\cos(\phi_2-2\phi_1)+\cos(\phi_2+2\phi_1)-2\cos(2\phi_1)-2\cos(2\phi_2).$$

Using standard trigonometric substitutions this expression reduces to

$$16\cos\left(\frac{\phi_1+\phi_2}{2}\right)\cos\left(\frac{\phi_1-\phi_2}{2}\right)\sin^2\left(\frac{\phi_1}{2}\right)\sin^2\left(\frac{\phi_2}{2}\right).$$

This determinant has to vanish for the consistency of Eqs. (62), (65), and (66) which is only valid for $\theta_1=\theta_2$, $\theta_1=\theta_0$, $\theta_2=\theta_0$, $\theta_1+\theta_2-2\theta_0=\pi$ or $\theta_1-\theta_2=\pi$.

The conditions $\theta_1=\theta_2$ or $\theta_1-\theta_2=\pi$ together with the condition

$$\frac{\partial\theta_1}{\partial z}=-\frac{\partial\theta_2}{\partial z}$$

make θ_1 and θ_2 independent of z, so Eqs. (58) and (62) show that r and θ_0 are also independent of z.

The condition $\theta_1+\theta_2-2\theta_0=\pi$ and Eqs. (65) and (66) make either r and the θ's independent of z or $\sin(\phi_2-\phi_1)=0$ which also implies z independence.

The condition $\theta_1=\theta_0$ (and similarly $\theta_2=\theta_0$) reduces Eqs. (62), (65), and (66) to the equation

$$\cos\left(\frac{\phi_2}{2}\right)\frac{\partial r}{\partial z}-\frac{r}{2}\sin\left(\frac{\phi_2}{2}\right)\frac{\partial\phi_2}{\partial z}=0$$

which integrates to

$$r\cos\left(\frac{\phi_2}{2}\right)=g(t,x,y),$$

where g is an arbitrary function of t, x, and y. A similar analysis using Eq. (57) gives the t independence of g and since under these conditions $\lambda_0+\lambda_1=0$ then from Eq. (56) A_α is indeterminate making λ_0 and μ_0 independent of x. This fact reduces g to depend only on one variable y and Eq. (61) implies that all the parameters depend upon only one variable, which is considered later in this section.

Assuming that these extra conditions are not satisfied then r, θ_0, θ_1, and θ_2 are independent of z and likewise from Eq. (57) they are independent of t. The consequences for the metric coefficients are that X and Y are independent of t and z. Since C_α is indeterminate, the functional dependencies of T and Z are also indeterminate.

Since all the variables on the right-hand side of Eq. (61) are functions of x and y only then Eq. (61) is essentially a function of x and y equal to zero, i.e., x and y are dependent variables. Hence, r, θ_0, θ_1, and θ_2 are functions of a single variable say x. Then a comparison of the derivatives of the tetrad vectors for A_α, D_α, and E_α allows the metric (45) to be written

$$ds^2 = W^2(x)d\Sigma^2 + X^2(x)dx^2 + Y^2(x)dy^2, \tag{67}$$

where $d\Sigma^2$ is a two-dimensional metric dependent only on t and z.

The field equations $R_{\alpha\beta} = \Lambda g_{\alpha\beta}$ can be investigated for this metric where the equation $R_{22} = \Lambda g_{22}$ gives

$$2\frac{YW_xY_x}{WX^2} + \frac{YY_{xx}}{X^2} - \frac{YX_xY_x}{X^3} = \Lambda Y^2 \tag{68}$$

and $R_{11} = \Lambda g_{11}$ gives

$$2\frac{W_{xx}}{W} - 2\frac{W_xX_x}{WX} + \frac{Y_{xx}}{Y} - \frac{X_xY_x}{XY} = \Lambda X^2. \tag{69}$$

Eliminating Λ gives

$$\frac{Y_x}{Y} - \frac{W_{xx}}{W_x} + \frac{X_x}{X} = 0 \tag{70}$$

which integrates to

$$XY = qW_x, \tag{71}$$

where q is a constant.

The equation $R_{33}/g_{33} = \Lambda$ is

$$\frac{K}{W^2} + \frac{(W_x)^2}{W^2X^2} + \frac{W_{xx}}{WX^2} - \frac{W_xX_x}{WX^3} + \frac{W_xY_x}{WX^2Y} = \Lambda, \tag{72}$$

where K is the Gaussian curvature of $d\Sigma^2$. Partial differentiation of Eq. (72) with respect to t and z shows that K is a constant.

Substituting Eq. (71) into Eq. (68) simplifies and rearranges to give

$$\frac{d}{dx}\left(YY_x\frac{W^2}{W_x}\right) = \Lambda q^2W^2W_x \tag{73}$$

which integrates twice to give

$$Y^2 = \frac{q^2}{3}\Lambda W^2 - 2\frac{p}{W} + 2c_1, \tag{74}$$

where p and c_1 are constants of integration.

Without loss of generality the transformation $W(x) \to x$ and a rescaling gives

$$Y^2 = c - \frac{\Lambda}{3}x^2 + \frac{m}{x}. \tag{75}$$

The value of the constant c depends upon the Einstein space condition and the form of the constant curvature metric. The general form of the metrics is

$$ds^2 = x^2\,d\Sigma^2 + Y^{-2}(x)dx^2 + Y^2(x)dy^2. \tag{76}$$

These metrics are similar to the Kottler form of the Einstein space (see Kramer *et al.*[4] and Petrov.[5] A full list is provided in Sec. VI.

In this section since $\epsilon_1=\epsilon_2=\pm 1$, then the signature of the embedding pseudo-Euclidean space E_6 is either 0 if $\epsilon_1=-1$ or 4 if $\epsilon_1=1$.

V. THE CASE $\epsilon_1=-\epsilon_2$

Letting $\epsilon_1=-\epsilon_2=\epsilon$ gives the equivalent of Eq. (7) as

$$A^2-B^2=(\sigma^2-\epsilon\Lambda)I, \tag{77}$$

where

$$\sigma^2=\frac{a^2-b^2}{4}.$$

The analysis follows the same course with trigonometric terms being replaced by hyperbolic ones. The same metrics are found showing that the metrics that are products of two 2-spaces of constant curvature and the modified Kottler metrics can be embedded in a pseudo-Euclidean space E_6 with signature 2.

It is possible that when $\epsilon_1=-\epsilon_2$ then $\sigma=0$, this degeneracy means that $a=b$ or $a=-b$ in both cases the type D condition on the Weyl tensor gives a flat space solution.

VI. A SUMMARY OF THE METRICS

This section contains a list of all the Petrov type D Einstein space–times of embedding class 2.

The following list gives the reducible metrics.

(1)

$$ds^2=-\frac{\sin^2(z)}{\Lambda}dt^2+\frac{dx^2}{\Lambda}+\frac{\sin^2(x)}{\Lambda}dy^2+\frac{dz^2}{\Lambda}, \tag{78}$$

both 2-spaces have positive curvature $K=\Lambda$.

(2)

$$ds^2=-\frac{\sinh^2(z)}{\Lambda}dt^2+\frac{dx^2}{\Lambda}+\frac{\sinh^2(x)}{\Lambda}dy^2+\frac{dz^2}{\Lambda}, \tag{79}$$

both 2-spaces have negative curvature $K=-\Lambda$.

(3)

$$ds^2=-\frac{dt^2}{\Lambda}+\frac{dx^2}{\Lambda}+\frac{\sin^2(x)}{\Lambda}dy^2+\frac{\sinh^2(t)}{\Lambda}dz^2, \tag{80}$$

$$ds^2=-\frac{dt^2}{\Lambda}+\frac{dx^2}{\Lambda}+\frac{\sinh^2(x)}{\Lambda}dy^2+\frac{\sin^2(t)}{\Lambda}dz^2, \tag{81}$$

one space has positive curvature the other negative curvature.

The scaling of the coordinates given in Sec. IV A gives the agreement with Petrov.[6]

The following list gives the generalized Kottler ones based upon $\theta_0=\theta_3$ in Eq. (12).

(1) A flat $\Sigma^2(z,t)$ the resulting metric is

$$ds^2=\left(-\frac{\Lambda}{3}x^2+\frac{m}{x}\right)^{-1}dx^2+\left(-\frac{\Lambda}{3}x^2+\frac{m}{x}\right)dy^2+x^2\,dz^2-x^2\,dt^2, \tag{82}$$

with $c=0$.

(2) A two-dimensional space–time with negative curvature is

$$ds^2=\left(1-\frac{\Lambda}{3}x^2+\frac{m}{x}\right)^{-1}dx^2+\left(1-\frac{\Lambda}{3}x^2+\frac{m}{x}\right)dy^2+x^2\sinh(t)^2\,dz^2-x^2\,dt^2, \tag{83}$$

with $c=1$.

(3) A two-dimensional space–time with positive curvature is

$$ds^2=\left(1-\frac{\Lambda}{3}x^2+\frac{m}{x}\right)^{-1}dx^2+\left(1-\frac{\Lambda}{3}x^2+\frac{m}{x}\right)dy^2+x^2\,dz^2-x^2\sin(z)^2\,dt^2, \tag{84}$$

with $c=1$.

Naturally, if alternative identifications of the θ's are taken, the following metric forms or similar are obtained.

(1)

$$ds^2=\left(-\frac{\Lambda}{3}x^2+\frac{m}{x}\right)^{-1}dx^2-\left(-\frac{\Lambda}{3}x^2+\frac{m}{x}\right)dt^2+x^2\,dy^2+x^2\,dz^2. \tag{85}$$

(2)

$$ds^2=\left(\frac{\Lambda}{3}t^2+\frac{m}{t}\right)dx^2-\left(\frac{\Lambda}{3}t^2+\frac{m}{t}\right)^{-1}dt^2+t^2\,dy^2+t^2\,dz^2. \tag{86}$$

(3)

$$ds^2=\left(-1+\frac{\Lambda}{3}x^2+\frac{m}{x}\right)dy^2-\left(-1+\frac{\Lambda}{3}t^2+\frac{m}{t}\right)^{-1}dt^2+t^2\sin(z)^2\,dy^2+t^2\,dz^2. \tag{87}$$

(4)

$$ds^2=\left(1-\frac{\Lambda}{3}x^2+\frac{m}{x}\right)^{-1}dx^2-\left(1-\frac{\Lambda}{3}x^2+\frac{m}{x}\right)dt^2+x^2\sin(z)^2\,dy^2+x^2\,dz^2. \tag{88}$$

The above metrics are the only possible Einstein spaces of embedding class 2. This implies that any type *D* Einstein space–times not of these forms are at least of embedding class 3. In a set of two papers[9,10] Van den Bergh has produced a classification of the symmetric tensors for the embedding class 2 problem and one of his applications is to the vacuum Petrov type *D* space–times.

It is a useful comparison to consider the limit as $\Lambda\to 0$ of the previous solutions to those in his paper. For the metrics (70)–(81) as $\Lambda\to 0$, $K\to 0$ and the resulting limit is flat space. As $\Lambda\to 0$ in the metrics listed in (82)–(88) they become either Ehlers–Kundt class A or class B metrics as defined in Kramer *et al.*[3] These results are in agreement with the results of Van den Bergh.[10]

The tensors $a^{\alpha}{}_{\beta}$ and $b^{\alpha}{}_{\beta}$ are not uniquely determined. The previous analysis has shown that different forms can lead to essentially the same embedding. This corresponds to the freedom of rotations in the two-dimensional space orthogonal to the four-dimensional Riemannian in the six-dimensional pseudo-Euclidean embedding space. The explicit embedding equations and the forms of $a^{\alpha}{}_{\beta}$ and $b^{\alpha}{}_{\beta}$ and their representations in terms of the curvature tensor for the embeddings developed in this paper are subjects for further investigation.

The *writhing number* of a curve in 3-space is the standard measure of the extent to which the curve wraps and coils around itself; it has proved its importance for molecular biologists in the study of knotted DNA and of the enzymes which affect it. The *helicity* of a vector field defined on a domain in 3-space is the standard measure of the extent to which the field lines wrap and coil around one another; it plays important roles in fluid dynamics and plasma physics. The *Biot–Savart operator* associates with each current distribution on a given domain the restriction of its magnetic field to that domain. When the domain is simply connected, the divergence-free fields which are tangent to the boundary and which minimize energy for given helicity provide models for stable force-free magnetic fields in space and laboratory plasmas; these fields appear mathematically as the extreme eigenfields for an appropriate modification of the Biot–Savart operator. Information about these fields can be converted into bounds on the writhing number of a given piece of DNA. The purpose of this paper is to reveal new properties of the Biot–Savart operator which are useful in these applications. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1329659]

I. INTRODUCTION

Let Ω be a compact domain with smooth boundary in 3-space, and let $\mathrm{VF}(\Omega)$ be the space of smooth vector fields on Ω with the L^2 inner product $\langle V,W\rangle=\int_\Omega V\cdot W d(\mathrm{vol})$. By ''smooth,'' equivalently C^∞, we mean that derivatives of all orders exist and are continuous.

If we think of the smooth vector field V on Ω as a distribution of electric current, then the Biot–Savart formula

$$\mathrm{BS}(V)(y)=(1/4\pi)\int_\Omega V(x)\times(y-x)/|y-x|^3 \ \mathrm{d}(\mathrm{vol}_x)$$

gives the resulting magnetic field $\mathrm{BS}(V)$ throughout 3-space. If we restrict this magnetic field to the domain Ω, then we get the *Biot–Savart operator*,

$$\mathrm{BS}:\mathrm{VF}(\Omega)\to\mathrm{VF}(\Omega).$$

Theorem A: *The equation* $\nabla\times\mathrm{BS}(V)=V$ *holds in* Ω *if and only if* V *is divergence-free and tangent to the boundary of* Ω.

[c)]Electronic mail: gluck@math.upenn.edu

It is well known that curl is a left inverse to the Biot–Savart operator when the input field V is divergence-free and tangent to the boundary. The new information is that this result holds in no other cases. The impact of this is that eigenvalue problems for the Biot–Savart operator, which are central to the study of helicity, cannot in general be converted to eigenvalue problems for curl (that is, to a system of partial differential equations).

Theorem B: *The kernel of the Biot–Savart operator is precisely the space of gradient vector fields which are orthogonal to the boundary of* Ω.

Actually, somewhat more is true. If V is a smooth gradient vector field defined on Ω and orthogonal to its boundary, then its magnetic field $\mathrm{BS}(V)=0$ throughout 3-space. Conversely, if V is a smooth vector field defined on Ω whose magnetic field $\mathrm{BS}(V)=0$ in Ω, then V is a gradient field orthogonal to the boundary of Ω, and hence $\mathrm{BS}(V)=0$ throughout 3-space.

Theorem C: *The image of the Biot–Savart operator is a proper subspace of the image of curl, whose orthogonal projection into the subspace of ''fluxless knots'' is one-to-one.*

Vector fields on the domain Ω which are divergence-free and tangent to its boundary are called *fluid knots*; we explain this terminology in Sec. IV. *Fluxless knots* are fluid knots with zero flux through every cross-sectional surface $(\Sigma,\partial\Sigma)\subset(\Omega,\partial\Omega)$. The above theorems lead to several interesting examples of ''impossible'' magnetic fields. Nevertheless, Theorem *C* falls short of giving a precise characterization of the image of the Biot–Savart operator, and hence of those fields in a domain Ω which are magnetic fields of current distributions within Ω.

Theorem D: *The Biot–Savart operator is a bounded operator, and hence extends to a bounded operator on the* L^2 *completion of its domain, where it is both compact and self-adjoint.*

The eigenfields of this operator which correspond to its extreme eigenvalues turn out to be the vector fields in Ω with minimum energy for given helicity. If we start with a vector field V which is divergence-free and tangent to the boundary of its domain Ω, that is, a fluid knot, then its magnetic field $\mathrm{BS}(V)$, though divergence-free, will in general not be tangent to the boundary of Ω. In such a case, we simply modify the Biot–Savart operator BS by following it by orthogonal projection back to the subspace of fluid knots. The eigenfields of this modified Biot–Savart operator which correspond to its extreme eigenvalues are then the fluid knots in Ω with minimum energy for given helicity. When the domain Ω is simply connected, these energy-minimizers model the stable plasma fields in Ω.

II. PRELIMINARIES

A. Writhing, helicity, and the Biot–Savart operator

The *writhing number* $\mathrm{Wr}(K)$ of a smooth curve K in 3-space, defined by the formula

$$\mathrm{Wr}(K)=(1/4\pi)\int_{K\times K}(dx/ds\times dy/dt)\cdot(x-y)/|x-y|^3\ \mathrm{ds}\ \mathrm{dt}, \tag{2.1}$$

was introduced by Călugăreanu[1–3] in 1959–1961 and named by Fuller[4] in 1971, and is the standard measure of the extent to which the curve wraps and coils around itself.

The *helicity* $H(V)$ of a smooth vector field V on the domain Ω in 3-space, defined by the formula

$$H(V)=(1/4\pi)\int_{\Omega\times\Omega}V(x)\times V(y)\cdot(x-y)/|x-y|^3\ \mathrm{d}(\mathrm{vol}_x)\ \mathrm{d}(\mathrm{vol}_y), \tag{2.2}$$

was introduced by Woltjer[5] in 1958 and named by Moffatt[6] in 1969, and is the standard measure of the extent to which the field lines wrap and coil around one another.

Clearly, helicity for vector fields is the analogue of writhing number for knots.

The helicity of V is closely related to its image under the Biot–Savart operator,

$$\begin{aligned} H(V) &= (1/4\pi)\int_{\Omega\times\Omega} V(x) \times V(y)\cdot(x-y)/|x-y|^3 \ \mathrm{d}(\mathrm{vol}_x)\ \mathrm{d}(\mathrm{vol}_y) \\ &= \int_\Omega V(y)\cdot\left[(1/4\pi)\int_\Omega V(x) \times (y-x)/|y-x|^3 \ \mathrm{d}(\mathrm{vol}_x)\right]\mathrm{d}(\mathrm{vol}_y) \\ &= \int_\Omega V(y)\cdot \mathrm{BS}(V)(y)\ \mathrm{d}(\mathrm{vol}_y) \\ &= \int_\Omega V\cdot \mathrm{BS}(V)\ \mathrm{d}(\mathrm{vol}), \end{aligned}$$

so the helicity of V is just the L^2 inner product of V and $\mathrm{BS}(V)$,

$$H(V) = \langle V, \mathrm{BS}(V)\rangle. \tag{2.3}$$

It is because of this formula that the Biot–Savart operator,

$$\mathrm{BS}:\mathrm{VF}(\Omega)\to\mathrm{VF}(\Omega), \tag{2.4}$$

plays such a prominent role in the study of writhing of knots and helicity of vector fields.

B. Applications: A quick guide to the literature

For a glance at the prehistory of the writhing number, see Gauss's half-page note[7] (1833) on an integral formula for the linking number of two disjoint closed curves in 3-space. Rewrite his expression in modern notation and let the two curves coincide and you will have the formula for the writhing number.

The writhing number has proved its importance for molecular biologists in the study of knotted duplex DNA and of the enzymes which affect it; see White,[8] Fuller,[9] Bauer, Crick, and White,[10] Wang,[11] Sumners,[12–14] and Cantarella, Kusner, and Sullivan.[15]

For an overview of the connection between knot theory and electrodynamics, see Lomonaco.[16]

Woltjer's formula for the helicity of a vector field arose from his interest in force-free magnetic fields. These are magnetic fields which are everywhere parallel to the current flows which give rise to them, so that the Lorentz force on the flowing charged particles is zero. Because the gross magnetic field in the Crab Nebula appeared to be steady over a number of years, Woltjer believed it to be force-free, and studied[17] it in great detail. Two early papers on force-free magnetic fields are Lundquist[18] and Chandrasekhar–Kendall.[19] Two more recent papers are Laurence and Avellaneda[20] and Tsuji.[21] Marsh's book[22] has an extensive and up-to-date bibliography on this subject.

For a study of the connection between writhing and helicity, see Berger and Field[23] and Moffatt and Ricca.[24,25]

For the connection between helicity and the ordinary and asymptotic Hopf invariants, see Whitehead[26] and Arnold.[27]

For an introduction to the spectral theory of the Biot–Savart operator and its use in determining upper bounds for writhing and helicity, see Ref. 28. For explicit computation of extreme eigenfields, see Refs. 29 and 30. For an analysis of isoperimetric problems connected with the Biot–Savart operator, see Ref. 31. For application to the qualitative study of stable plasma flows, see Cantarella.[32] For an overview of our work, see our survey paper.[33]

For further information on related spectral problems for the curl operator, see Yoshida and Giga.[34]

For the connection between this spectral theory and plasma physics, see Yoshida.[35]

For a study of magnetic field generation in electrically conducting fluids, see the book by Moffatt.[36]

For connections with dynamo theory, see the survey article by Childress.[37]

For many papers on the connections with the dynamics of fluids and plasmas, see the books by Moffatt and Tsinober[38] and by Moffatt, Zaslavsky, Comte, and Tabor.[39]

For the connections between force-free fields, contact topology and fluid dynamics, see Etnyre and Ghrist.[40]

C. The Hodge decomposition theorem

In this section we present the Hodge Decomposition Theorem for vector fields on bounded domains in R^3, which we will use throughout the paper. Although we state it below for the space $\mathrm{VF}(\Omega)$ of smooth vector fields on Ω with the usual L^2 inner product, it holds just as well for the L^2 completions of $\mathrm{VF}(\Omega)$ and of the various subspaces described below.

The papers of Weyl[41] and Friedrichs,[42] the notes of Blank, Friedrichs, and Grad,[43] and the book of Schwarz[44] are all good references; an exposition of this theorem in the form given below appears in Ref. 45.

Hodge Decomposition Theorem: *We have a direct sum decomposition of* $VF(\Omega)$ *into five mutually orthogonal subspaces*,

$$\mathrm{VF}(\Omega) = \mathrm{FK} \oplus \mathrm{HK} \oplus \mathrm{CG} \oplus \mathrm{HG} \oplus \mathrm{GG},$$

with

$$\begin{aligned} \ker\ \mathrm{curl} &= \mathrm{HK} \oplus \mathrm{CG} \oplus \mathrm{HG} \oplus \mathrm{GG}, \\ \mathrm{image}\ \mathrm{grad} &= \mathrm{CG} \oplus \mathrm{HG} \oplus \mathrm{GG}, \\ \mathrm{image}\ \mathrm{curl} &= \mathrm{FK} \oplus \mathrm{HK} \oplus \mathrm{CG}, \\ \ker\ \mathrm{div} &= \mathrm{FK} \oplus \mathrm{HK} \oplus \mathrm{CG} \oplus \mathrm{HG}, \end{aligned}$$

where

$$\mathrm{FK} = \mathrm{Fluxless\ Knots} = \{\nabla \cdot V = 0,\ V \cdot n = 0,\ \text{all interior fluxes} = 0\},$$

$$\mathrm{HK} = \mathrm{Harmonic\ Knots} = \{\nabla \cdot V = 0,\ \nabla \times V = 0,\ V \cdot n = 0\},$$

$$\mathrm{CG} = \mathrm{Curly\ Gradients} = \{V = \nabla\varphi,\ \nabla \cdot V = 0,\ \text{all boundary fluxes} = 0\},$$

$$\mathrm{HG} = \mathrm{Harmonic\ Gradients} = \{V = \nabla\varphi,\ \nabla \cdot V = 0,\ \varphi \ \text{locally constant on } \partial\Omega\},$$

$$\mathrm{GG} = \mathrm{Grounded\ Gradients} = \{V = \nabla\varphi,\ \varphi|_{\partial\Omega} = 0\},$$

and furthermore,

$$\mathrm{HK} \cong H_1(\Omega; R) \cong H_2(\Omega, \partial\Omega; R) \cong R^{\text{genus of } \partial\Omega},$$

$$\mathrm{HG} \cong H_2(\Omega; R) \cong H_1(\Omega, \partial\Omega; R) \cong R^{(\#\text{ components of } \partial\Omega) - (\#\text{ components of } \Omega)}.$$

We need to explain the meanings of the conditions which appear in the statement of this theorem.

The outward pointing unit vector field orthogonal to $\partial\Omega$ is denoted by n, so the condition $V \cdot n = 0$ indicates that the vector field V is tangent to the boundary of Ω.

Let Σ stand generically for any smooth surface in Ω with $\partial\Sigma\subset\partial\Omega$. Earlier, when commenting on the statement of Theorem C, we indicated this by writing $(\Sigma,\partial\Sigma)\subset(\Omega,\partial\Omega)$. Now, orient Σ by picking one of its two unit normal vector fields n. Then, for any vector field V on Ω, we can define the *flux* of V through Σ to be the value of the integral $\Phi=\int_\Sigma V\cdot n \ \ \mathrm{d(area)}$.

Assume that V is divergence-free and tangent to $\partial\Omega$. Then the value of this flux depends only on the homology class of Σ in the relative homology group $H_2(\Omega,\partial\Omega;Z)$. For example, if Ω is an n-holed solid torus, then there are disjoint oriented cross-sectional disks $\Sigma_1,\ldots,\Sigma_n$, positioned so that cutting Ω along these disks will produce a simply-connected region. The fluxes $\Phi_1,\ldots,\Phi_n$ of V through these disks determine the flux of V through any other cross-sectional surface.

If the flux of V through every smooth surface Σ in Ω with $\partial\Sigma\subset\partial\Omega$ vanishes, we say ''*all interior fluxes*$=0$.'' Then,

$$\mathrm{FK}=\{V\epsilon\ \ \mathrm{VF}(\Omega):\nabla\cdot V=0,\ V\cdot n=0,\ \ \text{all interior fluxes}=0\} \tag{2.5}$$

will be the subspace of *fluxless knots*, already mentioned when explaining the statement of Theorem C.

The subspace,

$$\mathrm{HK}=\{V\epsilon\ \ \mathrm{VF}(\Omega):\nabla\cdot V=0,\ \nabla\times V=0,\ V\cdot n=0\} \tag{2.6}$$

of *harmonic knots* is isomorphic to the absolute homology group $H_1(\Omega;R)$ and also, via Poincaré duality, to the relative homology group $H_2(\Omega,\partial\Omega;R)$, and is thus a finite-dimensional vector space, with dimension equal to the genus of $\partial\Omega$.

The orthogonal direct sum of these two subspaces,

$$\mathrm{K}(\Omega)=\mathrm{FK}\oplus\mathrm{HK} \tag{2.7}$$

is the subspace of $\mathrm{VF}(\Omega)$ consisting of all divergence-free vector fields defined on Ω and tangent to its boundary. These are the vector fields that represent current flows in the standard versions of the laws of Magnetostatics.

We called these vector fields *fluid knots* in the Introduction, and pause to explain this terminology. Given a knot in 3-space, we can choose a thin tubular neighborhood of the knot to be our domain Ω, and then choose a divergence-free vector field V in Ω, for example orthogonal to the cross-sectional disks and hence tangent to the boundary. In this way, questions about the geometry of the knot can sometimes profitably be reformulated as questions about the vector field V, our ''fluid knot.'' We did exactly this in our paper[28] when deriving an upper bound for the writhing number of a knot of given length and thickness.

If V is a vector field defined on Ω, we will say that *all boundary fluxes of V are zero* if the flux of V through each component of $\partial\Omega$ is zero. Then,

$$\mathrm{CG}=\{V\epsilon\,\mathrm{VF}(\Omega):V=\nabla\varphi,\ \ \nabla\cdot V=0,\ \ \text{all boundary fluxes}=0\} \tag{2.8}$$

will be called the subspace of *curly gradients* because these are the only gradients which lie in the image of curl.

Next we define the subspace of *harmonic gradients*,

$$\mathrm{HG}=\{V\epsilon\,\mathrm{VF}(\Omega):V=\nabla\varphi,\ \ \nabla\cdot V=0,\ \varphi\ \text{locally constant on}\ \partial\Omega\}, \tag{2.9}$$

meaning that φ is constant on each component of $\partial\Omega$. This subspace is isomorphic to the absolute homology group $H_2(\Omega;R)$ and also, via Poincaré duality, to the relative homology group $H_1(\Omega,\partial\Omega;R)$, and is hence a finite-dimensional vector space, with dimension equal to the number of components of $\partial\Omega$ minus the number of components of Ω.

The definition of the subspace of *grounded gradients*,

$$\mathrm{GG}=\{V\epsilon\,\mathrm{VF}(\Omega):V=\nabla\varphi,\ \ \varphi|_{\partial\Omega}=0\}, \tag{2.10}$$

is self-explanatory.

A vector field V belongs to the subspace $\mathrm{HG} \oplus \mathrm{GG}$ of $\mathrm{VF}(\Omega)$ if and only if it is the gradient of a smooth function φ on Ω which is constant on each component of $\partial\Omega$, or equivalently, is a gradient vector field which is orthogonal to $\partial\Omega$. Theorem B asserts that these vector fields form the kernel of the Biot–Savart operator.

The five orthogonal direct summands of $\mathrm{VF}(\Omega)$ can be characterized as follows:

$$\mathrm{FK} = (\ker\ \mathrm{curl})^{\perp},$$

$$\mathrm{HK} = (\ker\ \mathrm{curl}) \cap (\mathrm{image}\ \mathrm{grad})^{\perp},$$

$$\mathrm{CG} = (\mathrm{image}\ \mathrm{grad}) \cap (\mathrm{image}\ \mathrm{curl}),$$

$$\mathrm{HG} = (\ker\ \mathrm{div}) \cap (\mathrm{image}\ \mathrm{curl})^{\perp},$$

$$\mathrm{GG} = (\ker\ \mathrm{div})^{\perp}.$$

These characterizations bear witness to the geometric and analytic significance of the summands.

We end this section with examples of vector fields from each of the five summands.

1. FK=fluxless knots

Let Ω be a round ball of radius 1, centered at the origin in 3-space. Consider the vector field

$$V = -y\hat{\imath} + x\hat{\jmath}.$$

This is the velocity field for rotation of 3-space about the z-axis at constant angular speed. It is divergence-free and tangent to the boundary of the ball Ω, and hence belongs to the subspace FK of fluxless knots, because there are no harmonic knots on a ball.

2. HK=harmonic knots

Let Ω be a solid torus of revolution about the z-axis. Using cylindrical coordinates (r,φ,z), consider the vector field

$$V = (1/r)\,\hat{\varphi},$$

which is the magnetic field due to a steady current running up the z-axis. It is divergence-free and curl-free and tangent to the boundary of the solid torus Ω, and hence belongs to the subspace HK of harmonic knots.

3. CG=curly gradients

Let Ω be a round ball of radius 1, centered at the origin. Consider the harmonic function z, and the gradient field

$$V = \nabla z = \hat{k}.$$

This vector field is divergence-free and has zero flux through the one and only component of $\partial\Omega$, hence it belongs to the subspace CG of curly gradients.

4. HG=harmonic gradients

Let Ω be the region between two concentric round spheres, say of radius 1 and 2, centered at the origin. Using spherical coordinates (r,θ,φ), consider the harmonic function $1/r$, and its gradient vector field

$$V = \nabla(1/r) = (-1/r^2)\hat{r},$$

just the inverse square central field. Since the harmonic function $1/r$ is constant on each component of $\partial\Omega$, the vector field V belongs to the subspace HG of harmonic gradients. We may think of V as the electric field between two concentric spheres held at different potentials.

5. GG=grounded gradients

Let Ω be a round ball of radius 1, centered at the origin. Consider the function given by $r^2-1=x^2+y^2+z^2-1$, and the vector field

$$V=\nabla(r^2-1)=2x\hat{i}+2y\hat{j}+2z\hat{k}.$$

Since the function r^2-1 has constant value zero on the boundary of Ω, the vector field V belongs to the subspace GG of grounded gradients. We may view V as an electric field with interior charges inside a conducting boundary.

III. STANDARD INFORMATION ABOUT THE BIOT–SAVART OPERATOR

A. The basic facts

Given a smooth vector field V on Ω, the *vector potential* $\mathrm{A}(V)$ for $\mathrm{BS}(V)$ is defined by the formula,

$$\mathrm{A}(V)(y)=(1/4\pi)\int_\Omega V(x)/|y-x|\ \ \mathrm{d}(\mathrm{vol}_x). \tag{3.1}$$

Here is the classically known information about the Biot–Savart operator and its vector potential. Note that some of the assertions below hold for any vector field $V\epsilon\mathrm{VF}(\Omega)$, while others need the more restrictive assumption that V is divergence-free and tangent to the boundary of Ω, in other words, that V lies in the subspace $\mathrm{K}(\Omega)$ of fluid knots.

Standard Information: *Let Ω be a compact domain in 3-space with smooth boundary $\partial\Omega$. Let V be a smooth vector field defined on Ω. Then*

(1) $\mathrm{BS}(V)$ *and* $\mathrm{A}(V)$ *are well-defined on all of 3-space, that is, the improper integrals defining them converge everywhere;*
(2) $\mathrm{BS}(V)$ *and* $\mathrm{A}(V)$ *are of class C^∞ on Ω, and on the closure Ω' of $R^3-\Omega$.* $\mathrm{BS}(V)$ *is continuous on R^3, but its derivatives typically suffer jump discontinuities as one crosses $\partial\Omega$.* $\mathrm{A}(V)$ *is of class C^1 on R^3, but its second derivatives typically suffer jump discontinuities as one crosses $\partial\Omega$;*
(3) $\Delta\mathrm{A}(V)=-V$ *in Ω and* $\Delta\mathrm{A}(V)=0$ *in Ω', where Δ is the vector Laplacian;*
(4) $\nabla\times\mathrm{A}(V)=\mathrm{BS}(V)$ *on R^3;*
(5) If $V\epsilon\mathrm{K}(\Omega)$, *then* $\mathrm{A}(V)$ *is divergence-free on R^3;*
(6) $\nabla\cdot\mathrm{BS}(V)=0$ *in Ω and in Ω';*
(7) If $V\epsilon\mathrm{K}(\Omega)$, *then* $\nabla\times\mathrm{BS}(V)=V$ *in Ω and* $\nabla\times\mathrm{BS}(V)=0$ *in Ω';*
(8) If $V\epsilon\mathrm{K}(\Omega)$, *then* $\int_C\mathrm{BS}(V)\cdot ds=0$ *for all closed curves C on $\partial\Omega$ which bound in $R^3-\Omega$;*
(9) In general, $\mathrm{A}(V)$ *decays at ∞ like $1/r$ and* $\mathrm{BS}(V)$ *decays at ∞ like $1/r^2$; however, if* $V\epsilon\mathrm{K}(\Omega)$, *then* $\mathrm{A}(V)$ *decays at ∞ like $1/r^2$ and* $\mathrm{BS}(V)$ *decays at ∞ like $1/r^3$.*

Proofs of most of these basic facts can be found throughout the physics literature (see, for example, Griffiths[46]), with the exception of item (9), which we prove in the Appendix. Item (7) contains the first half of Theorem A; we will prove that immediately, since it affects the rest of the paper.

B. Proof of (7)

The argument to follow begins as in Griffiths,[46] pp. 215–217, but is then modified to suit our purpose.

To prove (7), we assume that V is a fluid knot, and must show that

$$\nabla_y \times \mathrm{BS}(V)(y) = V(y), \quad \text{when } y \in \Omega,$$
$$= 0, \qquad \text{when } y \in \Omega'.$$

From now on, we will use the shorthand notation $\{V(y) \text{ in } \Omega/0 \text{ in } \Omega'\}$, or simply $\{V(y)/0\}$, to express these two outcomes.

The above assertion will follow immediately from the next proposition, which will then serve as a springboard to the rest of the paper.

Proposition 1:

$$\nabla_y \times \mathrm{BS}(V)(y) = \{V(y) \text{ in } \Omega/0 \text{ in } \Omega'\} + (1/4\pi)\nabla_y \int_\Omega (\nabla_x \cdot V(x))/|y-x| \ \mathrm{d}(\mathrm{vol}_x)$$
$$-(1/4\pi)\nabla_y \int_{\partial\Omega} V(x)\cdot n/|y-x| \ \mathrm{d}(\mathrm{area}_x).$$

If V is divergence-free, then the second term on the right-hand side vanishes; if V is tangent to the boundary of Ω, then the third term on the right-hand side vanishes. If both hold, that is, if V is a fluid knot, then we get item (7).

We can view the statement of Proposition 1 as Maxwell's equation,

$$\nabla \times B = J + \partial E/\partial t, \tag{3.2}$$

as follows.

Let V represent a current distribution throughout the domain Ω. At time $t=0$, let the volume charge density ρ throughout Ω and the surface charge density σ along $\partial\Omega$ both be zero. Then set

$$\rho = -(\nabla \cdot V)t \ \text{ throughout } \ \Omega, \tag{3.3}$$

and

$$\sigma = (V\cdot n)t \ \text{ along } \ \partial\Omega. \tag{3.4}$$

Equation (3.3) for the volume charge density ρ is forced on us by the continuity equation,

$$\nabla \cdot V = -\partial\rho/\partial t. \tag{3.5}$$

Likewise, Eq. (3.4) for the surface charge density σ is forced on us by a version of the continuity equation appropriate to the boundary of our domain. The current V is simply carrying charge from locations within Ω and on its boundary to other such locations. Thus the surface charge density given by (3.4) has a time rate of change equal to the flux density of the current V through the boundary $\partial\Omega$.

Now the volume charge throughout Ω gives rise to a time varying electric field

$$E_\rho(y,t) = \left[(1/4\pi)\nabla_y \int_\Omega (\nabla_x \cdot V(x))/|y-x| \ \mathrm{d}(\mathrm{vol}_x) \right] t, \tag{3.6}$$

and the surface charge along $\partial\Omega$ gives rise to a time varying electric field,

$$E_\sigma(y,t) = \left[-(1/4\pi)\nabla_y \int_{\partial\Omega} V(x)\cdot n(x)/|y-x| \ \mathrm{d}(\mathrm{area}_x) \right] t, \tag{3.7}$$

both fields extending throughout 3-space.

The total electric field

$$E(y,t) = E_\rho(y,t) + E_\sigma(y,t) \tag{3.8}$$

has a time rate of change

$$\partial E/\partial t = \partial E_\rho/\partial t + \partial E_\sigma/\partial t = E'_\rho + E'_\sigma. \tag{3.9}$$

With this notation, the equation of Proposition 1 condenses to

$$\nabla \times \mathrm{BS}(V) = \{V/0\} + E'_\rho + E'_\sigma, \tag{3.10}$$

which is just Maxwell's Eq. (3.2). Proving Proposition 1 confirms these interpretations.

Proof of Proposition 1: We must evaluate

$$\begin{aligned}\nabla_y \times \mathrm{BS}(V)(y) &= \nabla_y \times (1/4\pi) \int_\Omega V(x) \times (y-x)/|y-x|^3 \ \ \mathrm{d}(\mathrm{vol}_x) \\ &= (1/4\pi) \int_\Omega \nabla_y \times \{V(x) \times (y-x)/|(y-x)|^3\} \ \ \mathrm{d}(\mathrm{vol}_x).\end{aligned} \tag{3.11}$$

We will need the following formula from vector calculus:

$$\nabla \times (A \times B) = (B \cdot \nabla)A - (A \cdot \nabla)B + A(\nabla \cdot B) - B(\nabla \cdot A). \tag{3.12}$$

Applying this formula to the integrand, we get

$$\begin{aligned}&\nabla_y \times \{V(x) \times (y-x)/|y-x|^3\} \\ &\quad = ((y-x)/|y-x|^3 \cdot \nabla_y) V(x) - (V(x) \cdot \nabla_y)((y-x)/|y-x|^3) \\ &\qquad + V(x) \nabla_y \cdot ((y-x)/|y-x|^3) - ((y-x)/|y-x|^3)(\nabla_y \cdot V(x)).\end{aligned} \tag{3.13}$$

The first and last terms on the right-hand side are zero, because they involve differentiation with respect to y of $V(x)$, which depends only on x. Thus,

$$\nabla_y \times \{V(x) \times (y-x)/|y-x|^3\} = V(x) \nabla_y \cdot ((y-x)/|y-x|^3) - (V(x) \cdot \nabla_y)((y-x)/|y-x|^3). \tag{3.14}$$

In the first term on the right-hand side, the second factor

$$\nabla_y \cdot ((y-x)/|y-x|^3) \tag{3.15}$$

is the divergence of the well known ''inverse square central field.'' Using spherical coordinates centered at x, this can be written as

$$\nabla \cdot \hat{r}/r^2 = (1/r^2)(\partial/\partial r)(r^2(1/r^2)) = 0, \tag{3.16}$$

away from the origin.

But the integral of $\nabla \cdot \hat{r}/r^2$ over any ball centered at the origin, when converted to a surface integral via the divergence theorem, is clearly 4π,

$$\int_{\mathrm{ball}} \nabla \cdot \hat{r}/r^2 \ \ \mathrm{d}(\mathrm{vol}) = \int_{\mathrm{sphere}} (\hat{r}/r^2) \cdot n \ \ \mathrm{d}(\mathrm{area}) = 4\pi. \tag{3.17}$$

Thus,

$$\nabla \cdot \hat{r}/r^2 = 4\pi \delta^3(r), \tag{3.18}$$

where $\delta^3(r)$ is the three-dimensional delta function; equivalently,

$$\nabla_y \cdot ((y-x)/|y-x|^3) = 4\pi\delta^3(y-x). \tag{3.19}$$

Hence,

$$(1/4\pi)\int_\Omega V(x)\nabla_y \cdot ((y-x)/|y-x|^3)\ \ \mathrm{d}(\mathrm{vol}_x) = (1/4\pi)\int_\Omega V(x) 4\pi\delta^3(y-x)\ \ \mathrm{d}(\mathrm{vol}_x)$$
$$= V(y)\ \ \text{in}\ \ \Omega\,/\,0\ \ \text{in}\ \ \Omega'. \tag{3.20}$$

Thus far, we have proved that

$$\nabla_y \times \mathrm{BS}(V)(y) = \{V(y)\,/\,0\} - (1/4\pi)\int_\Omega (V(x)\cdot\nabla_y)((y-x)/|y-x|^3)\ \ \mathrm{d}(\mathrm{vol}_x). \tag{3.21}$$

Now we focus on the second term on the right-hand side and must show that

$$-(1/4\pi)\int_\Omega (V(x)\cdot\nabla_y)((y-x)/|y-x|^3)\ \ \mathrm{d}(\mathrm{vol}_x)$$
$$= (1/4\pi)\nabla_y \int_\Omega (\nabla_x \cdot V(x))/|y-x|\ \ \mathrm{d}(\mathrm{vol}_x)$$
$$-(1/4\pi)\nabla_y \int_{\partial\Omega} V(x)\cdot n/|y-x|\ \ \mathrm{d}(\mathrm{area}_x). \tag{3.22}$$

We begin by writing each of the three terms in (3.22) in the form

$$\pm(1/4\pi)\nabla_y \int_\Omega (\text{something})\ \ \mathrm{d}(\mathrm{vol}_x). \tag{3.23}$$

Starting with the left-hand side of (3.22), we claim that its integrand can be rewritten as

$$(V(x)\cdot\nabla_y)((y-x)/|y-x|^3) = \nabla_y(V(x)\cdot(y-x)/|y-x|^3). \tag{3.24}$$

To see this, we need the formula from vector calculus,

$$\nabla(V\cdot W) = V\times(\nabla\times W) + W\times(\nabla\times V) + (V\cdot\nabla)W + (W\cdot\nabla)V. \tag{3.25}$$

We use this with $\nabla = \nabla_y$, $V = V(x)$, and $W = (y-x)/|y-x|^3$. Three of the four terms on the right-hand side of (3.25) will then be zero; the first is zero because $\nabla_y \times W = 0$; the second is zero because $\nabla_y \times V(x) = 0$; the fourth is zero because $(W\cdot\nabla_y)V(x) = 0$. Thus $\nabla_y(V\cdot W) = (V\cdot\nabla_y)W$, which is exactly our claim.

The first term on the right-hand side of (3.22) is already in the desired form.

The second term on the right-hand side of (3.22) can be rewritten as

$$\int_{\partial\Omega} V(x)\cdot n/|y-x|\ \ \mathrm{d}(\mathrm{area}_x) = \int_\Omega \nabla_x \cdot (V(x)/|y-x|)\ \ \mathrm{d}(\mathrm{vol}_x), \tag{3.26}$$

thanks to the divergence theorem.

Now that all the terms in (3.22) have been rewritten in the desired form, we claim that the integrands on both sides are equal, namely, that

$$-V(x)\cdot(y-x)/|y-x|^3 = (\nabla_x \cdot V(x))/|y-x| - \nabla_x \cdot (V(x)/|y-x|). \tag{3.27}$$

This is an immediate consequence of the formula

$$\nabla\cdot(fA)=(\nabla f)\cdot A+f(\nabla\cdot A), \tag{3.28}$$

and the proof of Proposition 1 is complete.

C. Examples

We give three examples to illustrate Proposition 1, each in ''bare bones'' format, and invite the interested reader to carry out the supporting calculations.

Example 1: In this example, we start with the vector field

$$V=\partial/\partial z=\hat{z} \tag{3.29}$$

on the ball Ω of radius a centered at the origin. Note that $V\epsilon\ \mathrm{CG}(\Omega)$.

Switching to spherical coordinates (r,θ,φ), a straightforward computation yields

$$\begin{aligned}\mathrm{BS}(V)&=(a^3/3)(\sin\theta)/r^2\hat{\varphi}\quad \text{for}\quad r\geqslant a\\ &=(1/3)r\sin\theta\hat{\varphi}\quad \text{for}\quad r\leqslant a.\end{aligned} \tag{3.30}$$

Note that inside the ball, $\mathrm{BS}(V)$ coincides with the velocity field of a body rotating with constant angular velocity about the z-axis.

Next we compute $\nabla\times\mathrm{BS}(V)$,

$$\nabla\times\mathrm{BS}(V)=(a^3/3)\{(2\cos\theta/r^3)\hat{r}+(\sin\theta/r^3)\hat{\theta}\}\quad \text{for}\quad r\geqslant a, \tag{3.31}$$

which is a standard dipole field, while

$$\nabla\times\mathrm{BS}(V)=(2/3)\{(\cos\theta)\hat{r}-(\sin\theta)\hat{\theta}\}=(2/3)V\quad \text{for}\quad r\leqslant a. \tag{3.32}$$

We invite the reader to check Proposition 1, equivalently the Maxwell equation (3.10), inside the domain Ω by directly computing that $E'_\sigma=(-1/3)V$ there.

Example 2 (see Example 4 of Sec. II C): In this example, we start with the function $f=1/r$ on the domain Ω between the spheres of radii 1 and 2 centered at the origin, and then consider the vector field

$$V=\nabla f=-\hat{r}/r^2 \tag{3.33}$$

on this domain. Note that the function f is harmonic, and is constant on each component of $\partial\Omega$. Therefore V lies in the subspace $\mathrm{HG}(\Omega)$ of harmonic gradients inside $\mathrm{VF}(\Omega)$. Borrowing once again from the future proof of Theorem B, we note that V lies in the kernel of the Biot–Savart operator.

We invite the reader to confirm Maxwell's equation (3.10) by checking that

$$\begin{aligned}E_\sigma&=\hat{r}/r^2\quad \text{inside}\quad \Omega,\\ &=0\qquad \text{outside}\quad \Omega.\end{aligned} \tag{3.34}$$

Example 3 (see Example 5 of Sec. II C): In this example, we start with the function $f(x,y,z)=x^2+y^2+z^2-1=r^2-1$ on the unit ball Ω centered at the origin, and then consider the vector field

$$V=\nabla f=2r\hat{r} \tag{3.35}$$

on this ball. Note that V lies in the subspace $\mathrm{GG}(\Omega)$ of grounded gradients inside $\mathrm{VF}(\Omega)$, and is therefore (borrowing from the future proof of Theorem B) in the kernel of the Biot–Savart operator BS.

With this in mind, we invite the reader to confirm Maxwell's equation (3.10) in this case by computing that

$$E_\rho = -2r\hat{r} \quad \text{inside } \Omega$$
$$= -2\hat{r}/r^2 \quad \text{outside } \Omega, \tag{3.36}$$

and that

$$E_\sigma = 0 \quad \text{inside } \Omega$$
$$= 2\hat{r}/r^2 \quad \text{outside } \Omega. \tag{3.37}$$

IV. PROOF OF THEOREM A

Recall the statement:

Theorem A: *The equation* $\nabla \times BS(V) = V$ *holds in* Ω *if and only if* V *is divergence-free and tangent to the boundary of* Ω.

The condition that V be divergence-free and tangent to the boundary of Ω can also be written as $V \epsilon \mathrm{K}(\Omega) = \mathrm{FK} \oplus \mathrm{HK}$, the subspace of fluid knots. For the same effort, we will also get

Addendum to Theorem A: *The equation* $\nabla \times BS(V) = 0$ *holds in the closure* Ω' *of* $R^3 - \Omega$ *if and only if* $V \epsilon FK \oplus HK \oplus HG \oplus GG$.

This condition on V is equivalent to V being orthogonal to the subspace CG of curly gradients in $\mathrm{VF}(\Omega)$. Then we will prove.

Corollary to Theorem A: *The vector potential* $A(V)$ *is divergence-free if and only if* V *is divergence-free and tangent to the boundary of* Ω.

A. Proof of Theorem A

Half of Theorem A has already appeared as item (7) in our list of Standard Information, and was proved in Sec. III B, namely, if $V \epsilon \mathrm{K}(\Omega) = \mathrm{FK} \oplus \mathrm{HK}$, then $\nabla \times \mathrm{BS}(V) = V$ in Ω.

By contrast, if $V \epsilon$ HG$\oplus$GG, then it would be impossible for $\nabla \times \mathrm{BS}(V)$ to equal V in Ω unless $V = 0$, since we know from the Hodge Decomposition Theorem that the image of curl is FK$\oplus$HK$\oplus$CG.

It remains to show that if V is in CG, then $\nabla \times \mathrm{BS}(V)$ can never equal V in Ω unless $V = 0$.

The proof will be based on the Maxwell equation,

$$\nabla_y \times \mathrm{BS}(V)(y) = \{V(y) \text{ in } \Omega \,/\, 0 \text{ in } \Omega'\} - (1/4\pi)\nabla_y \int_{x \epsilon \partial\Omega} V(x) \cdot n(x)/|x-y| \ \mathrm{d}(\mathrm{area}_x). \tag{4.1}$$

Following our discussion in Sec. III B, we can write the second term on the right-hand side of this equation as

$$E'_\sigma(y) = -(1/4\pi)\nabla_y \int_{x \epsilon \partial\Omega} V(x) \cdot n(x)/|x-y| \ \mathrm{d}(\mathrm{area}_x). \tag{4.2}$$

Although E'_σ is the time rate of change of the electrostatic field E_σ, it is also the same as the electrostatic field due to a charge density $\sigma(x) = V(x) \cdot n(x)$ along $\partial\Omega$, and so we can treat it as though it were an electrostatic field.

We write

$$E'_\sigma(y) = -\nabla_y \psi(y), \tag{4.3}$$

where

$$\psi(y) = (1/4\pi) \int_{x \in \partial\Omega} V(x) \cdot n(x) / |x-y| \ \ \mathrm{d}(\mathrm{area}_x). \tag{4.4}$$

Although we have in general been writing our gradient fields with a plus sign, as in the equation $V = \nabla\varphi$, we write electrostatic fields with a minus sign, $E'_\sigma = -\nabla\psi$, to follow standard convention.

While the electrostatic potential function ψ for a surface charge distribution σ is continuous, the electrostatic field E'_σ will in general have a jump discontinuity as we cross the surface. Nevertheless, we have $\nabla \cdot E'_\sigma = 0$ in Ω and $\nabla \cdot E'_\sigma = 0$ in Ω'.

We claim that if V is a nonzero vector field in CG, then E'_σ cannot be identically zero in Ω.

Recall the definition of the subspace CG of curly gradients. A smooth vector field V defined on Ω is in CG if and only if $V = \nabla\varphi$, where φ is a harmonic function on Ω, and where the flux of V through each component of $\partial\Omega$ is zero. That is, for each component $\partial\Omega_i$ of $\partial\Omega$, we have

$$\int_{\partial\Omega_i} V(x) \cdot n(x) \ \ \mathrm{d}(\mathrm{area}_x) = \int_{\partial\Omega_i} \sigma(x) \ \ \mathrm{d}(\mathrm{area}_x) = 0. \tag{4.5}$$

In other words, the total charge on each component of $\partial\Omega$ is zero.

Suppose now that $E'_\sigma = 0$ in Ω. We must show that $V = 0$.

First we will show that $E'_\sigma = 0$ in Ω', the closure of $R^3 - \Omega$.

The hypothesis that $E'_\sigma = 0$ inside Ω tells us that ψ must be constant on each component $\partial\Omega_i$ of $\partial\Omega' = \partial\Omega$.

Now we consider the field $\psi E'_\sigma$ in Ω', and compute its divergence (a standard trick in electrostatics),

$$\nabla \cdot (\psi E'_\sigma) = (\nabla\psi) \cdot E'_\sigma + \psi(\nabla \cdot E'_\sigma) = -E'_\sigma \cdot E'_\sigma = -|E'_\sigma|^2. \tag{4.6}$$

Hence,

$$\int_{\Omega'} |E'_\sigma|^2 \ \ \mathrm{d}(\mathrm{vol}) = -\int_{\Omega'} \nabla \cdot (\psi E'_\sigma) \ \ \mathrm{d}(\mathrm{vol}) = -\int_{\partial\Omega'} \psi E'_\sigma \cdot n' \, \mathrm{d}(\mathrm{area}), \tag{4.7}$$

where n' is the unit outward-pointing normal vector to Ω', so that $n' = -n$.

Using the divergence theorem in Ω' requires a comment, since one of its components is unbounded. That unbounded component should really be approximated by a bounded domain with one boundary component out near infinity. The flux of $\psi E'_\sigma$ through this boundary component goes to zero as it recedes towards infinity, because the area grows like r^2, while the field E'_σ decays like $1/r^2$ and the potential ψ decays like $1/r$.

With that said, we continue,

$$\int_{\Omega'} |E'_\sigma|^2 \ \ \mathrm{d}(\mathrm{vol}) = -\int_{\partial\Omega'} \psi E'_\sigma \cdot n' \, \mathrm{d}(\mathrm{area}) = -\sum_i \ \psi_i \int_{\partial\Omega_i} E'_\sigma \cdot n' \, \mathrm{d}(\mathrm{area}), \tag{4.8}$$

since ψ is constant, say with value ψ_i, on each component $\partial\Omega_i$ of the boundary.

Now, by Gauss' Law,

$$\begin{aligned} \int_{\partial\Omega_i} E'_\sigma \cdot n' \, d(\mathrm{area}) &= \pm \,\text{total charge ``inside'' } \partial\Omega_i \\ &= \pm \sum_{\text{some } j} \int_{\partial\Omega_j} \sigma(x) \ \ \mathrm{d}(\mathrm{area}_x) = 0, \end{aligned} \tag{4.9}$$

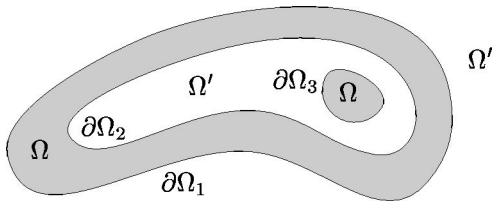

FIG. 1. Components of the domain Ω and of its complement, Ω'.

because the total charge on *each* component $\partial\Omega_j$ of $\partial\Omega$ is zero (see Fig. 1).

Thus, $\int_{\Omega'}|E'_\sigma|^2 d(\mathrm{vol})=0$, and hence $E'_\sigma\equiv 0$ in Ω'.

Now we have $E'_\sigma\equiv 0$ in Ω and also in Ω'. Then Gauss's Law, applied to the typical ''pill box'' neighborhood of a point on $\partial\Omega$, implies that the surface charge distribution σ is identically zero (see Fig. 2).

Since $\sigma(x)=V(x)\cdot n(x)$, this imples that V is tangent to the boundary of Ω, and hence $V\in \mathrm{K}(\Omega)$. But $\mathrm{K}(\Omega)\cap \mathrm{CG}=0$, so $V=0$.

This completes the proof of Theorem A.

B. Proof of Addendum to Theorem A

We know that if V lies in $\mathrm{K}(\Omega)=\mathrm{FK}\oplus\mathrm{HK}$, then $\nabla\times \mathrm{BS}(V)=0$ in Ω', according to item (7) in our list of Standard Information from Sec. III A.

Borrowing from the future, we will see in the proof of Theorem B that if $V\epsilon \mathrm{HG}\oplus\mathrm{GG}$, then $\mathrm{BS}(V)=0$ throughout 3-space, so that surely $\nabla\times \mathrm{BS}(V)=0$ in Ω'.

This gives us half of the Addendum to Theorem A.

It remains to show that if V is in CG, then $\nabla\times \mathrm{BS}(V)$ cannot be zero in Ω' unless $V=0$ in Ω.

The proof of this is based on the Maxwell equation (4.1), as was the proof of Theorem A; it is a copy of the argument given there, with the roles of Ω and Ω' reversed, so we omit further details.

C. Proof of Corollary to Theorem A

If V is divergence-free and tangent to the boundary of Ω, then we already know from item (5) in the list of Standard Information that the vector potential $A(V)$ is divergence-free.

Recall, also from that list, items

(3) $\Delta \mathrm{A}(V)=-V$, and

(4) $\nabla\times \mathrm{A}(V)=\mathrm{BS}(V)$ for all $V\epsilon$ $\mathrm{VF}(\Omega)$.

Now take the second derivative formula,

$$\nabla\times(\nabla\times W)=\nabla(\nabla\cdot W)-\Delta W \tag{4.10}$$

for any vector field W, and rewrite it with $\mathrm{A}(V)$ in place of W,

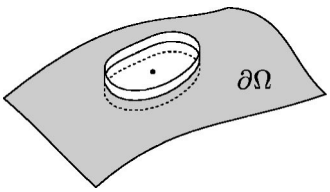

FIG. 2. A typical ''pill box'' neighborhood of a point on $\partial\Omega$.

$$\nabla\times(\nabla\times \mathrm{A}(V))=\nabla(\nabla\cdot \mathrm{A}(V))-\Delta \mathrm{A}(V). \tag{4.11}$$

Using items (3) and (4) above, substitute $\mathrm{BS}(V)$ for $\nabla\times \mathrm{A}(V)$ on the left-hand side, and V for $-\Delta \mathrm{A}(V)$ on the right-hand side, to get

$$\nabla\times \mathrm{BS}(V)=\nabla(\nabla\cdot \mathrm{A}(V))+V. \tag{4.12}$$

If $\mathrm{A}(V)$ is divergence-free, then we get

$$\nabla\times \mathrm{BS}(V)=V \quad \text{inside } \Omega, \tag{4.13}$$

which by Theorem A implies that $V\epsilon\, \mathrm{K}(\Omega)$.

We conclude that $\mathrm{A}(V)$ is divergence-free if and only if $V\epsilon\, \mathrm{K}(\Omega)$, which is exactly the assertion of the Corollary.

V. PROOF OF THEOREM B

A. Proof of Theorem B, easy direction

Recall the statement:

Theorem B: *The kernel of the Biot–Savart operator is precisely the space of gradient vector fields which are orthogonal to the boundary of* Ω.

The easy direction is to assume that V is a gradient vector field which is orthogonal to the boundary of Ω (equivalently, that $V\epsilon\, \mathrm{HG}\oplus\mathrm{GG}$), and then conclude that $\mathrm{BS}(V)=0$. We will do that here, and will actually show that $\mathrm{BS}(V)=0$ throughout all of 3-space, rather than just in Ω.

We begin with the following lemma, which is stated without proof on p. 60 of Griffiths.[46]

Lemma 1: *Let V be a smooth vector field on the domain* Ω*, and let n denote the outward pointing unit normal vector field to* $\partial\Omega$*. Then,*

$$\int_\Omega \nabla\times V\, \mathrm{d}(\mathrm{vol})=-\int_{\partial\Omega} V\times n\, \mathrm{d}(\mathrm{area}).$$

Proof: Start with the Divergence Theorem,

$$\int_\Omega \nabla\cdot V \mathrm{d}(\mathrm{vol})=\int_{\partial\Omega} V\cdot n\ \ \mathrm{d}(\mathrm{area}).$$

Then replace V by $V\times C$, where C is any constant vector,

$$\int_\Omega \nabla\cdot(V\times C)\ \ \mathrm{d}(\mathrm{vol})=\int_{\partial\Omega}(V\times C)\cdot n\ \ \mathrm{d}(\mathrm{area}).$$

Writing $\nabla\cdot(V\times C)=(\nabla\times V)\cdot C$ and moving C outside the integral, the left-hand side becomes

$$C\cdot\int_\Omega \nabla\times V\ \ \mathrm{d}(\mathrm{vol}).$$

Writing $(V\times C)\cdot n=-(V\times n)\cdot C$ and again moving C outside the integral, the right-hand side becomes

$$-C\cdot\int_{\partial\Omega} V\times n\ \ \mathrm{d}(\mathrm{area}).$$

Since the left- and right-hand sides are equal for all C, we must have

$$\int_\Omega \nabla \times V \ \ \mathrm{d}(\mathrm{vol}) = -\int_{\partial\Omega} V \times n \ \ \mathrm{d}(\mathrm{area}),$$

proving the lemma.

Suppose now that $V = \nabla\varphi$ is a gradient vector field on Ω which is orthogonal to the boundary, which means that φ is constant on each component $\partial\Omega_i$ of $\partial\Omega$. We must show that $\mathrm{BS}(V) = 0$.

Begin with the formula for the Biot–Savart operator,

$$\mathrm{BS}(V)(y) = (1/4\pi)\int_\Omega V(x) \times (y-x)/|y-x|^3 \ \ \mathrm{d}(\mathrm{vol}_x). \tag{5.1}$$

Fix y, and let $W = (y-x)/|y-x|^3$. Then,

$$\mathrm{BS}(V) = (1/4\pi)\int_\Omega (\nabla\varphi) \times W \ \ \mathrm{d}(\mathrm{vol}). \tag{5.2}$$

Now consider the vector field φW on Ω and take its curl,

$$\nabla \times (\varphi W) = (\nabla\varphi) \times W + \varphi(\nabla \times W) = (\nabla\varphi) \times W, \tag{5.3}$$

since $\nabla \times W = 0$. Thus

$$\mathrm{BS}(V) = (1/4\pi)\int_\Omega \nabla \times (\varphi W) \ \ \mathrm{d}(\mathrm{vol}). \tag{5.4}$$

We would like to use the preceding lemma to replace the right-hand side of this formula by the expression

$$-(1/4\pi)\int_{\partial\Omega} (\varphi W) \times n \ \ \mathrm{d}(\mathrm{area}). \tag{5.5}$$

But the vector field φW does not quite fit the hypothesis of the lemma, since it has an isolated singularity at the point y (which we can assume is in the interior of Ω). However, this singularity is ''radial;'' if we surround it by a small sphere, the vector field φW will be orthogonal to the sphere, and so the integral $\int (\varphi W) \times n \ \ \mathrm{d}(\mathrm{area})$ over this small sphere will be zero. It follows immediately that the lemma can be applied in this case, in spite of the singularity.

We do so, and continue

$$\begin{aligned} \mathrm{BS}(V) &= -(1/4\pi)\int_{\partial\Omega} (\varphi W) \times n \ \ \mathrm{d}(\mathrm{area}) \\ &= -(1/4\pi)\sum_i \varphi_i \int_{\partial\Omega_i} W \times n \ \ \mathrm{d}(\mathrm{area}), \end{aligned} \tag{5.6}$$

where φ_i is the constant value of φ on $\partial\Omega_i$.

Now we claim that, for each i,

$$\int_{\partial\Omega_i} W \times n \ \ \mathrm{d}(\mathrm{area}) = 0. \tag{5.7}$$

To see this, let Ω_i be the compact domain in 3-space bounded by $\partial\Omega_i$. Then, using the lemma once again,

$$\int_{\partial\Omega_i} W\times n \ \ \mathrm{d(area)} = \pm \int_{\Omega_i} \nabla\times W \ \ \mathrm{d(vol)} \tag{5.8}$$

with the + or − sign chosen according as n points into or out of Ω_i. In any case, $\nabla\times W=0$, so the integral vanishes.

Thus $\mathrm{BS}(V)=0$ throughout 3-space.

B. Proof of Theorem B, harder direction

The heart of the argument is the following energy estimate.

Proposition 2: *Let Ω be a compact domain with smooth boundary in 3-space, and V a smooth divergence-free vector field defined in Ω. Let E'_σ be the electrostatic field due to the charge distribution $\sigma(x)=V(x)\cdot n(x)$ along $\partial\Omega$. Then,*

$$\int_{3\text{-space}} |E'_\sigma|^2 \ \ \mathrm{d(vol)} \leqslant \int_\Omega |V|^2 \ \ \mathrm{d(vol)}.$$

That is, the energy of the electrostatic field E'_σ throughout all of 3-space is bounded from above by the energy of the original field V in Ω.

When V is not required to be divergence-free, the energy of the field E'_σ can be made arbitrarily large, while keeping the energy of V itself as small as desired: make $V(x)\cdot n(x)$ large along $\partial\Omega$, and then quickly taper V off to zero throughout most of Ω.

Proof of Proposition 2: Given a divergence-free vector field V, we can subtract from V its orthogonal projection into the space $\mathrm{K}(\Omega)=\mathrm{FK}\oplus\mathrm{HK}$ of fluid knots. This will leave the corresponding electrostatic field E'_σ unchanged, while at worst decreasing the energy in V.

So in proving the proposition, there is no loss in generality in assuming that V is already orthogonal to this subspace, and hence a gradient vector field...as well as being divergence-free. Thus we can write

$$V=\nabla\varphi \ \ \text{with} \ \ \Delta\varphi=0. \tag{5.9}$$

Likewise,

$$E'_\sigma(y)=-\nabla_y\psi(y), \tag{5.10}$$

where

$$\psi(y)=(1/4\pi)\int_{x\in\partial\Omega} V(x)\cdot n(x)/|x-y| \ \ \mathrm{d(area}_x). \tag{5.11}$$

Lemma 2: $$\int_{3\text{-space}} |E'_\sigma|^2 \mathrm{d(vol)} = \int_{\partial\Omega} \psi\partial\varphi/\partial n \,\mathrm{d(area)}.$$

Proof of Lemma 2: This is a standard result in electrostatics; see Griffiths[46] pp. 94–95. For convenience, we give the argument here.

Since the surface charge distribution σ along $\partial\Omega$ is given by

$$\sigma(x)=V(x)\cdot n(x)=(\nabla\varphi(x))\cdot n(x)=(\partial\varphi/\partial n)(x), \tag{5.12}$$

we can rewrite the equation to be proved as

$$\int_{3\text{-space}} |E'_\sigma|^2 \ \ \mathrm{d(vol)} = \int_{\partial\Omega} \psi\sigma \ \ \mathrm{d(area)}. \tag{5.13}$$

This more clearly displays the relation of the integrand on the right-hand side to the field E'_σ; the function σ is the surface charge distribution along $\partial\Omega$ which gives rise to the field E'_σ, while the function ψ is the electrostatic potential for E'_σ, that is, $E'_\sigma = -\nabla\psi$.

The proof is a little easier to express if we replace the surface charge distribution σ by a volume charge distribution ρ in a small neighborhood $N(\partial\Omega)$ of $\partial\Omega$, and let $E'_\rho = -\nabla\psi$ be the resulting electrostatic field, because in this situation we can write $\nabla \cdot E_\rho = \rho$.

With this understanding, we must show that

$$\int_{3\text{-space}} |E'_\rho|^2 \ \mathrm{d(vol)} = \int_{N(\partial\Omega)} \psi\rho \ \mathrm{d(vol)}. \tag{5.14}$$

To prove this, rewrite the integral on the right-hand side as

$$\int_{N(\partial\Omega)} \psi(\nabla \cdot E'_\rho) \ \mathrm{d(vol)}. \tag{5.15}$$

Next,

$$\nabla \cdot (\psi E'_\rho) = (\nabla\psi) \cdot E'_\rho + \psi(\nabla \cdot E'_\rho) = -|E'_\rho|^2 + \psi(\nabla \cdot E'_\rho). \tag{5.16}$$

Hence

$$\begin{aligned} \int_{N(\partial\Omega)} \psi\rho \ \mathrm{d(vol)} &= \int_{N(\partial\Omega)} \psi(\nabla \cdot E'_\rho) \ \mathrm{d(vol)} \\ &= \int_{N(\partial\Omega)} \nabla \cdot (\psi E'_\rho) \ \mathrm{d(vol)} + \int_{N(\partial\Omega)} |E'_\rho|^2 \ \mathrm{d(vol)}. \end{aligned} \tag{5.17}$$

If, in the integral on the left-hand side above, we replace the neighborhood $N(\partial\Omega)$ by any larger domain, call it Ω^*, the value of the integral will not change because $\rho = 0$ outside $N(\partial\Omega)$. And the equation above will still hold if we replace $N(\partial\Omega)$ by Ω^* in each of the three integrals,

$$\int_{\Omega^*} \psi\rho \ \mathrm{d(vol)} = \int_{\Omega^*} \nabla \cdot (\psi E'_\rho) \ \mathrm{d(vol)} + \int_{\Omega^*} |E'_\rho|^2 \ \mathrm{d(vol)}. \tag{5.18}$$

Apply the divergence theorem to the first integral on the right-hand side, so that we now have

$$\int_{\Omega^*} \psi\rho \ \mathrm{d(vol)} = \int_{\partial\Omega^*} (\psi E'_\rho) \cdot n \ \mathrm{d(area)} + \int_{\Omega^*} |E'_\rho|^2 \ \mathrm{d(vol)}. \tag{5.19}$$

Visualize the domain Ω^* growing larger and larger, with its boundary receding towards infinity. Then ψ decays like $1/r$, while E'_ρ decays like $1/r^2$ and the area of $\partial\Omega^*$ grows like r^2. Thus the value of the first integral on the right-hand side decays like $1/r$, and so goes to zero in the limit. Hence

$$\int_{N(\partial\Omega)} \psi\rho \ \mathrm{d(vol)} = \int_{3\text{-space}} |E'_\rho|^2 \ \mathrm{d(vol)}, \tag{5.20}$$

the desired result for volume charge distributions.

If we compress the neighborhood $N(\partial\Omega)$ towards the surface $\partial\Omega$, the above result for volume charge distributions will tend to the corresponding result for surface charge distributions,

$$\int_{\partial\Omega} \psi\sigma \ \mathrm{d(area)} = \int_{3\text{-space}} |E'_\sigma|^2 \ \mathrm{d(vol)}, \tag{5.21}$$

and the lemma is proved.

Completion of the proof of Proposition 2: Now we recall Green's first identity.

Let $A=\psi\nabla\varphi$. Then

$$\nabla\cdot A=\nabla\cdot(\psi\nabla\varphi)=\nabla\psi\cdot\nabla\varphi+\psi\Delta\varphi=\nabla\psi\cdot\nabla\varphi, \tag{5.22}$$

since $\Delta\varphi=0$.

Thus,

$$\int_\Omega -E'_\sigma\cdot V \ \ \mathrm{d(vol)}=\int_\Omega \nabla\psi\cdot\nabla\varphi \ \ \mathrm{d(vol)}=\int_\Omega \nabla\cdot A \ \ \mathrm{d(vol)}=\int_{\partial\Omega} A\cdot n \ \ \mathrm{d(area)}$$
$$=\int_{\partial\Omega}\psi\nabla\varphi\cdot n \ \ \mathrm{d(area)}=\int_{\partial\Omega}\psi\partial\varphi/\partial n \ \ \mathrm{d(area)}=\int_{3\text{-space}}|E'_\sigma|^2 \ \ \mathrm{d(vol)}, \tag{5.23}$$

by the lemma.

Hence,

$$\int_{3\text{-space}}|E'_\sigma|^2 \ \ \mathrm{d(vol)}=\int_\Omega -E'_\sigma\cdot V\mathrm{d(vol)}$$
$$\leqslant\left(\int_\Omega|E'_\sigma|^2 \ \ \mathrm{d(vol)}\right)^{1/2}\left(\int_\Omega|V|^2 \ \ \mathrm{d(vol)}\right)^{1/2}$$
$$\leqslant\left(\int_{3\text{-space}}|E'_\sigma|^2 \ \ \mathrm{d(vol)}\right)^{1/2}\left(\int_\Omega|V|^2 \ \ \mathrm{d(vol)}\right)^{1/2}, \tag{5.24}$$

and therefore

$$\int_{3\text{-space}}|E'_\sigma|^2 \ \ \mathrm{d(vol)}\leqslant\int_\Omega|V|^2 \ \ \mathrm{d(vol)}, \tag{5.25}$$

as claimed, finishing the proof of Proposition 2.

Completion of the proof of Theorem B: In the previous section, we showed that HG⊕GG, the space of gradient vector fields which are orthogonal to the boundary of Ω, lies within the kernel of the Biot–Savart operator $\mathrm{BS}:\mathrm{VF}(\Omega)\to\mathrm{VF}(\Omega)$.

Now we must show that there is nothing else in the kernel.

We will do this by assuming that V is orthogonal to GG (equivalently, is divergence-free) and that $\mathrm{BS}(V)=0$, and will show that V must lie in HG.

First we observe that, under these assumptions, V must be a gradient vector field.

To see this, consider the Maxwell equation in Ω,

$$\nabla_y\times\mathrm{BS}(V)(y)=V(y)-(1/4\pi)\nabla_y\int_{x\in\partial\Omega}V(x)\cdot n(x)/|x-y| \ \ \mathrm{d(area}_x), \tag{5.26}$$

written in the form appropriate for any divergence-free vector field V.

If V had a nonzero component in the subspace FK⊕HK of fluid knots, then that component would persist when we computed $\nabla\times\mathrm{BS}(V)$, since the Maxwell equation tells us that $\nabla\times\mathrm{BS}(V)$ differs from V by a gradient vector field. It follows that no such V could possibly be in the kernel of BS.

So we can assume that V is a gradient vector field, and write $V=\nabla\varphi$. Since V is orthogonal to GG, the function φ must be harmonic. To show that V lies in HG, we must show that the function φ is constant on each component of $\partial\Omega$.

To start on this, note that the second term on the right-hand side in the Maxwell equation above is the electrostatic field $E'_\sigma(y)$, and write that equation more succinctly as

$$\nabla \times \mathrm{BS}(V) = V + E'_\sigma. \tag{5.27}$$

Now if $\mathrm{BS}(V)=0$, then $E'_\sigma = -V$ in Ω.

It follows that E'_σ must be identically zero outside Ω because, by Proposition 2, it simply has no more energy.

This, in turn, implies that the electrostatic potential function ψ for the field E'_σ must be constant on each component of $\partial\Omega$.

But the three equations,

$$E'_\sigma = -\nabla\psi \quad (\text{everywhere}), \tag{5.28}$$

$$V = \nabla\varphi \quad (\text{inside } \Omega), \tag{5.29}$$

$$E'_\sigma = -V \quad (\text{inside } \Omega), \tag{5.30}$$

tell us that

$$\nabla\varphi = \nabla\psi \quad (\text{inside } \Omega), \tag{5.31}$$

and hence that

$$\varphi = \psi + \text{ some constant} \tag{5.32}$$

on each component of Ω, where the constant may depend on the component.

Thus φ inherits from ψ the property of being constant on each component of $\partial\Omega$, and hence $V=\nabla\varphi$ must lie in HG, the desired conclusion.

This completes the proof of Theorem B.

In fact, we have actually proved a bit more.

Theorem B′: *The kernel of $\nabla\times BS$, the composition of the curl and Biot–Savart operators, is also the space of gradient vector fields which are orthogonal to the boundary of Ω.*

This follows, with no further argument, because the only way we used the hypothesis that $\mathrm{BS}(V)=0$ in this section was to set $\nabla\times\mathrm{BS}(V)=0$ on the left-hand side of the Maxwell equation (5.27).

VI. PROOF OF THEOREM C

A. Statement and proof of Theorem C

Recall the statement:

Theorem C: *The image of the Biot–Savart operator is a proper subspace of the image of curl, whose orthogonal projection into the subspace of ''fluxless knots'' is one-to-one.*

This will follow immediately from Theorems B and B′ and (borrowing from the future) from Theorem D.

Proof:

Keep in mind the Hodge decomposition,

$$\mathrm{VF}(\Omega) = \mathrm{FK}\oplus\mathrm{HK}\oplus\mathrm{CG}\oplus\mathrm{HG}\oplus\mathrm{GG}. \tag{6.1}$$

We know from Theorem B that the kernel of the Biot–Savart operator BS is the subspace $\mathrm{HG}\oplus\mathrm{GG}$ of $\mathrm{VF}(\Omega)$.

We know from Theorem D that this operator is self-adjoint.

It follows that the image of BS lies within the orthogonal complement of its kernel, that is, within the subspace $\mathrm{FK}\oplus\mathrm{HK}\oplus\mathrm{CG}$, which is precisely the image of curl.

Alternatively, the formula $\nabla \times \mathrm{A}(V) = \mathrm{BS}(V)$, which appeared as item (4) on our list of Standard Information in Sec. III A, also tells us that the image of BS lies within the image of curl.

Now it follows from Theorems B and B′ together that

$$\mathrm{Image}(\mathrm{BS}) \cap \mathrm{Ker}(\mathrm{curl}) = \{0\}, \tag{6.2}$$

and since, by the Hodge Decomposition Theorem, the kernel of curl is $\mathrm{HK} \oplus \mathrm{CG} \oplus \mathrm{HG} \oplus \mathrm{GG}$, the orthogonal projection of the image of BS into FK must be one-to-one.

From this it also follows that the image of the BS is a proper subspace of the image of curl.

This completes the proof of Theorem C.

B. Impossible magnetic fields

We are looking for smooth vector fields U on a compact, smoothly bounded domain Ω in 3-space, for which it is impossible to find a smooth vector field V on Ω satisfying the equation $U = \mathrm{BS}(V)$. We will call such a field U an impossible magnetic field.

Of course, Eq. (6.2) tells us that any nonzero vector field U in $\mathrm{HK} \oplus \mathrm{CG} \oplus \mathrm{HG} \oplus \mathrm{GG}$ is an impossible magnetic field.

But here is a more interesting example.

Consider the velocity vector field U of a ''speeding bullet,'' as pictured below (see Fig. 3).

We visualize the unit ball Ω in 3-space as a lead bullet sitting in a cartridge which has been shot directly upwards from a rifled barrel, so that it spins as it moves forward. In cylindrical coordinates r, φ, z, the velocity vector field U is given by

$$U = r\hat{\varphi} + \hat{z}. \tag{6.3}$$

Note that the first summand $r\hat{\varphi}$ lies in FK, while the second summand $\hat{z}$ lies in CG.

Now look back to Example 1 in Sec. III C. There we started with the vector field $V = \hat{z}$ on the unit ball Ω and computed its magnetic field within the ball,

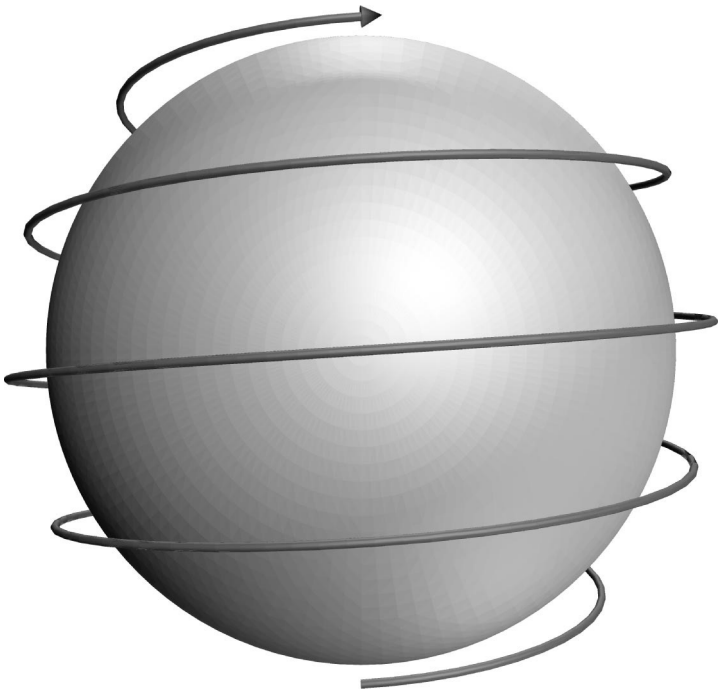

FIG. 3. An impossible magnetic field on the unit ball Ω.

$$\begin{aligned} \mathrm{BS}(V) &= (1/3) r \sin\theta \hat{\varphi} \quad \text{(spherical coordinates)} \\ &= (1/3) r \hat{\varphi} \quad \text{(cylindrical coordinates)}. \end{aligned} \tag{6.4}$$

So of course (settling back to cylindrical coordinates),

$$\mathrm{BS}(3V) = r\hat{\varphi}. \tag{6.5}$$

But this magnetic field on the unit ball ''poisons'' U as a candidate magnetic field, since U and $\mathrm{BS}(3V)$ have the same orthogonal projection into the space FK of fluxless knots. By Theorem C, the vector field U cannot possibly be the Biot–Savart transform of any smooth vector field on Ω.

VII. PROOF OF THEOREM D

It will be convenient to divide the statement and proof of Theorem D into three pieces, as follows:

(1) The Biot–Savart operator $\mathrm{BS}:\mathrm{VF}(\Omega)\to\mathrm{VF}(\Omega)$ is bounded, and hence extends to a bounded operator on the L^2 completion,

$$\mathrm{BS}:\overline{\mathrm{VF}}(\Omega)\to\overline{\mathrm{VF}}(\Omega);$$

(2) The operator $\mathrm{BS}:\overline{\mathrm{VF}}(\Omega)\to\overline{\mathrm{VF}}(\Omega)$ is compact, that is, it takes the unit ball in $\overline{\mathrm{VF}}(\Omega)$ to a set with compact closure in $\overline{\mathrm{VF}}(\Omega)$;

(3) The operator $\mathrm{BS}:\overline{\mathrm{VF}}(\Omega)\to\overline{\mathrm{VF}}(\Omega)$ is self-adjoint with respect to the L^2 inner product, that is, $\langle V_1, \mathrm{BS}(V_2)\rangle = \langle \mathrm{BS}(V_1), V_2\rangle$, for all vector fields V_1 and V_2 in $\overline{\mathrm{VF}}(\Omega)$.

A. A useful lemma

The proof that the Biot–Savart operator is bounded, as asserted in (1) above, will follow along the lines of the usual Young's inequality proof that convolution operators are bounded; see Folland,[47] p. 9, or Zimmer,[48] Proposition B.3 on p. 10. We extract this proof as a lemma, so that we can use it again in the proof of part (2).

Lemma 3: *Let $\phi(x)$ be a scalar-valued function with the property that*

$$N_\Omega(\phi) = \max_y \int_\Omega |\phi(y-x)| \ \ \mathrm{d}(\mathrm{vol}_x)$$

is finite, where the maximum is over all points $y \epsilon R^3$. Then the operator $T_\phi : \mathrm{VF}(\Omega)\to\mathrm{VF}(\Omega)$ defined by

$$T_\phi(V)(y) = \int_\Omega V(x) \times \phi(y-x) \, \frac{y-x}{|y-x|} \, \mathrm{d}(\mathrm{vol}_x)$$

is a bounded map with respect to the L^2 norm, and furthermore,

$$|T_\phi(V)| \leq N_\Omega(\phi)|V|.$$

Proof: Fix $y \epsilon \Omega$. Then, using the Cauchy–Schwarz inequality,

$$
\begin{aligned}
|T_\phi(V)(y)| &\leq \int_\Omega |V(x)||\phi(y-x)| \ \ \mathrm{d}(\mathrm{vol}_x) \\
&= \int_\Omega |V(x)\{\phi(y-x)\}^{1/2}| \ \ |\{\phi(y-x)\}^{1/2}| \ \ \mathrm{d}(\mathrm{vol}_x) \\
&\leq \left(\int_\Omega |V(x)|^2 |\phi(y-x)| \ \ \mathrm{d}(\mathrm{vol}_x) \right)^{1/2} \left(\int_\Omega |\phi(y-x)| \ \ \mathrm{d}(\mathrm{vol}_x) \right)^{1/2} \\
&\leq (N_\Omega(\phi))^{1/2} \left(\int_\Omega |\phi(y-x)| \ \ |V(x)|^2 \ \ \mathrm{d}(\mathrm{vol}_x) \right)^{1/2}. \qquad (7.1)
\end{aligned}
$$

We square both sides, integrate and use Fubini's theorem to get

$$
\begin{aligned}
\int_\Omega |T_\phi(V)(y)|^2 \ \ \mathrm{d}(\mathrm{vol}_y) &\leq N_\Omega(\phi) \int_\Omega \int_\Omega |\phi(y-x)||V(x)|^2 \ \ \mathrm{d}(\mathrm{vol}_x) \ \ \mathrm{d}(\mathrm{vol}_y) \\
&= N_\Omega(\phi) \int_\Omega |V(x)|^2 \left(\int_\Omega |\phi(y-x)| \ \ \mathrm{d}(\mathrm{vol}_y) \right) \mathrm{d}(\mathrm{vol}_x) \\
&\leq N_\Omega(\phi)^2 \int_\Omega |V(x)|^2 \ \ \mathrm{d}(\mathrm{vol}_x). \qquad (7.2)
\end{aligned}
$$

Taking square roots, we get

$$
|T_\phi(V)| \leq N_\Omega(\phi)|V|, \qquad (7.3)
$$

and conclude that T_ϕ is a bounded operator whose norm is at most $N_\Omega(\phi)$, as claimed.

B. Proof of (1)

Define the *optical size* of Ω, written $\mathrm{OS}(\Omega)$, to be the number

$$
\mathrm{OS}(\Omega) = \max_y \int_\Omega 1/|y-x|^2 \ \ \mathrm{d}(\mathrm{vol}_x), \qquad (7.4)
$$

where the maximum is taken over all points $y \in R^3$. The integral just above can be taken as a measure of the effort required to optically scan the domain Ω from the location y; the optical size of Ω is the maximum effort required to scan it from any location.

Then, in the language of Lemma 3,

$$
\begin{aligned}
\mathrm{BS}(V)(y) &= (1/4\pi) \int_\Omega V(x) \times (y-x)/|y-x|^3 \ \ \mathrm{d}(\mathrm{vol}_x) \\
&= T_{\phi_0}(V)(y), \qquad (7.5)
\end{aligned}
$$

where

$$
\phi_0(y-x) = (1/4\pi)(1/|y-x|^2). \qquad (7.6)
$$

The lemma yields immediately that, for $V \in \mathrm{VF}(\Omega)$,

$$
|\mathrm{BS}(V)| \leq (1/4\pi)\mathrm{OS}(\Omega)|V|, \qquad (7.7)
$$

and we conclude that $\mathrm{BS}:\mathrm{VF}(\Omega) \to \mathrm{VF}(\Omega)$ is a bounded operator.

Now let $\overline{\mathrm{VF}}(\Omega)$ denote the L^2 completion of the space $\mathrm{VF}(\Omega)$; we will refer to the elements of $\overline{\mathrm{VF}}(\Omega)$ as L^2 *vector fields*.

Then we can, and do, extend the Biot–Savart operator to a bounded operator,

$$\mathrm{BS}:\overline{\mathrm{VF}}(\Omega)\to\overline{\mathrm{VF}}(\Omega), \tag{7.8}$$

with the same bound as above.

This completes the proof of part (1).

C. Proof of (2)

To prove that the Biot–Savart operator is compact, we use two standard facts from functional analysis. First is the fact that for any compact domain Ω, if $\phi(x)$ is continuous on R^3, then the integral operator

$$(T_\phi f)(y)=\int_\Omega \phi(y-x)f(x)\ \ \mathrm{d}(\mathrm{vol}_x) \tag{7.9}$$

defines a compact operator on $L^2(\Omega)$; see Zimmer,[48] Theorem 3.1.5 on p. 53. It is stated there only for operators on scalar-valued functions, but the extension to vector-valued ones, using the definition given in Lemma 9.3, is trivial.

Second is the fact that the norm-limit of compact operators is compact; see Zimmer,[48] Lemma 3.1.3 on p. 52.

Now let

$$\phi_N(x)=\begin{cases} N^2/4\pi & \text{if } |x|\leqslant 1/N \\ 1/(4\pi|x|^2) & \text{if } |x|\geqslant 1/N. \end{cases} \tag{7.10}$$

Note that ϕ_N is a continuous function, and that

$$\begin{aligned} N_\Omega(\phi_0-\phi_N)&=\max_y\int_\Omega|\varphi_0(y-x)-\varphi_N(y-x)|\ \ \mathrm{d}(\mathrm{vol}_x)\\ &\leqslant(1/4\pi)\int_{|x|\leqslant 1/N}((1/|x|^2)-N^2)\ \ \mathrm{d}(\mathrm{vol}_x)\\ &\leqslant(1/4\pi)\int_{|x|\leqslant 1/N}(1/|x|^2)\ \ \mathrm{d}(\mathrm{vol}_x)=1/N. \end{aligned} \tag{7.11}$$

By the first functional analysis fact, T_{ϕ_N} is a compact operator from $\overline{\mathrm{VF}}(\Omega)$ to $\overline{\mathrm{VF}}(\Omega)$. By our Lemma, we see that as T_{ϕ_N} converges in norm to T_{ϕ_0}, the Biot–Savart operator, as $N\to\infty$. Using the second functional analysis fact, we conclude that $\mathrm{BS}:\overline{\mathrm{VF}}(\Omega)\to\overline{\mathrm{VF}}(\Omega)$ is a compact operator.

This completes the proof of part (2).

D. Proof of (3)

It is easy to see why the Biot–Savart operator is self-adjoint.

Suppose that V_1 and V_2 are smooth vector fields defined on Ω. Then

$$\begin{aligned}\langle V_1, \mathrm{BS}(V_2)\rangle &= \int_\Omega V_1(y)\cdot \mathrm{BS}(V_2)(y)\ \ \mathrm{d}(\mathrm{vol}_y)\\ &= \int_\Omega V_1(y)\cdot\left[(1/4\pi)\int_\Omega V_2(x)\times(y-x)/|y-x|^3\ \ \mathrm{d}(\mathrm{vol}_x)\right]\mathrm{d}(\mathrm{vol}_y)\\ &= (1/4\pi)\int_{\Omega\times\Omega} V_1(y)\times V_2(x)\cdot(y-x)/|y-x|^3\ \ \mathrm{d}(\mathrm{vol}_x)\ \ \mathrm{d}(\mathrm{vol}_y)\\ &= (1/4\pi)\int_{\Omega\times\Omega} V_2(x)\times V_1(y)\cdot(x-y)/|x-y|^3\ \ \mathrm{d}(\mathrm{vol}_y)\ \ \mathrm{d}(\mathrm{vol}_x)\\ &= \langle V_2, \mathrm{BS}(V_1)\rangle. \end{aligned} \tag{7.12}$$

It is a straightforward exercise to check that these improper integrals are all convergent.

Thus $\mathrm{BS}:\mathrm{VF}(\Omega)\to\mathrm{VF}(\Omega)$ is a self-adjoint operator, and therefore remains self-adjoint when extended to the L^2 completion $\overline{\mathrm{VF}}(\Omega)$ of $\mathrm{VF}(\Omega)$.

Theorem D is proved.

APPENDIX: THE DECAY RATE OF A(V) AND BS(V) AT INFINITY

In item (9) in our list of standard information from Sec. III A, we asserted that in general, $\mathrm{A}(V)$ decays at ∞ like $1/r$ and that $\mathrm{BS}(V)$ decays at ∞ like $1/r^2$. In the special case that $V\epsilon\mathrm{K}(\Omega)$, we asserted that $\mathrm{A}(V)$ decays at ∞ like $1/r^2$ and that $\mathrm{BS}(V)$ decays at ∞ like $1/r^3$.

We give the proofs here.

The defining formula for the vector potential,

$$\mathrm{A}(V)(y) = (1/4\pi)\int_\Omega V(x)/|y-x|\ \ \mathrm{d}(\mathrm{vol}_x), \tag{A1}$$

expresses an inverse first power law, with integration over a compact region Ω. It follows immediately that $\mathrm{A}(V)$ decays at infinity at least as fast as $1/r$.

When we say that $\mathrm{A}(V)$ *decays at infinity at least as fast* as $1/r$, we mean that the product $|\mathrm{A}(V)(y)||y|$ has a finite upper bound on R^3, and likewise for corresponding expressions used below.

The Biot–Savart formula,

$$\mathrm{BS}(V)(y) = (1/4\pi)\int_\Omega V(x)\times(y-x)/|y-x|^3\ \ \mathrm{d}(\mathrm{vol}_x), \tag{A2}$$

expresses an inverse square law, with integration over a compact region Ω. Again it follows immediately that $\mathrm{BS}(V)$ decays at infinity at least as fast as $1/r^2$.

The proof of the faster decay rates when $V\epsilon\ \mathrm{K}(\Omega)$ will be divided into two lemmas.

Lemma 4: *The following are equivalent:*

(1) $\mathrm{A}(V)$ *decays at infinity at least as fast as* $1/r^2$*;*
(2) $\mathrm{BS}(V)$ *decays at infinity at least as fast as* $1/r^3$*;*
(3) $\int_\Omega V\mathrm{d}(\mathrm{vol}) = 0$.

Proof:

It is an easy exercise to check that conditions (1) and (2) each imply (3). For example, when $|y|$ is very large, we have

$$|y|\mathrm{A}(V)(y)\approx(1/4\pi)\int_\Omega V(x)\ \ \mathrm{d}(\mathrm{vol}_x). \tag{A3}$$

If the integral of V is not zero, then $|y|^2|\mathrm{A}(V)(y)|$ certainly blows up at ∞. Thus condition (1) implies condition (3), and likewise, (2) implies (3).

Suppose now that condition (3) holds. Then,

$$\begin{aligned}|y|^2\mathrm{A}(V)(y)&=(1/4\pi)\int_\Omega |y|^2V(x)/|y-x|\ \ \mathrm{d}(\mathrm{vol}_x)\\ &=(1/4\pi)\int_\Omega |y|^2V(x)/|y-x|\ \ \mathrm{d}(\mathrm{vol}_x)-(1/4\pi)\int_\Omega |y|V(x)\ \ \mathrm{d}(\mathrm{vol}_x)\\ &=(1/4\pi)\int_\Omega \{(|y^2/|y-x|)-|y|\}V(x)\ \ \mathrm{d}(\mathrm{vol}_x),\end{aligned} \tag{A4}$$

where the integral added on the right-hand side is zero thanks to condition (3).

Now,

$$\{(|y|^2/|y-x|)-|y|\}=\{|y|/|y-x|\}\{|y|-|y-x|\}.$$

The first factor on the right-hand side approaches 1 as $y\to\infty$ because Ω is bounded. The second factor on the right-hand side is $\leqslant|x|$, and hence also bounded. Thus

$$\{(|y|^2/|y-x|)-|y|\}$$

is bounded as $y\to\infty$.

Since $\int_\Omega|V(x)|d(\mathrm{vol}_x)$ is certainly bounded, it follows that $|y|^2|\mathrm{A}(V)(y)|$ is bounded, and hence that $\mathrm{A}(V)$ decays at ∞ at least as fast as $1/r^2$. Thus condition (3) implies condition (1), as claimed.

Again suppose that condition (3) holds. Then

$$\begin{aligned}|y|^3\,\mathrm{BS}(V)(y)&=(1/4\pi)\int_\Omega V(x)\times(y-x)|y|^3/|y-x|^3\ \ \mathrm{d}(\mathrm{vol}_x)\\ &=(1/4\pi)\int_\Omega V(x)\times(y-x)|y|^3/|y-x|^3\ \ \mathrm{d}(\mathrm{vol}_x)-(1/4\pi)\int_\Omega V(x)\times y\ \ \mathrm{d}(\mathrm{vol}_x)\\ &=(1/4\pi)\int_\Omega V(x)\times\{((y-x)|y|^3/|y-x|^3)-y\}\ \ \mathrm{d}(\mathrm{vol}_x),\end{aligned} \tag{A5}$$

where again the integral added on the right-hand side is zero because of condition (3). Continuing,

$$\{((y-x)|y|^3/|y-x|^3)-y\}=\{y(|y|^3-|y-x|^3)/|y-x|^3\}-\{x|y|^3/|y-x|^3\}.$$

Processing the first term on the right-hand side,

$$\{y(|y|^3-|y-x|^3)/|y-x|^3\}=\{y/|y-x|\}\ \ \{|y|-|y-x|\}\ \ \{(|y|^2+|y||y-x|+|y-x|^2)/|y-x|^2\}.$$

The first factor on the right-hand side of this last equation is bounded as $y\to\infty$ because Ω is bounded. The second factor on the right-hand side is $\leqslant|x|$, and hence is also bounded. The third factor on the right-hand side approaches the value 3 as $y\to\infty$, and hence is also bounded. It follows that

$$\{y(|y|^3-|y-x|^3)/|y-x|^3\}$$

is bounded as $y\to\infty$.

Now the term

$$\{x|y|^3/|y-x|^3\}$$

is certainly bounded as $y\to\infty$, and so we conclude that

$$\{((y-x)|y|^3/|y-x|^3)-y\}$$

is also bounded as $y\to\infty$. From this it follows that

$$|y|^3\,\mathrm{BS}(V)(y)$$

is bounded for all y, and hence that $\mathrm{BS}(V)(y)$ decays at ∞ at least as fast as $1/r^3$. Thus condition (3) implies condition (2).

This completes the proof of Lemma 4.

Lemma 5: $\int_\Omega V(x)d(\mathrm{vol}_x)=0$ *for all* V *in* $\mathrm{FK}\oplus\mathrm{HK}\oplus\mathrm{HG}\oplus\mathrm{GG}$, *but this relation determines a codimension-three subspace of* CG.

Proof:

We begin with the proof that $\int_\Omega V(x)d(\mathrm{vol}_x)=0$ for all $V\epsilon\mathrm{FK}\oplus\mathrm{HK}=\mathrm{K}(\Omega)$.

The argument will be coordinate-wise, so that we can deal with scalar-valued integrals instead of vector-valued ones. So let us write the typical point of Ω as $x=(x_1,x_2,x_3)$, and then write $V(x)=(V_1(x),V_2(x),V_3(x))$.

Then

$$\nabla\cdot(x_1V)=(\nabla x_1)\cdot V+x_1(\nabla\cdot V)=(\nabla x_1)\cdot V=V_1, \tag{A6}$$

since V is divergence-free.

Hence,

$$\int_\Omega V_1(x)\ \ \mathrm{d}(\mathrm{vol}_x)=\int_\Omega\nabla\cdot(x_1V)\ \ \mathrm{d}(\mathrm{vol}_x)=\int_{\partial\Omega}x_1V\cdot n\ \ \mathrm{d}(\mathrm{area})=0, \tag{A7}$$

because V is tangent to $\partial\Omega$.

Of course the same argument holds for V_2 and V_3, so we conclude that

$$\int_\Omega V(x)\ \ \mathrm{d}(\mathrm{vol}_x)=0, \tag{A8}$$

as claimed.

Now we prove that $\int_\Omega V(x)\ \ \mathrm{d}(\mathrm{vol}_x)=0$ for all $V\epsilon\ \mathrm{HG}\oplus\mathrm{GG}$.

Write $V=\nabla\varphi$ with φ constant on each component of $\partial\Omega$.

We claim that

$$\int_\Omega V\ \ \mathrm{d}(\mathrm{vol})=\int_\Omega\nabla\varphi\ \ \mathrm{d}(\mathrm{vol})=\int_{\partial\Omega}\varphi n\ \ \mathrm{d}(\mathrm{area}). \tag{A9}$$

We see this as follows:

Let C be any constant vector. Then,

$$\nabla\cdot(\varphi C)=(\nabla\varphi)\cdot C+\varphi(\nabla\cdot C)=(\nabla\varphi)\cdot C. \tag{A10}$$

Hence

$$\left(\int_\Omega \nabla\varphi \ \ \mathrm{d(vol)}\right)\cdot C = \int_\Omega (\nabla\varphi)\cdot C \ \ \mathrm{d(vol)}$$
$$= \int_\Omega \nabla\cdot(\varphi C) \ \ \mathrm{d(vol)}$$
$$= \int_{\partial\Omega} (\varphi C)\cdot n \ \ \mathrm{d(area)}$$
$$= \left(\int_{\partial\Omega} \varphi n \ \ \mathrm{d(area)}\right)\cdot C. \tag{A11}$$

Since this is true for all constant vectors C, we must have

$$\int_\Omega \nabla\varphi \ \ \mathrm{d(vol)} = \int_{\partial\Omega} \varphi n \ \ \mathrm{d(area)}, \tag{A12}$$

as claimed.

Now suppose that

$$\partial\Omega = \partial\Omega_1 \cup \cdots \cup \partial\Omega_k \tag{A13}$$

is the decomposition of $\partial\Omega$ into its connected components, and let φ_i denote the constant value of the function φ on the boundary component $\partial\Omega_i$. Then

$$\int_\Omega V \ \ \mathrm{d(vol)} = \int_\Omega \nabla\varphi \ \ \mathrm{d(vol)} = \int_{\partial\Omega} \varphi n \ \ \mathrm{d(area)} = \sum_i \ \varphi_i \int_{\partial\Omega_i} n \ \ \mathrm{d(area)} = 0, \tag{A14}$$

because $\int n \ \ \mathrm{d(area)}$ over any closed surface in 3-space is always zero.

This completes the proof that $\int_\Omega V(x) \ \ \mathrm{d(vol}_x) = 0$ for all $V \in \mathrm{HG} \oplus \mathrm{GG}$.

The observation that this relation determines a codimension-three subspace of CG follows directly from the fact that the three constant vector fields $\hat{x}$, $\hat{y}$, and $\hat{z}$ are curly gradients, completing the proof of Lemma 5.

Clearly, Lemmas 4 and 5 imply the faster decay rates of $\mathrm{A}(V)$ and $\mathrm{BS}(V)$ when $V \in \mathrm{K}(\Omega)$, completing our argument.

ACKNOWLEDGMENTS

For those readers interested in the history of the Biot–Savart Law, we recommend R. A. R. Tricker's little volume, *Early Electrodynamics, The First Law of Circulation*.[49] It contains extensive translations of the works of Oerstead, Biot, Savart, and Ampere, and a detailed analysis of this fascinating period of scientific discovery and of the interactions amongst its principals.

We are deeply indebted to Linette Koren, the former Math–Physics librarian at the University of Pennsylvania, for her work on our behalf as a historical detective, and for obtaining copies of the original works of Oersted,[50] and of Biot and Savart.[51,52] We thank Mikhail Teytel for listening to earlier versions of this work and for sharing his knowledge and insight with us. And finally, we are grateful to our students Ilya Elson, Marcus Khuri, Viorel Mihalef, and Jason Parsley, for their substantial help in reviewing and revising the manuscript.

(Received 22 June 2000; accepted for publication 16 October 2000)

In this paper we continue the study of representation theory of formal distribution Lie superalgebras initiated by Cheng and Kac [Asian J. Math. **1**, 181–193 (1997); **2**, 153–156 (1998) (erratum)]. We study finite Verma-type conformal modules over the $N=2$, $N=3$ and the two $N=4$ superconformal algebras and also find explicitly all singular vectors in these modules. From our analysis of these modules we obtain a complete list of finite irreducible conformal modules over the $N=2$, $N=3$ and the two $N=4$ superconformal algebras. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1333698]

I. INTRODUCTION

Superconformal algebras have been playing an important role in the study of string theory and conformal field theory, which have been the subject of intensive study since the seminal paper.[1] Superconformal algebras may be viewed as natural superextensions of the Virasoro algebra and their roots in physics literature can be traced at least back to as early as the 1970s.[2] A mathematically rigorous definition of a superconformal algebra is as follows. It is a simple Lie superalgebra $\mathfrak{g}$ over the complex numbers $\mathbb{C}$ spanned by the modes of a finite family $\mathfrak{F}$ of mutually local fields satisfying the following two axioms:[3]

(1) $\mathfrak{F}$ contains the Virasoro field.
(2) The coefficients of the operator product expansions of members from $\mathfrak{F}$ are linear combinations of members from $\mathfrak{F}$ and their derivatives.

A Lie superalgebra $\mathfrak{g}$ satisfying the second axiom only is referred to as a *formal distribution Lie superalgebra* in Ref. 3.

In order to facilitate the study of formal distribution Lie superalgebras the notion of a *conformal superalgebra* was introduced in Ref. 3 (see Sec. II). It proves to be an effective tool for this purpose.

A natural class of representations of formal distribution Lie superalgebras to study is the class of *conformal modules*.[4] A conformal module is a pair consisting of a $\mathfrak{g}$-module V and a family $\mathcal{E}$ of fields whose modes span V such that members from $\mathfrak{F}$ and $\mathcal{E}$ are mutually local. Just as the study of formal distribution Lie superalgebras reduces to the study of conformal superalgebras, the study of conformal modules is essentially reduced to the study of modules over the corresponding conformal superalgebras.

The study of modules over the conformal superalgebra can further be reduced to the study of modules over the *extended annihilation subalgebra*, which is a semidirect sum of the subalgebra of positive modes of the corresponding formal distribution Lie superalgebra and a one-dimensional derivation. It is in this language that the problem of classifying finite irreducible

[a)]Electronic mail: chengsj@math.ntu.edu.tw
[b)]Electronic mail: nlam@mail.ncku.edu.tw

conformal modules over the Virasoro, $N=1$ (Neveu–Schwarz) and the current superalgebra was solved in Ref. 4.

The problem of classifying conformal modules over other superconformal algebras, which is the main theme of the present article, turns out to be more subtle. The main purpose here is to give a classification of finite irreducible conformal modules over the $N=2$, $N=3$ and the two $N=4$ superconformal algebras.

We first construct finite Verma-type conformal modules for a general superconformal algebra and prove that every finite irreducible conformal module is a homomorphic image of such a module. As a consequence we obtain a bijection between finite irreducible conformal modules of a superconformal algebra and finite-dimensional irreducible modules of a certain finite-dimensional reductive Lie (super)algebra (Corollary 3.1).

We then study these Verma-type modules in detail for the four members of the family of superconformal algebras mentioned above. It turns out that, unlike for the Virasoro and the $N=1$ (Neveu–Schwarz) superconformal algebras, the Verma-type modules for these superconformal algebras are in general reducible, and thus we need to analyze their submodules. This is accomplished by finding explicit formulas for all singular vectors inside such a module and then show that the submodule generated by these singular vectors is maximal (in all but two cases). We also find an explicit basis for this maximal submodule, which then enables us to give a quite explicit description of all finite irreducible conformal modules over these superconformal algebras.

This article is organized as follows. In Sec. II basic facts of formal distribution Lie superalgebras, conformal superalgebras and extended annihilation subalgebras are recalled. Section III is devoted to the study of a class of modules over a certain class of Lie superalgebras that include the annihilation subalgebra of every superconformal algebra. This class of modules gives rise to finite Verma-type conformal modules of superconformal algebras. The results of Sec. III are then used in Secs. IV–VII, where finite irreducible conformal modules over the $N=2$, $N=3$, the ''small'' $N=4$ and the ''big'' $N=4$ superconformal algebra, respectively, are classified.

In this article all vector spaces, (super)algebras and tensor products are over taken over the complex numbers $\mathbb{C}$.

II. PRELIMINARIES

In this section we review some of the basic facts on formal distribution Lie (super)algebras and conformal modules that will be used later on. The material here is taken from Refs. 3–5, and the reader is referred to these articles for more details.

A. Formal distribution Lie superalgebras

Recall that a *formal distribution* or a *field* with coefficients in a Lie superalgebra $\mathfrak{g}=\mathfrak{g}_{\bar{0}}+\mathfrak{g}_{\bar{1}}$ is a formal series of the form

$$a(z)=\sum_{n\in\mathbb{Z}} a_{[n]}z^{-n-1},$$

where $a_{[n]}\in\mathfrak{g}$ and z is an indeterminate.

Two formal distributions $a(z)$ and $b(z)$ with coefficients in $\mathfrak{g}$ are said to be mutually *local* if there exists $N\in\mathbb{Z}_+$ such that

$$(z-w)^N[a(z),b(w)]=0. \tag{2.1}$$

Let $\delta(z-w)=z^{-1}\Sigma_{n\in\mathbb{Z}}(z/w)^n$ be the formal delta function. Then (2.1) may be written as

$$[a(z),b(w)]=\sum_{j=0}^{N-1}(a_{(j)}b)(w)\partial_w^{(j)}\delta(z-w) \tag{2.2}$$

[here $\partial_w^{(j)}$ stands for $(1/j!)\partial^j/\partial w^j$] for some uniquely determined formal distributions $(a_{(j)}b)(w)$, and thus defines a $\mathbb{C}$-bilinear product $\cdot_{(j)}\cdot$ for each $j\in\mathbb{Z}_+$ on the space of all formal distributions with coefficients in $\mathfrak{g}$. Also $\partial_z a(z)=\Sigma_n(\partial a)_{[n]}z^{-n-1}$, where $(\partial a)_{[n]}=-na_{[n-1]}$, and hence the space of all formal distributions is also a (left) $\mathbb{C}[\partial_z]$-module.

A Lie superalgebra $\mathfrak{g}$ is called a *formal distribution Lie superalgebra*, if there exists a family $\mathfrak{F}$ of mutually local formal distributions whose coefficients span $\mathfrak{g}$. We will write $(\mathfrak{g},\mathfrak{F})$ for such a Lie superalgebra.

Given a formal distribution Lie superalgebra $(\mathfrak{g},\mathfrak{F})$, we may include $\mathfrak{F}$ in the minimal family $\overline{\mathfrak{F}}$ of mutally local distributions which is closed under ∂_z and all products $\cdot_{(j)}\cdot$. Then $\overline{\mathfrak{F}}$ is a *conformal superalgebra*, i.e., it is a left $\mathbb{Z}_2$-graded $\mathbb{C}[\partial]$-module R with a $\mathbb{C}$-bilinear product $a_{(n)}b$ for each $n\in\mathbb{Z}_+$ such that the following axioms hold $[a,b,c\in R;m,n\in\mathbb{Z}_+$ and $\partial^{(j)}=(1/j!)\,\partial^j]$ (cf. Refs. 6 and 7):

(C0) $a_{(n)}b=0$, for $n>>0$,
(C1) $(\partial a)_{(n)}b=-na_{(n-1)}b$,
(C2) $a_{(n)}b=(-1)^{p(a)p(b)}\Sigma_{j=0}^{\infty}(-1)^{j+n+1}\partial^{(j)}(b_{(n+j)}a)$,
(C3) $a_{(m)}(b_{(n)}c)=\Sigma_{j=0}^{\infty}\binom{m}{j}(a_{(j)}b)_{(m+n-j)}c+(-1)^{p(a)p(b)}b_{(n)}(a_{(m)}c)$.

It is convenient to write the products of $a,b\in R$ in the generating series form

$$a_\lambda b=\sum_{n=0}^{\infty}a_{(n)}b\frac{\lambda^n}{n!},$$

where λ is a formal indeterminate. Such an expression lies in $R[\lambda]$.

Conversely, if a conformal superalgebra $R=\oplus_{i\in I}\mathbb{C}[\partial]a^i$ is free $\mathbb{C}[\partial]$-module, we may associate to R a formal distribution Lie superalgebra $(\mathfrak{g}(R),\mathfrak{F}(R))$ with Lie superalgebra $\mathfrak{g}(R)$ spanned by $\mathbb{C}$-basis $a^i_{[m]}$ $(i\in I,\ m\in\mathbb{Z})$ and fields $\mathfrak{F}(R)=\{a^i(z)=\Sigma_{n\in\mathbb{Z}}a^i_{[n]}z^{-n-1}\}_{i\in I}$ with bracket [cf. (2.2)]:

$$[a^i(z),a^j(w)]=\sum_{k\in\mathbb{Z}_+}(a^i_{(k)}a^j)(w)\partial_w^{(k)}\delta(z-w),$$

so that $\overline{\mathfrak{F}(R)}=R$, giving rise to commutation relations $(m,n\in\mathbb{Z};\ i,j\in I)$

$$[a^i_{[m]},a^j_{[n]}]=\sum_{k\in\mathbb{Z}_+}\binom{m}{k}(a^i_{(k)}a^j)_{[m+n-k]}. \tag{2.3}$$

It follows that the Lie superalgebra $\mathfrak{g}$ of a formal distribution Lie superalgebra $(\mathfrak{g},\mathfrak{F})$ is isomorphic to $\mathfrak{g}(\overline{\mathfrak{F}})$ divided by an *irregular* ideal, that is an ideal which does not contain every $a_{[n]}$ for some nonzero element $a\in\overline{\mathfrak{F}}$.

Example 2.1: The (centerless) *Virasoro algebra* $\mathfrak{V}$ has a basis L_n $(n\in\mathbb{Z})$ with commutation relations

$$[L_m,L_n]=(m-n)L_{m+n}.$$

It is spanned by the coefficients of the field $L(z)=\Sigma_{n\in\mathbb{Z}}L_nz^{-n-2}$ satisfying

$$[L(z),L(w)]=\partial_wL(w)\,\delta(z-w)+2L(w)\partial_w\delta(z-w). \tag{2.4}$$

The conformal algebra associated to the Virasoro algebra is the *Virasoro conformal algebra* $R(\mathfrak{V})=\mathbb{C}[\partial]\otimes L$ with products $L_\lambda L=(\partial+2\lambda)L$.

Example 2.2: Let $\mathfrak{g}$ be a finite-dimensional Lie (super)algebra. Let $\tilde{\mathfrak{g}}=\mathfrak{g}\otimes\mathbb{C}[t,t^{-1}]$ denote the corresponding *current algebra* with bracket

$$[a\otimes f(t),b\otimes g(t)]=[a,b]\otimes f(t)g(t),\quad a,b\in\mathfrak{g};f(t),g(t)\in\mathbb{C}[t,t^{-1}].$$

For each $a\in\mathfrak{g}$ define a field $a(z)=\Sigma_{n\in\mathbb{Z}}(a\otimes t^n)z^{-n-1}$. Then $\tilde{\mathfrak{g}}$ is spanned by the coefficients of $a(z)$ satisfying

$$[a(z),b(w)]=[a,b](w)\,\delta(z-w). \tag{2.5}$$

The conformal (super)algebra associated to the current algebra is the *current conformal algebra* $R(\tilde{\mathfrak{g}})=\mathbb{C}[\partial]\otimes\mathfrak{g}$ with products $a_\lambda b=[a,b]$, $a,b\in\mathfrak{g}$.

Example 2.3: The semidirect sum $\mathfrak{V}\ltimes\tilde{\mathfrak{g}}$ is another example of a formal distribution Lie (super)algebra. The collection of fields is $\{L(z),a(z)|a\in\mathfrak{g}\}$ and we have in addition to (2.4) and (2.5)

$$[L(z),a(w)]=\partial_w a(w)\,\delta(z-w)+a(w)\,\partial_w\delta(z-w). \tag{2.6}$$

The conformal algebra associated to the semidirect sum of the Virasoro algebra and the current algebra is $R(\mathfrak{V}\ltimes\tilde{\mathfrak{g}})=R(\mathfrak{V})\ltimes R(\tilde{\mathfrak{g}})$. For $a\in\mathfrak{g}$ we have $L_\lambda a=(\partial+\lambda)a$.

B. Conformal modules

Let $(\mathfrak{g},\mathfrak{F})$ be a formal distribution Lie superalgebra. Let V be a $\mathfrak{g}$-module such that V is spanned over $\mathbb{C}$ by the coefficients of a family $\mathcal{E}$ of fields. If all $a(z)\in\mathfrak{F}$ are local with respect to all $v(z)\in\mathcal{E}$, then the pair $(V,\mathcal{E})$ is called a *conformal module* over $(\mathfrak{g},\mathfrak{F})$.

Now the family $\mathcal{E}$ of a conformal module $(V,\mathcal{E})$ over $(\mathfrak{g},\mathfrak{F})$ similarly can be included in a larger family $\overline{\mathcal{E}}$, which is still local with respect to the fields from $\overline{\mathfrak{F}}$, and invariant under ∂ and $a_{(j)}$, for all $a\in\overline{\mathfrak{F}}$ and $j\in\mathbb{Z}_+$. It can be shown that for $a,b\in\overline{\mathfrak{F}}$ and $v\in\overline{\mathcal{E}}$ $(m,n\in\mathbb{Z}_+)$ one has

$$[a_{(m)},b_{(n)}]v=\sum_{j=0}^{m}\binom{m}{j}(a_{(j)}b)_{(m+n-j)}v,\quad (\partial a)_{(n)}v=[\partial,a_{(n)}]v=-na_{(n-1)}v.$$

Thus it follows that any conformal module $(V,\mathcal{E})$ over a formal distribution Lie superalgebra $(\mathfrak{g},\mathfrak{F})$ gives rise to a module $M=\overline{\mathcal{E}}$ over the *conformal superalgebra* $R=\overline{\mathfrak{F}}$, defined as follows. It is a (left) $\mathbb{Z}_2$-graded $\mathbb{C}[\partial]$-module equipped with a family of $\mathbb{C}$-linear maps $a\to a^M_{(n)}$ of R to $\mathrm{End}_{\mathbb{C}}M$, for each $n\in\mathbb{Z}_+$, such that the following properties hold for $a,b\in R$ and $m,n\in\mathbb{Z}_+$:

(M0) $a^M_{(n)}v=0$, for $v\in M$ and $n>>0$,
(M1) $[a^M_{(m)},b^M_{(n)}]=\Sigma_{j=0}^{m}\binom{m}{j}(a_{(j)}b)^M_{(m+n-j)}$,
(M2) $(\partial a)^M_{(n)}=[\partial,a^M_{(n)}]=-na^M_{(n-1)}$.

Again it is convenient to write the action of an element $a\in R$ on an element $v\in M$ in the form of a generating series in $V[\lambda]$:

$$a_\lambda v:=\sum_{n=0}^{\infty}a_{(n)}v\frac{\lambda^n}{n!}.$$

Conversely, suppose that a conformal superalgebra $R=\oplus_{i\in I}\mathbb{C}[\partial]a^i$ is a free $\mathbb{C}[\partial]$-module and consider the associated formal distribution Lie superalgebra $(\mathfrak{g}(R),\mathfrak{F}(R))$. Let M be a module over the conformal superalgebra R and suppose that M is a free $\mathbb{C}[\partial]$-module with $\mathbb{C}[\partial]$-basis $\{v^\alpha\}_{\alpha\in J}$. This gives rise to a conformal module $V(M)$ over $\mathfrak{g}(R)$ with fields $\mathcal{E}=\{v^\alpha(z)=\Sigma_{n\in\mathbb{Z}}v^\alpha_{[n]}z^{-n-1}|\alpha\in J\}$ and $\mathbb{C}$-basis $v^\alpha_{[n]}$, defined by

$$a^i(z)v^\alpha(w)=\sum_{j\in\mathbb{Z}_+}(a^i_{(j)}v^\alpha)(w)\partial_w^{(j)}\delta(z-w).$$

A conformal module $(V,\mathcal{E})$ (respectively module M) over a formal distribution Lie superalgebra $(\mathfrak{g},\mathfrak{F})$ (respectively over a conformal superalgebra R) is called *finite*, if $\overline{\mathcal{E}}$ (respectively M) is a finitely generated $\mathbb{C}[\partial]$-module. A conformal module $(V,\mathcal{E})$ over $(\mathfrak{g},\mathfrak{F})$ is called *irreducible* if

there is no nontrivial invariant subspace which contains all $v_{[n]}$, $n\in\mathbb{Z}$, for some nonzero $v\in\overline{\mathcal{E}}$. An invariant subspace that does not contain all $v_{[n]}$, for some non-zero $v\in\mathcal{E}$, is called an *irregular submodule* and conformal modules that differ by an irregular submodule are called referred to as *equivalent* in Ref. 5. Clearly a conformal module is irreducible if and only if the associated module $\overline{\mathcal{E}}$ over the conformal superalgebra $\overline{\mathfrak{F}}$ is irreducible.

Remark 2.1: It follows from (M2) that an eigenvector $v\in M$ of the linear operator ∂ is an R-invariant, i.e., $a_{(n)}v=0$, for all $n\geqslant 0$. Thus a finite irreducible module over a conformal superalgebra R is either free over $\mathbb{C}[\partial]$ or else it is one-dimensional over $\mathbb{C}$.

Suppose that $(\mathfrak{g},\mathfrak{F})$ is a formal distribution Lie superalgebra such that $\mathfrak{g}(\overline{\mathfrak{F}})\cong\mathfrak{g}$. Our discussion implies that any irreducible conformal module $(V,\mathcal{E})$ over $(\mathfrak{g},\mathfrak{F})$ is a quotient of an irreducible conformal module of the form $V(M)$ divided by an irregular submodule, where M is an irreducible module over the conformal superalgebra $\overline{\mathfrak{F}}$. Hence, in particular, if $V(M)$ is irreducible as a $\mathfrak{g}$-module for every irreducible M, then every finite irreducible conformal module over $(\mathfrak{g},\mathfrak{F})$ is isomorphic to $V(M)$, for some finite irreducible $\overline{\mathfrak{F}}$-module M.

Example 2.4: The Virasoro algebra $\mathfrak{V}$ may be identified with the Lie algebra of regular vector fields on $\mathbb{C}^\times$, where $L_n=-t^{n+1}\,d/dt$, $n\in\mathbb{Z}$. For $\alpha,\Delta\in\mathbb{C}$ let

$$F_{\mathfrak{V}}(\alpha,\Delta)=\mathbb{C}[t,t^{-1}]e^{-\alpha t}dt^{1-\Delta}.$$

The Lie algebra $\mathfrak{V}$ acts on the space $F_{\mathfrak{V}}(\alpha,\Delta)$ in a natural way:

$$\left(f(t)\frac{\partial}{\partial t}\right)g(t)dt^{1-\Delta}=(f(t)g'(t)+(1-\Delta)g(t)f'(t))dt^{1-\Delta},$$

where $f(t)\in\mathbb{C}[t,t^{-1}]$ and $g(t)\in\mathbb{C}[t,t^{-1}]e^{-\alpha t}$. Letting $v_{[n]}=t^ne^{-\alpha t}dt^{1-\Delta}$ and $v(z)=\Sigma_{n\in\mathbb{Z}}v_{[n]}z^{-n-1}$ this action is equivalent to

$$L(z)v(w)=(\partial_w+\alpha)v(w)\,\delta(z-w)+\Delta v(w)\partial_w\delta(z-w).$$

Hence we have constructed a two-parameter family of conformal modules over $\mathfrak{V}$. This gives a family of $R(\mathfrak{V})$-modules $\mathbb{C}[\partial]\otimes\mathbb{C}v_\Delta$ with products $L_\lambda v_\Delta=(\alpha+\partial+\Delta\lambda)v_\Delta$. This module is irreducible if and only if $\Delta\neq 0$, in which case it will be denoted by $L_{\mathfrak{V}}(\alpha,\Delta)$. We set $L_{\mathfrak{V}}(\alpha,0)$ to be the one-dimensional (over $\mathbb{C}$) $R(\mathfrak{V})$-module on which ∂ acts as the scalar α.

Example 2.5: Let $\mathfrak{g}$ be a finite-dimensional simple Lie algebra and U^Λ the finite-dimensional irreducible module of highest weight Λ. Then $F_{\tilde{\mathfrak{g}}}(\Lambda)=U^\Lambda\otimes\mathbb{C}[t,t^{-1}]$ is naturally a module over $\tilde{\mathfrak{g}}$ with action given by

$$(a\otimes f(t))(u\otimes g(t))=au\otimes f(t)g(t),\quad a\in\mathfrak{g},u\in U^\Lambda;f(t),g(t)\in\mathbb{C}[t,t^{-1}]. \tag{2.7}$$

For each vector $u\in U^\Lambda$ define $u(z)=\Sigma_{n\in\mathbb{Z}}(u\otimes t^n)z^{-n-1}$ so that (2.7) is equivalent to

$$a(z)u(w)=au(w)\,\delta(z-w),$$

and hence $F_{\tilde{\mathfrak{g}}}(\Lambda)$ is conformal. This gives a family of $R(\tilde{\mathfrak{g}})$-modules, which is irreducible if and only if $\Lambda\neq 0$, in which case it will be denoted by $L_{\tilde{\mathfrak{g}}}(\Lambda)$. By $L_{\tilde{\mathfrak{g}}}(0)$ we will mean the trivial $R(\tilde{\mathfrak{g}})$-module. Similarly one defines the one-dimensional module $L_{\tilde{\mathfrak{g}}}(\alpha,0)$.

Example 2.6: $\tilde{\mathfrak{g}}$ acts on $F_{\mathfrak{V}\ltimes\tilde{\mathfrak{g}}}(\alpha,\Delta,\Lambda)=U^\Lambda\otimes F_{\mathfrak{V}}(\alpha,\Delta)$ similarly as in Example 2.5. However, on $F_{\mathfrak{V}\ltimes\tilde{\mathfrak{g}}}(\alpha,\Delta,\Lambda)$ we have also an action of $\mathfrak{V}$, thus making it into a module over $\mathfrak{V}\ltimes\tilde{\mathfrak{g}}$. This module defines an $R(\mathfrak{V}\ltimes\tilde{\mathfrak{g}})$-module which is irreducible if and only if $(\Delta,\Lambda)\neq(0,0)$, and in which case it will be denoted by $L_{\mathfrak{V}\ltimes\tilde{\mathfrak{g}}}(\alpha,\Delta,\Lambda)$. By $L_{\mathfrak{V}\ltimes\tilde{\mathfrak{g}}}(\alpha,0,0)$ we will mean the one-dimensional module on which ∂ acts as the scalar α.

The following theorem was proven in Ref. 4.

Theorem 2.1: *Let $\mathfrak{g}$ stand for a finite-dimensional simple Lie algebra. Any finite irreducible module over the conformal algebras $R(\mathfrak{V})$, $R(\tilde{\mathfrak{g}})$ and $R(\mathfrak{V}\ltimes\tilde{\mathfrak{g}})$ are as follows:*

(*i*) $L_{\mathfrak{V}}(\alpha,\Delta)$,
(*ii*) $L_{\tilde{\mathfrak{g}}}(\Lambda)$ *and* $L_{\tilde{\mathfrak{g}}}(\alpha,0)$,
(*iii*) $L_{\mathfrak{V}\ltimes\tilde{\mathfrak{g}}}(\alpha,\Delta,\Lambda)$.

Remark 2.2: We note that a similar statement as Theorem 2.1 part (*iii*) holds even if $\mathfrak{g}$ is replaced by the one-dimensional Lie algebra $\mathbb{C}a$. In this case $U^{\Lambda}=\mathbb{C}u$ with $au=\Lambda u$, $\Lambda\in\mathbb{C}$. Also, part (*ii*) remains true for all but three series of finite-dimensional simple Lie superalgebras.

C. Extended annihilation subalgebras

Given a formal distribution Lie superalgebra $(\mathfrak{g},\mathfrak{F})$ we let $\mathfrak{g}_+$ denote the $\mathbb{C}$-span of all $a_{[n]}$, where $n\geqslant 0$ and $a\in\mathfrak{F}$. Due to (2.3) $\mathfrak{g}_+$ is closed under the bracket and hence forms a subalgebra of $\mathfrak{g}$, which we will call the *annihilation algebra* of $(\mathfrak{g},\mathfrak{F})$. Let ∂ be the derivation of $\mathfrak{g}_+$ defined by $[\partial,a_{[n]}]=-na_{[n-1]}$, and consider the semi-direct sum of $\mathfrak{g}^+=\mathbb{C}\partial\ltimes\mathfrak{g}_+$. Then $\mathfrak{g}^+$ is called the *extended annihilated algebra* of $(\mathfrak{g},\mathfrak{F})$. The following proposition, which follows by comparing (M1) with (2.3), is important for the theory of conformal modules.

Proposition 2.1:[4] *Let R be a conformal superalgebra and $(\mathfrak{g}(R),R(\mathfrak{F}))$ be its associated formal distribution Lie superalgebra with extended annihilation algebra $\mathfrak{g}(R)^+$. Then a module over the conformal superalgebra R is precisely a $\mathfrak{g}(R)^+$-module M satisfying $a_{[n]}v=0$, for each $v\in M$, $a\in R$ and $n>>0$.*

Remark 2.3: Let R be a conformal superalgebra with $\mathbb{C}[\partial]$-basis $\{a^i|i\in I\}$ and M a free $\mathbb{C}[\partial]$-module with basis $\{v^j|j\in J\}$. Given $a^i_{(n)}v^j\in M$ for all $i\in I$, $j\in J$, $n\in\mathbb{Z}_+$, which is 0 for $n>>0$, condition (M2) uniquely extends the action of $a^i_{(n)}$ to all of M. If in addition (M1) holds, then M is an R-module. Hence the action of an R-module M is completely determined by the action of a $\mathbb{C}[\partial]$-basis of R on a $\mathbb{C}[\partial]$-basis of M.

Example 2.7: In the case of the Virasoro algebra $\mathfrak{V}$ the annihilation algebra $\mathfrak{V}_+$ is spanned by elements L_n, $n\geqslant -1$. In the case of the current algebra $\tilde{\mathfrak{g}}_+$ is spanned by $a\otimes t^n$, where $a\in\mathfrak{g}$ and $n\geqslant 0$, while in the case of $\mathfrak{V}\ltimes\tilde{\mathfrak{g}}$ it is $\mathfrak{V}_+\ltimes\tilde{\mathfrak{g}}_+$.

The problem of classifying conformal modules over $(\mathfrak{g},\mathfrak{F})$ is thus reduced to the problem of classifying a class of modules over $\mathfrak{g}(\bar{\mathfrak{F}})^+$. It is clear that in all our examples one has $\mathfrak{g}(\bar{\mathfrak{F}})=\mathfrak{g}$, and thus we are to study modules over $\mathfrak{g}^+$. Now if in addition there exists an element L_{-1} in $\mathfrak{g}_+$ such that $L_{-1}-\partial$ is central in $\mathfrak{g}^+$, then every irreducible representation of $\mathfrak{g}^+$ is an irreducible representation of $\mathfrak{g}_+$, on which $(L_{-1}-\partial)$ acts as a scalar $\alpha\in\mathbb{C}$. In the case of the $\mathfrak{V}$ and $\mathfrak{V}\ltimes\tilde{\mathfrak{g}}$ and the $N=2,3,4$ superconformal superalgebras, which we will define later, such an L_{-1} always exists so that we only need to consider representations of $\mathfrak{g}_+$. The irreducible representations of $\mathfrak{V}_+$ and $\mathfrak{V}_+\ltimes\tilde{\mathfrak{g}}_+$ that give rise to those in Theorem 2.1 are denoted by $L_{\mathfrak{V}_+}(\Delta)$ and $L_{\mathfrak{V}_+\ltimes\tilde{\mathfrak{g}}_+}(\Delta,\Lambda)$, respectively. The corresponding actions are clear and can be found in Ref. 4.

III. FINITE VERMA-TYPE CONFORMAL MODULES

Let $\mathcal{L}$ be a Lie superalgebra over $\mathbb{C}$ with a distinguished element ∂ and a descending sequence of subspaces $\mathcal{L}=\mathcal{L}_{-1}\supset\mathcal{L}_0\supset\mathcal{L}_1\supset\mathcal{L}_2\supset\cdots\supset\mathcal{L}_n\supset\cdots$, such that $[\partial,\mathcal{L}_k]=\mathcal{L}_{k-1}$, for all $k>0$. Let W be an $\mathcal{L}$-module, which is finitely generated over $\mathbb{C}[\partial]$, such that for all $w\in W$ there exists a non-negative integer k (depending on w) with $\mathcal{L}_k w=0$. For $m\geqslant -2$ set $W_m=\{w\in W|\mathcal{L}_{m+1}w=0\}$ and let M be the minimal non-negative integer such that $W_M\neq 0$.

Lemma 3.1:[4] *Suppose that $M\geqslant 0$. Then $\mathbb{C}[\partial]W_M=\mathbb{C}[\partial]\otimes W_M$ and hence $\mathbb{C}[\partial]W_M\cap W_M=W_M$. In particular W_M is a finite-dimensional vector space.*

Let $\mathfrak{g}$ be a Lie superalgebra satisfying the following three conditions.

(L1) $\mathfrak{g}$ is $\mathbb{Z}$-graded of finite depth $d\in\mathbb{N}$, i.e., $\mathfrak{g}=\oplus_{j\geqslant -d}\mathfrak{g}_j$ with $[\mathfrak{g}_i,\mathfrak{g}_j]\subset\mathfrak{g}_{i+j}$.

(L2) There exists a semisimple element $z\in\mathfrak{g}_0$ such that its centralizer in $\mathfrak{g}$ is contained in $\mathfrak{g}_0$.

(L3) There exists an element $\partial \in \mathfrak{g}_{-d}$ such that $[\partial, \mathfrak{g}_i] = \mathfrak{g}_{i-d}$, for $i \geqslant 0$.

Remark 3.1: If $\mathfrak{g}$ contains the grading operator with respect to its gradation, then condition (L2) is automatic.

Examples of Lie superalgebras satisfying (L1)–(L3) are provided by annihilation subalgebras of superconformal algebras, which we will describe in more detail.

Let t be an even indeterminate and $\xi_1, \ldots, \xi_N$ be N odd indeterminate. Denote by $\Lambda(N)$ the Grassmann superalgebra in the indeterminates $\xi_1, \ldots, \xi_N$ and set $\Lambda(1,N) := \mathbb{C}[t, t^{-1}] \otimes \Lambda(N)$. Let $\mathrm{W}(1,N)$ be the derivation superalgebra of $\Lambda(1,N)$. Then $\mathrm{W}(1,N)$ is a formal distribution Lie superalgebra.[8] Letting $\partial/\partial t$ and $\partial/\partial \xi_i$, for $i = 1, \ldots, N$, be the usual differential operators, every element in $D \in \mathrm{W}(1,N)$ can be written as[9]

$$D = a_0 \frac{\partial}{\partial t} + \sum_{i=1}^{N} a_i \frac{\partial}{\partial \xi_i}, \quad a_0, a_i, \ldots, a_N \in \Lambda(1,N).$$

The *standard gradation* of $\mathrm{W}(1,N)$ is obtained by setting the degree of t and ξ_i to be 1. Its annihilation subalgebra is $\mathrm{W}(1,N)_+ = \oplus_{j \geqslant -1} (\mathrm{W}(1,N))_j$. $\mathrm{W}(1,N)_+$ in this gradation contains its grading operator given by $z = t\,\partial/\partial t + \Sigma_{i=1}^{N} \xi_i\,\partial/\partial \xi_i$ so that (L2) is satisfied. Also choosing ∂ to be $\partial/\partial t$ it follows that (L3) is also satisfied so that $\mathrm{W}(1,N)$ is a Lie superalgebra of the type above. Note that $\mathrm{W}(1,N)_0 \cong \mathrm{gl}(1,N)$.

The subalgebra of divergence zero vector fields in $\mathrm{W}(1,N)$ contains an ideal of codimension 1. This ideal is its derived algebra and is the superconformal algebra $\mathrm{S}(1,N)$.[8] The standard gradation of $\mathrm{W}(1,N)_+$ induces a gradation on the annihilation subalgebra $\mathrm{S}(1,N)_+$ of $\mathrm{S}(1,N)$. Choosing $z = t\,\partial/\partial t + (1/N)\,\Sigma_{i=1}^{N} \xi_i\,\partial/\partial \xi_i$ along with $\partial = \partial/\partial t$ it follows that $\mathrm{S}(1,N)_+$ in this gradation also satisfies (L1)–L(3). Observe that $\mathrm{S}(1,N)_0 \cong \mathrm{sl}(1,N)$ and also that the ''small'' $N=4$ superconformal algebra (to be defined in Sec. VI) is isomorphic to $\mathrm{S}(1,2)$.[10]

The contact superalgebra $\mathrm{K}(1,N)$ is the subalgebra of $\mathrm{W}(1,N)$ defined by

$$\mathrm{K}(1,N) := \{D \in \mathrm{W}(1,N) \,|\, D\omega = f_D \omega, \quad \text{for some} \quad f_D \in \Lambda(1,N)\},$$

where $\omega := dt - \Sigma_{i=1}^{N} \xi_i d\xi_i$ is the standard contact form. Here the action of D on ω is the usual action of vector fields on differential forms.

The map from $\Lambda(1,N)$ to $\mathrm{K}(1,N)$ given by

$$f \to 2\,f \frac{\partial}{\partial t} + (-1)^{p(f)} \sum_{i=1}^{N} \left(\xi_i \frac{\partial f}{\partial t} + \frac{\partial f}{\partial \xi_i} \right) \left(\xi_i \frac{\partial}{\partial t} + \frac{\partial}{\partial \xi_i} \right)$$

is a bijection and hence it allows us to identify $\mathrm{K}(1,N)$ with the polynomial superalgebra $\Lambda(1,N)$. The Lie bracket in $\Lambda(1,N)$, also called the contact bracket, then reads for homogeneous elements $f, g \in \Lambda(1,N)$

$$[f,g] = (2-E) f \frac{\partial g}{\partial t} - \frac{\partial f}{\partial t} (2-E) g + (-1)^{p(f)} \sum_{i=1}^{N} \frac{\partial f}{\partial \xi_i} \frac{\partial g}{\partial \xi_i},$$

where $E = \Sigma_{i=1}^{N} \xi_i\,\partial/\partial \xi_i$ is the Euler operator.

When N is even it is sometimes more convenient to make the change of basis $\xi_j^+ = (1/\sqrt{2})\,(\xi_j + i\xi_{j+N/2})$ and $\xi_j^- = (1/\sqrt{2})\,(\xi_j - i\xi_{j+N/2})$, for $j = 1, \ldots, N/2$ and $i = \sqrt{-1}$, so that the contact bracket takes the split form:

$$[f,g] = (2-E) f \frac{\partial g}{\partial t} - \frac{\partial f}{\partial t} (2-E) g + (-1)^{p(f)} \sum_{i=1}^{N/2} \left(\frac{\partial f}{\partial \xi_i^+} \frac{\partial g}{\partial \xi_i^-} + \frac{\partial f}{\partial \xi_i^-} \frac{\partial g}{\partial \xi_i^+} \right),$$

where E again is the Euler operator $\Sigma_{i=1}^{N/2} (\xi_i^+\,\partial/\partial \xi_i^+ + \xi_i^-\,\partial/\partial \xi_i^-)$.

The contact superalgebra K(1,N) is a formal distribution Lie superalgebra with fields defined as follows: Let $I=\{i_1,\ldots,i_k\}$ be an ordered subset of $\{1,\ldots,N\}$, and denote by ξ_I the monomial $\xi_{i_1}\cdots\xi_{i_k}$. Each such monomial gives rise to a field $\xi_I(z)=\Sigma_{j\in\mathbb{Z}}\xi_I t^j z^{-j-1}$. Evidently the span of the coefficients of all such $\xi_I(z)$ is K(1,N). Furthermore, it is easy to check that these fields are mutually local and form a formal distribution Lie superalgebra. This Lie superalgebra becomes $\mathbb{Z}$-graded by putting the degree of $\xi_I t^n$ to $2n+k-2$. Obviously t is the grading operator of this gradation. This gradation of K(1,N) is usually referred to as its *standard gradation.*

The annihilation subalgebra K(1,N)$_+$ of K(1,N) is spanned by the basis elements $\xi_I t^n$, where $n\geqslant 0$ and I runs over all subsets of $\{i_1,\ldots,i_k\}$ ordered in (strictly) increasing order. The $\mathbb{Z}$-gradation from K(1,N) induces a gradation on K(1,N)$_+$ making it a $\mathbb{Z}$-graded Lie superalgebra of depth 2 so that $\mathrm{K}(1,N)_+=\oplus_{j=-2}^{\infty}(K(1,N)_+)_j$ satisfies (L1) and (L2). In this gradation it is easy to check that $[1,(K(1,N)_+)_j]=(K(1,N)_+)_{j-2}$ for all $j\geqslant 0$, so that K(1,N)$_+$ also satisfies condition (L3). It is easy to see that the annihilation subalgebra of the small $N=4$ superconformal algebra, which we define in Sec. VI, also satisfies conditions (L1)–(L3). Note that $\mathrm{K}(1,N)_0\cong c\,\mathrm{so}_N$, the direct sum of the Lie algebra so_N and the one-dimensional Lie algebra.

Finally, it follows from the description of the exceptional superconformal algebra CK_6 as a subalgebra of K(1,6) in Ref. 11 that its annihilation subalgebra $(\mathrm{CK}_6)_+=\oplus_{j\geqslant -2}(\mathrm{CK}_6)_j$ is a Lie superalgebra satisfying (L1)–(L3) with $(\mathrm{CK}_6)_0\cong c\,\mathrm{so}_6$.

The modules over the annihilation subalgebras that are equivalent to modules over the corresponding conformal superalgebras are then $\mathfrak{g}$-modules V satisfying the following conditions.

(V1) For all $v\in V$ there exists an integer $k_0\geqslant -d$ (depending on v) such that $\mathfrak{g}_k v=0$, for all $k\geqslant k_0$.

(V2) V is finitely generated over $\mathbb{C}[\partial]$.

We shall call $\mathfrak{g}$-modules satisfying these two properties *finite*. Let V be a finite irreducible $\mathfrak{g}$-module. For $n\geqslant -d-1$ set $V_n=\{v\in V|\mathfrak{g}_j v=0,\forall j>n\}$. Let N be the minimal integer such that $V_N\neq 0$. Such an N exists by (V1).

Lemma 3.2: If $N\geqslant 0$, then V_N is a finite-dimensional vector space over $\mathbb{C}$.

Proof: We let $\mathcal{L}=\mathfrak{g}$ and put $\mathcal{L}_j=\oplus_{i\geqslant jd}\mathfrak{g}_i$ so that we have a filtration of subspaces

$$\mathcal{L}\supset\mathcal{L}_0\supset\mathcal{L}_1\supset\mathcal{L}_2\supset\cdots\supset\mathcal{L}_n\supset\cdots,$$

with $[\partial,\mathcal{L}_i]=\mathcal{L}_{i-1}$, for all $i\geqslant 0$ by (L3). Let $W_m:=\{v\in V|\mathcal{L}_{m+1}v=0\}$ and let M be the minimal integer such that $W_M\neq 0$. Since $N\geqslant 0$ implies that $M\geqslant 0$, this setting puts us in the situation of Lemma 3.1, from which we conclude that W_M is a finite-dimensional vector space over $\mathbb{C}$. Of course $V_N\subset W_M$ and hence it follows that V_N is finite-dimensional as well. □

We obtain the following description of finite irreducible $\mathfrak{g}$-modules.

Theorem 3.1: *Let $\mathfrak{g}=\oplus_{j\geqslant -d}\mathfrak{g}_j$ be a Lie superalgebra satisfying conditions (L1)–(L3) and V be a finite irreducible $\mathfrak{g}$-module. There exists a finite-dimensional irreducible $\mathfrak{g}_0$-module U_0, extended trivially to an $\mathcal{L}_0(=\oplus_{j\geqslant 0}\mathfrak{g}_j)$-module, and a $\mathfrak{g}$-epimorphism φ: $\mathrm{Ind}_{\mathcal{L}_0}^{\mathfrak{g}}U_0\to V$.*

Proof: We will continue to use the notation defined earlier. First we show that $N\leqslant 0$. Suppose that $N>0$. It is easy to see that V_N is invariant under $\mathcal{L}_0$. Now there exists a basis $\{x_1,\ldots,x_m\}$ of $\mathfrak{g}_N$ together with nonzero complex number $\lambda_1,\ldots,\lambda_m$ such that $[z,x_i]=\lambda_i x$, where z is the element of (L2). Since V_N is a finite-dimensional vector space it follows in particular that x_i acts nilpotently on V_N for all $1\leqslant i\leqslant m$. But $[\mathfrak{g}_N,\mathfrak{g}_N]\subset\oplus_{j\geqslant N+1}\mathfrak{g}_j$ and so the action of the x_i's on V_N commutes. Therefore there exits a nonzero $v\in V_N$ such that $\mathfrak{g}_N v=0$. But in this case $V_{N-1}\neq 0$, which contradicts the minimality of N. Thus $N\leqslant 0$.

In the case when $N=0$, there exists an epimorphism of $\mathfrak{g}$-modules $\mathrm{Ind}_{\mathcal{L}_0}^{\mathfrak{g}}V_0\to V$, with V_0 finite-dimensional due to Lemma 3.2. By irreducibility of V it follows that $V_0=U_0$ is an irreducible $\mathfrak{g}_0$-module. Now if $N<0$, then there exists a nonzero vector v invariant under the action of $\mathfrak{g}_j$, for $j\geqslant 0$. Again we have an epimorphism of $\mathfrak{g}$-modules $\mathrm{Ind}_{\mathcal{L}_0}^{\mathfrak{g}}\mathbb{C}v\to V$. □

As a corollary of Theorem 3.1 we obtain the following.

Corollary 3.1: There exists a bijection between finite irreducible conformal modules of the

superconformal algebra $\mathfrak{g}$ *and finite-dimensional irreducible representations of the Lie (super)algebra* $\mathfrak{g}_0$, *where*

(*i*) $\mathfrak{g}=\mathrm{K}(1,N)$ *and* $\mathfrak{g}_0=c\mathrm{so}_N$,
(*ii*) $\mathfrak{g}=\mathrm{W}(1,N)$ *and* $\mathfrak{g}_0=\mathrm{gl}(1,N)$,
(*iii*) $\mathfrak{g}=\mathrm{S}(1,N)$ *and* $\mathfrak{g}_0=\mathrm{sl}(1,N)$, *and*
(*iv*) $\mathfrak{g}=CK_6$ *and* $\mathfrak{g}_0=c\mathrm{so}_6$.

Proof: By Theorem 3.1 every finite irreducible $\mathfrak{g}$-module is a homomorphic image of $\mathrm{Ind}_{\mathcal{L}_0}^{\mathfrak{g}}U_0$. Now the usual argument for highest weight representations implies that given a finite-dimensional irreducible $\mathfrak{g}_0$-module U_0 the $\mathfrak{g}$-module $\mathrm{Ind}_{\mathcal{L}_0}^{\mathfrak{g}}U_0$ contains a unique maximal submodule, from which the bijection then follows. □

Remark 3.2: It is usual to put a half-integer gradation on $\mathrm{K}(1,N)$ when thinking of it as a superconformal algebra. The grading operator of $\mathrm{K}(1,N)$ with respect to this gradation is then $t/2$ rather than t. In this gradation one has $\mathrm{K}(1,N)_+=\oplus_{j\geqslant -1}\mathfrak{g}_j$, where $j\in\frac{1}{2}\mathbb{Z}$. Theorem 3.1 of course remains valid after making some obvious changes regarding gradation. For a Lie superalgebra $\mathfrak{g}=\oplus_{j\geqslant -1}\mathfrak{g}_j$ with $j\in\frac{1}{2}\mathbb{Z}$, we will make it a convention to write $\mathfrak{g}_-$ for the subalgebra $\oplus_{j<0}\mathfrak{g}_j$.

IV. FINITE IRREDUCIBLE MODULES OVER THE $N=2$ CONFORMAL SUPERALGEBRA

The $N=2$ superconformal algebra is the formal distribution Lie superalgebra $\mathrm{K}(1,2)$. Letting ξ^+,ξ^- denote the two odd indeterminates (so that we are using the split contact form), this algebra is generated by the following four fields: $L(z)=\Sigma_{n\in\mathbb{Z}}-(t^{n+1}/2)z^{-n-2}$, $G^{\pm}(z)=\Sigma_{r\in(1/2)+\mathbb{Z}}\xi^{\pm}t^{r+1/2}z^{-r-3/2}$ and $J(z)=\Sigma_{n\in\mathbb{Z}}\xi^-\xi^+t^nz^{-n-1}$. Its corresponding conformal superalgebra is then generated freely over $\mathbb{C}[\partial]$ by $\{L,J,G^{\pm}\}$ with products

$$L_\lambda L=(\partial+2\lambda)L,\quad L_\lambda J=(\partial+\lambda)J,\quad L_\lambda G^{\pm}=(\partial+\tfrac{3}{2}\lambda)G^{\pm},$$

$$J_\lambda G^{\pm}=\pm G^{\pm},\quad G^+_\lambda G^-=(\partial+2\lambda)J+2L.$$

Letting $L_n=-t^{n+1}/2$, $G^{\pm}_r=\xi^{\pm}t^{r+1/2}$ and $J_n=\xi^-\xi^+t^n$ with $n\in\mathbb{Z}$, $r\in\frac{1}{2}+\mathbb{Z}$, the non-zero brackets in $\mathrm{K}(1,2)$ are ($m,n\in\mathbb{Z}$ and $r,s\in\frac{1}{2}+\mathbb{Z}$)

$$[L_m,L_n]=(m-n)L_{m+n},\quad [L_m,G^{\pm}_r]=\left(\frac{m}{2}-r\right)G^{\pm}_{m+r},\quad [L_m,J_n]=-nJ_{n+m},$$

$$[J_m,G^{\pm}_r]=\pm G^{\pm}_{m+r},\quad [G^+_r,G^-_s]=2L_{r+s}+(r-s)J_{r+s}.$$

The annihilation subalgebra $\mathfrak{g}=\mathrm{K}(1,2)_+$ is then spanned by L_m, J_n and $G^{\pm}_r$, where $m\geqslant -1$, $n\geqslant 0$ and $r\geqslant -\frac{1}{2}$. Note that letting $\mathfrak{g}_j$ be the span of X_j, where $X=L,J,G^{\pm}$, equips $\mathfrak{g}=\oplus_{j\geqslant -1}\mathfrak{g}_j$, $j\in\frac{1}{2}\mathbb{Z}$, with a (consistent) $\frac{1}{2}\mathbb{Z}$-gradation. We denote L_{-1} by ∂ from now on.

Let $\mathbb{C}v_{\Delta,\Lambda}$, $\Delta,\Lambda\in\mathbb{C}$, be the one-dimensional module over the abelian Lie algebra $\mathfrak{g}_0=\mathbb{C}L_0+\mathbb{C}J_0$, determined by

$$L_0v_{\Delta,\Lambda}=\Delta v_{\Delta,\Lambda},\quad J_0v_{\Delta,\Lambda}=\Lambda v_{\Delta,\Lambda}.$$

We may extend $\mathbb{C}v_{\Delta,\Lambda}$ to a module over $\mathcal{L}_0=\oplus_{j\geqslant 0}\mathfrak{g}_j$ by setting $\mathfrak{g}_jv_{\Delta,\Lambda}=0$, for $j>0$. Let $M_{\mathfrak{N}^2_+}(\Delta,\Lambda):=\mathrm{Ind}_{\mathcal{L}_0}^{\mathfrak{g}}\mathbb{C}v_{\Delta,\Lambda}$. We denote by N the unique maximal submodule of $M_{\mathfrak{N}^2_+}(\Delta,\Lambda)$. The quotient $M_{\mathfrak{N}^2_+}(\Delta,\Lambda)/N$ is the irreducible highest weight module $L_{\mathfrak{N}^2_+}(\Delta,\Lambda)$ of highest weight (Δ,Λ). By Theorem 3.1 $L_{\mathfrak{N}^2_+}(\Delta,\Lambda)$ for $\Delta,\Lambda\in\mathbb{C}$ form a complete list of finite irreducible $\mathrm{K}(1,2)_+$-modules. Our next objective is to give a more explicit description of N and hence of $L_{\mathfrak{N}^2_+}(\Delta,\Lambda)$.

It is clear that $\partial^kv_{\Delta,\Lambda}$, $\partial^kG^+_{-1/2}v_{\Delta,\Lambda}$, $\partial^kG^-_{-1/2}v_{\Delta,\Lambda}$ and $\partial^kG^+_{-1/2}G^-_{-1/2}v_{\Delta,\Lambda}$, $k\geqslant 0$, is a basis consisting of (L_0,J_0)-weight vectors for $M_{\mathfrak{N}^2_+}(\Delta,\Lambda)$ of (L_0,J_0)-weights $(\Delta+k,\Lambda)$, $(\Delta+k$

$+\frac{1}{2},\Lambda+1)$, $(\Delta+k+\frac{1}{2},\Lambda-1)$ and $(\Delta+k+1,\Lambda)$, respectively. A nonzero (L_0,J_0)-weight vector $v\in M_{\mathfrak{N}_+^2}(\Delta,\Lambda)$ is called a *singular vector* if $\mathfrak{g}_j v=0$, for all $j>0$. We call a singular vector *proper* if it is not a scalar multiple of the highest weight vector $v_{\Delta,\Lambda}$. Obviously $M_{\mathfrak{N}_+^2}(\Delta,\Lambda)$ is irreducible if and only if $M_{\mathfrak{N}_+^2}(\Delta,\Lambda)$ contains no proper singular vector. We now analyze singular vectors inside $M_{\mathfrak{N}_+^2}(\Delta,\Lambda)$.

Lemma 4.1: Let $k\geqslant 1$ and suppose that $w=\alpha\partial^k v_{\Delta,\Lambda}+\beta\partial^{k-1}G^+_{-1/2}G^-_{-1/2}v_{\Delta,\Lambda}$ is a singular vector of (L_0,J_0)-weight $(\Delta+k,\Lambda)$ in $M_{\mathfrak{N}_+^2}(\Delta,\Lambda)$, where $\alpha,\beta\in\mathbb{C}$. Then $k=1$. Furthermore, any proper singular vector of this form is a scalar multiple of either $G^+_{-1/2}G^-_{-1/2}v_{\Delta,\Lambda}$, in which case $\Delta=-\frac{1}{2}$ and $\Lambda=1$, or $(-2\partial+G^+_{-1/2}G^-_{-1/2})v_{\Delta,\Lambda}$, in which case $\Delta=-\frac{1}{2}$ and $\Lambda=-1$.

Proof: Note that w is singular if and only if $J_1 w=G^{\pm}_{1/2}w=0$. We compute

$$G^+_{1/2}w=(\alpha k-\beta(2\Delta+\Lambda))\partial^{k-1}G^+_{-1/2}v_{\Delta,\Lambda}=0, \tag{4.1}$$

$$G^-_{1/2}w=(\alpha k+\beta(2\Delta-\Lambda+2k))\partial^{k-1}G^-_{-1/2}v_{\Delta,\Lambda}=0, \tag{4.2}$$

$$J_1 w=(\alpha\Lambda k+\beta(2\Delta+\Lambda))\partial^{k-1}v_{\Delta,\Lambda}+\beta(k-1)\Lambda\partial^{k-2}G^+_{-1/2}G^-_{-1/2}v_{\Delta,\Lambda}=0. \tag{4.3}$$

But then $\beta\neq 0$, since otherwise (4.1) would imply that $k=0$. However, $\beta\neq 0$ together with (4.1) and (4.2) implies that

$$2\Delta+k=0. \tag{4.4}$$

Now (4.3) gives

$$\alpha\Lambda k+\beta(2\Delta+\Lambda)=0,\quad \beta(k-1)\Lambda=0. \tag{4.5}$$

Now if $k>1$, then (4.5) gives $\Lambda=0$ and $\Delta=0$. But then $k=0$ by (4.1). Hence $k=1$ so that by (4.4) we have $\Delta=-\frac{1}{2}$.

Now if $\alpha\neq 0$, we have from (4.1) and (4.3) $\alpha(1+\Lambda)=0$ and hence $\Lambda=-1$. The first equation of (4.5) then implies that $\alpha+2\beta=0$.

On the other hand, if $\alpha=0$, the first equation of (4.5) gives $\Lambda=1$. □

Lemma 4.2: Let $k\in\mathbb{Z}_+$.

(*i*) *If $\partial^k G^+_{-1/2}v_{\Delta,\Lambda}$ is a singular vector of (L_0,J_0)-weight $(\Delta+k+\frac{1}{2},\Lambda+1)$, then $k=0$ and $2\Delta-\Lambda=0$. Furthermore, in this case $G^+_{-1/2}v_{\Delta,\Lambda}$ is a singular vector.*

(*ii*) *If $\partial^k G^-_{-1/2}v_{\Delta,\Lambda}$ is a singular vector of (L_0,J_0)-weight $(\Delta+k+\frac{1}{2},\Lambda-1)$, then $k=0$ and $2\Delta+\Lambda=0$. Furthermore, in this case $G^-_{-1/2}v_{\Delta,\Lambda}$ is a singular vector.*

Proof: The lemma follows immediately from the following two equations:

$$G^-_{1/2}\partial^k G^+_{-1/2}v_{\Delta,\Lambda}=(2\Delta-\Lambda+2k)\partial^k v_{\Delta,\Lambda}+k\partial^{k-1}G^+_{-1/2}G^-_{-1/2}v_{\Delta,\Lambda}=0,$$

$$G^+_{1/2}\partial^k G^-_{-1/2}v_{\Delta,\Lambda}=(2\Delta+\Lambda)\partial^k v_{\Delta,\Lambda}+k\partial^{k-1}G^+_{-1/2}G^-_{-1/2}v_{\Delta,\Lambda}=0.$$

□

Thus Lemmas 4.1 and 4.2 prove the following.

Proposition 4.1: Any proper singular vector in $M_{\mathfrak{N}_+^2}(\Delta,\Lambda)$ is a scalar multiple of the following.

(*i*) *$G^+_{-1/2}v_{\Delta,\Lambda}$, in which case we have $2\Delta-\Lambda=0$. In the particular case of $\Delta=-\frac{1}{2}$ and $\Lambda=-1$ we have in addition $G^-_{-1/2}G^+_{-1/2}v_{\Delta,\Lambda}$.*

(*ii*) *$G^-_{-1/2}v_{\Delta,\Lambda}$, in which case we have $2\Delta+\Lambda=0$. In the particular case of $\Delta=-\frac{1}{2}$ and $\Lambda=1$ we have in addition $G^+_{-1/2}G^-_{-1/2}v_{\Delta,\Lambda}$.*

Let N be the subspace of $M_{\mathfrak{N}_+^2}(\Delta,\Lambda)$ given by

$$N=\mathbb{C}[\partial]G^+_{-1/2}v_{\Delta,\Lambda}+\mathbb{C}[\partial]G^-_{-1/2}G^+_{-1/2}v_{\Delta,\Lambda}, \quad \text{if } 2\Delta-\Lambda=0 \text{ and } \Lambda\neq 0,$$

$$N=\mathbb{C}[\partial]G^-_{-1/2}v_{\Delta,\Lambda}+\mathbb{C}[\partial]G^+_{-1/2}G^-_{-1/2}v_{\Delta,\Lambda}, \quad \text{if } 2\Delta+\Lambda=0 \text{ and } \Lambda\neq 0.$$

It follows from Proposition 4.1 that in either case N is a submodule of $M_{\mathfrak{N}_+^2}(\Delta,\Lambda)$.

Theorem 4.1: *The modules $L_{\mathfrak{N}_+^2}(\Delta,\Lambda)$, for $\Delta,\Lambda\in\mathbb{C}$, form a complete list of nonisomorphic finite (over $\mathbb{C}[\partial]$) irreducible* $\mathrm{K}(1,2)_+$*-modules. Furthermore, $L_{\mathfrak{N}_+^2}(\Delta,\Lambda)$ as a $\mathbb{C}[\partial]$-module has rank*

(*i*) 4, *in the case* $2\Delta\pm\Lambda\neq 0$,
(*ii*) 2, *in the case* $2\Delta\pm\Lambda=0$ *and* $2\Delta\mp\Lambda\neq 0$, *and*
(*iii*) 0, *in the case* $\Delta=\Lambda=0$.

Proof: If $2\Delta+\Lambda\neq 0$ and $2\Delta-\Lambda\neq 0$, then by Proposition 4.1 $M_{\mathfrak{N}_+^2}(\Delta,\Lambda)$ contains no proper singular vector and hence is irreducible.

Suppose that $2\Delta+\Lambda=0$ and $2\Delta-\Lambda\neq 0$. In this case consider the submodule of $M_{\mathfrak{N}_+^2}(\Delta,\Lambda)$ generated by the singular vector $G^-_{-1/2}v_{\Delta,\Lambda}$. This module is precisely N above and hence $M_{\mathfrak{N}_+^2}(\Delta,\Lambda)/N$ is freely generated over $\mathbb{C}[\partial]$ by $v_{\Delta,\Lambda}$ and $G^+_{-1/2}v_{\Delta,\Lambda}$. We claim that $M_{\mathfrak{N}_+^2}(\Delta,\Lambda)/N$ is irreducible. The even part of $\mathrm{K}(1,2)_+$ is isomorphic to the semi-direct sum of $\mathfrak{V}_+$ (generated by L_n) and $\tilde{\mathfrak{g}}_+$ (generated by J_n), where $\mathfrak{g}$ is the one-dimensional Lie algebra. We first consider $M_{\mathfrak{N}_+^2}(\Delta,\Lambda)/N$ as a module over the $\mathfrak{V}_+\ltimes\tilde{\mathfrak{g}}_+$. The vectors $v_{\Delta,\Lambda}$ and $G^+_{1/2}v_{\Delta,\Lambda}$ have (L_0,J_0)-weights (Δ,Λ) and $(\Delta+\frac{1}{2},\Lambda+1)$, respectively, and, furthermore, both are annihilated by L_n and J_n, for $n\geqslant 1$. Now since $2\Delta+\Lambda=0$ and $2\Delta-\Lambda\neq 0$, we have $(\Delta,\Lambda)\neq(0,0)$ and $(\Delta+\frac{1}{2},\Lambda+1)\neq(0,0)$. From this it follows that $M_{\mathfrak{N}_+^2}(\Delta,\Lambda)/N$ as a module over $\mathfrak{V}_+\ltimes\tilde{\mathfrak{g}}_+$ is a direct sum of two non-isomorphic irreducible modules, namely $\mathbb{C}[\partial]v_{\Delta,\Lambda}\cong L_{\mathfrak{V}_+\ltimes\tilde{\mathfrak{g}}_+}(\Delta,\Lambda)$ and $\mathbb{C}[\partial]G^+_{-1/2}v_{\Delta,\Lambda}\cong L_{\mathfrak{V}_+\ltimes\tilde{\mathfrak{g}}_+}(\Delta+\frac{1}{2},\Lambda+1)$ (see Sec. II for notation). But we have

$$G^-_{1/2}G^+_{-1/2}v_{\Delta,\Lambda}=(2\Delta-\Lambda)v_{\Delta,\Lambda}\neq 0,$$

which implies that as a $\mathrm{K}(1,2)_+$-module $L_{\mathfrak{N}_+^2}(\Delta,\Lambda)$ is irreducible.

The case when $2\Delta-\Lambda=0$ and $2\Delta+\Lambda\neq 0$ is completely analogous and we leave it to the reader.

Finally, in the case when $\Delta=\Lambda=0$, both $G^+_{-1/2}v_{\Delta,\Lambda}$ and $G^-_{-1/2}v_{\Delta,\Lambda}$ are proper singular vectors. Now the submodule in $M_{\mathfrak{N}_+^2}(0,0)$ generated by these two vectors contains $[G^+_{-1/2},G^-_{-1/2}]v_{\Delta,\Lambda}=2\partial v_{\Delta,\Lambda}$, and hence has codimension 1 over $\mathbb{C}$. So the resulting quotient is the trivial module. □

It follows that every finite irreducible module over the $N=2$ conformal superalgebra is of the form $L_{\mathfrak{N}^2}(\alpha,\Delta,\Lambda)$, where $\alpha,\Delta,\Lambda\in\mathbb{C}$. We will write down explicit formulas for the action of the conformal superalgebra on such irreducible modules in the generating series form. Since we have already explained in Sec. II how such formulas can be obtained in general, we will omit the proofs.

In the case when $2\Delta\pm\Lambda\neq 0$ the module $L_{\mathfrak{N}^2}(\alpha,\Delta,\Lambda)$ is generated freely over $\mathbb{C}[\partial]$ by two even vectors v,v^{+-} and two odd vectors v^+,v^-. We have the following action on the generators:

$$L_\lambda v=(\partial+\alpha+\Delta\lambda)v, \quad L_\lambda v^\pm=(\partial+\alpha+(\Delta+\tfrac{1}{2})\lambda)v^\pm,$$

$$L_\lambda v^{+-}=(\partial+\alpha+(\Delta+1)\lambda)v^{+-}+\left(\Delta+\frac{\Lambda}{2}\right)\lambda^2 v,$$

$$J_\lambda v=\Lambda v,\quad J_\lambda v^{\pm}=(\Lambda\pm 1)v^{\pm},\quad J_\lambda v^{+-}=\Lambda v^{+-}+(2\Delta+\Lambda)\lambda v,$$

$$G^{\pm}_\lambda v=v^{\pm},\quad G^{+}_\lambda v^{+}=G^{-}_\lambda v^{-}=0,\quad G^{+}_\lambda v^{-}=v^{+-}+(2\Delta+\Lambda)\lambda v,$$

$$G^{+}_\lambda v^{+-}=-\lambda(2\Delta+\Lambda)v^{+},\quad G^{-}_\lambda v^{+}=(2\partial+2\alpha+\lambda(2\Delta-\Lambda))v-v^{+-},$$

$$G^{-}_\lambda v^{+-}=(2\partial+2\alpha+(2\Delta+2-\Lambda)\lambda)v^{-}.$$

In the case when $2\Delta+\Lambda=0$ but $2\Delta-\Lambda\neq 0$ the module $L_{\mathfrak{N}^2}(\alpha,\Delta,\Lambda)$ is generated freely over $\mathbb{C}[\partial]$ by one even vector v and one odd vector v^{+}. The action is then given by

$$L_\lambda v=(\partial+\alpha+\Delta\lambda)v,\quad L_\lambda v^{+}=(\partial+\alpha+(\Delta+\tfrac{1}{2})\lambda)v^{+},$$

$$J_\lambda v=-2\Delta v,\quad J_\lambda v^{+}=(-2\Delta+1)v^{+},\quad G^{+}_\lambda v=v^{+},\quad G^{+}_\lambda v^{+}=0,$$

$$G^{-}_\lambda v=0,\quad G^{-}_\lambda v^{+}=(2\partial+2\alpha+4\Delta\lambda)v.$$

In the case $2\Delta-\Lambda=0$ but $2\Delta+\Lambda\neq 0$ the module $L_{\mathfrak{N}^2}(\alpha,\Delta,\Lambda)$ is generated freely over $\mathbb{C}[\partial]$ by one even vector v and one odd vector v^{-} with action:

$$L_\lambda v=(\partial+\alpha+\Delta\lambda)v,\quad L_\lambda v^{-}=(\partial+\alpha+(\Delta+\tfrac{1}{2})\lambda)v^{-},$$

$$J_\lambda v=2\Delta v,\quad J_\lambda v^{-}=(2\Delta-1)v^{-},\quad G^{+}_\lambda v=0,$$

$$G^{+}_\lambda v^{-}=(2\partial+2\alpha+4\Delta\lambda)v,\quad G^{-}_\lambda v=v^{-},\quad G^{-}_\lambda v^{-}=0.$$

Finally $L_{\mathfrak{N}^2}(\alpha,0,0)$ is the one-dimensional trivial module on which ∂ acts as the scalar α.

Remark 4.1: We note that the formulas above are obtained by first putting $v=v_{\Delta,\Lambda}$, $v^{\pm}=G^{\pm}_{-1/2}v_{\Delta,\Lambda}$ and $v^{+-}=G^{+}_{-1/2}G^{-}_{-1/2}v_{\Delta,\Lambda}$ and then compute the action of the operators L_n, J_m and $G^{\pm}_r$, for $n\geqslant -1$, $m\geqslant 0$ and $r\geqslant -\frac{1}{2}$ on these vectors. Translation into the language of conformal modules is an easy task using these formulas and we will omit this. Of course the parity of the vectors $v,v^{\pm},v^{+-}$ in all the examples above can be reversed. Finally, we note that the adjoint module is isomorphic to $L_{\mathfrak{N}^2}(0,1,0)$.

V. FINITE IRREDUCIBLE MODULES OVER THE *N*=3 CONFORMAL SUPERALGEBRA

The $N=3$ superconformal algebra is the formal distribution Lie superalgebra K(1,3). Letting ξ_1,ξ_2,ξ_3 be the three odd indeterminates K(1,3) is spanned over $\mathbb{C}$ by the following basis elements ($n\in\mathbb{Z}$ and $r\in\frac{1}{2}+\mathbb{Z}$):

$$L_n=-\frac{t^{n+1}}{2},\quad H_n=2i\xi_1\xi_2t^n,\quad E_n=(-\xi_1\xi_3-i\xi_2\xi_3)t^n,\quad F_n=(\xi_1\xi_3-i\xi_2\xi_3)t^n,$$

$$\Psi_r=-\xi_1\xi_2\xi_3t^{r-1/2},\quad h_r=-2i\xi_3t^{r+1/2},\quad e_r=(i\xi_1-\xi_2)t^{r+1/2},\quad f_r=(i\xi_1+\xi_2)t^{r+1/2}.$$

Let $\{H,E,F\}$ denote the standard basis of the Lie algebra sl_2 and $\{h,e,f\}$ denote the standard basis of its adjoint module. Furthermore, we let $(\cdot|\cdot)$ denote the non-degenerate invariant symmetric bilinear form on sl_2 with $(H|H)=2$. Keeping this notation in mind the commutation relations of K(1,3) are then given as follows (where $X,Y=H,E,F$ and $x,y=h,e,f$):

$$[L_m,L_n]=(m-n)L_{m+n},\quad [L_m,X_n]=-nX_{m+n},\quad [L_m,x_r]=\left(\frac{m}{2}-r\right)x_{m+r},$$

$$[L_m,\Psi_r]=\left(-\frac{m}{2}-r\right)\Psi_{m+r},\quad [X_m,Y_n]=[X,Y]_{m+n},\quad [X_m,\Psi_r]=0,$$

$$[X_m,y_r]=[X,y]_{m+r}+2m(X|Y)\Psi_{m+r},\quad [x_r,\Psi_s]=-X_{r+s},\quad [\Psi_r,\Psi_s]=0,$$

$$[x_r,y_s]=-(r-s)[X,Y]_{r+s}-4(X|Y)L_{r+s},$$

where $m,n\in\mathbb{Z}$ and $r,s\in\frac{1}{2}+\mathbb{Z}$. Above we have written $[X,y]$ for the action of X on y. The eight formal distributions generating this algebra are given by $L(z)=\Sigma_{n\in\mathbb{Z}}L_nz^{-n-2}$, $X(z)=\Sigma_{n\in\mathbb{Z}}X_nz^{-n-1}$, $x(z)=\Sigma_{r\in 1/2+\mathbb{Z}}x_rz^{-r-3/2}$ and $\Psi(z)=\Sigma_{r\in 1/2+\mathbb{Z}}\Psi_rz^{-r-1/2}$. The corresponding operator product expansions of these fields are easily derived from (2.3), and so we will omit them.

The annihilation subalgebra $\mathrm{K}(1,3)_+$ is equipped with a $\frac{1}{2}\mathbb{Z}$-gradation of depth 1, i.e., $\mathrm{K}(1,3)_+=\mathfrak{g}=\oplus_{j\geqslant -1}\mathfrak{g}_j$, $j\in\frac{1}{2}\mathbb{Z}$, and its zeroth graded component $\mathfrak{g}_0$ is isomorphic to a copy of $\mathrm{gl}_2\cong\mathrm{sl}_2\oplus\mathbb{C}L_0$, with H_0, E_0 and F_0 providing the standard basis for the copy of sl_2.

Let $U^{\Delta,\Lambda}$ be the finite-dimensional irreducible sl_2-module of highest weight $\Lambda\in\mathbb{Z}_+$ on which L_0 acts as the scalar Δ. We let $v_{\Delta,\Lambda}$ be a highest weight vector in $U^{\Delta,\Lambda}$. We extend $U^{\Delta,\Lambda}$ to a module over the subalgebra $\mathcal{L}_0=\oplus_{j\geqslant 0}\mathfrak{g}_j$ in a trivial way and call this $\mathcal{L}_0$-module also $U^{\Delta,\Lambda}$. By Theorem 3.1 every finite irreducible $\mathfrak{g}$-module is a homomorphic image of $M_{\mathfrak{N}_+^3}(\Delta,\Lambda)=\mathrm{Ind}_{\mathcal{L}_0}^{\mathfrak{g}}U^{\Delta,\Lambda}$ and furthermore $M_{\mathfrak{N}_+^3}(\Delta,\Lambda)$ has a unique maximal submodule N, whose irreducible quotient we denote by $L_{\mathfrak{N}_+^3}(\Delta,\Lambda)$.

Note that $M_{\mathfrak{N}_+^3}(\Delta,\Lambda)$ as a module over sl_2 is a direct sum of infinitely many copies of finite-dimensional irreducible representations. Since ∂ commutes with E_0, the E_0-invariant $M_{\mathfrak{N}_+^3}(\Delta,\Lambda)^{E_0}$ is a $\mathbb{C}[\partial]$-submodule of $M_{\mathfrak{N}_+^3}(\Delta,\Lambda)$, and hence is a free $\mathbb{C}[\partial]$-module. We can explicitly write down formulas for a $\mathbb{C}[\partial]$-basis of $M_{\mathfrak{N}_+^3}(\Delta,\Lambda)^{E_0}$. In the case when $\Lambda\geqslant 2$ the following is a $\mathbb{C}[\partial]$-basis:

$$a_1=v_{\Delta,\Lambda},\quad a_2=e_{-1/2}v_{\Delta,\Lambda},\quad a_3=(\Lambda h_{-1/2}+2e_{-1/2}F_0)v_{\Delta,\Lambda},$$

$$a_4=((\Lambda-1)(\Lambda f_{-1/2}-h_{-1/2}F_0)-e_{-1/2}F_0^2)v_{\Delta,\Lambda},$$

$$a_5=e_{-1/2}h_{-1/2}v_{\Delta,\Lambda},\quad a_6=(\Lambda e_{-1/2}f_{-1/2}-e_{-1/2}h_{-1/2}F_0)v_{\Delta,\Lambda},$$

$$a_7=((\Lambda-1)(\Lambda h_{-1/2}f_{-1/2}+4\partial F_0+2e_{-1/2}f_{-1/2}F_0)-e_{-1/2}h_{-1/2}F_0^2)v_{\Delta,\Lambda},$$

$$a_8=(e_{-1/2}h_{-1/2}f_{-1/2}-2\partial h_{-1/2})v_{\Delta,\Lambda}.$$

The cases $\Lambda=0,1$ are similar. Namely, when $\Lambda=1$ we have $a_4=a_7=0$, and the remaining six vectors form a $\mathbb{C}[\partial]$-basis. Finally, in the case when $\Lambda=0$, the terms $a_3=a_4=a_6=a_7=0$, so that $M_{\mathfrak{N}_+^3}(\Delta,0)^{E_0}$ has rank 4 over $\mathbb{C}[\partial]$. (Actually the vectors a_i depend on Λ, so it would be more appropriate to write something like a_i^Λ instead of just a_i. However, from the context it will always be clear what Λ is, so that it is safe to adopt the simpler notation of a_i.) We denote the coefficient of $v_{\Delta,\Lambda}$ in the expression a_i by u_i^Λ so that we have $a_i=u_i^\Lambda v_{\Delta,\Lambda}$, for $i=1,\ldots,8$. For example, $u_1^\Lambda=1$, while $u_2^\Lambda=e_{-1/2}$, etc. We note that finding all vectors in $M_{\mathfrak{N}_+^3}(\Delta,\Lambda)^{E_0}$ above amounts essentially to decomposing tensor products of irreducible representations of sl_2 and then finding the corresponding highest weight vectors of the irreducible components.

Similarly we call a nonzero (L_0,H_0)-weight vector v in $M_{\mathfrak{N}_+^3}(\Delta,\Lambda)$ *singular* if $v\in M_{\mathfrak{N}_+^3}(\Delta,\Lambda)^{E_0}$ and $\mathfrak{g}_jv=0$, for all $j>0$. As before a singular vector is called *proper* if it is not a scalar multiple of $v_{\Delta,\Lambda}$. Evidently $M_{\mathfrak{N}_+^3}(\Delta,\Lambda)$ is irreducible if and only if $M_{\mathfrak{N}_+^3}(\Delta,\Lambda)$ contains no proper singular vector. Our first objective is to classify singular vectors inside $M_{\mathfrak{N}_+^3}(\Delta,\Lambda)$.

Proposition 5.1: Any proper singular vector in $M_{\mathfrak{N}_+^3}(\Delta,\Lambda)$ *is of the form* ($\alpha\in\mathbb{C}$ *with* $\alpha\neq 0$)

(*i*) αa_2, *if* $4\Delta-\Lambda=0$,
(*ii*) αa_4, *if* $4\Delta+\Lambda+2=0$ *and* $\Lambda\geqslant 2$, *and*
(*iii*) αa_6, *if* $4\Delta+\Lambda+2=0$ *and* $\Lambda=1$.

Remark 5.1: The proof of the proposition is a straightforward, albeit a tedious, calculation. We will not give the details here, but instead just point out that a weight vector $v\in M_{\mathfrak{N}_+^3}(\Delta,\Lambda)^{E_0}$ is singular if and only if $f_{1/2}$ and $\Psi_{1/2}$ annihilate v. This fact simplifies the calculation significantly.

From Proposition 5.1 one obtains immediately the following.

Corollary 5.1: Suppose that (Δ,Λ) *does not satisfy either* $4\Delta-\Lambda=0$ *or* $4\Delta+\Lambda+2=0$ *and* $\Lambda\geqslant 1$. *Then* $L_{\mathfrak{N}_+^3}(\Delta,\Lambda)=M_{\mathfrak{N}_+^3}(\Delta,\Lambda)$ *is an irreducible* $\mathrm{K}(1,3)_+$*-module of rank* $8\Lambda+8$ *over* $\mathbb{C}[\partial]$.

Proposition 5.2: Suppose that $4\Delta-\Lambda=0$. *Then* $L_{\mathfrak{N}_+^3}(\Delta,\Lambda)$ *is a free* $\mathbb{C}[\partial]$*-module of rank* 4Λ.

Proof: By Proposition 5.1 a_2 is a singular vector in $M_{\mathfrak{N}_+^3}(\Lambda/4,\Lambda)$ of H_0-weight $\Lambda+2$. Consider N, the $\mathfrak{g}$-submodule generated by a_2. Then we have $N=U(\mathfrak{g}_-)V_2$, where V_2 is the irreducible sl_2-submodule generated by a_2. Note that the map $v_{\Lambda/4+1/2,\Lambda+2}\to a_2$ extends uniquely to an epimorphism of $\mathrm{K}(1,3)_+$-modules from $M_{\mathfrak{N}_+^3}(\Lambda/4+1/2,\Lambda+2)$ to N. In particular, it is an sl_2-module epimorphism. Now both modules are completely reducible sl_2-modules and hence this map sends E_0-invariants onto E_0-invariants. Since $M_{\mathfrak{N}_+^3}(\Lambda/4+1/2,\Lambda+2)^{E_0}$ is generated over $\mathbb{C}[\partial]$ by $\{u_i^{\Lambda+2}v_{\Lambda/4+1/2,\Lambda+2}|1\leqslant i\leqslant 8\}$, it follows that N^{E_0} is generated over $\mathbb{C}[\partial]$ by $\{u_i^{\Lambda+2}a_2|1\leqslant i\leqslant 8\}$. Now N^{E_0} is a $\mathbb{C}[\partial]$-submodule of $M_{\mathfrak{N}_+^3}(\Lambda/4,\Lambda)$, since $[\partial,E_0]=0$. Thus it is a free $\mathbb{C}[\partial]$-submodule generated by $\{u_i^{\Lambda+2}a_2|1\leqslant i\leqslant 8\}$. We compute

$$u_1^{\Lambda+2}a_2=a_2,\quad u_2^{\Lambda+2}a_2=0,\quad u_3^{\Lambda+2}a_2=-(\Lambda+4)a_5,$$

$$u_4^{\Lambda+2}a_2=-(\Lambda+3)a_6-4(\Lambda+1)(\Lambda+3)\partial a_1,\quad u_5^{\Lambda+2}a_2=0,$$

$$u_6^{\Lambda+2}a_2=-4(\Lambda+3)\partial a_2,\quad u_7^{\Lambda+2}a_2=(\Lambda+3)(\Lambda+2)a_8+2(\Lambda+3)\partial a_3,$$

$$u_8^{\Lambda+2}a_2=-2\partial a_5.$$

By inspection it is clear that the following is a set of $\mathbb{C}[\partial]$-generators for N^{E_0}:

$$S^\Lambda=\left\{a_2,a_5,a_6+4(\Lambda+1)\partial a_1,a_8+\frac{2}{\Lambda+2}\partial a_3\right\}.$$

First consider the case when $\Lambda\geqslant 2$. It follows from the description of S^Λ above that $\{a_1,a_3,a_4,a_7\}$ is a $\mathbb{C}[\partial]$-basis for the E_0-invariants of the quotient $M_{\mathfrak{N}_+^3}(\Lambda/4,\Lambda)/N$. Since a_1 and a_3 both have H_0-weight Λ, they generate two copies of the irreducible sl_2-module of dimension $\Lambda+1$. On the other hand, a_4 and a_7 both have weight $\Lambda-2$, and so they generate two copies of the irreducible sl_2-module of dimension $\Lambda-1$. Thus $M_{\mathfrak{N}_+^3}(\Lambda/4,\Lambda)/N$ is a free $\mathbb{C}[\partial]$-module of rank $2(\Lambda+1)+2(\Lambda-1)=4\Lambda$. So, in order to complete the proof it remains to show that $M_{\mathfrak{N}_+^3}(\Lambda/4,\Lambda)/N$ is irreducible.

Note that L_n, $n\geqslant -1$, together with E_0,H_0,F_0 generate a copy of $\mathfrak{V}_+\oplus\mathrm{sl}_2$ and so we may consider $M_{\mathfrak{N}_+^3}(\Lambda/4,\Lambda)/N$ as a module over $\mathfrak{V}_+\oplus\mathrm{sl}_2$. By parity consideration $M_{\mathfrak{N}_+^3}(\Lambda/4,\Lambda)/N$ is a direct sum of two $(\mathfrak{V}_+\oplus\mathrm{sl}_2)$-modules, namely $(M_{\mathfrak{N}_+^3}(\Lambda/4,\Lambda)/N)_{\bar{0}}=\mathbb{C}[\partial]V_1+\mathbb{C}[\partial]V_7$ and $(M_{\mathfrak{N}_+^3}(\Lambda/4,\Lambda)/N)_{\bar{1}}=\mathbb{C}[\partial]V_3+\mathbb{C}[\partial]V_4$, where V_i is the irreducible sl_2-module generated by a_i. It is subject to a direct verification that L_n, for $n\geqslant 1$, annihilates the vectors a_1,a_3,a_4,a_7 (in fact, one only needs to check that $L_1a_7=0$, others being trivial) and hence $M_{\mathfrak{N}_+^3}(\Lambda/4,\Lambda)/N$ as a $\mathfrak{V}_+$

$\oplus \mathrm{sl}_2$-module is a direct sum the following four non-isomorphic irreducible modules: $\mathbb{C}[\partial]V_3 \cong L_{\mathfrak{V}_+}(\Lambda/4+1/2)\boxtimes U^{\Lambda}$, $\mathbb{C}[\partial]V_4 \cong L_{\mathfrak{V}_+}(\Lambda/4+1/2)\boxtimes U^{\Lambda-2}$, $\mathbb{C}[\partial]V_1 \cong L_{\mathfrak{V}_+}(\Lambda/4)\boxtimes U^{\Lambda}$ and $\mathbb{C}[\partial]V_7 \cong L_{\mathfrak{V}_+}(\Lambda/4+1)\boxtimes U^{\Lambda-2}$, where we denote by U^{μ} the irreducible sl_2-module of highest weight μ. Now we compute

$$\Psi_{1/2}a_3 = -\Lambda(\Lambda+2)a_1, \quad f_{1/2}a_4 = (2\Lambda+2)F_0^2 a_1,$$
$$E_1 a_7 = 2\Lambda(\Lambda-1)(2\Lambda+2)a_1, \tag{5.1}$$

from which it follows that we may go from each irreducible $\mathfrak{V}_+ \oplus \mathrm{sl}_2$-component of $M_{\mathfrak{N}_+^3}(\Lambda/4,\Lambda)/N$ to the irreducible component containing the highest weight vectors, and hence the module $M_{\mathfrak{N}_+^3}(\Lambda/4,\Lambda)/N$ is irreducible.

Now if $\Lambda=1$, the vectors a_4 and a_7 are both zero. Therefore, the quotient $M_{\mathfrak{N}_+^3}(\Lambda/4,\Lambda)/N = \mathbb{C}[\partial]V_1 \oplus \mathbb{C}[\partial]V_3$. But then the first identity in (5.1) shows that $M_{\mathfrak{N}_+^3}(\Lambda/4,\Lambda)/N$ is irreducible. The rank of $L_{\mathfrak{N}_+^3}(\Lambda/4,\Lambda)$ is then $2(\Lambda+1)=4\Lambda$ in the case $\Lambda=1$.

Finally, when $\Lambda=0$, the vectors $a_3,a_4,a_6,a_7=0$, so that S^{Λ} reduces to $\{a_2,a_5,\partial a_1,a_8\}$. Therefore, $M_{\mathfrak{N}_+^3}(0,0)/N=\mathbb{C}a_1$ is the trivial module and so has rank 0. □

Proposition 5.3: Suppose that $4\Delta+\Lambda+2=0$ *and* $\Lambda\geq 1$. *Then* $L_{\mathfrak{N}_+^3}(\Delta,\Lambda)$ *is a free* $\mathbb{C}[\partial]$*-module of rank* $4\Lambda+8$.

Proof: By Proposition 5.1 a_4 is a singular vector of $M_{\mathfrak{N}_+^3}(-(\Lambda+2)/4,\Lambda)$ of H_0-weight $\Lambda-2$. Let N denote the $\mathfrak{g}$-submodule generated by a_4.

Consider first the case $\Lambda\geq 4$. As in the proof of Proposition 5.1, N^{E_0} is a free $\mathbb{C}[\partial]$-module generated over $\mathbb{C}[\partial]$ by $\{u_i^{\Lambda-2}a_4 | 1\leq i\leq 8\}$. We compute

$$u_1^{\Lambda-2}a_4 = a_4, \quad u_2^{\Lambda-2}a_4 = (\Lambda-1)a_6, \quad u_3^{\Lambda-2}a_4 = (\Lambda-2)a_7, \quad u_4^{\Lambda-2}a_4 = 0,$$
$$u_5^{\Lambda-2}a_4 = \Lambda(\Lambda-1)a_8 + 2(\Lambda-1)\partial a_3, \quad u_6^{\Lambda-2}a_4 = 0, \quad u_7^{\Lambda-2}a_4 = 0,$$
$$u_8^{\Lambda-2}a_4 = -2\partial a_7.$$

This implies that the set $S^{\Lambda}=\{a_4,(\Lambda-1)a_6,(\Lambda-2)a_7,\Lambda(\Lambda-1)a_8+2(\Lambda-1)\partial a_3,\partial a_7\}$ generates N^{E_0} over $\mathbb{C}[\partial]$ and so $\{a_1,a_2,a_3,a_5\}$ is a $\mathbb{C}[\partial]$-basis for $(M_{\mathfrak{N}_+^3}(-(\Lambda+2)/4,\Lambda)/N)^{E_0}$ in the case when $\Lambda\geq 4$.

Next consider the case $\Lambda=3$. In this case, letting N be as before, N^{E_0} is generated over $\mathbb{C}[\partial]$ by $\{u_i^{\Lambda-2}a_4 | 1\leq i\leq 8, i\neq 4,7\}$. Hence it follows from the above formulas that again $\{a_1,a_2,a_3,a_5\}$ is a $\mathbb{C}[\partial]$-basis for $(M_{\mathfrak{N}_+^3}(-(\Lambda+2)/4,\Lambda)/N)^{E_0}$.

In the case when $\Lambda=2$ we let N' denote the module generated by a_4. It follows that the vectors $\{u_1^{\Lambda-2}a_4, u_2^{\Lambda-2}a_4, u_5^{\Lambda-2}a_4, u_8^{\Lambda-2}a_4\}$ generate N'^{E_0} over $\mathbb{C}[\partial]$ so that $S^{\Lambda}=\{a_4,a_6,a_8+\partial a_3,\partial a_7\}$ generate N^{E_0}. Hence $(M_{\mathfrak{N}_+^3}(-(\Lambda+2)/4,\Lambda)/N')^{E_0}$ contains in addition a one-dimensional (over $\mathbb{C}$) subspace spanned by a_7. However, $\partial a_7=0$ in $M_{\mathfrak{N}_+^3}(-(\Lambda+2)/4,\Lambda)/N'$ and hence it is a $\mathfrak{g}$-invariant by Remark 2.1. In this case we set $N=N'+\mathbb{C}a_7$ so that the quotient module $(M_{\mathfrak{N}_+^3}(-(\Lambda+2)/4,\Lambda)/N)^{E_0}$ is again generated over $\mathbb{C}[\partial]$ by $\{a_1,a_2,a_3,a_5\}$.

Now a_1 and a_3 have H_0-weight Λ, while a_2 and a_5 have H_0-weight $\Lambda+2$. Thus $M_{\mathfrak{N}_+^3}(-(\Lambda+2)/4,\Lambda)/N$ has rank $2(\Lambda+1)+2(\Lambda+3)=4\Lambda+8$ over $\mathbb{C}[\partial]$. So it remains to show that $M_{\mathfrak{N}_+^3}(-(\Lambda+2)/4,\Lambda)/N$ is irreducible.

Again we consider $M_{\mathfrak{N}_+^3}(-(\Lambda+2)/4,\Lambda)/N$ as a module over $\mathfrak{V}_+\oplus\mathrm{sl}_2$. It is easy to check that L_n, $n\geq 1$, annihilates a_1,a_2,a_3,a_5. (Again one really only needs to check that $L_1a_5=0$.) Thus it follows in the case of $\Lambda\geq 3$ that $M_{\mathfrak{N}_+^3}(-(\Lambda+2)/4,\Lambda)/N$ is a direct sum of the following four non-isomorphic irreducible $\mathfrak{V}_+\oplus\mathrm{sl}_2$-modules: $\mathbb{C}[\partial]V_1 \cong L_{\mathfrak{V}_+}(-(\Lambda+2)/4)\boxtimes U^{\Lambda}$, $\mathbb{C}[\partial]V_2$

$\cong L_{\mathfrak{V}_+}(-\Lambda/4)\boxtimes U^{\Lambda+2}$, $\mathbb{C}[\partial]V_3 \cong L_{\mathfrak{V}_+}(-\Lambda/4)\boxtimes U^{\Lambda}$ and $\mathbb{C}[\partial]V_5 \cong L_{\mathfrak{V}_+}(-(\Lambda-2)/4)\boxtimes U^{\Lambda+2}$, where as before U^{μ} stands for the irreducible sl_2-module of highest weight μ and V_i is the sl_2-submodule generated by the vector a_i. Now we compute

$$f_{1/2}a_2 = 2(\Lambda+1)a_1, \quad \Psi_{1/2}a_3 = -\Lambda(\Lambda+2)a_1, \quad F_1 a_5 = -4(\Lambda+1)a_1, \tag{5.2}$$

from which again it follows that we may go from any irreducible $\mathfrak{V}_+ \oplus \mathrm{sl}_2$-component of $M_{\mathfrak{N}^3_+}(-(\Lambda+2)/4,\Lambda)/N$ to the component containing the highest weight vectors, and hence $M_{\mathfrak{N}^3_+}(-(\Lambda+2)/4,\Lambda)/N$ is irreducible.

As for the case $\Lambda=2$ we have $M_{\mathfrak{N}^3_+}(-(\Lambda+2)/4,\Lambda)/N$ as a $\mathfrak{V}_+ \oplus \mathrm{sl}_2$-module is also a direct sum of the $\mathbb{C}[\partial]V_1 \oplus \mathbb{C}[\partial]V_2 \oplus \mathbb{C}[\partial]V_3 \oplus \mathbb{C}[\partial]V_5$. The first three modules, as in the case of $\Lambda \geqslant 3$, are irreducible. However, $\mathbb{C}[\partial]V_5$ contains a unique irreducible submodule generated by the vector ∂a_5, which is isomorphic to $L_{\mathfrak{V}_+}(-1)\boxtimes U^{\Lambda+2}$. But then (5.2) together with the fact that

$$F_2 \partial a_1 = -24 a_1$$

shows that $M_{\mathfrak{N}^3_+}(-(\Lambda+2)/4,\Lambda)/N$ is irreducible in this case as well.

In the case when $\Lambda=1$ we have by Proposition 5.1 that a_6 is the unique (up to a scalar) singular vector inside $M_{\mathfrak{N}^3_+}(-\frac{3}{4},1)$. Let N denote the $\mathfrak{g}$-submodule generated by a_6. Since a_6 has H_0-weight 1, N^{E_0} is the free $\mathbb{C}[\partial]$-module generated by $\{u_i^{\Lambda}a_6 | 1 \leqslant i \leqslant 8, i \neq 4,7\}$. We have

$$u_1^{\Lambda}a_6 = a_6, \quad u_2^{\Lambda}a_6 = 0, \quad u_3^{\Lambda}a_6 = -3a_8 - 6\partial a_3,$$

$$u_5^{\Lambda}a_6 = 0, \quad u_6^{\Lambda}a_6 = -8\partial a_6, \quad u_8^{\Lambda}a_6 = -2\partial a_8 - 4\partial^2 a_3,$$

from which it follows that N^{E_0} is generated over $\mathbb{C}[\partial]$ by $S^{\Lambda} = \{a_6, a_8 + 2\partial a_3\}$. Since $a_4 = a_7 = 0$ in this situation, we see that $(M_{\mathfrak{N}^3_+}(-\frac{3}{4},1)/N)^{E_0}$ is generated over $\mathbb{C}[\partial]$ by the vectors a_1, a_2, a_3, a_5, just as in the case $\Lambda \geqslant 2$. Now the exact same argument as in the $\Lambda \geqslant 2$ case shows that $M_{\mathfrak{N}^3_+}(-\frac{3}{4},1)/N$ is irreducible and has rank $4\Lambda+8$ over $\mathbb{C}[\partial]$. □

We summarize the work in this section in the following theorem.

Theorem 5.1: *The modules $L_{\mathfrak{N}^3_+}(\Delta,\Lambda)$, for $\Delta \in \mathbb{C}$ and $\Lambda \in \mathbb{Z}_+$, form a complete list of non-isomorphic finite (over $\mathbb{C}[\partial]$) irreducible $\mathrm{K}(1,3)_+$-modules. Furthermore, $L_{\mathfrak{N}^3_+}(\Delta,\Lambda)$ as a $\mathbb{C}[\partial]$-module has rank*

(*i*) 4Λ, *in the case* $4\Delta - \Lambda = 0$,
(*ii*) $4\Lambda+8$, *the case* $4\Delta + \Lambda + 2 = 0$ *and* $\Lambda \geqslant 1$, *and*
(*iii*) $8\Lambda+8$, *in all other cases.*

Furthermore, the $\mathbb{C}[\partial]$-rank of $L_{\mathfrak{N}^3_+}(\Delta,\Lambda)_0^-$ equals the $\mathbb{C}[\partial]$-rank of $L_{\mathfrak{N}^3_+}(\Delta,\Lambda)_1^-$ in all cases.

Remark 5.2: Translating the above theorem back into the languages of modules over conformal superalgebras and of conformal modules is now a straightforward task. We thus have proved that all finite irreducible modules over the $N=3$ conformal superalgebra are of the form $L_{\mathfrak{N}^3}(\alpha,\Delta,\Lambda)$, where $\alpha,\Delta \in \mathbb{C}$ and $\Lambda \in \mathbb{Z}_+$. The definition of these modules and also the action of the $N=3$ conformal superalgebra on them are quite easy to obtain from our explicit description of a $\mathbb{C}[\partial]$-basis of these modules. To do so would, however, take up quite a significant portion of space, and thus we leave this task to the interested reader. We only remark that the adjoint module is isomorphic to $L_{\mathfrak{N}^3}(0,\frac{1}{2},0)$.

VI. FINITE IRREDUCIBLE MODULES OVER THE "SMALL" $N=4$ CONFORMAL SUPERALGEBRA

The "small" $N=4$ superconformal algebra is the following subalgebra of K(1,4): Let $\xi_1, \xi_2, \xi_3, \xi_4$ denote four odd indeterminates generating the Grassmann superalgebra $\Lambda(4)$. For a monomial ξ_I in $\Lambda(4)$ we let ξ_I^* be its Hodge dual, i.e., the unique monomial in $\Lambda(4)$ such that $\xi_I\xi_I^*=\xi_1\xi_2\xi_3\xi_4$. Then the small $N=4$ superconformal algebra is isomorphic to any of the following two subalgebras in K(1,4) spanned by the following basis elements ($n\in\mathbb{Z}$, $r\in\frac{1}{2}+\mathbb{Z}$, $\beta^2=1$):[11]

$$L_n^\beta=-\tfrac{1}{2}(t^{n+1}+\beta n(n+1)\xi_1\xi_2\xi_3\xi_4t^{n-1}),$$

$$H_n^\beta=i(\xi_1\xi_2-\beta\xi_3\xi_4)t^n,$$

$$E_n^\beta=\tfrac{1}{2}(-\xi_1\xi_3-\beta\xi_2\xi_4-i\xi_2\xi_3+i\beta\xi_1\xi_4)t^n,$$

$$F_n^\beta=\tfrac{1}{2}(\xi_1\xi_3+\beta\xi_2\xi_4-i\xi_2\xi_3+i\beta\xi_1\xi_4)t^n,$$

$$G_r^{-+\beta}=\frac{1}{\sqrt{2}}\left((\xi_3+i\xi_4)t^{r+1/2}-\beta\left(r+\frac{1}{2}\right)(\xi_3^*+i\xi_4^*)t^{r-1/2}\right),$$

$$G_r^{++\beta}=\frac{1}{\sqrt{2}}\left((\xi_1+i\xi_2)t^{r+1/2}-\beta\left(r+\frac{1}{2}\right)(\xi_1^*+i\xi_2^*)t^{r-1/2}\right),$$

$$G_r^{+-\beta}=\frac{1}{\sqrt{2}}\left((\xi_3-i\xi_4)t^{r+1/2}-\beta\left(r+\frac{1}{2}\right)(\xi_3^*-i\xi_4^*)t^{r-1/2}\right),$$

$$G_r^{--\beta}=\frac{1}{\sqrt{2}}\left((i\xi_2-\xi_1)t^{r+1/2}-\beta\left(r+\frac{1}{2}\right)(i\xi_2^*-\xi_1^*)t^{r-1/2}\right).$$

As before let $\{H,E,F\}$ denote the standard basis of the Lie algebra sl_2 and $\{G^{++},G^{-+}\}$ denote the standard basis of its standard module, i.e., $H\cdot G^{++}=G^{++}$, $H\cdot G^{-+}=-G^{-+}$, $E\cdot G^{++}=F\cdot G^{-+}=0$, $F\cdot G^{++}=G^{-+}$ and $E\cdot G^{-+}=G^{++}$. Likewise $\{G^{+-},G^{--}\}$ also denotes a copy of the standard basis of the standard sl_2-module with actions $H\cdot G^{+-}=G^{+-}$, $H\cdot G^{--}=-G^{--}$, $E\cdot G^{+-}=F\cdot G^{--}=0$, $F\cdot G^{+-}=G^{--}$ and $E\cdot G^{--}=G^{+-}$. With this notation in mind the commutation relations are then given as follows (where $X,Y=H,E,F$ and $x,y=G^{++},G^{-+},G^{+-},G^{--}$):

$$[L_m^\beta,L_n^\beta]=(m-n)L_{m+n}^\beta,\quad [L_m^\beta,X_n^\beta]=-nX_{m+n}^\beta,\quad [L_m^\beta,x_r^\beta]=\left(\frac{m}{2}-r\right)x_{m+r}^\beta,$$

$$[X_m^\beta,Y_n^\beta]=[X,Y]_{m+n}^\beta,\quad [X_m^\beta,y_r^\beta]=(X\cdot y)_{m+r}^\beta,\quad [x_r^\beta,x_s^\beta]=0,$$

$$[G_r^{++\beta},G_s^{+-\beta}]=(r-s)(1+\beta)E_{r+s}^\beta,\quad [G_r^{++\beta},G_s^{-+\beta}]=(r-s)(1-\beta)E_{r+s}^\beta,$$

$$[G_r^{++\beta},G_s^{--\beta}]=-(r-s)H_{r+s}^\beta-2L_{r+s}^\beta,\quad [G_r^{+-\beta},G_s^{-+\beta}]=(r-s)\beta H_{r+s}^\beta+2L_{r+s}^\beta,$$

$$[G_r^{+-\beta},G_s^{--\beta}]=-(r-s)(1-\beta)F_{r+s}^\beta,\quad [G_r^{-+\beta},G_s^{--\beta}]=-(r-s)(1+\beta)F_{r+s}^\beta,$$

where $m,n\in\mathbb{Z}$ and $r,s\in\frac{1}{2}+\mathbb{Z}$. The eight formal distributions generating this algebra are given by $L^\beta(z)=\Sigma_{n\in\mathbb{Z}}L_n^\beta z^{-n-2}$, $X^\beta(z)=\Sigma_{n\in\mathbb{Z}}X_n^\beta z^{-n-1}$, and $x^\beta(z)=\Sigma_{r\in(1/2)+\mathbb{Z}}x_r^\beta z^{-r-3/2}$. The operator product expansions of these fields are easily derived using (2.3).

We will denote the ''small'' $N=4$ superconformal algebra simply by SK(1,4) and assume for the rest of this section that we have chosen its realization as the subalgebra of K(1,4) with $\beta=1$ for future computational purposes. For simplicity we will drop the superscript β and write L_n for L_n^β, etc., when we mean $\beta=1$.

The annihilation subalgebra $\mathfrak{g}=\mathrm{SK}(1,4)_+$ of SK(1,4) is equipped with a $\frac{1}{2}\mathbb{Z}$-gradation of depth 1, i.e., $\mathfrak{g}=\oplus_{j\geqslant -1}\mathfrak{g}_j$, $j\in\frac{1}{2}\mathbb{Z}$, and its zeroth graded component $\mathfrak{g}_0$ is isomorphic to a copy of $\mathrm{gl}_2\cong\mathrm{sl}_2\oplus\mathbb{C}L_0$, with H_0, E_0 and F_0 providing the standard basis of the copy of sl_2. Again we let $U^{\Delta,\Lambda}$ be the finite-dimensional irreducible sl_2-module of highest weight $\Lambda\in\mathbb{Z}_+$ on which L_0 acts as the scalar Δ and $v_{\Delta,\Lambda}$ be a highest weight vector in $U^{\Delta,\Lambda}$. As in the case of $\mathrm{K}(1,3)_+$, we may extend $U^{\Delta,\Lambda}$ to a module over the subalgebra $\mathcal{L}_0=\oplus_{j\geqslant 0}\mathfrak{g}_j$ trivially and call this $\mathcal{L}_0$-module also $U^{\Delta,\Lambda}$. Again Theorem 3.1 tells us that every finite irreducible $\mathfrak{g}$-module is the quotient of $M_{\mathfrak{N}_+^4}(\Delta,\Lambda)=\mathrm{Ind}_{\mathcal{L}_0}^{\mathfrak{g}}U^{\Delta,\Lambda}$ by its unique maximal submodule, for some $\Delta\in\mathbb{C}$ and $\Lambda\in\mathbb{Z}_+$. We denote the unique irreducible quotient by $L_{\mathfrak{N}_+^4}(\Delta,\Lambda)$ so that every finite irreducible $\mathrm{SK}(1,4)_+$-module is of the form $L_{\mathfrak{N}_+^4}(\Delta,\Lambda)$, for $\Delta\in\mathbb{C}$ and $\Lambda\in\mathbb{Z}_+$.

Now $M_{\mathfrak{N}_+^4}(\Delta,\Lambda)$ is completely reducible as a module over $\mathrm{sl}_2=\mathbb{C}H_0+\mathbb{C}E_0+\mathbb{C}F_0$, and the subspace of E_0-invariants $M_{\mathfrak{N}_+^4}(\Delta,\Lambda)^{E_0}$ is a free $\mathbb{C}[\partial]$-submodule of $M_{\mathfrak{N}_+^4}(\Delta,\Lambda)$ due to $[E_0,\partial]=0$. We write down explicit formulas for a $\mathbb{C}[\partial]$-basis of $M_{\mathfrak{N}_+^4}(\Delta,\Lambda)^{E_0}$, which in the case when $\Lambda\geqslant 2$ takes the following form:

$$a_1=v_{\Delta,\Lambda},\quad a_2=G^{++}_{-1/2}v_{\Delta,\Lambda},\quad a_3=G^{+-}_{-1/2}v_{\Delta,\Lambda},\quad a_4=(\Lambda G^{-+}_{-1/2}-G^{++}_{-1/2}F_0)v_{\Delta,\Lambda},$$

$$a_5=(-\Lambda G^{--}_{-1/2}+G^{+-}_{-1/2}F_0)v_{\Delta,\Lambda},\quad a_6=G^{-+}_{-1/2}G^{++}_{-1/2}v_{\Delta,\Lambda},\quad a_7=G^{+-}_{-1/2}G^{--}_{-1/2}v_{\Delta,\Lambda},$$

$$a_8=G^{++}_{-1/2}G^{+-}_{-1/2}v_{\Delta,\Lambda},\quad a_9=(G^{-+}_{-1/2}G^{+-}_{-1/2}-G^{++}_{-1/2}G^{--}_{-1/2})v_{\Delta,\Lambda},$$

$$a_{10}=(-\Lambda G^{++}_{-1/2}G^{--}_{-1/2}+G^{++}_{-1/2}G^{+-}_{-1/2}F_0)v_{\Delta,\Lambda},$$

$$a_{11}=((\Lambda-1)(-\Lambda G^{-+}_{-1/2}G^{--}_{-1/2}+G^{-+}_{-1/2}G^{+-}_{-1/2}F_0+G^{++}_{-1/2}G^{--}_{-1/2}F_0)-G^{++}_{-1/2}G^{+-}_{-1/2}F_0^2)v_{\Delta,\Lambda},$$

$$a_{12}=G^{-+}_{-1/2}G^{++}_{-1/2}G^{+-}_{-1/2}v_{\Delta,\Lambda},\quad a_{13}=G^{++}_{-1/2}G^{+-}_{-1/2}G^{--}_{-1/2}v_{\Delta,\Lambda},$$

$$a_{14}=G^{-+}_{-1/2}G^{++}_{-1/2}(-\Lambda G^{--}_{-1/2}+G^{+-}_{-1/2}F_0)v_{\Delta,\Lambda},$$

$$a_{15}=(-\Lambda G^{-+}_{-1/2}G^{+-}_{-1/2}G^{--}_{-1/2}+G^{++}_{-1/2}G^{+-}_{-1/2}G^{--}_{-1/2}F_0)v_{\Delta,\Lambda},$$

$$a_{16}=G^{-+}_{-1/2}G^{++}_{-1/2}G^{+-}_{-1/2}G^{--}_{-1/2}v_{\Delta,\Lambda}.$$

Now in the case when $\Lambda=1$ we have $a_{11}=0$ so that the remaining 15 vectors form a $\mathbb{C}[\partial]$-basis for $M_{\mathfrak{N}_+^4}(\Delta,\Lambda)^{E_0}$, while in the case when $\Lambda=0$ we have $a_4=a_5=a_{10}=a_{11}=a_{14}=a_{15}=0$, so that $M_{\mathfrak{N}_+^4}(\Delta,0)^{E_0}$ has rank 10 over $\mathbb{C}[\partial]$. As in Sec. V, we denote the coefficient of $v_{\Delta,\Lambda}$ in the expression a_i by u_i^Λ so that we have $a_i=u_i^\Lambda v_{\Delta,\Lambda}$, for $i=1,\ldots,16$.

Singular vectors are then defined to be nonzero (L_0,H_0)-weight vectors $v\in M_{\mathfrak{N}_+^4}(\Delta,\Lambda)^{E_0}$ with $\mathfrak{g}_j v=0$, for all $j>0$. Similarly, we define *proper singular vectors*. Our approach is analogous to the one of Sec. V, that is, first to analyze singular vectors inside $M_{\mathfrak{N}_+^4}(\Delta,\Lambda)$. This is given by the following proposition, whose proof is again a straightforward calculation, which admittedly is rather tedious.

Proposition 6.1: A complete list of proper singular vectors inside $M_{\mathfrak{N}_+^4}(\Delta,\Lambda)$ is given by

(*i*) $2\Delta-\Lambda=0$.
(a) $\alpha a_2+\beta a_3$, $(\alpha,\beta)\neq(0,0)$,
(b) αa_8, $\alpha\neq 0$.

(*ii*) $2\Delta+\Lambda+2=0$ *and* $\Lambda\geqslant 2$.
(a) $\alpha a_4+\beta a_5$, $(\alpha,\beta)\neq(0,0)$,
(b) αa_{11}, $\alpha\neq 0$.
(*iii*) $2\Delta+\Lambda+2=0$ *and* $\Lambda=1$.
(a) $\alpha a_4+\beta a_5$, $(\alpha,\beta)\neq(0,0)$,
(b) $\alpha a_{14}+\beta(a_{15}-2\partial a_5)$, $(\alpha,\beta)\neq(0,0)$,
(c) $\alpha(a_{16}-2\partial a_{10})$, $\alpha\neq 0$.
(*iv*) $2\Delta+\Lambda+2=0$ and $\Lambda=0$.
(a) $\alpha a_6+\beta a_7+\gamma(a_9-2\partial a_1)$, $(\alpha,\beta,\gamma)\neq(0,0,0)$,
(b) $\alpha a_{13}+\beta(a_{12}+2\partial a_2)$, $(\alpha,\beta)\neq(0,0)$.

Remark 6.1: We note that in order to check that a weight vector $v\in M_{\mathfrak{N}_+^4}(\Delta,\Lambda)^{E_0}$ is singular, it is enough to check that v is annihilated by F_1, $G_{1/2}^{-+}$ and $G_{1/2}^{--}$.

Corollary 6.1: Suppose that (Δ,Λ) *does not satisfy either* $2\Delta-\Lambda=0$ *or* $2\Delta+\Lambda+2=0$. *Then* $L_{\mathfrak{N}_+^4}(\Delta,\Lambda)=M_{\mathfrak{N}_+^4}(\Delta,\Lambda)$ *is an irreducible* $\mathrm{SK}(1,4)_+$*-module of rank* $16\Lambda+16$ *over* $\mathbb{C}[\partial]$.

Proposition 6.2: Suppose that $2\Delta-\Lambda=0$. *Then* $L_{\mathfrak{N}_+^4}(\Delta,\Lambda)$ *is a free* $\mathbb{C}[\partial]$*-module of rank* 4Λ.

Proof: By Proposition 6.1 a_2 and a_3 are singular vectors in $M_{\mathfrak{N}_+^4}(\Lambda/2,\Lambda)$. Consider N_2 and N_3, the $\mathfrak{g}$-submodules generated by a_2 and a_3, respectively, and let $N=N_2+N_3$. Then we have $N_2=U(\mathfrak{g}_-)V_2$ and $N_3=U(\mathfrak{g}_-)V_3$, where V_2 and V_3 are the irreducible sl_2-submodules generated by a_2 and a_3, respectively. Let us first compute $N_2^{E_0}$. Since the H_0-weight of a_2 is $\Lambda+1$, we know that $N_2^{E_0}$ is a free $\mathbb{C}[\partial]$-module generated over $\mathbb{C}[\partial]$ by $\{u_i^{\Lambda+1}a_2|1\leqslant i\leqslant 16\}$. We have

$$u_1^{\Lambda+1}a_2=a_2,\quad u_2^{\Lambda+1}a_2=0,\quad u_3^{\Lambda+1}a_2=-a_8,\quad u_4^{\Lambda+1}a_2=(\Lambda+2)a_6,$$

$$u_5^{\Lambda+1}a_2=-a_9-a_{10}+2(\Lambda+2)\partial a_1,\quad u_6^{\Lambda+1}a_2=0,\quad u_7^{\Lambda+1}a_2=a_{13}-2\partial a_3,$$

$$u_8^{\Lambda+1}a_2=0,\quad u_9^{\Lambda+1}a_2=-a_{12}+2\partial a_2,\quad u_{10}^{\Lambda+1}a_2=a_{12}+2(\Lambda+2)\partial a_2,$$

$$u_{11}^{\Lambda+1}a_2=2(\Lambda+2)\partial a_4-(\Lambda+2)a_{14},\quad u_{12}^{\Lambda+1}a_2=0,\quad u_{13}^{\Lambda+1}a_2=-2\partial a_8,$$

$$u_{14}^{\Lambda+1}a_2=2(\Lambda+2)\partial a_6,\quad u_{15}^{\Lambda+1}a_2=-(\Lambda+2)a_{16}+2(\Lambda+1)\partial a_9-2\partial a_{10},\quad u_{16}^{\Lambda+1}a_2=-2\partial a_{12}.$$

Next we find $\mathbb{C}[\partial]$-generators of $N_3^{E_0}$. Similarly, $\{u_i^{\Lambda+1}a_3|1\leqslant i\leqslant 16\}$ generates $N_3^{E_0}$ over $\mathbb{C}[\partial]$:

$$u_1^{\Lambda+1}a_3=a_3,\quad u_2^{\Lambda+1}a_3=a_8,\quad u_3^{\Lambda+1}a_3=0,\quad u_4^{\Lambda+1}a_3=(\Lambda+1)a_9-a_{10},$$

$$u_5^{\Lambda+1}a_3=(\Lambda+2)a_7,\quad u_6^{\Lambda+1}a_3=a_{12},\quad u_7^{\Lambda+1}a_3=0,\quad u_8^{\Lambda+1}a_3=0,$$

$$u_9^{\Lambda+1}a_3=a_{13},\quad u_{10}^{\Lambda+1}a_3=(\Lambda+2)a_{13},\quad u_{11}^{\Lambda+1}a_3=-(\Lambda+2)a_{15},$$

$$u_{12}^{\Lambda+1}a_3=-a_{16},\quad u_{13}^{\Lambda+1}a_3=0,\quad u_{14}^{\Lambda+1}a_3=(\Lambda+2)a_{16},\quad u_{15}^{\Lambda+1}a_3=0,\quad u_{16}^{\Lambda+1}a_3=0.$$

It follows that N^{E_0} is generated over $\mathbb{C}[\partial]$ by the following set:

$$S^{\Lambda}=\{a_2,a_3,a_6,a_7,a_8,a_9-2\partial a_1,a_{10}-2(\Lambda+1)\partial a_1,a_{12},a_{13},a_{14}-2\partial a_4,a_{15},a_{16}\}.$$

Suppose that $\Lambda\geqslant 2$. From the description of S^{Λ} we see that $\{a_1,a_4,a_5,a_{11}\}$ is a $\mathbb{C}[\partial]$-basis for the E_0-invariants of the quotient $M_{\mathfrak{N}_+^4}(\Lambda/2,\Lambda)/N$. Since a_1 has H_0-weight Λ, it generates a copy of the irreducible sl_2-module of dimension $\Lambda+1$. Now a_4 and a_5 both have weight $\Lambda-1$, and so they generate two copies of the irreducible sl_2-module of dimension Λ. Finally, a_{11} has weight

$\Lambda-2$, and so it generates a copy of the irreducible sl_2-module of dimension $\Lambda-1$. Thus $M_{\mathfrak{N}_+^4}(\Lambda/2,\Lambda)/N$ is a free $\mathbb{C}[\partial]$-module of rank $(\Lambda+1)+2\Lambda+(\Lambda-1)=4\Lambda$. So we need to show that $M_{\mathfrak{N}_+^4}(\Lambda/2,\Lambda)/N$ is irreducible.

As in Sec. V L_n, $n\geqslant -1$, together with E_0,H_0,F_0 generate a copy of $(\mathfrak{V}_+\oplus\mathrm{sl}_2)$, which thus allow us to study the $(\mathfrak{V}_+\oplus\mathrm{sl}_2)$-module structure of $M_{\mathfrak{N}_+^4}(\Lambda/2,\Lambda)/N$. By parity consideration $M_{\mathfrak{N}_+^4}(\Lambda/2,\Lambda)/N$ is a direct sum of two modules, namely $(M_{\mathfrak{N}_+^4}(\Lambda/2,\Lambda)/N)_{\bar{0}}=\mathbb{C}[\partial]V_1+\mathbb{C}[\partial]V_{11}$ and $(M_{\mathfrak{N}_+^4}(\Lambda/2,\Lambda)/N)_{\bar{1}}=\mathbb{C}[\partial]V_4+\mathbb{C}[\partial]V_5$, where V_i is the irreducible sl_2-module generated by a_i. We can easily check that L_n, for $n\geqslant 1$, annihilates the vectors a_1,a_4,a_5,a_{11}. (Again the only nontrivial part is to check that $L_1a_{11}=0$.) Thus $M_{\mathfrak{N}_+^4}(\Lambda/2,\Lambda)/N$ as a $\mathfrak{V}_+\oplus\mathrm{sl}_2$-module is a direct sum of the following four irreducible modules: $\mathbb{C}[\partial]V_1\cong L_{\mathfrak{V}_+}(\Lambda/2)\boxtimes U^{\Lambda}$, $\mathbb{C}[\partial]V_4\cong L_{\mathfrak{V}_+}((\Lambda+1)/2)\boxtimes U^{\Lambda-1}$, $\mathbb{C}[\partial]V_5\cong L_{\mathfrak{V}_+}((\Lambda+1)/2)\boxtimes U^{\Lambda-1}$ and $\mathbb{C}[\partial]V_{11}\cong L_{\mathfrak{V}_+}((\Lambda+2)/2)\boxtimes U^{\Lambda-2}$, where as usual U^{μ} is the irreducible sl_2-module of highest weight μ. Note that, contrary to the $\mathrm{K}(1,3)_+$ case, the odd part here is a sum of two isomorphic modules. To conclude that $M_{\mathfrak{N}_+^4}(\Lambda/2,\Lambda)/N$ is irreducible, we show again that one may go from each irreducible $\mathfrak{V}_+\oplus\mathrm{sl}_2$-component to the irreducible component containing the $\mathfrak{g}$-highest weight vectors. But this follows from the following computation:

$$G_{1/2}^{++}(\alpha a_4+\beta a_5)=\beta\Lambda(2\Lambda+2)a_1,\quad \alpha,\beta\in\mathbb{C}, \tag{6.1}$$

$$G_{1/2}^{--}a_4=(2\Lambda+2)F_0a_1,\quad E_1a_{11}=\Lambda(\Lambda-1)(2\Lambda+2)a_1. \tag{6.2}$$

Now if $\Lambda=1$, the vector a_{11} is zero. Therefore the quotient $M_{\mathfrak{N}_+^4}(\Lambda/4,\Lambda)/N=\mathbb{C}[\partial]V_1\oplus\mathbb{C}[\partial]V_4\oplus\mathbb{C}[\partial]V_5$. But then (6.1) and the first identity in (6.2) show that $M_{\mathfrak{N}_+^4}(\Lambda/4,\Lambda)/N$ is irreducible. The rank of $L_{\mathfrak{N}_+^4}(\Lambda/4,\Lambda)$ is then $(\Lambda+1)+2\Lambda$, which equals to 4Λ, in the case $\Lambda=1$.

Finally, when $\Lambda=0$, the vectors $a_4=a_5=a_{10}=a_{11}=a_{14}=a_{15}=0$ so that S^{Λ} reduces to $\{a_2,a_3,a_6,a_7,a_8,a_9,\partial a_1,a_{12},a_{13},a_{16}\}$. Hence $M_{\mathfrak{N}_+^4}(0,0)/N=\mathbb{C}a_1$ is the trivial module and so has rank 0. □

Proposition 6.3: Suppose that $2\Delta+\Lambda+2=0$. *Then* $L_{\mathfrak{N}_+^4}(\Delta,\Lambda)$ *is a free* $\mathbb{C}[\partial]$*-module of rank* $4\Lambda+8$.

Proof: By Proposition 6.1 a_4 and a_5 are singular vectors of $M_{\mathfrak{N}_+^4}(-(\Lambda+2)2,\Lambda)$ in the case $\Lambda\geqslant 1$.

Assume first that $\Lambda\geqslant 3$. Let N_4 and N_5 be the $\mathfrak{g}$-submodules generated by a_4 and a_5, respectively. We form the $\mathfrak{g}$-submodule $N=N_4+N_5$ and consider N^{E_0}. The set $\{u_i^{\Lambda-1}a_4|1\leqslant i\leqslant 16\}$ is a set of $\mathbb{C}[\partial]$-generators for $N_4^{E_0}$, since a_4 has H_0-weight $\Lambda-1$. We have

$$u_1^{\Lambda-1}a_4=a_4,\quad u_2^{\Lambda-1}a_4=-\Lambda a_6,\quad u_3^{\Lambda-1}a_4=2\Lambda\partial a_1-\Lambda a_9+a_{10},\quad u_4^{\Lambda-1}a_4=0,$$

$$u_5^{\Lambda-1}a_4=-a_{11},\quad u_6^{\Lambda-1}a_4=0,\quad u_7^{\Lambda-1}a_4=-a_{15}+2\partial a_5,\quad u_8^{\Lambda-1}a_4=2\Lambda\partial a_2+\Lambda a_{12},$$

$$u_9^{\Lambda-1}a_4=a_{14}+2\partial a_4,\quad u_{10}^{\Lambda-1}a_4=(\Lambda-1)a_{14},\quad u_{11}^{\Lambda-1}a_4=0,\quad u_{12}^{\Lambda-1}a_4=2\Lambda\partial a_6,$$

$$u_{13}^{\Lambda-1}a_4=-\Lambda a_{16}+2\partial a_{10},\quad u_{14}^{\Lambda-1}a_4=0,\quad u_{15}^{\Lambda-1}a_4=-2\partial a_{11},\quad u_{16}^{\Lambda-1}a_4=2\partial a_{14}.$$

Similarly, the following is a set of $\mathbb{C}[\partial]$-generators for $N_5^{E_0}$:

$$u_1^{\Lambda-1}a_5=a_5,\quad u_2^{\Lambda-1}a_5=a_{10},\quad u_3^{\Lambda-1}a_5=-a_7,\quad u_4^{\Lambda-1}a_5=a_{11},\quad u_5^{\Lambda-1}a_5=0,$$

$$u_6^{\Lambda-1}a_5=a_{14},\quad u_7^{\Lambda-1}a_5=0,\quad u_8^{\Lambda-1}a_5=-\Lambda a_{13},\quad u_9^{\Lambda-1}a_5=a_{15},\quad u_{10}^{\Lambda-1}a_5=0,$$

$$u_{11}^{\Lambda-1}a_5=0,\quad u_{12}^{\Lambda-1}a_5=-a_{16},\quad u_{13}^{\Lambda-1}a_5=0,\quad u_{14}^{\Lambda-1}a_5=0,\quad u_{15}^{\Lambda-1}a_5=0,$$

$$u_{16}^{\Lambda-1}a_5=0.$$

Therefore,

$$S^{\Lambda}=\{a_4,a_5,a_6,a_7,a_9-2\partial a_1,a_{10},a_{11},a_{12}+2\partial a_2,a_{13},a_{14},a_{15},a_{16}\}$$

is a set of $\mathbb{C}[\partial]$-generators for N^{E_0}, which implies that $\{a_1,a_2,a_3,a_8\}$ is a $\mathbb{C}[\partial]$-basis for $(M_{\mathfrak{N}_+^4}(-(\Lambda+2)/2,\Lambda)/N)^{E_0}$ in the case when $\Lambda\geqslant 3$.

In the case when $\Lambda=2$ the set $\{u_i^{\Lambda-1}a_4,u_i^{\Lambda-1}a_5|1\leqslant i\leqslant 16,i\neq 11\}$ generates N^{E_0}. But $u_{11}^{\Lambda-1}a_4=u_{11}^{\Lambda-1}a_5=0$, and hence $\{a_1,a_2,a_3,a_8\}$ is also a $\mathbb{C}[\partial]$-basis for $(M_{\mathfrak{N}_+^4}(-(\Lambda+2)/2,\Lambda)/N)^{E_0}$ in this case as well.

In the case when $\Lambda=1$ we note that $a_{11}=0$ and $\{u_i^{\Lambda-1}a_4,u_i^{\Lambda-1}a_5|1\leqslant i\leqslant 16,i\neq 4,5,10,11,14,15\}$ generates N^{E_0} over $\mathbb{C}[\partial]$. From the formulas above one sees that a set of $\mathbb{C}[\partial]$-generators for N^{E_0} is given by the set S^{Λ} above, but with a_{11} removed. Hence the quotient module is again generated freely over $\mathbb{C}[\partial]$ by $\{a_1,a_2,a_3,a_8\}$.

Hence, in the case, when $\Lambda\geqslant 1$ the quotient module $(M_{\mathfrak{N}_+^4}(-(\Lambda+2)/2,\Lambda)/N)^{E_0}$ is generated freely over $\mathbb{C}[\partial]$ by $\{a_1,a_2,a_3,a_8\}$. Now a_1 has H_0-weight Λ, a_2 and a_3 both have H_0-weight $\Lambda+1$, and a_8 has H_0-weight $\Lambda+2$. Therefore $M_{\mathfrak{N}_+^4}(-(\Lambda+2)/2,\Lambda)/N$ has rank $(\Lambda+1)+2(\Lambda+2)+(\Lambda+3)=4\Lambda+8$ over $\mathbb{C}[\partial]$. So it remains to show that $M_{\mathfrak{N}_+^4}(-(\Lambda+2)/2,\Lambda)/N$ is irreducible.

We again study $M_{\mathfrak{N}_+^4}(-(\Lambda+2)/2,\Lambda)/N$ as a $\mathfrak{V}_+\oplus \mathrm{sl}_2$-module. It is easy to check that L_n, $n\geqslant 1$, annihilates a_1,a_2,a_3,a_8 and hence $M_{\mathfrak{N}_+^4}(-(\Lambda+2)/2,\Lambda)/N$ is a direct sum of the following four irreducible $\mathfrak{V}_+\oplus \mathrm{sl}_2$-modules: $\mathbb{C}[\partial]V_1\cong L_{\mathfrak{V}_+}(-(\Lambda+2)/2)\boxtimes U^{\Lambda}$, $\mathbb{C}[\partial]V_2\cong L_{\mathfrak{V}_+}(-(\Lambda+1)/2)\boxtimes U^{\Lambda+1}$, $\mathbb{C}[\partial]V_3\cong L_{\mathfrak{V}_+}(-(\Lambda+1)/2)\boxtimes U^{\Lambda+1}$ and $\mathbb{C}[\partial]V_8\cong L_{\mathfrak{V}_+}(-\Lambda/2)\boxtimes U^{\Lambda+2}$, where V_i is the sl_2-submodule generated by the vector a_i. Again $\mathbb{C}[\partial]V_2\cong\mathbb{C}[\partial]V_3$ as $\mathfrak{V}_+\oplus\mathrm{sl}_2$-modules. Now we compute

$$G_{1/2}^{--}(\alpha a_2+\beta a_3)=2\alpha(\Lambda+1)a_1,\quad \forall\,\alpha,\beta\in\mathbb{C},$$

$$G_{1/2}^{-+}a_3=-2(\Lambda+1)a_1,\quad F_1a_8=-2(\Lambda+1)a_1.$$

Therefore $M_{\mathfrak{N}_+^4}(-(\Lambda+2)/2,\Lambda)/N$ is irreducible.

Now consider the case of $\Lambda=0$. By Proposition 6.1 a_6, a_7 and $a_9-2\partial a_1$ are singular vectors inside $M_{\mathfrak{N}_+^4}(-1,0)$. Let N_6, N_7 and N_9 be the $\mathfrak{g}$-submodules generated by a_6, a_7 and $a_9-2\partial a_1$, respectively, and put $N=N_6+N_7+N_9$. We note that a_6, a_7 and $a_9-2\partial a_1$ have H_0-weight 0, hence $N_6^{E_0}$ is generated over $\mathbb{C}[\partial]$ by $\{u_i^{\Lambda}a_6|1\leqslant i\leqslant 16,i\neq 4,5,10,11,14,15\}$ and similarly for $N_7^{E_0}$ and $N_9^{E_0}$. We first compute a set of $\mathbb{C}[\partial]$-generators for $N_6^{E_0}$:

$$u_1^{\Lambda}a_6=a_6,\quad u_2^{\Lambda}a_6=0,\quad u_3^{\Lambda}a_6=2\partial a_2+a_{12},\quad u_6^{\Lambda}a_6=0,$$

$$u_7^{\Lambda}a_6=4\partial^2a_1-2\partial a_9+a_{16},\quad u_8^{\Lambda}a_6=0,\quad u_9^{\Lambda}a_6=4\partial a_6,$$

$$u_{12}^{\Lambda}a_6=0,\quad u_{13}^{\Lambda}a_6=4\partial^2a_2+2\partial a_{12},\quad u_{16}^{\Lambda}a_6=4\partial^2a_6.$$

A set of $\mathbb{C}[\partial]$-generators for $N_7^{E_0}$ is given as follows:

$$u_1^{\Lambda}a_7=a_7,\quad u_2^{\Lambda}a_7=a_{13},\quad u_3^{\Lambda}a_7=0,\quad u_6^{\Lambda}a_7=a_{16},\quad u_7^{\Lambda}a_7=0,$$

$$u_8^{\Lambda}a_7=0,\quad u_9^{\Lambda}a_7=0,\quad u_{12}^{\Lambda}a_7=0,\quad u_{13}^{\Lambda}a_7=0,\quad u_{16}^{\Lambda}a_7=0.$$

Finally, we have the following set of $\mathbb{C}[\partial]$-generators for $N_9^{E_0}$:

$$u_1^\Lambda(a_9-2\partial a_1)=a_9-2\partial a_1,\quad u_2^\Lambda(a_9-2\partial a_1)=-a_{12}-2\partial a_2,$$

$$u_3^\Lambda(a_9-2\partial a_1)=a_{13},\quad u_6^\Lambda(a_9-2\partial a_1)=-2\partial a_6,\quad u_7^\Lambda(a_9-2\partial a_1)=2\partial a_7,$$

$$u_8^\Lambda(a_9-2\partial a_1)=0,\quad u_9^\Lambda(a_9-2\partial a_1)=2a_{16},\quad u_{12}^\Lambda(a_9-2\partial a_1)=0,$$

$$u_{13}^\Lambda(a_9-2\partial a_1)=2\partial a_{13},\quad u_{16}^\Lambda(a_9-2\partial a_1)=2\partial a_{16}.$$

From this it follows that $\{a_6,a_7,a_9-2\partial a_1,a_{12}+2\partial a_2,a_{13},a_{16}\}$ generate N^{E_0} over $\mathbb{C}[\partial]$. But $a_4=a_5=a_{10}=a_{11}=a_{14}=a_{15}=0$, and thus $(M_{\mathfrak{N}_+^4}(-1,0)/N)^{E_0}$ is generated over $\mathbb{C}[\partial]$ by the vectors a_1, a_2, a_3 and a_8, which takes us back to the case when $\Lambda\geqslant 1$, except that here $\mathbb{C}[\partial]V_8$ is not irreducible. It contains a unique irreducible submodule isomorphic to $L_{\mathfrak{V}_+}(1)\boxtimes U^2$ generated by ∂a_8. But then the above calculation plus the fact that

$$F_2\partial a_8=-4(\Lambda+1)a_1$$

show that $M_{\mathfrak{N}_+^4}(-1,0)/N$ is irreducible of rank 8. □

Theorem 6.1: *The modules $L_{\mathfrak{N}_+^4}(\Delta,\Lambda)$, for $\Delta\in\mathbb{C}$ and $\Lambda\in\mathbb{Z}_+$, form a complete list of non-isomorphic finite (over $\mathbb{C}[\partial]$) irreducible* $\mathrm{SK}(1,4)_+$*-modules. Furthermore $L_{\mathfrak{N}_+^4}(\Delta,\Lambda)$ as a $\mathbb{C}[\partial]$-module has rank*

(*i*) 4Λ, *in the case* $2\Delta-\Lambda=0$,
(*ii*) $4\Lambda+8$, *in the case* $2\Delta+\Lambda+2=0$, *and*
(*iii*) $16\Lambda+16$, *in all other cases.*

Furthermore, the $\mathbb{C}[\partial]$-rank of $L_{\mathfrak{N}_+^4}(\Delta,\Lambda)_{\bar 0}$ equals the $\mathbb{C}[\partial]$-rank of $L_{\mathfrak{N}_+^4}(\Delta,\Lambda)_{\bar 1}$ in all cases.

Remark 6.2: Translating the above theorem into the languages of modules over conformal algebras and of conformal modules is again straightforward. We therefore obtain that all finite irreducible modules over the ''small'' $N=4$ conformal superalgebra are of the form $L_{\mathfrak{N}^4}(\alpha,\Delta,\Lambda)$, where $\alpha,\Delta\in\mathbb{C}$ and $\Lambda\in\mathbb{Z}_+$. The definition of these modules and also the action of the conformal superalgebra on them are easily gotten from our explicit description of a $\mathbb{C}[\partial]$-basis in this section and hence omitted, as to reproduce them would take up quite a significant amount of space. Again we only note that the adjoint module is isomorphic to $L_{\mathfrak{N}^4}(0,1,2)$.

VII. FINITE IRREDUCIBLE MODULES OVER THE ''BIG'' $N=4$ CONFORMAL SUPERALGEBRA

In this section we give a classification of finite irreducible conformal modules over the contact superalgebra K(1,4), also known as the ''big'' $N=4$ superconformal algebra. Our approach is based on our results obtained in Sec. VI.

Recall from Sec. VI that L_n^β, X_n^β and x_r^β, where $X=H,E,F$, $x=G^{++}$, G^{-+}, G^{+-}, G^{--}, $n\in\mathbb{Z}$, $r\in\frac{1}{2}+\mathbb{Z}$ and the fixed number β is either 1 or -1, provide a basis for a copy of SK(1,4) inside K(1,4). In this section it will be convenient to distinguish these two copies. We therefore denote the copy obtained by setting $\beta=1$ simply by SK(1,4), while the copy obtained by setting $\beta=-1$ we denote by $\overline{\mathrm{SK}}(1,4)$. It is easy to see from our formulas that $\mathrm{K}(1,4)=\mathrm{SK}(1,4)+\overline{\mathrm{SK}}(1,4)$. Similarly we distinguish the basis elements of SK(1,4) and $\overline{\mathrm{SK}}(1,4)$ as follows. The generators inside $\overline{\mathrm{SK}}(1,4)$ will be denoted by L_n,X_n,x_r, while generators inside $\overline{\mathrm{SK}}(1,4)$ will be denoted by $\overline{L_n},\overline{X_n},\overline{x_r}$, where again $X=H,E,F$, $x=G^{++}$, G^{-+}, G^{+-}, G^{--}. Of course we have $x_{-\frac{1}{2}}=\overline{x}_{-\frac{1}{2}}$, $L_{-1}=\overline{L}_{-1}$ and $L_0=\overline{L}_0$.

Remark 7.1: The map $\phi:\mathrm{SK}(1,4)\to\overline{\mathrm{SK}}(1,4)$ defined by $\phi(L_n)=\overline{L}_n$, $\phi(X_n)=\overline{X}_n$, $\phi(G_r^{++})=\overline{G}_r^{++}$, $\phi(G_r^{+-})=\overline{G}_r^{-+}$, $\phi(G_r^{-+})=\overline{G}_r^{+-}$ and $\phi(G_r^{--})=\overline{G}_r^{--}$, where $n\in\mathbb{Z}$ and $r\in\frac{1}{2}+\mathbb{Z}$ is an isomorphism of Lie superalgebras. Thus all formulas in Sec. VI with $\phi(L_n)$, $\phi(X_n)$ and $\phi(x_r)$ replacing L_n, X_n and x_r, respectively, remain valid.

Let $\mathfrak{g}=\mathrm{K}(1,4)_+$ be the annihilation subalgebra of K(1,4) so that we have $\mathfrak{g}=\mathrm{SK}(1,4)_+ +\overline{\mathrm{SK}}(1,4)_+$, the sum of the corresponding annihilation subalgebras. We have as before $\mathfrak{g}=\oplus_{j\geqslant -1}\mathfrak{g}_j$, where $j\in\frac{1}{2}+\mathbb{Z}$. Furthermore, $\mathfrak{g}_-=\mathrm{SK}(1,4)_-=\overline{\mathrm{SK}}(1,4)_-$ and $\mathfrak{g}_0=\mathbb{C}L_0\oplus\mathrm{sl}_2\oplus\overline{\mathrm{sl}}_2\cong c\mathrm{so}_4$, where sl_2 and $\overline{\mathrm{sl}}_2$ denote two copies of the Lie algebra sl_2, generated by H_0,E_0,F_0 and $\overline{H}_0,\overline{E}_0,\overline{F}_0$, respectively.

Let $U^{\Delta,\Lambda,\overline{\Lambda}}$ be the finite-dimensional irreducible $\mathrm{sl}_2\oplus\overline{\mathrm{sl}}_2$-module of highest weight $(\Lambda,\overline{\Lambda})\in\mathbb{Z}_+\times\mathbb{Z}_+$ on which L_0 acts as the scalar $\Delta\in\mathbb{C}$ and let $v_{\Delta,\Lambda,\overline{\Lambda}}$ denote a highest weight vector in $U^{\Delta,\Lambda,\overline{\Lambda}}$ so that $H_0v_{\Delta,\Lambda,\overline{\Lambda}}=\Lambda v_{\Delta,\Lambda,\overline{\Lambda}}$, $\overline{H}_0v_{\Delta,\Lambda,\overline{\Lambda}}=\overline{\Lambda}v_{\Delta,\Lambda,\overline{\Lambda}}$ and $L_0v_{\Delta,\Lambda,\overline{\Lambda}}=\Delta v_{\Delta,\Lambda,\overline{\Lambda}}$. Regarding $U^{\Delta,\Lambda,\overline{\Lambda}}$ as a module over $\mathcal{L}_0=\oplus_{j\geqslant 0}\mathfrak{g}_j$ it follows from Theorem 3.1 that every finite irreducible $\mathfrak{g}$-module is a quotient of $M_{\mathfrak{S}_+^4}(\Delta,\Lambda,\overline{\Lambda})=\mathrm{Ind}_{\mathcal{L}_0}^{\mathfrak{g}}U^{\Delta,\Lambda,\overline{\Lambda}}$. The unique irreducible quotient will be denoted by $L_{\mathfrak{S}_+^4}(\Delta,\Lambda,\overline{\Lambda})$.

Now $M_{\mathfrak{S}_+^4}(\Delta,\Lambda,\overline{\Lambda})$ is a completely reducible $\mathfrak{g}_0$-module, and the subspace of $\mathbb{C}E_0\oplus\mathbb{C}\overline{E}_0$-invariants, denoted by $M_{\mathfrak{S}_+^4}(\Delta,\Lambda,\overline{\Lambda})^{E_0,\overline{E}_0}$, is a free $\mathbb{C}[\partial]$-submodule of $M_{\mathfrak{S}_+^4}(\Delta,\Lambda,\overline{\Lambda})$. We write down explicit formulas for a $\mathbb{C}[\partial]$-basis for the space $M_{\mathfrak{S}_+^4}(\Delta,\Lambda,\overline{\Lambda})^{E_0,\overline{E}_0}$, which in the case when $\Lambda,\overline{\Lambda}\geqslant 2$ is as follows:

$$b_1=v_{\Delta,\Lambda,\overline{\Lambda}},\quad b_2=G_{-1/2}^{++}v_{\Delta,\Lambda,\overline{\Lambda}},$$

$$b_3=(\Lambda G_{-1/2}^{-+}-G_{-1/2}^{++}F_0)v_{\Delta,\Lambda,\overline{\Lambda}},\quad b_4=(\overline{\Lambda}G_{-1/2}^{+-}-G_{-1/2}^{++}\overline{F}_0)v_{\Delta,\Lambda,\overline{\Lambda}},$$

$$b_5=(\Lambda\overline{\Lambda}G_{-1/2}^{--}-\overline{\Lambda}G_{-1/2}^{+-}F_0-\Lambda G_{-1/2}^{-+}\overline{F}_0+G_{-1/2}^{++}F_0\overline{F}_0)v_{\Delta,\Lambda,\overline{\Lambda}},$$

$$b_6=G_{-1/2}^{++}G_{-1/2}^{+-}v_{\Delta,\Lambda,\overline{\Lambda}},\quad b_7=(\Lambda(G_{-1/2}^{-+}G_{-1/2}^{+-}+G_{-1/2}^{++}G_{-1/2}^{--})-2G_{-1/2}^{++}G_{-1/2}^{+-}F_0)v_{\Delta,\Lambda,\overline{\Lambda}},$$

$$b_8=((\Lambda-1)(-\Lambda G_{-1/2}^{-+}G_{-1/2}^{--}+G_{-1/2}^{-+}G_{-1/2}^{+-}F_0+G_{-1/2}^{++}G_{-1/2}^{--}F_0)-G_{-1/2}^{++}G_{-1/2}^{+-}F_0^2)v_{\Delta,\Lambda,\overline{\Lambda}},$$

$$b_9=G_{-1/2}^{++}G_{-1/2}^{-+}v_{\Delta,\Lambda,\overline{\Lambda}},b_{10}=(\overline{\Lambda}(G_{-1/2}^{++}G_{-1/2}^{--}-G_{-1/2}^{-+}G_{-1/2}^{+-})-2G_{-1/2}^{++}G_{-1/2}^{-+}\overline{F_0})v_{\Delta,\Lambda,\overline{\Lambda}},$$

$$b_{11}=((\overline{\Lambda}-1)(-\overline{\Lambda}G_{-1/2}^{+-}G_{-1/2}^{--}+G_{-1/2}^{+-}G_{-1/2}^{-+}\overline{F}_0+G_{-1/2}^{++}G_{-1/2}^{--}\overline{F}_0)-G_{-1/2}^{++}G_{-1/2}^{-+}\overline{F}_0^2)v_{\Delta,\Lambda,\overline{\Lambda}},$$

$$b_{12}=G_{-1/2}^{++}G_{-1/2}^{+-}G_{-1/2}^{-+}v_{\Delta,\Lambda,\overline{\Lambda}},\quad b_{13}=(\Lambda G_{-1/2}^{++}G_{-1/2}^{-+}G_{-1/2}^{--}-G_{-1/2}^{++}G_{-1/2}^{-+}G_{-1/2}^{+-})v_{\Delta,\Lambda,\overline{\Lambda}},$$

$$b_{14}=(\overline{\Lambda}G_{-1/2}^{++}G_{-1/2}^{+-}G_{-1/2}^{--}-G_{-1/2}^{++}G_{-1/2}^{+-}G_{-1/2}^{-+})v_{\Delta,\Lambda,\overline{\Lambda}},$$

$$b_{15}=(\Lambda G_{-1/2}^{-+}G_{-1/2}^{--}(\overline{\Lambda}G_{-1/2}^{+-}-G_{-1/2}^{++}\overline{F}_0)+\overline{\Lambda}G_{-1/2}^{++}G_{-1/2}^{+-}(G_{-1/2}^{--}F_0-G^{-+}F_0\overline{F}_0))v_{\Delta,\Lambda,\overline{\Lambda}},$$

$$b_{16}=(G_{-1/2}^{++}G_{-1/2}^{+-}G_{-1/2}^{-+}G_{-1/2}^{--}-\partial(G_{-1/2}^{-+}G_{-1/2}^{+-}+G_{-1/2}^{++}G_{-1/2}^{--}))v_{\Delta,\Lambda,\overline{\Lambda}}.$$

In the case when $\Lambda=\overline{\Lambda}=1$ (respectively $\Lambda=\overline{\Lambda}=0$) we have $b_8=b_{11}=0$ (respectively $b_3=b_4=b_5=b_7=b_8=b_{10}=b_{11}=b_{13}=b_{14}=b_{15}=0$), thus giving us 14 (respectively 6) generators. Other cases are easily described as well; however, we will not need them because of Proposition 7.1. Thus we will omit them.

We will, as before, denote the coefficient of $v_{\Delta,\Lambda,\overline{\Lambda}}$ in b_i by $u_i^{\Lambda,\overline{\Lambda}}$ for $1\leqslant i\leqslant 16$. In the case when $\Lambda=\overline{\Lambda}$, which is the only case we will be concerned with in what follows, we simply write u_i^{Λ} for $u_i^{\Lambda,\Lambda}$ and also $v_{\Delta,\Lambda}$ for $v_{\Delta,\Lambda,\Lambda}$.

Proposition 7.1: If $M_{\mathfrak{S}^4_+}(\Delta,\Lambda,\overline{\Lambda})$ is a reducible $\mathfrak{g}$-module, then either $2\Delta-\Lambda=2\Delta-\overline{\Lambda}=0$ or else $2\Delta+\Lambda+2=2\Delta+\overline{\Lambda}+2=0$. In particular, if $\Lambda\neq\overline{\Lambda}$, then $M_{\mathfrak{S}^4_+}(\Delta,\Lambda,\overline{\Lambda})$ is irreducible.

Proof: As a module over $\mathrm{SK}(1,4)_+$ we have $M_{\mathfrak{S}^4_+}(\Delta,\Lambda,\overline{\Lambda})=U(\mathfrak{g}_-)\otimes U^{\Delta,\Lambda,\overline{\Lambda}}$ is a direct sum of $\overline{\Lambda}+1$ copies of $M_{\mathfrak{N}^4_+}(\Delta,\Lambda)$, generated by the highest weight vectors $\overline{F}_0^j v_{\Delta,\Lambda,\overline{\Lambda}}$, where $0\leqslant j\leqslant\overline{\Lambda}$. Since the $\overline{H}_0$-weights of the $\overline{F}_0^j v_{\Delta,\Lambda,\overline{\Lambda}}$'s are all distinct for distinct j's, it follows that these modules as $\mathrm{SK}(1,4)_+\rtimes\mathbb{C}\overline{H}_0$-modules are all non-isomorphic. Therefore, if $M_{\mathfrak{N}^4_+}(\Delta,\Lambda)$ is irreducible over $\mathrm{SK}(1,4)_+$, then $M_{\mathfrak{S}^4_+}(\Delta,\Lambda,\overline{\Lambda})$ is irreducible over $\mathfrak{g}$. From this and Corollary 6.1 we thus conclude that in the case when $\Delta-2\Lambda\neq 0$ and $\Delta+2\Lambda+2\neq 0$ the $\mathfrak{g}$-module $M_{\mathfrak{S}^4_+}(\Delta,\Lambda,\overline{\Lambda})$ is irreducible.

By symmetry we conclude that if $\Delta-2\overline{\Lambda}\neq 0$ and $\Delta+2\overline{\Lambda}+2\neq 0$, then $M_{\mathfrak{S}^4_+}(\Delta,\Lambda,\overline{\Lambda})$ is irreducible over $\mathfrak{g}$ as well.

Therefore, $M_{\mathfrak{S}^4_+}(\Delta,\Lambda,\overline{\Lambda})$ is possibly reducible only if both Λ and $\overline{\Lambda}$ satisfy one of the two linear equations $\Delta-2x=0$ and $\Delta+2x+2=0$. But the case $\Delta-2\Lambda=0$ and $\Delta+2\overline{\Lambda}+2=0$ is not possible, since both Λ and $\overline{\Lambda}$ are non-negative integers. By the same token $\Delta-2\overline{\Lambda}=0$ and $\Delta+2\Lambda+2=0$ is not possible, either. Hence either we have $\Delta-2\Lambda=0$ and $\Delta-2\overline{\Lambda}=0$, or else $\Delta+2\Lambda+2=0$ and $\Delta+2\overline{\Lambda}+2=0$. In either case we must have $\Lambda=\overline{\Lambda}$. □

The next step is to analyze proper singular vectors inside $M_{\mathfrak{S}^4}(\Delta,\Lambda,\overline{\Lambda})$. (The definitions of singular vectors and proper singular vectors of $\mathfrak{g}$ are of course analogous.) By Proposition 7.1 proper singular vectors exist only if $\Lambda=\overline{\Lambda}$ with either $2\Delta+\Lambda=0$ or $2\Delta+\Lambda+2=0$.

Proposition 7.2: A complete list of proper singular vectors inside $M_{\mathfrak{S}^4_+}(\Delta,\Lambda,\Lambda)$ is given by

(*i*) αb_2, $\alpha\neq 0$, *in the case* $2\Delta-\Lambda=0$, *and*
(*ii*) αb_5, $\alpha\neq 0$, *in the case* $2\Delta+\Lambda+2=0$ *and* $\Lambda\geqslant 1$.

Proof: Since as a $\mathrm{SK}(1,4)_+$-module $M_{\mathfrak{S}^4}(\Delta,\Lambda,\Lambda)$ is a direct sum of $\Lambda+1$ copies of $M_{\mathfrak{N}^4}(\Delta,\Lambda)$ we obtain a description of the vector space spanned by all proper $\mathrm{SK}(1,4)_+$-singular vectors by virtue of Proposition 6.1. But as a $\overline{\mathrm{SK}}(1,4)_+$-module $M_{\mathfrak{S}^4}(\Delta,\Lambda,\Lambda)$ is also a direct sum of $\Lambda+1$ copies of $M_{\mathfrak{N}^4}(\Delta,\Lambda)$, from which we obtain similarly a description of the vector space spanned by all proper $\overline{\mathrm{SK}}(1,4)_+$-singular vectors (see Remark 7.1). The intersection of these two spaces is the space of proper singular vectors.

In the case when $2\Delta-\Lambda=0$ it follows from Proposition 6.1 that the space of proper $\mathrm{SK}(1,4)_+$-singular vectors is spanned by $G^{++}_{-1/2}\overline{F}_0^j v_{\Delta,\Lambda}$, $G^{+-}_{-1/2}\overline{F}_0^j v_{\Delta,\Lambda}$ and $G^{++}_{-1/2}G^{+-}_{-1/2}\overline{F}_0^j v_{\Delta,\Lambda}$, for $0\leqslant j\leqslant\Lambda$. On the other hand, the space of proper $\overline{\mathrm{SK}}(1,4)_+$-singular vectors is spanned by $G^{++}_{-1/2}F_0^j v_{\Delta,\Lambda}$, $G^{-+}_{-1/2}F_0^j v_{\Delta,\Lambda}$ and $G^{++}_{-1/2}G^{-+}_{-1/2}F_0^j v_{\Delta,\Lambda}$, for $0\leqslant j\leqslant\Lambda$. It is not hard to see that the intersection of these two spaces is the one-dimensional space spanned by $G^{++}_{-1/2}v_{\Delta,\Lambda}$, which is b_2.

Other cases are analogous and so we omit the details. □

Proposition 7.3: Suppose that $2\Delta-\Lambda=0$. Then $L_{\mathfrak{S}^4_+}(\Delta,\Lambda,\Lambda)$ is a free $\mathbb{C}[\partial]$-module of rank $8\Lambda(\Lambda+1)$.

Proof: By Proposition 7.2 b_2 is a singular vector in $M_{\mathfrak{S}^4_+}(\Lambda/2,\Lambda,\Lambda)$. Consider N, the $\mathfrak{g}$-submodule generated by b_2. Then we have $N=U(\mathfrak{g}_-)V$, where V is the irreducible $\mathrm{sl}_2\oplus\overline{\mathrm{sl}}_2$-submodule generated by b_2. Let us compute the space $N^{E_0,\overline{E}_0}$, the space of $(\mathbb{C}E_0\oplus\mathbb{C}\overline{E}_0)$-invariants inside N. Since the $(H_0,\overline{H}_0)$-weight of b_2 is $(\Lambda+1,\Lambda+1)$, we know that N^{E_0,E_0} is a free $\mathbb{C}[\partial]$-module generated over $\mathbb{C}[\partial]$ by $\{u_i^{\Lambda+1}b_2|1\leqslant i\leqslant 16\}$. We have

$$u_1^{\Lambda+1}b_2=b_2,\quad u_2^{\Lambda+1}b_2=0,\quad u_3^{\Lambda+1}b_2=-(\Lambda+2)b_9,\quad u_4^{\Lambda+1}b_2=-(\Lambda+2)b_6,$$

$$u_5^{\Lambda+1}b_2=-\frac{(\Lambda+2)}{2}(b_7+b_{10}+4(\Lambda+1)\partial b_1),\quad u_6^{\Lambda+1}b_2=0,\quad u_7^{\Lambda+1}b_2=-(\Lambda+3)b_{12},$$

$$u_8^{\Lambda+1}b_2=-(\Lambda+2)(b_{13}-2\partial b_3),\quad u_9^{\Lambda+1}b_2=0,\quad u_{10}^{\Lambda+1}b_2=(\Lambda+3)b_{12}-4(\Lambda+1)\partial b_2,$$

$$u_{11}^{\Lambda+1}b_2=-(\Lambda+2)(b_{14}-2\partial b_4),\quad u_{12}^{\Lambda+1}b_2=0,\quad u_{13}^{\Lambda+1}b_2=-2(\Lambda+2)\partial b_9,$$

$$u_{14}^{\Lambda+1}b_2=-2(\Lambda+2)\partial b_6,\quad u_{15}^{\Lambda+1}b_2=-4(\Lambda+1)\partial^2 b_1-(\Lambda+2)^2 b_{16}+(\Lambda+2)\partial b_7,$$

$$u_{16}^{\Lambda+1}b_2=-4\partial b_{12}.$$

It follows that $N^{E_0,\overline{E_0}}$ is generated over $\mathbb{C}[\partial]$ by the set

$$S^\Lambda=\Big\{b_2,b_6,b_7+b_{10}+4(\Lambda+2)\partial b_1,b_9,b_{12},b_{13}-2\partial b_3,b_{14}$$
$$-2\partial b_4,b_{16}-\left(\frac{1}{\Lambda+2}\right)\partial b_7-2\frac{(\Lambda+1)}{(\Lambda+2)^2}\partial^2 b_1\Big\}.$$

In the case when $\Lambda\geqslant 2$ it follows from the description of S^Λ that $\{b_1,b_3,b_4,b_5,b_8,b_{10}+2\Lambda\partial b_1,b_{11},b_{15}\}$ is a $\mathbb{C}[\partial]$-basis for the $(\mathbb{C}E_0\oplus\mathbb{C}\overline{E}_0)$-invariants of the quotient space $M_{\mathfrak{S}_+^4}(\Lambda/2,\Lambda,\Lambda)/N$. (The choice of $b_{10}+2\Lambda\partial b_1$ instead of just b_{10} will be explained later.)

The $(L_0,H_0,\overline{H}_0)$-weights of b_1, b_3, b_4, b_5, b_8, $b_{10}+2\Lambda\partial b_1$, b_{11}, b_{15} are (Δ,Λ,Λ), $(\Delta+\frac{1}{2},\Lambda-1,\Lambda+1)$, $(\Delta+\frac{1}{2},\Lambda+1,\Lambda-1)$, $(\Delta+\frac{1}{2},\Lambda-1,\Lambda-1)$, $(\Delta+1,\Lambda-2,\Lambda)$, $(\Delta+1,\Lambda,\Lambda)$, $(\Delta+1,\Lambda,\Lambda-2)$, and $(\Delta+\frac{3}{2},\Lambda-1,\Lambda-1)$, respectively. Hence $M_{\mathfrak{S}_+^4}(\Lambda/2,\Lambda,\Lambda)/N$ is a free $\mathbb{C}[\partial]$-module of rank $8\Lambda(\Lambda+1)$. So, we need to show that $M_{\mathfrak{S}_+^4}(\Lambda/2,\Lambda,\Lambda)/N$ is irreducible.

Now L_n, $n\geqslant -1$, together with E_0, H_0, F_0 and $\overline{E}_0$, $\overline{H}_0$, $\overline{F}_0$ generate a copy of $(\mathfrak{V}_+\oplus\mathrm{sl}_2\oplus\overline{\mathrm{sl}}_2)$, which thus allows us to study the $(\mathfrak{V}_+\oplus\mathrm{sl}_2\oplus\overline{\mathrm{sl}}_2)$-module structure of $M_{\mathfrak{S}_+^4}(\Lambda/2,\Lambda,\Lambda)/N$. We can easily check that L_n, for $n\geqslant 1$, annihilates the vectors b_1, b_3, b_4, b_5, b_8, $b_{10}+2\Lambda\partial b_1$, b_{11}, b_{15}. (We want to point out that b_{10} is not annihilated by L_n, for $n\geqslant 1$, hence the choice of $b_{10}+2\Lambda\partial b_1$.) Thus $M_{\mathfrak{S}_+^4}(\Lambda/2,\Lambda,\Lambda)/N$ as a $(\mathfrak{V}_+\oplus\mathrm{sl}_2\oplus\overline{\mathrm{sl}}_2)$-module is a direct sum of the following eight irreducible modules: $\mathbb{C}[\partial]V_1\cong L_{\mathfrak{V}_+}(\Lambda/2)\boxtimes U^{\Lambda,\Lambda}$, $\mathbb{C}[\partial]V_3\cong L_{\mathfrak{V}_+}((\Lambda+1)/2)\boxtimes U^{\Lambda-1,\Lambda+1}$, $\mathbb{C}[\partial]V_4\cong L_{\mathfrak{V}_+}((\Lambda+1)/2)\boxtimes U^{\Lambda+1,\Lambda-1}$, $\mathbb{C}[\partial]V_5\cong L_{\mathfrak{V}_+}((\Lambda+1)/2)\boxtimes U^{\Lambda-1,\Lambda-1}$, $\mathbb{C}[\partial]V_8\cong L_{\mathfrak{V}_+}((\Lambda+2)/2)\boxtimes U^{\Lambda-2,\Lambda}$, $\mathbb{C}[\partial]V_{10}\cong L_{\mathfrak{V}_+}((\Lambda+2)/2)\boxtimes U^{\Lambda,\Lambda}$, $\mathbb{C}[\partial]V_{11}\cong L_{\mathfrak{V}_+}((\Lambda+2)/2)\boxtimes U^{\Lambda,\Lambda-2}$, $\mathbb{C}[\partial]V_{15}\cong L_{\mathfrak{V}_+}((\Lambda+3)/2)\boxtimes U^{\Lambda-1,\Lambda-1}$, where V_i is the irreducible $\mathrm{sl}_2\oplus\overline{\mathrm{sl}}_2$-module generated by b_i, for $i\neq 10$, and V_{10} is generated by $b_{10}+2\Lambda\partial b_1$, and finally $U^{\mu,\mu'}$ denotes the irreducible $\mathrm{sl}_2\oplus\overline{\mathrm{sl}}_2$-module of highest weight (μ,μ'). Note that as $(\mathfrak{V}_+\oplus\mathrm{sl}_2\oplus\overline{\mathrm{sl}}_2)$-modules they are all non-isomorphic and thus to show that $M_{\mathfrak{S}_+^4}(\Lambda/2,\Lambda,\Lambda)/N$ is irreducible; it suffices to show that one may send a $(\mathfrak{V}_+\oplus\mathrm{sl}_2\oplus\overline{\mathrm{sl}}_2)$-highest weight vector in any irreducible $(\mathfrak{V}_+\oplus\mathrm{sl}_2\oplus\overline{\mathrm{sl}}_2)$-component to the irreducible component containing the $\mathfrak{g}$-highest weight vectors. This follows from the following computation:

$$G_{1/2}^{--}b_3=2(\Lambda+1)F_0b_1,\quad \overline{G}_{1/2}^{--}b_4=2(\Lambda+1)\overline{F}_0b_1,$$

$$G_{1/2}^{++}b_5=-2\Lambda^2(\Lambda+1)b_1,\quad E_1b_8=2\Lambda(\Lambda-1)(\Lambda+1)b_1,$$

$$\overline{F}_1(b_{10}+2\Lambda\partial b_1)=-2(\Lambda+2)\overline{F}_0b_1,\quad \overline{E}_1b_{11}=2\Lambda(\Lambda-1)(\Lambda+1)b_1,$$

$$\overline{G}^{++}_{3/2}\, b_{15} = -2\Lambda^2(\Lambda+1)b_1.$$

Now if $\Lambda=1$, the vectors $b_8=b_{11}=0$. Therefore, $M_{\mathfrak{S}^4_+}(\Lambda/2,\Lambda,\Lambda)/N$ is $\mathbb{C}[\partial]V_1\oplus\mathbb{C}[\partial]V_3\oplus\mathbb{C}[\partial]V_4\oplus\mathbb{C}[\partial]V_5\oplus\mathbb{C}[\partial]V_{10}\oplus\mathbb{C}[\partial]V_{15}$. But then the above calculation also shows that $M_{\mathfrak{S}^4_+}(\Lambda/2,\Lambda,\Lambda)/N$ is irreducible. The rank of $L_{\mathfrak{S}^4_+}(\Lambda/2,\Lambda,\Lambda)$ is then $4+3+3+1+4+1=16$, which is equal to $8\Lambda(\Lambda+1)$ in the case when $\Lambda=1$.

Finally, when $\Lambda=0$, the vectors $b_3=b_4=b_5=b_7=b_8=b_{10}=b_{11}=b_{13}=b_{14}=b_{15}=0$ and S^Λ reduce to $\{b_2,b_6,\partial b_1,b_9,b_{12},b_{16}\}$. Hence $M_{\mathfrak{S}^4_+}(0,0,0)/N=\mathbb{C}b_1$ is the trivial module and so has rank 0. □

Proposition 7.4: Suppose that $2\Delta+\Lambda+2=0$ *and* $\Lambda\geqslant 1$. *Then* $L_{\mathfrak{S}^4_+}(\Delta,\Lambda,\Lambda)$ *is a free* $\mathbb{C}[\partial]$*-module of rank* $8(\Lambda+1)(\Lambda+2)$.

Proof: By Proposition 7.2 b_5 is a singular vector in $M_{\mathfrak{S}^4_+}(-(\Lambda+2)/2,\Lambda,\Lambda)$. Let N be the $\mathfrak{g}$-submodule generated by b_5 so that $N=U(\mathfrak{g}_-)V$, where V is the irreducible $\mathrm{sl}_2\oplus\overline{\mathrm{sl}}_2$-submodule generated by b_5. Consider $N^{E_0,\overline{E}_0}$, the subspace in N of $\mathbb{C}E_0\oplus\mathbb{C}\overline{E}_0$-invariants. Now the $(H_0,\overline{H}_0)$-weight of b_5 is $(\Lambda-1,\Lambda-1)$ and so $N^{E_0,\overline{E}_0}$ is a free $\mathbb{C}[\partial]$-module generated over $\mathbb{C}[\partial]$ by $\{u_i^{\Lambda-1}b_5 \mid 1\leqslant i\leqslant 16\}$. We have

$$u_1^{\Lambda-1}b_5=b_5,\quad u_2^{\Lambda-1}b_5=\tfrac{1}{2}(b_7+b_{10}),\quad u_3^{\Lambda-1}b_5=-\Lambda b_8,\quad u_4^{\Lambda-1}b_5=-\Lambda b_{11},$$

$$u_5^{\Lambda-1}b_5=0,\quad u_6^{\Lambda-1}b_5=\Lambda b_{14},\quad u_7^{\Lambda-1}b_5=-(\Lambda-1)b_{15},\quad u_8^{\Lambda-1}b_5=0,$$

$$u_9^{\Lambda-1}b_5=\Lambda b_{13},\quad u_{10}^{\Lambda-1}b_5=(\Lambda-1)b_{15},\quad u_{11}^{\Lambda-1}b_5=0,$$

$$u_{12}^{\Lambda-1}b_5=\Lambda(\Lambda b_{16}+\partial b_7),\quad u_{13}^{\Lambda-1}b_5=0,\quad u_{14}^{\Lambda-1}b_5=0,\quad u_{15}^{\Lambda-1}b_5=0,$$

$$u_{16}^{\Lambda-1}b_5=\partial b_{15}.$$

It follows in the case $\Lambda\geqslant 2$ that $N^{E_0,\overline{E}_0}$ is generated over $\mathbb{C}[\partial]$ by the set

$$S^\Lambda=\{b_5,b_7+b_{10},b_8,b_{11},b_{13},b_{14},b_{15},\Lambda b_{16}+\partial b_7\}.$$

Hence in this case $\{b_1,b_2,b_3,b_4,b_6,b_9,b_{10}+2\Lambda\partial b_1,b_{12}\}$ is a $\mathbb{C}[\partial]$-basis for the $(\mathbb{C}E_0\oplus\mathbb{C}\overline{E}_0)$-invariants of $M_{\mathfrak{S}^4_+}(-(\Lambda+2)/2,\Lambda,\Lambda)/N$.

The $(L_0,H_0,\overline{H}_0)$-weights of b_1, b_2, b_3, b_4, b_6, b_9, $b_{10}+2\Lambda\partial b_1$, b_{12} are (Δ,Λ,Λ), $(\Delta+\frac{1}{2},\Lambda+1,\Lambda+1)$, $(\Delta+\frac{1}{2},\Lambda-1,\Lambda+1)$, $(\Delta+\frac{1}{2},\Lambda+1,\Lambda-1)$, $(\Delta+1,\Lambda+2,\Lambda)$, $(\Delta+1,\Lambda,\Lambda+2)$, $(\Delta+1,\Lambda,\Lambda)$, $(\Delta+\frac{3}{2},\Lambda+1,\Lambda+1)$, respectively. Hence $M_{\mathfrak{S}^4_+}(-(\Lambda+2)/2,\Lambda)/N$ is a free $\mathbb{C}[\partial]$-module of rank $8(\Lambda+1)(\Lambda+2)$. So, we need to show that $M_{\mathfrak{S}^4_+}(\Lambda/2,\Lambda,\Lambda)/N$ is irreducible.

Again we will study the $(\mathfrak{V}_+\oplus\mathrm{sl}_2\oplus\overline{\mathrm{sl}}_2)$-module structure of $M_{\mathfrak{N}^4_+}(\Lambda/2,\Lambda)/N$. We can check directly that L_n, for $n\geqslant 1$, annihilates the vectors b_1, b_2, b_3, b_4, b_6, b_9, $b_{10}+2\Lambda\partial b_1$, b_{12}. Thus $M_{\mathfrak{S}^4_+}(-(\Lambda+2)/2,\Lambda,\Lambda)/N$ as a $(\mathfrak{V}_+\oplus\mathrm{sl}_2\oplus\overline{\mathrm{sl}}_2)$-module is a direct sum of the following eight irreducible modules: $\mathbb{C}[\partial]V_1\cong L_{\mathfrak{V}_+}(-(\Lambda+2)/2)\boxtimes U^{\Lambda,\Lambda}$, $\mathbb{C}[\partial]V_2\cong L_{\mathfrak{V}_+}(-(\Lambda+1)/2)\boxtimes U^{\Lambda+1,\Lambda+1}$, $\mathbb{C}[\partial]V_3\cong L_{\mathfrak{V}_+}(-(\Lambda+1)/2)\boxtimes U^{\Lambda-1,\Lambda+1}$, $\mathbb{C}[\partial]V_4\cong L_{\mathfrak{V}_+}(-(\Lambda+1)/2)\boxtimes U^{\Lambda+1,\Lambda-1}$, $\mathbb{C}[\partial]V_6\cong L_{\mathfrak{V}_+}(-\Lambda/2)\boxtimes U^{\Lambda+2,\Lambda}$, $\mathbb{C}[\partial]V_9\cong L_{\mathfrak{V}_+}(-\Lambda/2)\boxtimes U^{\Lambda,\Lambda+2}$, $\mathbb{C}[\partial]V_{10}\cong L_{\mathfrak{V}_+}(-\Lambda/2)\boxtimes U^{\Lambda,\Lambda}$, $\mathbb{C}[\partial]V_{12}\cong L_{\mathfrak{V}_+}(-(\Lambda-1)/2)\boxtimes U^{\Lambda+1,\Lambda+1}$, where V_i is the irreducible $\mathrm{sl}_2\oplus\overline{\mathrm{sl}}_2$-module generated by b_i, for $i\neq 10$, and V_{10} is generated by $b_{10}+2\Lambda\partial b_1$, and $U^{\mu,\mu'}$ is the irreducible $\mathrm{sl}_2\oplus\overline{\mathrm{sl}}_2$-module of highest weight (μ,μ'). Note these modules are all irreducible. Note further that they are all non-isomorphic. So as before, to show that $M_{\mathfrak{S}^4_+}(-(\Lambda+2)/2,\Lambda,\Lambda)/N$ is irre-

ducible, it suffices to show that one may send a $(\mathfrak{V}_+ \oplus \mathrm{sl}_2 \oplus \overline{\mathrm{sl}}_2)$-highest weight vector in any irreducible $(\mathfrak{V}_+ \oplus \mathrm{sl}_2 \oplus \overline{\mathrm{sl}}_2)$-component to the irreducible component containing the $\mathfrak{g}$-highest weight vectors. For this purpose we compute

$$G^{--}_{1/2} b_2 = 2(\Lambda+1) b_1, \quad \overline{G}^{+-}_{1/2} b_3 = -2\Lambda(\Lambda+1) b_1,$$

$$G^{-+}_{1/2} b_4 = -2\Lambda(\Lambda+1) b_1, \quad F_1 b_6 = -2(\Lambda+1) b_1,$$

$$\overline{F}_1 b_9 = -2(\Lambda+1) b_1 \quad \overline{F}_1 (b_{10} + 2\Lambda \partial b_1) = 2\Lambda \overline{F}_0 b_1,$$

$$\overline{G}^{--}_{3/2} b_{12} = 8(\Lambda+1) b_1.$$

This settles the case when $\Lambda \geqslant 2$.

In the case when $\Lambda = 1$, $N^{E_0, \overline{E}_0}$ is generated over $\mathbb{C}[\partial]$ by

$$S^{\Lambda} = \{b_5, b_7 + b_{10}, b_{13}, b_{14}, b_{16} + \partial b_7, \partial b_{15}\}.$$

Therefore, $M_{\mathfrak{S}^4_+}(-(\Lambda+2)/2, \Lambda, \Lambda)/N$ contains a ∂-invariant (and hence $\mathfrak{g}$-invariant) vector b_{15}. Since in this case the vectors $b_8 = b_{11} = 0$, $M_{\mathfrak{S}^4_+}(-(\Lambda+2)/2, \Lambda, \Lambda)/(N + \mathbb{C}b_{15})$ as a $\mathfrak{V}_+ \oplus \mathrm{sl}_2 \oplus \overline{\mathrm{sl}}_2$-module is isomorphic to $\mathbb{C}[\partial]V_1 \oplus \mathbb{C}[\partial]V_2 \oplus \mathbb{C}[\partial]V_3 \oplus \mathbb{C}[\partial]V_4 \oplus \mathbb{C}[\partial]V_6 \oplus \mathbb{C}[\partial]V_9 \oplus \mathbb{C}[\partial]V_{10} \oplus \mathbb{C}[\partial]V_{12}$. Every component is irreducible except for $\mathbb{C}[\partial]V_{12}$, which contains a unique (irreducible) $\mathfrak{V}_+ \oplus \mathrm{sl}_2 \oplus \overline{\mathrm{sl}}_2$-submodule isomorphic to $L_{\mathfrak{V}_+}(1) \otimes U^{2,2}$ generated by the highest weight vector ∂b_{15}. But then the above calculation plus the fact that

$$\overline{G}^{--}_{5/2} \partial b_{12} = 24(\Lambda+1) \partial b_1$$

also shows that $M_{\mathfrak{S}^4_+}(-(\Lambda+2)/2, \Lambda, \Lambda)/(N + \mathbb{C}b_{15})$ is irreducible. □

We summarize the results of this section in the following theorem.

Theorem 7.1: *The modules $L_{\mathfrak{S}^4_+}(\Delta, \Lambda, \overline{\Lambda})$, for $\Delta \in \mathbb{C}$ and $\Lambda, \overline{\Lambda} \in \mathbb{Z}_+$, form a complete list of non-isomorphic finite (over $\mathbb{C}[\partial]$) irreducible $\mathrm{K}(1,4)_+$-modules. Furthermore, $L_{\mathfrak{S}^4_+}(\Delta, \Lambda, \overline{\Lambda})$ as a $\mathbb{C}[\partial]$-module has rank*

(*i*) $8\Lambda(\Lambda+1)$, *in the case* $2\Delta - \Lambda = 0$ *and* $\Lambda = \overline{\Lambda}$,
(*ii*) $8(\Lambda+1)(\Lambda+2)$, *in the case* $2\Delta + \Lambda + 2 = 0$ *and* $\Lambda = \overline{\Lambda}$, *and*
(*iii*) $16(\Lambda+1)(\overline{\Lambda}+1)$, *in all other cases.*

*Furthermore, the $\mathbb{C}[\partial]$-rank of $L_{\mathfrak{S}^4_+}(\Delta, \Lambda, \overline{\Lambda})^-_0$ equals the $\mathbb{C}[\partial]$-*rank of $L_{\mathfrak{S}^4_+}(\Delta, \Lambda, \overline{\Lambda})^-_1$ *in all cases.*

Remark 7.2: Again the translation into the languages of modules over conformal algebras and of conformal modules is straightforward and hence is omitted. We thus obtain that all finite irreducible modules over the ''big'' $N=4$ conformal superalgebra are of the form $L_{\mathfrak{S}^4}(\alpha, \Delta, \Lambda, \overline{\Lambda})$, where $\alpha, \Delta \in \mathbb{C}$ and $\Lambda, \overline{\Lambda} \in \mathbb{Z}_+$. Again the definition of these modules and the action of the conformal superalgebra on them are easily derived from our explicit description of a $\mathbb{C}[\partial]$-basis in this section. We note that the adjoint module is isomorphic to $M_{\mathfrak{S}^4}(0,0,0,0)$. This module is not simple, since K(1,4) is not a simple Lie superalgebra. Its derived algebra $\mathrm{K}(1,4)'$ (which is a simple formal distribution Lie superalgebra) is an ideal in K(1,4) of codimension 1.[10] Since the annihilation subalgebra of $\mathrm{K}(1,4)'$ and K(1,4) are identical, and hence their conformal modules are identical. Therefore the results in this section also give explicit description of irreducible conformal modules over $\mathrm{K}(1,4)'$. We finally remark that the $\mathrm{K}(1,4)'$ as a conformal module over K(1,4) corresponds to $L_{\mathfrak{S}^4}(0, \frac{1}{2}, 1, 1)$.

(Received 19 April 2000; accepted for publication 24 July 2000)

An additive braided coproduct (also be called braided coaddition) is introduced on the quantized braided matrices (QBMs). It gives QBMs another braided-Hopf algebra structure. The coaddition is also shown to be compatible with the existing coproduct such that they together form a so-called quantized-braided ring. And some quantized braided differential operator bialgebras (Hopf algebras) relating to this braided coaddition are constructed. These give a unification and generalization of the known results about braided and quantum matrices. Moreover, the coaddition construction and the related differential calculi on the QBMs are further extended to a kind of more general quantum matrix algebraic systems. Some examples are also given. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1326457]

I. INTRODUCTION

Quantized braided matrices (groups) [QBM(Gs)] were proposed by Hlavaty[1] years ago, they are a kind of more general algebraic structures that contain the usual quantum matrices (groups),[2–4] braided matrices (groups),[5–7] quantum supermatrices (supergroups),[8] quantum anyonic matrices (groups),[9] and μ-braided GL_q matrices (groups)[10] as special cases. Thus the theory of QBM(G)s has, among others, a remarkable advantage that enable us to study two quite different kinds of noncommutativities (associated, respectively, with quantization and general braid statistics) in a unified way. Some of properties and applications of the QBM(G)s have been discussed recently.[11–13]

In this paper, we consider some other features of QBM(G)s. We introduce an additive braided coproduct (also be called braided coaddition) on the QBMs and show that it is compatible with the existing (multiplicative) coproduct in a way obeying some quantized braided codistributivity axiom. Moreover, we construct corresponding braided differential calculi on the QBMs and discuss some related results. These are motivated by the works of Meyer[14] and Majid,[15] where the braided coadditions on braided and quantum matrices were introduced respectively. In some sense, the scheme of the present paper gives a unification and generalization of that in Refs. 14 and 15, the related results for the braided[14] and quantum[15] matrices can be obtained as special cases. Furthermore, we also find that the coaddition construction and some related results on the QBMs can even be further extended to a kind of more general algebraic systems.

We begin in Sec. II by recalling some notion and results about the QBM(G)s. In Sec. III we introduce braided coaddition on QBMs and show that it and the existing coproduct together form a so-called quantized-braided ring. The braided differential operators with respect to the coaddition are introduced in Sec. IV and their bialgebra structures are given. Section V gives some example to explain the formulations of Secs. III and IV. In Sec. VI the braided coaddition and associated differential operator algebras on QBMs are further generalized to more general algebraic systems. Finally, Sec. VII contains some conclusions and discussions.

II. QUANTIZED BRAIDED MATRICES

Here we briefly recall some related results about the QBM(G)s from Refs. 1 and 11, these are useful in the discussions later.

Let $T=\{T_j^i\}_{i,j=1}^N$ be a matrix of N^2 elements T_j^i and $R,Z\in M_N(\mathbf{C})\otimes M_N(\mathbf{C})$ be an R-matrix pair satisfying the set of quantum Yang–Baxter-type equations,[1]

$$\begin{aligned} &R_{12}R_{13}R_{23}=R_{23}R_{13}R_{12}, \quad Z_{12}Z_{13}Z_{23}=Z_{23}Z_{13}Z_{12},\\ &R_{12}Z_{13}Z_{23}=Z_{23}Z_{13}R_{12}, \quad Z_{12}Z_{13}R_{23}=R_{23}Z_{13}Z_{12}, \end{aligned} \tag{2.1}$$

then the quantized braided matrix bialgebra, denoted by $A(R,Z)$, is generated by T_j^i and 1 with the following algebra relations,

$$R_{12}Z_{12}^{-1}T_1Z_{12}T_2=Z_{21}^{-1}T_2Z_{21}T_1R_{12}, \tag{2.2}$$

the coproduct and counit

$$\Delta(T_j^i)=T_k^i\otimes T_j^k, \quad \varepsilon(T_j^i)=\delta_j^i, \tag{2.3}$$

and the braiding

$$\Psi(Z_{12}^{-1}T_1\otimes Z_{12}T_2)=T_2Z_{12}^{-1}\otimes T_1Z_{12}. \tag{2.4}$$

Throughout this paper, we always assume R, Z both to be invertible, and for $a\otimes b$, $c\otimes d\in A(R,Z)\otimes A(R,Z)$, the product in the (braided) tensor product algebra is given by

$$(a\otimes b)(c\otimes d)=a\Psi(b\otimes c)d \tag{2.5}$$

as in Ref. 15.

If we also introduce an antipode in $A(R,Z)$, then we obtain a quantized braided group.[1]

We mention some special cases of QBM(G)s: When $Z=R$ or $Z=I$ while R is any regular solution of the quantum Yang–Baxter equation (QYBE), then $A(R,Z)$ is reduced to the ordinary braided matrix (group) or quantum matrix (group), respectively; If Z is diagonal and R is some specified $R(q)$, then $A(R(q),Z)$ gives the μ-braided GL_q matrices (groups) considered in Ref. 10, etc.

Moreover, we have the following:[11]

Proposition 2.1: Defining $R^{(n)}\equiv(ZP)^nR(Z^{-1}P)^n$, if (R,Z) is an R-matrix pair satisfying (2.1), then $(R^{(n)},Z)$ satisfies (2.1), too, for each integer $n=0,\pm1,\pm2,\ldots$. Here P is the usual permutation matrix. □

Some times we need certain restricted conditions on R-matrices. A matrix solution R of the QYBE is called being Hecke-type if it satisfies

$$(PR-q)(PR+q^{-1})=0, \quad \text{or} \quad PRPR=1+\lambda PR \tag{2.6}$$

for suitable q and $\lambda=q-q^{-1}$.

Proposition 2.2: If R is Hecke-type, then so is $R^{(n)}$ for each $n=0,\pm1,\pm2,\ldots$.

Proof: The $R^{(n)}$ is defined in Proposition 2.1, thus $PR^{(n)}=(PZ)^nPR(PZ)^{-n}$. So from Eq. (2.6) we have

$$PR^{(n)}PR^{(n)}=(PZ)^nPRPR(PZ)^{-n}=(PZ)^n(1+\lambda PR)(PZ)^{-n}=1+\lambda PR^{(n)}. \quad \square$$

III. BRAIDED COADDITION ON QUANTIZED BRAIDED MATRICES

In this section we show that besides the coproduct (2.3) with the braiding (2.4), another kind of additive coproduct (or called braided coaddition) can also be introduced in $A(R,Z)$.

Theorem 3.1: Let the R-matrix pair (R,Z) obey Eqs. (2.1). Let R be Hecke type-and Z have the second inverse $\tilde{Z}\equiv((Z^{t_2})^{-1})^{t_2}$ (t_2 denotes transposition in the second factor). Then in the matrix algebra defined by (2.2), we can introduce the following additive coproduct, counit, and antipode:

$$\underline{\Delta}T\otimes 1+1\otimes T,\quad \underline{\varepsilon}T=0,\quad \underline{S}T=-T, \tag{3.1}$$

such that the relations (2.2), (3.1) give a braided-Hopf algebra with the braiding

$$\underline{\Psi}(T_1\otimes Z_{12}T_2)=Z_{12}R_{21}Z_{21}^{-1}T_2\otimes Z_{21}T_1R_{12}. \tag{3.2}$$

This braided-Hopf algebra will be denoted by $A(R,Z)$.

Proof: For the brevity of notations, we write (recall $R^{(n)}$ in Proposition 2.1)

$$\hat{R}_{12}\equiv R_{12}^{(1)}=Z_{12}R_{21}Z_{21}^{-1}, \tag{3.3}$$

thus the braiding (3.2) can be written as $\Psi(T_1\otimes Z_{12}T_2)=\hat{R}_{12}T_2\otimes Z_{21}T_1R_{12}$.

That the relation (2.2) defines an associative algebra has been pointed out by Hlavaty.[1] Here we have to check that Ψ, Δ, S, ε in (3.2), (3.1) are all well-defined when extended to products and satisfy the axioms of braided-Hopf algebra. First, we show that Ψ extends to tensor products according to the rules of braiding. In fact, from (3.2) we calculate (the meaning of Ψ_{ij} can easily be seen in the following calculations and the computations have generality because of the existence of $\tilde{Z}$)

$$\begin{aligned}
&\underline{\Psi}_{23}\underline{\Psi}_{13}\underline{\Psi}_{12}(T_1\otimes Z_{12}T_2\otimes Z_{13}Z_{23}T_3)\\
&\quad=\underline{\Psi}_{23}\underline{\Psi}_{13}(\hat{R}_{12}T_2\otimes Z_{21}T_1\otimes R_{12}Z_{13}Z_{23}T_3)\\
&\quad=\underline{\Psi}_{23}\underline{\Psi}_{13}(\hat{R}_{12}T_2\otimes Z_{21}Z_{23}T_1\otimes Z_{13}T_3R_{12})\\
&\quad=\underline{\Psi}_{23}(\hat{R}_{12}T_2\otimes Z_{21}Z_{23}\hat{R}_{13}T_3\otimes Z_{31}T_1R_{13}R_{12})\\
&\quad=\underline{\Psi}_{23}(\hat{R}_{12}\hat{R}_{13}T_2\otimes Z_{23}T_3\otimes Z_{21}Z_{31}T_1R_{13}R_{12})\\
&\quad=\hat{R}_{12}\hat{R}_{13}\hat{R}_{23}T_3\otimes Z_{32}T_2R_{23}\otimes Z_{21}Z_{31}T_1R_{13}R_{12}\\
&\quad=\hat{R}_{12}\hat{R}_{13}\hat{R}_{23}T_3\otimes Z_{32}Z_{31}T_2\otimes Z_{21}T_1R_{23}R_{13}R_{12};
\end{aligned}$$

$$\begin{aligned}
&\underline{\Psi}_{12}\underline{\Psi}_{13}\underline{\Psi}_{23}(T_1\otimes Z_{12}T_2\otimes Z_{13}Z_{23}T_3)\\
&\quad=\underline{\Psi}_{12}\underline{\Psi}_{13}(T_1\otimes Z_{12}Z_{13}\hat{R}_{23}T_3\otimes Z_{32}T_2R_{23})\\
&\quad=\underline{\Psi}_{12}\underline{\Psi}_{13}(\hat{R}_{23}T_1\otimes Z_{13}T_3\otimes Z_{12}Z_{32}T_2R_{23})\\
&\quad=\underline{\Psi}_{12}(\hat{R}_{23}\hat{R}_{13}T_3\otimes Z_{31}T_1\otimes R_{13}Z_{12}Z_{32}T_2R_{23})\\
&\quad=\underline{\Psi}_{12}(\hat{R}_{23}\hat{R}_{13}T_3\otimes Z_{31}Z_{32}T_1\otimes Z_{12}T_2R_{13}R_{23})\\
&\quad=\hat{R}_{23}\hat{R}_{13}T_3\otimes Z_{31}Z_{32}\hat{R}_{12}T_2\otimes Z_{21}T_1R_{12}R_{13}R_{23}\\
&\quad=\hat{R}_{23}\hat{R}_{13}\hat{R}_{12}T_3\otimes Z_{32}Z_{31}T_2\otimes Z_{21}T_1R_{12}R_{13}R_{23},
\end{aligned}$$

these two results are equal from relations (2.1). And in the above calculations we have used (2.1) and Proposition 2.1 many times.

Noted that in terms of $\hat{R}$, Eq. (2.2) can be written as $\hat{R}_{21}T_1Z_{12}T_2=T_2Z_{21}T_1R_{12}$, the extension of the braiding to products is then in such a way that $\underline{\Psi}$ is functorial with respect to the product, in the sense

$$\begin{aligned}\underline{\Psi}(\hat{R}_{21}T_1Z_{12}T_2\otimes Z_{13}Z_{23}T_3)&=(id\otimes\cdot)(\underline{\Psi}\otimes id)(id\otimes\underline{\Psi})(\hat{R}_{21}T_1\otimes Z_{12}T_2\otimes Z_{13}Z_{23}T_3)\\&=\hat{R}_{21}\hat{R}_{23}\hat{R}_{13}T_3\otimes Z_{31}Z_{32}T_1Z_{12}T_2R_{13}R_{23}\\&=\hat{R}_{13}\hat{R}_{23}T_3\otimes\hat{R}_{21}Z_{31}Z_{32}T_1Z_{12}T_2R_{13}R_{23}\\&=\hat{R}_{13}\hat{R}_{23}T_3\otimes Z_{32}Z_{31}\hat{R}_{21}T_1Z_{12}T_2R_{13}R_{23},\end{aligned}$$

to see that this extension is well-defined, we also calculate

$$\begin{aligned}\underline{\Psi}(T_2Z_{21}T_1R_{12}\otimes Z_{13}Z_{23}T_3)&=(id\otimes\cdot)(\underline{\Psi}\otimes id)(id\otimes\underline{\Psi})(T_2\otimes Z_{21}T_1\otimes Z_{23}Z_{13}T_3R_{12})\\&=\hat{R}_{13}\hat{R}_{23}T_3\otimes Z_{32}Z_{31}T_2Z_{21}T_1R_{23}R_{13}R_{12},\end{aligned}$$

which are consistent by the relation (2.2) and the QYBE about R. The extension to the high orders of products can then be computed in an entirely similar way. Hence, $\underline{\Psi}$ is well-defined and functorial with respect to the product.

Next we extend Δ to products in such a way that it is a homomorphism to the braided tensor product like (2.5). This is consistent because

$$\begin{aligned}\underline{\Delta}(R_{12}Z_{12}^{-1}T_1Z_{12}T_2)&=R_{12}Z_{12}^{-1}(T_1\otimes 1+1\otimes T_1)Z_{12}(T_2\otimes 1+1\otimes T_2)\\&=R_{12}Z_{12}^{-1}T_1Z_{12}T_2\otimes 1+R_{12}Z_{12}^{-1}T_1Z_{12}\otimes T_2\\&\quad+R_{12}R_{21}Z_{21}^{-1}T_2Z_{21}\otimes T_1R_{12}+1\otimes R_{12}Z_{12}^{-1}T_1Z_{12}T_2\\&=R_{12}Z_{12}^{-1}T_1Z_{12}T_2\otimes 1+R_{12}Z_{12}^{-1}T_1Z_{12}\otimes T_2\\&\quad+(1+\lambda R_{12}P_{12})Z_{21}^{-1}T_2Z_{21}\otimes T_1R_{12}+1\otimes R_{12}Z_{12}^{-1}T_1Z_{12}T_2;\end{aligned}$$

$$\begin{aligned}\underline{\Delta}(Z_{21}^{-1}T_2Z_{21}T_1R_{12})&=Z_{21}^{-1}(T_2\otimes 1+1\otimes T_2)Z_{21}(T_1\otimes 1+1\otimes T_1)R_{12}\\&=Z_{21}^{-1}T_2Z_{21}T_1R_{12}\otimes 1+Z_{21}^{-1}T_2Z_{21}\otimes T_1R_{12}\\&\quad+R_{12}Z_{21}^{-1}T_1Z_{12}\otimes T_2R_{21}R_{12}+1\otimes Z_{21}^{-1}T_2Z_{21}T_1R_{12}\\&=Z_{21}^{-1}T_2Z_{21}T_1R_{12}\otimes 1+Z_{21}^{-1}T_2Z_{21}\otimes T_1R_{12}\\&\quad+R_{12}Z_{12}^{-1}T_1Z_{12}\otimes T_2(1+\lambda P_{12}R_{12})+1\otimes Z_{21}^{-1}T_2Z_{21}T_1R_{12},\end{aligned}$$

where we have used the Hecke property (2.6) of R. These two results are equal due to the relation (2.2). Hence Δ is well-defined. It is trivial to see that the braiding $\underline{\Psi}$ is functorial with respect to the coproduct $\underline{\Delta}$.

Finally, for a braided-Hopf algebra, the antipode by definition is braided antimultiplicative in the sense $\underline{S}(ab)=\cdot\underline{\Psi}(\underline{S}a\otimes\underline{S}b)$. Then we can calculate that

$$\underline{S}(\hat{R}_{21}T_1Z_{12}T_2)=\cdot\underline{\Psi}(\hat{R}_{21}\underline{S}T_1\otimes Z_{12}\underline{S}T_2)=\hat{R}_{21}\hat{R}_{12}T_2Z_{21}T_1R_{12}=\hat{R}_{21}T_1Z_{12}T_2R_{21}R_{12},$$

where the relation (2.2) has been used. On the other hand,

$$\underline{S}(T_2Z_{21}T_1R_{12})=\cdot\underline{\Psi}(\underline{S}T_2\otimes Z_{21}\underline{S}T_1R_{12})=\hat{R}_{21}T_1Z_{12}T_2R_{21}R_{12}.$$

So we have $S(\hat{R}_{21}T_1Z_{12}T_2)=S(T_2Z_{21}T_1R_{12})$. On the high orders of products the calculations are similar. Thus S is well-defined.

Other axioms such as $\cdot(S\otimes id)\circ\Delta=\cdot(id\otimes S)\circ\Delta=\eta\circ\varepsilon$, etc. are easily verified. □

We have had two coproducts [of multiplicative one in (2.3) and additive one in (3.1)] on $A(R,Z)$. They are compatible in a way that corresponds to the usual distributivity axiom, which can be shown as follows:

Definition 3.2: If a quantized braided bialgebra (A,Δ,ε) has also a second braided Hopf algebra structure $(A,\underline{\Delta},\varepsilon,S)$ for the same algebra A and obeys the codistributivity axioms

$$(id\otimes\cdot)\circ\Delta_{A\otimes A}\circ\underline{\Delta}=(\underline{\Delta}\otimes id)\circ\Delta,\quad(\cdot\otimes id)\circ\Delta_{A\otimes A}\circ\underline{\Delta}=(id\otimes\underline{\Delta})\circ\Delta, \tag{3.4}$$

where $\Delta_{A\otimes A}=(id\otimes\Psi\otimes id)(\Delta\otimes\Delta)$ is the coproduct in the braided tensor product coalgbra related to Δ, then we call the algebraic system $(A,\Delta,\varepsilon;\underline{\Delta},\varepsilon,S)$ a quantized-braided ring. Δ and $\underline{\Delta}$ are called braided comutiplication and braided coaddition, respectively.

Proposition 3.3: The quantized braided bialgebra $[A(R,Z),\Delta,\varepsilon]$ given by (2.2)–(2.4) together with the braided Hopf algebra structure $[A(R,Z),\underline{\Delta},\varepsilon,S]$ in Theorem 3.1 forms a quantized-braided ring.

Proof: Here we have also used $A(R,Z)$ to denote the algebra defined only by (2.2). We have to prove the codistributivity conditions (3.4). They hold trivially on the generators. On the products $T_1Z_{12}T_2$, we have for the first condition

$$\begin{aligned}
&(id\otimes\cdot)\circ\Delta_{A\otimes A}\circ\underline{\Delta}(T_1Z_{12}T_2)\\
&\quad=(id\otimes\cdot)\Delta_{A\otimes A}(T_1Z_{12}T_2\otimes 1+1\otimes T_1Z_{12}T_2+T_1\otimes Z_{12}T_2+\hat{R}_{12}T_2\otimes Z_{21}T_1R_{12})\\
&\quad=(id\otimes\cdot)(id\otimes\Psi\otimes id)(T_1Z_{12}T_2\otimes Z_{12}^{-1}T_1Z_{12}T_2\otimes 1\otimes 1+1\otimes 1\otimes T_1Z_{12}T_2\otimes Z_{12}^{-1}T_1Z_{12}T_2\\
&\qquad+T_1\otimes T_1\otimes Z_{12}T_2\otimes T_2+\hat{R}_{12}T_2\otimes T_2\otimes Z_{21}T_1\otimes T_1R_{12})\\
&\quad=T_1Z_{12}T_2\otimes 1\otimes Z_{12}^{-1}T_1Z_{12}T_2+1\otimes T_1Z_{12}T_2\otimes Z_{12}^{-1}T_1Z_{12}T_2+T_1\otimes Z_{12}T_2\otimes Z_{12}^{-1}T_1Z_{12}T_2\\
&\qquad+\hat{R}_{12}T_2\otimes Z_{21}T_1\otimes Z_{21}^{-1}T_2Z_{21}T_1R_{12}\\
&\quad=(T_1Z_{12}T_2\otimes 1+1\otimes T_1Z_{12}T_2+T_1\otimes Z_{12}T_2+\hat{R}_{12}T_2\otimes Z_{21}T_1R_{12})\otimes Z_{12}^{-1}T_1Z_{12}T_2\\
&\quad=(\underline{\Delta}\otimes id)(T_1Z_{12}T_2\otimes Z_{12}^{-1}T_1Z_{12}T_2)=(\underline{\Delta}\otimes id)\circ\Delta(T_1Z_{12}T_2),
\end{aligned}$$

where we have used the relations (2.2)–(2.4) and (3.1), (3.2). The general case can be verified in a similar way duo to the consistency of the coproducts, braidings with the algebra relation (2.2), and similarly for the second codistributivity axiom. □

We conclude this section with a restatement of Theorem 3.1 in another form, which is more convenient to some discussions later.

Lemma 3.4: Let (R,Z) be an N-dimensional R-matrix pair as in Sec. II and let R be Hecke type, Z have the second inverse $\tilde{Z}$, then

$$\mathbf{R}^{AB}_{CD}=\hat{R}^{c_0\alpha}_{\beta b_0}Z^{b_1\beta}_{\gamma a_0}R^{a_1\gamma}_{\delta d_1}\tilde{Z}^{\delta d_0}_{c_1\alpha} \tag{3.5}$$

satisfies the N^2-dimensional QYBE with multi-indices $A=(a_1,a_0)$, $B=(b_1,b_0)$, etc. Moreover, if we define another matrix

$$\mathbf{R}'^{AB}_{CD}=\hat{R}^{-1\,\delta c_0}_{\quad b_0\alpha}Z^{b_1\alpha}_{\beta a_0}R^{a_1\beta}_{\gamma d_1}\tilde{Z}^{\gamma d_0}_{c_1\delta}, \tag{3.6}$$

then $\mathbf{R}$, $\mathbf{R}'$ satisfy the mixed QYBEs,

$$\mathbf{R}'_{12}\mathbf{R}_{13}\mathbf{R}_{23}=\mathbf{R}_{23}\mathbf{R}_{13}\mathbf{R}'_{12}, \quad \mathbf{R}_{12}\mathbf{R}_{13}\mathbf{R}'_{23}=\mathbf{R}'_{23}\mathbf{R}_{13}\mathbf{R}_{12} \tag{3.7}$$

and the relations

$$(\mathbf{PR}+1)(\mathbf{PR}'-1)=(\mathbf{PR}'-1)(\mathbf{PR}+1)=0. \tag{3.8}$$

Proof: Recall that $\hat{R}$ is given by (3.3), then the fact that $\mathbf{R}$ satisfies QYBE and $\{\mathbf{R},\mathbf{R}'\}$ satisfy Eqs. (3.7) can be verified directly by writing them in terms of R, Z and using relations (2.1) and Proposition 2.1 repeatedly. As for the relations (3.8), we shall equivalently show $\mathbf{PRPR}'=\mathbf{PR}'\mathbf{PR}=\mathbf{PR}-\mathbf{PR}'+1$. From (3.5), (3.6) we have

$$\begin{aligned}(\mathbf{PRPR}')^{AB}_{EF}&=\mathbf{R}^{BA}_{DC}\mathbf{R}'^{CD}_{EF}\\&=\hat{R}^{d_0\alpha}_{\beta a_0}Z^{a_1\beta}_{\gamma b_0}R^{b_1\gamma}_{\delta c_1}\tilde{Z}^{\delta c_0}_{d_1\alpha}\hat{R}^{-1}{}^{\delta' e_0}_{d_0\alpha'}Z^{d_1\alpha'}_{\beta' c_0}R^{c_1\beta'}_{\gamma' f_1}\tilde{Z}^{\gamma' f_0}_{e_1\delta'}\\&=\hat{R}^{d_0\alpha}_{\beta a_0}Z^{a_1\beta}_{\gamma b_0}R^{b_1\gamma}_{\delta c_1}\hat{R}^{-1}{}^{\delta' e_0}_{d_0\alpha}R^{c_1\delta}_{\gamma' f_1}\tilde{Z}^{\gamma' f_0}_{e_1\delta'}=\delta^{e_0}_{a_0}Z^{a_1\beta}_{\gamma b_0}R^{b_1\gamma}_{\delta c_1}R^{c_1\delta}_{\gamma' f_1}\tilde{Z}^{\gamma' f_0}_{e_1\beta},\end{aligned}$$

$$\begin{aligned}(\mathbf{PR}'\mathbf{PR})^{AB}_{EF}&=\mathbf{R}'^{BA}_{DC}\mathbf{R}^{CD}_{EF}\\&=\hat{R}^{-1}{}^{\delta d_0}_{a_0\alpha}Z^{a_1\alpha}_{\beta b_0}R^{b_1\beta}_{\gamma c_1}\tilde{Z}^{\gamma c_0}_{d_1\delta}\hat{R}^{e_0\alpha'}_{\beta' d_0}Z^{d_1\beta'}_{\gamma' c_0}R^{c_1\gamma'}_{\delta' f_1}\tilde{Z}^{\delta' f_0}_{e_1\alpha'}\\&=\hat{R}^{-1}{}^{\delta d_0}_{a_0\alpha}Z^{a_1\alpha}_{\beta b_0}R^{b_1\beta}_{\gamma c_1}\hat{R}^{e_0\alpha'}_{\delta d_0}R^{c_1\gamma}_{\delta' f_1}\tilde{Z}^{\delta' f_0}_{e_1\alpha'}=\delta^{e_0}_{a_0}Z^{a_1\alpha}_{\beta b_0}R^{b_1\beta}_{\gamma c_1}R^{c_1\gamma}_{\delta' f_1}\tilde{Z}^{\delta' f_0}_{e_1\alpha}.\end{aligned}$$

By using the Hecke property of R and Proposition 2.2, we can further have

$$(\mathbf{PRPR}')^{AB}_{EF}=\delta^{e_0}_{a_0}Z^{a_1\beta}_{\gamma b_0}(\delta^{\gamma}_{\gamma'}\delta^{b_1}_{f_1}+\lambda P^{\gamma b_1}_{c_1\delta}R^{c_1\delta}_{\gamma' f_1})\tilde{Z}^{\gamma' f_0}_{e_1\beta}=\delta^{AB}_{EF}+\lambda\,\delta^{e_0}_{a_0}Z^{a_1\beta}_{\gamma b_0}R^{b_1\gamma}_{\gamma' f_1}\tilde{Z}^{\gamma' f_0}_{e_1\beta},$$

$$\begin{aligned}(\mathbf{PR})^{AB}_{EF}-(\mathbf{PR}')^{AB}_{EF}&=(\hat{R}^{e_0\alpha}_{\beta a_0}-\hat{R}^{-1}{}^{\alpha e_0}_{a_0\beta})Z^{a_1\beta}_{\gamma b_0}R^{b_1\gamma}_{\delta f_1}\tilde{Z}^{\delta f_0}_{e_1\alpha}\\&=\lambda\,\delta^{e_0}_{a_0}\delta^{\alpha}_{\beta}Z^{a_1\beta}_{\gamma b_0}R^{b_1\gamma}_{\delta f_1}\tilde{Z}^{\delta f_0}_{e_1\alpha}=\lambda\,\delta^{e_0}_{a_0}Z^{a_1\alpha}_{\gamma b_0}R^{b_1\gamma}_{\delta f_1}\tilde{Z}^{\delta f_0}_{e_1\alpha}.\end{aligned}$$

Hence, (3.8) is satisfied. □

In terms of $\mathbf{R}$, $\mathbf{R}'$ and from Lemma 3.4, we have the following:

Proposition 3.5: Introducing the notation $T_A=T^{a_0}_{a_1}$, then the algebra relation (2.2) and braiding relation (3.2) can be rewritten, respectively, as

$$T_AT_B=T_DT_C\mathbf{R}'^{CD}_{AB}, \tag{3.9}$$

$$\underline{\Psi}(T_A\otimes T_B)=T_D\otimes T_C\mathbf{R}^{CD}_{AB}. \tag{3.10}$$

Moreover, on the algebra given by the relation (3.9) one can express the (additive) coproduct $\underline{\Delta}$, counit $\underline{\varepsilon}$ and braided-antipode $\underline{S}$ as

$$\underline{\Delta}T_A=T_A\otimes 1+1\otimes T_A, \quad \underline{\varepsilon}T_A=0, \quad \underline{S}T_A=-T_A, \tag{3.11}$$

which form a braided-Hopf algebra with braiding (3.10).

Proof: The equivalence of the algebra relation (2.2) with (3.9), the braiding (3.2) with (3.10) can be verified by direct calculations, in these processes the existence of R^{-1}, Z^{-1}, and $\tilde{Z}$ is crucial. From Lemma 3.4, the second part of the Proposition can be obtained by following the results of Majid in Ref. 16. This is a restatement of Theorem 3.1 in braided vector form. □

When some suitable restrictions are imposed on the R-matrix pair (R,Z), we can obtain some special cases of the above results. For examples, when $Z=I$, R is a regular solution of QYBE, then Theorem 3.1, Propositions 3.3, 3.5 reduce to the corresponding results for the ordinary (non-braided) quantum matrices;[15] When $Z=R$, the Proposition 3.5 gives the related results for the (nonquantized) braided matrices.[14] So the results here can be regarded as a generalization and unification of the results for quantum and braided matrices.

IV. BRAIDED DIFFERENTIALS ON THE QBM BIALGEBRAS

One of the applications of the new braided addition law in Sec. III is to introduce braided differential operators on the underlying quantized braided matrix space $A(R,Z)$. Denote $\Delta T=T\otimes 1+1\otimes T\equiv U+T$ and let $f(T)$ be a function of T, then similar to Ref. 15, the corresponding differentials

$$\partial^I\equiv\partial^{i_1}_{i_0}=\frac{\partial}{\partial T^{i_0}_{i_1}}:\quad \underline{A}(R,Z)\mapsto\underline{A}(R,Z)$$

are defined by

$$\partial^I f(T)=[T_I^{-1}(f(U+T)-f(T))]\big|_{U=0}=\text{coeff of } T_I \text{ in } f(U+T), \tag{4.1}$$

here we have the braid statistics $T_1Z_{12}U_2=\hat{R}_{12}U_2Z_{21}T_1R_{12}$ from (3.2). In terms of $\mathbf{R}$, $\mathbf{R}'$ introduced in Sec. III, the algebra of $\{\partial^I\}$ can be constructed explicitly following Ref. 17.

Proposition 4.1: The braided differential operators $\partial=\{\partial^{i_1}_{i_0}\}$ (written as a matrix) form a braided-Hopf algebra with the relations,

$$R_{21}\partial_1\tilde{Z}_{21}\partial_2=\partial_2\tilde{Z}_{12}\partial_1\hat{R}_{12},\quad \underline{\Psi}(\partial_1\otimes\tilde{Z}_{21}\partial_2)=R_{12}\partial_2\otimes\tilde{Z}_{12}\partial_1\hat{R}_{12}, \tag{4.2}$$

$$\underline{\Delta}(\partial)=\partial\otimes 1+1\otimes\partial,\quad \underline{\varepsilon}(\partial)=0,\quad \underline{S}(\partial)=-\partial. \tag{4.3}$$

Proof: Here, it is convenient to use the formula associated to the data in Lemma 3.4 and Proposition 3.5. Following Ref. 17, the braided derivatives obey the braided vector algebra relations and braidings

$$\partial^I\partial^J=\mathbf{R}'^{IJ}_{AB}\partial^B\partial^A,\quad \underline{\Psi}(\partial^I\otimes\partial^J)=\mathbf{R}^{IJ}_{AB}\partial^B\otimes\partial^A \tag{4.4}$$

for $\mathbf{R}$ and $\mathbf{R}'$ in (3.5) and (3.6). These form a braided-Hopf algebra with the operations in (4.3). Writing out (4.4) in terms of R, Z, then by some calculations we obtain explicit relations and braidings in (4.2). □

We point out that the braided-Hopf algebra given by (4.2), (4.3) as well as one given in Theorem 3.1 both are special cases of some more general braided-Hopf algebra given in Sec. VI later.

Next we mention the corresponding braided Heisenberg–Weyl algebra. the general scheme in Ref. 17 gives the relations

$$\partial^I T_J-T_A\mathbf{R}^{AI}_{JB}\partial^B=\delta^I_J, \tag{4.5}$$

in our case these are

$$\partial^{i_1}_{i_0}T^{j_0}_{j_1}-\hat{R}^{j_0\alpha}_{\beta i_0}Z^{i_1\beta}_{\gamma a_0}T^{a_0}_{a_1}R^{a_1\gamma}_{\delta b_1}\partial^{b_1}_{b_0}\tilde{Z}^{\delta b_0}_{j_1\alpha}=\delta^{i_1}_{j_1}\delta^{j_0}_{i_0}, \tag{4.6}$$

which is the algebra of (R,Z)-quantum mechanics generated by the quantized braided ''momenta'' $\partial^{i_1}_{i_0}$ acting on the quantized braided coordinate functions $T^{j_0}_{j_1}$.

For the special case $Z=I$, Proposition 4.1 and relations (4.6) are reduced to the corresponding results related (nonbraided) quantum matrices.[15]

V. EXAMPLE

To illustrate the formulas in Secs. III and IV, here we give an example.

Taking

$$R=\begin{pmatrix} q & 0 & 0 & 0 \\ 0 & 1 & \lambda & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & q \end{pmatrix}, \quad Z=\begin{pmatrix} r & 0 & 0 & 0 \\ 0 & u & 0 & 0 \\ 0 & 0 & v & 0 \\ 0 & 0 & 0 & w \end{pmatrix}, \tag{5.1}$$

$$T=\begin{pmatrix} \mathrm{a} & \mathrm{b} \\ \mathrm{c} & \mathrm{d} \end{pmatrix}, \quad \lambda=q-q^{-1}, \quad ruvw\neq 0,$$

then from (2.2) and (3.2), the corresponding $\underline{A}(R,Z)$ has the algbra relations

$$\begin{gathered} v\,\mathrm{ba}=qr\,\mathrm{ab}, \quad r\,\mathrm{ca}=qv\,\mathrm{ac}, \quad ur\,\mathrm{cb}=vw\,\mathrm{bc}, \\ u\,\mathrm{db}=qw\,\mathrm{bd}, \quad w\,\mathrm{dc}=qu\,\mathrm{cd}, \quad \mathrm{da}=\mathrm{ad}+\lambda v^{-1} r\,\mathrm{cb}, \end{gathered} \tag{5.2}$$

and the braidings

$$\begin{gathered} \underline{\Psi}(\mathrm{a}\otimes\mathrm{a})=q^2\mathrm{a}\otimes\mathrm{a}, \quad \underline{\Psi}(\mathrm{a}\otimes\mathrm{b})=q(v/r)\mathrm{b}\otimes\mathrm{a}, \quad \underline{\Psi}(\mathrm{a}\otimes\mathrm{c})=q(r/v)\mathrm{c}\otimes\mathrm{a}, \\ \underline{\Psi}(\mathrm{a}\otimes\mathrm{d})=\mathrm{d}\otimes\mathrm{a}, \quad \underline{\Psi}(\mathrm{b}\otimes\mathrm{a})=q(r/v)\mathrm{a}\otimes\mathrm{b}+q\lambda\,\mathrm{b}\otimes\mathrm{a}, \quad \underline{\Psi}(\mathrm{b}\otimes\mathrm{b})=q^2\mathrm{b}\otimes\mathrm{b}, \\ \underline{\Psi}(\mathrm{b}\otimes\mathrm{c})=(ur/vw)\mathrm{c}\otimes\mathrm{b}+\lambda(u/w)\mathrm{d}\otimes\mathrm{a}, \quad \underline{\Psi}(\mathrm{b}\otimes\mathrm{d})=q(u/w)\mathrm{d}\otimes\mathrm{b}, \\ \underline{\Psi}(\mathrm{c}\otimes\mathrm{a})=q\lambda\,\mathrm{c}\otimes\mathrm{a}+q(u/r)\mathrm{a}\otimes\mathrm{c}, \\ \underline{\Psi}(\mathrm{c}\otimes\mathrm{b})=(vw/ur)\mathrm{b}\otimes\mathrm{c}+\lambda(v/r)\mathrm{d}\otimes\mathrm{a}, \\ \underline{\Psi}(\mathrm{c}\otimes\mathrm{d})=q(w/u)\mathrm{d}\otimes\mathrm{c}, \quad \underline{\Psi}(\mathrm{d}\otimes\mathrm{a})=\mathrm{a}\otimes\mathrm{d}+\lambda^2\mathrm{d}\otimes\mathrm{a}+\lambda(w/u)\mathrm{b}\otimes\mathrm{c}+\lambda(r/v)\mathrm{c}\otimes\mathrm{b}, \\ \underline{\Psi}(\mathrm{d}\otimes\mathrm{b})=q(w/u)\mathrm{b}\otimes\mathrm{d}+q\lambda\,\mathrm{d}\otimes\mathrm{b}, \quad \underline{\Psi}(\mathrm{c}\otimes\mathrm{c})=q^2\mathrm{c}\otimes\mathrm{c}, \\ \underline{\Psi}(\mathrm{d}\otimes\mathrm{c})=q(u/w)\mathrm{c}\otimes\mathrm{d}+q\lambda\,\mathrm{d}\otimes\mathrm{c}, \quad \underline{\Psi}(\mathrm{d}\otimes\mathrm{d})=q^2\mathrm{d}\otimes\mathrm{d}. \end{gathered} \tag{5.3}$$

Then $\tilde{\mathrm{a}}=\mathrm{a}\otimes 1+1\otimes\mathrm{a}$, $\tilde{\mathrm{b}}=\mathrm{b}\otimes 1+1\otimes\mathrm{b}$, $\tilde{\mathrm{c}}=\mathrm{c}\otimes 1+1\otimes\mathrm{c}$, $\tilde{\mathrm{d}}=\mathrm{d}\otimes 1+1\otimes\mathrm{d}$ satisfy the same relations as a, b, c, d do in (5.2).

Moreover, denoting the related differential operators by

$$\partial=\begin{pmatrix} \partial_a & \partial_b \\ \partial_c & \partial_d \end{pmatrix},$$

then formulas (4.2) give the relations

$$\begin{gathered} v\,\partial_a\partial_b=qr\,\partial_b\partial_a, \quad r\,\partial_a\partial_c=qv\,\partial_c\partial_a, \quad ur\,\partial_b\partial_c=vw\,\partial_c\partial_b, \\ u\,\partial_b\partial_d=qw\,\partial_d\partial_b, \quad w\,\partial_c\partial_d=qu\,\partial_d\partial_c, \quad \partial_a\partial_d=\partial_d\partial_a+\lambda r^{-1} v\,\partial_c\partial_b \end{gathered} \tag{5.4}$$

and braidings

$$\underline{\Psi}(\partial_a\otimes\partial_a)=q^2\partial_a\otimes\partial_a,\quad \underline{\Psi}(\partial_a\otimes\partial_b)=qrv^{-1}\partial_b\otimes\partial_a+q\lambda\partial_a\otimes\partial_b,$$

$$\underline{\Psi}(\partial_a\otimes\partial_c)=qvr^{-1}\partial_c\otimes\partial_a+q\lambda\partial_a\otimes\partial_c,\quad \underline{\Psi}(\partial_b\otimes\partial_a)=q(v/r)\partial_a\otimes\partial_b,$$

$$\underline{\Psi}(\partial_a\otimes\partial_d)=\partial_d\otimes\partial_a+\lambda^2\partial_a\otimes\partial_d+\lambda(v/r)\partial_d\otimes\partial_b+\lambda(u/w)\partial_b\otimes\partial_c,$$

$$\underline{\Psi}(\partial_b\otimes\partial_b)=q^2\partial_b\otimes\partial_b,\quad \underline{\Psi}(\partial_b\otimes\partial_c)=(vw/ur)\partial_c\otimes\partial_b+\lambda(w/u)\partial_a\otimes\partial_d,$$

$$\underline{\Psi}(\partial_b\otimes\partial_d)=q(w/u)\partial_d\otimes\partial_b+q\lambda\partial_b\otimes\partial_d,\quad \underline{\Psi}(\partial_c\otimes\partial_a)=q(r/v)\partial_a\otimes\partial_c, \tag{5.5}$$

$$\underline{\Psi}(\partial_c\otimes\partial_b)=(ru/vw)\partial_b\otimes\partial_c+\lambda(r/v)\partial_a\otimes\partial_d,\quad \underline{\Psi}(\partial_c\otimes\partial_c)=q^2\partial_c\otimes\partial_c,$$

$$\underline{\Psi}(\partial_c\otimes\partial_d)=q(u/w)\partial_d\otimes\partial_c+q\lambda\partial_c\otimes\partial_d,\quad \underline{\Psi}(\partial_d\otimes\partial_a)=\partial_a\otimes\partial_d,$$

$$\underline{\Psi}(\partial_d\otimes\partial_b)=q(u/w)\partial_b\otimes\partial_d,\quad \underline{\Psi}(\partial_d\otimes\partial_c)=q(w/u)\partial_c\otimes\partial_d,$$

$$\underline{\Psi}(\partial_d\otimes\partial_d)=q^2\partial_d\otimes\partial_d.$$

The corresponding Heisenberg–Weyl algebra can also be obtained from (4.6) by some tedious but straightforward calculations which will not be given here for saving space.

The above results contain 2-dim superquantum matrices as special cases and when $r=u=v=w=1$, these reduce to the results about $M_q(2)$ in Ref. 15.

VI. SOME FURTHER GENERALIZED RESULTS

in this section we show that the braided coaddition can even be introduced on some more general quantized (matrix) algebras. For certain special case, they recover the results in Sec. III. Moreover, the braided-Hopf algebra generated by $\{\partial^{i_1}_{i_0}\}$ in Proposition 4.1 is also an example of the extended algebra in this section.

Definition 6.1: Consider an ordered sequence of three numerical matrices Q, R, $Z\in M_N\otimes M_N$, if Q, R are invertible solutions of QYBE and Z satisfies the following mixed QYBEs:

$$Z_{12}Z_{13}Q_{23}=Q_{23}Z_{13}Z_{12},\quad R_{12}Z_{13}Z_{23}=Z_{23}Z_{13}R_{12}, \tag{6.1}$$

then we call the sequence an *R-matrix triple* and denote it by (Q,R,Z).

Theorem 6.2: Let (Q,R,Z) be an R-matrix triple, let also Q, R be Hecke-type and Z have the second inverse $\tilde{Z}$. Then a braided-Hopf algebra $A(Q,R,Z)$ can be constructed as follows:

$\underline{A}(Q,R,Z)$ is generated by $T=\{T^i_j\}^N_{i,j=1}$ and $\overline{1}$ with the algebra relations

$$Q_{21}T_1Z_{12}T_2=T_2Z_{21}T_1R_{12}, \tag{6.2}$$

the (additive) coproduct, counit and braided antipode

$$\underline{\Delta}(T)=T\otimes 1+1\otimes T,\quad \underline{\varepsilon}(T)=0,\quad \underline{S}(T)=-T, \tag{6.3}$$

and the braiding

$$\underline{\Psi}(T_1\otimes Z_{12}T_2)=Q_{12}T_2\otimes Z_{21}T_1R_{12}. \tag{6.4}$$

Proof: The fact that (6.2) can consistently define an associative algebra has been pointed out by Friedel and Maillet[18] in some more general form. The remainder part of the theorem can be

verified by a way similar to the proof of Theorem 3.1. For example, the coproduct Δ in (6.3) can be consistently extended to products of generators as a algebra homomorphism with the braided tensor product, this can be shown by the following calculations:

$$\begin{aligned}\underline{\Delta}(Q_{21}T_1Z_{12}T_2)&=Q_{21}(T_1\otimes 1+1\otimes T_1)Z_{12}(T_2\otimes 1+1\otimes T_2)\\&=Q_{21}T_1Z_{12}T_2\otimes 1+Q_{21}T_1Z_{12}\otimes T_2+Q_{21}Q_{12}T_2Z_{21}\otimes T_1R_{12}+1\otimes Q_{21}T_1Z_{12}T_2\\&=Q_{21}T_1Z_{12}T_2\otimes 1+Q_{21}T_1Z_{12}\otimes T_2+(1+\lambda P_{12}Q_{12})T_2Z_{21}\otimes T_1R_{12}\\&\quad+1\otimes Q_{21}T_1Z_{12}T_2;\end{aligned}$$

$$\begin{aligned}\underline{\Delta}(T_2Z_{21}T_1R_{12})&=(T_2\otimes 1+1\otimes T_2)Z_{21}(T_1\otimes 1+1\otimes T_1)R_{12}\\&=T_2Z_{21}T_1R_{12}\otimes 1+T_2Z_{21}\otimes T_1R_{12}+Q_{21}T_1Z_{12}\otimes T_2R_{21}R_{12}+1\otimes T_2Z_{21}T_1R_{12}\\&=T_2Z_{21}T_1R_{12}\otimes 1+T_2Z_{21}\otimes T_1R_{12}+Q_{21}T_1Z_{12}\otimes T_2(1+\lambda P_{12}R_{12})\\&\quad+1\otimes T_2Z_{21}T_1R_{12},\end{aligned}$$

where we have used the braiding (6.4) and the Hecke property of Q, R. The verifications of the consistency for $\underline{\Psi}$, $\underline{S}$, $\underline{\varepsilon}$ in (6.4), (6.3) are omitted because of their similarity to that for Theorem 3.1. □

We would like to point out that the results in Lemma 3.4 and Proposition 3.5 can also be extended to $A(Q,R,Z)$. By the calculations similar to Sec. III, we have

Proposition 6.3: Let (Q,R,Z) be an R-matrix triple and satisfy the conditions in Theorem 6.2. Now defining

$$\mathbf{Q}^{AB}_{CD}=Q^{c_0\alpha}_{\beta b_0}Z^{b_1\beta}_{\gamma a_0}R^{a_1\gamma}_{\delta d_1}\tilde{Z}^{\delta d_0}_{c_1\alpha},\quad \mathbf{Q}'^{AB}_{CD}=Q^{-1\,\delta c_0}_{\quad b_0\alpha}Z^{b_1\alpha}_{\beta a_0}R^{a_1\beta}_{\gamma d_1}\tilde{Z}^{\gamma d_0}_{c_1\delta},\tag{6.5}$$

then they satisfy the following equations:

$$\begin{gathered}\mathbf{Q}_{12}\mathbf{Q}_{13}\mathbf{Q}_{23}=\mathbf{Q}_{23}\mathbf{Q}_{13}\mathbf{Q}_{12},\quad \mathbf{Q}'_{12}\mathbf{Q}_{13}\mathbf{Q}_{23}=\mathbf{Q}_{23}\mathbf{Q}_{13}\mathbf{Q}'_{12},\quad \mathbf{Q}_{12}\mathbf{Q}_{13}\mathbf{Q}'_{23}=\mathbf{Q}'_{23}\mathbf{Q}_{13}\mathbf{Q}_{12},\\(\mathbf{PQ}+1)(\mathbf{PQ}'-1)=(\mathbf{PQ}'-1)(\mathbf{PQ}+1)=0.\end{gathered}\tag{6.6}$$

Moreover, the relations

$$\begin{gathered}T_AT_B=T_DT_C\mathbf{Q}'^{CD}_{AB},\quad \underline{\Psi}(T_A\otimes T_B)=T_D\otimes T_C\mathbf{Q}^{CD}_{AB},\\\underline{\Delta}T_A=T_A\otimes 1+1\otimes T_A,\quad \underline{\varepsilon}T_A=0,\quad \underline{S}T_A=-T_A\end{gathered}\tag{6.7}$$

give a covecter braided group[16] version of $A(Q,R,Z)$.

Proof: The proof is similar to that of Lemma 3.4 and Proposition 3.5, and will be omitted. □

As done in Sec. IV, the corresponding braided differential calculus and braided Heisenberg–Weyl algebra, etc. can also be constructed. If we require Z to be a regular solution of QYBE and Q to be taken as $Q=\hat{R}=ZPRZ^{-1}P$, then the results here are reduced to the ones of Secs. III and IV. Moreover, we point out that the braided differential operator Hopf algebra in Proposition 4.1 can also be regarded as a special case of $A(Q,R,Z)$ as long as we take $T=\partial$ (as a matrix) and take the related R-matrix triple as $(R,\hat{R},P\tilde{Z}P)$. That the triple $(R,\hat{R},P\tilde{Z}P)$ is indeed an R-matrix triple as required in Theorem 6.2 can be verified from the relations obeyed by the original R, Z.

VII. CONCLUSIONS AND DISCUSSIONS

Besides the usual (multiplicative) coproduct, we have introduced another kind of (additive) coproduct on the QBMs. With this so-called braided coaddition, the QBMs acquire a braided-Hopf algebra structure. We also show that these two coproducts together make QBM a quantized-braided ring, which is an analog of the ordinary matrix ring. Motivated by Ref. 15, we then construct the corresponding differential operator bialgebras (braided Hopf algebras) acting on QBMs and the related quantized braided Heisenberg–Weyl algebras, which can be regarded as a mathematical description of some multiparameter deformed quantum systems with general braid statistics.

The discussions of this paper extend the related schemes for braided matrices[14] and quantum matrices[15] to a more general one and unify these different results into a *single* structure. Moreover, we find that the braided coaddition and differentiation operations can be introduced on some further generalized algebraic systems. When taking some special cases, the related results in Refs. 14 and 15 are recovered, respectively. In Sec. V a simple but genuine quantized braided example is given, other examples can be obtained by taking some specified R-matrix pair (R,Z), see, e.g., Refs. 12, 10, etc.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 42, NUMBER 2 FEBRUARY 2001

Bounded solutions of a second order evolution equation and applications

Hugo Leiva[a)]
Universidad de los Andes, Facultad de Ciencias, Departamento de Matemática, Mérida 5101, Venezuela

(Received 18 November 1999; accepted for publication 26 July 2000)

In this paper we study the following abstract second order differential equation with dissipation in a Hilbert space H: $u''+cu'+dA\,u+kG(u)=P(t)$, $u\in H$, $t\in\mathbb{R}$, where c, d and k are positive constants, $G:H\to H$ is a Lipschitzian function and $P:\mathbb{R}\to H$ is a continuous and bounded function. $A:D(A)\subset H\to H$ is an unbounded linear operator which is self-adjoint, positive definite and has compact resolvent. Under these conditions we prove that for some values of d, c and k this system has a bounded solution which is exponentially asymptotically stable. Moreover; if $P(t)$ is almost periodic, then this bounded solution is also almost periodic. These results are applied to a very well known second order system partial differential equations; such as the sine-Gordon equation, The suspension bridge equation proposed by Lazer and McKenna, etc. © *2001 American Institute of Physics.*
[DOI: 10.1063/1.1312195]

I. INTRODUCTION

In this paper, we study the existence and the asymptotic behavior of the bounded solutions of the following abstract second order differential equation with dissipation:

$$u''+cu'+dAu+kG(u)=P(t),\quad u\in H,\quad t\in\mathbb{R}, \tag{1.1}$$

where H is a Hilbert space, c, d and k are positive constants, $P:\mathbb{R}\to H$ is a continuous and bounded function and $G:H\to H$ is a Lipschitzian function, i.e., there exists $L>0$ such that

$$\|G(U_1)-G(U_2)\|\leqslant L\|U_1-U_2\|,\quad U_1,U_2\in H. \tag{1.2}$$

$A:D(A)\subset H\to H$ is an unbounded linear operator, self-adjoint, positive definite and has compact resolvent. Under these conditions stated on A we have the following.

The spectrum $\sigma(A)$ of A consisting of isolated eigenvalues,

$$0<\lambda_1<\lambda_2<\ldots<\lambda_n\to\infty,$$

each one with finite multiplicity γ_j equal to the dimension of the corresponding eigenspace and the following.

(a) There exists a complete orthonormal set $\{\phi_{j,k}\}$ of eigenvector of A in H.
(b) For all $x\in D(A)$ we have

$$Ax=\sum_{j=1}^{\infty}\lambda_j\sum_{k=1}^{\gamma_j}\langle x,\phi_{j,k}\rangle\phi_{j,k}=\sum_{j=1}^{\infty}\lambda_jE_jx, \tag{1.3}$$

where $\langle\cdot,\cdot\rangle$ is the inner product in H and

a)Electronic mail: hleiva@ciens.ula.ve

$$E_j x = \sum_{k=1}^{\gamma_j} <x, \phi_{j,k}> \phi_{j,k}.$$

So, $\{E_j\}$ is a family of complete orthogonal projections in H and

$$x = \sum_{j=1}^{\infty} E_j x, \quad x \in H.$$

(c) $-A$ generates an analytic semigroup $\{e^{-At}\}$ given by

$$e^{-At}x = \sum_{j=1}^{\infty} e^{-\lambda_j t} E_j x, \quad x \in H.$$

Many very well known systems of partial differential equations can be written in the form of system (1.1).

Example 1.1: The sine-Gordon Equation with Dirichlet boundary conditions,

$$\begin{cases} U_{tt} + cU_t - dU_{xx} + k \sin U = p(t,x), \quad 0 < x < l, \quad t \in \mathbb{R}, \\ U(t,0) = U(t,l) = 0, \quad t \in \mathbb{R}, \end{cases} \tag{1.4}$$

where c and k are positive constants, $p: \mathbb{R} \times [0,l] \to \mathbb{R}$ is continuous and bounded. In this case we take: $H = L^2(0,l)$ and $A\phi = -\phi_{xx}$ with domain $D(A) = H^2 \cap H_0^1$. $G(u) = \sin u$ and $P(t) = p(t,\cdot)$

Example 1.2: The suspension bridge model proposed by Lazer and McKenna (see Refs. 1 and 2),

$$\begin{cases} U_{tt} + cU_t + dU_{xxxx} + kU^+ = p(t,x), \quad 0 < x < l, \quad t \in \mathbb{R}, \\ U(t,0) = U(t,l) = U_{xx}(t,0) = U_{xx}(t,l) = 0, \quad t \in \mathbb{R}, \end{cases} \tag{1.5}$$

where c, d and k are positive constants, $p: \mathbb{R} \times [0,l] \to \mathbb{R}$ is continuous and bounded. In this case we take $H = L^2(0,l)$ and $A\phi = -\phi_{xxxx}$ with domain

$$D(A) = \{\phi \in H : \phi_{xxxx} \in H; \phi(0) = \phi(l) = \phi_{xx}(0) = \phi_{xx}(l) = 0\}.$$

$G(U) = U^+$ and $P(t) = p(t,\cdot)$.

Example 1.3: We consider a system of sine-Gordon equations occurring in the Josephson junctions (see Levi[3]),

$$\begin{cases} U_{tt} + cU_t - d\Delta U + k \sin U + k(U - V) = p_1(t,x), \\ V_{tt} + cV_t - d\Delta V + k \sin V + k(V - U) = p_2(t,x), \\ U(t,x) = V(t,x) = 0 \quad \text{on} \quad \partial\Omega \times \mathbb{R}, \end{cases} \tag{1.6}$$

where Ω is a smooth bounded domain in $\mathbb{R}^n$. In this case we take $H = L^2(\Omega) \times L^2(\Omega)$, $A(\phi_1, \phi_2) = (-\Delta\phi_1, -\Delta\phi_2)$ with domain $D(A) = (H_0^1(\Omega) \cap H^2(\Omega))^2$.

A finite dimensional version of the system (1.1) ($H = \mathbb{R}^n$ and an $A - n \times n$ matrix) has been studied in Refs. 4, 5 and 6, where they proved the existence of a bounded solution of this equation, which is exponentially stable, and applied those results to the spatial discretization of the systems (1.4) and (1.5). For an infinite dimensional second order evolution equation we can see Ref. 7, where they study the existence of bounded solutions for the telegraph equation. Here we study the existence, the stability, the almost-periodicity and the smoothness (classic solution) of the bounded solution. Specifically, we prove the following theorem.

Theorem 1.1: *If G and P are of C^1 class and for some c, d y k we have that*

$$\mathrm{Re}\left\{\frac{c\pm\sqrt{c^2-4\,d\lambda_j}}{2}\right\}>kL,\quad j=1,2,3,\ldots, \tag{1.7}$$

then (1.1) has one and only one bounded solution $u(t)$ defined on $\mathbb{R}$, i.e.,

$$\sup_{t\in\mathbb{R}}\{\|u(t)\|^2+\|\dot{u}(t)\|^2\}<\infty.$$

Moreover, this bounded solution is the only bounded solution of the equation (1.1) and is exponentially stable, and if $P(t)$ is almost periodic, then $u(t)$ is also almost periodic.

The criterion for almost-periodicity of a **bounded** solution of first and second order Cauchy problem are given in Ref. 8, Theorems 4.3 and 4.5. But, the existence of the bounded solutions is not considered there. On the other hand, our method is very simple, we just rewrite the equation (1.1) as a first order system of abstract ordinary differential equations. Next, we prove that the linear part of this equation generates a C_0-group which decays exponentially to zero. After that, we find a formula for the **mild** bounded solution of this system. From this formula we can prove the existence, the stability and the almost-periodicity of the **mild** bounded solution easily. Finally, we prove that this mild bounded solution is a classic solution of (1.1); that is to say, we prove the smoothness of the bounded solution (see Theorem 3.2).

II. PRELIMINARY RESULTS

Before we prove the main theorems of this paper, we shall prove some preliminary results to be used in the next section. The equation (1.1) can be rewritten as a first order system of ordinary differential equations in the space $W=H\times H$ as follows:

$$w'+\mathcal{A}w+k\mathcal{G}(w)=\mathcal{P}(t),\quad w\in W,\quad t\in\mathbb{R}, \tag{2.1}$$

where $v=u'$ and

$$w=\begin{pmatrix}u\\ v\end{pmatrix},\ \mathcal{G}=\begin{pmatrix}0\\ G(u)\end{pmatrix},\ \mathcal{P}=\begin{pmatrix}0\\ P(t)\end{pmatrix}\quad\text{and}\quad \mathcal{A}=\begin{pmatrix}0 & -I_H\\ dA & cI_H\end{pmatrix}, \tag{2.2}$$

is an unbounded linear operator with domain $D(\mathcal{A})=D(A)\times H$.

In this section we shall study the linear part of the equation (2.1); that is to say, the equation

$$w'+\mathcal{A}w=0,\ w\in W,\ t\in\mathbb{R}. \tag{2.3}$$

To this end, we shall define the following family of a complete orthogonal family of projections in W:

$$\hat{E}_j=\begin{pmatrix}E_j & 0\\ 0 & E_j\end{pmatrix},\quad j=1,2,\ldots, \tag{2.4}$$

and consider the family of 2×2 matrices,

$$B_j=\begin{pmatrix}0 & -1\\ d\lambda_j & c\end{pmatrix}. \tag{2.5}$$

Then, from (1.3) we get that

$$\mathcal{A}w=\sum_{j=1}^{\infty}B_j\hat{E}_jw,\ w\in D(\mathcal{A}). \tag{2.6}$$

On the other hand, the eigenvalues of the matrix B_j are given by

$$\rho(j)=\frac{c\pm\sqrt{c^2-4\,d\lambda_j}}{2},\quad j=1,2,\ldots, \tag{2.7}$$

which are simple if $c\neq=2\sqrt{d\lambda_j},\quad j=1,2,\ldots$.

The following Theorem can be proved in a similiar way as Theorem 2.1 in the following.

Theorem 2.1: *Suppose that* $c\neq 2\sqrt{d\lambda_j}$, $j=1,2,\ldots$. *Then: we have the following.*

(a) The operator $-\mathcal{A}$ *generates a* C_0*-group* $e^{-\mathcal{A}t}$ *given by*

$$e^{-\mathcal{A}t}w=\sum_{j=1}^{\infty} e^{-B_j t}\hat{E}_j w w\in W,\ \ t\in\mathbb{R}. \tag{2.8}$$

(b) The spectrum $\sigma(-\mathcal{A})$ *of* $-\mathcal{A}$ *is given by*

$$\sigma(-\mathcal{A})=\left\{\frac{-c\pm\sqrt{c^2-4\,d\lambda_j}}{2},\quad j=1,2,\ldots\right\}.$$

(c) We have the following estimates:

$$\|e^{-\mathcal{A}t}\|\leqslant e^{-\beta t},\quad t\geqslant 0, \tag{2.9}$$

$$\|e^{-\mathcal{A}t}\|\leqslant e^{-\alpha t},\quad t\leqslant 0, \tag{2.10}$$

where α, β *are positive numbers and*

$$-\beta=-\beta(c,d)=\max\left\{\mathrm{Re}(\rho_j)=\mathrm{Re}\left(\frac{-c\pm\sqrt{c^2-4\,d\lambda_j}}{2}\right):j=1,2,\ldots,i=1,2\right\},$$

$$-\alpha=-\alpha(c,d)=\min\left\{\mathrm{Re}(\rho_j)=\mathrm{Re}\left(\frac{-c\pm\sqrt{c^2-4\,d\lambda_j}}{2}\right):j=1,2,\ldots,i=1,2\right\}.$$

Corollary 2.1: The initial value problem,

$$\begin{cases} w'+\mathcal{A}w=0,\\ w(t_0)=w_0, \qquad w_0\in D(\mathcal{A}),\end{cases}$$

has the unique solution

$$w(t)=e^{-\mathcal{A}(t-t_0)}w_0=\sum_{j=1}^{\infty}\{e^{-\rho_1(j)(t-t_0)}Q_1(j)w_0+e^{-\rho_2(j)(t-t_0)}Q_2(j)w_0\}, \tag{2.11}$$

where $\{Q_i(j):i=1,2\}_{j=1}^{\infty}$ *is a complete orthogonal system of projections in* W.

III. EXISTENCE OF MILD BOUNDED SOLUTIONS

In this section we shall prove the existence of mild bounded solutions of the system (2.1), which gives us the first part of the proof of Theorem 1.1.

Definition 3.1 (mild solution): For mild solution $w(t)$ of (2.1) with initial condition $w(t_0)=w_0\in W$, we understand a function given by

$$w(t)=e^{-\mathcal{A}(t-t_0)}w_0+\int_{t_0}^{t}e^{-\mathcal{A}(t-s)}\{-k\mathcal{G}(w(s))+\mathcal{P}(s)\}ds,\quad t\in\mathbb{R}. \tag{3.1}$$

Remark 3.1: It is easy to prove that any solution of (2.1) is a solution of (3.1). It may be thought that a solution of (3.1) is always a solution of (2.1) but this is not true in general. However, we shall prove in Theorem 3.2 that bounded solutions of (3.1) are solutions of (2.1).

We shall consider $W_b = C_b(\mathbb{R}, W)$ the space of bounded and continuous functions defined in $\mathbb{R}$ taking values in $W = H \times H$. W_b is a Banach space with suprem norm

$$\|w\|_b = \sup\{\|w(t)\|_W : t \in \mathbb{R}\}, \quad w \in W_b .$$

A ball of radio $\rho > 0$ and center zero in this space is given by

$$B_\rho^b = \{w \in W_b : \|w(t)\|_b \leqslant \rho, \quad t \in \mathbb{R}\}.$$

The proof of the following lemma is similar to Lemma 3.1 of Ref. 4.

Lemma 3.1: Let w be in W_b. Then, w is a mild solution of (2.1) if and only if w is given by

$$w(t) = \int_{-\infty}^{t} e^{-\mathcal{A}(t-s)}\{-k\mathcal{G}(w(s)) + \mathcal{P}(s)\}ds, \quad t \in \mathbb{R}. \tag{3.2}$$

The following theorem refers to mild bounded solutions of system (2.1). Even though the proof is similar to Theorem 3.2 of Ref. 4, we will give the proof.

Theorem 3.1: *If for some c, d y k we have that*

$$\mathrm{Re}\left\{\frac{c \pm \sqrt{c^2 - 4\,d\lambda_j}}{2}\right\} > kL, \quad j = 1,2,3,\ldots, \tag{3.3}$$

then Eq. (2.1) has one and only one bounded mild solution $w_b(t)$.

Moreover, this bounded solution is the only bounded solution of Eq. (3.1) and is exponentially stable.

Proof: Condition 3.3 implies that for $\rho > 0$ big enough we have the following estimate:

$$0 < L_p + k\|G(0)\| = \sup_{s \in \mathbb{R}} \|P(s)\| + k\|G(0)\| < (\beta(c,d) - kL)\rho. \tag{3.4}$$

For the existence of such a solution, we shall prove that the following operator has a unique fixed point in the ball B_ρ^b, $T : B_\rho^b \to B_\rho^b$,

$$(Tw)(t) = \int_{-\infty}^{t} e^{-\mathcal{A}(t-s)}\{-k\mathcal{G}(w(s)) + \mathcal{P}(s)\}ds, \quad t \in \mathbb{R}.$$

In fact, for $w \in B_\rho^b$ we have

$$\|Tw(t)\| \leqslant \int_{-\infty}^{t} e^{-\beta(t-s)}\{kL\|w(s)\| + k\|G(0)\| + L_p\} \leqslant \frac{(kL)\rho + k\|G(0)\| + L_p}{\beta}.$$

The condition (3.4) implies that

$$kL\rho + k\|G(0)\| + L_p < \beta\rho \Leftrightarrow \frac{kL\rho + k\|G(0)\| + L_p}{\beta} < \rho.$$

Therefore, $Tw \in B_\rho^b$ for all $w \in B_\rho^b$.

Now, we shall see that T is a contraction mapping. In fact, for all $w_1, w_2 \in B_\rho^b$ we have that

$$\|Tw_1(t) - Tw_2(t)\| \leqslant \int_{-\infty}^{t} e^{-\beta(t-s)} kL\|w_1(s) - w_2(s)\|ds \leqslant \frac{kL}{\beta}\|w_1 - w_2\|_b, \quad t \in \mathbb{R}.$$

Hence,

$$\|w_1 - Tw_2\|_b \leqslant \frac{kL}{\beta}\|Tw_1 - w_2\|_b, \quad w_1, w_2 \in B_\rho^b.$$

The condition (3.4) implies that

$$0 < \beta - kL \Leftrightarrow kL < \beta \Leftrightarrow \frac{kL}{\beta} < 1.$$

Therefore, T has a unique fixed point w_b in B_ρ^b,

$$w_b(t) = (Tw_b)(t) = \int_{-\infty}^{t} e^{-\mathcal{A}(t-s)}\{-k\mathcal{G}(w_b(s)) + \mathcal{P}(s)\}ds, \quad t \in \mathbb{R}.$$

From Lemma 3.1, w_b is a bounded solution of Eq. (3.1). Since condition (3.4) holds for any $\rho > 0$ big enough independent of $kL < \beta(c,d)$, then w_b is the unique bounded solution of Eq. (3.1).

To prove that $w_b(t)$ is exponentially stable in the large, we shall consider any other solution $w(t)$ of (3.1) and consider the following estimate:

$$\|w(t) - w_b(t)\| \leqslant \left\| e^{-\mathcal{A}t}(w(0) - w_b(0)) + \int_0^t e^{-\mathcal{A}(t-s)}\{k\mathcal{G}(w(s)) - k\mathcal{G}(w_b(s))\}ds \right\|$$

$$\leqslant e^{-\beta t}\|(w(0) - w_b(0))\| + \int_0^t e^{-\beta(t-s)}kL\|w(s) - w_b(s)\|ds.$$

Then,

$$e^{\beta t}\|w(t) - w_b(t)\| \leqslant \|(w(0) - w_b(0))\| + \int_0^t e^{\beta s}kL\|w(s) - w_b(s)\|ds.$$

Hence, applying the Gronwall's inequality we obtain

$$\|w(t) - w_b(t)\| \leqslant e^{(kL_\rho - \beta)t}\|(w(0) - w_b(0))\|, \quad t \geqslant 0.$$

From (3.4) we get that $kL - \beta < 0$ and therefore $w_b(t)$ is exponentially stable in the large. □

Corollary 3.1: The bounded solution $w_b(\cdot, P)$ of (3.1) given by Theorem 3.1 depends continuously on $P \in C_b(\mathbb{R}, H)$. Moreover,

$$\|w_b(\cdot, P_1) - w_b(\cdot, P_2)\|_b \leqslant \frac{1}{\beta - kL}\|P_1 - P_2\|_b, \quad P_1, P_2 \in C_b(\mathbb{R}, H).$$

We conclude this part with the following lemma about almost-periodicity of the bounded solutions of Eq. (3.1). Although the proof is similar to the one given in Ref. 4 for Lemma 3.2, we will give it again.

Lemma 3.2: If $P(t)$ is almost periodic, then the unique bounded solution of Eq. (3.1) given by Theorem 3.1 is also almost periodic.

Proof: To prove this lemma, we shall use the following well known fact, due to Bohr. A function $f \in C(\mathbb{R}; W)$ is almost periodic (*a.p.*; according to Bohr) if and only if the Hull $H(f)$ of f is compact in the topology of uniform convergence.

Where $H(f)$ is the closure of the set of translates of f under the topology of uniform convergence,

$$H(f) = \overline{\{f_\tau : \tau \in \mathbb{R}\}}, \quad f_\tau(t) = f(t + \tau), \quad t \in \mathbb{R}.$$

Since the limit of a uniformly convergent sequence of *a.p.* functions is *a.p.*, then the set A_ρ of *a.p.* functions in the ball B_ρ^b is closed, where ρ is given by Theorem 3.1.

Claim: The contraction mapping T given in Theorem 3.1 leaves A_ρ invariant. In fact, if $w \in A_\rho$, then $f(t)=-k\mathcal{G}(w(t))+\mathcal{P}(t)$ is also an *a.p.* function. Now, consider the function

$$F(t)=(Tw)(t)=\int_{-\infty}^{t} e^{-\mathcal{A}(t-s)}\{-k\mathcal{G}(w(s))+\mathcal{P}(s)\}ds$$

$$=\int_{-\infty}^{t} e^{-\mathcal{A}(t-s)}f(s)ds, \quad t\in\mathbb{R}.$$

Then, it is enough to establish that $H(F)$ is compact in the topology of uniform convergence. Let $\{F_{\tau_k}\}$ be any sequence in $H(F)$. Since f is *a.p.* we can select from $\{f_{\tau_k}\}$ a Cauchy subsequence $\{f_{\tau_{k_j}}\}$, and we have that

$$F_{\tau_{k_j}}(t)=F(t+\tau_{k_j})=\int_{-\infty}^{t+\tau_{k_j}} e^{-\mathcal{A}(t+\tau_{k_j}-s)}f(s)ds=\int_{-\infty}^{t} e^{-\mathcal{A}(t-s)}f(s+\tau_{k_j})ds.$$

Hence,

$$\|F_{\tau_{k_j}}(t)-F_{\tau_{k_i}}(t)\|\leqslant\int_{-\infty}^{t}\|e^{-\mathcal{A}(t+-s)}\|\|f(s+\tau_{k_j})-f(s+\tau_{k_i})\|ds$$

$$\leqslant\|f_{\tau_{k_j}}-f_{\tau_{k_i}}\|_b\int_{-\infty}^{t} e^{-\beta(t-s)}\,ds=\frac{1}{\beta}\|f_{\tau_{k_j}}-f_{\tau_{k_i}}\|_b.$$

Therefore, $\{F_{\tau_{k_j}}\}$ is a Cauchy sequence. So, $H(F)$ is compact in the topology of uniform convergence, F is *a.p.* and $TA_\rho\subset A_\rho$.

Now, the unique fixed point of T in the ball B_ρ^b lies in A_ρ. Hence, the unique bounded solution $w_b(t)$ of Eq. (3.1) given in Theorem 3.1 is also almost periodic. □

A. Proof of Theorem 1.1

In this part, we shall prove that the mild bounded solution $w_b(t)$ of Eq. (2.1) is also a classic solution of this equation; that is to say, we shall prove the smoothness of this solution. With this we conclude the proof of Theorem 1.1.

Theorem 3.2: *Under the hypotheses of Theorem 3.1. If G and P are of C^1 class, then $w_b(t)$ satisfies (2.1) and*

$$w_b(\cdot)\in C_b(\mathbb{R};D(\mathcal{A})).$$

Moreover, if $w_b(t)=(u_b(t),v_b(t))^T$, then $v_b(t)=u_b'(t)$,

$$u_b\in C_b(\mathbb{R};D(A)),\quad u_b'\in C_b(\mathbb{R};D(A^{1/2})),\quad u_b''\in C_b(\mathbb{R};H),$$

and

$$u_b''+cu_b'+dAu_b+kG(u_b)=P(t),\quad t\in\mathbb{R}.$$

Proof: Define the function $F(t)=-k\mathcal{G}(w_b(t))+\mathcal{P}(t)$. Then

$$F(t)=\begin{pmatrix}0\\ f(t)\end{pmatrix},$$

where $f(t)=-kG(u_b(t))+P(t)$, $w_b(t)=(u_b(t),v_b(t))^T$ and $f\in C_b(\mathbb{R};H)$.

Now, consider the second order equation,

$$u''+cu'+dAu=f(t),\ \ u\in H,\ \ t\in\mathbb{R}. \tag{3.5}$$

Then, from Proposition 1.3 in Ref. 9, p. 182, Eq. (3.5) admits a unique solution u which satisfies

$$u\in C_b(\mathbb{R};H),\ \ u'\in C_b(\mathbb{R};H).$$

Therefore, $w(t)=(u(t),u'(t))^T$ is a bounded solution of the integral equation,

$$w(t)=e^{-\mathcal{A}(t-t_0)}w(t_0)+\int_{t_0}^{t}e^{-\mathcal{A}(t-s)}F(s)ds,\ \ t\in\mathbb{R}.$$

Then, taking limit as t_0 goes to $-\infty$, we get that

$$w(t)=\int_{-\infty}^{t}e^{-\mathcal{A}(t-s)}F(s)ds=\int_{-\infty}^{t}e^{-\mathcal{A}(t-s)}\{-k\mathcal{G}(w(s))+\mathcal{P}(s)\}ds.$$

Hence, $w_b(t)=w(t)=(u(t),u'(t))$, so

$$f(t)=-kG(u(t))+P(t)\quad\text{and}\ \ f\in C_b^1(\mathbb{R};H).$$

Then, using the second part of Proposition 1.3 in Ref. 9, p. 182, we get that

$$u\in C_b(\mathbb{R};D(A)),\ \ u'\in C_b(\mathbb{R};D(A^{1/2}))\quad\text{and}\ \ u''\in C_b(\mathbb{R};H).$$

□

As an application of these results we can consider the sine-Gordon equation with Dirichlet boundary condition (1.4). In the same way, one can consider many other examples like (1.5) and (1.6).

Corollary 3.2: If in the system (1.4) the function $t\to p(t,\cdot)\in L^2(0,L)$ is of C^1 class, then for some values of c, d and k the system (1.4) admits a unique solution u such that

$$u\in C_b(\mathbb{R};H^2\cap H_0^1),\ \ u'\in C_b(\mathbb{R};H_0^1)\quad\text{and}\ \ u''\in C_b(\mathbb{R};L^2(0,L)).$$

A mathematical proof of a result derived from the application of the Thompson–Lampard theorem of electrostatics

Daniel A. Morales
Facultad de Ciencias, Universidad de Los Andes, Mérida 5101, Venezuela

(Received 22 May 2000; accepted for publication 27 September 2000)

We give an entirely mathematical demonstration and a generalization of a recent result obtained from the application of the Thompson–Lampard theorem of electrostatics, i.e., $\Sigma_{n\ \mathrm{even}}[8\sin^2(n\pi a/2)\sinh^2(n\pi a/2)]/[n\sinh(n\pi)]+\Sigma_{n\ \mathrm{odd}}[8\cos^2(n\pi a/2)\cosh^2(n\pi a/2)]/[n\sinh(n\pi)]=\ln 2$. It is shown that, as it should be, the result of the left-hand side, $\ln 2$, is independent of the value of a. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1332123]

I. INTRODUCTION

Recently, Jackson[1] has presented a beautiful and pedagogical discussion of the Thompson–Lampard theorem of electrostatics.[2–4] As a consequence of the application of the theorem to several geometries, some curious results about series and products emerged. One of these results concerns the unbelievable relation

$$S=\sum_{n\ \mathrm{even}}\frac{8\sin^2(n\pi a/2)\sinh^2(n\pi a/2)}{n\sinh(n\pi)}+\sum_{n\ \mathrm{odd}}\frac{8\cos^2(n\pi a/2)\cosh^2(n\pi a/2)}{n\sinh(n\pi)}=\ln 2, \tag{1}$$

valid for $0\leqslant a<1$. When $a=0$, Eq. (1) becomes

$$\sum_{n\ \mathrm{odd}}\frac{8}{n\sinh(n\pi)}=\ln 2, \tag{2}$$

from where the relation

$$\prod_{k=0}^{\infty}\left[\frac{1+\exp[-(2k+1)\pi]}{1-\exp[-(2k+1)\pi]}\right]^8=2 \tag{3}$$

is obtained.

Although these relations are derived from the application of the theorem, Jackson was able to give an independent, mathematical proof, only in the case of $a=0$ but was unable to provide a mathematical proof of the general case for $0\leqslant a<1$. About the general case he commented that ''its proof (for me at least) depends on the validity of the theorem.''

It is our aim in this paper to provide such a proof, showing that indeed the two terms in (1) add to $\ln 2$, independent of a, $0\leqslant a<1$. Along the way, we give a new formula, involving trigonometric functions and exponentials which is not found explicitly, in Gradshteyn and Ryzhik[5] but which is needed in our proof. We start our proof providing a generalization of (1) and showing that the generalized sum can be written in terms of Jacobi's theta functions. We then study the particular case of Eq. (1) and show that the two terms in S add to $\ln 2$, independent of a.

II. GENERALIZATION OF EQ. (1) AND ITS EXPRESSION IN TERMS OF JACOBI'S THETA FUNCTIONS

The mathematical structure of S expressed by the sum in Eq. (1) lead us to suggest the following generalization, denoted by S_g:

$$S_g=\sum_{n\ \text{even}}\frac{8\sin(n\pi a/2)\sin(n\pi b/2)\sinh(n\pi a/2)\sinh(n\pi b/2)}{n\sinh(n\pi)}+\sum_{n\ \text{odd}}\frac{8\cos(n\pi a/2)\cos(n\pi b/2)\cosh(n\pi a/2)\cosh(n\pi b/2)}{n\sinh(n\pi)} \tag{4}$$

$$\equiv S_1+S_2. \tag{5}$$

If one expresses the hyperbolic functions in (4) in terms of exponentials, S_1 can be written as

$$\begin{aligned}S_1&=4\sum_{n\ \text{even}}\frac{\sin(n\pi a/2)\sin(n\pi b/2)}{n}e^{n\pi a/2}(1-e^{-n\pi a})e^{n\pi b/2}(1-e^{-n\pi b})e^{-n\pi}(1-e^{-2n\pi})^{-1}\\&=4\sum_{n\ \text{even}}\frac{\sin(n\pi a/2)\sin(n\pi b/2)}{n}e^{-n\pi(1-a/2-b/2)}(1-e^{-n\pi a})(1-e^{-n\pi b})\sum_{k=0}^{\infty}e^{-2n\pi k}\\&=4\sum_{k=0}^{\infty}\left\{\sum_{n\ \text{even}}\frac{\sin(n\pi a/2)\sin(n\pi b/2)}{n}e^{-n\pi(1-a/2-b/2+2k)}\right.\\&\quad-\sum_{n\ \text{even}}\frac{\sin(n\pi a/2)\sin(n\pi b/2)}{n}e^{-n\pi(1+a/2-b/2+2k)}\\&\quad-\sum_{n\ \text{even}}\frac{\sin(n\pi a/2)\sin(n\pi b/2)}{n}e^{-n\pi(1-a/2+b/2+2k)}\\&\quad\left.+\sum_{n\ \text{even}}\frac{\sin(n\pi a/2)\sin(n\pi b/2)}{n}e^{-n\pi(1+a/2+b/2+2k)}\right\}.\end{aligned} \tag{6}$$

We now apply formula 1.462 of Gradshteyn and Ryzhik,[5]

$$\sum_{k=1}^{\infty}\frac{\sin kx\sin ky}{k}\exp[-2k|t|]=\frac{1}{4}\ln\left[\frac{\sin^2\frac{x+y}{2}+\sinh^2 t}{\sin^2\frac{x-y}{2}+\sinh^2 t}\right], \tag{7}$$

to evaluate the sums inside $\{\}$ in (6). For that let $n_{\text{even}}=2j$. We then obtain

$$\begin{aligned}S_1=\frac{1}{2}\sum_{k=0}^{\infty}\left\{\ln\left[\frac{\sin^2\pi(a+b)/2+\sinh^2\pi(1-a/2-b/2+2k)}{\sin^2\pi(a-b)/2+\sinh^2\pi(1-a/2-b/2+2k)}\right]\right.\\-\ln\left[\frac{\sin^2\pi(a+b)/2+\sinh^2\pi(1+a/2-b/2+2k)}{\sin^2\pi(a-b)/2+\sinh^2\pi(1+a/2-b/2+2k)}\right]\\-\ln\left[\frac{\sin^2\pi(a+b)/2+\sinh^2\pi(1-a/2+b/2+2k)}{\sin^2\pi(a-b)/2+\sinh^2\pi(1-a/2+b/2+2k)}\right]\\\left.+\ln\left[\frac{\sin^2\pi(a+b)/2+\sinh^2\pi(1+a/2+b/2+2k)}{\sin^2\pi(a-b)/2+\sinh^2\pi(1+a/2+b/2+2k)}\right]\right\}.\end{aligned} \tag{8}$$

Now, consider the sum S_2, and let us express the hyperbolic functions in terms of exponentials

$$
\begin{aligned}
S_2 &= 4\sum_{n\ \text{odd}} \frac{\cos n\pi a/2 \cos n\pi b/2}{n} e^{n\pi(a+b)/2}(1+e^{-n\pi a})(1+e^{-n\pi b})e^{-n\pi}(1-e^{-2n\pi})^{-1} \\
&= 4\sum_{n\ \text{odd}} \frac{\cos n\pi a/2 \cos n\pi b/2}{n} e^{n\pi[(a+b)/2-1]}(1+e^{-n\pi a})(1+e^{-n\pi b})\sum_{k=0}^{\infty} e^{-2n\pi k} \\
&= 4\sum_{k=0}^{\infty}\left\{\sum_{n\ \text{odd}} \frac{\cos n\pi a/2 \cos n\pi b/2}{n} e^{-n\pi[1-(a+b)/2+2k]}\right. \\
&\quad + \sum_{n\ \text{odd}} \frac{\cos n\pi a/2 \cos n\pi b/2}{n} e^{-n\pi[1-(a-b)/2+2k]} \\
&\quad + \sum_{n\ \text{odd}} \frac{\cos n\pi a/2 \cos n\pi b/2}{n} e^{-n\pi[1-(b-a)/2+2k]} \\
&\quad \left. + \sum_{n\ \text{odd}} \frac{\cos n\pi a/2 \cos n\pi b/2}{n} e^{-n\pi[1+(a+b)/2+2k]}\right\}. \qquad (9)
\end{aligned}
$$

To evaluate the sums inside $\{\}$ in (9) we will need a formula like (7) but involving cosines instead of sines. Since such a formula is not found in Gradhsteyn and Rhyzik,[5] we will derive it in Appendix A. Using now the formula (A6) we can evaluate the sums in Eq. (9). We get

$$S_2 = \sum_{n=1}^{24}\sum_{k=0}^{\infty} s_{nk}, \qquad (10)$$

where

$$s_{1k} = -\tfrac{1}{2}\ln(1-e^{-\pi[1-(a+b)/2+2k]+i\pi(a-b)/2}), \qquad (11)$$

$$s_{2k} = -\tfrac{1}{2}\ln(1-e^{-\pi[1-(a+b)/2+2k]-i\pi(a-b)/2}), \qquad (12)$$

$$s_{3k} = -\frac{1}{4}\ln\left[\frac{\sin^2\dfrac{\pi(a+b)}{4}+\sinh^2\dfrac{\pi}{2}\left[1-\dfrac{a+b}{2}+2k\right]}{\sin^2\dfrac{\pi(a-b)}{4}+\sinh^2\dfrac{\pi}{2}\left[1-\dfrac{a+b}{2}+2k\right]}\right], \qquad (13)$$

$$s_{4k} = \tfrac{1}{4}\ln(1-e^{-2\pi[1-(a+b)/2+2k]+i\pi(a-b)}), \qquad (14)$$

$$s_{5k} = \tfrac{1}{4}\ln(1-e^{-2\pi[1-(a+b)/2+2k]-i\pi(a-b)}), \qquad (15)$$

$$s_{6k} = \frac{1}{8}\ln\left[\frac{\sin^2\dfrac{\pi(a+b)}{2}+\sinh^2\pi\left[1-\dfrac{a+b}{2}+2k\right]}{\sin^2\dfrac{\pi(a-b)}{2}+\sinh^2\pi\left[1-\dfrac{a+b}{2}+2k\right]}\right], \qquad (16)$$

$$s_{7k} = -\tfrac{1}{2}\ln(1-e^{-\pi[1-(a-b)/2+2k]+i\pi(a-b)/2}), \qquad (17)$$

$$s_{8k} = -\tfrac{1}{2}\ln(1-e^{-\pi[1-(a-b)/2+2k]-i\pi(a-b)/2}), \qquad (18)$$

$$s_{9k}=-\frac{1}{4}\ln\left[\frac{\sin^2\frac{\pi(a+b)}{4}+\sinh^2\frac{\pi}{2}\left[1-\frac{a-b}{2}+2k\right]}{\sin^2\frac{\pi(a-b)}{4}+\sinh^2\frac{\pi}{2}\left[1-\frac{a-b}{2}+2k\right]}\right], \tag{19}$$

$$s_{10k}=\tfrac{1}{4}\ln(1-e^{-2\pi[1-(a-b)/2+2k]+i\pi(a-b)}), \tag{20}$$

$$s_{11k}=\tfrac{1}{4}\ln(1-e^{-2\pi[1-(a-b)/2+2k]-i\pi(a-b)}), \tag{21}$$

$$s_{12k}=\frac{1}{8}\ln\left[\frac{\sin^2\frac{\pi(a+b)}{2}+\sinh^2\pi\left[1-\frac{a-b}{2}+2k\right]}{\sin^2\frac{\pi(a-b)}{2}+\sinh^2\pi\left[1-\frac{a-b}{2}+2k\right]}\right], \tag{22}$$

$$s_{13k}=-\tfrac{1}{2}\ln(1-e^{-\pi[1-(b-a)/2+2k]+i\pi(a-b)/2}), \tag{23}$$

$$s_{14k}=-\tfrac{1}{2}\ln(1-e^{-\pi[1-(b-a)/2+2k]-i\pi(a-b)/2}), \tag{24}$$

$$s_{15k}=-\frac{1}{4}\ln\left[\frac{\sin^2\frac{\pi(a+b)}{4}+\sinh^2\frac{\pi}{2}\left[1-\frac{b-a}{2}+2k\right]}{\sin^2\frac{\pi(a-b)}{4}+\sinh^2\frac{\pi}{2}\left[1-\frac{b-a}{2}+2k\right]}\right], \tag{25}$$

$$s_{16k}=\tfrac{1}{4}\ln(1-e^{-2\pi[1-(b-a)/2+2k]+i\pi(a-b)}), \tag{26}$$

$$s_{17k}=\tfrac{1}{4}\ln(1-e^{-2\pi[1-(b-a)/2+2k]-i\pi(a-b)}), \tag{27}$$

$$s_{18k}=\frac{1}{8}\ln\left[\frac{\sin^2\frac{\pi(a+b)}{2}+\sinh^2\pi\left[1-\frac{b-a}{2}+2k\right]}{\sin^2\frac{\pi(a-b)}{2}+\sinh^2\pi\left[1-\frac{b-a}{2}+2k\right]}\right], \tag{28}$$

$$s_{19k}=-\tfrac{1}{2}\ln(1-e^{-\pi[1+(a+b)/2+2k]+i\pi(a-b)/2}), \tag{29}$$

$$s_{20k}=-\tfrac{1}{2}\ln(1-e^{-\pi[1+(a+b)/2+2k]-i\pi(a-b)/2}), \tag{30}$$

$$s_{21k}=-\frac{1}{4}\ln\left[\frac{\sin^2\frac{\pi(a+b)}{4}+\sinh^2\frac{\pi}{2}\left[1+\frac{a+b}{2}+2k\right]}{\sin^2\frac{\pi(a-b)}{4}+\sinh^2\frac{\pi}{2}\left[1+\frac{a+b}{2}+2k\right]}\right], \tag{31}$$

$$s_{22k}=\tfrac{1}{4}\ln(1-e^{-2\pi[1+(a+b)/2+2k]+i\pi(a-b)}), \tag{32}$$

$$s_{23k}=\tfrac{1}{4}\ln(1-e^{-2\pi[1+(a+b)/2+2k]-i\pi(a-b)}), \tag{33}$$

$$s_{24k}=\frac{1}{8}\ln\left[\frac{\sin^2\frac{\pi(a+b)}{2}+\sinh^2\pi\left[1+\frac{a+b}{2}+2k\right]}{\sin^2\frac{\pi(a-b)}{2}+\sinh^2\pi\left[1+\frac{a+b}{2}+2k\right]}\right]. \tag{34}$$

Now, adding Eqs. (8) and (10) and after a large number of simplifications, factorizations and use of the elementary properties of trigonometric and hyperbolic functions, we obtain

$$\begin{aligned} S_g &= S_1 + S_2 \\ &= \sum_{k=0}^{\infty} \ln \frac{N_k}{D_k} \\ &= \ln \prod_{k=0}^{\infty} \frac{N_k}{D_k} \\ &= \ln \frac{\Pi_{k=0}^{\infty} N_k}{\Pi_{k=0}^{\infty} D_k}, \end{aligned} \tag{35}$$

where

$$\begin{aligned} N_k = &(1+xy^{1+i}z^{-(1+i)})(1+xy^{1-i}z^{i-1})(1+xy^{i-1}z^{1-i})(1+xy^{-(1+i)}z^{1+i}) \\ &\times (1+xy^{1-i}z^{1-i})(1+xy^{1+i}z^{1+i})(1+xy^{i-1}z^{i-1})(1+xy^{-(1+i)}z^{-(1+i)}) \end{aligned} \tag{36}$$

and

$$\begin{aligned} D_k = &(1-xy^{1+i}z^{1-i})(1-xy^{1-i}z^{1+i})(1-xy^{i-1}z^{-(1+i)})(1-xy^{-(1+i)}z^{i-1}) \\ &\times (1-xy^{i-1}z^{1+i})(1-xy^{-(1+i)}z^{1-i})(1-xy^{1+i}z^{i-1})(1-xy^{1-i}z^{-(1+i)}) \end{aligned} \tag{37}$$

with

$$x = (e^{-\pi})^{1+2k} \equiv q^{1+2k}, \tag{38}$$

$$y = e^{\pi a/2}, \quad z = e^{\pi b/2}. \tag{39}$$

Consider now the following product[6]

$$f(t) = \prod_{k=0}^{\infty} (1 \pm q^{1+2k}t)(1 \pm q^{1+2k}t^{-1}) \tag{40}$$

and let $t = e^{2iu}$. Then, Eq. (40) can be written as

$$f(u) = \prod_{k=0}^{\infty} (1 \pm 2q^{1+2k}\cos 2u + q^{2+4k}). \tag{41}$$

We will make use now of Eqs. (40) and (41) to relate the products in Eq. (35) with ratios of Jacobi's theta functions. The numerator of the logarithm of Eq. (35) can be written as

$$\begin{aligned} \prod_{k=0}^{\infty} N_k = \prod_{k=0}^{\infty} &(1+q^{1+2k}(y/z)^{1+i})(1+q^{1+2k}(y/z)^{-(1+i)})(1+q^{1+2k}(y/z)^{1-i}) \\ &\times (1+q^{1+2k}(y/z)^{i-1})(1+q^{1+2k}(yz)^{1-i})(1+q^{1+2k}(yz)^{i-1}) \\ &\times (1+q^{1+2k}(yz)^{1+i})(1+q^{1+2k}(yz)^{-(1+i)}) \end{aligned} \tag{42}$$

with

$$y/z = e^{\pi(a-b)/2}, \tag{43}$$

$$yz = e^{\pi(a+b)/2}. \tag{44}$$

Similarly, the denominator of the logarithm of Eq. (35) can be written as

$$\begin{aligned}\prod_{k=0}^{\infty} D_k = \prod_{k=0}^{\infty} & (1-q^{1+2k}y^{1+i}z^{1-i})(1-q^{1+2k}y^{-(1+i)}z^{i-1})(1-q^{1+2k}y^{1-i}z^{1+i}) \\ & \times(1-q^{1+2k}y^{i-1}z^{-(1+i)})(1-q^{1+2k}y^{i-1}z^{1+i})(1-q^{1+2k}y^{1-i}z^{-(1+i)}) \\ & \times(1-q^{1+2k}y^{-(1+i)}z^{1-i})(1-q^{1+2k}y^{1+i}z^{i-1}).\end{aligned} \tag{45}$$

We see that each pair of terms in Eqs. (42) and (45) has the form given by Eq. (40). Thus, we can write Eqs. (42) and (45) as product of functions of the form given by Eq. (41).

Thus, Eq. (35) can be written as

$$S_g = \ln \frac{f(u_1)f(u_2)f(u_3)f(u_4)}{g(u_5)g(u_6)g(u_7)g(u_8)}, \tag{46}$$

where

$$u_1 = \frac{\pi}{4}(1-i)(a-b), \tag{47}$$

$$u_2 = -\frac{\pi}{4}(i+1)(a-b), \tag{48}$$

$$u_3 = -\frac{\pi}{4}(i+1)(a+b), \tag{49}$$

$$u_4 = \frac{\pi}{4}(1-i)(a+b), \tag{50}$$

$$u_5 = \frac{\pi}{4}(a-b) - i\frac{\pi}{4}(a+b), \tag{51}$$

$$u_6 = \frac{\pi}{4}(b-a) - i\frac{\pi}{4}(a+b), \tag{52}$$

$$u_7 = \frac{\pi}{4}(a+b) + i\frac{\pi}{4}(a-b), \tag{53}$$

$$u_8 = -\frac{\pi}{4}(a+b) + i\frac{\pi}{4}(a-b), \tag{54}$$

while $f(u_i)$ and $g(u_j)$ are the $f(u)$ functions in Eq. (41) with the plus and minus signs, respectively.

Relating the $f(u_i)$ and $g(u_j)$ to Jacobi's theta functions $\theta_3(u_i)$ and $\theta_4(u_j)$, which in their infinite product representations are given by[6–9]

$$\theta_3(u) = G\prod_{n=1}^{\infty}(1+2q^{2n-1}\cos 2u + q^{4n-2}), \tag{55}$$

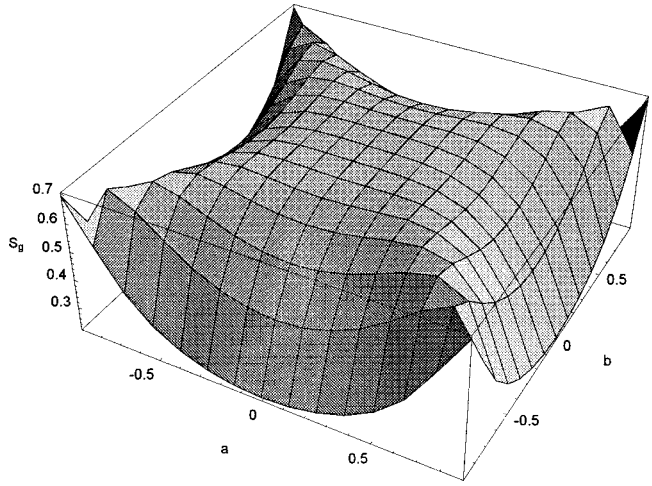

FIG. 1. Plot of the periodic function S_g as a function of the parameters a and b, in the interval $-1<a,\ b<1$.

$$\theta_4(u)=G\prod_{n=1}^{\infty}(1-2q^{2n-1}\cos 2u+q^{4n-2}), \tag{56}$$

with

$$G=\prod_{n=1}^{\infty}(1-q^{2n}), \tag{57}$$

we have, finally,

$$S_g=\ln\frac{\theta_3(u_1)\theta_3(u_2)\theta_3(u_3)\theta_3(u_4)}{\theta_4(u_5)\theta_4(u_6)\theta_4(u_7)\theta_4(u_8)}. \tag{58}$$

Figure 1 shows a plot of S_g in terms of the parameters a and b in the interval $-1<a,\ b<1$. As seen S_g is not a constant for arbitrary values of the parameters. However, in Sec. IV we provide a proof that for $a=b$, $S_g=S$ is indeed a constant and also prove, in general, the nonconstancy of S_g for arbitrary values of a and b $(a\neq b)$.

III. EQUATION (1) IN TERMS OF JACOBI'S THETA FUNCTIONS

When $a=b$ Eq. (58) becomes [recall that $\theta_3(u)$ and $\theta_4(v)$ are even functions of their arguments]

$$S=\ln\left[\frac{\theta_3\left(\frac{\pi a}{2}(1+i)\right)\theta_3\left(\frac{\pi a}{2}(1-i)\right)(\theta_3(0))^2}{\left(\theta_4\left(\frac{\pi a}{2}i\right)\right)^2\left(\theta_4\left(\frac{\pi a}{2}\right)\right)^2}\right]. \tag{59}$$

If $a=0$, use of Eqs. (55)–(57) reveals that the expression inside $\{\}$ in (59) reduces to the one given by Jackson,[1] i.e.,

$$S=\ln\prod_{k=0}^{\infty}\left(\frac{1+e^{-\pi(1+2k)}}{1-e^{-\pi(1+2k)}}\right)^8$$

$$=\ln\left(\frac{\theta_3(0)}{\theta_4(0)}\right)^4$$

$$=\ln\frac{1}{k'^2}$$

$$=\ln 2, \tag{60}$$

where k' is the complementary modulus.[6]

Our purpose now is to demonstrate that S is a constant, independent of a, and equal to $\ln 2$.

IV. PROOF THAT *S* IS A CONSTANT FOR ALL *a*

We will give two demonstrations of the proposition that S is a constant, independent of a and equal to $\ln 2$. The first proof is based on the manipulation of some relations between Jacobi's theta functions, while the second one is more formal and makes use of Liouville theorems of doubly periodic functions.

A. Demonstration 1

Let us write Eq. (59) as

$$S=\ln\left[\frac{\theta_3(z+zi)\,\theta_3(z-zi)(\theta_3(0))^2}{(\theta_4(zi))^2(\theta_4(z))^2}\right]$$

$$=\ln\left\{\left(\frac{\theta_3(0)}{\theta_4(0)}\right)^4\left(\frac{A}{B}\right)\right\}, \tag{61}$$

where

$$A=\frac{\theta_3(z+zi)\,\theta_3(z-zi)}{(\theta_3(0))^2}, \tag{62}$$

$$B=\frac{(\theta_4(z)\,\theta_4(zi))^2}{(\theta_4(0))^4}, \tag{63}$$

and $z=\pi a/2$.

Our aim now is to prove that A/B in Eq. (61) is equal to 1, that is, $A=B$. In order to do so we will use some relations among theta functions to reduce B to A. The relevant theorems for our proof are given in Appendix B to which we will be referring in the steps that follow.

First, by (B1),

$$(\theta_4(0))^4B=(\theta_4(z))^2(\theta_4(zi))^2$$

$$=(\theta_4(0))^2\theta_4(z+zi)\,\theta_4(z-zi)+(\theta_1(z))^2(\theta_1(zi))^2. \tag{64}$$

Also, by (B2),

$$(\theta_3(0))^4(\theta_4(0))^4B=(\theta_3(0))^4(\theta_4(0))^2\theta_4(z+zi)\,\theta_4(z-zi)+(\theta_3(0))^4(\theta_1(z))^2(\theta_1(zi))^2$$

$$=(\theta_3(0))^2(\theta_1(z))^2(\theta_2(zi))^2(\theta_4(0))^2+(\theta_3(0))^2(\theta_4(0))^2(\theta_3(z))^2(\theta_4(zi))^2$$

$$+(\theta_3(0))^4(\theta_1(z))^2(\theta_1(zi))^2. \tag{65}$$

On the other hand, by (B2) with $v=0$,

$$(\theta_3(0))^2(\theta_4(zi))^2=(\theta_1(zi))^2(\theta_2(0))^2+(\theta_3(zi))^2(\theta_4(0))^2. \tag{66}$$

Thus, substituting Eq. (66) into Eq. (65) we obtain

$$(\theta_3(0))^4(\theta_4(0))^4B=(\theta_3(0))^2(\theta_1(z))^2(\theta_2(zi))^2(\theta_4(0))^2+(\theta_3(z))^2(\theta_4(0))^2(\theta_1(zi))^2(\theta_2(0))^2$$
$$+(\theta_3(z))^2(\theta_4(0))^2(\theta_3(zi))^2(\theta_4(0))^2+(\theta_3(0))^4(\theta_1(z))^2(\theta_1(zi))^2. \tag{67}$$

Using (B3) and (B4) we get

$$(\theta_4(0))^2=k'(\theta_3(0))^2, \tag{68}$$

$$(\theta_2(0))^2=k(\theta_3(0))^2, \tag{69}$$

since $\theta_1(0)=0$.

Thus, substituting Eqs. (68) and (69) into Eq. (67) one obtains

$$(\theta_3(0))^4(\theta_4(0))^4B=(\theta_3(0))^4[k'(\theta_1(z))^2(\theta_2(zi))^2+k'k(\theta_3(z))^2(\theta_1(zi))^2$$
$$+k'^2(\theta_3(z))^2(\theta_3(zi))^2+(\theta_1(z))^2(\theta_1(zi))^2]. \tag{70}$$

Applying (B4) in (40) we obtain

$$(\theta_4(0))^4B=-k'^2(\theta_1(z))^2(\theta_1(zi))^2+k'k(\theta_1(z))^2(\theta_3(zi))^2+k'k(\theta_3(z))^2(\theta_1(zi))^2$$
$$+k'^2(\theta_3(z))^2(\theta_3(zi))^2+(\theta_1(z))^2(\theta_1(zi))^2. \tag{71}$$

Since $q=e^{-\pi(K'/K)}$ by definition, $K(k)$ being the complete elliptic integral of first class and k its modulus,[6] it implies, in our case where $q=e^{-\pi}$, that

$$\begin{aligned} K(k)&=K'(k)\\ &=K(k')\\ &=K(\sqrt{1-k^2}) \end{aligned} \tag{72}$$

or

$$k'=k=\frac{1}{\sqrt{2}}. \tag{73}$$

Then, it follows that Eq. (71) can be written as

$$2(\theta_4(0))^4B=(\theta_1(z))^2(\theta_1(zi))^2+(\theta_3(z))^2(\theta_3(zi))^2$$
$$+((\theta_1(z))^2(\theta_3(zi))^2+(\theta_3(z))^2(\theta_1(zi))^2). \tag{74}$$

Using the so-called Jacobi's imaginary transformations[7]

$$\theta_1(z,\tau)=\alpha\theta_1(z\tau',\tau')/i, \tag{75}$$

$$\theta_3(z,\tau)=\alpha\theta_3(z\tau',\tau'), \tag{76}$$

$$\alpha=\frac{1}{\sqrt{-i\tau}}e^{i\tau'z^2/\pi},\quad \tau'=-\frac{1}{\tau}, \tag{77}$$

and the fact that, in our case, $\tau=\tau'=i$, we can prove that the third term in (74) vanishes. Thus, Eq. (74) reduces to

$$B=\frac{(\theta_3(z))^4-(\theta_1(z))^4}{2\alpha^2(\theta_4(0))^4} \tag{78}$$

with $\alpha=e^{-z^2/\pi}$.

Second, starting from Eq. (62) and employing (B5), (68), (73), and (75)–(77) we get

$$\begin{aligned} A&=\frac{(\theta_1(z))^2(\theta_1(zi))^2+(\theta_3(z))^2(\theta_3(zi))^2}{2(\theta_4(0))^4}\\ &=\frac{(\theta_3(z))^4-(\theta_1(z))^4}{2\alpha^2(\theta_4(0))^4}\\ &=B. \end{aligned} \tag{79}$$

Consequently, we have proved that

$$S=\ln\left\{\left(\frac{\theta_3(0)}{\theta_4(0)}\right)^4\right\} \tag{80}$$

$$=\ln 2, \tag{81}$$

where (81) follows from (68) and (73).

B. Demonstration 2

Demonstration 1 can be called a *tour de force* demonstration. Here, we will give a simpler and more elegant demonstration which can be accomplished by the direct application of some general theorems about elliptic functions.

Consider the function S as given in (61). First, we will show that S is an elliptic function of periods $\pi/2$ and $(\pi/2)\,i$. This implies that the function will have the same value each time a changes by one.

Thus, changing $z\to z+(\pi/2)$ we change $S\to S'$, where

$$S'=\frac{\theta_3(z+zi+\frac{1}{2}\pi+\frac{1}{2}\pi i)\,\theta_3(z-zi+\frac{1}{2}\pi-\frac{1}{2}\pi i)\,\theta_3^2(0)}{\theta_4^2(zi+\frac{1}{2}\pi i)\,\theta_4^2(z+\frac{1}{2}\pi)}. \tag{82}$$

Now, applying the fundamental properties of these theta functions (see basic property table on p. 319 of Ref. 9), we get

$$S'=\frac{\theta_1(z+zi)\,\theta_1(zi-z)\,\theta_3^2(0)}{\theta_1^2(zi)\,\theta_3^2(z)}. \tag{83}$$

To show that indeed $S=S'$ we use (B6) and (B7), and apply to the first term of the right-hand side of each equation Jacobi's imaginary transformations (75)–(77) and

$$\theta_2(z,\tau)=\alpha\,\theta_4(z\tau',\tau'). \tag{84}$$

We get (with $u=z$ and $v=zi$, and recalling that, in our problem, $\tau=i$, and, consequently, $\tau'=i$)

$$\theta_3^2(0)\,\theta_3(z+zi)\,\theta_3(z-zi)=2\,\theta_4^2(z)\,\theta_4^2(zi), \tag{85}$$

$$\theta_3^2(0)\,\theta_1(z+zi)\,\theta_1(z-zi)=-2\,\theta_3^2(z)\,\theta_1^2(zi) \tag{86}$$

or

$$\frac{\theta_3(z+zi)\,\theta_3(z-zi)}{\theta_1(z+zi)\,\theta_1(zi-z)}=\frac{\theta_4^2(z)\,\theta_4^2(zi)}{\theta_3^2(z)\,\theta_1^2(zi)}. \tag{87}$$

Then, substituting (87) in (83) we obtain that $S'=S$. By a similar procedure we can prove that $(\pi/2)\,i$ is also a period of S. Thus, S is an elliptic function of periods $\pi/2$ and $(\pi/2)\,i$.

We now prove that S is an elliptic function of order less than two, and, by Liouville theorem,[9,10] a constant.

Since, in the problem we are dealing with, z is real, S has only one zero which occurs when $z=\pi/2$, i.e., $\theta_3[(\pi/2)+(\pi/2)\,i]=0$. Then, since the number of zero's of an elliptic function is equal to the number of poles in the fundamental parallelogram we conclude that S is an elliptic function of order one, and, by Liouville theorem, a constant.[11] Another way to analyze this is the following. Since when $z=\pi/2$ the function $\theta_4^2(zi)$ in the denominator of S has a double zero and the function $\theta_3(z+zi)$ has a single zero, this single zero will knock a zero of $\theta_4^2(zi)$ and, consequently, S will have only one pole and will be an elliptic function of order one and, by Liouville theorem, a constant.

The constant value of S in the fundamental parallelogram is found by selecting an appropriate value of z, which in our case is, naturally, 0 (corresponding to $a=0$). Thus, putting $z=0$ in Eq. (61) we get

$$S=\ln\left(\frac{\theta_3(0)}{\theta_4(0)}\right)^4$$

$$=\ln 2.$$

Further, it can be shown by the same methodology that when $a\neq b$, S_g is an elliptic function of periods 0 in $\pi(a-b)/4$ and π in $\pi(a+b)/4$ (i.e., periods 2 in a and b), and periods 0 in $\pi(a-b)/4$ and πi in $\pi(a+b)/4$ (i.e., periods $2i$ in a and b). Also, it can be shown that when $a\neq b$ S_g is an elliptic function of order two and, by Liouville theorem, is not a constant.

V. CONCLUSIONS

A recent mathematical result,[1] Eq. (1), derived as a consequence of the application of the Thompson–Lampard theorem of electrostatics,[2–4] has been given an entirely mathematical proof. Our approach has been, first, to generalize the left-hand side of Eq. (1) in terms of two parameters and to express it in terms of the logarithm of a ratio of products of Jacobi's theta functions of the types $\theta_3(x)$ and $\theta_4(x)$. Second, we have proved that the constancy of the sum indicated corresponds to the particular case when both parameters are equal to each other. We have done this by either of two procedures. The first one was based on the manipulation of some relations among Jacobi's theta functions, and the second one made use of Liouville theorem of the theory of doubly periodic functions.[9,10]

APPENDIX A: A FORMULA INVOLVING A SUM OF PRODUCTS OF COSINES AND EXPONENTIALS

Here we will derive a formula involving a sum of a product of cosines and exponentials.

Using the following relations[5]

$$\cos(x-y)=\cos x\cos y+\sin x\sin y, \tag{A1}$$

$$\sum_{k=1}^{\infty}\frac{p^k\cos kx}{k}=\ln\frac{1}{\sqrt{1-2p\cos x+p^2}}, \tag{A2}$$

with $p=e^{-2|t|}$, and Eq. (7) we obtain

$$\begin{aligned}
&\sum_{k=1}^{\infty}\frac{\cos kx\cos ky}{k}e^{-2k|t|}\\
&\quad=\sum_{k=1}^{\infty}\frac{\cos k(x-y)}{k}e^{-2k|t|}-\sum_{k=1}^{\infty}\frac{\sin kx\sin ky}{k}e^{-2k|t|}\\
&\quad=-\tfrac{1}{2}\ln(1-e^{-2|t|+i(x-y)})-\tfrac{1}{2}\ln(1-e^{-2|t|-i(x-y)})\\
&\qquad-\frac{1}{4}\ln\left[\frac{\sin^2\dfrac{x+y}{2}+\sinh^2|t|}{\sin^2\dfrac{x-y}{2}+\sinh^2|t|}\right].
\end{aligned}\tag{A3}$$

On the other hand,

$$\sum_{n=1}^{\infty}\frac{\cos nx\cos ny}{n}e^{-2n|t|}=\sum_{n\ \text{even}}\frac{\cos nx\cos ny}{n}e^{-2n|t|}+\sum_{n\ \text{odd}}\frac{\cos nx\cos ny}{n}e^{-2n|t|}.\tag{A4}$$

The sum over n even in the preceding equation can be evaluated easily using (A3),

$$\begin{aligned}
\sum_{n\ \text{even}}\frac{\cos nx\cos ny}{n}e^{-2n|t|}&=\sum_{j=1}^{\infty}\frac{\cos 2jx\cos 2jy}{2j}e^{-2j(2|t|)}\\
&=-\tfrac{1}{4}\ln(1-e^{-4|t|+2i(x-y)})-\tfrac{1}{4}\ln(1-e^{-4|t|-2i(x-y)})\\
&\quad-\frac{1}{8}\ln\left[\frac{\sin^2(x+y)+\sinh^2 2|t|}{\sin^2(x-y)+\sinh^2 2|t|}\right].
\end{aligned}\tag{A5}$$

We now substitute (A3) and (A5) in (A4) and solve the sum over n odd obtaining

$$\begin{aligned}
&\sum_{n\ \text{odd}}\frac{\cos nx\cos ny}{n}e^{-2n|t|}\\
&\quad=-\tfrac{1}{2}\ln(1-e^{-2|t|+i(x-y)})-\tfrac{1}{2}\ln(1-e^{-2|t|-i(x-y)})\\
&\qquad-\frac{1}{4}\ln\left[\frac{\sin^2\dfrac{x+y}{2}+\sinh^2|t|}{\sin^2\dfrac{x-y}{2}+\sinh^2|t|}\right]+\frac{1}{4}\ln(1-e^{-4|t|+2i(x-y)})+\frac{1}{4}\ln(1-e^{-4|t|-2i(x-y)})\\
&\qquad+\frac{1}{8}\ln\left[\frac{\sin^2(x+y)+\sinh^2 2|t|}{\sin^2(x-y)+\sinh^2 2|t|}\right].
\end{aligned}\tag{A6}$$

APPENDIX B: RELATIONS AMONG JACOBI'S THETA FUNCTIONS RELEVANT TO THE PRESENT WORK

In this appendix we list the relevant theta function relations[6] that will be needed in the proof presented in Sec. IV:

$$\theta_4^2(0)\,\theta_4(u+v)\,\theta_4(u-v)=\theta_4^2(u)\,\theta_4^2(v)-\theta_1^2(u)\,\theta_1^2(v),\tag{B1}$$

$$\theta_3^2(0)\,\theta_4(u+v)\,\theta_4(u-v)=\theta_1^2(u)\,\theta_2^2(v)+\theta_3^2(u)\,\theta_4^2(v), \tag{B2}$$

$$\theta_4^2(u)=k\,\theta_1^2(u)+k'\,\theta_3^2(u), \tag{B3}$$

$$\theta_2^2(u)=-k'\,\theta_1^2(u)+k\,\theta_3^2(u), \tag{B4}$$

$$\theta_3^2(0)\,\theta_3(u+v)\,\theta_3(u-v)=\theta_1^2(u)\,\theta_1^2(v)+\theta_3^2(u)\,\theta_3^2(v), \tag{B5}$$

$$\theta_3^2(0)\,\theta_3(u+v)\,\theta_3(u-v)=\theta_2^2(u)\,\theta_2^2(v)+\theta_4^2(u)\,\theta_4^2(v), \tag{B6}$$

$$\theta_3^2(0)\,\theta_1(u+v)\,\theta_1(u-v)=\theta_1^2(u)\,\theta_3^2(v)-\theta_3^2(u)\,\theta_1^2(v). \tag{B7}$$

(Received 3 August 2000; accepted for publication 25 October 2000)

This article presents a generalization of the standard Darboux transform applied to Sturm–Liouville differential equations. This is achieved with the aid of an ansatz as a particular solution for the Riccati relationship involved, which in turn led us to obtain its generalized Darboux solution that contains, as a particular case, the standard Darboux transform. The proposed generalized Darboux transform (GDT), applied to the quantum mechanical field, gives the opportunity to prove the existence of standard and generalized Darboux potentials that match with the so-called isospectral potentials. This is exemplified by obtaining, through the GDT, a set of standard and generalized Darboux potentials that form the partner of the one-dimensional harmonic oscillator model for any quantum principal number. The worked example indicates how the GDT can be used to obtain the isospectral potentials associated to any known specific potential. We consider also the application of our method as proposed to the theory of solitons in order to show why the GDT will be important in other fields of application where the standard Darboux transform is usually concerned.
[DOI: 10.1063/1.1334904]

I. INTRODUCTION

Although the Darboux transform was given a long time ago,[1] such an exceptional procedure is actually of great interest as has been demonstrated by several applications in the theory of solitons.[2–4] Essentially, the Darboux proposition is based on the covariance properties of ordinary and partial differential equations with respect to a gauge transformation in the special case of the Sturm–Liouville relationship. Moreover, the N-times repeated Darboux transform has been given by Crum[5] and applied for radial Schrödinger equations.[6] Furthermore, in the field of quantum mechanics, several studies have turned to the Gelfand–Levitan procedure[7] for the inverse scattering method to generate anharmonic potentials.[8] Other research has been directed to standard and modified factorizations and SUSY[9] in relation to the so-called isospectral potentials.[10] In this regard, Korolev[11] has disclosed the interplay between Liouville equations and Darboux transform in relation to the isospectral problem. Besides, Morales and Peña[12] have recently proposed a procedure to obtain all the related isospectral potentials, standard, modified and generalized, proving also[13] that their modified potentials match those obtained by means of the standard Darboux transform. Taking into consideration the aforesaid aspects, in this work we extend the procedure that we have already proposed, aiming to find the matching that corresponds to generalized potentials. Then we proceeded to follow the spirit of the method used to obtain generalized potentials, in order to generalize the Darboux transform with the purpose to transcend the scope of the standard Darboux transform field. Thus, in the next section the standard Darboux transform is reviewed within the frame of the Sturm–Liouville equations in such a way that in Sec. III we give

[a]Electronic mail: jmr@correo.azc.uam.mx

the corresponding generalization. Specifically, the generalized Darboux transform applied to quantum mechanical problems is given in Sec. IV where we analyze the problem of isospectrality. Finally, just as an example, the usefulness of the proposed generalized Darboux transform, on quantum mechanical situations, is shown by obtaining the corresponding standard and generalized Darboux potentials that are partner to the one-dimensional harmonic oscillator potential model. In order to compare our findings with results already published we give explicitly the set of isospectral potentials that corresponds to each eigenvalue of the former Hamiltonian as well as the general formula for the generalized and standard Darboux potentials for any arbitrary n quantum principal number. This example shows straightforwardly by how to generalize any known potential model exactly solved, for which it will be possible, in the same manner, to improve any application where the standard Darboux transform is involved as shown in Sec. V with an application to the theory of solitons.

II. THE STANDARD DARBOUX TRANSFORM

According to the Darboux statement of the Sturm–Liouville equation

$$-\psi''+u(x)\psi=\lambda\psi, \tag{1}$$

if ψ_1 and λ_1 exist and are such that

$$-\psi_1''+u(x)\psi_1=\lambda_1\psi_1, \tag{2}$$

then the Darboux transform

$$\varphi=\psi'-\sigma_1(x)\psi \tag{3}$$

is a solution of

$$-\varphi''+U(x)\varphi=\lambda\varphi, \tag{4}$$

where

$$\sigma_1(x)=\psi_1'/\psi_1 \tag{5}$$

which is equivalent to

$$\psi_1=e^{\int\sigma_1(x)dx}. \tag{6}$$

Clearly, the Sturm–Liouville relationship given in Eq. (1) is covariant with respect to the Darboux transform on condition that

$$U(x)=U_{\mathrm{D}}(x)=u(x)-2\sigma_1'(x), \tag{7}$$

where the subscript D is used to denote $U_{\mathrm{D}}(x)$ as the ''standard Darboux potential'' when concerned with quantum mechanical applications.

III. THE GENERALIZED DARBOUX TRANSFORM

In order to differentiate the purpose of this work regarding the so-called generalized Darboux transform,[2] or Crum generalization,[5] it is important to point out that we are not involved with the N-times repeated Darboux transform. We are interested in the use of the Darboux transformation method in order to obtain the *generalized Darboux solution* which includes the *standard Darboux solution* as particular case, i.e., to find our generalized Darboux transform (GDT).

According to this, it should be noticed that the Darboux transform given in Eq. (3) fulfills the covariance of Eq. (4) on condition that

$$(\lambda - u(x) + 2\sigma_1'(x))\sigma_1(x)\psi - u'(x)\psi + \sigma_1(x)\psi'' + \sigma_1''(x)\psi = 0, \tag{8}$$

which is equivalent to showing that

$$(\sigma_1''(x) + 2\sigma_1(x)\sigma_1'(x) - u'(x))\psi = 0. \tag{9}$$

That is, the relationship

$$\sigma_1''(x) + 2\sigma_1(x)\sigma_1'(x) - u'(x) = 0 \tag{10}$$

can be written as

$$\frac{d}{dx}(\sigma_1'(x) + \sigma_1^2(x) - u(x)) = 0, \tag{11}$$

which leads to

$$\sigma_1'(x) + \sigma_1^2(x) - u(x) = B \tag{12}$$

where B is a constant.

Regarding this point, it can be shown that the Riccati equation

$$y' = Q(x)y^2 + P(x)y + R(x) \tag{13}$$

has the general solution[14]

$$y = y_p + \frac{b}{\mu}, \tag{14}$$

where y_p is a particular solution and

$$\mu = e^{-\int^x [2Q(x)y_p + P(x)]dx}\left(\gamma - b\int^x e^{\int^x [2Q(x)y_p + P(x)]dx} Q(x)dx\right), \tag{15}$$

γ and b being constants. This means that we can consider $\sigma_1(x) = \sigma_{p_1}(x)$ as a particular solution of the specific Riccati relationship

$$\sigma_{p_1}'(x) + \sigma_{p_1}^2(x) - u(x) = C, \tag{16}$$

where C is any constant, in such a way that the corresponding generalized solution of Eq. (12) is

$$\sigma_{g_1}(x) = \sigma_{p_1}(x) + \frac{b}{\rho_1(x)}, \tag{17}$$

where the subindex g is used to denote the general solution and

$$\rho_1(x) = e^{2\int \sigma_{p_1}(x)dx}\left(\gamma + b\int e^{-2\int \sigma_{p_1}(x)dx}dx\right). \tag{18}$$

At this point, just before considering the generalized Darboux transform, it is very important to notice that we can use Eq. (15) to identify the particular potential $u(x)$ from an appropriate ansatz $\sigma_{p_1}(x)$ in order to find the Darboux potential. Such a procedure is by far simpler than the usual procedure requiring the knowledge of both the particular solution ψ_1 and the eigenvalue λ_1 associated to $u(x)$. Instead, with the identification of the former potential from Eq. (16) it is possible to perform the direct calculation of the $U_D(x)$ Darboux potential by means of

$$U_{\mathrm{D}}(x)=u(x)-2\sigma'_{p_1}(x). \tag{19}$$

Finally, for the full eigenfunction spectra, the generalized Darboux transform is given by

$$\varphi_g=\left(\frac{d}{dx}-\sigma_{g_1}(x)\right)\psi, \tag{20}$$

where $\sigma_{g_1}(x)=\varphi'_{g_1}/\varphi_{g_1}$ is such that

$$\varphi_{g_1}=e^{\int(\sigma_{p_1}(x)+\,b/\rho_1(x))dx}=\psi_1\left(\gamma+\int\frac{b\,dx}{\psi_1^2}\right). \tag{21}$$

This transformed function, φ_g, is a solution of

$$-\varphi''_g+U_{\mathrm{GD}}(x)\varphi_g=\lambda\varphi_g, \tag{22}$$

where

$$U_{\mathrm{GD}}(x)=U_{\mathrm{D}}(x)-2b\frac{d}{dx}\left(\frac{1}{\rho_1(x)}\right) \tag{23}$$

is the ''generalized Darboux potential'' appropriate for situations in quantum mechanics.

IV. THE GENERALIZED DARBOUX TRANSFORM IN QUANTUM MECHANICS

In order to show the usefulness of the generalized Darboux transform in quantum mechanics, this section is devoted to analyzing the isospectrality of the $U_{\mathrm{GD}}(x)$ associated Hamiltonian as well as to find the Darboux potentials, standard and generalized, for the specific case of the one-dimensional harmonic oscillator (HO) model.

A. Isospectrality of the $U_{\mathrm{GD}}(x)$ associated Hamiltonian

In order to prove the isospectrality of the generalized Hamiltonian that involves the potential $U_{\mathrm{GD}}(x)$, it is important to remember that the generalized Darboux transform applied to quantum mechanics can be seen by means of the Schrödinger relationship

$$H_g\varphi_g=E_g\varphi_g, \tag{24}$$

where H_g is given by

$$H_g=-\frac{d^2}{dx^2}+U_{\mathrm{GD}}(x) \tag{25}$$

assuming natural units $\hbar^2/2m=1$. In such a case, according to the generalized Darboux transform given in Eq. (20), it follows that

$$H_g\varphi_g=\left(-\frac{d^2}{dx^2}+u(x)-2\sigma'_{g_1}\right)\left(\frac{d}{dx}-\sigma_{g_1}\right)\psi, \tag{26}$$

which is equivalent to

$$H_g\varphi_g=-\psi'''+\sigma_{g_1}\psi''+\sigma''_{g_1}\psi+u(x)\psi'-u(x)\sigma_{g_1}\psi+2\sigma_{g_1}\sigma'_{g_1}\psi. \tag{27}$$

On the other hand, the use of the Sturm–Liouville relationship given by Eq. (1) leads to

$$\psi'''=(u(x)-\lambda)\psi'+u'(x)\psi. \tag{28}$$

With this identity and with the corresponding second derivative ψ'', Eq. (27) is rewritten as

$$H_g\varphi_g=\lambda(\psi'-\sigma_{g_1}\psi)+(\sigma''_{g_1}-u'(x)+2\sigma_{g_1}\sigma'_{g_1})\psi. \tag{29}$$

Finally, due to the fact that σ_{g_1} is a solution of Eq. (12), we use in Eq. (28) the Darboux transform given in Eq. (19) in order to obtain

$$H_g\varphi_g=\lambda\varphi_g, \tag{30}$$

which means that the relation $\lambda=E_g$ proves the isospectrality of the Darboux generalized Hamiltonian. In a similar way one can prove the isospectrality of the Hamiltonian associated to the standard Darboux potential.

B. The Darboux potentials of the HO model for specific principal quantum numbers

In order to find the corresponding standard and generalized Darboux potentials that are associated to the one-dimensional harmonic oscillator model, the algorithm to be used is straightforward: from the Schrödinger relationship we choose a particular eigenfunction ψ_1 in order to find λ_1 (or vice versa) to determine the function $\sigma_p(x)$ that will be necessary for obtaining the standard Darboux potential $U_{\mathrm{D}}(x)$ as well as the generalized wavefunction ψ_g. This last wavefunction is used to find the corresponding $\sigma_g(x)$ that will permit us to obtain the generalized Darboux potential.

In the present case, the Schrödinger relationship is given by

$$\left(-\frac{\hbar^2}{2m}\frac{d^2}{dx^2}+V_{\mathrm{HO}}(x)\right)\psi_n=\lambda_n\psi_n, \tag{31}$$

where $V_{\mathrm{HO}}(x)=\frac{1}{2}m\omega^2x^2$ is the one-dimensional harmonic oscillator potential and where $n=0, 1, 2, 3,\ldots$. Next, it will be shown that for each n there exists a standard and a generalized Darboux potential that are partners to the former potential.

When $n=0$ we have

$$\psi_0=\left(\frac{1}{\pi}\right)^{1/4}e^{-(m\omega/2\hbar)x^2}\quad\text{and}\quad\lambda_0=\frac{\hbar\omega}{2} \tag{32}$$

for which, according to Eq. (5), it follows that

$$\sigma_{p_0}(x)=-\frac{m\omega}{\hbar}x \tag{33}$$

and, consequently, from Eq. (7), the standard Darboux potential becomes

$$V_{\mathrm{D}_0}(x)=\tfrac{1}{2}m\omega^2x^2+\hbar\omega, \tag{34}$$

where the subscript $_0$ in $V_{\mathrm{D}}(x)$ is used to emphasize that this potential comes from the choice of $n=0$. Also, it should be remembered that we have used $\hbar^2/m=2$.

Similarly, for the generalized Darboux potential the wavefunction

$$\psi_{g_0}=e^{-(m\omega/2\hbar)x^2}\left(\gamma+b\int e^{(m\omega/\hbar)x^2}dx\right) \tag{35}$$

is used in Eq. (17) in order to find

$$\sigma_{g_0}(x) = -\frac{m\omega}{\hbar}x + \frac{be^{(m\omega/\hbar)x^2}}{\gamma + b\int^x e^{(m\omega/\hbar)x^2}dx} \tag{36}$$

which, after using Eq. (23), leads to

$$V_{\mathrm{DG}_0}(x) = \frac{1}{2}m\omega^2x^2 + \hbar\omega - \frac{\hbar^2}{m}\frac{d}{dx}\left(\frac{be^{(m\omega/\hbar)x^2}}{\gamma + b\int^x e^{(m\omega/\hbar)x^2}dx}\right). \tag{37}$$

This potential has been identified by Mielnik[8] as a new isospectral potential that matches the spectra obtained for the harmonic oscillator Hamiltonian.

When $n=1$, following the procedure already displayed, we have

$$\psi_1 = \sqrt{\frac{2m\omega}{\hbar\sqrt{\pi}}}xe^{-(m\omega/2\hbar)x^2} \quad \text{and} \quad \lambda_1 = \frac{3\hbar\omega}{2} \tag{38}$$

for which

$$\sigma_{p_1}(x) = \frac{1}{x} - \frac{m\omega}{\hbar}x \tag{39}$$

and, consequently,

$$V_{\mathrm{D}_1}(x) = \frac{1}{2}m\omega^2x^2 + \hbar\omega\left(1 + \frac{\hbar}{m\omega x^2}\right) \tag{40}$$

is the standard Darboux potential associated to $n=1$.

Consequently, for the generalized Darboux potential we use Eq. (17) in order to find

$$\sigma_{g_1}(x) = \frac{1}{x} - \frac{m\omega}{\hbar}x + \frac{be^{(m\omega/\hbar)x^2}/x^2}{\gamma + b\int^x (e^{(m\omega/\hbar)x^2}/x^2)\,dx} \tag{41}$$

and Eq. (23) to obtain

$$V_{\mathrm{DG}_1}(x) = \frac{1}{2}m\omega^2x^2 + \hbar\omega + \frac{\hbar^2}{m}\left\{\frac{1}{x^2} - \frac{d}{dx}\left(\frac{be^{(m\omega/\hbar)x^2}/x^2}{\gamma + b\int^x (e^{(m\omega/\hbar)x^2}/x^2)\,dx}\right)\right\}, \tag{42}$$

which is an isospectral potential set that comes from the second eigenfunction of the harmonic oscillator potential.

In the case of $n=2$, we have

$$\psi_2 = \left(\frac{1}{8\sqrt{\pi}}\right)^{1/2}\left(\frac{4m\omega}{\hbar}x^2 - 2\right)e^{-(m\omega/2\hbar)x^2} \quad \text{and} \quad \lambda_2 = \frac{5\hbar\omega}{2} \tag{43}$$

for which

$$\sigma_{p_2}(x) = \frac{4(m\omega/\hbar))x}{2(m\omega/\hbar)x^2 - 1} - \frac{m\omega}{\hbar}x \tag{44}$$

and

$$V_{D_2}(x) = \frac{1}{2}m\omega^2x^2 + \hbar\omega\left\{1 - \frac{4}{2(m\omega/\hbar)x^2 - 1} + \left(\frac{4\sqrt{m\omega/\hbar}x}{2(m\omega/\hbar)x^2 - 1}\right)^2\right\} \tag{45}$$

is the standard Darboux potential associated to $n=2$.

Similarly, the generalized Darboux potential that corresponds to this case is obtained from

$$\sigma_{g_2}(x)=\frac{4(m\omega/\hbar)x}{2(m\omega/\hbar)x^2-1}-\frac{m\omega}{\hbar}x+\frac{be^{(m\omega/\hbar)x^2}/(2(m\omega/\hbar)x^2-1)^2}{\gamma+b\int^x[e^{(m\omega/\hbar)x^2}/(2(m\omega/\hbar)x^2-1)^2]\,dx} \tag{46}$$

and Eq. (23) in order to have

$$V_{\mathrm{DG}_2}(x)=\frac{1}{2}m\omega^2x^2+\hbar\omega\left\{1-\frac{4}{2(m\omega/\hbar)x^2-1}+\left(\frac{4\sqrt{m\omega/\hbar}x}{2(m\omega/\hbar)x^2-1}\right)^2 - \frac{\hbar}{m\omega}\frac{d}{dx}\left(\frac{b\,e^{(m\omega/\hbar)x^2}/(2(m\omega/\hbar)x^2-1)^2}{\gamma+b\int^x[e^{(m\omega/\hbar)x^2}/(2(m\omega/\hbar)x^2-1)^2]\,dx}\right)\right\} \tag{47}$$

from the eigenvalue $n=2$ of the harmonic oscillator potential.

C. The Darboux potentials of the HO model for any *n* eigenfunction

As can be appreciated in the preceding paragraph, the choice of each quantum number leads to specific eigenvalues for which one can find each time the corresponding standard and generalized Darboux potentials. In this section we give the general formulas that allow us to obtain the Darboux potentials in the most general case, any n quantum principal number. That is, by using the wavefunction

$$\psi_n=C_ne^{-(m\omega/2\hbar)x^2}H_n\left(\sqrt{\frac{m\omega}{\hbar}}x\right)\quad\text{and}\quad\lambda_n=\hbar\omega\left(n+\frac{1}{2}\right), \tag{48}$$

where $C_n=(\sqrt{\pi}n!2^n)^{-1/2}$, it follows that

$$\sigma_{p_n}(x)=\frac{d}{dx}\ln H_n\left(\sqrt{\frac{m\omega}{\hbar}}x\right)-\left(\frac{m\omega}{\hbar}\right)x \tag{49}$$

in order to get

$$\sigma'_{g_n}(x)=\sigma'_{p_n}(x)+\frac{b}{\rho_n(x)} \tag{50}$$

where

$$\frac{1}{\rho_n(x)}=\frac{d}{bdx}\ln\left(\gamma+\int\frac{be^{(m\omega/\hbar)x^2}dx}{H_n^2(\sqrt{m\omega/\hbar}x)}\right). \tag{51}$$

Hence, the n-generalized Darboux potential becomes

$$V_{\mathrm{DG}_n}(x)=\frac{1}{2}m\omega^2x^2+\hbar\omega-\frac{\hbar^2}{m}\frac{d^2}{dx^2}\ln\left(H_n\left(\sqrt{\frac{m\omega}{\hbar}}x\right)\left(\gamma+\int\frac{be^{(m\omega/\hbar)x^2}dx}{H_n^2(\sqrt{m\omega/\hbar}x)}\right)\right), \tag{52}$$

which reduces, for $b=0$ and $\gamma=1$, to the n-standard Darboux potential

$$V_{\mathrm{D}_n}(x)=\frac{1}{2}m\omega^2x^2+\hbar\omega\left(1-\frac{\hbar}{m\omega}\frac{d^2}{dx^2}\ln H_n\left(\sqrt{\frac{m\omega}{\hbar}}x\right)\right). \tag{53}$$

These Darboux potentials are isospectral with respect to the original Hamiltonian of the standard HO with the corresponding wavefunctions

$$\varphi_{Dg_n}=\left(\frac{d}{dx}-\sigma_{g_n}(x)\right)\psi_n \tag{54}$$

and

$$\varphi_{D_n}=\psi_n'-\sigma_{p_n}(x)\psi_n \tag{55}$$

as mentioned before.

With this example, we have shown the usefulness of the proposed generalized Darboux transform in quantum mechanical problems dedicated to obtain new sets of isospectral potentials which, as shown above, are the standard and generalized Darboux potentials. That is, the application to other specific potential models different from the case here exemplified is straightforward. For these, it can be easily proved that the generalized Darboux transform leads to various new isospectral potentials recently published, such as the free particle,[12] Hulthen,[13] hydrogenic and isotonic,[15] Morse,[16] Coulomb,[17] anharmonic oscillators[18] and other potential models.

In any case, the use of different eigenfunctions leads to different varieties of potential that can give more possibilities to understand exactly solved problems. That is, it is interesting to know whether there are some physical quantities which can be used to characterize different potentials, in the same class, with the same energy spectrum, as solution of relevant physical problems. So, the importance of the isospectral potentials is equivalent to the importance of supersymmetry in quantum mechanics due to the fact that the Darboux transform provides a basis for the supersymmetry theory.[11] In a similar way, the generalized Darboux transform applied to other fields, such as solitons, should improve the findings already published elsewhere as will be shown in the next section with the linear Bargmann potential[19] as a worked example.

V. THE GENERALIZED DARBOUX TRANSFORM AND SOLITONS

The connection between a nonlinear partial differential equation that exhibits soliton behavior, the Korteweg–deVries (KdV) relationship, and a linear eigenvalue problem such as the Schrödinger equation is well known. In fact, although the partial differential equations that govern the motion of solitons are nonlinear, they are closely related to the Sturm–Liouville equations for which the analytical expressions that describe multisoliton interactions are merely Bargmann potentials. Thus, as another example of the usefulness of the proposed generalized Darboux transform, in this section we consider its application in solitons by assuming that the Sturm–Liouville equation

$$y''+(k^2-u(x))y=0 \tag{56}$$

has as solution

$$y=e^{ikx}F(k,x). \tag{57}$$

According to our method, applying Eq. (5) to the linear k form

$$F(k,x)=2k+ia(x) \tag{58}$$

leads to

$$\sigma_{p_1}(x)=\frac{2ik^2+ia'(x)-ka(x)}{2k+ia(x)} \tag{59}$$

for which Eq. (16), with $C=-k^2$, is written as

$$ia''(x)-2ka'(x)=u(x)(2k+ia(x)). \tag{60}$$

The above relationship for $k\neq 0$ gives place to the conditions

$$u(x)=-a'(x) \quad \text{and} \quad a''(x)=a(x)u(x) \tag{61}$$

that are put together in order to find the equivalent of Eq. (11),

$$\frac{d}{dx}\left(a'(x)+\frac{1}{2}a^2(x)\right)=0. \tag{62}$$

Thus, integration of the latter equation yields the Riccati relationship

$$a'(x)+\tfrac{1}{2}a^2(x)=2\mu^2, \tag{63}$$

which, with $a(x)=2g'(x)/g(x)$, leads to the second order differential equation

$$g''(x)-\mu^2 g(x)=0 \tag{64}$$

which has as solution

$$g(x)=\alpha e^{\mu x}+\beta e^{-\mu x}. \tag{65}$$

That is,

$$\frac{1}{2\mu}a(x)=\frac{\alpha e^{\mu x}-\beta e^{-\mu x}}{\alpha e^{\mu x}+\beta e^{-\mu x}}=\tanh(\mu x-\phi), \tag{66}$$

where $\phi=\frac{1}{2}\ln\beta/\alpha$, permits us to obtain the linear Bargmann potential[19]

$$u(x)=-2\mu^2\,\mathrm{sech}^2(\mu x-\phi) \tag{67}$$

that is the single soliton solution of the Korteweg–deVries relationship[20]

$$u(x)_t-6u(x)u(x)_x+u(x)_{xxx}=0 \tag{68}$$

on condition that $\phi_t=4\mu^3$. As usual, the subscripts in KdV mean total derivative with respect to the index variable.

On the other hand, due to the fact that Eq. (16) indicates that $u(x)$ is given in terms of $\sigma_{p_1}(x)$, it becomes that $\sigma_{p_1}(x)=\sigma(x)$ is at the time a solution of

$$\sigma(x)_t=(-\sigma(x)_{xx}+2\sigma(x)^3+6k^2\sigma(x))_x \tag{69}$$

which has been identified as the modified KdV relationship.

Thus, in a similar way it can be shown that the associated Darboux potential given in Eq. (19) is a solution of

$$U_{\mathrm{D}}(x)_t=-U_{\mathrm{D}}(x)_{xxx}+6U_{\mathrm{D}}(x)U_{\mathrm{D}}(x)_x \tag{70}$$

as well as the generalized Darboux potential that corresponds to the Bargmann model. The details of these calculations and a more complete analysis on this application will be given in a forthcoming publication. However, we hope that with these examples we have shown the usefulness of the GDT and that the method proposed has significance and interest beyond that of a purely mathematical device.

VI. CONCLUDING REMARKS

In the present work the standard Darboux transform applied to Sturm–Liouville problems has been generalized. This generalization has been possible due to the fact that the standard Darboux transform is related to Riccati-type equations whose general solutions can be obtained straightforwardly. As a useful application of the generalized Darboux transform we consider explicitly the quantum mechanical problem associated to the one-dimensional harmonic oscillator potential. As expected, we obtain the generalized and standard Darboux potentials associated to the harmonic oscillator model, one for each quantum principal number. Besides, a general formula for the corresponding Darboux potential for any n is given. In all cases considered, the standard and generalized Darboux potentials correspond to a new set of isospectral potentials whose energy is that of the former potential, indicating a direct procedure for generalizing any known potential model. Similarly, in other fields where the standard Darboux transform is involved, our proposition of generalized Darboux transform will be an important improvement *vis a vis* to other alternative procedures usually used with similar purposes such as that exemplified with the treatment of the linear Bargmann potential in the theory of solitons.

ACKNOWLEDGMENTS

We want to acknowledge the referee for having pointed out to us the convenience of including an example of the usefulness of the proposed generalized Darboux transform in solitons theory, which has improved the results presented here. (Received 30 October 2000; accepted for publication 7 November 2000)

[DOI: 10.1063/1.1337797]

First, there is a typographical error in Eq. (4.50a). This equation, cf. (A37a), should read

$$\mathrm{tr}(x_{(i_1}\cdots x_{i_4)}) = \tfrac{1}{12} d^{(2)}_{(i_1 i_2} d^{(2)}_{i_3 i_4)}\,. \tag{4.50a}$$

Second, Eqs. (4.41a) and (4.41b) as well as (4.43a) and (4.43b) are inconsistent with (A40b) and (A42c) and (A42d) due to the normalization of $A = a_j x_j$ in Appendix A7(i). We wish to retain the definition $A = a_j x_j$, and so the former set of equations have to be corrected:

$$\mathrm{tr}(x_{(i_1}\cdots x_{i_8)}) = -\tfrac{5}{12}\delta_{(i_1 i_2}\delta_{i_3 i_4}\delta_{i_5 i_6}\delta_{i_7 i_8)} + \tfrac{4}{3}\delta_{(i_1 i_2} d^{(6)}_{i_3\cdots i_8)}\,, \tag{4.41a}$$

$$\mathrm{tr}(x_{(i_1}\cdots x_{i_{10})}) = -\tfrac{1}{2}\delta_{(i_1 i_2}\delta_{i_3 i_4}\delta_{i_5 i_6}\delta_{i_7 i_8}\delta_{i_9 i_{10})} + \tfrac{5}{4}\delta_{(i_1 i_2}\delta_{i_3 i_4} d^{(6)}_{i_5\cdots i_{10})}\,, \tag{4.41b}$$

and

$$\mathrm{tr}(F_{(i_1}\cdots F_{i_6)}) = 30\,\delta_{(i_1 i_2}\delta_{i_3 i_4}\delta_{i_5 i_6)} - 26\, d^{(6)}_{(i_1\cdots i_6)}\,, \tag{4.43a}$$

$$\mathrm{tr}(F_{(i_1}\cdots F_{i_8)}) = \tfrac{515}{6}\,\delta_{(i_1 i_2}\delta_{i_3 i_4}\delta_{i_5 i_6}\delta_{i_7 i_8)} - \tfrac{320}{3}\,\delta_{(i_1 i_2} d^{(6)}_{i_3\cdots i_8)}\,. \tag{4.43b}$$

Uncertainty for spin systems

Nuno Barros e Sá[a)]
Fysikum, Stockholms Universitet, Box 6730, 113 85 Stockholm, Sweden
and DCTD, Universidade dos Açores, 9500 Ponta Delgada, Portugal

(Received 22 September 2000; accepted for publication 2 November 2000)

A modified definition of quantum mechanical uncertainty Δ for spin systems, which is invariant under the action of SU(2), is suggested. Its range is shown to be $\hbar^2 j \leqslant \Delta \leqslant \hbar^2 j(j+1)$ within any irreducible representation j of SU(2) and its mean value in Hilbert space computed using the Fubini–Study metric is determined to be $\text{mean}(\Delta) = \hbar^2 j(j+1/2)$. The most used sets of coherent states in spin systems coincide with the set of minimum Δ uncertainty states. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1336515]

I. INTRODUCTION

Coherent states are an important tool in the study of wave phenomena finding many relevant applications in quantum physics.[1,2] The familiar Glauber states[3,4] can be equivalently defined as the elements of the orbit of the Heisenberg–Weyl group which contains the ground state, as the eigenstates of the annihilation operator or as the minimum uncertainty wave packets. Following these different definitions there are different approaches to the generalization of the concept of coherent states, the one based on the first definition[5] being the most popular. The generalization procedure has been extended to include spin systems[6,7] and others.[8–11] A full account of applications of coherent states in different areas of physics can be found in Ref. 12. In the group theoretical approach to coherent states Hilbert space is decomposed into the union of disjoint sets of coherent states, the group orbits. For spin systems the orbit space (the set of orbits) is composed almost entirely of three-dimensional orbits with the exception of a finite number of two-dimensional orbits which consist of the eigenvectors of $\mathbf{r}\cdot\mathbf{J}$, with $\mathbf{J}$ the generators of the Lie algebra of SU(2) and $\mathbf{r}$ any numeric vector.[13,14] In each irreducible representation of SU(2) there is one particular orbit which admits an analytic representation in the complex plane,

$$|z\rangle = \frac{1}{(1+|z|^2)^j} e^{zJ_-}|j\rangle.$$

It turns out that this orbit is singled out by the structure of orbit space; it is the two-dimensional orbit composed of the eigenvectors of $\mathbf{r}\cdot\mathbf{J}$ with the highest absolute value of its eigenvalue.[14] However the states belonging to this orbit are not all minimum uncertainty states; they do not even have constant uncertainty.

Uncertainty is an important property of a physical state, and it would be desirable to keep it playing a major role in the definition of coherent states. Minimum uncertainty states have been studied in Ref. 15 and, in the context of spin systems, states saturating the equality in the Heisenberg relation have been studied in Ref. 16 and called intelligent states. States saturating the equality in the Robertson relation have also been studied.[17,18] One unsatisfactory feature of intelligent states and of the commonly used definition of uncertainty for spin systems is that they are not invariants under the action of SU(2). As a consequence sets of coherent states based on these definitions cannot be represented as orbits of SU(2). This is in contrast with the situation in

a)Electronic mail: nunosa@alf.uac.pt

particle mechanics where the Heisenberg inequality and the uncertainty function used are invariants under the action of the Heisenberg–Weyl group. Here we propose a new definition of uncertainty for spin systems,

$$\Delta = \Delta J_x^2 + \Delta J_y^2 + \Delta J_z^2,$$

which is a positive increasing function of the variances and which is invariant under the action of SU(2). It obeys the following invariant inequalities,

$$\hbar^2 j \leqslant \Delta \leqslant \hbar^2 j(j+1),$$

which play the role of uncertainty relations. As an immediate application we show that the particular set of coherent states which admits an analytic representation in the complex plane coincides with the set of minimum uncertainty states for this inequality. We use the Fubini–Study metric to compute the mean value of the uncertainty Δ in Hilbert space with the result,

$$\text{mean}(\Delta) = \hbar^2 j(j+\tfrac{1}{2}),$$

for any irreducible representation j. This shows that in higher dimensional representation spaces of SU(2) most of the states have high values of uncertainty. In particular one has

$$\lim_{j\to\infty} \frac{\text{mean}(\Delta)}{\max(\Delta)} = 1. \tag{1}$$

The paper is organized as follows: In Sec. II we review some mathematical definitions concerning group orbits and invariants, the Glauber coherent states and their generalization, and the construction of spin coherent states. In Sec. III we discuss the issue of Heisenberg-type inequalities and uncertainty relations. We propose the new definition of uncertainty Δ for spin systems and we state and prove the statements about Δ made above. We include an appendix on how to average quantities in CP^N using the Fubini–Study metric.

II. REVIEW OF GROUP ORBITS AND COHERENT STATES

A. Group orbits and invariants

Let $U(g)$ be a representation of the Lie group G on the Hilbert space $\mathcal{H}$. The G-orbit through $|\phi\rangle \in \mathcal{H}$ is the subset of $\mathcal{H}$ given by

$$\mathcal{C}_\phi = \{|\psi\rangle \in \mathcal{H} : |\psi\rangle = U(g)|\phi\rangle,\ g \in G\}. \tag{2}$$

It follows that

$$\dim \mathcal{C}_\phi \leqslant \dim G \quad \text{and} \quad \dim \mathcal{C}_\phi \leqslant \dim \mathcal{H}. \tag{3}$$

The relation "$|\phi'\rangle$ lies on the same orbit as $|\phi\rangle$" is clearly an equivalence relation: reflexive, symmetric and transitive. As a consequence $\mathcal{H}$ can be partitioned into disjoint orbits

$$\mathcal{H} = \bigcup_\phi \mathcal{C}_\phi, \tag{4}$$

where the label ϕ runs over orbits (equivalence classes) and not over vectors. The quotient space $\mathcal{H}/G$ is called the orbit space. A function $f(|\psi\rangle)$ in Hilbert space $\mathcal{H}$ is said to be G-invariant if

$$f(U(g)|\psi\rangle) = f(|\psi\rangle), \quad \forall g \in G, \quad \forall |\psi\rangle \in \mathcal{H}. \tag{5}$$

It follows that G-invariant functions are also functions on orbit space $\mathcal{H}/G$.

For more information on these issues see, for instance, Refs. 19 and 20,

B. Glauber states

The familiar Glauber states $|q,p\rangle$ in particle mechanics can be seen as the G-orbit of the Heisenberg–Weyl group through the vacuum state $|0\rangle$,

$$|q,p\rangle = U(q,p)|0\rangle, \tag{6}$$

where $U(p,q)$ is the Weyl operator,

$$U(q,p) = e^{i(pQ-qP)/\hbar}. \tag{7}$$

They are eigenstates of the annihilation operator and they admit the useful analytic representation in the complex plane,

$$|p,q\rangle = e^{(za^+ - z^* a)}|0\rangle = e^{-|z|^2/2}\sum_n \frac{z^n}{\sqrt{n!}}|n\rangle, \tag{8}$$

with $z=(q+ip)/\sqrt{2\hbar}$. It can be shown that the Glauber states are minimum uncertainty states since

$$\Delta Q^2 = \Delta P^2 = \hbar/2, \tag{9}$$

and the equality sign is satisfied in the Heisenberg uncertainty relation (sometimes the square root of this relation is used; here we prefer this form)

$$\Delta Q^2 \Delta P^2 \geqslant \hbar^2/4. \tag{10}$$

The remaining G-orbits of the Heisenberg–Weyl group can be seen as generalized coherent states[5,12] but they are not eigenstates of any particularly simple operator, they do not admit an analytic representation in the complex plane, and they are not minimum uncertainty states. Nevertheless they have constant values of uncertainty since both factors ΔQ^2 and ΔP^2 are G-invariant functions.[14]

C. Spin coherent states

The group SU(2) admits representations classified according to integer and semi-integer values j with the Casimir operator $J^2 = j(j+1)\hbar^2$. Let $\mathcal{H}$ be a Hilbert space carrying one such representation. Sets of generalized coherent states can be generated as the orbits of SU(2) in $\mathcal{H}$,

$$\mathcal{C}_\phi = \{|\mathbf{r}\rangle \in \mathcal{H} : |\mathbf{r}\rangle = U(\mathbf{r})|\phi\rangle, \mathbf{r} \in (4\pi)^3\} \tag{11}$$

$$U(\mathbf{r}) = e^{i\mathbf{r}\cdot\mathbf{J}/\hbar}, \tag{12}$$

where we used the so-called canonical group coordinates for generality.

Using the group parameterization

$$U(z,\theta) = N e^{zJ_-/\hbar} e^{-z^* J_+/\hbar} e^{-i\theta J_z/\hbar}, \tag{13}$$

where $J_\pm$ are the ladder operators $J_\pm = J_x \pm iJ_y$, and choosing the fiducial state $|\phi\rangle$ to be an eigenstate of J_z, $|m\rangle$ with $m=-j,\ldots,j$, one has[7]

$$|z;m\rangle = U(z)|m\rangle = N e^{zJ_-/\hbar} e^{-z^* J_+/\hbar}|m\rangle, \tag{14}$$

where the phase factor resulting from $e^{-i\theta J_z/\hbar}$ has been ignored and N stands for a normalization factor. Further choosing $|j\rangle$ as the fiducial state one has $e^{-z^* J_+/\hbar}|j\rangle = |j\rangle$ and

$$|z\rangle = \frac{1}{(1+|z|^2)^j} e^{zJ_-}|j\rangle, \tag{15}$$

after determination of the normalization factor. This analytic representation is not available in general for the sets (12) generated from arbitrary fiducial vectors. The analogous relation for spin systems to the Heisenberg inequality for canonically conjugate operators (10) is

$$\Delta J_x^2 \Delta J_y^2 \geqslant \frac{\hbar^2}{4} \overline{J_z}^2. \tag{16}$$

Notice the important difference with (10) that now the right-hand side of the inequality is not a constant. Following Ref. 16 we shall call the left-hand side of (16) the uncertainty $\Delta J_x^2 \Delta J_y^2$. Then it is clear that the set of states for which the equality in (16) is saturated and the set of states of minimum uncertainty are not the same. Moreover none of them coincide with any set of coherent states (11). On the other hand in particle mechanics the Glauber states satisfy the Heisenberg inequality and they are states of minimum uncertainty. In Ref. 16 the spin states satisfying the equality sign in (16) have been called intelligent states. They are given by

$$|\tau,N\rangle = \frac{A_N}{(1+|\tau|^2)^j} \sum_{l=0}^{N} \binom{N}{l} (2j-l)! \left(-\frac{2}{\hbar}\tau J_+\right)^l e^{\tau J_+/\hbar}|-j\rangle, \tag{17}$$

where N is a discrete label satisfying $0 \leqslant N \leqslant 2j$ and τ is a continuous label which can be either real or purely imaginary. A_N is a normalization factor.

Finally we comment that the space of physical states for the irreducible representation j of SU(2) is CP^N with $N=2j$ (see the Appendix),

$$j \to \dim \mathcal{H} = 2j+1 \to \text{projective space} : CP^{2j}. \tag{18}$$

Its real dimension is $4j$.

III. UNCERTAINTY

A. Uncertainty relations

We recall the inequality valid for Hermitian operators A and B,[21]

$$\Delta A^2 \Delta B^2 \geqslant \tfrac{1}{4}(\sigma_{AB}^2 - \overline{[A,B]}^2), \tag{19}$$

where ΔA and ΔB are the standard deviations of the operators A and B

$$\Delta A^2 = \overline{A^2} - \overline{A}^2 = \langle\psi|A^2|\psi\rangle - \langle\psi|A|\psi\rangle^2. \tag{20}$$

and where

$$\sigma_{AB} = \overline{\{A,B\}} - 2\overline{A}\,\overline{B} \geqslant 0 \tag{21}$$

is the covariance of A and B. Since for Hermitian operators σ_{AB} is real and $\overline{[A,B]}$ is purely imaginary, both parcels on the right-hand side of (19) are positive and one can state that

$$\Delta A^2 \Delta B^2 \geqslant -\tfrac{1}{4}\overline{[A,B]}^2. \tag{22}$$

This is called the Heisenberg relation while (19) is often called the Robertson relation. For canonically conjugate operators Q and P one has $[Q,P]=i\hbar$ and the Heisenberg uncertainty relation (10) follows immediately from (22). For spin systems (16) follows from $[J_x,J_y] = i\hbar J_z$. Notice that the equality can hold only if $\sigma_{AB}=0$. The left-hand side of the Heisenberg

inequality (22) is sometimes called the uncertainty. It is invariant under the action of the Heisenberg–Weyl group. And the right-hand side of (22) is a constant. It is therefore natural to assign a particular physical significance to $\Delta Q^2 \Delta P^2$ and to the states satisfying the equality sign in this inequality. But the left hand side of the analogous spin inequality (16) is not invariant under the action of SU(2) neither is its right hand side a constant. Therefore there seems to be no reason why $\Delta J_x^2 \Delta J_y^2$ should play a role for spin systems similar to the one played by $\Delta Q^2 \Delta P^2$ in particle mechanics, nor why states saturating the equality in (22) or in (19) should be particularly distinguished. Such states (intelligent states) have been studied in Ref. 16 and in Refs. 17 and 18, respectively, and may certainly be important for the study of spin systems with Hamiltonians that break the SU(2) symmetry such as systems under the action of one particular magnetic field pointing in the *z*-direction, but in what concerns the study of CP^N as the representation space for spin systems prior to the definition of the Hamiltonian one should look for a *G*-invariant definition of uncertainty. We look for an uncertainty function which is positive and which increases with increasing values of the variances of the elements of the Lie algebra. The following additive rather than multiplicative combination of variances does the job,

$$\Delta = \Delta J_x^2 + \Delta J_y^2 + \Delta J_z^2. \tag{23}$$

The following results hold:

(I) The uncertainty Δ is *G*-invariant and therefore it is constant within sets of coherent states generated as orbits of SU(2) in CP^N;

(II) The uncertainty Δ is bounded from below and from above

$$\hbar^2 j \leqslant \Delta \leqslant \hbar^2 j(j+1). \tag{24}$$

All values within this range are present in Hilbert space except for the representation $j = 1/2$ where all states have the same uncertainty $\Delta = \hbar^2 j$;

(III) The set

$$\{|\psi\rangle \in \mathcal{H}: \Delta(|\psi\rangle) = \hbar^2 j\} \tag{25}$$

of minimum uncertainty vectors in the irreducible representation j of SU(2) coincides with the set of coherent states

$$|z\rangle = (1+|z|^2)^{-j} e^{zJ_-}|j\rangle \tag{26}$$

generated as an orbit of SU(2) in $\mathcal{H}$ and admitting an analytic representation in the complex plane;

(IV) The mean value evaluated with the volume element naturally associated to the Fubini–Study metric of uncertainty on the whole of Hilbert space is given by

$$\text{mean}(\Delta) = \hbar^2 j(j+1/2) \tag{27}$$

for any irreducible representation j of SU(2). Notice that the last statement is consistent with the second one for the $j = 1/2$ representation.

B. Proof

(I) We have

$$U^+(\mathbf{r}) J_i U(\mathbf{r}) = \Lambda_i^j(\mathbf{r}) J_j, \tag{28}$$

where Λ_i^j are the matrices of the adjoint representation of SU(2), satisfying

$$\Lambda_i^j(\mathbf{r}) \Lambda_i^k(\mathbf{r}) = \delta^{jk}, \forall \mathbf{r}. \tag{29}$$

The mean values of J_i transforms, within an orbit, according to the adjoint representation too,

$$\overline{J_i} = \langle \mathbf{r}|J_i|\mathbf{r}\rangle = \langle \phi|U^+(\mathbf{r}) J_i U(\mathbf{r})|\phi\rangle = \Lambda_i^j(\mathbf{r}) \langle \phi|J_j|\phi\rangle. \tag{30}$$

Then $\overline{J_i J_i}$ is a G-invariant function

$$\overline{J_i J_i} = \Lambda_i^j(\mathbf{r})\langle\phi|J_j|\phi\rangle\Lambda_i^k(\mathbf{r})\langle\phi|J_k|\phi\rangle = \langle\phi|J_i|\phi\rangle\langle\phi|J_i|\phi\rangle. \tag{31}$$

This is one example of a wider set of invariants defined in Ref. 14. The Casimir operator $J_i J_i$ is invariant within the whole representation and consequently $\overline{J_i J_i}$ is G-invariant. Then,

$$\Delta = \sum_{i=x,y,z} \Delta J_i^2 = \sum_{i=x,y,z} \overline{J_i J_i} - \overline{J_i J_i} \tag{32}$$

is the difference between two G-invariant functions and is therefore G-invariant too.

(II) It is always possible to choose a representative $|\psi\rangle = \Sigma_{m=-j}^{m} c_m|m\rangle$ within each orbit such that $\langle\psi|\mathbf{J}|\psi\rangle = \overline{J_z}\mathbf{e}_z$. Then $\overline{J_i J_i} = \overline{J_z}^2$. But

$$\overline{J_z} = \sum_{m=-j}^{j} m\hbar|c_m|^2 \Rightarrow |\overline{J_z}| \leqslant \hbar j. \tag{33}$$

Therefore $\overline{J_i J_i} \leqslant \hbar^2 j^2$, and this inequality is valid all over Hilbert space since it concerns a G-invariant function. On the other hand it is obvious that $\overline{J_i J_i} \geqslant 0$. Since $J_i J_i = \hbar^2 j(j+1)$ it follows that

$$0 \leqslant \overline{J_i J_i} \leqslant \hbar^2 j^2 \Leftrightarrow \hbar^2 j \leqslant \Delta \leqslant \hbar^2 j(j+1). \tag{34}$$

Now we consider the one-parameter set of vectors

$$|\alpha\rangle = \cos\alpha|j\rangle + \sin\alpha|-j\rangle \quad \text{with} \quad \alpha \in [0, \pi/2]. \tag{35}$$

We have

$$\begin{aligned} &\overline{J_x} = \hbar\sqrt{j/2}\sin(2\alpha)\,\delta_j^{1-j},\ \overline{J_y} = 0,\ \overline{J_z} = \hbar j\cos(2\alpha) \\ &\Rightarrow \overline{J_i J_i} = \begin{cases} \hbar^2 j^2 & \text{for } j = 1/2 \\ \hbar^2 j^2\cos^2(2\alpha) & \text{for } j \neq 1/2. \end{cases} \end{aligned} \tag{36}$$

There is only one orbit in the $j = 1/2$ representation;[14] since Δ is G-invariant it can only assume the value $\hbar^2 j^2$. On the other hand, for $j \neq 1/2$ it is clear that $\overline{J_i J_i}$ maps α onto $[0, \hbar^2 j^2]$, and the statements about the range of $\overline{J_i J_i}$ in Hilbert space are proven.

(III) We notice from (33) that the maximum value of $\overline{J_i J_i}$ is attained only at the vectors $|j\rangle$ and $|-j\rangle$ which we know to belong to the same orbit.[14] This single orbit coincides with the set (15) of coherent states $|z\rangle$ since for $z = 0$ we have $|z\rangle = |j\rangle$.

(IV) We use the coordinates (A16) defined in the Appendix to label physical states

$$|\psi\rangle = \sum_{m=-j}^{j} c_m|m\rangle = \sum_{n=0}^{N} Z_n(\theta_i, \beta_j)|n - N/2\rangle = |\{\theta_i\}, \{\beta_j\}\rangle. \tag{37}$$

Using the standard representation of the generator J_z of the SU(2) Lie algebra[22] its mean value on a state $|\{\theta_i\}, \{\beta_j\}\rangle$ is

$$\overline{J_z} = \sum_{m=-j}^{j} |c_m|^2 \hbar m = \hbar \sum_{n=0}^{N} x_n^2 \left(n - \frac{N}{2}\right). \tag{38}$$

The mean value of $\overline{J_z}^2$ in the whole of Hilbert space is thus [see (A24) in the appendix],

$$\text{mean}(\overline{J_z}^2)=\frac{\hbar^2}{V_N}\int_{CP^N}dv\,\overline{J_z}^2=\frac{\hbar^2}{V_N}\sum_{m,n=0}^{N}\left[\left(m-\frac{N}{2}\right)\left(n-\frac{N}{2}\right)\int_{CP^N}dv\,(x_m x_n)^2\right]. \tag{39}$$

Now we compute

$$\int_{CP^N}dv\,(x_m x_n)^2=\frac{\pi^N}{(N+2)!}(1+\delta_{mn}) \tag{40}$$

and

$$\sum_{m,n=0}^{N}\left(m-\frac{N}{2}\right)\left(n-\frac{N}{2}\right)(1+\delta_{mn})=\sum_{n=0}^{N}\left(n-\frac{N}{2}\right)^2=\frac{N(N+1)(N+2)}{12} \tag{41}$$

to arrive at

$$\text{mean}(\overline{J_z}^2)=\frac{\hbar^2}{V_N}\frac{\pi^N}{(N+2)!}\frac{N(N+1)(N+2)}{12}=\frac{\hbar^2 N}{12}. \tag{42}$$

By symmetry one has

$$\text{mean}(\overline{J_x}^2)=\text{mean}(\overline{J_y}^2)=\text{mean}(\overline{J_z}^2), \tag{43}$$

and consequently

$$\text{mean}(\overline{J_i J_i})=3\,\text{mean}(\overline{J_z}^2)=\frac{\hbar^2 N}{4}=\frac{\hbar^2 j}{2}. \tag{44}$$

The mean value of uncertainty (32) in Hilbert space is therefore

$$\text{mean}(\Delta)=\text{mean}(\overline{J_i J_i})-\text{mean}(\overline{J_i J_i})=\hbar^2 j(j+1)-\frac{\hbar^2 j}{2}=\hbar^2 j\left(j+\frac{1}{2}\right). \tag{45}$$

APPENDIX: THE FUBINI–STUDY METRIC AND THE VOLUME ELEMENT IN CP^N

Two vectors in Hilbert space $\mathcal{H}$ differing by a multiplicative non-zero complex constant α represent the same physical state,

$$|z'\rangle\sim|z\rangle \quad \text{if} \quad |z'\rangle=\alpha|z\rangle. \tag{A1}$$

Therefore the space of physical states is the space of rays in Hilbert space or projective space, that is the space of equivalence classes defined by (A1) and excluding the vector $|\psi\rangle=0$. The projective spaces constructed from finite-dimensional Hilbert spaces are called CP^N and are well studied spaces.[23,24] The superscript N stands for their complex dimension which is one unit lower then the complex dimension of the Hilbert space from which they are constructed. If $|n\rangle$ is a basis for $(N+1)$-dimensional Hilbert space any vector $|\psi\rangle$ can be written as

$$|\psi\rangle=\sum_{n=0}^{N}Z_n|n\rangle. \tag{A2}$$

The complex numbers Z_n are homogeneous coordinates in $\mathcal{H}$ and they can also be used as coordinates in CP^N provided one makes the identifications

$$Z'_n \sim Z_n \text{ if } \exists \alpha : \forall n, Z'_n = \alpha Z_n . \tag{A3}$$

We start by reminding the reader that the unit N-sphere can be defined as the hyper-surface in $(N+1)$-dimensional Euclidean space with coordinates $x_i, i=0,..,N$ that satisfies

$$\sum_{i=0}^{N} x_i^2 = 1. \tag{A4}$$

Intrinsic coordinates θ_i can be defined by

$$x_i = \cos\theta_i \prod_{j=i+1}^{N} \sin\theta_j . \tag{A5}$$

Their range is $(0,\pi)$ except for θ_1 with range $(0,2\pi)$. $\theta_0 = 0$ is not a coordinate. The metric induced on the N-sphere by its embedding in $(N+1)$-dimensional Euclidean space in this coordinates is diagonal with components

$$g_{ii} = \left(\prod_{j=i+1}^{N} \sin\theta_j \right)^2 , \tag{A6}$$

and the volume element is

$$dv = \prod_{i=1}^{N} \sin^{(n-1)}\theta_i d\theta_i . \tag{A7}$$

Real projective space RP^N follows the same construction with the range of θ_1 being $(0,\pi)$ too, plus the identifications

$$(0,\theta_2,\ldots,\theta_N) \equiv (\pi, \pi-\theta_2,\ldots,\pi-\theta_N). \tag{A8}$$

For quantum mechanical purposes the metric of interest in CP^N is the Fubini–Study metric.[24] Its line element in the homogeneous coordinates Z_i is

$$ds^2 = \frac{1}{X^2}\sum_{i=0}^{N} dZ_i d\overline{Z_i} - \frac{1}{X^4}\sum_{i=0}^{N} dZ_i \overline{Z_i} \sum_{j=0}^{N} Z_j d\overline{Z_j} , \tag{A9}$$

where we have defined

$$X^2 = \sum_{i=0}^{N} Z_i \overline{Z_i} . \tag{A10}$$

Splitting the complex homogeneous coordinates into their absolute values and phases

$$Z_i = X_i e^{i\alpha_i}, \tag{A11}$$

the Fubini–Study metric splits into two blocks relative to the X_i and to the α_i,

$$ds^2 = ds_X^2 + ds_\alpha^2, \tag{A12}$$

with

$$ds_X^2=\frac{1}{X^2}\left(\sum_{i=0}^{N} dX_i^2-dX^2\right), \tag{A13}$$

$$ds_\alpha^2=\frac{1}{X^2}\sum_{i=0}^{N} X_i^2 d\alpha_i^2-\frac{1}{X^4}\left(\sum_{i=0}^{N} x_i^2 d\alpha_i\right)^2. \tag{A14}$$

The intrinsic coordinates on the sphere (A5) and the phases relative to α_0

$$\beta_i=\alpha_i-\alpha_0, \quad i=1,...,N \tag{A15}$$

can be used as intrinsic coordinates on CP^N. However we should remark that the ranges of all the coordinates θ_i are $(0,\pi/2)$ since the X_i are absolute values and cannot therefore be negative. Moreover these coordinates are clearly singular whenever $\theta_i=\{0,\pi/2\}$. The relation of this coordinates with the homogeneous ones is

$$Z_i=Xe^{i\alpha_0}x_i(\theta_j)e^{i\beta_i}. \tag{A16}$$

Plugging this expression into the previous formulas for the line elements (A13)–(A14) one gets

$$ds_X^2=\sum_{i=0}^{N} dx_i^2=\sum_{i=1}^{N} g_{ii}d\theta_i^2, \tag{A17}$$

$$ds_\alpha^2=\sum_{i=1}^{N} x_i^2 d\beta_i^2-\left(\sum_{i=1}^{N} x_i^2 d\beta_i\right)^2=\sum_{i,j=1}^{N} h_{ij}d\beta_i d\beta_j. \tag{A18}$$

The first is the line element in the unit sphere (A6) and in the phase line element ds_α^2 we have defined the metric

$$h_{ij}=x_i^2(\delta_{ij}-x_j^2) \tag{A19}$$

with inverse

$$h^{ij}=\frac{1}{x_0^2}+\frac{\delta_{ij}}{x_i^2}. \tag{A20}$$

The volume element for the phase coordinates is

$$\begin{aligned} dv_\alpha&=\sqrt{\det(h_{ij})}\prod_{k=1}^{N} d\beta_k \\ &=\sqrt{\det(\delta_{ij}-x_j^2)}\prod_{k=1}^{N} x_k d\beta_k \\ &=\sqrt{1-\sum_{i=1}^{N} x_i^2}\prod_{k=1}^{N} x_k d\beta_k \\ &=\prod_{i=0}^{N} x_i\prod_{j=1}^{N} d\beta_j=\prod_{i=1}^{N} \cos\,\theta_i \sin^i\,\theta_i d\beta_i, \end{aligned} \tag{A21}$$

where we used (A5) for x_i in the last equality. Using (A7) for dv_X the combined volume element is

$$dv = dv_X dv_\alpha = \prod_{i=1}^{N} \cos\theta_i \, \sin^{2i-1}\theta_i d\theta_i d\beta_i \, . \tag{A22}$$

The total volume of CP^N becomes easy to compute

$$V_N = \prod_{i=1}^{N} \int_0^{\pi/2} d\theta_i \cos\theta_i \sin^{2i-1}\theta_i \int_0^{2\pi} d\beta_i = \prod_{i=1}^{N} \frac{1}{2i} 2\pi = \frac{\pi^N}{N!} . \tag{A23}$$

Now we are able to compute mean values of functions in Hilbert space as their integral in CP^N weighted with the Fubini–Study volume element (A22) and divided by the volume V_N of CP^N (A23). Since the functions we are interested in are of the type $<\psi|A|\psi> = \overline{A}$ we shall write explicitly mean$(\overline{A})$ to emphasize that the mean value is not taken on quantum states but rather on the whole of CP^N,

$$\text{mean}(\overline{A}) = \frac{1}{V_N} \int_{CP^N} dv \overline{A} . \tag{A24}$$

Three-quark exchange operators, crossing matrices and Fierz transformations in SU(2) and SU(3)

V. Dmitrašinović[a)]
Research Center for Nuclear Physics, Osaka University, Mihogaoka 10-1, Ibaraki, Osaka 560-0047, Japan

(Received 24 August 2000; accepted for publication 12 December 2000)

We give explicit expressions for the three-quark exchange operators, crossing matrices and Fierz transforms for the SU(2) and SU(3) groups. We identify the invariant terms in these operators and express them in terms of Casimir operators.
 [DOI: 10.1063/1.1347393]

I. INTRODUCTION

Dirac[1] was the first to express the two-particle spin-exchange operator,

$$\mathrm{P}_{12}=\tfrac{1}{2}+\tfrac{1}{2}\,\boldsymbol{\tau}_1\cdot\boldsymbol{\tau}_2\,, \tag{1}$$

in terms of Pauli matrices $\boldsymbol{\tau}_{1,2}$ of the two particles, where $\boldsymbol{\tau}\cdot\boldsymbol{\tau}=\Sigma_{a=1}^{3}\tau^a\tau^a$. This, and the following result:

$$\mathrm{P}_{12}\boldsymbol{\tau}_1\cdot\boldsymbol{\tau}_2=\tfrac{3}{2}-\tfrac{1}{2}\,\boldsymbol{\tau}_1\cdot\boldsymbol{\tau}_2\,, \tag{2}$$

are equivalent to a ''Fierz reordering formula'' for the quartic field interaction, or to the SU(2) crossing matrix,

$$\mathbf{C}=\frac{1}{2}\begin{pmatrix}1 & 1\\ 3 & -1\end{pmatrix}, \tag{3}$$

for two-body processes. The same trick has been extended to the SU(3) Lie algebra,

$$\mathrm{P}_{12}=\tfrac{1}{3}+\tfrac{1}{2}\boldsymbol{\lambda}_1\cdot\boldsymbol{\lambda}_2\,, \tag{4a}$$

$$\mathrm{P}_{12}\boldsymbol{\lambda}_1\cdot\boldsymbol{\lambda}_2=\tfrac{16}{9}-\tfrac{1}{3}\boldsymbol{\lambda}_1\cdot\boldsymbol{\lambda}_2\,, \tag{4b}$$

again only for two particles,[2] with the resulting crossing matrix (or the equivalent Fierz reordering formulas for bilinear products of Gell–Mann matrices) being

$$\mathbf{C}=\begin{pmatrix}\frac{1}{3} & \frac{1}{2}\\ \frac{16}{9} & -\frac{1}{3}\end{pmatrix}. \tag{5}$$

Here the lower index indicates the number of the quark, λ^a are the Gell–Mann matrices, and f^{abc}, d^{abc} are the usual SU(3) structure constants.

In the meantime a need has arisen for tri-linear Fierz formulas/crossing relations in connection with applications of the three-flavor 't Hooft interaction.[3] Such relations do not seem to exist in the literature.[4–6] In this paper we present the corresponding three-body exchange operators for quarks

a)Electronic mail: dmitra@rcnp.osaka-u.ac.jp

[particles in the fundamental representation of SU(2) and/or SU(3)], as well as the equivalent Fierz reordering formulas for the sextic field interaction.

II. THREE-QUARK EXCHANGE OPERATORS

A. The SU(2) algebra

1. Three-body exchange operators

Using the symmetric group $\mathcal{S}_3$ it is straightforward, if tedious, to derive the SU(2) version of the three-quark/spin exchange operator,

$$\mathrm{P}_{123}=\mathrm{P}_{23}\mathrm{P}_{12}=\frac{1}{4}+\frac{1}{4}\sum_{i<j}^{3}\boldsymbol{\tau}_i\cdot\boldsymbol{\tau}_j+\frac{i}{4}\varepsilon^{abc}\boldsymbol{\tau}_1^a\boldsymbol{\tau}_2^b\boldsymbol{\tau}_3^c, \tag{6a}$$

$$\mathrm{P}_{132}=\mathrm{P}_{123}^2=\frac{1}{4}+\frac{1}{4}\sum_{i<j}^{3}\boldsymbol{\tau}_i\cdot\boldsymbol{\tau}_j-\frac{i}{4}\varepsilon^{abc}\boldsymbol{\tau}_1^a\boldsymbol{\tau}_2^b\boldsymbol{\tau}_3^c. \tag{6b}$$

Similar results are

$$\mathrm{P}_{123}\sum_{i<j}^{3}\boldsymbol{\tau}_i\cdot\boldsymbol{\tau}_j=\frac{1}{2}\left(9+\sum_{i<j}^{3}\boldsymbol{\tau}_i\cdot\boldsymbol{\tau}_j-3i\varepsilon^{abc}\boldsymbol{\tau}_1^a\boldsymbol{\tau}_2^b\boldsymbol{\tau}_3^c\right), \tag{7a}$$

$$\mathrm{P}_{132}\sum_{i<j}^{3}\boldsymbol{\tau}_i\cdot\boldsymbol{\tau}_j=\frac{1}{4}\left(9+\sum_{i<j}^{3}\boldsymbol{\tau}_i\cdot\boldsymbol{\tau}_j+3i\varepsilon^{abc}\boldsymbol{\tau}_1^a\boldsymbol{\tau}_2^b\boldsymbol{\tau}_3^c\right), \tag{7b}$$

as well as

$$i\mathrm{P}_{123}\varepsilon^{abc}\boldsymbol{\tau}_1^a\boldsymbol{\tau}_2^b\boldsymbol{\tau}_3^c=\frac{1}{2}\left(-3+\sum_{i<j}^{3}\boldsymbol{\tau}_i\cdot\boldsymbol{\tau}_j-i\varepsilon^{abc}\boldsymbol{\tau}_1^a\boldsymbol{\tau}_2^b\boldsymbol{\tau}_3^c\right), \tag{8a}$$

$$i\mathrm{P}_{132}\varepsilon^{abc}\boldsymbol{\tau}_1^a\boldsymbol{\tau}_2^b\boldsymbol{\tau}_3^c=\frac{1}{2}\left(3-\sum_{i<j}^{3}\boldsymbol{\tau}_i\cdot\boldsymbol{\tau}_j-i\varepsilon^{abc}\boldsymbol{\tau}_1^a\boldsymbol{\tau}_2^b\boldsymbol{\tau}_3^c\right). \tag{8b}$$

2. Crossing matrix

These results are summarized by the crossing matrices:

$$\mathbf{C}=\frac{1}{4}\begin{pmatrix}1&1&1\\9&1&-3\\-6&2&-2\end{pmatrix}, \tag{9}$$

for P_{123}, and

$$\mathbf{C}^2=\frac{1}{4}\begin{pmatrix}1&1&-1\\9&1&3\\6&-2&-2\end{pmatrix}, \tag{10}$$

for P_{132}. A valuable check is the constraint $\mathbf{C}^3=1$.

3. Three-body Fierz identities

$$\delta_{\alpha\delta}\delta_{\gamma\rho}\delta_{\sigma\beta}=\tfrac{1}{4}(\delta_{\alpha\beta}\delta_{\gamma\delta}\delta_{\sigma\rho}+\delta_{\alpha\beta}\boldsymbol{\tau}_{\gamma\delta}\cdot\boldsymbol{\tau}_{\sigma\rho}+\delta_{\gamma\delta}\boldsymbol{\tau}_{\alpha\beta}\cdot\boldsymbol{\tau}_{\sigma\rho}+\delta_{\sigma\rho}\boldsymbol{\tau}_{\gamma\delta}\cdot\boldsymbol{\tau}_{\alpha\beta}+i\varepsilon^{abc}\boldsymbol{\tau}^a_{\alpha\beta}\boldsymbol{\tau}^b_{\gamma\delta}\boldsymbol{\tau}^c_{\sigma\rho}), \tag{11a}$$

$$\delta_{\alpha\rho}\delta_{\gamma\beta}\delta_{\sigma\delta}=\tfrac{1}{4}(\delta_{\alpha\beta}\delta_{\gamma\delta}\delta_{\sigma\rho}+\delta_{\alpha\beta}\boldsymbol{\tau}_{\gamma\delta}\cdot\boldsymbol{\tau}_{\sigma\rho}+\delta_{\gamma\delta}\boldsymbol{\tau}_{\alpha\beta}\cdot\boldsymbol{\tau}_{\sigma\rho}+\delta_{\sigma\rho}\boldsymbol{\tau}_{\gamma\delta}\cdot\boldsymbol{\tau}_{\alpha\beta}-i\varepsilon^{abc}\boldsymbol{\tau}^a_{\alpha\beta}\boldsymbol{\tau}^b_{\gamma\delta}\boldsymbol{\tau}^c_{\sigma\rho}), \tag{11b}$$

$$\delta_{\alpha\delta}\boldsymbol{\tau}_{\gamma\rho}\cdot\boldsymbol{\tau}_{\sigma\beta}+\delta_{\gamma\rho}\boldsymbol{\tau}_{\alpha\delta}\cdot\boldsymbol{\tau}_{\sigma\beta}+\delta_{\sigma\beta}\boldsymbol{\tau}_{\gamma\rho}\cdot\boldsymbol{\tau}_{\alpha\delta}=\tfrac{1}{4}(9\,\delta_{\alpha\beta}\delta_{\gamma\delta}\delta_{\sigma\rho}+\delta_{\alpha\beta}\boldsymbol{\tau}_{\gamma\delta}\cdot\boldsymbol{\tau}_{\sigma\rho}+\delta_{\gamma\delta}\boldsymbol{\tau}_{\alpha\beta}\cdot\boldsymbol{\tau}_{\sigma\rho}+\delta_{\sigma\rho}\boldsymbol{\tau}_{\gamma\delta}\cdot\boldsymbol{\tau}_{\alpha\beta}-3i\varepsilon^{abc}\boldsymbol{\tau}^a_{\alpha\beta}\boldsymbol{\tau}^b_{\gamma\delta}\boldsymbol{\tau}^c_{\sigma\rho}), \tag{12a}$$

$$\delta_{\alpha\rho}\boldsymbol{\tau}_{\gamma\beta}\cdot\boldsymbol{\tau}_{\sigma\delta}+\delta_{\gamma\beta}\boldsymbol{\tau}_{\alpha\rho}\cdot\boldsymbol{\tau}_{\sigma\delta}+\delta_{\sigma\beta}\boldsymbol{\tau}_{\gamma\rho}\cdot\boldsymbol{\tau}_{\alpha\delta}=\tfrac{1}{4}(9\,\delta_{\alpha\beta}\delta_{\gamma\delta}\delta_{\sigma\rho}+\delta_{\alpha\beta}\boldsymbol{\tau}_{\gamma\delta}\cdot\boldsymbol{\tau}_{\sigma\rho}+\delta_{\gamma\delta}\boldsymbol{\tau}_{\alpha\beta}\cdot\boldsymbol{\tau}_{\sigma\rho}+\delta_{\sigma\rho}\boldsymbol{\tau}_{\gamma\delta}\cdot\boldsymbol{\tau}_{\alpha\beta}+3i\varepsilon^{abc}\boldsymbol{\tau}^a_{\alpha\beta}\boldsymbol{\tau}^b_{\gamma\delta}\boldsymbol{\tau}^c_{\sigma\rho}), \tag{12b}$$

$$i\varepsilon^{abc}\boldsymbol{\tau}^a_{\alpha\delta}\boldsymbol{\tau}^b_{\gamma\rho}\boldsymbol{\tau}^c_{\sigma\beta}=\tfrac{1}{2}(-3\,\delta_{\alpha\beta}\delta_{\gamma\delta}\delta_{\sigma\rho}+\delta_{\alpha\beta}\boldsymbol{\tau}_{\gamma\delta}\cdot\boldsymbol{\tau}_{\sigma\rho}+\delta_{\gamma\delta}\boldsymbol{\tau}_{\alpha\beta}\cdot\boldsymbol{\tau}_{\sigma\rho}+\delta_{\sigma\rho}\boldsymbol{\tau}_{\gamma\delta}\cdot\boldsymbol{\tau}_{\alpha\beta}-i\varepsilon^{abc}\boldsymbol{\tau}^a_{\alpha\beta}\boldsymbol{\tau}^b_{\gamma\delta}\boldsymbol{\tau}^c_{\sigma\rho}), \tag{13a}$$

$$i\varepsilon^{abc}\boldsymbol{\tau}^a_{\alpha\rho}\boldsymbol{\tau}^b_{\gamma\beta}\boldsymbol{\tau}^c_{\sigma\delta}=\tfrac{1}{2}(3\,\delta_{\alpha\beta}\delta_{\gamma\delta}\delta_{\sigma\rho}-(\delta_{\alpha\beta}\boldsymbol{\tau}_{\gamma\delta}\cdot\boldsymbol{\tau}_{\sigma\rho}+\delta_{\gamma\delta}\boldsymbol{\tau}_{\alpha\beta}\cdot\boldsymbol{\tau}_{\sigma\rho}+\delta_{\sigma\rho}\boldsymbol{\tau}_{\gamma\delta}\cdot\boldsymbol{\tau}_{\alpha\beta})-i\varepsilon^{abc}\boldsymbol{\tau}^a_{\alpha\beta}\boldsymbol{\tau}^b_{\gamma\delta}\boldsymbol{\tau}^c_{\sigma\rho}). \tag{13b}$$

B. The SU(3) algebra

1. Three-body exchange operators

Similarly, we have

$$\mathrm{P}_{123}=\frac{1}{9}+\frac{1}{6}\sum_{i<j}^{3}\boldsymbol{\lambda}_i\cdot\boldsymbol{\lambda}_j+\frac{1}{4}d^{abc}\boldsymbol{\lambda}_1^a\boldsymbol{\lambda}_2^b\boldsymbol{\lambda}_3^c+\frac{i}{4}f^{abc}\boldsymbol{\lambda}_1^a\boldsymbol{\lambda}_2^b\boldsymbol{\lambda}_3^c, \tag{14a}$$

$$\mathrm{P}_{132}=\frac{1}{9}+\frac{1}{6}\sum_{i<j}^{3}\boldsymbol{\lambda}_i\cdot\boldsymbol{\lambda}_j+\frac{1}{4}d^{abc}\boldsymbol{\lambda}_1^a\boldsymbol{\lambda}_2^b\boldsymbol{\lambda}_3^c-\frac{1}{4}if^{abc}\boldsymbol{\lambda}_1^a\boldsymbol{\lambda}_2^b\boldsymbol{\lambda}_3^c, \tag{14b}$$

as well as similar relations for the operators,

$$\mathrm{P}_{123}\sum_{i<j}^{3}\boldsymbol{\lambda}_i\cdot\boldsymbol{\lambda}_j=\frac{1}{9}+\frac{1}{6}\sum_{i<j}^{3}\boldsymbol{\lambda}_i\cdot\boldsymbol{\lambda}_j+\frac{1}{4}d^{abc}\boldsymbol{\lambda}_1^a\boldsymbol{\lambda}_2^b\boldsymbol{\lambda}_3^c+\frac{i}{4}f^{abc}\boldsymbol{\lambda}_1^a\boldsymbol{\lambda}_2^b\boldsymbol{\lambda}_3^c, \tag{15a}$$

$$\mathrm{P}_{132}\sum_{i<j}^{3}\boldsymbol{\lambda}_i\cdot\boldsymbol{\lambda}_j=\frac{1}{9}+\frac{1}{6}\sum_{i<j}^{3}\boldsymbol{\lambda}_i\cdot\boldsymbol{\lambda}_j+\frac{1}{4}d^{abc}\boldsymbol{\lambda}_1^a\boldsymbol{\lambda}_2^b\boldsymbol{\lambda}_3^c-\frac{1}{4}if^{abc}\boldsymbol{\lambda}_1^a\boldsymbol{\lambda}_2^b\boldsymbol{\lambda}_3^c, \tag{15b}$$

and

$$\mathrm{P}_{123}d^{abc}\boldsymbol{\lambda}_1^a\boldsymbol{\lambda}_2^b\boldsymbol{\lambda}_3^c=\frac{80}{81}-\frac{5}{27}\sum_{i<j}^{3}\boldsymbol{\lambda}_i\cdot\boldsymbol{\lambda}_j+\frac{13}{18}d^{abc}\boldsymbol{\lambda}_1^a\boldsymbol{\lambda}_2^b\boldsymbol{\lambda}_3^c-\frac{5}{18}if^{abc}\boldsymbol{\lambda}_1^a\boldsymbol{\lambda}_2^b\boldsymbol{\lambda}_3^c, \tag{16a}$$

$$\mathrm{P}_{132}d^{abc}\boldsymbol{\lambda}_1^a\boldsymbol{\lambda}_2^b\boldsymbol{\lambda}_3^c=\frac{80}{81}-\frac{5}{27}\sum_{i<j}^{3}\boldsymbol{\lambda}_i\cdot\boldsymbol{\lambda}_j+\frac{13}{18}d^{abc}\boldsymbol{\lambda}_1^a\boldsymbol{\lambda}_2^b\boldsymbol{\lambda}_3^c+\frac{5}{18}if^{abc}\boldsymbol{\lambda}_1^a\boldsymbol{\lambda}_2^b\boldsymbol{\lambda}_3^c, \tag{16b}$$

$$\mathrm{P}_{123}if^{abc}\boldsymbol{\lambda}_1^a\boldsymbol{\lambda}_2^b\boldsymbol{\lambda}_3^c=-\frac{16}{9}+\frac{1}{3}\sum_{i<j}^{3}\boldsymbol{\lambda}_i\cdot\boldsymbol{\lambda}_j+\frac{1}{2}d^{abc}\boldsymbol{\lambda}_1^a\boldsymbol{\lambda}_2^b\boldsymbol{\lambda}_3^c-\frac{1}{2}if^{abc}\boldsymbol{\lambda}_1^a\boldsymbol{\lambda}_2^b\boldsymbol{\lambda}_3^c, \tag{16c}$$

$$\mathrm{P}_{132} if^{abc}\boldsymbol{\lambda}_1^a\boldsymbol{\lambda}_2^b\boldsymbol{\lambda}_3^c = \frac{16}{9} - \frac{1}{3}\sum_{i<j}^{3}\boldsymbol{\lambda}_i\cdot\boldsymbol{\lambda}_j - \frac{1}{2}d^{abc}\boldsymbol{\lambda}_1^a\boldsymbol{\lambda}_2^b\boldsymbol{\lambda}_3^c - \frac{1}{2}if^{abc}\boldsymbol{\lambda}_1^a\boldsymbol{\lambda}_2^b\boldsymbol{\lambda}_3^c . \tag{16d}$$

2. Crossing matrix

This leads to the following first cyclic permutation three-quark crossing matrix:

$$\mathbf{C} = \begin{pmatrix} \frac{1}{9} & \frac{1}{6} & \frac{1}{4} & \frac{1}{4} \\ \frac{16}{9} & \frac{2}{3} & -\frac{1}{2} & \frac{1}{2} \\ \frac{80}{81} & -\frac{5}{27} & \frac{13}{18} & -\frac{5}{18} \\ -\frac{16}{9} & \frac{1}{3} & \frac{1}{2} & -\frac{1}{2} \end{pmatrix}. \tag{17}$$

Similarly, for the second cyclic permutation we find

$$\mathbf{C}^2 = \begin{pmatrix} \frac{1}{9} & \frac{1}{6} & \frac{1}{4} & -\frac{1}{4} \\ \frac{16}{9} & \frac{2}{3} & -\frac{1}{2} & -\frac{1}{2} \\ \frac{80}{81} & -\frac{5}{27} & \frac{13}{18} & \frac{5}{18} \\ \frac{16}{9} & -\frac{1}{3} & -\frac{1}{2} & -\frac{1}{2} \end{pmatrix}, \tag{18}$$

and, of course satisfying $\mathbf{C}^3 = 1$.

3. Three-body Fierz identities

$$\begin{aligned}\delta_{\alpha\delta}\delta_{\gamma\rho}\delta_{\sigma\beta} = {}& \tfrac{1}{9}\,\delta_{\alpha\beta}\delta_{\gamma\delta}\delta_{\sigma\rho} + \tfrac{1}{6}(\delta_{\alpha\beta}\boldsymbol{\lambda}_{\gamma\delta}\cdot\boldsymbol{\lambda}_{\sigma\rho} + \delta_{\gamma\delta}\boldsymbol{\lambda}_{\alpha\beta}\cdot\boldsymbol{\lambda}_{\sigma\rho} + \delta_{\sigma\rho}\boldsymbol{\lambda}_{\gamma\delta}\cdot\boldsymbol{\lambda}_{\alpha\beta}) \\ & + \tfrac{1}{4}d^{abc}\boldsymbol{\lambda}^a_{\alpha\beta}\boldsymbol{\lambda}^b_{\gamma\delta}\boldsymbol{\lambda}^c_{\sigma\rho} + \tfrac{1}{4}if^{abc}\boldsymbol{\lambda}^a_{\alpha\beta}\boldsymbol{\lambda}^b_{\gamma\delta}\boldsymbol{\lambda}^c_{\sigma\rho},\end{aligned} \tag{19a}$$

$$\begin{aligned}\delta_{\alpha\rho}\delta_{\gamma\beta}\delta_{\sigma\delta} = {}& \tfrac{1}{9}\,\delta_{\alpha\beta}\delta_{\gamma\delta}\delta_{\sigma\rho} + \tfrac{1}{6}(\delta_{\alpha\beta}\boldsymbol{\lambda}_{\gamma\delta}\cdot\boldsymbol{\lambda}_{\sigma\rho} + \delta_{\gamma\delta}\boldsymbol{\lambda}_{\alpha\beta}\cdot\boldsymbol{\lambda}_{\sigma\rho} + \delta_{\sigma\rho}\boldsymbol{\lambda}_{\gamma\delta}\cdot\boldsymbol{\lambda}_{\alpha\beta}) \\ & + \tfrac{1}{4}d^{abc}\boldsymbol{\lambda}^a_{\alpha\beta}\boldsymbol{\lambda}^b_{\gamma\delta}\boldsymbol{\lambda}^c_{\sigma\rho} - \tfrac{1}{4}if^{abc}\boldsymbol{\lambda}^a_{\alpha\beta}\boldsymbol{\lambda}^b_{\gamma\delta}\boldsymbol{\lambda}^c_{\sigma\rho},\end{aligned} \tag{19b}$$

$$\begin{aligned}\delta_{\alpha\delta}\boldsymbol{\lambda}_{\gamma\rho}\cdot\boldsymbol{\lambda}_{\sigma\beta} + \delta_{\gamma\rho}\boldsymbol{\lambda}_{\alpha\delta}\cdot\boldsymbol{\lambda}_{\sigma\beta} + \delta_{\sigma\beta}\boldsymbol{\lambda}_{\gamma\rho}\cdot\boldsymbol{\lambda}_{\alpha\delta} = {}& \tfrac{2}{3}(\delta_{\alpha\beta}\boldsymbol{\lambda}_{\gamma\delta}\cdot\boldsymbol{\lambda}_{\sigma\rho} + \delta_{\gamma\delta}\boldsymbol{\lambda}_{\alpha\beta}\cdot\boldsymbol{\lambda}_{\sigma\rho} + \delta_{\sigma\rho}\boldsymbol{\lambda}_{\gamma\delta}\cdot\boldsymbol{\lambda}_{\alpha\beta}) \\ & + \tfrac{16}{9}\,\delta_{\alpha\beta}\delta_{\gamma\delta}\delta_{\sigma\rho} - \tfrac{1}{2}d^{abc}\boldsymbol{\lambda}^a_{\alpha\beta}\boldsymbol{\lambda}^b_{\gamma\delta}\boldsymbol{\lambda}^c_{\sigma\rho} \\ & + \tfrac{1}{2}if^{abc}\boldsymbol{\lambda}^a_{\alpha\beta}\boldsymbol{\lambda}^b_{\gamma\delta}\boldsymbol{\lambda}^c_{\sigma\rho},\end{aligned} \tag{20a}$$

$$\begin{aligned}d^{abc}\boldsymbol{\lambda}^a_{\alpha\delta}\boldsymbol{\lambda}^b_{\gamma\rho}\boldsymbol{\lambda}^c_{\sigma\beta} = {}& -\tfrac{5}{27}(\delta_{\alpha\beta}\boldsymbol{\lambda}_{\gamma\delta}\cdot\boldsymbol{\lambda}_{\sigma\rho} + \delta_{\gamma\delta}\boldsymbol{\lambda}_{\alpha\beta}\cdot\boldsymbol{\lambda}_{\sigma\rho} + \delta_{\sigma\rho}\boldsymbol{\lambda}_{\gamma\delta}\cdot\boldsymbol{\lambda}_{\alpha\beta}) + \tfrac{80}{81}\,\delta_{\alpha\beta}\delta_{\gamma\delta}\delta_{\sigma\rho} \\ & + \tfrac{13}{18}d^{abc}\boldsymbol{\lambda}^a_{\alpha\beta}\boldsymbol{\lambda}^b_{\gamma\delta}\boldsymbol{\lambda}^c_{\sigma\rho} - \tfrac{5}{18}if^{abc}\boldsymbol{\lambda}^a_{\alpha\beta}\boldsymbol{\lambda}^b_{\gamma\delta}\boldsymbol{\lambda}^c_{\sigma\rho},\end{aligned} \tag{21a}$$

$$\begin{aligned}d^{abc}\boldsymbol{\lambda}^a_{\alpha\rho}\boldsymbol{\lambda}^b_{\gamma\beta}\boldsymbol{\lambda}^c_{\sigma\delta} = {}& -\tfrac{5}{27}(\delta_{\alpha\beta}\boldsymbol{\lambda}_{\gamma\delta}\cdot\boldsymbol{\lambda}_{\sigma\rho} + \delta_{\gamma\delta}\boldsymbol{\lambda}_{\alpha\beta}\cdot\boldsymbol{\lambda}_{\sigma\rho} + \delta_{\sigma\rho}\boldsymbol{\lambda}_{\gamma\delta}\cdot\boldsymbol{\lambda}_{\alpha\beta}) + \tfrac{80}{81}\,\delta_{\alpha\beta}\delta_{\gamma\delta}\delta_{\sigma\rho} \\ & + \tfrac{13}{18}d^{abc}\boldsymbol{\lambda}^a_{\alpha\beta}\boldsymbol{\lambda}^b_{\gamma\delta}\boldsymbol{\lambda}^c_{\sigma\rho} + \tfrac{5}{18}if^{abc}\boldsymbol{\lambda}^a_{\alpha\beta}\boldsymbol{\lambda}^b_{\gamma\delta}\boldsymbol{\lambda}^c_{\sigma\rho},\end{aligned} \tag{21b}$$

$$if^{abc}\boldsymbol{\lambda}^a_{\alpha\delta}\boldsymbol{\lambda}^b_{\gamma\rho}\boldsymbol{\lambda}^c_{\sigma\beta}=\tfrac{1}{3}(\delta_{\alpha\beta}\boldsymbol{\lambda}_{\gamma\delta}\cdot\boldsymbol{\lambda}_{\sigma\rho}+\delta_{\gamma\delta}\boldsymbol{\lambda}_{\alpha\beta}\cdot\boldsymbol{\lambda}_{\sigma\rho}+\delta_{\sigma\rho}\boldsymbol{\lambda}_{\gamma\delta}\cdot\boldsymbol{\lambda}_{\alpha\beta})-\tfrac{16}{9}\delta_{\alpha\beta}\delta_{\gamma\delta}\delta_{\sigma\rho}$$
$$+\tfrac{1}{2}d^{abc}\boldsymbol{\lambda}^a_{\alpha\beta}\boldsymbol{\lambda}^b_{\gamma\delta}\boldsymbol{\lambda}^c_{\sigma\rho}-\tfrac{1}{2}if^{abc}\boldsymbol{\lambda}^a_{\alpha\beta}\boldsymbol{\lambda}^b_{\gamma\delta}\boldsymbol{\lambda}^c_{\sigma\rho}, \tag{22a}$$

$$if^{abc}\boldsymbol{\lambda}^a_{\alpha\rho}\boldsymbol{\lambda}^b_{\gamma\beta}\boldsymbol{\lambda}^c_{\sigma\delta}=-\tfrac{1}{3}(\delta_{\alpha\beta}\boldsymbol{\lambda}_{\gamma\delta}\cdot\boldsymbol{\lambda}_{\sigma\rho}+\delta_{\gamma\delta}\boldsymbol{\lambda}_{\alpha\beta}\cdot\boldsymbol{\lambda}_{\sigma\rho}+\delta_{\sigma\rho}\boldsymbol{\lambda}_{\gamma\delta}\cdot\boldsymbol{\lambda}_{\alpha\beta})+\tfrac{16}{9}\delta_{\alpha\beta}\delta_{\gamma\delta}\delta_{\sigma\rho}$$
$$-\tfrac{1}{2}d^{abc}\boldsymbol{\lambda}^a_{\alpha\beta}\boldsymbol{\lambda}^b_{\gamma\delta}\boldsymbol{\lambda}^c_{\sigma\rho}-\tfrac{1}{2}if^{abc}\boldsymbol{\lambda}^a_{\alpha\beta}\boldsymbol{\lambda}^b_{\gamma\delta}\boldsymbol{\lambda}^c_{\sigma\rho}. \tag{22b}$$

III. COMMENTS

Two of the three operators $\Sigma^3_{i<j}\boldsymbol{\lambda}_i\cdot\boldsymbol{\lambda}_j, d^{abc}\boldsymbol{\lambda}^a_1\boldsymbol{\lambda}^b_2\boldsymbol{\lambda}^c_3, if^{abc}\boldsymbol{\lambda}^a_1\boldsymbol{\lambda}^b_2\boldsymbol{\lambda}^c_3$ are SU(3) invariants, i.e., they can be expressed in terms of the two Casimir operators of SU(3) as follows:

$$\sum_{i<j}^{3}\boldsymbol{\lambda}_i\cdot\boldsymbol{\lambda}_j=2C^{(1)}-4, \tag{23a}$$

$$d^{abc}\boldsymbol{\lambda}^a_1\boldsymbol{\lambda}^b_2\boldsymbol{\lambda}^c_3=\tfrac{4}{3}[C^{(2)}-\tfrac{5}{2}C^{(1)}+\tfrac{20}{3}]; \tag{23b}$$

where the two Casimir operators of SU(3) are defined as $C^{(1)}=\mathbf{F}^2, C^{(2)}=d^{abc}\mathbf{F}^a\mathbf{F}^b\mathbf{F}^c$ and $\mathbf{F}^a$ are the SU(3) algebra generators. The third operator, $if^{abc}\boldsymbol{\lambda}^a_1\boldsymbol{\lambda}^b_2\boldsymbol{\lambda}^c_3$, is a peculiar object: it is an SU(3) invariant, because it commutes with the SU(3) generators $\mathbf{F}^a=1/2(\boldsymbol{\lambda}^a_1+\boldsymbol{\lambda}^a_2+\boldsymbol{\lambda}^a_3)$ in the special case when these generators are formed from three Gell–Mann matrices, but it is also an off-diagonal operator [it annihilates the two three-quark SU(3) eigenstates with definite exchange symmetry properties, i.e., the **1** and **10**, and turns one **8** state into another] that cannot be expressed in terms of Casimir operators. This result does not violate the Casimir–v.d. Waerden theorem relating the rank of the group to the number of independent invariant operators, as it is representation dependent. This example, however, points out the existence of such invariants which is not widely known.

(Received 25 February 2000; accepted for publication 10 November 2000)

We derive an asymptotic formula for the eigenvalues of the Aharonov–Bohm annular billiard (ABAB) that improves and corrects previous estimates. Employing semiclassical arguments we relate the limitations of the procedure to the topology of the classical phase space of the system. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1341235]

I. INTRODUCTION

In recent years, the interest in quantum billiards has increased considerably. Owing to advances in nanotechnology, it has been possible to fabricate small devices in which the carriers are mainly scattered by the boundaries of the sample.[1] The high resemblance between these systems, commonly referred to as quantum dots, and the quantum billiards, it is very appealing to study the transport properties of ballistic samples employing quantum billiards as models.

Quantum billiards threaded by a magnetic flux ϕ are suitable configurations to model problems related to persistent currents.[2,3] These equilibrium currents are a consequence of the nature of the eigenfunctions' flux sensitivity, which is strictly of the Aharonov–Bohm type.[4,5] The current, at zero temperature, carried by the level E_n is $I \propto \partial E_n / \partial \phi$. The first theoretical works on persistent currents have been in one-dimensional (1D) ring geometries,[6] in two-dimensional (2D) the computations have been performed employing discrete models or cylindrical geometries.[7,8] In the last case, the mathematical description of the problem is essentially the same as for the ring geometries because the eigenenergies are pure quadratic forms of the two quantum numbers with a functional dependence on the flux that is identical to 1D systems.

To describe the real ''rings'' employed in the experiments on persistent currents,[9] it seems to be more suitable to consider the 2D Aharonov–Bohm annular billiard (ABAB) depicted in Fig. 1. The eigenenergies for this system can be numerically determined from the zeros of the cross products of Bessel functions, but a closed analytical formula for the eigenvalues does not exist.

In a recent paper Samandra and Healy introduced an asymptotic formula for the eigenvalues of a charged particle confined in an annular shell in which there was a cylindrically symmetric static magnetic field inside the inner cylinder.[10] This configuration is equivalent to thread the annular shell by an static magnetic flux ϕ and, therefore, equivalent to the ABAB. In this article we present an asymptotic analytical formula for the eigenenergies of the ABAB that corrects and improves the previous one.[10] Moreover, we will show that the eigenenergies obtained in Ref. 10 fail to describe quantum states that are present at all the energy scales, even in the semiclassical limit. These states are associated with classical orbits that do not hit the inner radius of the ABAB and cannot be described by the asymptotic expansion presented in Ref. 10. We find that the eigenenergies for these states can be obtained, under certain conditions, through the Debye's expansion for the zeros of the Bessel functions of first kind.

The paper is organized as follows. In Sec. II we introduce the system and summarize the results concerning the solutions of the Schrödinger equation. In Sec. III we obtain the asymptotic expansion for the eigenenergies and compare it to the one obtained in Ref. 10. Part of this section

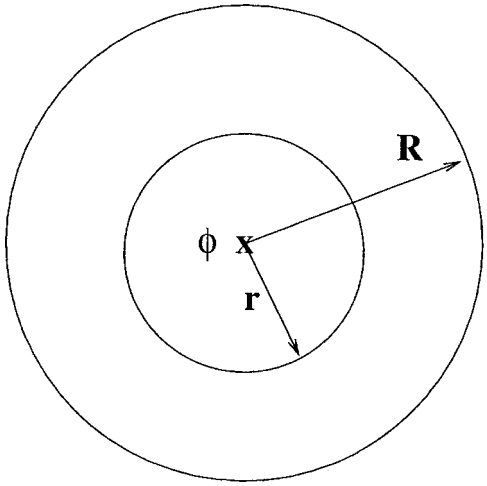

FIG. 1. Aharonov–Bohm annular billiard (ABAB) threaded by a magnetic flux ϕ. The inner and outer radii are denoted r and R, respectively.

is devoted to a detailed discussion about the limitations of the analytical results. We present in Sec. IV the numerical results and in Sec. V the concluding remarks.

II. THE AHARONOV–BOHM ANNULAR CAVITY

In this section we introduce the ABAB and the relevant equations involved in the problem. The annular shell is defined in terms of the polar coordinates (ρ, θ). The radial coordinate ρ varies between r and R and the azimutal angle $0 \leqslant \theta \leqslant 2\pi$ (see Fig. 1). We take the area equal to π and we define the parameter $\lambda = R/r$, such that $R = \lambda/\sqrt{\lambda^2 - 1}$ and $r = 1/\sqrt{\lambda^2 - 1}$. When $\lambda \to 1$ the system resembles a 1D ring, while for $\lambda > 1$ it is an annular cavity.

We fix the gauge $\mathbf{A} = \phi/(2\pi\rho)\hat{\theta}$, where $\hat{\theta}$ is the azimutal unit vector, and there is no magnetic field piercing the body of the annulus.

The single particle spectrum results from the eigenvalue equation

$$\Delta\Psi + \frac{2i\alpha}{\rho^2}\frac{\partial\Psi}{\partial\theta} - \frac{\alpha^2}{\rho^2}\Psi + k^2\Psi = 0, \tag{2.1}$$

where Δ is the Laplacian in polar coordinates. We define the scaled flux $\alpha = \phi/\phi_0$ with $\phi_0 = hc/e$ the flux quantum. We use units such $\hbar^2/2m = 1$, so the energy is $E = k^2$.

We apply Dirichlet boundary conditions at $\rho = r$ and $\rho = R$ and periodic boundary condition in the azimutal direction. The Eq. (2.1) is separable in polar coordinates and we factorize $\Psi(\rho, \theta) = \mathcal{F}(\rho)\exp(im\theta)$ with $m = 0, \pm 1, \pm 2, \ldots$ the orbital quantum number. The wave numbers $k_{\nu,n}$ result from the solution of the equation

$$J_\nu(z\lambda)N_\nu(z) - J_\nu(z)N_\nu(z\lambda) = 0, \quad \nu \equiv m - \alpha, \tag{2.2}$$

where we have defined $z \equiv kr$ and $n = 1,2\ldots$, is the radial quantum number. J_ν and N_ν are the Bessel functions of the first and second kind, respectively. The corresponding eigenfunctions $\Psi(\rho, \theta)$ are

$$\Psi_{\nu,n}(\rho, \theta) = A_{\nu,n}\exp(im\theta)[J_\nu(k_{\nu,n}\rho)N_\nu(k_{\nu,n}r) - J_\nu(k_{\nu,n}r)N_\nu(k_{\nu,n}\rho)], \tag{2.3}$$

where $A_{\nu,n}$ is the normalization constant.

All the eigenstates and all the equilibrium physical properties of the system are periodic functions of the flux with period ϕ_0. Moreover, as the energy spectrum is symmetric with respect to $\phi=\phi_0/2$, in the following the parameter α will take values between 0 and 1/2. For $\alpha\neq 0$, the states with m and $-m$ are, in general, not degenerate.

We remark that the eigenenergies $E_{\nu,n}$ cannot be written down as simple functions of the numbers ν and n as it happens, for example, in the case of the cylindrical geometries where the eigenenergies are pure quadratic functions of both quantum numbers. Moreover, there is not a closed analytical expression for the eigenenergies of the Aharonov–Bohm annular cavity.

III. THE ASYMPTOTIC EXPANSION FOR THE EIGENENERGIES

To derive an estimate for the eigenenergies $E_{\nu,n}$, we begin rewriting the asymptotic expansion of the nth zero of Eq. (2.2) that appears in Ref. 11, in such a way that the dependence on n, that is hidden in the expression given in Ref. 11 becomes explicit:

$$k_{\nu,n}\approx n\pi\frac{\sqrt{\lambda^2-1}}{\lambda-1}+\frac{(\lambda-1)\sqrt{\lambda^2-1}}{2n\pi\lambda}\nu^2-\frac{(\lambda-1)\sqrt{\lambda^2-1}}{8n\pi\lambda}+\frac{(\lambda-1)^3\sqrt{\lambda^2-1}}{n^3\pi^3}Q+\frac{(\lambda-1)^5\sqrt{\lambda^2-1}}{n^5\pi^5}P, \tag{3.1}$$

with

$$Q\equiv\nu^4\left(16f(\lambda)-\frac{1}{4\lambda^2}\right)+\nu^2\left(\frac{1}{8\lambda^2}-104f(\lambda)\right)-25f(\lambda)-\frac{1}{64\lambda^2},$$

$$P\equiv-\frac{f(\lambda)(-25+4\nu^2)(-1+4\nu^2)^2}{2\lambda}+\frac{(-1+4\nu^2)^3}{256\lambda^3}+\frac{(-1+\lambda^5)(-1+4\nu^2)}{5120(\lambda-1)\lambda^5}(1073-456\nu^2+16\nu^4). \tag{3.2}$$

As Eq. (3.1) is asymptotic in $1/n$, the symbol $\approx$ comes from neglecting all the terms of $\mathcal{O}(1/n^7)$ and higher. We have defined for convenience

$$f(\lambda)\equiv(\lambda^3-1)/(384\lambda^3(\lambda-1)).$$

Equation (3.1) contains terms in orders $\mathcal{O}(1/n)$, $\mathcal{O}(1/n^3)$, and $\mathcal{O}(1/n^5)$ that must be taken into account for small n and values of $\lambda\gtrsim 1$. One can solve by numerical methods Eq. (2.2) to obtain the (exact) eigenvalues of the ABAB. This will be done in the next section. Nevertheless, we now want to stress that for fixed values of λ and $n>1$, the accuracy of the expansion Eq. (3.1) to the exact eigenvalues depends, not only on n, but also on the other quantum number m through ν.

We expand Eq. (3.1) explicitly as a function of both quantum numbers m and n. Keeping the terms up to order α^2 (this is not a crude approximation taking into account that α varies between 0 and 1/2) we obtain the corresponding eigenenergies

$$E_{\nu,n}\equiv E_{m,n}(\alpha)\approx A\alpha^2+B\alpha+C+\mathcal{O}(\alpha^3), \tag{3.3}$$

with A, B, and C polynomials in the quantum number m

$$A\equiv a_0+a_2m^2+a_4m^4+a_6m^6+a_8m^8+a_{10}m^{10}, \tag{3.4}$$

$$B\equiv b_1m+b_3m^3+b_5m^5+b_7m^7+b_9m^9, \tag{3.5}$$

$$C\equiv c_0+c_2m^2+c_4m^4. \tag{3.6}$$

In the Appendix we write down the explicit formulae for the coefficients a_i which although rather cumbersome, will be useful in the following. They are analytic functions of the parameter λ and the radial quantum number n.

The second-order approximation Eq. (3.3) is not the Taylor expansion in α of the eigenenergies. The coefficients in Eqs. (3.4)–(3.6) have been obtained from the asymptotic expansion Eq. (3.1) that, when the radial quantum number $n \lesssim m$, does not work. This important fact has not been taken into account in Ref. 10. Moreover, even in the limit $n \gg m$ the results of Ref. 10 are, in general, very poor estimates of the eigenenergies. To clarify this point we compare Eq. (3.3) to the equation obtained in Ref. 10 for the eigenenergies, that we have rewritten in the form of Eq. (3.3)

$$\tilde{E}_{m,n}(\alpha) = \tilde{A}\alpha^2 + \tilde{B}\alpha + \tilde{C}, \tag{3.7}$$

with

$$\tilde{A} \equiv \frac{\lambda^2 - 1}{\lambda},$$

$$\tilde{B} \equiv -\left(\frac{\lambda^2 - 1}{\lambda}\right) 2m, \tag{3.8}$$

$$\tilde{C} \equiv n^2\pi^2 \left(\frac{\lambda + 1}{\lambda - 1}\right) + \frac{(\lambda^2 - 1)}{\lambda}(m^2 - 1/4).$$

Comparing Eqs. (3.4)–(3.6) [and the Eq. (A1) for a_i] to Eq. (3.8) we conclude that, even in the limit $n \gg m$, it is only for $\lambda = 1 + \epsilon (\epsilon \ll 1)$ that the Eqs. (3.7) and (3.8) give satisfactory values for the eigenenergies of the ABAB. In this case the annulus resembles a thin cylindrical surface of height $(\lambda - 1)/\sqrt{\lambda^2 - 1} = R - r$. Let us remark that for a cylindrical surface of area $L \times L_y$, the exact eigenenergies are parabolas as a function of α. The corresponding coefficients are: $A = (2\pi/L)^2$ (without any dependence on the quantum numbers) for the quadratic term, $B = 2m(2\pi/L)^2$ (depending only on the orbital quantum number m) for the linear term, and the constant term $C = (n\pi/L_y)^2$ which is a function only of the transverse quantum number n.

On the contrary, Eqs. (3.4)–(3.6) are valid for larger values of λ. As an example, Fig. 2 shows a plot of the coefficients A [Eq. (3.4)] and $\tilde{A}$ as a function of the quantum number m for $\lambda = 10$ and $n = 30$. In the same figure the empty circles are the exact numerical values for this coefficient (obtained following the prescription that will be describe in the next section). Whereas the coefficient $\tilde{A}$ only gives the constant value for $m = 0$, the behavior of A is quite satisfactory for values of $m \lesssim 10$. Nevertheless, for $m \lesssim n$ the coefficients given in Eqs. (3.4)–(3.6) do not reproduce the actual values obtained in the numerical computations. The inclusion of additional terms in these equations does not give a better approximation to the eigenenergies. Under the present condition, Eqs. (3.4)–(3.6) are not perturbative because $|m/n| \gtrsim 1$, and any truncation of the expansion is misleading.

The difficulty to obtain a uniform perturbative expansion for the eigenenergies of the ABAB is related to the very different characteristics of the eigenstates as a function of the quantum numbers. This fact can be understood through semiclassical arguments. Since the problem is integrable, the classical phase space is foliated by tori that are labeled by the values of the actions $I_i(l,E), i = 1,2$, with l and E the angular momentum and the energy, respectively.[12] Moreover, this kind of system can be quantized through the E.B.K rule that establishes a correspondence between each eigenstate and a classical torus labeled by $I_i = (k_i + \alpha_i/4)\hbar$, where k_i is an integer and α_i is the Maslov index that depends on the topology of the classical orbits of the system.[13]

Given the values of l and E, and according to the ratio $\eta \equiv l\sqrt{(\lambda^2 - 1)/E}$, we can distinguish two type of classical orbits: Those that do not hit the inner circle ($\eta > 1$), and orbits that hit the inner circle ($\eta < 1$). The special value of $\eta_c = 1$ corresponds to orbits that are tangent to the inner

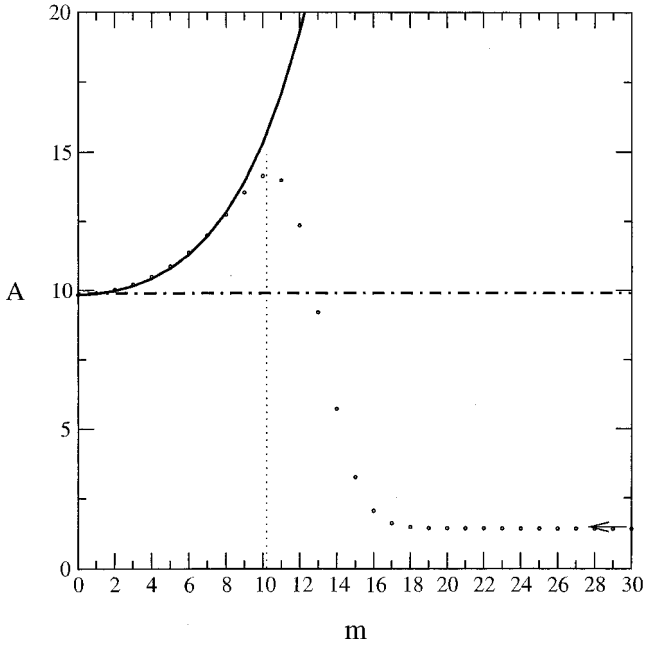

FIG. 2. Coefficient A obtained from Eq. (3.4) (solid lined) and $\tilde{A}$ obtained from Eq. (3.8) (dotted-dashed line) as a function of the quantum number m, for $n=30$ and $\lambda=10$. The empty circles correspond to the numerical values A_{mn} for $n=30$ obtained in Sec. IV. The vertical dotted line is the value m_c defined in Eq. (4.3). The left down arrow indicates the analytical estimate A_e [Eq. (4.4)] for values of $m>m_c$.

circle. The parameter η is the ratio between the radius of the caustic of the classical orbit for a disk of radius $R=\lambda/\sqrt{(\lambda^2-1)}$ and the inner radius of the ABAB, $r=1/\sqrt{(\lambda^2-1)}$.

According to the preceding remarks, given two values of the quantum numbers m and n the classical motion associated to the quantized torus will correspond either to $\eta>1$ or to $\eta<1$. Therefore, two kind of eigenstates are expected according to the value of η. Equation (3.3) is valid for quantum states such that $\eta<1$ and becomes a better approximation as η decreases.

For $\eta>1$, the classical motion on the ABAB is indistinguishable from that on a disk of radius R. Therefore, one would expect that analytical expressions for the eigenvalues corresponding to such a quantum states could be obtained from the Debye's asymptotic expansions for the Bessel functions of the first kind.[11]

However, it is well-known that the Debye's expansions fail to describe states localized on the whispering gallery modes.[14] In terms on the parameter $\epsilon\equiv\sqrt{E/(\lambda^2-1)}\lambda/l$ the whispering gallery modes correspond to $\epsilon\to 1$. As ϵ increases from 1 the Debye's expansion improves. Therefore, the Debye's expansion will be useful to describe states in the ABAB if the conditions $\eta>1$ and $\epsilon>1$ are simultaneously satisfied. As $\eta\cdot\epsilon=\lambda$, the fraction of such states increases with λ.

Figure 3 shows in the k-l plane the two critical lines labeled L_1 and L_2 defined, respectively by the equations $\eta_c=1$ and $\epsilon_c=1$ for $\lambda=10$. The states lying on the shadowed region in between L_1 and L_2 can be approximated by the Debye expansion. As a consequence, while for $\eta<1$ the eigenenergies for the ABAB are given by Eq. (3.1), for $\eta>1$ they could be obtained through the Debye's approximation. In the next section we will explore this approach.

It is important to emphasize that the nature of the failure of the Debye's expansion is quite different from that of the expansion Eq. (3.1). While the former is originated by the pathological behavior of the semiclassical approximation when the classical motion exhibits caustics,[14] the second one is due to the impossibility of the perturbative expansion Eq. (3.1) to cross the separatrix defined by $\eta=\eta_c$. In the next section we will show how this separatrix affects the actual eigenenergies.

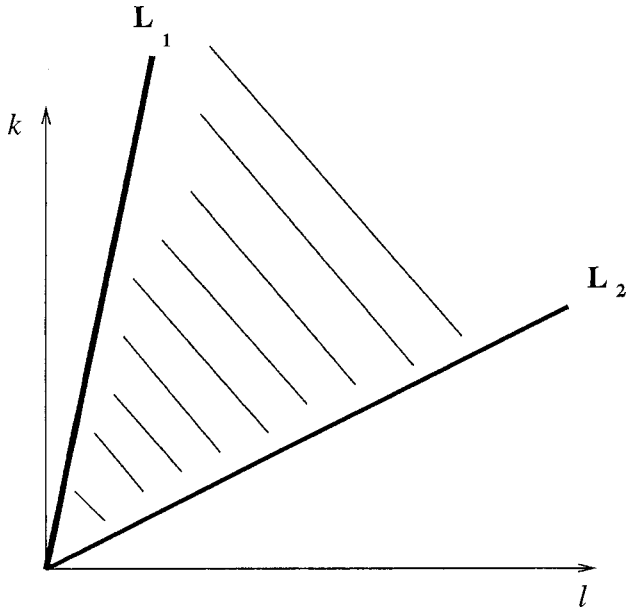

FIG. 3. Critical lines labeled L_1 and L_2 defined, respectively, by the equations $\eta_c=1$ and $\epsilon_c=1$ for $\lambda=10$. The states lying on the shadowed region in between L_1 and L_2 can be approximated by the Debye's expansion.

IV. NUMERICAL RESULTS AND ANALYTICAL ESTIMATES

To obtain each eigenenergy $E_{m,n}$ as a function of the flux α, we have numerically solved Eq. (2.2) employing the Newton–Raphson method. For a given value of λ, we have repeated this procedure for six equally spaced values of α between 0 and 1/2. Then we have fitted the numerical values with a quadratic function that minimizes the sum of the squares of the deviations from the numerical values. Figure 4 shows a region of the energy spectrum as a function of α for $\lambda=10$, obtained by the described procedure. The dotted lines are the quadratic fits, superimposed on the numerical values (circles). In the following we will consider

$$E_{m,n}=A_{mn}(\lambda)\alpha^2+B_{mn}(\lambda)\alpha+C_{mn}(\lambda), \tag{4.1}$$

where A_{mn}, B_{mn}, and C_{mn} have been obtained from the quadratic fit mentioned above.

To illustrate the statements of the preceding section, we will analize the coefficient A_{mn} as a function of both quantum numbers for two values of the parameter λ. Figure 5 shows a surface plot of the coefficient A_{mn} as a function of m and n for $\lambda=10$. We can see a pronounced crest separating two plateaux. One of them (labeled as *I*) corresponds to values of the quantum numbers m and n such that $\eta<1$. The other plateau (labeled as *II*) corresponds to $\eta>1$. The values of the coefficient A_{mn} that correspond to eigenstates such that $\eta\approx1$ are launched on the crest of the surface plot. The crest is a quantum signature of the classical separatrix previously mentioned. For this value of λ the fraction of states on the plateau *II* is much greater than the fraction of those on the plateau *I*.

Figure 6 shows a surface plot of the coefficient A_{mn} as a function of m and n for $\lambda=2$. The exhibited behavior is qualitatively the same as in Fig. 5. Nevertheless, opposite to the previous case, the fraction of states on the plateau *II* is smaller than the fraction of those on the plateau *I*.

As we have mentioned in Sec. III, Fig. 2 shows a transverse section of the surface plot Fig. 5 for $n=30$, together with the coefficient A evaluated for $n=30$ [Eq. (3.4)] and the coefficient $\tilde{A}$ given in Eq. (3.8) that only reproduces the plateau *I* ($A=9.9$ for the present value of $\lambda=10$). On the other hand, the coefficient A follows quite satisfactory the numerical values up to the crest of the plot, but it fails to reproduce the behavior of A_{mn} in the complete range of values of m.

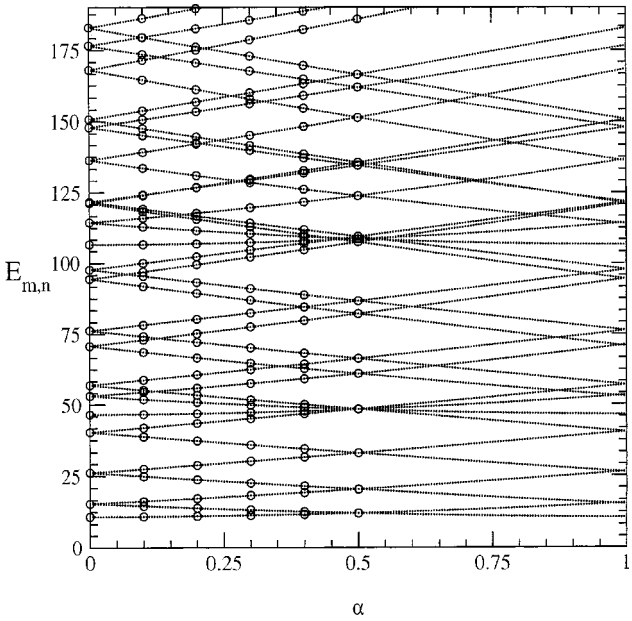

FIG. 4. Single particle energy levels as a function of the adimensional flux α, corresponding to the lowest region of the spectrum for the ABAB with $\lambda = 10$. The circles correspond to exact values obtained from the zeros of the cross products of Bessel functions. The small dotted lines are the quadratic fits obtained in Eq. (4.1). See the text for details.

To reproduce the numerical values A_{mn} in the region of the second plateau *II* we employ the Debye's approximation[11] that gives the asymptotic expansion for the zeros of the Bessel functions of the first kind $J_\nu(kR)$. If $j_{\nu,n}$ is a zero, $E_{\nu,n}=(j_{\nu,n}/R)^2$ will be the eigenenergy. Expanding $E_{\nu,n}$ as a function of the flux $\alpha(\nu=m-\alpha)$ and keeping the terms up to second order in α, we finally obtain

$$E_{m,n}\sim\frac{1}{R^2}\left[\left(\frac{\pi^2}{4}-1\right)\alpha^2+2m\left(\frac{\pi^2}{4}-1\right)\alpha+\pi^2\left(n^2+\left(\frac{\pi^2}{4}-1\right)m^2+\frac{1}{16}\right)\right]. \tag{4.2}$$

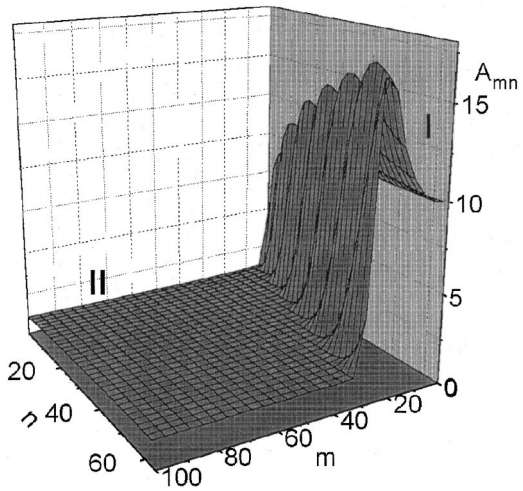

FIG. 5. Surface plot of the coefficient A_{mn} as a function of the quantum numbers m and n for $\lambda = 10$. The plateau labeled with I corresponds to values $\eta<1$, whereas the plateau labeled with II to $\eta>1$.

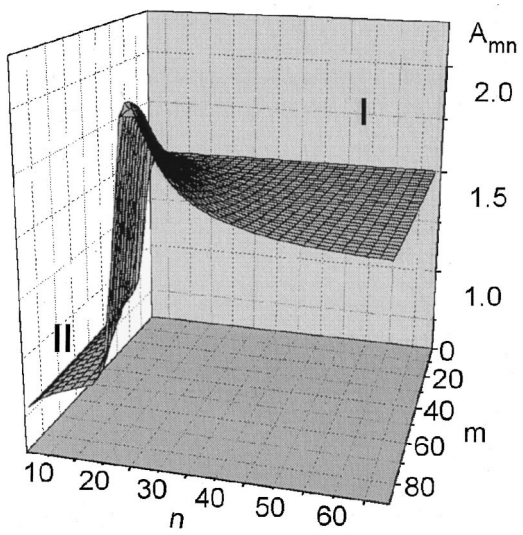

FIG. 6. Surface plot of the coefficient A_{mn} as a function of the quantum numbers m and n for $\lambda=2$. The plateau labeled with I corresponds to values $\eta<1$, whereas the plateau labeled with II to $\eta>1$.

The prefactor in the quadratic term of Eq. (4.2) gives the estimate of A_{mn} in the region of the second plateau *II* ($\eta>1$). For $\lambda=10$ is $R=1.005$ and the value of the coefficient is 1.452. This value is indicated in the right down part of Fig. 2 by an arrow and it agrees with the numerical values of A_{mn} on the plateau *II*.

Equation (4.2) can be used to obtain the critical condition $\eta_c=1$, in the *n*-*m* plane ($\eta_c=1$ defines the line L_1 in *k*-*l* plane). For a given value of the radial quantum number n, $\eta_c=1$ determines a critical value for the orbital quantum number m_c given by

$$m_c\sqrt{\frac{\lambda^2}{\pi^2}+1-\frac{\pi^2}{4}}\simeq n, \tag{4.3}$$

where the fact that $m\equiv l$ was used. Figure 7 shows in the *n*-*m* plane the critical line defined by the

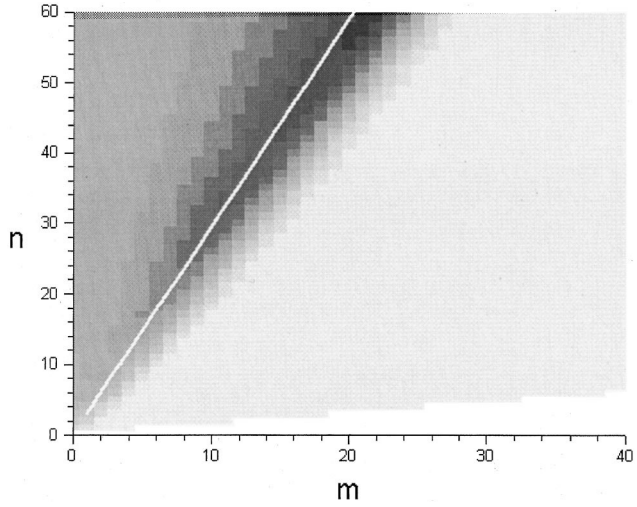

FIG. 7. Gray level density plot in the *m*-*n* plane corresponding to the surface plot Fig. 5. The solid white line is the critical line defined in Eq. (4.3) for $\lambda=10$.

Eq. (4.3) for $\lambda=10$ together with the gray scale density plot of the numerical values of A_{mn} taken from Fig. 5. In the present figure the crest of the surface plot Fig. 5 corresponds to the highest gray level intensity region in where, as expected, the critical line Eq. (4.3) is launched. As a consequence of the preceding analysis, we establish the following functional form to evaluate the coefficients $A_{mn}(\lambda)$

$$A_e=\begin{cases} \text{A given by Eq. (3.4),} & \text{for } m\leqslant m_c \\ \left(\dfrac{\pi^2}{4}-1\right)\dfrac{(\lambda^2-1)}{\lambda}, & \text{for } m>m_c \end{cases}, \tag{4.4}$$

where m_c is given in Eq. (4.3).

V. CONCLUDING REMARKS

In the present article we have explored the possibility to obtain an analytical expansion for the eigenenergies of the Aharonov–Bohm annular billiard valid for the whole range of values of the two relevant quantum numbers. We have shown that the well-known expansion for the zeros of the cross products of Bessel functions fail to reproduce the actual behavior of the eigenenergies for some kind of states that are present in all regions of the spectrum (namely for quantum states such that the parameter $\eta>1$). Based on semiclassical arguments we have demonstrated that these quantum states are associated with classical orbits that do not hit the inner circle of the annulus. These orbits, when the system is a genuine annulus ($\lambda>1$), are relevant in all the energy scales. For $\eta>1$ and $\lambda>1$, we have shown that the eigenenergies of the ABAB can be obtained through the Debye's expansions for the zeros of the Bessel functions of first kind, if the condition $\epsilon>1$ is also acomplished. As $\eta\cdot\epsilon=\lambda$, the fraction of states whose eigenenergies can be approximated by the Debye's expansion increases with λ. We have illustrated our results proposing an analytical estimate A_e, that reproduces quite satisfactory the exact numerical values $A_{mn}(\lambda)$ at both sides of the critical line defined in m-n plane by the Eq. (4.3), irrespective of the value of the parameter ϵ. That is, although the Debye's expansions fail for $\epsilon\to1$, the numerical values A_{mn} are not sensitive to that limit. Therefore, the value predicted by A_e for $m>m_c$ is valid even in the limit $\epsilon\to1$. We should remark that doing analogous calculations to those performed in Sec. IV, it is possible to derive the analytical estimates for the numerical coefficients B_{mn} and C_{mn}. This should be equivalent, in view of Eq. (4.1), to find an analytical expansion for the eigenenergies of the ABAB valid at both sides of the critical line $\eta_c=1$.

Last but not least, we would like to remark that the present study is far from being purely academic. The analytical expression of the eigenenergies as a function of the normalized flux α can be employed to determine the actual prefactors in the magnitude of the typical persistent current for a ballistic ABAB with N carriers, $I_{\text{typ}}\equiv\sqrt{\int_0^1 I^2 d\alpha}$.

In a recent paper it was found that $I_{\text{typ}}\propto A_T/N^{1/4}$, being $A_T\equiv\Sigma_{m,n}A_{mn}(\lambda)$.[3] Taking into account the analytical expression given in Eq. (4.4) we have obtained, to leading order in N

$$A_T=N\frac{(\lambda^2-1)}{\lambda}\left(\frac{\pi^2}{4}-1+\frac{(8-\pi^2)(\lambda-1)}{\pi(\lambda+1)\sqrt{4(\lambda^2+\pi^2)-\pi^4}}\right)+\mathcal{O}(N^{1/2}),$$

which gives a value of I_{typ} 1.4–1.5 times larger than the obtained in case of employing Eq. (3.8). This result could help to understand the existent discrepancy between the large experimental values of the persistent current measured in all the experiments performed up to date, and previous theoretical estimates that did not consider the corrections introduced in the present work.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 42, NUMBER 3 MARCH 2001

Classical analogs of quasifree quantum stochastic processes given by stochastic states of the quantized electromagnetic field

C. Hertfelder[a] and B. Kümmerer
Mathematisches Institut A, Universität Stuttgart, Pfaffenwaldring 57, 70569 Stuttgart, Germany

(Received 28 July 2000; accepted for publication 29 November 2000)

The mathematical model describing a light beam prepared in an arbitrary quantum optical state is a quasifree quantum stochastic process on the C^* algebra of the canonical commutatation relations. For such quantum stochastic processes the concept of stochastic states is introduced. Stochastic quantum states have a classical analog in the following sense: If the light beam is prepared in a stochastic state, one can construct a generalized classical stochastic process, such that the distributions of the quantum observables and the classical random variables coincide. A sufficient algebraic condition for the stochasticity of a quantum state is formulated. The introduced formalism generalizes the Wigner representation from a single field mode to a continuum of modes. For the special case of a single field mode the stochasticity condition provides a new criterion for the positivity of the Wigner function related to the given state. As an example the quantized eletromagnetic field in empty space at temperature $T=0$ is discussed. It turns out that the corresponding classical stochastic process is not a white noise but a colored noise with a linearly increasing spectrum. © *2001 American Institute of Physics.*

I. INTRODUCTION

The physical system considered throughout this paper is a light beam propagating in free space into the x direction of a fixed coordinate system. The beam is assumed to be prepared in an arbitrary quantum optical state. This situation can be described mathematically by a quasifree quantum stochastic process on the C^* algebra of the canonical commutation relations (CCR algebra).[1] Investigating this quantum stochastic process, the main question is the following: For which quantum optical states is it possible to construct a corresponding classical stochastic process, such that the classical random variables have the same distributions as the quantum observables in the given state?

The paper is organized as follows: in Sec. II we summarize some facts about the quantization of infinite dimensional linear Hamiltonian systems, i.e., of systems with the following properties: The state space is a linear space on which the Hamilton function is a strictly positive quadratic form determining the so called energy scalar product. The dynamics of the system defines a strongly continuous group of unitary transformations on state space. The described quantization procedure generalizes the quantization approach of Mackey[2] to the infinite dimensional case. It is closely related to some work of Lewis and Maassen,[3] Hinz[4] and to the Segal–Weinless-approach to quantization.[5,6]

In order to connect this quantization procedure to the Fock space formalism generally used in quantum optics,[7] it is necessary to identify the up to unitary equivalence uniquely determined Fock representation of the resulting CCR algebra. However, it is well known that there is an infinity of

[a]Permanent address: Carl Zeiss Lithos GmbH, Carl Zeiss Strasse, 73447 Oberkochen, Germany. Electronic mail: claudia.hertfelder@zeiss.de

inequivalent Fock states on the CCR algebra over an infinite dimensional real symplectic space.[8] As a main result of Sec. II it is shown that among these Fock states there is exactly one, which is left invariant by the dynamics of the system. The Fock representation corresponding to this state connects the described quantization procedure to the Fock space formalism used in quantum optics. Generalizing a uniqueness result of Kay[9] an explicit construction of the invariant Fock state is given.

In Sec. III the quantization procedure is applied to the electromagnetic field. A one dimensional light beam is described as a linear Hamiltonian system, its time invariant Fock state is determined and the quasifree quantum stochasic process describing the quantized field in a given state is defined.

In Sec. IV a class of quantum optical states having a classical analog in the following sense is introduced: There exists a generalized classical stochastic process in the sense of Hida,[10] whose generalized random variables have the same distributions as the quantized observables in the given quantum state. Such states are called stochastic states. The generalized classical stochastic process corresponding to an arbitrary stochastic state of the quantized electromagnetic field is constructed.

In Sec. V we provide some deeper insight into the mathematical structure of stochastic states. On the basis of the Kolmogorov decomposition of positive definite kernels a sufficient algebraic condition for the stochasticity of a quantum state is formulated. The approach generalizes the well known Wigner representation[11] to a continuum of field modes. For a single mode the stochastic states correspond to the states whose Wigner spectrum[12] contains the points 0 and 1. In Ref. 12 these states are identified as mixed states with a positive Wigner function. Restricted to the one dimensional case, the stochasticity condition leads to a new criterion for the positivity of the Wigner function.

In Sec. VI the invariant Fock state describing the free electromagnetic field at temperature $T=0$ is discussed as an example for a stochastic quantum state. As it turns out, the corresponding generalized classical stochastic process is not a white noise, but a colored noise with a linearly increasing spectrum. This provides a new argument for an experimantally motivated assumption of Gardiner,[13] that the spectrum of the quantized electromagnetic field at $T=0$, which cannot be directly observed by photon counting, might be linearly increasing.

II. QUANTIZATION OF LINEAR HAMILTONIAN SYSTEMS

A triple $[\mathcal{H},\langle\cdot,\cdot\rangle,(U_t=e^{At})_t]$ consisting of a real Hilbert space $\mathcal{H}$ with scalar product $\langle\cdot,\cdot\rangle$ and a strongly continuous one parameter group of unitary transformations $(U_t)_{t\in\mathbb{R}}$ with a densely defined, skew adjoint, injective generator $A:\mathcal{D}(A)\to\mathcal{H}$ is called a *linear Hamiltonian system*, if the following conditions hold: The energy of the system prepared in an arbitrary state $f\in\mathcal{H}$ is given by the expression $\frac{1}{2}\langle f,f\rangle$. The unitary group $(U_t)_{t\in\mathbb{R}}$ describes the dynamics of the system, i.e., starting in the state $f_0\in\mathcal{H}$ at time $t=0$, the state at time $t>0$ will be $f_t=U_tf_0$. Since we consider only systems in continuous time, we write $(U_t)_t$ in the following. We call the scalar product $\langle\cdot,\cdot\rangle$ the *energy scalar product* and $\mathcal{H}$ the *state space* of the system.

Given a linear Hamiltonian system $[\mathcal{H},\langle\cdot,\cdot\rangle,(U_t=e^{At})_t]$, the starting point for its quantization is the corresponding *symplectic system* $[D,\sigma,(\tilde{U}_t)_t]$. It consists by definition of the real linear space $D:=\mathcal{D}(A)\subseteq\mathcal{H}$, the nondegenerate symplectic form $\sigma:D\times D\to\mathbb{R}:(f,g)\mapsto\langle Af,g\rangle$ and the symplectic dynamics $(\tilde{U}_t)_t:=(U_{-t})_t$, which leaves the symplectic form σ invariant. The pair (D,σ) is called a *symplectic space*.

For any $f\in D$ the corresponding *classical linear observable* $\varphi(f)$ is defined as the linear functional,

$$\varphi(f):\mathcal{H}\to\mathbb{R}:g\mapsto\langle g,f\rangle.$$

Parallel to the Heisenberg picture, we will use on the level of quantum mechanics, we fix the states $f\in\mathcal{H}$ and let the observables $\varphi(f)$ evolve in time. Their time evolution is given by $\varphi_t(f)=\phi(\tilde{U}_tf)$, $\forall f\in D$, $t\in\mathbb{R}$.

In this setting the problem of quantizing a linear Hamiltonian system can be formulated as follows: For any classical linear observable $\varphi(f)$ find a corresponding *quantum observable* $\Phi(f)$, i.e., a densely defined, self-adjoint operator $\Phi(f)$ acting on a complex Hilbert space $\mathcal{F}$, such that the *canonical commutation relations*,

$$[\Phi(f),\Phi(g)]=-i\sigma(f,g)\mathbf{1}_{\mathcal{F}},\quad \forall f,g\in D,$$

are fullfilled on a properly chosen dense subspace of $\mathcal{F}$. $\mathbf{1}_{\mathcal{F}}$ denotes the identity on $\mathcal{F}$. Note that we have set $\hbar=1$.

It is well known that this problem can be solved in the following way: Let $\mathrm{CCR}(D,\sigma)$ the CCR algebra over the symplectic space (D,σ),[14] which is by definition the up to C^* isomorphism uniquely determined C^* algebra generated by unitary elements $\{W(f):f\in D\}$, which fullfill the *canonical commutation relations* in their *Weyl form*,

$$W(f)W(g)=e^{i\sigma(f,g)}W(f+g),\quad \forall f,g\in D. \tag{1}$$

Take a regular state ψ on $\mathrm{CCR}(D,\sigma)$ and denote the corresponding Gelfand Naimark Segal (GNS) representation[15] by $(\mathcal{F}_\psi,\Pi_\psi,\xi_\psi)$. $\mathcal{F}_\psi$ is a complex Hilbert space, $\Pi_\psi:\mathrm{CCR}(D,\sigma)\to\mathcal{B}(\mathcal{F}_\psi)$ denotes the representation itself, which is a $*$ homomorphism from the C^* algebra $\mathrm{CCR}(D,\sigma)$ into the bounded linear operators $\mathcal{B}(\mathcal{F}_\psi)$ on $\mathcal{F}_\psi$, and $\xi_\psi\in\mathcal{F}_\psi$ is a cyclic vector, i.e., the vectors $\{\Pi_\psi(W(f)):f\in D\}$ span a dense subspace of $\mathcal{F}_\psi$. The GNS representation of $\mathrm{CCR}(D,\sigma)$ corresponding to a given state is unique up to unitary equivalence. The unitary operators $\{W_\psi(f):=\Pi_\psi(W(f)):f\in D\}$ are called *Weyl operators*. Since ψ is regular, by definition the map $\mathbb{R}\ni t\mapsto W_\psi(tf)$ defines for every $f\in D$ a strongly continuous group of unitary operators acting on $\mathcal{F}_\psi$. Starting from the relations (1), it follows that the unbounded, self-adjoint generators $\{B_\psi(f):=(d/dt)\,W_\psi(tf)|_{t=0}:f\in D\}$, the so called *field operators*, fullfill the commutation relations

$$[B_\psi(f),B_\psi(g)]=-2i\sigma(f,g)\mathbf{1}_{\mathcal{F}_\psi},\quad \forall f,g\in D,$$

on a properly chosen dense subspace of $\mathcal{F}_\psi$. Therefore the *quantized observables*,

$$\Phi_\psi(f):=\frac{1}{\sqrt{2}}B_\psi(f),\quad \forall f\in D,$$

solve the quantization problem formulated above.

The symplectic dynamics $(\tilde{U}_t)_t$ induces on the C^* algebra $\mathrm{CCR}(D,\sigma)$ the quasifree automorphism group $(\beta_t)_t$ determined by

$$\beta_t(W(f))=W(\tilde{U}_tf),\quad \forall f\in D,t\in\mathbb{R}. \tag{2}$$

The resulting time evolution of the quantized observables is

$$B_\psi(f)_t=B_\psi(\tilde{U}_tf),\quad \forall f\in D,t\in\mathbb{R}.$$

The GNS Hilbert space $\mathcal{F}_\psi$ and the quantized observables $\Phi_\psi(f)$ depend on the chosen state ψ. The representation generally used in quantum optics is the so called *Fock representation*: the GNS Hilbert space $\mathcal{F}_\psi$ is the symmetric Fock space $\mathcal{F}^+(\mathcal{K})$ over the so called *one particle space* $\mathcal{K}$, which is a properly chosen complex Hilbert space. (The examples considered in this paper are $\mathcal{K}=\mathbb{C}$ for a single field mode and $\mathcal{K}=L^2(\mathbb{R}_+)$ for the light beam propagating in one dimension of space.) The cyclic vector ξ_ψ is the *vacuum vector* $\Omega=1\oplus0\oplus0\cdots\in\mathcal{F}^+(\mathcal{K})$. The Fock representation is unitary equivalent to the GNS representation of the C^* algebra $\mathrm{CCR}(\mathcal{K})$ over the complex Hilbert space $\mathcal{K}$ induced by the state ψ_F with the generating functional

$$\psi_F(W(\tilde{f}))=e^{-(1/2)\|\tilde{f}\|^2_{\mathcal{K}}},\quad \forall \tilde{f}\in\mathcal{K}.$$

By definition the CCR algebra CCR($\mathcal{K}$) over a **complex** Hilbert space $\mathcal{K}$ is generated by the unitary elements $\{W(\tilde{f}):\tilde{f}\in\mathcal{K}\}$ fullfilling the relations

$$W(\tilde{f})W(\tilde{g})=e^{i\mathrm{Im}\langle\tilde{f},\tilde{g}\rangle}W(\tilde{f}+\tilde{g}),\quad \forall \tilde{f},\tilde{g}\in\mathcal{K}.$$

However starting from a given linear Hamiltonian system, the solution of the quantization problem leads to the CCR algebra CCR(D,σ) over the **real** symplectic space (D,σ). In the rest of this section we will be concerned with connecting the real quantization procedure described above to the complex picture generally used in quantum optics. The bridge will be a construction called *unitary embedding*.

Let (D,σ) a symplectic space and $\alpha:D\times D\to\mathbb{R}$ a positive bilinear form, such that

$$\sigma(f,g)^2\leqslant\alpha(f,f)\alpha(g,g),\quad \forall f,g\in D.$$

Then there is exactly one so called *quasifree state* ψ_α on CCR(D,σ), such that

$$\psi_\alpha(W(f))=e^{-(1/2)\alpha(f,f)},\quad \forall f\in D.$$

A *Fock state* is a quasifree state ψ_α on CCR(D,σ) with the additional property that D carries the structure of a complex linear space with complex scalar product $\langle\cdot,\cdot\rangle_c$, such that

$$\langle f,g\rangle_c=\alpha(f,g)+i\sigma(f,g),\quad \forall f,g\in D.$$

There is a common way to supply a real symplectic space (D,σ) with the structure of a complex scalar product space: Let $J:D\to D$ a linear map, such that $J^2=-\mathbf{1}$, $\sigma(Jf,f)\geqslant 0$, $\forall f\in D$, $\sigma(Jf,f)=0$ iff $f=0$ and $\sigma(Jf,Jg)=\sigma(f,g)$, $\forall f,g\in D$. Then J is called a *complex structure* on the symplectic space (D,σ). With the definitions

$$(x+iy)f:=xf+yJf,\quad \forall x,\ y\in\mathbb{R},f\in D,$$

and

$$\langle f,g\rangle_c:=\sigma(Jf,g)+i\sigma(f,g),\quad \forall f,g\in D,$$

D becomes a complex scalar product space, which will be denoted in the following by D_J. Note that for any complex structure J on (D,σ) the real scalar product,

$$\alpha_J:D\times D\to\mathbb{R}:(f,g)\mapsto\sigma(Jf,g),$$

uniquely determines a Fock state on CCR(D,σ). This state will be denoted in the following by ψ_J.

Theorem 1: *Let* $[\mathcal{H},\langle\cdot,\cdot\rangle,(U_t=e^{At})_t]$ *be a linear Hamiltonian system and* $[D,\sigma,(\tilde{U}_t)_t]$ *the corresponding symplectic system. Let* $A=-J|A|$ *the unique polar decomposition of the infinitesimal generator* A *into the positive operator* $|A|=\sqrt{A^*A}$ *and the partial isometry* $-J$. *Then* J *is a complex structure on* (D,σ) *and the Fock state* ψ_J *on* CCR(D,σ) *is the only Fock state on* (D,σ) *which is left invariant by the automorphism group* $(\beta_t)_t$ *defined in Eq. (2).*

Proof: From the fact that A is injective and skew adjoint one deduces that the partial isometry J is unitary with $J^*=J^{-1}=-J$ and that J is a complex structure. Because $A=-J|A|=-A^*=-|A|J$ it holds $JA=AJ$ or equivalently $\tilde{U}_tJ=J\tilde{U}_t$, $\forall t\in R$. From here it follows directly that

$$\alpha(\tilde{U}_t f,\tilde{U}_t g)=\sigma(J\tilde{U}_t f,\tilde{U}_t g)$$
$$=\sigma(\tilde{U}_t J f,\tilde{U}_t g)$$
$$=\sigma(Jf,g)=\alpha(f,g),\quad \forall f,g\in D,t\in\mathbb{R},$$

which proves the asserted time invariance of ψ_J.

For the proof of uniqueness assume the existence of another time invariant Fock state $\psi_{\tilde{J}}$ on CCR(D,σ) or equivalently of another complex structure $\tilde{J}$ on (D,σ) with $\tilde{J}A=A\tilde{J}$. Since A is injective and skew adjoint, ran$A$ is a dense subspace of $\mathcal{H}$. Consequently from

$$\langle\tilde{J}Af,\tilde{J}g\rangle=\langle A\tilde{J}f,\tilde{J}g\rangle=\sigma(\tilde{J}g,\tilde{J}g)=\sigma(f,g)$$
$$=\langle Af,g\rangle=\forall f,g\in\mathcal{H},$$

it follows that $\tilde{J}$ is isometric and therefore unitary, since $\tilde{J}^2=-\mathbf{1}$. Now it is obvious that $\tilde{J}^*=\tilde{J}^{-1}=-\tilde{J}$. Since $\tilde{J}A$ is easily shown to be a positive operator, since $\tilde{J}(-J)$ is unitary and since the polar decomposition is unique, from $\mathbf{1}(\tilde{J}A)=\tilde{J}(-J)|A|$ it follows $\mathbf{1}=\tilde{J}(-J)$ or $\tilde{J}=J$. ■

Definition 1: Let $[D,\sigma,(\tilde{U}_t)_t]$ *be the symplectic system corresponding to a given linear Hamiltonian system* $[\mathcal{H},\langle\cdot,\cdot\rangle,(U_t=e^{At})_t]$, *and let J be the unique complex structure defined in Theorem 1. A real linear map* $\mathcal{I}:D\to\mathcal{K}_0\subseteq\mathcal{K}$, *where* $\mathcal{K}_0$ *is a dense subspace of a complex Hilbert space* $\mathcal{K}$, *is called a* unitary embedding *of the given linear Hamiltonian system, if* $\mathcal{I}$ *is unitary as a map from the complex scalar product space* D_J to $\mathcal{K}_0$.

Given a unitary embedding $\mathcal{I}:D\to\mathcal{K}_0\subseteq\mathcal{K}$, the map $I_0:\mathrm{CCR}(D,\sigma)\ni W(f)\mapsto W(\mathcal{I}f)\in\mathrm{CCR}(\mathcal{K})$ extends to a C^* isomorphism $I:\mathrm{CCR}(D,\sigma)\to\mathrm{CCR}(\mathcal{K}_0)$. The Fock state ψ_J is mapped onto the state $\psi_J\circ I^{-1}$ with the generating functional,

$$\psi_J\circ I^{-1}(W(\tilde{f}))=\psi_J(W(\mathcal{I}^{-1}\tilde{f}))$$
$$=e^{-(1/2)\,\alpha_J(\mathcal{I}^{-1}\tilde{f},\mathcal{I}^{-1}\tilde{g})}$$
$$=e^{-(1/2)\,\|\tilde{f}\|^2_{\mathcal{K}}},\quad \forall\tilde{f}\in\mathcal{K}_0.$$

Therefore the GNS representation of CCR(σ,D) corresponding to the Fock state ψ_J and the GNS representation of CCR$(\mathcal{K}_0)$ corresponding to the state $\psi_J\circ I^{-1}$ are unitary equivalent. Since the latter can be realized in the usual manner on the symmetric Fock space $\mathcal{F}^+(\mathcal{K})$, the connection between the real quantization procedure and the complex picture used in quantum optics, we were looking for, is given by the unitary embedding $\mathcal{I}:D_J\to\mathcal{K}_0\subseteq\mathcal{K}$ under the condition that $\mathcal{I}$ is chosen such that $\mathcal{K}$ coincides with the complex one particle space of the considered system.

III. QUANTIZATION OF THE FREE ELECTROMAGNETIC FIELD

Specializing the Maxwell equations,

$$\mathrm{div}\,\vec{E}=0,\quad \mathrm{div}\,\vec{B}=0,$$

$$\mathrm{rot}\,\vec{E}=-\frac{\partial\vec{B}}{\partial t},\quad \mathrm{rot}\,\vec{B}=\frac{1}{c^2}\frac{\partial\vec{E}}{\partial t},$$

to the case of a linear in the y direction polarized light beam propagating into the x direction of a fixed coordinate system, leads to the *linear Hamiltonian system*,

$$[\mathcal{H}=L^2_r(\mathbb{R}),\langle\cdot,\cdot\rangle,(U_t)_t=(S_{-ct})_t]. \tag{3}$$

The *state space* $\mathcal{H}=L^2(\mathbb{R})$ is the Hilbert space of real valued quadratic integrable functions on the real axis with the energy scalar product $\langle f,g\rangle=\int_{-\infty}^{\infty}f(x)g(x)dx$. In the following we will often consider functions in the Schwartz space $\mathcal{S}_r:=\mathcal{S}_r(\mathbb{R})\subseteq\mathcal{H}$ of real valued rapidly decreasing functions. Since the magnetic induction vector $(0,0,B)^T$ is always orthogonal to the electric field vector $(0,E,0)^T$ and $cB(x,t)=E(x,t)$, $\forall x,t\in\mathbb{R}$, the state of the light beam is completely determined by the scalar electric field amplitude $E\in\mathcal{H}$.

We consider a cylindric volume of space with cross section F in the yz plane and infinite extension in the x direction. Given a function $E_0\in\mathcal{S}_r$ describing the electric field at time $t=0$, we define the corresponding *state* of the light beam as

$$f_0(x):=\sqrt{2\epsilon_0 F}E_0(x),\quad \forall x\in\mathbb{R}.$$

Then the electromagnetic energy contained in the considered volume can be written as

$$W_F(E_0)=\epsilon_0 F\int_{-\infty}^{\infty}E_0(x)^2dx=\frac{1}{2}\langle f_0,f_0\rangle.$$

The *dynamics* $(S_{-ct})_t$ is the right shift with the velocity of light c,

$$S_{-ct}(f)(x)=f(x-ct),\quad \forall x,\ t\in\mathbb{R},\ f\in\mathcal{S}_r.$$

The skew adjoint infinitesimal generator of the dynamics $A:\mathcal{D}(A)=H_r^1(\mathbb{R})\to\mathcal{H}:f\mapsto -cf'$, which is defined on the Sobolev space $H_r^1(\mathbb{R})$ of real valued absolutely continuous functions with a quadratic integrable derivative, is obviously injective, since constant functions are not in $L_r^2(\mathbb{R})$. In the following we use the notation $A=-c\,(d/dx)$.

The *symplectic system* corresponding to the linear Hamiltonian system (3) is

$$[D=\mathcal{D}(A)=H_r^1(\mathbb{R}),\sigma,(S_{ct})_t],\tag{4}$$

with the symplectic form

$$\sigma(f,g)=\int_{-\infty}^{\infty}(-cf'(x))g(x)dx,\quad \forall f,g\in D,$$

and the left shift $(S_{ct})_t$.

Since the polar decomposition of the generator $A=-c\,(d/dx)$ is obvious in the Fourier transformed picture, we will construct the complex structure J determining the time invariant Fock state of the light beam with the help of Fourier transformation,

$$\hat{f}(k):=FT(f)(k):=\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty}f(x)e^{-ikx}dx,\quad \forall f\in\mathcal{S}_r.$$

Proposition 1: The unique complex structure J determining the time invariant Fock state ψ_J of the linear Hamiltonian system (3) according to Theorem 1 is

$$J=FT^{-1}\circ M_{i\,\mathrm{sign}(k)}\circ FT,$$

where $M_{i\mathrm{sign}(k)}$ denotes pointwise multiplication with

$$i\mathrm{sign}(k)=\begin{cases}+i, & \text{for } k>=0,\\ -i, & \text{for } k<0.\end{cases}$$

Proof: Since the multiplication operator $M_{c|k|}$ is obviously positive and the polar decomposition is unique, the statement follows immediately from

$$\widehat{Af}(k)=(-\widehat{cf'})(k)=-ick\hat{f}(k)=-(i\mathrm{sign}(k))(c|k|)\hat{f}(k),\quad \forall k\in\mathbb{R},$$

or in formal notation,

$$FT\circ A=FT\circ(-J|A|)=(-M_{i\mathrm{sign}(k)}M_{c|k|})\circ FT. \qquad \blacksquare$$

Note that the Fourier transformation maps real valued elements $f\in\mathcal{H}$ onto symmetric complex elements $\hat{f}\in L^2_{\mathrm{sym}}(\mathbb{R}):=\{h\in L^2(\mathbb{R}):h(-k)=\overline{h(k)}a.e.\}$ and that the multiplication operator $M_{i\mathrm{sign}(k)}$ leaves the subspace $L^2_{\mathrm{sym}}(\mathbb{R})\subseteq L^2(\mathbb{R})$ invariant.

Next we will construct the unitary embedding $\mathcal{I}$ that connects the formalism described above to the Fock space formalism. The complex one particle space used in quantum optics for the description of a one dimensional quantized light beam is the complex Hilbert space $\mathcal{K}:=L^2(\mathbb{R}_+)$ of quadratic integrable functions on the positive real axis $\mathbb{R}_+=[0,\infty[$, referring to the continuum of positive frequencies contained in the light beam.

Proposition 2: Let $\mathcal{K}_0:=\{h\in\mathcal{K}:\int_0^\infty k|h(k)|^2dk<\infty\}\subseteq\mathcal{K}$ *and define the orthogonal projection* $P_{[0,\infty[}:L^2(\mathbb{R})\to\mathcal{K}:f\mapsto\chi_{[0,\infty[}f$, *where* $\chi_{[0,\infty[}$ *denotes the characteristic function of the interval* $[0,\infty[$. *Then the real linear map,*

$$\mathcal{I}:D\to\mathcal{K}_0:f\mapsto -i\sqrt{2}(M_{\sqrt{ck}}\circ P_{[0,\infty[}(\hat{f})), \tag{5}$$

is a unitary embedding of the linear Hamiltonian system (3).

Proof: A direct computation shows that $\mathcal{I}$ is a complex linear map from the complex scalar product space D_J into the complex Hilbert space $\mathcal{K}$. It is isometric, because

$$\begin{aligned}\langle\mathcal{I}f,\mathcal{I}f\rangle_{\mathcal{K}}&=2\int_0^\infty ck|\hat{f}(k)|^2dk\\&=\int_{-\infty}^\infty c|k||\hat{f}(k)|^2dk\\&=\langle|A|f,f\rangle=\alpha_J(f,f),\quad\forall f\in D_J.\end{aligned}$$

Furthermore $\mathcal{I}$ is a surjective map from D_J onto $\mathcal{K}_0$, since

$$\begin{aligned}&f\in D_J\subseteq\mathcal{H}\Leftrightarrow f\in\mathcal{H}\text{ and }f\in H^1(\mathbb{R})\\&\Leftrightarrow\hat{f}\in L^2_{\mathrm{sym}}(\mathbb{R})\text{ and}\int_{-\infty}^\infty k^2|\hat{f}(k)|^2dk=2\int_0^\infty k|\sqrt{k}\hat{f}(k)|^2dk<\infty\\&\Leftrightarrow\mathcal{I}f\in\mathcal{K}_0\subseteq\mathcal{K}.\end{aligned}\qquad\blacksquare$$

With the help of this unitary embedding the quantized electric field operator as it is found in quantum optics literature,[16]

$$\mathbf{E}(x,t)=\frac{i\sqrt{c}}{\sqrt{4\pi\epsilon_0 F}}\int_0^\infty(e^{ikx}e^{-i\omega t}a_k-e^{-ikx}e^{i\omega t}a_k^+)\sqrt{k}dk,$$

can be connected to the mathematical quantization approach described above as follows: The measurement of the classical electric field amplitude $E(x,t)$ at the point $x\in\mathbb{R}$ at time $t\in\mathbb{R}$ is described in a distributional sense by the linear observable $\varphi((1/\sqrt{2\epsilon_0 F})\,\delta_{x-ct})$, where δ_{x-ct} denotes the delta distribution at the point $x-ct\in\mathbb{R}$. The corresponding quantized observable represented on the Fock space $\mathcal{F}_+(L^2(\mathbb{R}_+))$ is formally given by

$$\Phi_{\mathcal{F}}\left(\mathcal{I}\left(\frac{1}{\sqrt{2\epsilon_0 F}}\delta_{x-ct}\right)\right) = -\frac{\sqrt{c}}{\sqrt{2\pi\epsilon_0 F}}\Phi_{\mathcal{F}}(i\sqrt{k}e^{-ik(x-ct)})$$

$$= -\frac{i\sqrt{c}}{\sqrt{4\pi\epsilon_0 F}}\int_0^\infty (e^{ikx}e^{-i\omega t}a_k - e^{-ikx}e^{i\omega t}a_k^+)\sqrt{k}dk$$

$$= \mathbf{E}(x,t),$$

with $w=ck$, $\Phi_{\mathcal{F}}(\tilde{f}) = (1/\sqrt{2})(a(\tilde{f}) + a^+(\tilde{f}))$, $\forall \tilde{f} \in \mathcal{K}$ and $a_k := a(\delta_k)$, $a_k^+ := a^+(\delta_k)$, where a_k and a_k^+ denote the annihilation and creation operator of a photon in the field mode k. Note that this observable does not exist in a strict sense, because classical linear observables $\varphi(f)$ and their quantized couterparts $\Phi_{\mathcal{F}}(\mathcal{I}f)$ are only defined for test functions $f \in D$. But it can be approximated by properly defined quantized observables.

IV. STOCHASTIC STATES OF THE QUANTIZED ELECTROMAGNETIC FIELD

Definition 2: Let ψ be a regular state on the CCR algebra $\mathrm{CCR}(\mathcal{K}=L^2(\mathbb{R}_+))$ *of the quantized electromagnetic field. The familiy of quantized observables* $\Lambda_\psi := \{\Phi_\psi(\tilde{f}) : \tilde{f} \in \mathcal{I}\mathcal{S}_r \subseteq \mathcal{K}\}$ *is called the* quasifree quantum stochastic process given by the state ψ.

Λ_ψ is a family of self-adjoint operators acting on the GNS Hilbert space $\mathcal{F}_\psi$. As usual the *distribution* μ_ψ of the quantized observable $\Phi_\psi(\tilde{f})$, which is now interpreted as a quantum random variable, is defined as the spectral measure of the self-adjoint operator $\Phi_\psi(\tilde{f})$ in the state ψ.

Next we will introduce a class of quantum states for which Λ_ψ has a classical analog.

Definition 3: A state ψ on $CCR(\mathcal{K})$ is called a stochastic state *if its generating functional,*

$$G_\psi : \mathcal{K} \to \mathbb{C} : \tilde{f} \mapsto G_\psi(\tilde{f}) := \psi(W(\tilde{f})),$$

is continuous and the kernel,

$$k : \mathcal{K} \times \mathcal{K} \to \mathbb{C} : (\tilde{g}, \tilde{f}) \mapsto G_\psi(\tilde{f} - \tilde{g}),$$

is positive definite, i.e., $\Sigma_{i,j=1}^n \overline{\lambda_i}\lambda_j k(\tilde{f}_i, \tilde{f}_j) \geqslant 0$, $\forall n \in \mathbb{N}$ *and for arbitrary elements* $\lambda_1, \ldots, \lambda_n \in \mathbb{C}$, $\tilde{f}_1, \ldots, \tilde{f}_n \in \mathcal{K}$.

For the special case $\mathcal{K}=\mathbb{C}$ of a single field mode the definition of stochastic states reduces to the definition of so called η-positive states with $\eta=0$ and $\eta=1$ given in Ref. 12. As it is shown there, these states are one to one with the states having a positive Wigner function.

Starting from a stochastic state ψ of the electromagnetic field we will associate in the following a classical analog to the quantum stochastic process Λ_ψ. Let $\mathcal{S}_r \subseteq \mathcal{H} \subseteq \mathcal{S}_r'$ be the real countable nuclear Hilbert space introduced in Ref. 10, where $\mathcal{S}_r$ denotes the space of real valued Schwartz functions, $\mathcal{H}=L_r^2(\mathbb{R})$ denotes the real state space of the linear Hamiltonian system describing the considered light beam and $\mathcal{S}_r'$ denotes the tempered distributions.

Proposition 3: Let G_ψ be the generating functional of a stochastic state ψ of the quantized electromagnetic field on $CCR(\mathcal{K}=L^2(\mathbb{R}_+))$ and let $\mathcal{I}: D \to \mathcal{K}_0$ the unitary embedding defined in Eq. (5). Then the functional,

$$C_\psi : \mathcal{S}_r \to \mathbb{R} : f \mapsto G_\psi\left(\frac{1}{\sqrt{2}}\mathcal{I}f\right), \tag{6}$$

is a characteristic functional, i.e., it is continuous and positive definite with $C_\psi(0)=1$.

Proof: Since $\mathcal{S}_r \subseteq D$ and $\mathcal{I}: D \to \mathcal{K}_0$ is isometric and therefore continuous with respect to the scalar product $\alpha_J(\cdot,\cdot) = \langle |A| \cdot, \cdot \rangle$ on $D \subseteq \mathcal{H}$ and since G_ψ is continuous as a map from $\mathcal{K}_0$ to $\mathbb{C}$, C_ψ is continuous with respect to the scalar product α_J. With $|A| = |c\,(d/dx)|$ it follows from the

definition of the topology on $\mathcal{S}_r$ that C_ψ is continuous with respect to this topology as well (see Ref. 10). The positive definiteness of C_ψ is shown by a direct computation starting from the positive definiteness of G_ψ. $C_\psi(0)=G_\psi(0)=1$ is obvious. ■

According to the theorem of Bochner and Minlos (see Ref. 10) for any characteristic functional C on $\mathcal{S}_r$ there exists exactly one probability measure ν on $(\mathcal{S}_r',\Sigma)$, where Σ denotes a suitable constructed σ algebra over $\mathcal{S}_r'$, such that

$$C(f)=\int_{\mathcal{S}_r'} e^{i\langle f,x\rangle} d\nu(x), \quad \forall f\in\mathcal{S}_r.$$

The random variables,

$$X_f:(\mathcal{S}_r',\Sigma,d\nu)\to\mathbb{R}:x\mapsto\langle f,x\rangle,$$

where $\langle\cdot,\cdot\rangle$ denotes the canonical bilinear form connecting $\mathcal{S}_r$ with its dual $\mathcal{S}_r'$, build the *generalized classical stochastic process* $\{X_f:f\in\mathcal{S}_r\}$ induced by the characteristic functional C.

Starting from a stochastic state ψ of the quantized electromagnetic field the characteristic functional defined in Eq. (6) induces a corresponding generalized classical stochastic process $Y_\psi:=\{X_f:f\in\mathcal{S}_r\}$. The following proposition shows that Y_ψ can be seen as a classical analog of the quasifree quantum stochastic process Λ_ψ.

Proposition 4: Let Λ_ψ the quasifree quantum stochastic process of the quantized electromagnetic field given by a stochastic state ψ and let Y_ψ be the corresponding generalized classical stochastic process. Then for any $f\in\mathcal{S}_r$ the distribution ν_f of the generalized classical random variable $X_f\in Y_\psi$ and the distribution μ_f of the quantized random variable $\Phi_\psi(\mathcal{I}f)\in\Lambda_\psi$ coincide.

Proof: For any $t\in\mathbb{R}$, $f\in\mathcal{S}_r$ it holds on one hand side,

$$C(tf)=\int_{\mathcal{S}_r'} e^{it<f,x>} d\nu(x)=\int_{\mathcal{S}_r'} e^{itX_f(x)} d\nu(x)$$

$$=\int_{\mathbb{R}} e^{ity} d\nu_f(y),$$

and on the other hand side,

$$C(tf)=G_\psi\left(\frac{1}{\sqrt{2}}\mathcal{I}tf\right)=\psi\left(W\left(\frac{1}{\sqrt{2}}\mathcal{I}tf\right)\right)$$

$$=\psi(e^{itB_\psi((1/\sqrt{2})\mathcal{I}f)})$$

$$=\psi(e^{it\Phi_\psi(\mathcal{I}f)})$$

$$=\int_{\mathbb{R}} e^{ity}\, d\mu_f(y).$$

The assertion follows from the uniqueness of Fourier transformation. ■

V. A STOCHASITICITY CRITERION

Since it can be difficult to prove the positive definiteness of the characteristic functional directly, there is a need for a stochasiticity criterion which is easier to check. Such a criterion will be provideed in the following.

Lemma 1: Let $\mathcal{K}$ be a complex Hilbert space. Then there exist real orthogonal projections p_1, $p_2:\mathcal{K}\to\mathcal{K}$ onto closed real subspaces $\mathcal{K}_1:=p_1\mathcal{K},\mathcal{K}_2:=p_2\mathcal{K}$ such that $p_1+p_2=\mathbf{1}\mathcal{K}$, $\mathcal{K}_2=i\mathcal{K}_1$,

$\mathrm{Re}\langle p_1\tilde{f},p_2\tilde{f}\rangle_{\mathcal{K}}=0$ *and* $\mathrm{Im}\langle p_1\tilde{f},p_1\tilde{g}\rangle_{\mathcal{K}}=\mathrm{Im}\langle p_2\tilde{f},p_2\tilde{g}\rangle_{\mathcal{K}}=0,\forall\tilde{f},\tilde{g}\in\mathcal{K}$. ($p_1,p_2$ *being real projections means that they are real linear, idempotent and self-adjoint with respect to the real scalar product* $\mathrm{Re}\langle\cdot,\cdot\rangle_{\mathcal{K}}$.)

Proof: Take an arbitrary orthogonal basis $\{\tilde{h}_k:k\in\mathbb{N}\}\subseteq\mathcal{K}$ and define for every $\tilde{f}=\Sigma_k\alpha_k\tilde{h}_k\in\mathcal{K}$,

$$p_1\tilde{f}:=\sum_k \mathrm{Re}(\alpha_k)\tilde{h}_k,\quad p_2\tilde{f}:=\sum_k \mathrm{Im}(\alpha_k)\tilde{h}_k. \qquad \blacksquare$$

Definition 4: Under the conditions described above, the decomposition,

$$\tilde{f}=p_1\tilde{f}+p_2\tilde{f}:=\tilde{f}_1+\tilde{f}_2,\quad \forall\tilde{f}\in\mathcal{K},$$

is called a generalized decomposition into real and imaginary parts.

Theorem 2: *A state ψ on $CCR(\mathcal{K})$ is a stochastic state, if its generating functional G_ψ is continuous and if there is at least one generalized decomposition $\tilde{f}=\tilde{f}_1+\tilde{f}_2$, $\forall\tilde{f}\in\mathcal{K}$ into real and imaginary parts, such that G_ψ fullfills the factorization condition*

$$G_\psi(\tilde{f})=G_\psi(\tilde{f}_1)G_\psi(\tilde{f}_2),\quad \forall\tilde{f}\in\mathcal{K}.$$

Proof: In the GNS representation $(\Pi_\psi,\mathcal{F}_\psi,\xi_\psi)$ the vectors,

$$\{\gamma_{\tilde{f}}:=W_\psi(\tilde{f})\xi_\psi:\tilde{f}\in\mathcal{K}\}\subseteq\mathcal{F}_\psi,$$

span a dense subspace of $\mathcal{F}_\psi$ and fullfill the condition

$$\langle\gamma_{\tilde{f}},\gamma_{\tilde{g}}\rangle=G_\psi(\tilde{f}-\tilde{g})e^{i\,\mathrm{Im}\langle\tilde{f},\tilde{g}\rangle},\quad \forall\tilde{f},\tilde{g}\in\mathcal{K}.$$

(See Ref. 14.) In other words $(\mathcal{F}_\psi,\gamma_{\tilde{f}})$ provides a Kolmogorov decomposition[17] of the positive definite kernel,

$$k:\mathcal{K}\times\mathcal{K}\to\mathbb{C}:(\tilde{g},\tilde{f})\mapsto G_\psi(\tilde{f}-\tilde{g})e^{i\,\mathrm{Im}\langle\tilde{f},\tilde{g}\rangle}.$$

For every $\tilde{f}=\tilde{f}_1+\tilde{f}_2\in\mathcal{K}$ define the vector

$$\eta_{\tilde{f}}:=\gamma_{\tilde{f}_1}\otimes\gamma_{\tilde{f}_2}\in\mathcal{F}_\psi\otimes\mathcal{F}_\psi,$$

in the Hilbert space tensor product $\mathcal{F}_\psi\otimes\mathcal{F}_\psi$ and let $\mathcal{G}$ be the complex Hilbert space spanned by the vectors $\{\eta_{\tilde{f}}:\tilde{f}\in\mathcal{K}\}$. Then $(\mathcal{G},\eta_{\tilde{f}})$ provides a Kolmogorov decomposition for the kernel,

$$k_0:\mathcal{K}\times\mathcal{K}\to\mathbb{C}:(\tilde{g},\tilde{f})\mapsto G_\psi(\tilde{f}-\tilde{g}),$$

since it holds

$$\begin{aligned}
\langle\eta_{\tilde{f}},\eta_{\tilde{g}}\rangle&=\langle\gamma_{\tilde{f}_1}\otimes\gamma_{\tilde{f}_2},\gamma_{\tilde{g}_1}\otimes\gamma_{\tilde{g}_2}\rangle\\
&=\langle\gamma_{\tilde{f}_1},\gamma_{\tilde{g}_1}\rangle\langle\gamma_{\tilde{f}_2},\gamma_{\tilde{g}_2}\rangle\\
&=G_\psi(\tilde{f}_1-\tilde{g}_1)e^{i\,\mathrm{Im}\langle\tilde{f}_1,\tilde{g}_1\rangle}G_\psi(\tilde{f}_2-\tilde{g}_2)e^{i\,\mathrm{Im}\langle\tilde{f}_2,\tilde{g}_2\rangle}\\
&=G_\psi(\tilde{f}_1-\tilde{g}_1)G_\psi(\tilde{f}_2-\tilde{g}_2)\\
&=G_\psi(p_1(\tilde{f}-\tilde{g}))G_\psi(p_2(\tilde{f}-\tilde{g}))\\
&=G_\psi(\tilde{f}-\tilde{g}),\quad \forall\tilde{f},\tilde{g}\in\mathcal{K}.
\end{aligned}$$

Because a kernel has a Kolmogorov decomposition if and only if it is positive definite, the proof is complete. ■

VI. THE ELECTROMAGNETIC FIELD AT $T=0$

At $T=0$ the quantized electromagnetic field is described by the Fock state ψ_F on CCR($\mathcal{K}=L^2(\mathbb{R})$) with the generating functional

$$G_{\mathrm{F}}(\tilde{f})=e^{-(1/2)\|\tilde{f}\|_{\mathcal{K}}^2}, \quad \forall \tilde{f}\in\mathcal{K}.$$

Since for any generalized decomposition into real and imaginary part it holds that

$$\begin{aligned} G_{\mathrm{F}}(\tilde{f}_1+\tilde{f}_2)&=e^{-(1/2)\|\tilde{f}_1+\tilde{f}_2\|_{\mathcal{K}}^2}\\ &=e^{-(1/2)\mathrm{Re}\langle \tilde{f}_1+\tilde{f}_2,\tilde{f}_1+\tilde{f}_2\rangle_{\mathcal{K}}}\\ &=e^{-(1/2)(\langle \tilde{f}_1,\tilde{f}_1\rangle_{\mathcal{K}}+\langle \tilde{f}_2,\tilde{f}_2\rangle_{\mathcal{K}})}=G_{\mathrm{F}}(\tilde{f}_1)G_F(\tilde{f}_2), \quad \forall \tilde{f}\in\mathcal{K}, \end{aligned}$$

ψ_{F} is a stochastic state. Consequently the quasifree quantum stochastic process $\Lambda_{\mathrm{F}}=\{\Phi_{\mathrm{F}}(\tilde{f}):\tilde{f}\in\mathcal{I}\mathcal{S}_r\}$ given by ψ_{F} has a classical analog $Y_f=\{X_f:f\in\mathcal{S}_r\}$. This analog will be constructed in the following.

The quantum observables $\Phi_{\mathrm{F}}(\tilde{f})$ act on the symmetric Fock space $\mathcal{F}_+(\mathcal{K})$. Y_{F} is uniquely determined by its characteristic functional,

$$C_{\mathrm{F}}(f)=G_{\mathrm{F}}\left(\frac{1}{\sqrt{2}}\mathcal{I}f\right)=e^{-(1/4)\|\mathcal{I}f\|_{\mathcal{K}}^2}, \quad \forall f\in\mathcal{S}_r.$$

Since the unitary embedding $\mathcal{I}$ is isometric with respect to the scalar product $\langle |A|\cdot,\cdot\rangle$ on $\mathcal{S}_r\subseteq\mathcal{H}$, it follows that

$$C_{\mathrm{F}}(f)=e^{-(1/4)\langle |A|f,f\rangle}, \quad \text{with } A=-c\frac{d}{dx}, \ \forall f\in\mathcal{S}_r.$$

The characteristic functional C_{F} determines a zero mean Gaussian generalized stochastic process with covariance,

$$\mathrm{cov}(X_f,X_g)=\int_{\mathcal{S}_r'}X_f(x)X_g(x)d\mu_{\mathrm{F}}(x)=\langle |A|f,g\rangle, \quad \forall f,g\in\mathcal{S}_r$$

(see Ref. 10).

Obviously Y_{F} is not a white but a colored noise. Its spectrum is given by the linearly increasing spectrum of the positive operator $|A|=FT^{-1}\circ M_{|ck|}\circ FT$. This result provides a new argument for an assumption of Gardiner, that the spectrum of the electromagnetic field at $T=0$, which cannot be observed by photon counting, might be linearly increasing. (Received 27 September 2000; accepted for publication 28 November 2000)

This paper describes an integrable Yang–Mills–Higgs system on (2+1)-dimensional de Sitter space–time. It is the curved-space–time analog of the Bogomolnyi equations for monopoles on $\mathbf{R}^3$. A number of solutions, of various types, are constructed. © *2001 American Institute of Physics.*

I. INTRODUCTION

The background to this paper is the question of the existence of integrable nonlinear partial differential equations (and more specifically of soliton equations) in curved space–times. For a given (fixed) space–time M, are there integrable systems which live on M (i.e., are covariantly coupled to its geometry)? In general, this places severe restrictions both on M and on the equations that are coupled to it. In this paper, we concentrate on one example, namely an integrable Yang–Mills–Higgs system on (2+1)-dimensional de Sitter space–time.

In effect, this generalizes examples which have long been known. Consider the chiral equation $g^{\mu\nu}\partial_\mu(U^{-1}\partial_\nu U)=0$, where $U(x^\mu)$ takes values in a Lie group, and where $g_{\mu\nu}$ is the metric of M. This system is integrable if M is (1+1)-dimensional (this being related to conformal invariance). In higher-dimensional flat space–times, the chiral equation is not integrable;[1] and this is probably also the case for curved space-times of dimension greater than two. But if one modifies the equation by adding a torsion term, then integrability is possible;[1,2] in particular, there is an integrable (modified) chiral equation in flat three-dimensional space–time $\mathbf{R}^{2+1}$. The system is equivalent to one involving a gauge field (Yang–Mills field) coupled to a Higgs field, and may be seen to arise from the self-dual Yang–Mills equations in $\mathbf{R}^{2+2}$, by dimensional reduction. The soliton solutions can be understood in terms of algebraic geometry, and the soliton dynamics is (in general) nontrivial.[3–10]

Other ways of reducing the self-dual Yang–Mills equations in $\mathbf{R}^{2+2}$ can lead to integrable Yang–Mills–Higgs systems in curved (2+1)-dimensional space–times. These are the Lorentzian analog of hyperbolic monopoles, which live on (positive-definite) hyperbolic 3-space. The space–time has to have constant curvature; and so there are two Lorentzian possibilities, namely anti-de Sitter and de Sitter space–time. Some preliminary results on the anti-de Sitter case have appeared previously;[11] the present paper deals with the de Sitter case. In particular, we construct various explicit solutions. One new feature that appears here is associated with the nontrivial topology of de Sitter space.

II. (2+1)-DIMENSIONAL DE SITTER SPACE–TIME

(2+1)-dimensional de Sitter space–time M is the manifold $\mathbf{R}\times S^2$ equipped with the metric

$$ds^2=g_{\mu\nu}\,dx^\mu\,dx^\nu=\cosh^2 T(d\theta^2+\sin^2\theta\,d\varphi^2)-dT^2. \tag{1}$$

Here $T\in\mathbf{R}$ is a time coordinate, and (θ,φ) are polar coordinates on the spatial sphere. It is a space of constant curvature, with scalar curvature $R=6$ (conventions are those of Ref. 12).

There is a relation between this space–time M and flat (2+2)-dimensional space $\mathbf{R}^{2+2}$, and we shall use this to obtain equations on M from equations on $\mathbf{R}^{2+2}$. The relation is as follows. Let u and w be complex coordinates on $\mathbf{R}^{2+2}$, so that its metric is $du\,d\overline{u}-dw\,d\overline{w}$. First, define new coordinates $(\theta,\varphi,\tilde{\theta},\tilde{\varphi})$ by

$$u=\frac{(\sin\theta)\mathrm{e}^{-i\varphi}}{(\cos\theta+\cos\tilde{\theta})},\quad w=\frac{(\sin\tilde{\theta})\mathrm{e}^{i\tilde{\varphi}}}{(\cos\theta+\cos\tilde{\theta})}. \tag{2}$$

Then

$$du\,d\overline{u}-dw\,d\overline{w}=2(\cos\theta+\cos\tilde{\theta})^{-1}\,ds^2_{\tilde{M}}, \tag{3}$$

where

$$ds^2_{\tilde{M}}=(d\theta^2+\sin^2\theta\,d\varphi^2)-(d\tilde{\theta}^2+\sin^2\tilde{\theta}\,d\tilde{\varphi}^2). \tag{4}$$

In other words, R^{2+2} is conformal to part of the product $\tilde{M}=S^2\times S^2$; we interpret (θ,φ) as polar coordinates on the first sphere of $\tilde{M}$, and $(\tilde{\theta},\tilde{\varphi})$ on the second. The 4-space $\tilde{M}$ is conformally flat and has vanishing scalar curvature; it is a double cover of a conformal compactification[13,14] of $\mathbf{R}^{2+2}$.

The next step is to reduce to 2+1 dimensions: this is done by factoring out by the Killing vector $\partial/\partial\tilde{\varphi}$, i.e., by a rotation of the second sphere. First we remove $\tilde{\theta}=0$ and $\tilde{\theta}=\pi$, which are fixed points of the rotation. On the complement of these fixed points, we can write

$$ds^2_{\tilde{M}}=\sin^2\tilde{\theta}\ [\mathrm{cosec}^2\tilde{\theta}(d\theta^2+\sin^2\theta\,d\varphi^2-d\tilde{\theta}^2)-d\tilde{\varphi}^2]. \tag{5}$$

So $\tilde{M}$ (minus the fixed points) is conformal to the product of S^1 and a space with topology $\mathbf{R}\times S^2$ and metric

$$ds^2=\mathrm{cosec}^2\tilde{\theta}(d\theta^2+\sin^2\theta\,d\varphi^2-d\tilde{\theta}^2). \tag{6}$$

This is exactly (2+1)-dimensional de Sitter space–time (1), where the coordinates T and $\tilde{\theta}$ are related by $\tanh T=-\cos\tilde{\theta}$.

III. INTEGRABLE EQUATIONS ON *M*

In view of the conformal relation between $\tilde{M}$ and M, we may obtain integrable equations on M by reducing conformally-invariant integrable equations on $\tilde{M}$ (or $\mathbf{R}^{2+2}$). The simplest conformally-invariant equation on $\tilde{M}$ is the conformally-invariant wave equation. Bearing in mind the absence of scalar curvature, this has the form

$$\Delta\chi-\tilde{\Delta}\chi=0, \tag{7}$$

where Δ and $\tilde{\Delta}$ are the Laplacians on the two spheres. The $\tilde{\varphi}$-independent solutions of (7) correspond to solutions of the conformally-invariant wave equation on M, namely,

$$g^{\mu\nu}\nabla_\mu\nabla_\nu\Psi-\Psi=0, \tag{8}$$

where χ and Ψ are related by the relevant conformal factor, $\Psi=(\mathrm{sech}\,T)\chi$. Solutions can be obtained (in terms of Legendre polynomials and spherical harmonics) by separating variables or

by twistor methods.[13] For example, the simplest case $\chi=1$ (constant) gives $\Psi=\operatorname{sech} T$, i.e., a solution of (8) which is spatially constant. Using $l=1$ spherical harmonics yields the examples $\Psi=\operatorname{sech} T\tanh T\cos\theta$, $\Psi=\operatorname{sech} T\tanh T\sin\theta\cos\varphi$, etc.

Another example, and the one which we concentrate on in this article, is that of the self-dual Yang–Mills equations (these are integrable on any conformally-flat 4-space, and so in particular on $\tilde{M}$). When we reduce to the (2+1)-dimensional space–time M, the self-dual Yang–Mills field becomes a Yang–Mills–Higgs system (Φ,A_μ) satisfying the Bogomolny-type equations,

$$D_\alpha\Phi=\tfrac{1}{2}\eta_{\alpha\beta\gamma}F^{\beta\gamma}. \tag{9}$$

The Higgs field Φ (taking values in the Lie algebra G of the gauge group) is identified with the $\tilde{\varphi}$-component $A_{\tilde{\varphi}}$ of the gauge potential, with the remaining three components A_μ becoming a gauge potential on M. As usual, D_α denotes the covariant derivative $D_\alpha\Phi=\partial_\alpha\Phi+[A_\alpha,\Phi]$, $F_{\mu\nu}$ is the gauge field $[D_\mu,D_\nu]$, and $\eta_{\alpha\beta\gamma}=[-\det(g_{\mu\nu})]^{1/2}\varepsilon_{\alpha\beta\gamma}$ is the volume 3-form on M. In terms of the polar coordinates $(\theta,\tilde{\theta},\varphi)$, Eq. (9) is

$$\begin{aligned} D_{\tilde{\theta}}\Phi&=(\sin\tilde{\theta}\ /\sin\theta)F_{\theta\varphi},\\ D_\theta\Phi&=(\sin\tilde{\theta}\ /\sin\theta)F_{\tilde{\theta}\varphi},\\ D_\varphi\Phi&=(\sin\tilde{\theta}\sin\theta)F_{\theta\tilde{\theta}}. \end{aligned} \tag{10}$$

So (9), or equivalently (10), form a set of covariant integrable partial differential equations on M. They are linear if the gauge algebra G is abelian, but otherwise are nonlinear. In the remaining sections, we shall construct and examine some solutions of (10), for gauge algebras u(1) and su(2).

IV. A U(1) EXAMPLE

For gauge algebra $G=u(1)$, Eqs. (10) reduce to

$$\partial_\alpha\Phi=\tfrac{1}{2}\eta_{\alpha\beta\gamma}F^{\beta\gamma}, \tag{11}$$

where $F_{\mu\nu}=\partial_\mu A_\nu-\partial_\nu A_\mu$. Note that from (11) it follows immediately that $g^{\mu\nu}\nabla_\mu\nabla_\nu\Phi=0$; so this case is related to, but different from, that of the wave equation (8) discussed previously. Since space is a sphere S^2, there can be nontrivial topology: U(1) gauge fields over S^2 are classified topologically by the integer

$$k=\frac{-\mathrm{i}}{2\pi}\int_\Sigma F_{\mu\nu}dx^\mu\wedge dx^\nu, \tag{12}$$

where Σ is a space section (spacelike surface with topology S^2).

An example of a topologically nontrivial solution of (11) is

$$\Phi=\tfrac{1}{2}\mathrm{i}k(\cos\tilde{\theta}-1),\quad A_\varphi=\tfrac{1}{2}\mathrm{i}k(\cos\theta-1),\quad A_\theta=0=A_{\tilde{\theta}}.$$

For smoothness, we need $A_\varphi=0$ at $\theta=0,\pi$; so the above gauge potential has a singularity at $\theta=\pi$. This is the familiar ''Dirac-string'' singularity, and is removable: the gauge-transformed potential

$$A_\varphi+\exp(-\mathrm{i}k\varphi)\partial_\varphi\exp(\mathrm{i}k\varphi)=\tfrac{1}{2}\mathrm{i}k(\cos\theta+1)$$

is smooth near $\theta=\pi$. In other words, this Maxwell–Higgs system is smooth throughout M. The apparent singularities are a consequence of the fact that the gauge field is topologically nontrivial:

its magnetic charge equals k. Furthermore, it is spatially-homogeneous: note in particular that Φ depends only on the time coordinate $\tilde{\theta}$, and that the gauge 2-form [the integrand of (12)] is a (time-dependent) multiple of the spatial area element $\sin\theta\, d\theta\wedge d\varphi$.

V. SPATIALLY-HOMOGENEOUS SU(2) SOLUTIONS

Spatially-homogeneous SU(2) fields may be characterized as follows. Temporarily, think of the spatial 2-sphere as the unit sphere in $\mathbf{R}^3$, with coordinates $x^j=(x^1,x^2,x^3)$. Take the Higgs field and gauge potential to have the form

$$\Phi = \mathrm{i}g(\tilde{\theta})x^j\sigma_j\,,$$

$$A_j = \mathrm{i}f(\tilde{\theta})\varepsilon_{jkl}x^l\sigma^k, \tag{13}$$

$$A_{\tilde{\theta}}=0, \quad \text{(a gauge choice)},$$

where σ_j are the the Pauli matrices, and f and g are two scalar functions of $\tilde{\theta}$ only. This implements SO(3) symmetry: recall, for example, that the spherically-symmetric 1-monopole in $\mathbf{R}^3$ has the ''hedgehog'' form (13). The components A_θ and A_φ are obtained from A_j in the obvious way, by transforming to polar coordinates. Although Φ and A_μ depend on the spatial variables (θ,φ), the effect of a spatial rotation is to make a gauge transformation; and gauge-invariant quantities such as $-\mathrm{tr}\,\Phi^2=2g^2$ depend only on $\tilde{\theta}$.

Substituting (13) into (10) gives the pair of ordinary differential equations

$$g'=2f(1-f)\sin\tilde{\theta}, \quad f'=g(2f-1)/\sin\tilde{\theta}. \tag{14}$$

Eliminating g from these leaves an equation for f which, after the transformation

$$f(\tilde{\theta})=\tfrac{1}{2}(\mathrm{e}^{2T}+1)P(T)+\tfrac{1}{2}, \quad \tanh T=-\cos\tilde{\theta},$$

is

$$P''=(P')^2/P-4\mathrm{e}^{2T}P^3, \tag{15}$$

where $P'=dP/dT$. This is the third Painlevé equation P_{III}. In terms of the variable $t=\mathrm{e}^T=\tan(\tilde{\theta}/2)\in(0,\infty)$, it takes the more usual form

$$\ddot{P}=(\dot{P})^2/P-\dot{P}/t-4P^3, \tag{16}$$

where $\dot{P}=dP/dt$. Solutions of (15) or (16) therefore determine spatially-homogeneous SU(2) solutions of the Yang–Mills–Higgs–Bogomolny equations (10).

VI. THE TWISTOR CORRESPONDENCE

One can in principle construct all solutions of the self-dual Yang–Mills equations, and hence of (10), by using the twistor correspondence.[15,14] The details of the construction are well-known, and here we simply give some brief details in order to establish notation and conventions.

Twistor space is the complex projective space $\mathbf{CP}^3$, with homogeneous coordinates $Z^\alpha=(Z^0,Z^1,Z^2,Z^3)$. (Strictly speaking, the twistor space of $\tilde{M}$ is a non-Hausdorff space[14] obtained by glueing together two copies of $\mathbf{CP}^3$; but for simplicity we shall avoid going into the details of this.) The correspondence between $\mathbf{CP}^3$ and $\tilde{M}$ is expressed by the relations

$$Z^0=uZ^2+wZ^3, \quad Z^1=\overline{w}Z^2+\overline{u}Z^3. \tag{17}$$

Here u and w are the complex coordinates defined by (2) (recall that they only cover ''half'' of $\tilde{M}$—it is for this reason that the true twistor space is a non-Hausdorff ''doubling'' of $\mathbf{CP}^3$).

A matrix-valued twistor function $F(Z^\alpha)$ is said to be *real* if $F^\dagger = F$, where $F^\dagger(Z^\alpha) = F(\overline{Z^1}, \overline{Z^0}, \overline{Z^3}, \overline{Z^2})^*$, and $*$ denotes complex conjugate transpose. There is a correspondence between certain holomorphic vector bundles over twistor space, and solutions of the self-dual Yang–Mills equations on $\tilde{M}$; in particular, if $F(Z^\alpha)$ is a real ''patching matrix'' for a vector bundle of rank n, then ''splitting'' F yields a self-dual U(n) gauge field. In addition to being real, the matrix function $F(Z^\alpha)$ has to be homogeneous of degree zero in Z^α; and in order to have $\tilde{\varphi}$-invariance, we require F to be annihilated by the vector field

$$V = Z^3 \frac{\partial}{\partial Z^3} - Z^2 \frac{\partial}{\partial Z^2} + Z^1 \frac{\partial}{\partial Z^1} - Z^0 \frac{\partial}{\partial Z^0}. \tag{18}$$

For example, all three requirements (reality, homogeneity and V-invariance) are met by the (scalar) function $Q = (Z^0 Z^1 + Z^2 Z^3)/(Z^2 Z^3)$. Indeed, the line bundle defined by the patching matrix $F = Q^k$, where k is an integer, yields the U(1) solution of Sec. IV.

VII. AN SU(2) EXAMPLE

In order to obtain SU(2) solutions by this construction, we look for examples of 2×2 twistor matrices $F(Z^\alpha)$ which are upper-triangular, and which are equivalent to ''real'' matrices. Given an upper-triangular F, one can obtain explicit expressions for Φ and A_μ (see, for example, Sec. 8.2 of Ref. 15). The analog of the 'tHooft ansatz, and its generalizations (corresponding to example 8.2.3 of Ref. 15) does not work—it produces only SU(1,1) fields. But the analog (changed-signature version) of example 8.2.4 of Ref. 15 does work, and produces SU(2) solutions in our case. Some brief details are as follows.

Write $\zeta = Z^3/Z^2$, and think of $F(Z^\alpha)$ as defining a vector bundle by the patching relation $\hat{\psi} = F\psi$, where ψ and $\hat{\psi}$ are (2-vector) fiber-coordinates over $U = \{|\zeta| \leqslant 1\}$ and $\hat{U} = \{|\zeta| \geqslant 1\}$, respectively. Take $F(Z^\alpha)$ to have the form

$$F(Z^\alpha) = \begin{pmatrix} \zeta^k \mathrm{e}^f & 2Q^{-1} \cosh f \\ 0 & \zeta^{-k} \mathrm{e}^{-f} \end{pmatrix}, \tag{19}$$

where k is a positive integer, $f(Z^\alpha)$ is real, and $Q = P/(Z^2 Z^3)^k$ with $P(Z^\alpha)$ being a real polynomial (homogeneous of degree $2k$). Then, because

$$R(Z^\alpha) = \begin{pmatrix} 0 & -1 \\ 1 & \zeta^k Q \end{pmatrix}$$

is holomorphic on U and FR is real, it follows that the construction will yield a real [i.e., SU(2)-valued] solution.

As an example of this construction, take $P = (Z^0 Z^1 + Z^2 Z^3)$ and $k = 1$ (or $k = -1$, which leads to the same solution). The simplest choice for f, namely, $f = 0$, gives nothing new: the field is then effectively abelian, and is an embedding into SU(2) of the U(1) solution described in Sec. IV. To get something genuinely non-abelian, we may take $f = \log Q$, where $Q = (Z^0 Z^1 + Z^2 Z^3)/(Z^2 Z^3)$, so that

$$F(Z^\alpha) = \begin{pmatrix} \zeta Q & 1 + Q^{-2} \\ 0 & (\zeta Q)^{-1} \end{pmatrix}. \tag{20}$$

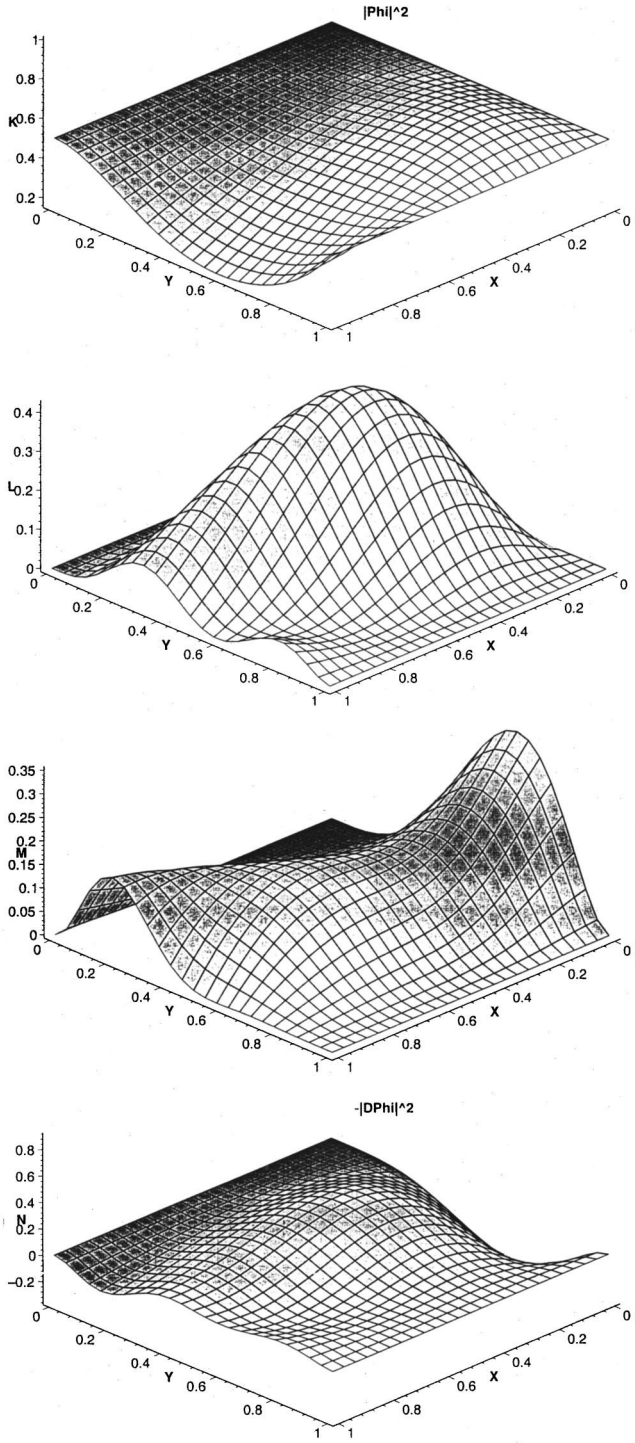

FIG. 1. The quantities $K=-\operatorname{tr}\Phi^2$, $L=-\sin^2\tilde{\theta}\operatorname{tr}(D_{\tilde{\theta}}\Phi)^2$, $M=-\sin^2\tilde{\theta}\operatorname{tr}[(D_\theta\Phi)^2+(D_\varphi\Phi)^2/\sin^2\theta]$ and $N=g^{\mu\nu}\operatorname{tr}[(D_\mu\Phi)(D_\nu\Phi)]$ as functions of $X=\cos^2(\theta/2)$ and $Y=\cos^2(\tilde{\theta}/2)$.

The procedure[15] referred to above then yields explicit (although rather complicated) expressions for Φ and A_μ, as rational functions of $\cos\theta$, $\cos\tilde{\theta}$, and $\exp(i\varphi)$. The dependence on φ can be compensated by a gauge transformation, so in effect the solution depends only on θ and $\tilde{\theta}$: it is an SO(2)-invariant solution of the Yang–Mills–Higgs equations (9) on M.

The functions are somewhat simpler when expressed in terms of the variables $X=\cos^2(\theta/2)$ and $Y=\cos^2(\tilde{\theta}/2)$; for example, $-\operatorname{tr}\Phi^2=\frac{1}{2}H(X,Y)/(1+X^2Y^2)^2$, where

$$H(X,Y)=1+16X^4Y^6-24X^4Y^5+9X^4Y^4+16X^2Y^4-8X^2Y^3-6X^2Y^2-16XY^4+16XY^3.$$

Figure 1 contains plots of four gauge-invariant quantities, namely,

$$K:=-\operatorname{tr}\Phi^2,$$

$$L:=-\sin^2\tilde{\theta}\,\operatorname{tr}(D_{\tilde{\theta}}\Phi)^2,$$

$$M:=-\sin^2\tilde{\theta}\,\operatorname{tr}[(D_\theta\Phi)^2+(D_\varphi\Phi)^2/\sin^2\theta],$$

$$N:=L-M=g^{\mu\nu}\operatorname{tr}[(D_\mu\Phi)(D_\nu\Phi)],$$

as functions of ''spatial latitude'' X and ''time'' Y. A couple of features that may be noted are:

(1) In the distant future or past (i.e., as $Y\to 1$ or $Y\to 0$), the field approaches a ''vacuum value,'' where $-\operatorname{tr}\Phi^2=\frac{1}{2}$ and $-\operatorname{tr}(D_\mu\Phi)^2=0$;
(2) At the point $X=0$ on the spatial sphere, we have $-\operatorname{tr}\Phi^2=\frac{1}{2}$, $-\operatorname{tr}(D_{\text{time}}\Phi)^2=0$ and $-\operatorname{tr}(D_{\text{space}}\Phi)^2=16Y^4(Y-1)^2$.

VIII. CONCLUDING REMARKS

For the corresponding systems in (2+1)-dimensional flat[2] and anti-de Sitter[11] space–time, there are localized soliton solutions; and a single soliton travels (as one would expect) along a timelike geodesic. More investigation is needed to determine whether the same is true in the de Sitter case. The method used to construct solutions in the former cases does not work so well here; the construction of Sec. VII is, by contrast, the analog of one which yields the one-monopole solution[15] of the Yang–Mills–Higgs–Bogomolnyi equations on $\mathbf{R}^3$. One question, therefore, is whether there is a meaningful correspondence between between these two systems, i.e., between the Yang–Mills–Higgs systems on $\mathbf{R}^3$ and on (2+1)-dimensional de Sitter space.

In addition to exact solution methods, one may wish to investigate the equations numerically, as was done in the flat case.[5] For this, an alternative sigma-model or chiral-model formulation is useful; and this may be of interest in any event. For example, there exists a gauge in which $A_{\bar{u}}=H^{-1}\partial_{\bar{u}}H$ and $A_w=H^{-1}\partial_w H$, where H takes values in the complexified gauge group [i.e., SL(2,C) if $G=\mathrm{su}(2)$]. Then the Hermitian matrix $K=HH^*$ satisfies

$$\partial_u(K^{-1}\partial_{\bar{u}}K)-\partial_{\bar{w}}(K^{-1}\partial_w K)=0. \tag{21}$$

And this single matrix equation (21) is equivalent, after transforming coordinates as in (2) and imposing a suitable dependence on $\tilde{\varphi}$, to the Yang–Mills–Higgs equations (10).

Let H_1, H_2 be complex Hilbert spaces, H be their Hilbert tensor product and let tr_2 be the operator of taking partial trace, with respect to the space H_2, of trace class operators in H. The operation tr_2 maps states in H (=positive trace class operators in H with trace equal to 1) into states in H_1. In this paper we give the full description of mappings that are linear right inverse to tr_2. More precisely, we prove that any affine mapping $F(W)$ of the convex set of states in H_1 into the states in H that is right inverse to tr_2 is given by $W \mapsto W \otimes D$ for some state D in H_2. In addition we investigate a representation of the quantum mechanical state space by probability measures on the set of pure states and a representation—used in the theory of stochastic Schrödinger equations—by probability measures on the Hilbert space. We prove that there are no affine mappings from the state space of quantum mechanics into these spaces of probability measures. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1343882]

I. INTRODUCTION

In quantum mechanics the states of a physical system are given by the statistical operators or density matrices in the Hilbert space associated to this system. The state of a subsystem is uniquely calculated as the reduced statistical operator by the partial trace. But it seems that the inverse problem, to define a linear mapping from the set of states of a subsystem to the set of states of an enlarged system such that the reduced state coincides with the original state, has not been studied systematically in the literature. In this article we want to investigate this lifting problem of states and the adjoint problem of reducing observables in some detail.

In the sequel all Hilbert spaces are assumed to be complex (and separable). For any Hilbert space we denote by $\mathcal{L}(H)$ the (complex) vector space of all linear bounded operators in H; by $\mathcal{L}^a(H)$ we denote the real vector subspace of $\mathcal{L}(H)$ consisting of all self-adjoint operators from $\mathcal{L}(H)$, by $\mathcal{L}^+(H)$ we denote the cone of positive operators within $\mathcal{L}(H)$ [and hence within $\mathcal{L}^a(H)$]. The (complex) vector space of all trace class operators in H is denoted by $\mathcal{L}_1(H)$. In addition we use the following notations: $\mathcal{L}_1^+(H) = \mathcal{L}^+(H) \cap \mathcal{L}_1(H)$, $\mathcal{L}_1^a(H) = \mathcal{L}_1^+(H) \cap \mathcal{L}^a(H)$, and $\mathcal{D}(H)$ is the convex set of all operators from $\mathcal{L}_1^+(H)$ having trace equal to one. If H is the Hilbert space associated to a physical system, then the elements of $\mathcal{L}^a(H)$ represent the (bounded) observables of the system, the elements of $\mathcal{D}(H)$ represent (mixed and pure) states, and the closed subset $\mathcal{P}(H) \subset \mathcal{D}(H)$ of rank one projection operators represents the pure states.

If $\mathcal{S}$ and $\mathcal{E}$ are physical systems with Hilbert spaces H_S and H_E, then the Hilbert space of the composite system—denoted by $\mathcal{S} \times \mathcal{E}$—of these systems is the Hilbert tensor product of Hilbert spaces H_S and H_E, i.e., $H = H_S \otimes H_E$. The scalar product in H is written as $\langle , \rangle_H$; the corresponding notations are used for scalar products in H_S and H_E. Hence $\mathcal{S}$ is a subsystem of the quantum system $\mathcal{S} \times \mathcal{E}$, and the system $\mathcal{E}$ can be interpreted as an environment of H_S. For any state W

$\in \mathcal{D}(H)$ of the total system $\mathcal{S}\times\mathcal{E}$ the state of the system $\mathcal{S}$—called the reduced state—is given by the partial trace $\mathrm{tr}_{H_E} W \in \mathcal{D}(H_S)$. This partial trace is uniquely defined for all $W \in \mathcal{L}_1(H)$ as the operator $\mathrm{tr}_{H_E} W \in \mathcal{L}_1(H_S)$ which satisfies the identity $\langle \mathrm{tr}_{H_E} W x_1, x_2\rangle_{H_S} = \Sigma_j \langle W(x_1 \otimes e_j^E), (x_2 \otimes e_j^E)\rangle_H$ for an orthonormal basis $\{e_j^E\}$ of H_E and all $x_1, x_2 \in H_S$. The mapping $W \to \mathrm{tr}_{H_E} W$, $\mathcal{L}_1(H) \to \mathcal{L}_1(H_S)$, is obviously linear and continuous.

By the partial trace we can calculate the Schrödinger dynamics of the subsystem $\mathcal{S}$—the so called reduced dynamics—from the Schrödinger dynamics of the whole system $\mathcal{S}\times\mathcal{E}$. But in general, this dynamics does not depend linearly on the initial state of the subsystem; see Remark 2. In order to obtain the linear dependence one has to find a linear solution for the lifting problem, which can be formulated as follows. For any state $W_S \in \mathcal{L}_1(H_S)$ to find a state $F(W_S) \in \mathcal{L}_1(H)$ such that $\mathrm{tr}_{H_E} F(W_S) = W_S$; such a mapping F_S is called the lifting.

The simplest solution of this problem is given by the mapping $F_D : \mathcal{L}_1(H_S) \to \mathcal{L}_1(H)$, $W \mapsto W \otimes D$, where D is an element of $\mathcal{L}_1(H_E)$, which is usually called a reference state. This choice is well known from the theory of open systems, see, e.g., Refs. 1–3.

The main theorem of the paper—Theorem 1 of the next section—implies that actually any linear lifting coincides with F_D, for some D.

Remark 1: The vector space $\mathcal{L}^a(H)$ of bounded observables can be identified with the space of continuous affine linear functionals on the state space $\mathcal{D}(H)$ equipped with the topology induced by the trace norm $\|.\|_1$ of $\mathcal{L}_1(H) \supset \mathcal{D}(H)$; see, e.g., Ref. 4. Affine linearity means that such a functional $f : \mathcal{D}(H) \to \mathbb{R}$ respects the mixing property: $f(\alpha W_1 + \beta W_2) = \alpha f(W_1) + \beta f(W_2)$ for $0 \leqslant \alpha, \beta \leqslant 1$ with $\alpha + \beta = 1$, and $W_1, W_2 \in \mathcal{D}(H)$. In fact, any such a functional can be uniquely extended to a continuous $\mathbb{C}$-linear functional $\overline{f} : \mathcal{L}_1(H) \to \mathbb{C}$, see, e.g., Ref. 5. Since $\mathcal{L}(H)$ is dual to $\mathcal{L}_1(H)$, with the duality pairing

$$\mathcal{L}(H) \times \mathcal{L}_1(H) \to \mathbb{C} : (A, W) \mapsto \langle A, W\rangle \equiv \mathrm{tr}_H AW, \tag{1}$$

there exists $A_f \in \mathcal{L}(H)$ such that for any $W \in \mathcal{L}_1(H)$ the identity $\overline{f}(W) = \mathrm{tr}_H WA_f$ is true.

On the other side, according to Gleason's theorem,[6] the state space $\mathcal{D}(H)$ can be identified with the set of linear functionals $\omega : \mathcal{L}(H) \to \mathbb{C}$ having the following properties:

(1) *if $A \in \mathcal{L}^+(H)$ then $\omega(A) \geqslant 0$;*
(2) *$\omega(Id) = 1$;*
(3) *$\omega(\Sigma_j P_j) = \Sigma_j \omega(P_j)$ for any finite or countable family of mutually orthogonal projectors.*

For any ω which satisfies these constraints there exists an element $W_\omega \in \mathcal{D}(H)$ such that $\omega(A) = \mathrm{tr}_H W_\omega A$ is true for all $A \in \mathcal{L}(H)$. The natural norm of the state space is $\sup_{\|A\|=1} |\omega(A)|$ which coincides with the trace norm of W_ω.

Remark 2: The time evolution of a composite system with Hilbert space $H = H_S \otimes H_E$ in the Schrödinger picture is given by a family Φ_t, $t \in \mathbb{R}$ or $t \in \mathbb{R}_+$, of continuous affine linear mappings $\Phi_t : \mathcal{D}(H) \to \mathcal{D}(H)$. We normalize these evolutions by $\Phi_0(W) = W$. The affine linear mappings Φ_t can be extended to $\mathbb{C}$-linear mappings on $\mathcal{L}_1(H)$, again denoted by Φ_t. In the usual case of a Hamiltonian (unitary) dynamics we have $\Phi_t(W) = U(t) W U^+(t)$ with the unitary group $U(t)$ on H generated by the Hamiltonian. But more general evolutions like semigroups are admitted in the sequel. The mappings Φ_t have unique extensions to continuous $\mathbb{C}$-linear mappings $\overline{\Phi}_t$ of $\mathcal{L}_1(H)$ into $\mathcal{L}_1(H)$. The duality (1) then allows us to determine the Heisenberg evolution, a family Ψ_t of continuous linear operators on $\mathcal{L}(H)$. Any Schrödinger evolution Φ_t on $\mathcal{D}(H_S \otimes H_E)$ induces a unique time evolution $\rho_t = tr_{H_E} \Phi_t(W)$ of the system H_S. In order to obtain a linear dependence on the initial state $\rho = \rho_{t=0}$ we need an affine linear mapping F of $\mathcal{D}(H_S)$ into $\mathcal{D}(H_S \otimes H_E)$. Then the mapping $\rho \mapsto W = F(\rho) \mapsto \rho_t = \mathrm{tr}_{H_E} \Phi_t(W)$ is a linear time evolution on $\mathcal{D}(H_S)$. This time evolution has the correct initial condition $\rho_{t=0} = \rho$ if F satisfies the constraint $\mathrm{tr}_{H_E} F(\rho) = \rho$. The Heisenberg dynamics of the system then follows from the duality (1) applied to $\mathcal{L}(H_S)$ and $\mathcal{L}_1(H_S)$.

The paper is organized a follows. In Sec. II we prove the main result of the paper—Theorem 1—describing all linear liftings. In Sec. III we consider a theorem—Theorem 2—that is in a sense dual to Theorem 1 and describes a reduction of observables of the system H to observables of the system H_S.

In the final section (Sec. IV) we consider the case of a classical state space, i.e., a space of probability measures, and the representation of the quantum mechanical state space $\mathcal{D}(H)$ by probability measures either on the set of pure states—the Choquet representation—or on the Hilbert space—a representation used in the theory of stochastic Schrödinger equations. The space $\mathcal{D}(H)$ is a convex set with the closed set $\mathcal{P}(H)$ of pure states as extremal points. Any $W \in \mathcal{D}(H)$ can be represented by an integral over the pure states $W=\int_{\mathcal{P}(H)}\mu(dP)\,P$, where $\mu(dP)$ is a probability measure on $\mathcal{P}(H)$. Since this representation has been derived by Choquet for general convex sets, see, e.g., Ref. 7, we denote the (nonunique) measure $\mu(dP)$ as Choquet measure of W. In Theorem 3 we prove that there does not exist a linear mapping γ from the space $\mathcal{D}(H)$ into the set of probability measures on the set $\mathcal{P}(H)$ such that the measure $\gamma(W)$ is the Choquet measure of the state $W \in \mathcal{D}(H)$. This theorem is in fact a consequence of Theorem 1. In Sec. IV we deduce Theorem 3 from the structural difference between the classical and the quantum mechanical state spaces. Both these spaces are convex sets. But the classical state space is a simplex whereas $\mathcal{D}(H)$ not; see, e.g., Ref. 8. Finally we investigate the representation of the state space by probability measures on the Hilbert space. Also in this case the structural difference between the quantum mechanical state space and the space of probability measures does not allow an affine linear mapping from $\mathcal{D}(H)$ into the measure space.

II. LINEAR LIFTINGS

The main result of the paper is the following theorem.

Theorem 1: *Let* $F:\mathcal{D}(H_S)\to\mathcal{D}(H_S\otimes H_E)$ *be an affine linear mapping such that* $\mathrm{tr}_{H_E}F(\rho)=\rho$ *for all* $\rho\in\mathcal{D}(H_S)$. *Then there exists an element* $\rho_E\in\mathcal{D}(H_E)$ *such that* $F(\rho)=\rho\otimes\rho_E$.

Proof: The mapping F can be extended (uniquely) to the $\mathbb{C}$-linear mapping of $\mathcal{L}_1(H_S)$ into $\mathcal{L}_1(H_S\otimes H_E)$ that we shall denote by the same symbol. This extension has the following properties:

$$F(\mathcal{L}_1^{+}(H_S))\subset\mathcal{L}_1^{+}(H_S\otimes H_E), \tag{2}$$

$$F(\mathcal{L}_1^{a}(H_S))\subset\mathcal{L}_1^{a}(H_S\otimes H_E); \tag{3}$$

we shall use these properties later.

Let $\{e_i, i\in\mathbb{N}\}$ (respectively, $\{f_j, j\in\mathbb{N}\}$) be an orthonormal basis in H_S (respectively, in H_E). Without loss of generality we assume H_S and H_E to be infinite-dimensional. Then $H=\mathrm{span}\{e_i\otimes f_j,\ i\in\mathbb{N}, j\in\mathbb{N}\}$. We realize $\mathcal{L}_1(H_S)$ as a vector space of complex valued functions on $\mathbb{N}^2$: $g_{ij}\in\mathbb{C}: i\in\mathbb{N}, j\in\mathbb{N}$. Analogously, we realize $\mathcal{L}_1(H)=\mathcal{L}_1(H_S\otimes H_E)$ as a vector space of complex valued functions on $\mathbb{N}^4$: $F(g)_{ij}^{kl}, i,j,k,l\in\mathbb{N}$. We say that $b_{ij}, i,j\in\mathbb{N}$ is a (k,l)-component of $F\in\mathcal{L}_1(H)$ and denote it by $(F)^{kl}$ if $F_{ij}^{kl}=b_{ij}$ for all $i,j\in\mathbb{N}$. We say that F has only the components of some type if all components of other types are equal to zero. Let us note that

$$\mathrm{tr}_{H_E}F(g)=g\Leftrightarrow\sum_{i=1}^{\infty}F(g)_{ii}^{kl}=g_{kl},\quad\forall k,l\in\mathbb{N}. \tag{4}$$

Consider the following basis $\{g^{kl}, k\leqslant l, g^{kl*}, k<l\}$ in $\mathcal{L}_1(H_S)$:

$$g_{ij}^{kl}=\begin{cases}1, & \text{if } (i,j)\in\{(k,k),(k,l),(l,k),(l,l)\},\\ 0, & \text{otherwise,}\end{cases} \qquad g_{ij}^{kl*}=\begin{cases}1, & \text{if } (i,j)=(k,k),\\ i, & \text{if } (i,j)=(k,l),\\ -i, & \text{if } (i,j)=(l,k),\\ 1, & \text{if } (i,j)=(l,l),\\ 0, & \text{otherwise.}\end{cases}$$

First, all g^{kl} and g^{kl*} are positive operators, therefore $F(g^{kl})$ and $F(g^{kl*})$ are also positive and hence $F(g^{kl})_{ii}^{mm}\geqslant 0$ and $F(g^{kl*})_{ii}^{mm}\geqslant 0$ for all $i,m\in\mathbb{N}$. Due to (4) $\Sigma_{i=1}^{\infty}F(g^{kl})_{ii}^{mm}=g_{mm}^{kl}=0$ for $m\neq k, m\neq l$ and $\Sigma_{i=1}^{\infty}F(g^{kl*})_{ii}^{mm}=g_{mm}^{kl*}=0$ for $m\neq k, m\neq l$. From this follows that

$$F(g^{kl})_{ii}^{mm}=0,\ m\neq k,\ m\neq l,\ i\in\mathbb{N};\quad F(g^{kl*})_{ii}^{mm}=0,\ m\neq k,\ m\neq l,\ i\in\mathbb{N}. \tag{5}$$

Second, all g^{kl} and g^{kl*} are self-adjoint, therefore $F(g^{kl})$ and $F(g^{kl*})$ are also self-adjoint and hence

$$F(g^{kl})_{ji}^{nm}=\overline{F(g^{kl})_{ij}^{mn}} \text{ and } F(g^{kl*})_{ji}^{nm}=\overline{F(g^{kl*})_{ij}^{mn}}, \quad \text{for all } i,j,k,l,m,n\in\mathbb{N}. \tag{6}$$

□

The further proof is organized as follows. First, we show that $F(g^{kk})$ has only a (k,k)-component (Step 1), $F(g^{kl}),k<l$ [resp., $F(g^{kl*}),k<l$] has only (k,k)-, (k,l)-, (l,k)-, (l,l)-components (Step 2). Furthermore, we prove that nonzero components of $F(g^{kl})$ are equal (Step 3) and that nonzero components of $F(g^{kl*})$ satisfy $(F)^{kk}=-i(F)^{kl}=i(F)^{lk}=(F)^{ll}$ (Step 4). Finally, we denote elements of the only nonzero component of $F(g^{11})$ by a_{ij} and show that any nonzero component of $F(g^{kl})$ is equal to a_{ij} (Step 5) and that the nonzero components of $F(g^{kl*})$ satisfy $(F)^{kk}=-i(F)^{kl}=i(F)^{lk}=(F)^{ll}=a_{ij}$ (Step 6), which completes the proof.

In the proof we shall also use the following (obvious) lemma.

Lemma 1: Let $a\geqslant 0, b\geqslant 0, c\geqslant 0$ be real numbers; then

$$\begin{aligned}&\{(t,p)\in\mathbb{R}^2:(1+t)(1+p)\geqslant 1, t+1\geqslant 0\}\\ &\quad\subset\{(t,p)\in\mathbb{R}^2:(b+at)(b+cp)\geqslant b^2, b+at\geqslant 0\}\\ &\quad\Leftrightarrow a=c\leqslant b.\end{aligned}$$

Proof of Theorem 1 (continued):

Step 1. Consider $g^{kk}\in\mathcal{L}_1(H_S),k\in\mathbb{N}$ and restrict $F(g^{kk})$ to the space $\langle e_m\otimes f_i, e_n\otimes f_j\rangle$, where $(m,n)\neq(k,k)$. In this basis $F(g^{kk})$ has the form

$$\begin{pmatrix} F(g^{kk})_{ii}^{mm} & F(g^{kk})_{ji}^{nm}\\ F(g^{kk})_{ij}^{mn} & F(g^{kk})_{jj}^{nn}\end{pmatrix}.$$

Because either $m\neq k$ or $n\neq k$ we have due to (5) that either $F(g^{kk})_{ii}^{mm}=0$ or $F(g^{kk})_{jj}^{nn}=0$. $F(g^{kk})$ is positive, hence $F(g^{kk})_{ii}^{mm}F(g^{kk})_{jj}^{nn}-F(g^{kk})_{ji}^{nm}F(g^{kk})_{ij}^{mn}\geqslant 0$. Combining these conditions together with (6) we get

$$F(g^{kk})_{ij}^{mn}=0,\ \forall i,\ j,m,n\in\mathbb{N},\ (m,n)\neq(k,k),$$

i.e., $F(g^{kk})$ has only a (k,k)-component.

Step 2. Consider $g^{kl}\in\mathcal{L}_1(H_S),k,l\in\mathbb{N},k<l$ and restrict $F(g^{kl})$ to the subspace $\langle e_m\otimes f_i, e_n\otimes f_j\rangle$, where (m,n) does not take values (k,k), (k,l), (l,k), (l,l). In this basis $F(g^{kl})$ has the form

$$\begin{pmatrix} F(g^{kl})_{ii}^{mm} & F(g^{kl})_{ji}^{nm} \\ F(g^{kl})_{ij}^{mn} & F(g^{kl})_{jj}^{nn} \end{pmatrix}.$$

Due to the conditions on (m,n) it follows from (5) that either $F(g^{kl})_{ii}^{mm}=0$ or $F(g^{kl})_{jj}^{nn}=0$. $F(g^{kl})$ is positive, hence $F(g^{kl})_{ii}^{mm}F(g^{kl})_{jj}^{nn}-F(g^{kl})_{ji}^{nm}F(g^{kl})_{ij}^{mn}\geqslant 0$. Combining this condition together with (6) we get

$$F(g^{kl})_{ij}^{mn}=0, \quad \forall i,\ j,m,n\in\mathbb{N}, \quad \text{with } (m,n)\notin\{(k,k),(k,l),(l,k),(l,l)\},$$

i.e., $F(g^{kl})$ has only (k,k)-, (k,l)-, (l,k)-, (l,l)-components.

Analogously (substituting $g^{kl}*$ for g^{kl}) we prove that $F(g^{kl}*)$ has only (k,k)-, (k,l)-, (l,k)-, (l,l)-components.

Step 3. First, let us show that the main diagonals of the nonzero components of $F(g^{kl})$ are equal, i.e., $F(g^{kl})_{ii}^{kk}=F(g^{kl})_{ii}^{kl}=F(g^{kl})_{ii}^{lk}=F(g^{kl})_{ii}^{ll}$. Restrict $F(g^{kl})$ to the subspace $\langle e_k\otimes f_i, e_l\otimes f_i\rangle$. In this basis $F(g^{kl})$ has the form

$$\begin{pmatrix} F(g^{kl})_{ii}^{kk} & F(g^{kl})_{ii}^{lk} \\ F(g^{kl})_{ii}^{kl} & F(g^{kl})_{ii}^{ll} \end{pmatrix}.$$

This matrix is positive, hence $F(g^{kl})_{ii}^{kk}F(g^{kl})_{ii}^{ll}-F(g^{kl})_{ii}^{lk}F(g^{kl})_{ii}^{kl}\geqslant 0$, i.e., $|F(g^{kl})_{ii}^{kl}|\leqslant\sqrt{F(g^{kl})_{ii}^{kk}F(g^{kl})_{ii}^{ll}}$ [note that $F(g^{kl})_{ii}^{kk}$ and $F(g^{kl})_{ii}^{ll}$ are real and non-negative]. Due to (4) $\Sigma_{i=1}^{\infty}F(g^{kl})_{ii}^{kk}=\Sigma_{i=1}^{\infty}F(g^{kl})_{ii}^{kl}=\Sigma_{i=1}^{\infty}F(g^{kl})_{ii}^{lk}=\Sigma_{i=1}^{\infty}F(g^{kl})_{ii}^{ll}=1$ and hence

$$\begin{aligned} 1=\sum_{i=1}^{\infty}\operatorname{Re}F(g^{kl})_{ii}^{kl}\leqslant\sum_{i=1}^{\infty}|F(g^{kl})_{ii}^{kl}|&\leqslant\sum_{i=1}^{\infty}\sqrt{F(g^{kl})_{ii}^{kk}F(g^{kl})_{ii}^{ll}} \\ &\leqslant\sum_{i=1}^{\infty}\frac{F(g^{kl})_{ii}^{kk}+F(g^{kl})_{ii}^{ll}}{2}=1, \end{aligned}$$

and therefore all parts of the inequality must be equal. We have

$$\sqrt{F(g^{kl})_{ii}^{kk}F(g^{kl})_{ii}^{ll}}=\frac{F(g^{kl})_{ii}^{kk}+F(g^{kl})_{ii}^{ll}}{2}\Rightarrow F(g^{kl})_{ii}^{kk}=F(g^{kl})_{ii}^{ll}$$

and

$$\operatorname{Re}F(g^{kl})_{ii}^{kl}=|F(g^{kl})_{ii}^{kl}|=F(g^{kl})_{ii}^{kk}\Rightarrow F(g^{kl})_{ii}^{kl}=F(g^{kl})_{ii}^{lk}=F(g^{kl})_{ii}^{kk}.$$

Hence the diagonal elements $F(g^{kl})_{ii}^{kk}=F(g^{kl})_{ii}^{kl}=F(g^{kl})_{ii}^{lk}=F(g^{kl})_{ii}^{ll}$ are equal.

Second, let us show that the corresponding nondiagonal elements of the nonzero components of $F(g^{kl})$ are equal, i.e., $F(g^{kl})_{ij}^{kk}=F(g^{kl})_{ij}^{kl}=F(g^{kl})_{ij}^{lk}=F(g^{kl})_{ij}^{ll}$, where $i\neq j$. Denote $a_i=F(g^{kl})_{ii}^{kk}$. Restrict $F(g^{kl})$ to the subspace $\langle e_k\otimes f_i, e_k\otimes f_j, e_l\otimes f_j\rangle$. In this basis $F(g^{kl})$ has the form

$$\begin{pmatrix} F(g^{kl})_{ii}^{kk} & F(g^{kl})_{ji}^{kk} & F(g^{kl})_{ji}^{lk} \\ F(g^{kl})_{ij}^{kk} & F(g^{kl})_{jj}^{kk} & F(g^{kl})_{jj}^{lk} \\ F(g^{kl})_{ij}^{kl} & F(g^{kl})_{jj}^{kl} & F(g^{kl})_{jj}^{ll} \end{pmatrix}=\begin{pmatrix} a_i & \overline{y} & \overline{x} \\ y & a_j & a_j \\ x & a_j & a_j \end{pmatrix}=A.$$

If $a_j=0$ then obviously $x=y=0$ as A is positive. If $a_j\neq 0$ then

$$\det A=-y(\overline{y}a_j-\overline{x}a_j)+x(\overline{y}a_j-\overline{x}a_j)=-a_j|y-x|^2\geqslant 0\Rightarrow x=y,$$

and we have derived $F(g^{kl})_{ij}^{kk}=F(g^{kl})_{ij}^{kl}=F(g^{kl})_{ij}^{lk}=F(g^{kl})_{ij}^{ll}$, for all i,j.

Step 4. First, let us prove $F(g^{kl*})^{kk}_{ii}=-iF(g^{kl*})^{kl}_{ii}=iF(g^{kl*})^{lk}_{ii}=F(g^{kl*})^{ll}_{ii}$, i.e., that this condition holds on the main diagonals of nonzero components of $F(g^{kl*})$. Analogously to the previous step, we get $|F(g^{kl*})^{kl}_{ii}|\leqslant\sqrt{F(g^{kl*})^{kk}_{ii}F(g^{kl*})^{ll}_{ii}}$ [note that $F(g^{kl*})^{kk}_{ii}$ and $F(g^{kl*})^{ll}_{ii}$ are real and non-negative]. Due to (4) $\Sigma_{i=1}^{\infty}F(g^{kl*})^{kk}_{ii}=\Sigma_{i=1}^{\infty}F(g^{kl*})^{ll}_{ii}=1$, $\Sigma_{i=1}^{\infty}F(g^{kl*})^{kl}_{ii}=i$, $\Sigma_{i=1}^{\infty}F(g^{kl*})^{lk}_{ii}=-i$ and hence

$$1=\sum_{i=1}^{\infty}\operatorname{Im}F(g^{kl*})^{kl}_{ii}\leqslant\sum_{i=1}^{\infty}|F(g^{kl*})^{kl}_{ii}|\leqslant\sum_{i=1}^{\infty}\sqrt{F(g^{kl*})^{kk}_{ii}F(g^{kl})^{ll}_{ii}}$$

$$\leqslant\sum_{i=1}^{\infty}\frac{F(g^{kl*})^{kk}_{ii}+F(g^{kl*})^{ll}_{ii}}{2}=1,$$

and therefore all parts of inequality must be equal. Analogously to the previous step we have

$$F(g^{kl*})^{kk}_{ii}=F(g^{kl*})^{ll}_{ii}$$

and

$$\operatorname{Im}F(g^{kl*})^{kl}_{ii}=|F(g^{kl*})^{kl}_{ii}|=F(g^{kl*})^{kk}_{ii}\Rightarrow F(g^{kl*})^{kl}_{ii}=F(g^{kl*})^{lk}_{ii}=F(g^{kl*})^{kk}_{ii},$$

and hence $F(g^{kl*})^{kk}_{ii}=-iF(g^{kl*})^{kl}_{ii}=iF(g^{kl*})^{lk}_{ii}=F(g^{kl*})^{ll}_{ii}$.

Second, let us show that this property holds also for corresponding nondiagonal elements of the nonzero components of $F(g^{kl*})$, i.e., $F(g^{kl*})^{kk}_{ij}=-iF(g^{kl*})^{kl}_{ij}=iF(g^{kl*})^{lk}_{ij}=F(g^{kl*})^{ll}_{ij}$ if $i\neq j$.

Denote $a_i=F(g^{kl*})^{kk}_{ii}$. Restrict $F(g^{kl*})$ to the subspace $\langle e_k\otimes f_i,e_k\otimes f_j,e_l\otimes f_j\rangle$. In this basis $F(g^{kl*})$ has the form

$$\begin{pmatrix}F(g^{kl*})^{kk}_{ii} & F(g^{kl*})^{kk}_{ji} & F(g^{kl*})^{lk}_{ji}\\ F(g^{kl*})^{kk}_{ij} & F(g^{kl*})^{kk}_{jj} & F(g^{kl*})^{lk}_{jj}\\ F(g^{kl*})^{kl}_{ij} & F(g^{kl*})^{kl}_{jj} & F(g^{kl*})^{ll}_{jj}\end{pmatrix}=\begin{pmatrix}a_i & \overline{y} & \overline{x}\\ y & a_j & ia_j\\ x & -ia_j & a_j\end{pmatrix}=A.$$

If $a_j=0$ then obviously $x=iy=0$ as A is positive. If $a_j\neq 0$ then

$$\det A=-y(\overline{y}a_j-i\overline{x}a_j)+x(-i\overline{y}a_j-\overline{x}a_j)=-a_j|iy-x|^2\geqslant 0\Rightarrow x=iy,$$

and hence $F(g^{kl*})^{kk}_{ij}=-iF(g^{kl*})^{kl}_{ij}=iF(g^{kl*})^{lk}_{ij}=F(g^{kl*})^{ll}_{ij}$ holds for all i,j.

Step 5. First, let us show that the main diagonals of nonzero components of all $F(g^{kl})$, $k\leqslant l$, are equal, i.e., we have to prove

$$F(g^{kk})^{kk}_{ii}=F(g^{ll})^{ll}_{ii}=F(g^{kl})^{kl}_{ii},\quad\text{for all}\quad k<l.$$

Consider $g(t)=g^{kl}+tg^{kk}+pg^{ll}$, where $t+p+tp\geqslant 0$, $p+1\geqslant 0$ and $k<l$. The operator $g(t)$ is positive hence $F(g(t))$ is also positive. Restrict $F(g(t))$ to the subspace $\langle e_k\otimes f_i,e_l\otimes f_i\rangle$. In this basis $F(g(t))$ has the form

$$\begin{pmatrix}F(g(t))^{kk}_{ii} & F(g(t))^{lk}_{ii}\\ F(g(t))^{kl}_{ii} & F(g(t))^{ll}_{ii}\end{pmatrix}=\begin{pmatrix}F(g^{kl})^{kk}_{ii}+tF(g^{kk})^{kk}_{ii} & F(g^{kl})^{lk}_{ii}\\ F(g^{kl})^{kl}_{ii} & F(g^{kl})^{ll}_{ii}+pF(g^{ll})^{ll}_{ii}\end{pmatrix}.$$

This matrix is positive, hence

$$(F(g^{kl})^{kk}_{ii}+tF(g^{kk})^{kk}_{ii})(F(g^{kl})^{ll}_{ii}+pF(g^{ll})^{ll}_{ii})\geqslant(F(g^{kl})^{kl}_{ii})^2$$

[note that $F(g^{kl})^{kl}_{ii}$, $F(g^{kl})^{kk}_{ii}+tF(g^{kk})^{kk}_{ii}$, and $F(g^{kl})^{ll}_{ii}+pF(g^{ll})^{ll}_{ii}$ are real and non-negative]. We apply Lemma 1 with $a=F(g^{kk})^{kk}_{ii}$, $b=F(g^{kl})^{kl}_{ii}$, $c=F(g^{ll})^{ll}_{ii}$, which gives us

$$F(g^{kk})^{kk}_{ii}=F(g^{ll})^{ll}_{ii}\leqslant F(g^{kl})^{kl}_{ii}.$$

Taking into account the fact that $\Sigma_{i=1}^{\infty}F(g^{kk})^{kk}_{ii}=\Sigma_{i=1}^{\infty}F(g^{ll})^{ll}_{ii}=\Sigma_{i=1}^{\infty}F(g^{kl})^{kl}_{ii}=1$ we get

$$F(g^{kk})^{kk}_{ii}=F(g^{ll})^{ll}_{ii}=F(g^{kl})^{kl}_{ii}.$$

Second, let us show that the remaining elements of the nonzero components of $F(g^{kl}),k\leqslant l$ are equal. For that purpose we prove

$$F(g^{kk})^{kk}_{ij}=F(g^{ll})^{ll}_{ij}=F(g^{kl})^{kl}_{ij},\ \text{for all}\ i\neq j\ \text{and all}\ k<l$$

using again the operator $g(t)$. Denote $a_i=F(g^{kl})^{kk}_{ii}$. Restrict $F(g(t))$ to the subspace $\langle e_k\otimes f_i,e_k\otimes f_j,e_l\otimes f_j\rangle$. In this basis $F(g(t))$ has the form

$$\begin{aligned}
&\begin{pmatrix} F(g(t))^{kk}_{ii} & F(g(t))^{kk}_{ji} & F(g(t))^{lk}_{ji}\\ F(g(t))^{kk}_{ij} & F(g(t))^{kk}_{jj} & F(g(t))^{lk}_{jj}\\ F(g(t))^{kl}_{ij} & F(g(t))^{kl}_{jj} & F(g(t))^{ll}_{jj}\end{pmatrix}\\
&=\begin{pmatrix} F(g^{kl})^{kk}_{ii}+tF(g^{kk})^{kk}_{ii} & F(g^{kl})^{kk}_{ji}+tF(g^{kk})^{kk}_{ji} & F(g^{kl})^{lk}_{ji}\\ F(g^{kl})^{kk}_{ij}+tF(g^{kk})^{kk}_{ij} & F(g^{kl})^{kk}_{jj}+tF(g^{kk})^{kk}_{jj} & F(g^{kl})^{lk}_{jj}\\ F(g^{kl})^{kl}_{ij} & F(g^{kl})^{kl}_{jj} & F(g^{kl})^{ll}_{jj}+pF(g^{ll})^{ll}_{jj}\end{pmatrix}\\
&=\begin{pmatrix} a_i+ta_i & x+ty & x\\ \overline{x}+t\overline{y} & a_j+ta_j & a_j\\ \overline{x} & a_j & a_j+pa_j\end{pmatrix}\\
&=A.
\end{aligned}$$

If $a_j=0$ then obviously $x=y=0$ as A is positive. If $a_j\neq 0$ then

$$\begin{aligned}
\det A=&\,a_ia_j^2(1+t)^2(1+p)+(x+ty)a_j\overline{x}+x(\overline{x}+t\overline{y})a_j-xa_j(1+t)\overline{x}\\
&-(x+ty)(\overline{x}+t\overline{y})a_j(1+p)-a_ia_j^2(1+t)\\
=&-\frac{a_j}{1+t}|x(1+t)-(x+ty)|^2\geqslant 0\Rightarrow x=y.
\end{aligned}$$

This means that

$$F(g^{kl})^{kk}_{ij}=F(g^{kk})^{kk}_{ij}.$$

Step 6. First, let us show that the main diagonals of nonzero components of all $F(g^{kl*})$, $k<l$ satisfy the equality

$$F(g^{kk})^{kk}_{ii}=-iF(g^{kl*})^{kl}_{ii}=iF(g^{kl*})^{lk}_{ii}=F(g^{ll})^{ll}_{ii}.$$

Thereby we use the same arguments as in the previous step considering the operator $g^*(t)=g^{kl*}+tg^{kk}+pg^{ll}$, where $t+p+tp\geqslant 0$, $p+1\geqslant 0$ and $k<l$. The operator $g^*(t)$ is positive, hence $F(g^*(t))$ is also positive. Restrict $F(g^*(t))$ to the subspace $\langle e_k\otimes f_i,e_l\otimes f_i\rangle$. In this basis $F(g^*(t))$ has the form

$$\begin{pmatrix} F(g^*(t))^{kk}_{ii} & F(g^*(t))^{lk}_{ii}\\ F(g^*(t))^{kl}_{ii} & F(g^*(t))^{ll}_{ii}\end{pmatrix}=\begin{pmatrix} F(g^{kl*})^{kk}_{ii}+tF(g^{kk})^{kk}_{ii} & -F(g^{kl*})^{kl}_{ii}\\ F(g^{kl*})^{kl}_{ii} & F(g^{kl*})^{ll}_{ii}+pF(g^{ll})^{ll}_{ii}\end{pmatrix}. \tag{7}$$

Note that $-iF(g^{kl*})^{kl}_{ii}$, $F(g^{kl*})^{kk}_{ii}+tF(g^{kk})^{kk}_{ii}$, and $F(g^{kl*})^{ll}_{ii}+pF(g^{ll})^{ll}_{ii}$ are real and nonnegative. The matrix (7) is positive, hence

$$(F(g^{kl*})^{kk}_{ii}+tF(g^{kk})^{kk}_{ii})(F(g^{kl*})^{kk}_{ii}+pF(g^{ll})^{ll}_{ii})\geqslant -|F(g^{kl*})^{kl}_{ii}|^2=|-iF(g^{kl*})^{kl}_{ii}|^2.$$

We apply Lemma 1 with $a=F(g^{kk})^{kk}_{ii}$, $b=-iF(g^{kl*})^{kl}_{ii}$, $c=F(g^{ll})^{ll}_{ii}$, which gives us

$$F(g^{kk})^{kk}_{ii}=F(g^{ll})^{ll}_{ii}\leqslant -iF(g^{kl*})^{kl}_{ii}.$$

Taking into account the fact that $\Sigma_{i=1}^{\infty}F(g^{kk})^{kk}_{ii})=\Sigma_{i=1}^{\infty}F(g^{ll})^{ll}_{ii}=-\Sigma_{i=1}^{\infty}iF(g^{kl*})^{kl}_{ii}=1$ we get

$$F(g^{kk})^{kk}_{ii}=-iF(g^{kl*})^{kl}_{ii}=iF(g^{kl*})^{lk}_{ii}=F(g^{ll})^{ll}_{ii},\ \text{for all}\ k<l.$$

Second, let us show that the remaining elements of the nonzero components of $F(g^{kl*})$, $k<l$, satisfy

$$F(g^{kk})^{kk}_{ij}=F(g^{kl*})^{kk}_{ij},\ \text{if}\ i\neq j,$$

using again the operator $g^*(t)$. Denote $a_i=F(g^{kl*})^{kk}_{ii}$. Restrict $F(g^*(t))$ to the subspace $\langle e_k\otimes f_i, e_k\otimes f_j, e_l\otimes f_j\rangle$. In this basis $F(g^*(t))$ has the form

$$\begin{pmatrix} F(g^*(t))^{kk}_{ii} & F(g^*(t))^{kk}_{ji} & F(g^*(t))^{lk}_{ji} \\ F(g^*(t))^{kk}_{ij} & F(g^*(t))^{kk}_{jj} & F(g^*(t))^{lk}_{jj} \\ F(g^*(t))^{kl}_{ij} & F(g^*(t))^{kl}_{jj} & F(g^*(t))^{ll}_{jj} \end{pmatrix}$$

$$=\begin{pmatrix} F(g^{kl*})^{kk}_{ii}+tF(g^{kk})^{kk}_{ii} & F(g^{kl*})^{kk}_{ji}+tF(g^{kk})^{kk}_{ji} & F(g^{kl*})^{lk}_{ji} \\ F(g^{kl*})^{kk}_{ij}+tF(g^{kk})^{kk}_{ij} & F(g^{kl*})^{kk}_{jj}+tF(g^{kk})^{kk}_{jj} & F(g^{kl*})^{lk}_{jj} \\ F(g^{kl*})^{kl}_{ij} & F(g^{kl*})^{kl}_{jj} & F(g^{kl*})^{ll}_{jj}+pF(g^{ll})^{ll}_{jj} \end{pmatrix}$$

$$=\begin{pmatrix} a_i+ta_i & x+ty & -ix \\ \overline{x}+t\overline{y} & a_j+ta_j & -ia_j \\ i\overline{x} & ia_j & a_j+pa_j \end{pmatrix}=A.$$

If $a_j=0$ then obviously $x=y=0$ as A is positive. If $a_j\neq 0$ then, analogously to the previous step,

$$\det A=-\frac{a_j}{1+t}|x(1+t)-(x+ty)|^2\geqslant 0\Rightarrow x=y.$$

This means that

$$F(g^{kl*})^{kk}_{ij}=F(g^{kk})^{kk}_{ij}.$$

Denote $a_{ij}=F(g^{11})^{11}_{ij}$ and consider $\rho_E\in\mathcal{L}_1^+(H_S)$ that has the form a_{ij} in the basis $\{e_i, i\in\mathbb{N}\}$. It is easy to see now that $F(\rho)=\rho\otimes\rho_E$ for each $\rho\in\mathcal{L}_1(H)$. The theorem is proved. □

Remark 3: The theorem implies that the linear lifting F is continuous.

Remark 4: If we skip the constraint $\mathrm{tr}_{H_E}F(\rho)=\rho$, *more general liftings are possible. Let* $\rho_E\in\mathcal{D}(H_E)$ *be a reference state, and* K_n *a family of bounded operators in* H *which satisfy* $\Sigma_n K_n^+K_n=Id$; *then*

$$\rho\mapsto F(\rho)=\sum_n K_n(\rho\otimes\rho_E)K_n^+ \tag{8}$$

is a linear and continuous mapping $\mathcal{D}(H_S)\to\mathcal{D}(H)$. Such liftings are used in general investigations of the process of measurement[9] *and in information theory; see, e.g., Ref. 10.*

Remark 5: It is well known that any mixed state ρ of a system $\mathcal{S}$ can be obtained as the reduced state of a pure state in an extended system $\mathcal{S}\times\mathcal{E}$, if only $\dim H_E \geqslant \dim H_S$; *see, e.g., Ref. 11. But due to Theorem 1 the pure state cannot depend linearly on the state ρ. The representation by a pure state is actually a generalization of the classical Gram's theorem from linear algebra. To see this let H_S be realized as $\mathcal{L}_2(\Omega,\mathcal{B}_\Omega,\mu_\Omega)$ where Ω is a set, $\mathcal{B}_\Omega$ is a σ-algebra of its subsets, μ_Ω a non-negative σ-additive measure on $\mathcal{B}_\Omega$. Then the space $H=H_S\otimes H_E$ is isomorphic to the space $\mathcal{L}_2(\Omega,\mathcal{B}_\Omega,\mu_\Omega,H_E)$ of H_E-valued Bochner square μ_Ω-integrable functions on Ω. The corresponding isomorphic map $H_S\otimes H_E\to\mathcal{L}_2(\Omega,\mathcal{B}_\Omega,\mu_\Omega,H_E)$ is denoted by φ. On the other hand, the space $H_S\otimes H_S$ can be realized as $\mathcal{L}_2(\Omega\times\Omega,\mathcal{B}_\Omega\otimes\mathcal{B}_\Omega,\mu_\Omega\otimes\mu_\Omega)$, and hence the space $\mathcal{L}_1(H_S)$ can be considered as a vector subspace of the latter space which includes all Hilbert–Schmidt operators in H_S. Any normalized vector $a\in H_S\otimes H_E$, $\|a\|=1$, spans a one-dimensional subspace of $H_S\otimes H_E$ and defines a unique projection operator $P_a\in\mathcal{D}(H_S\otimes H_E)$. If $f_a\in\mathcal{L}_2(\Omega,\mathcal{B}_\Omega,\mu_\Omega,H_E)$ is defined by $f_a=\varphi(a)$ then the reduced state of the pure state P_a is given by*

$$S(\omega_1,\omega_2)=\langle f_a(\omega_1),f_a(\omega_2)\rangle_{H_E}. \tag{9}$$

Now the generalization of Gram's theorem can be formulated as follows: For any $S\in\mathcal{L}_1^+(H_S)$ there exists a vector $a\in H_S\otimes H_E$, $\|a\|=1$, for which (9) holds. If Ω is a finite set and μ_Ω is the counting measure, we obtain the classical Gram's theorem.

III. REDUCING OBSERVABLES

The problem of linear liftings of states is closely related to the problem of reducing observables of the total system H to observables of the subsystem H_S.

Lemma 2: Let $F:\mathcal{L}_1(H_S)\to\mathcal{L}_1(H_S\otimes H_E)$ be a continuous mapping and let $F^*:\mathcal{L}(H_S\otimes H_E)\to\mathcal{L}(H_S)$ be its adjoint mapping; then $F^*(B\otimes\mathrm{Id}_E)=B$ for all $B\in\mathcal{L}(H_S)$ iff $\mathrm{tr}_{H_E}F(\rho)=\rho$ for all $\rho\in\mathcal{L}_1(H_S)$.

Proof: If $B\in\mathcal{L}(H_S)$ then, according to the definition of the duality between $\mathcal{L}(H)$ and $\mathcal{L}_1(H)$, $\langle B\otimes\mathrm{Id}_E,F(\rho)\rangle=\mathrm{tr}_H(B\otimes\mathrm{Id}_E)F(\rho)=\mathrm{tr}_{H_S}B\rho=\langle B,\rho\rangle$. This identity together with the definition of the duality between $\mathcal{L}(H_S)$ and $\mathcal{L}_1(H_S)$ implies that

$$F^*(B\otimes\mathrm{Id})=B. \tag{10}$$

On the other hand, if F^* satisfies (10) then, for $B\in\mathcal{L}(H_S)$ and $\rho\in\mathcal{L}_1(H_S)$,

$$\langle B\otimes\mathrm{Id}_E,F(\rho)\rangle=\langle F^*(B\otimes\mathrm{Id}_E),\rho\rangle=\langle B,\rho\rangle=\mathrm{tr}_{H_S}B\rho. \tag{11}$$

But $\langle B\otimes\mathrm{Id}_E,F(\rho)\rangle=\mathrm{tr}_{H_S}B(\mathrm{tr}_{H_E}F(\rho))$. Hence $\langle B,\rho\rangle=\mathrm{tr}_{H_S}B\rho=\langle B,\mathrm{tr}_{H_E}F(\rho)\rangle$, and as the latter identity holds for any B, we finally obtain $\rho=\mathrm{tr}_{H_E}F(\rho)$. The lemma is proved. □

Theorem 1 and Lemma 2 imply the following theorem.

Theorem 2: *If $R:\mathcal{L}(H_S\otimes H_E)\to\mathcal{L}(H_S)$ is a linear mapping, continuous in the ultraweak or $(\sigma(\mathcal{L}(H),\mathcal{L}_1(H)),\sigma(\mathcal{L}(H_S),\mathcal{L}_1(H_S)))$ topology; see, e.g., Sec. VI.6 of Ref. 4, and if $R(B\otimes\mathrm{Id}_E)=B$ is true for all $B\in\mathcal{L}(H_S)$ then there exists an element $\rho_E\in\mathcal{D}(H_S)$ such that $R(A)=\mathrm{tr}_{H_E}A(\mathrm{Id}_S\otimes\rho_E)$ for all $A\in\mathcal{L}(H)$.*

IV. PROBABILITY MEASURES

The classical analog of the case considered in Theorem 1 is much simpler and admits nonfactorizing answers. Let T be a topological space; then $\mathcal{C}_b(T)$ is the vector space of all bounded continuous functions on T, $\mathcal{M}(T)$ is the vector space of all Borel (signed) measures on T equipped with the topology $\sigma(\mathcal{M}(T),\mathcal{C}_b(T))$, and $\mathcal{M}_p(T)$ is the closed convex set of probability measures on T. The Dirac measure at point $t\in T$ will be denoted by δ_t. Let Q and P be

topological spaces, $E=Q\times P$ the product space, and $\mathcal{G}:\mathcal{M}_p(E)\to\mathcal{M}_p(Q)$ be the mapping induced by the projection $\mathrm{pr}_Q:E\to Q$. The mapping $\mathcal{G}$ can be (uniquely) extended by linearity to an $\mathbb{R}$-linear mapping $\mathcal{M}(E)\to\mathcal{M}(Q)$. For any measure $\mu\in\mathcal{M}(E)$ the measure $\mathcal{G}\mu\in\mathcal{M}(Q)$ is called the marginal of μ. The right inverse of $\mathcal{G}$ will be called a lifting.

Lemma 3: Let $f:Q\to\mathcal{M}_p(E)$ be a continuous function such that $\mathcal{G}f(q)=\delta_q$; then the mapping $\mathcal{F}:\mathcal{M}(Q)\to\mathcal{M}(E)$, defined by

$$\mathcal{F}\nu:=\int_Q f(q)\,\nu(dq), \tag{12}$$

is a linear lifting. Any linear lifting has this representation.

Proof: Take the Dirac measure δ_q; then the integral is $\mathcal{F}\delta_q=f(q)\in\mathcal{M}_p(E)$ and we have $\mathcal{G}F\,\delta_q=\mathcal{G}f(q)=\delta_q$. The general case follows by linearity and continuity. On the other hand, if G is a linear lifting, then (12) follows with the function $f(q)=\mathcal{F}\delta_q$. □

If $f(q)$ factorizes into $f(q)=\delta_q\times\chi$ with $\chi\in\mathcal{M}(P)$, the lifting (12) factorizes into $\mathcal{F}(\nu)=\nu\times\chi$. But one can obviously choose nonfactorizing functions $f(q)$ such that $\mathcal{F}(\nu)$ is not a product measure. To give an explicit example we split Q into two disjoint measurable sets $Q=Q_1\cup Q_2$ and denote by $\chi_1(q)$ and $\chi_2(q)$ the characteristic functions of the sets Q_1 and Q_2. Then

$$f(q)=\chi_1(q)\,\delta_q\times\delta_{p_1}+\chi_2(q)\,\delta_q\times\delta_{p_2}, \tag{13}$$

with two points $p_j\in P$, $j=1,2$, $p_1\neq p_2$, yields an example of a nonfactorizing lifting.

The state space $\mathcal{D}(H)$ of a quantum mechanical system is a closed convex set with the pure states $\mathcal{P}(H)$ as extremal points. Any $W\in\mathcal{D}(H)$ can be represented by the Choquet integral,[7]

$$W=\int_{\mathcal{P}(H)} P\;\mu(dP), \tag{14}$$

where $\mu(dP)$ is a—in general nonunique—measure in the convex set $\mathcal{M}_p(\mathcal{P}(H))$ of probability measures on $\mathcal{P}(H)$; see, e.g., Ref. 12. This representation relates the quantum mechanical state space with the space of probability measures, and one might ask whether it is possible to find an affine linear mapping $\gamma:\mathcal{D}(H)\to\mathcal{M}(\mathcal{P}(H))$ such that (12) is valid for all $W\in\mathcal{D}(H)$ with the measure $\mu(dP)=\gamma_W(dP)$.

Theorem 3: *There does not exist an affine linear mapping $\gamma:\mathcal{D}(H)\to\mathcal{M}_p(\mathcal{P}(H))$ such that the representation* (12) *holds for all $W\in\mathcal{D}(H)$ with $\mu(dP)=(\gamma W)(dP)$.*

Proof: If such a mapping γ exists then any pure state has to be represented by an atomic measure on the one-point set containing just this pure state. Moreover this mapping can be extended to an $\mathbb{R}$-linear mapping $\gamma:\mathcal{L}_1^a(H)\to\mathcal{M}(\mathcal{P}(H))$. Since there are finite sets of pure states which are linearly dependent in $\mathcal{L}_1^a(H)$—e.g., any four projection operators on the Hilbert subspace $\mathbb{C}^2$ of $\mathcal{H}$—whereas the set of atomic measures is linear independent in $\mathcal{M}(\mathcal{P}(H))$ we obtain a contradiction to the linearity of γ. □

The proof given here exploits the different structures of the convex sets $\mathcal{D}(H)$ and $\mathcal{M}_p(\mathcal{P}(H))$: the space of measures is a simplex whereas $\mathcal{D}(H)$ not. Theorem 3 is also closely related to Theorem 1; it is actually a consequence of it. To see that implication assume such an affine linear mapping γ exists. Then the lifting problem of Sec. II has the following solution in contradiction to Theorem 1.

In the first step the statistical operator $\rho\in\mathcal{D}(H_S)$ is mapped onto the measure $\gamma\rho\in\mathcal{M}_p(\mathcal{P}(H_S))$. Following Lemma 3 we can lift this measure to a measure $\sigma\in\mathcal{M}_p(\mathcal{P}(H_S)\times\mathcal{P}(H_E))$. Thereby we can choose a lifting such that σ is not a product measure; take, e.g., (13). The operator

$$W=\int_{\mathcal{P}(H_S)\times\mathcal{P}(H_E)} P_S\otimes P_E\sigma(dP_S\times dP_E) \tag{15}$$

has the partial trace $\mathrm{tr}_{H_E}W=\int_{\mathcal{P}(H_S)}P_S(\gamma\rho)(dP_S)=\rho$. All steps of the mapping $\rho\to W$ are affine linear. Since the measure σ does not factorize, the statistical operator W has not the product form $\rho\otimes\rho_E$, and we have obtained a contradiction to Theorem 1.

In addition to the representation of states by a probability distribution on the set of pure states there exists a representation of any state by a random vector distributed by a probability measure on the Hilbert space. Such a representation is used in the theory of Schrödinger (–Belavkin) stochastic equations (see Refs. 13, 14 and references therein), which gives both a phenomenological description of continuous measurements and a Markovian approximations for the reduced dynamics.

By $\mathcal{M}(H)$ we denote the space of all σ-additive signed measures on the σ-algebra of Borel subsets of H. The space of probability measures on H is denoted by $\mathcal{M}_p(H)$, the set of all measures concentrated on $H\backslash\{0\}$ by $\mathcal{M}^0(H)$, and the set of all probability measures concentrated on $H\backslash\{0\}$ by $\mathcal{M}_p^0(H)=\mathcal{M}^0(H)\cap\mathcal{M}_p(H)$.

In the theory of stochastic Schrödinger equations a probability measure $\nu\in\mathcal{M}_p^0(H)$ represents the state $B\in\mathcal{D}(H)$ if

$$\int_H\langle z,Az\rangle\|z\|^{-2}\nu(dz)=\omega_B(A)\equiv\mathrm{tr}_H AB \tag{16}$$

is valid for all observables $A\in\mathcal{L}(H)$. Thereby any measure $\nu\in\mathcal{M}_p^0(H)$ represents a state, and any state $W\in\mathcal{D}(H)$ can be represented by such a measure.

For the proof of the first statement take $A\in\mathcal{L}(H)$. Then the function $|\langle z,Az\rangle|\|z\|^{-2}$ is bounded by $\|A\|$ for all $z\neq 0$, and the integral $\omega_\nu(A):=\int_H\|z\|^{-2}\langle z,Az\rangle\nu(dz)$ is defined. Moreover, it is easy to see that all the demands of Gleason's theorem, see Remark 1, are fulfilled. Hence there exists a state $W\in\mathcal{D}(H)$ such that $\omega_\nu(A)=\mathrm{tr}_H AW$.

On the other hand, given a statistical operator a probability measure for the representation (16) can be constructed as follows. For any $B\in\mathcal{D}(H)$, let $\nu_B^0\in\mathcal{M}_p^0(H)$ be a probability measure with the correlation operator B, i.e., for all $z_1,z_1\in H$ the identity $\langle z_1,Bz_2\rangle=\int\langle z_1,z\rangle\langle z,z_2\rangle\nu_B^0(dz)$ is true. It is worth noticing that among the measures ν_B^0 there exist precisely one Gaussian measure with zero mean value. The positive measure $\nu_B\in\mathcal{M}^0(H)$ is then defined by $\nu_B=\langle z,z\rangle\nu_B^0=\|z\|^2\nu_B^0$; i.e., for any Borel subset $\mathcal{A}$ of $H^{\mathbb{R}}$ we have $\nu_B(\mathcal{A})=\int_{\mathcal{A}}\langle z,z\rangle\nu_B^0(dz)$. The identity $\mathrm{tr}_H B=1$ implies that ν_B is a probability measure on H; in fact $\nu_B(H)=\int\langle z,z\rangle\nu_B^0(dz)=\mathrm{tr}_H B=1$. For any observable $A\in\mathcal{L}(H)$ the function $H\mapsto\mathbb{R}^1: z\mapsto(1/\|z\|^2)\langle z,Az\rangle$ is a random variable on the probability space (H,ν_B). The mean value $\overline{A}$ of this random variable,

$$\overline{A}=\int_H\langle z,Az\rangle\|z\|^{-2}\nu_B(dz)=\int_H\langle z,Az\rangle\nu_B^0(dz)=\mathrm{tr}_H AB,$$

is exactly the expectation of the observable A in the state $B\in\mathcal{D}(H)$. Hence the measure $\nu_B\in\mathcal{M}_p^0(H)$ represents the state B.

There exists an affine linear mapping from the measures $\nu\in\mathcal{M}_p^0(H)$ into the set of measures of the Choquet representation. Let $\varphi: H\backslash\{0\}\to\mathcal{P}(H)$ be the mapping $a\mapsto P_a$, where P_a is the projection operator onto the subspace $\{\lambda a|\lambda\in\mathbb{C}\}$, i.e., $P_a b=\langle b|a\rangle\|a\|^{-2}a$ for all $b\in H$. Then the measure $\nu\varphi^{-1}\in\mathcal{M}_p(\mathcal{P}(H))$ is defined by $\nu\varphi^{-1}(\mathcal{R})=\nu(\varphi^{-1}(\mathcal{R}))$ for any measurable set $\mathcal{R}\subset\mathcal{P}(H)$ of projection operators. This mapping $\nu\mapsto\nu\varphi^{-1}$ is affine linear. If $\nu\in\mathcal{M}_p^0$ represents a state $W\in\mathcal{D}(H)$, then (16) and the definition of $\nu\varphi^{-1}$ yield

$$\langle z_1|Wz_2\rangle \overset{(16)}{=} \int_H \langle z_1|z\rangle\langle z|z_2\rangle \|z\|^{-2}\nu(dz) = \int_{\mathcal{P}(H)} \langle z_1|Pz_2\rangle(\nu\varphi^{-1})(dP).$$

But that means $W=\int_{\mathcal{P}(H)}P(\nu\varphi^{-1})(dP)$, and $\nu\varphi^{-1}$ is the Choquet measure of the state W.

The measures in the representation (16) are highly nonunique; the arbitrariness is even larger than in the case of the Choquet representation, and one might ask again for an affine linear lifting $\mathcal{D}(H)\to\mathcal{M}_p^0(H)$. But assume such an affine linear lifting $\gamma:\mathcal{D}(H)\to\mathcal{M}_p^0(H)$ exists, then it induces an affine linear lifting $\mathcal{D}(H)\to\mathcal{M}_p(\mathcal{P}(H))$ by $W\mapsto\gamma(W)\mapsto(\gamma(W))\varphi^{-1}$ and we have obtained a contradiction to Theorem 3.

Corollary 1: There does not exist an affine linear mapping $\gamma:\mathcal{D}(H)\to\mathcal{M}_p^0(H)$ *such that for any* $W\in\mathcal{D}(H)$ *the measure* $\gamma(W)$ *represents the state* W.

A generalized Weyl relation approach to the time operator and its connection to the survival probability

Manabu Miyamoto[a)]
Department of Physics, Waseda University, Tokyo 169-8555, Japan

(Received 23 June 2000; accepted for publication 1 December 2000)

The time operator, an operator which satisfies the canonical commutation relation with the Hamiltonian, is investigated, on the basis of a certain algebraic relation for a pair of operators T and H, where T is symmetric and H self-adjoint. This relation is equivalent to the Weyl relation, in the case of self-adjoint T, and is satisfied by the Aharonov–Bohm time operator T_0 and the free Hamiltonian H_0 for the one-dimensional free-particle system. In order to see the qualitative properties of T_0, the operators T and H satisfying this algebraic relation are examined. In particular, it is shown that the standard deviation of T is directly connected to the survival probability, and H is absolutely continuous. Hence, it is concluded that the existence of the operator T implies the existence of scattering states. It is also shown that the minimum uncertainty states do not exist. Other examples of these operators T and H, than the one-dimensional free-particle system, are demonstrated. [DOI: 10.1063/1.1346598]

I. INTRODUCTION

The concept of the time operator is strongly connected with the time–energy uncertainty relation. The time operator, denoted by T, is usually defined to satisfy the canonical commutation relation (CCR) with the Hamiltonian H: $[T,H]=i$ (see Ref. 1 and the references therein). If such an operator were defined consistently on the Hilbert space corresponding to a certain quantum system, then the time–energy uncertainty relation could be automatically reduced from the Cauchy–Schwarz inequality, as in the case between the position and momentum operators on $L^2(\mathbf{R}^1)$. For instance, if we take the operator T_0 suggested by Aharonov and Bohm,[2] as a time operator for the one-dimensional free-particle system (1DFPS), we formally have $[T_0,H_0]=i$ and derive the uncertainty relation between T_0 and H_0. Here $H_0:=P^2/2$ is the free Hamiltonian for the 1DFPS, and T_0 is defined as

$$T_0:=\tfrac{1}{2}(QP^{-1}+P^{-1}Q), \tag{1}$$

where Q and P are the position and momentum operators on $L^2(\mathbf{R}^1)$ (a more precise definition is given in Sec. III). T_0 is often called the Aharonov–Bohm time operator. It is, however, not clear whether the inverse P^{-1} could be well-defined. We should also remember the criticism posed by Pauli,[3] although it is not rigorous, that the time operator cannot necessarily be defined for all quantum systems without contradiction. Furthermore the physical meaning of the time operator, if any, still remains unclear.

We shall base our discussion on the axiomatic quantum mechanics. Then it is possible to comment on the above difficulties from the axiomatic points of view. We first see that the inverse P^{-1} is a well-defined self-adjoint operator on $L^2(\mathbf{R}^1)$ (more details are given in Sec. III). Recently, the operator T_0 was shown to be well-defined, and its mathematical character was clarified, through the study of the time-of-arrival problem.[4] Observe that in Pauli's criticism, it is implicitly

a)Electronic mail: miyamo@hep.phys.waseda.ac.jp

assumed that if there exists a self-adjoint operator T which satisfies the CCR with the Hamiltonian H for some system,

$$TH\psi - HT\psi = i\psi, \quad \forall \psi \in \mathrm{Dom}(TH) \cap \mathrm{Dom}(HT), \tag{2}$$

one would be able to derive the following relation:

$$He^{i\epsilon T}\psi = e^{i\epsilon T}(H+\epsilon)\psi, \quad \forall \psi \in \mathrm{Dom}(H), \quad \forall \epsilon \in \mathbf{R}^1. \tag{3}$$

We have to be careful, however, about this kind of logic, since it is not generally true whereas its converse is true. For example, consider a pair of operators, the position and momentum operators on $L^2([0,1])$, Q and P, for the above T and H, respectively.[5] They satisfy Eq. (2) but Eq. (3) is satisfied only for the particular values $\epsilon = 2\pi n, n \in \mathbf{Z}$, since, in order that P be self-adjoint, the domain $\mathrm{Dom}(P)$ has to be supplemented with a boundary condition $\psi(0) = \theta\psi(1)$ with a fixed $\theta \in \mathbf{C}$, $|\theta| = 1$, $\forall \psi \in \mathrm{Dom}(P)$.[6] Furthermore, there is no *a priori* reason why we have to consider the time operator an observable, that is, a self-adjoint operator: we do not have any interpretation of the time operator as an observable. In this paper, we shall require the time operator to be symmetric, satisfying Eq. (2) with the Hamiltonian, but not necessarily to be self-adjoint.

The investigation of the time operator is important to understanding the time–energy uncertainty relation, and may have a significance for the analysis of the dynamics of quantum systems. A reason for the latter is that the time operator is directly connected to the Hamiltonian through the CCR, and this is algebraically so strong a relation between operators as to prescribe qualitative aspects of their spectra, we can expect that the time operator brings us information about qualitative aspects of the time evolution of quantum systems. Hence, our purposes here are to examine for which quantum systems such a symmetric time operator is allowed to exist consistently, and to disclose its relevance to the dynamics of the quantum system under consideration.

From what is mentioned above, the investigation of the time operator is involved in that of the commutator (not necessarily canonical). The connection between the commutator of the form $[H, iA] = C$ $(C \geqslant 0)$ and the spectra of self-adjoint operators, H, A, and C, has been widely studied by Putnam,[7] Kato,[8] Lavine,[9,10] and others (see also Ref. 11). We here, however, restrict our consideration to the more strong form, which will be called the ''T-weak'' Weyl relation.

Definition 1.1: Let $\mathcal{H}$ be a Hilbert space, T be a symmetric operator on $\mathcal{H}$, and H be a self-adjoint operator on $\mathcal{H}$. If, for any $\psi \in \mathrm{Dom}(T)$ and for any $t \in \mathbf{R}^1$, the relations $e^{-itH}\psi \in \mathrm{Dom}(T)$ and

$$Te^{-itH}\psi = e^{-itH}(T+t)\psi \tag{4}$$

hold, then a pair of operators T and H is said to satisfy the T-weak Weyl relation (T-weak WR), or T (H) is said to satisfy the T-weak WR with H (T).

One can find, from the above definition, that $\mathrm{Dom}(Te^{-itH}) = \mathrm{Dom}(T)$, $\forall t \in \mathbf{R}^1$. Thus the T-weak WR are represented merely by

$$Te^{-itH} = e^{-itH}(T+t), \quad \forall t \in \mathbf{R}^1. \tag{5}$$

Here it should be notified that there is the excellent work about the T-weak WR, done by Schmüdgen[12] (also see the references therein). In his work, he found, under a mild regularity condition, that T and H is unitary equivalent to the momentum operator, satisfying some boundary condition, and the position operator on a certain Hilbert space.

It will follow that the time operator T_0, in Eq. (1), is a symmetric operator on $L^2(\mathbf{R}^1)$ and one of its symmetric extensions, denoted by $\tilde{T}_0$, satisfies the $\tilde{T}_0$-weak WR with H_0 (see Sec. III). Thus as long as it is to see the qualitative properties of T_0 (or $\tilde{T}_0$), it may suffice to examine the T-weak WR and the operators T and H satisfying this relation, by paying a particular attention to their spectra and to the uncertainty relation between them. From another viewpoint to the T-weak WR

than that of Schmüdgen, we have obtained the fact that the time operator is deeply connected to the survival probablility. Indeed, if a pair of operators T and H satisfies the T-weak WR, the following inequality:

$$\frac{4(\Delta T)_\psi^2 \|\psi\|^2}{t^2} \geqslant |\langle \psi, e^{-itH}\psi\rangle|^2 \tag{6}$$

holds for every $\psi \in \mathrm{Dom}(T)$ and for every $t \in \mathbf{R}^1\setminus\{0\}$, where $(\Delta T)_\psi$ is the standard deviation of T with respect to ψ, and $|\langle \psi, e^{-itH}\psi\rangle|^2$ is the survival probability of ψ at time t. This is shown in Theorem 4.1. As an application of this inequality, we have Corollary 4.3 which states that H has no point spectrum. Furthermore, it is shown that H is absolutely continuous,[13] as in Theorem 4.4. This means that the existence of the time operator, which satisfies the T-weak WR with the Hamiltonian for some system, infers that the system consists of only scattering states. Also, in Theorem 5.1, the absence of minimum-uncertainty states, for the uncertainty relation between T and H, is proved, under some condition satisfied by the operators $\tilde{T}_0$ and H_0.

In Sec. II, the connection among the CCR, Weyl relation, and T-weak WR is mentioned. Section III is devoted to the brief study of the Aharonov–Bohm time operator in Eq. (1), to see a sign of the deep connection between the operator T and the survival probability, followed by several statements in Sec. IV. They include the inequality (6) and the spectral properties of both T and H, e.g., Theorem 4.4. Theorem 5.1 is proved in Sec. V. Further discussion about the time operator is developed in Sec. VI, on the basis of the results of the preceding sections and of the theory of Schrödinger operators. We mention other quantum systems than the 1DFPS for which an operator T exists, to satisfy the T-weak WR with the Hamiltonian. In fact, for a certain class of quantum systems, time operators are easily constructed by unitary transformations of $\tilde{T}_0$. Concluding remarks are given in Sec. VII.

II. THE CANONICAL COMMUTATION RELATION, WEYL RELATION, AND *T*-WEAK WEYL RELATION

The T-weak WR in Eq. (4) or (5) is characterized more clearly, in the Heisenberg picture. The T-weak WR is represented, in an alternative form, as

$$T_t = T + tI, \quad \forall t \in \mathbf{R}^1, \tag{7}$$

where $T_t := e^{itH}Te^{-itH}$. It is now clear that T, which satisfies the T-weak WR with H, is shifted proportionally to the time parameter t in the Heisenberg picture. This fact bring us an image of time for T. We also see, from this form, that T is necessarily unbounded. It is, however, noted that in our investigation the T-weak WR in Eq. (5) is more convenient than in Eq. (7). The connection among the Weyl relation (WR),[14] the CCR and the T-weak WR is very important, when one considers whether a symmetric operator T, satisfying the T-weak WR with the Hamiltonian for some system, is the time operator. Recall that the latter is defined as a symmetric operator satisfying the CCR with the same Hamiltonian as in Eq. (2). In this respect, we put forward the next proposition.

Proposition 2.1: Let $\mathcal{H}$ be a Hilbert space, T be a closed symmetric operator on $\mathcal{H}$, and H be a self-adjoint operator on $\mathcal{H}$. If a pair of operators T and H satisfies the T-weak WR, then there is a dense subspace $\mathcal{D}\subset\mathcal{H}$ such that

(i) $\mathcal{D}\subset \mathrm{Dom}(TH)\cap\mathrm{Dom}(HT)$,
(ii) $H:\mathcal{D}\to\mathcal{D}$,
(iii) *The CCR holds in the meaning of that $TH-HT=i$ on $\mathrm{Dom}(TH)\cap\mathrm{Dom}(HT)$. Moreover, if T is self-adjoint, then the operators T and H satisfy the WR,*

$$e^{-isT}e^{-itH} = e^{-ist}e^{-itH}e^{-isT}, \quad \forall s, \ \forall t \in \mathbf{R}^1. \tag{8}$$

The above (i), (ii), and (iii) are proved in the same manner as in the proof,[15] by noting the strong continuity of $Te^{-itH}\psi$, $\forall\psi\in\mathrm{Dom}(T)$, by virtue of the T-weak WR, and the closedness of T, and also by considering the subspace spaned by the following subset of $\mathcal{H}$, as a subspace $\mathcal{D}$ in this proposition:

$$\left\{\psi_f\in\mathcal{H}\,\middle|\,\psi_f:=\int_{-\infty}^{\infty}f(s)e^{-isH}\psi\,ds,\forall f\in C_0^{\infty}(\mathbf{R}^1)\ \text{ and }\ \forall\psi\in\mathrm{Dom}(T)\right\},$$

where the integral is defined by Riemann's sense and thus a strong limit. The last part of the proposition is proved as follows. In the case of T being self-adjoint, we see, from the T-weak WR (5), that $\forall\phi\in\mathcal{H}$ and $\forall\psi\in\mathrm{Dom}(T)$,

$$\begin{aligned}\int_{\mathbf{R}^1}\lambda\,d\langle\phi,e^{itH}F(\lambda)e^{-itH}\psi\rangle&=\langle\phi,e^{itH}Te^{-itH}\psi\rangle\\&=\langle\phi,(T+t)\psi\rangle\\&=\int_{\mathbf{R}^1}(\lambda+t)d\langle\phi,F(\lambda)\psi\rangle=\int_{\mathbf{R}^1}\lambda\,d\langle\phi,F_t(\lambda)\psi\rangle,\end{aligned}$$

where $\{F(B)|B\in\mathbf{B}^1\}$ is the spectral measure of T, $\mathbf{B}^1$ is the σ-field which is generated by all open sets of $\mathbf{R}^1$, and $F_t(B):=F(\{\lambda-t|\lambda\in B\})$. From the uniqueness of the spectral resolution, this means that $e^{itH}F(B)e^{-itH}=F_t(B)$, for all $t\in\mathbf{R}^1$. Then it follows that $\forall\psi\in\mathcal{H}$ and $\forall s\in\mathbf{R}^1$,

$$\begin{aligned}\langle\psi,e^{itH}e^{-isT}e^{-itH}\psi\rangle&=\int_{\mathbf{R}^1}e^{-is\lambda}d\langle\psi,e^{itH}F(\lambda)e^{-itH}\psi\rangle\\&=\int_{\mathbf{R}^1}e^{-is\lambda}d\langle\psi,F_t(\lambda)\psi\rangle=\int_{\mathbf{R}^1}e^{-is(\lambda+t)}d\langle\psi,F(\lambda)\psi\rangle=\langle\psi,e^{-ist}e^{-isT}\psi\rangle.\end{aligned}$$

By using the polarization identity, we can obtain the WR (8). According to von Neumann's uniqueness theorem, with respect to the solution of the WR,[14] we had better to define T, which appears in the T-weak WR, as a symmetric operator, to allow the operator H (corresponding to the Hamiltonian) to be bounded from below. We note here that if a symmetric operator T satisfies the T-weak WR with some self-adjoint operator H, then the closure of T, denoted by $\overline{T}$, also satisfies the $\overline{T}$-weak WR with the same H. This is easily verified by the usual calculation. It is guaranteed, from this proposition, that a symmetric operator T, satisfying the T-weak WR with the Hamiltonian for some system, is the time operator, and thus it is significant to examine the T-weak WR in the general analysis of the time operator. As a summary, we remark again that the following relations:

$$\mathrm{WR}\Rightarrow T-\text{weak WR}\Rightarrow\mathrm{CCR}$$

hold, in the sense of Proposition 2.1, even though, in general the converses do not hold, as is already mentioned in Sec. I.

III. THE AHARONOV–BOHM TIME OPERATOR

Let us consider the Hilbert space $L^2(\mathbf{R}^1)$. The operator T_0 on $L^2(\mathbf{R}^1)$ in Eq. (1),

$$T_0:=\tfrac{1}{2}(QP^{-1}+P^{-1}Q),$$

is defined in its domain $\mathrm{Dom}(T_0):=\mathrm{Dom}(QP^{-1})\cap\mathrm{Dom}(P^{-1}Q)$, where P is the momentum operator on $L^2(\mathbf{R}^1)$ for the 1DFPS, and P^{-1} its inverse. In the axiomatic quantum mechanics, P is defined as $P:=-iD_x$, where D_x is a differential operator on $L^2(\mathbf{R}^1)$, and its domain consists of the L^2-functions which belong to $AC(\mathbf{R}^1)$, and satisfy that their derivatives are also included in

$L^2(\mathbf{R}^1)$.[5] $AC(\Omega)$ (Ω is an open set of $\mathbf{R}^1$) is the set of functions on Ω, which are absolutely continuous on all bounded closed intervals of Ω. The free Hamiltonian H_0 for this system is $H_0 := P^2/2$. The position operator Q on $L^2(\mathbf{R}^1)$ is defined as an operator of multiplication by x on $L^2(\mathbf{R}^1)$, denoted by M_x, and its domain consists of L^2-functions, defined by ψ, such that $\int_{\mathbf{R}^1}|x\psi(x)|^2dx$ is finite. It is noted that in the definition of T_0, P^{-1} is well-defined and becomes a self-adjoint operator on $L^2(\mathbf{R}^1)$. This is because, for any self-adjoint operator A, if its inverse A^{-1} exists, A^{-1} should be self-adjoint.[16] In our case, P^{-1} exists since P is an injection, i.e., $\mathrm{Ker}(P^{-1})=\{0\}$, where $\mathrm{Ker}(A) := \{\psi \in \mathrm{Dom}(A) \mid A\psi = 0\}$.

In the momentum representation of T_0, we have

$$FT_0F^{-1} = \tfrac{1}{2}(iD_kM_{1/k} + M_{1/k}iD_k),$$

and its domain

$$\begin{aligned}\mathrm{Dom}(FT_0F^{-1}) &= \mathrm{Dom}(D_kM_{1/k}) \cap \mathrm{Dom}(M_{1/k}D_k)\\ &= \{\psi \in \mathrm{Dom}(M_{1/k}) \mid M_{1/k}\psi \in \mathrm{Dom}(D_k)\}\\ &\quad \cap \{\psi \in \mathrm{Dom}(D_k) \mid D_k\psi \in \mathrm{Dom}(M_{1/k})\},\end{aligned} \tag{9}$$

where F is the Fourier transformation from $L^2(\mathbf{R}^1)$ onto $L^2(\mathbf{R}^1_k)$, and use has been made of the relations $FQF^{-1} = iD_k$, $FPF^{-1} = M_k$, and $FP^{-1}F^{-1} = M_{1/k}$. At first sight, $\mathrm{Dom}(T_0)$ seems to be rather restricted, because of the existence of P^{-1} in the definition of T_0. The following simple example by Kobe[1] may be considered to support this anticipation.

Example 1: Let us consider the functions $\phi_n(k) := k^n N_n e^{-a_0k^2} \in L^2(\mathbf{R}^1_k)$, where $n \in \mathbf{Z}$, $n \geqslant 0$, $a_0 > 0$, and N_n is a normalization factor. We see that for any integer $n \geqslant 2$, $\phi_n \in \mathrm{Dom}(FT_0F^{-1})$. The action of FT_0F^{-1} on each $\phi_n (n \geqslant 2)$ is, by direct calculation,

$$FT_0F^{-1}\phi_n(k) = \frac{i}{2}[(2n-1)k^{n-2} - 2a_0k^{n-1} - 2a_0k^n]N_ne^{-a_0k^2}.$$

In the case of $n = 0, 1$, however, the right-hand side of the above equation is formally not square integrable, and thus $\phi_0, \phi_1 \notin \mathrm{Dom}(FT_0F^{-1})$.

Notice that in spite of this example, $\mathrm{Dom}(T_0)$ is dense in $L^2(\mathbf{R}^1)$. This can be seen from the fact that the subspace $\mathcal{C}_\mathrm{i}$ is included in $\mathrm{Dom}(FT_0F^{-1})$ and is dense in $L^2(\mathbf{R}^1_k)$. $\mathcal{C}_\mathrm{i}$ is defined as

$$\mathcal{C}_\mathrm{i} := \{\psi \in C_0^\infty(\mathbf{R}^1_k) \mid \mathrm{supp}\,\psi \subset \mathbf{R}^1_k \backslash \{0\}\}, \tag{10}$$

where supp ψ denotes the support of ψ, i.e., the closure of $\{k \in \mathbf{R}^1_k \mid \psi(k) \neq 0\}$. Therefore the adjoint operator of T_0, denoted by T_0^*, can be defined. Then, T_0 is symmetric, because

$$T_0^* \supset \tfrac{1}{2}((QP^{-1})^* + (P^{-1}Q)^*) \supset \tfrac{1}{2}((P^{-1})^*Q^* + Q^*(P^{-1})^*) = T_0,$$

where we have used the fact that $Q^* = Q$ and $(P^{-1})^* = P^{-1}$. It is noted that T_0 and H_0 do not satisfy the T_0-weak WR, $T_0e^{-itH_0} = e^{-itH_0}(T_0 + t)$, $\forall t \in \mathbf{R}^1$. Because $\mathrm{Dom}(FT_0F^{-1})$ in Eq. (9) is not invariant under the action of $e^{-itM_{k^2/2}}$ for all $t \neq 0$, that is for any $t \neq 0$, there is some vector $\psi \in \mathrm{Dom}(FT_0F^{-1})$ satisfying $e^{-itM_{k^2/2}}\psi \notin \mathrm{Dom}(FT_0F^{-1})$. For instance, consider the following L^2-function g of $k \in \mathbf{R}^1_k$:

$$g(k) := \begin{cases} e^{-1/k^2}\dfrac{1}{1+|k|^s} & (k \neq 0),\\ 0 \quad (k = 0), \end{cases}$$

where $1/2 < s \leqslant 3/2$. Then g is C^∞-function. One can see that $g \in \mathrm{Dom}(FT_0F^{-1})$, however, $e^{-itM_{k^2/2}}g \notin \mathrm{Dom}(FT_0F^{-1})$, $\forall t \neq 0$. This follows from the fact that $e^{-itM_{k^2/2}}g \notin \mathrm{Dom}(D_k)$, $\forall t$

$\neq 0$. Here we introduce a symmetric extension of T_0 on $L^2(\mathbf{R}^1)$, denoted by $\tilde{T}_0$, which will satisfy the $\tilde{T}_0$-weak WR with H_0, and is defined, in the momentum representation, as follows:

$$\mathrm{Dom}(F\tilde{T}_0F^{-1}) := \left\{ \psi \in L^2(\mathbf{R}^1_k) \;\middle|\; \begin{array}{c} \psi \in AC(\mathbf{R}^1_k\backslash\{0\}), \lim_{k\to 0}\dfrac{\psi(k)}{|k|^{1/2}} = 0, \\ \text{and} \\ \displaystyle\int_{\mathbf{R}^1_k\backslash\{0\}} \left| \frac{d\psi(k)/k}{dk} + \frac{1}{k}\frac{d\psi(k)}{dk} \right|^2 dk < \infty \end{array} \right\},$$

and its action,

$$F\tilde{T}_0F^{-1}\psi(k) = \frac{i}{2}\left(\frac{d\psi(k)/k}{dk} + \frac{1}{k}\frac{d\psi(k)}{dk} \right), \quad \text{a.e. } k \in \mathbf{R}^1_k\backslash\{0\}, \quad \forall \psi \in \mathrm{Dom}(F\tilde{T}_0F^{-1}). \tag{11}$$

It is seen that $\mathrm{Dom}(F\tilde{T}_0F^{-1})$ is a subspace of $L^2(\mathbf{R}^1_k)$, and $F\tilde{T}_0F^{-1}$ is a linear operator on $L^2(\mathbf{R}^1_k)$.

Proposition 3.1: $\tilde{T}_0$ is a symmetric extension of T_0.

Proof: $F\tilde{T}_0F^{-1}$ being symmetric follows from that $\forall \psi, \forall \phi \in \mathrm{Dom}(F\tilde{T}_0F^{-1})$,

$$\begin{aligned} &\int_{(0,\infty)} \overline{\phi}(k)\frac{i}{2}\left(\frac{d\psi(k)/k}{dk} + \frac{1}{k}\frac{d\psi(k)}{dk} \right) dk - \int_{(0,\infty)} \frac{-i}{2}\left(\frac{d\overline{\phi}(k)/k}{dk} + \frac{1}{k}\frac{d\overline{\phi}(k)}{dk} \right)\psi(k)\,dk \\ &\quad = i\left(\lim_{b\to\infty}\frac{\overline{\phi}(b)\psi(b)}{b} - \lim_{a\downarrow 0}\frac{\overline{\phi}(a)\psi(a)}{a} \right) = 0, \end{aligned}$$

where $\lim_{b\to\infty}\overline{\phi}(b)\psi(b)/b = 0$ and $\lim_{a\downarrow 0}\overline{\phi}(a)\psi(a)/a = 0$ are used. The former is brought from the integrability of $\overline{\phi}(k)\psi(k)$, and the latter from the boundary conditions of $\overline{\phi}(k)$ and $\psi(k)$ at the origin. By considering the left half-line in the same manner, we can obtain that $\forall \psi, \forall \phi \in \mathrm{Dom}(F\tilde{T}_0F^{-1})$, $\langle \phi, F\tilde{T}_0F^{-1}\psi\rangle = \langle F\tilde{T}_0F^{-1}\phi, \psi\rangle$, that is, $F\tilde{T}_0F^{-1}$ is symmetric. To see that $\tilde{T}_0$ is an extension of T_0, i.e., $\tilde{T}_0 \supset T_0$, it is sufficient that every $\psi \in \mathrm{Dom}(FT_0F^{-1})$ satisfies the boundary condition at the origin, which appears in the definition of $\mathrm{Dom}(F\tilde{T}_0F^{-1})$. This is easily verified as follows. Consider a $\psi \in \mathrm{Dom}(FT_0F^{-1})$ in Eq. (9); then $\psi(k)/k$ belongs to $AC(\mathbf{R}^1_k)$, and thus, $\lim_{k\to 0}\psi(k)/k$ exists. Thus $\lim_{k\to 0}|\psi(k)/|k|^{1/2}| = \lim_{k\to 0}|k|^{1/2}|\psi(k)/k| = 0$. □

This operator may be more understood, from the view of the energy representation which was emphasized by Egusquiza and Muga, and many other authors (see Ref. 4 and the references therein).

It is, now, noted that $\mathrm{Dom}(\tilde{T}_0)$ is an invariant subspace of e^{-itH_0}. Because, for every $\psi \in \mathrm{Dom}(F\tilde{T}_0F^{-1})$ and $t \in \mathbf{C}$ $(\mathrm{Im}t \leqslant 0)$, $\lim_{k\to 0}e^{-itk^2/2}\psi(k)/|k|^{1/2} = 0$, and for almost everywhere $k \in \mathbf{R}^1_k\backslash\{0\}$,

$$\frac{i}{2}\left(\frac{de^{-itk^2/2}\psi(k)/k}{dk} + \frac{1}{k}\frac{de^{-itk^2/2}\psi(k)}{dk} \right) = te^{-itk^2/2}\psi(k) + e^{-itk^2/2}\frac{i}{2}\left(\frac{d\psi(k)/k}{dk} + \frac{1}{k}\frac{d\psi(k)}{dk} \right),$$

where the right-hand side is square-integrable. Therefore $e^{-itM_{k^2/2}}\psi$ is included in $\mathrm{Dom}(F\tilde{T}_0F^{-1})$, and, as a result, $\tilde{T}_0$ can satisfy the $\tilde{T}_0$-weak WR with H_0,

$$\tilde{T}_0e^{-itH_0} = e^{-itH_0}(\tilde{T}_0 + t), \quad \forall t \in \mathbf{C}(\mathrm{Im}t \leqslant 0), \tag{12}$$

whereas T_0 does not satisfy the T_0-weak WR with H_0. It is seen that $\tilde{T}_0$ is not self-adjoint. Because, if it was so, $\tilde{T}_0$ and H_0 would have to satisfy the WR from Proposition 2.1. The latter is, however, in contradiction to the non-negativity $H_0 \geqslant 0$.

Consider the subspace $\mathcal{C}_{\rm i}$ in Eq. (10). It is easily seen that $\mathcal{C}_{\rm i}$ is an invariant subspace of $F\tilde{T}_0F^{-1}$, that is, $F\tilde{T}_0F^{-1}:\mathcal{C}_{\rm i}\to\mathcal{C}_{\rm i}$. Thus $F\tilde{T}_0F^{-1}$ can act any times on $\mathcal{C}_{\rm i}$. In the position representation, this property is described as $\tilde{T}_0: F^{-1}\mathcal{C}_{\rm i}\to F^{-1}\mathcal{C}_{\rm i}$ where $F^{-1}\mathcal{C}_{\rm i}:=\{\psi\in L^2(\mathbf{R}^1)|\,\psi = F^{-1}\eta, \eta\in\mathcal{C}_{\rm i}\}$. $\mathcal{C}_{\rm i}$ may be regarded as an important subspace which determines the property of $\tilde{T}_0$. Indeed, using the $\tilde{T}_0$-weak WR in Eq. (12), we can obtain the following statement:

Proposition 3.2: For any non-negative integer n, m and for any $\psi,\phi\in F^{-1}\mathcal{C}_{\rm i}$,

$$\lim_{t\to\pm\infty}|t|^n\left|\frac{d^m\langle\phi,e^{-itH_0}\psi\rangle}{dt^m}\right|=0.$$

That is, the probability amplitude, $\langle\phi,e^{-itH_0}\psi\rangle$, is a rapidly decreasing function of $t\in\mathbf{R}^1$.

Proof: Let $\psi,\phi\in F^{-1}\mathcal{C}_{\rm i}$. Since $F^{-1}\mathcal{C}_{\rm i}$ is an invariant subspace of $\tilde{T}_0$, thus $\tilde{T}_0\phi,\tilde{T}_0\psi\in F^{-1}\mathcal{C}_{\rm i}$. By using Eq. (12), we have

$$\langle\phi,e^{-itH_0}\tilde{T}_0\psi\rangle=\langle\phi,(\tilde{T}_0-t)e^{-itH_0}\psi\rangle=\langle\tilde{T}_0\phi,e^{-itH_0}\psi\rangle-t\langle\phi,e^{-itH_0}\psi\rangle, \tag{13}$$

where $\langle\cdot,\cdot\rangle$ denotes the inner product in $L^2(\mathbf{R}^1)$. Note that $\forall\psi\in L^2(\mathbf{R}^1)$, $\mathrm{w}-\lim_{t\to\pm\infty}e^{-itH_0}\psi=0$,[17] because H_0 is (spectrally) absolutely continuous.[13] This means that $\lim_{t\to\pm\infty}\langle\phi,e^{-itH_0}\tilde{T}_0\psi\rangle=\lim_{t\to\pm\infty}\langle\tilde{T}_0\phi,e^{-itH_0}\psi\rangle=0$, which leads to the relation $\lim_{t\to\pm\infty}t\langle\phi,e^{-itH_0}\psi\rangle=0$. In order to show that for any integer $n\geqslant 2$ and for any $\psi,\phi\in\mathcal{C}_{\rm i}$, $\lim_{t\to\pm\infty}t^n\langle\phi,e^{-itH_0}\psi\rangle=0$, we observe that $\tilde{T}_0{}^k:F^{-1}\mathcal{C}_{\rm i}\to F^{-1}\mathcal{C}_{\rm i}$, and that the following relations similar to Eq. (13) hold for every $n\in\mathbf{N}$:

$$\begin{aligned}\langle\phi,e^{-itH_0}\tilde{T}_0{}^{n+1}\psi\rangle&=\langle\phi,(\tilde{T}_0-t)^{n+1}e^{-itH_0}\psi\rangle\\&=\sum_{k=0}^{n}(-t)^k\binom{n+1}{k}\langle\tilde{T}_0{}^{n+1-k}\phi,e^{-itH_0}\psi\rangle+(-t)^{n+1}\langle\phi,e^{-itH_0}\psi\rangle.\end{aligned}$$

Then $\lim_{t\to\pm\infty}t^n\langle\phi,e^{-itH_0}\psi\rangle=0$ is proved recursively for any integer $n\geqslant 2$. In order to show that $\langle\phi,e^{-itH_0}\psi\rangle$ is infinitely differentiable on $\mathbf{R}^1$, it is sufficient to use the fact that $\forall\psi\in F^{-1}\mathcal{C}_{\rm i}$, $e^{-itH_0}\psi$ is infinitely and strongly differentiable on $\mathbf{R}^1$, and $F^{-1}\mathcal{C}_{\rm i}$ is also an invariant subspace of H_0, that is, $H_0:F^{-1}\mathcal{C}_{\rm i}\to F^{-1}\mathcal{C}_{\rm i}$. □

We note that $\forall\psi,\phi\in F^{-1}\mathcal{C}_{\rm i}$, $\langle\phi,e^{-itH_0}\psi\rangle$ converges to 0 as $t\to\pm\infty$, more rapidly than any inverse-power of t. This fact is not trivial and is seen from the next example.

Example 2: Define the survival probability of ψ as a function of $t\in\mathbf{R}^1$, i.e., $P_\psi(t):=|\langle\psi,e^{-itH_0}\psi\rangle|^2$, where ψ is an arbitrary element in $L^2(\mathbf{R}^1_k)$. Then, for a particular ϕ_n, $n\geqslant 2$ in Example 1, $P_{\phi_n}(t)=(1+t^2/16a_0^2)^{-n-1/2}$ and this converges to 0 as $t\to\pm\infty$ as, at most, a power function of t.

From the above statement and example, we may expect that there is a connection between T_0 (or $\tilde{T}_0$) and the survival probability. This expectation is also inspired from the works done by Bhattacharyya.[18]

IV. CONNECTION BETWEEN THE TIME OPERATOR AND THE SURVIVAL PROBABILITY

If we assume the existence of a symmetric operator T which satisfies the T-weak WR with the Hamiltonian for some system, i.e., the time operator, several statements are derived, in a rigorous form, which concern to the connection between the time operator and the survival probability. Before deriving these statements, we introduce a few definitions. Let T be a symmetric operator on the Hilbert space $\mathcal{H}$ and define

$$\langle T\rangle_\psi := \langle \psi, T\psi\rangle, \quad (\Delta T)_\psi := \|(T-\langle T\rangle_\psi)\psi\|, \quad \forall \psi \in \mathrm{Dom}(T), \tag{14}$$

where $\langle \cdot, \cdot \rangle$ denotes the inner product in $\mathcal{H}$, and $\|\cdot\|$ the norm in $\mathcal{H}$, defined by this inner product. $\langle T\rangle_\psi$ and $(\Delta T)_\psi$ are, respectively, called the expectation and standard deviation of T with respect to the state ψ.

Theorem 4.1: *Let T be a symmetric operator on $\mathcal{H}$, and H be a self-adjoint operator on $\mathcal{H}$. Then if a pair of operators T and H satisfies the T-weak WR, the inequality (6) holds.*

Proof: Let us define self-adjoint operators $\cos(tH) := (e^{itH}+e^{-itH})/2$ and $\sin(tH) := (e^{itH} - e^{-itH})/2i$. Then, from the T-wea WR in Eq. (5), we can obtain two commutation relations,

$$[T, \cos(tH)] = -it\sin(tH), \quad [T, \sin(tH)] = it\cos(tH). \tag{15}$$

From the above commutation relations, we can derive the uncertainty relations. From the first relation in Eq. (15), we have that

$$(\Delta T)_\psi^2 \|\cos(tH)\psi\|^2 \geqslant \frac{t^2}{4}|\langle \psi, [T, \cos(tH)]\psi\rangle|^2 = \frac{t^2}{4}|\mathrm{Im}\langle \psi, e^{-itH}\psi\rangle|^2,$$

$\forall \psi \in \mathrm{Dom}(T)$, $\forall t \in \mathbf{R}^1$. Similarly, the second relation in Eq. (15) gives us an inequality,

$$(\Delta T)_\psi^2 \|\sin(tH)\psi\|^2 \geqslant \frac{t^2}{4}|\mathrm{Re}\langle \psi, e^{-itH}\psi\rangle|^2, \quad \forall \psi \in \mathrm{Dom}(T), \ \forall t \in \mathbf{R}^1.$$

Adding these inequalities together, and taking into account the relation $\|\cos(tH)\psi\|^2 + \|\sin(tH)\psi\|^2 = \|\psi\|^2$, the inequality (6) can be obtained. □

Two corollarys follow from the inequality (6).

Corollary 4.2: Let T be a symmetric operator on $\mathcal{H}$, and H be a self-adjoint operator on $\mathcal{H}$. Then if a pair of operators T and H satisfies the T-weak WR, T has no point spectrum.

Proof: Suppose that there existed an eigenvector $\psi_0 \in \mathrm{Dom}(T)$ belonging to an eigenvalue $\lambda \in \mathbf{R}^1$ of T, that is, $T\psi_0 = \lambda\psi_0$ and $\|\psi_0\| = 1$. Then we see that $(\Delta T)_{\psi_0} = 0$, from the definition in Eq. (14). It follows, from Theorem 4.1, that $\langle \psi_0, e^{-itH}\psi_0\rangle = 0$, $\forall t \in \mathbf{R}^1\backslash\{0\}$. Since e^{-itH} is strongly continuous at any $t \in \mathbf{R}^1$, we have that $\|\psi_0\|^2 = \lim_{t\to 0}\langle \psi_0, e^{-itH}\psi_0\rangle = 0$, and this is in contradiction to the premise. Thus T has no point spectrum. □

Corollary 4.3: Let T be a symmetric operator on $\mathcal{H}$, and H be a self-adjoint operator on $\mathcal{H}$. If a pair of operators T and H satisfies the T-weak WR, then H has no point spectrum.

Proof: Since $\mathrm{Dom}(T)$ is dense in $\mathcal{H}$, for each $\psi \in \mathcal{H}$ there is a sequence $\{\psi_n\}_{n=1}^\infty \subset \mathrm{Dom}(T)$, satisfying $\psi_n \to \psi$, $n \to \infty$. It follows that

$$\begin{aligned}|\langle \psi, e^{-itH}\psi\rangle - \langle \psi_n, e^{-itH}\psi_n\rangle| &= |\langle \psi, e^{-itH}\psi\rangle - \langle \psi, e^{-itH}\psi_n\rangle + \langle \psi, e^{-itH}\psi_n\rangle - \langle \psi_n, e^{-itH}\psi_n\rangle| \\ &\leqslant \|e^{itH}\psi\|\|\psi - \psi_n\| + \|\psi - \psi_n\|\|e^{-itH}\psi_n\| \leqslant (\|\psi\| + \|\psi_n\|)\|\psi - \psi_n\|,\end{aligned}$$

and thus,

$$\begin{aligned}\lim\ \sup_{t\to\pm\infty}|\langle \psi, e^{-itH}\psi\rangle| &\leqslant \lim\ \sup_{t\to\pm\infty}|\langle \psi_n, e^{-itH}\psi_n\rangle| + (\|\psi\| + \|\psi_n\|)\|\psi - \psi_n\| \\ &= (\|\psi\| + \|\psi_n\|)\|\psi - \psi_n\|,\end{aligned}$$

where we use the inequality (6) and $\psi_n \in \mathrm{Dom}(T)$, in the last equality. Note that the above inequality holds for any $n \in \mathbf{N}$. Thus, in the limit $n \to \infty$, we obtain that

$$\forall \psi \in \mathcal{H}, \quad \lim_{t\to\pm\infty}\langle \psi, e^{-itH}\psi\rangle = 0. \tag{16}$$

This means that H has no point spectrum. Because if H has a nonempty point spectrum, say $\lambda \in \mathbf{R}^1$, then there is a corresponding eigenvector ψ_λ, which satisfies $H\psi_\lambda = \lambda\psi_\lambda$. Obviously ψ_λ does not satisfy the above condition (16). □

Moreover, it is seen that H is absolutely continuous, under the same assumption as in Corollary 4.3. Its proof is, essentially, based on the theorem in Ref. 19. For later convenience, here we introduce the closed subspace of $\mathcal{H}$, with respect to a self-adjoint operator H on $\mathcal{H}$, that is, $\mathcal{H}_{\mathrm{ac}}(H) := \{\psi \in \mathcal{H} | \|E(\cdot)\psi\|^2 \text{is absolutely continuous}\}$, where $\{E(B) \mid B \in \mathbf{B}^1\}$ is the spectral measure of H.[20]

Theorem 4.4: *Let T be a symmetric operator on $\mathcal{H}$, and H be a self-adjoint operator on $\mathcal{H}$. If a pair of operators T and H satisfies the T-weak WR, then*

$$\|E(B)\psi\|^2 \leqslant \|T\psi\|\|\psi\||B|, \tag{17}$$

for all $\psi \in \mathrm{Dom}(T)$ and all $B \in \mathbf{B}^1$, where $|B|$ is the Lebesgue measure of B. In particular, H is absolutely continuous.

Proof: Let us, first, derive the inequality that, $\forall \epsilon > 0$, $\forall \lambda \in \mathbf{R}^1$, and $\forall \psi \in \mathrm{Dom}(T)$,

$$|\mathrm{Im}\langle \psi, R(\lambda + i\epsilon)\psi\rangle| \leqslant \pi \|T\psi\|\|\psi\|, \tag{18}$$

where $R(\lambda \pm i\epsilon) := (H - (\lambda \pm i\epsilon))^{-1}$. It is seen that

$$\begin{aligned} i\,\mathrm{Im}\langle \psi, R(\lambda + i\epsilon)\psi\rangle &= \frac{1}{2}\int_{\mathbf{R}^1}\left(\frac{1}{\lambda' - \lambda - i\epsilon} - \frac{1}{\lambda' - \lambda + i\epsilon}\right) d\langle \psi, E(\lambda')\psi\rangle \\ &= \frac{i}{2}\int_{\mathbf{R}^1}\left[\int_0^\infty (e^{-it(\lambda' - \lambda - i\epsilon)} + e^{it(\lambda' - \lambda + i\epsilon)})dt\right] d\langle \psi, E(\lambda')\psi\rangle \\ &= i\int_0^\infty e^{-\epsilon t}\langle \psi, \cos t(H - \lambda)\psi\rangle dt \\ &= \lim_{\delta \downarrow 0}\int_\delta^\infty \frac{e^{-\epsilon t}}{t}\langle \psi, [T, \sin t(H - \lambda)]\psi\rangle dt, \end{aligned} \tag{19}$$

where Fubini's theorem has been used in the third equality, and Eq. (15) in the last. To evaluate Eq. (19), it is sufficient to see that

$$\lim_{\delta \downarrow 0}\int_\delta^\infty \frac{e^{-\epsilon t}}{t}\langle T\psi, \sin t(H - \lambda)\psi\rangle dt. \tag{20}$$

We define, here, a function $f(\epsilon, \lambda): (0, \infty) \times \mathbf{R}^1 \to \mathbf{R}^1$, as follows:

$$f(\epsilon, \lambda) := \int_0^\infty e^{-\epsilon t}\frac{\sin t\lambda}{t} dt.$$

$f(\epsilon, \lambda)$ is continuous on $(0, \infty) \times \mathbf{R}^1$, because of the fact that $|e^{-\epsilon t}\sin t\lambda/t| \leqslant e^{-\epsilon t}|\lambda|$ for any $t > 0$, and of the use of the dominated convergence theorem. Furthermore, since $\forall \epsilon > 0$, $\forall \lambda \in \mathbf{R}^1$ $e^{-\epsilon t}\sin t\lambda$ is integrable on $[0, \infty)$, $f(\epsilon, \lambda)$ is differentiable with respect to any $\epsilon > 0$, for each fixed λ. Thus, it is obtained, through the partial integrations, that $\forall \lambda \neq 0$,

$$\partial_\epsilon f(\epsilon, \lambda) = -\frac{1}{\lambda}\frac{1}{1 + \epsilon^2/\lambda^2}.$$

Note that $\forall \lambda \in \mathbf{R}^1$, $\lim_{\epsilon \to \infty} f(\epsilon, \lambda) = 0$, we obtain

$$f(\epsilon,\lambda)=\pm\frac{\pi}{2}-\frac{1}{\lambda}\int_0^{\epsilon}\frac{1}{1+\tau^2/\lambda^2}d\tau, \tag{21}$$

where each $\pm$ corresponds to the sign of λ. From this expression, $f(\epsilon,\lambda)$ is bounded, i.e. $|f(\epsilon,\lambda)|\leqslant\pi/2$. Equation (20) is expressed by $f(\epsilon,\lambda)$,

$$\begin{aligned}\lim_{\delta\downarrow 0}\int_{\delta}^{\infty}\frac{e^{-\epsilon t}}{t}\langle T\psi,\sin t(H-\lambda)\psi\rangle dt&=\lim_{\delta\downarrow 0}\int_{\delta}^{\infty}\frac{e^{-\epsilon t}}{t}\left[\int_{\mathbf{R}^1}\sin t(\lambda'-\lambda)d\langle T\psi,E(\lambda')\psi\rangle\right]dt\\&=\lim_{\delta\downarrow 0}\int_{\mathbf{R}^1}\left[\int_{\delta}^{\infty}e^{-\epsilon t}\frac{\sin t(\lambda'-\lambda)}{t}dt\right]d\langle T\psi,E(\lambda')\psi\rangle\\&=\int_{\mathbf{R}^1}f(\epsilon,\lambda'-\lambda)d\langle T\psi,E(\lambda')\psi\rangle=\langle T\psi,f(\epsilon,H-\lambda)\psi\rangle,\end{aligned}$$

where Fubini's theorem is used in the second equality, and the dominated convergence theorem is in the third. Substituting above relation into Eq. (19),

$$i\,\mathrm{Im}\langle\psi,R(\lambda+i\epsilon)\psi\rangle=\langle T\psi,f(\epsilon,H-\lambda)\psi\rangle-\langle f(\epsilon,H-\lambda)\psi,T\psi\rangle.$$

Note that $\|f(\epsilon,H-\lambda)\|\leqslant\pi/2$, then Equation (18) is obtained. Equation (17) follows from Eq. (18) through Stone's formula. By virtues of Eq. (17) and the denseness of $\mathrm{Dom}(T)$ in $\mathcal{H}$, it is seen that H is absolutely continuous. □

V. ABSENCE OF MINIMUM-UNCERTAINTY STATES

When a pair of operators T and H satisfies the T-weak WR, the following uncertainty relation between them:

$$(\Delta T)_{\psi}(\Delta H)_{\psi}\geqslant\tfrac{1}{2},\quad\forall\psi\in\mathrm{Dom}(TH)\cap\mathrm{Dom}(HT)\ \ (\|\psi\|=1), \tag{22}$$

is automatically derived, from the CCR between T and H, the validity of which follows from Proposition 2.1 (a more detailed explanation will be given in the proof of Theorem 5.1). For operators Q and P in Sec. III, it is well known that there is a state $\psi\in\mathrm{Dom}(QP)\cap\mathrm{Dom}(PQ)$ $(\|\psi\|=1)$, which minimizes the uncertainty, that is, a Gaussian packet. The following statement, on the contrary, shows that, under some additional conditions, there is no state $\psi\in\mathrm{Dom}(TH)\cap\mathrm{Dom}(HT)$ $(\|\psi\|=1)$ which satisfies the equality in Eq. (22).

Theorem 5.1: *Let T be a symmetric operator on $\mathcal{H}$, H be a self-adjoint operator on $\mathcal{H}$, and these operators satisfy the T-weak WR. Then if H is non-negative and if the T-weak WR is analytically continued for all $t\in\mathbf{C}$ $(\mathrm{Im}\,t\leqslant 0)$, the equality in Eq. (22) can never be satisfied by any $\psi\in\mathrm{Dom}(TH)\cap\mathrm{Dom}(HT)$ $(\|\psi\|=1)$.*

In order to prove this theorem, let us first consider two lemmas.

Lemma 5.2: Let T and H be symmetric operators on $\mathcal{H}$, and they satisfy the CCR $TH-HT=i$, on a subspace of $\mathrm{Dom}(TH)\cap\mathrm{Dom}(HT)$, denoted by $\mathcal{D}$. Then neither eigenvector of T nor that of H belongs to $\mathcal{D}$.

Proof: Assume that an eigenvector of T, $\psi_\lambda\neq 0$, belonging to an eigenvalue λ exists in $\mathcal{D}$. Then $T\psi_\lambda=\lambda\psi_\lambda$, and thus we have $\langle\psi_\lambda,(TH-HT)\psi_\lambda\rangle=0$. On the other hand, the condition in this lemma requires that $\langle\psi_\lambda,(TH-HT)\psi_\lambda\rangle=i\|\psi_\lambda\|^2\neq 0$. Thus the subspace $\mathcal{D}$ contains no eigenvector of T. The rest of the proof for H can be done, as in the same way for T. □

Lemma 5.3: Let T and H be symmetric operators on $\mathcal{H}$, and let them satisfy the CCR $TH-HT=i$, on a subspace of $\mathrm{Dom}(TH)\cap\mathrm{Dom}(HT)$, denoted by $\mathcal{D}$. If a state $\eta\in\mathcal{D}$ $(\|\eta\|=1)$ and a pair of complex numbers $a,b\in\mathbf{C}$, satisfying the following two equalities:

$$(T+aH+b)\eta=0, \tag{23}$$

$$\langle T\eta,H\eta\rangle+\langle H\eta,T\eta\rangle-2\langle T\rangle_\eta\langle H\rangle_\eta=0, \tag{24}$$

exist, then $\mathrm{Re}\,a=0$ *and* $\mathrm{Im}\,a>0$.

Proof: Let η be a state which satisfies the conditions in this lemma. Then we have that

$$\langle T\eta,H\eta\rangle+\langle H\eta,T\eta\rangle=\langle\eta,(HT+i)\eta\rangle+\langle H\eta,T\eta\rangle=i-2a\|H\eta\|^2-2b\langle\eta,H\eta\rangle.$$

From Eq. (23), we also have that

$$2\langle T\rangle_\eta\langle H\rangle_\eta=-2\langle\eta,(aH+b)\eta\rangle\langle\eta,H\eta\rangle=-2a\langle\eta,H\eta\rangle^2-2b\langle\eta,H\eta\rangle.$$

Therefore the condition Eq. (24) leads us to the relation

$$i-2a\|H\eta\|^2=-2a\langle\eta,H\eta\rangle^2. \tag{25}$$

Let us consider the real and imaginary parts of the above equality, separately. It follows, from the real part $(\mathrm{Re}\,a)\|H\eta\|^2=(\mathrm{Re}\,a)\langle\eta,H\eta\rangle^2$, that $\mathrm{Re}\,a=0$. This is because if $\mathrm{Re}\,a\neq0$, then $\|H\eta\|^2-\langle\eta,H\eta\rangle^2=0$ and this means that η is an eigenvector of H, belonging to the eigenvalue $\langle\eta,H\eta\rangle$, in spite of the premise $\eta\in\mathcal{D}$ $(\|\eta\|=1)$. This is in contradiction to Lemma 5.2. It is also seen, from the imaginary part, $1-2(\mathrm{Im}\,a)\|H\eta\|^2=-2(\mathrm{Im}\,a)\langle\eta,H\eta\rangle^2$, that $\mathrm{Im}\,a>0$. □

Proof of Theorem 5.1: Let $\psi\in\mathrm{Dom}(TH)\cap\mathrm{Dom}(HT)$ and $\|\psi\|=1$. Since the T-weak WR holds for T and H, the CCR in Eq. (2) follows. Then the uncertainty relation between T and H, in Eq. (22), is derived as

$$\begin{aligned}(\Delta T)_\psi(\Delta H)_\psi&=\|(T-\langle T\rangle_\psi)\psi\|\|(H-\langle H\rangle_\psi)\psi\|\\&\geqslant|\langle(T-\langle T\rangle_\psi)\psi,(H-\langle H\rangle_\psi)\psi\rangle|\\&\geqslant|\mathrm{Im}\langle(T-\langle T\rangle_\psi)\psi,(H-\langle H\rangle_\psi)\psi\rangle|\\&=\tfrac{1}{2}|\langle T\psi,H\psi\rangle-\langle H\psi,T\psi\rangle|=\tfrac{1}{2}.\end{aligned}$$

In the second line, which is nothing but the Cauchy–Schwarz inequality, the equality holds if and only if there exists a complex number $\alpha\in\mathbf{C}$, satisfying

$$(T-\langle T\rangle_\psi)\psi+\alpha(H-\langle H\rangle_\psi)\psi=0.$$

In the third line, the equality holds if and only if

$$\mathrm{Re}\langle(T-\langle T\rangle_\psi)\psi,(H-\langle H\rangle_\psi)\psi\rangle=\langle T\psi,H\psi\rangle+\langle H\psi,T\psi\rangle-2\langle T\rangle_\psi\langle H\rangle_\psi=0.$$

In order to show that no $\psi\in\mathrm{Dom}(TH)\cap\mathrm{Dom}(HT)$ $(\|\psi\|=1)$ can satisfy the equality in the uncertainty relation between T and H, in Eq. (22), it is sufficient to see that the above two conditions cannot be satisfied simultaneously, for any $\psi\in\mathrm{Dom}(TH)\cap\mathrm{Dom}(HT)$ $(\|\psi\|=1)$ and for any $\alpha\in\mathbf{C}$. Observe that these conditions take just the same form as the two equalities (23) and (24) in Lemma 5.3.

Let us now assume that there exist such a state $\eta\in\mathrm{Dom}(TH)\cap\mathrm{Dom}(HT)$ $(\|\eta\|=1)$, and a pair of complex numbers $a,b\in\mathbf{C}$, that satisfy both of Eqs. (23) and (24), and derive a contradiction. Lemma 5.3 implies that the parameter a is pure imaginary and is expressed as $a=iq$, $q>0$, to lead to $T\eta+iqH\eta+b\eta=0$. Then we must have that $-q\langle\eta,H\eta\rangle=\mathrm{Im}\,b\leqslant0$, because $\langle\eta,T\eta\rangle\in\mathbf{R}^1$ and $H\geqslant0$ (see the conditions of Theorem 5.1). It is also noted that e^{-itH} is bounded and $e^{-itH}H\subset He^{-itH}$, for all $t\in\mathbf{C}$ $(\mathrm{Im}\,t\leqslant0)$. Then it follows that $Te^{-itH}\eta=e^{-itH}(T\eta+t\eta)=(-iqH-b+t)e^{-itH}\eta$. Since $\mathrm{Im}\,b\leqslant0$ and $\mathrm{Im}\,t\leqslant0$, we can put $t=b$ and obtain $Te^{-ibH}\eta=-iqHe^{-ibH}\eta$. It is here noted that $e^{-ibH}\eta\neq0$, because e^{-ibH} is an injection and $\eta\neq0$. This is seen from the following relations:

$$\|e^{-ibH}\eta\|^2=\int_{[0,\infty)}|e^{-ib\lambda}|^2 d\|E(\lambda)\eta\|^2\geqslant\int_{[0,N]}|e^{-ib\lambda}|^2 d\|E(\lambda)\eta\|^2$$

$$\geqslant \inf_{\lambda\in[0,N]}|e^{-ib\lambda}|^2\int_{[0,N]} d\|E(\lambda)\eta\|^2$$

$$=e^{-2|\mathrm{Im}\, b|N}\int_{[0,N]} d\|E(\lambda)\eta\|^2,$$

where $\{E(B)|B\in\mathbf{B}^1\}$ is the spectral measure of H, N is an arbitrary natural number, and we have used the fact that the spectrum of H should be included in $[0,\infty)$, because $H\geqslant 0$. Providing that $e^{-ibH}\eta=0$, one would obtain that $0=\lim_{N\to\infty}\int_{[0,N]}d\|E(\lambda)\eta\|^2=\|\eta\|^2$, which contradicts $\|\eta\|=1$. By taking the inner products between $e^{-ibH}\eta$ and each side of $Te^{-ibH}\eta=-iqHe^{-ibH}\eta$, we have

$$\langle e^{-ibH}\eta, Te^{-ibH}\eta\rangle=-iq\langle e^{-ibH}\eta, He^{-ibH}\eta\rangle.$$

Notice that the both sides of this equality have to vanish. Since $q>0$ and $e^{-ibH}\eta\neq 0$, we have that $0=\langle e^{-ibH}\eta, He^{-ibH}\eta\rangle=\langle H^{1/2}e^{-ibH}\eta, H^{1/2}e^{-ibH}\eta\rangle=\|H^{1/2}e^{-ibH}\eta\|^2$, where $H^{1/2}$ is a self-adjoint operator, satisfying $H=H^{1/2}H^{1/2}$ and $H^{1/2}\geqslant 0$. Thus $He^{-ibH}\eta=0$. It is also seen that $e^{-ibH}\eta\in\mathrm{Dom}(TH)\cap\mathrm{Dom}(HT)$, because $\eta\in\mathrm{Dom}(TH)\cap\mathrm{Dom}(HT)$. These facts are in contradiction to Lemma 5.2. Therefore, Eqs. (23) and (24) in Lemma 5.3 cannot be satisfied simultaneously. This means that the equality, in the uncertainty relation between T and H in Eq. (22), never holds under the condition of Theorem 5.1. □

The question about minimum-uncertainty states is motivated by the following result by Kobe:[1]

$$\lim_{n\to\infty}(\Delta\tilde{T}_0)_{F^{-1}\phi_n}(\Delta H_0)_{F^{-1}\phi_n}=\tfrac{1}{2},$$

where ϕ_n $(n\geqslant 2)$ is defined as in Example 1. Note, however, that ϕ_n does not converge in the L^2-norm, as $n\to\infty$. This Kobe's result implies the absence of minimum-uncertainty states. This result was also derived by Wigner[21] and Baute *et al.*,[22] in different ways from ours. It should be notified that the absence of minimum-uncertainty states expresses a crucial difference between the Weyl relation and the T-weak WR.

VI. CONSTRUCTION OF THE TIME OPERATORS FOR GENERAL QUANTUM SYSTEMS

We first summarize the several results so far obtained about the time operator T_0 in Eq. (1), or its extension $\tilde{T}_0$ in Eq. (11), for the 1DFPS.

Example 3: $\tilde{T}_0$ satisfies the $\tilde{T}_0$-weak WR with H_0, as is seen in Eq. (12). Then we have the following properties about $\tilde{T}_0$.

(i) The inequality (6) between $(\Delta\tilde{T}_0)_\psi$ and the survival probability of ψ holds for all $\psi\in\mathrm{Dom}(\tilde{T}_0)$ (Theorem 4.1).
(ii) $\tilde{T}_0$ has no point spectrum (Corollary 4.2).
(iii) The inequality (17) holds for all $\psi\in\mathrm{Dom}(\tilde{T}_0)$ and all $B\in\mathbf{B}^1$ (Theorem 4.4).
(iv) The uncertainty relation (22) between $\tilde{T}_0$ and H_0 holds on $\mathrm{Dom}(\tilde{T}_0H_0)\cap\mathrm{Dom}(H_0\tilde{T}_0)$ (Proposition 2.1), although there exists no state in $\mathrm{Dom}(\tilde{T}_0H_0)\cap\mathrm{Dom}(H_0\tilde{T}_0)$, which satisfies equality in the uncertainty relation between $\tilde{T}_0$ and H_0 (Theorem 5.1).

It is seen, from the above (i), that the Gaussian packet $F\phi_0$ in Example 1 is not included in $\mathrm{Dom}(\tilde{T}_0)$. Because, for large $|t|$, the survival probability of the Gaussian packet for the 1DFPS decays with an inverse-power law $|t|^{-1}$, and this is in contradiction to the behavior of the survival

probability predicted by the inequality (6). It is, however, noticed that this kind of estimation about the domain $\mathrm{Dom}(\tilde{T}_0)$ is valid for the one-dimensional case. Because, as the dimension becomes higher, the survival probability decays faster, in general than $|t|^{-2}$. We also obtain, from the inequality (6) for $\tilde{T}_0$ and H_0, that

$$2\sqrt{2}(\Delta\tilde{T}_0)_\psi \geqslant \tau_h(\psi), \tag{26}$$

where $\tau_h(\psi)$ is defined as $\tau_h(\psi) := \sup\{t \geqslant 0 \,|\, |\langle \psi, e^{-itH_0}\psi\rangle|^2 = 1/2\}$, $\forall \psi \in \mathrm{Dom}(\tilde{T}_0)$ $(\|\psi\| = 1)$. This relation is important, to give the direct connection between $(\Delta\tilde{T}_0)_\psi$ and the measurable quantity $\tau_h(\psi)$, although we do not know whether $\tilde{T}_0$ itself is an observable. Let us also consider the physical meaning of the above (iii). The following inequality is derived from Eq. (17):

$$\|E_{H_0}(B)\psi\|^2 \leqslant (\Delta\tilde{T}_0)_\psi |B|,$$

for all $\psi \in \mathrm{Dom}(\tilde{T}_0)$ $(\|\psi\| = 1)$ and $B \in \mathbf{B}^1$, because of the fact that the $\tilde{T}_0$-weak WR is not changed, with replacing $\tilde{T}_0$ by $\tilde{T}_0 - \langle \tilde{T}_0 \rangle_\psi$. Note that $\|E_{H_0}(B)\psi\|^2$ is the probability which one finds a measured energy-value in the range B for the fixed ψ. Suppose that $(\Delta\tilde{T}_0)_\psi$ is small; then the probability $\|E_{H_0}(B)\psi\|^2$ should be uniformly small for all $B \in \mathbf{B}^1$. This concludes that the probability distribution $\|E_{H_0}(\cdot)\psi\|^2$ has a broad deviation, for $\|E_{H_0}(\mathbf{R}^1)\psi\|^2 = 1$. Hence $(\Delta\widetilde{H_0})_\psi$ must be large and this result is consistent with the uncertainty relation.

In order to find other quantum systems than the 1DFPS, for which a time operator exists, let us recall the results obtained by Putnam, in the theory of Schrödinger operators.[23] According to this theorem, if a potential $V(x)$ is a real-valued measurable function on $\mathbf{R}^1$ satisfying $0 \leqslant V(x) \leqslant \mathrm{const}$, *a.e.* and $V(x) \in L^1(\mathbf{R}^1)$; then H_0 and $H_1 := H_0 + V(x)$ defined on $L^2(\mathbf{R}^1)$ are absolutely continuous, and furthermore the wave operators $U_\pm := \mathrm{s}-\lim_{t \to \pm\infty} e^{itH_1}e^{-itH_0}$ exist and are unitary operators satisfying $H_1 = U_\pm H_0 U_\pm^*$. For our purpose, we first define the operators $T_{1,\pm} := U_\pm \tilde{T}_0 U_\pm^*$ on $L^2(\mathbf{R}^1)$, where $U_\pm$ are the wave operators defined in this Putnam's theorem. Then $T_{1,\pm}$ are symmetric and satisfy the $T_{1,\pm}$-weak WR with H_1, i.e.,

$$T_{1,\pm}e^{-itH_1} = e^{-itH_1}(T_{1,\pm} + t),$$

which are nothing but the unitary transformations of Eq. (12). These operators $T_{1,\pm}$ are the time operators we have sought for other quantum systems than the 1DFPS, and they satisfy all the properties, described in Example 3, with this H_1.

For a quantum system which allows bound states, we can also construct a time operator satisfying the T-weak WR with the Hamiltonian H, by restricting it to act on the set of scattering states. The latters are usually identified with the subspace $\mathcal{H}_{\mathrm{ac}}(H)$ of the Hilbert space $\mathcal{H}$ under consideration. Because, in this case, the wave operator (if exits) is not a unitary operator on $\mathcal{H}$ in general, that is, the range $\mathrm{Ran}(U_\pm)$ becomes a proper subspace of $\mathcal{H}$. In fact, according to Kuroda,[24] if the potential $V(x)$ is a real-valued measurable function on $\mathbf{R}^1$ satisfying $V(x) \in L^1(\mathbf{R}^n) \cap L^2(\mathbf{R}^n)$, $n \leqslant 3$, and the Hamiltonian H_1 on $L^2(\mathbf{R}^1)$ is defined as $H_1 := H_0 + V(x)$, then the wave operators $U_\pm$ exist and are complete, i.e., $\mathrm{Ran}(U_\pm) = L^2_{\mathrm{ac}}(H_1)$, where $L^2_{\mathrm{ac}}(H_1)$ is a subspace in $L^2(\mathbf{R}^1)$, similarly defined as $\mathcal{H}_{\mathrm{ac}}(H)$ just before Theorem 4.4. As in the same way for Putnam's theorem, by the use of the wave operators $U_\pm$ defined for H_0 and H_1 in this Kuroda's theorem, we can define the operators $T_{1,\pm} := U_\pm \tilde{T}_0 U_\pm^*$ on $L^2_{\mathrm{ac}}(H_1)$ and their domains, $\mathrm{Dom}(T_{1,\pm}) := U_\pm \mathrm{Dom}(\tilde{T}_0)$. Then they are symmetric operators on $L^2_{\mathrm{ac}}(H_1)$, and satisfy

$$T_{1,\pm}e^{-itH_{1,ac}} = e^{-itH_{1,ac}}(T_{1,\pm} + t).$$

$H_{1,\mathrm{ac}}$ is defined as $H_{1,\mathrm{ac}} := H_1|_{L^2_{\mathrm{ac}}(H_1)} = U_\pm H_0 U_\pm^*$, and is called the (spectrally) absolutely continuous part of H_1.[13] By the unitary equivalence, Example 3 is also valid for the pair $T_{1,\pm}$ and $H_{1,\mathrm{ac}}$.

We cannot, however, extend these $T_{1,\pm}$ to the densely defined symmetric operators on $L^2(\mathbf{R}^1)$, so that they satisfy the $T_{1,\pm}$-weak WR with H_1, when H_1 has a point spectrum, i.e., $L^2_{\rm pp}(H_1) \neq \{0\}$. This is because such an extension contradicts Corollary 4.3 and Theorem 4.4.

VII. CONCLUDING REMARKS

Analyzing the T-weak Weyl relation (T-weak WR) in Eq. (4), and obtaining several statements about the time operator, we have seen that the Aharonov–Bohm time operator T_0 in Eq. (1) [or its symmetric extension $\tilde{T}_0$ in Eq. (11)] is characterized by the $\tilde{T}_0$-weak WR in Eq. (12). We have, in particular, recognized the fact that the time operator is deeply connected to the survival probability. In relation to this considerable connection, we would like, first, to revisit the inequality (6) in Theorem 4.1, Theorem 4.4, and their implications.

The inequality (6) is important to bring us a possibility of understanding the time operator from the two different points. The first point is related to the measurement of the survival probability. Since the inequality (26) derived from the inequality (6) gives the quantitative relation between the standard deviation of the time operator $\tilde{T}_0$ and the maximum half-time of the survival probability in the 1DFPS, we may associate the time operator in quantum systems, with both the real and theoretical measurements of the survival probability. Another point is related to the connection with the dynamics of quantum systems. In order to see this possibility, we may refer to Proposition 3.2, and Corollary 4.3 which is one of the applications of the inequality (6). These facts imply a possibility of associating the time operator (or its domain), with the scattering state and its dynamics, through the survival probability.

As a remark on Theorem 4.4, the following suggestion by Putnam should be recalled, that is, the existence of the absolutely continuous part of the Hamiltonian can be inferred from the behavior of specific observables.[25] He considered the following system, in which there is a self-adjoint operator A_0 satisfying $A_t = A_0 + tI$, $\forall t \in \mathbf{R}^1$, where $A_t := e^{itH} A_0 e^{-itH}$ and H is the Hamiltonian for this system. He showed that H must be absolutely continuous (note that this is the case to which the last statement in Proposition 2.1 is applicable). The essence of its proof, that is, the uniqueness of the spectral resolution of A_0, also implies that if A_0 is maximally symmetric (not necessarily self-adjoint), H must be absolutely continuous. Because A_0 is uniquely represented by the generalized resolution of identity.[26] In this context, Theorem 4.4 is a generalization of the above statement by Putnam, to nonmaximally symmetric operators. However the absolute continuity of H seems to be obvious in the light of the works by Schmüdgen.[12] Because, under some condition, H is unitary equivalent to the position operator. Here we would like to emphasize the inequality (17), rather than the absolute continuity of H, which is explained as follows.

The proof of the absolute continuity of H, which satisfies the T-weak Weyl relation with T, depends on Eq. (17). It is similar to the following inequality which was derived by Putnam[27] and Kato,[8] on the study of the commutator of the form, $[H, iA] = C$, where H, A and C are bounded self-adjoint operators, and $C \geqslant 0$,

$$\|C^{1/2} E_H(B)\psi\|^2 \leqslant \|A\| \|\psi\|^2 |B|, \quad \forall \psi \in \mathcal{H}, \ \forall B \in \mathbf{B}^1. \tag{27}$$

It is seen that Eq. (17) is an unbounded case of theirs, and is not trivial. Because one cannot replace directly C with the identity, for both bounded H and A. They showed, through Eq. (27), that H is absolutely continuous, provided that $\mathrm{Ker}(C) = \{0\}$, i.e., $\overline{\mathrm{Ran}(C)} = \mathcal{H}$. This statement is sometimes valid when the above H and A are unbounded, however, its proof originates in the more fundamental notion, T-smoothness,[8] rather than the inequality like the above one, and the appropriate technique. Lavine applied it to Schrödinger operators in an especially good manner.[9–11] It should be noted that his work is closely related to the our problem. He found self-adjoint operators A which satisfy $[H, iA] = C$, with a certain class of Schrödinger operators H and positive bounded C. In the case of the absolute continuity of the free Hamiltonian H_0, we can choose the self-adjoint operator $A := (f(P)Q + Qf(P))/2$, where $f(P) := P(P^2 + \delta^2)^{-1}$ and $C := Pf(P)$. When $\delta > 0$, A is self-adjoint, because $\mathrm{Ker}(A^* \mp i) = \{0\}$. And also C is bounded and

$C>0$. They satisfy $[H_0, iA]=C$ and one can consider the case that a parameter δ approaches to 0, which is just $A=T_0$. Hence this scheme has the advance in the approach to the absolute continuity of H_0 and its connection with the Aharonov–Bohm time operator T_0.

(Received 26 June 2000; accepted for publication 1 September 2000)

The Green's function for relativistic spinless Aharonov–Bohm–Coulomb (ABC) system on the pseudo-sphere $\Lambda^{(2)}$ is calculated using Kleinert's path integral representation for relativistic spinless particles. The energy spectrum and the corresponding wave functions are extracted for bound and scattering states. The results in the nonrelativistic and flat space limits are considered. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1329660]

I. INTRODUCTION

Quantum motion on spaces with constant curvature, positive as well negative, is of great interest for various fields of theoretical physics.[1] Examples are provided by the structure of the pseudo-sphere $\Lambda^{(2)}$, which makes it very interesting in Polyakov path integral approach to string theory and in $(1+1)$-dimensional quantum gravity.[2] We can also cite the path integral treatment of the nonrelativistic Kepler problem in space of constant curvature.[3] On the other hand, the path integral formalism is the most suitable tool to treat topological defects such as the Aharonov–Bohm (AB) effect. The path integral treatment of a nonrelativistic particle on the hyperbolic plane under the action of the AB field has been done recently.[4]

In this paper we would like to add, to the short list of solvable path integrals for relativistic systems,[5,6] another application, namely the relativistic spinless Aharonov–Bohm–Coulomb (ABC) system on the pseudo-sphere $\Lambda^{(2)}$.

In Sec. II, we present a brief review of the path integral formulation on spaces with constant curvature. In Sec. III, using the Duru–Kleinert's technique of space–time transformations, we obtain in a closed form the Green's function for the relativistic ABC system. In Sec. IV the energy spectrum and the wave functions for bound states are explicitly evaluated and the special cases of the flat space limit and the nonrelativistic limit are considered. In Sec. V, using the integral representation of the Green's function, we deduce the scattering states. Our concluding remarks are given in Sec. VI.

II. PATH INTEGRAL REPRESENTATION ON $\Lambda^{(2)}$

The spherical coordinates in the pseudo-Euclidean space $E_{2,1}$ are given by

$$x^1 = r\sinh\tau\sin\varphi, \quad x^2 = r\sinh\tau\cos\varphi, \quad x^3 = r\cosh\tau, \tag{1}$$

where $r>0, \tau>0$ and $\varphi\in[0,2\pi)$.

The discretized propagator of a free particle moving in such a space is given by[7]

$$K(\mathbf{x}_b,\mathbf{x}_a;T)=\lim_{N\to\infty}\int\prod_{n=1}^{N}\left(\frac{m}{2\pi i\varepsilon}\right)\left(\frac{mi}{2\pi\varepsilon}\right)^{1/2N-1}\prod_{n=1}^{N-1}dx_n^1dx_n^2dx_n^3$$
$$\times\prod_{n=1}^{N}\exp\left\{\frac{im}{2\varepsilon}[(\Delta x_n^1)^2+(\Delta x_n^2)^2-(\Delta x_n^3)^2]\right\}$$
$$=\lim_{N\to\infty}\int\prod_{n=1}^{N}\left(\frac{m}{2\pi i\varepsilon}\right)\left(\frac{mi}{2\pi\varepsilon}\right)^{1/2N-1}\prod_{n=1}^{N-1}r_n^2dr_n\sinh\tau_nd\tau_nd\varphi_n$$
$$\times\prod_{n=1}^{N}\exp\left\{-\frac{im}{2\varepsilon}\Delta r_n^2-\frac{im}{\varepsilon}r_nr_{n-1}[1+(\mathbf{e}_n,\mathbf{e}_{n-1})]\right\}. \tag{2}$$

A regularizating scheme for this path integral consists in adding, to the mass, a small positive imaginary term for the compact variables (x^1 and x^2) and a small negative imaginary term for the noncompact variable (x^3). The particular form of the measure, which is a consequence of the indefinite metric, is necessary to obtain the correct normalization contition, $\lim_{T\to0}K(\mathbf{x}_{b,},\mathbf{x}_a;T)=\delta(\mathbf{x}_b-\mathbf{x}_a)$.

The scalar product between the unit vectors $\mathbf{e}_n$ and $\mathbf{e}_{n-1}$ is given by

$$(\mathbf{e}_n,\mathbf{e}_{n-1})=-[\sinh\tau_n\sinh\tau_{n-1}(1-\cos\Delta\varphi_n)+\cosh\Delta\tau_n]. \tag{3}$$

The propagator on the pseudo-sphere $\Lambda^{(2)}$ is easily obtained by fixing r_n to a constant R via the relation

$$\lim_{\epsilon\to0}\left(\frac{mi}{2\pi\varepsilon}\right)^{1/2}\exp\left(-\frac{im}{2\varepsilon}(r_n-r_{n-1})^2\right)=\delta(r_n-r_{n-1}). \tag{4}$$

Then performing the integrations over r_j in (2), we obtain

$$K(\mathbf{x}_b,\mathbf{x}_a;T)=\frac{1}{R^2}\lim_{N\to\infty}\int\prod_{n=1}^{N}\left(\frac{mR^2}{2\pi i\varepsilon}\right)\prod_{n=1}^{N-1}\sinh\tau_nd\tau_nd\varphi_n$$
$$\times\prod_{n=1}^{N}\exp\left\{-\frac{im}{\varepsilon}R^2[1+(\mathbf{e}_n,\mathbf{e}_{n-1})]\right\}. \tag{5}$$

Let us set $v_n=-mR^2\sinh\tau_n\sinh\tau_{n-1}$. Using the decomposition

$$e^{i/\varepsilon\,v_n\cos\Delta\varphi_n}=\sum_{l_n=-\infty}^{\infty}I_{l_n}\left(\frac{iv_n}{\varepsilon}\right)e^{il_n\Delta\varphi_n}, \tag{6}$$

and the following relation valid for $\varepsilon\to0$:

$$I_{l_n}\left(\frac{iv_n}{\varepsilon}\right)\approx\sqrt{\frac{\varepsilon}{2\pi iv_n}}\exp\left(\frac{iv_n}{\varepsilon}-\frac{\varepsilon}{2iv_n}\left(l_n^2-\frac{1}{4}\right)\right), \tag{7}$$

we obtain

$$K(\mathbf{x}_b,\mathbf{x}_a;T)=[R^4\sinh\tau_b\sinh\tau_a]^{-1/2}\lim_{N\to\infty}\int\prod_{n=1}^{N}\frac{1}{2\pi}\left(\frac{mR^2}{2\pi i\varepsilon}\right)$$
$$\times\prod_{n=1}^{N-1}d\tau_n d\varphi_n\prod_{n=1}^{N}\exp\left\{-\frac{im}{\varepsilon}R^2[1-\cosh\Delta\varphi_n]\right\}$$
$$\times\sum_{l_n=-\infty}^{\infty}\exp\left(-\frac{i\varepsilon}{2mR^2}\frac{l_n^2-\frac{1}{4}}{\sinh\tau_n\sinh\tau_{n-1}}\right)e^{il_n\Delta\varphi_n}. \tag{8}$$

The $N-1$ successive integrations over the variables φ_n produce the factor $\Pi_{n=1}^{N-1}2\pi\delta_{l_n,l_{n-1}}$, such that the propagator becomes

$$K(\mathbf{x}_b,\mathbf{x}_a;T)=[R^4\sinh\tau_b\sinh\tau_a]^{-1/2}\lim_{N\to\infty}\int\prod_{n=1}^{N}\left(\frac{mR^2}{2\pi i\varepsilon}\right)^{1/2N-1}\prod_{n=1}d\tau_n\sum_{l=-\infty}^{\infty}\frac{e^{il(\varphi_b-\varphi_a)}}{2\pi}$$
$$\times\prod_{n=1}^{N}\exp\left\{-\frac{im}{\varepsilon}R^2[1-\cosh\Delta\tau_n]-\frac{i\varepsilon}{2mR^2}\frac{l^2-\frac{1}{4}}{\sinh\tau_n\sinh\tau_{n-1}}\right\}. \tag{9}$$

Now we use the approximation valid for $\varepsilon\to 0$

$$1-\cosh\Delta\tau_n\approx-\tfrac{1}{2}(\Delta\tau_n)^2-\tfrac{1}{24}(\Delta\tau_n)^4. \tag{10}$$

We note that $(\Delta\tau_n)^4/\varepsilon=O(\varepsilon)$ and hence contributes to the path integral. Its contribution can be evaluated via the procedure of McLaughlin–Schulman[8] based on the formula

$$\int_{-\infty}^{+\infty}\exp(-ax^2+bx^4)dx=\int_{-\infty}^{+\infty}\exp\left(-ax^2+\frac{3b}{4a^2}\right)dx, \tag{11}$$

valid for large a and $\mathrm{Re}a>0$ and for b purely imaginary or even with a negative imaginary part. The condition on a can be satisfied by adding a small imaginary part to the mass in the kinetic term.

Finally the path integral representation of the propagator on the pseudo-sphere $\Lambda^{(2)}$ is given by

$$K(\mathbf{x}_b,\mathbf{x}_a;T)=[R^4\sinh\tau_b\sinh\tau_a]^{-1/2}\sum_{l=-\infty}^{\infty}\frac{e^{il(\varphi_b-\varphi_a)}}{2\pi}\lim_{N\to\infty}\int\prod_{n=1}^{N}\left(\frac{mR^2}{2\pi i\varepsilon}\right)^{1/2N-1}\prod_{n=1}d\tau_n$$
$$\times\exp\left\{i\sum_{n=1}^{N}\left[\frac{mR^2}{2\varepsilon}(\Delta\tau_n)^2-\varepsilon\left(\frac{1}{2mR^2}\frac{l^2-1/4}{\sinh\tau_n\sinh\tau_{n-1}}+\frac{1}{8mR^2}\right)\right]\right\}. \tag{12}$$

III. RELATIVISTIC ABC ON $\Lambda^{(2)}$

The Green's function of a relativistic particle in a $(D+1)$-dimensional Minkowski space is given by Kleinert's path integral representation[9]

$$G(\mathbf{x}_b,\mathbf{x}_a;E)=\frac{1}{2mc}\int_0^\infty dL\int\mathcal{D}\rho(t)\Phi[\rho(t)]\int\mathcal{D}\mathbf{x}(t)\exp(i\mathcal{A}), \tag{13}$$

with the action

$$\mathcal{A}=\int_0^T dt\left[\frac{m}{2\rho(t)}\dot{\mathbf{x}}^2(t)+\frac{e}{c}\mathbf{A}\dot{\mathbf{x}}(t)+\rho(t)\frac{(E-V(\mathbf{x}))^2}{2mc^2}-\rho(t)\frac{mc^2}{2}\right]. \tag{14}$$

Here $\mathbf{A}$ and $V(\mathbf{x})$ are, respectively, the vector and scalar potentials, L is a length defined by

$$L=\int_0^T dt\rho(t), \tag{15}$$

and $\Phi[\rho(t)]$ is a gauge-fixing functional of the dimensionless fluctuating scale variable $\rho(t)$ which obeys the condition

$$\int D\rho(t)\Phi[\rho(t)]=1. \tag{16}$$

In the following we fix the value of $\rho(t)$ to unity by simply choosing $\Phi[\rho(t)]=\delta[\rho(t)-1]$ and we consider the case of rotationally invariant scalar potential.

We begin our investigation of the relativistic spinless ABC system by considering the Coulomb potential on $\Lambda^{(2)}$ defined by[3,4]

$$V(\tau)=-\frac{\alpha}{R}(\coth\tau-1), \tag{17}$$

where the coupling constant α is the analogue of e^2 on a flat space.

Using the path integral representation (12), the Green's function for the relativistic Coulomb field on $\Lambda^{(2)}$ is given by

$$\begin{aligned}
&G(\mathbf{x}_b,\mathbf{x}_a;E)\\
&\quad=[R^4\sinh\tau_b\sinh\tau_a]^{-1/2}\left(\frac{1}{2mc}\right)\int_0^\infty dT\lim_{N\to\infty}\int\prod_{n=1}^{N}\left(\frac{mR^2}{2\pi i\varepsilon}\right)^{1/2}\prod_{n=1}^{N-1}d\tau_n\\
&\qquad\times\sum_{l=-\infty}^{\infty}\frac{e^{il(\varphi_b-\varphi_a)}}{2\pi}\exp\left\{i\epsilon\sum_{n=1}^{N}\left[\frac{mR^2}{2\varepsilon^2}(\Delta\tau_n)^2\right.\right.\\
&\qquad\left.\left.+\left(A\coth\tau_n-\frac{B_l}{\sinh\tau_n\sinh\tau_{n-1}}+C\right)\right]\right\}.
\end{aligned} \tag{18}$$

In the limit $N\to\infty$ we have

$$\begin{aligned}
G(\mathbf{x}_b,\mathbf{x}_a;E)&=[R^4\sinh\tau_b\sinh\tau_a]^{-1/2}\left(\frac{1}{2mc}\right)\int_0^\infty dT\sum_{l=-\infty}^{\infty}\frac{e^{il(\varphi_b-\varphi_a)}}{2\pi}\\
&\quad\times\int_{\tau_a}^{\tau_b}\mathcal{D}\tau(t)\exp\left\{i\int_0^T dt\left[\frac{mR^2}{2}\dot{\tau}^2+A\coth\tau-\frac{B_l}{\sinh^2\tau}+C\right]\right\},
\end{aligned} \tag{19}$$

where we have set $\mathcal{D}\tau(t)=\lim_{N\to\infty}\Pi_{n=1}^{N}(mR^2/2\pi i\varepsilon)^{1/2}\Pi_{n=1}^{N-1}d\tau_n$ and

$$A=\frac{\alpha}{mc^2R}\left(E-\frac{\alpha}{R}\right), \tag{20}$$

$$B_l=\frac{1}{2mR^2}\left(l^2-\frac{1}{4}\right)-\frac{\alpha^2}{2mc^2R^2}, \tag{21}$$

$$C=\frac{1}{2mc^2}\left[\left(\frac{\alpha}{R}\right)^2+\left(E-\frac{\alpha}{R}\right)^2\right]-\frac{1}{8mR^2}-\frac{mc^2}{2}. \tag{22}$$

According to an ansatz by Kuperin *et al.*[10] for the AB field we write the magnetic interaction in (14) as

$$A_{\mathrm{mag}} = -2\pi n \nu, \tag{23}$$

where we have set

$$n = \frac{1}{2\pi}\int_0^T \dot{\varphi}(t)dt, \quad \nu = -\frac{e}{2\pi c}\int d^2x B_3. \tag{24}$$

Here n is a topological invariant, $\varphi(t) = \arctan(x^2/x^1)$ is the azimuthal angle around the AB tube, B_3 represents the magnetic field confined to an infinitely thin tube along the third axis and $\int d^2x B_3$ is the flux through the tube.

Adding (23) to the action in (19) and converting the sum over the azimuthal quantum number l to an integral via the Poisson's summation formula

$$\sum_{l=-\infty}^{\infty} f(l) = \int_{-\infty}^{+\infty} d\mu \sum_{p=-\infty}^{\infty} e^{2i\pi p\mu} f(\mu), \tag{25}$$

we write the Green's function for the ABC system in the following form:

$$G(\mathbf{x}_b, \mathbf{x}_a; E) = \sum_{l=-\infty}^{\infty} \frac{e^{il(\varphi_b - \varphi_a)}}{2\pi} G_{l+\nu}(\tau_b, \tau_a; E), \tag{26}$$

where the radial part is given by

$$G_{l+\nu}(\tau_b, \tau_a; E) = [R^4 \sinh\tau_b \sinh\tau_a]^{-1/2}\left(\frac{1}{2mc}\right)\int_0^\infty dT \times \int_{\tau_a}^{\tau_b} \mathcal{D}\tau(t) \exp\left\{ i\int_0^T dt\left[\frac{mR^2}{2}\dot{\tau}^2 + A\coth\tau - \frac{B_{l+\nu}}{\sinh^2\tau} + C\right]\right\}, \tag{27}$$

with $B_{l+\nu}$ defined by Eq. (21).

This is exactly the path integral representation of the Manning–Rosen potential[11] analyzed by several authors.[12]

In order to link Eq. (27) with the Green's function for the motion of a mass point near the surface of a sphere in four dimensions projected in a state of fixed angular momentum, we use Duru–Kleinert's technique of space–time transformations.[13,14]

Indeed we introduce the following space transformation $\tau \in [0,\infty) \to \theta \in [0,\pi)$

$$\tanh\frac{\tau}{2} = \frac{1-\cos(\theta/2)}{1+\cos(\theta/2)}, \tag{28}$$

combined to the path-dependent time transformation $t \to s$

$$dt = ds \tan^2\frac{\theta}{2}. \tag{29}$$

Taking into account all the contributions arising from the slicing of the path-dependent time, the Green's function (27) becomes

$$G_{l+\nu}(\tau_b,\tau_a;E)=\frac{2}{R^2}\left[\sin\frac{\theta_b}{2}\sin\frac{\theta_a}{2}\right]^{-1/2}\left(\frac{1}{2mc}\right)\int_0^S dS\int \mathcal{D}\theta(s)$$
$$\times\exp\left\{i\int_0^S ds\left[\frac{mR^2}{8}\dot{\theta}^2+\frac{A+C+1/8mR^2}{\cos^2(\theta/2)}-\frac{4B_{l+\nu}+3/8mR^2}{\sin^2(\theta/2)}+A-C\right]\right\}. \tag{30}$$

Following Ref. 14, let us introduce the following parameters:

$$m_1=\tfrac{1}{2}(\sqrt{-2mR^2(A+C)})+\sqrt{1+8mR^2B_{l+\nu}}), \tag{31}$$

$$m_2=\tfrac{1}{2}(\sqrt{-2mR^2(A+C)})-\sqrt{1+8mR^2B_{l+\nu}}), \tag{32}$$

$$E_{PT'}=A-C-\tfrac{1}{8}mR^2. \tag{33}$$

Then (30) is given by

$$G_{l+\nu}(\tau_b,\tau_a;E)=\frac{4}{R^2}\sqrt{\cos(\theta_b/2)\cos(\theta_a/2)}\left(\frac{1}{2mc}\right)$$
$$\times\sum_{L=\max(m_1,m_2)}\frac{i}{E_{PT'}-((L+1)^2-1/4)/2mR^2}$$
$$\times\frac{L+1}{2}d^{L/2}_{m_1,m_2}(\theta_b)d^{L/2}_{m_1,m_2}(\theta_a), \tag{34}$$

where $d^L_{m,n}(\theta)$ is the analytical continuation of the Wigner function.

The summation over L in (34) is performed with the help of Sommerfeld–Watson's transformation,[15,16] which is essentially based on the following substitution:

$$\sum_L \rightarrow\frac{1}{2i}\int_C d\sigma\frac{e^{-2i\pi\sigma}}{\sin\pi\sigma}, \tag{35}$$

where the contour of integration C is the entire real axis in a counterclockwise direction.

Then following Ref. 17, we put the Green's function in the following compact form:

$$G_{l+\nu}(\tau_b,\tau_a;E)=-im\sqrt{\cos(\theta_b/2)\cos(\theta_a/2)}\left(\frac{1}{2mc}\right)\Gamma(m_1-L_E)\Gamma(L_E-m_1+1)$$
$$\times d^{L_E}_{m_1,-m_2}(\theta_b-\pi)d^{L_{E^*}}_{m_1,m_2}(\theta_a), \tag{36}$$

where $\theta_b<\theta_a$ and L_E is given by

$$L_E=-\frac{1}{2}+\sqrt{\frac{1}{16}+\frac{mR^2}{2}E_{PT'}}=-\frac{1}{2}[1-\sqrt{2mR^2(A-C)}]. \tag{37}$$

Using the old variables we obtain the radial part of the Green's function in the following closed form:

$$G_{l+\nu}(\tau_b,\tau_a;E)=-im\left(\frac{1}{2mc}\right)\left(\frac{1-\tanh(\tau_b/2)}{1+\tanh(\tau_b/2)}\right)^{1/2}\left(\frac{1-\tanh(\tau_a/2)}{1+\tanh(\tau_a/2)}\right)^{1/2}$$
$$\times\Gamma(m_1-L_E)\Gamma(L_E-m_1+1)d^{L_E}_{m_1,-m_2}(\theta(\tau_b)-\pi)d^{L_{E^*}}_{m_1,m_2}(\theta(\tau_a)), \tag{38}$$

with $\theta(\tau)$ defined by (28).

IV. BOUND STATES

The allowed energy levels are extracted from the poles of $\Gamma(m_1-L_E)$ in (38) which occur when the argument is a negative integer $-n_r$

$$m_1-L_E=-n_r, \quad n_r=0,1,2,3,\ldots. \tag{39}$$

Using the expressions (31) and (37), it is easy to show that

$$C+\frac{2mR^2A^2}{N^2}+\frac{N^2}{8mR^2}=0, \tag{40}$$

where

$$N=2n_r+s+1, s=\sqrt{1+8mR^2B_{l+\nu}}. \tag{41}$$

The solutions of (40) give the energy spectrum for the relativistic ABC system on $\Lambda^{(2)}$

$$E_{n_r}-\frac{\alpha}{R}=\pm mc^2\left[\frac{1+(1-(2\alpha/c)^2-N^2)/(2mcR)^2}{1+(2\alpha/Nc)^2}\right]^{1/2}. \tag{42}$$

The maximum number of bound states is given by

$$N_{\max}=\{\sqrt{(2mcR)^2-(2\alpha/c)^2+1}\}. \tag{43}$$

Here the symbol $\{k\}$ means the largest integer smaller than k.

The corresponding energy eigenfunctions for the bound states are now derived from the residues of the Green's function at the poles

$$\Gamma(m_1-L_E)\approx\frac{(-1)^{n_r}}{n_r!}\frac{1}{m_1-L_E+n_r}. \tag{44}$$

After some mathematical manipulations we find

$$\begin{aligned}\Gamma(m_1-L_E)\approx&\frac{(-1)^{n_r+1}}{n_r!}\left(\frac{E-\alpha/R}{mc^2}\right)^2\frac{2mc^2}{(E-\alpha/R)^2-(E_{n_r}-\alpha/R)^2}\\&\times\frac{16m^2R^4A^2/N^2-N^2}{2mR^2N}\left[1+\frac{1-(2\alpha/c)^2-N^2}{(2mcR)^2}\right]^{-1}.\end{aligned} \tag{45}$$

Now using the following symmetry relation:[18]

$$d^{L_E}_{m_1,-m_2}(\theta-\pi)=(-1)^{m_1-L_E}d^{L_E}_{m_1,m_2}(\theta), \tag{46}$$

and the relation connecting the Wigner function and the hypergeometric function

$$\begin{aligned}d^{L_E}_{m_1,m_2}(\theta)=&\left[\frac{\Gamma(L_E+m_1+1)\Gamma(L_E-m_2+1)}{\Gamma(L_E-m_1+1)\Gamma(L_E+m_2+1)}\right]^{1/2}\frac{1}{\Gamma(m_1-m_2+1)}\\&\times\left(\frac{1-\cos(\theta)}{2}\right)^{(m_1-m_2)/2}\left(\frac{1+\cos(\theta)}{2}\right)^{(m_1+m_2)/2}\\&\times{}_2F_1\left(-L_E+m_1,L_E+m_1+1,m_1-m_2+1;\frac{1-\cos(\theta)}{2}\right),\end{aligned} \tag{47}$$

we obtain the following decomposition of the radial Green's function:

$$G_{l+\nu}(\tau_b,\tau_a;E)=\frac{1}{2mc}\sum_{N=s+1}^{N_{\max}}\left(\frac{E-\alpha/R}{mc^2}\right)^2\frac{2imc^2}{(E-\alpha/R)^2-(E_{n_r}-\alpha/R)^2}\Psi_{n_r}(\tau_b)\Psi^*_{n_r}(\tau_a), \tag{48}$$

where the radial wave functions are

$$\begin{aligned}\Psi_{n_r}(\tau)=&\left[\frac{16m^2R^4A^2/N^2-N^2}{2R^2N}\right]^{1/2}\left[1+\frac{1-(2\alpha/c)^2-N^2}{(2mcR)^2}\right]^{-1/2}\\&\times\frac{2^{m_1-m_2}}{\Gamma(m_1-m_2+1)}\left[\frac{\Gamma(L_E+m_1+1)\Gamma(L_E-m_2+1)}{\Gamma(L_E-m_1+1)\Gamma(L_E+m_2+1)}\right]^{1/2}\\&\times(1-\tanh\tau/2)^{m_1+m_2+1/2}(1+\tanh\tau/2)^{-2m_1-1/2}(\tanh\tau/2)^{(m_1-m_2)/2}\\&\times{}_2F_1\left(-L_E+m_1,L_E+m_1+1,m_1-m_2+1;\frac{4\tanh\tau/2}{(1+\tanh\tau/2)^2}\right),\end{aligned} \tag{49}$$

with

$$m_{1,2}=mR^2\left(\frac{A_{n_r}}{N}-\frac{N}{4mR^2}\right)\pm\frac{s}{2},\quad L_E=-\frac{1}{2}+mR^2\left(\frac{A_{n_r}}{N}+\frac{N}{4mR^2}\right), \tag{50}$$

and A_{n_r} is the expression of A given by (18) with E replaced by E_{n_r}.

In the following we treat two important cases namely, the relativistic ABC in a flat space and the nonrelativistic ABC on the pseudo-sphere. To this aim we first expand s in terms of (α/c) which is the analog of the fine structure constant in the flat space

$$s=2|l+\nu|\left[1-\frac{(\alpha/c)^2}{2|l+\nu|^2}-\frac{(\alpha/c)^4}{8|l+\nu|^4}-\cdots\right]. \tag{51}$$

Then the energy levels are rewritten as

$$\begin{aligned}E_{n_r}-\frac{\alpha}{R}=\pm mc^2\Bigg\{&1-\frac{1}{2}\left(\frac{\alpha}{c}\right)^2\left[\frac{\tilde{N}^2-1/4}{m^2\alpha^2R^2}+\frac{1}{\tilde{N}^2}\right]-\frac{1}{2}\left(\frac{\alpha}{c}\right)^4\Bigg[\left(\frac{\tilde{N}^2-1/4}{2m^2\alpha^2R^2}\right)^2\\&+\frac{\tilde{N}^2-1/4}{2m^2\alpha^2R^2\tilde{N}^2}+\frac{3}{4\tilde{N}^4}+\frac{1}{\tilde{N}^3|l+\nu|}+\frac{1}{m^2\alpha^2R^2}\frac{n_r+1/2}{|l+\nu|}\Bigg]-\cdots\Bigg\},\end{aligned} \tag{52}$$

where

$$\tilde{N}=|l+\nu|+n_r+\tfrac{1}{2}. \tag{53}$$

A. Nonrelativistic limit

In the nonrelativistic limit $c\to\infty$, expression (52) reduces to the energy spectrum for the nonrelativistic ABC system on $\Lambda^{(2)4}$

$$E_{n_r}=\frac{\alpha}{R}-\frac{\tilde{N}^2-1/4}{2mR^2}-\frac{m\alpha^2}{2\tilde{N}^2}. \tag{54}$$

The corresponding wave function is easily obtained from (49) by making use of the following relations:

$$m_{1,2}=-\frac{m\alpha R^2}{2\tilde{N}}\left(\frac{\tilde{N}^2-1/4}{2mR^2}-\frac{m\alpha^2}{2\tilde{N}^2}\right)-\frac{\tilde{N}}{2}\pm 2|l+\nu|, \tag{55}$$

$$L_E=-\frac{1}{2}-\frac{m\alpha R^2}{2\tilde{N}}\left(\frac{\tilde{N}^2-1/4}{2mR^2}-\frac{m\alpha^2}{2\tilde{N}^2}\right)+\frac{\tilde{N}}{2}. \tag{56}$$

B. Flat space limit

In the flat space limit $R\to\infty$, the energy levels reduce to

$$E_{n_r}=\pm mc^2\left\{1-\frac{1}{2}\frac{(\alpha/c)^2}{\tilde{N}^2}-\frac{1}{2}\frac{(\alpha/c)^4}{\tilde{N}^3}\left[\frac{1}{\tilde{N}-n_r-1/2}-\frac{3}{4\tilde{N}}\right]+\cdots\right\}. \tag{57}$$

For the wave function, it is easy to show that

$$\lim_{R\to\infty}\frac{16m^2R^4A^2/N^2-N^2}{2mR^2N}=\left(\frac{8\alpha^2E^2}{N^3c^4}\right). \tag{58}$$

Using the radial variable $r=R\tau$ in Euclidean spaces, we obtain for $R\to\infty$

$$(1-\tanh\tau/2)^{m_1+m_2+1/2}(1+\tanh\tau/2)^{-2m_1-1/2}(\tanh\tau/2)^{(m_1-m_2)/2}\to\left(\frac{r}{2R}\right)^{s/2}e^{-2\alpha E/Nc^2 r}. \tag{59}$$

Now using the following relation[19] valid for $|z|\to\infty$:

$$\frac{\Gamma(z+a)}{\Gamma(z)}\to z^a, \tag{60}$$

we show that

$$\frac{\Gamma(L_E+m_1+1)\Gamma(L_E-m_2+1)}{\Gamma(L_E-m_1+1)\Gamma(L_E+m_2+1)}\to\frac{\Gamma(n_r+s+1)}{\Gamma(n_r+1)}\left(\frac{2\alpha Er}{(2n_r+s+1)c^2}\right)^s. \tag{61}$$

On the other hand we have

$$\lim_{R\to\infty}{}_2F_1\left(-L_E+m_1,L_E+m_1+1,m_1-m_2+1;\frac{4\tanh\tau/2}{(1+\tanh\tau/2)^2}\right)={}_1F_1\left(-n_r,s+1;\frac{4\alpha E}{Nc^2}r\right). \tag{62}$$

Collecting all the terms leads to

$$\Psi_{n_r}(r)=\frac{1}{\sqrt{r}}\frac{1}{\Gamma(1+s)}\sqrt{\frac{\Gamma(n_r+s+1)}{\Gamma(n_r+1)}}\frac{2}{2n_r+s+1}\frac{1}{\tilde{a}_H^{1/2}}\left(\frac{4r}{(2n_r+s+1)\tilde{a}_H}\right)^{(s+1)/2}$$
$$\times e^{-2r/(2n_r+s+1)\tilde{a}_H}{}_1F_1\left(-n_r,s+1;\frac{4\alpha E}{(2n_r+s+1)c^2}r\right), \tag{63}$$

where $\tilde{a}_H=a_H(mc^2/E)$ and a_H is Bohr radius. Expressions (57) and (63) are exactly the ones obtained recently in Ref. 5.

V. SCATTERING STATES

We begin by considering the reduced Green's function defined in Eq. (38)

$$g_{l+\nu}(\tau_b,\tau_a;E)=-im\Gamma(m_1-L_E)\Gamma(L_E-m_1+1)d^{L_E}_{m_1,-m_2}(\theta_b-\pi)d^{L_E*}_{m_1,m_2}(\theta_a). \tag{64}$$

This can be rewritten in the following integral form:[20]

$$g_{l+\nu}(\tau_b,\tau_a;E)=\frac{m}{2\pi}\oint_C\frac{dE}{E^2-E_k^2}(2E)\Gamma(m_1-L_E)\Gamma(L_E-m_1+1)\times d^{L_E}_{m_1,-m_2}(\theta_b-\pi)d^{L_E*}_{m_1,m_2}(\theta_a), \tag{65}$$

where the contour C is a semicircle in the upper half plane.

Using the spectral decomposition of the Manning–Rosen propagator,[12] we easily get the continuous spectrum for a relativistic particle moving on the pseudo-sphere $\Lambda^{(2)}$

$$E_k^2=m^2c^4+\frac{c^2}{R^2}\left(k^2+\frac{1}{4}\right). \tag{66}$$

In comparison with the flat space continuous spectrum we have the correspondence

$$k_f^2\rightarrow(k^2+\tfrac{1}{4})/R^2. \tag{67}$$

In the following we restrict ourself to positives energies and write (65) as

$$g_{l+\nu}(\tau_b,\tau_a;E)=\frac{1}{2\pi R^2}\oint_C kdk\left(\frac{E}{mc^2}\right)^2\frac{2mc^2}{E^2-E_k^2}\times\frac{\Gamma(m_1-L_E)\Gamma(L_E-m_1+1)}{[1+(1/mcR)^2(k^2+1/4)]}d^{L_E}_{m_1,-m_2}(\theta_b-\pi)d^{L_E*}_{m_1,m_2}(\theta_a). \tag{68}$$

It is easy to show that

$$m_1=\frac{s}{2}+\frac{ik}{2},\quad m_2=-\frac{s}{2}+\frac{ik}{2},\quad L_E=\frac{\gamma-1}{2}, \tag{69}$$

where we have set $\gamma=\sqrt{2mR^2(A-C)}$. Taking into account the asymptotic behavior of the Wigner's functions, we write (68) in the form

$$g_{l+\nu}(\tau_b,\tau_a;E)=-\frac{1}{2\pi R^2}\int_{-\infty}^{\infty}kdk\left(\frac{E}{mc^2}\right)^2\frac{2mc^2}{E^2-E_k^2}\times\frac{\Gamma((1+s-\gamma+ik)/2)\Gamma((1-s+\gamma-ik)/2)}{[1+(1/mcR)^2(k^2+1/4)]}\times d^{(\gamma-1)/2}_{m_1,-m_2}(\theta_b-\pi)d^{(\gamma-1)/2*}_{m_1,m_2}(\theta_a). \tag{70}$$

Thanks to the following properties:[18]

$$d^{-L-1}_{m_1,m_2}(\theta)=d^{L}_{m_1,m_2}(\theta),\quad d^{L}_{-m_2,-m_1}(\theta)=(-1)^{2(m_2-m_1)}d^{L}_{m_1,m_2}(\theta), \tag{71}$$

we show that (71) becomes

$$g_{l+\nu}(\tau_b,\tau_a;E)=\frac{(-1)^{(s-1)/2}}{2\pi R^2}\int_0^\infty kdk\left(\frac{E}{mc^2}\right)^2\frac{2mc^2}{E^2-E_k^2}\frac{e^{i\pi\gamma/2}}{[1+(1/mcR)^2(k^2+1/4)]}$$
$$\times\{e^{\pi k/2}\Gamma((1+s-\gamma+ik)/2)\Gamma((1-s+\gamma-ik)/2)$$
$$-e^{-\pi k/2}\Gamma((1+s-\gamma-ik)/2)\Gamma((1-s+\gamma+ik)/2)\}$$
$$\times d^{(\gamma-1)/2}_{m_1,m_2}(\theta_b)d^{(\gamma-1)/2*}_{m_1,m_2}(\theta_a). \tag{72}$$

Now using the following identity which is a consequence of Gauss's transformation formula:[19]

$$e^{i\pi a/2}\frac{\Gamma(b-a)\Gamma(a-b+1)}{\Gamma(b)\Gamma(1-b)}+e^{i\pi b/2}\frac{\Gamma(a-b)\Gamma(b-a+1)}{\Gamma(a)\Gamma(1-a)}=1, \tag{73}$$

we get

$$g_{l+\nu}(\tau_b,\tau_a;E)=\frac{i}{2\pi R^2}\int_0^\infty kdk\frac{2mc^2}{E^2-E_k^2}\left(\frac{E}{mc^2}\right)^2\frac{1}{[1+(1/mcR)^2(k^2+1/4)]}$$
$$\times\frac{\Gamma((1+s-\gamma+ik)/2)\Gamma((1-s+\gamma-ik)/2)(k\to-k)}{|\Gamma(ik)|^2}$$
$$\times d^{(\gamma-1)/2}_{m_1,m_2}(\theta_b)d^{(\gamma-1)/2*}_{m_1,m_2}(\theta_a). \tag{74}$$

Finally the continuous part of the radial Green's function is given by

$$G_{l+\nu}(\tau_b,\tau_a;E)=\frac{1}{2mc}\int_0^\infty\frac{dk}{R}\frac{2imc^2}{E^2-E_k^2}\left(\frac{E}{mc^2}\right)^2\Psi_k(\tau_b)\Psi_k^*(\tau_a), \tag{75}$$

where the normalized continuous wave functions are

$$\Psi_k(\tau)=\sqrt{\frac{1}{\pi R}}\frac{2^s}{\sqrt{1+(k^2+1/4)/(mcR)^2}}$$
$$\times\frac{[\Gamma((1+s-\gamma+ik)/2)\Gamma((1+s+\gamma+ik)/2)(k\to-k)]^{1/2}}{|\Gamma(ik)|\Gamma(1+s)}$$
$$\times(1-\tanh\tau/2)^{ik+1/2}(1+\tanh\tau/2)^{-ik-s-1/2}(\tanh\tau/2)^{s/2}$$
$$\times{}_2F_1\left((1+s-\gamma+ik)/2,(1+s+\gamma+ik)/2,1+s;4\frac{\tanh\frac{\tau}{2}}{\left(1+\tanh\frac{\tau}{2}\right)^2}\right). \tag{76}$$

We go now to the flat space limit $R\to\infty$. To this aim we use the correspondence (67) between k on the pseudo-sphere and k_f on the flat space.

Owing to the following relations valid for $R\to\infty$

$$\gamma\to-\frac{2i\alpha}{c^2k_f}E_{k_f}, \tag{77}$$

$$\frac{[\Gamma((1+s-\gamma+ik)/2)\Gamma((1+s+\gamma+ik)/2)(k\to-k)]^{1/2}}{|\Gamma(ik)|\Gamma(1+s)}$$
$$\to|\Gamma((s+1)/2+i\alpha E_{k_f}/c^2k_f)|(Rk_f)^{(s+1)/2}, \tag{78}$$

$$(1-\tanh\tau/2)^{ik+1/2}(1+\tanh\tau/2)^{-ik-s-1/2}(\tanh\tau/2)^{s/2}\rightarrow\left(\frac{r}{2R}\right)^{s/2}e^{-ik_f r}, \tag{79}$$

and

$$ {}_2F_1\left((1+s-\gamma+ik)/2,(1+s+\gamma+ik)/2,1+s;4\,\frac{\tanh\frac{\tau}{2}}{\left(1+\tanh\frac{\tau}{2}\right)^2}\right)$$
$$\rightarrow {}_1F_1((1+s)/2+i\alpha E_{k_f}/c^2k_f,1+s;2ik_f r), \tag{80}$$

we obtain the following representation of the Green's function for the relativistic spinless ABC system in a flat space:

$$G_{l+\nu}(r_b,r_a;E)=\frac{1}{2mc}\int_0^\infty dk_f\,\frac{2imc^2}{E^2-E_{k_f}^2}\left(\frac{E}{mc^2}\right)^2\Psi_{k_f}(r_b)\Psi_{k_f}^*(r_a), \tag{81}$$

where the continuous wave function $\Psi_{k_f}(r)$ is given by[21]

$$\Psi_{k_f}(r)=\frac{1}{\sqrt{2\pi r}}\,\frac{1}{\sqrt{1+(k_f/mc)^2}}\,\frac{|\Gamma((s+1)/2+i\alpha E_{k_f}/c^2k_f)|}{\Gamma(1+s)}$$
$$\times e^{\pi\alpha E_{k_f}/2c^2k_f}(2k_f r)^{(1+s)/2}e^{-ik_f r}\,{}_1F_1((1+s)/2+i\alpha E_{k_f}/c^2k_f,1+s;2ik_f r). \tag{82}$$

The correctness of this expression is assured by the presence of the factor $e^{-\pi\alpha E_{k_f}/2c^2k_f}$, which is essential for the particle density at $r=0$. However this factor has been missing in path integral treatments based on the SU(1, 1) group manifold.[3,22]

VI. CONCLUSION

In this paper we have explicitly evaluated the Green's function for the relativistic spinless Aharonov–Bohm–Coulomb system on the pseudo-sphere $\Lambda^{(2)}$ using Kleinert's path integral representation for the motion of relativistic spinless particles in $(D+1)$-dimensional Minkowski space. We have obtained the energy spectrum and the corresponding wave-functions for bound states. The scattering states are deduced from the integral representation of the Green's function. In the nonrelativistic limit and the flat space limit our results are in agreement with those of the literature. We hope that the results presented in this paper may be useful to investigate other features, like the interference pattern, of the Aharonov–Bohm–Coulomb system on the pseudo-sphere $\Lambda^{(2)}$.

Alternative $SU(N)$ Skyrme models and their solutions

H. J. Wospakrik[a] and W. J. Zakrzewski[b]
Department of Mathematical Sciences, University of Durham, Durham DH1 3LE, United Kingdom

(Received 15 September 2000; accepted for publication 1 December 2000)

We consider alternative $SU(N)$ Skyrme models in 3 spatial dimensions. We show that when $N=2$ they reduce to the usual $SU(2)$ Skyrme model but for $N\geqslant 3$ they are different. We show that the harmonic map ansatz previously applied to the usual Skyrme models can also be applied to these models giving spherically symmetric solutions (when the number of projectors is $N-1$) and low energy field approximants when the number of projectors is lower. We compare our results with the results for the usual Skyrme models. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1346596]

I. INTRODUCTION

The usual Skyrme model was originally proposed by Skyrme,[1] and recently, since Witten's demonstration that it arises in the large N_c limit[2] of QCD, it has been used to study various properties of low energy mesons and baryons.[3]

While the basic fields of the model describe mesons the topologically nontrivial solutions of the model, known as skyrmions, are identified with classical ground states of light nuclei. Although the preliminary results of the investigations of the implications of this idea are very encouraging[4] a thorough understanding of the structure and dynamics of multi-skyrmion configurations is required before a more qualitative assessment of the validity of this application can be made.

The $SU(N)$ Skyrme models, usual or alternative, involves fields which take value in $SU(N)$; i.e., are described by $SU(N)$ valued functions of $\vec{x}$ and t. The two classes of models differ only in the form of their Lagrangians and so in their equations of motion.

Multi-skyrmions are stationary points (either minima or saddle points) of the static energy functional, which, for the usual Skyrme models, is given by

$$E=\frac{1}{12\pi^2}\int_{R^3}\left\{-\frac{1}{2}\mathrm{Tr}(\partial_i U\,U^{-1})^2-\frac{1}{16}\mathrm{Tr}[\partial_i U\,U^{-1},\ \partial_j U\,U^{-1}]^2\right\}d^3\vec{x}, \tag{1}$$

where $U(\vec{x})\in SU(N)$.

The equations for multi-skyrmions, in the usual Skyrme model, are therefore

$$\partial_i(\partial_i U\,U^{-1}-\tfrac{1}{4}[\partial_j U\,U^{-1},[\partial_j U\,U^{-1},\partial_i U\,U^{-1}]])=0. \tag{2}$$

In these expressions we have, for simplicity, set the mass terms to zero. This has been done for convenience, as the conventional mass terms introduce only small changes.

Finiteness of the energy functional, for the usual Skyrme models and for the, soon to be introduced, alternative Skyrme models, requires that $U(\vec{x})$ approaches a constant matrix at spatial infinity, which can be reduced to the identity matrix by a global chiral transformation. So, without any loss of generality, one normally imposes the following boundary conditions on U: $U\to I$ as $|\vec{x}|\to\infty$.

[a]Electronic mail: H.J.Wospakrik@durham.ac.uk
[b]Electronic mail: W.J.Zakrzewski@durham.ac.uk

Since $U \to I$ as $|\vec{x}| \to \infty$ is a mapping from $S^3 \to SU(N)$, it can be classified by the third homotopy group $\pi_3(SU(N)) \equiv Z$ or, equivalently, by the integer valued winding number

$$B = \frac{1}{24\pi^2} \int_{R^3} \varepsilon_{ijk} \, \mathrm{Tr}(\partial_i U \, U^{-1} \partial_j U \, U^{-1} \partial_k U \, U^{-1}) d^3\vec{x}, \tag{3}$$

which is a topological invariant which classifies the solitonic sectors in the model. And following the idea of Skyrme[1] and Witten,[2] B is to be identified with the baryon number of the field configuration.

Until very recently most of the studies involving the Skyrme model have concentrated on the $SU(2)$ version of the model and its embeddings into $SU(N)$. However, when one considers $SU(N)$, for $N \geqslant 3$, one has to bear in mind that the Skyrme model is not unique. In fact, there are two possible versions of the fourth-order Skyrme term[5] and so in this paper we initiate the study of the model based on the alternative form of the fourth-order Skyrme term.

Thus instead of looking at

$$-\tfrac{1}{16} \mathrm{Tr}[\partial_i U \, U^{-1}, \ \partial_j U \, U^{-1}]^2 \tag{4}$$

in (1) we consider

$$\tfrac{1}{8} (\mathrm{Tr}(\partial_i U \, U^{-1} \, \partial_i U \, U^{-1}))^2 - \tfrac{1}{8} (\mathrm{Tr}(\partial_i U \, U^{-1} \, \partial_j U \, U^{-1}))^2. \tag{5}$$

Note that when $N=2$ the two expressions are the same. To see this we introduce

$$R_i = U^{-1} \, \partial_i U = i R_i^k \sigma^k, \tag{6}$$

where σ^k, $k=1,2,3$, are Pauli matrices. Then, using the properties of Pauli matrices, we find that

$$\mathrm{Tr}(\partial_i U \, U^{-1} \, \partial_j U \, U^{-1}) = -2(R_i^k R_j^k), \tag{7}$$

and so

$$\begin{aligned} -\tfrac{1}{16} \mathrm{Tr}[\partial_i U \, U^{-1}, \ \partial_j U \, U^{-1}]^2 &= \tfrac{1}{2}[(R_i^k R_i^k)^2 - R_i^k R_j^k R_i^l R_j^l] \\ &= \tfrac{1}{8} (\mathrm{Tr}(\partial_i U \, U^{-1} \, \partial_i U \, U^{-1}))^2 \\ &\quad - \tfrac{1}{8} (\mathrm{Tr}(\partial_i U \, U^{-1} \, \partial_j U \, U^{-1}))^2. \end{aligned} \tag{8}$$

However, for $N>2$ the two expressions are different.

Until very recently very little attention has been paid to field configurations describing many skyrmions in $SU(N)$ models which were not embeddings of $SU(2)$ skyrmions. Although some work has been done earlier[6,7] the real progress has only been made since Houghton, Manton and Sutcliffe had produced their harmonic map ansatz.[8]

This ansatz, when generalized to $SU(N)$ models,[9] has lead to the construction of whole families of solutions of $SU(N)$ Skyrme models—with spherically symmetric energy densities.[10] Moreover, it also presents field configurations, which though not solutions of the equations, are close to them—thus providing us with good approximants to other solutions.[9]

In this paper we apply the same ideas to the alternative Skyrme models. We find that, although the actual values of energies etc., and the properties of the field configurations, are different, the situation is qualitatively the same as in the usual Skyrme models; the harmonic map ansatz produces good approximants and the appropriate multiprojector fields provide solutions of the full equations (the only difference lies in the profile functions).

In the next section, for completeness, we discuss the harmonic maps ansatz and its generalization to $SU(N)$ fields. In the following section we present the discussion of the one projector

approximants. In it we study the $SU(N)$ fields with $N=3,4$ and 5, and compare the values of energies of such fields in the usual and the alternative Skyrme models. This is followed by sections on the spherically symmetric solutions of the alternative Skyrme models and a discussion of some of their properties.

II. HARMONIC MAPS

In Ref. 9 the $SU(2)$ ansatz of Houghton *et al.*[8] was generalized to the usual $SU(N)$ Skyrme models. This generalization involved rewriting the expression of Houghton *et al.* as a projector from S^2 to CP^{N-1}. It not only gave a new way of interpreting old results but also a new way of deriving expressions for low energy $SU(N)$ field configurations which are **not** simple embeddings of $SU(2)$ fields. In particular, the energy distributions of the field configurations given in Ref. 9 exhibited symmetries very different from those of the embeddings.

The method of Ref. 9 was then generalized further in Ref. 10, to involve more projectors. This generalization exploited some ideas from the theory of harmonic maps of $S^2\to CP^{N-1}$ and $S^2\to U(N)$.[11] Here, for completeness, we follow Ref. 10 and recall some properties of harmonic maps $S^2\to CP^{N-1}$.

We recall[12] that an N dimensional space possesses a ''natural'' set of mutually orthogonal projectors constructed from $S^2\to CP^{N-1}$ maps. To construct them we proceed as follows.

First we write each projector P as

$$P(V)=\frac{V\otimes V^\dagger}{|V|^2}, \tag{9}$$

where V is an N-component complex vector dependent on ξ and its complex conjugate $\bar{\xi}$. These are related to the more familiar θ and φ, which locally parametrize S^2, via $\xi=\tan(\theta/2)\,e^{i\varphi}$.

Then for the first projector we take $V=f(\xi)$, i.e., an analytic vector of ξ. Its components are chosen to be polynomials in ξ. Next we construct further vectors V^α, $\alpha=1,2,\ldots,$ by

$$V^\alpha=\frac{\partial^\alpha}{\partial\xi^\alpha}V, \tag{10}$$

and Gram Schmidt orthogonalize the whole sequence.

It is then easy to check[12] that the kth vector, $k=0,1,\ldots,$ in the resultant sequence of vectors, can be written as $P_+^k f$ and considered as having come from a sequence of k successive application to f of the operator P_+ defined by its action on any vector $v\in \mathrm{C}^N$ as

$$P_+ v=\partial_\xi v-\frac{v\,(v^\dagger\,\partial_\xi v)}{|v|^2}, \tag{11}$$

i.e., $P_+^k v=P_+(P_+^{k-1}v)$.

Then as further projectors we take projectors given by (9) with V given by $P_+^k f$. This way we end up with

$$P_0=P(f),\quad P_1=P(P_+f),\quad P_2=P(P_+^2 f),\quad \ldots,\quad P_k=P(P_+^k f), \tag{12}$$

and note, that due to the orthogonality of P_i, $\Sigma_{k=0}^{N-1}P_k=1$.

The orthogonality properties of our projectors follow from their construction and translate into the following properties of $P_+^k f$ when f is holomorphic:

$$(P_+^k f)^\dagger\,P_+^l f=0,\quad k\neq l, \tag{13}$$

$$\partial_{\bar{\xi}}(P_+^k f)=-P_+^{k-1}f\frac{|P_+^k f|^2}{|P_+^{k-1}f|^2},\quad \partial_\xi\left(\frac{P_+^{k-1}f}{|P_+^{k-1}f|^2}\right)=\frac{P_+^k f}{|P_+^{k-1}f|^2}. \tag{14}$$

It is easy to check that for $SU(N)$ the last projector P_{N-1} in this sequence corresponds to an anti-analytic vector; [i.e., up to an overall factor, which cancels in (9), the components of $V=P_+^{N-1}f$ are functions of only $\bar{\xi}$].

As $\Sigma_{k=0}^{N-1}P_k=1$ we see that for $SU(N)$ only $N-1$ projectors are independent.

The properties (13)–(14) are independent of the choice of the starting vector f. However, there are further properties of vectors $P_+^k f$ which depend on f. Namely, in Ref. 10 it was shown that if, for a given N, we choose the vector f to be given by

$$N=2, \quad f=(1,\xi)^t, \tag{15}$$

$$N=3, \quad f=(1,\sqrt{2}\,\xi,\xi^2)^t, \tag{16}$$

$$N=4, \quad f=(1,\sqrt{3}\xi,\sqrt{3}\,\xi^2,\xi^3)^t, \tag{17}$$

$$N=n, \quad f=(f_0,f_1,\ldots,f_{n-1})^t: \quad f_k=\xi^k\sqrt{C_k^{n-1}}, \tag{18}$$

where C_k^{n-1} denotes the binomial coefficients, then not only $|f|^2$ is a power of $(1+|\xi|^2)$ but so are also all $|P_+^k f|^2$, for $k=1,2,\ldots,N-1$. In fact, in Ref. 10 it was shown that

$$|P_+^k f|^2=k!(N-1)(N-2)\cdots(N-k)(1+|\xi|^2)^{N-2k-1}.$$

The reason for choosing vectors of the form (18) is that they correspond to spherically symmetric configurations.

Let us note that in the mathematical literature our sequence of vectors $P_+^k f$, $k=0,1,\ldots,$ is called the Veronese sequence.[13] In Refs. 9 and 10 it was then shown that for the usual $SU(N)$ Skyrme models it is convenient to take our sequence of projectors (12) and so to consider U of the form

$$\begin{aligned} U&=\exp\left[-ig_0\left(\frac{I}{N}-P_0\right)-ig_1\left(\frac{I}{N}-P_1\right)-\ldots-ig_{N-2}\left(\frac{I}{N}-P_{N-2}\right)\right] \\ &=e^{-ig_0/N}(I+A_0P_0)\,e^{-ig_1/N}(I+A_1P_1)\ldots e^{-ig_{N-2}/N}(I+A_{N-1}P_{N-2}), \end{aligned} \tag{19}$$

where $g_k=g_k(r)$, for $k=0,\ldots,N-2$, are the profile functions and $A_k=e^{ig_k}-1$. The profile functions $g_k(r)$ are required to satisfy the boundary conditions $g_k(\infty)=0$ and $g_k(0)=2\alpha\pi$, where $\alpha=0$ or ±1. The vector V in the projector P_i is given by $V=P_+^i f$, and so depends only on θ,φ, and r is the usual radial variable. Then, as shown in Ref. 10, the full equations for the field U are automatically satisfied if the appropriate equations (just ordinary differential equations) for the profile functions $g_k(r)$ are satified.

If we take a smaller number of projectors (i.e., fewer than $N-1$) and/or take different initial vectors f, the resultant field does not solve the full equations but may provide a good approximation to such a solution. Good, in the sense that the energy (and even the energy density) of the configuration (for a ''good'' choice of the vector f) is very close to an exact solution (which had to be found numerically); this was checked for different vectors f for the $SU(2)$ model where the numerical solutions are known. The same is expected to be the case for other $SU(N)$ models.

In the next sections we show that the same is true for the alternative Skyrme models.

III. SOME APPROXIMATE SOLUTIONS OF THE ALTERNATIVE $SU(N)$ SKYRME MODELS

In this section we look at the 1 projector approximants to the minimal field configuration of the alternative Skyrme models and compare them with the similar approximations to the solutions of the usual Skyrme models.

To do this we note, using the definition

$$R_i = U^{-1}\,\partial_i U, \tag{20}$$

where $i=x,y,z$, that the alternative Skyrme term is proportional to

$$K(x,y) = \mathrm{Tr}\,R_x^2\,\mathrm{Tr}\,R_y^2 - (\mathrm{Tr}\,R_x R_y)^2, \tag{21}$$

plus $K(x,z)+K(z,y)$—i.e., the corresponding (xz) and (zy) contributions. The usual related Skyrme term is

$$M(x,y) = \mathrm{Tr}\,(R_x R_x R_y R_y - R_x R_y R_x R_y), \tag{22}$$

plus the corresponding $M(y,z)$ and $M(z,x)$ contributions.

Next we change variables $(x,y,z)\to(r,\xi,\bar{\xi})$, as discussed in the previous section; i.e., r is the radial variable ($r=\sqrt{x^2+y^2+z^2}$) and ξ and $\bar{\xi}$ are related to the spherical angles (θ,φ).

If we now use our harmonic map ansatz [taking only the first projector in (19) and putting $g_0=2g$],

$$U = e^{-2ig/N}\,(1+(e^{2ig}-1)P), \tag{23}$$

we find that

$$R_x = -\frac{2ig_x}{N}1 + 2ig_x P + HP_\xi\frac{1-\xi^2}{2r} - \bar{H}P_{\bar{\xi}}\frac{1-\bar{\xi}^2}{2r}, \tag{24}$$

$$R_y = -\frac{2ig_y}{N}1 + 2ig_y P + HP_\xi\frac{i(1+\xi^2)}{2r} + \bar{H}P_{\bar{\xi}}\frac{i(1+\bar{\xi}^2)}{2r}, \tag{25}$$

and

$$R_z = -\frac{2ig_z}{N}1 + 2ig_z P - HP_\xi\frac{\xi}{r} + \bar{H}P_{\bar{\xi}}\frac{\bar{\xi}}{r}, \tag{26}$$

where $H=e^{2ig}-1$.

Moreover, as $V=f$ is a function of only ξ,

$$P = \frac{ff^\dagger}{|f|^2}, \quad P_\xi = \frac{P_+ ff^\dagger}{|f|^2}, \quad P_{\bar{\xi}} = \frac{f(P_+ f)^\dagger}{|f|^2}. \tag{27}$$

Next we calculate various terms in the energy. We look at various products of R_i and take appropriate traces. Then using the orthogonality properties of vectors f and $P_+ f$ and

$$\mathrm{Tr}\,P = 1, \quad \mathrm{Tr}\,1 = N, \quad \mathrm{Tr}P_\xi P_{\bar{\xi}} = \frac{|P_+ f|^2}{|f|^2} = \mathcal{B}, \tag{28}$$

$$\mathrm{Tr}\,P_\xi P_{\bar{\xi}} P_\xi P_{\bar{\xi}} = \frac{|P_+ f|^4}{|f|^4} = \mathcal{B}^2, \tag{29}$$

we find, for the usual Skyrme model [for the (x,y) contribution],

$$M(x,y) = \mathcal{B}^2(\gamma_x\delta_y - \delta_x\gamma_y) - \mathcal{B}(\gamma_x\beta_y - \beta_x\gamma_y)(\delta_x\beta_y - \beta_x\delta_y), \tag{30}$$

while for the alternative Skyrme term the $\mathcal{B}^2$ term is the same and the $\mathcal{B}$ term is altered to

$$\mathcal{B}\to\mathcal{B}^{\frac{2(N-1)}{N}}=\mathcal{B}A_N, \tag{31}$$

where

$$A_N=\frac{2(N-1)}{N}. \tag{32}$$

In the expression above β_i, γ_i and δ_i are the coefficients of P, $P_{\bar{\xi}}$ and P_ξ, respectively, in the expansion of R_i (24)–(26).

Adding all the contributions, and the contribution of the usual (σ model) terms we find that while the energy of the usual Skyrme model is given by

$$E_u=\frac{1}{3\pi}\int dr\left(A_N g_r^2 r^2+2\mathcal{N}\sin^2 g\,(1+g_r^2)+\mathcal{I}\frac{\sin^4 g}{r^2}\right), \tag{33}$$

its value in the alternative model is given by

$$E_a=\frac{1}{3\pi}\int dr\left(A_N g_r^2 r^2+2\mathcal{N}\sin^2 g\,(1+A_N g_r^2)+\mathcal{I}\frac{\sin^4 g}{r^2}\right), \tag{34}$$

where

$$\mathcal{N}=\frac{i}{2\pi}\int d\xi\, d\bar{\xi}\,\mathrm{tr}(|\partial_\xi P|^2), \tag{35}$$

$$\mathcal{I}=\frac{i}{4\pi}\int d\xi\, d\bar{\xi}\,(1+|\xi|^2)^2\,\mathrm{tr}([\partial_\xi P,\partial_{\bar{\xi}}P])^2. \tag{36}$$

Note that $\mathcal{N}$ is the expression for the energy of the 2-dimensional $CP^{(N-1)}$ sigma model, so $\mathcal{N}$ is given by the degree of f. It should be noted that Eq. (34) implies that the same projector minimizes the energy in both the usual and alternative Skyrme models within this ansatz.

Note also that for $N=2$ both expressions agree, as they should.

Which energy E_u or E_a is larger for the same projector? Clearly, as all the terms in E_u and E_a are positive, $E_a>E_u$. This is true even though both expressions (33) and (34) have to be extremized first for the shape of the profile function $g(r)$ [subject to the conditions: $g(0)=\pi$, $g(\infty)=0$]; i.e., we have to solve the resultant equation for g and then calculate the value of E_u or E_a.

However, note that the profile function $g(r)$, corresponding to E_a, when put into the expression for E_u will give a lower value; taking $g(r)$ which extremizes E_u can only lower this value further.

So we conclude that the energies of the harmonic field approximants are higher in the alternative models than in the usual Skyrme models. How much higher? To assess this we took maps of the form (18) (with n replaced by $n+1$) for which $N=n+1$ and one can compute that $\mathcal{N}=n$ and $\mathcal{I}=n^2$. We have calculated the corresponding energies for a few special cases with $n=2$, 3 and 4, and we have found that for $n=2$ $E_u=2.44404$, $E_a=2.70614$ while for $n=3$ and $n=4$ the corresponding numbers are $E_u=3.64410$, $E_a=4.18918$ and $E_u=4.83792$, $E_a=5.66929$, respectively. We see that the difference (and even the relative difference) grows with n. These numerical values were obtained both by the shooting method and by the finite difference scheme with 48,000 grid points and lattice spacing $\delta r=10^{-3}$.

IV. SPHERICALLY SYMMETRIC SOLUTIONS—GENERAL DISCUSSION

Next we show that, like for the usual Skyrme models, our ansatz (19) gives us also many exact solutions of the alternative Skyrme models. In fact, we will show that for each $SU(N)$ model our ansatz involving $N-1$ projectors leads to exact solutions involving $N-1$ profile functions.

To show this, like for the usual Skyrme models,[10] we first rewrite our equations for U, which for the alternative models are given by

$$\partial_i[\partial_i U\, U^{-1} - \tfrac{1}{2}(\mathrm{Tr}(\partial_j U\, U^{-1})^2)\partial_i U\, U^{-1} + \tfrac{1}{2}(\mathrm{Tr}(\partial_i U\, U^{-1}\, \partial_j U\, U^{-1}))\partial_j U U^{-1}] = 0, \quad (37)$$

in spherical polar coordinates (r,θ,φ).

We then use R_i given by the definition (20) and find that these equations take the form

$$\partial_r\left[r^2\left(R_r - \frac{1}{2}(A_r - B_r)\right)\right] + \frac{1}{\sin\theta}\partial_\theta\left[\sin\theta\left(R_\theta - \frac{1}{2}(A_\theta - B_\theta)\right)\right] + \frac{1}{\sin^2\theta}\partial_\varphi\left[R_\varphi - \frac{1}{2}(A_\varphi - B_\varphi)\right] = 0, \quad (38)$$

where

$$A_d = \left[\mathrm{Tr}\, R_r^2 + \frac{1}{r^2}\left(\mathrm{Tr}\, R_\theta^2 + \frac{1}{\sin^2\theta}\mathrm{Tr}\, R_\varphi^2\right)\right]R_d, \quad (39)$$

$$B_d = \mathrm{Tr}(R_d R_r)R_r + \frac{1}{r^2}\left[\mathrm{Tr}(R_d R_\theta)R_\theta + \frac{1}{\sin^2\theta}\mathrm{Tr}(R_d R_\varphi)R_\varphi\right], \quad (40)$$

and $d = r,\theta,\varphi$. Next we note that with U given by the ansatz (19),

$$R_r = -i\sum_{k=0}^{N-2}\dot{g}_k\left(\frac{1}{N} - P_k\right), \quad (41)$$

where $\dot{g}_k = dg_k/dr$. To proceed further we introduce the holomorphic variables ξ and $\bar{\xi}$ and find that

$$R_\xi = \exp\left(-i\sum_{k=0}^{N-2} g_k P_k\right)\left[\exp\left(i\sum_{l=0}^{N-2} g_l P_l\right)\right]_\xi .$$

Using the orthogonality properties of the projectors we rewrite this as

$$R_\xi = \left[1 + \sum_{k=0}^{N-2}(e^{-ig_k} - 1)P_k\right]\left[\sum_{l=0}^{N-2}(e^{ig_l} - 1)P_{l\xi}\right] = \sum_{k=1}^{N-1}[e^{-i(g_k - g_{k-1})} - 1]\frac{V_k V_{k-1}^\dagger}{|V_{k-1}|^2}, \quad (42)$$

where $V_k = P_+^k f$ and where $g_{N-1} = 0$. Moreover, $R_{\bar{\xi}} = -(R_\xi)^\dagger$. Next we note that

$$\partial_\theta = \frac{(1+|\xi|^2)}{2|\xi|}(\xi\partial_\xi + \bar{\xi}\partial_{\bar{\xi}}), \quad (43)$$

$$\partial_\varphi = i(\xi\partial_\xi - \bar{\xi}\partial_{\bar{\xi}}), \quad (44)$$

which allows us to rewrite all the terms in (39) and (40) in terms of R_ξ, $R_{\bar{\xi}}$ and R_r giving

$$r^2(A_r-B_r)=\frac{(1+|\xi|^2)^2}{2}[2\,\mathrm{Tr}(R_\xi R_{\bar\xi})R_r-\mathrm{Tr}(R_rR_\xi)R_{\bar\xi}-\mathrm{Tr}(R_rR_{\bar\xi})R_\xi], \tag{45}$$

and

$$\begin{aligned}&\sin\theta(A_\theta-B_\theta)+i(A_\varphi-B_\varphi)\\&\quad=2\bar\xi\left[(\mathrm{Tr}\,R_r^2)R_{\bar\xi}-\mathrm{Tr}(R_{\bar\xi}R_r)R_r-\frac{(1+|\xi|^2)^2}{2r^2}\{\mathrm{Tr}(R_\xi^2)R_\xi-\mathrm{Tr}(R_\xi R_{\bar\xi})R_{\bar\xi}\}\right].\end{aligned} \tag{46}$$

Reexpressing all the derivatives involving ∂_θ and ∂_φ in terms of ∂_ξ and $\partial_{\bar\xi}$ using (43) and (44) we find that the equations (38) become

$$\begin{aligned}&\partial_r(r^2R_r)+\frac{(1+|\xi|^2)^2}{2}(\partial_\xi R_{\bar\xi}+\partial_{\bar\xi}R_\xi)-\frac{(1+|\xi|^2)^2}{4}\partial_r[\{\mathrm{Tr}(R_\xi R_{\bar\xi})R_r-\mathrm{Tr}(R_rR_\xi)R_{\bar\xi}\}+(\xi\leftrightarrow\bar\xi)]\\&\quad-\frac{(1+|\xi|^2)^2}{4}[\partial_\xi\{\mathrm{Tr}(R_r^2)R_{\bar\xi}-\mathrm{Tr}(R_{\bar\xi}R_r)R_r\}+(\xi\leftrightarrow\bar\xi)]+\frac{(1+|\xi|^2)^2}{4r^2}\\&\quad\times\left[\partial_\xi\left\{\frac{(1+|\xi|^2)^2}{2}(\mathrm{Tr}(R_\xi^2)R_\xi-\mathrm{Tr}(R_\xi R_{\bar\xi})R_\xi\right\}+(\xi\leftrightarrow\bar\xi)\right]=0.\end{aligned} \tag{47}$$

Next we calculate the traces. From the expressions for R_r as given by (41) we find that

$$\mathrm{Tr}(R_r^2)=\frac{1}{N}\left(\sum_{i=0}^{N-2}\dot g_i\right)^2-\sum_{i=0}^{N-2}\dot g_i^2\,. \tag{48}$$

On the other hand, from (42) we find that

$$\mathrm{Tr}(R_\xi R_{\bar\xi})=-2\sum_{i=1}^{N-1}(1-\cos(g_{i-1}-g_i))\frac{|V_i|^2}{|V_{i-1}|^2}. \tag{49}$$

For the other traces the orthogonality of the vectors V makes them vanish, i.e.,

$$\mathrm{Tr}(R_rR_\xi)=\mathrm{Tr}(R_\xi^2)=\mathrm{Tr}(R_{\bar\xi}^2)=0. \tag{50}$$

Using these results and the fact that $\mathrm{Tr}(R_r^2)$ is independent of $(\xi,\bar\xi)$ we see that (47) reduces to

$$\begin{aligned}&\partial_r\left[\left(r^2-\frac{1}{2}Q\right)R_r\right]+\frac{(1+|\xi|^2)^2}{2}\left[(\partial_\xi R_{\bar\xi}+\partial_{\bar\xi}R_\xi)\left\{1-\frac{1}{2}\mathrm{Tr}(R_r^2)\right\}\right.\\&\qquad\left.-\frac{1}{4r^2}\{\partial_\xi(QR_{\bar\xi})+\partial_{\bar\xi}(QR_\xi)\}\right]=0,\end{aligned} \tag{51}$$

where

$$Q=Q(r,\xi,\bar\xi)=(1+|\xi|^2)^2\,\mathrm{Tr}(R_\xi R_{\bar\xi}). \tag{52}$$

Next we note that

$$\partial_r(r^2R_r)=2rR_r+r^2R_{rr}=-i\sum_{k=0}^{N-2}\left(\frac{1}{N}-P_k\right)(2r\dot g_k+r^2\ddot g_k), \tag{53}$$

and that

$$\partial_{\xi} R_{\bar{\xi}} + \partial_{\bar{\xi}} R_{\xi} = \sum_{k=1}^{N-1} h_k \frac{|V_k|^2}{|V_{k-1}|^2} (P_k - P_{k-1}), \tag{54}$$

where h_k are only functions of g_l.

For our choice of vectors V corresponding to the map (18), we find that $|V_k|^2/|V_{k-1}|^2$ is proportional to $1/(1+|\xi|^2)^2$ and so all the dependence on ξ and $\bar{\xi}$ in (51) resides only in the projectors. The terms involving $\partial_r(r^2 R_r)$ give us expressions involving $1/N - P_k$ while all other terms give us expressions involving $P_k - P_{k-1}$. It is easy to check that all N projectors arise in our expressions but we can always reexpress P_{N-1} in terms of the previous ones so we end up with $N-1$ factors involving $P_k - 1/N$ (for $k=0,\ldots,N-2$). To satisfy our equations (51) the coefficients of such factors have to vanish. This requirement gives us $N-1$ equations for $N-1$ functions g_i. Hence, if these equations have solutions, we have solutions of the equations of the alternative $SU(N)$ Skyrme models.

To find the $N-1$ equations for g_i we can either look in detail at all our terms in (51) or put our expression into (1) with (4)→(5), integrate out ξ and $\bar{\xi}$ variables and derive the equations for the profile functions $g_i(r)$. The two methods give the same equations. In the next section we use the second one as we want to determine the energies of our solutions. The first method is described in the Appendix.

Note that, like for the usual Skyrme models, the whole procedure hinges on having $N-1$ profile functions and on the very special form of our vectors V. Had we taken other vectors f, and so V, we would have not gotten all the ξ and $\bar{\xi}$ dependence residing only in the projectors and had we taken less than $N-1$ profile functions and projectors we would have gotten too many equations for our functions. It is only in the case of $N-1$ projectors that we get the right number of equations and our equations of motion (PDE's) reduce to a system of ODE's.

V. EQUATIONS FOR THE PROFILE FUNCTIONS

To derive the equation for our profile functions g_i we rewrite our energy function [(1) with (4)→(5)] in terms of r, ξ and $\bar{\xi}$. We find

$$E = -\frac{i}{12\pi^2} \int \frac{d\xi\, d\bar{\xi}}{(1+|\xi|^2)^2} r^2\, dr \left[\mathrm{Tr}(R_r^2) + \frac{1}{r^2} Q \left(1 - \frac{1}{2} \mathrm{Tr}(R_r^2) - \frac{1}{8r^2} Q \right) \right], \tag{55}$$

where Q is given by (52).

Next, we use the fact that

$$\frac{|V_k|^2}{|V_{k-1}|^2} = \frac{k(N-k)}{(1+|\xi|^2)^2}, \tag{56}$$

and find that $\mathrm{Tr}|R_{\xi}|^2$ has a factor $1/(1+|\xi|^2)^2$ showing us that the function Q is independent of ξ and $\bar{\xi}$. Thus as

$$i \int d\xi\, d\bar{\xi} \frac{1}{(1+|\xi|^2)^2} = 2\pi, \tag{57}$$

we find that the ξ and $\bar{\xi}$ integration gives us

$$E=\frac{1}{6\pi}\int r^2 dr\left[\left(-\frac{1}{N}\left(\sum_{i=0}^{N-2}\dot{g}_i\right)^2+\sum_{i=0}^{N-2}\dot{g}_i^2\right)\left(1+\frac{1}{r^2}\sum_{k=1}^{N-1}D_k\right)\right.$$
$$\left.+\frac{2}{r^2}\sum_{i=1}^{N-1}D_i\left(1+\frac{1}{4r^2}\sum_{k=1}^{N-1}D_k\right)\right], \tag{58}$$

where $D_k=k(N-k)(1-\cos(g_{k-1}-g_k))$.

Next we observe that, apart from the first two terms above, all the dependence on the profile functions g_k comes via their combinations g_k-g_{k-1}. To exploit this observation we change variables and introduce F_k defined by

$$F_k=g_k-g_{k+1}\quad (k=0,\ldots,N-2), \tag{59}$$

where, of course, $F_{N-2}=g_{N-2}$. Next we note that

$$\frac{\partial\mathcal{E}}{\partial\dot{F}_l}=\left[-\frac{2(l+1)}{N}\sum_{i=0}^{N-2}(i+1)\dot{F}_i+2\sum_{i=0}^{l}\left(\sum_{j=i}^{N-2}\dot{F}_j\right)\right]\left[r^2+\sum_{k=1}^{N-1}D_k\right], \tag{60}$$

where $\mathcal{E}$ denotes the integrand of E and $D_k=k(N-k)(1-\cos F_{k-1})$.

We can now determine our equations for the functions F_i and so also for g_i. They are

$$\left[-\frac{l+1}{N}\sum_{i=0}^{N-2}(i+1)\ddot{F}_i+\sum_{i=0}^{l}\sum_{j=i}^{N-2}\ddot{F}_j\right]A_{N2}+\frac{2}{r}\left[-\frac{l+1}{N}\sum_{i=0}^{N-2}(i+1)\dot{F}_i+\sum_{i=0}^{l}\sum_{j=i}^{N-2}\dot{F}_j\right]A_{N1}$$
$$-\frac{1}{r^2}[(l+1)(N-l-1)\sin F_l]A_{N0}=0, \tag{61}$$

where

$$A_{N2}=1+\frac{1}{r^2}\sum_{k=1}^{N-1}D_k,$$
$$A_{N1}=1+\frac{1}{2r}\sum_{k=1}^{N-1}\dot{D}_k, \tag{62}$$
$$A_{N0}=-\frac{1}{2N}\left(\sum_{i=0}^{N-2}(i+1)\dot{F}_i\right)^2+\frac{1}{2}\sum_{i=0}^{N-2}\left(\sum_{j=i}^{N-2}\dot{F}_j\right)^2+1+\frac{1}{2r^2}\sum_{k=1}^{N-1}D_k,$$

and where $\dot{D}_k=k(N-k)\dot{F}_{k-1}\sin(F_{k-1})$.

Note that the equations (61) have to be solved numerically. To do this we have to consider each N and diagonalize the terms involving second derivatives. In the next two sections, to compare the obtained results with the results discussed in Ref. 10, we look in detail at the simplest cases of $N=3$, 4 and 5, which involve 2, 3 or 4 functions.

VI. GENERAL TOPOLOGICAL PROPERTIES AND SYMMETRIES

Let us first note that the topological properties of our solutions are controlled by the values of F_i at 0.

To see this we rewrite the topological charge B, (3) in our variables. We get

$$B=\frac{1}{8\pi^2}\int dr\,d\xi\,d\bar{\xi}\,\mathrm{Tr}(R_r[R_\xi,R_{\bar{\xi}}]). \tag{63}$$

Using the expression for R_ξ in (42), we find that the commutator $[R_\xi, R_{\bar{\xi}}]$ is given by

$$[R_\xi,\ R_{\bar{\xi}}]=2\sum_{k=1}^{N-1}(P_{k-1}-P_k)C_k, \tag{64}$$

where $C_k=(1-\cos F_{k-1})(|V_k|^2/|V_{k-1}|^2)$.

Then, using this result and R_r as given in (41) we find that, when we take the trace, the terms involving $\dot{g}_k/N$ in R_r cancel and we are left with

$$\begin{aligned} B&=-\frac{i}{4\pi^2}\int dr\,d\xi\,d\bar{\xi}\sum_{k=0}^{N-2}\dot{F}_k(1-\cos F_k)\frac{|V_{k+1}|^2}{|V_k|^2}\\ &=\frac{1}{2\pi}\int dr\sum_{k=0}^{N-2}\dot{F}_k(1-\cos F_k)(k+1)(k+1-N)\\ &=\frac{1}{2\pi}\sum_{k=0}^{N-2}(k+1)(k+1-N)[F_k-\sin F_k]_{r=0}^{r=\infty}. \end{aligned} \tag{65}$$

As $g_k(\infty)=0$ we see that the only contributions to the topological charge come from $F_k(0)$.

Our $N-1$ equations (61) for functions F_k, $k=0,\ldots,N-2$ and so g_i have many symmetries. These symmetries allow us to find special solutions which involve only a smaller number of functions. So, before looking at special cases, let us mention some of these symmetries.

The main symmetry, which is relatively easy to spot is the symmetry under the independent interchanges,

$$F_0\leftrightarrow F_{N-2},\quad F_1\leftrightarrow F_{N-3},\quad F_k\leftrightarrow F_{N-k-2},\quad \ldots. \tag{66}$$

To see this symmetry we look at the expression for the energy and note that as

$$D_k=k(N-k)(1-\cos F_{k-1}),$$

D_k have this symmetry; i.e., $D_k\leftrightarrow D_{N-k}$, when $F_{k-1}\leftrightarrow F_{N-k-1}$.

This symmetry is evident in all terms involving D_k's and so we are left with having to look at the terms involving $\dot{F}_k$'s.

However, clearly the terms involving $\dot{F}_k^2 D_{k+1}$ have this symmetry as they come in the combination

$$\sum_{k=0}^{N-2}\dot{F}_k^2 D_{k+1}=\sum_{k=0}^{N-2}\dot{F}_k^2(k+1)(N-k-1)(1-\cos F_k). \tag{67}$$

Next we rewrite the remaining terms as

$$-\frac{1}{N}\left(\sum_{i=0}^{N-2}\dot{g}_i\right)^2+\sum_{i=0}^{N-2}\dot{g}_i^2=-\frac{1}{N}\left(\sum_{i=0}^{N-2}(i+1)\dot{F}_i\right)^2+\sum_{i=0}^{N-2}\left(\sum_{j=i}^{N-2}\dot{F}_j\right)^2 \tag{68}$$

and note that the coefficient of $\dot{F}_i^2$ is given by

$$-\frac{1}{N}(i+1)^2+(i+1)=(i+1)\frac{(N-i-1)}{N}, \tag{69}$$

which is also the coefficient of $\dot{F}_{N-i-2}^2$. Moreover, as the coefficient of $\dot{F}_i\dot{F}_j$ (when $i>j$) is

$$2i-\frac{2}{N}(i+1)(j+1), \tag{70}$$

which is also the coefficient of $\dot{F}_{N-i-2}\dot{F}_{N-j-2}$ we see that we have demonstrated the validity of our symmetry.

VII. SPECIAL CASES

Now we look at the cases of low N.

A. *SU*(3)

In the $SU(3)$ case we have two functions: F_0 and F_1. The radial energy density $\mathcal{E}$ is given by

$$\mathcal{E}=\frac{2}{3}(\dot{F}_0^2+\dot{F}_1^2+\dot{F}_0\dot{F}_1)[r^2+2(1-\cos F_0)+2(1-\cos F_1)]+4[(1-\cos F_0)+(1-\cos F_1)]$$
$$\times\left[1+\frac{1}{2r^2}(1-\cos F_0)+\frac{1}{2r^2}(1-\cos F_1)\right]. \tag{71}$$

The equations for F_0 and F_1 are

$$\begin{aligned}(2\ddot{F}_0+\ddot{F}_1)A_{32}+\frac{2}{r}(2\dot{F}_0+\dot{F}_1)A_{31}-\frac{6}{r^2}(\sin F_0)A_{30}=0,\\ (\ddot{F}_0+2\ddot{F}_1)A_{32}+\frac{2}{r}(\dot{F}_0+2\dot{F}_1)A_{31}-\frac{6}{r^2}(\sin F_1)A_{30}=0,\end{aligned} \tag{72}$$

where

$$\begin{aligned}A_{32}&=1+\frac{2}{r^2}(1-\cos F_0)+\frac{2}{r^2}(1-\cos F_1),\\ A_{31}&=1+\frac{1}{r}\dot{F}_0\sin F_0+\frac{1}{r}\dot{F}_1\sin F_1,\\ A_{30}&=\frac{1}{3}(\dot{F}_0^2+\dot{F}_1^2+\dot{F}_0\dot{F}_1)+1+\frac{1}{r^2}(1-\cos F_0)+\frac{1}{r^2}(1-\cos F_1).\end{aligned} \tag{73}$$

The equations (72) can be solved for the two functions F_0 and F_1. Clearly, we cannot put either of them to zero but, due to the symmetry, we can take $F_0=F_1=F$ in which case both equations reduce to

$$\ddot{F}\left[1+\frac{4}{r^2}(1-\cos F)\right]+\frac{2}{r}\dot{F}+\frac{2}{r^2}\sin F\left[\dot{F}^2-1-\frac{2}{r^2}(1-\cos F)\right]=0. \tag{74}$$

This equation coincides with the equation of the usual $SU(2)$ Skyrme model after rescaling the coordinate $r=2\tilde{r}$. Performing this coordinate rescaling in the corresponding energy integral, we find that its energy is $E=8\times 1.232$, i.e., is exactly 8 times the energy of one $SU(2)$ skyrmion [taking $F(0)=2\pi$]. This agrees with our numerical result 9.85242 obtained from (74) [within our numerical accuracy the energy of one $SU(2)$ skyrmion is 1.23146]. The topological charge of this configuration is clearly $B=4$, so energy per baryon is 2 times the energy of one $SU(2)$ skyrmion.

In addition, there is a further symmetry; we can put $F_0=-F_1=G$. In this case both equations reduce to

$$\ddot{G}\left[1+\frac{4}{r^2}(1-\cos G)\right]+\frac{2}{r}\dot{G}+\frac{2}{r^2}\sin G\left[\dot{G}^2-3-\frac{6}{r^2}(1-\cos G)\right]=0. \tag{75}$$

This case, as $F_0=g_0-g_1$ and $F_1=g_1$, corresponds to the case of $g_0=0$ and so our solution involves only one projector, namely P_1. Its topological charge is $B=2-2=0$ and its energy is 5.11338. A similar solution was discussed, in the usual Skyrme model case, in Ref. 9 (there its energy is 3.861).

In general, however, our solutions depend on two functions F_0 and F_1. For example, by imposing the boundary conditions: $F_0(0)=2\pi, F_0(\infty)=0$ and $F_1(0)=0, F_1(\infty)=0$ in (72) we found that the energy of this solution is $E=2.61503$ and its baryon number is $B=2$. (In the usual Skyrme model, a similar solution has energy 2.3764.)

B. *SU*(4)

In this case we have three functions F_0, F_1 and F_2. The energy density becomes

$$\begin{aligned}\mathcal{E}=&\tfrac{1}{4}[3\dot{F}_0^2+4\dot{F}_1^2+3\dot{F}_2^2+4\dot{F}_0\dot{F}_1+2\dot{F}_0\dot{F}_2+4\dot{F}_1\dot{F}_2][r^2+3(1-\cos F_0)+4(1-\cos F_1)\\&+3(1-\cos F_2)]+2[3(1-\cos F_0)+4(1-\cos F_1)+3(1-\cos F_2)]\\&\times\left[1+\frac{3}{4r^2}(1-\cos F_0)+\frac{1}{r^2}(1-\cos F_1)+\frac{3}{4r^2}(1-\cos F_2)\right].\end{aligned} \tag{76}$$

The equations for F_0, F_1 and F_2 are very complicated. They read as

$$\begin{aligned}&(3\ddot{F}_0+2\ddot{F}_1+\ddot{F}_2)A_{42}+\frac{2}{r}(3\dot{F}_0+2\dot{F}_1+\dot{F}_2)A_{41}-\frac{12}{r^2}(\sin F_0)A_{40}=0,\\&(\ddot{F}_0+2\ddot{F}_1+\ddot{F}_2)A_{42}+\frac{2}{r}(\dot{F}_0+2\dot{F}_1+\dot{F}_2)A_{41}-\frac{8}{r^2}(\sin F_1)A_{40}=0,\\&(\ddot{F}_0+2\ddot{F}_1+3\ddot{F}_2)A_{42}+\frac{2}{r}(\dot{F}_0+2\dot{F}_1+3\dot{F}_2)A_{41}-\frac{12}{r^2}(\sin F_2)A_{40}=0,\end{aligned} \tag{77}$$

where

$$\begin{aligned}A_{42}=&1+\frac{3}{r^2}(1-\cos F_0)+\frac{4}{r^2}(1-\cos F_1)+\frac{3}{r^2}(1-\cos F_2),\\A_{41}=&1+\frac{3}{2r}\dot{F}_0\sin F_0+\frac{2}{r}\dot{F}_1\sin F_1+\frac{3}{2r}\dot{F}_2\sin F_2,\\A_{40}=&\frac{3}{8}\left(\dot{F}_0^2+\frac{4}{3}\dot{F}_1^2+\dot{F}_2^2+\frac{4}{3}\dot{F}_0\dot{F}_1+\frac{2}{3}\dot{F}_0\dot{F}_2+\frac{4}{3}\dot{F}_1\dot{F}_2\right)\\&+1+\frac{3}{2r^2}(1-\cos F_0)+\frac{2}{r^2}(1-\cos F_1)+\frac{3}{2r^2}(1-\cos F_2).\end{aligned} \tag{78}$$

These equations have the previously mentioned symmetry $F_0\leftrightarrow F_2$ which allows us to set $F_0=F_2=F$ while keeping F_1 arbitrary. In this case the above equations reduce to the following two coupled equations:

$$(2\ddot{F}+\ddot{F}_1)\tilde{A}_{42}+\frac{2}{r}(2\dot{F}+\dot{F}_1)\tilde{A}_{41}-\frac{6}{r^2}(\sin F)\tilde{A}_{40}=0,$$
$$(\ddot{F}+\ddot{F}_1)\tilde{A}_{42}+\frac{2}{r}(\dot{F}+\dot{F}_1)\tilde{A}_{41}-\frac{4}{r^2}(\sin F_1)\tilde{A}_{40}=0, \tag{79}$$

where

$$\tilde{A}_{42}=1+\frac{6}{r^2}(1-\cos F)+\frac{4}{r^2}(1-\cos F_1),$$
$$\tilde{A}_{41}=1+\frac{3}{r}\dot{F}\sin F+\frac{2}{r}\dot{F}_1\sin F_1, \tag{80}$$
$$\tilde{A}_{40}=\left(\dot{F}^2+\frac{1}{2}\dot{F}_1^2+\dot{F}\dot{F}_1\right)+1+\frac{3}{r^2}(1-\cos F)+\frac{2}{r^2}(1-\cos F_1).$$

By imposing $F(0)=2\pi, F(\infty)=0$ and $F_1(0)=0, F_1(\infty)=0$ the corresponding solution is found to have energy 13.2006 and its baryon number is 6.

If we further set $F_1=F=G$ then the above coupled equations reduce to

$$\ddot{G}\left[1+\frac{10}{r^2}(1-\cos G)\right]+\frac{2}{r}\dot{G}+\frac{1}{r^2}\sin G\left[5\dot{G}^2-2-\frac{10}{r^2}(1-\cos G)\right]=0. \tag{81}$$

This equation coincides with the usual $SU(2)$ Skyrme model equation, after rescaling the coordinate $r=\sqrt{10}\tilde{r}$. Performing this coordinate rescaling in the corresponding energy integral we find that this configuration has energy $E=10\sqrt{10}\times 1.232$. Our numerical result for the energy obtained from (81) is 38.9551 which is in good agreement with the above exact result. Note that the topological charge of this solution is 10, so energy per baryon is $\sqrt{10}$ times the energy of one $SU(2)$ skyrmion.

Another solution can be found by setting $F_0=-F_2=Z$. Then the equations have a solution if $F_1=0$. This case corresponds to $g_0=0$ and $g_1=g_2$ and so, effectively, the field configuration is described by a one projector of rank two; namely, P_1+P_2. The corresponding equation for Z is

$$\ddot{Z}\left[1+\frac{6}{r^2}(1-\cos Z)\right]+\frac{2}{r}\dot{Z}+\frac{3}{r^2}\sin Z\left[\dot{Z}^2-2-\frac{6}{r^2}(1-\cos Z)\right]=0. \tag{82}$$

This solution has energy 9.39388 and its charge is $B=3-3=0$.

When we use all 3 functions we get results which depend on $F_i(0)$. In the following table we present our results for E_a and compare them with the similar results for E_u derived in the usual Skyrme models.[10]

$F_0(0)$	$F_1(0)$	$F_2(0)$	B	E_a	E_u
2π	0	0	3	3.96601	3.518
0	2π	0	4	5.87187	4.788
2π	0	2π	6	13.2006	7.22553
2π	2π	0	7	18.9833	8.45219
2π	2π	2π	10	38.9551	12.32
2π	-2π	2π	6–4	14.3419	8.852
2π	2π	-2π	7–3	20.5668	9.896
2π	0	-2π	3–3	9.39388	6.63422
-2π	2π	0	4–3	9.07753	6.61478

We see that our energies are higher (especially for larger values of B).

C. *SU*(5)

This time we have four functions F_0, F_1, F_2 and F_3. The energy density becomes

$$\begin{aligned}\mathcal{E}=&\tfrac{2}{5}[2\dot{F}_0^2+3\dot{F}_1^2+3\dot{F}_2^2+2\dot{F}_3^2+3\dot{F}_0\dot{F}_1+2\dot{F}_0\dot{F}_2+\dot{F}_0\dot{F}_3+4\dot{F}_1\dot{F}_2+2\dot{F}_1\dot{F}_3+3\dot{F}_2\dot{F}_3]\\&\times[r^2+2\{2(1-\cos F_0)+3(1-\cos F_1)+3(1-\cos F_2)+2(1-\cos F_3)\}]\\&+4[2(1-\cos F_0)+3(1-\cos F_1)+3(1-\cos F_2)+2(1-\cos F_3)]\\&\times\left[1+\frac{1}{2r^2}\{2(1-\cos F_0)+3(1-\cos F_1)+3(1-\cos F_2)+2(1-\cos F_3)\}\right].\end{aligned}\tag{83}$$

The equations for F_0, F_1, F_2 and F_3 are now given by

$$\begin{aligned}&(4\ddot{F}_0+3\ddot{F}_1+2\ddot{F}_2+\ddot{F}_3)A_{52}+\frac{2}{r}(4\dot{F}_0+3\dot{F}_1+2\dot{F}_2+\dot{F}_3)A_{51}-\frac{20}{r^2}(\sin F_0)A_{50}=0,\\&(3\ddot{F}_0+6\ddot{F}_1+4\ddot{F}_2+2\ddot{F}_3)A_{52}+\frac{2}{r}(3\dot{F}_0+6\dot{F}_1+4\dot{F}_2+2\dot{F}_3)A_{51}-\frac{30}{r^2}(\sin F_1)A_{50}=0,\\&(2\ddot{F}_0+4\ddot{F}_1+6\ddot{F}_2+3\ddot{F}_3)A_{52}+\frac{2}{r}(2\dot{F}_0+4\dot{F}_1+6\dot{F}_2+3\dot{F}_3)A_{51}-\frac{30}{r^2}(\sin F_2)A_{50}=0,\\&(\ddot{F}_0+2\ddot{F}_1+3\ddot{F}_2+4\ddot{F}_3)A_{52}+\frac{2}{r}(\dot{F}_0+2\dot{F}_1+3\dot{F}_2+4\dot{F}_3)A_{51}-\frac{20}{r^2}(\sin F_3)A_{50}=0,\end{aligned}\tag{84}$$

where

$$\begin{aligned}A_{52}=&1+\frac{2}{r^2}[2(1-\cos F_0)+3(1-\cos F_1)+3(1-\cos F_2)+2(1-\cos F_3)],\\A_{51}=&1+\frac{1}{r}[2\dot{F}_0\sin F_0+3\dot{F}_1\sin F_1+3\dot{F}_2\sin F_2+2\dot{F}_3\sin F_3],\\A_{50}=&\frac{1}{5}[2\dot{F}_0^2+3\dot{F}_1^2+3\dot{F}_2^2+2\dot{F}_3^2+3\dot{F}_0\dot{F}_1+2\dot{F}_0\dot{F}_2+\dot{F}_0\dot{F}_3+4\dot{F}_1\dot{F}_2+2\dot{F}_1\dot{F}_3+3\dot{F}_2\dot{F}_3]\\&+1+\frac{1}{r^2}[2(1-\cos F_0)+3(1-\cos F_1)+3(1-\cos F_2)+2(1-\cos F_3)].\end{aligned}\tag{85}$$

It is easy to spot, as we have mentioned before, that these expressions have symmetries $F_0\leftrightarrow F_3$ and, independently, $F_1\leftrightarrow F_2$.

So we can seek solutions involving only two functions $F_0=F_3=F$ and $F_1=F_2=G$. If we impose this condition our equations reduce to the following two coupled equations:

$$\begin{aligned}&(\ddot{F}+\ddot{G})\tilde{A}_{52}+\frac{2}{r}(\dot{F}+\dot{G})\tilde{A}_{51}-\frac{4}{r^2}(\sin F)\tilde{A}_{50}=0,\\&(\ddot{F}+2\ddot{G})\tilde{A}_{52}+\frac{2}{r}(\dot{F}+2\dot{G})\tilde{A}_{51}-\frac{6}{r^2}(\sin G)\tilde{A}_{50}=0,\end{aligned}\tag{86}$$

where

$$\tilde{A}_{52}=1+\frac{4}{r^2}[2(1-\cos F)+3(1-\cos G)],$$

$$\tilde{A}_{51}=1+\frac{2}{r}[2\dot{F}\sin F+3\dot{G}\sin G], \tag{87}$$

$$\tilde{A}_{50}=[\dot{F}^2+2\dot{G}^2+2\dot{F}\dot{G}]+1+\frac{2}{r^2}[2(1-\cos F)+3(1-\cos G)].$$

By imposing $F(0)=0,F(\infty)=0$ and $G(0)=2\pi,G(\infty)=0$, the corresponding solution is found to have energy 37.3436 and its baryon number is 12. We observe that the equations (86) coincide with the equations (79) in the $SU(4)$ case, after rescaling the coordinate $r=\sqrt{2}\tilde{r}$. Performing this coordinate rescaling in the corresponding energy integral of (86), we find that its energy is $2\sqrt{2}$ times the energy of (79) which agrees with our numerical results above.

Note that if in addition, we further let $G=F$ then the above coupled equations reduce to

$$\ddot{F}\left[1+\frac{20}{r^2}(1-\cos F)\right]+\frac{2}{r}\dot{F}+\frac{2}{r^2}\sin F\left[5\dot{F}^2-1-\frac{10}{r^2}(1-\cos F)\right]=0. \tag{88}$$

This equation, again, coincides with the usual $SU(2)$ Skyrme model equation after rescaling the coordinate $r=\sqrt{20}\tilde{r}$ and from the corresponding energy integral we find that its energy is $E=20\sqrt{20}\times 1.232$. Our numerical result for the energy obtained from (88) is 110.251 which is also in good agreement with the above exact result. As its topological charge is 20 we see that the energy per baryon of this solution is $\sqrt{20}$ times the energy of one $SU(2)$ skyrmion.

There is still a further symmetry, which we could exploit, and which allows us to put $F_0=-F_3=Y$ and $F_1=-F_2=Z$. The corresponding equations for Y and Z are

$$\begin{aligned}(3\ddot{Y}+\ddot{Z})\tilde{A}_{52}+\frac{2}{r}(3\dot{Y}+\dot{Z})\tilde{A}_{51}-\frac{20}{r^2}(\sin Y)\tilde{A}_{50}=0,\\ (\ddot{Y}+2\ddot{Z})\tilde{A}_{52}+\frac{2}{r}(\dot{Y}+2\dot{Z})\tilde{A}_{51}-\frac{30}{r^2}(\sin Z)\tilde{A}_{50}=0,\end{aligned} \tag{89}$$

where

$$\tilde{A}_{52}=1+\frac{4}{r^2}[2(1-\cos Y)+3(1-\cos Z)],$$

$$\tilde{A}_{51}=1+\frac{2}{r}[2\dot{Y}\sin Y+3\dot{Z}\sin Z], \tag{90}$$

$$\tilde{A}_{50}=\frac{1}{5}[3\dot{Y}^2+2\dot{Z}^2+2\dot{Y}\dot{Z}]+1+\frac{2}{r^2}[2(1-\cos Y)+3(1-\cos Z)].$$

This case corresponds to $g_0=0$ and $g_1=g_3$ and so the corresponding field configurations are described by two projectors—namely P_2 and P_1+P_3. By imposing $Y(0)=2\pi,Y(\infty)=0$ and $Z(0)=0,Z(\infty)=0$, we found that this configuration has energy 13.4618. Its charge is $B=4-4=0$.

More general solutions, however, depend on all four functions.

Finally, let us note that for $SU(N)$ with $N>2$, when all profile functions F_i are the same, i.e., $F_0=F_1=\cdots=F_{N-2}=F$ the equations (61) reduce to the single equation

$$\ddot{F}\left[1+\frac{\tilde{B}}{r^2}(1-\cos F)\right]+\frac{2}{r}\dot{F}+\frac{2}{r^2}\sin F\left[\frac{\tilde{B}}{4}\dot{F}^2-1-\frac{\tilde{B}}{2r^2}(1-\cos F)\right]=0, \tag{91}$$

and the corresponding energy integral (58) reduces to

$$E=\frac{1}{6\pi}\int r^2\,dr\left[\frac{\tilde{B}}{2}\dot{F}^2\left(1+\frac{\tilde{B}}{r^2}(1-\cos F)\right)+2\frac{\tilde{B}}{r^2}(1-\cos F)+\frac{\tilde{B}^2}{2r^4}(1-\cos F)^2\right], \tag{92}$$

where

$$\tilde{B}=\frac{(N-1)N(N+1)}{6}, \tag{93}$$

and $\tilde{B}$ is the baryon number of our configuration.

We observe that by rescaling the radial coordinate r to

$$r=\tilde{r}\sqrt{\tilde{B}}, \tag{94}$$

the equation (91) reduces to the usual $SU(2)$ Skyrme model equation (in the coordinate $\tilde{r}$) and the energy integral (92) becomes

$$E=\tilde{B}\sqrt{\tilde{B}}\,E_{SU(2)}, \tag{95}$$

where $E_{SU(2)}$ is the energy integral of the usual $SU(2)$ Skyrme model (in the coordinate $\tilde{r}$). Thus this configuration has energy $E=\tilde{B}\sqrt{\tilde{B}}\times 1.232$ [taking $F(0)=2\pi$], which agrees with our results for the cases: $N=3$, 4 and 5 above. As the baryon number of this configuration is $\tilde{B}$, the energy per baryon is $\sqrt{\tilde{B}}$ times the energy of one $SU(2)$ skyrmion.

VIII. CONCLUSIONS

In this paper we have discussed the alternative $SU(N)$ Skyrme models. We have shown that for $N=2$ they reduce to the usual Skyrme models but for $N\neq 2$ they are different.

We have also shown that to study these models we can use the rational map ansatz[8] in the form of its generalization to the usual Skyrme models.[9]

Like for the usual Skyrme models when we use only one projector we find field configurations which have low energies and which we hope are close to the true solutions of this model. We have also found that, as in the case of usual Skyrme models, the use of $N-1$ projectors constructed from the Veronese sequence of vectors gives us radially symmetric solutions of the alternative models. These solutions are characterized by the appropriate profile functions, which have to be determined numerically. In some cases we can exploit symmetries of the energy densities and reduce the number of functions.

Thus, almost everything works exactly like for the usual Skyrme models; only the equations for the profile functions are a little modified. When we have solved the equations for the profile functions we have found that the solutions of the alternative models have energies higher than the corresponding solutions of the usual models. This can be traced to the extra terms in the expression for the energy density after the integration over the angular variables has been performed which give an additional positive contribution to the total energy.

It is not clear, both for the usual and alternative models, how to generalize the harmonic map ansatz to derive an analytical or quasi-analytical form of the nonradially symmetric solutions.

APPENDIX: DERIVATION OF EQUATIONS (61)

In this appendix, we derive the equations for the profile functions g_k directly from the equations (51). To do this we look in detail at all the terms in these equations.

Using the very special form of our vectors V, we find that

$$\partial_\xi R_{\bar{\xi}} + \partial_{\bar{\xi}} R_\xi = \frac{2i}{(1+|\xi|^2)^2} \sum_{k=1}^{N-1} k(N-k)\sin(g_{k-1}-g_k)(P_k - P_{k-1}), \tag{A1}$$

and

$$Q = (1+|\xi|^2)^2 \,\mathrm{Tr}(R_\xi R_{\bar{\xi}}) = -2\sum_{k=1}^{N-1} D_k, \tag{A2}$$

where $D_k = k(N-k)(1-\cos(g_{k-1}-g_k))$. The term R_r is given in (41), while $\mathrm{Tr}(R_r^2)$ is given in (48).

Using these results we find that (51) reduce to the the following factorized form:

$$\sum_{k=0}^{N-2} \left[\left(P_k - \frac{1}{N} \right) \alpha_k + (P_{k+1} - P_k)\beta_{k+1} \right] = 0, \tag{A3}$$

where

$$\alpha_k = \partial_r [(r^2 - \tfrac{1}{2}Q)\dot{g}_k], \tag{A4}$$

and

$$\beta_k = k(N-k)\sin(g_{k-1}-g_k)\left[1 - \frac{1}{2}\mathrm{Tr}(R_r^2) - \frac{1}{4r^2}Q \right]. \tag{A5}$$

Next we take the inner product of (A3) with the vectors V_m $(m=0,1,\ldots,N-2)$ from the right. Using

$$P_k V_m = \left(\frac{V_k V_k^\dagger}{|V_k|^2} \right) V_m = V_k \delta_{km},$$

where δ_{km} is the Kronecker's delta, and the fact that the vectors V_k are independent, we see that the requirement of the vanishing of the corresponding coefficients leaves us with

$$\left(\alpha_k - \frac{1}{N} \sum_{n=0}^{N-2} \alpha_n \right) + (\beta_k - \beta_{k+1}) = 0. \tag{A6}$$

Finally, using the relation

$$\sum_{k=0}^{l} (\beta_k - \beta_{k+1}) = -\beta_{l+1}, \tag{A7}$$

for $(l=0,1,\ldots,N-2)$, as $\beta_0 = 0$ $(g_{-1}=0)$, and summing (A6) from $k=0$ to l yields

$$\sum_{k=0}^{l} \alpha_k - \frac{(l+1)}{N} \sum_{n=0}^{N-2} \alpha_n - \beta_{l+1} = 0. \tag{A8}$$

Introducing $F_k = g_k - g_{k+1}$ we find that the equations (A8) coincide with the equations for the profile functions that we have derived from the energy integral in Sec. V, i.e., Eqs. (61).

Solutions of the Yang–Mills–Higgs equations in 2+1-dimensional anti-de Sitter space–time

Zixiang Zhou[a)]
Institute of Mathematics, Fudan University, Shanghai 200433, Peoples Republic of China

(Received 5 September 2000; accepted for publication 6 November 2000)

The solutions of the Bogomolny equation in $2+1$-dimensional anti-de Sitter space–time are obtained by using Darboux transformations with both constant spectral parameters and variable ''spectral parameters.'' These solutions give the Yang–Mills–Higgs fields in $2+1$-dimensional anti-de Sitter space–time. Some examples in the SU(2) case are considered and qualitative asymptotic behaviors of the solutions as $t\to\infty$ are discussed in detail. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1337799]

I. INTRODUCTION

The Yang–Mills–Higgs fields satisfying the Bogomolny equations in $\mathbf{R}^3$ and $\mathbf{R}^{2,1}$ were widely investigated and the equations are known to be integrable. On the other hand, the Yang–Mills–Higgs fields satisfying the Bogomolny equations in some curved spaces such as the hyperbolic space H^3, the $2+1$-dimensional anti-de Sitter space–time are also integrable.[1–3] In the present paper, we consider the solutions of the Bogomolny equation in the $2+1$-dimensional anti-de Sitter space–time, the Lax pair of which has been known and the soliton solutions (with constant spectral parameters) were also obtained.[3]

With the Darboux transformation method, we obtain exact multisoliton solutions. Moreover, the ''spectral parameters'' in the construction of Darboux transformation can depend on the space–time variables as in some other problems with dimensions $\geqslant 3$, like the self-dual Yang–Mills equation, modified principal chiral field, the Bolgomolny equation in $\mathbf{R}^3$, etc.[4–8] These kinds of equations are also called breaking soliton equations, since the spectral parameter may not be constant and satisfies an equation whose solution can blow up at finite time.[9,10]

In Secs. II and III the Darboux transformations for $\mathrm{GL}(N,\mathbf{C})$ and $\mathrm{U}(N)$ cases are discussed. As a special case, the general construction of soliton solutions is given in Sec. IV. Then, in Sec. V, some examples of single solitons and multisolitons are considered, with both constant spectral parameters and variable ''spectral parameters.'' Their qualitative asymptotic behavior as $t\to\infty$ is discussed in detail. When the spectral parameters are constants, we find solutions globally defined on the whole $2+1$-dimensional anti-de Sitter space–time. When the ''spectral parameters'' are not constants, the solutions derived here are only locally defined in $2+1$-dimensional anti-de Sitter space–time.

Our problem is as follows.

Let M be a three-dimensional Lorentz manifold with metric g. A_μ is a gauge potential and Φ is a (scalar) Higgs field, both of which are valued in the Lie algebra of a Lie group G. Hereafter, we always suppose G is a matrix Lie group and the matrices in G are of order N.

The $2+1$-dimensional anti-de Sitter space–time is the universal covering space of the hyperboloid

$$U^2+V^2-X^2-Y^2=1 \tag{1.1}$$

in $\mathbf{R}^{2,2}$ with the metric

a)Electronic mail: zxzhou@guomai.sh.cn

$$ds^2 = -dU^2 - dV^2 + dX^2 + dY^2. \tag{1.2}$$

Define

$$r = \frac{1}{U+X}, \quad x = \frac{Y}{U+X}, \quad t = -\frac{V}{U+X}, \tag{1.3}$$

then a part of the $2+1$-dimensional anti-de Sitter space–time with $U+X>0$ is represented by the Poincaré coordinates (r,x,t) with $r>0$ and the metric is

$$ds^2 = r^{-2}(-dt^2 + dr^2 + dx^2) = r^{-2}(dr^2 + du\, dv), \tag{1.4}$$

where $u=x+t$, $v=x-t$.

The Yang–Mills–Higgs field in $2+1$-dimensional anti-de Sitter space–time satisfies the Bogomolny equation[1,11]

$$D\Phi = *F, \tag{1.5}$$

or, written in terms of the components,

$$D_\mu \Phi = \frac{1}{2\sqrt{|g|}} g_{\mu\nu} \epsilon^{\nu\alpha\beta} F_{\alpha\beta}, \tag{1.6}$$

where the action of the covariant derivative $D_\mu = \partial_\mu + A_\mu$ on Φ is $D_\mu \Phi = \partial_\mu \Phi + [A_\mu, \Phi]$, $\partial_\mu = \partial/\partial x^\mu$. $\{F_{\mu\nu}\}$ is the curvature corresponding to $\{A_\mu\}$, $F_{\mu\nu} = [D_\mu, D_\nu]$.

With the Poincaré coordinates (1.3), (1.6) becomes

$$D_u \Phi = rF_{ur}, \quad D_v \Phi = -rF_{vr}, \quad D_r \Phi = -2rF_{uv}. \tag{1.7}$$

It was proposed in Ref. 3 that this system of nonlinear partial differential equations had a Lax pair

$$\begin{aligned} &(rD_r + \Phi - 2(\zeta - u)D_u)\psi = 0, \\ &\left(2D_v + \frac{\zeta - u}{r} D_r - \frac{\zeta - u}{r^2}\Phi\right)\psi = 0, \end{aligned} \tag{1.8}$$

where $D_\mu \psi = \partial_\mu \psi + A_\mu \psi$ and ζ is a complex spectral parameter. That is, (1.7) is the integrability condition of the overdetermined system (1.8).

II. DARBOUX TRANSFORMATION IN GL(N,C) CASE

In this section, we consider the case $G = \mathrm{GL}(N, \mathbf{C})$. This is the simplest case because no reduction should be considered. Let

$$\tilde{\psi} = (\zeta - u)R\psi - T\psi, \tag{2.1}$$

where $R(u,v,r)$ and $T(u,v,r)$ are $N \times N$ matrices and R is invertible, then the transformation $\psi \to \tilde{\psi}$ is called a Darboux transformation (of degree one) if there are $(\tilde{A}_\mu, \tilde{\Phi})$ such that

$$\begin{aligned} &(r\tilde{D}_r + \tilde{\Phi} - 2(\zeta - u)\tilde{D}_u)\tilde{\psi} = 0, \\ &\left(2\tilde{D}_v + \frac{\zeta - u}{r}\tilde{D}_r - \frac{\zeta - u}{r^2}\tilde{\Phi}\right)\tilde{\psi} = 0 \end{aligned} \tag{2.2}$$

hold. Here $\tilde{D}_\mu=\partial_\mu+\tilde{A}_\mu$.

We should first determine R and T so that (2.1) is a Darboux transformation. For given (A,Φ), $(\tilde{A},\tilde{\Phi})$ and arbitrary matrix function Q, let

$$\Delta_\mu Q=\partial_\mu Q+\tilde{A}_\mu Q-QA_\mu,$$
$$\delta Q=\tilde{\Phi}Q-Q\Phi. \tag{2.3}$$

Expressed in ψ, both equations of (2.2) are polynomials of ζ of degree two. The coefficients of the second, first, and zeroth order of ζ in the two equations of (2.2) lead to

$$\Delta_u R=0,\quad r\Delta_r R+2\Delta_u T+\delta R+2R=0,$$
$$r\Delta_r T+\delta T=0, \tag{2.4}$$

and

$$\Delta_r R-\frac{1}{r}\delta R=0,\quad 2\Delta_v R-\frac{1}{r}\Delta_r T+\frac{1}{r^2}\delta T=0,$$
$$\Delta_v T=0. \tag{2.5}$$

These two systems are equivalent to

$$\Delta_u R=0, \tag{2.6}$$

$$\Delta_v T=0, \tag{2.7}$$

$$\Delta_v R=\frac{1}{r}\Delta_r T, \tag{2.8}$$

$$\Delta_r R+\frac{1}{r}\Delta_u T+\frac{1}{r}R=0, \tag{2.9}$$

$$\Delta_r R-\frac{1}{r}\delta R=0, \tag{2.10}$$

$$\Delta_r T+\frac{1}{r}\delta T=0. \tag{2.11}$$

$\tilde{A}_u$ and $\tilde{A}_v$ are solved from (2.6) and (2.7) as

$$\tilde{A}_u=RA_uR^{-1}-(\partial_u R)R^{-1}, \tag{2.12}$$

$$\tilde{A}_v=TA_vT^{-1}-(\partial_v T)T^{-1}, \tag{2.13}$$

while (2.10) and (2.11) lead to

$$\tilde{A}_r=\frac{1}{2}(TA_r-\partial_r T)T^{-1}+\frac{1}{2}(RA_r-\partial_r R)R^{-1}+\frac{1}{2r}(T\Phi T^{-1}-R\Phi R^{-1}), \tag{2.14}$$

$$\tilde{\Phi}=\frac{r}{2}(TA_r-\partial_r T)T^{-1}-\frac{r}{2}(RA_r-\partial_r R)R^{-1}+\frac{1}{2}(T\Phi T^{-1}+R\Phi R^{-1}). \tag{2.15}$$

Now let Z be an $N\times N$ matrix function of (u,v,r), H be a solution of

$$\begin{aligned} &r((\partial_r H)H^{-1}+A_r)+\Phi-2((\partial_u H)H^{-1}+A_u)S=0,\\ &2((\partial_v H)H^{-1}+A_v)+\frac{1}{r}((\partial_r H)H^{-1}+A_r)S-\frac{1}{r^2}\Phi S=0, \end{aligned} \tag{2.16}$$

where $S=HZH^{-1}-u$, then S satisfies

$$\begin{aligned} \partial_r S&=H\left(\partial_r Z-\frac{2}{r}(\partial_u Z)(Z-u)\right)H^{-1}+\frac{2}{r}S+\frac{2}{r}(\partial_u S)S-[A_r,S]+\frac{2}{r}[A_u,S]S-\frac{1}{r}[\Phi,S],\\ \partial_v S&=H\left(\partial_v Z+\frac{1}{2r}(\partial_r Z)(Z-u)\right)H^{-1}-\frac{1}{2r}(\partial_r S)S-[A_v,S]-\frac{1}{2r}[A_r,S]S+\frac{1}{2r^2}[\Phi,S]S. \end{aligned} \tag{2.17}$$

Remark 1: If Z is diagonal and $Z=\mathrm{diag}(\zeta_1,...,\zeta_N)$, then $H=(h_1,\ldots,h_N)$ where h_i is a column solution of the Lax pair (1.8) with $\zeta=\zeta_i(u,v,r)$.

If $T=RS$, then (2.8) and (2.9) hold if and only if

$$\begin{aligned} &\partial_r Z-\frac{2}{r}(\partial_u Z)(Z-u)=0,\\ &\partial_v Z+\frac{1}{2r}(\partial_r Z)(Z-u)=0. \end{aligned} \tag{2.18}$$

Therefore, we have

Theorem 1: *Suppose $R(u,v,r)$ is an arbitrary invertible matrix function. If $Z(u,v,r)$ is an $N\times N$ matrix solution of (2.18) and H is a solution of (2.16) with $S=HZH^{-1}-u$, then $\psi\mapsto\tilde{\psi}=(\zeta-u)R\psi-RS\psi$ is a Darboux transformation for (1.8).*

If $Z=\mathrm{diag}(\zeta_1,...,\zeta_N)$, then each ζ_i is a solution of

$$\begin{aligned} &\partial_r\zeta-\frac{2}{r}(\zeta-u)\partial_u\zeta=0,\\ &\partial_v\zeta+\frac{1}{2r}(\zeta-u)\partial_r\zeta=0. \end{aligned} \tag{2.19}$$

Apart from the constant solution, the general nonconstant solution of (2.19) is given implicitly by

$$v-\frac{r^2}{\zeta-u}=C(\zeta), \tag{2.20}$$

where C is an arbitrary holomorphic function. We still call ζ_i as a ''spectral parameter.'' However, here the ''spectral parameters'' ζ_i's in Z can be either constant or variable. In the latter case, they are given by (2.20).

Remark 2: Note that the spectral parameter ζ in the Lax pair is still a complex constant. Only ζ_i's in Z can depend on (u,v,r).

According to Theorem 1, we can get the exact solution of (1.7) from a known solution of (1.7) and the corresponding solution of the linear system (2.16). When Z is diagonal, solving (2.16) is equivalent to solving (1.8).

Theorem 1 gives the construction of Darboux transformations of degree one. The Darboux transformations of higher degrees can be obtained by the composition of several Darboux transformations of degree one.

III. DARBOUX TRANSFORMATION IN THE U(N) CASE

When $G=\mathrm{U}(N)$, the Lie algebra consists of all anti-Hermitian matrices. Hence $A_\mu^*=-A_\mu$, $\Phi^*=-\Phi$.

In order to construct Darboux transformation which keeps this reduction, some constraints on ζ_j's and h_j's should be added.

Suppose ψ is a solution of (1.8), ϕ is a solution of (1.8) with $\zeta\to\overline{\zeta}$. Then

$$\begin{aligned} &r\partial_r(\phi^*\psi)-2(\zeta-u)\partial_u(\phi^*\psi)=0,\\ &2\partial_v(\phi^*\psi)+\frac{\zeta-u}{r}\partial_r(\phi^*\psi)=0. \end{aligned} \tag{3.1}$$

It is uniquely solvable for a given initial value of $\phi^*\psi$ at $r=r_0>0$ and $v=v_0$. Hence if $\phi^*\psi|_{r=r_0,v=v_0}=0$, then $\phi^*\psi=0$ identically for $r>0$.

Let ζ_0 be a constant number or a nonconstant solution of (2.19). Take $Z=\mathrm{diag}(\zeta_1,...,\zeta_N)$ with $\zeta_j=\zeta_0$ or $\overline{\zeta_0}$, $H=(h_1,\ldots,h_N)$ where h_j is a column solution of (1.8) with $\zeta=\zeta_j$ such that $\det H\neq 0$ and $h_i^*h_j=0$ for $\zeta_i=\overline{\zeta_j}$. Then, the Darboux transformation given by Theorem 1 keeps the U(N) reduction. That is, $\tilde{A}_\mu^*=-\tilde{A}_\mu$, $\tilde{\Phi}^*=-\tilde{\Phi}$. This is proved similarly to the U(N) reduction for other systems like the AKNS system.

Darboux transformation of higher degree can be obtained by composition of Darboux transformations of degree one. However, when $G=\mathrm{U}(N)$, there is the following special and more explicit construction.

Let $\zeta^{(i)}$ $(i=1,\ldots,r)$ be constant numbers or nonconstant solutions of (2.19), $h^{(i)}$ be a column solution of (1.8) with $\zeta=\zeta^{(i)}$. Consider the composition of r Darboux transformations of degree one. In the ith Darboux transformation, let

$$Z=Z^{(j)}\equiv\mathrm{diag}(\zeta^{(j)},\overline{\zeta}^{(j)},\ldots,\overline{\zeta}^{(j)}),\quad H=H^{(j)}\equiv(h_1^{(j)},\ldots,h_N^{(j)}), \tag{3.2}$$

where $h_1^j=h^{(j)}$ and $h_k^{(j)}$ $(k=2,3,\ldots,n)$ are solutions of (1.8) with $\zeta=\overline{\zeta}^{(j)}$ and satisfy $h_k^{(j)*}h^{(j)}=0$. In this case, the Darboux transformation of degree r can be constructed in the following way, which does not depend on $h_k^{(j)}$ $(j=1,2,\ldots,r;\ k=2,3,\ldots,n)$.

Let

$$\Gamma_{ij}=\frac{h^{(i)*}h^{(j)}}{\overline{\zeta}^{(i)}-\zeta^{(j)}}, \tag{3.3}$$

then $G=(G_{ij})$ with

$$G_{ij}=\prod_{j=1}^{r}(\zeta-\overline{\zeta}^{(j)})\left(1+\sum_{i,j=1}^{r}\frac{h^{(i)}(\Gamma^{-1})_{ij}h^{(j)*}}{\zeta-\overline{\zeta}^{(j)}}\right) \tag{3.4}$$

is a Darboux matrix for (1.8).[6,7]

IV. SOLITON SOLUTIONS

Soliton solutions are obtained in the following way.

Take seed solution $A_\mu=0$ $(\mu=u,v,r)$, $\Phi=0$. Considering the gauge equivalence in (2.12), we can always choose $R=1$ and $T=S$. From (2.12)–(2.15), (2.17), and (2.18), we have

$$\tilde{A}_u=0,\quad \tilde{A}_v=-(\partial_vS)S^{-1}=\frac{1}{2r}\partial_rS, \tag{4.1}$$

$$\tilde{A}_r=-\frac{1}{2}(\partial_r S)S^{-1}=-\frac{1}{r}(\partial_u S+1),\quad \tilde{\Phi}=-\frac{r}{2}(\partial_r S)S^{-1}=-\partial_u S-1,$$

and

$$\tilde{F}_{uv}=[\tilde{D}_u,\tilde{D}_v]=\frac{1}{2r}\partial_u\partial_r S,$$

$$\tilde{F}_{ur}=[\tilde{D}_u,\tilde{D}_r]=-\frac{1}{r}\partial_u\partial_u S, \tag{4.2}$$

$$\tilde{F}_{vr}=[\tilde{D}_v,\tilde{D}_r]=-\frac{1}{2r}(\partial_r\partial_r+2\partial_u\partial_v)S+\frac{1}{2r^2}\partial_r S-\frac{1}{2r^2}[\partial_r S,\partial_u S].$$

Here we always suppose Z is diagonal with $Z=\mathrm{diag}(\zeta_1,\ldots,\zeta_N)$. Then the corresponding h_i's are solved from (1.8) explicitly.

Case 1: ζ_i is a constant.

Then h_i satisfies

$$\begin{aligned} r\partial_r h_i-2(\zeta_i-u)\partial_u h_i=0,\\ 2\partial_v h_i+\frac{\zeta_i-u}{r}\partial_r h_i=0. \end{aligned} \tag{4.3}$$

Hence

$$h_i=f_i(\omega(\zeta_i)), \tag{4.4}$$

where f_i is an arbitrary holomorphic vector function of $\omega(\zeta_i)$ and

$$\omega(\zeta)=v-\frac{r^2}{\zeta-u}. \tag{4.5}$$

Case 2: ζ_i is not a constant.

According to (2.20), ζ_i satisfies

$$v-\frac{r^2}{\zeta_i-u}=C_i(\zeta_i), \tag{4.6}$$

where C_i is an arbitrary holomorphic function. h_i should be a solution of (4.3) with this ζ_i, which is

$$h_i=f_i(\zeta_i), \tag{4.7}$$

where f_i is an arbitrary holomorphic vector function. The Darboux transformation is also given by $S=HZH^{-1}-u$ with $H=(h_1,\ldots,h_N)$ when $\det H\neq 0$.

Multisolitons can be obtained by the composition of Darboux transformations of degree one or by (3.3) and (3.4) directly in U(N) case.

V. EXAMPLES FOR SU(2) CASE

Now we consider the soliton solutions for the simplest non-Abelian group $G=\mathrm{SU}(2)$.

A. Single soliton solutions with constant spectral parameter

Take ζ_0 to be a complex constant which is not real, $Z=\mathrm{diag}(\zeta_0,\overline{\zeta_0})$. Let $\tau=\omega(\zeta_0)$, then

$$H=\begin{pmatrix}\alpha(\tau) & -\overline{\beta(\tau)}\\ \beta(\tau) & \overline{\alpha(\tau)}\end{pmatrix}, \tag{5.1}$$

where α, β are two holomorphic functions. Let $\sigma(\tau)=\beta(\tau)/\alpha(\tau)$, then

$$S=\frac{\zeta_0-\overline{\zeta_0}}{1+|\sigma|^2}\begin{pmatrix}1 & \overline{\sigma}\\ \sigma & |\sigma|^2\end{pmatrix}+\overline{\zeta_0}-u, \tag{5.2}$$

$$\tilde{\Phi}=-\partial_u S-1=\frac{\zeta_0-\overline{\zeta_0}}{(1+|\sigma|^2)^2}\begin{pmatrix}(|\sigma|^2)_u & \overline{\sigma}^2\sigma_u-\overline{\sigma}_u\\ \sigma^2\overline{\sigma}_u-\sigma_u & -(|\sigma|^2)_u\end{pmatrix}, \tag{5.3}$$

and

$$-\mathrm{tr}\,\tilde{\Phi}^2=\frac{8(\mathrm{Im}\,\zeta_0)^2}{(1+|\sigma|^2)^2}|\partial_u\sigma|^2. \tag{5.4}$$

According to (1.1) and (4.5),

$$\tau=\frac{\zeta_0(Y+V)(U+X)-1-Y^2+V^2}{(\zeta_0(U+X)-Y+V)(U+X)}=\frac{\zeta_0(Y+V)+X-U}{\zeta_0(U+X)-Y+V}. \tag{5.5}$$

Denote

$$\xi=\zeta_0(Y+V)+X-U,\quad \eta=\zeta_0(X+U)-Y+V, \tag{5.6}$$

then both ξ and η cannot be zero anywhere on (1.1) when ζ_0 is not real. Hence τ is a smooth function of U,V,X,Y on (1.1). Moreover,

$$\partial_u\tau=-\frac{r^2}{(\zeta_0-u)^2}=-\frac{1}{\eta^2}. \tag{5.7}$$

Since $\sigma(\tau)$ is a meromorphic function of τ, suppose $\sigma(\tau)=\sigma_1(\tau)/\sigma_2(\tau)$ where $\sigma_1(\tau)$ and σ_2 are two holomorphic functions of τ without common zero. According to (5.4),

$$-\mathrm{tr}\,\tilde{\Phi}^2=\frac{8(\mathrm{Im}\,\zeta_0)^2|\sigma_2(\tau)\partial_\tau\sigma_1(\tau)-\sigma_1(\tau)\partial_\tau\sigma_2(\tau)|^2}{(|\sigma_1(\tau)|^2+|\sigma_2(\tau)|^2)^2}|\eta|^{-4}. \tag{5.8}$$

Hence, $\tilde{\Phi}$ can be extended smoothly to (1.1). Likewise, according to (4.1),

$$\begin{aligned}-\mathrm{tr}\,\tilde{A}_u^2=0,\quad -\mathrm{tr}\,\tilde{A}_v^2&=\frac{8(\mathrm{Im}\,\zeta_0)^2(|\sigma_2(\tau)\partial_\tau\sigma_1(\tau)-\sigma_1(\tau)\partial_\tau\sigma_2(\tau)|^2}{(|\sigma_1(\tau)|^2+|\sigma_2(\tau)|^2)^2}(U+X)^2|\eta|^{-2},\\ -\mathrm{tr}\,\tilde{A}_r^2&=\frac{8(\mathrm{Im}\,\zeta_0)^2(|\sigma_2(\tau)\partial_\tau\sigma_1(\tau)-\sigma_1(\tau)\partial_\tau\sigma_2(\tau)|^2}{(|\sigma_1(\tau)|^2+|\sigma_2(\tau)|^2)^2}(U+X)^2|\eta|^{-4}.\end{aligned} \tag{5.9}$$

Therefore, the solution $(\tilde{\Phi},\tilde{A}_u,\tilde{A}_v,\tilde{A}_r)$ is smooth on (1.1), hence is smooth on the whole $2+1$-dimensional anti-de Sitter space–time.

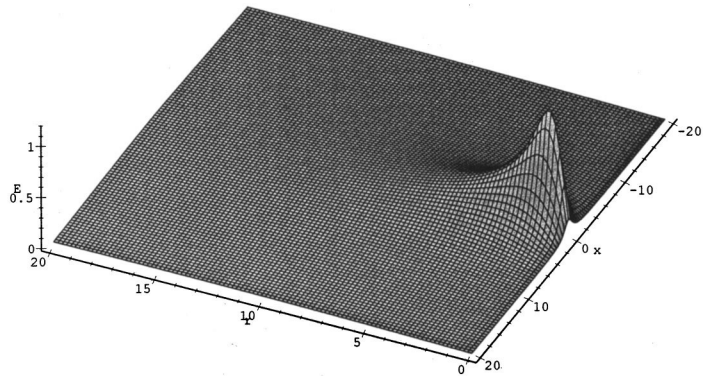

FIG. 1.

The infinity of the $2+1$-dimensional anti-de Sitter space–time includes only $r\to 0$. However, for the parameter space (t,r,x) $(r>0)$ with fixed t, the infinity of the derived half plane contains $r\to 0$ and $r^2+x^2\to\infty$. Here we call a solution localized if $-\operatorname{tr}\tilde{\Phi}^2\to 0$ when $r\to 0$ or $r^2+x^2\to\infty$ for fixed t.

Example 1: If $\zeta_0=\mathrm{i}$, $\tau=\omega(\zeta_0)$, $\sigma(\tau)=\tau$, this is just the localized solution (25) of Ref. 3, and

$$-\operatorname{tr}\tilde{\Phi}^2=\frac{8r^4}{((r^2+x^2-t^2)^2+2x^2+2t^2+1)^2}.$$

Let

$$x=tR\cos\theta,\quad r=tR\sin\theta. \tag{5.10}$$

When t and θ are fixed, $-\operatorname{tr}\tilde{\Phi}^2$ is a function of R only. Its maximum appears at $R=\pm\sqrt{t^2+1}/t$. Hence as $t\to\infty$, the ridge of the solution locates on the circle $x^2+r^2=t^2+1$.

Figures 1 and 2 describe this soliton at $t=0$ and $t=10$, respectively. In Figs. 1 and 2, the vertical axis is $(-\operatorname{tr}\tilde{\Phi}^2)^{1/4}$.

Example 2: $\tau=\omega(\zeta_0)$, $\sigma(\tau)$ is a polynomial of τ of degree k $(k\geqslant 1)$.

If $r\to 0$, then $\tau\to v$, $\partial_v\tau\to 1$ and all the other derivatives of τ (including derivatives of higher orders) tend to zero. According to (5.4), $-\operatorname{tr}\tilde{\Phi}^2\to 0$.

If $r^2+x^2\to\infty$, then (for fixed t)

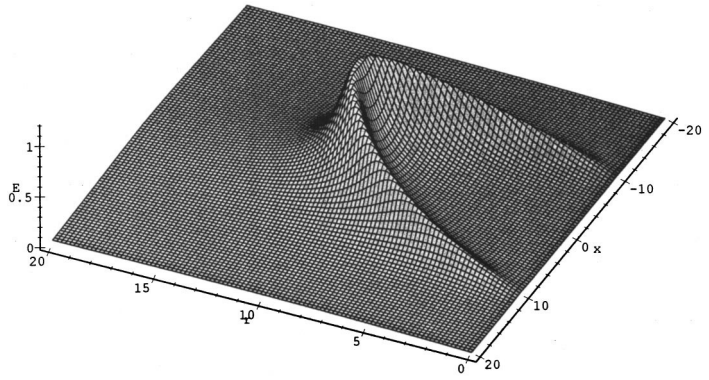

FIG. 2.

$$\tau=\frac{\zeta_0(x-t)-(r^2+x^2-t^2)}{\zeta_0-x-t}\to\infty. \tag{5.11}$$

Moreover, when t fixed, r^2+x^2 and $|\tau|$ are large enough, we have the estimates

$$\begin{aligned}&\frac{|\tau|^{k+1}|\partial_\tau\sigma|}{1+|\sigma|^2}\leqslant C_1\frac{|\tau|^{k+1}|\tau|^{k-1}}{1+|\tau|^{2k}}\leqslant C_1,\\ &\left|\frac{\partial_u\tau}{\tau^2}\right|(r^2+x^2)=\frac{r^2}{|\zeta_0(x-t)-(r^2+x^2-t^2)|^2}(r^2+x^2)\leqslant C_2,\end{aligned} \tag{5.12}$$

where C_1 and C_2 are independent of x and r, but may depend on ζ_0 and t. According to (5.4),

$$-\operatorname{tr}\tilde{\Phi}^2\leqslant\frac{8(\operatorname{Im}\zeta_0)^2C_1^2C_2^2}{|\tau|^{2k-2}}\frac{1}{(x^2+r^2)^2}\to 0. \tag{5.13}$$

Hence the solution is also localized whenever $\sigma(\tau)$ is a nonconstant polynomial of τ.

Now we consider the asymptotic behavior of the solution as $t\to\infty$ for $\zeta_0=i$. The following discussion in this example is qualitative and not rigorous.

Suppose all the roots of $\sigma(\tau)$ are simple roots. Denote $E=-\operatorname{tr}\tilde{\Phi}^2$. By (5.4), when τ is near a root of $\sigma(\tau)$, E may be large. Hence when τ is near a root of $\sigma(\tau)$, perhaps there will be a ridge in the graph of E.

From (4.5), the real and imaginary parts of $\tau=\omega(i)$ are

$$\begin{aligned}\operatorname{Re}\tau&=\frac{x-t+(x+t)(r^2+x^2-t^2)}{1+(x+t)^2},\\ \operatorname{Im}\tau&=\frac{r^2}{1+(x+t)^2}.\end{aligned} \tag{5.14}$$

When t is large and $x+t$ is not very small,

$$\operatorname{Re}\tau\approx\frac{r^2+x^2-t^2}{x+t}. \tag{5.15}$$

For a root ρ of $\sigma(\cdot)$, the points with

$$\frac{r^2+x^2-t^2}{x+t}=\operatorname{Re}\rho \tag{5.16}$$

are on the circle

$$C:\quad r^2+(x-\tfrac{1}{2}\operatorname{Re}\rho)^2=(t+\tfrac{1}{2}\operatorname{Re}\rho)^2. \tag{5.17}$$

On this circle C, for fixed t and $\operatorname{Re}\rho$, $\operatorname{Im}\tau$ can be expressed by x as

$$\operatorname{Im}\tau=\frac{t^2-x^2+\operatorname{Re}\rho(x+t)}{1+(x+t)^2}. \tag{5.18}$$

By computing $(\mathrm{d}/\mathrm{d}x)\operatorname{Im}\tau$, we know that $\operatorname{Im}\tau$ decreases when x increases if $x\geqslant -t+1$ and $t\geqslant -\operatorname{Re}\rho/2$. Hence it is easy to derive that $|\operatorname{Im}\tau|\leqslant 2$ when $t>|\operatorname{Re}\rho|$ and $x\geqslant 0$. Therefore, when $|\operatorname{Im}\rho|$ is not large, there will be a ridge of E on C.

When $|\operatorname{Im}\rho|\geqslant 1$, E is large on C only when $\operatorname{Im}\tau\approx\operatorname{Im}\rho$. If t is large and $x+t$ is not very small,

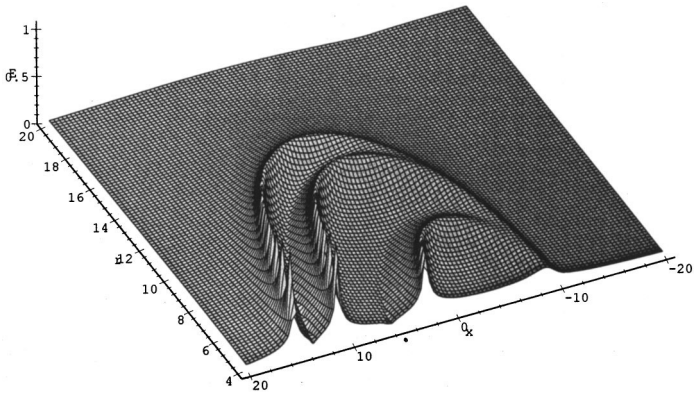

FIG. 3.

$$\operatorname{Im}\tau \approx \frac{t-x+\operatorname{Re}\rho}{x+t}. \tag{5.19}$$

The equation

$$\frac{t-x+\operatorname{Re}\rho}{x+t}=\operatorname{Im}\rho \tag{5.20}$$

has a unique solution

$$x=\frac{-(\operatorname{Im}\rho-1)t+\operatorname{Re}\rho}{\operatorname{Im}\rho+1}. \tag{5.21}$$

If $\operatorname{Im}\rho \gg 1$, then when t is large enough, x satisfies $-t \leqslant x \leqslant t+\operatorname{Re}\rho$. Hence there exists unique $r>0$ such that $(x,r)\in C$. This means that when $\operatorname{Im}\rho \gg 1$, there will be a peak rather than a ridge. If $\operatorname{Im}\rho \ll -1$, then when t is large enough, $x<-t$. Hence there does not exist $r>0$ such that $(x,r)\in C$, that is, there is neither ridge nor peak in the graph of E.

The above-presented discussion on the graph of E is summarized as follows. As $t\to\infty$, a root ρ with $|\operatorname{Im}\rho| \ll 1$ corresponds to a ridge, a root ρ with $\operatorname{Im}\rho \gg 1$ corresponds to a peak, and a root ρ with $\operatorname{Im}\rho \ll -1$ corresponds to nothing.

Figure 3 ($t=10$) shows the solution for

$$\sigma(\tau)=(\tau-2)(\tau-6)(\tau+6), \tag{5.22}$$

which has three real roots. It is plotted for $r \geqslant 4$ because the ridge is perpendicular to $r=0$ and the figures cannot be plotted well near $r=0$. Figure 4 shows its local behavior for a part of the region with $0 \leqslant r \leqslant 4$.

Figure 5 ($t=10$) shows the solution for

$$\sigma(\tau)=(\tau-2)(\tau-6)(\tau+6)(\tau-2i)(\tau-6i)(\tau+6i), \tag{5.23}$$

which has three real roots and three purely imaginary roots, but one imaginary root has the negative imaginary part. The solution has three ridges and two peaks.

Figure 6 ($t=10$) shows the solution for

$$\sigma(\tau)=(\tau-2-2i)(\tau-6-6i)(\tau+6-4i), \tag{5.24}$$

which has no real roots. In Fig. 6, there are three peaks.

Figure 7 ($t=10$) shows the solution for

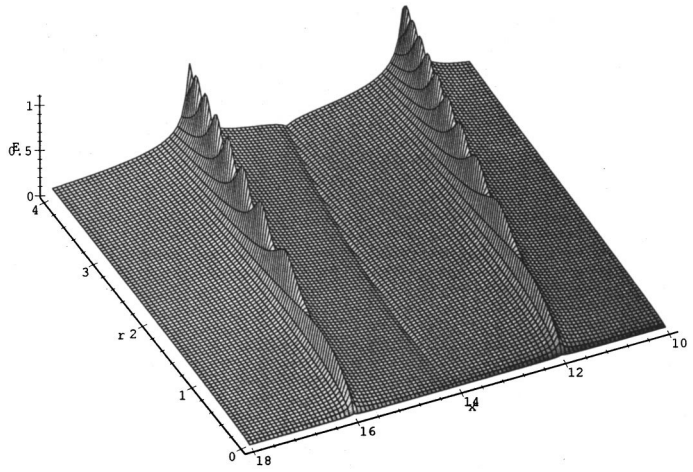

FIG. 4.

$$\sigma(\tau)=(\tau-2-2i)(\tau-6-6i)(\tau+6+6i), \tag{5.25}$$

which has no real roots, and only two roots have positive imaginary parts. In Fig. 7, there are only two peaks.

In all these figures (Figs. 3–7), the vertical axis is $(-\operatorname{tr}\tilde{\Phi}^2)^{1/8}$.

Example 3: $\zeta_0=i$, $\tau=\omega(i)$, $\sigma(\tau)=\sin(\mu\tau)$ where μ is a real constant.

If $r\to 0$, then $\tau\to v$, hence $E\to 0$. When the point $(x,r)\to\infty$ along the straight line $r=kx+b$ (k,b are real constants), (5.14) gives

$$\begin{aligned}\operatorname{Im}\tau&=\frac{(kx+b)^2}{1+(x+t)^2}\to k^2,\\ \operatorname{Re}\tau&=\frac{x-t+(x+t)((kx+b)^2+x^2-t^2)}{1+(x+t)^2}\sim(k^2+1)x.\end{aligned} \tag{5.26}$$

Denote $\mu\tau=p+qi$ where p and q are real, then

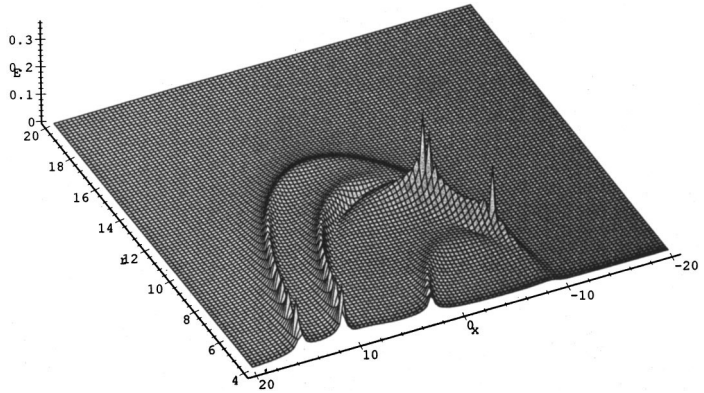

FIG. 5.

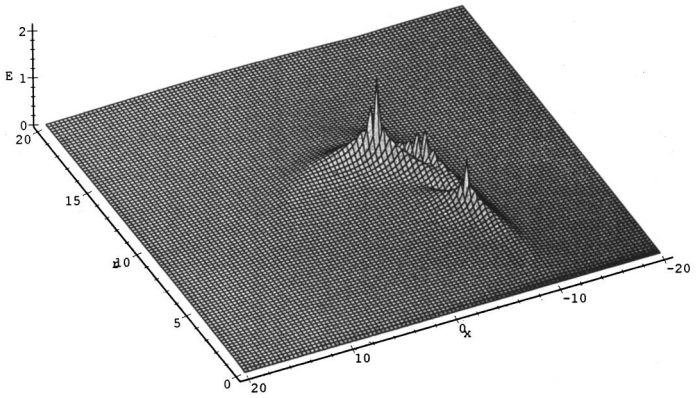

FIG. 6.

$$E=\frac{16\mu^2(\cosh(2q)+\cos(2p))}{(\cosh(2q)-\cos(2p)+2)^2}\frac{r^4}{(1+(x+t)^2)^2}\sim\frac{16\mu^2k^4(\cosh(2\mu k^2)+\cos(2\mu(k^2+1)x)}{(\cosh(2\mu k^2)-\cos(2\mu(k^2+1)x)+2)^2} \tag{5.27}$$

as $x^2+r^2\to\infty$. Hence the solution is bounded, but not localized in our definition [on the half (r,x,t) space]. However, as is shown, E tends to zero at the infinity of the $2+1$-dimensional anti-de Sitter space–time ($r=0$).

This solution is shown in Fig. 8 ($t=10$).

B. Single soliton solutions with nonconstant "spectral parameter"

In this case, ζ_0 should satisfy

$$v-\frac{r^2}{\zeta_0-u}=C(\zeta_0). \tag{5.28}$$

S, $\tilde{\Phi}$ are given by (5.2) and (5.3), and $-\operatorname{tr}\tilde{\Phi}^2$ is given by (5.4). However, in these expressions, ζ_0 is no longer a constant.

Contrary to the case where ζ_0 is a constant, here the solutions are defined only on the half (r,x,t) space. In general, they cannot be extended to the whole $2+1$-dimensional anti-de Sitter space–time.

Example 4: $C(\zeta_0)=C_0$ (constant), then

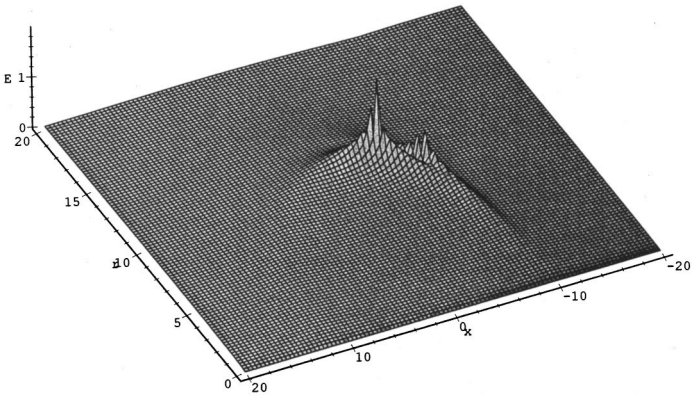

FIG. 7.

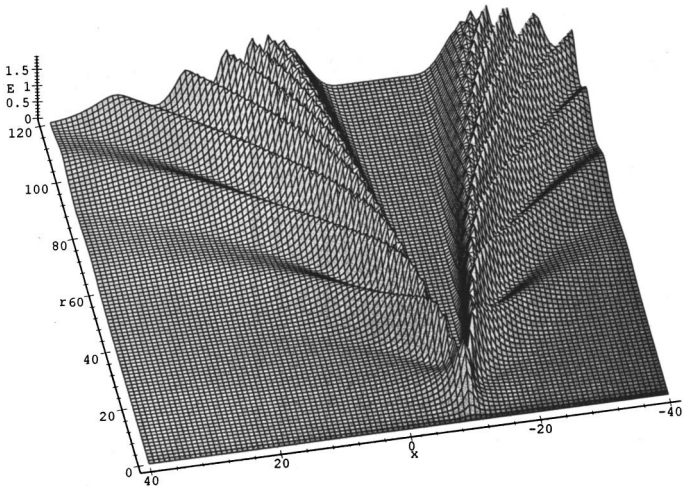

FIG. 8.

$$\zeta_0 = u - \frac{r^2}{C_0 - v}. \tag{5.29}$$

Let

$$H = \begin{pmatrix} \alpha(\zeta_0) & -\overline{\beta(\zeta_0)} \\ \beta(\zeta_0) & \overline{\alpha(\zeta_0)} \end{pmatrix},$$

where α and β are holomorphic functions of ζ_0 and $\sigma = \beta(\zeta_0)/\alpha(\zeta_0)$, then the Darboux matrix S is also given by (5.2). For example, if $\sigma(\zeta) = \zeta$ and $C_0 = i$, then $-\operatorname{tr}\tilde{\Phi}^2$ is completely the same as that in Example 1.

Example 5: $C(\zeta_0) = \zeta_0 + C_0$ where $C_0 = \alpha + \beta i$, α and β are real constants with $\beta \neq 0$, $\sigma(\zeta_0) = \zeta_0$.

Then

$$\zeta_0^2 - (u + v - C_0)\zeta_0 + uv + r^2 - C_0 u = 0. \tag{5.30}$$

The criteria of this quadratic equation is

$$\begin{aligned} \Delta &= (u + v - C_0)^2 - 4(uv + r^2 - C_0 u) \\ &= (u - v + C_0)^2 - 4r^2 \\ &= (2t + \alpha)^2 - 4r^2 - \beta^2 + 2\beta(2t + \alpha)i. \end{aligned} \tag{5.31}$$

When $t > -\alpha/2$, the imaginary part of Δ is never zero. Hence we can choose

$$\zeta_0 = \frac{u + v - C_0 + \sqrt{(u - v + C_0)^2 - 4r^2}}{2}, \tag{5.32}$$

where the square root takes the specific branch in the upper half-plane.

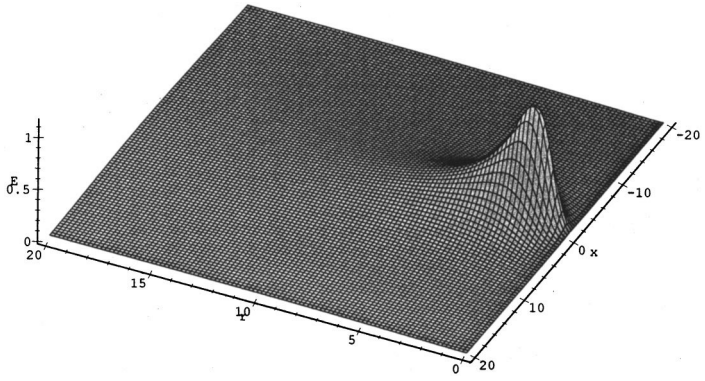

FIG. 9.

If $r\to 0$, then $\zeta_0\to u$, $\partial_u\zeta_0\to 1$ and all the other derivatives of ζ_0 tend to zero. Hence by (5.4), $-\mathrm{tr}\tilde{\Phi}^2\to 0$.

If $x^2+r^2\to\infty$ (t fixed),

$$\frac{|\zeta_0|}{\sqrt{x^2+r^2}}=\frac{1}{\sqrt{x^2+r^2}}\left|\frac{2x-C_0+\sqrt{(2t+C_0)^2-4r^2}}{2}\right|\to 1,$$

$$|\partial_u\zeta_0|=\frac{1}{2}\left|1+\frac{2t+C_0}{\sqrt{(2t+C_0)^2-4r^2}}\right|\leqslant C_3,\quad \frac{|\mathrm{Im}\,\zeta_0|}{r}\leqslant 2, \tag{5.33}$$

where C_3 is independent of x and r, but may depend on t, α, and β. According to (5.4) for $\sigma(\zeta_0)=\zeta_0$, $-\mathrm{tr}\,\tilde{\Phi}^2\to 0$ as $x^2+r^2\to\infty$. Hence the solution is also localized. However, it cannot be extended to the whole $2+1$-dimensional anti-de Sitter space–time smoothly because of the condition $t>-\alpha/2$.

This soliton is shown in Fig. 9 ($t=1$) and Fig. 10 ($t=10$) for $\alpha=0$ and $\beta=2$.

Example 6: $C(\zeta_0)=\zeta_0+C_0$, $C_0=\alpha+\beta i$ ($\beta\neq 0$) as previously, $\sigma(\zeta_0)$ is a polynomial of ζ_0 of degree k.

Then similar to (5.12), we have the estimates

$$\frac{|\zeta_0|^{k+1}|\partial_{\zeta_0}\sigma|}{1+|\sigma|^2}\leqslant C_1\frac{|\zeta_0|^{k+1}|\zeta_0|^{k-1}}{1+|\zeta_0|^{2k}}\leqslant C_1, \tag{5.34}$$

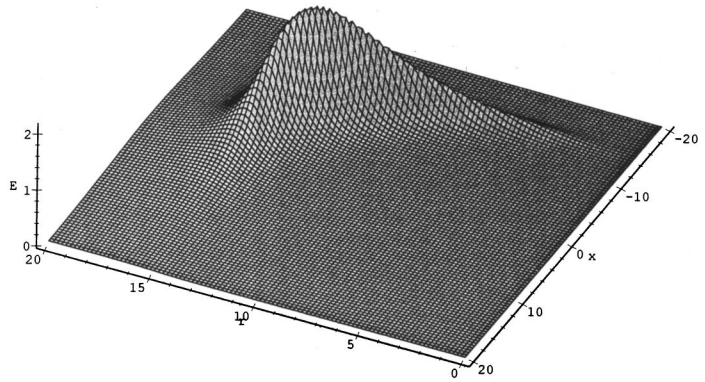

FIG. 10.

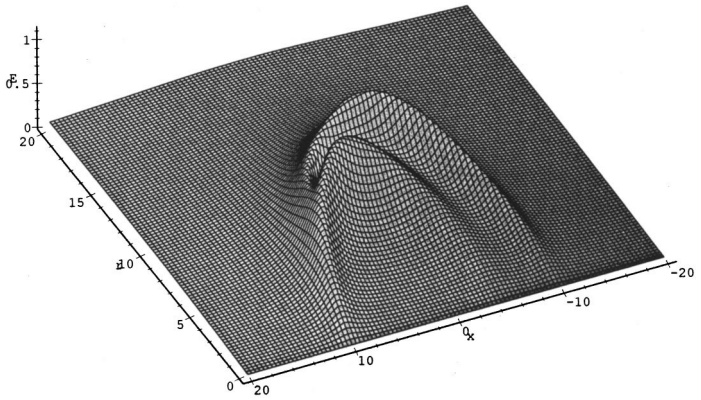

FIG. 11.

$$\left|\frac{\partial_u \zeta_0}{\zeta_0^2}\right|(r^2+x^2)\leqslant 2C_3$$

as $x^2+r^2\to\infty$ by (5.33). From (5.4), when $x^2+r^2\to\infty$,

$$-\operatorname{tr}\tilde{\Phi}^2\leqslant \frac{128C_1^2C_3^2}{|\zeta_0|^{2k-2}}\frac{r^2}{(r^2+x^2)^2}\to 0. \tag{5.35}$$

The solution is localized. As in the last example, this solution cannot be extended to the whole $2+1$-dimensional anti-de Sitter space–time.

C. Double soliton solutions

Double soliton solutions are obtained by Darboux transformations of degree two. Here we only show the following simple case for constant spectral parameters. In more complicated cases the double soliton solutions can also be derived similarly.

Example 7: Let $\zeta_1=i$, $\zeta_2=5+2i$, $\tau_j=\omega(\zeta_j)$, $\sigma_j(\tau_j)=\tau_j$ $(j=1,2)$. The double soliton is shown in Fig. 11 $(t=10)$.

Quadratic Poisson algebras of two-dimensional classical superintegrable systems and quadratic associative algebras of quantum superintegrable systems

C. Daskaloyannis[a)]
Department of Physics, Aristotle University of Thessaloniki, 54006 Thessaloniki, Greece

(Received 27 March 2000; accepted for publication 13 December 2000)

The integrals of motion of the classical two-dimensional superintegrable systems with quadratic integrals of motion close in a restrained quadratic Poisson algebra, whose the general form is investigated. Each classical superintegrable problem has a quantum counterpart, a quantum superintegrable system. The quadratic Poisson algebra is deformed into a quantum associative algebra, the finite-dimensional representations of this algebra are calculated by using a deformed parafermion oscillator technique. It is shown that the finite dimensional representations of the quadratic algebra are determined by the energy eigenvalues of the superintegrable system. The calculation of energy eigenvalues is reduced to the solution of algebraic equations, which are universal, that is for all two-dimensional superintegrable systems with quadratic integrals of motion. © *2001 American Institute of Physics.*
[DOI: 10.1063/1.1348026]

I. INTRODUCTION

In classical mechanics, an integrable system is a system possessing more constants of motion than just the energy one. A comprehensive review of the two-dimensional integrable classical systems is given by Hietarinta,[1] where the space was assumed to be a flat real one. The case of nonflat space is under current investigation.[2,3] An interesting subset of the totality of integrable systems is the set of systems, which possess a maximum number of integrals, these systems are termed as superintegrable ones. The Coulomb and the harmonic oscillator potentials are the most familiar classical superintegrable systems, whose their quantum counterpart has nice symmetry properties, which are described by the $so(2N)$ and $su(N)$ Lie algebras, respectively.

The Hamiltonian of a classical system is generally a quadratic function of the momenta. All the ''nondegenerate'' superintegrable systems with quadratic integrals of motion in a complex flat space have been classified recently by Kalnins, Miller and Pogosyan.[4] In that paper the term ''nondegenerate'' means that the potential depends on four independent parameters. These potentials are indeed separable in more than one orthogonal system of coordinates. This classification enlarges the class of the known two-dimensional superintegrable systems with quadratic integrals of motion in the real flat space. These potentials are simultaneously separable in more than two orthogonal coordinate systems.[5] The notions of the multiseparability and superintegrability do not coincide. There are several known examples, the most illustrative one is the anisotropic harmonic oscillator with a rational ratio of frequencies. These potentials do not possess quadratic integrals of motion. An example, where the integrals of motion are quadratic ones but nonseparable in more than one system of coordinates, is given in Ref. 6.

The integrals of motion of a two-dimensional superintegrable system in flat space close in a restrained classical Poisson algebra.[4,7–9] The general form of the Poisson algebra has been studied in Ref. 4. In the case of the potentials with two quadratic integrals of motion the Poisson algebra is a quadratic Poisson algebra. In Ref. 4 these quadratic Poisson algebras are listed for all super-

a)Electronic address: daskalo@auth.gr

integrable systems in the complex flat space. In Ref. 10 the quadratic algebras for the superintegrable on the sphere are given for all classified cases.

The study of the quadratic Poisson algebras is a matter under investigation, related to several branches of physics as the solution of the classical Yang–Baxter equation,[11] the two-dimensional superintegrable systems in flat space or on the sphere,[9] the statistics[12] or the case of ''exactly solvable'' classical problems.[13]

The quantization of a classical integrable system corresponds generally to a quantum integrable system. The mechanism of quantum deformation of a classical system to a quantum one is not fully understood. Initially the problem of quantization of classical superintegrable system was viewed as a relatively simple and somehow trivial problem,[14] but several authors have proved that this quantization procedure has to add correction terms to the integrals of motion or to the Hamiltonian, these correction terms are of order $\mathcal{O}(\hbar^2)$.[15,16] The result of the quantum deformation of a superintegrable system is realized by the shift of the classical Poisson algebra to some quantum polynomial associative algebra. The same fact is true in the case of quadratic Poisson algebra corresponding to the Yang–Baxter equation,[11] which is turned into a quantum quadratic associative algebra[17] with four generators. The same idea was discussed in reference Ref. 13, where the classical problems, which are expressed by a quadratic Poisson algebra, are mapped to quantum ones described by the corresponding quantum operator quadratic algebra. The same shift is indeed true for the superintegrable systems, where the classical ones correspond to the quantum ones and the classical quadratic Poisson algebra is mapped to a quadratic associative algebra.[18–22]

The deformation of the classical Poisson algebra to a quadratic associative algebra implies a deformation of the parameters of the quadratic algebra.[4] The general form of the quadratic algebras, which are encountered in the case of the two-dimensional quantum superintegrable systems, is investigated in this paper. In Refs. 7, 8, 18–20,23–26 there was conjectured that the energy eigenvalues correspond to finite-dimensional representations of the latent quadratic algebras. Granovskii *et al.* in Ref. 13 studied the representations of the quadratic Askey–Wilson algebras $QAW(3)$. In their work using there the proposed ladder representation, the finite dimensional representations are calculated and this method was applied to several superintegrable systems.[18–20,24,26] Another method[7,8] for calculating the finite dimensional representations is the use of the deformed oscillator algebra[27] and their finite-dimensional version which are termed as ''generalized deformed parafermionic algebras.''[28] Our main task in this paper is to reduce the calculations of eigenvalues to a system of two algebraic equations with two parameters to be determined. These equations are universal equations, which are valid of all superintegrable systems, with quadratic integrals of motion.

This paper is organized as follows: In Sec. II the general form of the quadratic Poisson algebra for a two-dimensional system with quadratic integrals of motion is derived. In Sec. III the special form of the Poisson algebra of the known two-dimensional superintegrable systems in flat space is written. In Sec. IV the quantum version of the Poisson quadratic algebra is studied. The deformed parafermionic oscillator algebra is reviewed and the oscillator realization of the quadratic algebras is realized. The finite-dimensional representations of the quadratic algebras are generated by using the technique of deformed parafermionic algebras. The problem is reduced to the solution of a system of two algebraic equations in Sec. VI. In Sec. VII the energy eigenvalues of all the known superintegrable systems in the flat two-dimensional space are determined by solving the appropriate algebraic equations. Finally, in Sec. VIII there is a discussion of the results of this paper.

II. QUADRATIC POISSON ALGEBRAS

Let us consider a two-dimensional superintegrable system. The general form of the Hamiltonian is

$$H=a(q_1,q_2)p_1^2+2b(q_1,q_2)p_1p_2+c(q_1,q_2)p_2^2+V(q_1,q_2); \tag{1}$$

this Hamiltonian is a quadratic form of the momenta. The system is superintegrable, therefore

there are two additional integrals of motion A and B. In that section, we assume that these integrals of motion are quadratic functions of the momenta, i.e., they are given by the general forms:

$$A=A(q_1,q_2,p_1,p_2)=c(q_1,q_2)p_1^2+2d(q_1,q_2)p_1p_2+e(q_1,q_2)p_2^2 + f(q_1,q_2)p_1+g(q_1,q_2)p_2+Q(q_1,q_2).$$

The integral of motion B is assumed to be indeed a quadratic form, which is analogous to above one:

$$B=B(q_1,q_2,p_1,p_2)=h(q_1,1_2)p_1^2+2k(q_1,q_2)p_1p_2+l(q_1,q_2)p_2^2 + m(q_1,q_2)p_1+n(q_1,q_2)p_2+S(q_1,q_2).$$

By definition the following relations are satisfied:

$$\{H,A\}_P=\{H,B\}_P=0, \tag{2}$$

where $\{\,.\,,.\,\}_P$ is the usual Poisson bracket.

From the integrals of motion A, B, we can construct the integral of motion:

$$C=\{A,B\}_P\,. \tag{3}$$

The integral of motion C is not a new independent integral of motion, which is a cubic function of the momenta. The integral C is not independent from the integrals H, A and B as it will be shown later. The fact that the integral C is a cubic function of momenta implies the impossibility of expressing C as a polynomial function of the other integrals, which are quadratic functions of momenta. Starting from the integral of motion C, we can construct the (nonindependent) integrals $\{A,C\}_P$ and $\{B,C\}_P$. These integrals are quartic functions of the momenta, i.e., functions of fourth order. Therefore these integrals could be expressed as quadratic combinations of the integrals H, A and B. Therefore the following relations are assumed to be valid:

$$\{A,C\}_P=\alpha A^2+\beta B^2+2\gamma AB+\delta A+\epsilon B+\zeta \tag{4}$$

and

$$\{B,C\}_P=aA^2+bB^2+2cAB+dA+eB+z. \tag{5}$$

By taking an appropriate linear combination of the integrals A and B, we can always consider the case $\beta=0$.

The Jacobi equality for the Poisson brackets induces the relation

$$\{A,\{B,C\}_P\}_P=\{B,\{A,C\}_P\}_P\,.$$

The following relations:

$$b=-\gamma,\quad c=-\alpha \text{ and } e=-\delta$$

must be satisfied.

The integrals A, B and C satisfy the quadratic Poisson algebra:

$$\{A,B\}_P=C,$$

$$\{A,C\}_P=\alpha A^2+2\gamma AB+\delta A+\epsilon B+\zeta, \tag{6}$$

$$\{B,C\}_P=aA^2-\gamma B^2-2\alpha AB+dA-\delta B+z,$$

where α, γ, a are constants and

$$\delta=\delta(H)=\delta_0+\delta_1 H,$$

$$\epsilon=\epsilon(H)=\epsilon_0+\epsilon_1 H,$$

$$\zeta=\zeta(H)=\zeta_0+\zeta_1 H+\zeta_2 H^2,$$

$$d=d(H)=d_0+d_1 H,$$

$$z=z(H)=z_0+z_1 H+z_2 H^2,$$

where δ_i, ϵ_i, ζ_i, d_i and z_i are constants. The associative algebra, whose the generators satisfy equations (6), is the general form of the closed Poisson algebra of the integrals of superintegrable systems with integrals quadratic in momenta.

The quadratic Poisson algebra (6) possess a Casimir which is a function of momenta of degree 6 and it is given by

$$\begin{aligned}K=&C^2-2\alpha A^2B-2\gamma AB^2-2\delta AB-\epsilon B^2-2\zeta B\\&+\frac{2}{3}aA^3+dA^2+2zA\\=&k_0+k_1H+k_2H^2+k_3H^3.\end{aligned}\tag{7}$$

Obviously

$$\{K,A\}_P=\{K,B\}_P=\{K,C\}_P=0.$$

Therefore the integrals of motion of a superintegrable two-dimensional system with quadratic integrals of motion close a constrained classical quadratic Poisson algebra (6), corresponding to a Casimir equal at most to a cubic function of the Hamiltonian (7).

In the general case of a superintegrable system the integrals are not necessarily quadratic functions of the momenta, but rather polynomial functions of the momenta. The case of the systems with a quadratic and a cubic integral of motion are recently studied by Tsiganov.[29] The general form of the Poisson algebra of generators A, B and C is characterized by a polynomial function $h(A,B)$, which satisfy the following equations:

$$\begin{aligned}\{A,B\}_P&=C,\\\{A,C\}_P&=\partial h/\partial B,\\\{B,C\}_P&=-\partial h/\partial A.\end{aligned}\tag{8}$$

The above general forms of the Poisson algebra were introduced by Kalnins, Miller and Pogosyan.[4] The Casimir of the algebra is given by

$$K=K(H)=C^2-2h(A,B),\quad \{K,A\}_P=\{K,B\}_P=0,\tag{9}$$

where $h(A,B)$ is a polynomial function of the integrals of motion A and B. These relations are also discussed in Ref. 4 in a slightly different context.

In the case of the quadratic Poisson algebra (6) the form of the function $h(A,B)$ is given by the equation

$$\begin{aligned}h(A,B)=&-\frac{a}{3}A^3+\alpha A^2B+\gamma AB^2\\&-\frac{d}{2}A^2+\delta AB+\frac{\epsilon}{2}B^2-zA+\zeta B.\end{aligned}$$

In the general case of a two-dimensional superintegrable system, with quadratic Hamiltonian, one integral A of order m in momenta and one integral B of order n $(n \geqslant m)$, the form of the function $h(A,B)$, in most cases, can be given by the general form

$$h(A,B)=h_0(A)+h_1(A)B+h_2(A)B^2,$$

where $h_i(A)$ are polynomials of the integrals A and H. The proof of this assumption is based on the dependence of the integrals of motion on the momenta. This is true almost for the potentials with a cubic integral of motion.

III. POISSON ALGEBRAS FOR SUPERINTEGRABLE SYSTEMS

Let us consider the superintegrable systems with quadratic integrals of motion, these potentials are given by several authors starting from different but comparable points of view. In Refs. 1, 2 the integrals of motion are generated by solving the Darboux conditions for the integrability of quadratic integrals. In Ref. 5 the Hamilton–Jacobi equation is solved by the separation of variables and the two-dimensional Hamiltonians which are separable in more than one coordinate system are obtained. The separation of variables is essential for solving the quantum counterpart of the superintegrable system and the solution of the associate Schrödinger equations is given in Ref. 9. Using this method the quantum superintegrable systems have been solved on the sphere[9] and the hyperboloid.[9,22] From a classical point of view the super integrable systems are given in Ref. 3, while the case of a pseudo Euclidean kinetic term has been studied in Ref. 2. The extension on the systems with a quadratic and a cubic integral of motion is sytematized in Ref. 29.

In this section we consider the case of superintegrable systems given in Ref. 9, because in the next sections we study the quantum counterparts of these potentials. The study of these cases has been extended in the complex flat space in Ref. 4.

In this paper the following superintegrable systems are considered.

Potential (i):

$$H=\frac{1}{2}\left(p_x^2+p_y^2+\omega^2 r^2+\frac{\mu_1}{x^2}+\frac{\mu_2}{y^2}\right).$$

This potential has the following independent integrals of motion:

$$A=p_x^2+\omega^2 x^2+\frac{\mu_1}{x^2}$$

and

$$B=(xp_y-yp_x)^2+r^2\left(\frac{\mu_1}{x^2}+\frac{\mu_2}{y^2}\right).$$

The constants, which characterize the corresponding quadratic algebra (6), are given by

$$\begin{array}{lll} \alpha=-8, & \gamma=0, & \delta=16H, \\ \epsilon=-16\omega^2, & \zeta=16(\mu_1+\mu_2)\omega^2, & \\ a=0, & d=0, & z=16(\mu_2-\mu_1)\omega^2, \end{array}$$

the value of the Casimir (7) is

$$K=-16((\mu_2-\mu_1)^2\omega^2+4\mu_1 H^2).$$

Potential (ii):

$$H=\frac{1}{2}\left(p_x^2+p_y^2+\omega^2(4x^2+y^2)+\frac{\mu}{y^2}\right).$$

This potential has the following independent integrals of motion:

$$A=p_x^2+4\omega^2x^2$$

and

$$B=(xp_y-yp_x)p_y+\frac{\mu x}{y^2}-\omega^2xy^2.$$

The constants, which characterize the corresponding quadratic algebra (6), are given by

$$\begin{aligned}&\alpha=0, \quad \gamma=0, \quad \delta=0,\\ &\epsilon=-16\omega^2, \quad \zeta=0,\\ &a=-6, \quad d=16H, \quad z=8\mu\omega^2-8H^2,\end{aligned}$$

the value of the Casimir (7) is

$$K=0.$$

Potential (iii):

$$H=\frac{1}{2}\left(p_x^2+p_y^2+\frac{k}{r}+\frac{1}{r}\left(\frac{\mu_1}{r+x}+\frac{\mu_2}{r-x}\right)\right).$$

This potential has the following independent integrals of motion:

$$A=(xp_y-yp_x)^2+r\left(\frac{\mu_1}{r+x}+\frac{\mu_2}{r-x}\right)$$

and

$$B=(xp_y-yp_x)p_y-\frac{\mu_1}{2r}\frac{r-x}{r+x}+\frac{\mu_2}{2r}\frac{r+x}{r-x}+\frac{kx}{2r}.$$

The constants, which characterize the corresponding quadratic algebra (6), are given by

$$\begin{aligned}&\alpha=0, \quad \gamma=0, \quad \delta=0,\\ &\epsilon=0, \quad \zeta=-\mu_1\mu_2/2,\\ &a=0, \quad d=-2H, \quad z=4\frac{\mu_1^2-\mu_2^2}{4},\end{aligned}$$

the value of the Casimir (7) is

$$K=2(\mu_1-\mu_2)^2H-k^2(\mu_1+\mu_2).$$

Potential (iv):

$$H=\frac{1}{2}\left(p_x^2+p_y^2+\frac{k}{r}+\mu_1\frac{\sqrt{r+x}}{r}+\mu_2\frac{\sqrt{r-x}}{r}\right).$$

This potential has the following independent integrals of motion:

$$A=(yp_x-xp_y)p_y+\frac{\mu_1(r-x)\sqrt{r+x}}{2r}-\frac{\mu_2(r+x)\sqrt{r-x}}{2r}-\frac{kx}{2r}$$

and

$$B=(xp_y-yp_x)p_x-\frac{\mu_1 x\sqrt{r-x}}{2r}+\frac{\mu_2 x\sqrt{r+x}}{2r}-\frac{ky}{2r}.$$

The constants, which characterize the corresponding quadratic algebra (6), are given by

$$\alpha=0,\qquad \gamma=0,\qquad \delta=0,$$
$$\epsilon=2H,\quad \zeta=-\mu_1\mu_2/2,$$
$$a=0,\qquad d=-2H,\qquad z=\frac{\mu_1^2-\mu_2^2}{4},$$

the value of the Casimir (7) is

$$K=-k^2H/2-k(\mu_1^2+\mu_2^2)/4.$$

IV. THE QUADRATIC ASSOCIATIVE ALGEBRA

The quantum counterparts of the classical systems, which have been studied in Sec. II, are quantum superintegrable systems. The quadratic classical Poisson algebra (6) possesses a quantum counterpart, which is a quadratic associative algebra of operators. The form of the quadratic algebra is similar to the classical Poisson algebra, the involved constants are generally functions of $\hbar$ and they should coincide with the classical constants in the case $\hbar\to 0$. Let us consider the quadratic associative algebra generated by the generators $\{A, B, C\}$, which satisfy the commutation relations,

$$[A,B]=C,$$
$$[A,C]=\alpha A^2+\beta B^2+\gamma\{A,B\}+\delta A+\epsilon B+\zeta, \tag{10}$$
$$[B,C]=aA^2+bB^2+c\{A,B\}+dA+eB+z.$$

After rotating the generators A and B, we can always consider the case $\beta=0$.

The Jacobi equality for the commutator induces the relation

$$[A,[B,C]]=[B,[A,C]],$$

the following relations:

$$b=-\gamma,\quad c=-\alpha\quad\text{and}\quad e=-\delta,$$

must be satisfied, and consequently the general form of the quadratic algebra (10) can be explicitly written as follows:

$$[A,B]=C, \tag{11}$$
$$[A,C]=\alpha A^2+\gamma\{A,B\}+\delta A+\epsilon B+\zeta, \tag{12}$$
$$[B,C]=aA^2-\gamma B^2-\alpha\{A,B\}+dA-\delta B+z. \tag{13}$$

The Casimir of this algebra is given by

$$K=C^2-\alpha\{A^2,B\}-\gamma\{A,B^2\}+(\alpha\gamma-\delta)\{A,B\}+(\gamma^2-\epsilon)B^2+(\gamma\delta-2\zeta)B+\frac{2a}{3}A^3+\left(d+\frac{a\gamma}{3}+\alpha^2\right)A^2+\left(\frac{a\epsilon}{3}+\alpha\delta+2z\right)A, \tag{14}$$

another useful form of the Casimir of the algebra is given by

$$K=C^2+\frac{2a}{3}A^3-\frac{\alpha}{3}\{A,A,B\}-\frac{\gamma}{3}\{A,B,B\}+\left(\frac{2\alpha^2}{3}+d+\frac{2a\gamma}{3}\right)A^2+\left(-\epsilon+\frac{2\gamma^2}{3}\right)B^2+\left(-\delta+\frac{a\gamma}{3}\right)\{A,B\}+\left(\frac{2\alpha\delta}{3}+\frac{a\epsilon}{3}+\frac{d\gamma}{3}+2z\right)A+\left(-\frac{\alpha\epsilon}{3}+\frac{2\delta\gamma}{3}-2\zeta\right)B+\frac{\gamma z}{3}-\frac{\alpha\zeta}{3}, \tag{15}$$

where

$$\{A,B,C\}=ABC+ACB+BAC+BCA+CAB+CBA.$$

This quadratic algebra has many similarities to the Racah algebra $QR(3)$, which is a special case of the Askey–Wilson algebra $QAW(3)$. The algebra (11)–(13) does not coincide with the Racah algebra $QR(3)$, if $a\neq 0$ in the relation (13). A representation theory can be constructed by following the same procedures as they were described by Granovskii, Lutzenko and Zhedanov in Refs. 13, 18, 19. In this paper we shall give another realization of this algebra using the deformed oscillator techniques.[27] The finite-dimensional representations of the algebra (10) will be constructed by constructing a realization of the algebra with the generalized parafermionic algebra introduced by Quesne.[28]

V. DEFORMED PARAFERMIONIC ALGEBRA

Let us now consider a realization of the algebra (11)–(13), by using the deformed oscillator technique, i.e., by using a deformed oscillator algebra[27] $\{b^\dagger,b,\mathcal{N}\}$, which satisfies the

$$[\mathcal{N},b^\dagger]=b^\dagger,\quad [\mathcal{N},b]=-b,\quad b^\dagger b=\Phi(\mathcal{N}),\quad bb^\dagger=\Phi(\mathcal{N}+1), \tag{16}$$

where the function $\Phi(x)$ is a ''well behaved'' real function which satisfies the boundary condition

$$\Phi(0)=0,\ \text{and}\ \Phi(x)>0,\quad \text{for}\ x>0. \tag{17}$$

As it is well known[27] this constraint imposes the existence a Fock type representation of the deformed oscillator algebra, i.e., there is a Fock basis $|n>$, $n=0,1,\ldots$, such that

$$\mathcal{N}|n\rangle=n|n\rangle,$$

$$b^\dagger|n\rangle=\sqrt{\Phi(n+1)}|n+1\rangle,\quad n=0,1,\ldots,$$

$$b|0\rangle=0,$$

$$b|n\rangle=\sqrt{\Phi(n)}|n-1\rangle,\quad n=1,2,\ldots.$$

The generalized deformed algebra given in Ref. 27 is equivalent to several deformed oscillator schemes as the Odaka–Kishi–Kamefuchi unification scheme,[30] the Beckers–Debergh unification scheme,[31] The Fibonacci oscillator,[32] for a discussion of deformation schemes see Ref. 33.

In the case of nilpotent deformed oscillator algebras, there is a positive integer p, such that

$$b^{p+1}=0,\ (b^{\dagger})^{p+1}=0;$$

the above equations imply that

$$\Phi(p+1)=0. \tag{19}$$

In that case the deformed oscillator (16) has a finite-dimensional representation, with dimension equal to $p+1$, these kinds of oscillators are called deformed parafermion oscillators of order p.

An interesting property of the deformed parafermionic algebra is that the existence of a faithful finite-dimensional representation of the algebra implies that

$$\mathcal{N}(\mathcal{N}-1)(\mathcal{N}-2)\cdots(\mathcal{N}-p)=0. \tag{20}$$

The above restriction and the constraints (17) and (19) imply that the general form of the structure function $\Phi(\mathcal{N})$ has the general form[28]

$$\Phi(\mathcal{N})=\mathcal{N}(p+1-\mathcal{N})(a_0+a_1\mathcal{N}+a_2\mathcal{N}^2+\cdots a_{p-1}\mathcal{N}^{p-1}).$$

A systematic study and applications of the parafermionic oscillator is given in references Refs. 28, 34–36.

We shall show that there is a realization of the quadratic algebra, such that

$$A=A(\mathcal{N}), \tag{21}$$

$$B=b(\mathcal{N})+b^{\dagger}\rho(\mathcal{N})+\rho(\mathcal{N})b, \tag{22}$$

where the $A(x)$, $b(x)$ and $\rho(x)$ are functions, which will be determined. In that case (11) implies

$$C=[A,B]\Rightarrow C=b^{\dagger}\Delta A(\mathcal{N})\rho(\mathcal{N})-\rho(\mathcal{N})\Delta A(\mathcal{N})b, \tag{23}$$

where

$$\Delta A(\mathcal{N})=A(\mathcal{N}+1)-A(\mathcal{N}).$$

Using Eqs. (21), (22) and (12) we find

$$\begin{aligned}
[A,C]&=[A(\mathcal{N}),b^{\dagger}\Delta A(\mathcal{N})\rho(\mathcal{N})-\rho(\mathcal{N})\Delta A(\mathcal{N})b]\\
&=b^{\dagger}(\Delta A(\mathcal{N}))^2\rho(\mathcal{N})+\rho(\mathcal{N})(\Delta A(\mathcal{N}))^2b\\
&=\alpha A^2+\gamma\{A,B\}+\delta A+\epsilon B+\zeta\\
&=b^{\dagger}(\gamma(A(\mathcal{N}+1)+A(\mathcal{N}))+\epsilon)\rho(\mathcal{N})\\
&\quad+\rho(\mathcal{N})(\gamma(A(\mathcal{N}+1)+A(\mathcal{N}))+\epsilon)b\\
&\quad+\alpha A(\mathcal{N})^2+2\gamma A(\mathcal{N})b(\mathcal{N})+\delta A(\mathcal{N})+\epsilon B(\mathcal{N})+\zeta;
\end{aligned} \tag{24}$$

therefore we have the following relations:

$$(\Delta A(\mathcal{N}))^2=\gamma(A(\mathcal{N}+1)+A(\mathcal{N}))+\epsilon, \tag{25}$$

$$\alpha A(\mathcal{N})^2+2\gamma A(\mathcal{N})b(\mathcal{N})+\delta A(\mathcal{N})+\epsilon b(\mathcal{N})+\zeta=0, \tag{26}$$

while the function $\rho(\mathcal{N})$ can be arbitrarily determined. In fact this function can be fixed, in order to have a polynomial structure function $\Phi(x)$ for the deformed oscillator algebra (16).

The solutions of equation (25) depend on the value of the parameter γ, while the function $b(\mathcal{N})$ is uniquely determined by Eq. (26) (provided that almost one of the parameters γ or ϵ is not zero). At this stage, the cases $\gamma\neq 0$ or $\gamma=0$ should be treated separately. We can see the following.

Case 1: $\gamma\neq 0$

In that case the solutions of Eqs. (25) and (26) are given by

$$A(\mathcal{N})=\frac{\gamma}{2}\left((\mathcal{N}+u)^2-1/4-\frac{\epsilon}{\gamma^2}\right), \tag{27}$$

$$b(\mathcal{N})=-\frac{\alpha((\mathcal{N}+u)^2-1/4)}{4}+\frac{\alpha\epsilon-\delta\gamma}{2\gamma^2} -\frac{\alpha\epsilon^2-2\delta\epsilon\gamma+4\gamma^2\zeta}{4\gamma^4}\frac{1}{((\mathcal{N}+u)^2-1/4)}. \tag{28}$$

Case 2: $\gamma=0$, $\epsilon\neq 0$

The solutions of Eqs. (25) and (26) are given by

$$A(\mathcal{N})=\sqrt{\epsilon}(\mathcal{N}+u), \tag{29}$$

$$b(\mathcal{N})=-\alpha(\mathcal{N}+u)^2-\frac{\delta}{\sqrt{\epsilon}}(\mathcal{N}+u)-\frac{\zeta}{\epsilon}. \tag{30}$$

The constant u will be determined later.

Using the above definitions of equations $A(\mathcal{N})$ and $b(\mathcal{N})$, the left hand side and right hand side of Eq. (13) give the following equation:

$$\begin{aligned}&2\Phi(\mathcal{N}+1)\left(\Delta A(\mathcal{N})+\frac{\gamma}{2}\right)\rho(\mathcal{N})-2\Phi(\mathcal{N})\left(\Delta A(\mathcal{N}-1)-\frac{\gamma}{2}\right)\rho(\mathcal{N}-1)\\ &\quad=aA^2(\mathcal{N})-\gamma b^2(\mathcal{N})-2\alpha A(\mathcal{N})b(\mathcal{N})+dA(\mathcal{N})-\delta b(\mathcal{N})+z.\end{aligned} \tag{31}$$

Equation (14) gives the following relation:

$$\begin{aligned}K=&\Phi(\mathcal{N}+1)(\gamma^2-\epsilon-2\gamma A(\mathcal{N})-\Delta A^2(\mathcal{N}))\rho(\mathcal{N})\\ &+\Phi(\mathcal{N})(\gamma^2-\epsilon-2\gamma A(\mathcal{N})-\Delta A^2(\mathcal{N}-1))\rho(\mathcal{N}-1)-2\alpha A^2(\mathcal{N})b(\mathcal{N})\\ &+(\gamma^2-\epsilon-2\gamma A(\mathcal{N}))b^2(\mathcal{N})+2(\alpha\gamma-\delta)A(\mathcal{N})b(\mathcal{N})+(\gamma\delta-2\zeta)b(\mathcal{N})\\ &+\tfrac{2}{3}aA^3(\mathcal{N})+(d+\tfrac{1}{3}a\gamma+\alpha^2)A^2(\mathcal{N})+(\tfrac{1}{3}a\epsilon+\alpha\delta+2z)A(\mathcal{N}).\end{aligned} \tag{32}$$

Equations (31) and (32) are linear functions of the expressions $\Phi(\mathcal{N})$ and $\Phi(\mathcal{N}+1)$; then the function $\Phi(\mathcal{N})$ can be determined, if the function $\rho(\mathcal{N})$ is given. The solution of this system, i.e., the function $\Phi(\mathcal{N})$ depends on two parameters u and K and it is given by the following formulas.

Case 1: $\gamma\neq 0$

$$\rho(\mathcal{N})=\frac{1}{3\cdot 2^{12}\cdot\gamma^8(\mathcal{N}+u)(1+\mathcal{N}+u)(1+2(\mathcal{N}+u))^2}$$

and

$$\Phi(\mathcal{N}) = -3072\gamma^6 K(-1+2(\mathcal{N}+u))^2$$
$$-48\gamma^6(\alpha^2\epsilon-\alpha\delta\gamma+a\epsilon\gamma-d\gamma^2)\cdot(-3+2(\mathcal{N}+u))(-1+2(\mathcal{N}+u))^4(1+2(\mathcal{N}+u))$$
$$+\gamma^8(3\alpha^2+4a\gamma)(-3+2(\mathcal{N}+u))^2(-1+2(\mathcal{N}+u))^4(1+2(\mathcal{N}+u))^2$$
$$+768(\alpha\epsilon^2-2\delta\epsilon\gamma+4\gamma^2\zeta)^2+32\gamma^4(-1+2(\mathcal{N}+u))^2(-1-12(\mathcal{N}+u)$$
$$+12(\mathcal{N}+u)^2)\cdot(3\alpha^2\epsilon^2-6\alpha\delta\epsilon\gamma+2a\epsilon^2\gamma+2\delta^2\gamma^2-4d\epsilon\gamma^2+8\gamma^3 z+4\alpha\gamma^2\zeta)$$
$$-256\gamma^2(-1+2(\mathcal{N}+u))^2\cdot(3\alpha^2\epsilon^3-9\alpha\delta\epsilon^2\gamma+a\epsilon^3\gamma+6\delta^2\epsilon\gamma^2-3d\epsilon^2\gamma^2$$
$$+2\delta^2\gamma^4+2d\epsilon\gamma^4+12\epsilon\gamma^3 z-4\gamma^5 z+12\alpha\epsilon\gamma^2\zeta-12\delta\gamma^3\zeta+4\alpha\gamma^4\zeta). \tag{33}$$

Case 2: $\gamma=0$, $\epsilon\neq 0$

$$\rho(\mathcal{N})=1,$$

$$\Phi(\mathcal{N}) = \frac{1}{4}\left(-\frac{K}{\epsilon}-\frac{z}{\sqrt{\epsilon}}-\frac{\delta}{\sqrt{\epsilon}}\frac{\zeta}{\epsilon}+\frac{\zeta^2}{\epsilon^2}\right)$$
$$-\frac{1}{12}\left(3d-a\sqrt{\epsilon}-3\alpha\frac{\delta}{\sqrt{\epsilon}}+3\left(\frac{\delta}{\sqrt{\epsilon}}\right)^2-6\frac{z}{\sqrt{\epsilon}}+6\alpha\frac{\zeta}{\epsilon}-6\frac{\delta}{\sqrt{\epsilon}}\frac{\zeta}{\epsilon}\right)(\mathcal{N}+u)$$
$$+\frac{1}{4}\left(\alpha^2+d-a\sqrt{\epsilon}-3\alpha\frac{\delta}{\sqrt{\epsilon}}+\left(\frac{\delta}{\sqrt{\epsilon}}\right)^2+2\alpha\frac{\zeta}{\epsilon}\right)(\mathcal{N}+u)^2$$
$$-\frac{1}{6}\left(3\alpha^2-a\sqrt{\epsilon}-3\alpha\frac{\delta}{\sqrt{\epsilon}}\right)(\mathcal{N}+u)^3+\frac{1}{4}\alpha^2(\mathcal{N}+u)^4. \tag{34}$$

The above formula is valid for $\epsilon>0$.

VI. FINITE-DIMENSIONAL REPRESENTATIONS OF QUADRATIC ALGEBRAS

Let us consider a representation of the quadratic algebra, which is diagonal to the generator A and the Casimir K. Using the parafermionic realization defined by Eqs. (21) and (22), we see that is this a representation diagonal to the parafermionic number operator $\mathcal{N}$ and the Casimir K. The basis of a such representation corresponds to the Fock basis of the parafermionic oscillator, i.e., the vectors $|k, n>$, $n=0,1,\ldots$, of the carrier Fock space satisfy the equations

$$\mathcal{N}|k,n\rangle = n|k,n\rangle, \quad K|k,n\rangle = k|k,n\rangle .$$

The structure function (33) [or, respectively, (33)] depend on the eigenvalues of the of the parafermionic number operator $\mathcal{N}$ and the Casimir K. The vectors $|k,n\rangle$ are also eigenvectors of the generator A, i.e.,

$$A|k,n\rangle = A(k,n)|k,n\rangle.$$

In the case $\gamma\neq 0$ we find from Eq. (27),

$$A(k,n)=\frac{\gamma}{2}\left((n+u)^2-1/4-\frac{\epsilon}{\gamma^2}\right).$$

In the case $\gamma=0$, $\epsilon\neq 0$ we find from Eq. (29),

$$A(k,n)=\sqrt{\epsilon}(n+u).$$

If the deformed oscillator corresponds to a deformed parafermionic oscillator of order p then the two parameters of the calculation k and u should satisfy the constraints (17) and (19) of the system:

$$\Phi(0,u,k)=0,$$
$$\Phi(p+1,u,k)=0; \tag{35}$$

then the parameter $u=u(k,p)$ is a solution of the system of Eqs. (35).

Generally there are many solutions of the above system, but a unitary representation of the deformed parafermionic oscillator is restrained by the additional restriction

$$\Phi(x)>0, \text{ for } x=1,2,\ldots,p\ .$$

We must point out that the system (35) corresponds to a representation with dimension equal to $p+1$.

The proposed method of calculation of the representation of the quadratic algebra is an alternative to the method given by Granovskii *et al.*[13,18–20] and reduces the search of the representations to the solution of a system of polynomial equations (35). Also it is applied to an algebra not included in the cases of the algebras, which are treated in the above references. We must point out, that there are several papers on the representations of quadratic (or generally polynomial algebras),[37–43] these algebras are deformations of the su(2) or osp(1/2) algebras. The general form of the quadratic algebra, which is studied in this paper, is different by definition from the deformed versions of su(2) or osp(1/2).

VII. QUADRATIC ALGEBRAS FOR THE QUANTUM SUPERINTEGRABLE SYSTEMS

In this section, we shall give an example of the calculation of eigenvalues of a superintegrable two-dimensional system, by using the methods of the previous section. The calculation by an empirical method was performed in Ref. 8 and the solution of the same problem by using the separation of variables was studied in Ref. 9. Here in order to show the effects of the quantization procedure we do not use $\hbar=1$ as considered in Refs. 8 and 9. That means that the following commutation relations are taken into consideration:

$$[x,p_x]=i\hbar, \quad [y,p_y]=i\hbar.$$

A. Potential (i)

$$H=\frac{1}{2}\left(p_x^2+p_y^2+\omega^2r^2+\frac{\mu_1}{x^2}+\frac{\mu_2}{y^2}\right).$$

This potential has the following independent integrals of motion:

$$A=p_x^2+\omega^2x^2+\frac{\mu_1}{x^2}$$

and

$$B=(xp_y-yp_x)^2+r^2\left(\frac{\mu_1}{x^2}+\frac{\mu_2}{y^2}\right).$$

The constants, which characterize the corresponding quadratic algebra (10), are given by

$$\alpha=8\hbar^2, \qquad \gamma=0, \qquad \delta=-16h^2H,$$
$$\epsilon=16\hbar^2\omega^2, \quad \zeta=-16\hbar^2(\mu_1+\mu_2)\omega^2+8\hbar^4\omega^2,$$
$$a=0, \qquad d=16\hbar^4, \qquad z=-16\hbar^2(\mu_2-\mu_1)\omega^2-16\hbar^4H;$$

the value of the Casimir (14) is

$$K=16\hbar^2((\mu_2-\mu_1)^2\omega^2+4\mu_1H^2)-16\hbar^4(3H^2+2\hbar^2\omega^2-2(\mu_1+\mu_2)).$$

For simplicity reasons we introduce the positive parameters k_1 and k_1, which are related to the potential parameters μ_1 and μ_2 by the relations

$$\mu_1=(k_1^2-\tfrac{1}{4})\hbar^2, \quad \mu_2=(k_2^2-\tfrac{1}{4})\hbar^2.$$

This quadratic algebra corresponds to the case $\gamma=0$ and $\epsilon>0$ of the algebra given by Eqs. (11)–(13). In that case, the structure function (34) of the deformed parafermionic algebra of Sec. V can be given by the simple form

$$\Phi(x)=16\hbar^4\left(x+u-\frac{1}{2}-\frac{k_1}{2}\right)\left(x+u-\frac{1}{2}+\frac{k_1}{2}\right)$$
$$\times\left(x+u-\frac{1}{2}-\frac{k_2}{2}-\frac{E}{2\hbar\omega}\right)\left(x+u-\frac{1}{2}+\frac{k_2}{2}-\frac{E}{2\hbar\omega}\right).$$

In the above formula E is the eigenvalue of the energy. The values of the parameters u and E corresponding to the representation of the parafermionic algebra of dimension $p+1$ are determined by the restrictions (35), which are transcribed as

$$\Phi(0)=0, \quad \Phi(p+1)=0.$$

One should notice that only the solutions which correspond to positive eigenvalues of the integral A must be retained. The acceptable solutions are four and correspond to the following values of the parameters u and E:

$$u=\frac{1}{2}+\frac{\epsilon_1k_1}{2}, \quad E=2\hbar\omega\left(p+1+\frac{\epsilon_1k_1+\epsilon_2k_2}{2}\right),$$

where $\epsilon_i=\pm1$. The corresponding structure function is

$$\Phi(x)=16\hbar^4x(p+1-x)(x+\epsilon_1k_1)(p+1-x+\epsilon_2k_2).$$

The corresponding eigenvalues of the operator A are given by

$$A(m)=4\hbar\omega\left(m+\frac{1+\epsilon_1k_1}{2}\right), \quad m=0,1,\ldots,p.$$

The structure function $\Phi(x)$ should be a positive function, for $x=1,2,\ldots,p$ therefore the constants k_i are restricted by the relations

$$\epsilon_1k_1>-1, \quad \epsilon_2k_2>-1.$$

B. Potential (ii)

$$H=\frac{1}{2}\left(p_x^2+p_y^2+\omega^2(4x^2+y^2)+\frac{\mu}{y^2}\right).$$

This potential has the following independent integrals of motion:

$$A=p_x^2+4\omega^2x^2$$

and

$$B=\frac{1}{2}\{xp_y-yp_x,p_y\}+\frac{\mu x}{y^2}-\omega^2xy^2.$$

The constants, which characterize the corresponding quadratic algebra (10), are given by

$$\begin{aligned}&\alpha=0, && \gamma=0, && \delta=0,\\ &\epsilon=16\hbar^2\omega^2, && \zeta=0, &&\\ &a=6\hbar^2, && d=-16\hbar^2H, && z=-8\hbar^2(\mu\omega^2-H^2)+6\hbar^4\omega^2;\end{aligned}$$

the value of the Casimir (14) is

$$K=64\hbar^4\omega^2H.$$

For simplicity reasons we introduce the positive parameter k, which is related to the potential parameter μ by the relation

$$\mu=(k^2-\tfrac{1}{4})\hbar^2.$$

This quadratic algebra corresponds to the case $\gamma=0$ and $\epsilon>0$ of the algebra given by Eqs. (11)–(13). In that case, the structure function (34) of the deformed parafermionic algebra of Sec. V can be given by the simple form

$$\Phi(x)=8\hbar^3\omega\left(x+u-\frac{1}{2}\right)\left(x+u-\frac{1}{2}-\frac{k}{2}-\frac{E}{2\hbar\omega}\right)\left(x+u-\frac{1}{2}+\frac{k}{2}-\frac{E}{2\hbar\omega}\right).$$

In the above formula E is the eigenvalue of the energy. The values of the parameters u and E corresponding to the representation of the parafermionic algebra of dimension $p+1$ are determined by the restrictions (35), which are transcribed as

$$\Phi(0)=0, \quad \Phi(p+1)=0.$$

One should notice that only the solutions which correspond to positive eigenvalues of the integral A must be retained. The acceptable solutions are four and correspond to the following values of the parameters u and E:

$$u=\frac{1}{2}, \quad E=2\hbar\omega\left(p+1+\frac{\epsilon k}{2}\hbar\right),$$

where $\epsilon=\pm1$. The corresponding structure function is

$$\Phi(x)=4\hbar^3x(p+1-x)(p+1-x+\epsilon k).$$

The structure function should be a positive function; therefore the values of the parameter k are restrained by

$$\epsilon k > -1.$$

The eigenvalues of the operator A are given by

$$A(m) = 4\hbar\omega(m + \tfrac{1}{2}), \quad m = 0,1,\ldots,p.$$

C. Potential (iii)

$$H = \frac{1}{2}\left(p_x^2 + p_y^2 + \frac{k}{r} + \frac{1}{r}\left(\frac{\mu_1}{r+x} + \frac{\mu_2}{r-x} \right) \right).$$

In Ref. 9 the parabolic coordinates have been used:

$$\begin{aligned} x &= \frac{1}{2}(\xi^2 - \eta^2), \quad & p_x &= \frac{\xi}{\xi^2+\eta^2} p_\xi - \frac{\eta}{\xi^2+\eta^2} p_\eta, \\ y &= \xi\eta, & p_y &= \frac{\eta}{\xi^2+\eta^2} p_\xi + \frac{\xi}{\xi^2+\eta^2} p_\eta, \\ [\xi, p_\xi] &= i\hbar, & [\eta, p_\eta] &= i\hbar. \end{aligned}$$

For comparison reasons we quote all the relations in both cartesian and parabolic systems, so

$$H = \frac{1}{\xi^2+\eta^2}\left(\frac{1}{2}(p_\xi^2 + p_\eta^2) + k + \frac{\mu_1}{\xi^2} + \frac{\mu_2}{\eta^2} \right).$$

This potential has the following independent integrals of motion:

$$\begin{aligned} A &= (xp_y - yp_x)^2 + r\left(\frac{\mu_1}{r+x} + \frac{\mu_1}{r-x} \right) \\ &= \frac{1}{2}\left(\frac{1}{2}(\eta p_\xi - \xi p_\eta)^2 + (\xi^2+\eta^2)\left(\frac{\mu_1}{\xi^2} + \frac{\mu_2}{\eta^2} \right) \right). \end{aligned}$$

and

$$\begin{aligned} B &= \frac{1}{2}\left(\{xp_y - yp_x, p_y\} - \frac{\mu_1}{r}\frac{r-x}{r+x} + \frac{\mu_2}{r}\frac{r+x}{r-x} + \frac{kx}{r} \right) \\ &= \frac{1}{\xi^2+\eta^2}\left(\frac{1}{2}(\xi^2 p_\eta^2 - \eta^2 p_\xi^2) + \mu_2\frac{\xi^2}{\eta^2} - \mu_1\frac{\eta^2}{\xi^2} + \frac{k}{2}\frac{\xi^2-\eta^2}{\xi^2+\eta^2} \right). \end{aligned}$$

The constants, which characterize the corresponding quadratic algebra (10), are given by

$$\begin{aligned} &\alpha = 0, && \gamma = 2\hbar^2, && \delta = 0, \\ &\epsilon = -\hbar^4, && \zeta = -\hbar^2 k(\mu_1 - \mu_2), && \\ &a = 0, && d = 8\hbar^2 H, && z = -\hbar^2(4(\mu_1+\mu_2)H - k^2/2) + \hbar^4 H; \end{aligned}$$

the value of the Casimir (14) is

$$K = -\hbar^2(2(\mu_1-\mu_2)^2 H - k^2(\mu_1+\mu_2)) - 2\hbar^4\left((\mu_1+\mu_2)H - \frac{k^2}{4} \right) + \hbar^6 H.$$

For simplicity reasons we introduce the positive parameters k_1 and k_1, which are related to the potential parameters μ_1 and μ_2 by the relations

$$\mu_1=\frac{\hbar^2}{2}\left(k_1^2-\frac{1}{4}\right),\quad \mu_2=\frac{\hbar^2}{2}\left(k_2^2-\frac{1}{4}\right).$$

This quadratic algebra corresponds to the case $\gamma\neq 0$ of the algebra given by Eqs. (11)–(13). In that case, the structure function (33) of the deformed parafermionic algebra of Sec. V can be given by the simple form

$$\Phi(x)=3\cdot 2^{14}\hbar^{16}(2x-1+k_1+k_2)(2x-1+k_1-k_2)(2x-1-k_1+k_2)$$
$$\cdot(2x-1-k_1-k_2)(8\hbar^2Hx^2-8\hbar^2Hx+2\hbar^2H+k^2)$$

In the above formula E is the eigenvalue of the energy. The values of the parameters u and E corresponding to the representation of the parafermionic algebra of dimension $p+1$ are determined by the restrictions (35), which are transcribed as

$$\Phi(0)=0,\quad \Phi(p+1)=0.$$

One should notice, that only the solutions which correspond to positive eigenvalues of the integral A must be retained. The acceptable solutions are four and correspond to the following values of the parameters u and E:

$$u=\frac{1}{2}(2+\epsilon_1k_1+\epsilon_2k_2),\quad E=-\frac{k^2}{2\hbar^2(2(p+1)+\epsilon_1k_1+\epsilon_2k_2)^2},$$

where $\epsilon_i=\pm 1$. The corresponding structure function is

$$\Phi(x)=3\cdot 2^{20}\cdot k^2\hbar^{16}\cdot x(p+1-x)(x+\epsilon_1k_1)(x+\epsilon_2k_2)\cdot(x+\epsilon_1k_1+\epsilon_2k_2)$$
$$\times\frac{(x+p+1+\epsilon_1k_1+\epsilon_2k_2)}{(2(p+1)+\epsilon_1k_1+\epsilon_2k_2)^2}.$$

The eigenvalues of the operator A are given by the formula

$$A(m)=\hbar^2\left(m+\epsilon_1k_1+\epsilon_2k_2+\frac{3}{2}\right)^2,\quad m=0,1,\ldots,p.$$

The positive sign of the structure function for $x=1,2,\ldots,p$ is obtained when

$$\epsilon_1k_1>-1,\quad \epsilon_2k_2>-1\quad\text{and}\quad \epsilon_1k_1+\epsilon_2k_2>-1.$$

D. Potential (iv)

$$H=\frac{1}{2}\left(p_x^2+p_y^2+\frac{k}{r}+\mu_1\frac{\sqrt{r+x}}{r}+\mu_2\frac{\sqrt{r-x}}{r}\right)$$

$$=\frac{1}{\xi^2+\eta^2}\left(\frac{1}{2}(p_\xi^2+p_\eta^2)+k+\mu_1\xi+\mu_2\eta\right).$$

This potential has the following independent integrals of motion:

$$A=\frac{1}{2}\left(\{(yp_x-xp_y),p_y\}+\frac{\mu_1(r-x)\sqrt{r+x}}{r}-\frac{\mu_2(r+x)\sqrt{r-x}}{r}-\frac{kx}{r}\right)$$

$$=\frac{1}{2(\xi^2+\eta^2)}(\eta^2p_\xi^2-\xi^2p_\eta^2+k(\eta^2-\xi^2)+2\xi\eta(\mu_1\eta-\mu_2\xi))$$

and

$$B=\frac{1}{2}\left(\{xp_y-yp_x,p_x\}-\frac{\mu_1 x\sqrt{r-x}}{r}+\frac{\mu_2 x\sqrt{r+x}}{r}-\frac{ky}{r}\right)$$

$$=-\frac{1}{2(\xi^2+\eta^2)}(\xi\eta(p_\xi^2+p_\eta^2)-(\xi^2+\eta^2)p_\xi p_\eta+2k\xi\eta$$
$$+(\mu_2\xi-\mu_1\eta)(\eta^2-\xi^2)).$$

The constants, which characterize the corresponding quadratic algebra (10), are given by

$$\alpha=0,\quad \gamma=0,\quad \delta=0,$$
$$\epsilon=-2\hbar^2H,\quad \zeta=\hbar^2\mu_1\mu_2/2,$$
$$a=0,\quad d=2\hbar^2H,\quad z=-\hbar^2(\mu_1^2-\mu_2^2)/4,$$

the value of the Casimir (14) is

$$K=\hbar^2k^2H/2+\hbar^2k(\mu_1^2+\mu_2^2)/4+\hbar^4H^2.$$

This quadratic algebra corresponds to the case $\gamma=0$ and $\epsilon>0$ of the algebra given by Eqs. (11)–(13). It is worth noticing that algebra is extremely simple, which can be reduced to the usual $su(2)$. We prefer to treat this algebra with the proposed methods in this paper for pedagogical reasons. The existence of the finite-dimensional representations of this algebra implies that the coefficient ϵ in Eq. (12) should be positive, therefore the energy operator H must have energy eigenvalues $E<0$. For simplicity reasons we introduce the new parameters:

$$\varepsilon=\sqrt{-2E}/\hbar,\quad \lambda=k/\hbar^2,$$

$$\nu_1=\mu_1/\hbar^2,\quad \nu_2=\mu_2/\hbar^2,\quad \nu^2=\nu_1^2+\nu_2^2.$$

The structure function (34) of the deformed parafermionic algebra of Sec. V can be given by the form

$$\Phi(x)=\frac{\hbar^4}{16\varepsilon^4}\left(\nu_1^2-\lambda\varepsilon^2+2\left(x+u-\frac{1}{2}\right)\varepsilon^3\right)\left(\nu_2^2-\lambda\varepsilon^2-2\left(x+u-\frac{1}{2}\right)\varepsilon^3\right).$$

In the above formula the parameter ε is related to the the eigenvalue E of the energy. The values of the parameters u and ε, corresponding to the representation of the parafermionic algebra of dimension $p+1$, are determined by the restrictions (35), which are transcribed as

$$\Phi(0)=0,\quad \Phi(p+1)=0.$$

The first condition can be used for determining the acceptable values of the parameter u. Two possible solutions are found:

$$u=u_1=\frac{\nu_2^2-\lambda\varepsilon^2+\varepsilon^3}{2\varepsilon^3},\tag{36}$$

$$u=u_2=-\frac{\nu_1^2-\lambda\varepsilon^2-\varepsilon^3}{2\varepsilon^3}.\tag{37}$$

Using these solutions and the condition $\Phi(p+1)=0$, we find that ε must satisfy two possible cubic equations:

$$u_1 \to 2(p+1)\varepsilon^3 - 2\lambda\varepsilon^2 + \nu^2 = 0, \tag{38}$$

$$u_2 \to 2(p+1)\varepsilon^3 + 2\lambda\varepsilon^2 - \nu^2 = 0. \tag{39}$$

If ε is a solution of Eq. (38) then $-\varepsilon$ is the solution of the other equation (39); therefore there is at least one solution which is positive. This solution leads to the structure function

$$\Phi(x) = \frac{\varepsilon^2}{4} x(p+1-x),$$

which is positive for $x = 1,2,\ldots,p$.

VIII. DISCUSSION

If we compare the quadratic associative algebra, introduced in Sec. IV with the corresponding Poisson algebra given in Sec. II, we see that in general, the quantum constants are similar to the classical ones up to a factor equal to $-h^2$, but there are quantum corrections of order h^4 and h^6. The knowledge of the classical constants of the Poisson algebra is not sufficient to reproduce the rules of quantum associative operator algebra. Therefore, the passage from the classic Poisson algebra to the noncommutative quantum algebra cannot be realized by simple replacements of the Poisson brackets by commutators and by a symmetrization procedure.

The energy eigenvalues of Sec. VII corroborate the results of Ref. 9 [the differences in the case of the potential (iv) are due to some misprints in that reference]. The calculation of the energy eigenvalues in Ref. 9 was achieved by solving the corresponding Schrödinger differential equations, while in this paper the energy eigenvalues are obtained by algebraic methods. The advantage of the proposed method is that the energy eigenvalues are reduced to simple algebraic calculations of the roots of polynomial equations, whose form is universally determined by the structure functions (33), (33) and the system (35). These equations are valid for any two-dimensional superintegrable system with integrals of motion, which are quadratic functions of the momenta. The same equations should be valid in the case of two-dimensional superintegrable systems in curved space.[44] The superintegrable systems bring up the open problem of the quantization of a Poisson algebra in a well determined context, because these systems and their quantum counterparts are explicitly known.

From the above discussion several open problems are risen.

- The calculation of the classical Poisson algebras and their quantum counterparts for the totality of the two-dimensional problems in curved space. This study will lead to the calculation of the energy eigenvalues by algebraic methods. In Ref. 10 the case of the complex sphere has been investigated.
- The two-dimensional ''nondegenerate'' [4] superintegrable systems are classified by the values of the constants of the Darboux equations[3,4] and the constants of the system. The relation of these constants with the constants of the quadratic Poisson algebra is not yet known.
- The Poisson algebras for the Drach superintegrable systems with a cubic integral of motion were written by using a classical analog of the deformed parafermionic algebra.[29] Their quantum counterparts and the calculation of their energy eigenvalues are topics under investigation.
- The Poisson algebras and the associated quantum counterparts for the three-dimensional superintegrable systems are not yet fully studied. Recently[45] the quantum quadratic algebras have been written down, but a systematic calculation of energy eigenvalues has not been performed yet.

The above points show that, the study of nonlinear Poisson algebras and their quantum counterparts are topics of interest.

(Received 14 June 2000; accepted for publication 16 October 2000)

Asymptotics of electromagnetic radiation off a spherical superconductor is analyzed in terms of creeping waves. Temporal damping behavior of the charge distribution on the surface when the sphere is rendered superconducting is studied and is compared with that on a superconductor with an infinite plane surface. Finally, the coherent states of light waves outside a spherical superconductor and a superconductor with an infinite plane surface are constructed. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1331100]

I. INTRODUCTION

Arnold Sommerfeld, student of Boltzmann and teacher of Debye, Bethe, Heisenberg, Herzfeld, and many another distinguished physicists, established not once, but twice a standard of thoroughness for the analysis of a field of mathematical physics. First, he treated the propagation of the electromagnetic field à la Maxwell in geometry after geometry of this, that, or the other interesting symmetry, and, second, he analyzed the atomic structure à la Bohr, Heisenberg, Jordan, Schrödinger, and Pauli and its correlation with the observed pattern configurations can be attributed to Sommerfield, who put out Volume VI (partial differential equations in physics) while slashing his way into the heartland of atomic physics. But had there stood at his side an Arnold Sommerfeld clone who could have continued with the analysis of electromagnetic field configurations of interesting symmetry, there surely would have appeared at least one more volume on the subject.

We do not have to look far to find the obvious candidate for the first chapter in that Volume IV. Kamerlingh Onnes, working in his Leiden low-temperature laboratory, had in 1911 just discovered superconductivity. At last one could visualize an interesting configuration of spherical symmetry. Here, we spell out the simple model and analyze the associated field configuration. As is well known, the spherical superconductor has two modes, TE and TM. Neither mode of oscillation is stationary. Both damp. Characteristic features of these modes are the appearance of new integers in addition to familiar spherical harmonic indices l and m. These integers also appear in the homogeneous integral equation for light waves hitting the sphere and undergoing diffraction behind the sphere. Analytic approximate expressions for these eigenvalues were already obtained by Debye, Sommerfeld, and others. We try to give the physical meanings to this new characteristic integer in this paper.

Normal modes of oscillation for infinite plane superconductors are stationary. But, we shall show that physics on the plane looks similar to the physics on the sphere, by looking at the time dependence of the decaying charge distribution, when a sphere with axially symmetric charge distribution on one hand, and a plane with sinusoidal charge distribution on the other hand, are suddenly rendered superconducting.

[a)]Electronic mail: mwakano@main.teikyo-u.ac.jp

Finally, we construct the coherent state (''coherent'' means here that the superposed solitary waves progress keeping their forms unaltered) for electromagnetic waves outside a spherical superconductor and an infinite plane superconductor. For a spherical superconductor we have a reasonable result, and for a plane superconductor we have a perfectly satisfactory result.

II. SIMPLE MODEL

A. The Hamilton–Jacobi theory of a pseudophoton

Before we discuss in detail the asymptotics of electromagnetic radiation off a spherical superconductor, we recall how light waves diffract behind a spherical superconductor when they hit it, simply by using classically the concept of a pseudophoton.[1]

We start with the basic equation of a pseudophoton,

$$k_r^2+\frac{(l+\frac{1}{2})^2}{r^2}=\frac{\omega^2}{c^2}. \tag{2.1}$$

We rewrite this equation as follows:

$$\frac{c^2}{\alpha_1}\left\{p_r^2+\frac{\alpha_\theta^2}{r^2}\right\}=\alpha_1, \tag{2.2}$$

where we have

$$\alpha_\theta=(l+\tfrac{1}{2})\hbar, \tag{2.3}$$

and

$$\alpha_1=\hbar\omega. \tag{2.4}$$

Using Hamilton's characteristic function, $W=W_1(r)+\alpha_\theta\theta$, we have

$$\frac{c^2}{\alpha_1}\left\{\left(\frac{\partial W_1}{\partial r}\right)^2+\frac{\alpha_\theta^2}{r^2}\right\}=\alpha_1. \tag{2.5}$$

Therefore we have

$$W=\int dr\left(\frac{\alpha_1^2}{c^2}-\frac{\alpha_\theta^2}{r^2}\right)^{1/2}+\alpha_\theta\theta. \tag{2.6}$$

Then, the Hamilton–Jacobi theory gives us

$$t+\beta_1=\frac{\partial W}{\partial\alpha_1} \tag{2.7}$$

and

$$\beta_2=\frac{\partial W}{\partial\alpha_\theta}. \tag{2.8}$$

We solve these equations and we obtain

$$r=\left\{c^2t^2+\left(l+\frac{1}{2}\right)^2\frac{c^2}{\omega^2}\right\}^{1/2} \tag{2.9}$$

and

$$r=\frac{\left(l+\frac{1}{2}\right)\frac{c}{\omega}}{\cos\theta}, \tag{2.10}$$

where we have put $\beta_1=\beta_2=0$.

These expressions give a simple picture of a pseudophoton that creeps around and peels off the surface of a spherical superconductor, and underlies a full analysis in the following chapters.

B. Quantum theory of a pseudophoton

In this section, we discuss the field configurations outside a spherical superconductor, when the charge distribution over a spherical superconductor and therefore the electromagnetic field outside it oscillates, simply by using quantum mechanically the concept of a pseudophoton.

Here we, again, begin with the basic formula for the motion of a pseudophoton,

$$k_r^2+\frac{(l+\frac{1}{2})^2}{r^2}=\frac{\omega^2}{c^2}. \tag{2.1}$$

Transforming this equation into the quantum mechanical form, we have

$$-\frac{d^2S}{dr^2}+\frac{(l+\frac{1}{2})^2}{r^2}S=\frac{\omega^2}{c^2}S. \tag{2.11}$$

For large r, we have

$$-\frac{d^2S}{dr^2}=\frac{\omega^2}{c^2}S. \tag{2.12}$$

The solution of this equation is certainly

$$S(r)=e^{-i(\omega/c)r}. \tag{2.13}$$

Thus we put

$$S(r)=H(r)e^{-i(\omega/c)r}. \tag{2.14}$$

Then, the differential equation that $H(r)$ satisfies, is

$$\frac{d^2H}{dr^2}-i\frac{2\omega}{c}\frac{dH}{dr}-\frac{(l+\frac{1}{2})^2}{r^2}H=0. \tag{2.15}$$

We put

$$r=i\frac{c}{2\omega}z. \tag{2.16}$$

Then, we have

$$\frac{d^2H}{dz^2}+\frac{dH}{dz}-\frac{(l+\frac{1}{2})^2}{z^2}H=0. \tag{2.17}$$

The solution of this equation is given by

$$H(z)=z^{1/2}e^{-z/2}Z_{[l(l+1)+1/2]^{1/2}}\left(i\frac{z}{2}\right). \tag{2.18}$$

Or, we have

$$H(r)=e^{-i(\pi/4)}\left(\frac{2\omega}{c}r\right)^{1/2}e^{i(\omega/c)r}Z_{[l(l+1)+1/2]^{1/2}}\left(\frac{\omega}{c}r\right). \tag{2.19}$$

Here Z_ν is a cylindrical function. Since we are dealing with a pseudophoton, we have, putting $\omega/c=k$, the following results:

$$S(r)=(2kr)^{1/2}e^{-i(\pi/4)}J_{[l(l+1)+1/2]^{1/2}}(kr). \tag{2.20}$$

Or

$$S(r)=(2kr)^{1/2}e^{-i(\pi/4)}N_{[l(l+1)+1/2]^{1/2}}(kr). \tag{2.21}$$

Finally, we have, for $r\to\infty$,

$$S(r)\sim\frac{2}{\pi^{1/2}}e^{-i(\pi/4)}\cos\left\{kr-\frac{(2[l(l+1)+\frac{1}{2}]^{1/2}+1)\pi}{4}\right\}. \tag{2.22}$$

Or

$$S(r)\sim\frac{2}{\pi^{1/2}}e^{-i(\pi/4)}\sin\left\{kr-\frac{(2[l(l+1)+\frac{1}{2}]^{1/2}+1)\pi}{4}\right\}. \tag{2.23}$$

We rewrite the expression for $S(r)$ in the following way:

$$S(r)=\frac{2}{\pi^{1/2}}e^{-i(\pi/4)}krj_{[l(l+1)+1/2]^{1/2}-1/2}(kr). \tag{2.24}$$

Or

$$S(r)=\frac{2}{\pi^{1/2}}e^{-i(\pi/4)}krn_{[l(l+1)+1/2]^{1/2}-1/2}(kr). \tag{2.25}$$

Also, we have

$$S(r)=\frac{2}{\pi^{1/2}}e^{-i(\pi/4)}krh^{(1)}_{[l(l+1)+1/2]^{1/2}-1/2}(kr). \tag{2.26}$$

Further, we have, by adding the angular dependence and the time-dependent factor,

$$S(r,\theta,t)=\frac{2}{\pi^{1/2}}e^{-i(\pi/4)}krh^{(1)}_{[l(l+1)+1/2]^{1/2}-1/2}(kr)P_l(\cos\theta)e^{-i\omega t}. \tag{2.27}$$

Now we ask the boundary condition for the wave function of a pseudophoton, on the surface of a spherical superconductor with radius a:

$$S(r,\theta,t)_{r=a}=0. \tag{2.28}$$

This condition leads to the same condition as that in the TE mode (see Chap. III) for large l in which we are interested, such that

$$\{h^{(1)}_{[l(l+1)+1/2]^{1/2}-1/2}(kr)\}_{r=a}=0. \tag{2.29}$$

Also, we can ask the regularity condition for the wave function of a pseudophoton, on the surface of a spherical superconductor:

$$\left\{\frac{\partial}{\partial r}S(r,\theta,t)\right\}_{r=a}=0. \tag{2.30}$$

This condition leads to the same condition as that in the TM mode (see Chap. III) for large l, such that

$$\left\{\frac{d}{dr}[rh^{(1)}_{[l(l+1)+1/2]^{1/2}-1/2}(kr)]\right\}_{r=a}=0. \tag{2.31}$$

Either one of the above boundary conditions is equally definite to fix the eigenvalues.

Finally, we give the asymptotic formula of $S(r,\theta,t)$ for $r\to\infty$,

$$S(r\to\infty,\theta,t)\sim\frac{2}{\pi^{1/2}}\exp\left\{i\left(kr-\frac{(2[l(l+1)+\frac{1}{2}]^{1/2}+2)\pi}{4}\right)\right\}P_l(\cos\theta)e^{-i\omega t}. \tag{2.32}$$

Since the eigenvalues for both conditions have the negative imaginary parts, this expression shows the characteristic, spatially increasing, and temporally decreasing behavior.

Now we go over to the detailed analysis of TE and TM modes and their related subjects of the charge distribution over a spherical superconductor and the electromagnetic field outside it.

III. TRANSVERSE ELECTRIC MODES AND TRANSVERSE MAGNETIC MODES OF A SPHERICAL SUPERCONDUCTOR

As the student of wave mechanics works out the solution of the Schrödinger equation for the $1s$, $2p$, $3d$, $4f$, and further states of the electron moving around the hydrogen nucleus, he sees the first maximum of the wave function becomes more and more sharply defined and moving outward in clearer and clearer correspondence to the radius of the corresponding classical circular Bohr orbit. Does any similar asymptotology hold for the modes of oscillation of electromagnetic field around a spherical superconductor (and the accompanying vibrations of the electric charge on the surface of the superconductor)?

This question arose in a junior level course that one of us taught at the University of Texas at Austin in 1975 when, among the homework, the student encountered the following question from the familiar text of Jackson:[2]

> 16.10 Discuss the normal modes of oscillation of a perfectly conducting solid sphere of radius a in free space. (This problem was solved by J.J. Thomson in the 1880(s.)
> (a) Determine the characteristic equations for the eigenfrequencies for TE and TM modes of oscillation. Show that the roots for ω always have a negative imaginary part, assuming a time dependence of $e^{-i\omega t}$.
> (b) Calculate the eigenfrequencies for the $l=1$ and $l=2$ TE and TM modes. Tabulate the wavelength (defined in terms of the real part of the frequency) in units of the radius a and the decay time (defined as the time taken for the energy to fall to e^{-1} of its initial value) in units of the transit time (a/c) for each of the modes.

In this problem there are two conditions at one boundary, the surface of the superconducting sphere $(r=a)$, rather than one condition, $\psi=0$ (3.1), at two locations ($r=0$ and $r=$infinity), but their power to fix the eigenvalues is equally definite.

For concreteness we picture a sphere of radius a on the surface of which we spray an axially symmetric distribution of electric charge $\sigma(\theta)=\sigma_0 P_l(\cos\theta)$. At time $t=0$ we render the sphere superconducting. The charge thereupon goes into a superposition of damped oscillations. But with what frequencies and what damping constants, we ask, knowing that the electromagnetic field for some modes is transverse electric (TE) and for the others is transverse magnetic (TM).

For transverse electric (TE) modes of oscillation of the electromagnetic field one may write[3]

$$\mathbf{E}=\mathbf{r}\times\text{grad}\,\psi, \tag{3.2}$$

(guaranteeing that **E** stands perpendicular to **r**) and

$$\mathbf{B}=\left(\frac{1}{i\omega}\right)\mathbf{del}\times\mathbf{E}, \tag{3.3}$$

where

$$\psi(r,\theta,\varphi,t)=h_l^{(1)}(kr)Y_l^m(\theta,\varphi)e^{-ikct}, \tag{3.4}$$

with $h_l^{(1)}$ the spherical Hankel function of the first kind.[3] It satisfies the differential equation

$$\frac{d^2h_l^{(1)}}{dz^2}+\frac{2}{z}\frac{dh_l^{(1)}}{dz}+\left[1-\frac{l(l+1)}{z^2}\right]h_l^{(1)}=0, \tag{3.5}$$

and admits an expression in the form

$$h_l^{(1)}(z)=z^{-(l+1)}[\text{polynomial in } z \text{ of order } l]e^{iz}. \tag{3.6}$$

For transverse magnetic (TM) modes of oscillation of the electromagnetic field one may write[3]

$$\mathbf{H}=\mathbf{r}\times\text{grad}\,\psi, \tag{3.7}$$

(guaranteeing that **H** stands perpendicular to **r**) and

$$\mathbf{E}=\left(\frac{i}{\omega\varepsilon_0}\right)\mathbf{del}\times\mathbf{H}. \tag{3.8}$$

On the surface, the tangential component of the electric field for each mode of oscillation must vanish at all times, whence every spherical Hankel function that is relevant must satisfy the eigenvalue condition

$$h_l^{(1)}(ka)=0, \tag{3.9}$$

for TE modes, and

$$\left\{\frac{d}{dr}[rh_l^{(1)}(kr)]\right\}_{r=a}=0, \tag{3.10}$$

for TM modes. One of the students, Iraj Emami, went beyond the Jackson problem in its stated form and sought the 41 roots (3.10) for $l=40$. For this purpose Emami programmed a computer to get the real part of each root, to about 8 decimals, and likewise the imaginary part. His results appear in Fig. 1(a). Figure 1(a): complex roots of Eq. (3.10) for TM modes with a spherical Hankel function of the first kind of order $l=40$ as determined to perhaps around eight places of decimals by Iraj Emami in the spring of 1983, about the time when he was called back to Iran for military service. In this figure, a parameter, $K=[ka-(l+\frac{1}{2})]/(l+\frac{1}{2})^{1/3}$ is plotted. Contrary to the

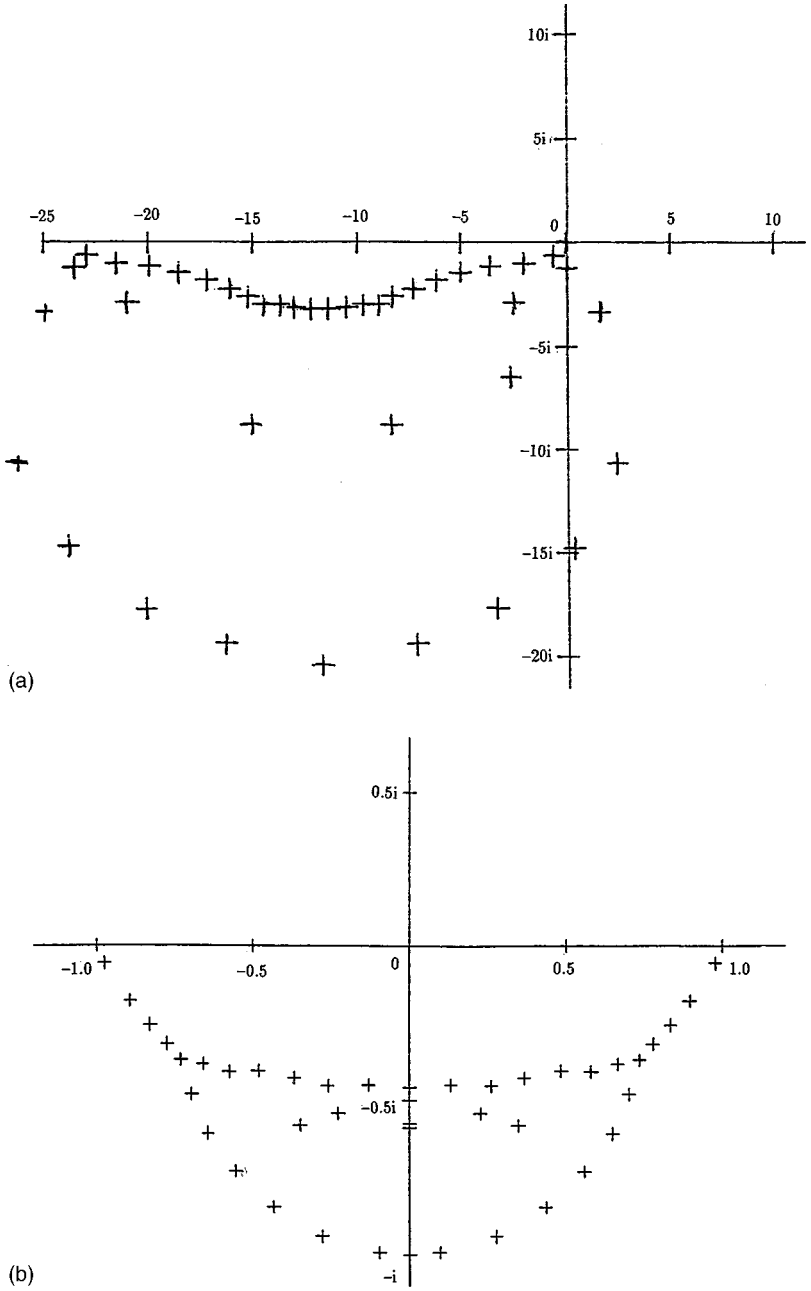

FIG. 1. (a) The complex roots of Eq. (3.10) for TM modes with a spherical Hankel function of the first kind, of order $l=40$, as determined to around eight places of decimals by Iraj Emami. (b) The 41 complex roots of Eq. (3.10) normalized by $l(=40)$, obtained to eight places of decimals by one of us (M.W.).

note that Emami left, and also to other calculations of him for several l values smaller than 40, in Fig. 1(a), only 40 roots are shown instead of 41 roots. All attempts have failed to contact him to get his participation in this report. On leaving Austin he had said, ''Don't worry about me. The Iraqis can't shoot straight.'' Maybe he was wrong. To examine the reproducibility of his result, we show, in Fig. 1(b), 41 complex roots of Eq. (3.10) normalized by $l(=40)$, obtained to eight places of decimals by one of us (M.W.). We could say that the diagrams have some features in common.

The pattern of complex frequencies in Fig. 1(a) fall into oval, below, and above a bow. Supply some simple physical interpretation of these two features, we asked ourselves and a succession of

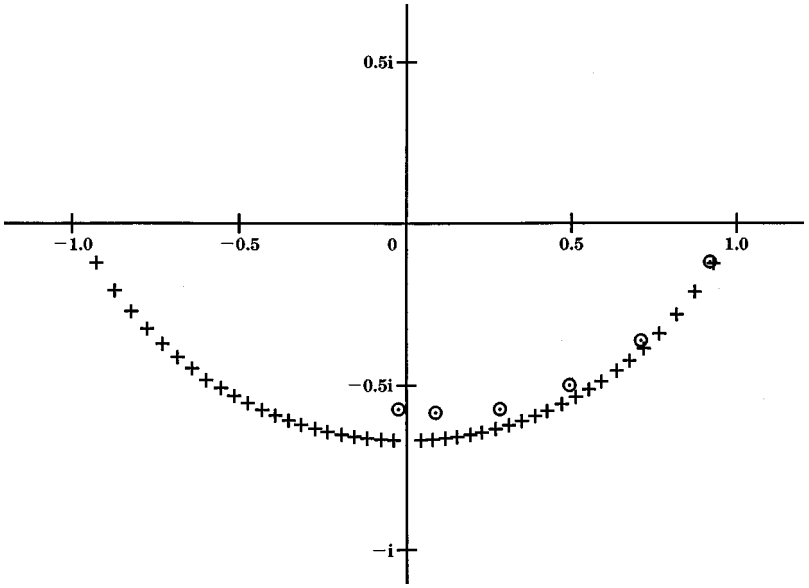

FIG. 2. Complex eigenvalues for the 45 characteristic modes of decay of the transverse electric field around a charged superconductor. All expressed in units of the basic frequency, cl/a. Crosses: our calculations; circles: the prediction of the asymptotic formula of Debye (Ref. 9) and Sommerfeld (Ref. 10).

distinguished visitors. ''Crazy'' replied one after several hours of study, and rightly so, we now realize, because Fig. 1(a) is mistaken, through not having been calculated to enough decimal places. That perceptive visitor was later honored with a knighthood, but not for this. Clarity first came when one of us (M.W.) repeated the calculations to a higher number of decimal places, 16 for the real part and 16 for the imaginary part, by finding 45 roots of a polynomial of 45th order with real coefficients in (3.9) for TE modes, yielding the pattern of complex eigenvalues of Fig. 2.

Both modes of oscillation appear as poles in the S matrix for the scattering of a plane electromagnetic wave by a spherical superconductor.[3] The TM modes of oscillation describe the temporal behavior of the charge distribution on a sphere, which is rendered superconducting at $t=0$, while for $t<0$, the charge is distributed axially symmetrically and given by $\sigma(\theta) = \sigma_0 P_l(\cos\theta)$. We start with the following integral expression:

$$E_r(r,\theta,t) = \frac{\sigma_0}{\varepsilon_0}\left(\frac{a}{r}\right) P_l(\cos\theta)\,\frac{1}{2\pi i}\int \frac{dk}{k}\left\{\frac{-l}{\left\{\frac{d}{dz}[zh_l^{(1)}(z)]\right\}_{z=ka}}\right\}$$

$$\times[A(k,a)h_l^{(2)}(kr)+h_l^{(1)}(kr)]e^{-ikct}, \tag{3.11}$$

$$A(k,a) = -\frac{\left\{\frac{d}{dr}[rh_l^{(1)}(kr)]\right\}_{r=a}}{\left\{\frac{d}{dr}[rh_l^{(2)}(kr)]\right\}_{r=a}}, \tag{3.12}$$

$$\left\{\frac{d}{dr}[rh_l^{(1)}(k_l^n r)]\right\}_{r=a} = 0. \tag{3.13}$$

The integration should be performed along the real axis except for going below zero, in the complex k plane. Equation (3.12) for factor $A(k,a)$ arises from the boundary condition that the tangential component of the electric field must vanish on the surface of the spherical superconductor, as guaranteed by

$$E_\theta(r,\theta,t)=\frac{\sigma_0}{\varepsilon_0}\left(\frac{a}{r}\right)\frac{P_l^1(\cos\theta)}{l(l+1)}\frac{1}{2\pi i}\int\frac{dk}{k}\left\{\frac{-l}{\left\{\frac{d}{dz}[zh_l^{(1)}(z)]\right\}_{z=ka}}\right\}$$
$$\times\left\{\frac{d}{dr}[A(k,a)rh_l^{(2)}(kr)+rh_l^{(1)}(kr)]\right\}e^{-ikct} \tag{3.14}$$

and

$$E_\varphi=0. \tag{3.15}$$

For the space–time points, $(r-a-ct)>0$, we have

$$E_r(r,\theta)=\frac{\sigma_0}{\varepsilon_0}\left(\frac{a}{r}\right)^{(l+2)}P_l(\cos\theta) \tag{3.16}$$

and

$$E_\theta(r,\theta)=-\frac{\sigma_0}{\varepsilon_0}\left(\frac{a}{r}\right)^{(l+2)}\frac{P_l^1(\cos\theta)}{(l+1)}, \tag{3.17}$$

where we have $P_l^1(\cos\theta)=(d/d\theta)P_l(\cos\theta)$.

For the space–time points, $(r-a-ct)<0$, we have

$$E_r(r,\theta,t)=\frac{\sigma_0}{\varepsilon_0}\left(\frac{a}{r}\right)P_l(\cos\theta)\sum_n\frac{l}{[l(l+1)-(k_l^na)^2]}\frac{h_l^{(1)}(k_l^nr)}{h_l^{(1)}(k_1^na)}e^{-ik_l^nct} \tag{3.18}$$

and

$$E_\theta(r,\theta,t)=\frac{\sigma_0}{\varepsilon_0}\left(\frac{a}{r}\right)\frac{P_l^1(\cos\theta)}{(l+1)}\sum_n\frac{1}{[l(l+1)-(k_l^na)^2]}\frac{\frac{d}{dr}[rh_l^{(1)}(k_l^nr)]}{h_l^{(1)}(k_l^na)}e^{-ik_l^nct}. \tag{3.19}$$

For $r=a$ and $t=0$, Eq. (3.18) reduces to $E_r(\theta)=(\sigma_0/\epsilon_0)P_l(\cos\theta)$. Here we have used the relation[4]

$$\frac{h_l^{(1)}(z)}{\frac{d}{dz}[zh_l^{(1)}(z)]}=\sum_n\frac{z_l^n}{[l(l+1)-(z_l^n)^2](z-z_l^n)}. \tag{3.20}$$

The charge distribution on the surface of a sphere for $t>0$, is given by

$$\sigma(\theta,t)=\sigma_0P_l(\cos\theta)\sum_n\frac{l}{[l(l+1)-(k_l^na)^2]}e^{-ik_l^nct}. \tag{3.21}$$

A very naive insight [5] to understanding the pattern of eigenfrequencies in Fig. 2 can be gained from the studies done for the creeping waves going into the shadow region around the surface (1) of the cylindrical perfect conductor,[6] when the light wave hits the cylinder perpendicularily to its

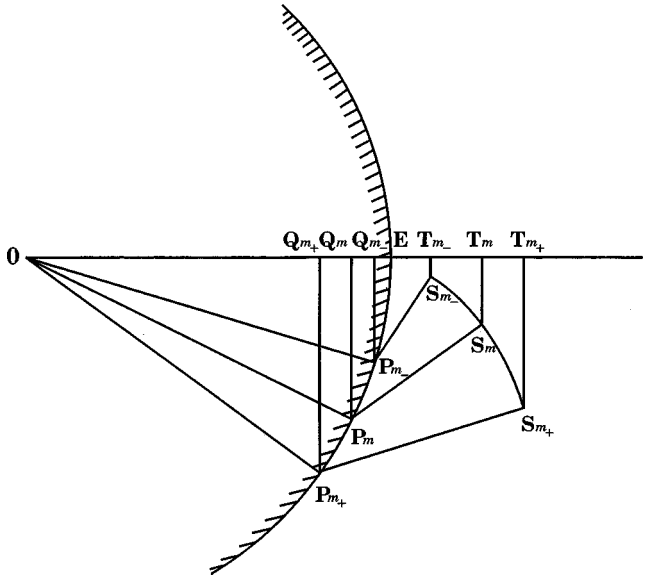

FIG. 3. Two light rays meet at a point S_m. The length, S_mT_m is the path difference between the light ray coming from a point P_m and the light ray coming from a point lying, on the straight line, T_mS_m, and far from a point T_m by the length, Q_mP_m, and is equal to $m\times$(the wavelength of the light). Here the length, P_mS_m is equal to the length, P_mQ_m. Angle, $\angle Q_mP_mS_m$ is nearly twice angle, $\angle EOP_m$. The figure is just schematic alone. These situations are same for other light rays drawn here. Thus the length, $S_{m+}T_{m+}$ is equal to $(m+1/4)\times$(the wavelength of the light), and the length, $S_{m-}T_{m-}$, is equal to $(m-1/4)\times$(the wavelength of the light).

axis, and (2) of the spherical perfect conductor,[7] when the light wave hits the sphere from its north pole, along the z axis. The damping factors of the wave amplitude in both cases are shown, by Franz,[8] to have the content equivalent to the Debye[9] and Sommerfeld[10] formula for eigenvalues of TM modes,

$$l=ka+\frac{1}{2}(ka)^{1/3}\left(\frac{3\pi}{4}\right)^{2/3}(4m+1)^{2/3}e^{i\pi/3},$$
$$m=0,1,2,3,\cdots, \tag{3.22}$$

and for TE modes,

$$l=ka+\frac{1}{2}(ka)^{1/3}\left(\frac{3\pi}{4}\right)^{2/3}(4m-1)^{2/3}e^{i\pi/3}$$
$$m=1,2,3,\cdots\ . \tag{3.23}$$

As m increases, the corresponding creeping wave is localized farther and farther from the surface.[11] The pattern of this localization can be inferred from the following simple consideration. Let us think of a plane electromagnetic wave hitting a sphere. The interference phenomena of the light going straightforwardly and the light reflected on the surface of a sphere are shown in Fig. 3. (Here we do not take into account the polarization effect of the light.)

In Fig. 3, the width $T_{m_-}T_{m_+}$ is the mth trapped or localized region of energy produced by the constructive interference of two light rays, one coming straightforwardly and the other reflected on the surface of a sphere. Following the concept of a creeping wave, we assume that the light rays within this width go around the circular small zone apart from the surface by the distance, ET_m. One can easily calculate the time ΔT_m needed for the pseudophoton[1] coming grazingly at point E

in Fig. 3 to clear the mth trapped region. The inverse of the angle $\Delta\varphi_m$ spanned by the light ray circulating within the mth trapped region for the time ΔT_m gives the angularwise decay rate of a creeping wave in our picture. We have

$$0.63(ka)^{1/3}, \quad 2.31(ka)^{1/3}, \ 3.68(ka)^{1/3}, \cdots, \tag{3.24}$$

while the Debye and Sommerfeld formula gives, for TM modes,

$$0.77(ka)^{1/3}, \quad 2.24(ka)^{1/3}, \quad 3.32(ka)^{1/3}, \cdots \tag{3.25}$$

The largest decay rate is simply given by the WKB approximation method as follows:[12]

$$\omega_{\text{imaginary}} = -0.6627\left(l+\frac{1}{2}\right)\frac{c}{a}. \tag{3.26}$$

The corresponding decay factor of the electromagnetic field around an oscillating charged spherical superconductor, is $\exp[-ct/a/0.6627(l+\frac{1}{2})]$. Therefore the effective reduced wavelength, $\lambda/2\pi$ is $a/0.6627(l+\frac{1}{2}) = (1+0.5090)a/(l+\frac{1}{2})$. This means that in terms of a creeping wave, the effective radius is elongated by $0.5a$ from the surface of a sphere, and the pseudophoton departs this outermost trapped region when it moves over one reduced wavelength.

In the trapped regions near the surface of a cylindrical or spherical superconductor, the property of light waves as an aggregate of photons is evident, but in those far from the surface, the property as an individual photon is evident. Further, in the latter case, the following quite an elementary argument suggests, implicitly, the appearance of quantum h.

The angular momentum A of a circulating pseudophoton over a circle with radius $1.5a$ is given as follows:

$$A = 1.5ap, \tag{3.27}$$

where the momentum p of a pseudophoton is equal to $\hbar k$, by de Broglie's relation. Thus we have

$$A = 1.5a\hbar k. \tag{3.28}$$

Further, we have, for the quantized angular momentum of a circulating pseudophoton,

$$A = l\hbar. \tag{3.29}$$

Therefore, we have the final equation,

$$l = 1.5ak. \tag{3.30}$$

That is, quantum h is implicitly included in this equation. These considerations correspond to the situation in the hydrogen atom stated in the beginning.

At this point, we consider the resonance curve of normal oscillations for TE modes. The cross section[3] for scattering of plane light waves by a spherical superconductor of radius a is given by

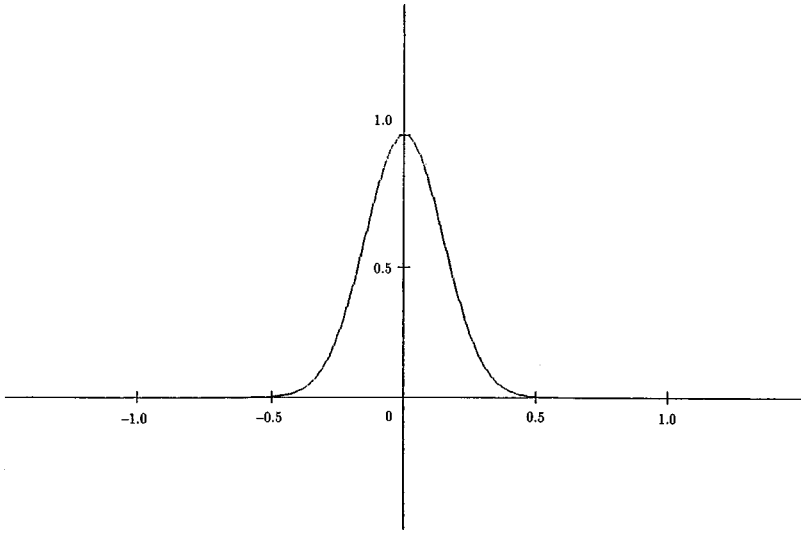

FIG. 4. Diagram for the resonance factor, Eq. (3.33) for $l=45$ of the TE mode appearing in the total scattering cross section of the light by a spherical superconductor is drawn. The curve is plotted as a function of $z=ka$. All quantities, $z, z_{\text{real}}^{(k)}$ and $z_{\text{imag}}^{(k)}$ are normalized by $l(=45)$. The horizontal axis stands for z, and the vertical axis stands for the resonance factor, Eq. (3.33). The diagram does not show the slightest indication of the resonance feature of the individual mode.

$$\sigma=\frac{2\pi}{k^2}\sum_l (2l+1)(|a_l|^2+|b_l|^2),$$

$$a_l=-\frac{j_l(ka)}{h_l^{(1)}(ka)}, \tag{3.31}$$

$$b_l=-\left\{\frac{\dfrac{d}{dr}[rj_l(kr)]}{\dfrac{d}{dr}[rh_l^{(1)}(kr)]}\right\}_{r=a}.$$

Let us consider the resonance factor produced by the zeros of $h_l^{(1)}(z)$ in the complex z plane. We use the following representation for $h_l^{(1)}(z)$:

$$h_l^{(1)}(z)=\frac{e^{iz}}{z^{(l+1)}}(\text{polynomial in } z \text{ of order } l)$$

$$=\frac{e^{iz}}{z^{(l+1)}}f(0)\left(1-\frac{z}{z^{(1)}}\right)\left(1-\frac{z}{z^{(2)}}\right)\cdots\left(1-\frac{z}{z^{(l)}}\right). \tag{3.32}$$

Here $f(0)$ is the value of the polynomial at $z=0$, and $z^{(k)}$ is the kth complex root of $h_l^{(1)}(z)=0$. Then the resonance curve is given by the following expression:

$$\Pi_{k=1}^{l}\frac{[(z_{\text{real}}^{(k)})^2+(z_{\text{imag}}^{(k)})^2]}{[(z-z_{\text{real}}^{(k)})^2+(z_{\text{imag}}^{(k)})^2]}. \tag{3.33}$$

We present this resonance curve for $l=45$ in Fig. 4. Here we do not have the slightest indication of a resonance feature in the individual mode.

IV. NORMAL MODES IN A SUPERCONDUCTOR WITH AN INFINITE PLANE SURFACE

The superconductor with an infinite plane surface is an insulator for $t<0$. We take the charge to be distributed according to the surface density, $\sigma(x)=\sigma_0\cos(kx)$. The corresponding electromagnetic fields in space are

$$E_x(x,z)=\frac{\sigma_0}{\epsilon_0}\sin(kx)e^{-kz},$$

$$E_y=0,$$

$$E_z(x,z)=\frac{\sigma}{\epsilon_0}\cos(kx)e^{-kz},$$

$$\mathbf{H}=0. \tag{4.1}$$

The electric energy associated with the charge distribution on the surface is

$$U_{\text{charge}}=\frac{1}{2}\int\int dx\,dy\,\sigma(x)\phi(x)$$

$$=\frac{\sigma_0^2}{2\epsilon_0 k}\int\int dx\,dy\cos^2(kx)$$

$$=\frac{\sigma_0^2}{4\epsilon_0 k}\int\int dx\,dy. \tag{4.2}$$

Here $\phi(x)=(\sigma_0/\epsilon_0 k)\cos(kx)$ is the electric potential on the surface. The transition from the second to the last equation in (4.2) is performed by taking the average over x dependence, as done in the following discussion as well.

On the other hand, the electric energy stored in space is

$$U_{\text{field}}=\int\int\int dx\,dy\,dz\,\frac{\epsilon_0}{2}(E_x^2+E_z^2)$$

$$=\frac{\sigma_0^2}{4\epsilon_0 k}\int\int dx\,dy. \tag{4.3}$$

We see that the electric energy, U_{charge} associated with the charge distribution on the surface is equal to the electric energy, U_{field} stored in space as it should be in static electricity.

At time $t=0$ we render the substance superconducting. General solutions are stationary and given by

$$
\begin{aligned}
E_x(x,z,t) &= k_z \sin(kx)\sin(k_z z)\cos(\omega t),\\
E_y &= 0,\\
E_z(x,z,t) &= k \cos(kx)\cos(k_z z)\cos(\omega t),\\
H_x &= 0,\\
H_y(x,z,t) &= -\frac{\omega}{\mu_0 c^2}\sin(kx)\cos(k_z z)\sin(\omega t),\\
H_z &= 0,
\end{aligned}
\tag{4.4}
$$

where we have $\omega = c(k^2+k_z^2)^{1/2}$.

Then we superpose the individual electromagnetic field components with a weight factor, $(2\sigma_0/\pi\epsilon_0)/(k^2+k_z^2)$. We write down the resulting electromagnetic field components below. For $z>ct$ we have

$$
\begin{aligned}
E_x(x,z) &= \frac{\sigma_0}{\epsilon_0}\sin(kx)e^{-kz},\\
E_y &= 0,\\
E_z(x,z) &= \frac{\sigma_0}{\epsilon_0}\cos(kx)e^{-kz},\\
\mathbf{H} &= 0.
\end{aligned}
\tag{4.5}
$$

For $z<ct$ we have

$$
\begin{aligned}
E_x(x,z,t) &= -\left(\frac{2}{\pi}\right)^{1/2}\frac{\sigma_0}{\epsilon_0}\sin(kx)\,\frac{z}{k^{1/2}ct(c^2t^2-z^2)^{1/4}}\sin\left[k(c^2t^2-z^2)^{1/2}+\frac{\pi}{4}\right],\\
E_y &= 0,\\
E_z(x,z,t) &= \left(\frac{2}{\pi}\right)^{1/2}\frac{\sigma_0}{\epsilon_0}\cos(kx)\,\frac{(c^2t^2-z^2)^{1/4}}{k^{1/2}ct}\cos\left[k(c^2t^2-z^2)^{1/2}+\frac{\pi}{4}\right],\\
H_x &= 0,\\
H_y(x,z,t) &= -\left(\frac{2}{\pi}\right)^{1/2}\frac{\sigma_0}{\epsilon_0\mu_0 c}\sin(kx)\,\frac{1}{k^{1/2}(c^2t^2-z^2)^{1/4}}\sin\left[k(c^2t^2-z^2)^{1/2}+\frac{\pi}{4}\right],\\
H_z &= 0.
\end{aligned}
\tag{4.6}
$$

Now we define the total electromagnetic field energy stored in the whole space surrounding the infinite superconducting plane surface,

$$
U_{\text{field}}(t) = \int\int dx\,dy\int_{ct}^{\infty} dz\,\frac{\epsilon_0}{2}(E_x^2+E_z^2) + \int\int dx\,dy\int_0^{ct} dz\left[\frac{\epsilon_0}{2}(E_x^2+E_z^2)+\frac{\mu_0}{2}H_y^2\right]. \tag{4.7}
$$

Inserting Eqs. (4.5) and (4.6) into Eq. (4.7), we have the final result,

$$U_{\text{field}}(t)=\frac{\sigma_0^2}{4\epsilon_0 k}\left[e^{-2kct}+1+\frac{1}{2kct}\mathbf{H}_1(2kct)\right]\int\int dx\,dy. \tag{4.8}$$

Here the function $\mathbf{H}_1(2kct)$ is the Struve function, which is defined by[13]

$$\mathbf{H}_\nu(z)=\sum_{m=0}^{\infty}\frac{(-1)^m\left(\frac{z}{2}\right)^{\nu+2m+1}}{\Gamma\left(m+\frac{3}{2}\right)\Gamma\left(\nu+m+\frac{3}{2}\right)}. \tag{4.9}$$

When z is large, we can better use the following expression:[13]

$$\mathbf{H}_\nu(z)=Y_\nu(z)+\frac{1}{\pi}\sum_{m=0}^{\infty}\frac{\Gamma(m+\frac{1}{2})}{\Gamma\left(\nu+\frac{1}{2}-m\right)\left(\frac{z}{2}\right)^{2m-\nu+1}}. \tag{4.10}$$

Thus we have

$$U_{\text{field}}(t=\infty)=\frac{\sigma_0^2}{4\epsilon_0 k}\int\int dx\,dy. \tag{4.11}$$

Now we calculate the charge distribution on the surface for $t>0$. We start with the correct expression,

$$\sigma(x,t)=\sigma_0\cos(kx)\left(\frac{2}{\pi}\right)\int_0^{\pi/2}d\phi\cos\left(\frac{kct}{\cos\phi}\right). \tag{4.12}$$

For large times, we can make an approximation, $\cos\phi=1-\phi^2/2$, which is equivalent to that in the case where smaller values of ϕ are important. We have

$$\sigma(x,t)=\sigma_0\cos(kx)\left(\frac{2}{\pi kct}\right)^{1/2}\cos\left(kct+\frac{\pi}{4}\right). \tag{4.13}$$

This is equivalent to that derived from Eq. (4.6). For small times, we can make an approximation, $1/\cos\phi=\tan\phi$, which is equivalent to that in the case where values of ϕ near $\pi/2$ are important. We have

$$\begin{aligned}\sigma(x,t)&=\sigma_0\cos(kx)\left(\frac{2}{\pi}\right)\int_0^{\pi/2}d\phi\cos(kct\tan\phi)\\&=\sigma_0\cos(kx)e^{-kct}.\end{aligned} \tag{4.14}$$

This result can be derived exactly in the following way:

$$\begin{aligned}\int_0^{\pi/2}d\phi\cos\left(\frac{kct}{\cos\phi}\right)&=\int_1^{\infty}d\tau\frac{\cos(kct\tau)}{\tau(\tau^2-1)^{1/2}}\\&=\frac{\pi}{2}-\pi\sum_{n=0}^{\infty}J_{2n+1}(z).\end{aligned} \tag{4.15}$$

The transition to the last expression is performed by using the formulas on pp. 546–547 of Ref. 13. Further we have the relation

$$\int dz\, J_0(z) = 2\sum_{n=0}^{\infty} J_{2n+1}(z). \tag{4.16}$$

For small values of z we have the following expansion formula:

$$J_0(z) = 1 - \frac{z^2}{4} + \frac{z^4}{64} - \cdots. \tag{4.17}$$

Thus we have the expression of the charge distribution for small values of t given by

$$\sigma(x,t) = \sigma_0 \cos(kx)\left[1 - kct + \frac{(kct)^3}{12} - \frac{(kct)^5}{320} + \cdots\right]. \tag{4.18}$$

This equation verifies Eq. (4.14).

Thus, we see that the temporal damping pattern of the charge distribution on the infinite superconducting plane surface contains a continuous form from e^{-kct} to $1/(kct)^{1/2}$. From this situation, the infinite plane superconductor could be regarded as an approximation of a spherical superconductor in the sense that large decay factors make the oscillation of the charge distribution to decrease faster at smaller times, and at larger times the charge distribution oscillates with smaller decay factors.

The similarity of the infinite plane superconductor to the spherical superconductor can be seen in the surface diffraction wave (for a cylinder or a sphere, this is called ''creeping wave''). In fact, when the plane incident wave hits the infinite very thin plane superconductor, the surface diffraction wave on the surface in the shadow region, decreases proportionally to $\exp(ikr)/(kr)^{1/2}$ as r goes to infinity.[14] This implies no radiation loss during the wave propagation, because this expression expresses just the propagation of the cylindrical wave starting at the infinite edge of the infinite plane superconductor. On the other hand, for the radius of a sphere going to infinity, the creeping wave becomes an undamped plane Maxwell wave of infinite extent in the radial direction.

V. COHERENT STATES

A. A spherical superconductor

As stated in the Introduction, ''coherent'' means here that the superposed solitary waves progress keeping their forms unaltered for electromagnetic waves both outside a spherical superconductor and outside an infinite plane superconductor.

Now we pursue another analogy for the connection of two pictures of the hydrogen atom electron, (1) as a point going around and around in a circular orbit and (2) as a Schrödinger wave function spreading out all over the space. This connection is done by superposing waves within a certain effective range of n values to build a wave packet. It goes around and around like a point. We stated that the Debye and Sommerfeld formula has the content equivalent to the damping factor in the amplitude of the waves creeping into the shadow region around the surface of a spherical superconductor. This content is exemplified in the φ dependence of the light wave amplitude near the equator, when the wave hits the sphere along the x axis. As a preliminary work to study this characteristic, we superpose electromagnetic waves with spherical harmonic indices, l and m, such that $(l,m) = \cdots,(42,42),(43,43),(44,44),(45,45),\cdots$.

For this purpose we write down the electromagnetic field components for TM modes:

$$
\begin{aligned}
E_r &= \frac{-i}{\omega\epsilon_0}\frac{l(l+1)}{r}\psi, \\
E_\theta &= \frac{-i}{\omega\epsilon_0}\frac{1}{r}\frac{\partial}{\partial r}\left(r\frac{\partial\psi}{\partial\theta}\right), \\
E_\varphi &= \frac{m}{\omega\epsilon_0}\frac{1}{r\sin\theta}\frac{\partial}{\partial r}(r\psi), \\
H_r &= 0, \\
H_\theta &= \frac{-im}{\sin\theta}\psi, \\
H_\varphi &= \frac{\partial}{\partial\theta}\psi,
\end{aligned}
\tag{5.1}
$$

where ψ is given by Eq. (3.4). According to the prescription stated above we superpose the electromagnetic field components such that

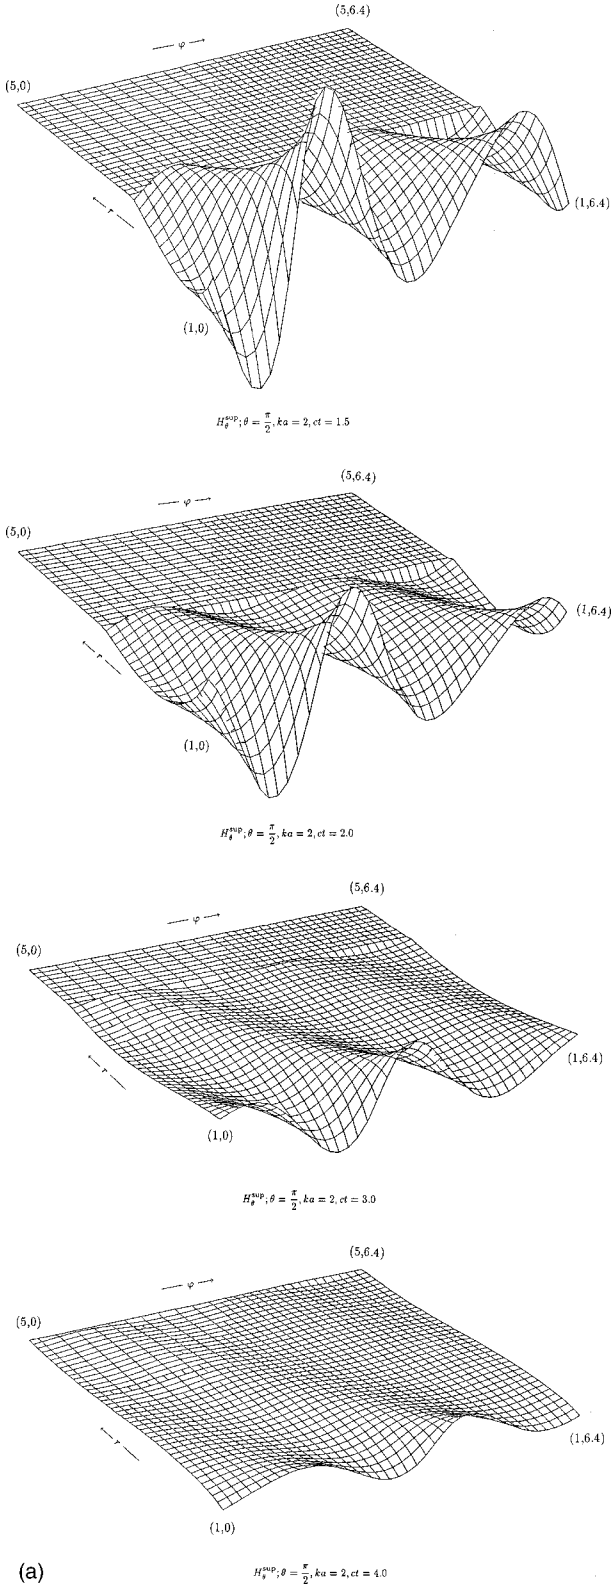
$$
\begin{aligned}
H_\theta^{\mathrm{sup}} &= \sum_l \frac{\frac{l_{\mathrm{imag}}}{\pi}}{(l-l_{\mathrm{real}})^2+l_{\mathrm{imag}}^2}\left(\frac{-il}{\sin\theta}\right)\frac{h_l^{(1)}(k_l^{\mathrm{lowest}}r)}{h_l^{(1)}(k_l^{\mathrm{lowest}}a)}(\sin\theta)^l e^{il\varphi}e^{-ik_l^{\mathrm{lowest}}ct}, \\
l_{\mathrm{real}} &= ka+\frac{1}{2}(ka)^{1/3}\left(\frac{3\pi}{4}\right)^{2/3}\cos\frac{\pi}{3}, \\
l_{\mathrm{imag}} &= \frac{1}{2}(ka)^{1/3}\left(\frac{3\pi}{4}\right)^{2/3}\sin\frac{\pi}{3}.
\end{aligned}
\tag{5.2}
$$

Here the superscript, ''*lowest*'' in k_l^{lowest} stands for the eigenvalue with the lowest decay rate in magnitude and the largest real part for given l, that is, the trajectory, $m=0$ in the Debye and Sommerfeld formula for TM modes. Calculations are shown in Figs. 5(a)–5(d).

From Figs. 5(a)–5(d), we could well infer that the electromagnetic fields of the creeping wave are not restricted on the surface of the sphere, but spread out in the space, apart from the surface, even at very small times. More interesting results concerning this important point might be obtained when we choose next to the *lowest* mode, in l_{real} and l_{imag} in the weight factor of Eq. (5.2). The fact that so much difference between Fig. 5(a) and Fig. 5(b) is not seen, might be due to the fact that high l's values do not make significant contributions to H_θ^{sup}. From Figs. 5(c) and 5(d), we see that the wave amplitude gets concentrated more and more near the surface of the sphere, as ka increases. Energy conservation cannot be discussed from these figures, because now we are limiting ourselves to the essential features of the creeping wave, the r dependence and φ dependence that it takes near the equator as time goes on, which is realized in the formation of H_θ^{sup} in Eq. (5.2).

B. A superconductor with an infinite plane surface

For the present purpose, we had better take the following general solutions for electromagnetic fields in the free space:



(a)

FIG. 5. The superposed magnetic field component, $H_\theta^{\mathrm{sup}}(r,\theta,\varphi,t)$ outside a spherical superconductor is shown for $ka=2$ and $\theta=\pi/2$, $\pi/4$ [(a) and (b)] and $ka=5$, 10, and $\theta=\pi/2$ [(c) and (d)]. We made the calculations of wave amplitudes until the distance where $(r-a-ct)\leqslant 0$, and beyond that distance, we made them equal to zero. All lengths, r and ct, are measured in unit a. Coordinates, (r,φ) stand for r values and φ values, which they take when the amplitudes of electromagnetic fields are zero, and in figures, they are drawn on the positions that the amplitudes actually take at corresponding cases and corresponding times.

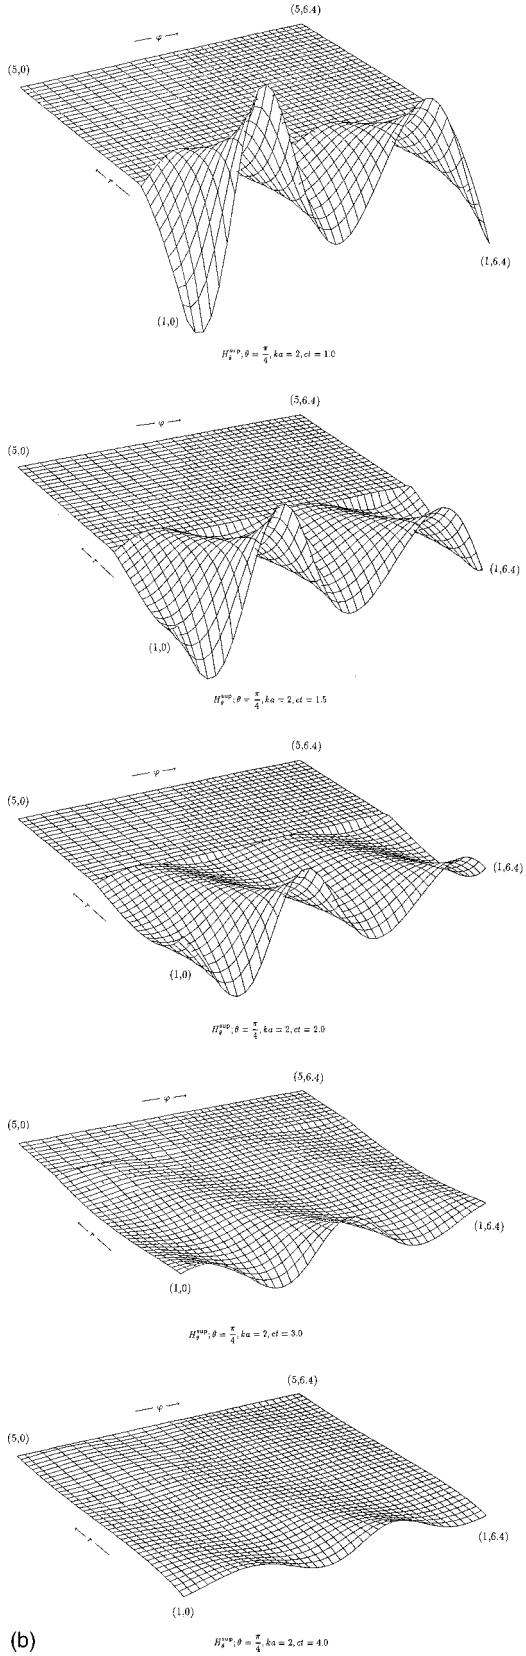


FIG. 5 (*Continued.*)

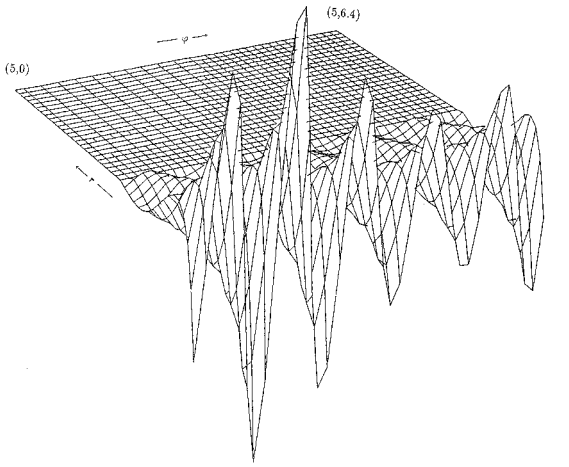
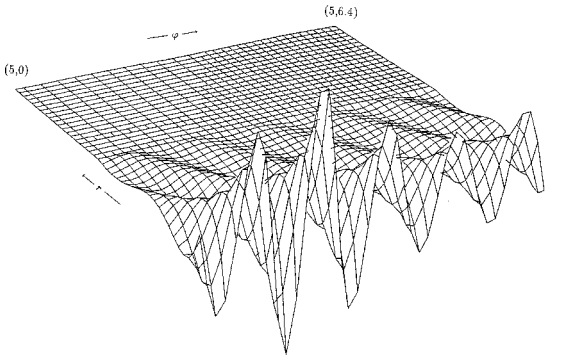
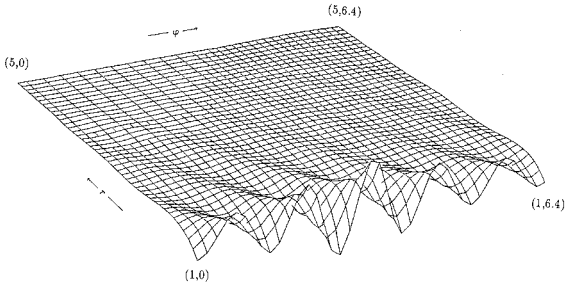


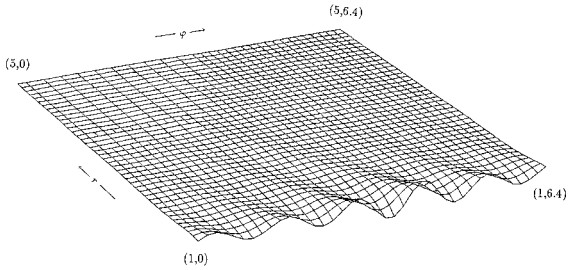
$H_\theta^{\text{sup}}; \theta = \frac{\pi}{2}, ka = 5, ct = 1.5$



$H_\theta^{\text{sup}}; \theta = \frac{\pi}{2}, ka = 5, ct = 2.0$



$H_\theta^{\text{sup}}; \theta = \frac{\pi}{2}, ka = 5, ct = 3.0$



(c) $H_\theta^{\text{sup}}; \theta = \frac{\pi}{2}, ka = 5, ct = 4.0$

FIG. 5 (*Continued.*)

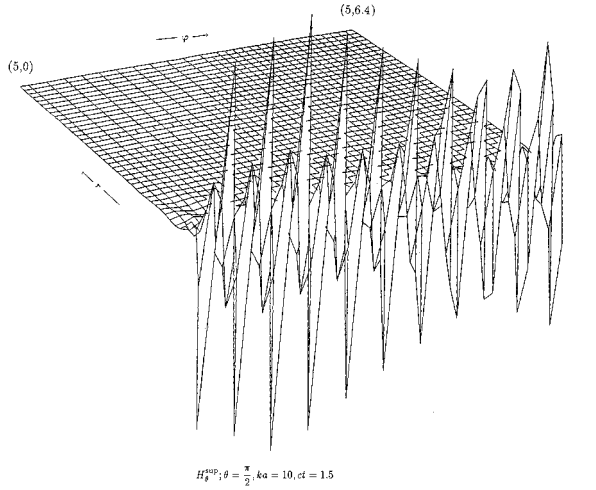


FIG. 5 (*Continued.*)

$$
\begin{aligned}
E_x(x,z,t) &= k_z \sin(k_z z) e^{i(kx-\omega t)},\\
E_y &= 0,\\
E_z(x,z,t) &= ik \cos(k_z z) e^{i(kx-\omega t)},\\
H_x &= 0,\\
H_y(x,z,t) &= -i \frac{\omega}{\mu_0 c^2} \cos(k_z z) e^{i(kx-\omega t)},\\
H_z &= 0,
\end{aligned}
\tag{5.3}
$$

where we have $\omega = c(k^2 + k_z^2)^{1/2}$.

We superpose these expressions by multiplying with a Gaussian weight factor, $a^2 e^{-(k_z a)^2}$ and integrating in k_z from 0 to ∞. Here a is an arbitrary length.
For $ct = 0$ we have

$$
\begin{aligned}
E_x^{\sup}(x,z) &= \frac{\pi^{1/2} z}{4a} e^{-z^2/4a^2} e^{ikx},\\
E_y^{\sup} &= 0,\\
E_z^{\sup}(x,z) &= i \frac{\pi^{1/2} ka}{2} e^{-z^2/4a^2} e^{ikx},\\
H_x^{\sup} &= 0,\\
H_y^{\sup}(x,z) &= -i \frac{\pi^{1/2}}{2\mu_0 c} \left(k^2 a^2 - \frac{z^2}{4a^2} \right)^{1/2} e^{-z^2/4a^2} e^{ikx},\\
H_z^{\sup} &= 0.
\end{aligned}
\tag{5.4}
$$

For $ct > z$ we have

$$
\begin{aligned}
E_x^{\sup}(x,z,t) &= \frac{(2\pi)^{1/2} e^{-i(3\pi/4)}}{2} \frac{(ka)^{3/2} z c t a^{1/2}}{(c^2 t^2 - z^2)^{5/4}} e^{-(ka)^2 z^2/(c^2 t^2 - z^2)} e^{ik[x-(c^2 t^2 - z^2)^{1/2}]},\\
E_y^{\sup} &= 0,\\
E_z^{\sup}(x,z,t) &= \frac{(2\pi)^{1/2} e^{i(\pi/4)}}{2} \frac{(ka)^{3/2} c t a^{1/2}}{(c^2 t^2 - z^2)^{3/4}} e^{-(ka)^2 z^2/(c^2 t^2 - z^2)} e^{ik[x-(c^2 t^2 - z^2)^{1/2}]},\\
H_x^{\sup} &= 0,\\
H_y^{\sup}(x,z,t) &= -\frac{(2\pi)^{1/2} e^{i(\pi/4)}}{2\mu_0 c} \frac{(ka)^{3/2} (ct)^2 a^{1/2}}{(c^2 t^2 - z^2)^{5/4}} e^{-(ka)^2 z^2/(c^2 t^2 - z^2)} e^{ik[x-(c^2 t^2 - z^2)^{1/2}]},\\
H_z^{\sup} &= 0.
\end{aligned}
\tag{5.5}
$$

Next, we superpose electromagnetic field components given by Eqs. (5.4) and (5.5) by multiplying with a Gaussian weight factor, $a e^{-(ka)^2}$, and integrating in k from 0 to ∞. For $ct = 0$ we have

$$E_x^{\sup}(x,z)=\frac{\pi^{1/2}}{4}\frac{z}{a}e^{-z^2/4a^2}\left[\frac{\pi^{1/2}}{2}e^{-x^2/4a^2}+i\frac{x}{2a}e^{-x^2/4a^2}\,{}_1F_1\left(\frac{1}{2};\frac{3}{2};\frac{x^2}{4a^2}\right)\right],$$

$$E_y^{\sup}=0,$$

$$E_z^{\sup}(x,z)=i\frac{\pi^{1/2}}{4}e^{-z^2/4a^2}\left[{}_1F_1\left(1;\frac{1}{2};-\frac{x^2}{4a^2}\right)+i\frac{\pi^{1/2}}{2}\frac{x}{a}e^{-x^2/4a^2}\right],$$

$$H_x^{\sup}=0,$$

$$H_y^{\sup}(x,z)=-i\frac{\pi^{1/2}}{4\mu_0 c}e^{-z^2/4a^2}\left[{}_1F_1\left(1;\frac{1}{2};-\frac{x^2}{4a^2}\right)+i\frac{\pi^{1/2}}{2}\frac{x}{a}e^{-x^2/4a^2}\right],$$

$$H_z^{\sup}=0. \tag{5.6}$$

For $ct>z$ we have

$$E_x^{\sup}(x,z,t)=\frac{(2\pi)^{1/2}e^{-i(3\pi/4)}}{4}\frac{za^{1/2}}{(ct)^{3/2}}F(x,z,t),$$

$$E_y^{\sup}=0,$$

$$E_z^{\sup}(x,z,t)=\frac{(2\pi)^{1/2}e^{i(\pi/4)}}{4}\frac{(c^2t^2-z^2)^{1/2}a^{1/2}}{(ct)^{3/2}}F(x,z,t),$$

$$H_x^{\sup}=0,$$

$$H_y^{\sup}(x,z,t)=-\frac{(2\pi)^{1/2}e^{i(\pi/4)}}{4\mu_0 c}\frac{a^{1/2}}{(ct)^{1/2}}F(x,z,t),$$

$$H_z^{\sup}=0. \tag{5.7}$$

Here we have

$$\begin{aligned}F(x,z,t)=&\Gamma\left(\frac{5}{4}\right)\,{}_1F_1\left(\frac{5}{4};\frac{1}{2};-\frac{(c^2t^2-z^2)[x-(c^2t^2-z^2)^{1/2}]^2}{4c^2t^2a^2}\right)\\&+i\frac{(c^2t^2-z^2)^{1/2}}{ct}\frac{[x-(c^2t^2-z^2)^{1/2}]}{a}e^{-(c^2t^2-z^2)[x-(c^2t^2-z^2)^{1/2}]^2/4c^2t^2a^2}\\&\times{}_1F_1\left(-\frac{3}{2};\frac{3}{2};\frac{(c^2t^2-z^2)[x-(c^2t^2-z^2)^{1/2}]^2}{4c^2t^2a^2}\right).\end{aligned} \tag{5.8}$$

We show $E_z^{\sup}(x,z,t)$ and $H_y^{\sup}(x,z,t)$ in Fig. 6, by taking their real parts. We made the calculations of wave amplitude until the distance, $(z-ct)\leqslant 0$, and beyond that distance we made them equal to zero. Therefore, the wave amplitude at $ct=0$ and those for $ct>0$ are not directly connected. The value at $z=0$ of the wave amplitude at $ct=0$ should be smoothly connected to the limiting value at $ct=0$ continued from $ct>0$, of the wave amplitude for $ct>0$. The fact that it does not look so in figures is due to the stationary phase approximations used in obtaining Eq. (5.5). Waves propagate in the x direction and simultaneously in the z direction as time goes on, without loss of the energy, and as a bulk.

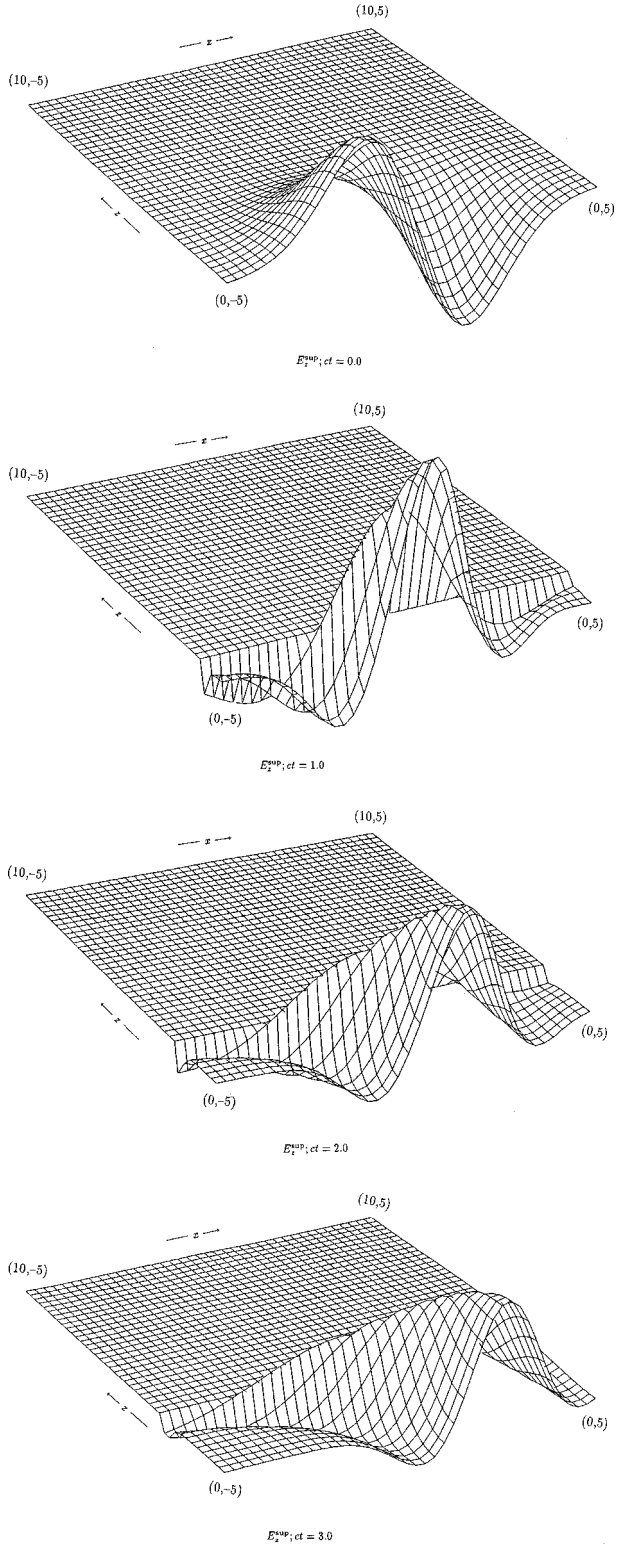

FIG. 6. Temporal behaviors of electromagnetic components, $E_x^{\mathrm{sup}}(x,z,t)$ and $H_y^{\mathrm{sup}}(x,z,t)$ in x and z space are drawn. Coordinates (z,x) stand for z values and x values, which they take when the amplitudes of electromagnetic fields are equal to zero, and in figures, they are drawn at the positions that the amplitudes actually take for corresponding cases and corresponding times. Electromagnetic waves move simultaneously to the z direction and x direction, as time goes on, without loss of the energy, and as a bulk.

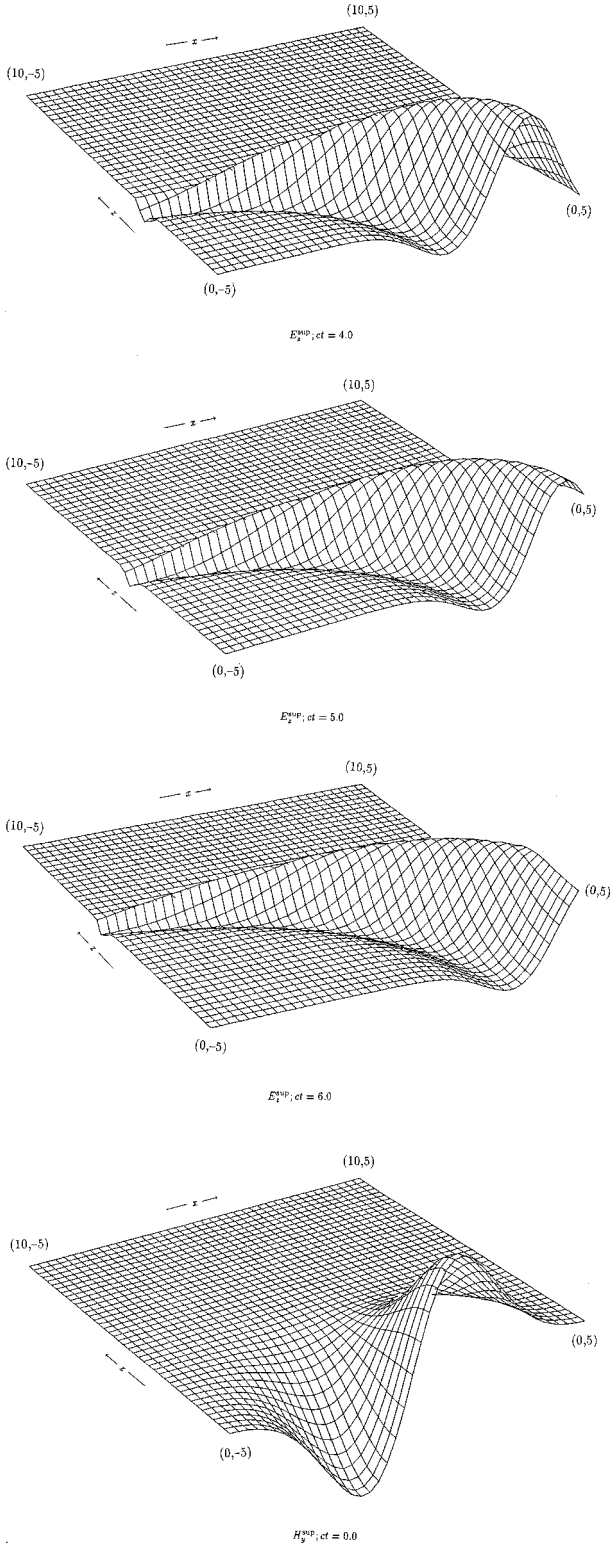

FIG. 6 (*Continued.*)

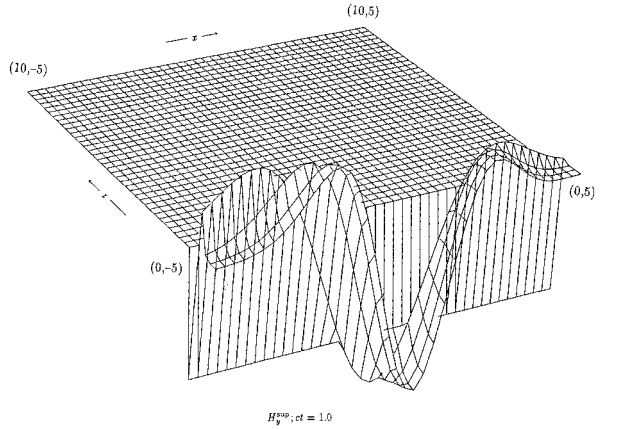
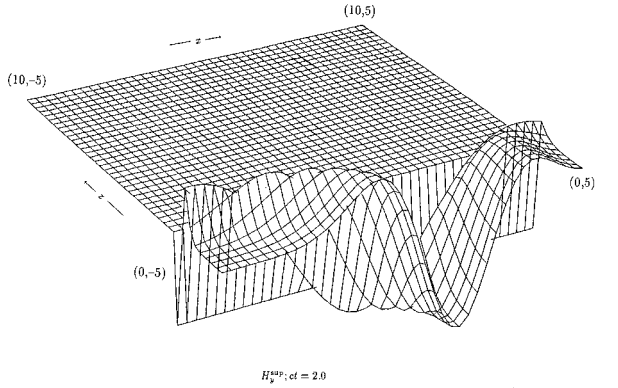
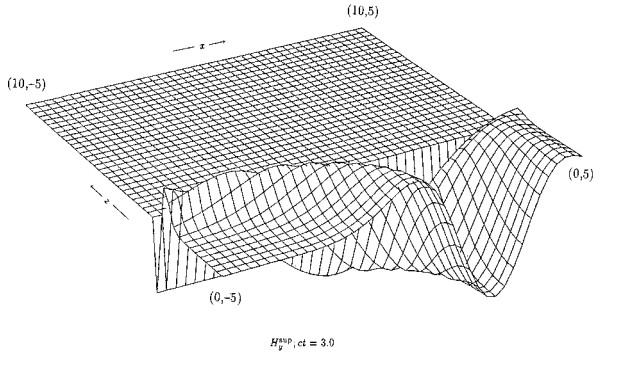


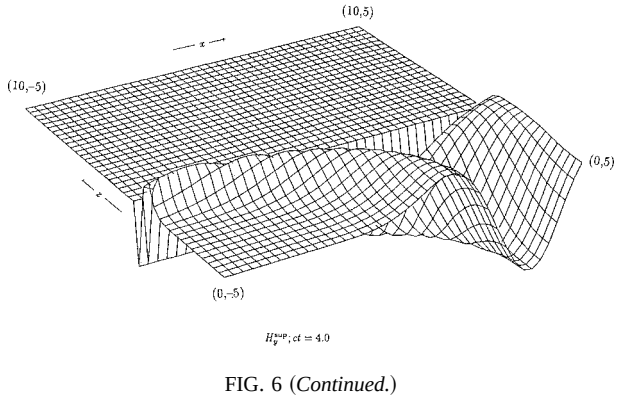
$H_y^{sup}; ct = 1.0$



$H_y^{sup}; ct = 2.0$



$H_y^{sup}, ct = 3.0$



$H_y^{sup}; ct = 4.0$

FIG. 6 (*Continued.*)

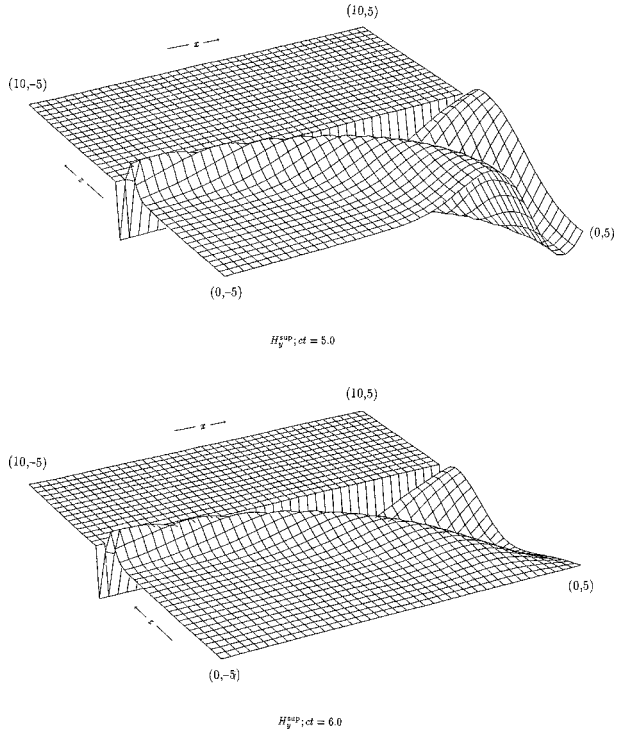


FIG. 6 (*Continued.*)

VI. SUMMARY

With a classical model of pseudophotons we obtained the qualitative picture of light waves diffracting a spherical superconductor. A quantum mechanical treatment of the same model gave the well-known TE and TM modes of an oscillating charged spherical superconductor with oscillating electromagnetic fields surrounding it.

Then we studied the temporal behavior of the charge distribution of the sphere and the electromagnetic field outside it, when the sphere with the axially symmetric charge distribution is suddenly rendered superconducting. A similar analysis was also made for an infinite plane superconductor. All complex eigenvalues for TM modes appear for given spherical harmonic index l in the first case, while continuous eigenvalues for given wave number k appear in the latter case. Nevertheless, physics looks similar in two cases.

The eigenvalues of TE and TM modes for a spherical superconductor are well approximated by the Debye and Sommerfeld formula. In this formula, a new characteristic integer appears in addition to spherical harmonic indices, l and m. Guided by the simple model stated above, and following the physical picture suggested by the works[6,7] by Franz and Deppermann (see Chap. III), we give a heuristic interpretation to the damping factor of the diffracting light waves in the shadow region of a spherical superconductor. This explanation automatically gives the physical meaning to the characteristic integer stated above.

We have made the computation of eigenvalues of Eq. (3.9) for TE modes, and Eq. (3.10) for TM modes, until spherical harmonic index $l=45$. With these values of TM modes we constructed the temporally changing states of coherent electromagnetic waves surrounding a spherical superconductor. The same analysis has been done for electromagnetic waves outside an infinite plane superconductor, and we obtained reasonable results in both cases.

ACKNOWLEDGMENTS

We obtain an exact expression for the equation of state for a classical 2-dimensional gravitating system, using Tsallis's statistical mechanics. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1335553]

I. INTRODUCTION

The statistical mechanical description of gravitating systems, regarding the granularity of matter, is very important to the study of astrophysical systems. Unfortunately, there are only a few toy models that can be analytically worked. However, due to the long-range nature of gravity, some additional problems arise when standard statistical mechanics is applied to these systems—the divergences of phase volume $g(E)$ in the microcanonical description and partition function in the canonical description, in the short and long distances of gravitational potential. Depending on the system, divergence in a short distance may occur in one or both descriptions.[1]

An other approach which is usually employed to describe the gravitating systems is based on the distribution function $f(\mathbf{x},\mathbf{v},\mathbf{t})$ in phase space, by considering the smooth gravitational potential and ignoring the granularity of the system. However, this approach applied to the equilibrium configuration due to some mechanisms like violent relaxation, also leads to a problem of infinite total mass.[2]

Recently, an alternative entropy function called Tsallis's entropy[3] has been used by Plastino to study the problem above. The author has shown that Tsallis's entropy can determine the meaningful distribution function as described by polytropic models,[4] and it may represent an important starting point for investigating the subject by using Tsallis's description.

In this paper, for simplicity, we study the two-dimensional gravitating system by using Tsallis's description and we obtain the corresponding exact equation of state, regarding the granularity of the system.

II. TSALLIS FORMALISM

In this section, we introduce some quantities of Tsallis's formalism, for simplicity, based on unnormalized constraints (second version).[3] We also present the relations between the second and the third (normalized constraints[5]) versions for the q-averages. Tsallis's entropy with probability p_i is given by

$$S_q = k\frac{1-\Sigma_{i=1}^{W} p_i^q}{q-1}, \tag{1}$$

a)Electronic mail: kwok@dfi.uem.br

where k is a positive constant, W is total number of microscopic configurations of the system and q is a real parameter. It should be noted that the standard entropy is recovered from (1) by taking it to the limit $q\to 1$. For simplicity, $k=1$, hereafter.

The connection with thermodynamics is obtained by extremizing S_q with the constraints

$$E_q=\langle H\rangle_q=\sum_{i=1}^{W} p_i^q \varepsilon_i \tag{2}$$

and

$$\sum_{i=1}^{W} p_i=1, \tag{3}$$

where E_q is the generalized internal energy. Hence, the probability of the canonical ensemble is given by

$$p_i=\frac{[1-\beta(1-q)\varepsilon_i]^{1/(1-q)}}{Z_q}, \tag{4}$$

where

$$Z_q=\sum_{i=1}^{W} [1-\beta(1-q)\varepsilon_i]^{1/(1-q)} \tag{5}$$

is the partition function of a canonical ensemble and β is a Lagrange multiplier. In order to retain a consistent probabilistic interpretation (eigenvalues of p_i must be nonnegative real numbers monotonically decreasing with the energy), the cut-off condition imposes $p_i(\varepsilon_i)=0$ whenever $[1-(1-q)\beta H]\leqslant 0$ ($\{\varepsilon_i\}$ is the set of eigenvalues of the Hamiltonian H).[3,5,6] From Eqs. (4) and (5) we can easily verify that

$$-\frac{\partial}{\partial\beta}\frac{Z_q^{1-q}-1}{1-q}=E_q. \tag{6}$$

Other useful relations:

$$\frac{Z_q^{1-q}-1}{1-q}+\beta E_q=S_q \tag{7}$$

and

$$\frac{\partial S_q}{\partial E_q}=\frac{1}{T}, \tag{8}$$

with $T\equiv 1/\beta$. From the definition of generalized free energy,

$$F_q=E_q-TS_q, \tag{9}$$

we obtain that

$$F_q=-\frac{1}{\beta}\frac{Z_q^{1-q}-1}{1-q}. \tag{10}$$

Notice that the constraint (2) is unnormalized, i.e., $\langle 1\rangle_q \neq 1$. A formulation based on the normalized constraint, has been worked in Ref. 5. The relation between the averages obtained within these formulations, based on the unnormalized and normalized constraints, can be established as follows:

$$\langle\langle \mathcal{O}\rangle\rangle_q(\beta)=\frac{\langle \mathcal{O}\rangle_q(\beta')}{\langle 1\rangle_q(\beta')}, \tag{11}$$

where $\langle\langle \mathcal{O}\rangle\rangle_q$ is the normalized constraint and β' is given by

$$\beta'=\frac{\beta}{\mathrm{Tr}\,\rho_q^q+(1-q)\beta\langle\langle H\rangle\rangle_q}. \tag{12}$$

III. 2-DIMENSIONAL GRAVITATING SYSTEM

The Hamiltonian of a two-dimensional gravitating system of N particles is given by

$$H=\sum_{i=1}^{N}\frac{P_i^2}{2m}+\frac{1}{2}\sum_{i\neq j}2Gm^2\ln|\mathbf{x}_i-\mathbf{x}_j|. \tag{13}$$

It should be noted that this system is analogous to that of 2-dimensional plasma when the constant (Gm^2) is replaced by $(-e_ie_j)$, where e_ie_j are the charges of particles.[7] Although the functional forms of these systems are similar, their physical properties are different because the charge particles may create screening.[8]

It is easy to show that the phase volume $g(E)$ of the system above, in the microcanonical ensemble, does not diverge since the particles are confined inside a large square box with length $2L$ $(-L,+L)$.[1] However, $g(E)$ cannot be analytically calculated.

In a canonical description, the central quantity is the partition function. From it one can calculate any thermodynamical quantity. It is given by

$$Z(\beta)=\int_{-L}^{+L}\prod_{i=1}^{N}\mathrm{d}^2P_i\,\mathrm{d}^2x_i\exp(-\beta H), \tag{14}$$

in classical statistical mechanics. Integrating out the momenta we obtain

$$Z(\beta)=\left(\frac{2\pi m}{\beta}\right)^N\int_{-L}^{+L}\prod_{i=1}^{N}\mathrm{d}^2x_i\exp\left(-\beta\sum_{i\neq j}Gm^2\ln|\mathbf{x}_i-\mathbf{x}_j|\right). \tag{15}$$

We observe that this last integral does not exist near the origin, except for

$$\beta<\beta_c=2[Gm^2(N-1)]^{-1}. \tag{16}$$

This means that below T_c the partition function diverges.

We now calculate the equation of state of the system above by using Tsallis's description. As in standard statistical mechanics, we replace the sum of Eq. (5) by the following integral:

$$Z_q(\beta)=\int_{-L}^{+L}\prod_{i=1}^{N}\mathrm{d}^2P_i\,\mathrm{d}^2x_i[1-\beta(1-q)H]^{1/(1-q)}. \tag{17}$$

We should note that Z_q does not exist near the origin for $q>1$. For this reason, we restrict our analysis for $q<1$. Moreover, we also assume that the particles are confined inside a large box which each x_i given by $(-L,+L)$, in order to maintain the integral (17) finite for large x_i. It

should be also noticed that the integration of Z_q over the momenta has a cutoff and should be adequately treated. To do so, we use the following integral representation of the gamma function:[9]

$$\frac{e^{ab}b^{z-1}}{2\pi}\int_{-\infty}^{+\infty}\mathrm{d}t\,\frac{e^{ibt}}{(a+\mathrm{i}t)^z}=\begin{cases}\dfrac{1}{\Gamma(z)} & \text{for} \quad b>0,\\ 0 & \text{for} \quad b<0,\end{cases} \tag{18}$$

by setting $b=[1-(1-q)\beta\Sigma_{i=1}^{N}(P_i^2/2m)/(1+\beta(q-1)\Sigma_{i\neq j}Gm^2\ln|\mathbf{x}_i-\mathbf{x}_j|)]^{1/(1-q)}$, $a=1$ and $z-1=1/(1-q)$. The representation (18) was also used in Ref. 10. An other integral representation valid for $q<1$ was established by Prato,[11] while the integral representation for $q>1$ was established by Hilhorst and was applied to study noninteracting particles.[12] Using Eq. (18) to take into account the cutoff of Eq. (17), we obtain

$$Z_q(\beta)=A\int_{-L}^{+L}\mathrm{d}^2x_1\ldots.\mathrm{d}^2x_N\left(1+\beta(q-1)\sum_{i\neq j}Gm^2\ln|\mathbf{x_i}-\mathbf{x_j}|\right)^{N+1/(1-q)}, \tag{19}$$

where

$$A=\left(\frac{2\pi m}{\beta(1-q)}\right)^N\frac{\Gamma\left(1+\dfrac{1}{1-q}\right)}{\Gamma\left(1+N+\dfrac{1}{1-q}\right)}. \tag{20}$$

We note that the integral (19) is similar of that of phase volume [see Eq. (3.40) of Ref. 1]. It has the form $\int\mathrm{d}x\,x[\ln(x^{\beta(1-q)Gm^2})^{-1}]^{N+1/(1-q)}$ in polar coordinates and it transforms into $\int\mathrm{d}z\,z^{N+1/(1-q)}\exp[-2z/(\beta(1-q)Gm^2)]$ with the variable $z=-\ln x^{(\beta(1-q)Gm^2)}$. Near the origin ($x\to 0$ and $z\to\infty$), the exponential function suppresses the power function, therefore, the integral does not diverge. This means that the partition function (19) is finite. We now redefine the variables $y_i=x_i/L$ in Eq. (19); then we get

$$Z_q(\beta,L)=A\int_{-1}^{1}\mathrm{d}^2y_1\ldots\mathrm{d}^2y_N\times\left[1+(q-1)\beta Gm^2\left(N(N-1)\ln L+\sum_{i\neq j}\ln|\mathbf{y_i}-\mathbf{y_j}|\right)\right]^{N+1/1(-q)}. \tag{21}$$

Differentiating $Z_q(\beta,L)$ with respect to L and using the following expression for the pressure:

$$P=-\frac{\partial F_q}{\partial V}=\frac{1}{\beta Z_q^q}\frac{\partial Z_q}{\partial V}, \tag{22}$$

where V is the two-dimensional volume (L^2), we obtain

$$P=\frac{N}{V\beta}\left\{Z_q^{1-q}-[1+N(1-q)]\frac{N-1}{2}\beta Gm^2H(\beta,L)\right\} \tag{23}$$

and

$$H(\beta,L)=A\int_{-L}^{+L}\mathrm{d}^2x_1\ldots\mathrm{d}^2x_N\left(1+\beta(q-1)\sum_{i\neq j}Gm^2\ln|\mathbf{x_i}-\mathbf{x_j}|\right)^{-1+N+1/(1-q)}. \tag{24}$$

Although the partition function Z_q is finite, the pressure P becomes negative for all V if $[1+N(1-q)](N-1)\beta Gm^2H(\beta,L)/(2Z_q^{1-q})>1$. Using now the expressions (9) and (10), we can write the expression (23) as follows:

$$P=\frac{N}{V\beta}\left\{1-\frac{N-1}{2}\beta Gm^2-(1-q)\beta\left[F_q+\frac{N-1}{2}Gm^2S_q\right]\right\}. \tag{25}$$

For $q\to 1$, we recover the standard result[1]

$$P=\frac{N}{V\beta}\left\{1-\frac{N-1}{2}\beta Gm^2\right\}. \tag{26}$$

For completeness, we now discuss about the three-dimensional gravitating system. In this case, the Hamiltonian is given by

$$H=\sum_{i=1}^{N}\frac{P_i^2}{2m}-\frac{1}{2}\sum_{i\neq j}\frac{Gm^2}{|\mathbf{x_i}-\mathbf{x_j}|}. \tag{27}$$

The phase volume $g(E)$ of this system diverges for $N\geqslant 3$.[1] In the standard canonical ensemble, the partition function diverges near the origin because the integrand has the form $r^2\exp(1/r)$. In the case of Tsallis's description, for $q<1$, we have

$$Z_q(\beta)=B\int_{-L}^{+L}\prod_{i=1}^{N}\mathrm{d}^3x_i\left[1+\beta(1-q)\frac{1}{2}\sum_{i\neq j}\frac{Gm^2}{|\mathbf{x_i}-\mathbf{x_j}|}\right]^{3N/2+1/(1-q)}, \tag{28}$$

where

$$B=\left(\frac{2\pi m}{\beta(1-q)}\right)^{3N/2}\frac{\Gamma\left(1+\dfrac{1}{1-q}\right)}{\Gamma\left(1+\dfrac{3N}{2}+\dfrac{1}{1-q}\right)}. \tag{29}$$

The integral to be calculated in (28) is of the form

$$\int_0^{\varepsilon}\mathrm{d}x\,x^2\left[1+\beta(1-q)\frac{1}{2}\frac{Gm^2}{x}\right]^{3N/2+1/(1-q)}=\lim_{\varepsilon\to 0}x^{3-1/(1-q)-3N/2}, \tag{30}$$

which diverges for $N\geqslant 2-2/[3(1-q)]$. This condition is more restrictive than that given in the calculation of phase volume.

Let us now consider the third version of Tsallis's statistics,[5] with the use of normalized constraint $E_q^{(3)}=\Sigma_{i=1}^{W}p_i^q\varepsilon_i/\Sigma_{j=1}^{W}p_j^q$. The partition function of the system (13), for $q<1$, is given by

$$(Z_q^{(3)}(\beta))^2=A\int_{-L}^{+L}\prod_{i=1}^{N}\mathrm{d}^2x_i\left\{(Z_q^{(3)})^{1-q}+\beta(1-q)\left[E_q^{(3)}-\sum_{i\neq j}Gm^2\ln|\mathbf{x_i}-\mathbf{x_j}|\right]\right\}^{N+1/(1-q)}, \tag{31}$$

in which we have integrated out all the momenta. We now change the variables $y_i=x_i/L$, then

$$(Z_q^{(3)}(\beta,L))^2=A\int_{-1}^{+1}\Pi_{i=1}^{N}\mathrm{d}^2y_i\times L^{2N}\left\{(Z_q^{(3)})^{1-q}+\beta(1-q)\left[E_q^{(3)}-\sum_{i\neq j}Gm^2\ln(L|\mathbf{y_i}-\mathbf{y_j}|)\right]\right\}^{N+1/(1-q)}. \tag{32}$$

We observe that this last equation depends implicitly on $Z_q^{(3)}$ and L. Thus, it turns out to be very difficult (according to our analysis) to obtain an exact expression for the equation of state.

IV. CONCLUSION

Contrary to standard statistical mechanics, we have shown that Tsallis's statistical mechanics[3] can describe the toy model of the two-dimensional gravitating system, in a canonical ensemble, without divergence near the origin of gravitational potential, even for $N \gg 1$. Moreover, for the limit $q \to 1$, we have recovered the standard result. Since the partition function Z_q is finite for $q < 1$, the system is thermodynamically acceptable, in principle. In the three-dimensional gravitating system, the phase volume diverges for $N \geqslant 3$. In Tsallis's description, the condition of divergence for Z_q is more restrictive than that given by phase volume, i.e., it diverges for $N > 2 - 2/[3(1-q)]$. This last condition is not thermodynamically acceptable because none of the thermodynamic quantities is well-defined for $N > 1$.

Despite the success of Tsallis's statistics applied to several systems,[13] a deeper investigation into the subject is needed to understand this interesting generalization of standard statistical mechanics.

How does a shock in supersonic flow grow out of smooth data?

Shuxing Chen[a)]

(Received 7 October 1999; accepted for publication 30 November 2000)

This paper is devoted to the precise description of the process of formation and construction of shock waves. If a steady supersonic flow moves above a concavely curved wall, then the flow is compressed by the bending wall, and a suspended shock will be formed in the flow field. This fact with the existence of solution having an assigned singularity structure is rigorously proved. It is indicated that the suspended shock will start from the cusp of the envelope of λ_+ characteristics. Moreover, some estimates describing the behavior of the solution near the cusp are also obtained. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1343094]

I. INTRODUCTION

In the study of the quasilinear hyperbolic system of conservation laws a most important phenomena is that smooth initial data may develop discontinuities. The fact corresponding to such phenomena in fluid dynamics is that supersonic flow often contains shocks and other singularities in the flow field, even though all data to determine the flow are smooth. Besides some of the simplest examples for the Cauchy problem of the scalar equation (see Refs. 1 and 2), Sideris proved in Refs. 3 and 4 that under rather general assumptions the smooth solution of the Euler system, describing compressible flow, must blow up in finite time. In the case of steady flow, when a supersonic flow passes around a smooth concave wall, the flow is compressive due to the bending of the wall. Then, a suspended shock will be formed in a bounded domain (see Refs. 5 and 6).

In this paper we will give a detailed analysis of the problem arising in supersonic flow past a bended rigid wall. Though people have known the fact from physical experience that a shock will be formed somewhere above the bended wall, more accurate information is obviously important. The information includes the location of blowup points and the precise structure and estimate of the solution near the place of blowup. It will not only offer us the knowledge of how the discontinuity comes from smooth data, but also gives us a preparation to construct a global solution. In this aspect we mention Alinhac's work on the mechanism of blowup. In Refs. 7 and 8, Alinhac introduces two kinds of mechanism of blowup, namely, ordinary differential equation blowup and geometric blowup. According to this classification the blowup caused by the curved rigid wall in steady supersonic flow belongs to geometric blowup. As we will show, the derivatives of solution become infinity at the point of blowup, while the solution itself remains bounded. Besides, the strength of the shock is zero at the blowup point and then gradually increases.

The process of shock formation for scalar quasilinear hyperbolic equations has been well known for a long time. In this case, the shock appears, starting from the cusp of the envelope of characteristics of the equation. Meanwhile the shock can be determined by solving an ordinary differential equation (see Refs. 1 and 2). In the case of the p system, Lebaud discussed the problem of shock formation under the assumption that one Riemann invariant remains constant in Ref. 9. For steady potential flow, which is an approximation of the Euler system under the assumption of ''isentropic'' and ''irrotational,'' such a discussion is also presented (see Ref. 6).

a)Electronic mail: sxchen@fudan.ac.cn

Certainly, people are more interested in the case without such assumptions, because in fact the flow will be neither isentropic nor irrotational once the shock appears. In this paper we will use the original Euler system to describe steady flow, and give a complete construction of the shock in the neighborhood of the starting point of the shock. In the whole paper we only consider the flow with two space variables.

The Euler system describing the two-dimensional steady flow is

$$\frac{\partial}{\partial x}\begin{pmatrix} \rho u \\ p+\rho u^2 \\ \rho uv \\ \rho uE+pu \end{pmatrix}+\frac{\partial}{\partial y}\begin{pmatrix} \rho v \\ \rho uv \\ p+\rho v^2 \\ \rho vE+pv \end{pmatrix}=0, \tag{1.1}$$

where (u,v), p, ρ, E represent components of velocity, pressure, density, and energy, respectively. For polytropic gas $E=\frac{1}{2}(q^2)+e, p=A(S)\rho^{\gamma}$, where S is entropy, γ is the adiabatic exponent, $q^2=u^2+v^2$, $e=p/(\gamma-1)\rho$, $A(S)=(\gamma-1)e^{c_v(S-S_0)}$ with c_v being a constant.

From (1.1) we know that along every streamline Bernoulli's relation holds

$$\frac{1}{2}(u^2+v^2)+\frac{a^2}{\gamma-1}=\text{const}, \tag{1.2}$$

where a is sonic speed, which is

$$a=\left(\frac{\mathrm{d}p}{\mathrm{d}\rho}\right)_S^{1/2}=A(S)\gamma\rho^{\gamma-1}=A(S)^{1/\gamma}\gamma p^{(\gamma-1)/\gamma}. \tag{1.3}$$

We also remark here that the constant in (1.2) may be different along different streamlines.

Assume that there is a curved wall with equation $y=f(x)$, $f(x)\in C^{p+1}$, $p\geqslant 4$, which satisfies

$$\begin{cases} f(x)\equiv 0, & x\leqslant 0, \\ f(x)>0, f'(x)>0, f''(x)>0, & x>0. \end{cases} \tag{1.4}$$

According to (1.4) the wall is curved up starting from the right side of the origin. Therefore, when a supersonic flow comes from the left side with velocity $(q_\infty,0)$, it is compressed in $x\geqslant 0$ by the wall. The compression will cause formation of a shock.

On the shock the solution of (1.1) is discontinuous, and the parameters of the flow on the both sides satisfy the Rankine–Hugoniot condition

$$\begin{gathered} \rho_0 u_{0n}=\rho_1 u_{1n}, \\ p_0+\rho_0 u_{0n}^2=p_1+\rho_1 u_{1n}^2, \\ u_{0t}=u_{1t}, \\ \frac{1}{2}q_0^2+\frac{\gamma p_0}{(\gamma-1)\rho_0}=\frac{1}{2}q_1^2+\frac{\gamma p_1}{(\gamma-1)\rho_1}, \end{gathered} \tag{1.5}$$

where u_n, u_t represent the normal and tangential components of velocity, the subscript ''0'' or ''1'' represents the value of corresponding quantities ahead or behind the shock. Besides, on the shock the entropy condition

$$S_1>S_0 \tag{1.6}$$

should also be satisfied. To simplify notations we often omit the subscript ''1,'' if no confusion is caused.

Ahead of the shock the flow is assumed to be uniform. So the constant in (1.3) equals $\frac{1}{2}u_0^2 + [1/(\gamma-1)]a_0^2$. Corespondingly, the system (1.12) can be reduced to a system with three equations

$$\begin{cases} K(p,\theta,S)\dfrac{\mathrm{d}p}{\mathrm{d}\ell_+} + \dfrac{\mathrm{d}\theta}{\mathrm{d}\ell_+} = 0, \\ \dfrac{\mathrm{d}S}{\mathrm{d}\ell_0} = 0, \\ K(p,\theta,S)\dfrac{\mathrm{d}p}{\mathrm{d}\ell_-} - \dfrac{\mathrm{d}\theta}{\mathrm{d}\ell_-} = 0, \end{cases} , \tag{1.7}$$

where

$$\frac{\mathrm{d}}{\mathrm{d}\ell_{\pm,0}} = \frac{\partial}{\partial x} + \lambda_{\pm,0}\frac{\partial}{\partial y}$$

is the directional derivative along the characteristics

$$\ell_{\pm,0}, \theta = \arctan\frac{v}{u}, K(p,\theta,S) = \frac{1}{\rho q^2 \tan A},$$

A is the Mach angle. Besides,

$$\lambda_\pm = \frac{uv \pm \sqrt{q^2-a^2}}{u^2-a^2}, \quad \lambda_0 = \frac{v}{u}. \tag{1.8}$$

It is convenient to introduce new unknown functions z, w, which amount to Riemannian invariants in the irrotational case. Let $z = \theta - F(q)$, $w = \theta + F(q)$ with

$$F(q) = \int \frac{\sqrt{q^2-a^2}}{aq}\mathrm{d}q,$$

(1.7) can be rewritten as

$$\begin{cases} \dfrac{\mathrm{d}z}{\mathrm{d}\ell_+} - \mathrm{d}\dfrac{\mathrm{d}S}{\mathrm{d}\ell_+} = 0, \\ \dfrac{\mathrm{d}S}{\mathrm{d}\ell_0} = 0, \\ \dfrac{\mathrm{d}w}{\mathrm{d}\ell_-} + \mathrm{d}\dfrac{\mathrm{d}S}{\mathrm{d}\ell_-} = 0, \end{cases} \tag{1.9}$$

where

$$d = \frac{1}{\gamma(\gamma-1)A(s)}\frac{a\sqrt{q^2-a^2}}{q^2}.$$

According to the shock theory of compressible flow (see Ref. 10), across λ_+ shock the jump of z is the main part of the jump of parameters of the flow, while the jump of w and S is only a quantity of third order, comparing the strength of shock.

Before the formation of shock the uniform upstream flow has become a nonuniform flow by the influence of the curved wall. If the wall is not greatly bended, the flow near the wall can be obtained by a characteristic method. The flow in this region is called the Prandtl–Meyer flow,

where all parameters keep constant on each λ_+ characteristic line. In this case, by viewing $u(x,y)$, $v(x,y)$ as a map from the plane (x,y) to the plane (u,v), the whole region of the Prandtl–Meyer flow is mapped to an epicycloidal (see Ref. 5)

$$\begin{cases} u = a_*(\cos\mu(\omega-\omega_*)\cos\omega + \mu^{-1}\sin\mu(\omega-\omega_*)\sin\omega), \\ v = a_*(\cos\mu(\omega-\omega_*)\sin\omega - \mu^{-1}\sin\mu(\omega-\omega_*)\cos\omega), \end{cases} \tag{1.10}$$

where

$$\mu = \left(\frac{\gamma-1}{\gamma+1}\right)^{1/2},$$

a_* is the critical sound speed, $\omega_* = \mu^{-1}\arccos(a_0/a_*)$, and a_0 is the sound speed of the upstream flow.

Since the direction of the velocity on the wall must be tangential to the surface of the body, we have at the point $(\overline{x}, f(\overline{x}))$

$$f'(\overline{x}) = \frac{\cos\mu(\omega-\omega_*)\sin\omega - \mu^{-1}\sin\mu(\omega-\omega_*)\cos\omega}{\cos\mu(\omega-\omega_*)\cos\omega + \mu^{-1}\sin\mu(\omega-\omega_*)\sin\omega}. \tag{1.11}$$

Correspondingly, we must require that the angle γ of the tangential line with the x axis is always less than ω_*, i.e.,

$$\arctan f'(\overline{x}) < \omega_* \quad \text{for any } \overline{x}. \tag{1.12}$$

The derivative of the right-hand side of (1.11) with respect to ω is

$$(\cos\mu(\omega-\omega_*)\cos\omega + \mu^{-1}\sin\mu(\omega-\omega_*)\sin\omega)^{-2}\mu^{-1}(\mu^{-1}-\mu)\sin^2\mu(\omega-\omega_*),$$

which is positive identically. Therefore, from the assumption $f''>0$ we know that (1.11) determines a one-to-one map between $\overline{x}$ and ω. Moreover, $\omega(\overline{x})$ is a C^p increasing function.

Notice that the geometric meaning of the parameter ω is the angle of y axis with the normal to λ_+ characteristics (see Ref. 5). Then the equation of the characteristics issuing from $(\overline{x}, f(\overline{x}))$ is

$$\begin{cases} x = \overline{x} + t\cos\left(\omega - \dfrac{\pi}{2}\right) = \overline{x} + t\sin\omega, \\ y = f(\overline{x}) + t\sin\left(\omega - \dfrac{\pi}{2}\right) = f(\overline{x}) - t\cos\omega, \end{cases} \tag{1.13}$$

where $\omega = \omega(\overline{x})$ is determined by (1.11).

The family of characteristics of (1.13) is compressed and then forms an envelope, because the wall is curved up. The envelope is determined by

$$\Delta \equiv \frac{\partial(x,y)}{\partial(t,\overline{x})} = 0. \tag{1.14}$$

Equation (1.14) implies

$$t = -\frac{1}{\omega'}(f'\sin\omega + \cos\omega).$$

Substituting it into (1.13) we obtain

$$\begin{cases} x=\overline{x}-\dfrac{1}{\omega'}(f'\sin\omega(\overline{x})+\cos\omega(\overline{x}))\sin\omega(\overline{x}), \\ y=f(\overline{x})+\dfrac{1}{\omega'}(f'\sin\omega(\overline{x})+\cos\omega(\overline{x}))\cos\omega(\overline{x}). \end{cases} \tag{1.15}$$

Simply denote (1.15) as $x=k(\overline{x})$, $y=h(\overline{x})$. If $k(\overline{x})$ takes its minimum at $\overline{x}=\overline{x_0}$:

$$k'(\overline{x_0})=0, \quad (\overline{x}-\overline{x_0})k'(\overline{x})>0, \tag{1.16}$$

then the envelope has a cusp at $(x_0,y_0)=(k(\overline{x_0}),h(\overline{x_0}))$, which will be the starting point of shock.

The main result of this paper is:

Theorem 1.1: Assume that a uniform upstream flow with velocity $(u_0,0)$ moves above the wall $y=f(x)$ from left to right, $u_0>a_0$, $f(x)$ satisfies (1.4), (1.11), and (1.16), then system (1.1) admits a solution, which is continuously differentiable in $x<x_0$ and has a shock $\Gamma: y=\phi(x)$ starting from the point (x_0,y_0). In the neighborhood Ω of (x_0,y_0), the solution is also continuously differentiable in $\Omega\backslash\Gamma$. Besides, the solution satisfies the Rankine–Hugoniot condition and entropy condition on Γ, and their estimates in Ω can be expressed through z,w,S as follows:

$$\begin{cases} \phi(x)=y_0+\alpha(x-x_0)+O((x-x_0)^2), \\ w=w_0+O((x-x_0)^{3/2}), \\ z=z_0+O((x-x_0)^3+(y-y_0-\alpha(x-x_0))^2)^{1/6}, \\ S=S_0+O((x-x_0)^{3/2}), \end{cases} \tag{1.17}$$

where w_0,z_0,S_0 are the values of the corresponding functions at the point (x_0,y_0), and α is the slope of the λ_+ characteristics at this point.

We remark here that some weaker singularities of the solution of (1.1) may propagate into the domain $x>x_0$ along the characteristics through (x_0,y_0), though the solution is continuous there.

The solution (z,w,S) in $x\geqslant x_0$ will be constructed by an iterative procedure. To this end we are going to construct a sequence of solutions $\{z^{(\nu)}(x,y)\}$, $\{w^{(\nu)}(x,y)\}$, $\{S^{(\nu)}(x,y)\}$ and a corresponding sequence $\phi^{(\nu)}(x)$ standing for the location of the approximate shock, and then prove the convergence of these sequences. Here we take $w^{(0)}(x,y)=w_0, S^{(0)}(x,y)=S_0$ as the first approximation of w and S, while $z^{(0)}(x,y)$ as well as the position of the approximate shock $y=\phi_0(x)$ are determined by a conservation law corresponding to the first equation of (1.9). Then the whole sequence $\{z^{(\nu)}\}$, $\{w^{(\nu)}\}\{S^{(\nu)}\}$ can be successively determined by the characteristic method, while $\{\phi^{(\nu)}(x)\}$ can be determined by the Rankine–Hugoniot condition correspondingly.

The remainder of this paper is arranged as follows: In Sec. II we give a first approximation of system (1.9), which defines $z^{(0)}(x,y)$, $\phi^{(0)}(x)$, and give some description of the approximation as a preparation for further discussion. In Sec. III we give an iterative scheme to construct the sequence of approximate solutions, and set up a proposition $F^{(\nu)}$, which indicates the estimates satisfied by the approximate solutions and which should be verified inductively later. According to this scheme, Sec. IV is devoted to the estimates of $\{z^{(\nu+1)}\}$, $\{w^{(\nu+1)}\}$, $\{S^{(\nu+1)}\}$, and $\{\phi^{(\nu)}\}$ under the assumption $F^{(\nu)}$. Section V is devoted to the estimates of derivatives of all these functions. Finally, in Sec. VI we establish the convergence of all these sequences, and then prove the main conclusion in this paper.

II. FIRST APPROXIMATION

As mentioned previously, we take $w^{(0)}(x,y)=w_0$, $S^{(0)}(x,y)=S_0$ as the first approximation of w,S in $x>x_0$. Since both $w^{(0)}$ and $S^{(0)}$ can be added by an arbitrary constant, so we simply take $w_0=S_0=0$. Take δ as a suitable small number, then $\Gamma:\{x=x_0-\delta, y>f(x_0-\delta)\}$ locates in the domain of Prandtl–Meyer flow. All parameters of the flow on Γ are known. So the flow near

(x_0,y_0) can also be determined by the data on Γ. It means that the problem to determine the solution near (x_0,y_0) can be reduced to a Cauchy problem of system (1.1) [or (1.9)] with data $w=S=0, z=z_0(y)\in C^p$ on Γ.

To seek the first approximation of $z(x,y)$ we substitute $w=S=0$ into (1.9). The first equation (1.9) is then reduced to

$$\partial_x z(x,y)+\lambda_+\partial_y z(x,y)=0, \tag{2.1}$$

where

$$\lambda_+=\frac{uv+a\sqrt{q^2-a^2}}{u^2-a^2}.$$

In the domain $x<x_0$, $w=S=0$ combined with the solution of the first equation (2.1) coincides with the solution of the whole system (1.9). Since the solution of (2.1) may have discontinuity in the domain $x\geqslant x_0$, to describe the discontinuity condition on shock we need to reduce (2.1) to a suitable form of conservation law and let the discontinuity condition for (2.1) coinside with the Rinkine–Hugoniot condition of (1.1).

Recall the definitions of z and w, we have $\theta=\frac{1}{2}(z+w), F(q)=\frac{1}{2}(w-z)$. Denote G as the inverse function of $F(q)$, then

$$q=G\left(\frac{w-z}{2}\right),$$

and

$$\lambda_+=\frac{G^2\cos\frac{z}{2}\sin\frac{z}{2}+\sqrt{G^2-(\gamma-1)\left(c_0-\frac{1}{2}G^2\right)}}{G^2\cos^2\frac{z}{2}-(\gamma-1)\left(c_0-\frac{1}{2}G^2\right)}, \tag{2.2}$$

where $G=G(-z/2)$.

Compare Eq. (2.1) with the conservation law of mass in (1.1). The first equation in (1.1) for $w=S=0$ can be written as

$$(\rho_z u+\rho u_z)z_x+(\rho_z v+\rho v_z)z_y=0. \tag{2.3}$$

On the other hand, under the assumption $S=\text{const}$ we have

$$qq_z+\frac{a^2}{\rho}\rho\rho_z=0.$$

Direct calculation implies

$$\rho_z u+\rho u_z=\frac{1}{2}\frac{\rho q^2 u}{a\sqrt{q^2-a^2}}-\frac{1}{2}\frac{\rho a u}{\sqrt{q^2-a^2}}-\frac{1}{2}\rho v, \tag{2.4}$$

$$\rho_z v+\rho v_z=\frac{1}{2}\frac{\rho q^2 v}{a\sqrt{q^2-a^2}}-\frac{1}{2}\frac{\rho a v}{\sqrt{q^2-a^2}}+\frac{1}{2}\rho u. \tag{2.5}$$

Moreover,

$$\lambda_+\left(\frac{\rho q^2 u}{a\sqrt{q^2-a^2}}-\frac{\rho a u}{\sqrt{q^2-a^2}}-\rho v\right)=\frac{\rho q^2 v}{a\sqrt{q^2-a^2}}-\frac{\rho a v}{\sqrt{q^2-a^2}}+\rho u.$$

Therefore, multiplying (2.1) by $(\rho_z u+\rho u_z)_{w=S=0}$ we obtain

$$((\rho u)_z)_{w=S=0}\partial_x z+((\rho v)_z)_{w=S=0}\partial_y z=0, \tag{2.6}$$

which coincides with (2.3).

To analyze the weak solution of (2.6), we view ρu as a new unknown function m. Notice that

$$(\rho u)_z>0$$

for $u>a$, then $m(z)$ is an increasing function, and (2.6) can be written as

$$m_x+f(m)_y=0. \tag{2.7}$$

Viewing the coordinate $\overline{y}$ on Γ as a parameter, the family of λ_+ characteristics can be denoted as

$$y=\overline{y}+xg(\overline{y}). \tag{2.8}$$

The envelope of the family (2.8) is

$$x=-\frac{1}{g'(\overline{y})},\quad y=\overline{y}-\frac{g(\overline{y})}{g'(\overline{y})}, \tag{2.9}$$

which is another form of (1.14). Correspondingly, we have

$$k(\overline{x})=-\frac{1}{g'(\overline{y})},\quad k'(\overline{x})=\frac{g''(\overline{y})}{g'(\overline{y})^2}\frac{d\overline{y}}{d\overline{x}}, \tag{2.10}$$

Let us choose $\overline{y_0}$, so that the straight line $y=\overline{y_0}+xg(\overline{y_0})$ is just the λ_+ characteristics through $(k(\overline{x_0}),h(\overline{x_0}))$. In view of the fact that the slope of λ_+ characteristics is positive and bounded away from zero, there is a constant c, such that $c^{-1}(x-x_0)\leqslant y-y_0\leqslant c(x-x_0)$. Hence

$$\begin{gathered}k'(\overline{x_0})=0\leftrightarrow g''(\overline{y_0})=0,\\ (\overline{x}-\overline{x_0})k'(\overline{x_0})\geqslant 0,\leftrightarrow(\overline{y}-\overline{y_0})g''(\overline{y})\geqslant 0.\end{gathered} \tag{2.11}$$

Generally, for the initial problem of quasilinear equation (2.7), when the family of characteristics forms an envelope with a cusp, the solution with a shock starting from the cusp has been constructed (see Refs. 1 and 2). Moreover, denote $x-x_0$ by $\tilde{x}$, $y-y_0-\alpha(x-x_0)$ with $\alpha=g(y_0)$ by $\tilde{y}$, and recalling the result in Ref. 9 we have the following propositions:

Lemma 2.1: If $f(m)\in C^\infty$, $m_0(y)=m(x_0-\delta,y)\in C^p$, then there is a weak solution $m(x,y)$ of (2.7) and a $C^{p/2}$ function $y=\phi(x)$ defined on $x\geqslant 0$, such that $m(x,y)$ is of C^p away from $y=\phi(x)$, and satisfies estimates

$$\begin{gathered}|m(x,y)-m(0,0)|\leqslant C(\tilde{x}^3+\tilde{y}^2)^{1/6},\\ |\partial_{\not}m(x,y)|\leqslant C(\tilde{x}^3+\tilde{y}^2)^{-1/6},\\ |\partial_y m(x,y)|\leqslant C(\tilde{x}^3+\tilde{y}^2)^{-1/3},\\ |\partial_{yy}m(x,y)|\leqslant C(\tilde{x}^3+\tilde{y}^2)^{-5/6},\end{gathered} \tag{2.12}$$

where $\partial_{\not}=\partial_x+\alpha\partial_y$. Besides, $z(x,y)$ satisfies the same estimates.

Lemma 2.2: The leftward characteristics $y=\eta_{\pm}(x,a,b)$ through point (a,b) with $a>0$ in the neighborhood of the origin (above or below x axis, respectively) does not intersect with the shock $y=\phi(x)$, and satisfies the estimates

$$\pm\eta_{\pm}(0,a,b)=\sqrt{a}+O(a)+|O(b^{1/3})|, \tag{2.13}$$

$$\pm(\eta_{\pm}(x,a,b)-b)=\sqrt{a}(a-x)+|O(b^{1/3}(a-x))|+O(a(a-x)). \tag{2.14}$$

Lemma 2.3: For any point (a,b) in the neighborhood of the origin, $\eta_{\pm}(x,a,b)$ satisfies

$$x^3+\eta_{\pm}(x,a,b)^2\geqslant\tfrac{5}{16}(a^3+b^2). \tag{2.15}$$

Lemma 2.4: Suppose that $\zeta(x,a,b)$ is a function satisfying

$$|\zeta(x,a,b)-\eta(x,a,b)|\leqslant Ca(a-x), \tag{2.16}$$

then for small a

$$0<-\int_0^a(\lambda_u\cdot u_y)(x,\zeta(x,a,b))\mathrm{d}x<\log\tfrac{3}{2}+C\sqrt{a}. \tag{2.17}$$

III. ITERATION SCHEME

Next we are going to improve the approximation of the sequence successively. To avoid the difficulty caused by the change of the location of the shock we perform a coordinate transformation to fix the location of the shock. Suppose that the location of the shock at νth step is $y=\phi^{(\nu)}(x)$, then the transformation is

$$T^{(\nu)}:\tilde{x}=x-x_0,\tilde{y}=\begin{cases}y-\phi^{(\nu)}(x), & \text{if } \geqslant x_0\\ y_0+\alpha(x-x_0), & \text{if } {}_0-\delta\leqslant x\leqslant x_0,\end{cases} \tag{3.1}$$

where α is the slope of λ^+ characteristics through (x_0,y_0). Obviously, the location of shock is fixed on $\tilde{x}=x_0$ by the transformation (3.1).

To simplify the notation we will denote $\tilde{x}$, $\tilde{y}$ by x,y again, move (x_0,y_0) to (0,0), and restrict our discussion on $\Omega=\Omega_0\cup\Omega_+\cup\Omega_-$, where

$$\Omega_0=\{(x,y),-\delta\leqslant x\leqslant 0,-\epsilon\leqslant y\leqslant\epsilon\},$$

$$\Omega_+=\left\{(x,y);0\leqslant x\leqslant\frac{\epsilon}{K},0\leqslant y\leqslant\epsilon-Kx\right\}, \tag{3.2}$$

$$\Omega_-=\left\{(x,y);0\leqslant x\leqslant\frac{\epsilon}{K},-\epsilon-Kx\leqslant y\leqslant 0\right\}.$$

Obviously, when ϵ is small, and K is large, the domain Ω locates above the rigid wall. Besides, $\Omega_{\pm}$ locates in the determinate region of Ω_0.

The approximate solutions $\{z^{(\nu)}\}$, $\{w^{(\nu)}\}$, $\{S^{(\nu)}\}$ and the approximate slope of shock $\{\sigma^{(\nu)}(x)\}$ are costructed as follows.

First, $w^{(0)}(x,y)=S^{(0)}(x,y)=0$, $z^{(0)}(x,y)$ is determined as the solution of (2.1), and $\sigma^{(0)}(x)$ is obtained in the process of determining $z^{(0}(x,y)$.

Now assume that $z^{(\nu)}$, $w^{(\nu)}$, $S^{(\nu)}$ are given, then $\rho^{(\nu)}$, $u^{(\nu)}$, $v^{(\nu)}$ are known correspondingly. Take

$$\sigma^{(\nu)}=\begin{cases} -\dfrac{[\rho^{(\nu)}v^{(\nu)}]}{[\rho^{(\nu)}u^{(\nu)}]}, & \geqslant 0 \\ \alpha, & <0, \end{cases} \tag{3.3}$$

where $[\cdot]$ means the difference of the lower limit from the upper limit of the quantity inside the brackets. Then, as indicated in Sec. II, $\sigma^{(\nu)}$ with $\nu=0$ in (3.3) coincides with the slope of the shock in the solution of Eq. (2.1).

In the sequel we define $z^{(\nu+1)}$, $w^{(\nu+1)}$, $S^{(\nu+1)}$ as the solution of the following linear system:

$$\left.\begin{array}{c} \partial_x z^{(\nu+1)}+(\lambda_+^{(\nu)}-\sigma^{(\nu)})\partial_y z^{(\nu+1)}-d^{(\nu)}(\partial_x S^{(\nu)}+(\lambda_+^{(\nu)}-\sigma^{(\nu)})\partial_y S^{(\nu)})=0, \\ \partial_x S^{(\nu+1)}+(\lambda_0^{(\nu)}-\sigma^{(\nu)})\partial_y S^{(\nu+1)}=0, \\ \partial_x w^{(\nu+1)}+(\lambda_-^{(\nu)}-\sigma^{(\nu)})\partial_y w^{(\nu+1)}+d^{(\nu)}(\partial_x S^{(\nu)}+(\lambda_-^{(\nu)}-\sigma^{(\nu)})\partial_y S^{(\nu)})=0 \end{array}\right), \tag{3.4}$$

satisfying initial conditions

$$w^{(\nu+1)}(-\delta,y)=0, S^{(\nu+1)}(-\delta,y)=0, z^{(\nu+1)}(-\delta,y)=z_0(y). \tag{3.5}$$

Problem (3.4),(3.5) can be solved by a characteristic method. Since λ_-, λ_0 characteristics may intersect with $y=0$, we have also to estimate $w^{(\nu+1)}$ and $S^{(\nu+1)}$ on $y=0$ in order to obtain estimates of $w^{(\nu+1)}$ and $S^{(\nu+1)}$ in Ω_-. This is given in the following lemma:

Lemma 3.1: On λ_+ shock

$$[\theta]=k[F(q)], \tag{3.6}$$

where k is a smooth function of $(\theta_u,\ \theta_\swarrow,\ q_u,\ q_\swarrow,\ \rho_u,\ \rho_\swarrow)$, and it tends to -1 as $[q]\to 0$. Here θ_u means the value of θ on the upper side of the shock, while $\theta_\swarrow$ means the value of θ on the lower side of the shock. The meaning q_u, $q_\swarrow$, ρ_u, $r_\swarrow$ are similar.

Proof: From the shock relation one has

$$\sigma=-\frac{[u]}{[v]}=\frac{[\rho v]}{[\rho u]}.$$

Write $u=q\cos\theta$, $v=q\cos\theta$, we obtain

$$\cos[\theta]=\frac{\rho_\swarrow q_\swarrow^2-\rho_u q_u^2}{(\rho_\swarrow+\rho_u)q_\swarrow q_u}, \tag{3.7}$$

then

$$\sin^2[\theta]=-\frac{(q_\swarrow+q_u)^2\left(\rho_+^2+q_u^2\dfrac{\rho_\swarrow^2-\rho_u^2}{q_\swarrow^2-q_u^2}\right)}{(\rho_\swarrow+\rho_u)^2 q_\swarrow^2 q_u^2}[q]^2. \tag{3.8}$$

When $[q]\to 0$, the limit of the coefficient of $[q]^2$ on the right-hand side equals

$$-\frac{4q^2}{4\rho^2 q^4}\left(\rho^2+q^2\frac{\rho}{q}\frac{\mathrm{d}\rho}{\mathrm{d}q}\right)=-\frac{1}{\rho q^2}\left(\rho+q\frac{\mathrm{d}\rho}{\mathrm{d}q}\right).$$

Since the difference of entropy across shock is a small quantity of third order of the strength of the shock, again using Bernoulli's relation (1.3) we have $\mathrm{d}S/\mathrm{d}q=0$, $q\,dq+(a^2/\rho)\,d\rho=0$. In view of $\sin[\theta]\sim[\theta]$ for $[\theta]\sim 0$, we have from (3.8)

$$[\theta]^2=E(\rho_\swarrow,\rho_u,q_\swarrow,q_u,\theta_\swarrow,\theta_u)[F(q)]^2,$$

where

$$\lim_{[q]\to 0} E=-\frac{1}{\rho q^2}\left(\rho+q\frac{d\rho}{dq}\right)\frac{1}{F'(q)^2}=-\frac{1}{\rho q^2}\frac{\rho(a^2-q^2)}{a^2}\frac{a^2q^2}{q^2-a^2}=1.$$

Furthermore, notice that $[\theta]$ and $[q]$ take different signs, then $[\theta]$ and $[F(q)]$ take different signs. Hence the coefficient k in (3.6) tends to -1 as $[q]\to 0$.

Lemma 3.2: If $w=S=0$ on the upper side of λ_+ shock, then

$$S_{\swarrow}=O([z]^3),\quad w_{\swarrow}=O([z]^3). \tag{3.9}$$

Proof: The first equality is well known, because the change of entropy across a shock is a small quanity of third order of the strength of the shock. To prove the second equality in (3.9), we apply Lemma 3.1, which implies

$$[\theta]=(-1+h(\theta_{\swarrow},\theta_u,q_{\swarrow},q_u,\rho_{\swarrow},\rho_u)[F(q)])[F(q)]. \tag{3.10}$$

Exchanging the subscript u and subscript $\swarrow$ in (3.10) causes the function h to change its sign. Therefore, (3.10) can be rewritten as

$$[\theta]=(-1+h_1[F(q)]^2)[F(q)].$$

Substituting $z=\theta-F(q), w=\theta+F(q)$ leads to

$$[z+w]^2=\left(1+\frac{h_2}{4}[z-w]^2\right)[z-w]^2,$$

$$[z+w]^2-[z-w]^2=\frac{h_2}{4}[z-w]^2.$$

The above-mentioned equality is equivalent to

$$w_{\swarrow}([z-w]+w_{\swarrow})=\tfrac{1}{16}h_2[z-w]^4$$

due to $w_r=0$. Denote

$$r=\frac{w_{\swarrow}}{[z-w]},$$

then r satisfies

$$r(1+r)=\tfrac{1}{16}h_2[z-w]^2. \tag{3.11}$$

By using the fact $[z-w]\to 0$ for $[z]\to 0$, we obtain $r=O([z-w]^2)$ from (3.11), and then $w_{\swarrow}=O([z-w]^3)$. Writing $[z-w]$ as $[z]+w_{\swarrow}$, the second equality of (3.10) is obtained immediately.

Next we will indicate that the sequence $\{z^{(\nu)}\}$, $\{w^{(\nu)}\}$, $\{S^{(\nu)}\}$, $\{\sigma^{(\nu)}\}$ is well defined, and the sequence is convergent. To do that, let us first set up a proposition $F^{(\nu)}$ as follows:

(1) $z^{(\nu)}(x,y), w^{(\nu)}(x,y), S^{(\nu)}(x,y)\in C^1(\overline{\Omega}_-\backslash(0,0))$,

(2) $|z^{(\nu)}(x,y)-z^{(0)}(x,y)|\leqslant Cx$,

(3) $|S^{(\nu)}(x,y), w^{(\nu)}(x,y)|\leqslant Cx^{3/2}$,

$$(4)\quad |\nabla_{x,y}(z^{(\nu)}-z^{(0)})|\leqslant C(x^3+y^2)^{-1/6},$$

$$(5)\quad |\nabla_{x,y}S^{(\nu)},\nabla_{x,y}w^{(\nu)}|\leqslant Cx^{1/2}.$$

Then we will prove these facts by induction with respect to ν.

IV. ESTIMATES OF $z^{(\nu+1)}$, $w^{(\nu+1)}$, $S^{(\nu+1)}$

In this section we are going to give estimates of $z^{(\nu+1)}$, $w^{(\nu+1)}$, $S^{(\nu+1)}$ from the validity of $F^{(\nu)}$. In the following discussion, ''C'' represents a constant independent of ν, which may take different values in different inequality.

Lemma 4.1: Under the assumption $F^{(\nu)}$,

$$|\sigma^{(\nu)}-\sigma^{(0)}|\leqslant Cx. \tag{4.1}$$

Proof: $\sigma^{(\nu)}$ is determined by (3.3). On the other hand, by using (2.6) $\sigma^{(0)}$ can also be written as

$$\sigma^{(0)}=\left(\frac{[f(m)]}{[m]}\right)_{z=z^{(0)}},$$

where $m=(\rho u)_{w=S=0}$, $f(m)=(\rho v)_{w=S=0}$. Notice that $z^{(\nu)}$, $S^{(\nu)}$, $w^{(\nu)}$ in Ω_+ is independent of ν, then

$$|\sigma^{(\nu)}-\sigma^{(0)}|=\left|\frac{[\rho v]}{[\rho u]}-\left(\frac{[\rho v]}{[\rho u]}\right)_{w=S=0,z=z^{(0)}}\right|\leqslant C(|z^{(\nu)}-z^{(0)}|+|S^{(\nu)}|+|w^{(\nu)}|). \tag{4.2}$$

Here all functions on the right-hand side of the inequality take value in domain Ω_-. Thus (4.1) is obtained from $F^{(\nu)}$.

Lemma 4.2: Under the assumption $F^{(\nu)}$,

$$|\eta^{(\nu)}(x,a,b)-\eta^{(0)}(x,a,b)|\leqslant Ca(a-x), \tag{4.3}$$

where $\eta^{(\nu)}(x,a,b)$ is a characteristic through (a,b) corresponding to the eigenvalue $\lambda_+^{(\nu)}-\sigma^{(\nu)}$.

Proof: From the definition of $\eta^{(\nu)}$,

$$\eta^{(\nu)}(x,a,b)=b+\int_a^x(\lambda_+^{(\nu)}(\alpha,\eta^{(\nu)}(\alpha,a,b))-\sigma^{(\nu)}(\alpha))\mathrm{d}\alpha. \tag{4.4}$$

To estimate $\eta^{(\nu)}(x,a,b)$ we introduce another iterative process. Temporarily fix ν, and determine a sequence $\{\zeta_n\}$ according to

$$\begin{aligned}\zeta_0(x,a,b)&=\eta^{(0)}(x,a,b),\\ \zeta_{n+1}(x,a,b)&=b+\int_a^x(\lambda_+^{(\nu)}(\alpha,\zeta_n(\alpha,a,b))-\sigma^{(\nu)}(\alpha))\mathrm{d}\alpha.\end{aligned} \tag{4.5}$$

Obviously, since $\eta^{(0)}$ satisfies the integral equation

$$\eta^{(0)}(x,a,b)=b+\int_a^x(\lambda_+^{(0)}(\alpha,\eta^{(0)}(\alpha,a,b))-\sigma^{(0)}(\alpha))\mathrm{d}\alpha$$

we have

$$\zeta_{n+1}(x,a,b)-\zeta_0(x,a,b)=\int_a^x \lambda_+^{(\nu)}(\alpha,\zeta_n(\alpha,a,b))-\lambda_+^{(0)}(\alpha,\zeta_0(\alpha,a,b))\mathrm{d}\alpha + \int_a^x (\sigma^{(0)}(\alpha)-\sigma^{(\nu)}(\alpha))\mathrm{d}\alpha.$$

Now we confirm that the sequence $\{\zeta_i(x,a,b)\}$ satisfies the estimate

$$|\zeta_i(x,a,b)-\zeta_0(x,a,b)|\leqslant Ca(a-x), \tag{4.6}$$

and the sequence $\{\zeta_i\}$ is convergent. Obviously, if these two facts are true, then the limit of $\{\zeta_i\}$ is just $\eta^{(\nu)}$, and (4.3) is valid.

The inequality (4.6) can be proved inductively. Evidently, it holds for $i=0$. Now if it holds for $i=n$, then

$$\begin{aligned}\zeta_{n+1}(x,a,b)-\zeta_0(x,a,b)&=\int_a^x\Big(\lambda_+^{(0)}(\alpha,\zeta_n(\alpha,a,b))-\lambda_+^{(0)}(\alpha,\zeta_0(\alpha,a,b))\mathrm{d}\alpha\\&\quad+\int_a^x \lambda_+^{(\nu)}(\alpha,\zeta_n(\alpha,a,b))-\lambda^{(0)}(\alpha,\zeta_n(\alpha,a,b))\mathrm{d}\alpha\\&\quad+\int_a^x(\sigma^{(0)}(\alpha)-\sigma^{(\nu)}(\alpha))\mathrm{d}\alpha.\end{aligned} \tag{4.7}$$

Notice that

$$\begin{aligned}&\left|\int_a^x \lambda_+^{(0)}(\alpha,\zeta_n(\alpha,a,b))-\lambda_+^{(0)}(\alpha,\zeta_0(\alpha,a,b))\mathrm{d}\alpha\right|\\&\quad\leqslant\left|\int_a^x\left(\frac{\partial\lambda_+^{(0)}}{\partial z}z_y^{(0)}(\alpha,\zeta_0+\theta(\zeta_n-\zeta_0))(\alpha,a,b)\right.\right.\\&\qquad\left.\left.\cdot(\zeta_n(\alpha,a,b)-\zeta_0(\alpha,a,b))\mathrm{d}\alpha\right|,\end{aligned}$$

where $0<\theta<1$. Because ζ_n is assumed to satisfy (4.6), then $\zeta_0+\theta(\zeta_n-\zeta_0)$ also satisfies (4.6). Therefore, Lemma 2.4 yields

$$\left|\int_a^x \lambda_+^{(0)}(\alpha,\zeta_n(\alpha,a,b))-\lambda_+^{(0)}(\alpha,\zeta_0(\alpha,a,b))\mathrm{d}\alpha\right|\leqslant\left(\log\frac{3}{2}+C\sqrt{a}\right)a(a-x). \tag{4.8}$$

Then, taking account of (4.1) and the estimate

$$|\lambda_+^{(\nu)}-\lambda_+^{(0)}|\leqslant\|\nabla\lambda_+\|_{L^\infty}(|z^{(\nu)}-z^{(0)}|+|w^{(\nu)}|+|S^{(\nu)}|)\leqslant C\alpha \tag{4.9}$$

derived from $F^{(\nu)}$, we obtain the validity of (4.6) for $i=n+1$. To obtain the convergence of $\{\zeta_n\}$, we estimate the difference $\zeta_{n+1}-\zeta_n$,

$$
\begin{aligned}
&|\zeta_{n+1}(x,a,b)-\zeta_n(x,a,b)| \\
&\quad\leqslant\left|\int_0^x(\partial_y\lambda_+^{(\nu)})(\alpha,((1-\theta)\zeta_{n-1}+\theta\zeta_n)(\alpha,a,b))\right. \\
&\qquad\left.\cdot(\zeta_n(\alpha,a,b)-\zeta_{n-1}(\alpha,a,b))d\alpha\right| \\
&\quad\leqslant\int_0^a|(\partial_y\lambda_+^{(\nu)})(\alpha,((1-\theta)\zeta_{n-1}+\theta\zeta_n)(\alpha,a,b)|\mathrm{d}\alpha\cdot\|\zeta_n-\zeta_{n-1}\|_{L^\infty}. \qquad (4.10)
\end{aligned}
$$

Since $\zeta_{n-1}+\theta(\zeta_n-\zeta_{n-1})$ satisfies the condition (4.6), then Lemma 2.4 implies

$$
\int_0^a|\partial_y\lambda_+^{(\nu)}(\alpha,\zeta_{n-1}+\theta(\zeta_n-\zeta_{n-1})(\alpha,a,b)|\mathrm{d}\alpha\leqslant\log\frac{3}{2}+C\sqrt{a}<\frac{1}{2}, \qquad (4.11)
$$

Therefore,

$$
\|\zeta_{n+1}-\zeta_n\|_{L^\infty}\leqslant\tfrac{1}{2}\|\zeta_n-\zeta_{n-1}\|_{L^\infty}, \qquad (4.12)
$$

which leads to the convergence of $\{\zeta_n\}$. By taking the limit in (4.5) and (4.6), we know the limit of ζ_n satisfies (4.4), and the limit is nothing but $\eta^{(\nu)}(\alpha,a,b)$. Hence (4.3) is also obtained.

Lemma 4.3: Under the assumption $F^{(\nu)}$,

$$
|(z^{\nu+1)}-z^{(0)})(x,y)|\leqslant Cx. \qquad (4.13)
$$

Proof: Denote $v(x,y)=(z^{(\nu+1)}-z^{(0)})(x,y)$, then $v(x,y)$ satisfies

$$
\partial_x v+(\lambda_+^{(\nu)}-\sigma^{(\nu)})\partial_y v=(-\lambda_+^{(\nu)}+\lambda_+^{(0)}+\sigma^{(\nu)}-\sigma^{(0)})\partial_y z^{(0)}+d^{(\nu)}(\partial_x S^{(\nu)}+(\lambda_+^{(\nu)}-\sigma^{(\nu)})\partial_y S^{(\nu)}). \qquad (4.14)
$$

The fact $S^{(\nu)}$, $w^{(\nu)}=0$ in $\Omega_0\cup\Omega_+$ is known. Then intergrating (4.14) along the characteristics $y=\eta_+(x,a,b)$ corresponding to the eigenvalue $\lambda_+^{(\nu)}-\sigma^{(\nu)}$, and taking the assumption $F^{(\nu)}$ into account, we have

$$
|v(x,y)|\leqslant\int_0^x|(-\lambda_+^{(\nu)}+\lambda_+^{(0)}+\sigma^{(\nu)}-\sigma^{(0)})\cdot(\partial_y z^{(0)})(\alpha,\eta_+(\alpha,x,y))|\mathrm{d}\alpha+\int_0^x C\alpha^{1/2}\mathrm{d}\alpha. \qquad (4.15)
$$

Lemma 2.1 indicates

$$
|\partial_y z^{(0)}(\alpha,\eta_+(\alpha,x,y))|\leqslant C(\alpha^3+\eta_+^2)^{-1/3}\leqslant C\alpha^{-1}.
$$

Again by using assumption $F^{(\nu)}$, we obtain from (4.15)

$$
|v(x,y)|\leqslant C\int_0^x\alpha\cdot\alpha^{-1}\,\mathrm{d}\alpha\leqslant Cx. \qquad (4.16)
$$

Lemma 4.4: Under the assumption $F^{(\nu)}$,

$$
|S^{(\nu+1)}(x,y),w^{(\nu+1)}(x,y)|\leqslant Cx^{1/2}. \qquad (4.17)
$$

Proof: $S^{(\nu+1)}(x,y)$ and $w^{(\nu+1)}(x,y)$ are identically zero in $\Omega_+\cup\Omega_0$. In the domain Ω_- the value of $S^{(\nu+1)},w^{(\nu+1)}$ in Ω_- can be obtained by integrating along $\not{\ell}_0$ or $\not{\ell}_-$ characteristics with their data on $x=0$ or $y=0$, respectively. On $x=0$ the data of $S^{(\nu+1)}$, $w^{(\nu+1)}$ are zero, while on $y=0$

$$|S^{(\nu+1)}(x,0_{\swarrow})|+|w^{(\nu+1)}(x,0_{\swarrow})|\leqslant C|[z^{(\nu+1)}(x,0)]^3|$$

due to (3.9), where $0_{\swarrow}$ means the limit from below. Notice that

$$[z^{(\nu+1)}(x,0)]=[z^{(\nu+1)}(x,0)-z^{(0)}(x,0)]+[z^{(0)}(x,0)]\leqslant Cx^{1/2}$$

by means of Lemma 2.1 and (4.16), then

$$|S^{(\nu+1)}(x,0_{\swarrow})|+|w^{(\nu+1)}(x,0_{\swarrow})|\leqslant Cx^{3/2}. \tag{4.18}$$

Denote $y'=\eta_0(x',x,y)$ the equation of characteristics $\swarrow_0$ from (x,y) corresponding to the eigenvalue $\lambda_0^{(\nu)}-\sigma^{(\nu)}$, namely

$$\begin{cases} \dfrac{\mathrm{d}\eta_0(x',x,y)}{dx'}=(\lambda_0^{(\nu)}-\sigma^{(\nu)})(x',\eta_0(x',x,y)), \\ \eta_0(x,x,y)=y, \end{cases} \tag{4.19}$$

then $S^{(\nu+1)}$ takes constant on $\swarrow_0$ by using (3.4), that is $S^{(\nu+1)}(x',\eta_0(x',x,y))$ is independent of x'. If $\swarrow_0$ intersects with the y axis before it meets the x axis, then $S^{(\nu+1)}(x,y)=0$. Otherwise,

$$S^{(\nu+1)}(x,y)=S^{(\nu+1)}(\xi^{(\nu)}(x,y),0_{\swarrow}), \tag{4.20}$$

where $\xi^{(\nu)}(x,y)$ is the coordinate of the intersection of $\swarrow_0$ with the x axis, and then satisfies $\eta_0(\xi^{(\nu)}(x,y),x,y))=0$. Hence

$$S^{(\nu+1)}(x,y)=O\big(\xi^{(\nu)}(x,y)^{3/2}\big)=O\big(x^{3/2}\big) \tag{4.21}$$

by virtue of $0\leqslant\xi^{(\nu)}(x,y)\leqslant x$.

Turn to the estimate of $w^{(\nu+1)}$. The estimate of $w^{(\nu+1)}(x,0_{\swarrow})$ on $y=0$ has been obtained by (4.18). Now if the characteristics $\swarrow_-$ corresponding to the eigenvalue $\lambda_-^{(\nu)}-\sigma^{(\nu)}$ intersects with $y=0$ at $\tilde{\xi}^{(\nu)}(x,y)$, then

$$w^{(\nu+1)}(x,y)=w^{(\nu+1)}(\tilde{\xi}^{(\nu)},0)+\int_{\tilde{\xi}^{(\nu)}}^{x}-d^{(\nu)}(\partial_x S^{(\nu)}+(\lambda_-^{(\nu)}-\sigma^{(\nu)})\partial_y S^{(\nu)})\mathrm{d}\alpha. \tag{4.22}$$

Then by using the estimate of $w^{(\nu+1)}(x,0_{\swarrow})$ and the assumption $F^{(\nu)}$ on $\nabla S^{(\nu)}$ we obtain

$$|w^{(\nu+1)}(x,y)|\leqslant C(\tilde{\xi}^{(\nu)})^{3/2}+C\int_{\tilde{\xi}^{(\nu)}}^{x}\alpha^{1/2}\,\mathrm{d}\alpha\leqslant Cx^{3/2}. \tag{4.23}$$

In the case when $\swarrow_-$ intersects with $x=0$ before it meets $y=0$, the initial value of $w^{(\nu+1)}$ is 0. And the required estimate can be derived in the same way.

V. ESTIMATES OF DERIVATIVES

Lemma 5.1: Under the assumption $F^{(\nu)}$,

$$|\nabla(z^{(\nu+1)}-z^{(0)})|\leqslant C(x^3+y^2)^{-1/6}. \tag{5.1}$$

Proof: Setting $v=\partial_y(z^{(\nu+1)}-z^{(0)})$, and differentiating the equation satisfied by v with respect to y we obtain

$$\partial_{\swarrow_+}(v-d^{(\nu)}S_y^{(\nu)})=r_1, \tag{5.2}$$

where

$$r_1=(-\lambda_+^{(\nu)}+\lambda_+^{(0)}+\sigma^{(\nu)}-\sigma^{(0)})\partial_{yy}z^{(0)}-\lambda_{+y}^{(\nu)}v$$
$$-(\lambda_{+y}^{(\nu)}-\lambda_{+y}^{(0)})\partial_y z^{(0)}+d_y^{(\nu)}S_x^{(\nu)}-d_x^{(\nu)}S_y^{(\nu)}+d^{(\nu)}\lambda_{+y}^{(\nu)}S_y^{(\nu)}.$$

Integrating along the characteristics $\not{\ell}_+$ yields

$$v(a,b)-d^{(\nu)}S_y^{(\nu)}(a,b)=\int_0^a r_1\,\mathrm{d}\alpha. \tag{5.3}$$

Applying Lemmas 2.1 and 2.3 and the assumption $F^{(\nu)}$, we have

$$\left|\int_0^a[(-\lambda_+^{(\nu)}+\lambda_+^{(0)}+\sigma^{(\nu)}-\sigma^{(0)})\partial_{yy}z^{(0)}]\mathrm{d}\alpha\right|$$
$$\leqslant\int_0^a C\alpha(\alpha^3+\eta^2)^{-5/6}\mathrm{d}\alpha$$
$$\leqslant\int_0^a C\alpha\mathrm{d}\alpha\cdot(a^3+b^2)^{-5/6}$$
$$\leqslant Ca^2(a^3+b^2)^{-5/6}$$
$$\leqslant C(a^3+b^2)^{-1/6},$$

$$\left|\int_0^a\partial_y(\lambda_+^{(\nu)}-\lambda_+^{(0)})\partial_y z^{(0)}\mathrm{d}\alpha\right|$$
$$\leqslant\int_0^a|\lambda_{+w}^{(\nu)}w_y^{(\nu)}+\lambda_{+z}^{(\nu)}(z_y^{(\nu)}-z_y^{(0)})+(\lambda_{+z}^{(\nu)}-\lambda_z^{(0)})z_y^{(0)}|\cdot|\partial_y z^{(0)}|\mathrm{d}\alpha$$
$$\leqslant C\int_0^a\left|(\alpha^3+\eta^2)^{-1/6}+\alpha^{-1/2}+\alpha(\alpha^3+\eta^2)^{-1/3}\right|\cdot(\alpha^3+\eta^2)^{-1/3}\mathrm{d}\alpha$$
$$\leqslant C\int_0^a\alpha^{-1/2}\mathrm{d}\alpha(a^3+b^2)^{-1/3}$$
$$\leqslant C(a^3+b^2)^{-1/6},$$

$$\left|\int_0^a(d_y^{(\nu)}S_x^{(\nu)}-d_x^{(\nu)}S_y^{(\nu)}+d^{(\nu)}\lambda_{+y}^{(\nu)}S_y^{(\nu)})\mathrm{d}\alpha\right|\leqslant C\int_0^a\alpha^{-1/2}\cdot\alpha^{1/2}\mathrm{d}\alpha\leqslant Ca.$$

Therefore,

$$|v-d^{(\nu)}S_y^{(\nu)}|\leqslant\int_0^a g(\alpha)|v|d\alpha+h(a,b), \tag{5.4}$$

where $|h(a,b)|\leqslant C(a^3+b^2)^{-1/6}$, $|g(\alpha)|\leqslant C\alpha^{-1/2}$. Namely, $v_1=v-d^{(\nu)}S_y^{(\nu)}$ satisfies

$$|v_1|\leqslant\int_0^a g(\alpha)|v_1|d\alpha+h_1(a,b),$$

where h_1 still satisfies $|h_1(a,b)|\leqslant C(a^3+b^2)^{-1/6}$.

Recall that Lemma 2.4 implies $\int_0^a g(\alpha)d\alpha\leqslant\log\frac{3}{2}+C\sqrt{a}$. Then by using Gronwall inequality v_1 is dominated by $C(a^3+b^2)^{-1/6}$, and so does v. Again using the system (3.4) we obtain the estimate of $\partial_x(z^{(\nu+1)}-z^{(0)})$. Hence (5.1) holds.

Lemma 5.2: Under the assumption $F^{(\nu)}$,

$$|\nabla S^{(\nu+1)}, \nabla w^{(\nu+1)}| \leqslant C x^{1/2}. \tag{5.5}$$

Proof: To obtain the estimate of $\nabla w^{(\nu+1)}$, we define $v_2(x,y) = w_y^{(\nu+1)} + d^{(\nu)} S_y^{(\nu)}(x,y)$. By differentiating the third equation of (3.4) we have

$$\partial_x v_2 + (\lambda_-^{(\nu)} - \sigma^{(\nu)}) \partial_y v_2 + \lambda_{-y}^{(\nu)} v_2 = -\lambda_{-y}^{(\nu)} d^{(\nu)} S_y^{(\nu)} - d_y^{(\nu)} S_x^{(\nu)} + d_x^{(\nu)} S_y^{(\nu)}. \tag{5.6}$$

Denoting the right-hand side by r_2, (5.6) can be rewritten as

$$\partial_{\swarrow_-} v_2 = r_2.$$

Then integrating (4.5) along $\swarrow_-$, we obtain

$$v_2(a,b) = v(\tilde{\xi}, 0_{\swarrow}) + \int_{\tilde{\xi}}^{a} \lambda_{-y}^{(\nu)} v_2 \, \mathrm{d}\alpha + \int_{\tilde{\xi}}^{a} r_2(\alpha) \mathrm{d}\alpha, \tag{5.7}$$

provided $\swarrow_-$ intersects with $y=0$ before it meets $x=0$. Otherwise, two integrals in (5.7) should be replaced by the corresponding integrals from 0 to a, while the term $v(\xi,0)$ should be replaced by 0.

Let us analyze three terms an the right-hand side of (5.7). The estimate (4.18) indicates

$$|w_x^{(\nu+1)}(\xi, 0_{\swarrow})| \leqslant C|\xi|^{1/2},$$

and the same estimate for $|w_y^{(\nu+1)}(\xi,0)|$ also holds, because $|\lambda_0|$ and $|\lambda_-|$ are bounded away from zero. The fact means $|v_2(\xi,0_{\swarrow})| \leqslant C|\xi|^{1/2}$. Moreover, according to the assumption $F^{(\nu)}$, r_2 satisfies

$$|r_2| \leqslant C(x^3 + y^2)^{-1/6} x^{1/2} \leqslant C,$$

then $\int_0^a r_2(\alpha)\mathrm{d}\alpha \leqslant Ca$, and (5.7) can be written as

$$v(a,b) = \int_{\xi}^{a} \lambda_{-y}^{(\nu)} v \, \mathrm{d}\alpha + O(a^{1/2}),$$

where $\lambda_{-y}^{(\nu)}$ is also dominated by $Cx^{-1/2}$. Therefore, we can use the same method in Lemma 4.1 to obtain

$$|v(a,b)| \leqslant Ca^{1/2}, \tag{5.8}$$

which implies $|w_y^{(\nu+1)}(a,b)| \leqslant Ca^{1/2}$, and again applying the system (3.4) itself yields $|w_x^{(\nu+1)}(a,b)| \leqslant Ca^{1/2}$.

The same method is available to estimate $\nabla S^{(\nu+1)}$. In the above-mentioned process replacing $w^{(\nu+1)}$ by $S^{(\nu+1)}$, $\lambda_-^{(\nu)}$ by $\lambda_0^{(\nu)}$, and $d^{(\nu)}$ by 0, we obtain $|\nabla S^{(\nu+1)}| \leqslant Cx^{1/2}$ immediately.

According to Lemma 4.2 and Lemmas 5.1 and 5.2 we know that the assumption $F^{(\nu)}$ implies the validity of $F^{(\nu+1)}$. Then $F^{(\nu)}$ holds for any ν by induction.

VI. CONVERGENCE

To obtain the convergence of $\{z^{(\nu)}\}$, $\{w^{(\nu)}\}$, $\{S^{(\nu)}\}$, we are going to prove the contractivity of these sequences. In the sequel we denote $e_z^{(\nu)} = z^{(\nu+1)} - z^{(\nu)}$, $e_w^{(\nu)} = w^{(\nu+1)} - w^{(\nu)}$, $e_s^{(\nu)} = S^{(\nu+1)} - S^{(\nu)}$ for notational simplicity, and will estimate these differences.

First, (3.3) implies that $|\sigma^{(\nu)} - \sigma^{(\nu-1)}|$ can be dominated by

$$C(\|e_z^{(\nu-1)}\|_{L^\infty} + \|e_w^{(\nu-1)}\|_{L^\infty} + \|e_s^{(\nu-1)}\|_{L^\infty}).$$

Since the formation of shock is caused by compression of λ^+ characteristics, the difference $e_z^{(\nu-1)}$ plays the principal role among these three terms.

Lemma 6.1: If ϵ is small and K is large in (3.2), then

$$|\sigma^{(\nu)}-\sigma^{(\nu-1)}|\leqslant C(\|e_s^{(\nu-1)}\|_{L^\infty}+\|e_w^{(\nu-1)}\|_{L^\infty})+\frac{1}{2}|\lambda_+'|\cdot\|e_z^{(\nu-1)}\|_{L^\infty}(1+O(x)). \tag{6.1}$$

Proof: Denote

$$H(z^{(\nu)},w^{(\nu)},S^{(\nu)})=\frac{[\rho^{(\nu)}v^{(\nu)}]}{[\rho^{(\nu)}u^{(\nu)}]}$$

then

$$\begin{aligned}|\sigma^{(\nu)}-\sigma^{(\nu-1)}|&=|H(z^{(\nu)},w^{(\nu)},S^{(\nu)})-H(z^{(\nu-1)},w^{(\nu-1)},S^{(\nu-1)})|\\&\leqslant C(\|e_w^{(\nu-1)}\|_{L^\infty}+\|e_s^{(\nu-1)}\|_{L^\infty})+|H(z^{(\nu)},w^{(\nu)},S^{(\nu)})-H(z^{(\nu-1)},w^{(\nu)},S^{(\nu)})|\\&\leqslant C(\|e_w^{(\nu-1)}\|_{L^\infty}+\|e_s^{(\nu-1)}\|_{L^\infty})+|H(z^{(\nu)},0,0)-H(z^{(\nu-1)},0,0)|\\&\quad+|(H(z^{(\nu)},w^{(\nu)},S^{(\nu)})-H(z^{(\nu)},0,0))\\&\quad-(H(z^{(\nu-1)},w^{(\nu)},S^{(\nu)})-H(z^{(\nu-1)},0,0))|.\end{aligned} \tag{6.2}$$

Here $H(z,0,0)$ is just the expression $[f(m)]/[m]$ in the Rankine–Hugoniot condition for (2.7), so

$$\begin{aligned}|H(z^{(\nu)},0,0)-H(z^{(\nu-1)},0,0)|&=\left(\frac{d}{dz}\frac{[f(m(z))]}{[m(z)]}\right)_{z=z^*}e_z^{(\nu-1)}\\&=\left(\frac{[m]f'(m)-[f(m)]}{[m]^2}\frac{dm}{dz}\right)_{z=z^*}e_z^{(\nu-1)}.\end{aligned}$$

Since

$$f''(m)\frac{dm}{dz}=\partial_z\lambda_+^{(0)},\quad \frac{[m]f'(m)-[f(m)]}{[m]^2}=-\frac{1}{2}f''(m^*),$$

we have

$$|H(z^{(\nu)},0,0)-H(z^{(\nu-1)},0,0)|=\left|\tfrac{1}{2}\partial_z\lambda_+^{(0)}+O(z^{(\nu)}-z^{(0)})\right|\cdot\left|e_z^{(\nu-1)}\right|.$$

Moreover, notice that the last term in (6.2) is dominated by $C(|w^{(\nu)}|+|S^{(\nu)}|)\|e_z^{(\nu-1)}\|_{L^\infty}$ we obtain (6.1).

Lemma 6.2: Under the assumption of Lemma 6.1

$$\|e_z^{(\nu)}\|_{L^\infty}\leqslant\tfrac{4}{5}\|e_z^{(\nu-1)}\|_{L^\infty}+C(\|e_s^{(\nu-1)}\|_{L^\infty}+\|e_w^{(\nu-1)}\|_{L^\infty}). \tag{6.3}$$

Proof: (3.4) implies

$$\begin{aligned}&(\partial_x+(\lambda_+^{(\nu)}-\sigma^{(\nu)}\partial_y)e_z^{(\nu)}\\&\quad=-(\lambda_+^{(\nu)}-\sigma^{(\nu)}-\lambda_+^{(\nu-1)}+\sigma^{(\nu-1)})\partial_y z^{(0)}\\&\qquad-(\lambda_+^{(\nu)}-\sigma^{(\nu)}-\lambda_+^{(\nu-1)}+\sigma^{(\nu-1)})\partial_y(z^{(\nu)}-z^{(0)})\\&\qquad+(d^{(\nu)}S_x^{(\nu)}-d^{(\nu-1)}S_x^{(\nu-1)})+d^{(\nu)}(\lambda_+^{(\nu)}-\sigma^{(\nu)})S_y^{(\nu)}-d^{(\nu-1)}\end{aligned}$$

$$\times(\lambda_+^{(\nu-1)}-\sigma^{(\nu-1)})S_y^{(\nu-1)}. \tag{6.4}$$

Integrating (6.4) along $\not{C}_+^{(\nu)}$ characteristics we have

$$e_z^{(\nu)}(x,y)=\int_0^x r_3(\alpha,\eta_+(\alpha,x,y))\mathrm{d}\alpha, \tag{6.5}$$

where r_3 represents the right-hand side of (6.4). Notice that

$$|\lambda_+^{(\nu)}-\lambda_+^{(\nu-1)}|\leqslant|e_z^{(\nu-1)}|\cdot|\partial_z\lambda_+^{(0)}+O(x)|+C(|e_s^{(\nu-1)}+e_w^{(\nu-1)}|),$$

$$|\sigma^{(\nu)}-e^{(\nu-1)}|\leqslant|\tfrac{1}{2}e_z^{(\nu-1)}|\cdot|\partial_z\lambda_+^{(0)}+O(x)|+C(|e_s^{(\nu-1)}|+e_w^{(\nu-1)}|),$$

and

$$\begin{aligned}|\partial_y z^{(0)}(\alpha,\eta^{(\nu)}(\alpha,x,y))|&\leqslant C(\alpha^3+|\eta^{(\nu)}(\alpha,x,y)|^2)^{-1/3}\\&\leqslant C_1(\alpha^3+|\eta(\alpha,x,y)|^2)^{-1/3}\\&\leqslant C_2(x^3+y^2)^{-1/3}\end{aligned}$$

by virture of Lemmas 2.3 and 4.2. Then by using Lemma 2.4

$$\begin{aligned}&\int_0^x|(\lambda_+^{(\nu)}-\sigma^{(\nu)}-\lambda_+^{(\nu-1)}+\sigma^{(\nu-1)})\partial_y z^{(0)}(\alpha,\eta^{(\nu)}(\alpha,x,y))|\mathrm{d}\alpha\\&\quad\leqslant\left(\frac{3}{2}\log\frac{3}{2}+C\sqrt{a}\right)(\|e_z^{(\nu-1)}\|_{L^\infty}+C(\|e_s^{(\nu-1)}\|_{L^\infty}+\|e_w^{(\nu-1)}\|_{L^\infty}).\end{aligned}$$

Besides, by using the assumption $F^{(\nu)}$, the integral of all other terms on the right-hand side of (6.4) are dominated by

$$C\sqrt{a}(\|e_z^{(\nu-1)}\|_{L^\infty}+\|e_s^{(\nu-1)}\|_{L^\infty}+\|e_w^{(\nu-1)}\|_{L^\infty}).$$

Therefore, for small a we have

$$\|e_z^{(\nu)}\|_{L^\infty}\leqslant\tfrac{4}{5}\|e_z^{(\nu-1)}\|_{L^\infty}+C(\|e_s^{(\nu-1)}\|_{L^\infty}+\|e_w^{(\nu-1)}\|_{L^\infty}).$$

Lemma 6.3: Under the assumption of Lemma 6.1 we can find a constant C_0 such that

$$\|e_z^{(\nu)}\|_{L^\infty}+C_0\|e_s^{(\nu)}\|_{L^\infty}+C_0\|e_w^{(\nu)}\|_{L^\infty}\leqslant\tfrac{9}{10}(\|e_z^{(\nu-1)}\|_{L^\infty}+C_0\|e_s^{(\nu-1)}\|_{L^\infty}+C_0\|e_w^{(\nu-1)}\|_{L^\infty}). \tag{6.6}$$

Proof: Lemma 3.2 indicates

$$\|e_s^{(\nu)}(x,0_{\not{C}})\|_{L^\infty}\leqslant Cx\|e_z^{(\nu)}\|_{L^\infty},\quad \|e_w^{(\nu)}(x,0_{\not{C}})\|_{L^\infty}\leqslant Cx\|e_z^{(\nu)}\|_{L^\infty}.$$

Substracting the second equation in (3.4) with index $\nu+1$ by the corresponding equation with index ν we obtain

$$\partial_x e_s^{(\nu)}+(\lambda_0^{(\nu)}-\sigma^{(\nu)})\partial_y e_s^{(\nu)}+(\lambda_0^{(\nu)}-\sigma^{(\nu)}-\lambda_0^{(\nu-1)}+\sigma^{(\nu-1)})\partial_y S^{(\nu)}=0. \tag{6.7}$$

Integrating (6.7) along $\not{C}_0$ characteristics yields (in the case when leftward characteristic $\not{C}_0$ intersects with $y=0$ before it meets $x=0$)

$$e_s^{(\nu)}(a,b)=e_s^{(\nu)}(x,0_{\not{C}})-\int_x^a(\lambda_0^{(\nu)}-\sigma^{(\nu)}-\lambda_0^{(\nu-1)}+\sigma^{(\nu-1)})\partial_y S^{(\nu)}\mathrm{d}\alpha. \tag{6.8}$$

Applying the proposition $F^{(\nu)}$ we have

$$\begin{aligned}\|e_s^{(\nu)}\|_{L^\infty} &\leqslant Cx\|e_z^{(\nu)}\|_{L^\infty}+C\sqrt{a}(\|e_z^{(\nu-1)}\|_{L^\infty}+\|e_s^{(\nu-1)}\|_{L^\infty}+\|e_w^{(\nu-1)}\|_{L^\infty})\\ &\leqslant C\sqrt{a}(\|e_z^{(\nu)}\|_{L^\infty}+\|e_z^{(\nu-1)}\|_{L^\infty}+\|e_s^{(\nu-1)}\|_{L^\infty}+\|e_w^{(\nu-1)}\|_{L^\infty}).\end{aligned} \tag{6.9}$$

When ℓ_0 intersect with $x=0$ before it meets $y=0$, the computation is similar.

By using the same method we have

$$\|e_w^{(\nu)}\|_{L^\infty}\leqslant C\sqrt{a}(\|e_z^{(\nu)}\|_{L^\infty}+\|e_z^{(\nu-1)}\|_{L^\infty}+\|e_s^{(\nu-1)}\|_{L^\infty}+\|e_w^{(\nu-1)}\|_{L^\infty}). \tag{6.10}$$

Then from (6.3), (6.9), and (6.11) we obtain

$$\begin{aligned}&\|e_z^{(\nu)}\|_{L^\infty}+2C\|e_s^{(\nu)}\|_{L^\infty}+2C\|e_w^{(\nu)}\|_{L^\infty}\\ &\quad\leqslant\left(\frac{4}{5}+4C^2\sqrt{a}\right)\|e_z^{(\nu-1)}\|_{L^\infty}+(C+4C^2\sqrt{a})\|e_s^{(\nu-1)}\|_{L^\infty}\\ &\qquad+(C+4C^2\sqrt{a})\|e_w^{(\nu-1)}\|_{L^\infty}+4C^2\sqrt{a}\|e_z^{(\nu)}\|_{L^\infty}.\end{aligned} \tag{6.11}$$

Let a satisfy $4C^2\sqrt{a}<\frac{1}{20}$ we obtain (6.6).

Proof of Theorem 1.1: From Lemma 6.3 we know the sequences $\{z^{(\nu)}(x,y)\}$, $\{w^{(\nu)}(x,y)\}$, $\{S^{(\nu)}(x,y)\}$ are uniformly convergent. Then from expression (3.3) of $\sigma^{(\nu)}(x)$ we also have the convergence of $\{\sigma^{(\nu)}(x)\}$. As the integral of $\sigma^{(\nu)}$, the location of approximate shock is also convergent.

The limit of the above-mentioned sequences satisfies the system (1.9). In fact, the proposition $F^{(\nu)}$ implies that the sequences $\{\nabla z^{(\nu)}\}$, $\{\nabla w^{(\nu)}\}$, $\{\nabla S^{(\nu)}\}$ are uniformly bounded in any domain $\omega\subset\Omega$ away from the point (x_0,y_0). Then using the standard argument on compact sequences we know $\{z^{(\nu)}\}$, $\{w^{(\nu)}\}$, $\{S^{(\nu)}\}$ and their derivatives are pointwise convergent. By taking limit we confirm that z,w,S satisfy (1.9).

Returning to original coordinates we have locally constructed a piecewise continuous solution with shock starting from the point (x_0,y_0). The strength of the shock is zero at the point and then graduately increases along with $x-x_0$. Meanwhile, the solution has bounded derivatives away from (x_0,y_0), and the estimates (1.16) hold near (x_0,y_0).

(Received 7 August 2000; accepted for publication 11 October 2000)

The Lagrangian proposed by York *et al.* and the covariant first-order Lagrangian for general relativity are reviewed. They both deal with the (vacuum) gravitational field on a reference background and were conjectured to be equivalent. The two corresponding actions are compared and we show that the first one can in fact be obtained from the latter under suitable hypotheses. A conditioned correspondence among Nöther conserved quantities of covariant first-order Lagrangian, Brown–York quasilocal energy and the standard ADM Hamiltonian is also established. [DOI: 10.1063/1.1336514]

I. INTRODUCTION

Many approaches to variational principles, conserved quantities, and related topics can be found in the current literature about general relativity (see, e.g., Refs. 1–13, and references quoted therein). We shall hereafter compare two of them, both dealing with a dynamical metric g and a reference background metric $\overline{g}$ over a space–time manifold M of arbitrary dimension n, with $n \geqslant 3$. A large part of the paper will deal with the explicit case $n=4$, in view of applications to standard general relativity. We shall deal with the vacuum case; the generalization to the matter case is straightforward.

The first action we shall deal with is based on the covariant first-order action functional for general relativity (see Refs. 12, 14–16). The second one[3,7] is based on the action functional due to York *et al.*, which is defined with the aim of dealing with the fixing of the $(n-1)$ metric induced on the boundary ∂D of any region D of space–time M.

In the present situation it seems to us that there are two (quite separated) groups of researchers on the subjects, each one using a single one of these variational principles and both claiming that the two approaches should be *basically* equivalent. Even though there is quite a widespread feeling that the two approaches in fact have to be (at least in most cases) equivalent, we are not aware of a rigorous theoretical comparison between these two variational principles in the current literature which clarifies the matter once and for all by proving if, how, and when they are really equivalent.

Furthermore, this situation is even worse when one considers conserved quantities. In the context of a covariant first-order Lagrangian, *energy* is in fact defined by the Nöther theorem in a covariant and geometrical framework (see Refs. 14 and 15). Brown and York gave an interesting alternative definition, the so-called *quasilocal energy*, oriented to statistical considerations. Both these *energies* are often quoted in the literature since they reproduce the ADM mass in the asymptotically flat case, though they have been recognized as also suitable for more general boundary conditions [e.g., in asymptotically anti-de Sitter (see Ref. 17) or asymptotically locally flat cases; see Refs. 18–21]. *Both* methods allow one to define the *energy within a finite region* as

[a]Electronic mail: fatibene@dm.unito.it
[b]Electronic mail: ferraris@dm.unito.it
[c]Electronic mail: francaviglia@dm.unito.it
[d]Electronic mail: raiteri@dm.unito.it

well as the total one. In this way, the advantages of the Brown–York framework can also be obtained by covariant first-order formalism and Nöther theorem.

We also remark that in both cases it has been recognized that *absolute conserved quantities* have a meaning just in particular cases, while for general boundary conditions just *conserved quantities relative to something* (e.g., *a reference background*) are meaningful. Furthermore, even ''*absolute*'' *conserved quantities* should be interpreted as *conserved quantities relative to some canonical background* (e.g., flat Minkowski space in asymptotically flat spaces). We also stress that reference backgrounds are particularly relevant in general relativity, as well as in other nonlinear field theories, since whenever fields are endowed with a vector space structure a canonical choice for the reference exists, namely the *zero* section. If the configuration bundle is not a vector bundle, as happens in general relativity (as well as, e.g., in Yang–Mills theories) there is instead no canonical choice for the vacuum state. The vacuum state thence has to be ''*arbitrarily*'' fixed. When doing that it sounds physically reasonable to also require the background to be a solution of field equations, so that the relative energy can be interpreted as the energy ''*spent to go*'' from the background solution to the dynamical one (and analogously for other physically relevant conserved quantities). Furthermore, it is essential that the choice of the reference background does not effect the evolution of the dynamical fields, i.e., these solutions have to be decoupled. In view of these considerations both the covariant first-order and the York action functionals incorporate the background from the very beginning.

Again these very evident similarities are not supported by a rigorous equivalence proof. Moreover, we are not aware of any detailed analysis which clarifies whether these analogies are unconditioned or are subjected to some restrictive hypotheses. We thence believe that the matter still deserves a detailed and rigorous investigation aimed to cover both the variational aspects as well as those related to conserved quantities.

Accordingly, in this paper we shall compare the covariant first-order Lagrangian and York action functionals. Since both these *labels* hide in themselves a number of slightly different variational principles, each one adapted to a particular situation, we shall briefly review the literature on the subject to fix notation.

In Sec. II we shall review some material about covariant first-order Lagrangian and its Nöther conserved quantities, while Sec. III is devoted to introducing the Brown–York approach and the notion of quasilocal energy. Sections II and III could be considered trivial by the appropriate research group, but (in view of the existing separation we mentioned before) we hope it will serve as a short review for the complementary group. They are therefore included to make the paper self-contained as well as for uniformity of notation. The most standard and technical aspects are omitted or reported in the Appendix.

In Sec. IV we shall compare the action functionals introduced in Secs. II and III. There we shall establish a conditioned equivalence which holds under suitable boundary prescriptions required on the metric g and the background $\overline{g}$. The fact that the claimed equivalence is not completely unconditioned is in our opinion particularly important, since it sets a basis to choose between the two methods. However, the requirements on boundary conditions needed to provide equivalence are sufficiently general to support the general belief that the two methods are *basically equivalent*.

In Sec. V we shall compare the conserved quantities reviewed in Secs. II and III. We shall obtain the standard ADM Hamiltonian as well as the quasilocal energy (under the aforementioned boundary conditions) as Nöther quantities associated with the covariant first-order Lagrangian. While the first comparison with the ADM Hamiltonian already appeared in literature (although in a simplified version; see Ref. 22 and references quoted therein) the second, i.e., the comparison between quasilocal energy and Nöther charges, is, as far as we know, new.

In Sec. VI we shall also discuss the very notion of *conserved quantity*. On the one hand, in fact, the Nöther theorem provides currents $\mathcal{E}$ which are *covariantly conserved*, i.e., $d\mathcal{E}=0$ identically or on shell (i.e., along solutions), meaning that their integral on the boundary ∂D of any n-region D in space–time M vanishes or, equivalently, that the conserved quantity obeys a continuity equation. On the other hand, physicists are often interested in quantities Q which are

conserved in time, meaning that, once an ADM foliation of a region of space–time has been chosen, such a quantity Q may be computed by integration on each leaf and it turns out to be independent of the particular leaf labeled by *time* t. Clearly, ADM foliations are far from unique and different foliations of the same region D correspond to different ways of defining *time*. Furthermore, such a quantity Q may be conserved in the time defined by an ADM foliation without being conserved with respect to other foliations (i.e., with respect to different time parameters). From a theoretical general relativity viewpoint, quantities conserved in time are not (manifestly) covariant in nature. They are, in fact, conserved with respect to a special parameter, while, at a fundamental level, the principle of general covariance forbids, at least in principle, the selection of a preferred time. Different sets of conditions under which conservation ''*in time*'' follows from covariant conservation will be discussed.

In Sec. VII we shall present two simple examples illustrating the difference between time-conserved and covariantly conserved quantities. The first one is the computation of various Nöther charges of the Schwarzschild solution relative to a Minkowski background matched on a *finite sphere*. Conservation in time of various foliations is analyzed and quasilocal energy is obtained via the Nöther theorem, in full agreement with previously known results (see Ref. 3). The second example is a Kerr solution matched at spatial infinity with the Minkowski metric. The Nöther conserved quantities are obtained. Such an example is interesting because it does not obey the same matching conditions required throughout the rest of the paper. Nevertheless it produces a current which is time conserved, showing that all the conditions discussed along the paper are sufficient but not necessary. We believe that these examples are important also from a pedagogical viewpoint.

In the Appendix we collect formulas which are used throughout the paper to translate covariant objects into objects adapted to the ADM foliation and vice versa. We omit the details about the geometric framework for variational calculus and refer the reader to Refs. 23 and 24, and references therein, for specifics.

II. THE COVARIANT FIRST-ORDER LAGRANGIAN

The covariant first-order action was introduced to set general relativity in a standard *covariant first-order* variational framework. As is well known, in fact, the Hilbert Lagrangian $L=(1/2\kappa)\sqrt{g}R\,\mathbf{ds}$ is second order in the metric field, so that field equations are expected to be of fourth order. Einstein field equations are second-order equations instead, as if the action were first order only. This is due to the well-known fact that *locally* second derivatives of the metric field appearing in the scalar curvature may be hidden under a divergence, thus not appearing in field equations (a fact which was clear to Einstein from the very beginning; see, e.g., Ref. 25). Of course, however, this cannot be done in general in a global and covariant way; that is why general relativity is usually considered as a second-order field theory or, whenever it is treated on a first-order basis, something is lost (e.g., covariance or boundary terms; see Refs. 4 and 5). The problem of a covariant splitting of the Hilbert Lagrangian can be globally solved by introducing a background connection $\overline{\Gamma}^{\alpha}_{\beta\nu}$. Hereafter, for reasons which will be clear later, we shall further restrict ourselves to introducing a background metric $\overline{g}_{\mu\nu}$ so that $\overline{\Gamma}^{\alpha}_{\beta\nu}$ is its Levi-Civita connection.

The *covariant first-order action functional in a region* $D\subset M$ is the following:

$$A_D[g,\overline{g}]=\frac{1}{2\kappa}\int_D\sqrt{g}R\,\mathbf{ds}-\frac{1}{2\kappa}\int_{\partial D}\sqrt{g}g^{\mu\nu}w^{\alpha}_{\mu\nu}\,\mathbf{ds}_{\alpha}-\frac{1}{2\kappa}\int_D\sqrt{\overline{g}}\overline{R}\,\mathbf{ds}, \tag{2.1}$$

where κ is a constant [$\kappa=8\pi G/c^4$ in general relativity with $\dim(M)=4$], $\sqrt{g}$ is the square root of the absolute value of the determinant of the dynamical metric g, $\sqrt{\overline{g}}=\sqrt{|\det\overline{g}|}$ is the analogous quantity for the background metric $\overline{g}$, and $\mathbf{ds}$ and $\mathbf{ds}_{\alpha}=\partial_{\alpha}\lrcorner\mathbf{ds}$ are the standard local bases for n forms and $(n-1)$ forms over M, respectively. We systematically denote by a bar the quantities referred to the background, i.e., we shall use the following notation:

$g_{\mu\nu}$	$\overline{g}_{\mu\nu}$	Covariant metric
$g^{\mu\nu}$	$\overline{g}^{\mu\nu}$	Contravariant metric
$\Gamma^{\alpha}_{\beta\nu}$	$\overline{\Gamma}^{\alpha}_{\beta\nu}$	Levi-Civita connection
$R^{\alpha}_{\beta\mu\nu}$	$\overline{R}^{\alpha}_{\beta\mu\nu}$	Riemann tensor
$R_{\mu\nu}=R^{\alpha}_{\mu\alpha\nu}$	$\overline{R}_{\mu\nu}=\overline{R}^{\alpha}_{\mu\alpha\nu}$	Ricci tensor
$R=g^{\mu\nu}R_{\mu\nu}$	$\overline{R}=\overline{g}^{\mu\nu}\overline{R}_{\mu\nu}$	Scalar curvature
$u^{\mu}_{\alpha\beta}=\Gamma^{\mu}_{\alpha\beta}-\delta^{\mu}_{(\alpha}\Gamma^{\epsilon}_{\beta)\epsilon}$	$\overline{u}^{\mu}_{\alpha\beta}=\overline{\Gamma}^{\mu}_{\alpha\beta}-\delta^{\mu}_{(\alpha}\overline{\Gamma}^{\epsilon}_{\beta)\epsilon}$	

We also introduced the following *relative quantities*:

$$q^{\mu}_{\alpha\beta}=\Gamma^{\mu}_{\alpha\beta}-\overline{\Gamma}^{\mu}_{\alpha\beta}, \quad w^{\mu}_{\alpha\beta}=u^{\mu}_{\alpha\beta}-\overline{u}^{\mu}_{\alpha\beta}.$$

The action functional (2.1) is associated with the so-called *covariant first-order Lagrangian*

$$L=\frac{1}{2\kappa}\left(\sqrt{g}R-d_{\alpha}(\sqrt{g}g^{\mu\nu}w^{\alpha}_{\mu\nu})-\sqrt{\overline{g}}\overline{R}\right)\mathbf{ds} \tag{2.2a}$$

or equivalently

$$L=\frac{1}{2\kappa}((\sqrt{g}g^{k\nu}-\sqrt{\overline{g}}\overline{g}^{\mu\nu})\overline{R}_{\mu\nu}+\sqrt{g}g^{\alpha\beta}(q^{\rho}_{\alpha\sigma}q^{\sigma}_{\rho\beta}-q^{\sigma}_{\sigma\rho}q^{\rho}_{\alpha\beta}))\mathbf{ds}. \tag{2.2b}$$

From (2.2a), it can easily be seen that the fields g and $\overline{g}$ do not interact and they both obey vacuum Einstein field equations (provided that variations are performed with suitable boundary conditions). From (2.2b), the Lagrangian is, however, recognized to be first order in g and second order in $\overline{g}$. Being both $q^{\mu}_{\alpha\beta}$ and $w^{\mu}_{\alpha\beta}$ tensors, L is a covariant Lagrangian. It is, of course, the truly covariant counterpart of the so-called Hilbert–Palatini first-order Lagrangian (see Ref. 26), to which it reduces by suitable noncovariant cancellations and background fixings. We stress that in the variational principle induced by (2.1) the dynamical metric g is endowed with a direct physical meaning, while the reference background metric $\overline{g}$ is, at least for the moment, introduced to provide covariance and as a reference value for conserved quantities, as discussed in the following. Notice that if the action (2.1) is computed for $g=\overline{g}$, then it identically vanishes.

The Nöther theorem (see, e.g., Refs. 14–16, 23, and references quoted therein) is related to the general covariance of the theory. It *algorithmically* defines a *Nöther conserved current*, i.e., a map $\mathcal{E}[\xi,\sigma]$ which associates with any space–time vector field ξ and any field configuration $\sigma=(g,\overline{g})$ an $(n-1)$-form $\mathcal{E}[\xi,\sigma]$ on space–time M of dimension n which is closed on-shell, i.e., when the configuration σ is a solution of field equations. For the action functional (2.1) we obtain

$$\begin{aligned}\mathcal{E}[\xi,\sigma]=\frac{1}{2\kappa}[&\sqrt{g}((g^{\lambda\alpha}g_{\mu\nu}-\delta^{(\lambda}_{\mu}\delta^{\alpha)}_{\nu})\nabla_{\alpha}\pounds_{\xi}g^{\mu\nu}-\xi^{\lambda}R)\\&-(\pounds_{\xi}(\sqrt{g}g^{\mu\nu}w^{\lambda}_{\mu\nu})-\xi^{\lambda}d_{\alpha}(\sqrt{g}g^{\mu\nu}w^{\alpha}_{\mu\nu}))\\&-\sqrt{\overline{g}}((\overline{g}^{\lambda\alpha}\overline{g}_{\mu\nu}-\delta^{(\lambda}_{\mu}\delta^{\alpha)}_{\nu}))\overline{\nabla}_{\alpha}\pounds_{\xi}\overline{g}^{\mu\nu}-\xi^{\lambda}\overline{R}]\mathbf{ds}_{\lambda}.\end{aligned} \tag{2.3}$$

The differential of the $(n-1)$-form $\mathcal{E}[\xi,\sigma]$ satisfies the following property:

$$d\mathcal{E}[\xi,\sigma]=\mathcal{W}[\xi,\sigma], \tag{2.4}$$

where $\mathcal{W}[\xi,\sigma]=-(1/2\kappa)(G_{\mu\nu}\pounds_{\xi}g^{\mu\nu}-\overline{G}_{\mu\nu}\pounds_{\xi}\overline{g}^{\mu\nu})$ **ds** is proportional to field equations. Consequently, the Nöther current $\mathcal{E}[\xi,\sigma]$ is closed along solutions.

Of course, the Nöther currents, as well as the conserved quantities associated with them, explicitly depend on boundary terms in the Lagrangian. This is a very well known feature in Physics, as it can be simply seen, e.g., in thermodynamics. It is in fact well known that boundary

terms are related to boundary conditions. Different boundary terms need different boundary conditions to keep field equations satisfied by action extremals (see Refs. 7, 27, and 28). And it is well known that, e.g., for a correct definition of energy in thermodynamics, different boundary conditions correspond to different definitions of energy, such as *internal energy*, *free energy*, etc. We stress that all these energies are *true* physical energies of thermodynamical systems. Which one has to be used in practice is determined by the particular system under consideration and the boundary conditions *we* decided to impose. As it is physically relevant to notice, we may decide to keep temperature fixed on the boundary of a gas box or we may impose adiabatic conditions; this different choice corresponds to a different apparatus which selects a different energy flow through the boundary so that the boundary conditions are satisfied. We stress that this corresponds to an external action on the system which turns out to change the physical energy of the system itself. In the covariant first-order approach to general relativity something fully analogous holds: The background $\overline{g}$ canonically selects both the boundary conditions and the corresponding energy to be used and different choices of the background correspond to different physically meaningful definitions of energy.

As shown in Refs. 23 and 24, one can also define the *superpotential* $\mathcal{U}[\xi,\sigma]$ and the *reduced current* $\tilde{\mathcal{E}}[\xi,\sigma]$ as those currents such that

$$\mathcal{E}[\xi,\sigma]=\tilde{\mathcal{E}}[\xi,\sigma]+d\mathcal{U}[\xi,\sigma], \tag{2.5}$$

where the reduced current is required to vanish on shell.

The *conserved quantity in a* $(n-1)$*-region* Ω is defined as

$$Q_\Omega[\xi,\sigma]=\int_\Omega \mathcal{E}[\xi,\sigma]=\int_\Omega \tilde{\mathcal{E}}[\xi,\sigma]+\int_{\partial\Omega}\mathcal{U}[\xi,\sigma]=\int_{\partial\Omega}\mathcal{U}[\xi,\sigma], \tag{2.6}$$

where, in the last equality, σ is assumed to be a solution so that $\tilde{\mathcal{E}}[\xi,\sigma]=0$.

In the case of the first-order covariant action functional (2.1) we obtain in particular:

$$\begin{aligned}\mathcal{U}[\xi,\sigma]&=\frac{1}{2\kappa}[\sqrt{g}\nabla^\beta.\xi^\alpha+\sqrt{g}g^{\mu\nu}w^\beta_{\mu\nu}\xi^\alpha-\sqrt{\overline{g}}\overline{\nabla}^\beta.\xi^\alpha]\mathbf{ds}_{\alpha\beta},\\ \tilde{\mathcal{E}}[\xi,\sigma]&=\frac{1}{\kappa}[\sqrt{g}g^{\mu\lambda}G_{\mu\nu}\xi^\nu-\sqrt{\overline{g}}\overline{g}^{\mu\lambda}\overline{G}_{\mu\nu}\xi^\nu]\mathbf{ds}_\lambda .\end{aligned} \tag{2.7}$$

The conserved quantity $Q_\Omega[\xi,\sigma]$ depends on the dynamical metric g and on the reference background metric $\overline{g}$. It has to be interpreted as the *relative conserved quantity of g with respect to* $\overline{g}$. If one chooses g to be a solution asymptotically flat according to one of the current definitions (e.g., the Kerr–Newman solution), assuming $\overline{g}$ to be the flat reference background (which matches the dynamical metric at infinity where ''infinity'' is prescribed by the definition of asymptotic flatness) and Ω to be a spacelike hypersurface in M, then $Q_\Omega[\xi,\sigma]$ reproduces the expected value for mass (by choosing $\xi=\partial_t$, i.e., the vector field which corresponds to asymptotic time translation) and angular momentum (by choosing $\xi=-\partial_\phi$, i.e., the vector field which corresponds to asymptotic rotation; see, e.g., Refs. 11, 15, and 23). Furthermore, the same results are achieved for nonasymptotically flat solutions by choosing suitable reference backgrounds. Examples are the $(2+1)$ BTZ solution (which is asymptotically anti-de Sitter; see Ref. 16), the Euclidean Taub–Bolt solution (which is asymptotically locally flat; see Ref. 29). In addition, the same techniques are successfully used in *gauge-natural theories*, i.e., when the field theory owns both covariance and gauge invariance (e.g., BCEA theory, Einstein–Maxwell theory; see Refs. 23 and 30).

We stress that the conserved quantities $Q_\Omega[\xi,\sigma]$ associated with the covariant first-order action principle (2.1) *are not* affected by the anomalous factor problems as are the ones associated with the standard Hilbert–Einstein Lagrangian (see Refs. 14 and 16).

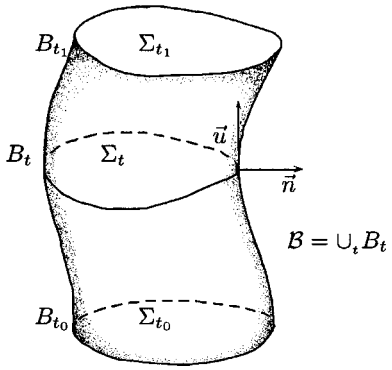

FIG. 1.

III. YORK'S VARIATIONAL PRINCIPLE

York's action was originally introduced (see Refs. 3, 7, and 31) to provide a variational principle suited to deal with the boundary conditions which are specified by keeping the induced metric on ∂D fixed. Boundary terms are added to the standard Hilbert–Einstein action $(1/2\kappa)\int_D R\sqrt{g}\,\mathbf{ds}$. They are exactly needed so that the boundary contribution to the variation of the action vanishes when the induced $(n-1)$ metric is kept fixed on ∂D.

York's action functional is adapted to an ADM foliation induced by dragging a spacelike hypersurface Σ along a timelike vector field ζ.

An ADM foliation of a space–time region D is obtained and it is parametrized by the affine parameter t of ζ (see Fig. 1). The region D is thence topologically the product of Σ times a real line interval $[t_0,t_1]$. Let the generic leaf be Σ_t and B_t its boundary, which is obviously $(n-2)$ dimensional. Let us then denote by $\vec{u}$ the future directed timelike unit normal to the leaf Σ_t.

The boundary ∂D is formed by the union of all $(n-2)$-boundaries B_t, which will be denoted by $\mathcal{B}$, together with the initial and final leaves Σ_{t_0} and Σ_{t_1} of the sandwich, which will be called *lids*. Let us denote by $\vec{n}$ the outward spacelike unit normal to $\mathcal{B}$, by γ_{ij} the metric induced by g on $\mathcal{B}$, by h_{ab} the metric induced on Σ_t, and by σ_{AB} the metric induced on the $(n-2)$-boundary B_t. Here and in the sequel indices run in the following ranges: Greek indices from 0 to $n-1$, lower case Roman letters $a,b,\ldots$ from 1 to $n-1$, lower case middle Roman letters $i,j,\ldots$ take the values 0,2,...,$n-1$, and upper case Roman letters $A,B,\ldots$ range from 2 to $n-1$ (see also the Appendix for the notation).

We shall finally denote by Θ_{ij} the extrinsic curvature of $\mathcal{B}$ in the space–time M, by K_{ab} the extrinsic curvature of Σ_t in M, and by $\mathcal{K}_{AB}$ the extrinsic curvature of B_t in Σ_t (see the Appendix). We shall denote by $\Theta=\gamma^{ij}\Theta_{ij}$, $K=h^{ab}K_{ab}$, and $\mathcal{K}=\sigma^{AB}\mathcal{K}_{AB}$ the traces of the extrinsic curvatures of $\mathcal{B}$, Σ_t, and B_t, respectively. It is assumed that the dynamical metric g and the reference background $\overline{g}$ induce the same metric γ_{ij} on $\mathcal{B}$. Furthermore, let us also assume that the hypersurfaces $\mathcal{B}$ and Σ_t *intersect orthogonally* (or equivalently that $\vec{n}$ and $\vec{u}$ are orthogonal on any B_t, i.e., $u^\mu n_{\mu|\mathcal{B}}=0$). We stress that here we are considering a region D in which the timelike vector field ζ has no fixed points, so that the hypersurfaces Σ_t do not intersect each other and span the whole region D. Let us also denote by Π^{ij} and P^{ab} the *gravitational momenta* conjugated to the metrics γ_{ij} and h_{ab}, respectively; they are given by

$$\Pi^{ij}=-\frac{1}{2\kappa}\sqrt{\gamma}(\Theta\gamma^{ij}-\Theta^{ij}),$$
$$P^{ab}=\frac{1}{2\kappa}\sqrt{h}(Kh^{ab}-K^{ab}). \tag{3.1}$$

According to this notation, York's action in the presence of a background $\overline{g}$ may be written as

$$I_D[g,\overline{g}]=I_D[g]-I_D[\overline{g}], \tag{3.2}$$

where the functional $I_D[g]$ is defined by

$$I_D[g]=\frac{1}{2\kappa}\int_D \sqrt{g}R\,\mathbf{ds}+\frac{1}{\kappa}\int_{\Sigma_{t_0}}^{\Sigma_{t_1}} Ku^\alpha\sqrt{g}\,\mathbf{ds}_\alpha-\frac{1}{\kappa}\int_{\mathcal{B}}\Theta n^\alpha\sqrt{g}\,\mathbf{ds}_\alpha \tag{3.3}$$

and $I_D[\overline{g}]$ is the same functional calculated for the background $\overline{g}$. Notice that $\sqrt{g}u^\alpha\,\mathbf{ds}_\alpha=\sqrt{h}\,\mathrm{d}^3x$ and $\sqrt{g}n^\alpha\,\mathbf{ds}_\alpha=\sqrt{\gamma}\,d^3x$ are the volume elements on Σ_t and $\mathcal{B}$, respectively. In the functional (3.3) we also set the convenient notation

$$\int_{\Sigma_{t_0}}^{\Sigma_{t_1}}\equiv\int_{\Sigma_{t_1}}-\int_{\Sigma_{t_0}}.$$

In the current literature, there exists a whole family of action functionals similar to (3.2) each adapted to the particular problem under consideration. In general, one can add to the functional (3.3) an arbitrary functional depending on the data fixed on the boundary, i.e., depending on the boundary metric (see Ref. 3). This arbitrariness does not affect the equations of motion since the boundary metric is kept fixed in the variational principle. The choice (3.2) is motivated by the requirement $I_D[\overline{g},\overline{g}]=0$, i.e., the requirement that the action functional vanishes when computed with $g=\overline{g}$. The same property is satisfied by (2.1).

Moreover, under additional hypotheses, the integral on the lids Σ_{t_0} and Σ_{t_1} in (3.3) is usually discarded since the lids are either ignored or identified. This is usually done by restricting to situations in which the lids are not present (e.g., by considering a noncompact region D in which t_0 and t_1 are let to tend to $-\infty$ and ∞, respectively) or are identified. [Identification is obtained, e.g., when the solution is time periodic, as may happen in the Euclidean sector (see Refs. 32, 27, and 19) and in approaches based on path integrals for evaluating the grand-canonical partition function or the density of states for general relativity, where the sum over periodic histories has to be considered (see Ref. 27). In all those cases the boundary ∂D is *required* to have the topology $\partial\Sigma\times S^1$, i.e., it is assumed to be a single boundary component $\partial D=\mathcal{B}$.]

Accordingly, let us assume from now on that lids are not present unless otherwise stated. The quasilocal energy $E[g]$ (for motivations and details see Ref. 3), i.e., the energy of a region of finite spatial extent, is obtained by considering the change of the action in time, where changes in time are governed by the lapse N on the boundary $\mathcal{B}$. We stress that the interpretation of this quantity as the energy of a gravitating system was suggested in Ref. 3 through a Hamilton–Jacobi analysis of the action functional. It is given by

$$E_t[g]=\frac{1}{\kappa}\int_{B_t}\mathcal{K}\sqrt{\sigma}\,\mathrm{d}^2x, \tag{3.4}$$

where $\sqrt{\sigma}\,\mathrm{d}^2x$, is the volume element on B_t. A contribution analogous to (3.4) comes from the background action $I_D[\overline{g}]$ in (3.2). Assuming that the induced three metric γ and $\overline{\gamma}$ are matched on the surface $\mathcal{B}$ we finally have

$$E_t[g,\overline{g}]=\frac{1}{\kappa}\int_{B_t}(\mathcal{K}-\overline{\mathcal{K}})\sqrt{\sigma}\,\mathrm{d}^2x. \tag{3.5}$$

This is the explicit expression of Brown and York quasilocal energy computed for the action functional (3.2).

Another standard quantity which can be defined by the (3.2) action functional is the ADM Hamiltonian. It is obtained by a $(3+1)$ decomposition of the action which leads by standard techniques to

$$I_D[g]=\int \mathrm{d}t \int_{\Sigma_t}(P^{ab}\partial_t h_{ab}-N\mathcal{H}-N_a\mathcal{H}^a)\mathrm{d}^3x$$
$$-\int \mathrm{d}t\int_{B_t}\left(\frac{N}{\kappa}\mathcal{K}+N^a 2\frac{P^{bc}}{\sqrt{h}}n_b\sigma_{ac}\right)\sqrt{\sigma}\,\mathrm{d}^2x, \tag{3.6}$$

where

$$\mathcal{H}=-\frac{1}{2\kappa}\sqrt{h}\mathcal{R}+\frac{\kappa}{\sqrt{h}}(2P_{ab}P^{ab}-P^a_aP^b_b),$$
$$\mathcal{H}^a=-2D_bP^{ab} \tag{3.7}$$

are the Hamiltonian and the momentum constraint, respectively. The Hamiltonian for vacuum general relativity is thus identified with the term

$$H(g)=\int_{\Sigma_t}(N\mathcal{H}+N_a\mathcal{H}^a)\mathrm{d}^3x+\frac{1}{\kappa}\int_{B_t}(N\mathcal{K}-N^aK^{bc}n_b\sigma_{ac})\sqrt{\sigma}\,\mathrm{d}^2x. \tag{3.8}$$

In the latter term we have taken into account that $h^{bc}n_b\sigma_{ac}=0$ (see the Appendix for details).

The Hamiltonian $H(g)$ is the sum of a *constrained volume* term, which is vanishing when computed on a solution, and a *boundary* term.

We may repeat the above-mentioned analysis also for the background action functional $I_D[\overline{g}]$ obtaining an Hamiltonian $H(\overline{g})$ which agrees with (3.8) provided that we replace the terms there involved with the corresponding barred ones. The total Hamiltonian $H(g,\overline{g})$ is then given by the following difference:

$$H(g,\overline{g})=H(g)-H(\overline{g}). \tag{3.9}$$

When it is evaluated on solutions of field equations, the constrained volume terms vanish and (3.9) reduces to the boundary terms:

$$H(g,\overline{g})\simeq\frac{1}{\kappa}\int_{B_t}(N\mathcal{K}-N^aK^{bc}n_b\sigma_{ac})\sqrt{\sigma}\,\mathrm{d}^2x$$
$$-\frac{1}{\kappa}\int_{B_t}(\overline{N\mathcal{K}}-\overline{N}^a\overline{K}^{bc}\overline{n}_b\overline{\sigma}_{ac})\sqrt{\overline{\sigma}}\,\mathrm{d}^2x, \tag{3.10}$$

where the symbol $\simeq$ denotes equality on shell.

Moreover, if the metric g and its relative background $\overline{g}$ agree on the boundary the Hamiltonian simplifies as follows:

$$H(g,\overline{g})\simeq\frac{1}{\kappa}\int_{B_t}\{N(\mathcal{K}-\overline{\mathcal{K}})-N^a(K^{bc}-\overline{K}^{bc})n_b\sigma_{ac}\}\sqrt{\sigma}\,\mathrm{d}^2x. \tag{3.11}$$

The *mass* associated with the time translation $t^\mu=Nu^\mu+N^\mu$, relative to two solutions g and $\overline{g}$, is simply defined to be the value of the Hamiltonian (3.10). Clearly the mass $H(\overline{g},\overline{g})$ of the background is equal to zero.

Notice that, whenever it is possible to choose a Gaussian gauge, i.e., setting $N=1$ and $N^a=0$ in (3.11), we obtain the quasilocal energy (3.5) (see Ref. 3).

In Ref. 33 it was shown that the definition (3.10) agrees with the expressions of energy already defined in the literature for space–times with different asymptotic behavior.

IV. COMPARISON OF THE ACTION FUNCTIONALS

We shall here decompose the first-order covariant action functional (2.1) along an ADM foliation of D in order to prove that the action functional (3.2) and (2.1) are equal if the four-metrics g and $\overline{g}$ are required to coincide on ∂D.

Of course, the ADM splitting breaks down the explicit covariance in the action allowing a comparison with respect to the same ADM foliation. In particular, the boundary term in the covariant action (2.1) splits into a contribution on $\mathcal{B}$ and a contribution on the *lids* Σ_{t_0} and Σ_{t_1}.

Let us consider local coordinates (t,r,x^A) adapted both to $\mathcal{B}$ and the ADM splitting on D. In this coordinate system $\mathcal{B}$ has the expression $r=$constant while the leaves Σ_t are the hypersurfaces of equation $t=$constant. The metric tensor g can be split with respect to the ADM foliation obtaining

$$\begin{aligned} g=g_{\mu\nu}\,\mathrm{d}x^\mu\otimes\mathrm{d}x^\nu&=(h_{\mu\nu}-u_\mu u_\nu)\mathrm{d}x^\mu\otimes\mathrm{d}x^\nu\\ &=-N^2\,\mathrm{d}t^2+h_{ab}(\mathrm{d}x^a+N^a\,\mathrm{d}t)\otimes(\mathrm{d}x^b+N^b\,\mathrm{d}t). \end{aligned} \tag{4.1}$$

Similarly, one can consider the foliation of space–time in the hypersurfaces $r=$constant and obtain

$$\begin{aligned} g=g_{\mu\nu}\,\mathrm{d}x^\mu\otimes\mathrm{d}x^\nu&=(\gamma_{\mu\nu}+n_\mu n_\nu)\mathrm{d}x^\mu\otimes\mathrm{d}x^\nu\\ &=V^2\,\mathrm{d}r^2+\gamma_{ij}(\mathrm{d}x^i+V^i\,\mathrm{d}r)\otimes(\mathrm{d}x^j+V^j\,\mathrm{d}r). \end{aligned} \tag{4.2}$$

Analogous expressions can be obtained for the reference background metric $\overline{g}$. Let us evaluate the boundary term of the covariant first-order action functional (2.1) on $\mathcal{B}$ and on the lids Σ_{t_0} and Σ_{t_1}, i.e.,

$$A_{\mathcal{B}}=-\frac{1}{2\kappa}\int_{\mathcal{B}}\sqrt{g}g^{\mu\nu}w^\alpha_{\mu\nu}\,\mathbf{ds}_\alpha,\quad A^{\Sigma_{t_1}}_{\Sigma_{t_0}}=-\frac{1}{2\kappa}\int^{\Sigma_{t_1}}_{\Sigma_{t_0}}\sqrt{g}g^{\mu\nu}w^\alpha_{\mu\nu}\,\mathbf{ds}_\alpha. \tag{4.3}$$

By using results which are summarized in the Appendix [see Eqs. (A18) and (A23)] one obtains

$$\begin{aligned} A_{\mathcal{B}}=-\frac{1}{2\kappa}\int_{\mathcal{B}}g^{\mu\nu}w^\alpha_{\mu\nu}n_\alpha\sqrt{\gamma}\,\mathrm{d}^3x=-\frac{1}{2\kappa}\int_{\mathcal{B}}\Bigg\{&2\Theta-\overline{\Theta}_{ij}\left(\frac{\overline{V}}{V}\overline{\gamma}^{ij}+\frac{V}{\overline{V}}\gamma^{ij}\right)\\ &-\frac{\overline{\Theta}_{ij}}{V\overline{V}}(V^i-\overline{V}^i)(V^j-\overline{V}^j)+\frac{1}{V\overline{V}}\partial_i\overline{V}(V^i-\overline{V}^i)-\frac{1}{V}\overline{\mathcal{D}}_i(V^i-\overline{V}^i)\Bigg\}\sqrt{\gamma}\,\mathrm{d}^3x, \end{aligned} \tag{4.4}$$

where $\overline{\mathcal{D}}_i$ is the covariant derivative with respect to the three-metric $\overline{\gamma}_{ij}$ induced on $\mathcal{B}$ by the background metric $\overline{g}$, while V and V^i are the *radial lapse* and the *radial shift* [see (4.2)].

Analogously, on the lids the ADM splitting of the boundary term (4.3) gives an extra contribution of the following form:

$$\begin{aligned} A^{\Sigma_{t_1}}_{\Sigma_{t_0}}&=+\frac{1}{2\kappa}\int^{\Sigma_{t_1}}_{\Sigma_{t_0}}g^{\mu\nu}w^\alpha_{\mu\nu}u_\alpha\sqrt{h}\,\mathrm{d}^3x\\ &=-\frac{1}{2\kappa}\int^{\Sigma_{t_1}}_{\Sigma_{t_0}}\Bigg\{-2K+\overline{K}_{ab}\left(\frac{\overline{N}}{N}\overline{h}^{ab}+\frac{N}{\overline{N}}h^{ab}\right)-\frac{\overline{K}_{ab}}{N\overline{N}}(N^a-\overline{N}^a)(N^b-\overline{N}^b)\\ &\quad-\frac{1}{N\overline{N}}\partial_a\overline{N}(N^a-\overline{N}^a)+\frac{1}{N}\overline{D}_a(N^a-\overline{N}^a)\Bigg\}\sqrt{h}\,\mathrm{d}^3x, \end{aligned} \tag{4.5}$$

where $\overline{D}_a$ is the covariant derivative with respect to the three-metric $\overline{h}_{ab}$ induced on Σ by the background metric $\overline{g}$, while N and N^a are the lapse and the shift of the metric [see (4.1)]. We stress that no matching condition is required to obtain the above-mentioned results. The behaviors of the metrics g and $\overline{g}$ are completely unrelated until now. In general the two action functionals (2.1) and (3.2) are fairly different.

However, let us assume that the dynamical metric g and the background $\overline{g}$ coincide on the hypersurface $\mathcal{B}$ so that, in particular, they induce the same three-metric on $\mathcal{B}$ (i.e., $\gamma_{ij}|_{\mathcal{B}}=\overline{\gamma}_{ij}|_{\mathcal{B}}$) and they have the same *radial* lapse function (i.e. $V|_{\mathcal{B}}=\overline{V}|_{\mathcal{B}}$) and *radial* shift vector (i.e. $V^i|_{\mathcal{B}}=\overline{V}^i|_{\mathcal{B}}$). Then, under these additional hypotheses, the contribution $A_{\mathcal{B}}$ reduces to

$$A_{\mathcal{B}}=-\frac{1}{\kappa}\int_{\mathcal{B}}(\sqrt{\gamma}\Theta-\sqrt{\overline{\gamma}}\overline{\Theta})\mathrm{d}^3x=-\frac{1}{\kappa}\int_{\mathcal{B}}(\sqrt{g}\Theta-\sqrt{\overline{g}}\overline{\Theta})n^\alpha\,\mathbf{ds}_\alpha. \tag{4.6}$$

Analogously, if the metric g and $\overline{g}$ are required to agree on the lids (i.e., if $h_{ij}=\overline{h}_{ij}$, $N=\overline{N}$, and $N^i=\overline{N}^i$ on Σ_{t_0} and Σ_{t_1}), then the contribution (4.5) on the lids reduces to

$$A^{\Sigma_{t_1}}_{\Sigma_{t_0}}=\frac{1}{\kappa}\int_{\Sigma_{t_0}}^{\Sigma_{t_1}}(\sqrt{h}K-\sqrt{\overline{h}}\overline{K})\mathrm{d}^3x=\frac{1}{\kappa}\int_{\Sigma_{t_0}}^{\Sigma_{t_1}}(\sqrt{g}K-\sqrt{\overline{g}}\overline{K})u^\alpha\,\mathbf{ds}_\alpha. \tag{4.7}$$

Then the boundary term in the covariant first-order action (2.1) can be written as

$$A_{\mathcal{B}}+A^{\Sigma_{t_1}}_{\Sigma_{t_0}}=-\frac{1}{\kappa}\int_{\mathcal{B}}(\sqrt{g}\Theta-\sqrt{\overline{g}}\overline{\Theta})n^\alpha\mathbf{ds}_\alpha+\frac{1}{\kappa}\int_{\Sigma_{t_0}}^{\Sigma_{t_1}}(\sqrt{g}K-\sqrt{\overline{g}}\overline{K})u^\alpha\,\mathbf{ds}_\alpha \tag{4.8}$$

and the action functionals (2.1) and (3.2) clearly coincide.

We stress that this result has been obtained by requiring the aforementioned matching conditions between g and $\overline{g}$ on the complete boundary $\partial D=\mathcal{B}+\Sigma_{t_1}-\Sigma_{t_0}$ of the region D.

We should also remark that for time-independent solutions the matching on the lids cannot be required, because if the two metrics g and $\overline{g}$ agree on a spacelike hypersurface Σ_t, they necessarily agree on the whole region D. Also for this reason, the contributions on the lids are never considered in applications.

The matching condition of the four-metrics g and $\overline{g}$ is a stronger requirement than the one introduced in Ref. 10. There, only the induced three-metrics γ_{ij} and $\overline{\gamma}_{ij}$ are required to agree on $\mathcal{B}$, where $\mathcal{B}$ is let to tend to *infinity*. Although the matching of the four-metrics at infinity is not too hard to be implemented in applications (see Refs. 15, 16, and 19), we are aware that this matching, when possible, may become hard to implement in a *finite region*. Here the matching is required to have a direct theoretical comparison between the action functionals (2.1) and (3.2) (and between their Hamiltonians and conserved charges).

V. QUASILOCAL ENERGY AS A NÖTHER CURRENT

Nöther theorem provides a map Q which associates to each space–time vector field ξ a covariantly conserved quantity $Q[\xi]$ [see Eqs. (2.6) and (2.7)]. The quantity Q will be compared with the standard ADM Hamiltonian and with the quasilocal energy defined in Sec. III.

Let us consider the covariant conserved quantity $Q_{\Sigma_t}[\xi,\sigma]$ for the first-order action functional (2.1) in the domain Σ_t and relative to a vector field ξ and a section $\sigma=(g,\overline{g})$. As we have already outlined in Sec. II, the quantity $Q_{\Sigma_t}[\xi,\sigma]$ is defined to be the integral of the superpotential (2.7) on the two-dimensional surfaces B_t (see Fig. 1 for the notation). Since the Lagrangian (2.1) decomposes in three terms [see Eq. (2.2a)], we can also decompose each derived quantity (in particular the superpotential, the Nöther currents, and the conserved quantities) in three terms. In particular,

$$Q^{\mathrm{tot}}_{\Sigma_t}[\xi,\sigma]=Q_{\Sigma_t}[\xi,g]+Q_{\Sigma_t}[\xi,g,\overline{g}]+Q_{\Sigma_t}[\xi,\overline{g}], \tag{5.1}$$

where

$$Q_{\Sigma_t}[\xi,g]=\frac{1}{2\kappa}\int_{B_t}\sqrt{g}\nabla^{\beta}\xi^{\alpha}\,\mathbf{ds}_{\alpha\beta},$$

$$Q_{\Sigma_t}[\xi,g,\overline{g}]=\frac{1}{2\kappa}\int_{B_t}\sqrt{g}g^{\mu\nu}w^{\beta}_{\mu\nu}\xi^{\alpha}\,\mathbf{ds}_{\alpha\beta}, \tag{5.2}$$

$$Q_{\Sigma_t}[\xi,\overline{g}]=-\frac{1}{2\kappa}\int_{B_t}\sqrt{\overline{g}}\overline{\nabla}^{\beta}\xi^{\alpha}\,\mathbf{ds}_{\alpha\beta}.$$

In order to simplify the ADM decomposition of the expression (5.1) so to be able to compare the results obtained with the standard ones of Sec. III and Ref. 3 let us assume, as usual, that the metrics g and $\overline{g}$ are matched on the hypersurface $\mathcal{B}$ and that the boundaries are orthogonal (i.e., $u^{\mu}n_{\mu}|_{\mathcal{B}}=0$).

[We stress that under our viewpoint the matching condition between g and $\overline{g}$ is unessential, since Nöther currents are always covariantly conserved. One may consider the second example analyzed in Sec. VII, where the Kerr solution is studied and its *mass* inside the finite R sphere is obtained with respect to a flat background matched at spatial infinity. In this section we require the matching on $\mathcal{B}$ in order to compare the Nöther charges' expression with the aforementioned standard $(3+1)$ Hamiltonian and quasilocal energy.]

Let us also assume that the vector field ξ is tangent to the hypersurface $\mathcal{B}$ (i.e., $\xi^{\mu}n_{\mu}|_{\mathcal{B}}=0$). First of all let us consider the first contribution $Q_{\Sigma_t}[\xi,g]$ into (5.1), i.e., the integral of the Komar superpotential. It may be rewritten as

$$Q_{\Sigma_t}[\xi,g]=\frac{1}{2\kappa}\int_{B_t}(u_{\beta}n_{\alpha}-u_{\alpha}n_{\beta})g^{\beta\mu}\nabla_{\mu}\xi^{\alpha}\sqrt{\sigma}\,\mathrm{d}^2x. \tag{5.3}$$

Taking formula (A9) repeatedly into account together with the condition of orthogonal boundaries $u^{\mu}n_{\mu}|_{\mathcal{B}}=0$ and the condition $\xi^{\mu}n_{\mu}|_{\mathcal{B}}=0$ we finally obtain

$$Q_{\Sigma_t}[\xi,g]=\frac{1}{\kappa}\int_{B_t}\{\Theta_{\mu\alpha}u^{\mu}\xi^{\alpha}\}\sqrt{\sigma}\,\mathrm{d}^2x+\frac{1}{2\kappa}\int_{B_t}u_{\alpha}\pounds_{\xi}n^{\alpha}\sqrt{\sigma}\,\mathrm{d}^2x. \tag{5.4}$$

A similar expression may be found for the third contribution $Q_{\Sigma_t}[\xi,\overline{g}]$ into formula (5.2), i.e., the Komar contribution of the matched bakground $\overline{g}$:

$$Q_{\Sigma_t}[\xi,\overline{g}]=-\frac{1}{\kappa}\int_{B_t}\{\overline{\Theta}_{\mu\alpha}u^{\mu}\xi^{\alpha}\}\sqrt{\sigma}\,\mathrm{d}^2x-\frac{1}{2\kappa}\int_{B_t}u_{\alpha}\pounds_{\xi}\overline{n}^{\alpha}\sqrt{\sigma}\,\mathrm{d}^2x. \tag{5.5}$$

It now remains to calculate the second contribution $Q_{\Sigma_t}[\xi,g,\overline{g}]$ into formula (5.2). We stress that this is the contribution arising from the boundary term into the action functional (2.1). By standard techniques it can be recasted as

$$Q_{\Sigma_t}[\xi,g,\overline{g}]=-\frac{1}{\kappa}\int_{B_t}u_{\alpha}\xi^{\alpha}(\Theta-\overline{\Theta})\sqrt{\sigma}\,\mathrm{d}^2x. \tag{5.6}$$

[Notice that only the projection $u_{\alpha}\xi^{\alpha}$ of the vector field ξ^{α} along the timelike normal u^{α} gives a contribution to the term $Q_{\Sigma_t}[\xi,g,\overline{g}]$. This is the reason why the boundary term into the action

(2.1) allows one to correct the anomalous factor of the Komar superpotential which, as we said previously, appears in the computation of mass while it does not enter in the computation of angular momentum.]

The *conserved quantity* in the region Σ_t relative to the infinitesimal generator of space–time symmetries ξ is then given by the sum of (5.4), (5.5), and (5.6). Using (A11) and since in this case $K_{\mu\nu}u^\nu=0$ and $\sigma^\mu_\nu u^\nu=0$ it can be recasted as

$$Q^{\mathrm{tot}}_{\Sigma_t}[\xi,\sigma]=-\frac{1}{\kappa}\int_{B_t}\{u_\alpha\xi^\alpha(\mathcal{K}-\overline{\mathcal{K}})+\sigma^\rho_\alpha\xi^\alpha n^\beta(K_{\rho\beta}-\overline{K}_{\rho\beta})\}\sqrt{\sigma}\,\mathrm{d}^2x$$
$$+\frac{1}{2\kappa}\int_{B_t}u_\alpha(\pounds_\xi n^\alpha-\pounds_\xi\overline{n^\alpha})\sqrt{\sigma}\,\mathrm{d}^2x. \tag{5.7}$$

Let us stress that, until now, no assumption has been made on the vector field ξ, apart from the requirement $\xi^\mu n_\mu|_{\mathcal{B}}=0$.

An easy computation shows that *the difference* $u_\alpha(\pounds_\xi n^\alpha-\pounds_\xi\overline{n^\alpha})$ is always zero if the metrics g and $\overline{g}$ are matched on $\mathcal{B}$. Furthermore, the terms $u_\alpha\pounds_\xi n^\alpha$ and $u_\alpha\overline{\pounds_\xi n^\alpha}$ appearing in the last contribution to (5.7) *separately* disappear if we choose ξ to be tangent to the two-surfaces B_t, that is $\xi^\mu u_\mu|_{B_t}=0$, or also if we choose ξ to be the timelike vector field ∂_t, i.e., $\xi^\alpha=Nu^\alpha+N^\alpha$. In both cases the flow of the vector field ξ maps each hypersurface Σ_t into itself or, respectively, into another surface $\Sigma_{t'}$. Since the vector field n^α is tangent to each Σ_t it also turns out that $\pounds_\xi n^\alpha$ is tangent to Σ_t and then $u_\alpha\pounds_\xi n^\alpha=0$ in these cases.

Hence if we specialize formula (5.7) for the vector field $\xi=\partial_t$ we obtain the covariant conserved quantity which we call the *Hamiltonian* of the system. It is given by

$$Q^{\mathrm{tot}}_{\Sigma_t}[\partial_t,\sigma]=\frac{1}{\kappa}\int_{B_t}\{N(\mathcal{K}-\overline{\mathcal{K}})-N^a(K^{bc}-\overline{K}^{bc})n_b\sigma_{ac}\}\sqrt{\sigma}\,\mathrm{d}^2x \tag{5.8}$$

and it coincides exactly with the expression of the $(3+1)$ Hamiltonian (3.11).

Let us notice that this definition of the Hamiltonian can be correctly considered as the definition of a *covariant* ADM formulation (see Refs. 22, 34, and 35). In fact it does not require, *a priori*, a $(3+1)$ decomposition of space–time. We stress that in the covariant ADM approach, the Hamiltonian, or energy, contained in a three-dimensional region Ω and relative to a solution σ, is defined by (2.6) as a Nöther conserved quantity:

$$Q^{\mathrm{tot}}_{\Omega}[\xi,\sigma]=\int_{\partial\Omega}\mathcal{U}[\xi,\sigma]. \tag{5.9}$$

This is a well-posed definition of the Hamiltonian provided only that the nonvanishing vector field ξ be transverse to the hypersurface Ω. Hence, by considering the parameter of the flow of ξ as the ''time'' parameter and transporting Ω along the flow of ξ we obtain a world tube foliated by hypersurfaces diffeomorphic to Ω. In this covariant context, rather than starting from a preferred local foliation into hypersurfaces, the starting point is a nonvanishing vector field the flow of which defines the local time, i.e., the flow of evolution. Then, by specializing the definition (5.9) to the ADM foliation depicted in Fig. 1, under the additional assumptions of orthogonal boundaries and of the matching between the metric and its background, the *covariant* Hamiltonian $Q^{\mathrm{tot}}_{\Sigma_t}[\partial_t,\sigma]$ exactly coincides with the standard Hamiltonian $H(g,\overline{g})$ derived from a $(3+1)$ splitting of the York action functional [see Eq. (3.11)].

Another relevant Nöther conserved quantity is obtained by specializing formula (5.7) to a vector field $\xi^\alpha=N^\alpha$ tangent to the two-surfaces B_t, i.e., $N^\alpha u_\alpha|_{B_t}=0$ and $\sigma^\rho_\alpha N^\alpha=N^\rho$. Because of the vanishing of the first and third terms on the right-hand side of (5.7) we obtain

$$Q^{\mathrm{tot}}_{\Sigma_t}[N^\alpha,\sigma]=-\frac{1}{\kappa}\int_{B_t}N^\alpha n^\beta(K_{\alpha\beta}-\overline{K}_{\alpha\beta})\sqrt{\sigma}\,\mathrm{d}^2x. \tag{5.10}$$

In asymptotically flat space–times when ξ corresponds to a rotation at spatial infinity, the Nöther charge (5.10) may be taken as the definition of *angular momentum*.

The last Nöther charge we consider is the one relative to the unit vector field $\xi=u$ normal to the leaves of the ADM foliation. From (5.7) we obtain

$$Q^{\mathrm{tot}}_{\Sigma_t}[u,\sigma]=\frac{1}{\kappa}\int_{B_t}(\mathcal{K}-\overline{\mathcal{K}})\sqrt{\sigma}\,\mathrm{d}^2x. \tag{5.11}$$

We observe that it agrees with the definition (3.5) of quasilocal energy. In the aforementioned hypotheses, *quasilocal energy may then be considered as a Nöther charge associated with the normal generator of the ADM foliation.*

VI. TIME CONSERVATION

Despite the fact that quantities conserved along the *time* of a fixed ADM foliation are not manifestly covariant in nature they may be interesting to investigate. In our perspective, in fact, they can be obtained from covariantly conserved quantities. To be more precise, we can consider a variational principle, a space–time vector field ξ which is an infinitesimal generator of Lagrangian symmetries and a solution of field equations. Then we can compute covariantly conserved currents $\mathcal{E}[\xi]$ by Nöther theorem. Let us then fix a spacelike $(n-1)$-region Σ and integrate the Nöther current on it to define a conserved quantity $Q_\Sigma[\xi,\sigma]$ [see (2.6)]. Any timelike vector field ζ then allows one to evolve the region Σ along its flow, parameterized by its affine parameter t. Under this viewpoint, the question arises whether there exists a vector field ζ (possibly depending on the region Σ) such that the covariantly conserved quantity generated by ξ is also conserved in the ''time'' induced by ζ. At a first glance, if we have $\partial D=\Sigma_{t_1}-\Sigma_{t_0}+\mathcal{B}$ (see Fig. 1), conservation in time is equivalent to requiring that the integral of the Nöther current $\mathcal{E}[\xi]$ on $\mathcal{B}$ vanishes (for any time interval $[t_0,t_1]$). In fact, we have the covariant conservation law $\mathrm{d}\mathcal{E}[\xi]=0$, so that

$$0=\int_D\mathrm{d}\mathcal{E}[\xi]=\int_{\partial D}\mathcal{E}[\xi]=\int_{\Sigma_{t_1}}\mathcal{E}[\xi]-\int_{\Sigma_{t_0}}\mathcal{E}[\xi]+\int_{\mathcal{B}}\mathcal{E}[\xi]\Rightarrow\int_{\Sigma_{t_1}}\mathcal{E}[\xi]-\int_{\Sigma_{t_0}}\mathcal{E}[\xi]=-\int_{\mathcal{B}}\mathcal{E}[\xi]. \tag{6.1}$$

Thence the conserved quantity $\int_{\Sigma_t}\mathcal{E}[\xi]$ computed on a leaf does not depend on the particular leaf if and only if $\int_{\mathcal{B}}\mathcal{E}[\xi]=0$ (for any time interval $[t_0,t_1]$). Physically speaking, this amount to require that the flow of the current $\mathcal{E}[\xi]$ through $\mathcal{B}$ is vanishing. Clearly, different ADM foliations may evolve Σ in different ways. In general, just a few of them will lead to time-conserved quantities. The vanishing of $\int_{\mathcal{B}}\mathcal{E}[\xi]$ then has to be guaranteed by additional hypotheses, possibly in many different ways. Under stronger hypotheses on ξ (or on ζ, or on the boundary conditions which g and $\overline{g}$ have to satisfy) the set of ADM foliations leading to time-conserved quantities with respect to different times may be possibly enlarged. Different sets of conditions which guarantee time conservation will be discussed in the following and we shall compare them to those found in the current literature; see also Sec. VII for some examples.

Here we shall discuss two different sets of sufficient conditions for time conservation. The quantities (5.8), (5.10), and (5.11) are all covariantly conserved quantities independent of the hypothesis that ξ is or is not a Killing vector field. In fact they have been defined by means of Nöther theorem through a construction which relies only on the covariant nature of the Lagrangian. Hence, on a solution of field equations, the covariant conservation law $d_\mu\mathcal{E}^\mu[\xi,\sigma]=0$ always holds for the Nöther current $\mathcal{E}[\xi,\sigma]$ and for all vector fields ξ. This property, together with the property of existence of superpotentials for any natural theory, has allowed us to define the covariantly conserved Nöther charges $Q^{\mathrm{tot}}_\Omega[\xi,\sigma]$ [see (2.6)]. On the contrary the charges $Q^{\mathrm{tot}}_{\Sigma_t}[\xi,\sigma]$

are *conserved in ''time''* if they do not depend on the chosen hypersurface Σ_t, i.e., if $Q^{\mathrm{tot}}_{\Sigma_t}[\xi,\sigma] = Q^{\mathrm{tot}}_{\Sigma_{t'}}[\xi,\sigma]$. This is a stronger condition that has to be supported by additional requirements. If $\mathcal{B}$ is the three-dimensional region such that $\Sigma_{t'} - \Sigma_t + \mathcal{B}$ is the boundary of a region D, from the conservation law $d_\mu \mathcal{E}^\mu[\xi,\sigma] = 0$ we obtain, as we already claimed, a time-conserved quantity if $\int_{\mathcal{B}} \mathcal{E}^\mu \, \mathrm{d}s_\mu = 0$. A stronger condition amounts to requiring that the integrand be equal to zero on $\mathcal{B}$, i.e., $\mathcal{E}^\mu n_\mu|_{\mathcal{B}} = 0$. In this case $Q^{\mathrm{tot}}[\xi,\sigma]$ is conserved not only with respect to the given foliation in hypersurfaces Σ_t but it is time conserved with respect to the time of *any* foliation of the same region D.

For the action functional (2.1) the Nöther current (2.3) may be rewritten as

$$\mathcal{E}^\alpha[\xi,\sigma] = \frac{1}{2\kappa}\{(\sqrt{g}g^{\mu\nu} - \sqrt{\overline{g}}\overline{g}^{\mu\nu})\pounds_\xi \overline{u}^\alpha_{\mu\nu} - \pounds_\xi(\sqrt{g}g^{\mu\nu})w^\alpha_{\mu\nu} - \xi^\alpha \mathcal{L}\}. \tag{6.2}$$

The corresponding quantity $\mathcal{E}^\mu n_\mu|_{\mathcal{B}}$ will be equal to zero if some condition is verified. We do not explicitly know a set of necessary requirements for the occurrence of this situation; we can only provide two examples of sufficient conditions.
We may require, as a first example, that the following properties hold true:

(A) the vector field ξ is a Killing vector field for the metric, i.e., $\pounds_\xi g_{\mu\nu} = 0$;
(B) the vector field ξ is a symmetry for the background in the sense that $\pounds_\xi \overline{u}^\alpha_{\mu\nu} = 0$;
(C) ξ is tangent to the boundary $\mathcal{B}$, i.e., $\xi^\mu n_\mu|_{\mathcal{B}} = 0$.

These three requirements together ensure that $\mathcal{E}^\mu n_\mu|_{\mathcal{B}} = 0$. These properties are clearly satisfied if we are dealing with the Killing vector fields of an asymptotically flat stationary solution and we choose the flat metric as a background. Nevertheless, we stress that the time-conserved quantities $Q^{\mathrm{tot}}_{\Sigma_t}[\xi,\sigma] = \int_{B_t} \mathcal{U}[\xi,\sigma]$ can be computed on a finite region, i.e., it is not necessary that B_t is identified with spatial infinity. Moreover, we have not explicitly required the matching between the metrics on $\mathcal{B}$ (see the example of the Kerr metric in Sec. VII).

Another set of sufficient conditions may be imposed to fulfill the condition $\mathcal{E}^\mu n_\mu|_{\mathcal{B}} = 0$. They closely resemble the ones of Ref. 3. We may require the matching of the metrics on the boundary $\mathcal{B}$ [so that the first term in (6.2) vanishes] and we again require ξ to be tangent to the boundary $\mathcal{B}$: $\xi^\mu n_\mu|_{\mathcal{B}} = 0$ [in order to make the third term in (6.2) vanishing when contracted with the normal n_α]. We are left with the following term:

$$\int_{\mathcal{B}} \mathcal{E}^\alpha \, \mathrm{d}s_\alpha = -\frac{1}{2\kappa}\int_{\mathcal{B}} \pounds_\xi(\sqrt{g}g^{\mu\nu})w^\alpha_{\mu\nu}\mathbf{ds}_\alpha .$$

Owing to the matching requirement $g_{\mu\nu}|_{\mathcal{B}} = \overline{g}_{\mu\nu}|_{\mathcal{B}}$ the latter expression may be recasted into the equivalent form:

$$\int_{\mathcal{B}} \mathcal{E}^\alpha \, \mathrm{d}s_\alpha = \int_{\mathcal{B}} (\Pi^{ij} - \overline{\Pi}^{ij})\pounds_\xi \gamma_{ij} \, \mathrm{d}^3x.$$

It vanishes if we require ξ to be a Killing vector of the boundary three-metric: $\pounds_\xi \gamma_{ij} = \mathcal{D}_i\xi_j + \mathcal{D}_i\xi_j = 0$. Hence, also in this latter situation, we obtain time-conserved quantities $Q^{\mathrm{tot}}_{\Sigma_t}[\xi,\sigma]$ for the time t of *any foliation* of D in hypersurfaces Σ_t.

VII. EXAMPLES

Here we shall discuss some simple examples to illustrate and clarify some of the topics introduced previously in the paper.

Let us first consider the conserved quantities of the Schwarzschild solution given in its standard form:

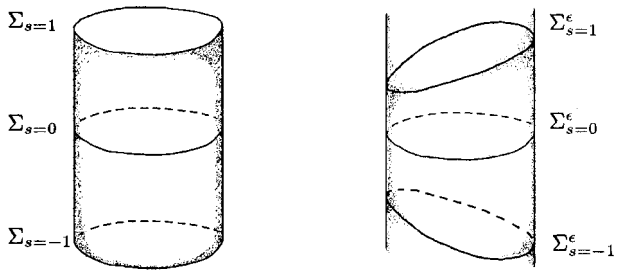

FIG. 2.

$$g = -\left(1 - \frac{2M}{\rho}\right) dt^2 + \frac{1}{\left(1 - \frac{2M}{\rho}\right)} d\rho^2 + \rho^2 (d\theta^2 + \sin^2\theta\, d\phi^2). \tag{7.1}$$

For computational convenience we rewrite it in isotropic coordinates (t, r, θ, ϕ):

$$g = -\frac{(2r-M)^2}{(2r+M)^2} dt^2 + \left(1 + \frac{M}{2r}\right)^4 (dr^2 + r^2(d\theta^2 + \sin^2\theta\, d\phi^2)), \tag{7.2}$$

where, see Ref. 6,

$$2r = -M + \rho + \sqrt{\rho(\rho - 2M)} \Leftrightarrow \rho = \frac{(M+2r)^2}{4r}. \tag{7.3}$$

Let us choose as a background the Minkowski space–time in isotropic coordinates

$$\overline{g} = -\frac{(2R-M)^2}{(2R+M)^2} dt^2 + \left(1 + \frac{M}{2R}\right)^4 (dr^2 + r^2(d\theta^2 + \sin^2\theta\, d\phi^2)). \tag{7.4}$$

The background $\overline{g}$ is in fact a flat metric as one can easily check by direct computation of the Riemann tensor. Furthermore, the two metrics g and $\overline{g}$ are matched on the hypersurface $\mathcal{B}$ defined by the equation $r = R$.

Let us then consider a family of foliations of the region $r \leqslant R$ generated by the infinitesimal generator

$$\zeta = (1 + \epsilon(\sin(\phi) + 1))\partial_t, \tag{7.5}$$

where ϵ is a (small) parameter. The flow parameter is denoted by s so that, if Σ is a spacelike hypersurface, it can be dragged along the flow Φ_s of ζ to obtain the foliation:

$$\Sigma^{\epsilon}_s = \{s \ \text{constant}\}, \quad s = t/(1 + \epsilon(\sin(\phi) + 1)).$$

Since s denotes the affine parameter along the flow of ζ, it can be interpreted as the *time* associated with the ADM foliation. We remark that we are in the hypothesis of orthogonal boundaries as required throughout the paper. Notice also that for $\epsilon = 0$ we recover the ordinary asymptotic time translation $\zeta = \partial_t$ and the ordinary ADM foliation by the hypersurfaces $t = \text{constant}$ (see Fig. 2).

Let us then choose the (three-parameter) vector field

$$\xi = \alpha\partial_t + (\beta + \gamma \sin(\theta)\cos\phi)\partial_\phi \tag{7.6}$$

(where α, β, and γ are three real constants), which is a generator of symmetries for the first-order Lagrangian (2.1). We remark that ξ is a well-defined vector field on $\mathcal{B}$; in particular it extends to $\theta=0$ and $\theta=\pi$. For $\alpha=1$ and $\beta=\gamma=0$, ξ reduces to the ordinary time translation $\xi=\partial_t$ so that we expect the corresponding conserved quantity $Q^{\mathrm{tot}}_{\Sigma^\epsilon_s}[\xi]$ to be interpreted as the *mass* of g *relative* to $\overline{g}$ on the leaf Σ^ϵ_s in the region $r\leqslant R$. We also stress that for $\gamma=0$ the vector field ξ is a Killing vector both for g and $\overline{g}$. On the contrary, for $\gamma\neq 0$, ξ is not Killing both for g and $\overline{g}$. In the case $\gamma\neq 0$, ξ does not have a direct physical interpretation, though it is a symmetry generator for the Lagrangian (2.1) and it algorithmically generates the covariant Nöther conserved quantity $Q^{\mathrm{tot}}_{\Sigma^\epsilon_s}[\xi]$. We shall use it to illustrate how time conservation may be related to covariant conservation along different foliations.

If we calculate the Nöther conserved quantity [according to Eq. (5.1) with $2k=16\pi$, i.e., in geometric units $G=c=1$] we get the following result:

$$
\begin{aligned}
Q_{\Sigma^\epsilon_s}[\xi,g] &= \alpha\frac{M}{2}-\gamma\frac{\pi}{16}R\left(1-\frac{M}{2R}\right)^2 s\epsilon,\\
Q_{\Sigma^\epsilon_s}[\xi,g,\overline{g}] &= \left(\alpha\frac{M}{2}-\gamma\frac{\pi M}{16}s\epsilon\right)\left(1-\frac{M}{R}\right),\\
Q_{\Sigma^\epsilon_s}[\xi,g] &= \gamma\frac{\pi R}{16}\left(1-\frac{M^2}{4R^2}\right)s\epsilon,\\
Q^{\mathrm{tot}}_{\Sigma^\epsilon_s}[\xi] &= \alpha\left(M-\frac{M^2}{2R}\right)+\gamma\left(\frac{\pi M^2}{32R}s\epsilon\right).
\end{aligned}
\tag{7.7}
$$

Thus, when ξ is the Killing vector ∂_t ($\alpha=1$, $\beta=\gamma=0$) the *relative mass*

$$
Q^{\mathrm{tot}}_{\Sigma^\epsilon_s}[\partial_t]=M-\frac{M^2}{2R} \tag{7.8}
$$

is time conserved along any foliation of the family generated by ζ, since it does not depend on the affine parameter s. We also stress that the *conserved quantity* (i.e., letting R tend to infinity) is always $Q^{\mathrm{tot}}_{\infty}[\partial_t]=M$, i.e., it reduces to the expected value for total mass.

If $\gamma\neq 0$ the vector ξ is not Killing. Despite the fact that the conserved quantity is not time conserved in general, it is still time conserved along a particular foliation [namely, the one corresponding to $\epsilon=0$, i.e., $\zeta=\partial_t$; see Fig. 2(a)]. We remark that in this case the flow of the Nöther current $\mathcal{E}[\xi]=\mathcal{E}^\mu\mathbf{ds}_\mu$ through $\partial\Sigma_s$ vanishes even if $\mathcal{E}^\mu n_\mu|_{\mathcal{B}}\neq 0$.

On the contrary, when $\epsilon\neq 0$ [see Fig. 2(b)] the Nöther charge $Q^{\mathrm{tot}}_{\Sigma^\epsilon_s}$ explicitly depends on the time s, i.e., on the particular leaf on which it is computed.

We finally remark that in any case the quantity $Q^{\mathrm{tot}}_{\Sigma^\epsilon_s}[\xi]$ given by Eq. (7.7) is covariantly conserved (as any Nöther conserved quantity is) and it consequently obeys a continuity equation.

To wrap up this first example let us now compute the quasilocal energy (5.11). We consider the case depicted in Fig. 2(a), i.e., the foliation induced by $\zeta=\partial_t$. We choose, as infinitesimal symmetry ξ, the unit timelike normal u:

$$
\xi=u=\frac{2r+M}{2r-M}\,\partial_t\,. \tag{7.9}
$$

If we calculate the Nöther conserved quantity (5.1) we now obtain the following result:

$$
\begin{aligned}
Q_{\Sigma_t}[u,g] &= \frac{1}{4}\frac{M(2R+M)}{2R-M},\\
Q_{\Sigma_t}[u,g,\bar{g}] &= \frac{1}{2}\frac{(2R^2-MR-M^2)M}{R(2R-M)},\\
Q_{\Sigma_t}[u,\bar{g}] &= \frac{1}{4}\frac{M(4R^2-M^2)}{(2R-M)^2},\\
Q^{\mathrm{tot}}_{\Sigma_t}[u] &= M+\frac{M^2}{2R}.
\end{aligned}
\tag{7.10}
$$

In spherical coordinates (t,ρ,θ,ϕ) the fourth expression of (7.10) may be rewritten as

$$
Q^{\mathrm{tot}}_{\Sigma_t}[u]=\rho_0\left[1-\sqrt{1-\frac{2M}{\rho_0}}\right], \tag{7.11}
$$

where $2R=-M+\rho_0+\sqrt{\rho_0(\rho_0-2M)}$; see (7.3). As expected, expression (7.11) perfectly agrees with the value of the energy computed in Ref. 3, formula (6.14).

Let us now consider another example of a conserved quantity in a finite region D. It is a completely different example since it does not require the matching of the solutions on the boundary $\mathcal{B}$ of the finite region under consideration. Neither is the condition of orthogonal boundaries required here.

Let us consider the Kerr space–time in ingoing Kerr–Schild coordinates (t,r,θ,ϕ), given by

$$
g=\bar{g}+2Mr\rho^{-2}[dt+dr-a\sin^2\theta\, d\phi]^2, \tag{7.12}
$$

where $\rho^2=r^2+a^2\cos^2\theta$, $M^2\geqslant a^2$. Let us choose the flat background $\bar{g}$ as

$$
\bar{g}=-dt^2+[dr-a\sin^2\theta\, d\phi]^2+\rho^2[d\theta^2+\sin^2\theta\, d\phi^2]. \tag{7.13}
$$

The metrics g and $\bar{g}$ are matched at infinity. Let us consider the regions D *inside* the hypersurface $\mathcal{B}$ defined by $r=R$ and the ADM foliation $\Sigma_t=\{t=\text{constant}\}$ generated by the vector field ∂_t. We stress that g and $\bar{g}$ do not match on $\mathcal{B}$ unless R is let to tend to infinity.

Let us finally choose as the symmetry generator the (two-parameter) vector

$$
\xi=\alpha\partial_t+\beta\partial_\phi, \tag{7.14}
$$

which is a Killing vector for both g and $\bar{g}$ (α and β are two real constants).

The Nöther conserved quantities one obtains are

$$
\begin{aligned}
Q_\Sigma[\xi,g] &= \left(\alpha\frac{M}{2}-\beta Ma\right),\\
Q_\Sigma[\xi,g,\bar{g}] &= \alpha\frac{M}{2},\\
Q_\Sigma[\xi,\bar{g}] &= 0,\\
Q^{\mathrm{tot}}_\Sigma[\xi] &= \alpha M-\beta Ma,
\end{aligned}
\tag{7.15}
$$

which reproduce the expected values of the *relative mass* and of the *angular momentum* in the region $t=$ constant and $r\leqslant R$. Notice that the result is independent of R meaning that all the energy and angular momentum is ''buried in the singularity.'' We remark that setting anywhere $a=0$ the

Schwarzschild solution is recovered. The relative mass M we obtain in this case [see Eq. (7.15) with $\alpha=1$, $\beta=0$] does not agree with the value found previously [see Eq. (7.8)] because of the two different matches selected.

We remark that the quantities (7.15) are also time conserved (even if the metrics are not matched at $\mathcal{B}$). In fact the flow integral $\int_{\mathcal{B}}\mathcal{E}$ vanishes since ξ is tangent to $\mathcal{B}$ and it is a Killing vector of both g and $\overline{g}$ (see Sec. VI). Notice also that $\mathcal{E}^{\alpha}n_{\alpha}=0$, i.e., the Nöther current has no flow through any part of $\mathcal{B}$. Consequently, the associated conserved quantity is time conserved along *any* ADM foliation of the region D.

[The calculations in this section have been carried out by using tensor package of MAPLEV, see Ref. 36. They are the very direct application of formula (5.1), just computed on the configuration $(g,\overline{g})$.]

VIII. CONCLUSION AND PERSPECTIVES

We proved that once suitable matching conditions are required (i.e., the four-metrics g and $\overline{g}$ are required to agree on the boundary of the region under consideration) the two action functionals (2.1) and (3.2) agree. Consequently the action functional (3.2) may be considered as the ADM counterpart of the covariant action functional (2.1).

The second important result achieved here is the use of the Nöther theorem to define conserved quantities in a finite region and the characterization of the quasilocal energy as the Nöther charge associated with the (timelike) unit vector normal to the leaves of the ADM foliation [see (5.11)].

These seem to be new results which should enable us to extend the analysis further ahead to the prescription for the entropy in general relativity. In fact, the quasilocal energy as well as the action functional (3.2) also appeared as the starting point of a statistically oriented approach to black hole entropy (see Refs. 17, 27, 19, 33, 20, 21, and references therein). A different approach to black hole entropy based on the Nöther approach (see Refs. 16, 23, 29, 37 and references therein) may be found in the literature. In view of the present comparison between the covariant first-order approach (which the Nöther approach is based on) and the York's action functional (which quasilocal energy is based on) as well as between the Nöther charges and the quasilocal energy themselves, we believe that the two different approaches to entropy can be now successfully compared (see also Refs. 38 and 39).

Another interesting perspective is to extend the present comparison to the more general situation of nonorthogonal boundaries which sometimes appeared in the literature (see Refs. 8–10). It would be of some interest to know whether nonorthogonality of the boundaries in the ADM decomposition of the covariant action functional (2.1) exactly produces the additional boundary terms which are derived for the (modified) York's action (see Ref. 9), as we guess to be true.

APPENDIX: NOTATION

In order to make this paper self-contained here we briefly summarize some of the formulas and expressions which are used throughout the paper. We follow the convention and notation adopted in Ref. 3 and we also refer the reader to Fig. 1 for notation.

We assume the hypersurfaces Σ_t to be spacelike and we assume the hypersurface $\mathcal{B}$ to be timelike. The metric $h_{\mu\nu}$ induced on the hypersurfaces Σ_t may be written as

$$h_{\mu\nu}=g_{\mu\nu}+u_{\mu}u_{\nu}, \tag{A1}$$

while for the metric $\gamma_{\mu\nu}$ on the hypersurface $\mathcal{B}$ we have

$$\gamma_{\mu\nu}=g_{\mu\nu}-n_\mu n_\nu \tag{A2}$$

(in the sequel Greek indices are always raised and lowered with the four-dimensional metric). The two vectors $\vec{u}$ and $\vec{n}$ denote the future directed unit normal to Σ_t and the outward pointing unit normal to the hypersurfaces $\mathcal{B}$, respectively. They satisfy the normalization relations $u^\mu u_\mu=-1$ and $n^\mu n_\mu=1$, respectively. Any space–time tensor may be projected onto the hypersurfaces Σ_t by means of the projection tensor:

$$h^\mu_\nu=\delta^\mu_\nu+u^\mu u_\nu. \tag{A3}$$

Any tensorial object may be also projected onto $\mathcal{B}$ with the projection tensor

$$\gamma^\mu_\nu=\delta^\mu_\nu-n^\mu n_\nu. \tag{A4}$$

The two-metric $\sigma_{\mu\nu}$ on the boundaries B_t is given by

$$\sigma_{\mu\nu}=\gamma_{\mu\nu}+u_\mu u_\nu=h_{\mu\nu}-n_\mu n_\nu \tag{A5}$$

and the respective projection tensor is $\sigma^\mu_\nu=g^{\mu\rho}\sigma_{\rho\nu}$.

The extrinsic curvatures $K_{\mu\nu}$ of Σ_t in M, $\Theta_{\mu\nu}$ of $\mathcal{B}$ in M and $\mathcal{K}_{\mu\nu}$ of B_t embedded in Σ_t are defined, respectively, as follows:

$$\begin{aligned} K_{\mu\nu}&=-h^\alpha_\mu\nabla_\alpha u_\nu,\\ \Theta_{\mu\nu}&=-\gamma^\alpha_\mu\nabla_\alpha n_\nu,\\ \mathcal{K}_{\mu\nu}&=-\sigma^\alpha_\mu D_\alpha n_\nu, \end{aligned} \tag{A6}$$

where D_α denotes the covariant derivative on Σ_t compatible with the metric h.

The extrinsic curvature $K_{\mu\nu}$ is a *symmetric tensor on* Σ_t, i.e., it satisfies the conditions $K_{\mu\nu}u^\mu=0$, $K_{\mu\nu}h^\mu_\rho=K_{\rho\nu}$. Instead the extrinsic curvature $\Theta_{\mu\nu}$ is a symmetric tensor on $\mathcal{B}$: $\Theta_{\mu\nu}n^\mu=0$, $\Theta_{\mu\nu}\gamma^\mu_\rho=\Theta_{\rho\nu}$, while the extrinsic curvature $\mathcal{K}_{\mu\nu}$ is a symmetric tensor on B_t, i.e., $\mathcal{K}_{\mu\nu}u^\mu=\mathcal{K}_{\mu\nu}n^\mu=0$.

We also denote by

$$\begin{aligned} a^\nu&=u^\mu\nabla_\mu u^\nu,\\ b^\nu&=n^\mu\nabla_\mu n^\nu \end{aligned} \tag{A7}$$

the (covariant) *accelerations* of the two normals u^μ and n^μ, respectively. They satisfy the orthogonality properties: $u^\mu a_\mu=0$ and $n^\mu b_\mu=0$.

By making use of the property (A4), we obtain

$$\nabla_\nu n^\mu=\delta^\alpha_\nu\nabla_\alpha n^\mu=\gamma^\alpha_\nu\nabla_\alpha n^\mu+n^\alpha n_\nu\nabla_\alpha n^\mu. \tag{A8}$$

Taking into account definitions (A6) and (A7) we have

$$\nabla_\nu n^\mu=-\Theta^\mu_\nu+n_\nu b^\mu. \tag{A9}$$

Performing calculations in the same manner for the vector u^μ, it is easy to check the analogous relation:

$$\nabla_\nu u^\mu=-K^\mu_\nu-u_\nu a^\mu. \tag{A10}$$

Moreover, projecting the indices of the extrinsic curvature $\Theta_{\mu\nu}$ normally and tangentially to the hypersurfaces Σ_t we obtain the useful formula (see Ref. 3 for detailed computations):

$$\Theta_{\mu\nu}=\mathcal{K}_{\mu\nu}+u_\mu u_\nu n_\alpha a^\alpha+2\sigma^\alpha_{(\mu}u_{\nu)}n^\beta K_{\alpha\beta}. \tag{A11}$$

[We recall that this relation is true only under the assumption of orthogonal boundaries, i.e., $u^\mu n_\mu|_{\mathcal{B}}=0$.] Contracting the latter expression with $g^{\mu\nu}$ we also easily obtain

$$\Theta=\mathcal{K}-n_\alpha a^\alpha. \tag{A12}$$

Let us now consider the ADM decomposition of the metric:

$$\begin{aligned} g=g_{\mu\nu}\,\mathrm{d}x^\mu\otimes\mathrm{d}x^\nu&=(h_{\mu\nu}-u_\mu u_\nu)\,\mathrm{d}x^\mu\otimes\mathrm{d}x^\nu\\ &=-N^2\,\mathrm{d}t^2+h_{ab}(\mathrm{d}x^a+N^a\,\mathrm{d}t)\otimes(\mathrm{d}x^b+N^b\,\mathrm{d}t). \end{aligned} \tag{A13}$$

The coordinate system $(x^\mu)=(t,x^a)=(t,r,x^A)$ is adapted both to $\mathcal{B}$ and to the ADM foliation on D. The surfaces Σ_t are surfaces of constant t while $\mathcal{B}$ is the hypersurface of constant r. In other words, indices $a,b,c,\ldots$ run from 1 to 3 and denote indices on the spacelike hypersurfaces Σ_t, while indices $A,B,C,\ldots$ run from 2 to 3 and they instead denote indices on the boundary B_t of Σ_t. Hence, tensors on Σ_t are labeled by early Roman letters $a,b,\ldots$. When they are considered as tensors on space–time M the same tensors are instead denoted by Greek letters. For example, the extrinsic curvature K in (A6) can be denoted as $K_{\mu\nu}$ or K_{ab}, according to notational convenience.

The unit normal is given by $(u_\mu)=(-N,0,0,0)$ while the timelike coordinate vector field $\vec{\partial}_0=\partial/\partial t$ reads as $\vec{\partial}_0=N\vec{u}+\vec{N}$, N being the lapse function and $\vec{N}=(N^\mu)=(0,N^a)$ the spatial shift vector: $\vec{N}\cdot\vec{u}=N^\mu u_\mu=0$ (we remind the reader that if we also assume the vector field $\vec{\partial}_0$ be tangent to the three-dimensional hypersurface $\mathcal{B}$, the orthogonal boundary conditions reads as $\vec{N}\cdot\vec{n}|_{\mathcal{B}}=N^\mu n_\mu|_{\mathcal{B}}=0$. Nevertheless this latter hypothesis will be not relevant for the computations in the rest of this Appendix). The extrinsic curvature $K_{\mu\nu}$ and the acceleration a^μ defined in (A6) and (A7), respectively, read as

$$\begin{aligned} K_{ab}&=-N\Gamma^0_{ab}=\frac{1}{2N}[-\partial_0 h_{ab}+D_aN_b+D_bN_a],\\ (a^\mu)&=(0,a^b)=\left(0,\frac{\partial^b N}{N}\right). \end{aligned} \tag{A14}$$

(Roman indices are here raised and lowered with the three-metric h_{ab}.)

The Levi-Civita connection coefficients are given by

$$\begin{aligned} \Gamma^0_{0a}&=\frac{1}{N}(\partial_a N-N^bK_{ba}),\\ \Gamma^0_{ab}&=-\frac{K_{ab}}{N},\\ \Gamma^0_{00}&=\frac{\partial_0 N}{N}+\frac{N^b}{N}\partial_b N-\frac{N^aN^b}{N}K_{ab},\\ \Gamma^a_{b0}&=-NK^a_b+\frac{N^aN^c}{N}K_{cb}+D_bN^a-\frac{N^a}{N}\partial_b N,\\ \Gamma^a_{bc}&={}^3\Gamma^a_{bc}+\frac{N^a}{N}K_{bc} \end{aligned} \tag{A15}$$

(where ${}^3\Gamma^a_{bc}$ denotes the Levi-Civita connection of the three-metric h_{ab}). A similar splitting may be performed with the background metric $\overline{g}$; we obviously obtain the same relations by replacing the objects involved with the corresponding barred ones. By means of formula (A15) one may easily compute the quantities $u^\mu_{\alpha\beta}=\Gamma^\mu_{\alpha\beta}-\delta^\mu_{(\alpha}\Gamma^\epsilon_{\beta)\epsilon}$. For example, one can verify the following:

$$g^{\mu\nu}u^0_{\mu\nu}=-\frac{2}{N}K^a_a+\frac{1}{N^2}\partial_a N^a \tag{A16}$$

and

$$g^{\mu\nu}\overline{u}^0_{\mu\nu}=\overline{K}_{ab}\left[\frac{1}{N^2\overline{N}}(\overline{N}^a-N^a)(\overline{N}^b-N^b)-\frac{1}{N}\left(\frac{\overline{N}}{N}\overline{h}^{ab}+\frac{N}{\overline{N}}h^{ab}\right)\right]$$
$$-\frac{1}{\overline{N}N^2}(\overline{N}^a-N^a)\partial_a\overline{N}+\frac{1}{N^2}\partial_a\overline{N}^a+\frac{\overline{N}^b}{N^2}{}^3\overline{\Gamma}^a_{ab}-\frac{N^b}{N^2}{}^3\overline{\Gamma}^a_{ab}, \tag{A17}$$

which together give

$$g^{\mu\nu}w^\alpha_{\mu\nu}u_\alpha=g^{\mu\nu}(u^\alpha_{\mu\nu}-\overline{u}^\alpha_{\mu\nu})u_\alpha=-Ng^{\mu\nu}(u^0_{\mu\nu}-\overline{u}^0_{\mu\nu}). \tag{A18}$$

The latter term is involved in the contribution on the lids of the boundary term in the action functional (2.1). To evaluate instead the action functional contribution on the hypersurface $\mathcal{B}$ we have to make use of the adapted splitting of the metric:

$$g=g_{\mu\nu}\,\mathrm{d}x^\mu\otimes\mathrm{d}x^\nu=(\gamma_{\mu\nu}+n_\mu n_\nu)\mathrm{d}x^\mu\otimes\mathrm{d}x^\nu$$
$$=V^2\,\mathrm{d}r^2+\gamma_{ij}(\mathrm{d}x^i+V^i\,\mathrm{d}r)\otimes(\mathrm{d}x^j+V^j\,\mathrm{d}r), \tag{A19}$$

where $(x^i)=(t,x^A)$. Middle Roman letters $i,j,k,\ldots$ denote indices on the timelike hypersurface $\mathcal{B}$ while x^A $(A=2,3)$ again denote the coordinates over the two-dimensional surfaces B_t. The function V is the *radial lapse* while V^i is the *radial shift*. Hence the unit, outward pointing, radial normal $\vec{n}$ reads as $\vec{n}=(1/V)[\vec{\partial}_r-V^i\vec{\partial}_i]$. The extrinsic curvature Θ_{ij} of the ''cylinder'' $\mathcal{B}=\{r\ \text{constant}\}$ is given by

$$\Theta_{ij}=V\Gamma^r_{ij}=\frac{1}{2V}[-\partial_r\gamma_{ij}+\mathcal{D}_iV_j+\mathcal{D}_jV_i], \tag{A20}$$

where $\mathcal{D}_i$ denotes the covariant derivative on $\mathcal{B}$ induced by the Levi-Civita connection ${}^3\Gamma^i_{jk}$ of the three-metric γ_{ij}. The coefficients of the four-dimensional Levi-Civita connection can now be decomposed as

$$\Gamma^r_{ri}=\frac{1}{V}(\partial_iV+V^j\Theta_{ji}),$$

$$\Gamma^r_{ij}=\frac{\Theta_{ij}}{V},$$

$$\Gamma^r_{rr}=\frac{1}{V}\partial_rV+\frac{V^i}{V}\partial_iV+\frac{V^iV^j}{V}\Theta_{ij}, \tag{A21}$$

$$\Gamma^i_{jr}=-V\Theta^i_j-\frac{V^iV^k}{V}\Theta_{kj}+\mathcal{D}_jV^i-\frac{V^i}{V}\partial_jV,$$

$$\Gamma^i_{jk} = {}^3\Gamma^i_{jk} - \frac{V^i}{V}\Theta_{jk}.$$

The latter expressions are not simply obtained from (A15) by exchanging tensors on Σ_t with the corresponding tensors on $\mathcal{B}$. Because the metrics h_{ab} and γ_{ij} have different signatures, a change of sign may appear in some terms of (A21) if compared with the decomposition (A15).

By means of (A21), the following expressions are then easily computed:

$$\begin{aligned} g^{\mu\nu}u^r_{\mu\nu} &= \frac{2}{V}\Theta^i_i - \frac{1}{V^2}\partial_i V^i, \\ g^{\mu\nu}\overline{u}^r_{\mu\nu} &= \overline{\Theta}_{ij}\left[\frac{1}{V^2\overline{V}}(\overline{V^i}-V^i)(\overline{V^j}-V^j) + \frac{1}{V}\left(\frac{\overline{V}}{V}\overline{\gamma}^{ij} + \frac{V}{\overline{V}}\gamma^{ij}\right)\right] \\ &\quad + \frac{1}{\overline{V}V^2}(\overline{V^i}-V^i)\partial_i\overline{V} - \frac{1}{V^2}\partial_i\overline{V^i} - \frac{\overline{V^j}}{V^2}{}^3\overline{\Gamma}^i_{ij} + \frac{V^j}{V^2}{}^3\overline{\Gamma}^i_{ij}. \end{aligned} \tag{A22}$$

Expressions (A22) gives

$$g^{\mu\nu}w^\alpha_{\mu\nu}n_\alpha = g^{\mu\nu}(u^\alpha_{\mu\nu} - \overline{u}^\alpha_{\mu\nu})n_\alpha = Vg^{\mu\nu}(u^r_{\mu\nu} - \overline{u}^r_{\mu\nu}), \tag{A23}$$

which is the contribution on $\mathcal{B}$ of the boundary term in the action functional (2.1).

We stress that in (A18) and (A23) computations are performed without any hypothesis of orthogonal boundaries and without requiring any matching conditions between the metric g and its background $\overline{g}$.

Far field behavior of noncompact static spherically symmetric solutions of Einstein SU(2) Yang Mills equations

Alexander N. Linden[a)]

(Received 22 December 1998; accepted for publication 2 June 2000)

There exist static spherically symmetric solutions of the Einstein equations with cosmological constant Λ coupled to the SU(2) Yang Mills equations that are smooth at the origin $r=0$ and with a horizon which can be transformed away with a change of coordinates in which the radius increases across the singularity. We establish the global behavior of these solutions. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1287918]

I. INTRODUCTION

Reference 1 analyzes spherically symmetric static solutions of the Einstein SU(2) Yang Mills equations with small positive cosmological constant that are smooth at the origin of spherical symmetry. In particular, it is proven that the presence of a positive cosmological constant Λ causes each such solution to give rise to a horizon at some $r_c \leqslant \sqrt{3/\Lambda}$. For small Λ a class of solutions was found in which this singularity is only due to choice of Schwarzschild coordinates and can be transformed away with a Kruskal-type change of coordinates in such a way that r increases in the extended solution. Furthermore, the Yang Mills curvature is well behaved under the change of coordinates. In this paper we prove that such solutions are defined globally in Schwarzschild coordinates and that the solutions (except for the one coordinate singularity) are everywhere smooth. We also determine their asymptotic behavior.

With a spherical symmetric metric

$$ds^2 = C^2 A\, dt^2 - \frac{1}{A} dr^2 - r^2\, d\Omega^2 \tag{1-1}$$

($d\Omega^2 = d\phi^2 + \sin^2\phi\, d\theta^2$, the standard metric on the unit 2-sphere) and spherically symmetric connection on an SU(2) bundle,

$$\omega = a(r,t)\tau_3\, dt + b(r,t)\tau_3\, dr + w(r,t)\tau_2\, d\phi + (\cos\phi\tau_3 - w(r,t)\sin\phi\tau_1)\, d\theta, \tag{1-2}$$

the Einstein–Yang Mills equations take the form of three ordinary differential equations for the coefficients A, C, and w,

$$rA' + 2Aw'^2 = 1 - A - \frac{(1-w^2)^2}{r^2} - \Lambda r^2, \tag{1-3}$$

$$r^2 A w'' + r\left(1 - A - \frac{(1-w^2)^2}{r^2} - \Lambda r^2\right) w' + w(1-w^2) = 0, \tag{1-4}$$

and

$$rC' = 2w'^2 C. \tag{1-5}$$

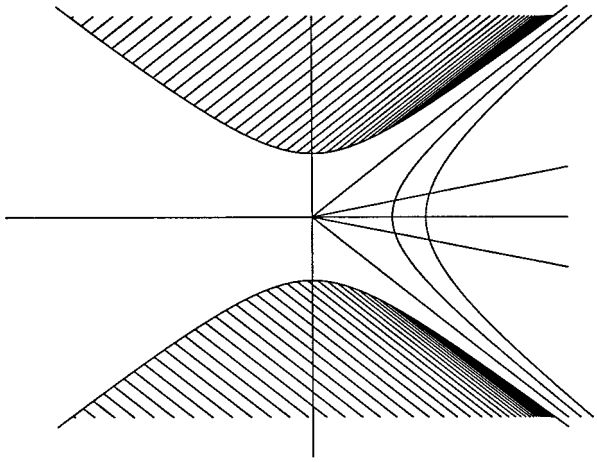

FIG. 1. Space–time geometry near $r=r_h$. The space–time manifold M is the unshaded region. The hyperbolas are curves of constant r and the rays through the origin are curves of constant t. The rays at angles $\pm 45°$ represent $t=\pm\infty$, respectively. The hyperbola for $r=r_h$ degenerates to the point at the origin.

The τ_i in Eq. (1-2) are the following matrices which form a basis of SU(2):

$$\tau_1=i/2\begin{bmatrix}0 & -1\\ -1 & 0\end{bmatrix},\quad \tau_2=i/2\begin{bmatrix}0 & i\\ -i & 0\end{bmatrix},\quad \tau_3=i/2\begin{bmatrix}-1 & 0\\ 0 & 1\end{bmatrix}.$$

By appropriate change of gauge, one of a and b can be made to vanish. We assume that in this gauge, the other vanishes too.

There are known explicit solutions to Eqs. (1-3)–(1-5). Among these is the Schwarzchild–deSitter metric with constant Yang Mills connection

$$ds^2=\left(1-\frac{\Lambda r^2}{3}\right)dt^2-\left(1-\frac{\Lambda r^2}{3}\right)^{-1}dr^2-r^2\,d\Omega^2,\quad w\equiv 1. \tag{1-6}$$

This solution is defined for all r and is smooth except at the horizon which occurs on the sphere $r=r_h=\sqrt{3/\Lambda}$, and serves as a prototype of solutions which have the following characteristic:

$$\lim_{r\nearrow r_h} w^2(r)<\infty \quad\text{and}\quad \lim_{r\nearrow r_h} A'(r)<0. \tag{1-7}$$

We call solutions that satisfy Eq. (1-7) *noncompact*. For such solutions, a change in coordinates (t,r) to new coordinates (u,v) can be found that transforms the metric (1-1) to

$$ds^2=g(u,v)(du^2-dv^2)-r^2(u,v)\,d\Omega^2, \tag{1-8}$$

such that $g\neq 0$ in a neighborhood of the singularity at r_h.[2,3] Constant r and t curves are shown in Fig. 1.

II. GLOBAL BEHAVIOR

We now prove that any solution of Eqs. (1-3)–(1-5) that satisfies Eq. (1-7) behaves qualitatively like the solution (1-6); namely, the solution is defined and smooth for all $r\neq r_h$, the metric approaches the metric (1-6) as $r\nearrow\infty$, and the Yang Mills connection approaches a finite w_∞ asymptotically as $r\nearrow\infty$.

Because the singularity at r_h of such a solution is only a coordinate singularity and because of condition (1-7), the solution $(A(r),w(r),C(r))$ can be extended to some $\rho>r_h$. We define ρ to be the largest value for which the solution is valid and such that $A(r)<0$ for all $r\in(r_h,\rho)$.

We now define the function

$$h(r)=(1-w^2)^2-2r^2Aw'^2. \tag{2-1}$$

The global smoothness and asymptotic behavior of w, A and C will follow from the following:

Lemma 2.1: $\lim_{r\nearrow\rho}h(r)$ *exists and is finite.*

Proof: A simple calculation yields

$$h'(r)=2rw'^2(\Phi+2Aw'^2-2A), \tag{2-2}$$

where

$$\Phi(r)=1-A-\frac{(1-w^2)^2}{r^2}-\Lambda r^2. \tag{2-3}$$

To simplify notation, we define

$$k(r)=\frac{\Phi+2Aw'^2-2A}{r}, \tag{2-4}$$

and rewrite Eq. (2-2) as

$$h'=2r^2w'^2k. \tag{2-5}$$

Another routine calculation yields

$$r^2k'+2r(w'^2+1)k+2p=0, \tag{2-6}$$

where

$$p=1-\frac{2(1-w^2)^2}{r^2}-2Aw'^2. \tag{2-7}$$

Clearly, since $r_h>1/\sqrt{\Lambda}$ and $A(r_h)=0$,

$$k(r_h)=\frac{\Phi(r_h)}{r_h}<0. \tag{2-8}$$

We claim, furthermore, that $k<0$ for all $r\in(r_h,\rho)$. For otherwise, let $\tilde{r}$ be the smallest $r\in(r_h,\rho)$ that satisfies

$$k(\tilde{r})=0. \tag{2-9}$$

Equations (2-5) and (2-1) imply

$$h(r)<h(r_h)<1 \text{ for all } r\in[r_h,\tilde{r}]; \tag{2-10}$$

in particular, $(1-w^2(\tilde{r}))^2<1$ and since $\tilde{r}>\sqrt{2}$,

$$\left[\frac{2(1-w^2)^2}{r^2}\right]_{r=\tilde{r}}<1. \tag{2-11}$$

Therefore,

$$p(\tilde{r})>0. \tag{2-12}$$

Now, on the one hand, from Eqs. (2-6), (2-9), and (2-12) it follows that

$$k'(\tilde{r})<0. \tag{2-13}$$

On the other hand, because of Eq. (2-8) and the definition of $\tilde{r}$, we must have

$$k'(\tilde{r})\geqslant 0. \tag{2-14}$$

Since both Eqs. (2-13) and (2-14) cannot hold, there can be no $\tilde{r}$ that satisfies Eq. (2-9). This establishes the claim. Since $h>0$ for all $r\in(r_h,\rho)$, the Lemma follows. ■

We shall prove that $\rho=\infty$. Assuming this, we have the following:

Corollary 2.1: $A\sim-\Lambda r^2/3$.

Proof: Lemma 2.1 implies that $\lim_{r\nearrow\infty}[(1-w^2)^2/r+2rAw'^2](r)=0$. Equation (1-3) then gives, for any $\epsilon>0$, an $\bar{r}$ such that

$$|1-\Lambda r^2-(rA)'|<\frac{\epsilon}{r} \tag{2-15}$$

whenever $r>\bar{r}$. Integrating Eq. (2-15) from $\bar{r}$ to any $r>\bar{r}$ implies

$$\left|1-\frac{\Lambda r^2}{3}+\frac{c}{r}-A\right|<\frac{\epsilon\ln r}{r} \tag{2-16}$$

(c is a constant of integration). The result follows upon taking the limit as $r\nearrow\infty$. ■

Corollary 2.2: $\lim_{r\nearrow r_h}w'(r)=0$ *and* $\lim_{r\nearrow r_h}w(r)$ *exists and is finite.*

Corollary 2.3: $\lim_{r\nearrow\infty}C(r)$ *exists and is finite.*

Proof: Choosing $C(0)=1$ and integrating Eq. (1-5) gives

$$C(r)=e^{\int_0^r 2w'^2(s)/s\,ds}. \tag{2-17}$$

From Eq. (2-17) it is clear that $\lim_{r\nearrow\infty}C(r)$ exists although, *a priori*, it might be infinite. Lemma 2.1 and Corollary 2.1 imply $w'^2\sim r^{-4}$. Consequently,

$$\int_0^\infty\frac{2w'^2}{r}<\infty.$$

■

Substituting corollaries (2.1) and (2.2) into Eq. (1-1) and scaling t by a factor of $[\lim_{r\nearrow\infty}C(r)]^{-1}$ yields a metric that is asymptotic to Eq. (1-6). It is also clear that the Yang Mills field vanishes as $r\nearrow\infty$.

It remains to prove the following:

Theorem I: $\rho=\infty$.

Proof: From Lemma 2.1 it follows that $\overline{\lim}_{r\nearrow\rho}w^2(r)<\infty$. Substituting this into Eq. (1-3) gives $\lim_{r\nearrow\rho}A'(r)>-\infty$. Thus, $\lim_{r\nearrow\rho}A(r)$ exists. Standard results now imply $\rho<\infty$ only if one of the following holds:

(1) $A(\rho)=0$,
(2) $\underline{A(\rho)}<0$ and $\overline{\lim}_{r\nearrow\rho}w'^2(r)=\infty$, or
(3) $\overline{\lim}_{r\nearrow\rho}w'^2(r)<\infty$ and $\underline{\lim}_{r\nearrow\rho}A'^2(r)=\infty$.

We now eliminate all three possibilities.

Case 1. We first claim that

$$\lim_{r\nearrow\rho}Aw'^2(r)\ \text{ exists and is finite.} \tag{2-18}$$

Clearly, $Aw'^2 \leqslant 0$ in the interval $[r_h, \rho]$; i.e., Aw'^2 is bounded from above. It suffices to prove that near ρ, $(Aw'^2)'$ is bounded also from below.

Now, because $\lim_{r \nearrow \rho} A(r) = 0$ and $r_h > 1/\sqrt{\Lambda}$, there exist $\epsilon > 0$ and $\delta > 0$ such that $\Phi < -\epsilon$, and consequently,

$$\Phi + 2Aw'^2 < -\epsilon, \quad \text{whenever} \quad r \in (\rho - \delta, \rho). \tag{2-19}$$

Also, Lemma 2.1 implies the existence of $M > 0$ such that $w < M$. For arbitrary constant β, we obtain easily from Eqs. (1-3) and (1-4) the following equation:

$$r^2(Aw'^\beta)' + rw'^\beta[(\beta - 1)\Phi + 2Aw'^2] + \beta w w'^{\beta - 1}(1 - w^2) = 0. \tag{2-20}$$

With $\beta = 2$, this becomes Eq. (2-21):

$$r^2(Aw'^2)' + rw'^2[\Phi + 2Aw'^2] + 2ww'(1 - w^2) = 0. \tag{2-21}$$

From Eq. (2-21) and inequality (2-19) it follows that

$$(Aw'^2)' \geqslant \frac{3M(1 - M^2)}{\rho^2} \tag{2-22}$$

whenever $w'^2 \leqslant 1$ and $r \in (\rho - \delta, \rho)$. Also, whenever $w'^2 > 1$ and $r \in (\rho - \delta, \rho)$,

$$(Aw'^2)' > \frac{w'}{r^2}[r\epsilon w' - 2M(1 - M^2)]. \tag{2-23}$$

It is clear from inequalities (2-22) and (2-23) that $(Aw'^2)'$ is bounded from below. This establishes (2-18).

To eliminate this case, we note that on the one hand, $\lim_{r \nearrow \rho} Aw'^2(r) < 0$. Indeed, if $\lim_{r \nearrow \rho} Aw'^2(r) = 0$, then Eq. (1-3) would give

$$\overline{\lim}_{r \nearrow \rho}(rA)' = \overline{\lim}_{r \nearrow \rho} \Phi(r) \leqslant \lim_{r \nearrow \rho}(1 - \Lambda r^2) < 0.$$

However, because $rA < 0$ throughout the interval (r_h, ρ) and $A(\rho) = 0$, we must have $\overline{\lim}_{r \nearrow \rho}(rA)'(r) \geqslant 0$.

On the other hand, the assumption $\lim_{r \nearrow \rho} Aw'^2(r) < 0$ leads to a contradiction. Indeed, since $\lim_{r \nearrow \rho} A(r) = 0$, we must have

$$\lim_{r \nearrow \rho} w'^2(r) = \infty.$$

The invariance of Eqs. (1-3) and (1-4) under the transformation $w \mapsto -w$ allows us to assume, without any loss of generality, that $\lim_{r \nearrow \rho} w'(r) = +\infty$. We next consider Eq. (2-20) with $\beta = 3$ to obtain

$$r^2(Aw'^3)' + rw'^3(2\Phi + 2Aw'^2) + 3ww'^2(1 - w^2) = 0. \tag{2-24}$$

Near ρ, $\Phi < 0$ and thus

$$2\Phi + 2Aw'^2 < \lim_{r \nearrow \rho} Aw'^2(r) < -c < 0$$

for some $c > 0$. Also, Lemma 2.1 implies w is bounded. These facts imply that in Eq. (2-24) the second term on the left dominates the third term on the same side. It follows that

$$\lim_{r\nearrow\rho}(Aw'^3)'=+\infty. \tag{2-25}$$

However, $\lim_{r\nearrow\rho}Aw'^2(r)<0$ implies that $\lim_{r\nearrow\rho}Aw'^3=-\infty$. Therefore

$$\underline{\lim}_{r\nearrow\rho}(Aw'^3)'(r)=-\infty.$$

But this contradicts Eq. (2-25). This eliminates Case 1.

Case 2. Without any loss of generality, we assume that

$$\overline{\lim}_{r\nearrow\rho}w'(r)=+\infty \quad \text{and} \quad \lim_{r\nearrow\rho}A(r)<0.$$

Thus, there exists a sequence $\{r_n\}\nearrow\rho$ such that $\lim_{n\to\infty}(Aw')(r_n)=-\infty$ and $\lim_{n\to\infty}(Aw')'=-\infty$. Equation (2-20) with $\beta=1$ gives

$$r^2(Aw')'+2rw'^2(Aw')+w(1-w^2)=0. \tag{2-26}$$

Evaluating Eq. (2-26) at r_n implies $\lim_{n\to\infty}w(r_n)=-\infty$. We claim that

$$\lim_{r\nearrow\rho}w(r)=-\infty. \tag{2-27}$$

For if not, then there exist $c>0$ and a sequence $\{s_n\}\nearrow\rho$ such that $w(s_n)>-c$, $2s_nAw'^3(s_n)\nearrow+\infty$, and $(Aw')'(s_n)>0$. This in turn implies that, for sufficiently large n,

$$[r^2(Aw')'+2rAw'^3+w(1-w^2)]_{r=s_n}>0,$$

contradicting Eq. (2-26). This establishes Eq. (2-27).

Similarly, we assert that

$$\underline{\lim}_{r\nearrow\rho}w'(r)\geqslant 0.$$

For otherwise, there exists a sequence $\{t_n\}\nearrow\rho$ such that $Aw'(t_n)>0$ and $(Aw')'(t_n)>0$. Now,

$$[r^2(Aw')'+2rAw'^3+w(1-w^2)]_{r=t_n}>0$$

which also contradicts Eq. (2-26).

Since $\lim_{r\nearrow\rho}w(r)=-\infty$ implies $\lim_{r\nearrow\rho}w'(r)<0$, Case 2 is impossible.

Case 3. Equation (1-3) gives $M>\overline{0}$ such that

$$(rA)'=1-\frac{(1-w^2)^2}{r^2}-\Lambda r^2-2Aw'^2>-M$$

throughout the interval (r_h,ρ). It follows that $\lim_{r\nearrow\rho}(rA)$, and thus, also $\lim_{r\nearrow\rho}A(r)$ exist and are finite provided $\rho<\infty$. Now, Eq. (1-3), written as

$$A'=\frac{1}{r}\left[1-\frac{(1-w^2)^2}{r^2}-\Lambda r^2-2Aw'^2\right],$$

shows that in the finite interval $[r_h,\rho)$ A' is bounded on both sides. ■

(Received 7 March 2000; accepted for publication 13 December 2000)

In the present article we develop the spectral analysis of Schrödinger operators on lattice-type graphs. For the basic example of a cubic periodic graph the problem is reduced to the spectral analysis of certain regular differential operators on a fundamental star-like subgraph with a selfadjoint condition at the central node and quasiperiodic conditions at the boundary vertices. Using an explicit expression for the resolvent of lattice-type operator we develop in the second section appropriate Lippmann–Schwinger techniques for the perturbed periodic operator and construct the corresponding scattering matrix. It serves as a base for the approximation of the multi-dimensional Schrödinger operator by a one-dimensional operator on the graph: in the third section of the paper for given N-dimensional Schrödinger operators with rapidly decreasing potential we construct a lattice-type operator on a cubic graph embedded into $\mathbf{R}^N$ and show that the original N-dimensional scattering problem can be approximated in a proper sense by the corresponding scattering problem for the perturbed lattice operator.
[DOI: 10.1063/1.1347395]

I. INTRODUCTION

Modern interest in spectral properties of Schrödinger operators on graphs and corresponding scattering problems arises from the natural expectation that a dense lattice may serve as a natural approximation for the corresponding solid body. This basic idea is intensely exploited when constructing approximate solutions of partial differential equations on *zero-dimensional* meshes.[1]

From a geometrical point of view, graphs are *one-dimensional* objects, but they have new interesting properties, which distinguish one-dimensional Schrödinger operators on graphs from one-dimensional Schrödinger operators on finite and infinite intervals. One property is the absence of a ''global'' solution of the Cauchy problem. Still we may describe the whole set of solutions of the corresponding homogeneous differential equation on a graph as a *spline* of solutions of local Cauchy problems for ordinary differential equations on edges. But now the whole structure of the finite-dimensional subspace of solutions of the homogeneous equation depends on the *topology* of the graph. Hence we see that Schrödinger operators on graphs have interesting mathematical structures which take an intermediate position between ordinary and partial differential equations. On the other hand, this makes them a useful tool for mathematical modeling and for a study of real physical systems, like nanowires, thin waveguides and networks. This is the reason of recent

a)Electronic mail: imelniko@ulb.ac.be

interest in differential operators on graphs, both for pure mathematics[2–12] and applications.[13–18]

In the present article we study cubic lattice type graphs in $\mathbf{R}^N$. Lattice type graphs are periodic infinite graphs with no infinite edges. Our main objective is to study the possibility of an approximation of high-dimensional Schrödinger dynamics by corresponding dynamics on lattice-type graphs. One-dimensional geometry of graphs makes the spectral analysis and solution of scattering problems essentially less difficult than in high-dimensional systems. On the other hand, the *partial discretization* of the problem obtained by replacing the differential equation on the multi-dimensional space by the corresponding problem for an ordinary differential operator on the lattice-type graph, may serve not only for the aims of computing with use of the corresponding *one-dimensional* (or, generally, *multi-dimensional*) *meshes* viewed as approximations of domains of the original space, but also for qualitative modeling of spectral properties of the original multi-dimensional Schrödinger operator. This modeling is more natural, due to the continuous nature of graphs, compared with discrete zero-dimension lattice approximations of high-dimensional domains[19,20] normally used for the construction of approximate solutions of partial differential equations.

The article is organized as follows. In Sec. II we consider the Schrödinger operator on a periodic cubic lattice graph in $\mathbf{R}^N$. We would like to notice that we generalize results of Exner, who studied[9] the Schrödinger operator on a cubic lattice type graph in $\mathbf{R}^2$. We derive the dispersion equation and explicit expressions for Bloch waves, for the resolvent kernel and obtain the Krein's formula for the finitely perturbed periodic lattice. In Sec. III we consider the Schrödinger operator $H=-\Delta+V(\mathbf{X})$ in Euclidean space $\mathbf{R}^N$ supplied with the cubic lattice-type graph Γ with edges of the length $2a$. For given H we construct a family of Schrödinger operators $L^{(a)}$ on Γ which have the following property: the restrictions of the solutions of the equation $H\mathcal{U}=\lambda\mathcal{U}+F$ onto the lattice Γ are asymptotically close to the solutions of the equation $L^{(a)}u=\lambda u+F|_\Gamma$ when $a\to 0$. We construct an effective equation for the resolvent of the operator $L^{(a)}$ and prove that it is of the Hilbert–Schmidt type, thus allowing for a straightforward numerical solution by iterative methods. Finally we compare the scattering matrix for the operators $L^{(a)}$ on the graph Γ with the scattering matrix of the original N-dimensional operator H.

II. ONE-BODY PROBLEM ON CUBIC LATTICE-TYPE GRAPHS

A. Periodic cubic graph in $\mathbf{R}^N$

In this section we consider a periodic cubic graph Γ in Euclidean space $\mathbf{R}^N$. We assume that the edges of the graph are parallel to the vectors of a fixed orthogonal and normalized basis $\{e_i\}$, $i=1,2,\ldots,N$. If each edge of the graph has length $2a$, then the whole graph may be produced by shifts of a fragment Ω_a of the graph Γ (see Fig. 1) which is called a fundamental subgraph (the fundamental domain of the subgroup of all translations in the basic directions by distances multiple of $2a$):

$$\Omega_a := \{-a<x_s<a,\ \ s=1,2,\ldots,N\}.$$

Denoting by μ the Lebesgue measure on Γ we may consider the Hilbert Space $\mathcal{H}=L_2(\Gamma)$ of all square-integrable functions on Γ. It is clear that $\mathcal{H}$ may be interpreted as an orthogonal sum of a countable number of copies of $L_2(\Omega_a)$:

$$\mathcal{H}=L_2(\Gamma)=l_2(\mathbf{Z}^2,L_2(\Omega_a)).$$

In accordance with the last decomposition any function $u(X)\in\mathcal{H}$ may be represented as a function of two variables: the discrete variable $\mathbf{m}$ which numerates the tiles $\Omega_{a,\mathbf{m}}$ of all discrete translations (multiple to $2a$) of the fundamental subgraph Ω_a, and the inner coordinate x which defines the position of the point inside the given tile:

$$u(X)=u(x,\mathbf{m}),\quad \text{if}\quad X=2a\sum_{i=1}^{N} m_i e_i+x,$$

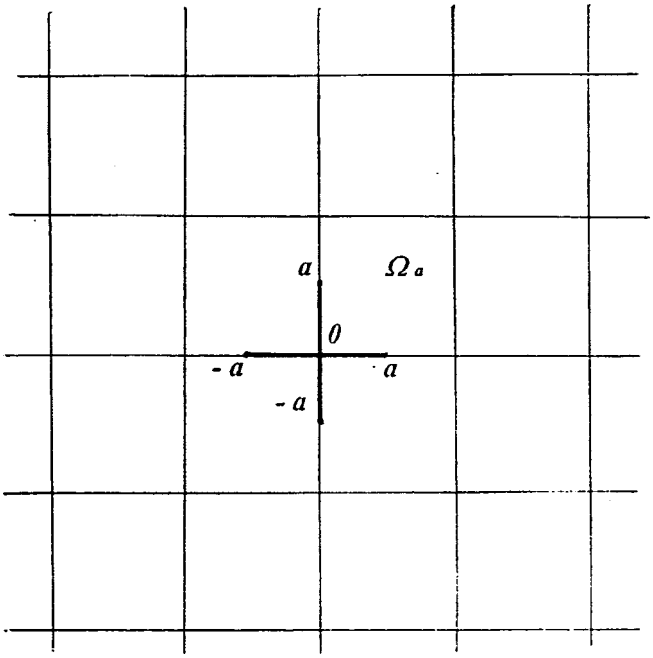

FIG. 1. Cubic lattice type graph Γ_a and its fundamental subgraph Ω_a in $\mathbf{R}^2$.

$$x=\{x_i\}_{i=1}^N, \quad -a<x_i<a; \quad \mathbf{m}=\{m_i\}_{i=1}^N \in \mathbf{Z}^N.$$

We introduce the differential operator L_γ acting in the Hilbert space $\mathcal{H}$ on smooth functions as a second order differentiation in basic direction e_i on each edge parallel to e_i.

$$L_\gamma u=-\frac{d^2u}{dx^2}.$$

One may easily check that this operator is symmetric on the domain of all smooth functions with compact support submitted to the following boundary condition at each node $\mathbf{m}$ $:=(2am_1,2am_2,2am_3,\ldots 2am_n)$:

$$\begin{gathered} u(\mathbf{m}\pm 0e_i)=u(\mathbf{m}\pm 0e_k):=u(\mathbf{m}), \quad 1\leqslant i,k\leqslant N, \\ \sum_{i=1}^N \left[\frac{du}{dx_i}(\mathbf{m}+0e_i)-\frac{du}{dx_i}(\mathbf{m}-0e_i)\right]:=[u'](\mathbf{m})=\gamma(\mathbf{m})u(\mathbf{m}), \end{gathered} \tag{1}$$

where $\gamma(\mathbf{m})=\overline{\gamma}(\mathbf{m})$. One may also easily check, using the strong subordination condition and embedding theorems, that for each *bounded sequence* $\gamma(\mathbf{m})$ the closure of the operator L_γ is a self-adjoint operator in $\mathcal{H}$ defined on the orthogonal sum of the Sobolev spaces W_2^2 on the edges submitted to the above boundary condition (1) at the nodes of the lattice. Our next aim is to explore the spectral structure of L_γ in the simplest case when the function γ is constant: $\gamma(\mathbf{m})=\gamma$. We do it for general N, but for the convenience of the reader we supply some figures for the simplest nontrivial case $N=2$. In this case the infinite graph Γ is represented by a square lattice of nodes each one connected with four neighbors (see Fig. 1). The internode distance is $2a$. This graph can be represented in the form (1) where the fundamental subgraph Ω_a shown in Fig. 1 is a union of four branches $(0,\pm ae_i):=\Omega_a^{i,\pm}$ with a common origin. In this case the total number of edges attached to each node is equal to $2N=4$.

The periodic self-adjoint operator L_γ is singular. Following Gelfand's approach[21] we reduce the construction of the spectral decomposition for it to an analysis of the regular Sturm–Liouvilles problem for the operator L_γ^P on the fundamental subgraph Ω_a:

$$L_\gamma^P u := -\frac{d^2}{dx^2}\Xi_\lambda^P = \lambda \Xi_\lambda^P,$$

with the boundary condition (1) at the node and special quasiperiodic conditions at the ends of branches of Ω_a^s fixed by the vector parameter $P=(p_1,p_2,\ldots,p_s,\ldots,p_N)$. We call this vector parameter varying on N-dimensional torus $\mathbf{T}^N$ a *quasimomentum* and write down the boundary conditions as

$$\Xi_\lambda^P(\mathbf{m}+ae_s)=e^{ip_s}\Xi_\lambda^P(\mathbf{m}-ae_s), \quad -\pi<p_s<\pi, \quad s=1,2,3,\ldots,N. \tag{2}$$

The operator L_γ may be represented as

$$L_\gamma = \int_{\mathbf{T}^N} \oplus L_\gamma^P d^N P,$$

which reduces the spectral analysis of operator L_γ to the spectral analysis of the operators L_γ^P.

Lemma 1: For any quasimomentum P the spectrum σ_γ^P of the operator L_γ^P is real, discrete and bounded from below. It has multiplicity one for almost all P. The eigenvalues $\lambda=k^2$ may be calculated as the roots of the transcendental equation,

$$\sum_{s=1}^{N} \cos p_s + \frac{\gamma \sin 2ka}{2k} = N\cos 2ka. \tag{3}$$

The components of the eigenfunctions on the branches of the fundamental subgraph may be constructed in the form

$$\Xi_\lambda^P := \sum_{s=1}^{N} \oplus \Xi_\lambda^{p_s}, \quad \Xi_\lambda^{p_s}(x_s)=\frac{G_\lambda^{p_s}(x_s,0)}{G_\lambda^{p_s}(0,0)}, \quad s=1,2,3,\ldots,N, \tag{4}$$

where $G_\lambda^{p_s}(x,y)$ is the Green's function of the one-dimensional quasiperiodic problem [integral kernel of the resolvent $(L_\gamma^P-\lambda)^{-1}$] on the s-branch Ω_s of the fundamental subgraph $-a<x_s<a$. Then

$$G_\lambda^p(0,0)=\frac{\sin ka}{2k(\cos p-\cos 2ka)},$$

$$\Xi_\lambda^{p_s}(x_s)=\frac{e^{-ip/2}}{2\sin ka}\left[e^{-ik(x+a/2)}\sin\left(\frac{ka-p}{2}\right)+e^{ik(x+a/2)}\sin\left(\frac{ka+p}{2}\right)\right], \quad -a<x_s<0,$$

$$\Xi_\lambda^{p_s}(x_s)=\frac{e^{ip/2}}{2\sin ka}\left[e^{-ik(x-a/2)}\sin\left(\frac{ka+p}{2}\right)+e^{ik(x-a/2)}\sin\left(\frac{ka-p}{2}\right)\right], \quad 0<x_s<a.$$

The normalizing coefficients $\rho_\lambda^P=\int_\Omega|\Xi_\lambda^P(x)|^2\,d\mu$ of the eigenfunctions $\Xi_\lambda^P(x)=\{\Xi_\lambda^{p_s}(x_s),\ s=1,2,\ldots N\}$ are calculated as

$$\rho_\lambda^P = 2Na+\gamma\frac{ka\cos 2ka-\sin 2ka}{2ak^2\sin 2ka},$$

and are positive on the spectrum σ_γ^P of the regular periodic problem. The spectral resolution and the Green's function of the regular quasiperiodic problem are represented by the spectral series converging in L_2 for $x \neq y$:

$$\sum_\lambda \Xi_\lambda^P(x)\langle \Xi^P, f\rangle \frac{1}{\rho_\lambda^P} = f(x),$$

$$G_\lambda^P(x,y) = \sum_\lambda \frac{\Xi_\lambda^P(x)\overline{\Xi_\lambda^P}(y)}{\lambda(P)-\lambda}\frac{1}{\rho_\lambda^P}.$$

Proof: Consider the following ratio of Green's functions of the quasiperiodic problem on the s-branch of the fundamental subgraph:

$$\Xi_\lambda^{p_s}(x_s) = \frac{G_\lambda^{p_s}(x,0)}{G_\lambda^{p_s}(0,0)}, \quad s = 1,2,3,\ldots,N. \tag{5}$$

Then the quasiperiodicity condition is automatically fulfilled, and the boundary condition at the node is fulfilled for values of the spectral parameter λ which satisfy the dispersion equation we derive now. Note that $\Xi_\lambda^{p_s}(0) = 1$ and the jump-condition $G_\lambda'(+0,0) - G_\lambda'(-0,0) = -1$ is fulfilled at the pole 0. Then the dispersion equation for $\Xi_\lambda^P := \Sigma_s \oplus \Xi_\lambda^{p_s}$ has the form

$$\sum_{s=1}^N \frac{1}{G_\lambda^{p_s}(0,0)} + \gamma = 0. \tag{6}$$

At the value $\mathbf{m} = 0$ we calculate the expression for the Green's function G_λ^p in explicit form:

$$G_\lambda^p(x,y) = \sum_{l=-\infty}^{\infty} e^{-ipl}\frac{e^{ik|x-y+2al|}}{2ik} = \frac{e^{ik|x-y|}}{2ik} + \frac{1}{2ik}\frac{e^{i(2ka-p)}}{1-e^{i(2ka-p)}}e^{ik(x-y)} + \frac{1}{2ik}\frac{e^{i(ka+p)}}{1-e^{i(ka+p)}}e^{ik(y-x)}, \quad k^2 = \lambda,$$

which implies $G_\lambda^p(0,0) = \sin 2ka/2k(\cos p - \cos 2ka)$. Then the dispersion equation acquires the form

$$\sum_{s=1}^N \cos p_s + \frac{\gamma \sin 2ka}{2k} = N\cos 2ka, \quad k^2 = \lambda. \tag{7}$$

The solutions λ of this equation give the spectrum σ_γ^P of the regular spectral problem on the fundamental subgraph with the quasiperiodic boundary condition (2). The spectrum σ_γ^P depends on the quasimomentum $P = (p_1, p_2, \ldots, p_N)$. Hence due to the general spectral properties of the periodic problems[21] the spectrum σ_γ of the periodic operator on the whole space is calculated as a union of all σ_γ^P,

$$\sigma_\gamma = \bigcup_{P \in \mathbf{T}^N} \sigma_\gamma^P.$$

The restrictions of the eigenfunctions of the periodic problem from the whole lattice (Bloch-functions) onto the fundamental subgraph are calculated as eigenfunctions of the regular quasiperiodic spectral problem with all possible quasimomenta. It is easy to check that each s-component of it on the s-branch $-a < x_s < a$ of the fundamental subgraph may be calculated as

$$\Xi_\lambda^P(x_s)=\frac{\cos p_s-\cos(2ka)}{\sin 2ka}\,2kG_{k^2}(x_s,0),\quad s=1,2,3,\ldots,N,\quad \lambda=k^2, \tag{8}$$

and then may be continued on the whole graph via the quasiperiodicity condition (2).

To calculate the spectral density of the periodic problem we need the normalizing coefficients of the Bloch waves for the regular problem with fixed $P=(p_1,p_2,\ldots,p_N)$ on the fundamental subgraph centered at $\mathbf{m}=\mathbf{0}$. According to the previous analysis, the s-component of the Bloch wave $\Xi_\lambda^{p_s}(x)$ is presented for $x=x_s$ as the ratio

$$\Xi_P(x_s)=\frac{G_\lambda^{p_s}(x,0)}{G_\lambda^{p^s}(0,0)}=\frac{\dfrac{e^{ik|x|}}{2ik}+\dfrac{1}{4k}\dfrac{e^{i(2ka-p)/2}}{\sin\left(\dfrac{2ka-p}{2}\right)}e^{ikx}+\dfrac{1}{4k}\dfrac{e^{i(2ka+p)/2}}{\sin\left(\dfrac{2ka+p}{2}\right)}e^{-ikx}}{G_\lambda^p(0,0)},\quad p:=p_s. \tag{9}$$

For $x<0$, that is on the branch $\Omega_a^{s,-}$ of the fundamental subgraph, the numerator of the Bloch wave (9) may be represented as

$$\begin{aligned}G_\lambda^p(x,0)&=\frac{1}{2ik}\left[e^{-ikx}\frac{i}{2}\frac{e^{-i(2ka+p)/2}}{\sin\left(\dfrac{2ka+p}{2}\right)}+e^{ikx}\frac{i}{2}\frac{e^{i2ka-p/2}}{\sin\left(\dfrac{2ka-p}{2}\right)}\right]\\&=\frac{e^{-ip/2}}{4k}\left[\frac{e^{-ik(x+a)}\sin\left(\dfrac{2ka-p}{2}\right)+e^{ik(x+a)}\sin\left(\dfrac{2ka+p}{2}\right)}{\cos p-\cos 2ka}\right],\\&\qquad x<0.\end{aligned}$$

The same numerator on the complementary branch Ω_a^{s+} (for $x>0$) is given by the formula

$$G_\lambda^p(x,0)=\frac{e^{ip/2}}{4k}\left[\frac{e^{-ik(x-a)}\sin\left(\dfrac{2ka+p}{2}\right)+e^{ik(x-a)}\sin\left(\dfrac{2ka-p}{2}\right)}{\cos p-\cos 2ka}\right],\quad x>0.$$

The normalizing coefficient $\int_\Omega|\Xi^P|^2dx$ of the Bloch-wave is calculated as a sum of integrals of the squares of all components of the Bloch-wave over all branches $\Omega_a^{s\pm}$ of the fundamental subgraph Ω_a:

$$\sum_{s=1}^N\frac{[\mathcal{J}_-^s+\mathcal{J}_+^s]}{|G_\lambda^{p_s}(0,0)|^2},$$

where $\mathcal{J}_\pm^s=\int_{\Omega_a^{s\pm}}|G_\lambda^{p_s}(x,0)|^2\,dx$. These integrals are positive and they are represented by the formula

$$\begin{aligned}\mathcal{J}_\pm^s=\frac{a}{4k^2|\cos p-\cos 2ka|^2}&\left[\sin^2\left(\frac{2ka-p}{2}\right)+\sin^2\left(\frac{2ka+p}{2}\right)\right.\\&\left.+2\sin\left(\frac{2ka+p}{2}\right)\sin\left(\frac{2ka-p}{2}\right)\frac{\sin 2ka}{2ka}\right],\quad p:=p_s.\end{aligned}$$

Summing the result over all branches and using the dispersion equation (3) we obtain for the integral over the fundamental subgraph:

$$\int_{\Omega_a} |\Xi_\lambda^P|^2\, dx = 2Na + \gamma \frac{2ka\cos 2ka - \sin 2ka}{2ak^2 \sin 2ka} \equiv \rho_\lambda^P. \tag{10}$$

Hence the spectral expansion for the regular spectral problem on the fundamental subgraph with the quasiperiodic boundary conditions (2) has the form

$$\sum_\lambda \Xi_\lambda^P(x)\Xi_\lambda^P(y)\frac{1}{\rho_\lambda^P} = \delta(x-y), \tag{11}$$

where the summation is over the spectrum $\lambda \in \sigma_P^\gamma$ of the regular quasiperiodic problem. The expression for the square norm ρ_λ^P remains positive on the spectrum σ where the dispersion equation (3) is valid for $-\pi < p_s < \pi$. In particular we see that the norm of the Bloch-functions (4) for Kirchhoff's (''zero-current'') boundary conditions $\gamma = 0$ is trivial, $\rho_\lambda^P = 2aN$.

□

The spectral properties of the periodic operator L_γ on the whole graph Γ may be easily derived from the spectral properties of the regular operator L_γ^P on the fundamental subgraph. We already mentioned that $\sigma_\gamma = \cup_P \sigma_\gamma^P$, and the eigenfunctions of the periodic problem (Bloch functions) may be obtained as the quasiperiodic continuation of the eigenfunctions Ξ_λ^P of the regular quasiperiodic problem. The spectral resolution for the periodic problem and the resolvent kernel may be obtained by averaging the corresponding expressions for the regular problem over the elementary cube of the dual lattice of quasimomenta $-\pi < p_s < \pi$, $s = 1,2,\ldots,N$:

$$\frac{1}{(2\pi)^N}\int_{\mathbf{T}^N} \sum_{\lambda \in \sigma_\gamma^P} \Xi_\lambda^P(x)\overline{\Xi_\lambda^P}(y)\frac{1}{\rho_\lambda^P} d^N P = \delta(x-y). \tag{12}$$

Each term of the series (12) above represents a spectral band of the periodic problem defined by corresponding branch $\lambda(P)$ of the solution of the dispersion equation (3), $P \in \mathbf{T}^N$. The resolvent kernel $G_z^\gamma(x,y)$ of the periodic problem [the integral kernel of the operator $R_\gamma(z) = (L_\gamma - z)^{-1}$] may be represented now as a spectral integral:

$$G_z^\gamma(x,y) = \frac{1}{(2\pi)^N}\int_{\mathbf{T}^N} \sum_{\lambda \in \sigma_\gamma^P} \frac{\Xi_\lambda^P(x)\overline{\Xi_\lambda^P}(y)}{\lambda(P) - z}\frac{d^N P}{\rho_\lambda^P}. \tag{13}$$

B. Perturbation in a finite number of nodes

Consider now a perturbed periodic lattice with only finite number $M < \infty$ of nodes $(\mathbf{m}_1, \mathbf{m}_2, \ldots \mathbf{m}_M)$ affected. Actually we replace[22–24] the standard boundary condition with $\gamma(\mathbf{m}) = \gamma$ [see the second condition in Eq. (1)] at the nodes $\mathbf{m}_1, \mathbf{m}_2, \ldots, \mathbf{m}_M$ by the local boundary condition

$$[u'](\mathbf{m}_r) = (\gamma + \beta_r)u(\mathbf{m}_r), \quad r = 1,2,\ldots,M, \tag{14}$$

with real β_r. Our next aim is to construct the resolvent and scattered waves of the corresponding self-adjoint operator $L_{\gamma\beta}$. We shall obtain both applying the Krein formula for generalized resolvents to our case. In fact we will rederive this remarkable formula in the present context; see also Refs. 24–26.

For given nodes $\mathbf{m}_1, \mathbf{m}_2, \mathbf{m}_3, \ldots, \mathbf{m}_M$ consider the finite-dimensional Hilbert space $\mathcal{E}$ of complex M-vectors $U = (u_1, u_2, u_3, \ldots, u_M)$. Each continuous function u on the cubic lattice may generate a corresponding vector $\vec{u}$ by the rule $(\vec{u})_s = u(\mathbf{m}_s)$, $s = 1,2,\ldots,M$. The scalar product in $\mathcal{E}$ we denote as $<\vec{u},\vec{v}>_\mathcal{E} = \Sigma_{s=1}^M u_s\overline{v_s}$. We need also a *real* scalar product in $\mathcal{E}$ with complex conjugation absent on the second term. We denote it just by the angular brackets $\langle \vec{u},\vec{v}\rangle = \Sigma_{s=1}^M u_s v_s$. We also consider a finite-dimensional operator $\mathcal{G}_\lambda^\gamma$ in $\mathcal{E}$ defined by the matrix

$$(\mathcal{G}_\lambda^\gamma)_{st} = G_\lambda^\gamma(\mathbf{m}_s, \mathbf{m}_t).$$

The operator defined in $\mathcal{E}$ by the diagonal matrix $\mathrm{diag}\{\beta_s\}$ will be denoted by

$$\mathcal{B} := \mathrm{diag}\{\beta_s\}.$$

Theorem 1: *The resolvent kernel $G_\lambda^\beta(x,y), x,y \in \Gamma$, of the operator $L_{\gamma\beta}$ is represented by the following Krein formula:*

$$G_\lambda^{\gamma\beta}(x,y) = G_\lambda^\gamma(x,y) - \left\langle \vec{G}_\lambda^\gamma(x), \frac{I}{I+\mathcal{B}\mathcal{G}_\lambda^\gamma} \vec{G}_\lambda^\gamma(x) \right\rangle, \tag{15}$$

where $\vec{G}_\lambda^\gamma(x)$ is an M-dimensional vector-function with the components $G_\lambda^\gamma(x,\mathbf{m}_s)$, $s = 1,2,\ldots,M$. The spectrum of the operator $L_{\gamma\beta}$ consists of an absolutely-continuous branch(es) which coincides with the (absolutely-continuous) spectrum σ_γ of L_γ and a finite number of eigenvalues in each spectral gap, which may be found from the dispersion equation $\det[I+\mathcal{B}\mathcal{G}_\lambda^\gamma] = 0$. *The scattered waves Φ_λ^P which serve as eigenfunctions of the absolutely-continuous spectrum of the operator $L_{\gamma\beta}$ are parameterized by the quasimomenta P of the initial Bloch-waves and may be constructed in analogy to the resolvent kernel*:

$$\Phi_\lambda^P = \Xi_\lambda^P(x) - \left\langle \vec{G}_\lambda^\gamma(x), \frac{I}{I+\mathcal{B}\mathcal{G}_\lambda^\gamma} \vec{\Xi}_\lambda^P \right\rangle. \tag{16}$$

Proof: We begin with an auxiliary statement concerning the resolvent of the periodic problem. Let us denote by $[']_\mathbf{m} - \gamma I_\mathbf{m}$ the following boundary value at the node $\mathbf{m}$ for the function u defined on the cubic graph:

$$([']_\mathbf{m} - \gamma I_\mathbf{m})u := \sum_{i=1}^N \left[\frac{du}{dx_i}(\mathbf{m}+0e_i) - \frac{du}{dx_i}(\mathbf{m}-0e_i) \right] - \gamma u(\mathbf{m}).$$

Then for the resolvent kernel $G_\lambda^\gamma(x,s)$ the following statement is true:

$$([']_\mathbf{m} - \gamma I_\mathbf{m}) G_\lambda^\gamma(x,\mathbf{s}) = -\delta_{\mathbf{ms}}. \tag{17}$$

Indeed, let us introduce the delta-function $\delta(x-\mathbf{m})$ attached to the node $\mathbf{m}$ of the cubic graph. It may be represented as a sum of delta-functions constructed on the one-dimensional branches of the fundamental subgraph as

$$\delta(x-\mathbf{m}) = \frac{1}{N} \sum_{i=1}^N \delta(x_i - m_i), \tag{18}$$

since both left and right parts define the same functional on the class of all continuous functions on the graph. This means that the periodic operator L_γ may be represented as

$$L_\gamma = -\frac{d^2}{dx^2} + \gamma \sum_\mathbf{m} \delta(x-\mathbf{m}),$$

and the Green's function $G_\lambda^\gamma(x,\mathbf{s})$ which satisfies the equation

$$-\frac{d^2}{dx^2} G_\lambda^\gamma(x,\mathbf{n}) + \gamma \sum_\mathbf{m} \delta(x-\mathbf{m}) G_\lambda^\gamma(x,\mathbf{n}) = \lambda G_\lambda^\gamma(x,\mathbf{n}) + \delta(x-\mathbf{n}),$$

may be integrated on a small subgraph $\Omega_{\epsilon,\mathbf{m}} = (-\epsilon < x_i - 2am_i < \epsilon,\ \epsilon \ll 1)$ which gives the following result due to (27):

$$\lim_{\epsilon\to 0}\int_{\Omega_\epsilon}(L^\gamma-\lambda I)G_\lambda^\gamma(x,\mathbf{n})d\mu=\delta_{\mathbf{mn}}.$$

The left side of the last formula coincides with $([']_{\mathbf{m}}-\gamma I_{\mathbf{m}})G_\lambda^\gamma(x,\mathbf{n})$, as announced. It is clear that the statement is true for any bounded sequence $\gamma(\mathbf{m})$ depending on $\mathbf{m}$ as well.

To prove the first relation (15) we consider the Ansatz for the resolvent kernel of the perturbed periodic operator in the form

$$G_\lambda^{\gamma\beta}(x,y)=G_\lambda^\gamma(x,y)+\sum_{t=1}^{M}A_tG_\lambda^\gamma(x,\mathbf{m}_t). \tag{19}$$

Then applying the operation $[']_{\mathbf{m}_r}-\gamma I_{\mathbf{m}_r}$ to the ansatz $G_\lambda^{\gamma\beta}(x,\mathbf{m}_s)$ we obtain the vector $-\delta_{sr}-\Sigma_{t=1}^{M}A_t\delta_{st}$ in $\mathcal{E}$. On the other hand if the boundary condition (14) for $G_\lambda^{\gamma\beta}(x,\mathbf{m}_s)$ is fulfilled, then this vector must coincide with the vector $\beta_rG_\lambda^\gamma(\mathbf{m}_r,\mathbf{m}_s)+\Sigma_{t=1}^{M}G_\lambda^\gamma(\mathbf{m}_r,\mathbf{m}_t)A_t$. This gives a *finite-dimensional* equation for A_t, $t=1,2,...,N$.

$$-(I+\mathcal{B}\mathcal{G})\vec{A}=\vec{G}_\lambda.$$

If the operator $I+\mathcal{B}\mathcal{G}_\lambda$ is invertible, then the vector $\vec{A}$ of coefficients A_t may be obtained as

$$\vec{A}=-\frac{I}{I+\mathcal{B}\mathcal{G}_\lambda}\vec{G}_\lambda,$$

which gives the first relation (15). The second relation (16) may be obtained in a similar way by using the ansatz

$$\Phi_\lambda^P(x)=\Xi_\lambda^P(x)+\sum_{t=1}^{M}A_tG_\lambda^\gamma(x,\mathbf{m}_t).$$

□

III. APPROXIMATION OF *N*-DIMENSIONAL SCHRÖDINGER DYNAMICS BY DYNAMICS ON CUBIC GRAPH

A. Approximation theorems

We have seen above that quantum systems on the corresponding embedded graphs inherit some basic spectral features from relevant systems on bulk space. On the other hand, the less the dimension of mesh we are using for approximation of the multi-dimensional problem, the easier the corresponding computing; see the article[20] by McCormic. At the same time the analysis for *one-dimensional* graphs may be developed in terms of solutions of corresponding Cauchy problems for *ordinary* differential equations on the edges of the graph, which is almost as simple to solve with the use of modern computers as discrete equations. But the continuous nature of ordinary differential equations allows us to observe high-energy phenomena in a most natural form. In particular one may derive the realistic asymptotic formulas, e.g., for a description of the scattering processes. This is our motivation for analyzing Schrödinger dynamics in N-dimensional space in terms of the corresponding dynamics on one-dimensional cubic graphs filling the whole space $\mathbf{R}^N$.

Let us consider a Schrödinger operator in $\mathbf{R}^N$,

$$H=-\Delta+V(\mathbf{X}),\quad \mathbf{X}\in\mathbf{R}^N, \tag{20}$$

with a continuous, rapidly decreasing potential $V(\mathbf{X})\in L_2(\mathbf{R}^N)\cap C(\mathbf{R}^N)$. For any $a>0$ we can discretize the space $\mathbf{R}^N$ representing it as a tiling

$$\mathbf{R}^N = K_a \times \mathbf{Z}^N := \bigcup_{\mathbf{m}\in\mathbf{Z}^N} K_{a\mathbf{m}},$$

where the tile $K_{a\mathbf{m}}$ is produced by the shift of the basic tile K_a,

$$K_a = \{\mathbf{x}: |\mathbf{x}_j| \leqslant a;\ \ j = 1,2,\ldots,N\}.$$

Here and in what follows we use the following notations:

$\mathbf{x} = \{\mathbf{x}_j\}_{j=1}^N$ is a point of N-dimensional cube K_a with the edges of the length $2a$ parallel to the vectors of a standard orthogonal and normalized basis $\{e_i\}_{i=1}^N$;

$\mathbf{X} = \{\mathbf{X}_j\}_{j=1}^N = 2a\mathbf{m} + \mathbf{x}$, $\mathbf{m}\in\mathbf{Z}^N$, is a point of $\mathbf{R}^N$ with coordinates;

$\mathbf{X}_j = 2a\mathbf{m}_j + \mathbf{x}_j$ with respect to the basis $\{e_i\}_{i=1}^N$;

$\mathbf{X}_\mathbf{m} = 2a\mathbf{m}$ is the $\mathbf{m}$-th node of the cubic lattice with the edge $2a$.

Together with the space $\mathbf{R}^N$ we consider a graph Γ_a which has the structure of a cubic lattice:

$$\Gamma_a = \Omega_a \times \mathbf{Z}^N,$$

where Ω_a is a union of N pairwise orthogonal edges $[-ae_i, ae_i]$ directed along the basic vector of the same orthogonal and normalized basis $\{e_i\}_{i=1}^N$ and having only one common point at the origin. The structure of this lattice is obviously compatible with the tiling introduced above in the sense that the graph Γ_a can be naturally embedded in the space $\mathbf{R}^N$ as a cubic lattice with the step $2a$ so that the fundamental subgraph of it forms the boundary of the fundamental domain K_a of the subgroup of the shift group forming the tiling above. Indeed, when using the following notations:

x is a point of the fundamental subgraph $\Omega_a = \cup_{j=1}^N [-ae_j, ae_j] := \cup_{j=1}^N \Omega_a^j$;

X is a point of the graph Γ_a; $X = 2a\mathbf{m} + x$, $\mathbf{m}\in\mathbf{Z}^N$;

$X_\mathbf{m} = 2a\mathbf{m}$ is the $\mathbf{m}$-th node of the graph Γ_a;

x_j is a point of the interval $\Omega_a^j = [-ae_j, ae_j]$ (the j-edge of the fundamental subgraph $\Omega_a \subset \Gamma_a$),

we describe the *natural embedding* of the graph Γ_a into $\mathbf{R}^N$ as an identification of points $\mathbf{X}_\mathbf{m}$ and X_m and a realization of the edges of the graph as intervals parallel to coordinate axes in $\mathbf{R}^N$ connected to the orthogonal basis $\{e_i\}_{i=1}^N$. In particular the fundamental subgraph Ω_a is then embedded into the cube K_a such that each j-axis of this cube $\{\mathbf{X}: \mathbf{X}_l = 0, l \neq j\}$ corresponds to the component Ω_a^j of the fundamental subgraph and $x_j = \mathbf{x}_j$.

One can consider the Hilbert space $\mathcal{H}_a$ of functions on the graph Γ_a:

$$\mathcal{H}_a = L_2(\Gamma_a, \nu\, dX) = l_2(\mathbf{Z}^N, L_2(\Omega_a, \nu\, dx)) = l_2\left(\mathbf{Z}^N, \sum_{j=1}^N \oplus L_2([-a,a], \nu\, dx_j)\right),$$

where the coefficient in the measure

$$\nu = (2a)^{N-1}/N \tag{21}$$

is chosen in order to preserve the measure under the embedding described above:

$$\int_{K_a} d^N\mathbf{x} = \nu \int_{\Omega_a} dx. \tag{22}$$

The Laplace operator on the graph is given as

$$L_0^{(a)} = -N \sum_{\mathbf{m}\in\mathbf{Z}^N} \sum_{j=1}^N \oplus \partial_{x_j}^2 := -N\frac{d^2}{dx^2}, \tag{23}$$

in the Hilbert space $\mathcal{H}_a$ with the domain $D^{(a)}$ described as a linear variety,

$$l_2\left(\mathbf{Z}^N, \sum_{j=1}^{N} \oplus W_2^2([-a,a]\setminus\{0\}, \nu\, dx_j)\right),$$

of all W_2^2-smooth elements in $\mathcal{H}_2$ which satisfy the boundary condition (1) with $\gamma=0$ (Kirchhoff's ''zero-current'' condition).

We shall approximate the initial Schrödinger operator (20) in $\mathbf{R}_N$ by the following Schrödinger operator on the graph:

$$L^{(a)} = L_0^{(a)} + q_a(X), \tag{24}$$

with the (generalized) potential $q_a(X)=q_a(x,\mathbf{m})$ which will be specified later.

It is obvious that general elements of the basic Hilbert space $L_2(\mathbf{R}^N)$ of all square-integrable functions on $\mathbf{R}^N$ cannot be restricted onto the embedded one-dimensional graph as square-integrable functions. In fact we need even more. The restrictions of functions on $\mathbf{R}^N$ to the lattice Γ_a should be in a proper sense twice differentiable. Exact additional conditions of the smoothness of elements of the original Hilbert space $L_2(\mathbf{R}_N)$ may be easily derived from Sobolev's embedding theorems,[27] but for the moment we just consider the trivial class $W_2^l(\mathbf{R}^N)$, $2l>N$ which consists of continuous ($\mathrm{Lip}_{1/l+1}$) Lipshitz-functions in $\mathbf{R}^N$ and the class

$$\mathcal{F} := W_2^l(\mathbf{R}^N), \quad 2l-N>4,$$

which gives after restriction onto the one-dimensional lattice Γ_a functions in $C^{2+(1/l+1)}(\Gamma_a)$. Below we prove two preparatory statements which will be summarized later in form of the theorem on approximations announced above.

Lemma 2: For any function $u\in W_2^l(\mathbf{R}^N)$, $2l>N$ its restriction u_a onto the graph Γ_a belongs to $L_2(\Gamma_a)\cap \mathrm{Lip}_{2l-N/2(2l-N+2)}$, and the modulo of continuity,

$$\omega_{\mathbf{X}}^u(\delta) := \sup_{|\mathbf{K}|\leqslant\delta} |u(\mathbf{X}+\mathbf{K})-u(\mathbf{X})|,$$

of the function u at the point $\mathbf{X}\in\mathbf{R}^N$ is a square-integrable function of $\mathbf{X}$ in $\mathbf{R_N}$ for any $\delta\ll 1$:

$$\int_{\mathbf{R}^N} |\omega_{\mathbf{X}}^u(\delta)|^2\, d\mathbf{X}^N \leqslant C\delta^{2/(l+1)} \|u\|_{W_2^1}^2.$$

The restriction operator $u\mapsto u_a$ is asymptotically isometric for $a\to 0$:

$$\left|\int_{\mathbf{R}^N} |u|^2\, d\mathbf{X}^N - \int_{\Gamma_a} |u_a|^2(X)\,\nu\, dX\right| \leqslant aC_0\left[\int_{\mathbf{R}_N} |u|^2\, d\mathbf{X}^N + \int_{\mathbf{R}^N} |\nabla u|^2 d\mathbf{X}^N\right] + a^{2l}\left(a+\frac{1}{a}\right) C_l \int_{\mathbf{R}^N} |\nabla^l u|^2\, d\mathbf{X}^N.$$

Similarly, there is a constant $C<\infty$, such that for any functions $u,v\in W_2^l(\mathbf{R}^N)$, $2l>N$, and its restrictions u_a, v_a onto the graph Γ_a,

$$\left|\int_{\mathbf{R}^N} u\overline{v}\, d\mathbf{X}^N - \int_{\Gamma_a} u_a\overline{v}_a \nu\, dX\right| \leqslant aC[\|u\|_{W_2^l}^2 + \|v\|_{W_2^l}^2].$$

Proof: We begin with the proof of the second statement. Note first of all that in the case $2l>N$ the function $u\in W_2^l$ in the unit cube K_1 may be estimated as

$$\sup_{K_1} |u|^2 \leqslant C_0 \int_{K_1} |u|^2\, d\mathbf{x}^N + C_l \int_{K_1} |\nabla^l u|^2\, d\mathbf{x}^N,$$

and the increment of u on any direct path $(\mathbf{x},\mathbf{x}')$ in the unit cube the following estimate holds with some absolute constants C_1, C_l:

$$|u(\mathbf{x})-u(\mathbf{x}')|^2 \leqslant \left[\int_{(\mathbf{x},\mathbf{x}')} |\nabla u|(s)\,ds\right]^2 \leqslant C_0 \int_{K_1} |\nabla u|^2\, d\mathbf{x}^N + C_l \int_{K_1} |\nabla^l u|^2 d\mathbf{x}^N.$$

By scaling this gives

$$\sup_{\mathbf{x}\in K_a} |u|^2 \leqslant C_0 (2a)^{-N} \int_{K_a} |u|^2\, d\mathbf{x}^N + (2a)^{2l-N} C_l \int_{K_a} |\nabla^l u|^2\, d\mathbf{x}^N,$$

$$\sup_{\mathbf{x},\mathbf{x}'\in K_a} |u(\mathbf{x})-u(\mathbf{x}')|^2 \leqslant C_0 (2a)^{2-N} \int_{K_a} |\nabla u|^2\, d\mathbf{x}^N + (2a)^{2l-N} C_l \int_{K_1} |\nabla^l u|^2\, d\mathbf{x}^N.$$

Hence for the real function u the estimate for the increment of u^2 for $u \in W_2^l(K_a)$ along any direct path $(\mathbf{x}, \mathbf{x}')$, in K_a may be reduced to an estimation of the product

$$|u^2(\mathbf{x})-u^2(\mathbf{x}')| = |u(\mathbf{x})+u(\mathbf{x}')\|u(\mathbf{x})-u(\mathbf{x}')|,$$

which may be transformed with use of Cauchy's inequality to the form

$$|u^2(\mathbf{x})-u^2(\mathbf{x}')| \leqslant \left[(2a)^{1-N} C_0 \int_{K_a} (|u|^2+|\nabla u|^2) d\mathbf{x}^N + (2a)^{2l-N}\left(2a+\frac{1}{2a}\right) C_l \int_{K_a} |\nabla^l u|^2\, d\mathbf{x}^N\right].$$

Having j fixed somehow we choose the point $\mathbf{x}' = X'$ on Ω_a^j and then integrate over K_a and sum over all j and over the tiling $K_{\mathbf{m}}$. Then redefining we obtain the estimate for the integral over Lebesgue measure μ on the lattice Γ:

$$\left|\int_{\mathbf{R}^N} |u|^2\, d\mathbf{X}^N - \frac{(2a)^{N-1}}{N} \int_{\Gamma_a} |u_a|^2\, dX\right| \leqslant \left[\frac{(2a)}{N} C_0 \int_{\mathbf{R}^N} (|u|^2+|\nabla u|^2) d\mathbf{X}^N + (2a)^{2l-N} \times \left(2a+\frac{1}{2a}\right)\frac{C_l}{N} \int_{K_a} |\nabla^l u|^2\, d\mathbf{x}^N\right].$$

To obtain a similar estimate for complex-valued functions one may derive it separately for real and imaginary parts of them, and then add both parts. The final result for the estimation of the scalar product $\langle u,v\rangle$ is obtained with use of the polarization identity.

Using the assertion proved above we may reduce the verification of the first statement of the lemma to the proof of the corresponding fact in $\mathbf{R}^N$. This may be easily derived for rapidly decreasing smooth functions. The increment of the function $u(\mathbf{X})$ may be estimated in the usual way:

$$u(\mathbf{X}+\mathbf{K})-u(\mathbf{X}) = \frac{1}{(2\pi)^{N/2}} \int_{\mathbf{R}_N} e^{i\mathbf{P}\mathbf{X}} \frac{(-1+e^{\mathbf{P}\mathbf{K}})}{(1+\mathbf{P}^2)^{l/2}} u(\mathbf{P})(1+\mathbf{P}^2)^{l/2}\, d\mathbf{P}^N.$$

Denoting the Fourier transform by $\mathbf{F}$ we may rewrite the last expression in the form

$$u(\mathbf{X}+\mathbf{K})-u(\mathbf{X}) = \mathbf{F}^{-1} A(\mathbf{K},*)\mathbf{F}(1+D^2)^{l/2} u(\mathbf{X}),$$

where A is the pseudo-differential operator with the symbol

$$A(\mathbf{K},\mathbf{P}) = \frac{e^{i\mathbf{P}\mathbf{K}}}{(1+\mathbf{P}^2)^{l/2}},$$

and D^2 is the Laplace operator in $L_a(\mathbf{R}^N)$. Using the uniform estimate $|A(\mathbf{K},\mathbf{P})| \leqslant C\delta^{1/(1+l)}$ for the symbol in the ball $|K| \leqslant \delta$ and the unitarity of the Fourier-transform in $L_2(\mathbf{R}^N)$ we see that for any continuous function $K(\mathbf{X})$, $|K(\mathbf{X})| \leqslant \delta$ we may estimate $\int_{\mathbf{R}^N} |u(\mathbf{X}+\mathbf{K}(\mathbf{X}))-u(\mathbf{X})|^2\, d\mathbf{X}^N$ by the product $C\delta^{2/(1+l)}\|u\|^2_{W_2^l(\mathbf{R}^N)}$. The function $K(\mathbf{X})$ may be chosen such that

$$|u(\mathbf{X}+\mathbf{K}(\mathbf{X}))-u(\mathbf{X})| = \sup_{|\mathbf{X}|\leqslant\delta} |u(\mathbf{X}+\mathbf{K}(\mathbf{X}))-u(\mathbf{X})| = \omega^u_{\mathbf{X}}(\delta).$$

This gives the first statement of the lemma.

□

Lemma 2 permits us to substitute the pre-Hilbert space of all W_2^l-smooth, $2l>N$, square-integrable functions in $\mathbf{R}^N$ by the pre-Hilbert space of Lipshits–continuous functions on the cubic graph. We need one more step to substitute the Laplace operator on $\mathbf{R}^N$ by the Laplace on the cubic lattice, $-\Delta \to L_0^a$.

Define the classes

$$\mathcal{F}_0 := W_2^l(\mathbf{R}^N); \quad \mathcal{F}_2 := W_2^{l+2}(\mathbf{R}^N).$$

Then the following statement may be considered as a motivation for the substitution of the Laplace operator $-\Delta$ by the operator L_0^a on the graph.

Lemma 3: The restriction u_a of any function $u \in \mathcal{F}_2$ onto the graph Γ_a,

$$u_a(x) := u(\mathbf{X}), \quad if \quad \mathbf{X} = X \in \Gamma_a,$$

in $C^{2+(2l-N)/2(2l-N+2)}(\Gamma_a) \cap L_2(\Gamma_a)$ exists and the diagram

$$\begin{array}{ccc} u & \xrightarrow{\text{differentiation}} & -\Delta u \\ \downarrow \text{restriction} & & \text{restriction} \downarrow \\ u_a & \xrightarrow{\text{differentiation}} & L_0^a u_a \leftrightarrow -\Delta u|_a \end{array} \tag{25}$$

is ''almost commutative'' in the following weak sense: for any test-function $\varphi \in W_2^l(\Gamma_a)$ the weak deviation of $L_0^a u_a$ **from** $-\Delta u|_a$ for small a may be estimated as

$$\left| \int_{\Gamma_a} (L_0^a u_a + \Delta u|_a)\, \overline{\varphi}\, \nu\, dx \right| \leqslant \mathbf{C} a^{1/(l+1)},$$

where $\mathbf{C}$ is a constant depending on $\|u\|^2_{W_2^{l+2}(\mathbf{R}^N)}$, $\|\varphi\|^2_{W_2^l(\Gamma_a)}$.

Proof: Due to Lemma 2 it is sufficient to derive the required estimate on the fundamental subgraph and then sum it over the whole tiling. If we denote by $u_0(\mathbf{m})$, $\mathbf{u_s}(\mathbf{m})$, $\mathbf{u_{st}}(\mathbf{m})$, respectively, the values of the function u and the values of its first derivatives with respect to x_s and second derivatives with respect to x_s, x_t at the node $\mathbf{m}$, we may write down the Taylor formula on the tile $\Omega_{a,\mathbf{m}}$ for the function u,

$$u(2a\mathbf{m}+\mathbf{x}) = u_0(\mathbf{m}) + \sum_s u_s(\mathbf{m})\mathbf{x}_s + \tfrac{1}{2}\sum_{s,t} u_{st}(\mathbf{m})\mathbf{x}_s\mathbf{x}_t + O(\omega^u_{\mathbf{m}}(|\mathbf{x}|)),$$

and for the restriction u_a of u onto the lattice Γ_a, $x \in \Omega_a^s$:

$$u_a(2a\mathbf{m}+x_s) = u_0(\mathbf{m}) + u_s(\mathbf{m})x_s + \tfrac{1}{2}u_{ss}(\mathbf{m})x_s^2 + O(\omega^u_{\mathbf{m}}(|\mathbf{x}|)).$$

A straightforward calculation of the multi-dimensional Laplace on u gives on the tile $\Omega_{\mathbf{m}}$:

$$\Delta u = \sum u_{ss}(\mathbf{m}) + O(\omega_{\mathbf{m}}^{\Delta u}(|x_s|)), \tag{26}$$

where $\omega_{\mathbf{m}}^{f}(\delta)$ stands for the modulo of continuity of the function f on the tile $\Omega_{\mathbf{m}}$. The application of the lattice Laplace L_0^a to the branch $\Omega_{a,\mathbf{m}}^s$ of the tile $\Omega_{a,\mathbf{m}}$ gives

$$L_0^a u_a = N u_{ss} + O(\omega_{\mathbf{m}}^{u}(|x_s|)). \tag{27}$$

It is clear that the last two expressions (26), (27) have a lot in common: the restriction of the first of them onto the branch $\Omega_{a,\mathbf{m}}^s$ gives $\Sigma u_{ss}(\mathbf{m}) + O(\omega_{\mathbf{m}}^{u}(a))$, hence integrating over $\Omega_{a,\mathbf{m}}$ with the test-function φ we obtain

$$\varphi(2a\mathbf{m} + x_s) = \varphi(2a\mathbf{m}) + O(\omega_{\mathbf{m}}^{\varphi}(|x_s|)).$$

Summing over s, $s = 1,2,\ldots,N$ and $\mathbf{m}$ results in

$$\begin{aligned}\left| \int_{\Gamma_a} [(-\Delta u)|_{\Gamma_a} - L_0^a u_a] \varphi \nu \, dX \right| \leqslant \mathbf{C} \sum_{\mathbf{m}} \Bigg\{ & \left(\int_{\Omega_{a,\mathbf{m}}} |\varphi|^2 \nu \, dx \right)^{1/2} \left(\int_{\Omega_{a,\mathbf{m}}} |\omega_{\mathbf{m}}^{D^2 u}(x)|^2 \, dx \right)^{1/2} \\ & + \left(\int_{\Omega_{a,\mathbf{m}}} |\omega_{\mathbf{m}}^{\varphi}(x)|^2 \nu \, dx \right)^{1/2} \left(\int_{\Omega_{a,\mathbf{m}}} |D^2 u|^2 \nu \, dx \right)^{1/2} \\ & + \left(\int_{\Omega_{a,\mathbf{m}}} |\omega_{\mathbf{m}}^{D^2 u}(x)|^2 \, dx \right)^{1/2} \left(\int_{\Omega_{a,\mathbf{m}}} |\omega_{\mathbf{m}}^{\varphi}(x)|^2 \nu \, dx \right)^{1/2} \Bigg\},\end{aligned}$$

where $\mathbf{C}$ is an absolute constant and $|D^2 u|^2$, $|\omega_{\mathbf{m}}^{D^2 u}|^2$ stay for sums of squares of second derivatives and of the moduli of continuity of them, respectively. The integrals of the squares of the moduli of continuity may be estimated via the mean-value theorem as

$$\int_{\Omega_{a,\mathbf{m}}} |\omega_{\mathbf{m}}^{f}(x)|^2 \nu \, dx \leqslant (2a)^N |\omega_{\mathbf{m}}^{f}(2a)|^2,$$

and hence

$$\sum_{\mathbf{m}} \int_{\Omega_{a,\mathbf{m}}} |\omega_{\mathbf{m}}^{f}(x)|^2 \nu \, dx \leqslant \sum_{\mathbf{m}} (2a)^N |\omega_{\mathbf{m}}^{f}(2a)|^2,$$

which coincides with an integral sum for the integral $\int_{\Gamma_a} |\omega_X^f(2a)|^2 \nu \, dx$. Using the local estimate for $X \in \Omega_{a,\mathbf{m}}$,

$$\omega_{\mathbf{m}}^{f}(2a) \leqslant \omega_X^f(4a),$$

we may substitute the integral sum by the integral $\int_{\Gamma_a} |\omega_X^f(4a)|^2 \nu \, dx$ and estimate it using Lemma 2. These steps give the announced estimate with some constant $\mathbf{C}$ depending on $\|u\|_{W_2^{l+2}(\mathbf{R}^N)}, \|\varphi\|_{W_2^l(\Gamma_a)}$.

□

Consider a pair of differential equations,

$$-\Delta \mathcal{U} + V(\mathbf{X})\mathcal{U} = \lambda \mathcal{U} + F,$$

$$L_0^{(a)} u + q(x) u = \lambda u + F_a,$$

with nonhomogeneous terms $F \in W_2^l(\mathbf{R}^N)$ and with $F_a = F|_{\Gamma_a}$. To approximate the multi-dimensional dynamics in $\mathbf{R}^N$ by the corresponding one-dimensional dynamics on the graph Γ_a we have to compare the resolvents of corresponding Schrödinger operators. For given continuous potential $V(\mathbf{X})$ in $\mathbf{R}^N$ [see Eq. (20)], we have to construct a potential $q_a(X)$ (continuous, singular or generalized) on the graph Γ_a [see Eq. (24)] so that following diagram:

$$\begin{array}{ccc} -\Delta\mathcal{U} + V(X)\mathcal{U} = \lambda\mathcal{U} + F & \overset{\text{solution}}{\rightarrow} & \mathcal{U}(\mathbf{X}) \\ \downarrow \text{approximation} & & \text{restriction} \downarrow \\ L_0^{(a)} u + q(x)u := L^{(a)} u = \lambda u + F|_{\Gamma_a} & \overset{\text{solution}}{\rightarrow} & u(X) \rightarrow_{a\to 0} \mathcal{U}|_{\Gamma_a} \end{array} \tag{28}$$

is ''approximately commutative'' in a sense similar to one of the diagrams discussed in Lemma 3. Now the exact meaning of the diagram (28) is clarified by the following.

Theorem 2: *Let $H = -\Delta + V(\mathbf{X})$ be a Schrödinger operator in $L_2(\mathbf{R}^N)$ with a real uniformly bounded square-integrable and continuous potential $V(\mathbf{X})$. Consider the family of lattice-type graphs Γ_a naturally embedded into $\mathbf{R}^N$ as described above and the family $\{L^{(a)}\}$ of operators (each acting in its own space $\mathcal{H}_a$) given by Eq. (24) with the generalized delta-functional potentials,*

$$q_a(X) = (2N\nu)^{-1} \sum_{\mathbf{m}\in\mathbf{Z}^N} \delta(X - X_{\mathbf{m}}) \int_{K_a} V(\mathbf{x} + 2a\mathbf{m}) d^N\mathbf{x}. \tag{29}$$

Then for any pair of test functions $\Upsilon(\mathbf{X}) \in \mathcal{F}_2$, $\Psi(\mathbf{X}) \in \mathcal{F}_0$ and the restrictions $\upsilon^{(a)}(X), \psi^{(a)}$ onto the graph Γ_a the following weak approximation property is valid when $a \to 0$:

$$|\langle H\Upsilon, \Psi\rangle_{L_2(\mathbf{R}^N)} - \langle L^a \upsilon^{(a)}, \psi^{(a)}\rangle_{\mathcal{H}^{(a)}}| \leqslant \mathbf{C} a^{1(l+1)} \|\Upsilon\|_{W_2^{l+2}(\mathbf{R}^N)} \|\Psi\|_{W_2^l(\mathbf{R}^N)}. \tag{30}$$

Proof: First let us notice that the choice of the (generalized) potential $q_a(x)$ is not unique; however, the one given leads to an essential simplification.

The comparison of the bilinear forms of the differential operator parts Δ and $L^{(a)}$ was done in Lemma 3. It remains to compare the parts which contain the potentials. Using Taylor expansions for the test functions Υ and Ψ, we have for instance,

$$\Upsilon(\mathbf{x}, \mathbf{m}) = \upsilon^{(a)}(2a\mathbf{m}) + \sum_{l=1}^{2} \sum_{n\geqslant 1} \frac{\partial^n \Upsilon}{\partial \mathbf{x}_l^n}(2a\mathbf{m}) \frac{\mathbf{x}^n}{n!} + O(\omega_{\mathbf{m}}^{D^2\Upsilon}(2a)),$$

where the symbolic notations for a high-order differential are used. Therefore we may obtain the approximate formula for the bilinear term with the potential

$$\begin{aligned} \langle V\Upsilon, \Psi\rangle_{L_2(\mathbf{R}^N)} &= \sum_{\mathbf{m}\in\mathbf{Z}^N} \int_{K_a} V(\mathbf{x} + 2a\mathbf{m}) \Upsilon(\mathbf{x} + 2a\mathbf{m}) \overline{\Psi}(\mathbf{x} + \mathbf{m}) d\mathbf{x}^N \\ &= \sum_{\mathbf{m}\in\mathbf{Z}^N} \upsilon^{(a)}(2a\mathbf{m}) \overline{\psi^{(a)}}(2a\mathbf{m}) \int_{K_a} V(\mathbf{x} + \mathbf{m}) d\mathbf{x} + a^{1/(1+l)} [\|\Upsilon\|_{W_2^l(\mathbf{R}^N)} \|\Psi\|_{W_2^l(\mathbf{R}^N)}]. \end{aligned}$$

Due to the continuity of the restrictions υ, ψ we may approximate the potential $V(\mathbf{X})$ by the combination $q_a(X)$ of delta functions on the lattice Γ_a attached to the points $2a\mathbf{m}$ [see Eq. (29)]. Using the bracket notations for functionals on continuous functions we have

$$\upsilon^{(a)}(2a\mathbf{m})\overline{\psi^{(a)}}(2a\mathbf{m})=\int_{\Gamma_a}\delta(X-2a\mathbf{m})\upsilon^{(a)}(X)\overline{\psi^{(a)}}(X)dX=\nu^{-1}\langle\delta(X-X_M)\upsilon^{(a)}(X),\psi^{(a)}(X)\rangle_{\mathcal{H}_a},$$

hence

$$\begin{aligned}\langle V(\mathbf{X})\Upsilon,\Psi\rangle_{L_2(\mathbf{R}^N)}&=\nu^{-1}\sum_{\mathbf{m}\in\mathbf{Z}^N}\langle\delta(X-X_\mathbf{m})\upsilon^{(a)},\psi^{(a)}\rangle_{\mathcal{H}_a}\int_{K_a}V(\mathbf{x}+\mathbf{m})d\mathbf{x}^N\\&\quad+O(a^{1/(1+l)}[\|\Upsilon\|_{W_2^l(\mathbf{R}^N)}\|\Psi\|_{W_2^l(\mathbf{R}^N)}])\\&=\langle q_a(X)\upsilon^{(a)},\psi^{(a)}\rangle_{\mathcal{H}_a}+O(a^{1/(1+l)}[\|\Upsilon\|_{W_2^l(\mathbf{R}^N)}\|\Psi\|_{W_2^l(\mathbf{R}NN)}]).\end{aligned}\tag{31}$$

Using Lemma 3 and Eq. (30) concludes the proof of the theorem.

□

We see now that the family of the operators $L^{(a)}$ on the graphs Γ_a approximates in the weak sense the N-dimensional Schrödinger operator H when $a\to 0$. This result will now lead to the desired interpretation of the ''weak commutativity'' of the diagram (28).

Definition 1: The function $\mathcal{U}\in\mathcal{F}_2$ is called a weak solution of the equation

$$-\Delta\mathcal{U}+V\mathcal{U}=\lambda\mathcal{U}+F,\quad F\in\mathcal{F},\tag{32}$$

if for all test-functions $\Psi\in\mathcal{F}_0$ the following equation holds:

$$\langle(-\Delta+V-\lambda)\mathcal{U},\Psi\rangle_{L_2(\mathbf{R}^N)}=\langle F,\Psi\rangle_{L_2(\mathbf{R}^N)}.$$

Definition 2: The function $u\in W_2^l(\Gamma_a)$ is called a weak solution of the equation solution,

$$L_0^{(a)}u+q_au=\lambda u+f,\tag{33}$$

if for all restrictions ψ of the test-functions $\Psi\in\mathcal{F}_0$ onto the lattice Γ_a the following equation holds:

$$\langle(H_0^{(a)}+q-\lambda)u,\psi\rangle_{\mathcal{H}_a}=\langle f,\psi\rangle_{\mathcal{H}_a},$$

for all functions $\psi\in\mathcal{H}_a$.

The following theorem is valid.

Theorem 3: *If $\mathcal{U}$ is a weak solution of Eq. (32), then its restriction $\mathcal{U}|_{\Gamma_a}$ to the graph Γ_a is approximated by a weak solution of Eq. (33) with $f=F|_{\Gamma_a}$ in the following sense:*

$$\langle(L_0^{(a)}+q-\lambda)\mathcal{U}|_{\Gamma_a},\psi\rangle_{\mathcal{H}_a}-\langle F|_{\Gamma_a},\psi\rangle_{\mathcal{H}_a}\to 0,\ \text{if}\ a\to 0,\tag{34}$$

for any $\psi\in\mathcal{H}_a$, where $q_a(x)$ is given by Eq. (29).

Proof: The class $\mathcal{F}_2$ of test functions is dense in the space $L_2(\mathbf{R}^N)$, therefore we can restrict our consideration to the case $\mathcal{U}\in\mathcal{F}_2$. Applying Theorem 2 we have

$$\langle(-\Delta+V)\mathcal{U},\Psi\rangle_{L_2(\mathbf{R}^N)}=\langle(L_0^{(a)}+q_a)\mathcal{U}|_{\Gamma_a},\Psi|_{\Gamma_a}\rangle_{\mathcal{H}_a}+O(a^{1/(1+l)}[|U|_{W_2^{l+2}(\mathbf{R}^N)}|\Psi|_{W_2^l(\mathbf{R}^N)}]).$$

Following the pattern of the proof of Theorem 2 one can see that

$$\langle\mathcal{U},\Psi\rangle_{L_2(\mathbf{R}^N)}=\langle\mathcal{U}|_{\Gamma_a},\Psi|_{\Gamma_a}\rangle_{\mathcal{H}_a}+O(a^{1/(1+l)}[|U|_{W_2^l(\mathbf{R}^N)}|\Psi|_{W_2^l(\mathbf{R}^N)}]);$$

$$\langle F,\Psi\rangle_{L_2(\mathbf{R}^N)}=\langle F|_{\Gamma_a},\Psi|_{\Gamma_a}\rangle_{\mathcal{H}_a}+O(a^{1/(1+l)}[|F|_{W_2^l(\mathbf{R}^N)}|\Psi|_{W_2^l(\mathbf{R}^N)}]);$$

for any $\mathcal{U}\in\mathcal{F}_2,\Psi,F\in\mathcal{F}_0$. The function $\mathcal{U}\in\mathcal{F}_2\subset\mathcal{F}_0$ is a weak solution of Eq. (32), and the restriction $\mathcal{F}_0|_{\Gamma_a}$ of the class $\mathcal{F}_0$ to the graph Γ_a is dense in the space $\mathcal{H}_a$; therefore formula (34) is true.

□

The last statement confirms the ''approximate commutativity'' of diagram (28) in the weak sense when $a\to 0$, thus motivating the study of the operators $L^{(a)}$.

B. Analysis of operators $L^{(a)}$

Due to the specific (delta-functional) perturbation, the easiest way to investigate the operators $H^{(a)}$ is to use the Lippmann–Schwinger equation for the resolvents,

$$R(z)=R_0(z)-R_0(z)q_aR(z), \tag{35}$$

where we omit index a and use the notations

$$R_0(z)=(L_0^{(a)}-z)^{-1};$$

$$R(z)=(L^{(a)}-z)^{-1}=(L_0^{(a)}+q_a(X)-z)^{-1}. \tag{36}$$

The unperturbed resolvent $R_0(z)$ was constructed in Sec. II A through its kernel (the Green's function) $G_z^\gamma(x,y)$ [see Eq. (13)]. The case under consideration is given by $\gamma=0$ (Kirchhoff's condition). In this case we see from Eq. (3) that the spectrum of the unperturbed operator $L_0^{(a)}$ being the union of spectra of fiber the operators $L_0^{(a)P}$, $P\in\mathbf{T}^N$, is absolutely continuous and fills the positive semiaxis. Indeed, $-1\leqslant(1/N)\sum_{s=1}^N\cos p_s\leqslant 1$ for all $P=\{p_s\}_{s=1}^N\in\mathbf{T}^N$, and $(1/N)\sum_{s=1}^N\cos p_s$ takes all values in the interval $[-1,1]$ when P varies on $\mathbf{T}^N$. Therefore, solutions k of Eq. (3) in case $\gamma=0$ fill the whole real axis after integration over $\mathbf{T}^N$, and the spectrum $\sigma_0\ni\lambda=k^2$ of the operator $L_0^{(a)}$ fills the positive semiaxis.

The kernel of the unperturbed resolvent (the Green's function) constructed in Sec.II A has a tensor structure. We denote its tensor elements as $R_{\mathbf{mm}'}^{(0)jj'}(x,x',z)$, $1\leqslant j,j'\leqslant N$, $\mathbf{m},\mathbf{m}'\in\mathbf{Z}^N$. Tensor elements of the local perturbation $q_a(X)$ given by Eq. (29) are

$$q_{\mathbf{mm}'}^{jj'}(x,x')=\nu^{-2}V_{\mathbf{m}}\delta_{\mathbf{mm}'}\delta_{jj'}\delta(x')\delta(x), \tag{37}$$

where

$$V_{\mathbf{m}}\overset{\text{def}}{=}\int_{K_a}V(\hat{X},\mathbf{m})d^N\hat{X}. \tag{38}$$

Therefore the Lippmann–Schwinger equation (35) for the tensor elements of the perturbed resolvent takes the form

$$R_{\mathbf{mm}'}^{jj'}(x,x',z)=R_{\mathbf{mm}'}^{(0)jj'}(x,x',z)-\sum_{\mathbf{n}\in\mathbf{Z}^N}V_{\mathbf{n}}\sum_{l=1}^N R_{\mathbf{mn}}^{(0)jl}(x,0,z)R_{\mathbf{nm}'}^{lj'}(0,x',z), \tag{39}$$

which for $x=0$ implies

$$R_{\mathbf{mm}'}^{jj'}(0,x',z)=R_{\mathbf{mm}'}^{(0)jj'}(0,x',z)-\sum_{\mathbf{n}\in\mathbf{Z}^N}V_P\sum_{l=1}^N R_{\mathbf{mn}}^{(0)jl}(0,0,z)R_{\mathbf{nm}'}^{lj'}(0,x',z). \tag{40}$$

Let us show that the elements $R_{\mathbf{mn}}^{(0)jl}(0,0,z)$ do not depend on j,l. Indeed, let $r_0^P(z)=(L_0^{(a)P}-z)^{-1}$ be the resolvent of the fiber operator $L_0^{(a)P}$. Using the spectral decomposition a tensor element of its kernel can be constructed in terms of the eigenfunctions [see Eq. (13)]:

$$r^P_{(0)jl}(x,x',z)=\sum_{n=-\infty}^{\infty}\frac{\Xi^{p_j}_{Nk_n^2(P)}(x)\overline{\Xi}^{p_l}_{Nk_n^2(P)}(x')}{Nk_n^2(P)-z},$$

where $Nk_n^2(P)$ are the eigenvalues of the operator $L_0^{(a)P}$. One can check by straightforward calculations that in our case ($\gamma=0$) the eigenfunctions have the form

$$\Xi^{p_l}_{Nk_n^2}(x)=\begin{cases}(Na\nu)^{-1/2}[\cos k_n x+\alpha_l^-\sin k_n x], & -a\leqslant x<0,\\ (Na\nu)^{-1/2}[\cos k_n x-\alpha_l^+\sin k_n x], & 0<x\leqslant a,\end{cases}\tag{41}$$

where

$$\alpha_l^{\pm}=\frac{e^{\pm ip_l}-\cos 2k_n a}{\cos 2k_n a}.$$

Using Eq. (41), we have

$$r^P_{(0)jl}(0,0,z)=\frac{1}{2\nu Na}\sum_{n=-\infty}^{\infty}\frac{1}{Nk_n^2(P)-z},$$

where $k_n(P)$ are the solutions of Eq. (3) with $\gamma=0$. Therefore we can see for any j, $l=1,2,\ldots,N$

$$\begin{aligned}\mathcal{A}_{\mathbf{mn}}(z)&\overset{\text{def}}{=}R^{(0)jl}_{\mathbf{mn}}(0,0,z)\\&=\frac{1}{(2\pi)^N}\int_{\mathbf{T}^N}r^P_{(0)jl}(0,0,z)e^{i(\mathbf{m}-\mathbf{n},P)}\,d^NP\\&=\frac{1}{2\nu Na(2\pi)^N}\int_{\mathbf{T}^N}e^{i(\mathbf{m}-\mathbf{n},P)}\sum_{n=-\infty}^{\infty}\frac{d^N\Theta}{Nk_n^2(\Theta)-z}.\end{aligned}\tag{42}$$

From Eqs. (39), (40), (42) we have

$$R^{jj'}_{\mathbf{mm}'}(0,x',z)=R^{(0)jj'}_{\mathbf{mm}'}(0,x',z)-\sum_{\mathbf{n}\in\mathbf{Z}^N}\mathcal{A}_{\mathbf{mn}}(z)V_{\mathbf{n}}\sum_{l=1}^{N}R^{jj'}_{\mathbf{nm}'}(0,x',z).\tag{43}$$

Summation over $j=1,2,\ldots,N$ gives

$$\sum_{j=1}^{N}R^{jj'}_{\mathbf{mm}'}(0,x',z)=\sum_{j=1}^{N}R^{(0)jj'}_{\mathbf{mm}'}(0,x',z)-N\sum_{\mathbf{n}\in\mathbf{Z}^N}\mathcal{A}_{\mathbf{mn}}(z)V_P\sum_{l=1}^{N}R^{jj'}_{\mathbf{nm}'}(0,x',z).\tag{44}$$

One can also check that $\Sigma_{j=1}^N R^{(0)jl}_{\mathbf{mm}'}(0,x,z)$ does not depend on index l. Indeed, using Eq. (13) we have

$$\sum_{j=1}^{N}R^{(0)jl}_{\mathbf{mm}'}(0,x,z)=\sum_{j=1}^{N}\int_{\mathbf{T}^N}d^NPe^{i(\mathbf{m}-\mathbf{m}',P)}\sum_{n=-\infty}^{\infty}\frac{\Xi^{p_j}_{Nk_n^2(P)}(0)\overline{\Xi}^{p_l}_{Nk_n^2(P)}(x)}{Nk_n^2(P)-z}.$$

Therefore, using Eq. (41) we get

$$\sum_{j=1}^{N}R^{(0)jl}_{\mathbf{mm}'}(0,x,z)=\frac{1}{\nu a}\int_{\mathbf{T}^N}d^NPe^{i(\mathbf{m}-\mathbf{m}',P)}\sum_{n=-\infty}^{\infty}\frac{1}{Nk_n^2(P)-z}(\cos k_n(P)x+\alpha_l(P)\sin k_n(P)x).$$

The only possible dependence on l is given through the coefficients $\alpha_l^{\pm}$ defined in Eq. (41). Therefore, the only l-dependent contribution to the latter expression is given by

$$\frac{1}{\nu a}\int_{\mathbf{T}^N} d^N P e^{\pm i p_l} e^{i(\mathbf{m}-\mathbf{m}',P)} \sum_{n=-\infty}^{\infty} \frac{\sin k_n(P)x}{Nk_n^2(P)-z}.$$

From Eq. (3) at $\gamma=0$ we see that $k_n^2(P)$ is invariant with respect to every permutation of indices $P=(p_1,p_2,\ldots,p_N)\to P'=(p_{l_1},p_{l_2},\ldots,p_{l_N})$. Therefore the same is true for the function $\Sigma_{n=-\infty}^{\infty}\sin k_n(P)x/Nk_n^2(P)-z$. Hence, the latter integral actually does not depend on l, and the same is true for $\Sigma_{j=1}^{N} R_{\mathbf{mm}'}^{(0)jj'}(0,x,z)$. Therefore we can introduce the notation

$$G_{\mathbf{mm}'}^{(0)}(x,z)\overset{\text{def}}{=}\sum_{j=1}^{N} R_{\mathbf{mm}'}^{(0)jl}(0,x,z),$$

and from Eq. (44) see that

$$G_{\mathbf{mm}'}(x,z)\overset{\text{def}}{=}\sum_{j=1}^{N} R_{\mathbf{mm}'}^{jl}(0,x,z)$$

does not depend on l as well. Eq. (40) implies

$$G_{\mathbf{mm}'}(x,z)=G_{\mathbf{mm}'}^{(0)}(x,z)-N\sum_{\mathbf{n}\in\mathbf{Z}^N}\mathcal{A}_{\mathbf{mn}}(z)V_P G_{\mathbf{nm}'}(x,z). \tag{45}$$

Combining Eqs. (39), (40), (43), (44) we can express the tensor elements of the perturbed resolvent in terms of solutions of Eq. (45):

$$R_{\mathbf{mm}'}^{jj'}(x,x',z)=R_{\mathbf{mm}'}^{(0)jj'}(x,x',z)-\sum_{\mathbf{n}\in\mathbf{Z}^N}V_{\mathbf{n}}\sum_{l=1}^{N}R_{\mathbf{mn}}^{(0)jl}(x,0,z)$$
$$\times\left(R_{\mathbf{nm}'}^{(0)lj'}(0,x',z)-\sum_{\mathbf{n}'\in\mathbf{Z}^N}\mathcal{A}_{\mathbf{nn}'}(z)V_{\mathbf{n}'}G_{\mathbf{n}'\mathbf{m}'}(x',z)\right). \tag{46}$$

Therefore, the construction of the resolvent of the operator $L^{(a)}$ is reduced to the solution of the effective tensor equation (45). Let us notice that x and z play the role of parameters in this effective equation. We omit the parameter x in the further notations and rewrite the effective equation (45) in the tensor form

$$G(z)=G^{(0)}(z)-N\mathcal{A}(z)\hat{V}G, \tag{47}$$

where tensor elements of the tensors $G(z)$, $G^0(z)$ and $\mathcal{A}(z)$ are $G_{\mathbf{mm}'}(x,z)$, $G_{\mathbf{mm}'}^{(0)}(x,z)$ and $\mathcal{A}_{\mathbf{mm}'}(z)$, respectively; $\hat{V}$ stands for a diagonal tensor with the elements $V_{\mathbf{m}}$.

We can formulate the above result in the form of the following.

Lemma 4: The tensor elements of the resolvent $R(Z)=(L_0^{(a)}+q(X)-z)^{-1}$ are given by Eq. (46), where the tensor $G(z)$ is the solution of the equation (47).

In order to study properties of the equation (47) we need the following technical result.

Lemma 5: The function

$$\tau_z(P)\overset{\text{def}}{=}\sum_{n=-\infty}^{\infty}\frac{1}{Nk_n^2(P)-z} \tag{48}$$

has bounded derivatives $\partial_{p_1p_2\ldots p_N}^N\tau_z(P)$ *on* $\mathbf{T}^N$ *for all* $z\in\mathbf{C}\setminus\mathbf{R}_+$.

Proof: Introducing the notation

$$\mu(P)\overset{\text{def}}{=}\frac{1}{N}\sum_{j=1}^{N}\cos p_j\,.$$

Due to Eq. (3) at $\gamma=0$ we have

$$k_n(P)=\frac{1}{2a}\left((-1)^n\,\mathrm{Arccos}\{\mu(P)\}+2\pi\left[\frac{n+1}{2}\right]\right),\quad n\in\mathbf{Z},\tag{49}$$

where the square bracket $[z]$ stand for the integer part of z and the inverse cosine function is assumed to take values in the interval $0\leqslant \mathrm{Arccos}\ \mu<\pi$. Hence the function $\tau_z(P)$ depends on the single variable $\mu(P)$ only,

$$\tau_z(\mu)=\sum_{n=-\infty}^{\infty}\chi_z^n(\mu),$$

where

$$\chi_z^n(\mu)\overset{\text{def}}{=}\frac{1}{N\left\{(-1)^n\mathrm{Arccos}\,\mu+2\pi\left[\frac{n+1}{2}\right]\right\}^2-z},\tag{50}$$

and one can calculate

$$\partial^2_{p_jp_l}\mu(P)=\delta_{jl}N^{-1}\sin p_j\,,$$

$$\begin{aligned}\partial^N_{p_1p_2\ldots p_N}\tau_z(\mu(P))&=\left(\prod_{j=1}^{N}\frac{\partial\mu(P)}{\partial p_j}\frac{\partial}{\partial\mu}\right)\tau_z(\mu)\\&=(-N)^N\frac{\partial^N\tau_z(\mu)}{\partial\mu^N}\prod_{j=1}^{N}\sin p_j\\&=(-N)^N\sum_{n=-\infty}^{\infty}\frac{\partial^N\chi_z^n(\mu)}{\partial\mu^N}\prod_{j=1}^{N}\sin p_j\,.\end{aligned}\tag{51}$$

The function $\mathrm{Arccos}(\mu)$ is an infinitely differentiable function everywhere in the open interval $(-1,1)\ni\mu$. Since $d/d\mu\,\mathrm{Arccos}(\mu)=-(1-\mu^2)^{-1/2}$, the derivatives $(d^s/d\mu^s)\,\mathrm{Arccos}(\mu)$ in the points $\mu=\pm1$ have has only singularities defined by the factor $(1-\mu^2)^{-s+1/2}$. The derivative $(d^N/d\mu^N)\,\chi_z^n(\mu)$ has no other singularities for any $z\in\mathbf{C}\backslash\mathbf{R}_+$ and contains the derivatives $(d^s/d\mu^s)\mathrm{Arccos}(\mu)$ with $s=0,1,2,\ldots,N$. Hence it is finite everywhere in the open interval $(-1,1)\ni\mu$ and can have poles of the order not higher than $(1-\mu^2)^{-N+1/2}$ in the points $\mu=\pm1$. However, due to the definition of function $\mu(P)$ if $\mu=\pm1$ then $\cos p_j=\pm1$ for all $j=1,1,\ldots,d$, thus $\sin p_j=0$ for all $j=1,2,\ldots,N$. Therefore the function $\Pi_{j=1}^N\sin p_j$ has zeros of the order $(1-\mu^2)^N$ in these points. Consequently, the functions $[\partial^N\chi_z^n(\mu(P))/\partial\mu^N]\,\Pi_{j=1}^N\sin\theta_j$ are bounded in the closed interval $[-1,1]\ni\mu$ (i.e., in the whole torus $\mathbf{T}^N\ni P$) for any $n\in\mathbf{Z}$ and any $z\in\mathbf{C}\backslash\mathbf{R}_+$.

One can also check that

$$\chi_z^n(\mu(P))=O(n^2)(1+o(1));$$

$$\left|\frac{\partial^N\chi_z^n(\mu(P))}{\partial\mu^N}\right|\leqslant O(n^2)(1+o(1)),$$

when $n\to\pm\infty$ for all $P\in\mathbf{T}^N$, $z\in\mathbf{C}\setminus\mathbf{R}_+$. Hence the series (49) converges.

□

The following statement is true.

Theorem 4: *For any potential $V(\mathbf{X})\in L_2(\mathbf{R}^N)\cap C(\mathbf{R}^N)$ the operator $\mathcal{A}(z)\hat{V}$ is a Hilbert–Schmidt operator in the space $l_2(\mathbf{Z}^N)$ for all $z\in\mathbf{C}\setminus\mathbf{R}_+$ if the tensor elements $\mathcal{A}_{\mathbf{mm}'}(z)$ are given by Eq. (42) and $\hat{V}$ is the diagonal tensor with elements $V_{\mathbf{m}}=\int_{K_a}V(\hat{X},\mathbf{m})d^N\hat{X}$, $\mathbf{m}\in\mathbf{Z}^N$.*

Proof: It suffices to prove that

$$\sum_{\mathbf{m},\mathbf{n}\in\mathbf{Z}^N}|(\mathcal{A}(z)\hat{V})_{\mathbf{mn}}|^2<\infty. \tag{52}$$

We have

$$\sum_{\mathbf{m},\mathbf{n}}|(\mathcal{A}(z)\hat{V})_{\mathbf{mn}}|^2=(Na(2\pi)^N)^{-2}\sum_{\mathbf{m},\mathbf{n}}\left|\int_{\mathbf{T}^N}e^{i(\mathbf{m}-\mathbf{n},P)}\tau_z(P)d^NP\int_{K_a}V(\hat{X},P)d^N\hat{X}\right|^2$$

$$=(Na(2\pi)^N)^{-2}\sum_{\mathbf{q}}\left|\int_{\mathbf{T}^N}e^{i(\mathbf{q},P)}\tau_z(P)d^NP\right|^2\sum_{\mathbf{n}}\left|\int_{K_a}V(\hat{X},\mathbf{n})d^N\hat{X}\right|^2. \tag{53}$$

First, using the Hölder inequality we estimate

$$\sum_{\mathbf{n}}\left|\int_{K_a}V(\hat{X},\mathbf{n})d^N\hat{X}\right|^2\leqslant(2a)^N\sum_{\mathbf{n}}\int_{K_a}|V(\hat{X},\mathbf{n})|^2\,d^N\hat{X}$$

$$=(2a)^N\int_{\mathbf{R}^N}|V(\mathbf{X})|^2\,d^N\mathbf{X}$$

$$=(2a)^N||V(\mathbf{X})||^2_{L_2(\mathbf{R}^N)}<\infty. \tag{54}$$

Next, using Lemma 5 we can integrate by parts and get the estimation

$$\sum_{\mathbf{n}\in\mathbf{Z}^N}\left|\int_{\mathbf{T}^N}e^{i(\mathbf{n},P)}\tau_z(P)d^NP\right|^2$$

$$=\left|\int_{\mathbf{T}^N}\tau_z(P)d^NP\right|^2+\sum_{n_1n_2\dots n_N\neq0}\left|\frac{1}{\Pi_{j=1}^Nn_j}\int_0^{2\pi}dp_1\dots\int_0^{2\pi}dp_N\,\partial^N_{p_1p_2\dots p_N}\tau_z(P)\prod_{j=1}^N e^{in_jp_j}\right|^2$$

$$\leqslant\left|\int_{\mathbf{T}^N}\tau_z(P)d^NP\right|^2+\left(\int_{\mathbf{T}^N}|\partial^N_{p_1p_2\dots p_N}\tau_z(P)|d^NP\right)^2\sum_{n_1n_2\dots n_N\neq0}\frac{1}{\Pi_{j=1}^Nn_j^2}$$

$$=\left|\int_{\mathbf{T}^N}\tau_z(P)d^NP\right|^2+\left(\frac{\pi}{3}\right)^N\left(\int_{\mathbf{T}^N}|\partial^N_{p_1p_2\dots p_N}\tau_z(P)|d^NP\right)^2<\infty. \tag{55}$$

Combining Eqs. (53)–(55) and Lemma 5 we get the proof.

□

This theorem allows us to use iteration methods in order to find the solutions of Eq. (48) and construct the resolvent of the operator $L^{(a)}$.

C. Scattering matrix

In order to discuss scattering for the pair of operators $L_0^{(a)}$ and $L^{(a)}$ it is enough to impose the condition[28]

$$\left|\int_{\Omega_a}q(x+2a\mathbf{m})dx\right|\leqslant\frac{C}{1+|\mathbf{m}|^{2+\varepsilon}},\quad\varepsilon>0.$$

By construction it is equivalent to the following condition on the potential $V(\mathbf{X})$:

$$\left| \int_{K_a} V(\mathbf{x}+2a\mathbf{m})d^N\mathbf{x} \right| \leqslant \frac{C}{1+|\mathbf{m}|^{2+\varepsilon}}.$$

Under this condition we will calculate the scattering matrix for the pair of operators $L_0^{(a)}$, $L^{(a)}$. We start with the equation for the T-matrix:[28]

$$T(z)=q_a-q_aR_0(z)T(z), \tag{56}$$

which can be solved in the same manner as the Lippmann–Schwinger equation (35) for the resolvent. Indeed, substituting Eq. (29) into Eq. (56) we have for the tensor elements of the kernel of the T-matrix,

$$T^{jj'}_{\mathbf{mm}'}(x,x',z)=\nu^{-2}V_{\mathbf{m}}\delta(x)C^{jj'}_{\mathbf{mm}'}(x',z), \tag{57}$$

where

$$C^{jj'}_{\mathbf{mm}'}(x,z)\overset{\text{def}}{=}\nu^{-2}\delta(x-x')\,\delta_{\mathbf{mm}'}\delta_{jj'}-\sum_{\mathbf{n}}\sum_{l}\int_0^a dy R^{(0)jl}_{\mathbf{mn}}(0,y,z)T^{lj'}_{\mathbf{nm}'}(y,x,z).$$

Hence $C^{jj'}_{\mathbf{mm}'}(x,z)$ obeys the following equation:

$$C^{jj'}_{\mathbf{mm}'}(x,z)=\nu^{-2}\delta(x)\,\delta_{\mathbf{mm}'}\delta_{jj'}-\sum_{\mathbf{n}}\sum_{l}V_{\mathbf{n}}R^{(0)jl}_{\mathbf{mn}}(0,0,z)C^{lj'}_{\mathbf{mn}'}(x,z). \tag{58}$$

Using the fact that the coefficients $R^{(0)jl}_{\mathbf{mn}}(0,0,z)$ do not depend on indices j,l, we denote

$$J^l_{\mathbf{mn}}(x,z)\overset{\text{def}}{=}\sum_{j=1}^{2N}C^{(0)jl}_{\mathbf{mn}}(x,z) \tag{59}$$

and get

$$Q^l_{\mathbf{mm}'}(x,z)=\delta(x)\,\delta_{\mathbf{mm}'}-N\sum_{\mathbf{n}}\mathcal{A}_{\mathbf{mn}}V_PQ^l_{\mathbf{nm}'}(x,z). \tag{60}$$

This equation shows that $J^l_{\mathbf{mm}'}(x,z)$ does not depend on the index l. Therefore it can be omitted and we get the equation

$$\sum_{\mathbf{n}}(\delta_{\mathbf{mn}}+N\mathcal{A}_{\mathbf{mn}}V_P)J_{\mathbf{nm}'}(x,z)=\nu^{-2}\delta(x)\,\delta_{\mathbf{mm}'}, \tag{61}$$

or in tensor form,

$$(I+N\mathcal{A}(z)\hat{V})J(x,z)=\nu^{-2}\delta(x)I. \tag{62}$$

By Eqs. (56)–(60) tensor elements of the T-matrix can be expressed in terms of the solution of Eq. (62) as

$$T^{jj'}_{\mathbf{mm}'}(x,x',z)=\nu^{-2}\delta(x)\,\delta(x')V_{\mathbf{m}}\left(\delta_{\mathbf{mm}'}\delta_{jj'}-\sum_{\mathbf{n}}\mathcal{A}_{\mathbf{mn}}(z)V_{\mathbf{n}}(I+N\mathcal{A}(z)\hat{V})^{-1}_{\mathbf{nm}'}\right)$$

$$=\nu^{-2}\delta(x)\,\delta(x')V_{\mathbf{m}}(\delta_{mm'}\delta_{jj'}-(\mathcal{A}(z)\hat{V}(I+N\mathcal{A}(z)\hat{V})^{-1})_{\mathbf{mm}'}).$$

Introducing the notation

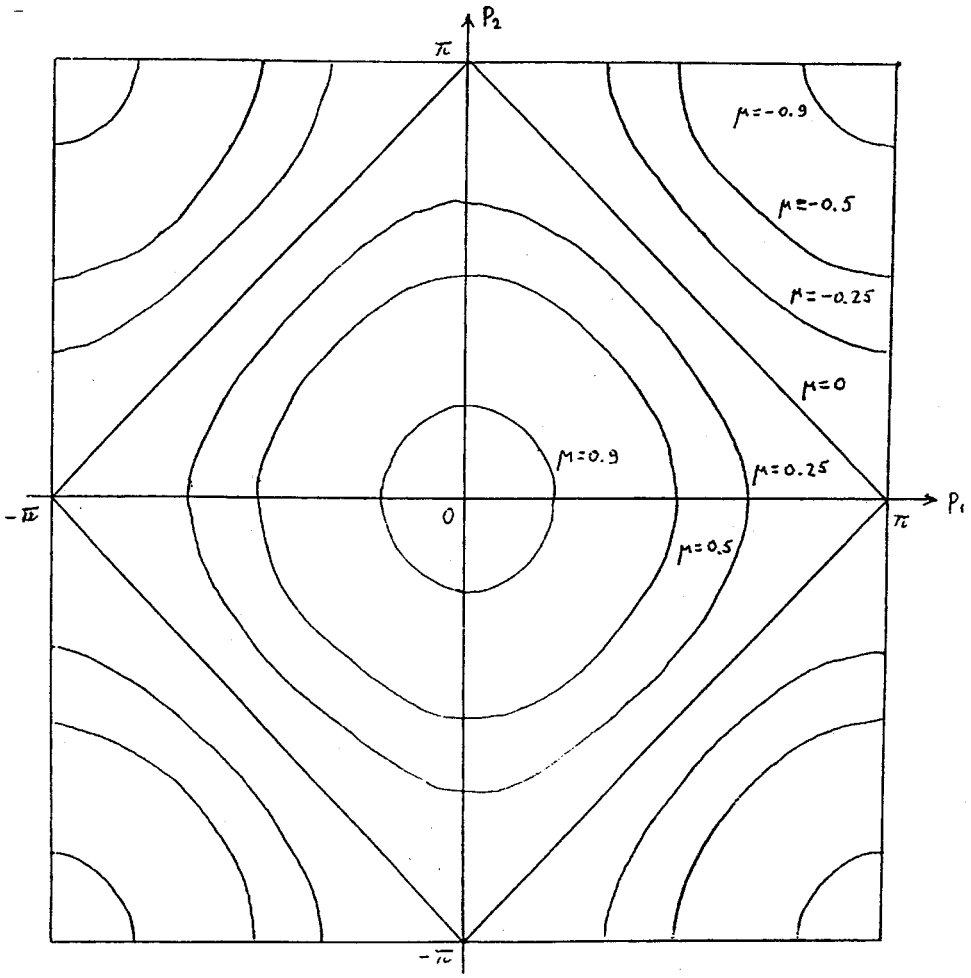

FIG. 2. Isoenergetic surfaces $\mu(P)=\text{const}$ of the Hamiltonian $L^{(a)}$ in the quasimomentum torus $\mathbf{T}^N$ in case $N=2$.

$$\mathcal{D}(z)\overset{\text{def}}{=}\mathcal{A}(z)\hat{V}(I+N\mathcal{A}(z)\hat{V})^{-1}, \tag{63}$$

we can write down the latter formula as

$$T^{jj'}_{\mathbf{mm}'}(x,x',z)=\nu^{-2}\delta(x)\,\delta(x')V_{\mathbf{m}}(\delta_{\mathbf{mm}'}\delta_{jj'}-\mathcal{D}_{\mathbf{mm}'}(z)). \tag{64}$$

Knowing the kernel of the T-matrix we can construct the scattering matrix in the standard way.[28] In order to construct the scattering matrix for a fixed energy, let us define the isoenergetic surface $\mathcal{T}_\lambda\subset\mathbf{T}^N$ for any fixed energy $\lambda>0$ as follows. The set of all possible quasimomenta P for the fixed energy λ:

$$\mathcal{T}_\lambda\overset{\text{def}}{=}\{P\in\mathbf{T}^N:\mu(P)=\cos 2a\sqrt{\lambda/N}\},$$

where $\mu(P)=(1/N)\,\Sigma_{j=1}^{N}\cos p_j$. Isoenergetic surfaces in case $N=2$ are shown in Fig. 2. Due to Eq. (3) with $\gamma=0$ for a fixed energy $\lambda=Nk_n^2(P)$ we have $\cos 2ak_n(P)=\mu(P)$. Let us fix some energy $\lambda>0$ and suppose that $P,P'\in\mathcal{T}_\lambda$. The corresponding unit vectors are denoted by $\hat{P},\hat{P}'$.

The corresponding wave functions of the unperturbed Hamiltonian $L_0^{(a)}$ given by Eq. (23) we denote by Ξ_λ^P, $\Xi_\lambda^{P'}$. We can calculate the kernel of the scattering operator in the unperturbed representation as[28]

$$S_\lambda(P,P') = \delta(\hat{P}-\hat{P}') - 2\pi i \langle T(\lambda+i0)\Xi_\lambda^{P'}, \Xi_\lambda^P \rangle_{\mathcal{H}_a}.$$

For fixed energy $\lambda = Nk_n^2(P)$ we can write

$$S_{nn'}(P,P') = \delta_{nn'}[\,\delta(\hat{P}-\hat{P}') - 2i\pi\delta(\mu(P)-\mu(P'))\langle T(Nk_n^2(P)+i0)\Xi_{Nk_n^2}^{P'}, \Xi_{Nk_n^2}^P\rangle_{\mathcal{H}_a}]. \tag{65}$$

This leads to the following statement.

Theorem 5: *Under the condition of the existence of the scattering matrix for the pair of operators* $L_0^{(a)}$, $L_0^{(a)}+q_a$, *its matrix elements* $S_{nn'}(P,P')$ *for fixed energy* $\lambda = Nk_n^2(P)$ *are given by the following formula*:

$$S_{nn'}(P,P') = \delta_{nn'}\Bigg[\,\delta(\hat{P}-\hat{P}') - \delta(\mu(P)-\mu(P'))\Bigg(\frac{2\pi i}{a\nu}\sum_{\mathbf{m}} V_{\mathbf{m}} e^{-i(P-P',\mathbf{m})} + \frac{2\pi i N}{a\nu}\sum_{\mathbf{m}} V_{\mathbf{m}} e^{-i(P,\mathbf{m})}\sum_{\mathbf{m}'} \mathcal{D}_{\mathbf{m}\mathbf{m}'}(Nk_n^2(P)+i0)e^{i(P',\mathbf{m}')}\Bigg)\Bigg], \tag{66}$$

where $\mathcal{D}_{\mathbf{m}\mathbf{m}'}(z)$ *are the tensor elements of the tensor* $\mathcal{D}(z)$ *given by Eq. (64).*

The proof is obvious by substituting Eqs. (41), (64) into Eq. (65).

□

A natural question appears. Is the above constructed scattering matrix for the system on the graph Γ_a related to the scattering matrix associated with the original N-dimensional Schrödinger dynamics? In order to clarify this question one has to construct the ''representative'' of the plane wave $e^{i(Q,X)}$; $Q,X \in \mathbf{R}^N$, on the graph Γ_a, observe its scattering under the evolution on Γ_a, and, finally, associate the resulting scattered waves in Γ_a with scattered waves in $\mathbf{R}^N$.

We propose the following procedure. As the main aim in the description of scattering processes is to obtain the angular distribution of the scattered wave given the incoming plane wave, we have to establish a correspondence between the direction of the propagation of the plane wave $e^{i(Q,\mathbf{X})}$ and of its Γ_a-''representative.'' In this context, the correspondence between the angle $\hat{Q} = Q/|Q|$ and the direction of the wave propagation in Γ_a should be kept intact. The following steps meet this requirement.

(1) Given the $\mathbf{R}^N$-plane wave $e^{i(Q,\mathbf{X})}$ we calculate the quasimomentum $P_Q = 2aQ(\mathrm{mod}\,2\pi)$.
(2) We calculate the function $\mu(P_Q) = (1/N)\sum_{j=1}^N \cos(P_Q)_j = (1/N)\sum_{j=1}^N \cos 2aq_j$. In case $\mu(P_Q)<0$ or $\mu(P_Q)>0$ (as illustrated in Fig. 3 for $N=2$) we fix the direction of the quasimomentum P_Q, i.e., the ray Λ_Q with the origin in the point $P_+ = \{p_j = 0\}_{j=1}^N$ [for $\mu(P_Q)>0$] or in the point $P_- = \{p_j = \pi\}_{j=1}^N$ [for $\mu(P_Q)>0$] and containing the point P_Q.
(3) Given the $\mathbf{R}^N$-dynamics energy $E = |Q|^2$, we introduce the value $\tilde{\mu}_Q \overset{\text{def}}{=} \cos 2a|Q|$. Then, for any quasimomentum $P \in \tilde{\mathcal{T}}_Q$ on the isoenergetic surface $\tilde{\mathcal{T}}_Q = \{P:\mu(P) = \tilde{\mu}_Q\}$ (see Fig. 3) we have the correspondence between the $\mathbf{R}^N$-energy and the Γ_a-energy.
(4) We find the intersection point $\tilde{P}_Q = \tilde{\mathcal{T}}_Q \cap \Lambda_Q$. The quasimomentum $\tilde{P}_Q$ corresponds to the Γ_a-energy equal to $|Q|^2$ (because $\tilde{P}_Q \in \tilde{\mathcal{T}}_Q$), if the number of the mode n: $E = |Q|^2 = Nk_n^2(\tilde{P}_Q)$ is chosen properly (see step 5). On the other hand, it corresponds to the same direction of the wave propagation as the $\mathbf{R}^N$-plane wave $e^{i(Q,\mathbf{X})}$ (because $\tilde{\Theta}_Q \in \Lambda_Q$).

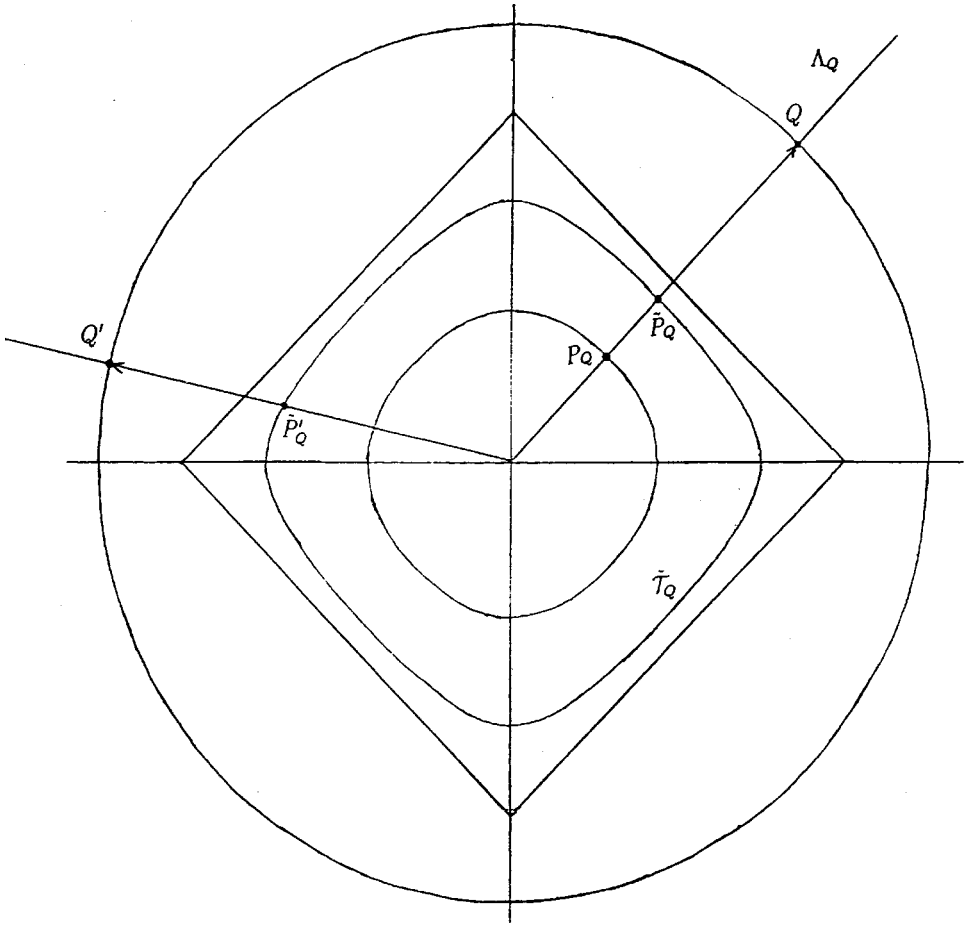

FIG. 3. Procedure for the approximation of the scattering of N-dimensional plane wave $e^{i(Q,\mathbf{X})}$ through the scattering process on the graph Γ_a.

(5) Given the $\mathbf{R}^N$-dynamics energy $E=|Q|^2$, we calculate the number of the mode of the corresponding wave function in Γ_a:

$$n_Q=\left[\frac{2a}{\pi}|Q|\right].$$

(6) ' We take the corresponding eigenfunction $\Xi^{\tilde{P}_Q}_{Nk^2_{n_Q}}(x)$ of the fiber Hamiltonian $L_0^{(a)\tilde{P}_Q}$ and consider the function

$$\Xi^{\tilde{P}_Q}_{Nk^2_{n_Q}}(x)e^{i(\mathbf{m},\tilde{P}_Q)}, \tag{67}$$

as the ''representative'' of the $\mathbf{R}^N$-plane wave $e^{i(Q,\mathbf{X})}$ on the graph Γ_a. By construction, this wave propagates in the same direction as $e^{i(Q,\mathbf{X})}$ and has the same Γ_a-energy $Nk^2_{n_Q}(\tilde{P}_Q)=|Q|^2$ as the $\mathbf{R}^N$-energy of the plane wave $e^{i(Q,\mathbf{X})}$.

(7) We consider the scattering of the wave (67) in the graph Γ_a:

$$S:\Xi^{\tilde{P}_Q}_{Nk^2_{n_Q}}(x)e^{i(\mathbf{m},\tilde{P}_Q)}\mapsto\int_{\tilde{\mathcal{T}}_Q}S_{n_Qn_Q}(\tilde{P}'_Q,\tilde{P}_Q)\Xi^{\tilde{P}'_Q}_{Nk^2_{n_Q}}(x)e^{i(\mathbf{m},\tilde{P}'_Q)}d\tilde{P}'_Q.$$

The scattered wave thus obtained is a composition of the waves $\Xi^{\tilde{P}'_Q}_{Nk^2_{n_Q}}(x)e^{i(\mathbf{m},\tilde{P}'_Q)}$, $\tilde{P}'_Q\in\tilde{\mathcal{T}}_Q$ (see Fig. 3).

(8) For every $\tilde{P}'_Q \in \tilde{\mathcal{T}}_Q$ we calculate the momentum $Q' = \tilde{P}'_Q(|Q|/|\tilde{P}'_Q|)$ (see Fig. 3) and construct the $\mathbf{R}^N$-plane wave $e^{i(Q',\mathbf{X})}$. It propagates in the same direction as the Γ_a-wave $\Xi^{\tilde{P}'_Q}_{Nk^2_{n_Q}}(x)e^{i(\mathbf{m},\tilde{P}'_Q)}$ and has the energy $|Q'|^2 = |Q|^2$.

(9) We define the action of the approximate scattering matrix for the $\mathbf{R}^N$-dynamics as

$$\mathbf{S}_a^{approx}: e^{i(Q,\mathbf{X})} \mapsto \int_{\tilde{\mathcal{T}}_Q} S_{n_Q n_Q}(\tilde{P}'_Q, \tilde{P}_Q) e^{i|Q|(\tilde{P}'_{Q'}|\tilde{P}'_Q|,\mathbf{X})}\, d\tilde{P}'_Q. \tag{68}$$

This 9-step procedure is necessary. Indeed a simple restriction of the plane wave $e^{(Q,\mathbf{X})}$ to the graph Γ_a,

$$e^{i(Q,X)}|_{\Gamma_a} = v_Q(x)e^{i2a(\mathbf{m},P_Q)}, \tag{69}$$

where $P_Q = 2aQ(\mathrm{mod}\, 2\pi)$, i.e., $(P_Q)_l = 2aq_l(\mathrm{mod}\, 2\pi)$, $l = 1,2,\ldots,N$, and $v^j_Q(x_j) = e^{iq_j x_j}$, brings the following difficulty. Function (69) is associated with the quasimomentum $P_Q = 2aQ(\mathrm{mod}2\pi)$, but it corresponds to a wave packet containing components with different energies. Indeed, one can decompose the function $v_Q(x)$ defined on the fundamental subgraph Ω_a in terms of the eigenfunctions of the fiber Hamiltonian $L_0^{(a)P_Q}$:

$$v_Q(x) = \sum_{n\geqslant 0} c^n_Q \Xi^{P_Q}_{Nk^2_n}(x),$$

where

$$c^n_Q = \langle v_Q(x), \Xi^{P_Q}_{Nk^2_n}\rangle_{L_2(\Omega_a)},$$

and Eq. (69) can be rewritten as

$$e^{i(Q,X)}|_{\Gamma_a} = \sum_{n\geqslant 0} c^n_Q \Xi^{P_Q}_{Nk^2_n}(x)e^{i2a(\mathbf{m},P_Q)}. \tag{70}$$

This is a wave packet with the components all having the same quasimomentum $P_Q = 2aQ(\mathrm{mod}\, 2\pi)$ but different energies $Nk^2_n(P_Q)$. However, all these energies may be different from the energy $|Q|^2$ of the plane wave $e^{i(Q,\mathbf{X})}$ if the latter is considered in the frame of the original N-dimensional Schrödinger dynamics. Indeed, this energy equals

$$|Q|^2 = \sum_{l=1}^{N} q_l^2, \tag{71}$$

while the energies $Nk^2_n(\Theta_P)$ are determined by the equation

$$\cos 2ak_n(P_Q) = \mu(P_Q) = \frac{1}{N}\sum_{l=1}^{N} \cos(P_Q)_l = \frac{1}{N}\sum_{l=1}^{N} \cos 2aq_l,$$

i.e.,

$$Nk^2_n(P_Q) = \frac{N}{4a^2}\left((-1)^n \mathrm{Arccos}\left(\frac{1}{N}\sum_{l=1}^{N} \cos 2aq_l\right) + 2\pi\left[\frac{n+1}{2}\right]\right)^2. \tag{72}$$

Obviously, the right hand sides of Eqs. (71) and (72) are different for almost all sets $\{q_l\}$. Therefore, if we have the same direction of the wave propagation in $\mathbf{R}^N$ and in Γ_a [i.e., the quasimomentum $P = P_Q = 2aQ(\mathrm{mod}\, 2\pi)$], we cannot, in the general case, have the correspon-

dence of the energies. This is a manifestation of the fact that the relations between energy and momentum (quasimomentum) are not the same for the dynamics in $\mathbf{R}^N$ and in Γ_a. Therefore, if one takes the function (69) as the ''representative'' of the plane wave $e^{i(Q,\mathbf{X})}$, the scattering process in Γ_a will not preserve the energy of the $\mathbf{R}^N$-dynamics. It makes it difficult to approximate in this way the $\mathbf{R}^N$-scattering process by the Γ_a-scattering process. This problem does not appear if one uses the 9-step procedure described above.

Three families of exact solutions for two-dimensional gravity minimally coupled to electrodynamics are obtained in the context of $\mathcal{R}=T$ theory. It is shown, by supersymmetric formalism of quantum mechanics, that the quantum dynamics of a neutral bosonic particle on static backgrounds with both varying curvature and electric field is exactly solvable. © *2001 American Institute of Physics.*
[DOI: 10.1063/1.1343093]

I. INTRODUCTION

It is well-known that Einstein's gravitational theory in two-dimensions is trivial. This is because the Einstein tensor is identically zero for all two-dimensional metrics. Consequently, the Einstein equations require the energy-momentum tensor to be vanished and this result is inconsistent with some nontrivial matter configurations.[1] Also, in the mathematical language the Euler class χ of a compact and two-dimensional manifold M with boundary ∂M is defined by[2]

$$2\pi\chi=\frac{1}{2}\int_M d^2x\sqrt{-g}\mathcal{R}-\int_{\partial M}\sqrt{-g}K,$$

where $\mathcal{R}$ is the Ricci scalar and K is the trace of the extrinsic curvature K_{ij}. Therefore, if we demand more useful information on a two-dimensional space–time a different gravitational action is required. An interesting action for two-dimensional gravity has been derived in the context of string theory.[3] However, despite the string theory approach it has been recently shown that gravity in two-dimensions is not necessarily trivial.[1,4] Of particular interest among these new approaches is the $\mathcal{R}=T$ theory of two-dimensional gravity in which the scalar curvature $\mathcal{R}$ is equal to the trace of the energy-momentum tensor T.[1,4] This theory has provided some remarkable classical and semiclassical results such as: Well defined Newtonian limit,[5] black hole solutions,[4,6] gravitational radiation, Friedmann–Robertson–Walker (FRW) cosmology, gravitational collapse,[7] black hole radiation,[8] and their thermodynamical properties.[4] On the other hand, there are some similarities between four-dimensional and two-dimensional gravity. Therefore, the study of classical and quantum behavior of $\mathcal{R}=T$ theory of two-dimensional gravity may help us to get a deeper insight into the problems involved in four-dimensional gravity.

In this paper (We use the units in which $\hbar=c=8\pi G=1$.), we find families of exact solutions of two-dimensional $\mathcal{R}=T$ type gravity minimally coupled to electrodynamics. Then, we investigate the quantum dynamics of a neutral bosonic particle on the obtained class of static solutions by using the supersymmetric quantum mechanics and obtain the energy spectrum and eigenfunctions exactly. In Secs. II and III, we introduce the model and obtain three families of exact solutions for: (a) two-dimensional manifolds with constant curvature and varying electric field, (b) two-

a)Author to whom correspondence should be addressed. Electronic mail: f-darabi@cc.sbu.ac.ir

dimensional manifolds with varying curvature and constant electric field, and (c) two-dimensional manifolds with both varying curvature and electric field. Then, in Sec. IV the quantum dynamics of a neutral bosonic particle on the obtained static backgrounds with both varying curvature and electric field is investigated in the context of supersymmetric quantum mechanics. The paper ends with a brief conclusion.

II. THE MODEL

It is well-known that in two dimensions one can write locally the metric in the form[9]

$$g(X)=e^{\phi(X)}\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}, \tag{1}$$

where $X:=(t,x)$ and $\phi(X)$ is a scalar field. The Ricci scalar for the metric (1) is given by

$$\mathcal{R}(X)=e^{-\phi(X)}(\partial_x^2-\partial_t^2)\phi(X). \tag{2}$$

Now, we put the matter as a Maxwell field with strength tensor $F_{\mu\nu}(\mu,\nu=0,1)$ on the above two dimensional Lorentzian geometry. We are interested in $\mathcal{R}=T$ theory of two-dimensional gravity in which ''T'' is the trace of electromagnetic energy-momentum tensor given by

$$T_{\alpha\beta}=-\epsilon(F_{\alpha\mu}F^{\mu}_{\beta}-\tfrac{1}{4}g_{\alpha\beta}F_{\lambda\sigma}F^{\lambda\sigma}), \tag{3}$$

where $|\epsilon|=1$ and its sign is arbitrary. The $T_{\alpha\beta}$ in Eq. (3) is the special case of one which was already considered by Mann *et al.*[6] for charged point particles.

The coupled Einstein–Maxwell field equations are as follows:[6]

$$\mathcal{R}=T, \tag{4}$$

$$\frac{1}{\sqrt{-g}}\partial_\nu(\sqrt{-g}F^{\mu\nu})=J^\mu, \tag{5}$$

where the first is the Einstein gravity in two-dimensions and the second is the Maxwell equation in two-dimensional curved space–time from which the current conservation is easily derived. We note that the electromagnetic field $F_{\mu\nu}$ in two-dimensions has only one independent nonzero component as electric field namely

$$F_{tx}=E(X). \tag{6}$$

Therefore, considering the form of strength tensor $F_{\mu\nu}$ in Eq. (6) the trace of energy-momentum tensor (3) is obtained as

$$T=\epsilon e^{-2\phi}E^2. \tag{7}$$

Substituting the scalar curvature (2) and the trace (7) into Eq. (4) we have

$$(\partial_t^2-\partial_x^2)\phi(X)+\epsilon e^{-\phi(X)}E^2(X)=0. \tag{8}$$

III. THREE FAMILIES OF EXACT SOLUTIONS

Now, we classify the solutions of Einstein–Maxwell field equations in three categories.

A. 2D manifolds with constant scalar curvature and varying electric field

Assuming the constant scalar curvature $\mathcal{R}(X)=\mathcal{R}_0$ and considering Eq. (4) we find the varying electric field as

$$E(X)=\pm\sqrt{\frac{\mathcal{R}_0}{\epsilon}}e^{\phi(X)}. \tag{9}$$

In Eq. (9) the parameter ϵ is suitably chosen so that for negative or positive scalar curvature $\mathcal{R}_0$ the electric field is always a real quantity. In this way, for $\mathcal{R}_0<0$ (one-sheet hyperboloid or a half plane) and for $\mathcal{R}_0>0$ (a strip or a half plane) we should correspond $T<0$ and $T>0$, respectively. Using (9), Eq. (8) becomes

$$(\partial_t^2-\partial_x^2)\phi(X)+\mathcal{R}_0 e^{\phi(X)}=0, \tag{10}$$

which is known as Liouville equation.[10] It is worth noting that Eq. (10) was considered, at first, in the study of *pure mathematical theory* of two-dimensional surfaces with constant curvature and is derived here through the *physical* $\mathcal{R}=T$ theory of gravity in two-dimensions with constant curvature. Of course, it is not so surprising because in the matter coupled gravity theory here, with dynamical variables $g_{\mu\nu},F_{\mu\nu}$, and ϕ, the condition $\mathcal{R}=T$ may give rise to a dynamical equation in gravity (geometry) sector with variables $\mathcal{R},\phi$, and by taking a constant value for $\mathcal{R}$ it falls into the Liouville's mathematical context. In other words, Eq. (10) is the Liouville equation in which the constancy of curvature is introduced through the physical theory as $\mathcal{R}=T=\text{Const}$.
General solutions of Eq. (10) is given by[11]

$$\phi(x^+,x^-)=\log\frac{8A'_+(x^+)A'_-(x^-)}{|\mathcal{R}_0|\left[A_+(x^+)-\dfrac{|\mathcal{R}_0|}{\mathcal{R}_0}A_-(x^-)\right]^2}, \tag{11}$$

where

$$A'_\pm:=\frac{dA_\pm}{dx^\pm},\quad x^\pm=t\pm x.$$

Substituting the solutions for ϕ, Eq. (11), into Eqs. (1) and (9) the metric solution and electric field are explicitly obtained with respect to arbitrary functions $A_\pm(x^\pm)$ as

$$ds^2=\frac{8A'_+(x^+)A'_-(x^-)}{|\mathcal{R}_0|\left[A_+(x^+)-\dfrac{|\mathcal{R}_0|}{\mathcal{R}_0}A_-(x^-)\right]^2}dx^+dx^-, \tag{12}$$

$$E(x^+,x^-)=\pm\sqrt{\frac{\mathcal{R}_0}{\epsilon}}\frac{8A'_+(x^+)A'_-(x^-)}{|\mathcal{R}_0|\left[A_+(x^+)-\dfrac{|\mathcal{R}_0|}{\mathcal{R}_0}A_-(x^-)\right]^2}. \tag{13}$$

Using Eq. (5) one can easily show that the covariant current J^μ corresponding to the solutions (12), (13) vanishes. The metric (12) describes a family of two-dimensional Lorentzian manifolds with the same constant curvature $\mathcal{R}_0$. In Ref. 11 it was shown that all two-dimensional Lorentzian manifolds with the same constant curvature are locally isometric. Therefore, as a result, it may be said that all metrics defined by (12) are locally isometric.

B. 2D manifolds with varying scalar curvature and constant electric field

In this case, by assumption of a constant electric field as $E(X)=E_0$ Eq. (8) is written as

$$(\partial_t^2-\partial_x^2)\phi(X)+\epsilon E_0^2 e^{-\phi(X)}=0. \tag{14}$$

As before, one can show that general solution to Eq. (14) is given by

$$\phi(x^+,x^-)=-\log\frac{8B'_+(x^+)B'_-(x^-)}{E_0^2\left[B_+(x^+)+\frac{1}{\epsilon}B_-(x^-)\right]^2}, \tag{15}$$

where $B_\pm(x^\pm)$ are arbitrary functions of their arguments. Considering the solution (15) the metric solution and the scalar curvature are given as

$$ds^2=\frac{E_0^2\left[B_+(x^+)+\frac{1}{\epsilon}B_-(x^-)\right]^2}{8B'_+(x^+)B'_-(x^-)}dx^+dx^-, \tag{16}$$

$$\mathcal{R}(x^+,x^-)=\frac{64\epsilon}{E_0^2}\left[\frac{B'_+(x^+)B'_-(x^-)}{\left[B_+(x^+)+\frac{1}{\epsilon}B_-(x^-)\right]^2}\right]^2. \tag{17}$$

The current **J** corresponding to the solutions (16) and (17) has the components

$$J^\pm=\mp 2E_0e^{-2\phi}\partial_\mp\phi, \tag{18}$$

where the functions ϕ are given by Eq. (15).

C. 2D manifolds with varying scalar curvature and varying electric field

In this case considering Eqs. (2) and (8) the following relation between the scalar curvature and the electric field is obtained

$$E(X)=e^{\phi(X)}\sqrt{\frac{\mathcal{R}(X)}{\epsilon}}. \tag{19}$$

For each given function $\phi(X)$ one can find, using Eqs. (1), (2), and (19), the corresponding metric solution and electric field. Moreover, the current which produces the electric field (19) is obtainable by Eq. (5). For example, for ϕ as merely a function of spatial coordinate x, namely for a static space–time, we find $J^x=0$ and that the static electric field is produced by J^t component. The importance of two-dimensional manifolds with both varying scalar curvature and electric field in the static case, as will be shown in the next section, is that the quantum dynamics of a neutral bosonic particle on these manifolds is solvable exactly by using the *Supersymmetric quantum mechanics* and *Shape invariance*.

IV. QUANTUM DYNAMICS OF A NEUTRAL BOSONIC PARTICLE ON STATIC 2D MANIFOLDS WITH VARYING SCALAR CURVATURE AND VARYING ELECTRIC FIELD

Quantization of particle dynamics in two-dimensions with constant curvature for both massive and massless particles was investigated in Ref. 11. Here, our aim is to quantize the particle dynamics on the manifold discussed in Sec. III C of the previous section in the static case. Quantum dynamics of a massive neutral bosonic particle is described by two-dimensional Klein–Gordon equation

$$\frac{1}{\sqrt{-g}}\partial_\alpha(\sqrt{-g}g^{\alpha\beta}\partial_\beta)\Psi(X)+m^2\Psi(X)=0,$$

where m is the mass of the particle. Assuming the scalar wave function $\Psi(X)$ as

$$\Psi(x,t)=e^{-i\mathcal{E}t}\psi(x),$$

the Klein–Gordon equation on the two-dimensional (2D) manifold obtained by the metric (1) in the static case $[\phi=\phi(x)]$ becomes

$$\left[-\frac{d^2}{dx^2}+m^2(e^{\phi(x)}-1)\right]\psi(x)=(\mathcal{E}^2-m^2)\psi(x). \tag{20}$$

Equation (20) is mathematically equivalent to one-dimensional time-independent Schrödinger equation. We use the supersymmetric quantum mechanics to solve this equation. In supersymmetric quantum mechanics the *creation* and *annihilation* operators are defined, respectively, as[12,13]

$$\mathcal{A}^{\dagger}:=-\frac{d}{dx}+W(x),$$

$$\mathcal{A}:=\frac{d}{dx}+W(x),$$

where $W(x)$ is called the *Superpotential*. The supersymmetric *Partner* Hamiltonians namely $H_+=\mathcal{A}\mathcal{A}^{\dagger}, H_-=\mathcal{A}^{\dagger}\mathcal{A}$ have the following form:

$$H_{\pm}=-\frac{d^2}{dx^2}+V_{\pm}(x) \tag{21}$$

where the partner potentials $V_{\pm}(x)$ are given with respect to the superpotential $W(x)$ as

$$V_{\pm}(x)=W^2(x)\pm\frac{dW(x)}{dx}. \tag{22}$$

If the partner potentials $V_{\pm}(a_0,x)$ (with a_0 as a constant parameter) are related according to the relation

$$V_+(a_0,x)=V_-(a_1,x)+R(a_1), \tag{23}$$

then they are called *Shape-invariant* potentials.[14] In Eq. (23), $a_1=F(a_0)$ is a new set of parameters and the term $R(a_1)$ is x independent. For shape-invariant potentials given by Eq. (23) the spectrum and eigenfunctions are obtained by algebraic approach.[12] Comparing the left-hand side of Eq. (20) with Eq. (21) we deduce

$$m^2(e^{\phi_{\pm}(x)}-1)=V_{\pm}(x), \tag{24}$$

which relates the conformal factors $e^{\phi_{\pm}(x)}$ to the partner potentials $V_{\pm}(x)$. In fact, the supersymmetry and conformal degree of freedom let us to have two sets of two-dimensional static manifolds with varying curvature

$$ds_{\pm}^2=e^{\phi_{\pm}(x)}(dt^2-dx^2),$$

together with static electric fields $E_{\pm}(x)$. For example, by a suitable choice for the conformal factor as

$$e^{\phi_-(x)}=\frac{\omega}{2m^2}\left(\frac{\omega}{2}x^2-1\right)+1, \tag{25}$$

we may consider the following superpotential

$$W(x)=\tfrac{1}{2}\omega x, \quad \omega>0, \tag{26}$$

where ω is a quantity with the dimension of $(mass)^2$ or $(length)^{-2}$ in the units $\hbar=c=1$. Now, in order to study the one set of solutions we calculate the partner potential $V_-(x)$, by using Eq. (24), as

$$V_-(x)=\frac{\omega}{2}\left(\frac{\omega}{2}x^2-1\right). \tag{27}$$

Using Eq. (24) we can obtain the energy and wave function[12,13]

$$\mathcal{E}_n^2=m^2+n\omega, \quad n=0,1,2,\ldots,$$

$$\psi_n(x)=C_n\exp\left(-\frac{\omega}{4}x^2\right)H_n\left(\sqrt{\frac{\omega}{2}}x\right), \tag{28}$$

where C_n is the normalization constant. The static metric solution and electric field corresponding to the conformal factor given by (25) are as follows:

$$ds_-^2=\left[1+\frac{\omega}{2m^2}\left(\frac{\omega}{2}x^2-1\right)\right](dt^2-dx^2), \tag{29}$$

$$E_-(x)=\sqrt{\frac{\omega^2}{2m^2\epsilon}\frac{1-\frac{\omega}{2m^2}\left(\frac{\omega}{2}x^2+1\right)}{1+\frac{\omega}{2m^2}\left(\frac{\omega}{2}x^2-1\right)}}. \tag{30}$$

The current corresponding to the electric field (30) has the nonvanishing component

$$J^t(x)=-e^{-\phi_-(x)}\partial_x[e^{-\phi_-(x)}E_-(x)]. \tag{31}$$

It is easy to show that for $1-2m^2/\omega\geqslant 0$ the metric (29) is degenerate at

$$x=\pm\sqrt{\frac{2}{\omega}\left(1-\frac{2m^2}{\omega}\right)}. \tag{32}$$

On the other hand, by calculating the Ricci scalar corresponding to the metric (29) as

$$\mathcal{R}=\frac{\omega^2}{2m^2}\frac{1-\frac{\omega}{2m^2}-\frac{\omega^2x^2}{4m^2}}{\left[1+\frac{\omega}{2m^2}\left(\frac{\omega}{2}x^2-1\right)\right]^3}, \tag{33}$$

we find that the geometry defined by (29) has also essential singularities at the points (32). The general existence of these *naked* singular points indicates that the particle dynamics is exactly solvable in the part of the manifold not including these singular points. Alternatively, it seems possible to avoid the singular behavior only in a sub-class of manifold by appropriate choices of the values on ω and m. To this end, we may restrict ourselves to the values of m and ω satisfying the relation $1-2m^2/\omega<0$, which makes the metric (29) free of singularity. Then, we have

$$\begin{cases} \mathcal{R}=0 & \text{at the points} \quad x_0^{\pm}=\pm\sqrt{-\frac{2}{\omega}\left(1-\frac{2m^2}{\omega}\right)} \\ \mathcal{R}>0 & \text{for the range} \quad x_0^-<x<x_0^+ \\ \mathcal{R}<0 & \text{for } x>x_0^+ \quad \text{and } x<x_0^- \end{cases}.$$

Finally, we point out that for each partner potential $V_+(x)$ corresponding to the conformal factor $e^{\phi_+(x)}$ we may obtain a set of static two-dimensional manifolds with varying curvature together with nonvanishing electric field with nontrivial current distribution. Obviously, the same procedure may be exactly applied for other shape-invariant potentials given by Refs. 12 and 13.

V. CONCLUDING REMARKS

In this paper we have found three families of exact solutions for two-dimensional $\mathcal{R}=T$ theory of gravity minimally coupled to electrodynamics. By the study of quantum dynamics of a neutral bosonic particle on a static two-dimensional space–time background we have shown that: *Supersymmetric formalism of quantum mechanics leads to two disjoint sets of static two-dimensional manifolds with both varying curvature and electric field*. It is possible to solve exactly the quantum dynamics of a neutral bosonic particle on these manifolds. It seems that the study of quantum dynamics of a fermionic particle in two-dimensional space–time may lead to two-dimensional Lorentzian manifolds as the solutions of 2D gravity coupled to electrodynamics and also to the quantum solvability of particle dynamics on these manifolds.[15]

(Received 5 July 2000; accepted for publication 29 November 2000)

Combined (q,h)-deformations proposed by Kupershmidt and Ballesteros–Herranz–Parashar are studied. In each case a transformation is shown to lead to an equivalent, standard q-deformation. We briefly indicate that appropriate singular limits of the same type of transformations can however lead from standard biparametric (p,q)-deformations to nonhybrid but biparametric nonstandard (g,h) ones. Finally a case of hybrid (q,h)-deformation is recalled, related to the superalgebra $GL(1|1)$. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1343881]

I. INTRODUCTION

Not only the standard q-deformation but also the nonstandard (Jordanian) h-deformation of $GL(2)$ can be considered to be well-known. In each of these domains biparametric generalizations, (p,q) and (g,h), respectively, have been studied by a number of authors. A large number of previous sources are cited in Refs. 1 and 2. The dual quantum algebras of GL_{pq} and GL_{gh} were found in Refs. 3 and 4, respectively. Here we are concerned with certain proposals for combining these two distinct types into (q,h)-deformations. They will often be denoted as hybrid ones. In particular, we analyze the results of Kupershmidt[1] and of Ballesteros–Herranz–Parashar.[2] In each case, we show that a well-defined transformation eliminates h leaving a standard q-deformation. This transformation is not an arbitrary twist, but a straightforward similarity relation performed by a tensor square of an operator. This will be demonstrated explicitly in Secs. II and III.

In Sec. II we start, in fact, with the 3-parameter (q,h,h') deformation of Ref. 1. Already at this level we are able to construct a similarity transformation reducing the formalism to a 1-parameter deformation. The surviving single parameter q' is expressed explicitly as a function

of (q,h,h'). For the case particularly advocated in Ref. 1, namely $h'=0$, one has simply $q'=q$.

In Sec. III we start by transforming the $R_{q,h}$ matrix of Ref. 2 to R_q. Then we show how their relevant results can be much better understood in the context of an explicitly presented, ''coalgebra conserving'' map. This illuminates several aspects and goes beyond the case of 4×4 matrices.

In Sec. IV we add some comments on maps and singular limits of transformations. Their nontrivial consequences[5–8] are indicated by citing appropriate references. The passage from a standard biparametric (p,q)-deformation to a nonstandard (g,h) one is presented in this context.

In Sec. V we arrive (at last) to a hybrid (q,h)-deformation where h cannot be transformed away. This turns out to be a hybrid deformation of the superalgebra $GL(1|1)$, already studied in Ref. 9. It is located as the case $R_{H1.2}$ in the classification of 4×4 R-matrices in Ref. 10, which we briefly recall.

Finally we would like to come back to Secs. II and III. Instead of briefly stating the equivalence $(q,h)\rightarrow(q)$, we have chosen to present our elementary analysis explicitly and in some detail. We consider this worthwhile for dissipating some confusions. Several authors have presented attractive looking hybrid deformations without noticing disguised equivalences. We ourselves devoted time and effort to their study before reducing them to usual deformations. We hope that our analysis will create a more acute awareness of traps in this domain.

II. KUPERSHMIDT'S (q,h,h') AND (q,h) DEFORMATIONS

We start by noting that the group relations given by the set of equations (5) of Ref. 1 can be written as

$$\begin{aligned} ca&=ac, \quad bd=db,\\ cb&=qbc-hac-h'db,\\ ad&=da+(q-1)bc-hac-h'db,\\ qba&=ab+ha^2+h'b^2-h(da-bc),\\ cd&=q\,dc-hc^2-h'd^2+h'(da-bc). \end{aligned} \tag{II.1}$$

From the second and the third equations of (II.1) one obtains

$$ad-qbc+hac+h'bd=da-bc=ad-cb. \tag{II.2}$$

Substituting from (II.2) the l.h.s. for $(da-bc)$ in the fourth and fifth equations of (II.1) one gets back exactly (5) of Ref. 1. Compared to his original version ours has the following advantages.

- Adopting the ordering,
$$d>a>b>c; \tag{II.3}$$
all the terms in increasing order $(ca,\ bd,\ldots)$ are on the l.h.s. of (II.1), whereas the square terms and terms in decreasing order are on the r.h.s. This solves the ordering problem encountered in Ref. 1 when h' was taken different from 0.
- The roles of the parameters h,h' are now more simple and symmetrical. The terms bilinear in them (like $hh'bd$ and h'^2bd) do not appear in (II.1). The corresponding complementary (upper and lower triangular) linear contributions of h and h' in the R-matrix to be presented below correspond directly to this feature [the possibility of linearizing the contributions in (II.1)].
- The simpler form of (II.1) facilitates the construction of the R-matrix form of the RTT relations. This, in turn, facilitates the construction of the explicit similarity transformation leading to a 1-parametric equivalent deformation,

$$(q,h,h') \leftrightarrow q', \tag{II.4}$$

where q' is a specific function of (q,h,h') to be presented below. We could have derived the same final results using the more complicated version of (II.1) in Ref. 1. But (II.1) is preferable.

A. Solution of the RTT constraints

Let

$$T=\begin{pmatrix} a & b \\ c & d \end{pmatrix}, \quad T_1 = T\otimes 1, \quad T_2 = 1\otimes T, \tag{II.5}$$

where a,b,c,d satisfy (II.1) and let R satisfy

$$RT_1T_2 = T_2T_1R. \tag{II.6}$$

Using (II.1) systematically, one obtains a solution involving an arbitrary parameter κ. It is

$$R=\begin{pmatrix} 1 & -h\kappa & h\kappa & 0 \\ 0 & q\kappa & (1-q\kappa) & 0 \\ 0 & (1-\kappa) & \kappa & 0 \\ 0 & -h'\kappa & h'\kappa & 1 \end{pmatrix}. \tag{II.7}$$

This does *not* satisfy the Yang–Baxter (YB) relations for all values of κ. In fact, in order that R satisfies YB the parameter κ must satisfy the following quadratic equation:

$$\kappa^2(q+hh') - \kappa(q+1) + 1 = 0. \tag{II.8}$$

(Thus, for example, the particularly simple form for $\kappa = 1$ does not satisfy YB unless $hh' = 0$.) The presence of κ at this stage permits the existence of two solutions satisfying YB constraints and related through $R \leftrightarrow R_{21}^{-1}$.

We find it convenient for the similarity transformation to be introduced below to write down the two solutions of (II.8) in the following manner:

$$\kappa = \kappa_1 = (1+\eta^{-1}h)^{-1}, \quad \kappa = \kappa_2 = (1+\eta h')^{-1}, \tag{II.9}$$

where the parameter η satisfies the quadratic

$$\eta^{-1}h + \eta h' = q - 1. \tag{II.10}$$

Our equation (II.10) is the same as the one used in Ref. 1 Eq. (15), to eliminate h' at the level of the vector basis of the Poisson bracket algebra. But the rôle of our η (corresponding to t in Ref. 1) is different. We continue to allow h' to be arbitrary and finally use a similarity transformation to arrive at an equivalent 1-parameter deformation.

B. Similarity transformation to a 1-parameter deformation

Define

$$G=\begin{pmatrix} 1 & \eta \\ \zeta & (1+\eta\zeta) \end{pmatrix}, \quad G^{-1}=\begin{pmatrix} (1+\eta\zeta) & -\eta \\ -\zeta & 1 \end{pmatrix}, \tag{II.11}$$

where the parameters η,ζ are given by

$$h=(q-1)\frac{\eta(1+\eta\zeta)}{1+2\eta\zeta},\quad h'=(q-1)\frac{\eta}{1+2\eta\zeta},\tag{II.12}$$

or

$$\eta=(2h')^{-1}((q-1)\pm\lambda),\quad \eta^{-1}=(2h)^{-1}((q-1)\mp\lambda),$$
$$\zeta=\mp h'\lambda^{-1},\quad \lambda=\sqrt{(q-1)^2-4hh'}.\tag{II.13}$$

(For $\lambda=0$, ζ diverges. This point should be approached as a limit after transforming.)

One obtains, after subtle simplifications,

$$R'=(G\otimes G)R(G^{-1}\otimes G^{-1})=\begin{pmatrix}1&0&0&0\\0&\kappa/\kappa_1&(1-\kappa/\kappa_1)&0\\0&(1-\kappa/\kappa_2)&\kappa/\kappa_2&0\\0&0&0&1\end{pmatrix},\tag{II.14}$$

where κ_1,κ_2 are given by (II.9). [In light of the remarks following (II.13), note that ζ does not appear in R', only η through κ_1 and κ_2. Reality restrictions are discussed at the end of this section.]

Now the statement leading to (II.9) is evident: for $\kappa=\kappa_1$ one gets

$$R'=\begin{pmatrix}1&0&0&0\\0&1&0&0\\0&(1-\kappa_1/\kappa_2)&\kappa_1/\kappa_2&0\\0&0&0&1\end{pmatrix},\tag{II.15}$$

the standard lower triangular form of the YB solution for the single parameter κ_1/κ_2. Similarly, for $\kappa=\kappa_2$, one gets

$$R'=\begin{pmatrix}1&0&0&0\\0&\kappa_2/\kappa_1&(1-\kappa_2/\kappa_1)&0\\0&0&1&0\\0&0&0&1\end{pmatrix},\tag{II.16}$$

the standard upper-triangular YB solution for the single parameter κ_2/κ_1. In fact (II.15) and (II.16) are related as the pair R', $(R'_{21})^{-1}$.

Let us now define

$$T'=\begin{pmatrix}a'&b'\\c'&d'\end{pmatrix},\tag{II.17}$$

such that it satisfies

$$R'T'_1T'_2=T'_2T'_1R'.\tag{II.18}$$

The group relations turn out to be independent of the parameter κ of (II.14) [just as (II.1) are independent of κ in (II.7)]. One obtains

$$c'a'=a'c',\quad b'd'=d'b',\quad c'b'=q'b'c',$$
$$a'd'=d'a'+(q'-1)b'c',\quad q'b'a'=a'b',\quad c'd'=q'd'c',\tag{II.19}$$

where we have set

$$q' = \frac{\kappa_2}{\kappa_1} = \frac{1+\eta^{-1}h}{1+\eta h'}, \tag{II.20}$$

with $\eta^{-1}h+\eta h' = q-1$. Note that

$$\begin{aligned} &\text{for } h'=0, \quad q'=q; \\ &\text{for } h=0, \quad q'=q^{-1}. \end{aligned} \tag{II.21}$$

A more complete discussion of the domains of q' follows below.

Setting $h=h'=0$ in (II.1) and adding primes one obtains (II.19).

The relations (II.19) can also be obtained from (II.1) by transforming with G. We have preferred to construct the corresponding R-matrices first from their intrinsic interest and also for elucidating the significance of the free parameter κ arising at the RTT level before imposing the YB constraints.

In Ref. 1, after setting $h'=0$ the (q,h) deformed system is reformulated using a certain ordering. Our preceding study contains the R-matrix for this case as the particular one obtained by setting in (II.7),

$$\begin{aligned} &\kappa=\kappa_2=(1+\eta h')^{-1}=1 \quad (\text{for } h'=0), \\ &\kappa_1=(1+\eta^{-1}h)^{-1}=q^{-1} \end{aligned} \tag{II.22}$$

giving

$$R' = \begin{pmatrix} 1 & -h & h & 0 \\ 0 & q & (1-q) & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}. \tag{II.23}$$

The transformation to 1-parameter form is now by

$$G = \begin{pmatrix} 1 & \eta \\ 0 & 1 \end{pmatrix}, \quad \text{with } \zeta=0, \ \eta=\frac{h}{q-1}, \tag{II.24}$$

in (II.11). The upper triangular form (II.16) now becomes

$$R' = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & q & (1-q) & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}. \tag{II.25}$$

The transformed (a,b,c,d), namely (a',b',c',d'), now satisfies (II.19) with $q'=q$.

The results for $h'=0$ can be obtained directly by starting with a (q,h) system given by (16) of Ref. 1 with one necessary correction. The group relations should be written as

$$ba = q^{-1}a(b+ha) - q^{-1}hda + q^{-2}hc(b+ha),$$

$$bd = db,$$

$$bc=q^{-1}c(b+ha),$$

$$ad=da+(1-q^{-1})cb-q^{-1}hca, \tag{II.26}$$

$$ac=ca,$$

$$dc=q^{-1}c(d+hc).$$

[The last two terms of the first equation has each an extra factor q^{-1} as compared to (16) of Ref. 1. Setting $h'=0$ in (5) of Ref. 1 and reordering one indeed gets our version. Starting directly with (II.26), the RTT relations and the YB constraints can indeed be shown to lead to (II.23). Then (II.24) eliminates h leading to (II.25) and to (II.19) with $q'=q$. The case $h=0$ can be treated quite analogously setting (taking the lower sign in (II.13) for η,ζ.]

$$\eta=0, \quad G=\begin{pmatrix} 1 & 0 \\ \zeta & 1 \end{pmatrix}, \quad \zeta=\frac{h'}{q-1}. \tag{II.27}$$

In Ref. 1 h' was eliminated at the stage of Poisson brackets and h was retained. It was assumed that one thus obtains an authentic 2-parameter (q,h)-deformation. We have shown that this is not the case. Our transformation for the original (q,h,h') case shows that, from the start, one has always been dealing with a heavily disguised q-deformation. This statement should however be qualified by taking a closer look at different domains of the parameter space of (q,h,h'). We consider below real values of (q,h,h').

For both $(h,h')\neq 0$ (the cases $h'=0$ and $h=0$, with $q'=q$ and $q'=q^{-1}$, respectively, can be considered simply and analogously), from (II.20),

$$q'=\frac{q+1\pm\sqrt{(q-1)^2-4hh'}}{q+1\mp\sqrt{(q-1)^2-4hh'}}. \tag{II.28}$$

Apart from the very special case

$$q=-1, \quad q'=-1, \tag{II.29}$$

we note that more generally (i) for any q and $hh'<0$ and (ii) for $(q-1)^2>4hh'>0$, q' is always real. We consider this as the generic case.

Another very special case is (for $hh'>0$) $|q-1|=2\sqrt{hh'}$ when $q'=1$. See the remark following (II.13) concerning this singular point. Here one has a classical solution with commuting a',b',c',d' !

For $hh'>0$ and $|q-1|<2\sqrt{hh'}$, $q'=e^{\pm i\delta}$, a complex phase. Here q' can even be a root of unity. Thus starting from a complex deformation, one can obtain by the transformation with G an equivalent deformation with 3 real parameters related through (II.28).

III. THE BALLESTEROS–HERRANZ–PARASHAR CASE

A. Transformation to R_q

The Ballesteros–Herranz–Parashar (BHP) two-parametric deformation (Sec. 4 of Ref. 2) leads to the R-matrix

$$R_{q,h}=\begin{pmatrix} 1 & h & -qh & h^2 \\ 0 & q & 1-q^2 & qh \\ 0 & 0 & q & -h \\ 0 & 0 & 0 & 1 \end{pmatrix}. \tag{III.1}$$

The authors present it as a superposition of standard (q) and nonstandard (h) deformations. It has indeed the attractive property that for $h=0$ and $q=1$, respectively, one obtains the standard R_q and the nonstandard R_h matrices.

Now consider a similarity transformation of $R_{q,h}$ by $M\otimes M$ where

$$M=\begin{pmatrix} x & y \\ 0 & 1 \end{pmatrix}, \quad M^{-1}=x^{-1}\begin{pmatrix} 1 & -y \\ 0 & x \end{pmatrix}, \tag{III.2}$$

with $y=h/(q-1)$ $(h\neq 0,\ q\neq 1)$ and x is an arbitrary nonzero parameter. In the notation of Ref. 2,

$$y=\frac{a_+}{2a} \quad (q=e^a). \tag{III.3}$$

One obtains, independently of the choice of x,

$$(M^{-1}\otimes M^{-1})R_{q,h}(M\otimes M)=\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & q & 1-q^2 & 0 \\ 0 & 0 & q & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}=R_q\,. \tag{III.4}$$

Thus it is seen that h can be transformed away.

B. A coalgebra preserving map

The significance of this equivalence (and that of the related Hopf algebraic results of Ref. 2) are better understood in the context of a simple class of coalgebra preserving maps, presented below. (The content of the mapping can be considered, in a certain sense, to be trivial. Elucidating this aspect is precisely our purpose.) These maps can be generalized to higher dimensional algebras. But we here consider only $\mathcal{U}_q(gl(2))$.

One starts with the standard $\mathcal{U}_q(sl(2))$ algebra,

$$\begin{aligned} &[J_0,J_\pm]=\pm 2J_\pm\,, \quad (q^{J_0}J_\pm=q^{\pm 2}J_\pm q^{J_0}), \\ &[J_+,J_-]=\frac{q^{J_0}-q^{-J_0}}{q-q^{-1}}\equiv[J_0], \end{aligned} \tag{III.5}$$

with the coalgebra structure

$$\begin{aligned} \Delta(J_0)&=J_0\otimes 1+1\otimes J_0 \quad (\Delta(q^{J_0})=q^{J_0}\otimes q^{J_0}), \\ \Delta(J_\pm)&=q^{J_0/2}\otimes J_\pm+J_\pm\otimes q^{-J_0/2}, \\ S(q^{J_0/2})&=q^{-J_0/2}, \\ S(J_\pm)&=-q^{-J_0/2}J_\pm q^{J_0/2}, \\ \epsilon(q^{J_0/2})&=1, \quad \epsilon(J_\pm)=0. \end{aligned} \tag{III.6}$$

[Note that for the antipode S, we have not replaced $q^{-J_0/2}J_\pm q^{J_0/2}$ by $q^{\mp 1}J_\pm$. This last form uses (III.5) which will be modified by the map, keeping the structure (III.6) intact in terms of the new generators.]

Next one sets

$$J_0' = J_0,$$

$$J_+' = J_+,$$

$$J_-' = b_1 J_- + b_2 (q^{J_0/2} - q^{-J_0/2}) + b_3 J_+ . \tag{III.7}$$

Choosing (with $q = e^a$)

$$b_1 = \frac{\sinh(a)}{a}, \quad b_2 = -\frac{a_+}{2a^2}, \quad b_3 = -\frac{a_+^2}{4a^2}, \tag{III.8}$$

one obtains the case (4.6) of Ref. 2 [our (J_0', J_+', J_-') corresponding to their (J_3', J_+, J_-)]. Indeed

$$[J_0', J_+'] = 2J_+',$$

$$[J_0', J_-'] = -2J_-' - \frac{a_+}{a} \frac{\sinh(aJ_0'/2)}{a/2} - \frac{a_+^2}{a^2} J_+', \tag{III.9}$$

$$[J_+', J_-'] = \frac{\sinh(aJ_0')}{a} + \frac{a_+}{a} \frac{e^a - 1}{2a} (e^{-aJ_0'/2} J_+' + J_+' e^{aJ_0'/2}).$$

Moreover, the coalgebra structure induced by this map has the same expression in terms of the new generators, i.e.,

$$\Delta(J_0') = J_0' \otimes 1 + 1 \otimes J_0',$$

$$\Delta(J_\pm') = q^{J_0'/2} \otimes J_\pm' + J_\pm' \otimes q^{-J_0'/2}, \tag{III.10}$$

and so on. This is achieved under the single condition that the coefficients of $q^{\pm J_0}$ in (III.7) are opposite. [Note that the latter statement would be true also if, in addition, we write $J_+' = a_1 J_+ + a_2 (q^{J_0/2} - q^{-J_0/2}) + a_3 J_-$.] The whole Hopf algebra described by (J_0', J_+', J_-') then reproduces that of BHP. This means that the BHP Hopf algebra is equivalent to $\mathcal{U}_q(gl(2))$.

IV. COMMENTS ON SINGULAR LIMITS OF TRANSFORMATIONS

Up to now we have been considering regular, invertible transformations making evident the trivial nature of the passage

$$R_q \leftrightarrow R_{q,h}. \tag{IV.1}$$

The map (III.7) is consistent with this due to the conservation of the structure of the coalgebra. When a map has to be followed by a twist[11,12] to arrive at a sought for coalgebra, the situation can be of interest. It has been shown elsewhere[5] how the universal $\mathcal{R}_h$ matrix (introduced first in Ref. 13) can be obtained, through a twist, starting from the trivial classical one [$\mathcal{U}_h(sl(2))$ is a triangular Hopf algebra]. Another interesting possibility is the use of a transformation singular in the limit $q \to 1$ but in such a specific fashion that [$G(q,h)$ being singular at $q=1$],

$$(G(q,h)^{-1} \otimes G(q,h)^{-1} R_q G(q,h) \otimes G(q,h))|_{q=1} = R_h. \tag{IV.2}$$

In contrast to (IV.1) this passage is noninvertible and the end-product is not a hybrid $R_{q,h}$ but a nonstandard R_h. This can be considered as an operator equation between universal R-matrices and G given by (as shown in Ref. 6):

$$G(q,h)=E_q(\eta J_+), \quad \text{with} \quad \eta=\frac{h}{q-1} \tag{IV.3}$$

and

$$E_q(x)=\sum_{n=0}^{\infty}\frac{x^n}{[n]!}, \quad [n]\equiv\frac{q^n-q^{-n}}{q-q^{-1}}. \tag{IV.4}$$

Alternatively (IV.2) can be regarded as a matrix equation implementing $j_1\otimes j_2$ representations. This technique can be generalized to $GL(N)_q$[6] and also to obtain nonstandard quasi-Hopf algebras.[7]

Note that in (IV.2) η has the same form as in (II.11) or (III.2). But the crucial difference is that one takes the limit $q\to 1$.

In the above-mentioned references universal $\mathcal{R}$-matrices have been studied but only for R_q and R_h. Here, in conclusion, we indicate how one can treat the biparametric case involving $R_{p,q}$ and $R_{g,h}$. (Note that no hybrid deformation is involved here.) We restrict the study to the fundamental case of 4×4 matrices.

We start with

$$R_{pq}=\begin{pmatrix} p & 0 & 0 & 0 \\ 0 & pq & p-q & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & p \end{pmatrix}, \tag{IV.5}$$

and define [with $j_1\otimes j_2=\frac{1}{2}\otimes\frac{1}{2}$ in (IV.3)]

$$G=\begin{pmatrix} 1 & \eta \\ 0 & 1 \end{pmatrix}, \tag{IV.6}$$

but now η will be chosen differently. One obtains

$$(G^{-1}\otimes G^{-1})R_{p,q}(G\otimes G)=\begin{pmatrix} p & p(1-q)\eta & (q-1)\eta & (1-p)(q-1)\eta^2 \\ 0 & pq & p-q & q(p-1)\eta \\ 0 & 0 & 1 & (1-p)\eta \\ 0 & 0 & 0 & p \end{pmatrix}. \tag{IV.7}$$

Now let $q\to 1$ and $p\to 1$ in such a fashion that

$$\left(\frac{q-1}{p-1}\right)^{1/2}=\lambda=\text{const.} \tag{IV.8}$$

Set

$$\eta=\frac{\eta_0}{((p-1)(q-1))^{1/2}}, \quad \lambda\eta_0=h, \quad \lambda^{-1}\eta_0=-g. \tag{IV.9}$$

Then

$$((G^{-1}\otimes G^{-1})R_{p,q}(G\otimes G))\big|_{(p\to 1,q\to 1)}=\begin{pmatrix} 1 & -h & h & gh \\ 0 & 1 & 0 & -g \\ 0 & 0 & 1 & g \\ 0 & 0 & 0 & 1 \end{pmatrix}. \tag{IV.10}$$

Thus we obtained the 2-parametric nonstandard R-matrix. For $g=h$ and $g=0$, we obtain the two known forms of R_h. The 2-parametric universal colored, nonstandard R-matrix for deformed $gl(2)$ is obtained in Sec. 3 of Ref. 8 implementing a twist. Here we presented the 4×4 case to show how η is quite simply modified from (IV.3) to (IV.9) as one passes from the 1- to the 2-parametric case.

V. AN AUTHENTIC HYBRID (q,h) DEFORMATION: $GL_{q,h}(1|1)$

In Sec. II and Sec. III we have shown that the hybrid (q,h) deformations in Refs. 1 and 2 are in fact disguised q-ones. In the search of hybrid deformation we also check with the classification of 4×4 R-matrices in Ref. 10. There we find seven triangular cases:

$$R_{S2,1}=\begin{pmatrix} 1 & 0 & 0 & 0 \\ & p & 1-pq & 0 \\ & & q & 0 \\ & & & 1 \end{pmatrix}, \tag{V.1}$$

$$R_{S2,2}=\begin{pmatrix} 1 & 0 & 0 & 0 \\ & p & 1-pq & 0 \\ & & q & 0 \\ & & & -pq \end{pmatrix}, \tag{V.2}$$

$$(R_{H1,3})_{|_{k=1,p=-h,q=-g}}=\begin{pmatrix} 1 & -h & h & gh \\ & 1 & 0 & -g \\ & & 1 & g \\ & & & 1 \end{pmatrix}, \tag{V.3}$$

$$(R_{H2,3})_{|_{k=1},p=x_1,q=x_2,s=x_3}=\begin{pmatrix} 1 & x_1 & x_2 & x_3 \\ & 1 & 0 & x_2 \\ & & 1 & x_1 \\ & & & 1 \end{pmatrix}, \tag{V.4}$$

$$R_{S0,1}=\begin{pmatrix} 1 & 0 & 0 & 1 \\ & 1 & 0 & 0 \\ & & 1 & 0 \\ & & & 1 \end{pmatrix}, \tag{V.5}$$

$$R_{S0,2}=\begin{pmatrix} 1 & 0 & 0 & 1 \\ & -1 & 0 & 0 \\ & & -1 & 0 \\ & & & 1 \end{pmatrix}, \tag{V.6}$$

$$R_{q,h}=(R_{H1,2})_{|_{p=1,k=h}}=\begin{pmatrix} 1 & 0 & 0 & h \\ & 1 & 1-q & 0 \\ & & q & 0 \\ & & & -q \end{pmatrix}. \tag{V.7}$$

Note that in Ref. 10 the R-matrices are given in two versions: homogeneous $R_{H\ldots}$ and scaled $R_{S\ldots}$. The scaled versions are simpler but in some cases, in order not to lose some symmetry among the parameters we use the homogeneous versions with only an overall rescaling.

The case $R_{S2,1}$ is the 2-parameter p,q deformation, $GL_{pq}(2)$, the dual of which is given in Ref. 3. The case $R_{S2,2}$ is a superalgebra—the known p,q deformation of $GL_{pq}(1|1)$, the dual of which is given in Refs. 14–16.

Remark: Note that here (and below for $R_{q,h}$) we consider ordinary, not graded, R-matrices. The results can be translated to the graded formalism. There is a one-to-one correspondence between the results obtained through the two approaches (which was noticed first for solutions of YBE and graded YBE in Ref. 17). This correspondence may be given also through ''transmutation'' in the sense of Ref. 18. This aspect is considered in the context of $sl(1|2)$ in Ref. 19. In our paper the superalgebraic aspect becomes evident after implementation of the RTT formalism.

In the third case we have written the homogeneous version $R_{H1,3}$ of Ref. 10 with $k=1$ and renamed parameters. This seems the natural scaling (and not the $R_{S1,3}$). The result is indeed with 2 parameters, i.e., this is the 2-parameter Jordanian $GL_{gh}(2)$. The dual was found in Ref. 4.

In the fourth case we have written the homogeneous version $R_{H2,3}$ of Ref. 10 with $k=1$ and renamed parameters. From the RTT relations we obtain the following:

$$
\begin{gathered}
acx_1+cax_2+c^2x_3=0,\\
ac-ca+c^2x_2=0,\\
-ac+ca+c^2x_1=0,\\
-c^2x_1+cd-dc=0,\\
-c^2x_2-cd+dc=0,\\
c^2x_3+c\,dx_1+dc\,x_2=0,\\
ad-cax_1+c\,dx_2-da=0,\\
-acx_2-ad+da+dc\,x_1=0,\\
bc-cax_2-cb+dc\,x_2=0,\\
-acx_1-bc+cb+c\,dx_1=0,\\
-a^2x_1+ab+a\,dx_1-ba+cbx_2+c\,dx_3=0,\\
-a^2x_2-ab+ba+bcx_1+da\,x_2+dc\,x_3=0,\\
bd-cax_3-cbx_1-da\,x_2-db+d^2x_2=0,\\
-acx_3-a\,dx_1-bcx_2-bd+db+d^2x_1=0,\\
-a^2x_3-abx_1-bax_2+b\,dx_1+db\,x_2+d^2x_3=0.
\end{gathered}
\tag{V.8}
$$

It is necessary to consider several cases.

(1) In the case $x_1+x_2\neq 0$ (and arbitrary x_3) from the above follow:

$$
\begin{gathered}
c^2=0,\quad ca=ac=0,\quad dc=cd=0,\\
da=ad,\quad cb=bc,\\
a^2=d^2=ad+bc
\end{gathered}
\tag{V.9}
$$

$$ab=bd=ba+(x_1-x_2)bc, \quad db=bd+(x_2-x_1)bc.$$

These relations make the resulting algebra rather degenerate. Moreover, in order to build a PBW basis we have to look also for higher order relations. For instance, using these relations we obtain

$$a^3=a^2d+abc=a^2d.$$

Furthermore one can eliminate $bc=a^2-ad$, and $bd=ba+(x_1-x_2)(a^2-ad)$. From all these it follows that the PBW basis may have only the following monomials:

$$b^n a^k, \quad a^{\ell} d, \quad c, \quad n,k\in\mathbb{Z}_+, \quad \ell=0,1. \tag{V.10}$$

(2) Next we consider the case $x_1=-x_2=h$, $x_3\neq -h^2$; then from (V.8) follows that

$$\begin{gathered} c^2=0, \quad ca=ac=0, \quad dc=cd=0, \\ da=ad, \quad cb=bc, \quad a^2=d^2, \\ ab=ba+h(a^2+bc-ad), \quad db=bd-h(a^2+bc-ad). \end{gathered} \tag{V.11}$$

The resulting algebra is also degenerate, though the above relations are less restrictive than the previous case and the possible PBW basis is richer:

$$b^n a^k d^{\ell}, \quad b^n c^{\ell}, \quad n,k\in\mathbb{Z}_+, \quad \ell=0,1. \tag{V.12}$$

(3) Finally in the case $x_1=-x_2=h$, $x_3=-h^2$ this coincides with the case $R_{H1,3}$ when $g=-h$.

The fifth case $R_{S0,1}$ is a special case of $R_{H2,3}$ when $x_1=x_2=0$, $x_3=1$. Thus, the resulting algebra relations are obtained from (V.11) setting $h=0$.

In the sixth case $R_{S0,2}$ the RTT relations give

$$\begin{gathered} c^2=0, \quad ca=ac=0, \quad dc=cd=0, \\ da=ad, \quad cb=bc, \quad a^2=d^2, \\ ab+ba=0, \quad db+bd=0. \end{gathered} \tag{V.13}$$

This is a superalgebra, also degenerate like the previous two cases. The PBW basis would be as in (V.12).

Finally, we are left with the seventh case, which we have anticipated to be a hybrid one by the notation $R_{q,h}$. Note that setting $q=1$,

$$R_h=R_{1,h}=\begin{pmatrix} 1 & 0 & 0 & h \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & -1 \end{pmatrix}, \tag{V.14}$$

still depends on h and is triangular (in the sense $R_{21}=R^{-1}$).

Now we obtain the RTT relations by implementing (V.7) in (II.6) with (II.5):

$$\begin{gathered} ba=ab+hcd, \quad ca=q^{-1}ac, \\ da=ad-(1-q^{-1})bc, \quad cb=q^{-1}bc, \\ db=-bd+hq^{-1}ac, \quad dc=-qcd, \\ c^2=0, \quad ha^2=(q+1)b^2+hd^2. \end{gathered} \tag{V.15}$$

This is a superalgebra which we shall denote by $GL_{q,h}(1|1)$. It was first written in Ref. 9, where also the dual quantum algebra was given. This is indeed a hybrid deformation of $GL(1|1)$ since it is known from Ref. 10 that no transformation of the form

$$R_{qh} \rightarrow (M \otimes M) R_{qh} (M^{-1} \otimes M^{-1}) \tag{V.16}$$

can lead to R_q.

Using the transformation (V.16) with

$$M = \begin{pmatrix} x & y \\ 0 & x^{-1} \end{pmatrix}, \tag{V.17}$$

one gets

$$R_{q,h} = \begin{pmatrix} 1 & 0 & 0 & hx^4 - (1+q)(xy)^2 \\ 0 & 1 & 1-q & -2xy \\ 0 & 0 & q & -2qxy \\ 0 & 0 & 0 & -q \end{pmatrix}, \tag{V.18}$$

For no choice of x,y one obtains for the transformed R the form $R_{q;h=0}$, in contrast with the results of Secs. II and III.

For $1+q \neq 0$ one may choose to eliminate the top right hand element by setting $y = \pm x(h/(1+q))^{1/2}$. Denoting $h' = -2xy$,

$$R_{q,h} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 1-q & h' \\ 0 & 0 & q & qh' \\ 0 & 0 & 0 & -q \end{pmatrix}. \tag{V.19}$$

In conclusion we repeat that in order to display the sharp contrast between the mixed deformations of Secs. II and III and the present case we have restricted our considerations in both cases to similarity transformations, i.e., coboundary twists $\mathcal{F} \equiv (g^{-1} \otimes g^{-1}) \Delta(g)$, which transform $\mathcal{R}$-matrices as $\mathcal{R}^{\mathcal{F}} \equiv \mathcal{F}_{21} \mathcal{R} \mathcal{F}^{-1} = (g^{-1} \otimes g^{-1}) \mathcal{R} (g \otimes g)$. Other interesting aspects can be explored by implementing more general twists. We refer to the discussion in Ref. 20 concerning the three deformed versions of $gl(1|1)$.

(Received 1 September 2000; accepted for publication 6 November 2000)

The method of symmetry reduction is systematically applied to derive several classes of invariant solutions for the generalized Weierstrass system inducing constant mean curvature surfaces and to the associated two-dimensional nonlinear sigma model. A classification of subgroups with generic orbits of codimension one of the Lie point symmetry group for these systems provides a tool for introducing symmetry variables and reduces the initial systems to different nonequivalent systems of ordinary differential equations. We perform a singularity analysis for them in order to establish whether these ordinary differential equations have the Painlevé property. These ordinary differential equations can then be transformed to standard forms and next solved in terms of elementary and Jacobi elliptic functions. This results in a large number of new solutions and in some cases new interesting constant mean curvature surfaces are found. Furthermore, this symmetry analysis is extended to include conditional symmetries by subjecting the original system to certain differential constraints. In this case, several new types of nonsplitting algebraic, trigonometric, and hyperbolic multisoliton solutions have been obtained in explicit form. Some physical interpretation of these results in the areas of fluid membranes, string theory, two-dimensionl gravity, and cosmology are given. [DOI: 10.1063/1.1337796]

I. INTRODUCTION

The expressions describing minimal surfaces imbedded in three-dimensional Euclidean space were first formulated by Enneper and Weierstrass[1,2] one and a half centuries ago. They start by introducing two holomorphic functions $\psi(z)$, $\phi(z)$ and three complex valued functions ω_1, ω_2, and ω_3 which satisfy the following system of equations

$$\partial\omega_1 = i(\psi^2+\phi^2), \quad \partial\omega_2 = \psi^2-\phi^2, \quad \partial\omega_3 = -2\psi\phi, \quad \bar{\partial}\psi = 0, \quad \bar{\partial}\phi = 0, \tag{1.1}$$

where the derivatives are abbreviated $\partial = \partial/\partial z$ and $\bar{\partial} = \partial/\partial\bar{z}$. The bar denotes the complex conjugate. They show that if the system of three real-valued functions $X_i(z,\bar{z}), i = 1,2,3$ are considered as a coordinate system for a surface immersed in $\mathbb{R}^3$, defined as

$$X_1 = \mathrm{Re}\,\omega_1 = \mathrm{Re}\int_C i(\psi^2+\phi^2)\,\mathrm{d}z,$$

$$X_2 = \mathrm{Re}\,\omega_2 = \mathrm{Re}\int_C (\psi^2-\phi^2)\,\mathrm{d}z, \tag{1.2}$$

[a]Electronic mail: bracken@crm.umontreal.ca
[b]Electronic mail: grundlan@crm.umontreal.ca

$$X_3 = \mathrm{Re}\,\omega_3 = -\mathrm{Re}\int_C 2\psi\phi\,\mathrm{d}z$$

(where C is any contour in the domain of common holomorphicity of both functions ψ and ϕ), then the functions $X_i(z,\overline{z})$ determine a minimal surface. The minimal lines on this surface are given by the parametric lines $z=$ constant and $\overline{z}=$ constant, respectively.

More recently, this idea was substantially generalized by Konopelchenko,[3] who established the connection between certain classes of constant mean curvature surfaces and the trajectories of an infinite-dimensional Hamiltonian system. Namely, he considered the nonlinear Dirac-type system of equations for two complex valued functions ψ_1 and ψ_2 given by

$$\begin{aligned} &\partial\psi_1 = p\psi_2, \quad \overline{\partial}\psi_2 = -p\psi_1, \\ &\overline{\partial}\overline{\psi}_1 = p\overline{\psi}_2, \quad \partial\overline{\psi}_2 = -p\overline{\psi}_1, \\ &p = |\psi_1|^2 + |\psi_2|^2. \end{aligned} \tag{1.3}$$

The system (1.3) possesses several conserved quantities,[4] including the following.

(1) The conservation of current

$$J = \overline{\psi}_1\partial\psi_2 - \psi_2\partial\overline{\psi}_1, \tag{1.4}$$

which satisfies

$$\overline{\partial}J = \overline{\partial}(\overline{\psi}_1\partial\psi_2 - \psi_2\partial\overline{\psi}_1) = -p(\partial p) + p(\partial p) \equiv 0, \tag{1.5}$$

whenever (1.3) holds.

(2) The conservation of a potential function

$$\partial(\psi_1^2) + \overline{\partial}(\psi_2^2) = 0, \quad \overline{\partial}(\psi_1^2) + \partial(\overline{\psi}_2^2) = 0. \tag{1.6}$$

(3) Another conserved quantity,

$$\partial(\psi_1\overline{\psi}_2) + \overline{\partial}(\overline{\psi}_1\psi_2) = 0.$$

Making use of these conserved quantities, there exists three real valued functions $X_i(z,\overline{z})$, $i=1,2,3$, such that

$$\begin{aligned} X_1 + iX_2 &= 2i\int_\gamma (\overline{\psi}_1^2\,\mathrm{d}z' - \overline{\psi}_2^2\,\mathrm{d}\overline{z}'), \\ X_1 - iX_2 &= 2i\int_\gamma (\psi_2^2\,\mathrm{d}z' - \psi_1^2\,\mathrm{d}\overline{z}'), \\ X_3 &= -2\int_\gamma (\overline{\psi}_1\psi_2\,\mathrm{d}z' + \psi_1\overline{\psi}_2\,\mathrm{d}\overline{z}'). \end{aligned} \tag{1.7}$$

On account of system (1.3), the right-hand side of (1.7) does not depend on the choice of contour γ in $\mathbb{C}$. We treat the functions $X^i(z,\overline{z})$ as the coordinates of a surface immersed into $\mathbb{R}^3$. The Gaussian curvature, the constant mean curvature, and first fundamental form of the surface are given by[3]

$$K=-\frac{\partial\overline{\partial}(\ln p)}{p^2},\quad H=1,\quad \Omega=4p^2\,\mathrm{d}z\mathrm{d}\overline{z}, \tag{1.8}$$

in isothermic coordinates, respectively. Konopelchenko called the modified version (1.3) of the Weierstrass–Enneper system (1.1) the generalized Weierstrass (GW) system. These formulas are the starting point for the symmetry analysis in this paper, and we will refer to it as such. The theory of constant mean curvature surfaces has had a great impact on many problems with physical applications. In particular, the model has found many applications to such diverse areas as in the fields of two-dimensional gravity,[5,6] quantum field theory,[5,7] statistical physics,[8,9] and fluid dynamics.[10,11] It is worth mentioning an application of recent interest, namely, the propagation of a string through space–time.[12] It describes a surface called its world sheet. When one quantizes a string, the result is an ordinary two-dimensional point particle quantum field theory on a given surface. Thus, one can say that first quantized string theory is the study of conformal field theories on Riemann surfaces. Another relevant application of recent interest is in the area of statistical mechanics. Any two-dimensional statistical system near a second-order phase transition can be described by a conformally invariant theory.[8] Near a phase transition, fluctuations of the fields are correlated over very long length scales and appear on all scales essentially equally. Since no scale is preferred, it becomes scale or conformally invariant. Thus, the specific lattice becomes relatively unimportant, and so a type of universal behavior is displayed. A recent interesting application is to the theory of fluid membranes,[8] in which one introduces the free energy per molecule f_e. Then two invariants of the surface which appear directly in the theory are the mean curvature H and Gaussian curvature K. Since the free energy of a fluid membrane must be invariant under rotations of the coordinate system, f_e must be a function of H, H^2, and K to the order we consider

$$f_e(\Sigma,H,K)=f_0(\Sigma)+f_1(\Sigma)H+f_2(\Sigma)H^2+f_3(\Sigma)K,$$

where Σ is the equilibrium area per molecule and the coefficients $f_i, i=0,1,2,3$ are typically functions of Σ, which itself may depend on the curvature. The free energy of the flat film is f_0 and f_1, f_2, and f_3 are the derivatives of the free energy with respect to H, H^2, and K, respectively. One then minimizes f_e to find the equilibrium area per molecule of the curved interface. This defines the curvature free energy. Physically speaking, it is found that if the chains are allowed to adjust their area per molecule depending on the curvature, the monolayer will be less rigid upon bending than with a fixed area per molecule. We would like to stress that results for these curvatures can be obtained from the solutions of the GW system (1.3), which is the object of our study here.

It has been demonstrated[13] that GW system (1.3) can be decoupled into a direct sum of elliptic Sh–Gordon and Laplace equations. If we change the dependent variables ψ_1 and ψ_2 in (1.3) to the new dependent variables p and J, then the GW system (1.3) can be written in the equivalent form

$$\partial\overline{\partial}\ln p=\frac{|J|^2}{p^2}-p^2,\quad \overline{\partial}J=0. \tag{1.9}$$

It was shown using the conditional symmetry method,[14] that the GW system admits an auto-Bäcklund transformation for any holomorphic function J,

$$\partial p=-\lambda q p^2+\frac{\partial q}{q}p-\frac{\lambda J}{q},\quad \overline{\partial}p=-\frac{\overline{J}}{\lambda q}p^2-\frac{\overline{\partial}q}{q}p-\frac{q}{\lambda},\quad \overline{\partial}J=0,\quad \lambda\in\mathbb{C}, \tag{1.10}$$

where the function q satisfies the elliptic Sh–Gordon equation (1.9). The arbitrary complex constant λ is the Bäcklund parameter. The compatibility condition for (1.10) reproduces the system (1.9) in the variable q. It has also been shown,[14] that for a chosen solution q of (1.9), the symmetry group G of the overdetermined system (1.9) and (1.10) with two-dimensional orbits has

a complete set of two functionally independent invariants. Thus, the solution p of the initial equations (1.9) and (1.10) can be expressed in terms of these invariants. In other words, they are invariant under the finite Abelian Lie algebra given by

$$Z_1=\partial-\left(\frac{\lambda J}{q}-\frac{\partial q}{q}p+\lambda q p^2\right)\partial_p,\quad Z_2=\overline{\partial}-\left(\frac{q}{\lambda}+\frac{\overline{\partial}q}{q}p+\frac{\overline{J}}{\lambda q}p^2\right)\partial_p,\quad \overline{\partial}J=0, \tag{1.11}$$

where these vector fields are parametrized by the function q which satisfies (1.9), and constant $\lambda\in\mathbb{C}$. The difference between the classical symmetry reduction and the conditional one[15] is that the group associated with a classical approach to system (1.9) maps all solutions into other solutions of the same system, whereas for a conditional symmetry method, the associated group G maps only a subset of solutions of system (1.9) into solutions of the overdetermined system, that is, the original system (1.9) subjected to given differential constraints (1.10).

Furthermore, by linearizing the Riccati system (1.10), that is, by taking the homogeneous coordinates ϕ_1 and ϕ_2 in (1.10) such that $p=\phi_1/\phi_2$, we obtain, for any holomorphic function J, the associated linear spectral problem for (1.9),

$$\partial\begin{pmatrix}\phi_1\\ \phi_2\end{pmatrix}=\begin{pmatrix}\dfrac{\partial q}{2q} & -\dfrac{\mu J}{q}\\ \mu q & -\dfrac{\partial q}{2q}\end{pmatrix}\begin{pmatrix}\phi_1\\ \phi_2\end{pmatrix},\quad \overline{\partial}\begin{pmatrix}\phi_1\\ \phi_2\end{pmatrix}=\begin{pmatrix}-\dfrac{\overline{\partial}q}{2q} & -\dfrac{q}{\mu}\\ \dfrac{\overline{J}}{\mu q} & \dfrac{\overline{\partial}q}{2q}\end{pmatrix}\begin{pmatrix}\phi_1\\ \phi_2\end{pmatrix},\quad \overline{\partial}J=0. \tag{1.12}$$

The permutability theorem for the auto-Bäcklund transformation for system (1.3) has recently been formulated by the authors[14] and new classes of nonsplitting multisoliton solutions of system (1.3) have been obtained.

The objective of this paper is a systematic analysis of GW system (1.3) from the symmetry group point of view. We focus on constructing several classes of solutions obtained from the symmetry reduction method.[16,17] It will be demonstrated that the symmetry reduction method applied directly to GW system (1.3) provides limited classes of solutions. However, large classes of solutions of GW system (1.3) can be obtained from a systematic use of the subgroup structure of the invariance group of the sigma model associated with the GW system. Among analytic solutions of (1.3) which are particularly important are those which can be expressed in terms of Jacobi elliptic functions, since they lead to solutions which are not necessarily local.[2] In view of the integrals (1.7), the presented method can provide new, interesting surfaces with constant mean curvature. Our motivation in the present paper is to report on a systematic way of constructing these types of solutions of (1.3), and discuss solitonlike applications. Among these solutions which are particularly significant are those whose total energy

$$E=\int_D\left(p^2+\frac{|J|^2}{p^2}\right)\mathrm{d}x\,\mathrm{d}y,\quad D\in\mathbb{R}^2, \tag{1.13}$$

is finite over all space.

This paper is organized as follows. Section II is devoted to the construction of Lie point symmetries and their subalgebras for GW system (1.3). The reductions of (1.3) to ordinary differential equations (ODEs) requires consideration of three-dimensional subalgebras. The general integrals of these ODEs are presented. In Sec. III, we investigate the connection between GW system (1.3) and a two-dimensional nonlinear sigma model. This link together with conservation laws for (1.3) allows us to establish several useful transformations which simplify the structure of GW system (1.3). Section IV deals with the associated sigma model. The symmetry algebra, list of representatives of conjugacy classes of subalgebras, the corresponding invariants, and reduced differential equations are given. Solutions of GW system (1.3) are provided by means of a number of reduced equations of the associated sigma model. In some cases, solitary and doubly periodic

solutions of the GW system in terms of Jacobi elliptic functions are obtained. Section V contains the extension of the classical Lie approach to group invariant solutions of (1.3) admitting differential constraints (DCs). Each of the solutions presented provides us with different classes of constant mean curvature surface imbedded in three-dimensional Euclidean space. Section VI discusses in detail a set of DCs which allow GW system (1.3) to become a decoupled linear system of equations, and we solve these in terms of Bessel functions of zero order. Section VII contains a future outlook concerning surfaces immersed in multidimensional spaces.

II. THE SYMMETRY GROUP, ITS SUBALGEBRAS, AND THEIR REDUCTIONS TO ODEs

The symmetry group of GW system (1.3) can be computed using the appropriate MACSYMA program.[18] This provides us with a set of determining equations from which we can find the symmetry algebra L of infinitesimal symmetries of system (1.3). It is spanned by the vector fields

$$
\begin{aligned}
&T_1=\partial, \quad T_2=\overline{\partial},\\
&D_1=z\partial-\tfrac{1}{2}(\overline{\psi}_1\partial_{\overline{\psi}_1}+\psi_2\partial_{\psi_2}), \quad D_2=\overline{z}\overline{\partial}-\tfrac{1}{2}(\psi_1\partial_{\psi_1}+\overline{\psi}_2\partial_{\overline{\psi}_2}),\\
&K_1=z^2\partial-z(\overline{\psi}_1\partial_{\overline{\psi}_1}+\psi_2\partial_{\psi_2}), \quad K_2=\overline{z}^2\overline{\partial}-\overline{z}(\psi_1\partial_{\psi_1}+\overline{\psi}_2\partial_{\overline{\psi}_2}),\\
&H=\psi_1\partial_{\psi_1}-\overline{\psi}_1\partial_{\overline{\psi}_1}+\psi_2\partial_{\psi_2}-\overline{\psi}_2\partial_{\overline{\psi}_2}.
\end{aligned}
\tag{2.1}
$$

The physical interpretation of the Lie algebra L is as follows. Here, T_1 and T_2 generate translations in the z and $\overline{z}$ directions, respectively. The generators D_1 and D_2 correspond to two different types of dilations and the generators K_1 and K_2 represent two types of conformal transformations. The generator H reflects the fact that the GW system is invariant under phase transformations. To show this, it is convenient to use polar coordinates for the functions ψ_j, that is to put

$$
\psi_j=R_j e^{i\alpha_j}, \quad j=1,2, \tag{2.2}
$$

and then write the generator H in terms of R_j and α_j. In this case, the field H takes the simple form

$$
H=-i(\partial_{\alpha_1}+\partial_{\alpha_2}).
$$

The nonzero commutation relations for the algebra (2.1) are given by

$$
[D_i,K_i]=K_i, \quad [T_i,K_i]=2D_i, \quad [T_i,D_i]=T_i, \quad i=1,2.
$$

We see that the Lie algebra can be decomposed into a direct sum of two sl(2,$\mathbb{C}$) subalgebras in addition with generator H. The vector field H represents the center of the Lie algebra L. Thus we find that

$$
L=\{\mathrm{sl}(2,\mathbb{C})\}_1\oplus\{sl(2,\mathbb{C})\}_2\oplus H, \tag{2.3}
$$

where the subalgebras $\{\mathrm{sl}(2,\mathbb{C})\}_i$ are spanned by $\{T_i,D_i,K_i\}$, $i=1,2$, respectively. Subalgebras of the direct sum $\{\mathrm{sl}(2,\mathbb{C})\}_1\oplus\{\mathrm{sl}(2,\mathbb{C})\}_2$ can be classified by using an adaptation of the Goursat twist method to Lie algebras.[19,20] Note that the vector fields K_i can be rectified by a point transformation involving independent and dependent variables in such a way that K_i is equivalent to T_i. This fact simplifies considerably the classification of subalgebras of L.

The results for representatives of the conjugacy classes of one-dimensional subalgebras of the symmetry algebra L are listed in Table I using a standard method.[21] The discrete transformations of GW system (1.3) were used in order to restrict the range of parameters appearing in the classification. The proposition is that any one-dimensional subalgebra of L is conjugate under the

TABLE I. The one-dimensional subalgebras of (2.1) leading to a system of first order ODEs where α, $\beta \in \mathbb{C}$. Similar results to those of L_4 are obtained for $L_6 = D_2 + \beta H$ when z is replaced by $\overline{z}$, $(\psi_1, \overline{\psi}_1, \psi_2, \overline{\psi}_2)$ is replaced by $(\psi_2, \overline{\psi}_2, \psi_1, \overline{\psi}_1)$ and for $L_7 = T_2 + \epsilon H$ to those of L_5 when $\overline{z}$ is replaced by z and $(\psi_1, \overline{\psi}_1, \psi_2, \overline{\psi}_2)$ is replaced by $(\overline{\psi}_1, \psi_1, \overline{\psi}_2, \psi_2)$, respectively.

action of the group G to precisely one algebra L_j, $1 \leqslant j \leqslant 7$ in the list. No two members occurring in the list are mutually conjugate. The list of invariants of the corresponding Lie subalgebras and also the corresponding reduced ODEs are given in Table I. The functions A, B, C, D, and ξ denote the five invariants for the given subalgebras L_j, where ξ is the symmetry variable. The main feature of the symmetry reduction method is that the set of symmetry variables enables us to reduce, after some transformations, the original system of PDEs to sets of four coupled ODEs. These ODEs can very often be explicitly integrated in terms of known functions or at least their singularity structure can be investigated using the Painlevé test.[22] It is shown in many cases that the result of the test is positive for the reduced systems of ODEs. After some change of variables, these ODEs can be written in closed analytic form which can be decoupled and solved in many cases. The Lie algebra obtained from the infinitesimal symmetries of the GW system (1.3), listed in Table I, have to obey the restriction coming from the requirement that the quantities z and $\overline{z}$ as well as the values of ψ_i and $\overline{\psi}_i$ cannot be viewed as independent variables in $\mathbb{C}$, respectively, as demanded by symmetry criterion. This fact is a strong limitation on the admitted class of invariant solutions of (1.3). Thus if we interpret z and $\overline{z}$ as coordinates in the complex plane $\mathbb{C}$, and ψ_i and $\overline{\psi}_i$ as complex conjugate valued functions on $\mathbb{C}$, then the following is a list of representatives of conjugacy classes of one-dimensional subalgebras, the corresponding invariants, and their associated reductions and solutions of (1.3). The four invariants A, B, C, D depend on the argument ξ. Here, we only summarize the results in Table I.

We classify two-dimensional subalgebras of the symmetry algebra (2.1) into conjugacy classes under the action of the symmetry group G including discrete transformations of (1.3). It turns out that only two classes of two-dimensional subalgebras exist for GW system (1.3). They can be represented by

$$L_{2,1} = \{D_1, T_1 + aH\}, \quad L_{2,2} = \{D_2, T_2 + aH\}, \quad a \in \mathbb{C}.$$

The corresponding invariant solutions of the reduced equations of GW system (1.3) lead to trivial constant solutions.

Let us now sum up the results. We remark that solutions of the GW system obtained from one- and two-dimensional reductions are elementary solutions, that is, constant, algebraic polynomial and exponential solutions. Thus the classical symmetry reduction method in the version presented here does not prove to be a very useful tool, since it leads to rather limited classes of solutions. In the framework of group theoretical methods applied to PDEs, there exists in the recent liturature several approaches such as nonclassical and conditional symmetry methods[23,24] which evolved in the process of extending Lie's classical theory of symmetry for PDEs. This approach consists basically in modifying the original system by adding to it certain differential constraints for which a symmetry criterion is identically satisfied. The overdetermined system of equations obtained in this way admits, in some cases, a larger class of Lie point symmetry groups and consequently, can provide other classes of solutions of the original system than the ones obtained by the classic approach. Thus, one of our objectives is to study the conditional symmetries of the GW system and look for new classes of solutions, which is presented in Sec. IV.

III. THE ASSOCIATED SIGMA MODEL EQUATIONS

In our investigation it is more convenient to introduce a new dependent variable which links the GW system with the Euclidean sigma model. Such a link has been discovered first by Kenmotsu[25] for the linear Weierstrass equations inducing mean curvature surfaces. This will be extended to the case of the GW system, and it will allow us to establish several useful transformations in order to simplify the structure of system (1.3).

Let us define a new complex variable

$$\rho=\frac{\psi_1}{\overline{\psi}_2}, \tag{3.1}$$

and its complex conjugate. Differentiating (3.1) with respect to ∂ and using the relation

$$p=|\psi_2|^2(1+|\rho|^2),$$

we obtain

$$\partial\rho=(1+|\rho|^2)^2\psi_2^2. \tag{3.2}$$

Note that $\partial\rho$ and ψ_2^2 have the same polar angle in the complex plane, since they are related by a real quantity $(1+|\rho|^2)^2$. Taking into account (3.1) we get the following transformation from the variable ρ into the variables ψ_1 and ψ_2:

$$\psi_1=\epsilon\rho\frac{(\overline{\partial\rho})^{1/2}}{1+|\rho|^2},\quad \psi_2=\epsilon\frac{(\partial\rho)^{1/2}}{1+|\rho|^2},\quad \epsilon=\pm 1. \tag{3.3}$$

According to Ref. 26, if ψ_1 and ψ_2 are solutions of GW system (1.3), then the function ρ defined by (3.1) is a solution to the two-dimensional Euclidean sigma-model equations

$$\text{(i)}\quad \partial\overline{\partial}\rho-\frac{2\overline{\rho}}{1+|\rho|^2}\partial\rho\,\overline{\partial}\rho=0,\quad \text{(ii)}\quad \partial\overline{\partial}\overline{\rho}-\frac{2\rho}{1+|\rho|^2}\partial\overline{\rho}\,\overline{\partial}\overline{\rho}=0. \tag{3.4}$$

Conversely, according to Ref. 26, if ρ is a solution of the sigma model (3.4), then the solutions ψ_1 and ψ_2 of GW system (1.3) have the form (3.3). Hence, some classes of solutions to GW system (1.3) can be obtained directly by applying the transformation (3.3) to the solutions of the sigma-

model (3.4). For example, a very large class of solutions can be found simply by requiring the holomorphicity or antiholomorphicity of the function ρ. This choice for the function ρ leads to so-called splitting solutions (1.3), which satisfy the Laplace equation

$$\partial\bar{\partial}\rho=0,$$

and have been extensively investigated in Ref. 14 and 26. We discuss in detail a technique for constructing nonsplitting solutions of (1.3) for which $\partial\bar{\partial}\rho\neq 0$ holds in Secs. V and VI. Note that the only trivial solution of GW system (1.3) is the null solution $\psi_i\equiv 0$, which corresponds to ρ equal to any constant.

The conservation of current (1.5) and conservation of a potential function imply that there exists a complex function $g:\mathbb{C}\to\mathbb{C}$ such that

$$\psi_1=\epsilon(\bar{\partial}g)^{1/2},\quad \psi_2=\epsilon(\partial g)^{1/2},\quad \epsilon=\pm 1. \tag{3.5}$$

Substituting these into the GW system (1.3), we obtain the following second order system of PDEs:

$$\begin{aligned}\partial\bar{\partial}g&=2i\epsilon[(\bar{\partial}g)(\partial\bar{g})^{1/2}(\partial g)^{1/2}+(\bar{\partial}g)^{1/2}(\partial g)(\bar{\partial}\bar{g})^{1/2}],\\ \bar{\partial}\partial\bar{g}&=-2i\epsilon[(\partial\bar{g})(\bar{\partial}g)^{1/2}(\bar{\partial}\bar{g})^{1/2}+(\partial\bar{g})^{1/2}(\bar{\partial}\bar{g})(\partial g)^{1/2}].\end{aligned} \tag{3.6}$$

Hence,[27] if g is a solution of the system (3.6), then the functions ψ_1 and ψ_2 defined by (3.5) satisfy the GW system (1.3). Under the above-mentioned conservation law, we can formulate the following.

Proposition 1: If ψ_1 and ψ_2 are solutions of GW system (1.3), then the current J in terms of the function ρ defined by (3.1) takes the form

$$J(z,\bar{z})=-\frac{\partial\rho\,\partial\bar{\rho}}{(1+|\rho|^2)^2}, \tag{3.7}$$

and is a holomorphic function, $\bar{\partial}J=0$.

Proof: Indeed, differentiation of Eq. (3.1) with respect to z gives transformation (3.3). Substituting Eq (3.3) into expression (1.7), we get

$$\begin{aligned}J&=\frac{\bar{\rho}\,\partial^2\rho}{2(1+|\rho|^2)^2}-\frac{\bar{\rho}\partial\rho}{(1+|\rho|^2)^3}(\rho\partial\bar{\rho}+\bar{\rho}\partial\rho)-\frac{\partial\rho\,\partial\bar{\rho}}{(1+|\rho|^2)^3}-\frac{\bar{\rho}\,\partial^2\rho}{2(1+|\rho|^2)^2}+\bar{\rho}^2\frac{(\partial\rho)^2}{(1+|\rho|^2)^3}\\ &=-\frac{\partial\rho\,\partial\bar{\rho}}{(1+|\rho|^2)^2}.\end{aligned} \tag{3.8}$$

Differentiation of (3.8) yields

$$\bar{\partial}J=\frac{(\bar{\partial}\partial\rho)(\partial\bar{\rho})+(\partial\rho)(\bar{\partial}\partial\bar{\rho})}{(1+|\rho|^2)^2}-2\frac{(\partial\rho)(\partial\bar{\rho})(\rho\bar{\partial}\bar{\rho}+\bar{\rho}\bar{\partial}\rho)}{(1+|\rho|^2)^3}. \tag{3.9}$$

Substituting sigma model equation (3.4) into (3.9), we obtain that (3.9) is identically satisfied

$$2\bar{\rho}(\partial\rho)(\bar{\partial}\rho)(\partial\bar{\rho})+2\rho(\partial\bar{\rho})(\bar{\partial}\bar{\rho})(\partial\rho)-2\rho(\partial\rho)(\partial\bar{\rho})(\bar{\partial}\bar{\rho})-2\bar{\rho}(\partial\rho)(\partial\bar{\rho})(\bar{\partial}\rho)\equiv 0,$$

which completes the proof. Q.E.D.

Proposition 2: If ρ is a solution of sigma model system (3.4), then the functions ψ_1 and ψ_2 defined by (3.3) in terms of ρ satisfy the conservation of potential (1.6) identically.

Proof: Indeed, substituting (3.3) into expression (1.6), we obtain

$$2\rho\,\partial\rho\frac{\overline{\partial\rho}}{(1+|\rho|^2)^2}+\rho^2\frac{\partial\overline{\partial\rho}}{(1+|\rho|^2)^2}-2\rho^2\frac{\overline{\partial\rho}}{(1+|\rho|^2)^3}(\overline{\rho}\partial\rho+\rho\partial\overline{\rho})$$
$$+\frac{\overline{\partial}\partial\rho}{(1+|\rho|^2)^2}-2\frac{\partial\rho}{(1+|\rho|^2)^3}(\overline{\rho}\overline{\partial}\rho+\rho\overline{\partial\rho})=0.$$

By virtue of sigma model equations (3.4), the above-mentioned equation is an identity,

$$\rho\,\partial\rho\,\overline{\partial\rho}-\frac{\rho}{1+|\rho|^2}(1+|\rho|^2)\,\partial\rho\,\overline{\partial\rho}\equiv 0.$$

An analogous result holds for the conjugate equation. Q.E.D.

IV. GROUP INVARIANT SOLUTIONS OF THE SIGMA MODEL

This section is devoted to finding explicit solutions of GW system (1.3) based on transformation (3.3) and uses a variety of classes of invariant solutions of the sigma model (3.4). In order to construct and investigate solutions of sigma model (3.4) obtained by means of the symmetry reduction method[16,17] to ODEs, we need to find its symmetry group G, and then classify all subgroups G_i of G having generic orbits of codimension one in the space of independent variables. We then find the associated invariants of each of its subgroups G_i, and perform for each of these invariants the symmetry reduction of (3.4) to a system of ODEs and then solve these ODEs. The last step requires that a singularity analysis be carried out to determine whether they are of the Painlevé type, and thus whether all their critical points are fixed, or independent of the initial data.

The reductions of sigma model (3.4) to systems of ODEs require consideration of one-dimensional subalgebras of the symmetry algebra of (3.4). Using the MACSYMA program,[18] we find that the classical symmetry groups G of the sigma model equations (3.4) are the conformal and scaling transformations. The corresponding symmetry algebra L is spanned by the vector fields

$$X^1=\xi(z)\partial,\quad X^2=\eta(\overline{z})\overline{\partial},\quad D=\rho\partial_\rho-\overline{\rho}\partial_{\overline{\rho}}. \tag{4.1}$$

Here, ξ and η are arbitrary functions of z and $\overline{z}$, respectively. Now, since the distribution of the vector fields (4.1) is Abelian, it determines that the algebra $\mathcal{L}$ can be decomposed as a direct sum of two infinite-dimensional simple Lie subalgebras with direct sum given by a one-dimensional algebra generated by D,

$$\mathcal{L}=\{X^1\}\oplus\{X^2\}\oplus D. \tag{4.2}$$

If we assume that the functions ξ and η are analytic in a proper open subset Ω of $\mathbb{C}$, then they can be developed in a Laurent series. In this case, we can provide a basis for two centerless Virasoro algebras. Finite-dimensional subalgebras of $\{X^1\}$ and $\{X^2\}$ are spanned only by

$$\{\partial\},\{\partial,z\partial\},\{\partial,z\partial,z^2\partial\},\cdots,\quad \{\overline{\partial}\},\{\overline{z}\overline{\partial}\},\{\overline{\partial},\overline{z}\overline{\partial},\overline{z}^2\partial\},\cdots, \tag{4.3}$$

respectively. The invariant solutions of the one-dimensional subalgebras (4.3) are only holomorphic or antiholomorphic functions and lead to splitting solutions of (3.4), which have been discussed in detail in Ref. 26. According to Refs. 21 and 28, we can apply the method of classifying finite subalgebras of direct-sum algebras (4.2). Here, we state only the result of this classification. We give in the following a list of representatives of conjugacy classes of one-dimensional subalgebras of symmetry algebra $\mathcal{L}$. The statement is that any one-dimensional subalgebra of $\mathcal{L}$ is conjugate under G to give precisely one algebra $L_{1,j}(j=1,\ldots,5)$ in the list and no two members of this list are mutually conjugate. The results are summarized by the following cases:

$$L_{1,1}=\partial, \quad L_{1,2}=D,$$
$$L_{1,3}=\partial+\overline{\partial}, \quad L_{1,4}=D+\partial, \quad L_{1,5}=D+\partial+\overline{\partial}. \tag{4.4}$$

Note that complex conjugate subalgebras to those given in (4.4) were excluded in our classification list. The discrete subgroups of system (3.4) presented in the Appendix were used to restrict the range of parameters appearing in this classification.

For computational purposes, it is useful to examine the real system of PDEs equivalent to the two-dimensional Euclidean sigma model equations (3.4). If we introduce the polar coordinates

$$\rho=\mathrm{R}e^{i\phi} \tag{4.5}$$

into system (3.4), then the real and imaginary parts of the so obtained equations have the following form for the unknown functions R and ϕ:

$$\phi_{xx}+\phi_{yy}+\frac{2(1-R^2)}{R(1+R^2)}(R_x\phi_x+R_y\phi_y)=0, \tag{4.6i}$$

$$R_{xx}+R_{yy}-\frac{R(1-R^2)}{1+R^2}(\phi_x^2+\phi_y^2)-\frac{2R}{1+R^2}(R_x^2+R_y^2)=0. \tag{4.6ii}$$

Note that if we put $R=1$, then (4.6ii) is identically satisfied and the first one reduces to the Laplace equation for the phase ϕ. This implies that ϕ has to be a periodic, harmonic function with a period equal to 2π. Otherwise, if the period of ϕ is not 2π, then the solution (4.6) may become a multivalued function. In our analysis, if we construct solutions that disobey the above-mentioned restriction, then these solutions have to be excluded from our consideration in general.

Equation (4.6) is invariant under the discrete transformations generated by the reflections

$$x\to\epsilon_1 x, \quad y\to\epsilon_2 y, \quad R\to\epsilon_3 R, \quad \phi\to\epsilon_4\phi, \quad \epsilon_i=\pm 1, \quad i=1,\ldots,4, \tag{4.7i}$$

and also the inversion given by

$$R\to\frac{1}{\eta}, \quad \phi\to\phi. \tag{4.7ii}$$

Making use of the MACSYMA program[18] for determining the symmetry algebra of a differential equation, we find that the symmetry algebra $\mathcal{L}$ of Eq. (4.6) is spanned by the following vector fields:

$$X^1=\tfrac{1}{2}\xi(z)(\partial_x-i\partial_y), \quad X^2=\tfrac{1}{2}\overline{\xi}(\overline{z})(\partial_x+i\partial_y), \quad \Phi=\partial_\phi, \tag{4.8}$$

where ξ is an arbitrary function of $z=x+iy$ and $\overline{\xi}$ denotes its complex conjugate. Note the vector fields X^1 and X^2 can be rectified by any conformal transformation $z=z(u)$ and $\overline{z}=\overline{z}(\overline{u})$,

$$X^1=\xi(z)\partial\to\partial_u, \quad X^2=\overline{\xi}(\overline{z})\overline{\partial}\to\partial_{\overline{u}}.$$

It is easy to check that this transformation preserves the form of the sigma model equation (3.4).

For computational purposes, it is useful to change the base of vector fields (4.8). The corresponding symmetry algebra $\mathcal{L}$ is spanned by

$$\alpha^{\pm}=X^1\pm\overline{X^1}=\tfrac{1}{2}\{(\xi\pm\overline{\xi})\partial_x-i(\xi\mp\overline{\xi})\partial_y\}, \quad \Phi=\partial_\phi,$$

since we have

$$\alpha^{+}=X^1+\overline{X^1}=X^2+\overline{X^2}, \quad \alpha^{-}=-i(X^1-\overline{X^1})=-i(X^2-\overline{X^2}).$$

The algebra $\mathcal{L}$ can be decomposed as a direct sum of two infinite-dimensional simple Lie subalgebras with direct sum composed of a one-dimensional algebra generated by Φ,

$$\mathcal{L}=\{\alpha^+\}\oplus\{\alpha^-\}\oplus\{\Phi\}. \tag{4.9}$$

Note that the vector field Φ commutes with the vector fields α^+ and α^-, so it represents the center of the algebra $\mathcal{L}$. Assuming that the function ξ is analytic in a proper open subset of $\mathcal{D}\subset\mathbb{C}$, we can develope ξ as a power series and can provide the following basis:

$$\begin{aligned}\alpha_n^+&=X^1+\overline{X^1}=\frac{1}{2}\{(x+iy)^n+(x-iy)^n\}\partial_x-\frac{i}{2}\{(x+iy)^n-(x-iy)^n\}\partial_y,\\ \alpha_n^-&=-i(X^1-\overline{X^1})=-\frac{i}{2}\{(x+iy)^n-(x-iy)^n\}\partial_x-\frac{1}{2}\{(x+iy)^n+(x-iy)^n\}\partial_y,\end{aligned} \tag{4.10}$$

where $n\in\mathbb{Z}^+$. The vector fields (4.10) generate an infinite-dimensional simple algebra that contains only one finite-dimensional subalgebra spanned by

$$\begin{aligned}&P_1=\partial_x,\quad P_2=\partial_y,\\ &D=x\partial_x+y\partial_y,\quad L_3=y\partial_x-x\partial_y,\\ &C_1=(x^2-y^2)\partial_x+2xy\,\partial_y,\quad C_2=2xy\,\partial_x-(x^2-y^2)\,\partial_y,\end{aligned} \tag{4.11}$$

which corresponds to the case in which the index $n=0,1,2$ in Eq. (4.10). The physical interpretation of this Lie algebra is the following. The operators P_1 and P_2 generate translations in the x and y directions, respectively. The vector fields D and L_3 correspond to dilation and rotation, respectively. The operators C_1 and C_2 generate two different types of conformal transformations. The nonvanishing commutation relations for the algebra (4.11) are given by

$$\begin{aligned}&[C_1,L_3]=C_1,\quad [C_1,D]=-C_2,\quad [C_1,P_1]=-2D,\quad [C_1,P_2]=2L_3,\\ &[C_2,L_3]=-C_2,\quad [C_2,D]=C_1,\quad [C_2,P_1]=-2L_3,\quad [C_2,P_2]=-2D,\\ &[L_3,P_1]=P_2,\quad [L_3,P_2]=-P_1,\quad [D,P_1]=-P_1,\quad [D,P_2]=-P_2.\end{aligned} \tag{4.12}$$

These relations show that this algebra is isomorphic to the $O(3,1)$ algebra. We refer the reader to Ref. 17 and 29 for details of the classification of subalgebras of the symmetry algebra $O(3,1)$ into conjugacy classes under the action of the symmetry group G. In our case, among all nonconjugate subalgebras, the ones that have generic orbits of codimension one in the space of independent variables and three in the space of independent and dependent variables $\{x,y,R,\phi\}$ reduce the original system (4.6) to a system of ODEs via the symmetry reduction method. The one-dimensional subalgebras are given by

$$P_1+b\Phi,\quad L_3+b\Phi,\quad D+b\Phi,\quad D+aL_3+b\Phi, \tag{4.13}$$

where a and b are real parameters. The discrete subgroups (4.7) admitted by (4.6) were used to restrict the range of parameters occurring in this classification. In order to find the reduction associated with subalgebras (4.13), we compute for each of them the corresponding invariants by solving the PDE

$$XH(x,y,R,\phi)=0, \tag{4.14}$$

where H is an auxilliary function of four variables (x,y,R,ϕ), and X is one of the generators listed in (4.13). The solution of (4.14) is found by integrating the associated characteristic system.

TABLE II. The symmetry reduction for Eq. (4.6).

No	Algebra	Symmetry variable ξ	One-dimensional orbits of subgroups	Coefficients of the reduction to ODEs (3.16)	Reduction to second order ODE
1.	$P_1+b\Phi$	y	$R=R(\xi)$	$g=g_0, h=0, s=0$	$\ddot{R}-\frac{2R}{1+R^2}\dot{R}^2-A^2g_0^2\frac{(1-R^2)(1+R^2)^3}{R^3}$
			$\phi=bx+F(\xi)$	$l=1, m=0$	$-\frac{R(1-R^2)}{1+R^2}=0$
2.	$L_3+b\Phi$	$\sqrt{x^2+y^2}$	$R=R(\xi)$	$\frac{\dot{g}}{g}=-\frac{1}{\xi}, h=0, s=0$	$\ddot{R}-\frac{2R}{1+R^2}\dot{R}^2+\frac{1}{\xi}\dot{R}$
			$\phi=b\sin^{-1}\frac{x}{\sqrt{x^2+y^2}}$	$l=\frac{b^2}{\xi^2}, m=0$	$-\frac{A^2C^2}{\xi^2}\frac{(1-R^2)(1+R^2)^3}{R^3}$
			$+F(\xi)$		$-\frac{b^2}{\xi^2}\frac{R(1-R^2)}{1+R^2}=0$
3.	$D+b\Phi$	$\frac{x}{y}$	$R=R(\xi)$	$\frac{\dot{g}}{g}=-\frac{2\xi}{1+\xi^2}, h=\frac{b}{\xi(1+\xi^2)}$	$\ddot{R}-\frac{2R}{1+R^2}\dot{R}^2+\frac{2\xi}{1+\xi^2}\dot{R}$
			$\phi=b\ln x+F(\xi)$	$s=-\frac{b}{\xi^2(1+\xi^2)}, l=\frac{b^2}{\xi^2(1+\xi^2)}$	$-\frac{A(\xi)^2C^2}{(1+\xi^2)^2}\frac{(1-R^2)(1+R^2)^3}{R^3}$
				$m=-\frac{4b}{(1+\xi^2)^2}$	$-\frac{R(1-R^2)}{(1+\xi^2)^2(1+R^2)}=0$
4.	$D+aL_3+b\Phi$	$\ln\sqrt{x^2+y^2}$	$R=R(\xi)$	$g=g_0, h=-\frac{2b}{1+a^2}, l=\frac{b^2}{1+a^2}$	$\ddot{R}-\frac{2R}{1+R^2}\dot{R}^2-A^2g_0^2\frac{(-R^2)(1+R^2)^3}{R^3}$
	$a>0$	$+\frac{1}{a}\tan^{-1}\frac{x}{y}$	$\phi=-\frac{b}{a}\tan^{-1}\frac{x}{y}$	$s=0, m=0$	$+\frac{R(1-R^2)}{1+R^2}b^2\left(\frac{3-a^2}{(1+a^2)^2}\right)=0$
			$+F(\xi)$		

The result of it is that we find three invariants ξ, R, and F which are listed for all cases in Table II. The orbits of the subgroups of G for all considered cases (4.13) can be expressed in terms of two functions R and ϕ in the following form:

$$R=R(\xi), \quad \phi=\alpha(x,y)+F(\xi), \quad \xi=\xi(x,y), \tag{4.15}$$

where α and ξ are given functions of x and y for each subalgebra. Here, the function ξ is the symmetry variable of the invariance subgroup having generic orbits of codimension one. Substituting each specific form (4.15) into system (4.6) leads to the coupled system of ODEs in terms of the symmetry variable ξ only

$$\begin{aligned} &\text{(i)} \quad \ddot{R}-\frac{2R}{1+R^2}\dot{R}^2-\frac{R(1-R^2)}{1+R^2}\dot{\phi}^2-\frac{\dot{g}}{g}\dot{R}-2h\frac{R(1-R^2)}{1+R^2}\dot{\phi}-l\frac{R(1-R^2)}{1+R^2}=0,\\ &\text{(ii)} \quad \ddot{\phi}+2\dot{R}\dot{\phi}\frac{(1-R^2)}{R(1+R^2)}-\frac{\dot{g}}{g}\dot{\phi}+2h\frac{(1-R^2)}{R(1+R^2)}\dot{R}+s=0, \end{aligned} \tag{4.16}$$

where functions g, h, l, and s are given for each of the subalgebras in Table II. The dot means differentiation with respect to ξ. The results of these calculations are summarized in Table II for each of the subalgebras.

The obtained reduced system of ODEs (4.16) has a form similar to the one obtained from the symmetry reduction method for the CP^1 sigma model in $(2+1)$ dimensions as given in Ref. 30. So, following the procedure presented in Ref. 30, Eq. (4.16) can be solved in an analogous way. The results of the Painlevé analysis for system (4.16) and the integration of these reduced ODEs

in terms of elementary functions, Jacobi elliptic functions, or Painlevé transcendents are summarized in Table II. The system of ODEs (4.16) for R and ϕ can be decoupled. If we perform the transformation,

$$\dot{\phi}=V-h, \tag{4.17}$$

on equation (4.16ii), then the function V has to satisfy the nonhomogeneous ODE

$$\dot{V}+2\dot{R}\frac{1-R^2}{R(1+R^2)}V-\frac{\dot{g}}{g}V-m=0, \tag{4.18}$$

where

$$m=\dot{h}-\frac{\dot{g}}{g}h-s_0. \tag{4.19}$$

Let us consider two cases separately.

(1) When $m=0$ Eq. (4.18) is an homogeneous ODE for the function V. This case corresponds to subalgebras $\{P_1+b\Phi\}$, $\{L_3+b\Phi\}$ and $\{D+aL_3+b\Phi\}$ (see Table II). The general integral of the homogeneous ODE (4.18) has the form

$$V=Ag\frac{(1+R^2)^2}{R^2}, \quad A\in\mathbb{R}. \tag{4.20}$$

Hence, transformation (4.17) becomes

$$\dot{\phi}=Ag\frac{(1+R^2)^2}{R^2}-h. \tag{4.21}$$

Elimination of $\dot{\phi}$ from (4.21) and (4.16i) gives

$$\ddot{R}-\frac{2R}{1+R^2}\dot{R}^2-\frac{\dot{g}}{g}\dot{R}-A^2g^2\frac{(1-R^2)(1+R^2)^3}{R^3}+(h^2-l)\frac{R(1-R^2)}{1+R^2}=0. \tag{4.22}$$

(2) When $m\neq 0$ Eq. (4.18) is a nonhomogeneous ODE for the function V. This case is related to subalgebra $D+b\Phi$, as in Table II. The general solution of ODE (4.18) is obtained by the method of variation of parameters and has the following form:

$$V=A(\xi)g\frac{(1+R^2)^2}{R^2}, \tag{4.23}$$

with

$$A(\xi)=\int\frac{mR^2}{g(1+R^2)^2}d\xi'. \tag{4.24}$$

Substituting (4.23) and (4.24) into (4.17), we can eliminate $\dot{\phi}$ from (4.16i), and we get (4.22). In order to construct solutions of (4.22), we have to analyze the singularity structure in the sense of Painlevé and Gambier[31,32] and transform these equations to one of the standard forms listed in Ref. 33. If we perform the transformation of the dependent variable in (4.22) given by

$$R(\xi)=(-U(\xi))^{1/2}, \tag{4.25}$$

then the function U has to satisfy the second-order ODE

$$\ddot{U}=\left(\frac{1}{2U}-\frac{1}{1-U}\right)\dot{U}^2-\frac{\dot{g}}{g}\dot{U}+\frac{2C^2}{g^2}\frac{(1+U)(1-U)^3}{U}. \tag{4.26}$$

Changing the independent variable

$$\eta=\int_{\xi_0}^{\xi}\frac{dt}{g(t)}, \quad g(t)\neq 0, \tag{4.27}$$

in (4.26), we obtain the following ODE in the η variable:

$$\ddot{U}=\left(\frac{1}{2U}-\frac{1}{1-U}\right)\dot{U}^2+\frac{2C^2}{U}(1+U)(1-U)^3. \tag{4.28}$$

If $C=0$, then from (4.17), $\phi=\phi_0$, and Eq. (4.28) becomes Eq. (PXXXVII) listed by Ince[33] with the solution given by

$$U=\tanh^2(K_1\eta+K_2), \quad K_1,K_2\in\mathbb{R}. \tag{4.29}$$

If $C\neq 0$, then Eq. (4.28) is Eq. (PXXXVIII) listed in Ince,[33] where in Ince's notation, $\beta=-\alpha=2C^2$ and $\gamma=\delta=0$. This equation admits a first integral and can be reduced to a first-order ODE for U,

$$U'=-4C^2U^4+4C_1U^3+8(C^2-C_1)U^2+4C_1U-4C^2, \quad C_1\in\mathbb{C}, \tag{4.30}$$

where differentiation is with respect to η. Equation (4.30) can be written in equivalent form for $C\neq 0$,

$$U'^2=-4C^2(U-U_1)(U-U_2)(U-U_3)(U-U_4), \tag{4.31}$$

where U_i, $i=1,\cdots,4$ denote the constant roots of the right-hand side of (4.31). These roots can be expressed in terms of the constants C and C_1. It is well known[30] that the behavior of the solutions of (4.31) depends upon the relationships between the roots of the quartic polynomial on the right-hand side of (4.31). This equation is a known equation which can be solved in terms of elliptic Jacobi functions (see Byrd and Friedman[34]) or in the degenerate cases, as when the roots have multiplicity greater than one, in terms of elementary algebraic functions with one or two simple poles, trigonometric and hyperbolic solitons.

Localized solutions can also be obtained. Suppose that $C=0$, then (4.30) takes the form

$$\dot{U}^2=(4C_1U^2-2(B+4C_1)U+4C_1)U.$$

When $C_1=0$, this can be integrated easily to give

$$U=D\exp(\pm\sqrt{-2B}\,\eta). \tag{4.32}$$

When $C_1\neq 0$, one can write the quadratic in factorized form

$$\dot{U}^2=4C_1(U-U_1)(U-U_2)U,$$

where the roots are given as follows:

$$U_{1,2}=(n+1)\pm\sqrt{n(n+2)}, \tag{4.33}$$

with $n=B/4C_1$. We have summarized all individual possibilities in Tables III–V. It is worth noting, in the case of elliptic doubly periodic solutions of (4.31), we can construct global solutions of GW system through the use of transformation (3.3). Note that nonsingular periodic solutions

TABLE III. The elliptic solutions of the sigma model (4.6), $\rho = R\exp(i\phi)$ with $R = \sqrt{-U(\eta)}$.

No.	Order of roots	Function $U(\eta)$	Function β modulus k
1.	$U_1 > U_2 \geqslant U > 0$	$U_2 sn^2\left(\frac{\sqrt{4K}}{\beta}(\eta-\eta_0),k\right)$	$\beta = \frac{2}{\sqrt{U_1}}$, $k^2 = \frac{U_2}{U_1}$
2.	$U_1 > U_2 > U \geqslant 0$	$\frac{U_1U_2\left(1-sn^2\left(\frac{\sqrt{4K}}{\beta}(\eta-\eta_0),k\right)\right)}{U_1-U_2sn^2\left(\frac{\sqrt{4K}}{\beta}(\eta-\eta_0),k\right)}$	$\beta = \frac{2}{\sqrt{U_1}}, k^2 = \frac{U_2}{U_1}$
3.	$U_1 \geqslant U > U_2 > 0$	$\frac{U_1U_2}{U_1-(U_1-U_2)sn^2\left(\frac{\sqrt{4K}}{\beta}(\eta-\eta_0),k\right)}$	$\beta = \frac{2}{\sqrt{U_1}}, k^2 = \frac{U_1-U_2}{U_1}$
4.	$U_1 > U \geqslant U_2 > 0$	$U_1-(U_1-U_2)sn^2\left(\frac{\sqrt{4K}}{\beta}(\eta-\eta_0),k\right)$	$\beta = \frac{2}{\sqrt{U_1}}, k^2 = \frac{U_1-U_2}{U_1}$
5.	$U > U_1 > U_2 > 0$	$-\frac{U_1-U_2sn^2\left(\frac{\sqrt{4K}}{\beta}(\eta-\eta_0),k\right)}{sn^2\left(\frac{\sqrt{4K}}{\beta}(\eta-\eta_0),k\right)-1}$	$\beta = \frac{2}{\sqrt{U_1}}, k^2 = \frac{U_2}{U_1}$
6.	$\infty > U \geqslant U_1 > U_2 > 0$	$\frac{U_1}{sn^2\left(\frac{\sqrt{4K}}{\beta}(\eta-\eta_0),k\right)}$	$\beta = \frac{2}{\sqrt{U_1}}, k^2 = \frac{U_2}{U_1}$

can be physically interpreted as elementary excitations, kinks as domain walls, and bumps as nucleation centers. Singular solutions represent static defect structures—''charges'' with the quantity which defines order. Some of them develop from a point or a line into a growing sphere or a cylinder g.[35]

As an example to illustrate how this method works, let us write the functions ψ_i for a particular case of the roots of (4.31) and two cases 1 and 4 listed in Table II. Suppose that three of the roots are the same, so that $U_4 = U_3 = U_2 < U \leqslant U_1 < 0$. Equation (4.31) can be integrated and we can solve to obtain U as given in Table V as follows:

$$U = \frac{U_2C^2(U_1-U_2)^2(\eta-\eta_0)^2+U_1}{C^2(U_1-U_2)^2(\eta-\eta_0)^2+1}.$$

For the symmetry algebras $\{P_1+b\Phi\}$ and $\{D+aL_3+b\Phi\}$ in Table II, $g = g_0$ is constant, so from (4.27), we obtain

$$\eta-\eta_0 = \frac{1}{g_0}(\xi-\xi_0),$$

and putting (4.25) into (4.21), we get

$$\phi = -g_0A\int \frac{(1-U)^2}{U}d\xi - h\xi.$$

In the case of subalgebra $\{P_1+b\Phi\}$, for which the symmetry variable is given by $\xi = y$, and $h = 0$, we can determine the function ρ given by (4.5) in the following form:

TABLE IV. The elliptic solutions of the sigma model (4.6), $R=\sqrt{-U(\eta)}$ with $(\dot{U})^2=-4C^2(U-U_1)(U-U_2)(U-U_3)(U-U_4)$ $C\neq 0$ and phase ϕ specified in this table, and $A^2=(U_1-b_1)^2+a_1^2$, $B^2=(U_2-b_1)^2+a_1^2$ $a_1=-(c-\overline{c})^2/4$, and $b_1=(c+\overline{c})/2$.

9.	$U_4\leqslant U\leqslant U_3<U_2<U_1$	$\dfrac{U_1(U_3-U_4)sn^2[\beta(\eta-\eta_0),k]+U_4(U_1-U_3)}{(U_3-U_4)sn^2[\beta(\eta-\eta_0),k]+U_1-U_3}$	$k^2=\dfrac{(U_1-U_2)(U_3-U_4)}{(U_1-U_3)(U_2-U_3)}$ $\beta=C\sqrt{(U_1-U_3)(U_2-U_4)}$ $C\neq 0$
10.	$U_4<U_3<U_2\leqslant U\leqslant U_1<0$	$\dfrac{U_4(U_1-U_2)sn^2[\beta(\eta-\eta_0),k]+U_1(U_2-U_4)}{(U_1-U_2)sn^2[\beta(\eta-\eta_0),k]+U_2-U_4}$	$k^2=\dfrac{(U_1-U_2)(U_3-U_4)}{(U_1-U_3)(U_2-U_3)}$ $\beta=C\sqrt{(U_1-U_3)(U_2-U_4)}$ $C\neq 0,B>4(C^2+(-K))>0$

$$\rho=\mathrm{Re}^{i\phi}=\sqrt{-\frac{U_2C^2g_0^{-2}(U_1-U_2)^2(y-y_0)^2+U_1}{C^2g_0^{-2}(U_1-U_2)^2(y-y_0)^2+1}}\exp\Bigg[i\Bigg(bx+\frac{g_0^2A}{C}\tan^{-1}((y-y_0)\times(U_2-U_1)g_0^{-1}C)-\frac{g_0^2A(U_2-U_1)}{CU_2(U_1U_2)^{1/2}(U_1-U_2)}\tan^{-1}\Bigg(\frac{U_2C(U_2-U_1)^2(y-y_0)}{g_0(U_1U_2)^{1/2}(U_1-U_2)}\Bigg)-g_0A\frac{(U_2-1)^2}{U_2}y\Bigg)\Bigg].$$

To evaluate the ψ_i, one next calculates the derivatives $\partial\rho$ and $\overline{\partial\rho}$, and then substitutes these into transformation (3.3). To abbreviate the notation, let us define the quantities

$$k=C^2g_0^{-2}(U_1-U_2)^2,\quad f=g_0(U_1U_2(U_1-U_2)^2)^{1/2},\quad Q=g_0^2(A(U_2-U_1)/CU_2). \tag{4.34}$$

Then for the case of the subalgebra $\{P_1+b\Phi\}$, the ψ_i are as follows:

$$\psi_1=\epsilon\frac{\rho}{1-U}\Bigg[-\frac{iU_2k(\xi-\xi_0)}{2Rk(\xi-\xi_0)^2+1}-\frac{1}{2}iRk(\xi-\xi_0)-iR\Bigg(\frac{1}{2}b+\frac{ig_0A(U_2-U_1)}{2(1+(U_2-U_1)^2g_0^{-2}C^2(\xi-\xi_0)^2)}$$
$$-\frac{ig_0QU_2C(U_2-U_1)^2}{2(f^2+U_2^2C^2(U_2-U_1)^4(\xi-\xi_0)^2)}-\frac{ig_0A(U_2-1)^2}{2U_2}\Bigg)\Bigg]^{1/2}\exp(-i\phi/2),$$

$$\psi_2=\frac{\epsilon}{1-U}\Bigg[\frac{iU_2k(\xi-\xi_0)}{2Rk(\xi-\xi_0)^2+1}+\frac{1}{2}iRk(\xi-\xi_0)+iR\Bigg(\frac{1}{2}b-\frac{ig_0A(U_2-U_1)}{2(1+(U_2-U_1)^2g_0^{-2}C^2(\xi-\xi_0)^2)}$$
$$+\frac{ig_0QCU_2(U_2-U_1)^2}{2(f^2+U_2^2C^2(U_2-U_1)^4(\xi-\xi_0)^2)}+\frac{ig_0A(U_2-1)^2}{2U_2}\Bigg)\Bigg]^{1/2}\exp(i\phi/2). \tag{4.35}$$

For the subalgebra $\{D+aL_3+b\Phi\}$, the function ρ given by (4.5) can be written down in terms of the symmetry variable abbreviated as $\xi=\ln\sqrt{x^2+y^2}+(1/a)\tan^{-1}x/y$ and $h=2b/(1+a^2)$,

$$\rho=\sqrt{-\frac{U_2C^2g_0^{-2}(U_1-U_2)^2(\xi-\xi_0)^2+U_1}{C^2g_0^{-2}(U_1-U_2)^2(\xi-\xi_0)^2+1}}\exp\Bigg[i\Bigg(-\frac{b}{a}\tan^{-1}\frac{x}{y}+\frac{g_0^2A}{C}\Bigg)\tan^{-1}((\xi-\xi_0)(U_2$$
$$-U_1)g_0^{-1}C)-\frac{g_0^2A(U_2-U_1)}{CU_2(U_1U_2)^{1/2}(U_1-U_2)}\tan^{-1}\Bigg(\frac{U_2C(U_2-U_1)^2(\xi-\xi_0)}{g_0(U_1U_2)^{1/2}(U_1-U_2)}-g_0A\frac{(U_2-1)^2}{U_2}\xi$$
$$+\frac{2b}{1+a^2}\xi\Bigg)\Bigg].$$

Defining the additional variables

$$s_1=1+\frac{x^2}{y^2},\quad s_2=\frac{1}{2iy}+\frac{x}{2y^2},\quad \tilde{s}_2=\frac{1}{2iy}-\frac{x}{2y^2},\quad w_1=\frac{1}{2z}+\frac{is_2}{as_1},\quad w_2=\frac{1}{2\bar{z}}+\frac{i\tilde{s}_2}{as_1},$$

and with k, f, and Q defined by (4.34), the functions ψ_i are calculated by differentiating ρ and using transformation (3.3)

$$\psi_1=\epsilon\frac{\rho}{1-U}\Bigg[-\frac{U_2k(\xi-\xi_0)w_2}{(k(\xi-\xi_0)^2+1)R}+\frac{(U_2k(\xi-\xi_0)^2+U_1)k(\xi-\xi_0)w_2}{R(k(\xi-\xi_0)^2+1)^2}-iR\Bigg(-\frac{ib\tilde{s}_2}{as_1}$$
$$+\frac{g_0A(U_2-U_1)w_2}{1+(U_2-U_1)^2g_0^{-2}C^2(\xi-\xi_0)^2}-\frac{g_0QCU_2(U_2-U_1)^2w_2}{f^2+U_2^2C^2(U_2-U_1)^4(\xi-\xi_0)^2}-\frac{g_0A(U_2-1)^2}{U_2}w_2$$
$$+\frac{2b}{1+a^2}w_2\Bigg)\Bigg]^{1/2}\exp(-i\phi/2),$$

$$\psi_2=\frac{\epsilon}{1-U}\Bigg[-\frac{U_2k(\xi-\xi_0)w_1}{(k(\xi-\xi_0)^2+1)R}+\frac{(U_2k(\xi-\xi_0)^2+U_1)k(\xi-\xi_0)w_1}{R(k(\xi-\xi_0)^2+1)^2}+iR\Bigg(-\frac{ibs_2}{as_1}$$
$$+\frac{g_0A(U_2-U_1)w_1}{1+(U_2-U_1)^2g_0^{-2}C^2(\xi-\xi_0)^2}-\frac{g_0QCU_2(U_2-U_1)^2w_1}{f^2+U_2^2C^2(U_2-U_1)^4(\xi-\xi_0)^2}-\frac{g_0A(U_2-1)^2}{U_2}w_1$$
$$+\frac{2b}{1+a^2}w_1\Bigg)\Bigg]^{1/2}\exp(i\phi/2). \tag{4.36}$$

A class of solutions of (4.26), which are different from those obtained above, can be constructed by introducing the change of independent variables

$$\eta = \int g(\xi)\, \mathrm{d}\xi, \tag{4.37}$$

into (4.26). We obtain

$$U'' = \left(\frac{1}{2U} + \frac{1}{U-1}\right) U'^2 + 2\frac{g'}{g} U' - \frac{2C^2}{g^4}(1-U)^2\left(\frac{1}{U} - U\right), \tag{4.38}$$

where differentiation is with respect to η. Note that if $g = g_0$, then we obtain the previously discussed case (PXXXVIII). The symmetry reduction to ODE (4.38) with $g = A\xi$ is related to the symmerty algebra L_3. In this case, Eq. (4.38) is the standard form for the fifth Painlevé transcendent,[33] where in Ince's notation, $\beta = -\alpha = 2C^2/A^4$ and $\gamma = \delta = 0$. However, if we make the transformation

$$g = \exp\left(\int_{\xi_0}^{\xi} r(\eta)\, \mathrm{d}\eta \right),$$

for which the function r is given by one of the following two cases

$$r = \frac{1}{A\xi^2}, \quad r = \frac{2\xi}{A(1+\xi^2)^2},$$

which are related to the algebra L_3 or D, respectively, then Eq. (4.38) is Eq. (PXXXX) listed in Ref. 33. According to Ref. 33, Eq. (4.38) can be reduced to the first-order ODE after the transformation

$$\frac{1}{u-1} u' - B e^{-2\int r\, \mathrm{d}\eta} u = -2w, \quad B \in \mathbb{R},$$

to a Riccati equation of the form

$$w' + w^2 + 2rw - \tfrac{1}{2} B^2 e^{-4\int r\, \mathrm{d}\eta} = E e^{-2\int r\, \mathrm{d}\eta}. \tag{4.39}$$

If g in Eq. (4.38) is a constant, then we can perform a new transformation on the independent variable

$$\eta = e^{i g_0 (\xi - \xi_0)},$$

into (4.38) and obtain

$$U'' = \left(\frac{1}{2U} + \frac{1}{U-1}\right) U'^2 - \frac{1}{\eta} U' + \frac{2C^2}{g^4}(1-U)^2\left(\frac{1}{U} - U\right). \tag{4.40}$$

This is the equation for the fifth Painlevé transcendent, where in Ince's notation, $\beta = -\alpha = 2C^2/g_0^4$ and $\gamma = \delta = 0$, which is related to the reduction obtained from the symmetry algebras P_1 and $\{D + aL_3\}$, respectively.

In many solitonlike problems in field theory, the field configuration of finite energy (1.13) is relevant to many applications.[5,8,9] Such a situation takes place for the following reductions: In the case of Eq. (4.29), we obtain a kink soliton solution. Bump-type solutions appear in 3 and 4 of Table V. Localized solitonlike solutions are listed in Tables III and IV, cases 1–8, and Table V, cases 7–10.

V. THE NONSPLITTING SOLUTIONS OF THE GENERALIZED WEIERSTRASS SYSTEM

Now we discuss the case when some classes of solutions of GW system (1.3) can be obtained from transformation (3.3) for which the solutions of the sigma model (3.4) are invariant under the scaling transformation D as given in (4.1). This means that we subject system (1.3) to the algebraic constraint

$$|\rho|^2=1. \tag{5.1}$$

It follows from (5.1) that sigma model (3.4) can be written

$$\partial\overline{\partial}\rho-\overline{\rho}\partial\rho\overline{\partial}\rho=0, \quad \overline{\partial}\partial\overline{\rho}-\rho\partial\overline{\rho}\overline{\partial}\overline{\rho}=0, \tag{5.2}$$

and has a solution of the exponential form

$$\rho=e^{i\varphi}, \tag{5.3}$$

where φ is any real harmonic function of z and $\overline{z}$, since from (3.4), we get the following identity:

$$\partial\overline{\partial}\rho-\overline{\rho}\partial\rho\overline{\partial}\rho=e^{i\varphi}(i\partial\overline{\partial}\varphi-\partial\varphi\overline{\partial}\varphi)+e^{i\varphi}(e^{-i\overline{\varphi}}e^{i\varphi}\partial\varphi\overline{\partial}\varphi)\equiv 0.$$

The transformation (3.3) becomes

$$\psi_1=\frac{\epsilon}{2}e^{i\varphi/2}(\overline{\partial}\varphi)^{1/2}, \quad \psi_2=\frac{\epsilon}{2}e^{i\varphi/2}(\partial\varphi)^{1/2}, \quad \epsilon=\pm 1,$$

and satisfies GW system (1.3).

In this section, we shall study nonsplitting solutions of overdetermined system (3.4) and (5.1) depending on one arbitrary complex valued function of one complex variable z and its complex conjugate

$$\rho=\frac{f(z)}{\overline{f(z)}}.$$

In this case, transformation (3.3) defined in terms of a function f takes the form

$$\psi_1=\frac{\epsilon}{2\overline{f}}(f\,\overline{\partial f})^{1/2}, \quad \psi_2=\frac{\epsilon}{2\overline{f}}(\overline{f}\partial f)^{1/2}, \quad p=\frac{1}{2}\left|\frac{\partial f}{f}\right|.$$

The associated surface determined from Eq. (1.7) becomes

$$\begin{aligned}
X_1+iX_2&=\frac{i}{2}\int_\gamma\left(\frac{\overline{f}\partial f}{f^2}\mathrm{d}z'-\frac{\overline{\partial f}}{\overline{f}}\mathrm{d}\overline{z}'\right),\\
X_1-iX_2&=\frac{i}{2}\int_\gamma\left(\frac{\partial f}{f}\mathrm{d}z'-\frac{f\overline{\partial f}}{\overline{f}^2}\mathrm{d}\overline{z}'\right),\\
X_3&=-\frac{1}{2}\int_\gamma\left(\frac{\partial f}{f}\mathrm{d}z'+\frac{\overline{\partial f}}{\overline{f}}\mathrm{d}\overline{z}'\right).
\end{aligned} \tag{5.4}$$

The constant mean curvature surfaces corresponding to (5.4) for $f(z)=z^n$, $n=6,8,9$ are shown in Figs. 1–3. The induced metric on the surface and its Gaussian curvature (1.8) are given by

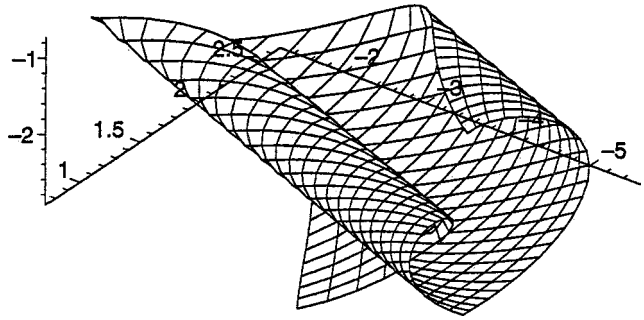

FIG. 1. The constant mean curvature surface for the case (5.4) with $f(z)=z^6$.

$$ds^2=\left|\frac{\partial f}{f}\right|^2 dz\, d\bar{z}, \quad K=-\left(\frac{1}{2}\left|\frac{\partial f}{f}\right|\right)^{-2}\partial\bar{\partial}\left(\ln\left|\frac{\partial f}{f}\right|\right)=0,$$

respectively.

Note that if function ρ is a solution of (3.4), and ρ satisfies algebraic condition (5.1), then both of the functions ρ^{-1} and $\bar{\rho}$ are also solutions of Eq. (3.4). In fact, the derivatives of ρ are

$$\partial\bar{\rho}=-\frac{1}{\rho^2}\partial\rho, \quad \bar{\partial}\bar{\rho}=-\frac{1}{\rho^2}\bar{\partial}\rho, \quad \partial\bar{\partial}\bar{\rho}=\frac{2}{\rho^3}(\partial\rho\,\bar{\partial}\rho)-\frac{1}{\rho^2}\partial\bar{\partial}\rho. \tag{5.5}$$

Substituting (5.5) into Eq. (3.4), we obtain

$$2\frac{\partial\rho\,\bar{\partial}\rho}{\rho^3}-\frac{1}{\rho^2}\partial\bar{\partial}\rho-\frac{1}{\rho^3}\partial\rho\bar{\partial}\rho=0,$$

which is just the identity

$$\partial\bar{\partial}\rho-\frac{1}{\rho}\partial\rho\,\bar{\partial}\rho\equiv 0,$$

since $\bar{\rho}=1/\rho$, and whenever (3.4) holds. Then we have the following Propositions.

Proposition 3: Suppose that for any complex-valued function F of class C^1, the function ρ satisfies the algebraic condition (5.1) and the differential constraints

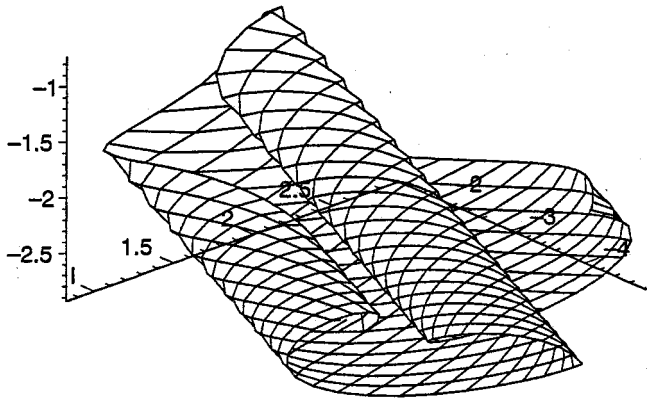

FIG. 2. The constant mean curvature surface for the case (5.4) with $f(z)=z^8$.

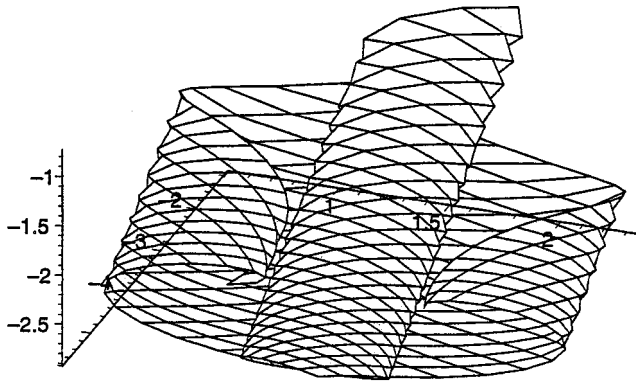

FIG. 3. The constant mean curvature surface for the case (5.4) with $f(z)=z^9$.

$$\partial\rho = F(z)\rho, \quad \overline{\partial}\rho = -\overline{F}(\overline{z})\rho. \tag{5.6}$$

Then the complex valued function ρ is a nonsplitting solution of the system (3.4). The associated surface has zero Gaussian curvature (1.8).

Proof: Note that from Eq. (5.6), we have

$$\overline{\partial}\partial\rho = F(z)\overline{\partial}\rho.$$

Thus, system (3.4) is identically satisfied, since

$$F(\overline{\partial}\rho) - \overline{\rho}(F\rho)(-F\rho) = F(-\overline{F}\rho) - F\overline{F}\rho \equiv 0$$

holds. Moreover, from (3.3), we get

$$\partial\psi_1 = \frac{\epsilon}{4}(\overline{F}\rho)^{1/2}F, \quad \overline{\partial}\psi_2 = -\frac{\epsilon}{4}(F\rho)^{1/2}\overline{F}, \quad p = \frac{1}{2}(F\overline{F})^{1/2}, \quad \epsilon = \pm 1.$$

So in view of (4.7), the GW system is also identically satisfied. Moreover, we have

$$\partial \ln p = \frac{\partial p}{p} = \frac{\partial F}{2F},$$

which implies that $\overline{\partial}(\partial p) = 0$, since F is a function of only z. Thus from formula (1.8), the Gaussian curvature K is zero. Q.E.D.

We now discuss the possibility of constructing more general classes of solutions of GW system (1.3) which are based on nonlinear superpositions of N elementary solutions of sigma model (3.4).

Proposition 4: (Factorization) Suppose that for each $i=1,\ldots,N$ the complex valued functions ρ_i satisfy the sigma model system (3.4) and the conditions $|\rho_i|^2 = 1$. Then the product function

$$\rho = \prod_{i=1}^{N} \rho_i \tag{5.7}$$

is also a solution of system (3.4). The corresponding solution of the GW system (1.3) takes the following factorized form:

$$\psi_1 = \frac{1}{2}\epsilon \prod_{i=1}^{N} \rho_i \left(\overline{\partial} \prod_{j=1}^{N} \overline{\rho_j} \right)^{1/2}, \quad \psi_2 = \frac{1}{2}\epsilon \left(\partial \prod_{j=1}^{N} \rho_j \right)^{1/2}.$$

Proof: It suffices to prove this for $N=2$, and then to invoke induction to extend this to any N. Suppose that ρ_1,ρ_2 are solutions to (3.4). Substituting the function $\rho=\rho_1\rho_2$ into (3.4), we obtain

$$(\overline{\partial}\partial\rho_1)\rho_2+\partial\rho_1\overline{\partial}\rho_2+\overline{\partial}\rho_1\partial\rho_2+\rho_1\overline{\partial}\partial\rho_2-\overline{\rho}_1\rho_2\partial\rho_1\overline{\partial}\rho_1-\overline{\partial}\rho_1\partial\rho_2-\partial\rho_1\overline{\partial}\rho_2-\rho_1\overline{\rho}_2\partial\rho_2\overline{\partial}\rho_2$$
$$=\rho_2(\overline{\partial}\partial\rho_1-\overline{\rho}_1\partial\rho_1\overline{\partial}\rho_1)+\rho_1(\overline{\partial}\partial\rho_2-\overline{\rho}_2\partial\rho_2\overline{\partial}\rho_2)=0,$$

whenever the functions ρ_i satisfy sigma model equations (3.4). Thus, the product of two solutions is a solution. Consequently, proceeding inductively from the product form of ρ given in (5.7), if the equation is satisfied for a solution with k factors, it is satisfied for a solution with $k+1$ factors. Substituting (5.7) into (3.3), we obtain ψ_1 and ψ_2 which satisfy system (1.3). Q.E.D.

Propositions 3 and 4 provide us with the possibility of constructing a class of nonsplitting solutions of Eq. (1.3). We now present several examples of such solutions.

(1) Let us discuss now the construction of an algebraic multisoliton solution of the GW system (1.3). First, we look for a particular class of rational solutions of (3.4) admitting simple poles at the points $\overline{z}=\overline{a_j}$,

$$\rho_j=\frac{z-a_j}{\overline{z}-\overline{a}_j},\quad a_j\in\mathbb{C},\quad j=1,\ldots,N. \tag{5.8}$$

By virtue of Propositions 3 and 4, a more general case than (5.8) can be constructed by taking products over j in (5.8), when the solution ρ_j of (3.4) admits an arbitrary number of simple poles,

$$\rho=\prod_{k=1}^{N}\frac{z-a_k}{\overline{z}-\overline{a}_k},\quad a_k\in\mathbb{C}, \tag{5.9}$$

where we assume that all a_k are distinct. Note that the complex function ρ admits a removable singularity since

$$\lim_{z\to a_k}(\overline{z}-\overline{a}_k)\left(\frac{z-a_k}{\overline{z}-\overline{a}_k}\right)=0,$$

and thus

$$\lim_{z\to a_k}(\overline{z}-\overline{a}_k)\prod_{j=1}^{N}\left(\frac{z-a_j}{\overline{z}-\overline{a}_j}\right)=0.$$

In that case the function ρ satisfies both conditions $\partial\overline{\partial}\rho\neq 0$ and $|\rho|^2=1$. Substituting (5.9) into (3.4), we obtain that Eq. (3.4) is satisfied identically, where the required first derivatives of ρ are given by

$$\partial\rho=\sum_{j=1}^{N}\frac{1}{(z-a_j)}\rho\equiv F(z)\rho,\quad \overline{\partial}\rho=-\sum_{j=1}^{N}\frac{1}{(\overline{z}-\overline{a}_j)}\rho\equiv-\overline{F}(\overline{z})\rho. \tag{5.10}$$

Substituting (5.9) and (5.10) into (3.3), we determine the explicit form of an algebraic multisoliton solution of the GW system

$$\psi_1=\frac{\epsilon}{2}\left(\sum_{j=1}^{N}\frac{1}{(\overline{z}-\overline{a}_j)}\overline{\rho}\right)^{1/2},\quad \psi_2=\frac{\epsilon}{2}\left(\sum_{j=1}^{N}\frac{1}{(z-a_j)}\rho\right)^{1/2},\quad \epsilon=\pm 1. \tag{5.11}$$

For the case $N=1$, substituting (5.11) into relation (1.4), we obtain that the corresponding constant mean curvature surface is determined by

$$(X_1^2+X_2^2)^2-\left(2+\frac{a^2}{4}e^{2X_3}\right)(X_1^2+X_2^2)+\frac{a^2}{2}e^{2X_3}X_2+1-\frac{a^2}{4}e^{2X_3}=0.$$

(2) Another class of rational solutions can be written down by noting that, by Proposition 4, a new solution can be found by taking products of ρ_k with itself k times and so

$$\rho_k=\left(\frac{z-a_k}{\overline{z}-\overline{a}_k}\right)^k$$

satisfies identically Eq. (3.4) for any integer k and complex a_k. Consequently, we can generalize the form of this solution to another type of nonsplitting multisoliton solution of (3.4) by applying Proposition 4 again and forming products over k. This solution is generated by a ρ of the form

$$\rho=\prod_{k=1}^{N}\left(\frac{z-a_k}{\overline{z}-\overline{a}_k}\right)^k. \tag{5.12}$$

Note that for each a_k, the function ρ has a removable singularity. So in this case, the function ρ satisfies $|\rho|^2=1$, and the derivatives of ρ are given by

$$\partial\rho=\sum_{k=1}^{N}\frac{k}{z-a_k}\rho\equiv H\rho,\quad \overline{\partial}\rho=-\sum_{k=1}^{N}\frac{k}{\overline{z}-\overline{a}_k}\rho\equiv\overline{H}\rho. \tag{5.13}$$

Substituting (5.12) and (5.13) into Eq. (3.4), we find that

$$\overline{\partial}\partial\rho-\overline{\rho}\partial\rho\overline{\partial}\rho=-\sum_{k=1}^{N}\frac{k}{z-a_k}\sum_{j=1}^{N}\frac{j}{\overline{z}-\overline{a}_j}\rho+\overline{\rho}\sum_{k=1}^{N}\frac{k}{z-a_k}\rho\sum_{j=1}^{N}\frac{j}{\overline{z}-\overline{a}_j}\rho=0.$$

From (5.12) and (5.13), we can determine through the transformation (3.3) the explicit form of an algebraic multisoliton solution of the GW system

$$\psi_1=\frac{\epsilon}{2}\left(\sum_{k=1}^{N}\frac{k}{(\overline{z}-\overline{a}_k)}\overline{\rho}\right)^{1/2},\quad \psi_2=\frac{\epsilon}{2}\left(\sum_{k=1}^{N}\frac{k}{(z-a_k)}\rho\right)^{1/2}. \tag{5.14}$$

Similarly, these solutions as in the previous case (5.11) also admit simple poles at $z=a_k$

(3) An interesting class of nonsplitting solution can be found by applying Proposition 4 to ρ_k a total of n times for a fixed number n, to obtain a new solution, and then applying Proposition 4 again by taking products over k,

$$\rho=\prod_{k=1}^{N}\left(\frac{z-a_k}{\overline{z}-\overline{a}_k}\right)^n. \tag{5.15}$$

The function ρ satisfies (5.1), and the derivatives of ρ are given by

$$\partial\rho=n\sum_{j=1}^{N}\frac{1}{(z-a_j)}\rho,\quad \overline{\partial}\rho=-n\sum_{j=1}^{N}\frac{1}{(\overline{z}-\overline{a}_j)}\rho. \tag{5.16}$$

From (3.3), the solution of GW system (1.3) in this case takes the form

$$\psi_1=\frac{\epsilon}{2}\left(n\sum_{j=1}^{N}\frac{1}{(\overline{z}-\overline{a}_j)}\overline{\rho}\right)^{1/2},\quad \psi_2=\frac{\epsilon}{2}\left(n\sum_{j=1}^{N}\frac{1}{(z-a_j)}\rho\right)^{1/2}. \tag{5.17}$$

Note that the function ψ_i admits only simple poles.

(4) There exists an exponential class of nonsplitting solution of GW system (1.3) which is generated by the products of functions of the form $\rho_j = e^{\overline{\alpha_i} z - \alpha_i \overline{z}}$ as follows:

$$\rho = \prod_{j=1}^{N} \rho_j = e^{\overline{A} z - A \overline{z}}. \tag{5.18}$$

This satisfies condition (5.1), and generates, using Proposition 4, the following class of solutions of GW system (1.3):

$$\psi_1 = \frac{\epsilon}{2} A^{1/2} e^{(\overline{A} z - A \overline{z})/2}, \quad \psi_2 = \frac{\epsilon}{2} \overline{A}^{1/2} e^{(\overline{A} z - A \overline{z})/2}. \tag{5.19}$$

(5) An explicit class of solutions to GW system (1.3) admitting two arbitrary real-valued functions of one real variable can be constructed based on the idea of Proposition 4. Suppose that h and χ are real-valued functions of one variable $s = z + \overline{z}$, then the following function

$$\rho = e^{-i\chi(s)} \frac{c_1 e^{h(s)} + c_2 e^{-h(s)}}{\overline{c_1} e^{h(s)} + \overline{c_2} e^{-h(s)}}, \quad c_1, c_2 \in \mathbb{C}, \tag{5.20}$$

satisfies the constraint (5.1) and system (3.4), provided that the condition $c_1 \overline{c_2} - c_2 \overline{c_1} = 0$ on the complex constants c_1 and c_2 holds. Defining the quantities

$$f^{(\pm)}(s) = c_1 e^{h(s)} \pm c_2 e^{-h(s)},$$

and using Proposition 2, we can write a general solution of the sigma model (3.4) as follows:

$$\rho = \exp\left[-i \sum_{j=1}^{N} \chi_j(s) \right] \prod_{i=1}^{N} \frac{f_i^{(+)}(s)}{\overline{f_i^{(+)}}(s)}. \tag{5.21}$$

So, we have

$$\partial\rho = \left[-i \sum_{j=1}^{N} \chi_j' + \sum_{k=1}^{N} \frac{f_k^{(-)} h_k'}{f_k^{(+)}} - \sum_{k=1}^{N} \frac{\overline{f_k^{(-)}} h_k'}{\overline{f_k^{(+)}}} \right] \rho, \tag{5.22}$$

where the prime represents differentiation of χ and h with respect to s. Substituting (5.21) and (5.22) into transformation (3.3), we determine explicitly the corresponding form of multisoliton solution of GW system (1.3),

$$\begin{aligned} \psi_1 &= \frac{\epsilon}{2} \left(\rho \left[i \sum_{j=1}^{N} \chi_j' + \sum_{k=1}^{N} \frac{\overline{f_k^{(-)}} h_k'}{\overline{f_k^{(+)}}} - \sum_{k=1}^{N} \frac{\overline{f_k^{(-)}} h_k'}{\overline{f_k^{(+)}}} \right] \right)^{1/2}, \\ \psi_2 &= \frac{\epsilon}{2} \left(\rho \left[-i \sum_{j=1}^{N} \chi_j' + \sum_{k=1}^{N} \frac{f_k^{(-)} h_k'}{f_k^{(+)}} - \sum_{k=1}^{N} \frac{\overline{f_k^{(-)}} h_k'}{\overline{f_k^{(+)}}} \right] \right)^{1/2}. \end{aligned} \tag{5.23}$$

Note that solutions (5.23) do not admit any singularities when $c_1 \neq c_2$.

(6) Using Proposition 4, an interesting class of periodic nonsplitting solutions of (3.4) satisfying the algebraic constraint (5.1) has the form

$$\rho = \exp\left(\sum_{j=1}^{N} (\cos(z - a_j) - \cos(\overline{z} - \overline{a_j})) \right). \tag{5.24}$$

The derivatives of ρ are given by

$$\partial\rho=-\sum_{j=1}^{N}\sin(z-a_j)\rho,\quad \overline{\partial}\rho=\sum_{j=1}^{N}\sin(\overline{z}-\overline{a}_j)\rho.$$

Then using (3.3), we can find that the solutions of GW system (1.3) are

$$\psi_1=\frac{\epsilon}{2}\left(-\sum_{j=1}^{N}\sin(\overline{z}-\overline{a}_j)\overline{\rho}\right)^{1/2},\quad \psi_2=\frac{\epsilon}{2}\left(-\sum_{j=1}^{N}\sin(z-a_j)\rho\right)^{1/2},\quad p=\frac{1}{2}\left|\sum_{j=1}^{N}\sin(z-a_j)\right|. \tag{5.25}$$

Note that solutions (5.19) and (5.25) do not admit any singularities. When $N=1$, the associated constant mean curvature surface can be computed from relation (1.7),

$$u(X_1+iX_2)=-iv,\quad v(X_1-iX_2)=iu,\quad uv=e^{2X_3},$$

where $u=\exp(\cos(z-a))$ and $v=\exp(\cos(\overline{z}-\overline{a}))$. The corresponding surface is a cylinder having X_3 as a symmetry axis since X_1 and X_2 satisfy $X_1^2+X_2^2=1$. Similar calculations to the one given by (5.24) can be performed when cos in (5.24) is replaced by trigonometric and hyperbolic functions sin and cosh or sinh, respectively. This procedure provides us with several classes of periodic solutions of GW system (1.3).

Finally, one can apply Proposition 4 again to solutions of the form (5.24) of sigma model (3.4) by replacing the cos function by sin and taking products of these resulting solutions, namely (5.24) and the modified one,

$$\begin{aligned}\rho&=\exp\left(\sum_{j=1}^{N}(\cos(z-a_j)-\cos(\overline{z}-\overline{a}_j)+\sin(z-a_j)-\sin(\overline{z}-\overline{a}_j))\right)\\&=\exp\left(\sum_{j=1}^{N}\left(-2\sin\left(\frac{z+\overline{z}-a_j-\overline{a}_j}{2}\right)\sin\left(\frac{z-\overline{z}-a_j+\overline{a}_j}{2}\right)\right.\right.\\&\quad\left.\left.+2\cos\left(\frac{z+\overline{z}-a_j-\overline{a}_j}{2}\right)\sin\left(\frac{z-\overline{z}-a_j+\overline{a}_j}{2}\right)\right)\right).\end{aligned} \tag{5.26}$$

The corresponding solution of GW system (1.3) has the form

$$\begin{aligned}\psi_1&=\frac{1}{2}\epsilon\left(\overline{\rho}\sum_{j=1}^{N}(-\sin(\overline{z}-\overline{a}_j)+\cos(\overline{z}-\overline{a}_j))\right)^{1/2},\\\psi_2&=\frac{1}{2}\epsilon\left(\rho\sum_{j=1}^{N}(-\sin(z-a_j)+\cos(z-a_j))\right)^{1/2}.\end{aligned} \tag{5.27}$$

Note that there exists a resemblance of function ρ given by (5.26) to a Calogero–Sutherland type potential.[36] A large class of hyperbolic nonsplitting solution can be obtained by replacing the trigonometric functions appearing in (5.26) by hyperbolic functions, and these solutions lead to spherical surfaces, namely, $X_1^2+X_2^2+X_3^2=1$. Solutions which yield cylinders and spheres can have applications to certain types of cosmological models.[5]

Recently, a new approach to classical configurations of strings in three-dimensional Euclidean space has been proposed.[6,12] It is basically done by representing the Euler–Lagrange equation for the Nambu–Goto–Polyakov action in a simple form. One then looks for common solutions of this equation and the GW system. From a physical point of view, it has been proposed to describe QCD flux tubes in this way. Conformal invariance is important here because one is involved in the

construction of a Lorentz invariant extended object. The world sheet of the string will obey a two-dimensional wave equation, and using the conformal invariance of this equation, by a suitable choice of conformal frame, one may get rid of the vibrations in, for example, the timelike direction.

In the case in which the mean curvature is constant, the Euler–Lagrange equation reduces to the Liouville equation in the variable $\theta=\ln p^2$ as follows, $\partial\bar{\partial}\theta+\beta e^{\theta}=0$. All of the new solutions here can be made to satify this if β is taken to be zero. Konopelchenko[6] has pointed out that the Liouville equation is of importance since it can be thought of as describing a theory of metrics. In fact, the idea that a geometric realization of gravity as extended two-dimensional gravity involves $\mathbb{R}^3$ surfaces of constant mean curvature.[6] Generalized exponential solutions generated by (1.3) in the case $\partial p=\bar{\partial}\bar{p}$ have applications to gravity. In a certain limit of Laplace–Beltrami gravity, the action of the theory corresponds to the action of the sigma model and the equation of motion then corresponds to (3.4). It turns out[6] that multi-instanton or anti-instanton solutions of the form (5.9) are the only solutions of (3.4) with finite action.

VI. DIFFERENTIAL CONSTRAINTS AND SOLUTIONS OF THE GW SYSTEM

We now discuss the existence of certain classes of solutions to the GW system (1.3) which can be obtained by subjecting (1.3) to specific differential constraints which allows us to reduce the overdetermined system to a system admitting a first integral. This fact simplifies considerably the process of solving the initial system (1.3) and consequently, certain classes of nonsplitting solutions can be constructed.

First let us discuss the case when we append two differential constraints to GW system (1.3) of the form

$$\psi_1\partial\bar{\psi}_1+\bar{\psi}_2\partial\psi_2=0,\quad \bar{\psi}_1\bar{\partial}\psi_1+\psi_2\bar{\partial}\bar{\psi}_2=0. \tag{6.1}$$

In terms of the complex functions ψ_i, it has been shown[26] that the reduction of the overdetermined system composed of (1.3) and (6.1) is equivalent to a linear decoupled system

$$\bar{\partial}\partial\psi_i+p_0^2\psi_i=0,\quad i=1,2, \tag{6.2}$$

with the first integral of the motion

$$|\psi_1|^2+|\psi_2|^2=p_0\in\mathbb{R}. \tag{6.3}$$

Indeed, making use of GW system (1.3) and condition (6.1), we have

$$\partial p=\psi_1(\partial\bar{\psi}_1)+\bar{\psi}_2(\partial\psi_2)=0,\quad \bar{\partial}\bar{p}=\bar{\psi}_1(\bar{\partial}\psi_1)+\psi_2(\bar{\partial}\bar{\psi}_2)=0. \tag{6.4}$$

This means that p is a real constant. The overdetermined system (1.3) and (6.1) admits a three-dimensional symmetry group, namely, the similitude group Sim(2,$\mathbb{C}$). Its Lie subalgebra of algebra (2.1) is spanned by $\{T_1,T_2,H\}$ and the corresponding invariant is given by (6.3).

Now let us express the constraints in (6.4) in terms of the function ρ. Taking into account (3.4), the differential constraints in (6.4) become

$$\frac{\partial p}{\bar{\psi}_2}=\rho\partial\bar{\psi}_1+\partial\psi_2=\frac{\epsilon}{2}(\partial\rho)^{-1/2}\partial^2\rho-\epsilon\frac{(\partial\rho)^{1/2}}{1+|\rho|^2}(\rho\partial\bar{\rho}+\bar{\rho}\partial\rho)+\epsilon\rho\frac{(\partial\rho)^{1/2}(\partial\bar{\rho})}{1+|\rho|^2}=0,\quad \epsilon=\pm1, \tag{6.5}$$

and its respective complex conjugate. As a result, the overdetermined system composed of Eqs. (3.4) and (6.5) for the function ρ take the form

$$\begin{aligned}&\bar\partial\partial\rho-\frac{2\bar\rho}{1+|\rho|^2}\partial\rho\bar\partial\rho=0,\quad \partial\bar\partial\bar\rho-\frac{2\rho}{1+|\rho|^2}\partial\bar\rho\bar\partial\bar\rho=0,\\&\partial^2\rho-\frac{2\bar\rho}{1+|\rho|^2}(\partial\rho)^2=0,\quad \bar\partial^2\bar\rho-\frac{2\rho}{1+|\rho|^2}(\bar\partial\bar\rho)^2=0.\end{aligned}\tag{6.6}$$

We show now that if the current J given by (3.7) is constant, then all second derivatives of ρ are determined in terms of ρ and their first derivatives. In fact, differentiating the current J with respect to ∂ we get

$$(1+|\rho|^2)(\partial\bar\rho\partial^2\rho+\partial\rho\partial^2\bar\rho)-2\,\partial\rho\partial\bar\rho(\bar\rho\partial\rho+\rho\partial\bar\rho)=0.$$

Taking into account the system (6.6), we obtain

$$\partial^2\bar\rho-\frac{2\rho}{1+|\rho|^2}(\partial\bar\rho)^2=0,\quad \bar\partial^2\rho-\frac{2\bar\rho}{1+|\rho|^2}(\bar\partial\rho)^2=0.\tag{6.7}$$

Hence, all second-order derivatives of ρ are known in terms of ρ and its derivatives. Note that all compatibility conditions are identically satisfied whenever Eq. (3.4) holds. Moreover, the nonsplitting exponential class of solution (5.18) is a solution of the system (6.6) and (6.7). Thus, we can formulate the following:

Proposition 5: The overdetermined system (6.6) and (6.7) for the function ρ admits a first integral of the form

$$\frac{(\partial\rho\,\bar\partial\bar\rho)^{1/2}}{1+|\rho|^2}=p_0,\quad p_0\in\mathbb{R}.\tag{6.8}$$

Proof: Differentiating the left-hand side of (6.8) with respect to ∂, we obtain

$$\partial\left(\frac{(\partial\rho\bar\partial\bar\rho)^{1/2}}{1+|\rho|^2}\right)=\frac{(\partial\rho)^{-1/2}(\bar\partial\bar\rho)^{1/2}}{2(1+|\rho|^2)}\left[(\bar\partial\bar\rho)\partial^2\rho+\partial\rho(\partial\bar\partial\bar\rho)-2\frac{(\partial\rho)(\bar\partial\bar\rho)}{1+|\rho|^2}(\partial\rho\,\bar\rho+\rho\partial\bar\rho)\right].\tag{6.9}$$

Substituting (6.6) and (6.7) into system (6.9), this is identically zero, since

$$\frac{2\bar\rho}{1+|\rho|^2}(\bar\partial\bar\rho)(\partial\rho)^2+\frac{2\rho}{1+|\rho|^2}\partial\rho\partial\bar\rho\bar\partial\bar\rho-\frac{2\bar\rho}{1+|\rho|^2}\bar\partial\bar\rho(\partial\rho)^2-\frac{2\rho}{1+|\rho|^2}\partial\rho\partial\bar\rho\bar\partial\bar\rho\equiv0.$$

Similarly, differentiating the left-hand side of (6.8) with respect to $\bar\partial$ and making use of (6.6) and (6.7), we obtain that the resulting equation is identically satisfied. Q.E.D.

Proposition 6: If the functions ψ_1 and ψ_2 satisfy the overdetermined system composed of the initial value problem for GW system (1.3) with $\psi_i(0)=0$ and differential constraints (6.1),

$$\begin{aligned}&\partial\psi_1=p\psi_2,\quad \bar\partial\psi_2=-p\psi_1,\quad \psi_i(0)=0,\\&\psi_1\partial\bar\psi_1+\bar\psi_2\partial\psi_2=0,\quad \bar\psi_1\bar\partial\psi_1+\psi_2\bar\partial\bar\psi_2=0,\end{aligned}\tag{6.10}$$

then the general solution has the form

$$\psi_i=J_0(p_0\sqrt{(z-z_i^1)(\bar z-\bar z_i^2)}),\quad p_0\in\mathbb{R},\quad z_i^1,z_i^2\in\mathbb{C},\quad i=1,2,\tag{6.11}$$

where J_0 is a Bessel function of order zero. The general solution of (6.6) and (6.7) has the form

$$\rho=\frac{J_0(p_0\sqrt{(z-z_1^1)(\overline{z}-\overline{z}_1^2)})}{J_0(p_0\sqrt{(z-z_2^1)(\overline{z}-\overline{z}_2^2)})}. \tag{6.12}$$

Proof: If the function W is a solution of the second-order differential equation

$$s_iW^{(2)}(s_i)+W^{(1)}(s_i)+p_0^2W(s_i)=0, \tag{6.13}$$

where the differentiation of W is with respect to s_i, then the general solution of the system (6.2) has the form

$$\psi_i=W(s_i),$$

where

$$s_i=\frac{1}{4p_0^2}(z-z_i^1)(\overline{z}-\overline{z}_i^2), \quad p_0\in\mathbb{R}, \quad z_i^1,z_i^2\in\mathbb{C}.$$

After a change of variable $s_i=r_i^2$, the differential equation (6.13) is reduced to the Bessel equation

$$r_i^2J''(r_i)+r_iJ'(r_i)+4p_0^2r_i^2J(r_i)=0,$$

and the general solution is given by

$$\psi_i=J_0(p_0\sqrt{s_i})=\sum_{k=0}^{\infty}\frac{(-1)^k}{k!^2}(p_0^{2k}(z-z_i^1)^k(\overline{z}-\overline{z}_i^2)^k),$$

and hence (6.10) holds. Then using the definition (3.1) for the function ρ, we find that the general solution of the overdetermined system (6.6) and (6.7) is given by (6.12). Q.E.D.

Finally, let us discuss the case when the GW system (1.3) is subjected to a single constraint

$$\psi_1\partial\overline{\psi}_1+\overline{\psi}_2\partial\psi_2-\epsilon(\overline{\psi}_1\overline{\partial}\psi_1+\psi_2\overline{\partial\psi}_2)=0, \quad \epsilon=\pm1. \tag{6.14}$$

This is a weaker condition than (6.1), since two constraints have been combined. In terms of the complex function ρ, Eq. (6.14) becomes

$$\left(\partial^2\rho-\frac{2\overline{\rho}}{1+|\rho|^2}(\partial\rho)^2\right)\overline{\partial\rho}-\epsilon\left(\overline{\partial}^2\overline{\rho}-\frac{2\rho}{1+|\rho|^2}(\overline{\partial\rho})^2\right)\partial\rho=0. \tag{6.15}$$

Note that if the function ρ satisfies the overdetermined system composed of Eqs. (3.4) and (6.15), then there exists a conserved quantity

$$\frac{(\partial\rho)^{1/2}(\overline{\partial\rho})^{1/2}}{1+|\rho|^2}=p(z+\epsilon\overline{z}). \tag{6.16}$$

In fact, from Eq. (6.16) and taking into account Eqs. (3.4) and (6.15), we obtain

$$(\partial-\epsilon\overline{\partial})\left(\frac{(\partial\rho)^{1/2}(\overline{\partial\rho})^{1/2}}{1+|\rho|^2}\right)=p\left\{\frac{\partial^2\rho}{2\partial\rho}-\frac{\overline{\rho}\partial\rho}{1+|\rho|^2}-\epsilon\left(\frac{\overline{\partial}^2\overline{\rho}}{2\overline{\partial\rho}}-\frac{\rho\overline{\partial\rho}}{1+|\rho|^2}\right)\right\}\equiv0. \tag{6.17}$$

Hence, the quantity p is a real valued function of the argument $s=z+\epsilon\overline{z}$. This means that the solution of the system (1.3) and (6.14) is invariant under a two-dimensional symmetry algebra $\{T_1+\epsilon T_2,H\}$. This class of solutions has been discussed in detail in Ref. 27.

VII. SUMMARY AND CONCLUDING REMARKS

The main aim of the paper has been to provide a great variety of exact analytic solutions through the systematic use of the subgroup structure of the invariance group of the generalized Weierstrass system. We concentrated mainly on classical symmetries as well on conditional symmetries for the GW system. The latter case refers to the symmetry of the overdetermined system obtained by supplementing the original system (1.3) with the differential constraints (6.1), and the original system (3.4) subjected to constraints (5.1). Thus, the solutions obtained for this overdetermined system are invariant under the action of the conditional symmetry algebras. They were investigated and a procedure for constructing them was proposed. We can summarize the results which were obtained using both symmetry methods in our work in the following cases:

(1) Elementary solutions, that is, constant, algebraic with one or two simple poles, trigonometric and hyperbolic solutions.
(2) Doubly periodic solutions which can be expressed in terms of Jacobi elliptic functions sn, cn, and dn.
(3) Some of the reduced equations can be written in terms of Painlevé transcendents.

It is worth noting that the symmetry analysis of the sigma model (3.4) provides much larger classes of solutions to the original system (1.3) by means of transformation (3.3), than the symmetry analysis of GW system applied directly. This is due to the fact that there exists a gauge freedom in the definition of the function ρ, since the numerator and denominator of (3.1) can be multiplied by any complex function. Note also that the inverse mapping of (3.1) is a double valued function, and is provided by (3.3). We found that when, at least locally, the solutions of GW system (1.3) are single valued as a function of its complex independent variables, the system is a completely integrable one. Such a phenomena has been known since the the time of Kovalevsky[37] in connection with the equations of the spinning top. In this case, the single-valued solutions of these equations are integrable, and wide classes of solutions have been constructed.

The construction of constant mean curvature surfaces which are embedded in three-dimensional Euclidean space, by means of expression (1.7), is more difficult to integrate explicitly in the case when solutions of (1.3) are expressed in terms of Jacobi elliptic functions. In many of these cases, we deal with hyperelliptic integrals and the formulas obtained are quite complex expressions, and we skip them. However, the qualitative features, such as asymptotic behavior, geometrical description, of these integrals can be investigated numerically (i.e., their singularity structure such as the existence of different types of poles, etc.).

The question arises whether our approach can be extended to GW systems describing surfaces immersed in multidimensional Euclidean and pseudo-Riemannian spaces and if this may provide new classes of solutions. Recently, such generalization of the GW system has been achieved by Konopelchenko *et al.*[12,38,39] where, in particular, the explicit representations for generic surfaces conformally immersed into multidimensional Euclidean and pseudo-Euclidean spaces with different signatures have been derived.

In particular, the Dirac-type system for the four complex-valued functions ψ_α and φ_α describing constant mean curvature surfaces immersed in four-dimensional Euclidean space is given by[37]

$$\partial\psi_\alpha = p\varphi_\alpha, \quad \bar{\partial}\varphi_\alpha = -p\psi_\alpha, \quad \bar{\partial}\bar{\psi}_\alpha = p\bar{\varphi}_\alpha, \quad \partial\bar{\varphi}_\alpha = -p\bar{\psi}_\alpha, \quad \alpha = 1,2, \tag{7.1}$$

where the following notation has been introduced:

$$p = (u_1 u_2)^{1/2}, \quad u_\alpha = |\psi_\alpha|^2 + |\varphi_\alpha|^2, \quad \alpha = 1,2. \tag{7.2}$$

The GW system (7.1) possesses several conserved quantities and admits compatible differential constraints, among them the following:

$$\text{(i)} \quad \partial(\psi_\alpha\psi_\beta) + \bar{\partial}(\varphi_\alpha\varphi_\beta) = 0, \quad \bar{\partial}(\bar{\psi}_\alpha\bar{\psi}_\beta) + \partial(\bar{\varphi}_\alpha\bar{\varphi}_\beta) = 0, \quad \alpha \neq \beta = 1,2,$$

$$\begin{aligned}
&\text{(ii)} \quad \partial(\psi_\alpha\overline{\varphi}_\beta)-\overline{\partial}(\varphi_\alpha\overline{\psi}_\beta)=0, \quad \overline{\partial}(\overline{\psi}_\alpha\varphi_\beta)-\partial(\overline{\varphi}_\alpha\psi_\beta)=0 \quad \alpha\neq\beta=1,2,\\
&\text{(iii)} \quad \varphi_\alpha\partial\overline{\varphi}_\alpha+\overline{\psi}_\alpha\partial\psi_\alpha=0, \quad \overline{\varphi}_\alpha\overline{\partial}\varphi_\alpha+\psi_\alpha\overline{\partial\psi}_\alpha=0, \quad \alpha=1,2,\\
&\text{(iv)} \quad \partial(\ln\psi_\alpha)\overline{\partial}(\ln\varphi_\alpha)=-p^2, \quad \overline{\partial}(\ln\overline{\psi}_\alpha)\partial(\ln\overline{\varphi}_\alpha)=-p^2, \quad \alpha=1,2..
\end{aligned} \tag{7.3}$$

It has been shown,[38] that for each pair of complex fields $(\psi_\alpha,\varphi_\alpha)$ resulting from system (7.1), a set of constant mean curvature surfaces is obtained by means of the following parametrization:

$$(z,\overline{z})\to\mathbf{r}=(X_1(z,\overline{z}),\ldots,X_4(z,\overline{z})),$$

such that

$$\begin{aligned}
X_1+iX_2&=\int_\Gamma(i\overline{\psi_1\psi_2}\,\mathrm{d}z'-i\overline{\varphi_1\varphi_2}\,\mathrm{d}\overline{z}'),\\
X_1-iX_2&=\int_\Gamma(i\varphi_1\varphi_2\,\mathrm{d}z-i\psi_1\psi_2\,\mathrm{d}\overline{z}),\\
X_4+iX_3&=\int_\Gamma(-i\overline{\psi}_2\varphi_1\,\mathrm{d}z'-i\psi_1\overline{\varphi}_2\,\mathrm{d}\overline{z}'),\\
X_4-iX_3&=\int_\Gamma(i\overline{\psi}_1\varphi_2\,\mathrm{d}z'+i\psi_2\overline{\varphi}_1\,\mathrm{d}\overline{z}'),
\end{aligned} \tag{7.4}$$

where Γ is any contour in $\mathbb{C}$. Note the functions $X_i(z,\overline{z})$ are real valued functions since Eq. (7.3) holds. These functions can be identified with the components of a position vector $\mathbf{r}$ of a surface imbedded in $\mathbb{R}^4$.

Making use of (7.2), one can differentiate p to obtain

$$\begin{aligned}
p\partial\overline{\partial}p-\partial p\overline{\partial}p=&-\frac{1}{2p^2}(\partial u_1u_2+u_1\partial u_2)(\overline{\partial}u_1u_2+u_1\overline{\partial}u_2)+\frac{1}{2}(\partial\overline{\partial}u_1u_2+\overline{\partial}u_1\partial u_2+\partial u_1\overline{\partial}u_2\\
&+u_1\partial\overline{\partial}u_2).
\end{aligned} \tag{7.5}$$

Substituting the derivatives of u_α, namely,

$$\partial u_1=\psi_1\partial\overline{\psi}_1+\overline{\varphi}_1\partial\varphi_1, \quad \partial u_2=\psi_2\partial\overline{\psi}_2+\overline{\varphi}_2\partial\varphi_2,$$

and their conjugates, as well as their second derivatives,

$$\partial\overline{\partial}u_1=\partial\overline{\psi}_1\overline{\partial}\overline{\psi}_1+\partial\varphi_1\overline{\partial}\overline{\varphi}_1-p^2u_1, \quad \partial\overline{\partial}u_2=\partial\overline{\psi}_2\overline{\partial}\overline{\psi}_2+\partial\varphi_2\overline{\partial}\overline{\varphi}_2-p^2u_2,$$

into Eq. (7.5), we get the following expression:

$$\begin{aligned}
p\partial\overline{\partial}p-\partial p\overline{\partial}p=&\frac{1}{2p^2}[u_2^2(|\varphi_1|^2\overline{\partial}\psi_1\partial\overline{\psi}_1-\overline{\varphi}_1\overline{\psi}_1\partial\varphi_1\overline{\partial}\psi_1-\psi_1\varphi_1\partial\overline{\psi}_1\overline{\partial}\overline{\varphi}_1+|\psi_1|^2\partial\varphi_1\overline{\partial}\overline{\varphi}_1)\\
&+u_1^2(|\varphi_2|^2\partial\overline{\psi}_2\overline{\partial}\psi_2-\overline{\varphi}_2\overline{\psi}_2\partial\varphi_2\overline{\partial}\psi_2-\varphi_2\psi_2\partial\overline{\psi}_2\overline{\partial}\overline{\varphi}_2+|\psi_2|^2\partial\varphi_2\overline{\partial}\overline{\varphi}_2)-2p^6].
\end{aligned} \tag{7.6}$$

Defining the quantities $J_1=\varphi_1\partial\overline{\psi}_1-\overline{\psi}_1\partial\varphi_1$ and $J_2=\varphi_2\partial\overline{\psi}_2-\overline{\psi}_2\partial\varphi_2$, and dividing both sides by p^2, it is straightforward to show that Eq. (7.6) can be written in the form

$$\partial\overline{\partial}(\ln p)=\frac{1}{2p^4}[u_2^2|J_1|^2+u_1^2|J_2|^2-2p^6]. \tag{7.7}$$

In the next stage of this research, using group theoretical techniques, the authors plan to generate in a systematic way large classes of solutions of GW system (7.1), which can be expressed as elementary and doubly periodic functions which are written in terms of the Jacobi elliptic functions. These solutions will lead to the construction of several classes of constant mean curvature surfaces embedded in four-dimensional Euclidean space by making use of Eq. (7.4), which can describe more diverse types of surfaces than the ones discussed in three-dimensional space.

ACKNOWLEDGMENTS

The authors thank Professor B. Konopelchenko, University of Lecce, and Professor P. Winternitz, Université de Montréal, for helpful discussions on this topic. This work was supported by a research grant from NSERC of Canada and Fonds FCAR du Gouvernment du Québec.

APPENDIX

It is worth noting that the sigma model equations (3.4) are invariant under discrete transformations generated by

(i) the reflections

$$\begin{aligned} &Z_1: z\to z, \quad \overline{z}\to -\overline{z}, \quad \rho\to\rho, \quad \overline{\rho}\to\overline{\rho},\\ &Z_2: z\to z, \quad \overline{z}\to\overline{z}, \quad \rho\to -\rho, \quad \overline{\rho}\to -\overline{\rho},\\ &Z_3: z\to -z, \quad \overline{z}\to\overline{z}, \quad \rho\to -\rho, \quad \overline{\rho}\to\overline{\rho}, \end{aligned} \tag{A1}$$

and their complex conjugates;

(ii) the inversion

$$I: z\to z, \quad \overline{z}\to\overline{z}, \quad \rho\to\frac{1}{\overline{\rho}}, \quad \overline{\rho}\to\frac{1}{\rho}; \tag{A2}$$

(iii) the Caley transformation which maps the circle into the upper half plane

$$C: z\to z, \quad \overline{z}\to\overline{z}, \quad \rho\to\frac{1+i\eta}{1-i\eta}, \quad \overline{\rho}\to\frac{1-i\overline{\eta}}{1+i\overline{\eta}}; \tag{A3}$$

(iv) the generalized $U(2)$ transformation for any $a,b\in\mathbb{C}$,

$$U: z\to z, \quad \overline{z}\to\overline{z}, \quad \rho\to\frac{a\eta+b}{-\overline{b}\eta+\overline{a}}, \quad \overline{\rho}\to\frac{\overline{a\eta}+\overline{b}}{-b\overline{\eta}+a}, \quad a,b\in\mathbb{C}. \tag{A4}$$

Note that the inversion transformation (iii) preserves the form of the sigma model equations (3.4), since substituting (A2) into (3.4i), we get (3.4ii). Clearly, applying this mapping a second time, we obtain (3.4i) again. This means that the square of the mapping has the same effect as the identity transformation. Note also that transformations (iii) and (iv) preserve the form of Eq. (3.4). Substituting (A3) or (A4) into the sigma model equations (3.4), we get

$$\partial\overline{\partial}\rho-\frac{2\overline{\rho}}{1+|\rho|^2}\partial\rho\overline{\partial}\rho=\frac{\eta+i}{(1+i\eta)^3(1+|\eta|^2)}\left(\partial\overline{\partial}\eta-\frac{2\overline{\eta}}{1+|\eta|^2}\partial\eta\overline{\partial}\eta\right)=0,$$

and

$$\partial\overline{\partial}\rho-\frac{2\overline{\rho}}{1+|\rho|^2}\partial\rho\overline{\partial}\rho=\frac{(|a|^2+|b|^2)}{(\overline{b}\eta-\overline{a})^2}\left(\partial\overline{\partial}\eta-\frac{2\overline{\eta}}{1+|\eta|^2}\partial\eta\overline{\partial}\eta\right)=0,$$

respectively. The discrete subgroups were used to limit the range of parameters occurring in the classification list of one-dimensional subalgebras of the symmetry algebra of sigma model (3.4).

(Received 2 February 2000; accepted for publication 21 August 2000)

We construct a differential calculus on the quantum supergroup $GL_h(1|1)$ and obtain the h-deformed superalgebra of $GL_h(1|1)$. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1319856]

I. INTRODUCTION

In the last few years, the theory of quantum (super) groups like GL(2), GL(1|1), etc. were generalized in two ways. Both of the generalizations are based on the deformation of the algebra of functions on the matrix (super) groups generated by coordinate functions T^i_j which normally commute. These deformations of Lie (super) groups are algebraic structures depending on one (or more) continuous parameter. We have a standard Lie (super) group for particular values of the deformation parameters. Quantum (super) groups[1,2] present the examples of (graded) Hopf algebras. They have found application in diverse areas of physics and mathematics.[3]

The q-deformation of Lie (super) groups can be realized on a quantum (super) space in which coordinates are noncommuting.[2] Recently the differential calculus on noncommutative (super) space has been intensively studied both by mathematicians and mathematical physicists. There is much activity in differential geometry[4] on quantum groups. Throughout the recent development of differential calculus on the quantum groups two principal concepts are readily seen. The first of them, formulated by Woronowicz,[5] is known as bicovariant differential calculus on the quantum groups. Another concept, introduced by Woronowicz[6] and Schirmacher *et al.*[7] proceeds from the requirement of a calculus only. There are many papers in this field.[8] We shall consider the second concept.

Another type of deformation, the so-called h-deformation, which is a new class of quantum deformations of Lie groups and Lie algebras, has recently been intensively studied.[9] This deformation may be obtained as a contraction of the q-deformation.[10] There is much interest in studies relating to various aspects of the h-deformed algebra. The differential geometry of $SL_h(2)$ was given in Ref. 11. In this work, we introduce a differential calculus on the quantum supergroup $GL_h(1|1)$. This quantum supergroup was obtained in Ref. 12 using a contraction procedure given in Ref. 10.

Let us briefly discuss the content of the article. In the second section, the basic notations of the Hopf algebra structure on the quantum supergroup $GL_h(1|1)$ are introduced. In the third section we shall obtain the commutation relations for the matrix elements and their differentials so we have a differential algebra. This differential algebra (extended algebra) has a Hopf algebra structure. Later, we shall construct the Cartan–Maurer one-forms and obtain the needed commutation relations. Using these commutation relations, we shall describe the quantum algebra for the vector fields (superalgebra generators) for $GL_h(1|1)$ and derive the commutation relations between the matrix elements and the algebra generators. We shall also show that the obtained quantum algebra can be rederived using the partial derivatives and their relations.

II. THE ALGEBRA OF FUNCTIONS ON $GL_h(1|1)$

Elementary properties of quantum supergroup $GL_h(1|1)$ are described in Ref. 12. We state briefly the properties we are going to need in this work. Here we denote q-deformed objects by

a)Electronic mail: sacelik@yildiz.edu.tr

primed quantities. Unprimed quantities will represent transformed coordinates. As usual, it is known that even (bosonic) objects commute with everything and odd (Grassmann) objects anticommute among themselves. In this work, to obtain the quantum supergroup $\mathrm{GL}_h(1|1)$, we shall only assume that odd elements β and γ anticommute with the ''new'' deformation parameter h.

Let us begin with the q-deformed counterparts of $\mathrm{GL}(1|1)$. The quantum supergroup $\mathrm{GL}_q(1|1)$ is defined by the matrices of the form

$$T'=\begin{pmatrix} a' & \beta' \\ \gamma' & d' \end{pmatrix},$$

where the matrix entries satisfy the following commutation relations:[2]

$$\begin{gathered} a'\beta'=q\beta' a', \quad d'\beta'=q\beta' d', \\ a'\gamma'=q\gamma' a', \quad d'\gamma'=q\gamma' d', \\ \beta'\gamma'+\gamma'\beta'=0, \quad \beta'^2=0=\gamma'^2, \\ a'd'=d'a'+(q-q^{-1})\gamma'\beta'. \end{gathered} \tag{1}$$

We now consider the following similarity transformation:[10]

$$T=\begin{pmatrix} a & \beta \\ \gamma & d \end{pmatrix}=g^{-1}T'g, \tag{2}$$

where

$$g=\begin{pmatrix} 1 & 0 \\ h/(q-1) & 1 \end{pmatrix}, \quad h^2=0. \tag{3}$$

Assuming that β and γ anticommute with the Grassmann number h and substituting (2) into (1), we arrive at the following relations:[12]

$$\begin{gathered} a\beta=\beta a, \quad a\gamma=\gamma a+ha^2(1-\mathcal{D}_h^{-1}), \\ d\beta=\beta d, \quad d\gamma=\gamma d+hd^2(\mathcal{D}_h-1), \\ \beta^2=0, \quad \gamma^2=h\gamma d(1-\mathcal{D}_h), \\ \beta\gamma=-\gamma\beta+h\beta d(1-\mathcal{D}_h), \\ ad=da+h\beta d(\mathcal{D}_h-1), \end{gathered} \tag{4}$$

where

$$\mathcal{D}_h=ad^{-1}-\beta d^{-1}\gamma d^{-1} \tag{5}$$

is the quantum superdeterminant of T. It can be checked that $\mathcal{D}_h$ commutes with all matrix elements of T. Note that, by imposing the relation

$$\mathcal{D}_h=1$$

as an interesting case, we obtain the classical special supergroup $SL(1|1)$, instead of $SL_h(1|1)$. In other words, the restriction of the superdeterminant to unity does not give the quantum supergroup $SL_h(1|1)$. It is known that, in the q-deformed case, the restriction to unity ($\mathcal{D}_q = ad^{-1} - \beta d^{-1}\gamma d^{-1} = 1$) gives the quantum supergroup $SL_q(1|1)$.

Let us denote the algebra generated by the elements a, β, γ, d with the relations (4) by $\mathcal{A}$. We know that the algebra $\mathcal{A}$ is a graded Hopf algebra with the following co-structures: the usual coproduct

$$\Delta: \mathcal{A} \to \mathcal{A} \otimes \mathcal{A}, \quad \Delta(T^i_j) = T^i_k \otimes T^k_j, \tag{6}$$

the counit

$$\varepsilon: \mathcal{A} \to \mathcal{C}, \quad \varepsilon(T^i_j) = \delta^i_j, \tag{7}$$

and the coinverse $S: \mathcal{A} \to \mathcal{A}$,

$$S(T) = T^{-1} = \begin{pmatrix} a^{-1} + a^{-1}\beta d^{-1}\gamma a^{-1} & -a^{-1}\beta d^{-1} \\ -d^{-1}\gamma a^{-1} & d^{-1} + d^{-1}\gamma a^{-1}\beta d^{-1} \end{pmatrix}. \tag{8}$$

It is not difficult to verify the following properties of the co-structures:

$$(\Delta \otimes \mathrm{id}) \circ \Delta = (\mathrm{id} \otimes \Delta) \circ \Delta, \tag{9a}$$

$$\mu \circ (\varepsilon \otimes \mathrm{id}) \circ \Delta = \mu' \circ (\mathrm{id} \otimes \varepsilon) \circ \Delta, \tag{9b}$$

$$m \circ (S \otimes \mathrm{id}) \circ \Delta = \varepsilon = m \circ (\mathrm{id} \otimes S) \circ \Delta, \tag{9c}$$

where id denotes the identity mapping, $\mu: \mathcal{C} \otimes \mathcal{A} \to \mathcal{A}$, and $\mu': \mathcal{A} \otimes \mathcal{C} \to \mathcal{A}$ are the canonical isomorphisms, defined by $\mu(k \otimes a) = ka = \mu'(a \otimes k)$, $\forall a \in \mathcal{A}$, $\forall k \in \mathcal{C}$, and m is the multiplication map $m: \mathcal{A} \otimes \mathcal{A} \to \mathcal{A}$, $m(a \otimes b) = ab$.

The multiplication in $\mathcal{A} \otimes \mathcal{A}$ follows the rule

$$(A \otimes B)(C \otimes D) = (-1)^{p(B)p(C)} AC \otimes BD, \tag{10}$$

where $p(X)$ is the z_2-grade of X.

III. DIFFERENTIAL CALCULUS ON $GL_h(1|1)$

In this section, we shall build up the differential calculus on the quantum supergroup $GL_h(1|1)$. The differential calculus on the quantum supergroups involves functions on the supergroup, differentials and differential forms.

A. Differential algebra

We first note the properties of the exterior differential. We can introduce the exterior differential d to be an operator that is nilpotent and obeys the graded Leibniz rule:

$$\mathrm{d}^2 = 0, \tag{11a}$$

and

$$\mathrm{d}(fg) = (\mathrm{d}f)g + (-1)^{p(f)} f(\mathrm{d}g), \tag{11b}$$

where f and g are functions of the matrix elements. Note that, since the deformation parameter h is an odd (Grassmann) number, it must anticommute with the exterior differential d. In fact,

$$\mathrm{d}(hf) = (-1)^{p(h)} h(\mathrm{d}f) = -h(\mathrm{d}f) \Rightarrow \mathrm{d}h = -h\mathrm{d}. \tag{11c}$$

We have seen, in the previous section, that $\mathcal{A}$ is an associative algebra generated by the matrix elements of T with the relations (4). A differential algebra on $\mathcal{A}$ is a z_2-graded associative algebra Γ equipped with an operator d given in (11). Also the algebra Γ has to be generated by $\mathcal{A}\cup\mathrm{d}\mathcal{A}$.

First, we wish to obtain the relations between the matrix elements of T and their differentials. To do this, we shall use the method of Ref. 13. For this reason, we decompose the algebra $\mathcal{A}$ into subalgebras. We denote by $\mathcal{A}_{a'\beta'}$ the algebra generated by the elements a' and β' with the relations

$$a'\beta'=q\beta'a', \quad \beta'^2=0. \tag{12}$$

Then, a possible set of commutation relations between generators of $\mathcal{A}_{a'\beta'}$ and $\mathrm{d}\mathcal{A}_{\mathrm{d}a'\mathrm{d}\beta'}$ is of the form

$$\begin{aligned} a'\mathrm{d}a'&=A_1\mathrm{d}a'a',\\ a'\mathrm{d}\beta'&=F_{11}\mathrm{d}\beta'a'+F_{12}\mathrm{d}a'\beta',\\ \beta'\mathrm{d}a'&=F_{21}\mathrm{d}a'\beta'+F_{22}\mathrm{d}\beta'a',\\ \beta'\mathrm{d}\beta'&=A_2\mathrm{d}\beta'\beta', \end{aligned} \tag{13}$$

where the coefficients A_i and F_{ij} are related to the complex deformation parameter q. To determine them we use the consistency of calculus (see, for details, Ref. 13). Continuing in this way, we can obtain the other relations.

Let us now substitute the matrix elements of $\mathrm{d}T'$,

$$\mathrm{d}T'=\begin{pmatrix}\alpha' & b'\\ c' & \delta'\end{pmatrix}=\begin{pmatrix}\alpha-\dfrac{h}{q-1}b & b\\ c+\dfrac{h}{q-1}(\delta-\alpha) & \delta-\dfrac{h}{q-1}b\end{pmatrix}, \tag{14}$$

and T' into (13). After rather complicated and tedious calculations by using the consistency of calculus, as the final result one has the following commutation relations:

$$\begin{aligned} &a\alpha=\alpha a+h(\alpha\beta-ba), \quad ab=ba-hb\beta,\\ &ac=ca+h(\alpha a-c\beta+\delta a),\\ &a\delta=\delta a+h(ba+\delta\beta),\\ &\beta\alpha=-\alpha\beta+hb\beta, \quad \beta b=b\beta,\\ &\beta c=c\beta+h(\alpha+\delta)\beta, \quad \beta\delta=-\delta\beta-hb\beta,\\ &\gamma\alpha=-\alpha\gamma+h(\alpha a+\alpha d+b\gamma),\\ &\gamma b=b\gamma+hb(a+d),\\ &\gamma c=c\gamma+h(\alpha\gamma+ca+cd+\delta\gamma),\\ &\gamma\delta=-\delta\gamma+h(\delta a+\delta d-b\gamma),\\ &d\alpha=\alpha d-h(\alpha\beta+bd), \quad db=bd+hb\beta,\\ &dc=cd+h(\alpha d+c\beta+\delta d), \end{aligned} \tag{15}$$

$$d\delta = \delta d + h(bd - \delta\beta).$$

It is easy to verify that the deformation parameter h anticommutes with α and δ. In fact, since $ah = ha$ we have

$$0 = \mathrm{d}(ah - ha) = \alpha h + h\alpha.$$

To find the commutation relations between differentials, we apply the exterior differential d on the relations (15) and use the nilpotency of d with (11c). Then it is easy to see that

$$\begin{gathered}
\alpha b = b\alpha + hb^2, \quad \alpha c = c\alpha + h(cb + \delta\alpha), \\
\delta b = b\delta - hb^2, \quad \delta c = c\delta - h(cb - \alpha\delta), \\
\alpha^2 = h\alpha b, \quad \alpha\delta = -\delta\alpha + h(\delta - \alpha)b, \\
\delta^2 = -h\delta b, \quad bc = cb + h(\delta + \alpha)b.
\end{gathered} \tag{16}$$

These relations are the relations of $\mathrm{Gr}_h(1|1)$ in Ref. 14. Note that the central element of $\mathrm{d}\mathcal{A}$, which is generated by the elements α, b, c, δ with the relations (16), is

$$\hat{\mathcal{D}} = bc^{-1} - \alpha c^{-1}\delta c^{-1}. \tag{17}$$

However, the element $\hat{\mathcal{D}}$ also commutes with the generators of $\mathcal{A}$. So, the element $\hat{\mathcal{D}}$ is the central element of the algebra $\mathcal{A}$, too. Thus $\hat{\mathcal{D}}$ is the central element of the differential algebra Γ.

An interesting note is also the following. The central element of the q-deformed differential algebra[13] is only the element $\hat{\mathcal{D}}$. However, the superdeterminant of $T \in \mathrm{GL}_h(1|1)$ commutes with the generators of $\mathrm{d}\mathcal{A}$, too. So the superdeterminant $\mathcal{D}_h$ is also a central element for the h-deformed differential algebra Γ.

B. Hopf algebra structure on Γ

We first note that consistency of a differential calculus with commutation relations (4) means that the algebra Γ is a graded associative algebra generated by the elements of the set $\{a, \beta, \gamma, d, \alpha, b, c, \delta\}$. So, it is sufficient to only describe the actions of co-maps on the subset $\{\alpha, b, c, \delta\}$.

We consider a map $\phi_R : \Gamma \to \Gamma \otimes \mathcal{A}$ such that

$$\phi_R \circ \mathrm{d} = (\mathrm{d} \otimes \mathrm{id}) \circ \Delta. \tag{18}$$

and define a map Δ_R as follows:

$$\Delta_R(u_1 \mathrm{d}v_1 + \mathrm{d}v_2 u_2) = \Delta(u_1)\phi_R(\mathrm{d}v_1) + \phi_R(\mathrm{d}v_2)\Delta(u_2). \tag{19}$$

Then it can be checked that the map Δ_R leaves invariant the relations (15) and (16). One can also check that the following identities are satisfied:

$$(\Delta_R \otimes \mathrm{id}) \circ \Delta_R = (\mathrm{id} \otimes \Delta) \circ \Delta_R, \quad (\mathrm{id} \otimes \epsilon) \circ \Delta_R = \mathrm{id}. \tag{20}$$

However, we do not have a coproduct for the differential algebra because the map ϕ_R does not give an analog for the derivation property (11), yet. So we consider another map $\phi_L : \Gamma \to \mathcal{A} \otimes \Gamma$ such that

$$\phi_L \circ \mathrm{d} = (\tau \otimes \mathrm{d}) \circ \Delta \tag{21}$$

and a map Δ_L with again (19) by replacing L with R. Here $\tau:\Gamma\to\Gamma$ is the linear map of degree zero which gives $\tau(u)=(-1)^{p(u)}u$. The map Δ_L also leaves invariant the relations (15) and (16), and the following identities are satisfied:

$$(\mathrm{id}\otimes\Delta_L)\circ\Delta_L=(\Delta\otimes\mathrm{id})\circ\Delta_L, \quad (\epsilon\otimes\mathrm{id})\circ\Delta_L=\mathrm{id}. \tag{22}$$

To denote the coproduct, counit and coinverse which will be defined on the algebra Γ with those of $\mathcal{A}$ may be inadvisable. For this reason, we shall denote them with a different notation. Let us define the map $\hat{\Delta}$ as

$$\hat{\Delta}=\Delta_R+\Delta_L, \tag{23}$$

which will allow us to define the coproduct of the differential algebra. We denote the restriction of $\hat{\Delta}$ to the algebra $\mathcal{A}$ by Δ and the extension of Δ to the differential algebra Γ by $\hat{\Delta}$. It is possible to interpret the relation

$$\hat{\Delta}|_{\mathcal{A}}=\Delta \tag{24}$$

as the definition of $\hat{\Delta}$ on the generators of $\mathcal{A}$ and (23) as the definition of $\hat{\Delta}$ on differentials. One can see that $\hat{\Delta}$ is a coproduct for the differential algebra Γ where

$$\hat{\Delta}(\mathrm{d}T^i_j)=\mathrm{d}T^i_k\otimes T^k_j+(-1)^{p(T^i_k)}T^i_k\otimes\mathrm{d}T^k_j. \tag{25}$$

It is not difficult to verify the following conditions:

(a) Γ is an $\mathcal{A}$-bimodule.

(b) Γ is an $\mathcal{A}$-bicomodule with left and right coactions Δ_L and Δ_R, respectively, making Γ a left and right $\mathcal{A}$-comodule with (20) and (22), and

$$(\Delta_L\otimes\mathrm{id})\circ\Delta_R=(\mathrm{id}\otimes\Delta_R)\circ\Delta_L, \tag{26}$$

which is the $\mathcal{A}$-bimodule property. So, the triple $(\Gamma,\Delta_L,\Delta_R)$ is a bicovariant bimodule over Hopf algebra $\mathcal{A}$. In additional, since

(c) (Γ,d) is a first order differential calculus over $\mathcal{A}$, and

(d) d is both a left and a right comodule map, i.e., for all $u\in\mathcal{A}$,

$$(\tau\otimes\mathrm{d})\Delta(u)=\Delta_L(\mathrm{d}u), \quad (\mathrm{d}\otimes\mathrm{id})\Delta(u)=\Delta_R(\mathrm{d}u), \tag{27}$$

the quadruple $(\Gamma,\mathrm{d},\Delta_L,\Delta_R)$ is a first order bicovariant differential calculus over Hopf algebra $\mathcal{A}$.

Now let us return to the Hopf algebra structure of Γ. If we define a counit $\hat{\epsilon}$ for the differential algebra as

$$\hat{\epsilon}\circ\mathrm{d}=\mathrm{d}\circ\epsilon=0 \tag{28}$$

and

$$\hat{\epsilon}|_{\mathcal{A}}=\epsilon, \quad \epsilon|_{\Gamma}=\hat{\epsilon}, \tag{29}$$

we have

$$\hat{\epsilon}(\mathrm{d}T^i_j)=0, \tag{30}$$

where

$$\hat{\epsilon}(u_1\mathrm{d}v_1+\mathrm{d}v_2u_2)=\epsilon(u_1)\hat{\epsilon}(\mathrm{d}v_1)+\hat{\epsilon}(\mathrm{d}v_2)\epsilon(u_2). \tag{31}$$

Here we used the fact that $\mathsf{d}(1)=0$.

As the next step we obtain a coinverse $\hat{S}$. For this, it suffices to define $\hat{S}$ such that

$$\hat{S}\circ\mathsf{d}=\mathsf{d}\circ S \tag{32}$$

and

$$\hat{S}|_{\mathcal{A}}=S, \quad S|_{\Gamma}=\hat{S}, \tag{33}$$

where

$$\hat{S}(u_1\mathsf{d}v_1+\mathsf{d}v_2u_2)=\hat{S}(\mathsf{d}v_1)S(u_1)+S(u_2)\hat{S}(\mathsf{d}v_2). \tag{34}$$

Thus the action of $\hat{S}$ on the generators α, b, c and γ is as follows:

$$\hat{S}(\mathsf{d}T^i_j)=-(-1)^{p[(T^{-1})^i_k]}(T^{-1})^i_k\mathsf{d}T^k_l(T^{-1})^l_j. \tag{35}$$

Note that it is easy to check that $\hat{\epsilon}$ and $\hat{S}$ leave invariant the relations (15) and (16). Consequently, we can say that the structure $(\Gamma,\hat{\Delta},\hat{\epsilon},\hat{S})$ is a graded Hopf algebra.

C. Cartan–Maurer one-forms and their relations

To complete the differential geometric scheme we need the Cartan–Maurer one-forms. As in analogy with the one-forms on a Lie group in classical differential geometry, one can construct the matrix valued one-form Ω where

$$\Omega=\mathsf{d}T\ \ T^{-1}. \tag{36}$$

So, we can write the matrix elements (one-forms) of Ω as follows:

$$\begin{aligned} w_1&=\alpha A+bC, \quad u=\alpha B+bD,\\ w_2&=\delta D+cB, \quad v=cA+\delta C, \end{aligned} \tag{37}$$

where $T^{-1}=\left(\begin{smallmatrix}A & B\\ C & D\end{smallmatrix}\right)$. We now wish to find the commutation relations of the matrix entries of T with those of Ω. So we need the commutation relations between the matrix elements of T and T^{-1}, which may be computed directly, as follows:

$$\begin{gathered} aA=Aa+h(A-D)\beta, \quad aB=Ba,\\ aC=Ca+h(1-\mathcal{D}_h), \quad aD=Da,\\ \beta A=A\beta, \quad \beta B=-B\beta,\\ \beta C=-C\beta+h(D-A)\beta, \quad \beta D=D\beta,\\ \gamma A=A\gamma+h(1-\mathcal{D}_h^{-1}),\\ \gamma B=-B\gamma+h(A-D)\beta,\\ \gamma C=-C\gamma, \quad \gamma D=D\gamma+h(\mathcal{D}_h-1),\\ dA=Ad, \quad dC=Cd+h(\mathcal{D}_h^{-1}-1),\\ dB=Bd, \quad dD=Dd+h(D-A)\beta. \end{gathered} \tag{38}$$

Using these relations, we now find the commutation relations of the matrix entries of T with those of Ω :

$$
\begin{gathered}
aw_1 = w_1 a - hua, \quad au = ua, \\
av = va + h(w_1 + w_2)a, \quad aw_2 = w_2 a + hua, \\
\beta w_1 = -w_1 \beta + hu\beta, \quad \beta u = u\beta, \\
\beta v = v\beta + h(w_1 + w_2)\beta, \quad \beta w_2 = -w_2 \beta - hu\beta, \\
\gamma w_1 = -w_1 \gamma + h(2w_1 a + u\gamma), \quad \gamma u = u\gamma + 2hua, \\
\gamma v = v\gamma + h(w_1 \gamma + 2va + w_2 \gamma), \quad \gamma w_2 = -w_2 \gamma + h(2w_2 a - u\gamma), \\
dw_1 = w_1 d - h(2w_1 \beta + ud), \quad du = ud + 2hu\beta, \\
dv = vd + h(w_1 d + 2v\beta + w_2 d), \quad dw_2 = w_2 d + h(ud - 2w_2 \beta).
\end{gathered}
\tag{39}
$$

To obtain the commutation relations among the Cartan—Maurer one-forms, we use the commutation relations of the matrix elements of T^{-1} with the differentials of the group parameters which are given in the following:

$$
\begin{gathered}
A\alpha = \alpha A + h(bA - \alpha B), \quad Ab = bA + hbB, \\
Ac = cA - h(\alpha A + \delta A - cB), \quad A\delta = \delta A - h(bA + \delta B), \\
B\alpha = -\alpha B - hbB, \quad Bb = bB, \\
Bc = cB - h(\alpha + \delta)B, \quad B\delta = -\delta B + hbB, \\
C\alpha = -\alpha C - h(\alpha A + \alpha D + bC), \quad Cb = bC - hb(A + D), \\
Cc = cC - h(\alpha C + cA + cD + \delta C), \\
C\delta = -\delta C + h(bC - \delta A - \delta D), \\
D\alpha = \alpha D + h(\alpha B + bD), \quad Db = bD - hbB, \\
Dc = cD - h(\alpha D + cB + \delta D), \quad D\delta = \delta D + h(\delta B - bD).
\end{gathered}
\tag{40}
$$

Using these relations, we obtain the commutation relations of the Cartan–Maurer forms with the differentials of the matrix elements of T as follows:

$$
\begin{gathered}
w_1 \alpha = -\alpha w_1 - h\alpha u, \quad w_1 b = bw_1 - hbu, \\
w_1 c = cw_1 - hcu, \quad w_1 \delta = -\delta w_1 - h\delta u, \\
u\alpha = \alpha u, \quad ub = bu, \\
uc = cu, \quad u\delta = \delta u, \\
v\alpha = \alpha v + h\alpha(w_1 - w_2), \quad vb = bv - hb(w_1 - w_2), \\
vc = cv - hc(w_1 - w_2), \quad v\delta = \delta v + h\delta(w_1 - w_2),
\end{gathered}
\tag{41}
$$

$$w_2\alpha=-\alpha w_2-h\alpha u,\quad w_2b=bw_2-hbu,$$

$$w_2c=cw_2-hcu,\quad w_2\delta=-\delta w_2-h\delta u.$$

We now obtain the commutation relations of the Cartan–Maurer forms,

$$w_1u=uw_1-2hu^2,\quad w_2u=uw_2,$$

$$w_1v=vw_1+2h(w_1w_2-uv),\quad w_2v=vw_2,$$

$$w_1w_2=-w_2w_1-2huw_2, \tag{42}$$

$$w_1^2=-2huw_1,\quad w_2^2=0,$$

$$uv=vu-2huw_2.$$

It can be checked that the elements $\mathcal{D}_h$ and $\hat{\mathcal{D}}$ commute with the Cartan–Maurer one-forms, i.e, both of the $\mathcal{D}_h$ and $\hat{\mathcal{D}}$ are still central elements. In the q-deformation, $\mathcal{D}_q$ does not commute with the Cartan–Maurer forms.

Of course, the relations (4), (15), (16), and (38)–(42) can be obtained with the help of a matrix R that acts on the square tensor space of the supergroup. The matrix R is a solution of the quantum supergroup equation. The quantum supergroup relations (4) follows from the equation

$$RT_1T_2=T_2T_1R,$$

where, in usual grading tensor notation, $T_1=T\otimes I$ and $T_2=I\otimes T$ and

$$R=\begin{pmatrix}1&0&0&0\\-h&1&0&0\\h&0&1&0\\0&h&h&1\end{pmatrix}.$$

The relations (15) are equivalent to the equation

$$T_1'\hat{T}_2=R^{-1}\hat{T}_2T_1R,$$

where

$$T_1'=(-1)^{p(T_1)}T_1,\quad \hat{T}_2=\mathrm{d}T_2.$$

Applying the exterior differential d on both sides of the above equation, one has

$$(\hat{T}_1)'\hat{T}_2=R\hat{T}_2'\hat{T}_1R,\quad (\hat{T}_1)'=d(T_1'),$$

which is equivalent to the relations (16). Similarly, the relations (39), (41) and (42) can be written, in a compact form, as follows, respectively:

$$T_1'\Omega_2=R^{-1}\Omega_2RT_1,$$

$$\hat{T}_1'\Omega_2=R\Omega_2'R\hat{T}_1,$$

$$\Omega_1'R^{-1}\Omega_2R=-R\Omega_2'R\Omega_1.$$

Note that one can check that the action of d on (39), (41) and also (42) is consistent. These relations allow us to evaluate the quantum superalgebra of $\mathrm{GL}_h(1|1)$ by relating the generators of the superalgebra to the one-forms.

IV. QUANTUM SUPERALGEBRA

The commutation relations of Cartan–Maurer forms allow us to construct the algebra of the generators. To obtain the quantum superalgebra of the algebra generators we first write the Cartan–Maurer forms as

$$\begin{aligned} \alpha &= w_1 a + u\gamma, \quad b = w_1\beta + ud, \\ \delta &= w_2 d + v\beta, \quad c = w_2\gamma + va. \end{aligned} \tag{43}$$

The differential d can then be expressed in the form

$$\mathsf{d} = w_1 T_1 + w_2 T_2 + u\nabla_+ + v\nabla_- . \tag{44}$$

Here T_1, T_2 and $\nabla_\pm$ are the quantum superalgebra generators. We now shall obtain the commutation relations of these generators. Considering an arbitrary function f of the matrix elements of T and using the nilpotency of the exterior differential d one has

$$(\mathsf{d}w_i)T_i f + (\mathsf{d}u_i)\nabla_i f = w_i \mathsf{d}T_i f - u_i \mathsf{d}\nabla_i f, \tag{45}$$

where

$$w_i \in \{w_1, w_2\}, \quad u_i \in \{u, v\}, \quad \nabla_i \in \{\nabla_+, \nabla_-\}.$$

So we need the four two-forms. To obtain these, using the nilpotency of the differential d, we can write $\mathsf{d}\Omega$ of the form

$$\mathsf{d}\Omega = \sigma_3 \Omega \sigma_3 \Omega, \quad \sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}. \tag{46}$$

In terms of the two-forms, these become

$$\begin{aligned} \mathsf{d}w_1 &= w_1^2 - uv, \quad \mathsf{d}u = w_1 u - u w_2, \\ \mathsf{d}w_2 &= w_2^2 - vu, \quad \mathsf{d}v = w_2 v - v w_1 . \end{aligned} \tag{47}$$

Using the Cartan–Maurer equations we find the following commutation relations for the quantum superalgebra:

$$\begin{gathered} T_1 T_2 - T_2 T_1 = 2h\nabla_- T_1, \\ T_1\nabla_+ - \nabla_+ T_1 = -\nabla_+ + 2h(T_1^2 - T_1), \\ T_2\nabla_+ - \nabla_+ T_2 = \nabla_+ - 2h(T_2 T_1 + T_2 - \nabla_+\nabla_-), \\ T_1\nabla_- - \nabla_- T_1 = \nabla_- , \\ T_2\nabla_- - \nabla_- T_2 = -\nabla_- , \\ \nabla_+^2 = -2hT_1\nabla_+ , \quad \nabla_-^2 = 0, \\ \nabla_-\nabla_+ + \nabla_+\nabla_- = T_1 + T_2 - 2h\nabla_- T_1 . \end{gathered} \tag{48}$$

The commutation relations (48) of the algebra generators should be consistent with monomials of the matrix elements of T. To do this, we evaluate the commutation relations between the generators of algebra and the matrix elements of T. The commutation relations of the generators with the matrix elements can be extracted from the Leibniz rule:

$$\mathrm{d}(af)=(\mathrm{d}a)f+a(\mathrm{d}f)\Rightarrow(w_iT_i+u_i\nabla_i)a=\mathrm{d}a+a(w_iT_i+u_i\nabla_i), \tag{49}$$

etc. This yields

$$\begin{gathered}
T_1a=a+aT_1-ha\nabla_-,\\
T_1\beta=\beta+\beta T_1+h\beta\nabla_-,\\
T_1\gamma=\gamma T_1+h(2aT_1+\gamma\nabla_-),\\
T_1d=dT_1+h(2\beta T_1-d\nabla_-),\\
T_2a=aT_2-ha\nabla_-,\\
T_2\beta=\beta T_2+h\beta\nabla_-,\\
T_2\gamma=\gamma+\gamma T_2+h(2aT_2+\gamma\nabla_-),\\
T_2d=d+dT_2+h(2\beta T_2-d\nabla_-),\\
\nabla_+a=\gamma+a\nabla_+-ha(T_1-T_2),\\
\nabla_+\beta=d-\beta\nabla_+-h\beta(T_1-T_2),\\
\nabla_+\gamma=-\gamma\nabla_+-h(2a\nabla_-+\gamma T_1-\gamma T_2),\\
\nabla_+d=d\nabla_++h(2\beta\nabla_+-dT_1+dT_2),\\
\nabla_-a=a\nabla_-,\quad \nabla_-\beta=-\beta\nabla_-,\\
\nabla_-\gamma=a-\gamma\nabla_--2ha\nabla_-,\\
\nabla_-d=\beta+d\nabla_-+2h\beta\nabla_-.
\end{gathered} \tag{50}$$

V. CONCLUSION

To conclude, we introduce here commutation relations between the matrix elements and their partial derivatives and thus illustrate the connection between the relations in Sec. IV and the relations which will be now obtained.

To proceed, let us first obtain the relations of the matrix elements with their partial derivatives. We know that the exterior differential d can be expressed in the form

$$\mathrm{d}f=(\alpha\partial_a+b\partial_\beta+c\partial_\gamma+\delta\partial_d)f. \tag{51}$$

Then, replacing f with af, etc., we obtain the following commutation relations:

$$\begin{gathered}
\partial_aa=1+a\partial_a-h(\beta\partial_a+a\partial_\gamma),\\
\partial_a\beta=\beta\partial_a+h\beta\partial_\gamma,\\
\partial_a\gamma=\gamma\partial_a+h(a\partial_a+d\partial_a+\gamma\partial_\gamma),
\end{gathered}$$

$$
\begin{aligned}
&\partial_a d = d\partial_a + h(\beta\partial_a - d\partial_\gamma),\\
&\partial_\beta a = a\partial_\beta - h(a\partial_a - a\partial_d + \beta\partial_\beta),\\
&\partial_\beta \beta = 1 - \beta\partial_\beta - h\beta(\partial_a - \partial_d),\\
&\partial_\beta \gamma = -\gamma\partial_\beta - h(a\partial_\beta + \gamma\partial_a - \gamma\partial_d + d\partial_\beta),\\
&\partial_\beta d = d\partial_\beta + h(\beta\partial_\beta - d\partial_a + d\partial_d),\\
&\partial_\gamma a = a\partial_\gamma - h\beta\partial_\gamma, \quad \partial_\gamma \beta = -\beta\partial_\gamma,\\
&\partial_\gamma \gamma = 1 - \gamma\partial_\gamma - h(a\partial_\gamma + d\partial_\gamma),\\
&\partial_\gamma d = d\partial_\gamma + h\beta\partial_\gamma,\\
&\partial_d a = a\partial_d - h(a\partial_\gamma + \beta\partial_d),\\
&\partial_d \beta = \beta\partial_d + h\beta\partial_\gamma,\\
&\partial_d \gamma = \gamma\partial_d + h(a\partial_d + \gamma\partial_\gamma + d\partial_d),\\
&\partial_d d = 1 + d\partial_d + h(\beta\partial_d - d\partial_\gamma).
\end{aligned}
\tag{52}
$$

We thus find the commutation relations between the derivatives. These relations can be obtained by using the nilpotency of the exterior differential d and they have the form

$$
\begin{aligned}
&\partial_a\partial_\beta = \partial_\beta\partial_a + h(\partial_d\partial_a - \partial_\beta\partial_\gamma - \partial_a^2),\\
&\partial_d\partial_\beta = \partial_\beta\partial_d - h(\partial_a\partial_d + \partial_\beta\partial_\gamma - \partial_d^2),\\
&\partial_a\partial_\gamma = \partial_\gamma\partial_a, \quad \partial_d\partial_\gamma = \partial_\gamma\partial_d,\\
&\partial_\beta\partial_\gamma = -\partial_\gamma\partial_\beta + h\partial_\gamma(\partial_a - \partial_d),\\
&\partial_\beta^2 = h\partial_\beta(\partial_a - \partial_d), \quad \partial_\gamma^2 = 0,\\
&\partial_a\partial_d = \partial_d\partial_a + h\partial_\gamma(\partial_d - \partial_a).
\end{aligned}
\tag{53}
$$

The (graded) Hopf algebra structure for ∂ is given by

$$
\begin{aligned}
&\Delta(\partial_a) = \partial_a\otimes\partial_a + \partial_\beta\otimes\partial_\gamma, \quad \Delta(\partial_\beta) = \partial_a\otimes\partial_\beta + \partial_\beta\otimes\partial_d,\\
&\Delta(\partial_d) = \partial_d\otimes\partial_d + \partial_\gamma\otimes\partial_\beta, \quad \Delta(\partial_\gamma) = \partial_\gamma\otimes\partial_a + \partial_d\otimes\partial_\gamma,\\
&\varepsilon(\partial_a) = 1 = \varepsilon(\partial_d), \quad \varepsilon(\partial_\beta) = 0 = \varepsilon(\partial_\gamma),\\
&S(\partial_a) = \partial_a^{-1} + \partial_a^{-1}\partial_\beta\partial_d^{-1}\partial_\gamma\partial_a^{-1}, \quad S(\partial_\beta) = -\partial_a^{-1}\partial_\beta\partial_d^{-1},\\
&S(\partial_d) = \partial_d^{-1} + \partial_d^{-1}\partial_\gamma\partial_a^{-1}\partial_\beta\partial_d^{-1}, \quad S(\partial_\gamma) = -\partial_d^{-1}\partial_\gamma\partial_a^{-1},
\end{aligned}
\tag{54}
$$

provided that the formal inverses ∂_a^{-1} and ∂_d^{-1} exist. However, these co-maps do not leave invariant the relations (52).

We know, from Sec. IV, that the exterior differential d can be expressed in the form (31), which we repeat here:

$$\mathrm{d}f=(w_1T_1+u\nabla_+ +v\nabla_- +w_2T_2)f. \tag{55}$$

Considering (51) together (55) and using (43) one has

$$\begin{aligned} T_1&=a\partial_a+\beta\partial_\beta, \quad \nabla_+=\gamma\partial_a+d\partial_\beta,\\ T_2&=d\partial_d+\gamma\partial_\gamma, \quad \nabla_-=a\partial_\gamma+\beta\partial_d. \end{aligned} \tag{56}$$

Using the relations (52) and (53), one can check that the relations of the generators in (56) coincide with (48). It can also be verified that the action of the generators in (56) on the group parameters coincide with (50).

The classical limit $h\to 0$ of the differential calculus is the undeformed (ordinary) differential calculus.

Note that if we make the identification

$$u\to\frac{x}{2}, \quad w_1\to\theta,$$

where x and θ are the coordinates of superplane, we have

$$x\theta=\theta x+hx^2, \quad \theta^2=-hx\theta.$$

One of the interesting problems may be to construct linear connections[15] on the h-superplane.

(Received 26 June 2000; accepted for publication 17 November 2000)

We provide two criteria on the existence of stationary states for quantum dynamical semigroups. The first one is based on the semigroup itself, while the second criterion is based on the generator which is in general unbounded and interpreted as a sesquilinear form. These results are illustrated by physical examples drawn from quantum optics. © *2001 American Institute of Physics.*

I. INTRODUCTION

Quantum dynamical semigroups (QDS) appeared for the first time in the physical literature during the 1970s motivated by studies on the evolution of open systems.

This class of semigroups is indeed an appropriate noncommutative counterpart of the classical Markov theory. On the other hand, numerous important properties of open systems, like the approach to equilibrium, represented by a normal stationary state, can be properly analyzed within the mathematical framework of QDS.

In 1978, the seminal paper of Frigerio[1] showed the importance of assuming the existence of a normal faithful stationary state to study ergodic properties of QDS. Indeed, under that hypothesis, the family of fixed points of the semigroup becomes a von Neumann algebra and a unique conditional expectation onto that algebra does exist. This allows to prove the Ergodic theorem for QDS. As for the stronger result on the weak convergence of the so-called predual semigroup of the given QDS, the crucial hypothesis is the existence of a normal stationary state (see Refs. 2 and 3). This is often taken for granted as a ''physical reasonable'' hypothesis.

In spite of their importance, truly applicable methods to prove the existence of normal stationary states, for an infinite dimensional system, are lacking in the extensive literature on QDS.

This paper is aimed at providing powerful, although simple, criteria for the existence of stationary states for QDS. Assume a quantum dynamical semigroup $(\mathcal{T}_t)_{t\geqslant 0}$, with generator $\mathcal{L}$, be given over the von Neumann algebra $\mathcal{B}(h)$ of all bounded linear operators on a complex separable Hilbert space h. Loosely speaking, a normal stationary state exists, whenever one can find two self-adjoint operators X, Y where, in addition, X is positive and Y is bounded from below, with finite dimensional spectral projections associated with bounded intervals such that either

$$\int_0^\infty \mathcal{T}_s(Y)\,ds \leqslant X \tag{1}$$

or

$$\mathcal{L}(X) \leqslant -Y. \tag{2}$$

The first inequality clearly reads as a property of the potential associated with the semigroup $(\mathcal{T}_t)_{t\geqslant 0}$. The inequality (2) allows us, under favorable circumstances, to deduce (1). Moreover it is easier to check in the physical applications where the generator usually is given instead of the semigroup. For this reason we think that it is the main result of this paper.

The plan of the paper is as follows. Section II contains some general results on QDS on $\mathcal{B}(h)$ and on tightness (relative compactness) of sets of normal states. This allows us to prove our first criterion for the existence of stationary states based on the inequality (1). The main result, based on the inequality (2), is proved in Sec. IV. Finally, Sec. V contains applications to physical models arising in quantum optics (Alli–Sewell and Jaynes–Cummings).

II. PRELIMINARIES

Let h be a complex separable Hilbert space and let $\mathcal{B}(h)$ be the von Neumann algebra of all bounded linear operators on h. The identity operator on h will be denoted by $\mathbb{1}$.

A quantum dynamical semigroup (QDS) on $\mathcal{B}(h)$ is a w^* continuous semigroup $\mathcal{T}=(\mathcal{T}_t;t\geqslant 0)$ of normal completely positive maps on $\mathcal{B}(h)$. It is conservative or Markov if $\mathcal{T}_t(\mathbb{1})=\mathbb{1}$ for all $t\geqslant 0$. In this case we shall call $\mathcal{T}$ a quantum Markov semigroup (QMS).

The infinitesimal generator, denoted by $\mathcal{L}$, is the operator in $\mathcal{B}(h)$ whose domain is given by the set $D(\mathcal{L})$ of all $x\in\mathcal{B}(h)$ for which the w^* limit of $t^{-1}(\mathcal{T}_t(x)-x)$ exists when $t\to 0$; such a limit defines $\mathcal{L}(x)$.

The predual space of $\mathcal{B}(h)$ is the Banach space $\mathcal{I}_1(h)$, the space of trace-class operators on h. The subspace of $\mathcal{I}_1(h)$ of all positive trace-class operators with unit trace is the set of normal states, which we denote by $\mathcal{S}$. Throughout this paper we will limit ourselves to consider nothing but normal states. Note that $\mathcal{T}_t$ is the dual of an operator $\mathcal{T}_{*t}$ defined on $\mathcal{I}_1(h)$, which is called the predual of $\mathcal{T}_t$.

Definition II.1: A normal state ρ is stationary (or invariant) for a QDS $\mathcal{T}$ if $\mathrm{tr}(\rho\mathcal{T}_t(x))=\mathrm{tr}(\rho x)$ for all $t\geqslant 0$ and all $x\in\mathcal{B}(h)$.

A sequence of states $(\rho_n)_n$ is said to converge *weakly* to $\rho\in\mathcal{S}$ if it converges in the weak topology of the Banach space $\mathcal{I}_1(h)$, i.e.,

$$\lim_{n\to\infty}\mathrm{tr}(\rho_n x)=\mathrm{tr}(\rho x)$$

for all $x\in\mathcal{B}(h)$.

We recall here a useful result on weak convergence of states.

Definition II.2: A sequence of normal states $(\rho_n)_n$ is tight if for any $\epsilon>0$ there exists a finite rank projection p and $n_0\in\mathbb{N}$ such that

$$\mathrm{tr}(\rho_n p)\geqslant 1-\epsilon,$$

for all $n\geqslant n_0$.

Theorem II.1: Any tight sequence of normal states admits a weakly convergent subsequence.

The reader is referred to Ref. 4 Lemma 4.3, p. 291 or Ref. 5 Theorem 2, p. 27 (see also Ref. 6, Appendix 1.4) for the proof. A detailed exposition of this kind of result is contained in Ref. 7.

We recall also the following well-known fact.

Proposition II.1: For each normal state ρ all the weak limits of the family

$$\frac{1}{t}\int_0^t \mathcal{T}_{*s}(\rho)\,ds,\quad t>0$$

on sequences $(t_n)_{n\geqslant 1}$ diverging to infinity are normal stationary states for $\mathcal{T}$.

For each self-adjoint operator Y, bounded from below, we denote by $Y\wedge r$ the truncated operator

$$Y\wedge r=YE_r+rE_r^{\perp},\tag{3}$$

where E_r denotes the spectral projection of Y associated with the interval $[-\infty, r]$.

We are now in a position to prove our first result on the existence of normal stationary states.

Theorem II.2: Let $\mathcal{T}$ be a QMS. Suppose that there exist two self-adjoint operators X and Y with X positive and Y bounded from below and with finite dimensional spectral projections associated with bounded intervals such that

$$\int_0^t \langle u, \mathcal{T}_s(Y \wedge r)u\rangle ds \leqslant \langle u, Xu\rangle \tag{4}$$

for all $t, r \geqslant 0$ and all $u \in D(X)$. Then the QMS $\mathcal{T}$ has a normal stationary state.

Proof: Let $-b$ (with $b>0$) be a lower bound for Y. Note that, for each $r \geqslant 0$ we have

$$Y \wedge r \geqslant -bE_r + rE_r^{\perp} = -(b+r)E_r + r\mathbb{1},$$

so that (4) yields

$$-(b+r)\int_0^t \langle u, \mathcal{T}_s(E_r)u\rangle ds + rt\|u\|^2 \leqslant \langle u, Xu\rangle$$

for all $u \in D(X)$. Normalize u and denote by $|u\rangle\langle u|$ the pure state with unit vector u. Dividing by $t(b+r)$, for all $t, r>0$ we have then

$$\frac{1}{t}\int_0^t \mathrm{tr}(\mathcal{T}_{*s}(|u\rangle\langle u|)E_r)ds \geqslant \frac{r}{b+r} - \frac{\langle u, Xu\rangle}{t(b+r)}.$$

It follows that, for all $\varepsilon>0$, there exists $t(\varepsilon)>0$, $r(\varepsilon)>0$ such that

$$\frac{1}{t}\int_0^t \mathrm{tr}(\mathcal{T}_{*s}(|u\rangle\langle u|)E_{r(\varepsilon)})ds \geqslant 1-\varepsilon$$

for all $t>t(\varepsilon)$. Therefore the family of normal states

$$\frac{1}{t}\int_0^t \mathcal{T}_{*s}(|u\rangle\langle u|)ds, \quad t>t(\varepsilon)$$

is tight. The conclusion follows then from Theorem II.1 and Proposition II.1. □

Remark: It is worth noticing that we wrote the inequality (4) with truncations (integral on $[0,t]$, and $Y \wedge r$) in order to cope with divergence of the integral and unboundedness of Y. Defining appropriately the supremum of a family of self-adjoint operators and then the potential $\mathcal{U}$ for positive self-adjoint operators, formula (4) can be written as

$$\mathcal{U}(Y) \leqslant X.$$

In the applications, however, the QMS usually is not explicitly given. Therefore we shall look for conditions involving the infinitesimal generator. To this end we introduce now the class of QMS with possibly unbounded generators that concerns our research. This is sufficiently general to cover a wide class of applications.

III. THE MINIMAL QUANTUM DYNAMICAL SEMIGROUP

The characterization of a QMS from its generator has been obtained for the first time by Gorini, Kossakowsky, and Sudharshan in Ref. 8 in the finite dimensional case. This result was extended later by Lindblad to the case of an infinite dimensional Hilbert space in the celebrated paper.[9] However, Lindblad restricted himself to consider *bounded generators*, or equivalently, uniformly continuous semigroups. This hypothesis is hardly satisfied in physical models, for

instance in those commonly arising in quantum optics. For that reason several authors, starting from Davies,[10] have been looking for a characterization of nonuniformly continuous QDS for which the generator is usually given as a sesquilinear form, appearing in the so-called *master equations*. At present there is not a definite answer to this question because, even ''good forms'' could have an infinite family of associated QDS which renders the characterization ambiguous. As a way to solve this ambiguity, the notion of *minimal quantum dynamical semigroup* has been proposed by Davies and used by different authors to enlarge the class of semigroups which can be used in applications to Physics. This notion is recalled here for easier reference in the sequel.

Let G and L_ℓ, ($\ell \geqslant 1$) be operators in h which satisfy the following hypothesis:

(**H**) G is the infinitesimal generator of a strongly continuous contraction semigroup in h, $D(G)$ is contained in $D(L_\ell)$, for all $\ell \geqslant 1$, and, for all $u,v \in D(G)$, we have

$$\langle Gv,u\rangle + \sum_{\ell=1}^{\infty} \langle L_\ell v, L_\ell u\rangle + \langle v, Gu\rangle = 0.$$

Under the above assumption (**H**), for each $x \in \mathcal{B}(h)$ let $\mathfrak{L}(x)$ be the sesquilinear form on h with domain $D(G)\times D(G)$ defined by

$$\mathfrak{L}(x)(v,u) = \langle Gv, xu\rangle + \sum_{\ell=1}^{\infty} \langle L_\ell v, xL_\ell u\rangle + \langle v, xGu\rangle. \tag{5}$$

It is well known (see, e.g., Ref. 10, Sec. 3, and Ref. 11, Sec. 3.3) that, given a domain $D \subseteq D(G)$, which is a core for G, it is possible to build up a QDS, called the *minimal* QDS, satisfying the equation

$$\langle v, \mathcal{T}_t(x)u\rangle = \langle v, xu\rangle + \int_0^t \mathfrak{L}(\mathcal{T}_s(x))(v,u)ds, \tag{6}$$

for $u,v \in D$.

This equation, however, in spite of the hypothesis (**H**) and the fact that D is a core for G, does not necessarily determine a unique semigroup. The minimal QDS is characterized by the following property: for any w^* continuous family $(\mathcal{T}_t)_{t\geqslant 0}$ of positive maps on $\mathcal{B}(h)$ satisfying (6) we have $\mathcal{T}_t^{(\min)}(x) \leqslant \mathcal{T}_t(x)$ for all positive $x \in \mathcal{B}(h)$ and all $t \geqslant 0$ (see, e.g., Ref. 11, Theorem 3.21).

Let $\mathcal{T}_*^{(\min)}$ denote the predual semigroup on $\mathcal{I}_1(h)$ with infinitesimal generator $\mathcal{L}^{(\min)}$. It is worth noticing here that $\mathcal{T}_*^{(\min)}$ is a *weakly* continuous semigroup on the Banach space $\mathcal{I}_1(h)$, hence it is *strongly* continuous. The linear span $\mathcal{V}$ of elements of $\mathcal{I}_1(h)$ of the form $|u\rangle\langle v|$ is contained in the domain of $\mathcal{L}^{(\min)}$. Thus we can write the equation (6) as follows:

$$\mathrm{tr}(|u\rangle\langle v|\mathcal{T}_t(x)) = \mathrm{tr}(|u\rangle\langle v|x) + \int_0^t \mathrm{tr}(\mathcal{L}_*^{(\min)}(|u\rangle\langle v|)\mathcal{T}_s(x))ds.$$

This equation reveals that the solution to (6) is unique whenever the linear manifold $\mathcal{L}_*^{(\min)}(\mathcal{V})$ is big enough. Indeed, the following characterization holds.

Proposition III.1: Under the assumption (**H**) the following conditions are equivalent:

(i) the minimal QDS is Markov [i.e., $\mathcal{T}_t^{(\min)}(\mathbb{1}) = \mathbb{1}$],
(ii) $(\mathcal{T}_t^{(\min)})_{t\geqslant 0}$ is the unique w^*-continuous family of positive contractive maps on $\mathcal{B}(h)$ satisfying (6) for all positive $x \in \mathcal{B}(h)$ and all $t \geqslant 0$,
(iii) the domain $\mathcal{V}$ is a core for $\mathcal{L}_*^{(\min)}$.

We refer to Ref. 10 Theorem 3.2 or Ref. 11, Prop. 3.31 (respectively, Ref. 11 Theorem 3.21) for the proof of the equivalence of (i) and (iii) [respectively, (i) and (ii)].

The above discussion has shown the importance of getting a minimal quantum dynamical semigroup which preserves the identity, that is, a quantum Markov semigroup. Chebotarev and Fagnola have obtained an easier criterion to verify the Markov property (see Ref. 12, Theorem 4.4, p. 394). We will recall later this result in one of our applications.

IV. MAIN RESULT

Definition IV.1: Given two self-adjoint operators X, Y, with X positive and Y bounded form below, we write $\mathfrak{L}(X)\leqslant -Y$ on D, whenever the inequality

$$\langle Gu, Xu\rangle + \sum_{\ell=1}^{\infty} \langle X^{1/2}L_\ell u, X^{1/2}L_\ell u\rangle + \langle Xu, Gu\rangle \leqslant -\langle u, Yu\rangle, \tag{7}$$

holds for all u in a linear manifold D dense in h, contained in the domains of G, X, and Y, which is a core for X and G, such that $L_\ell(D)\subseteq D(X^{1/2})$, $(\ell\geqslant 1)$.

Theorem IV.1: Assume that the hypothesis (**H**) holds and that the minimal QDS associated with G, $(L_\ell)_{\ell\geqslant 1}$ is Markov. Suppose that there exist two self-adjoint operators X and Y, with X positive and Y bounded from below and with finite dimensional spectral projections associated with bounded intervals, such that

(i) $\mathfrak{L}(X)\leqslant -Y$ on D,
(ii) G is relatively bounded with respect to X,
(iii) $L_\ell(n+X)^{-1}(D)\subseteq D(X^{1/2})$ $(n,\ell\geqslant 1)$.

Then the minimal QDS associated with G, $(L_\ell)_{\ell\geqslant 1}$ has a normal stationary state.

It is worth noticing that the above sufficient conditions always hold for a finite dimensional space h. Indeed, by the hypothesis (**H**), it suffices to take $X=\mathbb{1}$, $Y=0$, and $D=h$.

We begin the proof by building up approximations $\mathcal{T}^{(n)}$ of $\mathcal{T}^{(\min)}$.

Lemma IV.1: Under the hypotheses of Theorem IV.1, for all integer $n\geqslant 1$ the operators $G^{(n)}$ and $L_\ell^{(n)}$ with domain D defined by

$$G^{(n)}=nG(n+X)^{-1}, \quad L_\ell^{(n)}=nL_\ell(n+X)^{-1},$$

admit a unique bounded extension. The operator on $\mathcal{B}(h)$ defined by

$$\mathcal{L}^{(n)}(x)=G^{(n)*}x+\sum_{\ell} L_\ell^{(n)*}xL_\ell^{(n)}+xG^{(n)} \tag{8}$$

$(n\geqslant 1)$ generates a uniformly continuous QDS $\mathcal{T}^{(n)}$.

Proof: First notice that $G^{(n)}$ and the $L_\ell^{(n)}$'s are bounded. Indeed, by the hypothesis (ii), the resolvent $(n+X)^{-1}$ maps h into the domain of the operators G and L_ℓ, therefore, $G^{(n)}$ and $L_\ell^{(n)}$ are everywhere defined. Moreover, since G is relatively bounded with respect to X, there exist two constants c_1, $c_2>0$ such that, for each $u\in h$ we have

$$\|nG(n+X)^{-1}u\|\leqslant c_1\|nX(n+X)^{-1}u\|+c_2\|n(n+X)^{-1}u\|.$$

By well-known properties of the Yosida approximation the right-hand side is bounded by $(nc_1+c_2)\|u\|$.

On the other hand, by (**H**), for each $u\in h$ we also have

$$\sum_{\ell=1}^{\infty}\|nL_\ell(n+X)^{-1}u\|^2=-2\Re\langle n(n+X)^{-1}u, G^{(n)}u\rangle\leqslant 2(nc_1+c_2)\|u\|^2.$$

Thus the $L_\ell^{(n)}$'s are bounded. Moreover, replacing u,v in condition (**H**) by $n(n+X)^{-1}u$, $u\in h$, leads to

$$\langle u,\mathcal{L}^{(n)}(\mathbb{1})u\rangle = 2\Re\langle u,G^{(n)}u\rangle + \sum_{\ell=1}^{\infty}\|L_\ell^{(n)}u\|^2$$

$$= 2\Re\langle X(n+X)^{-1}u,G^{(n)}u\rangle$$

$$\leqslant 2(nc_1+c_2)\|u\|^2.$$

It follows that the sum $\Sigma_{\ell=1}^{\infty}L_\ell^{(n)*}L_\ell^{(n)}$ converges strongly. Therefore by Lindblad's theorem (see Refs. 9 and 13), the equation (8) defines the generator of a uniformly continuous QDS. □

We recall the following well-known result on semigroup convergence.

Proposition IV.1: Let A, $A^{(n)}$ $(n\geqslant 1)$ be infinitesimal generators of strongly continuous contraction semigroups $(T_t)_{t\geqslant 0}$, $(T_t^{(n)})_{t\geqslant 0}$ on a Banach space and let D_0 be a core for A. Suppose that each element x of D_0 belongs to the domain of $A^{(n)}$ for n big enough and the sequence $(A^{(n)}x)_{n\geqslant 1}$ converges strongly to Ax. Then the operators $T_t^{(n)}$ converge strongly to T_t uniformly for t in bounded intervals.

We refer to Ref. 14, Theorem 1.5, p. 429, Theorem 2.16, p. 504 for the proof.

We shall need also the following elementary lemma.

Lemma IV.2: Let $(r_\ell)_{\ell\geqslant 1}$, $(s_\ell^{(n)})_{\ell\geqslant 1}$ $(n\geqslant 1)$ be square-summable sequences of positive real numbers such that, for every $\ell\geqslant 1$, $s_\ell^{(n)}\to 0$ as n tends to infinity and there exists a positive constant c such that

$$\sum_{\ell\geqslant 1}(s_\ell^{(n)})^2\leqslant c$$

for every $n\geqslant 1$. Then

$$\lim_{n\to\infty}\sum_{\ell\geqslant 1} r_\ell s_\ell^{(n)} = 0.$$

Proof: Suppose that our conclusion is false. Then, by extracting a subsequence (in n) if necessary, we can choose $\varepsilon>0$ such that, for every n,

$$\sum_{\ell\geqslant 1} r_\ell s_\ell^{(n)} > \varepsilon. \tag{9}$$

The sequences $s^{(n)}$ can be viewed as vectors in $l^2(\mathbb{N}^*)$ uniformly bounded in norm by c. Therefore we can extract a subsequence $(n_m)_{m\geqslant 1}$ such that $(s^{(n_m)})_{m\geqslant 1}$ converges weakly as m tends to infinity. Since $s_\ell^{(n)}\to 0$ as n tends to infinity for each $\ell\geqslant 1$, it follows that the weak limit must be the vector 0. This contradicts (9). □

Lemma IV.3: Let $G^{(n)}$, $L_\ell^{(n)}$ the operators on h defined in Lemma IV.1. Then, under the hypotheses of Theorem IV.1, for all $u\in D(X)$, we have

$$\lim_{n\to\infty} G^{(n)}u = Gu, \quad \lim_{n\to\infty} L_\ell^{(n)}u = L_\ell u.$$

Moreover the operators $\mathcal{T}_{*t}^{(n)}$ on $\mathcal{I}_1(h)$ converge strongly, as n tends to infinity, to $\mathcal{T}_{*t}$, uniform for t in bounded intervals.

Proof: For all $u\in D(X)$, we have

$$\|G^{(n)}u-Gu\| = \|G(n(n+X)^{-1}-\mathbb{1})u\|$$

$$\leqslant c_1\|(n(n+X)^{-1}-\mathbb{1})Xu\| + c_2\|(n(n+X)^{-1}-\mathbb{1})u\|.$$

Therefore the sequence $(G^{(n)}u)_{n\geqslant 1}$ converges strongly to Gu as n tends to infinity by well-known properties of Yosida approximations. Moreover, by (**H**), for $u\in D(X)$, we have also

$$\sum_{\ell=1}^{\infty} \|L_\ell^{(n)}u - L_\ell u\|^2 = -2\Re\langle (n(n+X)^{-1}-\mathbb{1})u, G(n(n+X)^{-1}-\mathbb{1})u\rangle. \tag{10}$$

This shows the convergence of sequences $(L_\ell^{(n)}u)_{n\geqslant 1}$ to $L_\ell u$ for all $\ell \geqslant 1$.

For all $u,v \in D(X)$ we have

$$\mathcal{L}_*^{(n)}(|u\rangle\langle v|) - \mathcal{L}_*^{(\min)}(|u\rangle\langle v|) = |(G^{(n)}-G)u\rangle\langle v| + |u\rangle\langle (G^{(n)}-G)v| + \sum_{\ell=1}^{\infty} |(L_\ell^{(n)}-L_\ell)u\rangle\langle v| + \sum_{\ell=1}^{\infty} |u\rangle\langle (L_\ell^{(n)}-L_\ell)v|.$$

Therefore the trace norm of $\mathcal{L}_*^{(n)}(|u\rangle\langle v|) - \mathcal{L}_*^{(\min)}(|u\rangle\langle v|)$ can be estimated by

$$\|v\|\cdot\|(G^{(n)}-G)u\| + \|u\|\cdot\|(G^{(n)}-G)v\| + \sum_{\ell=1}^{\infty} \|L_\ell u\|\cdot\|(L_\ell^{(n)}-L_\ell)v\| + \sum_{\ell=1}^{\infty} \|L_\ell v\|\cdot\|(L_\ell^{(n)}-L_\ell)u\|.$$

Clearly the first two terms vanish as n tends to infinity. Moreover, by the inequality (10), since the operators $X(n+X)^{-1}$ are contractive, we have

$$\begin{aligned}\sum_{\ell=1}^{\infty} \|L_\ell^{(n)}u - L_\ell u\|^2 &\leqslant 2\|(n+X)^{-1}Xu\|\cdot\|(G^{(n)}-G)u\| \\ &\leqslant 2\|u\|(c_1\|(n(n+X)^{-1}-\mathbb{1})Xu\| + c_2\|(n(n+X)^{-1}-\mathbb{1})u\|) \\ &= 2\|u\|(c_1\|(X(n+X)^{-1})Xu\| + c_2\|(X(n+X)^{-1})u\|) \\ &\leqslant 2\|u\|(c_1\|Xu\| + c_2\|u\|).\end{aligned}$$

An application of Lemma IV.2 shows then that the trace norm of $\mathcal{L}_*^{(n)}(|u\rangle\langle v|) - \mathcal{L}_*^{(\min)}(|u\rangle\langle v|)$ converges to 0 as n tends to infinity.

Since the minimal QDS associated with G, $(L_\ell)_{\ell\geqslant 1}$ is Markov and $D(X)$ is a core for G (it contains D), the linear manifold generated by $|u\rangle\langle v|$ with $u \in D(X)$ is a core for $\mathcal{L}_*^{(\min)}$. The conclusion follows then from Proposition IV.1. □

Lemma IV.4: Let $Y \wedge r$ the operator defined by (3) and let $X^{(n)} = nX(n+X)^{-1}$ $(n \geqslant 1)$. Define $Y_r^{(n)} = n^2(n+X)^{-1}(Y\wedge r)(n+X)^{-1}$. Then, under the hypotheses of Theorem IV.1, the operator

$$X^{(n)} - \int_0^t \mathcal{T}_s^{(n)}(Y_r^{(n)})\,ds$$

is positive for each $t \geqslant 0$.

Proof: Notice that $Y_r \leqslant Y$. Therefore, by the hypothesis (i) of Theorem IV.1, we have the inequality

$$\langle Gu, Xu\rangle + \sum_{\ell=1}^{\infty} \langle X^{1/2}L_\ell u, X^{1/2}L_\ell u\rangle + \langle Xu, Gu\rangle \leqslant -\langle u, (Y\wedge r)u\rangle, \tag{11}$$

for all $u \in D$.

The domain D being a core for X and G being relatively bounded with respect to X, for every $u \in D(X)$ we can find a sequence $(u_n)_{n\geqslant 1}$ in D such that $(Xu_n)_{n\geqslant 1}$ converges to Xu and

$(Gu_n)_{n\geqslant 1}$ converges to Gu. Then the convergence of $(L_\ell u_n)_{n\geqslant 1}$ to $L_\ell u$ (for all $\ell\geqslant 1$) follows readily form the hypothesis (**H**). Moreover, for every $n,m\geqslant 1$, the inequality (11) yields

$$\sum_{\ell=1}^{\infty} \|X^{1/2}L_\ell(u_n-u_m)\|^2 \leqslant -2\Re\langle G(u_n-u_m),X(u_n-u_m)\rangle - \langle (u_n-u_m),(Y\wedge r)(u_n-u_m)\rangle.$$

Therefore, replacing u by u_n, and letting n tend to infinity we show that (11) holds for all $u \in D(X)$.

Since $n(n+X)^{-1}$ is a contraction and $Y_r \leqslant Y$, under the hypotheses of Theorem IV.1, for all $u \in h$, we have

$$\begin{aligned}\langle u,\mathcal{L}^{(n)}(X^{(n)})u\rangle &\leqslant 2\Re\langle G^{(n)}u,X^{(n)}u\rangle + \sum_{\ell=1}^{\infty}\langle X^{1/2}L_\ell^{(n)}u,X^{1/2}L_\ell^{(n)}u\rangle \\ &\leqslant -\langle n(n+X)^{-1}u,Y_r n(n+X)^{-1}u\rangle \\ &= -\langle u,Y_r^{(n)}u\rangle.\end{aligned}$$

It follows then $\mathcal{L}^{(n)}(X^{(n)}) \leqslant -Y_r^{(n)}$.

Now, notice that

$$\frac{d}{dt}\left(X^{(n)} - \mathcal{T}_t^{(n,\eta)}(X^{(n)}) - \int_0^t \mathcal{T}_s^{(n)}(Y_r^{(n)})ds\right) = -\mathcal{T}_t^{(n)}(\mathcal{L}^{(n)}(X^{(n)}) + Y_r^{(n)}) \geqslant 0.$$

Therefore,

$$X^{(n)} - \int_0^t \mathcal{T}_s^{(n)}(Y_r^{(n)})ds \geqslant \mathcal{T}_t^{(n)}(X^{(n)}) \geqslant 0$$

for all $t\geqslant 0$. □

Proof (of Theorem IV.1): By Lemma IV.4 for each $u \in D(X)$, $t,r\geqslant 0$, and $n\geqslant 1$, we have

$$\int_0^t \mathrm{tr}(\mathcal{T}_{*s}^{(n)}(|u\rangle\langle u|)Y_r^{(n)})ds \leqslant \langle u,X^{(n)}u\rangle.$$

The sequence $(Y_r^{(n)})_{n\geqslant 1}$ converges strongly to $Y\wedge r$. Thus, by Lemma IV.3, we can let n tend to infinity to obtain

$$\int_0^t \mathrm{tr}(\mathcal{T}_{*s}(|u\rangle\langle u|)(Y\wedge r))ds \leqslant \langle u,Xu\rangle.$$

This inequality coincides with (4). Therefore Theorem IV.1 follows from Theorem II.2. □

V. APPLICATIONS

V.1. A multimode Dicke laser model. We follow Alli and Sewell[15] where a model is proposed for a Dicke laser or maser. We begin by establishing the corresponding notations.

The system consists of N identical two-level atoms coupled with the radiation corresponding to n modes. Therefore, one can choose the Hilbert space h which consists of the tensor product of N copies of $\mathbb{C}^2$ and n copies of $l^2(\mathbb{N})$. To simplify notations we simply identify any operator acting on a factor of the above tensor product with its canonical extension to h.

Let σ_1, σ_2, σ_3 be the Pauli matrices and define the spin raising and lowering operators $\sigma_\pm = (\sigma_x \pm \sigma_y)/2$. The atoms are located on the sites $r=1,\ldots,N$ of a one-dimensional lattice, so

that we denote by $\sigma_{\epsilon,r}(\epsilon=1,2,3,+,-)$ the spin component of the atom at the site r. The free evolution of the atoms is described by a generator $\mathcal{L}_{\mathrm{mat}}$ which is bounded and given in Lindblad form as

$$\mathcal{L}_{\mathrm{mat}}(x)=i[H,x]-\frac{1}{2}\sum_j\ (V_j^*V_jx-2V_j^*xV_j+xV_j^*V_j), \tag{12}$$

where the sum contains a finite number of elements, H is self-adjoint and the V_j's are bounded operators.

Moreover, we denote by a_j^*, a_j, the creation and annihilation operators corresponding to the jth mode of the radiation $(j=1,\ldots,n)$. These operators satisfy the canonical commutation relations:

$$[a_j,a_k^*]=\delta_{jk}I,\quad [a_j,a_k]=0.$$

The free evolution of the radiation is given by the formal generator

$$\mathcal{L}_{\mathrm{rad}}(x)=\sum_{\ell=1}^{n}\ (\kappa_\ell(-a_\ell^*a_\ell x+2a_\ell^*xa_\ell-xa_\ell^*a_\ell)+i\omega_\ell[a_\ell^*a_\ell,x]), \tag{13}$$

where κ_ℓ are the damping and ω_ℓ are the frequencies corresponding to the ℓth mode of the radiation.

The coupling between the matter and the radiation corresponds to a Hamiltonian interaction of the form

$$H_{\mathrm{int}}=\frac{i}{N^{1/2}}\sum_{r=1}^{N}\sum_{\ell=1}^{n}\lambda_\ell(\sigma_{-,r}a_\ell^*\mathrm{e}^{-2\pi ik_\ell r}-\sigma_{+,r}a_\ell\mathrm{e}^{2\pi ik_\ell r}), \tag{14}$$

where k_ℓ is the wave number of the ℓth mode and the λ's are real valued, N independent coupling constants.

With the above notations, the formal generator of the whole dynamics is given by

$$\mathcal{L}(x)=\mathcal{L}_{\mathrm{mat}}(x)+\mathcal{L}_{\mathrm{rad}}(x)+i[H_{\mathrm{int}},x]. \tag{15}$$

To identify L_ℓ and G in our notations, we use in force the convention on the abridged version of tensor products with the identity. That is, here we find

$$L_\ell=\sqrt{\kappa_l}a_\ell,\quad (\ell=1,\ldots,n) \tag{16}$$

All the remaining L_ℓ's are bounded operators. Among them a finite number (indeed $3N$) coincides with some of the V_j's appearing in (12) and the others vanish.

So that the operator G becomes formally

$$G=-\frac{1}{2}\sum_\ell\ (\kappa_\ell-2i\omega_\ell)a_\ell^*a_\ell-iH-iH_{\mathrm{int}}, \tag{17}$$

where the sum contains only a finite number of nonzero terms.

To make the above expression rigorous some preliminary work is needed. Call $(f_m)_{m\geqslant 0}$ the canonical orthonormal basis on the space $l^2(\mathbb{N})$. In the radiation space, which consists of the tensor product of n copies of $l^2(\mathbb{N})$, we denote

$$f_\alpha=f_{\alpha_1}^{(1)}\otimes\cdots\otimes f_{\alpha_n}^{(n)},$$

where $\alpha=(\alpha_1,\ldots,\alpha_n)$ and $f_{\alpha_\ell}^{(\ell)}$ is an element of the canonical basis of the ℓ copy of $l^2(\mathbb{N})$. Thus, $(f_\alpha)_{\alpha\in\mathbb{N}^n}$ is the canonical orthonormal basis of the radiation space.

With these notations we have

$$a_\ell^* f_\alpha=\sqrt{\alpha_\ell+1}\,f_{\alpha+1_\ell},\quad a_\ell f_\alpha=\begin{cases}\sqrt{\alpha_\ell}\,f_{\alpha-1_\ell}, & \text{if } \alpha_\ell>0,\\ 0, & \text{if } \alpha_\ell=0,\end{cases} \tag{18}$$

where 1_ℓ is the vector with a 1 at the ℓth coordinate and zero elsewhere.

Thus, the operator G is well defined over vectors of the form uf_α where $u\in\mathbb{C}^{2N}$ and the symbol of tensor product is dropped.

It can be shown (e.g., as in Ref. 11, Prop. 4.9) that the closure of G generates a strongly continuous contraction semigroups and the hypothesis (**H**) is easily checked. Therefore, we choose X formally given by $X=\Sigma_{\ell=1}^n a_\ell^* a_\ell$. That is, $Xuf_\alpha=|\alpha|uf_\alpha$, where $|\alpha|=\alpha_1+\cdots+\alpha_n$.

Since $X^k uf_\alpha=|\alpha|^k uf_\alpha$ it follows that the linear span of vectors of the form uf_α is a dense subset of the analytic vectors for X. Therefore, by a theorem of Nelson (see, e.g., Ref. 16), X is essentially self-adjoint on the referred domain. From now on we identify X with its closure which is self-adjoint.

We show now that H_{int} is relatively bounded with respect to X. Let ξ be a finite linear combination of elements of the form $u_\alpha f_\alpha$. By Schwarz' inequality, and elementary inequalities like $\sqrt{t+s}\leqslant\sqrt{t}+\sqrt{s}\leqslant\sqrt{2(t+s)}$, $2\sqrt{ts}\leqslant\epsilon t+\epsilon^{-1}s$, we obtain

$$\begin{aligned}\|H_{\text{int}}\xi\|&\leqslant\frac{1}{N^{1/2}}\sum_{r=1}^N\sum_{\ell=1}^n|\lambda_\ell|(\|a_\ell^*\xi\|+\|a_\ell\xi\|)\\&\leqslant\frac{1}{N^{1/2}}\sum_{r=1}^N\sum_{\ell=1}^n|\lambda_\ell|(4\langle\xi,a_\ell^*a_\ell\xi\rangle+2\|\xi\|^2)^{1/2}\\&\leqslant\frac{1}{N^{1/2}}\left[\sum_{r=1}^N\sum_{\ell=1}^n 2(|\lambda_\ell|^2\langle\xi,a_\ell^*a_\ell\xi\rangle)^{1/2}+\sqrt{2}\sum_{r=1}^N\sum_{\ell=1}^n|\lambda_\ell|\|\xi\|\right]\\&\leqslant\frac{1}{N^{1/2}}\left[\sum_{r=1}^N\sum_{\ell=1}^n(\epsilon\|a_\ell^*a_\ell\xi\|+\epsilon^{-1}|\lambda_\ell|^2\|\xi\|)+\sqrt{2}\sum_{r=1}^N\sum_{\ell=1}^n|\lambda_\ell|\|\xi\|\right].\end{aligned}$$

Finally, by the elementary inequality $\Sigma_{\ell=1}^n\|s_\ell\|\leqslant\sqrt{n}\|\Sigma_{\ell=1}^n s_\ell\|$, it follows

$$\|H_{\text{int}}\xi\|\leqslant\frac{n^{1/2}\epsilon}{N^{1/2}}\sum_{r=1}^N\left\|\sum_{\ell=1}^n a_\ell^*a_\ell\xi\right\|+\frac{1}{N^{1/2}}\sum_{r=1}^N\sum_{\ell=1}^n(\sqrt{2}+\epsilon^{-1}|\lambda_\ell|)|\lambda_\ell|\|\xi\|$$

$$\leqslant\epsilon N^{1/2}n^{1/2}\|X\xi\|+\frac{1}{N^{1/2}}\sum_{r=1}^N\sum_{\ell=1}^n(\sqrt{2}+\epsilon^{-1}|\lambda_\ell|)|\lambda_\ell|\|\xi\|,$$

thus, choosing $2\epsilon<(Nn)^{-1/2}$, the above inequality yields the required relative boundedness of H_{int} with respect to X. Note that the domain of G coincides with the domain of X.

To apply our main result, we fix the domain D as the space of vectors ξ which are finite linear combinations of the form $u_\alpha f_\alpha$. Notice that this is an invariant for X, G, and all the L_ℓ's. To identify an appropriate operator Y to have $\mathcal{L}(X)\leqslant -Y$, we first perform the computation of $\mathcal{L}(X)$.

For the sake of clarity, we avoid handling forms in the computations below. However, the reader may easily notice that all the expressions are well defined since the domain D is invariant under the action of the operators X, G, and L_ℓ.

First, it holds $\mathcal{L}_{\mathrm{mat}}(X)=0$. Second, a straightforward computation using the canonical commutation relations, yields

$$\mathcal{L}_{\mathrm{rad}}(X)=-2\sum_{\ell=1}^{n}\kappa_\ell a_\ell^* a_\ell.$$

Another easy computation leads us to

$$i[H_{\mathrm{int}},X]=-iN^{-1/2}\sum_{r=1}^{N}\sum_{\ell=1}^{n}\lambda_\ell(\sigma_{-,r}a_\ell e^{-2\pi ik_\ell r}+\sigma_{+,r}a_\ell^* e^{2\pi ik_\ell r}).$$

Summing up,

$$\mathfrak{L}(X)=-2\sum_{\ell=1}^{n}\kappa_\ell a_\ell^* a_\ell-\frac{i}{N^{1/2}}\sum_{r=1}^{N}\sum_{\ell=1}^{n}\lambda_\ell(\sigma_{-,r}a_\ell e^{-2\pi ik_\ell r}+\sigma_{+,r}a_\ell^* e^{2\pi ik_\ell r}).$$

To identify Y it suffices to control the term $i[H_{\mathrm{int}},X]$. For each $\xi\in D$, it follows

$$\begin{aligned}
|\langle\xi,i[H_{\mathrm{int}},X]\xi\rangle| &= \frac{1}{N^{1/2}}\left|\sum_{r=1}^{N}\sum_{\ell=1}^{n}\lambda_\ell\langle\xi,(\sigma_{-,r}a_\ell e^{-2\pi ik_\ell r}+\sigma_{+,r}a_\ell^* e^{2\pi ik_\ell r}\xi\rangle\right| \\
&\leqslant \frac{1}{2N^{1/2}}\sum_{r=1}^{N}\sum_{\ell=1}^{n}2|\lambda_\ell|\|\xi\|(\|a_\ell\xi\|+\|a_\ell^*\xi\|) \\
&\leqslant \frac{\epsilon}{2N^{1/2}}\sum_{r=1}^{N}\sum_{\ell=1}^{n}(\langle\xi,a_\ell^* a_\ell\xi\rangle+\langle\xi,a_\ell a_\ell^*\xi\rangle)+\frac{1}{2\epsilon N^{1/2}}\sum_{r=1}^{N}\sum_{\ell=1}^{n}|\lambda_\ell|^2\|\xi\|^2 \\
&\leqslant \epsilon N^{1/2}\langle\xi,X\xi\rangle+\frac{\epsilon N^{1/2}n}{2}\|\xi\|^2+\frac{1}{2\epsilon N^{1/2}}\sum_{r=1}^{N}\sum_{\ell=1}^{n}|\lambda_\ell|^2\|\xi\|^2.
\end{aligned}$$

So that choosing $0<\epsilon<(2/N^{1/2})\min_{1\leqslant\ell\leqslant n}\kappa_\ell$ the required operator Y may be taken as

$$Y=\left(2\min_{1\leqslant\ell\leqslant n}\kappa_\ell-\epsilon N^{1/2}\right)(X+c),$$

where $c>0$ is a suitable constant.

The spectrum of X coincides with $\mathbb{N}$. For each $m\in\mathbb{N}$, the corresponding eigenspace is generated by the f_α with $|\alpha|=m$. Therefore, it follows that all spectral projections of X and Y associated with bounded intervals are finite dimensional.

In Ref. 15 it is proven that the minimal QDS with G, L_ℓ is Markov.

To summarize, our main theorem combined with the Markov property of the semigroup imply the following corollary.

Corollary V.1: There exists a normal stationary state for the multimode Dicke model.

To finish with this example we want to comment that one can prove the Markov property alternatively, following similar arguments to those used to check the hypotheses of our main theorem. Indeed, it suffices to apply the Proposition below from Ref. 12 with $C=X$ to show that the minimal QDS is conservative.

Proposition V.1: Under the hypothesis (**H**) suppose that there exists a self-adjoint operator C in h with the following properties:

(a) the domain of G is contained in the domain of $C^{1/2}$ and is a core for $C^{1/2}$,
(b) the linear manifold $L_\ell(D(G^2))$ is contained in the domain of $C^{1/2}$,
(c) there exists a self-adjoint operator Φ, with $D(G)\subseteq D(\Phi^{1/2})$ and $D(C)\subseteq D(\Phi)$, such that, for all $u\in D(G)$, we have

$$-2\Re\langle u,Gu\rangle=\sum_\ell \|L_\ell u\|^2=\|\Phi^{1/2}u\|^2,$$

(a) for all $u\in D(C^{1/2})$ we have $\|\Phi^{1/2}u\|\leqslant\|C^{1/2}u\|$,
(b) for all $u\in D(G^2)$ the following inequality holds

$$2\Re\langle C^{1/2}u,C^{1/2}Gu\rangle+\sum_{\ell=1}^{\infty}\|C^{1/2}L_\ell u\|^2\leqslant b\|C^{1/2}u\|^2, \tag{19}$$

where b is a positive constant depending only on G, L_ℓ, C.

Then the minimal QDS is Markov.

V.2 The Jaynes–Cummings model. We follow our paper[17] to introduce the Jaynes–Cummings model in quantum optics. To this aim we use the same space $h=l^2(\mathbb{N})$, since here $n=1$, we drop the index ℓ from the notations of creation and annihilation operators and S denotes the right-shift operator.

In this framework the formal generator is given by

$$\mathcal{L}(x)=-\frac{\mu^2}{2}(a^*ax-2a^*xa+xa^*a)-\frac{\lambda^2}{2}(aa^*x-2axa^*+xaa^*)$$
$$+R^2(\cos(\phi\sqrt{aa^*})x\cos(\phi\sqrt{aa^*})-x)+R^2\sin(\phi\sqrt{aa^*})S^*xS\sin(\phi\sqrt{aa^*}),$$

where λ, μ, R, and ϕ are positive constants. In Ref. 17 the rigorous construction of the minimal QDS was done showing also that it is identity preserving.

The above Jaynes–Cummings generator has a faithful normal stationary state if and only if $\mu^2>\lambda^2$. This state can be computed explicitly. The interested reader is referred to Ref. 17.

To check conditions of Theorem IV.1, one can take $X=a^*a$, the value of $\mathcal{L}(X)$ becoming

$$\mathcal{L}(X)=-(\mu^2-\lambda^2)a^*a+R^2\sin^2(\phi\sqrt{aa^*}).$$

Thus, it suffices to take $Y=(\mu^2-\lambda^2)a^*a-R^2$ to prove the existence of a stationary state via our main result.

To prove the necessity, one can follow the argument explained in Ref. 17 inspired from classical probability.

Thus, in this case, our result IV.1 turns out to be sharp.

VI. FINAL COMMENTS

Theorems II.2 and IV.1 provide a useful method for deciding whether a normal stationary state exists for a given physical model, when this is not given at the outset. Some other concrete examples of application will be considered by the authors in a forthcoming paper.

On the other hand, the natural question which arises is whether there exists a *faithful* normal stationary state for a given quantum dynamical semigroup. An answer to this supplementary question will be provided in Ref. 18.

Recursion operators of some equations of hydrodynamic type

M. Gürses[a] and K. Zheltukhin
Department of Mathematics, Faculty of Sciences, Bilkent University, 06533 Ankara—Turkey

(Received 7 August 2000; accepted for publication 28 November 2000)

We give a general method for constructing recursion operators for some equations of hydrodynamic type, admitting a nonstandard Lax representation. We give several examples for $N=2$ and $N=3$ containing the equations of shallow water waves and its generalizations with their first two general symmetries and their recursion operators. We also discuss a reduction of $N+1$ systems to N systems of some new equations of hydrodynamic type. © *2001 American Institute of Physics.*
[DOI: 10.1063/1.1346597]

I. INTRODUCTION

Most of the integrable nonlinear partial differential equations admit Lax representations,

$$L_t=[A,L], \tag{1}$$

where L is a pseudo-differential operator of order m and A is a pseudo-differential operator. Recently[1] we established a new method for such integrable equations to construct their recursion operators. This method uses the hierarchy of equations,

$$L_{t_n}=[A_n,L], \tag{2}$$

and the Gel'fand–Dikkii[2] construction of the A_n-operators. Defining an operator R_n in the form

$$A_n=LA_{n-m}+R_n, \tag{3}$$

one then obtains relations among the hierarchies,

$$L_{t_n}=LL_{t_{n-m}}+[R_n;L]. \tag{4}$$

This equation allows to find L_{t_n} in terms of $L_{t_{n-m}}$. It is important to note that one does not need to know the exact form of A_n. For further details of the method see Ref. 1.

In Ref. 1 we introduced a direct method to determine a recursion operator of a system of evolution equations when its Lax representation is known. It has no direct reference to the Hamiltonian operators. Hence one may be able to determine the recursion operators when any one of the Hamiltonian operators are degenerate. In the same paper we gave several applications of the method. In all these examples we have considered the Lax representation is given either in a pseudo-differential operator or in matrix form (taking values in some lower dimensional Lie algebras). We call such Lax representations as standard Lax representation. On the other hand there are some systems of evolution equations, such as the equations of hydrodynamic type, which are obtained by nonstandard Lax represenations used in the present paper. We first show that the method introduced in Ref. 1 is also applicable here in the case of systems of equations of hydrodynamic types and we give several examples for illustration. These equations and their Hamil-

[a]Electronic mail: gurses@fen.bilkent.edu.tr

tonian formulation (sometimes called the dispersion-less KdV system) were studied by Dubrovin and Novikov.[3] See Ref. 4 for more details on this subject (see also Ref. 5). It is known that these equations admit a nonstandard Lax representation,

$$\frac{\partial L}{\partial t}=\{A,L\}_k, \tag{5}$$

where A,L are differentiable functions of t,x,p on a Poisson manifold M with local coordinates (x,p) and $\{,\}_k$ is the Poisson bracket. On M we take this Poisson bracket $\{,\}_k=p^k\{,\}$, where $\{,\}$ is the canonical Poisson bracket and k is an integer. For more information on Poisson manifolds see Refs. 6 and 7. Equations of hydrodynamic type with the above Lax representations were studied in Refs. 8–11. Having such a Lax representation, we can consider a whole hierarchy of equations,

$$\frac{\partial L}{\partial t_n}=\{A_n,L\}_k. \tag{6}$$

We can also represent function A_n in the form given in (3) and apply our method[1] for the construction of a recursion operator for the equation (6). There are some other works[12–14] which also give recursion operators of some equations of hydrodynamic type. The form of these operators are different than the recursion operators presented in this work. Our method[1] produces recursion operators for hydrodynamic type of equations in the form $\mathcal{R}=A+B\,D^{-1}$ where A and B are functions of dynamical variables and their derivatives. All higher symmetries obtained by the repeated application of this recursion operator to translational symmetries also belong to the hydrodynamic type of equations. The recursion operators obtained in Refs. 12–14 are of the form $\mathcal{R}=C\,D+A+B\,D^{-1}E$, where A,B,C, and E are functions of dynamical variables and their derivatives.

In the next section we discuss the Lax representation with Poisson brackets for polynomial Lax functions. In Sec. III we give the method of construction of the recursion operators following Ref. 1. In Sec. IV we give several examples for $k=0$ and $k=1$. In Sec. V we consider the Poisson bracket for general k and let

$$L=p+S+Pp^{-1}, \tag{7}$$

and find the Lax equations and the corresponding recursion operator for $N=2$. In Sec. VI we consider the Lax function

$$L=p^{\gamma-1}+u+\frac{v^{\gamma-1}}{(\gamma-1)^2}p^{-\gamma+1}, \tag{8}$$

and take $k=0$. We obtain the equations corresponding to the polytropic gas dynamics and its recursion operators.[6,10] It is interesting to note that the systems of equations and their recursion operators obtained in Secs. V and VI are transformable into each other. In Sec. VII we give a method reduction from an $N+1$ system to an N system and from an $N+1$ system to an $N-1$ system by letting one of the symmetrical variables (defined in the text) either to zero or equating to another variable. The systems obtained by the reduction are equivalent to the systems obtained by the Lax function (in symmetrical variables) having zeros with multiplicities greater than one. Reduced systems are shown to be also integrable, i.e., they admit recursion operators.

II. LAX FORMULATION WITH POISSON BRACKET

We start with the definition of the standard Poisson bracket. Let $f(x,p)$ and $g(x,p)$ be differentiable functions of their arguments. Then the standard Poisson bracket is defined by (see Refs. 6 and 9 for more details)

$$\{f,g\}=\frac{\partial f}{\partial p}\frac{\partial g}{\partial x}-\frac{\partial f}{\partial x}\frac{\partial g}{\partial p}. \tag{9}$$

We give a slight modification of this bracket as[9]

$$\{f,g\}_k=p^k\{f,g\}, \tag{10}$$

where k is an integer. It is easy to prove that $\{,\}_k$ also defines a Poisson bracket for all $k\in\mathbb{Z}$. Although this bracket is equivalent to $\{,\}$, under $p^k(d/dp)=d/dq$ where q is the new variable, we shall keep using it. The main reason is technical. There is a nice duality between the systems obtained by polynomial Lax representation, $L=p^N+\cdots$, with Poisson bracket $\{,\}_k$ and by Lax represention $L=p^\gamma[p^N+\cdots]$ with Poisson bracket $\{,\}$. For illustration we have examples, equations governing the polytropic gas dynamics, given in Propositions 6 and 7.

For each $k\in\mathbf{Z}$ we can consider hierarchies of equations of hydrodynamic type, defined in terms of the Lax function,

$$L=p^{N-1}+\sum_{i=-1}^{N-2}p^iS_i(x,t), \tag{11}$$

by the Lax equation

$$\frac{\partial L}{\partial t_n}=\{(L^{n/(N-1)})_{\geqslant -k+1};L\}_k, \tag{12}$$

where $n=j+l(N-1)$ and $j=1,2,\ldots,(N-1), l\in\mathbf{N}$. So we have a hierarchy for each k and $j=1,\ldots,(N-1)$. Also, we require $n\geqslant -k+1$ to ensure that $(L^{n/(N-1)})_{\geqslant -k+1}$ is not zero. With the choice of Poisson brackets $\{,\}_k$, we must take a certain part of the series expansion of $L^{n/(N-1)}$ to get the consistent equation (12). This part is $(L^{n/(N-1)})_{\geqslant -k+1}$.

The Lax function (11) can also be written in terms of symmetric variables $u_1,\ldots,u_N$,

$$L=\frac{1}{p}\prod_{j=1}^{N}(p-u_j), \tag{13}$$

that is $u_1,\ldots,u_N$ are roots of the polynomial

$$p^{N-1}+S_{N-2}p^{N-2}+\ldots+S_{-1}p^{-1}.$$

In new variables the equation (12) is invariant under transposition of variables.

III. RECURSION OPERATORS

For each hierarchy of the equations (12), depending on the pair (N,k), we can find a recursion operator.

Lemma 1: For any n,

$$L_n=LL_{n-(N-1)}+\{R_n;L\}_k, \tag{14}$$

where function R_n has a form

$$R_n=\sum_{i=0}^{N-2}p^{i-k}A_i(S_{-1}\ldots S_{N-2},\partial S_{-1}/\partial t_{n-(N-1)}\ldots\partial S_{N-2}/\partial t_{n-(N-1)}). \tag{15}$$

Proof:

$$(L^{n/(N-1)})_{\geqslant -k+1}=[L(L^{n/(N-1)-1})_{\geqslant -k+1}+L(L^{n/(N-1)-1})_{<-k+1}]_{\geqslant -k+1}.$$

So,

$$(L^{n/(N-1)})_{\geqslant -k+1}=L(L^{n/(N-1)-1})_{\geqslant -k+1}+(L(L^{n/(N-1)-1})_{<-k+1})_{\geqslant -k+1}$$
$$-(L(L^{n/(N-1)-1})_{\geqslant -k+1})_{<-k+1}. \tag{16}$$

If we put

$$R_n=(L(L^{n/(N-1)-1})_{<-k+1})_{\geqslant -k+1}-(L(L^{n/(N-1)-1})_{\geqslant -k+1})_{<-k+1},$$

then

$$(L^{n/(N-1)})_{\geqslant -k+1}=L(L^{n/(N-1)-1})_{\geqslant -k+1}+R_n.$$

Hence,

$$L_n=\{(L^{n/(N-1)})_{\geqslant -k+1};L\}_k=\{L(L^{n/(N-1)-1})_{\geqslant -k+1}+R_n;L\}_k=LL_{n-(N-1)}+\{R_n;L\}_k, \tag{17}$$

and (14) is satisfied. Evaluating powers of $(L(L^{n/(N-1)-1})_{<-k+1})_{\geqslant -k+1}$ and $-(L(L^{n/(N-1)-1})_{\geqslant -k+1})_{<-k+1}$ we get that R_n has form (15). □

Lemma 2: A recursion operator for the hierarchy (12) is given by equalities, for $m=N-2,N-3,\ldots,-1$,

$$\frac{\partial S_m}{\partial t_n}=\sum_{j=-1}^{m+1} S_j \frac{\partial S_{m-j}}{\partial t_{n-(N-1)}}+\sum_{j=-1}^{m+1}(j+1-k)A_{j+1}S_{m-j,x}-\sum_{j=-1}^{m+1}(m-j)A_{j+1,x}S_{m-j}, \tag{18}$$

where to simplify the above formula we have defined that $S_{N-1}=1$ and $S_{N-1,x}=0$, $(\partial S_{N-1}/\partial t_n)=0$. *Coefficients* $A_{N-2},A_{N-3},\ldots,A_0$ *can be found from the recursion relations, for* $m=N-2,\ldots,-1$,

$$(N-1)A_{m,x}=\sum_{j=m}^{N-1} S_j \frac{\partial S_{(N-2)+m-j}}{\partial t_{n-(N-1)}}+\sum_{j=m}^{N-2}(j+1-k)A_{j+1}S_{N-2+m-j,x}$$
$$-\sum_{j=m}^{N-2}(N-2+m-j)A_{j+1,x}S_{N-2+m-j}. \tag{19}$$

Proof: Let us write the equality (14), using (15) for R_n,

$$\sum_{i=-1}^{N-2} p^i \frac{\partial S_i}{\partial t_n}=\left(p^{N-1}+\sum_{i=-1}^{N-2}p^i S_i\right)\left(\sum_{i=-1}^{N-2}p^i \frac{\partial S_{(N-2)+m-j}}{\partial t_{n-(N-1)}}\right)+p^k\left(\sum_{j=0}^{N-1}(j-k)p^{j-k-1}A_j\right)$$
$$\times\left(\sum_{j=-1}^{N-2}p^j S_{j,x}\right)-p^k\left(\sum_{j=0}^{N-1}p^{j-k}A_{j,x}\right)\left((N-1)p^{N-2}+\sum_{j=-1}^{N-2}jp^{j-1}S_j\right).$$

To have the equality, the coefficients of $p^{2N-3},\ldots,p^{N-1}$ and p^{-2} must be zero; it gives recursion relations to find $A_{N-2},\ldots,A_0$. The coefficients of $p^{N-2},\ldots,p^{-1}$ give the expressions for $\partial S_{N-2}/\partial t_{n,}\ldots,\partial S_{-1}/\partial t_n$. □

Although the recursion operator $\mathcal{R}$, given by (18), is a pseudo-differential operator, but it gives a hierarchy of local symmetries starting from the equation itself. Indeed, equalities (18), (19)

give expressions $\partial S_{N-2}/\partial t_{n,\ldots,}\partial S_{-1}/\partial t_n$ in terms of $S_{N-2},\ldots,S_{-1}$ and $\partial S_{N-2}/\partial t_{n-(N-1),\ldots,}$ $\partial S_{-1}/\partial t_{n-(N-1)}$. Hence, the recursion operator $\mathcal{R}$ is constructed in such a way that

$$\{(L^{n/(N-1)+1})_{\geqslant -k+1};L\}_k=\mathcal{R}(\{(L^{n/(N-1)})_{\geqslant -k+1};L\}_k). \tag{20}$$

IV. SOME INTEGRABLE SYSTEMS

We shall consider first some examples for $k=0$, $k=1$ and the general case in the next section.

A. Multicomponent hierarchy containing also the shallow water wave equations, $k=0$

This hierarchy corresponds to the case $k=0$. Let us give the first equation of hierarchy and a recursion operator for $N=2,3$.

Proposition 1: In the case $N=2$ one has the Lax function,

$$L=p+S+P\,p^{-1},$$

and the Lax equation for $n=2$, given by (47), when $k=0$,

$$\begin{aligned}\tfrac{1}{2}S_t&=SS_x+P_x,\\ \tfrac{1}{2}P_t&=SP_x+PS_x,\end{aligned} \tag{21}$$

and the recursion operator, given by (48),

$$\mathcal{R}=\begin{pmatrix} S+S_xD_x^{-1} & 2\\ 2P+P_xD_x^{-1} & S\end{pmatrix}. \tag{22}$$

These equations are known as the shallow water wave equations or as the equations of polytropic gas dynamics for $\gamma=2$ (See Sec. VI).

The first two symmetries of the system (21) are given by

$$S_{t_1}=(S^3+6SP)_x,$$

$$P_{t_1}=(3S^2P+3P^2)_x, \tag{23}$$

$$S_{t_2}=(S^4+12S^2P+6P^2)_x,$$

$$P_{t_2}=(4S^3P+12SP^2)_x. \tag{24}$$

These are all commuting symmetries.

Remark 1: In symmetric variables the system (21) is written as

$$\begin{aligned}\tfrac{1}{2}u_t&=(u+v)u_x+uv_x,\\ \tfrac{1}{2}v_t&=vu_x+(u+v)v_x,\end{aligned} \tag{25}$$

and the recursion operator (22) takes the form

$$\mathcal{R}=\begin{pmatrix} u+v+u_xD_x^{-1} & 2u+u_xD_x^{-1}\\ 2v+v_xD_x^{-1} & u+v+v_xD_x^{-1}\end{pmatrix}. \tag{26}$$

Proposition 2: In the case $N=3$ one has the Lax function

$$L=p^2+pS+P+p^{-1}Q,$$

and the Lax equation with $n=3$ is

$$\begin{aligned}
\tfrac{1}{3}S_t&=(\tfrac{1}{2}P-\tfrac{1}{8}S^2)S_x+\tfrac{1}{2}SP_x+Q_x,\\
\tfrac{1}{3}P_t&=\tfrac{1}{2}QS_x+(\tfrac{1}{8}S^2+\tfrac{1}{2}P)P_x+SQ_x,\\
\tfrac{1}{3}Q_t&=\tfrac{1}{4}SQS_x+\tfrac{1}{2}QP_x+(\tfrac{1}{8}S^2+\tfrac{1}{2}P)Q_x.
\end{aligned}\tag{27}$$

The recursion operator, corresponding to this equation, is

$$\mathcal{R}=\begin{pmatrix}
-\dfrac{S^2}{4}+P+P_xD_x^{-1}-\dfrac{S_x}{4}D_x^{-1}\cdot S & \dfrac{S}{2}+\dfrac{S_x}{2}D_x^{-1} & 3\\
\dfrac{3Q}{2}+\left(Q_x+\dfrac{P_xS}{2}\right)D_x^{-1}-\dfrac{P_x}{4}D_x^{-1}\cdot S & P+\dfrac{P_x}{2}D_x^{-1} & 2S\\
\dfrac{SQ}{4}+\left(\dfrac{SQ_x}{2}+\dfrac{S_xQ}{2}\right)D_x^{-1}-\dfrac{Q_x}{4}D_x^{-1}\cdot S & \dfrac{3Q}{2}+\dfrac{Q_x}{2}D_x^{-1} & P
\end{pmatrix}.\tag{28}$$

Proof: Using (19) we find the function R_n and using (18) we find the recursion operator (28). □

Remark 2: In symmetric variables the equation (27) is written as

$$\begin{aligned}
\tfrac{1}{3}u_t&=(-\tfrac{1}{8}u^2+\tfrac{1}{2}(uv+uw+vw)+\tfrac{1}{8}(v+w)^2)u_x+(\tfrac{1}{4}u^2+\tfrac{1}{4}uv+\tfrac{3}{4}uw)v_x+(\tfrac{1}{4}u^2+\tfrac{1}{4}uw+\tfrac{3}{4}uv)w_x,\\
\tfrac{1}{3}v_t&=(\tfrac{1}{4}v^2+\tfrac{1}{4}uv+\tfrac{3}{4}vw)u_x+(\tfrac{1}{4}v^2+\tfrac{1}{4}vw+\tfrac{3}{4}uv)w_x+(-\tfrac{1}{8}v^2+\tfrac{1}{2}(uv+uw+vw)+\tfrac{1}{8}(u+w)^2)v_x,\\
\tfrac{1}{3}w_t&=(\tfrac{1}{4}w^2+\tfrac{1}{4}uw+\tfrac{3}{4}wv)u_x+(\tfrac{1}{4}w^2+\tfrac{1}{4}wv+\tfrac{3}{4}uw)v_x+(-\tfrac{1}{8}w^2+\tfrac{1}{2}(uv+uw+vw)+\tfrac{1}{8}(v+u)^2)w_x,
\end{aligned}\tag{29}$$

and the recursion operator takes the form (A1) given in the Appendix.

B. Toda hierarchy ($k=1$)

Toda hierarchy corresponds to the case $k=1$.[9] Let us give the first equation of hierarchy and a recursion operator for $N=2$ and $N=3$.

Proposition 3: In the case $N=2$ and $n=1$ one has the Lax function

$$L=p+S+P\,p^{-1},$$

and the Lax equation for $n=1$, given by (41),

$$\begin{aligned}
S_t&=P_x,\\
P_t&=PS_x,
\end{aligned}\tag{30}$$

and the recursion operator, given by (42),

$$\mathcal{R}=\begin{pmatrix} S & 2+P_xD_x^{-1}\cdot P^{-1}\\ 2P & S+S_xPD_x^{-1}\cdot P^{-1}\end{pmatrix}.\tag{31}$$

The first two symmetries of the equation (30) are given by

$$S_{t_1}=(2SP)_x,$$
$$P_{t_1}=P(2P+S^2)_x, \tag{32}$$

$$S_{t_2}=(3S^2P+3P^2)_x,$$
$$P_{t_2}=P(6PS+S^3)_x. \tag{33}$$

Remark 3: In symmetric variables the equation (30) is written as

$$u_t=uv_x,$$
$$v_t=vu_x, \tag{34}$$

and the recursion operator (31) takes the form

$$\mathcal{R}=\begin{pmatrix} u+v+uv_xD_x^{-1}\cdot u^{-1} & 2u+uv_xD_x^{-1}\cdot v^{-1} \\ 2v+vu_xD_x^{-1}\cdot u^{-1} & u+v+vu_xD_x^{-1}\cdot v^{-1} \end{pmatrix}. \tag{35}$$

Proposition 4: In the case $N=3$ and $n=1$ one has the Lax function

$$L=p^2+pS_1+P+p^{-1}Q,$$

and the Lax equation with $n=1$ is

$$S_t=P_x-\tfrac{1}{2}SS_x,$$
$$P_t=Q_x, \tag{36}$$
$$Q_t=\tfrac{1}{2}QS_x.$$

The recursion operator, corresponding to this equation, is

$$\mathcal{R}=\begin{pmatrix} P-\frac{1}{4}S^2+(\frac{1}{2}P_x-\frac{1}{4}SS_x)D_x^{-1} & \frac{1}{2}S & 3+2Q_xD_x^{-1}\cdot Q^{-1} \\ \frac{3}{2}Q+\frac{1}{2}Q_xD_x^{-1} & P & 2S+(SQ)_xD_x^{-1}\cdot Q^{-1} \\ \frac{1}{4}SQ+\frac{1}{4}S_xQD_x^{-1} & \frac{3}{2}Q & P+P_xQD_x^{-1}\cdot Q^{-1} \end{pmatrix}. \tag{37}$$

Proof: Using equalities (19) we find the function R_n and using (18) we find the recursion operator (37). □

Remark 4: In symmetric variables the equation (36) is written as

$$u_t=\tfrac{1}{2}u(-u_x+v_x+w_x),$$
$$v_t=\tfrac{1}{2}v(+u_x-v_x+w_x), \tag{38}$$
$$w_t=\tfrac{1}{2}w(+u_x+v_x-w_x),$$

and the recursion operator takes the form (A2) given in the Appendix.

V. LAX EQUATION FOR GENERAL *k*

We shall only consider the case where $N=2$. We have the Lax function

$$L=p+S+Pp^{-1}, \tag{39}$$

and the Lax equation

$$\frac{\partial L}{\partial t_n}=\{(L^n)_{\geqslant -k+1};L\}_k. \tag{40}$$

We consider two cases $k\geqslant 1$ and $k\leqslant 0$.

A. The first case $k\geqslant 1$

Proposition 5: In the case $N=2$ and $k\geqslant 1$ one has the Lax equation

$$\begin{aligned} S_t&=kP^{k-1}P_x,\\ P_t&=kP^kS_x, \end{aligned} \tag{41}$$

and the recursion operator for this equation is

$$\mathcal{R}=\begin{pmatrix} S+(1-k)S_xD_x^{-1} & 2+kP^{k-1}P_xD_x^{-1}\cdot P^{-k}\\ 2P+(1-k)P_xD_x^{-1} & S+kS_xP^kD_x^{-1}\cdot P^{-k}\end{pmatrix}. \tag{42}$$

Proof: The smallest power of p in L^n is $-n$. To have powers less than $-k+1$ we must put $n=k$. If there are no such powers then Poisson brackets are $\{(L^n);L\}_k=0$.

Let us calculate the Lax equation,

$$L_t=\{(L^k)_{\geqslant -k+1};L\}_k=-\{(L^k)_{\leqslant -k};L\}_k.$$

We have $(L^k)_{\leqslant -k}=[(p+S+Pp^{-1})^k]_{\leqslant -k}=P^kp^{-k}$, thus

$$L_t=-\{P^kp^{-k};p+S+Pp^{-1}\}_k.$$

And we get the equation (41). Using (18), (19) we find the recursion operator (42). □

First two symmetries are given as follows:

$$\begin{aligned} S_{t_1}&=(k+1)(P^kS)_x,\\ P_{t_1}&=(k+1)P^k\left(P+\frac{k}{2}S^2\right)_x. \end{aligned} \tag{43}$$

$$\begin{aligned} S_{t_2}&=(k+1)(k+2)\left(\frac{1}{2}P^kS^2+\frac{1}{k+1}P^{k+1}\right)_x,\\ P_{t_2}&=(k+1)(k+2)P^k\left(PS+\frac{k}{6}S^3\right)_x. \end{aligned} \tag{44}$$

Remark 5: In symmetric variables the equation (41) is written as

$$\begin{aligned} u_t&=ku^kv^{k-1}v_x,\\ v_t&=ku^{k-1}v^ku_x, \end{aligned} \tag{45}$$

and the recursion operator (42) takes the form

$$\mathcal{R}=\begin{pmatrix} u+v+(1-k)u_xD_x^{-1}+ & 2u+(1-k)u_xD_x^{-1}+ \\ ku^kv^{k-1}v_xD_x^{-1}\cdot u^{-k}v^{-k+1} & ku^kv^{k-1}v_xD_x^{-1}\cdot u^{-k+1}v^{-k} \\ 2v+(1-k)v_xD_x^{-1}+ & u+v+(1-k)v_xD_x^{-1}+ \\ ku^{k-1}v^ku_xD_x^{-1}\cdot u^{-k}v^{-k+1} & ku^{k-1}v^ku_xD_x^{-1}\cdot u^{-k+1}v^{-k} \end{pmatrix}. \tag{46}$$

B. The second case $k\leqslant 0$

Proposition 6: In the case $N=2$ and $k\leqslant 0$ one has the Lax equation

$$\begin{aligned} S_t&=(-k+2)(-k+1)SS_x+(-k+2)P_x, \\ P_t&=(-k+2)(-k+1)SP_x+(-k+2)S_xP, \end{aligned} \tag{47}$$

and the recursion operator for this equation is

$$\mathcal{R}=\begin{pmatrix} S+(1-k)S_xD_x^{-1} & 2+kP^{k-1}P_xD_x^{-1}\cdot P^{-k} \\ 2P+(1-k)P_xD_x^{-1} & S+kS_xP^kD_x^{-1}\cdot P^{-k} \end{pmatrix}. \tag{48}$$

Proof: The largest power of p in L^n is p^n. To have powers larger than $-k+1$ we must put $n=-k+1$. Then we have

$$(L^{-k+1})_{\geqslant -k+1}=[(p+S+Pp^{-1})^{-k+1}]_{\geqslant -k+1}=p^{-k+1};$$

thus

$$L_t=\{p^{-k+1};p+S+Pp^{-1}\}_k.$$

Then the Lax equation becomes

$$\begin{aligned} S_t&=S_x, \\ P_t&=P_x. \end{aligned}$$

This is a trivial equation; let us calculate the second symmetry. We have $(L^{-k+2})_{\geqslant -k+1}=[(p+S+Pp^{-1})^{-k+1}]_{\geqslant -k+1}=p^{-k+2}+(-k+2)Sp^{-k+1}$, thus

$$L_t=\{p^{-k+2}+(-k+2)Sp^{-k+1};p+S+Pp^{-1}\}_k.$$

We get the equation (47). Using (18), (19) we find the recursion operator (48). □

First two symmetries are given as follows:

$$\begin{aligned} S_{t_1}&=(k-2)(k-3)(PS+\tfrac{1}{6}(1-k)S^3)_x, \\ P_{t_1}&=(k-2)(k-3)(SS_xP+\tfrac{1}{2}(1-k)S^2P_x+PP_x), \end{aligned} \tag{49}$$

$$\begin{aligned} S_{t_2}&=(2-k)(3-k)(4-k)\left(\frac{1}{2}S^2P+\frac{1}{6}S^4+\frac{1}{2(2-k)}P^2\right)_x, \\ P_{t_2}&=(2-k)(3-k)(4-k)\left(\frac{1}{2}S^2S_xP+\frac{1}{6}(1-k)S^3P_x+SPP_x+\frac{1}{(2-k)}P^2S_x\right). \end{aligned} \tag{50}$$

Remark 6: In symmetric variables the equation (47) is written as

$$u_t=(-k+2)(1-k)(u+v)u_x+(-k+2)uv_x,$$

$$v_t=(-k+2)vu_x+(-k+2)(1-k)(u+v)v_x, \tag{51}$$

and the recursion operator (48) takes the form

$$\mathcal{R}=\begin{pmatrix} u+v+(1-k)u_xD_x^{-1}+ & 2u+(1-k)u_xD_x^{-1}+ \\ ku^kv^{k-1}v_xD_x^{-1}\cdot u^{-k}v^{-k+1} & ku^kv^{k-1}v_xD_x^{-1}\cdot u^{-k+1}v^{-k} \\ 2v+(1-k)v_xD_x^{-1}+ & u+v+(1-k)v_xD_x^{-1}+ \\ ku^{k-1}v^ku_xD_x^{-1}\cdot u^{-k}v^{-k+1} & ku^{k-1}v^ku_xD_x^{-1}\cdot u^{-k+1}v^{-k} \end{pmatrix}. \tag{52}$$

In this section, to obtain the recursion operators we have considered two different cases $k\leqslant 0$ and $k\geqslant 1$ to simplify some technical problems in the method. At the end we obtained recursion operators having the same forms (42) and (48). Hence any one of these represent the recursion operator for $k\in\mathbb{Z}$. It seems, comparing the results, that the systems of equations in one case are symmetries of the other case. For instance, the system (47) is a symmetry of system (41). Hence we may consider only one case with recursion operator (42) for all integer values of k.

VI. LAX FUNCTION FOR POLYTROPIC GAS DYNAMICS

In this section we consider another Lax function, introduced in Ref. 10,

$$L=p^{\gamma-1}+u+\frac{v^{\gamma-1}}{(\gamma-1)^2}p^{-\gamma+1}, \tag{53}$$

and the Lax equation

$$\frac{\partial L}{\partial t}=\frac{\gamma-1}{\gamma}\{(L^{\gamma/(\gamma-1)})_{\geqslant 1},L\}_0, \tag{54}$$

gives the equations of the polytropic gas dynamics.

Proposition 7: The Lax equation corresponding to (54) is

$$u_t+uu_x+v^{\gamma-2}v_x=0,$$

$$v_t+(uv)_x=0. \tag{55}$$

Proof: Expanding the function (53) around the point $p=\infty$, we have

$$\left(p^{\gamma-1}+u+\frac{v^{\gamma-1}}{(\gamma-1)^2}p^{-\gamma+1}\right)^{\gamma/(\gamma-1)}=p^{\gamma}+\frac{\gamma}{\gamma-1}pu+\ldots;$$

all other terms have negative powers of p. Therefore

$$(L^{\gamma/(\gamma-1)})_{\geqslant 1}=p^{\gamma}+\frac{\gamma}{\gamma-1}pu,$$

and the Lax equation (54) corresponds to (55). □

Proposition 8: The recursion operator for the equation (55) is

$$\mathcal{R}=\begin{pmatrix} u+\dfrac{u_x}{\gamma-1}D_x^{-1} & \dfrac{2v^{\gamma-2}}{\gamma-1}+\dfrac{(v^{\gamma-2})_x}{\gamma-1}D_x^{-1} \\ \dfrac{2v}{\gamma-1}+\dfrac{v_x}{\gamma-1}D_x^{-1} & u+\dfrac{\gamma-2}{\gamma-1}u_xD_x^{-1} \end{pmatrix}. \tag{56}$$

Proof: Using the equation

$$\frac{\partial L}{\partial t_{n+1}} = L\frac{\partial L}{\partial t_n} + \{R_n, L\},$$

in the same way as for the polynomial Lax function one can find the recursion operator (56). □

It is interesting to note that the equation (47) and equations of polytropic gas dynamics (55) are related by the following change of variables:

$$S = \frac{u}{(-k+2)(-k+1)}, \qquad P = \frac{v^{1/(-k+1)}}{(-k+2)^2}, \tag{57}$$

where $\gamma = (-k+2)/(-k+1)$. We note that under this change of variables recursion operator (48) is mapped to the recursion operator (56).

VII. REDUCTION

In this section we consider reductions of the equation (12), written in symmetric variables, by setting $u_1 = 0$, or $u_1 = u_N, \ldots$, or $u_1 = u_2 = \cdots, = u_N$. These reductions correspond to the Lax equations with different Lax functions. For reduction $u_1 = 0$ we have a polynomial Lax function with simple roots $L = (p-u_N)\cdots(p-u_2)$ and for reduction $u_N = u_1$ we have a polynomial Lax function with a root of multiplicity two $L = (1/p)(p-u_N)^2(p-u_{N-1})\ldots(p-u_2)$, etc. We note that instead of working on the Lax functions with higher multiplicities like the last example one can take a polynomial Lax function without any multiplicities and perform the reductions we propose in this section.

A. Reduction $u_1 = 0$

Let us write the equation (12) as

$$\Delta(u_N, \ldots, u_1) = 0, \tag{58}$$

where Δ is a differential operator. Then

$$\Delta(u_N, \ldots, u_1)|_{u_1=0} = \begin{pmatrix} \tilde{\Delta}(u_N, \ldots, u_2), \\ 0 \end{pmatrix}, \tag{59}$$

where $\tilde{\Delta}$ is another differential operator. Indeed, following Ref. 8 for the Lax function $L = (1/p)\,\Pi_{j=1}^{N}(p-u_j)$ we have

$$\frac{\partial L}{\partial t} = L\sum_{j=1}^{N}\frac{u_{j,t}}{p+u_j},$$

$$\frac{\partial L}{\partial x} = L\sum_{j=1}^{N}\frac{u_{j,x}}{p+u_j},$$

and

$$\frac{\partial L}{\partial p} = L\left(-\frac{1}{p} + \sum_{j=1}^{N}\frac{1}{p+u_j}\right).$$

Thus $u_{j,t} = \mathrm{Res}_{p=-u_j}\{M, L\}_k$, where $M = (L^{n/(N-1)})_{\geqslant -k+1}$. The Lax equation (12) can be written as

$$\sum_{j=1}^{N}\frac{u_{j,t}}{p+u_j}=p^kM_p\sum_{j=1}^{N}\frac{u_{j,x}}{p+u_j}-p^kM_x\left(-\frac{1}{p}+\sum_{j=1}^{N}\frac{1}{p+u_j}\right). \tag{60}$$

Note that p^kM_x and p^kM_p are polynomials. So, if we put $u_1=0$ and calculate the residue of the right hand side at $p=0$ we get (59). A new equation,

$$\tilde{\Delta}(u_N,\ldots,u_2)=0, \tag{61}$$

is also integrable and a recursion operator of this equation can be obtained as a reduction of the recursion operator of the equation (58). Let $\mathcal{R}$ be the recursion operator of (58) given by Lemma 2, then

$$\mathcal{R}|_{u_1=0}=\left(\begin{array}{c|c}\tilde{R} & *\\ \hline 0\cdots 0 & 0\end{array}\right). \tag{62}$$

Indeed, we found the recursion operator using formula (14). This formula can be written as

$$\sum_{j=1}^{N}\frac{u_{j,t_n}}{p+u_j}=LL_{n-(N-1)}+p^kR_{n,p}\sum_{j=1}^{N}\frac{u_{j,x}}{p+u_j}-p^kR_{n,x}\left(-\frac{1}{p}+\sum_{j=1}^{N}\frac{1}{p+u_j}\right) \tag{63}$$

and in the same way as for the reduction of (58) we have (62); note, that $p^kR_{n,x}$ and $p^kR_{n,p}$ are also polynomials.

Lemma 3: The operator $\tilde{R}$ is a recursion operator of the equation (61).

Proof: Equation (61) is an evolution equation, so, to prove that $\tilde{R}$ is a recursion operator we must prove that for any solution $(u_N,\ldots,u_2)$ of (61) the following equality holds (see Ref. 6):

$$D_{\tilde{\Delta}}\tilde{R}=\tilde{R}D_{\tilde{\Delta}},$$

where $D_{\tilde{\Delta}}$ is a Frechet derivative of $\tilde{\Delta}$.

If $(u_N,\ldots,u_2)$ is a solution of (61) then $(u_N,\ldots,u_2,u_1=0)$ is a solution of (58) and for the solution $(u_N,\ldots,u_2,u_1=0)$ we have

$$D_\Delta\mathcal{R}=\mathcal{R}D_\Delta. \tag{64}$$

Next

$$D_\Delta|_{u_1=0}=\left(\begin{array}{c|c}\tilde{D} & *\\ \hline 0\cdots 0 & *\end{array}\right)$$

and

$$\mathcal{R}|_{u_1=0}=\left(\begin{array}{c|c}\tilde{R} & *\\ \hline 0\cdots 0 & 0\end{array}\right).$$

Hence by (64) we have $\tilde{D}\tilde{R}=\tilde{R}\tilde{D}$. Calculating the Frechet derivative, we take derivatives with respect to one variable, considering other variables as constants. Thus, to calculate $\tilde{D}$ we can put $u_1=0$ and differentiate with respect to other variables or we can first differentiate and then put $u_1=0$. It means that $\tilde{D}=D_{\tilde{\Delta}}$ and

$$D_{\tilde{\Delta}}\tilde{R}=\tilde{R}D_{\tilde{\Delta}}.$$

□

Let us consider the reduction of systems, given by Remark 2 and Remark 4 and their recursion operators.

Proposition 9: Putting $w=0$ in (38) and (A2) we obtain a new system,

$$u_t=\tfrac{1}{2}u(-u_x+v_x),$$
$$v_t=\tfrac{1}{2}v(+u_x-v_x), \tag{65}$$

and its recursion operator,

$$\mathcal{R}=\begin{pmatrix} -uv+\frac{u}{4}(u+v) & -\frac{u}{4}(u+v) \\ +\frac{u}{4}(u_x-v_x)D_x^{-1} & +\frac{u}{4}(u_x-v_x)D_x^{-1} \\ -\frac{v}{4}(u+v) & -uv+\frac{v}{4}(u+v) \\ +\frac{v}{4}(-u_x+v_x)D_x^{-1} & +\frac{v}{4}(-u_x+v_x)D_x^{-1} \end{pmatrix}, \tag{66}$$

respectively. □

Proposition 10: Putting $w=0$ in (29) and (A1) we obtain a new system,

$$\tfrac{1}{3}u_t=(-\tfrac{1}{8}u^2+\tfrac{1}{2}uv+\tfrac{1}{8}v^2)u_x+(\tfrac{1}{4}u^2+\tfrac{1}{4}uv)v_x,$$
$$\tfrac{1}{3}v_t=(\tfrac{1}{4}v^2+\tfrac{1}{4}uv)u_x+(-\tfrac{1}{8}v^2+\tfrac{1}{2}uv+\tfrac{1}{8}u^2)v_x, \tag{67}$$

and its recursion operator,

$$\mathcal{R}=\begin{pmatrix} -\frac{u^2}{4}+\frac{3uv}{4}+\left(\frac{u_xv}{2}+\frac{uv_x}{2}\right)D_x^{-1} & \frac{u}{4}(u+v)+\left(\frac{u_xv}{2}+\frac{uv_x}{2}\right)D_x^{-1} \\ -\frac{u_x}{4}D_x^{-1}\cdot u+\frac{u_x}{4}D_x^{-1}\cdot v & +\frac{u_x}{4}D_x^{-1}\cdot u-\frac{u_x}{4}D_x^{-1}\cdot v \\ \frac{v}{4}(u+v)+\left(\frac{uv_x}{2}+\frac{u_xv}{2}\right)D_x^{-1} & -\frac{v^2}{4}+\frac{3uv}{4}+\left(\frac{uv_x}{2}+\frac{u_xv}{2}\right)D_x^{-1} \\ -\frac{v_x}{4}D_x^{-1}\cdot u+\frac{v_x}{4}D_x^{-1}\cdot v & +\frac{v_x}{4}D_x^{-1}\cdot u-\frac{v_x}{4}D_x^{-1}\cdot v \end{pmatrix}, \tag{68}$$

respectively. □

It is worth mentioning that by reduction we obtain a new equation. For example, consider the case $k=0$. The equation (25), corresponding to $N=2$, and reduction of the equation (29), corresponding to $N=3$, are not related by a linear transformation of variables. Indeed, in the equation (25) coefficients of u_x,v_x are linear in u,v but in the equation (67) coefficients of u_x,v_x contain quadratic terms. Hence they cannot be related by a linear transformation.

B. Reduction $u_N=u_1$

It follows from (60) that the Lax equation (12) can be written as

$$u_{i,t}=\sum_{j=1}^{N} h_i^j(u_N,\ldots,u_1)u_{j,x}, \tag{69}$$

where $i,j=1,\ldots,N$ and $h_i^j=h_1(u_i,u_N,\ldots,\hat{u}_i,\ldots,u_1)$ when $i\neq j$ and $h_i^i=h_2(u_i,u_N,\ldots,\hat{u}_i,\ldots,u_1)$, the overcaret denotes the absence of the corresponding variable. It also follows from (60) that the functions $h_1(x_N,\ldots,x_1)$ and $h_2(x_N,\ldots,x_1)$ are symmetric under permutations of variables $x_{N-1},\ldots,x_1$.

Reduction $u_N=u_1$ gives us a new integrable equation,

$$
\begin{aligned}
u_{N,t} &= (h_N^N(u_N,u_{N-1},\ldots,u_2,u_N)+h_N^1(u_N,u_{N-1},\ldots,u_2,u_N))u_{N,x} \\
&\quad + \sum_{j=2}^{N-1} h_N^j(u_N,u_{N-1},\ldots,u_2,u_N)u_{j,x}, \\
u_{i,t} &= 2h_i^N(u_N,u_{N-1},\ldots,u_2,u_N)u_{N,x}+\sum_{j=2}^{N-1} h_i^j(u_N,u_{N-1},\ldots,u_2,u_N)u_{j,x},
\end{aligned}
\tag{70}
$$

where $i=(N-1),\ldots,2$.

The Frechet derivative of (69), under condition $u_N=u_1$, has the form

$$
D_\Delta|_{u_N=u_1}=\begin{pmatrix}
a_{11} & a_{12} & \cdots & a_{1(N-1)} & a_{1N} \\
a_{21} & a_{22} & \cdots & a_{2(N-1)} & a_{21} \\
\vdots & \vdots & \cdots & \vdots & \vdots \\
a_{(N-1)1} & a_{(N-1)2} & \cdots & a_{(N-1)(N-1)} & a_{(N-1)1} \\
a_{1N} & a_{12} & \cdots & a_{1(N-1)} & a_{11}
\end{pmatrix}, \tag{71}
$$

where a_{ij}, $i,j=1,\ldots,N$ are differential operatos. So, the Frechet derivative of (70) can be writen as

$$
\bar{D_\Delta}=\begin{pmatrix}
a_{11}+a_{1N} & a_{12} & \cdots & a_{1(N-1)} \\
2a_{21} & a_{22} & \cdots & a_{2(N-1)} \\
\vdots & \vdots & \cdots & \vdots \\
2a_{(N-1)1} & a_{(N-1)2} & \cdots & a_{(N-1)(N-1)}
\end{pmatrix}. \tag{72}
$$

Now let us write the recurcion operator of (69), given by Lemma 2. From (63) it follows that, under condition $u_N=u_1$, it has the form

$$
\mathcal{R}|_{u_N=u_1}=\begin{pmatrix}
b_{11} & b_{12} & \cdots & b_{1(N-1)} & b_{1N} \\
b_{21} & b_{22} & \cdots & b_{2(N-1)} & b_{21} \\
\vdots & \vdots & \cdots & \vdots & \vdots \\
b_{(N-1)1} & b_{(N-1)2} & \cdots & b_{(N-1)(N-1)} & b_{(N-1)1} \\
b_{1N} & b_{12} & \cdots & b_{1(N-1)} & b_{11}
\end{pmatrix}, \tag{73}
$$

where b_{ij}, $i,j=N,\ldots,1$ are differential operators.

Now we can write a recursion operator for Eq. (70),

$$
\bar{\mathcal{R}}=\begin{pmatrix}
b_{11}+b_{1N} & b_{12} & \cdots & b_{1(N-1)} \\
2b_{21} & b_{22} & \cdots & b_{2(N-1)} \\
\vdots & \vdots & \cdots & \vdots \\
2b_{(N-1)1} & b_{(N-1)2} & \cdots & b_{(N-1)(N-1)}
\end{pmatrix}. \tag{74}
$$

The form of (74) can be deduced by applaing operator $\mathcal{R}|_{u_N=u_1}$ to a symmetry $(\partial u_N/\partial t_n,\partial u_{N-1}/\partial t_{n,\ldots,}\partial u_2/\partial t_n,\partial u_n/\partial t_n)$.

Lemma 4: The operator $\bar{R}$ in (74) is a recursion operator of the equation (70).

Proof: Equation (70) is an evolution equation, so, to prove that $\bar{R}$ is a recursion operator we must prove that for any solution $(u_N,\ldots,u_2)$ of (70) the following equality holds (see Ref. 6):

$$
D_{\bar{\Delta}}\bar{R}=\bar{R}D_{\bar{\Delta}}.
$$

If $(u_N,\ldots,u_2)$ is a solution of (70) then $(u_N,\ldots,u_2,u_1=u_N)$ is a solution of (69) and for the solution $(u_N,\ldots,u_2,u_1=u_N)$ we have

$$D_\Delta \mathcal{R}=\mathcal{R} D_\Delta . \tag{75}$$

One can show that from commutation of (71) and (73) follows the commutation of (72) and (74) that is equality (75). □

Let us consider reduction of systems, given by Remark 2 and Remark 4 and their recursion operators.

Proposition 11: Putting $w=u$ in (38) and (A2) we obtain a new system,

$$\begin{aligned} u_t&=\tfrac{1}{2}uv_x,\\ v_t&=\tfrac{1}{2}v(2u_x-v_x), \end{aligned} \tag{76}$$

and its recursion operator

$$\mathcal{R}=\begin{pmatrix} -(2uv+u^2)-\frac{3}{2}uv & -\frac{1}{4}u(2u+v)-\frac{3}{2}u^2\\ +\frac{1}{2}uv_xD_x^{-1} & +\frac{1}{4}u(2u_x-v_x)D_x^{-1}\\ -2u(uv)_xD_x^{-1}\cdot u^{-1} & -u(uv)_xD_x^{-1}\cdot v^{-1}\\ -\frac{1}{2}v(2u+v)-3uv & -(2uv+u^2)+\frac{1}{4}v(2u+v)\\ +\frac{1}{2}v(-2u_x+v_x)D_x^{-1} & +\frac{1}{4}v(2-u_x+v_x)D_x^{-1}\\ -2v(uv)_xD_x^{-1}\cdot u^{-1} & -v(u^2)_xD_x^{-1}\cdot v^{-1} \end{pmatrix}. \tag{77}$$

□

Proposition 12: Putting $w=u$ in (29) and (A1) we obtain a new system,

$$\begin{aligned} \tfrac{1}{3}u_t&=(u^2+2uv+\tfrac{1}{8}v^2)u_x+(u^2+\tfrac{1}{4}uv)v_x,\\ \tfrac{1}{3}v_t&=(\tfrac{1}{2}v^2+2uv)u_x+(-\tfrac{1}{8}v^2+uv+u^2)v_x, \end{aligned} \tag{78}$$

and its recursion operator,

$$\mathcal{R}=\begin{pmatrix} u^2+\frac{7}{2}uv+(u^2+uv)_xD_x^{-1} & 2u^2+\frac{1}{4}uv+\frac{1}{2}(u^2+uv)D_x^{-1}\\ +\frac{1}{2}u_xD_x^{-1}\cdot v & +\frac{1}{2}u_xD_x^{-1}\cdot u-\frac{1}{4}u_xD_x^{-1}\cdot v\\ 4uv+\frac{1}{2}v^2+2(uv)_xD_x^{-1} & -\frac{1}{4}v^2+\frac{3}{2}uv+u^2+(uv)_xD_x^{-1}\\ +\frac{1}{2}v_xD_x^{-1}\cdot v & +\frac{1}{2}v_xD_x^{-1}\cdot u-\frac{1}{4}v_xD_x^{-1}\cdot v \end{pmatrix}. \tag{79}$$

□

We may go on introducing new reductions. For instance a reduction of the type $u_1=u_2=u_N$, $(N>3)$, reduces an N-system to an $(N-2)$-system. One may obtain this $(N-2)$-system also from the polynomial Lax function having the form $L=p^{-1}(p-u_1)^3(p-u_3)\cdots(p-u_{N-1})$ (a zero of L with multiplicity three). In this way one obtains an infinite number of different classes of $N=2$, $N=3$ systems.

VIII. CONCLUSION

We have constructed the recursion operators of some equations of hydrodynamic type. The form of the these operators fall into the class of pseudo-differential operators $A+BD^{-1}$ where A and B are functions of dynamical variables and their derivatives. The generalized symmetries of these equations are local and all belong to the same class (i.e., they are also equations of hydro-

dynamic type). We have introduced a method of reduction which leads also to integrable classes. Depending upon the type of reductions we may obtain infinitely many different classes of $N=k$ systems. These properties, the bi-Hamiltonian structure of the equations we obtained and equations with rational Lax functions, will be communicated elsewhere.

The q-Laplace operator and q-harmonic polynomials on the quantum vector space

N. Z. Iorgov and A. U. Klimyk[a)]
Institute for Theoretical Physics, Kiev 03143, Ukraine

(Received 21 July 2000; accepted for publication 6 November 2000)

The aim of this paper is to study q-harmonic polynomials on the quantum vector space generated by q-commuting elements $x_1, x_2, \ldots, x_n$. They are defined as solutions of the equation $\Delta_q p = 0$, where p is a polynomial in $x_1, x_2, \ldots, x_n$ and the q-Laplace operator Δ_q is determined in terms of q-derivatives. The projector $H_m : \mathcal{A}_m \to \mathcal{H}_m$ is constructed, where $\mathcal{A}_m$ and $\mathcal{H}_m$ are the spaces of homogeneous (of degree m) polynomials and q-harmonic polynomials, respectively. By using these projectors, a q-analog of classical associated spherical harmonics is constructed. They constitute an orthonormal basis of $\mathcal{H}_m$. A q-analog of separation of variables is given. Representations of the nonstandard q-deformed algebra $U_q'(\mathrm{so}_n)$ [which plays the role of the rotation group $\mathrm{SO}(n)$ in the case of classical harmonic polynomials] on the spaces $\mathcal{H}_m$ are explicitly constructed. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1343092]

I. INTRODUCTION

The Laplace operator, harmonic polynomials, and related separations of variables are of a great importance for physics and mathematics. They are closely related to the rotation groups $\mathrm{SO}(n)$ and to its subgroups (see, e.g., Ref. 1, Chap. 10).

Harmonic polynomials are defined by the equation $\Delta p = 0$, where Δ is the Laplace operator and p belongs to the space $\mathcal{R}$ of polynomials on the Euclidean space $E_n \sim \mathbb{R}^n$. The space $\mathcal{H}$ of all harmonic polynomials on E_n decomposes as a direct sum of the subspaces $\mathcal{H}_m$ of homogeneous harmonic polynomials of degree m: $\mathcal{H} = \oplus_{m=0}^{\infty} \mathcal{H}_m$. The Laplace operator Δ on the n-dimensional Euclidean (vector) space E_n commutes with the natural action of the rotation group $\mathrm{SO}(n)$ on this space. This means that the subspaces $\mathcal{H}_m$ are invariant with respect to $\mathrm{SO}(n)$. The irreducible representation T_m of the group $\mathrm{SO}(n)$ with highest weight $(m,0,\ldots,0)$ is realized on $\mathcal{H}_m$.

The Laplace operator Δ permits separation of variables on the space $\mathcal{H}_m$. In other words, there exist different coordinate systems (spherical, polyspherical, etc.) on $E_n \sim \mathbb{R}^n$ and for each of them it is possible to find the corresponding basis of the space of solutions of the equation $\Delta p = 0$ consisting of products of functions depending on separated variables. To different coordinate systems there correspond different separations of variables. From the other side, to different coordinate systems there correspond different chains of subgroups of the group $\mathrm{SO}(n)$ (see Ref. 1, Chap. 10, for details of this correspondence). The basis of the space $\mathcal{H}_m$ in separated variables, e.g., in spherical coordinates, consists of products of certain Gegenbauer polynomials multiplied by r^m, where r is the radius. These polynomials (considered only on the sphere S^{n-1}) are matrix elements of the class 1 [with respect to the subgroup $\mathrm{SO}(n-1)$] irreducible representations T_m of $\mathrm{SO}(n)$ belonging to the zero column. The basis of $\mathcal{H}_m$ in polyspherical separated variables consists of products of Jacobi polynomials multiplied by r^m. Considered on S^{n-1}, these polynomials are zero column matrix elements of the representation T_m with respect to the subgroup $\mathrm{SO}(p) \times \mathrm{SO}(n-p)$ for a certain value of p (see Ref. 1, Sec. 10.2).

Many new directions of mathematical physics are related to quantum groups and noncommutative geometry. It is natural to generalize the above-described theory to noncommutative spaces.

a)Electronic mail: aklimyk@gluk.apc.org

Such generalizations can be of a great importance for further development of some branches of mathematical and theoretical physics related to noncommutative geometry.

The aim of this paper is to construct a q-deformation of the above-described classical theory. In the q-case, instead of the Euclidean space we take the quantum vector space. It is defined in terms of the associative algebra $\mathcal{A}$ generated by the elements $x_1, x_2, \ldots, x_n$, satisfying the defining relations $x_i x_j = q x_j x_i$ for $i < j$. These elements play the role of Cartesian coordinates of E_n.

The q-Laplace operator Δ_q on $\mathcal{A}$ is defined in terms of q-derivatives [see formula (12)]. There exists no quantum group G_q which would relate to Δ_q as the rotation group $\mathrm{SO}(n)$ relates to the classical Laplace operator. For this reason, we involve into the theory a nonstandard q-deformation of the universal enveloping algebra $U(\mathrm{so}_n)$ of the Lie algebra so_n. This q-deformed associative algebra [we denote it by $U'_q(\mathrm{so}_n)$] is obtained by deformation of the defining relations for the elements $I'_{i,i-1} = E_{i,i-1} - E_{i-1,i}$, $i = 2,3,\ldots,n$, of $U(\mathrm{so}_n)$, where E_{ks} are the $n \times n$ matrices with entries $(E_{ks})_{ij} = \delta_{ki}\delta_{sj}$. The algebra $U'_q(\mathrm{so}_n)$ was constructed in Ref. 2. (It was shown in Ref. 3 that this algebra is related to the algebra of observables for quantum gravity constructed in Ref. 4.) The algebra $U'_q(\mathrm{so}_n)$ replaces the group $\mathrm{SO}(n)$ for the q-Laplace operator.

q-harmonic polynomials on the quantum vector space are defined as elements p of $\mathcal{A}$ (that is, polynomials in $x_1, x_2, \ldots, x_n$) for which $\Delta_q p = 0$. By using the algebra $U'_q(\mathrm{so}_n)$ (instead of the rotation group $\mathrm{SO}(n)$ in the classical case) we construct for q-harmonic polynomials a theory similar to the theory for classical harmonic polynomials described previously. Namely, we construct projectors $H_m : \mathcal{A}_m \to \mathcal{H}_m$, where $\mathcal{A}_m$ and $\mathcal{H}_m$ are the subspaces of homogeneous (of degree m) polynomials in $\mathcal{A}$ and in the space $\mathcal{H}$ of all q-harmonic polynomials from $\mathcal{A}$, respectively. Using these projectors we construct in $\mathcal{H}_m$ a q-analog of associated spherical harmonics with respect to the subalgebra $U'_q(\mathrm{so}_{n-1})$. They constitute an orthonormal basis of the space $\mathcal{H}_m$ corresponding to the chain of the subalgebras $U'_q(\mathrm{so}_n) \supset U'_q(\mathrm{so}_{n-1}) \supset U'_q(\mathrm{so}_{n-2}) \supset \cdots \supset U'_q(\mathrm{so}_2)$. Here we obtain a q-analog of the spherical separated coordinates. We construct explicitly the representation T_m of the algebra $U'_q(\mathrm{so}_n)$ on the space $\mathcal{H}_m$ and identify it with one of the representations of $U'_q(\mathrm{so}_n)$ known from literature. It is a class 1 [with respect to the subalgebra $U'_q(\mathrm{so}_{n-1})$] irreducible representation. Then we construct a q-analog of associated spherical harmonics with respect to the subalgebra $U'_q(\mathrm{so}_p) \times U'_q(\mathrm{so}_{n-p})$, where $1 < p < n-1$. Again, these harmonics constitute a basis of $\mathcal{H}_m$ corresponding to the separation of variables related to this subalgebra. We explicitly construct the representation T_m of $U'_q(\mathrm{so}_n)$ in this basis.

Our constructions use essentially the results of Ref. 5, where the operator Δ_q and the spaces $\mathcal{H}_m$ were defined.

Everywhere in the following we suppose that q is not a root of unity.

II. THE q-DEFORMED ALGEBRA $U'_q(\mathrm{so}_n)$

There exist the well known Drinfeld–Jimbo quantum algebras $U_q(\mathrm{so}_n)$ corresponding to the Lie algebras of the types B_l and D_l. However, they are not satisfactory from the point of view of some problems in quantum physics and representation theory. In particular, the reductions $U_q(\mathrm{so}_n) \supset U_q(\mathrm{so}_{n-1})$ and the embedding $U_q(\mathrm{so}_n) \subset U_q(\mathrm{sl}_n)$ are not allowed. For this reason, an analog of the Gel'fand–Tsetlin bases for finite-dimensional irreducible representations of $U_q(\mathrm{so}_n)$ does not exists. To be able to exploit reductions of such types, we have to consider q-deformations of the universal enveloping algebra $U(\mathrm{so}_n)$ of the Lie algebra so_n defined in terms of the generators $I_{k,k-1} = E_{k,k-1} - E_{k-1,k}$ [where E_{is} is the matrix with entries $(E_{is})_{rt} = \delta_{ir}\delta_{st}$] rather than by means of Cartan subalgebras and root elements. To construct such deformations we have to deform trilinear relations for elements $I_{k,k-1}$ instead of Serre's relations (as in the case of Drinfeld–Jimbo quantum algebras). As a result, we obtain the associative algebra which is denoted as $U'_q(\mathrm{so}_n)$.

This q-deformation was first constructed in Ref. 2. It permits the reduction $U'_q(\mathrm{so}_{n-1}) \subset U'_q(\mathrm{so}_n)$. Moreover, this q-deformed algebra $U'_q(\mathrm{so}_n)$ can be embedded into the Drinfeld–Jimbo algebra $U_q(\mathrm{sl}_n)$ (see Ref. 6). As a disadvantage of the algebra $U'_q(\mathrm{so}_n)$ we have

to mention difficulties with a Hopf algebra structure. Nevertheless, $U_q'(\mathrm{so}_n)$ turns out to be a coideal in $U_q(\mathrm{sl}_n)$.

The q-deformed algebra $U_q'(\mathrm{so}_n)$ is defined as the associative algebra (with a unity) generated by the elements $I_{i,i-1}$, $i=2,3,\ldots,n$, satisfying the defining relations

$$I_{i,i-1}I_{i-1,i-2}^2-(q+q^{-1})I_{i-1,i-2}I_{i,i-1}I_{i-1,i-2}+I_{i-1,i-2}^2I_{i,i-1}=-I_{i,i-1}, \tag{1}$$

$$I_{i,i-1}^2I_{i-1,i-2}-(q+q^{-1})I_{i,i-1}I_{i-1,i-2}I_{i,i-1}+I_{i-1,i-2}I_{i,i-1}^2=-I_{i-1,i-2}, \tag{2}$$

$$[I_{i,i-1},I_{j,j-1}]=0, \quad |i-j|>1, \tag{3}$$

where $[\cdot,\cdot]$ denotes the usual commutator. In the limit $q\to 1$, formulas (1)–(3) give the relations defining the universal enveloping algebra $U(\mathrm{so}_n)$ (see Ref. 7). Note also that relations (1) and (2) principally differ from the q-deformed Serre relations in the approach of Drinfeld in Ref. 8 and Jimbo in Ref. 9 (see also Ref. 10) to quantum algebras $U_q(\mathrm{so}_n)$ by the presence of a nonzero right-hand side. It is evident from (1) to (3) that we can construct for $U_q'(\mathrm{so}_n)$ the chain of subalgebras

$$U_q'(\mathrm{so}_n)\supset U_q'(\mathrm{so}_{n-1})\supset\cdots\supset U_q'(\mathrm{so}_3)\supset U_q'(\mathrm{so}_2),$$

where the subalgebras $U_q'(\mathrm{so}_k)$ are generated by the elements $I_{i,i-1}$, $i=2,3,\ldots,k$, respectively. Recall that in the standard Drinfeld–Jimbo approach to the definition of quantum algebras, the algebras $U_q(\mathrm{so}_{2m})$ and the algebras $U_q(\mathrm{so}_{2m+1})$ are distinct series of quantum algebras which are constructed independently of each other.

The algebra $U_q'(\mathrm{so}_n)$ can be embedded into the Drinfeld–Jimbo quantum algebra $U_q(\mathrm{sl}_n)$. The last algebra is generated by the elements $k_i\equiv q^{h_i}$, $k_i^{-1}\equiv q^{-h_i}$, e_i, f_i, $i=1,2,\ldots,n-1$, satisfying the relations $k_ik_i^{-1}=k_i^{-1}k_i=1$, $k_ik_j=k_jk_i$ and

$$k_ie_jk_i^{-1}=q^{a_{ij}}e_j, \quad k_if_jk_i^{-1}=q^{-a_{ij}}f_j,$$

$$[e_i,f_j]\equiv e_if_j-f_je_i=\delta_{ij}\frac{k_i-k_i^{-1}}{q-q^{-1}},$$

$$e_i^2e_{i\pm1}-(q+q^{-1})e_ie_{i\pm1}e_i+e_{i\pm1}e_i^2=0,$$

$$f_i^2f_{i\pm1}-(q+q^{-1})f_if_{i\pm1}f_i+f_{i\pm1}f_i^2=0,$$

$$[e_i,e_j]=[f_i,f_j]=0, \quad |i-j|>1,$$

where $a_{ii}=2$, $a_{i,i\pm1}=-1$ and $a_{ij}=0$ for $|i-j|>1$. Then there exists a unique homomorphism

$$\varphi: U_q'(\mathrm{so}_n)\to U_q(\mathrm{sl}_n) \tag{4}$$

such that $\varphi(I_{i+1,i})=f_i-qq^{-h_i}e_i$ (see Ref. 6). Moreover, this homomorphism is an embedding, that is, a one-to-one mapping (see Refs. 5 and 11).

III. CLASS 1 REPRESENTATIONS OF $U_q'(\mathrm{so}_n)$

We shall use the term ''a class 1 representation'' for those finite-dimensional irreducible representations of $U_q'(\mathrm{so}_n)$ which contain the trivial representation of the subalgebra $U_q'(\mathrm{so}_{n-1})$. In the case of the algebra $U_q'(\mathrm{so}_3)$, class 1 representations are defined with respect to the commutative subalgebra $U_q'(\mathrm{so}_2)$, generated by one element I_{21}.

The algebra $U_q'(\mathrm{so}_n)$ has two types of finite-dimensional irreducible representations (see Ref. 12): representations of the classical type (at $q\to 1$ they turn into corresponding irreducible repre-

sentations of the Lie algebra so_n) and representations of the nonclassical type (they have no classical analog). It is seen from the formulas for representations of the nonclassical type that none of these representations can be of class 1.

Analyzing the representations of the classical type (formulas for these representations see, e.g., those in Ref. 12) we see that like the classical case, class 1 representations are characterized by ''a highest weight'' $(m_n,0,\ldots,0)$, where m_n is a non-negative integer. These representations are denoted R_{m_n}. Under restriction onto the subalgebra $U_q'(\mathrm{so}_{n-1})$ the representation R_{m_n} decomposes into those and only those class 1 representations $R_{m_{n-1}}$ of this subalgebra for which

$$m_n \geqslant m_{n-1} \geqslant 0 \quad \text{if} \quad n>3, \quad -m_3 \leqslant m_2 \leqslant m_3 \quad \text{if} \quad n=3.$$

The orthonormal basis obtained by restriction of class 1 representations T_{m_n} onto the subalgebras $U_q'(\mathrm{so}_k)$, $k=n-1,n-2,\ldots,2$, is nothing but a q-analog of the Gel'fand–Tsetlin basis. We denote the Gel'fand–Tsetlin basis elements of the representation space of R_{m_n} by

$$|m_n,m_{n-1},m_{n-2},\ldots,m_3,m_2\rangle,$$

where m_k characterizes the set $(m_k,0,\ldots,0)$ of integers giving the class 1 representation R_{m_k} of $U_q'(\mathrm{so}_k)$. With respect to this basis the operators $R_{m_n}(I_{k,k-1})$ of the representation R_{m_n} of $U_q'(\mathrm{so}_n)$ are given by

$$R_{m_n}(I_{21})|m_n,m_{n-1},\ldots,m_2\rangle = i[m_2]|m_n,m_{n-1},\ldots,m_2\rangle, \tag{5}$$

$$\begin{aligned} R_{m_n}(I_{k,k-1})|m_n,m_{n-1},\ldots,m_2\rangle = {} & ([m_k+m_{k-1}+k-2][m_k-m_{k-1}])^{1/2} \\ & \times A(m_{k-1})|m_n,\ldots,m_k,m_{k-1}+1,m_{k-2},\ldots m_2\rangle \\ & -([m_k+m_{k-1}+k-3][m_k-m_{k-1}+1])^{1/2} \\ & \times A(m_{k-1}-1)|m_n,\ldots,m_k,m_{k-1}-1,m_{k-2},\ldots,m_2\rangle, \end{aligned} \tag{6}$$

where $n \geqslant k \geqslant 3$, the symbol $[m] \equiv [m]_q$ denotes a q-number defined as

$$[m]=\frac{q^m-q^{-m}}{q-q^{-1}},$$

and

$$A(m_{k-1})=\left(\frac{[m_{k-1}+m_{k-2}+k-3][m_{k-1}-m_{k-2}+1]}{[2m_{k-1}+k-3][2m_{k-1}+k-1]}\right)^{1/2}.$$

Note that in the case $k=3$ we have to put $m_1=0$ in formula (6); then for $A(m_2)$ we have the expression $([m_2][m_2+1]/[2m_2][2m_2+2])^{1/2}$.

IV. REPRESENTATIONS ON THE QUANTUM VECTOR SPACE

Let $\mathcal{A} \equiv \mathbb{C}[x_1,x_2,\ldots,x_n]$ be the associative algebra (with unity) generated by elements $x_1,x_2,\ldots,x_n$ satisfying the defining relations $x_ix_j=qx_jx_i$, $i<j$. This algebra is called the algebra of functions on the n-dimensional quantum vector space. Elements of $\mathcal{A}$ are called polynomials on this quantum vector space and are denoted by $p \equiv p(x_1,x_2,\ldots,x_n) \equiv p(\mathbf{x})$.

We define on $\mathcal{A}$ the q-differentiations ∂_i and ∂_i' which are linear operators acting as $\partial_i p = \partial_i' p = 0$ on monomials p not containing x_i and as

$$\partial_i = \check{x}_i^{-1}\frac{\gamma_i-\gamma_i^{-1}}{q-q^{-1}}, \quad \partial_i' = \hat{x}_i^{-1}\frac{\gamma_i-\gamma_i^{-1}}{q-q^{-1}} \tag{7}$$

on monomials containing x_i, where $\hat{x}_i$ and $\check{x}_i$ are the operators of left and right multiplication by x_i, respectively, and

$$\gamma_i p(x_1,\dots,x_n)=p(x_1,\dots,x_{i-1},qx_i,x_{i+1},\dots,x_n).$$

$$\gamma_i^{-1} p(x_1,\dots,x_n)=p(x_1,\dots,x_{i-1},q^{-1}x_i,x_{i+1},\dots,x_n).$$

We have $\partial_i\hat{x}_j=\hat{x}_j\partial_i$, $i\neq j$, and

$$\partial_i\partial_j=q^{-1}\partial_j\partial_i, \quad \partial_i\check{x}_j=q\check{x}_j\partial_i, \quad i<j,$$

$$\gamma_i\hat{x}_j=q^{\delta_{ij}}\hat{x}_j\gamma_i, \quad \gamma_i\partial_j=q^{-\delta_{ij}}\partial_j\gamma_i.$$

It is possible to introduce a q-analog of the Fischer scalar product on $\mathcal{A}$ (see Ref. 5). It is defined by

$$\langle p_1,p_2\rangle=p_1(\partial_1',\dots,\partial_n')p_2^*|_{x=0}, \tag{8}$$

where p_2^* is the polynomial p_2 in which numerical coefficients are replaced by complex conjugate ones, $p_1(\partial_1',\dots,\partial_n')$ means the q-differential operator obtained from a polynomial p by replacement of x_i by ∂_i', $i=1,2,\dots,n$, and the symbol $p|_{x=0}$ means a constant term of the polynomial p.

We can define an action of the quantum algebra $U_q(\mathrm{sl}_n)$ on the space $\mathcal{A}$ determining its representation on $\mathcal{A}$. This action is given by

$$\rho(k_i)=\gamma_i\gamma_{i+1}^{-1}, \quad \rho(e_i)=\check{x}_i\gamma_i\partial_{i+1}, \quad \rho(f_i)=\check{x}_{i+1}\gamma_i^{-1}\partial_i. \tag{9}$$

The action ρ and formulas (4) lead to the representation $T=\rho\circ\varphi$ of $U_q'(\mathrm{so}_n)$ on $\mathcal{A}$. We introduce the notation $\theta_j=T(I_{j+1,j})$, $i=1,2,\dots,n-1$. Then it is easy to calculate that

$$\theta_j=\check{x}_{j+1}\gamma_j^{-1}\partial_j-\check{x}_j\gamma_{j+1}\partial_{j+1} \tag{10}$$

(see also Ref. 5).

The representation T of $U_q'(\mathrm{so}_n)$ is reducible. It is easy to check by using the explicit form (10) of the operators θ_j that the subspaces $\mathcal{A}_m\in\mathcal{A}$ of homogeneous polynomials of degrees m are invariant with respect to this representation. Clearly,

$$\mathcal{A}=\bigoplus_{m=0}^{\infty}\mathcal{A}_m.$$

We denote the restriction of the representation T to the subspace $\mathcal{A}_m$ by $T^{(m)}$.

The representation ρ of $U_q(\mathrm{sl}_n)$ on the space $\mathcal{A}$ is also reducible, and the subspaces $\mathcal{A}_m$ are invariant for this representation. We denote the restriction of the representation ρ of $U_q(\mathrm{sl}_n)$ to the space $\mathcal{A}_m$ by ρ_m. A direct calculation shows that the representation ρ_m is irreducible and has the highest weight $(m,0,\dots,0)$. The monomials $x_1^{m_1}x_2^{m_2}\cdots x_n^{m_n}$, $m_1+m_2+\cdots+m_n=m$, are weight vectors of this representation. The highest weight vector coincides with x_1^m.

In general, the representations $T^{(m)}$ of $U_q'(\mathrm{so}_n)$ on the spaces $\mathcal{A}_m$ are reducible. It is checked by a direct computation that the element

$$Q=x_1^2+q^{-1}x_2^2+\cdots+q^{-n+1}x_n^2\in\mathcal{A}_2 \tag{11}$$

is invariant with respect to the representation $T^{(2)}$ (and hence with respect to the representation T), that is, $T^{(2)}(I_{k,k-1})Q=0$ for $k=2,3,\dots,n$. Similarly, the element $Q^k\in\mathcal{A}_{2k}$ is invariant with respect to the representation $T^{(2k)}$.

To the element (11) there corresponds the operator

$$\hat{Q}=\hat{x}_1^2+q^{-1}\hat{x}_2^2+\cdots+q^{-n+1}\hat{x}_n^2$$

on $\mathcal{A}$ which commutes with operators of the representation T. We also consider on $\mathcal{A}$ the operator

$$\Delta_q\equiv\Delta=q^{n-1}\partial_1^2+q^{n-2}\partial_2^2+\cdots+\partial_n^2. \tag{12}$$

It is called the *q-Laplace operator* on the quantum vector space. It is clear that $\Delta:\mathcal{A}_m\to\mathcal{A}_{m-2}$.

The following relations are proved by direct calculations (see Ref. 5):

$$\Delta\hat{Q}^k-\hat{Q}^k\Delta=\hat{Q}^{k-1}[2k]\{q^{2k+n-2}\gamma^2\}, \tag{13}$$

$$\Delta(Q^k)=Q^{k-1}[2k][2k+n-2], \tag{14}$$

where $[r]$ are q-numbers and

$$\{a\}=\frac{a-a^{-1}}{q-q^{-1}}.$$

We also have

$$\hat{Q}^*=q^{-n+1}\Delta,\quad \Delta^*=q^{n-1}\hat{Q},\quad \theta_j^*=-\theta_j,$$

where an asterisk means Hermitian conjugation with respect to the scalar product (8) (see Ref. 5).

A polynomial $p\in\mathcal{A}$ is called *q-harmonic* if $\Delta p=0$. The linear subspace of $\mathcal{A}$ consisting of all q-harmonic polynomials is denoted by $\mathcal{H}$. Let $\mathcal{H}_m=\mathcal{A}_m\cap\mathcal{H}$. Then

$$\mathcal{H}=\bigoplus_{m=0}^{\infty}\mathcal{H}_m.$$

Similar to the classical case, the space $\mathcal{A}_m$ can be represented in the form of the direct sum (see Ref. 5)

$$\mathcal{A}_m=\mathcal{H}_m\oplus Q\mathcal{A}_{m-2}. \tag{15}$$

This decomposition has the following consequence:

$$\mathcal{A}_m=\bigoplus_{0\leqslant 2j\leqslant m}Q^j\mathcal{H}_{m-2j} \tag{16}$$

(the summation here is over $j=0,1,2,\ldots,\lfloor m/2\rfloor$, where $\lfloor m/2\rfloor$ is the integral part of $m/2$). The following proposition is proved in Ref. 5:

Proposition 1: The q-Laplace operator Δ commutes with all operators of the representation T of $U_q'(\mathrm{so_n})$.

It follows from Proposition 1 that the subspace $\mathcal{H}_m$ is invariant with respect to the representation $T^{(m)}$. We denote the restriction of this representation to $\mathcal{H}_m$ by T_m. Since Q is invariant with respect to $U_q'(\mathrm{so}_n)$, it follows from (16) that

$$T^{(m)}=\bigoplus_{0\leqslant 2j\leqslant m}T_{m-2j}. \tag{17}$$

In the following we identify the representations T_{m-2j} with the corresponding representations of Sec. III.

Proposition 2: If $h_m(\mathbf{x})\in\mathcal{H}_m$, then $\tilde{h}_{m-1}(\mathbf{x}):=\gamma_n^{-1}\partial_n h_m(\mathbf{x})\in\mathcal{H}_{m-1}$ and

$$\hat{h}_{m+1}(\mathbf{x}) := h_m(\mathbf{x})x_n - \frac{Q\gamma_n^{-1}\partial_n h_m(\mathbf{x})}{[n+2m-2]} \in \mathcal{H}_{m+1}. \tag{18}$$

Proof: Since $\tilde{h}_{m-1} \in \mathcal{A}_{m-1}$ and $\hat{h}_{m+1} \in \mathcal{A}_{m+1}$, it is enough to prove that $\Delta\tilde{h}_{m-1}=0$ and $\Delta\hat{h}_{m+1}=0$. The first relation follows from the equalities

$$\Delta(\gamma_n^{-1}\partial_n) = (\partial_n^2 + q\Delta_{(n-1)})\gamma_n^{-1}\partial_n = q^{-2}\gamma_n^{-1}\partial_n(\partial_n^2 + q\Delta_{(n-1)}) = q^{-2}(\gamma_n^{-1}\partial_n)\Delta,$$

where $\Delta_{(n-1)}) = q^{n-2}\partial_1^2 + q^{n-3}\partial_2^2 + \cdots + \partial_{n-1}^2$ is the q-Laplace operator for the elements $x_1, x_2, \ldots, x_{n-1}$. In order to prove the relation $\Delta\hat{h}_{m+1}=0$ we first note that for $p \in \mathcal{A}$ one has

$$\begin{aligned}
\partial_n^2(p(\mathbf{x})x_n) &= \partial_n\left(\left(\frac{\gamma_n - \gamma_n^{-1}}{q-q^{-1}}p(\mathbf{x})x_n\right)x_n^{-1}\right) = \partial_n\left(\frac{q\gamma_n - q^{-1}\gamma_n^{-1}}{q-q^{-1}}p(\mathbf{x})x_n x_n^{-1}\right) \\
&= \frac{q^2\gamma_n - q^{-2}\gamma_n^{-1}}{q-q^{-1}}\partial_n p(\mathbf{x}) = \left(q^2\frac{\gamma_n - \gamma_n^{-1}}{q-q^{-1}} + \frac{q^2-q^{-2}}{q-q^{-1}}\gamma_n^{-1}\right)\partial_n p(\mathbf{x}) \\
&= q^2(\partial_n^2 p(\mathbf{x}))x_n + [2]\gamma_n^{-1}\partial_n p(\mathbf{x}).
\end{aligned}$$

Hence,

$$\begin{aligned}
\Delta(h_m(\mathbf{x})x_n) &= (\partial_n^2 + q\Delta_{(n-1)})(h_m(\mathbf{x})x_n) = \partial_n^2(h_m(\mathbf{x})x_n) + q^3(\Delta_{(n-1)}h_m(\mathbf{x}))x_n \\
&= q^2(\Delta h_m(\mathbf{x}))x_n + [2]\gamma_n^{-1}\partial_n h_m(\mathbf{x}) = [2]\tilde{h}_{m-1}(\mathbf{x}).
\end{aligned} \tag{19}$$

Using relation (13) at $k=1$ we also have

$$\Delta(Q\gamma_n^{-1}\partial_n h_m(\mathbf{x})) = Q\Delta\tilde{h}_{m-1}(\mathbf{x}) + [2][n+2m-2]\tilde{h}_{m-1}(\mathbf{x}). \tag{20}$$

Now the relation $\Delta\hat{h}_{m+1}=0$ follows from (19) and (20). Proposition is proved.

It is shown in Ref. 5 that $\mathcal{A} \simeq \mathbb{C}[Q]\otimes\mathcal{H}$. This decomposition is a q-analog of the theorem on separation of variables for Lie groups in an abstract form (see, e.g., Ref. 13). We have

$$\mathcal{A} \simeq \mathbb{C}[Q]\otimes\mathcal{H} \simeq \mathbb{C}[Q]\otimes\bigoplus_{m\geqslant 0}\mathcal{H}_m = \bigoplus_{m\geqslant 0}(\mathbb{C}[Q]\otimes\mathcal{H}_m). \tag{21}$$

If $h_m(\mathbf{x}) \in \mathcal{H}_m$ and $h_s'(\mathbf{x}) \in \mathcal{H}_s$, then [since $\hat{Q}^* = q^{-n+1}\Delta$ with respect to the scalar product (8)] we have

$$\langle Q^k h_m, Q^l h_s'\rangle = q^{k(-n+1)}\langle h_m, \Delta^k Q^l h_s'\rangle.$$

Using (13) we derive that $\Delta(Q^l h_s') = Q^{l-1}[2l][2l+n+2s-2]h_s'$. Applying repeatedly this formula we obtain from the previous formula that

$$\langle Q^k h_m, Q^l h_s'\rangle = \delta_{kl}q^{k(-n+1)}[2l]!!\frac{[2k+n+2s-2]!!}{[n+2s-2]!!}\langle h_m, h_s'\rangle. \tag{22}$$

Remark: In an analogy with the classical case, we may consider the scalar product (8) as an integral of the function $p_1 p_2^*$. Then the formula (22) means a fulfillment of ''integration'' with respect to the q-radial part. Like in the classical case, the scalar product $\langle h_m, h_s'\rangle$ can be treated as ''integration'' over q-spherical coordinates for q-harmonic polynomials.

A direct calculation shows that

$$\langle Q^l, Q^s\rangle = q^{l(1-n)}\langle 1, \Delta^l Q^s\rangle = \delta_{ls}q^{l(-n+1)}\frac{[2l]!![2l+n-2]!!}{[n-2]!!}. \tag{23}$$

V. THE PROJECTION $\mathcal{A}_m \to \mathcal{H}_m$

The decomposition (15) is orthogonal with respect to the scalar product (8). Let us construct the projector $H_m : \mathcal{A}_m = \mathcal{H}_m \oplus Q\mathcal{A}_{m-2} \to \mathcal{H}_m$. We present this projector in the form

$$H_m p = \sum_{k=0}^{\lfloor m/2 \rfloor} \alpha_k \hat{Q}^k \Delta^k p, \quad \alpha_k \in \mathbb{C}, \quad p \in \mathcal{A}_m, \tag{24}$$

where $\lfloor m/2 \rfloor$ means the integral part of $m/2$. We have to calculate values of the coefficients α_k. In order to do this, we act by the q-Laplace operator Δ upon both parts of (24) and use the relation (13). Under this action, the left-hand side vanishes. Equating the right-hand side to 0, we derive a recurrence relation for α_k which gives

$$\begin{aligned} \alpha_k &= \frac{(-1)^k}{[2k]!![n+2m-4][n+2m-6]\cdots[n+2m-2k-2]} \\ &= \frac{(-1)^k [n+2m-2k-4]!!}{[2k]!![n+2m-4]!!}, \end{aligned} \tag{25}$$

where $[s]!! = [s][s-2][s-4]\cdots[2]$ (or $[1]$) and $[0]!! = 1$.

Note that the coefficients α_k are determined by the recurrence relation uniquely up to a constant. In (25) we chose this constant in such a way that $H_m p = p$ for $p \in \mathcal{H}_m$. This means that $H_m^2 = H_m$.

Proposition 3: (a) The operator H_m commutes with the operators θ_j of the representation $T^{(m)}$ of $U_q'(\mathrm{so_n})$. (b) Considering the scalar product (8) on the space $\mathcal{A}_m$ we have $H^* = H$.

Proof: The assertion (a) follows from the fact that θ_j commutes with $\hat{Q}$ and Δ. The assertion (b) is a consequence of the equalities $\hat{Q}^* = q^{-n+1}\Delta$ and $\Delta^* = q^{n-1}\hat{Q}$.

Let us show how to construct by using the operator H_m a zonal polynomial [that is an invariant element with respect to the subalgebra $U_q'(\mathrm{so}_{n-1})$] in the space $\mathcal{H}_m$. In order to do this, we have to take a polynomial $p \in \mathcal{A}_m$ invariant with respect to $U_q'(\mathrm{so}_{n-1})$ and to act upon it by the operator H_m. Since the projector H_m commutes with the action of $U_q'(\mathrm{so}_{n-1})$, a polynomial obtained in this way is a zonal polynomial. Clearly, the polynomial $p(x) = x_n^m$ belongs to $\mathcal{A}_m$ and is invariant under the action of $U_q'(\mathrm{so}_{n-1})$. We have

$$\begin{aligned} \varphi_m' &:= H_m x_n^m = \sum_{k=0}^{\lfloor m/2 \rfloor} \alpha_k \hat{Q}^k \Delta^k x_n^m = \sum_{k=0}^{\lfloor m/2 \rfloor} \alpha_k \hat{Q}^k \partial_n^{2k} x_n^m \\ &= \sum_{k=0}^{\lfloor m/2 \rfloor} (-1)^k \frac{[m]![n+2m-2k-4]!!}{[m-2k]![2k]!![n-2m-4]!!} Q^k x_n^{m-2k}. \end{aligned} \tag{26}$$

Using the notation

$$(a;q)_s = (1-a)(1-qa)(1-q^2a)\cdots(1-q^{s-1}a),$$

we reduce the zonal polynomial (26) to the form

$$\varphi_m' = \sum_{k=0}^{\lfloor m/2 \rfloor} \frac{(q^{-2m};q^4)_k (q^{-2m+2};q^4)_k}{(q^4;q^4)_k (q^{-2n-4m+8};q^4)_k} q^{-k(n-5)} Q^k x_n^{m-2k}. \tag{27}$$

It concides with the formula for a zonal polynomial found by another method in Ref. 5.

VI. q-ANALOG OF ASSOCIATED SPHERICAL HARMONICS WITH RESPECT TO $U_q'(\mathrm{so}_{n-1})$

It is known (see Ref. 1, Chaps. 9 and 10) that in the space of classical homogeneous harmonic polynomials there exist different orthonormal bases. They correspond to different separations of variables. Each separation of variables corresponds to a certain chain of subgroups of the rotation group $\mathrm{SO}(n)$. We show in the following that a similar picture has place for spaces $\mathcal{H}_m$ of homogeneous q-harmonic polynomials.

In the classical case, the tree method distinguishes different separations of variables or, equivalently, different chains of subgroups of $\mathrm{SO}(n)$. The same tree method can be used for q-harmonic polynomials, but instead of chains of subgroups of $\mathrm{SO}(n)$ we have to take the corresponding chains of subalgebras of the algebra $U_q'(\mathrm{so}_n)$.

The aim of this section is to construct an orthonormal basis of the space $\mathcal{H}_m$ of homogeneous q-harmonic polynomials which corresponds to the chain

$$U_q'(\mathrm{so}_n)\supset U_q'(\mathrm{so}_{n-1})\supset\cdots\supset U_q'(\mathrm{so}_3)\supset U_q'(\mathrm{so}_2), \tag{28}$$

where $U_q'(\mathrm{so}_2)$ is the commutative subalgebra generated by the element I_{21}. This basis is a q-analog of the well-known set of associated spherical harmonics which are products of certain Gegenbauer polynomials (see, Ref. 1, Chap. 9).

Proposition 4: Let $h_s(\mathbf{x}')$ be a homogeneous harmonic polynomial of degree s in $\mathbf{x}'=(x_1,x_2,\ldots,x_{n-1})$. Then for $x_n^{m-s}h_s(\mathbf{x}')\in\mathcal{A}_m$ we have

$$H_m(x_n^{m-s}h_s(\mathbf{x}'))=\left(\sum_{k=0}^{\lfloor (m-s)/2\rfloor}\frac{(-1)^k q^{-2sk}[m-s]![2m+n-2k-4]!!}{[m-s-2k]![2k]!![2m+n-4]!!}Q^k x_n^{m-s-2k}\right)h_s(\mathbf{x}'). \tag{29}$$

Proof: Since

$$\Delta_{(n-1)}(x_n^{m-s}h_s(\mathbf{x}'))=x_n^{m-s}(\Delta_{(n-1)}h_s(\mathbf{x}'))=0,$$

where $\Delta_{(n-1)}$ is the q-Laplace operator for the elements $x_1,x_2,\ldots,x_{n-1}$, we have

$$\Delta(x_n^{m-s}h_s(\mathbf{x}'))=(q\Delta_{(n-1)}+\partial_n^2)(x_n^{m-s}h_s(\mathbf{x}'))=q^{-2s}[m-s][m-s-1]x_n^{m-s}h_s(\mathbf{x}').$$

Applying repeatedly the last relation to the right-hand side of the equality

$$H_m(x_n^{m-s}h_s(\mathbf{x}'))=\sum_{k=0}^{\lfloor m/2\rfloor}\alpha_k\hat{Q}^k\Delta_{(n)}^k(x_n^{m-s}h_s(\mathbf{x}'))$$

we derive the relation (29). The proposition is proved.

We denote by $\hat{t}_s^{n,m}(Q,x_n)$ the expression at $h_s(\mathbf{x}')$ on the right-hand side of (29):

$$\hat{t}_s^{n,m}(Q,x_n)=\sum_{k=0}^{\lfloor (m-s)/2\rfloor}\frac{(-1)^k q^{-2sk}[m-s]![2m+n-2k-4]!!}{[m-s-2k]![2k]!![2m+n-4]!!}Q^k x_n^{m-s-2k}. \tag{30}$$

In particular, we have $\hat{t}_0^{n,m}(Q,x_n)=\varphi_m'=H_m x_n^m$.

In order to construct an orthonormal basis of $\mathcal{H}_m$, we have to normalize expression (29). Let us first consider a normalization of φ_m'. We have

$$\langle\varphi_m',\varphi_m'\rangle=\langle H_m x_n^m,H_m x_n^m\rangle=\langle x_n^m,H_m^*H_m x_n^m\rangle=\langle x_n^m,H_m x_n^m\rangle=\langle x_n^m,\varphi_m'\rangle=c_m^{(0)}\langle x_n^m,x_n^m\rangle,$$

where $c_m^{(0)}$ is the coefficient at x_n^m in expression (27) for φ_m' [the last equality is due to the definition (8) of the scalar product]. We have

$$c_m^{(0)}=\sum_{k=0}^{\lfloor m/2\rfloor}\frac{(q^{-2m};q^4)_k(q^{-2m+2};q^4)_k}{(q^{-2n-4m+8};q^4)_k}\frac{q^{k(-2n+6)}}{(q^4;q^4)_k}$$
$$={}_2\varphi_1(q^{-2m},q^{-2m+2};q^{8-2n-4m};q^4,q^{-2n+6}).$$

This q-hypergeometric series can be summed by means of the formula

$${}_2\varphi_1(a,q^{-n};c;q,cq^n/a)=\frac{(c/a;q)_n}{(c;q)_n} \tag{31}$$

(see Ref. 14, Sec. 1.5). As a result, we derive that

$$c_m^{(0)}=\frac{(q^{-2(n+m-3)};q^4)_{m/2}}{(q^{-2(n+2m-4)};q^4)_{m/2}} \quad \text{if} \quad m-s \quad \text{is} \quad \text{even},$$

$$c_m^{(0)}=\frac{(q^{-2(n+m-4)};q^4)_{(m-1)/2}}{(q^{-2(n+2m-4)};q^4)_{(m-1)/2}} \quad \text{if} \quad m-s \quad \text{is} \quad \text{odd}.$$

Since $\langle x_n^m,x_n^m\rangle=(\partial_n')^n x_n^m=[n]!$, then the normalized zonal polynomial from $\mathcal{H}_m$ has a form

$$\varphi_m=(c_m^{(0)}[m]!)^{-1/2}\varphi_m'.$$

Now let τ_s^m denote expression (29). We similarly have

$$\langle\tau_s^m,\tau_s^m\rangle=\langle H_m(x_n^{m-s}h_s(\mathbf{x}')),H_m(x_n^{m-s}h_s(\mathbf{x}'))\rangle=\langle x_n^{m-s}h_s(\mathbf{x}'),\tau_s^m\rangle$$
$$=c_m^{(s)}\langle x_n^{m-s}h_s(\mathbf{x}'),x_n^{m-s}h_s(\mathbf{x}')\rangle=c_m^{(s)}q^{-s(m-s)}\langle h_s(\mathbf{x}')x_n^{m-s},x_n^{m-s}h_s(\mathbf{x}')\rangle$$
$$=c_m^{(s)}q^{-s(m-s)}[m-s]!\langle h_s(\mathbf{x}'),h_s(\mathbf{x}')\rangle,$$

where $c_m^{(s)}$ is the coefficient at x_n^{m-s} in expression (30) for $\hat{t}_s^{n,m}(Q,x_n)$. We obtain from (30) that

$$c_m^{(s)}=\sum_{k=0}^{\lfloor (m-s)/2\rfloor}\frac{(q^{-2(m-s)};q^4)_k(q^{-2(m-s)+2};q^4)_k}{(q^{-2n-4m+8};q^4)_k}\frac{q^{k(-2n-4s+6)}}{(q^4;q^4)_k}$$
$$={}_2\varphi_1(q^{2(s-m)},q^{2(s-m)+2};q^{8-2n-4m};q^4,q^{6-2n-4s}).$$

This q-hypergeometric series can be summed by means of formula (31) and we receive

$$c_m^{(s)}=\frac{(q^{2(-n-m-s+3)};q^4)_{(m-s)/2}}{(q^{2(-n-2m+4)};q^4)_{(m-s)/2}} \quad \text{if} \quad m-s \quad \text{is} \quad \text{even}, \tag{32}$$

$$c_m^{(s)}=\frac{(q^{2(-n-m-s+4)};q^4)_{(m-s-1)/2}}{(q^{2(-n-2m+4)};q^4)_{(m-s-1)/2}} \quad \text{if} \quad m-s \quad \text{is} \quad \text{odd}. \tag{33}$$

Instead of $\hat{t}_s^{n,m}(Q,x_n)$ we shall use the normalized expression

$$t_s^{n,m}(Q,x_n)=\frac{q^{s(m-s)/2}}{\sqrt{c_m^{(s)}[m-s]!}}\hat{t}_s^{n,m}(Q,x_n). \tag{34}$$

In order to construct an orthonormal basis of the space $\mathcal{H}_m$ in an explicit form, we take into account that

$$\langle t_s^{n,m}(Q,x_n)h_s(\mathbf{x}'),t_s^{n,m}(Q,x_n)h_s(\mathbf{x}')\rangle=\langle h_s(\mathbf{x}'),h_s(\mathbf{x}')\rangle.$$

We apply the previous reasoning of this section to homogeneous q-harmonic polynomials of $x_1,x_2,\ldots,x_{n-1}$. As a result, we obtain q-harmonic polynomials of the form

$$t_s^{n,m}(Q,x_n)t_r^{n-1,s}(Q_{n-1},x_{n-1})h_r(\mathbf{x}''), \quad s=0,1,2,\ldots,m, \quad r=0,1,2,\ldots,s,$$

where

$$Q_{n-1}=x_1^2+q^{-1}x_2^2+\cdots+q^{-n+2}x_{n-1}^2, \quad \mathbf{x}''=(x_1,x_2,\ldots,x_{n-2}),$$

$h_r(\mathbf{x}'')$ are elements of the space of homogeneous q-harmonic polynomials of degree r in $x_1,x_2,\ldots,x_{n-2}$, and $t_r^{n-1,s}(Q_{n-1},x_{n-1})$ is defined by (30) and (34).

Continuing this procedure, we obtain the normalized polynomials of $\mathcal{H}_m$ of the form

$$\begin{aligned}\Xi_{\mathbf{m}}(\mathbf{x})&\equiv\Xi_{m,m_{n-1},m_{n-2},\ldots,m_2}(\mathbf{x})\\&=t_{m_{n-1}}^{n,m}(Q,x_n)t_{m_{n-2}}^{n-1,m_{n-1}}(Q_{n-1},x_{n-1})\cdots t_{m_2}^{3,m_3}(Q_3,x_3)t^{2,m_2}(x_1,x_2),\end{aligned} \tag{35}$$

$$m\geqslant m_{n-1}\geqslant m_{n-2}\geqslant\cdots\geqslant m_3\geqslant|m_2|, \tag{36}$$

where the polynomials $t^{2,m_2}(x_1,x_2)$ are determined in the following way. A complete set of linearly independent harmonic polynomials in x_1 and x_2 coincides with

$$z^{(0)}\equiv 1, \quad z^{(s)}=(ix_1+x_2)(ix_1+qx_2)\cdots(ix_1+q^{s-1}x_2), \quad s>0,$$

$$z^{(s)}=(ix_1-x_2)(ix_1-qx_2)\cdots(ix_1-q^{-s+1}x_2), \quad s<0$$

(see Ref. 5). A direct computation shows that $c^{(0)}\equiv\langle z^{(0)},z^{(0)}\rangle=1$ and

$$c^{(s)}\equiv\langle x^{(s)},x^{(s)}\rangle=c^{(-s)}\equiv\langle x^{(-s)},x^{(-s)}\rangle=2q^{s(s-1)/2}[s][2s-2]!!, \quad s>0.$$

We set

$$t^{2,m_2}(x_1,x_2)=(c^{(m_2)})^{-1/2}z^{(m_2)}.$$

To every set of integers $m_{n-1},m_{n-2},\ldots,m_3,m_2$ satisfying the condition (36) corresponds a polynomial (35). (For fixed m_3 the number m_2 takes the values $-m_3,-m_3-1,\ldots,m_3$.) A direct calculation shows that the number of these polynomials is equal to the dimension of the space $\mathcal{H}_m$ given in Corollary 3.1.4 of Ref. 5. From the other side, the polynomials (35) are pairwise orthogonal [a proof of this fact is fulfilled by taking into account the definition (8) of the scalar product and repeating the above-mentioned reasoning of this section]. This means that *the set of all polynomials (35) constitute an orthonormal basis of the space $\mathcal{H}_m$. This basis corresponds to the chain of subalgebras (28).*

Representation of the basis of the space $\mathcal{H}_m$ of solutions of the equation $\Delta p_m=0$ in the form (35) gives us a q-analog of separation of variables of the classical analysis. This q-separation of variables corresponds to the chain of subalgebras (28). q-analogs of other types of separations of variables will be given in the following.

VII. REPRESENTATION OF $U_q'(\mathrm{so}_n)$ ON $\mathcal{H}_m$

In this section we derive how the operators θ_j act upon the basis elements (35).

Lemma 1: Let $h_m(\mathbf{x})=\hat{t}_s^{n,m}(Q,x_n)h_s(\mathbf{x}')$, where $\hat{t}_s^{n,m}$ is given by (30) and $h_s(\mathbf{x}')$ is a homogeneous q-harmonic polynomial of degree s in $\mathbf{x}'=(x_1,x_2,\ldots,x_{n-1})$. Then for the corresponding q-harmonic polynomials $\tilde{h}_{m-1}(\mathbf{x})$ and $\hat{h}_{m+1}(\mathbf{x})$, given by Proposition 2, we have

$$\tilde{h}_{m-1}(\mathbf{x})=q^{-s}[m-s]\frac{[n+m+s-3]}{[n+2m-4]}\hat{t}_s^{n,m-1}(Q,x_n)h_s(\mathbf{x}'), \tag{37}$$

$$\hat{h}_{m+1}(\mathbf{x})=q^s\hat{t}_s^{n,m+1}(Q,x_n)h_s(\mathbf{x}'). \tag{38}$$

Proof: It was proved in Sec. VI that

$$h_m(\mathbf{x})=c_m^{(s)}x_n^{m-s}h_s(\mathbf{x}')+\alpha Q_{n-1}x_n^{m-s-2}h_s(\mathbf{x}')+\beta Q_{n-1}x_n^{m-s-4}h_s(\mathbf{x})+\cdots,$$

where α and β are certain coefficients (we do not need their explicit form) and $c_m^{(s)}$ is given by (32) and (33). Therefore, for $\tilde{h}_{m-1}(\mathbf{x})=\gamma_n^{-1}\partial_n h_m(\mathbf{x})$ we have

$$\tilde{h}_{m-1}(\mathbf{x})=q^{-s}q^{-(m-s-1)}[m-s]c_m^{(s)}x_n^{m-s-1}h_s(\mathbf{x}')+\alpha' Q_{n-1}x_n^{m-s-3}h_s(\mathbf{x}')+\cdots. \tag{39}$$

This polynomial is of the form $\tilde{h}_{m-1}(\mathbf{x})=\sigma\hat{t}_s^{n,m-1}(Q,x_n)h_s(\mathbf{x}')$, where σ is a constant and $h_s(\mathbf{x}')$ is as noted earlier. To show this we note that by Proposition 2 we have $\tilde{h}_{m-1}(\mathbf{x})\in\mathcal{H}_{m-1}$. Therefore, $\tilde{h}_{m-1}(\mathbf{x})$ is a linear combination of the basis polynomials (35) taken for $\mathcal{H}_{m-1}$. In the set of these basis polynomials there is a single polynomial of the form $p(Q,x_n)h_s(\mathbf{x}')$. Up to a constant it coincides with $\hat{t}_s^{n,m-1}(Q,x_n)h_s(\mathbf{x}')$. This proves the desired form of $\tilde{h}_{m-1}(\mathbf{x})$.

In order to compute the constant σ in $\tilde{h}_{m-1}(\mathbf{x})=\sigma\hat{t}_s^{n,m-1}(Q,x_n)h_s(\mathbf{x}')$ we represent $\tilde{h}_{m-1}(\mathbf{x})$ in the form

$$\tilde{h}_{m-1}(\mathbf{x})=\sigma(c_{m-1}^{(s)}x_n^{m-s-1}h_s(\mathbf{x}')+\alpha'' Q_{n-1}x_n^{m-s-3}h_s(\mathbf{x}')+\cdots). \tag{40}$$

Comparing the coefficients at $x_n^{m-s-1}h_s(\mathbf{x}')$ in (39) and (40) we derive that

$$\sigma=q^{-m+1}[m-s]\frac{c_m^{(s)}}{c_{m-1}^{(s)}}=q^{-s}[m-s]\frac{[n+m+s-3]}{[n+2m-4]}.$$

This proves relation (37).

Now for our $h_m(\mathbf{x})$ we consider the expression $\hat{h}_{m+1}(\mathbf{x})$ given by (18). We have

$$h_m(\mathbf{x})x_n=q^s c_m^{(s)}x_n^{m-s+1}h_s(\mathbf{x}')+\cdots,$$

$$\frac{Q\gamma_n^{-1}\partial_n h_m(\mathbf{x})}{[n+2m-2]}=\frac{q^{1-n}q^{-m+1}[m-s]}{[n+2m-2]}c_m^{(s)}x_n^{m-s+1}h_s(\mathbf{x}')+\cdots,$$

where the dots mean summands with lower degrees of x_n. Making some calculations with q-numbers we derive from these equalities that

$$\hat{h}_{m+1}(\mathbf{x})=\frac{q^m[n+m+s-2]}{[n+2m-2]}x_n^{m-s+1}h_s(\mathbf{x}')+\cdots. \tag{41}$$

Taking into account that $\hat{h}_{m+1}\in\mathcal{H}_{m+1}$ and using the above-mentioned reasoning of this proof, one easily proves that $\hat{h}_{m+1}(\mathbf{x})=\tau\hat{t}_s^{n,m+1}(Q,x_n)h_s(\mathbf{x}')$, where τ is a constant. In order to calculate this constant, we represent $\hat{h}_{m+1}$ in the form

$$\hat{h}_{m+1}(\mathbf{x})=\tau(c_{m+1}^{(s)}x_n^{m-s+1}h_s(\mathbf{x}')+\cdots). \tag{42}$$

Comparing the coefficients at $x^{m-s+1}h_s(\mathbf{x}')$ in (41) and (42), we derive that

$$\tau=\frac{q^m[n+m+s-2]}{[n+2m-2]}\frac{c_m^{(s)}}{c_{m+1}^{(s)}}=q^s.$$

This proves relation (38). The lemma is proved.

Theorem 1: *The operators* $T_m(I_{k,k-1})=\theta_{k-1}$, $k=2,3,\ldots,n$, *act upon the basis elements* $\Xi_{\mathbf{m}}\equiv|\mathbf{m}\rangle$, *given by (35), as*

$$T_m(I_{k,k-1})|\mathbf{m}\rangle=-([m_k+m_{k-1}+k-2][m_k-m_{k-1}])^{1/2}A(m_{k-1})|\mathbf{m}_{k-1}^{+}\rangle+([m_k+m_{k-1}+k-3]\times[m_k-m_{k-1}+1])^{1/2}A(m_{k-1}-1)|\mathbf{m}_{k-1}^{-}\rangle,\quad k\neq 2,$$

$$T_m(I_{21})|\mathbf{m}\rangle=i[m_2]|\mathbf{m}\rangle,$$

where $m_n\equiv m$, $\mathbf{m}_{k-1}^{\pm}$ *denote the set of the numbers* $\mathbf{m}$ *with* m_{k-1} *replaced by* $m_{k-1}\pm 1$, *respectively, and*

$$A(m_{k-1})=\left(\frac{[m_{k-1}+m_{k-2}+k-3][m_{k-1}-m_{k-2}+1]}{[2m_{k-1}+k-3][2m_{k-1}+k-1]}\right)^{1/2}.$$

Proof: Let us find how the operator

$$T_m(I_{n,n-1})\equiv\theta_{n-1}=\check{x}_n\gamma_{n-1}^{-1}\partial_{n-1}-\check{x}_{n-1}\gamma_n\partial_n$$

acts upon the polynomial $x_n^{m-s}\hat{t}_r^{n-1,s}(Q_{n-1},x_{n-1})h_r(\mathbf{x}'')$, where $h_r(\mathbf{x}'')$ is a homogeneous q-harmonic polynomial in $x_1,x_2,\ldots,x_{n-2}$. We have

$$\check{x}_n\gamma_{n-1}^{-1}\partial_{n-1}(x_n^{m-s}\hat{t}_r^{n-1,s}(Q_{n-1},x_{n-1})h_r(\mathbf{x}''))=\check{x}_n(x_n^{m-s}\gamma_{n-1}^{-1}\partial_{n-1}\hat{t}_r^{n-1,s}(Q_{n-1},x_{n-1})h_r(\mathbf{x}''))=q^{s-1}x_n^{m-s+1}\gamma_{n-1}^{-1}\partial_{n-1}\hat{t}_r^{n-1,s}h_r(\mathbf{x}'').$$

Using Lemma 1 we derive that

$$\check{x}_{n-1}\gamma_n\partial_n(x_n^{m-s}\hat{t}_r^{n-1,s}h_r(\mathbf{x}''))=q^{m-2s-1}[m-s]\check{x}_{n-1}(x_n^{m-s-1}\hat{t}_r^{n-1,s}h_r(\mathbf{x}''))=q^{m-2s-1}[m-s]x_n^{m-s-1}\left(q^r\hat{t}_r^{n-1,s+1}h_r(\mathbf{x}'')+\frac{Q_{n-1}\gamma_{n-1}^{-1}\partial_{n-1}\hat{t}_r^{n-1,s}h_r(\mathbf{x}'')}{[n+2s-3]}\right),$$

where $\hat{t}_r^{n-1,s}\equiv\hat{t}_r^{n-1,s}(Q_{n-1},x_{n-1})$. Using the above-given equalities and the relation

$$x_n^{m-s-1}Q_{n-1}=q^{-2(m-s-1)}(Q-q^{-n+1}x_n^2)x_n^{m-s-1}=q^{-2(m-s-1)}Qx_n^{m-s-1}-q^{-2(m-s-1)-n+1}x_n^{m-s+1}$$

we obtain that

$$\theta_{n-1}(x_n^{m-s}\hat{t}_r^{n-1,s}h_r(\mathbf{x}''))=\left(q^{s-1}+q^{-2(m-s)-n+3}\frac{q^{m-2s-1}[m-s]}{[n+2s-3]}\right)x_n^{m-s+1}\gamma_{n-1}^{-1}\partial_{n-1}\hat{t}_r^{n-1,s}h_r(\mathbf{x}'')-q^{m-2s+r-1}[m-s]x_n^{m-s-1}\hat{t}_r^{n-1,s+1}h_r(\mathbf{x}'')-\frac{q^{-m+1}}{[n+2s-3]}Qx_n^{m-s-1}\partial_n\hat{t}_r^{n-1,s}h_r(\mathbf{x}'').$$

Now we act by the projection operator H_m upon both sides of this relation, taking into account that the last summand on the right-hand side belongs to $\mathrm{Ker}\, H_m$. Since θ_{n-1} commutes with H_m (see Proposition 3), we derive

$$\theta_{n-1}(\hat{t}_s^{n,m}\hat{t}_r^{n-1,s}h_r(\mathbf{x}''))=-q^{m-2s+r-1}[m-s]\hat{t}_{s+1}^{n,m}\hat{t}_r^{n-1,s+1}h_r(\mathbf{x}'')$$
$$+q^{-m+2s-r-1}[s-r]\frac{[n+m+s-3][n+s+r-4]}{[n+2s-3][n+2s-5]}\hat{t}_{s-1}^{n,m}\hat{t}_r^{n-1,s-1}h_r(\mathbf{x}'').$$

If we rewrite this formula for the normalized polynomials $\Xi_{\mathbf{m}}$, then we obtain the action formula for the operator $T_m(I_{n,n-1})=\theta_{n-1}$, given by the formulation of the theorem.

The above-given proof is valid for the action of any operator $T_m(I_{j,j-1})=\theta_{j-1}$, $j\geqslant 3$, since θ_{j-1} act upon basis polynomials (35) on the right. The formula for $T_m(I_{21})$ is derived in Ref. 5. The theorem is proved.

Comparing the operators $T_m(I_{k,k-1})$ of Theorem 1 with the operators of the irreducible representation R_m of $U_q'(\mathrm{so}_n)$ from Sec. III we obtain

Corollary: The representation T_m realized on the space $\mathcal{H}_m$ of homogeneous q-harmonic polynomials is equivalent to the class 1 irreducible representation R_m of $U_q'(\mathrm{so_n})$.

VIII. q-ANALOG OF ASSOCIATED SPHERICAL HARMONICS WITH RESPECT TO $U_q'(\mathrm{so}_p)\times U_q'(\mathrm{so}_{n-p})$

In Sec. VI we found an orthonormal basis of the space $\mathcal{H}_m$ of homogeneous harmonic polynomials corresponding to the chain of subalgebras (28). In this section we shall find orthonormal bases of the same space corresponding to the reductions

$$U_q'(\mathrm{so}_n)\supset U_q'(\mathrm{so}_p)\times U_q'(\mathrm{so}_{n-p}). \tag{43}$$

As in the classical case (see Ref. 1, Chap. 10), further reductions can be made as in (28) or as (43). In particular, the usual tree method (see Ref. 1, Sec. 10.2) can be used to describe different chains of subalgebras corresponding to different orthonormal bases of $\mathcal{H}_m$.

We represent the set $\mathbf{x}=(x_1,x_2,\ldots,x_n)$ as $\mathbf{x}=(\mathbf{y},\mathbf{t})$, where $\mathbf{y}=(x_1,x_2,\ldots,x_p)$ and $\mathbf{t}=(x_{p+1},x_{p+2},\ldots,x_n)$. Then the q-Laplace operator Δ can be written as

$$\Delta=q^{n-p}\Delta_{(\mathbf{y})}+\Delta_{(\mathbf{t})},$$

where $\Delta_{(\mathbf{y})}$ and $\Delta_{(\mathbf{t})}$ are the q-Laplace operators for $\mathbf{y}$ and $\mathbf{t}$, respectively.

In order to find bases of $\mathcal{H}_m$ corresponding to the reduction (43) we take non-negative numbers s_1 and s_2 such that m and s_1+s_2 are of the same evenness and $m-s_1-s_2\geqslant 0$. Let us find a harmonic projection of the function

$$Q_{\mathbf{t}}^{(m-s_1-s_2)/2}h_{s_1}(\mathbf{t})h_{s_2}(\mathbf{y})\in\mathcal{A}_m,$$

where $Q_{\mathbf{t}}:=x_{p+1}+q^{-1}x_{p+2}+\cdots+q^{-(n-p)+1}x_n$ and $h_{s_1}(\mathbf{t})$ [respectively $h_{s_2}(\mathbf{y})$] is a homogeneous of degree s_1 (respectively, of degree s_2) harmonic polynomial in $\mathbf{t}$ (respectively, in $\mathbf{y}$). By definition (7) of the derivatives ∂_i from (12), we have

$$\Delta(Q_{\mathbf{t}}^r h_{s_1}(\mathbf{t})h_{s_2}(\mathbf{y}))=\Delta_{(\mathbf{t})}(Q_{\mathbf{t}}^r h_{s_1}(\mathbf{t})h_{s_2}(\mathbf{y}))+q^{n-p}Q_{\mathbf{t}}^r h_{s_1}(\mathbf{t})\Delta_{(\mathbf{y})}h_{s_2}(\mathbf{y})$$
$$=q^{-2s_2}\Delta_{(\mathbf{t})}(Q_{\mathbf{t}}^r h_{s_1}(\mathbf{t}))h_{s_2}(\mathbf{y}),$$

where $r=(m-s_1-s_2)/2$. Taking into account relation (13) we obtain

$$\Delta(Q_{\mathbf{t}}^r h_{s_1}(\mathbf{t})h_{s_2}(\mathbf{y}))=q^{-2s_2}Q_{\mathbf{t}}^{r-1}[2r][2r+n-p+2s_1-2]h_{s_1}(\mathbf{t})h_{s_2}(\mathbf{y}).$$

Repeatedly applying this formula we derive

$$
\begin{aligned}
&H_m(Q_{\mathbf{t}}^r h_{s_1}(\mathbf{t})h_{s_2}(\mathbf{y}))\\
&\quad=\sum_{k=0}^{\lfloor m/2\rfloor}\alpha_k\hat{Q}^k\Delta^k(Q_{\mathbf{t}}^r h_{s_1}(\mathbf{t})h_{s_2}(\mathbf{y}))\\
&\quad=\left(\sum_{k=0}^{r}\frac{(-1)^k q^{-2s_2k}[2r]!!}{[n+2m-4]!!}\,\frac{[2r+n-p+2s_1-2]!![n+2m-2k-4]!!}{[2r-2k]!![2r+n-p+2s_1-2k-2]!![2k]!!}Q^kQ_{\mathbf{t}}^{r-k}\right)\\
&\qquad\times h_{s_1}(\mathbf{t})h_{s_2}(\mathbf{y}),
\end{aligned}
\tag{44}
$$

where, as before, $r=(m-s_1-s_2)/2$.

We denote by $\hat{t}_{s_1,s_2}^{n,p;\,m}(Q_{\mathbf{t}},Q_{\mathbf{y}})$ the expression at $h_{s_1}(\mathbf{t})h_{s_2}(\mathbf{y})$ on the right-hand side of (44):

$$
\begin{aligned}
\hat{t}_{s_1,s_2}^{n,p;\,m}(Q_{\mathbf{t}},Q_{\mathbf{y}})&=\sum_{k=0}^{r}\frac{(-1)^k q^{-2s_2k}[2r]!!}{[n+2m-4]!!}\\
&\quad\times\frac{[2r+n-p+2s_1-2]!![n+2m-2k-4]!!}{[2r-2k]!![2r+n-p+2s_1-2k-2]!![2k]!!}Q^kQ_{\mathbf{t}}^{r-k}.
\end{aligned}
\tag{45}
$$

In particular,

$$
\hat{t}_{0,0}^{n,p;\,m}(Q_{\mathbf{t}},Q_{\mathbf{y}})=\frac{[2r]!![2r+n-p-2]!!}{[n+2m-4]!!}\sum_{k=0}^{r}\frac{(-1)^k[n+2m-2k-4]!!Q^kQ_{\mathbf{t}}^{r-k}}{[2r-2k]!![2r+n-p-2k-2]!![2k]!!},
\tag{46}
$$

where m is even, is a zonal polynomial of the space $\mathcal{H}_m$ with respect to the subalgebra $U_q'(\mathrm{so}_p)\times U_q'(\mathrm{so}_{n-p})$. When m is not even, then the space $\mathcal{H}_m$ does not have a zonal polynomial.

In order to normalize expression (45) we have to calculate the coefficient $c_m^{(s_1,s_2)}$ at $Q_{\mathbf{t}}^r$ in $\hat{t}_{s_1,s_2}^{n,p;\,m}(Q_{\mathbf{t}},Q_{\mathbf{t}})$. It follows from (45) and from $Q=Q_{\mathbf{y}}+q^{-p}Q_{\mathbf{t}}$ that

$$
\begin{aligned}
c_m^{(s_1,s_2)}&=\sum_{k=0}^{r}\frac{(-1)^k q^{-2s_2k-pk}[2r]!!}{[n+2m-4]!!}\,\frac{[2r+n-p+2s_1-2]!![n+2m-2k-4]!!}{[2r-2k]!![2r+n-p+2s_1-2k-2]!![2k]!!}\\
&={}_2\varphi_1(q^{-2(2r+n-p+2s_1-2)},q^{-4r};\quad q^{-2n-4m+8};\quad q^4,q^{4-4s_2-2p}).
\end{aligned}
$$

By formula (31) we have

$$
c_m^{(s_1,s_2)}=\frac{(q^{4-4s_2-2p-4r};q^4)_r}{(q^{-2n-4m+8};q^4)_r}.
$$

Repeating the reasoning of Sec. VI for derivation of formula (34), we fulfill a normalization of expression (45). The normalized expression has the form

$$
t_{s_1,s_2}^{n,p;\,m}(Q_{\mathbf{t}},Q_{\mathbf{y}})=\left(\frac{[n+2s_1-p-2]!!q^{(n-p-1)r+2s_2r+s_1s_2}}{[2r]!![2s_1+n+2r-p-2]!!c_m^{(s_1,s_2)}}\right)^{1/2}\hat{t}_{s_1,s_2}^{n,p;\,m}(Q_{\mathbf{t}},Q_{\mathbf{y}}).
$$

In order to construct an orthonormal basis of the space $\mathcal{H}_m$ corresponding to the reduction $U_q'(\mathrm{so}_n)\supset U_q'(\mathrm{so}_p)\times U_q'(\mathrm{so}_{n-p})$ in an explicit form, we note that

$$
\langle t_{s_1,s_2}^{n,p;\,m}(Q_{\mathbf{t}},Q_{\mathbf{y}})h_{s_1}(\mathbf{t})h_{s_2}(\mathbf{y}),t_{s_1,s_2}^{n,p;\,m}(Q_{\mathbf{t}},Q_{\mathbf{y}})h_{s_1}(\mathbf{t})h_{s_2}(\mathbf{y})\rangle=\langle h_{s_1}(\mathbf{t}),h_{s_1}(\mathbf{t})\rangle\langle h_{s_2}(\mathbf{y}),h_{s_2}(\mathbf{y})\rangle.
$$

Therefore, for construction of such a basis we have to take orthonormal bases $h^{(i)}_{s_1}(\mathbf{t})$ and $h^{(j)}_{s_2}(\mathbf{y})$ of the spaces $\mathcal{H}^{(\mathbf{t})}_{s_1}$ and $\mathcal{H}^{(\mathbf{y})}_{s_2}$ of homogeneous q-harmonic polynomials in $\mathbf{t}$ and $\mathbf{y}$, respectively, and to construct the products

$$t^{n,p;\,m}_{s_1,s_2}(Q_{\mathbf{t}},Q_{\mathbf{y}})h^{(i)}_{s_1}(\mathbf{t})h^{(j)}_{s_2}(\mathbf{y}), \tag{47}$$

$$s_1+s_2\equiv m(\mathrm{mod}\,2),\quad s_1+s_2\leqslant m,\quad i=1,2,\ldots,\dim\mathcal{H}^{(\mathbf{t})}_{s_1},\quad j=1,2,\ldots,\dim\mathcal{H}^{(\mathbf{y})}_{s_2}.$$

It is easy to calculate that the number of elements (47) is equal to $\dim\mathcal{H}_m$. From the other side, it is proved as in the case of the basis elements (35) that the elements (47) are orthogonal to each other. Therefore, the polynomials (47) constitute an orthonormal basis of the space $\mathcal{H}_m$. In particular, we can take the elements $\Xi_{\mathbf{s}_1}(\mathbf{t})$, $\mathbf{s}_1=(s_1,s_1',\ldots)$, and $\Xi_{\mathbf{s}_2}(\mathbf{y})$, $\mathbf{s}_2=(s_2,s_2',\ldots)$, of the type (35) as orthonormal bases of the spaces $\mathcal{H}^{(\mathbf{t})}_{s_1}$ and $\mathcal{H}^{(\mathbf{y})}_{s_2}$, respectively. Then the elements

$$t^{n,p;\,m}_{s_1,s_2}(Q_{\mathbf{t}},Q_{\mathbf{y}})\Xi_{\mathbf{s}_1}(\mathbf{t})\Xi_{\mathbf{s}_2}(\mathbf{y}) \tag{48}$$

form an orthonormal basis of $\mathcal{H}_m$ corresponding to the chain

$$U'_q(\mathrm{so}_n)\supset U'_q(\mathrm{so}_p)\times U'_q(\mathrm{so}_{n-p})\supset U'_q(\mathrm{so}_{p-1})\times U'_q(\mathrm{so}_{n-p-1})\supset\cdots. \tag{49}$$

As was mentioned previously, in order to construct different orthonormal bases of $\mathcal{H}_m$ the tree method from Sec. 10.2 in Ref. 1 can be used. To different trees there correspond different chains of subalgebras of $U'_q(\mathrm{so}_n)$ and orthonormal bases corresponding to them. As in Sec. VI, in this way we obtain q-analogs of different separation of variables.

In the following, for derivation of formulas of action of the operators θ_j upon basis elements corresponding to the reduction (49), we need another basis of $\mathcal{H}_m$. It is obtained from the basis (48) if the elements $\Xi_{\mathbf{s}_1}(\mathbf{t})$ of $\mathcal{H}^{(\mathbf{t})}_{s_1}$ are replaced by the polynomials $\tilde{\Xi}_{\mathbf{s}_1}(\mathbf{t})$, where $\tilde{\Xi}_{\mathbf{s}_1}(\mathbf{t})$ is obtained from $\Xi_{\mathbf{s}_1}(\mathbf{t})$ by replacement of $x_{p+1},x_{p+2},\ldots,x_n$ by $x_n,x_{n-1},\ldots,x_{p+1}$, respectively, and q by q^{-1}. It is proved by a direct calculation that $\Delta_{\mathbf{t}}\tilde{\Xi}_{\mathbf{s}_1}(\mathbf{t})=0$. Thus, we have the orthonormal basis

$$\Xi^{n,p}_{\mathbf{s}_1,\mathbf{s}_2}(\mathbf{x})=t^{n,p;\,m}_{s_1,s_2}(Q_{\mathbf{t}},Q_{\mathbf{y}})\tilde{\Xi}_{\mathbf{s}_1}(\mathbf{t})\tilde{\Xi}_{\mathbf{s}_2}(\mathbf{y}) \tag{50}$$

of $\mathcal{H}_m$.

For calculation in the following we shall use the polynomials

$$\tilde{h}^{n-p}_{s_1,s_2}(\mathbf{t}):=\tilde{t}^{\,p,s_1}_{s_1'}(Q_{\mathbf{t}},x_{p+1})\tilde{h}_{s_1'}(\mathbf{t}') \tag{51}$$

multiple to $\tilde{\Xi}_{s_1}(\mathbf{t})$, where $\mathbf{t}'=(x_{p+2},x_{p+3},\ldots,x_n)$ and $\tilde{t}^{\,p,s_1}_{s_1'}(Q_{\mathbf{t}},x_{p+1})$ and $\tilde{h}_{s_1'}(\mathbf{t}')$ are obtained from $\hat{t}^{\,p,s_1}_{s_1'}(Q_{\mathbf{t}},x_n)$ and $h_{s_1'}(x_{p+1},\ldots,x_{n-1})$ by the replacement mentioned previously. For the polynomials (51) the following lemma is proved in the same way as Lemma 1.

Lemma 2: The following relations are true in the space of q-harmonic polynomials in $x_{p+1},x_{p+2},\ldots,x_n$:

$$\gamma_{p+1}\partial_{p+1}\tilde{h}^{n-p}_{s_1,s_1'}(\mathbf{t})=q^{s_1'}[s_1-s_1']\frac{[n-p+s_1+s_1'-3]}{[n-p+2s_1-4]}\tilde{h}^{n-p}_{s_1-1,s_1'}(\mathbf{t}),$$

$$\tilde{h}^{n-p}_{s_1,s_1'}(\mathbf{t})x_{p+1}-\frac{q^{n-p-1}Q_{\mathbf{t}}\gamma_{p+1}\partial_{p+1}\tilde{h}^{n-p}_{s_1,s_1'}(\mathbf{t})}{[n-p+2s_1-2]}=q^{-s_1'}\tilde{h}^{n-p}_{s_1+1,s_1'}(\mathbf{t}).$$

IX. REPRESENTATIONS T_m IN $U'_q(\mathrm{so}_p)\times U'_q(\mathrm{so}_{n-p})$ BASIS

The aim of this section is to derive formulas giving the action of the operators θ_j upon the basis (50) corresponding to the reduction (49).

First, we obtain the action of the operator $T_m(I_{p+1,p})=\theta_p$ upon non-normalized basis vectors. For this, we calculate

$$\theta_p(Q_{\mathbf{t}}^r h_{s_1}(\mathbf{t})h_{s_2}(\mathbf{y}))=Q_{\mathbf{t}}^r h_{s_1}(\mathbf{t})x_{p+1}q^{s_2-1}(\gamma_p^{-1}\partial_p h_{s_2}(\mathbf{y}))-q^{-s_2}(\gamma_{p+1}\partial_{p+1}(Q_{\mathbf{t}}^r h_{s_1}(\mathbf{t}))h_{s_2}(\mathbf{y})x_p,$$

where $h_{s_1}\in\mathcal{H}_{s_1}^{(\mathbf{t})}$ and $h_{s_2}\in\mathcal{H}_{s_2}^{(\mathbf{y})}$. Using the Leibnitz rule

$$\partial_{p+1}(f_1(x_{p+1},\ldots,x_n)f_2(x_{p+1},\ldots,x_n))=(\gamma_{p+1}^{-1}f_1)(\partial_{p+1}f_2)+(\partial_{p+1}f_1)(\gamma_{p+1}\gamma_{p+2}\cdots\gamma_n f_2)$$

we obtain

$$\begin{aligned}\gamma_{p+1}\partial_{p+1}(Q_{\mathbf{t}}^r h_{s_1}(\mathbf{t}))&=\gamma_{p+1}((\gamma_{p+1}^{-1}Q_{\mathbf{t}}^r)\partial_{p+1}h_{s_1}(\mathbf{t})+(\partial_{p+1}Q_{\mathbf{t}}^r)(\gamma_{p+1}\gamma_{p+2}\ldots\gamma_n h_{s_1}(\mathbf{t})))\\&=Q_{\mathbf{t}}^r(\gamma_{p+1}\partial_{p+1}h_{s_1}(\mathbf{t}))+(\gamma_{p+1}\partial_{p+1}Q_{\mathbf{t}}^r)q^{s_1}\gamma_{p+1}h_{s_1}(\mathbf{t})\\&=Q_{\mathbf{t}}^r(\gamma_{p+1}\partial_{p+1}h_{s_1}(\mathbf{t}))+[2r]q^{2r+2s_1-1}Q_{\mathbf{t}}^{r-1}h_{s_1}(\mathbf{t})x_{p+1},\end{aligned}$$

where

$$\gamma_{p+1}\partial_{p+1}Q_{\mathbf{t}}^r=Q_{\mathbf{t}}^{r-1}x_{p+1}q^{2r-1}[2r].$$

By means of this relation and Lemmas 1 and 2 we get

$$\begin{aligned}\theta_p(Q_{\mathbf{t}}^r h_{s_1}(\mathbf{t})h_{s_2}(\mathbf{y}))=&\frac{q^{s_2-2s_1-2r}[n-4+2s_1+2s_2+2r]}{[n-p+2s_1-2][p+2s_2-2]}Q_{\mathbf{t}}^{r+1}(\gamma_{p+1}\partial_{p+1}\tilde{h}_{s_1,s_1'}^{n-p}(\mathbf{t}))\\&\times(\gamma_p^{-1}\partial_p h_{s_2,s_2'}^p(\mathbf{y}))+q^{s_2-s_1'-2r-1}\frac{[p+2s_2+2r-2]}{[p+2s_2-2]}Q_{\mathbf{t}}^r\tilde{h}_{s_1+1,s_1'}^{n-p}(\mathbf{t})\\&\times(\gamma_p^{-1}\partial_p h_{s_2,s_2'}^p(\mathbf{y}))-q^{-s_2+s_2'+2r}\frac{[n-p+2s_1+2r-2]}{[n-p+2s_1-2]}Q_{\mathbf{t}}^r\\&\times(\gamma_{p+1}\partial_{p+1}\tilde{h}_{s_1,s_1'}^{n-p}(\mathbf{t}))h_{s_2+1,s_2'}^p(\mathbf{y})\\&-q^{2s_1-s_2-s_1'+s_2'+2r-1}[2r]Q_{\mathbf{t}}^{r-1}\tilde{h}_{s_1+1,s_1'}^{n-p}(\mathbf{t})h_{s_2+1,s_2'}^p(\mathbf{y}),\end{aligned}\tag{52}$$

where the expressions $\gamma_{p+1}\partial_{p+1}\tilde{h}_{s_1,s_1'}^{n-p}(\mathbf{t})$ and $\gamma_p^{-1}\partial_p h_{s_2,s_2'}^p(\mathbf{y})$ are equal to

$$\gamma_{p+1}\partial_{p+1}\tilde{h}_{s_1,s_1'}^{n-p}(\mathbf{t})=q^{s_1'}[s_1-s_1']\frac{[n-p+s_1+s_1'-3]}{[n-p+2s_1-4]}\tilde{h}_{s_1-1,s_1'}^{n-p}(\mathbf{t}),$$

$$\gamma_p^{-1}\partial_p h_{s_2,s_2'}^p(\mathbf{y})=q^{-s_2'}[s_2-s_2']\frac{[p+s_2+s_2'-3]}{[p+2s_2-4]}h_{s_2-1,s_2'}^p(\mathbf{y}).$$

Acting by H_m upon both sides of (52) and taking into account that H_m commutes with θ_p, we obtain the action formula for the non-normalized vectors. It follows from this formula how θ_p acts upon normalized polynomials $\Xi_{\mathbf{s}_1,\mathbf{s}_2}^{n,p}(\mathbf{x})\equiv|m;\mathbf{s}_1,\mathbf{s}_2\rangle$, where, as before, $\mathbf{s}_1=(s_1,s_1',s_1'',\ldots)$, $\mathbf{s}_2=(s_2,s_2',s_2'',\ldots)$. This action is given by

$$\theta_p|m;\mathbf{s}_1,\mathbf{s}_2\rangle=-K_{s_1}L_{s_2}([m-s_1-s_2][m+s_1+s_2+n-2])^{1/2}|m;\mathbf{s}_1^{+1},\mathbf{s}_2^{+1}\rangle$$
$$+K_{s_1}L_{s_2-1}([m-s_1+s_2+p-2][m+s_1-s_2+n-p])^{1/2}|m;\mathbf{s}_1^{+1},\mathbf{s}_2^{-1}\rangle$$
$$-K_{s_1-1}L_{s_2}([m+s_1-s_2+n-p-2][m-s_1+s_2+p])^{1/2}|m;\mathbf{s}_1^{-1},\mathbf{s}_2^{+1}\rangle$$
$$+K_{s_1-1}L_{s_2-1}([m-s_1-s_2+2][m+s_1+s_2+n-4])^{1/2}|m;\mathbf{s}_1^{-1},\mathbf{s}_2^{-1}\rangle,$$

where $\mathbf{s}_i^{\pm 1}$ is the set $\mathbf{s}_i$ with s_i replaced by $s_i\pm 1$, respectively, and

$$K_{s_1}=\left(\frac{[s_1-s_1'+1][s_1+s_1'+n-p-2]}{[2s_1+n-p][2s_1+n-p-2]}\right)^{1/2},$$

$$L_{s_2}=\left(\frac{[s_2-s_2'+1][s_2+s_2'+p-2]}{[2s_2+p][2s_2+p-2]}\right)^{1/2}.$$

This formula coincides with one given for this type of irreducible representation of $U_q'(\mathrm{so}_n)$ in Ref. 15.

The action of operators θ_k, $1\leqslant k<p$, upon the basis (50) is given by the formulas of Theorem 1 written for the algebra $U_q'(\mathrm{so}_p)$ with $m_p=s_2$, $m_{p-1}=s_2',\ldots$. The action of operators θ_k, $p<k<n$, is given by the formulas of Theorem 1 for the operators $-\theta_{n-k}$ of the algebra $U_q'(\mathrm{so}_{n-p})$, respectively, with $m_{n-p}=s_1$, $m_{n-p-1}=s_1',\ldots$.

X. SPECTRAL DECOMPOSITIONS OF SOME REPRESENTATIONS

The above-obtained results allow us to decompose the reducible representations constructed in the previous sections into irreducible constituents. In Sec. IV we gave the representation ρ_m of $U_q(\mathrm{sl}_n)$ on the space $\mathcal{A}_m$ of homogeneous polynomials. It is an irreducible representation with highest weight $(m,0,\ldots,0)$. The restriction of this representation to the subalgebra $U_q'(\mathrm{so}_n)$ was denoted by $T^{(m)}$. Since for $T^{(m)}$ we have the decomposition (17) and $T_{m-2j}\sim R_{m-2j}$, where R_k are the irreducible class 1 representations of $U_q'(\mathrm{so}_n)$, then

$$\rho_m\downarrow_{U_q'(\mathrm{so}_n)}=\bigoplus_{0\leqslant 2j\leqslant m}R_{m-2j},\quad T^{(m)}=\bigoplus_{0\leqslant 2j\leqslant m}R_{m-2j},$$

where summations are such as in (17).

The results of Sec. IX show how the restriction of the representation $T_m\sim R_m$ of $U_q'(\mathrm{so}_n)$ onto the subalgebra $U_q'(\mathrm{so}_p)\times U_q'(\mathrm{so}_{n-p})$ decomposes into irreducible representations:

$$R_m\downarrow_{U_q'(\mathrm{so}_p)\times U_q'(\mathrm{so}_{n-p})}=\bigoplus_{s_1,s_2}(R_{s_1}\times R_{s_2}),$$

where summation is over non-negative integers s_1 and s_2 such that $s_1+s_2\equiv 0(\mathrm{mod}\,m)$ and $s_1+s_2\leqslant m$.

The formulas

$$ke=q^4ek,\quad kf=q^{-4}fk,\quad ef-fe=\frac{k-k^{-1}}{q^2-q^{-2}}$$

determine the quantum algebra $U_{q^2}(\mathrm{sl}_2)$. The algebra homomorphism $\omega: U_{q^2}(\mathrm{sl}_2)\to\mathcal{A}$ uniquely determined by

$$w(e)=\frac{\hat{Q}}{q+q^{-1}},\quad w(f)=-\frac{\Delta}{q+q^{-1}},\quad \omega(k)=q^n\gamma_1^2\cdots\gamma_n^2\equiv q^n\gamma^2$$

is a representation of $U_{q^2}(\mathrm{sl}_2)$ (see Ref. 5). Since the operators $\omega(e)$, $\omega(f)$, and $\omega(k)$ commute with the operators θ_j (see Ref. 5), the representation $\omega \times T$ of the algebra $U_{q^2}(\mathrm{sl}_2) \times U'(\mathrm{so}_n)$ acts on $\mathcal{A}$, where T is determined by formula (10). This representation is reducible. Let us decompose it into irreducible components.

By (21), we have $\mathcal{A} = \oplus_{m \geqslant 0}(\mathbb{C}[Q] \otimes \mathcal{H}_m)$. The subspaces $\mathbb{C}[Q] \otimes \mathcal{H}_m$ are irreducible under $U_{q^2}(\mathrm{sl}_2) \times U'(\mathrm{so}_n)$, since the space $\mathbb{C}[Q]$ is pointwise invariant under $U'(\mathrm{so}_n)$ and for $f \in \mathbb{C}[Q]$ and $h_m \in \mathcal{H}_m$ we have

$$\hat{Q}(f(Q) \otimes h_m) = Qf(Q) \otimes h_m, \tag{53}$$

$$\Delta(Q^r \otimes h_m) = [2r][2r+2m+n-2]Q^{r-1} \otimes h_m, \tag{54}$$

$$k(Q^r \otimes h_m) = q^n \gamma^2 (Q^r \otimes h_m) = q^{4r+2m+n}(Q^r \otimes h_m). \tag{55}$$

These formulas show that $U_{q^2}(\mathrm{sl}_2)$ acts on $\mathbb{C}[Q]$ and $U'(\mathrm{so}_n)$ acts on $\mathcal{H}_m$. However, this action of $U_{q^2}(\mathrm{sl}_2)$ depends on the component $\mathcal{H}_m$. Taking the basis

$$|r\rangle := [2r]!\, Q^r, \quad r = 0,1,2,\ldots,$$

in the space $\mathbb{C}[Q]$, we find from (53) to (55) that

$$\omega(f)|r\rangle = -[r+m-1+n/2]_{q^2}|r-1\rangle,$$

$$\omega(e)|r\rangle = [r+1]_{q^2}|r+1\rangle, \quad \omega(k)|r\rangle = (q^2)^{m+2r+n/2}|r\rangle.$$

Comparing this representation with the known irreducible representations of $U_{q^2}(\mathrm{sl}_2)$ (see, e.g., Ref. 16) we derive that the irreducible representation of $U_{q^2}(\mathrm{sl}_2)$ of the discrete series with lowest weight $m+n/2$ is realized on the component $\mathbb{C}[Q]$ of the space $\mathbb{C}[Q] \otimes \mathcal{H}_m$. We denote this representation of $U_{q^2}(\mathrm{sl}_2)$ by $D_{m+n/2}$.

Thus, we derived that on the subspace $\mathbb{C}[Q] \otimes \mathcal{H}_m$ of the space $\mathcal{A}$ acts the irreducible representation $D_{m+n/2} \times T_m$ of the algebra $U_{q^2}(\mathrm{sl}_2) \times U'(\mathrm{so}_n)$. This means that for the reducible representation $\omega \otimes T$ we have the following decomposition into irreducible components:

$$\omega \otimes T = \bigoplus_{m=0}^{\infty} D_{m+n/2} \times T_m.$$

It is a q-analog of the corresponding decomposition of the classical case (see Ref. 1, Sec. 12.3).

Diagram projection rules for recoupling diagrams in the Racah–Wigner category

William P. Joyce[a)]

(Received 17 April 2000; accepted for publication 20 November 2000)

This paper gives three important techniques for recoupling coefficients of an arbitrary number or irreducible representations: factorization as a product of smaller degree recoupling coefficients, diagram projection projecting a recoupling diagram to obtain constraints on recoupling coefficients, and primitive expansion expressing a recoupling coefficient in terms of primitive recoupling coefficients. The first technique reduces a recoupling coefficient to its essential and simplest form. The second is many faceted allowing one to work at the recoupling level. Importantly, recoupling diagrams can be used to construct a complete set of constraints on the recoupling coefficients. The third allows large degree recoupling coefficients to be expressed in terms of primitive recoupling coefficients. An example of this is the fact that the $9j$ symbol is defined by the $3j$ and $6j$ symbols. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1339830]

I. INTRODUCTION

The central goals of group representation theory[1] are to determine the representations of a group, determine which of these are irreducible, and decompose any representation into a direct sum of irreducible representations. The converse, namely given the irreducible representations and rules concerning direct sum decomposition determine the original group, is given by Tannaka–Krein duality.[2] The Racah–Wigner calculus[3,4] assumes this knowledge and proceeds to unravel the properties of the mappings between representations. This falls squarely into the realm of category theory[5] and homological algebra. The important properties are Schur's lemma, naturality, coherence,[6] and universal property.

Furthermore, given the number of labels often needed to index a recoupling coefficient, it is important to choose appropriate notation. This notation has to be precise to account for the complex relationships between labels yet still represent the underlying structure of recoupling. This we achieve through a suitable bra ket format together with the pictorial power of binary trees. Also the often complex relationships between mappings requires a mathematical formalism to cope with the ideas involved; such a formalism is best given using category theory which provides a concrete link between binary trees and the bra ket notation. In recent years category theory is finding relevance to knot theory and quantum groups.[7]

The formulation of the Racah–Wigner calculus as a ring category is given in Joyce and Butler,[8] Joyce.[9] The original sources on ring categories are Kelly[10] and Laplaza.[11] The reader should consult these sources for a complete understanding of the category theoretic issues. This paper gives concise definitions for statement, coupling, recoupling, and recoupling coefficient. The notion of coupling relies on the concept of universal property and the notion of recoupling on naturality and coherence; all ideas only found in category theory. The recoupling coefficient is generated through the notion of a projection scheme. This paper utilizes these notions to give three important techniques for effectively handling recoupling coefficients: factorization of recoupling coefficients as a product of lower degree recoupling coefficients (without summation), expansion in terms of primitive recoupling coefficients, and a set of rules for obtaining recoupling coefficient

a)Electronic mail: joyce@ics.mq.edu.au

constraints corresponding to a given recoupling diagram. These three techniques provide us with the basic tools to handle recoupling coefficient equations at the formal recoupling level.

An important application of these techniques is to obtain recoupling coefficient constraints underlying any recoupling diagram. It is a mechanical application of the rules, regardless of the number of irreducible representations coupled together, to obtain the equations of constraint. The constraint equations can be reduced further using primitive expansions. The primitive expansion technique allows one to write a general recoupling coefficient in terms of primitive associativity and commutativity recoupling coefficients. These ideas underlie a paper in preparation devoted to the algorithmic calculation of general recoupling coefficients from an initial set. The method is by direct calculation and unlike present methods; for example, see Butler *et al.*,[12] Searle,[13] and Searle and Butler.[14] All of these methods are based on solving linear recursion equations.

Finally, we use the method of diagram projection to determine complete sets of constraints on the recoupling coefficients. For the diagrams of a symmetric tensor category we deduce the symmetry, pentagon, and hexagon equations. For the j symbols of Wigner we deduce the symmetry, Biedenharn–Elliott and Racah backcoupling equations.

In what follows the following conventions are assumed. The group G underlying all representations is assumed to be reductive. The set Irr_G is a family of irreducible representations of G containing exactly one representation for each isomorphism class. The elements of Irr_G serve to label the isomorphism classes of irreducible representations. We call the elements of Irr_G irreps for short. The Racah–Wigner category $\mathbf{RW}_G$ is generated from Irr_G as a full ring subcategory of $\mathbf{URep}_G$. $\mathbf{URep}_G$ is the category of unitary representations whose objects are unitary representations of G and morphisms are G-equivariant linear maps (intertwining operators). Moreover, $\mathbf{URep}_G$ is a ring category with bifunctors direct sum $\oplus:\mathbf{URep}_G\times\mathbf{URep}_G\rightarrow\mathbf{URep}_G$ and tensor product $\otimes:\mathbf{URep}_G\times\mathbf{URep}_G\rightarrow\mathbf{URep}_G$. The objects of $\mathbf{RW}_G$ are all finite words of irreps generated by direct sum and tensor product. The important point is that we have made a choice of irreducible representation for each isomorphism class and restricted our attention to that set. The morphisms of $\mathbf{RW}_G$ are those inherited from $\mathbf{URep}_G$.

II. COUPLING

The notion of coupling is essential to the construction of recoupling coefficients. In this section we give a precise definition and the properties of couplings required by latter sections. Coupling provides the link between the notion of recoupling and recoupling coefficient. A coupling is a prescription for decomposing the tensor product of two irreps μ and ν into a direct sum

$$\mu\otimes\nu\cong\bigoplus_{\lambda\in\mathrm{Irr}_G} m_\lambda^{\mu,\nu}\lambda, \tag{1}$$

where $m_\lambda^{\mu,\nu}$ is the multiplicity of λ in $\mu\otimes\nu$. We assume the convention that if $m_\lambda^{\mu,\nu}=0$ then λ is not part of the direct sum.

Definition 1: A coupling between two irreps μ and ν is a family of bra kets $\{\langle k\lambda|\mu.\nu\rangle:\mu\otimes\nu\rightarrow\lambda\}_{k\lambda}$ where $k=1,2,\ldots,m_\lambda^{\mu,\nu}$ for each λ, satisfying the universal property of a category product: Let a be a representation. Given a family $\{\langle k\lambda|f|a\rangle:a\rightarrow\lambda\}_{k\lambda}$ of bra kets there exists a unique map $\langle\mu.\nu|f|a\rangle:a\rightarrow\mu.\nu$ such that the diagram of Fig. 1 commutes, or equivalently $\langle k\lambda|f|a\rangle=\langle k\lambda|\mu.\nu\rangle\langle\mu.\nu|f|a\rangle$.

A coupling projects out the components of the direct sum decomposition from a tensor product of two irreps. This is equivalent to choosing a basis for the vector space of intertwining operators from $\mu\otimes\nu$ to λ. Dual to the notion of coupling is that of a co-coupling, embedding the components of the direct sum decomposition into the tensor product of two irreps. This is equivalent to choosing a basis for the vector space of intertwining operators from λ to $\mu\otimes\nu$. The unique existence for expressions of vectors as linear combinations of basis vectors is expressed in lemma 1.

Lemma 1: For every coupling $\{\langle k\lambda|\mu.\nu\rangle\}_{k\lambda}$ there exists a unique family of bra kets $\{\langle\mu.\nu|k\lambda\rangle:\lambda\rightarrow\mu\otimes\nu\}_{k\lambda}$ with the following properties:

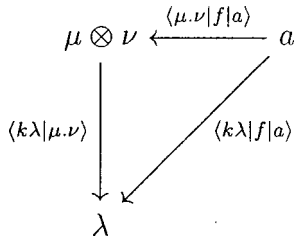

FIG. 1. The universal property of a category product.

(i) The bra kets $\{\langle \mu.\nu|k\lambda\rangle\}_{k\lambda}$ *have the universal property of a category coproduct: Let a be a representation. Given a family* $\{\langle a|f|k\lambda\rangle:\lambda\to a\}_{k\lambda}$ *of bra kets there exists a unique* $\langle a|f|\mu.\nu\rangle:\mu\otimes\nu\to a$ *such that the diagram of Fig. 2 commutes, or equivalently* $\langle a|f|k\lambda\rangle = \langle a|f|\mu.\nu\rangle\langle\mu.\nu|k\lambda\rangle$.

(ii) Every coupling bra ket has a co-coupling bra ket left inverse

$$\langle k\lambda|\mu\nu\rangle\langle\mu.\nu|k\lambda\rangle = 1_\lambda\,, \tag{2}$$

(*iii*)

$$\sum_{k\lambda} \langle\mu.\nu|k\lambda\rangle\langle k\lambda|\mu.\nu\rangle = 1_{\mu.\nu}\,. \tag{3}$$

The family of bra kets $\{\langle \mu.\nu|k\lambda\rangle\}_{k\lambda}$ is called a co-coupling and said to be the dual of the coupling $\{\langle k\lambda|\mu.\mu\rangle\}_{k\lambda}$. The dual co-coupling brackets are often denoted $\{\overline{\langle k\lambda|\mu.\nu\rangle}\}_{k\lambda}$.

An orthogonal choice of coupling can always be made as attested by lemma 2.

Lemma 2: Given irreps μ *and* ν *there exists an orthogonal coupling. That is,*

$$\langle k\lambda|\mu.\nu\rangle\langle\mu.\nu|k'\lambda'\rangle = \delta_{kk'}\delta_{\lambda\lambda'}\,. \tag{4}$$

A collection of couplings is called a family if for every ordered pair of irreps (μ,ν) there exists a unique coupling in the collection with domain $\mu\otimes\nu$.

III. RECOUPLING

In order to give a precise definition of recoupling we need to introduce the notion of a statement. Loosely a statement of irreps is any binary bracketed *n*-fold tensor product of irreps. We make this precise using the connection between binary trees and binary bracketings. Let *B* be a binary tree. We define the map

$$B\mapsto [\_]^B:\bigoplus_{n=1}^{\infty}\left(\prod_{i=1}^{n}\mathrm{Irr}_G\right)\to \mathbf{RW}_G \tag{5}$$

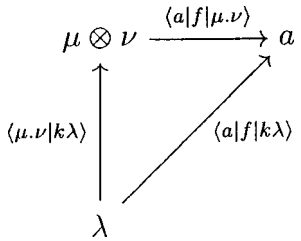

FIG. 2. The universal property of a category coproduct.

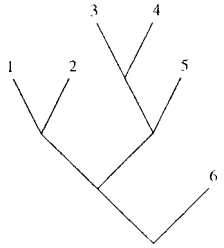

FIG. 3. Binary tree representation of the statement $((\lambda_1\otimes\lambda_2)\otimes((\lambda_3\otimes\lambda_4)\otimes\lambda_5))\otimes\lambda_6$.

by $(\lambda_1,\ldots,\lambda_n)\mapsto[\otimes_i]^B\lambda_i$ where the square brackets around the direct sum means that the irreps have been bracketed according to the binary tree B in the standard way. A full description of this association is given in Joyce[9] and Biedenharn and Louck.[3] A brief outline will now be given. The irreps of an ordered pair $(\lambda_1,\ldots,\lambda_n)$ are bijectively mapped onto the terminal vertices of the binary tree B starting with the left hand side terminal vertex and then working ones way around the terminal vertices of the binary tree in order. Each internal vertex represents a bracketed product of the left hand side branch with the right hand side branch. Inductively this generates a binary bracketed tensored product of the irreps $\lambda_1,\ldots,\lambda_n$. Each object $[\otimes_i]^B\lambda_i$ is called a statement of irreps. The number of irreps defines the length of the statement. For example, the statement $((\lambda_1\otimes\lambda_2)\otimes((\lambda_3\otimes\lambda_4)\otimes\lambda_5))\otimes\lambda_6$ of length six is represented by the binary tree of Fig. 3.

The permutation groups have an obvious action on an n-fold Cartesian product of irreps: Let $\pi\in S_n$ then

$$\pi:\prod_{i=1}^{n}\ \mathrm{Irr}_G\to\prod_{i=1}^{n}\ \mathrm{Irr}_G,(\lambda_1,\ldots,\lambda_n)\mapsto(\lambda_{\pi(1)},\ldots,\lambda_{\pi(n)}). \tag{6}$$

Hence we can define the obvious extension; the map $(\pi,B)\mapsto[\pi\_]^B$. Moreover, each map $[\pi\_]^B$ extends to a functor from the n-fold Cartesian product $\Pi_{i=1}^n\mathbf{RW}_G$ to $\mathbf{RW}_G$, again in an obvious way.

Intuitively a recoupling is an isomorphism between the two statements which at a formal level reorders and rebrackets the irreps. There is a potential problem of consistency where two alternative chains of composed isomorphisms representing recouplings achieving the same formal recoupling may differ. This is avoided by using the natural isomorphisms of associativity and commutativity provided by $\mathbf{RW}_G$ to generate the recoupling isomorphisms. The consistency issue is resolved in the affirmative by the coherence property of $\mathbf{RW}_G$. See Joyce[9] and Mac Lane[5] for the details. We make the following formal definition of a recoupling.

Definition 2: A recoupling rebracketing B as B' and reordering according to the permutation π is the natural isomorphism $\imath_\pi^{B'B}:[\_]^B\to[\pi\_]^{B'}$ generated by the multiplicative associativity and commutativity natural isomorphisms in $\mathbf{RW}_G$.

The degree of a recoupling is defined to be the length of the statement it acts upon.

IV. RECOUPLING COEFFICIENTS

In this section we set up a procedure for obtaining the recoupling coefficients corresponding to a recoupling using a family of couplings. Consider a statement $S=[\lambda_1,\ldots,\lambda_n]^B=[\otimes_{i=1}^n]^B\lambda_i$. We make the following useful definitions. A consecutive pair $\lambda_i\otimes\lambda_{i+1}$ of irreps bracketed together within the statement S is called a couple. The degree of a couple is the number of brackets it is embedded within. The degree of the statement S is defined to be the maximum degree of all its couples. We denote the degree of S by $\deg(S)$. As an example consider the statement $((\lambda_1\otimes\lambda_2)\otimes((\lambda_3\otimes\lambda_4)\otimes\lambda_5))\otimes\lambda_6$ of length six. The couples are $\lambda_1\otimes\lambda_2$ and $\lambda_3\otimes\lambda_4$ with degrees 1 and 2, respectively. Hence the degree of this statement is $\deg(S)=2$.

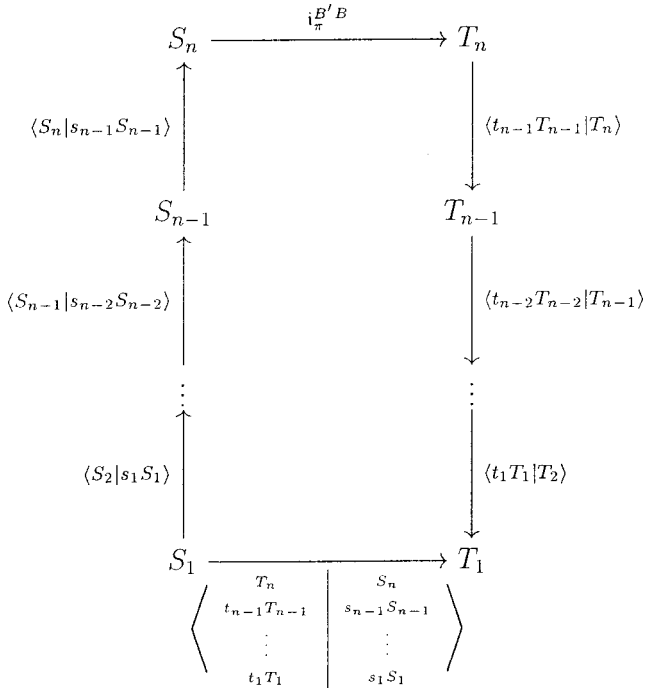

FIG. 4. Construction of recoupling coefficients.

To mechanize the projection of a statement S_n, where the subscript n is the length of the statement, we introduce the notion of a projection scheme which is a finite sequence $S_n,\ldots,S_1$ of statements, of decreasing degree constructed as follows. Let S_n be the given statement of length n. Define the statement S_{n-1} to be the statement of length $n-1$ derived from S_n as follows: Reading from left to right locate the first couple of degree $\deg(S_n)$. We call this the principal couple of S_n. We replace this couple with a dummy irrep label. This label stands in for the irreps in the decomposition of the principal couple and is said to be an internal irrep label. Note that we will also associate a dummy multiplicity label of which more will be said later. Continuing this process inductively we obtain a finite sequence $S_n,\ldots,S_1$ of statements. The last statement has length one and is a single irrep. The sequence obtained in this way we call the projection scheme of S_n. The number of (dummy) internal irreps is one less than the length of the statement and largely independent of the degree of the statement.

Let $\mathfrak{i}_\pi^{B'B}: S_n \to T_n$ be a recoupling of degree n between the statements S_n and T_n. The recoupling component bra kets for the recoupling are obtained as suggested by the diagram of Fig. 4. The vertical arms of the diagram represent the projection schemes for S_n and T_n. The vertical arrow at the ith level and on the left (resp. right) hand side of the diagram represents a co-coupling bra ket $\langle s_i \lambda | \mu.\nu \rangle$ (resp. coupling bra ket $\langle t_i \lambda | \mu.\nu \rangle$) taking the principal couple, $\mu \otimes \nu$ of S_{i+1} (resp. T_{i+1}) to the corresponding internal irrep λ of S_i (resp. T_i). Note that s_i (resp. t_i) is the multiplicity label appearing in the recoupling bra ket. In future the vertical arrows will only be labeled with the multiplicity instead of the entire bra ket. By Schur's lemma the recoupling bra kets are nonzero only if $S_1 = T_1$ and, moreover, are multiples of the identity. These multiples are called recoupling coefficients. We denote a recoupling coefficient with the same symbol as its recoupling bra ket. The order of a recoupling coefficient is defined to be the length n of the statement recoupled.

As an example of the procedure consider the recoupling depicted by the diagram in Fig. 5. In this example the vertical arrows are labeled by the multiplicity labels of the (co-)coupling brackets. The bottom horizontal arrow is the recoupling coefficient, denoted by

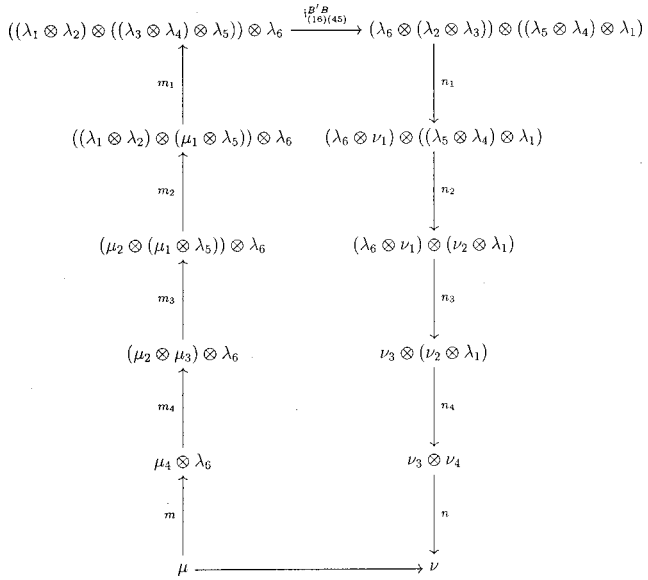

FIG. 5. Construction of the recoupling coefficients corresponding to the recoupling $i^{B'B}_{(16)(45)}:((\lambda_1\otimes\lambda_2)\otimes((\lambda_3\otimes\lambda_4)\otimes\lambda_5))\otimes\lambda_6\rightarrow(\lambda_6\otimes(\lambda_2\otimes\lambda_3))\otimes((\lambda_5\otimes\lambda_4)\otimes\lambda_1)$.

$$
\left\langle \begin{array}{ccccccccc}
(\lambda_6 & & (\lambda_2 & & \lambda_3)) & & ((\lambda_5 & & \lambda_4) & & \lambda_1) \\
& (\lambda_6 & & n_1\nu_1) & & ((\lambda_5 & & \lambda_4) & & \lambda_1) & \\
& & (\lambda_6 & & \nu_1) & & (n_2\nu_2 & & \lambda_1) & & \\
& & & n_3\nu_3 & & (\nu_2 & & \lambda_1) & & & \\
& & & & \nu_3 & & n_4\nu_4 & & & & \\
& & & & & n\nu & & & & &
\end{array} \right|
\left| \begin{array}{ccccccccc}
((\lambda_1 & & \lambda_2) & & ((\lambda_3 & & \lambda_4) & & \lambda_5)) & & \lambda_6 \\
& ((\lambda_1 & & \lambda_2) & & (m_1\mu_1 & & \lambda_5)) & & \lambda_6 & \\
& & (m_2\mu_2 & & (\mu_1 & & \lambda_5)) & & \lambda_6 & & \\
& & & (\mu_2 & & m_3\mu_3) & & \lambda_6 & & & \\
& & & & m_4\mu_4 & & \lambda_6 & & & & \\
& & & & & m\mu & & & & &
\end{array} \right\rangle . \tag{7}
$$

Note that for simplicity the tensor product symbols are not written in the recoupling coefficient at all and each multiplicity label appears below the couple it originates from and in front of the internal irrep to which it corresponds.

V. RECOUPLING COEFFICIENT FACTORIZATION

Often a recoupling coefficient can be factored as a product of smaller degree recoupling coefficients. This is always the case if the recoupling only modifies isolated subsections of the statement. A procedure will be developed here to reduce a recoupling coefficient to a product of essential (sub)recoupling coefficients. First we develop further the connection between binary trees and statements.

As we have seen, a statement S_n of length n is represented by a binary tree B_n with n terminal vertices. This binary tree can also represent the projection scheme for S_n. By removing the principal couple from B_n and labeling the new terminal vertex with the internal irrep label, one

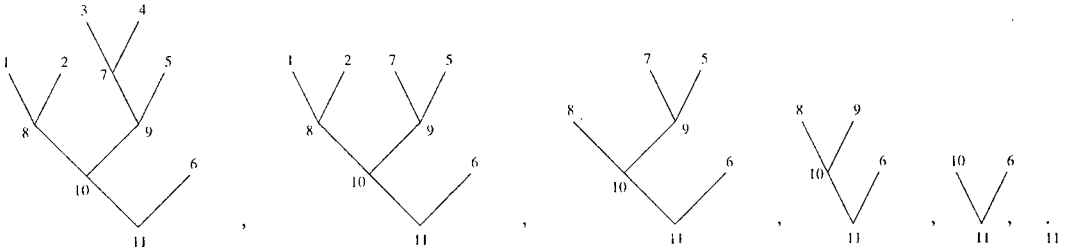

FIG. 6. Projection scheme of the statement $((\lambda_1\otimes\lambda_2)\otimes((\lambda_3\otimes\lambda_4)\otimes\lambda_5))\otimes\lambda_6$.

obtains the binary tree B_{n-1} representing the statement S_{n-1}. This process inductively generates the sequence $B_n,\ldots,B_1$ of binary trees corresponding to the projection scheme $S_n,\ldots,S_1$. Moreover, we can label the internal vertices of the binary trees with the dummy variables introduced by the projection scheme. Since such a close connection exists between binary trees and statements then we often denote the binary trees $B_n,\ldots,B_1$ by their corresponding statements $S_n,\ldots,S_1$. For example, consider the statement $((\lambda_1\otimes\lambda_2)\otimes((\lambda_3\otimes\lambda_4)\otimes\lambda_5))\otimes\lambda_6$ of Fig. 3. The binary tree sequence representing the projection scheme of this statement is given in Fig. 6.

Finally we introduce the following definition. Given an internal vertex μ for a binary tree B, define $B(\mu)$ to be the maximal binary subtree embedded in B with principal vertex μ. This $B(\mu)$ is obtained by removing the portion of the binary tree below the vertex μ.

The factorization of recoupling coefficients is in two steps. The first is more of a cosmetic simplification. Let $\mathrm{i}_\pi^{T_nS_n}:S_n\to T_n$ be the recoupling we wish to reduce. Given internal vertices μ of S_n and ν of T_n such that the binary subtrees $S_n(\mu)$ and $T_n(\nu)$ have the same set of terminal vertices then we identify the internal irrep labels ($\mu=\nu$). This makes sense because of the following.

Proposition 1: Let $\mathrm{i}_\pi^{T_nS_n}:S_n\to T_n$ *be a recoupling. If there exist internal vertices* μ, ν *such that the binary subtrees* $S_n(\mu)$ *and* $T_n(\nu)$ *have the same set of terminal vertex labels then*

$$\left\langle \begin{array}{c|c} T_n & S_n \\ t_{n-1}T_{n-1} & t_{n-1}S_{n-1} \\ \vdots & \vdots \\ t_1T_1 & s_1S_1 \end{array} \right\rangle \neq 0 \tag{8}$$

only if $\mu=\nu$.

This is a result of Schur's lemma and the linearity of couplings and recouplings.

The second step of the factorization is as follows. We divide each of the binary trees S_n and T_n into a finite sequence of nontrivial binary subtrees. We begin by taking S_n and T_n to be the initial sequences. Suppose there exist nontrivial binary trees B_S and B_T such that B_S is a subtree of S_n and B_T is a subtree of T_n. Furthermore, suppose B_S and B_T have the same set of vertex labels. (Note that the order of labeling may differ.) We divide the binary tree S_n at the vertex labeled by the principal vertex of B_S and replace S_n in the sequence with these two binary trees retaining the left/right hand distinction. Similarly divide T_n at the vertex labeled by the principal vertex of B_T and replace T_n in the sequence. Inductively we repeat this process on each member of the two growing sequences of binary trees until all pairs of nontrivial such binary trees have been exhausted. Thus S_n and T_n have each been divided into a finite sequence of binary trees. Denote these sequences by $(S_{n_1,1},\ldots,S_{n_m,m})$ and $(T_{n_1,1},\ldots,T_{n_m,m})$, respectively, where m is the number of binary trees and n_k is the number of terminal vertices of the kth binary tree. For each $k=1,2,...,m$ there is a recoupling $\mathrm{i}_k:S_{n_k,k}\to T_{n_k,k}$. Moreover, the original recoupling is given by composing the i_k's. This composition is independent of order.

Theorem 1: *The factorization procedure outlined above gives rise to the following factorization:*

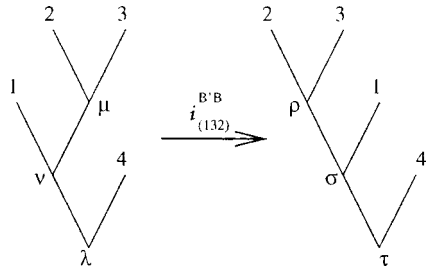

FIG. 7. Binary tree representation of the recoupling $i^{B'B}_{(132)}:(\lambda_1\otimes(\lambda_2\otimes\lambda_3))\otimes\lambda_4\rightarrow((\lambda_2\otimes\lambda_3)\otimes\lambda_1)\otimes\lambda_4$.

$$\left\langle \begin{array}{c|c} S_n & T_n \\ s_{n-1}S_{n-1} & t_{n-1}T_{n-1} \\ \vdots & \vdots \\ s_1S_1 & t_1T_1 \end{array} \right\rangle = \prod_{k=1}^{m} \left\langle \begin{array}{c|c} S_{n_k,k} & T_{n_k,k} \\ s_{n_k-1,k}S_{n_k-1,k} & t_{n_k-1,k}T_{n_k-1,k} \\ \vdots & \vdots \\ s_{1,k}S_{1,k} & t_{1,k}T_{1,k} \end{array} \right\rangle , \tag{9}$$

where $T_1=S_1=T_{1,k}=S_{1,k}$.

To illustrate the above factorization process consider the following recoupling $i^{B'B}_{(132)}:(\lambda_1\otimes(\lambda_2\otimes\lambda_3))\otimes\lambda_4\rightarrow((\lambda_2\otimes\lambda_3)\otimes\lambda_1)\otimes\lambda_4$. This recoupling is depicted by Fig. 7. The first step of the factorization procedure relabels ρ with μ, σ with ν, and τ with λ. The second step results in the sequences of binary trees given by Fig. 8 and the recouplings indicated between corresponding members. Finally by Theorem 1 we obtain the recoupling factorization

$$\left\langle \begin{array}{ccccc|ccccc} ((\lambda_2 & & \lambda_3) & & \lambda_1) & \lambda_4 & (\lambda_1 & & (\lambda_2 & & \lambda_3)) & \lambda_4 \\ & (m'\mu & & \lambda_1) & & \lambda_4 & & (\lambda_1 & & m\mu) & & \lambda_4 \\ & & n'\nu & & \lambda_4 & & & & n\nu & & \lambda_4 & \\ & & & k'\lambda & & & & & & k\lambda & & \end{array} \right\rangle$$

$$= \left\langle \begin{array}{ccc|ccc} \nu & & \lambda_4 & \nu & & \lambda_4 \\ & k'\lambda & & & k\lambda & \end{array} \right\rangle \left\langle \begin{array}{ccc|ccc} \mu & & \lambda_1 & \lambda_1 & & \mu \\ & n'\nu & & & n\nu & \end{array} \right\rangle$$

$$\cdot \left\langle \begin{array}{ccc|ccc} \lambda_2 & & \lambda_3 & \lambda_2 & & \lambda_3 \\ & m'\mu & & & m\mu & \end{array} \right\rangle . \tag{10}$$

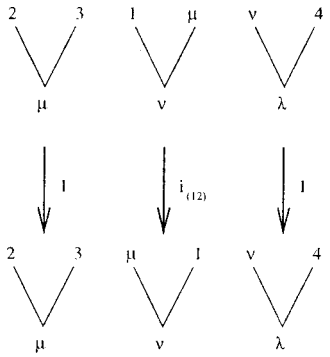

FIG. 8. Binary tree factorization of the recoupling $i^{B'B}_{(132)}:(\lambda_1\otimes(\lambda_2\otimes\lambda_3))\otimes\lambda_4\rightarrow((\lambda_2\otimes\lambda_3)\otimes\lambda_1)\otimes\lambda_4$.

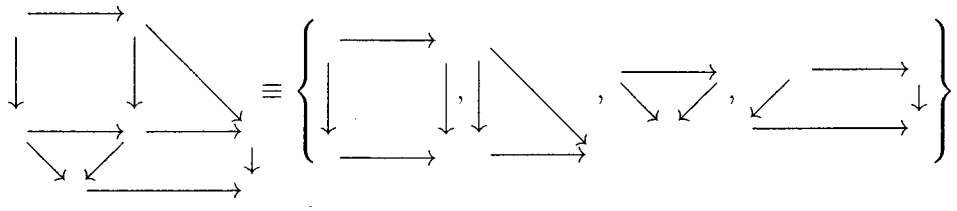

FIG. 9. An example of fragmentation.

Two of these are recoupling coefficients arising from identity recouplings. If the couplings are orthogonal then the identity recoupling coefficients are Kronecker deltas. Hence the recoupling coefficient would further reduce to

$$\delta_{kk'}\delta_{mm'}\left\langle \begin{matrix} \mu & & \lambda_1 \\ & n'\nu & \end{matrix} \middle| \begin{matrix} \lambda_1 & & \mu \\ & n\nu & \end{matrix} \right\rangle. \tag{11}$$

In this case an imposing recoupling coefficient was reduced to a product of small recoupling coefficients.

VI. RECOUPLING DIAGRAM PROJECTION RULES

Recouplings are isomorphisms that formally reorganize statements of irreps. Hence recouplings give rise to the notion of a recoupling diagram such as those in Figs. 11–17. These diagrams represent differing sequences of formal rearrangements resulting in the same recoupling. Because recouplings are isomorphisms there is no guarantee that differing sequences achieving the same recoupling compose to give the same isomorphism. Any diagram for which they are the same is said to commute. Recall that each recoupling corresponds to a recoupling coefficient. Hence the commutativity of a recoupling diagram is equivalent to a collection of constraint equations on the recoupling coefficients. In principle the manipulation of recoupling coefficient equations can be replaced by the formal manipulation of recoupling diagrams (or equivalently binary trees). To perform this replacement one requires a procedure for obtaining equations of constraint from recoupling diagrams. We call this process diagram projection. This section develops a set of simple rules which perform the task of diagram projection.

A recoupling diagram is any two dimensional connected directed graph such that each vertex has at least two arrows and no edges cross. The edges are labeled by statements and each arrow corresponds to the obvious recoupling. For examples see the various recoupling diagrams given in Figs. 11–17. Every recoupling diagram is equivalent to a collection of polygonal diagrams. Moreover, a minimal collection is given by the polygons bounding each interior region of the diagram. We call this process fragmentation and each polygon a fragment. For an example of fragmentation see Fig. 9.

Recall that each vertex of a diagram generates a projection scheme. Hence every arrow (or recoupling) can be projected onto its corresponding recoupling coefficient. The projection of a polygonal recoupling diagram results in a polygonal diagram whose arrows are recoupling bra kets and vertices are single irrep statements. Such a diagram is equivalent to an equation of constraint. Projecting the collection of fragments for a diagram gives the collection of constraints equivalent to the commutativity of the original recoupling diagram. The process may be visualized by the scheme given in Fig. 10.

The procedure for obtaining the constraint equation from a given recoupling polygon is given by the following set of rules.

Theorem 2: (*Polygonal Diagram Projection Rules*) *A given polygonal recoupling diagram commutes if and only if the recoupling coefficient constraint constructed by the following rules holds:*

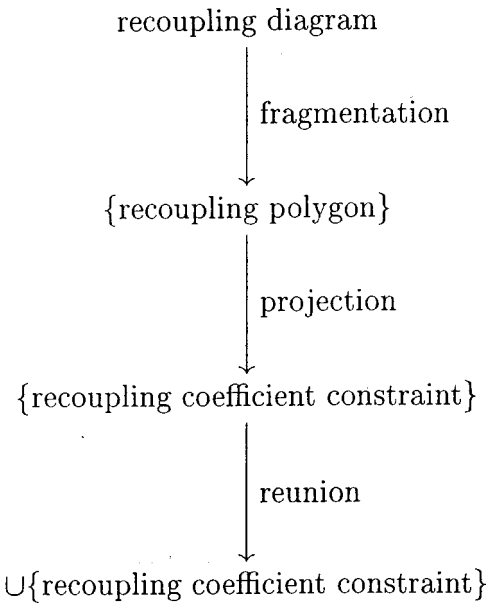

FIG. 10. Schematic depicting the extraction of the recoupling coefficient constraints corresponding to a recoupling diagram.

(i) Choose two vertices (possibly the same vertex) as a start and end vertex to split the polygonal diagram into two (resp. one) directed chains;
(ii) represent each arrow by the factorization of its corresponding recoupling coefficient;
(iii) compose the recoupling coefficients from right to left along each directed chain;
(iv) sum over all internal irrep labels and multiplicity labels that appear first in a ket and last in a bra (reading from left to right) for each recoupling expression;
(v) equate the recoupling coefficient expressions obtained. (Equate to the identity recoupling coefficient if there is only one expression.);
(vi) contract all identity recoupling coefficients with other recoupling coefficients where possible.

Two illustrations of the diagram projection rules are given in the proof of Theorem 3. We further illustrate these rules by deriving the generalized orthogonality condition satisfied by every recoupling coefficient. Let $\mathfrak{i}:S_n\rightarrow T_n$ be a recoupling. Consider the diagram projection of the trivial recoupling diagram given in Fig. 11. Diagram projection of this diagram, using the rules for polygonal diagram projection, gives the generalized recoupling coefficient orthogonality constraint

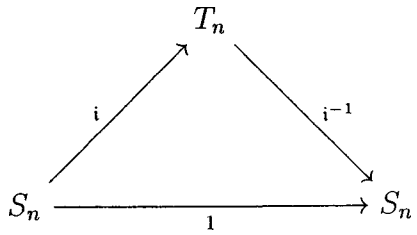

FIG. 11. The recoupling diagram $i^{-1}i=1$.

$$\sum_{i=1}^{n-1}\sum_{t_iT_i}\left\langle\begin{array}{c|c}S_n & T_n\\ s'_{n-1}S'_{n-1} & t_{n-1}T_{n-1}\\ \vdots & \vdots\\ s'_1S'_1 & t_1T_1\end{array}\right\rangle\left\langle\begin{array}{c|c}T_n & S_n\\ t_{n-1}T_{n-1} & s_{n-1}S_{n-1}\\ \vdots & \vdots\\ t_1T_1 & s_1S_1\end{array}\right\rangle=\left\langle\begin{array}{c|c}S_n & S_n\\ s'_{n-1}S'_{n-1} & s_{n-1}S_{n-1}\\ \vdots & \vdots\\ s'_1S'_1 & s_1S_1\end{array}\right\rangle. \tag{12}$$

If the couplings are orthogonal then the identity bra ket is a product of Kronecker deltas giving the standard orthogonality of recoupling coefficients. In particular the generalized orthogonality conditions for associative, commutative, and identity recoupling coefficients are given by taking $\mathfrak{i}$ to be $\mathfrak{a}$, $\mathfrak{c}$ and 1, respectively.

Note that not all recoupling diagrams give constraints on the recoupling coefficients as the following demonstrates.

Proposition 2: Given a recoupling polygon, then it is a natural diagram if and only if its diagram projection gives rise to no recoupling constraint.

This follows by noting that a polygon is a natural diagram if and only if the projection schema are not entangled. Hence the constraint obtained after diagram projection has recoupling coefficients with either an exact match on the other side of the expression or their inverse on the same side. Either way the sum over labels are not entangled and allow one to simply cancel coefficients on opposite sides or contract on the same side of the equation. Ultimately the constraint collapses completely to the equality of identity recoupling coefficients.

VII. RECOUPLING COEFFICIENT EXPANSION

Every recoupling can be built from a composed sequence of primitive recouplings. We call this a primitive expansion for the recoupling. In a symmetric tensor category the building block recouplings are the natural isomorphisms

$$\begin{gathered}1:1\to 1,\quad \alpha\mapsto 1_\alpha:\alpha\to\alpha,\\ \mathfrak{c}:\otimes\to\otimes\tau,\quad (\alpha,\beta)\mapsto\mathfrak{c}_{\alpha,\beta}:\alpha\otimes\beta\to\beta\otimes\alpha,\\ \mathfrak{a}:\otimes(\otimes\times 1)\to\otimes(1\times\otimes),\quad (\alpha,\beta,\gamma)\mapsto\mathfrak{a}_{\alpha,\beta,\gamma}:(\alpha\otimes\beta)\otimes\gamma\to\alpha\otimes(\beta\otimes\gamma),\end{gathered} \tag{13}$$

where τ is the flip map taking $(\alpha,\beta)\mapsto(\beta,\alpha)$. The primitive recouplings are those natural isomorphisms constructed from exactly one $\mathfrak{a}$ or $\mathfrak{c}$, as many 1s as required concatenated through $\otimes$ and finally binary bracketed. An example is $\mathfrak{i}:(((\lambda_1\otimes\lambda_2)\otimes\lambda_3)\otimes\lambda_4)\otimes\lambda_5\to\lambda_5\otimes((\lambda_2\otimes\lambda_3)\otimes(\lambda_1\otimes\lambda_4))$ given by the primitive expansion $\mathfrak{i}=(1.\mathfrak{a})[1.((1.\mathfrak{c}).1)][1.(\mathfrak{a}.1)]\mathfrak{c}$ where the recouplings $1.\mathfrak{a}$, $1.((1.\mathfrak{c}).1)$, $1.(\mathfrak{a}.1)$, and $\mathfrak{c}$ are primitive. Note that this is far from the only choice of primitive expansion for $\mathfrak{i}$.

A recoupling $\mathfrak{i}$ with a primitive expansion $\mathfrak{p}_1\ldots\mathfrak{p}_m$ forms the obvious polygonal recoupling diagram. Diagram projection of this diagram gives a primitive expansion of the recoupling coefficient for $\mathfrak{i}$ thus

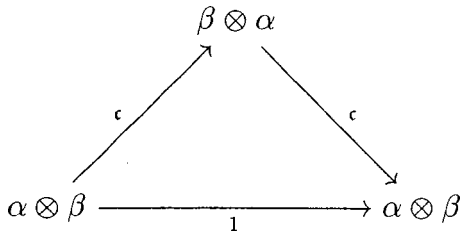

FIG. 12. The symmetry diagram.

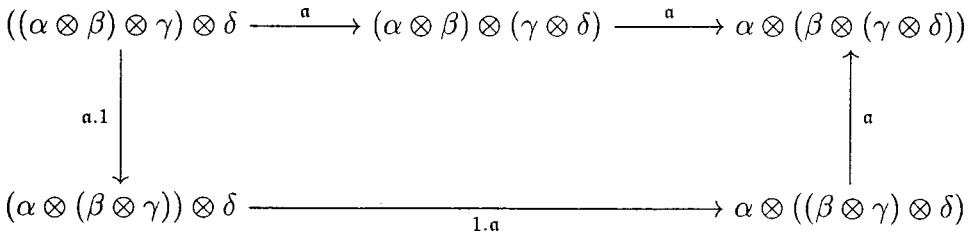

FIG. 13. The pentagon diagram.

$$\langle \vdots | \mathfrak{i} | \vdots \rangle = \sum_{\cdots} \langle \vdots | \mathfrak{p}_1 | \vdots \rangle \cdots \langle \vdots | \mathfrak{p}_m | \vdots \rangle, \tag{14}$$

where each $\langle \vdots | \mathfrak{p}_i | \vdots \rangle$ represents the recoupling coefficient factorization of the recoupling coefficient corresponding to $\mathfrak{p}_i$ and summation is over all labels appearing only on the left hand side of the expression.

VIII. COMPLETE SETS OF RECOUPLING COEFFICIENT CONSTRAINTS

There are many ways to recouple two statements that are obtained from differing sequences of formal rearrangements on statements of irreps. For example, the pentagon diagram given in Fig. 13 shows two different paths recoupling $((\alpha\otimes\beta)\otimes\gamma)\otimes\delta$ to $\alpha\otimes(\beta\otimes(\gamma\otimes\delta))$. The property of oherence demands that these two paths compose to give the same isomorphism. More generally coherence demands that all formally constructed recoupling diagrams commute. The standard coherence result of Mac Lane[5] in symmetric tensor categories guarantees that all (formal) recoupling diagrams commute if and only if the symmetry, pentagon, and hexagon diagrams given in Figs. 12, 13, and 14 commute.

A (minimal) generating set of recoupling coefficient constraints is obtained by diagram projecting the symmetry, pentagon, and hexagon diagrams.

Theorem 3: *All recoupling diagrams commute if and only if the following list of recoupling coefficient constraints hold:*

(i) The symmetry equation

$$\sum_l \left\langle \begin{matrix} \alpha & & \beta \\ & k'\lambda & \end{matrix} \middle| \begin{matrix} \beta & & \alpha \\ & l\lambda & \end{matrix} \right\rangle \left\langle \begin{matrix} \beta & & \alpha \\ & l\lambda & \end{matrix} \middle| \begin{matrix} \alpha & & \beta \\ & k\lambda & \end{matrix} \right\rangle = \left\langle \begin{matrix} \alpha & & \beta \\ & k'\lambda & \end{matrix} \middle| \begin{matrix} \alpha & & \beta \\ & k\lambda & \end{matrix} \right\rangle, \tag{15}$$

(ii) The pentagon equation

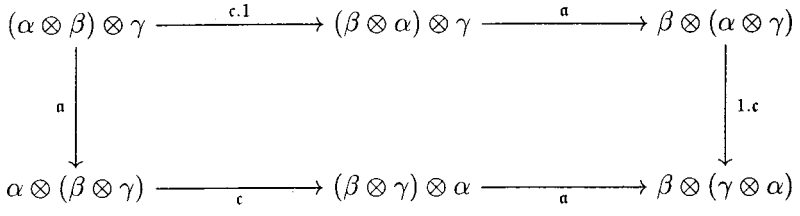

FIG. 14. The hexagon diagram.

$$\sum_{k'} \left\langle \begin{matrix} \alpha & & (\beta & & \rho) \\ & \alpha & & s\sigma & \\ & & l\lambda & & \end{matrix} \middle| \begin{matrix} (\alpha & & \beta) & & \rho \\ & m\mu & & & \\ & & k'\lambda & & \end{matrix} \right\rangle$$
$$\cdot \left\langle \begin{matrix} \mu & & (\gamma & & \delta) \\ & \mu & & r\rho & \\ & & k'\lambda & & \end{matrix} \middle| \begin{matrix} (\mu & & \gamma) & & \delta \\ & n\nu & & & \\ & & k\lambda & & \end{matrix} \right\rangle$$
$$= \sum_{\eta s' n'} \left\langle \begin{matrix} \beta & & (\gamma & & \delta) \\ & \beta & & r\rho & \\ & & s\sigma & & \end{matrix} \middle| \begin{matrix} (\beta & & \gamma) & & \delta \\ & h\eta & & & \\ & & s'\sigma & & \end{matrix} \right\rangle$$
$$\cdot \left\langle \begin{matrix} \alpha & & (\eta & & \delta) \\ & \alpha & & s'\sigma & \\ & & l\lambda & & \end{matrix} \middle| \begin{matrix} (\alpha & & \eta) & & \delta \\ & n'\nu & & & \\ & & k\lambda & & \end{matrix} \right\rangle$$
$$\cdot \left\langle \begin{matrix} \alpha & & (\beta & & \gamma) \\ & \alpha & & h\eta & \\ & & \eta'\nu & & \end{matrix} \middle| \begin{matrix} (\alpha & & \beta) & & \gamma \\ & m\mu & & & \gamma \\ & & n\nu & & \end{matrix} \right\rangle, \tag{16}$$

(iii) The hexagon equation

$$\sum_{m'n'} \left\langle \begin{matrix} \gamma & & \alpha \\ & n\nu & \end{matrix} \middle| \begin{matrix} \alpha & & \gamma \\ n'\nu & & \end{matrix} \right\rangle \left\langle \begin{matrix} \beta & & (\alpha & & \gamma) \\ & \beta & & n'\nu & \\ & & l\lambda & & \end{matrix} \middle| \begin{matrix} (\beta & & \alpha) & & \gamma \\ & m'\mu & & & \\ & & k\lambda & & \end{matrix} \right\rangle$$
$$\cdot \left\langle \begin{matrix} \beta & & \alpha \\ & m'\mu & \end{matrix} \middle| \begin{matrix} \alpha & & \beta \\ & m\mu & \end{matrix} \right\rangle$$
$$= \sum_{\eta k' l'} \left\langle \begin{matrix} \beta & & (\gamma & & \alpha) \\ & \beta & & n\nu & \\ & & l\lambda & & \end{matrix} \middle| \begin{matrix} (\beta & & \gamma) & & \alpha \\ & h\eta & & & \\ & & l'\lambda & & \end{matrix} \right\rangle \left\langle \begin{matrix} \eta & & \alpha \\ & l'\lambda & \end{matrix} \middle| \begin{matrix} \alpha & & \alpha \\ & & k'\lambda \end{matrix} \right\rangle$$
$$\times \left\langle \begin{matrix} \alpha & & (\beta & & \gamma) \\ & \alpha & & h\eta & \\ & & k'\lambda & & \end{matrix} \middle| \begin{matrix} (\alpha & & \beta) & & \gamma \\ & m\mu & & & \\ & & k\lambda & & \end{matrix} \right\rangle. \tag{17}$$

Proof: The proof is by diagram projection of the symmetry, pentagon, and hexagon diagrams. The symmetry equation follows immediately. Cutting the pentagon diagram at the top left hand side and top right hand side vertices [rule (i)], diagram projection gives [rules (ii) to (v)]

$$\sum_{m'k'r'} \left\langle \begin{matrix} \alpha & & (\beta & & \rho) \\ & \alpha & & s\sigma & \\ & & l\lambda & & \end{matrix} \middle| \begin{matrix} (\alpha & & \beta) & & \rho \\ & m'\mu & & & \\ & & k'\lambda & & \end{matrix} \right\rangle$$
$$\times \left\langle \begin{matrix} \gamma & & \delta \\ & r\rho & \end{matrix} \middle| \begin{matrix} \gamma & & \delta \\ & r'\rho & \end{matrix} \right\rangle \cdot \left\langle \begin{matrix} \mu & & (\gamma & & \delta) \\ & \mu & & r'\rho & \\ & & k'\lambda & & \end{matrix} \middle| \begin{matrix} (\mu & & \gamma) & & \delta \\ & n\nu & & & \\ & & k\lambda & & \end{matrix} \right\rangle$$
$$\times \left\langle \begin{matrix} \alpha & & \beta \\ & m'\mu & \end{matrix} \middle| \begin{matrix} \alpha & & \beta \\ & m\mu & \end{matrix} \right\rangle$$

$$= \sum_{\eta h' s' n' p q} \left\langle \begin{matrix} \beta & & (\gamma & & \delta) \\ & \beta & & r\rho & \\ & & s\sigma & & \end{matrix} \middle| \begin{matrix} (\beta & & \gamma) & & \delta \\ & h'\eta & & & \\ & & & s'\sigma & \end{matrix} \right\rangle$$

$$\times \left\langle \begin{matrix} \alpha & & \sigma \\ & l\lambda & \end{matrix} \middle| \begin{matrix} \alpha & & \sigma \\ & q\lambda & \end{matrix} \right\rangle \cdot \left\langle \begin{matrix} \alpha & & (\eta & & \delta) \\ & \alpha & & s'\sigma & \\ & & q\lambda & & \end{matrix} \middle| \begin{matrix} (\alpha & & \eta) & & \delta \\ & n'\nu & & & \\ & & & p\lambda & \end{matrix} \right\rangle$$

$$\times \left\langle \begin{matrix} \beta & & \gamma \\ & h'\eta & \end{matrix} \middle| \begin{matrix} \beta & & \gamma \\ & h\eta & \end{matrix} \right\rangle \cdot \left\langle \begin{matrix} \alpha & & (\beta & & \gamma) \\ & \alpha & & h\eta & \\ & & n'\nu & & \end{matrix} \middle| \begin{matrix} (\alpha & & \beta) & & \gamma \\ & m\mu & & & \\ & & & n\nu & \end{matrix} \right\rangle$$

$$\times \left\langle \begin{matrix} \nu & & \delta \\ & p\lambda & \end{matrix} \middle| \begin{matrix} \nu & & \delta \\ & k\lambda & \end{matrix} \right\rangle. \tag{18}$$

Similarly cutting the hexagon diagram at the top left hand and bottom right hand vertices [rule (i)], diagram projection gives [rules (i) to (v)]

$$\sum_{k' l' m' n'} \left\langle \begin{matrix} \gamma & & \alpha \\ & n\nu & \end{matrix} \middle| \begin{matrix} \alpha & & \gamma \\ & n'\nu & \end{matrix} \right\rangle \left\langle \begin{matrix} \beta & & \nu \\ & l\lambda & \end{matrix} \middle| \begin{matrix} \beta & & \nu \\ & l'\lambda & \end{matrix} \right\rangle$$

$$\times \left\langle \begin{matrix} \beta & & (\alpha & & \gamma) \\ & \beta & & n'\nu & \\ & & l'\lambda & & \end{matrix} \middle| \begin{matrix} (\beta & & \alpha) & & \gamma \\ & m'\mu & & & \\ & & & k'\lambda & \end{matrix} \right\rangle$$

$$\times \left\langle \begin{matrix} \beta & & \alpha \\ & m'\mu & \end{matrix} \middle| \begin{matrix} \alpha & & \beta \\ & m\mu & \end{matrix} \right\rangle \cdot \left\langle \begin{matrix} \mu & & \gamma \\ & k'\lambda & \end{matrix} \middle| \begin{matrix} \mu & & \gamma \\ & k\lambda & \end{matrix} \right\rangle$$

$$= \sum_{\eta h' k' l'} \left\langle \begin{matrix} \beta & & (\gamma & & \alpha) \\ & \beta & & n\nu & \\ & & l\lambda & & \end{matrix} \middle| \begin{matrix} (\beta & & \gamma) & & \alpha \\ & h'\eta & & & \\ & & & l'\lambda & \end{matrix} \right\rangle$$

$$\times \left\langle \begin{matrix} \eta & & \alpha \\ & l'\lambda & \end{matrix} \middle| \begin{matrix} \alpha & & \eta \\ & k'\lambda & \end{matrix} \right\rangle \cdot \left\langle \begin{matrix} \beta & & \gamma \\ & h'\eta & \end{matrix} \middle| \begin{matrix} \beta & & \gamma \\ & h\eta & \end{matrix} \right\rangle$$

$$\times \left\langle \begin{matrix} \alpha & & (\beta & & \gamma) \\ & \alpha & & h\eta & \\ & & k'\lambda & & \end{matrix} \middle| \begin{matrix} (\alpha & & \beta) & & \gamma \\ & m\mu & & & \\ & & & k\lambda & \end{matrix} \right\rangle. \tag{19}$$

Finally, the pentagon and hexagon equations follow by contracting the identities with the non-identity recoupling coefficients in the above two equations [rule (vi)]. The validity of this rule is seen by projecting the trivial diagrams $1^2=1$, $\mathfrak{i}1=\mathfrak{i}$ and $1\mathfrak{i}=1$.

IX. THE WIGNER *j* SYMBOLS

In this section we derive a set of constraints for the Wigner 3j and 6j symbols that turn out to give the symmetry equation, the Biedenharn–Elliott equation, and the Racah backcoupling equation. These equations arise from an alternative choice of primitive recouplings and consequently an alternative collection of recoupling diagrams guaranteeing coherence.[9] Define the primitive recouplings

$$3\mathrm{j}: \otimes \to \otimes\tau, \quad (\alpha,\beta) \mapsto \mathfrak{c}_{\alpha,\beta}: \alpha\otimes\beta \to \beta\otimes\alpha \tag{20}$$

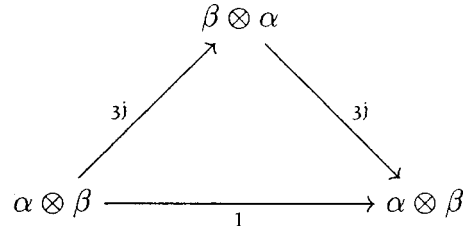

FIG. 15. The symmetry diagram.

$$6\mathrm{j}:\otimes(\otimes\times 1)\to\otimes(\otimes\times 1)\tau_{(13)},\quad(\alpha,\beta,\gamma)\mapsto[(\mathfrak{c}.1)\mathfrak{ca}]_{\alpha,\beta,\gamma}:(\alpha\otimes\beta)\otimes\gamma\to(\gamma\otimes\beta)\otimes\alpha. \quad (21)$$

These primitive recouplings are formally transpositions. The 3j recoupling flips two irrep statements. The 6j recoupling interchanges the first and third irrep (sub)statements in a binary bracketed triplet. Loosely speaking the first generates the $3j$ symbol and the second the $6j$ symbol. Specifically from Joyce[9] the 3j symbol is given by

$$\{(12),\alpha\beta\lambda\}^{k}_{l}=\left\langle \begin{matrix}\beta & & \alpha\\ & l\lambda^{*} & \end{matrix}\middle|\begin{matrix}\alpha & & \beta\\ & k\lambda^{*} & \end{matrix}\right\rangle \quad (22)$$

and the $6j$ symbol by

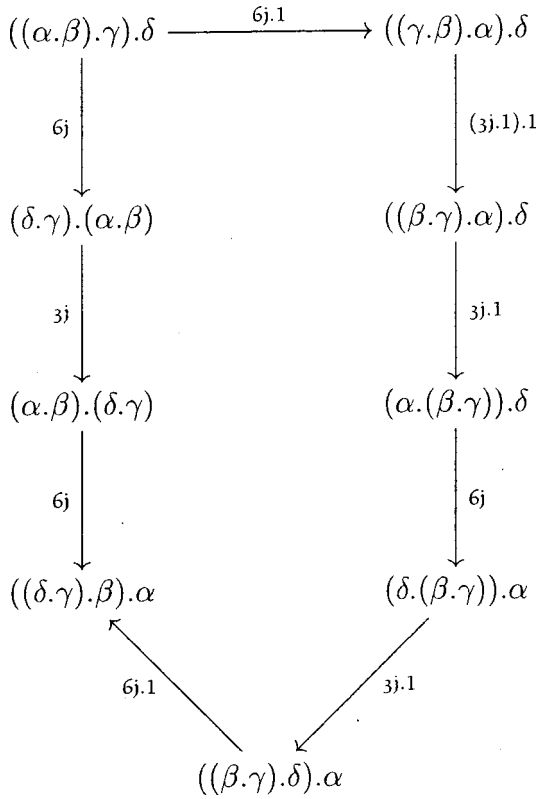

FIG. 16. A nonagonal diagram.

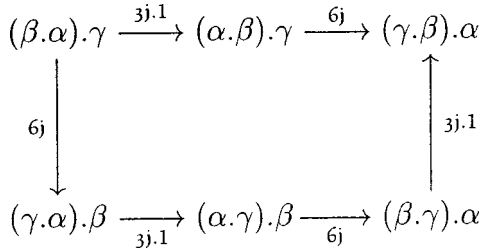

FIG. 17. A hexagonal diagram.

$$\begin{Bmatrix} \alpha & \beta & \mu \\ \gamma & \lambda & \nu \end{Bmatrix}_{lnkm} = \sum_{rs} \{\lambda\}\{*,\alpha\beta\mu\}^{m}_{r}\{*,\mu^{*}\gamma\lambda^{*}\}^{k}_{s} \cdot \left\langle \begin{matrix} (\gamma & & \beta) & & \alpha \\ & n\nu & & \alpha & \\ & & l\lambda & & \end{matrix} \middle| \begin{matrix} (\alpha & & \beta) & & \gamma \\ & r\mu^{*} & & \gamma & \\ & & s\lambda & & \end{matrix} \right\rangle . \tag{23}$$

These symbols differ from the usual definitions (see Butler[15]) by dimension factors and historical phase choices both of which are unnecessary complications.[9] Note that the 6j symbol is defined without using 3j symbols and consequently should not be viewed as being generated by the $\mathfrak{a}$ recoupling. The 3j symbol is equivalent to the M matrices of Derome and Sharp[16] and the $\{*,\mu^{*}\gamma\lambda^{*}\}^{k}_{s}$ symbols to the A matrices of Derome and Sharp.[16]

Direct substitution of $\mathfrak{c}$=3j and $\mathfrak{a}$=3j(3j.1)6j into the symmetry, pentagon, and hexagon diagrams gives an equivalent set of recoupling coherence conditions given by Figs. 15, 16, and 17. Diagram projection of the recoupling diagrams in Figs. 15, 16, and 17 gives the following result by the previous theorem.

Theorem 4: *All recoupling diagrams commute if and only if the following list of recoupling coefficient constraints hold.*

(i) The symmetry equation

$$\sum_{l} \{(12),\beta\alpha\lambda\}^{l}_{k'}\{(12),\alpha\beta\lambda\}^{k}_{l} = \left\langle \begin{matrix} \alpha & & \beta \\ & k'\lambda & \end{matrix} \middle| \begin{matrix} \alpha & & \beta \\ & k\lambda & \end{matrix} \right\rangle , \tag{24}$$

(ii) The Biedenharn–Elliott equation

$$\begin{aligned} &\sum_{ra} \{\lambda\}(\{*,\alpha\beta\mu\}^{-1})^{r}_{a}\{(12),\beta\alpha\mu\}^{m}_{r}\begin{Bmatrix} \alpha & \beta & \mu \\ \gamma & \lambda & \nu \end{Bmatrix}_{lnka} \\ &\quad = \sum_{\sigma stuvpqw} (\{*,\alpha\gamma\sigma^{*}\}^{-1})^{t}_{p}(\{*,\sigma\beta\lambda^{*}\}^{-1})^{v}_{q}(\{*,\beta\alpha\mu\})^{-1^{m}}_{w} \\ &\qquad \cdot \{(12),\beta\gamma\nu^{*}\}^{s}_{n}\{(12),\gamma\alpha\sigma^{*}\}^{u}_{t}\begin{Bmatrix} \alpha & \gamma & \sigma^{*} \\ \beta & \lambda & \nu \end{Bmatrix}_{lsqp} \cdot \begin{Bmatrix} \beta & \alpha & \mu \\ \gamma & \lambda & \sigma \end{Bmatrix}_{vukw} , \end{aligned} \tag{25}$$

(iii) The Racah backcoupling equation

$$\sum_{abf} \{\sigma\}\{\eta\}(\{*,\mu^*\rho\lambda^*\}^{-1})^b_f\{(12),\rho\mu^*\lambda^*\}^a_b \cdot \begin{Bmatrix} \alpha & \beta & \mu \\ \rho & \lambda & \eta \end{Bmatrix}_{lnfm} \begin{Bmatrix} \mu^* & \gamma & \sigma^* \\ \delta & \lambda & \rho \end{Bmatrix}_{arks}$$

$$= \sum_{\nu cdpntqjvu} (\{*,\beta\gamma\nu^*\})^{-1^n}_j(\{*,\nu\delta\eta^*\}^{-1})^c_u(\{*,\alpha\nu\sigma^*\}^{-1})^p_v$$

$$\cdot\{(12),\delta\nu\eta^*\}^d_c\{(12),\nu\alpha\sigma^*\}^q_p\{(12),\gamma\beta\nu^*\}^t_n$$

$$\cdot \begin{Bmatrix} \beta & \gamma & \nu^* \\ \delta & \eta & \rho \end{Bmatrix}_{hruj} \begin{Bmatrix} \alpha & \nu & \sigma^* \\ \delta & \lambda & \eta \end{Bmatrix}_{ldkv} \begin{Bmatrix} \alpha & \beta & \mu \\ \gamma & \sigma & \nu \end{Bmatrix}_{qtsm}. \tag{26}$$

Diagram projection of the symmetry, nonagonal, and hexagonal diagrams given in Figs. 15, 16, and 17, followed by substitution of each j symbol for its corresponding recoupling coefficient and finally rearrangement and contraction of terms gives the three, j symbol constraints in the hypothesis. The explicit details are to be found in Joyce.[9]

X. CONCLUSION

We have given a concise definition to the concept of coupling and its important properties. Note that we did not require the couplings to be orthogonal. The notion of a projection scheme was defined giving a canonical mechanism for obtaining recoupling coefficients from a recoupling. The language of category theory was found to be the best framework for these ideas. These definitions were a necessary prerequisite to what followed.

Next we gave three important and useful techniques for recoupling coefficients. The first, recoupling coefficient factorization allows one to write a recoupling as a product (without summation) of smaller degree coefficients. The second, primitive expansion, allows a recoupling coefficient to be expressed in terms of primitive recoupling coefficients. The third and most useful, diagram projection, allows one to obtain the underlying recoupling coefficient constraints associated with a recoupling diagram. This affords one the convenience of working at the combinatorial recoupling level. The recoupling coefficient constraints may be obtained at any stage using the rules of diagram projection. A forthcoming paper will use this idea to give an algorithm for the direct calculation of recoupling coefficients that is not based on solving linear recursion equations.

The diagram projection rules allow one to obtain a complete set of constraints for the recoupling coefficients. We diagram projected the recoupling diagrams defining a symmetric tensor category to obtain the symmetry, pentagon, and hexagon equations. These form a complete set of constraints having less recoupling coefficient factors than the classical Biedenharn–Elliott and Racah backcoupling equations and are a viable alternative for any computation scheme. Finally, we gave the recouplings corresponding to the j symbols of Wigner, derived a collection of recoupling diagrams guaranteeing coherence, and recovered from these using diagram projection the Biedenharn–Elliott and Racah backcoupling equations.

Quotient of a loop group and Witten genus

Rémi Léandre
Universite Nancy I, Departement de Mathematiques, Institut Elie Cartan, 54000 Vandoeuvre-les-Nancy, France

(Received 3 March 2000; accepted for publication 29 August 2000)

We define a Dirac–Ramond operator over the quotient $(LG)/H$ of a loop group by a subgroup H of the compact Lie group G. We state the conjecture that its equivariant Index with respect of the natural circle action over the quotient of the loop group is equal to the Witten genus of the homogeneous manifold G/H. We motivate the conjecture by a short time argument which allows to come back to a Dirac–Ramond operator at the manner of Taubes on a limit model where all the computations can be done by hand. © *2001 American Institute of Physics.*

I. INTRODUCTION

Let us consider the free loop space $L(M)$ of a compact manifold; it is endowed with a natural circle action. The fixed point set of this circle action is the manifold itself.

In finite dimension, when there is a circle action over a manifold, there are two types of relations between the fixed point set and the total space. It is the purpose of the Berline–Vergne localization formulas[1] and of the Lefschetz formulas.[2,3] In the first case, we localize the integrals over the fixed point set; in the second case, using the method of Taubes,[3] we localize the operators over the fixed point set.

Over the loop space, the Berline–Vergne localization formulas give the index theorem for the Dirac operator over a manifold.[4,5] If we localize an operator, this gives the Index theorem over the loop space, which gives quantities which are very important for algebraic topology as it was noticed by Witten.[6–8]

The problem for Lefschetz formula over the loop space is that it is purely hypothetical. Taubes[3] gives a rigorous construction for a limit model. He considers as model of the free loop space the family of flat loops on the tangent space. He considers a measure over the flat loop space, which lives over random distributions, and whose choice comes from quantum field theory. So we cannot curve its model.

There is another way to attack the problem of defining the Dirac–Ramond operator over the loop space and others geometrical operators: it is the way followed by Léandre-Roan,[9] Jones-Léandre,[10] and Léandre[11] (see in Ref. 12 the survey of Léandre). We consider the Brownian bridge measure. There is a tangent Hilbert space, which allows us to state integration by parts formulas over the free loop space. Reference 9 meets the problem that the tangent Hilbert space is not stable by Lie brackets; a connection allows us to compute a regularized stochastic exterior derivative and to compute its adjoint. This gives a rigorous approach to the Euler–Poincaré characteristic of Dixon–Harvey–Vafa–Witten of an orbifold.[13] Reference 11 meets the same problem for the Dolbeault operator over the loop space of a Kaehler manifold, with the natural polarization over the loop space which results from the polarization of the Kaehler manifold. This gives a rigorous approach to Hirzebruch's genus of level N.[14]

The problem is to construct the Dirac–Ramond operator over the loop space. Reference 10 present only a beginning of construction of it. Namely, if we follow Taubes approach to construct the Dirac–Ramond operator over the free loop space, we have to extend over the free loop space the natural polarization which arises from Fourier series. This leads to complicated considerations.

We remark that over a loop group, if we consider the tangent space of a loop group, we do not meet the previous difficulties. For instance, the tangent space of a loop group is stable by Lie

bracket. This allows us to compute a true exterior derivative and its adjoint (and not a regularized one as in Refs. 10 and 9) in Ref. 15. The polarization by Fourier series is well defined over the loop group. But the Witten genus of a group is trivial, because the tangent bundle of a Lie group G is trivial.

The idea is to consider $(LG)/H$ where H is a maximal torus of G, where G is a noncommutative Lie group. It inherits clearly a circle action over it, and its fixed point set coincides with a countable disjoint unions of the homogeneous space G/H.

So the natural conjecture is the following:

Conjecture (Bismut): Over $(LG)/H$, there is a Dirac–Ramond–Taubes operator which is invariant under the natural circle action over $(LG)/H$ and it is possible to define its ''renormalized'' equivariant Index which is equal to the Witten genus of G/H.

The purpose of this work is to give a stochastic approach to this conjecture.

We construct in the first part an H-equivariant operator over LG, which generalizes the construction of Taubes. For that, we suppose that the homogeneous space G/H is Kaehlerian and spin. This operator is invariant under the natural circle action over LG. The space of functionals over $(LG)/H$ can be seen as a functional over LG which is invariant under the H action, which induces an action by isometries over it. Since H is finite dimensional, the analysis over $(LG)/H$ comes ultimately to the analysis over LG for H invariant functionals. This allows us to define a Dirac–Ramond operator over $(LG)/H$, which follows precisely the prescriptions of Taubes.

In a second time, we consider the loop group in small time, and we repeat the considerations in this loop group context of Refs. 9, 10, and 11 to motivate the conjecture. We deform the Hilbert space of the theory and we arrive at the limit to a limit operator at the manner of Taubes, whose equivariant index is the Witten genus G/H. The price to pay in order to be able to do the asymptotic expansion of the Dirac–Ramond–Taubes operator near the constant loops is that we have to change completely the structure of the considered Dirac operator. In particular we suppose G/H spin and Kaehlerian, and we work in order to perform Bismut's dilatation over the small elements of $(LG)/H$. The reader interested by short time asymptotic expansion can see the surveys of Kusuoka,[16] Watanabe,[17] and Léandre.[18]

The question which is put by this work is the following: Taubes construction of the Dirac–Ramond operator over the loop space is a construction by hand, which avoids the theory of spin representation of loop group. On the other hand, there is a theory of spinor fields over the loop space,[19–21] and in particular, by using the fact that there is a measure over the loop space, the definition of Hilbert spaces of sections of the spin bundle over the loop space,[22–24] where the Dirac–Ramond operator should act. What is the relation between the two point of view?

We refer to the two surveys of Léandre[12,25] for the interaction between analysis over loop space and topology.

II. CONSTRUCTION OF THE DIRAC–RAMOND–TAUBES OPERATOR

Let G be a compact simply connected Lie group. We consider the Killing metric over its Lie algebra Lie G. We consider the Brownian motion over G staring from g. It is the solution of the following stochastic differential equation starting from g:

$$dg_s = g_s dB_s, \tag{2.1}$$

where B_s is a Brownian motion over Lie G and where d denotes the Stratonovitch differential. It has an heat kernel $p_t(g,g')$ with respect to the Haar measure $d\pi(g)$ over G. Over the free loop group of G called $L(G)$ of continuous loops, we consider the following measure:

$$d\mu_{G,1} = \frac{p_1(g,g)d\pi(g)\otimes dP_{1,g}}{\int p_1(g,g)dg}, \tag{2.2}$$

where $P_{1,g}$ is the law of the Brownian bridge starting from g and arriving in g in time 1. For a cylindrical functional $F(g_{s_1},\ldots,g_{s_r})$, $s_1<s_2<\cdots<s_r$, we have a more explicit description of $\mu_{G,1}$ in terms of the heat kernel,

$$E[F(g_{s_1},\ldots,g_{s_r})]=\frac{1}{\int p_1(g,g)d\pi(g)}\int\ldots\int p_{s_2-s_1}(g_1,g_2)$$

$$p_{s_3-s_2}(g_2,g_3)\ldots p_{s_r-s_1}(g_r,g_1)F(g_1,\cdots,g_r)d\pi(g_1)\cdots d\pi(g_r). \tag{2.3}$$

Let us remark that by the symmetry of Eq. (2.1), $p_1(g,g)=p_1(e,e)$ such that $\int p_1(g,g)d\pi(g)=p_1(e,e)$.

We consider as tangent space of an element $g_.$ of the loop group the set of $X_.$ where $X_s=g_sK_s$ such that $K_0=K_1$ and where the path $K_.$ in the Lie algebra of G is of finite energy. We introduce the following Hilbert structure:

$$\|X_.\|_{g_.}=\int_0^1|K_s|^2ds+\int_0^1|K_s'|^2ds. \tag{2.4}$$

There is a natural circle action over $L(G)$; if $q=\exp[2i\pi t]$ belongs to the circle, $q(g_.)_s=g_{s-t}$.

This natural circle action preserves the measure as well the tangent bundle of the loop group: it preserves therefore the metric, since g induce a rotation from Lie(G) into the tangent space of G at g. If we complify the tangent space of $g_.$ $T_{g_.}$ into $T_{g_.}\otimes C$ and if the real complex structure (2.4) is transformed into the natural complex Hilbert structure over the complexified tangent space, there is a natural orthonormal basis of $T_{g_.}\otimes C$ starting from a real orthonormal basis e_i of Lie(G). It is given by

$$X_n(e_i)_s=g_s\frac{\exp[2\pi ins]e_i}{\sqrt{Cn^2+1}}. \tag{2.5}$$

This splits $T_{g_.}\otimes C$ into H_-+E+H_+. H_+ corresponds to a strictly positive n, H_- corresponds to $n<0$, and E to $n=0$. We have therefore a polarization over the loop group which comes from the Fourier expansion.

We remark that the tangent bundle is stable by Lie bracket. If $X_s=g_sK_s(X)$ and $Y_s=g_sK_s(Y)$, where $K_s(X)$ and $K_s(Y)$ are deterministic, we have

$$[X,Y]_s=g_s[K_s(X),K_s(Y)]. \tag{2.6}$$

Moreover, H_+ and H_- are stable by the Lie bracket. Under the natural circle action by q in the circle, $X_n(e_i)_.$ behaves as q^{-n} if e_i is deterministic.

There is a Levi-Civita connection over $L(G)$ which is given for real vector fieds $X_.$, $Y_.$, and $Z_.$ by a formula of [K.N] p. 160. We have

$$2\langle\nabla_{X_.}Y_.,Z_.\rangle=X_..\langle Y_.,Z_.\rangle+Y_..\langle X_.,Z_.\rangle-Z_..\langle X_.,Y_.\rangle+\langle[X_.,Y_.],Z_.\rangle$$
$$+\langle[Z_.,X_.],Y_.\rangle+\langle X_.,[Z_.,Y_.]\rangle. \tag{2.7}$$

If we consider the vector fields $X_n(e_i)_.$ for e_i deterministic, $\langle X_n(e_i)_.,X_m(e_j)\rangle=\delta_{n,m}\delta_{i,j}$ and

$$\langle\nabla_{X_{p(e)_.}}X_n(f)_.,X_m(f')_.\rangle=C(p,n,m,e,f,f') \tag{2.8}$$

is deterministic. Moreover, (2.7) show, if n and m are positive, that $\nabla_{X_n(e_i)_.}X_m(e_j)_.$ is a linear combination of $X_{n+m}(e_k)_.$

The problem is to understand E now. For that we introduce a compact Lie group H which is a maximal torus of G. We suppose that G/H is spin and Kaehlerian. We suppose that the Kaehler structure is compatible with the action of G over G/H. We can decompose the complexified Lie algebra of G into $n_+ + \mathrm{Lie}(H) + n_-$. Let us detail how we proceed. Let us introduce the canonical projection $p: G \to G/H$. G becomes a fibration over G/H with fiber H. Let us consider $g \in p^{-1}(x)$, where x denoted the typical element of G/H. At g, the complexified tangent space of G, $T_g \otimes C$, has the direct orthogonal decomposition $n_+(g) + T_{p^{-1}(x)} \otimes C + n_-(g)$. The fact that we have a Kaehler structure over G/H implies that $[h, f_+]$ belongs still in n_+ if h belongs to the Lie algebra of H and if f_+ belongs to n_+. The analogous statement remains true for n_-. By the action of G, $n_+(g)$ can be identified with the set of $T^{1,0}$ vectors $\partial/\partial z$ over G/H and $n_-(g)$ can be identified with the sets of $T^{0,1}$ vectors $\partial/\partial\overline{z}$ over G/H. (Let us recall that $T^{1,0}$ is the set of eigenvectors $\partial/\partial z$ associated with the eigenvalue i for the complex structure J over G/H and that $T^{0,1}$ is the set of eigenvectors $\partial/\partial\overline{z}$ associated with the eigenvalue $-i$ for the complex structure J.)

We deduce a decomposition of E into $N_+ + O + N_-$ which is orthogonal. Moreover, this decomposition is invariant by rotation, because the action of $g \in G$ preserves the Kaehler structure of G/H.

Let us recall that over G/H, there is a $\overline{\partial}$ operator: $T^{1,0}$ forms are called dz and $T^{0,1}$ forms are called $d\overline{z}$. We introduce the Levi-Civita connection over G/H: it preserves, since G/H is supposed Kaehlerian, the decomposition of the complexified tangent space in $T^{1,0}$ and in $T^{0,1}$. The same is true for the forms. We consider the bundle $\Lambda(T^{0,1})$ and we consider the $\overline{\partial}$ operator,

$$\overline{\partial}_f = \sum d\overline{z}_i \wedge \nabla_{\partial/\partial\overline{z}_i} \tag{2.9}$$

for the Levi-Civita connection (see Ref. 26) where we take the sum over a local orthonormal basis of $T^{0,1}$. We can tensorize this operator by an auxiliary complex hermitian bundle ξ endowed with an Hermitian connection.

This allows us to construct the Dirac operator over G/H in terms of a twisted Dolbeault operator, if we suppose G/H spin (see Ref. 26, p. 186). We consider a square root of the canonical bundle $\Lambda^{n,0}$, whose curvature is given by $2R$, which is a closed $4\pi i Z$ valued form over G/H. We consider its dual ξ', which can be endowed with a Hermitian structure and a connection whose curvature is $-R$. We consider the $\overline{\partial}$ operator twisted by ξ'. This gives a realization of the Dirac operator over G/H.

Let $-R$ be the curvature of ξ'. We construct a complex line bundle over $L(G)$ by proceeding as follows; we consider the form $-p^*R$ over G: it is $2\pi i Z$ valued. We construct the form $\sigma = -\int_0^1 p^*(R)(g_s)(.)ds$ over $L(G)$. It is still closed $2i\pi Z$ valued. This form determines, since G is supposed simply connected and therefore $L(G)$ is simply connected, a complex line bundle ξ_∞ over $L(G)$. Let us recall[20,27,24,28] how to do it, in order to construct it. In order to simplify the exposure, we will work over the Hoelder loop space $L_{1/2-\epsilon}(G)$: it is possible to assume this because the Brownian loop is almost surely Hoelder,

$$\sup \frac{d(g_s, g_t)}{d(s,t)^{1/2-\epsilon}} < \infty, \tag{2.10}$$

where $d(g_s, g_t)$ denoted the Riemannian distance over the group between g_s and g_t and $d(s,t)$ denoted the Riemannian distance over the circle between s and t. This will allow us to produce smooth sections of the line bundle ξ_∞, whose existence is strongly based upon the existence of partition of unity over the loop space, which does not exist if the loops $g_.$ are only continuous.

We consider the system of balls $B(g_{\alpha.}; \delta)$ for the uniform distance of radius δ and of center the smooth loop $g_{\alpha.}$. We construct over this ball the curve

$$l_\alpha(g_.)(t)_s = \exp[t(g_s - g_{\alpha,s})], \tag{2.11}$$

where we consider the exponential of the Lie group. Let us explain what we mean by this notation: there is a unique geodesic joining $g_{\alpha,s}$ to g_s whose driving vector is denoted by $g_s - g_{\alpha,s}$ and belongs to the tangent space of G in $g_{\alpha,s}$. We consider the geodesic joining $g_{\alpha,s}$ to g_s, which coincide since we consider over G the binvariant metric with the traditional exponential over a Lie group, since g_s and $g_{\alpha,s}$ are closed. If $g_.$ belongs to the intersection of $B(g_{\alpha.};\delta)$ and of $B(g_{\beta.};\delta)$, we can construct a system of transition functionals as follows: we join the two loops $l_\alpha(g_.)(t)_.$ and $l_\beta(g_.)(t)_.$ by using the Lie group exponential. This constitutes a small triangle. We use the fact that $\Pi_2(G)=0$ in order to find a big triangle whose boundary is any path joining $e_.$ to $g_{\alpha.}$, the exponential curve joining $g_{\alpha.}$ to $g_{\beta.}$ and any curve joinning $g_{\beta.}$ to $e_.$. We produced a distinguished surface $S_{\alpha,\beta}(g_.)$ in $L_{1/2-\epsilon}(G)$ whose boundary is the distinguished path $l_\alpha(g_.)$ joining $e_.$ to $g_.$ and the path $l_\beta(g_.)$ circled in the opposite sense.

We put

$$\rho_{\alpha,\beta}(g_.)=\exp\left[-2i\pi\int_{S_{\alpha,\beta}(g_.)}\sigma\right]. \tag{2.12}$$

It is a smooth functional in the traditional sense over the intersection of the two ball $B(g_{\alpha.};\delta)$ and $B(g_{\beta.};\delta)$ (and not in the generalized sense of the infinite dimensional analysis). We get clearly, since σ is Z-valued, over $B(g_{\alpha_1.};\delta)\cap B(g_{\alpha_2.};\delta)\cap B(g_{\alpha_3.};\delta)$,

$$\rho_{\alpha_1,\alpha_2}(g_.)\rho_{\alpha_2,\alpha_3}(g_.)\rho_{\alpha_3,\alpha_1}(g_.)=1. \tag{2.13}$$

This determines a complex line bundle endowed with a natural Hermitian structure over it.

We define a Hermitian connection form over the small ball $B(g_{\alpha.};\delta)$,

$$A_\alpha(g_.)(X_.)=\int_0^1\sigma(d/dt\, l_\alpha(g_.)(t),D_{X_.}l_\alpha(g_.)(t)). \tag{2.14}$$

Let us remark that this Calculus does not need all the schochastic apparatus of Refs. 22–24 and 28, because the quantities are here surely defined. The next lemma uses deeply that there exist a partition of unity over $L_{1/2-\epsilon}(G)$ associated with the cover $B(g_{\alpha.};\delta)$ (see Ref. 28):

Lemma II.1: There exists a smooth section τ_{ξ_∞} of ξ_∞ such that for all $m>1$,

$$\sum_{n,i}E[|\nabla_{X_n(e_i)_.}\tau_{\xi_\infty}|^{2m}]<\infty. \tag{2.15}$$

Proof: We choose the section over $B(g_{\alpha.};\delta)$ which corresponds to any cylindrical functional in the trivialization given for $A_\alpha(g_.)$. It is not smooth. We multiply it by a mollifer; it is possible, because we consider the Hoelder loop space. We follow Ref. 28. Let us introduce a smooth function f from $[0,\infty]$ into $[1,\infty]$ which is exactly exactly on $[0,\delta']$ for $\delta'<\delta$. We suppose that f behaves as $|\delta''-r|^{-n}$ for a big integer n when $r\to\delta''_-$ for some $\delta''<\delta$ and is infinite for $r>\delta''$. We introduce a smooth function h from $[1,\infty]$ into $[0,1]$ with compact suppost which is equal to 1 only at 1. We consider the functional,

$$F_\alpha(g_.)=h\left(\int_0^1 f(d(g_s,g_{\alpha,s}))ds\right). \tag{2.16}$$

F_α is smooth with support included in $B(g_{\alpha.};\delta)$, because we work over the Hoelder loop space (This property is wrong over the continuous loop space). Moreover,

$$X_n(e_i)_\cdot . F_\alpha(g_\cdot) = h'\left(\int_0^1 f(d(g_s, g_{\alpha,s}))ds \right) \times \int_0^1 f'(d(g_s, g_{\alpha,s}) \langle d'(g_s, g_{\alpha,s}), X_n(e_i)_s \rangle ds. \tag{2.17}$$

We get

$$|X_n(e_i)_\cdot . F_\alpha(g_\cdot)|^2 \leqslant C\left(h'\left(\int_0^1 f(d(g_s, g_{\alpha,s}))ds \right)^2 \int_0^1 |f'(d(g_s, g_{\alpha,s}))|^2 ds \times \int_0^1 |\langle d'(g_s, g_{\alpha,s}), X_n(e_i)_s \rangle|^2 1_{B(g_{\alpha,s};\delta)}(g_s) ds. \tag{2.18}$$

The product of the two first term in the right-hand side of (2.18) is bounded in all the L^p by the exponential inequality. The last term has a bound in n and i in $1/(cn^2+1)$. ◇

Over $L_{1/2-\epsilon}(G)$, we can consider the following natural action of H: $g_\cdot \to g_\cdot h$. This preserves the measure, the tangent space as well as the Hilbert space structure over the Hilbert space. It commutes with the natural circle action over the loop group. Since σ is invariant under the action of H over the loop group, the action of H over the loop group lifts to an action of H over ξ_∞, which preserves the Hermitian structure and the connection. It transforms clearly a smooth section of ξ_∞ into a smooth section (in the traditional sense). Moreover, if τ_{ξ_∞} satifies to (2.15), $\tau_{\xi_\infty}.h$ satisfies still to (2.15). We can produce an H-invariant section by using $\int_H \tau_{\xi_\infty}.h d\pi(h)$. The space of H-invariant sections and of finite linear combinations of H-invariant sections produced by Lemma II.1 is dense in the space of L^2 H-invariant section of ξ_∞.

This allows us to construct the Hilbert space of the theory; we consider $\Lambda(H_-)$ the Fermionic Fock bundle of the bundle H_- and $\Lambda(N_-)$ the space of forms associated with the bundle spanned by $X_0(f_i)_\cdot, f_i$. being a orthonormal basis of n_-. We consider the bundle $\Xi = \Lambda(H_-) \otimes \Lambda(N_-) \otimes \xi_\infty$. It is a Hermitian bundle over the Holderian loop group, endowed with a product connection. Over $\Lambda(H_-)$, we consider the lift to the Levi-Civita connection defined by (2.7). Over $\Lambda(N_-)$, we consider the connection given by $\nabla_\cdot X_0(f_j)_\cdot = 0$ if f_j is a deterministic orthonormal basis of n_-. This connection is clearly invariant by rotation. Over ξ_∞, we consider the connection which is invariant under the H-action. The H-action over the Hoelder loop group lift to Ξ. More precisely a vector $X_n(e_i)_\cdot$ is transformed under the H-action into a vector $X_n(h^{-1}e_i h)$. This lift keeps the metric and is compatible with the connection which are considered.

Moreover the natural circle action over the loop groups lifts to $\Lambda(H_-)$, and the connection and the Hermitian metric are compatible with this lift, because the Levi-Civita connection is invariant under the circle action, because the circle acts by isometries. The same considerations work for $\Lambda(N_-)$ and for ξ_∞, because the form σ which determines ξ_∞ is invariant under the circle action.

The Hilbert space $E_H[\Xi]$ of the theory is the space of sections τ_Ξ of Ξ which are invariant under the H-action and which are in L^2: this means that $E[|\tau_\Xi|^2] < \infty$.

We will define a dense core $\Lambda_H[\Xi]$, where we can define a regularized Dirac–Ramond–Taubes operator, which is symmetric, therefore closable.

Let us introduce $I = ((n_1, i_1), \ldots, (n_r, i_r))$ for $n_i < 0$ and let us consider $X_{I_\cdot} = X_{n_1}(e_{i_1})_\cdot \wedge \ldots X_{n_r}(e_{i_r})_\cdot$. Let f_j a given deterministic orthonormal basis of n_-. Let J be equal to $(j_1, \ldots, j_r)$ and let $Y_{J_\cdot}$ be equal to $X_0(f_{j_1})_\cdot \wedge \ldots \wedge X_{j_0}(f_{j_r})_\cdot \ldots$. Let $F_{I,J,K}(g_\cdot)$ be a cylindrical function and let $\tau_{\xi_\infty,K}$ a finite family of sections of τ_{ξ_∞} satisfying (2.15).

A typical section τ_{Ξ} of the core $\Lambda_H[\Xi]$ is a section which is a finite sum of the type,

$$\tau_{\Xi}=\sum F_{I,J,K}(g_.)X_{I.}\wedge Y_{J.}\otimes \tau_{\xi_\infty,K}, \tag{2.19}$$

where we afterwards average under the H-action in order to get H-invariant sections of Ξ. Moreover, it is a dense subspace of the Hilbert space $E_H[\Xi]$. We remark that $\Lambda_H[\Xi]$ is invariant under the natural circle action over the loop group. It is clearly true for $X_{I.}$ and $Y_{J.}$, and for the cylindrical functioanls $F_{I,J,K}(g_.)$ whose set is invariant under the circle action. This result arises for $\tau_{\xi_\infty,K}$ because the space of sections τ_{ξ_∞} satisfying (2.15) is invariant under the circle action.

We consider as an operator,

$$\overline{\partial}_{r,\infty}=\sum_{n>0,i} X_n(e_i)_.\wedge\nabla_{X_n(e_i)_.}+\sum_{f_j} X_0(f_j)_.\wedge\nabla_{X_0(f_j)_.}. \tag{2.20}$$

$X_n(e_i)_.$ corresponds to the form $Y_.\to<Y_.,X_n(e_i)_.>$ in the wedge product. By antilinearity of the Hermitian product, it behaves as q^n under the action of $q\in S_1$, if it is considered as a form. Unfortunately, $\overline{\partial}_{r,\infty}$ is not well defined over $\Lambda_H[\Xi]$. In order to see that, we have to estimate $\nabla_{X_{m(e_i)_.}}X_k(e_j)_.$ when $m\to\infty$. Let us denote by $\overline{X_.}$ the natural conjugation of a vector field $X_.$ which arises from Fourier series. Let us suppose that $X_.$, $Y_.$, and $Z_.$ are 3 vector fields of the type $X_n(e_k)_.$ with e_k deterministic. By (2.7), we have

$$2\langle\nabla_{X_.}Y_.,Z_.\rangle=\langle[X_.,Y_.],Z_.\rangle+\langle Y_.,[Z_.,\overline{X_.}]\rangle+\langle X_.,[Z_.,\overline{Y_.}]\rangle. \tag{2.21}$$

We deduce that

$$\nabla_{X_{m(e_i)_.}}X_l(e_j)_.=\sum_k \alpha_k(i,j)X_{m+l}(e_k)_.\frac{\sqrt{C(m+l)^2+1}}{\sqrt{C(m^2)+1}\sqrt{Cl^2+1}} \tag{2.22}$$

for $m>0$ and $l>0$. Therefore $\overline{\partial}_{r,\infty}\tau_{\Xi}$ has absolutely no reason to belong to $E_H[\Xi]$, if τ_{Ξ} belongs to $\Lambda_H[\Xi]$.

In order to overcome this difficulty, we will change of connection. We choose

$$\nabla_.X_m(e_i)_.=0. \tag{2.23}$$

This connection is clearly invariant by rotation because the vector field $X_n(e_i)_.$ considered as a vector field behaves as q^{-n} under the natural action of the element q of the circle. Moreover this connection is clearly invariant under the H-action, because a vector $X_n(e_i)_.$ is transformed under the H-action in a vector $X_n(h^{-1}e_ih)_.$. Therefore, if we change in the definition (2.19) of $\overline{\partial}_{r,\infty}$ of connection following the last prescriptions, $\overline{\partial}_{r,\infty}(\tau_{\Xi})$ belongs to $E_H[\Xi]$ as soon as τ_{Ξ} belongs to $E_H[\Xi]$ because $X_m(e_i)_..F_{I,J,K}(g_.)$ as a behavior in $C/\sqrt{Cm^2+1}$ when $m\to\infty$ and because (2.15).

Let us recall that over the Loop group, we have some integration by parts formulas called the Albévério–Hoegh–Krohn integration by parts formulas (Refs. 29 and 30). There exists a functional $\mathrm{div}(X_n(e_i)_.)$ which belongs to all the L^p over the loop group such that for all cylindrical functional F,

$$E[X_n(e_i)_..F]=E[F\,\mathrm{div}(X_n(e_i)_.)]. \tag{2.24}$$

We deduce, since the connection is ∇ is Hermitian over Ξ, that we can compute the formal adjoint of $\overline{\partial}_{r,\infty}$ called $\overline{\partial}^*_{r,\infty}$,

$$\overline{\partial}^{*}_{r,\infty}=\sum_{n<0,i}\left(-\nabla_{X_n(e_i)_\cdot}i_{X_{-n}(e_i)_\cdot}+\operatorname{div}X_n(e_i)_\cdot i_{X_{-n}(e_i)_\cdot}\right)$$

$$+\sum_{j}\left(-\nabla_{X_0(f'_j)_\cdot}i_{X_0(f_j)}+\operatorname{div}X_0(f'_j)_\cdot i_{X_0(f_j)_\cdot}\right), \tag{2.25}$$

where f'_j is the orthonormal basis of n_+ corresponding to the orthonormal basis f_j of n_-. $i_{X_\cdot}$ denotes the interior product by a vector field $X_\cdot$. The sum is in fact finite if τ_Ξ belongs to $\Lambda_H[\Xi]$. We take $\operatorname{div}X_n(e_i)_\cdot$ for $n<0$ in (2.25), because we consider complexified L^2 Hilbert space.

This motivates the following definition:

Definition II.2: We call regularized Dirac–Ramond–Taubes operator over the quotient of the loop group the operator,

$$D_{r,\infty}=\overline{\partial}_{r,\infty}+\overline{\partial}^{*}_{r,\infty}. \tag{2.26}$$

It is defined over $\Lambda_H[\Xi]$, symmetric and therefore closable over $E_H[\Xi]$.

Let us compute the fixed point set under the circle action of $(LG)/H$. It is the only place in this work where it is important to suppose that H is a torus.

Let $g_\cdot$ be a representative of an element of the fixed point set. We have, for all s,

$$g_{s+t}=g_s k_t \tag{2.27}$$

for k_t in H and

$$g_{s+t+t'}=g_{s+t}k_{t'}=g_s k_t k_{t'}=g_s k_{t+t'}. \tag{2.28}$$

It follows that $k_t=\exp[et]$ for e belonging to the Lie algebra of H. We identify $g\exp[e.]$ and $g'\exp[e'.]$ we get for a given element h' of H,

$$g\exp[et]=g'\exp[e't]k. \tag{2.29}$$

Therefore, $g=g'k$, and since H is commutative, $e=e'$. Moreover, since we consider loops, e must belong to the canonical lattice L of Lie H of e such that $\exp[e]=1$

We have proved:

Theorem II.3: The fixed point set of $(LG)/H$ under the natural circle action is $G/H\times L$.

III. LIMIT THEOREMS

We consider over the group the equation

$$dg_{\epsilon,s}=g_{\epsilon,s}(\epsilon dB_s) \tag{3.1}$$

starting from g, where B_s is a Brownian motion over the the Lie algebra of G.

It has an heat kernel $p_{s,\epsilon}(g,g')$. Moreover, $p_{1,\epsilon}(g,g)=p_{1,\epsilon}(e,e)$ clearly. Over the loop group, we consider the probability measure $d\mu_{G,\epsilon}=d\pi g\otimes dP_\epsilon(g)$. $P_\epsilon(g)$ is the law of the diffusion $g_{\epsilon,\cdot}$ starting from g constrained to come back at g. We consider a new Hilbert structure for vector fields of the type $X_s=g_s K_s$. It is given by

$$\|X_\cdot\|^2_{g_\cdot,\epsilon}=\int_0^1(|K_s|^2+\epsilon^{-2}|d/dsK_s|^2)ds, \tag{3.2}$$

where $K_\cdot$ is a finite energy application from the circle into the Lie algebra of H. This Hilbert structure is invariant under rotation.

An orthogonal basis of the tangent space is given by

$$X_{n,\epsilon}(e_i)_s = g_{\epsilon,s}\frac{\exp[2i\pi ns]e_i}{\sqrt{Cn^2\epsilon^{-2}+1}}, \tag{3.3}$$

where e_i is an orthonormal basis of the orthogonal of the Lie algebra of G.

Let us compute the divergence of a vector field $X^1_{n,\epsilon}(e_i)_.$ for $\mu_{G,\epsilon}$. For that, we consider $g^\lambda_{\epsilon,s} = \exp[\lambda(\cos[2\pi ns]e_i/\sqrt{cn^2\epsilon^{-2}+1})]$. We consider Eq. (3.1) starting from e. $g_{\epsilon,.}g^\lambda_{\epsilon,.}$ is the solution of a differential equation starting from $g^\lambda_{\epsilon,0}$,

$$d(g_{\epsilon,s}g^\lambda_{\epsilon,s}) = (g_\epsilon dg^\lambda_{\epsilon,s}) + g_{\epsilon,s}(\epsilon dB_s)g^\lambda_{s,\epsilon}. \tag{3.4}$$

It follows that the law of $g_{\epsilon,s}g^\lambda_{\epsilon,.}$ is equivalent to the original law, if we do not fix the starting point and the end point, that is if we consider the free path group, because the Haar measure is invariant under rotation and because $(g^\lambda_{\epsilon,s})^{-1}(dB_s)g^\lambda_{\epsilon,s}$ is still the differential of a Brownian motion on the Lie algebra of G. By differentiating in $\lambda = 0$, we get infinitisimal integration by parts formulas. By using, the quasisure analysis,[31] this integration by parts formulas can be desintegrated over the loop group. For cylindrical functionals F, we get

$$E[X^1_{n,\epsilon}(e_i)_..F] = E[F\ \mathrm{div}\, X^1_{n,\epsilon}(e_i)_.], \tag{3.5}$$

where $\mathrm{div}\, X^1_{n,\epsilon}(e_i)_.$ behaves in small time in $C\int_0^1\langle\exp[2i\pi ns]e_i, dB_s\rangle$ because the law of $g_{\epsilon,.}$ has an equivalent in $g\exp[\epsilon B_. + O(\epsilon^2)]$, where $B_.$ is a flat Brownian bridges over the Lie algebra of G. We have supposed that $g_{\epsilon,.}$ starts from g.

So we have the lemma:

Lemma III.1: In law, when $\epsilon \to 0$, we have over the loop group,

$$\mathrm{div}\, X_{n,\epsilon}(e_i)_. \to \int_0^1 C\langle\exp[2i\pi ns]e_i, dB_s\rangle, \tag{3.6}$$

where B_s is a flat Brownian bridge over the Lie algebra of G.

Let us remark that if we consider the vector field $X_{0,\epsilon}(e_i)_. = g_{\epsilon,.}e_i$, its divergence is equal to 0, because the probability law $P_\epsilon(g)$ is equal to the probability law of $P_\epsilon(gg')$ by the transformation $g_. \to g_.g'$.

This leads to the introduction of a limit limit model, according Taubes.

Let us recall that G is endowed with the Haar measure $d\pi(.)$. G/H is equipped of a Kaehler structure and over G/H, there is the complex line bundle ξ', which allows to define the spin structure. We consider the projection p: $G \to G/H$, and the line bundle $p^*\xi'$, and the bundle $p^*(T(G/H))$. We consider the bundle V_g of ge, e belonging to the orthogonal of the Lie algebra of Lie H. It is isomorphic to the bundle $p^*(T(G/H))$. It is constituted of vector ge orthogonal to vectors ge_i where e_i belongs to the Lie algebra of H. It can be assimilitated to vectors of the shape e where e belongs to the orthogonal of the Lie algebra of H. Let us recall that the complexification of the orthogonal of the Lie algebra of H in the Lie algebra of G can be splitt in $n_+(g) + n_-(g)$ Moreover, this decomposition is invariant under the action of H by inner product. We consider the family of flat Brownian bridges $g_{\mathrm{flat}_.}$ in $V_.$ starting from 0 in V_g endowed with the measure $d\pi(g)\otimes dP_{1,g,\mathrm{flat}}$. It is the same as $gB^1_s(g)$, where $B^1_s(g)$ is a Brownian bridge in the orthogonal of Lie H. The tangent space is the space $X_{l,t}$ of path in V_g with finite energy. As the Hilbert norm, we take

$$\|X_{l,0}\|^2 + \int_0^1 \|d/ds X_{l,t}\|^2 dt = \|X_{l,.}\|^2_1. \tag{3.7}$$

For forms, we take the Hilbert structure,

$$\int_0^1 |X_{l,t}|^2 dt + \int_0^1 |d/dt X_{l,t}|^2 dt = \|X_l\|_2^2. \tag{3.8}$$

It has the orthogonal basis $g\int_0^{\cdot} \exp[2i\pi ns]e_i = X_{n,l}(e_i)$ if $n \neq 0$ and $ge_i = X_{0,l}(e_i)_{\cdot}$ if $n=0$. The complexified tangent space, considered as forms, for the Hilbert structure $\|.\|_2^2$ has an orthonormal basis $\overline{X}_{n,l}(e_i)_s = g\,(\exp[2i\pi ns]/\sqrt{Cn^2+1})\,e_i$ for $n \neq 0$. This splits the space of finite energy paths with values in V_g in $H_{\text{flat},+} + H_{\text{flat},-}$, where $H_{\text{flat},+}$ corresponds to positive n and $H_{\text{flat}-}$ to negative n in the choice of $\overline{X}_{n,l}(e_i)$. We consider the bundle $n_-(g)$ over G and we introduce the following limit bundle:

$$\Xi_l = \Lambda(H_{\text{flat},-}) \otimes \Lambda(n_-(g)) \otimes p^*\xi'. \tag{3.9}$$

The two last parts in Ξ_l are pullback bundles by the evaluation map $g_{\text{flat},\cdot} \to g$ of bundles over G. This bundle inherites a natural H-action, by transforming $\overline{X}_{n,l}(e_i)$ into $\overline{X}_{n,l}(h^{-1}e_i h)$, where h is an element of h and by transforming $X_0(f)$ into $X_0(h^{-1}fh)$, and by an immediate action over $p^*\xi$.

We consider the Bosonic Fock space $B(V_g)$ over $g_{\text{flat},\cdot}$ in V_g and we consider the bundle over G,

$$B(V_g) \otimes \Xi_l. \tag{3.10}$$

Over this limit supersymmetric Fock bundle, we have a connection, which acts as follow: we take the derivative of e_i in $\overline{X}_{n,l}(e_i)_{\cdot}$ for the trivial connection of G. [let us recall that V_g is isomorphic to $p^*T(G/H)$], which is equal to the pullback of the canonical connection over ξ', and which acts over the Wick polynomial $:\langle e_i \alpha_i g, g_{\text{flat},\cdot}\rangle:$ by taking the derivative of e_i and of g in the following formula, but not of $dB^1_{\cdot}(g)$. Namely for α_s a smooth path, we have

$$\begin{aligned}
\langle ge_i\alpha_{\cdot}, g_{\text{flat},\cdot}\rangle &= \int_0^1 \langle ge_i\alpha_s, dg_{\text{flat},s}\rangle \\
&= \int_0^1 \langle ge_i\alpha_s, gdB^1_s(g)\rangle \\
&= \int_0^1 \langle e_i, dB_s(g)\rangle.
\end{aligned} \tag{3.11}$$

This induces a connection over the bundle over G $B(V_g) \otimes \Xi_l$. This bundle inherites clearly an H-action, which is compatible with the connection.

We will construct a core where a ''limit'' Dirac–Ramond operator will act. Let us denote this core $\Lambda_H(\Xi_l)$. We consider the set of finite combination of $:\langle ge_i'\alpha_i, g_{\text{flat},\cdot}\rangle: \otimes \overline{X}_{-n,l}(e_i)_{\cdot} \wedge \overline{X}_{0,l}(f_j')_{\cdot} \otimes \psi$, where e_i depends only on g ($e_i g$ belongs in fact to V_g), f_j' depends only on g, the section ψ on $p^*\xi'$ depends only on g. We consider a finite wedge product of forms $\overline{X}_{-n,l}(e_i)_{\cdot}$, with a different convention of sign from (2.21), because these expressions are considered as forms and not as vectors. The same remarks works for $\overline{X}_{0,l}(f_j')_{\cdot}$. We remark that each of the elements of $\Lambda_H(\Xi_l)$ is not invariant under the H-action, in order to get a section of Ξ_l which is invariant under the H-action, we average it under the H-action.

We consider as orthogonal basis of the path with values in V_g of finite energy the set constituted of paths $g\int_0^t \exp[2i\pi ns]e_i\,ds = X_{n,l}(e_i)_t$ and $X_{0,l}(f_j) = gf_j$ and $X_0(f_j') = gf_j'$.
