$$\begin{aligned}
&\exp[-(i/\hbar)\vec{q_0}\cdot\overrightarrow{\mathbf{P}_*}]|\vec{p},\vec{q}\rangle=|\vec{p},\vec{q}+\vec{q_0}\rangle,\\
&\exp[(i/\hbar)\vec{p_0}\cdot\overrightarrow{\mathbf{Q}_*}]|\vec{p},\vec{q}\rangle=\exp[(i/\hbar)\vec{p_0}\cdot\vec{q}]|\vec{p}+\vec{p_0},\vec{q}\rangle,\\
&\exp[-(i/\hbar)\vec{\omega}\cdot\overrightarrow{\mathbf{J}_*}]|\vec{p},\vec{q}\rangle=|\mathcal{R}_{\vec{\omega}}(\vec{q}),\mathcal{R}_{\vec{\omega}}(\vec{p})\rangle,
\end{aligned} \tag{58}$$

where $\mathcal{R}_{\vec{\omega}}$ is the geometrical rotation.

The index ''*'' on $\overrightarrow{\mathbf{P}_*}$, $\overrightarrow{\mathbf{Q}_*}$ and $\overrightarrow{\mathbf{J}_*}$ is used to distinguish these ''prequantum operators'' from the true quantum ones that will be obtained by our procedure of quantization.

Now, while the old generators $\mathbf{X}_{\vec{p}}$ and $\mathbf{X}_{\vec{q}}$ were commuting, the new ones $\overrightarrow{\mathbf{P}_*}$ and $\overrightarrow{\mathbf{Q}_*}$ verify

$$[\mathbf{P}_{*i},\mathbf{Q}_{*j}]=-i\hbar\,\delta_{ij}. \tag{59}$$

In fact, for any component of the operators $\overrightarrow{\mathbf{P}_*}$, $\overrightarrow{\mathbf{Q}_*}$, and $\overrightarrow{\mathbf{J}_*}$, the expression of the commutator $(i/\hbar)[\mathbf{A},\mathbf{B}]$ exactly corresponds to the Poisson bracket of the associated classical observables ($\vec{p}$, $\vec{q}$, $\vec{l}$):

$$\begin{aligned}
&[\mathbf{P}_{*i},\mathbf{P}_{*j}]=[\mathbf{Q}_{*i},\mathbf{Q}_{*j}]=0,\\
&[\mathbf{P}_{*i},\mathbf{Q}_{*j}]=-i\hbar\,\delta_{ij},\\
&[\mathbf{J}_{*i},\mathbf{J}_{*j}]=i\hbar\,\epsilon_{ijk}\mathbf{J}_{*k},\\
&[\mathbf{J}_{*i},\mathbf{Q}_{*j}]=i\hbar\,\epsilon_{ijk}\mathbf{Q}_{*k},\\
&[\mathbf{J}_{*i},\mathbf{P}_{*j}]=i\hbar\,\epsilon_{ijk}\mathbf{P}_{*k}.
\end{aligned} \tag{60}$$

So, independent of our specific procedure of quantization of observables based on projection, it is natural to expect that these operators $\vec{\mathbf{P}}_*$, $\vec{\mathbf{Q}}_*$, and $\vec{\mathbf{J}}_*$ are the right representations of momentum, position and angular momentum.

We will find that our procedure of quantization confirms this hypothesis.

D. Angular momentum and spin

Starting from $\vec{\mathbf{P}}_*$, $\vec{\mathbf{Q}}_*$, and $\vec{\mathbf{J}}_*$, we define two new generators called $\vec{\mathbf{L}}_*$ and $\vec{\mathbf{S}}_*$:

$$\begin{aligned} \vec{\mathbf{L}}_* &= \vec{\mathbf{Q}}_* \wedge \vec{\mathbf{P}}_*, \\ \vec{\mathbf{S}}_* &= \vec{\mathbf{J}}_* - \vec{\mathbf{L}}_* = -i\hbar \vec{p} \wedge \vec{\nabla}_p - \hbar^2 \vec{\nabla}_p \wedge \vec{\nabla}_q. \end{aligned} \tag{61}$$

$\vec{\mathbf{L}}_*$ and $\vec{\mathbf{S}}_*$ are generators of rotations since their components verify $[\mathbf{A}_i, \mathbf{A}_j] = i\hbar \epsilon_{ijk} \mathbf{A}_k$. But, moreover, we have

$$[\mathbf{S}_{*i}, \mathbf{Q}_{*j}] = [\mathbf{S}_{*i}, \mathbf{P}_{*j}] = 0. \tag{62}$$

So, anticipating on the remainder, $\vec{\mathbf{L}}_*$ generates orbital rotations, while $\vec{\mathbf{S}}_*$ defines internal rotations: we find some spin representation.

Nevertheless, since $\vec{\mathbf{S}}_*$ is built with true vectors, it only generates integer spins.

This means that we cannot recover half-integer spins only starting with our configuration space $\mathcal{H} = L^2(\mathcal{C})$. If we want to recover all possible values of spin, we must add some external degrees of freedom to our Hilbert space.

More precisely, we must assume that the basis of $\mathcal{H}$ is $\{|\vec{p}, \vec{q}\rangle \otimes |\epsilon\rangle\}$ with $\epsilon = 0, \pm 1$. The value $\epsilon = 0$ corresponds to the previous case of integer spins, while the new values $\epsilon = \pm 1$ describe the half-integer components. We must also modify the generator $\vec{J}_*$ of rotations to take into account rotations of new degrees of freedom:

$$\vec{\mathbf{J}}_* = \hbar \vec{\mathbf{X}}_I + \frac{\hbar}{2} \vec{\Sigma}, \tag{63}$$

where $\vec{\Sigma}$ applied to $|\epsilon = 0\rangle$ gives 0, and applied to $|\epsilon = \pm 1\rangle$, $\vec{\Sigma}$ reduces to Pauli matrices.

Of course the operators $\vec{\mathbf{P}}_*$, $\vec{\mathbf{Q}}_*$, and $\vec{\mathbf{L}}_*$ are unchanged, and only $\vec{\mathbf{S}}_*$ is modified.

In the remainder we do not develop any further this extended framework, because the heaviness of the formalism hides the ideas involved in our procedure of quantization. So we continue to use our Hilbert space generated by the basis $\{|\vec{p}, \vec{q}\rangle\}$, but now we know that this framework can only generate integer spins, and so all the following is devoted to bosonic particles.

E. Discrete symmetries

1. Parity

Parity is defined as the linear operator $\mathbf{K}_P$ acting on states $|\vec{p}, \vec{q}\rangle$ as

$$\mathbf{K}_P |\vec{p}, \vec{q}\rangle = |-\vec{p}, -\vec{q}\rangle. \tag{64}$$

2. Time reversal

Classically speaking, time reversal transforms a state $(\vec{p}, \vec{q})$ into $(-\vec{p}, \vec{q})$. Then we can try to represent time reversal as a linear operator acting on states $|\vec{p}, \vec{q}\rangle$, such that $\mathbf{K}_T |\vec{p}, \vec{q}\rangle = |-\vec{p}, \vec{q}\rangle$. But if we take this definition, the linear condition is incompatible with Galilei boosts, because of the supplementary phase factor introduced into the representation. To obtain a consistent result, we must assume that $\mathbf{K}_T$ is an antilinear operator. So, we define $\mathbf{K}_T$ as an antilinear operator such that

$$\mathbf{K}_T |\vec{p}, \vec{q}\rangle = |-\vec{p}, \vec{q}\rangle. \tag{65}$$

3. Symplectic transform

The symmetry $\mathbf{K}_S$ has been defined in Sec. VII B 1, and by construction $\mathbf{K}_S$ commutes with all the previous symmetries.

VIII. IRREDUCIBLE REPRESENTATION OF THE GALILEI GROUP

Computations on the irreducible representations of the Galilei group in phase space have already been published[31] (for the Poincaré group, see Ref. 32); for the case of scalar particles (see Ref. 6, Chap. 1).

We recall here this analysis in order to prove the consistency of our approach and also to introduce specific notations.

A. Subspaces of irreducible representation of P_* and Q_*

We have seen that the generators $\overrightarrow{\mathbf{P}_*}$ and $\overrightarrow{\mathbf{Q}_*}$ verify $[\mathbf{P}_{*i},\mathbf{Q}_{*j}]=-i\hbar\,\delta_{ij}$ and we know that irreducible representations of these relations are obtained by $\overrightarrow{\mathbf{P}_*}\equiv -i\hbar\overrightarrow{\nabla}_x$ and $\overrightarrow{\mathbf{Q}_*}\equiv\vec{x}$ (for the moment $\vec{x}$ must be only seen as a parameter). So we look for (unbounded) states "$|\vec{x},\alpha\rangle$" such that

$$\begin{aligned}\langle\vec{x},\alpha|\overrightarrow{\mathbf{P}_*}|\vec{p},\vec{q}\rangle&=-i\hbar\overrightarrow{\nabla}_x\langle\vec{x},\alpha|\vec{p},\vec{q}\rangle,\\ \langle\vec{x},\alpha|\overrightarrow{\mathbf{Q}_*}|\vec{p},\vec{q}\rangle&=\vec{x}\langle\vec{x},\alpha|\vec{p},\vec{q}\rangle.\end{aligned}\tag{66}$$

If we call $\phi=\langle\vec{p},\vec{q}|\vec{x},\alpha\rangle$, using the explicit expression of $\overrightarrow{\mathbf{P}_*}$ and $\overrightarrow{\mathbf{Q}_*}$, we obtain

$$\begin{aligned}(\overrightarrow{\nabla}_q+\overrightarrow{\nabla}_x)\,\phi&=0,\\ i\hbar\overrightarrow{\nabla}_p\phi&=(\vec{x}-\vec{q})\,\phi.\end{aligned}\tag{67}$$

The general solution of this system is

$$\phi=\Phi(\vec{x}-\vec{q})\exp[-(i/\hbar)\vec{p}\cdot(\vec{x}-\vec{q})],\tag{68}$$

where Φ is an arbitrary function.

So the states' $\{|\vec{x},\alpha\rangle\}$ solutions of the problem are given by

$$\langle\vec{p},\vec{q}|\vec{x},\alpha\rangle=\Phi_\alpha(\vec{x}-\vec{q})\exp[-(i/\hbar)\vec{p}\cdot(\vec{x}-\vec{q})].\tag{69}$$

Computing the scalar product $\langle\vec{y},\beta|\vec{x},\alpha\rangle$ we obtain

$$\begin{aligned}\langle\vec{y},\beta|\vec{x},\alpha\rangle&=\langle\langle\beta|\alpha\rangle\rangle\,\delta(\vec{y}-\vec{x})\\ \langle\langle\beta|\alpha\rangle\rangle&=h^3\int d^3\vec{q}\,\Phi^*_\beta(\vec{q})\Phi_\alpha(\vec{q}),\end{aligned}\tag{70}$$

where $h=2\pi\hbar$ is the Planck constant and $\langle\langle\beta|\alpha\rangle\rangle$ defines a reduced scalar product on the fields Φ_α.

Now, if we take a complete orthonormal basis $\{\Phi_n\}$ for the reduced scalar product ($\langle\langle n|m\rangle\rangle=\delta_{n,m}$), the states $\{|\vec{x},n\rangle\}$ define a complete orthogonal basis for our configuration space and we can define the bounded projectors Π_n onto each subspace generated by the states $\{|\vec{x},n\rangle\}_{\vec{x}\in\mathbf{R}^3}$:

$$\Pi_n=\int d^3\vec{x}|\vec{x},n\rangle\langle\vec{x},n|.\tag{71}$$

Moreover, we have also the closure relation

$$\sum_n \Pi_n = \mathbf{1}_{\mathcal{H}}. \tag{72}$$

Each of these Π_n defines a subspace of irreducible representation of the commutation relations between $\overrightarrow{\mathbf{P}_*}$ and $\overrightarrow{\mathbf{Q}_*}$, so

$$[\overrightarrow{\mathbf{P}_*}, \Pi_n] = [\overrightarrow{\mathbf{Q}_*}, \Pi_n] = 0. \tag{73}$$

The action of space translations and Galilei boosts generated by $\overrightarrow{P_*}$ and $\overrightarrow{Q_*}$ on each subspace is given by

$$\begin{aligned} \exp[-(i/\hbar)\vec{q_0}\cdot\overrightarrow{\mathbf{P}_*}]|\vec{x},n\rangle &= |\vec{x}+\vec{q_0},n\rangle, \\ \exp[(i/\hbar)\vec{q_0}\cdot\overrightarrow{\mathbf{Q}_*}]|\vec{x},n\rangle &= \exp[(i/\hbar)\vec{p_0}\cdot\vec{x}]|\vec{x},n\rangle. \end{aligned} \tag{74}$$

Now, we look at irreducible representations of the rotation group, taking into account the previous results.

B. Irreducible representations of rotations

We have previously seen that the generator of rotations is $\overrightarrow{\mathbf{J}_*} = \overrightarrow{\mathbf{L}_*} + \overrightarrow{\mathbf{S}_*}$ with $[\overrightarrow{\mathbf{L}_*}, \overrightarrow{\mathbf{S}_*}] = 0$. Then,

$$\exp[-(i/\hbar)\vec{\omega}\cdot\overrightarrow{\mathbf{J}_*}] = \exp[-(i/\hbar)\vec{\omega}\cdot\overrightarrow{\mathbf{L}_*}]\exp[-(i/\hbar)\vec{\omega}\cdot\overrightarrow{\mathbf{S}_*}]. \tag{75}$$

Since by construction $\overrightarrow{\mathbf{L}_*} = \overrightarrow{\mathbf{Q}_*} \wedge \overrightarrow{\mathbf{P}_*}$ acts on each subspace Π_n as the usual quantum operator of orbital angular momentum, we have

$$\exp[-(i/\hbar)\vec{\omega}\cdot\overrightarrow{\mathbf{J}_*}]|\vec{x},n\rangle = \exp[-(i/\hbar)\vec{\omega}\cdot\overrightarrow{\mathbf{S}_*}]|\mathcal{R}_{\vec{\omega}}(\vec{x}),n\rangle. \tag{76}$$

Then irreducible representations of rotations are only dependent on the generators $\overrightarrow{\mathbf{S}_*}$. Moreover, we know that these representations are obtained by states $|S,m_S\rangle$ such that $\overrightarrow{\mathbf{S}_*}^2|S,m_S\rangle = \hbar^2 S(S+1)$ and $\mathbf{S}_{*z}|S,m_S\rangle = \hbar m_S|S,m_S\rangle$. Then we look for states $|\vec{x},S,m_S\rangle$ solving the problem.

The action of $\overrightarrow{\mathbf{S}_*}$ on $|\vec{x},n\rangle$ is given by

$$\langle\vec{p},\vec{q}|\overrightarrow{\mathbf{S}_*}|\vec{x},n\rangle = i\hbar\overrightarrow{\nabla}_p \wedge (\vec{p} + i\hbar\overrightarrow{\nabla}_q)\langle\vec{p},\vec{q}|\vec{x},n\rangle. \tag{77}$$

Taking the explicit expression (69) of $\langle\vec{p},\vec{q}|\vec{x},n\rangle$ we obtain

$$\langle\vec{p},\vec{q}|\overrightarrow{\mathbf{S}_*}|\vec{x},n\rangle = -i\hbar(\vec{x}-\vec{q}) \wedge \vec{\nabla}\Phi_n(\vec{x}-\vec{q})\exp[-(i/\hbar)\vec{p}\cdot(\vec{x}-\vec{q})]. \tag{78}$$

So $\overrightarrow{\mathbf{S}_*}$ only acts on the field Φ_n as the usual quantum orbital angular operator. Then we know that irreducible representations are obtained by spherical harmonics and the states $|\vec{x},S,m_S\rangle$ are defined by

$$\begin{aligned} \langle\vec{p},\vec{q}|\vec{x},S,m_S\rangle &= \Phi_{S,m_S}(\vec{x}-\vec{q})\exp[-(i/\hbar)\vec{p}\cdot(\vec{x}-\vec{q})], \\ \Phi_{S,m_S}(\vec{x}) &= \Psi(\|\vec{x}\|)Y_S^{m_S}(\vec{x}/\|\vec{x}\|). \end{aligned} \tag{79}$$

Here Ψ is an arbitrary function normalized with the reduced scalar product defined in (70):

$$\int_0^\infty x^2 dx |\Psi(x)|^2 = h^{-3}. \tag{80}$$

Now the action of the rotation group on the orthogonal basis $|\vec{x},S,m_S\rangle$ can be deduced from (76):

$$\exp[-(i/\hbar)\vec{\omega}\cdot\overrightarrow{\mathbf{J}_*}]|\vec{x},S,m\rangle = \sum_{m_1} R^S_{m_1,m}(\vec{\omega})|\mathcal{R}_{\vec{\omega}}(\vec{x}),S,m_1\rangle, \tag{81}$$

where $R^S_{m_1,m}(\vec{\omega})$ is the irreducible matrix of rotation.

C. Conclusion

The final result is that irreducible subspaces of the Galilei group are given by the projectors Π_S on the states generated by the orthogonal basis $\{|\vec{x},S,m\rangle\}$, that is,

$$\Pi_S = \sum_m \int d^3\vec{x}|\vec{x},S,m\rangle\langle\vec{x},S,m|. \tag{82}$$

Each of these subspaces depends of course on the value of S (integer), but also depends on an arbitrary function Ψ normalized in (80).

D. Action of discrete symmetries on an irreducible subspace

1. Parity

Following the definition (64) of the operator $\mathbf{K}_P$ we find

$$\langle\vec{p},\vec{q}|\mathbf{K}_P|\vec{x},S,m_S\rangle = \Phi_{S,m_S}(\vec{x}+\vec{q})\exp[(i/\hbar)\vec{p}\cdot(\vec{x}+\vec{q})]. \tag{83}$$

Now, using the parity of the spherical harmonics, we find

$$\mathbf{K}_P|\vec{x},S,m_S\rangle = (-1)^S|-\vec{x},S,m_S\rangle. \tag{84}$$

2. Time reversal

Following the definition (65) of the antilinear operator $\mathbf{K}_T$ we find

$$\langle\vec{p},\vec{q}|\mathbf{K}_T|\vec{x},S,m_S\rangle = \Phi^*_{S,m_S}(\vec{x}-\vec{q})\exp[-(i/\hbar)\vec{p}\cdot(\vec{x}-\vec{q})]. \tag{85}$$

Using the definition of Φ_{S,m_S} and the relation between spherical harmonics and its conjugate, we find

$$\langle\vec{p},\vec{q}|\mathbf{K}_T|\vec{x},S,m\rangle = (-1)^m\Psi^*(|\vec{x}-\vec{q}|)Y_S^{-m}\exp[-(i/\hbar)\vec{p}\cdot(\vec{x}-\vec{q})]. \tag{86}$$

We deduce that each subspace Π_S is invariant by time reversal, only if the unknown function Ψ verifies $\Psi^* = \alpha\Psi$.

Since Ψ is always defined up to a constant phase factor, **we assume in the remainder that Ψ is real**.

Then $\mathbf{K}_T$ is an antilinear operator that verifies

$$\mathbf{K}_T|\vec{x},S,m_S\rangle = (-1)^{m_S}|\vec{x},S,-m_S\rangle. \tag{87}$$

3. Symplectic transform

Using the definition (51) of the operator $\mathbf{K}_S$ we find

$$\langle \vec{p},\vec{q}|\mathbf{K}_S|\vec{x},S,m_S\rangle = \Phi_{S,m_S}(\vec{q}-\vec{x})\exp[-(i/\hbar)\vec{p}\cdot(\vec{x}-\vec{q})]. \tag{88}$$

Because of the parity of spherical harmonics, we find

$$\mathbf{K}_S|\vec{x},S,m_S\rangle = (-1)^S|\vec{x},S,m_S\rangle. \tag{89}$$

Then the nonclassical symmetry $\mathbf{K}_S$ acts on $|\vec{x},S,m_S\rangle$ as an intrinsic parity.

We conclude that the discrete symmetries $\mathbf{K}_P$, $\mathbf{K}_T$, and $\mathbf{K}_S$ are represented on each subspace Π_S, if we assume the unknown function Ψ to be real.

This condition on Ψ can be found in Ref. 6 (Chap. 1) in the study of ''stochastic probability currents,'' but it is not deduced from symmetry arguments as in our case.

IX. AXIOM OF QUANTIZATION

Any subspace $\mathcal{H}_S = \mathrm{Ran}(\Pi_S)$ corresponds to our requirements defined in Sec. VI C and a quantization is the projection from the global Hilbert space $\mathcal{H}$ on one of these subspaces $\mathcal{H}_S$.

As expected, the action of all symmetries on the states ''$|\vec{x},S,m_S\rangle$'' corresponds exactly with the quantum definition. But for the moment the quantities $\vec{x},S,m_S$ are only mathematical parameters and are not related to physical observables (even if we can guess their meaning).

On the other hand, each $\mathcal{H}_S$ is defined by the integer parameter S and the real function $\Psi(x)$. The essential effect of this function is to introduce a specific length scale λ as a characteristic of the representation. To make explicit this dependence, we reduce $\Psi(x)$ to a purely mathematical (dimensionless) function Ψ_0 by the scaling

$$\Psi(x) = (\lambda h)^{-3/2}\Psi_0(x/\lambda). \tag{90}$$

The condition of normalization (80) becomes

$$\int_0^\infty u^2 du \Psi_0(u)^2 = 1. \tag{91}$$

Finally, if we look at the main physical consequences of our procedure of quantization, we see that the important result is that a particle associated with a subspace $\mathcal{H}_S$ possesses an internal structure. This structure is defined by the intrinsic properties for rotations (spin S), and by a specific length scale λ. Through λ and Ψ, we recover the old idea of ''proper wave function'' first introduced by Landé[33] and Born[34] to describe elementary particles that are not pointlike. This result (and the consequences on measurement) is also obtained by Prugovečki (Ref. 6, Chap. 1, pp. 25 and 60). In fact, our idea of quantization can be seen as the reverse procedure of Prugovečki's approach (obtaining phase space representation of quantum mechanics).

At this stage, if we want to give a physical meaning to λ, we must specify what we mean by ''particles.'' Of course, elementary objects such as electrons or protons (in nonrelativistic mechanics) are particles, but atoms with frozen internal degrees of freedom can be also seen as particles.

A. The case of elementary particles

In nonrelativistic quantum mechanics, we cannot build a natural length scale λ for a true particle, but in relativistic quantum mechanics the Compton wave length $\lambda_c = h/Mc$ defines such intrinsic length scale. So it is natural to look at λ as the preceding of the relativistic quantity λ_c. This means that λ must always be a very small quantity (in regard to all other classical length scales).

B. The case of complex particles (atoms)

First, we must assume that all internal degrees of freedom are frozen, to be able to describe the system only using external dynamical quantities. In this case λ simply represents the geometrical size of the system. Moreover, we must always assume that λ is very small in regard to all other classical length scales of the problem, because the existence of some length scale of order of λ implies a dynamical effect on the internal degrees of freedom of the system.

X. THE BASIC QUANTIZED OBSERVABLES

In all the remainder the subspace $\mathcal{H}_S$ is assumed to be fixed, and following always our procedure of Sec. VI C, we can look how classical observables are transformed through quantization.

We recall that, starting from a classical quantity $f(\vec{p},\vec{q})$, we build first the associated classical operator **f**, and then we quantify **f** by taking the projection $\Pi_S \cdot \mathbf{f} \cdot \Pi_S$. The idea of projecting classical operators (stochastic observables) on irreducible subspaces in order to obtain quantum equations can be also found in Ref. 6, but it is not used as a general procedure to replace the correspondence principle and rebuild quantum mechanics.

A. Quantum operators of position and momentum

So, we define the quantum operator of position $\vec{\mathbf{Q}}$ and momentum $\vec{\mathbf{P}}$ as

$$\begin{aligned} \vec{\mathbf{Q}} &= \Pi_S \vec{\mathbf{q}} \Pi_S, \\ \vec{\mathbf{P}} &= \Pi_S \vec{\mathbf{p}} \Pi_S. \end{aligned} \tag{92}$$

First, we remark that the action of the symplectic transform K_S on the states $|\vec{x},S,m_S\rangle$ (89) implies

$$K_S \Pi_S = \Pi_S K_S = (-1)^S \Pi_S. \tag{93}$$

Now, we have the definitions (57) of $\overrightarrow{P_*}$ and $\overrightarrow{Q_*}$:

$$\begin{aligned} \overrightarrow{P_*} &= (\tfrac{1}{2})(\vec{\mathbf{p}} + K_S \vec{\mathbf{p}} K_S), \\ \overrightarrow{Q_*} &= (\tfrac{1}{2})(\vec{\mathbf{q}} + K_S \vec{\mathbf{q}} K_S). \end{aligned} \tag{94}$$

Projecting these relations with Π_S and taking into account (93), we obtain

$$\begin{aligned} \Pi_S \overrightarrow{P_*} &= \Pi_S \overrightarrow{P_*} \Pi_S = \Pi_S \vec{\mathbf{p}} \Pi_S = \vec{\mathbf{P}}, \\ \Pi_S \overrightarrow{Q_*} &= \Pi_S \overrightarrow{Q_*} \Pi_S = \Pi_S \vec{\mathbf{q}} \Pi_S = \vec{\mathbf{Q}} \end{aligned} \tag{95}$$

(we recall that by construction Π_S commutes with $\overrightarrow{P_*}$ and $\overrightarrow{Q_*}$).

So,

$$\begin{aligned} \langle \vec{x},S,m|\vec{\mathbf{P}}|\vec{y},S,m_1\rangle &= -i\hbar(\vec{\nabla}\delta)(\vec{x}-\vec{y})\,\delta_{m,m_1}, \\ \langle \vec{x},S,m|\vec{\mathbf{Q}}|\vec{y},S,m_1\rangle &= \vec{x}\,\delta(\vec{x}-\vec{y})\,\delta_{m,m_1}. \end{aligned} \tag{96}$$

Conclusion

We find that the quantized version $\vec{\mathbf{P}}$ and $\vec{\mathbf{Q}}$ of the classical observables $\vec{p}$ and $\vec{q}$ correspond precisely with the usual quantum operators.

Moreover, these operators are also the restriction of the generators of translations and Galilei boosts. This means that, in the ''quantum world,'' these observables are exactly the generators of symmetries (translation and Galilei boosts) as in the classical picture through Poisson brackets. (We also notice that our procedure allows us to remove the ambiguity between ''passive and active'' representations of $\vec{p}$ and $\vec{q}$.)

But, we will see in the following section, that this conclusion cannot be extended to angular momentum because of spin: the projection of the classical angular momentum $\vec{\mathbf{q}}\wedge\vec{\mathbf{p}}$ is not in general the restriction of the generator of rotations $\overrightarrow{J_*}$. In this case we must use other arguments to choose the quantum observable associated with angular momentum.

B. Quantum angular momentum and spin

We know from (57) that the generator of rotations is $\overrightarrow{\mathbf{J}_*}=-i\hbar(\vec{q}\wedge\overrightarrow{\nabla_q}+\vec{p}\wedge\overrightarrow{\nabla_p})$ and by construction Π_S commutes with $\overrightarrow{\mathbf{J}_*}$. Moreover, we have seen in (60) that the commutators of $\overrightarrow{\mathbf{P}_*}$, $\overrightarrow{\mathbf{Q}_*}$, and $\overrightarrow{\mathbf{J}_*}$ correspond exactly to the expression of the Poisson brackets of the classical quantities $\vec{p}$, $\vec{q}$ and $\vec{l}=\vec{q}\wedge\vec{p}$. Now, since we have proved that the restrictions $\vec{\mathbf{P}}$ and $\vec{\mathbf{Q}}$ of $\overrightarrow{\mathbf{P}_*}$ and $\overrightarrow{\mathbf{Q}_*}$ are the quantum operators of momentum and position, we can also guess that the ''quantum angular momentum'' $\vec{\mathbf{J}}$ is the restriction of the generator $\overrightarrow{\mathbf{J}_*}$. So we define

$$\vec{\mathbf{J}}=\Pi_S\overrightarrow{\mathbf{J}_*}=\overrightarrow{\mathbf{J}_*}\Pi_S=\Pi_S\overrightarrow{\mathbf{J}_*}\Pi_S. \tag{97}$$

Of course the general definitions of Sec. III for observables attest that $\vec{\mathbf{J}}$ (as a self-adjoint operator commuting with Π_S) is mathematically a possible observable. But up to now, we have only defined the quantum version of classical observables by our procedure of quantization. So we must first find the relation connecting $\vec{\mathbf{J}}$ to the quantized version $\Pi_S\vec{l}\Pi_S$ of the classical angular momentum $\vec{l}=\vec{q}\wedge\vec{p}$. The following lines are devoted to this question.

Taking into account the explicit expression of $\overrightarrow{\mathbf{P}_*}$ and $\overrightarrow{\mathbf{Q}_*}$, we rewrite $\overrightarrow{\mathbf{J}_*}$ as

$$\overrightarrow{\mathbf{J}_*}=\vec{\mathbf{q}}\wedge\overrightarrow{\mathbf{P}_*}+\overrightarrow{\mathbf{Q}_*}\wedge\vec{\mathbf{p}}-\vec{\mathbf{q}}\wedge\vec{\mathbf{p}}. \tag{98}$$

Using the equations (95) related to $\vec{\mathbf{P}}$ and $\vec{\mathbf{Q}}$ we find

$$\vec{\mathbf{J}}=2\vec{\mathbf{Q}}\wedge\vec{\mathbf{P}}-\Pi_S\vec{\mathbf{q}}\wedge\vec{\mathbf{p}}\Pi_S. \tag{99}$$

But we know also that the generator of rotations $\overrightarrow{\mathbf{J}_*}$ can be divided into $\overrightarrow{\mathbf{J}_*}=\overrightarrow{\mathbf{L}_*}+\overrightarrow{\mathbf{S}_*}$ with $\overrightarrow{\mathbf{L}_*}=\overrightarrow{\mathbf{Q}_*}\wedge\overrightarrow{\mathbf{P}_*}$, and by construction Π_S commutes with $\overrightarrow{\mathbf{L}_*}$ and $\overrightarrow{\mathbf{S}_*}$. So we can define two new quantum observables $\vec{\mathbf{L}}$ and $\vec{\mathbf{S}}$ as the restriction of $\overrightarrow{\mathbf{L}_*}$ and $\overrightarrow{\mathbf{S}_*}$**:**

$$\begin{aligned}\vec{\mathbf{L}}&=\Pi_S\overrightarrow{\mathbf{L}_*}=\overrightarrow{\mathbf{L}_*}\Pi_S=\vec{\mathbf{Q}}\wedge\vec{\mathbf{P}},\\ \vec{\mathbf{S}}&=\Pi_S\overrightarrow{\mathbf{S}_*}=\overrightarrow{\mathbf{S}_*}\Pi_S,\\ \vec{\mathbf{J}}&=\vec{\mathbf{L}}+\vec{\mathbf{S}}.\end{aligned} \tag{100}$$

We call $\vec{\mathbf{L}}$ ''orbital angular momentum'' and $\vec{\mathbf{S}}$ ''spin momentum.'' Now using Eqs. (99) and (100) we find finally

$$\Pi_S\vec{\mathbf{q}}\wedge\vec{\mathbf{p}}\Pi_S=\vec{\mathbf{L}}-\vec{\mathbf{S}}=\vec{\mathbf{Q}}\wedge\vec{\mathbf{P}}-\vec{\mathbf{S}}. \tag{101}$$

This shows that the quantized version of the classical angular momentum $\vec{l}=\vec{q}\wedge\vec{p}$ does not correspond in general to the generator $\vec{\mathbf{J}}$ (or $\vec{\mathbf{L}}$).

In fact, we find that $\Pi_S\vec{\mathbf{q}}\wedge\vec{\mathbf{p}}\Pi_S=\vec{\mathbf{L}}=\vec{\mathbf{J}}$ only in the case of scalar particles ($S=0$).

Then, for $S=0$, it is true that the quantized version of the classical angular momentum $\vec{l}=\vec{q}\wedge\vec{p}$ is the generator $\vec{\mathbf{J}}=\vec{\mathbf{L}}=\vec{\mathbf{Q}}\wedge\vec{\mathbf{P}}$ of rotations. This is because we call $\vec{\mathbf{L}}$ ''orbital angular momentum.'' But this correspondence fails for $S\neq 0$, because of the spin variables.

This result is very simple to understand, if we recall that $\vec{\mathbf{S}}$ cannot be obtained as the quantization of any classical observable. So, introducing spins in our formalism is equivalent to defining nonclassical observables. Then each subspace Π_S, for $S\neq 0$, cannot be described using only quantized version of classical observables, and this generates the nonequivalence between $\Pi_S\vec{\mathbf{I}}\Pi_S$ and $\vec{\mathbf{J}}$ (or $\vec{\mathbf{L}}$).

Nevertheless, if we look at the case $S\neq 0$ as an extension of $S=0$, we **must postulate** that $\vec{\mathbf{J}}$ is the physical quantum observable of angular momentum, precisely because $\vec{\mathbf{J}}$ is always the generator of rotations. Moreover, $\vec{\mathbf{L}}$ and $\vec{\mathbf{S}}$ are also quantum observables as the generator of orbital rotations and as the generator of spin rotations.

Finally, the parameter S and the nonclassical observable $\vec{\mathbf{S}}$ only appear because we look for irreducible representations of the Galilei group, in order to apply our general procedure of quantization. Then we recover the usual result that spins are ''purely quantum objects.''

Conclusion

We summarize the previous discussion in two points:

(i) In the case of scalar particles ($S=0$), it is true that the generator of rotations $\vec{\mathbf{J}}=\vec{\mathbf{L}}=\vec{\mathbf{Q}}\wedge\vec{\mathbf{P}}$ is the quantized version of the classical angular momentum $\vec{l}=\vec{q}\wedge\vec{p}$. This is because we call $\vec{\mathbf{L}}$ ''orbital angular momentum.''

(ii) In the case of nonscalar particles ($S\neq 0$), it is false that the generator of rotations $\vec{\mathbf{J}}=\vec{\mathbf{L}}+\vec{\mathbf{S}}=\vec{\mathbf{Q}}\wedge\vec{\mathbf{P}}+\vec{\mathbf{S}}$ is the quantized version of $\vec{l}=\vec{q}\wedge\vec{p}$. We must postulate that $\vec{\mathbf{J}}$ is the physical observable of angular momentum precisely because $\vec{\mathbf{J}}$ is always the generator of rotations. The operators $\vec{\mathbf{L}}$ and $\vec{\mathbf{S}}$ are also quantum observables as generators of orbital rotations and spin rotations (in fact $\vec{\mathbf{L}}=\Pi_S\vec{\mathbf{q}}\Pi_S\wedge\Pi_S\vec{\mathbf{p}}\Pi_S\neq\Pi_S\vec{\mathbf{q}}\wedge\vec{\mathbf{p}}\Pi_S$).

XI. SEMI-CLASSICAL PROPERTIES

This section is certainly the closest to Prugovečki's monograph,[6] because we recover the central part played by coherent states of the Galilei group to connect quantum operators with classical formulas. In fact, we recover the positive operator value (POV) measure that constitutes a ''stochastic phase-space system of covariance'' for the Galilei group. So, we do not develop in details the consequences on the stochastic level and measurements that can be found in Ref. 6.

A. Semi-classical states and semi-classical events

1. Semi-classical states

In the global Hilbert space $\mathcal{H}$, we have the closure relation

$$\mathbf{1}_{\mathcal{H}}=\int d^3\vec{p}\,d^3\vec{q}\,|\vec{p},\vec{q}\rangle\langle\vec{p},\vec{q}|. \tag{102}$$

Then,

$$\Pi_S=\int d^3\vec{p}\,d^3\vec{q}\,\Pi_S|\vec{p},\vec{q}\rangle\langle\vec{p},\vec{q}|\Pi_S. \tag{103}$$

We deduce that the states $|\xi_{\vec{p},\vec{q}},S\rangle=\Pi_S|\vec{p},\vec{q}\rangle$ define an overcomplete basis of our physical Hilbert space $\mathcal{H}_S$ (cf. Sec. VI B 3).

Moreover, using (79),

$$\langle\xi_{\vec{p},\vec{q}},S|\xi_{\vec{p},\vec{q}},S\rangle=\sum_m\int d^3\vec{x}\,|\Phi_{S,m}(\vec{x})|^2=(2S+1)h^{-3}. \tag{104}$$

These coherent states for the Galilei group have many applications in standard quantum dynamics (Omnès,[18] Perelomov or Klauder[5]). In Prugovečki's work,[6] these states introduce the "resolution generator" that represents the "proper wave function" of an extended test particle and allow us to give a concrete connection between standard quantum mechanics and its "stochastic phase-space" representation.

2. Semi-classical configuration events

If we take a classical event "A" in phase space, it is represented in $\mathcal{H}$ by the projector $\Pi(A)$:

$$\Pi(A)=\int_A d^3\vec{p}\,d^3\vec{q}\,|\vec{p},\vec{q}\rangle\langle\vec{p},\vec{q}|. \tag{105}$$

Quantizing $\Pi(A)$, we obtain $\Pi_S(A)$:

$$\Pi_S(A)=\Pi_S\Pi(A)\Pi_S=\int_A d^3\vec{p}\,d^3\vec{q}\,|\xi_{\vec{p},\vec{q}},S\rangle\langle\xi_{\vec{p},\vec{q}},S|. \tag{106}$$

As indicated in Sec. VI B 3, $\Pi_S(A)$ is no longer a true projector, and then $\Pi_S(A)$ must be seen as a "fuzzy" quantum event (quasiprojector), or a semi-classical event (Omnès[18]). In Prugovečki's monograph,[6] $\Pi_S(A)$ is exactly the POV measure that gives a system of covariance for the Galilei group.

Now, taking the trace of $\Pi_S(A)$, we obtain

$$\mathrm{Tr}(\Pi_S(A))=(2S+1)\mathcal{V}(A)h^{-3}, \tag{107}$$

where $\mathcal{V}(A)$ is the volume of "A" in phase space.

Then $\mathrm{Tr}(\Pi_S(A))$ gives exactly the semi-classical number of quantum states contained in the volume "A" of phase space.

B. Semi-classical states and quantum observables

1. Expectation values

For $\vec{\mathbf{P}}$, $\vec{\mathbf{Q}}$, $\vec{\mathbf{L}}=\vec{\mathbf{Q}}\wedge\vec{\mathbf{P}}$ and $\vec{\mathbf{S}}$, we find after some algebra

$$\begin{aligned}
\langle\xi_{\vec{p},\vec{q}},S|\vec{\mathbf{P}}|\xi_{\vec{p},\vec{q}},S\rangle&=\mathcal{N}\vec{p},\\
\langle\xi_{\vec{p},\vec{q}},S|\vec{\mathbf{Q}}|\xi_{\vec{p},\vec{q}},S\rangle&=\mathcal{N}\vec{q},\\
\langle\xi_{\vec{p},\vec{q}},S|\vec{\mathbf{L}}|\xi_{\vec{p},\vec{q}},S\rangle&=\mathcal{N}\vec{q}\wedge\vec{p},\\
\langle\xi_{\vec{p},\vec{q}},S|\vec{\mathbf{S}}|\xi_{\vec{p},\vec{q}},S\rangle&=0,
\end{aligned} \tag{108}$$

where $\mathcal{N}=\langle\xi_{\vec{p},\vec{q}},S|\xi_{\vec{p},\vec{q}},S\rangle=(2S+1)h^{-3}$.

These results are precisely what we expect for semi-classical states.

2. Splitting of observables on semi-classical states

Moreover, since $\vec{\mathbf{P}}=\Pi_S\vec{\mathbf{p}}\Pi_S$ and $\vec{\mathbf{Q}}=\Pi_S\vec{\mathbf{q}}\Pi_S$, we have

$$\begin{aligned}
\vec{\mathbf{P}}&=\int d^3\vec{p}\,d^3\vec{q}\,\vec{p}\,|\xi_{\vec{p},\vec{q}},S\rangle\langle\xi_{\vec{p},\vec{q}},S|,\\
\vec{\mathbf{Q}}&=\int d^3\vec{p}\,d^3\vec{q}\,\vec{q}\,|\xi_{\vec{p},\vec{q}},S\rangle\langle\xi_{\vec{p},\vec{q}},S|.
\end{aligned} \tag{109}$$

More generally, the quantized version $\mathbf{F}$ of any classical observable $f(\vec{p},\vec{q})$ possesses the splitting

$$\mathbf{F}=\Pi_S f(\vec{\mathbf{p}},\vec{\mathbf{q}})\Pi_S=\int d^3\vec{p}\,d^3\vec{q}\,f(\vec{p},\vec{q})|\xi_{\vec{p},\vec{q}},S\rangle\langle\xi_{\vec{p},\vec{q}},S|. \tag{110}$$

C. Quantized observables and statistics

The following formulas are also found in Refs. 6 and 14 (they are obtained in order to complete the formulation of quantum statistical mechanics on stochastic phase space).

For statistics, Sec. VI B shows that we must introduce a density operator $\mathbf{D}$ with $\Pi_S\mathbf{D}=\mathbf{D}\Pi_S=\mathbf{D}$.

Moreover, the expectation values of position and momentum are given by $\langle\vec{\mathbf{P}}\rangle=\mathrm{Tr}(\mathbf{D}\cdot\vec{\mathbf{P}})$, and $\langle\vec{\mathbf{Q}}\rangle=\mathrm{Tr}(\mathbf{D}\cdot\vec{\mathbf{Q}})$.

But because $\vec{\mathbf{P}}=\Pi_S\vec{\mathbf{p}}\Pi_S$, $\vec{\mathbf{Q}}=\Pi_S\vec{\mathbf{q}}\Pi_S$, and $\mathbf{D}=\Pi_S\mathbf{D}\Pi_S$, we also have $\langle\vec{\mathbf{P}}\rangle=\mathrm{Tr}(\mathbf{D}\cdot\vec{\mathbf{p}})$, and $\langle\vec{\mathbf{Q}}\rangle=\mathrm{Tr}(\mathbf{D}\cdot\vec{\mathbf{q}})$. So we can use our results of Sec. III B 3 on classical observables to obtain

$$\begin{aligned}1=\mathrm{Tr}(\mathbf{D})&=\int d^3\vec{p}\,d^3\vec{q}\,\rho(\vec{p},\vec{q}),\\ \langle\vec{\mathbf{P}}\rangle&=\int d^3\vec{p}\,d^3\vec{q}\,\vec{p}\,\rho(\vec{p},\vec{q}),\\ \langle\vec{\mathbf{Q}}\rangle&=\int d^3\vec{p}\,d^3\vec{q}\,\vec{q}\,\rho(\vec{p},\vec{q}),\end{aligned} \tag{111}$$

where $\rho(\vec{p},\vec{q})=\langle\vec{p},\vec{q}|\mathbf{D}|\vec{p},\vec{q}\rangle$ is a positive function since $\mathbf{D}$ is a positive operator.

As mentioned in Sec. III B 3, we recover that $\rho(\vec{p},\vec{q})$ is a true classical probability density, but $\hbar$ dependent, because $\mathbf{D}=\Pi_S\mathbf{D}\Pi_S$ depends in general on $\hbar$ through Π_S. Moreover, Eqs. (111) show that the quantum expectation values of $\vec{\mathbf{P}}$ and $\vec{\mathbf{Q}}$ can always be expressed with a classical formula, using a $\hbar$-dependent density of probability.

More generally, any expectation value $\langle\mathbf{F}\rangle=\mathrm{Tr}(\mathbf{D}\cdot\mathbf{F})$ of a quantized observable $\mathbf{F}$ obtained from a classical quantity $f(\vec{p},\vec{q})$ by $\mathbf{F}=\Pi_S f(\vec{\mathbf{p}},\vec{\mathbf{q}})\Pi_S$ verifies

$$\langle\mathbf{F}\rangle=\int d^3\vec{p}\,d^3\vec{q}\,f(\vec{p},\vec{q})\rho(\vec{p},\vec{q}). \tag{112}$$

So, for any quantum observable $\mathbf{F}$ deducible from a classical one $f(\vec{p},\vec{q})$ by our procedure of quantization, the expectation value is obtained by a classical formula, using the density $\rho(\vec{p},\vec{q})=\langle\vec{p},\vec{q}|\mathbf{D}|\vec{p},\vec{q}\rangle$.

Nevertheless, these semi-classical expressions cannot be extended to nonclassical observables like $\vec{\mathbf{S}}$ because we cannot find any classical quantity associated with $\vec{\mathbf{S}}$.

XII. QUANTUM DYNAMICS

As mentioned in Sec. II B 1 and developed in Secs. II B 3 and V, classical dynamics on $\mathcal{H}$ is induced by a classical observable H through the weak dynamical equations (7) which give the evolution of expectation values. Moreover, the evolution of a state ϕ is defined by a unitary operator U_{t_1,t_0} such that $\phi_{t_1}=U_{t_1,t_0}(\phi_{t_0})$ and Eqs. (7) can be written as Eqs. (27) that we recall here:

$$\begin{aligned}\frac{d}{dt}\langle\phi_t|\vec{\mathbf{q}}|\phi_t\rangle&=\langle\phi_t|\overrightarrow{\nabla}_p H(\vec{\mathbf{p}},\vec{\mathbf{q}},t)|\phi_t\rangle,\\ \frac{d}{dt}\langle\phi_t|\vec{\mathbf{p}}|\phi_t\rangle&=-\langle\phi_t|\overrightarrow{\nabla}_q H(\vec{\mathbf{p}},\vec{\mathbf{q}},t)|\phi_t\rangle.\end{aligned} \tag{113}$$

Remark: We can find in Ref. 6 (Chap. 3) the reverse procedure, that is, the method to recover classical equations, starting from quantum equations on stochastic phase space.

A. The quantum operator of evolution: Schrödinger equation

Now, since the physical Hilbert space is $\mathcal{H}_S$, $\mathcal{H}_S$ must be invariant under evolution and then $\Pi_S U_{t_1,t_0} = U_{t_1,t_0}\Pi_S$. So for any trajectory of states $\phi_t = U_{t,t_0}(\phi_{t_0}) \in \mathcal{H}_S$. Equations (113) of Sec. V A (where quantization is missing) have not to be changed, but now we must make explicit the condition $|\phi_t\rangle = \Pi_S|\phi_t\rangle$:

$$\begin{aligned}\frac{d}{dt}\langle\phi_t|\Pi_S\vec{\mathbf{q}}\Pi_S|\phi_t\rangle &= \langle\phi_t|\Pi_S\overrightarrow{\nabla}_p H(\vec{\mathbf{p}},\vec{\mathbf{q}},t)\Pi_S|\phi_t\rangle,\\ \frac{d}{dt}\langle\phi_t|\Pi_S\vec{\mathbf{p}}\Pi_S|\phi_t\rangle &= -\langle\phi_t|\Pi_S\overrightarrow{\nabla}_q H(\vec{\mathbf{p}},\vec{\mathbf{q}},t)\Pi_S|\phi_t\rangle.\end{aligned} \tag{114}$$

Using the definition of $\vec{\mathbf{P}}$ and $\vec{\mathbf{Q}}$, Eqs. (114) become

$$\begin{aligned}\frac{d}{dt}\langle\phi_t|\vec{\mathbf{Q}}|\phi_t\rangle &= \langle\phi_t|\Pi_S\overrightarrow{\nabla}_p H(\vec{\mathbf{p}},\vec{\mathbf{q}},t)\Pi_S|\phi_t\rangle,\\ \frac{d}{dt}\langle\phi_t|\vec{\mathbf{P}}|\phi_t\rangle &= -\langle\phi_t|\Pi_S\overrightarrow{\nabla}_q H(\vec{\mathbf{p}},\vec{\mathbf{q}},t)\Pi_S|\phi_t\rangle.\end{aligned} \tag{115}$$

Before any further computation, we want first to point out that, by construction, our new dynamical equations (115) for expectation values of $\vec{\mathbf{P}}$ and $\vec{\mathbf{Q}}$ always have the same semi-classical expression given by (7) where the classical density ρ_t is given by $\rho_t(\vec{p},\vec{q}) = |\langle\vec{p},\vec{q}|\phi_t\rangle|^2$.

Now, in order to write (115) in a simplified manner, we need the following technical remarks.

Remark: General relations between commutators and derivation. We have seen that any classical quantity $f(\vec{p},\vec{q})$ is represented on $\mathcal{H}$ by the operator $\mathbf{f} = f(\vec{\mathbf{p}},\vec{\mathbf{q}})$. Taking the definition (57) of the generators $\overrightarrow{\mathbf{P}_*}$ and $\overrightarrow{\mathbf{Q}_*}$ we have

$$\begin{aligned}[\overrightarrow{\mathbf{P}_*}, f(\vec{\mathbf{p}},\vec{\mathbf{q}})] &= -i\hbar\overrightarrow{\nabla}_q f(\vec{\mathbf{p}},\vec{\mathbf{q}}),\\ [\overrightarrow{\mathbf{Q}_*}, f(\vec{\mathbf{p}},\vec{\mathbf{q}})] &= i\hbar\overrightarrow{\nabla}_p f(\vec{\mathbf{p}},\vec{\mathbf{q}}).\end{aligned} \tag{116}$$

If we project these equations on $\mathcal{H}_S$, we obtain

$$\begin{aligned}[\vec{\mathbf{P}}, \Pi_S f(\vec{\mathbf{p}},\vec{\mathbf{q}})\Pi_S] &= -i\hbar\Pi_S\overrightarrow{\nabla}_q f(\vec{\mathbf{p}},\vec{\mathbf{q}})\Pi_S,\\ [\vec{\mathbf{Q}}, \Pi_S f(\vec{\mathbf{p}},\vec{\mathbf{q}})\Pi_S] &= i\hbar\Pi_S\overrightarrow{\nabla}_p f(\vec{\mathbf{p}},\vec{\mathbf{q}})\Pi_S.\end{aligned} \tag{117}$$

This shows how commutators between $\vec{\mathbf{P}}$, $\vec{\mathbf{Q}}$ and quantized observables $\Pi_S\mathbf{f}\Pi_S$ are connected to derivations.

We are ready now to write Eqs. (115) in a simplified way, using (117):

$$\begin{aligned}\frac{d}{dt}\langle\phi_t|\vec{\mathbf{Q}}|\phi_t\rangle &= i\hbar^{-1}\langle\phi_t|[\Pi_S H(\vec{\mathbf{p}},\vec{\mathbf{q}},t)\Pi_S, \vec{\mathbf{Q}}]|\phi_t\rangle,\\ \frac{d}{dt}\langle\phi_t|\vec{\mathbf{P}}|\phi_t\rangle &= i\hbar^{-1}\langle\phi_t|[\Pi_S H(\vec{\mathbf{p}},\vec{\mathbf{q}},t)\Pi_S, \vec{\mathbf{P}}]|\phi_t\rangle.\end{aligned} \tag{118}$$

So, if we introduce the quantized observable $\mathbf{H}(t) = \Pi_S H(\vec{\mathbf{p}},\vec{\mathbf{q}},t)\Pi_S$ associated with the classical Hamiltonian $H(\vec{p},\vec{q},t)$, previous equations become

$$\frac{d}{dt}\langle\phi_t|\vec{\mathbf{Q}}|\phi_t\rangle = i\hbar^{-1}\langle\phi_t|[\mathbf{H}(t),\vec{\mathbf{Q}}]|\phi_t\rangle,$$
$$\frac{d}{dt}\langle\phi_t|\vec{\mathbf{P}}|\phi_t\rangle = i\hbar^{-1}\langle\phi_t|[\mathbf{H}(t),\vec{\mathbf{P}}]|\phi_t\rangle, \tag{119}$$

or, for any initial state $\phi_0 \in \mathcal{H}_S$,

$$\frac{d}{dt}\langle\phi_0|U^\dagger_{t,t_0}\vec{\mathbf{Q}}U_{t,t_0}|\phi_0\rangle = i\hbar^{-1}\langle\phi_0|U^\dagger_{t,t_0}[\mathbf{H}(t),\vec{\mathbf{Q}}]U_{t,t_0}|\phi_0\rangle,$$
$$\frac{d}{dt}\langle\phi_0|U^\dagger_{t,t_0}\vec{\mathbf{P}}U_{t,t_0}|\phi_0\rangle = i\hbar^{-1}\langle\phi_0|U^\dagger_{t,t_0}[\mathbf{H}(t),\vec{\mathbf{P}}]U_{t,t_0}|\phi_0\rangle. \tag{120}$$

We know that these equations are solved if U_{t,t_0} is the unitary group generated by $\mathbf{H}(t)$:

$$i\hbar\frac{d}{dt}U_{t,t_0} = \mathbf{H}(t)U_{t,t_0},$$
$$U_{t_0,t_0} = \mathbf{1}. \tag{121}$$

So any trajectory of states $|\phi_t\rangle$ verifies the equation

$$i\hbar\frac{d}{dt}|\phi_t\rangle = \mathbf{H}(t)|\phi_t\rangle. \tag{122}$$

This is precisely the general form of Schrödinger equation.

So, symbolically speaking, we have solved the problem of quantum dynamics.

To finish, let us remark that the expectation value $\langle\phi_t|\mathbf{H}(t)|\phi_t\rangle$ possesses also a semi-classical expression:

$$\langle\phi_t|\mathbf{H}(t)|\phi_t\rangle = \int d^3\vec{p}\,d^3\vec{q}\,\rho_t H(\vec{p},\vec{q},t), \tag{123}$$

where $\rho_t(\vec{p},\vec{q}) = |\langle\vec{p},\vec{q}|\phi_t\rangle|^2$, because $\mathbf{H}(t) = \Pi_S H(\vec{\mathbf{p}},\vec{\mathbf{q}},t)\Pi_S$ is the quantized version of the classical Hamiltonian (cf. Sec. X E).

Conclusion

Of course we have recovered that the evolution of states is given by Schrödinger equation. But we want to remark that our starting point for dynamics was uniquely the "weak dynamical equations" introduced early in Sec. II B 3, and by construction they are always valid using the pseudo-classical density $\rho_t(\vec{p},\vec{q}) = |\langle\vec{p},\vec{q}|\phi_t\rangle|^2$. So, we have shown, in fact, that weak dynamical equations possess solutions in $\rho_t(\vec{p},\vec{q})$ that do not follow the Liouville equation, and these other solutions are those given by quantum dynamics.

Of course, it remains to make explicit the quantum Hamiltonian $\mathbf{H}(t)$ to prove that we recover the usual expression of the Schrödinger equation. This is done in the last paragraph.

B. The quantum Hamiltonian

The general form of the classical Hamiltonian $H(\vec{p},\vec{q},t)$ is

$$H = \frac{1}{2M}(\vec{p} - e\vec{A}(\vec{q},t))^2 + V(\vec{q},t), \tag{124}$$

the quantum Hamiltonian being $\mathbf{H}(t)=\Pi_S H(\vec{\mathbf{p}},\vec{\mathbf{q}},t)\Pi_S$. The idea of using projection of the external fields as $\Pi_S V(\vec{\mathbf{q}},t)\Pi_S$ to describe the interaction of an ''extended particle'' can be found in Ref. 6, but it is not deduced from a general procedure as in our point of view. It is rather induced from external arguments. Of course some of the following computations are in the previous reference, but we prefer to recall the full procedure to obtain a global result.

To simplify computations, we study independently the free Hamiltonian, the case of interaction with a potential energy and the case of interaction with a magnetic field.

1. The free quantum Hamiltonian

The quantum Hamiltonian **H** reduces to

$$\mathbf{H}=\frac{1}{2M}\Pi_S\vec{\mathbf{p}}^2\Pi_S. \tag{125}$$

Taking into account the expression of $\langle\vec{p},\vec{q}|\vec{x},S,m\rangle$, we compute the matrix element $\langle\vec{x},S,m|\vec{\mathbf{p}}^2|\vec{y},S,m_1\rangle$ and we find

$$\langle\vec{x},S,m|\vec{\mathbf{p}}^2|\vec{y},S,m_1\rangle=-\hbar^2(\Delta\delta)(\vec{x}-\vec{y})h^3\int d^3\vec{q}\,\Phi^*_{S,m}(\vec{x}-\vec{q})\Phi_{S,m_1}(\vec{y}-\vec{q}). \tag{126}$$

From the properties of $\Delta\delta$, this expression can be split into

$$\begin{aligned}
&\langle\vec{x},S,m|\vec{\mathbf{p}}^2|\vec{y},S,m_1\rangle=A+B+C,\\
&A=-\hbar^2(\Delta\delta)(\vec{x}-\vec{y})h^3\int d^3\vec{q}\,\Phi^*_{S,m}(\vec{x}-\vec{q})\Phi_{S,m_1}(\vec{x}-\vec{q}),\\
&B=-2\hbar^2(\vec{\nabla}\delta)(\vec{x}-\vec{y})h^3\int d^3\vec{q}\,\Phi^*_{S,m}(\vec{x}-\vec{q})(\vec{\nabla}\Phi_{S,m_1})(\vec{x}-\vec{q}),\\
&C=-\hbar^2\delta(\vec{x}-\vec{y})h^3\int d^3\vec{q}\,\Phi^*_{S,m}(\vec{x}-\vec{q})(\Delta\Phi_{S,m_1})(\vec{x}-\vec{q}).
\end{aligned} \tag{127}$$

Taking into account the properties of orthogonality and normalization of the fields $\Phi_{S,m}$, we first obtain

$$A=-\hbar^2(\Delta\delta)(\vec{x}-\vec{y})\,\delta_{m,m_1}. \tag{128}$$

Now, because of the parity of $\Phi_{S,m}$, we have

$$B=0. \tag{129}$$

Finally, if we use the explicit expression (79) of $\Phi_{S,m}$ and the expression of Δ in spherical coordinates, we find

$$\begin{aligned}
&C=K\delta(\vec{x}-\vec{y})\,\delta_{m,m_1},\\
&K=\hbar^2h^3\int_0^\infty dr\{[(r\Psi)']^2+S(S+1)\Psi^2\}.
\end{aligned} \tag{130}$$

Now, we want to use the scaling on the function $\Psi(x)$ introduced in Sec. IX to exhibit the dependence of the representation in a scale length λ. We recall that we take a dimensionless mathematical function Ψ_0 such that $\Psi(x)=(\lambda h)^{-3/2}\Psi_0(x/\lambda)$. Using this scaling, we find that the previous constant K is

$$K=(\hbar\chi/\lambda)^2,$$
$$\chi^2=\int_0^\infty du\{[(u\Psi_0)']^2+S(S+1)\Psi_0^2\}, \tag{131}$$

where χ^2 is a dimensionless positive coefficient.

If we summarize this computation, we have

$$\langle\vec{x},S,m|\mathbf{H}|\vec{y},S,m_1\rangle=-(\hbar^2/2M)(\Delta\delta)(\vec{x}-\vec{y})\,\delta_{m,m_1}+E_0\,\delta(\vec{x}-\vec{y})\,\delta_{m,m_1},$$
$$E_0=\hbar^2\chi^2\lambda^{-2}/2M, \tag{132}$$

or in the operator formalism

$$\mathbf{H}=\frac{1}{2M}\vec{\mathbf{P}}^2+E_0. \tag{133}$$

We recover the usual quantum Hamiltonian of the free particle with a supplementary constant E_0. Of course this constant does not modify dynamical properties and we can simply ignore it.

But if we want to give a physical meaning to this term, we must say that the particle possesses an intrinsic proper energy. So, exactly as in Sec. IX, we must distinguish the case of true elementary particles from the case of more complex systems.

a. The case of elementary particles. For a true particle, the only possible definition of E_0 is the mass energy of the particle. Of course, we cannot directly find E_0 in the framework of nonrelativistic mechanics and then $E_0=Mc^2$ must be induced from external arguments. But if we assume this formula, we find that the scale length λ verifies

$$\lambda=\lambda_c\frac{\chi}{2\sqrt{2}\,\pi}, \tag{134}$$

where $\lambda_c=h/Mc$ is the Compton wave length.

So we recover the intuitive result of Sec. IX, where we have recognized in λ the Compton wave length. Since we are in nonrelativistic mechanics, λ must always be a very small quantity in regard to all other length scales.

b. The case of complex systems. As mentioned in Sec. IX, if the particle possesses an internal structure, we must assume that all internal degrees of freedom are frozen, and then E_0 represents the internal energy.

2. Quantum Hamiltonian with a potential energy

The quantum Hamiltonian $\mathbf{H}(t)$ reduces to

$$\mathbf{H}(t)=\frac{1}{2M}\Pi_S\vec{\mathbf{p}}^2\Pi_S+\Pi_S V(\vec{\mathbf{q}},t)\Pi_S. \tag{135}$$

Taking into account the result on the free case, we have

$$\mathbf{H}(t)=\frac{1}{2M}\vec{\mathbf{P}}^2+E_0+\Pi_S V(\vec{\mathbf{q}},t)\Pi_S. \tag{136}$$

So we have only to specify the matrix element $\langle\vec{x},S,m|V(\vec{\mathbf{q}},t)|\vec{y},S,m_1\rangle$.

After some algebra, we find

$$\langle \vec{x},S,m|V(\vec{\mathbf{q}},t)|\vec{y},S,m_1\rangle = \delta(\vec{x}-\vec{y})h^3 \int d^3\vec{q}\,V(\vec{x}-\vec{q},t)\Phi^*_{S,m}(\vec{q})\Phi_{S,m_1}(\vec{q}). \tag{137}$$

Using our scaling on the function Ψ in $\Phi_{S,m}$, we have

$$\langle \vec{x},S,m|V(\vec{\mathbf{q}},t)|\vec{y},S,m_1\rangle = \delta(\vec{x}-\vec{y}) \int d^3\vec{u}\,V(\vec{x}-\lambda\vec{u},t)\Psi_0(u)^2 Y^m_S(\hat{u})^* Y^{m_1}_S(\hat{u}), \tag{138}$$

where $\hat{u}=\vec{u}/|\vec{u}|$.

Now, if we want to simplify the previous expression, we must take into account the magnitude of λ in comparison with the length scale of variation of $V(\vec{x})$. We have seen in the previous section that λ must always be very small in regard to all other length scales, so we can use the following development in the equation (138):

$$V(\vec{x}-\lambda\vec{u},t) \simeq V(\vec{x},t) - \lambda\vec{u}\cdot\vec{\nabla}V(\vec{x},t) + \lambda^2\epsilon. \tag{139}$$

Taking into account the parity of the spherical harmonics, we obtain that the first order in λ vanishes and

$$\langle \vec{x},S,m|V(\vec{\mathbf{q}},t)|\vec{y},S,m_1\rangle = (V(\vec{x},t)\,\delta_{m,m_1} + \lambda^2\epsilon)\delta(\vec{x}-\vec{y}). \tag{140}$$

Then, up to the second order in λ, the operator $\Pi_S V(\vec{\mathbf{q}},t)\Pi_S$ can be identified with $V(\vec{\mathbf{Q}},t)$. So if we neglect the corrections in λ^2, we conclude that the quantum Hamiltonian $\mathbf{H}(t)$ is

$$\mathbf{H}(t) = \frac{1}{2M}\vec{\mathbf{P}}^2 + E_0 + V(\vec{\mathbf{Q}},t). \tag{141}$$

We recover the usual Hamiltonian of quantum mechanics.

a. The harmonic case. In the particular case where $V(\vec{\mathbf{q}}) = \frac{1}{2}m\omega^2\vec{\mathbf{q}}^2$, we can compute completely the operator $\Pi_S V(\vec{\mathbf{q}})\Pi_S$ and we obtain

$$\Pi_S V(\vec{\mathbf{q}})\Pi_S = V(\vec{\mathbf{Q}}) + E_1, \tag{142}$$

where E_1 is a supplementary constant energy given by

$$E_1 = \frac{1}{2}m\omega^2\lambda^2\eta^2 \quad \text{with} \quad \eta^2 = \int_0^\infty u^4 du\,\Psi_0(u)^2. \tag{143}$$

b. Conclusion. We recover the quantum operator of potential energy, but we see that the operator $V(\vec{\mathbf{Q}},t)$ is only an approximation (up to second order in λ) of the true quantized operator $\Pi_S V(\vec{\mathbf{q}},t)\Pi_S$. So, the prescription of the correspondence principle corresponds in fact to the limiting case $\lambda \to 0$. But, if it is possible to take this limit for $\Pi_S V(\vec{\mathbf{q}},t)\Pi_S$, we cannot do so directly with the free part of the Hamiltonian because $E_0 \propto 1/\lambda^2$: we need first to renormalize the free Hamiltonian. Moreover, if we take this limit, we lose our ''connection with the classical world'' because the value $\lambda = 0$ is forbidden for reasons of normalization: λ can be as small as you want but never cancelled.

To conclude, we can say that this approach specifies the limit of the usual correspondence principle which postulates that the classical potential $V(\vec{q},t)$ must be directly lifted into quantum Hamiltonian. In fact, mathematically speaking, the true operator $\Pi_S V(\vec{\mathbf{q}},t)\Pi_S$ depends on S and λ, but because λ is always very small (in nonrelativistic mechanics), we can physically ignore it.

The idea of using the projected field $\Pi_S V(\vec{\mathbf{q}},t)\Pi_S$ for an extended particle and the corresponding computation can be found in Ref. 6.

3. Quantum Hamiltonian with a magnetic field

To simplify computations, we only study the case of a uniform magnetic field $\vec{B}$ associated with the potential vector $\vec{A}(\vec{q})=\frac{1}{2}\vec{B}\wedge\vec{q}$. The quantum Hamiltonian $\mathbf{H}$ is

$$\mathbf{H}=\frac{1}{2M}\Pi_S[\vec{\mathbf{p}}-e\vec{A}(\vec{\mathbf{q}})]^2\Pi_S. \tag{144}$$

Developing the previous expression, we have

$$\mathbf{H}=\frac{1}{2M}\Pi_S\vec{\mathbf{p}}^2\Pi_S-\frac{e}{M}\Pi_S\vec{\mathbf{p}}\cdot\vec{A}(\vec{\mathbf{q}})\Pi_S+\frac{e^2}{2M}\Pi_S\vec{A}(\vec{\mathbf{q}})^2\Pi_S. \tag{145}$$

Using the expression of the free Hamiltonian we obtain

$$\mathbf{H}=\frac{1}{2M}\vec{\mathbf{P}}^2+E_0+\mathbf{H}_1+\mathbf{H}_2,$$

$$\mathbf{H}_1=-\frac{e}{M}\Pi_S\vec{\mathbf{p}}\cdot\vec{A}(\vec{\mathbf{q}})\Pi_S, \tag{146}$$

$$\mathbf{H}_2=\frac{e^2}{2M}\Pi_S\vec{A}(\vec{\mathbf{q}})^2\Pi_S.$$

We first look at $\mathbf{H}_1$, using the explicit form of $\vec{A}(\vec{q})$:

$$\mathbf{H}_1=-\frac{e}{2M}\Pi_S\vec{\mathbf{p}}\cdot(\vec{B}\wedge\vec{\mathbf{q}})\Pi_S=-\frac{e}{2M}\vec{B}\cdot\Pi_S\vec{\mathbf{q}}\wedge\vec{\mathbf{p}}\Pi_S. \tag{147}$$

But we have seen in Sec. X B that $\Pi_S\vec{\mathbf{q}}\wedge\vec{\mathbf{p}}\Pi_S=\vec{\mathbf{Q}}\wedge\vec{\mathbf{P}}-\vec{\mathbf{S}}$. Then,

$$\mathbf{H}_1=-\frac{e}{2M}\vec{B}\cdot(\vec{\mathbf{Q}}\wedge\vec{\mathbf{P}})+\frac{e}{2M}\vec{B}\cdot\vec{\mathbf{S}}. \tag{148}$$

We can transform again the first term to obtain

$$\mathbf{H}_1=-\frac{e}{M}(\vec{A}(\vec{\mathbf{Q}})\cdot\vec{\mathbf{P}}+\vec{\mathbf{P}}\cdot\vec{A}(\vec{\mathbf{Q}}))+\frac{e}{2M}\vec{B}\cdot\vec{\mathbf{S}}. \tag{149}$$

Since $\mathbf{H}_2$ can be seen as a harmonic potential energy, we can use the result of the previous paragraph to obtain

$$\mathbf{H}_2=\frac{e^2}{2M}\vec{A}(\vec{\mathbf{Q}})^2+E_1. \tag{150}$$

If we collect all the results, we conclude that the quantum Hamiltonian is

$$\mathbf{H}=\frac{1}{2M}[\vec{\mathbf{P}}-e\vec{A}(\vec{\mathbf{Q}})]^2+\frac{e}{2M}\vec{B}\cdot\vec{\mathbf{S}}+E_0+E_1. \tag{151}$$

So we find that our projection of the classical Hamiltonian (where spin is missing) generates directly an interaction between spin and magnetic field. Of course, if we believe in this formula,

we must say that the particle possesses a magnetic momentum $\vec{\boldsymbol{\mu}}_0 = -(e/2M)\vec{\mathbf{S}}$. Unfortunately $\vec{\boldsymbol{\mu}}_0$ does not correspond in general to the true value of $\vec{\boldsymbol{\mu}}$. The reason is that $\vec{\boldsymbol{\mu}}_0$ only describes the part of $\vec{\boldsymbol{\mu}}$ deducible from our classical Hamiltonian.

In fact, when $\vec{B}$ is uniform, we can add to $\mathbf{H}$ any supplementary term as $\mathbf{H}_I = -(g+1)(e/2M)\vec{B}\cdot\vec{\mathbf{S}}$ without changing the equations of motion for $\vec{\mathbf{P}}$ and $\vec{\mathbf{Q}}$. So, because $\vec{\mathbf{S}}$ is not a classical observable, the part of $\mathbf{H}$ that specifies the evolution of $\vec{\mathbf{S}}$ is not given by our procedure, which is only based on the classical observables $\vec{\mathbf{P}}$ and $\vec{\mathbf{Q}}$. The term $-\vec{\boldsymbol{\mu}}_0\cdot\vec{B}$ must be only seen as an indication on the form of interaction between $\vec{\mathbf{S}}$ and $\vec{B}$. Of course, adding $\mathbf{H}_I$ to our Hamiltonian allows us to recover the usual formula for $\vec{\boldsymbol{\mu}}$.

Finally, if we assume $\vec{B}$ to be nonuniform, we see that the new Hamiltonian $\mathbf{H}_I$ introduces a new dynamical coupling between classical observables and $\vec{\mathbf{S}}$. This purely quantum effect (on expectation values) cannot be reproduced by our procedure.

XIII. CONCLUSION

This analysis shows how the overlapped components of classical and quantum mechanics can be separated to give a complete sequential structure that allows a better understanding of the role of each ingredient. Moreover, we can get rid of too crude rules of quantization based only on pairs of canonical coordinates, which do not explain why only one system of canonical coordinates gives the right quantization. Our procedure also allows one to give a satisfactory explanation of the apparent illogical process that consists in building quantum dynamical equations only using classical quantities (the classical potential energy, for example). Moreover, we recover the central part played by coherent states to connect classical and quantum objects.

As specified in the Introduction and all through the text, Prugovečki's work contains a great number of key points common with this article. The main differences with this article are in the point of view (leading idea) and the way of putting together the mathematical elements. But in both cases we find the same important physical result: in general, a particle must be dressed with a ''proper wave function'' that introduces a specific length scale. All the consequences on the localizability of particles are not developed in this article, since they can be found in Prugovečki's monograph.[6]

Nevertheless, as indicated in the Introduction, this article is not ''logically complete'' because general quantum axiomatics are not rebuilt (as a change of mathematical language) from ideas of classical mechanics. So, we can look at the beginnning of this article as a ''middle-point,'' the first part will be published later.

To conclude, we can consider two natural directions of generalizations of our procedure: the first one concerns the multiparticle case and second quantization, the second one is of course special relativity (that should be intimately related to Prugovečki's work).

ACKNOWLEDGMENTS

It is a pleasure to acknowledge useful discussions with Dr. A. Valance. We also thank Dr. J. Mourad for helpful comments and corrections of many language errors.

Classical limit of fermions in phase space

A. O. Bolivar[a)]
IMECC-UNICAMP, Instituto de Matematica, C.P. 6065, 13083-970 Sao Paulo, Brazil

(Received 18 January 2001; accepted for publication 11 May 2001)

Using the mathematical structure of the Grassmann algebra, studied by Schönberg, we write down the Pauli equation and the Dirac equation in phase space. In addition, in order to investigate the physical nature of the spin degree of freedom inherent in these equations we set up a novel classical limiting process $\hbar \to 0$. Thus we are able to derive relativistic and nonrelativistic classical statistical mechanics, for particle with spin 1/2, within a geometric algebra framework. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1386411]

I. INTRODUCTION

Alternative formulations of the Dirac equation aim to reveal new mathematical and physical interpretations hidden in the ordinary formulation. Following this spirit, attempts of expressing the Dirac theory using a quaternionic algebra[1–4] or in terms of geometric algebra, *à la* Hestenes,[5–7] show some nontrivial results:

(i) the usual Schrödinger equation presents spin;[5,6,1]
(ii) the Dirac equation can be formulated without making reference to matrices and complex numbers;[7,8]
(iii) one avoids anomalies, ambiguities, and inconsistencies with regard to the conservation laws once calculated by using the usual methods.[9]

It is worth noticing that these algebraic versions of the Dirac equation lie on configuration space. Another way to formulate the Dirac theory is in terms of the geometric algebra, *à la* Schönberg,[10–12] initiated by Bohm and Hiley[13] and developed by Holland.[14] Here the Dirac theory lies on phase space. It is important therefore to explore some possible relations between these two algebraic-geometrical approaches. To this end, following the Bohm–Hiley–Holland method, we obtain the Pauli equation in *phase space* and point out its relationship with the Schrödinger equation (in phase space, as well). Thus we answer in a natural way how the spin may appear in the Schrödinger theory.

The present work aims also to connect the quantum theory with the classical one. We define in Sec. II a classical limiting method and apply it to the Schrödinger equation in terms of wave function $\psi(q,t)$ and Wigner function $W(q,p,t)$; we also apply this method to the usual Dirac equation. After presenting some elements of the Schönberg geometric algebra (Sec. III), in Secs. IV and V we evaluate the classical limit of the Dirac and Pauli equations in phase space, respectively. In Sec. VI final remarks are included.

II. THE CLASSICAL LIMIT $\hbar \to 0$

In order to define a classical limiting method of quantum dynamics we inspire ourselves on the purely formal works by Hermann.[15,16] The fundamental idea is to start from a given (quantum) differential equation

$$\mathcal{O}_\hbar \Xi_\hbar = 0 \tag{1}$$

[a)]Permanent address: Instituto Cultural Eudoro de Sousa, Departamento Mário Schönberg de Física, Ceilândia, 7221-970, C. P. 7316, D. F., Brazil. Electronic mail: bolivar@ime.unicamp.br

and to perform the transformation

$$\Xi'_\hbar = e^{\alpha\xi/\hbar}\Xi_\hbar \tag{2}$$

characterized by the arbitrary parameter α and by the function ξ (without $\hbar$); thus Eq. (1) turns to be

$$\overline{\mathcal{O}}^{\xi}_{\hbar}\Xi'_\hbar = 0. \tag{3}$$

By taking $\hbar \to 0$ in Eq. (3) we obtain an equation of motion only for ξ, so that any quantal information contained in Eq. (1) or (3) disappears in the classical domain. Provided asymptotic conditions are obeyed by the function $\Xi'_\hbar$ and its derivatives in the limit $\hbar \to 0$, the resulting equation for ξ is called the classical limit of Eq. (1). In other words, in our method the classical limit of quantum dynamics occurs without requiring the convergence of the function $\Xi'_\hbar$ as $\hbar \to 0$.

Below we are going to apply this method to the usual Schrödinger and Dirac equations.

A. Classical limit of the Schrödinger equation in configuration space

Let us consider a particle (an electron, for example) with mass m, charge $|e|$ under the influence of an external scalar potential $V(q^k,t)$ and of electromagnetic fields described by the equation $(k=1,2,3)$

$$\imath\hbar\frac{\partial\psi}{\partial t} + \frac{\hbar^2}{2m}\frac{\partial^2\psi}{\partial q^k \partial q^k} - \frac{e\hbar\imath}{c}A_K\frac{\partial\psi}{\partial q^k} - \left[\frac{e\hbar\imath}{2mc}\frac{\partial A_k}{\partial q^k} + \frac{e^2}{2mc^2}A_k^2 - e\phi - V\right]\psi = 0 \tag{4}$$

[$A_k(q^k,t)$ being the components of the vector potential and $\phi(q^k,t)$ a scalar potential; c is the speed of light]. The transformation (2), with $\Xi = \psi(q^k,t)$, leads Eq. (4) to

$$\mathcal{O}^{\xi}\psi' + \hbar\mathcal{O}^{\xi}_{(1)}\psi' + \hbar^2\mathcal{O}^{\xi}_{(2)}\psi' = 0, \tag{5}$$

where

$$\mathcal{O}^{\xi} = -\imath\alpha\frac{\partial\xi}{\partial t} - \frac{\alpha^2}{2m}\left(\frac{\partial\xi}{\partial q^k}\right)^2 + \frac{\imath e\alpha}{mc}A_k\frac{\partial\xi}{\partial q^k} + \frac{e^2}{2mc^2}A_k^2 + e\phi + V, \tag{6}$$

$$\mathcal{O}^{\xi}_{(1)} = \imath\frac{\partial}{\partial t} - \left[\frac{\alpha}{m}\frac{\partial\xi}{\partial q^k} - \frac{\imath e}{mc}A_k\right]\frac{\partial}{\partial q^k} - \left[\frac{\alpha}{2mc}\frac{\partial^2\xi}{\partial q^k\partial q^k} + \frac{\imath e}{2mc}\frac{\partial A_k}{\partial q^k}\right], \tag{7}$$

$$\mathcal{O}^{\xi}_{(2)} = \frac{1}{2m}\frac{\partial^2}{\partial q^k\partial q^k}. \tag{8}$$

Now by making $\hbar \to 0$ in Eq. (5) we arrive at

$$\frac{\partial S}{\partial t} + \frac{1}{2m}\left(\frac{\partial S}{\partial q^k} - \frac{e}{c}A_k\right)^2 + e\phi + V = 0, \tag{9}$$

which is the classical Hamilton–Jacobi equation, since

$$\lim_{\hbar\to 0}\psi' \sim \psi'' \neq 0, \tag{10}$$

$$\lim_{\hbar\to 0}\hbar\psi' \sim 0, \tag{11}$$

$$\lim_{\hbar\to 0} \hbar \frac{\partial \psi'}{\partial x} \sim 0 \quad (x=t,q^k), \tag{12}$$

$$\lim_{\hbar\to 0} \hbar^2 \frac{\partial^2 \psi'}{\partial q^k \partial q^k} \sim 0. \tag{13}$$

The symbol $\sim$ denotes asymptotics and therefore one does not require the existence of the classical limit of ψ'. It is important to remark that the parameter α in Eq. (5) has to be equal to ι. The identification $\xi \equiv S$ is only possible because

$$\lim_{\hbar\to 0} \hat{p}'_k = \lim_{\hbar\to 0} \left[e^{-\iota\xi/\hbar} \left(\frac{\hbar}{\iota} \frac{\partial}{\partial q^k} \right) e^{\iota\xi/\hbar} \right] = \frac{\partial \xi}{\partial q^k} = p_k . \tag{14}$$

[In the Wentzel–Kramers–Brillouin (WKB) method[17,18] such identification is introduced *ad hoc*.] It follows also that the classical limit of the commutator, i.e.,

$$\lim_{\hbar\to 0} [e^{-\iota\xi/\hbar} (\hat{q}^k \hat{p}_k - \hat{p}_k \hat{q}^k) e^{\iota\xi/\hbar} = \iota\hbar], \tag{15}$$

is $q^k p_k - p_k q^k = 0$. So we are able to answer the question: "How do noncommuting observables disappear in the classical limit." [19] (The WKB method[17,18] does not answer this question.)

As an example of the asymptotic behavior (10)–(13) let us consider the function $\psi = e^{\iota[S+(\hbar/\iota)S_1+(\hbar/\iota)^2 S_2+\cdots]/\hbar}$ and perform the transformation (2). It follows then that with this ψ' conditions (11)–(13) are obeyed, while by using the WKB approximation ($\hbar\to 0$)[17,18] about ψ' we obtain an asymptotic function $\psi'' = e^{S_1+(\hbar/\iota)S_2}$ satisfying the condition (10). Here an important point to be emphasized is that the superposition of two WKB functions, which in turn is not a WKB one, also does obey all Eqs. (10)–(13). This means that the validity conditions of the WKB method are only sufficient, but not necessary, for the classical limit of the Schrödinger equation.

B. Classical limit of the Schrödinger equation in phase space

Our classical limiting process is not constrained to configuration space. Starting with the Schrödinger equation (4) at point $q_1^k = q^k + \eta^k \hbar/2$ and its complex-conjugate at point $q_2^k = q^k - \eta^k \hbar/2$, and using the Wigner function[20]

$$W(q^k, p_k, t) = \frac{1}{(2\pi)^3} \int \rho(q_1^k, q_2^k, t) e^{-\iota p_k \eta^k} d^3\eta, \tag{16}$$

ρ being the density matrix, we obtain the Schrödinger equation in phase space

$$\iota\hbar \frac{\partial W}{\partial t} + \frac{\iota\hbar}{m} \left(p_k - \frac{e}{c} A_k \right) \frac{\partial W}{\partial q^k} + \frac{\iota e\hbar}{mc} \left(p_k - \frac{e}{c} A_k \right) \frac{\partial A_k}{\partial q^i} \frac{\partial W}{\partial p_i} + \mathcal{I} = 0 \tag{17}$$

with

$$\mathcal{I} = \int e \left[\phi\left(q^i + \frac{\hbar\eta^i}{2} \right) - \phi\left(q^i - \frac{\hbar\eta^i}{2} \right) \right] + \left[V\left(q^i + \frac{\hbar\eta^i}{2} \right) - V\left(q^i - \frac{\hbar\eta^i}{2} \right) \right] e^{-\iota p^k \eta_k} d^3\eta. \tag{18}$$

We expand the potentials ϕ and V in a Taylor series and next perform the transformation (2) with $\alpha^2 \approx 0$; by taking into account the conditions

$$\lim_{\hbar\to 0} W' \sim W'' \neq 0, \tag{19}$$

$$\lim_{\hbar\to 0}\hbar^n W'\sim 0 \quad (n=2,4,6,...,\infty), \tag{20}$$

$$\lim_{\hbar\to 0}\hbar\frac{\partial W'}{\partial x}\sim 0 \quad (x=t,q^k), \tag{21}$$

$$\lim_{\hbar\to 0}\hbar^j\frac{\partial^n W'}{\partial q^n\partial q^n}\sim 0 \quad (j,n=1,2,3,...,\infty) \tag{22}$$

[in expression (22) $n\leqslant j$ for j even and $n=j$ for j odd], we find the classical Liouville equation

$$\frac{\partial F}{\partial t}+\frac{1}{m}\left(p_k-\frac{e}{c}A_k\right)\frac{\partial F}{\partial q^k}+\left[\frac{e}{mc}\left(p_k-\frac{e}{c}A_k\right)\frac{\partial A_k}{\partial q^i}-\frac{\partial V}{\partial q^i}-e\frac{\partial\phi}{\partial q^i}\right]\frac{\partial F}{\partial p_i}=0, \tag{23}$$

where $\xi\equiv F(q^k,p_k,t)\geqslant 0$ is the probability density function. Even though our procedure of calculating the classical limit is mathematically admissible, we may justify its physical consistence only operationally. The physical significance behind the condition $\alpha^2\approx 0$ is not still clear for us.

C. Classical limit of the Dirac equation in configuration space

We perform upon the Dirac equation[21] describing a particle with spin 1/2,

$$\gamma^\mu\left(\hbar\frac{\partial}{\partial q^\mu}-\frac{\iota e}{c}A_\mu\right)\psi+mc\psi=0, \tag{24}$$

the transformation (2) with $\alpha=\iota$, take $\hbar\to 0$, and obtain

$$\gamma^\mu\left(\frac{\partial\xi}{\partial q^\mu}+\frac{\iota e}{c}A_\mu\right)+\iota mc=0 \tag{25}$$

since

$$\lim_{\hbar\to 0}\psi'\sim\psi''\neq 0, \tag{26}$$

$$\lim_{\hbar\to 0}\hbar\frac{\partial\psi'}{\partial q^\mu}\sim 0. \tag{27}$$

By squaring Eq. (25) we arrive at the relativistic Hamilton–Jacobi equation without spin:[22]

$$\left(\frac{\partial S}{\partial q^\mu}+\frac{\iota e}{c}A_\mu\right)^2+m^2c^2=0. \tag{28}$$

In the next section we present some elements of the Grassmann algebra using the Schönberg approach[10–12] in order to reformulate the algebraic content of the Dirac and Pauli equations.

III. THE GRASSMANN–SCHÖNBERG ALGEBRA G_n

Here we want to show only how the Clifford and Grassmann algebras appear connected in the Schönberg works.[10–12] Let us start with n-dimensional two Clifford algebras given by

$$[\gamma_i^{(+)},\gamma_j^{(+)}]_+=+2\eta_{ij}1_{C_n},\quad [\gamma_i^{(-)},\gamma_j^{(-)}]_+=-2\eta_{ij}1_{C_n}, \tag{29}$$

where $[A,B]_+ = AB + BA$ and 1_{C_n} is the unity of the algebra. The $\gamma_i^{(+)}$'s generate a Clifford algebra C_n^+ associated with the positive metric $+\eta_{ij}$ and the $\gamma_i^{(-)}$'s generate a Clifford algebra corresponding to the negative metric $-\eta_{ij}$ such that

$$[\gamma_i^{(+)}, \gamma_j^{(-)}]_+ = 0. \tag{30}$$

Defining the element

$$\omega = \gamma_1^{(+)} \cdots \gamma_n^{(+)} \gamma_1^{(-)} \cdots \gamma_n^{(-)}, \tag{31}$$

which anticommutes with the $\gamma_i^{(+)}$'s and $\gamma_i^{(-)}$'s, i.e.,

$$[\omega, \gamma_i^{(+)}]_+ = 0, \quad [\omega, \gamma_j^{(-)}]_+ = 0, \tag{32}$$

and also the elements

$$\overline{\gamma_i} = \gamma_i^{(+)}, \quad \bar{\bar{\gamma}}_i = \omega \gamma_i^{(-)}, \tag{33}$$

it is straightforward to verify that $\overline{\gamma_i}$ and $\bar{\bar{\gamma}}_i$ generate two Clifford algebras with the same metric η_{ij}:

$$[\overline{\gamma_i}, \overline{\gamma_j}]_+ = 2\eta_{ij} 1_{C_n} = [\bar{\bar{\gamma}}_i, \bar{\bar{\gamma}}_j]_+, \quad [\overline{\gamma_i}, \bar{\bar{\gamma}}_j]_- = 0. \tag{34}$$

The derivation of (29) and (30) from (34) is obtained by defining the element $\overline{\omega} = \overline{\gamma_1} \cdots \overline{\gamma_n} \bar{\bar{\gamma}}_1 \cdots \bar{\bar{\gamma}}_n = \omega$ and using $\overline{\gamma_i} = \gamma_i^{(+)}$ and $\gamma_i^{(-)} = \omega \bar{\bar{\gamma}}_i$ with $\omega^2 = 1_{C_n}$.

The connection with the Grassmann algebra is realized by introducing the terms $\hat{a}_i$ and $\hat{b}_i$ defined by

$$\hat{a}_1 = \frac{\gamma_i^{(+)} + \gamma_i^{(-)}}{2}, \quad \hat{b}_i = \frac{\gamma_i^{(+)} - \gamma_i^{(-)}}{2}, \tag{35}$$

which obey the following anticommutative relations:

$$[\hat{a}_i, \hat{a}_j]_+ = 0 = [\hat{b}_i, \hat{b}_j]_+, \quad [\hat{a}_i, \hat{b}_j]_+ = \eta_{ij} 1_{G_n}, \tag{36}$$

1_{G_n} being the unity of the n-dimensional Grassmann algebra G_n. In this algebra one can build the idempotent P

$$P = \hat{a}_1 \hat{b}_1 \cdots \hat{a}_n \hat{b}_n \Rightarrow P^2 = P \tag{37}$$

such that

$$\hat{a}_i P = 0 = P \hat{b}_i. \tag{38}$$

With the introduction of the algebraic elements $\mathbf{e}_{j_1 \cdots j_r}^{k_1 \cdots k_r}$ (Ref. 12)

$$\mathbf{e}_{j_1 \cdots j_r}^{k_1 \cdots k_v} = \hat{b}_{k_1} \cdots \hat{b}_{k_v} P \hat{a}_{j_r} \cdots \hat{a}_{j_1}, \tag{39}$$

it follows from the ortogonality rule

$$\mathbf{e}_{j_1 \cdots j_r}^{k_1 \cdots k_v} \mathbf{e}_{h_1 \cdots h_s}^{i_1 \cdots i_u} = \delta_{r,u} \delta_{j_1 \cdots j_r}^{i_1 \cdots i_u} \mathbf{e}_{h_1 \cdots h_s}^{k_1 \cdots k_v} \tag{40}$$

$(r,s,u,v=0,...,n;i_1,j_1,k_1,h_1<\cdots<i_u,j_r,k_v,h_s;i,j,k,h=1,...,n)$ that Eq. (39) does form a set of 2^{2n} linearly independent elements and therefore it does constitute a basis for G_n. Hence the general element $\Gamma\in G_n$ reads

$$\Gamma=\sum_{r,v}^{0,...,n}\frac{1}{r!v!}[A]^{j_1\cdots j_r}_{k_1\cdots k_v}\mathbf{e}^{k_1\cdots k_v}_{j_1\cdots j_r}, \tag{41}$$

where the coefficients $[A]$'s are antisymmetrical with respect to the j's and k's separately. P is a primitive idempotent because $\Gamma P\Gamma=[A]\Gamma$, $\forall\Gamma\in G_n$. The unity element of G_n is given by

$$1_{G_n}=\sum_{r}^{0,...,n}\frac{1}{r!}\mathbf{e}^{j_1\cdots j_r}_{j_1\cdots j_r} \tag{42}$$

with implicit sum in $j(=1,...,n)$. Multiplying (41) to the left by P we obtain the Schönberg spinor

$$\Psi=\sum_{r}^{0,...,n}\frac{1}{r!}[A]_{k_1\cdots k_r}\mathbf{e}^{k_1\cdots k_r} \tag{43}$$

as a general element of G_nP (the minimal left ideal of G_n) which is an n-dimensional linear space with 2^n linearly independent elements.

IV. CLASSICAL LIMIT OF THE DIRAC EQUATION IN PHASE SPACE

We initially start from the Dirac equation and its adjoint for the wave function ψ of an electron with mass m and charge $|e|$ at two points q_1^μ and q_2^μ of space–time:

$$[\gamma^\mu\pi_\mu(q_1^\alpha)+mc]\psi(q_1^\alpha)=0, \tag{44}$$

$$\overline{\psi}(q_2^\nu)[\pi_\mu^\dagger(q_2^\alpha)\gamma^\mu-mc]=0. \tag{45}$$

Here $\pi_\mu(q_1^\alpha)=\hbar(\partial/\partial q_1^\mu)-(\imath e/c)A_\mu(q_1^\alpha)$, $\pi_\mu^\dagger(q_2^\alpha)=\hbar(\partial/\partial q_2^\mu)+(\imath e/c)A_\mu(q_2^\alpha)$, $\overline{\psi}=\psi^\dagger\gamma^4$, and $A_\mu=(\mathbf{A},\imath A_0)$, where $\mathbf{A}$ is the potential vector and A_0 the scalar potential. The Dirac matrices γ^μ generate the Clifford algebra C_4 with unity 1_{C_4}:

$$[\gamma^\mu,\gamma^\nu]_+=2g^{\mu\nu}1_{C_4} \tag{46}$$

$[g^{\mu\nu}=\mathrm{diag}(1,1,1,-1)]$. We multiply (44) by $\overline{\psi}(q_2^\alpha)$ and (45) by $\psi(q_1^\alpha)$ and obtain two equations for the density matrix $\rho(q_1^\alpha,q_2^\alpha)=\psi(q_1^\alpha)\overline{\psi}(q_2^\alpha)$, interpreted here as a general element of the Clifford algebra, i.e.,

$$\rho=C_0.1_{C_4}+C_\mu\gamma^\mu+C_{\mu\nu}\gamma^\mu\gamma^\nu+C_{\mu\nu\lambda}\gamma^\mu\gamma^\nu\gamma^\lambda+C_{\mu\nu\lambda\alpha}\gamma^\mu\gamma^\nu\gamma^\lambda\gamma^\alpha, \tag{47}$$

where the C's are coefficients of q_1^α and q_2^α. We now lift these two equations to a higher dimension space that we call *superspace*,[13,14]

$$[\tilde{\gamma}^\mu\pi_\mu(q_1^\alpha)+mc]\xi=0, \tag{48}$$

$$[\tilde{\gamma}^\mu\pi_\mu^\dagger(q_2^\alpha)-mc]\xi=0, \tag{49}$$

with

$$\tilde{\gamma}^\mu=\gamma^\mu\otimes 1_{C_4},\quad \tilde{\gamma}^\mu=1_{C_4}\otimes\gamma^\mu,\quad \xi\equiv\xi(q_1^\alpha,q_2^\alpha)=(\rho\otimes 1_{C_4})\Lambda. \tag{50}$$

The symbol $\otimes$ denotes the direct product. The arrows above γ^{μ} indicate the sense in which the multiplication is realized about ξ. The element Λ is a primitive idempotent belonging to the algebra of *superspace* $G_4 = C_4 \otimes C_4$. The density supermatrix $\rho(q_1^{\alpha}, q_2^{\alpha}) \otimes 1_{C_4}$ then should be associated with two Clifford algebras with the same metric

$$\rho \otimes 1_{C_4} = d_0 . 1_{C_4} + \cdots + d_{\mu\nu\lambda\alpha} \vec{\gamma}^{\mu} \vec{\gamma}^{\nu} \vec{\gamma}^{\lambda} \vec{\gamma}^{\alpha} = \sum_{A}^{16} d_A \vec{\gamma}^{A}, \tag{51}$$

$$\rho \otimes 1_{C_4} = d_0 . 1_{C_4} + \cdots + d_{\mu\nu\lambda\alpha} \tilde{\gamma}^{\mu} \tilde{\gamma}^{\nu} \tilde{\gamma}^{\lambda} \tilde{\gamma}^{\alpha} = \sum_{A}^{16} d_A \tilde{\gamma}^{A}. \tag{52}$$

With $\Lambda \equiv P$ the function ξ is considered as the Schönberg spinor $\Psi \in G_4 P$ given by (43), i.e., ξ is an element belonging to the minimal left ideal of the algebra G_4 because defining

$$\vec{\gamma}^{\mu} = \hat{a}^{\mu} + \hat{b}^{\mu} \tag{53}$$

and

$$\tilde{\gamma}^{\mu} = \omega(\hat{a}^{\mu} - \hat{b}^{\mu}) \tag{54}$$

we have

$$\vec{\gamma}^{j_1} \cdots \vec{\gamma}^{j_k} P = \hat{a}^{j_1} \cdots \hat{a}^{j_k} P, \quad \tilde{\gamma}^{j_1} \cdots \tilde{\gamma}^{j_k} P = \hat{a}^{g_1} \cdots \hat{a}^{j_k} P. \tag{55}$$

Using (53), (54), and $\omega^2 = 1_{G_4}$, Eqs. (48) and (49) can be written in terms of $\hat{a}^{\mu}$, $\hat{b}^{\mu}$ as

$$[(\hat{a}^{\mu} + \hat{b}^{\mu}) \pi_{\mu}(q_1^{\alpha}) + mc] \Psi = 0, \tag{56}$$

$$[(\hat{a}^{\mu} - \hat{b}^{\mu}) \pi_{\mu}^{\dagger}(q_2^{\alpha}) - \omega mc] \Psi = 0. \tag{57}$$

Adding and subtracting (56) and (57), changing the variables

$$q^{\alpha} = \frac{q_1^{\alpha} + q_2^{\alpha}}{2}, \quad \eta^{\alpha} = \frac{q_1^{\alpha} - q_2^{\alpha}}{\hbar}, \tag{58}$$

and performing the relativistic Wigner transformation

$$\mathcal{W}(q^{\alpha}, p_{\alpha}) = \frac{1}{(2\pi)^4} \int \Psi\left(q^{\alpha} + \frac{\hbar \eta^{\alpha}}{2}, q^{\alpha} - \frac{\hbar \eta^{\alpha}}{2} \right) e^{-\iota p_{\alpha} \eta^{\alpha}} d^4 \eta, \tag{59}$$

we obtain two Dirac equations in relativistic quantum phase space

$$O^{\mu} \mathcal{W} \equiv \hat{a}^{\mu} \hbar \left(\frac{\partial}{\partial q^{\mu}} - \frac{e}{c} \frac{\partial A_{\mu}}{\partial q^{\alpha}} \frac{\partial}{\partial p_{\alpha}} \right) \mathcal{W} - 2\iota \hat{b}^{\mu} \left(p_{\mu} + \frac{e}{c} A_{\mu} \right) \mathcal{W} = mc(\omega - 1) \mathcal{W}, \tag{60}$$

$$\overline{O}^{\mu} \mathcal{W} \equiv \hat{b}^{\mu} \hbar \left(\frac{\partial}{\partial q^{\mu}} - \frac{e}{c} \frac{\partial A_{\mu}}{\partial q^{\alpha}} \frac{\partial}{\partial p_{\alpha}} \right) \mathcal{W} - 2\iota \hat{a}^{\mu} \left(p_{\mu} + \frac{e}{c} A_{\mu} \right) \mathcal{W} = -mc(\omega + 1) \mathcal{W}, \tag{61}$$

with the following approximation:

$$A_{\mu}\left(q^{\alpha} \pm \frac{\hbar}{2} \eta^{\alpha} \right) \approx A_{\mu}(q^{\alpha}) \pm \frac{\hbar}{2} \eta^{\alpha} \frac{\partial A_{\mu}}{\partial q^{\alpha}}. \tag{62}$$

Now squaring Eqs. (60) and (61), i.e., evaluating the relations

$$(O^{\beta}O^{\mu}+O^{\mu}O^{\beta})\mathcal{W}=4m^2c^2(1-\omega)^2\mathcal{W}, \tag{63}$$

$$(\overline{O}^{\beta}\overline{O}^{\mu}+\overline{O}^{\mu}\overline{O}^{\beta})\mathcal{W}=4m^2c^2(1+\omega)^2\mathcal{W}, \tag{64}$$

we obtain, after adding (63) and (64), the Dirac equation in Liouvillian form

$$\frac{\iota\hbar}{m}g^{\beta\mu}\left(p_{\mu}+\frac{e}{c}A_{\mu}\right)\frac{\partial\mathcal{W}}{\partial q^{\beta}}+\left[\frac{\hbar\mu_0}{4}S^{\beta\mu}_{(+)}\frac{\partial F_{\beta\mu}}{\partial q^{\alpha}}-\frac{\iota\hbar e}{mc}g^{\beta\mu}\left(p_{\mu}+\frac{e}{c}A_{\mu}\right)\frac{\partial A_{\beta}}{\partial q^{\alpha}}\right]\frac{\partial\mathcal{W}}{\partial p^{\alpha}}=\Delta\mathcal{W} \tag{65}$$

with

$$\Delta=mc^2-\iota\mu_0 S^{\beta\mu}_{(-)}F_{\beta\mu}. \tag{66}$$

Here $\mu_0=e\hbar/2mc$ is the magnetic moment of the electron spin, whereas

$$S^{\beta\mu}_{(+)}=\hat{a}^{\beta}\hat{a}^{\mu}+\hat{b}^{\beta}\hat{b}^{\mu},\quad S^{\beta\mu}_{(-)}=\hat{a}^{\mu}\hat{b}^{\beta}-\hat{a}^{\beta}\hat{b}^{\mu} \tag{67}$$

are spin terms coupled to the electromagnetic field. [Without these terms (67) the function $\mathcal{W}$ cannot be interpreted as a constant of the motion due to the presence of mass in Eq. (65). This detail is neglected in Refs. 13 and 14.] The relativistic Wigner function $\mathcal{W}(q^{\alpha},p_{\alpha})$ is an algebraic spinor of the form (43) due to the fact that

$$\mathcal{W}(q^{\alpha},p_{\alpha})=\sum_{s}^{0,\ldots,4}\frac{1}{s!}W_{j_i\cdots j_s}\mathbf{e}^{j_1\cdots j_s}, \tag{68}$$

where the coefficients W are the following functions of q^{μ},p_{μ}:

$$W_{j_1\cdots j_s}=\frac{1}{(2\pi)^4}\int A_{j_1\cdots j_s}e^{-\iota p_{\alpha}\eta^{\alpha}}d^4\eta. \tag{69}$$

It follows then that the information about the spin degree of freedom should also appear in the tensorial structure of $\mathcal{W}$ because we believe that in the absence of field ($A_{\mu}=0$) the particle still has *objectively* spin. Without the spin freedom we have a relativistic equation in phase space for a scalar function $W(q_{\alpha},p_{\alpha})$ describing a fermion.

Now performing the transformation (2) in relativistic quantum phase space given by

$$\mathcal{W}'=T_{\mathcal{F}}\mathcal{W},\quad T_{\mathcal{F}}=e^{\iota\mathcal{F}/\hbar}, \tag{70}$$

and making $\hbar\to 0$ we obtain

$$\frac{1}{m}g^{\beta\mu}\left(p_{\mu}+\frac{e}{c}A_{\mu}\right)\frac{\partial\mathcal{F}}{\partial q^{\beta}}+\left[\frac{e}{mc}g^{\beta\mu}\left(p_{\mu}+\frac{e}{c}A_{\mu}\right)\frac{\partial A_{\beta}}{\partial q^{\alpha}}\right]\frac{\partial\mathcal{F}}{\partial p^{\alpha}}=mc^2\mathcal{F}, \tag{71}$$

since $\lim_{\hbar\to 0}\mathcal{W}'\sim\mathcal{W}''\neq 0$, $\lim_{\hbar\to 0}\hbar\partial\mathcal{W}'/\partial x\sim 0(x=q^{\alpha},p_{\alpha})$. Here $\mathcal{F}$ is the element

$$\mathcal{F}=\sum_{t}^{0,\ldots,4}\frac{1}{t!}F^{k_1\cdots k_t}_{k_1\cdots k_t}\mathbf{e}^{k_1\cdots k_t}_{k_1\cdots k_t} \tag{72}$$

of the algebra G_4 because $T_{\mathcal{F}}^{-1}T_{\mathcal{F}}=T_{\mathcal{F}}T_{\mathcal{F}}^{-1}=1_{G_4}\Rightarrow\mathcal{F}\in G_4$ [see Eq. (40)].

Equation (71) is the relativistic Liouville equation for the probability distribution function $\mathcal{F}(q^{\mu},p_{\mu})$ for a classical system with spin 1/2.

V. CLASSICAL LIMIT OF THE PAULI EQUATION IN PHASE SPACE

It is well known that the nonrelativistic limit of the Dirac equation is the Pauli equation. Our objective in this section is also to write down the Pauli equation in phase space within the Schönberg geometric algebra. Starting from the usual Pauli equation[23] at point q_1^k,

$$\imath\hbar\frac{\partial\psi}{\partial t}+\frac{\hbar^2}{2m}\frac{\partial^2\psi}{\partial q_1^k\partial q_1^k}-\frac{e\hbar\imath}{c}A_k\frac{\partial\psi}{\partial q_1^k}-\frac{e\hbar\imath}{2mc}\frac{\partial A_k}{\partial q_1^k}\psi-\frac{e^2}{2mc^2}A_k^2\psi-e\phi\psi+\frac{e\hbar}{2mc}\sigma_kB^k\psi=0, \tag{73}$$

where B^k are the magnetic field components, and its complex conjugate at point q_2^k, following the Bohm–Hiley–Holland method presented in Sec. IV, we arrive at the Pauli equation in *superspace*,

$$\begin{aligned}\imath\hbar\frac{\partial\xi}{\partial t}-\frac{\hbar^2}{2m}\left[\frac{\partial^2\xi}{\partial q_2^k\partial q_2^k}-\frac{\partial^2\xi}{\partial q_1^k\partial q_1^k}\right]-\frac{\imath e\hbar}{mc}\left[A_k(q_1^i)\frac{\partial\xi}{\partial q_1^i}+A_k(q_2^i)\frac{\partial\xi}{\partial q_2^i}\right]-\frac{e\imath\hbar}{2mc}\left(\frac{\partial A_k}{\partial q_1^k}+\frac{\partial A_k}{\partial q_2^k}\right)\xi\\ -\frac{e^2}{2mc^2}[A_k^2(q_1^i)-A_k^2(q_2^i)]\xi-e[\phi(q_1^i)-\phi(q_2^i)]\xi-\frac{e\hbar}{2mc}[B^k(q_2^k)\xi\tilde{\sigma}_k-B^k(q_1^k)\vec{\sigma}_k\xi]\end{aligned} \tag{74}$$

with

$$\xi(q_1^k,q_2^k,t)=[\rho(q_1^k,q_2^k,t)\otimes 1_{C_3}\otimes 1_{C_3}]\Lambda, \tag{75}$$

$$\vec{\sigma}_k=(\sigma_k\otimes 1_{C_3}\otimes 1_{C_3}),\quad \tilde{\sigma}_k=(1_{C_3}\otimes 1_{C_3}\otimes\sigma_k). \tag{76}$$

In phase space we find

$$\begin{aligned}\imath\hbar\frac{\partial\mathcal{W}}{\partial t}+\frac{\imath\hbar}{m}\left(p_k-\frac{e}{c}A_k\right)\frac{\partial\mathcal{W}}{\partial q^k}+\frac{\imath e\hbar}{mc}\left(p_k-\frac{e}{c}A_k\right)\frac{\partial A_k}{\partial q^i}\frac{\partial\mathcal{W}}{\partial p_i}\\ +\int e\left[\phi\left(q^i+\frac{\hbar\eta^i}{2}\right)-\phi\left(q^i-\frac{\hbar\eta^i}{2}\right)\right]\Psi e^{-\imath p_k\eta^k}d^3\eta+\mathcal{N}\mathcal{W}=0,\end{aligned} \tag{77}$$

with

$$\mathcal{N}=\mu_0S_{(-)}^kB_k=\mu_0[(\hat{a}^k+\hat{b}^k)-\omega(\hat{a}^k-\hat{b}^k)]B_k. \tag{78}$$

The solution of (77), $\mathcal{W}\in G_3P$, has the form

$$\mathcal{W}(q^k,p_k,t)=W+W_i\mathbf{e}^i+W_{ij}\mathbf{e}^{ij}+W_{ijl}\mathbf{e}^{ijl}. \tag{79}$$

Again the spin appears generating a coupling between its magnetic moment and the magnetic field and also in the tensorial structure of $\mathcal{W}$ (79). Neglecting the magnetic moment ($\mu_0=0$) we note that Eq. (77) is the Schrödinger equation (with spin) in phase space. Considering only the scalar part of $\mathcal{W}$, i.e., $\mathcal{W}\equiv W$, we reobtain Eq. (17) which does not contain spin. Thus with the reformulation of the Pauli equation in phase space on the basis of the geometric algebra we conclude that the spin freedom *may* be present in the Schrödinger theory. Therefore Hestenes' statement[5] ''spin is already in the Schrödinger equation'' seems to us very strong.

When we calculate the classical limit of Eq. (77), after performing the transformation (2), for $\Psi\equiv\mathcal{W}$ and $\alpha^2\approx 0$, and taking the limit $\hbar\to 0$, we get

$$\frac{\partial\mathcal{F}}{\partial t}+\frac{1}{m}\left(p_k-\frac{e}{c}A_k\right)\frac{\partial\mathcal{F}}{\partial q^k}+\left[\frac{e}{mc}\left(p_k-\frac{e}{c}A_k\right)\frac{\partial A_k}{\partial q^i}-e\frac{\partial\phi}{\partial q^i}\right]\frac{\partial\mathcal{F}}{\partial p_i}=0 \tag{80}$$

with $\mathcal{F}\in G_3$, that is, Eq. (80) is the Liouville equation with spin 1/2 in the nonrelativistic domain. If this degree of freedom is neglected we obtain Eq. (23) (without spin).

VI. CONCLUDING REMARKS

It is common (in the textbook literature) to find, associated with the problem of the classical limit of quantum mechanics, the well-known Ehrenfest theorem. Although Pauli[22] emphasized in 1933 that the transition *quantum→classical* is not complete using such a theorem, only recently[24] one has shown definitely that the validity conditions of the Ehrenfest theorem are neither necessary nor sufficient to characterize the classical domain. Alternatively, in this article we have defined a general method of evaluating the classical limit $\hbar\to 0$ of quantum-mechanical equations of motion depending on the asymptotic (or semiclassical) behavior of the quantum state, thus avoiding the question whether the classical limit of a quantum statum is an ensemble of classical trajectories or a single classical trajectory.[24] Applying it to the Schrödinger equation we showed that the validity conditions of the WKB approximation are only sufficient, but not necessary, to obtain the classical Hamilton–Jacobi equation, while the classical limit of the Schrödinger equation in terms of Wigner function leads correctly to the Liouville equation without using the high-temperature condition of Ref. 25.

In Refs. 13 and 14 Bohm, Hiley, and Holland studied the Dirac equation in phase space by means of geometric algebra. In the present article we were also able to put the Pauli equation (and consequently the Schrödinger equation) within this same algebraic structure. In our approach spin is seen as giving rise to a magnetic moment which couples with the external magnetic field and as a tensorial property inherent in the Schönberg–Grassmann algebra. This interpretation is different from that given in Refs. 13 and 14 where in the absence of spin the Schönberg spinor $\mathcal{W}$, solution of Eq. (65), is considered as a constant of the motion.

When we calculate the classical limit of the Pauli equation and the Dirac equation in phase space we get two peculiar results from our classical limiting process. The first one concerns the physical nature of spin: this degree of freedom is a property hidden in the antisymmetric tensors; this occurs both in the classical domain and the quantum one. The other result supports the view that the coupling between the magnetic moment, generated by the spin, and electromagnetic field is the intrinsically quantum feature.

Finally we point out that our present work leaves two questions open:

(α) What is the physical reason for the assumption that the parameter α, in the definition of the classical limiting process (2), should be considered arbitrary?

(β) What are the advantages of formulating (relativistic and nonrelativistic) classical statistical mechanics in terms of geometric algebra?

We hope that future papers can clarify these questions.

(Received 4 April 2001; accepted for publication 14 May 2001)

The variable phase approach to potential scattering with regular spherically symmetric potentials satisfying Eq. (1), and studied by Calogero in his book [*Variable Phase Approach to Potential Scattering* (Acadamic, New York, 1967)] is revisited, and we show directly that it gives the absolute definition of the phase-shifts, i.e., the one which defines $\delta_\ell(k)$ as a continuous function of k for all $k \geqslant 0$, up to infinity, where $\delta_\ell(\infty)=0$ is automatically satisfied. This removes the usual ambiguity $\pm n\pi$, n integer, attached to the definition of the phase-shifts through the partial wave scattering amplitudes obtained from the Lippmann–Schwinger integral equation, or via the phase of the Jost functions. It is then shown rigorously, and also on several examples, that this definition of the phase-shifts is very general, and applies as well to all potentials which have a strong repulsive singularity at the origin, for instance those which behave like gr^{-m}, $g>0$, $m \geqslant 2$, etc. We also give an example of application to the low-energy behavior of the S-wave scattering amplitude in two dimensions, which leads to an interesting result. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1389090]

I. INTRODUCTION

In quantum scattering theory with a spherically symmetric potential $V(r)$, the phase-shift, defined for each partial-wave by the asymptotic behavior of the radial wave function at large distances, has the usual ambiguity of $\pm \pi n$, n integer. When the potential is regular, i.e., is $L^1(a,\infty)$, and satisfies the Bargmann–Jost–Kohn condition[1–3]

$$\int_0^\infty r|V(r)|\,dr<\infty, \tag{1}$$

one can show that the phase-shift $\delta_\ell(k)$ at infinite energy satisfies the condition

$$\mathrm{tg}\,\delta_\ell(\infty)=0, \quad \text{or} \quad \sin\delta_\ell(\infty)=0, \tag{2}$$

so that one can make the ''canonical'' choice

$$\delta_\ell(\infty)=0, \tag{3}$$

and then proceed downwards by continuity for finite values of k.

The same ambiguity exists, of course, when the phase-shift is defined through the phase of the Jost function[1–3]. The problem becomes even more serious when the potential is singular and repulsive near $r=0$, and short-range otherwise:

[a)]Dedicated to Professor Shinsho Oryu for his 60th anniversary.
[b)]Electronic mail: khosrow.chadan@th.u-psud.fr

$$V(r) \underset{r\to 0}{\simeq} g r^{-m}, \quad g>0, \quad m>2; \quad \underset{r\to 0}{\simeq} g \exp(\alpha/r), \quad g>0, \quad \alpha>0; \quad \text{etc.} \tag{4}$$

In these cases, one can still define the S-matrix, $S_\ell = \exp(2i\delta_\ell(k))$, with a continuous phase-shift $\delta_\ell(k)$, which is again given by the asymptotic behavior of the wave function for $r\to\infty$. However, now, one has[4–6]

$$\delta_\ell(\infty) = -\infty, \tag{5}$$

and this adds to the difficulty of finding a unique phase-shift.

From the above remarks, it would seem therefore satisfactory to find a unique definition of the phase-shift itself by some formula containing $V(r)$ and the wave function, and such that (3) is automatically satisfied when the potential satisfies (1), and then, to see whether such a definition can be extended, eventually with some modification, to potentials which are singular at $r=0$ or at $r=\infty$ (long range).

The answer to the above quest has already been found, although not written down explicitly in the form (20) we give later. It is given by the variable phase method.[7] To simplify the algebra, and see what is essential, let us take the case of the S-wave, $\ell=0$. We have the radial Schrödinger equation

$$\begin{gathered} \varphi''(k,r) + k^2 \varphi(k,r) = V(r)\varphi(k,r) \\ r \in [0,\infty), \quad \varphi(0)=0, \quad \varphi'(0)=1. \end{gathered} \tag{6}$$

If we write now the wave function as

$$\begin{gathered} \varphi = A(k,r)\sin[kr+\delta(k,r)], \\ A(k,r) \geqslant 0, \quad A(k,0)\neq 0, \quad \delta(k,0)=0, \end{gathered} \tag{7}$$

it can be shown that one has formally the differential equation[7]

$$\begin{gathered} \frac{d}{dr}\delta(k,r) = -\frac{1}{k}V(r)\sin^2[kr+\delta(k,r)], \\ \delta(k,0)=0, \end{gathered} \tag{8}$$

and then

$$A(k,r) = \frac{1}{k}\exp\frac{1}{2}k\int_0^r V(t)\sin 2[kt+\delta(k,t)]\,dt, \tag{9}$$

provided (8) has a solution, and the integral in (9) is finite. We shall see this in a moment. In essence, A is the amplitude of the wave function φ, whose oscillations are given by $\sin[kr+\delta(k,r)]$. The function $\delta(k,r)$ can be interpreted as the local phase-shift since $\delta(k,R)$ is the phase-shift due to the cut potential $V(r)\theta(R-r)$. The total phase-shift is defined as

$$\delta(k) = \lim_{r\to\infty} \delta(k,r). \tag{10}$$

In order to see whether (8) has a unique solution, we can write it as

$$\delta(k,r) = -\frac{1}{k}\int_0^r V(t)\sin^2[kt+\delta(k,t)]\,dt. \tag{11}$$

One can then try to solve this nonlinear integral equation by iteration, starting from the zeroth order approximation

$$\delta^{(0)}(k,r)=0. \tag{12}$$

Numerical calculations show that this process is fast converging for usual regular potentials used in nuclear physics, and indeed has been used in practice.

From (11), it is obvious that the phase-shift is given by

$$\delta(k)=-\frac{1}{k}\int_0^\infty V(r)\sin^2[kr+\delta(k,r)]dr. \tag{13}$$

This formula shows that, for short-range potentials, the tail of the integral,

$$\left|-\frac{1}{k}\int_R^\infty V(r)\sin^2[kr+\delta(k,r)]dr\right|\leqslant\frac{1}{k}\int_R^\infty|V(r)|dr, \tag{14}$$

can be made very small if we choose R larger than the ''range'' of the potential.

In order to study the nonlinear integral equation (11) in a rigorous way, we can use the inequality[1,3]

$$|\sin x|\leqslant C\frac{|x|}{1+|x|},\quad x\ \text{real}, \tag{15}$$

where C is an appropriate constant. Noting that $x/(1+x)$ is an increasing function of x for x positive, we have

$$|\sin(x+y)|\leqslant C\frac{|x+y|}{1+|x+y|}\leqslant C\frac{|x|+|y|}{1+|x|+|y|}. \tag{16}$$

Using this in the integral equation (11), we find

$$|\delta(k,r)|\leqslant\frac{C^2}{k}\int_0^r|V(t)|\left[\frac{kt+|\delta(k,t)|}{1+kt+|\delta(k,t)|}\right]^2dt,\quad k>0. \tag{17}$$

It is then obvious that an upper bound $\Delta(k,r)$ for $|\delta(k,r)|$ is obtained from the solution of the integral equation

$$\Delta(k,r)=\frac{C^2}{k}\int_0^r|V(t)|\left[\frac{kt+\Delta(k,t)}{1+kt+\Delta(k,t)}\right]^2dt. \tag{18}$$

We can again solve this integral equation by iteration, starting from $\Delta^{(0)}=0$. It is obvious here that the solution cannot become infinite at any point on $[0,\infty)$. Indeed, if $\Delta(k,r)$ becomes infinite at $r=r_1$, then, as $r\uparrow r_1$, the fraction in (18) becomes one, and since V is supposed to be L^1, we get a contradiction.

We show in Appendix A that the equation (18) has always a unique solution for all values of $k>0$, provided V satisfies (1), and therefore that (11) also has a unique solution. We show also that $\lim_{k\to\infty}\Delta(k,\infty)=0$, from which we conclude then directly that we have (3). However, it is not really necessary to use the integral equation. Indeed, as we shall see in the next section, we can express the right-hand side of (11) in terms of the regular solution φ given by (6), and its derivative φ', to obtain the new formulas

$$\delta(k,r)=-k\int_0^r V(t)\frac{\varphi^2(k,t)}{\varphi'^2(k,t)+k^2\varphi^2(k,t)}dt, \tag{19}$$

and

$$\delta(k) = -k \int_0^\infty V(r) \frac{\varphi^2}{\varphi'^2 + k^2 \varphi^2} dr. \tag{20}$$

We shall see in the next section how to generalize these equations to higher ℓ. Likewise, the amplitude $A(k,r)$ can also be written as[7]

$$A(k,r) = \frac{1}{k} \sqrt{\varphi'^2 + k^2 \varphi^2}. \tag{21}$$

Now, we know, quite generally, that for potentials satisfying (1), the wave function $\varphi(k,r)$ exists for all values of k, real or complex, and all values of $r \geqslant 0$.[1–3] Likewise for $\varphi'(k,r)$, and we have, of course,

$$\varphi'(k,0) = 1, \quad \varphi(k,r) \underset{r \to 0}{=} r + r o(1). \tag{22}$$

Moreover, we have also that φ and φ', for any fixed real $k > 0$, are real and continuous function of r, and bounded as $r \to \infty$. Also, from the general theory of differential equations, we know that, for any k, φ and φ' cannot vanish simultaneously at any point $r = r_0 \geqslant 0$, since this would entail that $\varphi \equiv 0$, a contradiction with $\varphi'(k,0) = 1$. It follows that, because of (1), the integrals in (19) and (20) are absolutely convergent for all real values of $k > 0$, and define continuous functions of k. Therefore, (19) and (20) define, in a very nice and simple way, the ''local'' and the total phase-shift, respectively. We shall come in the third section to the case $k = 0$.

Several remarks are now in order. First of all, (20) shows that, for a potential of a given sign, the phase-shift has the opposite sign, something well-knowna,[1,2] and also obvious on (11) and (13). Second, it is obvious on (19) and (20) that the phase-shift is independent of the amplitude of φ. Multiplying φ by a constant factor $\lambda(k)$ independent of r leaves (19) and (20) invariant. This is as expected, of course. Finally, from (21) we find

$$A(k,r) > 0, \quad A(k,0) = \frac{1}{k} \neq 0, \tag{23}$$

which was assumed in (7). Now, for $r \to \infty$, the asymptotic behavior of φ and φ' are given by[1–3]

$$\varphi(k,r) \underset{r \to \infty}{\simeq} \frac{|F(k)|}{k} \sin(kr + \delta) + o(1), \tag{24}$$

and

$$\varphi'(k,r) \underset{r \to \infty}{\simeq} |F(k)| \cos(kr + \delta) + o(1), \tag{25}$$

where $F(k)$ is the Jost function, which never vanishes for $k > 0$.[1–3] Using now (24) and (25) in (21), we find

$$A(k,\infty) = \frac{|F(k)|}{k}, \tag{26}$$

and this, used in (7), leads again to (24), a consistency check.

We have now to see whether, for regular potentials satisfying (1), the phase-shift defined by (20) satisfies (3): $\delta(\infty) = 0$. This is very easy to check. Indeed, for k real and going to infinity, we have uniformly in r,[1,3] for any $r \in [0,R]$, $R < \infty$,

$$\varphi(k,r) \underset{k\to\infty}{=} \frac{\sin kr}{k} + \frac{1}{k}o(1), \tag{27}$$

and

$$\varphi'(k,r) \underset{k\to\infty}{=} \cos kr + o(1). \tag{28}$$

Using these in (20), together with (14), leads to

$$\delta(k) \underset{k\to\infty}{\simeq} -k\int_0^R V(r)\frac{\sin^2 kr}{k^2}dr = -\int_0^R V(r)\frac{1-\cos 2kr}{2k}dr = -\int_0^R V(r)dr\int_0^r \sin 2ktdt$$
$$= -\int_0^R \sin 2ktdt\left(\int_t^R V(r)dr\right). \tag{29}$$

Now, in general, $W(t)=\int_t^\infty V(r)dr$ is $L^1(0,\infty)$. Indeed

$$\int_0^\infty |W(t)|\,dt = \int_0^\infty dt\left|\int_t^\infty V(r)dr\right| \leq \int_0^\infty dt\int_t^\infty |V(r)|\,dr = \int_0^\infty |V(r)|\,dr\int_0^r dt = \int_0^\infty r|V(r)|\,dr < \infty \tag{30}$$

by virtue of (1). Therefore, in the last integral in (29) we have a Fourier sine transform of an L^1 function. From the Riemann–Lebesgue lemma, it follows that, as $k\to\infty$, it vanishes. Therefore, $\delta(k\to\infty)=0$. This argument, which is quite general, can be made more precise (see Appendix B). It follows that the definition of the phase-shift given by (20) in terms of the well-defined regular solution φ, (6), is indeed an absolute definition of $\delta(k)$ for all $k>0$ satisfying automatically (3).

We shall see later that (20) can be extended to potentials which are outside the Bargmann–Jost–Kohn class, especially to those potentials which are strongly repulsive at $r=0$. We are going now to give first the derivation of (8), (9) and (21). These are found essentially in Ref. 7, except for the integral forms (19) and (20), which are the basic equations of our article. We reproduce the proofs for the convenience of the reader.

II. DERIVATION OF (19) AND (20)

We follow the usual method given in Ref. 7 for deriving the differential equation (8). Differentiating (7), we find

$$\varphi' = A'\sin(kr+\delta) + A(k+\delta')\cos(kr+\delta). \tag{31}$$

We have here two unknown functions A and δ, and only one equation, the Schrödinger equation (6), at our disposal. We can therefore impose a relation between A and δ. We impose

$$A'\sin(kr+\delta) + A\delta'\cos(kr+\delta) = 0. \tag{32}$$

It follows that (31) becomes simply

$$\varphi' = Ak\cos(kr+\delta). \tag{33}$$

Differentiating now this, and using the Schrödinger equation (6), we find the new equation

$$A'k\cos(kr+\delta) - Ak\delta'\sin(kr+\delta) = VA\sin(kr+\delta). \tag{34}$$

Combining this with (32), we find the differential phase equation (8) and the amplitude equation (9), a complete set equivalent to the Schrödinger equation (6).

However, we can go back again to φ and φ', using (7) and (33). Adding their squares, we find[4]

$$A^2(k,r)=\frac{1}{k^2}(\varphi'^2+k^2\varphi^2). \tag{35}$$

It follows that (8) can be written

$$\delta'=-\frac{1}{k}V\sin^2(kr+\delta)=-\frac{1}{k}V\frac{\varphi^2}{A^2}$$

$$=-kV\frac{\varphi^2}{\varphi'^2+k^2\varphi^2}. \tag{36}$$

This is the basic equation, giving the ''local'' phase-shift $\delta(k,r)$ in terms of φ and φ'. Integrating it, we find

$$\delta(k,r)=-k\int_0^r V(t)\frac{\varphi^2(k,t)}{\varphi'^2(k,t)+k^2\varphi^2(k,t)}dt, \tag{37}$$

where the initial condition $\delta(k,0)=0$ has been used. Making now $r\to\infty$, we get the total phase-shift, (20). We have already checked that in (19) and (20) the integrals are absolutely convergent, and define continuous functions of k for all $k>0$.

A. Higher waves

The method for $\ell\neq 0$ is quite similar.[7] We have to deal now with the radial Schrödinger equation

$$\varphi_\ell''(k,r)+k^2\varphi_\ell(k,r)=\left[\frac{\ell(\ell+1)}{r^2}+V(r)\right]\varphi_\ell(k,r), \tag{38a}$$

and its free counterpart when $V=0$:

$$\frac{d^2}{dr^2}\begin{pmatrix}u_\ell\\ v_\ell\end{pmatrix}+k^2\begin{pmatrix}u_\ell\\ v_\ell\end{pmatrix}=\frac{\ell(\ell+1)}{r^2}\begin{pmatrix}u_\ell\\ v_\ell\end{pmatrix}. \tag{38b}$$

These free solutions are given by[1–3,7,8]

$$u_\ell(kr)=\sqrt{\frac{\pi kr}{2}}J_{\ell+1/2}(kr)\underset{r\to 0}{=}\frac{(kr)^{\ell+1}}{(2\ell+1)!!}+\cdots,$$

$$v_\ell(kr)=\sqrt{\frac{\pi kr}{2}}N_{\ell+1/2}(kr)\underset{r\to 0}{=}\frac{(2\ell-1)!!}{(kr)^\ell}+\cdots, \tag{39a}$$

$$(2\ell+1)!!=\frac{\Gamma(2\ell+2)}{2^\ell\Gamma(\ell+1)},\quad \ell>-\frac{1}{2}.$$

We have also

$$u_\ell(kr) \underset{r\to\infty}{=} \sin(kr-\tfrac{1}{2}\ell\pi)+\cdots,$$
$$v_\ell(kr) \underset{r\to\infty}{=} \cos(kr-\tfrac{1}{2}\ell\pi)+\cdots. \tag{39b}$$

Their Wronkian is given by

$$W(u_\ell,v_\ell)\equiv u'_\ell v_\ell - u_\ell v'_\ell = k. \tag{40}$$

As for the regular solution $\varphi_\ell(k,r)$, it is customary to normalize it such that[1–3]

$$\varphi_\ell(k,r) \underset{r\to 0}{\simeq} \frac{r^{\ell+1}}{(2\ell+1)!!}+\cdots. \tag{41}$$

Now, again, under the condition (1) on the potential, one can show that both φ and φ' exist for all real or complex values of k, all $r\geqslant 0$, and are continuous in both variables.[1–3] Moreover, one has the asymptotic behaviors

$$\varphi_\ell(k,r) \underset{r\to\infty}{=} \frac{|F_\ell(k)|}{k^{\ell+1}}\sin\left(kr-\frac{1}{2}\ell\pi+\delta_\ell(k)\right)+o(1),$$
$$\varphi'_\ell(k,r) \underset{r\to\infty}{=} \frac{|F_\ell(k)|}{k^{\ell}}\cos\left(kr-\frac{1}{2}\ell\pi+\delta_\ell(k)\right)+o(1), \tag{42}$$

where $F_\ell(k)$ is the Jost function, well-defined and continuous for all $k\geqslant 0$. For k real, one has also, uniformly in r for any $r\in[0,R]$, $R<\infty$,

$$\varphi_\ell(k,r) \underset{k\to\infty}{=} \frac{\sin kr}{k^{\ell+1}}+\frac{o(1)}{k^{\ell+1}},$$
$$\varphi'_\ell(k,r) \underset{k\to\infty}{=} \frac{\cos kr}{k^{\ell}}+\frac{o(1)}{k^{\ell}}. \tag{43}$$

We write now

$$\varphi_\ell(k,r)=A_\ell(k,r)[u_\ell(kr)\cos\delta_\ell(k,r)+v_\ell(kr)\sin\delta_\ell(k,r)], \tag{44}$$

$A_\ell(k,r)\neq 0$ for all $r\geqslant 0$, $\delta_\ell(k,0)=0$. We have now again two unknown functions A_ℓ and δ_ℓ, and only one (differential) equation to determine them. We can therefore impose a relation between A_ℓ and δ_ℓ. Simplifying the writing, we impose

$$A'[u\cos\delta+v\sin\delta]+A[-u\sin\delta+v\cos\delta]\delta'=0. \tag{45}$$

Differentiating now (44) and taking into account (45), we find

$$\varphi'=A[u'\cos\delta+v'\sin\delta]. \tag{46}$$

One more differentiation gives us now

$$\varphi''=A'[u'\cos\delta+v'\sin\delta]+A[u''\cos\delta+v''\sin\delta]+A[-u'\sin\delta+v'\cos\delta]\delta'. \tag{47}$$

Using now (38a) for φ'', and (38b) for u'' and v'', we find from (47)

$$A'[u'\cos\delta+v'\sin\delta]+A[-u'\sin\delta+v'\cos\delta]\delta'=VA[u\cos\delta+v\sin\delta]. \tag{48}$$

We have now two equations, namely (45) and (48), to determine A and δ. We can write them, symbolically, as

$$aA' + bA\delta' = 0, \tag{49}$$

$$cA' + dA\delta' = aVA. \tag{50}$$

Eliminating A', and using $A \neq 0$ and (40), we find

$$ad - bc = -(u'v - uv') = -k \tag{51}$$

and

$$\delta'_\ell = -\frac{1}{k} V(r)[u_\ell \cos \delta_\ell + v_\ell \sin \delta_\ell]^2, \tag{52}$$

to which we have to add $\delta_\ell(k,0) = 0$. Likewise, eliminating δ', we find

$$kA'_\ell = V(r)A_\ell[u_\ell \cos \delta_\ell + v_\ell \sin \delta_\ell][-u_\ell \sin \delta_\ell + v_\ell \cos \delta_\ell]. \tag{53}$$

As it is easily seen, we have again equations very similar to the equations for $\ell = 0$. Once (52) is solved, with the boundary condition $\delta_\ell(k,0) = 0$, we can replace its solution δ_ℓ in (53), and integrate it to get A_ℓ:

$$A_\ell(k,r) = A_\ell(k,0) \exp\left[\frac{1}{k}\int_0^r \cdots\right]. \tag{54}$$

However, as we saw previously, we can write both δ_ℓ and A_ℓ in terms of φ_ℓ. From (44) and (46), we can calculate $\sin \delta_\ell$ and $\cos \delta_\ell$:

$$\sin \delta = \frac{u'\varphi - u\varphi'}{kA}, \tag{55}$$

$$\cos \delta = \frac{v\varphi' - v'\varphi}{kA}. \tag{56}$$

Using now $\sin^2 \delta + \cos^2 \delta = 1$, we get

$$A_\ell^2 = \frac{1}{k^2}[(u_\ell \varphi'_\ell - u'_\ell \varphi_\ell)^2 + (v_\ell \varphi'_\ell - v'_\ell \varphi_\ell)^2]. \tag{57}$$

Using also (55) and (56) in (52) and remembering (40), we get

$$\delta'_\ell = -\frac{1}{k} V(r) \frac{\varphi_\ell^2(k,r)}{A_\ell^2(k,r)}. \tag{58}$$

Integrating this now, we have

$$\delta_\ell(k,r) = -k\int_0^r V(t) \frac{\varphi_\ell^2(k,t)}{[(u_\ell \varphi'_\ell - u'_\ell \varphi_\ell)^2 + (v_\ell \varphi'_\ell - v'_\ell \varphi_\ell)^2]} dt. \tag{59}$$

All these formulas, so far purely formal, are very similar to those for $\ell = 0$. However, using now the behaviors of φ, φ', u, u', v, v' for $r \to 0$, we can check that all our above formulas are meaningful, i.e., the integrals are convergent at $r = 0$. Again, it is clear from (57) that $A_\ell(k,r) \neq 0$ for all $r \geqslant 0$. Indeed, if A_ℓ is zero at $r = r_0$, we must have, according to (57), $u\varphi' - u'\varphi$

$=0$ and $v\varphi'-v'\varphi=0$ at this point. Calculating again φ and φ' from these two equations, we find that, if $k\neq 0, \varphi=\varphi'=0$ at $r=r_0$. And this entails that $\varphi\equiv 0$ everywhere, a contradiction with (41). Therefore, our assumption on A_ℓ is satisfied: $A_\ell(k,r)$, for $k>0$, never vanishes for $r\in[0,\infty)$.

Let us now look at the behavior of $\delta_\ell(k,r)$, (59), $k>0$ for $r\to 0$, $\ell>-\frac{1}{2}$. From (39a) and (41), it is easily seen that the numerator behaves like $r^{2\ell+2}$ whereas the denominator becomes a positive constant. Therefore, we have, for $k>0$,

$$\delta_\ell(k,r)\underset{r\to 0}{\simeq}\text{const}\int_0^r t^{2\ell+2}V(t)\,dt=r^{2\ell+1}o(1). \tag{60}$$

This shows that our assumption on $\delta_\ell(k,r)$ is also satisfied: $\delta_\ell(k,0)=0$. Using (60) in (53), we find also that we have a convergent integral in (54). This completes the validity of the method and its consistency.

We have now to look at (57) and (59) for $r\to\infty$. From (39b) and (42), we find easily, for all $k>0$, that we have

$$A_\ell^2(k,\infty)=\frac{|F_\ell(k)|^2}{k^{2\ell+2}}\Rightarrow A_\ell(k,\infty)=\frac{|F_\ell(k)|}{k^{\ell+1}}, \tag{61}$$

where $F_\ell(k)$ is the Jost function, finite and continuous for all $k\geqslant 0$.[1–3] From (59) for $r\to\infty$, we find

$$\delta_\ell(k)=-k\int_0^\infty V(r)\frac{\varphi_\ell^2(k,r)}{[(u_\ell'\varphi_\ell-u_\ell\varphi_\ell')^2+(v_\ell'\varphi_\ell-v_\ell\varphi_\ell')^2]}dr, \tag{62}$$

and it is easily checked from (39b) and (42) that the integral here is well-defined and absolutely convergent, and since φ, φ', u, u', v and v' are all continuous functions of k for all $k>0$,[8] the same is true for $\delta_\ell(k)$: the phase-shift is a continuous function of k for all $k>0$. To check (3), we can use (43) in (62), and we find, as for the case $\ell=0$, that $\delta_\ell(\infty)=0$. Moreover, $k^{\ell+1}A_\ell$ and δ_ℓ are also continuous functions of k for all $k>0$. They are given, respectively, by (57) and (59). The physical phase-shift is given by (62), an absolutely convergent integral for all $k>0$ under the assumption (1), and one has also (3). Therefore, (62) gives an absolute definition of the phase-shift $\delta_\ell(k)$ in general for all k, and for potentials satisfying (1). We shall see in the next section that (20) and (62) are valid also for singular repulsive potentials as well. The case $k=0$ will be considered at the end of the next section.

Remark: Making $\ell=0$, one finds, as expected, all the formulas we found previously for the S-wave. Before ending this section, let us mention that by combining (38a) and (38b), and integrating from 0 to r, using the appropriate boundary conditions at $r=0$, namely (39a), (40), and (41), to evaluate the integrated terms, one can calculate $u'\varphi-u\varphi'$ and $v'\varphi-v\varphi'$, so that (62) can be written, for $\ell>-\frac{1}{2}$, also as

$$\delta_\ell(k)=-k\int_0^\infty V(r)\frac{\varphi_\ell^2(k,r)}{(\int_0^r u_\ell\varphi_\ell V dt)^2+(k^{-\ell}+\int_0^r v_\ell\varphi_\ell V dt)^2}dr. \tag{63}$$

Note here that we have now precise boundary conditions at $r=0$ for all the functions entering in (63), so that care must be taken in using it, whereas in (20) and (62), the normalization of φ at $r=0$ does not matter. For $-\frac{1}{2}\leqslant\ell<0$, as we shall see in the next section, (62) and (63) are valid provided we use there the ''distinguished'' pure Bessel solution for φ, given by the integral equation (68). Indeed, now, both free solutions $u_\ell=\sqrt{r}J_{\ell+1/2}(kr)$ and $v_\ell=\sqrt{r}N_{\ell+1/2}(kr)$ vanish at $r=0$, and so, as free solution, we can start from any combination $au_\ell+bv_\ell$, and use it as the inhomogeneous term in (68). We get then always a solution φ_ℓ with $\varphi(k,0)=0$. The ''distinguished'' solution is the one with $b=0$.

III. DOMAIN OF VALIDITY OF (20) AND (62)

As we have seen, formulas (20) for the S-wave, or its generalization (62) for higher waves, are valid for all $k>0$ and all $\ell \geqslant 0$, provided the potential satisfies the integrability condition (1): $rV(r) \in L^1(0,\infty)$. Roughly speaking, this means that V is less singular than r^{-2} at the origin. We may now ask whether they are also valid for potentials having stronger singularity there, for instance $V(r) \sim g r^{-m}$, $m \geqslant 2$, $g>0$, or $g \exp(\alpha/r^n)$, $g>0$, $\alpha>0$, $n>0$, etc., as $r \to 0$. Rather than developing the general formalism for such general singular potentials (singular and repulsive at the origin), we shall consider explicit examples, and leave the full theory for a forthcoming paper.

(i) We consider the formula (20) for the S-wave, and take boldly the potential to be the centrifugal barrier

$$V(r) = \frac{\ell(\ell+1)}{r^2}, \quad \ell>0, \tag{64}$$

in the Schrödinger equation (6). The wave function is now just, up to an unimportant constant multicative factor, $\varphi = \sqrt{kr} J_{\ell+1/2}(kr)$ which is of the form $\phi(kr)$. It is easily seen that (20) is well-defined because the integral is convergent (absolutely) both at $r=0$ and $r=\infty$. If we make the change of variable $z=kr$ in it, we find, by writing $\varphi' = k\,(d/dz)\,\phi = k\dot{\phi}(z)$, $\dot{} = d/dz$,

$$\delta = -\ell(\ell+1) \int_0^\infty \frac{\phi^2(z)}{[\dot{\phi}^2(z) + \phi^2(z)]} dz, \tag{65}$$

where $\phi = \sqrt{z} J_{\ell+1/2}(z)$. This last formula is now independent of k. The same is therefore true for the original formula (20) with our $\varphi(k,r)$. We can therefore calculate it at any value of k, for instance, for $k=0$. Using (39a), we find

$$\delta = -\ell(\ell+1) \int_0^\infty \frac{dz}{[(\ell+1)^2 + z^2]} = -\ell \int_0^\infty \frac{dt}{1+t^2} = -\ell \frac{\pi}{2}. \tag{66}$$

This is exactly the phase-shift of the centrifugal barrier $\ell(\ell+1)/r^2$ since, without this potential, the wave function is $\sin kr$, and with the potential, $\varphi \cong \text{const} \times \sin(kr - \frac{1}{2}\ell\pi)$, as $r \to \infty$, according to (42).

In conclusion, our formula (20) is valid for repulsive singular potentials g/r^2, $g>0$, which violate (1) both at $r=0$ and $r=\infty$.

(ii) We consider now the previous example, but with $-\frac{1}{2} \leqslant \ell < 0$. Here, proceeding as before, we find, as expected, again (66). Note that δ is now positive because the potential $\ell(\ell+1)/r^2$ is negative. For $\ell = -\frac{1}{2}$, the full solution is $\varphi = \sqrt{kr} J_0(kr)$, so that $\varphi \sim \sqrt{r}$ and $\varphi' \sim 1/(2\sqrt{r})$ as $r \to 0$.

Remark: Formula (20) was proved for regular potentials. In all rigor, in order to apply it to the centrifugal barrier potential $\ell(\ell+1)/r^2$, we must first regularize this at the origin, for instance by cutting it by $\theta(r-\varepsilon)$, and then make $\varepsilon \downarrow 0$, or by replacing r in the denominator by $(r+\varepsilon)$, and again take the limit $\varepsilon \downarrow 0$. However, as we saw, at the limit, we have already an absolutely convergent integral for all $\ell \geqslant -\frac{1}{2}$. Also, the derivation of (20) was based on the assumption $\varphi'(0)=1$, i.e., $\varphi(r) \simeq r + \cdots$ for $r \to 0$. However, for $\ell \neq 0$, we have rather $\varphi_\ell \simeq r^{\ell+1} + \cdots$. The extra factor r^ℓ comes from the regularized formula for the amplitude A in the limit $\varepsilon \downarrow 0$, as can easily be seen.[7]

(iii) We consider now (13) with

$$V(r) = \frac{\ell(\ell+1)}{r^2} + V_1(r), \quad \ell \geqslant -\frac{1}{2}, \tag{67}$$

assuming that $rV_1(r)\in L^1(0,\infty)$. Consider first $\ell>-\frac{1}{2}$. As we saw, the presence of this "weak perturbation," as compared to $\ell(\ell+1)/r^2$, does not modify the behavior of the regular solution φ_ℓ at $r=0$, given by (41), to be compared with (39a).[1–3] And since (20), as we just saw, works with $\ell(\ell+1)/r^2$, $\ell\geqslant-\frac{1}{2}$, applied to the regular solution φ_ℓ, it should work also when we add V_1, provided we use always pure Bessel functions as free solutions. This means that the Volterra integral equation which combines the Schrödinger equation and the boundary condition at $r=0$ is

$$\varphi_\ell(k,r)=\frac{1}{k^{\ell+1}}u_\ell(kr)+\int_0^r G_\ell(k;r,r')V(r')\varphi_\ell(k,r')dr',$$
$$G_\ell(k;r,r')=\frac{1}{k}[u_\ell(kr)v_\ell(kr')-u_\ell(kr')v_\ell(kr)]. \tag{68}$$

We consider now $\ell=-\frac{1}{2}$. As has been shown in Ref. 9, in order to formulate a decent scattering theory leading to the asymptotic form (42) with a well-defined Jost function $F_\ell(k)$ and a well-defined phase-shift δ_ℓ, one has to make stronger assumptions on V than (1), namely,

$$\int_0^\infty r|V(r)|(1+|\log r|)\,dr<\infty,$$
$$\int_a^\infty r|V(r)|(\log r)^2\,dr<\infty,\quad a>0. \tag{69}$$

This will be used later for $\ell=-\frac{1}{2}$, and $k\to0$, where we give more details.

In conclusion, formula (20) is valid for (67) and the regular solution φ_ℓ. Therefore, we have now two methods to deal with (67). The first one is to apply (62) to V_1, and the second one to apply (20) to the full potential (67). In any case, we get, of course, the full phase-shift

$$\delta_\ell^{\text{total}}=\delta_\ell-\tfrac{1}{2}\ell\pi, \tag{70}$$

δ_ℓ being the physical phase-shift due to V_1, which is what interests us in scattering theory. Remember that, in (20) or (62), φ is always the full solution: solution of (38a) with $V=V_1$, or (6) with (67), always together with (41).

(iv) We consider now more singular potentials, namely $V(r)=g/r^m$, $m>2$, $g>0$. Here, it is known that the solution of the Schrödinger equation (1) which vanishes at $r=0$ behaves there as[1–6]

$$\varphi_\ell(k,r)\underset{r\to0}{\simeq}[V(r)]^{-1/4}\exp\left(-\int_r^\infty[V(t)]^{1/2}dt\right)=\phi_0(r)=g^{-1/4}r^{m/4}\exp\left[-\sqrt{g}\frac{2}{m-2}\frac{1}{r^{(m-2)/2}}\right], \tag{71}$$

independent of k and ℓ. The wave function φ and all of its derivatives $\varphi^{(n)}$ vanish exponentially at $r=0$. Notice that we can omit the factor $g^{-1/4}$ in front of the last expression since our formulas for the phase-shifts are homogeneous in φ. In fact, at $k=0$, the Schrödinger equation is soluble exactly, and its solution is,[4] up to an unimportant constant multiplicative factor,

$$\varphi_\ell(k=0,r)=\sqrt{r}K_{(2\ell+1)/(m-2)}\left(\frac{2\sqrt{g}}{m-2}r^{-(m-2)/2}\right), \tag{72}$$

where K_ν is the modified Hankel function.[8] Using the asymptotic behavior of $K_\nu(x)$ for $x\to\infty$, we find indeed, up to constant multiplicative factors, the behavior shown in (71). On the other hand,

we know that now, because of the strong singularity of V at $r=0$, the phase-shift does not go to zero as $k\to\infty$, contrary to the case of regular potentials satisfying (1). Rather, one has the high energy behavior[5,6]

$$\delta_{\ell}(k) \underset{k\to\infty}{=} -Ag^{1/m}k^{(m-2)/m}+\cdots, \tag{73}$$

where

$$A=\frac{\sqrt{\pi}}{2}\frac{\Gamma(1-1/m)}{\Gamma(3/2-1/m)}. \tag{74}$$

Since the main term in (73) is independent of ℓ, we shall consider the case $\ell=0$ to simplify the algebra, and therefore use (20). In this formula, the integral can be split into $\int_0^R+\int_R^\infty$. For the second integral, we have

$$\left|k\int_R^\infty \cdots\right| < \frac{g}{k}\int_R^\infty \frac{dr}{r^m} = O(k^{(m-2)/m+\varepsilon}), \tag{75}$$

ε very small (>0), as $k\to\infty$, provided $R=O(k^{-2/m+\varepsilon})$. The contribution of (75) can therefore be neglected if we compare with (73). Note that $R\to 0$ as $k\to\infty$. In the first integral, we can therefore replace, in first approximation, φ by ϕ_0 given in (71), and independent of k. We find then

$$-gk\int_0^R \frac{1}{r^m}\frac{\phi_0^2}{\phi_0'^2+k^2\phi_0^2}dr = -gk\int_0^R \frac{1}{((m/4)\,r^{m/2-1}+\sqrt{g})^2+k^2r^m}dr. \tag{76}$$

Making now the change of variable $x=k^{2/m}r$, letting $k\to\infty$, and noting that $k^{2/m}R\to\infty$, we find

$$-gk\int_0^R \cdots \underset{k\to\infty}{\simeq} -gk^{(m-2)/m}\int_0^\infty \frac{dx}{g+x^m} = -g^{1/m}k^{(m-2)/m}\int_0^\infty \frac{dt}{1+t^m}. \tag{77}$$

It follows that the approximate value of $\delta(k)$ behaves asymptotically as

$$\delta_{\text{app}}(k) \underset{k\to\infty}{\simeq} -Bg^{1/m}k^{(m-2)/m},\quad B=\int_0^\infty \frac{dt}{1+t^m}. \tag{78}$$

This coincides with (73) up to a numerical factor, and is obtained without much effort, as we see.

The above argument to obtain (78) is, of course, heuristic because (71) is uniform in k only for $k\in[0,K]$, $K<\infty$. But it can be made more precise and quite rigorous. In a forth-coming paper, we shall develop a technique to deal with all these problems in a unified way.

Remark: The remark at the end of (*ii*) applies here, too. We must regularize first the potential, and then let $\varepsilon\downarrow 0$. The exponential decrease of φ as $r\to 0$ comes then from the amplitude A in the limit $\varepsilon\downarrow 0$.

A. A low-energy example

Our last example is the low energy behavior of the phase-shift for $\ell=-\frac{1}{2}$, where the potential is assumed to be repulsive ($V\geqslant 0$), and to satisfy the integrability conditions

$$\int_0^\infty r|V(r)|(1+|\log r|)\,dr<\infty, \tag{79}$$

and

$$\int_a^\infty r|V(r)|(\log r)^2\,dr<\infty,\quad a>0. \tag{80}$$

This corresponds to the S-wave Schrödinger equation in two space dimensions, and is interesting to study.[9]

As we saw in (iii), we must use here only the pure "Bessel" solutions. This means that the solution φ is the solution of the integral equation (68) for $\ell=-\frac{1}{2}$:

$$\varphi(k,r)=\sqrt{kr}J_0(kr)+\int_0^r G(k,r,r')V(r')\varphi(k,r')dr', \tag{81}$$

where the Green's function is given by

$$G=\frac{\pi}{2}\sqrt{rr'}[J_0(kr)N_0(kr')-J_0(kr')N_0(kr)]. \tag{82}$$

The occurrence of $\log r$ in (79) is due to the presence of $\log(kr)$ in N_0. Here, φ is normalized somewhat differently, but we know that the normalization of φ does not matter in (20) and (62). In (63), φ is normalized now as to $\varphi\simeq\sqrt{r}$ for $r\to 0$.

It is then shown in the above reference that the phase-shift, i.e., the phase-shift $\delta_0(k)$ of the S-wave in the two dimensional space problem, has the universal behavior

$$\delta_0(k)\underset{k\to 0}{\simeq}\frac{-\pi/2}{|\log k|}+\cdots, \tag{83}$$

i.e., the main term is independent of the potential.

We are going to find (83) by using the formula (63) for $\ell=-\frac{1}{2}$, in which φ_ℓ is given as above, and, for $z\to 0$,[8]

$$\begin{aligned} J_0(z)&=1-\frac{z^2}{4}+\cdots,\\ N_0(z)&=\frac{2}{\pi}\left[\log\frac{z}{2}+\gamma\right]J_0(z)+O(z^2). \end{aligned} \tag{84}$$

From the integral equation for φ, it can be easily shown that, under the assumptions (79) and (80), the low-energy behavior of φ is given by $\varphi\underset{k\to 0}{\simeq}\sqrt{kr}J_0(kr)\simeq\sqrt{kr}+\cdots$, which we have to normalize to $\varphi\simeq\sqrt{r}$, and, for u and v, in order to comply with (40), we must take

$$\begin{aligned} u&\simeq\sqrt{kr}+\cdots,\\ v&\simeq-\sqrt{kr}\log kr+\cdots. \end{aligned} \tag{85}$$

Using now the above low energy behaviors in (63), we find

$$\delta(k)\underset{k\to 0}{\simeq}-\int_0^\infty\frac{rV(r)}{(\int_0^r tV(t)\,dt)^2+(1-\int_0^r tV(t)\log kt\,dt)^2}dr. \tag{86}$$

Since V was assumed to be positive, we can introduce the new variable $X=X(r)$ by

$$X(r)=|\log k|\int_0^r tV(t)dt,\quad dX=|\log k|rVdr, \tag{87}$$

which is a one-to-one mapping from $r\in[0,\infty)$ to $X\in[0,|\log k|A]$, where $A=\int_0^\infty r|V(r)|dr$. Letting now $k\to 0$, we find easily from (86)

$$\delta(k)\underset{k\to 0}{\simeq}-\frac{1}{|\log k|}+\cdots. \tag{88}$$

Here again, as for the case of singular potentials, we do not get the exact constant $\pi/2$ because we use $\varphi\simeq\sqrt{r}$, which is not uniform on the entire r-axis. We shall come back to this in more detail in a forthcoming paper.

B. The case $k=0$

Let us consider now $k=0$ in (20). It is known that, under (1), one has[1–3]

$$\varphi(0,r)\underset{r\to\infty}{=}\varphi'(0,\infty)r+D+o(1), \tag{89}$$

where $\varphi'(0,\infty)$ is finite or zero, and D is finite also. Making now $k=0$ in (20), we find, for the S-wave scattering length[1,2]

$$a_0=\lim_{k\to 0}\frac{-\delta_0(k)}{k}=\int_0^\infty\frac{\varphi^2(0,r)}{\varphi'^2(0,r)}V(r)\,dr. \tag{90}$$

At the origin $r=0$, there is no convergence problem since $\varphi'(k,0)=1$ for all k. However, at $r=\infty$, because of (89), we must assume

$$\int_R^\infty r^2|V(r)|\,dr<\infty \tag{91}$$

in order to secure proper convergence, which is also well-known.[1,2] But this is not yet the end. We must also be sure that $\varphi'(0,r)$ does not vanish for $r>0$. This is surely the case if V is positive,[1,2] but cannot be guaranteed otherwise. In conclusion, (91) is valid only when $\varphi'(0,r)\neq 0$ for all $r>0$. For higher waves, in order to have proper convergence at $r=\infty$, one needs[1,2]

$$\int_0^\infty r^{2\ell+2}|V(r)|\,dr<\infty \tag{92}$$

and again the nonvanishing of the denominators in (20) or (62). We shall see in a forthcoming paper, how to modify these formulas in the presence of bound states. However, we know that in all cases, $\delta_\ell(k)$ is continuous down to $k+0$, and one has the Levinson theorem $\delta(+0)=n\pi$, where n is the number of bound states.[1–3,7]

C. Two-potential case

Formulas (62) and (63), as it is obvious, can of course be applied in the case where we have two potentials:

$$V=V_1+V_2, \tag{93}$$

both satisfying (1). Here, we can apply either (20) to V, or (62) and (63) to V_2, where u_ℓ and v_ℓ are now replaced by two appropriate independent solutions of the Schrödinger equation φ_1 and ψ_1, normalized according to (40):

$$W[\varphi_1,\psi_1]=\varphi_1'\psi_1-\varphi_1\psi_1'=k. \tag{94}$$

With (20), we would get the full phase-shift, and with (62) or (63), the phase-shift δ_2 due to V_2.

APPENDIX A

We have to study here the integral equation (18):

$$\Delta(k,r)=\frac{D}{k}\int_0^r|V(t)|\left[\frac{kt+\Delta(k,t)}{1+kt+\Delta(k,t)}\right]^2dt. \tag{A1}$$

We solve it by iteration, starting from

$$\Delta^{(0)}(k,r)=0. \tag{A2}$$

Since $x/(1+x)$ is an increasing function of x for $x\geqslant 0$, we get the increasing sequence of iterations

$$\Delta^{(1)}(k,r)<\Delta^{(2)}(k,r)<\cdots, \tag{A3}$$

where

$$\begin{aligned}\Delta^{(1)}(k,r)&=\frac{D}{k}\int_0^r|V(t)|\left(\frac{kt}{1+kt}\right)^2dt,\\ \Delta^{(n)}(k,r)&=\frac{D}{k}\int_0^r|V(t)|\left(\frac{kt+\Delta^{(n-1)}(k,t)}{1+kt+\Delta^{(n-1)}(k,t)}\right)^2dt.\end{aligned} \tag{A4}$$

(i) Assume now first that V is integrable at $r=0$ and therefore is $L^1(0,\infty)$. It is then obvious that the increasing sequence of iterations is bounded by

$$\overline{\Delta}(k,r)=\frac{D}{k}\int_0^r|V(t)|dt,\quad r\geqslant 0,\quad k>0. \tag{A5}$$

It has therefore a limit, and one has the solution

$$\Delta(k,r)=\lim_{n\to\infty}\Delta^{(n)}(k,r)\leqslant\overline{\Delta}(k,r) \tag{A6a}$$

for all $r\geqslant 0$, and all $k>0$. For $r\to\infty$, the same statement is valid. Indeed, if we note that both $\Delta(k,r)$ and $\overline{\Delta}(k,r)$ are increasing functions of r, it follows that we have, when $r\to\infty$,

$$\Delta(k)=\lim_{r\to\infty}\Delta(k,r)\leqslant\overline{\Delta}(k)=\lim_{r\to\infty}\overline{\Delta}(k,r)=\frac{D}{k}\int_0^\infty|V(t)|dt. \tag{A6b}$$

It is then obvious from (A5) that we have $\Delta(k\to\infty)=0$, which gives in turn (3), as expected.

(ii) If we have only (1): $rV(r)\in L^1$, we must refine slightly our argument. Since our problem is now the convergence of the integral in $\Delta^{(n)}(k,r)$ at $r=0$, we consider r very small. Now, as it is obvious, another sequence of upper bounds for $\Delta^{(n)}(k,r)$ is obtained by using the drastic inequality $x/(1+x)<x$ in (A1). We obtain in this way a sequence of upper bounds for $\Delta^{(n)}$ from the sequence of iterations of

$$\bar{\bar{\Delta}}(k,r)=\frac{D}{k}\int_0^r|V(t)|[kt+\bar{\bar{\Delta}}(k,t)]^2dt. \tag{A7}$$

Putting $\bar{\Delta}=k\omega$, we get

$$\omega(k,r)=D\int_0^r|V(t)|(t+\omega)^2dt, \tag{A8}$$

which is in fact independent of k, and must be iterated now. The above equation is nothing else than the integral equation for minus the local scattering length

$$a(r)=\lim_{k\to 0}\frac{-\delta(k,r)}{k} \tag{A9}$$

for the potential $-D|V(r)|$, and has been studied in the book of Calogero,[7] Chaps. 11 and 12, where it is shown that the iteration of (A8) leads to an absolutely convergent series expansion for the solution, provided r is small enough and $rV(r)\in L^1$. Alternatively, (A8) is nothing else than the Riccati equation

$$\omega'(r)=D|V(r)|[r+\omega(r)]^2 \tag{A10}$$

with $\omega(0)=0$, which has also been thoroughly studied in the books of Hille[10] and Coddington and Levinson,[11] to which we refer the reader, with the same conclusion.

Once we secure the solution of (A7) in a small interval $[0,r_0]$, with $\Delta(k,0)=0$, we can then start at $r=r_0$. Consider instead of (A1) the integral equation,

$$\Delta(k,r)=\Delta(k,r_0)+\frac{D}{k}\int_{r_0}^r|V(t)|\left[\frac{kt+\Delta(k,t)}{1+kt+\Delta(k,t)}\right]^2dt, \tag{A11}$$

and proceed as before, by iteration. Here, we need only $V\in L^1(r_0,\infty)$. We get then again an increasing sequence bounded by

$$\Delta(k,r_0)+\frac{D}{k}\int_{r_0}^\infty|V(t)|dt, \tag{A12}$$

with the same conclusions as before for the existence of the limit of the iterations, etc. However, the high-energy behavior of $\delta(k,r)$ cannot be obtained from the above analysis.

A different method, which supercedes the above considerations, and provides at the same time the high-energy limit of $\delta(k,r)$ and of $\delta(k)=\delta(k,\infty)$ is as follows. It consists in neglecting Δ in the denominator of the right-hand side of (A1):

$$\Delta(k,r)\leqslant\frac{D}{k}\int_0^r|V(t)|\left[\frac{kt+\Delta(k,t)}{1+kt}\right]^2dt\leqslant\frac{D}{k}\int_0^r\frac{r}{t}|V(t)|\left[\frac{kt+\Delta}{1+kt}\right]^2dt. \tag{A13}$$

Writing now $\Delta=r\omega$, the two ends of (A13) lead us to the integral equation

$$\omega=\frac{D}{k}\int_0^r t|V(t)|\frac{(k+\omega)^2}{(1+kt)^2}dt \tag{A14}$$

whose solution provides still a stronger upper bound for $\Delta(k,r)$. Now, it is trivial to solve (A14). We just differentiate it, and integrate the differential equation, taking into account $\omega(k,0)=0$. This solution is just

$$\omega(k,r)=\frac{kI(k,r)}{1-I(k,r)},$$
$$I(k,r)=D\int_0^r \frac{t|V(t)|}{(1+kt)^2}dt. \tag{A15}$$

The solutions exists as long as $I(k,r)<1$, that is, in the interval $[0,r_0)$, where $r_0(k)$ is given by

$$D\int_0^{r_0} \frac{r|V(r)|}{(1+kr)^2}dr=1. \tag{A16}$$

Note that, in any fixed interval $[0,R]$, $R\leqslant\infty$, we have

$$\lim_{k\to\infty} I(k,r)=0. \tag{A17}$$

Indeed, from (A15), and using $1+kt\geqslant 1$ and $1+kt>kt$, we have

$$I(k,r)\leqslant I(k,\infty)\leqslant D\int_0^\infty \frac{t|V(t)|}{1+kt}dt=J(k,\infty)\leqslant \int_0^\varepsilon t|V(t)|dt+\frac{1}{k}D\int_\varepsilon^\infty |V(t)|dt, \tag{A18}$$

where, in obvious notations, $J(k,r)$ is defined by $D\int_0^r[t|V(t)|/(1+kt)]dt$. Now, we can first make ε small enough, independent of k, in order to make the first integral on the right-hand side as small as we wish. Once ε is fixed, we can then make k large enough in order to make also the second integral as small as we wish. This proves (A17).

Remark: It is obvious that (A17) is uniform in any finite interval $0\leqslant r\leqslant R$.

As a consequence of (A17), $r_0(k)$ defined by (A16) satisfies

$$\lim_{k\to\infty} r_0(k)=\infty, \tag{A19}$$

so that, the larger k is, the larger is the domain of validity of (A15). In any case, by making k large enough, and combining (A15) and (A17), we can have, uniformly in r in $[0,R]$,

$$\omega(k,r)\leqslant 2kI(k,r),\quad k>K, \tag{A20}$$

and we know that $r\omega(k,r)$ is an upper bound for $\Delta(k,r)$. We can therefore, for k large enough, use (A20) in (A1):

$$\Delta(k,r)=\frac{D}{k}\int_0^r |V(t)|[\cdots]^2dt\leqslant\frac{D}{k}\int_0^r |V(t)|[\cdots]^1dt\leqslant\frac{D}{k}\int_0^r |V(t)|,$$
$$\frac{kt+2ktI(k,t)}{1+kt}dt=J(k,r)+2D\int_0^r\frac{t|V(t)|}{1+kt}I(k,t)dt\leqslant J(k,r)+2I(k,r)J(k,r). \tag{A21}$$

Now, as we saw for (A19), both I and J go to zero as $k\to\infty$, uniformly in r for r in any finite interval $[0,R]$. Therefore,

$$\lim_{k\to\infty}\Delta(k,r)=0,\quad 0\leqslant r\leqslant R. \tag{A22}$$

Once we have shown the existence of the solution $\Delta(k,r)$ in $[0,R]$, we can proceed as for (A11), write, for $r>R$,

$$\Delta(k,r)=\Delta(k,R)+\frac{D}{k}\int_R^r|V(t)|\left[\frac{kt+\Delta(k,t)}{1+kt+\Delta(k,t)}\right]^2dt, \tag{A23}$$

and proceed again by iteration. This way of proceeding is legitimate since (A1), or (18), was obtained from the differential equation (8) and the bound (16). We can therefore start at any point $r=R$, and integrate after, provided we know $\delta(k,R)$. And we obtain a bigger upper bound if we replace $|\delta(k,R)|$ by $\Delta(k,R)$. The process is now very similar to what we had in (i). We get an increasing sequence of iterations $\Delta^{(n)}(k,r)$, with $\Delta^{(0)}(k,r)=\Delta(k,R)$, and a global upper bound for all $\Delta^{(n)}(k,r)$:

$$\Delta^{(n)}(k,r)\leqslant\Delta_0(k)=\Delta(k,R)+\frac{D}{k}\int_R^\infty|V(t)|dt, \tag{A24}$$

valid for all $r>R$, including $r=\infty$, and all n. The sequence has therefore a limit, and this limit provides the solution $\Delta(k,r)$ of (A1) for all $r\geqslant R$, including $r=\infty$, with $R<r_0(k)$, and $r_0(k)$ given by (A16). Since we have also proved the existence of the solution in $[0,r_0]$, we have therefore proved the existence of the solution of (A1) for all $r\geqslant 0$. Obviously, we have

$$\Delta(k,0)=0. \tag{A25a}$$

Therefore, we have, for $r>R$,

$$\Delta(k,r)\leqslant\Delta(k,R)+\frac{D}{k}\int_R^\infty|V(t)|dt. \tag{A25b}$$

If we note also that $\Delta(k,r)$ is an increasing function of r, we secure the existence of $\Delta(k)=\Delta(k,\infty)$, and from (A22) and (A24), we obviously have, for the phase-shift

$$\lim_{k\to\infty}\delta(k)\leqslant\lim_{k\to\infty}\Delta(k)=\lim_{k\to\infty}\Delta(k,\infty)=0. \tag{A26}$$

This completes our proof for the general case where $rV(r)\in L^1(0,\infty)$.

APPENDIX B

Here, we shall show that, for regular potentials satisfying (1), one can make (3) more precise if one knows the detail behavior of the potential when $r\to 0$. One has, indeed, the following:

Theorem 1:[12] Let us assume that V is continuous and bounded, away from the origin, in $[0,R]$, $R<\infty$, and is such that

$$\lim_{r\to 0}r^{1+\alpha}V(r)=V_0,\quad 0<\alpha<1. \tag{B1}$$

We have then, as $k\to\infty$,

$$\delta(k)=\frac{-V_0}{\alpha}\cos\left(\frac{\pi\alpha}{2}\right)\Gamma(1-\alpha)\frac{1}{(2k)^{1-\alpha}}+\cdots, \tag{B2}$$

and, conversely, (B2) entails (B1).

We shall give the proof for the S-wave, $\ell=0$. The proof for higher waves is quite similar. Because of (14), we can just limit ourselves to (29):

$$\delta(k)\cong-\int_0^R dt\sin 2kt\left(\int_t^R V(r)dr\right). \tag{B3}$$

For the asymptotic behavior of this integral (as $k\to\infty$,) we can now use the following theorem of Titchmarsh.[13]

Theorem 2: Let $f(x)$ and $f'(x)$ be integrable over any finite interval not ending at $x=0$; let $x^{1+\alpha}f'(x)$ be bounded for all x, and let $f(x)\sim x^{-\alpha}$ as $x\to 0$. Then, denoting by F_0 the limit of $x^{1+\alpha}f'(x)$ as $x\to 0$, we have

$$\int_0^\infty f(x)\sin kx\,dx = F_0\Gamma(1-\alpha)\cos\frac{\pi\alpha}{2}\,\frac{1}{k^{1-\alpha}}(1+o(1)), \tag{B4}$$

as $k\to\infty$. The converse theorem is also true if we deal with finite intervals in (B4) since we can define the Fourier inverse transforms in a straightforward manner. This is indeed the case in (B3).

Our Theorem 1 follows now immediately from the theorem of Titchmarsh applied to (B3). Moreover, it is a Tauberian kind theorem, i.e., its converse is also true if we remember that the Fourier transform of an L^1 function $f(x)$ is a continuous function $F(k)$ of k. More refined theorems containing logarithmic terms can also be proved. Examples are treated in Calogero's book.[7] For higher waves, the proof is similar by using (39b) and (43) in (62).

(Received 21 February 2001; accepted for publication 4 June 2001)

We study transport in quantum systems consisting of a finite array of N identical single-channel scatterers. A general expression of the S matrix in terms of the individual-element data obtained recently for potential scattering is rederived in this wider context. It shows in particular how the band spectrum of the infinite periodic system arises in the limit $N\to\infty$. We illustrate the result on two kinds of examples. The first are serial graphs obtained by chaining loops or T-junctions. Another example concerns geometric scatterers where the individual element consists of a surface with a pair of leads; we show that apart from the resonances coming from the decoupled-surface eigenvalues, such scatterers exhibit the high-energy behavior typical for the δ' interaction for the physically interesting couplings. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1389287]

I. INTRODUCTION

A rapid progress in experimental solid state physics has expanded dramatically the list of situations in which consequences of the basic equations of quantum mechanics may be tested, since the interaction is prescribed by the experimentalist by the shape design of the structure in question, material choice, etc. One of the frequently occuring cases in mesoscopic transport involves a passage of a quantum particle through a *serial*—or finitely periodic—structure obtained by arraying a certain number N of identical scatterers.

Our aim in the present article is to study this situation under the assumption that the individual scatterers have a single transport mode. For a collection of mesoscopic elements connected by quantum wires, this is certainly an idealization. We can adopt this approximation provided the transverse modes in the wires are well separated and the distances between the scatterers are large enough so that the intermode coupling and influence of the evanescent modes can be neglected.

Such a single-mode transport is often investigated in literature, with the S-matrix obtained either ''inductively'' by adding the scatterers successively or by means of the transfer matrix method. It is difficult to collect all relevant references but a representative sample is given in Ref. 1; an extension of this ''factorization'' method to scattering on graphs was proposed recently in Ref. 2. On the other hand, the mentioned methods are typically used to evaluate the S-matrix

numerically and give little insight, say, into its dependence on the number N of the scatterers. To this purpose a transparent expression for the S-matrix is needed.

Such closed-form formulas were derived recently in one-dimensional potential scattering, first for an array of δ interactions[3–5] and then for an arbitrary finitely periodic potential;[6,7] also the number of bound states has been discussed in this setting.[8,9] When this work was in its final stage, another analysis of this situation appeared[3] which investigated in detail the distribution of scattering resonances and the corresponding time delay. Our main observation is that the input for the S-matrix expression are the individual-element scattering data, and thus the result can be applied to scattering on an array of arbitrary ''black boxes.'' The aim of the present paper is to rederive the result of Refs. 6 and 7 in this more general context and to illustrate it on several examples of nonpotential scattering.

They fall into two categories. First, in Sec. III, we consider two cases of serial graphs, an array of loops joined by leads and exposed to a homogeneous magnetic field, and a ''comb-shaped'' graph, i.e., a line with a family of identical appendices. A less conventional example is discussed in Sec. IV, where scatterers of dimension two are coupled by single mode leads. We derive a general S-matrix expression and analyze in detail the particular case when the scatterers are spheres. The latter was previously discussed in Ref. 10; in distinction to this paper we use a physically reasonable coupling between the spheres and the leads. For a single scatterer we prove existence of resonance peaks and the background which dominates at large energies and decays not slower than E^{-1} as $E\to\infty$. Furthermore, we conjecture that the ''coarse grained'' transmission probability (averaged locally over the resonances) has the E^{-1} decay typical for the δ' interaction. In all three examples we analyze the dependence of scattering quantities on the parameters. In particular, we illustrate how the band spectrum arises when the number of arrayed scatterers tends to infinity.

II. SERIAL STRUCTURE TRANSPORT

A. Preliminaries

Consider an equidistant array $\{\mathcal{S}_j : j=0,\dots,N-1\}$ of identical scatterers placed at the line points $x_0+j\mathrm{l}$. The spacing $\mathrm{l}\geqslant 0$ in this convention includes only the distance between $\mathcal{S}_j$ and $\mathcal{S}_{j+1}$, not the possible size of the scatterers themselves.

Let us review briefly basic notions concerning a single-mode scattering on a sole scatterer $\mathcal{S}$ placed conventionally at the point $x_0=0$. On the two halflines attached to $\mathcal{S}$ the particle moves as free, so the on-shell S-matrix at energy k^2,

$$\begin{pmatrix} B_+ \\ B_- \end{pmatrix} = S \begin{pmatrix} A_+ \\ A_- \end{pmatrix}, \tag{2.1}$$

couples the coefficients of the asymptotic solutions

$$\psi(x) = \begin{cases} A_+ e^{ikx} + B_- e^{-ikx} + \cdots, & x<0, \\ B_+ e^{ikx} + A_- e^{-ikx} + \cdots, & x>0. \end{cases} \tag{2.2}$$

In particular, we have

$$S = \begin{pmatrix} t & \tilde{r} \\ r & \tilde{t} \end{pmatrix}, \tag{2.3}$$

where r,t and $\tilde{r},\tilde{t}$ are the left-to-right and right-to-left reflection and transmission amplitudes, respectively. We shall consider only the nondissipative situation when S is unitary; its dependence on the momentum k will be indicated only if necessary.

Since the interaction responsible for the scattering is localized by assumption, solutions to the Schrödinger equation acquire the asymptotic form outside the scatterer. Hence S may be expressed

alternatively in terms matrices used in the theory of ordinary differential equations. One is the ''coefficient'' transfer matrix M relating the solutions to the left and to the right of the scatterer by

$$\begin{pmatrix} B_+ \\ A_- \end{pmatrix} = M \begin{pmatrix} A_+ \\ B_- \end{pmatrix}. \tag{2.4}$$

It is straightforward to see that

$$M = \frac{1}{\tilde{t}} \begin{pmatrix} t\tilde{t} - r\tilde{r} & \tilde{r} \\ -r & 1 \end{pmatrix}, \tag{2.5}$$

and, vice versa,

$$r = -\frac{M_{21}}{M_{22}}, \quad t = M_{11} - \frac{M_{12}M_{21}}{M_{22}}, \quad \tilde{r} = \frac{M_{12}}{M_{22}}, \quad \tilde{t} = \frac{1}{M_{22}}. \tag{2.6}$$

Another one is the transfer matrix which relates the values and derivatives of the two solutions,

$$\begin{pmatrix} u(0+) \\ u'(0+) \end{pmatrix} = L \begin{pmatrix} u(0-) \\ u'(0-) \end{pmatrix}. \tag{2.7}$$

Substituting the boundary values of $u(x) = e^{ikx} + re^{-ikx}$ for $x<0$ and $u(x) = te^{ikx}$ for $x>0$ into this relation, we get a pair of equations for r,t which is solved by

$$\begin{aligned} r &= -\frac{L_{21} + ik(L_{22} - L_{11}) + k^2 L_{12}}{L_{21} - ik(L_{22} + L_{11}) - k^2 L_{12}}, \\ t &= -\frac{2ik \det L}{L_{21} - ik(L_{22} + L_{11}) - k^2 L_{12}}. \end{aligned} \tag{2.8}$$

In the same way we get the right-to-left amplitudes,

$$\begin{aligned} \tilde{r} &= -\frac{L_{21} + ik(L_{11} - L_{22}) + k^2 L_{12}}{L_{21} - ik(L_{22} + L_{11}) - k^2 L_{12}}, \\ \tilde{t} &= -\frac{2ik}{L_{21} - ik(L_{22} + L_{11}) - k^2 L_{12}}. \end{aligned} \tag{2.9}$$

Combining (2.5) with (2.8) and (2.9) we can express the ''coefficient'' transfer matrix as

$$M = \frac{1}{2ik} \begin{pmatrix} L_{21} + ik(L_{11} + L_{22}) - k^2 L_{12} & L_{21} + ik(L_{11} - L_{22}) + k^2 L_{12} \\ -L_{21} + ik(L_{11} - L_{22}) - k^2 L_{12} & -L_{21} + ik(L_{11} + L_{22}) + k^2 L_{12} \end{pmatrix}. \tag{2.10}$$

The class of admissible transfer matrices is restricted by the S-matrix unitarity. In particular, the conservation of probability current, $|r|^2 + |t|^2 = |\tilde{r}|^2 + |\tilde{t}|^2 = 1$, implies $|\det L| = 1$; we shall write therefore

$$\det L = \frac{t}{\tilde{t}} =: e^{2i\varphi}. \tag{2.11}$$

One can also express L by means of the other two matrices. For instance, suppose that (2.3) is given. Using the relation (2.7) with the boundary values for the left-to-right scattering, the same for the right-to-left case with the explicitly written L^{-1} and $t=\tilde{t}\det L$, we get a system of four linear equations for L_{jk},

$$\begin{aligned} &L_{11}(1+r)+ikL_{12}(1-r)=t, \quad L_{21}(1+r)+ikL_{22}(1-r)=ikt, \\ &L_{22}(1+\tilde{r})+ikL_{12}(1-\tilde{r})=t, \quad L_{21}(1+\tilde{r})+ikL_{11}(1-\tilde{r})=ikt. \end{aligned} \tag{2.12}$$

Only three of them are independent; it is straightforward to see that the first with the third equation, and the second with the fourth equation lead to the same relation which is solved by

$$L_{22}=L_{11}\frac{(1+r)(1-\tilde{r})}{(1-r)(1+\tilde{r})}-\frac{t(r-\tilde{r})}{(1-r)(1+\tilde{r})}.$$

The same pairs of equations allow us to express L_{12} and L_{21} in terms of L_{11} and L_{22}; in combination with the last relation we find

$$L_{12}=-L_{11}\frac{(1+r)}{ik(1-r)}+\frac{t}{ik(1+\tilde{r})}, \quad L_{21}=-ikL_{11}\frac{(1-\tilde{r})}{ik(1+\tilde{r})}+\frac{ikt}{(1+\tilde{r})}.$$

We have still the condition (2.11). Computing the determinant with the help of the above relations, we get

$$\det L=\frac{t(2L_{11}-t)}{(1-r)(1+\tilde{r})}=\frac{t}{\tilde{t}}.$$

One can express L_{11} from here and substitute into the formulas for the other elements; this yields finally

$$L=\frac{1}{2\tilde{t}}\begin{pmatrix} t\tilde{t}+(1+r)(1-\tilde{r}) & \dfrac{1}{ik}[t\tilde{t}-(1+r)(1+\tilde{r})] \\ ik[t\tilde{t}-(1-r)(1-\tilde{r})] & t\tilde{t}+(1-r)(1+\tilde{r}) \end{pmatrix}. \tag{2.13}$$

The determinant of this matrix is equal to the middle expression of (2.11) and, substituting into (2.8) and (2.9), one can check that (2.13) indeed represents the inverse transformation.

Furthermore, the unitarity of S has a stronger consequence. It is well known that a general 2×2 unitary matrix can be parametrized by four real numbers as

$$e^{i\xi}\begin{pmatrix} e^{i(\alpha+\delta)}\cos\beta & e^{i(\delta-\alpha)}\sin\beta \\ -e^{i(\alpha-\delta)}\sin\beta & e^{-i(\alpha+\delta)}\cos\beta \end{pmatrix}.$$

Using this for S given by (2.3) and substituting into (2.13) we find that

$$L=e^{i\varphi}\mathcal{L}, \quad \mathcal{L} \text{ real with } \det\mathcal{L}=1, \tag{2.14}$$

where $\varphi:=\alpha+\delta$. Notice that M given by (2.10) has then the following property:

$$\overline{M}_{11}=e^{-2i\varphi}M_{22}, \quad \overline{M}_{12}=e^{-2i\varphi}M_{21}. \tag{2.15}$$

B. Recursive relations for scattering amplitudes

Before we derive the mentioned closed-form expression, let us recall the usual factorization technique. We index the transmission and reflection amplitudes for the array by N. In analogy with (2.3) we have

$$\begin{pmatrix} B_-^N \\ B_+^N \end{pmatrix} = \begin{pmatrix} r_N & \tilde{t}_N \\ t_N & \overline{\varepsilon}^{2(N-1)}\tilde{r}_N \end{pmatrix} \begin{pmatrix} A_+^N \\ A_-^N \end{pmatrix}, \tag{2.16}$$

where $\varepsilon := e^{ikl}$. Next we add the $(N+1)$-th scatterer to the right side of the array for which

$$\begin{pmatrix} B_- \\ B_+ \end{pmatrix} = \begin{pmatrix} \varepsilon^{2N} r & \tilde{t} \\ t & \overline{\varepsilon}^{2N}\tilde{r} \end{pmatrix} \begin{pmatrix} A_+ \\ A_- \end{pmatrix}, \tag{2.17}$$

where, of course, $B_+^N = A_+$ and $B_- = A_-^N$. In analogy with (2.5) we rewrite the last two relations in the "coefficient" transfer matrix form. Multiplying the two matrices we get

$$\begin{pmatrix} B_+ \\ A_- \end{pmatrix} = M \begin{pmatrix} A_+^N \\ B_-^N \end{pmatrix}$$

with

$$M := \begin{pmatrix} \dfrac{1}{\tilde{t}\tilde{t}_N}((t\tilde{t} - r\tilde{r})(t_N\tilde{t}_N - r_N\tilde{r}_N\overline{\varepsilon}^{2(N-1)}) - r_N\tilde{r}\overline{\varepsilon}^{2N}) & \dfrac{1}{\tilde{t}\tilde{t}_N}((t\tilde{t} - r\tilde{r})\tilde{r}_N + \overline{\varepsilon}^{2N}\tilde{r}) \\ \dfrac{1}{\tilde{t}\tilde{t}_N}(-\varepsilon^{2N} r(t_N\tilde{t}_N - r_N\tilde{r}_N) - r_N) & \dfrac{1}{\tilde{t}\tilde{t}_N}(1 - \varepsilon^{2N} r\tilde{r}_N) \end{pmatrix}.$$

Comparing this with (2.6) we find the sought-after recursive relations

$$\tilde{r}_{N+1} = \overline{\varepsilon}^{2N}\tilde{r} + \frac{\tilde{r}_N\tilde{t}t}{1 - \varepsilon^{2N}\tilde{r}_N r}, \quad \tilde{t}_{N+1} = \frac{\tilde{t}\tilde{t}_N}{1 - \varepsilon^{2N} r\tilde{r}_N}. \tag{2.18}$$

If we modify the argument by adding the $(N+1)$-th scatterer to the left of the array, we get in the same way

$$r_{N+1} = \varepsilon^{2N} r + \frac{r_N\tilde{t}t}{1 - \overline{\varepsilon}^{2N}\tilde{r}r_N}, \quad t_{N+1} = \frac{tt_N}{1 - \overline{\varepsilon}^{2N} r_N\tilde{r}}. \tag{2.19}$$

Since the "component" S-matrices are unitary, it is straightforward to check by induction that the same is true for the total S-matrix. The relations (2.18) and (2.19) have a transparent meaning: expanding the fractions into geometric series we obtain expressions containing sums of contributions from various scattering processes.

C. The S-matrix expression

While the factorization technique described above is general, it does not relate directly the S-matrices of an individual scatterer and that of the whole array. Such a formula is particularly useful when the scatterers involved are identical. To deal with this situation, notice first that in view of (2.15) we can write the M matrix of the jth scatterer as

$$M_j = e^{i\varphi} \begin{pmatrix} \overline{R} & \overline{\varepsilon}^{2j}\overline{S} \\ \varepsilon^{2j} S & R \end{pmatrix}, \tag{2.20}$$

where $\varepsilon := e^{ikl}$ as above and

$$R := e^{-i\varphi} M_{22} = \frac{e^{-i\varphi}}{\tilde{t}} = \frac{e^{i\varphi}}{t} = \frac{\mathcal{L}_{11}+\mathcal{L}_{22}}{2} + i\left(\frac{\mathcal{L}_{21}}{2k} - \frac{k}{2}\mathcal{L}_{12}\right),$$
$$S := e^{-i\varphi} M_{21} = -\frac{e^{-i\varphi} r}{\tilde{t}} =: -\frac{e^{i\varphi} r}{t} = \frac{\mathcal{L}_{11}-\mathcal{L}_{22}}{2} + i\left(\frac{\mathcal{L}_{21}}{2k} + \frac{k}{2}\mathcal{L}_{12}\right). \tag{2.21}$$

By definition the ''coefficient'' transfer matrix of the array is obtained by multiplying successively the matrices (2.20). We denote $M^{(n)} := M_n M_{n-1} \cdots M_0$. It is easy to compute the first few matrices $M^{(n)}$; this inspires us to look for the general product in the form

$$M^{(n)} = e^{i(n+1)\varphi} \begin{pmatrix} \overline{\varepsilon}^{n+1} |S|^{n+1} \overline{\gamma_n} & \overline{\varepsilon}^n \overline{S} |S|^n \overline{\delta_n} \\ \varepsilon^n S |S|^n \delta_n & \varepsilon^{n+1} |S|^{n+1} \gamma_n \end{pmatrix}, \tag{2.22}$$

where the coefficients have to satisfy the recursive relations

$$\gamma_{n+1} = \zeta \gamma_n + \overline{\delta_n}, \quad \delta_{n+1} = \zeta \delta_n + \overline{\gamma_n} \tag{2.23}$$

with $\delta_0 = 1$ and

$$\gamma_0 = \zeta := \frac{\overline{\varepsilon} R}{|S|}, \tag{2.24}$$

which follows from $M^{(n+1)} = M_{n+1} M^{(n)}$. Since

$$\det M_j = e^{2i\varphi}(|R|^2 - |S|^2) = e^{2i\varphi} \frac{1-|r|^2}{|\tilde{t}|^2} = e^{2i\varphi}, \tag{2.25}$$

and, consequently, $\det M^{(n)} = e^{2i(n+1)\varphi} |S|^{2n+2} (|\gamma_n|^2 - |\delta_n|^2) = e^{2i(n+1)\varphi}$, we have

$$\gamma_n = e^{i\theta_n} \sqrt{|\delta_n|^2 + |S|^{-2n-2}} \tag{2.26}$$

with a phase factor to be determined. Substituting into the relations (2.23) we get

$$e^{i\theta_{n+1}} \sqrt{|\delta_{n+1}|^2 + |S|^{-2n-4}} = \zeta e^{i\theta_n} \sqrt{|\delta_n|^2 + |S|^{-2n-2}} + \delta_n,$$
$$\delta_{n+1} = \zeta \delta_n + e^{-i\theta_n} \sqrt{|\delta_n|^2 + |S|^{-2n-2}}. \tag{2.27}$$

We express $e^{i\theta_n}$ from the second equation and substitute into the first one; this yields

$$\delta_{n+2} - (\zeta + \overline{\zeta}) \delta_{n+1} + (|\zeta|^2 - 1) \delta_n = 0. \tag{2.28}$$

Now $\delta_0 = 1$ and $\delta_1 = \zeta + \overline{\zeta}$, so (2.28) is solved by

$$\delta_n = (|\zeta|^2 - 1)^{n/2} U_n\left(\frac{\zeta + \overline{\zeta}}{2\sqrt{|\zeta|^2 - 1}}\right),$$

where U_n is the Chebyshev polynomial of the second kind. Since $|\zeta|^2 - 1 = |S|^{-2}$ by (2.25), its argument can be more compactly written as $\mathrm{Re}(\overline{\varepsilon} R)$. Using (2.26) and (2.27) again, we find $M^{(n)} = e^{2i(n+1)\varphi} \mathcal{M}^{(n)}$ with

$$\mathcal{M}^{(n)}=\begin{pmatrix} \overline{\varepsilon}^{n+1}e^{-i\theta_n}\sqrt{1+|S|^2U_n(\mathrm{Re}(\overline{\varepsilon}R))^2} & \overline{\varepsilon}^{n}\overline{S}U_n(\mathrm{Re}(\overline{\varepsilon}R)) \\ \varepsilon^{n}SU_n(\mathrm{Re}(\overline{\varepsilon}R)) & \varepsilon^{n+1}e^{i\theta_n}\sqrt{1+|S|^2U_n(\mathrm{Re}(\overline{\varepsilon}R))^2} \end{pmatrix}, \quad (2.29)$$

where

$$e^{i\theta_n}=\frac{U_{n+1}(\mathrm{Re}(\overline{\varepsilon}R))-\varepsilon\overline{R}U_n(\mathrm{Re}(\overline{\varepsilon}R))}{\sqrt{1+|S|^2U_n^2(\mathrm{Re}(\overline{\varepsilon}R))}}. \quad (2.30)$$

Now we may employ (2.5) and (2.11) to find the sought-after formulas for the array of N scatterers; it is sufficient to put $n=N-1$. We arrive at the following conclusion:

Theorem II.1: *With the given notation, the transmission and reflection amplitudes of an N-element serial structure express as*

$$t_N=\frac{\overline{\varepsilon}^{N}e^{-i\theta_{N-1}}}{\sqrt{1+|S|^2U_{N-1}(\mathrm{Re}(\overline{\varepsilon}R))^2}} \quad (2.31)$$

$$r_N=-\frac{\overline{\varepsilon}e^{-i\theta_{N-1}}SU_{N-1}(\mathrm{Re}(\overline{\varepsilon}R))}{\sqrt{1+|S|^2U_{N-1}(\mathrm{Re}(\overline{\varepsilon}R))^2}}, \quad (2.32)$$

where the phase factor is given by (2.30). In the same way the right-to-left amplitudes are $\tilde{t}_N=t_Ne^{-2iN\varphi}$ *and*

$$\tilde{r}_N=-\frac{\overline{\varepsilon}^{2N-1}e^{-i\theta_{N-1}}\overline{S}U_{N-1}(\mathrm{Re}(\overline{\varepsilon}R))}{\sqrt{1+|S|^2U_{N-1}(\mathrm{Re}(\overline{\varepsilon}R))^2}}.$$

In particular, the transmission and reflection probabilities are the same in both directions and equal

$$|t_N|^2=\frac{1}{1+|S|^2U_{N-1}(\mathrm{Re}(\overline{\varepsilon}R))^2}, \quad |r_N|^2=\frac{|S|^2U_{N-1}(\mathrm{Re}(\overline{\varepsilon}R))^2}{1+|S|^2U_{N-1}(\mathrm{Re}(\overline{\varepsilon}R))^2}. \quad (2.33)$$

Recall that

$$|S|^2=\left|\frac{r}{t}\right|^2, \quad \mathrm{Re}(\overline{\varepsilon}R)=\mathrm{Re}\left(\frac{e^{-i(kl+\varphi)}}{\tilde{t}}\right)=\mathrm{Re}\left(\frac{e^{-i(kl-\varphi)}}{t}\right);$$

it is obvious from (2.33) that the probability current is preserved.

D. Relation to band spectra of periodic systems

An advantage of the above formula is that it makes clear the relation between serial structure and their infinite analogs. Consider an infinite periodic array of identical scatterers $\mathcal{S}$ joined by line segments of length l. The one-period transfer matrix is $T=L\,\mathcal{U}_l(k)$, where

$$\mathcal{U}_l(k):=\begin{pmatrix} \cos kl & \frac{1}{k}\sin kl \\ -k\sin kl & \cos kl \end{pmatrix}$$

coresponds to the segment. The band spectrum of the problem is given by the Bloch condition, $\det(T-e^{i\theta})=0$, or

$$e^{2i\theta}-e^{i\theta}\mathrm{tr}\,T+\det T=0. \quad (2.34)$$

In view of (2.11), $\det T=\det L=e^{2i\varphi}$, so the condition may be written as

$$e^{-i\varphi}\mathrm{tr}\, T=2\cos(\theta-\varphi).$$

To express the lhs, we employ (2.13) which yields

$$\mathrm{tr}\, T=\mathrm{tr}\, T\cos kl+\left(\frac{1}{k}L_{21}-kL_{12}\right)\sin kl=\frac{t\tilde{\bar{t}}-r\tilde{\bar{r}}}{\tilde{t}}e^{ikl}+\frac{1}{\tilde{t}}e^{-ikl},$$

and since

$$\frac{t\tilde{\bar{t}}-r\tilde{\bar{r}}}{\tilde{t}}=\frac{e^{2i\varphi}}{\bar{\tilde{t}}}$$

by (2.5) and (2.15), we arrive finally at

$$\mathrm{Re}(\bar{\varepsilon}R)=\frac{e^{i(kl+\varphi)}}{2\bar{\tilde{t}}}+\frac{e^{-i(kl+\varphi)}}{2\tilde{t}}=\cos(\theta-\varphi). \tag{2.35}$$

The lhs as a function of k is typically oscillating. Since the amplitude $|t|^{-1}>1$ unless the single-element scattering is reflectionless, the periodic spectrum has gaps in general.

The relations (2.33) show how the band spectrum arises in the limit $N\to\infty$ of the serial-structure scattering. The Chebyshev polynomials

$$U_n(x)=\sum_{m=0}^{[n/2]}(-1)^m\frac{(n-m)!}{m!(n-2m)!}(2x)^{n-2m} \tag{2.36}$$

are oscillating within the interval $[-1,1]$. The easiest way to see that is to use the representation

$$U_n(x)=\frac{\sin(n+1)\xi}{\sin\xi},\quad \xi:=\arccos x. \tag{2.37}$$

Thus U_{N-1} has $N-1$ roots in $[-1,1]$ and each band contains at least $N-1$ points where $|t_N(k)|^2=1$. Possible additional points with this property can come from zeros of the single-element reflection coefficient. Properties of Chebyshev polynomials yield also lower bounds to the envelope of the transmission probability oscillations. The representation (2.37) implies $|U_n(x)|\leqslant(1-x^2)^{-1/2}$ for $|x|<1$, and therefore

$$|t_N(k)|^2\geqslant\frac{1-(\mathrm{Re}(\bar{\varepsilon}R))^2}{1+|S|^2-(\mathrm{Re}(\bar{\varepsilon}R))^2}=\frac{|t(k)|^2-(\mathrm{Re}(\tilde{t}(k)e^{i(kl+\varphi)}))^2}{1-(\mathrm{Re}(\tilde{t}(k)e^{i(kl+\varphi)}))^2}. \tag{2.38}$$

If $|t(\cdot)|^2$ is a slowly varying function, the rhs reaches its maximum $|t(k)|^2$ in the middle of the band; it is zero at the band edges. However, the transmission can vanish within a band only due to a single-element full reflection. This follows from another upper bound,[11] $|U_n(x)|\leqslant(n+1)$ for $|x|\leqslant 1$, which yields $|t_N|^2\geqslant(1+N^2|S|^2)^{-1}$ or

$$|t_N(k)|^2\geqslant\frac{|t(k)|^2}{1+(N-1)|r(k)|^2}. \tag{2.39}$$

On the other hand, to see the behavior of the reflection and transmission amplitudes in the gaps of the periodic spectrum, we have to estimate the Chebyshev polynomials outside $[-1,1]$. By analytical continuation, the relation (2.37) gives $U_n(x)=\sinh((n+1)\operatorname{arcosh} x)/\sinh(\operatorname{arcosh} x)$, so

$$U_n(x)=\sum_{k=0}^{n}(x+\sqrt{x^2-1})^{n-2k}.$$

Then we have, for instance, the following estimates

$$n+x^n\leqslant U_n(x)\leqslant(n+1)(x+\sqrt{x^2-1})^n. \tag{2.40}$$

The first inequality yields an upper bound,

$$|t_N(k)|^2\leqslant\frac{1}{1+(N-1+(\mathrm{Re}(\overline{\varepsilon}R))^{N-1})^2}. \tag{2.41}$$

It is clear that $|t_N(k)|^2=1$ holds only if the same is true for $|t(k)|^2$; in all the other cases it behaves as $o((\mathrm{Re}(\overline{\varepsilon}R))^{2N-2})$ as $N\to\infty$. On the other hand, $|t_N(k)|^2=0$ holds only if a single scatterer has a full reflection at this energy, otherwise the second inequality of (2.40) together with $|\mathrm{Re}(\overline{\varepsilon}R)|\leqslant|t(k)|^{-1}$ and the unitarity relation gives

$$|t_N(k)|^2\geqslant\frac{|t(k)|^{2N}}{|t(k)|^{2N}+N^2|r(k)|^2(1+|r(k)|)^{2N-2}}. \tag{2.42}$$

III. SERIAL GRAPHS

As we have said we want now to illustrate the above results on several examples which go beyond the usual one-dimensional potential scattering. In this section we shall discuss the situation where the serial structure is a graph.

Although nonrelativistic quantum mechanics for quantum particles confined to a graph has been considered already several decades ago in connection with the free-electron models of hydrocarbons.[12] it became a subject of intense interest only recently as a tool to describe systems of quantum wires—see Refs. 13–29 and references therein. There are also other systems for which graph description could prove to be useful, such as objects composed of carbon nanotubes.[30,31]

Graph systems are attractive because they are often explicitly solvable; on the mathematical level they represent systems of ordinary differential equations in contrast to partial differential equations with nontrivial boundary conditions needed to describe quantum wire systems in higher dimensions. At the same time, the simplified description may still preserve basic features of the real system. Of course, replacing a branched waveguide system by its skeleton graph is a nontrivial approximation, but we shall avoid discussing this point here; some comments can be found in Refs. 19 and 32 and references given there.

A. Loop arrays

In our first example an individual scatterer is a planar loop $\mathcal{L}$ with a pair of external leads placed into a homogeneous magnetic field cf. Fig. 1.

We suppose that the field is perpendicular to the graph plane. The corresponding vector potential in the circular gauge is $\vec{A}(\vec{x})=(-\frac{1}{2}By,\frac{1}{2}Bx,0)$ and

$$\int_{\mathcal{L}}\vec{A}(\vec{x})\,d\vec{x}=\frac{BS}{L_1+L_2}=\frac{\Phi}{L_1+L_2},$$

where S is the loop area, L_j are the lengths of its two branches, and Φ is the corresponding magnetic flux.

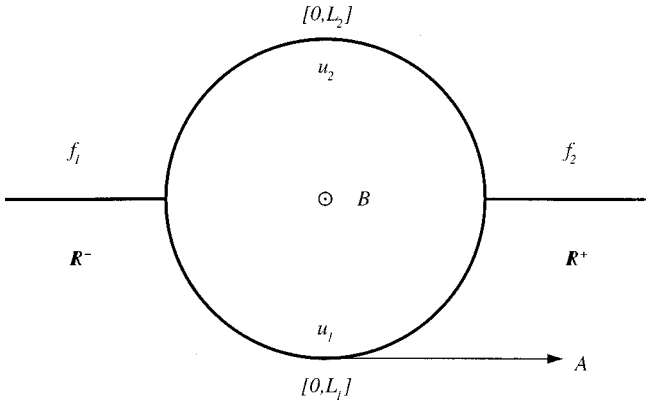

FIG. 1. A loop–graph scatterer in a magnetic field.

Such a scattering system has been considered earlier—see Refs. 33, 17 and 27 and references therein. The Hilbert space for the graph of Fig. 1 is the orthogonal sum of four L^2 spaces referring to the graph links; its elements will be denoted as (f_1,u_1,u_2,f_2) with the coordinates at the loop taken anticlockwise. We suppose that the particle has a unit charge and apart from the magnetic field it moves as free on the graph. There are various ways how to couple the operators $(-i\partial_x - A)^2$ from different graph links in a self-adjoint way.[28,24,29] For the sake of simplicity we restrict ourselves to the usual δ coupling, i.e., we impose the boundary conditions

$$\begin{aligned} f_1(0)=u_1(0)=u_2(L_2), \quad -f_1'(0)+u_1'(0)-u_2'(L_2)=\alpha_1 f_1(0), \\ f_2(0)=u_2(0)=u_1(L_1), \quad f_2'(0)-u_1'(L_1)+u_2'(0)=\alpha_2 f_2(0), \end{aligned} \tag{3.1}$$

where the function and derivative values mean the appropriate one-sided limits. On the other hand, we do not suppose in general that α_1,α_2 and L_1,L_2 are the same.

Substituting into (3.1) the boundary values of the generalized eigenfunctions on the loop, $u_j(x)=A_j e^{-i(A-k)x}+B_j e^{-i(A+k)x}$, $j=1,2$, we get a system of six equations. Eliminating from here A_j,B_j we arrive at the relations

$$f_2(0)=\frac{1}{2kD}((i\alpha_1 B+2kC)f_1(0)+iBf_1'(0))$$

$$f_2'(0)=\frac{1}{2kD}((i\alpha_1\alpha_2 B+2(\alpha_1+\alpha_2)kC-4ik^2E_-E_+)f_1(0)+(2kC+i\alpha_2 B)f_1'(0)),$$

determining the transfer matrix, where

$$B=(\varepsilon_{1+}-\varepsilon_{1-})(\varepsilon_{2-}-\varepsilon_{2+})=4e^{-i\Phi}\sin kL_1\sin kL_2,$$

$$C=-\varepsilon_{1-}\varepsilon_{2-}+\varepsilon_{1+}\varepsilon_{2+}=2ie^{-i\Phi}\sin k(L_1+L_2),$$

$$D=\varepsilon_{2+}-\varepsilon_{2-}+\varepsilon_{2+}\varepsilon_{2-}(\varepsilon_{1+}-\varepsilon_{1-}),$$

$$E_\pm=1-\varepsilon_{1\pm}\varepsilon_{2\pm}=2i\,e^{-i\Phi/2}e^{\pm ik(L_1+L_2)/2}\sin\left(\frac{\pm k(L_1+L_2)-\Phi}{2}\right),$$

$$\varepsilon_{j\pm}=e^{i(-A\pm k)L_j},\quad j=1,2.$$

The reflection and transmission amplitudes are given by

$$r(k)=\frac{-i\alpha_1\alpha_2 B+k((\alpha_2-\alpha_1)B-2(\alpha_1+\alpha_2)C)+ik^2(4E_-E_+-B)}{i\alpha_1\alpha_2 B+k(\alpha_2+\alpha_1)(2C+B)-ik^2(4E_-E_++B+4C)},$$
$$t(k)=\frac{4ik^2De^{-2i\Phi}}{i\alpha_1\alpha_2 B+k(\alpha_2+\alpha_1)(2C+B)-ik^2(4E_-E_++B+4C)}, \tag{3.2}$$

respectively. Since $B,C,E_\pm$ as well as D^2 are 2π-periodic functions of the magnetic flux, the same is valid for the reflection and transmission *probabilities*. Recall that if we put $e=\hbar=c=1$, then 2π is the magnetic flux quantum in these units.

B. Band spectrum of an infinite loop array

We illustrate the relation of transmission probabilities of a finite array of loops and the spectrum of the corresponding infinite system on Fig. 2. As already mentioned $|t_N(k)|^2$ is a 2π-periodic function and, because the condition (2.35) determining the band spectrum of the infinite system can be reformulated as $0<|\mathrm{Re}(\overline{\varepsilon R})|<1$, we show dependence on Φ only in the range $[0,2\pi]$ {$|\mathrm{Re}(\overline{\varepsilon R})|$ is also a 2π-periodic function}. We choose loops with different L_1, L_2 and α_1, α_2. Even for a relatively small number of loops $N=6$ the values of $|t_N(k)|^2$ are clearly nonzero in areas of parameters Φ and k where there are bands of the infinite system and negligible where there are gaps.

C. Comb graphs

Our next example concerns the case of a comb-shaped graph, i.e., a line with a finite number N of identical appendices attached to it at equally spaced points. Such systems have been discussed recently[34] following earlier studies of a single-stub waveguide.[35–38]

Comparing to the previous work and the preceding example, we shall discuss comb-shaped graphs in a more thorough way. First of all, instead of the δ-coupling used above (or the Griffith's boundary conditions in the terminology of Ref. 34) we allow for the most general self-adjoint way in which the stubs can be attached to continuous wavefunctions on the line. This amounts to imposing at the junctions the boundary conditions adopted from an earlier treatment of the T-shaped graph.[24] Should the Hamiltonian be time-reversal invariant, the junction is then characterized by three real parameters. In this framework we are able to handle imperfect contacts;[20] moreover, it is straightforward to modify the results derived below to graphs with a δ'-coupling which corresponds to the situation where the junction itself represents a complicated geometric scatterer (see Refs. 15 and 19; more about that will be said in the next section). Computing the S-matrix we also assume that the particle is under the influence of a potential on the stubs; this makes it possible to investigate how the band-form zones of high transmission which arise for $N\gg 1$ change when an external field is applied.

The formula derived in the previous section allows us to express the transmission and reflection probabilities. In addition to them, one is able to generalize the result of Ref. 24 to the present situation and to find an explicit Krein-formula expression for the resolvent of the comb-graph Hamiltonian. This allows us to study their resonance structure of the problem which arises from perturbation of the disconnected-stub discrete spectrum embedded into the continuum of the line motion. The mentioned expression yields an equation from which the resolvent singularities on the second sheet can be found.

After this introduction, let us describe the model. For a greater generality we suppose first that the appendices are not necessarily identical. The graph Γ_N will therefore consist of a line with a finite sequence $\{(s-1)\mathrm{l}\}_{s=1}^N$ of points at which appendices of finite lengths L_s are attached (see Fig. 3).

The state Hilbert space of the problem is then $\mathcal{H}\equiv L^2(\Gamma_N):=L^2(\mathbb{R})\oplus(\oplus_{s=1}^N L^2(0,L_s))$; we shall write its elements as columns

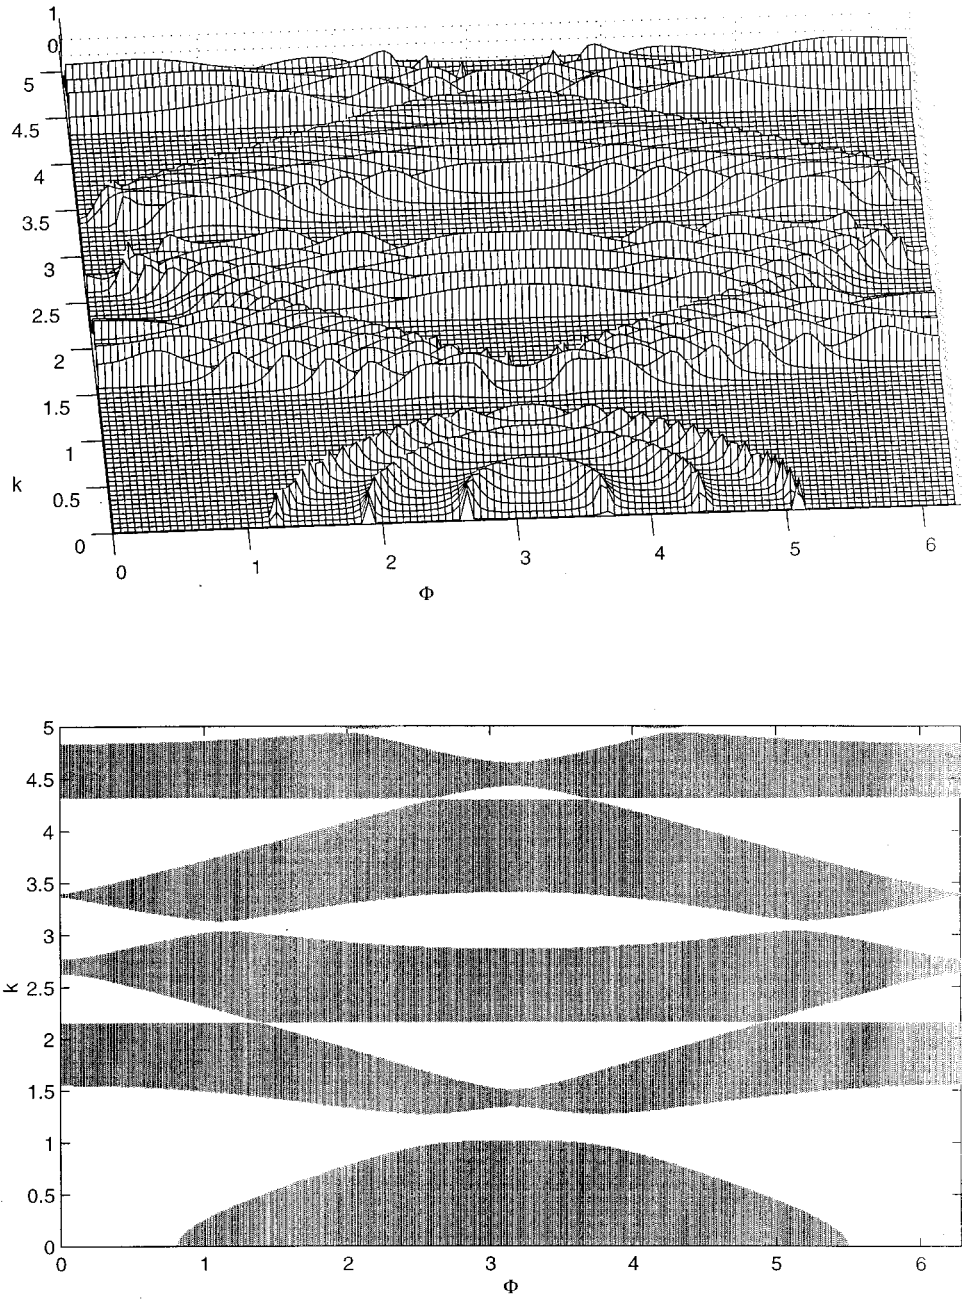

FIG. 2. The relation of transmission probabilities of a finite array of loops ($N=6$) and the spectrum of the corresponding infinite system, $L_1=0.5$, $L_2=1.5$, $l=\sqrt{2}$, $\alpha_1=-1$, and $\alpha_2=-2$. The upper figure shows $|t(k,\Phi)|^2$ (varying from 0 to 1), while the lower one show the band spectrum of the infinite periodic system.

$$\psi=\begin{pmatrix} f \\ u_1 \\ \vdots \\ u_N \end{pmatrix}.$$

We suppose that the motion at the backbone line is free while the particle is exposed to potentials V_s on the "teeth;" hence the Hamiltonian of a nonrelativistic particle of mass $m=\frac{1}{2}$ living on Γ_N acts as

FIG. 3. A comb-shaped graph.

$$(H\psi)_1(x) := -f''(x), \quad (H\psi)_{s+1}(x) := (-u_s'' + V_s u_s)(x), \quad s = 1, \ldots, N, \tag{3.3}$$

out of the junctions. To make it a self-adjoint operator one has to choose again properly the boundary conditions which couple the wavefunctions at the branching points of the graph in such a way that the probability current conservation at the vertices is conserved. As we have said, we shall require continuity of the line component f of ψ at the junctions; to keep a manageable number of parameters we assume the Dirichlet conditions at the end of the stubs. Consequently, the domain of the Hamiltonian consists of all $\psi \in \mathcal{H}$ with $f \in AC^2(\mathbb{R})$ and $u_s \in AC^2(0, L_s)$ satisfying the conditions[24]

$$\begin{gathered} f((s-1)\mathrm{l}+) = f((s-1)\mathrm{l}-) =: f((s-1)\mathrm{l}), \\ u_s(0) = b_s f((s-1)\mathrm{l}) + c_s u_s'(0), \\ f'((s-1)\mathrm{l}+) - f'((s-1)\mathrm{l}-) = d_s f((s-1)\mathrm{l}) - b_s u_s'(0), \\ u_s(L_s) = 0 \end{gathered} \tag{3.4}$$

for $s = 1, \ldots, N$. In general, b_s may be complex, however, we restrict from the start to Hamiltonians which are time-reversal invariant and suppose that the coefficient matrices $\mathbb{K}_s = \left(\begin{smallmatrix} b_s & c_s \\ d_s & -b_s \end{smallmatrix}\right)$ are real. The sth appendix is decoupled from the line by putting $b_s = 0$; it is then described by the operator $h_{c_s} := -d^2/dx^2 + V_s$ specified by the decoupled condition

$$u_s(0) - c_s u_s'(0) = 0 \tag{3.5}$$

at the junction.

In what follows we concentrate on the finite periodic case where $L_s = L$, $V_s = V$, and $\mathbb{K}_s = \mathbb{K}$; the operator specified by the boundary conditions (3.4) will be denoted as $H_N \equiv H_N(\mathbb{K}, V)$. The potential V is supposed to belong to $L^1(0, L)$.

D. Scattering on a comb graph

To write the scattering matrix we need some notation. Let u_L be the unique solution to the appendix Schrödinger equation,

$$-u_L'' + V u_L = k^2 u_L \tag{3.6}$$

with the energy k^2 and the normalized Dirichlet condition at the outer endpoint, $u_L(L) = 1$ $-u_L'(L) = 0$. If all the junctions are described by the parameters b, c, d in (3.4), we put

$$\beta := \frac{d}{2k} + \frac{b^2}{2k}\left(\frac{u_L'}{c u_L' - u_L}\right)(0), \quad \zeta := \cos k\mathrm{l} + \beta \sin k\mathrm{l}, \tag{3.7}$$

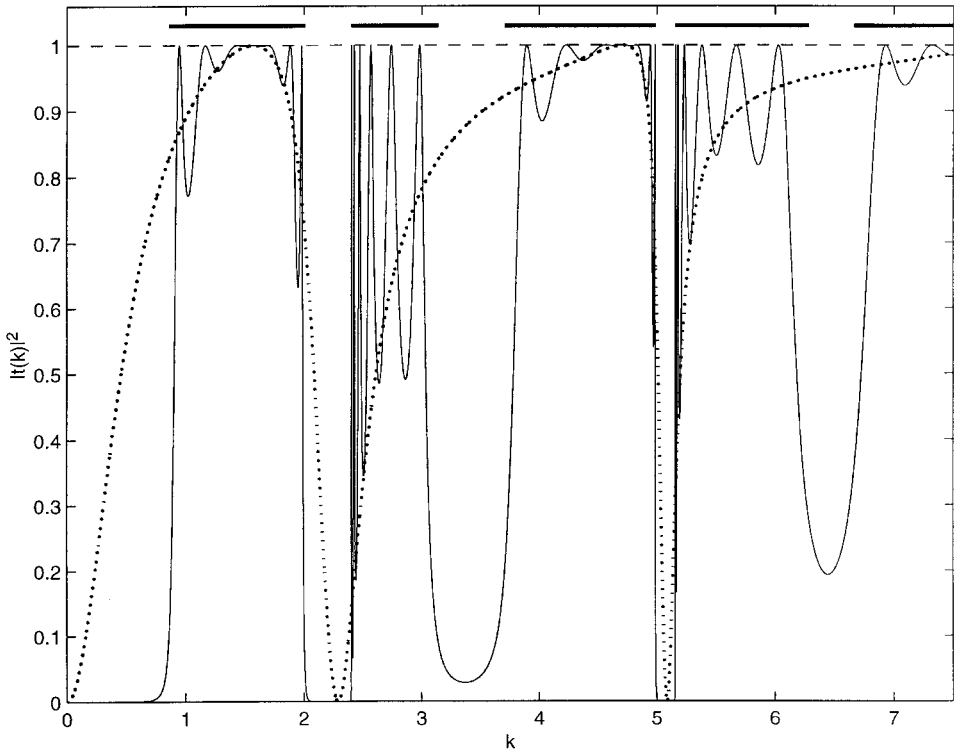

FIG. 4. The relation of transmission probabilities of a single appendix (dotted line), a finite array of appendices ($N=7$) (full line), and the spectrum of the corresponding infinite system (thick lines above). The parameters are $b=1.2$, $c=0.5$, $d=0$, $L=1$, and $\mathrm{l}=1$.

and denote again $\varepsilon := e^{ik\mathrm{l}}$. For a single stub, $s=N=1$, we insert a generalized eigenvector of the form $\binom{f}{\alpha u_1}$ into the boundary conditions (3.4) and express $f(0+), f'(0+)$ by means of the left-sided limits; this yields the single-element transfer matrix which can be written with the help of (3.7) as

$$L_\beta = \begin{pmatrix} 1 & 0 \\ 2k\beta & 1 \end{pmatrix},$$

so $R=1+i\beta$ and $S=i\beta$. Furthermore, $\mathrm{Re}(\overline{\varepsilon}\overline{R})=\zeta$. Using then the explicit expression (2.30) of the phase factor together with (2.31) and (2.32), we may write the left-to-right scattering amplitudes as

$$r_N = \frac{i\beta U_{N-1}(\zeta)}{\varepsilon U_{N-2}(\zeta) - (1+i\beta)U_{N-1}(\zeta)}, \quad t_N = -\frac{\varepsilon^{1-N}}{\varepsilon U_{N-2}(\zeta) - (1+i\beta)U_{N-1}(\zeta)}. \tag{3.8}$$

In particular, the reflection and transmission probabilities are

$$|t_N(k)|^2 = 1 - |r_N(k)|^2 = \frac{1}{1+\beta^2 U_{N-1}(\zeta)^2}. \tag{3.9}$$

Let us now illustrate how the the transmission probability depends on the number of the teeth and the parameters of the junctions. Figure 4 shows a typical example of the situation. For a certain set of parameters b, c, and d we compare $|t(k)|^2$ for one and seven appendices with an infinite array of them. The band spectrum is marked by thick lines above. The suppression of the

transmission coefficient at those values of k where the infinite system shows gaps is evident even for a relatively small number of elementary scatterers, $N=7$. In each band we distinguish $N-1$, i.e., six values of k_i when $|t(k_i)|^2=1$ as it should be—cf.(2.37). In addition the first and third band contain an additional value of k_a for which $|t(k_a)|^2=1$ and these values coincide with the values of k for which a single appendix allows a perfect transmission. The values of k for which the reflection is total fall into gaps of the infinite system as it should be (cf. the end of Sec. II D).

In addition to the S-matrix one can ask about scattering resonances for the comb graphs. The particular character of the coupling (3.4) makes it possible to find the resonance condition as a direct generalization of the argument given in Ref. 24. It turns out that the corresponding poles of the analytically continued resolvent appear at the points where the denominators in (3.8) vanish.

E. Band spectrum of an infinite comb and resonances

We discuss only the case of free appendices here, i.e., $V_s=0$. Investigation of nonzero potentials represents no complication in general conception. Typical spectra of an infinite comb are presented on Fig. 5. The parameters of such a structure could be divided into two groups, viz. l,L and b,c,d. The dependence on l is rather simple; a change of l results in scaling of spectrum in k. This is the consequence of the fact that the transfer matrix T depends only on the product $k\mathrm{l}$. This is the reason why we show all the spectra for $\mathrm{l}=1$ only. The dependence on L is more complicated as can be inferred from Fig. 5.

A striking feature of such a spectrum are sudden transitions of bands to gaps or vice versa at $k\mathrm{l}=n\pi$, $n\in\mathbb{Z}$ for almost all L. This can be understood, if we write down the Bloch condition explicitly as

$$\beta(k)\sin(k\mathrm{l})+\cos(k\mathrm{l})=\cos(\theta).$$

Clearly, this is always fulfilled for $k\mathrm{l}=n\pi$, unless β has a singularity at $n\pi/\mathrm{l}$. Therefore $k=n\pi/\mathrm{l}$ belongs always to the band in this case. The situations when $\beta(n\pi/\mathrm{l})$ is infinite requires a further analysis. An effect of a small change ϵ in k can be estimated from $\beta(k+\epsilon)\epsilon\mathrm{l}+1=(-1)^n\cos(\theta)$. With the exception of points where $\beta(n\pi/\mathrm{l})=0$, small change of ϵ does not change the sign of β, while the change of sign of ϵ leads to the change of sign of $\beta(k+\epsilon)\epsilon\mathrm{l}$. Only in the vicinity of points where $\beta(n\pi/\mathrm{l})=0$ can the sign of $\beta(k+\epsilon)\epsilon\mathrm{l}$ rest unchanged, cf. Fig 5.

Of the three parameters determining the coupling of an appendix to the backbone line, i.e., b,c,d, we find b as the most suitable to begin with. Putting $b=0$ effectively switches off the appendices as already mentioned in Sec. III B. This implies that we have eigenvalues k_n^2 embedded in the continuum, where k_n are solutions of (3.5). These values of momentum play an important role from three points of view. First, k_n's are the values for which $u_L(0)=0$ and the number of zeros of u increases by one when k passes to higher values; this means that the whole $\mathbb{R}^+$ is divided into disjoint intervals by these values (for a given L). On the other hand, a band can belong to two intervals (although this happens only for some L) and states of the same band can be described by wave functions with different numbers of zeros of u's. Also, and this situation is far more frequent, one interval can contain two or more bands, so that the number of zeros of u is not directly related to the ordinal number of a band.

In order to reveal the second role of these values of k_n's, we have to a return to finite number of appendices attached to the line. If we begin with one appendix only, direct calculation shows that $t(k_n)=0$ and $r(k_n)=-1$. Therefore, regardless of the number of appendices N, the full reflection takes place, i.e., $t_N=0, r_N=-1$.

We close this section with discussion of scattering resonances of our system. Recently, it was shown[3] that there is a certain "band" structure in the spectrum of resonances and that this spectrum converges to the energy band spectrum of the infinite periodic system in the limit of an infinite number of scatterers. The authors also show that one should expect $N-1$ resonances in each band if the system consists of N identical cells. These conclusions are in accordance with our results but for one difference—the number of resonances in a band is $2N-1$. It is a consequence of the fact that the origin of resonances is twofold here. $N-1$ resonances comes from the spacial

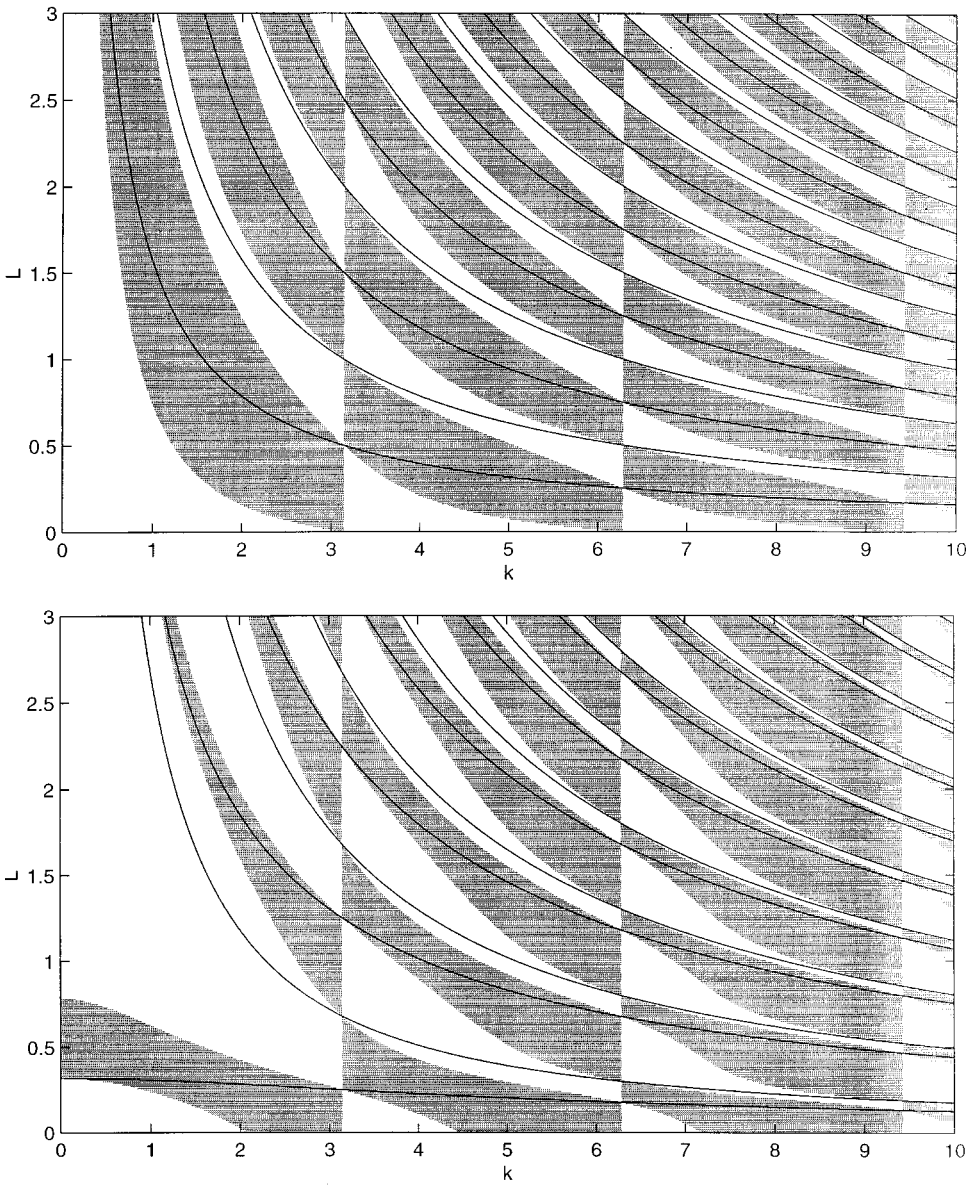

FIG. 5. The band spectra of infinite arrays of appendices. The upper figure is for $b=1$, $c=d=0$, and the lower one for $b=3$, $c=0.5$, and $d=-11$. The spacing is chosen $l=1$ in both cases. The full lines show the role of perfect transmission (the lines in the bands) and total reflection (the lines in the gaps) for a single appendix.

order of our periodical structure as in Ref. 3 and the remaining N ones have their origin in k_n^2, which is an N-fold eigenvalue for the case of $b=0$. As $|b|$ grows this degenercy is lifted and we find N resonances in the vicinity of k_n^2. This is the third role of k_n. The $N-1$ resonances related to the spatial setting travel from $-\infty$, and for small b these two sets are well separated as is shown on Fig. 6.

There are situations when a resonance or a bound state appears at $k=0$. The manifestation of this instance is that $|t(0)|^2=1$. This can take place even in the case of one appendix. The expression (5) of Ref. 24 with explicit form of $u_L(0)$ shows that this can happen as soon as the condition

$$d(c+L)+b^2=0$$

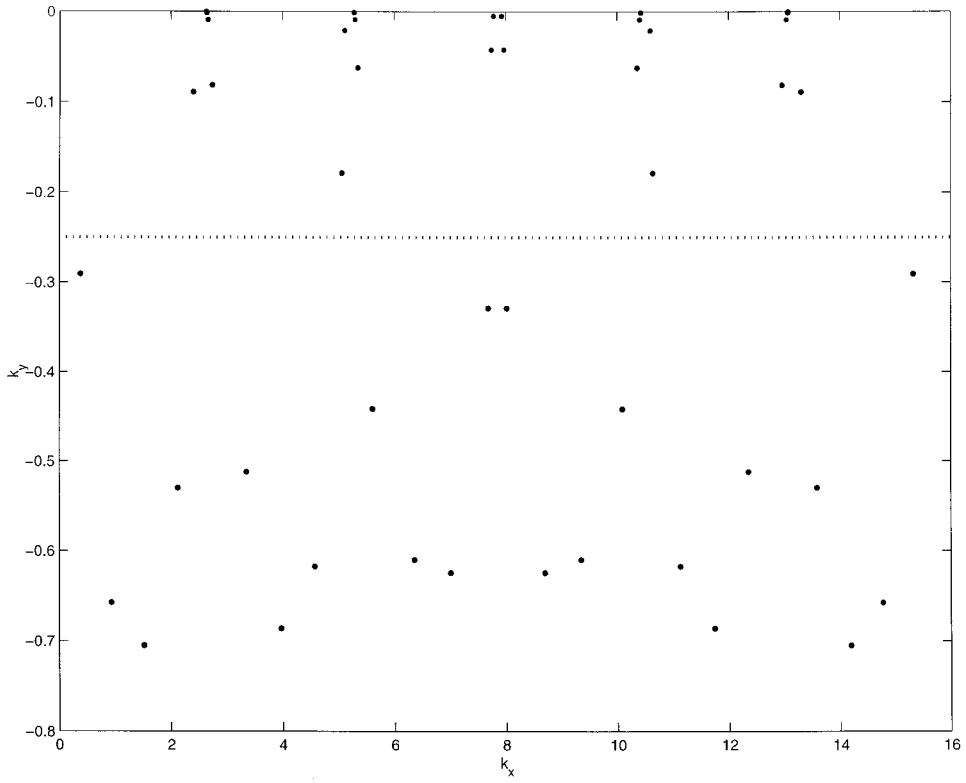

FIG. 6. This figure shows positions of resonances for $N=5$ appendices and $b=0.4$, $c=d=0$, and $L=1.2$. The dotted line separates the two sets of resonances. The resonances closer to the real axis have their origin in N-fold eigenvalues for $b=0$; increasing $|b|$ lifts the degeneracy and pushes the resonances from the real line. The rest of the resonances (below the dotted line) has the origin in the serial arrangement of individual scatterers.

is fulfilled. Provided that this condition holds, there is perfect transmission at $k=0$ for any number of appendices, i.e., $t_N(0)=1$. Besides this there could be other situations when $t_N(0)=1$ for $N>1$. If there exists such an $n=1,\ldots,N-1$ that

$$\cos\left(\frac{n\pi}{N}\right)=1+\frac{(dc+dL+b^2)\mathrm{l}}{2(c+L)},$$

we have again $t_N(0)=1$. This corresponds to $U_{N-1}(\zeta(0))=0$ in (3.9). Direct inspection confirms that the wavefunction does not belong to $L^2(\Gamma_N)$ and that these states are resonances (and not bound states).

IV. SERIAL STRUCTURES OF MIXED DIMENSIONALITY

In this section we want to treat the situation when the scatterers connected by single-mode leads have a higher dimension. For the sake of simplicity, we shall consider only the simplest possibility when the dimension is two, i.e., the scatterer is a surface. Such systems can be realized in both the solid state (recall, e.g., the ''bamboo defects'' in nanotubes[39]) and electromagnetism (for flat resonators), but we avoid discussing examples and the conditions under which these models are realistic. We suppose that the surface is smooth, bounded, and connected, with or without the boundary. Although it makes no difficulty to let the particle on the surface interact with an external potential field, we will regard it as free, i.e., its Hamiltonian will be (in appropriate units) just the corresponding Laplace-Beltrami operator.

A. Coupling of leads to a surface

The basic question for the described serial structures is the way in which the leads are coupled to the scatterers. The physical condition is again a conservation of the probability current, which translates into the self-adjointness requirement of the corresponding Hamiltonian. Since the coupling is local, we may disregard geometrical peculiarities of the lead and the surface and consider the setting when a halfline is attached to a plane. The state Hilbert space is then $L^2(\mathbb{R}^-) \oplus L^2(\mathbb{R}^2)$ and the Hamiltonian acts on its elements $\binom{\phi_1}{\phi_2}$ as $\binom{-\phi_1''}{-\Delta\phi_2}$. To make it self-adjoint one has to impose suitable boundary conditions which couple the wavefunctions at the junction. A general solution to this problem is given in Ref. 23. The conditions are of the form

$$\phi_1'(0-) = A\phi_1(0-) + BL_0(\phi_2), \quad L_1(\phi_2) = C\phi_2(0-) + DL_0(\phi_2), \tag{4.1}$$

together with several ''exceptional'' classes, where

$$L_0(\phi_2) = \lim_{r\to 0+} \frac{\phi_2(\vec{x})}{\ln r},$$

$$L_1(\phi_2) = \lim_{r\to 0+} (\phi_2(\vec{x}) - L_0(\phi_2)\ln r)$$

with $r := |\vec{x}|$ are the generalized boundary values in the plane, and the coefficients A, B, C, D depend on four real parameters; evaluating the boundary form, it is straightforward to see that they satisfy restrictions

$$A, D \in \mathbb{R}, \quad B = 2\pi\overline{C}. \tag{4.2}$$

A disadvantage of this result is that it tells us nothing about physical relevance of the coefficients values in the boundary conditions (4.1). The choice of the coupling depends on particular properties of the junction it models, of course, but one would like to select a subclass representing a ''natural'' coupling. One way to achieve this goal was suggested in Ref. 40: comparing the scattering matrix of the junction given by (4.1) with the low-energy behavior of scattering in the system of a plane to which a cylindrical ''tube'' is attached, and taking into account the condition (4.2), we arrive at the identification

$$A = \frac{1}{2\rho}, \quad B = \sqrt{\frac{2\pi}{\rho}}, \quad C = \frac{1}{\sqrt{2\pi\rho}}, \quad D = -\ln\rho, \tag{4.3}$$

where ρ is the contact radius. Physical relevance of these conditions was illustrated in Ref. 40 by explaining the experimentally observed distribution of resonances in a microwave resonator with a thin antenna. Motivated by this, we will use in the following (4.1) and (4.3) to describe the coupling between the leads and the scatterers.

B. The single-element S-matrix

Using the local character of the boundary conditions derived above we apply them to coupling of a pair of halfline leads to an arbitrary surface G. The only restriction is that that the junction may not belong to the boundary of G if it has any. We shall compute the transfer and scattering matrices for such a system.

As we have said, the Hamiltonian is a Laplace-Beltrami operator on the state Hilbert space $L^2(G)$ of the scatterer. We shall characterize it by its Green's function $G(.,.;k)$, i.e., the integral kernel of its resolvent which exists whenever k^2 does not belong to the spectrum. Its actual form

depends on the geometry of G but we shall not need it. What is important is the character of its singularity. As a smooth manifold, G admits in the vicinity of any point a local Cartesian chart and the Green's function behaves as that of Laplacian in the plane,

$$G(x,y;k)=-\frac{1}{2\pi}\ln|x-y|+\mathcal{O}(1), \quad |x-y|\to 0. \tag{4.4}$$

Looking for scattering solutions to the Schrödinger equation, we need a general solution to the Laplace-Beltrami equation on G for the energy k^2. Without loss of generality, we may write it as

$$u(x)=a_1G(x,x_1;k)+a_2G(x,x_2;k), \tag{4.5}$$

where x_1,x_2 are two different points of G at which the leads are attached. The generalized boundary values (labeled by the point at which they are taken) of this solution are then

$$L_0[x_j]=-\frac{a_j}{2\pi}, \quad L_1[x_j]=a_j\xi(x_j,k)+a_{3-j}G(x_1,x_2;k) \tag{4.6}$$

for $j=1,2,$ where

$$\xi(x_j;k)=\lim_{x\to x_j}\left[G(x,x_j;k)+\frac{\ln|x-x_j|}{2\pi}\right]. \tag{4.7}$$

Next we denote the wavefunction on the jth lead as u_j. For simplicity we use the abbreviations u_j,u_j' for its boundary values; then the boundary conditions (4.1) yield

$$u_1'=A_1u_1-\frac{B_1a_1}{2\pi}, \quad a_1\xi_1+a_2g=C_1u_1-\frac{D_1a_1}{2\pi},$$

$$u_2'=-A_2u_2+\frac{B_2a_2}{2\pi}, \quad a_2\xi_2+a_1g=C_2u_2-\frac{D_2a_2}{2\pi},$$

where $g:=G(x_1,x_2;k)$. In the the first equation of the second pair we have changed sign, because the second lead is identified with $\mathbb{R}^+$. It is straightforward to rewrite these equations as a linear system with the unknown u_2,u_2',a_1,a_2 and to solve it; this gives, in particular, the transfer matrix,

$$L=\frac{1}{gC_2}\begin{pmatrix} C_1Z_2+2\pi\dfrac{A_1}{B_1}\Delta & -2\pi\dfrac{\Delta}{B_1} \\ B_2C_2\left(\dfrac{C_1}{2\pi}-Z_1\dfrac{A_1}{B_1}\right)-C_1A_2Z_2-2\pi\dfrac{A_1A_2}{B_1}\Delta & 2\pi\dfrac{A_2}{B_1}\Delta+\dfrac{B_2C_2Z_1}{B_1} \end{pmatrix}, \tag{4.8}$$

where $Z_j:=D_j/2\pi+\xi_j$ and $\Delta:=g^2-Z_1Z_2$. Using (4.2) we find easily

$$\det L=-\frac{B_2C_1}{B_1C_2}=-\frac{\overline{C_2}C_1}{\overline{C_1}C_2}, \tag{4.9}$$

so $\det L=1$ if the junctions are identical or the coefficients C_j are real. The second possibility is if the couplings are invariant with respect to the time reflection, which we shall suppose in the following. In that case the transfer matrix simplifies to the form

$$L=\frac{1}{g}\begin{pmatrix} Z_2+\dfrac{A}{C^2}\Delta & -2\dfrac{\Delta}{C^2} \\ C^2-A(Z_1+Z_2)-\dfrac{A^2}{C^2}\Delta & \dfrac{A}{C^2}\Delta+Z_1 \end{pmatrix}, \tag{4.10}$$

in particular,

$$L=\frac{1}{g}\begin{pmatrix} Z_1+\pi\Delta & -2\pi\rho\Delta \\ \dfrac{1}{2\rho}\left(\dfrac{1}{\pi}-Z_1-Z_2-\pi\Delta\right) & Z_1+\pi\Delta \end{pmatrix} \tag{4.11}$$

for the physically most interesting class of couplings (4.3). The S-matrix of our geometric scatterer is then given by the relations (2.31) and (2.32); in the case (4.11) we have

$$\begin{aligned} r(k)&=-\frac{\pi\Delta+Z_1+Z_2-\pi^{-1}+2ik\rho(Z_2-Z_1)+4\pi k^2\rho^2\Delta}{\pi\Delta+Z_1+Z_2-\pi^{-1}+2ik\rho(Z_1+Z_2+2\pi\Delta)-4\pi k^2\rho^2\Delta}, \\ t(k)&=-\frac{4ik\rho g}{\pi\Delta+Z_1+Z_2-\pi^{-1}+2ik\rho(Z_1+Z_2+2\pi\Delta)-4\pi k^2\rho^2\Delta}. \end{aligned} \tag{4.12}$$

To make use of these formulas, we need to know g,Z_1,Z_2,Δ as functions of the momentum k. By assumption the manifold G is compact, so the spectrum $\{\lambda_n\}_{n=1}^{\infty}$ of the Hamitonian is purely discrete and the corresponding eigenfunctions $\{\phi(x)_n\}_{n=1}^{\infty}$ form an orthonormal basis in $L^2(G)$. The usual Green's function expression then gives

$$g(k)=\sum_{n=1}^{\infty}\frac{\phi_n(x_1)\overline{\phi_n(x_2)}}{\lambda_n-k^2}. \tag{4.13}$$

To express the remaining three values we have to compute the regularized limit (4.7). Expanding the logarithm into the Taylor series, we can rewrite the sublimit expression as

$$G(x_j+\sqrt{\varepsilon}n,x_j;k)+\frac{\ln\sqrt{\varepsilon}}{2\pi}=\sum_{n=1}^{\infty}\left(\frac{\phi_n(x_j+\sqrt{\varepsilon}n)\phi_n(x_j)}{\lambda_n-k^2}-\frac{(1-\varepsilon)^n}{4\pi n}\right),$$

where n is a unit vector in the local chart around the point x_j. Unfortunately, interchanging the limit with the sum is not without risk since the latter does not converge uniformly. To see that the result may indeed depend on the regularization procedure, it is sufficient to replace $\sqrt{\varepsilon}$ by $c\sqrt{\varepsilon}$ on the lhs. To form the idea about this nonuniqueness, let us compute the difference

$$\xi(x_j,k)-\xi(x_j,k')=\lim_{\varepsilon\to 0+}\sum_{n=1}^{\infty}\left(\frac{\phi_n(x_j+\sqrt{\varepsilon n})\overline{\phi_n(x_j)}}{\lambda_n-k^2}-\frac{\phi_n(x_j+\sqrt{\varepsilon n})\overline{\phi_n(x_j)}}{\lambda_n-k'}\right).$$

This sum is already uniformly convergent, because by standard semiclassical estimates (Ref. 41, XIII.16) the sequence $\{\|\phi_n\|_\infty\}_{n=1}^{\infty}$ is bounded with our assumptions and $\lambda_n=4\pi|G|^{-1}n+\mathcal{O}(1)$ as $n\to\infty$, so

$$\frac{1}{\lambda_n-k^2}-\frac{1}{\lambda_n-k'^2}\sim\frac{1}{n^2},$$

and therefore

$$\xi(x_j,k)-\xi(x_j,k')=\sum_{n=1}^{\infty}\left(\frac{|\phi_n(x_j)|^2}{\lambda_n-k^2}-\frac{|\phi_n(x_j)|^2}{\lambda_n-k'^2}\right). \tag{4.14}$$

From the same reason

$$\tilde{\xi}(x_j,k):=\sum_{n=1}^{\infty}\left(\frac{|\phi_n(x_j)|^2}{\lambda_n-k^2}-\frac{1}{4\pi n}\right) \tag{4.15}$$

makes sense and $\xi(x_j,k)-\tilde{\xi}(x_j,k)$ is independent of k. We have therefore

$$\xi(x_j,k)=\sum_{n=1}^{\infty}\left(\frac{|\phi_n(x_j)|^2}{\lambda_n-k^2}-\frac{1}{4\pi n}\right)+c(G). \tag{4.16}$$

The constant depends only on the manifold G. We will neglect it in the following, because its nonzero value means just a coupling constant renormalization: D_j has to be changed to $D_j+2\pi c(G)$. For a flat rectangular G, we found in Ref. 40 an agreement with the experiment using $c(G)=0$.

C. A "bubble" on the line

To make the above consideration more concrete, we shall concentrate in the rest of this section on a single example. We are going to consider the case when G is a sphere of radius R with the leads attached at the poles, which is the system proposed by Kiselev.[10] The most important result of this paper was that apart from the resonances coming from the bound states on the sphere, such a scatterer has the high-energy behavior similar to that of the so-called δ' interaction,[42,15,43] i.e., the transmission probability *decays* as E^{-1} for $E\to\infty$. This was established in Ref. 10 up to a logarithmic correction. The difference here is that we shall use the physically interesting coupling (4.3), while Ref. 10 employed a two-dimensional subset of the conditions (4.1) disjoint with the above one. This leads to a different S-matrix, and while the indicated high-energy behavior remains preserved, the argument used in Ref. 10 to demonstrate it has to be changed in numerous places; this is why we present its modified version here.

The sphere Hamiltonian is chosen in the standard way. Using the spherical coordinates, we write it as

$$H_G=\frac{1}{R^2}\frac{\partial^2}{\partial\theta^2}+\frac{\cot\theta}{R^2}\frac{\partial}{\partial\theta}+\frac{1}{R^2\sin^2\theta}\frac{\partial^2}{\partial\varphi^2} \tag{4.17}$$

with the usual domain. For the sake of simplicity we put $R=1$ in the following; the results for a general R can be obtained by a scaling transformation. The spectrum of H_G then consists of the eigenvalues $\lambda_{l,m}=l(l+1)$, $l=0,1,\ldots$, $m=-l,-l+1,\ldots,l$ of multiplicity $2l+1$ to which the eigenfunctions

$$\phi_l^m(\theta,\psi)=\sqrt{\frac{(2l+1)(l-|m|)!}{4\pi(l+|m|)!}}P_l^{|m|}(\cos\theta)e^{im\varphi}$$

correspond. The junctions x_1,x_2 we place at the points $\theta=0$ and $\theta=\pi$, respectively, where

$$P_l^{|m|}(\pm1)=(-1)^l\delta_{0,|m|},$$

so only states with $m=0$ can be coupled to the leads. To express the S-matrix, we need the quantities

$$g(k)=\frac{1}{4\pi}\sum_{l=1}^{\infty}\frac{2l+1}{l(l+1)-k^2}(-1)^l, \tag{4.18}$$

$$Z_j(k)=Z(k):=\frac{1}{4\pi}\sum_{l=1}^{\infty}\left(\frac{2l+1}{l(l+1)-k^2}-\sum_{j=0}^{2l}\frac{1}{l^2+j+1}\right)-\frac{\ln\rho}{2\pi}+c(G), \tag{4.19}$$

where ρ is the junction diameter which is supposed to be the same for $j=1,2$. The relations (4.12) yield, in particular, the transmission probability in the form

$$t(k)=\frac{4\pi ik\rho g(k)}{1-2\pi Z(k)(1+2ik\rho)-\pi^2\Delta(k)(1+2ik\rho)^2}, \tag{4.20}$$

where $\Delta(k)=(g(k)-Z(k))(g(k)+Z(k))$.

To prove that (4.20) behaves as indicated above at large values of $E=k^2$, we need several auxiliary results.

Lemma IV.1: The function $Z(\cdot)+(-1)^l g(\cdot)$ is strictly increasing on the intervals $(l(l-1),l(l+1))$.

Proof: We have

$$Z'(k)+(-1)^l g'(k)=2k\sum_{j=0}^{\infty}\frac{2j+1}{(j(j+1)-E)^2}(1+(-1)^{j+l})>0.$$

■

Lemma IV.2: We have

$$g(k)=\frac{(-1)^l}{4\pi}\left(-\frac{2l-1}{l(l-1)-E}+\frac{2l+1}{l(l+1)-E}\right)+\mathcal{O}(1)$$

for $E\in(l(l-1),l(l+1))$ and any positive integer l with the error term independent of l. Moreover, there is a $K>0$ such that $g(k)\geqslant K$ holds for all k large enough.

Proof: The error can be estimated explicitly; we shall show that

$$\left|g(k)-\frac{(-1)^l}{4\pi}\left(-\frac{2l-1}{l(l-1)-E}+\frac{2l+1}{l(l+1)-E}\right)\right|<\frac{1}{2\pi}. \tag{4.21}$$

To this end we have to find a bound to (4.18) on the interval $(l(l-1),l(l+1))$ with the two singular terms removed. The terms to the left and to the right of this pair form alternative sequences with the decreasing modulus, and as such each of them may be estimated by the (modulus of) the first term of such a sequence, i.e., by

$$\frac{1}{4\pi}\left|\frac{2l-3}{(l-1)(l-2)-E}\right| \quad \text{and} \quad \frac{1}{4\pi}\left|\frac{2l+3}{(l+1)(l+2)-E}\right|,$$

respectively. Taking the maxima of these expressions and summing them we arrive at (4.21). To get the second claim, we have have to compare this result with a lower bound to the modulus of the sum of the two singular terms. The minimum $\pi^{-1}+\mathcal{O}(l^{-1})$ of the latter is reached at $E=l^2-\frac{1}{4}+\mathcal{O}(l^{-2})$, so this part wins over the other one once the error terms become small enough. ■

Lemma IV.3: For a positive integer l and $E\in(l(l-1),l(l+1))$ we have

$$Z(k)=\frac{1}{4\pi}\left(\frac{2l-1}{l(l-1)-E}+\frac{2l+1}{l(l+1)-E}\right)-\frac{\ln l}{2\pi}+\mathcal{O}(1), \tag{4.22}$$

where the error term is independent of l.

Proof: We again split the two singular terms in (4.22) and write the rest as $Z_-(k,l)+Z_+(k,l)-(\ln\rho)2\pi+c(G)$, where

$$Z_-(k,l):=\frac{1}{4\pi}\sum_{j=1}^{l-2}\left(\frac{2j+1}{j(j+1)-E}-\sum_{n=0}^{2j}\frac{1}{j^2+n+1}\right),$$

$$Z_+(k,l):=\frac{1}{4\pi}\sum_{j=l+1}^{\infty}\left(\frac{2j+1}{j(j+1)-E}-\sum_{n=0}^{2j}\frac{1}{j^2+n+1}\right).$$

It is easy to see that

$$\sum_{n=0}^{2j}\frac{1}{j^2+n+1}=\frac{2}{j}+\mathcal{O}(j^{-2})$$

as $j\to\infty$, so the jth term in $Z_\pm(k,l)$ can be estimated from above by

$$\frac{1}{4\pi}\left(\frac{2j+1}{j(j+1)-l(l+1)}-\frac{2}{j}+\mathcal{O}(j^{-2})\right)$$

and from below by the same expression with $l(l+1)$ replaced by $l(l-1)$. Using the identity

$$\frac{2j+1}{j(j+1)-l(l+1)}=\frac{1}{j+l+1}-\frac{1}{l-j}$$

we find

$$4\pi Z_-(k,l)=\left(-\sum_{m=2}^{l-1}+\sum_{m=l+2}^{2l-1}-2\sum_{m=1}^{l-2}\right)\frac{1}{m}+\sum_{m=1}^{l-2}\mathcal{O}(m^{-2})=-3\ln l+\mathcal{O}(1),$$

$$\begin{aligned}4\pi Z_+(k,l)&=\lim_{n\to\infty}\left[\left(\sum_{m=1}^{n-l}+\sum_{m=2l+2}^{n+l+1}-2\sum_{m=l+1}^{n}\right)\frac{1}{m}+\sum_{m=l+1}^{n}\mathcal{O}(m^{-2})\right]\\&=\lim_{n\to\infty}\ln\frac{(n-l)((n+l+1)}{n^2}+\ln(l+1)+\mathcal{O}(1)=\ln l+\mathcal{O}(1).\end{aligned}$$

Summing the expressions we get the upper bound in (4.22); the lower one is obtained in the same way. ■

Lemma IV.4: For any l large enough the interval $(l(l-1),l(l+1))$ contains a point μ_l such that $\Delta(\sqrt{\mu_l})=0$. The number μ_l has the following properties:

(i) $l(l+1)-\mu_l=2l(\ln l)^{-1}(1+\mathcal{O}(1))$,

(ii) $\dfrac{2l+1}{l(l+1)-E}\leqslant\ln l+\mathcal{O}(1)$ *for* $E\leqslant\mu_l$,

(iii) $\dfrac{2l-1}{l(l-1)-E}=\mathcal{O}(1)$ *for* $E>\mu_l$, *and*

(iv) finally, $\dfrac{Z(\sqrt{\mu_l})}{|g(\sqrt{\mu_l})|}=-1+\mathcal{O}((\ln l)^{-1})$.

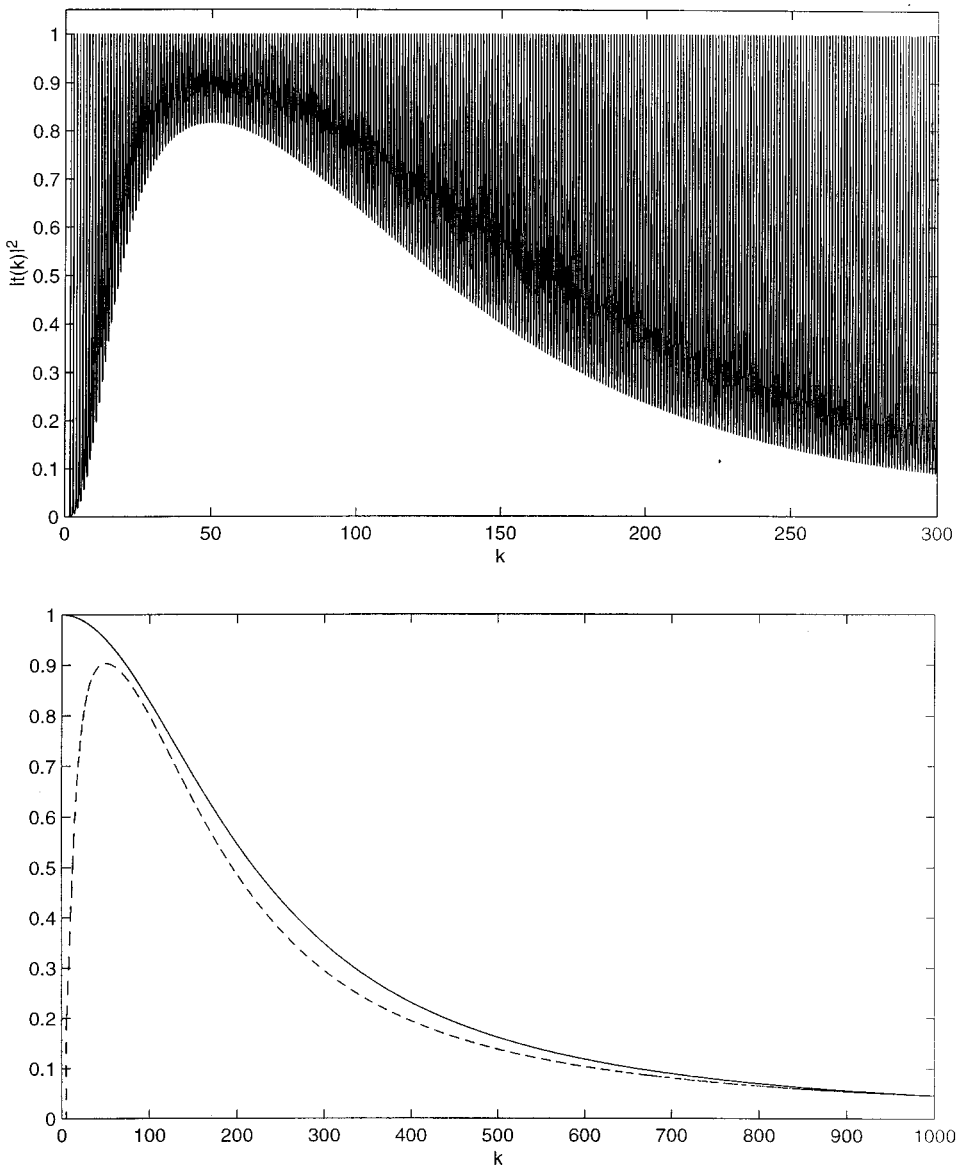

FIG. 7. The transition probability of a sphere of unit radius on a line ($\rho=0.01$). The lower graph compares the asymptotic behavior of $|t(k)|^2$ for δ'-interaction with suitably chosen strength and that of averaged transmission probability plotted in the upper graph. The averaging is done over ten neighboring peaks of each point.

Proof: Fix l. We have $Z(k)^2-g(k)^2=(Z(k)+(-1)^l g(k))(Z(k)-(-1)^l g(k))$, and by the preceding lemmas these expressions equal

$$\frac{1}{2\pi}\frac{2l\pm 1}{l(l\pm 1)-E}-\frac{1}{2\pi}\ln\rho+\mathcal{O}(1).$$

The term with the minus sign is negative in $(l(l-1),l(l+1))$ provided l is large enough. The other term is sign changing for large l so it has has a root. In view of Lemma 4.1 there is just one μ_l such that

$$\frac{2l+1}{l(l+1)-\mu_l}-\ln l+\mathcal{O}(1)=0\,; \tag{4.23}$$

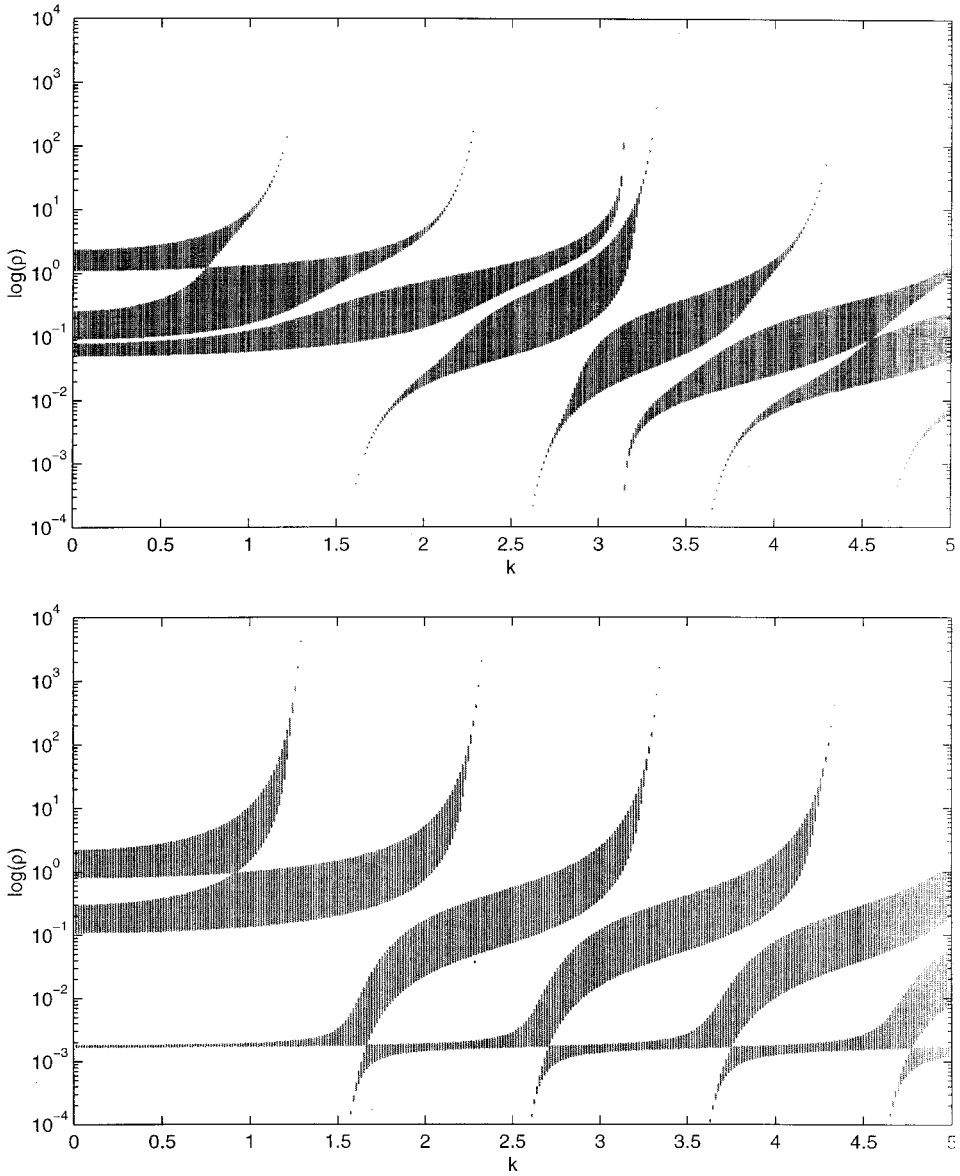

FIG. 8. Band spectrum of an infinite ''bubble'' array. The spheres are of unit radius, the spacing is $l=1$ (upper figure) and $l=0.01$ (lower figure), ρ is the contact radius.

this proves *(i)*. The relation (4.23) yields also the next two claims:

$$\frac{2l+1}{l(l+1)-E} \leqslant \frac{2l+1}{l(l+1)-\mu_l} = \ln l + \mathcal{O}(1) \tag{4.24}$$

and

$$\left|\frac{2l-1}{l(l-1)-E}\right| \leqslant \frac{2l-1}{\mu_l - l(l-1)} = \frac{2l-1}{2l(1-[1+\mathcal{O}(1)]/[\ln l])} = \mathcal{O}(1). \tag{4.25}$$

Finally, *(iv)* follows from *(ii)* and *(iii)* which yield

$$Z(\sqrt{\mu_l})=\frac{1}{4\pi}(\ln l+\mathcal{O}(1))-\frac{1}{2\pi}\ln l+\mathcal{O}(1)=-\frac{1}{4\pi}\ln l+\mathcal{O}(1)$$

and $|g(\sqrt{\mu_l})|=(1/4\pi)\ln l+\mathcal{O}(1)$. ■

Now we are in position to prove the main result of this subsection:

Theorem IV.5: Let $K_\varepsilon:=\mathbb{R}\setminus\cup_{l=2}^{\infty}(\mu_l-\varepsilon(l)(\ln l)^{-2},\mu_l+\varepsilon(l)(\ln l)^{-2})$, *where* $\varepsilon(\cdot)$ *is a positive strictly increasing function which tends to* ∞ *and obeys the inequality* $|\varepsilon(x)|\leqslant x\ln x$ *for* $x>1$. *Then there is a positive* c *such that the transmission probability satisfies the bound*

$$|t(k)|^2\leqslant c\varepsilon(l)^{-2} \tag{4.26}$$

for $k^2\in K_\varepsilon\cap(l(l-1),l(l+1))$ *and any* l *large enough. On the other hand, there are sharp resonance peaks localized on* K_ε,

$$|t(\sqrt{\mu_l})|^2=1+\mathcal{O}((\ln l)^{-1}) \tag{4.27}$$

as $l\to\infty$.

Proof: In the first part we are going to estimate the modulus of the numerator in (4.20) from below. The leading term at high energies is the one with $\Delta(k)$; we shall estimate it on the set K_ε; i.e., away of the zeros of the coefficient. Consider the neighborhood

$$I_l:=(\mu_l-2l(\ln l)^{-1},\mu_l+2l(\ln l)^{-1})$$

of μ_l on which the following estimates are valid:

$$\begin{aligned}\frac{1}{2k}(Z'(k)+(-1)^l g'(k))&=\sum_{m=0}^{\infty}\frac{2m+1}{m(m+1)-E}(1+(-1)^{l+m})\\&=\left(\sum_{m=0}^{l-2}+\sum_{m=l+1}^{\infty}\right)\frac{2m+1}{(m(m+1)-E)^2}(1+(-1)^{l+m})\\&\quad+\frac{2(2l+1)}{(l(l+1)-E)^2}\\&\geqslant\frac{2(2l+1)}{(l(l+1)-E)^2}\\&\geqslant\frac{2(2l+1)}{(l(l+1)-\mu_l+2l(\ln l)^{-1})^2}=\frac{2(2l+1)}{(2l(\ln l)^{-1}(2+\mathcal{O}(1))^2}\geqslant c_1\frac{(\ln l)^2}{l}\end{aligned}$$

for some $c_1>0$. Combining this result with Lemma 4.1 we are able to say how the factors constituting $\Delta(k)$ are separated from zero for $E\in(l(l-1),l(l+1))$, which does not belong to the interval $(\mu_l-\varepsilon(l)(\ln l)^{-2},(\mu_l+\varepsilon(l)(\ln l)^{-2})\subset I_l$:

$$|Z(k)+(-1)^l g(k)|\geqslant\varepsilon(l)(\ln l)^{-2}c_1 l^{-1}(\ln l)^2=c_1 l^{-1}\varepsilon(l). \tag{4.28}$$

Now we begin estimating the modulus of the transmission amplitude from below. In the following, c_j always means a positive constant. Using the expression (4.20) we get a simple lower bound,

$$|t(k)|\leqslant\frac{4\pi\rho}{|[1-2\pi Z(k)]/k|g(k)|-[\pi^2\Delta(k)/|g(k)|](k^{-1}-4k\rho^2)|}, \tag{4.29}$$

obtained by neglecting the imaginary part of the denominator. First we shall show that

$$\frac{1-2\pi Z(E)}{k|g(k)|}=\mathcal{O}(1) \tag{4.30}$$

as $l\to\infty$. Using Lemmas 4.2 and 4.3 we estimate this expression by

$$\frac{|\ln l+\mathcal{O}(1)|}{kK}+\frac{1}{2\pi k}\left|\frac{(2l+1)/[l(l+1)-E]+(2l-1)/[l(l-1)-E]}{(2l+1)/[l(l+1)-E]-(2l-1)/[l(l-1)-E]-2}\right|\leqslant c_2,$$

where in the second term we have used the explicit lower bound on $|g(k)|$, estimated the modulus of the fraction by $(2l+1)/(l-1)\leqslant 5$, and employed finally $k=\sqrt{E}=l+\mathcal{O}(1)$. For the second term in the denominator of (4.29) we shall show that

$$\frac{\pi^2\Delta(k)}{|g(k)|}(k^{-1}-4k\rho^2)\geqslant c_3\varepsilon(l) \tag{4.31}$$

holds for all $E\in(l(l-1),l(l+1))\setminus(\mu_l-\varepsilon(l)(\ln l)^{-2},\mu_l+\varepsilon(l)(\ln l)^{-2})$, which will give (4.26) with $c:=(c_3/4\pi\rho)^2$. Consider first the case $E\leqslant\mu_l$, when (4.28) together with Lemmas 4.4(ii) yields

$$\begin{aligned}
&\pi^2|k^{-1}-4k\rho^2|\,\frac{|Z(k)+(-1)^l g(k)||Z(k)-(-1)^l g(k)|}{|(1/4\pi)\,((2l+1)/[l(l+1)-E]-(2l-1)/[l(l-1)-E])+\mathcal{O}(1)|}\\
&\quad\geqslant 4\pi^2\rho^2k|1-(2\rho k)^{-2}|\,\frac{c_1 l^{-1}\varepsilon(l)\,(1/2\pi)\,|(2l-1)/[l(l-1)-E]-\ln l+\mathcal{O}(1)|}{|-(1/4\pi)(2l-1)/[l(l-1)-E]-(1/4\pi)\ln l+\mathcal{O}(1)|}\\
&\quad\geqslant c_4 k\,\frac{\varepsilon(l)}{l}\geqslant c_5\varepsilon(l),
\end{aligned}$$

where in the last step we used again $k=l+\mathcal{O}(1)$. Let further $E>\mu_l$. We divide the argument into two parts. First we suppose

$$\frac{2l+1}{l(l+1)-E}\leqslant 2\ln l;$$

then

$$\begin{aligned}
&\pi^2|k^{-1}-4k\rho^2|\,\frac{|Z(k)+(-1)^l g(k)||Z(k)-(-1)^l g(k)|}{|(1/4\pi)\,((2l+1)/[l(l+1)-E]-(2l-1)/[l(l-1)-E])+\mathcal{O}(1)|}\\
&\quad\geqslant 4\pi^2\rho^2k|1-(2\rho k)^{-2}|\,\frac{c_1 l^{-1}\varepsilon(l)|\ln l+\mathcal{O}(1)|}{|\ln l+\mathcal{O}(1)|}\geqslant c_6\varepsilon(l)
\end{aligned}$$

by (4.28) and Lemma 4.4(iii). On the other hand, if

$$\frac{2l+1}{l(l+1)-E}\geqslant 2\ln l, \tag{4.32}$$

the same expression is bounded from below by

$$\begin{aligned}
&4\pi^2\rho^2k|1-(2\rho k)^{-2}|\,\frac{|(1/4\pi)(2l+1)/[l(l+1)-E]+\mathcal{O}(1)||(1/2\pi)\ln l+\mathcal{O}(1)|}{|(1/4\pi)(2l+1)/[l(l+1)-E]+\mathcal{O}(1)|}\\
&\quad\geqslant c_7 k|1-(2\rho k)^{-2}|\ln l\geqslant c_8\varepsilon(l),
\end{aligned}$$

where the denominator and the first term in the numerator have been estimated by means of (4.23) and (4.32), in the second term we have neglected one of the two terms of the same sign, and the last inequality follows from the fact that $x \ln x \geqslant \varepsilon(x)$ by assumption. To conclude the proof of (4.26), it is sufficient to put $c_3 := \min\{c_5, c_6, c_8\}$ in (4.31).

The rest is easier; the existence of resonance peaks at which the sphere is almost transparent follows from the relations

$$
\begin{aligned}
|t(\mu_l)| &= \left| \frac{1}{4\pi\rho\sqrt{\mu_l}\, g(\sqrt{\mu_l})} - \frac{Z(\sqrt{\mu_l})}{g(\sqrt{\mu_l})} \left(i + \frac{1}{2\rho\sqrt{\mu_l}} \right) \right|^{-1} \\
&= \left| \left(i + \frac{1}{2\rho\sqrt{\mu_l}} \right) (1 + \mathcal{O}((\ln l)^{-1})) + \frac{1}{\rho\sqrt{\mu_l}} (\ln l + \mathcal{O}(1)) \right|^{-1} \\
&= |i + \mathcal{O}((\ln l)^{-1})|^{-1} = 1 + \mathcal{O}((\ln l)^{-1}),
\end{aligned}
$$

where we have used Lemma 4.4(iv). ■

The proved theorem can be illustrated by numerically evaluated transmission probability $|t(k)|^2$. The curve oscillates almost regularly, but with the amplitude spanning from small values to unity for sufficiently large k. The lower enveloping curve of $|t(k)|^2$ behaves as $(E \ln E)^{-1}$ as we proved earlier. The analogous conclusion for another (unphysical) coupling between the sphere and the leads were compared in Ref. 10 to scattering properties of the δ'-interaction, the transmission of which decays like E^{-1} as $E \to \infty$. We conjecture that the ''bubble'' has exactly this asymptotic if $|t(k)|^2$ is replaced by its ''smoothed,'' i.e., locally averaged version. The conjecture is supported by Fig. 7; it compares an averaged $|t(k)|^2$ of a ''bubble'' on the line and $|t(k)|^2$ of δ'-interaction. The averaging is done over ten neighboring peaks of a given point. The strength of the δ'-interaction is chosen so as to reach the same value of $|t(k)|^2$ at a distant k. These two curves seem to have the same asymptotic behavior.

Let us finally use the result to express scattering on an array of bubble scatterers and compare it with the band spectrum of the periodic system. This is done on Fig. 8 which shows the band spectrum of an infinite array of bubbles on the line. What is different from analogical spectra of loop or comb arrays is the concentration of bands to small values ρ (note the logarithmic scale).

(Received 9 April 2001; accepted for publication 21 May 2001)

There are only three stable singularities of a differentiable map between three-dimensional manifolds, namely folds, cusps and swallowtails. A Skyrme configuration is a map from space to SU_2, and its singularities correspond to the points where the baryon density vanishes. In this article we consider the singularity structure of Skyrme configurations. The Skyrme model can only be solved numerically. However, there are good analytic ansätze. The simplest of these, the rational map ansatz, has a nongeneric singularity structure. This leads us to introduce a nonholomorphic ansatz as a generalization. For baryon numbers 2, 3, and 4, the approximate solutions derived from this ansatz are closer in energy to the true solutions than any other ansatz solution. We find that there is a tiny amount of negative baryon density for baryon number 3, but none for 2 or 4. We comment briefly on the relationship to Bogomolny–Prasad–Sommerfield monopoles. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1388199]

I. INTRODUCTION

The Skyrme model is a nonlinear SU_2 field theory.[1] In addition to the fundamental excitations, the spectrum also includes topologically charged soliton solutions. The model was proposed by Skyrme as a theory of nuclear physics in which the fundamental excitations are pions and the solitons are nucleons. The Skyrme energy function is

$$E=\int\left\{-\frac{1}{2}\mathrm{Tr}\,(R_iR_i)-\frac{1}{16}\mathrm{Tr}([R_i,R_j][R_i,R_j])\right\}\mathrm{d}^3x, \tag{1}$$

where R_i is the su_2-valued current $R_i=(\partial_iU)U^{-1}$. The SU_2-valued field U is required to attain its vacuum value, the identity, at spatial infinity and, so, it is a map between topological three-spheres. This is the origin of the topological charge, B.

The one-Skyrmion is spherical and is given by the hedgehog ansatz

$$U_1(\mathbf{x})=\exp(if(r)\hat{\mathbf{n}}\cdot\boldsymbol{\sigma}), \tag{2}$$

where $\hat{\mathbf{n}}=\hat{\mathbf{x}}$ is the outward pointing unit normal and $\boldsymbol{\sigma}=(\sigma_1,\sigma_2,\sigma_3)$ are the Pauli matrices. $f(r)$ is a shape function and is usually determined numerically. It is very well approximated by the kink profile:[2] $f(r)=4\arctan(\exp(-r))$. The one-Skyrmion has six zero modes: three translational modes and three isospin modes corresponding to global SU_2 transformations.

Two well-separated Skyrmions attract or repel, depending upon their mutual isospin orientation. Two attracting one-Skyrmions will move towards each other and form a bound state whose

a)Electronic mail: houghton@maths.tcd.ie
b)Electronic mail: s.krusch@damtp.cam.ac.uk

energy is 0.95 times the energy of two one-Skyrmions. This two-Skyrmion is torus shaped[3,4] and is axially symmetric, in the sense that axial rotations in space are equivalent to isospin rotations, which are conjugations of U by a constant SU_2 matrix.

In the Skyrme model, the classical B-nucleon nucleus is a B-Skyrmion; that is, a minimum energy Skyrme field with topological charge B. For B from 3 to 22, the Skyrmion has been calculated numerically by evolving an attractive configuration.[5–7] All the known Skyrmions have the bulk of their energy density on a fullerene-like shell. A geometric interpretation of this shell-like structure was given in Ref. 8. Furthermore, Skyrmions often have a very symmetrical shape.

A. The rational map ansatz

The rational map ansatz introduced in Ref. 9 is a simple ansatz for Skyrmions. It is similar to the one-Skyrmion (2). The one-Skyrmion is a hedgehog map in which the outward pointing unit normal, $\hat{\mathbf{n}}$, maps a two-sphere identically to a two-sphere. In the ansatz, the hedgehog map is replaced by a more general holomorphic map, $\hat{\mathbf{n}}_R$, from Riemann sphere to Riemann sphere. The rational map ansatz is given by

$$U(r,z)=\exp(if(r)\hat{\mathbf{n}}_R\cdot\boldsymbol{\sigma}), \tag{3}$$

where

$$\hat{\mathbf{n}}_R=\frac{1}{1+|R|^2}(2\,\mathrm{Re}(R),2\,\mathrm{Im}(R),1-|R|^2) \tag{4}$$

and $R(z)$ is a holomorphic map in z. Here, z is related to the standard angular coordinates ϕ and θ by the stereographic projection $z=\tan(\theta/2)\exp(i\phi)$. R is also a stereographic coordinate on the Riemann sphere. In the ansatz, this Riemann sphere is a latitudinal two-sphere in $SU_2\cong S^3$.

The ansatz maps spheres around the origin in space to latitudinal two-spheres in SU_2. The shape function f is a function of r only, so each map between two-spheres is identical. The boundary conditions on f are $f(0)=\pi$ and $f(\infty)=0$. These conditions are determined by requiring that U is well defined at the origin and attains the vacuum value at infinity. In principle, we could have $f(0)=N_f\pi$ for any nonzero integer N_f, but solutions with $N_f>1$ have rather high energy and so we only consider $N_f=1$.

Thus, the ansatz depends on a holomorphic map between two-spheres. Any holomorphic map of finite topological charge can be written as a rational map

$$R(z)=\frac{p(z)}{q(z)}, \tag{5}$$

where p and q are polynomials in z. The topological charge, N_R, of the map is equal to the algebraic degree and this, in turn, is given by the maximal degree of the two polynomials.

The easiest way to calculate the energy of an ansatz field is to use the geometric formulation of the Skyrme model.[10] A Skyrme field is a map between three-manifolds with metrics and so there is a strain tensor. This is given by

$$D_{ij}=-\tfrac{1}{2}\mathrm{Tr}(R_iR_j). \tag{6}$$

The static energy, E, and the baryon number, B, of a Skyrme field can be written in terms of the eigenvalues, λ_1^2, λ_2^2, and λ_3^2, of this tensor:

$$E=\int(\lambda_1^2+\lambda_2^2+\lambda_3^2+\lambda_1^2\lambda_2^2+\lambda_2^2\lambda_3^2+\lambda_1^2\lambda_3^2), \tag{7}$$

$$B=\frac{1}{2\pi^2}\int \lambda_1\lambda_2\lambda_3 . \tag{8}$$

The strain tensor of the ansatz field (3) can be calculated to give

$$B=\frac{2}{\pi}\int (-f'\sin^2 f)\mathrm{d}r\,\frac{1}{4\pi}\int \left(\frac{1+|z|^2}{1+|R|^2}\left|\frac{\mathrm{d}R}{\mathrm{d}z}\right|\right)^2 \frac{2i\,\mathrm{d}z\,\mathrm{d}\bar{z}}{(1+|z|^2)^2}, \tag{9}$$

$$=N_R , \tag{10}$$

where N_R is the degree of the rational map.

Similarly, the energy E is given by

$$E=4\pi\int \left(f'^2 r^2+2N_R(f'^2+1)\sin^2 f+\mathcal{I}\,\frac{\sin^4 f}{r^2}\right)\mathrm{d}r, \tag{11}$$

where

$$\mathcal{I}=\frac{1}{4\pi}\int \left(\frac{1+|z|^2}{1+|R|^2}\left|\frac{\mathrm{d}R}{\mathrm{d}z}\right|\right)^4 \frac{2i\,\mathrm{d}z\,\mathrm{d}\bar{z}}{(1+|z|^2)^2}. \tag{12}$$

Thus, the minimum energy ansatz field is found by choosing polynomials p and q which minimize $\mathcal{I}$ and then calculating the shape function f numerically. These minimum energy ansatz fields have been calculated for all the known Skyrmions and are found to have energies that exceed the true, numerically determined, minima[7,9] by less than 3%.

B. The rational map ansatz and negative baryon density

The accuracy of the ansatz is established by observing how close in energy the minimum energy ansatz configurations are to the true minima. In other words, it is not known whether the ansatz fields resemble the true fields in regions where the energy density is low. In fact, for the approximate fields calculated within the ansatz, the region of zero baryon density has a rather special structure. There are $2B-2$ radial half-lines which meet at the origin and extend out to infinity. The zeros of the baryon density correspond to the folds in the Skyrme fields, considered as maps between three-spheres. Line-like zeros are not generic. It is possible that these nongeneric zeros are a natural consequence of minimizing the Skyrme energy.[11,12] However, it may be that this is a weakness of the rational map ansatz and Skyrmions have a more generic folding structure.

If it is a weakness, it is not a very serious one. Most current interest is in finding minimum energy Skyrme configurations. However, the issue of determining the structure of Skyrme fields in the regions where there is little energy may be of some practical importance, for example, in calculations in which the Skyrmion fields are used as backgrounds for fermion excitations modeling heavy flavors (see Ref. 13).

In this article, we consider the consequences of generalizing the rational map ansatz to include a larger class of maps. These maps permit a more natural, though not wholly generic, folding structure. This generalized ansatz is not as convenient as the original one. However, it does result in ansatz fields which are even closer to the true minima.

Our interest in this problem is partly motivated by BPS monopoles. There are many interesting similarities between Skyrmions and BPS monopoles. For example, there are two rational map descriptions of monopoles,[14,15] and it is widely believed that the space of attracting Skyrmions is related to the space of monopoles. It was discovered in Ref. 29 that the tetrahedral three-monopole has a negative multiplicity Higgs zero. Subsequent examination revealed that the octahedral five-monopole also has extra zeros but the cubic four-monopole does not.[17]

There is evidence that this pattern is mimicked by Skyrmions for $B=3$ and 4. These Skyrmions were studied in Ref. 18 using the Atiyah–Manton ansatz.[19] It was observed that there is no negative baryon density in the approximate four-Skyrmion, but there is in the approximate three-Skyrmion case. In the approximate three-Skyrmion there is a region of negative baryon density surrounding the origin. This extends out along four thin tubes which twice pinch to points and then widen at very large distance until they merge and form another region of negative baryon density at spatial infinity.

In this article, we generalize the rational map ansatz so that there can be negative baryon density. We calculate ansatz fields that approximate the true minima more closely than the original rational map ansatz. The ansatz for the three-Skyrmion has tubes of negative baryon density extending out from the origin; the ansatz for the four-Skyrmion does not. Furthermore, there is an octahedrally symmetric $B=5^*$ saddle-point configuration. The ansatz for this saddle point also has negative baryon density.

Thus, our investigation adds to the evidence that there may be regions of negative baryon density in certain Skyrmions. This occurs in those examples where the corresponding monopole has negative multiplicity Higgs zeros. Of course, our conclusions are based on an ansatz and the true solution does not necessarily possess the same singularity structure. Unfortunately, it is difficult to observe negative baryon density directly in the numerical solutions.

C. Singularities of differentiable maps

The theory of singularities deals with smooth maps between manifolds. One of its main aims is to classify the points where the Jacobian of a map does not have maximal rank. These are the singularities. Some singularities are unstable, in the sense that a small perturbation of the map can alter the nature of the singularity. For maps between low dimensional manifolds, there are only a small number of stable singularities. In this section, we describe the three stable singularities of smooth maps between three-dimensional manifolds. We will follow Ref. 20.

Let $f:M\to N$ be a map from a three-dimensional manifold M to a three-dimensional manifold N. Locally, there are coordinates $\{y_1,y_2,y_3\}$ on N and $\{x_1,x_2,x_3\}$ on M so that

$$\begin{aligned} y_1&=f_1(x_1,x_2,x_3),\\ y_2&=f_2(x_1,x_2,x_3),\\ y_3&=f_3(x_1,x_2,x_3). \end{aligned} \tag{13}$$

The matrix $J=(\partial f_i/\partial x_j)$ is the Jacobian matrix of the map. The singularities are the points where $\det J=0$. There are only three stable singularities: folds, cusps and swallowtails. These are described by giving their normal forms. The normal form is a standard choice of coordinates for the neighborhood of the singularity. Any stable singularity can be expressed locally in terms of the corresponding normal form by a smooth change of variables.

The simplest singularity is the fold, which can be visualized as the line along which a piece of paper has been folded. A fold has the normal form

$$\begin{aligned} y_1&=x_1^2,\\ y_2&=x_2,\\ y_3&=x_3. \end{aligned} \tag{14}$$

It is worth considering the number of preimages of the map. For points of N with $y_1>0$ there are two preimages, whereas for points with $y_1<0$ there are no preimages. The fold is located at $y_1=0$, which has one preimage. Restricted to the set of points $y_1=0$, f maps the x_2x_3-plane onto the y_2y_3-plane.

The Jacobian matrix of this map is

$$J=\begin{pmatrix} 2x_1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}. \tag{15}$$

It is singular at $x_1=0$, which, of course, is the location of the fold. The rank of the Jacobian matrix at the fold is two. In fact, this is true of all three stable singularities. Any singularity with a rank one or rank zero Jacobian matrix is unstable.

Two folds can end on a cusp. This has the normal form:

$$\begin{aligned} y_1&=x_1^3+x_1x_2, \\ y_2&=x_2, \\ y_3&=x_3. \end{aligned} \tag{16}$$

In order to get a better understanding of this singularity, we calculate the Jacobian matrix:

$$J=\begin{pmatrix} 3x_1^2+x_2 & x_1 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}. \tag{17}$$

J does not have maximal rank for $x_1^2=-x_2/3$. This is a pair of folds. The cusp occurs at the line $(0,0,x_3)$ where the two folding surfaces $(\pm\sqrt{-x_2/3},x_2,x_3)$ meet.

The most complicated stable singularity is called the swallowtail and its normal form is

$$\begin{aligned} y_1&=x_1^4+x_1^2x_2+x_1x_3, \\ y_2&=x_2, \\ y_3&=x_3. \end{aligned} \tag{18}$$

In this case, the Jacobian matrix is given by

$$J=\begin{pmatrix} 4x_1^3+2x_1x_2+x_3 & x_1^2 & x_1 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}. \tag{19}$$

The points of the folds satisfy the equation $x_3=-4x_1^3-2x_1x_2$. The folds meet to form four cusp lines which meet at the origin. The origin is the swallowtail.

This classification is known as Whitney's theorem. This theorem states that a map of a three-dimensional manifold to a three-dimensional manifold is stable at a point if, and only if, the map can be described in local coordinates in one of the four forms: a regular point with $y_1=x_1$, $y_2=x_2$, and $y_3=x_3$ or one of the three singular forms given above. Furthermore, maps with stable singularities are dense in the space of all smooth maps: any map can be approximated arbitrarily closely by a map with stable singularities.

II. FOLDING AND RATIONAL MAPS

We begin this section by showing that the simplest singularity of the rational map ansatz is unstable. This will lead us to introduce the nonholomorphic rational map ansatz in the following section. Furthermore, we show that for $B>1$ there is an unstable singularity at the origin.

In the holomorphic rational map ansatz there is a map from $\mathbf{R}^3$ to S^3 which maps $(r,z,\overline{z})$ to $(f(r),R(z),\overline{R}(\overline{z}))$. Away from the origin, we can define local coordinates $\{\mathrm{Re}(z),\mathrm{Im}(z),x_3\}$ and $\{y_1,y_2,y_3\}$ such that

$$y_1=\mathrm{Re}(R),$$
$$y_2=\mathrm{Im}(R), \tag{20}$$
$$y_3=x_3.$$

The simplest rational map with a singularity is

$$R(z)=z^2, \tag{21}$$

which gives

$$y_1=x_1^2-x_2^2,$$
$$y_2=2x_1x_2, \tag{22}$$
$$y_3=x_3.$$

The Jacobian matrix has rank one for the line $(0, 0, x_3)$. This is not one of the stable singularities.

Let us consider small perturbations around (21). Adding terms proportional to z only shifts the singularity. Therefore, we consider the following map:

$$R(z,\overline{z})=z^2+2\epsilon\overline{z}. \tag{23}$$

Since multiplying ϵ by a phase $e^{i\phi}$ only rotates the singularities by ϕ, we can take ϵ to be real. Using real coordinates, the Jacobian matrix can be written as

$$J=\begin{pmatrix} 2x_1+2\epsilon & -2x_2 & 0 \\ 2x_2 & 2x_1-2\epsilon & 0 \\ 0 & 0 & 1 \end{pmatrix}. \tag{24}$$

The Jacobian matrix is singular for $x_1^2+x_2^2=\epsilon^2$. Therefore, the singular points lie on a cylinder with radius ϵ. They can be parametrized by $x_1=\epsilon\cos\alpha$ and $x_2=\epsilon\sin\alpha$ for $\alpha\in[0,2\pi]$, x_3 is arbitrary. Restricting the map to the singular surface, labeled by α and x_3, we can calculate the cusp lines. The surface is singular where

$$\frac{dy_1}{d\alpha}=\frac{dy_2}{d\alpha}=\frac{dy_3}{d\alpha}=0, \tag{25}$$

therefore, the cusps form lines where α is zero, $2\pi/3$ or $4\pi/3$, and x_3 is arbitrary.

In Fig. 1, we show the image of a set of concentric circles of radius ρ in the x_1x_2-plane. By rescaling space and target space coordinates, the value of ϵ can be changed. For convenience, we set $\epsilon=1$ in the figure. For small radius, ρ, the $\overline{z}$ term is dominant and the image of the circle is a deformed circle. As the radius increases, the circle becomes more and more deformed. The $\rho=1$ circle maps to the singular curve. This curve has three spikes. The points of these spikes are the cusps and running between them are three folds. Above this value of ρ, the map folds back on itself. The points inside the fold have four preimages: a $\rho<1$ preimage with negative Jacobian and three $\rho>1$ preimages with positive Jacobians. Eventually, the image circle passes completely through the folding region: for $\rho>3$ the image is a trefoil shape. Every point outside the fold has just two preimages, each with positive Jacobian.

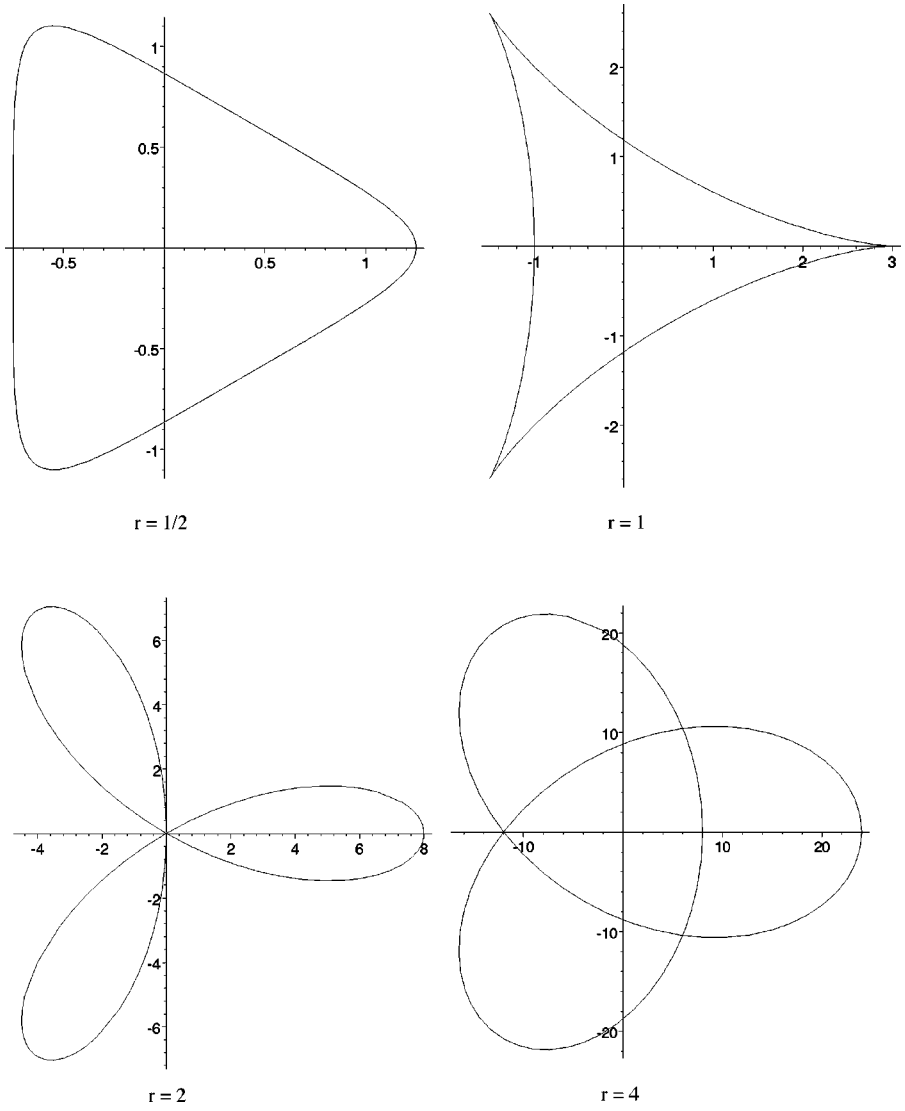

FIG. 1. The image of concentric circles $z=\rho e^{i\phi}$ of various radii ρ under $R(z,\bar{z})=z^2+2\bar{z}$. Note that the scale is different for each graph.

In general, the map $R(z)=z^n$ for $n\geqslant 2$ has an unstable singularity on the x_3-axis. This unstable singularity can be removed by adding an anti-holomorphic perturbation. The perturbed map $R(z)=z^n+n\epsilon\bar{z}$ has a folding surface at $z=\epsilon\exp(i\alpha)$. There are $n+1$ cusps which are located at $\alpha=2\pi k/(n+1)$ where $k=0,\ldots,n$. This map possesses a natural C_{n+1}-symmetry, which maps the cusps into each other.

It is worth noting that z^2 is a stable singularity within the set of holomorphic functions, whereas z^n for $n>2$ is unstable even as a holomorphic map. Therefore, we do not expect the latter singularities to occur for a generic holomorphic map.

Let us also consider the singularities of the rational map ansatz at the origin. Locally, the shape function can be written as

$$f(r)=\pi-Ar^{\nu}+O(r^{\nu+1}), \tag{26}$$

where A is an arbitrary positive constant and

$$\nu = -\tfrac{1}{2} + \tfrac{1}{2}\sqrt{8B+1}. \tag{27}$$

For $B=1$ this exponent is equal to one. This means that the Jacobian has full rank at the origin. However, for $B>1$ the exponent ν is greater than one. In this case the Jacobian of the rational map ansatz has rank zero. Moreover, the derivative $R_z(z)$ vanishes for certain values of z. Therefore, lines of degenerate singularities with rank one Jacobian matrices meet at the origin. Here they form an even more degenerate singularity with a rank zero Jacobian matrix. In Sec. III B, we argue that for $B=3$ there is a more likely singularity configuration close to the origin.

A. Nonholomorphic rational maps

The rational map ansatz restricts the ansatz fields in three different ways. It requires that concentric two-spheres around the origin in space are mapped to two-spheres in SU_2. It also requires that this map is the same for all concentric two-spheres, and it requires that the map between two-spheres is a holomorphic map. Our intention here is to relax the third of these conditions. We will consider a larger class of maps. The maps we will consider will be rational maps in the sense that they will have the form of a ratio between polynomials. However, the polynomials will depend on $\overline{z}$ as well as z, so they will not be holomorphic maps.

To begin with, we consider the ansatz

$$U(r,z,\overline{z}) = \exp(if(r)\hat{\mathbf{n}}_R\cdot\boldsymbol{\sigma}), \tag{28}$$

where, as before,

$$\hat{\mathbf{n}}_R = \frac{1}{1+|R|^2}(2\mathrm{Re}(R),2\mathrm{Im}(R),1-|R|^2) \tag{29}$$

but, without assuming R is holomorphic,

$$R = R(z,\overline{z}). \tag{30}$$

In order to derive the energy, E, we calculate the eigenvalues λ_1^2, λ_2^2 and λ_3^2 of the strain tensor (6). The strain tensor can be written as

$$(D_{ij}) = \begin{pmatrix} f'^2 & 0 & 0 \\ 0 & A(R_z+R_{\overline{z}})(\overline{R}_z+\overline{R}_{\overline{z}}) & iA(R_z\overline{R}_z-R_{\overline{z}}\overline{R}_{\overline{z}}) \\ 0 & iA(R_z\overline{R}_z-R_{\overline{z}}\overline{R}_{\overline{z}}) & -A(R_z-R_{\overline{z}})(\overline{R}_z-\overline{R}_{\overline{z}}) \end{pmatrix}, \tag{31}$$

where

$$A = \left(\frac{1+|z|^2}{1+|R|^2}\frac{\sin f}{r}\right)^2, \tag{32}$$

and has eigenvalues

$$\begin{aligned} \lambda_1^2 &= f'^2, \\ \lambda_2^2 &= \left(\frac{|R_z|+|R_{\overline{z}}|}{r}\frac{1+|z|^2}{1+|R|^2}\sin f\right)^2, \\ \lambda_3^2 &= \left(\frac{|R_z|-|R_{\overline{z}}|}{r}\frac{1+|z|^2}{1+|R|^2}\sin f\right)^2. \end{aligned} \tag{33}$$

Notice that λ_2^2 and λ_3^2 are only equal if $R_z^-=0$, or $R_z=0$. In the first case, the energy of the holomorphic rational map ansatz (11) is reproduced. The second case corresponds to a purely anti-holomorphic ansatz and is just the holomorphic ansatz composed with a reflection.

Using Eq. (7) the energy E can be rewritten as

$$E=4\pi\int\left(r^2f'^2+2\mathcal{J}(f'^2+1)\sin^2f+\mathcal{I}\frac{\sin^4f}{r^2}\right)\mathrm{d}r, \tag{34}$$

where $\mathcal{I}$ and $\mathcal{J}$ are given

$$\mathcal{J}=\frac{1}{4\pi}\int\left(\frac{(|R_z|^2+|R_z^-|^2)(1+|z|^2)^2}{(1+|R|^2)^2}\right)\frac{2i\ \mathrm{d}z\mathrm{d}\bar{z}}{(1+|z|^2)^2} \tag{35}$$

and

$$\mathcal{I}=\frac{1}{4\pi}\int\left(\frac{(|R_z|^2-|R_z^-|^2)(1+|z|^2)^2}{(1+|R|^2)^2}\right)^2\frac{2i\ \mathrm{d}z\mathrm{d}\bar{z}}{(1+|z|^2)^2}. \tag{36}$$

As in the holomorphic ansatz, $\mathcal{I}$ is essentially the integral of the square of the Jacobian. However, $\mathcal{J}$ is not the integral of the Jacobian of R.

There is a close relationship between this energy functional and the baby Skyrme model on a two-sphere. The baby Skyrme model[21,22] is a sigma-model in $(2+1)$ dimensions with a fourth order Skyrme-like interaction. The baby-Skyrme model on the two-sphere is of independent interest, primarily because there is a phase transition as the radius of the sphere is changed.[23,24]

On a unit two-sphere, the baby Skyrme fields map S^2 to S^2 and the energy functional is of the form $g_1\mathcal{J}+g_2\mathcal{I}$ where g_1 and g_2 are coupling constants. $\mathcal{J}$ is the sigma-model energy and $\mathcal{I}$ is the Skyrme energy. For a given shape function, f, the energy E in (34) is of this form with g_1 and g_2 calculated by integrating the shape function over r.

Obviously, it would be possible to regard the holomorphic maps between two-spheres as ansätze for baby Skyrme fields. For a holomorphic map, $\mathcal{J}$ is equal to the topological degree. Thus, the holomorphic map which minimizes $\mathcal{I}$ gives the best approximation to the energy minimizing baby Skyrme field. In other words, to find the baby Skyrme energy minimizing holomorphic map, the values of g_1 and g_2 need not be known. This is one of the reasons why the original rational map ansatz is so convenient to use: the rational map is found first and the shape function is then determined numerically.

For more general maps we need to employ an iterative algorithm. First, using the $\mathcal{I}$ minimizing holomorphic rational map, a shape function can be calculated numerically. This gives provisional values for the coupling constants g_1 and g_2. The next step is to minimize the baby-Skyrme energy with these values of g_1 and g_2. This determines a new map between the Riemann spheres. The original shape function is not optimized for this new map, so a new shape function must be calculated. A new profile function gives new coupling constants and so the whole procedure has to be iterated. In practice, this procedure is simplified by the fact that we only consider one-parameter families of nonholomorphic rational maps.

Another major advantage of using holomorphic maps is that there is only a finite-dimensional family of holomorphic maps of given topological degree. In contrast, the space of general maps between two-spheres of a given degree is infinite dimensional. One way to avoid this problem would be to minimize the baby Skyrme model numerically. However, our interest here is in the folding behavior of minimum energy Skyrmions and so we would prefer to find an approximate analytic solution whose folding behavior we can analyze. For this reason, we will restrict our attention to maps of the form

$$R(z,\overline{z})=\frac{p(z,\overline{z})}{q(z,\overline{z})}, \tag{37}$$

where p and q are polynomials in both z and $\overline{z}$. We will call the polynomial degree of this map (N_1,N_2), where N_1 is the maximal holomorphic degree of the polynomials p and q and N_2 is their maximal antiholomorphic degree. By counting the number of preimages of a given value of R and taking into account the sign of the Jacobian at each preimage, it follows that a general map of this form has topological degree N_1-N_2. Some maps will have a different degree because p and q may have a common factor. Maps of this type are called spurious.

According to formula (8), the baryon number is

$$B=\frac{2}{\pi}\int f'\sin^2 f\,\mathrm{d}r\,\frac{1}{4\pi}\int\frac{(|R_z|^2-|R_{\overline{z}}|^2)(1+|z|^2)^2}{(1+|R|^2)^2}\,\frac{2i\,\mathrm{d}z\mathrm{d}\overline{z}}{(1+|z|^2)^2}. \tag{38}$$

B is no longer an integral over squares, as it was for the holomorphic rational map ansatz. It is possible that the baryon density could be locally negative. We will find that this is what happens for certain values of B.

B. Symmetric nonholomorphic rational maps

The Skyrmions that we are interested in are symmetrical: the three-Skyrmion is tetrahedrally symmetric and the four-Skyrmion is octahedrally symmetric.[5] Rather than minimizing the ansatz energy over the whole space of maps, we restrict our attention to maps that have the same symmetry as the numerically determined minimum energy solution.

An SO_3 rotation g acts on the Riemann sphere z as a Möbius transformation

$$z\mapsto g(z)=\frac{\alpha z+\beta}{-\overline{\beta}z+\overline{\alpha}}, \tag{39}$$

where $|\alpha|^2+|\beta|^2=1$. There is also a Möbius action on the rational maps. A Möbius transformation of the rational map is equivalent to a global group transformation of the corresponding Skyrme fields. A Skyrme field is symmetric under a rotation, g, if the rotated fields are a global group transformation of the original fields. In the same way, the rational map $R(z,\overline{z})$ is symmetric under g if

$$R(g(z),\overline{g(z)})=\frac{\alpha' R(z,\overline{z})+\beta'}{-\overline{\beta}' R(z,\overline{z})+\overline{\alpha}'}, \tag{40}$$

where α' and β' are not necessarily the same as α and β.

Symmetric nonholomorphic rational maps can be calculated using elementary representation theory. In this subsection, we describe this construction. In the next section, we will derive nonholomorphic rational maps for various B.

The Riemann sphere is isomorphic to $\mathbf{CP}^1$, the one-dimensional complex projective space. $\mathbf{CP}^1$ can be labeled by a pair of complex numbers $[u,v]$, where the square bracket indicates the relation

$$[u,v]\cong[\lambda u,\lambda v] \tag{41}$$

with $\lambda\in\mathbf{C}^\times$. These homogeneous coordinates, u and v, are related to the inhomogeneous coordinate by $z=u/v$. The rotation group acts linearly on the homogenous coordinates and, so, it is easier to use these coordinates to describe the representation theory. However, we switch to

inhomogeneous coordinates whenever they are more convenient. Similarly, we can label the Riemann sphere by the complex conjugates of u and v, $[\overline{u},\overline{v}]$, also subject to relation (41). A nonholomorphic rational map takes the form

$$R(u,v,\overline{u},\overline{v})=[p(u,v,\overline{u},\overline{v}),q(u,v,\overline{u},\overline{v})]. \tag{42}$$

This rational map must be well-defined under the relation (41). Therefore, p and q have to be homogeneous: they are of the form

$$p(u,v,\overline{u},\overline{v})=\sum_{i=0}^{N_1}\sum_{j=0}^{N_2} a_{ij}u^i v^{N_1-i}\overline{u}^j\overline{v}^{N_2-j}, \tag{43}$$

$$q(u,v,\overline{u},\overline{v})=\sum_{i=0}^{N_1}\sum_{j=0}^{N_2} b_{ij}u^i v^{N_1-i}\overline{u}^j\overline{v}^{N_2-j}. \tag{44}$$

It should be noted that the topological degree does not depend on the value of N_1+N_2, it only depends on their difference. Choosing N_1 and N_2 corresponds to a truncation of the possible maps between Riemann spheres. This truncation is similar to truncating a Fourier expansion. In this article we will consider nonholomorphic maps with N_2 equal one or two.

Under an SO_3 rotation about the unit vector $\hat{\mathbf{n}}$ by an angle θ, the $[u,v]$ coordinates transform by an SU_2 transformation $\exp(i(\theta/2)\hat{\mathbf{n}}\cdot\boldsymbol{\sigma})$. The SO_3 action on the Riemann sphere $[u,v]$ can now be written as

$$\begin{aligned} u&\mapsto u'=(a_0+ia_3)u+(a_2+ia_1)v,\\ v&\mapsto v'=(-a_2+ia_1)u+(a_0-ia_3)v, \end{aligned} \tag{45}$$

where $a_i=n_i\sin(\theta/2)$ and $a_0=\cos(\theta/2)$. The coordinates $[\overline{u},\overline{v}]$ transform as the complex conjugate of (45). Let G be the double group of a finite subgroup of SO_3. The rational map $[p,q]$ is G invariant if an SU_2 transformation of $[u,v]$ and $[\overline{u},\overline{v}]$ is equivalent to an SU_2 transformation of $[p,q]$.

A homogeneous polynomial of degree N in z transforms as $\mathbf{N+1}$, the $(N+1)$-dimensional irreducible representation of SU_2. It follows that the homogeneous polynomial p of degree N_1 in z and degree N_2 in $\overline{z}$ transforms as $(\mathbf{N_1+1})\otimes(\mathbf{N_2+1})$. This representation can be decomposed into irreducible representations of some finite group G. These decompositions can be calculated using the characters. Tables of these decompositions can be found, for example, in Ref. 25.

By decomposing the $(\mathbf{N_1+1})\otimes(\mathbf{N_2+1})$ as a representation of G we can determine whether or not there is a G invariant degree (N_1,N_2) rational map. In fact, the rational map $[p,q]$ can be G-invariant in two different ways. One possibility is that

$$(\mathbf{N_1+1})\otimes(\mathbf{N_2+1})\big|_G=E\oplus \text{ other irreducible representations of } G, \tag{46}$$

and $\{p,q\}$ form a basis for the two-dimensional irreducible representation E. This means p and q are transformed into linear combinations of each other under Möbius transformations of z. Moreover, by a choice of basis, these combinations are unitary. This is always possible, because every representation of a finite group is equivalent to a unitary representation.[26] The second possibility is that

$$(\mathbf{N_1+1})\otimes(\mathbf{N_2+1})\big|_G=A_1\oplus A_2\oplus \text{other irreducible representations of } G, \tag{47}$$

and p is a basis for A_1, and q is a basis of A_2. Here, A_1 and A_2 are two different one-dimensional representations of G. In this case, there is a one-parameter family of G-symmetric rational maps: namely $R=[p,aq]$. The parameter a can be chosen to be real, because a Möbius transformation of R can change the phase of a.

Of course, there is also a one-parameter family when

$$(\mathbf{N_1+1})\otimes(\mathbf{N_2+1})\big|_G = 2E \oplus \text{other irreducible representations of } G \tag{48}$$

because, in this case, there is a one-parameter family of choices of an E inside $2E$. In order to construct a basis of this one-parameter family, we can construct a projector $P_{\alpha\beta}$. Given a representation ρ and a two-dimensional unitary representation $\rho^{(2)}_{\alpha\beta}$, the projector is given by

$$P_{\alpha\beta}=\frac{2}{|G|}\sum_{g\in G}\rho^{(2)}_{\alpha\beta}(g^{-1})\rho(g). \tag{49}$$

For details of this construction, see Refs. 9 and 27. It is not always necessary to construct projectors. In the $B=2$ case discussed later, the invariant map is calculated by direct calculation and in the $B=3$ case it is derived from other, previously known, examples.

III. SKYRMIONS FROM NONHOLOMORPHIC RATIONAL MAPS

In this section, we use nonholomorphic rational maps to approximate the Skyrmions with baryon numbers 2–4. In each of these cases, there is a one-parameter family of maps with the correct symmetry. Once the approximating map is found, we can discuss the folding structure. We also consider the $B=5^*$ octahedral saddle point which also has a one-parameter family of symmetric maps. It is more tractable than the five-Skyrmion, because the five-Skyrmion is not very symmetrical.

A. $B=2$: The torus

For $B=2$, the holomorphic rational map which minimizes $\mathcal{I}$ is

$$R(z)=z^2. \tag{50}$$

It has the same D_∞ symmetry as the true solution. There is an axial symmetry

$$R(e^{i\chi}z)=e^{2i\chi}R(z) \tag{51}$$

and a symmetry under rotation by π around an orthogonal axis

$$R\left(\frac{1}{z}\right)=\frac{1}{R(z)}. \tag{52}$$

The group theory methods discussed in the last section are not really needed here. The most general D_∞-symmetric map can be calculated by writing out the general (3,1) rational map and applying the symmetries (51) and (52). It is

$$R(z,\overline{z})=\frac{az^2(z\overline{z}+1)+bz^2(z\overline{z}-1)}{a(z\overline{z}+1)+b(-z\overline{z}+1)}. \tag{53}$$

The true solution also has a reflection symmetry. In the holomorphic case, that reflection symmetry is $R(\overline{z})=\overline{R(z)}$. If we impose the same symmetry for the nonholomorphic map, then the parameters a and b have to be real, up to a common phase. Moreover, since the pair (a,b) and $(\lambda a,\lambda b)$ gives rise to the same rational map for all $\lambda\in\mathbf{C}^\times$, we can set $a=\cos\theta$ and $b=\sin\theta$. The polynomials have been chosen such that the value $\theta=0$ corresponds to the holomorphic rational (2,0) map. θ is in the range $[-\pi/2,\pi/2]$, because under $\theta\mapsto\theta+\pi$ both $\sin\theta$ and $\cos\theta$ change sign.

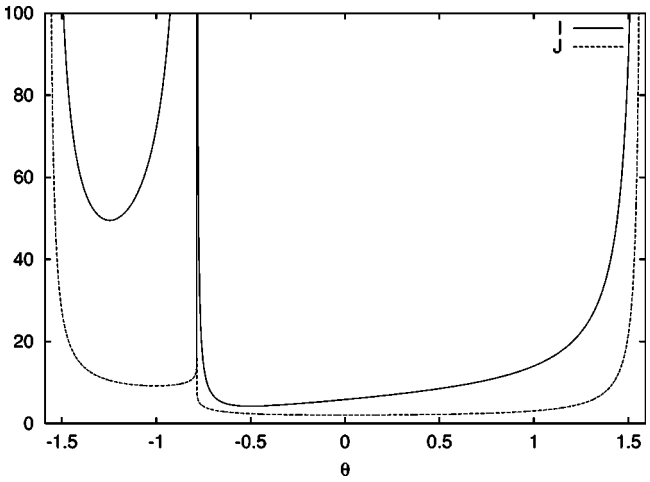

FIG. 2. $\mathcal{I}$ and $\mathcal{J}$ as a function of θ for $B=2$.

In Fig. 2, we show the value of $\mathcal{J}$ and $\mathcal{I}$ as a function of θ. There are two poles, one at $\theta=-\pi/4$ and another at $\theta=\pm\pi/2$. Both of these poles correspond to points where the maps are spurious. At $\theta=-\pi/4$, the cancellation of the common factor changes the topological degree,

$$R(z,\overline{z})|_{\theta=-\pi/4}=\frac{z}{z}, \tag{54}$$

whereas at $\theta=\pm\pi/2$ it does not:

$$R(z,\overline{z})|_{\theta=\pm\pi/2}=-z^2. \tag{55}$$

Thus, while the integrals are nonsingular at $\theta=\pm\pi/2$, they diverge as this value of θ is approached. These poles are considered in detail in Ref. 27. In Ref. 27, it is also shown that there is some negative baryon density only if $-\pi/2<\theta<-\pi/4$ or $\pi/4<\theta<\pi/2$.

To find the best approximation to the true minimum, we calculate the value of θ which minimizes the energy. The energy is a combination of $\mathcal{I}$ and $\mathcal{J}$. The optimal value for $\mathcal{J}$ is at the holomorphic rational map value $\theta=0$. However, $\mathcal{I}$ is minimal for $\theta\approx-0.503$. Minimizing energy (34) with respect to θ numerically, using the golden rule algorithm,[28] gives an optimal value of $\theta\approx-0.202$. The energy per Skyrmion calculated with this method is $E/B\approx1.191$. In contrast, for the holomorphic rational map $\theta=0$, we obtain $E/B\approx1.208$. The true value of the energy per Skyrmion is $E/B\approx1.1791$. For the energy minimizing value of θ, the baryon density is positive everywhere except at the origin. Thus, we find that there is no negative baryon density for $B=2$, even though there is a significant improvement in the energy. It seems that the axial symmetry stabilizes the unstable singularity.

B. $B=3$: The tetrahedron

The three-Skyrmion has tetrahedral symmetry T. The holomorphic rational map ansatz is

$$\begin{aligned} p_T(z)&=-i\sqrt{3}z^2+1,\\ q_T(z)&=z^3-i\sqrt{3}z, \end{aligned} \tag{56}$$

and $\{p_T,q_T\}$ is a basis for the E_2' in

$$\mathbf{4}|_T=E_2'\oplus E_3'. \tag{57}$$

TABLE I. The decomposition of irreducible representations of SU_2 as representations of T.

$\mathbf{1}\vert_T = A_1$
$\mathbf{2}\vert_T = E_1'$
$\mathbf{3}\vert_T = F$
$\mathbf{4}\vert_T = E_2' \oplus E_3'$
$\mathbf{5}\vert_T = A_2 \oplus A_3 \oplus F$
$\mathbf{6}\vert_T = E_1' \oplus E_2' \oplus E_3'$
$\mathbf{7}\vert_T = A_1 \oplus 2F$

The decompositions can be easily derived from the characters. Tables of these decompositions can also be found in, for example, Ref. 25. For convenience, a short table is given in Table I.

Here, we are interested in the nonholomorphic maps of degree (4,1). These correspond to the ten-dimensional representation $\mathbf{5}\otimes\mathbf{2}$ and can be decomposed into

$$\begin{aligned} \mathbf{5}\otimes\mathbf{2} &= \mathbf{6}\oplus\mathbf{4}, \\ (\mathbf{6}\oplus\mathbf{4})\vert_T &= E_1{}' \oplus 2E_2{}' \oplus 2E_3{}'. \end{aligned} \tag{58}$$

Both $\{1,z\}$ and $\{1,\overline{z}\}$ are a basis of the irreducible representation $E_1{}'$ of T. When they are multiplied, they decompose into $A_1 \oplus F$. For convenience, a multiplication table for the tetrahedral group is given in Table II.

A basis for this A_1 is

$$k = z\overline{z} + 1. \tag{59}$$

Furthermore, because $A_1 \otimes E_2' = E_2'$, $\{kp_T, kq_T\}$ is a basis for an E_2' inside $\mathbf{5}\otimes\mathbf{2}$. Explicitly, this basis is

$$\begin{aligned} p_1(z,\overline{z}) &= i\sqrt{3}z^3\overline{z} + i\sqrt{3}z^2 - z\overline{z} - 1, \\ q_1(z,\overline{z}) &= z^4\overline{z} + z^3 - i\sqrt{3}z^2\overline{z} - i\sqrt{3}z. \end{aligned} \tag{60}$$

The rational map for this basis is spurious: $[p_1,q_1] = [kp_T, kq_T] = [p_T, q_T]$. The common factor of k cancels. However, when we have a second independent basis, $\{p_2,q_2\}$, we will be able to form nonspurious linear combinations involving p_1 and q_1.

To find an independent pair of basis vectors in $2E_2'$, we use the A_2 in $\mathbf{5}\vert_T = A_2 + A_3 + F$. A basis for this A_2 is the Klein polynomial

$$k_f = z^4 - 2i\sqrt{3}z^2 + 1. \tag{61}$$

TABLE II. A multiplication table for the irreducible representations of T.

A_1	A_2	A_3	F	E_1'	E_2'	E_3'	$\otimes$
A_1	A_2	A_3	F	E_1'	E_2'	E_3'	A_1
	A_3	A_1	F	E_2'	E_3'	E_1'	A_2
		A_2	F	E_3'	E_1'	E_2'	A_3
			$A_1 \oplus A_2 \oplus A_3 \oplus 2F$	$E_1' \oplus E_2' \oplus E_3'$	$E_1' \oplus E_2' \oplus E_3'$	$E_1' \oplus E_2' \oplus E_3'$	F
				$A_1 \oplus F$	$A_2 \oplus F$	$A_3 \oplus F$	E_1'
					$A_3 \oplus F$	$A_1 \oplus F$	E_2'
						$A_2 \oplus F$	E_3'

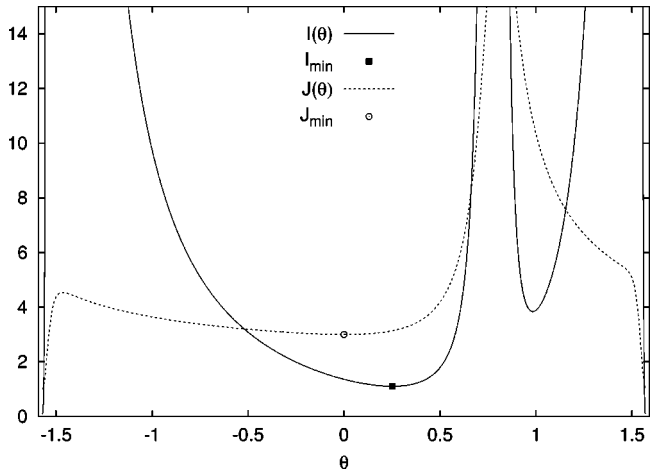

FIG. 3. $\mathcal{I}$ and $\mathcal{J}$ as a function of θ for $B=3$. Here $\mathcal{I}$ is rescaled by a factor of 10.

This is often called the face polynomial, because its zeros are the face points of a tetrahedron. Of course, the distinction between this and the vertex polynomial is a matter of convention. Now, $A_2\otimes E_1'=E_2'$ and so the required basis for E_2' can be found by multiplying k_f by $[1,-\overline{z}]$. Thus, a second basis is given by

$$\begin{aligned} p_2(z,\overline{z}) &= z^4-2i\sqrt{3}z^2+1, \\ q_2(z,\overline{z}) &= -z^4\overline{z}+2i\sqrt{3}z^2\overline{z}-\overline{z}. \end{aligned} \tag{62}$$

As with the other basis pair, the rational map for this basis is spurious: $[p_2,q_2]=[k_f,k_f\overline{z}]=[1,-\overline{z}]$.

A general T-symmetric nonholomorphic rational map of degree 3 is given by

$$R(z,\overline{z})=\frac{\cos\ \theta p_1+\sin\ \theta e^{i\phi}p_2}{\cos\ \theta q_1+\sin\ \theta e^{i\phi}q_2}. \tag{63}$$

The two angles θ and ϕ parametrize all maps. When $\theta=0$ this map is spurious and reduces to the tetrahedrally symmetric degree (3,0) rational map studied in Ref. 9. $\theta=\pm\pi/2$ is also spurious, here the map reduces to a degree (0,1) map. In this case, the cancellation changes the topological degree of the map. It is expected that $\mathcal{I}$ tends to infinity as this value of θ is approached.

For $\phi=0$, the map also has an additional reflection symmetry and the symmetry group becomes T_d. Since the numerically determined minimum seems to have this symmetry, it is expected that the best result from the rational map ansatz will come from $\phi=0$. We have confirmed this and will restrict our discussion to this case.

In Fig. 3, we display $\mathcal{I}$ and $\mathcal{J}$ as a function of the angle θ. The minimum of $\mathcal{J}$ is still at the rational map value $\theta=0$ with $\mathcal{J}=3$. However, the minimum of $\mathcal{I}$ is at $\theta\approx0.252$ with $\mathcal{I}\approx11.04$. The minimum of the energy can now be calculated by varying θ, using a simple minimization scheme in which the shape function is recalculate at each step. We obtain $E/B\approx1.160$ for $\theta\approx0.155$. The holomorphic rational map value is $E/B\approx1.184$, whereas the exact solution has $E/B\approx1.1462$. Therefore, the nonholomorphic rational map ansatz is a significant improvement.

Furthermore, there are regions of negative baryon density. In the holomorphic ansatz the singularities of the rational maps correspond to points on the face centers of a tetrahedron. Let us consider the baryon density near these points. The determinant of the Jacobian of the map R is proportional to the baryon density in (38):

$$B_R=\frac{(|R_z|^2-|R_{\bar{z}}|^2)(1+|z|^2)^2}{4\pi(1+|R|^2)^2}, \tag{64}$$

where we have integrated over r using the boundary conditions on f.

It is convenient to reorient the map (63) using the Möbius transformation

$$z\mapsto\frac{2z+(\sqrt{3}-1)(1+i)}{(1-\sqrt{3})(1-i)z+2}. \tag{65}$$

If the holomorphic map (56) is rotated in this way, it is singular at $z=0$, that is, B_R for the holomorphic map vanishes at $z=0$. If we rotate the nonholomorphic map (63) by the same Möbius transformation and expand B_R in terms of z and $\bar{z}$ we obtain

$$B_R\approx -0.17+10.8z\bar{z}, \tag{66}$$

where θ has been set to the energy minimizing value 0.155. For $z=0$ the baryon density is negative and, to lowest order in z and $\bar{z}$, the folds lie on a circle around the origin in the z-plane. Thus, the nonholomorphic rational map ansatz predicts tubes of negative baryon density. In fact, the total negative baryon density, B_-, can be calculated numerically. It is $B_-\approx 0.000\,089$.

Finally, we discuss the general singularity structure of the three-Skyrmion. All the singularities are of z^2 type and break up into three cusps connected by folds. This is compatible with the tetrahedral symmetry. Therefore, a three-Skyrmion consists of four tubes of folds, one through each of the faces of the tetrahedron. Each of these tubes contains three cusp lines. There are 12 cusp lines in total.

Unfortunately, it is difficult to directly examine the Skyrmion at the origin and at infinity using these methods. It is possible to speculate on what the singularity structure is, based on the assumption that the singularities are all generic.

From the discussion in Sec. I C we know that four cusp lines meet in a swallowtail. The cusp lines have to respect the tetrahedral symmetry. If the singularities are generic, they must meet in a swallowtail. Therefore, the 12 cusp lines cannot meet at the origin but have to split up earlier.

Considering only the cusp structure, one possible configuration would be that the three cusp lines of each fold tube meet in a swallowtail, resulting in one further cusp. The simplest tetrahedrally symmetric configuration would be that this cusp meets similar cusps of the remaining three fold tubes at the origin. However, we also know that the instanton approximation to the three-Skyrmion has negative baryon density at the origin,[18] whereas this possible configuration does not, because it has a singularity at the origin.

The following configuration is more likely. Each cusp of the fold splits up into three cusps at a swallowtail at some distance from the origin. Two of the cusp lines connect to the remaining two swallowtails of the fold tube. The last cusp line connects to the nearest swallowtail belonging to a different fold tube. This configuration is again tetrahedrally symmetric. Moreover, at the origin the baryon density is nonzero. We will call the cusp lines which follow the fold tubes *long cusp lines*, the cusp lines which connect swallowtails of the same fold tube *short cusp lines* and the cusp lines which connect swallowtails of different fold tubes *medium cusp lines*. In this configuration there are 12 long cusp lines, six medium cusp lines, and 12 short cusp lines. Note that the medium cusp lines lie on the edges of a tetrahedron.

In order to decide the sign of the baryon density at the origin, it is worth considering the folds of this configuration. Folds separate positive from negative baryon density. Moreover, precisely two folds end in one cusp. There are three folding surfaces in each fold tube. Each of these folding surfaces ends in two long cusp lines and one short cusp line. There are four additional folding surfaces, which can be visualized as the sides of a tetrahedron. Each of these folding surfaces ends

TABLE III. The decomposition of the irreducible representations of SU_2 as representations of O.

$\mathbf{1}\|_O = A_1$
$\mathbf{2}\|_O = E_1'$
$\mathbf{3}\|_O = F_1$
$\mathbf{4}\|_O = G'$
$\mathbf{5}\|_O = E \oplus F_2$
$\mathbf{6}\|_O = E_2' \oplus G'$
$\mathbf{7}\|_O = A_2 \oplus F_1 \oplus F_2$
$\mathbf{8}\|_O = E_1' \oplus E_2' \oplus G'$
$\mathbf{9}\|_O = A_1 \oplus E \oplus F_1 \oplus F_2$

in three medium cusp lines and three short cusp lines. These are all the folding surfaces because precisely two folding surfaces end in each of the cusps. Therefore, the baryon density at the origin has the same sign as the baryon density inside the fold tubes.

Thus, the baryon density at the origin is negative, as it is in the instanton ansatz.[18] In the instanton configuration the negative baryon density tubes pinch at two points. It is not possible to decide using our methods whether this is a peculiarity of the instanton ansatz or a feature of the three-Skyrmion.

C. $B=4$: The cube

The minimum energy $B=4$ configuration looks like a cube and has octahedral symmetry O. The corresponding invariant holomorphic map is

$$\begin{aligned} p_O(z) &= 2\sqrt{3}z^2, \\ q_O(z) &= z^4 + 1. \end{aligned} \tag{67}$$

These polynomials are a basis of the E in

$$\mathbf{5}\|_O = E \oplus F_2 . \tag{68}$$

As before, these decompositions can be easily calculated, but, for convenience, a table of them is given in Table III.

In the tetrahedral case, there was a unique invariant (3,0) map and a one-parameter family of (4,1) maps. The same thing does not happen here: if we consider (5,1) maps we obtain

$$\begin{aligned} \mathbf{6} \otimes \mathbf{2} &= \mathbf{7} \oplus \mathbf{5}, \\ (\mathbf{7} \oplus \mathbf{5})\|_O &= A_2 \oplus E \oplus F_1 \oplus 2F_2 , \end{aligned} \tag{69}$$

and the E is just the spurious map $[kp_O, kq_O] = [p_O, q_O]$. $k = 1 + z\bar{z}$ is the invariant polynomial discussed earlier. In other words, the only invariant (5,1) map reduces to the holomorphic map.

This means that, in order to derive a one-parameter family of invariant rational maps, we need to consider degree (6,2):

$$\begin{aligned} \mathbf{7} \otimes \mathbf{3} &= \mathbf{9} \oplus \mathbf{7} \oplus \mathbf{5}, \\ (\mathbf{9} \oplus \mathbf{7} \oplus \mathbf{5})\|_O &= A_1 \oplus A_2 \oplus 2E \oplus 2F_1 \oplus 3F_2 . \end{aligned} \tag{70}$$

Thus, there is a one-parameter family corresponding to the $2E$.

Since $\mathbf{3} \otimes \mathbf{3} = \mathbf{5} \oplus \mathbf{3} \oplus \mathbf{1}$ there is an essentially unique degree (2,2) SU_2 invariant. This is k^2 and so $(k^2 p_O, k^2 q_O)$ spans an E inside the $2E$. Explicitly this is

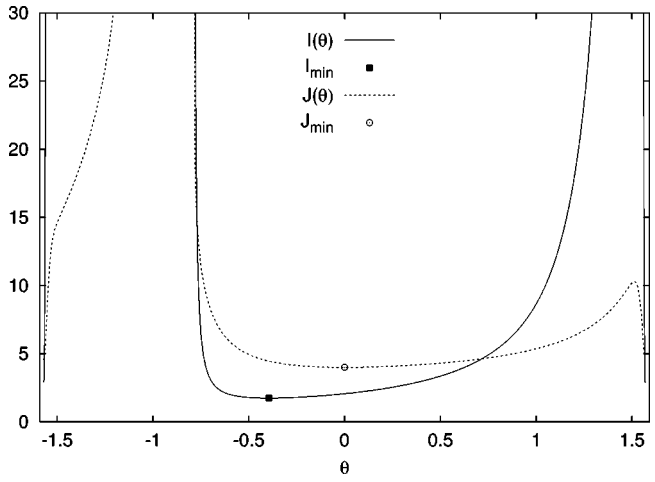

FIG. 4. $\mathcal{I}$ and $\mathcal{J}$ as a function of θ for $B=4$. Here $\mathcal{I}$ is rescaled by a factor of 10.

$$p_1(z,\overline{z})=2\sqrt{3}(z^4\overline{z^2}+2z^3\overline{z}+z^2),$$
$$q_1(z,\overline{z})=z^6\overline{z^2}+2z^5\overline{z}+z^4+z^2\overline{z^2}+2z\overline{z}+1. \tag{71}$$

By calculating the projection matrix we can derive another pair of basis vectors in $2E$:

$$p_2(z,\overline{z})=\sqrt{3}(-z^6+z^4\overline{z^2}-8z^3\overline{z}+z^2-\overline{z^2}),$$
$$q_2(z,\overline{z})=-z^6\overline{z^2}+4z^5\overline{z}-7z^4-7z^2\overline{z^2}+4z\overline{z}-1, \tag{72}$$

and the general invariant rational map has the same form as in the three-Skyrmion case, (63). As before, $\phi=0$ imposes the reflection symmetry of the true solution, and $\theta=0$ corresponds to the holomorphic map.

In Fig. 4 we show $\mathcal{I}$ and $\mathcal{J}$ as a function of the angle θ. At $\theta=0$ the graph of $\mathcal{J}$ has its global minimum. There is a local minimum at $\theta=\pm\pi/2$. The minimum value of $\mathcal{I}$ does not occur at the rational map value but at $\theta\approx-0.40$. Therefore, there is the possibility of deriving a lower energy. Indeed, minimizing the energy with respect to θ leads to $E=1.127$ for $\theta\approx-0.138$. This energy is only 0.6% above the true solution. By contrast the holomorphic rational map ansatz energy is 1.5% above the true solution.

As before, we can examine the baryon density in the neighborhood of a singularity of the holomorphic ansatz. In this case, the map is already oriented so that the holomorphic map has a singularity at $z=0$. Setting $\theta=-0.138$ and expanding the density, B_R, in powers of z and $\overline{z}$ we obtain

$$B_R\approx 2.54z\overline{z}. \tag{73}$$

Therefore, B_R vanishes at $z=0$, and there is no negative baryon density anywhere to lowest order.

D. $B=5^*$: The octahedron

The $B=5^*$ saddle point is octahedral in shape. The group theory involved in this example is very like the group theory required for $B=3$. There is a holomorphic map

$$p_O(z)=z^5-5z,$$
$$q_O(z)=-5z^4+1, \tag{74}$$

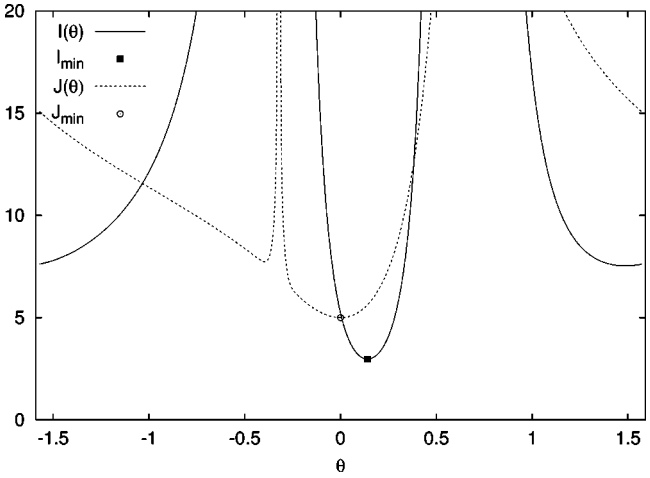

FIG. 5. $\mathcal{I}$ and $\mathcal{J}$ as a function of θ for $B=5^*$. Here $\mathcal{I}$ is rescaled by a factor of 10.

corresponding to the E_2' in

$$\mathbf{6}|_O = E_2' \oplus G'. \tag{75}$$

The generalization to (6,1) maps leads to a one-parameter family because

$$\mathbf{7} \otimes \mathbf{2} = \mathbf{8} \oplus \mathbf{6},$$

$$(\mathbf{8} \oplus \mathbf{6})|_O = E_1' \oplus 2E_2' \oplus 2G'. \tag{76}$$

Multiplying the holomorphic maps by the SU_2 invariant, $k = z\bar{z} + 1$, gives

$$\begin{aligned} p_1(z,\bar{z}) &= z^6\bar{z} + z^5 - 5z^2\bar{z} - 5z, \\ q_1(z,\bar{z}) &= -5z^5\bar{z} - 5z^4 + z\bar{z} + 1, \end{aligned} \tag{77}$$

and calculating the projection matrices gives

$$\begin{aligned} p_2(z,\bar{z}) &= 3z^6\bar{z} - 23z^5 - 15z^2\bar{z} + 11z, \\ q_2(z,\bar{z}) &= 11z^5\bar{z} - 15z^4 - 23z\bar{z} + 3. \end{aligned} \tag{78}$$

Thus, as before, a one-parameter family of invariant maps is given by (62) with $\phi = 0$. $\theta = 0$ gives the holomorphic map.

In Fig. 5 we display the graphs of $\mathcal{I}$ and $\mathcal{J}$ as a function of θ. There is a global minimum of $\mathcal{J}$ at the rational map value $\mathcal{J} = 5$. The graph of $\mathcal{I}$ has a minimum at $\theta \approx 0.141$. Minimizing the energy with respect to θ results in $E = 1.157$ for $\theta \approx 0.082$. This energy is only 1.7% above the true energy. In comparison, the energy of the holomorphic rational map ansatz is 8.3% above the true energy. This significant improvement gives an indication that negative baryon density plays an important role in this case. A local expansion shows that the nonholomorphic rational map has negative Jacobian determinant when z takes the values of the singularities of the holomorphic rational map. Finally, the integral of the negative baryon density is $B_- \approx 0.000\,97$, which is a factor of 10 larger than for $B = 3$.

IV. CONCLUSION

This article was motivated by the theory of singularities of differentiable maps and, in particular, by Whitney's theorem. This theorem states that there are only three types of stable singularities of maps between three-manifolds. We showed that the holomorphic rational map ansatz for Skyrmions[9] does not have a stable singularity structure: it does not even allow folding. We introduced a nonholomorphic rational map ansatz that allows folding. For baryon numbers 2, 3, and 4, the approximate solutions derived from this ansatz are closer in energy to the true Skyrmions than any other ansatz solution.

The key idea of the nonholomorphic rational map ansatz is to construct maps between Riemann spheres which are not holomorphic but have the same symmetry as the true solutions. We described this construction in detail and calculated the nonholomorphic rational maps for baryon numbers 2, 3, and 4, and for the octahedrally symmetric $B=5^*$ saddle point. Nonholomorphic rational maps can have folding and, therefore, negative baryon density. We found that there is negative baryon density for $B=3$ and $B=5^*$ but not for $B=2$ and $B=4$.

By decomposing group representations we showed that there is a one-parameter family of tetrahedrally symmetric (4,1) maps. These maps have topological degree three. The ansatz energy was minimized within this family to find the best approximation to the three-Skyrmion. The (4,1) maps have antiholomorphic degree one and so they are minimal generalizations of the original holomorphic map. For $B=5^*$ the situation is similar: there is a one-parameter family of octahedrally symmetric (6,1) maps. However, for $B=4$ the (5,1) maps do not contain a one-parameter family of octahedral maps, only the (6,2) maps do. The (5,1) maps can be thought of as the first order effect, and the (6,2) maps as a second order effect. In fact, for $B=4$, the holomorphic rational map is remarkably close to the true solution. The energy error is 1.5%. The holomorphic rational map approximation to the three-Skyrmion has an error of 3.3%. $B=7$ seems to be similar to $B=4$. The seven-Skyrmion is dodecahedral and it is easy to check that only the (10,3) maps contain a one-parameter family of icosahedrally symmetric maps. Again, the holomorphic rational map is extremely close to the true solution, with an error of only 1.1%. Therefore, we do not expect that negative baryon density occurs for $B=7$.

There is an icosahedrally-symmetric $B=11^*$ saddle point. The holomorphic rational map ansatz approximates it quite poorly. It predicts an energy which is far larger than 11 one-Skyrmions, whereas the true solution is a saddle-point solution with $E/B=1.158$. This can be viewed as an indication that negative baryon density plays a major role. The representation theory also suggests that there is negative baryon density because there is a one-parameter family of icosahedrally symmetric (12,1) maps.

It seems possible to decide heuristically whether or not a Skyrmion of a certain symmetry possesses negative baryon density. In Sec. I C we showed that a z^n singularity can be decomposed into folds which contain $n+1$ cusps and that there is a natural C_{n+1} symmetry which maps the cusps into each other. It seems likely that negative baryon density occurs if this C_{n+1} symmetry is compatible with the symmetry of the faces.

Direct computation shows that in the holomorphic rational map ansatz for $B=2$, 3, 4, 5^*, 7 and 11^* all the singularities are of z^2 type. Therefore, negative baryon density occurs, if the faces have a C_3 symmetry. The faces of the tetrahedron, the octahedron and the icosahedron are equilateral triangles. This is consistent with what we found: there is negative baryon density for $B=3$ and 5^*. It suggests that there is also negative baryon density for $B=11^*$. On the other hand, the faces of a torus are round, the faces of a cube are squares and the faces of a dodecahedron are pentagons. Correspondingly, we did not find any negative baryon density for $B=2$ and 4 and do not expect negative baryon density for $B=7$.

In the three-Skyrmion case we discussed the singularity structure at the origin. Assuming tetrahedral symmetry and generic singularities we conjectured a configuration with 16 folding surfaces, 30 cusp lines and 12 swallowtails. This is compatible with the instanton calculations in Ref. 18.

It appears that there are a large number of swallowtails, cusps and folds for both the three-Skyrmion and $B=5^*$ saddle point, but nongeneric singularities for the two- and four-Skyrmions.

TABLE IV. The numerical results.

	True[a]	Holomorphic[b]		Minimizing $\mathcal{I}$ [c]		Minimizing energy[d]			
B	E/B	$\mathcal{I}$	E/B	$\mathcal{I}$	E/B	$\mathcal{J}$	$\mathcal{I}$	B_-	E/B
1	1.2322	1	1.232	1	0	1	1	0	1.232
2	1.1791	5.81	1.208	4.20	0	2.04	4.98	0	1.191
3	1.1462	13.58	1.184	11.04	0.000 88	3.04	11.48	0.000 09	1.160
4	1.1201	20.65	1.137	17.50	0	4.04	18.95	0	1.127
5*	1.138	52.10	1.232	29.72	0.008 41	5.20	32.93	0.000 97	1.157

[a]These are the energies obtained in Ref. 7 by numerical minimization of the Skyrme energy.
[b]These are the values obtained in Ref. 9 using the holomorphic ansatz.
[c]$\mathcal{I}$ is minimized within the class of maps considered.
[d]These are the best results obtained with the nonholomorphic rational map ansatz.

Thus, while it may be that in nonextremal Skyrme configurations there are certain folding features associated with each interacting one-Skyrmion, this is not necessarily apparent in the extremal configurations.

It might be interesting to examine the number of antivacuum points, that is, the number of points where $U=-1$. A one-Skyrmion is centered around a single antivacuum point and, in a configuration of well-separated Skyrmions, the individual Skyrmions can be thought of as being positioned at the antivacuum points. However, as the Skyrmions approach each other, there may be more antivacuum points, some with positive Jacobian and some with negative. This is certainly what is implied by the folding seen in the three-Skyrmion and $B=5^*$ saddle point, and by the corresponding monopole configurations.

The topological charge of a BPS monopole is equal to the number of zeros of the Higgs field provided that the zeros are counted with their multiplicity. Furthermore, well-separated one-monopoles are centered around a zero of the Higgs field. However, the total number of zeros can exceed the topological charge. In Ref. 29, three-monopole fields were calculated using the mixture of analytic and numerical methods first described in Refs. 30 and 16. It was found that the number of zeros of the Higgs field can be as high as seven, with five zeros of positive winding number and two of negative winding number. In Ref. 17, the cubic four-monopole, octahedral five-monopole and dodecahedral seven-monopole calculated in Refs. 30, 16, and 31 were examined and it was found that zeros with negative winding number occur for the octahedral five-monopole but not for the cubic four-monopole and the dodecahedral seven-monopole. This pattern is mimicked by what we have found for Skyrmions. This possibility was discussed in Ref. 17.

It is also interesting that in monopole dynamics, as an individual monopole approaches other monopoles, its zero of the Higgs field often splits into three zeros, two with positive winding and one with negative winding.[29,17] Perhaps something similar happens in the case of Skyrmions.

ACKNOWLEDGMENTS

We would like to thank N. S. Manton for useful discussion and for drawing our attention to the literature concerning the singularities of differentiable maps. One of us, S.K., thanks PPARC and the Studienstiftung des deutschen Volkes for financial assistance.

APPENDIX: NUMERICAL RESULTS

For convenience the main numerical results have been gathered together in Table IV. As discussed earlier, the table shows that the minima of $\mathcal{I}$ and $\mathcal{J}$ do not coincide and so the more general nonholomorphic rational map ansatz is closer to the true energy than the holomorphic ansatz. However, only for $B=3$ and $B=5^*$ are there regions of negative baryon density. These regions are quite small.

The onset of superconductivity in a domain with a corner

Hala T. Jadallah[a)]
Department of Mathematics, Indiana University, Bloomington, Indiana 47405

(Received 5 September 2000; accepted for publication 8 May 2001)

We study the variational problem related to the onset of superconductivity that identifies the transition from the normal state to the superconducting state of a sample in the presence of an applied magnetic field. Our concern is a thin sample whose 2-D cross-section has a corner. In particular, we focus on the quarter-plane. We show a first eigenfunction minimizing the associated Rayleigh quotient exists and decays away from the corner. We also give a rigorous upper bound for the eigenvalue which is related to the critical temperature at which superconductivity emerges. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1387466]

I. INTRODUCTION

Superconductivity is a phenomenon characterized by the loss of electric resistivity and the expulsion of magnetic fields attempting to penetrate a sample. The onset of superconductivity is observed when a sample is cooled below a certain critical temperature. When the material is subjected to an applied magnetic field, the value of this critical temperature is lowered even further. In particular, very large magnetic fields destroy superconductivity. In the absence of superconducting behavior, the sample is in the so-called normal state, where it retains normal conductivity and permeability to magnetic fields.

Ginzburg–Landau theory provides a good framework to understand some aspects of superconductivity.[1] When a 2-D cross-section Ω of a thin cylindrical sample is subjected to a perpendicular uniform applied magnetic field of magnitude h and the sample is surrounded by insulating media, the free energy is described by

$$G(\Psi,\mathbf{A})=\int_{\Omega}\frac{1}{2}|(i\nabla+\mathbf{A})\Psi|^2+\frac{\mu}{4}(|\Psi|^2-1)^2dxdy+\frac{\kappa^2}{2\mu}\int_{\mathbf{R}^2}|\nabla\times\mathbf{A}-h\hat{\mathbf{z}}|^2dxdy.$$

Here we have chosen a nondimensionalization with respect to a characteristic radius R of the cross-section.[2] The function $\Psi:\Omega\to\mathbf{C}^2$ is the order parameter whose modulus is the density of superconducting electrons. The vector field $\mathbf{A}:\mathbf{R}^2\to\mathbf{R}^2$ is the magnetic potential with $\nabla\times\mathbf{A}=(0,0,A_x^{(2)}-A_y^{(1)})$ being the induced magnetic field. The GL parameter κ is the ratio of two material characteristic lengths and μ is a temperature related parameter defined by

$$\mu=\frac{R^2(T_c-T)}{\xi_0^2T_c}.$$

Here T is the temperature, T_c is the critical temperature in the absence of the applied magnetic field and ξ_0 is the coherence length at zero temperature.

For the pair $(\Psi,\mathbf{A})$ to be achievable physical states, for a given temperature and applied magnetic field strength h, they should be stable critical points of the free energy G. In particular, as Giorgi and Phillips proved in Ref. 3, for very large values of h the only critical point is the normal state in which $\Psi\equiv0$ and $\mathbf{A}=h\mathbf{A_n}$ such that $\nabla\times\mathbf{A_n}=\hat{\mathbf{z}}$.

a)Electronic mail: hjadalla@indiana.edu

Our interest lies in studying the onset of superconductivity as it bifurcates from the normal solution. This occurs as the temperature drops below the critical value and the normal state is no longer a stable physical state. We look at the second variation of G at $(0,h\mathbf{A_n})$ to detect such a change in behavior:

$$\delta^2 G((0,h\mathbf{A_n});\phi,\mathbf{B}) = \int_\Omega |(i\nabla + h\mathbf{A_n})\phi|^2 - \mu|\phi|^2 + \frac{\kappa^2}{\mu}|\nabla\times\mathbf{B}|^2 dxdy.$$

The second variation is positive for values of μ below the value determined by the minimization problem:

$$\lambda(h) = \inf_{\phi\in H^1(\Omega)} \frac{\int_\Omega |(i\nabla + h\mathbf{A_n})\phi|^2 dxdy}{\int_\Omega |\phi|^2 dxdy}. \tag{1.1}$$

Hence, the normal state is no longer stable for values of $\mu > \lambda(h)$.

A critical point of the variational problem (1.1) satisfies the linear elliptic eigenvalue problem:

$$(i\nabla + h\mathbf{A_n})^2\Psi = \lambda(h)\Psi \quad \text{in } \Omega, \tag{1.2}$$

$$(i\nabla + h\mathbf{A_n})\Psi\cdot\nu = 0 \quad \text{on } \partial\Omega, \tag{1.3}$$

where ν is the outer unit normal vector to $\partial\Omega$. Alternatively, this problem arises from linearizing the Euler–Lagrange system of the free energy $G(\Psi,\mathbf{A})$ about the normal state.

In an attempt to study the effect of the boundary on the onset of superconductivity, Saint James and de Gennes[4] considered the case in which Ω is the half-plane with applied magnetic field strength $h=1$. They found that the solution of the eigenvalue problem concentrates on the boundary and decays exponentially towards the interior. They approximate the minimum eigenvalue of the half-plane to be about 0.59. From now on we will denote this eigenvalue $\lambda(1)$ of the half-plane by $\lambda_{\mathbf{H}}$.

More recently, using a perturbation method for nonlinear bifurcation problems initiated by Millman and Keller,[5] Chapman[6] pursued a more complete formal analysis of the half-plane. Shifting the investigation to samples with bounded cross-section, Bauman Phillips and Tang[7] investigated stability issues in great detail via bifurcation theory with regard to the onset of superconductivity in a disc. They showed that the minimum eigenvalue for the disc is lower than that for the half-plane by a term proportional to the curvature of the disc. Along with that they showed that superconductivity emerges uniformly around the boundary of the disc with a big vortex at the core.

Bernoff and Sternberg[8] pursued the case of a general bounded domain with smooth boundary. Using formal asymptotics they found that the first eigenfunction would concentrate exponentially at the boundary point of maximum curvature. Again, they found that the minimum eigenvalue is less than that for the half-plane by a term proportional to the maximum curvature of the boundary. The expansion for $\lambda(h)$ on bounded smooth domains was found to take the form

$$\lambda(h) \sim \lambda_{\mathbf{H}} h - \frac{\kappa_{\max}}{3I_0} h^{1/2} \quad \text{for } h \gg 1, \tag{1.4}$$

where $\kappa_{\max}$ is the maximum curvature on the boundary of the domain and I_0 is a universal constant. A rigorous argument capturing the first term in this expansion can be found in Refs. 9 and 10. Note the implication here is that superconductivity is induced at a higher temperature in domains with a large maximum curvature.

Naturally this leads one to look at domains with corners where the curvature is infinite. In this article we will study domains with right angles. One might then expect that at the transition, the order parameter concentrates at the corner. By analogy with the case of smooth bounded domains, where the expansion of the minimum eigenvalue has the value for the half-plane at the leading

order [cf. (1.4)], one would expect for square domains that the leading order value would correspond to the quarter-plane. This yields our motivation in this article to study the problem on the quarter-plane.

A striking feature of the eigenvalue problem on the half-plane is the nonexistence of an L^2 eigenfunction. This can be understood intuitively when one recognizes that the boundary of this domain consists of an infinite straight line. As all points along the boundary look the same, one would not expect any decay along that direction. To make this nonexistence rigorous is nontrivial however (see Refs. 11 and 10). On the other hand, in this article we establish the existence and exponential decay of the minimizer for the quarter-plane, $\mathbf{Q}$. This is a major difference from the half-plane problem.

Theorem 1.1: *There exists a function $\Psi_\infty \in H^1(Q)$ that minimizes the energy*

$$\lambda_{\mathbf{Q}} \equiv \inf_{\Psi \in H^1(\mathbf{Q})} \frac{\int_{\mathbf{Q}} |(i\nabla + \mathbf{A})\Psi|^2 dxdy}{\int_{\mathbf{Q}} |\Psi|^2 dxdy}. \tag{1.5}$$

In particular, Ψ_∞ satisfies the problem

$$(i\nabla + \mathbf{A})^2 \Psi_\infty = \lambda_{\mathbf{Q}} \Psi_\infty \quad \text{in } \mathbf{Q}, \tag{1.6}$$

$$(i\nabla + \mathbf{A})\Psi_\infty \cdot \nu = 0 \quad \text{on } \partial\mathbf{Q}. \tag{1.7}$$

Moreover, for every multi-index α, there exist positive constants c_1^α and c_2^α such that

$$|D^\alpha \Psi_\infty(z)| \leqslant c_1^\alpha e^{-c_2^\alpha |z|} \quad \text{for all } z \in \mathbf{Q}. \tag{1.8}$$

By using similar methods we also show that the first eigenfunction in a square decays exponentially away from the four corners, cf. Theorem 3.2. The proof of Theorem 1.1 requires finding a minimizing sequence which we choose to be a sequence of minimizers of the variational problem on squares of increasing size so that they approach the quarter-plane in the limit. However, if we consider the variational problem as it is, the solution may concentrate at all four corners. As we expect a solution for the quarter-plane to concentrate at the one corner only and to decay exponentially towards the interior, we impose the Dirichlet boundary condition on the sides of the square that lie inside the quarter-plane in building our minimizing sequence.

The compactness of this sequence comes from uniform exponential estimates. For that purpose we down scale all the squares of increasing size to the unit square. With this rescaling, each function in the minimizing sequence is a minimizer on the unit square with increasing magnetic field strength. The method used in proving the exponential decay on the unit square is a blow-up argument used by del Pino, Felmer, and Sternberg[10] where they proved an exponential decay of the minimizer on the half-plane and for arbitrary bounded smooth domains away from the boundary.

On the experimental front, physicists are interested in the onset of superconductivity in many topologies including mesoscopic squares of size $2-4$ μm. In their experiments they study the temperature/field transition line (see, e.g., Refs. 12–14). In Ref. 15 we did numerical simulations using the linearized Ginzburg–Landau problem on the unit square. Our results were in good agreement with the experimental data for certain ranges for the field. Moreover, by an elementary rescaling along with the exponential decay for the eigenfunction for the problem on the quarter-plane, one can show that for large magnetic field strength the minimum eigenvalue for the unit square $\lambda(h) \sim \lambda_{\mathbf{Q}} h$, where $\lambda_{\mathbf{Q}}$ is the minimum eigenvalue for the quarter-plane. We found using finite element methods that $\lambda_{\mathbf{Q}}$ take the approximate value of 0.55. Note that the quarter-plane value is smaller than the value for the half-plane.

While in this article we address the case of a domain with a right angle corner, we intend to turn our attention next to study the nature of the dependence of the minimum eigenvalue (and

hence the temperature) on the angle in the corner. There are some numerical studies on wedges of differing angles suggesting that the eigenvalue is a monotone increasing function of the angle (see Refs. 16 and 17).

Simultaneous to our study, Almog[18] has been studying the problem on the half-infinite strip and in long rectangles of fixed width. Using Fourier transform techniques, he studies the decay of the order parameter and the location of the vortices. His approach is totally different from the one we are presenting here. We feel that our results complement his nicely, in that we are proving the *a priori* decay of the eigenfunction, thus extending the validity of Almog's use of Fourier transform techniques. He also constructs a test function which he uses to prove that the eigenvalue for the half-infinite strip is strictly less than that for the infinite strip. We will use a variant of his construction to prove a similar result comparing the smallest eigenvalue for the half-plane and the quarter-plane.

We organize the article as follows. In Section II we compare the eigenvalues of the problem on different domains and with different boundary conditions. In Sec. III we prove the exponential decay of the minimizer on the unit square for sufficiently large field strength h. We conclude in Sec. IV with the existence Theorem 1.1 in the quarter-plane.

II. EIGENVALUES: GAPS AND BOUNDS

In this section we discuss the minimum eigenvalue of the problem on different domains: the plane, the half-plane, the half-line and the quarter-plane with natural boundary conditions. In addition, we compare the minimum eigenvalue of the problem on the quarter-plane under different boundary conditions. We also discuss the relation between the eigenvalues of the quarter-plane and squares.

We denote the quarter-plane by $\mathbf{Q}=\{(x,y):x>0,y>0\}$, the half-plane by $\mathbf{H}=\{(x,y):x>0\}$ and the square of side ℓ by $Q_\ell=\{(x,y):0<x<\ell,0<y<\ell\}$.

For any domain Ω we define the h-dependent Rayleigh quotient related to (1.2) and (1.3):

$$R_\Omega(u,h)=\frac{\int_\Omega|(i\nabla+h\mathbf{A})u|^2dxdy}{\int_\Omega|u|^2dxdy},$$

and an h-independent Rayleigh quotient:

$$R_\Omega(u)=\frac{\int_\Omega|(i\nabla+\mathbf{A})u|^2dxdy}{\int_\Omega|u|^2dxdy}.$$

Here $\mathbf{A}$ is a vector field describing the normal state which satisfies

$$\nabla\times\mathbf{A}\equiv(0,0,A_x^{(2)}-A_y^{(1)})=(0,0,1). \tag{2.1}$$

We note that the infima of these Rayleigh quotients are independent of the particular choice of $\mathbf{A}$ in the light of the gauge invariance recorded in the following lemma:

Lemma 2.1: For $\psi\in H^1(\Omega,\mathbf{C})$, $\phi\in H^1(\Omega,\mathbf{R})$ *and* $\mathbf{A}\in C^1(\mathbf{R}^2,\mathbf{R}^2)$, *we have*

$$\int_\Omega|(i\nabla+\mathbf{A})\psi|^2dxdy=\int_\Omega|(i\nabla+\mathbf{A}+\nabla\phi)\psi e^{i\phi}|^2dxdy.$$

Moreover, if ψ *solves the equation*

$$(i\nabla+\mathbf{A})^2\psi=\lambda\psi \quad in \quad \Omega,$$

then $\tilde{\psi}=\psi e^{i\phi}$ *solves the equation*

$$(i\nabla+\mathbf{A}+\nabla\phi)^2\tilde{\psi}=\lambda\tilde{\psi} \quad in \quad \Omega.$$

We start with the following lemma concerning the minimization problem on the full-plane $\mathbf{R}^2$:

Lemma 2.2 (cf. Refs. 10 and 11). *For* $\mathbf{A}:\mathbf{R}^2\to\mathbf{R}^2$ *satisfying (2.1), we have*

$$\lambda_{\mathbf{R}^2}\equiv \inf_{\psi\in H^1(\mathbf{R}^2)} \frac{\int_{\mathbf{R}^2}|(i\nabla+\mathbf{A})\psi|^2 dxdy}{\int_{\mathbf{R}^2}|\psi|^2 dxdy}=1.$$

The proof uses the Gaussian as a test function and makes use of Fourier series techniques.

Now we consider the 2-D problem on the half-plane $\mathbf{H}$ which is connected to the 1-D problem on the half-line given by

$$-\psi''+(x-\beta)^2\psi=\lambda\psi \quad x\in(0,\infty), \tag{2.2}$$

$$\psi'(0)=0 \quad \psi(\infty)=0. \tag{2.3}$$

This connection comes up when one seeks a solution to (1.2) and (1.3) with $\mathbf{A}=(0,x)$ via separation of variables. Then one finds that Ψ has the form $\Psi(x,y)=\psi(x)e^{i\beta y}$ for any real number β. Recall that because of gauge invariance the choice of the vector field $\mathbf{A}$ leaves the modulus unchanged and the eigenvalue the same. For each $\beta\in\mathbf{R}$, the first eigenvalue $\lambda(\beta)$ can be captured by minimizing the associated Rayleigh quotient:

$$\lambda(\beta)=\inf_{\psi\in H^1((0,\infty))}\frac{\int_0^\infty(\psi')^2+(x-\beta)^2\psi^2 dx}{\int_0^\infty\psi^2 dx}. \tag{2.4}$$

Minimizing over β one finds the following.

Theorem 2.3: (cf. Refs. 19 and 20)

(i) There is a unique number $\beta^*\in\mathbf{R}$ *such that*

$$\lambda_1\equiv\lambda(\beta^*)=\inf_{\beta\in\mathbf{R}}\lambda(\beta), \quad \beta^*=\sqrt{\lambda_1}.$$

(ii) The corresponding first eigenfunction $\psi_1(x)$ *decays exponentially as* $x\to\infty$.

Proof: See Refs. 19 and 20.

We note that standard numerical schemes yield that $\lambda_1\approx 0.59$.

Proposition 2.4: The value λ_1, *defined in Theorem 2.3, is the same as the first eigenvalue for the half-plane. That is,*

$$\lambda_1=\lambda_{\mathbf{H}}\equiv \inf_{\phi\in H^1(\mathbf{H})} R_{\mathbf{H}}(\phi).$$

The proof involves straightforward use of the Fourier transform. See Ref. 11.

Next we turn to the eigenvalue problem on squares and their relation to the eigenvalue problem on the quarter-plane. We want to minimize the Rayleigh quotient on the unit square, among competitors that vanish on the sides of the square that lie inside the quarter-plane. We denote this portion of ∂Q_1 by $\Gamma_D^1=\{(x,y)\in\partial Q_1: x=1 \text{ or } y=1\}$. More precisely, we consider

$$\lambda(h)=\inf_{\substack{u\in H^1(Q_1)\\ u=0 \text{ on } \Gamma_D^1}} R_{Q_1}(u,h). \tag{2.5}$$

We will frequently invoke the transformation $\tilde{z}=\sqrt{h}\,z$, for $z\in Q_1$. This maps Q_1 onto $Q_{\sqrt{h}}$. As a result, this transformation allows us to rewrite the Rayleigh quotient on Q_1 as

$$R_{Q_1}(u,h)=hR_{Q_{\sqrt{h}}}(u).$$

This implies that

$$\frac{\lambda(h)}{h} = \inf_{\substack{u \in H^1(Q_{\sqrt{h}}) \\ u=0 \text{ on } \Gamma_D^{\sqrt{h}}}} R_{Q_{\sqrt{h}}}(u), \tag{2.6}$$

where obviously $\Gamma_D^{\sqrt{h}} = \{(x,y) \in \partial Q_{\sqrt{h}} : x = \sqrt{h} \text{ or } y = \sqrt{h}\}$.

We find out that these eigenvalues have the following property:

Lemma 2.5: The sequence $\{\lambda(h)/h\}_{h>0}$ *is a monotone decreasing sequence.*

Proof: First note that for any $h>0$ the minimizer to (2.6) exists by the direct method of the calculus of variations. Now suppose that $h_1 < h_2$. Let v_{h_1} be a minimizer of the problem on $Q_{\sqrt{h_1}}$. With v_{h_1} vanishing on $\Gamma_D^{\sqrt{h_1}}$ we may extend it to be zero on $\mathbf{Q} - Q_{\sqrt{h_1}}$. Hence v_{h_1} can be viewed as a competitor for the eigenvalue problem on $Q_{\sqrt{h_2}}$. Therefore,

$$\frac{\lambda(h_2)}{h_2} \leqslant R_{Q_{\sqrt{h_2}}}(v_{h_1}) = R_{Q_{\sqrt{h_1}}}(v_{h_1}) = \frac{\lambda(h_1)}{h_1}.$$

Thus $\{\lambda(h)/h\}_{h>0}$ is decreasing. ■

Remark 2.6: As a result of this lemma the sequence $\{\lambda(h)/h\}_{h>0}$ is bounded and $\lim_{h\to\infty} \lambda(h)/h$ exists. Furthermore, using a similar argument to the previous lemma one finds $\lambda_{\mathbf{Q}} \leqslant \lambda(h)/h$, for $h>0$. In fact, as a by-product of Theorem 4.1 we will find that $\lambda_{\mathbf{Q}} = \lim_{h\to\infty} \lambda(h)/h$.

In Ref. 18, Almog studies the related problem on the infinite strip and the half-infinite strip of a fixed width. In determining that the eigenvalues for the full strip and the semi-strip are separated, he provides a key test function that makes use of the first eigenfunction of the 1-D problem on a finite interval. By making an analogous construction in a quarter-plane we obtain the following result.

Theorem 2.7: (Cf. Ref. 18, Lemma 3.)

(i) For any vector fields $\mathbf{A}:\mathbf{R}^2 \to \mathbf{R}^2$ *and* $\mathbf{B}:\mathbf{R}^2 \to \mathbf{R}^2$ *with* $\nabla \times \mathbf{A} = \nabla \times \mathbf{B} = (0,0,1)$,

$$\lambda_{\mathbf{Q}} \equiv \inf_{\phi \in H^1(\mathbf{Q})} \frac{\int_{\mathbf{Q}} |(i\nabla + \mathbf{A})\phi|^2 dxdy}{\int_{\mathbf{Q}} |\phi|^2 dxdy} < \inf_{\eta \in H^1(\mathbf{H})} \frac{\int_{\mathbf{H}} |(i\nabla + \mathbf{B})\eta|^2 dxdy}{\int_{\mathbf{H}} |\eta|^2 dxdy} \equiv \lambda_{\mathbf{H}}.$$

(ii) One also has

$$\lim_{h\to\infty} \frac{\lambda(h)}{h} < \lambda_{\mathbf{H}}.$$

The proof follows by evaluating the Rayleigh quotient on the quarter-plane with $\mathbf{A} = (0, x)$ and

$$\phi(x,y) = C(\epsilon)\psi_1(x)e^{i\beta^* y}(e^{-\epsilon y} + i\epsilon^{1/2}(x-\beta^*)e^{-y}), \tag{2.7}$$

where $\epsilon>0$, $C(\epsilon)$ is a positive constant such that $\epsilon < C^2(\epsilon) < 2\epsilon$ and $\psi_1(x)$ is the first eigenfunction introduced in Theorem 2.3. This choice of the test function gives

$$\lambda_{\mathbf{Q}} \leqslant \lambda_1 - 2\epsilon^{3/2}C_1 + \epsilon^2 C_2,$$

where C_1 and C_2 are positive real numbers independent of ϵ. The conclusion *(i)* of the theorem is complete in light of Proposition 2.4.

As we mentioned in Remark 2.6 the limit in *(ii)* exists. Then for the minimization problem (2.6), we use a similar construction to (2.7) but replace $\psi_1(x)$ by $\psi_1(x)\rho_h(x,y)$ where $h\to\infty$ and ρ_h is a cutoff function that vanishes on $Q - Q_{\sqrt{h}}$, in particular it vanishes on $\Gamma_D^{\sqrt{h}}$. This makes the test function a valid competitor for the mixed Neumann Dirichlet problem on a square of side $\sqrt{h}$.

Since $\psi_1(x)$ decays exponentially, the error involved when taking the limit is exponentially small. Hence (ii) follows. ■

Remark 2.8: As we noted earlier, one can numerically approximate $\lambda_{\mathbf{H}} \approx 0.59$. However, a rigorous analyical estimate of $\lambda_{\mathbf{H}} < 1$ can be seen by making a construction similar to (2.7) but using the 2-D Gaussian which is the first eigenfunction associated with $\lambda_{\mathbf{R}^2}$, the first eigenvalue for the problem on the full plane $\mathbf{R}^2$. With $\mathbf{A} = \frac{1}{2}(-y,x)$ we use the test function:

$$\eta(x,y) = \tilde{C}(\epsilon) e^{-(x^2+y^2)/4}(1 + i\epsilon y),$$

where $1/2\pi \leqslant \tilde{C}(\epsilon) \leqslant 1/\pi$. Plugging the test function in the Rayliegh quotient we find that

$$\lambda_{\mathbf{H}} \leqslant 1 - \frac{\epsilon}{\sqrt{2\pi}} + 2\epsilon^2.$$

Now we introduce some related eigenvalue problems that will emerge in the next section. In all of these, **A** satisfies (2.1). We start with the Dirichlet problem,

$$\lambda_{HD} = \inf_{\substack{\phi \in H^1(\mathbf{H}) \\ \phi = 0 \text{ on } \partial\mathbf{H}}} \frac{\int_{\mathbf{H}} |(i\nabla + \mathbf{A})\phi|^2 dxdy}{\int_{\mathbf{H}} |\phi|^2 dxdy} \equiv \inf_{\substack{\phi \in H^1(\mathbf{H}) \\ \phi = 0 \text{ on } \partial\mathbf{H}}} R_{\mathbf{H}}(\phi), \tag{2.8}$$

and the associated problem,

$$(i\nabla + \mathbf{A})^2 \Psi = \lambda \Psi \quad \text{in } \mathbf{H}, \tag{2.9}$$

$$\Psi = 0 \quad \text{on } \partial\mathbf{H}. \tag{2.10}$$

Similarly we consider the Dirichlet problem in **Q**,

$$\lambda_{QD} = \inf_{\substack{\phi \in H^1(\mathbf{Q}) \\ \phi = 0 \text{ on } \partial\mathbf{Q}}} \frac{\int_{\mathbf{Q}} |(i\nabla + \mathbf{A})\phi|^2 dxdy}{\int_{\mathbf{Q}} |\phi|^2 dxdy} \equiv \inf_{\substack{\phi \in H^1(\mathbf{Q}) \\ \phi = 0 \text{ on } \partial\mathbf{Q}}} R_{\mathbf{Q}}(\phi), \tag{2.11}$$

and the associated problem

$$(i\nabla + \mathbf{A})^2 \Psi = \lambda \Psi \quad \text{in } \mathbf{Q}, \tag{2.12}$$

$$\Psi = 0 \quad \text{on } \partial\mathbf{Q}. \tag{2.13}$$

Finally we introduce the eigenvalue problem for mixed Neumann and Dirichlet boundary conditions in the quarter-plane:

$$\lambda_{QM} = \inf_{\substack{\phi \in H^1(\mathbf{Q}) \\ \phi = 0 \text{ on } \Gamma_D}} \frac{\int_{\mathbf{Q}} |(i\nabla + \mathbf{A})\phi|^2 dxdy}{\int_{\mathbf{Q}} |\phi|^2 dxdy} \equiv \inf_{\substack{\phi \in H^1(\mathbf{Q}) \\ \phi = 0 \text{ on } \Gamma_D}} R_{\mathbf{Q}}(\phi), \tag{2.14}$$

where $\Gamma_D = \{(x,y) \in \partial\mathbf{Q} : x = 0 \text{ and } y \geqslant 0\}$, and consider the associated problem:

$$(i\nabla + \mathbf{A})^2 \Psi = \lambda \Psi \quad \text{in } \mathbf{Q}, \tag{2.15}$$

$$(i\nabla + \mathbf{A})\Psi \cdot (0,-1) = 0 \quad \text{on } \Gamma_N, \tag{2.16}$$

$$\Psi = 0 \quad \text{on } \Gamma_D, \tag{2.17}$$

where $\Gamma_N = \{(x,y) \in \partial\mathbf{Q} : y = 0 \text{ and } x > 0\}$.

In the next lemma we compare these different eigenvalues.

Lemma 2.9:

(i) $\lambda_{\mathbf{H}} \leqslant \lambda_{QM} \leqslant \lambda_{QD}$.
(ii) $\lambda_{\mathbf{H}} \leqslant \lambda_{HD}$.

Proof: To prove $\lambda_H \leqslant \lambda_{QM}$, consider any competitor for the mixed boundary value problem on the quarter-plane (2.15)–(2.17), $\Psi \in H^1(\mathbf{Q})$, $\Psi \equiv 0$ on Γ_D. We define $\tilde{\Psi}$ on $\mathbf{H}$ by extending Ψ to be identically zero on the left quarter plane. Now $R_{\mathbf{H}}(\tilde{\Psi}) = R_{\mathbf{Q}}(\Psi)$ implies that $\lambda_{\mathbf{H}} \leqslant R_{\mathbf{Q}}(\Psi)$ for any $\Psi \in H^1(\mathbf{Q})$ with $\Psi \equiv 0$ on Γ_D, so we conclude that $\lambda_{\mathbf{H}} \leqslant \lambda_{QM}$. The inequality $\lambda_{QM} \leqslant \lambda_{QD}$ is trivial since a competitor for the Dirichlet problem is also a competitor for the variational problem with mixed boundary conditions. Similarly $\lambda_{\mathbf{H}} \leqslant \lambda_{HD}$. ■

The next lemma affirms the nonexistence of nontrivial bounded solutions for the boundary value problems (2.9) and (2.10), (2.12) and (2.13), and (2.15)–(2.17), where λ is below the associated first eigenvalues. By a solution we mean a classical solution to the partial differential equation (PDE), classically satisfying the boundary conditions away from the corner (for the case $\mathbf{Q}$) and lying in $H^2_{\mathrm{loc}}(\mathbf{Q})$ in this case.

Lemma 2.10:

(i) *If* $\lambda < \lambda_{\mathbf{R}^2}$, *then there are no nontrivial bounded solutions to the equation* $(i\nabla + \mathbf{A})^2 \Psi = \lambda \Psi$ *in* $\mathbf{R}^2$.
(ii) *If* $\lambda < \lambda_{\mathbf{H}}$, *then there are no nontrivial bounded solutions to the equation* $(i\nabla + \mathbf{A})^2 \Psi = \lambda \Psi$ *on* $\mathbf{H}$ *satisfying* $(i\nabla + \mathbf{A})\Psi \cdot (-1,0) = 0$ *on* $\partial \mathbf{H}$.
(iii) *If* $\lambda < \lambda_{HD}$, *then there are no nontrivial bounded solutions to (2.9) and (2.10).*
(iv) *If* $\lambda < \lambda_{QM}$, *then there are no nontrivial bounded solutions to (2.15)–(2.17).*
(v) *If* $\lambda < \lambda_{QD}$, *then there are no nontrivial bounded solutions to (2.12) and (2.13).*

Proof: Property (i) is proved in Ref. 11 (Prop. 2.3) and property *(ii)* is proved in Ref. 11 Lemma 5.1 Also, an alternative proof is given in Ref. 10, Theorem 3.2. Property *(iii)* is proved similar to (ii). To prove (iv), we follow the proof of Ref. 11, Lemma 5.1. The argument proceeds by contradiction. Assume that ψ is a nontrivial bounded solution of (2.15)–(2.17) for $\lambda < \lambda_{QM}$. For each positive integer k, let η_k be a non-negative smooth cut off function such that $\mathrm{spt}(\eta_k) \subset B(0,2k)$, $\eta_k \equiv 1$ on $B(0,k)$, $|\nabla \eta_k| < 2/k$. Multiplying the PDE (2.15) by the test function $\eta_k \overline{\Psi}$ and using that $\Psi \in H^2_{loc}(\mathbf{Q})$, we may carry out integration by parts. We find that the boundary terms vanish due to the boundary conditions (2.16) and (2.17) and η_k vanishing on the $\partial B(0,2k)$. So we obtain the integral equation:

$$\int_{\mathbf{Q}} |(i\nabla + \mathbf{A})(\eta_k \Psi)|^2 = \lambda \int_{\mathbf{Q}} |\Psi|^2 |\eta_k|^2 + \int_{\mathbf{Q}} |\nabla \eta_k|^2 |\Psi|^2. \tag{2.18}$$

Since $(\eta_k \Psi) \in H^1(\mathbf{Q})$ is a competitor of the minimization problem we find that

$$(\lambda_{QM} - \lambda) \int_{\mathbf{Q}} |\eta_k|^2 |\Psi|^2 < \int_{\mathbf{Q}} |\nabla \eta_k|^2 |\Psi|^2.$$

Since $\Psi \in L^\infty(\mathbf{Q})$ we find for every positive integer k

$$(\lambda_{QM} - \lambda) \int_{B(0,k)} |\Psi|^2 \leqslant 4\pi \|\Psi\|_{L^\infty(\mathbf{Q})}.$$

Hence $\Psi \in L^2(\mathbf{Q})$. Therefore,

$$(\lambda_{QM}-\lambda)\leqslant \frac{4}{k^2}\frac{\|\Psi\|^2_{L^2(\mathbf{Q})}}{\|\Psi\|^2_{L^2(B(0,k))}},$$

and as $k\to\infty$ we conclude that $\lambda_{QM}=\lambda$, a contradiction.

Property *(v)* is proved similarly. ■

A. An upper bound on $\lambda_{\mathbf{Q}}$

Recall from Theorem 2.7 that $\lambda_{\mathbf{Q}}<\lambda_{\mathbf{H}}$. However, this theorem does not provide a quantitative value for the gap between the two values. Applying any of the standard numerical schemes, one finds $\lambda_{\mathbf{H}}=\lambda_1\approx 0.59$. Using finite elements, on the other hand, we find that $\lambda_{\mathbf{Q}}\approx 0.55$ (see Ref. 15). We conclude this section with a rigorous upper bound on $\lambda_{\mathbf{Q}}$ using a specific test function. References 17 and 21 made attempts to provide an upper bound on wedges using a similar construction; however, theirs lack a term similar to $e^{i(1/3)r^3q(\theta)}$.

Proposition 2.11: The eigenvalue $\lambda_{\mathbf{Q}}$ for the quarter-plane satisfies the upper bound $\lambda_{\mathbf{Q}}\leqslant 0.5772$

Proof: We define a test function on the quarter-plane. To this end, we describe the quarter-plane in polar coordinates $\{(r,\theta): r>0 \text{ and } 0\leqslant\theta\leqslant\pi/2\}$. The test function for (1.5) that we propose is

$$u(r,\theta)=e^{-(r^2/2)s(\theta)}e^{i(rp(\theta)+(1/2)r^2g(\theta)+(1/3)r^3q(\theta))}, \tag{2.19}$$

where $s(\theta)=a_0(5+\sin^2(2\theta))$, $g(\theta)=\frac{1}{4}\sin(4\theta)$, $p(\theta)=a_1\cos(2\theta)$, $q(\theta)=a_2(\cos(6\theta)-1.7\cos(2\theta))$.

Here a_0, a_1, and a_2 are real numbers which will be determined by minimizing the functional with the restriction that a_0 be positive. It is clear that $u\in C^\infty(\mathbf{Q})\cap H^1(\mathbf{Q})$. Due to gauge invariance of the energy and the choice of polar coordinates of the test function, it is convenient to choose $\mathbf{A}=\frac{1}{2}r(-\sin\theta,\cos\theta)=\frac{1}{2}r\mathbf{e}_\theta$, where $\mathbf{e}_\theta$ is the unit tangent vector.

Via change of variable we have for any function v:

$$|(i\nabla+\mathbf{A})v|^2=\left\{\left|\frac{\partial v}{\partial r}\right|^2+\frac{1}{r^2}\left|\frac{\partial v}{\partial\theta}\right|^2+\frac{i}{2}\left(\overline{v}\frac{\partial v}{\partial\theta}-v\frac{\partial\overline{v}}{\partial\theta}\right)+\frac{r^2}{4}|v|^2\right\}\equiv F\left[v,\frac{\partial v}{\partial r},\frac{\partial v}{\partial\theta}\right].$$

The Rayleigh quotient $R_{\mathbf{Q}}(u)$ would appear in polar coordinates in the form

$$R_Q(u)=\frac{\int_0^{\pi/2}\int_0^\infty F[u,\partial u/\partial r,\partial u/\partial\theta]r\,dr\,d\theta}{\int_0^{\pi/2}\int_0^\infty |u|^2 r\,dr\,d\theta}.$$

In computing $R_{\mathbf{Q}}(u)$ we write $|\partial u/\partial r|^2$, $|\partial u/\partial\theta|^2$, $-\mathrm{Im}(\overline{u}\partial u/\partial\theta)\equiv(i/2)(\overline{u}\partial u/\partial\theta-u\,\partial\overline{u}/\partial\theta)$ and $|u|^2$ in terms of s,g,p and q:

$$\left|\frac{\partial u}{\partial r}\right|^2=[r^2s(\theta)^2+(rg(\theta)+p(\theta)+r^2q(\theta))^2]e^{-r^2s(\theta)},$$

$$\left|\frac{\partial u}{\partial\theta}\right|^2=\left[\left(-\frac{1}{2}r^2s'(\theta)\right)^2+\left(\frac{1}{2}r^2g'(\theta)+rp'(\theta)+\frac{1}{3}r^3q'(\theta)\right)^2\right]e^{-r^2s(\theta)},$$

$$-\mathrm{Im}\left(\overline{u}\frac{\partial u}{\partial\theta}\right)=\left(-\frac{1}{2}r^2g'(\theta)-rp'(\theta)-\frac{1}{3}r^3q'(\theta)\right)e^{-r^2s(\theta)},$$

$$|u|^2=e^{-r^2s(\theta)}.$$

Recall that the functions s, g, p and q depend on free values a_0, a_1 and a_2. Therefore we write the energy to indicate this dependence:

$$R_Q(u)=\tilde{R}_Q(a_0,a_1,a_2)=\frac{I_1+I_2+I_3+I_4}{I_5},$$

where

$$\begin{aligned}
I_1&=\int_0^{\pi/2}\int_0^{\infty}\left|\frac{\partial u}{\partial r}\right|^2 r\,dr\,d\theta\\
&=\int_0^{\pi/2}\frac{s^2(\theta)}{2s^2(\theta)}+\frac{g^2(\theta)}{2s^2(\theta)}+\frac{p^2(\theta)}{2s(\theta)}+\frac{q^2(\theta)}{s^3(\theta)}\\
&\quad+\frac{2\sqrt{\pi}g(\theta)p(\theta)}{4s(\theta)^{3/2}}+\frac{6\sqrt{\pi}g(\theta)q(\theta)}{8s(\theta)^{5/2}}+\frac{p(\theta)q(\theta)}{2s(\theta)^2}\,d\theta,\\
I_2&=\int_0^{\pi/2}\int_0^{\infty}\frac{1}{r^2}\left|\frac{\partial u}{\partial \theta}\right|^2 r\,dr\,d\theta\\
&=\int_0^{\pi/2}\frac{s'(\theta)}{8s(\theta)^2}+\frac{g'(\theta)^2}{8s(\theta)^2}+\frac{p'(\theta)^2}{2s(\theta)}+\frac{q'(\theta)^2}{9s(\theta)^3}\\
&\quad+\frac{g'(\theta)p'(\theta)\sqrt{\pi}}{4s(\theta)^{3/2}}+\frac{\sqrt{\pi}g'(\theta)q'(\theta)}{8s(\theta)^{5/2}}+\frac{p'(\theta)q'(\theta)}{3s(\theta)^2}\,d\theta,\\
I_3&=\int_0^{\pi/2}\int_0^{\infty}-\mathrm{Im}\left(\overline{u}\frac{\partial u}{\partial \theta}\right) r\,dr\,d\theta\\
&=\int_0^{\pi/2}-\frac{g'(\theta)}{2s(\theta)^2}-\frac{\sqrt{\pi}p'(\theta)}{4s(\theta)^{3/2}}-\frac{\sqrt{\pi}q'(\theta)}{8s(\theta)^{5/2}}\,d\theta,\\
I_4&=\int_0^{\pi/2}\int_0^{\infty}\frac{r^2}{4}|u|^2 r\,dr\,d\theta\\
&=\int_0^{\pi/2}\frac{1}{8s(\theta)^2}\,d\theta,\\
I_5&=\int_0^{\pi/2}\int_0^{\infty}|u|^2 r\,dr\,d\theta\\
&=\int_0^{\pi/2}\frac{1}{2s(\theta)}\,d\theta.
\end{aligned}$$

Through a laborious but straightforward use of elementary integration techniques, we find that each term above can be integrated in closed form. To give a feel for that process we include the ones appearing in I_1:

$$\int_0^{\pi/2}\frac{g(\theta)^2}{s(\theta)^2}\,d\theta=\frac{1}{a_0^2\,32}\left[-4\theta-\frac{11\arctan(\sqrt{(5/6)}\cot(2\theta))}{\sqrt{30}}-\frac{\sin(4\theta)}{2(5+\sin(2\theta)^2)}\right]_0^{\pi/2},$$

$$\int_0^{\pi/2} \frac{p(\theta)^2}{2s(\theta)}\,d\theta = \frac{a_1^2}{2\,a_0}\left[-\theta - \sqrt{\frac{3}{10}}\arctan\left(\sqrt{\frac{5}{6}}\cot(2\theta)\right)\right]_0^{\pi/2},$$

$$\int_0^{\pi/2} \frac{q(\theta)^2}{s(\theta)^3}\,d\theta = \frac{a_2^2}{8000\,a_0^3}\left[\frac{10\,523\,927\arctan(\sqrt{(5/6)}\cot(2\theta))}{30\sqrt{30}} - 1\,280\,000\theta + \frac{37249\sin(4\theta)}{(5+\sin(2\theta)^2)^2} - \frac{1368563\sin(4\theta)}{60(5+\sin(2\theta)^2)}\right]_0^{\pi/2},$$

$$\int_0^{\pi/2} \frac{\sqrt{\pi}g(\theta)p(\theta)}{2s(\theta)^{3/2}}\,d\theta = \frac{a_1\sqrt{\pi}}{8a_0^{3/2}}\left[-\frac{\cos(2\theta)}{\sqrt{5+\sin^2(2\theta)}} + \arctan\left(\frac{\cos(2\theta)}{\sqrt{5+\sin^2(2\theta)}}\right)\right]_0^{\pi/2},$$

$$\int_0^{\pi/2} \frac{3\sqrt{\pi}g(\theta)q(\theta)}{4s(\theta)^{5/2}}\,d\theta = \frac{3a_2\sqrt{\pi}}{16a_0^{5/2}}\left[\frac{-193\cos^3(2\theta)}{180(5+\sin^2(\theta))^{3/2}} + \frac{4\cos(2\theta)}{(5+\sin^2(2\theta))^{1/2}} - 4\arctan\left(\frac{\cos(2\theta)}{\sqrt{5+\sin^2(2\theta)}}\right)\right]_0^{\pi/2},$$

$$\int_0^{\pi/2} \frac{p(\theta)q(\theta)}{s(\theta)^2}\,d\theta = \frac{a_1a_2}{a_0^2}\left[4\theta + \frac{2207\arctan(\sqrt{5/6}\cot(2\theta))}{200\sqrt{30}} + \frac{193\sin(4\theta)}{400(5+\sin^2(2\theta))}\right]_0^{\pi/2}.$$

To find the desired minimum value, we feed the energy $\tilde{R}(a_0,a_1,a_2)$ into Mathematica and minimize over the parameters a_0, a_1 and a_2. The minimum is acheived at the values $a_0 = 0.051\,853$, $a_1 = -0.052\,868\,9$, and $a_2 = 0.031\,566$. Substituting these values into $\tilde{R}_Q(a_0,a_1,a_2)$, the value obtained is 0.577 23. ■

III. EXPONENTIAL DECAY

The main theorem of this section provides exponential decay for minimizers of the eigenvalue problem on the unit square in the regime $h \gg 1$. The argument is inspired by that used in the proof in Ref. 10, Theorems 3.1 and 4.3, and uses a blow-up argument. In Theorem 3.1 they prove that the minimizer decays exponentially away from the boundary of the half-plane, while in Theorem 4.3, they prove that a minimizer of the problem on any smooth bounded domain decays exponentially away from the boundary. Turning to the case of the unit square, however, we shall see that new issues emerge which lead us to confront the eigenvalue problems (2.9)–(2.17) introduced in the previous section. Recall that $\Gamma_D^1 = \{(x,y) \in \partial Q_1 : x = 1 \text{ or } y = 1\}$.

Theorem 3.1: *Let* $\{\Psi^h\}$ *be any sequence of eigenfunctions that minimize the energy*

$$\lambda(h) = \inf_{\substack{\Psi \in H^1(Q_1) \\ \Psi = 0 \text{ on } \Gamma_D^1}} \frac{\int_{Q_1} |(i\nabla + h\mathbf{A})\Psi|^2 dxdy}{\int_{Q_1} |\Psi|^2},$$

normalized so that $\|\Psi^h\|_{L^2(Q_1)} = 1$. *Then there exists a constant* $h_0 > 0$ *and for every multi-index* α, *there exist positive constants* c_1^α *and* c_2^α *independent of* h *such that*

$$|D^\alpha \Psi^h(z)| \leqslant (\sqrt{h})^{|\alpha|} c_1^\alpha e^{-c_2^\alpha \sqrt{h}|z|} \quad \text{for all} \quad z = (x,y) \in Q_1 \quad \text{and} \quad h \geqslant h_0.$$

Theorem 3.2: *Let* $\{\Psi^h\}$ *be any sequence of eigenfunctions that minimize the energy*

$$\lambda(h)=\inf_{\Psi\in H^1(Q_1)}\frac{\int_{Q_1}|(i\nabla+h\mathbf{A})\Psi|^2dxdy}{\int_{Q_1}|\Psi|^2},$$

normalized so that $\|\Psi^h\|_{L^2(Q_1)}=1$. *Then there exists a constant* $h_0>0$ *and for every multi-index* α, *there exist positive constants* c_1^α *and* c_2^α *independent of* h *such that*

$$|D^\alpha\Psi^h(z)|\leqslant(\sqrt{h})^{|\alpha|}c_1^\alpha e^{-c_2^\alpha\sqrt{h}\tilde{d}(z)}\quad \textit{for all}\quad z=(x,y)\in Q_1\quad \textit{and}\quad h\geqslant h_0,$$

where

$$\tilde{d}(z)=\min_{1\leqslant i\leqslant 4} dist(z,p_i)\quad \textit{and}\quad p_i\in\{(0,0),(1,0),(0,1),(1,1)\}.$$

Theorem 3.3: *Let* Ψ *be any bounded solution to* $(i\nabla+\mathbf{A})^2\Psi=\lambda\Psi$ *in the quarter-plane* $\mathbf{Q}$, *with* $(i\nabla+\mathbf{A})\Psi\cdot\nu=0$ *on* $\partial\mathbf{Q}$. *Then if* $\lambda<\lambda_{\mathbf{H}}$, *for every multi-index* α *there exist positive constants* c_1^α *and* c_2^α *such that*

$$|D^\alpha\Psi(z)|\leqslant c_1^\alpha e^{-c_2^\alpha|z|}\quad \textit{for all}\quad z\in\mathbf{Q}.$$

Proof of Theorem 3.1; Note that a minimizer on Q_1 is a weak solution of the Euler–Lagrange equation. By standard elliptic regularity, one finds Ψ^h is C^∞ in the interior of Q_1, and C^1 up to the boundary away from the corners. Furthermore, by an elementary reflection argument one can argue that $\Psi^h\in H^2(Q_1)$. Hence, Ψ^h is a bounded classical solution to the eigenvalue problem:

$$(i\nabla+h\mathbf{A})^2\Psi^h=\lambda(h)\Psi^h\quad \text{in}\quad Q_1, \tag{3.1}$$

$$(i\nabla+h\mathbf{A})\Psi^h\cdot\nu=0\quad \text{in}\quad \Gamma_N^1, \tag{3.2}$$

$$\Psi^h=0\quad \text{in}\quad \Gamma_D^1, \tag{3.3}$$

where $\Gamma_N^1=\{(x,y)\in\partial Q_1: x=0 \text{ or } y=0\}$, $\Gamma_D^1=\{(x,y)\in\partial Q_1: x=1 \text{ or } y=1\}$ and ν is the outer unit normal vector on Γ_N^1.

Since Ψ^h is bounded on $\overline{Q_1}$ we renormalize Ψ^h such that $\|\Psi^h\|_{L^\infty(Q_1)}=1$. Recall that by gauge invariance, choosing a different potential that satisfies (2.1) modifies Ψ^h by $e^{i\phi}$ for a suitable ϕ independent of h, hence the above exponential estimate is altered only by choosing different constants. Here it is convenient to choose $\mathbf{A}=(0,x)$.

Let $\Omega(k,h,R)=\{z\in Q_1:|z|\geqslant Rk/\sqrt{h}\}$ where k is a positive integer, $h>0$ and $R>0$. Of course for certain values of h,R and k $\Omega(k,h,R)$ will be empty. The exponential decay is equivalent to establishing the claim: There exist positive real numbers R_0 and h_0 such that

$$\|\Psi^h\|_{L^\infty(\Omega(k+1,h,R))}<\tfrac{1}{2}\|\Psi^h\|_{L^\infty(\Omega(k,h,R))} \tag{3.4}$$

for all $h\geqslant h_0$, all $R\geqslant R_0$ and all positive integers k such that $\Omega(k+1,h,R)$ is nonempty.

Proceeding by contradiction, we assume there exist sequences $R_j\to\infty$, $h_j\to\infty$ and a sequence of positive integers k_j such that $\Omega(k_j+1,h_j,R_j)$ is nonempty and

$$\|\Psi^{h_j}\|_{L^\infty(\Omega(k_j+1,h_j,R_j))}\geqslant\tfrac{1}{2}\|\Psi^{h_j}\|_{L^\infty(\Omega(k_j,h_j,R_j))}\equiv\tfrac{1}{2}m_j. \tag{3.5}$$

Define $\tilde{\Psi}^{h_j}$ by

$$\tilde{\Psi}^{h_j}(z)=\frac{\Psi^{h_j}}{m_j}.$$

Notice that for all j

$$\|\tilde{\Psi}^{h_j}\|_{L^\infty(\Omega(k_j,h_j,R_j))}=1 \tag{3.6}$$

and

$$\tfrac{1}{2}\leqslant\|\tilde{\Psi}^{h_j}\|_{L^\infty(\Omega(k_j+1,h_j,R_j))}\leqslant 1. \tag{3.7}$$

Now, (3.7) allows us to choose z_j in $\Omega(k_j+1,h_j,R_j)$ such that

$$|\tilde{\Psi}^{h_j}(z_j)|\geqslant\tfrac{1}{2}. \tag{3.8}$$

From this point we proceed to use $\tilde{\Psi}^{h_j}$ to define a sequence of uniformly bounded nonvanishing functions on bigger and bigger balls, half-balls and quarter-balls to cover $\mathbf{R}^2$, $\mathbf{H}$, and $\mathbf{Q}$, respectively. Eventually, we want to establish compactness of this sequence to obtain a limit function that leads to a contradiction of condition (3.5).

To ensure that the sequence is nonvanishing we want our blow-ups to include the points z_j, since $\tilde{\Psi}^{h_j}(z_j)$ is bounded away from zero by (3.8). Therefore we focus on the location of z_j inside Q_1, in particular its distance from the boundary of Q_1 and the corners on the boundary. By the definition of $\Omega(k_j,h_j,R_j)$, we find this situation is best described by the quantities $\sqrt{h_j}\,\mathrm{dist}(z_j,\partial Q_1)$ and $\sqrt{h_j}\,\mathrm{dist}(z_j,p)$ where p is a corner point on the boundary. Taking the limit of these quantities, there are only three possibilities:

(1) $\lim_{h_j\to\infty}\sqrt{h_j}\,\mathrm{dist}(z_j,\partial Q_1)=\infty$.
(2) There exists a positive constant C_1 such that $\mathrm{dist}(z_j,\partial Q)\leqslant C_1/\sqrt{h_j}$ and $\lim_{h_j\to\infty}\sqrt{h_j}\,\mathrm{dist}(z_j,p)=\infty$, where p is any of the corner points on ∂Q_1.
(3) There exists a positive constant C_2 and a corner point $p_0\in\{(1,0),(0,1),(1,1)\}$ such that $\mathrm{dist}(z_j,p_0)\leqslant C_2/\sqrt{h_j}$.

We attempt to draw balls, half-balls or quarter-balls containing z_j as each case above allows. We have two concerns; one is to ensure that the functions inherit uniform boundedness via (3.6). This is attained by making sure that these sets containing z_j are subsets of $\Omega(k_j,h_j,R_j)$. The other concern is that these sets, when blown-up, should increase in size in order to cover the unbounded set $\mathbf{R}^2$, $\mathbf{H}$, or $\mathbf{Q}$.

The case (1) is very similar to the case dealt with in Ref. 10, Theorem 4.3. We only describe the spirit of the argument and work out more detail in the case (2). The condition given in (1) implies that the sequence is away from the boundary or approaches the boundary slowly. Hence we can take a ball centered at z_j with radius $\tilde{R}_j/\sqrt{h_j}$ where $\tilde{R}_j=\min\{R_j,\sqrt{h_j}\mathrm{dist}(z_j,\partial Q_1)\}$. Note that as $j\to\infty$, the balls $B(0,\tilde{R}_j)$ cover $\mathbf{R}^2$.

We define the sequence functions $f_j:B(0,\tilde{R}_j)\to\mathbf{C}$ by

$$f_j(x,y)=\tilde{\Psi}_j\left(\frac{x}{\sqrt{h_j}}+x_j,\frac{y}{\sqrt{h_j}}+y_j\right)e^{-i\sqrt{h_j}\,x_j\,y},$$

where $z_j=(x_j,y_j)$. Notice that by (3.6) and (3.8)

$$|f_j(0,0)|=|\tilde{\Psi}_j(z_j)|\geqslant\tfrac{1}{2}\quad\text{and}\quad\|f_j\|_{B(0,\tilde{R}_j)}\leqslant 1.$$

Moreover, f_j solves the PDE:

$$(i\nabla+\mathbf{A})^2 f_j=\frac{\lambda(h_j)}{h_j}f_j\ \text{ in }\ B(0,\tilde{R}_j). \tag{3.9}$$

Using the PDE (3.9) and standard elliptic regularity estimates on any fixed ball $B(0,S)$, one finds the sequence is compact in $C^2(B(0,S))$. Hence through a diagonalization argument, one can extract a subsequence that converges in C^2 on compact subsets of $\mathbf{R}^2$ to a function f_∞ that solves the PDE:

$$(i\nabla+\mathbf{A})^2 f_\infty = \lim_{h_j\to\infty} \frac{\lambda(h_j)}{h_j} f_\infty \quad \text{in } \mathbf{R}^2.$$

In light of Lemma 2.2, Lemma 2.7(ii) and Remark 2.8, $\lim_{h_j\to\infty}\lambda(h_j)/h_j<1$. This contradicts Lemma 2.10(i) and hence contradicts the inequality in (3.5).

Moving on to the next scenario, condition (2), we see the sequence $\{z_j\}$ must have a limit point on either Γ_N^1 or Γ_D^1. We will treat the case when the sequence is approaching the side $\{(0,y):0<y\leqslant 1\}\subset\Gamma_N^1$ in detail. The other side of Γ_N^1 is treated similarly. Afterwards, we will briefly comment on the case when the sequence is approaching Γ_D^1.

Suppose $z_j=(x_j,y_j)$ is approaching the side $\Gamma^1_{N,\text{left}}=\{(0,y)\in\partial Q_1:0<y<1\}$ or perhaps the corner point (0,1). Condition (2) implies that for j sufficiently large

$$x_j=\text{dist}(z_j,\Gamma^1_{N,\text{left}})<\frac{C_1}{\sqrt{h_j}}<\min\left\{\frac{R_j}{2\sqrt{h_j}},1-y_j\right\}. \tag{3.10}$$

We draw half-balls centered at the point $(0,y_j)$ with a radius $\tilde{R}_j/\sqrt{h_j}$ where $\tilde{R}_j=\min\{R_j/2,\sqrt{h_j}(1-y_j)\}$. Again notice that $\tilde{R}_j\to\infty$ as $j\to\infty$ so that the half-balls when blown up will cover the half-plane $\mathbf{H}$ and that the half-balls are inside $\Omega(k_j,h_j,R_j)\subset Q_1$.

We use the conventional notation for a half-ball of radius r, $B^+(0,r)=\{(x,y)\in B(0,r):x\geqslant 0\}$.

Now we define $f_j:B^+(0,\tilde{R}_j)\to\mathbf{C}$ by

$$f_j(x,y)=\tilde{\Psi}_j\left(\frac{x}{\sqrt{h_j}},\frac{y}{\sqrt{h_j}}+y_j\right).$$

Note that $(\sqrt{h_j}x_j,0)\in B^+(0,C_1)$ by (3.10). As a consequence of this and of (3.8), $|f_j(\sqrt{h_j}x_j,0)|=|\tilde{\Psi}_j(z_j)|\geqslant\frac{1}{2}$. Hence,

$$\sup_{B^+(0,C_1)}|f_j|\geqslant\tfrac{1}{2}. \tag{3.11}$$

In addition (3.6) leads to a uniform bound on f_j:

$$\|f_j\|_{L^\infty(B^+(0,\tilde{R}_j))}\leqslant 1. \tag{3.12}$$

Furthermore, f_j satisfies the equation

$$(i\nabla+\mathbf{A})^2 f_j=\frac{\lambda(h_j)}{h_j}f_j \quad \text{on } B^+(0,\tilde{R}_j), \tag{3.13}$$

$$(i\nabla+\mathbf{A})f_j\cdot\nu=0 \quad \text{on } \Gamma_N^{B^+}, \tag{3.14}$$

where $\Gamma_N^{B^+}=\{(x,y)\in\partial B^+(0,\tilde{R}_j):x=0\}$.

Now our objective is to show that the sequence f_j is compact in order to extract a subsequence that converges uniformly on compact subsets of $\mathbf{H}$. To that end we fix a half-ball $B^+(0,S)$. Let χ be a smooth cutoff function such that $\chi\equiv 1$ on the ball $B(0,S-1)$, $\chi\equiv 0$ on $\mathbf{H}-B(0,S)$ and $|\nabla\chi|\leqslant 2$.

We suppress the j index, multiply the PDE (3.13) by $\chi^2\overline{f}$ (where $\overline{f}$ is the complex conjugate of f), and integrate by parts to obtain

$$\int_{B^+(0,S)}\chi^2|\nabla f|^2+2\overline{f}\chi\nabla\chi\cdot\nabla f+\chi^2(2ix\overline{f}f_y+x^2|f|^2)dxdy=\frac{\lambda(h)}{h}\int_{B^+(0,S)}\chi^2|f|^2dxdy. \tag{3.15}$$

In integrating by parts one makes use of the Neumann boundary condition on $\Gamma_N^{B^+}$ and that χ vanishes on the rounded part of $B^+(0,S)$. Using the Cauchy–Schwartz inequality, the uniform bound on f, the local boundedness of $\mathbf{A}$ and χ, and boundedness of $\lambda(h)/h$ (Remark 2.6), we find for some positive constants C_1 and C_2

$$\int_{B^+(0,S-1)}|\nabla f|^2dxdy\leqslant C_1(S)\left(\int_{B^+(0,S-1)}|\nabla f|^2dxdy\right)^{1/2}+C_2(S). \tag{3.16}$$

With this and (3.12) we conclude that there is a constant $C(S)$ that does not depend on h such that

$$\|f\|_{H^1(B^+(0,S-1))}<C(S). \tag{3.17}$$

Reverting back to the notation f_j, we write $f_j=u_j+iv_j$ and express the PDE (3.13) as a system:

$$-\Delta u_j=2\mathbf{A}\cdot\nabla v_j-|\mathbf{A}|^2u_j+\frac{\lambda(h_j)}{h_j}u_j, \tag{3.18}$$

$$-\Delta v_j=2\mathbf{A}\cdot\nabla u_j-|\mathbf{A}|^2v_j+\frac{\lambda(h_j)}{h_j}v_j. \tag{3.19}$$

Since u_j and v_j are in $H^1(B^+(0,S-1))$, then by standard interior elliptic estimates, bootstrapping and Sobolev embedding we conclude that $f_j\in C^{2,\alpha}(\tilde{B}^+(0,S-1))$, where

$$\tilde{B}^+(0,S-1)=B^+(0,S-1)-\left\{(x,y)\in B^+(0,S-1):x<\frac{1}{S}\right\}.$$

Moreover, using boundary regularity estimates (cf. Ref. 22), bootstrapping and Sobolev embedding we obtain an estimate on the $C^{1,\alpha}(\overline{B^+(0,S-1)})$ norm of u_j+iv_j, where the estimate is independent of j. With regularity and uniform boundedness (3.12) we find f_j is a compact sequence in $C^{2,\alpha}(\tilde{B}^+(0,S-1))\cap\ C^{1,\alpha}(\overline{B^+(0,S-1)})$.

Using a standard diagonalization argument one obtains a subsequence converging on compact subsets of $\mathbf{H}$ to a function $f_\infty\in C^{2,\alpha}(\mathbf{H})\cap C^1(\overline{\mathbf{H}})$. This limit function, f_∞ solves the problem

$$-\Delta f_\infty+2i\mathbf{A}\cdot\nabla f_\infty+|\mathbf{A}|^2f_\infty=\lim_{j\to\infty}\frac{\lambda(h_j)}{h_j}f_\infty\ \text{ in }\ \mathbf{H}, \tag{3.20}$$

$$(i\nabla+\mathbf{A})f_\infty\cdot\nu=0\quad\text{ on }\ \partial\mathbf{H}. \tag{3.21}$$

Moreover, (3.11) implies

$$\sup_{\mathbf{H}}|f_\infty|\geqslant\tfrac{1}{2}.$$

Thus, f_∞ is a bounded nontrivial classical solution of the eigenvalue problem (3.20) and (3.21). By Theorem 2.7 *(ii)*, $\lim_{j\to\infty}\lambda(h_j)/h_j<\lambda_H$. On the other hand, Lemma 2.10 *(ii)* asserts that there is no such nontrivial bounded solution for the problem (3.20) and (3.21) in $\mathbf{H}$. Hence condition (3.5) is again contradicted.

If the sequence $\{z_j\}$ is approaching Γ_D^1 on which the Dirichlet condition holds, we follow the same lines as above with a slight difference. We find f_∞ that solves the problem (2.9) and (2.10) with $\lambda=\lim_{h_j\to\infty}\lambda(h_j)/h_j$. We invoke Lemma 2.9 *(ii)* and Lemma 2.10 *(iii)* to get the contradiction in this case.

In the case condition (3) holds, we assume first that $p_0=(1,0)$. Here we will draw quarter-balls centered at p_0.

We denote a quarter-ball centered at the origin with radius r by $B^q(0,r)=B(0,r)\cap\{(x,y):x\leqslant 0,y\geqslant 0\}$.

We define $f_j:B^q(0,R_j)\to\mathbf{C}$ by

$$f_j(x,y)=\tilde{\Psi}_j\left(1+\frac{x}{\sqrt{h_j}},\frac{y}{\sqrt{h_j}}\right)e^{-i\sqrt{h_j}y}.$$

Note that condition (3) implies that $(\sqrt{h_j}(x_j-1),\sqrt{h_j}y_j)\in B^q(0,C_2)$. So at these points

$$|f_j(\sqrt{h_j}(x_j-1),\sqrt{h_j}y)|=|\tilde{\Psi}_j(z_j)|\geqslant\tfrac{1}{2}.$$

Hence,

$$\sup_{B^q(0,C_2)}|f_j|\geqslant\tfrac{1}{2}. \tag{3.22}$$

Moreover, the f_j's are uniformly bounded with

$$\|f_j\|_{L^\infty(B^q(0,R_j))}\leqslant 1. \tag{3.23}$$

In addition, f_j solves the problem

$$(i\nabla+\mathbf{A})^2 f_j=\frac{\lambda(h_j)}{h_j}f_j \text{ in } B^q(0,R_j), \tag{3.24}$$

$$(i\nabla+\mathbf{A})f_j\cdot\nu=0 \text{ on } \{(x,0):-R_j<x<0\}, \tag{3.25}$$

$$f_j=0 \text{ on } \{(0,y):0<y<R_j\}. \tag{3.26}$$

Again we wish to establish compactness of the sequence $\{f_j\}$. To reach this goal, we follow the same approach as in dealing with condition (2). We find that for any fixed quarter-ball $B^q(0,S)$

$$\|f_j\|_{H^1(B^q(0,S-1))}\leqslant C(S). \tag{3.27}$$

We once again apply interior and global elliptic regularity theory to the problem (3.24)–(3.26). One finds uniform bounds on $\{f_j\}$ in $C^{2,\alpha}(\tilde{B}^q(0,S))\cap C^{1,\alpha}\hat{B}^q(0,S))\cap H^2(B^q(0,S-1))$, where

$$\tilde{B}^q(0,S-1)=B^q(0,S-1)-\left\{(x,y):x<\frac{1}{S}\text{ or }y<\frac{1}{S}\right\}$$

and

$$\hat{B}^q(0,S-1)=B^q(0,S-1)-B^q\left(0,\frac{1}{S}\right).$$

Using a diagonalization argument on bigger and bigger quarter-balls one can find a subsequence that converges on compact subsets of the left quarter-plane to a function f_∞. Since the problem is invariant under a 270° counter-clockwise rotation, so that **A** still satisfies (2.1), we may replace the left quarter-plane with the right quarter-plane **Q**. Thus, f_∞ solves

$$(i\nabla+\mathbf{A})^2 f_\infty = \lim_{h_j\to\infty} \frac{\lambda(h_j)}{h_j} f_\infty \quad \text{in} \quad \mathbf{Q}, \tag{3.28}$$

$$(i\nabla+\mathbf{A}) f_\infty \cdot \nu = 0 \quad \text{on} \quad \Gamma_N, \tag{3.29}$$

$$f_\infty = 0 \quad \text{on} \quad \Gamma_D, \tag{3.30}$$

and in light of (3.22) and (3.23), f_∞ satisfies

$$\sup_{\mathbf{Q}} |f_\infty| \geqslant \tfrac{1}{2} \quad \text{while} \quad \|f_\infty\|_{L^\infty(\mathbf{Q})} \leqslant 1.$$

These make f_∞ a nontrivial bounded classical solution to the eigenvalue problem (2.15)–(2.17) with $\lambda = \lim_{h_j\to\infty} \lambda(h_j)/h_j$. This contradicts Lemma 2.10(iv) since by Theorem 2.7 and Lemma 2.9(i), $\lim_{h_j\to\infty} \lambda(h_j)/h_j < \lambda_{QM}$.

In case $p_0=(0,1)$ the argument is similar to the above case. On the other hand, when $p_0=(1,1)$, our treatment leads us to a limit function that solves the problem (2.12) and (2.13) with Dirichlet boundary conditions on both sides. In this case we invoke Lemma 2.9(i) and Lemma 2.10(v) to reach a contradiction to condition (3.5). Thus claim (3.4) is established.

By this we have completed the proof of the exponential decay estimate:

$$|\Psi^h(z)| \leqslant c_1 e^{c_2\sqrt{h}|z|} \quad \text{for all} \quad z \in Q_1 \tag{3.31}$$

for some positive constants c_1 and c_2.

To obtain exponential decay of higher derivatives using (3.31) one follows the method used in Ref. 10. ■

Proof of Theorem 3.2: The proof is similar to the one above. The minimizers Ψ^h solve the eigenvalue problem;

$$(i\nabla+h\mathbf{A})^2\Psi^h = \lambda(h)\Psi^h \quad \text{in} \quad Q_1, \tag{3.32}$$

$$(i\nabla+h\mathbf{A})\Psi\cdot\nu = 0 \quad \text{on} \quad \partial Q_1. \tag{3.33}$$

This results in replacing the $\Omega(k,h,R)$ by the sets $\tilde{\Omega}(k,h,R)=\{z\in Q_1 : \tilde{d}(z) < Rk/\sqrt{h}\}$. Notice that the argument in the proof of Theorem 3.1 follows as above in obtaining the sequence $\{z_j\}$. We find that among the three conditions listed when taking the limit of the quantity $\sqrt{h_j}\,\mathrm{dist}(z,\partial Q_1)$, we are only confronted with conditions (1) and (2). Since only the Neumann condition holds on the boundary, we need only invoke Theorem 2.7 and Lemma 2.10(i) and (ii) to get a contradiction of a condition equivalent to (3.5). ■

Proof of Theorem 3.3: This is again proved by the blow-up technique, but it is easier than the previous two results. See the proof of Ref. 10, Theorem 3.1 for a similar argument. ■

IV. EXISTENCE OF A MINIMIZER

Theorem 4.1: *There exists a function $\Psi_\infty \in H^1(\mathbf{Q})$ that minimizes the energy*

$$\lambda_{\mathbf{Q}} \equiv \inf_{\Psi\in H^1(\mathbf{Q})} \frac{\int_{\mathbf{Q}} |(i\nabla+\mathbf{A})\Psi|^2 dxdy}{\int_{\mathbf{Q}} |\Psi|^2 dxdy}.$$

In particular, Ψ_∞ satisfies the PDE and the boundary conditions:

$$(i\nabla+\mathbf{A})^2\Psi=\lambda_Q\Psi \quad \text{in } \mathbf{Q}, \tag{4.1}$$

$$(i\nabla+\mathbf{A})\Psi\cdot\nu=0 \quad \text{on } \partial\mathbf{Q}. \tag{4.2}$$

Moreover, for every multi-index α, there exist positive constants c_1^α and c_2^α such that

$$|D^\alpha\Psi(z)|\leqslant c_1^\alpha e^{-c_2^\alpha|z|} \quad \text{for all } z\in\mathbf{Q}.$$

Proof: We obtain a minimizing sequence by considering $\{\Psi^h\}$, the set of minimizers of the variational problem (2.6). These exist by the direct method of the calculus of variations. Each is a classical solution of the eigenvalue problem:

$$(i\nabla+\mathbf{A})^2\Psi^h=\frac{\lambda(h)}{h}\Psi^h \quad \text{in } Q_{\sqrt{h}},$$

$$(i\nabla+\mathbf{A})\Psi^h\cdot\nu=0 \quad \text{on } \Gamma_N^{\sqrt{h}}, \tag{4.3}$$

$$\Psi^h=0 \quad \text{on } \Gamma_D^{\sqrt{h}}.$$

Again, we find that Ψ^h is in C^∞ inside $Q_{\sqrt{h}}$, C^1 up to the boundary of $Q_{\sqrt{h}}$ away from the corners and in $H^2(Q_{\sqrt{h}})$, hence bounded on the closure of $Q_{\sqrt{h}}$. Thus, we can renormalize Ψ^h so that

$$\|\Psi^h\|_{L^\infty}=1. \tag{4.4}$$

In addition, through the rescaling $\tilde{z}=\sqrt{h}\,z$, one can define $\tilde{\Psi}^h:Q_1\to\mathbf{C}$ by $\tilde{\Psi}^h(z)=\Psi^h(\tilde{z})$. Then $\tilde{\Psi}^h$ minimizes the h-dependent Rayleigh quotient (2.5) on Q_1. By Theorem 3.1 $\tilde{\Psi}$ obeys the exponential decay estimate for an h-independent constants c_1^α and c_2^α:

$$|D^\alpha\tilde{\Psi}^h(z)|\leqslant c_1^\alpha e^{-c_2^\alpha\sqrt{h}|z|} \quad \forall z\in Q_1$$

for every multi-index α and sufficiently large h.

Via the chain rule we have

$$D_{\tilde{z}}^\alpha\Psi^h(\tilde{z})=D_z^\alpha\tilde{\Psi}^h(z)(\sqrt{h})^{|\alpha|}.$$

Hence we have the estimate for Ψ^h on $Q_{\sqrt{h}}$:

$$|D^\alpha\Psi^h(z)|\leqslant c_1^\alpha e^{-c_2^\alpha|z|} \quad \forall z\in Q_{\sqrt{h}}, \tag{4.5}$$

for h sufficiently large.

From (4.5) we see that a subsequence of $\{\Psi^h\}$ will converge in $C^{2,\alpha}$ on compact subsets of $\mathbf{Q}$. Denoting this limit by Ψ_∞, we see that Ψ_∞ is a classical solution of the problem

$$(i\nabla+\mathbf{A})^2\Psi_\infty=\lim_{h_j\to\infty}\frac{\lambda(h_j)}{h_j}\Psi_\infty \quad \text{in } \mathbf{Q}, \tag{4.6}$$

$$(i\nabla+\mathbf{A})\Psi_\infty\cdot\nu=0 \qquad \text{on } \partial\mathbf{Q}. \tag{4.7}$$

Furthermore, in light of the uniform convergence of the subsequence of $\{\Psi^h\}$ on compact subsets of $\mathbf{Q}$, along with the exponential decay estimate (4.5), one obtains the same exponential decay estimate on Ψ_∞:

$$|D^{\alpha}\Psi_{\infty}(z)| \leq c_1^{\alpha} e^{-c_2^{\alpha}|z|} \quad \forall z \in \mathbf{Q}. \tag{4.8}$$

In particular, this shows that $\Psi_{\infty} \in H^1(\mathbf{Q})$, hence it is a competitor for the Rayleigh quotient on $\mathbf{Q}$.

To complete the proof, it remains to show that Ψ_{∞} is a minimizer and therefore

$$\lambda_{\mathbf{Q}} = \lim_{h_j \to \infty} \frac{\lambda(h_j)}{h_j} \tag{4.9}$$

(cf. Remark 2.6). Recalling the notation

$$R_{\Omega}(\phi) = \frac{\int_{\Omega} |(i\nabla + \mathbf{A})\phi|^2 dxdy}{\int_{\Omega} |\phi|^2 dxdy},$$

note that Ψ_{∞} will minimize if

$$R_{\mathbf{Q}}(\Psi_{\infty}) = \inf_{\phi \in H^1(Q)} R_{\mathbf{Q}}(\phi). \tag{4.10}$$

Proceeding by contradiction to establish (4.10), fix $\epsilon_0 > 0$, and, using the density of $C_0^{\infty}(\mathbf{Q})$ in $H^1(\mathbf{Q})$, suppose there is an $\eta \in C_0^{\infty}(\mathbf{Q})$ such that

$$R_{\mathbf{Q}}(\Psi_{\infty}) = R_{\mathbf{Q}}(\eta) + \epsilon_0. \tag{4.11}$$

Then we choose h_1 sufficiently large such that

(1) $spt(\eta) \subset Q_{h_1}$,

(2) $|R_Q(\Psi_{\infty}) - R_{Q_{\sqrt{h_1}}}(\Psi_{\infty})| < \frac{1}{2}\epsilon_0$, and

(3) $\forall h > h_1$,

$$|R_{Q_{\sqrt{h}}}(\Psi^h) - R_{Q_{\sqrt{h_1}}}(\Psi^h)| < \tfrac{1}{4}\epsilon_0. \tag{4.12}$$

Note that conditions (2) and (3) follow from the exponential decay estimates.

Now $\Psi^{h_1} \in H^1(Q_{\sqrt{h_1}})$ and can be extended to be identically zero outside $Q_{\sqrt{h_1}}$. Therefore, Ψ^{h_1} can be seen as a competitor on $Q_{\sqrt{h}}$ for $h > h_1$. Moreover, recall that Ψ^h is a minimizer of the eigenvalue problem on $Q_{\sqrt{h}}$ for all $h > 0$. Hence,

$$R_{Q_{\sqrt{h}}}(\Psi^h) \leq R_{Q_{\sqrt{h}}}(\Psi^{h_1}) = R_{Q_{\sqrt{h_1}}}(\Psi^{h_1}). \tag{4.13}$$

Since η is a competitor and Ψ^{h_1} is a minimizer for the problem on $Q_{\sqrt{h_1}}$, we have

$$R_{Q_{\sqrt{h_1}}}(\Psi^{h_1}) \leq R_{Q_{\sqrt{h_1}}}(\eta) = R_Q(\eta), \tag{4.14}$$

where the last equality is due to our choice of η with $\mathrm{spt}(\eta) \subset Q_{\sqrt{h_1}}$. Then by (4.11) and condition (2) in the choice of h_1, we find

$$R_{Q_{\sqrt{h_1}}}(\Psi^{h_1}) \leq R_Q(\Psi_{\infty}) - \epsilon_0 \tag{4.15}$$

$$\leq R_{Q_{\sqrt{h_1}}}(\Psi_{\infty}) + \frac{\epsilon_0}{2} - \epsilon_0 \tag{4.16}$$

$$= R_{Q_{\sqrt{h_1}}}(\Psi_{\infty}) - \frac{\epsilon_0}{2}. \tag{4.17}$$

Now combining (4.13) and (4.17) along with (4.12) we have

$$R_{Q_{\sqrt{h_1}}}(\Psi^h) < R_{Q_{\sqrt{h_1}}}(\Psi_\infty) - \frac{\epsilon_0}{4} \quad \forall h > h_1. \tag{4.18}$$

Since $\Psi^h \to \Psi_\infty$ uniformly in $C^{2,\alpha}(Q_{\sqrt{h_1}})$ we have

$$R_{Q_{\sqrt{h_1}}}(\Psi^h) \to R_{Q_{\sqrt{h_1}}}(\Psi_\infty) \text{ as } h \to \infty.$$

Then, taking the limit in (4.18) we obtain

$$R_{Q_{\sqrt{h_1}}}(\Psi_\infty) < R_{Q_{\sqrt{h_1}}}(\Psi_\infty) - \frac{\epsilon_0}{4},$$

a contradiction. Therefore,

$$\lambda_{\mathbf{Q}} = \lim_{h_j \to \infty} \frac{\lambda(h_j)}{h_j} \quad \text{and} \quad R_{\mathbf{Q}}(\Psi_\infty) = \lambda_{\mathbf{Q}},$$

i.e., Ψ_∞ is a minimizer. ■

(Received 14 December 2000; accepted for publication 30 March 2001)

Via a special dimensional reduction, that is, Fourier transforming over one of the coordinates of Casimir operator of su(2) Lie algebra and 4-oscillator Hamiltonian, we have obtained two- and three-dimensional Hamiltonian with shape invariance symmetry. Using this symmetry we have obtained their eigenspectrum. In the mean time we show equivalence of shape invariance symmetry and Lie algebraic symmetry of these Hamiltonians. © *2001 American Institute of Physics.*
[DOI: 10.1063/1.1380443]

I. INTRODUCTION

Exactly solvable quantum Hamiltonians (ESQH) have always attracted a lot of interest in theoretical physics and mathematical physics. Hence, construction of exactly solvable models is of great interest.[1–6] Familiar solvable potentials (particularly one-dimensional potentials) have the property of shape invariance. For these potentials, eigenvalues and eigenvectors can be derived using well-known methods of supersymmetric quantum mechanics together with shape invariant factorization. The majority of potentials have also been shown to poses a Lie algebraic symmetry and hence are also solvable by group theoretical techniques. Actually one can establish a connection between ESQH with shape invariance symmetry and ESQH with Lie algebraic symmetry and one can show that they are indeed equivalent.[7,8] One of the authors could give some two- and three-dimensional shape invariant Hamiltonians.[9–11] In these papers they have shown that the shape invariance symmetry of these models is due to existence of some Lie algebraic symmetry. Hence in this paper we construct new two- and three-dimensional (EQSH) with shape invariance symmetry, where su(2) and Heisenberg algebra are responsible for the existence of shape invariance symmetry in them.

This paper is organized as follows: In Sec. II, using the left and right invariant vector fields of su(2) Lie algebra we first construct its Casimir operator. Then via Fourier transformation over one of the coordinates we construct the two-dimensional Hamiltonian $H_q(\theta,\psi)$ which poses shape invariance symmetry. Using this symmetry we obtain its eigenspectrum analytically. In Sec. III starting with a Hamiltonian of 4-oscillator and Fourier transforming over one of the coordinates we obtain a three-dimensional Hamiltonian corresponding to motion of a charged particle in the presence of an electric field. We show that this three-dimensional Hamiltonian poses a shape invariance symmetry and using this symmetry we obtain its eigenspectrum. What is so important in both models, is that both Hamiltonians factorize shape invariantly into product of second order differential operators. These second order operators themselves consist of the product of first order differential operators. The paper ends with a brief conclusion.

II. TWO-DIMENSIONAL HAMILTONIAN OBTAINED FROM SU(2) MANIFOLD

A. Left and right invariant vector field of SU(2)

Considering the following parametrization of su(2) group manifold,[12]

$$\begin{aligned}\Lambda &= \exp(i\vec{\sigma}\cdot\vec{n}\psi)\\ &= A\begin{pmatrix}\exp(i\psi) & 0\\ 0 & \exp(-i\psi)\end{pmatrix}A^{-1}\\ &= \begin{pmatrix}\cos(\psi)-i\cos(\theta)\sin(\psi) & -i\sin(\theta)\sin(\psi)\exp(-i\phi)\\ -i\sin(\theta)\sin(\psi)\exp(i\phi) & \cos(\psi)+i\cos(\theta)\sin(\psi)\end{pmatrix},\end{aligned} \tag{2.1}$$

where σ_i, $i=1$, 2, and 3 are used Pauli matrices and $\vec{n}$ is unit vector defined as

$$\vec{n}=\sin(\theta)\cos(\phi)\vec{i}+\sin(\theta)\sin(\phi)\vec{j}+\cos(\theta)\vec{k}$$

and matrix A corresponds to coherent state representation of su(2) defined as[13]

$$A=\begin{pmatrix}1 & \tau\\ 0 & 1\end{pmatrix}\begin{pmatrix}\exp\left(\frac{\beta}{2}\right) & 0\\ 0 & \exp\left(\frac{-\beta}{2}\right)\end{pmatrix}\begin{pmatrix}1 & 0\\ -\tau^{\star} & 1\end{pmatrix},$$

with $\tau=\tan(\theta/2)\exp(-i\phi)$ and $\beta=\ln(1+\tau\tau^{\star})$.

In order to obtain the left and right invariant vector field su(2) manifold with the above parametrization, it is convenient first to calculate its left and right invariant one form defined as $\Lambda^{-1}d\Lambda$ and $d\Lambda\,\Lambda^{-1}$, respectively.[14]

As an example, writing left invariant one form

$$\Lambda^{-1}d\Lambda=e_{\alpha}^{a}\,d\xi^{\alpha}\,\sigma_a,$$

where e_{α}^{a} are 3-beins and $\xi^{\alpha}=(\theta,\phi,\psi)$ are coordinates of su(2) manifold. Defining the inverse of 3-bein $e_{a}^{\alpha}=g^{\alpha\beta}\delta_{ab}e_{\beta}^{b}$ with $g^{\alpha\beta}$ as inverse of metric $g_{\alpha\beta}$:

$$g_{\alpha,\beta}=\begin{pmatrix}1 & 0 & 0\\ 0 & \sin^2(\psi) & 0\\ 0 & 0 & \sin^2(\psi)\sin^2(\theta)\end{pmatrix},$$

then the left invariant vector fields are defined as

$$L_a=e_{a}^{\alpha}\frac{\partial}{\partial\xi^{\alpha}}.$$

Using the above prescription we obtain the following expression for left and right invariant vector fields of su(2), respectively:

$$L_{+}=\frac{i}{2}e^{i\phi}\left[\sin(\theta)\partial_{\psi}+(i+\cos(\theta)\cot(\psi))\partial_{\theta}+\left(-\cot(\theta)+i\frac{\cot(\psi)}{\sin(\theta)}\right)\partial_{\phi}\right], \tag{2.2}$$

$$L_{-}=\frac{i}{2}e^{-i\phi}\left[\sin(\theta)\partial_{\psi}+(-i+\cos(\theta)\cot(\psi))\partial_{\theta}+\left(-\cot(\theta)-i\frac{\cot(\psi)}{\sin(\theta)}\right)\partial_{\phi}\right], \tag{2.3}$$

$$L_3=\frac{i}{2}(-\cos(\theta)\partial_\psi+\sin(\theta)\cot(\psi)\partial_\theta-\partial_\phi), \tag{2.4}$$

$$R_+=\frac{i}{2}e^{i\phi}\left[\sin(\theta)\partial_\psi+(-i+\cos(\theta)\cot(\psi))\partial_\theta+\left(\cot(\theta)+i\frac{\cot(\psi)}{\sin(\theta)}\right)\partial_\phi\right], \tag{2.5}$$

$$R_-=\frac{i}{2}e^{-i\phi}\left[\sin(\theta)\partial_\psi+(i+\cos(\theta)\cot(\psi))\partial_\theta+\left(\cot(\theta)-i\frac{\cot(\psi)}{\sin(\theta)}\right)\partial_\phi\right], \tag{2.6}$$

$$R_3=\frac{i}{2}(-\cos(\theta)\partial_\psi+\sin(\theta)\cot(\psi)\partial_\theta+\partial_\phi), \tag{2.7}$$

where $L_\pm=L_1\pm iL_2$ and $R_\pm=R_1\pm iR_2$. It is straightforward to show that the left and right invariant vector fields fulfill the following su(2) Lie algebra:

$$[L_+,L_-]=2L_3,\quad [L_3,L_\pm]=\pm L_\pm, \tag{2.8}$$

$$[R_+,R_-]=-2R_3,\quad [R_3,R_\pm]=\mp R_\pm, \tag{2.9}$$

also, the left and right invariant generator commute with each other

$$[\vec{L},\vec{R}]=0. \tag{2.10}$$

Considering the Casimir operators of su(2) defined as

$$L^2=\tfrac{1}{2}(L_+L_-+L_-L_+)+L_3^2,$$

and ignoring the scale 1/4, we obtain

$$L^2=-\frac{1}{\sin^2(\psi)}\partial_\psi\sin^2(\psi)\partial_\psi-\frac{1}{\sin^2(\psi)}\left(\frac{1}{\sin(\theta)}\partial_\theta\sin(\theta)\partial_\theta+\frac{1}{\sin^2(\theta)}\partial_\phi^2\right), \tag{2.11}$$

in obtaining the above formula we have used the left invariant generators. It is straightforward to show that we can obtain the same result with right invariant generators, too, that is Casimir operator of left and right operators are the same.

B. $H_q(\theta,\psi)$ Hamiltonian

Here through dimensional reduction we show that the above Casimir operator reduces to a Hamiltonian of motion of a charged particle in the presence of electric field. Hence, first we make one-dimensional re'duction (eliminate the coordinate ϕ) through the usual Fourier transformation defined as

$$\tilde{f}(q)=\frac{1}{\sqrt{2\pi}}\int_0^{2\pi}f(\phi)\exp(-i\phi q)d\phi, \tag{2.12}$$

over an arbitrary function $f(\phi)$. Obviously the Casimir operator (2.11) reduces to the following operator:

$$L_q^2(\theta,\psi)=-\frac{1}{\sin^2(\psi)}\partial_\psi\sin^2(\psi)\partial_\psi-\frac{1}{\sin^2(\psi)}\left(\frac{1}{\sin(\theta)}\partial_\theta\sin(\theta)\partial_\theta-\frac{q^2}{\sin^2(\theta)}\right), \tag{2.13}$$

in the Hilbert space of Fourier transformed wave functions. In general, the nonrelativistic Hamiltonian of a charged particle over a two-dimensional with metric $g_{\mu\nu}$ in the presence of magnetostatic field $\vec{B}$ with vector potential $\vec{A}$ and electrostatic field $\vec{E}$ with scalar potential V can be written as[8,15]

$$H=-\frac{1}{\sqrt{g}}(\partial_\mu-iA_\mu)(\sqrt{g}g^{\mu\nu}(\partial_\nu-iA_\nu))+V, \tag{2.14}$$

where g is the determinant of metric $g_{\mu\nu}$. After similarity transformation of the Casimir operator (2.13) defined as

$$\tilde{L}_q^2(\theta,\psi)=\sin^{\frac{1}{2}}(\psi)L_q^2(\theta,\psi)\sin^{-\frac{1}{2}}(\psi),$$

we have

$$\tilde{L}_q^2(\theta,\psi)=-\frac{1}{\sin(\psi)}\partial_\psi\sin(\psi)\partial_\psi-\frac{1}{\sin^2(\psi)}\left(\frac{1}{\sin(\theta)}\partial_\theta\sin(\theta)\partial_\theta-\frac{q^2}{\sin^2(\theta)}\right)+\frac{1}{4}\cot^2(\psi)-\frac{1}{2}. \tag{2.15}$$

Comparing the operator (2.15) with the Hamiltonian (2.14) we obtain

$$g_{\psi\psi}=1,\quad g_{\theta\theta}=\sin^2(\psi),\quad g_{\psi\theta}=g_{\theta\psi}=0$$

and

$$A_\psi=0,\quad A_\theta=\frac{i}{2}\cot(\theta)=d\left(\frac{i}{2}\ln(\sin(\theta))\right). \tag{2.16}$$

It is trivial to see that the vector potential given in (2.16) corresponds to pure u(1) gauge field, hence it can eliminate the theory of the gauge transform $A\rightarrow A_\mu+\partial_\mu\chi$ with gauge function $\chi=(i/2)\ln(\sin(\theta))$. After the above gauge transformation the su(2) Casimir Hamiltonian reduces to

$$H_q(\theta,\psi)\equiv e^{-\chi}\tilde{L}_q^2(\theta,\psi)e^{\chi}=-\frac{1}{\sin(\psi)}\partial_\psi\sin(\psi)\partial_\psi-\frac{1}{\sin^2(\psi)}\partial_\theta^2+\frac{q^2-\frac{1}{4}}{\sin^2(\psi)\sin^2(\theta)}-\frac{3}{4}, \tag{2.17}$$

which can be interpreted as a nonrelativistic Hamiltonian of a point particle over two-dimensional sphere with metric

$$g_{\mu,\nu}=\begin{pmatrix}1 & 0\\ 0 & \sin^2(\psi)\end{pmatrix}$$

in the presence of electric field with scalar potential

$$V=\frac{q^2-\frac{1}{4}}{\sin^2(\psi)\sin^2(\theta)}-\frac{3}{4}.$$

Similarly, the left and right invariant vector fields given in (2.2)–(2.7) take the following form after the above given operations, that is, dimensional reduction, similarity transformation and gauge transformation:

$$\tilde{L}'_+(q)=\tilde{L}_+(q)+g(\theta,\psi,q),\quad \tilde{R}'_+(q)=\tilde{R}_+(q)-g^\star(\theta,\psi,q),$$

$$\tilde{L}'_-(q)=\tilde{L}_-(q)-g^\star(\theta,\psi,q),\quad \tilde{R}'_-(q)=\tilde{R}_-(q)+g(\theta,\psi,q),$$

$$\tilde{L}'_3(q)=\tilde{L}_3(q),\quad \tilde{R}'_3(q)=\tilde{R}_3(q),$$

where

$$\tilde{L}_+(q)=\frac{i}{2}\left(\sin(\theta)\partial_\psi+(i+\cos(\theta)\cot(\psi))\partial_\theta+i(q-1)\left(-\cot(\theta)+i\frac{\cot(\psi)}{\sin(\theta)}\right)\right)e^{-(\partial/\partial q)}, \tag{2.18}$$

$$\tilde{L}_-(q)=\frac{i}{2}\left(\sin(\theta)\partial_\psi+(-i+\cos(\theta)\cot(\psi))\partial_\theta+i(q+1)\left(-\cot(\theta)-i\frac{\cot(\psi)}{\sin(\theta)}\right)\right)e^{\partial/\partial q}, \tag{2.19}$$

$$\tilde{L}_3(q)=\frac{i}{2}(-\cos(\theta)\partial_\psi+\sin(\theta)\cot(\psi)\partial_\theta-iq), \tag{2.20}$$

$$\tilde{R}_+(q)=\frac{i}{2}\left(\sin(\theta)\partial_\psi+(-i+\cos(\theta)\cot(\psi))\partial_\theta+i(q-1)\left(\cot(\theta)+i\frac{\cot(\psi)}{\sin(\theta)}\right)\right)e^{-(\partial/\partial q)}, \tag{2.21}$$

$$\tilde{R}_-(q)=\frac{i}{2}\left(\sin(\theta)\partial_\psi+(i+\cos(\theta)\cot(\psi))\partial_\theta+i(q+1)\left(\cot(\theta)-i\frac{\cot(\psi)}{\sin(\theta)}\right)\right)e^{\partial/\partial q}, \tag{2.22}$$

$$\tilde{R}_3(q)=\frac{i}{2}(-\cos(\theta)\partial_\psi+\sin(\theta)\cot(\psi)\partial_\theta+iq) \tag{2.23}$$

with $g(\theta,\psi,q)$ is

$$g(\theta,\psi,q)=\frac{1}{4}\left(\cot(\theta)-i\frac{\cot(\psi)}{\sin(\theta)}\right)e^{\partial/\partial q},$$

where* means the usual complex conjugation. With some calculation one can show that the above algebra, that is, the commutation relations is unchanged under the above-mentioned transformation and the Hamiltonian $H_q(\theta,\psi)$ can be written in terms of generator (2.18)–(2.20) in the following form:

$$H_q(\theta,\psi)=\tfrac{1}{2}(\tilde{L}'_+(q)\tilde{L}'_-(q)+\tilde{L}'_-(q)\tilde{L}'_+(q))+\tilde{L}'_3(q)^2.$$

Hence, $H_q(\theta,\psi)$ is still Casimir operator su(2) Lie algebra with generator given in (2.18)–(2.23).

C. Algebraic solution of $H_q(\theta,\psi)$ Hamiltonian

In order to obtain eigenspectrum of Hamiltonian (2.17) by algebraic method, first we obtain eigenspectrum of the Casimir operator (2.11). Since this operator commutes with the left and right invariant generator given in (2.10), therefore, we can obtain representation of su(2) simply by finding simultaneous eigenfunctions of the set commuting operators (R_3,L_3,L^2). Denoting their simultaneous eigenfunction by $\chi^l_{m_L,m_R}(\theta,\psi,\phi)$, we can write

$$L^2\chi^l_{m_L,m_R}(\theta,\psi,\phi)=l(l+1)\chi^l_{m_L,m_R}(\theta,\psi,\phi), \tag{2.24}$$

$$L_3\chi^l_{m_L,m_R}(\theta,\psi,\phi)=m_L\chi^l_{m_L,m_R}(\theta,\psi,\phi), \tag{2.25}$$

$$R_3\chi^l_{m_L,m_R}(\theta,\psi,\phi)=m_R\chi^l_{m_L,m_R}(\theta,\psi,\phi). \tag{2.26}$$

Now solving the difference of the first order differential equations (2.25) and (2.26) we deduce that $\chi^l_{m_L,m_R}(\theta,\psi,\phi)$ is proportional to $e^{-i(m_R-m_L)\phi}$, hence we have $\chi^l_{m_L,m_R}(\theta,\psi,\phi)=e^{-i(m_R-m_L)\phi}f(\theta,\psi)$, where $f(\theta,\psi)$ can be determined from the solution of the sum of the equations (2.25) and (2.26), that is

$$-i\cos(\theta)\partial_\psi f(\theta,\psi)+i\sin(\theta)\cot(\psi)\partial_\theta f(\theta,\psi)=(m_L+m_R)f(\theta,\psi). \tag{2.27}$$

Now considering the highest weight defined by $m_L=-m_R=l$, that is the right-hand side of the Eq. (2.27) vanishes, hence it can be solved by characteristic method which leads to the following results:

$$\chi^l_{l,-l}(\theta,\psi,\phi)=\exp(2il\phi)f^{\max}(\sin(\psi)\sin(\theta)),$$

where $f^{\max}$ is an arbitrary function which can be determined by solving the first order differential equation:

$$R_+\chi^l_{l,-l}(\theta,\psi,\phi)=0,\quad L_+\chi^l_{l,-l}(\theta,\psi,\phi)=0.$$

Since the highest weight $\chi^l_{l,-l}$ belongs to the kernel of raising operators R_+ and L_+ therefore the sum of Eqs. (2.2) and (2.5) leads to

$$u\frac{df^{\max}(u)}{du}=2lf^{\max}(u),$$

where $u=\sin(\psi)\sin(\theta)$. Therefore solving the above equation we obtain $f^{\max}(u)=u^{2l}$, hence $\chi^l_{l,-l}(\theta,\psi,\phi)$ has the following form:

$$\chi^l_{l,-l}(\theta,\psi,\phi)=e^{2il\phi}(\sin(\psi)\sin(\theta))^{2l}. \tag{2.28}$$

The other eigenweights can be obtained through the operation of the lowering operator R_- and L_- over the highest eigenfunction, that is, we have

$$\chi^l_{m_L,m_R}(\theta,\psi,\phi)=(L_-)^{l-m_L}(R_-)^{l+m_R}(e^{2il\phi}(\sin(\psi)\sin(\theta))^{2l}). \tag{2.29}$$

In order to eliminate the coordinate ϕ, first we transfer the function $e^{2il\phi}$ to the left-hand side of the operators R_- and L_- in (2.29), then we get

$$\chi^l_{m_L,m_R}(\theta,\psi,\phi)=e^{i(m_L-m_R)\phi}L_-(m_L-m_R+1)L_-(m_L-m_R+2)$$
$$\cdots L_-(l-m_R)R_-(l-m_R+1)\cdots R_-(2l)(\sin(\psi)\sin(\theta))^{2l}, \tag{2.30}$$

where the operator $L_-(m)$ and $R_-(m)$ are defined as

$$L_-(m)=\frac{i}{2}\left(\sin(\theta)\partial_\psi+(-i+\cos(\theta)\cot(\psi))\partial_\theta+im\left(-\cot(\theta)-i\frac{\cot(\psi)}{\sin(\theta)}\right)\right), \tag{2.31}$$

$$R_-(m)=\frac{i}{2}\left(\sin(\theta)\partial_\psi+(i+\cos(\theta)\cot(\psi))\partial_\theta+im\left(\cot(\theta)-i\frac{\cot(\psi)}{\sin(\theta)}\right)\right). \tag{2.32}$$

Finally Fourier transformation of (2.30) leads to

$$\chi^{l}_{q,m}(\theta,\psi)=L_{-}(q+1)L_{-}(q+2)\cdots L_{-}\left(l+\frac{q-m}{2}\right)R_{-}\left(l+\frac{q-m}{2}+1\right)$$
$$\cdots R_{-}(2l)(\sin(\psi)\sin(\theta))^{2l}, \tag{2.33}$$

where $q=m_L-m_R$ and $m=m_L+m_R$.

Since the left and right invariant generator commute with each other, we can exchange these operators in (2.29) before Fourier transformation, but after Fourier transformation we can use only the relation $L_{-}(q)R_{-}(q-1)=R_{-}(q)L_{-}(q-1)$. Since the Hamiltonian $H_q(\theta,\psi)$ can be obtained from the relations (2.15) and (2.17) via similarity transform and gauge transform, that is, we have

$$H_q(\theta,\psi)=\exp(-\xi)L^2_q(\theta,\psi)\exp(\xi),\quad L^2_q(\theta,\psi)\chi^{l}_{q,m}(\theta,\psi)=l(l+1)\chi^{l}_{q,m}(\theta,\psi), \tag{2.34}$$

where $\xi=-\frac{1}{2}\ln(\sin(\psi)\sin(\theta))$. Hence the eigenfunction of Hamiltonian $H_q(\theta,\psi)$ can be written as

$$\tilde{\chi}^{l}_{q,m}(\theta,\psi)=\exp(-\xi)\chi^{l}_{q,m}(\theta,\psi). \tag{2.35}$$

D. Shape invariance symmetry of $H_q(\theta,\psi)$

Here in this section we show that the Hamiltonian $H_q(\theta,\psi)$ poses both degeneracy and shape invariance symmetry.[5,1,2] As it is shown in Sec. (II C), functions $\tilde{\chi}^{l}_{q,m}(\theta,\psi)=(\sin(\psi)\sin(\theta))^{\frac{1}{2}}\chi^{l}_{q,m}(\theta,\psi)$ are eigenfunctions of the Hamiltonian $H_q(\theta,\psi)$ with the corresponding eigenvalue $l(l+1)$. Since $|m_R|\leqslant l$ and $|m_L|\leqslant l$, therefore, $|q|\leqslant 2l$ and for a given value of q the parameter m can take the following values:

$$m=\begin{cases}0,\pm 2,\pm 4,\ldots,\pm(2l-|q|) & \text{for}\quad |q|=\text{even},\\ \pm 1,\pm 3,\ldots,\pm(2l-|q|) & \text{for}\quad |q|=\text{odd}.\end{cases} \tag{2.36}$$

Since the eigenvalue of Hamiltonian $H_q(\theta,\psi)$ is independent of m, therefore it has $(2l+1-|q|)$ degenerate states for a given l or given energy $l(l+1)$. To see the shape invariance symmetry of Hamiltonian $H_q(\theta,\psi)$, first we consider the Fourier transformed left and right invariant vector fields:

$$\tilde{L}_{+}(q)\equiv L_{+}(q-1)e^{-(\partial/\partial q)}$$
$$=\frac{i}{2}\left(\sin(\theta)\partial_{\psi}+(i+\cos(\theta)\cot(\psi))\partial_{\theta}+i(q-1)\left(-\cot(\theta)+i\frac{\cot(\psi)}{\sin(\theta)}\right)\right)e^{-(\partial/\partial q)}, \tag{2.37}$$

$$\tilde{L}_{-}(q)\equiv L_{-}(q+1)e^{\partial/\partial q}$$
$$=\frac{i}{2}\left(\sin(\theta)\partial_{\psi}+(-i+\cos(\theta)\cot(\psi))\partial_{\theta}+i(q+1)\left(-\cot(\theta)-i\frac{\cot(\psi)}{\sin(\theta)}\right)\right)e^{\partial/\partial q}, \tag{2.38}$$

$$\tilde{L}_3(q)\equiv L_3(q)=\frac{i}{2}(-\cos(\theta)\partial_{\psi}+\sin(\theta)\cot(\psi)\partial_{\theta}-iq), \tag{2.39}$$

and

$$\tilde{R}_{+}(q)\equiv R_{+}(q-1)e^{-(\partial/\partial q)}$$
$$=\frac{i}{2}\left(\sin(\theta)\partial_{\psi}+(-i+\cos(\theta)\cot(\psi))\partial_{\theta}+i(q-1)\left(\cot(\theta)+i\frac{\cot(\psi)}{\sin(\theta)}\right)\right)e^{-(\partial/\partial q)}, \tag{2.40}$$

$$\tilde{R}_-(q)\equiv R_-(q+1)e^{\partial/\partial q}$$

$$=\frac{i}{2}\left(\sin(\theta)\partial_\psi+(i+\cos(\theta)\cot(\psi))\partial_\theta+i(q+1)\left(\cot(\theta)-i\frac{\cot(\psi)}{\sin(\theta)}\right)\right)e^{\partial/\partial q}, \tag{2.41}$$

$$\tilde{R}_3(q)\equiv R_3(q)=\frac{i}{2}(-\cos(\theta)\partial_\psi+\sin(\theta)\cot(\psi)\partial_\theta+iq). \tag{2.42}$$

After some tedious algebraic calculation we can derive the following relation between the above operators:

$$L_3(q\pm1)L_\pm(q)-L_\pm(q)L_3(q)=\pm L_\pm(q), \tag{2.43}$$

$$R_3(q\pm1)R_\pm(q)-R_\pm(q)R_3(q)=\mp R_\pm(q), \tag{2.44}$$

the above relations indicate that Hamiltonian $H_q(\theta,\psi)$ poses shape invariance symmetry. Since by acting the operators $R_\pm(q)$ and $L_\pm(q)$ on both sides of eigenvalue equations:

$$L_q^2(\theta,\psi)\chi^l_{q,m}(\theta,\psi)=l(l+1)\chi^l_{q,m}(\theta,\psi),$$

$$R_3(q)\chi^l_{q,m}(\theta,\psi)=\frac{m-q}{2}\chi^l_{q,m}(\theta,\psi),$$

$$L_3(q)\chi^l_{q,m}(\theta,\psi)=\frac{m+q}{2}\chi^l_{q,m}(\theta,\psi),$$

we get

$$R_\pm(q)\chi^l_{q,m}(\theta,\psi)=A_\pm(q,m)\chi^l_{q\pm1,m\mp1}(\theta,\psi), \tag{2.45}$$

$$L_\pm(q)\chi^l_{q,m}(\theta,\psi)=B_\pm(q,m)\chi^l_{q\pm1,m\pm1}(\theta,\psi), \tag{2.46}$$

with

$$A_\pm(q,m)=\tfrac{1}{2}\sqrt{(2l\mp(m-q))(2l\pm(m-q)+2)}, \tag{2.47}$$

$$B_\pm(q,m)=\tfrac{1}{2}\sqrt{(2l\mp(m+q))(2l\pm(m+q)+2)}. \tag{2.48}$$

The above relations imply that the pair of operators (L_-,R_+) $[(L_+,R_-)]$ map degenerate eigenstates of Hamiltonian $H_q(\theta,\psi)$ for given value of q into each other, that is they decrease [increase] the quantum number m by 2 units as follows:

$$L_-(q+1)R_+(q)\chi^l_{q,m}(\theta,\psi)=A_+(q,m)B_-(q+1,m-1)\chi^l_{q,m-2}(\theta,\psi),$$

$$L_+(q-1)R_-(q)\chi^l_{q,m}(\theta,\psi)=A_-(q,m)B_+(q-1,m+1)\chi^l_{q,m+2}(\theta,\psi).$$

Now introducing the operator $Y_+(q):=L_+(q-1)R_-(q)$ and $Y_-(q):=L_-(q+1)R_+(q)$ as raising and lowering operators of degenerate states of Hamiltonian $H_q(\theta,\psi)$, then we have the following shape invariance like symmetry between the degenerate states of Hamiltonian $H_q(\theta,\psi)$:

$$Y_-(q)Y_+(q)\chi^l_{q,m}(\theta,\psi)=E(q,m)\chi^l_{q,m}(\theta,\psi),$$

$$Y_+(q)Y_-(q)\chi^l_{q,m+2}(\theta,\psi)=E(q,m)\chi^l_{q,m+2}(\theta,\psi),$$

where

$$E(q,m)=A_-(q,m)A_+(q,m+2)B_-(q+1,m+1)B_+(q-1,m+1).$$

Thus, for a given value of q, we can obtain eigenfunction of Hamiltonian $H_q(\theta,\psi)$ with eigenvalue $l(l+1)$, simply by acting the pairs of operators $(L_-,R_+)[(L_+,R_-)]$ over the highest weight [lowest weight], where here we have derived the eigenfunction $\chi^l_{q,m}(\theta,\psi)$ by acting the lowering operator over the highest eigenstate as follows:

$$\chi^l_{q,m}(\theta,\psi)=k^{-1}(Y_-(q))^{(2l-|q|-m)/2}\chi^l_{q,(2l-|q|)}(\theta,\psi), \tag{2.49}$$

where

$$k=B_-(q+1,m+1)B_-(q+1,m+3)$$
$$\times B_-(q+1,2l-|q|-1)A_+(q,m+2)A_+(q,m+4)\cdots A_+(q,2l-|q|),$$

using the relation (2.33) we can obtain the highest weight eigenstates for $q>0$ and $q<0$,

$$\chi^l_{q,(2l-|q|)}(\theta,\psi)=\begin{cases} L_-(q+1)L_-(q+2) & \\ \quad\times L_-(0)R_-(1)R_-(2)\ldots R_-(2l)(\sin(\theta)\sin(\psi))^{2l} & \text{for } q<0,\\ R_-(q+1)R_-(q+2)\ldots R_-(2l)(\sin(\theta)\sin(\psi))^{2l} & \text{for } q>0.\end{cases}$$

On the other hand, pair operators $(L_+,R_+)[(L_-,R_-)]$ leave the eigenvalue m and l unchanged while they increase [decrease] the parameter q by 2 units, that is they map eigenfunctions of the Hamiltonian corresponding to the same energy with different q into each other, that is they map isospectral Hamiltonians into each other with nothing but shape invariance, to show the shape invariance symmetry, we set the related operators over $\chi^l_{q,m}(\theta,\psi)$, we then obtain

$$L_+(q+1)R_+(q)\chi^l_{q,m}(\theta,\psi)=A_+(q,m)B_+(q+1,m-1)\chi^l_{q+2,m}(\theta,\psi),$$

$$L_-(q-1)R_-(q)\chi^l_{q,m}(\theta,\psi)=A_-(q,m)B_-(q-1,m+1)\chi^l_{q-2,m}(\theta,\psi).$$

Obviously, the combined actions of the above operators leave the eigenvalues m and l unchanged while changing the parameter q by 2 units. Hence we define the operator $X_+(q):=L_+(q+1)R_+(q)$ and $X_-(q):=L_-(q+1)R_-(q+2)$ as raising and lowering the operators of parameter q, then the shape invariance symmetry means

$$X_-(q)X_+(q)\chi^l_{q,m}(\theta,\psi)=N(q,m)\chi^l_{q,m}(\theta,\psi),$$

$$X_+(q)X_-(q)\chi^l_{q+2,m}(\theta,\psi)=N(q,m)\chi^l_{q+2,m}(\theta,\psi),$$

where

$$N(q,m)=A_+(q,m)A_-(q+2,m)B_+(q+1,m-1)B_-(q+1,m+1)$$

or

$$N(q,m)=\tfrac{1}{16}(2l-m-q)(2l+m+q+2)$$
$$\times\sqrt{(2l-m+q)(2l-m+q+4)(2l+m-q+2)(2l+m-q-2)}.$$

Since for fixed values of energy $l(l+1)$ and given values of m, the parameter q can take the following values:

$$q=(2l-|m|),(2l-|m|-2),\ldots,-(2l-|m|-2),-(2l-|m|).$$

Hence obtaining the highest eigenstates, by solving the following first order differential equation:

$$X_+(2l-|m|)\chi^l_{(2l-|m|),m}(\theta,\psi)=0,$$

where the integral leads to

$$\chi^l_{(2l-|m|),m}(\theta,\psi)=\begin{cases} L_-(2l-m+1)L_-(2l-m+2)\ldots L_-(2l)(\sin(\theta)\sin(\psi))^{2l} & \text{for } m<0,\\ R_-(2l-m+1)R_-(2l-m+2)\ldots R_-(2l)(\sin(\theta)\sin(\psi))^{2l} & \text{for } m>0.\end{cases}$$

Therefore using the shape invariance relation, we can obtain the eigenstates of Hamiltonian $H_q(\theta,\psi)$ by consecutive action of the q-lowering operator over the q-highest weight eigenstate,

$$\chi^l_{q,m}(\theta,\psi)=f^{-1}X_-(q)X_-(q+2)\cdots X_-(2l-|m|-4)X_-(2l-|m|-2)\chi^l_{(2l-|m|),m}(\theta,\psi)$$

$$f=A_(q+2,mA_(q+4,m\cdots A_-(2l-|m|,m)$$

$$\times B_-(q+1,m+1)B_-(q+3,m+1)\cdots B_-(2l-|m|-1,m+1).$$

III. THREE-DIMENSIONAL HAMILTONIAN OBTAINED FROM 4-OSCILLATORS

In this section using the su(2) parametrization of the preceding section, we obtain a special three-dimensional Hamiltonian from the Hamiltonian of 4-oscillator with the same frequency, where we obtain its spectrum via corresponding spectrum of 4-oscillator Hamiltonian. We show that thus obtained Hamiltonians poses shape invariance symmetry. The Hamiltonian of the 4-oscillator with the same frequency can be written as

$$H=-\frac{1}{2}\sum_{i=0}^{4}\left(P_i^2+\frac{1}{2}\omega^2x_i^2\right)$$

now making the following change of variable:

$$\begin{aligned} x_1&=-r\sin(\psi)\sin(\theta)\sin(\phi),\\ x_2&=r\sin(\psi)\sin(\theta)\cos(\phi),\\ x_3&=r\sin(\psi)\cos(\theta),\\ x_4&=r\cos(\psi),\end{aligned} \tag{3.1}$$

where ψ,θ,ϕ are the same coordinates used in the parametrization su(2) manifold, the Hamiltonian takes the following form:

$$H(r,\theta,\psi,\phi)=-\frac{1}{2}\left[\frac{1}{r^3}\partial_r r^3\partial_r + \frac{1}{r}\left(\partial_\psi^2+2\cot(\psi)\partial_\psi+\frac{1}{\sin^2(\psi)}\left(\partial_\theta^2+\cot(\theta)\partial_\theta+\frac{1}{\sin^2(\theta)}\partial_\phi^2\right)\right)\right]+\frac{1}{2}\omega^2r^2. \tag{3.2}$$

Since the angular part of the above Hamiltonian is the same as the one given in (2.11), therefore, its eigenspectrum can be obtained straightforwardly through routine separation of variables into radial and angular parts which we are not interested in here. Actually here we are concerned with the special Hamiltonian which can be obtained from this 4-oscillator Hamiltonian, that is, those Hamiltonians which pose shape invariance symmetry.

In order to achieve it, we write the above Hamiltonian in terms of raising and lowering operators defined in the usual way:

$$H=\omega(a_1^\dagger a_1+a_2^\dagger a_2+a_3^\dagger a_3+a_4^\dagger a_4+2), \tag{3.3}$$

where $a_i(a_i^\dagger)$ are defined as

$$a_i=\sqrt{\frac{\omega}{2}}\left(x_i+\frac{1}{\omega}\frac{d}{dx_i}\right),\quad a_i^\dagger=\sqrt{\frac{\omega}{2}}\left(x_i-\frac{1}{\omega}\frac{d}{dx_i}\right),$$

these operators have the following form in radial coordinate (3.1):

$$\begin{aligned}a_1(a_1^\dagger)=&\sqrt{\frac{\omega}{2}}\Bigg[-r\sin(\psi)\sin(\theta)\sin(\phi)+(-)\frac{1}{\omega}\Bigg(-\sin(\psi)\sin(\theta)\sin(\phi)\partial_r\\&-\frac{1}{r}\cos(\psi)\sin(\theta)\cos(\phi)\partial_\psi-\frac{1}{r}\frac{\cos(\theta)\sin(\phi)}{\sin(\psi)}\partial_\theta-\frac{1}{r}\frac{\cos(\phi)}{\sin(\psi)\sin(\theta)}\partial_\phi\Bigg)\Bigg],\end{aligned}$$

$$\begin{aligned}a_2(a_2^\dagger)=&\sqrt{\frac{\omega}{2}}\Bigg[r\sin(\psi)\sin(\theta)\cos(\phi)+(-)\frac{1}{\omega}\Bigg(\sin(\psi)\sin(\theta)\cos(\phi)\partial_r\\&+\frac{1}{r}\cos(\psi)\sin(\theta)\cos(\phi)\partial_\psi+\frac{1}{r}\frac{\cos(\theta)\cos(\phi)}{\sin(\psi)}\partial_\theta-\frac{1}{r}\frac{\sin(\phi)}{\sin(\psi)\sin(\theta)}\partial\phi\Bigg)\Bigg],\end{aligned}$$

$$\begin{aligned}a_3(a_3^\dagger)=&\sqrt{\frac{\omega}{2}}\Bigg[r\sin(\psi)\cos(\theta)+(-)\frac{1}{\Omega}\Bigg(\sin(\psi)\cos(\theta)\partial_r\\&+\frac{1}{r}\cos(\psi)\cos(\theta)\partial_\psi-\frac{1}{r}\frac{\sin(\theta)}{\sin(\psi)}\partial_\theta\Bigg)\Bigg],\end{aligned}$$

$$a_4(a_4^\dagger)=\sqrt{\frac{\omega}{2}}\left[r\cos(\psi)+(-)\frac{1}{\omega}\left(\cos(\psi)\partial_r-\frac{1}{r}\sin\psi\partial_\psi\right)\right].$$

Now defining the set of new operators $A_i(A_i^\dagger)$, $i=1, 2$ in terms of $a_i(a_i^\dagger)$:

$$A_1=\frac{1}{\sqrt{2}}(a_1+ia_2),\quad A_1^\dagger=\frac{1}{\sqrt{2}}(a_1^\dagger-ia_2^\dagger),$$

$$A_2=\frac{1}{\sqrt{2}}(a_1-ia_2),\quad A_2^\dagger=\frac{1}{\sqrt{2}}(a_1^\dagger+ia_2^\dagger),$$

where, these new operators have the following differential form in radial coordinates:

$$\begin{aligned}A_1=&\frac{i}{\sqrt{2}}\sqrt{\frac{\omega}{2}}e^{i\phi}\Bigg[r\sin(\psi)\sin(\theta)\\&+\frac{1}{\omega}\left(\sin(\psi)\sin(\theta)\partial_r-\frac{1}{r}\cos(\psi)\sin(\theta)\partial_\psi+\frac{1}{r}\frac{\cos(\theta)}{\sin(\psi)}\partial_\theta+\frac{1}{r}\frac{i}{\sin(\psi)\sin(\theta)}\partial\phi\right)\Bigg],\end{aligned}\tag{3.4}$$

$$A_1^\dagger=\frac{-i}{\sqrt{2}}\sqrt{\frac{\omega}{2}}e^{-i\phi}\Bigg[r\sin(\psi)\sin(\theta)+\frac{1}{\omega}\Bigg(\sin(\psi)\sin(\theta)\partial_r+\frac{1}{r}\cos(\psi)\sin(\theta)\partial_\psi+\frac{1}{r}\frac{\cos(\theta)}{\sin(\psi)}\partial_\theta-\frac{1}{r}\frac{i}{\sin(\psi)\sin(\theta)}\partial\phi\Bigg)\Bigg], \quad (3.5)$$

$$A_2=-\frac{i}{\sqrt{2}}\sqrt{\frac{\omega}{2}}e^{-i\phi}\Bigg[r\sin(\psi)\sin(\theta)+\frac{1}{\omega}\Bigg(\sin(\psi)\sin(\theta)\partial_r+\frac{1}{r}\cos(\psi)\sin(\theta)\partial_\psi+\frac{1}{r}\frac{\cos(\theta)}{\sin(\psi)}\partial_\theta-\frac{1}{r}\frac{i}{\sin(\psi)\sin(\theta)}\partial\phi\Bigg)\Bigg], \quad (3.6)$$

$$A_2^\dagger=\frac{i}{\sqrt{2}}\sqrt{\frac{\omega}{2}}e^{i\phi}\Bigg[r\sin(\psi)\sin(\theta)-\frac{1}{\omega}\Bigg(\sin(\psi)\sin(\theta)\partial_r+\frac{1}{r}\cos(\psi)\sin(\theta)\partial_\psi+\frac{1}{r}\frac{\cos(\theta)}{sin(\psi)}\partial_\theta+\frac{1}{r}\frac{i}{\sin(\psi)\sin(\theta)}\partial\phi\Bigg)\Bigg]. \quad (3.7)$$

It is also straightforward to show that they have the following commutator relations:

$$[A_i,A_j^\dagger]=\delta_{ij}, \quad [A_i,A_j]=[A_i^\dagger,A_j^\dagger]=0, \quad i,j=1,2,$$

the 4-oscillators Hamiltonian (3.3) can be written in terms of the new oscillators as follows:

$$H=\omega(A_1^\dagger A_1+A_2^\dagger A_2+a_3^\dagger a_3+a_4^\dagger a_4+2). \quad (3.8)$$

Now its eigenspectrum can be obtained by solving the following eigenvalue equation:

$$H\Psi_{(n_1,n_2,n_3,n_4)}(r,\theta,\phi,\psi)=E_{(n_1,n_2,n_3,n_4)}\Psi_{(n_1,n_2,n_3,n_4)}(r,\theta,\phi,\psi), \quad (3.9)$$

by the usual algebraic method, hence its eigenfunction can be written as

$$\Psi_{(n_1,n_2,n_3,n_4)}(r,\theta,\phi,\psi)=N(A_1^\dagger)^{n_1}(A_2^\dagger)^{n_2}(a_3^\dagger)^{n_3}(a_4^\dagger)^{n_4}\exp\left(-\frac{\omega}{2}r^2\right), \quad (3.10)$$

with $N=\omega/\pi\sqrt{n_1!n_2!n_3!n_4!}$ as normalization constant, and energy $E_{(n_1,n_2,n_3,n_4)}=(n_1+n_2+n_3+n_4+2)\omega$. Using the differential representation of the operator, the wave function (3.10) can be written in the following form:

$$\Psi_{(n_1,n_2,n_3,n_4)}(r,\theta,\phi,\psi)=N2^{(1/2)(n_1+n_2)}e^{i(n_2-n_1)\phi}e^{-(1/2)r^2}(r\sin(\psi)\sin(\theta))^{(n_1+n_2)}\times\mathcal{H}_{n_3}(r\sin(\psi)\cos(\theta))\mathcal{H}_{n_4}(r\cos(\psi))\sum_{i=0}^{n_1}(-1)^i i!\binom{n_1}{i}\binom{n_2}{i}\times(r\sin(\psi)\sin(\theta))^{2i}, \quad (3.11)$$

where $\mathcal{H}_n$ is Hermit polynomial of degree n and $\binom{n_1}{i}=n!/r!(n-r)!$. Now with the same prescription used in the preceding section, we can eliminate ϕ, by Fourier transforming over it, hence, Fourier transforming over ϕ, 4-oscillator Hamiltonian reduces to the following Hamiltonian:

$$H_m(r,\theta,\psi)=-\frac{1}{2}\left[\frac{1}{r^3}\partial_r r^3\partial_r + \frac{1}{r^2}\left(\partial_\psi^2+2\cot(\psi)\partial_\psi+\frac{1}{\sin^2(\psi)}\left(\partial_\theta^2+\cot(\theta)\partial_\theta-\frac{m^2}{\sin^2(\theta)}\right)\right)\right]+\frac{1}{2}\omega^2 r^2, \tag{3.12}$$

where after similarity transformation through function $r^{1/2}$, it reduces to

$$\begin{aligned}\tilde{H}_m(r,\theta,\psi)&=r^{1/2}H_m(r,\theta,\psi)r^{-1/2}\\&=-\frac{1}{2}\left[\frac{1}{r^2}\partial_r r^2\partial_r+\frac{1}{r^2}\left(\partial_\psi^2+2\cot(\psi)\partial_\psi+\frac{1}{\sin^2(\psi)}\left(\partial_\theta^2+\cot(\theta)\partial_\theta-\frac{m^2}{\sin^2(\theta)}\right)\right)\right]\\&\quad+\frac{1}{2}\omega^2 r^2+\frac{3}{8r^2}.\end{aligned} \tag{3.13}$$

On the other hand, the Hamiltonian $H_m(r,\theta,\psi)$ given by (3.12) can be written in the following form:

$$H_m(r,\theta,\psi)=\omega(A_1^\dagger(m+1)A_1(m)+A_2^\dagger(m-1)A_2(m)+a_3^\dagger a_3+a_4^\dagger a_4+2), \tag{3.14}$$

with

$$A_1(m)=\frac{i}{\sqrt{2}}\sqrt{\frac{\omega}{2}}\left[r\sin(\psi)\sin(\theta)+\frac{1}{\omega}\left(\sin(\psi)\sin(\theta)\partial_r-\frac{1}{r}\cos(\psi)\sin(\theta)\partial_\psi+\frac{1}{r}\frac{\cos(\theta)}{\sin(\psi)}\partial_\theta-\frac{1}{r}\frac{m}{\sin(\psi)\sin(\theta)}\right)\right], \tag{3.15}$$

$$A_1^\dagger(m)=-\frac{i}{\sqrt{2}}\sqrt{\frac{\omega}{2}}\left[r\sin(\psi)\sin(\theta)-\frac{1}{\omega}\left(\sin(\psi)\sin(\theta)\partial_r+\frac{1}{r}\cos(\psi)\sin(\theta)\partial_\psi+\frac{1}{r}\frac{\cos(\theta)}{\sin(\psi)}\partial_\theta+\frac{1}{r}\frac{m}{\sin(\psi)\sin(\theta)}\right)\right], \tag{3.16}$$

$$A_2(m)=-\frac{i}{\sqrt{2}}\sqrt{\frac{\omega}{2}}\left[r\sin(\psi)\sin(\theta)+\frac{1}{\omega}\left(\sin(\psi)\sin(\theta)\partial_r+\frac{1}{r}\cos(\psi)\sin(\theta)\partial_\psi+\frac{1}{r}\frac{\cos(\theta)}{\sin(\psi)}\partial_\theta+\frac{1}{r}\frac{m}{\sin(\psi)\sin(\theta)}\right)\right], \tag{3.17}$$

$$A_2^{\dagger}(m)=\frac{i}{\sqrt{2}}\sqrt{\frac{\omega}{2}}\Bigg[r\sin(\psi)\sin(\theta) - \frac{1}{\omega}\Bigg(\sin(\psi)\sin(\theta)\partial_r+\frac{1}{r}\cos(\psi)\sin(\theta)\partial_\psi+\frac{1}{r}\frac{\cos(\theta)}{sin(\psi)}\partial_\theta-\frac{1}{r}\frac{m}{\sin(\psi)\sin(\theta)}\Bigg)\Bigg]. \tag{3.18}$$

It is straightforward to derive the following relation between Hamiltonian (3.12) and operator $A_i(m)(A_i^{\dagger}(m))$, $i=1, 2$:

$$\begin{aligned} H(m-1)A_1^{\dagger}(m)-A_1^{\dagger}(m)H(m)&=\omega A_1^{\dagger}(m),\\ H(m+1)A_2^{\dagger}(m)-A_2^{\dagger}(m)H(m)&=\omega A_2^{\dagger}(m),\\ H(m+1)A_1(m)-A_1(m)H(m)&=-\omega A_1(m),\\ H(m-1)A_2(m)-A_2(m)H(m)&=-\omega A_2(m), \end{aligned} \tag{3.19}$$

where $H(m)\coloneqq H_m(r,\theta,\psi)$. The above relations indicate that the Hamiltonian (3.12) poses shape invariance symmetry, to see it, we consider the Fourier transformation of eigenvalue equation (3.9):

$$H(m)\Psi_{(n,m,n_3,n_4)}(r,\theta,\psi)=E_{(n,n_3,n_4)}\Psi_{(n,m,n_3,n_4)}(r,\theta,\psi), \tag{3.20}$$

where $n=n_1+n_2, m=n_2-n_1$, and $E_{(n,n_3,n_4)}=(n+n_3+n_4+2)\omega$. Since n_1 and n_2 are positive integer, therefore n is also a positive integer, but m is an integer. For a given value of m, the quantum number n can be either even integer or odd integer, since, quantum numbers n_1 and n_2 should vary by the same amount, so that m remains constant. Actually for given value of m, the quantum number n can take the following value:

$$n=|m|,|m|+2,|m|+4,\ldots,$$

on the other hand, for the value of n, the quantum number m can take the following values:

$$m=-n,-n+2,\ldots,n-2,n.$$

It is interesting to see that the energy of Hamiltonians $H_m(r,\theta,\psi)$ is independent of m, hence these Hamiltonians are isospectral which is due to existence of shape invariance symmetry as we show below.

Operating the operator $A_1^{\dagger}(m)$ on both sides of the eigenvalue relation (3.20) and using the relations (3.19), we get

$$H(m-1)(A_1^{\dagger}(m)\Psi_{n,m}(r,\theta,\psi))=(E_n+\omega)(A_1^{\dagger}(m)\Psi_{n,m}(r,\theta,\psi)),$$

therefore, $A_1^{\dagger}(m)\Psi_{n,m}(r,\theta,\psi))$ corresponds to the eigenfunction of $H(m-1)$ with corresponding eigenvalue E_{n+1}, that is

$$A_1^{\dagger}(m)\Psi_{n,m}(r,\theta,\psi)=\sqrt{\frac{n-m}{2}+1}\Psi_{n+1,m-1}(r,\theta,\psi),$$

where $\Psi_{n,m}(r,\theta,\psi)\coloneqq\Psi_{(n,m,n_3,n_4)}(r,\theta,\psi)$ and $E_n\coloneqq E_{(n,n_3,n_4)}$. Similarly operating operator $A_2^{\dagger}(m)$ on both sides of (3.20) and using (3.19) we get

$$H(m+1)(A_2^{\dagger}(m)\Psi_{n,m}(r,\theta,\psi))=(E_n+\omega)(A_2^{\dagger}(m)\Psi_{n,m}(r,\theta,\psi)),$$

which leads to

$$A_2^\dagger(m)\Psi_{n,m}(r,\theta,\psi)=\sqrt{\frac{n+m}{2}+1}\,\Psi_{n+1,m+1}(r,\theta,\psi).$$

Also by acting the operators $A_1(m)$ and $A_2(m)$ on the eigenvalue relation (3.20) and using the relations (3.19), we obtain

$$H(m+1)(A_1(m)\Psi_{n,m}(r,\theta,\psi))=(E_n-\omega)(A_1(m)\Psi_{n,m}(r,\theta,\psi)),$$

$$H(m-1)(A_2(m)\Psi_{n,m}(r,\theta,\psi))=(E_n-\omega)(A_2(m)\Psi_{n,m}(r,\theta,\psi)),$$

which imply the following relations:

$$A_1(m)\Psi_{n,m}(r,\theta,\psi)=\sqrt{\frac{n-m}{2}}\Psi_{n-1,m+1}(r,\theta,\psi),$$

$$A_2(m)\Psi_{n,m}(r,\theta,\psi)=\sqrt{\frac{n+m}{2}}\Psi_{n-1,m-1}(r,\theta,\psi).$$

From the above relations we conclude that the pair of operators $(A_2(m),A_1^\dagger(m))$ or $(A_2^\dagger(m),A_1(m))$ acting at eigenfunction $\Psi_{n,m}(r,\theta,\psi)$ of Hamiltonian $H(m)$, give the eigenfunction of the Hamiltonian $H(m\pm2)$ with the same energy as follows:

$$A_2(m-1)A_1^\dagger(m)\Psi_{n,m}(r,\theta,\psi)=\tfrac{1}{2}\sqrt{(n+m)(n-m+2)}\Psi_{n,m-2}(r,\theta,\psi),$$

$$A_2^\dagger(m+1)A_1(m)\Psi_{n,m}(r,\theta,\psi)=\tfrac{1}{2}\sqrt{(n-m)(n+m+2)}\Psi_{n,m-2}(r,\theta,\psi).$$

Now introducing the operators $A_-(m):=A_2(m-1)A_1^\dagger(m)$ and $A_+(m):=A_2^\dagger(m-1)A_1(m-2)$, we have

$$A_-(m)A_+(m)\Psi_{n,m-2}(r,\theta,\psi)=E(n,m)\Psi_{n,m-2}(r,\theta,\psi),$$

$$A_+(m)A_-(m)\Psi_{n,m}(r,\theta,\psi)=E(n,m)\Psi_{n,m}(r,\theta,\psi),$$

where

$$E(n,m)=\tfrac{1}{4}(n+m)(n-m+2).$$

The above relations show the existence of shape invariance symmetry between the Hamiltonian $H(m)$ and $H(m-2)$ with the same given eigenvalue E_n. Hence we can obtain the eigenfunction $\Psi_{n,m}(r,\theta,\psi)$ of Hamiltonian $H(m)$ by consecutive action of related raising operators over $\Psi_{n,n}(r,\theta,\psi)$:

$$\Psi_{n,m}(r,\theta,\psi)=c^{-1}A_-(m+2)A_-(m+4)\cdots A_-(n-2)A_-(n)\Psi_{n,n}(r,\theta,\psi),$$

where

$$c=\frac{1}{2^{(n-m)/2}}\sqrt{(n-m)!!2n(2n-2)\cdots(n+m+4)(n+m+2)}$$

and

$$(n-m)!!=(n-m)(n-m-2)\cdots4\times2,$$

$$\Psi_{n,n}(r,\theta,\psi)\equiv\Psi_{(n,n,n_3,n_4)}(r,\theta,\psi)=(a_3^\dagger)^{n_3}(a_4^\dagger)^{n_4}A_2^\dagger(n-1)A_2^\dagger(n-2)\cdots A_2^\dagger(1)A_2^\dagger(0)e^{-1/2\,\omega r^2}.$$

Of course we can obtain the eigenfunction $\Psi_{(n,m,n_3,n_4)}(r,\theta,\psi)$ by reduction of coordinate ϕ via Fourier transformation of (3.11), which have the following form:

$$\Psi_{(n,m,n_3,n_4)}(r,\theta,\psi)=N2^{n/2}e^{-(1/2)r^2}(r\sin(\psi)\sin(\theta))^n \times\mathcal{H}_{n_3}(\sin(\psi)\sin(\theta))\mathcal{H}_{n_4}(r\cos(\psi)) \times\sum_{i=0}^{(n-m)/2}(-1)^i i!\binom{\frac{n-m}{2}}{i}\binom{\frac{n+m}{2}}{i}(r\sin(\psi)\sin(\theta))^{2i}.$$

IV. CONCLUSION

In this work, Fourier transforming over three- and four-dimensional Hamiltonian associated with su(2) and Heisenberg Lie algebra we have been able to obtain two- and three-dimensional Hamiltonians with shape invariance symmetry. It would be interesting to obtain many-body Hamiltonians in one or higher dimension, which poses shape invariance symmetry by appropriate Fourier transformation over some coordinates of the Hamiltonian associated with higher ranks semisimple and nonsemisimple Lie algebra, which is under investigation.

ACKNOWLEDGMENT

We wish to thank Dr. S. K. A. Seyed Yagoobi for carefully reading the paper and for his constructive comments.

The Bargmann representation for the quantum mechanics on a sphere

K. Kowalski[a] and J. Rembieliński
Department of Theoretical Physics, University of Łódź, ul. Pomorska 149/153, 90-236 Łódź, Poland

(Received 9 November 2000; accepted for publication 18 April 2001)

The Bargmann representation is constructed corresponding to the coherent states for a particle on a sphere introduced in Kowalski and Rembieliński, J. Phys. A: **33**, 6035 (2000). The connection is discussed between the introduced formalism and the standard approach based on the Hilbert space of square integrable functions on a sphere S^2. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1385376]

I. INTRODUCTION

In our recent paper[1] the coherent states for a particle on a sphere have been introduced. As with the standard coherent states[2] those states are labeled by points of the classical phase space, i.e., the cotangent bundle T^*S^2. It is worthwhile to recall that the celebrated spin coherent states[3] are not related to the phase space for a particle on the sphere S^2. One of the most characteristic properties of coherent states is the existence of the Bargmann representation. Such a representation is of importance not only from the mathematical point of view. An example of applications are the Husimi functions, i.e., the elements of the Bargmann space, in the theory of quantum chaos. In this work we introduce the Bargmann representation referring to the coherent states for a particle on a sphere mentioned above. It should be noted that, in opposition to the case of the standard coherent states, the construction of such a Bargmann representation is a highly nontrivial problem. The paper is organized as follows. In Sec. II we recall the basic properties of the coherent states for a particle on a sphere. Sections III–V are devoted to the construction of the Bargmann representation. In Sec. VI we discuss the connection of the introduced Bargmann representation and the standard coordinate representation for the quantum mechanics on a sphere.

II. COHERENT STATES FOR A PARTICLE ON A SPHERE

Our purpose in this section is to recall the basic properties of the coherent states for a particle on a sphere introduced in Ref. 1. Those states are related to the $e(3)$ algebra of the form

$$[J_i,J_j]=\mathrm{i}\epsilon_{ijk}J_k, \quad [J_i,X_j]=\mathrm{i}\epsilon_{ijk}X_k, \quad [X_i,X_j]=0, \quad i,j,k=1,2,3. \tag{2.1}$$

The Casimir operators are given in a unitary irreducible representation by

$$\mathbf{X}^2=r^2, \quad \mathbf{J}\cdot\mathbf{X}=\lambda, \tag{2.2}$$

where a dot designates the scalar product. In Ref. 1 we restricted to the special case $\lambda=0$, so

$$\mathbf{J}\cdot\mathbf{X}=0. \tag{2.3}$$

The irreducible representation of (2.1) under the choice (2.3) is spanned by the common eigenvectors $|j,m;r\rangle$ of the operators $\mathbf{J}^2$, $\mathbf{X}^2$ and $\mathbf{J}\cdot\mathbf{X}$. We have

$$\mathbf{J}^2|j,m;r\rangle=j(j+1)|j,m;r\rangle,\ J_3|j,m;r\rangle=m|j,m;r\rangle, \tag{2.4a}$$

[a]Electronic mail: kowalski@krysia.uni.lodz.pl

$$\mathbf{X}^2|j,m;r\rangle = r^2|j,m;r\rangle,\ (\mathbf{J}\cdot\mathbf{X}/r)|j,m;r\rangle = 0, \tag{2.4b}$$

where $-j \leqslant m \leqslant j$. The operators $J_\pm = J_1 \pm iJ_2$, $X_\pm = X_1 \pm iX_2$ and X_3 act on the vectors $|j,m;r\rangle$ as follows:

$$J_\pm|j,m;r\rangle = \sqrt{(j\mp m)(j\pm m+1)}\,|j,m\pm 1;r\rangle, \tag{2.5a}$$

$$X_\pm|j,m;r\rangle = \mp\frac{r\sqrt{(j\pm m+1)(j\pm m+2)}}{\sqrt{(2j+1)(2j+3)}}|j+1,m\pm 1;r\rangle \pm \frac{r\sqrt{(j\mp m-1)(j\mp m)}}{\sqrt{(2j-1)(2j+1)}}|j-1,m\pm 1;r\rangle, \tag{2.5b}$$

$$X_3|j,m;r\rangle = \frac{r\sqrt{(j-m+1)(j+m+1)}}{\sqrt{(2j+1)(2j+3)}}|j+1,m;r\rangle + \frac{r\sqrt{(j-m)(j+m)}}{\sqrt{(2j-1)(2j+1)}}|j-1,m;r\rangle. \tag{2.5c}$$

The orthogonality and completeness conditions satisfied by the vectors $|j,m;r\rangle$ can be written as

$$\langle j,m;r|j',m';r\rangle = \delta_{jj'}\delta_{mm'}, \tag{2.6}$$

$$\sum_{j=0}^{\infty}\sum_{m=-j}^{j}|j,m;r\rangle\langle j,m;r| = I, \tag{2.7}$$

where I is the identity operator.

We are now in a position to introduce the coherent states for a particle on a sphere. Namely, these states are defined as the solution of the eigenvalue equation of the form

$$\mathbf{Z}|\mathbf{z}\rangle = \mathbf{z}|\mathbf{z}\rangle, \tag{2.8}$$

where $\mathbf{Z}$ is given by

$$\mathbf{Z} = \left(\frac{e^{1/2}}{\sqrt{1+4\mathbf{J}^2}}\sinh\tfrac{1}{2}\sqrt{1+4\mathbf{J}^2} + e^{1/2}\cosh\tfrac{1}{2}\sqrt{1+4\mathbf{J}^2}\right)\frac{\mathbf{X}}{r} + i\left(\frac{2e^{1/2}}{\sqrt{1+4\mathbf{J}^2}}\sinh\tfrac{1}{2}\sqrt{1+4\mathbf{J}^2}\right)\mathbf{J}\times\frac{\mathbf{X}}{r}, \tag{2.9}$$

where the cross designates the vector product. The operator $\mathbf{Z}$ and $\mathbf{z}\in\mathbf{C}^3$ obey

$$\mathbf{Z}^2 = 1,\ \mathbf{z}^2 = 1. \tag{2.10}$$

We also write down the following matrix representation of the operator $\mathbf{Z}$ which is crucial for the algebraic analysis of the problem:

$$e^{-(\boldsymbol{\sigma}\cdot\mathbf{J}+1)}\boldsymbol{\sigma}\cdot\mathbf{X} = \boldsymbol{\sigma}\cdot\mathbf{Z}, \tag{2.11}$$

where σ_i, $i=1,2,3$, are the Pauli matrices.

As with the standard coherent states we can generate the coherent states from the "fiducial vector" $|\mathbf{n}_3\rangle$ such that

$$\mathbf{Z}|\mathbf{n}_3\rangle = \mathbf{n}_3|\mathbf{n}_3\rangle, \tag{2.12}$$

where $\mathbf{n}_3 = (0,0,1)$, and

$$|\mathbf{n}_3\rangle = \sum_{j=0}^{\infty} e^{-(1/2)j(j+1)}\sqrt{2j+1}\,|j,0;r\rangle. \tag{2.13}$$

Namely, the coherent states are given by

$$|\mathbf{z}\rangle = \exp\left[\frac{\operatorname{arccosh} z_3}{\sqrt{1-z_3^2}}(\mathbf{z}\times\mathbf{n}_3)\cdot\mathbf{J}\right]|\mathbf{n}_3\rangle. \tag{2.14}$$

The projection of the coherent states (2.14) on the discrete basis vectors $|j,m;r\rangle$ is

$$\langle j,m;r|\mathbf{z}\rangle = e^{-(1/2)j(j+1)}\sqrt{2j+1}\frac{(2|m|)!}{|m|!}\sqrt{\frac{(j-|m|)!}{(j+|m|)!}}\left(\frac{-\epsilon(m)z_1+\mathrm{i}z_2}{2}\right)^{|m|}C_{j-|m|}^{|m|+1/2}(z_3), \tag{2.15}$$

where $\epsilon(m)$ is the sign of m, and $C_n^{\alpha}(x)$ are the Gegenbauer polynomials expressed with the help of the hypergeometric function ${}_2F_1(a,b,c;z)$ by

$$C_n^{\alpha}(x) = \frac{\Gamma(n+2\alpha)}{\Gamma(n+1)\Gamma(2\alpha)}\,{}_2F_1(-n,n+2\alpha,\alpha+\tfrac{1}{2};\tfrac{1}{2}(1-x)). \tag{2.16}$$

As mentioned earlier the coherent states are labeled by points of the classical phase space T^*S^2. The most natural complex parametrization of the phase space discussed in Ref. 1 is of the form

$$\mathbf{z} = \cosh|\mathbf{l}|\,\frac{\mathbf{x}}{r} + \mathrm{i}\frac{\sinh|\mathbf{l}|}{|\mathbf{l}|}\mathbf{l}\times\frac{\mathbf{x}}{r}, \tag{2.17}$$

where the vectors $\mathbf{l}$, $\mathbf{x}\in\mathbf{R}^3$, fulfill $\mathbf{x}^2 = r^2$ and $\mathbf{l}\cdot\mathbf{x} = 0$, that is $\mathbf{l}$ is the classical angular momentum and $\mathbf{x}$ is the radius vector of a particle on a sphere. Clearly, the vector $\mathbf{z}$ satisfies the second equation of (2.10). We point out that due to the quantum fluctuations the practically exact coincidence of average values of $\mathbf{J}$ and $\mathbf{X}$ in the normalized coherent state $|\mathbf{z}\rangle/\sqrt{\langle\mathbf{z}|\mathbf{z}\rangle}$, where $\mathbf{z}$ is given by (2.17), with $\mathbf{l}$ and $\mathbf{x}$, respectively, takes place for $|\mathbf{l}|\geqslant 10$.[1]

III. SCALAR PRODUCT

In this section we identify the Bargmann space of analytic functions corresponding to the coherent states for a particle on a sphere described above. We now restrict, without loss of generality, to the case with the unit sphere. On introducing the spherical coordinates $\mathbf{x} = (\sin\theta\cos\varphi, \sin\theta\sin\varphi, \cos\theta)$, and parametrizing the tangent vector $\mathbf{l}$ by its norm $|\mathbf{l}| \equiv l$ and the angle α between $\mathbf{l}$ and the meridian passing through the point with the radius vector $\mathbf{x}$, we obtain from (2.17) the following natural coordinates of the phase space compatible with the constraints:

$$\begin{aligned} z_1 &= \cosh l\,\sin\theta\cos\varphi + \mathrm{i}\sinh l(\sin\alpha\cos\varphi\cos\theta - \cos\alpha\sin\varphi),\\ z_2 &= \cosh l\,\sin\theta\sin\varphi + \mathrm{i}\sinh l(\sin\alpha\sin\varphi\cos\theta + \cos\alpha\cos\varphi),\\ z_3 &= \cosh l\cos\theta - \mathrm{i}\sinh l\sin\alpha\sin\theta. \end{aligned} \tag{3.1}$$

Taking into account the fact that $\mathbf{z}$ transforms as the vector we find that the Bargmann space should be specified by

$$\langle\phi|\psi\rangle = \frac{1}{8\pi^2}\int_0^{2\pi}d\varphi\int_0^{\pi}\sin\theta\,d\theta\int_0^{2\pi}d\alpha\int_0^{\infty}dl\,h(l)(\phi(\mathbf{z}^*(\theta,\varphi,\alpha,l)))^*\psi(\mathbf{z}^*(\theta,\varphi,\alpha,l)), \tag{3.2}$$

where $\phi(\mathbf{z}^*) = \langle\mathbf{z}|\phi\rangle$, $\mathbf{z}^* = (z_1^*, z_2^*, z_3^*)$, $h(l)$ is an unknown density and $\mathbf{z}(\theta,\varphi,\alpha,l)$ is expressed by (3.1). Clearly, the corresponding resolution of the identity can be written in the form

$$\frac{1}{8\pi^2}\int_0^{2\pi} d\varphi \int_0^{\pi} \sin\theta\, d\theta \int_0^{2\pi} d\alpha \int_0^{\infty} h(l)dl\, |\mathbf{z}(\theta,\varphi,\alpha,l)\rangle\langle \mathbf{z}(\theta,\varphi,\alpha,l)| = I. \tag{3.3}$$

In order to fix $h(l)$ consider the basis of the Bargmann space with the scalar product (3.2),

$$e_{jm}(\mathbf{z}(\theta,\varphi,\alpha,l)) = \langle j,m|\mathbf{z}\rangle, \tag{3.4}$$

where $|j,m\rangle \equiv |j,m;1\rangle$ and $\langle j,m;r|\mathbf{z}\rangle$ is given by (2.15) and (3.1). Using (3.2) and (3.4) we get after some calculation,

$$\begin{aligned}\langle j,m|j',m'\rangle &= \frac{1}{8\pi^2}\int_0^{2\pi} d\varphi \int_0^{\pi} \sin\theta\, d\theta \int_0^{2\pi} d\alpha \int_0^{\infty} dl\, h(l) \\ &\quad \times (e_{jm}(\mathbf{z}^*(\theta,\varphi,\alpha,l)))^* e_{j'm'}(\mathbf{z}^*(\theta,\varphi,\alpha,l)) \\ &= \delta_{jj'}\delta_{mm'} e^{-j(j+1)} \int_0^{\infty} dl\, h(l) P_j(\cosh 2l),\end{aligned} \tag{3.5}$$

where $P_n(z)$ are the Legendre polynomials such that

$$P_n(z) = \frac{1}{2^n n!}\frac{d^n}{dz^n}(z^2-1)^n. \tag{3.6}$$

Thus the normalization condition for the orthonormal basis $\{|j,m\rangle\}$ leads to the following equation on the density $h(l)$:

$$\int_0^{\infty} dl\, h(l) P_j(\cosh 2l) = e^{j(j+1)}. \tag{3.7}$$

We remark that the problem of the solution of this equation is highly nontrivial (see the Acknowledgements) and it is related to the so called problem of moments.[4] We now recall that the Legendre polynomials satisfy the differential equation

$$\left((z^2-1)\frac{d^2}{dz^2} + 2z\frac{d}{dz}\right) P_n(z) = n(n+1)P_n(z). \tag{3.8}$$

From (3.8) it follows easily that

$$\frac{1}{\sinh\rho}\,\frac{d}{d\rho}\sinh\rho\frac{d}{d\rho}P_n(\cosh\rho) = n(n+1)P_n(\cosh\rho). \tag{3.9}$$

We remark that the operator from the left hand side of (3.9) is simply the Laplacian for the two-dimensional hyperbolic space. Consider the heat kernel at the origin in hyperbolic space,[5] given by

$$k_{H^2}(\rho,t) = 2^{1/2}(4\pi t)^{-3/2} e^{-t/4} \int_{\rho}^{\infty} \frac{s e^{-s^2/4t}}{(\cosh s - \cosh\rho)^{1/2}} ds. \tag{3.10}$$

This heat kernel obeys the equation

$$\frac{\partial k_{H^2}}{\partial t} = \frac{1}{\sinh\rho}\,\frac{d}{d\rho}\sinh\rho\frac{d}{d\rho}k_{H^2}(\rho,t), \tag{3.11}$$

subject to the initial condition

$$2\pi \lim_{t\to 0} \int_0^\infty k_{H^2}(\rho,t) f(\rho) \sinh\rho \, d\rho = f(0), \tag{3.12}$$

where f is an arbitrary continuous function with at most exponential growth at infinity. Putting $f(\rho)=P_n(\cosh\rho)$, and making use of (3.11), (3.12) and the fact that $k_{H^2}(\rho,t)$ and $(d/d\rho)k_{H^2}(\rho,t)$ decay faster-than-exponentially, we get

$$2\pi \int_0^\infty k_{H^2}(\rho,t) P_n(\cosh\rho) \sinh\rho \, d\rho = e^{tn(n+1)}. \tag{3.13}$$

Hence, setting in (3.13) $\rho=2l$ and $t=1$, we finally find that the desired density $h(l)$ satisfying (3.7) is

$$h(l) = 4\pi k_{H^2}(2l,1) \sinh 2l \tag{3.14a}$$

$$= \frac{e^{-1/4} \sinh 2l}{\sqrt{2\pi}} \int_{2l}^\infty \frac{s e^{-s^2/4}}{(\cosh s - \cosh 2l)^{1/2}} ds. \tag{3.14a}$$

We have thus identified the Bargmann space for the quantum mechanics on a sphere specified by (3.2) and (3.14). Taking into account (3.1), (3.14a) and the relation which is an immediate consequence of (2.17) such that

$$\mathbf{z}\cdot\mathbf{z}^* = |\mathbf{z}|^2 = \cosh 2l, \tag{3.15}$$

the following form can be derived of the scalar product (3.2) written with the help of the complex variables $\mathbf{z}$ (3.1) analogous to the usual Bargmann representation[6] for the standard coherent states:

$$\langle \phi | \psi \rangle = \int_{\mathbf{z}^2=1} d\mu(\mathbf{z}) (\phi(\mathbf{z}^*))^* \psi(\mathbf{z}^*), \tag{3.16}$$

where

$$d\mu(\mathbf{z}) = \frac{1}{4\pi} k_{H^2}(\operatorname{arccosh}(\mathbf{z}\cdot\mathbf{z}^*),1) dz_1 \, dz_2 \, dz_3 \, dz_1^* \, dz_2^* dz_3^*, \tag{3.17}$$

and $\phi(\mathbf{z}^*)=\langle \mathbf{z}|\phi\rangle$. Evidently, the completeness of the coherent states can be written with the help of the measure $d\mu(\mathbf{z})$ as

$$\int_{\mathbf{z}^2=1} d\mu(\mathbf{z}) |\mathbf{z}\rangle\langle\mathbf{z}| = I. \tag{3.18}$$

IV. REPRODUCING KERNEL

As is well-known the existence of the reproducing kernel is one of the most characteristic properties of coherent states. In view of (3.18) the reproducing property can be written in the form

$$\phi(\mathbf{w}^*) = \int_{\mathbf{z}^2=1} d\mu(\mathbf{z}) \mathcal{K}(\mathbf{w}^*,\mathbf{z}) \phi(\mathbf{z}^*), \tag{4.1}$$

where $\phi(\mathbf{w}^*)=\langle \mathbf{w}|\phi\rangle$, and

$$\mathcal{K}(\mathbf{w}^*,\mathbf{z}) = \langle \mathbf{w}|\mathbf{z}\rangle. \tag{4.2}$$

It should be noted that the reproducing kernel $\mathcal{K}(\mathbf{w}^*,\mathbf{z})$ is the complex conjugate of the analytic function

$$\phi_{\mathbf{w}}(\mathbf{z}^*)=\langle \mathbf{z}|\mathbf{w}\rangle, \tag{4.3}$$

representing the abstract coherent state $|\mathbf{w}\rangle$ also called its symbol. The formula on the overlap $\langle \mathbf{z}|\mathbf{w}\rangle$ can be obtained from (2.14), (2.13) and (2.15). Namely, we have

$$\langle \mathbf{z}|\mathbf{w}\rangle=\sum_{j=0}^{\infty} e^{-j(j+1)}(2j+1)P_j(\mathbf{z}^*\cdot\mathbf{w}), \tag{4.4}$$

where $P_j(z)$ are the Legendre polynomials given by (3.6).

V. ACTION OF OPERATORS

We now discuss the action of operators in the Bargmann representation. We first observe that an immediate consequence of (2.8) is the following formula on the action of operators $\mathbf{Z}^\dagger$:

$$\mathbf{Z}^\dagger\phi(\mathbf{z}^*)=\mathbf{z}^*\phi(\mathbf{z}^*), \tag{5.1}$$

where $\phi(\mathbf{z}^*)=\langle \mathbf{z}|\phi\rangle$ and we recall that $\mathbf{z}^2=1$. Now consider the action of the operator $\mathbf{J}^2$. By (2.4a) the action of the operator $\mathbf{J}^2$ on the basis $e_{jm}(\mathbf{z}^*)=\langle \mathbf{z}|j,m\rangle$ of the Bargmann space is the following one:

$$\mathbf{J}^2 e_{jm}(\mathbf{z}^*)=j(j+1)e_{jm}(\mathbf{z}^*). \tag{5.2}$$

Using (2.15), the differential equation satisfied by the Gegenbauer polynomials of the form

$$\left((z^2-1)\frac{d^2}{dz^2}+(2\lambda+1)\frac{d}{dz}-n(2\lambda+n)\right)C_n^\lambda(z)=0, \tag{5.3}$$

and (5.2) we find that the operator $\mathbf{J}^2$ acts in the representation (3.16) as follows:

$$\mathbf{J}^2\phi(\mathbf{z}^*)=-\left(\mathbf{z}^*\times\frac{\partial}{\partial\mathbf{z}^*}\right)^2\phi(\mathbf{z}^*). \tag{5.4}$$

Taking into account (5.4) and (5.1) we obtain

$$\mathbf{J}\phi(\mathbf{z}^*)=-\mathrm{i}\left(\mathbf{z}^*\times\frac{\partial}{\partial\mathbf{z}^*}\right)\phi(\mathbf{z}^*). \tag{5.5}$$

The relation (5.5) can be easily checked on the basis $e_{jm}(\mathbf{z}^*)$ with the help of (2.15), (2.4a) and (2.5a). Further, using (2.5c), (2.15) and elementary properties of the Gegenbauer polynomials we get

$$X_3\phi(\mathbf{z}^*)=e^{-(1/2)\mathbf{J}^2}z_3^* e^{(1/2)\mathbf{J}^2}\phi(\mathbf{z}^*), \tag{5.6}$$

where the action of $\mathbf{J}^2$ is given by (5.4). The action of the remaining coordinates of the position operator $\mathbf{X}$ can be obtained by means of the following identity describing the complex rotation of $\mathbf{X}$:

$$e^{\mathbf{w}\cdot\mathbf{J}}\mathbf{X}e^{-\mathbf{w}\cdot\mathbf{J}}=\cosh\sqrt{\mathbf{w}^2}\,\mathbf{X}-\mathrm{i}\,\frac{\sinh\sqrt{\mathbf{w}^2}}{\sqrt{\mathbf{w}^2}}\mathbf{w}\times\mathbf{X}+\frac{1-\cosh\sqrt{\mathbf{w}^2}}{\mathbf{w}^2}\mathbf{w}(\mathbf{w}\cdot\mathbf{X}). \tag{5.7}$$

Namely, we have

$$X_1\phi(\mathbf{z}^*)=-\frac{\mathrm{i}}{\sinh 1}(e^{J_2-(1/2)\mathbf{J}^2}z_3^*e^{(1/2)\mathbf{J}^2-J_2}-\cosh 1\,e^{-(1/2)\mathbf{J}^2}z_3^*e^{(1/2)\mathbf{J}^2})\phi(\mathbf{z}^*), \tag{5.8a}$$

$$X_2\phi(\mathbf{z}^*)=\frac{\mathrm{i}}{\sinh 1}(e^{J_1-(1/2)\mathbf{J}^2}z_3^*e^{(1/2)\mathbf{J}^2-J_1}-\cosh 1\,e^{-(1/2)\mathbf{J}^2}z_3^*e^{(1/2)\mathbf{J}^2})\phi(\mathbf{z}^*), \tag{5.8b}$$

where the action of the operators J_i, $i=1,2$, and $\mathbf{J}^2$ is given by (5.5) and (5.4), respectively. Finally, taking into account the identity

$$\mathbf{Z}=e^{-(1/2)\mathbf{J}^2}\mathbf{X}e^{(1/2)\mathbf{J}^2}, \tag{5.9}$$

which is a straightforward consequence of (2.11) and the commutation relation

$$[\mathbf{J}^2,\boldsymbol{\sigma}\cdot\mathbf{X}]=-2(\boldsymbol{\sigma}\cdot\mathbf{J}+1)\boldsymbol{\sigma}\cdot\mathbf{X}, \tag{5.10}$$

following directly from (2.1) and (2.3), we obtain the action of the operator $\mathbf{Z}$. It follows that

$$Z_1\phi(\mathbf{z}^*)=-\frac{\mathrm{i}}{\sinh 1}(e^{J_2-\mathbf{J}^2}z_3^*e^{\mathbf{J}^2-J_2}-\cosh 1\,e^{-\mathbf{J}^2}z_3^*e^{\mathbf{J}^2})\phi(\mathbf{z}^*), \tag{5.11a}$$

$$Z_2\phi(\mathbf{z}^*)=\frac{\mathrm{i}}{\sinh 1}(e^{J_1-\mathbf{J}^2}z_3^*e^{\mathbf{J}^2-J_1}-\cosh 1\,e^{-\mathbf{J}^2}z_3^*e^{\mathbf{J}^2})\phi(\mathbf{z}^*), \tag{5.11b}$$

$$Z_3\phi(\mathbf{z}^*)=e^{-\mathbf{J}^2}z_3^*e^{\mathbf{J}^2}\phi(\mathbf{z}^*). \tag{5.11c}$$

VI. THE BARGMANN REPRESENTATION AND THE COORDINATE REPRESENTATION

In this section we discuss the relationship between the introduced Bargmann representation and the standard coordinate representation for the quantum mechanics on a sphere. We begin with recalling the basic facts about the coordinate representation. Consider the position operators $\mathbf{X}$ for a particle on a sphere satisfying the $e(3)$ algebra (2.1). Recall that we restrict to the irreducible representations which fulfil (2.3) and $\mathbf{X}^2=1$. The coordinate representation is spanned by the common eigenvectors $|\mathbf{x}\rangle$ of the position operators such that

$$\mathbf{X}|\mathbf{x}\rangle=\mathbf{x}|\mathbf{x}\rangle, \tag{6.1}$$

where $\mathbf{x}^2=1$. The resolution of the identity is of the form

$$\int_{\mathbf{x}^2=1}d\nu(\mathbf{x})|\mathbf{x}\rangle\langle\mathbf{x}|=I, \tag{6.2}$$

where $d\nu(\mathbf{x})=d\nu(\theta,\varphi)=\sin\theta\,d\varphi\,d\theta$, accordingly to the natural, i.e., spherical coordinates $\mathbf{x}=(\sin\theta\cos\varphi,\sin\theta\sin\varphi,\cos\theta)$ compatible with the constraint $\mathbf{x}^2=1$. The completeness gives rise to a functional representation of vectors such that

$$\langle\phi|\psi\rangle=\int_{\mathbf{x}^2=1}d\nu(\mathbf{x})\,\phi^*(\mathbf{x})\,\psi(\mathbf{x}), \tag{6.3}$$

where $\phi(\mathbf{x})=\langle\mathbf{x}|\phi\rangle$. Clearly, we can write the completeness condition (6.2) and the scalar product (6.3) as

$$\int_0^{2\pi}d\varphi\int_0^{\pi}\sin\theta\,d\theta|\theta,\varphi\rangle\langle\theta,\varphi|=I, \tag{6.4}$$

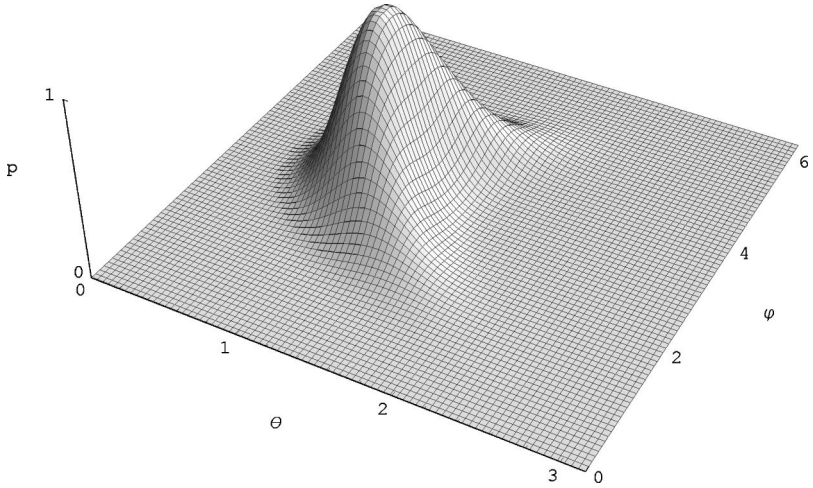

FIG. 1. The plot of the probability density given by (6.14) in the spherical coordinates $\mathbf{x}=(\sin\theta\cos\varphi,\ \sin\theta\sin\varphi,\cos\theta)$, where $\mathbf{z}=\cosh|\mathbf{l}|\overline{\mathbf{x}}+\mathrm{i}(\sinh|\mathbf{l}|/|\mathbf{l}|)\mathbf{l}\times\overline{\mathbf{x}}$ [see (2.17)] and $\overline{\mathbf{x}}=(\sin\overline{\theta}\cos\overline{\varphi},\sin\overline{\theta}\sin\overline{\varphi},\cos\overline{\theta})$ with $\overline{\theta}=\pi/3$ and $\overline{\varphi}=\pi$. The viewpoint slightly above the surface.

where $|\theta,\varphi\rangle\equiv|\mathbf{x}\rangle$, and

$$\langle\phi|\psi\rangle=\int_0^{2\pi}d\varphi\int_0^{\pi}\sin\theta\,d\theta\,\phi^*(\theta,\varphi)\psi(\theta,\varphi),\tag{6.5}$$

where $\phi(\theta,\varphi)=\langle\theta,\varphi|\phi\rangle$, respectively. The passage from the coordinate representation to the angular momentum representation generated by the vectors $|j,m\rangle$ satisfying (2.4) with $r=1$ is given by

$$\langle\theta,\varphi|j,m\rangle=Y_{jm}(\theta,\varphi)=(-1)^{(m-|m|)/2}\sqrt{\frac{(2j+1)(j-|m|)!}{4\pi(j+|m|)!}}P_j^{|m|}(\cos\theta)e^{\mathrm{i}m\varphi},\tag{6.6}$$

where $Y_{jm}(\theta,\varphi)$ are the spherical harmonics and $P_n^m(z)$ are the associated Legendre polynomials which can be defined by

$$P_n^m(z)=(-1)^m(1-z^2)^{m/2}\frac{d^m}{dz^m}P_n(z),\tag{6.7}$$

where $P_n(z)$ are the Legendre polynomials given by (3.6). Of course, $Y_{jm}(\theta,\varphi)$ form the orthonormal basis of the Hilbert space of the square integrable functions on a sphere S^2 specified by the scalar product (6.5). Taking into account (6.6) and the identity

$$C_{n-m}^{m+1/2}(z)=(-1)^m\frac{(1-z^2)^{-m/2}m!2^m}{(2m)!}P_n^m(z),\tag{6.8}$$

where $m+1$ is natural, we find that the kernel (6.6) can be written in the form analogous to (2.15) such that

$$\langle\mathbf{x}|j,m\rangle=\sqrt{\frac{2j+1}{4\pi}}\ \frac{(2|m|)!}{|m|!}\sqrt{\frac{(j-|m|)!}{(j+|m|)!}}\left(\frac{-\epsilon(m)x_1-\mathrm{i}x_2}{2}\right)^{|m|}C_{j-|m|}^{|m|+1/2}(x_3).\tag{6.9}$$

Now, let $|(\mathbf{x},\mathbf{l})\rangle$ designate the coherent state $|\mathbf{z}\rangle$ in accordance with the parametrization of the phase space given by (2.17). Equations (5.9), (2.15) and (6.9) taken together yield

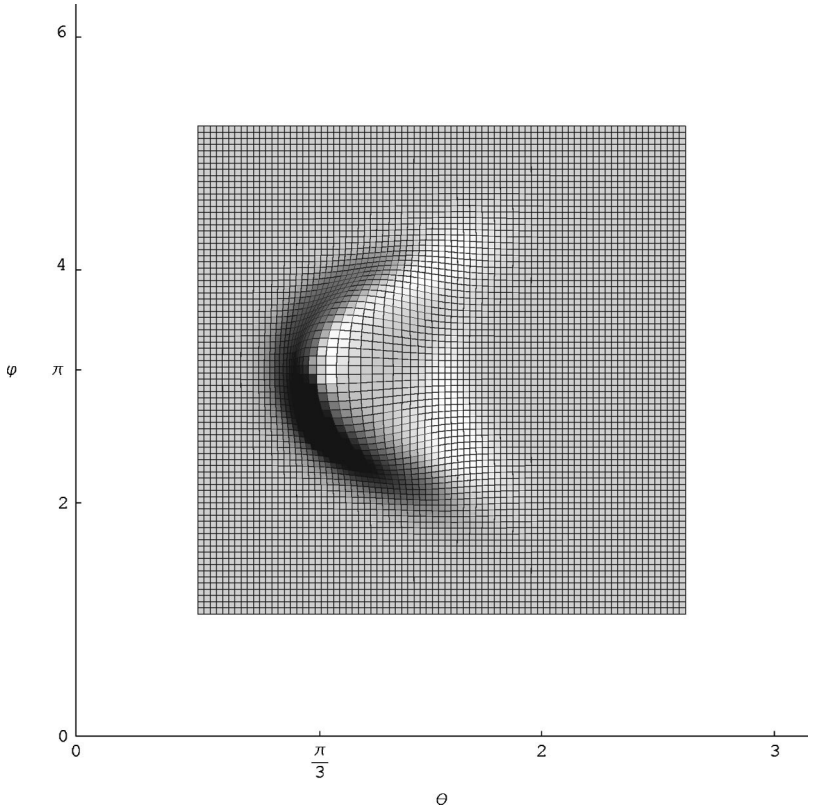

FIG. 2. The plot of the surface from Fig. 1 with the viewpoint directly above. The maximum of the probability density given by (6.14) at $\mathbf{x}=\overline{\mathbf{x}}$ is easily seen.

$$|(\mathbf{x},\mathbf{0})\rangle = \sqrt{4\pi}e^{-(1/2)\mathbf{J}^2}|\mathbf{x}\rangle. \tag{6.10}$$

Using (2.14), (6.10) and (2.13) and proceeding as with (4.4) we find that the passage from the coordinate representation to the coherent states representation is described by the matrix element

$$\langle \mathbf{x}|\mathbf{z}\rangle = \frac{1}{\sqrt{4\pi}} \sum_{j=0}^{\infty} e^{-(1/2)j(j+1)}(2j+1)P_j(\mathbf{x}\cdot\mathbf{z}). \tag{6.11}$$

Evidently, (6.11) defines a unitary map $U:\phi\rightarrow\tilde{\phi}$ from the standard Hilbert space of square integrable functions on the sphere S^2 with the scalar product (6.3) onto the Bargmann space of analytic functions specified by the scalar product (3.16), of the form

$$(U\phi)(\mathbf{z}^*) = \int_{\mathbf{x}^2=1} d\nu(\mathbf{x})k(\mathbf{x}\cdot\mathbf{z}^*)\phi(\mathbf{x}), \tag{6.12}$$

where $k(\mathbf{x}\cdot\mathbf{z})=\langle \mathbf{x}|\mathbf{z}\rangle$. The inverse operator U^{-1} is given by

$$(U^{-1}\tilde{\phi})(\mathbf{x}) = \int_{\mathbf{z}^2=1} d\mu(\mathbf{z})k(\mathbf{x}\cdot\mathbf{z})\tilde{\phi}(\mathbf{z}^*). \tag{6.13}$$

We finally discuss the probability density $p_{\mathbf{z}}(\mathbf{x})$ for the coordinates in the normalized coherent state $|\mathbf{z}\rangle/\sqrt{\langle \mathbf{z}|\mathbf{z}\rangle}$ such that

$$p_{\mathbf{z}}(\mathbf{x}) = \frac{|\langle \mathbf{x}|\mathbf{z}\rangle|^2}{\langle \mathbf{z}|\mathbf{z}\rangle}, \tag{6.14}$$

where $\langle \mathbf{x}|\mathbf{z}\rangle$ and $\langle \mathbf{z}|\mathbf{z}\rangle$ are given by (6.11) and (4.4), respectively. We recall that (6.14) is also called, especially in the context of the theory of quantum chaos the Husimi representation for the localized state on the sphere $|\mathbf{x}\rangle$. Let $\mathbf{z}=\cosh|\mathbf{l}|\overline{\mathbf{x}}+\mathrm{i}(\sinh|\mathbf{l}|/|\mathbf{l}|)\mathbf{l}\times\overline{\mathbf{x}}$ [see (2.17)], so $\overline{\mathbf{x}}$ corresponds to the position and $\mathbf{l}$ to the angular momentum of a particle on a sphere. From computer simmulations it follows that the function $p_{\mathbf{z}}(\mathbf{x})$ is peaked at $\mathbf{x}=\overline{\mathbf{x}}$ (see Figs. 1 and 2). Therefore the parameter $\mathbf{x}$ in the formula (2.17) can be really regarded as the classical position for a particle on a sphere.

VII. DISCUSSION

In this work we have introduced the Bargmann representation referring to the coherent states for a particle on a sphere. The very general construction of the Bargmann space, where the configuration space is a symmetric space, has been recently introduced by Stenzel.[7] As remarked by Hall[8] such construction generalizes the case discussed herein with the configuration space coinciding with the sphere S^2. Nevertheless, it is not formulated in terms of the usual scheme of construction of Bargmann spaces by means of the resolution of the identity for the corresponding coherent states. More precisely, the coherent states are not utilized at all in Ref. 7. The approach taken up in Ref. 7 is very general and as far as we are aware the observations of our work are one of the first concrete nontrivial examples of the general construction discussed in Ref. 7. On the other hand, the construction introduced by Stenzel shows that the formalism introduced in this paper has a deeper mathematical context. We finally point out that the results obtained herein seem to be of interest also in the theory of classical orthogonal polynomials in the complex domain as well as the theory of heat kernels.

ACKNOWLEDGMENTS

We would like to thank Brian Hall for invaluable comments, especially for pointing out the solution to Eq. (3.7) in terms of the heat kernel for the hyperbolic space. We are convinced that without the solution of (3.7) provided by Brian we could not write this paper. We are also greatful to the referee for helpful comments.

Algorithms to solve the (quantum) Sutherland model

Edwin Langmann
Mathematical Physics, Department of Physics, KTH, SCFAB, SE-106 91 Stockholm, Sweden

(Received 27 April 2001; accepted for publication 21 May 2001)

We give a self-contained presentation and comparison of two different algorithms to explicitly solve quantum many body models of indistinguishable particles moving on a circle and interacting with two-body potentials of $1/\sin^2$-type. The first algorithm is due to Sutherland and well-known; the second one is a limiting case of a novel algorithm to solve the elliptic generalization of the Sutherland model. These two algorithms are different in several details. We show that they are equivalent, i.e., they yield the same solution and are equally simple. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1389472]

I. INTRODUCTION

We recently presented a novel algorithm to solve the elliptic version of the (quantum) Calogero–Sutherland system.[1,2] In the trigonometric limit, such an algorithm was discovered already about 30 years ago by Sutherland.[3,4] Somewhat surprisingly, the former algorithm in that limit reduces to one which is different from Sutherland's, even though it yields the same solution and is equally simple. The purpose of this article is to give a detailed and self-contained comparison of these two algorithms, including a proof of their equivalence.

The Sutherland model is defined by the differential operator

$$H=-\sum_{j=1}^{N}\frac{\partial^2}{\partial x_j^2}+2\lambda(\lambda-1)\sum_{1\leqslant j<k\leqslant N}V(x_j-x_k) \tag{1}$$

with $-\pi\leqslant x_j\leqslant\pi$, $N=2,3,\ldots$, $\lambda>0$, and

$$V(r)=\frac{1}{4\sin^2(r/2)}. \tag{2}$$

[To ease notation, we set the length of space to 2π from the start. Of course, an arbitrary length $L>0$ can be easily introduced by rescaling $x_j\to(2\pi/L)x_j$, $H\to(2\pi/L)^2H$, etc.] This differential operator defines a self-adjoint operator on the Hilbert space of square integrable functions on $[-\pi,\pi]^N$, providing a quantum mechanical model for N indistinguishable particles moving on a circle of length 2π and interacting with a two body potential proportional to $V(r)$ where λ determines the coupling strength. (To be precise: This model corresponds to a particularly nice self-adjoint extension of this differential operator which, for $\lambda>1$, corresponds to the Friedrich's extension.[5]) To solve this model amounts to constructing a complete set of eigenfunctions and corresponding eigenvalues of this Hamiltonian.

The starting point for Sutherland's algorithm is the following.

Fact 1:[3] *The wave function*

$$\Psi_0(\mathbf{x})=\prod_{1\leqslant j<k\leqslant N}\psi(x_k-x_j)^{\lambda} \tag{3}$$

with

$$\psi(r)=\sin(r/2) \tag{4}$$

is the ground state of the Sutherland Hamiltonian, $H\Psi_0 = E_0\Psi_0$ with E_0 given in Eq. 9 below.

[To fix the phase of Ψ_0 above, one can interpret $\sin(r/2)^\lambda$ as $\lim_{\varepsilon\downarrow 0}\sin(r/2+\mathrm{i}\varepsilon)^\lambda$, for example. Anyway, the phase ambiguities associated with the exponentiated sines are irrelevant here. In Appendix B 1 we will have to be more careful about similar phase ambiguities in the functions $F(\mathbf{x};\mathbf{y})$ defined later.]

Exploiting this fact, Sutherland constructed all other eigenfunctions f using the following ansatz,

$$f(\mathbf{x}) = \Psi_0(\mathbf{x})\Phi(\mathbf{x}), \tag{5}$$

where Φ are symmetric polynomials (i.e., non-negative powers) in the variables $z_j = \exp(\mathrm{i}x_j)$.[4] The symmetric polynomials thus obtained are the so-called Jack polynomials which have been studied extensively in the mathematics literature, see, e.g., Refs. 6 and 7.

Our algorithm is based on the following.

Fact 2:[1] *The function*

$$F(\mathbf{x};\mathbf{y}) = \frac{\Pi_{1\leqslant j<k\leqslant N}\psi(x_k-x_j)^\lambda \Pi_{1\leqslant j<k\leqslant N}\psi(y_j-y_k)^\lambda}{\Pi_{j,k=1}^{N}\psi(x_j-y_k)^\lambda}, \tag{6}$$

$\psi(r)$ *as in Eq. (4), obeys the following identity,*

$$\sum_{j=1}^{N}\left(\frac{\partial^2}{\partial x_j^2}-\frac{\partial^2}{\partial y_j^2}\right)F(\mathbf{x};\mathbf{y}) = 2\lambda(\lambda-1)\sum_{1\leqslant j<k\leqslant N}(V(x_k-x_j)-V(y_j-y_k))F(\mathbf{x};\mathbf{y}) \tag{7}$$

with $V(r)$ *as in Eq. (2).*

Note that we can write this latter identity as

$$H(\mathbf{x})F(\mathbf{x};\mathbf{y}) = H(\mathbf{y})F(\mathbf{x};\mathbf{y}), \tag{8}$$

where H is the differential operator in Eq. (1) but acting on different arguments $\mathbf{x}$ and $\mathbf{y}$, as indicated. The idea of our algorithm is to take the Fourier transform of Eq. (8) with respect to the variables $\mathbf{y}$, and this yields an identity allowing us to construct eigenfunctions and the corresponding eigenvalues (Proposition 1).

It is interesting to note that Fact 2 holds true in the elliptic case as well [in this case, $\psi(r)$ is a Jacobi theta function $\vartheta_1(r/2)$ with *nome* $q=\exp(-\beta/2)$ and $V(r)$ is Weierstrass' elliptic function $\wp(r)$ with periods 2π and $\mathrm{i}\beta$],[1] in contrast to Fact 1.[8] For the convenience of the reader, an elementary proof of Fact 2 (in the trigonometric case) is given in Appendix A. (This proof uses Fact 1; a self-contained proof valid also in the elliptic case will be given in Ref. 3.)

The plan of the rest of this article is as follows. In Sec. II we review the Sutherland algorithm,[4] mainly to introduce our notation. Section III contains a detailed description of our algorithm. In the final section, Sec. IV, we give the arguments which prove that both algorithms are equivalent, despite various differences. Lengthy proofs are deferred to two Appendices.

II. SUTHERLAND'S ALGORITHM

We use $H\Psi_0 = E_0\Psi_0$ with[3]

$$E_0 = \tfrac{1}{12}\lambda^2 N(N^2-1) \tag{9}$$

and make the ansatz $f=\Phi\Psi_0$. With that the eigenvalue equation $Hf=Ef$ becomes $H'\Phi = E'\Phi$ with $E' = E-E_0$ and[4]

$$H' = -\sum_{j=1}^{N}\frac{\partial^2}{\partial x_j^2} - \mathrm{i}\lambda\sum_{1\leqslant j<k\leqslant N}\left(\frac{\mathrm{e}^{\mathrm{i}x_j}+\mathrm{e}^{\mathrm{i}x_k}}{\mathrm{e}^{\mathrm{i}x_j}-\mathrm{e}^{\mathrm{i}x_k}}\right)\left(\frac{\partial}{\partial x_j}-\frac{\partial}{\partial x_k}\right). \tag{10}$$

One now determines the action of H' on symmetric polynomials

$$S_{\mathbf{n}}(\mathbf{x})=\sum_{P}\prod_{j=1}^{N}\mathrm{e}^{\mathrm{i}n_j x_{Pj}} \tag{11}$$

where (we note in passing that n_j in Ref. 4 corresponds to n_{N+1-j} below)

$$n_1\geqslant n_2\geqslant\cdots\geqslant n_N\geqslant 0 \tag{12}$$

and the sum is over all permutations P of $\{1,2,\ldots,N\}$. Using the identity[4]

$$(\mathrm{e}^{\mathrm{i}x}+\mathrm{e}^{\mathrm{i}y})\left(\frac{\mathrm{e}^{\mathrm{i}kx}-\mathrm{e}^{\mathrm{i}ky}}{\mathrm{e}^{\mathrm{i}x}-\mathrm{e}^{\mathrm{i}y}}\right)=\mathrm{e}^{\mathrm{i}kx}+\mathrm{e}^{\mathrm{i}ky}+2\sum_{\nu=1}^{k-1}\mathrm{e}^{\mathrm{i}[(k-\nu)x+\nu y]}$$

for $k>0$, one obtains

$$H'S_{\mathbf{n}}=E'_{\mathbf{n}}S_{\mathbf{n}}+\lambda\sum_{1\leqslant j<k\leqslant N}(n_j-n_k)\sum_{\nu=1}^{n_j-n_k-1}S_{\mathbf{n}-\nu\mathbf{E}_{jk}}, \tag{13}$$

where we introduced the notation

$$(\mathbf{E}_{jk})_l=\delta_{jl}-\delta_{kl},\quad j,k,l=1,2,\ldots,N, \tag{14}$$

and defined

$$E'_{\mathbf{n}}=\sum_{j=1}^{N}n_j^2+\lambda\sum_{1\leqslant j<k\leqslant N}(n_j-n_k)=\sum_{j=1}^{N}(n_j^2+\lambda[N+1-2j]n_j). \tag{15}$$

We now introduce the notation

$$\underline{\boldsymbol{\mu}}=\sum_{1\leqslant j<k\leqslant N}\mu_{jk}\mathbf{E}_{jk} \tag{16}$$

for non-negative integers $\boldsymbol{\mu}_{jk}$, and observe that there is a natural order on the set of all these $\underline{\boldsymbol{\mu}}$ (which we can identify with $\mathbb{N}_0^{N(N-1)/2}$),

$$\underline{\boldsymbol{\mu}}<\underline{\boldsymbol{\mu}}'\quad\text{if}\quad\mu_{jk}<\mu'_{jk}\ \text{ for all }\ j<k. \tag{17}$$

It is obvious that $H'S_{\mathbf{n}}$ is a finite linear combination of symmetrized plane waves $S_{\mathbf{n}-\underline{\boldsymbol{\mu}}}$ with $\underline{\boldsymbol{\mu}}\geqslant\underline{\mathbf{0}}$. We thus can make the following ansatz for the eigenfunctions of H',

$$\Phi_{\mathbf{n}}=\sum_{\underline{\boldsymbol{\mu}}\geqslant\underline{\mathbf{0}}}c_{\underline{\boldsymbol{\mu}}}S_{\mathbf{n}-\underline{\boldsymbol{\mu}}} \tag{18}$$

with

$$c_{\underline{\boldsymbol{\mu}}}=0\quad\text{if}\quad(\mathbf{n}-\underline{\boldsymbol{\mu}})_j<(\mathbf{n}-\underline{\boldsymbol{\mu}})_k\ \text{ for at least one }\ j<k. \tag{19}$$

The latter condition shows that there are only a finite number of non-zero $c_{\underline{\boldsymbol{\mu}}}$, i.e., the $\Phi_{\mathbf{n}}$ are polynomials. Then $H'\Phi_{\mathbf{n}}=E'\Phi_{\mathbf{n}}$ implies $E'=E'_{\mathbf{n}}$ and the following recursion relations for the coefficients $c_{\underline{\boldsymbol{\mu}}}$,

$$[E'_{\mathbf{n}}-E'_{\mathbf{n}-\underline{\boldsymbol{\mu}}}]c_{\underline{\boldsymbol{\mu}}}=\lambda\sum_{1\leqslant j<k\leqslant N}\sum_{\nu=1}^{n_j-n_k}[(\mathbf{n}-\underline{\boldsymbol{\mu}})_j-(\mathbf{n}-\underline{\boldsymbol{\mu}})_k+2\nu]c_{\underline{\boldsymbol{\mu}}-\nu\mathbf{E}_{jk}} \tag{20}$$

(we used the fact that the functions $S_{\mathbf{n}}$ are linearly independent). We can set $c_{\mathbf{0}}=1$ (this fixes the normalization of the eigenfunctions) and then determine the other $c_{\boldsymbol{\mu}}$ recursively, which is possible provided that there is no resonance, i.e., if $E'_{\mathbf{n}}-E'_{\mathbf{n}+\boldsymbol{\mu}}$ is nonzero. This is the case: we shall prove at the end of this section that

$$E'_{\mathbf{n}}-E'_{\mathbf{n}-\boldsymbol{\mu}}=\sum_{j<k}\mu_{jk}[(\mathbf{n}-\boldsymbol{\mu})_j-(\mathbf{n}-\boldsymbol{\mu})_k+(n_j-n_k)+2\lambda(k-j)], \tag{21}$$

which is manifestly positive and shows that resonances indeed do not occur. This completes the construction of eigenfunctions and eigenvalues of the Sutherland model: Note that the symmetrized plane waves $S_{\mathbf{n}}$ provide a complete orthonormal basis of the corresponding noninteracting Hamiltonian (obtained by setting $\lambda=0$), and we have constructed eigenfunctions $f_{\mathbf{n}}=\Phi_{\mathbf{n}}\Psi_0$ and corresponding eigenvalues $E_{\mathbf{n}}=E'_{\mathbf{n}}+E_0$ with E_0 in Eq. (9), which are one-to-one to this free solution which is known to provide a complete basis.

Remark 1: We can write [cf. Eq. (15)] $E'_{\mathbf{n}}=\Sigma_j[n_j+\frac{1}{2}\lambda(N+1-2j)]^2-E'_0$ with

$$E'_0=\sum_{j=1}^{N}\frac{1}{4}\lambda^2(N+1-2j)^2. \tag{22}$$

It is easy to show that $E'_0=E_0$ [cf. Eq. (9)], which is somewhat remarkable and implies the following simple form of the eigenvalues,

$$E_{\mathbf{n}}=\sum_{j=1}^{N}\left(n_j+\lambda\left[\frac{1}{2}(N+1)-j\right]\right)^2. \tag{23}$$

The novel algorithm in the next section will yield this simple form of the eigenvalues directly.

For the convenience of the reader, we conclude this section with a proof of Eq. (21).

Proof of Eq. (21): Equation (15) implies

$$E'_{\mathbf{n}}-E'_{\mathbf{n}-\boldsymbol{\mu}}=\sum_j\mu_j[-\mu_j+2n_j+\lambda(N+1-2j)]$$

with

$$\mu_j=(\boldsymbol{\mu})_j=\sum_{k>j}\mu_{jk}-\sum_{k<j}\mu_{kj}. \tag{24}$$

Using

$$\sum_j\mu_j a_j=\sum_{j<k}\mu_{jk}(a_j-a_k) \tag{25}$$

we get

$$E'_{\mathbf{n}}-E'_{\mathbf{n}-\boldsymbol{\mu}}=\sum_{j<k}\mu_{jk}[(\mu_k-\mu_j)+2(n_j-n_k)+2\lambda(k-j)],$$

which proves Eq. (21). □

III. THE NOVEL ALGORITHM

This algorithm is based on the following proposition which, roughly speaking, is obtained by taking the Fourier transform of the remarkable identity in Eq. (8) with respect to **y**.

Proposition 1: Let H be as in Eqs. (1) and (2). Then

$$H\hat{F}(\mathbf{x};\mathbf{n})=E_{\mathbf{n}}\hat{F}(\mathbf{x};\mathbf{n})-\gamma\sum_{1\leqslant j<k\leqslant N}\sum_{\nu=1}^{\infty}\nu\hat{F}(\mathbf{x};\mathbf{n}+\nu\mathbf{E}_{jk}),\tag{26}$$

where

$$\hat{F}(\mathbf{x};\mathbf{n})=\mathcal{P}_{\mathbf{n}}(\mathbf{x})\Psi_0(\mathbf{x}),\quad \mathbf{n}\in\mathbb{Z}^N\tag{27}$$

with Ψ_0 *as in Eqs. (3) and (4) and*

$$\mathcal{P}_{\mathbf{n}}(\mathbf{x})=\lim_{\varepsilon\downarrow 0}\int_{-\pi}^{\pi}\frac{dy_1}{(2\pi)}e^{in_1y_1}\cdots\int_{-\pi}^{\pi}\frac{dy_l}{(2\pi)}e^{in_Ny_N}\frac{\Pi_{1\leqslant j<k\leqslant N}(1-e^{i(y_j-y_k)-(k-j)\varepsilon})^{\lambda}}{\Pi_{j,k=1}^{N}(1-e^{i(x_k-y_j)-j\varepsilon})^{\lambda}},\tag{28}$$

$\mathbf{E}_{jk}$ *as in Eq. (14),* $E_{\mathbf{n}}$ *in Eq. (23), and*

$$\gamma=2\lambda(\lambda-1).\tag{29}$$

(Proof in Appendix B 1.)

Remark 2: To see that these functions $\mathcal{P}_{\mathbf{n}}$ are well-defined, we note that they can be written as

$$\mathcal{P}_{\mathbf{n}}(\mathbf{x})=\oint_{\mathcal{C}_1}\frac{d\xi_1}{2\pi i\xi_1}\xi_1^{n_1}\cdots\oint_{\mathcal{C}_N}\frac{d\xi_N}{2\pi i\xi_N}\xi_N^{n_N}\frac{\Pi_{j<k}(1-\xi_j/\xi_k)^{\lambda}}{\Pi_{j,k}(1-e^{ix_k}/\xi_j)^{\lambda}}$$

with integration paths $\mathcal{C}_j:\xi_j=e^{\varepsilon j}e^{iy_j}$, $-\pi\leqslant y_j\leqslant\pi$, where $\varepsilon>0$ is arbitrary.

We now show that this proposition provides a solution algorithm: Eq. (26) implies that the action of H on the functions $\hat{F}(\mathbf{x};\mathbf{n})$ is triangular, i.e., $H\hat{F}(\mathbf{x};\mathbf{n})$ is a linear combination of functions $F(\mathbf{x};\mathbf{n}+\boldsymbol{\mu})$ with $\boldsymbol{\mu}\geqslant\underline{\mathbf{0}}$. We thus can make the following ansatz for eigenfunctions,

$$f_{\mathbf{n}}(\mathbf{x})=\sum_{\boldsymbol{\mu}\geqslant\underline{\mathbf{0}}}a_{\boldsymbol{\mu}}F(\mathbf{x};\mathbf{n}+\boldsymbol{\mu}),\tag{30}$$

and then $Hf_{\mathbf{n}}=Ef_{\mathbf{n}}$ implies

$$\sum_{\boldsymbol{\mu}\geqslant\underline{\mathbf{0}}}F(\mathbf{x};\mathbf{n}+\boldsymbol{\mu})\left([E_{\mathbf{n}+\boldsymbol{\mu}}-E]a_{\boldsymbol{\mu}}-\gamma\sum_{1\leqslant j<k\leqslant N}\sum_{\nu=1}^{\mu_{jk}}\nu a_{\boldsymbol{\mu}-\nu\mathbf{E}_{jk}}\right)=0.$$

We thus see that how we get a solution of $Hf_{\mathbf{n}}=Ef_{\mathbf{n}}$ is we set $E=E_{\mathbf{n}}$ and determine the coefficients $a_{\boldsymbol{\mu}}$ by the following recursion relations,

$$[E_{\mathbf{n}+\boldsymbol{\mu}}-E_{\mathbf{n}}]a_{\boldsymbol{\mu}}=\gamma\sum_{1\leqslant j<k\leqslant N}\sum_{\nu=1}^{\mu_{jk}}\nu a_{\boldsymbol{\mu}-\nu\mathbf{E}_{jk}},\tag{31}$$

which has triangular structure: we can set $a_{\underline{\mathbf{0}}}=1$ (this fixes the normalization), and then the other $a_{\boldsymbol{\mu}}$ can be determined recursively in terms of the $a_{\boldsymbol{\mu}'}$ where $\boldsymbol{\mu}'<\boldsymbol{\mu}$, at least if there is no resonance, i.e., if $E_{\mathbf{n}+\boldsymbol{\mu}}-E_{\mathbf{n}}$ does not vanish. This is true due to the following.

Lemma 1:

$$E_{\mathbf{n}+\boldsymbol{\mu}}-E_{\mathbf{n}}=\sum_{j=1}^{N}\mu_j^2+\sum_{1\leqslant j<k\leqslant N}2\mu_{jk}[(n_j-n_k)+\lambda(k-j)]\tag{32}$$

with μ_j *in Eq. (24), which is manifestly positive provided that Eq. (12) holds true.*

(Proof in Appendix B 2.)

Moreover, the following lemma shows that the $f_{\mathbf{n}}$ are in fact symmetric polynomials, i.e., a finite linear combination of the functions $S_{\mathbf{n}}$ in Eq. (11).

Lemma 2: The functions $\mathcal{P}_{\mathbf{n}}$ in Eq. (28) all are symmetric polynomials in the variables $z_j = \exp(\mathrm{i}x_j)$ which are nonzero only if

$$n_j + n_{j+1} + \ldots + n_N \geqslant 0 \quad \forall j = 1,2,\ldots,N. \tag{33}$$

They can be written as

$$\mathcal{P}_{\mathbf{n}}(\mathbf{x}) = \sum_{\mathbf{m}} p_{\mathbf{n},\mathbf{m}} S_{\mathbf{m}}(\mathbf{x}) \tag{34}$$

with $S_{\mathbf{m}}(\mathbf{x})$ as in Eq. (11), and the coefficients are

$$p_{\mathbf{n},\mathbf{m}} = \Sigma'' \prod_{1 \leqslant j' < k' \leqslant N} \prod_{j,k=1}^{N} \binom{\lambda}{\mu_{j'k'}} \binom{-\lambda}{\nu_{jk}} (-1)^{\mu_{j'k'} + \nu_{jk}}, \tag{35}$$

where the sum Σ'' is over all non-negative integers μ_{jk}, ν_{jk} restricted by the following $2N$ equations,

$$n_j = \sum_{l=1}^{N} \nu_{lj} + \sum_{l=1}^{j-1} \mu_{lj} - \sum_{l=j+1}^{N} \mu_{jl}, \quad m_j = \sum_{l=1}^{N} \nu_{jl}, \tag{36}$$

and $m_1 \geqslant m_2 \geqslant \cdots \geqslant m_N \geqslant 0$, implying in particular that there are only terms such that

$$\sum_{j=1}^{N} m_j = \sum_{j=1}^{N} n_j. \tag{37}$$

(Proof in Appendix B 3.)

Indeed, this lemma implies the sum in Eq. (30) has only a finite number of nonzero terms [since there is only a finite number of $\boldsymbol{\mu}$ such that $\mathbf{n}' = \mathbf{n} + \boldsymbol{\mu}$ obeys all the conditions in Eq. (33)], and thus the $f_{\mathbf{n}}$ are a finite number of terms each of which is a finite linear combination of functions $S_{\mathbf{n}}$ in Eq. (11).

IV. CONCLUSIONS

We can summarize our discussion in the previous sections as follows.

Proposition 2: For each $\mathbf{n} \in \mathbb{Z}^N$ such that $n_1 \geqslant n_2 \geqslant \cdots \geqslant n_N \geqslant 0$, the standard algorithm reviewed in Sec. III and the novel one presented in Sec. IV both yield an eigenfunction $f_{\mathbf{n}}$ of the Sutherland Hamiltonian H in Eq. (1). In both cases, this eigenfunction is of the form

$$f_{\mathbf{n}}(\mathbf{x}) = \Phi_{\mathbf{n}}(\mathbf{x}) \Psi_0(\mathbf{x})$$

with Ψ_0 in Eqs. (3) and (4) and $\Phi_{\mathbf{n}}$ a symmetric polynomial in the variables $z_j = \exp(\mathrm{i}x_j)$, and the corresponding eigenvalues $E_{\mathbf{n}}$ are given in Eq. (23).

It thus follows from Theorem 3.1 in Ref. 7 that, for nondegenerate eigenvalues $E_{\mathbf{n}}$, the eigenfunctions $f_{\mathbf{n}}$ obtained with the two algorithms are equal (up to normalization), and the functions $\Phi_{\mathbf{n}}$ are proportional to the so-called Jack polynomials (see Sec. 2 in Ref. 9 for details; this latter reference actually seems to suggest that this is true even for nondegenerate eigenvalues). We feel that this is quite remarkable since, even though the two algorithms look somewhat similar and both yield the same solution, there are several differences in details:

(i) The building blocks of the eigenfunctions in the novel algorithm are the functions $\mathcal{P}_{\mathbf{n}}$ defined in Eq. (28) and not the plane waves $S_{\mathbf{n}}$ in Eq. (11).

(ii) With the standard algorithm, one obviously obtains eigenfunctions with polynomials $\Phi_{\mathbf{n}}$ which have the form

$$\Phi_{\mathbf{n}} = \sum_{\mathbf{m} \leqslant \mathbf{n}} v_{\mathbf{n},\mathbf{m}} S_{\mathbf{m}},$$

where the partial order here is defined as

$$\mathbf{m} \leqslant \mathbf{n} : \Leftrightarrow \sum_{j=1}^{k} m_j \leqslant \sum_{j=1}^{k} n_j \quad \forall k = 1,2,\ldots,N. \tag{38}$$

[This is called *dominance ordering* in Ref. 7; the latter fact follows from Eq. (18) and $\mathbf{n} \geqslant \mathbf{n} - \boldsymbol{\mu}$ for all $\boldsymbol{\mu} \geqslant \underline{\mathbf{0}}$]. This is not at all obvious for the eigenfunctions obtained with the novel algorithm [but of course should be true as well, at least for nondegenerate eigenfunctions.]

(iii) In both algorithms it is important to rule out the occurrence of resonances, but the reason for that is different [cf. Eq. (21) with Lemma 1 above, and observe the different sign of $\boldsymbol{\mu}$].

(iv) In the novel algorithm the restriction in Eq. (12) can be dropped, and in fact the solutions thus obtained are relevant in the elliptic case.[1] There seems no way to drop this restriction in the standard algorithm.

(v) From Sutherland's algorithm it seems somewhat surprising that the eigenvalues all can be written in the simple form $E_{\mathbf{n}} = \Sigma_j P_j^2$, but from the novel algorithm this is obvious.

(vi) As discussed in the Introduction, the novel algorithm can be generalized to the elliptic case.[1,2]

APPENDIX A: PROOF OF FACT 2

We note that

$$F(\mathbf{x};\mathbf{y}) = \Psi_0(\mathbf{x})\Psi_0(\mathbf{y}) \frac{1}{\prod_{j,k=1}^{N} \psi(x_j - y_k)^{\lambda}}, \tag{A1}$$

with Ψ_0 in Eq. (3) and ψ in Eq. (4). Using $H\Psi_0 = E_0\Psi_0$ (Ref. 3) and the Leibniz rule of differentiation we obtain

$$H(\mathbf{x})F(\mathbf{x};\mathbf{y}) = \Bigg(E_0 + 2\lambda^2 \sum_{j,l} \sum_{k \neq j} \phi(x_j - x_k)\phi(x_j - y_l) + \sum_{j,k} \lambda \phi'(x_j - y_k) - \sum_{j,k,l} \lambda^2 \phi(x_j - y_k)\phi(x_j - y_l) \Bigg) F(\mathbf{x};\mathbf{y}),$$

where

$$\phi(r) = \psi'(r)/\psi(r) = \tfrac{1}{2}\cot(r/2) \tag{A2}$$

(the prime indicates differentiation). Thus

$$[H(\mathbf{x}) - H(\mathbf{y})]F(\mathbf{x};\mathbf{y}) = \lambda^2(\cdot)F(\mathbf{x};\mathbf{y})$$

with

$$(\cdot) \equiv \Bigg[\sum_{j,l} \sum_{k \neq j} 2\phi(x_j - x_k)\phi(x_j - y_l) - \sum_{j,k} \sum_{l \neq k} \phi(x_j - y_k)\phi(x_j - y_l) \Bigg] - [\mathbf{x} \leftrightarrow \mathbf{y}],$$

where "$[\mathbf{x}\leftrightarrow\mathbf{y}]$" means "the same terms but with $\mathbf{x}$ and $\mathbf{y}$ interchanged" (we used that all terms which are even under $[\mathbf{x}\leftrightarrow\mathbf{y}]$ cancel). Relabeling indices and using $\phi(-r)=-\phi(r)$ we rewrite

$$(\cdot)=\sum_{j,l}\sum_{k\neq j}[\phi(x_j-x_k)\phi(x_j-y_l)+\phi(x_k-x_j)\phi(x_k-y_l)-\phi(x_l-y_j)\phi(x_l-y_k)]-[\mathbf{x}\leftrightarrow\mathbf{y}]$$

$$=\sum_{j,l}\sum_{k\neq j}[\phi(x_j-x_k)\phi(x_j-y_l)+\phi(x_j-x_k)\phi(y_l-x_k)+\phi(y_l-x_j)\phi(y_l-x_k)]-[\mathbf{x}\leftrightarrow\mathbf{y}].$$

We now can use the trigonometric identity

$$\cot(x)\cot(y)+\cot(x)\cot(z)+\cot(y)\cot(z)=1 \quad \text{if } x+y+z=0, \tag{A3}$$

which shows that

$$\phi(x_j-x_k)\phi(x_j-y_l)+\phi(x_j-x_k)\phi(y_l-x_k)+\phi(y_l-x_j)\phi(y_l-x_k)=-\tfrac{1}{2}$$

and thus proves $(\cdot)=0$. □

APPENDIX B: OTHER PROOFS

1. Proof of Proposition 1

We first observe two simple but useful facts. First, the relation in Eq. (8) remains true if we replace $F(\mathbf{x};\mathbf{y})$ by

$$F'(\mathbf{x};\mathbf{y})=c\,\mathrm{e}^{\mathrm{i}P\sum_{j=1}^{N}(x_j-y_j)}F(\mathbf{x};\mathbf{y}) \tag{B1}$$

for arbitrary constants $P\in\mathbb{R}$ and $c\in\mathbb{C}$. [To see this, introduce center-of-mass coordinates $X=\sum_{j=1}^{N}x_j/N$ and $x_j'=(x_j-x_1)$ for $j=2,\ldots,N$, and similarly for y. Then $H(\mathbf{x})=-\partial^2/\partial X^2+H_c(\mathbf{x}')$, and similarly for $H(\mathbf{y})$. Invariance of Eq. (8) under $F\to\mathrm{e}^{-\mathrm{i}P(X-Y)N}F$ thus follows from $(\partial/\partial X+\partial/\partial Y)F(\mathbf{x};\mathbf{y})=0$, and the latter is implied by the obvious invariance of $F(\mathbf{x};\mathbf{y})$ under $x_j\to x_j+a$, $y_j\to y_j+a$, $a\in\mathbb{R}$. The invariance of Eq. (8) under $F\to cF$ is trivial, of course.] Second, the variables y_j in Eq. (8) need not be real but can be complex.

As mentioned, we intend to perform a Fourier transformation of the identity in Eq. (8), i.e., apply to it $(2\pi)^{-N}\int\mathrm{d}^N\mathbf{y}\,\mathrm{e}^{\mathrm{i}\mathbf{P}\cdot\mathbf{y}}$ with suitable momenta $\mathbf{P}$. We need to do this with care: first, the differential operator $H(\mathbf{y})$ has singularities at points $y_j=y_k$, and, second, the function $F(\mathbf{x};\mathbf{y})$ is not periodic in the variables y_j but changes by phase factors under $y_j\to y_j+2\pi$. We therefore need to specify suitable integration contours for the y_j's avoiding the singular points, and we need to choose the P_j so as to compensate the nonperiodicity. To do that, we replace the real coordinates y_j by

$$z_j=y_j-\mathrm{i}j\varepsilon \tag{B2}$$

with $\varepsilon>0$ a regularization parameter: as we will see, we can then integrate along the straight lines from $y_j=-\pi$ to π and after that perform the limit $\varepsilon\downarrow 0$. Since for all $j<k$, $z_j-z_k=y_j-y_k+\mathrm{i}\varepsilon_{kj}$ with $\varepsilon_{kj}=(k-j)\varepsilon>0$, we can use

$$\sin[(y+\mathrm{i}\varepsilon)/2]=\tfrac{1}{2}\,\mathrm{e}^{\mathrm{i}\pi/2}\mathrm{e}^{-\mathrm{i}y/2+\varepsilon/2}(1-\mathrm{e}^{\mathrm{i}y-\varepsilon}) \tag{B3}$$

for $\varepsilon>0$. Taking the log of this identity and differentiating we obtain $(1/2\cot[(y+\mathrm{i}\varepsilon)/2])=-\mathrm{i}/[1-\exp(\mathrm{i}y-\varepsilon)]$. Expanding the rhs in a geometric series and differentiating once more yields

$$\frac{1}{4\sin^2[(y+\mathrm{i}\varepsilon)/2]}=-\sum_{\nu=1}^{\infty}\nu\mathrm{e}^{\mathrm{i}\nu y-\nu\varepsilon}. \tag{B4}$$

This accounts for all singularities and branch cuts in a consistent way. To determine the suitable **P** use Eq. (B3) and compute

$$F(\mathbf{x};\mathbf{z})=(\cdots)\,\Psi_0(\mathbf{x})\check{\mathcal{P}}^{\varepsilon}(\mathbf{x};\mathbf{y})$$

with $\Psi_0(\mathbf{x})$ in Eqs. (3) and (4),

$$\check{\mathcal{P}}^{\varepsilon}(\mathbf{x};\mathbf{y})=\frac{\prod_{1\leqslant j<k\leqslant N}(1-e^{i(y_j-y_k)-(k-j)\varepsilon})^{\lambda}}{\prod_{j,k=1}^{N}(1-e^{i(x_j-y_k)-k\varepsilon})^{\lambda}} \tag{B5}$$

a function periodic in all the y_j, and

$$(\cdots)=\left(\frac{1}{2}e^{i\pi\lambda/2}\right)^{N(N-1)/2-N^2}\frac{\prod_{1\leqslant j<k\leqslant N}e^{-i\lambda(y_j-y_k)/2+\lambda(k-j)\varepsilon/2}}{\prod_{j,k=1}^{N}e^{-i\lambda(x_j-y_k)/2+\lambda k\varepsilon/2}}$$

$$=\text{const}\,e^{i\lambda N\Sigma_{j=1}^{N}(x_j-y_j)/2}e^{-i\lambda\Sigma_{j=1}^{N}(N+1-2j)y_j/2}$$

[we used $\Sigma_{j<k}(y_j-y_k)=\Sigma_j(N+1-2j)y_j$]. We thus see that we can choose P and c in Eq. (B1) such that

$$F'(\mathbf{x};\mathbf{z})=e^{-i\lambda\Sigma_{j=1}^{N}[(N+1)/2-j]y_j}\check{\mathcal{P}}^{\varepsilon}(\mathbf{x};\mathbf{y})\Psi_0(\mathbf{x}). \tag{B6}$$

We need to choose the Fourier variables $\mathbf{P}=(P_1,\ldots,P_N)$ such that $e^{i\mathbf{P}\cdot\mathbf{y}}F'(\mathbf{x};\mathbf{z})$ is periodic in all y_j, and this implies

$$P_j=n_j+\lambda[\tfrac{1}{2}(N+1)-j],\quad n_j\in\mathbb{Z}. \tag{B7}$$

We now can apply $(2\pi)^{-N}\int d^N\mathbf{y}\,e^{i\mathbf{P}\cdot\mathbf{y}}$ to the identity $H(\mathbf{x})F'(\mathbf{x};\mathbf{z})=H(\mathbf{z})F'(\mathbf{x};\mathbf{z})$. We recall

$$H(\mathbf{z})=-\sum_j\frac{\partial^2}{\partial y_j^2}+\gamma\sum_{j<k}\frac{1}{4\sin^2[(y_j-y_k+i(k-j)\varepsilon)/2]}$$

and use Eq. (B4). After taking the limit $\varepsilon\downarrow 0$ we obtain Eq. (26): the lhs is obvious (note that $\hat{F}$ is the Fourier transform of F'). The rhs has two terms. The first one is equal to $\Sigma_j P_j^2\hat{F}$ and comes from the derivative terms which we evaluated by partial integration. The second term is obtained from the $1/\sin^2$-terms in $H(\mathbf{z})F'$ which we computed using Eq. (B4). □

2. Proof of Lemma 1

We write $(\mathbf{n}+\boldsymbol{\mu})_j=n_j+\mu_j$ with μ_j in Eq. (16). Thus Eqs. (23) and (25) imply

$$E_{\mathbf{n}+\boldsymbol{\mu}}-E_{\mathbf{n}}=\sum_j\left(\mu_j^2+2\mu_j\left(n_j+\lambda\left[\frac{1}{2}(N+1)-j\right]\right)\right),$$

and with Eq. (25) we obtain Eq. (32). □

3. Proof of Lemma 2

It is straightforward to evaluate $\mathcal{P}_{\mathbf{n}}(\mathbf{x})$ in Eq. (28) by expanding all terms in Taylor series (using the binomial series) and then performing the y_j integrations which corresponds to a projection onto the y_j-independent terms. The result is

$$\mathcal{P}_{\mathbf{n}}(\mathbf{x})=\sum{}'\prod_{1\leqslant j'<k'\leqslant N}\prod_{j,k=1}^{N}\binom{\lambda}{\mu_{j'k'}}\binom{-\lambda}{\nu_{jk}}(-1)^{\mu_{j'k'}+\nu_{jk}}e^{i\nu_{jk}x_j} \tag{B8}$$

where the sum Σ' is over all non-negative integers $\mu_{kk'}$ and ν_{jl} such that

$$n_j - \sum_{l=1}^{N} \nu_{lj} - \sum_{l=1}^{j-1} \mu_{lj} + \sum_{l=j+1}^{N} \mu_{jl} = 0. \tag{B9}$$

Recalling the definition of $S_{\mathbf{n}}$ in Eq. (11) we obtain Eqs. (34)–(36).

We now argue that this latter system of equations can have solutions only if the conditions in Eq. (33) all hold, which implies that otherwise $\mathcal{P}_{\mathbf{n}}$ is zero. To see this we add up the last $N+1-k$ relation in Eq. (B9) ($k=N,N-1,\ldots,1$), and by a relabeling of indices we obtain

$$\sum_{j=k}^{N} n_j = \sum_{j=k}^{N} \sum_{l=1}^{N} \nu_{lj} + \sum_{l=1}^{k-1} \sum_{j=k}^{N} \mu_{lj}$$

where the rhs is always manifestly positive. This proves Eq. (33). Setting $k=1$ and comparing with Eq. (36) we obtain Eq. (37). Moreover, for fixed n_j, there are at most a finite number of different solutions of Eq. (B9), implying that $\mathcal{P}_{\mathbf{n}}$ is a polynomial. To see that we write Eq. (B9) as follows,

$$n_j + \sum_{l=j+1}^{N} \mu_{jl} = \sum_{l=1}^{N} \nu_{lj} + \sum_{l=1}^{j-1} \mu_{lj}, \tag{B10}$$

and determine possible solutions for decreasing values of j starting at $j=N$. It is easy to prove by induction that there is only a finite number of solutions

$$\{\nu_{lj}\}_{j,l=1}^{N}, \{\mu_{jl}\}_{1 \leqslant j < l \leqslant N} \in \mathbb{N}_0^{N^2 + N(N-1)/2}$$

of this system of equations: For $j=N$ we get

$$n_N = \sum_{l=1}^{N} \nu_{lN} + \sum_{l=1}^{N-1} \mu_{lN}$$

and there is obviously only a finite number of different solutions $\{\nu_{lN}\}_{l=1}^{N}, \{\mu_{lN}\}_{l=1}^{N-1}$ of that equation. If we consider Eq. (B10) for some $j=j_0<N$, the possible solutions for $\{\mu_{j_0,l}\}_{l>j_0}$ were already determined by the equations for $j>j_0$ and, by the induction hypothesis, there is only a finite number of them. One thus only has to consider a finite number of equations, and each of them obviously has only a finite number of solutions $\{\nu_{lj}\}_{l=1}^{N}, \{\mu_{lj}\}_{l=1}^{j-1}$. □

(Received 4 December 2000; accepted for publication 23 March 2001)

The perturbation theory over inverse interaction constant $1/g$ is constructed for Yang–Mills theory. It is shown that the new perturbation theory is free from the gauge ghosts and Gribov's ambiguities, and each order over $1/g$ presents the gauge-invariant quantity. It is remarkable that offered perturbation theory did not contain divergences, at least in the vector fields sector, and no renormalization procedure is necessary for it. © *2001 American Institute of Physics.*
[DOI: 10.1063/1.1380251]

I. INTRODUCTION

The perturbation theory for $(3+1)$-dimensional Yang–Mills field theory in the vicinity of the extremum $u^a_\mu(x)$ of the action will be described.[1] It is our first publication in this field and it seems reasonable to define from the very beginning the level of its completeness. Namely, we would like to show that, contrary to the ordinary perturbative QCD (pQCD), the offered theory may be used at arbitrary distances. Accordingly, the theory is free from divergences at least in the vector fields sector. Besides the perturbation theory is operated with transparently gauge invariant quantities and no ghosts and Gribov ambiguities would hinder the computations.

We will realize the perturbation theory in the factor space $\mathcal{G}/\mathcal{H}$, where $\mathcal{G}$ is the symmetry group of theory and $\mathcal{H}$ is the symmetry of $u^a_\mu(x)$. Introductory notes for this formalism were given in Ref. 2.

The usefulness of such choice follows from homogeneity and isotropy of $\mathcal{G}/\mathcal{H}$ in the semi-classical approximation. The developed perturbation theory is formulated to describe the violation of these property quantum excitations. One may note that we offer the realization of perturbation theory in terms of the action-angle type variables. As an example one may have in mind the factor space[3]

$$W_G = O(4,2)\times G/O(4)\times O(2), \tag{1}$$

where G is the non-Abelian gauge group.

The formalism will be demonstrated for simplest quantity—the vacuum-into-vacuum transition amplitude

$$\mathcal{Z}(u) = \langle \mathrm{vac};u|\mathrm{vac};u\rangle,$$

along the path $u^a_\mu(x)$. Moreover, following the idea that the calculation should be adjusted to the experiment's ability,[2] we will restrict ourselves to calculating only the modulo squire

$$\mathcal{N}(u) = |\langle \mathrm{vac};u|\mathrm{vac};u\rangle|^2 = |\mathcal{Z}(u)|^2,$$

[a)]Electronic mail: joseph@nu.jinr.ru
[b)]Electronic mail: sisakian@jinr.ru

since, being the unmeasurable quantity, the phase of $\mathcal{Z}(u)$ is not important from a physical point of view[4] (it is the principle of ''minimal necessity'' in our terminology).

This quantity $\mathcal{N}(u)$ would normalize the observables and is equal to squire of the volume of $\mathcal{G}/\mathcal{H}$, see Ref. 5. So, it defines a number of expected on the trajectory $u_{\mu a}(x)$ degrees of freedom, i.e. $(\ln \mathcal{N}(u))/2$ is proportional to the dimension of $\mathcal{G}/\mathcal{H}$. In the example (1):

$$\dim W_G = \dim G + 8 \tag{2}$$

since the $O(4)\times O(2)$-invariant solution $u_{\mu a}(x)$ breaks both the gauge and the spatial symmetries. Last one includes the translational and spatial conformal transformations.[3]

Having in consideration the probabilitylike quantity $\mathcal{N}(u)$, one can include into formalism the total probabilities conservation principle (see Ref. 2, where the role of unitarity condition in the formation of quantum dynamics is described in detail). So, one may prove that if we postulate the path-integral representation for $\mathcal{Z}(u)$, see (13) for the scalar field case, and take into account the S-matrix unitarity condition then, if the canonical perturbation series exist (at least in Borel sense), $\mathcal{N}$ has the following strict path-integral representation:

$$\mathcal{N} = e^{-i\mathcal{K}(je)} \int DM_j(A) e^{-2iU(A,e)}. \tag{3}$$

In this expression $\mathcal{K}(je)$ acts as the differential operator of the auxiliary variables $j_{a\mu}$ and $e_{a\mu}$ at $j_{a\mu} = e_{a\mu} = 0$, see (15) and (84), and the expansion of $\exp\{-i\mathcal{K}\}$ generates the perturbation series. The functional $U(A,e)$ defines interaction. It may be expressed through the input classical action, see (16) and (85). The main point of our consideration is the differential measure DM_j since it is δ-like:

$$DM_j(A) = \prod_{a,\mu} \prod_x \mathrm{d}A^{a\mu}(x)\, \delta\left(\frac{\delta S(A)}{\delta A^a_\mu(x)} + j^{a\mu}(x) \right), \tag{4}$$

where $S(A)$ is the classical Yang–Mills action. Notice that using the Fourier transform of functional δ-function in (4), one may easily find from (3) that $\mathcal{N}(u) = |\mathcal{Z}(u)|^2$.

The structure of representation (3) did not depend on the dimension of the system, concrete form of the Lagrangian, and other ''local'' properties of the theory. We will not repeat for this reason the derivation of (3) since it is the same as in Ref. 2 [and Ref. 6, where the $(1+1)$-dimensional exactly integrable field theory was considered].

Following the definitions of δ-function and operator $\mathcal{K}(je)$, one should start from the equation:

$$\frac{\delta S(A)}{\delta A^a_\mu(x)} = 0. \tag{5}$$

So, having a theory on the δ-like measure, we must consider[2] only the *strict* solution of Lagrange equation. Notice that Eq. (5) also has the ''trivial'' solution $A^a_\mu(x) = 0$, with the corresponding factor space W_0, $\dim W_0 = \dim G$, where G is the gauge group. The pQCD presents expansion around just this ''trivial'' solution.

Then, if the general position concerning initial data is analyzed, we should neglect this ''trivial'' solution since we will assume that our solution $u^a_\mu(x)$ is live in the factor space of $\dim(\mathcal{G}/\mathcal{H}) > \dim W_0$. This is a formal reason why the expansion in vicinity of $u_{\mu a}(x) \neq \mathrm{const}$ would be considered. Corresponding realization of the Yang–Mills theory would be the topological QCD (tQCD).

This selection rule[2] is our definition of the ground state. Its importance should be stressed. It says that first of all one should consider such solution of the Lagrange equation in the Minkowski space which is live in the factor space $\mathcal{G}/\mathcal{H}$ of highest dimension since, generally speaking, other orbits are realized on zero measure.[7]

The extraordinary role of the factor space has specific explanation. At first glance δ-likeness of measure (4) solves the problem of path integral calculation. But actually, to calculate the remaining integral in (3), measure (4) forces us to search new forms of perturbation theory. The formal reason is hidden in inhomogeneity of our Lagrange equation, see (4),[8]

$$-\frac{\delta S(A)}{\delta A^a_\mu(x)}=j^{a\mu}(x). \tag{6}$$

So, the exact solutions of this equation are unknown even in the expansion over $j^{a\mu}(x)$ form if the corresponding homogeneous equation (5) has nontrivial solution $u_{a\mu}(x)\neq\text{const}$.

Nevertheless one may try to solve this equation in the form of some perturbation series, expanding solution over $j^{a\mu}(x)$. This will lead to the theory which may have a near resemblance of the canonical one, see, e.g., Ref. 9, where the ''straight pass'' approximation was considered.

But the canonical perturbation theory for non-Abelian gauge theories have additional problems. First of all, the method of Faddeev–Popov,[10] introduced for separation of dynamical degrees of freedom from pure gauge ones, in most cases leads to the cumbersome perturbation theory with nonunitary ghost fields Lagrangian.[11] In the quantum gravity this, at first glance, technical complication, rises up to a fundamental one, see, e.g., Ref. 12.

Then, it was noted that it is impossible to fix the Coulomb gauge unambiguously for the Yang–Mills potentials of nontrivial topology.[13] Moreover, it was shown later that this conclusion did not depend on the chosen gauge, and is general for non-Abelian gauge theories[14] if the expansion is built around the nontrivial topology gauge orbits.[15]

We will realize another approach to the problem. Namely, we will consider the mapping into the corresponding to $u_{a\mu}=u_{a\mu}(x;\xi,\eta,\lambda_a)$ factor space. Formally the mapping can be performed since the δ-like measure (4) defines the necessary and sufficient set of contributions into the functional integral. We will find the explicit form of $\mathcal{K}$, U, and DM_j in the $\mathcal{G}/\mathcal{H}$ space. This is our first quantitative result.

Following the idea formulated in Ref. 2, we will formulate the transformation in such a way that $u_{a\mu}=u_{a\mu}(x;\xi,\eta,\lambda_a)$ would be the generator of transformation:

$$u_{a\mu}:A_{a\mu}(x)\to(\xi(t),\eta(t),\lambda_a(x)), \tag{7}$$

where the set $(\xi,\eta,\lambda_a)\in\mathcal{G}/\mathcal{H}$ will coincide at $j^{a\mu}(x)=0$ with integration parameters of Eq. (5), $\lambda_a(\mathbf{x})$ is the gauge phase and the variables ξ and η are the consequence of the spatial symmetry breaking. For example (1), $\dim(\xi+\eta)=8$. So, the combination of generators violated by $u_{a\mu}$ subgroup will be taken as the new quantum variables, instead of the Yang–Mills potentials $A_{\mu a}$. In other words, just the variables extracted by the Faddeev–Popov ansatz as the ''nonphysical'' ones would be the dynamical variables of the tQCD.

The problem of definition and farther quantization of the factor space was solved in Ref. 2. The method consists in formal mapping into the symplectic phase space W of the arbitrary high dimension, considering all dynamical variables of extended space as the q-numbers. It is the first step of calculations. Notice that the transformation always may be done canonically and the Jacobian of transformation would be equal to one. For this reason no ghost fields will appear.

Then the formalism allows to reduce W:

$$W=(\mathcal{G}/\mathcal{H})\times R^*. \tag{8}$$

This reduction of W up to $\mathcal{G}/\mathcal{H}$ is the second step of calculations. The realized transformation is singular since $\dim(\mathcal{G}/\mathcal{H})<\dim W$. Nevertheless we will be able to extract corresponding artifact infinity equal to the volume of R^* and cancel it by the normalization.

The proof that the set of q-numbers extracted this way is necessary and sufficient for quantization of the factor space $\mathcal{G}/\mathcal{H}$ will be crucial for our formalism. We will find that:

$$\mathcal{G}/\mathcal{H}=T^*V\times R, \tag{9}$$

where the quantum degrees of freedom only belong to the cotangent symplectic manifold T^*V[16] and R is the c-number parameter's subspace. The direct product (9) means that we will be able to isolate the quantum degrees of freedom from classical ones. So, it will be shown that $\lambda_a \in R$.

We will find that each order of the tQCD perturbation theory is transparently gauge invariant. This result seems natural since the gauge invariant quantity, the "probability" $\mathcal{N}(u)$, is calculated. Therefore, there will not be a necessity to fix the gauge and, therefore, no "copies" of Gribov[13] would arise. Moreover, it will be shown that no unphysical singularities connected to the Gribov's ambiguity[17] would occur in the formalism. This is our second quantitative result.

It is not hard to show, see also Ref. 2, that developed perturbation theory in the $\mathcal{G}/\mathcal{H}$ space presents expansion over $1/g$, where g is the interaction constant, and does not contain the terms $\sim g^n$, with $n>0$. Such type of perturbation theory, over $1/g$, presents a definite problem from ordinary renormalization procedures point of view.

Indeed, the ordinary quantum field theory scheme assumes the multiplicative renormalization of the interaction constant: the renormalized constant $g_R = Z^{1/2} g < \infty$ and the renormalization factor $Z = \infty$ because of the ultraviolet divergences. Then, having the expansion over $1/g$, we come to an evident contradiction: It is impossible to have the *infinite multiplicative* renormalizations in expansions over g and over $1/g$ simultaneously. For this reason this question would be considered in more detail in our approach. We will show that our perturbation theory would not contain the divergences and the problem with renormalization would not arise. This is our third result.

It should be noted here that these results have been proposed to be obtained in Ref. 18 to distinguish the quantization on the factor space, but now this is done for complete perturbation theory. However it is noteworthy that quantitative progress was achieved taking into account the unitarity condition.

It was mentioned in Ref. 2 that our perturbation theory, over $1/g$, is dual to ordinary one, over g.[19] So, we may realize the expansion over g, or over $1/g$, and the choice is defined only by convenience. If the states counted by the expansion over g and over $1/g$ belong to orthogonal Hilbert spaces[20] then there should not be any connection among terms of both expansions,[2] only the result of summation of series should coincide. For this reason our formalism did not hide the contradiction: The expansion over g may contain divergences and it needs the renormalization, but the expansion over $1/g$ may be divergence free and no renormalizations would be necessary in it.[21]

In the chosen way of calculations even the notion of *interacting* gluons in the Yang–Mills theory would disappear (as well as the pQCD Feynman diagrams). Yet, we cannot exclude the real (mass-shell) particle (gluon) emission[22] on the to-day level of understanding of abilities of our formalism and, therefore, we cannot prove that the states counted in the expansion over g and over $1/g$ belong to the orthogonal Hilbert space. So, we will leave unsolved the problem of colored quanta emission since the question of confinement demands more careful analysis.

The paper is organized as follows. Considering the solutions of Yang–Mills equation, one may use the *ansatz*:[23]

$$A^a_\mu(x) = \eta^a_{\mu\nu} \partial^\nu \ln \varphi(x), \tag{10}$$

where $\eta^a_{\mu\nu}$ are the real matrices. This ansatz reduces the Yang–Mills equation to the form:[3]

$$\partial^2 \varphi + \kappa \varphi^3 = 0, \tag{11}$$

where κ is the integration constant. So, in Sec. II we will formulate the ideology of mapping into the simpler factor space $W = O(4,2)/O(4) \times O(2)$ for scalar $O(4,2)$-invariant field theory with the action:

$$S(\varphi) = \int \mathrm{d}^4 x \left(\frac{1}{2} (\partial_\mu \varphi)^2 - \frac{\kappa}{4} \varphi^4 \right). \tag{12}$$

In Sec. III we will formulate the tQCD in the $\mathcal{G}/\mathcal{H}$ factor space.

II. SCALAR CONFORMALLY INVARIANT FIELD THEORY

A. Definitions

We concentrate our attention in the present section on the calculation of $|\mathcal{Z}(u)|^2$, where

$$\mathcal{Z}=\int D\varphi e^{iS(\varphi)} \tag{13}$$

and $S(\varphi)$ is the action defined in (12).

As was explained, the integral

$$\mathcal{N}\equiv|\mathcal{Z}|^2=e^{-i\mathcal{K}(je)}\int DM_j(\varphi,\pi)e^{-2iU(\varphi,e)} \tag{14}$$

will be analyzed instead of (13). Here

$$2\mathcal{K}(je)=\mathrm{Re}\int_{C_+}\mathrm{d}x\,\frac{\delta}{\delta j(x)}\,\frac{\delta}{\delta e(x)}\equiv\mathrm{Re}\int_{C_+}\mathrm{d}x\,\hat{j}(x)\hat{e}(x). \tag{15}$$

At the very end of calculations one should take the auxiliary variables j and e equal to zero. The interactions are introduced by the functional

$$-2U(\varphi,e)=S_{C_+}(\varphi+e)-S_{C_-}(\varphi-e)-2\,\mathrm{Re}\int_{C_+}\mathrm{d}^4x e\,\frac{\delta S(\varphi)}{\delta\varphi}$$

$$=2\kappa\,\mathrm{Re}\int_{C_+}\mathrm{d}x\,\varphi(x)e^3(x)+O(\epsilon). \tag{16}$$

The complex time formalism of Mills[24] was used and $S_{C_\pm}$ is the action defined on the complex time contour $C_\pm$. For sake of definiteness, we will use the complex time contours

$$C_\pm: t\to t\pm i\epsilon,\quad \epsilon\to+0,\quad |t|\leqslant\infty. \tag{17}$$

Let $\varphi_\pm$ be the fields on the $C_\pm$ branches of the Mills time contour and let $\partial C_\pm$ be the boundary of these branches. It was assumed the "periodic" (closed-path[6]) boundary condition:

$$\varphi_+(t\in\partial C_+)=\varphi_-(t\in\partial C_-), \tag{18}$$

when the representation (14) was derived. This boundary condition should be maintained in the factor space.

Notice that considering the theory with Lagrangian (12), one may write $U(\varphi,e)$ in the following equivalent form [with $O(\epsilon)$ accuracy]:

$$3!U(\varphi,e)=-\int\mathrm{d}^4xe(x)^3\frac{\delta^3}{\delta\varphi(x)^3}S(\varphi)=-\int\mathrm{d}^4x\left\{e(x)\frac{\delta}{\delta\varphi(x)}\right\}^3S(\varphi). \tag{19}$$

This representation is useful for investigation of the perturbation theory symmetry properties. The indication that the contribution belongs to the Mills time contour was not shown in (19) since it was assumed that, for instance,

$$\frac{\delta j(t\in C_a)}{\delta j(t'\in C_b)}=\delta_{ab}\delta(t-t'),\quad a,b=+,-. \tag{20}$$

For this reason it is sufficient to indicate the branch of the Mills contour only in the definition of the operator (15).

We will consider the ''phase space'' motion:

$$DM_j(\varphi,\pi)=\prod_x \mathrm{d}\varphi(x)\mathrm{d}\pi(x)\,\delta\left(\dot{\varphi}(x)-\frac{\delta H_j}{\delta\pi(x)}\right)\delta\left(\dot{\pi}(x)+\frac{\delta H_j}{\delta J(x)}\right). \tag{21}$$

It is important that the formalism involves the *total* Hamiltonian

$$H_j=\int \mathrm{d}^3x\left[\frac{1}{2}\pi^2+\frac{1}{2}(\nabla\varphi)^2+\frac{\kappa}{4}\varphi^4-j\varphi\right] \tag{22}$$

and the last term $\sim j\varphi$ may be interpreted as the time-dependent energy of random quantum excitations. It is evident that we may find the measure (9) if the first δ-function in (21) is used to calculate the integral over π. Thus, the representation (14), with the measure (21), may be considered as the ''first-order'' formalism.

This ends the definition of the field theory on the Dirac measure.

B. Mapping into the factor space

Having a theory defined on the δ-like measure, arbitrary transformations are easily available. We will start from the general situation introducing N fields $\{\xi(x),\eta(x)\}_N$, where N is arbitrary.

To perform the transformation:

$$(\varphi(x),\pi(x))\rightarrow\{\xi(x),\eta(x)\}_N \tag{23}$$

one should insert

$$1=\frac{1}{\Delta(\varphi,\pi)}\int D\xi D\eta\prod_x \delta(F_\xi(\varphi,\pi;\xi,\eta))\prod_x \delta(F_\eta(\varphi,\pi;\xi,\eta)) \tag{24}$$

into the integral (14). The functional δ-function $\Pi_x\delta$ has following properties:

$$\begin{gathered}\int DX\prod_x \delta(X(x))=1,\\ \int DX\prod_x \delta(\partial_\mu X(x))=\int\prod_x \mathrm{d}X(x)\,\delta(\partial_\mu X(x))=\int\prod_{x\neq x_\mu}\mathrm{d}X_{(\mu)}(x).\end{gathered} \tag{25}$$

Here $X_{(\mu)}(x)$ is the solution of equation $\partial_\mu X(x)=0$, i.e., is the arbitrary, including constant, x_μ independent function.

Having the measure (21) and inserting the unit (24) into (14) the integrals of type

$$\int D\xi D\eta D\varphi D\pi\Delta^{-1}(\varphi,\pi)\prod \delta(F_\xi(\varphi,\pi;\xi,\eta))\,\delta(F_\eta(\varphi,\pi;\xi,\eta))\,\delta\left(\dot{\varphi}-\frac{\delta H_j}{\delta\pi}\right)\delta\left(\dot{\pi}+\frac{\delta H_j}{\delta\varphi}\right) \tag{26}$$

would appear. Notice that the $(\dim\xi+\dim\eta)=N$ was chosen arbitrary.

It is important that both measures in (26), over (ξ,η) and over (φ,π), are δ-like. This allows one to change order of integration and integrate first over φ and π. It is natural, at first glance, to use for this purpose the last two δ-functions. Then the first ones will define the constraint. This scheme may restore the Wentzel–Kramers–Brillouin perturbation theory, if the unit (24) is reduced to the Faddeev–Popov *ansatz*.[2] But if the first two δ-functions of (26) are used to calculate the integrals over φ and π, we perform transformation to the new dynamical variables (ξ,η). Then the last two δ-functions will give the dynamical equations for (ξ,η). Both ways of computation would give the same result since one may use arbitrary δ-functions.

Thus, we wish to use the fact that the δ-like measure defines a complete set of contributions. Moreover, as follows from (14) and (15), the quantum perturbations, both in the $(\varphi,\pi)\in V$ and $(\xi,\eta)\in W$ spaces, would be generated by the same operator $\exp\{-i\mathcal{K}(je)\}$ and the interactions in both above-mentioned cases are described by the same functional $U(u,e)$. This circumstance allows one to describe the *quantum* dynamics in terms of new variables.

Then, if the ''phase space flow'' (u,p) belongs to the manifold $\mathcal{G}/\mathcal{H}$ completely, we should be able to ''restore'' it through the (u,p) flow. This is our key idea. We will see that this order of computation, inverse to the ordinary one,[25] is mostly natural for us since it allows one to start transformation from mostly general variables $(\xi,\eta)\in W$.

Following space–time local realization of the algebraic equations was offered in[2,6]

$$\begin{aligned} F_{\xi}(\varphi,\pi;\xi,\eta)&=\varphi(x)-u(x;\xi(x),\eta(x))=0,\\ F_{\eta}(\varphi,\pi;\xi,\eta)&=\pi(x)-p(x;\xi(x),\eta(x))=0, \end{aligned} \tag{27}$$

where $u=u(x;\xi(x),\eta(x))$, $p=p(x;\xi(x),\eta(x))$ are some *compound* functions. We will assume that this functions would be defined in accordance with our choice of $\mathcal{G}/\mathcal{H}$. The equalities (27) can be satisfied for arbitrary given $u(x;\xi(x),\eta(x)),p(x;\xi(x),\eta(x))$ and arbitrary N since integration over all $\varphi(x)$ and $\pi(x)$ is assumed.

Therefore, the integral in (24) is not equal to zero since, generally speaking, it always exist. The result of integration in (24) is denoted by $\Delta(\varphi,\ \pi)$ and in this sense the equality (24) is satisfied identically. The additional constraints for $u(x;\xi,\eta)$ and $p(x;\xi,\eta)$ will be offered later.

We will specify (27) adding the condition that the time dependence is hidden in $\xi(y,t)$ and $\eta(y,t)$, $x=(y,t)$, $\dim(y)=3$. Thus, we would use, instead of (27), the equations:

$$\varphi(y,t)=u(y;\xi(y,t),\eta(y,t)),\quad \pi(y,t)=p(y;\xi(y,t),\eta(y,t)). \tag{28}$$

In other aspects the functions $u(y;\xi,\eta),p(y;\xi,\eta)$ for the time being are arbitrary. Notice that the offered additional condition is evident since (u,p) would belong to $\mathcal{G}/\mathcal{H}$ completely. But, nevertheless, we will examine it.[26] Notice also the noncovariantness of equalities (28). This is a consequence of necessity of using the Hamiltonian formalism.[2]

The integration measures in (26) over $\xi(y,t)$ and $\eta(y,t)$ are defined on the total Mills time contour $C=C_{+}+C_{-}$:

$$\int_{C}\mathrm{d}t=\int_{C_{+}+C_{-}}\mathrm{d}t=\int_{C_{+}}\mathrm{d}t+\int_{C_{-}}\mathrm{d}t, \tag{29}$$

and the integration should be performed with boundary condition (18):

$$u(;\xi(,t\in\partial C_{+}),\eta(,t\in\partial C_{+}))=u(;\xi(,t\in\partial C_{-}),\eta(,t\in\partial C_{-})). \tag{30}$$

Depending on the topology of the trajectory $u(;\xi,\eta)$, this boundary condition may lead to nontrivial consequences.

The mapping (28) is generated by the function u:

$$u:(\varphi,\pi)\to(\xi,\eta) \tag{31}$$

since the ''first-order'' formalism is considered. It is important also to note that this transformation did not conserve the dimension:

$$\dim(\varphi,\pi)(y,t)\neq\dim(\xi,\eta)(y,t) \tag{32}$$

since $(\xi,\eta)\in\mathcal{G}/\mathcal{H}$ and $(\varphi,\pi)\in V$.

Proposition I: The Jacobian of transformation of the δ-like measure always can be done equal to one.

Using first two δ-functions in (26) to perform integration over $(\varphi,\ \pi)$ the Jacobian of the transformation (31) takes the form:

$$J=\frac{1}{\Delta(u,p)}\prod_{y,t}\ \delta\left(\dot{u}(y;\xi,\eta)-\frac{\delta H_j(u,p)}{\delta p(y;\xi,\eta)}\right)\delta\left(\dot{p}(y;\xi,\eta)+\frac{\delta H_j(u,p)}{\delta u(y;\xi,\eta)}\right), \tag{33}$$

where definitions (27) and (28) were used. Notice that $\Delta=\Delta(u,p)$, as a result of integration over φ and π.

We should diagonalize arguments of remaining δ-functions. For this purpose the following trick will be used.[2] So, for instance,

$$\delta\left(\dot{u}-\frac{\delta H_j}{\delta p}\right)=\delta\left(u_\xi\cdot\dot{\xi}+u_\eta\cdot\dot{\eta}-\frac{\delta H_j}{\delta p}\right)$$

$$=\delta\left(u_\xi\cdot\left\{\dot{\xi}-\frac{\delta h_j}{\delta\eta}\right\}+u_\eta\cdot\left\{\dot{\eta}+\frac{\delta h_j}{\delta\xi}\right\}+u_\xi\cdot\frac{\delta h_j}{\delta\eta}-u_\eta\cdot\frac{\delta h_j}{\delta\xi}-\frac{\delta H_j}{\delta p}\right),$$

where $u_X\equiv\partial u/\partial X$, $X=\xi,\ \eta$ and $h_j=h_j(\xi,\eta)$ is the auxiliary functional. Let us choose it by the equality:

$$u_\xi\cdot\frac{\delta h_j}{\delta\eta}-u_\eta\cdot\frac{\delta h_j}{\delta\xi}-\frac{\delta H_j}{\delta p}=\frac{\partial u}{\partial\xi}\cdot\frac{\delta h_j}{\delta\eta}-\frac{\partial u}{\partial\eta}\cdot\frac{\delta h_j}{\delta\xi}-\frac{\delta H_j}{\delta p}=\{u,h_j\}-\frac{\delta H_j}{\delta p}=0, \tag{34}$$

where $\{,\}$ is the Poisson bracket. The scalar product means that the sets $\{\xi\}$ and $\{\eta\}$ were ordered in such a way that the Poisson bracket would be well defined. This ordering is always possible iff W is the symplectic manifold.

Then, if (34) is satisfied,

$$\delta\left(\dot{u}-\frac{\delta H_j}{\delta p}\right)=\delta\left(u_\xi\left\{\dot{\xi}-\frac{\delta h_j}{\delta\eta}\right\}+u_\eta\left\{\dot{\eta}+\frac{\delta h_j}{\delta\xi}\right\}\right),$$

The analogous expression one may find for the second δ-function:

$$\delta\left(\dot{p}+\frac{\delta H_j}{\delta u}\right)=\delta\left(p_\xi\left\{\dot{\xi}-\frac{\delta h_j}{\delta\eta}\right\}+p_\eta\left\{\dot{\eta}+\frac{\delta h_j}{\delta\xi}\right\}\right),$$

and h_j and p should obey additional to (34) equality:

$$\{p,h_j\}+\frac{\delta H_j}{\delta u}=0. \tag{35}$$

On this stage two equalities (34) and (35) are the equations for functions $u(;\xi,\eta)$, $p(;\xi,\eta)$ and $h_j(\xi,\eta)$. Thus, being vague, this mechanism of mapping is able to endure more constraints.

Using the ordinary property of the δ-function:

$$\delta(a-b)=\int \mathrm{d}c\ \delta(c-a)\,\delta(c-b),$$

we can write that

$$J(\xi,\eta)=\frac{1}{\Delta(u,p)}\int D\xi' D\eta'\prod_x\ \delta(u_\xi\cdot\xi'+u_\eta\cdot\eta')\,\delta(p_\xi\cdot\xi'+p_\eta\cdot\eta')$$

$$\times\delta\left(\xi'-\left\{\dot{\xi}-\frac{\delta h_j}{\delta\eta}\right\}\right)\delta\left(\eta'-\left\{\dot{\eta}+\frac{\delta h_j}{\delta\xi}\right\}\right). \tag{36}$$

Let us assume that the functional integral $\Delta(u,p)$ may be written in the form:

$$\Delta(u,p)=\int D\xi' D\eta' \prod_{y,t} \delta(\varphi(y,t)-u(y;\xi+\xi',\eta+\eta'))\,\delta(\pi(y,t)-p(y;\xi+\xi',\eta+\eta'))$$

$$=\int D\xi' D\eta' \prod_{y,t} \delta(u_\xi \xi'+u_\eta \eta')\,\delta(p_\xi \xi'+p_\eta \eta')\neq 0. \tag{37}$$

This is possible since the functions $\varphi(y,t)$ and $\pi(y,t)$ were chosen in such a way that the equalities (27) are satisfied. The inequality (37) excludes the degeneracy. For this reason only $\xi'=\eta'=0$ are essential in the integral (37).

As a result the determinant $\Delta(u,p)$ is canceled identically:

$$DM_j(\xi,\eta)=\prod_{y,t} \mathrm{d}\xi(y,t)\,\eta(y,t)\,\delta\left(\dot{\xi}(y,t)-\frac{\delta h_j}{\delta\eta(y,t)}\right)\delta\left(\dot{\eta}(y,t)+\frac{\delta h_j}{\delta\xi(y,t)}\right) \tag{38}$$

since one may leave an arbitrary pair of δ functions in (36) and $\xi'=\eta'=0$ are essential. Therefore, because of cancellation of the functional determinants our perturbation theory would be free from the ghost fields. This considerably simplifies the described formalism. Notice that equalities (34), (35), and (37) should be satisfied to have this result.

The transformed measure (38) depends on the auxiliary functional $h_j=h_j(\xi,\eta)$, defined by equalities (34) and (35). So, choosing *arbitrary* $u(;\xi,\eta)$ and $p(;\xi,\eta)$ with the property (37), one may find h_j from (34) and (35), and then (38) would be the transformed measure.

Therefore, mapping (31) based on Eqs. (34) and (35) admits one more equation for $u(;\xi,\eta)$, $p(;\xi,\eta)$, and $h_j(\xi,\eta)$. We will consider the following example in the present paper. One may note from (38) that h_j has a meaning of transformed Hamiltonian of new equations:

$$\dot{\xi}(y,t)=\frac{\delta h_j(\xi,\eta)}{\delta\eta(y,t)},\quad \dot{\eta}(y,t)=-\frac{\delta h_j(\xi,\eta)}{\delta\xi(y,t)}. \tag{39}$$

Proposition II: If

$$h_j(\xi,\eta)=H_j(u,p). \tag{40}$$

then the Poisson equations (34), (35) would define the "phase space flow" (u,p).

Indeed, having in mind (28),

$$\dot{u}=u_\xi\dot{\xi}+u_\eta\dot{\eta}=u_\xi\frac{\delta h_j}{\delta\eta}-u_\eta\frac{\delta h_j}{\delta\xi}=\{u,h_j\}=\frac{\delta H_j}{\delta p}, \tag{41}$$

where (39) and then (34) were used. The same equation one may find for p:

$$\dot{p}=p_\xi\dot{\xi}+p_\eta\dot{\eta}=p_\xi\frac{\delta h_j}{\delta\eta}-p_\eta\frac{\delta h_j}{\delta\xi}=\{p,h_j\}=-\frac{\delta H_j}{\delta u}. \tag{42}$$

Therefore, having (40), Eqs. (34) and (35), simultaneously with (39), are equal to the Hamiltonian equations (41) and (42). Notice also that in this case the time dependence actually should be hidden into ξ and η.

It should be stressed also that as follows (41) and (42) fixed by (34), (35) and completed by (40) and (37) transformations are unique in those respects that other ''types'' of mapping would lead to ''unnatural,'' much more complicated, formalism.

Having (34), (35), (40) and taking into account (37), we get to the ''overdetermined'' system of constraints, which may be inconsistent. The Coulomb problem gives a quantum mechanical

example of such a system.[2] At all evidence, the $O(4)\times O(2)$-invariant solution did not also obey (37). On the other hand, if we reject (37) then the determinant $\Delta(u,p)$ is not canceled and the formalism would contain the ghosts.

C. Structure of dual perturbation theory

The problem of mapping for the degenerate case was solved in Ref. 2. It was assumed that one may ''softly'' take off the degeneracy, i.e., that there exist some parameter $\varepsilon\to 0$ which regulates the strength of degeneracy breaking and at $\varepsilon=0$ we have the degenerate limit.[27] The following proposition will be important in this connection.

Proposition III: The quantum perturbation conserves the topology of phase space flow.

Indeed, notice that Eqs. (34) and (35) should be satisfied for arbitrary $j(y,t)$. Let us consider the consequence of this proposition. Remembering (22), and using definition (40), we find that (34) at $j=0$ gives equality:

$$\{u_\xi p_\eta - u_\eta p_\xi - 1\}\frac{\delta H}{\delta p(y,t)} = \{u_\eta u_\xi - u_\xi u_\eta\}\frac{\partial H}{\partial u(y,t)}, \quad H = H_j|_{j=0}.$$

Here u and p are the compound functions of $\xi=\xi(y,t)$ and $\eta=\eta(y,t)$. This equality is identically satisfied if the space–time local Poisson brackets:

$$\{u(y,t),p(y,t)\}=1, \quad \{u(y,t),u(y,t)\}=0 \tag{43}$$

are satisfied. Equation (35) at $j=0$ adds the following conditions:

$$\{u(y,t),p(y,t)\}=1, \quad \{p(y,t),p(y,t)\}=0. \tag{44}$$

It is not hard to see that the higher orders over j did not give new conditions, i.e., the Poison algebra, completed by (40), is closed. In other words, the quantum perturbations conserve the topology[28] of the phase space flow.

Proposition III means that the quantum perturbations would not alter the structure of $u=u(;\xi,\eta)$ and $p=p(;\xi,\eta)$ and they are solutions of *classical* (homogeneous) equations:

$$\{u(y;\xi,\eta),h(\xi,\eta)\}=\frac{\delta H(u,p)}{\delta p(y;\xi,\eta)}, \quad \{p(y;\xi,\eta),h(\xi,\eta)\}=-\frac{\delta H(u,p)}{\delta u(y;\xi,\eta)}. \tag{45}$$

The j dependence is defined by Eq. (39) and is confined completely in ξ and η only.

So, we may start from a theory with generalized Hamiltonian:

$$h_j(\xi,\eta)=H_j(u,p)+\varepsilon\tilde{H}_j(u,p), \tag{46}$$

where the additive term $\sim\varepsilon\to 0$. This proposition means that the ''direct'' mechanism of degeneracy breaking is considered[27] and the Hamiltonian $h_j(\xi,\eta)$ may be chosen in such a way that some of the *derivatives* over auxiliary (artificial) fields ξ' and η' have a property:

$$u_{\xi'}\sim u_{\eta'}\sim p_{\xi'}\sim p_{\eta'}\sim\varepsilon\to 0, \quad (\xi',\eta')\in R^*. \tag{47}$$

This is enough to formulate conserving the phase space volume transformation of quantum theory.

Thus, we start from the variables $(\xi,\eta)\in W$ and scalar functions $u=u(y;\xi,\eta)$, $p=p(y;\xi,\eta)$. They should obey the inequality (37) and define the functional $h_j(\xi,\eta)$ through the equations (34) and (35). This allows one to cancel the determinant $\Delta(u,p)$. Then we extract the auxiliary variables ξ' and η' assuming (47). This will allow one to exclude the auxiliary variables and should reduce the system to a physical one. The physical content of this procedure was described in Ref. 2.

The following property of the perturbation theory in W space will be used to realize this program of reduction. As a result of our mapping the integral $\mathcal{N}$ takes the form:

$$\mathcal{N}(u)=e^{-i\mathcal{K}(je)}\int DM_j(\xi,\eta)e^{-2iU(u,e)}, \tag{48}$$

where $DM_j(\xi,\eta)$ is defined in (38). Notice that in this expression U depends on $u=u(y;\xi,\eta)$.

It was shown in Ref. 2 that the mapped representation (48) allows one to split the ''quantum force'' $j(y,t)$ and corresponding ''virtual field'' $e(y,t)$ on the projection on the axes of W. It is easy to find the result of this procedure:

$$2\mathcal{K}(je)=\mathrm{Re}\int_{C_+}\mathrm{d}^3x\,\mathrm{d}t\{\hat{j}_\xi(y,t)\cdot\hat{e}_\xi(y,t)+\hat{j}_\eta(y,t)\cdot e_\eta(y,t)\} \tag{49}$$

and

$$e=e_\xi\cdot\frac{\partial u}{\partial\eta}-e_\eta\cdot\frac{\partial u}{\partial\xi}. \tag{50}$$

The caret symbol in (49) means the derivative over the corresponding quantity. At the very end of the calculation one should take $j_X=e_X=0$, $X=(\xi,\eta)$. The scalar product means summation over all components of ξ and η.

Inserting (50) into (19) one can find that

$$\begin{aligned}-3!U(u,e)&=\int\mathrm{d}^3x\,\mathrm{d}t\left\{e_\xi\cdot\frac{\partial u}{\partial\eta}\frac{\delta}{\delta u}-e_\eta\cdot\frac{\partial u}{\partial\xi}\frac{\delta}{\delta u}\right\}^3S(u)\\&=\int\mathrm{d}^3x\,\mathrm{d}t\left\{e_\xi\cdot\frac{\partial u}{\partial\eta}\frac{\partial}{\partial u}-e_\eta\cdot\frac{\partial u}{\partial\xi}\frac{\partial}{\partial u}\right\}^3\mathcal{L}(u),\end{aligned} \tag{51}$$

where $\mathcal{L}(u)$ is the Lagrangian density. This shows that the interaction functional $U(u,e)$ has the symmetry properties of the Lagrangian density.

Formally the new perturbation generating operator (49) gives the same perturbation series, but with the rearranged sequence of terms, i.e., the splitting of j did not change the ''convergence'' of the perturbation series (over $1/\kappa$ since $u\sim1/\sqrt{k}$). At the same time, this splitting of the source j is useful since it allows one to analyze the excitation of each degree of freedom, i.e., of components of the phase space flow along the axis of W, independently.

Noting that e_X, $X=\xi,\eta$, is conjugate to j_X, it is easy to conclude that the action of the operator (49) leads to the operator

$$\left\{\frac{\delta}{\delta j_\xi}\cdot\frac{\partial u}{\partial\eta}\frac{\partial}{\partial u}-\frac{\delta}{\delta j_\eta}\cdot\frac{\partial u}{\partial\xi}\frac{\partial}{\partial u}\right\}\sim\{\hat{j}\wedge\hat{X}\}.$$

This operator is the invariant of canonical transformations. If by some reason $\mathrm{d}\omega_X^2=\hat{j}_X\wedge\hat{X}=0$, then the motion along the Xth axis will be classical. This is the mechanism of reduction of the quantum degrees of freedom. The important properties of our formalism were described in Ref. 2. We will continue this question in Sec. II D.

Proposition IV: New fields ξ and η cannot depend on the coordinate y if the scalar theory is considered, i.e.,

$$\xi=\xi(t),\quad \eta=\eta(t), \tag{52}$$

for scalar theory (12).

This conclusion follows from Proposition III. The reason is that the dynamical problem was divided into two parts. The first part of the problem consists in the solution of the *classical* equations (45). It defines a structure of the compound functions $u(y;\xi,\eta)$ and $p(y;\xi,\eta)$. The second part consists in the definition of the *time* dependence of (ξ,η) through Eqs. (39) and (40). Finally, if (ξ,η) in zero order over $j(y,t)$ are the y independent parameters, the quantum perturbations are unable to change this property.

It is noticeable that if $\xi=\xi(t)$ and $\eta=\eta(t)$ then we will find from (34) and (35), instead of (43) and (44), the *canonical* equal-time commutator relations:

$$\{u(y;\xi(t),\eta(t)),p(y';\xi(t),\eta(t))\}=\delta(y-y'). \tag{53}$$

Thus, our quantization scheme would restore the canonical one in the factor space W. In this sense the independence of ξ and η from y is natural.

Nevertheless it seems useful to demonstrate Proposition IV explicitly. The elements (49) and (38) are used in the Appendix to demonstrate the reduction:

$$(\xi,\eta)(y,t)\to(\xi,\eta)(t). \tag{54}$$

This involves reduction of the operators:

$$(\hat{j}_X,\hat{e}_X)(y,t)\to(\hat{j}_X,\hat{e}_X)(t),\quad X=\xi,\eta. \tag{55}$$

The structure of the corresponding perturbation theory is described in Sec. II D.

D. Reduction

Therefore, for considered scalar theory,

$$2\mathcal{K}(je)=\mathrm{Re}\int_{C_+}\mathrm{d}t\{\hat{j}_\xi(t)\cdot\hat{e}_\xi(t)+\hat{j}_\eta(t)\cdot e_\eta(t)\} \tag{56}$$

and

$$e(y;\xi(t),\eta(t))=e_\xi(t)\cdot\frac{\partial u(y;\xi(t),\eta(t))}{\partial\eta(t)}-e_\eta(t)\cdot\frac{\partial u(y;\xi(t),\eta(t))}{\partial\xi(t)}. \tag{57}$$

The result of the disappearance of y dependencies in ξ and η is a reduction of the field-theoretical problem to the quantum mechanical one. So, $L(u)=V(\xi,\eta)$ here play the role of the mechanical potential for a particle with the *phase space* coordinate (ξ,η).

The measure takes the form:

$$DM_j(\xi,\eta)=\prod_t\mathrm{d}\xi(t)\mathrm{d}\eta(t)\,\delta(\dot{\xi}(t)-\omega_\eta(\xi,\eta)-j_\xi(t))\,\delta(\dot{\eta}(t)+\omega_\xi(\xi,\eta)-j_\eta(t)), \tag{58}$$

where the "velocity"

$$\omega_X(\xi,\eta)=\frac{\partial h(\xi,\eta)}{\partial X}. \tag{59}$$

Let us remember now the definition (47):

$$u=u(y;\xi(t),\eta(t);\varepsilon\xi'(t),\varepsilon\eta'(t)),\quad \varepsilon\to0, \tag{60}$$

where

$$\dim\xi=n,\quad \dim\eta=m,\quad \dim(\xi+\xi')=\dim(\eta+\eta')=N. \tag{61}$$

Inserting (60) into Lagrangian, we find that

$$L(u)=\int \mathrm{d}^3x\mathcal{L}(u(y;\xi(t),\eta(t)))+O(\varepsilon). \tag{62}$$

We are now able to define the dimension of T^*V taking

$$N=\dim(\mathcal{G}/\mathcal{H}). \tag{63}$$

So, $N=8$ for example (1).

Proposition V: If we have (60) and (61) then

$$\dim T^*V=\min\{n,m\}. \tag{64}$$

Let us consider the following three possibilities to demonstrate this proposition.

(*a*) $n=m$, $N=2n$.

In this case the interaction functional $U(u,e)$ takes the form:

$$-3!U(u,e)=\int \mathrm{d}t\left\{\left(e_x\cdot\frac{\partial}{\partial\eta}-e_\eta\cdot\frac{\partial}{\partial\xi}\right)_n+\left(e_{x'}\cdot\frac{\partial}{\partial\eta'}-e_{\eta'}\cdot\frac{\partial}{\partial\xi'}\right)_{N-n}\right\}^3, \tag{65}$$

where (62) was used. The index n means that the scalar products include n terms, and N may be chosen equal to n. The measure

$$DM_j(\xi,\eta)=\prod_t \mathrm{d}^n\xi(t)\mathrm{d}^n\eta(t)\,\delta^{(n)}(\dot\xi-\omega_n-j_\xi)\,\delta^{(n)}(\dot\eta+\omega_\xi-j_\eta).$$

(*b*) $n>m$, $N=n+m$.

In this case

$$-3!U(u,e)=\int \mathrm{d}t\left\{\left(e_x\cdot\frac{\partial}{\partial\eta}-e_\eta\cdot\frac{\partial}{\partial\xi}\right)_m+\left(e'_\eta\cdot\frac{\partial}{\partial\xi}\right)_{(n-m)}\right\}^3 V(\xi,\eta), \tag{66}$$

since η' is absent in $V(\xi,\eta)$. Therefore, e'_η has only the $(n-m)$ components.

The measure takes the form:

$$DM_j(\xi,\eta)=\prod_t \mathrm{d}^n\xi(t)\mathrm{d}^m\eta(t)\mathrm{d}^{(n-m)}\eta'(t)\,\delta^{(m)}(\dot\xi-\omega_\eta-j_\xi)\,\delta^{(m)}(\dot\eta+\omega_\xi-j_\eta)$$
$$\times\,\delta^{(n-m)}(\dot\xi-j_\xi)\,\delta^{(n-m)}(\dot\eta'+\omega_\xi-j_{\eta'})$$

since $N=(n+m)$. Notice that η' is contained only in the argument of the last δ-function. For this reason we always can perform the shift: $\dot\eta'\to\dot\eta'-\omega_\xi+j_{\eta'}$. As a result:

$$DM_j(\xi,\eta)=\prod_t \mathrm{d}^m\xi(t)\,\eta^m(t)\,\delta^{(m)}(\dot\xi-\omega_\eta-j_\xi)\,\delta^{(m)}(\dot\eta+\omega_\xi-j_\eta)\,\delta^{(n-m)}(\dot\xi-j_\xi)\,\delta^{(n-m)}(\dot\eta')$$

and the $j_{\eta'}$ dependence disappears. For this reason the $\hat j_{\eta'}$ dependence in the operator $\mathcal{K}$ may be omitted. As a result,

$$2\mathcal{K}(je)=\mathrm{Re}\int_{C_+}\mathrm{d}t\{(\hat{j}_\xi\cdot\hat{e}_\xi)_m+(\hat{j}_\eta\cdot\hat{e}_\eta)_m+(\hat{j}_\xi\cdot\hat{e}_\xi)_{(n-m)}\}.$$

There is not an operator $\hat{e}'_\eta$ and, for this reason, one should take $e_{\eta'}$ equal to zero. Therefore,

$$-3!U(u,e)=\int\mathrm{d}t\left\{e_x\cdot\frac{\partial}{\partial\eta}-e_\eta\cdot\frac{\partial}{\partial\xi}\right\}_m^3 V(\xi,\eta) \tag{67}$$

and the $(n-m)$ components of e_ξ and j_ξ may be taken equal to zero everywhere:

$$2\mathcal{K}(je)=\mathrm{Re}\int_{C_+}\mathrm{d}t\{\hat{j}_\xi\cdot\hat{e}_\xi+\hat{j}_\eta\cdot\hat{e}_\eta\}_m. \tag{68}$$

Accordingly,

$$DM_j(\xi,\eta)=\mathrm{d}R\prod_t\mathrm{d}^m\xi(t)\mathrm{d}^m\eta(t)\,\delta^{(m)}(\dot{\xi}-\omega_\eta-j_\xi)\,\delta^{(m)}(\dot{\eta}+\omega_\xi-j_\eta), \tag{69}$$

where

$$\mathrm{d}R=d^{(N-2m)}\xi(0) \tag{70}$$

is the element of R. The trivial auxiliary elements were omitted.

The same analyses may be done for the case $n<m$.

As a result, assuming that η is the ''action'' variable,

$$\omega_\eta=\omega(\eta)\equiv\partial h(\eta)/\partial\eta,\quad \omega_\xi=0,$$

we can write:

$$DM_j(\xi,\eta)=\mathrm{d}R\prod_{i=1}^{\min\{m,n\}}\prod_t\mathrm{d}\xi_i(t)\,\eta_i(t)\,\delta(\dot{\xi}_i-\omega_i(\eta)-j_{i\xi})\,\delta(\dot{\eta}_i-j_{i\eta}). \tag{71}$$

Therefore,

$$W=T^*V\times R \tag{72}$$

and $\mathrm{d}R$ is the differential measure of the subspace R.

This ends the proof of Proposition V.

So, the equation for ξ and η take the form:

$$\dot{\xi}(t)=\omega(\eta)+j_\xi(t),\quad \dot{\eta}(t)=j_\eta(t). \tag{73}$$

The second equation is simply integrable:

$$\eta(t)=\eta_0+\int\mathrm{d}t'\,g(t-t')j_\eta(t')\equiv\eta_0+\eta_j(t). \tag{74}$$

Inserting this solution into the first equation in (73) one may find:

$$\xi(t)=\xi_0+\int\mathrm{d}t'\,g(t-t')\omega(\eta_0+\eta_j(t'))+\int\mathrm{d}t'\,g(t-t')j_\xi(t')\equiv\xi_0+\overline{\omega_j}(t)t+\xi_j(t), \tag{75}$$

where the abbreviation

$$\overline{\omega}(t)t=\int \mathrm{d}t'\, g(t-t')\omega(\eta_0+\eta_j(t')) \tag{76}$$

was used. The Green function $g(t-t')$ was defined in[2]

$$g(t-t')=\Theta(t-t'), \tag{77}$$

where $\Theta(t-t')$ is the step function with boundary property:

$$\Theta(0)=1. \tag{78}$$

As a result,

$$u=u(y;\xi_0+\overline{\omega}_j(t)t+\xi_j,\eta_0+\eta_j) \tag{79}$$

and the term

$$\sim\frac{1}{n!}\{-2iU(u,j)\}^n=O\left(\frac{1}{\kappa^n}\right)$$

gives the nth order of our perturbation theory over $1/\kappa$ since $u=O(1/\sqrt{\kappa})$.

III. NON-ABELIAN GAUGE FIELD THEORY

A. Yang–Mills theory on Dirac measure

The action of considered theory

$$S(A)=\frac{1}{2g}\int \mathrm{d}^4x F_{\mu\nu a}(A)F_a^{\mu\nu}(A) \tag{80}$$

is the $O(4,2)$ invariant and the Yang–Mills fields

$$F_{\mu\nu a}(A)=\partial_\mu A_{\nu a}-\partial_\nu A_{\mu a}-C_a^{bc}A_{\mu b}A_{\nu c} \tag{81}$$

are the covariant of non-Abelian gauge transformations. The gauge group will not be specified.

We will consider the integral

$$\mathcal{N}=e^{-i\mathcal{K}(je)}\int DM_j e^{-2iU(A,e)}, \tag{82}$$

where the measure

$$DM_j(A)=\prod_{\mu,a}\prod_x \mathrm{d}A_\mu^a(x,t)\,\delta(D_a^{\nu b}F_{\nu\mu b}-j_{\mu a}) \tag{83}$$

is manifestly conformal and gauge invariant if $j_{\mu a}=0$. The covariant derivative

$$D_a^{\mu b}=\partial^\mu\delta_a^b+C_a^{bc}A_c^\mu.$$

The perturbations generating operator

$$2\mathcal{K}(je)=\mathrm{Re}\int_{C_+}\mathrm{d}^4x\frac{\delta}{\delta j_a^\mu(x,t)}\frac{\delta}{\delta e_{\mu a}(x,t)}\equiv\mathrm{Re}\int_{C_+}\mathrm{d}^4x\hat{j}_{\mu a}(x,t)\hat{e}_a^\mu(x,t). \tag{84}$$

The auxiliary variables $j_{\mu a}$ and e_a^μ should be taken equal to zero at the very end of the calculations. The functional

$$-2U(A,e)=(S_{C_+}(A+e)-S_{C_-}(A-e))-2\,\mathrm{Re}\int_{C_+}\mathrm{d}^4x e_a^\mu(x)\frac{\delta S(A)}{\delta A_a^\mu}+O(\varepsilon) \tag{85}$$

describes interactions. All the above-mentioned quantities are defined on the Mills time contours

$$C_\pm : t\to t\pm i\epsilon,\quad \epsilon\to+0,\quad |t|\leqslant\infty. \tag{86}$$

This gives the rule as to avoid the light-cone singularities solving the equation:

$$D_a^{\nu b}F_{\mu\nu b}=j_{\mu a}. \tag{87}$$

One can omit in (85) terms $\sim\epsilon\to+0$. Therefore, $U(A,e)=O(e^3)$ and may contain only the odd powers of $e_{a\mu}$. This means that we may write $U(A,e)$ in the form:

$$U(A,e)=-\int\mathrm{d}^4x\left\{e_a^\mu(x)\frac{\delta}{\delta A_a^\mu(x)}\right\}^3 S(A), \tag{88}$$

see (19).

B. First-order formalism

The noncovariant first-order formulation in terms of the ''electric'' field

$$E_a^i=F_a^{i0}, \tag{89}$$

presents an introduction into the necessary for us Hamiltonian description. The action in this term has the form

$$S_{C_\pm}(A,F)=\frac{1}{g}\int_{C_\pm}\mathrm{d}^4x\left\{\dot{\mathbf{A}}_a\cdot\mathbf{E}_a+\frac{1}{2}(\mathbf{E}_a^2+\mathbf{B}_a^2(\mathbf{A}))-A_{0a}(\mathbf{D}\cdot\mathbf{E})_a\right\}, \tag{90}$$

where the ''magnetic'' field

$$B_{ia}(\mathbf{A})=(\mathrm{rot}\,\mathbf{A})_{ia}+\tfrac{1}{2}\epsilon_{ijk}[A_j,A_k]_a \tag{91}$$

is not the independent quantity and was introduced to shorten the formulas. Notice that A_{0a} did not contain the conjugate pair and the action S is linear over it.

The measure (83) may be written in the first-order formalism representation ($d\mathbf{A}_a=\prod_i \mathrm{d}A_{ia}$):

$$DM_j(\mathbf{A},\mathbf{P})=\prod_{a,i}\prod_x\mathrm{d}\mathbf{A}_{ai}(x)\mathrm{d}\mathbf{P}_{ai}(x)\,\delta(\mathbf{D}_a^b\cdot\mathbf{P}_b)\,\delta\left(\dot{\mathbf{P}}_a(x)+\frac{\delta H_j(\mathbf{A},\mathbf{P})}{\delta\mathbf{A}_a(x)}\right)\delta\left(\dot{\mathbf{A}}_a(x)-\frac{\delta H_j(\mathbf{A},\mathbf{P})}{\delta\mathbf{P}_a(x)}\right), \tag{92}$$

where $H_j(\mathbf{A},\mathbf{P})$ is the total Hamiltonian:

$$H_j=\frac{1}{2g}\int\mathrm{d}^3x(\mathbf{P}_a^2+\mathbf{B}_a^2(\mathbf{A}))+\int\mathrm{d}^3x\mathbf{j}_a\mathbf{A}_a, \tag{93}$$

$\mathbf{P}_a(x)\equiv\mathbf{E}_a(x)$ is the conjugate to $\mathbf{A}_a(x)$ momentum and $\mathbf{B}_a(\mathbf{A})$ was defined in (91). We may introduce into DM_j the additional δ-function:

$$\prod_a\prod_x\delta\left(\mathbf{B}_a^i-(\mathrm{rot}\,\mathbf{A})_a^i-\frac{1}{2}\varepsilon_{jk}^i[A^j,A^k]_a\right). \tag{94}$$

Then the Hamiltonian in (93) becomes symmetric over electric $\mathbf{E}_a$ and magnetic $\mathbf{B}_a$ fields.

Notice that the first δ-function in (92) is the consequence of linearity of the action over A_{0a}. The time component A_{0a} has the meaning of Lagrange multiplier for the Gauss law:

$$\mathbf{D}_a^b \cdot \mathbf{P}_b = 0. \tag{95}$$

It should be stressed that there is not an equation for the time component A_{0a}. Moreover, the A_{0a} dependence completely disappeared from formalism since the interaction functional $U(A,e)$ is defined by the third derivative over $A_{\mu a}$, see (88).

C. Mapping into the factor space

The measure (92) is not physical since it contains three (for given a) vector potentials $\mathbf{A}_a(x)$. To exclude the unphysical degree of freedom, the gauge fixing Faddeev–Popov *ansatz* is often used. But we will consider, as was described previously, another approach.

We will introduce the functional

$$\Delta(A,P) = \int D\xi D\eta \prod_a \delta(\mathbf{A}_a(x) - \mathbf{u}_a(x;\xi(x),\eta(x)))\,\delta(\mathbf{P}_a(x) - \mathbf{p}_a(x;\xi(x),\eta(x))) \tag{96}$$

to realize the transformation

$$u{:}(A,P)_a(x) \to (\xi,\eta)(x), \tag{97}$$

to the compound vector functions $(\mathbf{u},\mathbf{p})_a(x;\xi(x),\eta(x))$ of the space–time local parameters $(\xi,\eta)(x)$. It is assumed that $\Delta \neq 0$.

Performing transformation (97), we find:

$$DM_j(\xi,\eta) = \frac{1}{\Delta_c(u)} \prod_a \prod_x \mathrm{d}\xi \mathrm{d}\eta\, \mathrm{d}\lambda_a \mathrm{d}q_a\, \delta(\mathbf{D}_a^b \cdot \mathbf{p}_b)\, \delta\left(\dot{\mathbf{u}}_a(x) - \frac{\delta H_j}{\delta \mathbf{p}_a(x)}\right) \delta\left(\dot{\mathbf{p}}_a(x) + \frac{\delta H_j}{\delta \mathbf{u}_a(x)}\right). \tag{98}$$

Here the gauge phase λ_a and conjugate to it q_a was extracted from the set of variables ξ and η.

Using the result of Sec. III B, one may diagnolize arguments of δ-functions. As a results:

$$DM_j(\xi,\eta,\lambda,Q) = \prod_{x,t,a} \mathrm{d}\xi\, \mathrm{d}\eta\, \mathrm{d}\lambda\, \mathrm{d}q\, \delta(\mathbf{D}_a^b(\mathbf{u}) \cdot \mathbf{p}_b)\, \delta\left(\dot{\lambda}_a - \frac{\delta h_j}{\delta q_a}\right) \delta\left(\dot{q}_a + \frac{\delta h_j}{\delta \lambda_a}\right)$$
$$\times \delta\left(\dot{\xi} - \frac{\delta h_j}{\partial \eta}\right) \delta\left(\dot{\eta} + \frac{\partial h_j}{\partial \xi}\right). \tag{99}$$

Equality (99) holds iff h_j is defined by Poisson equations (for the three vectors given $\mathbf{u}_a$ and $\mathbf{p}_a$):

$$\{\mathbf{u}_a(x), h_j\} = \frac{\delta H_j}{\delta \mathbf{p}_a(x)}, \quad \{\mathbf{p}_a(x), h_j\} = -\frac{\delta H_j}{\delta \mathbf{u}_a(x)} \tag{100}$$

considering $(\xi,\ \eta)$ and (λ,q) in the Poisson brackets as the canonically conjugate pairs.

If we add to (100) one more equation:

$$h_j(\xi,\eta,\lambda,q) = H_j(\mathbf{u}_a,\mathbf{p}_a) \tag{101}$$

then, as was shown in Sec. III B, $\mathbf{u}_a$ and $\mathbf{p}_a$ should be solution of incident equations, assuming that (100) holds on the measure (99). Then

$$\mathbf{D}_a^b(u) \cdot \mathbf{p}_b \equiv 0 \tag{102}$$

since $\mathbf{p}_b$ is the solution of Eq. (100) at arbitrary $j_{\mu a}$. This remarkable result is the consequence of mapping into the invariant space $\mathcal{G}/\mathcal{H}$ to which the classical flow belongs completely. Therefore, the corresponding δ-function in (111) gives identically

$$\prod_x \delta(0).$$

This infinite factor should be canceled by normalization and will not be mentioned later. Note that the formalism contains one sources $\mathbf{j}_a$ conjugate to the coordinates $\mathbf{u}_a$ only, see (101) and (93).

So, the described mapping gives the measure:

$$DM_j(\xi,\eta,\lambda,Q)=\prod_{x,t;a} \mathrm{d}\lambda_a \mathrm{d}q_a \mathrm{d}\xi \mathrm{d}\eta\, \delta(\dot{\lambda}_a)\, \delta\left(\dot{q}_a+\frac{\delta h_j}{\delta \lambda_a}\right) \delta\left(\dot{\xi}-\frac{\partial h_j}{\partial \eta}\right) \delta\left(\dot{\eta}+\frac{\partial h_j}{\partial \xi}\right). \tag{103}$$

We have taken into account here that $(u,p)_a$ are q_a independent. The Hamiltonian h_j is defined by Eq. (101):

$$2gh_j=\int \mathrm{d}^3x(p_a^2+\mathbf{B}_a^2(u))+\int d^3x \mathbf{j}_a\mathbf{u}_a\equiv h+J, \tag{104}$$

where h is the unperturbated by $\mathbf{j}_a$ Hamiltonian.

Helping the Proposition V, we can exclude the q_a dependence:

$$DM_j(\xi,\eta,\lambda)=\mathrm{d}R\prod_{x;a} \mathrm{d}\lambda_a \mathrm{d}\xi \mathrm{d}\eta\, \delta(\dot{\lambda}_a)\, \delta(\dot{\xi}-\omega-j_\xi)\, \delta(\dot{\eta}-j_\eta), \tag{105}$$

where the ''velocity'' $\omega=\partial h/\partial\eta$. The perturbations generating operator takes the form:

$$2\mathcal{K}(je)=\int \mathrm{d}t\{\hat{j}_\xi \hat{e}_\xi+\hat{j}_\eta \hat{e}_\eta\}. \tag{106}$$

At the same time one should replace in (85) $\mathbf{e}_a$ on

$$\mathbf{e}_a(x)=e_\xi(t)\frac{\partial \mathbf{u}_a(x;\xi,\eta,\lambda)}{\partial\eta(t)}-e_\eta(t)\frac{\partial \mathbf{u}_a(x;\xi,\eta,\lambda)}{\partial\xi(t)}. \tag{107}$$

As follows from (105) we should consider the time independent gauge transformations:

$$\dot{\lambda}_a(x)=0. \tag{108}$$

To remove this constraint we should generalize Eq. (100). So, if we consider the equation:

$$\{\mathbf{u}_a(x;\xi,\eta,\lambda),h_j\}=\frac{\delta H_j}{\delta \mathbf{p}_a(x)}-\Omega_a(x)\frac{\partial \mathbf{u}(x;\xi,\eta,\lambda)}{\partial \lambda_a} \tag{109}$$

instead of the first equation in (100) then one should replace in (105)

$$\prod_{x,a} \mathrm{d}\lambda_a(x)\,\delta(\dot{\lambda}_a(x))\to\prod_{x;a} \mathrm{d}\lambda_a(x)\,\delta(\dot{\lambda}_a(x)-\Omega_a(x)), \tag{110}$$

where $\Omega_a(x)$ is the arbitrary function of y and t. This is the most general representation for gauge measure in our formalism.

As a result, the main elements of quantum Yang–Mills theory in the $\mathcal{G}/\mathcal{H}$ space looks as follows.

(i) The measure

$$DM_j(\xi,\eta,\lambda)=\mathrm{d}R\prod_{x;a}\mathrm{d}\lambda_a\mathrm{d}\xi\mathrm{d}\eta\,\delta(\dot\lambda_a(x)-\Omega_a(x))\,\delta(\dot\xi-\omega-j_\xi)\,\delta(\dot\eta-j_\eta). \tag{111}$$

Using definition (25), one may note that

$$\int\prod_{x,a}\mathrm{d}\lambda_a\,\delta(\dot\lambda_a(x)-\Omega_a(x))$$

means integration over all functions $\lambda_a(y,t)$ of the arbitrary given time dependence. At the same time

$$\frac{\int\Pi_{x;a}\mathrm{d}\lambda_a\,\delta(\dot\lambda_a(x)-\Omega_a(x))}{\int\Pi_{x;a}\mathrm{d}\lambda_a}\equiv 0. \tag{112}$$

Therefore our normalization on the gauge group volume differs from the ordinary one. But this will not affect the result since all contributions will be gauge invariant.

(ii) The quantum perturbation's generating operator

$$2\hat K(\mathbf{je})=\int dt\{\hat{\mathbf{j}}_\xi\cdot\hat{\mathbf{e}}_\xi+\hat{\mathbf{j}}_\eta\cdot\hat{\mathbf{e}}_\eta\}. \tag{113}$$

(iii) The interactions functional $U(\mathbf{u},\overline{e})$ depends on

$$\mathbf{e}_a=\mathbf{e}_\xi\cdot\frac{\partial\mathbf{u}_a}{\partial\eta}-\mathbf{e}_\eta\cdot\frac{\partial\mathbf{u}_a}{\partial\xi}. \tag{114}$$

Note the motion along λ orbits is exactly classical and the dependence of nondynamical variables has disappeared.

D. Gauge invariance

We wish to quantize the theory without gauge fixing *ansatz* and, therefore, the theory contains three *independent* potential $\mathbf{u_{ia}}$, $i=1,2,3$ for each color index a. We may avoid this problem with the unphysical degrees of freedom if the theory would depend only on the gauge-invariant observable quantities: the color electric, $\mathbf{E}_a$, and magnetic, $\mathbf{B}_a$, fields.

Proposition VI: Each order over $1/g$ *is explicitly gauge invariant.*

The interactions functional U has following explicit form:

$$-3!\,U(\mathbf{u},e)=\frac{1}{g}\int\mathrm{d}x\prod_{k=1}^{3}\left\{e_{a_k}\frac{\partial}{\partial u_{a_k}}\right\}F^{\mu\nu a}F_{\mu\nu a},$$

where e_a was defined in (114). Using this definition, we find:

$$-3!\,U(\mathbf{u},e)=\int\mathrm{d}x\prod_{k=1}^{3}\left\{\left[\mathbf{e}_\xi\cdot\frac{\partial\mathbf{u}_a}{\partial\eta}-\mathbf{e}_\eta\cdot\frac{\partial\mathbf{u}_a}{\partial\xi}\right]\frac{\partial}{\partial\mathbf{u}_{\mathbf{a}_k}}\right\}F^{\mu\nu a}F_{\mu\nu a}. \tag{115}$$

The summation over repeated indices is assumed.

The last expression is manifestly gauge invariant since the operator is singlet of gauge transformations and $F^{\mu\nu a}F_{\mu\nu a}$ is the gauge invariant quantity.

E. Divergences

Expression (115) may be written in the form:

$$-3!U(\mathbf{u},\overline{e})=\int \mathrm{d}t\prod_{k=1}^{3}\left\{\left[\mathbf{e}_{\xi}\cdot\frac{\partial\mathbf{u}_a}{\partial\eta}-\mathbf{e}_{\eta}\cdot\frac{\partial\mathbf{u}_a}{\partial\xi}\right]\frac{\partial}{\partial\mathbf{u}_{\mathbf{a_k}}}\right\}\mathcal{L}(u), \tag{116}$$

where

$$\mathcal{L}(u)=\int \mathrm{d}^3x F^{\mu\nu a}F_{\mu\nu a}$$

is the Yang–Mills Lagrangian.

Result of action of the perturbation generating operator gives the expression:

$$\mathcal{N}(u)=\int DM(\xi,\eta):e^{-2iU(u,e)}:, \tag{117}$$

where the operator

$$-3!(2i)^3\mathcal{U}(u,e)=\int \mathrm{d}t\prod_{k=1}^{3}\left\{\left[\frac{\delta}{\delta\mathbf{j}_{\xi}}\cdot\frac{\partial\mathbf{u}_a}{\partial\eta}-\frac{\delta}{\delta\mathbf{j}_{\eta}}\cdot\frac{\partial\mathbf{u}_a}{\partial\xi}\right]\frac{\partial}{\partial\mathbf{u}_a}\right\}\mathcal{L}(u), \tag{118}$$

where u_{ia} depends on the solution of equations:

$$\dot{\xi}-\omega(\eta)=j_{\xi},\quad \dot{\eta}=j_{\eta} \tag{119}$$

and the measure is j_X, $X=\xi,\eta$ independent:

$$DM=\mathrm{d}R\prod_a\prod_{y,t}D\lambda_a\delta(\dot{\lambda}_a-\Omega)\,\delta(\dot{\xi}-\omega(\eta))\,\delta(\dot{\eta}).$$

Such ''shift'' is possible since Eqs. (119) are linear over j_X.

We can conclude that if $u_{a\mu}$ is not singular,

$$|S(u)|<\infty, \tag{120}$$

then the theory did not contain divergences since the differential operator in (118) cannot change convergence of the time integrals. Notice that the $O(4)\times O(2)$ solution obeys this property.[3]

IV. CONCLUSION

It was shown that there exists such formulation of the quantum Yang–Mills theory which is (a) divergence free (at least in the vector fields sector), (b) did not contain the gauge ghosts, and (c) is sufficiently consistent, i.e., the quantization scheme is free from the Gribov ambiguities.

It was shown in Ref. 2 that if $\partial(\mathcal{G}/\mathcal{H})$ is the boundary then the quantum corrections are accumulated on this boundary, i.e., the intersection $\partial u_{a\mu}\cap\partial(\mathcal{G}/\mathcal{H})$, where $\partial u_{a\mu}$ is the flow in the $\mathcal{G}/\mathcal{H}$ coordinate system, defines the value of quantum corrections. If $\partial u_{a\mu}\cap\partial(\mathcal{G}/\mathcal{H})=0$ then the semiclassical approximation is exact. This is the crucial property of our topological QCD.

For this reason the tQCD seems attractive and the question of whether it takes the place of pQCD seems important. The experimentally examined consequences of the tQCD would be extremely interesting and they will be investigated in the first place.

Being convergent, the exactness of estimation of the measurables in tQCD should be higher then in the ''logarithmic'' pQCD. Moreover, the convergence means that the main contributions

are accumulated on the large distances. This property is typical for hadron physics. Therefore, the main point of our future publications would be the prediction of the small-scale effects, where we can compare our approach with pQCD.

ACKNOWLEDGMENTS

We would like to thank our colleagues in the Lab. of Theor. Phys. of JINR and especially V. Kadyshevski for fruitful interest to the described technique and underlying idea. We are thankful to V. Ter-Antonian for discussions. One of us (J.M.) would like to thank N. Russakovich and G. Chelkov for kind hospitality at the Lab. of Nucl. Probl. (JINR).

APPENDIX: REDUCTION OF THE SPACE DEGREES OF FREEDOM

Action of the operator $\exp\{-i\mathcal{K}\}$ leads to

$$\mathcal{N}(u)=\int DM_j(\xi,\eta):e^{-2i\mathcal{U}(u,j)}:, \tag{A1}$$

where

$$-3!(2i)^3\mathcal{U}(u,j)=\int \mathrm{d}^3x\,\mathrm{d}t\,\prod_{a,k}\left\{\left[\frac{\delta}{\delta\mathbf{j}_\xi}\cdot\frac{\partial\mathbf{u}_a}{\partial\eta}-\frac{\delta}{\delta\mathbf{j}_\eta}\cdot\frac{\partial\mathbf{u}_a}{\partial\xi}\right]\frac{\partial}{\partial\mathbf{u}_a}\right\}\mathcal{L}(u) \tag{A2}$$

and the colons in (A1) mean the ''normal product,'' when the variational derivatives over j_X in the expansion of $\exp\{-2i\mathcal{U}(u,j)\}$ stay to the left of all functions.

The measure

$$DM_j(\xi,\eta)=\prod_{y,t}\mathrm{d}\xi\mathrm{d}\eta\,\delta(\dot\xi-\omega_\eta-j_\xi)\,\delta(\dot\eta+\omega_\xi-j_\eta).$$

Then, to calculate the remaining integral in (A1), one should find solution of inhomogeneous equations:

$$\dot\xi(y,t)-\omega_\eta(y,t;\xi,\eta)=j_\xi(y,t),\quad \dot\eta(y,t)+\omega_\xi(y,t;\xi,\eta)=j_\eta(y,t), \tag{A3}$$

where

$$\omega_X(y,t;\xi,\eta)=\delta h(\xi,\eta)/\delta X(y,t).$$

As follows from (A2), if some operators $\hat j_{X'}$ over the ''auxiliary'' variable X' were not contain in $\mathcal{U}(u,j)$ then the auxiliary variables X' should obey the homogeneous, classical, equations, with $j_{X'}=0$ on the right-hand side.

The solutions of inhomogeneous equation (A3) will be searched expanding over j_X:

$$\begin{aligned}\xi(y,t)&=\xi^0(y,t)+\int \mathrm{d}^4x'\,\xi^1_\xi(y,t;y',t')j_\xi(y',t')+\int \mathrm{d}^4x'\,\xi^1_n(y,t;y',t')j_\eta(y',t')+\cdots,\\ \eta(y,t)&=\eta^0(y,t)+\int \mathrm{d}^4x'\,\eta^1_\eta(y,t;y',t')j_\eta(y',t')+\int \mathrm{d}^4x'\,\eta^1_\xi(y,t;y',t')j_\xi(y',t')+\cdots.\end{aligned} \tag{A4}$$

So, the equations:

$$\dot\xi^0(y,t)=\omega_\eta(y,t;\xi^0,\eta^0),\quad \dot\eta^0(y,t)=-\omega_\xi(y,t;\xi^0,\eta^0) \tag{A5}$$

should be solved in the lowest order over j_X. The function $u(y;\xi(y,t),\eta(y,t))$ should obey the ''boundary'' property:

$$u(y;\xi(y,t),\eta(y,t))|_{j=0}=u(y;\xi^0,\eta^0)=u(y,t;\xi_0,\eta_0), \tag{A6}$$

where ξ_0 and η_0 are the integration constants of the Lagrange equation (11). The equality (A6) defines the starting set of the necessary variables ξ and η. Notice that, as follows from Proposition III, the quantum perturbations should not change this set.

Let us distinguish the variables $\xi \in \mathcal{G}/\mathcal{H}$ by the equality:

$$\frac{\delta}{\delta\xi}h\bigg|_{j_x=0}=0. \tag{A7}$$

This assumes that the set η can be expressed through the set conserved generators. In example (1), they are the generators of translation and special conformal transformation. Notice that Proposition III means that the quantum perturbations did not alter this definition.

Inserting (A7) into (A5) we find at $j_X=0$ the equations:

$$\dot{\xi}^0(y,t)=\omega_\eta(\eta^0)\equiv\omega(\eta^0), \quad \dot{\eta}^0(y,t)=0. \tag{A8}$$

The functions with arbitrary y dependence may satisfy this equations. Using solution of this equation:

$$\xi^0(y,t)=\omega(\eta^0)t+\xi_0, \quad \eta^0(y,t)=\eta_0, \tag{A9}$$

where ξ_0 and η_0 are the integration constants, we will see that the dependence on y in (A6) did not play any role because of the degeneracy over y. For this reason we will put out the y dependence in ξ^0 and η^0.

It is not hard to show that the degeneracy over y will be conserved in arbitrary order over j_X. Indeed, inserting the expansions (A4) into Eq. (A3), we find in the first order over j_ξ:

$$\partial_t\xi^1_y(y,t;y',t')-\xi^1_\xi(y,t;y',t')\frac{\delta^2h(\xi,\eta)}{\delta\xi(y',t')\,\delta\xi(y,t)}\bigg|_{j=0}-\xi^1_\eta(y,t;y',t')\frac{\delta^2h(\xi,\eta)}{\delta\eta(y',t')\,\delta\xi(y,t)}\bigg|_{j=0}$$

$$=\delta(y-y')\,\delta(t-t').$$

Notice that

$$\frac{\delta h(\xi,\eta)}{\delta\xi(y,t)}\bigg|_{j=0}=\frac{\delta}{\delta\xi(y,t)}\{h(\xi,\eta)|_{j=0}\}=0,$$

where (A7) was used. Therefore, the equation for ξ^1_ξ has a structure:

$$\dot{\xi}^1_\xi(y,t;y',t')=\delta(y-y')\,\delta(t-t'), \tag{A10}$$

where the boundary conditions (A9) were applied. Notice that this equation is linear.

Inserting the solution of Eq. (A10):

$$\xi^1_\xi(y,t;y',t')=\delta(y-y')g(t-t'), \tag{A11}$$

where $g(t-t')$ is the Green function defined in Ref. 2, into (A4), we find the term

$$\sim\int \mathrm{d}t'\,g(t-t')j_\xi(y,t').$$

So, the y dependence is contained in the auxiliary source j_ξ only. For this reason it cannot play a dynamical role. The same phenomena one can observe considering other terms in the decomposition (A4).

Therefore, admitting that the quantum perturbations switched on adiabatically, i.e., may be taken into account perturbatively, and for this reason are unable to change the topology of the classical trajectory $u(y;\xi,\eta)$, Proposition III, one may conclude that it is enough to take $\xi=\xi(t)$ and $\eta=\eta(t)$ in the considered scalar theory.

[1] It is assumed that the interaction with matter fields may be included perturbatively. For this reason the quark degrees of freedom will not be taken into account in present paper.

[7] Following this selection rule, one should consider the factor space of highest dimension and we are not sure that the dimension offered in (1) factor space is the highest one. Nevertheless it is not entirely impossible that the $O(4)\times O(2)$ contribution is necessary and sufficient. In connection with discussed selection rule there is also the interesting question concerning the place of the KAM-theorem (Ref. 8) in quantum field theories.

[11] The number of Feynman diagrams of the pQCD in the given order of interaction constant g depends on the chosen gauge.
[12] B. DeWitt and C. Molina-Paris, hep-th/9808163.
[13] V. N. Gribov, Nucl. Phys. B **139**, 246 (1978).
[14] See I. M. Singer, Commun. Math. Phys. **60**, 7 (1978), M. F. Atiyah and J. D. S. Jones, *ibid.* **61**, 97 (1978).
[15] S. V. Shabanov, Phys. Rep. **326**, 1 (2000).
[16] This conclusion would be in accordance with the canonical formalism, where existence of the canonical commutator is the necessary and sufficient condition of quantization.
[17] To avoid the Gribov's copying of the gauge nonsinglet variables one may ''glue'' together theirs gauge copies (this is possible since they correspond to the same physical state), the details one may find in Ref. 15. But this eventually leads to deformation of the ''physical'' phase space of the gauge nonsinglet variables and the quantization of such spaces presents definite problem. Otherwise the dynamical variables would contain unphysical singularities (because of presence of bifurcation on the gauge copies).
[18] R. Jackiw, C. Nohl and C. Rebbi, *Particles and Fields*, Proceedings, Banff, Canada, 25 August–3 September 1977, edited by D. H. Boal and A. N. Kamal (Plenum, New York, 1978).
[19] Here the analogy of the interaction constant and the temperature is used. Then the g and $1/g$ decompositions mean, accordingly, the ''high-'' and ''low-temperature'' expansions.
[20] This property usually is postulated, see, e.g., R. Jackiw, Rev. Mod. Phys. **49**, 681 (1977), but it can be proved explicitly if the *topological* solitons are considered (Ref. 6).
[21] The intriguing question concerning ''asymptotic freedom'' in our perturbation theory will be considered in subsequent publications.
[22] The standard phenomenological reduction formalism may be used for this purpose (Ref. 6).
[23] E. Corrigan and D. Fairlie, Phys. Lett. B **67**, 69 (1977); F. Wilczek, in *Quark Confinement and Field Theory*, edited by D. Stump and D. Weingarten (Wiley, New York, 1977).
[24] R. Mills, *Propagators for Many-Particle Systems* (Gordon & Breach, New York, 1970).
[25] We would like to note here that the method of *canonical transformation*, used for definition of the classical phase flow (q,k), suppose (see Refs. 8 and 26) that the manifold $W\neq\varnothing$ is known. This means that the necessary complete set of first integrals in involution $J=J(q,k)$ is known. But wishing to perform the *arbitrary* transformation, when we did not know if the considered (infinite dimensional) system (12) is integrable or not, i.e., having no complete information about the necessary set of integrals, this approach seems noneffective.
[26] S. Smale, Invent. Math. **11**, 45 (1970); R. Abraham and J. E. Marsden, *Foundations of Mechanics* (Benjamin/Cummings, Reading, MA, 1978).
[27] In the case of Coulomb problem the degeneracy is connected with the conserved Runge–Lentz vector **n** and it may be destroyed by an external magnetic field. The last one induces precession of the vector **n**.
[28] Indeed, let us remind that in the result of the canonical momentum mapping $J:(q,k)\to(Q,K)$ we find $q(Q,K)$ and $k(Q,K)$. This function completed by Hamiltonian equations for Q and K solves the dynamical problem. Therefore, the time dependence is contained only in Q and K. But, as was mentioned in Ref. 25, the structure of W is *ad hoc* unknown for the field theory case. For this reason we later check this assumption.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 42, NUMBER 9 SEPTEMBER 2001

Coherent states for SU(3)

(Received 22 December 2000; accepted for publication 15 May 2001)

We define coherent states for SU(3) using six bosonic creation and annihilation operators. These coherent states are explicitly characterized by six complex numbers with constraints. For the completely symmetric representations $(n,0)$ and $(0,m)$, only three of the bosonic operators are required. For mixed representations (n,m), all six operators are required. The coherent states provide a resolution of identity, satisfy the continuity property, and possess a variety of group theoretic properties. We introduce an explicit parametrization of the group SU(3) and the corresponding integration measure. Finally, we discuss the path integral formalism for a problem in which the Hamiltonian is a function of SU(3) operators at each site. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1385563]

I. INTRODUCTION

Coherent states have been used for a long time in different areas of physics.[1,2] In the area of quantum optics, coherent states based on the Heisenberg–Weyl group (which are described later in this work) have been extensively used to study the interaction of a single mode of electromagnetic radiation with a two-level atomic system (for instance, the Jaynes–Cummings model).[3] Coherent states based on the noncompact Lie group SU(1,1) have also been used to study certain problems in quantum optics.[4] In condensed matter physics, coherent states for the Lie group SU(2) have been very useful for studying Heisenberg spin systems using the path integral formalism.[5–8] These studies have been generalized to systems with SU(N) symmetry, although such studies have usually been restricted to the completely symmetric representations.[6,9] However, there is a recent discussion of coherent states for arbitrary irreducible representations of SU(3) in Ref. 10. The purpose of our work is to discuss a coherent state formalism which is valid for all representations of SU(3), and to give an explicit characterization of them in terms of complex numbers and the states of some harmonic oscillators. (Our work differs in this respect from Ref. 10 which does not use harmonic oscillator operators to define the basis states.) As we will see, this way of characterization is very similar to those used for the Heisenberg–Weyl and SU(2) coherent states. But, there are certain additional features (such as tracelessness) which are redundant in the simpler case of SU(2).

One can imagine various possible applications of coherent states for SU(3). In quantum optics, coherent states for SU(3) may turn out to be useful for studying the interaction of a three-level atomic system with three modes of electromagnetic radiation (corresponding to the three possible energy differences of the atom). We should also mention that there have been many other studies of SU(3) in the recent mathematical physics literature, including the geometric phase for three-level systems[11] and the study of Clebsch–Gordon coefficients and the outer multiplicity problem.[12] These studies do not use coherent states; however, our work is likely to shed new light on some of these studies. For instance, we will use two triplets of complex numbers z and w which

[a)]Electronic mail: manu@boson.bose.res.in
[b)]Electronic mail: diptiman@cts.iisc.ernet.in

are similar to the ones used in Ref. 12, except that we will normalize the triplets to unity. Similarly, it is well known that the geometric phases in the different representations of SU(2) may be obtained by integrating around a closed loop the overlap of two coherent states which differ infinitesimally from each other.[7,8] In the same way, it should be possible to derive the geometric phases for SU(3) representations from the coherent states discussed below.

The organization of the article is as follows. Section II will motivate our ideas and techniques using two examples which are simpler than the SU(3) group. We start with the standard group theoretical definitions of the coherent states of the Heisenberg–Weyl and SU(2) groups. We then discuss another way of defining SU(2) coherent states using the Schwinger or Holstein–Primakoff representation of the Lie algebra of SU(2)[13] in terms of harmonic oscillator creation and annihilation operators. This definition is discussed in some detail as it can be extended to the SU(3) group. We then establish its equivalence with the standard group theoretical coherent state definition.[2] In Sec. III, we generalize the SU(2) Lie algebra in terms of harmonic oscillators to the SU(3) group, and construct the irreducible representations of SU(3). We describe the structure of SU(3) matrices in an explicit way, and provide an integration measure for this eight-dimensional manifold. In Sec. IV, we use this group structure to construct a set of SU(3) coherent states which are explicitly characterized by a set of complex numbers which are equivalent to eight real variables. We prove various identities expected for coherent states such as the resolution of identity and a transformation from a particular coherent state to the general coherent state. In Sec. V, we provide an alternative set of coherent states for SU(3) which require only five real variables; although these share some of the features of the coherent states defined in Sec. IV, they have a few limitations arising from the smaller number of variables used. In Sec. VI, we discuss how coherent states can be used to develop a path integral formalism for problems involving SU(3) variables.

II. HEISENBERG–WEYL AND SU(2) COHERENT STATES

There are many definitions of coherent states used in the literature. However, the most essential ingredients common in all these definitions are the continuity and completeness properties.[1]

(1) These are states in a Hilbert space $\mathcal{H}$ associated which are characterized by a set of continuous variables $\{\vec{z}\}$, and the coherent states $|\vec{z}\rangle$ are strongly continuous functions of the labels $\{\vec{z}\}$.
(2) There exists a positive measure $d\mu(\vec{z})$ such that the unit operator $\mathcal{I}$ admits the resolution of identity

$$\mathcal{I}=\int d\mu(\vec{z})|\vec{z}\rangle\langle\vec{z}|. \tag{1}$$

Given a group G, the coherent states in a given representation R are functions of q parameters denoted by $\{z_1,z_2,\ldots,z_q\}$, and are defined as

$$|\vec{z}\rangle\equiv T_R(g(\vec{z}))|0\rangle_R. \tag{2}$$

Here $T_R(g(\vec{z}))$ is a group element in the representation R, and $|0\rangle_R$ is a fixed vector belonging to R. In the simplest example of the Heisenberg–Weyl group, the Lie algebra contains three generators. It is defined in terms of creation annihilation operators $(a,a^\dagger)$ satisfying

$$[a,a^\dagger]=\mathcal{I},\quad [a,\mathcal{I}]=0,\quad [a^\dagger,\mathcal{I}]=0. \tag{3}$$

This algebra has only one infinite dimensional irreducible representation which can be characterized by occupation number states $|n\rangle\equiv(a^\dagger)^n/\sqrt{n!}\,|0\rangle$ with $n=0,1,2,\ldots$. A generic group element in (2) can be characterized by $T(g)=\exp(i\alpha\mathcal{I}+za^\dagger-\overline{z}a)$ with an angle α and a complex parameter z. Therefore,

$$|\alpha,z\rangle_\infty = \exp(i\alpha)|z\rangle, \quad |z\rangle = \exp(za^\dagger - \bar{z}a)|0\rangle = \sum_{n=0}^{\infty} F_n(z)|n\rangle, \tag{4}$$

where the sum runs over all the basis vectors of the infinite dimensional representation, and

$$F_n(z) = \frac{z^n}{\sqrt{n!}}\exp(-|z|^2/2) \tag{5}$$

are the coherent state expansion coefficients. This feature, i.e., an expansion of the coherent states in terms of basis vectors of a given representation with analytic functions of complex variables ($F_n(z)$) as coefficients, will also be present in the case of SU(2) and SU(3) groups. It is easy to see that Eq. (4) provides a resolution of identity as in (1) with the measure $d\mu(z) = dz d\bar{z}$.

We now briefly review the next simplest example, i.e., the coherent states associated with the SU(2) group. The SU(2) Lie algebra is given by a set of three angular momentum operators $\{\vec{J}\} \equiv \{J_1, J_2, J_3\}$ or equivalently by $\{J_+, J_-, J_3\}$, ($J_\pm \equiv J_1 \pm iJ_2$) satisfying

$$[J_3, J_\pm] = \pm J_\pm, \quad [J_+, J_-] = 2J_3. \tag{6}$$

The SU(2) group has a Casimir operator given by $\vec{J}\cdot\vec{J}$, and the different irreducible representations are characterized by its eigenvalues $j(j+1)$, where j is an integer or half-odd-integer. A given basis vector in representation j is labeled by the eigenvalue m of J_3 as $|j,m\rangle$. We characterize the SU(2) group elements U by the Euler angles, i.e., $U(\theta,\phi,\psi) \equiv \exp(i\phi J_3)\exp(i\theta J_2)\exp(i\psi J_3)$. The standard group theoretical definition (2) takes $|0\rangle_j$ in (2) to be the highest weight state $|j,j\rangle$ and is of the form

$$\begin{aligned} |\hat{n}(\theta,\phi)\rangle_j &= U(\theta,\phi,\psi)|j,j\rangle, \\ &= \sum_{m=-j}^{+j} C_m(\theta,\phi)|j,m\rangle, \end{aligned} \tag{7}$$

In (7), the coefficients $C_m(\theta,\phi)$ are given by

$$C_m(\theta,\phi) = e^{im\phi}\sqrt{\frac{(2j)!}{(j+m)!(j-m)!}}\left[\sin\frac{\theta}{2}\right]^{j-m}\left[\cos\frac{\theta}{2}\right]^{j+m}, \tag{8}$$

where we have ignored possible phase factors.

The algebra in Eq. (6) can be realized in terms of a doublet of harmonic oscillator creation and annihilation operators $\vec{a} \equiv (a_1, a_2)$ and $\vec{a}^\dagger \equiv (a_1^\dagger, a_2^\dagger)$, respectively.[13] They satisfy the simpler bosonic commutation relation $[a_i, a_j^\dagger] = \delta_{ij}$ with $i,j = 1,2$. The vacuum state is $|0,0\rangle$. In terms of these operators,

$$J^a \equiv \tfrac{1}{2}a_i^\dagger(\sigma^a)_{ij}a_j, \tag{9}$$

where σ^a denote the Pauli matrices. (We will generally use the convention that repeated indices are summed over). It is easy to check that the operators in (9) satisfy the SU(2) Lie algebra with the Casimir $\vec{J}\cdot\vec{J} \equiv \frac{1}{4}\vec{a}^\dagger\cdot\vec{a}(\vec{a}^\dagger\cdot\vec{a}+2)$. Thus the representations of SU(2) can be characterized by the eigenvalues of the occupation number operator; the spin value j is equal to $(N_1+N_2)/2$ where N_1 and N_2 are the eigenvalues of $a_1^\dagger a_1$ and $a_2^\dagger a_2$, respectively.

With these harmonic oscillator creation and annihilation operators, another definition of SU(2) coherent states is obtained by directly generalizing (4). We define a doublet of complex numbers (z_1, z_2) with the constraint $|z_1|^2 + |z_2|^2 = 1$; this gives three independent real parameters which define the sphere S^3. Let us parameterize

$$z_1 = \cos\chi e^{i\beta_1} \quad \text{and} \quad z_2 = \sin\chi e^{i\beta_2}, \tag{10}$$

where $0 \leqslant \chi \leqslant \pi/2$ and $0 \leqslant \beta_1, \beta_2 < 2\pi$. The integration measure on this space takes the form

$$d\Omega_{S^3} = \frac{1}{\pi^2} dz_1 d\bar{z_1} dz_2 d\bar{z_2} \delta(|z_1|^2 + |z_2|^2 - 1) = \frac{1}{2\pi^2} \cos\chi \sin\chi d\chi d\beta_1 d\beta_2, \tag{11}$$

where we have introduced a normalization factor so that $\int d\Omega_{S^3} = 1$. The SU(2) coherent state in the representation N is now defined as

$$|z_1, z_2\rangle_{N=2j} = \delta_{\vec{a}^\dagger \cdot \vec{a}, N} \sqrt{N!} \exp(\vec{z} \cdot \vec{a}^\dagger)|0,0\rangle = \sum_{N_1, N_2}{}' F_{N_1, N_2} |N_1, N_2\rangle_j . \tag{12}$$

In the second equation in (12), the Σ' implies that only the terms satisfying the constraint $a^\dagger \cdot a = N \equiv 2j$ are included or equivalently that

$$N_1 + N_2 = N. \tag{13}$$

With (13), the states $|N_1, N_2\rangle_j$ form a $(2j+1)$-dimensional representation of SU(2). The expansion coefficients $F_{N_1, N_2}(z_1, z_2)$ are analytic functions of (z_1, z_2) and are given by

$$F_{N_1, N_2} \equiv \left(\frac{N!}{N_1! N_2!} \right)^{1/2} z_1^{N_1} z_2^{N_2}. \tag{14}$$

Equations (12) and (14) are similar to (4) and (5), respectively. This will be generalized to the SU(3) case in Sec. III. It is easy to check that (12) provides the resolution of identity with the measure given in (11), namely,

$$\int d\Omega_{\mathrm{SU}(2)} |z_1, z_2\rangle_{jj} \langle z_1, z_2| = \frac{1}{2j+1} \sum_{m=-j}^{j} |j,m\rangle\langle j,m|. \tag{15}$$

Now we change variables from N_1 and $N_2 = 2j - N_1$ to $m = \frac{1}{2}(N_1 - N_2)$, and define

$$\omega \equiv \frac{z_1}{z_2} = e^{i\phi} \cot\frac{\theta}{2}. \tag{16}$$

These parameters are related to the ones given in (10) as $\theta = 2\chi$ and $\phi = \beta_1 - \beta_2$. We now consider an unit sphere S^2 with its south pole touching the point $\omega = 0$. The sphere is characterized by (θ, ϕ) where θ and ϕ are the polar and azimuthal angles, respectively. Using the stereographic projection, it is easy to verify that

$$|z_1, z_2\rangle_j = (z_1)^{2j} \sum_{m=-j}^{j} \sqrt{\frac{(2j)!}{(j+m)!(j-m)!}} (\omega)^{(m-j)} |j,m\rangle = |\hat{n}(\theta, \phi)\rangle_j , \tag{17}$$

where we have again ignored possible phase factors. Equation (17) can also be written as

$$|z_1, z_2\rangle_j = (z_1)^{2j} \exp\left(\frac{z_2}{z_1} J_- \right) |z_1 = 1,\, z_2 = 0\rangle_j , \tag{18}$$

where $|z_1 = 1,\, z_2 = 0\rangle_{N=2j} = |j,j\rangle$ and we have used the fact that $J_- = a_2^\dagger a_1$. Equations (17) and (18) establish the equivalence between the group theoretical theoretical definition (7) and the one using Schwinger bosons (12).

The stationary subgroup of a particular coherent state is defined as the subgroup H of the full group G which leaves that coherent state invariant up to a phase; the coherent states are functions

of the coset space G/H.[2] It is clear from the previous discussion that the stationary subgroup of the SU(2) coherent states is U(1); therefore the coherent states correspond to the coset space $\mathrm{SU}(2)/\mathrm{U}(1)=S^2$ which is parametrized by the angles (θ,ϕ).

III. SU(3) AND ITS REPRESENTATIONS

Let us first discuss a parametrization of SU(3) matrices, i.e., 3×3 unitary matrices with unit determinant. To motivate this, let us first consider a parametrization of SO(3) matrices. Consider a real vector of unit length of the form

$$\vec{p}=\begin{pmatrix}\sin\theta\cos\phi\\ \sin\theta\sin\phi\\ \cos\theta\end{pmatrix}. \tag{19}$$

The most general real vector q of unit length which is orthogonal to p is given by

$$\vec{q}=\begin{pmatrix}\cos\chi\cos\theta\cos\phi+\sin\chi\sin\phi\\ \cos\chi\cos\theta\sin\phi-\sin\chi\cos\phi\\ -\cos\chi\sin\theta\end{pmatrix}. \tag{20}$$

Finally, we define a third unit vector $\vec{r}=\vec{p}\times\vec{q}$, i.e., $r_1=p_2q_3-p_3q_2$, etc. Then a 3×3 matrix whose columns are given by the vectors p,q and r is an SO(3) matrix.

We will now generalize the previous construction to obtain an SU(3) matrix. A complex vector of unit norm is given by

$$\vec{z}=\begin{pmatrix}\sin\theta\cos\phi e^{i\alpha_1}\\ \sin\theta\sin\phi e^{i\alpha_2}\\ \cos\theta e^{i\alpha_3}\end{pmatrix}, \tag{21}$$

where $0\leqslant\theta,\phi\leqslant\pi/2$ and $0\leqslant\alpha_1,\alpha_2,\alpha_3<2\pi$. Then the integration measure for $\vec{z}$, which is equivalent to the sphere S^5, is given by

$$\begin{aligned}d\Omega_{S^5}&=\frac{2}{\pi^3}dz_1d\bar{z}_1dz_2d\bar{z}_2dz_3d\bar{z}_3\delta(|z_1|^2+|z_2|^2+|z_3|^2-1)\\ &=\frac{1}{\pi^3}\sin^3\theta\cos\theta\cos\phi\sin\phi d\theta d\phi d\alpha_1 d\alpha_2 d\alpha_3,\end{aligned} \tag{22}$$

which has been normalized to make $\int d\Omega_{S^5}=1$. The most general complex vector $\vec{w}$ of unit norm satisfying $\vec{z}\cdot\vec{w}=0$ is given by

$$\vec{w}=\begin{pmatrix}e^{i(\beta_1-\alpha_1)}\cos\chi\cos\theta\cos\phi+e^{i(\beta_2-\alpha_1)}\sin\chi\sin\phi\\ e^{i(\beta_1-\alpha_2)}\cos\chi\cos\theta\sin\phi-e^{i(\beta_2-\alpha_2)}\sin\chi\cos\phi\\ -e^{i(\beta_1-\alpha_3)}\cos\chi\sin\theta\end{pmatrix}, \tag{23}$$

where $0\leqslant\chi\leqslant\pi/2$ and $0\leqslant\beta_1,\beta_2<2\pi$ just as in the integration measure for S^3 in (11). We may now define a third complex vector of unit norm as $\vec{v}=\bar{\vec{z}}\times\vec{w}$, where $\bar{\vec{z}}\equiv\vec{z}^{\star}$. Then we can check that a 3×3 matrix whose columns are given by z, $\bar{w}$ and v, i.e.,

$$S=\begin{pmatrix} z_1 & \bar{w}_1 & \bar{z}_2 w_3-\bar{z}_3 w_2 \\ z_2 & \bar{w}_2 & \bar{z}_3 w_1-\bar{z}_1 w_3 \\ z_3 & \bar{w}_3 & \bar{z}_1 w_2-\bar{z}_2 w_1 \end{pmatrix} \tag{24}$$

is an SU(3) matrix.

The integration measure for the group SU(3) is given by a product of (22) and (11) as[14,15]

$$d\Omega_{\mathrm{SU}(3)}=\frac{1}{2\pi^5}\sin^3\theta\cos\theta\cos\phi\sin\phi\cos\chi\sin\chi d\theta d\phi d\chi d\alpha_1 d\alpha_2 d\alpha_3 d\beta_1 d\beta_2, \tag{25}$$

which is normalized so that $\int d\Omega_{\mathrm{SU}(3)}=1$. To prove Eq. (25), we note that the matrix in (24) can be written as a product of two SU(3) matrices, i.e., $S=A_3A_2$, where

$$A_3=\begin{pmatrix} \sin\theta\cos\phi e^{i\alpha_1} & \cos\theta\cos\phi e^{i\alpha_1} & -\sin\phi e^{-i\alpha_2-i\alpha_3} \\ \sin\theta\sin\phi e^{i\alpha_2} & \cos\theta\sin\phi e^{i\alpha_2} & \cos\phi e^{-i\alpha_1-i\alpha_2} \\ \cos\theta e^{i\alpha_3} & -\sin\theta e^{i\alpha_3} & 0 \end{pmatrix}, \tag{26}$$

and

$$A_2=\begin{pmatrix} 1 & 0 & 0 \\ 0 & \cos\chi e^{-i\beta_1} & \sin\chi e^{i\beta_2-i\alpha_1-i\alpha_2-i\alpha_3} \\ 0 & -\sin\chi e^{-i\beta_2+i\alpha_1+i\alpha_2+1\alpha_3} & \cos\chi e^{i\beta_1} \end{pmatrix}. \tag{27}$$

The structure of the matrix A_3 is determined entirely by the three-dimensional complex vector which forms its first column; hence the integration measure corresponding to it is given by (22). The matrix A_2 is determined by the two-dimensional complex vector which forms its second column; its contribution to the integration measure is therefore given by (11). Note that although the parameter appearing in A_2 is $\beta_2-\alpha_1-\alpha_2-\alpha_2$ instead of only β_2 as in (10), this makes no difference in the product measure given in (25) since the differentials $d\alpha_i$ already appear in the integration measure coming from A_3. Incidentally, this procedure generalizes to any SU(N); the integration measure is given by a product of measures for S^{2N-1}, S^{2N-3}, $\ldots$, S^3.[14]

In short, we have defined two complex vectors $\vec{z}=(z_1,z_2,z_3)$ and $\vec{w}=(w_1,w_2,w_3)$ in (21) and (23). These satisfy the constraints

$$\begin{aligned} \vec{\bar{z}}\cdot\vec{z}&=|z_1|^2+|z_2|^2+|z_3|^2=1, \\ \vec{\bar{w}}\cdot\vec{w}&=|w_1|^2+|w_2|^2+|w_3|^2=1, \end{aligned} \tag{28}$$

and

$$\vec{z}\cdot\vec{w}=z_1w_1+z_2w_2+z_3w_3=0. \tag{29}$$

These constraints leave eight real degrees of freedom as required for SU(3). We will take $\vec{z}$ and $\vec{w}$ to transform respectively as the 3 and $3^\star$ representation of SU(3). Thus an SU(3) transformation acts on the matrix S in Eq. (24) by multiplication from the left.

Let us now define two triplets of harmonic oscillator creation and annihilation operators (a_i,b_i), $i=1,2,3$, satisfying

$$\begin{aligned} [a_i,a_j^\dagger]&=\delta_{ij}, \quad [b_i,b_j^\dagger]=\delta_{ij}, \\ [a_i,b_j]&=0, \quad [a_i,b_j^\dagger]=0. \end{aligned} \tag{30}$$

We will often denote these two triplets by $(\vec{a},\vec{b})$ and the two number operators by $N_a(\equiv\vec{a}^\dagger\cdot\vec{a})$ and $N_b(\equiv\vec{b}^\dagger\cdot\vec{b})$. Similarly, their vacuum state is denoted by $|\vec{0}_a,\vec{0}_b\rangle$. Henceforth, we will ignore the subscripts a,b and will denote the vacuum state by $|\vec{0},\vec{0}\rangle$, and the eigenvalues of N_a, N_b by N and M, respectively.

Now let λ^a, $a=1,2,\ldots,8$ be the generators of SU(3) in the fundamental representation; they satisfy the SU(3) Lie algebra $[\lambda^a,\lambda^b]=if^{abc}\lambda^c$. Let us define the following operators

$$Q^a=a^\dagger\lambda^a a-b^\dagger\lambda^{*a}b, \tag{31}$$

where $a^\dagger\lambda^a a\equiv a_i^\dagger\lambda_{ij}^a a_j$, and $b^\dagger\lambda^{*a}b\equiv b_i^\dagger\lambda_{ij}^{*a}b_j$. To be explicit,

$$\begin{aligned}
Q^3&=\tfrac{1}{2}(a_1^\dagger a_1-a_2^\dagger a_2-b_1^\dagger b_1+b_2^\dagger b_2),\\
Q^8&=\frac{1}{2\sqrt{3}}(a_1^\dagger a_1+a_2^\dagger a_2-2a_3^\dagger a_3-b_1^\dagger b_1-b_2^\dagger b_2+2b_3^\dagger b_3),\\
Q^1&=\tfrac{1}{2}(a_1^\dagger a_2+a_2^\dagger a_1-b_1^\dagger b_2-b_2^\dagger b_1),\\
Q^2&=-\frac{i}{2}(a_1^\dagger a_2-a_2^\dagger a_1+b_1^\dagger b_2-b_2^\dagger b_1),\\
Q^4&=\tfrac{1}{2}(a_1^\dagger a_3+a_3^\dagger a_1-b_1^\dagger b_3-b_3^\dagger b_1),\\
Q^5&=-\frac{i}{2}(a_1^\dagger a_3-a_3^\dagger a_1+b_1^\dagger b_3-b_3^\dagger b_1),\\
Q^6&=\tfrac{1}{2}(a_2^\dagger a_3+a_3^\dagger a_2-b_2^\dagger b_3-b_3^\dagger b_2),\\
Q^7&=-\frac{i}{2}(a_2^\dagger a_3-a_3^\dagger a_2+b_2^\dagger b_3-b_3^\dagger b_2).
\end{aligned} \tag{32}$$

It can be checked that these operators satisfy the SU(3) algebra among themselves, i.e., $[Q^a,Q^b]=if^{abc}Q^c$. Further,

$$\begin{aligned}
&[Q^a,a_i^\dagger]=\lambda_{ji}^a a_j^\dagger,\quad [Q^a,b_i^\dagger]=-\lambda_{ji}^{*a}b_j^\dagger,\\
&[Q^a,a^\dagger\cdot a]=0,\quad [Q^a,b^\dagger\cdot b]=0,\\
&[Q^a,a^\dagger\cdot b^\dagger]=0,\quad [Q^a,a\cdot b]=0.
\end{aligned} \tag{33}$$

From Eqs. (33), it is clear that the three states $a_i^\dagger|\vec{0},\vec{0}\rangle$ with $(N=1,\ M=0)$ and $b_i^\dagger|\vec{0},\vec{0}\rangle$ with $(N=0,\ M=1)$ transform respectively as the fundamental representation (3) and its conjugate representation $(3^\star)$. By taking the direct product of N $\vec{a}^\dagger$'s and M $\vec{b}^\dagger$'s we can now form higher representations. We now define an operator

$$O^{i_1 i_2\cdots i_N}_{j_1 j_2\cdots j_M}\equiv a_{i_1}^\dagger a_{i_2}^\dagger\ldots a_{i_N}^\dagger b_{j_1}^\dagger b_{j_2}^\dagger\ldots b_{j_M}^\dagger. \tag{34}$$

Under SU(3) transformation the states defined as $|\tilde{\psi}\rangle_{(N,M)}\equiv O^{i_1 i_2\cdots i_N}_{j_1 j_2\cdots j_M}|\vec{0},\vec{0}\rangle$ will all have $N_a=N$ and $N_b=M$, and will transform among themselves. Further, $|\tilde{\psi}\rangle=N|\tilde{\psi}\rangle$ and $N_b|\tilde{\psi}\rangle=M|\tilde{\psi}\rangle$. However, these do not form an irreducible representation because $\vec{a}\cdot\vec{b}$ and $\vec{a}^\dagger\cdot\vec{b}^\dagger$ are

SU(3) invariant operators [see (33)]. A general basis vector in the irreducible representation (N,M) is obtained by subtracting the traces and completely symmetrizing in upper and lower indices.[16] More explicitly, a state in (N,M) representation is given by

$$
\begin{aligned}
|\psi\rangle^{i_1,i_2,\ldots i_N}_{j_1,j_2,\ldots,j_M} \equiv \Bigg[& O^{i_1 i_2 \cdots i_N}_{j_1 j_2 \cdots j_M} + L_1 \sum_{l_1=1}^{N} \sum_{k_1=1}^{M} \delta^{i_{l_1}}_{j_{k_1}} O^{i_1 i_2 .. i_{l_1-1} i_{l_1+1} .. i_N}_{j_1 j_2 .. j_{k_1-1} j_{k_1+1} \cdots j_M} \\
& + L_2 \sum_{l_1,l_2=1}^{N} \sum_{k_1,k_2=1}^{M} \delta^{i_{l_1}}_{j_{k_1}} \delta^{i_{l_2}}_{j_{k_2}} O^{i_1 i_2 .. i_{l_1-1} i_{l_1+1} .. i_{l_2-1} i_{l_2+1} .. i_N}_{j_1 j_2 .. j_{k_1-1} j_{k_1+1} .. j_{k_2-1} j_{k_2+1} \cdots j_M} \\
& + L_3 \sum_{l_1,l_2,l_3=1}^{N} \sum_{k_1,k_2,k_3=1}^{M} \delta^{i_{l_1}}_{j_{k_1}} \delta^{i_{l_2}}_{j_{k_2}} \delta^{i_{l_3}}_{j_{k_3}} O^{i_1 i_2 .. i_{l_1-1} i_{l_1+1} .. i_{l_2-1} i_{l_2+1} .. i_{l_3-1} i_{l_3+1} .. i_N}_{j_1 j_2 .. j_{k_1-1} j_{k_1+1} .. j_{k_2-1} j_{k_2+1} .. j_{k_3-1} j_{k_3+1} \cdots j_M} \\
& + \ldots + L_Q \sum_{l_1,l_2,l_3,..,l_Q=1}^{N} \sum_{k_1,k_2,k_3,..,k_Q=1}^{M} \delta^{i_{l_1}}_{j_{k_1}} \delta^{i_{l_2}}_{j_{k_2}} .. \delta^{i_{l_Q}}_{j_{k_Q}} \\
& \times O^{i_1 i_2 .. i_{l_1-1} i_{l_1+1} .. i_{l_2-1} i_{l_2+1} .. i_{l_Q-1} i_{l_Q+1} .. i_N}_{j_1 j_2 .. j_{k_1-1} j_{k_1+1} .. j_{k_2-1} j_{k_2+1} .. j_{k_Q-1} j_{k_Q+1} \cdots j_M} \Bigg] |\vec{0},\vec{0}\rangle, \qquad (35)
\end{aligned}
$$

where $Q = \mathrm{Min}(N,M)$,

$$
L_q \equiv \frac{(-1)^q (a^\dagger \cdot b^\dagger)^q}{q!(N+M+1)(N+M)(N+M-1)\cdots(N+M+2-q)}, \qquad (36)
$$

and all the sums in (35) are over different indices, i.e., $l_1 \neq l_2 \cdots \neq l_q$ and $k_1 \neq k_2 \neq \cdots \neq k_q$. The coefficients in Eq. (36) are chosen to satisfy the tracelessness condition

$$
\sum_{i_l,j_k=1}^{3} \delta^{i_l}_{j_k} |\psi\rangle^{i_1,i_2,\ldots i_N}_{j_1,j_2,\ldots,j_M} = 0, \quad \text{for all } l = 1,2,\ldots N, \quad \text{and } k = 1,2,\ldots M. \qquad (37)
$$

For future purposes, a more compact notation for describing all the states given above is to write

$$
O^{i_1 i_2 \cdots i_N}_{j_1 j_2 \cdots j_M} \equiv (a_1^\dagger)^{N_1} (a_2^\dagger)^{N_2} (a_3^\dagger)^{N_3} (b_1^\dagger)^{M_1} (b_2^\dagger)^{M_2} (b_3^\dagger)^{M_3}, \qquad (38)
$$

where (N_i, M_i) denote all the possible eigenvalues of the occupation number operators $(a_i^\dagger a_i, b_i^\dagger b_i)$ satisfying

$$
N_1 + N_2 + N_3 = N \quad \text{and} \quad M_1 + M_2 + M_3 = M. \qquad (39)
$$

The action of (38) on the vacuum is given by

$$
O^{N_1 N_2 N_3}_{M_1 M_2 M_3} |\vec{0},\vec{0}\rangle = (N_1! N_2! N_3! M_1! M_2! M_3!)^{1/2} |^{N_1 N_2 N_3}_{M_1 M_2 M_3}\rangle. \qquad (40)
$$

We can now write the basis vectors of the representation (N,M) as

$$
\begin{aligned}
|\psi\rangle^{i_1,i_2,\ldots i_N}_{j_1,j_2,\ldots,j_M} \equiv |\psi\rangle^{N_1 N_2 N_3}_{M_1 M_2 M_3} = & \left[O^{N_1 N_2 N_3}_{M_1 M_2 M_3} + \sum_{q=1}^{Q} L_q \sum_{[\vec{\alpha}]_q} \right] {}^{N_1}C_{\alpha_1}\, {}^{N_2}C_{\alpha_2}\, {}^{N_3}C_{\alpha_3}\, {}^{M_1}C_{\alpha_1}\, {}^{M_2}C_{\alpha_2} \\
& \times {}^{M_3}C_{\alpha_3}\, \alpha_1!\, \alpha_2!\, \alpha_3!\, O^{N_1-\alpha_1 N_2-\alpha_2 N_3-\alpha_3}_{M_1-\alpha_1 M_2-\alpha_2 M_3-\alpha_3} |\vec{0},\vec{0}\rangle. \qquad (41)
\end{aligned}
$$

In this equation, $[\vec{\alpha}]_q$ denotes the sets of three non-negative integers $(\alpha_1,\alpha_2,\alpha_3)$ satisfying $\alpha_1+\alpha_2+\alpha_3=q$, and $N_i-\alpha_i\geqslant 0$, $M_i-\alpha_i\geqslant 0$ for $i=1,2,3$. The $\Sigma_{[\vec{\alpha}]_q}$ denotes a summation over all sets of three such integers. In the notation of Eq. (41), the tracelessness condition (37) for the $(N+1, M+1)$ representation takes the form

$$\sum_{[\vec{\gamma}]_1} |\psi\rangle^{N_1+\gamma_1 N_2+\gamma_2 N_3+\gamma_3}_{M_1+\gamma_1 M_2+\gamma_2 M_3+\gamma_3}=0. \tag{42}$$

The definition in (41) satisfies the condition given in (42). This can be verified by using the identity

$$\begin{aligned}
&\sum_{[\vec{\gamma}]_1}\sum_{[\vec{\alpha}]_q} \alpha_1!\alpha_2!\alpha_3!{}^{N_1+\gamma_1}C_{\alpha_1}{}^{N_2+\gamma_2}C_{\alpha_2}{}^{N_3+\gamma_3}C_{\alpha_3}{}^{M_1+\gamma_1}C_{\alpha_1}{}^{M_2+\gamma_2}C_{\alpha_2}{}^{M_3+\gamma_3}C_{\alpha_3}\\
&\quad\times O^{N_1+\gamma_1-\alpha_1 N_2+\gamma_2-\alpha_2 N_3+\gamma_3-\alpha_3}_{M_1+\gamma_1-\alpha_1 M_2+\gamma_2-\alpha_2 M_3+\gamma_3-\alpha_3}\\
&\quad=\left[(N+M+2-q)\sum_{[\vec{\alpha}]_{q-1}}+(\vec{a}^\dagger\cdot\vec{b}^\dagger)\sum_{[\vec{\alpha}]_q}\right]\\
&\quad\times\alpha_1!\alpha_2!\alpha_3!{}^{N_1}C_{\alpha_1}{}^{N_2}C_{\alpha_2}{}^{N_3}C_{\alpha_3}{}^{M_1}C_{\alpha_1}{}^{M_2}C_{\alpha_2}{}^{M_3}C_{\alpha_3}O^{N_1-\alpha_1 N_2-\alpha_2 N_3-\alpha_3}_{M_1-\alpha_1 M_2-\alpha_2 M_3-\alpha_3}.
\end{aligned}\tag{43}$$

The dimension $D(N,M)$ of the representation (N,M) can be obtained as follows. For the $(N,0)$ representation, no tracelessness condition needs to be imposed, and the dimension is simply given by the number of states in Eq. (40) which satisfy $\Sigma_i N_i=N$ and $\Sigma_i M_i=0$. This gives $D(N,0)=(N+1)(N+2)/2$. Similarly, $D(0,M)=(M+1)(M+2)/2$. Now $D(N,M)$ is given by the number of states satisfying $\Sigma_i N_i=N$, $\Sigma_i M_i=M$, which is equal to the product $D(N,0)D(0,M)$, *minus* the number of states satisfying $\Sigma_i N_i=N-1$, $\Sigma_i M_i=M-1$, which is equal to $D(N-1,0)D(0,M-1)$; the subtraction is because of the tracelessness condition. This gives

$$D(N,M)=\tfrac{1}{2}(N+1)(M+1)(N+M+2). \tag{44}$$

IV. SU(3) COHERENT STATES

We now observe that the states in Eq. (35) can be extracted from the following generating function,

$$|\vec{z},\vec{w}\rangle_{(N,M)}\equiv\sqrt{N!M!}\,\exp(\vec{z}\cdot\vec{a}^\dagger+\vec{w}\cdot\vec{b}^\dagger)|\vec{0},\vec{0}\rangle, \tag{45}$$

where we have to project onto the subspace of states with $\vec{a}^\dagger\cdot\vec{a}=N$ and $\vec{b}^\dagger\cdot\vec{b}=M$ to obtain the representation (N,M). More explicitly,

$$|\vec{z},\vec{w}\rangle_{(N,M)}=\frac{(\vec{z}\cdot\vec{a}^\dagger)^N}{\sqrt{N!}}\frac{(\vec{w}\cdot\vec{b}^\dagger)^M}{\sqrt{M!}}|\vec{0},\vec{0}\rangle=\sum_{N_1,N_2,N_3}{}'\ \sum_{M_1,M_2,M_3}{}'\ F_{\vec{N},\vec{M}}(z_1,z_2,z_3;w_1,w_2,w_3)|^{N_1N_2N_3}_{M_1M_2M_3}\rangle. \tag{46}$$

In (46), Σ' implies that the occupation numbers (N_i,M_i) satisfy Eq. (39), and $F_{\vec{N},\vec{M}}(\vec{z},\vec{w})$ are given by

$$F_{\vec{N},\vec{M}}(\vec{z},\vec{w})=\left(\frac{N!M!}{N_1!N_2!N_3!M_1!M_2!M_3!}\right)^{1/2} z_1^{N_1}z_2^{N_2}z_3^{N_3}w_1^{M_1}w_2^{M_2}w_3^{M_3}. \tag{47}$$

On expanding the right hand side of (46), the coefficients of $z_1^{N_1}z_2^{N_2}z_3^{N_3}w_1^{M_1}w_2^{M_2}w_3^{M_3}$ give the basis vectors of SU(3) in the representation (N,M). It is important to note that the tracelessness conditions in Eq. (35) are *automatically* satisfied by the state in (46). This is because we can always replace $|^{N_1N_2N_3}_{M_1M_2M_3}\rangle$ by the SU(3) basis vectors $|\psi\rangle^{N_1N_2N_3}_{M_1M_2M_3}$ defined in (41).

It is instructive to consider a specific example here. The coherent state of the representation (1,1), i.e., the adjoint representation of SU(3), is given by

$$|\vec{z},\vec{w}\rangle_{(1,1)}=\sum_{i,j=1}^{3} z_i w_j a_i^\dagger b_j^\dagger|\vec{0},\vec{0}\rangle. \tag{48}$$

We then see that the sum of the coefficients of the three states $|^{100}_{100}\rangle$, $|^{010}_{010}\rangle$ and $|^{001}_{001}\rangle$ is zero due to the constraint in Eq. (29). Hence there are only eight linearly independent states on the right hand side of Eq. (48) as there should be; these eight states can be taken to be

$$\begin{gathered}|V_1\rangle=\frac{1}{\sqrt{2}}(|^{100}_{100}\rangle-|^{010}_{010}\rangle),\quad |V_2\rangle=\frac{1}{\sqrt{6}}(|^{100}_{100}\rangle+|^{010}_{010}\rangle-2|^{001}_{001}\rangle),\\ |V_3\rangle=|^{100}_{010}\rangle,\ |V_4\rangle=|^{010}_{100}\rangle,\\ |V_5\rangle=|^{100}_{001}\rangle,\ |V_6\rangle=|^{001}_{100}\rangle,\\ |V_7\rangle=|^{010}_{001}\rangle,\ |V_8\rangle=|^{001}_{010}\rangle.\end{gathered} \tag{49}$$

The states defined in Eq. (46) will be called the coherent state of the representation (N,M). Note that Eqs. (39), (46), and (47) are analogous to the corresponding SU(2) equations (13), (12), and (14) respectively. The SU(3) coherent states (46) are normalized to unity, i.e.,

$${}_{(N,M)}\langle\vec{z},\vec{w}|\vec{z},\vec{w}\rangle_{(N,M)}=1. \tag{50}$$

To prove this, we use the operator identities

$$e^Ae^B=e^Be^Ae^{[A,B]}\quad \text{and}\quad e^ABe^{-A}=B+[A,B], \tag{51}$$

which hold if $[A,B]$ commutes with both A and B. We find that

$$\langle\vec{0},\vec{0}|\exp[\bar{\vec{z}}\cdot\vec{a}+\bar{\vec{w}}\cdot\vec{b}]\exp[\vec{z}\cdot\vec{a}^\dagger+\vec{w}\cdot\vec{b}^\dagger]|\vec{0},\vec{0}\rangle=\exp[\bar{\vec{z}}\cdot\vec{z}+\bar{\vec{w}}\cdot\vec{w}]. \tag{52}$$

On comparing terms of order $(\bar{\vec{z}}\cdot\vec{z})^N(\bar{\vec{w}}\cdot\vec{w})^M$ on both sides of this equation and using the definition in (46), we obtain Eq. (50). In the same way, we can show that

$${}_{(N,M)}\langle\vec{z},\vec{w}|\vec{z}+d\vec{z},\vec{w}+d\vec{w}\rangle_{(N,M)}=1+N\sum_i \bar{z}_i dz_i+M\sum_i \bar{w}_i dw_i, \tag{53}$$

where $d\vec{z}$ and $d\vec{w}$ denote small deviations from $\vec{z}$ and $\vec{w}$. This equation will be used to derive the path integral formalism[6,7] in Sec. V, and it would also be useful for obtaining the geometric phase for systems with SU(3) symmetry.[11]

We can prove that the states defined in Eq. (46) satisfy the resolution of identity, i.e.,

$$\int d\Omega |\vec{z},\vec{w}\rangle_{(N,M)(N,M)}\langle\vec{z},\vec{w}| = \frac{1}{D(N,M)} \sum_{i=1}^{D(N,M)} |V_i\rangle\langle V_i|, \tag{54}$$

where V_i denotes a set of orthonormal basis vectors of (N,M). [See Eq. (49) for the explicit example of the representation (1,1).] To verify the normalization on the right-hand side of Eq. (54), it is convenient to look at a particular basis vector $|^{N00}_{0M0}\rangle$. [This has the maximum eigenvalue $(N+M)/2$ of the operator Q^3 given in Eq. (32).] From Eq. (46), the coefficient of this vector in the coherent state is given by $z_1^N w_2^M$. Integrating the modulus squared of this using Eqs. (21)–(25), we obtain the factor of $1/D(N,M)$ in Eq. (54). This is as it should be so that taking the trace of both sides of (54) gives unity.

A second property of coherent states is that they are overcomplete. This is clear for the states in (46) since they are continuous functions of the complex variables $(\vec{z},\vec{w})$, while the dimension of the representation (N,M) is finite.

The coherent states in (46) have a third property which is group theoretical, and is analogous to Eq. (18) for the SU(2) coherent states. Namely, we can go from a particular coherent state, say, $|z_1=1,w_2=1\rangle_{(N,M)}=|^{N00}_{0M0}\rangle$ to the general coherent state $|z,w\rangle_{(N,M)}$ by acting with an exponential of certain combinations of the SU(3) generators Q^a. First of all, we can check that

$$|z,w\rangle_{(N,M)} = z_1^N w_2^M \exp\left[\frac{z_2}{z_1}a_2^\dagger a_1 + \frac{z_3}{z_1}a_3^\dagger a_1 + \frac{w_1}{w_2}b_1^\dagger b_2 + \frac{w_3}{w_2}b_3^\dagger b_1\right]|z_1=1,w_2=1\rangle_{(N,M)}. \tag{55}$$

Then we can use Eq. (51) and the constraint (29) to rewrite this in the form[10]

$$|z,w\rangle_{(N,M)} = z_1^N w_2^M \exp\left[\frac{z_2}{z_1}(Q^1-iQ^2) + \frac{z_3}{z_1}(Q^4-iQ^5) - \frac{w_3}{w_2}(Q^6+iQ^7)\right]|z_1=1,w_2=1\rangle_{(N,M)}, \tag{56}$$

which is similar in structure to Eq. (18).

Another property of these coherent states which is important for their path integral applications is that the expectation value of the SU(3) operators (32) in a coherent state should be given by an SU(3) covariant function of $(\vec{z},\vec{w})$ and their complex conjugates. We find that

$${}_{(N,M)}\langle\vec{z},\vec{w}|Q^a|\vec{z},\vec{w}\rangle_{(N,M)} = N\overline{z_i}\lambda^a_{ij}z_j - M\overline{w_i}\lambda^{*a}_{ij}w_j. \tag{57}$$

This can be proved by using the identities in Eq. (51) to show that

$$\langle\vec{0},\vec{0}|\exp[\vec{\overline{z}}\cdot\vec{a}+\vec{\overline{w}}\cdot\vec{b}]a_i^\dagger a_j \exp[\vec{z}\cdot\vec{a}^\dagger+\vec{w}\cdot\vec{b}^\dagger]|\vec{0},\vec{0}\rangle = \overline{z_i}z_j \exp[\vec{\overline{z}}\cdot\vec{z}+\vec{\overline{w}}\cdot\vec{w}], \tag{58}$$

and a similar identity for the expectation value of $b_i^\dagger b_j$ in terms of $\overline{w_i}w_j$. Equation (57) can now be obtained by comparing terms of order $\overline{z}^N z^N \overline{w}^M w^M$ on the two sides of Eq. (58).

The stationary subgroup of the coherent states defined in this section is generally U(1)×U(1), corresponding to multiplying the vectors $\vec{z}$ and $\vec{w}$ by independent phase factors. These coherent states are therefore functions of the coset space SU(3)/U(1)×U(1).[10] However, for the completely symmetric representations $(N,0)$ and $(0,M)$, the coherent states use only three complex numbers ($\vec{z}$ or $\vec{w}$) which define the space $\mathrm{SU(3)/SU(2)}\sim S^5$; the stationary subgroup is then U(1) which corresponds to multiplying that complex vector by a phase factor. In those cases, the coherent states are functions of the coset space SU(3)/SU(2)×U(1).

V. AN ALTERNATIVE DEFINITION OF SU(3) COHERENT STATES

The SU(3) coherent states discussed in Sec. IV involve eight real parameters, and satisfy some simple group theoretic properties similar to the SU(2) coherent states of Sec. II. It is possible that there may be some applications of coherent states which do not require so many parameters. In

this section, we will discuss an alternative kind of coherent state which only requires five real parameters. We will see later that these coherent states suffer from some problems and they seem to lack some of the group theoretic properties precisely because they use fewer parameters.

We observe that the states in (35) can be extracted from the following generating function:

$$|\vec{z},\vec{\bar{z}}\rangle \equiv \exp(\vec{z}\cdot\vec{a}^\dagger)\exp(\vec{\bar{z}}\cdot\vec{b}^\dagger)\left[1+\sum_{q=1}^{Q} L_q\right]|\vec{0},\vec{0}\rangle, \tag{59}$$

and we have to project onto the subspace of states with $\vec{a}^\dagger\cdot\vec{a}=N$ and $\vec{b}^\dagger\cdot\vec{b}=M$ to obtain the representation (N,M). To be explicit,

$$|\vec{z},\vec{\bar{z}}\rangle_{(N,M)} = \left[\frac{(\vec{z}\cdot\vec{a}^\dagger)^N}{N!}\frac{(\vec{\bar{z}}\cdot\vec{b}^\dagger)^M}{M!}+\sum_{q=1}^{Q} L_q\frac{(\vec{z}\cdot\vec{a}^\dagger)^{N-q}}{(N-q)!}\frac{(\vec{\bar{z}}\cdot\vec{b}^\dagger)^{M-q}}{(M-q)!}\right]|\vec{0},\vec{0}\rangle. \tag{60}$$

On expanding the right hand side of (60), the coefficients of the tensors $z_{i_1}z_{i_2}\cdots z_{i_N}\bar{z}_{j_1}\bar{z}_{j_2}\cdots\bar{z}_{j_M}$ give the basis vectors of SU(3) in the representation (N,M).

The SU(3) coherent states in the representation (N,M) are defined as in Eq. (60),

$$\begin{aligned}|\vec{z},\vec{\bar{z}}\rangle_{(N,M)} &\equiv \frac{1}{N!M!}\sum_{i_1,i_2,\ldots}\sum_{j_1,j_2,\ldots} z_{i_1}z_{i_2}\cdots z_{i_N}\bar{z}_{j_1}\bar{z}_{j_2}\cdots\bar{z}_{j_M}|\psi\rangle^{i_1 i_2\cdots i_N}_{j_1 j_2\cdots j_M}\\ &= \sum_{N_1,N_2,N_3}\sum_{M_1,M_2,M_3}\frac{z_1^{N_1}z_2^{N_2}z_3^{N_3}\bar{z}_1^{M_1}\bar{z}_2^{M_2}\bar{z}_3^{M_3}}{N_1!N_2!N_3!M_1!M_2!M_3!}|\psi\rangle^{N_1N_2N_3}_{M_1M_2M_3}.\end{aligned} \tag{61}$$

To give a specific example, the coherent state of the representation (1,1) is given by

$$|\vec{z},\vec{\bar{z}}\rangle_{(1,1)} = \sum_{i,j=1}^{3} z_i\bar{z}_j a_i^\dagger b_j^\dagger|\vec{0},\vec{0}\rangle - \frac{1}{3}\sum_{i=1}^{3} a_i^\dagger b_i^\dagger|\vec{0},\vec{0}\rangle. \tag{62}$$

We will now prove that the states defined in (61) satisfy the resolution of identity,

$$\int d\Omega_{S^5}|\vec{z},\vec{\bar{z}}\rangle_{(N,M)(N,M)}\langle\vec{z},\vec{\bar{z}}| = 1. \tag{63}$$

To prove this, we use the definition (41) and the integration measure for $\vec{z}$ given in (22). We find that

$$\int d\Omega_{S^5}|z,\bar{z}\rangle\langle z,\bar{z}| = \mathcal{C}\sum_{N_i,M_i}\left(\sum_{\delta_i}\left(\prod_{i=1}^{3}\frac{(N_i+M_i+\delta_i)!}{(N_i+\delta_i)!(M_i+\delta_i)!}\right)|\psi\rangle^{N_1+\delta_1N_2+\delta_2N_3+\delta_3}_{M_1+\delta_1M_2+\delta_2M_3+\delta_3}\right)\ {}^{N_1N_2N_3}_{M_1M_2M_3}\langle\psi|, \tag{64}$$

where the δ_i are integers satisfying

$$\sum_{i=1}^{3}\delta_i = 0, \tag{65}$$

and the constant $\mathcal{C}$ is determined shortly. We now use the following property,

$$\sum_{\delta_i}\left(\prod_{i=1}^{3}\frac{(N_i+M_i+\delta_i)!}{(N_i+\delta_i)!(M_i+\delta_i)!}\right)|\psi\rangle^{N_1+\delta_1N_2+\delta_2N_3+\delta_3}_{M_1+\delta_1M_2+\delta_2M_3+\delta_3} = |\psi\rangle^{N_1N_2N_3}_{M_1M_2M_3}, \tag{66}$$

which is a consequence of Eq. (37) for the basis vectors of a representation of SU(3). Thus Eq. (64) can be simplified to

$$\int d\Omega_{S^5}|z,\overline{z}\rangle\langle z,\overline{z}| = \mathcal{C}\sum_{N_i,M_i} |\psi\rangle^{N_1N_2N_3}_{M_1M_2M_3}{}^{N_1N_2N_3}_{M_1M_2M_3}\langle\psi|. \tag{67}$$

The normalization constant $\mathcal{C}$ in Eq. (67) can be fixed by looking at one particular basis vector of the representation (N,M), say,

$$|\psi\rangle^{N00}_{0M0}. \tag{68}$$

From Eq. (61), the coefficient of this vector in the coherent state $|\vec{z},\vec{\overline{z}}\rangle$ is $z_1^N\overline{z_2}^M/(N!M!)$. Integrating this as in (22), we find that

$$\mathcal{C} = \frac{2}{N!M!(N+M+2)!}. \tag{69}$$

Finally, let us consider the analog of the property given in Eq. (57) for the (z,w) coherent states. We can prove that

$${}_{(N,M)}\langle\vec{z},\vec{\overline{z}}|Q^a|\vec{z},\vec{\overline{z}}\rangle_{(N,M)} = (N-M)\overline{z_i}\lambda^a_{ij}z_j. \tag{70}$$

To prove this, we use the identities in (51) to show that

$$\langle\vec{0},\vec{0}|\exp[\vec{\overline{z}}\cdot\vec{a}+\vec{z}\cdot\vec{b}]a_i^\dagger a_j\exp[\vec{z}\cdot\vec{a}^\dagger+\vec{\overline{z}}\cdot\vec{b}^\dagger]|\vec{0},\vec{0}\rangle = \overline{z_i}z_j\exp[2\vec{\overline{z}}\cdot\vec{z}]. \tag{71}$$

On expanding this equation and comparing terms which are of order N in both z_i and $\overline{z_i}$, we find that the expectation value of Q^a in the representation $(N,0)$ satisfies Eq. (70). In a similar way, we can prove Eq. (70) in the representation $(0,M)$. Finally, we can generalize the proof to the representation (N,M) by using Eq. (33); since Q^a commutes with $\vec{a}\cdot\vec{b}$ and $\vec{a}^\dagger\cdot\vec{b}^\dagger$, it commutes with the operators L_q which are require to enforce tracelessness in Eq. (35).

Note that (70) vanishes for the self-conjugate representations in which $N=M$. There is a similar problem for the differential change in overlap analogous to Eq. (53). We find that the coherent states defined in this section satisfy

$$\frac{\langle\vec{z},\vec{\overline{z}}|\vec{z}+d\vec{z},\vec{\overline{z}}+d\vec{\overline{z}}\rangle}{\langle\vec{z},\vec{\overline{z}}|\vec{z},\vec{\overline{z}}\rangle} = 1+N\sum_i \overline{z_i}dz_i + M\sum_i d\overline{z_i}z_i \tag{72}$$

in the representation (N,M). The left hand side of this equation is equal to 1 if $N=M$ due to the constraint $\Sigma_i\overline{z_i}z_i=1$. These two problems imply that the $(z,\overline{z})$ coherent states are unlikely to be useful for path integral applications in the representations with $N=M$.

For the $(z,\overline{z})$ coherent states, we have not yet found the construction of the group theoretical property analogous to (56) in the general representation (N,M). This would be an interesting topic for future studies.

The stationary subgroup of the coherent states defined in this section is $\mathrm{U}(1)=S^1$, corresponding to multiplying $\vec{z}$ by a phase factor. These coherent states are therefore functions of the manifold S^5/S^1.

VI. PATH INTEGRAL FORMALISM

We will now use the (z,w) coherent states presented in Sec. IV to derive the path integral for a problem which has SU(3) variables in some representation (N,M). (For convenience, we will drop the subscript (N,M) on the coherent states in this section.) We begin by discussing a problem

involving the Hamiltonian of a single site with a SU(3) variable. For any Hamiltonian which is a function of the SU(3) operators Q^a, we define its coherent state expectation value to be

$$E(z,\overline{z},w,\overline{w}) \equiv \langle z,w|\hat{H}|z,w\rangle. \tag{73}$$

If the Hamiltonian is linear in the SU(3) operators, i.e.,

$$\hat{H} = \sum_{a=1}^{8} c_a Q^a, \tag{74}$$

then Eq. (73) can be found using Eq. (57). But if the Hamiltonian is not linear in the SU(3) operators, then Eq. (73) has to be evaluated separately.

Let us now consider the propagator in imaginary time

$$G(z^{(F)},w^{(F)},z^{(I)},w^{(I)};T) = \langle z^{(F)},w^{(F)}|\exp(-T\hat{H})|z^{(I)},w^{(I)}\rangle, \tag{75}$$

where the superscripts I and F denote initial and final states, respectively, and we are suppressing the subscripts $i\,(=1,2,3)$ on z and w for the moment. We write the exponential in (75) as a product of $\mathcal{N}$ terms, and use the resolution of identity in (54) to insert a complete set of states between each pair of terms. A typical term looks like

$$\langle z^{(n+1)},w^{(n+1)}|\exp(-\epsilon\hat{H})|z^{(n)},w^{(n)}\rangle, \tag{76}$$

where $\epsilon = T/\mathcal{N}$. We are eventually interested in taking the limit $\mathcal{N}\to\infty$ holding T fixed. In that case, we may assume that $(z^{(n+1)},w^{(n+1)})$ is close to $(z^{(n)},w^{(n)})$ in (76), so that $dz_i^{(n)} = z_i^{(n+1)} - z_i^{(n)}$ and $dw_i^{(n)} = w_i^{(n+1)} - w_i^{(n)}$ are small. Using Eqs. (53) and (73), we can write (76) as

$$\begin{aligned}&\langle z^{(n+1)},w^{(n+1)}|\exp(-\epsilon\hat{H})|z^{(n)},w^{(n)}\rangle \\ &\quad = \exp\left[N\sum_i \overline{z}_i^{(n)} dz_i^{(n)} + M\sum_i \overline{w}_i^{(n)} dw_i^{(n)} - \epsilon E(z^{(n)},\overline{z^{(n)}},w^{(n)},\overline{w^{(n)}})\right]\end{aligned} \tag{77}$$

to first order in ϵ, $dz_i^{(n)}$ and $dw_i^{(n)}$. In the limit $\epsilon = d\tau \to 0$, we can write the propagator in (75) in the path integral form

$$G(z^{(F)},w^{(F)},z^{(I)},w^{(I)};T) = \int \mathcal{D}\Omega_{\mathrm{SU(3)}}(\tau)\exp(-S[z,w]),$$

where

$$S[z,w] = \int_0^T d\tau\left[-N\sum_i \overline{z}_i \frac{dz_i}{d\tau} - M\sum_i \overline{w}_i \frac{dw_i}{d\tau} + E(z,\overline{z},w,\overline{w})\right], \tag{78}$$

and

$$\mathcal{D}\Omega_{\mathrm{SU(3)}}(\tau) \equiv \prod_n d\Omega_{\mathrm{SU(3)}}(n),$$

and (z,w) are functions of τ which satisfy the boundary conditions $(z(0),w(0)) = (z^{(I)},w^{(I)})$ and $(z(T),w(T)) = (z^{(F)},w^{(F)})$. Note that we have written the functional integral measure in (78) in terms of the measure given in Eq. (25). Alternatively, we can write the functional integral measure in terms of $\mathcal{D}z\mathcal{D}\overline{z}\mathcal{D}w\mathcal{D}\overline{w}$ if we introduce appropriate Lagrange multiplier fields in the action S to enforce the constraints in Eqs. (28) and (29) at each time τ.

We can now generalize the above construction to a problem involving several sites which are labeled by a parameter x, provided that the Hamiltonian is linear in the SU(3) variables at *each* site. We introduce a coherent state at each site, and write the energy functional as

$$E[z,\bar{z},w,\bar{w}]=\langle z,w|\hat{H}|z,w\rangle, \quad \text{where } |z,w\rangle\equiv\prod_x |z(x),w(x)\rangle. \tag{79}$$

Then we can show that

$$\langle z^{(F)}(x),w^{(F)}(x)|\exp(-T\hat{H})|z^{(I)}(x),w^{(I)}(x)\rangle=\int \mathcal{D}\Omega_{\mathrm{SU(3)}}(x,\tau)\exp(-S[z,w]),$$

$$S[z,w]=\int_0^T d\tau\left[-\sum_x\left\{N\sum_i \bar{z}_i(x)\frac{dz_i(x)}{d\tau}-M\sum_i \bar{w}_i(x)\frac{dw_i(x)}{d\tau}\right\}+E[z,\bar{z},w,\bar{w}]\right], \tag{80}$$

$$\mathcal{D}\Omega_{\mathrm{SU(3)}}(x,\tau)\equiv\prod_{x,n} d\Omega_{\mathrm{SU(3)}}(x,n).$$

Note that the first two terms in the actions S given in Eqs. (78) and (80) are purely imaginary due to the constraints in (28). To show this explicitly, we can rewrite those terms as

$$\begin{aligned}\sum_i \bar{z}_i dz_i&=\frac{1}{2}\sum_i (\bar{z}_i dz_i-d\bar{z}_i z_i),\\ \sum_i \bar{w}_i dw_i&=\frac{1}{2}\sum_i (\bar{w}_i dw_i-d\bar{w}_i w_i).\end{aligned} \tag{81}$$

As an example of a problem to which this formalism can be applied, we can consider the SU(3) invariant Hamiltonian

$$\hat{H}=\sum_{x,y} J_{x,y}\sum_a Q^a(x)Q^a(y). \tag{82}$$

This is called the SU(3) Heisenberg model. It has been discussed extensively in the literature for the completely symmetric representations $(N,0)$;[6] for those representations, we can use the simpler measure $d\Omega_{S^5}$ given in Eq. (22) instead of $d\Omega_{\mathrm{SU(3)}}$. Our construction of coherent states now allows a study of the Heisenberg model in any representation (N,M).

VII. SUMMARY AND DISCUSSION

In this article we have exploited the representation of the SU(3) Lie algebra in terms of six harmonic oscillator creation and annihilation operators to generate all the representations of SU(3). This harmonic oscillator form of the algebra enables us to define the SU(3) coherent states in terms of two triplets of complex numbers. In this sense the SU(2) definition (12) and SU(3) definition (45) are analogous to that of the Heisenberg–Weyl coherent states (4). The SU(3) coherent states are characterized by two triplets of complex numbers with four real constraints. This explicit construction in terms of complex numbers can be used to derive the geometrical phase of SU(3). Further, the path integral formalism discussed in the previous section can be used to obtain the field theory for the SU(3) Heisenberg model and study its topological aspects as in the SU(2) case.[17] Work in this direction is in progress and will be reported elsewhere.

For any group G, we can use a certain number of harmonic oscillator operators to construct the group operators as in Eqs. (32) and (33). If we can find the appropriate set of complex numbers

which transform according to that group and satisfy the necessary constraints, we can use our method to provide an explicit complex number parametrization of the corresponding coherent states.

ACKNOWLEDGMENTS

We (MM and DS) would like to thank N. Mukunda and H. S. Sharatchandra for some discussions. MM would like to thank Samir Paul, Debashish Gangopadhyay, and Ranjan Choudhary for discussions on the SU(2) coherent states.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 42, NUMBER 9 SEPTEMBER 2001

Large-*N* theory from the axiomatic point of view

O. Yu. Shvedov[a)]
Sub-Department of Quantum Statistics and Field Theory, Department of Physics, Moscow State University, Vorobievy gory, Moscow 119899, Russia

(Received 22 September 2000; accepted for publication 18 May 2001)

The state space and observables for the leading order of the large-*N* theory are constructed. The obtained model (''theory of infinite number of fields'') is shown to obey Wightman-type axioms (including invariance under boost transformations). The considered class of exactly solvable relativistic quantum models involves good examples of theories containing such difficulties as volume divergences associated with the Haag theorem, Stueckelberg divergences, and infinite renormalization of the wave function. © *2001 American Institute of Physics.*

I. INTRODUCTION

There are different approaches to quantum field theory (QFT). Some of them are based on calculations of average values like Green functions, *S* matrix; for these purposes, different techniques can be applied: one can use the functional integral approach, write down the *T* exponent of the integral of interaction Lagrangian, solve the Dyson–Schwinger equations or use the Bogoliubov axiomatic approach.[1,2]

There are also ways to construct QFT with the help of equations of motion: one finds the classical Hamiltonian of the theory, canonically quantizes it, and writes the Schrodinger equation.

All approaches to QFT are somehow equivalent. On the one hand, one can obtain the *S* matrix and the Green functions by formally integrating equations of motion. On the other hand, one can obtain Wightman functions by analytic continuation of the Euclidean Green functions[2] and then apply the Wightman theorem[3,4] and reconstruct state space, evolution, and boost operators of the theory.

However, there are QFT divergences, so that it is necessary to perform renormalization of the theory in each approach. Renormalization is much easier in the *S* matrix (or Green functions) approach since they are manifestly covariant, contrary to the Hamiltonian method.

The approach, based on the equations, of motion contains additional difficulties associated with the problem of Stueckelberg divergences[5] and Haag theorem (see, for example, Refs. 2 and 4). Although the vacuum divergences associated with the Haag theorem can be removed within the perturbation theory with the help of the Faddeev transformation,[6] while Stueckelberg divergences can be treated in the analogous way,[7] renormalization of equations of motion is a strongly nontrivial problem even within the perturbation framework.

Unfortunately, for general QFT models, renormalization was performed even for the *S* matrix approach within the perturbation theory only: the Bogoliubov–Parasiuk theorem was proven.[1] However, if the Green functions of the theory are constructed only perturbatively, the possible application of the Wightman reconstruction theorem at least requires additional investigations, so that the problem of constructing the state space seems to be interesting even in the perturbation theory.

Large-*N* expansion is another approximate scheme for QFT.[8–10] This approximation, widely used in QFT allows us to obtain nonperturbative results and investigate the behavior of the Green functions, the effective action, dynamical and spontaneous symmetry breaking.

The traditional approaches to the $1/N$ expansion enable us to evaluate different quantities just

a)Electronic mail: olshv@ms2.inr.ac.ru; shvedov@qs.phys.msu.su

mentioned. However, some problems of the large-N theories remain to be understood. What are states and observables in the theory of infinite number of fields? Can one determine such a theory as a large-N limit?

From the axiomatic field theory point of view,[2–4] the relativistic QFT is constructed if:

(i) the Hilbert state space $\mathcal{H}$ is specified,
(ii) the operators $U_g:\mathcal{H}\to\mathcal{H}$ corresponding to the Poincare transformations g are specified; the group property $U_{g_1}U_{g_2}=U_{g_1g_2}$ is satisfied, and
(iii) the field operators are constructed.

The introduced objects should obey certain (Wightman-type) axioms.

It happens that the axiomatic formulation of the large-N QFT can be obtained within the third-quantized approach developed recently as discussed in Ref. 11. It allows us to construct not only known but also new formal asymptotic solutions to the large-N Schrodinger equation. The correspondence between third-quantized framework and standard large-N approaches is discussed in Ref. 11.

It is interesting that the large-N limit of QFT may be viewed as a theory of a variable number of fields. This is analogous to the statistical physics: the system of a large but fixed number of particles can be considered as a set of quasiparticles which can be created and annihilated. Analogously, the large-N field system can be treated from the ''quasifield'' point of view: there is an amplitude that there are no fields, that there is one field, two fields, etc. Thus, the large-N limit of QFT is *not* a field theory in the usual treatment since one can not define usual field operators. However, the property of the relativistic invariance remains. Moreover, we will introduce the analog of notion of field which is very useful for constructing boost transformations.

The models of an infinite number of fields constructed in this paper seem to be remarkable from the point of view of the constructive field theory.[12,13] The old problem of QFT is to construct the nontrivial model of field theory obeying all Wightman axioms. Such examples were constructed for the cases of two- and three-dimensional space–time. The models presented here are considered in higher dimensions.

The models considered in this paper are good examples of theories that contain such difficulties as Stueckelberg divergences[5] and volume divergences associated with the Haag theorem. There was a hypothesis[12] that the models with the Stueckelberg divergences can not be constructed with the help of the Hamiltonian methods. However, we show this hypothesis to be incorrect.

This paper is organized as follows. As an example, we consider the $\lambda(\varphi^a\varphi^a)^2$ model in $(d+1)$-dimensional space–time with the following Lagrangian:

$$\mathcal{L}=\frac{1}{2}\partial_\mu\varphi^a\partial_\mu\varphi^a-\frac{m^2}{2}\varphi^a\varphi^a-\frac{\lambda}{4N}(\varphi^a\varphi^a)^2,$$

we sum over repeated indices $a=1,\ldots,N$, and $\mu=0,\ldots,d$. In Sec. II, the $N=\infty$-limit of the model is heuristically constructed. The Hamiltonian, momentum, angular momentum, and boost generator are presented. It is heuristically shown that they formally obey usual commutation relations of the Poincare algebra. However, the divergences show us that the obtained expressions are not mathematically well-defined. Section III is devoted to the problem of renormalization of the Hamiltonian. The momentum and angular momentum are also investigated. The spectral and vacuum axioms are checked.

It is not easy to construct operators of boost transformation (Lorentz rotation) and check the group properties. It is convenient first to introduce the composed field being an analog of the large-N operator $\Sigma_{a=1}^N\varphi^a(x_1)\ldots\varphi^a(x_k)$. Such operators (multifields) being analogs of fields of ordinary QFT are constructed in Sec. IV. They are shown to be operator distributions. The cyclic property of the vacuum state is checked. The invariance of multifields under spatial rotations and space–time translations is checked. Section V deals with the construction of the operator of boost transformation. This allows us to construct the representation of the Poincare group and check the

relativistic invariance of the theory. The results of Sec. IV are essentially used. Section VI contains concluding remarks.

II. WHAT IS A THEORY OF INFINITE NUMBER OF FIELDS?

This section deals with investigation of the theory of N fields, $\varphi^1, \ldots, \varphi^N$ as $N \to \infty$. Such models were considered in context of calculations of physical quantities such as Green functions. It seems to be useful to formulate the $N=\infty$-theory: to determine the state space, Poincare transformations, field operators, etc.

A. Multifield canonical operator

In the functional Schrodinger representation, states of the N-field system at time t are specified by the functionals $\Psi_N^t[\varphi^1(\cdot), \ldots, \varphi^N(\cdot)]$ depending on the field configurations $\varphi^1(\mathbf{x}), \ldots, \varphi^N(\mathbf{x})$, and $\mathbf{x}=(x_1, \ldots, x_d)$. The inner product is formally written via the functional integral

$$(\Psi_N, \Psi_N) = \int D\varphi^1 \ldots D\varphi^N |\Psi_N[\varphi^1(\cdot), \ldots, \varphi^N(\cdot)]|^2.$$

The evolution equation has the form

$$i\frac{d}{dt}\Psi_N^t = \mathcal{H}_N \Psi_N^t, \tag{2.1}$$

with the Hamiltonian presented as a sum of the free Hamiltonian and interaction

$$\mathcal{H}_N = \int d\mathbf{x} \left[-\frac{1}{2}\frac{\delta^2}{\delta\varphi^a(\mathbf{x})\delta\varphi^a(\mathbf{x})} + \frac{1}{2}(\nabla\varphi^a)(\mathbf{x})(\nabla\varphi^a)(\mathbf{x}) + \frac{m^2}{2}\varphi^a(\mathbf{x})\varphi^a(\mathbf{x}) + \frac{\lambda}{4N}(\varphi^a(\mathbf{x})\varphi^a(\mathbf{x}))^2 \right]. \tag{2.2}$$

If one considers states of a few number of particles in comparison with N, one can suppose that almost all fields are in the vacuum state. This treatment leads us to the following structure of the wave functional Ψ_N^t. If all fields $\varphi^1, \ldots, \varphi^N$ are in the same (vacuum) state, the N-field state Ψ_N is

$$\Psi_N[\varphi^1(\cdot), \ldots, \varphi^N(\cdot)] = c\Phi_0[\varphi^1(\cdot)] \ldots \Phi_0[\varphi^N(\cdot)]. \tag{2.3}$$

If $(N-1)$ fields are in the state Φ_0, while 1 field is in the state f_1, the N-field state can be written as

$$\Psi_N[\varphi^1(\cdot), \ldots, \varphi^N(\cdot)] = \frac{1}{\sqrt{N}}\sum_{a=1}^{N} \Phi_0[\varphi^1(\cdot)] \ldots \Phi_0[\varphi^{a-1}(\cdot)] f_1[\varphi^a(\cdot)] \Phi_0 \times [\varphi^{a+1}(\cdot)] \ldots \Phi_0[\varphi^N(\cdot)]. \tag{2.4}$$

Without loss of generality, one can suppose that (Φ_0, and f_1)$=0$. Otherwise, one could decompose the functional f_1 into two parts, one of them being proportional to Φ_0, another being orthogonal to Φ_0. The case $f_1 = \text{const}\Phi_0$ does not lead to a new functional since expressions (2.3) and (2.4) coincide then.

Analogously, the state corresponding to $(N-k)$ fields in the vacuum state and k fields in the state $f_k(\varphi^1, \ldots, \varphi^k)$ being symmetric with respect to transpositions of $\varphi^1, \ldots, \varphi^k$ and satisfying the orthogonality condition

$$\int D\varphi_1 \Phi_0^*[\varphi^1(\cdot)] f_k[\varphi^1(\cdot), \ldots, \varphi^k(\cdot)] = 0 \tag{2.5}$$

has the form

$$\Psi_N[\varphi^1(\cdot), \ldots, \varphi^N(\cdot)] = \frac{1}{\sqrt{N^k k!}} \sum_{1 \leqslant a_1 \neq \ldots \neq a_k \leqslant N} f_k[\varphi^{a_1}(\cdot), \ldots, \varphi^{a_k}(\cdot)] \prod_{a \neq a_1 \ldots a_k} \Phi_0[\varphi^a(\cdot)]. \tag{2.6}$$

Finally, one can consider the superposition of states (2.6) with rapid decreasing at $k \to \infty$ set of norms $||f_k||$. This is the most general form of a state ''with a few number of particles,'' provided that one takes into account symmetric functionals Ψ only. Nonsymmetric functionals are investigated in Appendix B.

We see that symmetric states in the theory of a large number of fields occur to be specified by infinite sets

$$f = \begin{pmatrix} f_0 \\ f_1[\varphi^1(\cdot)] \\ \cdots \\ f_k[\varphi^1(\cdot), \ldots, \varphi^k(\cdot)] \\ \cdots \end{pmatrix} \tag{2.7}$$

where f_k are symmetric functionals satisfying Eq. (2.5). One can say that f_k is a probability amplitude that k fields are in the nonvacuum state. We see that the theory of a large number of fields is equivalent to the theory of a variable number of fields. This observation is analogous to the quasiparticle conception in statistical physics.

The mapping $K_N : f \mapsto \Psi_N$ of the form

$$(K_N f)[\varphi^1(\cdot), \ldots, \varphi^N(\cdot)] = \sum_{k=0}^{N} \frac{1}{\sqrt{N^k k!}} \sum_{1 \leqslant a_1 \neq \ldots \neq a_k \leqslant N} f_k[\varphi^{a_1}(\cdot), \ldots, \varphi^{a_k}(\cdot)] \prod_{a \neq a_1 \ldots a_k} \Phi_0[\varphi^a(\cdot)], \tag{2.8}$$

will be called as a multifield canonical operator analogous to the multiparticle canonical operator used in statistical physics.[11,14] The orthogonality condition (2.5) implies that

$$||K_N f||^2 = \sum_{k=0}^{N} \frac{N!}{N^k (N-k)!} ||f_k||^2 \to_{N \to \infty} \sum_{k=0}^{\infty} ||f_k||^2. \tag{2.9}$$

We see that sets (2.7) may be identified with states of the system of $N = \infty$ fields, while the relation (2.9) can be considered as an argument that the norm of a state should be chosen as

$$||f||^2 = \sum_{k=0}^{\infty} ||f_k||^2.$$

Thus, decomposition (2.8) gives us a relationship between the theory of a large number of fields and the theory of a variable number of fields.

B. Representation of operators

Let us write operators of physical quantities in the representation (2.7). It will be convenient to present them via the third-quantized creation and annihilation operators which can be

introduced as follows.[11] The creation operator $A^+[\varphi(\cdot)]$ increases the number of fields, i.e., transforms the set $f=(0,0,\ldots,0,f_{k-1},0,\ldots)$ into $(0,\ldots,0,(A^+[\varphi(\cdot)]f)_k,0,\ldots)$, The functional $(A^+[\varphi(\cdot)]f)_k[\varphi^1(\cdot),\ldots,\varphi^k(\cdot)]$ being the k-th component of the set $(A^+[\varphi(\cdot)]f)$ is expressed via the $(k-1)$-th component of f:

$$(A^+[\varphi(\cdot)]f)_k[\varphi^1(\cdot),\ldots,\varphi^k(\cdot)]$$
$$=\frac{1}{\sqrt{k}}\sum_{a=1}^{k}\delta(\varphi(\cdot)-\varphi^a(\cdot))f_{k-1}[\varphi^1(\cdot),\ldots,\varphi^{a-1}(\cdot),\varphi^{a+1}(\cdot),\ldots,\varphi^k(\cdot)]. \tag{2.10}$$

The annihilation operator $A^-[\varphi(\cdot)]$ is

$$(A^-[\varphi(\cdot)]f)_{k-1}[\varphi^1(\cdot),\ldots,\varphi^{k-1}(\cdot)]=\sqrt{k}f_k[\varphi(\cdot),\varphi^1(\cdot),\ldots,\varphi^{k-1}(\cdot)]. \tag{2.11}$$

The condition (2.5) is not invariant under transformations (2.10) and (2.11). Consider the modified creation and annihilation operators:

$$\tilde{A}^+[\varphi(\cdot)]=A^+[\varphi(\cdot)]-\Phi_0^*[\varphi(\cdot)]\int D\phi\Phi_0[\phi(\cdot)]A^+[\phi(\cdot)],$$

$$\tilde{A}^-[\varphi(\cdot)]=A^-[\varphi(\cdot)]-\Phi_0[\varphi(\cdot)]\int D\phi\Phi_0^*[\phi(\cdot)]A^-[\phi(\cdot)].$$

To write operators in the representation (3.7), consider the orthonormal basis $(\Phi_0,\Phi_1,\ldots)$ in the space of functionals,

$$\int D\varphi\Phi_i^*[\varphi(\cdot)]\Phi_j[\varphi(\cdot)]=\delta_{ij},$$

which contain the vacuum functional Φ_0 entering to expression (2.8). Investigate the following ''elementary'' operators

$$\mathcal{O}_N^{ij}\Psi[\varphi^1(\cdot),\ldots,\varphi^N(\cdot)]=\sum_{a=1}^{N}\Phi_i[\varphi^a(\cdot)]\int D\phi\Phi_j^*[\phi(\cdot)]\Psi$$
$$\times[\varphi^1(\cdot),\ldots,\varphi^{a-1}(\cdot),\phi(\cdot),\varphi^{a+1}(\cdot),\ldots,\varphi^N(\cdot)]. \tag{2.12}$$

Apply them to the expression (2.8). It is necessary to distinguish four cases.

(i) $i=j=0$.

Due to the condition (2.5), one has

$$(\mathcal{O}_N^{00}K_Nf)[\varphi^1(\cdot),\ldots,\varphi^N(\cdot)]$$
$$=\sum_{k=0}^{N}(N-k)\frac{1}{\sqrt{N^k k!}}\sum_{1\leqslant a_1\neq\ldots\neq a_k\leqslant N}f_k[\varphi^{a_1}(\cdot),\ldots,\varphi^{a_k}(\cdot)]\prod_{a\neq a_1\ldots a_k}\Phi_0[\varphi^a(\cdot)].$$

This means that the operator $\mathcal{O}_N^{00}$ acts in the space (3.7) as $N-\hat{n},$, i.e.,

$$\mathcal{O}_N^{00}K_Nf=K_N(N-\hat{n})f,$$

where $\hat{n}=\int D\varphi\tilde{A}^+[\varphi(\cdot)]\tilde{A}^-[\varphi(\cdot)]$ is the operator of number of fields,

$$(\hat{n}f)_k=kf_k.$$

(ii) $i=0, j\neq 0$.
It follows from the symmetry condition that

$$(\mathcal{O}_N^{0j}K_N f)[\varphi^1(\cdot),\ldots,\varphi^N(\cdot)]$$
$$=\sum_{k=0}^{N}\frac{1}{\sqrt{N^k k!}}\sum_{p=1}^{k}\frac{1}{\sqrt{k}}\sum_{1\leqslant a_1\neq\ldots\neq a_k\leqslant N}\Phi_0[\varphi^{a_p}(\cdot)]\left(\int D\phi\tilde{A}^-[\phi(\cdot)]\Phi_j^*[\phi(\cdot)]f\right)_{k-1}$$
$$\times[\varphi^{a_1}(\cdot),\ldots,\varphi^{a_{p-1}}(\cdot),\varphi^{a_{p+1}}(\cdot),\ldots,\varphi^{a_k}(\cdot)]\prod_{a\neq a_1\ldots a_k}\Phi_0[\varphi^a(\cdot)]. \tag{2.13}$$

After redefining $a_1=b_1,\ldots,a_{p-1}=b_{p-1}$, $a_{p+1}=b_p,\ldots,a_k=b_{k-1}$, and $a_k=b$, we obtain that the symbol Σ_k can be substituted by k, while Σ_j transforms to $(N-k+1)$. Thus, one obtains the following commutation rule:

$$\mathcal{O}_N^{0j}K_N f=K_N(N-\hat{n})\frac{1}{\sqrt{N}}\int D\phi\tilde{A}^-[\phi(\cdot)]\Phi_j^*[\phi(\cdot)]f.$$

(iii) $i\neq 0$, $j=0$.
Due to Eq. (2.5), we have

$$(\mathcal{O}_N^{i0}K_N f)[\varphi^1(\cdot),\ldots,\varphi^N(\cdot)]$$
$$=\sum_{k=0}^{N}\frac{1}{\sqrt{N^k k!}}\sum_{1\leqslant a_1\neq\ldots\neq a_k\leqslant N}f_k[\varphi^{i_1}(\cdot),\ldots,\varphi^{i_k}(\cdot)]$$
$$\sum_{a\neq a_1\ldots a_k}\Phi_i[\varphi^a(\cdot)]\prod_{b\neq a,a_1\ldots a_k}\Phi_0[\varphi^b(\cdot)]. \tag{2.14}$$

After symmetrization, the commutation rule takes the form

$$\mathcal{O}_N^{i0}K_N f=K_N\sqrt{N}\int D\phi\tilde{A}^+[\phi(\cdot)]\Phi_i[\phi(\cdot)]f.$$

(iv) $i\neq 0$, $j\neq 0$.
Analogously, we find that

$$\mathcal{O}_N^{ij}K_N f=K_N\int D\varphi\tilde{A}^+[\varphi(\cdot)]\Phi_i[\varphi(\cdot)]\int D\phi\tilde{A}^+[\phi(\cdot)]\Phi_j^*[\phi(\cdot)].$$

Any operator can be represented via elementary operators (2.12). Consider an example.
The operator $\Sigma_{a=1}^N\varphi^a(\mathbf{x})\varphi^a(\mathbf{x})$ is expressed as

$$\sum_{a=1}^{N}\varphi^a(\mathbf{x})\varphi^a(\mathbf{x})=\sum_{ij=0}^{\infty}\int D\phi\Phi_i^*[\phi(\cdot)]\phi(\mathbf{x})\phi(\mathbf{x})\Phi_j[\phi(\cdot)]\mathcal{O}_N^{ij}.$$

Therefore, the following commutation rule takes place:

$$\lambda\sum_{a=1}^{N}\varphi^a(\mathbf{x})\varphi^a(\mathbf{x})K_N=K_N\tilde{\mathcal{Q}}_N(\mathbf{x}),$$

where the operator $\tilde{\mathcal{Q}}_N(\mathbf{x})$ consists of the constant term of order $O(N)$, the linear in creation–annihilation operators term of order $O(\sqrt{N})$ and the regular as $N\to\infty$ term which is quadratic in creation and annihilation operators:

$$\tilde{\mathcal{Q}}_N(\mathbf{x})=\lambda(N-\hat{n})(\Phi_0,\phi(\mathbf{x})\phi(\mathbf{x})\Phi_0)+\lambda\sqrt{N}\int D\phi\tilde{A}^+[\phi(\cdot)]\phi(\mathbf{x})\phi(\mathbf{x})\Phi_0[\phi(\cdot)]$$
$$+\frac{\lambda}{\sqrt{N}}(N-\hat{n})\int D\phi\tilde{A}^-[\phi(\cdot)]\phi(\mathbf{x})\phi(\mathbf{x})\Phi_0^*[\phi(\cdot)]$$
$$+\lambda\int D\phi\tilde{A}^+[\phi(\cdot)]\phi(\mathbf{x})\phi(\mathbf{x})\tilde{A}^-[\phi(\cdot)]. \tag{2.15}$$

C. Evolution equation at $N=\infty$

Analogously to the previous Sec. II B, the operators $\Sigma_{a=1}^n(\nabla\varphi^a)^2(\mathbf{x})$ and $\Sigma_{a=1}^N(-\delta^2/\delta\varphi^a(\mathbf{x})\delta\varphi^a(\mathbf{x}))$ can be also written in the representation (2.7). Since the Hamiltonian (2.2) contains the considered operator expressions only, it can be also commuted with the multifield canonical operator,

$$\mathcal{H}_N K_N=K_N\tilde{\mathcal{H}}_N.$$

The transformed Hamiltonian $\tilde{\mathcal{H}}_N$ is

$$\tilde{\mathcal{H}}_N=\int d\mathbf{x}\Bigg[(N-\hat{n})(\Phi_0,\mathcal{E}_0(\mathbf{x})\Phi_0)+\sqrt{N}\int D\phi\tilde{A}^+[\phi(\cdot)]\mathcal{E}_0(\mathbf{x})\Phi_0[\phi(\cdot)]$$
$$+\frac{1}{\sqrt{N}}(N-\hat{n})\int D\phi\Phi_0^*[\phi(\cdot)]\mathcal{E}_0(\mathbf{x})\tilde{A}^-[\phi(\cdot)]$$
$$+\int D\phi\tilde{A}^+[\phi(\cdot)]\mathcal{E}_0(\mathbf{x})\tilde{A}^-[\phi(\cdot)]+\frac{1}{4N\lambda}\tilde{\mathcal{Q}}_N^2(\mathbf{x}),\Bigg] \tag{2.16}$$

where

$$\mathcal{E}_0(\mathbf{x})=-\frac{1}{2}\frac{\delta^2}{\delta\phi(\mathbf{x})\delta\phi(\mathbf{x})}+\frac{1}{2}(\nabla\phi)^2(\mathbf{x})+\frac{m^2}{2}\phi^2(\mathbf{x}).$$

Expression (2.16) contains the terms of order $O(N)$, $O(N^{1/2})$, and $O(1)$ and the terms damping as $N\to\infty$:

$$\tilde{\mathcal{H}}_N=N\tilde{\mathcal{H}}^0+N^{1/2}\tilde{\mathcal{H}}^1+\tilde{\mathcal{H}}^2+O(N^{-1/2}). \tag{2.17}$$

The operator $\tilde{\mathcal{H}}^0$ is a multiplication by the divergent c-number quantity

$$\tilde{\mathcal{H}}^0=\int d\mathbf{x}(\Phi_0,\mathcal{E}_0(\mathbf{x})\Phi_0)+\frac{\lambda}{4}\int d\mathbf{x}(\Phi_0,\phi(\mathbf{x})\phi(\mathbf{x})\Phi_0)^2.$$

As usual in QFT, the vacuum energy is set to zero by adding a constant to the Hamiltonian, so that the Hamiltonian is defined up to a constant, and the quantity $\tilde{\mathcal{H}}^0$ can be neglected.

The operator $\tilde{\mathcal{H}}^1$ is a linear combination of creation and annihilation operators:

$$\tilde{\mathcal{H}}^1=\int D\phi\tilde{A}^+[\phi(\cdot)]Z[\phi(\cdot)]+\int D\phi\tilde{A}^-[\phi(\cdot)]Z^*[\phi(\cdot)],$$

with

$$Z[\phi(\cdot)]=\int d\mathbf{x}\left[-\frac{1}{2}\frac{\delta^2}{\delta\phi(\mathbf{x})\delta\phi(\mathbf{x})}+\frac{1}{2}(\nabla\phi(\mathbf{x}))^2+\frac{m^2+\lambda(\Phi_0,\phi^2(\mathbf{x})\Phi_0)}{2}\phi^2(\mathbf{x})\right]\Phi_0[\phi(\cdot)].$$

The operator $\tilde{\mathcal{H}}^1$ vanishes if and only if

$$Z=\text{const}\,\Phi_0. \tag{2.18}$$

We choose the functional Φ_0 to be a vacuum state functional for the field of the mass μ,

$$\Phi_0[\phi(\cdot)]=\text{const}\exp\left[-\frac{1}{2}\int d\mathbf{x}\phi(\mathbf{x})\sqrt{-\Delta+\mu^2}\phi(\mathbf{x})\right], \tag{2.19}$$

so that Eq. (2.18) will take the form

$$\mu^2=m^2+\lambda(\Phi_0,\phi^2(\mathbf{x})\Phi_0). \tag{2.20}$$

This is a well-known equation in the $1/N$-expansion theory (see, for example, Ref. 9).

The remaining nonvanishing as $N\to\infty$ part of the Hamiltonian is quadratic in creation and annihilation operators,

$$\tilde{H}\equiv\tilde{\mathcal{H}}^2=\int D\phi\tilde{A}^+[\phi(\cdot)]:\int d\mathbf{x}\mathcal{E}(\mathbf{x}):\tilde{A}^-[\phi(\cdot)]+\frac{\lambda}{4}\int d\mathbf{x}Q_0^2(\mathbf{x}), \tag{2.21}$$

where: $\hat{O}:=\hat{O}-(\Phi_0,\hat{O}\Phi_0)$,

$$\mathcal{E}(\mathbf{x})=\left[-\frac{1}{2}\frac{\delta^2}{\delta\phi(\mathbf{x})\delta\phi(\mathbf{x})}+\frac{1}{2}(\nabla\phi(\mathbf{x}))^2+\frac{\mu^2}{2}\phi^2(\mathbf{x})\right],$$

$$Q_0(\mathbf{x})=\int D\phi(\tilde{A}^+[\phi(\cdot)]+\tilde{A}^-[\phi(\cdot)])\phi^2(\mathbf{x})\Phi_0[\phi(\cdot)].$$

Since the term (2.21) is the only term remaining as $N=\infty$, one can say that the theory of $N=\infty$ fields is as follows. States in this theory are sets (2.7) obeying Eq. (2.5). The Hamiltonian of the model has the form (2.21), the evolution equation is $i\dot{f}=\tilde{H}f$.

D. Representation of the Poincare algebra

We have specified the state space of the theory of $N=\infty$ fields and evolution operator. However, to construct the *relativistic* quantum theory, it is necessary to specify the operators $U_{\Lambda,a}$ corresponding to Poincare transformations

$$x'^{\mu}=\Lambda^{\mu}_{\nu}x^{\nu}+a^{\mu},\quad \mu,\nu=\overline{0,d},$$

where the matrix Λ of Lorentz transformation satisfies the property

$$\Lambda^T g\Lambda=g,$$

($g=\text{diag}\{1,-1,-1,\ldots\}$, Λ^T is the matrix transposed to Λ). The composition law of the Poincare transformations is

$$(\Lambda_1,a_1)(\Lambda_2,a_2)=(\Lambda_1\Lambda_2,a_1+\Lambda_1a_2),$$

so that any Poincare transformation can be presented as $(\Lambda,a)=(0,a)(\Lambda,0)$. Furthermore, one can introduce the local coordinates $\theta_{\lambda\mu}$ ($\lambda,\mu=\overline{1,d}$, $\theta_{\lambda\mu}=-\theta_{\mu\lambda}$) on the Lorentz group,[2] such that

$$\Lambda=\exp(\tfrac{1}{2}\theta_{\lambda\mu}l^{\lambda\mu}),$$

with

$$(l^{\lambda\mu})^{\alpha}_{\beta}=-g^{\lambda\alpha}\delta^{\mu}_{\beta}+g^{\mu\alpha}\delta^{\lambda}_{\beta}.$$

The operators $U_{\Lambda,a}$ are required to form the representation of the Poincare group, so that

$$U_{\Lambda_1,a_1}U_{\Lambda_2,a_2}=U_{(\Lambda_1,a_1)(\Lambda_2,a_2)}.$$

Making use of the theory of representations of the Lie groups, one finds[2]

$$U_{\Lambda,a}=\exp(i\tilde{P}^{\mu}a_{\mu})\exp\left(\frac{i}{2}\tilde{M}^{\lambda\mu}\theta_{\lambda\mu}\right),$$

for some operators $\tilde{P}^{\mu}$ and $\tilde{M}^{\lambda\mu}$ obeying the commutation relations of the Poincare algebra

$$[\tilde{P}^{\lambda},\tilde{P}^{\mu}]=0,\quad [\tilde{M}^{\lambda\mu},\tilde{P}^{\nu}]=i(g^{\mu\nu}\tilde{P}^{\lambda}-g^{\lambda\nu}\tilde{P}^{\mu}),$$

$$[\tilde{M}^{\lambda\mu},\tilde{M}^{\rho\sigma}]=-i(g^{\lambda\rho}\tilde{M}^{\mu\sigma}-g^{\mu\rho}\tilde{M}^{\lambda\sigma}+g^{\mu\sigma}\tilde{M}^{\lambda\rho}-g^{\lambda\sigma}\tilde{M}^{\mu\rho}). \tag{2.22}$$

Let us construct the operators $\tilde{P}^{\lambda}$ and $\tilde{M}^{\lambda\mu}$ for the $N=\infty$-theory. For the N-field theory, one has:[1]

$$\mathcal{P}^{\mu}_{N}=\int d\mathbf{x}\mathcal{T}^{\mu 0}_{N}(\mathbf{x}),\quad \mathcal{M}^{\mu\lambda}_{N}=\int d\mathbf{x}(x^{\mu}\mathcal{T}^{\lambda 0}_{N}(\mathbf{x})-x^{\lambda}\mathcal{T}^{\mu 0}_{N}(\mathbf{x})),$$

where we integrate over surface $x^0=0$, while

$$\mathcal{T}^{00}_{N}(\mathbf{x})=-\frac{1}{2}\frac{\delta^2}{\delta\varphi^a(\mathbf{x})\delta\varphi^a(\mathbf{x})}+\frac{1}{2}(\nabla\varphi^a)(\mathbf{x})(\nabla\varphi^a)(\mathbf{x})+\frac{m^2}{2}\varphi^a(\mathbf{x})\varphi^a(\mathbf{x})+\frac{\lambda}{4N}(\varphi^a(\mathbf{x})\varphi^a(\mathbf{x}))^2,$$

$$\mathcal{T}^{k0}_{N}(\mathbf{x})=\sum_{a=1}^{N}\left(\partial^k\varphi^a(\mathbf{x})\frac{1}{i}\frac{\delta}{\delta\varphi^a(\mathbf{x})}\right).$$

Let us commute these operators with the multifield canonical operator,

$$\mathcal{P}^{\mu}_{N}K_N=K_N\tilde{\mathcal{P}}^{\mu}_{N},\quad \mathcal{M}^{\mu\nu}_{N}K_N=K_N\tilde{\mathcal{M}}^{\mu\nu}_{N},$$

expand the result in $1/N$:

$$\tilde{\mathcal{P}}^{\mu}_{N}=N\tilde{\mathcal{P}}^{\mu,0}+N^{1/2}\tilde{\mathcal{P}}^{\mu,1}+\tilde{\mathcal{P}}^{\mu,2}+\ldots,\ \tilde{\mathcal{M}}^{\mu\nu}_{N}=N\tilde{\mathcal{M}}^{\mu\nu,0}+N^{1/2}\tilde{\mathcal{M}}^{\mu\nu,1}+\tilde{\mathcal{M}}^{\mu\nu,2}+\ldots.$$

It will be shown that the operators $\tilde{\mathcal{P}}^{\mu,0}$, $\tilde{\mathcal{P}}^{\mu,1}$, $\tilde{\mathcal{M}}^{\mu\nu,0}$, and $\tilde{\mathcal{M}}^{\mu\nu,1}$ vanish, so that the remaining nonvanishing at $N=\infty$ parts

$$\tilde{P}^{\mu}=\tilde{\mathcal{P}}^{\mu,2},\quad \tilde{M}^{\mu\nu}=\tilde{\mathcal{M}}^{\mu\nu,2},$$

should be viewed as generators of Poincare transformations in the $N=\infty$-theory.

Be mindful also that the operator $\tilde{\mathcal{P}}^{0}_{N}=\tilde{H}$ has been already constructed in Sec. II C.

Consider the operator

$$\mathcal{P}^{k}_{N}=\int d\mathbf{x}\sum_{a=1}^{N}\partial^k\varphi^a(\mathbf{x})\frac{1}{i}\frac{\delta}{\delta\varphi^a(\mathbf{x})}.$$

After commuting with multifield canonical operator, one has

$$\tilde{\mathcal{P}}^{k,0}=\left(\Phi_0,\int d\mathbf{x}\partial^k\phi(\mathbf{x})\frac{1}{i}\frac{\delta}{\delta\phi(\mathbf{x})}\Phi_0\right),$$

$$\tilde{\mathcal{P}}^{k,1}=\int D\phi(\tilde{A}^+[\phi(\cdot)]Z^k[\phi(\cdot)]+\tilde{A}^-[\phi(\cdot)]Z^{k*}[\phi(\cdot)]), \tag{2.23}$$

where

$$Z^k[\phi(\cdot)]=\int d\mathbf{x}\partial^k\phi(\mathbf{x})\frac{1}{i}\frac{\delta}{\delta\phi(\mathbf{x})}\Phi_0[\phi(\cdot)].$$

Since Φ_0 has been chosen to be a vacuum functional for the field of the mass μ, while the operator $\int d\mathbf{x}\partial^k\phi(\mathbf{x})\,1/i\,\delta/\delta\phi(\mathbf{x})$ is a momentum operator for the functional Schrodinger representation, one has $Z^k=0$, $\tilde{\mathcal{P}}^{k,0}=0$, and $\tilde{\mathcal{P}}^{k,1}=0$. Thus, the operator

$$\tilde{P}^k\equiv\tilde{\mathcal{P}}^{k,2}=\int D\phi\tilde{A}^+[\phi(\cdot)]:\int d\mathbf{x}\partial^k\phi(\mathbf{x})\frac{1}{i}\frac{\delta}{\delta\phi(\mathbf{x})}:\tilde{A}^+[\phi(\cdot)], \tag{2.24}$$

can be viewed as a momentum operator in the $N=\infty$ theory.

Analogously, we find that

$$\tilde{M}^{ml}=\tilde{\mathcal{M}}^{ml,2}=\int D\phi\tilde{A}^+[\phi(\cdot)]:\int d\mathbf{x}(x^m\partial^l\phi(\mathbf{x})-x^l\partial^m\phi(\mathbf{x}))\frac{1}{i}\frac{\delta}{\delta\phi(\mathbf{x})}:\tilde{A}^-[\phi(\cdot)]. \tag{2.25}$$

The boost operator presented as

$$\mathcal{M}^{k0}=\int d\mathbf{x}x^k\mathcal{T}^{00}(\mathbf{x}),$$

after commuting with the multiparticle canonical operator gives us:

$$\tilde{\mathcal{M}}^{k0,0}=\int d\mathbf{x}x^k(\Phi^0,\mathcal{E}_0(\mathbf{x})\Phi_0)+\frac{\lambda}{4}\int d\mathbf{x}x^k(\Phi_0,\phi(\mathbf{x})\phi(\mathbf{x})\Phi_0).$$

Since the integrand is an odd function with respect to x^m, it seems to be natural that $\tilde{\mathcal{M}}^{m0,0}=0$. The operator $\tilde{\mathcal{M}}^{k0,1}$ has the structure (2.23) with

$$Z^k[\phi(\cdot)]=\int d\mathbf{x}x^k\mathcal{E}(\mathbf{x})\Phi_0[\phi(\cdot)].$$

Since the vacuum state Φ_0 is invariant under boost transformations, while

$$\int d\mathbf{x}x^k\mathcal{E}(\mathbf{x}),$$

is a boost generator, one has $Z^k=0$ and $\tilde{\mathcal{M}}^{k0,1}=0$. The remaining term is

$$\tilde{M}^{k0}=\tilde{\mathcal{M}}^{k0,2}=\int D\phi\tilde{A}^+[\phi(\cdot)]\int d\mathbf{x}x^k:\mathcal{E}(\mathbf{x}):\tilde{A}^-[\phi(\cdot)]+\frac{\lambda}{4}\int d\mathbf{x}x^kQ_0^2(\mathbf{x}). \tag{2.26}$$

The commutation relations (2.22) are formally satisfied. Namely, the operators (2.21), (2.24), (2.25), and (2.26) can be presented as

$$\tilde{H}=\tilde{H}_0+\lambda\tilde{H}_1, \quad \tilde{P}^k=\tilde{P}^k_0,$$

$$\tilde{M}^{k0}=\tilde{M}^{k0}_0+\lambda\tilde{M}^{k0}_1, \quad \tilde{M}^{kl}=\tilde{M}^{kl}_0. \tag{2.27}$$

For $\lambda=0$-case, the check of relations (2.22) is identical to the standard check of the Poincare invariance of the free QFT. For the general case, it is sufficient to justify the following commutation relations:

$$[\tilde{H}_1,\tilde{P}^k_0]=0, \quad [\tilde{H}_1,\tilde{M}^{kl}_0]=0, \tag{2.28}$$

$$[\tilde{M}^{k0}_1,\tilde{P}^l_0]=-ig^{kl}\tilde{H}_1, \quad [\tilde{M}^{k0}_1,\tilde{M}^{mn}_0]=-i(g^{km}\tilde{M}^{0n}_1-g^{kn}\tilde{M}^{0m}_1). \tag{2.29}$$

$$[\tilde{M}^{k0}_1,\tilde{M}^{l0}_1]=0, \quad [\tilde{M}^{k0}_1,\tilde{H}_1]=0, \tag{2.30}$$

$$[\tilde{M}^{k0}_1,\tilde{H}_0]+[\tilde{M}^{k0}_0,\tilde{H}_1]=0, \quad [\tilde{M}^{k0}_1,\tilde{M}^{l0}_0]+[\tilde{M}^{k0}_0,\tilde{M}^{l0}_1]=0. \tag{2.31}$$

It is straightforward to check that

$$[\tilde{P}^l_0,Q_0(\mathbf{x})]=-i\partial^l Q_0(\mathbf{x}), \quad [\tilde{M}^{mn}_0,Q_0(\mathbf{x})]=-i(x^m\partial^n-x^n\partial^m)Q_0(\mathbf{x}).$$

We obtain relations (2.28) and (2.29) then. Equations (2.30) are corollaries of the property $[Q(\mathbf{x}),Q(\mathbf{y})]=0$. The relation $[\mathcal{E}(\mathbf{x}),Q_0(\mathbf{y})]\sim\delta(\mathbf{x}-\mathbf{y})$ imply Eq. (2.31). Thus, the formal Poincare invariance is checked. However, the divergences and renormalization have not been considered yet.

E. Mode decomposition

We have specified states of the $N=\infty$-theory as sets

$$f=\begin{pmatrix} f_0 \\ f_1[\varphi^1(\cdot)] \\ \cdots \\ f_k[\varphi^1(\cdot),\ldots,\varphi^k(\cdot)] \\ \cdots \end{pmatrix} \tag{2.32}$$

of symmetric functionals $f_k[\varphi^1,\ldots,\varphi^k]$ satisfying relation (2.5) such that

$$||f||^2=\sum_{k=0}^{\infty}\int D\varphi^1,\ldots,D\varphi^k|f[\varphi^1(\cdot),\ldots,\varphi^k(\cdot)]|^2<\infty.$$

However, this definition is ill defined since the measure of functional integration is not determined mathematically. Instead of constructing the measure, it is convenient to use another representation for the k-field functionals.

Consider the basis functionals

$$\Phi^{(n)}_{\mathbf{k}_1\ldots\mathbf{k}_n}[\varphi(\cdot)]=\frac{1}{\sqrt{n!}}a^+_{\mathbf{k}_1}\ldots a^+_{\mathbf{k}_n}\Phi_0[\varphi(\cdot)], \quad n=1,2,3,\ldots, \tag{2.33}$$

corresponding to n particles with momenta $\mathbf{k}_1,\ldots,\mathbf{k}_n$. The operators $a^+_{\mathbf{k}}$ are usual quantum field creation operators:

$$a^+_{\mathbf{k}}=\frac{1}{(2\pi)^{d/2}}\int d\mathbf{x}e^{i\mathbf{kx}}\left[\sqrt{\frac{\omega_{\mathbf{k}}}{2}}\varphi(\mathbf{x})-\frac{1}{\sqrt{2\omega_{\mathbf{k}}}}\frac{\delta}{\delta\varphi(\mathbf{x})}\right],$$

with $\omega_{\mathbf{k}}=\sqrt{\mathbf{k}^2+\mu^2}$. Integrating by parts and using the commutation relations between creation and annihilation operators, we find that the inner product (2.1) for the functionals (2.33) has the form

$$(\Phi^{(n)}_{\mathbf{k}_1\dots\mathbf{k}_n},\Phi^{(m)}_{\mathbf{p}_1\dots\mathbf{p}_m})=0,\quad m\neq n;$$

$$(\Phi^{(n)}_{\mathbf{k}_1\dots\mathbf{k}_n},\Phi^{(n)}_{\mathbf{p}_1\dots\mathbf{p}_n})=\frac{1}{n!}\sum_{\sigma}\ \delta(\mathbf{k}_1-\mathbf{p}_{\sigma_1})\dots\delta(\mathbf{k}_n-\mathbf{p}_{\sigma_n}),\tag{2.34}$$

the sum is taken over all transpositions of indices 1,...,n. Equations (2.34) can be viewed as a definition of the functional integral (2.1).

Decompose the functional f_k satisfying Eq. (2.5) as

$$\begin{aligned}&f_k(\varphi^1(\cdot),\dots,\varphi^k(\cdot))\\&\quad=\sum_{l_1\dots l_k=1}^{\infty}\int d\mathbf{p}^1_1\dots d\mathbf{p}^1_{l_1}\dots d\mathbf{p}^k_1\dots d\mathbf{p}^k_{l_k}f^k_{l_1;\mathbf{p}^1_1\dots\mathbf{p}^1_{l_1};\dots l_k,\mathbf{p}^k_1\dots\mathbf{p}^k_{l_k}}\Phi^{(l_1)}_{\mathbf{p}^1_1\dots\mathbf{p}^1_{l_1}}\\&\qquad[\phi^1(\cdot)]\dots\Phi^{(l_k)}_{\mathbf{p}^k_1\dots\mathbf{p}^k_{l_k}}[\phi^k(\cdot)].\end{aligned}$$

One can uniquely specify the set (2.32) of functionals by specifying the set of functionals

$$f^k_{l_1;\mathbf{p}^1_1\dots\mathbf{p}^1_{l_1};\dots l_k,\mathbf{p}^k_1\dots\mathbf{p}^k_{l_k}},\tag{2.35}$$

being symmetric under transpositions of $\mathbf{p}^m_i$ and $\mathbf{p}^m_j$, as well as under transpositions of sets $l_m,\mathbf{p}^m_1\dots\mathbf{p}^m_{l_m}$, and $l_s,\mathbf{p}^s_1\dots\mathbf{p}^s_{l_s}$. The quantity $||f||^2$ can be presented as

$$||f||^2=\sum_{k=0}^{\infty}\sum_{l_1\dots l_k=1}^{\infty}\int d\mathbf{p}^1_1\dots d\mathbf{p}^1_{l_1}\dots d\mathbf{p}^k_1\dots d\mathbf{p}^k_{l_k}|f^k_{l_1;\mathbf{p}^1_1\dots\mathbf{p}^1_{l_1};\dots l_k,\mathbf{p}^k_1\dots\mathbf{p}^k_{l_k}}|^2.$$

Creation and annihilation operators can be decomposed as

$$A^+[\varphi(\cdot)]=\sum_{n=0}^{\infty}\int d\mathbf{k}_1\dots d\mathbf{k}_n\Phi^{(n)*}_{\mathbf{k}_1\dots\mathbf{k}_n}[\varphi(\cdot)]A^{+(n)}_{\mathbf{k}_1\dots\mathbf{k}_n}.$$

$$A^-[\varphi(\cdot)]=\sum_{n=0}^{\infty}\int d\mathbf{k}_1\dots d\mathbf{k}_n\Phi^{(n)}_{\mathbf{k}_1\dots\mathbf{k}_n}[\varphi(\cdot)]A^{-(n)}_{\mathbf{k}_1\dots\mathbf{k}_n}.\tag{2.36}$$

The operators $A^{\pm(n)}_{\mathbf{k}_1\dots\mathbf{k}_n}$ defined as

$$A^{+(n)}_{\mathbf{k}_1\dots\mathbf{k}_n}=\int D\phi A^+[\phi(\cdot)]\Phi^{(n)}_{\mathbf{k}_1\dots\mathbf{k}_n}[\phi(\cdot)],\quad A^{-(n)}_{\mathbf{k}_1\dots\mathbf{k}_n}=\int D\phi A^-[\phi(\cdot)]\Phi^{*(n)}_{\mathbf{k}_1\dots\mathbf{k}_n}[\phi(\cdot)],$$

create (annihilate) the field in the n-particle state with momenta $\mathbf{k}_1,\dots,\mathbf{k}_n$. They are invariant under transpositions of momenta $\mathbf{k}_1,\dots,\mathbf{k}_n$ and obey the ordinary canonical commutation relations:

$$[A^{\pm(m)}_{\mathbf{k}_1\dots\mathbf{k}_m},A^{\pm(n)}_{\mathbf{p}_1\dots\mathbf{p}_n}]=0,\quad [A^{-(m)}_{\mathbf{k}_1\dots\mathbf{k}_m},A^{+(n)}_{\mathbf{p}_1\dots\mathbf{p}_n}]=0,m\neq n\tag{2.37}$$

$$[A^{-(m)}_{\mathbf{k}_1\dots\mathbf{k}_m}, A^{+(n)}_{\mathbf{p}_1\dots\mathbf{p}_n}] = \frac{1}{n!}\sum_{\sigma}\ \delta(\mathbf{k}_1-\mathbf{p}_{\sigma_1})\dots\delta(\mathbf{k}_n-\mathbf{p}_{\sigma_n}). \tag{2.38}$$

Any vector f can be written via creation operators and vacuum state

$$|0\rangle = \begin{pmatrix} 1 \\ 0 \\ \cdots \\ 0 \\ \cdots \end{pmatrix} \tag{2.39}$$

as follows:

$$f = \sum_{k=0}^{\infty}\frac{1}{\sqrt{k!}}\sum_{l_1\dots l_k=1}^{\infty}\int d\mathbf{p}^1_1\dots d\mathbf{p}^1_{l_1}\dots d\mathbf{p}^k_1\dots d\mathbf{p}^k_{l_k}$$
$$f^k_{l_1;\mathbf{p}^1_1\dots\mathbf{p}^1_{l_1};\dots l_k,\mathbf{p}^k_1\dots\mathbf{p}^k_{l_k}} A^{+(l_1)}_{\mathbf{p}^1_1\dots\mathbf{p}^1_{l_1}}\dots A^{+(l_k)}_{\mathbf{p}^k_1\dots\mathbf{p}^k_{l_k}}|0\rangle.$$

Making use of the QFT formulas:

$$\int d\mathbf{x}\mathcal{E}(\mathbf{x}) := \int d\mathbf{k}\omega_{\mathbf{k}}a^+_{\mathbf{k}}a^-_{\mathbf{k}},$$

$$\phi^2(\mathbf{x})\Phi_0 = \frac{1}{(2\pi)^d}\int\frac{d\mathbf{k}}{\sqrt{2\omega_{\mathbf{k}}}}\frac{d\mathbf{p}}{\sqrt{2\omega_{\mathbf{p}}}}e^{-i(\mathbf{k}+\mathbf{p})\mathbf{x}}a^+_{\mathbf{k}}a^+_{\mathbf{p}}\Phi_0, \tag{2.40}$$

one transforms expression (2.21) to the following form:

$$\tilde{H} = \sum_{n=1}^{\infty}\int d\mathbf{k}_1\dots d\mathbf{k}_n A^{+(n)}_{\mathbf{k}_1\dots\mathbf{k}_n}(\omega_{\mathbf{k}_1}+\dots+\omega_{\mathbf{k}_n})A^{-(n)}_{\mathbf{k}_1\dots\mathbf{k}_n}$$
$$+\frac{\lambda}{4}\int d\mathbf{x}\left(\frac{\sqrt{2}}{(2\pi)^d}\int\frac{d\mathbf{k}_1}{\sqrt{2\omega_{\mathbf{k}_1}}}\frac{d\mathbf{k}_2}{\sqrt{2\omega_{\mathbf{k}_2}}}(A^{+(2)}_{\mathbf{k}_1\mathbf{k}_2}e^{-i(\mathbf{k}_1+\mathbf{k}_2)\mathbf{x}}+A^{-(2)}_{\mathbf{k}_1\mathbf{k}_2}e^{i(\mathbf{k}_1+\mathbf{k}_2)\mathbf{x}})\right)^2. \tag{2.41}$$

Analogously,

$$\tilde{P}^l = \sum_{n=1}^{\infty}\int d\mathbf{k}_1\dots d\mathbf{k}_n A^{+(n)}_{\mathbf{k}_1\dots\mathbf{k}_n}(k^l_1+\dots+k^l_n)A^{-(n)}_{\mathbf{k}_1\dots\mathbf{k}_n},$$

$$\tilde{M}^{ml} = \sum_{n=1}^{\infty}\int d\mathbf{k}_1\dots d\mathbf{k}_n A^{+(n)}_{\mathbf{k}_1\dots\mathbf{k}_n}\sum_{s=1}^{n}\left(k^l_s i\frac{\partial}{\partial k^m_s}-k^m_s i\frac{\partial}{\partial k^l_s}\right)A^{-(n)}_{\mathbf{k}_1\dots\mathbf{k}_n},$$

$$\tilde{M}^{l0} = \sum_{n=1}^{\infty}\int d\mathbf{k}_1\dots d\mathbf{k}_n A^{+(n)}_{\mathbf{k}_1\dots\mathbf{k}_n}\sum_{s=1}^{n}\left(i\omega_{\mathbf{k}_s}\frac{\partial}{\partial k^l_s}+i\frac{k^l_s}{2\omega_{\mathbf{k}_s}}\right)A^{-(n)}_{\mathbf{k}_1\dots\mathbf{k}_n} \tag{2.42}$$
$$+\frac{\lambda}{4}\int d\mathbf{x}x^l\left(\frac{\sqrt{2}}{(2\pi)^d}\int\frac{d\mathbf{k}_1}{\sqrt{2\omega_{\mathbf{k}_1}}}\frac{d\mathbf{k}_2}{\sqrt{2\omega_{\mathbf{k}_2}}}(A^{+(2)}_{\mathbf{k}_1\mathbf{k}_2}e^{-i(\mathbf{k}_1+\mathbf{k}_2)\mathbf{x}}+A^{-(2)}_{\mathbf{k}_1\mathbf{k}_2}e^{i(\mathbf{k}_1+\mathbf{k}_2)\mathbf{x}})\right)^2.$$

F. Decomposition of the state space

We see that the Hilbert space of the $N=\infty$-theory can be presented as

$$\mathcal{F}(\oplus_{n=1}^{\infty}\mathcal{H}^{\vee n}) \tag{2.43}$$

(the notations of Appendix A are used), where $\mathcal{H}$ is a space of complex functions $f_{\mathbf{k}}$, $\mathbf{k}\in\mathbf{R}^d$ from $L^2(\mathbf{R}^d)$. Analogously to lemma A.8, the space (2.43) is isomorphic to

$$\mathcal{F}(\mathcal{H}^{\vee 2})\otimes\mathcal{F}(\mathcal{H}+\oplus_{n=3}^{\infty}\mathcal{H}^{\vee n})\equiv\mathcal{F}\otimes\check{\mathcal{F}}, \tag{2.44}$$

while the operators (2.41) and (2.42) can be viewed as the following operators in the space (2.44):

$$\tilde{H}=H\otimes 1+1\otimes\check{H},\quad \tilde{P}^k=P^k\otimes 1+1\otimes\check{P}^k,$$

$$\tilde{M}^{ml}=M^{ml}\otimes 1+1\otimes\check{M}^{ml},\quad \tilde{M}^{k0}=M^{k0}\otimes 1+1\otimes\check{M}^{k0}. \tag{2.45}$$

The operators $\check{H}$, $\check{P}^k$, $\check{M}^{kl}$, and $\check{M}^{k0}$ are the same as in the free theory:

$$\begin{aligned}
\check{H}&=\sum_{n=1,3,4,\dots}\int d\mathbf{k}_1\dots d\mathbf{k}_n A^{+(n)}_{\mathbf{k}_1\dots\mathbf{k}_n}(\omega_{\mathbf{k}_1}+\dots+\omega_{\mathbf{k}_n})A^{-(n)}_{\mathbf{k}_1\dots\mathbf{k}_n},\\
\check{P}^l&=\sum_{n=1,3,4\dots}\int d\mathbf{k}_1\dots d\mathbf{k}_n A^{+(n)}_{\mathbf{k}_1\dots\mathbf{k}_n}(k_1^l+\dots+k_n^l)A^{-(n)}_{\mathbf{k}_1\dots\mathbf{k}_n},\\
\check{M}^{ml}&=\sum_{n=1,3,4,\dots}\int d\mathbf{k}_1\dots d\mathbf{k}_n A^{+(n)}_{\mathbf{k}_1\dots\mathbf{k}_n}\sum_{s=1}^{n}\left(k_s^l i\frac{\partial}{\partial k_s^m}-k_s^m i\frac{\partial}{\partial k_s^l}\right)A^{-(n)}_{\mathbf{k}_1\dots\mathbf{k}_n},\\
\tilde{M}^{l0}&=\sum_{n=1,3,4,\dots}\int d\mathbf{k}_1\dots d\mathbf{k}_n A^{+(n)}_{\mathbf{k}_1\dots\mathbf{k}_n}\sum_{s=1}^{n}\left(i\omega_{\mathbf{k}_s}\frac{\partial}{\partial k_s^l}+i\frac{k_s^l}{2\omega_{\mathbf{k}_s}}\right)A^{-(n)}_{\mathbf{k}_1\dots\mathbf{k}_n}.
\end{aligned} \tag{2.46}$$

The only nontrivial part of operators (2.45) correspond to the space $\mathcal{F}(\mathcal{H}^{\vee 2})$:

$$\begin{aligned}
H&=\int d\mathbf{k}_1 d\mathbf{k}_2 A^{+(2)}_{\mathbf{k}_1\mathbf{k}_2}(\omega_{\mathbf{k}_1}+\omega_{\mathbf{k}_2})A^{-(2)}_{\mathbf{k}_1\mathbf{k}_2}+\frac{\lambda}{4}\int d\mathbf{x}\\
&\left(\frac{\sqrt{2}}{(2\pi)^d}\int\frac{d\mathbf{k}_1}{\sqrt{2\omega_{\mathbf{k}_1}}}\frac{d\mathbf{k}_2}{\sqrt{2\omega_{\mathbf{k}_2}}}(A^{+(2)}_{\mathbf{k}_1\mathbf{k}_2}e^{-i(\mathbf{k}_1+\mathbf{k}_2)\mathbf{x}}+A^{-(2)}_{\mathbf{k}_1\mathbf{k}_2}e^{i(\mathbf{k}_1+\mathbf{k}_2)\mathbf{x}})\right)^2.\\
\tilde{P}^l&=\int d\mathbf{k}_1 d\mathbf{k}_2 A^{+(2)}_{\mathbf{k}_1\mathbf{k}_2}(k_1^l+k_2^l)A^{-(2)}_{\mathbf{k}_1\mathbf{k}_2}\\
M^{ml}&=\int d\mathbf{k}_1 d\mathbf{k}_2 A^{+(2)}_{\mathbf{k}_1\mathbf{k}_2}\sum_{s=1}^{2}\left(k_s^l i\frac{\partial}{\partial k_s^m}-k_s^m i\frac{\partial}{\partial k_s^l}\right)A^{-(2)}_{\mathbf{k}_1\mathbf{k}_2}.
\end{aligned} \tag{2.47}$$

$$\begin{aligned}
M^{l0}&=\int d\mathbf{k}_1 d\mathbf{k}_2 A^{+(2)}_{\mathbf{k}_1\mathbf{k}_2}\sum_{s=1}^{2}\left(i\omega_{\mathbf{k}_s}\frac{\partial}{\partial k_s^l}+i\frac{k_s^l}{2\omega_{\mathbf{k}_s}}\right)A^{-(2)}_{\mathbf{k}_1\mathbf{k}_2}\\
&+\frac{\lambda}{4}\int d\mathbf{x}x^l\left(\frac{\sqrt{2}}{(2\pi)^d}\int\frac{d\mathbf{k}_1}{\sqrt{2\omega_{\mathbf{k}_1}}}\frac{d\mathbf{k}_2}{\sqrt{2\omega_{\mathbf{k}_2}}}(A^{+(2)}_{\mathbf{k}_1\mathbf{k}_2}e^{-i(\mathbf{k}_1+\mathbf{k}_2)\mathbf{x}}+A^{-(2)}_{\mathbf{k}_1\mathbf{k}_2}e^{i(\mathbf{k}_1+\mathbf{k}_2)\mathbf{x}})\right)^2.
\end{aligned}$$

The operators (2.45) correspond to the representation of the Poincare group in $\mathcal{F}\otimes\check{\mathcal{F}}$ of the form:

$$\tilde{U}_{\Lambda,a}=U_{\Lambda,a}\otimes\check{U}_{\Lambda,a},$$

with

$$U_{\Lambda,a}=\exp(iP_\mu a^\mu)\exp\left(\frac{i}{2}M^{\Lambda\mu}\theta_{\lambda\mu}\right),\quad \check{U}_{\Lambda,a}=\exp(i\check{P}_\mu a^\mu)\exp\left(\frac{i}{2}\check{M}^{\lambda\mu}\theta_{\lambda\mu}\right).$$

To express the operators $\check{U}_{\Lambda,a}$, it is convenient to introduce the operators $u_{\Lambda,a}$ of the unitary representation of the Poincare group in $\mathcal{H}$:

$$(u_{\Lambda,a}f)_{\mathbf{k}}=\exp(i\omega_{\mathbf{k}}a_0-i\mathbf{ka})\sqrt{\frac{(\Lambda^{-1})^0_n k^n+(\Lambda^{-1})^0_0\omega_{\mathbf{k}}}{\omega_{\mathbf{k}}}}f_{(\Lambda^{-1})^m_n k^n+(\Lambda^{-1})^m_0\omega_{\mathbf{k}}},\tag{2.48}$$

with generators

$$p^l=k^l,\quad p^0=\omega_{\mathbf{k}},\quad m^{l0}=i\left(\omega_{\mathbf{k}}\frac{\partial}{\partial k^l}+\frac{k^l}{2\omega_{\mathbf{k}}}\right),$$
$$m^{ln}=i\left(k^n\frac{\partial}{\partial k^l}-k^l\frac{\partial}{\partial k^n}\right).\tag{2.49}$$

By $\tilde{u}_{\Lambda,a}:\mathcal{H}\oplus\oplus_{n=3}^{\infty}\mathcal{H}^{\vee n}\to\mathcal{H}\oplus\oplus_{n=3}^{\infty}\mathcal{H}^{\vee n}$, we denote the operator

$$\tilde{u}_{\Lambda,a}(f_1,f_3,f_4,\dots)=(u_{\Lambda,a}f_1,u^{\otimes 3}_{\Lambda,a}f_3,u^{\otimes 4}_{\Lambda,a}f_4,\dots).$$

We can notice that

$$\check{U}_{\Lambda,a}=\mathcal{U}(\tilde{u}_{\Lambda,a})$$

(the notations of Appendix A are used).

Thus, the operators $\check{U}_{\Lambda,a}$ are constructed. The only nontrivial problem is to construct the representation of the Poincare group corresponding to the generators (2.47).

G. Problem of divergences

1. The Haag theorem and volume divergences

Apply the Hamiltonian (2.47) to the vacuum state. The result will be

$$H|0\rangle=\frac{\lambda}{4}\frac{2}{(2\pi)^d}\int\frac{d\mathbf{k}_1}{\sqrt{2\omega_{\mathbf{k}_1}}}\frac{d\mathbf{k}_2}{\sqrt{2\omega_{\mathbf{k}_2}}}\frac{d\mathbf{p}_1}{\sqrt{2\omega_{\mathbf{p}_1}}}\frac{d\mathbf{p}_1}{\sqrt{2\omega_{\mathbf{p}_2}}}A^+_{\mathbf{k}_1\mathbf{k}_2}A^+_{\mathbf{p}_1\mathbf{p}_2}\delta(\mathbf{k}_1+\mathbf{k}_2+\mathbf{p}_1+\mathbf{p}_2)|0\rangle,$$

where $A^+_{\mathbf{k}_1\mathbf{k}_2}\equiv A^{+(2)}_{\mathbf{k}_1\mathbf{k}_2}$. Because of the δ function, the quantity $||H\Phi^{(0)}||^2$ diverges. This is a volume divergence associated with the Haag theorem (see, for example, Ref. 2). An analogous infinite quantity appears when one applied the perturbation theory in λ for the evolution operator.

Within the perturbation theory, such difficulty can be resolved with the help of the Faddeev transformation.[6]

2. The Stueckelberg divergences

Even after removing the vacuum divergences, the problem is not completely resolved. If one considers the perturbation theory for the Schrodinger equation of motion, one finds that there are UV divergences even in the tree approximation. Namely, for the first order of the perturbation theory, one has

$$e^{iH_0t}\tilde{H}_1e^{-iH_0t}\equiv\tilde{H}_1(t)=\frac{1}{(2\pi)^d}\int\frac{d\mathbf{k}_1}{\sqrt{2\omega_{\mathbf{k}_1}}}\frac{d\mathbf{k}_2}{\sqrt{2\omega_{\mathbf{k}_2}}}\frac{d\mathbf{p}_1}{\sqrt{2\omega_{\mathbf{p}_1}}}\frac{d\mathbf{p}_1}{\sqrt{2\omega_{\mathbf{p}_2}}}$$
$$A^+_{\mathbf{k}_1\mathbf{k}_2}A^-_{\mathbf{p}_1\mathbf{p}_2}\delta(\mathbf{k}_1+\mathbf{k}_2-\mathbf{p}_1-\mathbf{p}_2)e^{-it(\omega_{\mathbf{k}_1}\omega_{\mathbf{k}_2}+\omega_{\mathbf{p}_1}+\omega_{\mathbf{p}_2})}. \tag{2.50}$$

Applying the first-order evolution operator

$$U_t=-i\lambda\int_0^t d\tau\tilde{H}_1(\tau),$$

to the vector

$$\Phi^0=\int d\mathbf{p}_1d\mathbf{p}_2A^+_{\mathbf{p}_1\mathbf{p}_2}\Phi^0_{\mathbf{p}_1\mathbf{p}_2},$$

we find

$$U_t\Phi^0=\int d\mathbf{p}_1d\mathbf{p}_2A^+_{\mathbf{p}_1\mathbf{p}_2}\Phi^t_{\mathbf{p}_1\mathbf{p}_2},$$

with

$$\Phi^t_{\mathbf{k}_1\mathbf{k}_2}=\frac{1}{(2\pi)^d}\frac{1}{\sqrt{2\omega_{\mathbf{k}_1}}}\frac{1}{\sqrt{2\omega_{\mathbf{k}_2}}}\int\frac{1}{\sqrt{2\omega_{\mathbf{p}_1}}}\frac{1}{\sqrt{2\omega_{\mathbf{p}_2}}}\delta(\mathbf{k}_1+\mathbf{k}_2-\mathbf{p}_1-\mathbf{p}_2)$$
$$\Phi^{(0)}_{\mathbf{p}_1\mathbf{p}_2}\frac{e^{-it(\omega_{\mathbf{k}_1}+\omega_{\mathbf{k}_2}-\omega_{\mathbf{p}_1}-\omega_{\mathbf{p}_2})}-1}{i(\omega_{\mathbf{k}_1}+\omega_{\mathbf{k}_2}-\omega_{\mathbf{p}_1}-\omega_{\mathbf{p}_2})}.$$

The integral

$$\int d\mathbf{k}_1d\mathbf{k}_2|\Phi^t_{\mathbf{k}_1\mathbf{k}_2}|^2,$$

diverges for $d\geqslant 4$. This is a Stueckelberg divergence.

III. CONSTRUCTION OF THE HAMILTONIAN

The purpose of this section is to define mathematically the operators in the Hilbert space that corresponds to the formal expression (2.47). For $d+1=4$ and 5, it is necessary to perform the infinite renormalization of the coupling constant, for $d+1\geqslant 6$, the model is nonrenormalizable. Sections II A–C deal with the heuristic construction of the Hamiltonian; in Sec. II D, representation for space–time translations and spatial rotations is constructed.

A. Diagonalization of the Hamiltonian

Since the Hamiltonian (2.47) is quadratic with respect to creation and annihilation operators, one can perform the canonical transformation of creation and annihilation operators in order to take the Hamiltonian to the canonical form.

It is convenient to introduce new variables,

$$Q_{\mathbf{Ps}}=\frac{1}{\sqrt{2\Omega_{\mathbf{Ps}}}}(A^{+}_{\mathbf{P}/2-\mathbf{s},\mathbf{P}/2+\mathbf{s}}+A^{-}_{-\mathbf{P}/2-\mathbf{s},-\mathbf{P}/2+\mathbf{s}}),$$
$$\Pi_{\mathbf{Ps}}=i\sqrt{\frac{\Omega_{\mathbf{Ps}}}{2}}(A^{+}_{\mathbf{P}/2-\mathbf{s},\mathbf{P}/2+\mathbf{s}}-A^{-}_{-\mathbf{P}/2-\mathbf{s},-\mathbf{P}/2+\mathbf{s}}). \tag{3.1}$$

Here,

$$\Omega_{\mathbf{Ps}}=\omega_{\mathbf{P}/2-\mathbf{s}}+\omega_{\mathbf{P}/2-\mathbf{s}}. \tag{3.2}$$

The operators (3.1) obey the properties:

$$Q_{\mathbf{Ps}}=Q_{\mathbf{P},-\mathbf{s}}=Q^{*}_{-\mathbf{P},\mathbf{s}},\Pi_{\mathbf{Ps}}=\Pi_{\mathbf{P},-\mathbf{s}}=\Pi^{*}_{-\mathbf{P},\mathbf{s}},$$

and canonical commutation relations:

$$[Q_{\mathbf{Ps}},Q_{\mathbf{P}'\mathbf{s}'}]=0,\quad [\Pi_{\mathbf{Ps}},\Pi_{\mathbf{P}'\mathbf{s}'}]=0,\quad [Q_{\mathbf{Ps}},\Pi_{\mathbf{P}'\mathbf{s}'}]=i\,\delta_{\mathbf{PP}'}\,\tfrac{1}{2}(\delta_{\mathbf{s}-\mathbf{s}'}+\delta_{\mathbf{s}+\mathbf{s}'}).$$

The Hamiltonian takes the following form up to an additive constant:

$$H=\frac{1}{2}\int d\mathbf{P}(\Pi_{\mathbf{P}},\Pi_{\mathbf{P}})+\frac{1}{2}\int d\mathbf{P}(Q_{\mathbf{P}},(M_P)^2\mathbf{Q}_{\mathbf{P}}). \tag{3.3}$$

Here $\Pi_{\mathbf{P}}$, $Q_{\mathbf{P}}$ are operator-valued even functions of the variable $\mathbf{s}$. The inner product (f,g) of two even functions $f_{\mathbf{s}}$ and $g_{\mathbf{s}}$ is, as usual, $\int d\mathbf{s} f^{*}_{\mathbf{s}} g_{\mathbf{s}}$. $(M_{\mathbf{P}})^2$ is the following operator in the space of even functions:

$$((M_{\mathbf{P}})^2\varphi)_{\mathbf{s}}=\Omega^2_{\mathbf{Ps}}\varphi_s+\frac{\lambda}{(2\pi)^d}\int d\mathbf{s}'\sqrt{\frac{2\Omega_{\mathbf{Ps}}}{2\omega_{\mathbf{P}/2+\mathbf{s}}2\omega_{\mathbf{P}/2-\mathbf{s}}}}\sqrt{\frac{2\Omega_{\mathbf{Ps}'}}{2\omega_{\mathbf{P}/2+\mathbf{s}'}2\omega_{\mathbf{P}/2-\mathbf{s}'}}}\varphi_{\mathbf{s}'}. \tag{3.4}$$

The operator (3.3) can be diagonalized by the following procedure:

$$Q_{\mathbf{P}}=\frac{1}{\sqrt{2M_{\mathbf{P}}}}(C^{+}_{\mathbf{P}}+C^{-}_{-\mathbf{P}}),$$
$$\Pi_{\mathbf{P}}=i\sqrt{\frac{M_{\mathbf{P}}}{2}}(C^{+}_{\mathbf{P}}-C^{-}_{-\mathbf{P}}), \tag{3.5}$$

where $C^{\pm}_{\mathbf{P}}$ are operator-valued functions $C^{\pm}_{\mathbf{Ps}}$ of the variable $\mathbf{s}$. They obey the usual canonical commutation relations:

$$[C^{-}_{\mathbf{Ps}},C^{+}_{\mathbf{Ps}}]=\delta_{\mathbf{PP}'}\,\tfrac{1}{2}(\delta_{\mathbf{s}-\mathbf{s}'}+\delta_{\mathbf{s}+\mathbf{s}'}),\quad [C^{\pm}_{\mathbf{Ps}},C^{\pm}_{\mathbf{Ps}}]=0.$$

The Hamiltonian takes the form:

$$H=\int d\mathbf{P}d\mathbf{s}d\mathbf{s}'C^{+}_{\mathbf{Ps}}(M_{\mathbf{P}})_{\mathbf{ss}'}C^{-}_{\mathbf{Ps}'}. \tag{3.6}$$

The $(M_{\mathbf{P}})_{\mathbf{ss}'}$ is a matrix element of the operator $M_{\mathbf{P}}$.

One should use then another, nonFock representation for the operators $A^{\pm}_{\mathbf{k}_1\mathbf{k}_2}$, which is a Fock representation for the transformed operators $C^{\pm}_{\mathbf{Ps}}$. The Hamiltonian (3.6) is then a self-adjoint operator if $M_{\mathbf{P}}$ is self-adjoint. The evolution operator is expressed via the unitary operator $e^{-iM_{\mathbf{P}}t}$. To construct $M_{\mathbf{P}}$, one should first check that $(M_{\mathbf{P}})^2$ is a positively definite self-adjoint operator

and define $M_{\mathbf{P}}\equiv\sqrt{(M_{\mathbf{P}})^2}$, making use of the functional calculus of self-adjoint operators. The operator $(M_{\mathbf{P}})^{1/2}$ entering to expression (3.5) can be constructed in analogous way.

B. Definition of the Hamiltonian and its properties

Formula (3.4) for the operator $(M_{\mathbf{P}})^2$ is not well defined since the vector

$$\sqrt{\frac{2\Omega_{\mathbf{Ps}}}{2\omega_{\mathbf{P}/2+\mathbf{s}'}2\omega_{\mathbf{P}/2-\mathbf{s}'}}},$$

considered as a function of $\mathbf{s}$ does not belong to L^2. The operator (3.4) is therefore analogous to the quantum mechanical Hamiltonian corresponding to the particle moving in the singular potential like δ function. The theory of singular potentials is developed in Ref. 15.

To construct mathematically the (unbounded) self-adjoint operator $(M_{\mathbf{P}})^2$, one may first construct the (bounded) operator $(M_{\mathbf{P}})^{-2}$, and prove that it is invertible and positively definite. Then, the operator $(M_{\mathbf{P}})^2$ is defined as $(M_{\mathbf{P}})^2\equiv((M_{\mathbf{P}})^{-2})^{-1}$.

To find the vector

$$\varphi=(M_{\mathbf{P}})^{-2}\psi,$$

one should solve the equation $\psi=(M_{\mathbf{P}})^2\varphi$. It has the following form:

$$\begin{aligned}\psi_{\mathbf{s}}&=\Omega_{\mathbf{Ps}}^2\varphi_{\mathbf{s}}+c\sqrt{\frac{2\Omega_{\mathbf{Ps}}}{2\omega_{\mathbf{P}/2+\mathbf{s}}2\omega_{\mathbf{P}/2-\mathbf{s}}}},\\ c&=\frac{\lambda}{(2\pi)^d}\int d\mathbf{s}\sqrt{\frac{2\Omega_{\mathbf{Ps}}}{2\omega_{\mathbf{P}/2+\mathbf{s}}2\omega_{\mathbf{P}/2-\mathbf{s}}}}\varphi_{\mathbf{s}}.\end{aligned}\tag{3.7}$$

Eqs. (3.7) imply that

$$c=\frac{\lambda_R^{\mathbf{P}}}{(2\pi)^d}\int d\mathbf{s}\sqrt{\frac{2\Omega_{\mathbf{Ps}}}{2\omega_{\mathbf{P}/2+\mathbf{s}}2\omega_{\mathbf{P}/2-\mathbf{s}}}}\frac{1}{\Omega_{\mathbf{Ps}}^2}\psi_{\mathbf{s}},\tag{3.8}$$

with the "renormalized" coupling constant $\lambda_R^{\mathbf{P}}$ expressed from the relation

$$\frac{1}{\lambda_R^{\mathbf{P}}}=\frac{1}{\lambda}+\frac{1}{(2\pi)^d}\int d\mathbf{s}\frac{2\Omega_{\mathbf{Ps}}}{2\omega_{\mathbf{P}/2+\mathbf{s}}2\omega_{\mathbf{P}/2-\mathbf{s}}}\frac{1}{\Omega_{\mathbf{Ps}}^2}.\tag{3.9}$$

The operator $(M_{\mathbf{P}})^{-2}$ has then the form

$$((M_{\mathbf{P}})^{-2}\psi)_{\mathbf{s}}=\frac{1}{\Omega_{\mathbf{Ps}}^2}\psi_{\mathbf{s}}-\frac{\lambda_R^{\mathbf{P}}}{(2\pi)^d}\chi_{\mathbf{Ps}}\int d\mathbf{s}'\,\chi_{\mathbf{Ps}'}\psi_{\mathbf{s}'},\tag{3.10}$$

with

$$\chi_{\mathbf{Ps}}=\frac{1}{\Omega_{\mathbf{Ps}}^2}\cdot\sqrt{\frac{2\Omega_{\mathbf{Ps}}}{2\omega_{\mathbf{P}/2+\mathbf{s}}2\omega_{\mathbf{P}/2-\mathbf{s}}}}.\tag{3.11}$$

The function (3.11) treated as a function of $\mathbf{s}$ belongs to L^2 for $d+1<6$. For these values of the space-time dimensionality, the operator $(M_{\mathbf{P}})^{-2}$ is bounded and self-adjoint, provided that the quantity $\lambda_R^{\mathbf{P}}$ is finite. Since the integral entering to the right-hand side of Eq. (3.9) diverges at d

$+1=4$ and 5, for these values of d it is necessary to perform infinite renormalization of the coupling constant. This means that λ should be chosen in such a way that $|\lambda_R^{\mathbf{P}}|<\infty$. The fact that λ is $\mathbf{P}$-independent means that

$$\frac{1}{\lambda_R^{\mathbf{P}_1}}-\frac{1}{\lambda_R^{\mathbf{P}_2}}=\frac{1}{(2\pi)^d}\int d\mathbf{s}\left[\frac{1}{2\Omega_{\mathbf{P}_1\mathbf{s}}\omega_{\mathbf{P}_1/2+\mathbf{s}}\omega_{\mathbf{P}_1/2-\mathbf{s}}}-\frac{1}{2\Omega_{\mathbf{P}_2\mathbf{s}}\omega_{\mathbf{P}_2/2+\mathbf{s}}\omega_{\mathbf{P}_2/2-\mathbf{s}}}\right]. \tag{3.12}$$

Note that the integral in the right-hand side of Eq. (4.12) is well defined at $d+1=4$ and 5, since

$$\frac{\partial}{\partial\mathbf{P}}\left(\frac{1}{2\Omega_{\mathbf{P}_2\mathbf{s}}\omega_{\mathbf{P}_2/2+\mathbf{s}}\omega_{\mathbf{P}_2/2-\mathbf{s}}}\right)=O(|\mathbf{s}|^{-5}),s\to\infty.$$

The fact that the operator (3.10) is invertible can be understood as follows. Suppose that $(M_{\mathbf{P}})^{-2}\psi=0$ for some ψ. This means that

$$\psi_{\mathbf{s}}=c\Omega_{\mathbf{P}\mathbf{s}}^2\chi_{\mathbf{P}\mathbf{s}}, \tag{3.13}$$

for some multiplier c. But the function (3.13) does not belong to L^2. Thus, the operator $(M_{\mathbf{P}})^{-2}$ is invertible.

To investigate the positive definiteness of the operator $(M_{\mathbf{P}})^{-2}$, calculate the integral

$$I(\mathbf{P},\epsilon)=\frac{1}{(2\pi)^d}\int\frac{d\mathbf{s}}{2\omega_{\mathbf{P}_2/2+\mathbf{s}}\omega_{\mathbf{P}_2/2-\mathbf{s}}}\frac{1}{\Omega_{\mathbf{P}_2\mathbf{s}}^2+\epsilon^2},$$

making use of the dimensional regularization. First of all, introduce new variables, $\mathbf{k}_1=\mathbf{P}/2+\mathbf{s}$, $\mathbf{k}_2=\mathbf{P}/2-\mathbf{s}$, so that $\int d\mathbf{s}\to\int d\mathbf{k}_1 d\mathbf{k}_2\delta(\mathbf{k}_1+\mathbf{k}_2-\mathbf{P})$. Next, use the identity

$$\frac{\omega_1+\omega_2}{2\omega_1\omega_2(\epsilon^2+(\omega_1+\omega_2)^2)}=\frac{1}{2\pi}\int\frac{d\xi}{(\omega_1^2+\xi^2)(\omega_2^2+(\xi-\epsilon)^2)},$$

so that

$$I(\mathbf{P},\epsilon)=\frac{1}{(2\pi)^{d+1}}\int\frac{d\mathbf{k}_1 d\mathbf{k}_2 d\xi\,\delta(\mathbf{k}_1+\mathbf{k}_2-\mathbf{P})}{(\xi^2+\omega_{\mathbf{k}_1}^2)((\xi-\epsilon)^2+\omega_{\mathbf{k}_2}^2)}.$$

Introduce, as usual, the α representation: $a^{-1}=\int_0^\infty d\alpha e^{-\alpha a}$. We get

$$I(\mathbf{P},\epsilon)=\frac{1}{(2\pi)^{d+1}}\int_0^\infty d\alpha\int_0^\infty d\beta e^{-\mu^2(\alpha+\beta)}\left(\frac{\pi}{\alpha+\beta}\right)^{d+1/2}e^{-\alpha\beta/\alpha+\beta(\mathbf{P}^2+\epsilon^2)}. \tag{3.14}$$

Therefore,

$$\frac{1}{\lambda_R^{\mathbf{P}}}-\frac{1}{\lambda_R^0}=\frac{1}{(2\pi)^{d+1}}\int_0^\infty d\alpha\int_0^\infty d\beta e^{-\mu^2(\alpha+\beta)}\left(\frac{\pi}{\alpha+\beta}\right)^{d+1/2}(e^{-\alpha\beta/\alpha+\beta\,\mathbf{P}^2}-1)<0. \tag{3.15}$$

The requirement $(M_{\mathbf{P}})^{-2}\geqslant 0$ is a corollary of the condition $\lambda_R^{\mathbf{P}}<0$. Inequality (3.15) implies that it is sufficient to require $\lambda_R<0$. This is a well known condition of absence of tachyons[16–19] in the large-N theory. Thus, we have constructed the Hamiltonian.

Another way to define the Hamiltonian is the following.[15] One can use the theory of self-adjoint extensions.[20] Consider the operator $\Omega_{\mathbf{P}\mathbf{s}}^2$ defined on the domain consisting of such φ that

$$\int d\mathbf{s}\varphi_{\mathbf{s}}\sqrt{\frac{2\Omega_{\mathbf{Ps}}}{2\omega_{\mathbf{P}/2+\mathbf{s}}2\omega_{\mathbf{P}/2-\mathbf{s}}}}=0.$$

If $d+1\geqslant 6$, the operator is essentially self-adjoint. This corresponds to the ''triviality'' (or non-renormalizability) of the model. If $d+1<6$, there is a one-parametric family of self-adjoint extensions specified by the parameter $\lambda_R^{\mathbf{P}}$. However, the condition (3.12) can not be obtained by the self-adjoint extension method. One should use another argumentation like Poincare invariance.

C. Momentum and angular momentum

Let us express the momentum and angular momentum operators via new creation and annihilation operators $C_{\mathbf{Ps}}^{\pm}$. It follows from Eqs. (3.1) that operators (2.47) can be written as

$$P^l=\int d\mathbf{P}d\mathbf{s}Q_{\mathbf{Ps}}P^l i\Pi_{-\mathbf{Ps}},$$
$$M^{ml}=\int d\mathbf{P}d\mathbf{s}Q_{\mathbf{Ps}}\left(iP^l\frac{\partial}{\partial P^m}+is^l\frac{\partial}{\partial s^m}-iP^m\frac{\partial}{\partial P^l}-is^m\frac{\partial}{\partial s^l}\right)i\Pi_{-\mathbf{Ps}}. \tag{3.16}$$

Since the kernel of the operator $M_{\mathbf{P}}^{-2}$ (3.10) is invariant under spatial rotations

$$\mathbf{P}\to O\mathbf{P},\quad \mathbf{s}\to O\mathbf{s},\quad \mathbf{s}'\to O\mathbf{s}',$$

with orthogonal matrix O, it commutes with the rotation operator of the form $Of_{\mathbf{Ps}}=f_{O\mathbf{P},O\mathbf{s}}$. Analogously, any function of M obey this property. Since the operator

$$iP^l\frac{\partial}{\partial P^m}+is^l\frac{\partial}{\partial s^m}-iP^m\frac{\partial}{\partial P^l}-is^m\frac{\partial}{\partial s^l},$$

is a generator of a rotation, it commutes with any function of M. Making use of this property, we find

$$M^{ml}=\int d\mathbf{P}d\mathbf{s}C_{\mathbf{Ps}}^{+}\left(iP^l\frac{\partial}{\partial P^m}+is^l\frac{\partial}{\partial s^m}-iP^m\frac{\partial}{\partial P^l}-is^m\frac{\partial}{\partial s^l}\right)C_{\mathbf{Ps}}^{-}.$$

Analogously,

$$P^l=\int d\mathbf{P}d\mathbf{s}C_{\mathbf{Ps}}^{+}P^l C_{\mathbf{Ps}}^{-}.$$

D. Representation for space–time translations and space rotations

The problem of divergences made us change the representation for the operators $A_{\mathbf{k}_1\mathbf{k}_2}^{\pm(2)}$. We have considered the space $\mathcal{H}_2\subset L^2(\mathbf{R}^{2d})$ of functions $f_{\mathbf{Ps}}$ which obey the property $f_{\mathbf{P},-\mathbf{s}}=f_{\mathbf{P},\mathbf{s}}$. The space $\mathcal{F}(\mathcal{H}_2)$ has been considered instead of $\mathcal{F}(\mathcal{H}^{\vee 2})$. Therefore, the space (3.44) is substituted by $\mathcal{F}(\mathcal{H}_2)\otimes\check{\mathcal{F}}$. One should define then operators H, P^l, M^{ml}, M^{m0}, and $U_{\Lambda,a}$ in $\mathcal{F}(\mathcal{H}_2)$ that corresponds to formal expressions (2.47). The operators H, P^l, M^{ml} have just been considered.

Let λ_R^0 be a fixed negative quantity. Set $\mathbf{P}_2=0$, $\mathbf{P}_1=\mathbf{P}$ in Eq. (3.12) and define the quantity $\lambda_R^{\mathbf{P}}$. Consider the operator $M^{-2}:\mathcal{H}_2\to\mathcal{H}_2$ of the form

$$(M^{-2}\psi)_{\mathbf{Ps}}=\Omega_{\mathbf{Ps}}^{-2}\psi_{\mathbf{Ps}}-\frac{\lambda_R^{\mathbf{P}}}{(2\pi)^d}\chi_{\mathbf{Ps}}\int d\mathbf{s}'\chi_{\mathbf{Ps}'}\psi_{\mathbf{Ps}'},$$

where $\chi_{\mathbf{Ps}}$ has the form (3.11). Since the operator M^{-2} is positively definite and self-adjoint, the self-adjoint positive operator $M \equiv (M^{-2})^{-1/2}$ is uniquely defined. The Hamiltonian operator is

$$H = \mathcal{F}(M),$$

(the notations from Appendix A are used), while

$$e^{-iHt} = \mathcal{U}(e^{-iMt}).$$

Analogously,

$$P^l = \mathcal{F}(P^l),$$

$$M^{ml} = \mathcal{F}\left(iP^l \frac{\partial}{\partial P^m} + is^l \frac{\partial}{\partial s^m} - iP^m \frac{\partial}{\partial P^l} - is^m \frac{\partial}{\partial s^l} \right).$$

The space rotations being Lorentz transformations with

$$\Lambda_i^0 = 0, \quad \Lambda_0^i = 0, \quad \Lambda_0^0 = 1, \tag{3.17}$$

are represented by the operators $U_{\Lambda,0} = \mathcal{U}(u_{\Lambda,0})$ with

$$(u_{\Lambda,0} f)_{\mathbf{Ps}} = f_{\Lambda^{-1}\mathbf{P}, \Lambda^{-1}\mathbf{s}}. \tag{3.18}$$

For space–time translations, one has

$$U_{1,a} = e^{iHt} e^{-iP^l a^l} = \mathcal{U}(e^{iMt} e^{-i\mathbf{Pa}}). \tag{3.19}$$

Thus, we have constructed the operators $U_{\Lambda,a}$ corresponding to the Poincare transformations obeying Eq. (3.17): $U_{\Lambda,a} = U_{0,a} U_{\Lambda,0}$.

Lemma 3.1: The group property

$$U_{\Lambda_1,a_1} U_{\Lambda_2,a_2} = U_{\Lambda_1\Lambda_2, a_1 + \Lambda_1 a_2}$$

is satisfied for Poincare transformations obeying Eq. (3.17).

Proof: It is sufficient to show that

$$U_{\Lambda_1\Lambda_2,0} = U_{\Lambda_1,0} U_{\Lambda_2,0}, \tag{3.20}$$

$$U_{1,a_1} U_{1,a_2} = U_{1,a_1+a_2}, \tag{3.21}$$

$$U_{\Lambda,0} U_{1,a} U_{\Lambda,0}^{-1} = U_{1,\Lambda a}. \tag{3.22}$$

The property (3.20) is an obvious corollary of the definition (3.18). Relation (3.21) is a corollary of the Stone theorem and the property

$$[e^{iMt}, e^{-i\mathbf{Pa}}] = 0. \tag{3.23}$$

Definition (3.18) and commutation relation

$$[u_{\Lambda,0}, e^{iMt}] = 0, \tag{3.24}$$

imply property (3.22). Lemma 3.1 is proved.

Let us check now some axioms of quantum field theory.

Lemma 3.2: (Existence and uniqueness of a vacuum). *For vector* $\Phi \in \mathcal{F}(\mathcal{H}_2)$, *the following statements are equivalent:*

(i) invariance under space–time translations: for all a

$$U_{0,a}\Phi=\Phi, \quad \text{and}$$

(ii) $\Phi=c|0>$ *for some multiplier* $c\in\mathbf{C}$.

The proof is obvious. We now investigate now spectral properties.

Lemma 3.3: The spectrum of the operator P^μ *is a subset of a set* $\{0\}\cup\{(\epsilon,\mathbf{p})|\epsilon^2-\mathbf{p}^2>0$.

Proof: It is sufficient to prove that $\sigma(M_{\mathbf{p}}^2)\subset(\mathbf{P}^2,\infty)$. The property $\epsilon^2\in\sigma(M_{\mathbf{p}}^2)$ means that the operator $\epsilon^2-M_{\mathbf{p}}^2$ is not boundedly invertible. Since

$$((\epsilon^2-M_{\mathbf{p}}^2)^{-1}\psi)_{\mathbf{s}}=(\epsilon^2-\Omega_{\mathbf{Ps}}^2)^{-1}\psi_{\mathbf{s}}+\frac{(\Omega_{\mathbf{Ps}}^2-\epsilon^2)^{-1}\Omega_{\mathbf{Ps}}^2\chi_{\mathbf{Ps}}\int d\mathbf{s}'\,\chi_{\mathbf{Ps}'}\Omega_{\mathbf{Ps}'}^2(\Omega_{\mathbf{Ps}'}^2-\epsilon^2)^{-1}}{\frac{(2\pi)^d}{\lambda_R^{\mathbf{P}}}-\int d\mathbf{s}\chi_{\mathbf{Ps}}^2\Omega_{\mathbf{Ps}}^4(\Omega_{\mathbf{Ps}}^{-2}-(\Omega_{\mathbf{Ps}}^2-\epsilon^2)^{-1})},$$

$\epsilon^2\in\sigma(M_2)$ if and only if

$$\epsilon=\omega_{\mathbf{P}/2-\mathbf{s}}+\omega_{\mathbf{P}/2+\mathbf{s}}, \tag{3.25}$$

for some $\mathbf{s}$ or

$$\frac{(2\pi)^d}{\lambda_R^{\mathbf{P}}}-\int d\mathbf{s}\chi_{\mathbf{Ps}}^2\Omega_{\mathbf{Ps}}^4(\Omega_{\mathbf{Ps}}^{-2}-(\Omega_{\mathbf{Ps}}^2-\epsilon^2)^{-1})=0. \tag{3.26}$$

Since $\omega_{\mathbf{P}/2+\mathbf{s}}+\omega_{\mathbf{P}/2-\mathbf{s}}\geqslant 2\omega_{\mathbf{P}/2}=\sqrt{\mathbf{P}^2+4\mu^2}>|\mathbf{P}|$, these values of ϵ obey the property $\epsilon^2\in(\mathbf{P}^2$ and $\infty)$. It follows from Eq. (3.14) that Eq. (3.26) can be transformed to the form

$$\frac{1}{(2\pi)^{d+1}}\int_0^\infty d\alpha\int_0^\infty d\beta e^{-\mu^2(\alpha+\beta)}\left(\frac{\pi}{\alpha+\beta}\right)^{d+1/2}(e^{-\alpha\beta/\alpha+\beta(\mathbf{P}^2-\epsilon^2)}-1)=-\frac{1}{\lambda_R^0}. \tag{3.27}$$

Since $\lambda_R^0<0$, the left-hand side of Eq. (3.27) should be positive. This means $\epsilon^2>\mathbf{P}^2$. Lemma is proved.

IV. COMPOSED FIELD OPERATORS

In Sec. III, we have constructed the Hamiltonian of the theory of ''infinite number of fields'' which was shown to be a self-adjoint operator in the Hilbert space. However, it is also necessary to check the property of the Poincare invariance.

To simplify the investigation, it is convenient to introduce an analog of the notion of a field which is very useful in traditional QFT: the Wightman axiomatic approach allows us to reduce the problem of Poincare invariance of the theory to the problem of Poincare invariance of Wightman functions.

However, it is not easy to introduce the field $\varphi^a(x)$ since we have not considered the non-symmetric N-field states yet. However, one can investigate the properties of the ''multifield operators'':

$$\mathcal{W}_{N,k}(x_1,\ldots,x_k)=\frac{1}{N}\sum_{a=1}^{N}\varphi^a(x_1)\ldots\varphi^a(x_k). \tag{4.1}$$

Consider this operator at $x_1^0=\ldots=x_k^0=0$. The results of Sec. II imply that

$$\mathcal{W}_{N,k}(x_1,\ldots,x_k)K_Nf=K_N\tilde{\mathcal{W}}_{N,k}(x_1,\ldots,x_k)f, \tag{4.2}$$

with

$$\tilde{\mathcal{W}}_{N,k}(\mathbf{x}_1,\ldots,\mathbf{x}_k)=\int D\phi|\Phi_0[\phi(\cdot)]|^2\phi(\mathbf{x}_1)\ldots\phi(\mathbf{x}_k)+N^{-1/2}\tilde{W}_k(\mathbf{x}_1,\ldots\mathbf{x}_k)+O(N^{-1}). \tag{4.3}$$

The operator $\tilde{W}_k$ can be presented as

$$\begin{aligned}\tilde{W}_k(\mathbf{x}_1,\ldots,\mathbf{x}_k)&=\int D\phi(\tilde{A}^+[\phi(\cdot)]+\tilde{A}^-[\phi(\cdot)])\phi(\mathbf{x}_1)\ldots\phi(\mathbf{x}_k)\Phi_0[\phi(\cdot)]\\&=\sum_{n=1}^{\infty}\int d\mathbf{p}_1\ldots d\mathbf{p}_n[A^{(n)+}_{\mathbf{p}_1\ldots\mathbf{p}_n}(\Phi^{(n)}_{\mathbf{p}_1\ldots\mathbf{p}_n},\phi(\mathbf{x}_1)\ldots\phi(\mathbf{x}_k)\Phi_0)\\&\quad+A^{(n)-}_{\mathbf{p}_1\ldots\mathbf{p}_n}(\Phi^{(n)}_{\mathbf{p}_1\ldots\mathbf{p}_n},\phi(\mathbf{x}_1)\ldots\phi(\mathbf{x}_k)\Phi_0)^*].\end{aligned} \tag{4.4}$$

One can expect that Heisenberg operator will also obey the relation of the type (4.3):

$$\begin{aligned}\tilde{\mathcal{W}}_{N,k}(x_1,\ldots,x_k)&=(\Phi_0[\phi(\cdot)],\phi(x_1)\ldots\phi(x_k)\Phi_0[\phi(\cdot)])\\&\quad+N^{-1/2}\tilde{W}_k(x_1,\ldots x_k)+O(N^{-1}).\end{aligned} \tag{4.5}$$

Here $\phi(x)$ is a Heisenberg operator of the free field of the mass μ. The property (4.5) is to be checked in Appendix B.

The multifield operators $\tilde{W}_k(x_1,\ldots,x_k)$ being analogs of fields are to be investigated.

A. Multifield operators

In this subsection, we compute the explicit form of the operators $\tilde{W}_k(x_1,\ldots,x_k)$.

The "k-field" (4.1) satisfies the Heisenberg equation

$$\left(\frac{\partial}{\partial x^\mu_A}\frac{\partial}{\partial x_{A\mu}}+m^2+\frac{\lambda}{N}\sum_{b=1}^{N}\varphi^b(x_A)\varphi^b(x_A)\right)\mathcal{W}_{N,k}(x_1,\ldots,x_k)=0.$$

The property (4.2) implies that

$$\left(\frac{\partial}{\partial x^\mu_A}\frac{\partial}{\partial x_{A\mu}}+m^2+\lambda\tilde{\mathcal{W}}_{N,2}(x_A,x_A)\right)\tilde{\mathcal{W}}_{N,k}(x_1,\ldots,x_k)=0.$$

Use now the property (4.5). One can notice that $m^2+\lambda(\Phi_0,\phi(x_A)\phi(x_A)\Phi_0)=\mu^2$. Therefore,

$$\begin{aligned}&\left(\frac{\partial}{\partial x^\mu_A}\frac{\partial}{\partial x_{A\mu}}+\mu^2+\frac{\lambda}{\sqrt{N}}\tilde{W}_2(x_A,x_A)+O(N^{-1})\right)((\Phi_0,\phi(x_1)\ldots\phi(x_k)\Phi_0)\\&\quad+N^{-1/2}\tilde{W}_k(x_1,\ldots,x_k)+O(N^{-1}))=0.\end{aligned} \tag{4.6}$$

The terms of order $O(1)$ give us an equation on the vacuum average value. It has the form

$$\left(\frac{\partial}{\partial x^\mu_A}\frac{\partial}{\partial x_{A\mu}}+\mu^2\right)(\Phi_0,\phi(x_1)\ldots\phi(x_k)\Phi_0)=0.$$

This equation is automatically satisfied. The terms of order $O(N^{1/2})$ lead to the nontrivial equation:

$$\left(\frac{\partial}{\partial x_A^\mu}\frac{\partial}{\partial x_{A\mu}}+\mu^2\right)\tilde{W}_k(x_1,\ldots,x_k)+Q(x_A)(\Phi_0,\phi(x_1)\ldots\phi(x_k)\Phi_0)=0, \tag{4.7}$$

with

$$Q(x_A)=\lambda\tilde{W}_2(x_A,x_A). \tag{4.8}$$

To perform an investigation of Eq. (4.7), it is convenient to introduce the linear combinations of the multifields $\tilde{W}_k$. It follows from the Wick theorem that the operators (4.4) can be presented as

$$\tilde{W}_k(\mathbf{x}_1,\ldots,\mathbf{x}_k)=\sum\ (\Phi_0,\phi(\mathbf{x}_{l_1^1})\phi(\mathbf{x}_{l_1^2})\Phi_0)\ldots(\Phi_0,\phi(\mathbf{x}_{l_\nu^1})\phi(\mathbf{x}_{l_\nu^2})\Phi_0)\hat{W}_{k-2\nu}(\mathbf{x}_{m_1},\ldots,\mathbf{x}_{m_{k-2\nu}}). \tag{4.9}$$

Here, the summation is performed over all decompositions of the set

$$\{1,2,\ldots,k\}=\{l_1^1,l_1^2\}\cup\ldots\cup\{l_\nu^1,l_\nu^2\}\cup\{m_1,\ldots,m_{k-2\nu}\},$$

while

$$l_1^1<l_1^2,\quad l_\nu^1<l_\nu^2,\quad m_1<\ldots<m_{k-2\nu},\quad k-2\nu>0.$$

The operator $\hat{W}_s(\mathbf{x}_1,\ldots,\mathbf{x}_s)$ entering to the formula (5.9) has the form

$$\hat{W}_s(\mathbf{x}_1,\ldots,\mathbf{x}_s)=\int d\mathbf{p}_1\ldots d\mathbf{p}_s[A^{(s)+}_{\mathbf{p}_1\ldots\mathbf{p}_s}(\Phi^{(s)}_{\mathbf{p}_1\ldots\mathbf{p}_s},:\phi(\mathbf{x}_1)\ldots\phi(\mathbf{x}_s):\Phi_0) + A^{(s)-}_{\mathbf{p}_1\ldots\mathbf{p}_s}(\Phi^{(s)}_{\mathbf{p}_1\ldots\mathbf{p}_s},:\phi(\mathbf{x}_1)\ldots\phi(\mathbf{x}_s):\Phi_0)^*]. \tag{4.10}$$

The notation :: is used for the Wick ordering of combinations of fields

$$\phi(\mathbf{x})=\frac{1}{(2\pi)^{d/2}}\int\frac{d\mathbf{k}}{\sqrt{2\omega_\mathbf{k}}}[a^+_\mathbf{k}e^{-i\mathbf{kx}}+a^-_\mathbf{k}e^{i\mathbf{kx}}].$$

Analogously, we define the Heisenberg operators $\hat{W}_s(x_1,\ldots,x_s)$ from the recursive relations

$$\tilde{W}_k(x_1,\ldots,x_k)=\sum\ (\Phi_0,\phi(x_{l_1^1})\phi(x_{l_1^2})\Phi_0)\ldots(\Phi_0,\phi(x_{l_\nu^1})\phi(x_{l_\nu^2})\Phi_0)\hat{W}_{k-2\nu}(x_{m_1},\ldots,x_{m_{k-2\nu}}). \tag{4.11}$$

Applying the Wick theorem to the combinations of the field and momenta operators

$$\pi(\mathbf{x})=\frac{1}{i}\frac{\delta}{\delta\phi(\mathbf{x})}=\frac{1}{(2\pi)^{d/2}}\int\frac{d\mathbf{k}}{\sqrt{2}}i\sqrt{\omega_\mathbf{k}}[a^+_\mathbf{k}e^{-i\mathbf{kx}}+a^-_\mathbf{k}e^{i\mathbf{kx}}],$$

we obtain in an analogous way that

$$\frac{\partial}{\partial x^0_{i_1}}\ldots\frac{\partial}{\partial x^0_{i_l}}\hat{W}_s(x_1,\ldots,x_s)$$

$$=\int d\mathbf{p}_1\ldots d\mathbf{p}_s[A^{(s)+}_{\mathbf{p}_1\ldots\mathbf{p}_s}(\Phi^{(s)}_{\mathbf{p}_1\ldots\mathbf{p}_s},:\phi(\mathbf{x}_1)\ldots\pi_{i_1}(\mathbf{x}_{i_1})\ldots\pi_{i_l}(\mathbf{x}_{i_1})\ldots\phi(\mathbf{x}_s):\Phi_0)$$

$$+A^{(s)-}_{\mathbf{p}_1\ldots\mathbf{p}_s}(\Phi^{(s)}_{\mathbf{p}_1\ldots\mathbf{p}_s},:\phi(\mathbf{x}_1)\ldots\pi_{i_1}(\mathbf{x}_{i_1})\ldots\pi_{i_l}(\mathbf{x}_{i_1})\phi(\mathbf{x}_s):\Phi_0)^*], \tag{4.12}$$

for $i_1<\ldots<i_l$, $x^0_1=\ldots=x^0_s=0$.

Let us find an equation on the operator $\hat{W}_s$. For $k=2$ and $\tilde{W}_2=\hat{W}_2$, so that

$$\left(\frac{\partial}{\partial x^\mu_A}\frac{\partial}{\partial x_{A\mu}}+\mu^2\right)\hat{W}_2(x_1,x_2)+Q(x_A)(\Phi_0,\phi(x_1)\phi(x_2)\Phi_0)=0. \tag{4.13}$$

For odd values of k, one has $(\Phi_0,\phi(x_1)\ldots\phi(x_k)\Phi_0)=0$, so that

$$\left(\frac{\partial}{\partial x^\mu_A}\frac{\partial}{\partial x_{A\mu}}+\mu^2\right)\tilde{W}_k(x_1,\ldots,x_k)=0.$$

It follows from the recursive relations that

$$\left(\frac{\partial}{\partial x^\mu_A}\frac{\partial}{\partial x_{A\mu}}+\mu^2\right)\hat{W}_k(x_1,\ldots,x_k)=0. \tag{4.14}$$

Let us show that Eq. (4.14) is also satisfied for even values of $k\neq 2$. For definiteness, consider the case $A=1$. The general case can be investigated analogously. The quantity

$$\left(\frac{\partial}{\partial x^\mu_1}\frac{\partial}{\partial x_{1\mu}}+\mu^2\right)\tilde{W}_k(x_1,\ldots,x_k),$$

entering to the left-hand side of Eq. (4.7) can be decomposed into two parts. One of them ecorresponds to the case $k-2\nu=2$, another to $k-2\mu>2$. The first part is

$$\left(\frac{\partial}{\partial x^\mu_1}\frac{\partial}{\partial x_{1\mu}}+\mu^2\right)\sum(\Phi_0,\phi(x_{l^1_1})\phi(x_{l^2_1})\Phi_0)\ldots(\Phi_0,\phi(x_{l^1_\nu})\phi(x_{l^2_\nu})\Phi_0)\hat{W}_2(x_1,x_{m_2})$$

$$=-Q(x_1)\sum(\Phi_0,\phi(x_1)\phi(x_{m_2})\Phi_0)(\Phi_0,\phi(x_{l^1_1})\phi(x_{l^2_1})\Phi_0)\ldots(\Phi_0,\phi(x_{l^1_\nu})\phi(x_{l^2_\nu})\Phi_0)$$

$$=-Q(x_1)(\Phi_0,\phi(x_1)\ldots\phi(x_k)\Phi_0). \tag{4.15}$$

The second part reads

$$\left(\frac{\partial}{\partial x^\mu_1}\frac{\partial}{\partial x_{1\mu}}+\mu^2\right)$$

$$\times\sum_{k-2\nu>2}(\Phi_0,\phi(x_{l^1_1})\phi(x_{l^2_1})\Phi_0)\ldots(\Phi_0,\phi(x_{l^1_\nu})\phi(x_{l^2_\nu})\Phi_0)\hat{W}_{k-2\nu}(x_{m_1},\ldots,x_{m_{k-2\nu}}). \tag{4.16}$$

It follows from Eq. (4.7) then that the quantity (4.16) should vanish. We obtain by induction that the functions $\hat{W}_4$, $\hat{W}_6$, etc. obey Eq. (4.14).

To find an explicit form of $\hat{W}_k$, prove the following proposition.

Proposition 4.1: Let

$$\left(\frac{\partial}{\partial x_A^\mu}\frac{\partial}{\partial x_{A\mu}}+\mu^2\right)f_k(x_1,\ldots,x_k)=0, \quad A=\overline{1,k} \tag{4.17}$$

and

$$\frac{\partial}{\partial x_{i_1}^0}\ldots\frac{\partial}{\partial x_{i_l}^0}f_k(x_1,\ldots,x_k)=0, \quad i_1<\ldots<i_l, \quad x_1^0=\ldots=x_k^0=0.$$

Then $f_k=0$.

Proof: Consider the spatial Fourier transformation $\tilde{f}_k(\mathbf{p}_1,t_1;\ldots;\mathbf{p}_k,$ and $t_k)$ of the function f_k. It obeys the set of equations

$$\left(\frac{\partial}{\partial t_A}\frac{\partial}{\partial t_A}+\omega_{\mathbf{p}_A^2}\right)\tilde{f}_k(\mathbf{p}_1,t_1;\ldots;\mathbf{p}_k,t_k)=0, \quad A=\overline{1,k},$$

with $\omega_{\mathbf{p}}=\sqrt{\mathbf{p}^2+\mu^2}$. This implies that

$$\tilde{f}_k(\mathbf{p}_1,t_1;\ldots;\mathbf{p}_k,t_k)=\sum_{\sigma_1,\ldots,\sigma_k\in\{-1,1\}}\alpha_{\sigma_1\ldots\sigma_k}(\mathbf{p}_1,\ldots,\mathbf{p}_k)e^{i\sigma_1\omega_{\mathbf{p}_1}t_1+\ldots+i\sigma_k\omega_{\mathbf{p}_k}t_k}.$$

One can express the coefficients α as

$$\alpha_{\sigma_1\ldots\sigma_k}(\mathbf{p}_1,\ldots,\mathbf{p}_k)=\left(\frac{1}{2}-\frac{i\sigma_1}{2\omega_{\mathbf{p}_1}}\right)\ldots\left(\frac{1}{2}-\frac{i\sigma_k}{2\omega_{\mathbf{p}_k}}\right)\tilde{f}_k(\mathbf{p}_1,t_1,\ldots,\mathbf{p}_k,t_k).$$

Therefore, $\alpha_{\sigma_1\ldots\sigma_k}(\mathbf{p}_1,\ldots,\mathbf{p}_k)=0$. This implies $f_k=0$. Proposition is proved.

Denote

$$\begin{aligned}\hat{W}_s^0(x_1,..,x_s)=\int d\mathbf{p}_1\ldots d\mathbf{p}_s[&A^{(s)+}_{\mathbf{p}_1\ldots\mathbf{p}_s}(\Phi^{(s)}_{\mathbf{p}_1\ldots\mathbf{p}_s},:\phi(x_1)\ldots\phi(x_s):\Phi_0)\\&+A^{(s)-}_{\mathbf{p}_1\ldots\mathbf{p}_s}(\Phi^{(s)}_{\mathbf{p}_1\ldots\mathbf{p}_s},:\phi(x_1)\ldots\phi(x_s):\Phi_0)^*].\end{aligned} \tag{4.18}$$

Consider the operator distribution $f_s=\hat{W}_s-\hat{W}_s^0$ obeying the condition of proposition 4.1. This implies $f_k=0$, so that $\hat{W}_s=\hat{W}_s^0$. The explicit form of the operator $\hat{W}_s$ is

$$\begin{aligned}&\hat{W}_s(\mathbf{x}_1,t_1,\ldots,\mathbf{x}_s,t_s)\\&=\frac{1}{(2\pi)^{sd/2}}\int\frac{d\mathbf{p}_1}{\sqrt{2\omega_{\mathbf{p}_1}}}\ldots\frac{d\mathbf{p}_s}{\sqrt{2\omega_{\mathbf{p}_s}}}\sqrt{k!}(A^{+(s)}_{\mathbf{p}_1\ldots\mathbf{p}_s}e^{i\omega_{\mathbf{p}_1}t_1+\ldots+i\omega_{\mathbf{p}_s}t_s-i\mathbf{p}_1\mathbf{x}_1-\ldots-i\mathbf{p}_s\mathbf{x}_s}\\&+A^{-(s)}_{\mathbf{p}_1\ldots\mathbf{p}_s}e^{-i\omega_{\mathbf{p}_1}t_1-\ldots-i\omega_{\mathbf{p}_s}t_s+i\mathbf{p}_1\mathbf{x}_1+\ldots+i\mathbf{p}_s\mathbf{x}_s}).\end{aligned} \tag{4.19}$$

Let $f\in\mathcal{S}(\mathbf{R}^{ds})$. Consider the operators

$$\hat{W}_s[f]=\int dx_1\ldots dx_s\hat{W}_s(x_1,\ldots,x_s)f(x_1,\ldots,x_s).$$

They are defined on the set $\check{D}$ of all finite vectors of $\check{\mathcal{F}}$. The set $\check{D}$ is invariant under the operator $\hat{W}_s[f]$.

Proposition 4.2: (1) $\hat{W}_s(x_1,\ldots,x_s)$ $(s\neq 2)$ *is an operator distribution. (2) The set*

$$\hat{W}_{s_1}[f_1]\ldots\hat{W}_{s_k}[f_k]|0>, \quad f_j\in\mathcal{S}(\mathbf{R}^{dj})$$

is a total set in $\check{\mathcal{F}}$. *The first statement is obvious. The second statement is a corollary of lemma A14.*

Thus, we see that the k-field $3\tilde{W}_k$ has the form (4.11), the operators $\hat{W}_s$ having the form (4.18) are already found. The remaining problem is to find the explicit form of the bifield $\hat{W}_2(x_1,$ and $x_2)$. Since an equation for the bifield contains the operator $Q(x)$ being an analog of the composed $\lambda\varphi^a\varphi^a$ field, let us investigate first its properties.

B. The $\lambda\varphi^a\varphi^a$ composed field

The operator $Q(x)=Q(\mathbf{x},t)$ can be presented as

$$\begin{aligned}Q(\mathbf{x},t)&=e^{iHt}\lambda\hat{W}_2(\mathbf{x},0,\mathbf{x},0)e^{-iHt}\\&=\lambda\frac{\sqrt{2}}{(2\pi)^d}\int\frac{d\mathbf{k}_1}{\sqrt{2\omega_{\mathbf{k}_1}}}\frac{d\mathbf{k}_2}{\sqrt{2\omega_{\mathbf{k}_2}}}(A^+_{\mathbf{k}_1\mathbf{k}_2}(t)e^{-i(\mathbf{k}_1+\mathbf{k}_2)\mathbf{x}}+A^-_{\mathbf{k}_1\mathbf{k}_2}(t)e^{i(\mathbf{k}_1+\mathbf{k}_2)\mathbf{x}}),\end{aligned}\tag{4.20}$$

where

$$A^{\pm}_{\mathbf{k}_1\mathbf{k}_2}(t)=e^{iHt}A^{\pm(2)}_{\mathbf{k}_1\mathbf{k}_2}e^{-iHt}.$$

After transformations (3.1) and (3.5), expression (4.20) takes the form

$$\begin{aligned}Q(\mathbf{x},t)&=\lambda\frac{\sqrt{2}}{(2\pi)^d}\int d\mathbf{P}d\mathbf{s}\sqrt{\frac{2\Omega_{\mathbf{Ps}}}{2\omega_{\mathbf{P}/2+\mathbf{s}}2\omega_{\mathbf{P}/2-\mathbf{s}}}}e^{-i\mathbf{Px}}Q_{\mathbf{Ps}}(t)\\&=\int d\mathbf{P}d\mathbf{s}(C^+_{\mathbf{Ps}}\gamma_{\mathbf{Ps}}(\mathbf{x},t)+C^-_{\mathbf{Ps}}\gamma^*_{\mathbf{Ps}}(\mathbf{x},t))\\&=C^+[\gamma(\mathbf{x},t)]+C^-[\gamma(\mathbf{x},t)],\end{aligned}$$

where

$$\gamma(\mathbf{x},t)=\frac{\sqrt{2}}{(2\pi)^d}e^{-i\mathbf{Px}}\frac{1}{\sqrt{2M}}e^{iMt}\lambda\Omega\chi.\tag{4.21}$$

Our purpose is to prove that $Q(x)$ is an operator distribution. Therefore, we should show that $(\chi(\mathbf{x},t))_{\mathbf{Ps}}$ can be viewed as a vector distribution. However, an infinite quantity λ^{-1} and function $\Omega^2\chi\notin L^2$ enter to Eq. (4.21). It is remarkable that these divergences can be eliminated: one can use the property:

$$M^{-2}\lambda\Omega^2\chi=\lambda_R\chi.$$

Here λ_R is an operator of multiplication by $\lambda^{\mathbf{P}}_R$. Thus, the vector function (4.21) can be written as

$$\gamma(\mathbf{x},t)=(2\pi)^{-d}e^{-i\mathbf{Px}}e^{iMt}M^{3/2}\lambda_R\chi.\tag{4.22}$$

One can present it as

$$\gamma(\mathbf{x},t)=(2\pi)^{-d}(-\Delta+1)^{m}\left(-\frac{\partial^2}{\partial t^2}\right)e^{-i\mathbf{P}\mathbf{x}}e^{iMt}M^{-1/2}(\mathbf{P}^2+1)^{-m}\lambda_R\chi.$$

Since $M^{-1/2}(\mathbf{P}^2+1)^{-m}\lambda_R\chi\in\mathcal{H}_2$ for sufficiently large m, the function $e^{-i\mathbf{P}\mathbf{x}}e^{iMt}M^{-1/2}(\mathbf{P}^2+1)^{-m}\lambda_R\chi$ is a bounded continuous vector function, we obtain from lemmas A.12 and A.13 that γ is a vector distribution. Lemma A.14 implies that $Q(\mathbf{x},t)$ is an operator distribution.

C. Canonical variables as operator distributions

The purpose of this subsection is to investigate the properties of the operators $Q_{\mathbf{Ps}}$ and $\Pi_{\mathbf{Ps}}$. These properties will be essentially used.

First of all, notice that

$$Q_{\mathbf{Ps}}=C^{+}[\xi_{\mathbf{Ps}}]+C^{-}[\xi_{-\mathbf{Ps}}],\quad \Pi_{\mathbf{Ps}}=C^{+}[\pi_{\mathbf{Ps}}]+C^{-}[\pi_{-\mathbf{Ps}}],$$

where $\xi_{\mathbf{Ps}}$ and $\pi_{\mathbf{Ps}}$ have the form

$$(\xi_{\mathbf{Ps}})_{\mathbf{P}'\mathbf{s}'}=\delta_{\mathbf{P}\mathbf{P}'}((2M_{\mathbf{P}}^{-1/2})_{\mathbf{s}\mathbf{s}'},\quad (\pi_{\mathbf{Ps}})_{\mathbf{P}'\mathbf{s}'}=i\delta_{\mathbf{P}\mathbf{P}'}((M_{\mathbf{P}}/2)^{-1/2})_{\mathbf{s}\mathbf{s}'}.$$

Consider the integrals

$$\int d\mathbf{P}d\mathbf{s}\varphi_{\mathbf{Ps}}\xi_{\mathbf{Ps}}=(2M)^{-1/2}\overline{\varphi},\tag{4.23}$$

$$\int d\mathbf{P}d\mathbf{s}\varphi_{\mathbf{Ps}}\pi_{\mathbf{Ps}}=i(M/2)^{1/2}\overline{\varphi},\tag{4.24}$$

where $\varphi_{\mathbf{Ps}}$ are complex functions from $\mathcal{S}(\mathbf{R}^{2d})$,

$$\overline{\varphi}_{\mathbf{Ps}}=\tfrac{1}{2}(\varphi_{\mathbf{Ps}}+\varphi_{\mathbf{P},-\mathbf{s}}).\tag{4.25}$$

Since $(2M)^{-1/2}$ is a bounded operator, the integral (4.23) is always defined. However, $(M/2)^{1/2}$ is not a bounded operator, so that quantity (4.24) may be not defined. We see that the expression for $\xi_{\mathbf{Ps}}$ defines a vector distribution, while $\pi_{\mathbf{Ps}}$ is not a vector distribution.

To consider objects like $\pi_{\mathbf{Ps}}$ as vector distributions, it is necessary to perform the renormalization procedure. Let

$$Q_{\mathbf{P}}(t)=\frac{1}{(2\pi)^d}\int d\mathbf{x}e^{i\mathbf{P}\mathbf{x}}Q(\mathbf{x},t)=-\ddot{R}_{\mathbf{P}}(t),$$

$$R_{\mathbf{P}}(t)=\frac{1}{(2\pi)^d}\int d\mathbf{x}e^{i\mathbf{P}\mathbf{x}}R(\mathbf{x},t)=C^{+}[r_{\mathbf{P}}(t)]+C^{-}[r_{-\mathbf{P}}(t)],$$

where

$$(r_{\mathbf{P}}(t))_{\mathbf{P}'\mathbf{s}'}=(2\pi)^{-d}\delta_{\mathbf{P}\mathbf{P}'}(e^{iMt}M^{-1/2}\lambda_R\chi)_{\mathbf{P}'\mathbf{s}'}$$

is a vector distribution.

Denote

$$\pi_{\mathbf{Ps}}^{ren}=\pi_{\mathbf{Ps}}-\frac{1}{\sqrt{2}}\Omega_{\mathbf{Ps}}^2\chi_{\mathbf{Ps}}\dot{r}_{\mathbf{P}}(0),\tag{4.26}$$

where $\chi_{\mathbf{Ps}}$ has the form (3.11). One has

$$\int d\mathbf{P}ds\pi^{ren}_{\mathbf{Ps}}\varphi_{\mathbf{Ps}}=i(M/2)^{1/2}\left[\overline{\varphi}-\frac{\lambda^R}{(2\pi)^d}\chi\int ds'\,\overline{\varphi}_{\mathbf{Ps}'}\Omega^2_{\mathbf{Ps}'}\chi_{\mathbf{Ps}'}\right]=i(M/2)^{1/2}M^{-2}\Omega^2\overline{\varphi}.$$

Since $\Omega^2\overline{\varphi}\in L^2$, while $M^{-3/2}$ is a bounded operator, $\pi^{ren}_{\mathbf{Ps}}$ is a vector distribution. We obtain from lemma A.14 the following proposition.

Proposition 4.5: $Q_{\mathbf{Ps}}$ and

$$\Pi^{ren}_{\mathbf{Ps}}=\Pi_{\mathbf{Ps}}-\frac{1}{\sqrt{2}}\Omega^2_{\mathbf{Ps}}\chi_{\mathbf{Ps}}\dot{R}_{\mathbf{P}}(0) \tag{4.27}$$

are operator distributions.

Investigate now the transformation properties of these distributions. Analogously to the previous subsection, we obtain

Proposition 4.6: For spatial rotations, the following properties are satisfied:

$$u_{\Lambda,0}\xi_{\mathbf{P},\mathbf{s}}=\xi_{\Lambda\mathbf{P},\Lambda\mathbf{s}},\quad u_{\Lambda,0}\pi^{ren}_{\mathbf{P},\mathbf{s}}=\pi^{ren}_{\Lambda\mathbf{P},\Lambda\mathbf{s}},\quad u_{\Lambda,0}r_{\mathbf{P}}(t)=r_{\Lambda\mathbf{P}}(t).$$

Corollary: Under conditions (3.17), the operators $Q_{\mathbf{Ps}}$, $\Pi^{ren}_{\mathbf{Ps}}$ obey the following transformation properties

$$U_{\Lambda,0}Q_{\mathbf{Ps}}U^{-1}_{\Lambda,0}=Q_{\Lambda\mathbf{P},\Lambda\mathbf{s}},\quad U_{\Lambda,0}\Pi^{ren}_{\mathbf{Ps}}U^{-1}_{\Lambda,0}=\Pi^{ren}_{\Lambda\mathbf{P},\Lambda\mathbf{s}},\quad U_{\Lambda,0}R_{\mathbf{P}}(t)U^{-1}_{\Lambda,0}=R_{\Lambda\mathbf{P}}(t),$$

$$U_{1,\mathbf{a}}Q_{\mathbf{Ps}}U^{-1}_{1,\mathbf{a}}=e^{-i\mathbf{Pa}}Q_{\mathbf{P},\mathbf{s}},\quad U_{1,\mathbf{a}}\Pi^{ren}_{\mathbf{Ps}}U^{-1}_{1,\mathbf{a}}=e^{-i\mathbf{Pa}}\Pi^{ren}_{\mathbf{P},\mathbf{s}},\quad U_{1,a}R_{\mathbf{P}}(t)U^{-1}_{1,a}=R_{\mathbf{P}}(t+a_0). \tag{4.28}$$

D. The bifield operator

In this section, we construct the bifield operator $\hat{W}_2(x_1, x_2)$ which obey Eq. (4.13) and initial conditions (4.12). We show it to be an operator distribution of $\mathbf{x}_1$ and $\mathbf{x}_2$ at fixed values of x^0_1, x^0_2. It can be also viewed as an operator distribution of x_1, and x_2.

First of all, consider the spatial Fourier transformation

$$\hat{W}_2(\mathbf{x},t_x;\mathbf{y},t_y)=\frac{1}{(2\pi)^d}\int d\mathbf{k}d\mathbf{p}w_2(\mathbf{k},t_x;\mathbf{p},t_y)e^{-i\mathbf{kx}-i\mathbf{py}}.$$

Initial conditions (4.12) can be presented in the following form

$$\begin{aligned}
w_2(\mathbf{k},0;\mathbf{p},0)&=\sqrt{\frac{\omega_{\mathbf{k}}+\omega_{\mathbf{p}}}{\omega_{\mathbf{k}}\omega_{\mathbf{p}}}}Q_{\mathbf{k}+\mathbf{p},\mathbf{k}-\mathbf{p}/2},\\
\frac{\partial}{\partial t_x}w_2(\mathbf{k},0;\mathbf{p},0)&=\sqrt{\frac{\omega_{\mathbf{k}}(\omega_{\mathbf{k}}+\omega_{\mathbf{p}})}{\omega_{\mathbf{p}}}}\Pi_{\mathbf{k}+\mathbf{p},\mathbf{k}-\mathbf{p}/2},\\
\frac{\partial}{\partial t_y}w_2(\mathbf{k},0;\mathbf{p},0)&=\sqrt{\frac{\omega_{\mathbf{p}}(\omega_{\mathbf{k}}+\omega_{\mathbf{p}})}{\omega_{\mathbf{k}}}}\Pi_{\mathbf{k}+\mathbf{p},\mathbf{k}-\mathbf{p}/2},\\
\frac{\partial}{\partial t_x}\frac{\partial}{\partial t_y}w_2(\mathbf{k},0;\mathbf{p},0)&=\sqrt{(\omega_{\mathbf{p}}(\omega_{\mathbf{k}}+\omega_{\mathbf{p}}))\omega_{\mathbf{k}}}Q_{\mathbf{k}+\mathbf{p},\mathbf{k}-\mathbf{p}/2}.
\end{aligned} \tag{4.29}$$

Eqs.(4.13) can be written as

$$\left(\frac{\partial^2}{\partial t_x \partial t_x}+\omega_{\mathbf{k}}^2\right) w_2(\mathbf{k},t_x;\mathbf{p},t_y)+\frac{1}{2\omega_{\mathbf{p}}} e^{-i\omega_{\mathbf{p}}(t_x-t_y)} Q_{\mathbf{k}+\mathbf{p}}(t_x)=0.$$
$$\left(\frac{\partial^2}{\partial t_y \partial t_y}+\omega_{\mathbf{p}}^2\right) w_2(\mathbf{k},t_x;\mathbf{p},t_y)+\frac{1}{2\omega_{\mathbf{k}}} e^{-i\omega_{\mathbf{k}}(t_x-t_y)} Q_{\mathbf{k}+\mathbf{p}}(t_y)=0. \tag{4.30}$$

These equations and initial conditions lead to the following formal solution

$$\begin{aligned} w_2(\mathbf{k},t_x;\mathbf{p},t_y)=&\sqrt{\frac{\omega_{\mathbf{k}}+\omega_{\mathbf{p}}}{\omega_{\mathbf{k}}\omega_{\mathbf{p}}}}\, Q_{\mathbf{k}+\mathbf{p},\mathbf{k}-\mathbf{p}/2}\cos(\omega_{\mathbf{k}}t_x+\omega_{\mathbf{p}}t_y)\\ &+\frac{1}{\sqrt{\omega_{\mathbf{k}}\omega_{\mathbf{p}}(\omega_{\mathbf{k}}+\omega_{\mathbf{p}})}}\,\Pi_{\mathbf{k}+\mathbf{p},\mathbf{k}-\mathbf{p}/2}\sin(\omega_{\mathbf{k}}t_x+\omega_{\mathbf{p}}t_y)\\ &-\int_0^{t_x} d\tau \frac{\sin(\omega_{\mathbf{k}}(t_x-\tau))}{\omega_{\mathbf{k}}}\,\frac{1}{2\omega_{\mathbf{p}}} e^{-i\omega_{\mathbf{p}}(\tau-t_y)} Q_{\mathbf{k}+\mathbf{p}}(\tau)\\ &-\int_0^{t_y} d\tau \frac{\sin(\omega_{\mathbf{p}}(t_y-\tau))}{\omega_{\mathbf{p}}}\,\frac{1}{2\omega_{\mathbf{k}}} e^{-i\omega_{\mathbf{k}}(t_x-\tau)} Q_{\mathbf{k}+\mathbf{p}}(\tau). \end{aligned} \tag{4.31}$$

This form is not suitable for investigation since $\Pi_{\mathbf{Ps}}$ has been discovered not to be a distribution, while $Q_{\mathbf{ps}}$ is a distribution rather that ordinary function. However, we can use the relation $Q=-\ddot{R}$ and integrate by parts. We obtain:

$$\begin{aligned} w_2(\mathbf{k},t_x;\mathbf{p},t_y)=&\sqrt{\frac{\omega_{\mathbf{k}}+\omega_{\mathbf{p}}}{\omega_{\mathbf{k}}\omega_{\mathbf{p}}}} Q_{\mathbf{k}+\mathbf{p},\mathbf{k}-\mathbf{p}/2}\cos(\omega_{\mathbf{k}}t_x+\omega_{\mathbf{p}}t_y)+\frac{1}{\sqrt{\omega_{\mathbf{k}}\omega_{\mathbf{p}}(\omega_{\mathbf{k}}+\omega_{\mathbf{p}})}}\,\Pi^{ren}_{\mathbf{k}+\mathbf{p},\mathbf{k}-\mathbf{p}/2}\\ &\times\sin(\omega_{\mathbf{k}}t_x+\omega_{\mathbf{p}}t_y)-\int_0^{t_x} d\tau \frac{\partial}{\partial\tau}\left(\frac{\sin(\omega_{\mathbf{k}}(t_x-\tau))}{\omega_{\mathbf{k}}}\,\frac{1}{2\omega_{\mathbf{p}}} e^{-i\omega_{\mathbf{p}}(\tau-t_y)}\right)\frac{\partial}{\partial\tau} R_{\mathbf{k}+\mathbf{p}}(\tau)\\ &-\int_0^{t_y} d\tau \frac{\partial}{\partial\tau}\left(\frac{\sin(\omega_{\mathbf{p}}(t_y-\tau))}{\omega_{\mathbf{p}}}\,\frac{1}{2\omega_{\mathbf{k}}} e^{-i\omega_{\mathbf{k}}(t_x-\tau)}\right)\frac{\partial}{\partial\tau} R_{\mathbf{k}+\mathbf{p}}(\tau). \end{aligned} \tag{4.32}$$

Since for any smooth function φ, the integral

$$\int_0^t d\tau \dot{R}_{\mathbf{P}}(\tau)\varphi(\tau)=R_{\mathbf{P}}(\tau)\varphi(\tau)\big|_0^t-\int_0^t d\tau \dot{\varphi}(\tau) R_{\mathbf{P}}(\tau)$$

is defined as an operator distribution of $\mathbf{P}$ ($R_{\mathbf{P}}(\tau)$ is a distribution of $\mathbf{P}$ at fixed τ), while $Q_{\mathbf{Ps}}$ and $\Pi^{ren}_{\mathbf{Ps}}$ are operator distributions, expression (4.32) gives us an operator distribution. Thus, we obtain the following proposition.

Proposition 4.7: $w_2(\mathbf{k},t_x;\mathbf{p},t_y)$ is:

(1) an operator distribution of $\mathbf{k}$ *and* $\mathbf{p}$ *at fixed* t_x, t_y, *and*

(2) an operator distribution of $\mathbf{k},t_x,\mathbf{p}$, *and* t_y.

Corollary of proposition 4.6 implies the following statement.

Proposition 4.8: The transformation properties of w_2 under spatial rotations and translations are:

$$U_{\Lambda,0} w_2(\mathbf{k},t_x,\mathbf{p},t_y)U^{-1}_{\Lambda,0}=w_2(\Lambda\mathbf{k},t_x,\Lambda\mathbf{p},t_y)$$
$$U_{1,a} w_2(\mathbf{k},t_x,\mathbf{p},t_y)U^{-1}_{1,a}=e^{-i(\mathbf{k}+\mathbf{p})\mathbf{a}} w_2(\mathbf{k},t_x;\mathbf{p},t_y). \tag{4.33}$$

Corollary: $\hat{W}(\mathbf{x},t_x;\mathbf{y},t_y)$ *is a* t_x*- and* t_y*-dependent operator distribution of* $\mathbf{x}$ *and* $\mathbf{y}$ *with the following transformation properties under spatial rotations and translations:*

$$U_{\Lambda,0}\hat{W}_2(\mathbf{x},t_x,\mathbf{y},t_y)U_{\Lambda,0}^{-1}=\hat{W}_2(\Lambda\mathbf{x},t_x,\Lambda\mathbf{y},t_y),$$
$$U_{1,a}\hat{W}_2(\mathbf{x},t_x,\mathbf{y},t_y)U_{1,a}^{-1}=\hat{W}_2(\mathbf{x}+\mathbf{a},t_x;\mathbf{y}+\mathbf{a},t_y). \tag{4.34}$$

$\hat{W}(x,y)$ *is also an operator distribution of* x *and* y.

Consider the operators

$$W_2[f,t_x,t_y]=\int d\mathbf{x}d\mathbf{y}\hat{W}_2(\mathbf{x},t_x;\mathbf{y},t_y)f(\mathbf{x},\mathbf{y}).$$

Proposition 4.9: The set of all finite linear combinations

$$\sum_n W_2[f_{n,1},t_{x,1}^n,t_{y,1}^n]\ldots W_2[f_{n,s_n},t_{x,s_n}^n,t_{y,s_n}^n]|0\rangle \tag{4.35}$$

is dense in $\mathcal{F}(\mathcal{H}_2)$.

To prove this proposition, it is sufficient to consider the case $t_{x,i}^n=t_{y,i}^n=0$ only and use lemma A.15.

One can also consider the operators

$$W_2[g]=\int dt_x dt_y d\mathbf{x}d\mathbf{y}W_2(\mathbf{x},t_x;\mathbf{y},t_y)g(\mathbf{x},t_x,\mathbf{y},t_y).$$

Proposition 4.10: The set of all finite linear combinations

$$\sum_n W_2[g_{n,1}]\ldots W_2[g_{n,s_n}]|0\rangle \tag{4.36}$$

is dense in $\mathcal{F}(\mathcal{H}_2)$.

To prove this proposition, it is sufficient to approximate the vector (4.35) by the vector (4.36) by choosing

$$g_{n,k}(\mathbf{x},t_x;\mathbf{y},t_y)=f_{n,k}(\mathbf{x},\mathbf{y})\frac{1}{\epsilon^2}\varphi(t_x/\epsilon,t_y/\epsilon)$$

for any smooth function $\varphi(\tau_x,\tau_y)$ with compact support such that $\int d\tau_x d\tau_y\varphi(\tau_x,\tau_y)=1$.

Thus, the cyclic property of the vacuum state is checked.

E. Invariance under time translations

The purpose of this subsection is to check the invariance property of the bifield under time translations:

$$U_{1,a}\hat{W}_2(\mathbf{x},t_x,\mathbf{y},t_y)U_{1,a}^{-1}=\hat{W}_2(\mathbf{x},t_x+t,\mathbf{y},t_y+t), \tag{4.37}$$

if $a^0=t$ and $\mathbf{a}=0$. Let us prove first the following proposition. Denote

$$Q_{\mathbf{Ps}}(T)=e^{iHT}Q_{\mathbf{Ps}}e^{-iHT},\quad \Pi_{\mathbf{Ps}}^{ren}(T)=e^{iHT}\Pi_{\mathbf{Ps}}^{ren}e^{-iHT}.$$

For smooth function $f(\tau)$, let

$$\int_0^T d\tau f(\tau)\frac{\partial}{\partial\tau}R_{\mathbf{P}}(\tau)\equiv f(\tau)R_{\mathbf{P}}(\tau)|_0^T-\int_0^T d\tau\frac{\partial f}{\partial\tau}R_{\mathbf{P}}(\tau).$$

Proposition 4.11: The following properties are satisfied:

$$\begin{aligned}
Q_{\mathbf{Ps}}(T)&=Q_{\mathbf{Ps}}\cos(\Omega_{\mathbf{Ps}}T)+\Pi_{\mathbf{Ps}}^{ren}\frac{sin(\Omega_{\mathbf{Ps}})T}{\Omega_{\mathbf{Ps}}}\\
&\quad-\int_0^T\frac{d\tau}{2\sqrt{\omega_{\mathbf{P}/2-\mathbf{s}}\omega_{\mathbf{P}/2+\mathbf{s}}\Omega_{\mathbf{Ps}}}}\frac{\partial}{\partial\tau}[\sin(\Omega_{\mathbf{Ps}}(T-\tau))]\frac{\partial}{\partial\tau}R_{\mathbf{P}}(\tau),\\
\Pi_{\mathbf{Ps}}^{ren}(T)&=\Pi_{\mathbf{Ps}}^{ren}\cos(\Omega_{\mathbf{Ps}}T)-Q_{\mathbf{Ps}}\Omega_{\mathbf{Ps}}\sin(\Omega_{\mathbf{Ps}}T)\\
&\quad-\int_0^T\frac{d\tau}{2}\sqrt{\frac{\Omega_{\mathbf{Ps}}}{\omega_{\mathbf{P}/2-\mathbf{s}}\omega_{\mathbf{P}/2+\mathbf{s}}}}\frac{\partial}{\partial\tau}[\cos(\Omega_{\mathbf{Ps}}(T-\tau))]\frac{\partial}{\partial\tau}R_{\mathbf{P}}(\tau).
\end{aligned}\tag{4.38}$$

Proof: First of all, notice that

$$\begin{aligned}
Q_{\mathbf{Ps}}(T)&=C^+[\xi_{\mathbf{Ps}}(T)]+C^-[\xi_{-\mathbf{Ps}}(T)],\\
\Pi_{\mathbf{Ps}}^{ren}(T)&=C^+[\pi_{\mathbf{Ps}}^{ren}(T)]+C^-[\pi_{-\mathbf{Ps}}^{ren}(T)],
\end{aligned}\tag{4.39}$$

where $\xi_{\mathbf{Ps}}(T)$ and $\pi_{\mathbf{Ps}}^{ren}(T)$ are the following vector distributions:

$$\begin{aligned}
(\xi_{\mathbf{Ps}}(T))_{\mathbf{P}'\mathbf{s}'}&=\delta_{\mathbf{PP}'}(e^{iM_{\mathbf{P}}T}(2M_{\mathbf{P}})^{-1/2})_{\mathbf{ss}'},\\
(\pi_{\mathbf{Ps}}^{ren}(T))_{\mathbf{P}'\mathbf{s}'}&=\delta_{\mathbf{PP}'}(i\Omega^2M_{\mathbf{P}}^{-2}(M_{\mathbf{P}}/2)^{1/2}e^{iM_{\mathbf{P}}T})_{\mathbf{ss}'}.
\end{aligned}\tag{4.40}$$

Formulas (4.38) mean that

$$\begin{aligned}
\xi_{\mathbf{Ps}}(T)&=\xi_{\mathbf{Ps}}\cos(\Omega_{\mathbf{Ps}}T)+\pi_{\mathbf{Ps}}^{ren}\frac{\sin(\Omega_{\mathbf{Ps}})T}{\Omega_{\mathbf{Ps}}}\\
&\quad-\int_0^T\frac{d\tau}{2\sqrt{\omega_{\mathbf{P}/2-\mathbf{s}}\omega_{\mathbf{P}/2+s}\Omega_{\mathbf{Ps}}}}\frac{\partial}{\partial\tau}[\sin(\Omega_{\mathbf{Ps}}(T-\tau))]\frac{\partial}{\partial\tau}r_{\mathbf{P}}(\tau),\\
\pi_{\mathbf{Ps}}^{ren}(T)&=\pi_{\mathbf{Ps}}^{ren}\cos(\Omega_{\mathbf{Ps}}T)-\xi_{\mathbf{Ps}}\Omega_{\mathbf{Ps}}\sin(\Omega_{\mathbf{Ps}}T)\\
&\quad-\int_0^T\frac{d\tau}{2}\sqrt{\frac{\Omega_{\mathbf{Ps}}}{\omega_{\mathbf{P}/2-\mathbf{s}}\omega_{\mathbf{P}/2+\mathbf{s}}}}\frac{\partial}{\partial\tau}[\cos(\Omega_{\mathbf{Ps}}(T-\tau))]\frac{\partial}{\partial\tau}r_{\mathbf{P}}(\tau).
\end{aligned}\tag{4.41}$$

Integrating relations (4.41) with the function $\varphi\in\mathcal{S}(\mathbf{R}^{2d})$ and applying the operator $(2M_P)^{1/2}$, we transform them to the form

$$e^{iMT}\overline{\varphi}=\cos(\Omega T)\overline{\varphi}+iM^{-1}\Omega\sin(\Omega T)\overline{\varphi}+\int_0^T d\tau(e^{iM\tau})^{\cdot}(\Omega^{-2}-M^{-2})\cos(\Omega(T-\tau))\Omega^2\overline{\varphi},\tag{4.42}$$

$$\begin{aligned}
ie^{iMT}M^{-1}\Omega^2\overline{\varphi}&=iM^{-1}\cos(\Omega T)\overline{\varphi}-\Omega\sin(\Omega T)\overline{\varphi}\\
&\quad-\int_0^T d\tau(e^{iMT})^{\cdot}(\Omega^{-2}-M^{-2})\Omega^3\sin(\Omega(T-\tau))\overline{\varphi}.
\end{aligned}\tag{4.43}$$

Here, Ω is the operator of multiplication by $\Omega_{\mathbf{p}_s}$. We have used the definition of the operator M^{-2}.

Relation (4.43) is a corollary of the relation (4.42) is sufficient to consider the time derivatives of Eq. (4.42). The simplest way to check Eq. (4.42) is to consider the Laplace transformations of the left-hand side

$$\int_0^\infty e^{iMT}e^{-\omega T}dT=\frac{1}{\omega-iM}, \tag{4.44}$$

and of the right-hand side:

$$\frac{\omega}{\omega^2+\Omega^2}+iM^{-1}\frac{\Omega^2}{\omega^2+\Omega^2}+\frac{iM}{\omega-iM}(\Omega^{-2}-M^{-2})\Omega^2\frac{\omega}{\omega^2+\Omega^2}. \tag{4.45}$$

Formulas (4.44) and (4.45) coincide. Thus, Eq. (4.42) is satisfied at $T>0$, the check procedure for $T<0$ is analogous. Proposition is proved.

Proposition 4.12: Relation (4.37) is satisfied.

Proof: One has

$$\begin{aligned}
e^{iHT}w_2(\mathbf{k},t_x;\mathbf{p},t_y)e^{-iHT}=&\sqrt{\frac{\omega_\mathbf{k}+\omega_\mathbf{p}}{\omega_\mathbf{k}\omega_\mathbf{p}}}Q_{\mathbf{k}+\mathbf{p};\mathbf{k}-\mathbf{p}/2}(T)\cos(\omega_\mathbf{k}t_x+\omega_\mathbf{p}t_y)\\
&+\frac{1}{\sqrt{\omega_\mathbf{k}\omega_\mathbf{p}(\omega_\mathbf{k}+\omega_\mathbf{p})}}\Pi_{\mathbf{k}+\mathbf{p};\mathbf{p}-\mathbf{k}/2}(T)\sin(\omega_\mathbf{k}t_x+\omega_\mathbf{p}t_y)\\
&-\int_0^{t_x}d\tau\frac{\sin(\omega_\mathbf{k}(t_x-\tau))}{2\omega_\mathbf{k}\omega_\mathbf{p}}e^{-i\omega_\mathbf{p}(\tau-t_y)}Q_{\mathbf{k}+\mathbf{p}}(\tau+T)\\
&-\int_0^{t_y}d\tau\frac{\sin(\omega_\mathbf{p}(t_y-\tau))}{2\omega_\mathbf{k}\omega_\mathbf{p}}e^{-i\omega_\mathbf{k}(t_x-\tau)}Q_{\mathbf{k}+\mathbf{p}}(\tau+T)
\end{aligned}$$

$$\begin{aligned}
w_2(\mathbf{k},t_x+T;\mathbf{p},t_y+T)=&\sqrt{\frac{\omega_\mathbf{k}+\omega_\mathbf{p}}{\omega_\mathbf{k}\omega_\mathbf{p}}}Q_{\mathbf{k}+\mathbf{p};\mathbf{k}-\mathbf{p}/2}\cos(\omega_\mathbf{k}(t_x+T)+\omega_\mathbf{p}(t_y+T))\\
&+\frac{1}{\sqrt{\omega_\mathbf{k}\omega_\mathbf{p}(\omega_\mathbf{k}+\omega_\mathbf{p})}}\Pi_{\mathbf{k}+\mathbf{p};\,\mathbf{p}-\mathbf{k}/2}\sin(\omega_\mathbf{k}(t_x+T)+\omega_\mathbf{p}(t_y+T))\\
&-\int_0^{t_x+T}d\tau\frac{\sin(\omega_\mathbf{k}(t_x+T-\tau))}{2\omega_\mathbf{k}\omega_\mathbf{p}}e^{-i\omega_\mathbf{p}(\tau-t_y-T)}Q_{\mathbf{k}+\mathbf{p}}(\tau)\\
&-\int_0^{t_y+T}d\tau\frac{\sin(\omega_\mathbf{p}(t_y+T-\tau))}{2\omega_\mathbf{k}\omega_\mathbf{p}}e^{-i\omega_\mathbf{k}(t_x+T-\tau)}Q_{\mathbf{k}+\mathbf{p}}(\tau).
\end{aligned} \tag{4.46}$$

It follows from proposition 4.11 that

$$e^{iHT}w_2(\mathbf{k},t_x;\mathbf{p},t_y)e^{-iHT}=w_2(\mathbf{k},t_x+T;\mathbf{p},t_y+T).$$

We obtain relation (4.37). Proposition is proved.

V. POINCARE INVARIANCE OF THE THEORY

The purpose of this section is to check the property of relativistic invariance of the theory which mean that: (a) the unitary representation of the Poincare group $(\Lambda,a)\mapsto\tilde{U}_{\Lambda,a}$ is constructed:

$$\widetilde{U}_{\Lambda_1,a_1}\widetilde{U}_{\Lambda_2,a_2}=\widetilde{U}_{(\Lambda_1,a_1)(\Lambda_2,a_2)}, \tag{5.1}$$

(b) the k-field operators $\widetilde{W}_k(x_1,\ldots,x_k)$ are Poincare invariant:

$$\widetilde{U}_{\Lambda,a}\widetilde{W}_k(x_1,\ldots,x_k)\widetilde{U}^{-1}_{\Lambda,a}=\widetilde{W}_k(\Lambda x_1+a,\ldots,\Lambda x_k+a), \tag{5.2}$$

and (c) the vacuum state is Poincare invariant:

$$\widetilde{U}_{\Lambda,a}|0\rangle=|0\rangle. \tag{5.3}$$

To simplify the problem, one should be mindful that the state space has been decomposed according to Eq. (2.44), while the operators $\widetilde{U}_{\Lambda,a}$ are looked for in the form $U_{\Lambda,a}\otimes\breve{U}_{\Lambda,a}$. The operators $\breve{U}_{\Lambda,a}$ have already been constructed in Sec. II F.

First of all, we investigate the property of invariance of the operators $\hat{W}_k(x_1,\ldots x_k)$ of the form (4.18) (at $k\neq 2$). These operators are of the form $1\otimes\hat{W}_k(x_1,\ldots x_k)$.

Lemma 5.1: (1) The vacuum state is invariant under action of operators $\breve{U}_{\Lambda,a}$ and (2) For $k\neq 2$, the operators $\hat{W}_k(x_1,\ldots,x_k)$ obey the property

$$\breve{U}_{\Lambda,a}\hat{W}_k(x_1,\ldots,x_k)\breve{U}^{-1}_{\Lambda,a}=\hat{W}_k(\Lambda x_1+a,\ldots,\Lambda x_k+a). \tag{5.4}$$

Proof: The first property is obvious. To prove the second property, it follows from Eq. (4.19), lemma A.11 and formula (2.48) imply that

$$\begin{aligned}\breve{U}_{\Lambda,a}\hat{W}_s(x_1,\ldots,x_s)\breve{U}^{-1}_{\Lambda,a}=\frac{\sqrt{s!}}{(2\pi)^{sd/2}}\int\frac{d\mathbf{p}_1}{\sqrt{2\omega_{\mathbf{p}_1}}}\ldots\frac{d\mathbf{p}_s}{\sqrt{2\omega_{\mathbf{p}_s}}}\\ \times(A^{+(s)}_{\mathbf{p}_1\ldots\mathbf{p}_s}e^{i(p_1+\ldots+p_s)a}e^{i(\Lambda^{-1}p_1\cdot x_1+\ldots+\Lambda^{-1}p_s\cdot x_s)}\\ +A^{-(s)}_{\mathbf{p}_1\ldots\mathbf{p}_s}e^{-i(p_1+\ldots+p_s)a}e^{-i(\Lambda^{-1}p_1\cdot x_1+\ldots+\Lambda^{-1}p_s\cdot x_s)}).\end{aligned} \tag{5.5}$$

Property $\Lambda^{-1}p\cdot x=p\cdot\Lambda x$ imply Eq. (5.4). Lemma is proved.

Lemma 5.2: Let $U_{\Lambda,a}$ be unitary operators in $\mathcal{F}$ such that (a) the group property

$$U_{\Lambda_1,a_1}U_{\Lambda_2,a_2}=U_{(\Lambda_1,a_1)(\Lambda_2,a_2)}, \tag{5.6}$$

is satisfied, (b) the bifield operator is invariant

$$U_{\Lambda,a}\hat{W}_2(x,y)U^{-1}_{\Lambda,a}=\hat{W}_2(\Lambda x+a,\Lambda y+a), \tag{5.7}$$

and (c) the vacuum state is invariant:

$$U_{\Lambda,a}|0\rangle=|0\rangle. \tag{5.8}$$

Then, the operators $\widetilde{U}_{\Lambda,a}=U_{\Lambda,a}\otimes\breve{U}_{\Lambda,a}$ obey properties (5.1)–(5.3).

This lemma is a direct corollary of lemma 5.1 and formula (4.9) for the operators $\widetilde{W}_k(x_1,\ldots,x_k)$.

The remaining problem is to construct operators $U_{\Lambda,a}$ satisfying relations (5.6)–(5.8). One possible way may be the following. The operators P^μ and M^{mn} in $\mathcal{F}$ have been already constructed. One should then try to construct the operator M^{0k} and check the commutation relations of the Poincare algebra.

However, the following problems arise in this approach. It is not easy to check the self-adjointness of the operator M^{0k} since it is an unbounded operator. Further, to construct the group representation from the algebra representation, one should check the conditions of the Nelson theorem[21] or investigate the properties of analytic vectors.[22–24]

Therefore, another approach will be used for constructing the operators $U_{\Lambda,a}$. First of all, we will check the invariance of the Wightman function

$$\langle 0|\hat{W}_2(x,y)\hat{W}_2(x',y')|0\rangle=\langle 0|\hat{W}_2(\Lambda x+a,\Lambda y+a)\hat{W}_2(\Lambda x'+a,\Lambda y'+a)|0\rangle. \tag{5.9}$$

Then, we will define the operator $U_{\Lambda,a}$ from the property

$$U_{\Lambda,a}\hat{W}_2(x_1,y_1)\ldots\hat{W}_2(x_k,y_k)|0\rangle=\hat{W}_2(\Lambda x_1+a,\Lambda y_1+a)\ldots\hat{W}_2(\Lambda x_k+a,\Lambda y_k+a)|0\rangle. \tag{5.10}$$

This definition will be shown to be correct if and only if the property (6.9) is satisfied. Let us investigate the properties of the Wightman functions.

A. The QQ propagator

First of all, we investigate the vacuum average value $\langle 0|Q(x)Q(y)|0\rangle$. It has the form

$$\langle 0|Q(x)Q(y)|0\rangle=\frac{1}{(2\pi)^{2d}}\int d\mathbf{P}(\lambda\Omega^2\chi,e^{i\mathbf{P}(\mathbf{x}-\mathbf{y})-iM(x^0-y^0)}M^{-1}\lambda\Omega^2\chi). \tag{5.11}$$

The vector $\lambda\Omega^2\chi$ is viewed as $\lambda_R M^2\chi$. To check the Poincare invariance of the average (5.11), present it as

$$\langle 0|Q(x)Q(y)|0\rangle=\frac{1}{(2\pi)^{d+1}}\int dPV(P)e^{-iP(x-y)},$$

with

$$V(P^0,\mathbf{P})=\frac{1}{(2\pi)^{d-1}}\int(\lambda\Omega^2\chi)_{\mathbf{Ps}}(\delta(M_{\mathbf{P}}-P^0)M_{\mathbf{P}}^{-1}\lambda\Omega^2\chi)_{\mathbf{Ps}}d\mathbf{s}. \tag{5.12}$$

Making use of the relations

$$\delta(M_{\mathbf{P}}-P^0)M_{\mathbf{P}}^{-1}=2\theta(P^0)\delta(M_{\mathbf{P}}^2-(P^0)^2),\quad 2\pi i\delta(x)=\frac{1}{x-i0}-\frac{1}{x+i0},$$

and

$$\int d\mathbf{s}(\lambda\Omega^2\chi)_{\mathbf{Ps}}\left(\frac{1}{M_{\mathbf{P}}^2+\epsilon^2}\lambda\Omega^2\chi\right)_{\mathbf{Ps}}=\lambda(2\pi)^d\left[1-\frac{1}{1+\lambda I(\mathbf{P},\epsilon)}\right],$$

we take the formula (5.12) to the form

$$V(P^0,\mathbf{P})=2i\theta(P^0)\left[\frac{\lambda}{1+\lambda I(\mathbf{P},i(P^0+i0))}-\frac{\lambda}{1+\lambda I(\mathbf{P},i(P^0-i0))}\right], \tag{5.13}$$

where I is of the form (3.14). We see that the function $\langle 0|Q(x)Q(y)|0\rangle$ is Poincare invariant.

It will be also necessary to calculate the propagator of the field Q. Formally, one has

$$\langle 0|TQ(x)Q(y)|0\rangle=\theta(x^0-y^0)\langle 0|Q(x)Q(y)|0\rangle-\theta(y^0-x^0)\langle 0|Q(y)Q(x)|0\rangle. \quad (5.14)$$

Equation (5.11) implies

$$\langle 0|TQ(x)Q(y)|0\rangle=\frac{1}{(2\pi)^{2d}}\int d\mathbf{P}(\lambda\Omega^2\chi,e^{i\mathbf{P}(\mathbf{x}-\mathbf{y})-iM|x^0-y^0|}M^{-1}\lambda\Omega^2\chi).$$

The Fourier transformation of the propagator which is defined from the relation

$$\langle 0|TQ(x)Q(y)|0\rangle=\frac{1}{(2\pi)^{d+1}}\int dPG_Q(P)e^{-iPx},$$

can be presented as

$$G_Q(P^0,\mathbf{P})=-2i\int d\mathbf{s}(\lambda\Omega^2\chi)_{\mathbf{Ps}}((M_{\mathbf{P}}^2-P_0^2-i0)^{-1}\lambda\Omega^2\chi)_{\mathbf{Ps}}=-2i\lambda+\frac{2i\lambda}{1+\lambda I(\mathbf{P},i(P^0+i0))}.$$

We see that formally calculated propagator consists of the singular part

$$\langle 0|TQ(x)Q(y)|0\rangle^{\text{sing}}=-2i\lambda\,\delta(x-y),$$

and of the regular (renormalized) part with the Fourier transformation

$$G_Q^{ren}(P^0,\mathbf{P})=\frac{2i\lambda}{1+\lambda I(\mathbf{P},i(P^0+i0))}. \quad (5.15)$$

However, this difficulty is usual: the T product is defined up to a quasilocal quantity being proportional to $\delta(x-y)$. Note also that the result (5.15) is in agreement with the approach based on the summation of Feynman graphs.[8]

Thus, we have obtained the following result.

Proposition 5.3: The average value $\langle 0|Q(x)Q(y)|0\rangle$ *is Poincare invariant. Its Fourier transformation has the form (5.13).*

B. The W_2Q average

The purpose of this subsection is to compute the average values

$$F_1(x,y,z)=\langle 0|\hat{W}_2(x,y)Q(z)|0\rangle,\quad F_2(x,y,z)=\langle 0|Q(z)\hat{W}_2(x,y)|0\rangle. \quad (5.16)$$

However, explicit formulas for the operators $\hat{W}_2$ are complicated, so that direct calculations are too difficult. Therefore, the indirect method will be used. First of all, these averages will be calculated at $x^0=y^0>z^0$ and $z^0>x^0=y^0$, correspondingly. Then, we will investigate the properties of the Fourier transformation of the averages. The equations on the averages will be obtained. Then, the solution of the equations will be found.

1. The $x^0=y^0$ case

Consider the average value $\langle 0|Tw_2(\mathbf{p},0;\mathbf{k},0)Q_{\mathbf{P}}(t)|0\rangle$. According to subsection IV. D

$$w_2(\mathbf{p},0;\mathbf{k},0)=\sqrt{\frac{\omega_{\mathbf{k}}+\omega_{\mathbf{p}}}{\omega_{\mathbf{k}}\omega_{\mathbf{p}}}}Q_{\mathbf{k}+\mathbf{p},\mathbf{k}-\mathbf{p}/2}. \quad (5.17)$$

Therefore,

$$\langle 0|Tw_2(\mathbf{p},0;\mathbf{k},0)Q_{\mathbf{p}}(t)|0\rangle = \frac{1}{(2\pi)^{2d}}\sqrt{\frac{\omega_{\mathbf{k}}+\omega_{\mathbf{p}}}{2\omega_{\mathbf{k}}\omega_{\mathbf{p}}}}\delta_{\mathbf{k}+\mathbf{p}+\mathbf{P},0}[\,\theta(-t)(e^{iMt}M^{-1}\lambda\Omega^2\chi)_{\mathbf{P},\mathbf{k}-\mathbf{p}/2}+\theta(t) \times(e^{-iMt}M^{-1}\lambda\Omega^2\chi)_{\mathbf{P},\mathbf{k}-\mathbf{p}/2}]. \tag{5.18}$$

Consider the Fourier transformation of the average (5.17) defined as

$$G(\mathbf{k},\mathbf{p},\epsilon)\,\delta_{\mathbf{k}+\mathbf{p},\mathbf{P}} = \int dt e^{-i\epsilon t}\langle 0|Tw_2(\mathbf{p},0;\mathbf{k},0)Q_{\mathbf{p}}(t)|0\rangle. \tag{5.19}$$

One has

$$G(\mathbf{k},\mathbf{p},\epsilon) = \frac{1}{(2\pi)^d}\sqrt{\frac{2(\omega_{\mathbf{k}}+\omega_{\mathbf{p}})}{\omega_{\mathbf{k}}\omega_{\mathbf{p}}}}\frac{1}{i}\left(\frac{1}{M^2_{\mathbf{k}+\mathbf{p}}-\epsilon^2-i0}\lambda\Omega^2\chi\right)_{\mathbf{k}+\mathbf{p},\mathbf{k}-\mathbf{p}/2}.$$

Making use of the definition of the operator $M^2_{\mathbf{p}}$, we obtain

$$G(\mathbf{k},\mathbf{p},\epsilon) = -\frac{1}{(2\pi)^d}\frac{2(\omega_{\mathbf{k}}+\omega_{\mathbf{p}})}{2\omega_{\mathbf{k}}2\omega_{\mathbf{p}}}\frac{1}{(\omega_{\mathbf{k}}+\omega_{\mathbf{p}})^2-\epsilon^2-i0}G^{ren}_Q(\epsilon,\mathbf{k}+\mathbf{p}).$$

Applying the Fourier transformation to Eq. (5.19), we obtain that

$$\langle 0|T\hat{W}_2(x,y)Q(z)|0\rangle = -i\int d\xi\langle 0|TQ(\xi)Q(z)|0\rangle^{ren}\langle 0|T\phi(x)\phi(y)|0\rangle\langle 0|T\phi(y)\phi(\xi)|0\rangle, \tag{5.20}$$

provided that $x=(\mathbf{x},0)$, $y=(\mathbf{y},0)$, and $z=(\mathbf{z},t)$, while $\langle 0|T\phi(x)\phi(y)|0\rangle$ is the usual propagator of the free scalar field

$$\langle 0|T\phi(x)\phi(y)|0\rangle = \frac{1}{(2\pi)^d}\int\frac{d\mathbf{k}}{2\omega_{\mathbf{k}}}e^{-i\mathbf{k}(\mathbf{x}-\mathbf{y})}e^{-i\omega_{\mathbf{k}}|x^0-y^0|}.$$

Formula (5.20) is valid not only at $x^0=y^0=0$ but also at $x^0=y^0\neq 0$ because of translation invariance properties (Sec. IV). Note also that formula (5.20) is in agreement with the approach based on the summation of Feynman graphs.[8]

Thus, the following result is obtained.

Proposition 5.4: The Green function $\langle 0|T\hat{W}_2(x,y)Q(z)|0\rangle$ *has the form (5.20), provided that* $x^0=y^0$.

2. Properties of the W_2 field

Consider the state $\hat{W}_2(x,y)|0\rangle$. Our purpose is to prove the following property.

Lemma 5.5: The Fourier transformation

$$\int dy\hat{W}_2(x,y)e^{-ipy}|0\rangle \tag{5.21}$$

vanishes at $p^0<0$.

Proof: Consider the vector

$$\int dt_y e^{i\epsilon t_y}w_2(\mathbf{k},t_x;\mathbf{p},t_y)|0\rangle, \tag{5.22}$$

provided that $\epsilon>0$. It is sufficient to show that it vanishes. The vector (5.22) can be presented as

$$C^+[\alpha(\mathbf{k},t_x;\mathbf{p},\boldsymbol{\epsilon})]|0\rangle,$$

with the following vector α:

$$(\alpha(\mathbf{k},t_x;\mathbf{p},\boldsymbol{\epsilon}))_{\mathbf{p}'\mathbf{s}'}=\frac{1}{2}e^{-i\omega_{\mathbf{k}}t_x}\delta_{\mathbf{k}+\mathbf{p},\mathbf{p}'}\Bigg[\sqrt{\frac{\omega_{\mathbf{k}}+\omega_{\mathbf{p}}}{\omega_{\mathbf{k}}\omega_{\mathbf{p}}}}(2M_{\mathbf{k}+\mathbf{p}})^{-1/2}_{\mathbf{k}-\mathbf{p}/2\,s'}$$
$$-\frac{1}{\sqrt{\omega_{\mathbf{k}}\omega_{\mathbf{p}}(\omega_{\mathbf{k}}+\omega_{\mathbf{p}})}}(M_{\mathbf{k}+\mathbf{p}}/2)^{1/2}_{\mathbf{k}-\mathbf{p}/2s'}$$
$$+\frac{1}{(2\pi)^d}\frac{1}{2\omega_{\mathbf{k}}\omega_{\mathbf{p}}}\left(\frac{1}{\omega_{\mathbf{k}}+\omega_{\mathbf{p}}+M_{\mathbf{k}+\mathbf{p}}}M^{-1/2}_{\mathbf{k}+\mathbf{p}}\lambda\Omega^2\chi\right)_{P's'}\Bigg]. \tag{5.23}$$

It follows from the definition of the operator $M_{\mathbf{p}}$ that the quantity (5.23) vanishes. Lemma is proved.

Corollary: The Fourier transformations

$$\int F_1(x,y,z)e^{ipx}dp, \quad \int dy e^{-ipy}F_2(x,y,z) \tag{5.24}$$

vanish at $p^0<0$.

3. Equations for average values

Let us obtain equations for vacuum averages (5.16). It follows from definition (4.32) that

$$\left(\frac{\partial}{\partial x^\mu}\frac{\partial}{\partial x^\mu}+\mu^2\right)\hat{W}_2(x,y)+Q(x)\langle 0|\phi(x)\phi(y)|0\rangle=0.$$

$$\left(\frac{\partial}{\partial y^\mu}\frac{\partial}{\partial y^\mu}+\mu^2\right)\hat{W}_2(x,y)+Q(y)\langle 0|\phi(x)\phi(y)|0\rangle=0.$$

Here, $\langle 0|\phi(x)\phi(y)|0\rangle$ is the vacuum average for the free scalar field.

Thus, we obtain the following statement.

Proposition 5.6: The functions (5.16) obey the following equations:

$$\left(\frac{\partial}{\partial x^\mu}\frac{\partial}{\partial x^\mu}+\mu^2\right)F_1(x,y,z)+\langle 0|Q(x)Q(z)|0\rangle\langle 0|\phi(x)\phi(y)|0\rangle=0.$$

$$\left(\frac{\partial}{\partial y^\mu}\frac{\partial}{\partial y^\mu}+\mu^2\right)F_1(x,y,z)+\langle 0|Q(y)Q(z)|0\rangle\langle 0|\phi(x)\phi(y)|0\rangle=0.$$

$$\left(\frac{\partial}{\partial x^\mu}\frac{\partial}{\partial x^\mu}+\mu^2\right)F_2(x,y,z)+\langle 0|Q(z)Q(x)|0\rangle\langle 0|\phi(x)\phi(y)|0\rangle=0. \tag{5.25}$$

$$\left(\frac{\partial}{\partial y^\mu}\frac{\partial}{\partial y^\mu}+\mu^2\right)F_2(x,y,z)+\langle 0|Q(z)Q(y)|0\rangle\langle 0|\phi(x)\phi(y)|0\rangle=0.$$

Let us prove the following lemma.

Lemma 5.7: Let $F_1(x,y,z)$ *and* $F_2(x,y,x)$ *be distributions obeying the following properties.*

(a) For some distributions, Φ_1 *and* Φ_2

$$F_1(x,y,z)=\Phi_1(x-z,y-z),\quad F_2(x,y,z)=\Phi_2(x-z,y-z),$$

(b) the functions F_1 and F_2 obey Eqs. (5.25),

(c) the Fourier transformations (5.24) vanish at $p^0<0$, and

(d) $F_1(x,y,z)=\langle 0|T\hat{W}_2(x,y)Q(z)|0\rangle$ at $x^0=y^0>z^0$; $F_2(x,y,z)=\langle 0|T\hat{W}_2(x,y)Q(z)|0\rangle$ at $x^0=y^0<z^0$. Then,

$$F_1(x,y,z)=\langle 0|\hat{W}_2(x,y)Q(z)|0\rangle,\quad F_2(x,y,z)=\langle 0|Q(z)\hat{W}_2(x,y)|0\rangle.$$

Proof: Consider the functions

$$\tilde{F}_1(x,y,z)=F_1(x,y,z)-\langle 0|\hat{W}_2(x,y)Q(z)|0\rangle,\quad \tilde{F}_2(x,y,z)=F_2(x,y,z)-\langle 0|Q(z)\hat{W}_2(x,y)|0\rangle.$$

One has $\tilde{F}_{1,2}(x,y,z)=\tilde{\Phi}_{1,2}(x-z,y-z)$. The functions $\tilde{\Phi}_{1,2}$ obey the following properties:

(a)

$$\left(\frac{\partial}{\partial x^\mu}\frac{\partial}{\partial x^\mu}+\mu^2\right)\tilde{\Phi}_{1,2}(x,y)=0,\quad \left(\frac{\partial}{\partial y^\mu}\frac{\partial}{\partial y^\mu}+\mu^2\right)\tilde{\Phi}_{1,2}(x,y)=0,$$

(b) Fourier transformations $\int dx\tilde{\Phi}_1(x,y)e^{ipx}$ and $\int dy\tilde{\Phi}_1(x,y)e^{-ipy}$ vanish if $p^0<0$,

(c) $\tilde{\Phi}_1(x,y)=0$ at $x^0=y^0>0$, and $\tilde{\Phi}_2(x,y)=0$ at $x^0=y^0<0$.

Properties (a) and (b) mean that

$$\tilde{\Phi}_1(x,y)=\int d\mathbf{k}d\mathbf{p}[\alpha^+_{\mathbf{kp}}e^{-i\omega_{\mathbf{k}}x^0+i\omega_{\mathbf{p}}y^0}+\alpha^-_{\mathbf{kp}}e^{-i\omega_{\mathbf{k}}x^0-i\omega_{\mathbf{p}}y^0}]e^{-i\mathbf{kx}-i\mathbf{py}};$$

$$\tilde{\Phi}_2(x,y)=\int d\mathbf{k}d\mathbf{p}[\beta^+_{\mathbf{kp}}e^{i\omega_{\mathbf{k}}x^0+i\omega_{\mathbf{p}}y^0}+\beta^-_{\mathbf{kp}}e^{-i\omega_{\mathbf{k}}x^0+i\omega_{\mathbf{p}}y^0}]e^{-i\mathbf{kx}-i\mathbf{py}},$$

for some $\alpha^\pm_{\mathbf{kp}}$, $\beta^\pm_{\mathbf{kp}}$. Property (c) means that

$$\alpha^+_{\mathbf{kp}}e^{i\omega_{\mathbf{p}}x^0}+\alpha^-_{\mathbf{kp}}e^{-i\omega_{\mathbf{p}}x^0}=0,\quad x^0>0;$$

$$\beta^+_{\mathbf{kp}}e^{i\omega_{\mathbf{k}}x^0}+\beta^-_{\mathbf{kp}}e^{-i\omega_{\mathbf{k}}x^0}=0,\quad x^0<0.$$

We obtain that $\alpha^\pm_{\mathbf{kp}}=0$ and $\beta^\pm_{\mathbf{kp}}=0$. Therefore, $\tilde{\Phi}_1=0$ and $\tilde{\Phi}_2=0$. Lemma is proved.

Lemma 5.8: The average values have the form

$$\begin{aligned}
F_1(x,y,z)&=\langle 0|\hat{W}_2(x,y)Q(z)|0\rangle\\
&=\frac{1}{i}\int d\xi[(\langle 0|T\phi(x)\phi(\xi)|0\rangle-\langle 0|\phi(x)\phi(\xi)|0\rangle)\langle 0|Q(\xi)Q(z)|0\rangle\langle 0|\phi(\xi)\phi(y)|0\rangle\\
&\quad+\langle 0|T\phi(y)\phi(\xi)|0\rangle-\langle 0|\phi(y)\phi(\xi)|0\rangle)\langle 0|Q(\xi)Q(z)|0\rangle\langle 0|\phi(x)\phi(\xi)|0\rangle\\
&\quad+\langle 0|\phi(x)\phi(\xi)|0\rangle\langle 0|\phi(y)\phi(\xi)|0\rangle\langle 0|TQ(\xi)Q(z)|0\rangle^{ren}]\\
F_2(x,y,z)&=\langle 0|Q(z)\hat{W}_2(x,y)|0\rangle\\
&=\frac{1}{i}\int d\xi[(\langle 0|T\phi(x)\phi(\xi)|0\rangle-\langle 0|\phi(\xi)\phi(x)|0\rangle)\langle 0|Q(z)Q(\xi)|0\rangle\langle 0|\phi(\xi)\phi(y)|0\rangle\\
&\quad+(\langle 0|T\phi(y)\phi(\xi)|0\rangle-\langle 0|\phi(\xi)\phi(y)|0\rangle)\langle 0|Q(z)Q(\xi)|0\rangle\langle 0|\phi(x)\phi(\xi)|0\rangle\\
&\quad+\langle 0|\phi(\xi)\phi(x)|0\rangle\langle 0|\phi(\xi)\phi(y)|0\rangle\langle 0|TQ(z)Q(\xi)|0\rangle^{ren}].
\end{aligned}\tag{5.26}$$

Proof: It is sufficient to check the conditions of lemma 5.7. Condition (a) is obvious. Equations (5.25) are corollaries of the property

$$\left(\frac{\partial}{\partial x^\mu}\frac{\partial}{\partial x^\mu}+\mu^2\right)\langle 0|T\phi(x)\phi(y)|0\rangle=\frac{1}{i}\delta(x-y). \tag{5.27}$$

Let us check the condition (c). Note that the Fourier transformations

$$\int dxe^{ipx}\langle 0|\phi(x)\phi(\xi)|0\rangle, \quad \int dxe^{ipx}\langle 0|Q(x)Q(\xi)|0\rangle$$

vanish if $p^0<0$. The same property is also valid for the function

$$\int dxe^{ipx}\langle 0|\phi(x)\phi(\xi)|0\rangle\langle 0|Q(x)Q(\xi)|0\rangle.$$

Since the integral operator with the kernel $\langle 0|T\phi(x)\phi(\xi)|0\rangle$ multiplies the Fourier transformation by $(\mu^2-p^2-i0)^{-1}$, the quantity

$$\int dxe^{ipx}F_1(x,y,z)$$

vanishes if $p^0<0$. The analogous property for the function F_2 is checked in the same way. Property (c) is checked.

To check property (d), note that under condition $x^0=y^0>z^0$, the function F_1 can be presented as

$$\begin{aligned}\frac{1}{i}\Big[&\int d\xi\langle 0|T\phi(x)\phi(\xi)-\phi(x)\phi(\xi)|0\rangle\langle 0|TQ(\xi)Q(z)|0\rangle^{ren}\langle 0|T\phi(\xi)\phi(y)|0\rangle\\ &+\int d\xi\langle 0|T\phi(y)\phi(\xi)-\phi(y)\phi(\xi)|0\rangle\langle 0|TQ(\xi)Q(z)|0\rangle^{ren}\langle 0|T\phi(x)\phi(\xi)|0\rangle\\ &+\int d\xi\langle 0|\phi(x)\phi(\xi)|0\rangle\langle 0|\phi(y)\phi(\xi)|0\rangle\langle 0|TQ(\xi)Q(z)|0\rangle^{ren}\Big]\end{aligned} \tag{5.28}$$

since the first and second integrands may be nonzero only at $\xi^0>x^0=y^0>z^0$. The obtained expression coincides with (5.20). Thus, property (d) is checked for the function F_1. The check for the function F_2 is analogous. Conditions of lemma 5.7 are checked. This implies lemma 5.8.

C. The W_2W_2 averages

The purpose of this subsection is to find explicit forms of the average value

$$F(x,y:x',y')=\langle 0|\hat{W}_2(x,y)\hat{W}_2(x'.y')|0\rangle. \tag{5.29}$$

We consider first the $x^0=y^0>x^{0\prime}=y^{0\prime}$ case. Then, equations on the function F will be obtained. The solution of this equation will be found.

1. The equal-time case

Consider the Green function

$$\langle 0|Tw_2(\mathbf{p},t;\mathbf{k},t)w_2(\mathbf{p}',\tau;\mathbf{k}',\tau)|0\rangle = \sqrt{\frac{\omega_{\mathbf{k}}+\omega_{\mathbf{p}}}{\omega_{\mathbf{k}}\omega_{\mathbf{p}}}}\sqrt{\frac{\omega_{\mathbf{k}'}+\omega_{\mathbf{p}'}}{\omega_{\mathbf{k}'}\omega_{\mathbf{p}'}}}\delta_{\mathbf{k}+\mathbf{p};\mathbf{k}'+\mathbf{p}'} \times\left(\frac{1}{2M_{\mathbf{k}+\mathbf{p}}}e^{-iM_{\mathbf{k}+\mathbf{p}}|t-\tau|}\right)_{\mathbf{k}-\mathbf{p}/2;\mathbf{k}'-\mathbf{p}'/2},$$

and its Fourier transformation

$$\delta_{\mathbf{k}+\mathbf{p};\mathbf{k}'+\mathbf{p}'}G_2(\mathbf{p},\mathbf{k},\mathbf{p}',\mathbf{k}',\epsilon)=\int dte^{i\epsilon t}\langle 0|Tw_2(\mathbf{p},t;\mathbf{k},t)w_2(\mathbf{p}',0;\mathbf{k}',0)|0\rangle. \tag{5.30}$$

One has

$$G_2(\mathbf{p},\mathbf{k},\mathbf{p}',\mathbf{k}',\epsilon)=\sqrt{\frac{\omega_{\mathbf{k}}+\omega_{\mathbf{p}}}{\omega_{\mathbf{k}}\omega_{\mathbf{p}}}}\sqrt{\frac{\omega_{\mathbf{k}'}+\omega_{\mathbf{p}'}}{\omega_{\mathbf{k}'}\omega_{\mathbf{p}'}}}\frac{1}{i}\left(\frac{1}{M^2_{\mathbf{k}+\mathbf{p}}-\epsilon^2-i0}\right)_{\mathbf{k}-\mathbf{p}/2;\mathbf{k}'-\mathbf{p}'/2}.$$

Making use of the definition of the operator $M^2_{\mathbf{P}}$, we obtain:

$$\begin{aligned}G_2(\mathbf{p},\mathbf{k},\mathbf{p}',\mathbf{k}',\epsilon)=&\sqrt{\frac{\omega_{\mathbf{k}}+\omega_{\mathbf{p}}}{\omega_{\mathbf{k}}\omega_{\mathbf{p}}}}\sqrt{\frac{\omega_{\mathbf{k}'}+\omega_{\mathbf{p}'}}{\omega_{\mathbf{k}'}\omega_{\mathbf{p}'}}}\frac{1}{2i}\frac{1}{(\omega_{\mathbf{k}}+\omega_{\mathbf{p}})^2-\epsilon^2-i0}\\ &\times\left(\delta_{\mathbf{k}-\mathbf{p}/2,\,\mathbf{k}'-\mathbf{p}'/2}+\delta_{\mathbf{k}-\mathbf{p}/2,\,\mathbf{p}'-\mathbf{k}'/2}\right)+\frac{1}{(2\pi)^d}\frac{\omega_{\mathbf{k}}+\omega_{\mathbf{p}}}{2\omega_{\mathbf{k}}\omega_{\mathbf{p}}}\frac{\omega_{\mathbf{k}'}+\omega_{\mathbf{p}'}}{2\omega_{\mathbf{k}'}\omega_{\mathbf{p}'}}\\ &\times\frac{1}{(\omega_{\mathbf{k}}+\omega_{\mathbf{p}})^2-\epsilon^2-i0}\frac{1}{(\omega_{\mathbf{k}'}+\omega_{\mathbf{p}'})^2-\epsilon^2-i0}G_Q^{ren}(\epsilon,\mathbf{k}+\mathbf{p}).\end{aligned} \tag{5.31}$$

Applying the Fourier transformation to expression (5.30), we obtain that

$$\begin{aligned}\langle 0|T\hat{W}_2(x,y)\hat{W}_2(x',y')|0\rangle=&\langle 0|T\phi(x)\phi(x')|0\rangle\langle 0|T\phi(y)\phi(y')|0\rangle+\langle 0|T\phi(x)\phi(y')|0\rangle\\ &\times\langle 0|T\phi(y)\phi(x')|0\rangle-\int d\xi d\xi'\langle 0|TQ(\xi)Q(\xi)|0\rangle^{ren}\\ &\times\langle 0|T\phi(x)\phi(\xi)|0\rangle\langle 0|T\phi(y)\phi(\xi)|0\rangle\\ &\times\langle 0|T\phi(\xi')\phi(x')|0\rangle\langle 0|T\phi(\xi')\phi(y')|0\rangle\end{aligned} \tag{5.32}$$

provided that $x^0=y^0=t$, $x^{0\prime}=y^{0\prime}=\tau$. Equation (5.32) is in agreement with the approach based on summation of Feynman graphs. We have obtained the following statement.

Proposition 5.9: The Green function F has the form (5.32) at $x^0=y^0$ and $x^{0\prime}=y^{0\prime}$.

The following statements are analogs of proposition 5.6 and corollary of lemma 5.5.

Proposition 5.10: The function F (5.29) obeys the following equations

$$\left(\frac{\partial}{\partial x^\mu}\frac{\partial}{\partial x^\mu}+\mu^2\right)F(x,y,x',y')=-\langle 0|\phi(x)\phi(y)|0\rangle\langle 0|Q(x)\hat{W}_2(x',y')|0\rangle,$$

$$\left(\frac{\partial}{\partial y^\mu}\frac{\partial}{\partial y^\mu}+\mu^2\right)F(x,y,x',y')=-\langle 0|\phi(x)\phi(y)|0\rangle\langle 0|Q(y)\hat{W}_2(x',y')|0\rangle,$$

$$\left(\frac{\partial}{\partial x'^{\mu}}\frac{\partial}{\partial x'^{\mu}}+\mu^2\right)F(x,y,x',y')=-\langle 0|\phi(x')\phi(y')|0\rangle\langle 0|\hat{W}_2(x',y')Q(x')|0\rangle,$$

$$\left(\frac{\partial}{\partial y'^{\mu}}\frac{\partial}{\partial y'^{\mu}}+\mu^2\right)F(x,y,x',y')=-\langle 0|\phi(x')\phi(y')|0\rangle\langle 0|\hat{W}_2(x',y')Q(y')|0\rangle, \quad (5.33)$$

Proposition 5.11: The Fourier transformations

$$\int dx e^{ipx}F(x,y,x',y'), \quad \int dy' e^{-ipy'}F(x,y,x',y') \quad (5.34)$$

vanish at $p^0<0$.

Lemma 5.12: Let $F(x,y,x',y')$ *be a distribution obeying the following properties: (a) the function F obey Eq. (5.33), and (b) the Fourier transformations (5.34) vanish at* $p^0<0$, *and (c) at* $x^0=y^0>x^{0\prime}=y^{0\prime}$

$$F(x,y;x',y')=\langle 0|T\hat{W}_2(x,y)\hat{W}_2(x',y')|0\rangle.$$

Then,

$$F(x,y;x',y')=\langle 0|\hat{W}_2(x,y)\hat{W}_2(x',y')|0\rangle.$$

Proof: Consider the function

$$\tilde{F}(x,y;x',y')=F(x,y;x',y')-\langle 0|\hat{W}_2(x,y)\hat{W}_2(x',y')|0\rangle$$

obeying the properties:

(a)

$$\left(\frac{\partial}{\partial x^{\mu}}\frac{\partial}{\partial x^{\mu}}+\mu^2\right)\tilde{F}(x,y,x',y')=0, \quad \left(\frac{\partial}{\partial y^{\mu}}\frac{\partial}{\partial y^{\mu}}+\mu^2\right)\tilde{F}(x,y,x',y')=0,$$

$$\left(\frac{\partial}{\partial x^{\mu\prime}}\frac{\partial}{\partial x^{\mu\prime}}+\mu^2\right)\tilde{F}(x,y,x',y')=0, \quad \left(\frac{\partial}{\partial y^{\mu\prime}}\frac{\partial}{\partial y\mu\prime}+\mu^2\right)\tilde{F}(x,y,x',y')=0, \quad (5.35)$$

(b) the Fourier transformations

$$\int dx e^{ipx}\tilde{F}(x,y,x',y'), \quad \int dy' e^{-ipy'}\tilde{F}(x,y,x',y')$$

vanish at $p^0<0$. (c) $\tilde{F}(x,y;x',y')=0$ at $x^0=y^0>x^{0\prime}=y^{0\prime}$.

Therefore,

$$\begin{aligned}\tilde{F}(x,y;x',y')=\int d\mathbf{k}d\mathbf{p}d\mathbf{k}'d\mathbf{p}'[&\alpha^{++}_{\mathbf{kpk'p'}}e^{i\omega_{\mathbf{k}}x^0+i\omega_{\mathbf{p}}y^0+i\omega_{\mathbf{k}'}x^{0\prime}-i\omega_{\mathbf{p}'}y^{0\prime}}\\&+\alpha^{+-}_{\mathbf{kpk'p'}}e^{i\omega_{\mathbf{k}}x^0+i\omega_{\mathbf{p}}y^0-i\omega_{\mathbf{k}'}x^{0\prime}-i\omega_{\mathbf{p}'}y^{0\prime}}+\alpha^{-+}_{\mathbf{kpk'p'}}e^{i\omega_{\mathbf{k}}x^0-i\omega_{\mathbf{p}}y^0+i\omega_{\mathbf{k}'}x^{0\prime}-i\omega_{\mathbf{p}'}y^{0\prime}}\\&+\alpha^{--}_{\mathbf{kpk'p'}}e^{i\omega_{\mathbf{k}}x^0-i\omega_{\mathbf{p}}y^0-i\omega_{\mathbf{k}'}x^{0\prime}-i\omega_{\mathbf{p}'}y^{0\prime}}]e^{-i(\mathbf{kx}+\mathbf{py}+\mathbf{k}'\mathbf{x}'+\mathbf{p}'\mathbf{y}')}. \quad (5.36)\end{aligned}$$

Relation (c) implies that

$$\alpha^{++}_{\mathbf{kpk'p'}} e^{i\omega_{\mathbf{p}} y^0 + i\omega_{\mathbf{k'}} x^{0\prime}} + \alpha^{+-}_{\mathbf{kpk'p'}} e^{i\omega_{\mathbf{p}} y^0 - i\omega_{\mathbf{k'}} x^{0\prime}} + \alpha^{-+}_{\mathbf{kpk'p'}} e^{-i\omega_{\mathbf{p}} y^0 + i\omega_{\mathbf{k'}} x^{0\prime}} + \alpha^{--}_{\mathbf{kpk'p'}} e^{-i\omega_{\mathbf{p}} y^0 - i\omega_{\mathbf{k'}} x^{0\prime}} = 0$$

at $x^0 = y^0 > x^{0\prime} = y^{0\prime}$. Therefore, all α vanish, so that $\tilde{F} = 0$. Lemma 5.12 is proved.

3. Explicit form of average values

Lemma 5.13: The function F has the form

$$\begin{aligned} F(x,y;x',y') &= \langle 0|\phi(x)\phi(x')|0\rangle\langle 0|\phi(y)\phi(y')|0\rangle + \langle 0|\phi(x)\phi(y')|0\rangle\langle 0|\phi(y)\phi(x')|0\rangle \\ &- i\int d\xi \langle 0|\phi(x)\phi(\xi)|0\rangle\langle 0|\phi(y)\phi(\xi)|0\rangle\langle 0|TQ(\xi)\hat{W}_2(x',y')|0\rangle \\ &- i\int d\xi [\langle 0|T\phi(x)\phi(\xi) - \phi(x)\phi(\xi)|0\rangle\langle 0|\phi(\xi)\phi(y)|0\rangle + \langle 0|T\phi(y)\phi(\xi) \\ &- \phi(y)\phi(\xi)|0\rangle\langle 0|\phi(x)\phi(\xi)|0\rangle]\langle 0|Q(\xi)\hat{W}_2(x',y')|0\rangle \\ &+ \int d\xi d\xi' \langle 0|T\phi(x')\phi(\xi') - \phi(x')\phi(\xi')|0\rangle\langle 0|T\phi(\xi')\phi(y') - \phi(\xi')\phi(y')|0\rangle \\ &\times \langle 0|\phi(x)\phi(\xi)|0\rangle\langle 0|\phi(y)\phi(\xi)|0\rangle\langle 0|TQ(\xi)Q(\xi')|0\rangle, \end{aligned} \tag{5.37}$$

where $\langle 0|TQ(\xi)\hat{W}_2(x',y')|0\rangle$ *is the function of the form (5.20).*

Since the straightforward check of the conditions of lemma 5.12 is analogous to proof of lemma 5.8, proof of lemma 5.13 is obvious.

Corollary: The function F is Poincare invariant:

$$F(x,y;x',y') = F(\Lambda x + a, \Lambda y + a, \Lambda x' + a, \Lambda y' + a).$$

D. Check of Poincare invariance

First of all, note that all Wightman functions are Poincare invariant.

Lemma 5.14: The following property is satisfied:

$$\langle 0|\hat{W}_2(x_1,y_1)\ldots\hat{W}_2(x_n,y_n)|0\rangle = \langle 0|\hat{W}_2(\Lambda x_1 + a, \Lambda y_1 + a)\ldots\hat{W}_2(\Lambda x_n + a, \Lambda y_n + a)|0\rangle.$$

To prove this lemma, it is sufficient to notice that operators $\hat{W}_2(x,y)$ are linear combinations of creation and annihilation operators, so that the Wick theorem is applicable.

Lemma 5.15: 1. There exists a unique unitary operator $U_{\Lambda,a}$ *obeying the properties:* $U_{\Lambda,a}|0\rangle = |0\rangle$,

$$U_{\Lambda,a}\hat{W}_2(x_1,y_1)\ldots\hat{W}_2(x_n,y_n)|0\rangle = \hat{W}_2(\Lambda x_1 + a, \Lambda y_1 + a)\ldots\hat{W}_2(\Lambda x_n + a, \Lambda y_n + a)|0\rangle \tag{5.38}$$

2. The group property (5.6) is satisfied, and 3. The invariance property (5.7) is satisfied.

Proof: Let $W_2[f] = \int dxdy\hat{W}_2(x,y)f(x,y)$,

$$\Phi = c|0\rangle + \sum_{n=1}^{N} W_2[f_{n,1}]\ldots W_2[f_{n,i_n}]0\rangle. \tag{5.39}$$

Set

$$U_{\Lambda,a}\Phi = c|0\rangle + \sum_{n=1}^{N} W_2[u_{\Lambda,a}f_{n,1}]\ldots W_2[u_{\Lambda,a}f_{n,i_n}]0\rangle$$

with

$$(u_{\Lambda,a}f)(x,y)=f(\Lambda^{-1}(x-a),\Lambda^{-1}(y-a)).$$

It follows from lemma 5.14 that $(U_{\Lambda,a}\Phi,U_{\Lambda,a}\Phi)=(\Phi,\Phi)$. This means that $U_{\Lambda,a}\Phi=0$, provided that $\Phi=0$. Thus, the mapping $U_{\Lambda,a}:\mathcal{D}\to\mathcal{D}$ is defined (here $\mathcal{D}$ is a set of all vectors of the form (5.38)). This mapping is a linear isometric (and therefore bounded) operator, while $\mathcal{D}$ is a dense subset of $\mathcal{F}$. Therefore, the operator $U_{\Lambda,a}$ can be uniquely extended to the space $\mathcal{F}$. Thus, there exists a unique isometric operator $U_{\Lambda,a}$ obeying the property (5.38).

Check the group property. Consider the operator

$$V=U_{\Lambda_1,a_1}U_{\Lambda_2,a_2}U_{((\Lambda_1,a_1)(\Lambda_2a_2))^{-1}}.$$

It satisfies the property:

$$V\hat{W}_2(x_1,y_1)\ldots\hat{W}_2(x_n,y_n)|0\rangle=\hat{W}_2(x_1,y_1)\ldots\hat{W}_2(x_n,y_n)|0\rangle$$

Thus, $V=1$. The group property is checked. One analogously proves that $U^{-1}_{\Lambda,a}=U_{(\Lambda,a)^{-1}}$, so that the isometric operator $U_{\Lambda,a}$ is unitary.

One also has

$$U_{\Lambda,a}\hat{W}_2(x,y)U^{-1}_{\Lambda,a}\hat{W}_2(x_1,y_1)\ldots\hat{W}_2(x_n,y_n)|0\rangle$$
$$=\hat{W}(\Lambda x+a,\Lambda y+a)\hat{W}_2(x_1,y_1)\ldots\hat{W}_2(x_n,y_n)|0\rangle.$$

Thus, the property (5.7) is satisfied on the subspace $\mathcal{D}\subset\mathcal{F}$. Lemma 5.15 is proved.

Thus, we have checked the property of Poincare invariance of the theory.

VI. CONCLUSIONS

An old problem of axiomatic and constructive field theory is to construct a nontrivial model of relativistic QFT which obey Wightman axioms. The known models successfully constructed[13] in two- and three-dimensional space–time do not contain such difficulties as Stueckelberg divergences and infinite renormalization of the wave function.

A suitable language to describe the states and observables of the large-N theory in the leading order of $1/N$-expansion is the notion of third quantization introduced in quantum cosmology[25,26] in order to describe processes with variable number of universes.

The third-quantized model considered in this paper may be viewed as a large-N limit of the ordinary field theory. However, it can be also interpreted as an independent model of relativistic quantum theory. We have seen that such properties as renormalizability are satisfied in higher dimensions with respect to ordinary field theories (cf. Ref. 27): the model (2.47) is renormalized at $d+1\leqslant 5$, while the $(\varphi^a\varphi^a)^2$ model is renormalized at $d+1\leqslant 4$ only. Thus, usage of third-quantized models leads to new types of renormalizable theories in higher dimensions.

For the simplicity, we have considered the large-N approximation for the $(\varphi^a\varphi^a)^2$ model only. One can also consider the $\varphi^a\varphi^a\Phi$ model. For this case, the phenomenon of infinite renormalization of the wave function should be investigated: it happens that indefinite inner product should be introduced in the state space.[28] Investigation of the large-N QED (quantum electrodynamics) in the third-quantized formulation gives us a good example of renormalizable gauge theory beyond perturbation theory.

APPENDIX A: SOME PROPERTIES OF THE FOCK SPACE

Let $\mathcal{H}$ be a Hilbert space. Denote by $\mathcal{H}^{\otimes n}=\mathcal{H}\otimes\ldots\otimes\mathcal{H}$ the n-th tensor degree of space $\mathcal{H}$. Let π be a transposition $(\pi_1,\ldots,\pi_n)$, $1\leqslant\pi_1\neq\ldots\neq\pi_n\leqslant n$ of numbers $(1,\ldots,n)$. Consider the operator $\hat{\pi}$ in $\mathcal{H}^{\otimes n}$ which is uniquely defined from the relation

$$\hat{\pi}(e_1\otimes\ldots\otimes e_n)=e_{\pi_1}\otimes\ldots\otimes e_{\pi_n},\quad e_1,\ldots,e_n\in\mathcal{H}.$$

By Sym, we denote the symmetrization operator

$$\mathrm{Sym}\,\Phi_n=\frac{1}{n!}\sum_{\pi}\hat{\pi}\Phi_n,\quad \Phi_n\in\mathcal{H}^{\otimes n},$$

which is a projector. Introduce the notation $\mathcal{H}^{\vee n}=\mathrm{Sym}\,\mathcal{H}^{\otimes n}$ for the symmetrized n-th tensor degree of $\mathcal{H}$. Denote also $\mathcal{H}^{\vee 0}=\mathbf{C}$.

Lemma A.1: The set $\{f^{\otimes n}\equiv f\otimes\ldots\otimes f|f\in\mathcal{H}\}$ *is a total set in* $\mathcal{H}^{\vee n}$.

Proof: Let $\Phi_n\in\mathcal{H}^{\vee n}$, $\Phi_n\perp f\otimes\ldots\otimes f$ for all $f\in\mathcal{H}$. It is necessary to prove that $\Phi_n=0$. For

$$f=\alpha_1e_1+\ldots+\alpha_ne_n,\quad \alpha_1,\ldots,\alpha_n\in\mathbf{C},\quad e_1,\ldots,e_n\in\mathcal{H}$$

one has

$$0=\sum_{i_1\ldots i_n=1}^{n}\alpha_{i_1}\ldots\alpha_{i_n}(\Phi_n,e_{i_1}\otimes\ldots\otimes e_{i_n}).$$

The right-hand side of this relation is a polynomial in $\alpha_1,\ldots,\alpha_n$. The coefficient of $\alpha_1\ldots\alpha_n$ should be equal to zero:

$$n!(\Phi_n,\mathrm{Sym}\,e_1\otimes\ldots\otimes e_n)=0. \tag{A1}$$

Relation (A1) is satisfied for all $e_1,\ldots,e_n\in\mathcal{H}$.

Let $f_1,f_2,\ldots$ be an orthonormal basis in $\mathcal{H}$. Then $\{f_{i_1}\otimes\ldots\otimes f_{i_n},i_1,\ldots,i_n=\overline{1,\infty}\}$ is an orthonormal basis in $\mathcal{H}^{\otimes n}$. The vector Φ_n can be presented as

$$\Phi_n=\sum_{i_1\ldots i_n=1}^{\infty}\Phi^n_{i_1\ldots i_n}f_{i_1}\otimes\ldots\otimes f_{i_n}.$$

Since

$$\mathrm{sym}\,\Phi_n=\sum_{i_1\ldots i_n=1}^{\infty}\frac{1}{n!}\sum_{\pi}\Phi^n_{i_{\pi_1}\ldots i_{\pi_n}}f_{i_1}\otimes\ldots\otimes f_{i_n},$$

$\Phi_n\in\mathcal{H}^{\vee n}$ if and only if $\Phi^n_{i_1\ldots i_n}$ is symmetric with respect to transpositions of $i_1,\ldots,i_n$.

For symmetric Φ^n one has

$$(\mathrm{Sym}\,f_{j_1}\otimes\ldots f_{j_n},\Phi_n)=\Phi^n_{j_1\ldots j_n}.$$

Thus, Eq. (A1) implies that $\Phi^n_{i_1\ldots i_n}=0$ and $\Phi_n=0$. Lemma is proved.

Definition A.1: The space

$$\mathcal{F}(\mathcal{H})=\oplus_{n=0}^{\infty}\mathcal{H}^{\vee n}$$

is a Fock space.

Let $f\in\mathcal{H}$. The creation and annihilation operators $A_n^+(f):\mathcal{H}^{\vee n-1}\to\mathcal{H}^{\vee n}$, $A_n^-(f):\mathcal{H}^{\vee n}\to\mathcal{H}^{\vee n-1}$ are defined from the relations:

$$A_n^+(f)e^{\otimes n-1}=\frac{1}{\sqrt{n}}\sum_{k=0}^{n-1} e^{\otimes k}\otimes f\otimes e^{\otimes(n-k-1)},$$
$$A_n^-(f)e^{\otimes n}=\sqrt{n}(f,e)e^{\otimes n-1}. \tag{A2}$$

Lemma A.2: The definition (A2) is correct. $A_n^\pm(f)$ are bounded operators and $||A_n^\pm(f)||\leqslant\sqrt{n}||f||$.

Proof: One has

$$||A_n^+(f)\sum_i e_i^{\otimes n-1}||\leqslant\frac{1}{\sqrt{n}}||\sum_i e_i^{\otimes k}\otimes f\otimes e_i^{\otimes(n-k-1)}||$$
$$=\frac{1}{\sqrt{n}}\sum_{k=0}^{n-1}||f||||\sum_i e_i^{\otimes n-1}||=\sqrt{n}||f||||\sum_i e_i^{\otimes n-1}||.$$

$$||A_n^-(f)\sum_i e_i^{\otimes n}||^2=||A_{n+1}^+(f)\sum_i e_i^{\otimes n}||^2-||f||^2||\sum_i e_i^{\otimes n}||^2\leqslant n||f||^2||\sum_i e_i^{\otimes n}||^2.$$

Lemma 2 is proved.

Definition A.2: The operators

$$A^+(f)(\Phi_0,\Phi_1,\Phi_2,\dots)=(0,A_1^+(f)\Phi_0,A_2^+(f)\Phi_1,\dots)$$

and

$$A^-(f)(\Phi_0,\Phi_1,\dots)=(A_1^-(f)\Phi_1,A_2^-(f)\Phi_2,\dots)$$

are called creation and annihilation operators in the Fock space. The finite vectors of the form $(\Phi_0,\dots,\Phi_n,0,0,\dots)$ belong to the domains of $A^\pm(f)$.

Definition A.3: The vector $|0\rangle=(1,0,0,\dots)$ is a vacuum vector.

Lemma A.3: The vector $f=(0,\dots,0,\mathrm{Sym}\,f_1\otimes\dots\otimes f_n,0,\dots)$ can be presented as

$$f=\frac{1}{\sqrt{n!}}A^+(f_1)\dots A^+(f_n)|0\rangle.$$

The proof is straightforward.

Lemma A.4: The following commutation relations take place:

$$[A^\pm(f_1),A^\pm(f_2)]=0 \text{ and } [A^-(f_1),A^+(f_2)]=(f_1,f_2).$$

The operators $A^+(f)$ and $A^-(f)$ are conjugated.

Definition A.4: A coherent state $C(f)$ is a vector $\Phi\in\mathcal{F}$ of the form $C(f)=\Phi=(\Phi_0,\Phi_1,\dots,\Phi_n,\dots)$ with $\Phi_n=1/\sqrt{n!}\,f^{\otimes n}$.

Lemma A.5: The following relations take place:

$$(C(f),C(f))=\exp(f,f), \quad \text{and } A^-(f)C(g)=(g,f)C(g).$$

Lemma A.6: Let $g\in\mathcal{H}$ and g_n, and $n=1,2,\dots$ be such a sequence of elements of $\mathcal{H}$ that $||g_n-g||\to_{n\to\infty}0$. Then $||C(g_n)-C(g)||\to_{n\to\infty}0$.

Proof: Let $\xi_n=g_n-g$. Then,

$$||C(g+\xi_n)-C(g)||^2=e^{(g,g)}[e^{(g,\xi_n)}e^{(\xi_n,g)}e^{(\xi_n,\xi_n)}-e^{(\xi_n,g)}-e^{(g,\xi_n)}+1]\to_{n\to\infty}0.$$

Lemma A.7: The set $\{C(f)|f\in\mathcal{H}\}$ *is a total set in* $\mathcal{F}(\mathcal{H})$.

Proof: Let $\Phi=(\Phi_0,\Phi_1,\ldots,\Phi_n,\ldots)\perp C(\alpha f)$ for all $\alpha\in\mathbf{C}$ and $f\in\mathcal{H}$. Therefore,

$$\sum_{n=0}^{\infty}\frac{\alpha^n}{\sqrt{n!}}(f^{\otimes n},\Phi_n)=0.$$

The series absolutely converges for all α because of the Cauchy–Bunyakovski inequality. Therefore, $(f^{\otimes n}$ and $\Phi_n)=0$ for all f, so that $\Phi_n=0$. Lemma is proved.

Lemma A.8: Let $\mathcal{H}=\mathcal{H}_1\oplus\mathcal{H}_2$. *Then, there exists a unique isomorphism* $I:\mathcal{F}(\mathcal{H}_1)\otimes\mathcal{F}(\mathcal{H}_2)\to\mathcal{F}(\mathcal{H})$ *such that*

$$I(C(f_1)\otimes C(f_2))=C(f_1\oplus f_2),\quad f_1\in\mathcal{H}_1,f_2\in\mathcal{H}_2. \tag{A3}$$

Proof: The mapping (A3) conserves the inner product. Therefore, formula (A3) uniquely defines an isometric operator. Lemma A.7 applied for the space $\mathcal{F}(\mathcal{H})$ implies that the set $I(C(f_1)\otimes C(f_2))$ is a total set in $\mathcal{F}(\mathcal{H})$, so that $I(\mathcal{F}(\mathcal{H}_1)\otimes\mathcal{F}(\mathcal{H}_2))=\mathcal{F}(\mathcal{H})$. Thus, I is an isomorphism. Lemma is proved.

Lemma A.9: Let $f=f_1+f_2$, $f_1\in\mathcal{H}_1$, $f_2\in\mathcal{H}_2$. *Then,*

$$I^{-1}A^{\pm}(f)I=A^{\pm}(f_1)\otimes 1+1\otimes A^{\pm}(f_2). \tag{A4}$$

Proof: It is sufficient to note that the matrix elements of the left-hand and right-hand sides of Eq. (A4) between $C(f_1)\otimes C(f_2)$ and $C(\tilde{f}_1)\otimes C(\tilde{f}_2)$ coincide.

Let U be a bounded operator in $\mathcal{H}$. By $\mathcal{U}(U)$, we denote the operator $\mathcal{U}(U):\mathcal{F}(\mathcal{H})\to\mathcal{F}(\mathcal{H})$ of the form

$$\mathcal{U}(U)(f_0,f_1,\ldots,f_n,\ldots)=(f_0,Uf_1,U\otimes Uf_2,\ldots,U^{\otimes n}f_n,\ldots).$$

Let $\mathcal{H}$ be a self-adjoint operator in $\mathcal{H}$. Consider the one-parametric group of unitary operators e^{-iHt}. The operator-valued mapping $t\mapsto\mathcal{U}(e^{-iHt})$ can be also viewed as a one-parametric group. According to the Stone theorem, it has the form

$$\mathcal{U}(e^{-iHt})=e^{-i\mathcal{F}(H)t},$$

for some self-adjoint operator $\mathcal{F}(H)$ in $\mathcal{F}(\mathcal{H})$. The explicit form of this operator is

$$(\mathcal{F}(H)f)_n=\sum_{k=0}^{n-1}1^{\otimes k}\otimes H\otimes 1^{\otimes(n-k-1)}f_n.$$

Let $\varphi_1,\varphi_2,\ldots$ be an orthonormal basis in $\mathcal{H}$. Let

$$Hf=\sum_{ij=1}^{\infty}H_{ij}\varphi_i(\varphi_j,f).$$

Proposition A.10:

$$\mathcal{F}(H)=\sum_{ij=1}^{\infty}H_{ij}A^{+}[\varphi_i]A^{-}[\varphi_j].$$

The proof is straightforward.

Lemma A.11: Let U *be an unitary operator in* $\mathcal{H}$, $f\in\mathcal{H}$. *Then,*

$$\mathcal{U}(U)A^{\pm}(f)\mathcal{U}(U)^{-1}=A^{\pm}(Uf). \tag{A5}$$

To prove the lemma, it is sufficient to consider the matrix elements of the sides of Eq. (A5) between coherent states.

Formulate now some results concerning vector and operator distributions. Let $\mathcal{S}(\mathbf{R}^n)$ be a space of complex smooth functions $u:\mathbf{R}^n\to\mathbf{C}$ such that

$$||u||_{l,m}=\max_{\alpha_1+\ldots+\alpha_n\leqslant l}\sup_{x\in\mathbf{R}^n}(1+|x|)^m\left|\frac{\partial^{\alpha_1+\ldots\alpha_n}u(x)}{\partial x_1^{\alpha_1}\ldots\partial x_n^{\alpha_n}}\right|\to_{k\to\infty}0.$$

We say that the sequence $\{u_k\}\in\mathcal{S}(\mathbf{R}^n),k=\overline{1,\infty}$ tends to zero if

$$||u_k||_{l,m}\to_{k\to\infty}0$$

for all l and m.

Definition A.5: Let $\mathcal{H}$ be a Hilbert space. A vector distribution f on $\mathbf{R}^n$ is a linear mapping $f:\mathcal{S}(\mathbf{R}^n)\to\mathcal{H}$ such that $||f(u_k)||\to_{k\to\infty}0$ if $u_k\to_{k\to\infty}0$.

Remark: We will write $f(\varphi)=\int dx f(x)\varphi(x)$ and say that $f(x)$ is a vector distribution of the argument $x\in\mathbf{R}^n$.

Lemma A.12: Let $f:\mathbf{R}^n\to\mathcal{H}$ be a strongly continuous bounded vector function. Then $f(\varphi)=\int dx f(x)\varphi(x)$ is a vector distribution.

Lemma A.13: Let f be a vector distribution. Then $\partial f/\partial x^{\alpha}$ is a vector distribution. The proof is straightforward.

Definition A.6: Let $\mathcal{D}\subset\mathcal{H}$ be a dense subset of $\mathcal{H}$. An operator distribution A is a linear mapping

$$\varphi\in\mathcal{S}(\mathbf{R}^n)\mapsto A(\varphi):\mathcal{D}\to\mathcal{D},$$

such that for all $\Phi\in\mathcal{D}$ the mapping $\varphi\mapsto A(\varphi)\Phi$ is a vector distribution.

Let $\mathcal{D}$ be a subset of the Fock space $\mathcal{F}(\mathcal{H})$ which consists of all finite vectors $(f_0,f_1,\ldots,f_k,0,\ldots)$.

Lemma A.14: Let f be a vector distribution. Then $A^{\pm}(f)$ is an operator distribution. Investigate now the cyclic property of the vacuum vector.

Let $\mathcal{G}\in\mathcal{H}\oplus\mathcal{H}$. Consider the operators

$$B(f,g)=A^{+}(f)+A^{-}(g),\quad \text{and}\,(f,g)\in\mathcal{G}.$$

By $I_1:\mathcal{H}\oplus\mathcal{H}\to\mathcal{H}$ we denote the operator $I_1(f,g)=f$.

Lemma A.15: Let $I_1\mathcal{G}$ be a dense subset of $\mathcal{H}$. Then the set of all linear combinations

$$\sum_n c_n B(f_{n,1},g_{n,1})\ldots B(f_{n,k_n},g_{n,k_n})|0\rangle,\quad (f_{i,k_i},g_{i,k_i})\in\mathcal{G} \tag{A6}$$

is dense in $\mathcal{F}(\mathcal{H})$.

Proof: Let $\Phi\in\mathcal{F}(\mathcal{H})$. One should prove that it can be approximated by the linear combination (A6). Lemma A.7 implies that it is sufficient to prove this statement for the coherent states $C(\varphi)$. Choose such a sequence $f_n\in I_1\mathcal{G}$ that $f_n\to\varphi$. Lemma A.6 implies that $C(\varphi)$ can be approximated by $C(f_n)$. Furthermore, the coherent state $C(f_n)$ can be approximated a by finite linear combination of vectors $(A^{+}(f_n))^m|0\rangle$. For some g_n one has $(f_n,g_n)\in\mathcal{G}$. The vector $(A^{+}(f_n))^m|0\rangle$ can be presented as a linear combination of vectors $(B(f_n,g_n))^k|0\rangle$, Lemma A.15 is proved.

APPENDIX B: WHAT IS FIELD?

In Sec. IV, we have investigated the commutation rule between operators $1/N\sum_{a=1}^{N}\varphi^a(x_1)\ldots\varphi^a(x_k)$ and multifield canonical operator

$$\frac{1}{N}\sum_{a=1}^{N}\varphi^a(x_1)\ldots\varphi^a(x_k)K_N=K_N[(\Phi_0,\phi(x_1)\ldots\phi(x_k)\Phi_0)+N^{-1/2}\tilde{W}_k(x_1,\ldots,x_k)+O(N^{-1})].$$

The operators $\tilde{W}_k(x_1,\ldots,x_k)$ acting in the space (2.43) of the theory of infinite number of fields were interpreted as multifield operators.

The purpose of this appendix is to construct analogs of the operators $\varphi^a(x)$ in the $N=\infty$-theory.

One can notice that conception of symmetric states only is not valid for this purpose. If the state $\Psi_N[\varphi^1,\ldots,\varphi^N]$ were symmetric with respect to transpositions of the fields $\varphi^1,\ldots,\varphi^N$, the state $\varphi^1(\mathbf{x})\Psi_N[\varphi^1,\ldots,\varphi^N]$ is not symmetric. Thus, it is necessary to consider the nonsymmetric solutions of Eq. (2.1).

Consider the states of large-N theory which are symmetric with respect to $N-s$ fields $\varphi^{s+1},\ldots,\varphi^N$ only, where s is a finite quantity. Analogously to Eq. (2.6), let Ψ_N be of the form

$$(K_N^s f)[\varphi^1,\ldots,\varphi^N]$$
$$=\sum_{k=0}^{N-s}\frac{\sqrt{k!}}{N^{k/2}}\sum_{s+1\leqslant a_1<\ldots<a_k\leqslant N} f_k[\varphi^1,\ldots,\varphi^s,\varphi^{a_1},\ldots,\varphi^{a_k}]\prod_{a>s,a\neq a_1\ldots a_k}\Phi_0[\varphi^a], \tag{B1}$$

where $f_k[\varphi^1,\ldots,\varphi^s,\phi^1,\ldots,\phi^k]$ are functionals being symmetric under transpositions of fields $\phi^1,\ldots,\phi^k$ and obeying the condition

$$\int D\phi_1\Phi_0^*[\phi_1]f_k[\varphi^1,\ldots,\varphi^s,\phi^1,\ldots,\phi^k]=0. \tag{B2}$$

We see that states under consideration are specified by infinite sets

$$\begin{pmatrix} f_0[\varphi^1,\ldots,\varphi^s] \\ f_1[\varphi^1,\ldots,\varphi^s,\phi^1] \\ \cdots \\ f_k[\varphi^1,\ldots,\varphi^s,\phi^1,\ldots,\phi^k] \\ \cdots \end{pmatrix}. \tag{B3}$$

The state space is then isomorphic to

$$\tilde{\mathcal{F}}_s=\mathcal{H}^{\otimes s}\otimes\mathcal{F}(\oplus_{n=1}^{\infty}\mathcal{H}^{\vee n}). \tag{B4}$$

Since the symmetric state can be viewed as a state of the form (B1), there should be exist an operator $I_s:\tilde{\mathcal{F}}_0\to\tilde{\mathcal{F}}_s$ such that

$$K_N^s I_s f=K_N f.$$

Let us present the explicit form of the operator I_1. One has

$$(K_N f)[\varphi^1,\ldots,\varphi^N]=\sum_{k=0}^{N}\frac{\sqrt{k!}}{N^{k/2}}\sum_{1\leqslant a_1<\ldots<a_k\leqslant N} f_k[\varphi^{a_1},\ldots,\varphi^{a_k}]\prod_{a\neq a_1\ldots a_k}\Phi_0[\varphi^a]$$
$$=\sum_{k=0}^{N}\frac{\sqrt{k!}}{N^{k/2}}\sum_{2\leqslant a_2<\ldots<a_k\leqslant N} f_k[\varphi^1,\varphi^{a_2},\ldots,\varphi^{a_k}]\prod_{a\neq 1,a_2,\ldots,a_k}\Phi_0[\varphi^a]$$
$$+\sum_{k=0}^{N}\frac{\sqrt{k!}}{N^{k/2}}\Phi_0[\varphi^1]\sum_{2\leqslant a_1<\ldots<a_k\leqslant N} f_k[\varphi^{a_1},\ldots,\varphi^{a_k}]\prod_{a\neq 1,a_2,\ldots,a_k}\Phi_0[\varphi^a]. \tag{B5}$$

We see that

$$(I_1 f)_k[\varphi^1,\phi^1,\ldots,\phi^k]=\Phi_0[\varphi^1]f_k[\phi^1,\ldots,\phi^k]+N^{-1/2}(\tilde{A}^-[\varphi^1]f)_k[\phi^1,\ldots,\phi^k]. \tag{B6}$$

One can also perform the symmetrization procedure for the vector (B1) and obtain the symmetric state. Therefore, there should exist an operator $S_s:\tilde{\mathcal{F}}_s\to\tilde{\mathcal{F}}_0$ such that

$$\mathrm{Sym}\,K_N^s f=K_N S_s f.$$

Construct the operator S_1. If

$$\int D\varphi^1 f_k[\varphi^1,\phi^1,\ldots,\phi^k]\Phi_0^*[\varphi^1]=0, \tag{B7}$$

one obtains from direct calculation that

$$(S_1 f)_k[\phi^1,\ldots,\phi^k]=N^{-1/2}\int D\varphi(\tilde{A}^+[\varphi]f)_k[\varphi,\phi^1,\ldots,\phi^k].$$

If

$$f_k[\varphi^1,\phi^1,\ldots,\phi^k]=\Phi_0[\varphi^1]g_k[\phi^1,\ldots,\phi^k], \tag{B8}$$

then

$$(S_1 f)_k[\phi^1,\ldots,\phi^k]=\frac{N-k}{N}g_k[\phi^1,\ldots,\phi^k].$$

Generally, f_k can be viewed as a superposition of vectors obeying conditions (B7) and (B8) correspondingly, so that

$$(S_1 f)_k[\phi^1,\ldots,\phi^k]=\left[1-\frac{\hat{n}}{N}\right]\int D\varphi\Phi_0^*[\varphi]f_k[\varphi,\phi^1,\ldots,\phi^k]$$
$$+N^{-1/2}\int D\varphi(\tilde{A}^+[\varphi]f)_k[\varphi,\phi^1,\ldots,\phi^k]. \tag{B9}$$

The Schrodinger field $\varphi^1(\mathbf{x})$ in $\tilde{\mathcal{F}}_1$ may be viewed as an operator of multiplication by $\varphi^1(\mathbf{x})$, since

$$\varphi^1(\mathbf{x})K_N^1=K_N^1\varphi^1(\mathbf{x}).$$

The multifield can be constructed from the field φ^1 as

$$\tilde{\mathcal{W}}_{N,k}(x_1,\ldots,x_k)=S_1\varphi^1(x_1)\ldots\varphi^1(x_k)I_1 \tag{B10}$$

since

$$\frac{1}{N}\sum_{a=1}^{N}\varphi^a(x_1)\ldots\varphi^a(x_k)=\mathrm{Sym}\,\varphi^1(x_1)\ldots\varphi^1(x_k).$$

One can notice from Eqs. (B6) and (B9), that formula (B10) is in agreement with the results of Sec. IV.

To construct the Heisenberg field operator $\varphi^1(x):\tilde{\mathcal{F}}_1\to\tilde{\mathcal{F}}_1$, it is necessary to commute the Hamiltonian operator $\mathcal{H}_N$ with the operator K_N^1. We obtain:

$$\mathcal{H}_N K_N^1=K_N^1\tilde{\mathcal{H}}_N^1, \tag{B11}$$

where

$$\tilde{\mathcal{H}}_N^1=\tilde{\mathcal{H}}_N+\int d\mathbf{x}\left[-\frac{1}{2}\frac{\delta^2}{\delta\varphi^1(\mathbf{x})\,\delta\varphi^1(\mathbf{x})}+\frac{1}{2}(\nabla\varphi^1)^2(\mathbf{x})+\frac{\mu^2}{2}(\varphi^1(\mathbf{x}))^2\right]+O(N^{-1/2}).$$

Therefore, the Heisenberg operator

$$\varphi^1(\mathbf{x},t)=e^{i\tilde{\mathcal{H}}_N^1 t}\varphi^1(\mathbf{x})e^{-i\tilde{\mathcal{H}}_N^1 t}$$

coincides with the operator of the free scalar field up to $O(N^{-1/2})$. Therefore, for operator $\tilde{\mathcal{W}}_{N,k}$ one has

$$\tilde{\mathcal{W}}_{N,k}(x_1,\ldots,x_k)=\int D\varphi^1\Phi_0^*[\varphi^1]\varphi^1(x_1)\ldots\varphi^1(x_k)\Phi_0[\varphi^1]+O(N^{-1/2}). \tag{B12}$$

This result confirms the hypothesis of Sec. IV.

In order to obtain the explicit form of the $O(N^{-1/2})$-term of formula (B12), it is necessary to compute the $O(N^{-1/2})$-term in Eq. (B11). The result is in agreement with Sec. IV.

(Received 4 December 2000; accepted for publication 4 April 2001)

It is shown that all four superintegrable quantum systems on the Euclidean plane possess the same underlying hidden algebra $sl(3)$. The gauge-rotated Hamiltonians, as well as their integrals of motion, once rewritten in appropriate coordinates, preserve a flag of polynomials. This flag corresponds to highest-weight finite-dimensional representations of the $sl(3)$-algebra, realized by first-order differential operators. © *2001 American Institute of Physics.*

I. INTRODUCTION

The purpose of this article is to establish a relation between two different concepts in quantum mechanics: superintegrability and exact solvability. More specifically, we relate these two concepts in nonrelativistic quantum mechanics in two-dimensional Euclidean space E_2.

The notion of integrability in quantum mechanics[1] comes naturally as a generalization of a similar notion in classical mechanics (see, e.g., Ref. 2). A quantum mechanical system in E_n described by the stationary Schrödinger equation

$$H\Psi = E\Psi, \quad H = -\tfrac{1}{2}\Delta + V(x_1, \ldots, x_n), \tag{1}$$

is completely integrable if there exists a set of $(n-1)$ algebraically independent linear operators $X_a, a = 1,2, \ldots, n-1$ commuting with the Hamiltonian and among each other

$$[H, X_a] = 0, \quad [X_a, X_b] = 0. \tag{2}$$

The system is it superintegrable if there exist k additional operators, Y_b, $b = 1, \ldots, k$, where $0 < k \leqslant (n-1)$, commuting with the Hamiltonian. It is "maximally superintegrable" if $k = n-1$.

The operators X_a, Y_b are usually assumed to be polynomials in the momenta $\{p_1, \ldots, p_n\}$ with coordinate dependent coefficients. A systematic search for superintegrable systems in E_2 and E_3 was conducted some time ago.[3–5] A restriction was imposed, namely that the operators X_a and Y_b should be second-order polynomials in momenta. It turned out that the existence of such commuting operators leads to the separation of variables in the Schrödinger equation. Superintegrable systems are actually *superseparable*: they allow the separation of variables in at least two coordinate systems.

A large body of literature exists on superintegrable systems in E_n.[3–17] In particular, it has been shown recently[17] that the superintegrable systems in E_2 are characterized by the existence of at least two generalized Lie symmetries.

Quantum mechanical problems which can be called it exactly solvable are defined quite differently. An exactly solvable quantum mechanical system can be characterized by the fact that in its solution space one can indicate explicitly an infinite flag of functional linear spaces, which is preserved by the Hamiltonian.[18] In general, the flag should be of such a type that a basis for the entire space of solutions is obtained as a union of bases for the invariant subspaces. In this paper the flag is constructed using polynomials in two variables that provide bases for finite-dimensional representations of $sl(3)$ (see the following). Therefore, the flag generates a dense subspace in the Hilbert space of the bound state eigenfunctions. We recall that a flag is formed by an infinite set of functional linear spaces which can be ordered in such a way that each of them properly contains the previous one as a subspace. One important particular example of these flags is given by finite-dimensional representation spaces of semi-simple Lie algebras of first order differential operators. In this case the Hamiltonian is an element of the universal enveloping algebra of a Lie algebra.

In order to clarify the situation let us consider as an example the case of one-dimensional (quasi)-exactly solvable problems.[19] Due to Sophus Lie it is known that the only Lie algebra of first-order differential operators which acts on the real line and possesses finite-dimensional representations is the $sl(2,\mathbb{R})$-algebra (for a discussion see, for example, e.g., Refs. 20 and 22), realized as

$$J_n^+ = x^2 d_x - nx, \quad J_n^0 = x d_x - \frac{n}{2}, \quad J_n^- = d_x. \tag{3}$$

For integer n the generators (3) possess a common invariant subspace $\mathcal{P}_n = \langle x^k | 0 \leqslant k \leqslant n \rangle$, which is the linear space of polynomials. It is evident that the spaces $\mathcal{P}_n$ as functions of the parameter n form a flag. This flag is preserved by any element of the universal enveloping algebra of the $sl(2,\mathbb{R})$ parabolic subalgebra J_n^0, J_n^- for any n. Therefore, an element of this enveloping algebra can be viewed as a Hamiltonian, which defines an exactly solvable system. In a similar manner one can introduce the notion of a quasi-exactly solvable problem for which the Hamiltonian possesses the invariant subspace $\mathcal{P}_n$. It can be proven[22] that a necessary and sufficient condition for a one-dimensional Hamiltonian to be quasi-exactly solvable is that it belongs to the universal enveloping algebra of the $sl(2,\mathbb{R})$-algebra taken in realization (3). (Up to change of variables and gauge transformation.)

For two-dimensional problems there exist four candidates for underlying hidden Lie algebra:[23,20,21,18] $sl(3,\mathbb{R})$, $sl(2,\mathbb{R}) \oplus sl(2,\mathbb{R}), o(3,1)$, a parametric family $gl(2,\mathbb{R}) \ltimes \mathbf{R}^{r+1}$ and some of their subalgebras. In particular, the algebra $gl(3,\mathbb{R}) \supset sl(3,\mathbb{R})$, realized as

$$\begin{gathered} J_1 = \partial_t, \quad J_2 = \partial_u, \\ J_3 = t\partial_t, \quad J_4 = u\partial_u, \quad J_5 = u\partial_t, \quad J_6 = t\partial_u, \\ J_7 = t^2\partial_t + tu\partial_u - nt, \quad J_8 = tu\partial_t + u^2\partial_u - nu, \\ X = n, \end{gathered} \tag{4}$$

will be used in this article as well as, more specifically the maximal parabolic subalgebra of $sl(3,\mathbb{R})$ formed by the generators $\{J_{1,\ldots,6}\}$.

For integer n the generators (4) possess a common invariant subspace $\mathcal{P}_n^{(2)} = \langle t^k u^m | 0 \leqslant k + m \leqslant n \rangle$, which is the linear space of polynomials. Similar to the case of $sl(2,\mathbb{R})$ the spaces $\mathcal{P}_n^{(2)}$ as functions of the parameter n form a flag. This flag is preserved by any element of the universal enveloping algebra of the parabolic subalgebra $\{J_{1,\ldots,6}\}$.[18] Therefore, an element of this enveloping algebra viewed as a Hamiltonian defines an *exactly solvable* system with the hidden algebra $sl(3,\mathbb{R})$.

Both superintegrable and exactly solvable systems have numerous applications in physics. Among the simplest superintegrable ones are the Coulomb system and the harmonic oscillator in spaces of any dimension. The celebrated many-body Calogero model is superintegrable as well as the Hartmann potential of quantum chemistry.[10,9]

II. HIDDEN ALGEBRA OF SUPERINTEGRABLE HAMILTONIANS

There exist precisely four quantum (and also classical) Hamiltonians defined on E_2, characterized by two integrals of motion, $[H,X_{1,2}]=0$, such that $X_{1,2}$ are quadratic in the momenta.[3,4,17] Thus, they are maximally superintegrable and for their classical counterparts all trajectories are closed. It was shown that these four Hamiltonians exhaust the list of two-dimensional Hamiltonians characterized by two integrals of motion in the form of second-order differential operators. They admit the separation of variables in two (or even more) different coordinate systems. We will show that all of them possess a hidden $sl(3,\mathbb{R})$ algebra. In particular, this implies that there exists a coordinate system where the Hamiltonian, as well as the integrals of motion, after a similarity transformation (gauge rotation) can be rewritten in terms of the generators of the maximal parabolic subalgebra of $sl(3,\mathbb{R})$. Furthermore, two of these Hamiltonians have a striking feature. For each of them, multiplied by a suitable factor f, there exists another set of two commuting operators, $[fH,Y_{1,2}]=0$. This can be considered as a generalization of the notion of integrability in quantum mechanics: commuting operators appear not for the Hamiltonian, but for the Hamiltonian multiplied by a factor.

Case I: The first Hamiltonian written in Cartesian coordinates is given by

$$H_{\mathrm{I}}\left(x,y;\frac{\omega^2}{2},\frac{A}{2},\frac{B}{2}\right)=-\frac{1}{2}(\partial_x^2+\partial_y^2)+\frac{\omega^2}{2}(x^2+y^2)+\frac{1}{2}\left(\frac{A}{x^2}+\frac{B}{y^2}\right), \tag{5}$$

where $A,B>-1/8$ are parameters. The corresponding Schrödinger equation separates in three different coordinate systems: Cartesian, polar, and elliptical. The eigenfunctions can be written in the form

$$\Psi_{n,m}(x,y)=x^{p_1}y^{p_2}L_n^{(-1/2+p_1)}(\omega x^2)L_m^{(-1/2+p_2)}(\omega y^2)\exp\left(-\frac{\omega x^2}{2}-\frac{\omega y^2}{2}\right), \tag{6}$$

where $L_k^{(\alpha)}(z)$ are Laguerre polynomials, $n,m=0,1,2,\ldots$ and the parameters $p_{1,2}$ are defined by $A=p_1(p_1-1),B=p_2(p_2-1)$. The degree of degeneracy of eigenstates is given by a number of partitions of an integer into the sum of two integers.

We perform a gauge rotation of $H_{\mathrm{I}}(x,y)$, using the ground state eigenfunction $\Psi_{0,0}(x,y)$ as a gauge factor and then a change of variables

$$\begin{aligned} h^I &\equiv \frac{1}{\omega}(\Psi_{0,0}(x,y))^{-1}H_I(x,y)\Psi_{0,0}(x,y)\big|_{t=\omega x^2,u=\omega y^2} \\ &=-2t\partial_t^2-2u\partial_u^2+2t\partial_t+2u\partial_u-(2p_1+1)\partial_t-(2p_2+1)\partial_u+1+p_1+p_2, \end{aligned} \tag{7}$$

with eigenvalues $E(n,m)=n+m,n,m=0,1,2,\ldots$.

It is easy to check that after a gauge rotation with the same gauge factor $\Psi_{0,0}(x,y)$ and a change of variables for the integrals of motion, we arrive at the operators

$$\hat{x}_C^{\mathrm{I}}=2t\partial_t^2-2u\partial_u^2-2t\partial_t+2u\partial_u+(2p_1+1)\partial_t-(2p_2+1)\partial_u-p_1+p_2, \tag{8}$$

$$\hat{x}_R^{\mathrm{I}}=4tu(\partial_t-\partial_u)^2+2[(2p_1+1)u-(2p_2+1)t](\partial_t-\partial_u)-(p_1+p_2)^2. \tag{9}$$

These three operators $h^{\mathrm{I}},\hat{x}_C^{\mathrm{I}},\hat{x}_R^{\mathrm{I}}$ obey the commutation relations

$$[h^{\mathrm{I}},\hat{x}_C^{\mathrm{I}}]=[h^{\mathrm{I}},\hat{x}_R^{\mathrm{I}}]=0,$$

and

$$[\hat{x}_C^{\mathrm{I}},\hat{x}_R^{\mathrm{I}}]=32tu\partial_{tuu}^3-32tu\partial_{ttu}^3-8t(2p_2+1-2u)\partial_{tt}^2+8u(2p_1+1-2t)\partial_{uu}^2+16[(2p_2+1)t-(2p_1+1)u]\partial_{tu}^2-4(2p_1+1)(2p_2+1-2u)\partial_t+4(2p_2+1)(2p_1+1-2t)\partial_u. \tag{10}$$

They generate an infinite-dimensional algebra.

The operators $h^{\mathrm{I}},\hat{x}_C^{\mathrm{I}},\hat{x}_R^{\mathrm{I}}$ as well as the commutator $[\hat{x}_C^{\mathrm{I}},\hat{x}_R^{\mathrm{I}}]$ can be immediately rewritten in terms of the generators $\{J_{1,\ldots,6}\}$ of the maximal parabolic subalgebra of $sl(3,\mathbb{R})$. They have the form

$$h^{\mathrm{I}}=-2J_3J_1-2J_4J_2+2J_3+2J_4-(2p_1+1)J_1-(2p_2+1)J_2, \tag{11}$$

$$\hat{x}_C^{\mathrm{I}}=2J_3J_1-2J_4J_2-2J_3+2J_4+(2p_1+1)J_1-(2p_2+1)J_2, \tag{12}$$

$$\hat{x}_R^{\mathrm{I}}=4J_3J_5+4J_4J_6-8J_3J_4+2(2p_1+1)J_5-2(2p_2+1)J_3-2(2p_1+1)J_4+2(2p_2+1)J_6. \tag{13}$$

The commutation relation (10) is rewritten as

$$[\hat{x}_C^{\mathrm{I}},\hat{x}_R^{I}]=32J_4J_3(J_2-J_1)-16J_4J_6+16J_3J_5+8(2p_1+1)J_4(J_2-2J_1)+8(2p_2+1)J_3(2J_2-J_1)+8(2p_1+1)J_5-8(2p_2+1)J_6+4(2p_1+1)(2p_2+1)(J_2-J_1). \tag{14}$$

Evidently, the operators (11)–(14) preserve a triangular flag of polynomials $\mathcal{P}^{(2)}$ in t,u:

$$h(t):\mathcal{P}_n(t,u)\mapsto\mathcal{P}_n(t,u),$$

where $\mathcal{P}_n(t,u)=\langle t^pu^q|0\leqslant p+q\leqslant n\rangle$. Hence, the operators $h^{\mathrm{I}},\hat{x}_C^{\mathrm{I}},\hat{x}_R^{\mathrm{I}}$ are characterized by infinitely many finite-dimensional invariant subspaces and thus possess infinitely many polynomial eigenfunctions.

Case II: The second superintegrable Hamiltonian can be separated in Cartesian and parabolic coordinates. In Cartesian coordinates it is given by

$$H_{\mathrm{II}}(x,y)=-\frac{1}{2}(\partial_x^2+\partial_y^2)+2\omega^2x^2+\frac{\omega^2}{2}y^2+\frac{B}{2y^2}, \tag{15}$$

where $B>-1/8$ is a parameter. The eigenfunctions and eigenvalues have the form

$$\Psi_{n,m}(x,y)=y^{p_2}H_n(\sqrt{2\omega}x)L_m^{(-1/2+p_2)}(\omega y^2)\exp\left(-\omega x^2-\frac{\omega y^2}{2}\right),$$

$$E_{n,m}=\omega\left[2(n+m)+p_2+\frac{3}{2}\right], \tag{16}$$

where $n,m=0,1,2,\ldots$; the parameter p_2 is defined by the relation $B=p_2(p_2-1)$. The degree of degeneracy is given by the number of partitions of a non-negative integer into the sum of two nonnegative integers.

We perform a gauge rotation of $H_{\rm II}(x,y)$ with the ground state eigenfunction (16), $\Psi_{0,0}(x,y)$ as a gauge factor and then a change of variables

$$h^{\rm II}\equiv\frac{1}{\omega}(\Psi_{0,0}(x,y))^{-1}H_{\rm II}(x,y)\Psi_{0,0}(x,y)\big|_{t=\sqrt{2\omega}x,u=\omega y^2}$$

$$=-\partial_t^2-2u\partial_u^2+2t\partial_t+(2u-1-2p_2)\partial_u+\frac{3}{2}+p_2. \tag{17}$$

It is easy to check that the operators

$$\hat{x}_C^{\rm II}=2\partial_t^2-4u\partial_u^2-4t\partial_t+2(2u-1-2p_2)\partial_u-1+2p_2, \tag{18}$$

$$\hat{x}_P^{\rm II}=-4tu\partial_u^2+4u\partial_{tu}^2-(2u-1-2p_2)\partial_t-2t(1+2p_2)\partial_u, \tag{19}$$

generate an infinite dimensional algebra. They obey the commutation relations

$$[h^{\rm II},\hat{x}_C^{\rm II}]=[h^{\rm II},\hat{x}_P^{\rm II}]=0,$$

and

$$[\hat{x}_C^{\rm II},\hat{x}_P^{\rm II}]=-32u\partial_{tuu}^3-16(1+2p_2-2u)\partial_{tu}^2+32tu\partial_{uu}^2$$
$$+8(1+2p_2-2u)\partial_t+16t(1+2p_2)\partial_u]. \tag{20}$$

The operators $h^{\rm II},\hat{x}_C^{\rm II},\hat{x}_P^{\rm II}$ as well as the commutator $[\hat{x}_C^{\rm II},\hat{x}_P^{\rm II}]$ can be immediately rewritten in terms of the generators (4) and have the form

$$h^{\rm II}=-J_1J_1-2J_4J_2+2J_3+2J_4-(1+2p_2)J_2+\tfrac{3}{2}+p_2, \tag{21}$$

$$\hat{x}_C^{\rm II}=2J_1J_1-4J_4J_2-4J_3+4J_4-2(1+2p_2)J_2-1+2p_2, \tag{22}$$

$$\hat{x}_P^{\rm II}=-4J_4J_6+4J_1J_4-2J_5+(1+2p_2)J_1-2(1+2p_2)J_6. \tag{23}$$

Evidently, operators (21)–(23) preserve the same triangular flag of polynomials as in case I but in variables x,u:

$$h(x,u):\mathcal{P}_n(x,u)\mapsto\mathcal{P}_n(x,u),$$

where $\mathcal{P}_n(x,u)=\langle x^pu^q|0\leqslant p+q\leqslant n\rangle$. Thus, the operators $h^{\rm II},\hat{x}_C^{\rm II},\hat{x}_P^{\rm II}$ have infinitely many finite dimensional invariant subspaces and infinitely many polynomial eigenfunctions.

Case III: The third superintegrable Hamiltonian

$$H_{\rm III}(x,y)=-\frac{1}{2}(\partial_x^2+\partial_y^2)+\frac{\alpha}{2r}+\frac{1}{4r^2}\left(\frac{\beta_1}{\cos^2\frac{\phi}{2}}+\frac{\beta_2}{\sin^2\frac{\phi}{2}}\right), \tag{24}$$

where $\beta_{1,2}>-1/8$ are parameters and $x=r\cos\phi,y=r\sin\phi$. It admits the separation of variables in polar and parabolic coordinates. In parabolic coordinates it has the form

$$H_{\rm III}(\xi,\eta)=-\frac{1}{2}\frac{1}{\xi^2+\eta^2}(\partial_\xi^2+\partial_\eta^2)+\frac{1}{\xi^2+\eta^2}\left(2\alpha+\frac{\beta_1}{\xi^2}+\frac{\beta_2}{\eta^2}\right), \tag{25}$$

with $x=\frac{1}{2}(\xi^2-\eta^2),y=\xi\eta$. The eigenfunctions corresponding to the energy E are

$$\Psi_{n,m}=\xi^{p_1}\eta^{p_2}L_n^{(-1/2+p_1)}(\sqrt{-2E}\,\xi^2)L_m^{(-1/2+p_2)}(\sqrt{-2E}\,\eta^2)e^{-\sqrt{-E/2}(\xi^2+\eta^2)}, \tag{26}$$

where $2\beta_1=p_1(p_1-1),2\beta_2=p_2(p_2-1)$. It is easy to see that the Schrödinger equation $H_{\rm III}\Psi=E\Psi$ can be transformed into

$$\left[-\frac{1}{2}(\partial_\xi^2+\partial_\eta^2)-E(\xi^2+\eta^2)+\frac{\beta_1}{\xi^2}+\frac{\beta_2}{\eta^2}\right]\Psi=-2\alpha\Psi. \tag{27}$$

We introduce the notation

$$Q_{\rm III}\equiv(\xi^2+\eta^2)(H_{\rm III}-E)-2\alpha. \tag{28}$$

Equation (27) can be written as

$$Q_{\rm III}\Psi=-2\alpha\Psi, \tag{29}$$

and $Q^{\rm III}$ can be related to $H^{\rm I}$,

$$Q_{\rm III}=H_{\rm I}(\xi,\eta;-E,\beta_1,\beta_2), \tag{30}$$

[cf. (5)]. We draw the striking conclusion that the Hamiltonian of the first problem (case I) written in Cartesian coordinates coincides with a modified third Hamiltonian $Q^{\rm III}$ written in parabolic coordinates (!). The parameter (-2α) plays the role of spectral parameter which is the energy in case I, $(-2\alpha)\leftrightarrow E^{\rm I}$. Thus, the analysis performed for case I can be repeated for this case.

We perform a gauge rotation of the operator $Q_{\rm III}$ with a gauge factor given by the multiplier figuring in Eq. (26),

$$M_{\rm III}=\xi^{p_1}\eta^{p_2}e^{-\sqrt{-E/2}(\xi^2+\eta^2)}. \tag{31}$$

Notice that in this case, contrary to those of $H_{\rm I}$ and $H_{\rm II}$, the gauge factor is not universal. It depends on the energy E. Thus E in the multiplier M is the considered energy, not the ground state one.

Thus we have

$$q^{\rm III}\equiv\frac{1}{\sqrt{-2E}}M_{\rm III}^{-1}Q_{\rm III}(x,y)M_{\rm III},$$

and with a change of coordinates $t=\sqrt{-2E}\,\xi^2,u=\sqrt{-2E}\,\eta^2$ we get

$$q^{\rm III}=-2t\partial_t^2-2u\partial_u^2+2t\partial_t+2u\partial_u-(2p_1+1)\partial_t-(2p_2+1)\partial_u+1+p_1+p_2. \tag{32}$$

This operator coincides *exactly* with the operator $h^{\rm I}$ (7). Its spectrum is equal to $-2\alpha/\sqrt{-E}=2(n+m)+1+p_1+p_2,n,m=0,1,2,\ldots$.

Thus, the operator $q^{\rm III}$ commutes with $\hat{x}_C^{\rm I},\hat{x}_R^{\rm I}$. We shall call these operators $\hat{x}_C^{\rm III},\hat{x}_R^{\rm III}$. The operator $q^{\rm III}$ can be rewritten in terms of the generators $\{J_{1,\ldots,6}\}$ of the maximal parabolic subalgebra of $sl(3,\mathbb{R})$ [see (4)] . We see that the Hamiltonian (24) is exactly solvable.

The above observation gives rise to an interesting question about the connection between the operators commuting with original Hamiltonian (24) and the operators $\hat{x}_C^{\rm III},\hat{x}_R^{\rm III}$.

The operators that commute with $Q_{\rm III}$ of Eq. (28) can be read off from those of case H_1. They are in parabolic coordinates

$$X_C^{\rm III}=-\frac{1}{2}(\partial_\xi^2-\partial_\eta^2)-E(\xi^2-\eta^2)+\frac{\beta_1}{\xi^2}-\frac{\beta_2}{\eta^2},$$
$$X_R^{\rm III}=(\xi\partial_\eta-\eta\partial_\xi)^2-2(\xi^2+\eta^2)\left(\frac{\beta_1}{\xi^2}+\frac{\beta_2}{\eta^2}\right). \tag{33}$$

The operators that commute with the original Hamiltonian $H_{\rm III}$ of Eq. (25), if written in parabolic coordinates, are[3,4,17]

$$X_P=\frac{1}{\xi^2+\eta^2}\left(\eta^2\partial_\xi^2-\xi^2\partial_\eta^2+2\alpha(\xi^2-\eta^2)-2\beta_1\frac{\eta^2}{\xi^2}+2\beta_2\frac{\xi^2}{\eta^2}\right),$$
$$X_R=(\xi\partial_\eta-\eta\partial_\xi)^2-2(\xi^2+\eta^2)\left(\frac{\beta_1}{\xi^2}+\frac{\beta_2}{\eta^2}\right). \tag{34}$$

Let us consider, quite generally, a Hamiltonian H and an operator Q, defined by

$$H=\frac{Q+K}{\xi^2+\eta^2}+E, \tag{35}$$

where K is a constant and E is the energy. Let X be an operator commuting with the Hamiltonian: $[H,X]=0$. The operator Q then satisfies

$$[Q,X]=(\xi^2+\eta^2)\left[X,\frac{1}{\xi^2+\eta^2}\right](\xi^2+\eta^2)(H-E). \tag{36}$$

Thus, if the operator X commutes with H (strongly, as an operator), it commutes weakly, on functions Ψ satisfying $(H-E)\Psi=0$, with Q. So, in order to relate operators that commute with H and those that commute with Q, we have to consider linear combinations of the type $AX_P+BX_R+f(\xi,\eta)\ (H-E)$. Here A and B are constants, but $f(\xi,\eta)$ can be any function, since $H-E$ vanishes on the ''energy shell.''

Let us return to the problem at hand, i.e., the system characterized by the Hamiltonian $H_{\rm III}$, or equivalently, by the operator $Q_{\rm III}$. We have the following simple relation between the original integrals X_P and X_R and the modified ones (33)

$$X_C^{\rm III}=-X_P+(\xi^2-\eta^2)(H-E),\quad X_R^{\rm III}=X_R. \tag{37}$$

Case IV: The fourth superintegrable Hamiltonian admits the separation of variables in two mutually perpendicular parabolic systems of coordinates. In the usual parabolic coordinates ξ,η it has the form

$$H_{\rm IV}(\xi,\eta)=-\frac{1}{2}\frac{1}{\xi^2+\eta^2}(\partial_\xi^2+\partial_\eta^2)+\frac{1}{\xi^2+\eta^2}(2\alpha+\beta\xi+\gamma\eta). \tag{38}$$

The eigenfunctions are products of Laguerre polynomials times an energy dependent multiplier, namely

$$M_{\rm IV}=(\xi-\beta/2E)^{p_1}(\eta-\gamma/2E)^{p_2}e^{-\sqrt{-E/2}[(\xi-\beta/2E)^2+(\eta-\gamma/2E)^2]}$$

with a condition $\alpha+\dfrac{\beta^2}{4E}+\dfrac{\gamma^2}{4E}+\sqrt{-2E}=0$ and $p_1,p_2=0,1$.

The corresponding Schrödinger equation $H_{\mathrm{IV}}\Psi=E\Psi$ can be rewritten as

$$\left[-\frac{1}{2}(\partial_\xi^2+\partial_\eta^2)-E\left(\xi-\frac{\beta}{2E}\right)^2-E\left(\eta-\frac{\gamma}{2E}\right)^2\right]\Psi=\left(-2\alpha-\frac{\beta^2+\gamma^2}{4E}\right)\Psi. \tag{39}$$

For the operator on the left-hand side we introduce the notation

$$Q_{\mathrm{IV}}\equiv(\xi^2+\eta^2)(H^{\mathrm{IV}}-E)-2\alpha-\frac{\beta^2+\gamma^2}{4E}.$$

Equation (39) can be written as

$$Q_{\mathrm{IV}}\Psi=\tilde{\alpha}\Psi,$$

with the new spectral parameter $\tilde{\alpha}=-2\alpha-(\beta^2+\gamma^2)/4E$.

The operator Q^{IV} can be related to H^{I},

$$Q_{\mathrm{IV}}=H_{\mathrm{I}}(\xi,\eta;-E,0,0), \tag{40}$$

[cf. (5) and (30)]. We see that similar to case III the Hamiltonian of case I written in Cartesian coordinates coincides with a modified fourth Hamiltonian Q_{IV} written in parabolic coordinates. The parameter $\tilde{\alpha}$ plays the role of a spectral parameter which was the energy in the first case, $\tilde{\alpha}\leftrightarrow E^{\mathrm{I}}$. Thus, the analysis performed for case I can be again repeated for this case.

Writing the gauge rotated operator Q_{IV} in new coordinates

$$t=\sqrt{-2E}(\xi-\beta/2E)^2,\quad u=\sqrt{-2E}(\eta-\gamma/2E)^2$$

we get

$$q^{\mathrm{IV}}\equiv\frac{1}{\sqrt{-2E}}M_{\mathrm{IV}}^{-1}Q_{\mathrm{IV}}(x,y)M_{\mathrm{IV}}$$

$$=-2t\partial_t^2-2u\partial_u^2+2t\partial_t+2u\partial_u-(2p_1+1)\partial_t-(2p_2+1)\partial_u+1+p_1+p_2.$$

This operator coincides *exactly* with the operator h^{I} (7) and q^{III} (32). Its spectrum is equal to $2(n+m)+1+p_1+p_2, n,m=0,1,2,\ldots$.

Thus, the operator q^{IV} commutes with $\hat{x}_C^{\mathrm{I}},\hat{x}_R^{\mathrm{I}}$. We shall call these operators $\hat{x}_C^{\mathrm{IV}},\hat{x}_R^{\mathrm{IV}}$. The operator q^{IV} (as well as $\hat{x}_C^{\mathrm{IV}},\hat{x}_R^{\mathrm{IV}}$) can be rewritten in terms of the generators $\{J_{1,\ldots,6}\}$ of the maximal parabolic subalgebra of $sl(3,\mathbb{R})$ [see (4)] and hence is exactly solvable.

As in case III one can give the connection between the operators commuting with original Hamiltonian (38) and the operators $\hat{x}_C^{\mathrm{IV}},\hat{x}_R^{\mathrm{IV}}$. The operators commuting with H_{IV} are[3,4,17]

$$X_1=\frac{1}{2(\xi^2+\eta^2)}\{\eta^2\partial_\xi^2-\xi^2\partial_\eta^2+2\alpha(\xi^2-\eta^2)+2\xi\eta(\gamma\xi-\beta\eta)\},$$

$$X_2=\frac{1}{(\xi^2+\eta^2)}\{\xi\eta(\partial_\xi^2+\partial_\eta^2)+(-\beta\eta+\gamma\xi)(\xi^2-\eta^2)-4\alpha\xi\eta\}-\partial_{\xi\eta}^2. \tag{41}$$

Two second order differential operators commuting with Q_{IV} of Eq. (40) can be related to (41) and are given by

$$Q^{(1)}=-2X_1+(\xi^2-\eta^2)(H_{\rm IV}-E)+\frac{\gamma^2-\beta^2}{4E}, \tag{42}$$

$$Q^{(2)}=X_2+2\xi\eta(H_{\rm IV}-E)-\frac{\beta\gamma}{2E}. \tag{43}$$

From this point of view the fourth superintegrable system is particularly simple. Explicitly, we have a new ''Hamiltonian''

$$Q_{\rm IV}=-\frac{1}{2}(\partial_\xi^2+\partial_\eta^2)-E\left[\left(\xi-\frac{\beta}{2E}\right)^2+\left(\eta-\frac{\gamma}{2E}\right)^2\right], \tag{44}$$

which corresponds to the harmonic oscillator, while one of the commuting operators satisfies

$$Q^{(1)}=X_C^{\rm I}, \tag{45}$$

where the integral $X_C^{\rm I}$ [see Eq. (8)] is written in the coordinates $(\xi-\beta/2E),(\eta-\gamma/2E)$.

In turn, the operator $\hat{X}_R^{\rm I}$ reduces to

$$\hat{X}_R^{\rm I}=\left[\left(\xi-\frac{\beta}{2E}\right)\partial_\eta-\left(\eta-\frac{\gamma}{2E}\right)\partial_\xi\right]^2\equiv L_z^2. \tag{46}$$

Thus, the superintegrable system characterized by the Hamiltonian $H_{\rm IV}(\xi,\eta)$ has been reduced to a harmonic oscillator with ''frequency'' $\omega=\sqrt{-E/2}$ and a displaced equilibrium point $\xi=\beta/2E$, $\eta=\gamma/2E$. It is well known that the harmonic oscillator is invariant under an SU(2) group. Indeed, we find that the ''Hamiltonian'' $Q_{\rm IV}$ commutes with $Q^{(1,2)}$ and L_z. The operators (42), (43), (44) and L_z form the basis of a $u(2)$ symmetry algebra with $Q_{\rm IV}$ as its center.

III. CONCLUSION

In general, integrability of a quantum system does not guarantee that spectrum and eigenfunctions can be found in sufficiently explicit form. The simplest example of this situation is given by one-dimensional quantum dynamics which is integrable for any potential. The main message of the present work is that the superintegrable systems on E_2 with the integrals given by second-order differential operators are exactly solvable as well. We conjecture that the property of exact solvability will remain valid for higher dimensional superintegrable systems of the above-mentioned type.

Note added in proof. Our conjecture on the exact solvability of general superintegrable systems has recently received further development. Indeed, all superintegrable systems with second order in momentum integrals of motion in a two-dimensional space of revolution with non-constant curvature were recently found (E. G. Kalnins, J. M. Kress, and P. Winternitz, Superintegrability in a two-dimensional space of nonconstant curvature, submitted for publication). All of them turned out to be exactly solvable.

Geometric quantization on the super-disk

Osman Teoman Turgut[a)]

(Received 14 December 2000; accepted for publication 1 March 2001)

In this article we discuss the geometric quantization on a certain type of infinite dimensional super-disk. Such systems are quite natural when we analyze coupled bosons and fermions. The large-N limit of a system like that corresponds to a certain super-homogeneous space. First, we define an example of a super-homogeneous manifold: a super-disk. We show that it has a natural symplectic form, and it can be used to introduce classical dynamics once a Hamiltonian is chosen. Existence of moment maps provide a Poisson realization of the underlying symmetry super-group. These are the natural operators to quantize via methods of geometric quantization, and we show that this can be done. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1387270]

I. INTRODUCTION

Geometric quantization is an interesting and useful program for quantizing systems whose phase spaces have a simple geometric description.[1] It is not always the case that the phase space has a nice geometric structure, and, even if it does, the result of quantizing via this method does not actually solve the problem, but in many cases just helps one to formulate it. The geometric approach to quantization goes back to works of Berezin[2–5] and at about the same time appeared in the mathematics literature as well.

In this work we will extend our previous analysis[6] to the context of super-geometry. This is interesting in two ways: one is purely mathematical, it gives a natural way to construct unitary representations of the underlying symmetry group. The other one is the possibility of understanding physical systems which have coupled bosons and fermions. Super-geometry sets the natural arena for formulating and studying these problems. Our approach originates from ideas of Rajeev on the large-N limit of field theories. Rajeev has shown that a proper large-N limit of quantum chromodynamics (QCD) in two dimensions has a natural phase space given by an infinite dimensional Grassmannian.[7] This general philosophy can be extended to other cases.[6,8] Whenever there is a mixture of fermions and bosons, the large-N phase space is expected to be a certain kind of super-homogeneous manifold. In gauge theory, we have shown that this space is given by a certain kind of super-Grassmannian.[8] If instead we are looking at a fermionic system which has only a finite number of degrees of freedom coupled to a bosonic field theory, its large-N limit can be formulated as a certain type of super-disk. This can be seen as follows: we get for such a system, in the language of creation and annihilation operators, bilinears of the form

$$N(p,q)=\frac{2}{N}:a^{\dagger\alpha}(p)a(q)_{\alpha}:,\quad M_{ij}=\frac{2}{N}\chi_i^{\dagger\alpha}\chi_{\alpha j},\quad Q_i(p)=\frac{2}{N}\chi_i^{\dagger\alpha}a_{\alpha}(p),\quad \overline{Q_i}(p)=\frac{2}{N}a^{\dagger\alpha}(p)\chi_{\alpha i}, \tag{1}$$

where we have a normal ordering : : for only the bosonic products and α denotes a ''color'' index. These operators are the natural ones for the large-N phase space of the theory. In general it may not be possible to express all the dynamical variables in terms of these bilinears, but if we restrict ourselves to the ''color invariant'' sector, these are the only ones we can compose. We note that

a)Electronic mail: turgutte@boun.edu.tr

this statement is strictly true when we look at a gauge theory in $1+1$ dimensions,[8] but for that we need infinite degrees of freedom for the fermions, and that requires an analog of the Grassmannian. In some other cases this is only an approximation to the full model, the validity of which has to be tested depending on the specifics. As an example we write down a nonrelativistic model, where a bosonic self-coupled field also couples with localized fermionic sources,

$$H=\int \left(:\nabla \phi^{\dagger\alpha}.\nabla \phi_\alpha + m^2 \phi^{\dagger\alpha}\phi_\alpha + \frac{\lambda^2}{2}(\phi^{\dagger\alpha}\phi_\alpha)^2: + g\sum_i \rho(x)(\phi_\alpha \chi_i^{\dagger\alpha}(t) + \phi^{\dagger\alpha}\chi_{\alpha i}(t)) \right). \quad (2)$$

These models may exhibit rather nontrivial dynamics, depending on the dimension we may need to renormalize the coupling constants. Our approach with Hilbert–Schmidt operators excludes cases which require renormalization, although a general super-disk is still present. The above operators actually provide a realization of the super-Lie algebra $U(\mathcal{H}^e_-, \mathcal{H}^e_+ | \mathcal{H}^o_+)$ as we will see. In fact, one can see that many super-Lie algebras have natural realizations by fermionic and bosonic operators.[9]

In this article we will only deal with the mathematical aspects of this problem and think of geometric quantization as a method for constructing the quantum Hilbert space where the dynamics takes place. Solving a specific model perhaps should be done first in the classical setting of the large-N limit.

II. THE SUPER-DISK

In this section we present a brief definition of the super-disk which we denote by D_1^I following Ref. 10; we mostly adopt their conventions. As we will see there is a small difference between our approach and this reference. In the same reference there is a nice discussion of other cases, which one can generalize in the same way, but we choose to look at the above simpler case for the sake of clarity. The previous paper by the same authors[11] give a more detailed discussion of the $U(1,1|1)$ case. Since the general case in Ref. 10 is treated in a sussinct manner, we prefer to give a detailed discussion and believe that some of the explicit formulas could be useful for the reader. The physically interesting case requires an additional complication compared to the one in Ref. 10: one should look at an infinite Grassmann algebra. We will briefly discuss this generalization, yet the results are not so simple and as rigorous as in the finite dimensional one. Some other useful sources are the lectures of Kostant[12] and the books by Berezin[13] and Manin.[14]

Let us consider two Hilbert spaces, $\mathcal{H}^e$ and $\mathcal{H}^o$, which correspond to the even and odd spaces, respectively. In physically interesting cases they are either both separable infinite dimensional, or the even one is separable infinite dimensional and the odd one is finite dimensional. To keep the rigor we will only deal with $\mathcal{H}^o_+$ finite dimensional, but arbitrarily large. Let us assume that its dimension is N; later on we will extend this to infinite dimensions. We will split the even space into positive and negative parts, each piece being infinite dimensional, $\mathcal{H}^e=\mathcal{H}^e_-\oplus\mathcal{H}^e_+$. We will really think of the odd part as the positive subspace and denote it as $\mathcal{H}^o_+$. This is just for convenience at the moment since we have not attached any physical significance to D_1^I.

We may denote the $\mathbf{Z}$ graded super-space as $\mathcal{H}$, which splits with respect to $\mathbf{Z}_2$ grading as $\mathcal{H}^e|\mathcal{H}^o$. It will be better to decompose this space as $\mathcal{H}=\mathcal{H}^e_-\oplus\mathcal{H}^e_+|\mathcal{H}^o_+$. Let us introduce the set of complex super matrices Z such that

$$Z=[w \quad \theta], \quad (3)$$

where $w:\mathcal{H}^e_+\to\mathcal{H}^e_-$ and $\theta:\mathcal{H}^o_+\to\mathcal{H}^e_-$. Furthermore, we require the following convergence conditions $w\in\mathcal{I}_2$ and $\theta\in\mathcal{I}_2$, where $\mathcal{I}_2$ denotes the Hilbert–Schmidt ideal in this context. A super space is given by the algebra of smooth functions living on it. In any given super-chart $\mathcal{U}$ we have $C^\infty(\mathcal{U})\approx C^\infty(U)\otimes\wedge(\mathbf{C}^s)$ for some s, and here U denotes the corresponding open set for the base manifold. [In Ref. 10 the underlying function algebra for the odd generators is chosen to be $\wedge(\mathbf{C}^{mq})$. We will instead take the set of generators as $\wedge(\mathbf{C}^n)$, and θ denotes the matrix of linear transformations from the super vector space $\mathcal{H}^o_+$ to $\mathcal{H}^e_-$.]

Let us explain the meaning of these convergence conditions: if we expand the matrix w into a series,

$$w = w_B + w_{a_1 a_2} \xi^{a_1} \xi^{a_2} + \cdots , \tag{4}$$

where ξ^a denotes half of the odd generators and this series terminates. There are also Hermitian conjugates, that is, we have a set of coordinates ξ^a and ξ^{*a}. (Since the base manifold is contractable, this expression is true; otherwise we need to assume it on any given chart.) Then, we assume that each one of these matrices is in the Hilbert–Schmidt class,[15] i.e., $w_B^\dagger w_B, w_{a_1 a_2}^\dagger w_{a_1 a_2}, \ldots, w_{12\ldots r}^\dagger w_{12\ldots r} \in \mathcal{I}_1$. Here we use $\mathcal{I}_1$ to denote trace class operators. This decomposition is basis dependent, but the condition is basis invariant. It is possible to see this by looking at a change of basis which is given by an invertible super-matrix (non-type changing one):

$$(SwS^{-1})_B = S_B w_B S_B^{-1} \cdots ,$$

$$(SwS^{-1})_{a_1 a_2 \cdots a_{2k}} = S_B w_{a_1 a_2 \cdots a_{2k}} S_B^{-1} + \cdots + S_{a_1 \cdots a_{2m}} w_{a_{2m+1} \cdots a_{2n}} S^{-1}_{a_{2n+1} \cdots a_{2k}} \cdots ,$$

etc., and we see that each component is replaced by a sum, each term of which is conjugated by some bounded operators. The conjugated elements themselves are of Hilbert–Schmidt class. From this we conclude that our condition is basis independent. We point out that some variants of this argument on the Hilbert–Schmidt condition will be used over and over again. We have the same for θ except that θ only has odd terms. Notice that the second of these conditions is automatically true since the odd space is finite dimensional. In a more general case we will mention later on, there will be extra convergence conditions on the odd generators. In this setting w is even and θ is odd. For computations it is sometimes better to decompose a given matrix into its ordinary part and its nilpotent part, just like a super number being decomposed into an ordinary complex number plus the rest. We use the terminology of deWitt[16] and call it body and soul decomposition. For example, $w = w_B + w_S$ and $\theta = \theta_S$. Let us define the restricted super-disk as the algebra of functions generated by the above set of super-operators Z with a further condition on w,

$$1 - w_B^\dagger w_B > 0. \tag{5}$$

Notice that we can interpret these to be the elements which generate the C^∞ functions on the super-disk. For later use we must give a meaning to $Z^\dagger Z$, so we define it to be the tensor product,

$$Z^\dagger Z = \begin{pmatrix} w^\dagger w & w^\dagger \theta \\ \theta^\dagger w & \theta^\dagger \theta \end{pmatrix}.$$

We do not demand any extra conditions on the θ variable. The inverse of $1 - Z^\dagger Z$ can be computed; we write

$$(1 - Z^\dagger Z)^{-1} = 1 + Z^\dagger (1 - ZZ^\dagger)^{-1} Z, \tag{6}$$

and similarly for w_B we have $(1 - w_B w_B^\dagger)^{-1} = 1 + w_B (1 - w_B^\dagger w_B)^{-1} w_B^\dagger$ and the operator on the right is well-defined due to positivity condition. This means that the inverse on the left also exists. Since we use a finite dimensional odd-space we can define

$$\begin{aligned} (1 - ZZ^\dagger)^{-1} &= (1 - w_B w_B^\dagger - w_B^\dagger w_S - w_S^\dagger w_B - w_S^\dagger w_S - \theta\theta^\dagger)^{-1} \\ &= [1 - (1 - w_B w_B^\dagger)^{-1} (w_B^\dagger w_S + w_S^\dagger w_B + w_S^\dagger w_S + \theta\theta^\dagger)]^{-1} (1 - w_B w_B^\dagger)^{-1}, \end{aligned}$$

the first inverse in the last term can be expressed via a terminating expansion,

$$[1-(1-w_Bw_B^\dagger)^{-1}(w_B^\dagger w_S+w_S^\dagger w_B+w_S^\dagger w_S+\theta\theta^\dagger)]^{-1}$$
$$=1+(1-w_Bw_B^\dagger)^{-1}(w_B^\dagger w_S+w_S^\dagger w_B+w_S^\dagger w_S+\theta\theta^\dagger)-\cdots$$
$$+(-1)^{s-1}[(1-w_Bw_B^\dagger)^{-1}(w_B^\dagger w_S+w_S^\dagger w_B+w_S^\dagger w_S+\theta\theta^\dagger)]^s,$$

where we assume that the degree of nilpotency of the supermatrix is $s+1$. We note that this is a general fact. If the body of a matrix is invertible, then the matrix is invertible. This series does not have to terminate in the infinite dimensional case, so one has to impose the invertibility condition separately, or assume that the infinite formal expansion can be given a meaning (see the book by deWitt[16]). The definition we propose later on may result in a deviation from the Kostant–Berezin–Leites definition.[12,13]

There is a natural super-operator on the space $\mathcal{H}$ given with respect to the above direct sum as

$$J=\begin{pmatrix}1&0&0\\0&-1&0\\0&0&-1\end{pmatrix}. \tag{7}$$

Similar to the finite dimensional case, we have an action of a certain super-pseudounitary group on the super-disk D_1^I. Let us define the set of superoperators $g:\mathcal{H}\to\mathcal{H}$ with a bounded inverse, such that they leave the operator J invariant:

$$gJg^\dagger=J. \tag{8}$$

Let us explicitly write this condition in a block decomposition:

$$g=\begin{pmatrix}A&B\\C&D\end{pmatrix}, \tag{9}$$

and here $A:\mathcal{H}_-^e\to\mathcal{H}_-^e$, $B:\mathcal{H}_+^e|\mathcal{H}_+^o\to\mathcal{H}_-^e$, $C:\mathcal{H}_-^e\to\mathcal{H}_+^e|\mathcal{H}_+^o$. Finally, $D:\mathcal{H}_+^e|\mathcal{H}_+^o\to\mathcal{H}_+^e|\mathcal{H}_+^o$. This representation is better suited for our needs. We have then

$$AA^\dagger-BB^\dagger=1,\quad CA^\dagger=DB^\dagger,\quad DD^\dagger-CC^\dagger=1. \tag{10}$$

Using the invertibility we see that $g^\dagger Jg=J$ is also true, hence we get

$$A^\dagger A-C^\dagger C=1,\quad A^\dagger B=C^\dagger D,\quad D^\dagger D-B^\dagger B=1. \tag{11}$$

The first one means, in terms of body and soul decomposition,

$$A_BA_B^\dagger-B_BB_B^\dagger=1,\quad A_S^\dagger A_B+A_B^\dagger A_S+A_S^\dagger A_S+C_B^\dagger C_S+C_S^\dagger C_B+C_S^\dagger C_S=0, \tag{12}$$

and similarly for the others. This means that the body parts of these matrices obey exactly the usual pseudounitary conditions, hence we can do everything in the same way like the non-super-case. Among these sets of operators we pick the ones which satisfy a convergence condition, written with respect to the direct sum decomposition $\mathcal{H}_-^e\oplus\mathcal{H}_+^e|\mathcal{H}_+^o$,

$$g=\begin{pmatrix}\mathcal{B}&\mathcal{I}_2&\mathcal{I}_2\\\mathcal{I}_2&\mathcal{B}&\mathcal{B}\\\mathcal{I}_2&\mathcal{B}&\mathcal{B}\end{pmatrix}, \tag{13}$$

and these conditions are imposed on the components of each term, i.e., if we expand the upper corner, $\beta=\beta_a\xi^a+\beta_{a_1a_2a_3}\xi^{a_1}\xi^{a_2}\xi^{a_3}+\cdots$, each term belongs to $\mathcal{I}_2$ and similarly for the other parts. We may also economically express these in the form $[J,g]\in\mathcal{I}_2$, with the above interpretation for the ideal. Therefore we can summarize the above set of operators in the form of a group:

$$U_1(\mathcal{H}^e_-,\mathcal{H}^e_+|\mathcal{H}^o_+)=\{g|g^{-1}\ \text{exists},\ [J,g]\in\mathcal{I}_2\quad\text{and}\ gJg^\dagger=J\},\tag{14}$$

where the ideal condition refers to our convention. The main point is to show that the convergence conditions hold after the multiplication. This follows the same line of arguments as before. If one writes explicitly the components, we see that each one is a finite sum of Hilbert–Schmidt operators. We leave it to the reader to check the details. This group is one possible super version of the pseudounitary group. We refer to this set as the restricted super-pseudounitary group.

Just like the classical case, the restricted super-pseudounitary group has an action on the super-disk D_1^I. This action is written in the super-operator language exactly as in the classical case:

$$Z\mapsto(AZ+B)(CZ+D)^{-1},\tag{15}$$

where we use

$$g=\begin{pmatrix}A & B\\ C & D\end{pmatrix}.\tag{16}$$

We need to clarify the action of C, if we denote C as $\binom{c}{\gamma}$,

$$CZ=C\otimes Z=\begin{pmatrix}cw & c\theta\\ \gamma w & \gamma\theta\end{pmatrix},\tag{17}$$

which shows that the action is well-defined and the resulting operator goes from $\mathcal{H}^e_+|\mathcal{H}^o_+$ to $\mathcal{H}^e_+|\mathcal{H}^o_+$, thus we can add D to this. Let us note that the inverse on the right exists. This is because the even part has an inverse and we can define the inverse by a terminating expansion. Just for an illustration we give the explicit version. The reader who is familiar with this kind of manipulations is advised to skip this part: We would like to show that $CZ+D$ has an inverse. We know that D^{-1} is well-defined, hence it is better to look at $D^{-1}CZ+1$. We use the following formula for the inverse of a super-matrix:

$$\begin{pmatrix}\tilde A & \tilde B\\ \tilde C & \tilde D\end{pmatrix}^{-1}=\begin{pmatrix}(\tilde A-\tilde B\tilde D^{-1}\tilde C)^{-1} & -\tilde A^{-1}\tilde B(\tilde D-\tilde C\tilde A^{-1}\tilde B)^{-1}\\ -\tilde D^{-1}\tilde C(\tilde A-\tilde B\tilde D^{-1}\tilde C)^{-1} & (\tilde D-\tilde C\tilde A^{-1}\tilde B)^{-1}\end{pmatrix}.\tag{18}$$

This can be written in the following form:

$$\begin{pmatrix}1+(d_{11}-\delta_{12}d_{22}^{-1}\delta_{21})^{-1}cw & ***\\ -d_{11}^{-1}\delta_{12}(d_{22}-\delta_{21}d_{11}^{-1}\delta_{12})^{-1}\gamma w & 1-d_{22}^{-1}\delta_{21}(d_{11}-\delta_{12}d_{22}^{-1}\delta_{21})^{-1}c\theta\\ *** & +(d_{22}-\delta_{21}d_{11}^{-1}\delta_{12})^{-1}\gamma\theta\end{pmatrix}.\tag{19}$$

To prove the invertibility, we do not need the explicit forms of the off-diagonal components. This is why they are not shown in the above matrix. The lower diagonal block is invertible, due to the nilpotency of the part added to 1. Hence we need to check only the upper diagonal block (actually, this is a general result). To do this we recall that the super-pseudounitarity means, $DD^\dagger=1+CC^\dagger$, written in terms of components. The upper block gives us $d_{11}d_{11}^\dagger=cc^\dagger+1-\delta_{12}\delta_{12}^\dagger$. This means that we can define an inverse square root of the above matrix; for this we use the following integral representation,

$$T^{-1/2}=\frac{1}{\pi}\int_0^\infty\frac{d\lambda}{\lambda^{1/2}}(T+\lambda I)^{-1}.\tag{20}$$

This formula is used for a positive operator and can be extended to the super case when the body of the super-matrix is positive. (This is the case for us as we will see shortly.) As a result we get

$$(d_{11}d_{11}^{\dagger})^{-1/2}=\frac{1}{\pi}\int_0^{\infty}\frac{d\lambda}{\lambda^{1/2}}[(c_Bc_B^{\dagger}+\lambda 1+1)^{-1}+(c_Bc_B^{\dagger}+\lambda 1+1)^{-1}f_S(c_Bc_B^{\dagger}+\lambda 1+1)^{-1}$$
$$+\cdots\ -(-1)^r((c_Bc_B^{\dagger}+\lambda 1+1)^{-1}f_S)^r(c_Bc_B^{\dagger}+\lambda 1+1)^{-1}].$$

Here we use $f_S=c_Bc_S^{\dagger}+c_Sc_B^{\dagger}+c_Sc_S^{\dagger}+\delta_{12}\delta_{12}^{\dagger}$, which is a nilpotent matrix, and we assumed that it has degree $r+1$. The first term is the usual term $(1+c_Bc_B^{\dagger})^{-1/2}$, the others are nilpotent contributions. Hence when we write this first diagonal block in this form,

$$1+u(1+c_Bc_B^{\dagger})^{-1/2}c_Bw_B+\text{nilpotent parts},\tag{21}$$

where u is a unitary piece that we cannot determine—stripped off from its possible nilpotent part. It is enough to show that this leading part is invertible, but that is the same as in the non-super case: $\|w_B^{\dagger}c_B^{\dagger}(1+c_Bc_B^{\dagger})^{-1/2}u^{\dagger}u(1+c_Bc_B^{\dagger})^{-1/2}c_Bw_B\|\leqslant\|w_B^{\dagger}w_B\|<1$. This implies that the series expansion will converge and we have an invertible element. This concludes our demonstration. Of course we have done more than just showing that the inverse is well-defined, we also got an expansion of the inverse, which is useful to show the convergence condition in the infinite dimensional case. There is a simpler way to show the invertibility, which we repeat here for clarity,

$$(CZ+D)=\begin{pmatrix} cw+d_{11} & c\theta+\delta_{12}\\ \gamma w+\delta_{21} & \gamma\theta+d_{22}\end{pmatrix},\tag{22}$$

and as we have observed for invertibility, it is enough to know the invertibility of the body parts. We have $d_{11}d_{11}^{\dagger}=cc^{\dagger}+1-\delta_{12}\delta_{12}^{\dagger}$, the body parts satisfy $(d_{11})_B(d_{11}^{\dagger})_B=1+c_Bc_B^{\dagger}$, and using the same argument as before this implies that the body is invertible (we already know d_{22} is invertible).

One can check that the resulting operator Z' is an element of the super-disk. We briefly indicate how this is done: The convergence conditions are easy since we have $Z\in\mathcal{I}_2$ and $B\in\mathcal{I}_2$. If we want to show that the resulting operator satisfies $1-w_B'^{\dagger}w_B'>0$, we look at $((AZ+B)(CZ+D)^{-1})_B$. This comes from w',

$$w'=(Aw+b)(cw+d_{11}-(c\theta+\delta_{12})(\gamma\theta+d_{22})^{-1}(\gamma w+\delta_{21}))^{-1},\tag{23}$$

which has body part

$$w_B'=(A_Bw_B+b_B)(c_Bw_B+(d_{11})_B)^{-1}.\tag{24}$$

We have from the pseudounitarity conditions $A_BA_B^{\dagger}-b_Bb_B^{\dagger}=1$, $c_BA_B^{\dagger}=(d_{11})_Bb_B^{\dagger}$, $(d_{11})_B(d_{11}^{\dagger})_B-c_Bc_B^{\dagger}=1$. But these are exactly the conditions for the ordinary pseudounitary group $U_1(\mathcal{H}_-^e,\mathcal{H}_+^e)$, hence the positivity condition follows as in the ordinary case. Of course the point is to show that the action is transitive, and hence to prove that the super-disk is a homogeneous manifold. Let us go over this point as well using similar techniques to the above proof. To prove this it is enough to show that the action is transitive over the generating set of elements for the $C^{\infty}(D_1^I)$ we introduced, $Z=[w\ \theta]$. (Notice that a super manifold is really defined through the algebra of functions living on it.) Let us show that we can obtain all the generators starting from $Z=0$ using the group action. Recall that the pseudounitarity imposes the following conditions,

$$AA^{\dagger}-BB^{\dagger}=1,\quad CA^{\dagger}=DB^{\dagger},\quad D^{\dagger}D-B^{\dagger}B=1.\tag{25}$$

The last one uses the opposite multiplication. For any $Z=BD^{-1}$, if we insert this into the last one we see that $D=(1-Z^{\dagger}Z)^{-1/2}U$, where U is an arbitrary super-unitary element acting on the same space, is a solution. Later on we will prove that this square root makes sense and the body belongs to the desired class, but first we will present the formal solution in the super-matrix form:

$$g=\begin{pmatrix} (1-ZZ^\dagger)^{-1/2}V & Z(1-Z^\dagger Z)^{-1/2}U \\ (1-Z^\dagger Z)^{-1}Z^\dagger(1-ZZ^\dagger)^{1/2}V & (1-Z^\dagger Z)^{-1/2}U \end{pmatrix}, \tag{26}$$

where $V\in U(\mathcal{H}^e_-)$ and $U\in U(\mathcal{H}^e_+|\mathcal{H}^o_+)$. In fact, this shows the ambiguity in the solution to be exactly the subset we mode out with. Let us prove the claim using the integral form of the square root of the matrix. We begin with A,

$$\begin{aligned}(1-ZZ^\dagger)^{-1/2}&=\frac{1}{\pi}\int_0^\infty \frac{d\lambda}{\lambda^{1/2}}(\lambda 1+1-ww^\dagger-\theta\theta^\dagger)^{-1}\\ &=(1-w_Bw_B^\dagger)^{-1/2}+\frac{1}{\pi}\int_0^\infty \frac{d\lambda}{\lambda^{1/2}}(\lambda 1+1-w_Bw_B^\dagger)^{-1}f_S(\lambda 1+1-w_Bw_B^\dagger)^{-1}\\ &\quad+\cdots-(-1)^r\frac{1}{\pi}\int_0^\infty \frac{d\lambda}{\lambda^{1/2}}(\lambda 1+1-w_Bw_B^\dagger)^{-1}[f_S(\lambda 1+1-w_Bw_B^\dagger)^{-1}]^r,\end{aligned}$$

where $f_S=w_Sw_B^\dagger+w_Bw_S^\dagger+w_Sw_S^\dagger+\theta\theta^\dagger$. All the terms are properly defined. Let us now indicate that D is well-defined. We do this for the upper corner only,

$$D=(1-Z^\dagger Z)^{-1/2}=\frac{1}{\pi}\int_0^\infty \frac{d\lambda}{\lambda^{1/2}}\begin{pmatrix} \lambda 1+1-w^\dagger w & -w^\dagger\theta \\ -\theta^\dagger w & \lambda 1+1-\theta^\dagger\theta \end{pmatrix}^{-1}. \tag{27}$$

[Just for fun, we suggest to the reader to show the following identity, which gives an alternative proof of the existence, $(1-Z^\dagger Z)^{-1/2}=1+Z^\dagger((1-ZZ^\dagger)^{-1/2}-\frac{1}{2}\int_0^1 dt(1-tZZ^\dagger)^{-1/2})Z$.] As a result of this expression we see that all the elements are well-defined and belong to the correct classes. In fact, we can write the expansion for d_{11},

$$\begin{aligned}d_{11}&=(1-w_B^\dagger w_B)^{-1/2}+\frac{1}{\pi}\int_0^\infty \frac{d\lambda}{\lambda^{1/2}}(\lambda 1+1-w_B^\dagger w_B)^{-1}\times(w_B^\dagger w_S+w_S^\dagger w_B+w_S^\dagger w_S\\ &\quad+w^\dagger\theta(\lambda 1+1-\theta^\dagger\theta)^{-1}\theta^\dagger w)(\lambda 1+1-w_B^\dagger w_B)^{-1}+\cdots,\end{aligned}$$

where the series terminates. One can see that the rest of it can be done in a simple way since the expressions for B, C have explicit multiplicative factors of Z, which is in the Hilbert–Schmidt class, so we skip the details for brevity. Let us also check again the stability subgroup of $Z=0$ is given by $U(\mathcal{H}^e_-)\times U(\mathcal{H}^e_+|\mathcal{H}^o_+)$. For $Z=0$, $Z'=BD^{-1}$; if we set this to zero, since D is invertible, we get $B=0$. From the invariance of J we get $AA^\dagger=1$ as well as $A^\dagger A=1$, and this together with $AC^\dagger-BD^\dagger=0$ implies $C=0$. The result of this is the diffeomorphim we are after:

$$D_1^I=U_1(\mathcal{H}^e_-,\mathcal{H}^e_+|\mathcal{H}^o_+)/U(\mathcal{H}^e_-)\times U(\mathcal{H}^e_+|\mathcal{H}^o_+). \tag{28}$$

We emphasize that the explicit coordinate Z shows that this is a super-complex manifold; the group action point of view instead shows that this space is a super-homogeneous space.

III. SUPER-SYMPLECTIC STRUCTURE

In this section we will discuss the classical mechanics on this super-disk. There is a natural super-symplectic structure, it is homogeneous and further more it is Kähler. This is a natural choice from the point of view of geometry and, as we will see, it also provides us a natural method of quantization, which is an extension of the Bargmann representation to this case.[6] The analysis of symmetric domains and the use of Toeplitz operators in the quantization problem is thoroughly discussed in the book by Upmeier.[17] We also recommend the articles by Borthwick *et al.*[18]

It will be simpler to use the following super-operator to show that the disk is a super-symplectic space,

$$\Phi=-1+2\begin{pmatrix}(1-ZZ^\dagger)^{-1} & -(1-ZZ^\dagger)^{-1}Z\\ Z^\dagger(1-ZZ^\dagger)^{-1} & -Z^\dagger(1-ZZ^\dagger)^{-1}Z\end{pmatrix}. \tag{29}$$

Notice that this operator is well-defined on $\mathcal{H}^e_-\oplus\mathcal{H}^e_+|\mathcal{H}^o_+$. The reader can check that

$$\Phi^2=1,\quad J\Phi^\dagger J=\Phi. \tag{30}$$

An important point is that the action of the group on Z becomes very simple on Φ, $Z\to g\circ Z$ induces $\Phi\to g\Phi g^{-1}$ (see the Appendix). $Z=0$ corresponds to $\Phi=J$, and we can check that $\Phi(Z)=g(Z)Jg(Z)^{-1}$ (see the Appendix). We may define a symplectic form on D_1^I using Φ; formally,

$$\Omega=\frac{i}{4}\mathrm{Str}\Phi d\Phi\wedge d\Phi. \tag{31}$$

What we mean by this two form is that if we take two vector fields V_u, V_v, which are generated by the action of the super-Lie group, we get a number:

$$\Omega(V_u,V_v)=\frac{i}{8}\mathrm{Str}J[[J,g^{-1}ug]_s,[J,g^{-1}vg]_s]_s. \tag{32}$$

Using the above formal expression, we see that Ω is closed and, furthermore, it is homogeneous. This easily follows from the transformation of Φ under the group action. One can actually see this by looking at its explicit form. The nondegeneracy and super-Kähler structures are best understood around J. Then we use the homogeneity to distribute this form over all the manifold. When we restrict ourselves to the point J:

$$\Omega|_{Z=0}=i\mathrm{Str}\begin{pmatrix}-dZ\wedge dZ^\dagger & 0\\ 0 & dZ^\dagger\wedge dZ\end{pmatrix}. \tag{33}$$

Here the two wedge products have different meanings: $dZ\wedge dZ^\dagger=dw\wedge dw^\dagger+d\theta\wedge d\theta$ and

$$dZ^\dagger\wedge dZ=\begin{pmatrix}dw^\dagger\wedge dw & dw^\dagger\wedge d\theta\\ d\theta^\dagger\wedge dw & d\theta^\dagger\wedge d\theta\end{pmatrix}. \tag{34}$$

Hence we can rewrite this expression as

$$\Omega|_{Z=0}=i\mathrm{Str}\begin{pmatrix}-dw\wedge dw^\dagger-d\theta\wedge d\theta^\dagger & 0\\ 0 & \begin{pmatrix}dw^\dagger\wedge dw & dw^\dagger\wedge d\theta\\ d\theta^\dagger\wedge dw & d\theta^\dagger\wedge d\theta\end{pmatrix}\end{pmatrix}. \tag{35}$$

By expanding the trace,

$$\begin{aligned}\Omega|_{Z=0}&=i\left[-\mathrm{Tr}dw\wedge dw^\dagger-\mathrm{Tr}d\theta\wedge d\theta^\dagger+\mathrm{Str}\begin{pmatrix}dw^\dagger\wedge dw & dw^\dagger\wedge d\theta\\ d\theta^\dagger\wedge dw & d\theta^\dagger\wedge d\theta\end{pmatrix}\right]\\ &=i[-\mathrm{Tr}dw\wedge dw^\dagger-\mathrm{Tr}d\theta\wedge d\theta^\dagger+\mathrm{Tr}dw^\dagger\wedge dw-\mathrm{Tr}d\theta^\dagger\wedge d\theta]\\ &=-2i\mathrm{Tr}dw\wedge dw^\dagger-2i\mathrm{Tr}d\theta\wedge d\theta^\dagger=-2i\mathrm{Tr}dZ\wedge dZ^\dagger.\end{aligned}$$

(This incidentally shows that the form is super-Kähler.[19,20,14]) By contracting this with two vector fields at the origin, we get

$$\Omega(V_u,V_v)|_{Z=0}=-2i[\mathrm{Tr}(b_1b_2^\dagger-b_2b_1^\dagger)+\mathrm{Tr}(\beta_1\beta_2^\dagger+\beta_2\beta_1^\dagger)]. \tag{36}$$

Notice that we use the vector $[b\ \beta]$ for the component u_{12} of the Lie algebra element (this could be somewhat confusing but we try to avoid the prolifiration of indices). Using the above form it is possible to prove the nondegeneracy; this is given in the Appendix. The symplectic form above provides us with a Poisson structure,

One can define classical dynamics on this super-space, given an even Hamiltonian, a physical observable, H. The time evolution of any observable O is given by

$$\frac{\partial O}{\partial t}=\{H,O\}_s. \tag{37}$$

One can naturally ask if there are moment maps which generate the goup action. It is not possible to use $F_u=(i/2)\mathrm{Str}\Phi u$ due to divergence of the trace, but it is possible to do a vacuum subtraction and get a convergent one. To prove this we use a rearrangement of the formula for Φ:

$$\Phi(Z)=J+\begin{pmatrix} 2Z(1-Z^\dagger Z)^{-1}Z^\dagger & -2(1-ZZ^\dagger)^{-1}Z \\ 2Z^\dagger(1-ZZ^\dagger)^{-1} & -2Z^\dagger(1-ZZ^\dagger)^{-1}Z \end{pmatrix}. \tag{38}$$

If we look at now the difference $\Phi(Z)-J$, the last part remains. The diagonal parts of this operator are better behaved than the off-diagonal parts, $Z(1-Z^\dagger Z)^{-1}Z^\dagger\in\mathcal{I}_1$, in our sense as one can see, and similarly for the other one. The off-diagonal parts are actually in $\mathcal{I}_2$. So when we look at $(\Phi(Z)-J)u$, we see that

$$\begin{pmatrix} \mathcal{I}_1 & \mathcal{I}_2 & \mathcal{I}_2 \\ \mathcal{I}_2 & \mathcal{I}_1 & \mathcal{I}_1 \\ \mathcal{I}_2 & \mathcal{I}_1 & \mathcal{I}_1 \end{pmatrix}\begin{pmatrix} \mathcal{B} & \mathcal{I}_2 & \mathcal{I}_2 \\ \mathcal{I}_2 & \mathcal{B} & \mathcal{B} \\ \mathcal{I}_2 & \mathcal{B} & \mathcal{B} \end{pmatrix}=\begin{pmatrix} \mathcal{I}_1 & \mathcal{I}_2 & \mathcal{I}_2 \\ \mathcal{I}_2 & \mathcal{I}_1 & \mathcal{I}_1 \\ \mathcal{I}_2 & \mathcal{I}_1 & \mathcal{I}_1 \end{pmatrix}. \tag{39}$$

Hence a conditional trace exists: if we throw away the nontrace parts, $\mathrm{Str}_J(\Phi(Z)-J)u=\frac{1}{2}\mathrm{Str}[(\Phi(Z)-J)u+J(\Phi(Z)-J)uJ]$ is actually convergent. We see that this is very similar to the ordinary disk case in Ref. 6.

A general discussion shows that we get a Poisson realization of the super-Lie algebra through the moment maps:

$$\{F_u,F_v\}_s=F_{[u,v]_s}+\Sigma_s(u,v). \tag{40}$$

It is possible to find this central term by evaluating everything at the origin, $\Phi=J$:

$$\Sigma_s(u,v)=\frac{i}{8}\mathrm{Str}\begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & -1 \end{pmatrix}\left[\left[\left[\begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & -1 \end{pmatrix},u\right],\left[\begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & -1 \end{pmatrix},v\right]\right]\right]_s$$

$$=\frac{i}{2}\mathrm{Str}_J[J,u]v.$$

It is interesting to write down the central term explicitly:

$$\Sigma_s(u,v)=-2i\mathrm{Str}\begin{pmatrix} b_1b_2^\dagger+\beta_1\beta_2^\dagger & * \\ * & \begin{pmatrix} b_1^\dagger b_2 & b_1^\dagger\beta_2 \\ \beta_1^\dagger b_2 & \beta_1^\dagger\beta_2 \end{pmatrix} \end{pmatrix}$$

$$=-2i(\mathrm{Tr}(b_1b_2^\dagger-b_2b_1^\dagger)+\mathrm{Tr}(\beta_1\beta_2^\dagger)-\mathrm{Tr}(\beta_1^\dagger\beta_2))$$

$$=-2i(\mathrm{Tr}(b_1b_2^\dagger-b_2b_1^\dagger)+\mathrm{Tr}(\beta_1\beta_2^\dagger+\beta_2\beta_1^\dagger)),$$

and we see that at each step the diagonals are in $\mathcal{I}_1$ and hence the traces are all well-defined. This is equal to the symplectic form at the origin we computed before using the explicit coordinate Z as it should be. This type of central term is expected when there are bosons and fermions mixed. An interesting discussion of such central extensions from the Fock space point of view is given in Ref. 21. In Ref. 22 $\mathbf{Z}_2$ graded Schwinger terms for neutral particles are worked out, and in Ref. 23 current super-algebras are studied providing a generalization of Mickelsson–Rajeev cocyle.[24] The use of pseudodifferential operators in this reference we believe is better motivated in these higher dimensional cases. There should be a similar extension of our results using this restricted class of operators.

We are therefore equipped with a powerful geometric setting to develop our geometric quantization program.

IV. GEOMETRIC QUANTIZATION

Our presentation here will be somewhat more concise; most of the computations can be done similar to our previous work, except one has to watch for the signs. The technical details and explanation of the main ideas are already given in Ref. 12. We recommend the examples in Refs. 19 and 20, and one can read a more general program in Ref. 25 (we believe it is interesting to follow the philosophy of the last reference).

We can follow exactly the same steps in Ref. 6 and introduce a prequantization line bundle (for ordinary geometric quantization we refer to Refs. 1 and 26–28), and we introduce a super-one form on this bundle:

$$\Theta_s=\frac{1}{\hbar}(\mathrm{Str}(1-Z^\dagger Z)^{-1}dZ^\dagger Z-\mathrm{Str}(1-Z^\dagger Z)^{-1}Z^\dagger dZ). \tag{41}$$

This is used to define the covariant derivate as in the nonsuper-case [strictly speaking in the model of super-sections this acts on the prolongation, $\Gamma(M,\wedge(\mathbf{C}^N)\otimes K)$ where K is a prequantum complex line bundle on the base M]:

$$\nabla_V=\mathcal{L}^s_V+\Theta_s(V), \tag{42}$$

where we used a superscript to denote the super-Lie derivative. For any given super-function, we have the vector field generated from the symplectic form,

$$\Omega(V_f,*)=-df. \tag{43}$$

Using this vector field a prequantization operator is obtained,

$$\tilde{f}=-i\hbar\nabla_{V_f}+f. \tag{44}$$

This gives us a representation of the Poisson brackets:

$$\widetilde{\{f,g\}}_s=-i\hbar[\tilde{f},\tilde{g}]_s. \tag{45}$$

As in the ordinary case, we need to restrict the prequantum Hilbert space, since the prequantization map does not lead to an irreducible representation. We will choose super-holomorphic functions,

$$\nabla_{Z^\dagger}\psi(Z,Z^\dagger)=0. \tag{46}$$

The super analysis is designed to provide a complete analogy to the usual analysis, hence most of what we said follows from routine yet long (and care required due to signs) computations.

We can solve for this holomorphicity condition as in the ordinary case:

$$\nabla_{Z^\dagger}\psi=0, \quad \psi(Z,Z^\dagger)=\mathrm{sdet}^{1/\hbar}(1-Z^\dagger Z)\Psi(Z), \tag{47}$$

where $\Psi(Z)$ denotes a super-holomorphic function on the disk. We define the super-determinant (or Berezinian) as

$$\mathrm{sdet}\begin{pmatrix}\tilde{A} & \tilde{B}\\ \tilde{C} & \tilde{D}\end{pmatrix}=\det(\tilde{A}-\tilde{B}\tilde{D}^{-1}\tilde{C})(\det\tilde{D})^{-1}, \tag{48}$$

where the operator is written according to the even and odd decomposition of the super Hilbert space. The infinite dimensionality of the underlying space requires the full operator to be of the form $1+\mathcal{I}_1$, otherwise one has to use a conditional determinant. The resulting operators for the moment maps acting on holomorphic sections will be exactly the same as in the ordinary case,

$$\hat{F}_u\Psi(Z)=-i\hbar\left[\mathcal{L}^S_{V_u}-\frac{1}{\hbar}\mathrm{Str}(u_{21}Z)\right]\Psi(Z), \tag{49}$$

where we have used the same letters to denote the components of the Lie algebra elements,

$$u=\begin{pmatrix}u_{11} & u_{12}\\ u_{21} & u_{22}\end{pmatrix},$$

not to bring new notation. Holomorphicity is clearly preserved and these are the correct operators to start a quantization program.

These moment maps can be integrated to a representation of a central extension of the super-pseudounitary group:

$$\rho(g^{-1})\Psi(Z)=\mathrm{sdet}^{-1/\hbar}(D^{-1}CZ+1)\Psi((AZ+B)(CZ+D)^{-1}). \tag{50}$$

This is a well-defined representation. Let us see that the determinant exits:

$$\begin{pmatrix}(d^{-1})_{11} & (\delta^{-1})_{12}\\ (\delta^{-1})_{21} & (d^{-1})_{22}\end{pmatrix}\begin{pmatrix}cw & c\theta\\ \gamma w & \gamma\theta\end{pmatrix}=\begin{pmatrix}\mathcal{B} & \mathcal{B}\\ \mathcal{B} & \mathcal{B}\end{pmatrix}\begin{pmatrix}\mathcal{I}_1 & \mathcal{I}_1\\ \mathcal{I}_1 & \mathcal{I}_1\end{pmatrix}=\begin{pmatrix}\mathcal{I}_1 & \mathcal{I}_1\\ \mathcal{I}_1 & \mathcal{I}_1\end{pmatrix}. \tag{51}$$

This shows that the determinant is absolutely convergent—independent of the basis chosen. The central term of the representation is given by

$$c_S(g_1,g_2)=\mathrm{sdet}^{1/\hbar}[(D_1D_2)^{-1}C_1B_2+1]. \tag{52}$$

Derivation of this super-central term does not present any more difficulties than the ordinary case (see the appendix of Ref. 29), the convergence issue follows the same lines as the above one and we leave the details to the reader.

V. INFINITE DIMENSIONAL CASE

We will propose a way of extending our results when $\mathcal{H}^o$ is infinite dimensional. In this section we will not repeat the previous arguments, since some of them are direct generalizations and some of them require a much deeper study. We plan to come back to those issues in another publication, so in this section we only give a sketch of ideas. While we were working on this problem, we became aware of a rather similar set of ideas by Schmidt in Ref. 30. Which set of ideas is more appropriate for our problem is not so clear to us at this moment, so we follow our point of view. We plan to take a more detailed study of all these issues in the future.

First we change our notion of a super-number:

$$z=z_B+\sum_{N=0}^{\infty}\sum_{a_1<a_2<\ldots<a_N} z_{a_1a_2\ldots a_N}\xi^{a_1}\xi^{a_2}\cdots\ \xi^{a_N}, \tag{53}$$

where we assume that the sums have square integrable coefficients $\Sigma_N^{\infty}\Sigma_{a_1<a_2<\ldots<a_N}|z_{a_1a_2\ldots a_N}|^2<\infty$. This makes the product of two super-numbers well-defined, hence it behaves much better than the formal sums and it is physically more transparent as well. The product becomes

$$(zt)_{a_1a_2\ldots a_N}=\sum_n z_{(a_1a_2\ldots a_n}t_{a_{n+1}\ldots a_N)}, \tag{54}$$

here $(\ldots)$ denotes an appropriate symmetrization of the indices, due to the ordering of the generators (keeping the previous ordering in mind). From a more abstract point of view, when we look at the algebra of smooth functions on this flat space we get $C^{\infty}(F)\approx\oplus_{l^2}\wedge^k\mathcal{H}$ and this is what defines the Cartesian product of super-numbers. We will naturally represent the right hand side as the naive Fock space of the Hilbert space: $\mathcal{F}(\mathcal{H})=\oplus_{l^2}\wedge^k\mathcal{H}$. (This is not the Fock space corresponding to the Dirac sea, it is the naive one.) We look at again the matrix algebra modeled on these super-numbers; they will be transformations from $Z:\mathcal{H}_+^e|\mathcal{H}_+^o\to\mathcal{H}_-^e$ written explicitly, $Z=Z_B+\Sigma_N\Sigma_{a_1<a_2<\ldots<a_N}Z_{a_1a_2\ldots a_N},\xi^{a_1}\xi^{a_2}\cdots\ \xi^{a_N}$, matrix coefficients satisfying

$$\sum_N\sum_{a_1<a_2<\ldots<a_N}\|Z_{a_1a_2\ldots a_N}\|_2^2<\infty, \tag{55}$$

where $\|*\|_2$ denotes the norm in the Hilbert–Schmidt ideal. This implies that we have a space of matrices which is modeled on $\mathcal{I}_2\otimes\mathcal{F}(\mathcal{H})$. We may use the above convergence condition to get an inner product:

$$\langle Z,W\rangle=\sum_N\sum_{a_1<a_2<\ldots<a_N}\mathrm{Tr}Z^{\dagger}_{a_1a_2\ldots a_N}W_{a_1\ldots a_N}. \tag{56}$$

We note that this abstract space is still a Hilbert space with the above inner product, and indeed that will equip us with all the luxuries of Hilbert spaces. We can prove by using standard techniques that the product of two such matrices, ZW, is still in the above class, i.e.,

$$\sum_N\sum_{a_1<a_2<\ldots<a_N}\|(ZW)_{a_1a_2\ldots a_N}\|_2^2=\sum_N\sum_{a_1<a_2<\ldots<a_N}\|\sum_n Z_{(a_1a_2\ldots a_n}W_{a_{n+1}\ldots a_N)}\|_2^2<\infty. \tag{57}$$

There is the same type of possible reorderings of the indices in this expression. The rest will follow exactly the same lines as before. The convergence conditions should be checked much more carefully this time.

The disk is defined as $1-w_B^{\dagger}w_B>0$, and $Z=[w\ \theta]$, where each one of these super-matrices satisfies the above condition for being in $\mathcal{I}_2$. We can define the same symplectic form,

$$\Omega(V_u,V_v)=\frac{i}{8}\mathrm{Str}J[[J,g^{-1}ug]_s,[J,g^{-1}vg]_s]_s; \tag{58}$$

here each term is in $\mathcal{I}_2$.

The rest of the arguments apart from the convergence issues are exactly the same, so we leave the details to a future work.

ACKNOWLEDGMENTS

The author would like to thank M. Arik, K. Gawedzki, P. Guha, G. Grahovski, J. Gracia-Bondia, A. Konechny, I. Mladenov, J. Mickelsson, A. Nersessian, R. Nest, S. G. Rajeev, C. Saclioglu, S. Scott, and M. Walze for discussions and several useful comments. The author also greatfully acknowledges the kind invitation from IHES while this work was in progress.

APPENDIX: TRANSFORMATION RULE OF Φ

For completeness we define here A^α where $0<\alpha<1$ and the body of the super-operator is positive,

$$A^\alpha=\frac{\sin\pi\alpha}{\pi}\int_0^\infty \frac{d\lambda}{\lambda^{1-\alpha}}(\lambda 1+A)^{-1}. \tag{A1}$$

The advantage of this expression is that we may actually expand the inverse and obtain a series for the super operator. Note that there is no simple recursive process when α is not a rational number.

In this part we will give a proof of the following transformation rule: $Z\mapsto g\circ Z$ implies $\Phi\mapsto g\Phi g^{-1}$. First we note that when $Z\mapsto(AZ+B)(CZ+D)^{-1}$, we have $(1-Z^\dagger Z)^{-1}\mapsto(CZ+D)(1-Z^\dagger Z)^{-1}(CZ+D)^{-1}$. Next we rewrite $\Phi(Z)$:

$$\Phi=-1+2\begin{pmatrix} K^{-1} & -K^{-1}Z \\ Z^\dagger K^{-1} & -Z^\dagger K^{-1}Z\end{pmatrix}=1+2\begin{pmatrix} Z^\dagger S^{-1}Z & -ZS^{-1} \\ S^{-1}Z^\dagger & -S^{-1}\end{pmatrix}, \tag{A2}$$

where $K=(1-ZZ^\dagger)$ and $S=(1-Z^\dagger Z)$. Using the previous observation we see that

$$\Phi(g\circ Z)=1+2\begin{pmatrix} (AZ+B)S^{-1}(AZ+B)^\dagger & -(AZ+B)S^{-1}(CZ+D)^\dagger \\ (CZ+D)S^{-1}(AZ+B)^\dagger & -(CZ+D)S^{-1}(CZ+D)^\dagger\end{pmatrix}. \tag{A3}$$

One can see that the previous expression can be written as

$$\Phi(g\circ Z)=1+2\begin{pmatrix} A & B \\ C & D\end{pmatrix}\begin{pmatrix} Z^\dagger S^{-1}Z & -ZS^{-1} \\ S^{-1}Z^\dagger & -S^{-1}\end{pmatrix}\begin{pmatrix} A^\dagger & -C^\dagger \\ -B^\dagger & D^\dagger\end{pmatrix}, \tag{A4}$$

which is precisely what we claimed. The next point to check is $\Phi(Z)=g(Z)Jg(Z)^{-1}=g(Z)g(Z)^\dagger J$:

$$\begin{aligned} g(Z)g(Z)^\dagger&=\begin{pmatrix} K^{-1/2} & ZS^{-1/2} \\ S^{-1/2}Z^\dagger K^{1/2} & S^{-1/2}\end{pmatrix}\begin{pmatrix} K^{-1/2} & K^{1/2}ZS^{-1} \\ S^{-1/2}Z^\dagger & S^{-1/2}\end{pmatrix} \\ &=\begin{pmatrix} K^{-1}+ZS^{-1}Z^\dagger+1-1 & 2ZS^{-1} \\ 2S^{-1}Z^\dagger & S^{-1}Z^\dagger KZS^{-1}+S^{-1}\end{pmatrix}.\end{aligned}$$

Multiply this with $J=\left(\begin{smallmatrix}1 & 0\\ 0 & -1\end{smallmatrix}\right)$. Then in the last line use $-(S^{-1}Z^\dagger KZS^{-1}+S^{-1})=-(S^{-1}Z^\dagger KK^{-1}Z+S^{-1})$, which gives $-(S^{-1}Z^\dagger Z+S^{-1})=S^{-1}(1-Z^\dagger Z)-S^{-1}-S^{-1}$. This gives $1-2S^{-1}$, and the result follows.

We will prove the nondegeneracy of the super-two form:

$$\Omega(V_u,V_v)|_{Z=0}=-2i\mathrm{Tr}(b_1b_2^\dagger-b_2b_1^\dagger)-2i\mathrm{Tr}(\beta_1\beta_2^\dagger+\beta_2\beta_1^\dagger). \tag{A5}$$

Here we write $V_u(Z)=u_{11}Z-Zu_{22}-Zu_{21}Z+u_{21}$, and similarly for the $V_u(Z^\dagger)$. Furthermore, we write $u_{12}=[b\ \beta]$, hoping that the use of the same letters for the Lie algebra elements will not cause any confusion. Let us expand each term as a super-matrix (ignoring the multiplicative factor $-2i$),

$$\mathrm{Tr}((b_1)_B(b_2)_B^\dagger-(b_2)_B(b_1)_B^\dagger)=0,$$

$$\mathrm{Tr}((b_1)_{a_1a_2}(b_2)_B^\dagger-(b_2)_{a_1a_2}(b_1)_B^\dagger)\xi^{a_1}\xi^{a_2}=0,$$

$$\mathrm{Tr}((b_1)_B(b_2)_{a_1a_2}^\dagger-(b_2)_B(b_1)_{a_1a_2}^\dagger)\xi^{*a_1}\xi^{*a_2}=0,$$

$$\begin{aligned}&\mathrm{Tr}((b_1)_{a_1a_2a_3a_4}(b_2)_B^\dagger\xi^{a_1}\xi^{a_2}\xi^{a_3}\xi^{a_4}+(b_1)_{a_1a_2}(b_2)_{a_3a_4}^\dagger\xi^{a_1}\xi^{a_2}\xi^{*a_3}\xi^{*a_4}\\&\quad+(b_1)_B(b_2)_{a_1a_2a_3a_4}^\dagger\xi^{*a_1}\xi^{*a_2}\xi^{*a_3}\xi^{*a_4})\\&\quad-\mathrm{Tr}((b_2)_{a_1a_2}(b_1)_{a_3a_4}^\dagger\xi^{a_1}\xi^{a_2}\xi^{*a_3}\xi^{*a_4}+(b_2)_B(b_1)_{a_1a_2a_3a_4}^\dagger\xi^{*a_1}\xi^{*a_2}\xi^{*a_3}\xi^{*a_4}\\&\quad+(b_2)_{a_1a_2a_3a_4}(b_1)_B^\dagger\xi^{a_1}\xi^{a_2}\xi^{a_3}\xi^{a_4})=0,\end{aligned}$$

$$\ldots,$$

where the dots refer to the continuation of this expansion. From these relations we conclude that an iterative process gives us the required nondegeneracy.

(Received 31 May 2000; accepted for publication 4 June 2001)

Cohomology of the bicomplex of exterior forms on the infinite-order jet space of a smooth fiber bundle of a field model is computed. This provides a solution of the global inverse problem of the calculus of variations in Lagrangian field theory and time-dependent mechanics. In the case of an affine fiber bundle, the outcomes to BRST theory are discussed. We show that there is no topological obstruction to constructing global descent equations in the even field sector of BRST theory. [DOI: 10.1063/1.1390328]

I. INTRODUCTION

Let $Y \to X$ be a smooth fiber bundle of a field model. We obtain cohomology of exterior forms on the infinite order jet space $J^\infty Y$ of $Y \to X$. The $J^\infty Y$ provides the most general framework for describing the dynamics of field systems on fiber bundles.[1] It consists of the equivalence classes of sections of $Y \to X$ identified by their Taylor series at points $x \in X$. The exterior differential d on $J^\infty Y$ splits into the sum of the vertical differential d_V and the horizontal (total) differential d_H. These differentials, together with the variational operator δ, constitute the variational bicomplex of exterior forms on $J^\infty Y$.

The following two differential algebras of exterior forms $\mathcal{O}^*_\infty$ and $\mathcal{T}^*_\infty$ are usually considered on $J^\infty Y$.

The first one is the direct limit of graded differential algebras of exterior forms on finite order jet manifolds. This algebra is most interesting for physical applications because it consists of exterior forms on finite order jet manifolds. Lagrangian field theory is phrased in terms of $\mathcal{O}^*_\infty$.[1] Extended to the jet space of ghosts and antifields, the algebra $\mathcal{O}^*_\infty$ is the main ingredient in the field-antifield BRST theory for studying BRST cohomology modulo d_H.[2–5] Passing to the direct limit of the de Rham complexes of exterior forms on finite order jet manifolds, de Rham cohomology of $\mathcal{O}^*_\infty$ has been found to coincide with de Rham cohomology of the fiber bundle Y.[6,7] However, this is not a way of studying other cohomology of the algebra $\mathcal{O}^*_\infty$.

To solve this problem, we enlarge $\mathcal{O}^*_\infty$ to the graded differential algebra $\mathcal{T}^*_\infty$ of exterior forms of locally finite order on $J^\infty Y$. This is the structure algebra of the sheaf of germs of exterior forms on finite order jet manifolds. The d_H and δ cohomology of $\mathcal{T}^*_\infty$ have been investigated in Refs. 8 and 9. Due to Lemma 2 below, we simplify this investigation and prove that the differential algebra $\mathcal{O}^*_\infty$ has the same d_H and δ cohomology as $\mathcal{T}^*_\infty$ (see Theorem 7). In particular, this provides a solution of the global inverse problem of the calculus of variations in Lagrangian field theory and time-dependent mechanics.

For applications to BRST theory, the case of an affine bundle $Y \to X$ is relevant. The BRST cohomology modulo d_H has been introduced in the case of a contractible fiber bundle $Y = \mathbb{R}^{n+m}$

$\to\mathbb{R}^n$ when the horizontal differential d_H is exact. Its exactness is essential for constructing the (local) descent equations. Here, we show that, in the case of an arbitrary affine bundle $Y\to X$, there is no topological obstruction to constructing global descent equations in the even field sector of BRST theory. Note that affine bundles provide a standard framework in quantum field theory. If $Y\to X$ is an affine bundle, d_H cohomology of $\mathcal{O}^*_\infty$ coincides with de Rham cohomology of the base X. It follows that every d_H-closed element ϕ of $\mathcal{O}^*_\infty$ can be written in the form

$$\phi=\varphi+d_H\xi, \quad \xi\in\mathcal{O}^*_\infty,$$

where φ is a closed form on X. Consequently, the obstruction to the exactness of the horizontal differential d_H lies only in exterior forms on X. Since the BRST operator eliminates these forms, the global descent equations can be constructed though their right-hand side is not zero. We come to the same result for the differential algebra $\mathcal{P}$ of exterior forms which are polynomials in field variables and for its subalgebra $\overline{\mathcal{P}}$ of x-independent forms. These are algebras which one deals with in the even field sector of BRST theory.

The article is organized as follows. In Sec. II, the differential algebras $\mathcal{O}^*_\infty$ and $\mathcal{T}^*_\infty$ on $J^\infty Y$ are introduced in an algebraic way. In Sec. III, the variational complex on $J^\infty Y$ is set. Section IV is devoted to cohomology of the differential algebra $\mathcal{T}^*_\infty$. In Sec. V, the isomorphism of d_H and δ cohomology of $\mathcal{O}^*_\infty$ to that of $\mathcal{T}^*_\infty$ is proved. In Sec. VI, a solution of the inverse problem of the calculus in variations in different classes of exterior forms is provided. Section VII is devoted to the cohomology of $\mathcal{O}^*_\infty$ in the case of an affine bundle. In Sec. VIII, cohomology of the polynomial algebras $\mathcal{P}$ and $\overline{\mathcal{P}}$ is described.

II. THE DIFFERENTIAL CALCULUS ON $J^\infty Y$

Smooth manifolds throughout are assumed to be real, finite-dimensional, Hausdorff, paracompact, and connected. Put further $\dim X=n\geqslant 1$.

Recall that the infinite order jet space $J^\infty Y$ of a smooth fiber bundle $Y\to X$ is defined as a projective limit $(J^\infty Y,\pi^\infty_r)$ of the inverse system

$$X\overset{\pi}{\leftarrow}Y\overset{\pi^1_0}{\leftarrow}\cdots\leftarrow J^{r-1}Y\overset{\pi^r_{r-1}}{\leftarrow}J^rY\leftarrow\cdots \tag{1}$$

of finite order jet manifolds J^rY of $Y\to X$, where π^r_{r-1} are affine bundles (see Refs. 1 and 5 for a survey of the infinite order jet technique). Endowed with the projective limit topology, $J^\infty Y$ is a paracompact Fréchet manifold.[8] A bundle coordinate atlas $\{U_Y,(x^\lambda,y^i)\}$ of $Y\to X$ yields the manifold coordinate atlas

$$\{(\pi^\infty_0)^{-1}(U_Y),(x^\lambda,y^i_\Lambda)\}, \quad 0\leqslant|\Lambda|,$$

of $J^\infty Y$, together with the transition functions

$$y'^i_{\lambda+\Lambda}=\frac{\partial x^\mu}{\partial x'^\lambda}d_\mu y'^i_\Lambda, \tag{2}$$

where $\Lambda=(\lambda_k\cdots\lambda_1)$, $\lambda+\Lambda=(\lambda\lambda_k\cdots\lambda_1)$ are symmetric multi-indices and d_λ denotes the total derivative

$$d_\lambda=\partial_\lambda+\sum_{|\Lambda|\geqslant 0}y^i_{\lambda+\Lambda}\partial^\Lambda_i.$$

With the inverse system (1), one has the direct system

$$\mathcal{O}^*(X) \xrightarrow{\pi^*} \mathcal{O}_0^* \xrightarrow{\pi_0^{1*}} \mathcal{O}_1^* \xrightarrow{\pi_1^{2*}} \cdots \xrightarrow{\pi_{r-1}^{r*}} \mathcal{O}_r^* \to \cdots \tag{3}$$

of graded differential $\mathbb{R}$-algebras $\mathcal{O}_r^*$ of exterior forms on finite order jet manifolds J^rY, where π_{r-1}^{r*} are pull-back monomorphisms. Its direct limit is the above-mentioned graded differential $\mathbb{R}$-algebra $(\mathcal{O}_\infty^*, \pi_r^{\infty *})$ of exterior forms on finite order jet manifolds modulo the pull-back identification. The $\mathcal{O}_\infty^*$ is a differential calculus over the $\mathbb{R}$-ring $\mathcal{O}_\infty^0$ of continuous real functions on $J^\infty Y$ which are the pull-back of smooth real functions on finite order jet manifolds by surjections π_r^∞.

Let us enlarge $\mathcal{O}_\infty^0$ to the $\mathbb{R}$-ring $\mathcal{T}_\infty^0$ of continuous real functions on $J^\infty Y$ such that, given $f \in \mathcal{T}_\infty^0$ and any point $q \in J^\infty Y$, there exists a neighborhood of q where f coincides with the pull-back of a smooth function on some finite order jet manifold. The reason lies in the fact that the paracompact space $J^\infty Y$ admits a partition of unity by elements of the ring $\mathcal{T}_\infty^0$.[8] Therefore, sheaves of $\mathcal{T}_\infty^0$-modules on $J^\infty Y$ are fine and, consequently, acyclic. Then, the abstract de Rham theorem on cohomology of a sheaf resolution (Theorem 2.12.1 in Ref. 10) can be called into play.

Remark 1: Throughout, we follow the terminology of Ref. 10 where by a sheaf S over a topological space Z is meant a sheaf bundle $S \to Z$. Accordingly, $\Gamma(S)$ denotes the canonical presheaf of sections of the sheaf S, and $\Gamma(Z,S)$ is the group of global sections of S. All sheaves in the following are ringed spaces, but we omit this terminology if there is no danger of confusion.

Let us define a differential calculus over the ring $\mathcal{T}_\infty^0$. Let $\mathfrak{O}_r^*$ be a sheaf of germs of exterior forms on the r-order jet manifold J^rY and $\Gamma(\mathfrak{O}_r^*)$ its canonical presheaf. There is the direct system of canonical presheaves

$$\Gamma(\mathfrak{O}_X^*) \xrightarrow{\pi^*} \Gamma(\mathfrak{O}_0^*) \xrightarrow{\pi_0^{1*}} \Gamma(\mathfrak{O}_1^*) \xrightarrow{\pi_1^{2*}} \cdots \xrightarrow{\pi_{r-1}^{r*}} \Gamma(\mathfrak{O}_r^*) \to \cdots,$$

where π_{r-1}^{r*} are pull-back monomorphisms with respect to open surjections π_{r-1}^r. Its direct limit $\mathfrak{O}_\infty^*$ is a presheaf of graded differential $\mathbb{R}$-algebras on $J^\infty Y$. Let $\mathfrak{T}_\infty^*$ be a sheaf constructed from $\mathfrak{O}_\infty^*$ and $\Gamma(\mathfrak{T}_\infty^*)$ its canonical presheaf. The structure algebra $\mathcal{T}_\infty^* = \Gamma(J^\infty Y, \mathfrak{T}_\infty^*)$ of the sheaf $\mathfrak{T}_\infty^*$ is a desired differential calculus over the $\mathbb{R}$-ring $\mathcal{T}_\infty^0$. There are the $\mathbb{R}$-algebra monomorphisms $\mathfrak{O}_\infty^* \to \Gamma(\mathfrak{T}_\infty^*)$ and $\mathcal{O}_\infty^* \to \mathcal{T}_\infty^*$.

For short, we agree to call elements of $\mathcal{T}_\infty^*$ the exterior forms on $J^\infty Y$. Restricted to a coordinate chart $(\pi_0^\infty)^{-1}(U_Y)$ of $J^\infty Y$, they can be written in the familiar coordinate form, where horizontal forms $\{dx^\lambda\}$ and contact one-forms $\{\theta_\Lambda^i = dy_\Lambda^i - y_{\lambda+\Lambda}^i dx^\lambda\}$ constitute the set of generators of the algebra $\mathcal{T}_\infty^*$. There is the canonical decomposition

$$\mathcal{T}_\infty^* = \oplus_{k,s} \mathcal{T}_\infty^{k,s}, \quad 0 \leqslant k, \quad 0 \leqslant s \leqslant n,$$

of $\mathcal{T}_\infty^*$ into $\mathcal{T}_\infty^0$-modules $\mathcal{T}_\infty^{k,s}$ of k-contact and s-horizontal forms, together with the corresponding projections

$$h_k : \mathcal{T}_\infty^* \to \mathcal{T}_\infty^{k,*}, \quad 0 \leqslant k, \quad h^s : \mathcal{T}_\infty^* \to \mathcal{T}_\infty^{*,s}, \quad 0 \leqslant s \leqslant n.$$

Accordingly, the exterior differential on $\mathcal{T}_\infty^*$ is decomposed into the sum $d = d_H + d_V$ of horizontal and vertical differentials such that

$$d_H \circ h_k = h_k \circ d \circ h_k, \quad d_H(\phi) = dx^\lambda \wedge d_\lambda(\phi), \quad \phi \in \mathcal{T}_\infty^*,$$

$$d_V \circ h^s = h^s \circ d \circ h^s, \quad d_V(\phi) = \theta_\Lambda^i \wedge \partial_\Lambda^i \phi.$$

III. THE VARIATIONAL COMPLEX

Being nilpotent, the differentials d_V and d_H provide the natural bicomplex $\{\mathcal{T}_\infty^{k,m}\}$ of the graded differential algebra $\mathcal{T}_\infty^*$. Here, we restrict our consideration to its row

$$0 \longrightarrow \mathbb{R} \longrightarrow \mathcal{T}^0_\infty \xrightarrow{d_H} \mathcal{T}^{0,1}_\infty \xrightarrow{d_H} \cdots \xrightarrow{d_H} \mathcal{T}^{0,n}_\infty, \tag{4}$$

called the horizontal complex. To complete it to the variational complex, let us consider the variational operator $\delta=\tau\circ d$ on $\mathcal{T}^{*,n}_\infty$ where τ is the projection $\mathbb{R}$-module endomorphism

$$\tau=\sum_{k>0}\frac{1}{k}\overline{\tau}\circ h_k\circ h^n,$$

$$\overline{\tau}(\phi)=(-1)^{|\Lambda|}\theta^i\wedge[d_\Lambda(\partial^\Lambda_i\rfloor\phi)], \quad 0\leqslant|\Lambda|, \quad \phi\in\mathcal{T}^{>0,n}_\infty,$$

of $\mathcal{T}^*_\infty$ such that $\tau\circ d_H=0$ (see, e.g., Refs. 1, 6, and 11). The variational operator on $\mathcal{T}^{*,n}_\infty$ is nilpotent, and obeys the relation

$$\delta\circ\tau-\tau\circ d=0. \tag{5}$$

Put $\mathfrak{E}_k=\tau(\mathfrak{T}^{k,n}_\infty)$ and $E_k=\tau(\mathcal{T}^{k,n}_\infty)$, $k>0$. Since τ is a projection operator, there are the isomorphisms

$$\Gamma(\mathfrak{E}_k)=\tau(\Gamma(\mathfrak{T}^{k,n}_\infty)), \quad E_k=\Gamma(J^\infty Y,\mathfrak{E}_k).$$

Let $\mathbb{R}$ denote the constant sheaf on $J^\infty Y$. With operators d_H and δ, we have the variational complex

$$0 \longrightarrow \mathbb{R} \longrightarrow \mathfrak{T}^0_\infty \xrightarrow{d_H} \mathfrak{T}^{0,1}_\infty \xrightarrow{d_H} \cdots \xrightarrow{d_H} \mathfrak{T}^{0,n}_\infty \xrightarrow{\delta} \mathfrak{E}_1 \xrightarrow{\delta} \mathfrak{E}_2 \longrightarrow \cdots \tag{6}$$

of the sheaf $\mathfrak{T}^*_\infty$ and the variational complex

$$0 \longrightarrow \mathbb{R} \longrightarrow \mathcal{T}^0_\infty \xrightarrow{d_H} \mathcal{T}^{0,1}_\infty \xrightarrow{d_H} \cdots \xrightarrow{d_H} \mathcal{T}^{0,n}_\infty \xrightarrow{\delta} E_1 \xrightarrow{\delta} E_2 \longrightarrow \cdots \tag{7}$$

of its structure algebra $\mathcal{T}^*_\infty$. The similar variational complex $\{\mathcal{O}^*_\infty,\overline{E}_k\}$ of the graded differential algebra $\mathcal{O}^*_\infty$ takes place. There are the well-known statements summarized usually as the algebraic Poincaré lemma (see, e.g., Refs. 11 and 12).

Lemma 1: If Y is a contractible fiber bundle $\mathbb{R}^{n+p}\to\mathbb{R}^n$, the variational complex $\{\mathcal{O}^*_\infty,\overline{E}_k\}$ of the graded differential algebra $\mathcal{O}^*_\infty$ is exact.

It follows that the variational complex of sheaves (6) is exact for any smooth fiber bundle $Y\to X$. Moreover, the sheaves $\mathfrak{T}^{*,n}$ in this complex are fine, and so are the sheaves $\mathfrak{E}_k$ in accordance with the following lemma.

Lemma 2: Sheaves $\mathfrak{E}_k$, $k>0$, are fine.

Proof: Though $\mathbb{R}$-modules $E_{k>1}$ fail to be $\mathcal{T}^0_\infty$-modules,[11] one can use the fact that the sheaves $\mathfrak{E}_{k>0}$ are projections $\tau(\mathfrak{T}^{k,n}_\infty)$ of sheaves of $\mathcal{T}^0_\infty$-modules. Let $\mathfrak{U}=\{U_i\}_{i\in I}$ be a locally finite open covering of $J^\infty Y$ and $\{f_i\in\mathcal{T}^0_\infty\}$ the associated partition of unity. For any open subset $U\subset J^\infty Y$ and any section φ of the sheaf $\mathfrak{T}^{k,n}_\infty$ over U, let us put $h_i(\varphi)=f_i\varphi$. Then, $\{h_i\}$ provide a family of endomorphisms of the sheaf $\mathfrak{T}^{k,n}_\infty$, required for $\mathfrak{T}^{k,n}_\infty$ to be fine. Endomorphisms h_i of $\mathfrak{T}^{k,n}_\infty$ also yield the $\mathbb{R}$-module endomorphisms

$$\overline{h_i}=\tau\circ h_i:\mathfrak{E}_k\xrightarrow{in}\mathfrak{T}^{k,n}_\infty\xrightarrow{h_i}\mathfrak{T}^{k,n}_\infty\xrightarrow{\tau}\mathfrak{E}_k$$

of the sheaves $\mathfrak{E}_k$. They possess the properties required for $\mathfrak{E}_k$ to be a fine sheaf. Indeed, for each $i\in I$, there is a closed set $\operatorname{supp} f_i\subset U_i$ such that $\overline{h_i}$ is zero outside this set, while the sum $\Sigma_{i\in I}\overline{h_i}$ is the identity morphism.

Thus, the variational complex (6) is a resolution of the constant sheaf $\mathbb{R}$ on $J^\infty Y$. Therefore, the above-mentioned abstract de Rham theorem (see Appendix A) can be utilized in order to find cohomology of the the variational complex (7) of the differential algebra $\mathcal{T}^*_\infty$.

IV. COHOMOLOGY OF $\mathcal{T}^*_\infty$

We start from the following facts.

Lemma 3: There is an isomorphism

$$H^*(J^\infty Y,\mathbb{R})=H^*(Y,\mathbb{R})=H^*(Y) \tag{8}$$

between cohomology $H^*(J^\infty Y,\mathbb{R})$ of $J^\infty Y$ with coefficients in the constant sheaf $\mathbb{R}$, that $H^*(Y,\mathbb{R})$ of Y, and de Rham cohomology $H^*(Y)$ of Y.

Proof: Since Y is a strong deformation retract of $J^\infty Y$ (see Appendix B), the first isomorphism in (8) follows from the Vietoris–Begle theorem,[13] while the second one is a consequence of the well-known de Rham theorem.

Lemma 4: Let us consider the de Rham complex of sheaves

$$0\to\mathbb{R}\to\mathfrak{T}^0_\infty\overset{d}{\to}\mathfrak{T}^1_\infty\overset{d}{\to}\cdots \tag{9}$$

on $J^\infty Y$ and the corresponding de Rham complex of their structure algebras

$$0\to\mathbb{R}\to\mathcal{T}^0_\infty\overset{d}{\to}\mathcal{T}^1_\infty\overset{d}{\to}\cdots. \tag{10}$$

There is an isomorphism

$$H^*(\mathcal{T}^*_\infty)=H^*(Y)$$

of de Rham cohomology $H^*(\mathcal{T}^*_\infty)$ of the graded differential algebra $\mathcal{T}^*_\infty$ to that $H^*(Y)$ of the fiber bundle Y.

Proof: The proof is obvious. The complex (9) is exact due to the Poincaré lemma, and is a resolution of the constant sheaf $\mathbb{R}$ on $J^\infty Y$ since $\mathfrak{T}^*_\infty$ are sheaves of $\mathcal{T}^0_\infty$-modules. Then, the abstract de Rham theorem and Lemma 3 complete the proof.

It follows that every closed form $\phi\in\mathcal{T}^*_\infty$ splits into the sum

$$\phi=\varphi+d\xi,\quad \xi\in\mathcal{T}^*_\infty, \tag{11}$$

where φ is a closed form on the fiber bundle Y. This splitting plays an important role in the sequel.

Turn now to the variational complex (6). Bearing in mind Lemma 3 and by virtue of the abstract de Rham theorem, we obtain the following.

Proposition 5: There is an isomorphism

$$H^*_{\rm var}(\mathcal{T}^*_\infty)=H^*(Y) \tag{12}$$

between cohomology $H^*_{\rm var}(\mathcal{T}^*_\infty)$ of the variational complex (7) and de Rham cohomology of the fiber bundle Y, namely,

$$H^{k<n}_{\rm var}(\mathcal{T}^*_\infty)=H^{k<n}(d_H;\mathcal{T}^*_\infty)=H^{k<n}(Y),$$

$$H^{k\geqslant n}_{\rm var}(\mathcal{T}^*_\infty)=H^{k-n}(\delta;\mathcal{T}^*_\infty)=H^{k\geqslant n}(Y),$$

where $H^*(d_H;\mathcal{T}^*_\infty)$ and $H^*(\delta;\mathcal{T}^*_\infty)$ denote d_H and δ cohomology of the differential algebra $\mathcal{T}^*_\infty$.

The isomorphism (12) recovers the result of Ref. 8 for $H^*_{\rm var}(\mathcal{T}^*_\infty)$ and that of Ref. 9 for $H^0(\delta;\mathcal{T}^*_\infty)$ and $H^1(\delta;\mathcal{T}^*_\infty)$, but let us say something more. The relation (5) for τ and the relation

$h_0 d = d_H h_0$ for h_0 define homomorphisms of the de Rham complex (10) of the algebra $\mathcal{T}^*_\infty$ to the variational complex (7). The corresponding homomorphism of their cohomology groups is an isomorphism by virtue of Lemma 4 and Proposition 5. Then, the splitting (11) leads to the following decompositions.

Proposition 6: Any d_H-closed form $\sigma \in \mathcal{T}^{0,m}_\infty$, $0<m<n$, is represented by the sum

$$\sigma = h_0\varphi + d_H\xi, \quad \xi \in \mathcal{T}^{0,m-1}_\infty, \tag{13}$$

where φ is a closed m-form on Y. Any δ-closed form $\sigma_k \in \mathcal{T}^{k,n}_\infty$, $k \geqslant 0$, is represented by the sum

$$\sigma_{k=0} = h_0\varphi + d_H\xi, \quad \xi \in \mathcal{T}^{0,n-1}_\infty, \tag{14}$$

$$\sigma_{k>0} = \tau(\varphi) + \delta(\xi), \quad \xi \in E_{k-1}, \tag{15}$$

where φ is a closed $(n+k)$-form on Y.

V. COHOMOLOGY OF $\mathcal{O}^*_\infty$

The following theorem gives us d_H and δ cohomology of the differential algebra $\mathcal{O}^*_\infty$. As was mentioned previously, de Rham cohomology of $\mathcal{O}^*_\infty$ is equal to that of Y.

Theorem 7: The differential algebra $\mathcal{O}^*_\infty$ has the same d_H and δ cohomology as $\mathcal{T}^*_\infty$, i.e.,

$$H^*(d_H;\mathcal{O}^*_\infty) = H^*(d_H;\mathcal{T}^*_\infty), \quad H^*(\delta;\mathcal{O}^*_\infty) = H^*(\delta;\mathcal{T}^*_\infty).$$

Proof: Let the common symbol D stand for the coboundary operators d_H and δ of the variational bicomplex. Bearing in mind the decompositions (13)–(15), it suffices to show that, if an element $\phi \in \mathcal{O}^*_\infty$ is D-exact with respect to the algebra $\mathcal{T}^*_\infty$ (i.e., $\phi = D\varphi$, $\varphi \in \mathcal{T}^*_\infty$), then it is D-exact in the algebra $\mathcal{O}^*_\infty$ (i.e., $\phi = D\varphi'$, $\varphi' \in \mathcal{O}^*_\infty$). Lemma 1 states that, if Y is a contractible fiber bundle and a D-exact form ϕ on $J^\infty Y$ is of finite jet order $[\phi]$ (i.e., $\phi \in \mathcal{O}^*_\infty$), there exists an exterior form $\varphi \in \mathcal{O}^*_\infty$ on $J^\infty Y$ such that $\phi = D\varphi$. Moreover, a glance at the homotopy operators for d_H and δ in Ref. 12 shows that the jet order $[\varphi]$ of φ is bounded for all exterior forms ϕ of fixed jet order. Let us call this fact the finite exactness of the operator D. Given an arbitrary fiber bundle Y, the finite exactness takes place on $J^\infty Y|_U$ over any open subset U of Y which is homeomorphic to a convex open subset of $\mathbb{R}^{\dim Y}$. Now, we show the following.

(i) Suppose that the finite exactness of the operator D takes place on $J^\infty Y$ over open subsets U, V of Y and their nonempty overlap $U \cap V$. Then, it is also true on $J^\infty Y|_{U\cup V}$.

(ii) Given a family $\{U_\alpha\}$ of disjoint open subsets of Y, let us suppose that the finite exactness takes place on $J^\infty Y|_{U_\alpha}$ over every subset U_α from this family. Then, it is true on $J^\infty Y$ over the union $\cup_\alpha U_\alpha$ of these subsets.

If assertions (i) and (ii) hold, the finite exactness of D on $J^\infty Y$ takes place because one can construct the corresponding covering of the manifold Y (see Lemma 9.5 in Ref. 14).

Proof of (i): Let $\phi = D\varphi \in \mathcal{O}^*_\infty$ be a D-exact form on $J^\infty Y$. By assumption, it can be brought into the form $D\varphi_U$ on $(\pi^\infty_0)^{-1}(U)$ and $D\varphi_V$ on $(\pi^\infty_0)^{-1}(V)$, where φ_U and φ_V are exterior forms of finite jet order. Due to the decompositions (13)–(15), one can choose the forms φ_U, φ_V such that $\varphi - \varphi_U$ on $(\pi^\infty_0)^{-1}(U)$ and $\varphi - \varphi_V$ on $(\pi^\infty_0)^{-1}(V)$ are D-exact forms. Let us consider the difference $\varphi_U - \varphi_V$ on $(\pi^\infty_0)^{-1}(U\cap V)$. It is a D-exact form of finite jet order which, by assumption, can be written as $\varphi_U - \varphi_V = D\sigma$ where an exterior form σ is also of finite jet order. Lemma 8 shows that $\sigma = \sigma_U + \sigma_V$ where σ_U and σ_V are exterior forms of finite jet order on $(\pi^\infty_0)^{-1}(U)$ and $(\pi^\infty_0)^{-1}(V)$, respectively. Then, putting

$$\varphi'_U = \varphi_U - D\sigma_U, \quad \varphi'_V = \varphi_V + D\sigma_V,$$

we have the form ϕ equal to $D\varphi'_U$ on $(\pi_0^\infty)^{-1}(U)$ and $D\varphi'_V$ on $(\pi_0^\infty)^{-1}(V)$, respectively. Since the difference $\varphi'_U-\varphi'_V$ on $(\pi_0^\infty)^{-1}(U\cap V)$ vanishes, we obtain $\phi=D\varphi'$ on $(\pi_0^\infty)^{-1}(U\cup V)$ where

$$\varphi' \stackrel{\text{def}}{=} \begin{cases} \varphi'|_U=\varphi'_U, \\ \varphi'|_V=\varphi'_V \end{cases}$$

is of finite jet order.

Proof of (ii): Let $\phi\in\mathcal{O}^*_\infty$ be a D-exact form on $J^\infty Y$. The finite exactness on $(\pi_0^\infty)^{-1}(\cup U_\alpha)$ holds since $\phi=D\varphi_\alpha$ on every $(\pi_0^\infty)^{-1}(U_\alpha)$ and, as was mentioned previously, the jet order $[\varphi_\alpha]$ is bounded on the set of exterior forms $D\varphi_\alpha$ of fixed jet order $[\phi]$.

Lemma 8: Let U and V be open subsets of a fiber bundle Y and $\sigma\in\mathfrak{O}^*_\infty$ an exterior form of finite jet order on $(\pi_0^\infty)^{-1}(U\cap V)\subset J^\infty Y$. Then, σ splits into a sum $\sigma_U+\sigma_V$ of exterior forms σ_U and σ_V of finite jet order on $(\pi_0^\infty)^{-1}(U)$ and $(\pi_0^\infty)^{-1}(V)$, respectively.

Proof: By taking a smooth partition of unity on $U\cup V$ subordinate to the cover $\{U,V\}$ and passing to the function with support in V, one gets a smooth real function f on $U\cup V$ which is 0 on a neighborhood of $U-V$ and 1 on a neighborhood of $V-U$ in $U\cup V$. Let $(\pi_0^\infty)^*f$ be the pull-back of f onto $(\pi_0^\infty)^{-1}(U\cup V)$. The exterior form $((\pi_0^\infty)^*f)\sigma$ is zero on a neighborhood of $(\pi_0^\infty)^{-1}(U)$ and, therefore, can be extended by 0 to $(\pi_0^\infty)^{-1}(U)$. Let us denote it σ_U. Accordingly, the exterior form $(1-(\pi_0^\infty)^*f)\sigma$ has an extension σ_V by 0 to $(\pi_0^\infty)^{-1}(V)$. Then, $\sigma=\sigma_U+\sigma_V$ is a desired decomposition because σ_U and σ_V are of finite jet order which does not exceed that of σ.

VI. THE GLOBAL INVERSE PROBLEM

The variational complex (7) provides the algebraic approach to the calculus of variations on fiber bundles.[1,6,11] For instance, the variational operator δ acting on $\mathcal{T}^{0,n}_\infty$ is the Euler–Lagrange map, while δ acting on E_1 is the Helmholtz–Sonin map. Let us relate the cohomology isomorphism (12) to the global inverse problem of the calculus in variations. As a particular repetition of Proposition 6, we come to its following solution in the class of exterior forms of locally finite jet order.

Theorem 9: A Lagrangian $L\in\mathcal{T}^{0,n}_\infty$ is variationally trivial, i.e., $\delta(L)=0$ if and only if

$$L=h_0\varphi+d_H\xi, \quad \xi\in\mathcal{T}^{0,n-1}_\infty, \tag{16}$$

where φ is a closed n-form on Y [see expression (14)].

Theorem 10: An Euler–Lagrange-type operator $\mathcal{E}\in E_1$ satisfies the Helmholtz condition $\delta(\mathcal{E})=0$ if and only if

$$\mathcal{E}=\delta(L)+\tau(\phi), \quad L\in\mathcal{T}^{0,n}_\infty, \tag{17}$$

where ϕ is a closed $(n+1)$-form on Y [see expression (15)].

Theorem 10 recovers the result of Refs. 9 and 8.

Theorem 7 provides the similar solution of the global inverse problem in the class of exterior forms of finite jet order. This is the case of higher order Lagrangian field theory. Namely, the theses of Theorems 9 and 10 remain true if all exterior forms in expressions (16) and (17) belong to $\mathcal{O}^*_\infty$. In this case, Theorem 10 contains the well-known result of Ref. 15. Thus, the obstruction to the exactness of the finite order calculus of variations is the same as for exterior forms of locally finite order, without minimizing the order of Lagrangians. The main point for physical applications is that this obstruction is given by closed forms on the fiber bundle Y, and is of first order.

Remark: The local exactness of the calculus of variations has been proved in the class of exterior forms of finite order by use of homotopy operators which do not minimize the order of Lagrangians (see, e.g., Refs. 11 and 12). The infinite variational complex of such exterior forms on $J^\infty Y$ has been studied by many authors (see, e.g., Refs. 1, 6, 11, and 12). However, these forms on $J^\infty Y$ fail to constitute a sheaf. Therefore, the cohomology obstruction to the exactness of the

calculus of variations has been obtained in the class of exterior forms of locally finite jet order which make up the differential algebra $\mathcal{T}^*_\infty$.[8,9] Several statements without proof were announced in Ref. 7. A solution of the global inverse problem in the calculus of variations in the class of exterior forms of a fixed jet order has been suggested in Ref. 9 by a computation of cohomology of the fixed order variational sequence (see Refs. 16 and 17 for another variant of such a variational sequence). The key point of this computation lies in the local exactness of the finite order variational sequence which, however, requires rather sophisticated *ad hoc* technique in order to be reproduced (see also Ref. 18). Therefore, the results of Ref. 9 were not widely recognized. The first thesis of Ref. 9 agrees with Theorem 9 for finite order Lagrangians, but says that the jet order of the form ξ in expression (16) is $k-1$ if L is a k-order variationally trivial Lagrangian. The second one states that a $2k$-order Euler–Lagrange operator can always be associated with a k-order Lagrangian.

Theorems 9 and 10 for elements of $\mathcal{O}^*_\infty$ provide a solution of the global inverse problem in time-dependent mechanics treated as a particular field theory on smooth fiber bundles over $X=\mathbb{R}$.[19] Note that, in time-dependent mechanics, the inverse problem is more intricate than in field theory. Given a second-order dynamic equation, one studies the existence of an associated Newtonian system and its equivalence to a Lagrangian one.[19] Since a fiber bundle $Y\to\mathbb{R}$ is trivial, de Rham cohomology of Y is equal to that of its typical fiber M, and so is de Rham cohomology $H^*(J^\infty Y)$ of $J^\infty Y$. The variational complex (7) in time-dependent mechanics takes the form

$$0\to\mathbb{R}\to\mathcal{T}^0_\infty\xrightarrow{d_t}\mathcal{T}^{0,1}_\infty\xrightarrow{\delta}E_1\xrightarrow{\delta}E_2\to\cdots.$$

Its cohomology coincides with de Rham cohomology of M. In particular, Theorem 9 states that a Lagrangian L of time-dependent mechanics is variationally trivial if and only if it takes the form

$$L=(\varphi_t+\varphi_i y^i_t)\mathrm{d}t+d_t\xi,$$

where $\varphi=\varphi_t\,\mathrm{d}t+\varphi_i\,\mathrm{d}y^i$ is a closed one-form on Y (see also Ref. 7).

VII. THE CASE OF AN AFFINE BUNDLE

Let $Y\to X$ be an affine bundle. Since X is a strong deformation retract of Y, de Rham cohomology of Y and, consequently, $J^\infty Y$ is equal to that of X. An immediate consequence of this fact is the following cohomology isomorphisms:

$$H^{<n}(d_H;\mathcal{O}^*_\infty)=H^{<n}(X),\quad H^0(\delta;\mathcal{O}^*_\infty)=H^n(X),\quad H^k(\delta;\mathcal{O}^*_\infty)=0.$$

It follows that every d_H-closed form $\phi\in\mathcal{O}^{0,m<n}_\infty$ is represented by the sum

$$\phi=\varphi+d_H\xi,\quad \xi\in\mathcal{O}^{0,m-1}_\infty, \tag{18}$$

where φ is a closed form on X. Similarly, any variationally trivial Lagrangian takes the form

$$L=\varphi+d_H\xi,\quad \xi\in\mathcal{O}^{0,n-1}_\infty,$$

where φ is a closed n-form on X. The decomposition (18) shows that, since the BRST operator eliminates exterior forms on X, there is no topological obstruction to constructing global descent equations in the physical field sector of BRST theory.

For applications to BRST theory, we will restrict our consideration to the horizontal complex (4) and the similar complex of the differential algebra $\mathcal{O}^*_\infty$. In the case of an affine bundle $Y\to X$, we can lower this complex onto the base X as follows.

Let us consider the open surjection $\pi^\infty: J^\infty Y\to X$ and the direct image $\{\pi^\infty_*\mathfrak{T}^*_\infty\}$ on X of the sheaf $\mathfrak{T}^*_\infty$. Its stalk over a point $x\in X$ consists of the equivalence classes of sections of the sheaf

$\mathfrak{T}^*_\infty$ which coincide on the inverse images $(\pi^\infty)^{-1}(U_x)$ of neighborhoods U_x of x. Put further the notation $\mathfrak{TX}^*_\infty = \pi^\infty_* \mathfrak{T}^*_\infty$. Since $\pi^\infty_* \mathbb{R} = \mathbb{R}$, we have the following complex of sheaves on X:

$$0 \longrightarrow \mathbb{R} \longrightarrow \mathfrak{TX}^0_\infty \xrightarrow{d_H} \mathfrak{TX}^{0,1}_\infty \xrightarrow{d_H} \cdots \xrightarrow{d_H} \mathfrak{TX}^{0,n}_\infty . \tag{19}$$

Every point $x \in X$ has a base of open contractible neighborhoods $\{U_x\}$ such that the sheaves $\mathfrak{T}^{0,*}_\infty$ of $\mathcal{T}^*_\infty$-modules are acyclic on the inverse images $(\pi^\infty)^{-1}(U_x)$ of these neighborhoods. Then, in accordance with the Leray theorem,[20] cohomology of $J^\infty Y$ with coefficients in the sheaves $\mathfrak{T}^{0,*}_\infty$ are isomorphic to that of X with coefficients in their direct images $\mathfrak{TX}^{0,*}_\infty$, i.e., the sheaves $\mathfrak{TX}^{0,*}_\infty$ on X are acyclic. Furthermore, Lemma 1 also shows that the complexes of sections of sheaves $\mathfrak{T}^{0,*}_\infty$ over $(\pi^\infty_0)^{-1}(U_x)$ are exact. It follows that the horizontal complex (19) on X is exact, and is a resolution of the constant sheaf $\mathbb{R}$ on X. Due to the $\mathbb{R}$-algebra isomorphism $\mathcal{T}^*_\infty = \Gamma(X, \mathfrak{TX}^*_\infty)$, one can think of the horizontal complex (4) as being the complex of the structure algebras of the sheaves in the horizontal complex (19) on X.

VIII. COHOMOLOGY OF POLYNOMIAL ALGEBRAS

Given the sheaf $\mathfrak{TX}^*_\infty$ on X, let us consider its subsheaf $\mathfrak{P}^*_\infty$ of germs of exterior forms which are polynomials in the fiber coordinates y^i_Λ, $|\Lambda| \geqslant 0$, of the topological fiber bundle $J^\infty Y \to X$. This property is coordinate independent due to the transition functions (2). The $\mathfrak{P}^*_\infty$ is a sheaf of $C^\infty(X)$-modules. Its structure algebra $\mathcal{P}^*_\infty$ is a $C^\infty(X)$-subalgebra of $\mathcal{T}^*_\infty$. For shot, one can say that $\mathcal{P}^*_\infty$ consists of exterior forms on $J^\infty Y$ which are locally polynomials in fiber coordinates y^i_Λ.

We have the subcomplex

$$0 \longrightarrow \mathbb{R} \longrightarrow \mathfrak{P}^0_\infty \xrightarrow{d_H} \mathfrak{P}^{0,1}_\infty \xrightarrow{d_H} \cdots \xrightarrow{d_H} \mathfrak{P}^{0,n}_\infty \tag{20}$$

of the horizontal complex (19) on X. As a particular variant of the algebraic Poincaré lemma, the exactness of the complex (20) follows from the form of the homotopy operator for d_H or can be proved in a straightforward way (see, e.g., Ref. 4). Since the sheaves $\mathfrak{P}^{0,*}_\infty$ of $C^\infty(X)$-modules on X are acyclic, the complex (20) is a resolution of the constant sheaf $\mathbb{R}$ on X. Hence, cohomology of the complex

$$0 \longrightarrow \mathbb{R} \longrightarrow \mathcal{P}^0_\infty \xrightarrow{d_H} \mathcal{P}^{0,1}_\infty \xrightarrow{d_H} \cdots \xrightarrow{d_H} \mathcal{P}^{0,n}_\infty \tag{21}$$

of the structure algebras $\mathcal{P}^{0,<n}_\infty$ of sheaves $\mathfrak{P}^{0,<n}_\infty$ is equal to that of X. It follows that every d_H-closed polynomial form $\phi \in \mathcal{P}^{0,m<n}_\infty$ splits into the sum

$$\phi = \varphi + d_H \xi, \quad \xi \in \mathcal{P}^{0,m-1}_\infty , \tag{22}$$

where φ is a closed form on X.

Let P^*_∞ be $C^\infty(X)$-subalgebra of the polynomial algebra $\mathcal{P}^*_\infty$ which consists of exterior forms which are polynomials in the fiber coordinates y^i_Λ. Obviously, P^*_∞ is a subalgebra of $\mathcal{O}^*_\infty$. In BRST theory, P^*_∞ is an algebra of exterior forms of even fields and antifields. As a repetition of Theorem 7, one can show that P^*_∞ have the same cohomology as $\mathcal{P}^*_\infty$, i.e., if ϕ in the decomposition (22) is an element of $P^{0,*}_\infty$ then ξ is so. It follows that, in the case of the polynomial algebra P^*_∞, we also have no topological obstruction to constructing global descent equations in BRST theory.

Let us consider the subsheaf $\overline{\mathfrak{P}}^*_\infty$ of the sheaf $\mathfrak{P}^*_\infty$ which consists of germs of x-independent polynomial forms. Its structure algebra $\overline{P}^*_\infty$ is a subalgebra of the algebra P^*_∞. We have the complex of sheaves

$$0 \longrightarrow \mathbb{R} \longrightarrow \overline{\mathfrak{P}}^0_\infty \xrightarrow{d_H} \overline{\mathfrak{P}}^{0,1}_\infty \xrightarrow{d_H} \cdots \xrightarrow{d_H} \overline{\mathfrak{P}}^{0,n}_\infty,$$

which fails to be exact. The obstruction to its exactness at the term $\overline{\mathfrak{P}}^{0,k}_\infty$ is provided by the germs of k-forms on X with constant coefficients.[4] Let us denote the sheaf of such germs by S^k_X. For any $0<k<n$, we have the short exact sequence of sheaves

$$0 \to \operatorname{Im} d_H \to \operatorname{Ker} d_H \to S^k_X \to 0$$

and the sequence of their structure modules

$$0 \to \Gamma(X, \operatorname{Im} d_H) \to \Gamma(X, \operatorname{Ker} d_H) \to \Gamma(X, S^k_X) \to 0,$$

which is exact because S^k_X is a subsheaf of $\mathbb{R}$-modules of the sheaf $\operatorname{Ker} d_H$. Then, the k-cohomology group of the horizontal complex

$$0 \longrightarrow \mathbb{R} \longrightarrow \overline{P}^0_\infty \xrightarrow{d_H} \overline{P}^{0,1}_\infty \xrightarrow{d_H} \cdots \xrightarrow{d_H} \overline{P}^{0,n}_\infty$$

of the algebra $\overline{P}^*_\infty$ is isomorphic to the $\mathbb{R}$-module $\Gamma(X, S^k_X)$ of global constant k-forms on the manifold X. If a manifold X is not locally affine, the module $\Gamma(X, S^{0,k}_\infty)$ is empty and, consequently, the differential d_H is exact on the algebra $\overline{\mathcal{P}}^{0,<n}$. In this case, there is no obstruction to constructing global descent equations. If a manifold X is locally affine, e.g., parallelizable, any d_H-closed element $\phi \in \overline{P}^{0,k}_\infty$, $0<k<n$, splits into the sum

$$\phi = \varphi + d_H \xi, \quad \varphi \in \Gamma(X, S^k_X), \quad \xi \in \overline{P}^{0,k-1}_\infty.$$

Since the BRST operator eliminates exterior forms on X, elements $\varphi \in \Gamma(X, S^k_X)$ also do not provide an obstruction to the existence of global descent equations.

Thus, we observe that, in the sector of even fields and antifields of BRST theory, there is no topological obstruction to constructing global descent equations.

APPENDIX A

We quote the following variant of the abstract de Rham theorem.

Let

$$0 \longrightarrow S \xrightarrow{h} S_0 \xrightarrow{h^0} S_1 \xrightarrow{h^1} \cdots \xrightarrow{h^{p-1}} S_p \xrightarrow{h^p} S_{p+1}, \quad p>1 \tag{23}$$

be an exact sequence of sheaves on a paracompact topological space Z, where the sheaves S_p and S_{p+1} are not necessarily acyclic, and let

$$\begin{aligned} &0 \longrightarrow \Gamma(Z,S) \xrightarrow{h_*} \Gamma(Z,S_0) \xrightarrow{h^0_*} \Gamma(Z,S_1) \xrightarrow{h^1_*} \\ &\cdots \xrightarrow{h^{p-1}_*} \Gamma(Z,S_p) \xrightarrow{h^p_*} \Gamma(Z,S_{p+1}) \end{aligned} \tag{24}$$

be the corresponding cochain complex of structure groups of these sheaves.

Theorem 11: The q-cohomology groups of the cochain complex (24) for $0 \leqslant q \leqslant p$ are isomorphic to the cohomology groups $H^q(Z,S)$ of Z with coefficients in the sheaf S.

APPENDIX B

We construct a homotopy from $J^\infty Y$ to Y in an explicit form. Let $\gamma_{(k)}$, $k \leqslant 1$, be global sections of the affine jet bundles $J^k Y \to J^{k-1} Y$. Then, we have a global section

$$\gamma: Y \ni (x^\lambda, y^i) \to (x^\lambda, y^i, y^i_\Lambda = \gamma^i_{(|\Lambda|)\Lambda} \circ \gamma_{(|\Lambda|-1)} \circ \cdots \circ \gamma_{(1)}) \in J^\infty Y \tag{25}$$

of the open surjection $\pi^\infty_0 : J^\infty Y \to Y$. Let us consider the map

$$[0,1]\times J^\infty Y \ni (t; x^\lambda, y^i, y^i_\Lambda) \to (x^\lambda, y^i, y'^i_\Lambda) \in J^\infty Y, \quad 0 < |\Lambda|, \tag{26}$$

$$y'^i_\Lambda = f_k(t) y^i_\Lambda + (1 - f_k(t))\, \gamma_{(k)}{}^i_\Lambda(x^\lambda, y^i, y^i_\Sigma), \quad |\Sigma| < k = |\Lambda|,$$

where $f_k(t)$ is a continuous monotone real function on $[0,1]$ such that

$$f_k(t) = \begin{cases} 0, & t \leqslant 1 - 2^{-k} \\ 1, & t \geqslant 1 - 2^{-(k+1)}. \end{cases} \tag{27}$$

A glance at the transition functions (2) shows that, although written in a coordinate form, this map is globally defined. It is continuous because, given an open subset $U_k \subset J^k Y$, the inverse image of the open set $(\pi^\infty_k)^{-1}(U_k) \subset J^\infty Y$, is the open subset

$$(t_k,1]\times(\pi^\infty_k)^{-1}(U_k) \cup (t_{k-1},1]\times(\pi^\infty_{k-1})^{-1}(\pi^k_{k-1}[U_k \cap \gamma_{(k)}(J^{k-1}Y)])$$

$$\cup \cdots \cup [0,1]\times(\pi^\infty_0)^{-1}(\pi^k_0[U_k \cap \gamma_{(k)} \circ \cdots \circ \gamma_{(1)}(Y)])$$

of $[0,1]\times J^\infty Y$, where $[t_r,1] = \operatorname{supp} f_r$. Then, the map (26) is a desired homotopy from $J^\infty Y$ to Y which is identified with its image under the global section (25).

A robust approach to protein foldability measures based on spin-glass models

Tapon Roy[a)]
Boehringer Ingelheim Pharmaceuticals, 900 Ridgebury Rd., Ridgefield, Connecticut 06877

(Received 30 October 2000; accepted for publication 14 March 2001)

Spin-glass models and related methods have been applied to protein folding problems, often by assuming an underlying Gaussian distribution for the energy level distribution. In this paper, we derive robust foldability measures that relax the Gaussian distribution assumption implicit in current foldability and energy gap measures. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1379746]

I. INTRODUCTION

Spin-glass models and their analogs have been applied to problems involving protein structures[1] and protein folding.[2–4] In particular, spin-glass models have been used to determine whether proteins can be characterized as to their foldability potential.[2] Spin glasses are magnetic systems whose periodicity (translational invariance) is broken by ''frozen randomness,'' characterized by metastable states with essentially indeterminate relaxation times to a stable phase. Spin glasses can be alloys of a nonmagnetic atom of a noble metal and a magnetic atom of a transition metal (like manganese or iron). Nonstoichiometric ternary alloys exhibiting a periodic crystalline structure, but with the magnetic atoms randomly scattered through the lattice sites are other types of spin glasses as are non-crystalline alloys of aluminum and gadolinium, where the atoms are in random spatial positions. Spin glasses all display similar thermodynamic behavior, notably, singularities at a critical temperature.[5]

II. SPIN-GLASS MODELS AND THE RANDOM ENERGY MODEL

The Sherrington–Kirkpatrick (SK) spin-glass model[6] is an Ising model in which spins are coupled by infinite-ranged random interactions. Their probability density is taken to be Gaussian in the conventional formulation. Following Petritis,[5] the SK model is of the mean-field type (the strength of the interactions between interacting magnetic atoms retains the same magnitude throughout the material) that is defined over sites $\Lambda_N=\{1,...,N\}$ with dual lattice Λ_N^* of Λ_N having a complete graph $K_N=\{\{i,j\}:i\in\Lambda_N, j\in\Lambda_N, i\neq j\}=\{\{i,j\}:i\in\Lambda_N, j\in\Lambda_N, i<j\}$ over N. Now consider a group of independent, centered, Gaussian random variables with variance $1:(J_{ij})_{\{i,j\}\in\Lambda_N^*}$ indexed by Λ_N^*. The interaction energy (Hamiltonian) of this model is

$$I_N(\sigma)=-\frac{1}{\sqrt{N}}\sum_{\{i,j\}\in\Lambda_N^*}J_{ij}\sigma_i\sigma_j. \tag{1}$$

The sum extends over $|\Lambda_N^*|=N(N-1)/2$ terms, and the normalization is in $\sqrt{N}$. The use of the normal distribution is for computational convenience, and the central limit theorem is far from being applicable in this case. Formulating (1) as a time-dependent stochastic process, we obtain the standard derivation:

a)Electronic mail: troy@rdg.boehringer-ingelheim.com

$$I_N(t,\sigma) := -\frac{1}{\sqrt{N}} \sum_{\{i,j\}\in\Lambda_N^*} B_{ij}(t)\sigma_i\sigma_j, \quad \sigma \in S_N := \{-1,+1\}^N, \tag{2}$$

where the $B_{i,j}$ are independent Brownian motions with variance $\mathbb{E}B_{i,j}^2 = t$ if $i<j$ and $\mathbb{E}B_{i,j}^2 = t/2$ if $i=j$. Let $E_\sigma(\cdot) = 2^{-N}\Sigma_{\sigma\in S_N}(\cdot)$ be the uniform probability on the configuration space S_N. The partition function with time dependence is then

$$Z_N(t) = E_\sigma \exp\{I_N(t,\sigma) - Nt/4\}, \tag{3}$$

which, apart from a minor term, defines the same Gibbs measure as (1) that we will denote $\rho_{N,t}$. Since $Z_N(t)$ is a positive martingale (a ''martingale'' represents a generalization of the concept of a sum of independent random variables) with mean 1, Z_N has stochastic differential $dZ_N(t)$ and log martingale M_N defined by the stochastic integral:

$$M_N(t) = \int_0^t Z_N(s)^{-1}\, dZ_N(s). \tag{4}$$

M_N is a centered martingale of the form

$$\langle M_N\rangle(t) = \int_0^t E^{\rho_{N,s}^{\otimes 2}}\left[\frac{1}{2}\left(\frac{\sigma.\sigma'}{\sqrt{N}}\right)^2\right] ds, \tag{5}$$

where $E^{\rho_{N,s}^{\otimes 2}}$ is the expectation over two independent replicas σ,σ' associated with the Gibbs measure $\rho_{N,s}$.

For the simplified (time-independent) Hamiltonian of (1), we can define a partition function as

$$Z_N = \sum_{\sigma\in\Sigma_N} \exp(-\beta I_N(\sigma)), \tag{6}$$

where β is the inverse temperature and is a random variable (for every fixed β). The quenched free energy is

$$F_N(\beta) = -\frac{1}{\beta}\log Z_N(\beta), \tag{7}$$

and the quenched specific free energy is defined by

$$f_N(\beta) = \frac{1}{|\Lambda_N|} F_N(\beta). \tag{8}$$

Due to computational difficulties involving the log term in (7), Edwards and Anderson[7] proposed the famous replica trick: instead of computing $\mathbb{E}\log Z_N$, they compute $\mathbb{E}Z_N^R$, where R is the number of replicas [independent copies of the model (in σ) all having the same random interactions J]. Thus, for positive R, one needs to compute the moments of the partition function. Parisi[8] and Mezard, Parisi, and Virasoro[9] observed that as a consequence of phase transition, there is a breaking of the symmetry group S_R over replicas, and that introducing infinite replica symmetry breaking, inducing an ultrametric structure to the space of states, provides a heuristic solution for the specific free energy that is in reasonable agreement with rigorous results. [Earlier, Mezard, Parisi, and Virasoro[10] discussed the fluctuations (of order $1/N$) of the free energy to define the pure state weights of the model. They explain how to obtain the replica symmetry-breaking solution of the SK model without introducing replicas.] Derrida[11,12] describes two simplified SK-based models, the random energy model (REM), and the generalized random energy model (GREM). In the

case of the REM model, the energy levels E_i form a system of independent, identically distributed variables, and the partition function is written as a sum over 2^N energy levels,

$$Z(\beta)=\sum_{i=1}^{2^N} \exp(-\beta E_i), \tag{9}$$

where β is the inverse temperature. For the GREM, correlations between the energy levels are introduced hierarchically. The energy levels are defined:

$$E_{k_1,\ldots,k_n}=\sqrt{N}\sum_{j=1}^{n} \sqrt{a_j}\epsilon^j_{k_1,\ldots,k_j}, \tag{10}$$

and the partition function is then

$$Z(\beta)=\sum_{k_1=1}^{\alpha_1^N} \cdots \sum_{k_n=1}^{\alpha_n^N} \exp\left(\beta\sqrt{N}\sum_{j=1}^{n} \sqrt{a_j}\epsilon^j_{k_1,\ldots,k_j}\right). \tag{11}$$

Spin-glass models have been used to describe protein folding, and to explain certain salient features such as abrupt transitions between folded and unfolded states; multiexponential kinetics; and misfolds, irreversible denaturation, and protein drift.[13]

III. FOLDABILITY AND ENERGY GAP

Briefly summarizing Buchler and Goldstein, the equilibrium glass transition temperature, T_g, or ''heteropolymer freezing'' temperature, is defined as the temperature where the protein chain entropy drops below zero and the chain attains one of its low-energy, metastable states. Using the REM (which does not incorporate conformation energy correlations), one can demonstrate that T_g demarcates the kinetic behavior into two classes. For $T>T_g$, the escape rate distribution from low-energy metastable states is lognormal, fast rates are much more likely than slow rates; for $T<T_g$, the kinetic distribution of rates becomes more uniform, so that both slow and fast escape rates become equally likely.[2] Using the REM (and setting k_B to one), one can determine that the equilibrium glass temperature is

$$T_g=\sqrt{\frac{\sigma^2}{2S_0}}, \tag{12}$$

where σ^2 is the variance or ''roughness'' (squared) of the REM energy distribution, and S_0 is the conformational entropy of the system. One can thus surmise that ''rougher'' energy landscapes lead to higher glass transition temperatures. The presence of protein drift, misfolds, irreversible denaturation, discrete intermediates, and multiexponential kinetics would indicate proteins with rougher energy landscapes than those that fold consistently and have single-exponential kinetics. Since the folded state must be thermodynamically preferable to other possible structures at equilibrium, it was postulated that optimal folding landscapes would tend to maximize folding temperature T_f, a measure of relative stability, and minimize T_g, that is, increase the ratio, T_f/T_g.[14–16] Using the REM, one can show that

$$\frac{T_f}{T_g}=\sqrt{\frac{\mathcal{F}^2}{2S_0}}+\sqrt{\frac{\mathcal{F}^2}{2S_0}-1},$$

where the foldability, $\mathcal{F}$, is

$$\mathcal{F}=\frac{\overline{E}-E_{\mathrm{ns}}}{\sigma} \tag{13}$$

where $\bar{E}$ is the average energy of the protein chain in all conformations, $E_{\rm ns}$ is the energy of the native structure, and σ is the ''roughness'' of the REM energy landscape. Monte Carlo kinetic and molecular dynamic simulations have shown that fast folding proteins had higher average foldabilities and larger T_f/T_g ratios.[15,16] The quantification of folding ability by $\mathcal{F}$ has contributed to further development of protein designability research.

An equivalent measure relating to folding kinetics is the energy gap, Δ_g, defined as

$$\Delta_g = E_g - E_{\rm ns}, \tag{14}$$

where E_g is the glass transition energy and $E_{\rm ns}$ is the native state energy.

For now, assume that the energy states are uncorrelated, using the REM model, one can show, in the limit of large proteins, that the energy distribution of compact states is of Gaussian form. The density of states of a REM heteropolymer sequence is denoted $\Omega(E) = n\rho_{\rm REM}(E)$, where n is the number of compact protein structures and $\rho_{\rm REM}(E)$ is a normalized Gaussian distribution:

$$\rho_{\rm REM}(E) = \frac{1}{\sigma\sqrt{2\pi}} e^{-(E-\bar{E})^2/2\sigma^2}, \tag{15}$$

where $\bar{E}$ is the average energy of the compact states and σ is the roughness of the energy density landscape. If we consider deriving the foldability of the native state, $\mathcal{F}$, as a function of the number of compact protein structures n, the condition that the native state energy $E_{\rm ns}$ has the lowest value among all other $n-1$ energies follows from native state uniqueness and thermodynamic considerations. One can thus describe the native state energy distribution in the REM by

$$\rho(E_{\rm ns}|n) = \rho_{\rm REM}\mathcal{P}(E_{\rm ns} < n-1). \tag{16}$$

Using (15), and assuming independence of energies, we obtain

$$\rho_{\rm REM}(E_{\rm ns}) = \frac{1}{\sigma\sqrt{2\pi}} e^{-(E_{\rm ns}-\bar{E})^2/2\sigma^2}, \tag{17}$$

and

$$\mathcal{P}(E_{\rm ns} < n-1) = \left[\int_{E_{\rm ns}}^{\infty} \rho_{\rm REM}(E)\,\delta E \right]^{(n-1)}, \tag{18}$$

combining, and normalizing $\left(\int_{-\infty}^{+\infty} \rho(E_{\rm ns}|n)\,\delta E_{\rm ns} = 1\right)$ gives the density of native states energies as

$$\rho(E_{\rm ns}|n) = n\rho_{\rm REM}(E_{\rm ns}) \left[\int_{E_{\rm ns}}^{\infty} \rho_{\rm REM}(E)\,\delta E \right]^{(n-1)}, \tag{19}$$

substituting (17) and evaluating (18), one obtains

$$\rho(E_{\rm ns}|n) = \frac{n}{\sigma\sqrt{2\pi}} e^{-(E_{\rm ns}-\bar{E})^2/2\sigma^2} \left[\frac{1}{2}\left(1 - {\rm Erf}\left(\frac{E_{\rm ns}-\bar{E}}{\sigma\sqrt{2}} \right) \right) \right]^{(n-1)}, \tag{20}$$

which is of the form of an extreme value distribution. To convert to foldability, we use (13) to obtain

$$\rho(\mathcal{F}) = \frac{n}{\sqrt{2\pi}} e^{-\mathcal{F}^2/2} \left[\frac{1}{2}\left(1 + {\rm Erf}\left(\frac{\mathcal{F}}{\sqrt{2}} \right) \right) \right]^{(n-1)}. \tag{21}$$

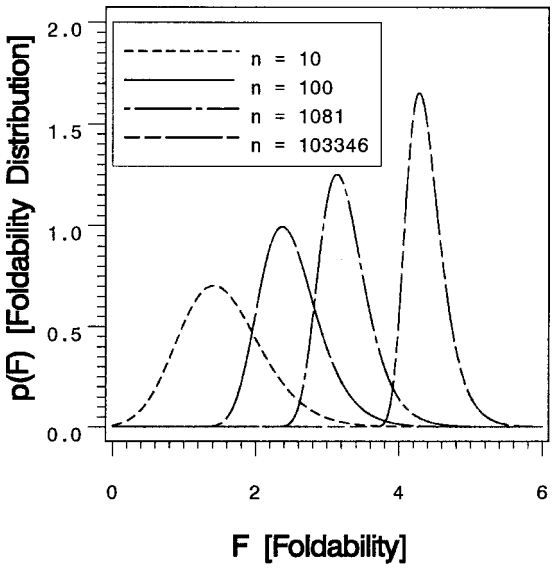

FIG. 1. Plot of the foldability distribution $\rho(\mathcal{F})$ for different numbers of compact energy states using the random energy model (based on Fig. 1 of Buchler and Goldstein).

Figure 1 displays foldability distribution curves for various values of n (this figure is based on Fig. 1 of Buchler and Goldstein). Having completed the summarization of the Buchler and Goldstein's derivation, we will now introduce the new methodology.

IV. ROBUST ESTIMATION

Though the assumption of a Gaussian distribution (from which the extreme value distribution shown above is derived) is conventional and definitely plausible, we need to be able to account for irregularities in the distribution, and keep in mind that ''large datasets of high quality show significant deviations from normality in cases which should be prime examples for the normal [Gaussian] law of errors....''.[17] To address this concern, we propose using a robust estimator, which is of an approximate parametric class. Robust methods allow us to retain the general parametric form of the model while compensating for deviations from the assumed distribution.[18,19] In statistical parlance ''robust'' methods are intermediate between the usual parametric (e.g., Gaussian assumption) techniques and nonparametric or distribution-free methods.

We can now derive a robust version of (21), by introducing the notion of the α-trimmed mean $(0<\alpha<\frac{1}{2})$, which is

$$T(F)=\int_{\alpha}^{1-\alpha} F^{-1}(t)dt/(1-2\alpha), \tag{22}$$

where $T(F)$ indicates a functional of the distribution of energies of compact states.[17] The trimmed mean is a robust estimator, and is intuitively appealing, since one removes the $[\alpha n]$ smallest and the $[\alpha n]$ largest energies (where $[\cdot]$ indicates the integer function), excluding E_{ns} from this operation, and then takes the mean of the remaining values. One can also replace σ with the standard deviation of this reduced set to produce a trimmed standard deviation, σ_t. Setting $\overline{E_t}=T(F)$, we now can define robust foldability as $\mathcal{F}_t=(\overline{E_t}-E_{\mathrm{ns}})/\sigma_t$, yielding

$$\rho(\mathcal{F}_t)=\frac{n-[2\alpha n]}{\sqrt{2\pi}}e^{-\mathcal{F}_t^2/2}\left[\frac{1}{2}\left(1+\mathrm{Erf}\left(\frac{\mathcal{F}_t}{\sqrt{2}}\right)\right)\right]^{(n-[2\alpha n]-1)}. \tag{23}$$

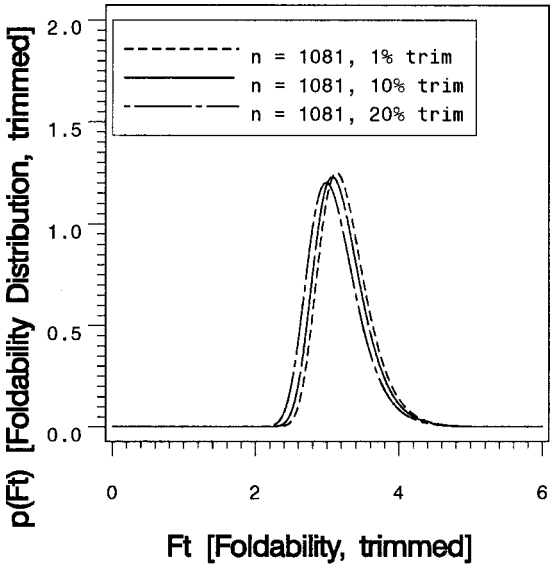

FIG. 2. Plot of the robust (trimmed) foldability distribution $\rho(\mathcal{F}_t)$ for various degrees of trimming for $n=1081$ compact energy states.

This relation is useful when the underlying energy distribution of compact states has a skewed, non-Gaussian character, or is predominantly Gaussian with outliers, and reduces to (21) when the underlying distribution is Gaussian or close to Gaussian, giving it wide applicability for the actual, nonidealized distributions one can see in practice. Figure 2 shows the trimmed foldability distributions for various levels of trimming when $n=1081$. Figure 3 plots the energy gap distributions for the same values of n that were used in Fig. 1 (this figure is based on Fig. 2 of Buchler and Goldstein, with the x-axis corrected). Note the small percentage of area under the curves in Fig. 3 for which $\Delta_g>0$, the weakest foldability criterion. Though foldability increases with n, only a small fraction of REM heteropolymer sequences tend to be foldable as protein size increases.

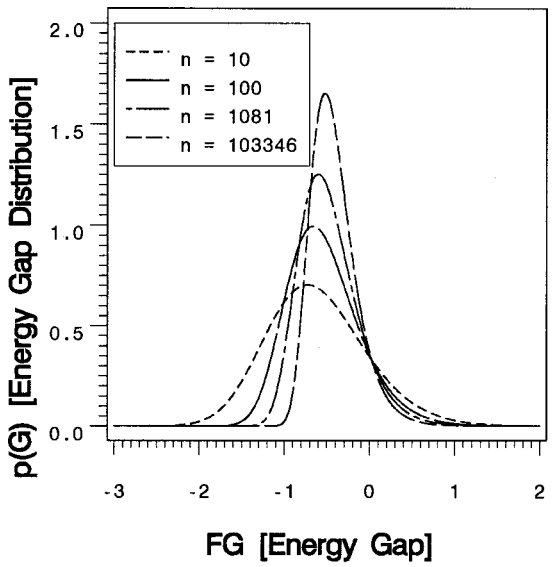

FIG. 3. Plot of the energy gap distribution $\rho(\Delta_g)$ for different numbers of compact energy states using the random energy model (based on Fig. 2 of Buchler and Goldstein with the x axis corrected).

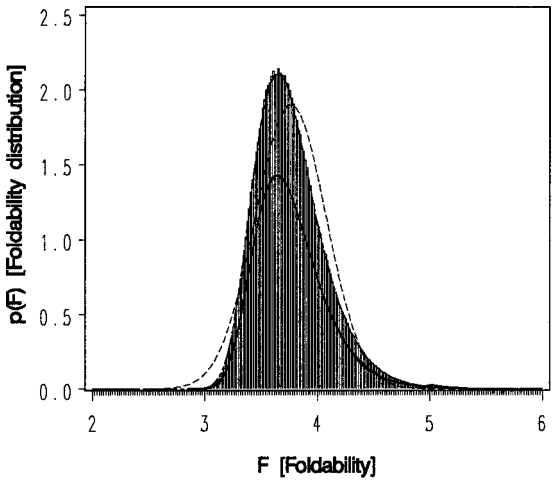

FIG. 4. Nonparametric kernel density (-------), normal (---), and $\rho(\mathcal{F})$ (—) fits to simulated noisy energy level data with outliers.

Using a similar argument as for foldability, we can obtain a robust version of the Buchler and Goldstein equation (13) for the energy gap distribution:

$$\rho(\Delta_{gt}) = \frac{n-[2\alpha n]}{\sqrt{2\pi}} e^{-(\sqrt{2\ln(n-[2\alpha n])}+\Delta_{gt})^2/2}\left[\frac{1}{2}\left(1+\mathrm{Erf}\left(\frac{\sqrt{2\ln(n-[2\alpha n])}+\Delta_{gt}}{\sqrt{2}}\right)\right)\right]^{(n-[2\alpha n]-1)}. \tag{24}$$

Note that $\rho(\Delta_{gt})$ is identical to $\rho(\mathcal{F}_t)$ except for the shifting factor $\sqrt{2\ln(n-[2\alpha n])}$.

An alternative method for deriving a robust estimator would be to find the trimming level and the value of m, in (25) below that causes the curve described by (25) to most closely approach the nonparametric kernel density estimation[20] fit (see Sec. V) to the energy levels histogram:

$$\rho(\mathcal{F}_p) = \frac{m}{\sqrt{2\pi}} e^{-(\mathcal{F}_p)^2/2}\left[\frac{1}{2}\left(1+\mathrm{Erf}\left(\frac{\mathcal{F}_p}{\sqrt{2}}\right)\right)\right]^{(m-1)}. \tag{25}$$

Here, $\mathcal{F}_p$ is based on the proportion of observations included to match the curves. More formally, consider a sequence of one-dimensional observations $X_1,\ldots,X_n$ that are independent and identically distributed. These observations belong to some sample space $\mathcal{S}$, which is a subset of the real line $\mathbb{R}$. As a measure of discrepancy, consider the Prokhorov distance[21] between two probability distributions $\mathcal{G}$ and $\mathcal{H}$ in $\mathcal{F}(\mathcal{S})$:

$$\pi(\mathcal{G},\mathcal{H})\inf\{\varepsilon;\mathcal{G}(A)\leqslant\mathcal{H}(A^{\varepsilon})+\varepsilon \quad \text{for all } A\}, \tag{26}$$

where A^{ε} is the set of all points with distance from A less than ε. Equation (25) results from matching (21) to the nonparametric kernel density curve with tolerance ε. Note that one could also use the Hellinger or Lévy distances or the bounded Lipschitz metric.[22]

V. EXAMPLE AND DISCUSSION

Figure 4 displays a foldability distribution that is somewhat irregular and has fairly long tails. This corresponds to an energy distribution of compact states that is moderately noisy with outliers. Superimposed on the histogram are three curves: the nonparametric kernel density fit, which can be made to fit any histogram to any degree of accuracy, and is used here as the reference curve, the best normal distribution fit, which is skewed to the right due to the long tail of the distribution, and the $\rho(\mathcal{F})$ fit to the distribution, which is more centered, but clearly is appreciably affected by the

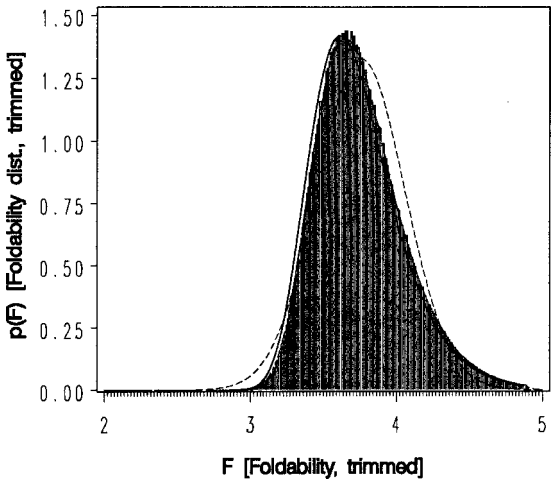

FIG. 5. Nonparametric kernel density (-———-), normal (---), and robust $\rho(\mathcal{F}_p)$ (—) fits to trimmed simulated noisy energy level data with outliers.

irregularities and long tails of the distribution. In Fig. 5, the trimmed foldability distribution is displayed. Note that the histogram bars appear slightly different from those of Fig. 4 due to recalculation after trimming. The best normal distribution fit is still somewhat skewed to the right, but the trimmed $\rho(\mathcal{F}_p)$ fit to the distribution nearly coincides with the reference curve, and is just slightly skewed left, since the left tail of the distribution is still a little long, though of low density. Thus, the robust trimmed estimator distinctly improves the fit to the distribution when noise and outliers are present.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 42, NUMBER 9 SEPTEMBER 2001

Translation-covariant Markovian master equation for a test particle in a quantum fluid

Bassano Vacchini[a)]
Dipartimento di Fisica dell'Università di Milano and Istituto Nazionale di Fisica Nucleare, Sezione di Milano, Via Celoria 16, I-20133, Milan, Italy

(Received 9 March 2001; accepted for publication 11 May 2001)

A recently proposed master equation in the Lindblad form is studied with respect to covariance properties and existence of a stationary solution. The master equation describes the interaction of a test particle with a quantum fluid, the so-called Rayleigh gas, and is characterized by the appearance of a two-point correlation function known as the dynamic structure factor, which reflects symmetry and statistical mechanics properties of the fluid. In the case of a free gas, all relevant physical parameters such as fugacity, ratio between the masses, momentum transfer, and energy transfer are put into evidence, giving an exact expansion of the dynamic structure factor. The limit in which these quantities are small is then considered. In particular, in the Brownian limit a Fokker–Planck equation is obtained in which the corrections due to quantum statistics can be explicitly evaluated and are given in terms of the Bose function $g_0(z)$ and the Fermi function $f_0(z)$. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1386409]

I. INTRODUCTION

The study of dissipative systems in a quantum mechanical framework is a subject of major interest for many physical communities especially in connection with applications. Recently, however, the subject has gained new interest also for physicists concerned with foundations of quantum mechanics, due to the relevance of the notion of decoherence as a gateway between the classical and quantum worlds.[1] This interest is strongly supported and partially motivated by a spectacular improvement in many experimental techniques useful for handling with great precision single- or few-particle systems, checking for coherence properties in their dynamical evolution.[2] In this connection models for quantum dissipation determined by the symmetry properties of the microphysical interaction and by symmetry and statistical mechanics properties of the environment could be of interest for a large class of phenomena. In the Markovian limit quantum-dynamical semigroups[3] seem the most natural quantum mechanical framework for the description of dissipative systems[4] and a lot of work has been done in this direction, both at rigorous and formal levels, especially with reference to the structural result of Lindblad, which fixes the form of the generator of a completely positive quantum-dynamical semigroup in the case of norm continuity.[5] In this article we will study in detail some structural properties of a recently proposed Markovian master equation for the description of the dynamics of a test particle in a fluid,[6–9] the so-called Rayleigh gas.[4] This simple but realistic model is of particular interest in statistical mechanics, being a paradigmatic example which opens the way to the study of interacting truly many-body systems. In the quantum regime a feature of independent interest is the relevance of quantum statistics of particles making up the fluid, especially in connection with the recent experimental realization of almost noninteracting degenerate gas samples of both Bose and Fermi particles.[10] The considered master equation was derived by assuming a translationally invariant interaction between the test particle and a homogeneous fluid, and has the general structure of a generator of translation-covariant dynamical semigroups considered in Ref. 11. In this way a direct

a)Electronic mail: bassano.vacchini@mi.infn.it

physical interpretation arises, at least in a particular case, of the general structure given in Ref. 11. Further symmetry or equilibrium properties, which are of fundamental relevance in order to determine the realm of validity of a given master equation,[9] are shown to be a direct consequence of particular physical features of the environment, embodied in a specific two-point correlation function, the so-called dynamic structure factor.[12]

The article is organized as follows: in Sec. II the master equation is introduced and the property of covariance with respect to translations and rotations is considered with reference to the corresponding symmetries of the environment embodied in its dynamic structure factor; moreover, the existence of a stationary solution is proved, provided the environment is in a β-KMS state.[13] In Sec. III the case of a free quantum gas is considered, the dynamic structure factor is explicitly calculated, its exact expansion with respect to the relevant physical parameters is obtained and in the limit of small fugacity z the expression for Maxwell–Boltzmann particles is recovered. In Sec. IV the Brownian limit in which the test particle is much heavier than the particles making up the gas is dealt with, together with the limit of small momentum transfer, leading from the master equation to a Fokker–Planck equation, strongly dependent on the statistics of the gas. In Sec. V the obtained results are briefly summarized and discussed.

II. GENERAL FEATURES OF THE MASTER EQUATION

Let us recall the general expression of the master equation proposed in Refs. 7 and 8 for the description of the motion of a test particle in a homogeneous fluid supposed to be at equilibrium, whose properties we are going to study. The obtained result is based on a scattering theory derivation, assuming a translationally invariant interaction in terms of two-particle collisions, and is expected to be valid on a time scale much longer than the relaxation time of the environment. In the Schrödinger picture the master equation is given by

$$\frac{d\hat{\varrho}}{dt}=\mathcal{M}[\hat{\varrho}]=-\frac{i}{\hbar}[\hat{H}_0,\hat{\varrho}]+\mathcal{L}[\hat{\varrho}], \tag{1}$$

where $\hat{H}_0=\hat{\boldsymbol{p}}^2/2M$ is the Hamiltonian of the free particle, M being the mass of the test particle, while the dissipative part is given by the following mapping with a Lindblad structure:

$$\mathcal{L}[\,\cdot\,]=\int_{\mathbf{R}^3}d\mu(\boldsymbol{q})\left[\hat{U}(\boldsymbol{q})\sqrt{S(\boldsymbol{q},\hat{\boldsymbol{p}})}\cdot\sqrt{S(\boldsymbol{q},\hat{\boldsymbol{p}})}\hat{U}^{\dagger}(\boldsymbol{q})-\frac{1}{2}\{S(\boldsymbol{q},\hat{\boldsymbol{p}}),\cdot\}\right], \tag{2}$$

where the integral is over the parameter space of the translation group in momentum space in three dimensions, the parameter $\boldsymbol{q}$ being the momentum transferred in a collision, $\{\hat{A},\hat{B}\}$ denotes the Jordan product $\hat{A}\circ\hat{B}=\hat{A}\hat{B}+\hat{B}\hat{A}$, and the operator $\hat{\boldsymbol{p}}$ is the generator of translations. The unitary operators $\hat{U}(\boldsymbol{q})=e^{(i/\hbar)\boldsymbol{q}\cdot\hat{\boldsymbol{x}}}$, $\boldsymbol{q}\in\mathbf{R}^3$, are the generators of translations in momentum space or boosts. The positive measure $d\mu(\boldsymbol{q})$ is given by

$$d\mu(\boldsymbol{q})=\frac{2\pi}{\hbar}(2\pi\hbar)^3 n|\tilde{t}(q)|^2 d^3\boldsymbol{q}, \tag{3}$$

thus being invariant under both rotations and translations. In fact n is the particle density in the macroscopic system, and the function $\tilde{t}(q)$, given by

$$\tilde{t}(q)=\int_{\mathbf{R}^3}d^3\boldsymbol{x}\frac{e^{(i/\hbar)\boldsymbol{q}\cdot\boldsymbol{x}}}{(2\pi\hbar)^3}t(x),$$

where $q=|\boldsymbol{q}|$ and $x=|\boldsymbol{x}|$, is the Fourier transform with respect to the transferred momentum $\boldsymbol{q}$ of the T matrix describing the translationally and rotationally invariant interaction between the test particle and the particles of the fluid, which is supposed to be energy independent. The function

$S(\boldsymbol{q},\boldsymbol{p})$, which appears operator-valued in (2), is a positive two-point correlation function known as the dynamic structure factor,[12] given by the Fourier transform with respect to energy transfer $E(\boldsymbol{q},\boldsymbol{p})$ and momentum transfer $\boldsymbol{q}$ of the time dependent pair correlation function of the fluid

$$S(\boldsymbol{q},\boldsymbol{p})=\frac{1}{2\pi\hbar}\int_{\mathbf{R}}dt\int_{\mathbf{R}^3}d^3\boldsymbol{x}\,e^{(i/\hbar)[E(\boldsymbol{q},\boldsymbol{p})t-\boldsymbol{q}\cdot\boldsymbol{x}]}G(\boldsymbol{x},t), \tag{4}$$

where $G(\boldsymbol{x},t)$ is the time dependent pair correlation function

$$G(\boldsymbol{x},t)=\frac{1}{N}\int_{\mathbf{R}^3}d^3\boldsymbol{y}\langle N(\boldsymbol{y})N(\boldsymbol{y}+\boldsymbol{x},t)\rangle, \tag{5}$$

$N(\boldsymbol{y})$ being the operator density of particles in the fluid and $\langle\cdots\rangle$ the ensemble average with respect to the state of the macroscopic system. The expression $E(\boldsymbol{q},\boldsymbol{p})$ gives the energy transfer in a collision where the test particle changes its momentum from $\boldsymbol{p}$ to $\boldsymbol{p}+\boldsymbol{q}$, so that

$$E(\boldsymbol{q},\boldsymbol{p})=E_{p+q}-E_p=\frac{q^2}{2M}+\frac{\boldsymbol{p}\cdot\boldsymbol{q}}{M}. \tag{6}$$

Note that in (4) we have used as variables momentum and energy transferred to the test particle. In the sequel we will use both the equivalent notations $S(\boldsymbol{q},\boldsymbol{p})$ and $S(\boldsymbol{q},E(\boldsymbol{q},\boldsymbol{p}))\equiv S(\boldsymbol{q},E)$, according to convenience. The dynamic structure factor is a very important physical quantity, giving the spectrum of spontaneous fluctuations of the system, and it is of direct experimental access: in fact, as first obtained by van Hove in a fundamental work,[14] it is directly related to the energy dependent differential cross-section per target particle describing scattering of a microscopic probe off a macroscopic sample through the formula

$$\frac{d^2\sigma}{d\Omega_{p'}dE_{p'}}=(2\pi\hbar)^6\left(\frac{M}{2\pi\hbar^2}\right)^2\frac{p'}{p}|\tilde{t}(q)|^2S(\boldsymbol{q},E), \tag{7}$$

referring to scattering of the microscopic probe from $\boldsymbol{p}$ to $\boldsymbol{p}'=\boldsymbol{p}+\boldsymbol{q}$. The dynamic structure factor is given in (7) as a function of momentum and energy transfer, which are the measured quantities in scattering experiments, the energy E being related to $\boldsymbol{q}$ and $\boldsymbol{p}$ through (6). The appearance of the dynamic structure factor in (7) gives the physical reason for its being positive definite for every system. The main point in (1) and (2) is the determination of the specific expressions for the measure $d\mu(\boldsymbol{q})$ given by (3), and of the operator valued function $S(\boldsymbol{q},\cdot)$, given by (4), which can only be obtained on the basis of a microphysical derivation of the equation, relying on some physical model. A general structure encompassing (2) has already been considered by Holevo in a purely mathematical context, studying the general structure of generators of translation-covariant dynamical semigroups.[11] In particular Holevo has proven that when the generator is bounded it must have a structure of the form (1) with $\mathcal{L}$ given by (2) provided all operators appearing in (1) and (2) are bounded[11] [see also Refs. 15 and 16, where further restrictions to the structure of (2) appear, to be discussed later on], and allowing, instead of the structure

$$\hat{U}(\boldsymbol{q})\sqrt{S(\boldsymbol{q},\hat{\boldsymbol{p}})}\cdot\sqrt{S(\boldsymbol{q},\hat{\boldsymbol{p}})}\hat{U}^\dagger(\boldsymbol{q})$$

appearing in (2), where $S(\boldsymbol{q},\hat{\boldsymbol{p}})$ is self-adjoint and positive, the more general structure

$$\hat{U}(\boldsymbol{q})L(\boldsymbol{q},\hat{\boldsymbol{p}})\cdot L^\dagger(\boldsymbol{q},\hat{\boldsymbol{p}})\hat{U}^\dagger(\boldsymbol{q}).$$

If the generator is unbounded also diffusion terms of the form considered in (37) may appear, and the operators appearing in (1) and (2) may be unbounded (see Ref. 11 for further details). In the

general model considered here the Hamiltonian is given by the unbounded operator $\hat{H}_0 = \hat{\boldsymbol{p}}^2/2M$, while the remaining part of the generator is determined by the explicit expression of the physical quantities $\tilde{t}(q)$ and $S(\boldsymbol{q},\boldsymbol{p})$, depending on the specific model for the fluid.

We now consider the behavior of (1) with respect to symmetry transformations. Let us consider a locally compact group G and a unitary representation $\hat{U}(g)$, with $g \in G$, on the Hilbert space of the system. Following Ref. 11 we say that a mapping $\mathcal{M}$ in the Schrödinger picture is G-covariant if it commutes with the mapping $\mathcal{U}_g[\,\cdot\,] = \hat{U}(g)\cdot\hat{U}^\dagger(g)$ for all $g \in G$:

$$\mathcal{M}[\mathcal{U}_g[\,\cdot\,]] = \mathcal{U}_g[\mathcal{M}[\,\cdot\,]]. \tag{8}$$

Let us first consider the case of spatial translations. Then the unitary operators are given by $\hat{U}(\boldsymbol{a}) = e^{-(i/\hbar)\boldsymbol{a}\cdot\hat{\boldsymbol{p}}}$ with $\boldsymbol{a} \in \mathbf{R}^3$ and exploiting

$$[\hat{U}(\boldsymbol{a}),\hat{H}_0] = 0,\ [\hat{U}(\boldsymbol{a}),S(\boldsymbol{q},\hat{\boldsymbol{p}})] = 0,$$

together with the Weyl CCR,

$$\hat{U}(\boldsymbol{q})\hat{U}(\boldsymbol{a}) = \hat{U}(\boldsymbol{a})\hat{U}(\boldsymbol{q})e^{(i/\hbar)\boldsymbol{a}\cdot\boldsymbol{q}},$$

one immediately has that the mapping $\mathcal{M}$ given by (1) is translation-covariant. This property goes back to homogeneity of the fluid and translational invariance of the interaction, as can be seen in the derivation of the master equation.[7,8] We then consider invariance under rotations, so that the relevant set of unitary operators takes the form $\hat{U}(R)$, with $R \in \mathbf{SO}(3)$. In this case exploiting $[\hat{U}(R),\hat{H}_0] = 0$ and the relations

$$\hat{U}^\dagger(R)\hat{U}(\boldsymbol{q})\hat{U}(R) = \hat{U}(R^{-1}\boldsymbol{q}),\ \hat{U}^\dagger(R)\hat{\boldsymbol{p}}\hat{U}(R) = R\hat{\boldsymbol{p}},$$

one has that $\mathcal{M}$ is rotation-covariant provided the dynamic structure factor satisfies for $R \in \mathbf{SO}(3)$

$$S(R\boldsymbol{q},R\boldsymbol{p}) = S(\boldsymbol{q},\boldsymbol{p}). \tag{9}$$

In fact, if (9) holds, one has

$$\begin{aligned}\mathcal{M}[\mathcal{U}_R[\,\cdot\,]] &= \int_{\mathbf{R}^3} d\mu(\boldsymbol{q})\ \hat{U}(R)\left[\hat{U}(R^{-1}\boldsymbol{q})\sqrt{S(\boldsymbol{q},R\hat{\boldsymbol{p}})}\cdot\sqrt{S(\boldsymbol{q},R\hat{\boldsymbol{p}})}\hat{U}^\dagger(R^{-1}\boldsymbol{q}) - \frac{1}{2}\{S(\boldsymbol{q},R\hat{\boldsymbol{p}}),\cdot\}\right]\hat{U}^\dagger(R)\\ &= \int_{\mathbf{R}^3} d\mu(\boldsymbol{q})\ \hat{U}(R)\left[\hat{U}(\boldsymbol{q})\sqrt{S(\boldsymbol{q},\hat{\boldsymbol{p}})}\cdot\sqrt{S(\boldsymbol{q},\hat{\boldsymbol{p}})}\hat{U}^\dagger(\boldsymbol{q}) - \frac{1}{2}\{S(\boldsymbol{q},\hat{\boldsymbol{p}}),\cdot\}\right]\hat{U}^\dagger(R)\\ &= \mathcal{U}_R[\mathcal{M}[\,\cdot\,]].\end{aligned}$$

On the other hand, (9) is directly linked to rotational invariance of the surrounding environment, as one can see observing that $E(\boldsymbol{q},\boldsymbol{p})$ as given by (6) satisfies

$$E(R\boldsymbol{q},R\boldsymbol{p}) = E(\boldsymbol{q},\boldsymbol{p}),$$

and considering the identity

$$\begin{aligned}S(R\boldsymbol{q},R\boldsymbol{p}) &= \frac{1}{2\pi\hbar}\int_{\mathbf{R}} dt \int_{\mathbf{R}^3} d^3\boldsymbol{x}\, e^{(i/\hbar)[E(R\boldsymbol{q},R\boldsymbol{p})t - R\boldsymbol{q}\cdot\boldsymbol{x}]}G(\boldsymbol{x},t)\\ &= \frac{1}{2\pi\hbar}\int_{\mathbf{R}} dt \int_{\mathbf{R}^3} d^3\boldsymbol{x} e^{(i/\hbar)[E(\boldsymbol{q},\boldsymbol{p})t - \boldsymbol{q}\cdot\boldsymbol{x}]}G(R\boldsymbol{x},t)\end{aligned}$$

so that (9) holds if and only if the pair correlation function is invariant under rotations,

$$G(R\boldsymbol{x},t)=G(\boldsymbol{x},t).$$

In order to proceed further and consider the existence of stationary solutions we make the natural assumption that the state of the macroscopic system, with respect to which the expectation value in (5) is calculated, is a β-KMS state, so that the relation

$$\langle \hat{A}(w)\hat{B}\rangle=\langle \hat{B}\hat{A}(w+i\hbar\beta)\rangle \tag{10}$$

holds. This in turn implies that the dynamic structure factor $S(\boldsymbol{q},\boldsymbol{p})$ satisfies an identity known as *detailed balance condition*,[12]

$$S(\boldsymbol{q},\boldsymbol{p})=e^{-\beta(q^2/2M+\boldsymbol{p}\cdot\boldsymbol{q}/M)}S(-\boldsymbol{q},\boldsymbol{p}+\boldsymbol{q}), \tag{11}$$

usually expressed in terms of the dependence on the transferred energy

$$S(\boldsymbol{q},E(\boldsymbol{q},\boldsymbol{p}))=e^{-\beta E(\boldsymbol{q},\boldsymbol{p})}S(-\boldsymbol{q},-E(\boldsymbol{q},\boldsymbol{p})), \tag{12}$$

the sign of the exponential being determined by the fact that we are considering momentum and energy transferred to the particle. It will prove useful for further considerations to introduce a symmetrized version of the dynamic structure factor, given by

$$\tilde{S}(\boldsymbol{q},E)=e^{(\beta/2)E}S(\boldsymbol{q},E) \tag{13}$$

or equivalently

$$\tilde{S}(\boldsymbol{q},\boldsymbol{p})=e^{(\beta/2)(q^2/2M+\boldsymbol{p}\cdot\boldsymbol{q}/M)}S(\boldsymbol{q},\boldsymbol{p}), \tag{14}$$

satisfying instead of (12) the more symmetric

$$\tilde{S}(\boldsymbol{q},E)=\tilde{S}(-\boldsymbol{q},-E),$$

so that (11) becomes

$$\tilde{S}(\boldsymbol{q},\boldsymbol{p})=\tilde{S}(-\boldsymbol{q},\boldsymbol{p}+\boldsymbol{q}). \tag{15}$$

We now look for a stationary solution of (1), given that the environment is in a β-KMS state, so that due to (10) the dynamic structure factor satisfies the detailed balance condition as in (11). According to translation covariance of the generators we look for a solution invariant under translation, of the form $\rho(\hat{\boldsymbol{p}})$. Since $[\hat{H}_0,\rho(\hat{\boldsymbol{p}})]=0$, $\rho(\hat{\boldsymbol{p}})$ will be a stationary solution of (1) provided

$$\begin{aligned}\mathcal{L}[\rho(\hat{\boldsymbol{p}})]&=\int_{\mathbf{R}^3}d\mu(\boldsymbol{q})\,[\hat{U}(\boldsymbol{q})S(\boldsymbol{q},\hat{\boldsymbol{p}})\rho(\hat{\boldsymbol{p}})\hat{U}^{\dagger}(\boldsymbol{q})-S(\boldsymbol{q},\hat{\boldsymbol{p}})\rho(\hat{\boldsymbol{p}})]\\&=\int_{\mathbf{R}^3}d\mu(\boldsymbol{q})\,[S(\boldsymbol{q},\hat{\boldsymbol{p}}-\boldsymbol{q})\rho(\hat{\boldsymbol{p}}-\boldsymbol{q})-S(\boldsymbol{q},\hat{\boldsymbol{p}})\rho(\hat{\boldsymbol{p}})]=0.\end{aligned} \tag{16}$$

Introducing the function

$$A(\boldsymbol{q},\boldsymbol{p})=S(\boldsymbol{q},\boldsymbol{p}-\boldsymbol{q})\rho(\boldsymbol{p}-\boldsymbol{q})-S(\boldsymbol{q},\boldsymbol{p})\rho(\boldsymbol{p}), \tag{17}$$

the requirement (16) becomes

$$\int_{\mathbf{R}^3} d\mu(\boldsymbol{q})\, A(\boldsymbol{q},\boldsymbol{p}) = 0. \tag{18}$$

A sufficient condition for (18) to be valid is that $A(\boldsymbol{q},\boldsymbol{p})$ be an odd function in $\boldsymbol{q}$, and we shall see that this is exactly the case if $\rho(\hat{\boldsymbol{p}})$ has the canonical structure $\rho_0(\hat{\boldsymbol{p}}) = e^{-\beta \hat{\boldsymbol{p}}^2/2M}$, with M the mass of the test particle and β the inverse temperature of the macroscopic system, as it is to be expected on physical grounds. Let $\rho_0(\hat{\boldsymbol{p}}) = e^{-\beta \hat{\boldsymbol{p}}^2/2M}$. Then

$$\rho_0(\boldsymbol{p}-\boldsymbol{q}) = \rho_0(\boldsymbol{p}) e^{-\beta(q^2/2M - \boldsymbol{p}\cdot\boldsymbol{q}/M)},$$

so that

$$A(\boldsymbol{q},\boldsymbol{p}) = \rho_0(\boldsymbol{p})[S(\boldsymbol{q},\boldsymbol{p}-\boldsymbol{q}) e^{-\beta(q^2/2M - \boldsymbol{p}\cdot\boldsymbol{q}/M)} - S(\boldsymbol{q},\boldsymbol{p})]$$

and exploiting (11)

$$A(\boldsymbol{q},\boldsymbol{p}) = \rho_0(\boldsymbol{p})[S(-\boldsymbol{q},\boldsymbol{p}) - S(\boldsymbol{q},\boldsymbol{p})],$$

which is manifestly odd in $\boldsymbol{q}$.

As mentioned earlier the structure given in (2) is a particular realization of the general expression considered in Ref. 11; however, it does not meet the more stringent requirements exhibited by the dissipative mapping considered in Ref. 16. According to Ref. 11 these requirements are unnecessary if one is looking for the most general translation-covariant generator and we shall show that in the present framework they would lead to unphysical results. In fact the structure proposed in Ref. 16 for the dissipative part would take in the Schrödinger picture the form

$$\mathcal{L}[\,\cdot\,] = \int_{\mathbf{R}^3} d\mu(\boldsymbol{q}) \left[P(\boldsymbol{q},\hat{\boldsymbol{p}}) \cdot P^{\dagger}(\boldsymbol{q},\hat{\boldsymbol{p}}) - \frac{1}{2}\{P^{\dagger}(\boldsymbol{q},\hat{\boldsymbol{p}}) P(\boldsymbol{q},\hat{\boldsymbol{p}}), \cdot\} \right], \tag{19}$$

with the further requirement

$$P^{\dagger}(\boldsymbol{q},\hat{\boldsymbol{p}}) = P(-\boldsymbol{q},\hat{\boldsymbol{p}}), \tag{20}$$

which in our case, since

$$P(\boldsymbol{q},\hat{\boldsymbol{p}}) = \hat{U}(\boldsymbol{q}) \sqrt{S(\boldsymbol{q},\hat{\boldsymbol{p}})} \tag{21}$$

is not satisfied, being equivalent to the requirement

$$\hat{U}(\boldsymbol{q}) \sqrt{S(\boldsymbol{q},\hat{\boldsymbol{p}})} = \hat{U}(\boldsymbol{q}) \sqrt{S(-\boldsymbol{q},\hat{\boldsymbol{p}}+\boldsymbol{q})},$$

which does not hold due to the presence of the factor $e^{-\beta(q^2/2M + \boldsymbol{p}\cdot\boldsymbol{q}/M)}$ in (11). If instead of the dynamic structure factor $S(\boldsymbol{q},\boldsymbol{p})$ one would consider the symmetrized dynamic structure factor $\tilde{S}(\boldsymbol{q},\boldsymbol{p})$ given by (14), so that $P(\boldsymbol{q},\boldsymbol{p})$ in (21) would be replaced by

$$\tilde{P}(\boldsymbol{q},\hat{\boldsymbol{p}}) = \hat{U}(\boldsymbol{q}) \sqrt{\tilde{S}(\boldsymbol{q},\hat{\boldsymbol{p}})},$$

then according to (15) the relation (20) would hold and the dissipative mapping $\mathcal{L}$ would conform to the structure proposed in Ref. 16. In this case, however, one would have the unphysical result that $\rho_0(\hat{\boldsymbol{p}}) = e^{-\beta \hat{\boldsymbol{p}}^2/2M}$ is no longer a stationary solution, because

$$\tilde{A}(\boldsymbol{q},\boldsymbol{p}) = \tilde{S}(\boldsymbol{q},\boldsymbol{p}-\boldsymbol{q})\rho_0(\boldsymbol{p}-\boldsymbol{q}) - \tilde{S}(\boldsymbol{q},\boldsymbol{p})\rho_0(\boldsymbol{p})$$

is no longer odd in $\boldsymbol{q}$. Other unphysical features linked to the further restriction (20) will be considered in Sec. IV. Note that these features can only be discovered with reference to a specific structure of a translation-covariant generator determined by starting from some microphysical model. In fact the restriction (20), though unnecessary from a mathematical standpoint, could have proven interesting as well from a physical point of view, thus suggesting the result of Ref. 16 as a useful starting point for phenomenological approaches. This does not seem to be the case, in fact the substitution $S(\boldsymbol{q},\boldsymbol{p})\to\widetilde{S}(\boldsymbol{q},\boldsymbol{p})$, natural in order to comply with Ref. 16, leads to unphysical results.

III. EXACT EXPRESSION FOR A FREE QUANTUM GAS

It is of course of interest to analyze the mapping $\mathcal{M}$ given in (1) for a model in which the dynamic structure factor of the fluid can be explicitly calculated: this is the case for an ideal quantum gas considered at finite temperature $T=1/\beta k$, where k is Boltzmann's constant, and obeying either Bose or Fermi statistics. Apart from simplicity, the case of a free gas can be of interest also in view of the recent experimental realization of dilute quantum samples of Bose or Fermi particles in the degenerate regime.[10] The dynamic structure factor for an ideal gas takes the form[12]

$$S_{\mathrm{B/F}}(\boldsymbol{q},\boldsymbol{p})=\frac{1}{n}\int_{\mathbf{R}^3}\frac{d^3\boldsymbol{k}}{(2\pi\hbar)^3}\,\langle n_k\rangle_{\mathrm{B/F}}(1\pm\langle n_{k-q}\rangle_{\mathrm{B/F}})\,\delta\left(\frac{(\boldsymbol{p}+\boldsymbol{q})^2}{2M}+\frac{(\boldsymbol{k}-\boldsymbol{q})^2}{2m}-\frac{\boldsymbol{p}^2}{2M}-\frac{\boldsymbol{k}^2}{2m}\right), \quad (22)$$

where the indexes B or F and signs $+$ or $-$ refer to Bose or Fermi statistics, respectively, M is the mass of the test particle, m is the mass of the particles making up the gas, n is the density of particles in the gas, and $\langle n_k\rangle_{\mathrm{B/F}}$ is

$$\langle n_k\rangle_{\mathrm{B/F}}=\frac{1}{z^{-1}e^{\beta\epsilon_k}\mp 1},\qquad \epsilon_k=\frac{\boldsymbol{k}^2}{2m},$$

where z is the fugacity of the gas, related to the chemical potential μ by $z=e^{\beta\mu}$. For a Bose gas at finite temperature $0\leqslant z<1$, while for a Fermi gas $z\geqslant 0$. The integral in (22) can be explicitly calculated both for bosons and fermions, giving the result (A6) obtained in Appendix A:

$$S_{\mathrm{B/F}}(\boldsymbol{q},\boldsymbol{p})=\mp\frac{1}{(2\pi\hbar)^3}\,\frac{2\pi m^2}{n\beta q}\,\frac{1}{1-e^{\beta E(\boldsymbol{q},\boldsymbol{p})}}\log\left[\frac{1\mp z\exp[-(\beta/8m)(2mE(\boldsymbol{q},\boldsymbol{p})+q^2)^2/q^2]}{1\mp z\exp[-(\beta/8m)(2mE(\boldsymbol{q},\boldsymbol{p})-q^2)^2/q^2]}\right], \quad (23)$$

with $q=|\boldsymbol{q}|$. In the same way one can consider the case of a free gas of particles satisfying Maxwell–Boltzmann statistics, thus having

$$S_{\mathrm{MB}}(\boldsymbol{q},\boldsymbol{p})=\frac{1}{n}\int_{\mathbf{R}^3}\frac{d^3\boldsymbol{k}}{(2\pi\hbar)^3}\,\langle n_k\rangle_{\mathrm{MB}}\,\delta\left(\frac{(\boldsymbol{p}+\boldsymbol{q})^2}{2M}+\frac{(\boldsymbol{k}-\boldsymbol{q})^2}{2m}-\frac{\boldsymbol{p}^2}{2M}-\frac{\boldsymbol{k}^2}{2m}\right), \quad (24)$$

with

$$\langle n_k\rangle_{\mathrm{MB}}=ze^{-\beta\epsilon_k},$$

so that the integral in (24) can also be explicitly calculated giving the expression (A8):

$$S_{\mathrm{MB}}(\boldsymbol{q},\boldsymbol{p})=\frac{1}{(2\pi\hbar)^3}\,\frac{2\pi m^2}{n\beta q}\,z\exp\left[-\frac{\beta}{8m}\,\frac{(2mE(\boldsymbol{q},\boldsymbol{p})+q^2)^2}{q^2}\right]. \quad (25)$$

A convenient way to write (23) and (25) for later expansions is in terms of the function

$$\sigma(\boldsymbol{q},\boldsymbol{p})=\frac{1}{2q}[q^2+2\alpha ME(\boldsymbol{q},\boldsymbol{p})], \tag{26}$$

where the ratio $\alpha=m/M$ between the masses of the particles of the gas and of the test particle has been put into evidence, thus obtaining, respectively,

$$S_{\mathrm{B/F}}(\boldsymbol{q},\boldsymbol{p})=\mp\frac{1}{(2\pi\hbar)^3}\frac{2\pi m^2}{n\beta q}\frac{1}{1-\exp[(\beta/2m)(2\sigma(\boldsymbol{q},\boldsymbol{p})q-q^2)]}\times\log\left[\frac{1\mp z\exp[-(\beta/2m)\sigma^2(\boldsymbol{q},\boldsymbol{p})]}{1\mp z\exp[-(\beta/2m)(\sigma(\boldsymbol{q},\boldsymbol{p})-q)^2]}\right] \tag{27}$$

and

$$S_{\mathrm{MB}}(\boldsymbol{q},\boldsymbol{p})=\frac{1}{(2\pi\hbar)^3}\frac{2\pi m^2}{n\beta q}z\exp\left[-\frac{\beta}{2m}\sigma^2(\boldsymbol{q},\boldsymbol{p})\right]. \tag{28}$$

We have thus put into evidence all the physical parameters which are of interest in specifying the physical model under consideration and its range of validity: $\boldsymbol{q}$, E, α, and z. In this perspective the expression for a gas of Maxwell–Boltzmann particles can also be obtained as expected from the dynamic structure factor for a Bose or Fermi gas in the limit of small fugacity z. In fact, starting from (27) and expanding the logarithm up to first order in z one has

$$\begin{aligned}S_{\mathrm{B/F}}(\boldsymbol{q},\boldsymbol{p},z\ll 1)&=\frac{1}{(2\pi\hbar)^3}\frac{2\pi m^2}{n\beta q}\frac{z}{1-\exp[(\beta/2m)(2\sigma(\boldsymbol{q},\boldsymbol{p})q-q^2)]}\\&\quad\times\left\{\exp\left[-\frac{\beta}{2m}\sigma^2(\boldsymbol{q},\boldsymbol{p})\right]-\exp\left[-\frac{\beta}{2m}(\sigma(\boldsymbol{q},\boldsymbol{p})-q)^2\right]\right\}\\&=\frac{1}{(2\pi\hbar)^3}\frac{2\pi m^2}{n\beta q}z\exp\left[-\frac{\beta}{2m}\sigma^2(\boldsymbol{q},\boldsymbol{p})\right]=S_{\mathrm{MB}}(\boldsymbol{q},\boldsymbol{p}).\end{aligned}$$

Both (23) and (25) or equivalently (27) and (28) are invariant under rotation, as one can see from the fact that they depend on $\boldsymbol{q}$ and $\boldsymbol{p}$ only through $E(\boldsymbol{q},\boldsymbol{p})$ and the modulus q of $\boldsymbol{q}$, so that

$$S_{\mathrm{B/F}}(R\boldsymbol{q},R\boldsymbol{p})=S_{\mathrm{B/F}}(\boldsymbol{q},\boldsymbol{p}),\quad S_{\mathrm{MB}}(R\boldsymbol{q},R\boldsymbol{p})=S_{\mathrm{MB}}(\boldsymbol{q},\boldsymbol{p}),$$

thus leading to a rotation-covariant mapping $\mathcal{M}$ when substituted in (1). In order to grant the existence of the stationary solution $\rho_0(\hat{\boldsymbol{p}})$ we have to check that the obtained expressions satisfy the principle of detailed balance. Starting from (23) we have, setting for simplicity $E(\boldsymbol{q},\boldsymbol{p})=E$ and inverting the argument of the logarithm,

$$\begin{aligned}e^{-\beta E}S_{\mathrm{B/F}}(-\boldsymbol{q},-E)&=\mp\frac{1}{(2\pi\hbar)^3}\frac{2\pi m^2}{n\beta q}\frac{e^{-\beta E}}{1-e^{-\beta E}}\log\left[\frac{1\mp z\exp[-(\beta/8m)(-2mE+q^2)^2/q^2]}{1\mp z\exp[-(\beta/8m)(-2mE-q^2)^2/q^2]}\right]\\&=\mp\frac{1}{(2\pi\hbar)^3}\frac{2\pi m^2}{n\beta q}\frac{1}{1-e^{\beta E}}\log\left[\frac{1\mp z\exp[-\beta/8m)(2mE+q^2)^2/q^2]}{1\mp z\exp[-(\beta/8m)(2mE-q^2)^2/q^2]}\right]\\&=S_{\mathrm{B/F}}(\boldsymbol{q},E),\end{aligned}$$

which proves (12). Similarly

$$e^{-\beta E}S_{\mathrm{MB}}(-\boldsymbol{q},-E)=\frac{1}{(2\pi\hbar)^3}\frac{2\pi m^2}{n\beta q}z\exp[-\beta E]\exp\left[-\frac{\beta}{8m}\frac{(-2mE+q^2)^2}{q^2}\right]$$
$$=\frac{1}{(2\pi\hbar)^3}\frac{2\pi m^2}{n\beta q}z\exp\left[-\frac{\beta}{8m}\frac{(2mE+q^2)^2}{q^2}\right]=S_{\mathrm{MB}}(\boldsymbol{q},E).$$

The master equation (1) for the Rayleigh gas in the case of a free gas of Bose or Fermi particles takes therefore the form

$$\frac{d\hat{\varrho}}{dt}=\mathcal{M}_{\mathrm{B/F}}[\hat{\varrho}]=-\frac{i}{\hbar}[\hat{H}_0,\hat{\varrho}]+\int_{\mathbf{R}^3}d\mu(\boldsymbol{q})$$
$$\times\left[\hat{U}(\boldsymbol{q})\sqrt{S_{\mathrm{B/F}}(\boldsymbol{q},\hat{\boldsymbol{p}})}\,\hat{\varrho}\,\sqrt{S_{\mathrm{B/F}}(\boldsymbol{q},\hat{\boldsymbol{p}})}\hat{U}^{\dagger}(\boldsymbol{q})-\frac{1}{2}\{S_{\mathrm{B/F}}(\boldsymbol{q},\hat{\boldsymbol{p}}),\hat{\varrho}\}\right],\qquad(29)$$

with $S_{\mathrm{B/F}}(\boldsymbol{q},\boldsymbol{p})$ given explicitly by (23), and a similar expression $\mathcal{M}_{\mathrm{MB}}$ can be considered for a free gas of Maxwell–Boltzmann particles. Both $\mathcal{M}_{\mathrm{B/F}}$ and $\mathcal{M}_{\mathrm{MB}}$ are translation- and rotation-covariant and admit the same stationary solution with the canonical structure $\rho_0(\hat{\boldsymbol{p}})$.

IV. BROWNIAN LIMIT

In the framework of an ideal gas considered in Sec. III, i.e., referring to $\mathcal{M}_{\mathrm{B/F}}$ and $\mathcal{M}_{\mathrm{MB}}$, we now want to consider the physically distinguished case in which the test particle is much heavier than the particles making up the gas, so that $\alpha=m/M$ is much smaller than one, the so-called Brownian limit. In order to do this we have to evaluate the dynamic structure factor for a free gas in the case $\alpha\ll 1$. The natural starting points are expressions (27) and (28) in which the factor α has been put into evidence through the function (26). In particular we have the relations

$$\frac{\beta}{2m}\sigma^2(\boldsymbol{q},\boldsymbol{p})=\frac{\beta}{8m}q^2+\frac{\beta}{2}\frac{1}{2M}[q^2+2\boldsymbol{p}\cdot\boldsymbol{q}]+\frac{\beta}{2}\frac{1}{q^2}\alpha\frac{1}{4M}[q^2+2\boldsymbol{p}\cdot\boldsymbol{q}]^2$$
$$=\frac{\beta}{8m}q^2+\frac{\beta}{2}E(\boldsymbol{q},\boldsymbol{p})+\frac{\beta}{2}\frac{m}{q^2}E^2(\boldsymbol{q},\boldsymbol{p}),$$

$$\frac{\beta}{2m}(\sigma(\boldsymbol{q},\boldsymbol{p})-q)^2=\frac{\beta}{8m}q^2-\frac{\beta}{2}\frac{1}{2M}[q^2+2\boldsymbol{p}\cdot\boldsymbol{q}]+\frac{\beta}{2}\frac{1}{q^2}\alpha\frac{1}{4M}[q^2+2\boldsymbol{p}\cdot\boldsymbol{q}]^2$$
$$=\frac{\beta}{8m}q^2-\frac{\beta}{2}E(\boldsymbol{q},\boldsymbol{p})+\frac{\beta}{2}\frac{m}{q^2}E^2(\boldsymbol{q},\boldsymbol{p}),\qquad(30)$$

$$\frac{\beta}{2m}(2\sigma(\boldsymbol{q},\boldsymbol{p})q-q^2)=\frac{\beta}{2M}[q^2+2\boldsymbol{p}\cdot\boldsymbol{q}]=\beta E(\boldsymbol{q},\boldsymbol{p}).$$

The Brownian limit can now be taken neglecting the terms of order α in (30) or equivalently considering small energy transfer, corresponding to a broader time scale, and keeping in (30) only the terms linear in E, disregarding higher powers of the energy transfer. The resulting dynamic structure factors, denoted by an index ∞, are given by

$$S^{\infty}_{\mathrm{B/F}}(\boldsymbol{q},\boldsymbol{p})=\mp\frac{1}{(2\pi\hbar)^3}\frac{2\pi m^2}{n\beta q}\frac{1}{1-e^{\beta[q^2/2M+\boldsymbol{q}\cdot\boldsymbol{p}/M]}}\log\left[\frac{1\mp ze^{-(\beta/8m)q^2}e^{-(\beta/2)[q^2/2M+\boldsymbol{q}\cdot\boldsymbol{p}/M]}}{1\mp ze^{-(\beta/8m)q^2}e^{+(\beta/2)[q^2/2M+\boldsymbol{q}\cdot\boldsymbol{p}/M]}}\right]\qquad(31)$$

and

$$S^{\infty}_{\mathrm{MB}}(\boldsymbol{q},\boldsymbol{p})=\frac{1}{(2\pi\hbar)^3}\frac{2\pi m^2}{n\beta q}ze^{-(\beta/8m)q^2}e^{-(\beta/2)[q^2/2M+\boldsymbol{q}\cdot\boldsymbol{p}/M]}, \tag{32}$$

respectively. Considering the corresponding expressions in terms of $E(\boldsymbol{q},\boldsymbol{p})$,

$$S^{\infty}_{\mathrm{B/F}}(\boldsymbol{q},E(\boldsymbol{q},\boldsymbol{p}))=\mp\frac{1}{(2\pi\hbar)^3}\frac{2\pi m^2}{n\beta q}\frac{1}{1-e^{\beta E(\boldsymbol{q},\boldsymbol{p})}}\log\left[\frac{1\mp ze^{-(\beta/8m)q^2}e^{-(\beta/2)\,E(\boldsymbol{q},\boldsymbol{p})}}{1\mp ze^{-(\beta/8m)q^2}e^{+(\beta/2)\,E(\boldsymbol{q},\boldsymbol{p})}}\right] \tag{33}$$

and

$$S^{\infty}_{\mathrm{MB}}(\boldsymbol{q},E(\boldsymbol{q},\boldsymbol{p}))=\frac{1}{(2\pi\hbar)^3}\frac{2\pi m^2}{n\beta q}ze^{-(\beta/8m)q^2}e^{-(\beta/2)\,E(\boldsymbol{q},\boldsymbol{p})}, \tag{34}$$

one immediately sees that rotational invariance is preserved in this approximation. One can check that also the detailed balance condition is not spoiled. In fact from (33) one has

$$\begin{aligned}e^{-\beta E}S^{\infty}_{\mathrm{B/F}}(-\boldsymbol{q},-E)&=\mp\frac{1}{(2\pi\hbar)^3}\frac{2\pi m^2}{n\beta q}\frac{e^{-\beta E}}{1-e^{-\beta E}}\log\left[\frac{1\mp ze^{-(\beta/8m)q^2}e^{+(\beta/2)\,E}}{1\mp ze^{-(\beta/8m)q^2}e^{-(\beta/2)\,E}}\right]\\&=\mp\frac{1}{(2\pi\hbar)^3}\frac{2\pi m^2}{n\beta q}\frac{1}{1-e^{\beta E}}\log\left[\frac{1\mp ze^{-(\beta/8m)q^2}e^{-(\beta/2)\,E}}{1\mp ze^{-(\beta/8m)q^2}e^{+(\beta/2)\,E}}\right]\\&=S^{\infty}_{\mathrm{B/F}}(\boldsymbol{q},E),\end{aligned}$$

and from (34)

$$e^{-\beta E}S^{\infty}_{\mathrm{MB}}(-\boldsymbol{q},-E)=\frac{1}{(2\pi\hbar)^3}\frac{2\pi m^2}{n\beta q}ze^{-(\beta/8m)q^2}e^{-\beta E(\boldsymbol{q},\boldsymbol{p})}e^{(\beta/2)\,E(\boldsymbol{q},\boldsymbol{p})}=S^{\infty}_{\mathrm{MB}}(\boldsymbol{q},E).$$

As a result, in place of (29) we now consider the mapping $\mathcal{M}^{\infty}_{\mathrm{B/F}}$:

$$\begin{aligned}\frac{d\hat{\varrho}}{dt}=\mathcal{M}^{\infty}_{\mathrm{B/F}}[\hat{\varrho}]&=-\frac{i}{\hbar}[\hat{H}_0,\hat{\varrho}]+\int_{\mathbf{R}^3}d\mu(\boldsymbol{q})\\&\times\left[\hat{U}(\boldsymbol{q})\sqrt{S^{\infty}_{\mathrm{B/F}}(\boldsymbol{q},\hat{\boldsymbol{p}})}\,\hat{\varrho}\,\sqrt{S^{\infty}_{\mathrm{B/F}}(\boldsymbol{q},\hat{\boldsymbol{p}})}\hat{U}^{\dagger}(\boldsymbol{q})-\frac{1}{2}\{S^{\infty}_{\mathrm{B/F}}(\boldsymbol{q},\hat{\boldsymbol{p}}),\hat{\varrho}\}\right],\end{aligned} \tag{35}$$

and similarly $\mathcal{M}^{\infty}_{\mathrm{MB}}$ for Maxwell–Boltzmann statistics. $\mathcal{M}^{\infty}_{\mathrm{B/F}}$ and $\mathcal{M}^{\infty}_{\mathrm{MB}}$ are still translation- and rotation-covariant and admit the same stationary solution with the canonical structure $\rho_0(\hat{\boldsymbol{p}})$.

In the master equation (1), or according to the physical system under consideration (29) or (35), the quantum scattering rate or transition probability appears through the dynamic structure factor and the square modulus of the Fourier transform of the T matrix determining the integration measure (3), these quantities being connected to the differential scattering cross-section by (7). In order to pass from the master equation to the related Fokker–Planck equation through a Kramers–Moyal expansion, as stressed by van Kampen[17] we need to put into evidence a small parameter governing the size of the fluctuations in the macroscopic system. In our case this parameter is naturally given by the momentum transfer $\boldsymbol{q}$, which through the dynamic structure factor is directly linked to the equilibrium fluctuations of the macroscopic system. Small $\boldsymbol{q}$ means long-wavelength fluctuations, corresponding to the macroscopic, long range properties of the environment. It is physically meaningful to consider both approximations $|\boldsymbol{q}|\ll 1$ and $\alpha\ll 1$, or equivalently small energy transfer, together, so that starting from the Maxwell–Boltzmann case,

$$\mathcal{M}^{\infty}_{\mathrm{MB}}[\cdot]=-\frac{i}{\hbar}[\hat{H}_0,\cdot]+z\frac{4\pi^2m^2}{\beta\hbar}\int_{\mathbf{R}^3}d^3\boldsymbol{q}\frac{|\tilde{t}(q)|^2}{q}e^{-(\beta/8m)(1+2\alpha)q^2}$$
$$\times\left[e^{(i/\hbar)\boldsymbol{q}\cdot\hat{\boldsymbol{x}}}e^{-(\beta/4M)\boldsymbol{q}\cdot\hat{\boldsymbol{p}}}.e^{-(\beta/4M)\boldsymbol{q}\cdot\hat{\boldsymbol{p}}}e^{-(i/\hbar)\boldsymbol{q}\cdot\hat{\boldsymbol{x}}}-\frac{1}{2}\{e^{-(\beta/2M)\boldsymbol{q}\cdot\hat{\boldsymbol{p}}},\cdot\}\right]$$

we expand the dissipative part of the mapping in the small parameter $\boldsymbol{q}$. We will expand the operators depending on $\boldsymbol{q}$ up to second order, so as to have contributions at most bilinear in the operators $\hat{\boldsymbol{x}}$ and $\hat{\boldsymbol{p}}$, position and momentum of the Brownian particle. We thus obtain a structure analogous to the classical Fokker–Planck equation, with a friction term linearly proportional to velocity: this class of models is known as quantum Brownian motion.[18–20] Recalling that $\alpha\ll 1$ and exploiting the symmetry properties of the integration measure the result for the dissipative part is[7]

$$-z\frac{2\pi^2m^2}{\beta\hbar}\int_{\mathbf{R}^3}d^3\boldsymbol{q}\frac{|\tilde{t}(q)|^2}{q}e^{-(\beta/8m)\,q^2}\sum_{i=1}^{3}\boldsymbol{q}_i^2$$
$$\times\left\{\frac{1}{\hbar^2}[\hat{\boldsymbol{x}}_i,[\hat{\boldsymbol{x}}_i,\cdot]]+\frac{\beta^2}{16M^2}[\hat{\boldsymbol{p}}_i,[\hat{\boldsymbol{p}}_i,\cdot]]+\frac{i}{\hbar}\frac{\beta}{2M}[\hat{\boldsymbol{x}}_i,\{\hat{\boldsymbol{p}}_i,\cdot\}]\right\},$$

where $i=1,2,3$ denotes Cartesian coordinates. Due to the isotropy of the environment we have $\boldsymbol{q}_i^2=\frac{1}{3}q^2$, so that we can define the coefficients

$$D_{pp}=\frac{2}{3}\frac{\pi^2m^2}{\beta\hbar}\int_{\mathbf{R}^3}d^3\boldsymbol{q}\,|\tilde{t}(q)|^2qe^{-(\beta/8m)\,q^2},$$

$$D_{xx}=\left(\frac{\beta\hbar}{4M}\right)^2D_{pp}, \tag{36}$$

$$\gamma=\left(\frac{\beta}{2M}\right)D_{pp},$$

and introduce the following mapping describing quantum dissipation:

$$\mathcal{L}_{\mathrm{QD}}[\cdot]=-\frac{D_{pp}}{\hbar^2}\sum_{i=1}^{3}[\hat{\boldsymbol{x}}_i,[\hat{\boldsymbol{x}}_i,\cdot]]-\frac{D_{xx}}{\hbar^2}\sum_{i=1}^{3}[\hat{\boldsymbol{p}}_i,[\hat{\boldsymbol{p}}_i,\cdot]]-\frac{i}{\hbar}\gamma\sum_{i=1}^{3}[\hat{\boldsymbol{x}}_i,\{\hat{\boldsymbol{p}}_i,\cdot\}], \tag{37}$$

thus coming to the Fokker–Planck equation

$$\frac{d\hat{\varrho}}{dt}=-\frac{i}{\hbar}[\hat{H}_0,\hat{\varrho}]+\mathcal{L}_{\mathrm{MB}}[\hat{\varrho}]=-\frac{i}{\hbar}[\hat{H}_0,\hat{\varrho}]+z\mathcal{L}_{\mathrm{QD}}[\hat{\varrho}]. \tag{38}$$

In view of the result (38) for the Fokker–Planck equation describing the motion of the Brownian particle in a gas obeying Maxwell–Boltzmann statistics, we now look for the corrections to (38) brought about by quantum statistics at finite temperature. As usual we will deal with both Bose and Fermi statistics, exploiting expression (B6) obtained in Appendix B by deriving an exact expansion for $S^{\infty}_{\mathrm{B/F}}(\boldsymbol{q},E)$:

$$S^{\infty}_{\mathrm{B/F}}(\boldsymbol{q},E)=S^{\infty}_{\mathrm{MB}}(\boldsymbol{q},E)\Bigg[\sum_{k=0}^{\infty}(\pm z)^k-\frac{\beta}{8m}q^2\sum_{k=1}^{\infty}(\pm)^k k z^k + \frac{1}{12}(\beta E)^2\sum_{k=1}^{\infty}(\pm)^k k z^k+\frac{1}{24}(\beta E)^2\sum_{k=1}^{\infty}(\pm)^k k^2 z^k+O(q^4)\Bigg], \tag{39}$$

where a suitable expansion in the small parameter $\boldsymbol{q}$ has already been performed. Let us first introduce the Bose–Einstein and the Fermi–Dirac functions,[21,22] given by

$$g_{\nu}(z)=\frac{1}{\Gamma(\nu)}\int_0^{+\infty}dx\,\frac{x^{\nu-1}}{z^{-1}e^x-1},\quad 0\leqslant z<1,\ \nu>0, \tag{40}$$

and

$$f_{\nu}(z)=\frac{1}{\Gamma(\nu)}\int_0^{+\infty}dx\,\frac{x^{\nu-1}}{z^{-1}e^x+1},\quad 0\leqslant z<\infty,\ \nu>0, \tag{41}$$

respectively, related for integer ν by $f_n(z)=-g_n(-z)$. These functions, typically appearing in the quantum statistical mechanics of Bose and Fermi systems, satisfy the recurrence relations

$$g_{\nu-1}(z)=z\frac{\partial}{\partial z}[g_{\nu}(z)],\quad f_{\nu-1}(z)=z\frac{\partial}{\partial z}[f_{\nu}(z)], \tag{42}$$

so that they can be defined also for $\nu\leqslant 0$. Starting from (42) and exploiting the following representations for $|z|<1$,

$$g_{\nu}(z)=\sum_{k=1}^{\infty}\frac{z^k}{k^{\nu}},\quad f_{\nu}(z)=\sum_{k=1}^{\infty}(-)^{k-1}\frac{z^k}{k^{\nu}},$$

one can write (39) in the Bose case as

$$S^{\infty}_{\mathrm{B}}(\boldsymbol{q},E)=S^{\infty}_{\mathrm{MB}}(\boldsymbol{q},E)\left[\frac{g_0(z)}{z}-\frac{\beta}{8m}q^2 g_{-1}(z)+\frac{1}{24}(\beta E)^2(g_{-2}(z)+2g_{-1}(z))+O(q^4)\right] \tag{43}$$

and in the Fermi case as

$$S^{\infty}_{\mathrm{F}}(\boldsymbol{q},E)=S^{\infty}_{\mathrm{MB}}(\boldsymbol{q},E)\left[\frac{f_0(z)}{z}+\frac{\beta}{8m}q^2 f_{-1}(z)-\frac{1}{24}(\beta E)^2(f_{-2}(z)+2f_{-1}(z))+O(q^4)\right], \tag{44}$$

where the functions appearing in (43) can be written for $0\leqslant z<1$ in closed form as

$$g_0(z)=\frac{z}{1-z},\qquad g_{-1}(z)=\frac{z}{(1-z)^2},\quad g_{-2}(z)=\frac{z+z^2}{(1-z)^3}, \tag{45}$$

while the functions appearing in (44) can be written for $0\leqslant z<\infty$ in closed form as

$$f_0(z)=\frac{z}{1+z}, \tag{46}$$

$$f_{-1}(z)=\frac{z}{(1+z)^2},\quad f_{-2}(z)=\frac{z-z^2}{(1+z)^3}.$$

To evaluate the corrections due to quantum statistics we note that when $S^{\infty}_{\mathrm{MB}}(\boldsymbol{q},E(\boldsymbol{q},\boldsymbol{p}))$ is substituted by an expression of the form

$$S^{\infty}_{\mathrm{MB}}(\boldsymbol{q},E(\boldsymbol{q},\boldsymbol{p}))A[1+2Bq^2+2C(\boldsymbol{p}\cdot\boldsymbol{q})^2],$$

so that keeping terms at most quadratic in $\boldsymbol{q}$ in the correction

$$\sqrt{S^{\infty}_{\mathrm{MB}}(\boldsymbol{q},E(\boldsymbol{q},\boldsymbol{p}))}\to\sqrt{S^{\infty}_{\mathrm{MB}}(\boldsymbol{q},E(\boldsymbol{q},\boldsymbol{p}))}\sqrt{A}[1+Bq^2+C(\boldsymbol{p}\cdot\boldsymbol{q})^2],$$

the mapping $\mathcal{M}^{\infty}_{\mathrm{MB}}$ always in the same approximation becomes

$$\begin{aligned}
&-\frac{i}{\hbar}[\hat{H}_0,\cdot]+A\int_{\mathbf{R}^3}d\mu(\boldsymbol{q})\left[\hat{U}(\boldsymbol{q})\sqrt{S^{\infty}_{\mathrm{MB}}(\boldsymbol{q},\hat{\boldsymbol{p}})}\cdot\sqrt{S^{\infty}_{\mathrm{MB}}(\boldsymbol{q},\hat{\boldsymbol{p}})}\hat{U}^{\dagger}(\boldsymbol{q})-\frac{1}{2}\{S^{\infty}_{\mathrm{MB}}(\boldsymbol{q},\hat{\boldsymbol{p}}),\cdot\}\right]\\
&\quad+2AB\int_{\mathbf{R}^3}d\mu(\boldsymbol{q})\,q^2\left[\hat{U}(\boldsymbol{q})\sqrt{S^{\infty}_{\mathrm{MB}}(\boldsymbol{q},\hat{\boldsymbol{p}})}\cdot\sqrt{S^{\infty}_{\mathrm{MB}}(\boldsymbol{q},\hat{\boldsymbol{p}})}\hat{U}^{\dagger}(\boldsymbol{q})-\frac{1}{2}\{S^{\infty}_{\mathrm{MB}}(\boldsymbol{q},\hat{\boldsymbol{p}}),\cdot\}\right]\\
&\quad+AC\int_{\mathbf{R}^3}d\mu(\boldsymbol{q})\,[\hat{U}(\boldsymbol{q})\sqrt{S^{\infty}_{\mathrm{MB}}(\boldsymbol{q},\hat{\boldsymbol{p}})}\{(\hat{\boldsymbol{p}}\cdot\boldsymbol{q})^2,\cdot\}\sqrt{S^{\infty}_{\mathrm{MB}}(\boldsymbol{q},\hat{\boldsymbol{p}})}\hat{U}^{\dagger}(\boldsymbol{q})-\{S^{\infty}_{\mathrm{MB}}(\boldsymbol{q},\hat{\boldsymbol{p}})(\hat{\boldsymbol{p}}\cdot\boldsymbol{q})^2,\cdot\}].
\end{aligned}\tag{47}$$

Looking at (47) one immediately sees that, keeping terms at most quadratic in $\boldsymbol{q}$, the last two terms are to be neglected, since the dynamic structure factor $S^{\infty}_{\mathrm{MB}}(\boldsymbol{q},\hat{\boldsymbol{p}})$ and the unitary operators $\hat{U}(\boldsymbol{q})$ can now only bring in a constant factor. The only change in the structure of the mapping is therefore given by the numerical factor A multiplying the dissipative part. This factor is actually given by $g_0(z)/z$ in the Bose case and by $f_0(z)/z$ in the Fermi case. The Fokker–Planck equation (38) in the case of Bose statistics of the gas therefore becomes

$$\frac{d\hat{\varrho}}{dt}=-\frac{i}{\hbar}[\hat{H}_0,\hat{\varrho}]+\mathcal{L}_{\mathrm{B}}[\hat{\varrho}]=-\frac{i}{\hbar}[\hat{H}_0,\hat{\varrho}]+g_0(z)\mathcal{L}_{\mathrm{QD}}[\hat{\varrho}],\tag{48}$$

while for Fermi particles one has

$$\frac{d\hat{\varrho}}{dt}=-\frac{i}{\hbar}[\hat{H}_0,\hat{\varrho}]+\mathcal{L}_{\mathrm{F}}[\hat{\varrho}]=-\frac{i}{\hbar}[\hat{H}_0,\hat{\varrho}]+f_0(z)\mathcal{L}_{\mathrm{QD}}[\hat{\varrho}],\tag{49}$$

and the following simple relations hold:

$$\begin{aligned}
&\mathcal{L}_{\mathrm{MB}}=z\mathcal{L}_{\mathrm{QD}},\\
&\mathcal{L}_{\mathrm{B}}=g_0(z)\mathcal{L}_{\mathrm{QD}}=\frac{z}{1-z}\mathcal{L}_{\mathrm{QD}}=\frac{1}{1-z}\mathcal{L}_{\mathrm{MB}},\\
&\mathcal{L}_{\mathrm{F}}=f_0(z)\mathcal{L}_{\mathrm{QD}}=\frac{z}{1+z}\mathcal{L}_{\mathrm{QD}}=\frac{1}{1+z}\mathcal{L}_{\mathrm{MB}}.
\end{aligned}\tag{50}$$

According to (50) and setting after (36)

$$\gamma_{\mathrm{MB}}=z\gamma=z\frac{\beta}{2M}D_{pp}=z\frac{1}{3}\frac{\pi^2m^2}{M\hbar}\int d^3\boldsymbol{q}\,|\tilde{t}(q)|^2qe^{-(\beta/8m)q^2},\tag{51}$$

one has the following very simple relation between the friction coefficients in (38) and (48) or (49):

$$\gamma_{\mathrm{B/F}}=\frac{\gamma_{\mathrm{MB}}}{1\mp z}. \tag{52}$$

The relationship between the Fokker–Planck equations for Maxwell–Boltzmann or Bose and Fermi statistics, as given, respectively, by (38), (48) and (49), is actually remarkably simple: they have the very same operator structure, apart from an overall coefficient depending on the fugacity of the gas, which determines the relative weight of the dissipative contribution to the dynamics. As it is to be expected, only the statistics of the reservoir is of relevance, since the test particle is a single particle. The Fokker–Planck equations obtained for the description of quantum dissipation may be compactly written:

$$\frac{d\hat{\varrho}}{dt}=-\frac{i}{\hbar}[\hat{H}_0,\hat{\varrho}]+\zeta(z)\mathcal{L}_{\mathrm{QD}}[\hat{\varrho}], \tag{53}$$

with $\zeta(z)$ defined as follows:

$$\zeta(z)=\begin{cases} z, & \text{Maxwell–Boltzmann,}\\ z/(1-z), & \text{Bose,}\\ z/(1+z) & \text{Fermi.}\end{cases} \tag{54}$$

We now briefly come back to the question dealt with at the end of Sec. II about the physical relevance of the structure of the translation-covariant master equation obtained in Ref. 16. As already stressed, the master equation (1), while having the general translation-covariant structure considered in Ref. 11, does not comply with the further restrictions given in Ref. 16, while this would be the case if instead of the dynamic structure factor $S(\boldsymbol{q},\boldsymbol{p})$ one would consider the symmetrized correlation function $\tilde{S}(\boldsymbol{q},\boldsymbol{p})$, which is an even function of $\boldsymbol{q}$ and $E(\boldsymbol{q},\boldsymbol{p})$. This could be considered a natural phenomenological ansatz in view of the result obtained in Ref. 16. In Sec. II we showed, however, that this substitution would spoil the existence of the expected stationary solution. More than this, if we now consider the Brownian limit, the symmetrized version of $S^{\infty}_{\mathrm{MB}}(\boldsymbol{q},\hat{\boldsymbol{p}})$, which can be immediately obtained from (34), reads

$$\tilde{S}^{\infty}_{\mathrm{MB}}(\boldsymbol{q},E(\boldsymbol{q},\boldsymbol{p}))=\frac{1}{(2\pi\hbar)^3}\frac{2\pi m^2}{n\beta q}ze^{-(\beta/8m)q^2},$$

so that the dependence on $\boldsymbol{p}$ is completely lost and the whole operator structure in (37) and (38) is washed out, apart from the double commutator with the position operators $\hat{\boldsymbol{x}}_i$. In particular the friction term is missing, so that, even though a Lindblad structure is retained, only a completely different physics can be described. In the same way, for the Bose or Fermi dynamic structure factor in the Brownian limit one has from (B6)

$$\tilde{S}^{\infty}_{\mathrm{B/F}}(\boldsymbol{q},E)=\tilde{S}^{\infty}_{\mathrm{MB}}(\boldsymbol{q},E)\Bigg[\sum_{k=0}^{\infty}(\pm z)^k-\frac{\beta}{8m}q^2\sum_{k=1}^{\infty}(\pm)^k kz^k + \frac{1}{12}(\beta E)^2\sum_{k=1}^{\infty}(\pm)^k kz^k+\frac{1}{24}(\beta E)^2\sum_{k=1}^{\infty}(\pm)^k k^2z^k+O(q^4)\Bigg],$$

and, once again, recalling (47) written in terms of $\tilde{S}^{\infty}_{\mathrm{MB}}$ rather than S^{∞}_{MB}, one sees that under the same approximations as before the operator structure in the dissipative part of both (48) and (49) is washed out apart from the contribution due to the double commutator in the position operators of the particle $\hat{\boldsymbol{x}}_i$.

We now consider some structural features of the mapping $\mathcal{L}_{\mathrm{QD}}$ given by (37) in terms of which the Fokker–Planck equation (53) encompassing all three statistics is given. G-covariance of $\mathcal{L}_{\mathrm{QD}}$ under translations and rotations immediately follows from its very structure and the transformation laws for the operators $\hat{\boldsymbol{x}}$ and $\hat{\boldsymbol{p}}$:

$$\hat{U}^{\dagger}(\boldsymbol{a})\hat{\boldsymbol{x}}\hat{U}(\boldsymbol{a})=\hat{\boldsymbol{x}}+\boldsymbol{a},\quad \hat{U}^{\dagger}(\boldsymbol{a})\hat{\boldsymbol{p}}\hat{U}(\boldsymbol{a})=\hat{\boldsymbol{p}},\quad \hat{U}^{\dagger}(R)\hat{\boldsymbol{x}}\hat{U}(R)=R\hat{\boldsymbol{x}},\quad \hat{U}^{\dagger}(R)\hat{\boldsymbol{p}}\hat{U}(R)=R\hat{\boldsymbol{p}}.$$

One can also see that an operator with the expected canonical structure is a stationary solution of (53) in that

$$\mathcal{L}_{\mathrm{QD}}[\rho_0(\hat{\boldsymbol{p}})]=0,$$

due to the relationship

$$\frac{\gamma}{D_{pp}}=\frac{\beta}{2M} \tag{55}$$

obeyed by the coefficients defined in (36) and entering in (37). A few more remarks are in order. The typical structure of translation-covariant mappings describing quantum dissipation in analogy with the classical Fokker–Planck equation that one finds in the physical literature is given by[23]

$$\mathcal{L}^{\chi}_{\mathrm{FP}}[\,\cdot\,]=-\frac{i}{\hbar}\gamma\sum_{i=1}^{3}[\hat{\boldsymbol{x}}_i,\{\hat{\boldsymbol{p}}_i,\cdot\}]-\frac{1}{\hbar^2}\frac{2M\gamma}{\beta}\sum_{i=1}^{3}[\hat{\boldsymbol{x}}_i,[\hat{\boldsymbol{x}}_i,\cdot]]-\chi\frac{\beta\gamma}{M}\sum_{i=1}^{3}[\hat{\boldsymbol{p}}_i,[\hat{\boldsymbol{p}}_i,\cdot]], \tag{56}$$

where the ratio between the first two coefficients, given by $\beta/2M$ as in (55), is fixed by the requirement that $\rho_0(\hat{\boldsymbol{p}})$ be a stationary solution, i.e., $\mathcal{L}^{\chi}_{\mathrm{FP}}[\rho_0(\hat{\boldsymbol{p}})]=0$, and the only freedom left, apart from the overall multiplying coefficient γ, is given by the adimensional factor χ. If one further asks that (56) can be cast in Lindblad form, so that $\mathcal{L}^{\chi}_{\mathrm{FP}}$ is the generator of a completely positive dynamical semigroup,[19] one has the further simple requirement[18,24]

$$\chi\geqslant\tfrac{1}{8}. \tag{57}$$

In fact under this condition, observing that for the operators

$$\hat{\boldsymbol{B}}_{i\pm}=\hat{\boldsymbol{x}}_i\pm i\kappa\hat{\boldsymbol{p}}_i$$

we have the identity

$$\hat{\boldsymbol{B}}_{i\pm}\cdot\hat{\boldsymbol{B}}^{\dagger}_{i\pm}-\tfrac{1}{2}\{\hat{\boldsymbol{B}}^{\dagger}_{i\pm}\hat{\boldsymbol{B}}_{i\pm},\cdot\}=-\tfrac{1}{2}\{[\hat{\boldsymbol{x}}_i,[\hat{\boldsymbol{x}}_i,\cdot]]+\kappa^2[\hat{\boldsymbol{p}}_i,[\hat{\boldsymbol{p}}_i,\cdot]]\pm 2i\kappa[\hat{\boldsymbol{x}}_i,\{\hat{\boldsymbol{p}}_i,\cdot\}]\mp i\kappa[\{\hat{\boldsymbol{x}}_i,\hat{\boldsymbol{p}}_i\},\cdot]\},$$

we may write $\mathcal{L}^{\chi}_{\mathrm{FP}}$ in an explicit Lindblad form in terms of the two generators

$$\hat{\boldsymbol{L}}_{i+}=\hat{\boldsymbol{x}}_i+i\frac{\hbar\beta}{M}\sqrt{\frac{\chi}{2}}\,\hat{\boldsymbol{p}}_i,\quad \hat{\boldsymbol{L}}_{i-}=\hat{\boldsymbol{x}}_i-i\frac{\hbar\beta}{M}\sqrt{\frac{\chi}{2}}\,\hat{\boldsymbol{p}}_i$$

according to

$$\mathcal{L}^{\chi}_{\mathrm{FP}}[\cdot]=+\frac{2\gamma M}{\hbar^2\beta}\left(1+\sqrt{\frac{1}{8\chi}}\right)\sum_{i=1}^{3}\left[\hat{\boldsymbol{L}}_{i+}\cdot\hat{\boldsymbol{L}}^{\dagger}_{i+}-\frac{1}{2}\{\hat{\boldsymbol{L}}^{\dagger}_{i+}\hat{\boldsymbol{L}}_{i+},\cdot\}\right]$$

$$+\frac{2\gamma M}{\hbar^2\beta}\left(1-\sqrt{\frac{1}{8\chi}}\right)\sum_{i=1}^{3}\left[\hat{\boldsymbol{L}}_{i-}\cdot\hat{\boldsymbol{L}}^{\dagger}_{i-}-\frac{1}{2}\{\hat{\boldsymbol{L}}^{\dagger}_{i-}\hat{\boldsymbol{L}}_{i-},\cdot\}\right]-\frac{i}{\hbar}\frac{\gamma}{2}\sum_{i=1}^{3}[\{\hat{\boldsymbol{x}}_i,\hat{\boldsymbol{p}}_i\},\cdot]. \tag{58}$$

The Fokker–Planck structure $\mathcal{L}_{\mathrm{QD}}$ falls within this class, with the coefficient γ given by (36) in terms of a suitable integral of the Fourier transform of the T matrix describing collisions at microphysical level. Moreover, it corresponds to the value $\chi=\frac{1}{8}$ in (57), so that

$$\mathcal{L}_{\mathrm{QD}}=\mathcal{L}^{1/8}_{\mathrm{FP}}. \tag{59}$$

This in turn implies that $\mathcal{L}_{\mathrm{QD}}$ can be written in a manifest Lindblad form in terms of a single generator for each Cartesian direction. We make the choice[7,24]

$$\hat{\boldsymbol{a}}_i=\frac{\sqrt{2}}{\lambda_M}\left(\hat{\boldsymbol{x}}_i+\frac{i}{\hbar}\frac{\lambda_M^2}{4}\hat{\boldsymbol{p}}_i\right),$$

where $\lambda_M=\sqrt{\hbar^2\beta/M}$, the thermal wavelength associated to the Brownian particle, is put into evidence, so that one has the commutation relations

$$[\hat{\boldsymbol{a}}_i,\hat{\boldsymbol{a}}^{\dagger}_j]=\delta_{ij}.$$

In such a way we have the alternative expression

$$\mathcal{L}_{\mathrm{QD}}[\cdot]=-\frac{D_{pp}}{\hbar^2}\frac{\lambda_M^2}{4}\sum_{i=1}^{3}\frac{i}{\hbar}[\{\hat{\boldsymbol{x}}_i,\hat{\boldsymbol{p}}_i\},\cdot]+\frac{D_{pp}}{\hbar^2}\lambda_M^2\sum_{i=1}^{3}\left[\hat{\boldsymbol{a}}_i\cdot\hat{\boldsymbol{a}}^{\dagger}_i-\frac{1}{2}\{\hat{\boldsymbol{a}}^{\dagger}_i\hat{\boldsymbol{a}}_i,\cdot\}\right], \tag{60}$$

in which the single generator feature is put into evidence.

V. CONCLUSIONS AND REMARKS

In this article we have considered the behavior with respect to covariance under translations and rotations, and the existence of a stationary solution of a recently proposed master equation (1) for the description of the interaction of a test particle with a fluid, a physical model corresponding to the so-called Rayleigh gas. The key result in (1) is the appearance of a two-point correlation function known as dynamic structure factor and given by (4), the general structure conforming to results already obtained in the mathematical literature for the generator of a translation-covariant dynamical semigroup. This correlation function, depending on symmetry and statistical mechanics properties of the fluid, directly determines the behavior of the master equation with respect to covariance under translations and rotations, and existence of a stationary solution with the expected canonical form. Considering the specific case of a free gas, the dynamic structure factor has been explicitly evaluated for Bose, Fermi, and Maxwell–Boltzmann statistics, and the dependence on the physical parameters determining the peculiar features of the model under consideration has been put into evidence in an exact expansion of the dynamic structure function. These parameters are the fugacity of the gas z, the ratio between mass of the gas particles and of the test particle α, the transferred momentum $\boldsymbol{q}$, and the transferred energy $E(\boldsymbol{q},\boldsymbol{p})$. Stability of the covariance properties of the master equation and of the existence of a stationary solution is then considered in the limit in which these parameters are small, together with the different explicit expressions of the master equation. In particular, in the Brownian limit $\alpha\ll 1$ and considering small momentum transfer, corresponding through the physical interpretation of the dynamic structure factor to long-wavelength fluctuations, a Fokker–Planck equation with a Lindblad structure is obtained, given by (53), where the results corresponding to Bose, Fermi, and Maxwell–Boltzmann statistics

are jointly considered. The correction due to quantum statistics in the Fokker-Planck equation is simply expressed through the Bose and Fermi functions given by (45) and (46), respectively.

ACKNOWLEDGMENTS

The author would like to thank Professor L. Lanz for his support during the whole work and Professor A. Barchielli and Professor A. S. Holevo for useful suggestions. He also thanks Dr. F. Belgiorno for careful reading of the manuscript. This work was supported by MURST under Cofinanziamento and Progetto Giovani.

APPENDIX A: DERIVATION OF EQ. (23) AND EQ. (25)

In this Appendix we want to explicitly calculate the expression of the dynamic structure factor for a free gas as a function of $\boldsymbol{q}$ and $\boldsymbol{p}$. Working at finite temperature we can carry out the calculation for both Bose and Fermi particles at the same time adopting the convention that the symbol $\pm$ means a $+$ sign for Bose particles and $-$ for Fermi particles. We start from the expression

$$S_{\mathrm{B/F}}(\boldsymbol{q},\boldsymbol{p})=\frac{1}{n}\int_{\mathbf{R}^3}\frac{d^3\boldsymbol{k}}{(2\pi\hbar)^3}\,\langle n_k\rangle_{\mathrm{B/F}}(1\pm\langle n_{k-q}\rangle_{\mathrm{B/F}})\,\delta\left(\frac{(\boldsymbol{p}+\boldsymbol{q})^2}{2M}+\frac{(\boldsymbol{k}-\boldsymbol{q})^2}{2m}-\frac{\boldsymbol{p}^2}{2M}-\frac{\boldsymbol{k}^2}{2m}\right)$$

with

$$\langle n_k\rangle_{\mathrm{B/F}}=\frac{1}{z^{-1}e^{\beta\epsilon_k}\mp 1},\qquad \epsilon_k=\frac{\boldsymbol{k}^2}{2m},$$

which can be found, for example, in Ref. 12 and corresponds to (4) for a free gas apart from a singular term proportional, in the continuum limit considered here, to $\delta^3(\boldsymbol{q})$, relevant only for $\boldsymbol{q}=0$ and not contributing to the master equation. In fact, in the derivation of the master equation the contributions for $\boldsymbol{q}=0$ exactly cancel out. This term according to (7) corresponds to forward scattering. We now have to evaluate the integral in $\boldsymbol{k}$. This is most easily done writing $S_{\mathrm{B/F}}(\boldsymbol{q},\boldsymbol{p})$ in the form

$$S_{\mathrm{B/F}}(\boldsymbol{q},\boldsymbol{p})=\frac{1}{n}\int_{\mathbf{R}^3}\frac{d^3\boldsymbol{k}}{(2\pi\hbar)^3}\,\langle n_k\rangle_{\mathrm{B/F}}(1\pm\langle n_{k-q}\rangle_{\mathrm{B/F}})\,\delta(E(\boldsymbol{q},\boldsymbol{p})+\epsilon_{k-q}-\epsilon_k)$$

and observing that

$$\langle n_k\rangle_{\mathrm{B/F}}(1\pm\langle n_{k-q}\rangle_{\mathrm{B/F}})=\frac{1}{1-e^{\beta(\epsilon_k-\epsilon_{k-q})}}(\langle n_k\rangle_{\mathrm{B/F}}-\langle n_{k-q}\rangle_{\mathrm{B/F}}),$$

so that one has

$$\begin{aligned}
S_{\mathrm{B/F}}(\boldsymbol{q},\boldsymbol{p})&=\frac{1}{n}\,\frac{1}{1-e^{\beta E(\boldsymbol{q},\boldsymbol{p})}}\int_{\mathbf{R}^3}\frac{d^3\boldsymbol{k}}{(2\pi\hbar)^3}\,(\langle n_k\rangle_{\mathrm{B/F}}-\langle n_{k-q}\rangle_{\mathrm{B/F}})\,\delta(E(\boldsymbol{q},\boldsymbol{p})+\epsilon_{k-q}-\epsilon_k)\\
&=\frac{1}{n}\,\frac{1}{1-e^{\beta E(\boldsymbol{q},\boldsymbol{p})}}\int_{\mathbf{R}^3}\frac{d^3\boldsymbol{k}}{(2\pi\hbar)^3}\,\{\langle n_k\rangle_{\mathrm{B/F}}\delta(E(\boldsymbol{q},\boldsymbol{p})+\epsilon_{k-q}-\epsilon_k)\\
&\quad-\langle n_k\rangle_{\mathrm{B/F}}\delta(E(\boldsymbol{q},\boldsymbol{p})+\epsilon_k-\epsilon_{k+q})\}\\
&=\frac{1}{n}\,\frac{2m}{1-e^{\beta E(\boldsymbol{q},\boldsymbol{p})}}\int_{\mathbf{R}^3}\frac{d^3\boldsymbol{k}}{(2\pi\hbar)^3}\,\langle n_k\rangle_{\mathrm{B/F}}\{\delta(2mE(\boldsymbol{q},\boldsymbol{p})+q^2-2\boldsymbol{k}\cdot\boldsymbol{q})\\
&\quad-\delta(2mE(\boldsymbol{q},\boldsymbol{p})-q^2-2\boldsymbol{k}\cdot\boldsymbol{q})\}.
\end{aligned}\tag{A1}$$

We are thus led to consider an integral of the form

$$\int_{\mathbf{R}^3} d^3\boldsymbol{k}\,\langle n_k\rangle_{\,\mathrm{B/F}}\,\delta(\,\eta-2\boldsymbol{k}\cdot\boldsymbol{q}) \tag{A2}$$

with η a real parameter. Denoting by ξ the cosine of the angle between $\boldsymbol{k}$ and $\boldsymbol{q}$ the integral in (A2) becomes

$$\begin{aligned} &2\pi\int_{-1}^{1} d\xi \int_0^{+\infty} dk\, k^2 \langle n_k\rangle_{\,\mathrm{B/F}}\,\delta(\,\eta-2\xi kq) \\ &\quad=\int_{-1}^{1} d\xi \int_0^{+\infty} dk\, k^2 \langle n_k\rangle_{\mathrm{B/F}} \int_{-\infty}^{+\infty} dp\, e^{ip(\,\eta-2\xi kq)} \\ &\quad=\int_{-\infty}^{+\infty} dk\, k\langle n_k\rangle_{\,\mathrm{B/F}} \int_{-\infty}^{+\infty} dp\, \frac{e^{ip(\,\eta+2kq)}}{i2pq}. \end{aligned} \tag{A3}$$

and, using the identity

$$k\langle n_k\rangle_{\,\mathrm{B/F}}=\pm\frac{m}{\beta}\frac{d}{dk}\log[1\mp ze^{-\epsilon_k}], \tag{A4}$$

we get, integrating by parts,

$$\begin{aligned} \int_{\mathbf{R}^3} d^3\boldsymbol{k}\,\langle n_k\rangle_{\,\mathrm{B/F}}\,\delta(\,\eta-2\boldsymbol{k}\cdot\boldsymbol{q}) &= \mp\frac{2\pi m}{\beta}\int_{-\infty}^{+\infty} dk\,\log[1\mp ze^{-\epsilon_k}]\int_{-\infty}^{+\infty}\frac{dp}{2\pi}\, e^{ip(\,\eta+2kq)} \\ &= \mp\frac{\pi m}{\beta q}\log\left\{1\mp z\exp\left[-\frac{\beta}{8m}\left(\frac{\eta}{q}\right)^2\right]\right\}. \end{aligned} \tag{A5}$$

Inserting the result (A5) in (A1) one immediately has

$$S_{\mathrm{B/F}}(\boldsymbol{q},\boldsymbol{p})=\mp\frac{1}{(2\pi\hbar)^3}\,\frac{2\pi m^2}{n\beta q}\,\frac{1}{1-e^{\beta E(\boldsymbol{q},\boldsymbol{p})}}\log\left[\frac{1\mp z\,\exp[-(\beta/8m)(2mE(\boldsymbol{q},\boldsymbol{p})+q^2)^2/q^2)]}{1\mp z\,\exp[-(\beta/8m)(2mE(\boldsymbol{q},\boldsymbol{p})-q^2)^2/q^2]}\right]. \tag{A6}$$

In a similar way, starting from the expression of a gas of Maxwell–Boltzmann particles

$$S_{\mathrm{MB}}(\boldsymbol{q},\boldsymbol{p})=\frac{1}{n}\int_{\mathbf{R}^3}\frac{d^3\boldsymbol{k}}{(2\pi\hbar)^3}\,\langle n_k\rangle_{\mathrm{MB}}\,\delta\left(\frac{(\boldsymbol{p}+\boldsymbol{q})^2}{2M}+\frac{(\boldsymbol{k}-\boldsymbol{q})^2}{2m}-\frac{\boldsymbol{p}^2}{2M}-\frac{\boldsymbol{k}^2}{2m}\right),$$

with

$$\langle n_k\rangle_{\mathrm{MB}}=ze^{-\beta\epsilon_k},$$

we write it in the form

$$\begin{aligned} S_{\mathrm{MB}}(\boldsymbol{q},\boldsymbol{p}) &= \frac{1}{n}\int_{\mathbf{R}^3}\frac{d^3\boldsymbol{k}}{(2\pi\hbar)^3}\,\langle n_k\rangle_{\mathrm{MB}}\,\delta(E(\boldsymbol{q},\boldsymbol{p})+\epsilon_{k-q}-\epsilon_k) \\ &= \frac{2m}{n}\int_{\mathbf{R}^3}\frac{d^3\boldsymbol{k}}{(2\pi\hbar)^3}\,\langle n_k\rangle_{\mathrm{MB}}\,\delta(2mE(\boldsymbol{q},\boldsymbol{p})+q^2-2\boldsymbol{k}\cdot\boldsymbol{q}). \end{aligned} \tag{A7}$$

Analogously to (A2) we have to consider

$$\int_{\mathbf{R}^3} d^3\boldsymbol{k}\,\langle n_k\rangle_{\mathrm{MB}}\,\delta(\eta-2\boldsymbol{k}\cdot\boldsymbol{q}),$$

which according to (A3) becomes

$$\int_{-\infty}^{+\infty} dk\,k\langle n_k\rangle_{\mathrm{MB}}\int_{-\infty}^{+\infty} dp\,\frac{e^{ip(\eta+2kq)}}{i2pq}.$$

Exploiting instead of (A4) the relation

$$k\langle n_k\rangle_{\mathrm{MB}}=-\frac{m}{\beta}\frac{d}{dk}ze^{-\epsilon_k}$$

we obtain

$$\int_{\mathbf{R}^3} d^3\boldsymbol{k}\,\langle n_k\rangle_{\mathrm{MB}}\,\delta(\eta-2\boldsymbol{k}\cdot\boldsymbol{q})=\frac{\pi m}{\beta q}z\exp\left[-\frac{\beta}{8m}\left(\frac{\eta}{q}\right)^2\right],$$

which has to be substituted in (A7) leading to

$$S_{\mathrm{MB}}(\boldsymbol{q},\boldsymbol{p})=\frac{1}{(2\pi\hbar)^3}\frac{2\pi m^2}{n\beta q}z\exp\left[-\frac{\beta}{8m}\frac{(2mE(\boldsymbol{q},\boldsymbol{p})+q^2)^2}{q^2}\right]. \tag{A8}$$

APPENDIX B: EXACT EXPANSION OF $S_{\mathrm{B/F}}$ AND DERIVATION OF EQ. (39)

We will now derive an expression for $S_{\mathrm{B/F}}(\boldsymbol{q},\boldsymbol{p})$ equivalent to (27), in which, however, a series expansion in powers of the fugacity z is put into evidence. The starting point is the Taylor expansion for the logarithm $\log(1+x)=\Sigma_{k=1}^{\infty}(-)^{k+1}x^k/k$, which leads us to write (27) in the form

$$S_{\mathrm{B/F}}(\boldsymbol{q},\boldsymbol{p})=\mp\frac{1}{(2\pi\hbar)^3}\frac{2\pi m^2}{n\beta q}\frac{1}{1-e^{(\beta/2m)(2\sigma(\boldsymbol{q},\boldsymbol{p})q-q^2)}}$$
$$\times\sum_{k=1}^{\infty}(-)^{k+1}\frac{(\mp z)^k}{k}e^{-(\beta/2m)\sigma^2(\boldsymbol{q},\boldsymbol{p})}[1-e^{k(\beta/2m)(2\sigma(\boldsymbol{q},\boldsymbol{p})q-q^2)}]. \tag{B1}$$

Considering now in (B1) a geometrical progression of reason $e^{(\beta/2m)(2\sigma(\boldsymbol{q},\boldsymbol{p})q-q^2)}$, according to the formula

$$1-x^k=(1-x)\sum_{n=0}^{k-1}x^n, \tag{B2}$$

Eq. (B1) becomes

$$S_{\mathrm{B/F}}(\boldsymbol{q},\boldsymbol{p})=\frac{1}{(2\pi\hbar)^3}\frac{2\pi m^2}{n\beta q}\sum_{k=1}^{\infty}(\pm)^{k+1}\frac{z^k}{k}e^{-k(\beta/2m)\sigma^2(\boldsymbol{q},\boldsymbol{p})}\sum_{n=0}^{k-1}e^{n(\beta/2m)(2\sigma(\boldsymbol{q},\boldsymbol{p})q-q^2)},$$

where it is to be noted that the sum over n is due to the presence of the statistical correction $1\pm\langle n_{k-q}\rangle_{\mathrm{B/F}}$ in (22) and disappears, being replaced by a factor of 1, if this correction is neglected. It is worthwhile to put into evidence a factor

$$\frac{1}{(2\pi\hbar)^3}\frac{2\pi m^2}{n\beta q}ze^{-(\beta/2m)\sigma^2(\boldsymbol{q},\boldsymbol{p})},$$

corresponding to the expression of the dynamic structure factor for a free gas of Maxwell–Boltzmann particles, thus obtaining

$$S_{\mathrm{B/F}}(\boldsymbol{q},\boldsymbol{p})=S_{\mathrm{MB}}(\boldsymbol{q},\boldsymbol{p})\left[1+\sum_{k=1}^{\infty}(\pm)^k\frac{z^k}{k+1}e^{-k(\beta/2m)\sigma^2(\boldsymbol{q},\boldsymbol{p})}\sum_{n=0}^{k}e^{n(\beta/2m)(2\sigma(\boldsymbol{q},\boldsymbol{p})q-q^2)}\right].$$

In the Brownian limit $\alpha\ll 1$ considered in Sec. IV, neglecting in (30) the contributions of order α, this expression goes simply over to

$$S^{\infty}_{\mathrm{B/F}}(\boldsymbol{q},\boldsymbol{p})=S^{\infty}_{\mathrm{MB}}(\boldsymbol{q},\boldsymbol{p})\left[1+\sum_{k=1}^{\infty}(\pm)^k\frac{z^k}{k+1}e^{-k(\beta/8m)q^2}e^{-k(\beta/2)[q^2/2M+\boldsymbol{q}\cdot\boldsymbol{p}/M]}\sum_{n=0}^{k}e^{n\beta[q^2/2M+\boldsymbol{q}\cdot\boldsymbol{p}/M]}\right], \tag{B3}$$

where $S^{\infty}_{\mathrm{B/F}}(\boldsymbol{q},\boldsymbol{p})$ and $S^{\infty}_{\mathrm{MB}}(\boldsymbol{q},\boldsymbol{p})$ are given, respectively, by (31) and (32). In terms of $E(\boldsymbol{q},\boldsymbol{p})$ Eq. (B3) takes the remarkably compact form

$$S^{\infty}_{\mathrm{B/F}}(\boldsymbol{q},E)=S^{\infty}_{\mathrm{MB}}(\boldsymbol{q},E)\left[1+\sum_{k=1}^{\infty}(\pm)^k\frac{z^k}{k+1}e^{-k(\beta/8m)q^2}e^{-k(\beta/2)E}\sum_{n=0}^{k}e^{n\beta E}\right], \tag{B4}$$

where $S^{\infty}_{\mathrm{B/F}}(\boldsymbol{q},E)$ and $S^{\infty}_{\mathrm{MB}}(\boldsymbol{q},E)$ are given by (33) and (34). We now go one step further noting that the following identity holds:

$$e^{-k(\beta/2)E}\sum_{n=0}^{k}e^{n\beta E}=\frac{\sinh[(k+1)(\beta/2)E]}{\sinh((\beta/2)E)},$$

which can be easily obtained exploiting (B2), so that (B4) becomes

$$S^{\infty}_{\mathrm{B/F}}(\boldsymbol{q},E)=S^{\infty}_{\mathrm{MB}}(\boldsymbol{q},E)\sum_{k=0}^{\infty}(\pm)^k\frac{z^k}{k+1}e^{-k(\beta/8m)q^2}\frac{\sinh[(k+1)(\beta/2)E]}{\sinh((\beta/2)E)}. \tag{B5}$$

Equation (B5) is the most convenient expression in order to consider the limit of small momentum transfer. Exploiting the expansion

$$\frac{\sinh[\frac{1}{2}(k+1)\beta E]}{\sinh(\frac{1}{2}\beta E)}=(k+1)\left[1+\frac{1}{24}(\beta E)^2(k^2+2k)+O(E^4)\right]$$

and recalling that E is given by (6) we may write (B5) as

$$\begin{aligned}S^{\infty}_{\mathrm{B/F}}(\boldsymbol{q},E)=S^{\infty}_{\mathrm{MB}}(\boldsymbol{q},E)\Bigg[&\sum_{k=0}^{\infty}(\pm z)^k-\frac{\beta}{8m}q^2\sum_{k=1}^{\infty}(\pm)^k kz^k\\&+\frac{1}{12}(\beta E)^2\sum_{k=1}^{\infty}(\pm)^k kz^k+\frac{1}{24}(\beta E)^2\sum_{k=1}^{\infty}(\pm)^k k^2z^k+O(q^4)\Bigg].\end{aligned} \tag{B6}$$

Recalling (B5) and the explicit expression of S^{∞}_{MB} given by (22) one also has

$$S^{\infty}_{\mathrm{B/F}}(\boldsymbol{q},E)=\pm\frac{1}{(2\pi\hbar)^3}\frac{2\pi m^2}{n\beta q}\frac{e^{-(\beta/2)E}}{\sinh((\beta/2)E)}\sum_{k=1}^{\infty}(\pm)^k\frac{z^k}{k}e^{-k(\beta/8m)q^2}\sinh\left(k\frac{\beta}{2}E\right)$$

and, exploiting[22]

$$\sum_{k=1}^{\infty} \frac{p^k}{k} \sinh(kx) = \operatorname{arth}\left[\frac{p \sinh x}{1 - p \cosh x}\right],$$

we obtain the alternative expression

$$S^{\infty}_{\mathrm{B/F}}(\boldsymbol{q},E) = \pm \frac{1}{(2\pi\hbar)^3} \frac{2\pi m^2}{n\beta q} \frac{e^{-(\beta/2)E}}{\sinh((\beta/2)E)} \operatorname{arth}\left[\frac{\pm z e^{-(\beta/8m)q^2} \sinh((\beta/2)E)}{1 \mp z e^{-(\beta/8m)q^2} \cosh((\beta/2)E)}\right] \tag{B7}$$

equivalent to (31) as can also be directly checked starting from the identity

$$\operatorname{arth} x = \frac{1}{2} \log\left[\frac{1+x}{1-x}\right]. \tag{B8}$$

Note that (31) and (B7) in the Fermi case can also be written in the form

$$S^{\infty}_{\mathrm{F}}(\boldsymbol{q},E) = -\frac{1}{(2\pi\hbar)^3} \frac{\pi m^2}{n\beta q} \frac{e^{-(\beta/2)E}}{\sinh((\beta/2)E)} \log\left[\frac{1 - [z/(1+z)](1 - e^{-(\beta/8m)q^2} e^{-(\beta/2)E})}{1 - [z/(1+z)](1 - e^{-(\beta/8m)q^2} e^{+(\beta/2)E})}\right]$$

and

$$S^{\infty}_{\mathrm{F}}(\boldsymbol{q},E) = -\frac{1}{(2\pi\hbar)^3} \frac{2\pi m^2}{n\beta q} \frac{e^{-(\beta/2)E}}{\sinh((\beta/2)E)} \operatorname{arth}\left[\frac{[z/(1+z)] e^{-(\beta/8m)q^2} \sinh((\beta/2)E)}{[z/(1+z)](1 - e^{-(\beta/8m)q^2} \cosh((\beta/2)E)) - 1}\right],$$

respectively, which can be useful if one is interested in an expansion for large values of z. According to (B8), also for $S_{\mathrm{B/F}}(\boldsymbol{q},E)$ given by (23) one has the alternative expression

$$S_{\mathrm{B/F}}(\boldsymbol{q},E) = \pm \frac{1}{(2\pi\hbar)^3} \frac{2\pi m^2}{n\beta q} \frac{e^{-(\beta/2)E}}{\sinh((\beta/2)E)} \operatorname{arth}\left[\frac{\pm z e^{-(\beta/8m)q^2} e^{-(\beta/2)(m/q^2)E^2} \sinh((\beta/2)E)}{1 \mp z e^{-(\beta/8m)q^2} e^{-(\beta/2)(m/q^2)E^2} \cosh((\beta/2)E)}\right]. \tag{B9}$$

The validity of the detailed balance condition for (B9) according to (12) can immediately be checked observing that both $\sinh x$ and $\operatorname{arth} x$ are odd functions, while $\cosh x$ is an even function.

We generalize results of Rauch-Wojciechowski, Marciniak and Lundmark, concerning a class of nonconservative Lagrangian systems, from the Euclidean to the Riemannian case. © *2001 American Institute of Physics.*
[DOI: 10.1063/1.1388030]

I. INTRODUCTION

In a number of recent publications,[1–4] Rauch-Wojciechowski, Marciniak, and Lundmark have discussed an interesting class of systems of second-order ordinary differential equations, whose members, when viewed as classical mechanical systems, are in a sense completely integrable. These systems originally generated interest because they are derived from the stationary flows of soliton-type evolution equations; but they have more recently been studied in their own right because they include well-known cases of integrable bi-Hamiltonian systems and cases where the Hamilton–Jacobi equation separates. Of these papers we will refer most often to Ref. 2, which contains the most general exposition of the theory which we seek to develop further. In particular, Ref. 2 deals with systems with n of degrees of freedom, and therefore subsumes (at least so far as the issues we intend to discuss are concerned) Ref. 4, which is largely restricted to systems with two degrees of freedom.

The systems of second-order equations under consideration take the general form of Lagrange's equations in mechanics:

$$\frac{d}{dt}\left(\frac{\partial T}{\partial \dot{q}^i}\right) - \frac{\partial T}{\partial q^i} = Q_i\,,$$

where T is the kinetic energy function and the ''generalized forces'' Q_i need not be derivable from a potential energy function. In all the publications mentioned above the kinetic energy is taken to have the Euclidean form, $T=\frac{1}{2}\Sigma(\dot{q}^i)^2$; we however will deal with the more general situation in which T is derived from a Riemannian metric, $T=\frac{1}{2}g_{ij}\dot{q}^i\dot{q}^j$. In addition, the systems are required to possess quadratic integrals of the motion, of a special kind, called by Lundmark integrals of cofactor type. Of particular interest are those systems which possess two independent quadratic integrals of cofactor type: such a system can be regarded as the restriction of a bi-Hamiltonian flow on a phase space of one more dimension, and has a further hierarchy of integrals in involution.

As we have just pointed out, the primary aim of our article is to derive in the Riemannian case results which parallel those that Lundmark *et al.* have obtained in the Euclidean one. In doing so we, of course, extend the range of application of their theory. However, in justifying our efforts we would put greater emphasis on the increased level of geometrical insight we have achieved into the results of the group in Linköping. In particular, we claim to have considerably clarified, by generalizing them;

a)Electronic mail: m.crampin@open.ac.uk

(1) the concept and properties of a cofactor system;
(2) the origin of the so-called ''fundamental equation'' involved in the definition of a cofactor pair system; and
(3) the construction of the bi-Hamiltonian structure associated with a cofactor pair system.

Several of the methods we use were developed in a recent paper on bi-Hamiltonian systems and conformal Killing tensors,[5] which was concerned with a certain class of conservative systems whose Hamilton–Jacobi equations separate; we will briefly indicate how such systems can be regarded as a subset of the cofactor pair systems discussed in this article.

The Linköping group refer to the differential equations they consider as ''Newton equations of quasi-Lagrangian type,'' because in the Euclidean case it turns out that when there is a quadratic first integral E the equations can formally be cast into the form $d/dt(\partial E/\partial \dot{q}^i)+\partial E/\partial q^i=0$, which resembles Lagrange's equations but has a wrong sign. This is, in our opinion, a complete artifact of the systems under consideration, which has nothing to do with the fundamental issues which are at stake. In fact, the more general systems on Riemannian spaces we will introduce simply do not have this very nonintrinsic property. We have therefore decided to describe them as ''nonconservative Lagrangian systems'' instead. In doing so we are conscious that our work, together with that of Rauch-Wojciechowski, Marciniak, Lundmark and others in this field, is closely connected with the researches of Bertrand and Darboux in the second half of the nineteenth century, which are summarized by Whittaker in articles 151 and 152 of Ref. 6.

The structure of this article is as follows. In Sec. II we recall some aspects of Poisson structures for later use. We concentrate in particular on the construction of a nonstandard Poisson structure on T^*Q out of the complete lift of a type $(1,1)$ tensor field on Q. In Sec. III, we take a non-conservative Lagrangian system as the starting point and investigate under what circumstances it has a quasi-Hamiltonian representation with respect to such a nonstandard Poisson structure. This leads us to an interesting class of special conformal Killing tensors J, which are discussed in more detail in Sec. IV. The main result in that section is that the cofactor tensor of such a J is a Killing tensor. Coming back then to the idea we started from, and inspired by the work of Lundmark[2] in the Euclidean case, we more formally introduce the notion of a cofactor system in Sec. V and complete the discussion of its quasi-Hamiltonian representation. In Sec. VI, we show how a cofactor system can also be given a Hamiltonian representation on an extended manifold. Section VII is about cofactor pair systems, that is, systems which have a double cofactor representation. We show how this leads to a gauged bidifferential calculus which provides an intrinsic generalization of the ''fundamental equations'' referred to above. We further establish complete integrability by exploiting the double Poisson structure on the extended space. Finally, we briefly explain the relation between this work and recent work on the separability of the Hamilton–Jacobi equation.

II. POISSON STRUCTURES

It will be convenient to recall some generalities here about Poisson structures, which will at the same time serve to fix the sign conventions which we will adopt.

A Poisson structure on a manifold M is a bivector field Π which satisfies $[\Pi,\Pi]=0$, where $[\cdot,\cdot]$ is the Schouten bracket. The associated Poisson bracket of functions f, g is given by $\{f,g\}=\Pi(df,dg)$; the vanishing of the Schouten bracket entails the Jacobi identity for the Poisson bracket. Also associated with such a bivector field is a map P of 1-forms to vector fields on M, given by $\langle P(\alpha),\beta\rangle=\Pi(\alpha,\beta)$ for any pair of 1-forms α, β. The vector field $P(dh)$ is the Hamiltonian vector field corresponding to the Hamiltonian function h. The Poisson structure is nonsingular if its Poisson map is.

Two Poisson structures Π_1, Π_2 are compatible if $[\Pi_1,\Pi_2]=0$. When this condition holds, $a_1\Pi_1+a_2\Pi_2$ is Poisson for any constants a_1 and a_2. The collection of Poisson bivectors $a_1\Pi_1+a_2\Pi_2$ is called a Poisson pencil.

Let $\phi:M\to M$ be a diffeomorphism. For any bivector field Π on M we can use ϕ^*, the map of forms induced by ϕ, to transform Π into a new bivector field Π_ϕ by

$$(\Pi_\phi)(\alpha,\beta)=\phi^{-1}{}^*\Pi(\phi^*\alpha,\phi^*\beta).$$

This is the natural extension to bivector fields of the map of vector fields induced by a diffeomorphism. The corresponding transform P_ϕ of the map P is given as a linear map $T_x^*M\to T_xM$, $x\in M$, by

$$P_\phi|_x=\phi_{*x}\circ P|_{\phi^{-1}(x)}\circ\phi_x^*.$$

There is no guarantee that Π_ϕ will be Poisson even when Π is: we will deal with a case in which it is below. For the present, merely note that if ϕ and ψ are two diffeomorphisms then $\Pi_{\phi\circ\psi}=(\Pi_\psi)_\phi$ and likewise $P_{\phi\circ\psi}=(P_\psi)_\phi$.

The cotangent bundle T^*Q of a manifold Q has a standard Poisson bivector Π_0 whose expression in terms of standard coordinates (q^i,p_i) is

$$\Pi_0=\frac{\partial}{\partial p_i}\wedge\frac{\partial}{\partial q^i}.$$

The corresponding Poisson map P_0 is given in terms of the canonical symplectic form ω by $P_0(\alpha)\lrcorner\omega=-\alpha$.

Let J be a nonsingular type (1,1) tensor field on Q. It defines a diffeomorphism $\hat{J}$ of T^*Q which is fiber preserving and linear on fibers, given by $\hat{J}(q^i,p_i)=(q^i,J_i^jp_j)$ (note that J acts here on covectors, that is to say, it is its adjoint that is involved). The bivector field $(\Pi_0)_{\hat{J}}=\Pi_J$ is a Poisson bivector if and only if the torsion, or Nijenhuis tensor, N_J of J is zero. When this is the case Π_J is compatible with Π_0, and we obtain an example of a Poisson–Nijenhuis structure. The corresponding Poisson map P_J is given by $P_J=\tilde{J}\circ P_0=P_0\circ\tilde{J}^*$, where $\tilde{J}$ is the complete lift of J, a type (1,1) tensor field on T^*Q, and $\tilde{J}^*$ is its adjoint (acting on 1-forms).

In the sequel we will carry out several coordinate calculations involving these constructs, in situations where we have a symmetric connection at our disposal. We therefore give coordinate representations of them using bases of local vector fields and 1-forms adapted to the connection, given by

$$\frac{\partial}{\partial q^i}+\Gamma_{ij}^k p_k\frac{\partial}{\partial p_j}=X_i,\quad \frac{\partial}{\partial p_i},$$

for vector fields, where $\Gamma_{ij}^k=\Gamma_{ji}^k$ are the connection coefficients, and

$$dq^i,\quad dp_i-\Gamma_{ij}^k p_k dq^j=\pi_i,$$

for 1-forms; these are dual bases. The indices i, j, k, etc., range over $1,2,\ldots,n=\dim M$, and the Einstein summation convention is in force. Then,

$$\tilde{J}=J_j^i\left(X_i\otimes dq^j+\frac{\partial}{\partial p_j}\otimes\pi_i\right)+(J_{i|j}^k-J_{j|i}^k)p_k\frac{\partial}{\partial p_i}\otimes dq^j.$$

The vertical bar divides off the differentiation index in a covariant differential from the other indices. The condition $N_J=0$ can be written:

$$J_l^k(J_{i|j}^l-J_{j|i}^l)=J_j^lJ_{i|l}^k-J_i^lJ_{j|l}^k.$$

In order to calculate Hamiltonian vector fields with respect to P_J it is enough to know $\tilde{J}$ since one can use either of the formulas $P_J=\tilde{J}\circ P_0$ and $P_J=P_0\circ\tilde{J}^*$; it is useful to remember that for a symmetric connection P_0 can be written

$$P_0=\frac{\partial}{\partial p_i}\wedge X_i\,.$$

However, to facilitate comparison with Refs. 2–4 we give the formula for P_J:

$$P_J=J^i_j\frac{\partial}{\partial p_j}\wedge X_i-\frac{1}{2}(J^k_{i|j}-J^k_{j|i})p_k\frac{\partial}{\partial p_i}\wedge\frac{\partial}{\partial p_j}.$$

Finally, we will have occasion to discuss situations where we have more than one type (1,1) tensor field at our disposal. In the first place, suppose that J has vanishing torsion, and that A is another type (1,1) tensor field such that JA also has vanishing torsion (where JA is the type (1,1) tensor field whose components are $J^i_kA^k_j$, that is, JA is the composition $J\circ A$ acting on vector fields). Then Π_{JA} is a Poisson bivector. It can be expressed in terms of Π_J by means of the formula $\Pi_{\phi\circ\psi}=(\Pi_\psi)_\phi$ with $\phi=\hat{A}$, $\psi=\hat{J}$: note that since A and J act on T^*Q by their adjoints, $\widehat{JA}=\hat{A}\circ\hat{J}$. Thus, $\Pi_{JA}=(\Pi_J)_{\hat{A}}$. It follows that for any Hamiltonian function H,

$$P_{JA}(d(\hat{A}^{-1}{}^*H))=\hat{A}_*P_J(dH).$$

Second, suppose that J and K both have vanishing torsion and that $[J,K]=0$ where $[\,\cdot\,,\cdot\,]$ here is the Nijenhuis bracket. Then $aJ+bK$ has vanishing torsion for all constants a and b, so that P_{aJ+bK} is a Poisson map for all a and b; and from the formula for P_J we see that $P_{aJ+bK}=aP_J+bP_K$. Thus, aP_J+bP_K is a Poisson pencil in this case.

III. NONCONSERVATIVE LAGRANGIAN SYSTEMS

A geometrical description of the kind of general Lagrange equations mentioned in the Introduction can be obtained as follows. Let S denote the canonical vertical endomorphism on a tangent bundle TQ and Γ a second-order differential equation field. As was described in Ref. 7, Γ represents a nonconservative Lagrangian system, if there exists a 1-form $\phi=dL-\mu$ on TQ, where L is a regular Lagrangian and μ is semibasic, such that $\mathcal{L}_\Gamma(S^*(\phi))=\phi$. It is easy to verify that, in coordinates (q^i,u^i) on TQ, this requirement means that

$$\Gamma\left(\frac{\partial L}{\partial u^i}\right)-\frac{\partial L}{\partial q^i}=-M_i\,,$$

where the M_i are the components of μ (the minus sign here is a matter of convention). We shall consider the particular case in which the nonconservative forces $-M_i$ do not depend on the velocities, so that μ is a 1-form on Q; and L is a pure kinetic energy Lagrangian. The latter means that the base manifold Q is assumed to be Riemannian (or pseudo-Riemannian) with metric tensor $g=(g_{ij})$, and that $L=T=\frac{1}{2}g_{ij}u^iu^j$. If Γ^i_{jk} are the Christoffel symbols for the corresponding Levi-Civita connection, and if we put $M^i=g^{ij}M_j$ as is usual, the resulting second-order differential equation field is of the form

$$\Gamma=u^i\frac{\partial}{\partial q^i}-(\Gamma^i_{jk}u^ju^k+M^i)\frac{\partial}{\partial u^i}.$$

Another way of characterizing such vector fields is to say that $\Gamma=\Gamma_0-M^V$, where Γ_0 is the geodesic field for the connection and M^V is the vertical lift of a vector field M on Q.

We will show that it is possible, in certain interesting cases, to find a quasi-Hamiltonian representation for such a system; that is to say, to represent it as a scalar multiple of a Hamiltonian vector field. However, we will not assume that the Poisson structure with respect to which this vector field is Hamiltonian is the standard one; instead, we will look for a suitable Poisson structure of the form Π_J defined by some type (1,1) tensor field J on Q whose torsion vanishes.

We use g to define a diffeomorphism $\hat{g}:TQ\to T^*Q$ by $p_i=g_{ij}u^j$. We will denote by $\hat{\Gamma}$ the transform of Γ by $\hat{g}$, that is, $\hat{\Gamma}=\hat{g}_*\Gamma$. We have

$$\hat{\Gamma}=g^{ij}p_jX_i-M_i\frac{\partial}{\partial p_i},$$

where the X_i are the vector fields on T^*Q adapted to the connection specified above.

Equip T^*Q with a Poisson structure Π_J and Poisson map P_J as described earlier. We wish to determine under what circumstances one can find a J with $N_J=0$ such that the given system satisfies $F\hat{\Gamma}=P_J(dH)$ for some functions F and H. We will now solve this problem under the assumption that H is quadratic in the momenta, so that $H=\frac{1}{2}A^{ij}p_ip_j+V$ for some symmetric tensor A and function V on Q; we will further assume that A is nonsingular.

For such H we find, after a little calculation, that

$$P_J(dH)=J^i_kA^{jk}p_jX_i-\left[\left(\frac{1}{2}J^l_iA^{jk}{}_{|l}-(J^j_{i|l}-J^j_{l|i})A^{kl}\right)p_jp_k+J^j_i\frac{\partial V}{\partial q^j}\right]\frac{\partial}{\partial p_i}.$$

For this to equal $F\hat{\Gamma}$ we must first have

$$J^i_kA^{jk}=Fg^{ij}.$$

Thus F must be a function on Q, so that the quadratic and zeroth-order terms in the other coefficients must be equated separately. As a result, we require that

$$J^l_iA^{jk}{}_{|l}=(J^j_{i|l}-J^j_{l|i})A^{kl}+(J^k_{i|l}-J^k_{l|i})A^{jl}$$

$$J^j_i\frac{\partial V}{\partial q^j}=FM_i.$$

On lowering the index i in the first condition we see that J_{ij} is a scalar multiple of the inverse of A^{ij}, and so is symmetric because A^{ij} is. By differentiating this equation and multiplying by J twice we obtain

$$J^m_jJ^n_kJ^l_iA^{jk}{}_{|l}=\frac{\partial F}{\partial q^l}J^{mn}J^l_i-FJ^l_iJ^{mn}{}_{|l}.$$

The second condition therefore can equivalently be replaced by

$$\frac{\partial F}{\partial q^l}J^{mn}J^l_i=F[J^l_iJ^{mn}{}_{|l}+g^{lm}J^n_k(J^k_{i|l}-J^k_{l|i})+g^{ln}J^m_k(J^k_{i|l}-J^k_{l|i})].$$

We now use the assumption that $N_J=0$ to rearrange the last four terms; when this is done, the first term on the right-hand side cancels, and after some indices have been lowered we obtain

$$\frac{\partial F}{\partial q^l}J_{jk}J^l_i=F(J^l_kJ_{ij|l}+J^l_jJ_{ik|l}-J^l_iJ_{jk|l}).$$

The part of this equation symmetric in i and j gives

$$J_{ij|k}=\tfrac{1}{2}(\alpha_ig_{jk}+\alpha_jg_{ik})$$

where we have written

$$\alpha_i = \frac{1}{F} J_i^j \frac{\partial F}{\partial q^j}.$$

The skew-symmetric part is then automatically satisfied. It further follows from the formula for $J_{ij|k}$ that $\alpha_k = (J_i^i)_{|k}$, or $\alpha = \alpha_i dq^i = d(\operatorname{tr} J)$. Hence, if $J_{ij|k}$ has the required structure, the α_i is actually determined, so that the relations $J_i^j \partial F/\partial q^j = F\alpha_i$ should be seen as equations for admissible functions F.

We next show that a particular solution for F is $\det J$. We have

$$\det J = \frac{1}{n!} \delta^{i_1 i_2 \cdots i_n}_{j_1 j_2 \cdots j_n} J^{j_1}_{i_1} J^{j_2}_{i_2} \cdots J^{j_n}_{i_n},$$

where $\delta^{i_1 i_2 \cdots i_n}_{j_1 j_2 \cdots j_n}$ is the generalized Kronecker delta (see, for example, Ref. 8). Thus

$$\frac{\partial}{\partial q^k} \det J = \frac{1}{(n-1)!} \delta^{i i_2 \cdots i_n}_{j j_2 \cdots j_n} J^j_{i|k} J^{j_2}_{i_2} \cdots J^{j_n}_{i_n}.$$

Now

$$\frac{1}{(n-1)!} \delta^{i i_2 \cdots i_n}_{j j_2 \cdots j_n} J^{j_2}_{i_2} \cdots J^{j_n}_{i_n} = C^i_j$$

is the cofactor tensor of J, which satisfies

$$J^i_k C^k_j = (\det J)\, \delta^i_j.$$

So, we may write

$$J^k_i \frac{\partial}{\partial q^k} \det J = J^k_i C^l_j J^j_{l|k} = \frac{1}{2} J^k_i C^l_j (\alpha_l \delta^j_k + \alpha^j g_{kl}) = \frac{1}{2} (J^j_i C^l_j \alpha_l + J^k_i C^l_k \alpha_l) = (\det J)\, \alpha_i,$$

where we have used the fact that C_{ij} is symmetric, which follows from the symmetry of J_{ij}.

Now suppose that F is any solution: we show that F is a constant multiple of $\det J$. We have

$$\frac{1}{F} J^j_i \frac{\partial F}{\partial q^j} = \alpha_i = \frac{1}{\det J} J^j_i \frac{\partial}{\partial q^j} \det J,$$

from which it follows that

$$J^j_i \frac{\partial}{\partial q^j} \left(\frac{F}{\det J} \right) = 0,$$

and so $F = k \det J$.

Once we have fixed a J in a quasi-Hamiltonian representation $F\hat{\Gamma} = P_J(dH)$ for the given system, multiplying F by a constant factor is a quite irrelevant degree of freedom, since it can be compensated for by adapting the Hamiltonian. So without loss of generality we can take $F = \det J$, when the first condition on J becomes $J^i_k A^{jk} = (\det J) g^{ij}$, and identifies A^i_j as the cofactor tensor of J^i_j. Finally, there is a restriction on the nonconservative forces, which must have the form

$$M_i = (\det J)^{-1} J_i^j \frac{\partial V}{\partial q^j}$$

for some function V on Q.

We shall return to the formulation of the conclusions of this analysis in Sec. V, after looking in more detail at the special kind of tensor fields J has revealed.

IV. SPECIAL CONFORMAL KILLING TENSORS

A tensor J which satisfies the condition $J_{ij|k} = \frac{1}{2}(\alpha_i g_{jk} + \alpha_j g_{ik})$ for some α_i has very interesting properties. In the first place, $J_{(ij|k)} = \alpha_{(i} g_{jk)}$ (brackets denote symmetrization), which says that J is a conformal Killing tensor of g; and furthermore $\alpha = \alpha_i dq^i$ is exact, so it is a conformal Killing tensor of gradient type. In the course of the argument in the previous section it was assumed that the torsion of J vanishes (this was necessary to ensure that Π_J is Poisson): but in fact the vanishing of the torsion is an easy consequence of the defining condition. Moreover, as we showed in Ref. 5, a conformal Killing tensor whose torsion vanishes and which has functionally independent eigenfunctions must necessarily satisfy this condition. A symmetric type (0,2) tensor J on Q such that

$$J_{ij|k} = \tfrac{1}{2}(\alpha_i g_{jk} + \alpha_j g_{ik}),$$

will therefore be called a *special conformal Killing tensor*. In the Euclidean case a tensor is a special conformal Killing tensor if and only if it is an elliptic coordinates matrix in Lundmark's terminology,[2] or a planar inertia tensor in Benenti's.[9]

We will deal only with special conformal Killing tensors which are nonsingular. The inverse of a type (1,1) tensor will be denoted by an overbar when we need to use indices.

The determinant of a type (1,1) tensor is a scalar (this is not so for a type (2,0) or (0,2) tensor), so whenever we use determinants it is to be assumed that the corresponding tensor is in type (1,1) form. This also applies to the formula $A = (\det J) J^{-1}$, which may be used to define the cofactor tensor of J when it is nonsingular. Elsewhere, the usual rules for raising and lowering indices apply. Thus, for example, $A_{ij} = (\det J)\overline{J}_{ij}$: it is symmetric if J is.

When J is special conformal Killing, by taking the covariant derivative of the equation $A_{ij} J_l^j = (\det J) g_{il}$ and using the defining condition one can deduce that

$$A_{ij|k} = (\det J)(\overline{J}_{ij}\overline{J}_{kl} - \tfrac{1}{2}\overline{J}_{ik}\overline{J}_{jl} - \tfrac{1}{2}\overline{J}_{il}\overline{J}_{jk})\alpha^l,$$

from which one easily derives the following remarkable property of any special conformal Killing tensor.

Proposition 1: The cofactor tensor of a nonsingular special conformal Killing tensor is a Killing tensor.

Proof: It follows immediately from the formula above that $A_{(ij|k)} = 0$. □

Note further that A has the same eigenvectors as J.

A special conformal Killing tensor J may be used to define a couple of differential operators with nice properties. In the first place, we can form the operator d_J in the sense of Frölicher–Nijenhuis theory:[10] this is the derivation of degree 1 of the exterior algebra $\wedge(Q)$ of forms on Q, over the algebra $C^\infty Q$ of real-valued C^∞ functions on Q, which anticommutes with the exterior derivative d (i.e., is a derivation of type d_*), and whose action on $C^\infty(Q)$ is given by $d_J f = J^*(df)$. Furthermore, d_J has the coboundary property $d_J{}^2 = 0$ because the torsion N_J is zero. What is more, since by assumption J is nonsingular, d_J satisfies a Poincaré lemma: that is to say, for a k-form θ, the condition $d_J\theta = 0$ is sufficient as well as necessary for the local existence of a $(k-1)$-form φ such that $\theta = d_J\varphi$. This result can be found in a paper by Willmore.[11]

In the previous section we came across an interesting property in which d_J is involved. We showed there that if J is a special conformal Killing tensor, $F=\det J$ satisfies $J_i^j\partial F/\partial q^j=F\alpha_i$ where $\alpha=d(\operatorname{tr}J)$. Hence,

$$d_J(\det J)=(\det J)\alpha=(\det J)d(\operatorname{tr}J).$$

(In fact this holds for any tensor J whose torsion vanishes.) By acting with d_J on both sides, it easily follows that $d_J\alpha=0$, that is, $d_Jd(\operatorname{tr}J)=0$. (In fact for any tensor J whose torsion vanishes, $d_J(\operatorname{tr}J)=\frac{1}{2}d(\operatorname{tr}J^2)$.)

These properties enable us to define the following differential operator D_J, which also acts on forms θ on Q; D_J will turn out to have an important role in relation to the fundamental equation mentioned in the Introduction.

$$D_J\theta=(\det J)^{-1}d_J((\det J)\theta)=d_J\theta+\alpha\wedge\theta.$$

Note that D_J is not a derivation (in the sense of Frölicher–Nijenhuis), but it is clear from the first expression that D_J satisfies $D_J{}^2=0$, so it is an example of a (scalar) gauged differential operator, in the terminology of Ref. 12. Moreover, we see that once again $D_J\theta=0$ is a sufficient condition for there to be a form φ (locally) such that $\theta=D_J\varphi$: we have $d_J((\det J)\theta)=0$, so there is a φ' such that $(\det J)\theta=d_J\varphi'$, when $\varphi=(\det J)^{-1}\varphi'$ satisfies $D_J\varphi=\theta$.

Note finally that the condition on the nonconservative forces derived in the previous section can now be written in coordinate-free form with the aid of the 1-form $\mu=M_idq^i$ of the beginning of that section. The condition reads

$$\mu=(\det J)^{-1}d_JV=D_J((\det J)^{-1}V).$$

Hence, in order for the nonconservative Lagrangian system Γ to have a quasi-Hamiltonian representation as described in the previous section, there must be a function $V'=(\det J)^{-1}V$ such that $\mu=D_JV'$. But so long as we are concerned only with local considerations, this is equivalent to the condition $D_J\mu=0$.

V. COFACTOR SYSTEMS

We can now describe explicitly the class of nonconservative Lagrangian systems Γ we are analyzing: they are those determined by a metric tensor g which admits a special conformal Killing tensor J, and a 1-form μ on the configuration manifold Q such that $D_J\mu=0$. Systems of this type, in the Euclidean case, are what Lundmark calls cofactor systems, though he does not define them in quite the same way; we will use the same terminology even though it does not really match our definition.

Definition: A nonconservative system Γ on TQ, generated by a metric tensor field g and a 1-form μ on Q, is said to be a *cofactor system*, if g admits a nonsingular special conformal Killing tensor J and μ satisfies $D_J\mu=0$.

The results of the preceding sections can now be summarized as follows.

Theorem 2: A nonconservative system Γ on TQ determined by the couple (g,μ) on Q, has a quasi-Hamiltonian representation $F\hat{\Gamma}=P_J(dH)$, where J is a type (1,1) tensor field on Q, and H is a function on T^*Q quadratic in momenta, if and only if it is a cofactor system.

Proof: The argument developed in Sec. III proves the following assertion: the condition $F\hat{\Gamma}=P_J(dH)$ with H quadratic, assuming $N_J=0$, is equivalent to the requirements for having a cofactor system. But as we observed in Sec. IV, a special conformal Killing tensor automatically has zero torsion. Therefore, conversely, every cofactor system has a quasi-Hamiltonian representation of the desired type. □

Notice that for a special conformal Killing tensor

$$P_J = J^i_j \frac{\partial}{\partial p_j} \wedge X_i - \frac{1}{4}(\alpha_i p_j - \alpha_j p_i) \frac{\partial}{\partial p_i} \wedge \frac{\partial}{\partial p_j}.$$

Lundmark *et al.* approach the analysis of nonconservative Lagrangian systems by discussing the conditions under which such a system has a quadratic first integral $E = \frac{1}{2}A_{ij}u^i u^j + V$. Any cofactor system has a quasi-Hamiltonian representation with a quadratic Hamiltonian, which then is necessarily conserved, but the cofactor systems are a subclass of the non-conservative Lagrangian systems with quadratic integrals. We will complete the picture by identifying exactly which of the properties or conditions we have encountered entail that the function $E = \frac{1}{2}A_{ij}u^i u^j + V$ is a constant of the motion. We have

$$\Gamma(E) = \frac{1}{2}A_{ij|k}u^i u^j u^k - \left(A_{ij}M^j - \frac{\partial V}{\partial q^i} \right) u^i.$$

Thus, in order that $\Gamma(E)$ be zero, A must satisfy $A_{(ij|k)} = 0$, which is to say that it must be a Killing tensor. Moreover, we must have $A^*\mu = dV$. As we have seen, the first condition is satisfied automatically when A is the cofactor tensor of a special conformal Killing tensor (but of course there may be Killing tensors which are not of this type), and the restriction on μ then takes the form $\mu = D_J((\det J)^{-1}V)$. These remarks are supposed to explain the origins of the ''cofactor system.''

We will also take this opportunity to comment on the use of the term ''quasi-Lagrangian'' to describe nonconservative Lagrangian systems with quadratic integrals in the Euclidean case. Note that the commutator of any second-order equation field $\Gamma = u^i \partial/\partial q^i + f^i \partial/\partial u^i$ on TQ with $\partial/\partial u^j$ is given by

$$\left[\Gamma, \frac{\partial}{\partial u^j} \right] = -\frac{\partial}{\partial q^j} - \frac{\partial f^i}{\partial q^j} \frac{\partial}{\partial u^i}.$$

It follows that for any first integral E of Γ we will have

$$\Gamma\left(\frac{\partial E}{\partial u^j} \right) + \frac{\partial E}{\partial q^j} = -\frac{\partial f^i}{\partial u^j} \frac{\partial E}{\partial u^i}.$$

Hence, if the right-hand sides of the given equations (i.e., the functions f^i) are velocity independent, it will trivially be the case that every first integral E leads to a relation which formally looks like Euler–Lagrange equations with the wrong sign. In the Euclidean case, in Cartesian coordinates, the right-hand sides are indeed velocity independent. However, if the space is not Euclidean the equations will certainly not have this feature; indeed, they will not even in the Euclidean case if curvilinear coordinates are used. On the other hand, as we have already seen and will see further in what follows, the systems we are considering do have all the intrinsic features which explain the essential properties of what were called quasi-Lagrangian systems in Refs. 2–4. It seems to us, therefore, that the fact that the systems considered there have quasi-Lagrangian representations is not significant.

Given the prominent role played by the function $\frac{1}{2}A_{ij}u^i u^j + V$ in the concept of a cofactor system, one might naturally ask why one should not, to obtain a quasi-Hamiltonian representation, map TQ to T^*Q by $u^i \mapsto A_{ij}u^j$ rather than $u^i \mapsto g_{ij}u^j$. To do so is equivalent to carrying out the map $\hat{A}$ on T^*Q. Note that since $JA = (\det J)I$, and the torsion of a multiple of the identity vanishes, P_{JA} is certainly a Poisson map. The dynamics is transformed to $\hat{A}_*\hat{\Gamma}$. In Sec. II we showed that $P_{JA}(d(\hat{A}^{-1}{}^*H)) = \hat{A}_* P_J(dH)$. It follows that

$$(\det J)\hat{A}_*\hat{\Gamma} = \hat{A}_* P_J(dH) = P_{JA}(d(\hat{A}^{-1}{}^*H)),$$

which is to say that $\hat{A}_*\hat{\Gamma}$ is quasi-Hamiltonian with respect to $P_{JA}=P_{(\det J)I}$, with Hamiltonian

$$\hat{A}^{-1}*H=(\det J)^{-1}\hat{J}^*H=(\det J)^{-1}(\tfrac{1}{2}A^{ij}J^k_iJ^l_jp_kp_l+V)=\tfrac{1}{2}J^{ij}p_ip_j+(\det J)^{-1}V.$$

This formulation, in the Euclidean case, is essentially that given by the second of the two non-standard Poisson structures in Ref. 3.

Once one has noticed this trick one realizes that there are other possible ways of obtaining a quasi-Hamiltonian representation of a cofactor system. Indeed, by applying the map $\hat{J}^{-1}$ one sees that there is a quasi-Hamiltonian representation with respect to the standard Poisson structure. However, when we come to discuss cofactor pair systems these alternatives will not do, because they will associate different vector fields on T^*Q with the original vector field Γ on TQ: it is far better to stick with the single vector field $\hat{\Gamma}=\hat{g}_*\Gamma$ on T^*Q and represent it in quasi-Hamiltonian form with respect to two Poisson structures.

VI. HAMILTONIAN STRUCTURE FOR A COFACTOR SYSTEM

We now show how to represent a cofactor system as a Hamiltonian vector field with respect to a Poisson structure defined on an extended manifold. This involves an application of what is in fact a general construction which applies to any quasi-Hamiltonian vector field. This construction is the subject of the following theorem.

Theorem 3: Let Π be a Poisson bivector on a manifold M, and Z a vector field on M with the property that there is a nowhere-vanishing function F such that FZ is a Hamiltonian vector field with respect to Π, with Hamiltonian function H. Then there is a Poisson bivector $\hat{\Pi}$ on $M\times\mathbb{R}$ which projects onto Π, and a vector field, Hamiltonian with respect to $\hat{\Pi}$, whose restriction to the zero section is Z. Furthermore, $H+zF$ is a Casimir of $\hat{\Pi}$ (where z is the coordinate on $\mathbb{R}$).

Proof: Let π denote the projection $\pi:M\times\mathbb{R}\to M$. We can extend Π to $M\times\mathbb{R}$ simply by ignoring z: that is, for 1-forms on M we put $\Pi(\pi^*\alpha,\pi^*\beta)=\Pi(\alpha,\beta)$, while $\Pi(dz,\cdot)=0$ (so that z is a Casimir for Π). We consider a bivector of the form

$$\hat{\Pi}=\Pi+(Z+zW)\wedge\frac{\partial}{\partial z},$$

where W is a vector field independent of z (that is, $\langle W,dz\rangle=0$ and $\mathcal{L}_{\partial/\partial z}W=0$), and seek a W for which $\hat{\Pi}$ is Poisson. If we find one, then the Hamiltonian vector field corresponding to $-z$ will be $Z+zW$, agreeing with Z on $z=0$; and the projection of $\hat{\Pi}$ to M will be Π (or in other words π will be a Poisson map). We require that $[\hat{\Pi},\hat{\Pi}]=0$. Now for any bivector field Ω and vector fields X, Y,

$$[\Omega+X\wedge Y,\Omega+X\wedge Y]=[\Omega,\Omega]+2(\mathcal{L}_X\Omega\wedge Y-X\wedge\mathcal{L}_Y\Omega-X\wedge Y\wedge[X,Y]),$$

so we require that

$$\mathcal{L}_{Z+zW}\Pi\wedge\frac{\partial}{\partial z}=(Z+zW)\wedge\frac{\partial}{\partial z}\wedge(-W)=Z\wedge W\wedge\frac{\partial}{\partial z}.$$

For any bivector field Ω, function f and vector field V,

$$\mathcal{L}_{fV}\Omega=f\mathcal{L}_V\Omega-V\wedge S(df),$$

where S is the map of 1-forms corresponding to Ω. So $[\hat{\Pi},\hat{\Pi}]=0$ is equivalent to

$$(\mathcal{L}_Z\Pi+z\mathcal{L}_W\Pi)\wedge\frac{\partial}{\partial z}=Z\wedge W\wedge\frac{\partial}{\partial z}.$$

The conditions for $\hat{\Pi}$ to be Poisson are

$$\mathcal{L}_Z\Pi = Z\wedge W,\ \mathcal{L}_W\Pi = 0.$$

Now $Z = F^{-1}P(dH)$, where P is the Poisson map corresponding to Π, so (since the Lie derivative of Π by a Hamiltonian vector field is zero)

$$\mathcal{L}_Z\Pi = -P(dH)\wedge P(dF^{-1}) = F^{-2}P(dH)\wedge P(dF),$$

so both requirements are satisfied if

$$W = F^{-1}P(dF).$$

That is to say,

$$\hat{\Pi} = \Pi + (Z + zF^{-1}P(dF))\wedge\frac{\partial}{\partial z} = \Pi + F^{-1}P(dH + z\,dF)\wedge\frac{\partial}{\partial z}$$

is a Poisson tensor on $M\times\mathbb{R}$.

It follows by a direct calculation that $H+zF$ is a Casimir of $\hat{\Pi}$. □

It is useful to note, for future reference, that in fact the bivector $\Pi + (kZ + zW)\wedge\partial/\partial z$ is Poisson for every constant k; or what amounts to the same thing, $\hat{\Pi}$ is compatible with the (highly degenerate) Poisson bivector $Z\wedge\partial/\partial z$. This is established by the following computation:

$$\begin{aligned}\left[\hat{\Pi}, Z\wedge\frac{\partial}{\partial z}\right] &= \mathcal{L}_Z\hat{\Pi}\wedge\frac{\partial}{\partial z} - Z\wedge\mathcal{L}_{\partial/\partial z}\hat{\Pi}\\ &= \left(\mathcal{L}_Z\Pi + z[Z,W]\wedge\frac{\partial}{\partial z}\right)\wedge\frac{\partial}{\partial z} - Z\wedge\left(\left[\frac{\partial}{\partial z}, Z + zW\right]\wedge\frac{\partial}{\partial z}\right)\\ &= (Z\wedge W)\wedge\frac{\partial}{\partial z} - Z\wedge\left(W\wedge\frac{\partial}{\partial z}\right) = 0.\end{aligned}$$

Of course the Hamiltonian vector field corresponding to $-z$ for this modified Poisson structure restricts on $z=0$ not to Z but to a constant multiple of it.

Returning to the case of a given cofactor system, we may use the construction in the theorem above to represent $\hat{\Gamma}$ as the restriction to $z=0$ of a Hamiltonian vector field on $T^*Q\times\mathbb{R}$. The function F in this case is $\det J$, which is a function on Q. The Hamiltonian vector field associated with $\det J$ by Π_J is $-(d_J(\det J))^V = -(\det J)\alpha^V$. Thus,

$$\hat{\Pi}_J = \Pi_J + (\hat{\Gamma} - z\alpha^V)\wedge\frac{\partial}{\partial z},$$

or in other words

$$\hat{P}_J = J^i_j\frac{\partial}{\partial p_j}\wedge X_i - \tfrac{1}{4}(\alpha_i p_j - \alpha_j p_i)\frac{\partial}{\partial p_i}\wedge\frac{\partial}{\partial p_j} + g^{ij}p_j X_i\wedge\frac{\partial}{\partial z} - (M_i + z\alpha_i)\frac{\partial}{\partial p_i}\wedge\frac{\partial}{\partial z}.$$

This agrees with the Poisson structure for a cofactor system in the n-dimensional Euclidean case given in Ref. 2 and in two dimensions in Ref. 4, and is the obvious generalization once one has realized that introducing the metric involves using the basis adapted to the connection.

Note that the Hamiltonian representation of the given cofactor system on $T^*Q\times\mathbb{R}$ is

$$\hat{\Gamma} - z\alpha^V = \hat{\Gamma}_0 - (\mu + z\alpha)^V,$$

so it is obtained by a kind of deformation of the nonconservative forces.

VII. COFACTOR PAIR SYSTEMS

We now consider nonconservative Lagrangian systems which are of cofactor type in two ways—what Lundmark calls cofactor pair systems.

Suppose that the metric g admits two independent special conformal Killing tensors J and K. The condition for a given system $\Gamma=\Gamma_0-M^V$ to be of cofactor type (at least locally) with respect to both J and K is that $D_J\mu=D_K\mu=0$. We must examine the relation between the operators D_J and D_K.

If J and K are two special conformal Killing tensors then clearly $aJ+bK$ is also a special conformal Killing tensor for any constants a, b, with corresponding 1-form $a\alpha+b\beta$, where $\alpha=d(\mathrm{tr}\,J)$, $\beta=d(\mathrm{tr}\,K)$. Using the representation $D_J\theta=d_J\theta+\alpha\wedge\theta$ we see that

$$D_{aJ+bK}=aD_J+bD_K,$$

since $D_J{}^2=D_K{}^2=D_{aJ+bK}{}^2=0$, it follows that

$$D_JD_K+D_KD_J=0.$$

It is worth pointing out that it also follows that the Nijenhuis bracket $[J,K]$ vanishes, and that $d_J\beta+d_K\alpha=0$. (Incidentally, for any pair of tensors such that $[J,K]=0$, $d_J(\mathrm{tr}\,K)+d_K(\mathrm{tr}\,J)=d(\mathrm{tr}\,JK)$.)

There are functions V' and W' so that $\mu=D_JV'=D_KW'$, where $V=(\det J)V'$ and $W=(\det K)W'$ are the ''potentials'' in the quadratic integrals of Γ. These functions satisfy

$$D_JD_KW'=0 \text{ and } D_KD_JV'=0,$$

since $D_JD_K+D_KD_J=0$, they are both solutions of the same equation:

$$D_JD_K\phi=0.$$

This is the generalization of the so-called ''fundamental equation'' of Refs. 1, 2, and 4. In view of the anticommutativity of the operators D_J and D_K, the 2-form $D_JD_K\phi$ is obviously skew symmetric in J and K. It is given in terms of the components of J and K by

$$D_JD_K\phi=(J_i^kK_j^l\phi_{|kl}+\tfrac{3}{2}(J_i^k\beta_j-K_i^k\alpha_j)\phi_{|k}+((J_i^k\beta_k)_{|j}+\alpha_i\beta_j))dq^i\wedge dq^j.$$

The term involving a covariant derivative of $J^*\beta$ may not seem to have the required skew-symmetry property at first sight, but is essentially $d_J\beta$, which is equal to $-d_K\alpha$.

We leave it to the reader to verify that this covariant fundamental equation reduces exactly to the one Lundmark put forward in coordinates for the Euclidean case. It suffices to take for the matrix J an expression of the form $J_{ij}=aq_iq_j+b_iq_j+b_jq_i+c_{ij}$ (the position of the indices is rather irrelevant in the Euclidean case, so we write them here as lower indices); accordingly, $\alpha_i=2(aq_i+b_i)$.

We now establish the complete integrability of a cofactor pair system. Since $D_{aJ+bK}\mu=aD_J\mu+bD_K\mu=0$, the vector field $\hat{\Gamma}$ corresponding to the given cofactor pair system is the restriction to $z=0$ of the Hamiltonian vector field of $-z$ for the Poisson structure

$$\hat{\Pi}(a,b)=\Pi_{aJ+bK}+(\hat{\Gamma}-z(a\alpha^V+b\beta^V))\wedge\frac{\partial}{\partial z}$$

for every a and b. Note that this is not the same as

$$a\left(\Pi_J+(\hat{\Gamma}-z\alpha^V)\wedge\frac{\partial}{\partial z}\right)+b\left(\Pi_K+(\hat{\Gamma}-z\beta^V)\wedge\frac{\partial}{\partial z}\right)$$

except when $a+b=1$, so this does not define a Poisson pencil as written. This is a minor difficulty, which can be dealt with by adding $(a+b-1)\hat{\Gamma}\wedge\partial/\partial z$ to $\hat{\Pi}(a,b)$, and using the standard results about Poisson pencils to prove complete integrability; however, it seems interesting, and more pleasing, to establish complete integrability directly.

We write $A(a,b)$ for the cofactor tensor of $aJ+bK$. It is a homogeneous polynomial of degree $n-1$ in a, b (where $n=\dim Q$). Let $V(a,b)$ be a solution of

$$D_{aJ+bK}((\det(aJ+bK)^{-1}V(a,b)))=\mu$$

or equivalently $dV(a,b)=A(a,b)^*\mu$; it is again a homogeneous polynomial in a and b of degree $n-1$. We set

$$A(a,b)=\sum_{m=1}^{n} A_{(m)}a^{n-m}b^{m-1}, \quad V(a,b)=\sum_{m=1}^{n} V_{(m)}a^{n-m}b^{m-1},$$

and thereby define n functions $H_{(m)}$ on T^*Q, $m=1,2,\ldots,n$ by

$$H_{(m)}=\tfrac{1}{2}A^{ij}_{(m)}p_ip_j+V_{(m)}.$$

Note that $H_{(1)}$ is the Hamiltonian function for $(\det J)\hat{\Gamma}$ with respect to Π_J, and $H_{(n)}$ the Hamiltonian function for $(\det K)\hat{\Gamma}$ with respect to Π_K.

Theorem 4: The functions $H_{(m)}$ are first integrals of $\hat{\Gamma}$ which are in involution with respect to the Poisson brackets associated with Π_J and Π_K.

Proof: We know that $C(a,b)=H(a,b)+z\det(aJ+bK)=\frac{1}{2}A(a,b)^{ij}p_ip_j+V(a,b)+z\det(aJ+bK)$ is a Casimir of $\hat{\Pi}(a,b)$, and $\hat{\Gamma}-z(a\alpha^V+b\beta^V)$ is a Hamiltonian vector field, for every a and b. So in particular $(\hat{\Gamma}-z(a\alpha^V+b\beta^V))C(a,b)\equiv 0$. Now $H(a,b)=\Sigma_{m=1}^{n}H_{(m)}$. On setting $z=0$ we find that $H_{(m)}$ is a first integral of $\hat{\Gamma}$ for $m=1,2,\ldots,n$. Now set

$$\det(aJ+bK)=\sum_{l=0}^{n}\Delta_{(l)}a^{n-l}b^{l}.$$

It then follows from the fact that $C(a,b)$ is a Casimir that (on T^*Q)

$$\{\cdot,H_{(m)}\}_J+\{\cdot,H_{(m-1)}\}_K=\Delta_{(m)}\hat{\Gamma}$$

for $2\leqslant m\leqslant n$, while $\{\cdot,H_{(1)}\}_J=(\det J)\hat{\Gamma}$ and $\{\cdot,H_{(n)}\}_K=(\det K)\hat{\Gamma}$ (which just confirms that $\hat{\Gamma}$ is Hamiltonian up to a scalar factor for the Poisson brackets determined by both J and K). It follows that

$$\{H_{(r)},H_{(s)}\}_J+\{H_{(r)},H_{(s-1)}\}_K=\Delta_{(m)}\hat{\Gamma}(H_{(r)})=0$$

for $1\leqslant r\leqslant n$ and $2\leqslant s\leqslant n$, from which the usual kind of induction argument leads to the $H_{(m)}$ being in involution with respect to both Poisson brackets. □

We make some final observations now, which will establish a link between our new results and related work in Hamilton–Jacobi theory. The cofactor tensor of $aJ+bK$ is a Killing tensor for every a, b (or at least those for which $aJ+bK$ is nonsingular). It follows that $A_{(m)}$ is a Killing tensor for each m. In particular, if $K=I$, and if J has functionally independent eigenfunctions, we generate from the one special conformal Killing tensor n independent Killing tensors, one of which is g and another of which is the cofactor tensor of J; and since the eigenvectors of $aJ+bI$ are the same as the eigenvectors of J, these Killing tensors have the same eigenvectors. Furthermore, they commute pairwise in the sense of their corresponding quadratic functions having vanishing Poisson bracket (in this case, $\{\cdot,\cdot\}_K$ is the standard Poisson bracket). It follows that these Killing tensors form a Stäckel system (for full details see, Ref. 13). Moreover, $\hat{\Gamma}$ is the

Hamiltonian flow of the Hamiltonian $\frac{1}{2}g^{ij}p_ip_j+V$, where $D_JdV=0$; it then follows by results of Refs. 5 and 14 that the Hamilton–Jacobi equation for this Hamiltonian is separable in orthogonal coordinates.

The fact that the existence of a special conformal Killing tensor leads to the orthogonal separability of the Hamilton–Jacobi equation for the geodesic flow was first pointed out by Benenti in Ref. 9. The more general case, in which there is a potential, has been discussed from points of view close to that of this article in Refs. 5 and 14. In Ref. 14 a bi-Hamiltonian structure was introduced, essentially equivalent to the Poisson pencil $\hat{\Pi}_{aJ+bI}$. In Ref. 5 the special nature of the conformal Killing tensor which plays such a central role in the theory was investigated.

VIII. CONCLUSIONS

As is often the case, the generalization of the results of Refs. 1–4 has led to the clarification of several of the concepts and methods used in these papers. In particular, the Poisson structures introduced there have been shown to be examples of two general constructions: first, the construction of a Poisson–Nijenhuis structure on a cotangent bundle via the complete lift of a type (1,1) tensor with vanishing torsion, which is well known; and second, the ''lifting'' of a Poisson structure and a quasi-Hamiltonian vector field to an extended space which is the subject of Theorem 3 above. This latter result appears to be new. It should be noted that it is not dependent on the existence of a bi-Hamiltonian or quasi-bi-Hamiltonian structure, but only on a single quasi-Hamiltonian vector field. Nevertheless, it clearly has potential application in the field of quasi-bi-Hamiltonian systems (as defined for example in Ref. 15), of which the case $K=I$ discussed at the end of the last section is an example. Indeed, the results obtained here for a particular class of what might be called bi-quasi-Hamiltonian systems should be capable of generalization to provide a theory of such systems. We are currently investigating this possibility. It is noteworthy that the differential operators D_J and D_K play an important role here, so that the theory of cofactor pairs provides an example of a gauged bidifferential calculus in the sense of Ref. 12; this seems to us to be likely to be a feature of the general theory of bi-quasi-Hamiltonian systems we have in mind. Finally, from the opposite point of view as one might say, the properties of cofactor tensors of special conformal Killing tensors have not been noticed before in published accounts of Benenti's theory of inertia tensors and the orthogonal separability of the Hamilton–Jacobi equation, so far as we are aware. An article on this subject (Ref. 13), has been submitted for publication. In Ref. 14, Ibort *et al.* speculate that there is ''a deep relation, still to be worked out, between the geometry of Killing tensors on a Riemannian manifold and the geometry of a particular class of Poisson manifolds.'' It seems to us that the remarkable properties of special conformal Killing tensors form part of this deep geometrical structure.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 42, NUMBER 9 SEPTEMBER 2001

A family of completely integrable multi-Hamiltonian systems explicitly related to some celebrated equations

Engui Fan[a)]
Institute of Mathematics, Fudan University, Shanghai 200433, People's Republic of China

(Received 2 October 2000; accepted for publication 4 June 2001)

By introducing a spectral problem with an arbitrary parameter, we derive a Kaup–Newell-type hierarchy of nonlinear evolution equations, which is explicitly related to many important equations such as the Kundu equation, the Kaup–Newell (KN) equation, the Chen–Lee–Liu (CLL) equation, the Gerdjikov–Ivanov (GI) equation, the Burgers equation, the modified Korteweg-deVries (MKdV) equation and the Sharma–Tasso–Olver equation. It is shown that the hierarchy is integrable in Liouville's sense and possesses multi-Hamiltonian structure. Under the Bargann constraint between the potentials and the eigenfunctions, the spectral problem is nonlinearized as a finite-dimensional completely integrable Hamiltonian system. The involutive representation of the solutions for the Kaup–Newell-type hierarchy is also presented. In addition, an N-fold Darboux transformation of the Kundu equation is constructed with the help of its Lax pairs and a reduction technique. According to the Darboux transformation, the solutions of the Kundu equation is reduced to solving a linear algebraic system and two first-order ordinary differential equations. It is found that the KN, CLL, and GI equations can be described by a Kundu-type derivative nonlinear Schrödinger equation involving a parameter. And then, we can construct the Hamiltonian formulations, Lax pairs and N-fold Darboux transformations for the Kundu, KN, CLL, and GI equations in explicit and unified ways. [DOI: 10.1063/1.1389288]

I. INTRODUCTION

It is well-known that given a properly chosen spectral problem, one can relate it to a hierarchy of nonlinear evolution equations. A central and difficult topic in the study of integrable systems is to find new Lax or Liouville integrable systems such as those associating with certain nonlinear evolution equations of physical significance.[1–10] Among them, three typical examples are Ablowitz-Kaup-Newell-Segur (AKNS), Wadati-Konno-Ichikawa (WKI), and KN hierarchies which contain the well-known Schrödinger equation, Korteweg–de Vries (KdV) equation, MKdV equation, Burgers equation, and KN equation as their special reductions. Especially, this approach plays an important role in the study of integrablity, Lax pair, conserved law, Hamiltonian structure, and Darboux transformation of nonlinear evolution equations. The demonstration of a bi-Hamiltonian structure for nonlinear evolution equations is a direct and elegant method of proving its complete integrability.[11–15] If a set of nonlinear evolution equations can be formulated as a Hamiltonian system in two distinct but compatible ways, then, by a theorem of Magri,[11,12] they rise to an infinite sequence of conserved Hamiltonians which are in involution with respect to either one of these two symplectic structures. Recently two other effective approaches that produce infinite-dimensional and finite-dimensional integrable Hamiltonian systems, respectively, also have been developed. The first one is the trace identity,[9] which is powerful for constructing infinite-dimensional Liouville integrable Hamiltonian systems. Starting from a properly spectral problem, many integrable hierarchies and their Hamiltonian structure have been obtained by applying this method.[9,10] The second one is called a nonlinearization technique,[16,17] which is also

a)Electronic mail: faneg@fudan.edu.cn

proved to be a powerful tool for obtaining new finite-dimensional integrable Hamiltonian systems from various soliton hierarchies. Under the Bargmann or Neumann constraints between the potentials and the eigenvalues which play a central role in the process of nonlinearization, the eigenvalue problem is nonlinearized as a finite-dimensional completely integrable system. The list covered the eigenvalue problems associated the well-known soliton hierarchies such as the AKNS, Jaulent-Miodek, KN examples, etc.[17–20]

The Darboux transformation method based Lax pairs have been proven to be one of the most fruitful algorithmic procedures to get explicit solutions of nonlinear evolution equations.[3,21] The first and successive Darboux transformations of trivial solutions are called single solitons and multi-solitons, respectively. The key for constructing a Darboux transformation is to expose a kind of covariant property that corresponding spectral problems possess. There are many tricks for getting explicit solutions to various soliton equations, including the KdV, Davey–Stewartson, self-dual Yang–Mills equations, etc.[21–28] In Refs. 22 and 23, a systematic method is presented to directly construct an explicit formula for N-fold Darboux transformation of AKNS hierarchy. This N-fold Darboux transformation formula can be interpreted as a nonlinear superposition of a single Darboux transformation. Moreover, the solutions of any systems in AKNS hierarchy are reduced to solving a linear algebraic system, which is very suitable for generating multi-soliton solutions by symbolic computation on a computer.

The nonlinear Schrödinger equation is one of the most generic soliton equations. To study the effect of higher order perturbations, various modifications and generalizations of the Schrödinger equation have been proposed and studied for years. Among them, there are four celebrated derivative nonlinear Schrödinger equations, which are the KN equation[6]

$$iq_t+q_{xx}+i(|q|^2q)_x=0, \tag{1}$$

the CLL equation[29,30]

$$iq_t+q_{xx}+i|q|^2q_x=0, \tag{2}$$

the GI equation[31,32]

$$iq_t+q_{xx}-iq^2q_x^*+\tfrac{1}{2}|q|^4q=0, \tag{3}$$

and the Kundu equation[32–34]

$$iq_t+q_{xx}+2i(2\delta+\alpha)|q|^2q_x+i(4\delta+\alpha)q^2q_x^*+\delta(4\delta+\alpha)|q|^4q=0, \tag{4}$$

where q^* denotes the complex conjugate of q. It is found that they may be transformed into each other by a gauge transformation, and the method of gauge transformation also can be applied to some generalized cases.[32,34] In recent years, the spectral problem, Hamiltonian structure, Painlevé property, exact solutions and other properties associated with the Kaup–Newell equation have been investigated in detail.[6,9,34,35] But little work has been done on the CLL, GI, and Kundu equations (2)–(4), since the corresponding results for these three equations may be obtained from KN equation (1) by some gauge transformation in principle.[33,35–37] However, it seems difficult to obtain their explicit results in this way, because we must solve integrable equation like (6) in practice. The integration will become very complicated with the increase of iterative times, especially in multi-soliton solutions.

The purpose of this article is to present some new explicit results on Eqs. (1)–(4) with the help of a spectral problem

$$y_x=Uy=\begin{pmatrix} -i\lambda^2-i\beta qr & \lambda q \\ \lambda r & i\lambda^2+i\beta qr \end{pmatrix}y, \tag{5}$$

where q, r are two potentials, and β is an arbitrary parameter. In the fact, the spectral problem (5) is a similar extension of the Kaup–Newell spectral problem.[6] By setting

$$\tilde{y}=\begin{pmatrix} \exp\left(-i\beta\int qr\,dx\right) & 0 \\ 0 & \exp\left(i\beta\int qr\,dx\right) \end{pmatrix} y,$$
$$q=\tilde{q}\exp\left(-2i\beta\int \tilde{q}\tilde{r}dx\right), \quad r=\tilde{r}\exp\left(2i\beta\int \tilde{q}\tilde{r}\,dx\right), \tag{6}$$

and by simple calculation, we know that the spectral problem (5) is equivalent to the standard Kaup–Newell spectral problem

$$\tilde{y}_x=\begin{pmatrix} -i\lambda^2 & \lambda\tilde{q} \\ \lambda\tilde{r} & i\lambda^2 \end{pmatrix}\tilde{y}. \tag{7}$$

In Ref. 38, for the special case of the spectral problem (5) ($\beta=\frac{1}{2}$), we ever derived a GI hierarchy and constructed an explicit Darboux transformation of the GI equation (1) by using a systematic technique. Here we would like to generalize these results and give some new and more general results. First, it interests us that the hierarchy corresponding to the spectral problem (5) is explicitly related to many important equations such as the Kundu, KN, CLL, GI, Burgers, MKdV, and Sharma–Tasso–Olver (STO) equations.[39–41] To our knowledge, except for the KN equation, the other six equations are not explicitly found in the Kaup–Newell hierarchy.[6,9] And only the GI and MKdV equations belong to the GI hierarchy.[38] Second, by introducing a modified function, we develop a more general method than that used in Refs. 23 and 38 in order to construct the explicit N-fold Darboux transformation for the Kundu equation (4). Third, it is found that the KN, CLL, and GI equations can be described by a Kundu-type equation. In this way, their Lax pairs, Hamiltonian formulations, and Darboux transformation are all given in a unified and explicit way.

This article is organized as follows. In Sec. II, we first derive Kaup–Newell-type hierarchy equations corresponding to the spectral problem (5). It is shown that the hierarchy is integrable in Liouville's sense and possesses multi-Hamiltonian structure by means of trace identity.[9] Then we show that several kinds of important equations such as Kundu, KN, CLL, GI, Burgers, MKdV, and STO equations all belong to the hierarchy as special reductions in Sec. III. In Sec. IV, through the nonlinearization of the eigenvalue, a completely integrable Bargmann system is obtained under a constraint between the potential and eigenfunctions. Moreover, the involutive solutions for the Kaup–Newell-type hierarchy is further constructed in Sec. V. In Sec. VI, a systematic technique is further developed to construct an explicit N-fold Darboux transformation for the coupled Kundu system with help of its Lax pairs. In this way, the solutions of the coupled Kundu equations are reduced to solving two linear algebraic systems and two first-order ordinary differential equations. The Darboux transformation of the coupled Kundu system is further reduced to the Darboux transformation of the Kundu equation via the reduction technique in Sec. VII.

II. THE KAUP–NEWELL-TYPE HIERARCHY AND ITS MULTI-HAMILTONIAN FORMULATION

We first solve the adjoint representation of spectral problem (5),

$$V_x=[U,V]=UV-VU,$$

with

$$V=\begin{pmatrix} a & b \\ c & -a \end{pmatrix}=\sum_{j=0}^{\infty}\begin{pmatrix} a_j & b_j \\ c_j & -a_j \end{pmatrix}\lambda^{-j},$$

and obtain the following recursive formulas:

$$a_{2j+1}=b_{2j}=c_{2j}=0,$$

$$a_{2jx}=qc_{2j+1}-rb_{2j+1}=-\beta qr(qc_{2j-1}-rb_{2j-1})-\tfrac{1}{2}i(qc_{2j-1x}+rb_{2j-1x}),$$

$$b_{2j+1}=\tfrac{1}{2}ib_{2j-1x}+iqa_{2j}-\beta qrb_{2j-1},$$

$$c_{2j+1}=-\tfrac{1}{2}ic_{2j-1x}+ira_{2j}-\beta qrc_{2j-1}.$$

The above recursion equations can be solved successively to deduce that by using Mathematica

$$a_0=-2i,\quad b_1=2q,\quad c_1=2r,\quad a_2=-iqr,$$

$$b_3=iq_x-(2\beta-1)q^2r,\quad c_3=-ir_x-(2\beta-1)qr^2,$$

$$a_4=\tfrac{1}{4}[2(rq_x-qr_x)+i(8\beta-3)q^2r^2],$$

$$b_5=\tfrac{1}{4}[-2q_{xx}-6i(2\beta-1)qrq_x-4i\beta q^2r_x+(8\beta^2-12\beta+3)q^3r^2],$$

$$c_5=\tfrac{1}{4}[-2r_{xx}+6i(2\beta-1)qrr_x+4i\beta r^2q_x+(8\beta^2-12\beta+3)q^2r^3], \tag{8}$$

$$a_6=\tfrac{1}{8}[2i(qr_{xx}+rq_{xx})+6(2\beta-1)(q^2rr_x-qr^2q_x)-2iq_xr_x-i\beta(24\beta^2-24\beta+5)q^3r^3],$$

and

$$\begin{pmatrix}c_{2j+1}\\ b_{2j+1}\end{pmatrix}=L_1L_2\begin{pmatrix}c_{2j-1}\\ b_{2j-1}\end{pmatrix},\quad j=1,2,\ldots, \tag{9}$$

where

$$L_1=\frac{1}{2}\begin{pmatrix}r\partial^{-1}r & -i+r\partial^{-1}q\\ i+q\partial^{-1}r & q\partial^{-1}q\end{pmatrix},\quad L_2=\begin{pmatrix}0 & \partial+2i\beta qr\\ \partial-2i\beta qr & 0\end{pmatrix}$$

are two skew-symmetric operators, that is, $L_1^*=-L_1$, $L_2^*=-L_2$.

Consider the auxiliary spectral problem

$$y_t=V^{(m)}y, \tag{10}$$

where

$$V^{(m)}=\begin{pmatrix}\Delta_m & 0\\ 0 & -\Delta_m\end{pmatrix}+\sum_{j=0}^{m}\begin{pmatrix}a_{2j}\lambda^{2(m-j)+2} & b_{2j+1}\lambda^{2(m-j)+1}\\ c_{2j+1}\lambda^{2(m-j)+1} & -a_{2j}\lambda^{2(m-j)+2}\end{pmatrix}.$$

Then the compatibility condition between (5) and (10) leads to

$$-i\beta(qr)_t=-i\beta(q_tr+r_tq)=\Delta_{mx},$$

$$q_t=b_{2m+1x}+2i\beta qrb_{2m+1}+2q\Delta_m,$$

$$r_t=c_{2m+1x}-2i\beta qrc_{2m+1}-2r\Delta_m,$$

from which we obtain

$$\Delta_m=-i\beta\partial^{-1}(qc_{2m+1x}+rb_{2m+1x})-2\beta^2\partial^{-1}qr(qc_{2m+1}-rb_{2m+1})=2\beta a_{2(m+1)}$$

and

$$\begin{pmatrix} q_t \\ r_t \end{pmatrix} = L_3 L_2 \begin{pmatrix} c_{2m+1} \\ b_{2m+1} \end{pmatrix}, \tag{11}$$

where

$$L_3 = \begin{pmatrix} 1-2i\beta q\partial^{-1} r & -2i\beta q\partial^{-1} q \\ 2i\beta r\partial^{-1} r & 1+2i\beta r\partial^{-1} q \end{pmatrix}.$$

By using (9) and (11), the desired Kaup–Newell-type hierarchy associated with spectral problem (5) is obtained as follows:

$$\begin{pmatrix} q_t \\ r_t \end{pmatrix} = (L_3 L_2) \begin{pmatrix} c_{2m+1} \\ b_{2m+1} \end{pmatrix} = (L_3 L_2)(L_1 L_2) \begin{pmatrix} c_{2m-1} \\ b_{2m-1} \end{pmatrix}$$

$$= (L_3 L_2)(L_1 L_2)^m \begin{pmatrix} 2r \\ 2q \end{pmatrix}, \quad m = 1,2,\ldots . \tag{12}$$

In the following we will establish the multi-Hamiltonian structure for the hierarchy (12) and show it is integrable in Liouville's sense. In order to apply trace identity,[9,10] we need to rewrite (12) in another form. Let

$$G_{2j+1} = (c_{2j+1} - 2i\beta r a_{2j}, b_{2j+1} - 2i\beta q a_{2j})^T.$$

Noting that $a_{2j} = \partial^{-1}(q c_{2j+1} - r b_{2j+1})$, then we have

$$(c_{2j+1}, b_{2j+1})^T = L_3^* G_{2j+1}, \quad j \geqslant 0,$$

where L_3^* denotes the conjugation operator of L_3. In this way, the evolution hierarchy (12) is written in the form

$$u_t = J G_{2m+1} = J L G_{2m-1} = \cdots = J L^m G_1, \tag{13}$$

where $G_1 = (2(1-2\beta)r, 2(1-2\beta)q)^T$, $u = (q,r)^T$, $J = L_3 L_2 L_3^*$, $L = {L_3^*}^{-1} L_1 L_2 L_3^*$.

Proposition 1: All operators JL^k $(k = 0,1,2,\ldots,m)$ are skew-symmetric.

Proof: Since L_1 and L_2 are skew-symmetric, it is clear that $J = L_3 L_2 L_3^*$ and $JL = L_3 L_2 L_1 L_2 L_3^*$ are skew-symmetric. Suppose that JL^{k-1} is skew-symmetric. Then it holds that

$$(JL^k)^* = (JL^{k-1}L)^* = L^*(JL^{k-1})^* = -L^* J L^{k-1}$$

$$= L^* J^* L^{k-1} = -JLL^{k-1} = -JL^k,$$

which implies that JL^k is skew-symmetric. The proof is completed.

Following the notation used in Ref. 9, we take Killing–Cartan form $\langle A,B \rangle$ is $tr(AB)$. Then direct calculation gives

$$\left\langle V, \frac{\partial U}{\partial q} \right\rangle = c\lambda - 2i\beta r a, \quad \left\langle V, \frac{\partial U}{\partial r} \right\rangle = b\lambda - 2i\beta q a,$$

$$\left\langle V, \frac{\partial U}{\partial \lambda} \right\rangle = -4ia\lambda + rb + qc.$$

By using trace identity, we have

$$\frac{\delta}{\delta u}(-4ia\lambda + rb + qc) = \lambda^{-\gamma} \frac{\partial}{\partial \lambda}(\lambda^{\gamma}(c\lambda - ira, b\lambda - iqa)^T),$$

which is equivalent to

$$\frac{\delta}{\delta u}(-4ia_{2m+2}+rb_{2m+1}+qc_{2m+1})=(-2m+\gamma)G_{2m+1}. \tag{14}$$

To fix the γ in (14), we let $m=0$ and find $\gamma=0$. Therefore we conclude that

$$G_{2m+1}=\frac{\delta H_m}{\delta u}, \tag{15}$$

where

$$H_0=2qr, \quad H_m=\frac{4ia_{2m+2}-rb_{2m+1}-qc_{2m+1}}{2m}, \quad m\geqslant 1. \tag{16}$$

Combining (13) with (15) gives the desired multi-Hamiltonian formulation of the hierarchy (12)

$$u_t=J\frac{\delta H_m}{\delta u}=JL\frac{\delta H_{m-1}}{\delta u}=\cdots=JL^m\frac{\delta H_0}{\delta u}, \quad m=1,2,\ldots . \tag{17}$$

Finally, we discuss the integrablity of the hierarchy (12) or (17). It is crucial to show the existence of infinite involutive conserved densities. Usually the inner product between two functions f and g is defined by $(f,g)=\int f\cdot g\,dx$, and the Poisson bracket is defined by $\{f,g\}=(\delta f/\delta u, J\,\delta g/\delta u)$. In particular, f and g are called involutive if $\{f,g\}=0$.

Proposition 2: The Hamiltonian functions $\{H_m\}$ $(m=0,1,\ldots)$ defined by (16) constitute common conserved densities for the whole hierarchy (17).

Proof: By using Proposition 1, we find that

$$\{H_n,H_m\}=\left(\frac{\delta H_n}{\delta u},J\frac{\delta H_m}{\delta u}\right)=(L^nG_1,JL^mG_1)=(L^nG_1,L^*JL^{m-1}G_1)$$

$$=(L^{n+1}G_1,JL^{m-1}G_1)=\{H_{n+1},H_{m-1}\}.$$

Repeating the previous argument gives

$$\{H_n,H_m\}=\{H_m,H_n\}=\{H_{m+n},H_0\}. \tag{18}$$

On the other hand, we find

$$\{H_m,H_n\}=(L^mG_1,JL^nG_1)=(J^*L^mG_1,L^nG_1)=-\{H_n,H_m\}. \tag{19}$$

Then combining (18) with (19) leads to

$$\{H_m,H_n\}=0,$$

which implies that $\{H_m\}$ are in involution. Furthermore, we have

$$\left(\int H_m\,dx\right)_t=\left(\frac{\delta H_m}{\delta u},u_t\right)=\left(\frac{\delta H_m}{\delta u},J\frac{\delta H_n}{\delta u}\right)=\{H_m,H_n\}=0,$$

which shows that $\{H_m\}$ are also conserved densities. The proof is completed.

In summary, we arrive at the followings

Theorem 1: (i) The hierarchy (17) is an integrable Hamiltonian system in the Liouville sense. (ii) The Hamiltonain functions $\{H_m\}$ are conserved densities of whole hierarchy (17) and they are involutive in pairs.

III. A REDUCTION AND SOME IMPORTANT EQUATIONS FROM THE KAUP–NEWELL-TYPE HIERARCHY

To indicate the interest of our Kaup–Newell-type hierarchy (12), we provide a reduction and some important equations that contain in the hierarchy and give explicit expressions of Hamiltonian structure and Lax pairs for these equations.

Example 1: As $\beta=0$, the spectral problem (5) reduces to Kaup–Newell spectral problem (7), and the hierarchy (12) leads to the well-known Kaup–Newell hierarchy

$$u_t=JL^m\begin{pmatrix}2r\\2q\end{pmatrix},\quad m=1,2,\ldots, \tag{20}$$

where

$$J=L_3L_2L_3^*|_{\beta=0}=\begin{pmatrix}0&\partial\\\partial&0\end{pmatrix},$$

$$L=L_3L_2L_1L_2L_3^*|_{\beta=0}=\frac{1}{2}\begin{pmatrix}\partial q\partial^{-1}q\partial & i\partial^2+\partial q\partial^{-1}r\partial\\ -i\partial^2+\partial r\partial^{-1}q\partial & \partial r\partial^{-1}r\partial\end{pmatrix}.$$

Obviously J and L are two skew-symmetric operators. The Kaup–Newell hierarchy (20) can be cast in multi-Hamiltonian formulations

$$u_t=J\frac{\delta H_m}{\delta u}=JL\frac{\delta H_{m-1}}{\delta u}=\cdots=JL^m\frac{\delta H_0}{\delta u},\quad m=1,2,\ldots,$$

where H_m are determined by (16) with $\beta=0$.

Example 2: The first system of the hierarchy (12) ($m=1$) is the coupled Kundu system

$$\begin{aligned}&iq_t+q_{xx}+2i(2\beta-1)qrq_x+i(4\beta-1)q^2r_x+\beta(4\beta-1)q^3r^2=0,\\&ir_t-r_{xx}+2i(2\beta-1)qrr_x+i(4\beta-1)r^2q_x-\beta(4\beta-1)q^2r^3=0.\end{aligned} \tag{21}$$

It can be reduced to the Kundu-type equation as $r=-q^*$,

$$iq_t+q_{xx}-2i(2\beta-1)|q|^2q_x-i(4\beta-1)q^2q_x^*+\beta(4\beta-1)|q|^4q=0, \tag{22}$$

which is the same with the equation (4) for $\delta=-\beta$, $\alpha=1$. As $\beta=0$, $\beta=\frac{1}{4}$ and $\beta=\frac{1}{2}$, Eq. (22) is separately reduced to the KN, CLL, and GI equations (1)–(3). Setting $r=i$, $\beta=\frac{1}{4}$ in system (21), we get a new complex Burgers equation

$$iq_t+q_{xx}+qq_x=0,$$

which becomes a real version if we let $i\lambda\to\lambda$ in the spectral problem (5).

Now according to Theorem 1, we conclude that Kundu system (21) is Liouville integrable and possesses the bi-Hamiltonian structure

$$u_t=J\frac{\delta H_1}{\delta u}=JL\frac{\delta H_0}{\delta u},$$

where Hamiltonian functions H_0 and H_1 are

$$H_0=2qr, \quad H_1=\tfrac{1}{2}[i(rq_x-qr_x)-(4\beta-1)q^2r^2]. \tag{23}$$

The Lax pairs corresponding to the system (21) may be given by the spectral problem (5) and the auxiliary problem

$$y_t=V^{(1)}y, \quad V^{(1)}=\begin{pmatrix} v_{11}^{(1)} & v_{12}^{(1)} \\ v_{21}^{(1)} & -v_{11}^{(1)} \end{pmatrix}, \tag{24}$$

with

$$v_{11}^{(1)}=-2i\lambda^4-iqr\lambda^2+\beta(rq_x-qr_x)+\tfrac{1}{2}i\beta(8\beta-3)q^2r^2,$$

$$v_{12}^{(1)}=2q\lambda^3+[iq_x-(2\beta-1)q^2r]\lambda, \quad v_{21}^{(1)}=2r\lambda^3+[-ir_x-(2\beta-1)qr^2]\lambda.$$

Example 3: With the help of Mathematica, we easily find that the second system of the hierarchy (12) $(m=2)$ is

$$\begin{aligned} &q_t+\tfrac{1}{4}[2q_{xxx}+6i(2\beta-1)r(qq_x)_x+6i(4\beta-1)qq_xr_x-6(2\beta-1)(4\beta-1)q^3rr_x \\ &\quad -3(8\beta^2-12\beta+3)q^2r^2q_x+4i\beta(2\beta-1)(4\beta-1)q^4r^3]=0, \\ &r_t+\tfrac{1}{4}[2r_{xxx}-6i(2\beta-1)q(rr_x)_x-6i(4\beta-1)rq_xr_x-6(2\beta-1)(4\beta-1)r^3qq_x \\ &\quad -3(8\beta^2-12\beta+3)q^2r^2r_x-4i\beta(2\beta-1)(4\beta-1)q^3r^4]=0, \end{aligned} \tag{25}$$

which reduces to the MKdV equation for $r=2$, $\beta=\frac{1}{2}$,

$$q_t+\tfrac{1}{2}(q_{xxx}+6q^2q_x)=0,$$

and the complex STO equation for $r=2$, $\beta=\frac{1}{4}$,

$$q_t+\tfrac{1}{2}[q_{xxx}-3i(qq_x)_x-3q^2q_x]=0. \tag{26}$$

If we let $i\lambda\to\lambda$ in the spectral problem (5), then we will get the real version of the STO equation that was studied by Olver and Gudkov:[39,41]

$$q_t+\tfrac{1}{2}[q_{xxx}-3(qq_x)_x-3q^2q_x]=0.$$

The system (25) is Liouville integrable and possesses the tri-Hamiltonian structure

$$u_t=J\frac{\delta H_2}{\delta u}=JL\frac{\delta H_1}{\delta u}=JL^2\frac{\delta H_0}{\delta u},$$

where Hamiltonian functions H_0, H_1 are determined by (23), and

$$H_2=\tfrac{1}{4}(4ia_6-rb_5-qc_5),$$

with a_6, b_5 and c_5 given by (8).

The Lax pairs corresponding to the system (25) are given by the spectral problem (5) and an auxiliary problem

$$y_t=V^{(2)}y=\begin{pmatrix} v_{11}^{(2)} & v_{12}^{(2)} \\ v_{21}^{(2)} & -v_{11}^{(2)} \end{pmatrix}y,$$

with

$$v_{11}^{(2)}=-2i\lambda^6-iqr\lambda^4+\tfrac{1}{4}[2(qr_x-rq_x)+i(8\beta-3)q^2r^2]\lambda^2+2\beta a_6,$$

$$v_{12}^{(2)}=2q\lambda^5+[iq_x-(2\beta-1)q^2r]\lambda^3+b_5\lambda,$$

$$v_{21}^{(2)}=2r\lambda^5+[-ir_x-(2\beta-1)qr^2]\lambda^3+c_5\lambda.$$

IV. A COMPLETELY INTEGRABLE BARGMANN SYSTEM

Let $\lambda_j(j=1,\ldots,N)$ be different eigenvalues of Eq. (5), and (ψ_j,ϕ_j) be associated eigenfunctions. Then the functional gradient λ_j with respect to $u=(q,r)^T$ is

$$\frac{\delta\lambda_j}{\delta u}=\left(\frac{\delta\lambda_j}{\delta q},\frac{\delta\lambda_j}{\delta r}\right)^T=\gamma_j^{-1}(\lambda_j\phi_j^2-2i\beta r\psi_j\phi_j,-\lambda_j\psi_j^2-2i\beta q\psi_j\phi_j)^T,$$

where $\gamma_j=\int(q\phi_j^2-r\psi_j^2+4i\lambda_j\psi_j\phi_j)\,dx$.

Proposition 3: J and $K=JL$ are Lenard's pair of operators

$$K\frac{\delta\lambda_j}{\delta u}=\lambda_j^2J\frac{\delta\lambda_j}{\delta u}, \tag{27}$$

and $\{G_{2j+1}\}$ are Lenard's sequence

$$JG_{2j+3}=KG_{2j+1},\quad j=0,1,\ldots. \tag{28}$$

Proof: Making use of the spectral problem (5), direct verification indicates that

$$L_3^*\frac{\delta\lambda_j}{\delta u}=\lambda_j\begin{pmatrix}\phi_j^2\\-\psi_j^2\end{pmatrix}, \tag{29}$$

$$L_1L_2\begin{pmatrix}\phi_j^2\\-\psi_j^2\end{pmatrix}=\lambda_j^2\begin{pmatrix}\phi_j^2\\-\psi_j^2\end{pmatrix}. \tag{30}$$

Substituting (29) into (30) and multiplying L_3L_2 on both sides of it, then (27) is obtained. Obviously (28) holds according to (13).

Consider the Bargmann constraint

$$G_1=\sum_{j=1}^{N}\gamma_j\frac{\delta\lambda_j}{\delta u}, \tag{31}$$

or equivalently

$$q=-\frac{\langle\wedge\psi,\psi\rangle}{2(1-2\beta+i\beta\langle\psi,\phi\rangle)},\quad r=\frac{\langle\wedge\phi,\phi\rangle}{2(1-2\beta+i\beta\langle\psi,\phi\rangle)}, \tag{32}$$

where $\psi=(\psi_1,\ldots,\psi_N)^T,\phi=(\phi_1,\ldots,\phi_N)^T,\wedge=\mathrm{diag}(\lambda_1,\ldots,\lambda_N)$, and $\langle\cdot,\cdot\rangle$ is the standard inner product in R^N. Under the Bargmann constraint (32), Eq. (5) is nonlinearized into a finite-dimensional Hamiltonian system

$$\begin{aligned}\psi_x&=-i\wedge^2\psi+\frac{i\beta\psi\langle\wedge\psi,\psi\rangle\langle\wedge\phi,\phi\rangle}{4(1-2\beta+i\beta\langle\psi,\phi\rangle)^2}-\frac{\wedge\phi\langle\wedge\psi,\psi\rangle}{2(1-2\beta+i\beta\langle\psi,\phi\rangle)}=-\frac{\partial H}{\partial\phi},\\ \phi_x&=i\wedge^2\phi-\frac{i\beta\phi\langle\wedge\psi,\psi\rangle\langle\wedge\phi,\phi\rangle}{4(1-2\beta+i\beta\langle\psi,\phi\rangle)^2}+\frac{\wedge\psi\langle\wedge\phi,\phi\rangle}{2(1-2\beta+i\beta\langle\psi,\phi\rangle)}=\frac{\partial H}{\partial\psi},\end{aligned} \tag{33}$$

whose Hamiltonian function H is

$$H=\langle i\wedge^2\psi,\phi\rangle+\frac{\langle\wedge\psi,\psi\rangle\langle\wedge\phi,\phi\rangle}{2(1-2\beta+i\beta\langle\psi,\phi\rangle)}. \tag{34}$$

The Poisson bracket of two functions in sympletic space $(R^{2N},d\psi\wedge d\phi)$ is defined as

$$(F,G)=\sum_{j=1}^{N}\left(\frac{\partial F}{\partial\psi_j}\frac{\partial G}{\partial\phi_j}-\frac{\partial F}{\partial\phi_j}\frac{\partial G}{\partial\psi_j}\right)=\left\langle\frac{\partial F}{\partial\psi},\frac{\partial G}{\partial\phi}\right\rangle-\left\langle\frac{\partial F}{\partial\phi},\frac{\partial G}{\partial\psi}\right\rangle,$$

which is skew-symmetric, bilinear and satisfies the Jacobi identity. In particular, F and G are called in involution if $(F,G)=0$. Now we consider the function system

$$F_m=2(1-2\beta+i\beta\langle\psi,\phi\rangle)\langle\wedge^{2m+2}\psi,\phi\rangle+\frac{1}{2}\sum_{j=0}^{m}\begin{vmatrix}\langle\wedge^{2(m-j)+1}\psi,\psi\rangle & \langle\wedge^{2(m-j)+2}\psi,\phi\rangle\\ \langle\wedge^{2j}\psi,\phi\rangle & \langle\wedge^{2j+1}\phi,\phi\rangle\end{vmatrix},$$

$$m=0,1,\ldots. \tag{35}$$

Proposition 4: The inner product $\langle\partial F_m/\partial\psi,\partial F_n/\partial\phi\rangle$ is symmetrical about m and n, i.e.,

$$\left\langle\frac{\partial F_m}{\partial\psi},\frac{\partial F_n}{\partial\phi}\right\rangle=\left\langle\frac{\partial F_n}{\partial\psi},\frac{\partial F_m}{\partial\phi}\right\rangle. \tag{36}$$

Proof: Noticing that

$$\begin{aligned}\frac{\partial F_m}{\partial\psi}&=2i\beta\phi\langle\wedge^{2m+2}\psi,\phi\rangle+(2+i\langle\psi,\phi\rangle)\wedge^{2m+2}\phi+\sum_{j=1}^{m}(\langle\wedge^{2(m-j)+1}\phi,\phi\rangle\wedge^{2j+1}\psi\\&\quad-\langle\wedge^{2(m-j)+2}\psi,\phi\rangle\wedge^{2j}\phi),\\\frac{\partial F_n}{\partial\phi}&=2i\beta\psi\langle\wedge^{2n+2}\psi,\phi\rangle+(2+i\langle\psi,\phi\rangle)\wedge^{2n+2}\psi+\sum_{j=1}^{m}(\langle\wedge^{2(n-j)+1}\psi,\psi\rangle\wedge^{2j+1}\phi\\&\quad-\langle\wedge^{2(n-j)+2}\psi,\phi\rangle\wedge^{2j}\psi).\end{aligned} \tag{37}$$

Through a series of direct calculations, it is easy to see that $\langle\partial F_m/\partial\psi,\partial F_n/\partial\phi\rangle$ is the sum of the symmetrical items about m and n. So (36) is proved.

Proposition 5: The functions defined by (35) are in involution in pair

$$(F_m,F_n)=0.$$

Proof: By Proposition 4, we have

$$\begin{aligned}(F_m,F_n)&=\left\langle\frac{\partial F_m}{\partial\psi},\frac{\partial F_n}{\partial\phi}\right\rangle-\left\langle\frac{\partial F_m}{\partial\phi},\frac{\partial F_n}{\partial\psi}\right\rangle\\&=\left\langle\frac{\partial F_n}{\partial\psi},\frac{\partial F_m}{\partial\phi}\right\rangle-\left\langle\frac{\partial F_m}{\partial\phi},\frac{\partial F_n}{\partial\psi}\right\rangle=0.\end{aligned}$$

Proposition 6: $(H,F_m)=0$.

Proof: As we did before, making use of (34) and (37) and through direct calculation, we have

$$(H,F_m)=\left\langle\frac{\partial H}{\partial\psi},\frac{\partial F_m}{\partial\phi}\right\rangle-\left\langle\frac{\partial H}{\partial\phi},\frac{\partial F_m}{\partial\psi}\right\rangle=0.$$

In summary, we conclude the following.

Theorem 2: The Hamiltonian system defined by (33) is completely integrable in the Liouville sense in the symplectic manifold $(R^{2N}, d\psi \wedge d\phi)$.

Theorem 3: Let (ψ, ϕ) be a solution of Bargmann system (33). Then q and r defined by (32) satisfy a stationary Kaup–Newell-type equation

$$X_{2N+1} + c_1 X_{2N-1} + \cdots + c_N X_1 = 0, \tag{38}$$

where $X_{2j+1} = JG_{2j+1}$, $j = 0,1,\ldots,N$, and $c_1, c_2, \ldots, c_N$ are suitably chosen constants.

Proof: Operating with $(J^{-1}K)^k$ upon the expression of (31) and in virtue of (27) and (28), we have

$$G_{2k+1} + \beta_1 G_{2k-1} + \cdots + \beta_k G_1 + \beta_{k+1} G_{-1} = \sum_{j=1}^{N} \gamma \lambda_j^{2k} \gamma_j \frac{\delta \lambda_j}{\delta u}, \tag{39}$$

where $\beta_1, \beta_2, \ldots, \beta_{k+1}$ are arbitrary constants, $G_{-1} = (0,0)^T$, and $\partial^{-1} 0 = 1$. Consider the polynomial

$$P(\lambda) = \prod_{j=1}^{N} (\lambda - \lambda_j^2) = p_0 \lambda^N + \cdots + p_N, \quad p_0 = 1.$$

Acting with the operator $J\Sigma_{k=1}^{N} p_{N-k}$ on (39), we have (38), where $c_1, \ldots, c_N$ depend on $\beta_1, \ldots, \beta_{k+1}$ and $\lambda_1, \ldots, \lambda_N$.

V. INVOLUTIVE SOLUTIONS OF KAUP–NEWELL-TYPE HIERARCHY

The involutive solutions of Kaup–Newell-type hierarchy associated with Bargmann system (33) can be further given. Consider the canonical system of F_m-flow

$$(F_m): \quad \begin{pmatrix} \psi_{t_m} \\ \phi_{t_m} \end{pmatrix} = \begin{pmatrix} \dfrac{\partial F_m}{\partial \psi} \\ \dfrac{\partial F_m}{\partial \phi} \end{pmatrix} = I \nabla F_m, \quad I = \begin{pmatrix} 0 & I_N \\ -I_N & 0 \end{pmatrix}, \tag{40}$$

where I_N is an $N \times N$ unit matrix. Let $g_m^{t_m}$ denote the solution operator of the initial value problem (40). Then the solutions of Eq. (40) are expressed as

$$\begin{pmatrix} \psi_{t_m} \\ \phi_{t_m} \end{pmatrix} = g_m^{t_m} \begin{pmatrix} \psi(0) \\ \phi(0) \end{pmatrix}.$$

Since any two F_k, F_l are in involution, we have[18,42] the following.

Proposition 7: (i) Any two canonical system (F_k), (F_l) are compatible. (ii) The Hamiltonian phase-flows $g_k^{t_m}$ and $g_m^{t_l}$ commute.

Denote the flow variables of (H) and (F_m) by $x = t_0$ and $t = t_m$, respectively. Then the involutive solution of the consistent (H) and (F_m),

$$\begin{pmatrix} \psi_{x,t_m} \\ \phi_{x,t_m} \end{pmatrix} = g_0^x g_m^{t_m} \begin{pmatrix} \psi(0,0) \\ \phi(0,0) \end{pmatrix},$$

is a smooth function of (x, t_m) in view of the commutativity of flow g_0^x and $g_m^{t_m}$.

Theorem 4: Let $(\psi(x,t_m), \phi(x,t_m))^T$ be an involutive solution of the consistent system (H), (F_m), and

$$q(x,t_m)=-\frac{\langle \wedge\psi,\psi\rangle}{2(1-2\beta+i\beta\langle\psi,\phi\rangle)},\quad r(x,t_m)=\frac{\langle \wedge\phi,\phi\rangle}{2(1-2\beta+i\beta\langle\psi,\phi\rangle)}.$$

Then we have (i) the equations (H), (F_m) are reduced to the spatial part and the time part, respectively, of Lax pairs for the high-order generalized Kaup–Newell equations

$$\begin{pmatrix}\psi_x\\ \phi_x\end{pmatrix}=\begin{pmatrix}-i\wedge^2-i\beta qr & \wedge q\\ \wedge r & i\wedge^2+i\beta qr\end{pmatrix}\begin{pmatrix}\psi\\ \phi\end{pmatrix},\tag{41}$$

$$\begin{pmatrix}\psi_{t_m}\\ \phi_{t_m}\end{pmatrix}=\sum_{j=0}^{m}c_jV_{\wedge}^{(m-j)}\begin{pmatrix}\psi\\ \phi\end{pmatrix},\tag{42}$$

where $V_{\wedge}^{(m-j)}$ is determined by (10) in which λ is replaced by $\wedge=\mathrm{diag}(\lambda_1,...,\lambda_N)$. (ii) $q(x,t_m)$ and $r(x,t_m)$ satisfy the high-order Kundu equation

$$(q_{t_m},r_{t_m})=X_{2m+1}+c_1X_{2m-1}+\cdots+c_mX_1.\tag{43}$$

Proof: Obviously (41) holds from (33) and (34). Making use of (28), (33) and (38), direct and tedious calculation leads to (42) and (43).

VI. DARBOUX TRANSFORMATION

In this section, we shall construct an N-fold Darboux transformation for the coupled Kundu system (21). The Darboux transformation is actually a special gauge transformation

$$\tilde{y}=Ty\tag{44}$$

of the solutions of the Lax pairs (5) and (24). It is required that $\tilde{y}$ also satisfies Lax pairs (5) and (24) with some $\tilde{U}$ and $\tilde{V}^{(1)}$, i.e.,

$$\tilde{y}_x=\tilde{U}\tilde{y},\quad \tilde{U}=(T_x+TU)T^{-1},\tag{45}$$

$$\tilde{y}_t=\tilde{V}^{(1)}\tilde{y},\quad \tilde{V}^{(1)}=(T_t+TV^{(1)})T^{-1}.\tag{46}$$

By cross differentiating (45) and (46), we get

$$\tilde{U}_t-\tilde{V}_x^{(1)}+[\tilde{U},\tilde{V}^{(1)}]=T(U_t-V_x^{(1)}+[U,V^{(1)}])T^{-1},\tag{47}$$

which implies that in order to make system (21) invariant under the gauge transformation (44), we should require $\tilde{U}$ and $\tilde{V}^{(1)}$, have the same forms as U and $V^{(1)}$, respectively. At the same time the old potentials q and r in U, $V^{(1)}$ will be mapped into new potentials $\tilde{q}$ and $\tilde{r}$ in $\tilde{U}$, $\tilde{V}^{(1)}$. This process can be done continually and usually it may yield a series of multi-soliton solutions. Based on the idea,[23,38] we can construct an N-fold Darboux transformation for coupled Kundu system (21) as follows:

Let $(\phi_1(x,t,\lambda),\phi_2(x,t,\lambda))^T$ and $(\psi_1(x,t,\lambda),\psi_2(x,t,\lambda))^T$ be two basic solutions of spectral problem (5) and (24), and use them to define two linear algebraic systems for A_k, B_k, C_k and D_k $(0\leqslant k\leqslant N-1)$:

$$\sum_{k=0}^{N-1}(A_k+\alpha_j\lambda_jB_k)\lambda_j^{2k}=-\lambda_j^{2N},\quad 1\leqslant j\leqslant 2N,\tag{48}$$

$$\sum_{k=0}^{N-1}(\lambda_jC_k+\alpha_jD_k)\lambda_j^{2k}=-\alpha_j\lambda_j^{2N},\quad 1\leqslant j\leqslant 2N,\tag{49}$$

with

$$\alpha_j=\frac{\phi_2(\lambda_j)-\gamma_j\psi_2(\lambda_j)}{\phi_1(\lambda_j)-\gamma_j\psi_1(\lambda_j)},\quad 1\leqslant j\leqslant 2N, \tag{50}$$

where λ_j and γ_j are some parameters suitably chosen, such that determinants of the coefficients for (48) and (49) are nonzero. Hence A_k, B_k, C_k, and D_k are uniquely determined by (48) and (49). Now we let

$$T=\begin{pmatrix} A(\lambda) & B(\lambda) \\ C(\lambda) & D(\lambda)\end{pmatrix}=Q\left(I\lambda^{2N}+\sum_{k=0}^{N-1}(Q_{2k}+\lambda Q_{2k+1})\lambda^{2k}\right), \tag{51}$$

which is a $(2N)$th order polynomial in λ with matrix coefficient, and

$$Q=\begin{pmatrix}\delta_N & 0\\ 0 & 1/\delta_N\end{pmatrix},\quad I=\begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix},$$

$$Q_{2k}=\begin{pmatrix}A_k & 0\\ 0 & D_k\end{pmatrix},\quad Q_{2k+1}=\begin{pmatrix}0 & B_k\\ C_k & 0\end{pmatrix},\quad 0\leqslant k\leqslant N-1,$$

where $\delta_N=\delta_N(x,t)$ is a function to be determined later, which plays an important role in constructing an explicit Darboux transformation of system (21) in this article. As $\delta_N=1$ or $Q=I$, the form of matrix T in (51) is exactly the same as that in our previous paper,[38] where we constructed a Darboux transformation for GI equation (3). From (48), (49) and (51), it is easy to see that $\det T(\lambda)$ is $(4N)$th order polynomial of λ, and $\pm\lambda_j$ $(1\leqslant j\leqslant 2N)$ are all its roots. Therefore we have

$$\det T(\lambda)=\prod_{j=1}^{2N}(\lambda^2-\lambda_j^2). \tag{52}$$

Proposition 8: Let δ_N satisfy a first-order ordinary equation

$$\partial_x\ln\delta_N=(2\beta-1)(rB_{N-1}-qC_{N-1}-2iB_{N-1}C_{N-1}). \tag{53}$$

Then matrix $\tilde{U}$ determined by (44) has the same form as U, that is,

$$\tilde{U}=\begin{pmatrix}-i\lambda^2-i\beta\tilde{q}\tilde{r} & \lambda\tilde{q}\\ \lambda\tilde{r} & i\lambda^2+i\beta\tilde{q}\tilde{r}\end{pmatrix},$$

where the transformations between q, r and $\tilde{q}$, $\tilde{r}$ are given by

$$\tilde{q}=\delta_N^2(q+2iB_{N-1}),\quad \tilde{r}=\delta_N^{-2}(r-2iC_{N-1}). \tag{54}$$

The transformation (44) and (54): $(y,q,r)\to(\tilde{y},\tilde{q},\tilde{r})$ is a Darboux transformation of the spectral problem (5).

Proof: Let $T^{-1}=T^*/\det T$ and

$$(T_x+TU)T^*=\begin{pmatrix}f_{11}(\lambda) & f_{12}(\lambda)\\ f_{21}(\lambda) & f_{22}(\lambda)\end{pmatrix}. \tag{55}$$

It is easy to see that $f_{11}(\lambda)$ and $f_{22}(\lambda)$ are (4N+2)th order polynomials in λ, and $f_{12}(\lambda)$ and $f_{21}(\lambda)$ are (4N+1)th order polynomials in λ.

On the other hand, making use of (5) and (48)–(50), we find that

$$\alpha_{jx}=\lambda_j r-\lambda_j q\alpha_j^2+2i(\lambda_j^2+\beta qr)\alpha_j,$$

$$A(\pm\lambda_j)=\mp\alpha_j B(\pm\lambda_j),\quad C(\pm\lambda_j)=\mp\alpha_j D(\pm\lambda_j).$$

From the above equalities, it is easy to verify that all $\pm\lambda_j$ $(1\leqslant j\leqslant 2N)$ are roots of $f_{kj}(\lambda)$ $(k,j=1,2)$, which together with (52) implies that $f_{kj}(\lambda)$ may be divided by $\det T$, and thus $(T_x+TU)T^{-1}$ is a second order polynomial in λ with matrix coefficients, that is,

$$T_x+TU=(\tilde{U}_2\lambda^2+\tilde{U}_1\lambda+\tilde{U}_0)T, \tag{56}$$

where the matrices $\tilde{U}_2(x,t)$, $\tilde{U}_1(x,t)$ and $\tilde{U}_0(x,t)$ do not depend on λ.

We denote $U=U_2\lambda^2+U_1\lambda+U_0$, with

$$U_2=\begin{pmatrix}-i & 0\\ 0 & i\end{pmatrix},\quad U_1=\begin{pmatrix}0 & q\\ r & 0\end{pmatrix},\quad U_0=\begin{pmatrix}-i\beta qr & 0\\ 0 & i\beta qr\end{pmatrix}.$$

Comparing the coefficients of λ^{2N+2}, λ^{2N+1}, and λ^{2N} in (56) yields

$$(2N+2)\text{th coeff.:}\ \ \tilde{U}_2=QU_2Q^{-1}=U_2,$$

$$(2N+1)\text{th coeff.:}\ \ \tilde{U}_1=(QU_1+[QQ_{2N-1},U_2])Q^{-1}=\begin{pmatrix}0 & \tilde{q}\\ \tilde{r} & 0\end{pmatrix},$$

$$(2N)\text{th coeff.:}$$

$$\tilde{U}_0=\partial_x\ln Q+(QU_0+QQ_{2N-1}U_1-\tilde{U}_1QQ_{2N-1}+[QQ_{2N-2},U_2])Q^{-1}=\begin{pmatrix}-i\beta\tilde{q}\tilde{r} & 0\\ 0 & i\beta\tilde{q}\tilde{r}\end{pmatrix},$$

where $\tilde{q}$ and $\tilde{r}$ are given by (54). The proof is completed.

Next we try to prove that $\tilde{V}^{(1)}$ in (46) has the same form as $V^{(1)}$ under the transformations (44) and (54).

Proposition 9: Suppose that δ_N satisfies another compatible first-order ordinary differential equation

$$\begin{aligned}\partial_t\ln\delta_N=&(2\beta-1)[i(qC_{N-1x}+rB_{N-1x})-i(q_xC_{N-1}+r_xB_{N-1})-2(B_{N-1}C_{N-1x}-B_{N-1x}C_{N-1})\\&-(4\beta-1)qr(rB_{N-1}-qC_{N-1})-i(r^2B_{N-1}^2+q^2C_{N-1}^2)-4(rB_{N-1}^2C_{N-1}\\&-qB_{N-1}C_{N-1}^2)+8i\beta qrB_{N-1}C_{N-1}+4iB_{N-1}^2C_{N-1}^2].\end{aligned} \tag{57}$$

Then matrix $\tilde{V}^{(1)}$ in (46) has the same form as $V^{(1)}$ under the same transformation (44) and (54).

Proof: In a way similar to Proposition 8, we can prove that $(T_t+TV^{(1)})T^{-1}$ is a fourth-order polynomial in λ with matrix coefficients, that is,

$$T_t+TV^{(1)}=(\tilde{V}_4\lambda^4+\tilde{V}_3\lambda^3+\tilde{V}_2\lambda^2+\tilde{V}_1\lambda+\tilde{V}_0)T. \tag{58}$$

We write $V^{(1)}$ in the form $V^{(1)}=V_4\lambda^4+V_3\lambda^3+V_2\lambda^2+V_1\lambda+V_0$, with

$$V_4=\begin{pmatrix}-2i & 0\\ 0 & 2i\end{pmatrix},\quad V_3=\begin{pmatrix}0 & 2q\\ 2r & 0\end{pmatrix},\quad V_2=\begin{pmatrix}-iqr & 0\\ 0 & iqr\end{pmatrix},$$

$$V_1=\begin{pmatrix}0 & iq_x-(2\beta-1)q^2r\\ -ir_x-(2\beta-1)qr^2 & 0\end{pmatrix},$$

$$V_0=\begin{pmatrix} \beta(rq_x-qr_x)+\frac{1}{2}i\beta(8\beta-3)q^2r^2 & 0 \\ 0 & -\beta(rq_x-qr_x)-\frac{1}{2}i\beta(8\beta-3)q^2r^2 \end{pmatrix}.$$

Comparing the coefficients of λ^{2N+j} $(j=0,1,2,3,4)$ yields

$$(2N+4)\text{th coeff.: } \tilde{V}_4=QV_4Q^{-1}=V_4,$$

$$(2N+3)\text{th coeff.: } \tilde{V}_3=(QV_3+[QQ_{2N-1},V_4])Q^{-1}=\begin{pmatrix} 0 & 2\tilde{q} \\ 2\tilde{r} & 0 \end{pmatrix},$$

$$\begin{aligned}(2N+2)\text{th coeff.: } \tilde{V}_2&=(QV_2+QQ_{2N-1}V_3-\tilde{V}_3QQ_{2N-1}+[QQ_{2N-2},V_4])Q^{-1}\\ &=\begin{pmatrix} -i\tilde{q}\tilde{r} & 0 \\ 0 & i\tilde{q}\tilde{r} \end{pmatrix},\end{aligned}$$

$$\begin{aligned}(2N+1)\text{th coeff.: } \tilde{V}_1&=(QV_1+QQ_{2N-1}V_2-\tilde{V}_2QQ_{2N-1})Q^{-1}\\ &\quad+(QQ_{2N-2}V_3-\tilde{V}_3QQ_{2N-2}+[QQ_{2N-3},V_4])Q^{-1},\end{aligned} \tag{59}$$

$(2N)$th coeff.:

$$\begin{aligned}\tilde{V}_0&=\partial_t\ln Q+(QV_0+QQ_{2N-1}V_1-\tilde{V}_1QQ_{2N-1}+QQ_{2N-2}V_2-\tilde{V}_2QQ_{2N-2}+QQ_{2N-3}V_3\\ &\quad-\tilde{V}_3QQ_{2N-3}+[QQ_{2N-4},V_4])Q^{-1}\\ &=\partial_t\delta_N+(QV_0+QQ_{2N-1}V_1-\tilde{V}_1QQ_{2N-1})Q^{-1}+\frac{1}{2}U_2\tilde{U}_1([QQ_{2N-3},V_4]+QQ_{2N-2}V_3\\ &\quad-\tilde{V}_3QQ_{2N-2})Q^{-1}-\frac{1}{2}([QQ_{2N-3},V_4]+Q_{2N-2}V_3-\tilde{V}_3Q_{2N-2})U_2U_1Q^{-1}.\end{aligned} \tag{60}$$

Again comparing the coefficient of λ^{2N-1} in (56) and noting that $V_4=2U_2$, $V_3=2U_1$, $\tilde{V}_3=2\tilde{U}_1$, $U_0=\beta V_2$, $\tilde{U}_0=\beta\tilde{V}_2$, we find that

$$\begin{aligned}&[QQ_{2N-3},V_4]+QQ_{2N-2}V_3-\tilde{V}_3QQ_{2N-2}\\ &\quad=-2Q_xQ_{2N-1}-2QQ_{2N-1x}+2\tilde{U}_0QQ_{2N-1}-2QQ_{2N-1}U_0.\end{aligned} \tag{61}$$

Substituting (61) into (59) and (60), direct calculation shows that $\tilde{V}_1$ and $\tilde{V}_0$ possess the same form as V_1 and V_0. By using (53), (54), and (57) and noting that q, r, $\tilde{q}$, $\tilde{r}$ satisfy the Kundu equation (21), in virtue of Mathematica direct and tedious verification shows that $\delta_{Nxt}=\delta_{Ntx}$, that is to say, Eqs. (53) and (57) are compatible. The theorem is completed.

Propositions 8 and 9 show that the transformations (44) and (54) change the Lax pairs (5) and (24) into other Lax pairs (45) and (46) of the same type. Therefore both of the Lax pairs lead to the same coupled Kundu system (21). We call the transformation $(y,q,r)\to(\tilde{y},\tilde{q},\tilde{r})$ a Darboux transformation of coupled Kundu system (21). In summary, we arrive at the following theorem.

Theorem 5: The solutions (q,r) of coupled Kundu system (21) are mapped into their new solution $(\tilde{q},\tilde{r})$ under Darboux transformation (44) and (54), where B_{N-1} and C_{N-1} are given by (48) and (49), and δ_N is determined by two first-order ordinary differential equations (53) and (57).

VII. REDUCTION OF DARBOUX AND ITS APPLICATION

In this section, the N-fold Darboux transformation of the Kundu equation (22) will be obtained from that of coupled Kundu system (21) by using a reduction technique. For this purpose we let $r=-q^*$, and choose two solutions of the Lax pairs (5) and (24) as

$$\phi(\lambda)=(\phi_1(\lambda),\phi_2(\lambda))^T,\quad \psi(\lambda)=(-\phi_2^*(\lambda^*),\phi_1^*(\lambda^*))^T,$$

and parameters

$$\lambda_{2j}=\lambda_{2j-1}^*,\quad \gamma_{2j}=-\gamma_{2j-1}^{*^{-1}},\quad 1\leqslant j\leqslant N.$$

Then it is easy to show that $\alpha_{2j}^{-1}=-\alpha_{2j-1}^*$, $D_k^*=A_k$, $C_k^*=-B_k$ $(0\leqslant k\leqslant N-1)$. In this way, the corresponding systems (48)–(50) are reduced to

$$\sum_{k=0}^{N-1}(A_k+\lambda_{2j-1}\alpha_{2j-1}B_k)\lambda_{2j-1}^{2k}=-\lambda_{2j-1}^{2N},\tag{62}$$

$$\sum_{k=0}^{N-1}(\alpha_{2j-1}^*A_k-\lambda_{2j-1}^*B_k)\lambda_{2j-1}^{*^{2k}}=-\alpha_{2j-1}^*\lambda_{2j-1}^{*^{2N}},\quad 1\leqslant j\leqslant N.\tag{63}$$

$$\alpha_{2j-1}=\frac{\phi_2(\lambda_{2j-1})-\gamma_{2j-1}\psi_2(\lambda_{2j-1})}{\phi_1(\lambda_{2j-1})-\gamma_{2j-1}\psi_1(\lambda_{2j-1})},\tag{64}$$

and Eqs. (53) and (57) are reduced to

$$\partial_x\delta_N=2(2\beta-1)[\mathrm{Im}(q^*B_{N-1})+i|B_{N-1}|^2],\tag{65}$$

$$\begin{aligned}\partial_t\delta_N=2(2\beta-1)[&-i\,\mathrm{Re}(q^*B_{N-1x}-q_x^*B_{N-1})-2\,\mathrm{Im}(B_{N-1}^*B_{N-1x})+(4\beta-1)|q|^2\,\mathrm{Im}(q^*B_{N-1})\\&-i\,\mathrm{Re}(q^{*^2}B_{N-1}^2)-4\,\mathrm{Im}(q^*|B_{N-1}|^2B_{N-1})+4i\beta|q|^2|B_{N-1}|^2+2i|B_{N-1}|^4].\end{aligned}\tag{66}$$

Based on these results we have the following theorem:

Theorem 6: Suppose that δ_N satisfies ordinary differential equations (65) and (66), and A_k, B_k are given by the linear algebraic system (62) and (63). Then solution q of Kundu equation (22) is mapped into its a new solution $\tilde{q}$ under the Darboux transformation

$$\tilde{q}=\delta_N^2(q+2iB_{N-1}).\tag{67}$$

In the following, we shall apply the Darboux transformation (67) to construct explicit solutions of Kundu equation (22). As usual, we make a Darboux transformation starting from a special solution of Eq. (21). Substituting $q=0$ $(q=r=0)$ into the Lax pairs (5) and (24), we find that two basic solutions can be chosen as

$$\phi(\lambda)=\begin{pmatrix}\exp(-i\lambda^2x-2i\lambda^4t)\\0\end{pmatrix},\quad \psi(\lambda)=\begin{pmatrix}0\\\exp(i\lambda^2x+2i\lambda^4t)\end{pmatrix}.$$

According to (64), we have

$$\alpha_{2j-1}=-\exp(2i\lambda_{2j-1}^2x+4i\lambda_{2j-1}^4t+\delta_j+i\mu_j),\quad 1\leqslant j\leqslant N,\tag{68}$$

where $\gamma_{2j-1}=\exp(\delta_j+i\mu_j)$. We shall discuss only the case $N=1$.

Let $\lambda_1=\xi_1+i\eta_1$ $(\xi_1\neq\eta_1)$. Then solving the linear algebraic system (62) and (63) yields

$$B_0=\frac{2i\xi_1\eta_1\exp(iY_1)}{\xi_1\cosh(X_1)+i\eta_1\sinh(X_1)}, \tag{69}$$

where

$$X_1=4\xi_1\eta_1x+16\xi_1\eta_1(\xi_1^2-\eta_1^2)t+\delta_1, \quad Y_1=-2(\xi_1^2-\eta_1^2)x+4(\xi_1^4-\eta_1^4-6\xi_1^2\eta_1^2)t+\mu_1. \tag{70}$$

By using (69), solving Eqs. (65) and (66) corresponding to $q=r=0$ by using Mathematica gives

$$\delta_1=\exp\{2(2\beta-1)[if(x,t)+(\xi_1^2+\eta_1^2)(\xi_1^2-\eta_1^2)^{-1}g(x,t)]\},$$

where

$$g(x,t)=\arctan[\xi_1^{-1}\eta_1\tanh(X_1)], \quad f(x,t)=-g(x,t)+\frac{\xi_1\eta_1(\xi_1^2+\eta_1^2)\sinh(2X_1)}{(\xi_1^2-\eta_1^2)^2+(\xi_1^4-\eta_1^4)\cosh(2X_1)}.$$

In this way, a one-soliton solution of the Kundu equation (21) is obtained with the help of the Darboux transformation (67):

$$\tilde{q}=2i\delta_1^2B_0.$$

The N-fold Darboux transformation (67) presented here has some merits. First, the solution $\tilde{q}$ in (67) is the N-fold Darboux transformation of the solution q. It can be interpreted as a nonlinear superposition of the initial solution q and N-soliton solution. It contains all pure N-soliton solutions of the Kundu equation in a unified form. Therefore, it provides unified and explicit N-soliton solutions for Kundu, KN, CLL, and GI equation. Second, the solutions of the Kundu equation are reduced to solving a linear algebraic system and two first-order ordinary differential equations. It is easy to produce its multi-soliton solutions by symbolic computation on a computer. At last, for the case $\beta=\frac{1}{2}$, all results obtained in this article can be reduced to the corresponding ones.[38]

Binary symmetry constraints of the $\mathcal{N}$-wave interaction equations in $1+1$ and $2+1$ dimensions are proposed to reduce the $\mathcal{N}$-wave interaction equations into finite-dimensional Liouville integrable systems. A new involutive and functionally independent system of polynomial functions is generated from an arbitrary order square matrix Lax operator and used to show the Liouville integrability of the constrained flows of the $\mathcal{N}$-wave interaction equations. The constraints on the potentials resulting from the symmetry constraints give rise to involutive solutions to the $\mathcal{N}$-wave interaction equations, and thus the integrability by quadratures are shown for the $\mathcal{N}$-wave interaction equations by the constrained flows. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1388898]

I. INTRODUCTION

It is a usual practice to utilize the idea of linearization in analyzing nonlinear differential or differential-difference equations (see, for example Refs. 1 and 2). The method of inverse scattering transform is an important application of such an idea to the theory of soliton equations,[3,4] which has been recognized as one of the most significant contributions in the field of applied mathematics in the second half of the last century. The general formulation of Lax pairs is a spectacular tool of realization of inverse scattering transform,[5] by which one can break a nonlinear problem into a couple of linear problems and then handle the resulting linear problems to solve the nonlinear problem.

Recently in the past decade, an unusual way of using the nonlinearization technique arose in the theory of soliton equations.[6–10] Although using the idea of nonlinearization is not normally considered to be a good direction in studying nonlinear equations, one gradually realizes that the nonlinearization technique provides a powerful approach for analyzing soliton equations, especially for showing the integrability by quadratures for soliton equations. The manipulation of nonlinearization not only leads to finite-dimensional Liouville integrable systems,[6–15] but also decomposes infinite-dimensional soliton equations, in whatever dimensions, into finite-dimensional Liouville integrable systems.[16–18] Moreover, it narrows the gap between infinite-dimensional soliton equations and finite-dimensional Liouville integrable systems,[11,16,18] and paves a method of separation of variables for soliton equations,[19,20] which can also be used to analyze the resulting finite-dimensional integrable systems.[21–23] Mathematically speaking, much excitement in the study of nonlinearization comes from a kind of specific symmetry constraints,[24–27] engendered from the variational derivative of the spectral parameter.[26,27] It is due to symmetry constraints that the nonlinearization technique is so powerful in showing the integrability by quadratures for soliton equations.[28,29] The study of symmetry constraints itself is an important part of the kernel of the mathematical theory of nonlinearization, which is also a common conceptional umbrella under which one can manipulate both mono-nonlinearization[6] and binary nonlinearization.[26]

However, all examples of application of the nonlinearization technique, discussed so far, are

related to lower-order matrix (here, and in what follows, a matrix is assumed to be square) spectral problems of soliton equations, most of which are only concerned with second-order traceless matrix spectral problems. On the one hand, there appears much difficulty in handling the Liouville integrability[30] of the so-called constrained flows generated from spectral problems, in the case of the third- and fourth-order matrix spectral problems.[28,31,32] It is a challenging task to extend the theory of nonlinearization to the case of higher-order matrix spectral problems. On the other hand, one also notices that mono-nonlinearization cannot be carried out in the cases of odd-order matrix spectral problems and even-order, including the simplest second-order, nontraceless matrix spectral problems. Even for even-order traceless matrix spectral problems, it is not clear how to determine pairs of canonical variables to obtain Hamiltonian structures of the constrained flows while doing mono-nonlinerization. Therefore, one has to take into account adjoint spectral problems and manipulate binary nonlinearization for the case of general matrix spectral problems. In the theory of binary nonlinearization,[33] there exists a natural way for determining symplectic structures to exhibit Hamiltonian forms of the constrained flows.

In this article, we would like to establish a concrete example to apply the nonlinearization technique to the case of higher-order matrix spectral problems, by manipulating binary nonlinearization for arbitrary-order matrix spectral problems associated with the $\mathcal{N}$-wave interaction equations in both $1+1$ and $2+1$ dimensions. The resulting theory will show a direct way for generating sufficiently many integrals of motion, and more importantly for proving the functional independence of the required integrals of motion, for the Liouville integrability of the constrained flows resulting from higher-order matrix spectral problems.

Let us recall some basic notation on binary nonlinearization (see, for example, Ref. 33 for a detailed description). Let us assume that we have a matrix spectral problem

$$\phi_x = U\phi = U(u,\lambda)\phi, \quad U=(U_{ij})_{r\times r}, \quad \phi=(\phi_1,\ldots,\phi_r)^T \tag{1.1}$$

with a spectral parameter λ and a potential $u=(u_1,\ldots,u_q)^T$. Suppose that the compatability conditions

$$U_{t_m} - V^{(m)}_x + [U,V^{(m)}] = 0, \quad m \geqslant 0,$$

of the spectral problem (1.1) and the associated spectral problems

$$\phi_{t_m} = V^{(m)}\phi = V^{(m)}(u,u_x,\ldots;\lambda)\phi, \quad V^{(m)}=(V^{(m)}_{ij})_{r\times r}, \quad m\geqslant 0, \tag{1.2}$$

determine an isospectral ($\lambda_{t_m}=0$) soliton hierarchy

$$u_{t_m} = X_m(u) = JG_m = J\frac{\delta \tilde{H}_m}{\delta u}, \quad m\geqslant 0, \tag{1.3}$$

where J is a Hamiltonian operator and $\tilde{H}_m$ are Hamiltonian functionals. Obviously, the compatability conditions of the adjoint spectral problem

$$\psi_x = -U^T(u,\lambda)\psi, \quad \psi=(\psi_1,\ldots,\psi_r)^T, \tag{1.4}$$

and the adjoint associated spectral problems

$$\psi_{t_m} = -V^{(m)T}\lambda = -V^{(m)T}(u,u_x,\ldots;\lambda)\psi \tag{1.5}$$

still give rise to the same hierarchy $u_{t_m}=X_m(u)$ defined by (1.3). It has been pointed out[16,26] that $J\delta\lambda/\delta u$ is a common symmetry of all equations in the hierarchy (1.3). Introducing N distinct eigenvalues $\lambda_1,\lambda_2,\ldots,\lambda_N$, we have

$$\phi^{(s)}_x = U(u,\lambda_s)\phi^{(s)}, \quad \psi^{(s)}_x = -U^T(u,\lambda_s)\psi^{(s)}, \quad 1\leqslant s\leqslant N, \tag{1.6}$$

and

$$\phi_{t_m}^{(s)}=V^{(m)}(u,u_x,\ldots;\lambda_s)\phi^{(s)},\quad \psi_{t_m}^{(s)}=-V^{(m)T}(u,u_x,\ldots;\lambda_s)\psi^{(s)},\quad 1\leqslant s\leqslant N, \tag{1.7}$$

where we set the corresponding eigenfunctions and adjoint eigenfunctions as $\phi^{(s)}$ and $\psi^{(s)}$, $1\leqslant s\leqslant N$. It is assumed that the conserved covariant G_{m_0} does not depend on any derivative of u with respect to x, and thus the so-called general binary Bargmann symmetry constraint reads as

$$X_{m_0}=\sum_{s=1}^{N} E_s\mu_s J\frac{\delta\lambda_s}{\delta u},\quad \text{i.e.,}\quad JG_{m_0}=J\sum_{s=1}^{N}\mu_s\psi^{(s)T}\frac{\partial U(u,\lambda_s)}{\partial u}\phi^{(s)}, \tag{1.8}$$

where μ_s, $1\leqslant s\leqslant N$, are arbitrary nonzero constants, and E_s, $1\leqslant s\leqslant N$, are normalized constants. The right-hand side of the symmetry constraint (1.8) is a linear combination of N symmetries

$$E_s J\frac{\delta\lambda_s}{\delta u}=J\psi^{(s)T}\frac{\partial U(u,\lambda_s)}{\partial u}\phi^{(s)},\quad 1\leqslant s\leqslant N.$$

Such symmetries are not Lie point, contact or Lie–Bäcklund symmetries, since $\phi^{(s)}$ and $\psi^{(s)}$ cannot be expressed in terms of x, u and derivatives of u with respect to x to some finite order. Suppose that (1.8) has an inverse function

$$u=\tilde{u}=\tilde{u}(\phi^{(1)},\ldots,\phi^{(N)};\psi^{(1)},\ldots,\psi^{(N)}). \tag{1.9}$$

Replacing u with $\tilde{u}$ in the system (1.6) or the system (1.7), we obtain the so-called spatial constrained flow:

$$\phi_x^{(s)}=U(\tilde{u},\lambda_s)\phi^{(s)},\quad \psi_x^{(s)}=-U^T(\tilde{u},\lambda_s)\psi^{(s)},\quad 1\leqslant s\leqslant N, \tag{1.10}$$

or the so-called temporal constrained flows:

$$\phi_{t_m}^{(s)}=V^{(m)}(\tilde{u},\tilde{u}_x,\ldots;\lambda_s)\phi^{(s)},\quad \psi_{t_m}^{(s)}=-V^{(m)T}(\tilde{u},\tilde{u}_x,\ldots;\lambda_s)\psi^{(s)},\quad 1\leqslant s\leqslant N. \tag{1.11}$$

The main problem of nonlinearization is to show that the spatial constrained flow (1.10) and the temporal constrained flows (1.11) under the control of (1.10) are Liouville integrable. Then if $\phi^{(s)}$ and $\psi^{(s)}$, $1\leqslant s\leqslant N$, solve two constrained flows (1.10) and (1.11) simultaneously, $u=\tilde{u}$ will give rise to a solution to the mth soliton equation $u_{t_m}=X_m(u)$. It also follows that the soliton equation $u_{t_m}=X_m(u)$ is decomposed into two finite-dimensional Liouville integrable systems, and $u=\tilde{u}$ presents a Bäcklund transformation between infinite-dimensional soliton equations and finite-dimensional Liouville integrable systems. More generally, if a soliton equation is associated with a set of spectral problems

$$\phi_{x_i}=U^{(i)}(u,\lambda)\phi,\quad 1\leqslant i\leqslant p,$$

then it will be decomposed into $p+1$ finite-dimensional Liouville integrable systems. The above whole process is called binary nonlinearization.[16,33]

This article is structured as follows. In Sec. II, we will present binary symmetry constraints of the $\mathcal{N}$-wave interaction equations in $1+1$ dimensions, and show Hamiltonian structures and Lax presentations of the corresponding constrained flows. In Sec. III, we consider the $2+1$ dimensional case. We will similarly construct binary symmetry constraints of the $\mathcal{N}$-wave interaction equations in $2+1$ dimensions, and discuss some properties of the corresponding constrained flows. In Sec. IV, we go on to propose an involutive system of functionally independent polynomial functions, generated from an arbitrary-order matrix Lax operator, along with an alternative involutive and functionally independent system. An **r**-matrix formulation will be established for

the Lax operator, and used to show the involutivity of the obtained system of polynomial functions, together with Newton's identities on elementary symmetric polynomials. A detailed proof will also be made for the functional independence of the system of polynomial functions by using the determinant property of the tensor product of matrices. In Sec. V, two applications of the involutive system engendered in Sec. IV will be given, which verify that all constrained flows associated with the $\mathcal{N}$-wave interaction equations in both $1+1$ and $2+1$ dimensions are Liouville integrable. Moreover, a kind of involutive solution of the $\mathcal{N}$-wave interaction equations in two cases will be depicted. These also show the integrability by quadratures for the $\mathcal{N}$-wave interaction equations. Finally, in Sec. VI, some concluding remarks will be given, together with conclusions.

II. BINARY SYMMETRY CONSTRAINTS IN 1+1 DIMENSIONS

A. $n\times n$ AKNS hierarchy and 1+1 dimensional $\mathcal{N}$-wave interaction equations

Let n be an arbitrary natural number strictly greater than 2. We begin with the $n\times n$ matrix AKNS spectral problem[34]

$$\phi_x = U\phi = U(u,\lambda)\phi, \quad U(u,\lambda) = \lambda U_0 + U_1(u), \quad \phi = (\phi_1,\ldots,\phi_n)^T, \tag{2.1}$$

with a spectral parameter λ and

$$U_0 = \mathrm{diag}(\alpha_1,\ldots,\alpha_n), \quad U_1(u) = (u_{ij})_{n\times n}, \tag{2.2}$$

where α_i, $1\leqslant i\leqslant n$, are distinct constants, and $u_{ii}=0$, $1\leqslant i\leqslant n$. The standard AKNS spectral problem, i.e., the spectral problem (2.1) with $n=2$, has been analyzed in Ref. 35, but it cannot generate any $\mathcal{N}$-wave interaction equations and thus it is not discussed here. In order to express related soliton equations in a compact form, we write down the potential u as

$$\begin{gathered} u=\rho(U), \quad \text{i.e., } u=(u_{21},u_{12},u_{13},u_{31},u_{23},u_{32})^T, \quad \text{when } n=3, \\ u=(u_{21},u_{12},u_{13},u_{31},u_{14},u_{41},u_{23},u_{32},\ldots,u_{n,n-1},u_{n-1,n})^T, \quad \text{when } n\geqslant 4, \end{gathered} \tag{2.3}$$

in which we arrange the exponents u_{ij} in a specific way, first from smaller to larger of the integers $k=i+j$ and then symmetrically for each set $\{u_{i,k-i}|1\leqslant i\leqslant k-1\}$.

Let us now consider the construction of the $1+1$ dimensional $\mathcal{N}$-wave interaction equations and its whole isospectral hierarchy associated with the spectral problem (2.1). We first solve the stationary zero-curvature equation for W:

$$W_x - [U,W] = 0, \quad W = (W_{ij})_{n\times n}, \tag{2.4}$$

which is equivalent to

$$\begin{gathered} W_{ij,x} + u_{ij}(W_{ii}-W_{jj}) + \sum_{\substack{k=1\\k\neq i,j}}^{n} (u_{kj}W_{ik} - u_{ik}W_{kj}) - \lambda(\alpha_i-\alpha_j)W_{ij} = 0, \quad i\neq j, \\ W_{ii,x} = \sum_{\substack{k=1\\k\neq i}}^{n} (u_{ik}W_{ki} - u_{ki}W_{ik}), \end{gathered} \tag{2.5}$$

where $1\leqslant i,j\leqslant n$. We look for a formal solution of the form

$$W = \sum_{l\geqslant 0} W_l \lambda^{-l}, \quad W_l = (W_{ij}^{(l)})_{n\times n}, \tag{2.6}$$

and thus (2.5) becomes the following recursion relation

$$W_{ii,x}^{(0)}=0, \quad W_{ij}^{(0)}=0, \quad i\neq j, \tag{2.7a}$$

$$W_{ij,x}^{(l)}+u_{ij}(W_{ii}^{(l)}-W_{jj}^{(l)})+\sum_{\substack{k=1\\k\neq i,j}}^{n}(u_{kj}W_{ik}^{(l)}-u_{ik}W_{kj}^{(l)})-(\alpha_i-\alpha_j)W_{ij}^{(l+1)}=0, \quad i\neq j, \tag{2.7b}$$

$$W_{ii,x}^{(l+1)}=\sum_{\substack{k=1\\k\neq i}}^{n}(u_{ik}W_{ki}^{(l+1)}-u_{ki}W_{ik}^{(l+1)}), \tag{2.7c}$$

where $1\leqslant i,j\leqslant n$ and $l\geqslant 0$. In particular, from the above recursion relation, we have that

$$W_{ii}^{(0)}=\beta_i=\text{const}, \quad W_{ij}^{(0)}=0, \quad 1\leqslant i\neq j\leqslant n, \tag{2.8}$$

and

$$W_{ii}^{(1)}=0, \quad W_{ij}^{(1)}=\frac{\beta_i-\beta_j}{\alpha_i-\alpha_j}u_{ij}, \quad 1\leqslant i\neq j\leqslant n. \tag{2.9}$$

We require that

$$W_{ij}^{(l)}|_{u=0}=0, \quad 1\leqslant i,j\leqslant n, \quad l\geqslant 1. \tag{2.10}$$

This condition (2.10) means to identify all constants of integration to be zero while using (2.7) to determine W, and thus all W_l, $l\geqslant 1$, will be uniquely determined. For example, we can obtain from (2.7) under (2.10) that

$$W_{ij}^{(2)}=\frac{\beta_i-\beta_j}{(\alpha_i-\alpha_j)^2}u_{ij,x}+\frac{1}{\alpha_i-\alpha_j}\sum_{\substack{k=1\\k\neq i,j}}^{n}\left(\frac{\beta_k-\beta_i}{\alpha_k-\alpha_i}-\frac{\beta_k-\beta_j}{\alpha_k-\alpha_j}\right)u_{ik}u_{kj}, \quad 1\leqslant i\neq j\leqslant n,$$
$$W_{ii}^{(2)}=\sum_{\substack{k=1\\k\neq i}}^{n}\frac{\beta_k-\beta_i}{(\alpha_k-\alpha_i)^2}u_{ik}u_{ki}, \quad 1\leqslant i\leqslant n. \tag{2.11}$$

It is easy to see that the recursion relation (2.7) can lead to

$$2u_{ij}\partial^{-1}u_{ij}W_{ji}^{(l)}+(\partial-2u_{ij}\partial^{-1}u_{ji})W_{ij}^{(l)}+\sum_{\substack{k=1\\k\neq i,j}}^{n}[u_{ij}\partial^{-1}u_{ik}W_{ki}^{(l)}+(u_{kj}-u_{ij}\partial^{-1}u_{ki})W_{ik}^{(l)}]$$
$$+\sum_{\substack{k=1\\k\neq i,j}}^{n}[u_{ij}\partial^{-1}u_{kj}W_{jk}^{(l)}-(u_{ik}+u_{ij}\partial^{-1}u_{jk})W_{kj}^{(l)}]=(\alpha_i-\alpha_j)W_{ij}^{(l+1)}, \quad i\neq j, \tag{2.12}$$

where $1\leqslant i,j\leqslant n$, $l\geqslant 1$, and ∂^{-1} is the inverse operator of $\partial=\partial/\partial x$. This can be written as the Lenard form

$$MG_{l-1}=JG_l, \quad l\geqslant 1, \tag{2.13}$$

where $G_l=\rho(W_{l+1})$ is generated from W_{l+1} in the same way as that for u, and J is a constant operator

$$\begin{cases} J=\mathrm{diag}((\alpha_1-\alpha_2)\sigma_0,(\alpha_1-\alpha_3)\sigma_0,(\alpha_2-\alpha_3)\sigma_0), & \text{when } n=3, \\ J=\mathrm{diag}(\underbrace{(\alpha_1-\alpha_2)\sigma_0,(\alpha_1-\alpha_3)\sigma_0,(\alpha_1-\alpha_4)\sigma_0,(\alpha_2-\alpha_3)\sigma_0,\ldots,(\alpha_{n-1}-\alpha_n)\sigma_0}_{n(n-1)/2}), & \\ & \text{when } n\geqslant 4, \end{cases} \tag{2.14}$$

with σ_0 being given by

$$\sigma_0=\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}.$$

For example, when $n\geqslant 4$, we have

$$G_{l-1}=(W_{21}^{(l)},W_{12}^{(l)},W_{31}^{(l)},W_{13}^{(l)},W_{41}^{(l)},W_{14}^{(l)},W_{32}^{(l)},W_{23}^{(l)},\ldots,W_{n,n-1}^{(l)},W_{n-1,n}^{(l)})^T, \quad l\geqslant 1, \tag{2.15}$$

the first of which reads as

$$\begin{aligned} G_0=\Big(& \frac{\beta_1-\beta_2}{\alpha_1-\alpha_2}u_{21},\frac{\beta_1-\beta_2}{\alpha_1-\alpha_2}u_{12},\frac{\beta_1-\beta_3}{\alpha_1-\alpha_3}u_{31},\frac{\beta_1-\beta_3}{\alpha_1-\alpha_3}u_{13},\frac{\beta_1-\beta_4}{\alpha_1-\alpha_4}u_{41}, \\ & \frac{\beta_1-\beta_4}{\alpha_1-\alpha_4}u_{14},\ldots,\frac{\beta_{n-1}-\beta_n}{\alpha_{n-1}-\alpha_n}u_{n,n-1},\frac{\beta_{n-1}-\beta_n}{\alpha_{n-1}-\alpha_n}u_{n-1,n}\Big)^T. \end{aligned} \tag{2.16}$$

The operators J and M are skew-symmetric and can be shown to be a Hamiltonian pair.[36,37]

We proceed to introduce the associated spectral problems with the spectral problem (2.1),

$$\phi_{t_m}=V^{(m)}\phi, \quad V^{(m)}=V^{(m)}(u,\lambda)=(\lambda^m W)_+, \quad m\geqslant 1, \tag{2.17}$$

where the symbol $+$ stands for the choice of the part of non-negative powers of λ. Note that we have

$$W_{lx}=[U_0,W_{l+1}]+[U_1,W_l], \quad l\geqslant 0,$$

and we can compute that

$$\begin{aligned} [U,V^{(m)}]&=\Big[\lambda U_0+U_1,\sum_{l=0}^{m}\lambda^{m-l}W_l\Big] \\ &=\sum_{l=0}^{m}[U_0,W_l]\lambda^{m+1-l}+\sum_{l=0}^{m}[U_1,W_l]\lambda^{m-l} \\ &=\sum_{l=0}^{m-1}[U_0,W_{l+1}]\lambda^{m-l}+\sum_{l=0}^{m}[U_1,W_l]\lambda^{m-l}, \end{aligned}$$

where we have used $[U_0,W_0]=0$. Therefore, under the isospectral conditions

$$\lambda_{t_m}=0, \quad m\geqslant 1, \tag{2.18}$$

the compatibility conditions of the spectral problem (2.1) and the associated spectral problems (2.17), i.e., the zero-curvature equations

$$U_{t_m}-V_x^{(m)}+[U,V^{(m)}]=0, \quad m\geqslant 1,$$

equivalently lead to

$$U_{1t_m}=W_{mx}-[U_1,W_m]=[U_0,W_{m+1}], \quad m\geqslant 1.$$

This gives rise to the so-called $n\times n$ AKNS soliton hierarchy

$$u_{t_m}=X_m:=JG_m, \quad m\geqslant 1, \tag{2.19}$$

where J and $G_m=\rho(W_{m+1})$ are determined by (2.14) and (2.13).

Applying the trace identity[38]

$$\frac{\delta}{\delta u}\int \mathrm{tr}\left(W\frac{\partial U}{\partial \lambda}\right)dx=\lambda^{-\gamma}\frac{\partial}{\partial\lambda}\lambda^{\gamma}\mathrm{tr}\left(W\frac{\partial U}{\partial u}\right),$$

where γ is a constant to be determined, we can obtain

$$\frac{\delta\tilde{H}_l}{\delta u_{ij}}=W_{ji}^{(l)}, \quad \tilde{H}_l:=-\frac{1}{l}\int(\alpha_1W_{11}^{(l+1)}+\alpha_2W_{22}^{(l+1)}+\ldots+\alpha_nW_{nn}^{(l+1)})\,dx, \quad l\geqslant 1, \tag{2.20}$$

in which $1\leqslant i\neq j\leqslant n$ and γ is determined to be zero. In this computation, we need to note that

$$\mathrm{tr}\left(W\frac{\partial U}{\partial\lambda}\right)=\mathrm{tr}(WU_0)=\sum_{l\geqslant 0}(\alpha_1W_{11}^{(l)}+\alpha_2W_{22}^{(l)}+\ldots+\alpha_nW_{nn}^{(l)})\lambda^{-l},$$

and

$$\mathrm{tr}\left(W\frac{\partial U}{\partial u_{ij}}\right)=\mathrm{tr}(WE_{ij})=W_{ji}=\sum_{l\geqslant 0}W_{ji}^{(l)}\lambda^{-l}, \quad 1\leqslant i\neq j\leqslant n,$$

where E_{ij} is an $n\times n$ matrix whose (i,j) entry is one but other entries are all zero. Therefore, the isospectral hierarchy (2.19) has a bi-Hamiltonian formulation

$$u_{t_m}=X_m=J\frac{\delta\tilde{H}_{m+1}}{\delta u}=M\frac{\delta\tilde{H}_m}{\delta u}, \quad m\geqslant 1. \tag{2.21}$$

The first nonlinear system in the hierarchy (2.19) is the $1+1$ dimensional $\mathcal{N}$-wave interaction equations[39]

$$u_{ij,t_1}=\frac{\beta_i-\beta_j}{\alpha_i-\alpha_j}u_{ij,x}+\sum_{\substack{k=1\\k\neq i,j}}^{n}\left(\frac{\beta_i-\beta_k}{\alpha_i-\alpha_k}-\frac{\beta_k-\beta_j}{\alpha_k-\alpha_j}\right)u_{ik}u_{kj}, \quad 1\leqslant i\neq j\leqslant n. \tag{2.22}$$

This system is actually equivalent to the following equation in the matrix form

$$U_{1t_1}=W_{1x}-[U_1,W_1], \tag{2.23}$$

which can be rewritten as

$$P_{t_1}=Q_x-[P,Q], \quad [U_0,Q]=[W_0,P], \tag{2.24}$$

where P and Q are assumed to be two off-diagonal potential matrices. Based on (2.23), a vector field $\rho(\delta P)$ is a symmetry of (2.22) if the matrix δP satisfies the linearized system of (2.22):

$$(\delta P)_{t_1}=(\delta Q)_x-[U_1,\delta Q]-[\delta P,W_1] \tag{2.25}$$

with δQ being determined by

$$[U_0,\delta Q]=[W_0,\delta P]. \tag{2.26}$$

The $\mathcal{N}$-wave interaction equations (2.22) contains a couple of physically important nonlinear models as special reductions,[40] for example, three-wave interaction equations arising in fluid dynamics and plasma physics,[41–43] with U being chosen to be an anti-Hermitian matrix. Its Darboux transformation has been established in Ref. 44, which allows one to construct soliton solutions in a purely algebraic way. The Darboux transformation has also been analyzed for the $\mathcal{N}$-wave interaction equations with additional linear terms.[45]

B. Binary symmetry constraints in 1+1 dimensional case

We would like to present binary symmetry constraints of the $1+1$ dimensional $\mathcal{N}$-wave interaction equations (2.22). To this end, we need to introduce the adjoint spectral problem of (2.1):

$$\psi_x=-U^T(u,\lambda)\psi, \quad \psi=(\psi_1,\ldots,\psi_n)^T, \tag{2.27}$$

and the adjoint associated spectral problem of (2.17):

$$\psi_{t_m}=-V^{(m)T}(u,\lambda)\psi, \tag{2.28}$$

where U and $V^{(m)}$ are given as in (2.1) and (2.17), respectively. The compatability condition of (2.27) and (2.28) still gives rise to $u_{t_m}=X_m$ defined by (2.19).

The variational derivative of the spectral parameter λ with respect to the potential u can be calculated by (see Refs. 26, 28, or 16 for a detailed deduction)

$$\frac{\delta\lambda}{\delta u}=E^{-1}\psi^T\frac{\partial U}{\partial u}\phi, \quad \text{i.e.,} \ \frac{\delta\lambda}{\delta u_{ij}}=E^{-1}\phi_i\psi_j, \quad 1\leqslant i\neq j\leqslant n, \tag{2.29}$$

where E is the normalized constant:

$$E=-\int_{-\infty}^{\infty}\psi^T\frac{\partial U}{\partial\lambda}\phi\,dx.$$

A direct calculation can show that the variational derivative satisfies the following equation:

$$M\frac{\delta\lambda}{\delta u}=\lambda J\frac{\delta\lambda}{\delta u}. \tag{2.30}$$

Since λ does not vary with respect to time, we have a specific common symmetry $J(\delta\lambda/\delta u)$ of the hierarchy (2.19). To carry out binary nonlinearization, we take a Lie point symmetry of the $\mathcal{N}$-wave interaction equations (2.22),

$$Y_0:=\rho([\Gamma,U_1]), \quad \Gamma=\mathrm{diag}(\gamma_1,\ldots,\gamma_n), \tag{2.31}$$

where $\gamma_1,\gamma_2,\ldots,\gamma_n$ are arbitrary distinct constants ($X_0=JG_0$ is an example with $\Gamma=W_0$). It can be easily checked that

$$(\delta P, \delta Q) = ([\Gamma, U_1], [\Gamma, W_1])$$

satisfies (2.25), and thus Y_0 is a symmetry of (2.22). Then, make the following binary Bargmann symmetry constraint

$$Y_0 = \mu E J \frac{\delta \lambda}{\delta u} = \mu J \psi^T \frac{\partial U}{\partial u} \phi, \tag{2.32}$$

where μ is an arbitrary nonzero constant, J is defined by (2.14), and ϕ and ψ are the eigenfunction and adjoint eigenfunction of (2.1) and (2.27), respectively. Upon introducing N distinct eigenvalues $\lambda_1, \lambda_2, \ldots, \lambda_N$, we obtain a general binary symmetry constraint

$$Y_0 = J \sum_{s=0}^{N} \mu_s \psi^{(s)T} \frac{\partial U(u, \lambda_s)}{\partial u} \phi^{(s)} := Z_0, \tag{2.33}$$

where μ_s, $1 \leqslant s \leqslant N$, are N nonzero constants, and $\phi^{(s)}$ and $\psi^{(s)}$, $1 \leqslant s \leqslant N$, are eigenfunctions and adjoint eigenfunctions defined by

$$\phi_x^{(s)} = U(u, \lambda_s)\phi^{(s)}, \quad \psi_x^{(s)} = -U^T(u, \lambda_s)\psi^{(s)}, \quad 1 \leqslant s \leqslant N, \tag{2.34}$$

and

$$\phi_{t_1}^{(s)} = V^{(1)}(u, \lambda_s)\phi^{(s)}, \quad \psi_{t_1}^{(s)} = -V^{(1)T}(u, \lambda_s)\psi^{(s)}, \quad 1 \leqslant s \leqslant N. \tag{2.35}$$

Let us rewrite the left-hand side of (2.33) as the matrix form

$$\delta P = \rho^{-1}(Z_0) = \left[U_0, \sum_{s=1}^{N} \mu_s \phi^{(s)} \psi^{(s)T} \right], \tag{2.36}$$

which allows us to prove, by a direct computation as in Ref. 46 but more conveniently, that the vector field $Z_0 = \rho(\delta P)$ is really a symmetry of the $\mathcal{N}$-wave interaction equations (2.22). Now the symmetry problem is equivalent to showing that

$$(\delta P, \delta Q) = \left(\left[U_0, \sum_{s=1}^{N} \mu_s \phi^{(s)} \psi^{(s)T} \right], \left[W_0, \sum_{s=1}^{N} \mu_s \phi^{(s)} \psi^{(s)T} \right] \right) \tag{2.37}$$

satisfies the linearized system (2.25), when $\phi^{(s)}$ and $\psi^{(s)}$, $1 \leqslant s \leqslant N$, satisfy (2.34) and (2.35). A detailed proof will be given in Appendix A.

Therefore, we have the following binary symmetry constraint:

$$Y_0 = J \sum_{s=0}^{N} \mu_s \psi^{(s)T} \frac{\partial U(u, \lambda_s)}{\partial u} \phi^{(s)}, \quad \text{i.e.,} \quad [\Gamma, U_1] = \left[U_0, \sum_{s=1}^{N} \mu_s \phi^{(s)} \psi^{(s)T} \right]. \tag{2.38}$$

When N and μ_s vary, (2.38) provides us with a set of binary symmetry constraints of the $\mathcal{N}$-wave interaction equations (2.22). Let us assume that

$$\phi^{(s)} = (\phi_{1s}, \phi_{2s}, \ldots, \phi_{ns})^T, \quad \psi^{(s)} = (\psi_{1s}, \psi_{2s}, \ldots, \psi_{ns})^T, \tag{2.39}$$

in order to get an explicit expression for u from the symmetry constraint (2.38), and introduce two diagonal matrices

$$A = \mathrm{diag}(\lambda_1, \ldots, \lambda_N), \quad B = \mathrm{diag}(\mu_1, \ldots, \mu_N), \tag{2.40}$$

which will be used throughout our discussion. Solving the Bargmann symmetry constraint (2.38) for u, we obtain

$$u_{ij}=\tilde{u}_{ij}:=\frac{\alpha_i-\alpha_j}{\gamma_i-\gamma_j}\langle\Phi_i,B\Psi_j\rangle,\quad 1\leqslant i\neq j\leqslant n, \tag{2.41}$$

where B is given by (2.40), and Φ_i and Ψ_i are defined by

$$\Phi_i=(\phi_{i1},\phi_{i2},\ldots,\phi_{iN})^T,\quad \Psi_i=(\psi_{i1},\psi_{i2},\ldots,\psi_{iN})^T,\quad 1\leqslant i\leqslant n, \tag{2.42}$$

and $\langle\cdot,\cdot\rangle$ denotes the standard inner-product of the Euclidean space $\mathbb{R}^N$.

Note that the compatability condition of (2.34) and (2.35) is still nothing but the $1+1$ dimensional $\mathcal{N}$-wave interaction equations (2.22). Now using (2.41), we nonlinearize the spatial part (2.34) and the temporal part (2.35) of spectral problems and adjoint spectral problems of the $\mathcal{N}$-wave interaction equations (2.22). Namely we replace u_{ij} with $\tilde{u}_{ij}$ in N replicas of the spectral problems and adjoint spectral problems (2.34) and N replicas of the associated spectral problems and adjoint associated spectral problems (2.35), and then obtain two constrained flows for the $\mathcal{N}$-wave interaction equations (2.22):

$$\phi_x^{(s)}=U(\tilde{u},\lambda_s)\phi^{(s)},\quad \psi_x^{(s)}=-U^T(\tilde{u},\lambda_s)\psi^{(s)},\quad 1\leqslant s\leqslant N, \tag{2.43}$$

and

$$\phi_{t_1}^{(s)}=V^{(1)}(\tilde{u},\lambda_s)\phi^{(s)},\quad \psi_{t_1}^{(s)}=-V^{(1)T}(\tilde{u},\lambda_s)\psi^{(s)},\quad 1\leqslant s\leqslant N, \tag{2.44}$$

where $\tilde{u}=\rho((\tilde{u}_{ij})_{n\times n})$ is defined like u. For example, when $n\geqslant 4$, we have

$$\tilde{u}=(\tilde{u}_{21},\tilde{u}_{12},\tilde{u}_{31},\tilde{u}_{13},\tilde{u}_{14},\tilde{u}_{41},\tilde{u}_{23},\tilde{u}_{32},\ldots,\tilde{u}_{n,n-1},\tilde{u}_{n-1,n})^T. \tag{2.45}$$

In order to analyze the Liouville integrability of the above two constrained flows, let us first introduce a symplectic structure

$$\omega^2=\sum_{i=1}^{n}Bd\Phi_i\wedge d\Psi_i=\sum_{i=1}^{n}\sum_{s=1}^{N}\mu_s d\phi_{is}\wedge d\psi_{is} \tag{2.46}$$

over $\mathbb{R}^{2nN}$, and then the corresponding Poisson bracket

$$\begin{aligned}\{f,g\}=\omega^2(Idg,Idf)&=\sum_{i=1}^{n}\left(\left\langle\frac{\partial f}{\partial\Psi_i},B^{-1}\frac{\partial g}{\partial\Phi_i}\right\rangle-\left\langle\frac{\partial f}{\partial\Phi_i},B^{-1}\frac{\partial g}{\partial\Psi_i}\right\rangle\right)\\&=\sum_{i=1}^{n}\sum_{s=1}^{N}\mu_s^{-1}\left(\frac{\partial f}{\partial\psi_{is}}\frac{\partial g}{\partial\phi_{is}}-\frac{\partial f}{\partial\phi_{is}}\frac{\partial g}{\partial\psi_{is}}\right),\quad f,g\in C^\infty(\mathbb{R}^{2nN}),\end{aligned} \tag{2.47}$$

where the vector field Idf is defined by

$$\omega^2(X,Idf)=df(X),\quad X\in T(\mathbb{R}^{2nN}).$$

A Hamiltonian system with a Hamiltonian H defined over the symplectic manifold $(\mathbb{R}^{2nN},\omega^2)$ is given by

$$\Phi_{it}=\{\Phi_i,H\}=-B^{-1}\frac{\partial H}{\partial\Psi_i},\quad \Psi_{it}=\{\Psi_i,H\}=B^{-1}\frac{\partial H}{\partial\Phi_i},\quad 1\leqslant i\leqslant n, \tag{2.48}$$

where t is assumed to be the evolution variable. Second, we need a matrix Lax operator

$$L^{(1)}(\lambda)=C_1+D_1(\lambda), \tag{2.49}$$

with C_1 and $D_1(\lambda)$ being defined by

$$C_1=\Gamma=\mathrm{diag}(\gamma_1,\ldots,\gamma_n),\quad D_1(\lambda)=(D_{ij}^{(1)}(\lambda))_{n\times n},\quad D_{ij}^{(1)}(\lambda)=\sum_{s=1}^{N}\frac{\mu_s}{\lambda-\lambda_s}\phi_{is}\psi_{js}, \tag{2.50}$$

where $1\leqslant i,\ j\leqslant n$. Note that upon taking binary nonlinearization, we obtain

$$U(\tilde{u},\lambda)=\lambda U_0+U_1(\tilde{u})=\lambda U_0+(\tilde{u}_{ij}),\ \ \tilde{u}_{ij}=\frac{\alpha_i-\alpha_j}{\gamma_i-\gamma_j}\langle\Phi_i,B\Psi_j\rangle, \tag{2.51}$$

$$V^{(1)}(\tilde{u},\lambda)=\lambda W_0+W_1(\tilde{u})=\lambda W_0+(\tilde{v}_{ij}),\ \ \tilde{v}_{ij}:=\frac{\beta_i-\beta_j}{\alpha_i-\alpha_j}\tilde{u}_{ij}=\frac{\beta_i-\beta_j}{\gamma_i-\gamma_j}\langle\Phi_i,B\Psi_j\rangle, \tag{2.52}$$

where $1\leqslant i,\ j\leqslant n$.

Theorem 2.1: *Under the symplectic structure (2.46), the spatial constrained flow (2.43) and the temporal constrained flow (2.44) for the 1+1 dimensional $\mathcal{N}$-wave interaction equations (2.22) are Hamiltonian systems with the evolution variables x and t_1, and the Hamiltonians*

$$H_1^x=-\sum_{k=1}^{n}\alpha_k\langle A\Phi_k,B\Psi_k\rangle-\sum_{1\leqslant k<l\leqslant n}\frac{\alpha_k-\alpha_l}{\gamma_k-\gamma_l}\langle\Phi_k,B\Psi_l\rangle\langle\Phi_l,B\Psi_k\rangle, \tag{2.53}$$

$$H_1^{t_1}=-\sum_{k=1}^{n}\beta_k\langle A\Phi_k,B\Psi_k\rangle-\sum_{1\leqslant k<l\leqslant n}\frac{\beta_k-\beta_l}{\gamma_k-\gamma_l}\langle\Phi_k,B\Psi_l\rangle\langle\Phi_l,B\Psi_k\rangle, \tag{2.54}$$

respectively, where A and B are defined by (2.40), and Φ_i and Ψ_i, $1\leqslant i\leqslant n$, are defined by (2.42). Moreover, they possess necessary Lax representations, i.e., we have

$$(L^{(1)}(\lambda))_x=[U(\tilde{u},\lambda),L^{(1)}(\lambda)],\quad (L^{(1)}(\lambda))_{t_1}=[V^{(1)}(\tilde{u},\lambda),L^{(1)}(\lambda)], \tag{2.55}$$

where $L^{(1)}(\lambda)$, U, and $V^{(1)}(\lambda)$ are given by (2.49)–(2.52), if (2.43) and (2.44) hold, respectively.

Proof: A direct calculation can show the Hamiltonian structures of the spatial constrained flow (2.43) and the temporal constrained flow (2.44) with H_1^x and H_1^t defined by (2.53) and (2.54). Let us then check the Lax representations. By using (2.43), we can compute that

$$\begin{aligned}
(L^{(1)}(\lambda))_x&=\sum_{s=1}^{N}\frac{\mu_s}{\lambda-\lambda_s}(\phi_x^{(s)}\psi^{(s)T}+\phi^{(s)}\psi_x^{(s)T})\\
&=\sum_{s=1}^{N}\frac{\mu_s}{\lambda-\lambda_s}(U(\tilde{u},\lambda_s)\phi^{(s)}\psi^{(s)T}-\phi^{(s)}\psi^{(s)T}U(\tilde{u},\lambda_s))\\
&=\sum_{s=1}^{N}\frac{\mu_s}{\lambda-\lambda_s}[U(\tilde{u},\lambda_s),\phi^{(s)}\psi^{(s)T}]\\
&=[U(\tilde{u},\lambda),L^{(1)}(\lambda)-C_1]-\left[U_0,\sum_{s=1}^{N}\mu_s\phi^{(s)}\psi^{(s)T}\right]\\
&=[U(\tilde{u},\lambda),L^{(1)}(\lambda)]+[C_1,U(\tilde{u},\lambda)]-\left[U_0,\sum_{s=1}^{N}\mu_s\phi^{(s)}\psi^{(s)T}\right]\\
&=[U(\tilde{u},\lambda),L^{(1)}(\lambda)]+[C_1,U_1(\tilde{u})]-\left[U_0,\sum_{s=1}^{N}\mu_s\phi^{(s)}\psi^{(s)T}\right].
\end{aligned}$$

This implies that $(L^{(1)}(\lambda))_x=[U(\tilde{u},\lambda),L^{(1)}(\lambda)]$ if and only if

$$[C_1,U_1(\tilde{u})]=\left[U_0,\sum_{s=1}^{N}\mu_s\phi^{(s)}\psi^{(s)T}\right].$$

The above equality equivalently requires the constraints on the potentials shown in (2.41). Therefore, the spatial constrained flow (2.43) has the necessary Lax representation defined as in (2.55). The proof of the other necessary Lax representation $(L^{(1)}(\lambda))_{t_1}=[V^{(1)}(\tilde{u},\lambda),L^{(1)}(\lambda)]$ is completely similar, and thus we omit it. The proof is finished. ■

We remark that the Lax representations (2.55) are not sufficient. Namely, we cannot obtain the spatial constrained flow (2.43) or the temporal constrained flow (2.44) from the corresponding Lax representation in (2.55). This can be easily observed by considering a special class of solutions of (2.55). For example, either any vector functions $\phi^{(s)}$ with $\psi^{(s)}=0$, $1\leqslant s\leqslant N$, or any vector functions $\psi^{(s)}$ with $\phi^{(s)}=0$, $1\leqslant s\leqslant N$, will solve (2.55), but it is easy to see that they do not always solve (2.43) [or (2.44)] since $\phi^{(s)}$ and $\psi^{(s)}$, $1\leqslant s\leqslant N$, have to solve some ordinary differential equations (ODEs) resulting from (2.43) [or (2.44)].

III. BINARY SYMMETRY CONSTRAINTS IN 2+1 DIMENSIONS

A. 2+1 dimensional $\mathcal{N}$-wave interaction equations

Let n be an arbitrary natural number strictly greater than 2. Similar to the case of the $1+1$ dimensional **N**-wave interaction equations, let us begin with the Lax system

$$F_y=JF_x+PF,\quad F_t=KF_x+QF,\quad F=(f_1,\ldots,f_n)^T \tag{3.1}$$

in $2+1$ dimensions. Here it is assumed that

$$J=\mathrm{diag}(J_1,\ldots,J_n),\quad K=\mathrm{diag}(K_1,\ldots,K_n),\quad J_i\neq J_j,\quad K_i\neq K_j,\quad 1\leqslant i\neq j\leqslant n, \tag{3.2}$$

are two constant diagonal matrices, and P and Q are two $n\times n$ off-diagonal potential matrices

$$P=P(x,y,t)=(p_{ij})_{n\times n},\quad Q=Q(x,y,t)=(q_{ij})_{n\times n}. \tag{3.3}$$

The compatability condition $F_{yt}=F_{ty}$ of the Lax system (3.1) reads as

$$[J,Q]=[K,P],\quad P_t-Q_y+[P,Q]+JQ_x-KP_x=0, \tag{3.4}$$

which is called the $2+1$ dimensional $\mathcal{N}$-wave interaction equations.[47] The equation $[J,Q]=[K,P]$ tells us that Q can be represented by P and vice versa, and so, practically, we have just one of two potential matrices to be solved. The adjoint system of the Lax system (3.1) is given by

$$G_y=JG_x-P^TG,\quad G_t=KG_x-Q^TG,\quad G=(g_1,\ldots,g_n)^T, \tag{3.5}$$

whose compatability condition $G_{yt}=G_{ty}$ still gives rise to the $2+1$ dimensional $\mathcal{N}$-wave interaction equations (3.4).

We first use a symmetry constraint of the $2+1$ dimensional $\mathcal{N}$-wave interaction equations (3.4) to change the above problem in $2+1$ dimensions to three problems in $1+1$ dimensions. As made in Refs. 48, and 49, we introduce the spectral problems

$$\phi_x=\Omega^x(F,G,\lambda)\phi=(\lambda\Omega_0^x+\Omega_1^x)\phi=\begin{pmatrix}\lambda I_n & F\\ G^T & 0\end{pmatrix}\phi, \tag{3.6a}$$

$$\phi_y=\Omega^y(P,F,G,\lambda)\phi=(\lambda\Omega_0^y+\Omega_1^y)\phi=\begin{pmatrix}\lambda J+P & JF\\ G^TJ & 0\end{pmatrix}\phi, \tag{3.6b}$$

$$\phi_t=\Omega^t(Q,F,G,\lambda)\phi=(\lambda\Omega_0^t+\Omega_1^t)\phi=\begin{pmatrix}\lambda K+Q & KF\\ G^TK & 0\end{pmatrix}\phi, \tag{3.6c}$$

where I_n is the nth-order identity matrix and $\phi=(\phi_1,\ldots,\phi_n,\phi_{n+1})^T$. The new extended potentials in the above spectral systems consist of not only the original potentials, P and Q, but also the solutions of the Lax system and the adjoint Lax system, F and G. The compatability conditions $\phi_{xy}=\phi_{yx}$, $\phi_{xt}=\phi_{tx}$, and $\phi_{yt}=\phi_{yt}$ give rise to the $2+1$ dimensional $\mathcal{N}$-wave interaction equations (3.4), the original Lax system (3.1) and its adjoint system (3.5), and the nonlinear symmetry constraint of (3.4):

$$P_x=[FG^T,J],\quad Q_x=[FG^T,K]. \tag{3.7}$$

It is easy to check that $(\delta P,\delta Q)=([FG^T,J],[FG^T,K])$ satisfies the linearized system of the $2+1$ dimensional $\mathcal{N}$-wave interaction equations (3.4):

$$[J,\delta Q]=[K,\delta P],\quad (\delta P)_t-(\delta Q)_y+[\delta P,Q]+[P,\delta Q]+J(\delta Q)_x-K(\delta P)_x=0, \tag{3.8}$$

when F and G solve the Lax system (3.1) and the adjoint Lax system (3.5), respectively. Therefore, (3.7) is really a symmetry constraint of the $2+1$ dimensional $\mathcal{N}$-wave interaction equations (3.4), since both sides of (3.7) are symmetries of (3.4). Now we see that the original problem in $2+1$ dimensions is transformed into three problems in $1+1$ dimensions. The spectral problems (3.6) are our starting point to make a link of the $2+1$ dimensional $\mathcal{N}$-wave interaction equations (3.4) to finite-dimensional integrable systems.

B. Binary symmetry constraints in 2+1 dimensional case

Let us start from the spectral problems in (3.6), which are similar to those for the $1+1$ dimensional $\mathcal{N}$-wave interaction equations (2.22). The main difference is that the coefficient matrix of λ in the x-part of the spectral problems (3.6) is

$$\Omega_0^x=\mathrm{diag}(\underbrace{1,\ldots,1}_{n},0), \tag{3.9}$$

whose diagonal entries are not distinct. However, the y-part of the spectral problems (3.6) has the same property as the spectral problem (2.1) in $1+1$ dimensions. Therefore, we use the y-part of the spectral problems (3.6) to compute the variational derivatives of λ:

$$\frac{\delta\lambda}{\delta p_{ij}}=E^{-1}\psi^T\frac{\partial\Omega^y}{\partial p_{ij}}\phi=E^{-1}\phi_i\psi_j,\quad \frac{\delta\lambda}{\delta q_{ij}}=E^{-1}\psi^T\frac{\partial\Omega^y}{\partial q_{ij}}\phi=E^{-1}\frac{J_i-J_j}{K_i-K_j}\phi_i\psi_j,\quad 1\leqslant i\neq j\leqslant n,$$

$$\frac{\delta\lambda}{\delta f_i}=E^{-1}\psi^T\frac{\partial\Omega^y}{\partial f_i}\phi=E^{-1}J_i\phi_{n+1}\psi_i,\quad \frac{\delta\lambda}{\delta g_i}=E^{-1}\psi^T\frac{\partial\Omega^y}{\partial g_i}\phi=E^{-1}J_i\phi_i\psi_{n+1},\quad 1\leqslant i\leqslant n,$$

where E is the normalized constant, and $\psi=(\psi_1,\ldots,\psi_n,\psi_{n+1})^T$ is an adjoint eigenfunction of the adjoint spectral problems

$$\psi_x=-(\Omega^x(F,G,\lambda))^T\psi=-(\lambda(\Omega_0^x)^T+(\Omega_1^x)^T)\psi=-\begin{pmatrix}\lambda I_n & G\\ F^T & 0\end{pmatrix}\psi, \tag{3.10a}$$

$$\psi_y=-(\Omega^y(P,F,G,\lambda))\psi=-(\lambda(\Omega_0^y)+(\Omega_1^y)^T)\psi=-\begin{pmatrix}\lambda J+P^T & JG\\ F^TJ & 0\end{pmatrix}\psi, \tag{3.10b}$$

$$\psi_t=-(\Omega^t(Q,F,G,\lambda))^T\psi=-(\lambda(\Omega_0^t)^T+(\Omega_1^t)^T)\psi=-\begin{pmatrix}\lambda K+Q^T & KG\\ F^TK & 0\end{pmatrix}\psi. \tag{3.10c}$$

These variational derivatives of λ give us a conserved covariant and also a clue to compute a required symmetry, expressed in terms of eigenfunctions and adjoint eigenfunctions.

As in the $1+1$ dimensional case, upon introducing N distinct eigenvalues $\lambda_1,\lambda_2,\ldots,\lambda_N$, we have

$$\phi_x^{(s)}=\Omega^x(u,\lambda_s)\phi^{(s)},\quad \phi_y^{(s)}=\Omega^y(u,\lambda_s)\phi^{(s)},\quad \phi_t^{(s)}=\Omega^t(u,\lambda_s)\phi^{(s)},\quad 1\leqslant s\leqslant N, \tag{3.11}$$

and

$$\psi_x^{(s)}=-(\Omega^x)^T(u,\lambda_s)\psi^{(s)},\quad \psi_y^{(s)}=-(\Omega^y)^T(u,\lambda_s)\psi^{(s)},\quad \psi_t^{(s)}=-(\Omega^t)^T(u,\lambda_s)\psi^{(s)},\quad 1\leqslant s\leqslant N, \tag{3.12}$$

where $\phi^{(s)}$ and $\psi^{(s)}$ are $n+1$ dimensional vector functions:

$$\phi^{(s)}=(\phi_{1s},\ldots,\phi_{ns},\phi_{n+1,s})^T,\quad \psi^{(s)}=(\psi_{1s},\ldots,\psi_{ns},\psi_{n+1,s})^T,\quad 1\leqslant s\leqslant N. \tag{3.13}$$

To carry out binary nonlinearization, we need to construct two special symmetries, one of which is a Lie point symmetry, and the other of which is not a Lie point, contact or Lie–Bäcklund symmetry, but generated from (3.11) and (3.12). Let us choose a set of $n+1$ arbitrary distinct constants $\delta_1,\ldots,\delta_n,\delta_{n+1}$, and set

$$\Delta=\mathrm{diag}(\delta_1,\ldots,\delta_n). \tag{3.14}$$

Similar to the $1+1$ dimensional case, it can be directly shown that

$$(\delta P,\delta Q,\delta F,\delta G)=([\Delta,P],[\Delta,Q],\Delta F-\delta_{n+1}F,\Delta G-\delta_{n+1}G) \tag{3.15}$$

and

$$\begin{gathered}\delta p_{ij}=(J_i-J_j)\langle\Phi_i,B\Psi_j\rangle,\quad \delta q_{ij}=(K_i-K_j)\langle\Phi_i,B\Psi_j\rangle,\quad 1\leqslant i\neq j\leqslant n,\\ \delta f_i=\langle\Phi_i,B\Psi_{n+1}\rangle,\quad \delta g_i=\langle\Phi_{n+1},B\Psi_i\rangle,\quad 1\leqslant i\leqslant n,\end{gathered} \tag{3.16}$$

are two symmetries of the equations (3.4), (3.1) and (3.5). That is to say, that they satisfy the linearized system of the equations (3.4), (3.1) and (3.5): the first subsystem (3.8) and the second subsystem

$$\begin{gathered}(\delta F)_y=J(\delta F)_x+(\delta P)F+P\,\delta F,\quad (\delta F)_t=K(\delta F)_x+(\delta Q)F+Q\,\delta F,\\ (\delta G)_y=J(\delta G)_x-(\delta P)^TG-P^T\delta G,\quad (\delta G)_t=K(\delta G)_x-(\delta Q)^TG-Q^T\delta G,\end{gathered} \tag{3.17}$$

for all solutions (P,Q,F,G) of (3.4), (3.1) and (3.5). Here we remind that

$$B=\mathrm{diag}(\mu_1,\ldots,\mu_N)^T$$

is defined by (2.40), $\langle\cdot,\cdot\rangle$ denotes the standard inner product of $\mathbb{R}^N$, and Φ_i and Ψ_i are similarly defined as

$$\Phi_i=(\phi_{i1},\phi_{i2},\ldots,\phi_{iN})^T,\quad \Psi_i=(\psi_{i1},\psi_{i2},\ldots,\psi_{iN})^T,\quad 1\leqslant i\leqslant n+1. \tag{3.18}$$

Now a binary Bargmann symmetry constraint of (3.4), (3.1) and (3.5) can be taken as

$$([\Delta,P])_{ij}=(J_i-J_j)\langle\Phi_i,B\Psi_j\rangle,\quad ([\Delta,Q])_{ij}=(K_i-K_j)\langle\Phi_i,B\Psi_j\rangle,\quad 1\leqslant i\neq j\leqslant n, \tag{3.19}$$

$$(\Delta F-\delta_{n+1}F)_i=\langle\Phi_i,B\Psi_{n+1}\rangle,\quad (\Delta G-\delta_{n+1}G)_i=\langle\Phi_{n+1},B\Psi_i\rangle,\quad 1\leqslant i\leqslant n. \tag{3.20}$$

This symmetry constraint gives us the following choice for the constraints on the extended potentials

$$p_{ij}=\tilde{p}_{ij}:=\frac{J_i-J_j}{\delta_i-\delta_j}\langle\Phi_i,B\Psi_j\rangle,\quad q_{ij}=\tilde{q}_{ij}:=\frac{K_i-K_j}{\delta_i-\delta_j}\langle\Phi_i,B\Psi_j\rangle,\quad 1\leqslant i\neq j\leqslant n, \tag{3.21}$$

$$f_i=\tilde{f}_i:=\frac{1}{\delta_i-\delta_{n+1}}\langle\Phi_i,B\Psi_{n+1}\rangle,\quad g_i=\tilde{g}_i:=\frac{1}{\delta_i-\delta_{n+1}}\langle\Phi_{n+1},B\Psi_i\rangle,\quad 1\leqslant i\leqslant n. \tag{3.22}$$

One can express the above symmetry constraint in another way. Actually, it can be proved that

$$(\delta P,\delta Q)=([\Delta,P],[\Delta,Q]),$$

and under the constraint (3.22),

$$\delta p_{ij}=(J_i-J_j)\langle\Phi_i,B\Psi_j\rangle,\quad \delta q_{ij}=(K_i-K_j)\langle\Phi_i,B\Psi_j\rangle,\quad 1\leqslant i\neq j\leqslant n,$$

are two symmetries of the $2+1$ dimensional $\mathcal{N}$-wave interaction equations (3.4).

Now plug the above expressions for the extended potentials, (3.21) and (3.22), into the spectral problems (3.6) and the adjoint spectral problems (3.10), and then we get the constrained flows

$$\phi_x^{(s)}=\Omega^x(\tilde{F},\tilde{G},\lambda_s)\phi^{(s)},\quad \psi_x^{(s)}=-(\Omega^x(\tilde{F},\tilde{G},\lambda_s))^T\psi^{(s)}, \tag{3.23}$$

$$\phi_y^{(s)}=\Omega^y(\tilde{P},\tilde{F},\tilde{G},\lambda_s)\phi^{(s)},\quad \psi_y^{(s)}=-(\Omega^y(\tilde{P},\tilde{F},\tilde{G},\lambda_s))^T\psi^{(s)}, \tag{3.24}$$

$$\phi_t^{(s)}=\Omega^t(\tilde{Q},\tilde{F},\tilde{G},\lambda_s)\phi^{(s)},\quad \psi_t^{(s)}=-(\Omega^t(\tilde{Q},\tilde{F},\tilde{G},\lambda_s))^T\psi^{(s)}, \tag{3.25}$$

where

$$\tilde{P}=(\tilde{p}_{ij})_{n\times n},\quad \tilde{Q}=(\tilde{q}_{ij})_{n\times n},\quad \tilde{F}=(\tilde{f}_1,\ldots,\tilde{f}_n)^T,\quad \tilde{G}=(\tilde{g}_1,\ldots,\tilde{g}_n)^T. \tag{3.26}$$

All these three constrained flows are systems of ordinary differential equations of ϕ_{is} and ψ_{is}, $1\leqslant i\leqslant n+1$, $1\leqslant s\leqslant N$.

We introduce the symplectic structure

$$\omega^2=\sum_{i=1}^{n+1}Bd\Phi_i\wedge d\Psi_i=\sum_{i=1}^{n+1}\sum_{s=1}^{N}\mu_s d\phi_{is}\wedge d\psi_{is} \tag{3.27}$$

over $\mathbb{R}^{2(n+1)N}$. The corresponding Poisson bracket and the corresponding Hamiltonian form with the Hamiltonian H and the evolution variable t are similarly taken as

$$\{f,g\}=\sum_{i=1}^{n+1}\left(\left\langle\frac{\partial f}{\partial\Psi_i},B^{-1}\frac{\partial g}{\partial\Phi_i}\right\rangle-\left\langle\frac{\partial f}{\partial\Phi_i},B^{-1}\frac{\partial g}{\partial\Psi_i}\right\rangle\right),\quad f,g\in C^\infty(\mathbb{R}^{2(n+1)N}), \tag{3.28}$$

$$\Phi_{it}=\{\Phi_i,H\}=-B^{-1}\frac{\partial H}{\partial\Psi_i},\quad \Psi_{it}=\{\Psi_i,H\}=B^{-1}\frac{\partial H}{\partial\Phi_i},\quad 1\leqslant i\leqslant n+1. \tag{3.29}$$

Similar to Theorem 2.1, we have the following.

Theorem 3.1: *Under the symplectic structure (3.27), three constrained flows (3.23), (3.24) and (3.25) are Hamiltonian systems with the evolution variables x, y and t, and the Hamiltonians*

$$H_2^x=-\sum_{k=1}^{n}\langle A\Phi_k,B\Psi_k\rangle-\sum_{k=1}^{n}\frac{1}{\delta_k-\delta_{n+1}}\langle\Phi_k,B\Psi_{n+1}\rangle\langle\Phi_{n+1},B\Psi_k\rangle, \tag{3.30}$$

$$H_2^y=-\sum_{k=1}^{n} J_k\langle A\Phi_k,B\Psi_k\rangle-\sum_{1\leqslant k<l\leqslant n}\frac{J_k-J_l}{\delta_k-\delta_l}\langle\Phi_k,B\Psi_l\rangle\langle\Phi_l,B\Psi_k\rangle$$
$$-\sum_{k=1}^{n}\frac{J_k}{\delta_k-\delta_{n+1}}\langle\Phi_k,B\Psi_{n+1}\rangle\langle\Phi_{n+1},B\Psi_k\rangle, \tag{3.31}$$

$$H_2^t=-\sum_{k=1}^{n} K_k\langle A\Phi_k,B\Psi_k\rangle-\sum_{1\leqslant k<l\leqslant n}\frac{K_k-K_l}{\delta_k-\delta_l}\langle\Phi_k,B\Psi_l\rangle\langle\Phi_l,B\Psi_k\rangle$$
$$-\sum_{k=1}^{n}\frac{K_k}{\delta_k-\delta_{n+1}}\langle\Phi_k,B\Psi_{n+1}\rangle\langle\Phi_{n+1},B\Psi_k\rangle, \tag{3.32}$$

respectively, where A and B are defined by (2.40), Φ_i *and* Ψ_i, $1\leqslant i\leqslant n+1$, *are defined by (3.18). Moreover, they possess the necessary Lax representations*

$$(L^{(2)}(\lambda))_x=[\Omega^x(\tilde{F},\tilde{G},\lambda),L^{(2)}(\lambda)], \tag{3.33}$$

$$(L^{(2)}(\lambda))_y=[\Omega^y(\tilde{P},\tilde{F},\tilde{G},\lambda),L^{(2)}(\lambda)], \tag{3.34}$$

$$(L^{(2)}(\lambda))_t=[\Omega^t(\tilde{Q},\tilde{F},\tilde{G},\lambda),L^{(2)}(\lambda)], \tag{3.35}$$

respectively, where $\tilde{P}$, $\tilde{Q}$, $\tilde{F}$ *and* $\tilde{G}$ *are given by (3.26), (3.21) and (3.22), and* $L^{(2)}(\lambda)$ *is defined by*

$$L^{(2)}(\lambda)=C_2+D_2(\lambda),\quad C_2=\mathrm{diag}(\Delta,\delta_{n+1})=\mathrm{diag}(\delta_1,\ldots,\delta_n,\delta_{n+1}),$$
$$D_2=(D_{ij}^{(2)})_{n+1,n+1},\quad D_{ij}^{(2)}=\sum_{s=1}^{N}\frac{\mu_s}{\lambda-\lambda_s}\phi_{is}\psi_{js},\quad 1\leqslant i,j\leqslant n+1. \tag{3.36}$$

Proof: It can be verified by a direct calculation that all three constrained flows (3.23)–(3.25) have the Hamiltonian structures under the symplectic structure (3.27) with the Hamiltonian functions H_2^x, H_2^y and H_2^t shown in (3.30)–(3.32). Let us now check three Lax representations (3.33)–(3.35). Since the proofs are similar for all three cases, we just show the second case, i.e., the Lax representation of the constrained flow (3.24). By using (3.24), we can compute that

$$(L^{(2)}(\lambda))_y=\sum_{s=1}^{N}\frac{\mu_s}{\lambda-\lambda_s}(\phi_y^{(s)}\psi^{(s)T}+\phi^{(s)}\psi_y^{(s)T})$$
$$=\sum_{s=1}^{N}\frac{\mu_s}{\lambda-\lambda_s}(\Omega^y(\tilde{P},\tilde{F},\tilde{G},\lambda_s)\phi^{(s)}\psi^{(s)T}-\phi^{(s)}\psi^{(s)T}\Omega^y(\tilde{P},\tilde{F},\tilde{G},\lambda_s))$$
$$=\sum_{s=1}^{N}\frac{\mu_s}{\lambda-\lambda_s}[\Omega^y(\tilde{P},\tilde{F},\tilde{G},\lambda_s),\phi^{(s)}\psi^{(s)T}]$$
$$=\sum_{s=1}^{N}\frac{\mu_s}{\lambda-\lambda_s}([\Omega^y(\tilde{P},\tilde{F},\tilde{G},\lambda),\phi^{(s)}\psi^{(s)T}]-[\Omega^y(\tilde{P},\tilde{F},\tilde{G},\lambda)$$
$$-\Omega^y(\tilde{P},\tilde{F},\tilde{G},\lambda_s),\phi^{(s)}\psi^{(s)T}])$$
$$=[\Omega^y(\tilde{P},\tilde{F},\tilde{G},\lambda),L^{(2)}(\lambda)-C_2]-\left[\Omega_0^y,\sum_{s=1}^{N}\mu_s\phi^{(s)}\psi^{(s)T}\right]$$
$$=[\Omega^y(\tilde{P},\tilde{F},\tilde{G},\lambda),L^{(2)}(\lambda)]-[\Omega_1^y(\tilde{P},\tilde{F},\tilde{G}),C_2]-\left[\Omega_0^y,\sum_{s=1}^{N}\mu_s\phi^{(s)}\psi^{(s)T}\right].$$

Therefore, it follows that $(L^{(2)}(\lambda))_y=[\Omega^y(\tilde{P},\tilde{F},\tilde{G},\lambda),L^{(2)}(\lambda)]$ if and only if

$$[C_2,\Omega_1^y(\tilde{P},\tilde{F},\tilde{G})]=\left[\Omega_0^y,\sum_{s=1}^{N}\mu_s\phi^{(s)}\psi^{(s)T}\right].$$

This equality equivalently requires the nonlinear constraints on the potentials defined by (3.21) and (3.22). Therefore, the constrained flow (3.24) has the necessary Lax representation shown in (3.34). The proof is finished. ■

We also remark that the Lax representations (3.33)–(3.35) are not sufficient to generate the corresponding constrained flows defined by (3.23)–(3.25), since the Gateaux derivative operators of the Lax operators Ω^x, Ω^y and Ω^t given in (3.23)–(3.25) are not injective. However, it will be shown that they are good enough in generating integrals of motion of the constrained flows.

IV. AN INVOLUTIVE AND FUNCTIONALLY INDEPENDENT SYSTEM OF POLYNOMIAL FUNCTIONS

Let m be an arbitrary natural number. We start from an mth-order matrix Lax operator

$$L(\lambda)=L(\lambda;c_1,\ldots,c_m)=C+D(\lambda), \tag{4.1}$$

with C and $D(\lambda)$ being defined by

$$C=\mathrm{diag}(c_1,\ldots,c_m),\quad D(\lambda)=(D_{ij}(\lambda))_{m\times m},\quad D_{ij}(\lambda)=\sum_{s=1}^{N}\frac{\mu_s}{\lambda-\lambda_s}\phi_{is}\psi_{js},\quad 1\leqslant i,j\leqslant m. \tag{4.2}$$

Here c_i, λ_s, and μ_s are arbitrary constants satisfying

$$\prod_{s=1}^{N}\mu_s\neq 0,\quad \lambda_i\neq\lambda_j,\quad 1\leqslant i\neq j\leqslant N, \tag{4.3}$$

and ϕ_{is} and ψ_{js} are pairs of canonical variables of the symplectic manifold $(\mathbb{R}^{2mN},\omega^2)$ with the symplectic structure

$$\omega^2=\sum_{i=1}^{m}\sum_{s=1}^{N}\mu_s d\phi_{is}\wedge d\psi_{is}. \tag{4.4}$$

The corresponding Poisson bracket reads as

$$\{f,g\}=\omega^2(Idg,Idf)=\sum_{i=1}^{m}\sum_{s=1}^{N}\mu_s^{-1}\left(\frac{\partial f}{\partial\psi_{is}}\frac{\partial g}{\partial\phi_{is}}-\frac{\partial f}{\partial\phi_{is}}\frac{\partial g}{\partial\psi_{is}}\right),\quad f,g\in C^\infty(\mathbb{R}^{2mN}). \tag{4.5}$$

A. r-matrix formulation

As usual, two special matrices defined by the tensor product of matrices are chosen as

$$L_1(\lambda)=L(\lambda)\otimes I_m,\quad L_2(\mu)=I_m\otimes L(\mu), \tag{4.6}$$

where I_m is the mth-order identity matrix, and

$$(A\otimes B)_{ij,kl}=a_{ik}b_{jl}\ \text{ if }\ A=(a_{ij})\ \text{ and }\ B=(b_{ij}). \tag{4.7}$$

We want to find an $m^2\times m^2$ matrix $\mathbf{r}=\mathbf{r}(\lambda,\mu)$ so that we have an $\mathbf{r}$-matrix formulation[50,51]

$$\{L(\lambda)\overset{\otimes}{,}L(\mu)\}=[\mathbf{r}(\lambda,\mu),L_1(\lambda)+L_2(\mu)], \tag{4.8}$$

with the Poisson bracket $\{L(\lambda)\overset{\otimes}{,}L(\mu)\}$ being defined by

$$(\{L(\lambda)\overset{\otimes}{,}L(\mu)\})_{ij,kl}=\{L_{ik}(\lambda),L_{jl}(\mu)\}=\omega^2(IdL_{jl}(\mu),IdL_{ik}(\lambda)),\quad 1\leqslant i,j,k,l\leqslant m, \tag{4.9}$$

where $L=(L_{ij})_{m\times m}$ is assumed. Let us first compute $\{L_{ij}(\lambda),L_{kl}(\mu)\}$. When $i\neq l$ and $j\neq k$, it is easy to obtain $\{L_{ij}(\lambda),L_{kl}(\mu)\}=0$. When $i\neq l$ and $j=k$, we have

$$\begin{aligned}\{L_{ij}(\lambda),L_{jl}(\mu)\}&=\sum_{s=1}^{N}\mu_s\frac{\phi_{is}}{\lambda-\lambda_s}\frac{\psi_{ls}}{\mu-\lambda_s}\\&=\sum_{s=1}^{N}\frac{1}{\mu-\lambda}\left(\frac{\mu_s}{\lambda-\lambda_s}-\frac{\mu_s}{\mu-\lambda_s}\right)\phi_{is}\psi_{ls}\\&=\frac{1}{\mu-\lambda}(L_{il}(\lambda)-L_{il}(\mu)).\end{aligned}$$

Similarly, when $i=l$ and $j\neq k$, we have

$$\{L_{ij}(\lambda),L_{ki}(\mu)\}=-\sum_{s=1}^{N}\mu_s\frac{\psi_{js}}{\lambda-\lambda_s}\frac{\phi_{ks}}{\mu-\lambda_s}=\frac{1}{\mu-\lambda}(L_{kj}(\mu)-L_{kj}(\lambda)),$$

and when $i=l$ and $j=k$, we have

$$\begin{aligned}\{L_{ij}(\lambda),L_{ji}(\mu)\}&=\sum_{s=1}^{N}\mu_s\frac{\phi_{is}}{\lambda-\lambda_s}\frac{\psi_{is}}{\mu-\lambda_s}-\sum_{s=1}^{N}\mu_s\frac{\psi_{js}}{\lambda-\lambda_s}\frac{\phi_{js}}{\mu-\lambda_s}\\&=\frac{1}{\mu-\lambda}[(L_{ii}(\lambda)-L_{ii}(\mu))-(L_{jj}(\lambda)-L_{jj}(\mu))].\end{aligned}$$

Therefore, we obtain

$$\{L_{ij}(\lambda),L_{kl}(\mu)\}=\begin{cases}0,\quad \text{when } i\neq l,\ j\neq k;\\ \dfrac{1}{\mu-\lambda}(L_{kj}(\mu)-L_{kj}(\lambda)),\quad \text{when } i=l,\ j\neq k;\\ \dfrac{1}{\mu-\lambda}(L_{il}(\lambda)-L_{il}(\mu)),\quad \text{when } i\neq l,\ j=k;\\ \dfrac{1}{\mu-\lambda}[(L_{ii}(\lambda)-L_{ii}(\mu))-(L_{jj}(\lambda)-L_{jj}(\mu))],\quad \text{when } i=l,\ j=k.\end{cases} \tag{4.10}$$

In view of this property, we claim that

$$\mathbf{r}(\lambda,\mu)=\frac{1}{\mu-\lambda}\mathcal{P},\quad \mathcal{P}=\sum_{p,q=1}^{m}E_{pq}\otimes E_{qp}, \tag{4.11}$$

where E_{pq} is an $m\times m$ matrix with the (p,q) entry being one but the others, zero. Let us second compute that

$$\left(\left[\frac{1}{\mu-\lambda}\mathcal{P},L_1(\lambda)+L_2(\mu)\right]\right)_{ij,kl}$$

$$=\frac{1}{\mu-\lambda}([\mathcal{P},L_1(\lambda)]+[\mathcal{P},L_2(\mu)])_{ij,kl}$$

$$=\frac{1}{\mu-\lambda}\sum_{p,q=1}^{m}([E_{pq},L(\lambda)]\otimes E_{qp}+E_{qp}\otimes[E_{pq},L(\mu)])_{ij,kl}$$

$$=\frac{1}{\mu-\lambda}\sum_{p,q=1}^{m}([E_{pq},L(\lambda)])_{ik}(E_{qp})_{jl}+(E_{qp})_{ik}[E_{pq},L(\mu)]_{jl}$$

$$=\frac{1}{\mu-\lambda}([E_{lj},L(\lambda)]_{ik}+[E_{ki},L(\mu))]_{jl},$$

where we have used $(A\otimes B)(A'\otimes B')=(AA')\otimes(BB')$. Further noting that

$$[E_{pq},L]=E_{pq}L-LE_{pq}=p\text{th}\begin{bmatrix} 0 & \cdots & \overset{q\text{th}}{-L_{1p}} & \cdots & 0 \\ \vdots & & \vdots & & \vdots \\ L_{q1} & \cdots & L_{qq}-L_{pp} & \cdots & L_{qm} \\ \vdots & & \vdots & & \vdots \\ 0 & \cdots & -L_{mp} & \cdots & 0 \end{bmatrix},$$

we have

$$\left(\left[\frac{1}{\mu-\lambda}\mathcal{P},L_1(\lambda)+L_2(\mu)\right]\right)_{ij,kl}$$

$$=\begin{cases} 0, & \text{when } i\neq l,\ j\neq k; \\ \dfrac{1}{\mu-\lambda}(L_{jk}(\lambda)-L_{jk}(\mu)), & \text{when } i=l,\ j\neq k; \\ \dfrac{1}{\mu-\lambda}(-L_{il}(\lambda)+L_{il}(\mu)), & \text{when } i\neq l,\ j=k; \\ \dfrac{1}{\mu-\lambda}[(L_{jj}(\lambda)-L_{ii}(\lambda))+(L_{ii}(\mu)-L_{jj}(\mu))], & \text{when } i=l,\ j=k. \end{cases} \tag{4.12}$$

Now (4.10) and (4.12) shed right on the following theorem.

Theorem 4.1: *If $L(\lambda)=L(\lambda;c_1,\ldots,c_m)$ is defined by (4.1) and (4.2), then the* **r***-matrix formulation*

$$\{L(\lambda)\overset{\otimes}{,}L(\mu)\}=[\mathbf{r}(\lambda,\mu),L(\lambda)\otimes I_m+I_m\otimes L(\mu)],\quad \mathbf{r}=\frac{1}{\mu-\lambda}\sum_{i,j=1}^{m}E_{ij}\otimes E_{ji} \tag{4.13}$$

holds for arbitrary constants $c_1,c_2,\ldots,c_m$.

It follows from (4.13) that

$$\{L^k(\lambda)\overset{\otimes}{,}L^l(\mu)\}=[\mathbf{r}^{k,l}(\lambda,\mu),L_1(\lambda)+L_2(\mu)],\quad k,l\geqslant 1, \tag{4.14}$$

where $\mathbf{r}^{k,l}(\lambda,\mu)$ is given by[52]

$$\mathbf{r}^{k,l}(\lambda,\mu)=\sum_{i=1}^{k}\sum_{j=1}^{l}L_1^{k-i}(\lambda)L_2^{l-j}(\mu)\mathbf{r}(\lambda,\mu)L_1^{i-1}(\lambda)L_2^{j-1}(\mu). \tag{4.15}$$

Since for $A=(a_{ij})_{m\times m}$ and $B=(b_{ij})_{m\times m}$ we have

$$\mathrm{tr}\{A\overset{\otimes}{,}B\}=\sum_{i,j=1}^{m}\{A\overset{\otimes}{,}B\}_{ij,ij}=\sum_{i,j=1}^{m}\{a_{ii},b_{jj}\}=\{\mathrm{tr}A,\mathrm{tr}B\}, \tag{4.16}$$

we can compute, based on (4.14), that

$$\begin{aligned}&\{\mathrm{tr}L^k(\lambda),\mathrm{tr}L^l(\mu)\}\\&=\mathrm{tr}\{L^k(\lambda)\overset{\otimes}{,}L^l(\mu)\}=\mathrm{tr}[\mathbf{r}^{k,l}(\lambda,\mu),L_1(\lambda)+L_2(\mu)]=0,\quad k,l\geqslant 1.\end{aligned} \tag{4.17}$$

This will be used to generate an involutive system of functions defined over the symplectic manifold $(\mathbb{R}^{2mN},\omega^2)$ for any natural number m.

B. An involutive and functionally independent system

Let us begin to construct an involutive system of polynomial functions by expanding

$$\det(\nu I_m-L(\lambda))=\nu^m-\mathcal{F}_\lambda^{(1)}\nu^{m-1}+\mathcal{F}_\lambda^{(2)}\nu^{m-2}+\cdots+(-1)^m\mathcal{F}_\lambda^{(m)},\quad \nu=\mathrm{const}, \tag{4.18}$$

where $\mathcal{F}_\lambda^{(k)}$, $1\leqslant k\leqslant m$, must read as

$$\mathcal{F}_\lambda^{(k)}=\mathcal{F}_\lambda^{(k)}(c_1,\ldots,c_m)=\sum_{1\leqslant j_1<j_2<\cdots<j_k\leqslant m}\begin{vmatrix}L_{j_1j_1}&L_{j_1j_2}&\cdots&L_{j_1j_k}\\L_{j_2j_1}&L_{j_2j_2}&\cdots&L_{j_2j_k}\\\vdots&\vdots&\ddots&\vdots\\L_{j_kj_1}&L_{j_kj_2}&\cdots&L_{j_kj_k}\end{vmatrix},\quad 1\leqslant k\leqslant m. \tag{4.19}$$

Here we mention once more that $L=(L_{ij})_{m\times m}$ is assumed. We define bilinear functions $\overset{ij}{Q}_\lambda$ on $\mathbb{R}^N$

$$\overset{ij}{Q}_\lambda=\sum_{s=1}^{N}\mu_s\frac{\phi_{is}\psi_{js}}{\lambda-\lambda_s}=\sum_{l\geqslant 0}\langle A^l\Phi_i,B\Psi_j\rangle\lambda^{-l-1},\quad 1\leqslant i,j\leqslant m, \tag{4.20}$$

where A and B are given by (2.40), and Φ_i and Ψ_i are defined as before,

$$\Phi_i=(\phi_{i1},\phi_{i2},\ldots,\phi_{iN})^T,\quad \Psi_i=(\psi_{i1},\psi_{i2},\ldots,\psi_{iN})^T,\quad 1\leqslant i\leqslant m. \tag{4.21}$$

Then we have

$$L_{ij}=\sum_{l\geqslant 0}\langle A^l\Phi_i,B\Psi_j\rangle\lambda^{-l-1}=\overset{ij}{Q}_\lambda,\quad 1\leqslant i\neq j\leqslant m,$$

$$L_{ii}=c_i+\sum_{l\geqslant 0}\langle A^l\Phi_i,B\Psi_i\rangle\lambda^{-l-1}=c_i+\overset{ii}{Q}_\lambda,\quad 1\leqslant i\leqslant m.$$

Therefore, the system of functions $\mathcal{F}_\lambda^{(k)}$ is transformed into

$$\mathcal{F}_\lambda^{(k)}=\sum_{1\leqslant j_1<j_2<\cdots<j_k\leqslant m}\begin{vmatrix} c_{j_1}+Q_\lambda^{j_1j_1} & Q_\lambda^{j_1j_2} & \cdots & Q_\lambda^{j_1j_k} \\ Q_\lambda^{j_2j_1} & c_{j_2}+Q_\lambda^{j_2j_2} & \cdots & Q_\lambda^{j_2j_k} \\ \vdots & \vdots & \ddots & \vdots \\ Q_\lambda^{j_kj_1} & Q_\lambda^{j_kj_2} & \cdots & c_{j_k}+Q_\lambda^{j_kj_k} \end{vmatrix}, \quad 1\leqslant k\leqslant m. \tag{4.22}$$

A set of more concrete formulas for computing $\mathcal{F}_\lambda^{(k)}$ will be given in Appendix B. Now we further expand $\mathcal{F}_\lambda^{(k)}$ as a power series of $1/\lambda$:

$$\mathcal{F}_\lambda^{(k)}=\mathcal{F}_\lambda^{(k)}(c_1,\ldots,c_m)=\sum_{l\geqslant 0}F_{kl}(c_1,\ldots,c_m)\lambda^{-l}, \quad 1\leqslant k\leqslant m. \tag{4.23}$$

Based on the formulas of $\mathcal{F}_\lambda^{(k)}$ in Appendix B, it is not difficult to find that

$$F_{k0}=F_{k0}(c_1,\ldots,c_m)=\sum_{1\leqslant j_1<j_2<\cdots<j_k\leqslant m}\prod_{p=1}^{k}c_{j_p},$$

$$\begin{aligned} F_{kl}&=F_{kl}(c_1,\ldots,c_m)\\ &=\sum_{1\leqslant j_1<j_2<\cdots<j_k\leqslant m}\sum_{r=1}^{\min(k,l)}\sum_{1\leqslant i_1<i_2<\cdots<i_r\leqslant k}\prod_{\substack{p=1\\ p\neq i_1,i_2,\cdots,i_r}}^{k}c_{j_p}\\ &\quad\times\sum_{\substack{p_1+p_2+\cdots+p_r=l-r\\ p_1,p_2,\cdots,p_r\geqslant 0}}\begin{vmatrix} \langle A^{p_1}\Phi_{j_{i_1}},B\Psi_{j_{i_1}}\rangle & \langle A^{p_2}\Phi_{j_{i_2}},B\Psi_{j_{i_1}}\rangle & \cdots & \langle A^{p_r}\Phi_{j_{i_r}},B\Psi_{j_{i_1}}\rangle \\ \langle A^{p_1}\Phi_{j_{i_1}},B\Psi_{j_{i_2}}\rangle & \langle A^{p_2}\Phi_{j_{i_2}},B\Psi_{j_{i_2}}\rangle & \cdots & \langle A^{p_r}\Phi_{j_{i_r}},B\Psi_{j_{i_2}}\rangle \\ \vdots & \vdots & \ddots & \vdots \\ \langle A^{p_1}\Phi_{j_{i_1}},B\Psi_{j_{i_r}}\rangle & \langle A^{p_2}\Phi_{j_{i_2}},B\Psi_{j_{i_r}}\rangle & \cdots & \langle A^{p_r}\Phi_{j_{i_r}},B\Psi_{j_{i_r}}\rangle \end{vmatrix}, \quad l\geqslant 1, \end{aligned} \tag{4.24}$$

which are all polynomials in the canonical variables ϕ_{is} and ψ_{is}, $1\leqslant i\leqslant m$, $1\leqslant s\leqslant N$.

Theorem 4.2: *For all constants $c_1,c_2,\ldots,c_m$, the polynomial functions in ϕ_{is} and ψ_{is}, $1\leqslant i\leqslant m$, $1\leqslant s\leqslant N$: $F_{il}(c_1,\ldots,c_m)$, $1\leqslant i\leqslant m$, $l\geqslant 1$, defined by (4.24), are in involution in pair with respect to the Poisson bracket (4.5).*

Proof: On the one hand, by using Newton's identities on elementary symmetric polynomials[53]

$$\zeta_k(\lambda)-\mathcal{F}_\lambda^{(1)}\zeta_{k-1}(\lambda)+\mathcal{F}_\lambda^{(2)}\zeta_{k-2}(\lambda)+\cdots+(-1)^{k-1}\mathcal{F}_\lambda^{(k-1)}\zeta_1(\lambda)+(-1)^k k\mathcal{F}_\lambda^{(k)}=0,$$

where $1\leqslant k\leqslant m$ and

$$\zeta_i(\lambda)=\operatorname{tr}L^i(\lambda), \quad 1\leqslant i\leqslant m,$$

we can have

$$\mathcal{F}_\lambda^{(k)}=\mathcal{F}_\lambda^{(k)}(\zeta_1(\lambda),\zeta_2(\lambda),\ldots,\zeta_k(\lambda)), \quad 1\leqslant k\leqslant m. \tag{4.25}$$

Therefore, we can compute that

$$\{\mathcal{F}_\lambda^{(k)},\mathcal{F}_\mu^{(i)}\}=\{\mathcal{F}_\lambda^{(k)}(\zeta_1(\lambda),\zeta_2(\lambda),\ldots,\zeta_k(\lambda)),\mathcal{F}_\mu^{(i)}(\zeta_1(\mu),\zeta_2(\mu),\ldots,\zeta_i(\mu))\}$$

$$=\sum_{l=1}^{k}\sum_{j=1}^{i}\frac{\partial\mathcal{F}_\lambda^{(k)}}{\partial\zeta_l(\lambda)}\frac{\mathcal{F}_\mu^{(i)}}{\partial\zeta_j(\mu)}\{\mathrm{tr}L^l(\lambda),\mathrm{tr}\,L^j(\mu)\}=0,\quad 1\leqslant k,i\leqslant m.$$

The last equality is a consequence of the involutivity of $\zeta_i(\lambda)$, $1\leqslant i\leqslant m$, shown in (4.17). On the other hand, we have

$$\{\mathcal{F}_\lambda^{(k)},\mathcal{F}_\mu^{(i)}\}=\sum_{l,j\geqslant 0}\{F_{kl},F_{ij}\}\lambda^{-l}\mu^{-j}.$$

It follows that the polynomial functions $F_{il}=F_{il}(c_1,\ldots,c_m)$, $1\leqslant i\leqslant m$, $l\geqslant 1$, are in involution in pair with respect to the Poisson bracket (4.5). ■

Let us now go on to show the functional independence of the polynomial functions $F_{is}(c_1,\ldots,c_m)$, $1\leqslant i\leqslant m$, $1\leqslant s\leqslant N$.

Theorem 4.3: *If all constants $c_1,c_2,\ldots,c_m$ are distinct, then the polynomial functions in ϕ_{is} and ψ_{is}, $1\leqslant i\leqslant m$, $1\leqslant s\leqslant N$: $F_{is}(c_1,\ldots,c_m)$, $1\leqslant i\leqslant m$, $1\leqslant s\leqslant N$, defined by (4.24), are functionally independent over a dense open subset of $\mathbb{R}^{2mN}$.*

Proof: Let P_0 be a point of $\mathbb{R}^{2mN}$ satisfying

$$\phi_{is}=\varepsilon,\quad 1\leqslant i\leqslant m,\quad 1\leqslant s\leqslant N,$$

where ε is a small constant. Keep (4.24) in mind, and then at this point P_0, we obviously have

$$\frac{\partial F_{is_1}}{\partial\psi_{js_2}}=\frac{\partial}{\partial\psi_{js_2}}\sum_{1\leqslant j_1<j_2<\cdots<j_i\leqslant m}\sum_{q=1}^{i}\prod_{\substack{p=1\\p\neq q}}^{i}c_{j_p}\langle A^{s_1-1}\Phi_{j_q},B\Psi_{j_q}\rangle+\mathrm{O}(\varepsilon^2)$$

$$=\varepsilon\sum_{\substack{1\leqslant j_1<j_2<\cdots<j_{i-1}\leqslant m\\ j_1,j_2,\cdots,j_{i-1}\neq j}}c_{j_1}c_{j_2}\cdots c_{j_{i-1}}\lambda_{s_2}^{s_1-1}\mu_{s_2}+\mathrm{O}(\varepsilon^2),\tag{4.26}$$

where $1\leqslant i,j\leqslant m$, $1\leqslant s_1,s_2\leqslant N$. In the above computation, only the term with $r=1$ in the expression (4.24) of F_{is} contributes to the first-order term of ε. Let the matrix Θ_N be defined by

$$\Theta_N=(\Theta_{ij}^{(N)})_{N\times N},\quad \Theta_{ij}^{(N)}=\lambda_i^{j-1}\mu_i,\quad 1\leqslant i,j\leqslant N,$$

whose determinant is easily found to be

$$\det(\Theta_N)=\prod_{i=1}^{N}\mu_i\prod_{1\leqslant i<j\leqslant N}(\lambda_j-\lambda_i).$$

Then at the point P_0, the Jacobian of the functions F_{is_1} with respect to ψ_{js_2} can be computed as follows

$$\frac{\partial(F_{11},\cdots,F_{1N},F_{21},\cdots,F_{2N},\cdots,F_{m1},\cdots,F_{mN})}{\partial(\psi_{11},\cdots,\psi_{1N},\psi_{21},\cdots,\psi_{2N},\cdots,\psi_{m1},\cdots,\psi_{mN})}$$

$$= \varepsilon^{mN} \begin{vmatrix} \Theta_N & \sum_{i=2}^{m} c_i\Theta_N & \sum_{2\leqslant i<j\leqslant m} c_ic_j\Theta_N & \cdots & \prod_{i=2}^{m} c_i\Theta_N \\ \Theta_N & \sum_{\substack{i=1\\ i\neq 2}}^{m} c_i\Theta_N & \sum_{\substack{1\leqslant i<j\leqslant m\\ i,j\neq 2}} c_ic_j\Theta_N & \cdots & \prod_{\substack{i=1\\ i\neq 2}}^{m} c_i\Theta_N \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \Theta_N & \sum_{i=1}^{m-1} c_i\Theta_N & \sum_{1\leqslant i<j\leqslant m-1} c_ic_j\Theta_N & \cdots & \prod_{i=1}^{m-1} c_i\Theta_N \end{vmatrix} + \mathrm{O}(\varepsilon^{mN+1})$$

$$= \varepsilon^{mN}\det(\Omega_m\otimes\Theta_N) + \mathrm{O}(\varepsilon^{mN+1})$$

$$= \varepsilon^{mN}(\det(\Omega_m))^N(\det(\Theta_N))^m + \mathrm{O}(\varepsilon^{mN+1})$$

$$= \varepsilon^{mN}\prod_{1\leqslant i<j\leqslant m}(c_i-c_j)^N\prod_{i=1}^{N}\mu_i\prod_{1\leqslant i<j\leqslant N}(\lambda_j-\lambda_i)^m + \mathrm{O}(\varepsilon^{mN+1}),$$

where we have used the determinant property of the tensor product of matrices and the determinant result of the matrix Ω_m in Appendix C. This allows us to conclude that if the constants $c_1,c_2,\ldots,c_m$ are distinct, the above Jacobian is not zero at P_0 when $\varepsilon\neq 0$ is small enough. Since the Jacobian is a polynomial function of ϕ_{is} and ψ_{is}, $1\leqslant i\leqslant m$, $1\leqslant s\leqslant N$, it is not zero over a dense open subset of $\mathbb{R}^{2mN}$. Therefore, the functions F_{is}, $1\leqslant i\leqslant m$, $1\leqslant s\leqslant N$, are functionally independent over that dense open subset of $\mathbb{R}^{2mN}$. The proof is completed. ■

C. An alternative involutive system to the F_{is}'s

We would like to express the involutive system of the polynomial functions F_{is} in another way, and so we introduce

$$s_0(v_1,\cdots,v_m)=1, \tag{4.27a}$$

$$s_k(v_1,\cdots,v_m)=\sum_{1\leqslant j_1<j_2<\cdots<j_k\leqslant m} v_{j_1}\cdots v_{j_k}, \quad 1\leqslant k\leqslant m, \tag{4.27b}$$

$$s_k(v_1,\cdots,v_m)=0, \quad \text{when } k\geqslant m+1 \text{ or } k\leqslant -1, \tag{4.27c}$$

where $v_1,v_2,\ldots,v_m$ are m numbers. Obviously, for $m\geqslant 2$, we have the following relation:

$$s_k(v_1,\ldots,v_m)=v_m s_{k-1}(v_1,\ldots,v_{m-1})+s_k(v_1,\ldots,v_{m-1}), \quad k\in\mathbb{Z}. \tag{4.28}$$

Let us now define

$$E_{1l}=F_{1l}, \quad E_{il}=(-1)^{i+1}F_{il}+\sum_{j=1}^{i-1}(-1)^{j+1}s_j(c_1,\ldots,c_m)E_{i-j,l}, \quad i\geqslant 2, \ l\geqslant 1. \tag{4.29}$$

From (4.29), we can have

$$F_{il}=\sum_{j=0}^{i-1}(-1)^{i-j+1}s_j(c_1,\ldots,c_m)E_{i-j,l}, \quad i,l\geqslant 1. \tag{4.30}$$

Therefore, by Proposition D.2 in Appendix D, we obtain

$$E_{il}=E_{il}(c_1,\ldots,c_m)$$
$$=\sum_{r=1}^{\min(i,l)}(-1)^{r+1}\sum_{1\leqslant j_1<j_2<\cdots<j_r\leqslant m}\ \sum_{\substack{l_1+l_2+\cdots+l_r=i-r\\ l_1,l_2,\cdots,l_r\geqslant 0}} c_{j_1}^{l_1}c_{j_2}^{l_2}\cdots c_{j_r}^{l_r}$$
$$\times\sum_{\substack{p_1+p_2+\cdots+p_r=l-r\\ p_1,p_2,\cdots,p_r\geqslant 0}}\begin{vmatrix}\langle A^{p_1}\Phi_{j_1},B\Psi_{j_1}\rangle & \langle A^{p_2}\Phi_{j_2},B\Psi_{j_1}\rangle & \cdots & \langle A^{p_r}\Phi_{j_r},B\Psi_{j_1}\rangle\\ \langle A^{p_1}\Phi_{j_1},B\Psi_{j_2}\rangle & \langle A^{p_2}\Phi_{j_2},B\Psi_{j_2}\rangle & \cdots & \langle A^{p_r}\Phi_{j_r},B\Psi_{j_2}\rangle\\ \vdots & \vdots & \ddots & \vdots\\ \langle A^{p_1}\Phi_{j_1},B\Psi_{j_r}\rangle & \langle A^{p_2}\Phi_{j_2},B\Psi_{j_r}\rangle & \cdots & \langle A^{p_r}\Phi_{j_r},B\Psi_{j_r}\rangle\end{vmatrix},\tag{4.31}$$

where $1\leqslant i\leqslant m$ and $l\geqslant 1$. Obviously, each E_{il} is a linear combination of the F_{il}'s, and hence $\{E_{ik},E_{jl}\}=0$ holds for all $1\leqslant i,j\leqslant m$ and $k,l\geqslant 1$. This means that the polynomial functions E_{is}, $1\leqslant i\leqslant m$, $1\leqslant s\leqslant N$, are also in involution in pair.

In order to show the functional independence of E_{is}, $1\leqslant i\leqslant m$, $1\leqslant s\leqslant N$, similar to the proof of Theorem 4.3, let P_0 be a point of $\mathbb{R}^{2mN}$ satisfying $\phi_{is}=\varepsilon$, $1\leqslant i\leqslant m$, $1\leqslant s\leqslant N$, where ε is a small constant. Then at this point P_0, we have

$$\frac{\partial E_{is_1}}{\partial\psi_{js_2}}=\varepsilon c_j^{i-1}\lambda_{s_2}^{s_1-1}\mu_{s_2}+\mathrm{O}(\varepsilon^2),\quad 1\leqslant i,j\leqslant m,\ \ 1\leqslant s_1,s_2\leqslant N.\tag{4.32}$$

Hence a direct argument can give rise to

$$\frac{\partial(E_{11},\cdots,E_{1N},E_{21},\cdots,E_{2N},\cdots,E_{m1},\cdots,E_{mN})}{\partial(\psi_{11},\cdots,\psi_{1N},\psi_{21},\cdots,\psi_{2N},\cdots,\psi_{m1},\cdots,\psi_{mN})}$$
$$=\varepsilon^{mN}\prod_{i=1}^{N}\mu_i\prod_{1\leqslant i<j\leqslant N}(\lambda_j-\lambda_i)^m\prod_{1\leqslant i<j\leqslant m}(c_j-c_i)^N+\mathrm{O}(\varepsilon^{mN+1}).\tag{4.33}$$

Therefore, if $c_1,c_2,\ldots,c_m$ are distinct, the above Jacobian is not zero at P_0 when $\varepsilon\neq 0$ is small enough. This implies that the functions E_{is}, $1\leqslant i\leqslant m$, $1\leqslant s\leqslant N$, are functionally independent over a dense open subset of $\mathbb{R}^{2mN}$.

Let us sum up these results in the following theorem.

Theorem 4.4: *All polynomial functions in ϕ_{is} and ψ_{is}, $1\leqslant i\leqslant m$, $1\leqslant s\leqslant N$: $E_{il}(c_1,\ldots,c_m)$, $1\leqslant i\leqslant m$, $l\geqslant 1$, defined by (4.31), are in involution in pair with respect to the Poisson bracket (4.5) for all constants $c_1,c_2,\ldots,c_m$. Moreover, among them the polynomial functions $E_{is}(c_1,\ldots,c_m)$, $1\leqslant i\leqslant m$, $1\leqslant s\leqslant N$, are functionally independent over a dense open subset of $\mathbb{R}^{2mN}$ for distinct constants $c_1,c_2,\ldots,c_m$.*

Note that all polynomial functions F_{il} are also linear combinations of the E_{il}'s. The above theorem actually shows us an alternative to the involutive and functionally independent system of the polynomial functions F_{is}, $1\leqslant i\leqslant m$, $1\leqslant s\leqslant N$. The E_{is}'s have the compact form for the constants $c_1,c_2,\ldots,c_m$, and thus it is more convenient to deal with them.

V. LIOUVILLE INTEGRABILITY AND INVOLUTIVE SOLUTIONS

Let us now turn to establish the Liouville integrability of the obtained constrained flows, and to present involutive solutions of the $\mathcal{N}$-wave interaction equations in both $1+1$ and $2+1$ dimensions. The involutive system of the polynomial functions

$$F_{is}=F_{is}(c_1,\ldots,c_m),\quad 1\leqslant i\leqslant m,\quad 1\leqslant s\leqslant N,$$

alternatively

$$E_{is}=E_{is}(c_1,\ldots,c_m),\quad 1\leqslant i\leqslant m,\quad 1\leqslant s\leqslant N,$$

will play an extremely important role in the following discussion.

A. Liouville integrability of the constrained flows

For the $1+1$ dimensional case, we have the matrix Lax operator as defined by (2.49) and (2.50), i.e.,

$$L^{(1)}(\lambda)=L^{(1)}(\lambda;\gamma_1,\ldots,\gamma_n)=C_1(\gamma_1,\ldots,\gamma_n)+D_1(\lambda),$$

where C_1 and $D_1(\lambda)$ are given by (2.50). Note that

$$\gamma_i\neq\gamma_j,\quad 1\leqslant i\neq j\leqslant n.$$

According to Theorems 4.2 and 4.3 for the case $m=n$ and $c_i=\gamma_i$, $1\leqslant i\leqslant n$, we know that $F_{is}(\gamma_1,\ldots,\gamma_n)$, $1\leqslant i\leqslant n$, $1\leqslant s\leqslant N$, defined by (4.24), are functionally independent over a dense open subset of $\mathbb{R}^{2nN}$ and in involution in pair with respect to the Poisson bracket (2.47), i.e.,

$$\{f,g\}=\sum_{i=1}^{n}\left(\left\langle\frac{\partial f}{\partial\Psi_i},B^{-1}\frac{\partial g}{\partial\Phi_i}\right\rangle-\left\langle\frac{\partial f}{\partial\Phi_i},B^{-1}\frac{\partial g}{\partial\Psi_i}\right\rangle\right),\quad f,g\in C^{\infty}(\mathbb{R}^{2nN}).$$

Theorem 5.1: *Let $\gamma_1,\gamma_2,\ldots,\gamma_n$ be n distinct numbers. Then the spatial constrained flow (2.43) and the temporal constrained flow (2.44) of the $1+1$ dimensional $\mathcal{N}$-wave interaction equations (2.22) are Liouville integrable Hamiltonian systems, which possess involutive and functionally independent integrals of motion*

$$F_{is}(\gamma_1,\ldots,\gamma_n),\quad 1\leqslant i\leqslant n,\quad 1\leqslant s\leqslant N,$$

defined by (4.24) in the case

$$m=n,\quad c_i=\gamma_i,\quad 1\leqslant i\leqslant n.$$

Proof: From the necessary Lax representations of the spatial constrained flow (2.43) and the temporal constrained flow (2.44),

$$(L^{(1)}(\lambda))_x=[U(\tilde{u},\lambda),L^{(1)}(\lambda)],\quad (L^{(1)}(\lambda))_{t_1}=[V^{(1)}(\tilde{u},\lambda),L^{(1)}(\lambda)],$$

which are shown in Theorem 2.1, we can obtain[26]

$$(L^{(1)}(\lambda))^i)_x=[U(\tilde{u},\lambda),(L^{(1)}(\lambda))^i],\quad (L^{(1)}(\lambda))^j)_{t_1}=[V^{(1)}(\tilde{u},\lambda),(L^{(1)}(\lambda))^j],\quad i,j\geqslant 1,$$

and thus we have

$$(\mathrm{tr}(L^{(1)}(\lambda))^i)_x=\mathrm{tr}((L^{(1)}(\lambda))^i)_x=\mathrm{tr}[U(\tilde{u},\lambda),(L^{(1)}(\lambda))^i]=0,\quad i\geqslant 1,$$

$$(\mathrm{tr}(L^{(1)}(\lambda))^j)_{t_1}=\mathrm{tr}((L^{(1)}(\lambda))^j)_{t_1}=\mathrm{tr}[V^{(1)}(\tilde{u},\lambda),(L^{(1)}(\lambda))^j]=0,\quad j\geqslant 1.$$

Therefore, $\mathcal{F}_{\lambda}^{(k)}(\gamma_1,\ldots,\gamma_n)$ are all generating functions of integrals of motion of (2.43) and (2.44) in the light of the expression (4.25) determined by Newton's identities. It follows that $F_{is}(\gamma_1,\ldots,\gamma_n)$, $1\leqslant i\leqslant n$, $1\leqslant s\leqslant N$, are all integrals of motion of the spatial constrained flow (2.43) and the temporal constrained flow (2.44). Note that all constants $\gamma_1,\gamma_2,\ldots,\gamma_n$ are distinct. Therefore, Theorems 4.2 and 4.3 in the case of $m=n$ and $c_i=\gamma_i$, $1\leqslant i\leqslant n$, together with Theorem 2.1, show that the spatial constrained flow (2.43) and the temporal constrained flow (2.44) are Liouville integrable Hamiltonian systems, which possess the involutive and functionally independent integrals of motion $F_{is}(\gamma_1,\ldots,\gamma_n)$, $1\leqslant i\leqslant n$, $1\leqslant s\leqslant N$. The proof is finished. ■

We remark that from the Lax representations shown in Theorem 2.1, we have

$$(\nu I_n - L^{(1)}(\lambda))_x = [U(\tilde{u},\lambda), \nu I_n - L^{(1)}(\lambda)],$$

$$(\nu I_n - L^{(1)}(\lambda))_{t_1} = [V^{(1)}(\tilde{u},\lambda), \nu I_n - L^{(1)}(\lambda)]$$

for any constant ν. It follows[54] that $\det(\nu I_n - L^{(1)}(\lambda))$ is a common generating function of integrals of motion of the constrained flows (2.43) and (2.44), and thus so are $\mathcal{F}_\lambda^{(k)}(\gamma_1,\ldots,\gamma_n)$, $1\leqslant k\leqslant n$. This is an alternative proof for showing that $\mathcal{F}_\lambda^{(k)}(\gamma_1,\ldots,\gamma_n)$, $1\leqslant k\leqslant n$, are the generating functions of integrals of motion of (2.43) and (2.44).

For the $2+1$ dimensional case, a completely similar argument can give rise to the following theorem on the Liouville integrability of the constrained flows (3.23)–(3.25) of the $2+1$ dimensional $\mathcal{N}$-wave interaction equations (3.4).

Theorem 5.2: *Let $\delta_1,\ldots,\delta_n,\delta_{n+1}$ be $n+1$ distinct numbers. Then all three constrained flows (3.23)–(3.25) of the $2+1$ dimensional $\mathcal{N}$-wave interaction equations (3.4) are Liouville integrable Hamiltonian systems, which possess the involutive and functionally independent integrals of motion*

$$F_{is}(\delta_1,\ldots,\delta_n,\delta_{n+1}), \quad 1\leqslant i\leqslant n+1, \quad 1\leqslant s\leqslant N,$$

defined by (4.24) in the case

$$m=n+1, \quad c_i=\delta_i, \quad 1\leqslant i\leqslant n+1.$$

B. Involutive solutions of the $\mathcal{N}$-wave interaction equations

We would like to show that the constrained flows provide involutive solutions to the $\mathcal{N}$-wave interaction equations in both $1+1$ and $2+1$ dimensions. For the $1+1$ dimensional case, we have the following result.

Theorem 5.3: *If $\phi_{is}(x,t_1)$ and $\psi_{is}(x,t_1)$, $1\leqslant i\leqslant n$, $1\leqslant s\leqslant N$, solve the spatial constrained flow (2.43) and the temporal constrained flow (2.44) simultaneously, then*

$$u_{ij}(x,t_1)=\frac{\alpha_i-\alpha_j}{\gamma_i-\gamma_j}\langle \Phi_i(x,t_1), B\Psi_j(x,t_1)\rangle, \quad 1\leqslant i\neq j\leqslant n, \tag{5.1}$$

with $\Phi_i(x,t_1)$ and $\Psi_i(x,t_1)$ being given by

$$\Phi_i(x,t_1)=(\phi_{i1}(x,t_1),\ldots,\phi_{iN}(x,t_1))^T, \quad \Psi_i(x,t_1)=(\psi_{i1}(x,t_1),\ldots,\psi_{iN}(x,t_1))^T, \quad 1\leqslant i\leqslant n,$$

solve the $1+1$ dimensional $\mathcal{N}$-wave interaction equations (2.22).

Proof: Note that the $1+1$ dimensional $\mathcal{N}$-wave interaction equations (2.22) is the compatability condition of the spectral problem (2.1) and the associated spectral problem (2.17) with $m=1$ or the adjoint spectral problem (2.27) and the adjoint associated spectral problem (2.28) with $m=1$ for whatever potential u. Therefore, the $1+1$ dimensional $\mathcal{N}$-wave interaction equations (2.22) are also the compatability condition of the spatial constrained flow (2.43) and the temporal constrained flow (2.44) under the constraint (2.41). Now $\phi_{is}(x,t_1)$ and $\psi_{is}(x,t_1)$, $1\leqslant i\leqslant n$, $1\leqslant s\leqslant N$, are assumed to solve (2.43) and (2.44) simultaneously, and thus the potential defined by (5.1) must satisfy the compatability condition of the spatial constrained flow (2.43) and the temporal constrained flow (2.44). This means that the potential defined by (5.1) must be a solution to the $1+1$ dimensional $\mathcal{N}$-wave interaction equations (2.22). The proof is finished. ■

We remark that a direct computation can also show the above theorem. For the $2+1$ dimensional case, a similar deduction can give rise to the following theorem.

Theorem 5.4: *If $\phi_{is}(x,t)$ and $\psi_{is}(x,t)$, $1\leqslant i\leqslant n+1$, $1\leqslant s\leqslant N$, solve the constrained flows (3.23)–(3.25) simultaneously, then*

$$p_{ij}(x,y,t)=\frac{J_i-J_j}{\delta_i-\delta_j}\langle\Phi_i(x,y,t),B\Psi_j(x,y,t)\rangle,\quad 1\leqslant i\neq j\leqslant n,$$
$$q_{ij}(x,y,t)=\frac{K_i-K_j}{\delta_i-\delta_j}\langle\Phi_i(x,y,t),B\Psi_j(x,y,t)\rangle,\quad 1\leqslant i\neq j\leqslant n, \tag{5.2}$$

with $\Phi_i(x,t)$ *and* $\Psi_i(x,t)$ *being given by*

$$\Phi_i(x,t)=(\phi_{i1}(x,t),\ldots,\phi_{iN}(x,t))^T,\quad \Psi_i(x,t)=(\psi_{i1}(x,t),\ldots,\psi_{iN}(x,t))^T,\quad 1\leqslant i\leqslant n+1,$$

solve the $2+1$ *dimensional* $\mathcal{N}$*-wave interaction equations (3.4).*

Also, one can find that

$$f_i=\frac{1}{\delta_i-\delta_{n+1}}\langle\Phi_i,B\Psi_{n+1}\rangle,\quad g_i=\frac{1}{\delta_i-\delta_{n+1}}\langle\Phi_{n+1},B\Psi_i\rangle,\quad 1\leqslant i\leqslant n \tag{5.3}$$

provide a solution to the Lax system (3.1) and the adjoint Lax system (3.5) with the potentials given by (5.2). What's more, (5.2) and (5.3) automatically satisfy our first symmetry constraint (3.7).

In the following theorem, the solutions given in Theorems 5.3 and 5.4 are shown to be involutive.

Theorem 5.5: *The Hamiltonians* H_1^x *and* $H_1^{t_1}$ *of the constrained flows in* $1+1$ *dimensions, defined by (2.53) and (2.54), are the second-order polynomial functions of* $E_{il}(\gamma_1,\ldots,\gamma_n)$, $1\leqslant i\leqslant n$, $l=1,2$, *and thus they commute, i.e.,*

$$\{H_1^x,H_1^{t_1}\}=0, \tag{5.4}$$

where the Poisson bracket $\{\cdot,\cdot\}$ *is defined by (2.47). The Hamiltonians* H_2^x, H_2^y *and* H_2^t *of the constrained flows in* $2+1$ *dimensions, defined by (3.30)–(3.32), are also the second-order polynomial functions of* $E_{il}(\delta_1,\ldots,\delta_n,\delta_{n+1})$, $1\leqslant i\leqslant n+1$, $l=1,2$, *and thus they commute with each other, i.e.,*

$$\{H_2^x,H_2^y\}=\{H_2^x,H_2^t\}=\{H_2^y,H_2^t\}=0, \tag{5.5}$$

where the Poisson bracket $\{\cdot,\cdot\}$ *is defined by* (3.28).

Proof: Directly from the explicit expression (4.31) of the E_{is}'s, we have

$$E_{i1}=\sum_{j=1}^{m}c_j^{i-1}\langle\Phi_j,B\Psi_j\rangle,\quad 1\leqslant i\leqslant m, \tag{5.6}$$

$$\begin{aligned}E_{i2}&=\sum_{j=1}^{m}c_j^{i-1}\langle A\Phi_j,B\Psi_j\rangle\\&\quad-\sum_{1\leqslant j<k\leqslant m}\frac{c_j^{i-1}-c_k^{i-1}}{c_j-c_k}(\langle\Phi_j,B\Psi_j\rangle\langle\Phi_k,B\Psi_k\rangle-\langle\Phi_j,B\Psi_k\rangle\langle\Phi_k,B\Psi_j\rangle)\\&=\sum_{j=1}^{m}c_j^{i-1}\mathcal{E}_j-\sum_{\substack{j,k=1\\j\neq k}}^{m}\frac{c_j^{i-1}}{c_j-c_k}\langle\Phi_j,B\Psi_j\rangle\langle\Phi_k,B\Psi_k\rangle,\quad 1\leqslant i\leqslant m,\end{aligned} \tag{5.7}$$

where the $\mathcal{E}_j$'s are defined as follows:

$$\mathcal{E}_j=\langle A\Phi_j,B\Psi_j\rangle+\sum_{\substack{k=1\\k\neq j}}^{m}\frac{1}{c_j-c_k}\langle\Phi_j,B\Psi_k\rangle\langle\Phi_k,B\Psi_j\rangle,\quad 1\leqslant j\leqslant m. \tag{5.8}$$

Now solving (5.6) for $\langle\Phi_i,B\Psi_i\rangle$, $1\leqslant i\leqslant m$, leads to

$$\langle\Phi_i,B\Psi_i\rangle=\left(\prod_{\substack{r=1\\r\neq i}}^{m}\frac{1}{c_i-c_r}\right)\sum_{j=1}^{m}(-1)^{m-j}s_{m-j}(c_1,\ldots,c_{i-1},\hat{c}_i,c_{i+1},\ldots,c_m)E_{j1},\quad 1\leqslant i\leqslant m, \tag{5.9}$$

where the s_j's are defined by (4.27) and $\hat{c}_i$ means that c_i does not appear. Therefore, each $\langle\Phi_i,B\Psi_i\rangle$ can be expressed as a linear combination of E_{i1}, $1\leqslant i\leqslant m$. Similarly, solving (5.7) for $\mathcal{E}_j$, $1\leqslant j\leqslant m$, leads to

$$\begin{aligned}\mathcal{E}_i=&\left(\prod_{\substack{r=1\\r\neq i}}^{m}\frac{1}{c_i-c_r}\right)\sum_{j=1}^{m}(-1)^{m-j}s_{m-j}(c_1,\ldots,c_{i-1},\hat{c}_i,c_{i+1},\ldots,c_m)\\&\times\left(E_{j2}+\sum_{\substack{k,l=1\\k\neq l}}^{m}\frac{c_k^{j-1}}{c_k-c_l}\langle\Phi_k,B\Psi_k\rangle\langle\Phi_l,B\Psi_l\rangle\right),\quad 1\leqslant i\leqslant m.\end{aligned} \tag{5.10}$$

This expression together with (5.9) implies that each $\mathcal{E}_j$ can be expressed as a linear combination of E_{i1} and E_{i2}, $1\leqslant i\leqslant m$.

In the $1+1$ dimensional case, we have $m=n$, $c_j=\gamma_j$, $1\leqslant j\leqslant n$. Hence

$$\mathcal{E}_j=\langle A\Phi_j,B\Psi_j\rangle+\sum_{\substack{k=1\\k\neq j}}^{n}\frac{1}{\gamma_j-\gamma_k}\langle\Phi_j,B\Psi_k\rangle\langle\Phi_k,B\Psi_j\rangle,\quad 1\leqslant j\leqslant n. \tag{5.11}$$

The Hamiltonians H_1^x and $H_1^{t_1}$ in Theorem 2.1 can be easily expressed as

$$H_1^x=-\sum_{k=1}^{n}\alpha_k\mathcal{E}_k,\quad H_1^{t_1}=-\sum_{k=1}^{n}\beta_k\mathcal{E}_k, \tag{5.12}$$

where the $\mathcal{E}_k$'s are defined by (5.11).

Likewise, in the $2+1$ dimensional case, we have $m=n+1$, $c_j=\delta_j$, $\quad 1\leqslant j\leqslant n+1$. Hence

$$\begin{aligned}\mathcal{E}_j=&\langle A\Phi_j,B\Psi_j\rangle+\sum_{\substack{k=1\\k\neq j}}^{n}\frac{1}{\delta_j-\delta_k}\langle\Phi_j,B\Psi_k\rangle\langle\Phi_k,B\Psi_j\rangle+\frac{1}{\delta_j-\delta_{n+1}}\langle\Phi_j,B\Psi_{n+1}\rangle\langle\Phi_{n+1},B\Psi_j\rangle,\\&1\leqslant j\leqslant n,\end{aligned} \tag{5.13}$$

$$\mathcal{E}_{n+1}=\langle A\Phi_{n+1},B\Psi_{n+1}\rangle+\sum_{k=1}^{n}\frac{1}{\delta_{n+1}-\delta_k}\langle\Phi_{n+1},B\Psi_k\rangle\langle\Phi_k,B\Psi_{n+1}\rangle. \tag{5.14}$$

The Hamiltonians H_2^x, H_2^y and H_2^t in Theorem 3.1 can be expressed as

$$H_2^x=-\sum_{k=1}^{n}\mathcal{E}_k,\quad H_2^y=-\sum_{k=1}^{n}J_k\mathcal{E}_k,\quad H_2^t=-\sum_{k=1}^{n}K_k\mathcal{E}_k, \tag{5.15}$$

where the $\mathcal{E}_k$'s are defined by (5.13).

Therefore, H_1^x and $H_1^{t_1}$ are linear combinations of $E_{il}(\gamma_1,\ldots,\gamma_n)$, $\quad 1\leqslant i\leqslant n$, $\quad l=1,2$, and H_2^x, H_2^y and H_2^t are linear combinations of $E_{il}(\delta_1,\ldots,\delta_n,\delta_{n+1})$, $\quad 1\leqslant i\leqslant n+1$, $\quad l=1,2$. It follows from Theorem 4.4 that H_1^x and $H_1^{t_1}$ are in involution, and H_2^x, H_2^y and H_2^t are in involution in pair, too. The proof is finished. ■

We remark that a direct computation can also give a proof for the involutive property of the Hamiltonians of the constrained flows in both $1+1$ and $2+1$ dimensions. Only a new set of equalities

$$\frac{a_j-a_i}{c_j-c_i}\frac{b_k-b_i}{c_k-c_i}-\frac{a_k-a_i}{c_k-c_i}\frac{b_j-b_i}{c_j-c_i}+\mathrm{cycle}(i,j,k)=0,\quad 1\leqslant i,j,k\leqslant n,$$

has to be utilized, where a_i, b_i, and c_i, $1\leqslant i\leqslant n$, are arbitrary constants. This just needs a direct check, too. However, the proof of Theorem 5.5 also gives rise to the explicit expressions for all Hamiltonians of the constrained flows in both $1+1$ and $2+1$ dimensions, in terms of the integrals of motion E_{is}.

Now if we denote the Hamiltonian flows of the spatial constrained flow (2.43) and the temporal constrained flow (2.44) by $g_x^{H_1^x}$ and $g_t^{H_1^{t_1}}$, respectively, then the above theorems present a kind of involutive solution to the $1+1$ dimensional $\mathcal{N}$-wave interaction equations (2.22):

$$\begin{aligned}u_{ij}(x,t_1)&=\frac{\alpha_i-\alpha_j}{\gamma_i-\gamma_j}\langle g_x^{H_1^x}g_t^{H_1^{t_1}}\Phi_{i0},g_x^{H_1^x}g_t^{H_1^{t_1}}B\Psi_{j0}\rangle\\&=\frac{\alpha_i-\alpha_j}{\gamma_i-\gamma_j}\langle g_t^{H_1^{t_1}}g_x^{H_1^x}\Phi_{i0},g_t^{H_1^{t_1}}g_x^{H_1^x}B\Psi_{j0}\rangle,\quad 1\leqslant i\neq j\leqslant n,\end{aligned}\tag{5.16}$$

where the initial values Φ_{i0} and Ψ_{i0} of Φ_i and Ψ_i can be taken to be any arbitrary constant vectors of the Euclidean space $\mathbb{R}^N$. Similarly, if we denote the Hamiltonian flows of the constrained flows (3.23)–(3.25) by $g_x^{H_2^x}$, $g_y^{H_2^y}$, and $g_t^{H_2^t}$, respectively, then the above theorems present a kind of involutive solutions to the $2+1$ dimensional $\mathcal{N}$-wave interaction equations (3.4):

$$\begin{aligned}p_{ij}(x,t)&=\frac{J_i-J_j}{\delta_i-\delta_j}\langle g_x^{H_2^x}g_y^{H_2^y}g_t^{H_2^t}\bar{\Phi}_{i0},g_x^{H_2^x}g_y^{H_2^y}g_t^{H_2^t}B\bar{\Psi}_{j0}\rangle\\&=\frac{J_i-J_j}{\delta_i-\delta_j}\langle g_y^{H_2^y}g_t^{H_2^t}g_x^{H_2^x}\bar{\Phi}_{i0},g_y^{H_2^y}g_t^{H_2^t}g_x^{H_2^x}B\bar{\Psi}_{j0}\rangle\\&=\frac{J_i-J_j}{\delta_i-\delta_j}\langle g_t^{H_2^t}g_x^{H_2^x}g_y^{H_2^y}\bar{\Phi}_{i0},g_t^{H_2^t}g_x^{H_2^x}g_y^{H_2^y}B\bar{\Psi}_{j0}\rangle\\&=\cdots,\quad 1\leqslant i\neq j\leqslant n,\end{aligned}\tag{5.17}$$

$$\begin{aligned}q_{ij}(x,t)&=\frac{K_i-K_j}{\delta_i-\delta_j}\langle g_x^{H_2^x}g_y^{H_2^y}g_t^{H_2^t}\bar{\Phi}_{i0},g_x^{H_2^x}g_y^{H_2^y}g_t^{H_2^t}B\bar{\Psi}_{j0}\rangle\\&=\frac{K_i-K_j}{\delta_i-\delta_j}\langle g_y^{H_2^y}g_t^{H_2^t}g_x^{H_2^x}\bar{\Phi}_{i0},g_y^{H_2^y}g_t^{H_2^t}g_x^{H_2^x}B\bar{\Psi}_{j0}\rangle\\&=\frac{K_i-K_j}{\delta_i-\delta_j}\langle g_t^{H_2^t}g_x^{H_2^x}g_y^{H_2^y}\bar{\Phi}_{i0},g_t^{H_2^t}g_x^{H_2^x}g_y^{H_2^y}B\bar{\Psi}_{j0}\rangle\\&=\cdots,\quad 1\leqslant i\neq j\leqslant n,\end{aligned}\tag{5.18}$$

where the initial values $\bar{\Phi}_{i0}$ and $\bar{\Psi}_{i0}$ of Φ_i and Ψ_i can also be taken to be any arbitrary constant vectors of the Euclidean space $\mathbb{R}^N$.

Note that all constrained flows in both $1+1$ and $2+1$ dimensions are Liouville integrable, and that the initial values of Φ_i and Ψ_i, $1\leqslant i\leqslant n$, can be arbitrarily chosen. Therefore, together with Theorems 5.1 and 5.2, the above involutive solutions also show us the richness of solutions and the integrability by quadratures for the $\mathcal{N}$-wave interaction equations in both $1+1$ and $2+1$ dimensions. Of importance is of course that binary symmetry constraints decompose the

$\mathcal{N}$-wave interaction equations in both $1+1$ and $2+1$ dimensions into finite-dimensional Liouville integrable Hamiltonian systems, and the resulting involutive solutions present the Bäcklund transformations between the $\mathcal{N}$-wave interaction equations in both $1+1$ and $2+1$ dimensions and these finite-dimensional Liouville integrable Hamiltonian systems.

VI. CONCLUSIONS AND REMARKS

We have introduced a class of special symmetry constraints, (2.38) in the $1+1$ dimensional case, and (3.19) and (3.20) in the $2+1$ dimensional case, for the $\mathcal{N}$-wave interaction equations in both $1+1$ and $2+1$ dimensions. These symmetry constraints nonlinearize the $n\times n$ spectral problem and adjoint spectral problem, (2.34) and (2.35), and the $(n+1)\times(n+1)$ spectral problem and adjoint spectral problem, (3.11) and (3.12), into finite-dimensional Liouville integrable Hamiltonian systems, and decompose the $\mathcal{N}$-wave interaction equations in both $1+1$ and $2+1$ dimensions into these finite-dimensional Liouville integrable Hamiltonian systems. A general involutive and functionally independent system of the polynomial functions $F_{is}(c_1,\ldots,c_m)$, $1\leqslant i\leqslant m$, $1\leqslant s\leqslant N$, or alternatively $E_{is}(c_1,\ldots,c_m)$, $1\leqslant i\leqslant m$, $1\leqslant s\leqslant N$, associated with an arbitrarily higher-order matrix Lax operator, was presented and used to show the Liouville integrability of the resulting constrained flows. The nonlinear constraints on the potentials, resulting from the symmetry constraints, also provide us with a class of Bäcklund transformations from the $\mathcal{N}$-wave interaction equations to the obtained finite-dimensional Liouville integrable systems. The involutive solutions to the $\mathcal{N}$-wave interaction equations are given through the constrained flows, and thus the integrability by quadratures has been exhibited for the $\mathcal{N}$-wave interaction equations. The special case with $\Gamma=W_0$, i.e., $\mathrm{diag}(\gamma_1,\ldots,\gamma_n)=\mathrm{diag}(\beta_1,\ldots,\beta_n)$ of two reductions of $n=3$ and $n=4$ in $1+1$ dimensions presents all results established in Refs. 31 and 32.

We point out that for a more general matrix Lax operator $L=C+D$ with any constant matrix $C=(c_{ij})_{m\times m}$ and the matrix D defined by (4.2), the **r**-matrix formulation (4.13) still holds. Therefore, an involutive system of polynomial functions can be generated, but we do not know what conditions on the matrix C can ensure the functional independence of that involutive system. We are also curious about other examples of higher-order matrix Lax operators which lead to involutive and functionally independent systems. Our crucial techniques to present the involutive and functionally independent system F_{is}, $1\leqslant i\leqslant m$, $1\leqslant s\leqslant N$, are the **r**-matrix formulation, Newton's identities on elementary symmetric polynomials, and the determinant property of tensor products of matrices; and the whole process of their applications provides an efficient way to show the involutive property and the functional independence.

Of course, one of the important results in binary nonlinearization is the integrability of soliton equations by quadratures, which implies that one can integrate soliton equations themselves by quadratures. However, the potentials obtained by symmetry constraints can be proved to belong to a kind of finite-gap-type solutions containing multi-soliton solutions, and thus they may not present solutions to given initial value and/or boundary problems of soliton equations. It is a challenging problem to establish a general theory of complete integrability for nonlinear differential and differential-difference equations, which should state what mathematical properties the equations must possess so that their solutions to initial value and/or boundary problems can also be determined by quadratures.

Symmetry constraints yield nonlinear constraints on potentials of soliton equations, and put linear spectral problems (linear with respect to eigenfunctions) into nonlinear constrained flows (nonlinear again with respect to eigenfunctions), which makes it more complicated to solve soliton equations. However, since spectral problems are overdetermined, one needs additional conditions (compatability conditions) to guarantee the existence of eigenfunctions of spectral problems. The symmetry property brings us the Liouville integrability for nonlinear constrained flows. Thus, symmetry constraints make up for the disadvantage of nonlinearization in manipulating binary nonlinearization. Of special interest in the study of symmetry constraints are creating new classical integrable systems,[55] which supplement the known class of integrable systems,[56] and exposing the integrability by quadratures for soliton equations by using constrained flows.[33]

The idea of binary nonlinearization is quite similar to that of using adjoint symmetries to generate conservation laws for differential equations, both Lagrangian and non-Lagrangian.[57] In binary nonlinearization, we adopt adjoint spectral problems to formulate Hamiltonian structures for constrained flows so that finite-dimensional Liouville integrable systems result. Note that there exist also some special symmetry constraints which do not yield Hamiltonian structures with constant coefficient symplectic forms, including both canonical and noncanonical ones, for constrained flows.[46] Therefore, it will be particularly interesting and important to classify symmetry constraints which exhibit Hamiltonian structures with constant and variable coefficient symplectic forms for constrained flows.

APPENDIX A: NON-LIE SYMMETRIES

Proposition A.1: If $\phi^{(s)}$ *and* $\psi^{(s)}$, $1\leqslant s\leqslant N$, *satisfy (2.34) and (2.35), then the vector field*

$$Z_0=J\sum_{s=1}^{N}\mu_s\psi^{(s)T}\frac{\partial U(u,\lambda_s)}{\partial u}\phi^{(s)}=\rho\left(\left[U_0,\sum_{s=1}^{N}\mu_s\phi^{(s)}\psi^{(s)T}\right]\right) \tag{A1}$$

is a symmetry of the $1+1$ *dimensional* $\mathcal{N}$*-wave interaction equations (2.22).*

Proof: It is required to show that

$$(\delta P,\delta Q)=\left(\left[U_0,\sum_{s=1}^{N}\mu_s\phi^{(s)}\psi^{(s)T}\right],\left[W_0,\sum_{s=1}^{N}\mu_s\phi^{(s)}\psi^{(s)T}\right]\right) \tag{A2}$$

satisfies the linearized system (2.25). By using (2.34) and (2.35), we can first compute that

$$\begin{aligned}\left(\sum_{s=1}^{N}\mu_s\phi^{(s)}\psi^{(s)T}\right)_{t_1}&=\sum_{s=1}^{N}\mu_s\phi^{(s)}_{t_1}\psi^{(s)T}+\sum_{s=1}^{N}\mu_s\phi^{(s)}\psi^{(s)T}_{t_1}\\&=\sum_{s=1}^{N}\mu_sV^{(1)}(u,\lambda_s)\phi^{(s)}\psi^{(s)T}-\sum_{s=1}^{N}\mu_s\phi^{(s)}\psi^{(s)T}V^{(1)}(u,\lambda_s)\\&=\sum_{s=1}^{N}\mu_s[V^{(1)}(u,\lambda_s),\phi^{(s)}\psi^{(s)T}]\\&=\sum_{s=1}^{N}\lambda_s\mu_s[W_0,\phi^{(s)}\psi^{(s)T}]+\left[W_1,\sum_{s=1}^{N}\mu_s\phi^{(s)}\psi^{(s)T}\right],\end{aligned}$$

and, similarly, we can have

$$\left(\sum_{s=1}^{N}\mu_s\phi^{(s)}\psi^{(s)T}\right)_{x}=\sum_{s=1}^{N}\lambda_s\mu_s[U_0,\phi^{(s)}\psi^{(s)T}]+\left[U_1,\sum_{s=1}^{N}\mu_s\phi^{(s)}\psi^{(s)T}\right].$$

Thus, noting the Jacobi identity, it follows that

$$
\begin{aligned}
(\delta P)_{t_1}-(\delta Q)_x &= \left[U_0,\left(\sum_{s=1}^{N}\mu_s\phi^{(s)}\psi^{(s)T}\right)_{t_1}\right]-\left[W_0,\left(\sum_{s=1}^{N}\mu_s\phi^{(s)}\psi^{(s)T}\right)_x\right]\\
&=\sum_{s=1}^{N}\lambda_s\mu_s([U_0,[W_0,\phi^{(s)}\psi^{(s)T}]]-[W_0,[U_0,\phi^{(s)}\psi^{(s)T}]])\\
&\quad+\left[U_0,\left[W_1,\sum_{s=1}^{N}\mu_s\phi^{(s)}\psi^{(s)T}\right]\right]-\left[W_0,\left[U_1,\sum_{s=1}^{N}\mu_s\phi^{(s)}\psi^{(s)T}\right]\right]\\
&=\left[U_0,\left[W_1,\sum_{s=1}^{N}\mu_s\phi^{(s)}\psi^{(s)T}\right]\right]-\left[W_0,\left[U_1,\sum_{s=1}^{N}\mu_s\phi^{(s)}\psi^{(s)T}\right]\right],
\end{aligned}
$$

where δP and δQ are defined by (A2). Then, again noting the Jacobi identity, we can have

$$
\begin{aligned}
&(\delta P)_{t_1}-(\delta Q)_x+[U_1,\delta Q]+[\delta P,W_1]\\
&\quad=\left[\sum_{s=1}^{N}\mu_s\phi^{(s)}\psi^{(s)T},[U_0,W_1]\right]-\left[\sum_{s=1}^{N}\mu_s\phi^{(s)}\psi^{(s)T},[W_0,U_1]\right]=0,
\end{aligned}
$$

in the last step of which we have used $[U_0,W_1]=[W_0,U_1]$. The proof is finished. ■

All of the symmetries presented in this proposition are not Lie point, contact, or Bäcklund symmetries, since they cannot be written in terms of the potentials u_{ij} and their spatial derivatives.

APPENDIX B: FORMULAS FOR COMPUTING $\mathcal{F}_\lambda^{(k)}$

Immediately from the expressions of $\mathcal{F}_\lambda^{(k)}$ in (4.22), we can obtain the following more concrete formulas for computing $\mathcal{F}_\lambda^{(k)}$:

$$
\mathcal{F}_\lambda^{(1)}=\sum_{i=1}^{m}(c_i+\overset{ii}{Q}_\lambda),
$$

$$
\mathcal{F}_\lambda^{(2)}=\sum_{1\leqslant i<j\leqslant m}\left(c_ic_j+c_j\overset{ii}{Q}_\lambda+c_i\overset{jj}{Q}_\lambda+\begin{vmatrix}\overset{ii}{Q}_\lambda & \overset{ij}{Q}_\lambda\\ \overset{ji}{Q}_\lambda & \overset{jj}{Q}_\lambda\end{vmatrix}\right),
$$

$$
\begin{aligned}
\mathcal{F}_\lambda^{(3)}=&\sum_{1\leqslant i<j<k\leqslant m}(c_ic_jc_k+c_ic_k\overset{jj}{Q}_\lambda+c_jc_k\overset{ii}{Q}_\lambda+c_ic_j\overset{kk}{Q}_\lambda)\\
&+\sum_{1\leqslant i<j<k\leqslant m}\left(c_i\begin{vmatrix}\overset{jj}{Q}_\lambda & \overset{jk}{Q}_\lambda\\ \overset{kj}{Q}_\lambda & \overset{kk}{Q}_\lambda\end{vmatrix}+c_j\begin{vmatrix}\overset{ii}{Q}_\lambda & \overset{ik}{Q}_\lambda\\ \overset{ki}{Q}_\lambda & \overset{kk}{Q}_\lambda\end{vmatrix}+c_k\begin{vmatrix}\overset{ii}{Q}_\lambda & \overset{ij}{Q}_\lambda\\ \overset{ji}{Q}_\lambda & \overset{jj}{Q}_\lambda\end{vmatrix}+\begin{vmatrix}\overset{ii}{Q}_\lambda & \overset{ij}{Q}_\lambda & \overset{ik}{Q}_\lambda\\ \overset{ji}{Q}_\lambda & \overset{jj}{Q}_\lambda & \overset{jk}{Q}_\lambda\\ \overset{ki}{Q}_\lambda & \overset{kj}{Q}_\lambda & \overset{kk}{Q}_\lambda\end{vmatrix}\right),\\
&\cdots,\\
\mathcal{F}_\lambda^{(k)}=&\sum_{1\leqslant j_1<j_2<\ldots<j_k\leqslant m}\left(\prod_{p=1}^{k}c_{j_p}+\sum_{i=1}^{k}\prod_{\substack{p=1\\p\neq i}}^{k}c_{j_p}\overset{j_ij_i}{Q}_\lambda+\sum_{1\leqslant i_1<i_2\leqslant k}\prod_{\substack{p=1\\p\neq i_1,i_2}}^{k}c_{j_p}\begin{vmatrix}\overset{j_{i_1}j_{i_1}}{Q}_\lambda & \overset{j_{i_1}j_{i_2}}{Q}_\lambda\\ \overset{j_{i_2}j_{i_1}}{Q}_\lambda & \overset{j_{i_2}j_{i_2}}{Q}_\lambda\end{vmatrix}\right)
\end{aligned}
$$

$$+\sum_{1\leqslant j_1<j_2<\ldots<j_k\leqslant m}\ \sum_{1\leqslant i_1<i_2<i_3\leqslant k}\ \prod_{\substack{p=1\\ p\neq i_1,i_2,i_3}}^{k} c_{j_p}\begin{vmatrix} {}^{j_{i_1}j_{i_1}}Q_\lambda & {}^{j_{i_1}j_{i_2}}Q_\lambda & {}^{j_{i_1}j_{i_3}}Q_\lambda \\ {}^{j_{i_2}j_{i_1}}Q_\lambda & {}^{j_{i_2}j_{2}}Q_\lambda & {}^{j_{i_2}j_{i_3}}Q_\lambda \\ {}^{j_{i_3}j_{i_1}}Q_\lambda & {}^{j_{i_3}j_{i_2}}Q_\lambda & {}^{j_{i_3}j_{i_3}}Q_\lambda \end{vmatrix}+\ldots$$

$$+\sum_{1\leqslant j_1<j_2<\ldots<j_k\leqslant m}\begin{vmatrix} {}^{j_1j_1}Q_\lambda & {}^{j_1j_2}Q_\lambda & \cdots & {}^{j_1j_k}Q_\lambda \\ {}^{j_2j_1}Q_\lambda & {}^{j_2j_2}Q_\lambda & \cdots & {}^{j_2j_k}Q_\lambda \\ \vdots & \vdots & \ddots & \vdots \\ {}^{j_kj_1}Q_\lambda & {}^{j_kj_2}Q_\lambda & \cdots & {}^{j_kj_k}Q_\lambda \end{vmatrix},$$

$$\ldots,$$

$$\mathcal{F}_\lambda^{(m)}=\prod_{p=1}^{m} c_p+\sum_{i=1}^{m}\prod_{\substack{p=1\\ p\neq i}}^{m} c_p\,{}^{ii}Q_\lambda+\sum_{1\leqslant i<j\leqslant m}\prod_{\substack{p=1\\ p\neq i,j}}^{m} c_p\begin{vmatrix} {}^{ii}Q_\lambda & {}^{ij}Q_\lambda \\ {}^{ji}Q_\lambda & {}^{jj}Q_\lambda \end{vmatrix}$$

$$+\sum_{1\leqslant i<j<k\leqslant m}\ \prod_{\substack{p=1\\ p\neq i,j,k}}^{k} c_p\begin{vmatrix} {}^{ii}Q_\lambda & {}^{ij}Q_\lambda & {}^{ik}Q_\lambda \\ {}^{ji}Q_\lambda & {}^{jj}Q_\lambda & {}^{jk}Q_\lambda \\ {}^{ki}Q_\lambda & {}^{kj}Q_\lambda & {}^{kk}Q_\lambda \end{vmatrix}+\ldots+\begin{vmatrix} {}^{11}Q_\lambda & {}^{12}Q_\lambda & \cdots & {}^{1m}Q_\lambda \\ {}^{21}Q_\lambda & {}^{22}Q_\lambda & \cdots & {}^{2r}Q_\lambda \\ \vdots & \vdots & \ddots & \vdots \\ {}^{m1}Q_\lambda & {}^{r2}Q_\lambda & \cdots & {}^{mm}Q_\lambda \end{vmatrix}.$$

APPENDIX C: THE DETERMINANT OF Ω_m

The following proposition has been used while showing the functional independence of the polynomial functions $F_{is}(c_1,\ldots,c_m)$, $1\leqslant i\leqslant m$, $1\leqslant s\leqslant N$, which is of interest itself.

Proposition C.1: Let $m\geqslant 2$, and $c_1,c_2,\ldots,c_m$ be constants. Then

$$\det(\Omega_m)=\begin{vmatrix} 1 & \sum_{i=2}^{m} c_i & \sum_{2\leqslant i<j\leqslant m} c_ic_j & \sum_{2\leqslant i<j<k\leqslant m} c_ic_jc_k & \cdots & \prod_{i=2}^{m} c_i \\ 1 & \sum_{\substack{i=1\\ i\neq 2}}^{m} c_i & \sum_{\substack{1\leqslant i<j\leqslant m\\ i,j\neq 2}} c_ic_j & \sum_{\substack{1\leqslant i<j<k\leqslant m\\ i,j,k\neq 2}} c_ic_jc_k & \cdots & \prod_{\substack{i=1\\ i\neq 2}}^{m} c_i \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & \sum_{i=1}^{m-1} c_i & \sum_{1\leqslant i<j\leqslant m-1} c_ic_j & \sum_{1\leqslant i<j<k\leqslant m-1} c_ic_jc_k & \cdots & \prod_{i=1}^{m-1} c_i \end{vmatrix}$$

$$=\prod_{1\leqslant i<j\leqslant m}(c_i-c_j). \tag{C1}$$

Proof: We prove this proposition by the principle of mathematical induction. It is obvious that (C1) is true when $m=2$. Suppose that (C1) is true when $m=l$. Let us verify that (C1) is also true when $m=l+1$. Note that

$$\sum_{\substack{1\leqslant i_1<i_2<\ldots<i_k\leqslant l+1\\ i_1,i_2,\ldots,i_k\neq j}} c_{i_1}c_{i_2}\ldots c_{i_k} - \sum_{\substack{1\leqslant i_1<i_2<\ldots<i_k\leqslant l+1\\ i_1,i_2,\ldots,i_k\neq i}} c_{i_1}c_{i_2}\ldots c_{i_k}$$

$$=(c_i-c_j)\sum_{\substack{1\leqslant i_1<i_2<\ldots<i_{k-1}\leqslant l+1\\ i_1,i_2,\ldots,i_{k-1}\neq i,j}} c_{i_1}c_{i_2}\ldots c_{i_{k-1}},$$

$$1\leqslant i,j\leqslant l+1, \quad 1\leqslant k\leqslant l.$$

For each $2\leqslant j\leqslant l+1$, we subtract

$$\sum_{2\leqslant i_1<i_2<\ldots<i_{j-1}\leqslant l+1}^{l+1} c_{i_1}c_{i_2}\ldots c_{i_{j-1}}\times \text{the first column of } \det(\Omega_{l+1})$$

from the jth column of $\det(\Omega_{l+1})$, and then we have

$$\det(\Omega_{l+1})$$

$$=\begin{vmatrix} 1 & 0 & 0 & 0 & \ldots & 0 \\ 1 & c_1-c_2 & (c_1-c_2)\sum_{i=3}^{l+1} c_i & (c_1-c_2)\sum_{3\leqslant i<j\leqslant l+1} c_ic_j & \ldots & (c_1-c_2)\prod_{i=3}^{l+1} c_i \\ 1 & c_1-c_3 & (c_1-c_3)\sum_{\substack{i=2\\ i\neq 3}}^{l+1} c_i & (c_1-c_3)\sum_{\substack{2\leqslant i<j\leqslant l+1\\ i,j\neq 3}} c_ic_j & \ldots & (c_1-c_3)\prod_{\substack{i=2\\ i\neq 3}}^{l+1} c_i \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & c_1-c_{l+1} & (c_1-c_{l+1})\sum_{i=2}^{l} c_i & (c_1-c_{l+1})\sum_{2\leqslant i<j\leqslant l} c_ic_j & \ldots & (c_1-c_{l+1})\prod_{i=2}^{l} c_i \end{vmatrix}$$

$$=\prod_{j=2}^{l+1}(c_1-c_j)\begin{vmatrix} 1 & \sum_{i=3}^{l+1} c_i & \sum_{3\leqslant i<j\leqslant l+1} c_ic_j & \ldots & \prod_{i=3}^{l+1} c_i \\ 1 & \sum_{\substack{i=2\\ i\neq 3}}^{l+1} c_i & \sum_{\substack{2\leqslant i<j\leqslant l+1\\ i,j\neq 3}} c_ic_j & \ldots & \prod_{\substack{i=2\\ i\neq 3}}^{l+1} c_i \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & \sum_{i=2}^{l} c_i & \sum_{2\leqslant i<j\leqslant l} c_ic_j & \ldots & \prod_{i=2}^{l} c_i \end{vmatrix} = \prod_{1\leqslant i<j\leqslant l+1}(c_i-c_j),$$

in the last step of which we have used the inductive assumption. This means that (C1) is also true when $m=l+1$, i.e., the inductive step is satisfied. Therefore, the formula (C1) is always true by the principle of mathematical induction. The proof is finished. ■

APPENDIX D: TWO IDENTITIES ON SYMMETRIC POLYNOMIALS

Let the s_j's be symmetric polynomials defined by (4.27).

Proposition D.1: For any integers r and i with $i\geqslant r\geqslant 1$, and any numbers $c_1,\ldots,c_r$, we have

$$\sum_{j=0}^{i-r}(-1)^j s_j(c_1,\ldots,c_r)\sum_{\substack{l_1+\ldots+l_r=i-r-j\\ l_1,\ldots,l_r\geqslant 0}} c_1^{l_1}\ldots c_r^{l_r}=\begin{cases}1, & \text{if } i=r,\\ 0, & \text{if } i>r.\end{cases} \tag{D1}$$

Proof: Use the principle of mathematical induction on r. When $r=1$ and $i=1$, the left-hand side of (D1) is 1. When $r=1$ and $i>1$, the left-hand side of (D1) is 0. Hence (D1) holds when $r=1$.

Now suppose that (D1) holds when $r=k$, i.e.,

$$\sum_{j=0}^{i-k}(-1)^j s_j(c_1,\ldots,c_k)\sum_{\substack{l_1+\ldots+l_k=i-k-j\\ l_1,\ldots,l_k\geqslant 0}} c_1^{l_1}\ldots c_k^{l_k}=\begin{cases}1, & \text{if } i=k,\\ 0, & \text{if } i>k.\end{cases} \tag{D2}$$

Then, when $r=k+1$, the left-hand side of (D1) is

$$\sum_{j=0}^{i-k-1}(-1)^j s_j(c_1,\ldots,c_{k+1})\sum_{\substack{l_1+\cdots+l_{k+1}=i-k-j-1\\ l_1,\cdots,l_{k+1}\geqslant 0}} c_1^{l_1}\cdots c_{k+1}^{l_{k+1}}. \tag{D3}$$

By using (4.28), it equals

$$\begin{aligned}&\sum_{j=0}^{i-k-1}(-1)^j\sum_{l_{r+1}=0}^{i-k-j-1} c_{k+1}^{l_{k+1}+1}s_{j-1}(c_1,\ldots,c_k)\sum_{\substack{l_1+\cdots+l_k=i-k-j-1-l_{k+1}\\ l_1,\ldots,l_k\geqslant 0}} c_1^{l_1}\cdots c_k^{l_k}\\ &\quad+\sum_{j=0}^{i-k-1}(-1)^j\sum_{l_{r+1}=0}^{i-k-j-1} c_{k+1}^{l_{k+1}}s_j(c_1,\ldots,c_k)\sum_{\substack{l_1+\cdots+l_k=i-k-j-1-l_{k+1}\\ l_1,\cdots,l_k\geqslant 0}} c_1^{l_1}\cdots c_k^{l_k}\\ &=\sum_{l_{r+1}=0}^{i-k-1} c_{k+1}^{l_{k+1}+1}\sum_{j=0}^{i-k-l_{k+1}-2}(-1)^{j+1}s_j(c_1,\ldots,c_k)\sum_{\substack{l_1+\cdots+l_k=i-k-j-l_{k+1}-2\\ l_1,\cdots,l_k\geqslant 0}} c_1^{l_1}\cdots c_k^{l_k}\\ &\quad+\sum_{l_{r+1}=0}^{i-k-1} c_{k+1}^{l_{k+1}}\sum_{j=0}^{i-k-l_{k+1}-1}(-1)^j s_j(c_1,\ldots,c_k)\sum_{\substack{l_1+\cdots+l_k=i-k-j-l_{k+1}-1\\ l_1,\cdots,l_k\geqslant 0}} c_1^{l_1}\cdots c_k^{l_k},\end{aligned} \tag{D4}$$

where an empty sum is understood to be zero.

When $i=k+1$, it is easy to see that (D4) equals 1. If $i>k+1$, then by (D2), the first sum equals

$$-c_{k+1}^{l_{k+1}+1}\big|_{l_{k+1}=i-k-2}=-c_{k+1}^{i-k-1}, \tag{D5}$$

and again, by (D2), the second sum equals

$$c_{k+1}^{l_{k+1}}\big|_{l_{k+1}=i-k-1}=c_{k+1}^{i-k-1}. \tag{D6}$$

Hence (D4) equals 0 if $i>k+1$, which implies that (D1) holds when $r=k+1$. Therefore, (D1) always holds by the principle of mathematical induction. The proposition is proved. ■

Proposition D.2: For any integers m, r, i with $i\geqslant r+1\geqslant 2$, m numbers $c_1,\ldots,c_m$, and r integers $j_1,\ldots,j_r$ with $1\leqslant j_1<\ldots<j_r\leqslant m$, we have

$$\sum_{j=0}^{i-r}(-1)^{i-r-j}s_j(c_1,\ldots,c_m)\sum_{\substack{l_1+\cdots+l_r=i-r-j\\ l_1,\ldots,l_r\geqslant 0}}c_{j_1}^{l_1}\cdots c_{j_r}^{l_r}=\sum_{\substack{1\leqslant\rho_1<\cdots<\rho_{i-r}\leqslant m\\ \rho_\alpha\neq j_\beta \text{ for all } \alpha,\beta}}c_{\rho_1}\cdots c_{\rho_{i-r}}. \quad \text{(D7)}$$

Proof: Without loss of generality, suppose that $j_i=i$ when $i=1,\ldots,r$, since each $s_j(c_1,\ldots,c_m)$ is symmetric with respect to $c_1,\ldots,c_m$. Then, (D7) becomes

$$\sum_{j=0}^{i-r}(-1)^{i-r-j}s_j(c_1,\ldots,c_m)\sum_{\substack{l_1+\cdots+l_r=i-r-j\\ l_1,\cdots,l_r\geqslant 0}}c_1^{l_1}\cdots c_r^{l_r}=\sum_{r+1\leqslant\rho_1<\cdots<\rho_{i-r}\leqslant m}c_{\rho_1}\cdots c_{\rho_{i-r}}. \quad \text{(D8)}$$

Obviously, for any fixed j with $r+1\leqslant j\leqslant m$, both sides of (D8) are linear with respect to c_j.

We use the principle of mathematical induction on i to prove (D8). When $i=r+1$, both sides of (D8) equal $c_{r+1}+\cdots+c_m$.

Suppose that (D8) holds when $i=k$ $(k>r)$. Then, when $i=k+1$, the left-hand side of (D8) reads as

$$R:=\sum_{j=0}^{k+1-r}(-1)^{k+1-r-j}s_j(c_1,\ldots,c_m)\sum_{\substack{l_1+\cdots+l_r=k+1-r-j\\ l_1,\cdots,l_r\geqslant 0}}c_1^{l_1}\cdots c_r^{l_r}$$

$$=\sum_{j=-1}^{k-r}(-1)^{k-r-j}s_{j+1}(c_1,\ldots,c_m)\sum_{\substack{l_1+\cdots+l_r=k-r-j\\ l_1,\cdots,l_r\geqslant 0}}c_1^{l_1}\cdots c_r^{l_r}. \quad \text{(D9)}$$

Then by (4.28), we have

$$\frac{\partial R}{\partial c_m}=\sum_{j=0}^{k-r}(-1)^{k-r-j}s_j(c_1,\ldots,c_{m-1})\sum_{\substack{l_1+\cdots+l_r=k-r-j\\ l_1,\cdots,l_r\geqslant 0}}c_1^{l_1}\cdots c_r^{l_r}. \quad \text{(D10)}$$

By the inductive assumption, it becomes

$$\frac{\partial R}{\partial c_m}=\sum_{r+1\leqslant\rho_1<\ldots<\rho_{k-r}\leqslant m-1}c_{\rho_1}\cdots c_{\rho_{k-r}}. \quad \text{(D11)}$$

Hence we obtain

$$R=\sum_{r+1\leqslant\rho_1<\cdots<\rho_{k-r}\leqslant m-1}c_{\rho_1}\cdots c_{\rho_{k-r}}c_m+R_1(c_1,\ldots,c_{m-1}), \quad \text{(D12)}$$

where R_1 is a polynomial. Since R is symmetric with respect to $c_{r+1},\ldots,c_m$, we have

$$R=\sum_{r+1\leqslant\rho_1<\cdots<\rho_{k+1-r}\leqslant m}c_{\rho_1}\cdots c_{\rho_{k+1-r}}+R_0(c_1,\ldots,c_r), \quad \text{(D13)}$$

where by setting $c_{r+1}=\cdots=c_m=0$ in (D9), R_0 is determined to be

$$R_0(c_1,\ldots,c_r)=\sum_{j=0}^{k+1-r}(-1)^{k+1-r-j}s_j(c_1,\ldots,c_r)\sum_{\substack{l_1+\cdots+l_r=k+1-r-j\\ l_1,\ldots,l_r\geqslant 0}}c_1^{l_1}\cdots c_r^{l_r}. \quad \text{(D14)}$$

By Proposition D.1, $R_0=0$ since $k+1=i>r$. Hence

$$R=\sum_{r+1\leqslant\rho_1<\cdots<\rho_{k+1-r}\leqslant m} c_{\rho_1}\cdots c_{\rho_{k+1-r}}, \tag{D15}$$

which implies that (D8) holds when $i=k+1$. Therefore, (D8) holds for all $i>r$ by the principle of mathematical induction. The proof is completed. ■

The identity (D7) is needed in presenting an alternative involutive system E_{is}'s to the F_{is}'s in Sec. IV C.

Dynamical systems, whose symplectic structure degenerates, becoming noninvertible at some points along the orbits, are analyzed. It is shown that for systems with a finite number of degrees of freedom, like in classical mechanics, the degeneracy occurs on domain walls that divide phase space into nonoverlapping regions, each one describing a nondegenerate system, causally disconnected from each other. These surfaces are characterized by the sign of the Liouville flux density on them, behaving as sources or sinks of orbits. In this latter case, once the system reaches the domain wall, it acquires a new gauge invariance and one degree of freedom is dynamically frozen, while the remaining degrees of freedom evolve regularly thereafter. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1389088]

I. INTRODUCTION

A number of dynamical systems of physical interest possess field-dependent symplectic forms which degenerate, becoming noninvertible for some particular configurations. Systems as diverse as vortex interactions in fluids,[1] and gravitation theories in dimensions $d>4$ containing higher powers of curvature in the Lagrangian exhibit this feature (see, e.g., Ref. 2). Models of this kind naturally arise in different contexts of current high energy physics, ranging from cosmology and brane worlds[3,4] to strings and M-theory.[5–7]

The problem is how to describe the evolution of the system near a degenerate configuration and, if it could reach such a state, how it would evolve afterwards. The standard hypotheses in the treatment of dynamical systems, however, exclude the possibility that the symplectic form may have nonconstant rank throughout phase space, even in classical mechanics (see, e.g., Refs. 8, and 9).

As a first step towards understanding the general problem, here we analyze degenerate dynamical systems in classical mechanics. We show that it is possible to fully characterize the evolution of these systems.

It should be emphasized that this degeneracy is independent of Poincaré's classification of singularities. A Poincaré singularity occurs at critical points of the Hamiltonian, which are generically isolated, whereas the symplectic form degenerates on surfaces which are generically domain walls. This kind of surface cannot be understood as dense sets of Poincaré singularities. Roughly speaking, a symplectic degeneracy is the counterpart of a Poincaré singularity in that, in the latter the gradient of the Hamiltonian vanishes, whereas the former can be interpreted as an infinite gradient.

The previous point can be made more explicit by considering the simplest example of a degenerate system, whose phase flow satisfies

$$\begin{pmatrix} 0 & x_2 \\ -x_2 & 0 \end{pmatrix} \begin{pmatrix} \dot{x}_1 \\ \dot{x}_2 \end{pmatrix} = \begin{pmatrix} E_1 \\ E_2 \end{pmatrix}, \tag{1}$$

with $E_1 E_2 \neq 0$, which degenerates at $x_2 = 0$. An equivalent formulation in the $x_2 \neq 0$ region is

$$\begin{pmatrix} \dot{x}_1 \\ \dot{x}_2 \end{pmatrix} = \frac{1}{x_2} \begin{pmatrix} -E_2 \\ E_1 \end{pmatrix}, \tag{2}$$

which can be viewed as a phase flow where the gradient of the Hamiltonian diverges as $x_2 \to 0$. The required symplectomorphism (canonical transformation) to obtain Eq. (2) from Eq. (1) is noninvertible throughout phase space, however.

II. FIRST-ORDER LAGRANGIANS AND THEIR SYMPLECTIC FORMS

Let us consider a system whose action is a one-form A, integrated over a $(0+1)$-dimensional worldline embedded in a $(2n+1)$-dimensional spacetime of signature $(-,+,\ldots,+)$,

$$S[z;1,2] = \int_1^2 A_\mu \dot{z}^\mu \, d\tau, \tag{3}$$

The field A_μ is a prescribed set of $2n+1$ functions of the embedding coordinates z^μ, which are the dynamical variables.[10] This action is manifestly invariant under reparametrizations of the worldline $\tau \to \tau'(\tau)$, and diffeomorphisms $z^\mu \to z'^\mu(z)$.[11] Identifying the affine parameter with the timelike embedding coordinate $z^0 := t$, so that $z^i = z^i(t)$, the action reads

$$S[z;1,2] = \int_{t_1}^{t_2} [A_i \dot{z}^i + A_0] \, dt. \tag{4}$$

The equations of motion are given by

$$F_{ij} \dot{z}^j + E_i = 0, \tag{5}$$

where we have defined $E_i \equiv \partial_i A_0 - \partial_0 A_i$ and $F_{ij} \equiv \partial_i A_j - \partial_j A_i$. In the following, we assume A_i and A_0 to be time-independent.

These dynamical systems are naturally classified according to the rank ρ of the symplectic form F_{ij}.[12] Thus, three cases are distinguished: (A) regular Hamiltonian systems, for which the symplectic form has constant maximal rank, $\rho(F_{ij}) = 2n$ throughout phase space Γ,[10] (B) singular or constrained Hamiltonian systems, which have a constant nonmaximal rank, $\rho(F_{ij}) = 2m < 2n$ throughout Γ,[9] and, (C) degenerate systems, which have nonconstant rank $\rho(F_{ij})$ throughout Γ.

III. DEGENERATE SYSTEMS

We will focus our discussion in the degenerate case (C), which has been traditionally left aside in the literature. We will assume that the zero-measure subset of Γ given by

$$\Sigma = \{ z \in \Gamma / F = 0 \}, \tag{6}$$

where $F := \det(F_{ij})$, is not dense. Thus, outside Σ, the symplectic form F_{ij} has a constant rank $2n$, and the dynamical structure there is described through case (A) above.[13]

Under these conditions, nothing prevents the system, starting from a generic state for which $F \neq 0$, from reaching a point on Σ after some finite time. Having this scenario in mind, we address the following points:

(i) the description of the locus of Σ,
(ii) classification of the phase flow near Σ, and
(iii) whether Σ can be reached and, in that case, the fate of the system thereafter.

A. Degeneracy surfaces Σ

As is well known, a skew-symmetric $2n \times 2n$ matrix $F_{ij}(z)$ can be brought into the block-diagonal form by an orthogonal transformation. Thus the two-form $\mathcal{F} = 1/2 F_{ij} dz^i \wedge dz^j$ can be block diagonalized in an open set, under a local $O(2n)$ coordinate transformation $z^i \to x^i(z)$,

$$\mathcal{F}=\sum_{r=1}^{n} f_r(z)dx^{2r-1}\wedge dx^{2r}. \tag{7}$$

However, *in open sets containing points of the degeneracy surfaces, the Darboux-like coordinates x^i cannot be brought into the standard canonical form, because at least one of the f_r's in (7) vanishes at* Σ. Hence, further (finite) rescalings cannot normalize the f_r's to 1. As a consequence, the set Σ is the union of the $(2n-1)$-dimensional surfaces

$$\Sigma_r=\{z\in\Gamma/f_r(z)=0\},$$

that is, $\Sigma=\cup_{r=1}^{n}\Sigma_r$.

Moreover, by virtue of the Bianchi identity $(d\mathcal{F}=0)$, it can be shown that $f_r(x)$ depends only on the pair of conjugate coordinates (x^{2r-1},x^{2r}). This means that the degeneracy surfaces are constant along the remaining coordinates.

We assume that the f_r's are smooth Morse functions on the corresponding $(x^{2r-1}-x^{2r})$ planes, which ensures that they possess only simple zeros except at isolated points; the cases where f_r has zeros of higher order can be thought of as the merging of simple zeros. Hence, the level curves $f_r(x^{2r-1},x^{2r})=0$ divide the $(x^{2r-1}-x^{2r})$-plane into nonoverlapping sets and therefore,

Lemma 1: The locus of the degeneracy surfaces Σ corresponds to a collection of domain walls, splitting the phase space Γ into a number of nonoverlapping regions.

B. Characterization of the phase flow near Σ

Generically, at a surface Σ_r the rank $\rho(F_{ij})$ is lowered by 2, and at points where k of these surfaces intersect, ρ is lowered by $2k$. In a sufficiently small neighborhood of the surface Σ_r, the behavior of the system is dominated by the dynamical variables $x^\alpha=(x^{2r-1}-x^{2r})$, whose corresponding equations of motion can be read from Eq. (5) as

$$\epsilon_{\alpha\beta}f(x)\dot{x}^\beta=-E_\alpha, \tag{8}$$

where for simplicity, we have set $r=1$, so that α and $\beta=1,2$ and $f:=f_1$. Near a degeneracy surface Σ_r, the remaining dynamical variables z^a $(a=3,\ldots,2n)$ behave like the phase space coordinates of a regular system.

Here it is assumed that E_α remains finite and does not vanish on Σ_1 (i.e., Poincaré singularities are assumed to be located outside Σ), therefore, Eq. (8) implies that the velocity becomes tangent to the (x^1-x^2) plane, because the components $\dot{x}^\alpha$ become unbounded as the orbit approaches Σ_1, while the other components $(\dot{z}^a)$ remain finite.

Due to the fact that f has a simple zero at Σ_1, $\dot{x}^\alpha$ reverses its sign across the degeneracy surface. Consequently, the phase flow evolves in opposite directions on each side of Σ. Thus, in a local neighborhood of Σ, one of the following three situations occur: (a) Orbits flow towards Σ and end there, (b) the orbits originate at the degeneracy surface and flow away from it, or (c) the orbits run parallel to Σ, but in opposite directions on each side.

Hence, the surfaces act as sinks or sources for the orbits in cases (a) and (b), respectively, which naturally suggests a classification of the local nature of Σ into $\Sigma^{(-)}$, $\Sigma^{(+)}$, and $\Sigma^{(0)}$ for the cases (a), (b) and (c), respectively (see Fig. 1).

In all three cases there is no flux across the degeneracy surface, and therefore, we have the following.

Lemma 2: The regions on either side of Σ are causally disconnected and dynamically independent from each other.

An immediate consequence of this is the violation of Liouville's theorem at the surfaces of degeneracy. In fact, outside the degeneracy surfaces, the Liouville current

$$j^i=\sqrt{F}\dot{z}^i \tag{9}$$

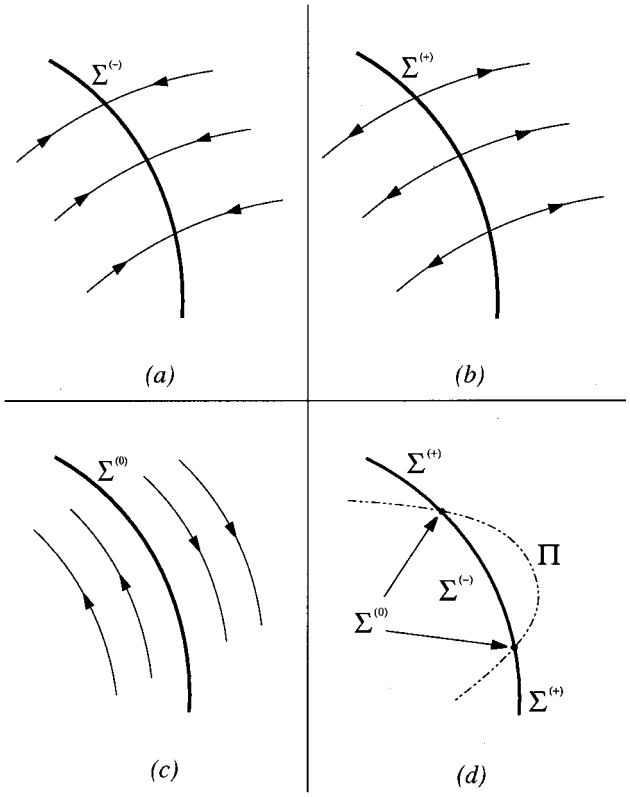

FIG. 1. (a), (b) and (c) show the qualitative local flow in the neighborhood of $\Sigma^{(+)}$, $\Sigma^{(-)}$ and $\Sigma^{(0)}$, respectively. The global structure of degeneracy surfaces is shown in (d).

is divergence-free ($\partial_i j^i = 0$) by virtue of the equations of motion and the identity $\partial_i(\sqrt{F}F^{ij}E_j) = 0$, with $F^{ij}F_{jk} = \delta^i_k$. This means that Liouville's theorem holds outside Σ, where the dynamical behavior is regular. Moreover, j^i has a finite limit as the system approaches a degeneracy surface, whose only nonvanishing components on each side of Σ are

$$j^\alpha = |f|\dot{x}^\alpha = sgn(f)\epsilon^{\alpha\beta}E_\beta . \tag{10}$$

The local character of the degeneracy surfaces Σ can be inferred from the flux of j^i across a pill box enclosing a portion of Σ. The flux density $\Phi = j^i n_i$ across the lids of the pill box is given by the projection of j^i along the normal to the surface $n_i = \partial_i F^{1/2}$, whose only nonvanishing components are $n_\alpha = \partial_\alpha |f|$, that is,

$$\Phi = -F^{1/2}F^{ij}E_j\partial_i F^{1/2} = \partial_\alpha f \epsilon^{\alpha\beta}E_\beta . \tag{11}$$

Note that Φ is not only finite, but continuous on Σ. Therefore, we have the following lemma.

Lemma 3: The local character of the degeneracy surfaces is given by $\Sigma^{(\eta)}$ with $\eta = sgn(\Phi)$. Furthermore, in general, Σ is globally piecewise attractive ($\Sigma^{(-)}$) or repulsive ($\Sigma^{(+)}$), and is of type $\Sigma^{(0)}$ at the intersections with the surfaces $\Pi = \{z \in \Gamma / \Phi(z) = 0\}$ [see Fig. 1.(d)].

Hence, $\Sigma^{(0)}$ generically corresponds to the boundaries between $\Sigma^{(-)}$ and $\Sigma^{(+)}$ (that is, $\Sigma^{(0)} = \partial\Sigma^{(-)}$) which is a subset of codimension 2 in phase space.

In the particular case, when both surfaces Σ and Π coincide on an open set, Σ is globally of type $\Sigma^{(0)}$. This occurs for example, if $E_i|_{\Sigma^{(0)}} = \partial_i(h(z^i)F^{1/2})$, whose only nonvanishing components are of the form $E_\alpha = \tilde{h}(z^a)\partial_\alpha f$ for some functions h and $\tilde{h} \neq 0$.[14]

C. Evolution towards $\Sigma^{(-)}$

The degeneracy surfaces $\Sigma^{(+)}$ and $\Sigma^{(-)}$ represent sets of initial and final states of the system, respectively. Configurations at a surface $\Sigma^{(+)}$ are unstable against small perturbations, and it seems unlikely that a system could be prepared there. On the other hand, if one considers the system at $\Sigma^{(-)}$, a small perturbation to move it away from the surface would require an infinite acceleration. In this sense, the surfaces $\Sigma^{(-)}$ represent stable final states for the evolution of the system, and any initial configuration sufficiently near the degeneracy surface is doomed to fall on it. Then, the question whether the system can be consistently defined on $\Sigma^{(-)}$ naturally arises.

For simplicity, let us consider a system possessing a single surface of degeneracy which is globally of type $\Sigma^{(-)}$. We will now show that when the system reaches $\Sigma^{(-)}$, two coordinates become nondynamical; the system acquires a new gauge symmetry on the degeneracy surface which corresponds to displacements along $\Sigma^{(-)}$, and one degree of freedom is lost.

Following Dirac's approach for constrained systems,[15] the action (4) possesses $2n$ primary constraints coming from the definition of the canonical momenta $p_i=\partial L/\partial \dot{z}^i$,

$$\phi_i(z,p)\equiv p_i-A_i(z,t)\approx 0, \tag{12}$$

whose Poisson brackets are $\{\phi_i,\phi_j\}=F_{ij}$. Outside $\Sigma^{(-)}$, the invertibility of F_{ij} implies that the constraints ϕ_i are second class. However, at the degeneracy surface, the rank of F_{ij} is reduced by two, thus, two of the ϕ's have vanishing Poisson brackets with the whole set of constraints.

Although the constraint structure changes abruptly at $\Sigma^{(-)}$, after the system reaches this surface, its evolution can be described by a standard constrained system, as can be seen through a suitable change of basis for the constraints ϕ_i.

Linear combinations of the form $\varphi_{(\alpha)}=e^i_{(\alpha)}\phi_i$ become first class provided $e^i_{(\alpha)}$ are null vectors of F_{ij}. This can only happen at the degeneracy surface, where there are two such vectors. They can be chosen so that one is tangent and the other is normal to the surfaces $F=\text{const}$, namely, $e^i_{(1)}F_{ij}=1/2\partial_j F$ and $e^i_{(2)}F_{ij}=F_{ij}\partial_i\sqrt{F}$. In Darboux-like coordinates, their only nonvanishing components are $e^\alpha_{(1)}=\epsilon^{\alpha\beta}\partial_\beta f$ and $e^\alpha_{(2)}=\delta^{\alpha\beta}\partial_\beta f$, with $\alpha=1,2$.

In the basis $\phi_i=\{\varphi_{(\alpha)};\phi_a\}$, with $a=3,\ldots,2n$, the constraint algebra reads

$$\begin{aligned}
&\{\varphi_{(\alpha)},\varphi_{(\beta)}\}\approx \tfrac{1}{4}\epsilon_{(\alpha)(\beta)}F^{-1/2}(\partial_i F)^2=f\epsilon_{(\alpha)(\beta)}|\partial f|^2,\\
&\{\varphi_{(\alpha)},\phi_b\}\approx e^i_{(\alpha)}F_{ib}=0,\\
&\{\phi_a,\phi_b\}=F_{ab}.
\end{aligned} \tag{13}$$

From this it is apparent that, on the surface $\Sigma^{(-)}$, the constraints $\varphi_{(\alpha)}$ have vanishing Poisson brackets, and are therefore candidates for first class constraints.

In order to examine whether $\varphi_{(\alpha)}$ are first or second class at the degeneracy surface ($f=0$), it is necessary to compute their Poisson brackets with f. The only nonvanishing bracket involving f is

$$\{f,\varphi_{(2)}\}=e^\alpha_{(2)}\partial_\alpha f=|\partial_\alpha f|^2, \tag{14}$$

which cannot vanish on Σ because, by hypothesis, f has a simple zeros there. This shows that $\varphi_{(1)}$ is first class, while $(f,\varphi_{(2)})$ form a conjugate pair of second class constraints.

The transformations generated by $\varphi_{(\alpha)}$ correspond to $\delta z^a=0$, and

$$\delta x^\alpha=\{x^\alpha,\xi^{(\beta)}\varphi_{(\beta)}\}=\xi^{(\beta)}e^\alpha_{(\beta)}=\xi^\alpha. \tag{15}$$

Thus, the constraints $\varphi_{(1)}$ and $\varphi_{(2)}$ generate tangent and normal displacements to $\Sigma^{(-)}$, respectively, as expected. Hence, $f\approx 0$ can be viewed as the gauge fixing condition associated with the "gauge generator" $\varphi_{(2)}$. This is summarized in the following.

Lemma 4: On the degeneracy surface $\Sigma^{(-)}$, the system acquires a new gauge invariance, because the second class constraint $\varphi_{(1)}$ becomes first class, while the number of second class constraints $(f,\varphi_{(2)},\phi_a)$ remains the same $(2n)$. Since each first class constraint eliminates one degree of freedom, we conclude that one degree of freedom is dynamically frozen on the degeneracy surface.

We illustrate these results in the following examples.

IV. EXAMPLES

A. Simplest degenerate system

The simplest case of a degenerate dynamical system is provided by the Lagrangian

$$L_D = A_\alpha \dot{x}^\alpha + A_0, \tag{16}$$

with $A_1=0$, $A_2=x_1x_2$, $A_0=-\nu x_1$. The symplectic form, $F_{\alpha\beta}=\epsilon_{\alpha\beta}x_2$, degenerates at the surface $x_2=0$, which is of type $\Sigma^{(\eta)}$, with $\eta=sgn(\nu)$. The orbits run perpendicular to $\Sigma^{(\eta)}$ and take a finite time to connect a point on the surface with a point outside.

This example captures the essence of the behavior of any degenerate system in a neighborhood of a degeneracy surface of type $\Sigma^{(+)}$ or $\Sigma^{(-)}$. In particular, the shock-wave solutions of Burgers' equation,

$$\partial_t u + u\partial_x u = \nu \partial_x^2 u, \tag{17}$$

which is relevant in the context of turbulence, exhibit this behavior. These solutions are of the form

$$u(x,t) = -2\nu \sum_{k=1}^{2n} (x - z_k(t))^{-1}, \tag{18}$$

where $z_k(t)$ are complex coordinates which come in conjugate pairs and satisfy a vortexlike equation.[16] The corresponding equations of motion for $z_k(t)$ can be obtained from an action of the form (4), which for $n=1$ and $z=x_1+ix_2$ reads

$$\begin{pmatrix} 0 & x_2 \\ -x_2 & 0 \end{pmatrix} \begin{pmatrix} \dot{x}_1 \\ \dot{x}_2 \end{pmatrix} = \begin{pmatrix} \nu \\ 0 \end{pmatrix}, \tag{19}$$

whose associated Lagrangian is precisely given by (16). This solution describes a one-dimensional shock wave centered at $x=x_1$, with peaks at $x=x_1\pm x_2(t)$ of height $\mp 2\nu/x_2(t)$, traveling outwards from x_1.

B. Coupling with a regular system

The next example examines explicitly the fate of a degenerate system when it reaches a surface of type $\Sigma^{(-)}$. A simple Lagrangian for which this occurs is of the form

$$L = L_D(x^\alpha) + L_R(z^a) - V_\lambda(x^\alpha, z^a). \tag{20}$$

Here,

$$L_D(x^\alpha) = A_\alpha \dot{x}^\alpha - H_D(x^\alpha), \tag{21}$$

with $\alpha=1,2$, is some two-dimensional degenerate system possessing a global surface of type $\Sigma^{(-)}$ at $f(x^\alpha)=0$; $L_R(z^a)$ is a regular system with Hamiltonian $H_R(z^a)$, and $V_\lambda(x^\alpha,z^a)$ is an interaction term of the form

$$V_\lambda = \lambda f(x^\alpha) H_R(z^a). \tag{22}$$

This coupling is chosen so that it vanishes on $\Sigma^{(-)}$ and does not change the flux density Φ there, so that the character of the degeneracy surface does not depend on the coupling constant λ. Note that this coupling would be trivial in the case of nondegenerate systems. Furthermore, the presence of H_R in the coupling implies that, besides the conservation of the total Hamiltonian $H=H_D+H_R+V_\lambda$, the equations of motion

$$\dot{z}^a=(1+\lambda f(x))F^{ab}\partial_b H_R \tag{23}$$

give rise to a separate conservation law for H_R, because $\dot{H}_R=\dot{z}^a\partial_a H_R=0$. In turn, this implies that the remaining equations of motion,

$$\epsilon_{\alpha\beta}f(x)\dot{x}^\beta=\partial_\alpha(H_D+\lambda f(x)H_R), \tag{24}$$

can be integrated as an autonomous two-dimensional subsystem. Once these equations have been solved, and their solutions substituted in (23), it is apparent that the solutions of Eq. (23) describe the same orbits as in the decoupled case ($\lambda=0$) but with a reparametrized time,

$$z^a(t)=z^a_{(\lambda=0)}(\tau),$$

with

$$\frac{d\tau}{dt}=1+\lambda f(x(t)).$$

Note that as the orbits approach the surface $\Sigma^{(-)}$, this time reparametrization remains finite.

Once the system reaches the degeneracy surface ($f(x)\to 0$), both time coordinates become identical and, *on* $\Sigma^{(-)}$, *all traces of the degenerate subsystem disappear, including the information about its initial conditions* $x^\alpha(t_0)$.

Thus from the moment the degeneracy surface is reached, the system becomes a regular one, described by $L_R(z^a)$, and the degrees of freedom of the degenerate system are forever lost.

In order to illustrate this point, consider the degenerate Lagrangian given by Eq. (16) with $\nu<0$, coupled with a one-dimensional harmonic oscillator in the form (22). In that case, the total energy is $\mathcal{E}=\mathcal{E}_R(1+\lambda x_2)+\nu x_1$, where $\mathcal{E}_R$ is the energy of the harmonic oscillator, which is separately conserved. Equation (24) is readily integrated as

$$x_2(t)=\pm\sqrt{2\nu t+(x_2(t_0))^2},$$

for $t<(x_2(t_0))^2/2\nu$, and $x_2(t)=0$ afterwards.

Hence, the harmonic oscillator coordinates $Z=z^1+iz^2$ evolve according to

$$Z(t)=Z_0\exp(i\tau),$$

with $|Z_0|^2=2\mathcal{E}_R$, where the reparametrized time is given by

$$\tau=t+\frac{\lambda}{3\nu}[2\nu t+(x_2(t_0))^2]^{3/2},$$

for $t<(x_2(t_0))^2/2\nu$, and $\tau=t$ afterwards.

V. DISCUSSION AND OVERVIEW

The degeneracy of the symplectic form opens up the possibility of a violation of Liouville's theorem. In fact, the divergence of the current $j^i=\sqrt{F}\dot{z}^i$ reads,

$$\partial_i j^i=-\partial_i[\sqrt{F}F^{ij}]\partial_j A_0-\sqrt{F}F^{ij}\partial_i\partial_j A_0.$$

If $A_0 = -H$ is continuous and differentiable, the second term in the R. H. S. vanishes identically. However, the first term can give rise to a non-zero contribution, responsible for the jump in the flow across Σ. In this sense, the problem we address here is the counterpart of Poincaré classical study of singularities in the phase flow. Both cases correspond to different classes of possible singularities in the phase flow, and, hence, the degeneracy surfaces cannot be understood as a dense set of Poincaré's singularities.

It is reasonable to expect that the extension of our analysis to field theory would lead to the possibility that the symplectic form degenerates for field configurations where some local degrees of freedom should freeze out and some field components become nondynamical. In the case of higher dimensional gravity, this means that as the system reaches a degeneracy surface, some dynamical components of the metric become redundant, which would correspond to a sort of dynamical dimensional reduction mechanism.

The quantum mechanical analysis of this kind of degenerate systems shows that there is no tunneling across a surface of degeneracy Σ, but there is a nonvanishing propagation amplitude between states in the bulk and on Σ.[17] These results would be relevant for the quantum Hall effect,[18] and also for strings propagating in a background possessing a nonconstant B-field.[19]

(Received 30 October 2000; accepted for publication 4 April 2001)

The two purposes of the article are (1) to present a regularization of the self-field of point-like particles, based on Hadamard's concept of ''partie finie,'' that permits in principle to maintain the Lorentz covariance of a relativistic field theory, and (2) to use this regularization for defining a model of stress-energy tensor that describes point-particles in post-Newtonian expansions (e.g., 3PN) of general relativity. We consider specifically the case of a system of two point-particles. We first perform a Lorentz transformation of the system's variables which carries one of the particles to its rest frame, next implement the Hadamard regularization within that frame, and finally come back to the original variables with the help of the inverse Lorentz transformation. The Lorentzian regularization is defined in this way up to any order in the relativistic parameter $1/c^2$. Following a previous work of ours, we then construct the delta-pseudo-functions associated with this regularization. Using an action principle, we derive the stress-energy tensor, made of delta-pseudo-functions, of point-like particles. The equations of motion take the same form as the geodesic equations of test particles on a fixed background, but the role of the background is now played by the regularized metric. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1384864]

I. INTRODUCTION

In recent years, the problem of the dynamics of gravitationally interacting compact objects in general relativity has received a lot of attention. This is due in part to the interest of the theoretical problem in its own, and in part to the ongoing development of laser-interferometric detectors for observing gravitational radiation. In the absence of an exact solution of the problem, one has recourse to successive post-Newtonian approximations (formal expansions in powers of $1/c$). Within such approximations, it makes sense to model the compact objects with some ''point-like particles,'' exactly as we do in a standard way within the Newtonian theory. However, the self-field of point-particles is infinite at the very location of a particle, and thus must be somehow regularized. The regularization is quite straightforward in the Newtonian theory, but it becomes nontrivial when going to high post-Newtonian approximations. Dealing with this problem, the present authors[1] developed a method for regularizing the infinite self-field of point-particles, which is based on the concept of ''partie finie,'' in the sense of Hadamard,[2,3] of a singular function at the place of one of its singular points (see, e.g., Refs. 4–7 for entries to the mathematical literature). We know that the Hadamard regularization yields the correct result for the equations of motion of two particles up to the so-called second and half post-Newtonian (2.5PN) approximation, corresponding to the order $1/c^5$ beyond the Newtonian acceleration. Indeed, the problem has been completely solved at that order;[8–19] notably some derivations make use of this regularization (e.g., Refs. 12 and 19). In the present state of the art, we are concerned with the 3PN (or $1/c^6$)

approximation.[20–25] In fact, starting at this high post-Newtonian order, the regularization may become physically incomplete because of the appearance of an undetermined coefficient in the equations of motion.[20–25]

The Hadamard regularization, investigated in Ref. 1, is performed in a three-dimensional Euclidean space with generic point $\mathbf{x}\in\mathbb{R}^3$, which is viewed as the spatial hypersurface labeled by $t=\text{const}$ in a global coordinate system $\{t,\mathbf{x}\}$ covering the whole space–time. In particular, the regularization involves a spatial average, performed at $t=\text{const}$, over the direction of approach to the singularity. As such a regularization makes use of a preferred spatial hypersurface $t=\text{const}$, it is clearly incompatible with the framework of special or general relativity, which embodies a global Lorentz (or Poincaré) frame invariance. Notably, we expect that the post-Newtonian equations of motion of point-like particles in harmonic coordinates (which we recall preserve the global Lorentz invariance) should exhibit at some stage a violation of the Lorentz invariance due to the latter regularization. The fact is that the breakdown of the Lorentz invariance due to the regularization occurs only at the very high 3PN approximation. Until the 2.5PN order, it is sufficient to regularize within a preferred slice $t=\text{const}$ of the harmonic coordinate system to obtain some Lorentz-invariant equations of motion.[19]

The first purpose of this article is to define a regularization *à la* Hadamard[2,3] that is compatible with the Lorentz structure of a relativistic field theory. This completes the definition, proposed in Ref. 1, of a specific version of the Hadamard regularization (based notably on a particular class of pseudo-functions). To achieve this purpose, we shall simply perform the standard Hadamard regularization within the hypersurface that is geometrically orthogonal, in the sense of the Minkowski metric, to the four-velocity of the particle. In separate papers,[24,25] we apply the latter ''Lorentzian'' regularization (together with the distributional derivatives introduced in Ref. 1) to the computation of the binary equations of motion at the 3PN order in harmonic coordinates and find that, indeed, it permits the preserving of their Lorentz invariance (in some case at the price of adjusting some parameter). A different approach to the problem of incorporating the Lorentz invariance in the 3PN equations of motion consists of deriving a generic regularized dynamics, within the ADM-Hamiltonian formalism of general relativity, involving an arbitrary regularization parameter, and determining this parameter uniquely by requiring the Lorentz invariance.[23] (See Sec. 2 in Ref. 25 for a discussion on our point-mass regularization and its relation to Ref. 23.)

Throughout the article, we assume the existence of a preferred Minkowski metric, as selected for instance by the condition of harmonic coordinates in general relativity, with respect to which the trajectories of particles are represented by accelerated world lines like in special relativity. Most of our investigation is valid not only in the case of the gravitational field but also for any Lorentz-tensor field propagating on the Minkowski background. Furthermore, we shall define the Lorentzian regularization in a sense of formal expansion series in $1/c^2$, so that all the formulas in the article will be given by some infinite series of relativistic corrections when c tends toward infinity. This is all we need for the derivation of the equations of motion to the 3PN order.[24,25]

Since we are interested in the application to the motion of two particles, we shall define the regularization around one of the particles (say particle 1), and shall consider that its acceleration is purely due to particle 2. (However, our definitions could be generalized to a system of N particles.) Notice that particle 2 enters this regularization scheme through the Lorentz transformation of its own variables to the rest frame of particle 1, and the replacement of the acceleration of 1 in terms of the equations of the binary motion. In general, working at some given relativistic order, we shall need to know the equations of motion up to a lower order only, therefore giving us the possibility of an iterative process. In this article, we always assume that we know the relevant equations of motion at this order, and that these are Lorentz-invariant.

Our second purpose is to derive an expression, compatible with the latter regularization, for the stress-energy tensor of point-like particles in post-Newtonian expansions of general relativity. Thanks to this regularization, we are able to give a sense to the value of the metric coefficients at the very location of the particle. Our basic assumption is that the matter action is the same as for *test* particles moving on a prescribed background gravitational field, except that the metric at the location of the particles is replaced by its regularized value in the sense of the (Lorentzian)

regularization. From this assumption, we prove that the Dirac measure in the stress-energy tensor must be replaced by a certain generalized function defined by means of the Hadamard prescription. In the case of two particles (the generalization to N particles is immediate), we obtain

$$T^{\mu\nu}_{\text{particle}}=\frac{m_1 c v_1^\mu v_1^\nu}{\sqrt{-[g_{\rho\sigma}]_1 v_1^\rho v_1^\sigma}}\,\text{Pf}\left(\frac{\Delta(\mathbf{x}-\mathbf{y}_1)}{\sqrt{g(t,\mathbf{x})}}\right)+1\leftrightarrow 2, \tag{1.1}$$

where m_1 is the mass of the particle 1, and $v_1^\mu=(c,\mathbf{v}_1)$ its coordinate velocity, i.e., $\mathbf{v}_1=d\mathbf{y}_1/dt$, $\mathbf{y}_1=\mathbf{y}_1(t)$ being the trajectory parametrized by the coordinate time t (the symbol $1\leftrightarrow 2$ denotes the same expression but corresponding to the second particle). The notation $[g_{\rho\sigma}]_1$ means that the metric $g_{\rho\sigma}(t,\mathbf{x})$ is to be computed at the point $\mathbf{x}=\mathbf{y}_1(t)$ following the regularization (of course $[g_{\rho\sigma}]_1$ depends on the positions and velocities of both particles 1 and 2). Note that the first factor in (1.1) is a mere function of time t. The second factor $\text{Pf}(\Delta(\mathbf{x}-\mathbf{y}_1)/\sqrt{g})$ is made of a special type of partie finie delta-pseudo-function associated with the regularization (following the definition given in Ref. 1). It involves (minus) the determinant of the metric $g_{\rho\sigma}$, namely g, evaluated at the point $(t,\mathbf{x})$, and a generalization $\text{Pf}\Delta(\mathbf{x}-\mathbf{y}_1)$ of the Dirac function defined in such a way that its action on a singular function yields the value of the function at the singular point in the sense of the regularization. Among the rules for handling the delta-pseudo-functions, we are allowed to write $\text{Pf}(\Delta(\mathbf{x}-\mathbf{y}_1)/\sqrt{g})=(1/\sqrt{g})\text{Pf}\Delta(\mathbf{x}-\mathbf{y}_1)$, whereas it is strictly forbidden to replace the latter quantity by $[1/\sqrt{g}]_1\text{Pf}\Delta(\mathbf{x}-\mathbf{y}_1)$.

The stress-energy tensor (1.1) takes the same form as the one of test particles moving in a fixed background, but with the role of the background played by the regularized metric generated by the bodies. In particular, the equations of motion obtained from the covariant conservation of that tensor ($\nabla_\nu T^{\mu\nu}_{\text{particle}}=0$) take the same form as the ''geodesic equations'' when considered with respect to the regularized metric. Our definition of the stress-energy tensor (1.1) constitutes a proposal that we have found to be the most natural in the problem of the equations of binary motion at the 3PN order,[24,25] but that we have not proved to be generally valid to higher post-Newtonian orders (nor of course when considered outside a framework of post-Newtonian expansions). The tensor (1.1) appears to be a good candidate for the characterization of point-like particles in post-Newtonian expansions of general relativity.

The plan of this article is the following. In Sec. II, we recall from Ref. 1 the material needed in the subsequent parts concerning the Hadamard regularization and the associated pseudo-functions. In Sec. III, we investigate the formulas needed to regularize, for the Lorentz transformation of some field point as well as two source points, and we define the new regularization around one of the particles as taking place within the instantaneous spatial hypersurface of the particle. In Sec. IV, we give the formulas for this regularization at the level of the first relativistic correction $1/c^2$. Finally, in Sec. V, we derive from an action principle our model of stress-energy tensor of point-like particles; the covariant conservation of this tensor leads to the equations of motion.

II. HADAMARD REGULARIZATION

To make the present article self-contained, we shall review in this section the classic notions of the Hadamard regularization of singular functions and divergent integrals,[2,3] as well as the construction, by Blanchet and Faye,[1] of a set of pseudo-functions associated with it. We follow closely the investigation of our previous article[1] and employ most of its notation. A coordinate system $\{t,\mathbf{x}\}$ being given on space–time (for instance, the harmonic coordinates used in Sec. IV), we consider some functions $F(\mathbf{x})$ defined on the spatial slice $t=\text{const}$, where $\mathbf{x}\in\mathbb{R}^3$ denotes the position in the slice. We say that the function $F(\mathbf{x})$ belongs to the class $\mathcal{F}$ if and only if F is a smooth function on $\mathbb{R}^3$ except at two isolated points $\mathbf{y}_1$ and $\mathbf{y}_2$, and admits around each of these points the following power-like singular expansions. Denoting by $r_1=|\mathbf{x}-\mathbf{y}_1|$ the spatial distance to the point 1, and by $\mathbf{n}_1=(\mathbf{x}-\mathbf{y}_1)/r_1$ the spatial direction of approach to 1, we assume that, for any $N\in\mathbb{N}$,

$$F(\mathbf{x}) = \sum_{a_0 \leqslant a \leqslant N} r_1^a \, {}_1f_a(\mathbf{n}_1) + o(r_1^N). \tag{2.1}$$

The coefficients ${}_1f_a$ of the various powers of r_1 are smooth functions of the unit vector $\mathbf{n}_1$, and the remainder tends to zero strictly more rapidly than r_1^N when $r_1 \to 0$. The powers a of r_1 in that expansion are assumed to be real, $a \in \mathbb{R}$, to range in discrete steps, i.e., $a \in (a_i)_{i \in \mathbb{N}}$, and to be bounded from below, i.e., $a_0 \leqslant a$ for some $a_0 \in \mathbb{R}$. Similarly, we assume the same type of expansion around point 2,

$$\forall N \in \mathbb{N}, \quad F(\mathbf{x}) = \sum_{b_0 \leqslant b \leqslant N} r_2^b \, {}_2f_b(\mathbf{n}_2) + o(r_2^N), \tag{2.2}$$

where $r_2 = |\mathbf{x} - \mathbf{y}_2|$ and $\mathbf{n}_2 = (\mathbf{x} - \mathbf{y}_2)/r_2$. Thus, to each function F in the class $\mathcal{F}$ are associated two discrete families of indices a and b, and two corresponding families of coefficients ${}_1f_a(\mathbf{n}_1)$ and ${}_2f_b(\mathbf{n}_2)$, all of them depending on F. We shall refer to the coefficients ${}_1f_a$ for which $a < 0$ (and similarly to ${}_2f_b$ when $b < 0$) as the *singular* coefficients of F in the expansion when $r_1 \to 0$. Since $a \geqslant a_0(F)$ and $b \geqslant b_0(F)$, the number of singular coefficients of F is always finite.

The so-called "partie finie" in the sense of Hadamard[2,3] of the singular function F at the location of the singular point $\mathbf{y}_1$ is equal to the angular average, say ${}_1\hat{f}_0$, of the zeroth-order coefficient, ${}_1f_0(\mathbf{n}_1)$, in the expansion of the function when $r_1 \to 0$ we assumed in (2.1); namely

$$(F)_1 = \underset{1}{\hat{f}_0} \equiv \int \frac{d\Omega_1}{4\pi} \, {}_1f_0(\mathbf{n}_1), \tag{2.3}$$

where $d\Omega_1 = d\Omega(\mathbf{n}_1)$ denotes the solid angle element of origin $\mathbf{y}_1$ and direction $\mathbf{n}_1$. The latter angular integration is performed within the coordinate hypersurface $t = \text{const}$. A crucial property of the Hadamard partie finie is its "nondistributivity" with respect to the multiplication, in the sense that

$$(FG)_1 \neq (F)_1 (G)_1 \tag{2.4}$$

in general. When applied to the gradient $\partial_i F$ of a function $F \in \mathcal{F}$, the definition (2.3) yields a useful formula which permits one to compute rapidly the partie finie of complicated expressions involving gradients:

$$(\partial_i F)_1 = 3 \left(\frac{n_1^i}{r_1} F \right)_1. \tag{2.5}$$

Closely related to the concept of partie finie of a singular function is the definition of the partie finie (Pf) of the divergent integral $\int d^3\mathbf{x} F$. Throughout this article, we assume that the functions decrease fast enough at infinity (when $|\mathbf{x}| \to +\infty$) so that the possible divergencies of integrals come only from the bounds located at the two singular points 1 and 2. The "partie-finie integral" reads[2,3] as

$$\mathrm{Pf}_{s_1, s_2} \int d^3\mathbf{x} F = \lim_{s \to 0} \left\{ \int_{\mathbb{R}^3 \setminus B_1(s) \cup B_2(s)} d^3\mathbf{x} F + 4\pi \sum_{a+3<0} \frac{s^{a+3}}{a+3} \left(\frac{F}{r_1^a} \right)_1 + 4\pi \ln\left(\frac{s}{s_1} \right) (r_1^3 F)_1 + 1 \leftrightarrow 2 \right\}. \tag{2.6}$$

The integral on the right side extends over $\mathbb{R}^3$ deprived from two closed spherical balls $B_1(s)$ and $B_2(s)$ of radius s centered on the two singularities [thus $B_1(s)$ and $B_2(s)$ are defined by $r_1 \leqslant s$ and $r_2 \leqslant s$]. The other terms, which are defined by means of the partie finie in the sense of (2.3), are chosen in such a way that the limit $s \to 0$ exists. The notation $1 \leftrightarrow 2$ indicates the same terms as the

two previous ones but corresponding to the other point. The summation index a satisfies $a_0 \leqslant a < -3$ (in particular the sum is always finite). Notice the two arbitrary constants s_1 and s_2 which are introduced in order to adimensionalize the arguments of the logarithms in (2.6); the partie finie owns an ambiguity through these constants (hence the notation Pf_{s_1,s_2}). The close connection between the partie finie of a singular function (2.3) and that of a divergent integral (2.6) is most easily seen from the fact that[1]

$$\mathrm{Pf} \int d^3\mathbf{x} \partial_i F = -4\pi (n_1^i r_1^2 F)_1 + 1 \leftrightarrow 2 \ . \tag{2.7}$$

Unlike in the case of continuous functions, the (partie finie) integral of a gradient is nonzero in general, and equal to the sum of the parties finies, in the sense of (2.3), of the surface integrals surrounding the singularities, in the limit where the surface areas tend to zero. This fact motivated the introduction and study in Ref. 1 of a new derivative operator acting on $\mathcal{F}$, satisfying a property of ''integration by parts'' implying that the integral of any gradient is always zero. This operator generalizes for the class of functions $\mathcal{F}$ the standard distributional derivative of Schwartz.[3]

Let us associate to any $F \in \mathcal{F}$ a pseudo-function denoted PfF and defined to be the following linear form acting on the class $\mathcal{F}$:

$$\forall G \in \mathcal{F}, \quad \langle \mathrm{Pf}F, G \rangle = \mathrm{Pf} \int d^3\mathbf{x} F G, \tag{2.8}$$

where the right side is a partie-finie integral in the sense of (2.6); we use a duality bracket to denote the result of the action of the pseudo-function PfF on G. A fundamental definition adopted in Ref. 1, and motivated by the application to physics, concerns the product of two pseudo-functions, or of a function and a pseudo-function, which is the ''*ordinary*'' pointwise product in the sense that

$$\mathrm{Pf}F . \mathrm{Pf}G = F . \mathrm{Pf}G = G . \mathrm{Pf}F = \mathrm{Pf}(FG). \tag{2.9}$$

Thus, for instance,

$$\langle \mathrm{Pf}F . \mathrm{Pf}G, H \rangle = \mathrm{Pf} \int d^3\mathbf{x} FGH. \tag{2.10}$$

The product (2.9) chosen in Ref. 1 dictates most of the subsequent properties of the pseudo-functions, as well as their generalized distributional derivatives. (Refer to Refs. 26–28 for mathematical treatises on generalized functions and distributions.) In particular, the derivatives do not in general satisfy the Leibniz rule for the derivation of the product, although they satisfy it in an ''integrated sense,'' according to the rule of integration by parts.

The Riesz[29] delta-function, given for $\varepsilon > 0$ by ${}_\varepsilon\delta(\mathbf{x}) = [\varepsilon(1-\varepsilon)/4\pi] |\mathbf{x}|^{\varepsilon - 3}$, tends, in the usual sense of distribution theory, towards the Dirac measure when $\varepsilon \to 0$. When considered with respect to the singular point $\mathbf{y}_1$, the Riesz delta-function allows us to define a useful element of our class,

$${}_\varepsilon\delta_1(\mathbf{x}) \equiv {}_\varepsilon\delta(\mathbf{x} - \mathbf{y}_1) = \frac{\varepsilon(1-\varepsilon)}{4\pi} r_1^{\varepsilon - 3} \in \mathcal{F}. \tag{2.11}$$

Therefore it is possible to associate to ${}_\varepsilon\delta_1$ (for any $\varepsilon > 0$) the pseudo-function $\mathrm{Pf}_\varepsilon \delta_1$ following the prescription (2.8). Applying the limit $\varepsilon \to 0$, we obtain[1]

$$\lim_{\varepsilon \to 0} \langle \mathrm{Pf}_\varepsilon \delta_1, F \rangle \equiv \lim_{\varepsilon \to 0} \mathrm{Pf} \int d^3\mathbf{x}_\varepsilon \delta_1 F = (F)_1, \tag{2.12}$$

where the value of F at the point 1 on the right side is defined by the prescription (2.3). This motivates us for introducing a new pseudo-function, which we shall call the delta-pseudo-function $\mathrm{Pf}\delta_1$, as the formal limit of the pseudo-functions $\mathrm{Pf}_\varepsilon\delta_1$ when $\varepsilon\to 0$. By definition,

$$\forall F\in\mathcal{F},\quad \langle \mathrm{Pf}\delta_1,F\rangle=(F)_1. \tag{2.13}$$

Clearly, the delta-pseudo-function $\mathrm{Pf}\delta_1$ generalizes the notion of Dirac distribution $\delta_1\equiv\delta(\mathbf{x}-\mathbf{y}_1)$ to the case where the ''test'' functions are singular and belong to the class $\mathcal{F}$. Extending the definition of the product (2.9) to include the delta-pseudo-function we pose

$$\mathrm{Pf}F.\mathrm{Pf}\delta_1=F.\mathrm{Pf}\delta_1=\mathrm{Pf}(F\delta_1), \tag{2.14}$$

as well as, for instance,

$$\mathrm{Pf}(F\delta_1).\mathrm{Pf}G=\mathrm{Pf}(F\delta_1).G=\mathrm{Pf}(FG\delta_1). \tag{2.15}$$

The new object $\mathrm{Pf}(F\delta_1)$ in (2.14) and (2.15) has no equivalent in distribution theory; it satisfies

$$\forall G\in\mathcal{F},\quad \langle \mathrm{Pf}(F\delta_1),G\rangle=(FG)_1. \tag{2.16}$$

We notice for future reference that a consequence of the ''nondistributivity'' of the Hadamard partie finie [see (2.4)] is that

$$\mathrm{Pf}(F\delta_1)\neq(F)_1\mathrm{Pf}\delta_1. \tag{2.17}$$

We are not allowed to replace a singular function that appears in factor of the delta-pseudo-function at point 1 by its regularized value at that point.

The derivative of the delta-pseudo-function $\mathrm{Pf}\delta_1$ was constructed in Ref. 1. As it turns out, it takes the form of an ''ordinary'' derivative: $\partial_i(\mathrm{Pf}\delta_1)=\mathrm{Pf}(\partial_i\delta_1)$; due to the presence of the delta-pseudo-function, there are no distributional terms associated with it. We have simply (from the rule of integration by parts)

$$\forall F\in\mathcal{F},\quad \langle \partial_i(\mathrm{Pf}\delta_1),F\rangle=-\langle \mathrm{Pf}\delta_1,\partial_iF\rangle=-(\partial_iF)_1. \tag{2.18}$$

The differentiation of the more complicated object $\mathrm{Pf}(F\delta_1)$ proceeds in the same way:

$$\forall G\in\mathcal{F},\quad \langle \partial_i[\mathrm{Pf}(F\delta_1)],G\rangle=-\langle \mathrm{Pf}(F\delta_1),\partial_iG\rangle=-(F\partial_iG)_1. \tag{2.19}$$

Note that, as a consequence of the identity (2.5), we can write for the intrinsic form of this object

$$\partial_i[\mathrm{Pf}(F\delta_1)]=\mathrm{Pf}\left[r_1^3\partial_i\left(\frac{F}{r_1^3}\right)\delta_1\right]. \tag{2.20}$$

Because the derivative of the delta-pseudo-function is equal to the ordinary one, the Leibniz rule for the derivative of a product happens to still hold. For instance, in the case of the product of $\mathrm{Pf}(F\delta_1)$ with some pseudo-function $\mathrm{Pf}G$, we have

$$\partial_i[\mathrm{Pf}(F\delta_1).\mathrm{Pf}G]=\partial_i[\mathrm{Pf}(F\delta_1)].\mathrm{Pf}G+\mathrm{Pf}(F\delta_1).\partial_i(\mathrm{Pf}G). \tag{2.21}$$

The proof uses the combination of (2.15) and (2.19).

III. LORENTZIAN REGULARIZATION

To define a Lorentzian regularization *à la* Hadamard (based on the investigation of Ref. 1 and on Sec. II), we now need to specify in a precise way the dependence of a function $F(\mathbf{x})$ in the class $\mathcal{F}$ on the ''source'' variables at the coordinate time t of a global frame $\{\mathbf{x},t\}$. We assume (as everywhere else in this article) that we are working at some given finite order in a relativistic or

post-Newtonian approximation. Up to a given order, we can choose as the source variables the two trajectories $\mathbf{y}_1(t)$ and $\mathbf{y}_2(t)$ in the frame $\{\mathbf{x},t\}$, and the two coordinate velocities $\mathbf{v}_1(t)=d\mathbf{y}_1/dt$ and $\mathbf{v}_2(t)=d\mathbf{y}_2/dt$ (the trajectories of the particles are timelike world lines in Minkowski space–time). Indeed, it is legitimate to assume only the latter source variables because, up to a given post-Newtonian order, we can order-reduce the accelerations and all derivatives of accelerations by means of the equations of motion of the particles up to the appropriate accuracy (in general the precision of the equations of motion needed for this order-reduction is one order less than the given post-Newtonian order at which we are performing a calculation). Of course, we are assuming that these equations of motion are known (they are known presently to the 2.5PN order,[13,14,19] and the general motivation of this work is to get them up to the 3PN order[22,24,25]). Thus, we assume that the function $F\in\mathcal{F}$ really reads

$$F(\mathbf{x},t)=F[\mathbf{x};\mathbf{y}_1(t),\mathbf{y}_2(t);\mathbf{v}_1(t),\mathbf{v}_2(t)]. \tag{3.1}$$

We denote with the same letter F, by a slight abuse of notation, the function of the field point $(\mathbf{x},t)$ and the functional of the field point and source variables on the right-hand-side. For definiteness, we assume that the two trajectories are smooth functions of time, i.e., $\mathbf{y}_1$, $\mathbf{y}_2\in C^\infty(\mathbb{R}^3)$, and that F is a smooth functional of the two velocities $\mathbf{v}_1$, $\mathbf{v}_2$ (see also Sec. IX of Ref. 1 for details about our assumptions). By (3.1), we mean that the dependence of F on the coordinate time t is through (and only through) the two instantaneous trajectories $\mathbf{y}_1$, $\mathbf{y}_2$ and velocities $\mathbf{v}_1$, $\mathbf{v}_2$. Note also that it is implicitly assumed with our notation (3.1) that the function F depends *locally* on time t (no dependence over the trajectories and velocities at some time earlier than t for instance). Furthermore, very often in applications, we shall find that the dependence of F on the spatial position $\mathbf{x}$ appears only via the two spatial distances to the source points, $\mathbf{r}_1(t)=\mathbf{x}-\mathbf{y}_1(t)$ and $\mathbf{r}_2(t)=\mathbf{x}-\mathbf{y}_2(t)$. In this article, we shall generally suppose, in order to simplify the presentation, that this is the case; namely, the function F, as a functional of the source variables, is

$$F(\mathbf{x},t)=F[\mathbf{r}_1(t),\mathbf{r}_2(t);\mathbf{v}_1(t),\mathbf{v}_2(t)]. \tag{3.2}$$

The hypothesis (3.2) does not constitute a very severe restriction. The extension to the more general case (3.1) is generally straightforward; moreover, (3.2) is always verified in the problem of the post-Newtonian equations of motion of binary systems. In this section, we shall define the Lorentzian regularized value of the function F at the location of the singularity 1, in contrast to the non-invariant regularized value defined by (2.3) within the "global" coordinate hypersurface $t=\text{const}$. We shall denote by $[F]_1$ the new Lorentzian regularization of F at point 1, defined within the instantaneous rest frame of particle 1 at $t'=\text{const}$ [in contrast with the notation $(F)_1$ used in (2.3) for the old regularization]. In addition, we shall introduce a delta-pseudo-function denoted by $\mathrm{Pf}\Delta_1$ associated with the new regularization [similar to the delta-pseudo-function $\mathrm{Pf}\delta_1$ which was defined in (2.13) in the case of the old regularization].

A. Lorentz transformation of the source variables

In this article, it is sufficient to consider only those homogeneous proper Lorentz transformations which change the velocity of a global inertial frame $\{x^\mu\}=\{ct,\mathbf{x}\}$. More specifically, let us consider the Lorentz boost

$$x'^\mu=\Lambda^\mu{}_\nu(\mathbf{V})x^\nu, \tag{3.3}$$

where the Lorentz matrix $\Lambda^\mu{}_\nu(\mathbf{V})$, depending on the constant boost velocity $\mathbf{V}$, is given by

$$\Lambda^0{}_0(\mathbf{V})=\gamma, \tag{3.4a}$$

$$\Lambda^i{}_0(\mathbf{V})=-\gamma\frac{V^i}{c}, \tag{3.4b}$$

$$\Lambda^0{}_j(\mathbf{V}) = -\gamma \frac{V_j}{c}, \tag{3.4c}$$

$$\Lambda^i{}_j(\mathbf{V}) = \delta^i_j + \frac{\gamma^2}{\gamma+1}\frac{V^i V_j}{c^2}. \tag{3.4d}$$

We indifferently denote the components of the boost vector by $\mathbf{V}=(V^i)=(V_i)$ (spatial indices $i,j=1,2,3$). The Lorentz factor γ reads

$$\gamma = \frac{1}{\sqrt{1-\mathbf{V}^2/c^2}}, \tag{3.5}$$

with $\mathbf{V}^2=\delta_{ij}V^iV^j$ (of course $|\mathbf{V}|<c$). The inverse transformation is $x^\nu=\Lambda_\mu{}^\nu(\mathbf{V})x'^\mu$ where the components of $\Lambda_\mu{}^\nu(\mathbf{V})=\eta_{\mu\rho}\eta^{\nu\sigma}\Lambda^\rho{}_\sigma(\mathbf{V})$ are obtained directly from (3.3) by changing $\mathbf{V}\to -\mathbf{V}$. The choice of sign made in the $0i$ components of the boost (3.4) is such that a particle which has velocity $\mathbf{V}$ at time t in the frame $\{x^\mu\}$ is at rest in the frame $\{x'^\mu\}$ at time t'.

We introduce on one side the space–time event Q, which represents for us a ''field'' point located outside the two world lines of the particles, and on the other side the space–time events P_1, M_1 and P_2, M_2, which are ''source'' points, lying respectively on the world lines of particles 1 and 2 (see later in this work for their definition). The coordinates of the event Q are $(t,\mathbf{x})$ in the frame $\{x^\mu\}$ and $(t',\mathbf{x}')$ in the frame $\{x'^\mu\}$. Sorting out the spatial and temporal indices in (3.3), we have

$$ct' = c\Lambda^0{}_0 t + \Lambda^0{}_j x^j, \tag{3.6a}$$

$$x'^i = c\Lambda^i{}_0 t + \Lambda^i{}_j x^j. \tag{3.6b}$$

The points P_1 and P_2 are now defined as the two events that are located on the trajectories of the particles and are ''simultaneous'' with the event Q in the frame $\{x^\mu\}$, i.e., that belong to the same spatial slice $t=\text{const}$ as Q. The coordinates of P_1 and P_2 in $\{x^\mu\}$ are denoted by $(t,\mathbf{y}_1)$ and $(t,\mathbf{y}_2)$, respectively, the two trajectories $\mathbf{y}_1=\mathbf{y}_1(t)$ and $\mathbf{y}_2=\mathbf{y}_2(t)$ being parametrized by the coordinate time t in that frame. On the other hand, in the new frame $\{x'^\mu\}$, the coordinates of P_1 and P_2 are $(\tau_1',\mathbf{z}_1')$ and $(\tau_2',\mathbf{z}_2')$. Evidently, the primed coordinates are related to the unprimed ones by the Lorentz boost (3.3), so that

$$c\tau_1' = c\Lambda^0{}_0 t + \Lambda^0{}_j y_1^j, \tag{3.7a}$$

$$z_1'^i = c\Lambda^i{}_0 t + \Lambda^i{}_j y_1^j, \tag{3.7b}$$

in the case of the event P_1 [where $y_1^j=y_1^j(t)$, $y_2^j=y_2^j(t)$], and

$$c\tau_2' = c\Lambda^0{}_0 t + \Lambda^0{}_j y_2^j, \tag{3.8a}$$

$$z_2'^i = c\Lambda^i{}_0 t + \Lambda^i{}_j y_2^j, \tag{3.8b}$$

in the case of the event P_2. In the new frame $\{x'^\mu\}$, the source events that are simultaneous with Q are not P_1 and P_2, but some other events M_1 and M_2, whose coordinates in the primed frame are thus $(t',\mathbf{y}_1')$ and $(t',\mathbf{y}_2')$; the coordinate time t' is the same as that of Q in the primed frame, and the spatial coordinates are the trajectories of the particles $\mathbf{y}_1'=\mathbf{y}_1'(t')$ and $\mathbf{y}_2'=\mathbf{y}_2'(t')$ which are labeled by t' in the new frame. Let $(\tau_1,\mathbf{z}_1)$ and $(\tau_2,\mathbf{z}_2)$ be the coordinates of M_1 and M_2 in the original frame $\{x^\mu\}$. By definition,

$$ct' = c\Lambda^0{}_0 \tau_1 + \Lambda^0{}_j z_1^j, \tag{3.9a}$$

$$y_1'^i = c\Lambda^i{}_0\tau_1 + \Lambda^i{}_j z_1^j, \tag{3.9b}$$

$$ct' = c\Lambda^0{}_0\tau_2 + \Lambda^0{}_j z_2^j, \tag{3.9c}$$

$$y_2'^i = c\Lambda^i{}_0\tau_2 + \Lambda^i{}_j z_2^j, \tag{3.9d}$$

where $y_1'^i = y_1'^i(t')$ and $y_2'^i = y_2'^i(t')$. Beware of our notation, where τ_1' (for instance) is the time coordinate of P_1 in $\{x'^\mu\}$ while τ_1 is the time coordinate in $\{x^\mu\}$ of the *different* event M_1. Since the events M_1 and M_2 are located on the world lines of the particles parametrized by $\mathbf{y}_1(t)$ and $\mathbf{y}_2(t)$ in $\{x^\mu\}$, it is clear that at time τ_1 in that frame their coordinates are related to the trajectories by

$$\mathbf{z}_1 = \mathbf{y}_1(\tau_1), \tag{3.10a}$$

$$\mathbf{z}_2 = \mathbf{y}_2(\tau_2). \tag{3.10b}$$

Similarly, from the fact that P_1 and P_2 are also on the world lines, which write as $\mathbf{y}_1'(t')$ and $\mathbf{y}_2'(t')$ in the frame $\{x'^\mu\}$, we deduce that their coordinates in $\{x'^\mu\}$ satisfy

$$\mathbf{z}_1' = \mathbf{y}_1'(\tau_1'), \tag{3.11a}$$

$$\mathbf{z}_2' = \mathbf{y}_2'(\tau_2'). \tag{3.11b}$$

By eliminating t' from the equations (3.6a) and (3.9a) we immediately obtain

$$c\Lambda^0{}_0(\tau_1 - t) = \Lambda^0{}_i(x^i - z_1^i), \tag{3.12}$$

or, equivalently, taking also into account (3.4),

$$\tau_1 - t = -\frac{1}{c^2}\mathbf{V}.(\mathbf{x} - \mathbf{z}_1), \tag{3.13}$$

where the usual Euclidean scalar product between (boldface) vectors is denoted by a dot. With the help of the latter formula for expressing τ_1, we can restate the belonging of $\mathbf{z}_1$ to the particle world line at time τ_1 [see (3.10a)] as

$$\mathbf{z}_1 = \mathbf{y}_1\left(t - \frac{1}{c^2}\mathbf{V}.(\mathbf{x} - \mathbf{z}_1)\right). \tag{3.14}$$

Recall that $\mathbf{z}_1$ is the spatial coordinate in the old frame of the event M_1 which is simultaneous with the field point Q in the *new* frame. Clearly, the equation (3.14) determines the vector $\mathbf{z}_1$ as a function of the coordinates $(t,\mathbf{x})$ of the field-point event Q (see the Appendix). Here, let us view $\mathbf{z}_1$ as a "vector" field $\mathbf{z}_1(\mathbf{x})$, solution of (3.14), lying in the three-dimensional space $t = \text{const}$. It is evident from (3.14) that the function $\mathbf{z}_1(\mathbf{x})$ admits a fixed point at $\mathbf{y}_1 = \mathbf{y}_1(t)$, in the sense that

$$\mathbf{z}_1(\mathbf{y}_1) = \mathbf{y}_1. \tag{3.15}$$

Unless specified otherwise [like in (3.14)], the notation $\mathbf{y}_1$ always means $\mathbf{y}_1(t)$. The mathematical justification of (3.15) is the following. From the fact that the world line of the particle is timelike we can write, for any instants $\hat{t}$ and $\overline{t}$, the inequality $|\mathbf{y}_1(\hat{t}) - \mathbf{y}_1(\overline{t})| < c|\hat{t} - \overline{t}|$. Hence, applying the definition (3.14), we find that our function $\mathbf{z}_1(\mathbf{x})$ obeys, for any positions $\hat{\mathbf{x}}$ and $\overline{\mathbf{x}}$, the further inequalities $|\mathbf{z}_1(\hat{\mathbf{x}}) - \mathbf{z}_1(\overline{\mathbf{x}})| < (1/c)|\mathbf{V}.(\hat{\mathbf{x}} - \overline{\mathbf{x}})| \leqslant |\mathbf{V}|/c|\hat{\mathbf{x}} - \overline{\mathbf{x}}|$. Now recall that $|\mathbf{V}|/c < 1$, so the latter inequalities mean exactly that the function $\mathbf{x} \to \mathbf{z}_1(\mathbf{x})$ is a *contracting* application with respect

to the usual Euclidean norm (i.e., it satisfies the property of Lipschitz with a ratio $k=|\mathbf{V}|/c$ strictly less than one). Therefore, by the theorem of Picard, the function admits a unique fixed point, which of course is nothing but $\mathbf{y}_1$. (Besides, at the location of the fixed point, we have $\tau_1=t$.)

In this article, we establish the general solution of the equation (3.14) in the form of an infinite (post-Newtonian) power series in $1/c^2$. We shall not discuss the convergence properties of this series and simply employ it to define the regularization up to any relativistic order. This is sufficient for the application to the problem of the equations of motion of particles in the post-Newtonian approximation. The general solution of (3.14), as determined in the Appendix, reads

$$\mathbf{z}_1=\mathbf{y}_1+\sum_{n=1}^{+\infty}\frac{(-)^n}{c^{2n}n!}\left(\frac{\partial}{\partial t}\right)^{n-1}[(\mathbf{V}.\mathbf{r}_1)^n\mathbf{v}_1], \tag{3.16}$$

with shorthand notations $\mathbf{y}_1=\mathbf{y}_1(t)$, $\mathbf{r}_1=\mathbf{x}-\mathbf{y}_1(t)$, and $\mathbf{v}_1=\mathbf{v}_1(t)$. The many derivatives $\partial/\partial t$ on the right side are partial time derivatives with respect to the coordinate time t, the spatial coordinate $\mathbf{x}$ being held constant. They act on $\mathbf{r}_1$ through the trajectory $\mathbf{y}_1$: we have $\partial\mathbf{r}_1/\partial t=-\mathbf{v}_1$ or $\partial(\mathbf{V}.\mathbf{r}_1)/\partial t=-\mathbf{V}.\mathbf{v}_1$ for instance. On the other side, they act of course on velocities and (derivatives of) accelerations: thus $\partial\mathbf{v}_1/\partial t=\mathbf{a}_1$, $\partial\mathbf{a}_1/\partial t=\mathbf{b}_1$, $\partial\mathbf{b}_1/\partial t=\mathbf{c}_1$, and so on, where $\mathbf{a}_1$, $\mathbf{b}_1$, $\mathbf{c}_1$ represent the acceleration, and its first and second derivatives (in these cases the partial derivative is a total derivative, e.g., $d\mathbf{v}_1/dt=\mathbf{a}_1$). Thus, to high post-Newtonian order, (3.16) contains many accelerations and derivatives of accelerations, but it is understood that this formula is order-reduced, consistent with the post-Newtonian order; i.e., all accelerations and derivatives of accelerations are to be replaced by the functionals of the positions and velocities deduced from the equations of motion. Combining (3.13) and (3.16), we easily find the corresponding solution for the time coordinate τ_1,

$$\tau_1=t+\sum_{n=1}^{+\infty}\frac{(-)^n}{c^{2n}n!}\left(\frac{\partial}{\partial t}\right)^{n-1}[(\mathbf{V}.\mathbf{r}_1)^n]. \tag{3.17}$$

[Of course, since $\mathbf{V}$ is a constant vector, it could be as well put outside the partial time derivative operators in both (3.16) and (3.17).] Finally, Eqs. (3.16) and (3.17) determine completely the space–time event M_1. From them, we can recover directly the fact that when $\mathbf{x}=\mathbf{y}_1$ (at the fixed point) then $\mathbf{z}_1=\mathbf{y}_1$ and $\tau_1=t$: there are on the right sides of both relations $n-1$ partial time derivatives acting on a term that involves the nth power $(\mathbf{V}.\mathbf{r}_1)^n$, so that at least one of the scalar products $\mathbf{V}.\mathbf{r}_1$ is left undifferentiated, and makes the sums in (3.16) and (3.17) vanish when $\mathbf{r}_1=0$. Replacing both $\mathbf{z}_1$ and τ_1 as given by the infinite post-Newtonian series back into the relation (3.10a), expressing both sides of the resulting equation as the same type of post-Newtonian series with the help of a formal Taylor expansion when $c\to\infty$, and finally equating all the coefficients of these two series yields an interesting mathematical formula relating together some sums of products of derivatives. This formula is derived in the Appendix (where we also present a direct proof of it). Notice that the same reasoning as before can be done on the coordinates of the event P_1 in the new frame, which we find to be given by

$$\mathbf{z}_1'=\mathbf{y}_1'+\sum_{n=1}^{+\infty}\frac{1}{c^{2n}n!}\left(\frac{\partial}{\partial t'}\right)^{n-1}[(\mathbf{V}.\mathbf{r}_1')^n\mathbf{v}_1'], \tag{3.18a}$$

$$\tau_1'=t'+\sum_{n=1}^{+\infty}\frac{1}{c^{2n}n!}\left(\frac{\partial}{\partial t'}\right)^{n-1}[(\mathbf{V}.\mathbf{r}_1')^n], \tag{3.18b}$$

where $\mathbf{y}_1'=\mathbf{y}_1'(t')$, $\mathbf{r}_1'=\mathbf{x}'-\mathbf{y}_1'(t')$, and $\mathbf{v}_1'=\mathbf{v}_1'(t')$. Evidently, the result (3.18) can also be deduced directly from (3.16) and (3.17) by changing $\mathbf{V}$ into $-\mathbf{V}$ and replacing all the non-primed variables by the corresponding primed ones.

We are now able to give all the transformation laws of field and source variables between the frames $\{x^\mu\}$ and $\{x'^\mu\}$. Of course, from (3.6), the transformation of the field variables is the standard Lorentz one,

$$t' = \gamma\left(t - \frac{1}{c^2}(\mathbf{V}.\mathbf{x}) \right), \tag{3.19a}$$

$$\mathbf{x}' = \mathbf{x} - \gamma\mathbf{V}\left(t - \frac{1}{c^2}\frac{\gamma}{\gamma+1}(\mathbf{V}.\mathbf{x}) \right). \tag{3.19b}$$

Concerning the source variables, we are interested in the expressions of the new positions $\mathbf{y}'_1(t')$, $\mathbf{y}'_2(t')$ and velocities $\mathbf{v}'_1(t')$, $\mathbf{v}'_2(t')$ in the new frame at time t'. These are straightforwardly obtained from inserting the results (3.16) and (3.17) into the equations (3.9), as well as the similar results corresponding to point 2. We find, for trajectories,

$$\begin{aligned}\mathbf{y}'_1 = \mathbf{y}_1 &- \gamma\mathbf{V}\left(t - \frac{1}{c^2}\frac{\gamma}{\gamma+1}(\mathbf{V}.\mathbf{x}) \right) \\ &+ \sum_{n=1}^{+\infty} \frac{(-)^n}{c^{2n} n!}\left(\frac{\partial}{\partial t}\right)^{n-1}\left[(\mathbf{V}.\mathbf{r}_1)^n \left(\mathbf{v}_1 - \frac{\gamma}{\gamma+1}\mathbf{V} \right) \right],\end{aligned} \tag{3.20a}$$

$$\begin{aligned}\mathbf{y}'_2 = \mathbf{y}_2 &- \gamma\mathbf{V}\left(t - \frac{1}{c^2}\frac{\gamma}{\gamma+1}(\mathbf{V}.\mathbf{x}) \right) \\ &+ \sum_{n=1}^{+\infty} \frac{(-)^n}{c^{2n} n!}\left(\frac{\partial}{\partial t}\right)^{n-1}\left[(\mathbf{V}.\mathbf{r}_2)^n \left(\mathbf{v}_2 - \frac{\gamma}{\gamma+1}\mathbf{V} \right) \right].\end{aligned} \tag{3.20b}$$

By subtracting the latter equations (3.20) to $\mathbf{x}'$ as given by (3.19b) we obtain the spatial distances $\mathbf{r}'_1 = \mathbf{x}' - \mathbf{y}'_1(t')$ and $\mathbf{r}'_2 = \mathbf{x}' - \mathbf{y}'_2(t')$ as

$$\mathbf{r}'_1 = \mathbf{r}_1 - \sum_{n=1}^{+\infty} \frac{(-)^n}{c^{2n} n!}\left(\frac{\partial}{\partial t}\right)^{n-1}\left[(\mathbf{V}.\mathbf{r}_1)^n \left(\mathbf{v}_1 - \frac{\gamma}{\gamma+1}\mathbf{V} \right) \right], \tag{3.21a}$$

$$\mathbf{r}'_2 = \mathbf{r}_2 - \sum_{n=1}^{+\infty} \frac{(-)^n}{c^{2n} n!}\left(\frac{\partial}{\partial t}\right)^{n-1}\left[(\mathbf{V}.\mathbf{r}_2)^n \left(\mathbf{v}_2 - \frac{\gamma}{\gamma+1}\mathbf{V} \right) \right]. \tag{3.21b}$$

These relations will play the crucial role in the definition of our Lorentzian regularization. Of interest also is the expression of the relative distance between the two particles, i.e., $\mathbf{y}'_{12} = \mathbf{y}'_1 - \mathbf{y}'_2 = \mathbf{r}'_2 - \mathbf{r}'_1$ given by

$$\mathbf{y}'_{12} = \mathbf{y}_{12} + \sum_{n=1}^{+\infty} \frac{(-)^n}{c^{2n} n!}\left(\frac{\partial}{\partial t}\right)^{n-1}\left[(\mathbf{V}.\mathbf{r}_1)^n \left(\mathbf{v}_1 - \frac{\gamma}{\gamma+1}\mathbf{V} \right) - (\mathbf{V}.\mathbf{r}_2)^n \left(\mathbf{v}_2 - \frac{\gamma}{\gamma+1}\mathbf{V} \right) \right]. \tag{3.22}$$

Finally, we compute the expressions of the coordinate velocities $\mathbf{v}'_1(t') = d\mathbf{y}'_1/dt'$ and $\mathbf{v}'_2(t') = d\mathbf{y}'_2/dt'$ in the new frame. They follow immediately from the law of transformation of the time derivative, $\partial'_t = \gamma\partial_t + \gamma V^i \partial_i$, and we obtain

$$\mathbf{v}'_1 = \frac{1}{\gamma}\mathbf{v}_1 - \mathbf{V} + \frac{1}{\gamma}\sum_{n=1}^{+\infty} \frac{(-)^n}{c^{2n} n!}\left(\frac{\partial}{\partial t}\right)^{n}\left[(\mathbf{V}.\mathbf{r}_1)^n \left(\mathbf{v}_1 - \frac{\gamma}{\gamma+1}\mathbf{V} \right) \right], \tag{3.23a}$$

$$\mathbf{v}_2'=\frac{1}{\gamma}\mathbf{v}_2-\mathbf{V}+\frac{1}{\gamma}\sum_{n=1}^{+\infty}\frac{(-)^n}{c^{2n}n!}\left(\frac{\partial}{\partial t}\right)^n\left[(\mathbf{V}.\mathbf{r}_2)^n\left(\mathbf{v}_2-\frac{\gamma}{\gamma+1}\mathbf{V}\right)\right]. \tag{3.23b}$$

Notice that although the velocities $\mathbf{v}_1'(t')$ and $\mathbf{v}_2'(t')$ are some mere functions of the coordinate time t' in the new frame, they depend, when expressed in terms of quantities belonging to the old frame, on both time *and* space coordinates t and $\mathbf{x}$. This is obvious because by changing the space coordinate $\mathbf{x}$ of the field point Q while keeping $t=\text{const}$ we change the time coordinate t' of the source events M_1 and M_2 and therefore the values of their particle velocities (soon as the trajectories are accelerated). This fact is important and has to be taken correctly into account in the regularization process defined in the next subsection. The inverse formulas are obtained in the same way by substituting (3.18) into the inverse of (3.7). They correspond of course to changing $\mathbf{V}$ into $-\mathbf{V}$ and replacing everywhere the unprimed labels by primed ones. We find, for the spatial distances and velocities,

$$\mathbf{r}_1=\mathbf{r}_1'-\sum_{n=1}^{+\infty}\frac{1}{c^{2n}n!}\left(\frac{\partial}{\partial t'}\right)^{n-1}\left[(\mathbf{V}.\mathbf{r}_1')^n\left(\mathbf{v}_1'+\frac{\gamma}{\gamma+1}\mathbf{V}\right)\right], \tag{3.24a}$$

$$\mathbf{r}_2=\mathbf{r}_2'-\sum_{n=1}^{+\infty}\frac{1}{c^{2n}n!}\left(\frac{\partial}{\partial t'}\right)^{n-1}\left[(\mathbf{V}.\mathbf{r}_2')^n\left(\mathbf{v}_2'+\frac{\gamma}{\gamma+1}\mathbf{V}\right)\right], \tag{3.24b}$$

$$\mathbf{v}_1=\frac{1}{\gamma}\mathbf{v}_1'+\mathbf{V}+\frac{1}{\gamma}\sum_{n=1}^{+\infty}\frac{1}{c^{2n}n!}\left(\frac{\partial}{\partial t'}\right)^{n}\left[(\mathbf{V}.\mathbf{r}_1')^n\left(\mathbf{v}_1'+\frac{\gamma}{\gamma+1}\mathbf{V}\right)\right], \tag{3.24c}$$

$$\mathbf{v}_2=\frac{1}{\gamma}\mathbf{v}_2'+\mathbf{V}+\frac{1}{\gamma}\sum_{n=1}^{+\infty}\frac{1}{c^{2n}n!}\left(\frac{\partial}{\partial t'}\right)^{n}\left[(\mathbf{V}.\mathbf{r}_2')^n\left(\mathbf{v}_2'+\frac{\gamma}{\gamma+1}\mathbf{V}\right)\right]. \tag{3.24d}$$

B. Definition of the regularization

Let us consider a function F belonging to the class $\mathcal{F}$ and being at the same time a *scalar* under Lorentz transformations, i.e., $F(\mathbf{x},t)=F'(\mathbf{x}',t')$. More precisely, we restrict ourselves to the case of a dependence on $\mathbf{x}$ only via the distances $\mathbf{r}_1$ and $\mathbf{r}_2$ [cf. (3.2)]; this means

$$F[\mathbf{r}_1(t),\mathbf{r}_2(t);\mathbf{v}_1(t),\mathbf{v}_2(t)]=F'[\mathbf{r}_1'(t'),\mathbf{r}_2'(t');\mathbf{v}_1'(t'),\mathbf{v}_2'(t');\mathbf{V}], \tag{3.25}$$

where we use the same slightly abusive notation as in (3.2), with addition, on the right side, of the explicit mention of the dependence over the boost vector $\mathbf{V}$. All the variables in both frames $\{x^\mu\}$ and $\{x'^\mu\}$ are related to each other by the formulas developed in the previous subsection. The regularization process goes as follows.

(i) Starting from $F[\mathbf{r}_1,\mathbf{r}_2;\mathbf{v}_1,\mathbf{v}_2]$ defined in the frame $\{x^\mu\}$, we first determine the new functional $F'[\mathbf{r}_1',\mathbf{r}_2';\mathbf{v}_1',\mathbf{v}_2';\mathbf{V}]$ in the boosted frame $\{x'^\mu\}$. To do so, we replace all the variables $\mathbf{r}_1$, $\mathbf{r}_2$, $\mathbf{v}_1$, $\mathbf{v}_2$ by their expressions in terms of the new ones $\mathbf{r}_1'$, $\mathbf{r}_2'$, $\mathbf{v}_1'$, $\mathbf{v}_2'$ as given by the formulas (3.24), in which it is understood that all the accelerations are order-reduced up to some given specified post-Newtonian order. Performing all the necessary post-Newtonian reexpansions to that order, we indeed obtain in that way (since F is a Lorentz scalar) the new functional F' of the new distances $\mathbf{r}_1'$, $\mathbf{r}_2'$ and velocities $\mathbf{v}_1'$, $\mathbf{v}_2'$. In addition, F' depends as expected on the constant $\mathbf{V}$ which is yet unspecified at this stage.

(ii) We compute the Hadamard regularization of F' at point 1 following exactly the same rules as defined in (2.3), but in the boosted frame $\{x'^\mu\}$ (in particular, within the coordinate slice $t'=\text{const}$). In words, we perform the expansion of F' when the spatial distance r_1' tends to zero, and obtain the same type of power-law expansion as in (2.1) [since the form of the relations (3.24) shows that the structure of the expansions in both frames must be the same]. However, we get

some primed functional coefficients ${}_1f'_a$ that differ from the unprimed coefficients ${}_1f_a$ appearing in (2.1). The boost vector $\mathbf{V}$ is simply held constant in the process. Thus, $\forall N \in \mathbb{N}$,

$$F'[\mathbf{r}'_1,\mathbf{r}'_2;\mathbf{v}'_1,\mathbf{v}'_2;\mathbf{V}] = \sum_{a_0 \leqslant a \leqslant N} r'^a_1 {}_1f'_a(\mathbf{n}'_1;\mathbf{y}'_{12};\mathbf{v}'_1,\mathbf{v}'_2;\mathbf{V}) + o(r'^N_1), \tag{3.26}$$

with the notation $r'_1 = |\mathbf{x}' - \mathbf{y}'_1|$, $\mathbf{n}'_1 = (\mathbf{x}' - \mathbf{y}'_1)/r'_1$, and $\mathbf{y}'_{12} = \mathbf{y}'_1 - \mathbf{y}'_2$. (The fact that the coefficients ${}_1f'_a$ depend on $\mathbf{y}'_{12}$ instead of the two individual trajectories $\mathbf{y}'_1$, $\mathbf{y}'_2$ is due to our restriction that F' depends on $\mathbf{x}'$ via the distances $\mathbf{r}'_1$ and $\mathbf{r}'_2$; also, the accelerations depend on the relative distance $\mathbf{y}'_{12}$.) Now, like in (2.3), we pick up the zeroth-order coefficient in the r'_1-expansion (3.26) and average over the angles. This defines a certain functional of the separation vector $\mathbf{y}'_{12}$, the velocities $\mathbf{v}'_1$, $\mathbf{v}'_2$ and the boost velocity $\mathbf{V}$,

$$\hat{f}'_{0\,1}(\mathbf{y}'_{12};\mathbf{v}'_1,\mathbf{v}'_2;\mathbf{V}) = \int \frac{d\Omega'_1}{4\pi} f'_{0\,1}(\mathbf{n}'_1;\mathbf{y}'_{12};\mathbf{v}'_1,\mathbf{v}'_2;\mathbf{V}). \tag{3.27}$$

We insist that the angular average is performed *in the new frame*, within the spatial hypersurface $t' = \text{const}$; in particular, the solid angle element in (3.27) is the one associated with the unit direction $\mathbf{n}'_1$ in that hypersurface: $d\Omega'_1 = d\Omega(\mathbf{n}'_1)$. Here again, $\mathbf{V}$ is considered as a simple constant "spectator" vector during the average.

(iii) We impose that the new frame is actually the rest frame of particle 1 at the event P_1. Recalling that the Lorentz boost (3.4) brings a particle with velocity $\mathbf{V}$ in the frame $\{x^\mu\}$ at rest in the frame $\{x'^\mu\}$, we see that we must choose

$$\mathbf{V} = \mathbf{v}_1(t). \tag{3.28}$$

We come back to the original variables in the unprimed frame by using the transformation laws (3.22) and (3.23), in the limit where the field point $\mathbf{x}$ tends to the source point $\mathbf{y}_1(t)$ (because we are located at the event P_1), with $\mathbf{V} = \mathbf{v}_1$ according to (3.28). Note that, in this limit $\mathbf{r}_1 \to \mathbf{0}$, the coordinate time t' of the event Q in the primed frame is equal to the coordinate time τ'_1 of the event P_1. It is important to realize that both the computation of the limit when $\mathbf{r}_1 \to \mathbf{0}$ and the replacement of the vector $\mathbf{V}$ by (3.28) are to be done *after* performing the many partial time differentiations in (3.22) and (3.23). Consider first the primed variable $\mathbf{y}'_{12}$, which is given by (3.22) where we apply the replacement $\mathbf{r}_1 = \mathbf{0}$ (as well as $\mathbf{V} = \mathbf{v}_1$). In (3.22) the $n-1$ partial time derivatives acting on the term proportional to $(\mathbf{V}.\mathbf{r}_1)^n$ will clearly lead to zero in the limit $\mathbf{r}_1 = \mathbf{0}$; indeed, by an argument met previously, there are not "enough" derivatives to make a nonzero contribution. So the variable to be used when coming back to the original frame is

$$\mathbf{y}'_{12} = \left(\mathbf{y}_{12} - \sum_{n=1}^{+\infty} \frac{(-)^n}{c^{2n} n!} \left(\frac{\partial}{\partial t} \right)^{n-1} \left[(\mathbf{V}.\mathbf{r}_2)^n \left(\mathbf{v}_2 - \frac{\gamma}{\gamma+1} \mathbf{V} \right) \right] \right) \Bigg|_{\substack{\mathbf{r}_2 = \mathbf{y}_{12} \\ \mathbf{V} = \mathbf{v}_1}}. \tag{3.29}$$

As indicated by the notation one must implement the replacements of $\mathbf{r}_2$ by $\mathbf{y}_{12}$ (this is equivalent to $\mathbf{r}_1 = \mathbf{0}$) and of $\mathbf{V}$ by $\mathbf{v}_1$ *after* the $n-1$ time differentiations. In the case of the primed velocity of particle 2, given by (3.23b), we simply have

$$\mathbf{v}'_2 = \left(\frac{1}{\gamma} \mathbf{v}_2 - \mathbf{V} + \frac{1}{\gamma} \sum_{n=1}^{+\infty} \frac{(-)^n}{c^{2n} n!} \left(\frac{\partial}{\partial t} \right)^n \left[(\mathbf{V}.\mathbf{r}_2)^n \left(\mathbf{v}_2 - \frac{\gamma}{\gamma+1} \mathbf{V} \right) \right] \right) \Bigg|_{\substack{\mathbf{r}_2 = \mathbf{y}_{12} \\ \mathbf{V} = \mathbf{v}_1}}. \tag{3.30}$$

The formulas (3.29) and (3.30) define, after order-reduction of the accelerations, some functionals $\mathbf{y}'_{12}[\mathbf{y}_{12};\mathbf{v}_1,\mathbf{v}_2]$ and $\mathbf{v}'_2[\mathbf{y}_{12};\mathbf{v}_1,\mathbf{v}_2]$ that we use for coming back to the initial frame $\{x^\mu\}$. Clearly, the primed velocity $\mathbf{v}'_1$ of point 1, at which we perform the regularization, deserves a special treatment. From (3.23a) we obtain

$$\mathbf{v}'_1=\left(\frac{1}{\gamma}\mathbf{v}_1-\mathbf{V}+\frac{1}{\gamma}\sum_{n=1}^{+\infty}\frac{(-)^n}{c^{2n}n!}\left(\frac{\partial}{\partial t}\right)^n\left[(\mathbf{V}.\mathbf{r}_1)^n\left(\mathbf{v}_1-\frac{\gamma}{\gamma+1}\mathbf{V}\right)\right]\right)\Bigg|_{\substack{\mathbf{r}_1=\mathbf{0}\\ \mathbf{V}=\mathbf{v}_1}}. \tag{3.31}$$

Here, there are n time derivatives which is *a priori* enough to make a contribution. The only possibility is to differentiate successively each of the n factors $\mathbf{V}.\mathbf{r}_1$, yielding for each of the terms in the sum $n!$ identical contributions. Hence, we arrive at a much simpler series,

$$\mathbf{v}'_1=\left(\frac{1}{\gamma}\mathbf{v}_1-\mathbf{V}+\frac{1}{\gamma}\sum_{n=1}^{+\infty}\left(\frac{\mathbf{V}.\mathbf{v}_1}{c^2}\right)^n\left(\mathbf{v}_1-\frac{\gamma}{\gamma+1}\mathbf{V}\right)\right)\Bigg|_{\mathbf{V}=\mathbf{v}_1}, \tag{3.32}$$

which can now easily be summed up. The result is

$$\mathbf{v}'_1=\left(\frac{(1/\gamma)\mathbf{v}_1-\mathbf{V}+[\gamma/(\gamma+1)(\mathbf{V}.\mathbf{v}_1/c^2)]\mathbf{V}}{1-\mathbf{V}.\mathbf{v}_1/c^2}\right)\Bigg|_{\mathbf{V}=\mathbf{v}_1}, \tag{3.33}$$

from which we immediately deduce that the primed velocity of particle 1 must be zero,

$$\mathbf{v}'_1=\mathbf{0}. \tag{3.34}$$

This is of course the expected result because the boost velocity was chosen to be equal to the instantaneous velocity of particle 1 in the unprimed frame at the instant t; however, the details of the above proof constitute a necessary consistency check of the formulas.

(iv) The choice of boost vector $\mathbf{V}=\mathbf{v}_1$, together with the equivalent statement that $\mathbf{v}'_1=\mathbf{0}$, as well as the expressions (3.29) and (3.30) defining the two functionals $\mathbf{y}'_{12}[\mathbf{y}_{12};\mathbf{v}_1,\mathbf{v}_2]$ and $\mathbf{v}'_2[\mathbf{y}_{12};\mathbf{v}_1,\mathbf{v}_2]$, are put into (3.27), which gave the result ${}_1\hat{f}'_0$ of the spherical average in the Hadamard regularization performed in the primed frame. Therefore, the regularized value of F at point 1 is defined by

$$[F]_1=\underset{1}{\hat{f}'_0}(\mathbf{y}'_{12}[\mathbf{y}_{12};\mathbf{v}_1,\mathbf{v}_2];\mathbf{0},\mathbf{v}'_2[\mathbf{y}_{12};\mathbf{v}_1,\mathbf{v}_2];\mathbf{v}_1). \tag{3.35}$$

The new regularization $[F]_1$ acts, like the old one $(F)_1$, as a certain functional of the relative distance $\mathbf{y}_{12}$ and the velocities $\mathbf{v}_1$, $\mathbf{v}_2$. However, in generic cases, $[F]_1$ differs from $(F)_1$ by relativistic terms at least of the order $1/c^2$ (we investigate in Sec. IV the exact relation between both regularizations to the first relativistic order $1/c^2$). In the problem of the post-Newtonian equations of motion, we have found[22,24] that the new regularization $[F]_1$ adds some extra terms to the acceleration computed using the regularization $(F)_1$; these new terms are of order 3PN and manage to make the 3PN equations of motion invariant with respect to Lorentz transformations. Indeed, with the regularization $(F)_1$ the Lorentz invariance of the equations of motion would be broken at the 3PN order. Finally, let us introduce as we did in Ref. 1 (see also Sec. II) a delta-pseudo-function associated with the new regularization $[F]_1$. By definition, the "Lorentzian" delta-pseudo-function denoted $\mathrm{Pf}\Delta_1$ [to contrast with the noninvariant one $\mathrm{Pf}\delta_1$ defined by (2.13)] is such that

$$\forall F\in\mathcal{F},\quad \langle \mathrm{Pf}\Delta_1,F\rangle=[F]_1, \tag{3.36}$$

where the right side is given by the new regularization (3.35). By definition, we have in the case of the new regularization the same laws for the multiplication as in Sec. II, for instance

$$FG.\mathrm{Pf}\Delta_1=\mathrm{Pf}(F\Delta_1).G=\mathrm{Pf}(F\Delta_1).\mathrm{Pf}G=\mathrm{Pf}(FG\Delta_1), \tag{3.37}$$

where the pseudo-function $\mathrm{Pf}(F\Delta_1)$ is defined by

$$\forall G\in\mathcal{F},\quad \langle \mathrm{Pf}(F\Delta_1),G\rangle=[FG]_1. \tag{3.38}$$

This pseudo-function $\mathrm{Pf}(F\Delta_1)$ is at the basis of our proposal for the stress-energy tensor of point-particles in Sec. V. And, like in the case of $\mathrm{Pf}(F\delta_1)$, we are not allowed to replace this pseudo-function by the product of the regularized value of the function times the delta-pseudo-function, namely,

$$\mathrm{Pf}(F\Delta_1)\neq[F]_1\mathrm{Pf}\Delta_1. \tag{3.39}$$

The derivatives of $\mathrm{Pf}\Delta_1$ and $\mathrm{Pf}(F\Delta_1)$ are constructed in the same way as for the original regularization in Sec. II. Therefore,

$$\forall G\in\mathcal{F},\quad \langle \partial_i[\mathrm{Pf}(F\Delta_1)],G\rangle=-\langle \mathrm{Pf}(F\Delta_1),\partial_i G\rangle=-[F\partial_i G]_1. \tag{3.40}$$

However, the identity (2.5) is not valid in the case of the new regularization, so we do not have a result similar to (2.20) [see (4.13) for the equivalent of (2.5) at the first relativistic order]. For the product of $\mathrm{Pf}(F\delta_1)$ with some $\mathrm{Pf}G$, the Leibniz rule holds:

$$\partial_i[\mathrm{Pf}(F\Delta_1).\mathrm{Pf}G]=\partial_i[\mathrm{Pf}(F\Delta_1)].\mathrm{Pf}G+\mathrm{Pf}(F\Delta_1).\partial_i(\mathrm{Pf}G). \tag{3.41}$$

This is a consequence of the definition (3.40) and the law (3.37).

IV. THE REGULARIZATION AT THE FIRST RELATIVISTIC ORDER

At this point, it is instructive (and useful in practice) to present the complete formulas that define the Lorentzian regularization $[F]_1$ at the level of the first relativistic corrections $1/c^2$, i.e., neglecting all the terms of order $O(1/c^4)$. [Notice that, consistent with Sec. III, we must consider that the boost vector $\mathbf{V}$ itself is of order $O(1)$, so that, for instance, the factor $\mathbf{V}^2/c^2$ really represents a small relativistic correction of the order $O(1/c^2)$.] Furthermore, we shall obtain at this $1/c^2$ level a formula linking the new regularization $[F]_1$ to the old one $(F)_1$. Like in Sec. III, we assume that the function F depends on $\mathbf{x}$ through the two distances $\mathbf{r}_1(t)$ and $\mathbf{r}_2(t)$ only; this implies a relation between the partial derivatives:

$$\partial_i F+\frac{\partial F}{\partial y_1^i}+\frac{\partial F}{\partial y_2^i}=0 \tag{4.1}$$

(where $\partial_i=\partial/\partial x^i$). We suppose also that F is a Lorentz scalar, cf. (3.25).

We follow the general specification for the regularization in Sec. III. We first express the vectorial distances $\mathbf{r}_1$, $\mathbf{r}_2$ and velocities $\mathbf{v}_1$, $\mathbf{v}_2$ in the boosted frame $\{x'^\mu\}$ using the transformation formulas (3.24) restricted to the order $1/c^2$. For the distances, we get

$$\mathbf{r}_1=\mathbf{r}_1'-\frac{1}{c^2}(\mathbf{V}.\mathbf{r}_1')\left[\mathbf{v}_1'+\frac{1}{2}\mathbf{V}\right]+O\left(\frac{1}{c^4}\right), \tag{4.2a}$$

$$\mathbf{r}_2=\mathbf{r}_2'-\frac{1}{c^2}(\mathbf{V}.\mathbf{r}_2')\left[\mathbf{v}_2'+\frac{1}{2}\mathbf{V}\right]+O\left(\frac{1}{c^4}\right). \tag{4.2b}$$

The relative distance $\mathbf{y}_{12}=\mathbf{r}_2-\mathbf{r}_1$ reads as

$$\mathbf{y}_{12}=\mathbf{y}'_{12}+\frac{1}{c^2}[-\tfrac{1}{2}(\mathbf{V}.\mathbf{y}'_{12})\mathbf{V}+(\mathbf{V}.\mathbf{r}'_1)\mathbf{v}'_1-(\mathbf{V}.\mathbf{r}'_2)\mathbf{v}'_2]+O\left(\frac{1}{c^4}\right), \tag{4.3}$$

while, for instance, the relative separation $r_{12}=|\mathbf{y}_{12}|$ is

$$r_{12}=r'_{12}\left(1+\frac{1}{c^2}\left[-\tfrac{1}{2}(\mathbf{V}.\mathbf{n}'_{12})^2+\frac{r'_1}{r'_{12}}(\mathbf{V}.\mathbf{n}'_1)(\mathbf{v}'_1.\mathbf{n}'_{12})-\frac{r'_2}{r'_{12}}(\mathbf{V}.\mathbf{n}'_2)(\mathbf{v}'_2.\mathbf{n}'_{12})\right]\right)+O\left(\frac{1}{c^4}\right), \tag{4.4}$$

where $\mathbf{n}'_1=\mathbf{r}'_1/r'_1$, $\mathbf{n}'_2=\mathbf{r}'_2/r'_2$, and $\mathbf{n}'_{12}=\mathbf{y}'_{12}/r'_{12}$. For the two velocities, we find

$$\mathbf{v}_1=\mathbf{v}'_1+\mathbf{V}+\frac{1}{c^2}([-\tfrac{1}{2}\mathbf{V}^2-\mathbf{V}.\mathbf{v}'_1]\mathbf{v}'_1-\tfrac{1}{2}(\mathbf{V}.\mathbf{v}'_1)\mathbf{V}+(\mathbf{V}.\mathbf{r}'_1)\mathbf{a}'_1)+O\left(\frac{1}{c^4}\right), \tag{4.5a}$$

$$\mathbf{v}_2=\mathbf{v}'_2+\mathbf{V}+\frac{1}{c^2}([-\tfrac{1}{2}\mathbf{V}^2-\mathbf{V}.\mathbf{v}'_2]\mathbf{v}'_2-\tfrac{1}{2}(\mathbf{V}.\mathbf{v}'_2)\mathbf{V}+(\mathbf{V}.\mathbf{r}'_2)\mathbf{a}'_2)+O\left(\frac{1}{c^4}\right), \tag{4.5b}$$

where the two accelerations $\mathbf{a}'_1$ and $\mathbf{a}'_2$ are to be replaced, consistent with the approximation, by their Newtonian values: $\mathbf{a}'_1=-(Gm_2/r'^2_{12})\,\mathbf{n}'_{12}+O(1/c^2)$ and $\mathbf{a}'_2=(Gm_1/r'^2_{12})\mathbf{n}'_{12}+O(1/c^2)$. [Notice that in Sec. III the regularization has been defined regardless of the type of special-relativistic interaction involved; in the case of electromagnetism, for instance, we should simply replace the accelerations by their Coulombian values in (4.5).]

Next, we substitute the expressions (4.2) and (4.5) into the scalar function $F[\mathbf{r}_1,\mathbf{r}_2;\mathbf{v}_1,\mathbf{v}_2]$ and perform the expansion to the first order. The result is the scalar function $F'[\mathbf{r}'_1,\mathbf{r}'_2;\mathbf{v}'_1,\mathbf{v}'_2;\mathbf{V}]$ in the new frame; thus

$$\begin{aligned}F'[\mathbf{r}'_1,\mathbf{r}'_2;\mathbf{v}'_1,\mathbf{v}'_2;\mathbf{V}]=F[\mathbf{r}'_1,\mathbf{r}'_2;\mathbf{v}'_1+\mathbf{V},\mathbf{v}'_2+\mathbf{V}]&+\frac{1}{c^2}(\mathbf{V}.\mathbf{r}'_1)[v'^i_1+\tfrac{1}{2}V^i]\frac{\partial F}{\partial y^i_1}\\&+\frac{1}{c^2}(\mathbf{V}.\mathbf{r}'_2)\left[v'^i_2+\frac{1}{2}V^i\right]\frac{\partial F}{\partial y^i_2}+\frac{1}{c^2}\left(\left[-\frac{1}{2}\mathbf{V}^2-\mathbf{V}.\mathbf{v}'_1\right]v'^i_1\right.\\&\left.-\frac{1}{2}(\mathbf{V}.\mathbf{v}'_1)V^i+(\mathbf{V}.\mathbf{r}'_1)a'^i_1\right)\frac{\partial F}{\partial v^i_1}+\frac{1}{c^2}\left(\left[-\frac{1}{2}\mathbf{V}^2-\mathbf{V}.\mathbf{v}'_2\right]v'^i_2\right.\\&\left.-\frac{1}{2}(\mathbf{V}.\mathbf{v}'_2)V^i+(\mathbf{V}.\mathbf{r}'_2)a'^i_2\right)\frac{\partial F}{\partial v^i_2}+O\left(\frac{1}{c^4}\right),\end{aligned} \tag{4.6}$$

where we have used $\partial F/\partial r^i_1=-\partial F/\partial y^i_1$ and $\partial F/\partial r^i_2=-\partial F/\partial y^i_2$. Note that, to this order, the partial derivatives in (4.6) can be evaluated at the primed values $\mathbf{r}'_1$, $\mathbf{r}'_2$ and $\mathbf{v}'_1+\mathbf{V}$, $\mathbf{v}'_2+\mathbf{V}$, or equivalently at the nonprimed ones $\mathbf{r}_1$, $\mathbf{r}_2$ and $\mathbf{v}_1$, $\mathbf{v}_2$. Now we pick up in the new frame the term of zeroth order in the expansion when $r'_1\to 0$, and perform the angular average with respect to the direction $\mathbf{n}'_1$. This yields the functional of the variables $\mathbf{y}'_{12}$, $\mathbf{v}'_1$, $\mathbf{v}'_2$, and $\mathbf{V}$ which has been defined in (3.27). Since these operations of expanding and averaging represent nothing but the Hadamard regularization in the old sense of (2.3), we can denote them by using the parenthesis appropriate for this regularization. Therefore,

$$\hat{f}'_{0\,1}(\mathbf{y}'_{12};\mathbf{v}'_1,\mathbf{v}'_2;\mathbf{V}) = \Bigg(F[\mathbf{r}_1,\mathbf{r}_1+\mathbf{y}'_{12};\mathbf{v}'_1+\mathbf{V},\mathbf{v}'_2+\mathbf{V}] + \frac{1}{c^2}(\mathbf{V}.\mathbf{r}_1)\left[v'^{i}_1 + \frac{1}{2}V^i \right]\frac{\partial F}{\partial y^i_1}$$
$$+ \frac{1}{c^2}(\mathbf{V}.\mathbf{r}_1+\mathbf{V}.\mathbf{y}'_{12})\left[v'^{i}_2 + \frac{1}{2}V^i \right]\frac{\partial F}{\partial y^i_2}$$
$$+ \frac{1}{c^2}\left(\left[-\frac{1}{2}\mathbf{V}^2 - \mathbf{V}.\mathbf{v}'_1 \right] v'^{i}_1 - \frac{1}{2}(\mathbf{V}.\mathbf{v}'_1)V^i + (\mathbf{V}.\mathbf{r}_1)a'^{i}_1 \right)\frac{\partial F}{\partial v^i_1}$$
$$+ \frac{1}{c^2}\left(\left[-\frac{1}{2}\mathbf{V}^2 - \mathbf{V}.\mathbf{v}'_2 \right] v'^{i}_2 - \frac{1}{2}(\mathbf{V}.\mathbf{v}'_2)V^i + [\mathbf{V}.\mathbf{r}_1+\mathbf{V}.\mathbf{y}'_{12}]a'^{i}_2 \right)\frac{\partial F}{\partial v^i_2}\Bigg)_1$$
$$+ O\left(\frac{1}{c^4}\right). \tag{4.7}$$

We have replaced here the vectorial distance $\mathbf{r}'_1$ by the unprimed notation $\mathbf{r}_1$, noticing that $\mathbf{r}'_1$ is the dummy variable with respect to which the regularization proceeds (with this notation $\mathbf{r}'_2$ is replaced by $\mathbf{r}_1+\mathbf{y}'_{12}$). Following (3.35), the Lorentzian regularization $[F]_1$ is achieved by posing $\mathbf{V}=\mathbf{v}_1$ and $\mathbf{v}'_1=\mathbf{0}$, as well as $\mathbf{y}'_{12}=\mathbf{y}'_{12}[\mathbf{y}_{12};\mathbf{v}_1,\mathbf{v}_2]$ and $\mathbf{v}'_2=\mathbf{v}'_2[\mathbf{y}_{12};\mathbf{v}_1,\mathbf{v}_2]$, where the latter functionals are defined in the general case by (3.29) and (3.30). It is convenient to obtain first an intermediate formula by setting $\mathbf{V}=\mathbf{v}_1$ and $\mathbf{v}'_1=\mathbf{0}$ in (4.7), and by replacing into the terms that are already of order $1/c^2$ the primed variables $\mathbf{y}'_{12}$ and $\mathbf{a}'_1$, $\mathbf{a}'_2$ by the unprimed ones. Using also the identity (4.1), we arrive at

$$[F]_1 = \Bigg(F[\mathbf{r}_1,\mathbf{r}_1+\mathbf{y}'_{12};\mathbf{v}_1,\mathbf{v}_1+\mathbf{v}'_2] + \frac{1}{2c^2}(\mathbf{v}_1.\mathbf{r}_1)v^i_1\partial_i F$$
$$+ \frac{1}{c^2}(\mathbf{v}_1.\mathbf{r}_1)\left[v^i_1\frac{\partial F}{\partial y^i_1} + v^i_2\frac{\partial F}{\partial y^i_2} + a^i_1\frac{\partial F}{\partial v^i_1} + a^i_2\frac{\partial F}{\partial v^i_2} \right] + \frac{1}{c^2}\left(\frac{1}{2}(\mathbf{v}_1.\mathbf{v}_2)v^i_1 + \left[\frac{1}{2}\mathbf{v}_1^2 - \mathbf{v}_1.\mathbf{v}_2 \right]v^i_2 \right.$$
$$\left. + (\mathbf{v}_1.\mathbf{y}_{12})a^i_2 \right)\frac{\partial F}{\partial v^i_2} + \frac{1}{c^2}(\mathbf{v}_1.\mathbf{y}_{12})\left[-\frac{1}{2}v^i_1 + v^i_2 \right]\frac{\partial F}{\partial y^i_2}\Bigg)_1 + O\left(\frac{1}{c^4}\right), \tag{4.8}$$

where $\mathbf{y}'_{12}$ and $\mathbf{v}'_2$ in the first term of the right side are given functions of $\mathbf{y}_{12}$, $\mathbf{v}_1$ and $\mathbf{v}_2$ obtained by approximating (3.29) and (3.30) to the first order. We find

$$\mathbf{y}'_{12} = \mathbf{y}_{12} + \frac{1}{c^2}(\mathbf{v}_1.\mathbf{y}_{12})\left[-\frac{1}{2}\mathbf{v}_1 + \mathbf{v}_2 \right] + O\left(\frac{1}{c^4}\right), \tag{4.9a}$$

$$\mathbf{v}'_2 = -\mathbf{v}_1 + \mathbf{v}_2 + \frac{1}{c^2}\left(-\frac{1}{2}(\mathbf{v}_1.\mathbf{v}_2)\mathbf{v}_1 + \left[-\frac{1}{2}\mathbf{v}_1^2 + \mathbf{v}_1.\mathbf{v}_2 \right]\mathbf{v}_2 - (\mathbf{v}_1.\mathbf{y}_{12})\mathbf{a}_2 \right) + O\left(\frac{1}{c^4}\right) \tag{4.9b}$$

(where the acceleration is equal to its Newtonian value). By inserting (4.9) into (4.8) and expanding to order $1/c^2$, it is easily seen that we cancel out exactly the two last terms on the right-hand side of (4.8), so that the result simplifies appreciably:

$$[F]_1 = \left(F[\mathbf{r}_1,\mathbf{r}_2;\mathbf{v}_1,\mathbf{v}_2] + \frac{1}{2c^2}(\mathbf{v}_1.\mathbf{r}_1)v_1^i\partial_i F + \frac{1}{c^2}(\mathbf{v}_1.\mathbf{r}_1)\left[v_1^i\frac{\partial F}{\partial y_1^i} + v_2^i\frac{\partial F}{\partial y_2^i} + a_1^i\frac{\partial F}{\partial v_1^i} + a_2^i\frac{\partial F}{\partial v_2^i}\right]\right)_1 + O\left(\frac{1}{c^4}\right). \tag{4.10}$$

Finally, we recognize on the right side the partial time derivative,

$$\partial_t F = v_1^i\frac{\partial F}{\partial y_1^i} + v_2^i\frac{\partial F}{\partial y_2^i} + a_1^i\frac{\partial F}{\partial v_1^i} + a_2^i\frac{\partial F}{\partial v_2^i}, \tag{4.11}$$

so that our final result writes

$$[F]_1 = \left(F + \frac{1}{c^2}(\mathbf{r}_1.\mathbf{v}_1)\left[\partial_t F + \frac{1}{2}v_1^i\partial_i F\right]\right)_1 + O\left(\frac{1}{c^4}\right). \tag{4.12}$$

The result (4.12) displays the first relativistic corrections brought about by our Lorentzian regularization $[F]_1$. As a check of the formula, let us apply it to the case of the special combination $\partial_i F - 3(n_1^i/r_1)F$ which, as we know from (2.5), has no partie finie at the point 1 in the sense of the old regularization. This is no longer true in the sense of the new regularization. Using the equation (4.12) we find instead

$$[\partial_i F]_1 = \left[3\frac{n_1^i}{r_1}\left(1 - \frac{1}{c^2}(\mathbf{n}_1.\mathbf{v}_1)^2\right)F - \frac{1}{c^2}v_1^i\partial_t F\right]_1 + O\left(\frac{1}{c^4}\right). \tag{4.13}$$

The check consists of remarking that because of (2.5) we have $(\partial_i' F' - 3(n'^i_1/r_1')F')_1 = 0$ in the rest frame of particle 1, therefore the equation $[\partial_i' F' - 3(n'^i_1/r_1')F']_1 = 0$ must hold in any frame by definition of the new regularization. In the frame where the particle velocity is $\mathbf{v}_1$ we have $\mathbf{r}_1' = \mathbf{r}_1 + (1/2c^2)(\mathbf{v}_1.\mathbf{r}_1)\mathbf{v}_1 + O(1/c^4)$ and $\partial_i' = \partial_i + (1/c^2)v_1^i\partial_t + (1/2c^2)v_1^iv_1^j\partial_j + O(1/c^4)$. Inserting these relations into the previous equation, and using the fact that F is a scalar, we recover the formula (4.13) after a short computation.

V. THE STRESS-ENERGY TENSOR OF POINT-PARTICLES

With the Lorentzian regularization in hand, we make a proposal for the description of point-like particles in (post-Newtonian approximations of) general relativity. We recall first the general context of the problem. We want to solve the field equations of general relativity by means of analytic post-Newtonian series, with matter source describing appropriately defined point-particles. The stress-energy tensor of the matter source is supposed to be spatially isolated; we recall that, in this case, general relativity admits the Poincaré group as a global symmetry. We assume the existence and unity of a global harmonic coordinate system, defined by the gauge conditions

$$\partial_\nu h^{\mu\nu} = 0\ , \tag{5.1a}$$

$$h^{\mu\nu} = \sqrt{g}g^{\mu\nu} - \eta^{\mu\nu}, \tag{5.1b}$$

where $g^{\mu\nu}$ denotes the inverse of the covariant metric $g_{\mu\nu}$, and where g is the opposite of its determinant. The harmonic gauge conditions (5.1) introduce a preferred Minkowskian structure, with Minkowski metric given by $\eta^{\mu\nu} = \mathrm{diag}(-1,1,1,1) = \eta_{\mu\nu}$. Thus, the gravitational field can be described in harmonic coordinates by the Lorentzian tensor field $h^{\mu\nu}$ propagating on the

Minkowskian background $\eta^{\mu\nu}$. Similarly, one can think of the trajectories of the particles as accelerated world lines in Minkowski space–time. Subject to the conditions (5.1) the Einstein field equations take the form of wave equations on the flat background,

$$\Box h^{\mu\nu}=\frac{16\pi G}{c^4}gT^{\mu\nu}+\Lambda^{\mu\nu}[h,\partial h,\partial^2 h], \tag{5.2}$$

where the flat d'Alembertian operator is given by $\Box=\eta^{\mu\nu}\partial_\mu\partial_\nu$. The right-hand side is made of the sum of the matter source term, with spatially compact support, plus the gravitational source term $\Lambda^{\mu\nu}$, given by a certain functional of the field variables $h^{\rho\sigma}$ and its first and second space–time derivatives, and at least of second order in h. A consequence of the harmonicity conditions is that

$$\partial_\nu\left(gT^{\mu\nu}+\frac{c^4}{16\pi G}\Lambda^{\mu\nu}\right)=0\ , \tag{5.3}$$

which is equivalent (through the contracted Bianchi identity) to the covariant conservation of the matter stress-energy tensor $T^{\mu\nu}$,

$$\nabla_\nu T^{\mu\nu}=0\ , \tag{5.4}$$

the latter equation being in turn equivalent to

$$\partial_\nu(\sqrt{g}g_{\lambda\mu}T^{\mu\nu})=\tfrac{1}{2}\sqrt{g}\partial_\lambda g_{\mu\nu}T^{\mu\nu}. \tag{5.5}$$

In this section we regard the matter tensor $T^{\mu\nu}$ as a Lorentz tensor defined with respect to the Minkowski metric $\eta_{\mu\nu}$ singled out by our choice of harmonic coordinates.

To define a model for point-like particles, we follow essentially the derivation of the stress-energy tensor of *test* masses moving on a fixed *smooth* background (see, e.g., Ref. 30, p. 360). However, in the case of ''self-gravitating'' particles, we do not have a smooth background at our disposal, and the metric becomes singular at the location of the point-masses. Essentially, we shall propose the value of the (post-Newtonian) metric coefficients on each of the particles to be given by the Lorentzian regularization defined in Sec. III. This entails supposing that the metric coefficients belong to the class of functions $\mathcal{F}$. This is correct up to the 2PN order;[19] however, we know that the expansion of the metric coefficients (in harmonic coordinates) near the particles, instead of being of the type (2.1) and (2.2), involve some logarithms of the distance to the singularities starting at 3PN order. It was shown[22] that, at this order, the logarithms can be considered as some constants and included into the definition of the partie finie; moreover, they can be finally eliminated from the equations of motion by a change of coordinates. This suggests that we might consider more generally the logarithms as some constants, motivating our assumption that $g_{\mu\nu}\in\mathcal{F}$. On the other hand, it is known[22,24] that the constants s_1 and s_2 entering the partie finie integral (2.6) must be adjusted in order that the equations of motion can be deducible from a Lagrangian, and in particular admit a conserved energy. For these reasons (presence of logarithms, equations of motion not directly admitting an energy), the following derivation of the stress-energy tensor for particles cannot be considered to be a rigorous proof. However, as we shall see, it is nicely consistent with the regularization, and its result satisfying. Our basic assumption is that the dynamics of the particles follows from the variation, with respect to the metric, of the action

$$I_{\text{particle}}=-m_1c\int_{-\infty}^{+\infty}dt\sqrt{-[g_{\mu\nu}]_1v_1^\mu v_1^\nu}+1\leftrightarrow 2, \tag{5.6}$$

where $v_1^\mu=(c,d\mathbf{y}_1/dt)$ denotes the coordinate velocity of particle 1 (we consider a two-body system, but the generalization to N bodies is immediate). The crucial point is that the value of $g_{\mu\nu}$ at 1 is assumed to be given by the Lorentzian regularization defined in Sec. III. We vary the action

(5.6) with respect to the metric, i.e., we imagine that $g_{\mu\nu}\in\mathcal{F}$ is subject to an infinitesimal variation $g_{\mu\nu}\to g_{\mu\nu}+\delta g_{\mu\nu}$ and compute the corresponding change in the action. However, we want the variation of the metric to correspond to the same matter system with two singularities 1 and 2. The evident and most natural way to ensure this is to suppose that $\delta g_{\mu\nu}\in\mathcal{F}$. Under the latter variation the regularized value of the metric at the point 1 undergoes the infinitesimal change $[g_{\mu\nu}]_1 \to[g_{\mu\nu}]_1+[\delta g_{\mu\nu}]_1$. Therefore, the variation of the action (5.6) reads as

$$\delta I_{\text{particle}}=\frac{1}{2}m_1 c\int_{-\infty}^{+\infty}dt\,\frac{v_1^\mu v_1^\nu}{\sqrt{-[g_{\rho\sigma}]_1 v_1^\rho v_1^\sigma}}[\delta g_{\mu\nu}]_1+1\leftrightarrow 2. \tag{5.7}$$

From the defining property (3.36) of the delta-pseudo-function $\text{Pf}\Delta_1$, we can rewrite (5.7) in the equivalent form

$$\delta I_{\text{particle}}=\frac{1}{2}m_1 c\int_{-\infty}^{+\infty}dt\,\frac{v_1^\mu v_1^\nu}{\sqrt{-[g_{\rho\sigma}]_1 v_1^\rho v_1^\sigma}}\langle \text{Pf}\Delta_1,\delta g_{\mu\nu}\rangle+1\leftrightarrow 2. \tag{5.8}$$

Now, recall that the duality bracket is defined by the partie finie of the three-dimensional integral [cf. (2.8)], so the latter expression can be cast into the standard form appropriate to the definition of a stress-energy tensor $T^{\mu\nu}_{\text{particle}}$, namely,

$$\delta I_{\text{particle}}=\frac{1}{2}\int_{-\infty}^{+\infty}dt\langle\sqrt{g}T^{\mu\nu}_{\text{particle}},\delta g_{\mu\nu}\rangle. \tag{5.9}$$

The only difference with the standard definition is that the partie finie takes care of the divergencies at the positions of the particles. By comparing (5.8) and (5.9), we readily find that the corresponding stress-energy tensor density is given by

$$\sqrt{g}T^{\mu\nu}_{\text{particle}}=m_1 c\frac{v_1^\mu v_1^\nu}{\sqrt{-[g_{\rho\sigma}]_1 v_1^\rho v_1^\sigma}}\text{Pf}\,\Delta_1+1\leftrightarrow 2. \tag{5.10}$$

The stress-energy tensor itself comes immediately from the rule of multiplication of pseudo-functions (3.37):

$$T^{\mu\nu}_{\text{particle}}=m_1 c\frac{v_1^\mu v_1^\nu}{\sqrt{-[g_{\rho\sigma}]_1 v_1^\rho v_1^\sigma}}\text{Pf}\left(\frac{\Delta_1}{\sqrt{g}}\right)+1\leftrightarrow 2, \tag{5.11}$$

This tensor takes the same form as the stress-energy tensor of test particles moving on a smooth background, except that the role of the background field is now played by the metric generated by the particles, regularized following the prescription (3.35). Notice in particular that the factor $1/\sqrt{g}$ inside the partie finie sign Pf should not be replaced by its regularized value at 1 [see (3.39)]. We propose the tensor (5.11) as a model of particles in the post-Newtonian approximation. From the product rules for pseudo-functions, we get the matter source term on the right-hand side of (5.2) as

$$gT^{\mu\nu}_{\text{particle}}=m_1 c\frac{v_1^\mu v_1^\nu}{\sqrt{-[g_{\rho\sigma}]_1 v_1^\rho v_1^\sigma}}\text{Pf}\,(\sqrt{g}\Delta_1)+1\leftrightarrow 2. \tag{5.12}$$

The post-Newtonian iteration of the field equations in Refs. 22 and 24 is based on the latter expression of the matter source term.

We now derive the equations of motion of particle 1 from the covariant conservation of the stress-energy tensor (5.11):

$$\nabla_\nu T^{\mu\nu}_{\text{particle}} = 0 \ . \tag{5.13}$$

Notice that thanks to the presence of the delta-pseudo-function, we know that the derivative is "ordinary" and satisfies the Leibniz rule in the sense of (3.41). Thus, we can transform $\nabla_\nu T^{\mu\nu}_{\text{particle}}$ in the standard way and find that the equation (5.13) is equivalent, like in the case of continuous sources, to the alternative form

$$\partial_\nu(\sqrt{g} g_{\lambda\mu} T^{\mu\nu}_{\text{particle}}) = \frac{1}{2}\sqrt{g}\partial_\lambda g_{\mu\nu} T^{\mu\nu}_{\text{particle}}. \tag{5.14}$$

Then, we integrate (5.14) over a closed volume V_1 surrounding particle 1 exclusively. The role of the three-dimensional integral is played here by the duality bracket defined by (2.8). Let us denote by $\mathbf{1}_{\mathrm{V}_1}$ the characteristic function of the volume V_1, such that $\mathbf{1}_{\mathrm{V}_1}(\mathbf{x}) = 1$ if $\mathbf{x} \in \mathrm{V}_1$ and $\mathbf{1}_{\mathrm{V}_1}(\mathbf{x}) = 0$ otherwise [notably, $\mathbf{1}_{\mathrm{V}_1}(\mathbf{y}_2) = 0$]. Thus, we consider

$$\langle \partial_\nu(\sqrt{g} g_{\lambda\mu} T^{\mu\nu}_{\text{particle}}), \mathbf{1}_{\mathrm{V}_1} \rangle = \left\langle \frac{1}{2}\sqrt{g}\partial_\lambda g_{\mu\nu} T^{\mu\nu}_{\text{particle}}, \mathbf{1}_{\mathrm{V}_1} \right\rangle. \tag{5.15}$$

(Though $\mathbf{1}_{\mathrm{V}_1}$ does not belong to the class $\mathcal{F}$, it is locally integrable on $\mathbb{R}^3$ and we know that the duality bracket applies on such functions as well; see Ref. 1.) The partial derivative ∂_ν on the left-hand side is split into a time derivative and a space derivative. Following the rule (3.40), the spatial derivative ∂_i is shifted to the right side of the bracket, where it applies on the characteristic function $\mathbf{1}_{\mathrm{V}_1}$. Because of the presence of the delta-pseudo-function, the derivative of $\mathbf{1}_{\mathrm{V}_1}$ is to be taken in an ordinary sense and is zero. Following the rule (9.7) in Ref. 1, an analogous reasoning is valid for the time-derivative $\partial_0 = (1/c)\partial_t$ which can thus simply be put outside the bracket. Thus, we get

$$\frac{d}{cdt}\{\langle \sqrt{g} g_{\lambda\mu} T^{\mu 0}_{\text{particle}}, \mathbf{1}_{\mathrm{V}_1} \rangle\} = \left\langle \frac{1}{2}\sqrt{g}\partial_\lambda g_{\mu\nu} T^{\mu\nu}_{\text{particle}}, \mathbf{1}_{\mathrm{V}_1} \right\rangle. \tag{5.16}$$

Next, we insert into (5.16) the specific expression (5.10) of the stress-energy density of particles. Because of the presence of the function $\mathbf{1}_{\mathrm{V}_1}$ only the part corresponding to particle 1 contributes, and we obtain

$$\frac{d}{dt}\left\{ \frac{v_1^\mu}{\sqrt{-[g_{\rho\sigma}]_1 v_1^\rho v_1^\sigma}} \langle \mathrm{Pf}(g_{\lambda\mu}\Delta_1), \mathbf{1}_{\mathrm{V}_1} \rangle \right\} = \frac{1}{2} \frac{v_1^\mu v_1^\nu}{\sqrt{-[g_{\rho\sigma}]_1 v_1^\rho v_1^\sigma}} \langle \mathrm{Pf}(\partial_\lambda g_{\mu\nu}\Delta_1), \mathbf{1}_{\mathrm{V}_1} \rangle. \tag{5.17}$$

Finally, the effect of the brackets on both sides of the latter equation is to take the value at point 1 in the sense of the Lorentzian regularization (3.35). Thereby our final result reads as

$$\frac{d}{dt}\left(\frac{[g_{\lambda\mu}]_1 v_1^\mu}{\sqrt{-[g_{\rho\sigma}]_1 v_1^\rho v_1^\sigma}} \right) = \frac{1}{2} \frac{[\partial_\lambda g_{\mu\nu}]_1 v_1^\mu v_1^\nu}{\sqrt{-[g_{\rho\sigma}]_1 v_1^\rho v_1^\sigma}}. \tag{5.18}$$

The equations of motion of particle 1 have the same formal structure as the geodesic equations of a test particle. In separate papers[22,24,25] we use (5.18) to derive explicitly the equations of motion of the two particles at the 3PN approximation.

ACKNOWLEDGMENTS

We thank Misao Sasaki, Hideyuki Tagoshi, and Takahiro Tanaka for stimulating discussions, and for the permission to reproduce their proof of the mathematical formula (A29) at the end of

the Appendix. The support of the JSPS short-term program for research in Japan is gratefully acknowledged for a visit of one of us (LB) at the University of Osaka during which this work was begun.

APPENDIX: SOLUTION OF THE EQUATION (3.14)

We are looking for the vector $\mathbf{z}_1$ satisfying the equation

$$\mathbf{z}_1=\mathbf{y}_1\left(t-\frac{1}{c^2}\mathbf{V}.(\mathbf{x}-\mathbf{z}_1)\right), \tag{A1}$$

where $\mathbf{y}_1(t)$ represents a given smooth (C^∞) time-like trajectory and $\mathbf{V}$ a constant vector with norm $|\mathbf{V}|<c$. Clearly, for a given trajectory, the solution $\mathbf{z}_1$ depends on the field point $\mathbf{x}$ as well as on time t. It was shown in the text after (3.15) that the application $\mathbf{x}\to\mathbf{z}_1$ is contracting with fixed point $\mathbf{y}_1$. Here, let us look for the solution $\mathbf{z}_1$ in the form of a function of the coordinates,

$$\mathbf{z}_1=\mathbf{z}_1(\mathbf{x},t). \tag{A2}$$

From (A1) we compute the partial derivatives of $\mathbf{z}_1$ with respect to t and x^i, considered to be independent, and readily obtain

$$\frac{\partial\mathbf{z}_1}{\partial x^i}=-\frac{1}{c^2}\left[V_i-\mathbf{V}.\frac{\partial\mathbf{z}_1}{\partial x^i}\right]\mathbf{v}_1\left(t-\frac{1}{c^2}\mathbf{V}.(\mathbf{x}-\mathbf{z}_1)\right), \tag{A3a}$$

$$\frac{\partial\mathbf{z}_1}{\partial t}=\left[1+\frac{1}{c^2}\mathbf{V}.\frac{\partial\mathbf{z}_1}{\partial t}\right]\mathbf{v}_1\left(t-\frac{1}{c^2}\mathbf{V}.(\mathbf{x}-\mathbf{z}_1)\right). \tag{A3b}$$

Contracting these equations with the vector $\mathbf{V}$ we can obtain the scalar products $\mathbf{V}.\partial\mathbf{z}_1/\partial x^i$ and $\mathbf{V}.\partial\mathbf{z}_1/\partial t$, and use them back into (A3) with the result that

$$\frac{\partial\mathbf{z}_1}{\partial x^i}=-\frac{1}{c^2}V_i\frac{\mathbf{v}_1}{1-\mathbf{V}.\mathbf{v}_1/c^2}, \tag{A4a}$$

$$\frac{\partial\mathbf{z}_1}{\partial t}=\frac{\mathbf{v}_1}{1-\mathbf{V}.\mathbf{v}_1/c^2}, \tag{A4b}$$

where the velocity $\mathbf{v}_1$ is evaluated at the instant $t-(1/c^2)\mathbf{V}.(\mathbf{x}-\mathbf{z}_1)$. In particular, we find that $\mathbf{z}_1$ must be a solution of the following first-order differential equation:

$$\frac{\partial\mathbf{z}_1}{\partial x^i}=-\frac{1}{c^2}V_i\frac{\partial\mathbf{z}_1}{\partial t}. \tag{A5}$$

Conversely, let us prove that a vector $\mathbf{z}_1$ that (i) satisfies the differential equation (A5) and (ii) admits $\mathbf{y}_1(t)$ as a *fixed* point, i.e., is such that

$$\mathbf{z}_1(\mathbf{y}_1(t),t)=\mathbf{y}_1(t) \tag{A6}$$

necessarily satisfies the original equation (A1). Such a $\mathbf{z}_1(\mathbf{x},t)$ being given, we perform in the equation (A5) the change of variables $(x^i,t)\to(\rho_1^i,\tau_1)$ defined by

$$\rho_1^i=x^i-z_1^i(\mathbf{x},t), \tag{A7a}$$

$$\tau_1 = t - \frac{1}{c^2}\mathbf{V}.(\mathbf{x}-\mathbf{z}_1(\mathbf{x},t)). \tag{A7b}$$

Using (A5) it is easy to obtain the laws of transformation of the partial derivatives:

$$\frac{\partial}{\partial \rho_1^i} = \frac{\partial}{\partial x^i} + \frac{1}{c^2} V_i \frac{\partial}{\partial t}, \tag{A8a}$$

$$\frac{\partial}{\partial \tau_1} = \frac{\partial}{\partial t} + B_j^i \frac{\partial z_1^j}{\partial t} \frac{\partial}{\partial x^i}, \tag{A8b}$$

where B_j^i denotes the matrix inverse of $A_k^j = \delta_k^j + (1/c^2) V_k (\partial z_1^j / \partial t)$ (i.e., $A_j^i B_k^j = \delta_k^i$; in the case considered here where the velocities are strictly less than c the matrix A_j^i is a deformation of the unit matrix and thus admits an inverse). Now, under the change of variables (A7) the differential equation (A5) becomes simply

$$\frac{\partial \mathbf{z}_1}{\partial \rho_1^i} = \mathbf{0}, \tag{A9}$$

whose general solution is an arbitrary function of the time variable τ_1. Therefore, there must exists a trajectory $\mathbf{Y}_1$ such that

$$\mathbf{z}_1 = \mathbf{Y}_1(\tau_1) = \mathbf{Y}_1\left(t - \frac{1}{c^2}\mathbf{V}.(\mathbf{x}-\mathbf{z}_1) \right). \tag{A10}$$

Imposing now that $\mathbf{y}_1(t)$ is a fixed point for this solution $\mathbf{z}_1$ in the sense of (A6) leads immediately to

$$\mathbf{Y}_1(t) = \mathbf{y}_1(t), \tag{A11}$$

so the equation (A1) is recovered exactly. Thus, solving (A1) is equivalent to solving the differential equation (A5) supplemented by the condition (A6). Notice that from (A1) or equivalently from (A5) and (A6) we find that $\mathbf{z}_1$ tends to the fixed point in the ''nonrelativistic'' limit $c \to +\infty$, i.e.,

$$\lim_{c \to +\infty} \{\mathbf{z}_1(\mathbf{x},t)\} = \mathbf{y}_1(t). \tag{A12}$$

This suggests to look for the solution $\mathbf{z}_1$ in the form of an infinite series of relativistic corrections of successive orders $1/c^{2n}$ [from (A5) we know that $\mathbf{z}_1$ is a function of $1/c^2$]. Thus, taking also into account the limit (A12), we pose

$$\mathbf{z}_1(\mathbf{x},t) = \mathbf{y}_1(t) + \sum_{n=1}^{+\infty} \frac{1}{c^{2n}} \overset{n}{\mathbf{Z}}_1(\mathbf{x},t), \tag{A13}$$

and we look for each one of the unknown coefficients $\overset{n}{\mathbf{Z}}_1(\mathbf{x},t)$. By placing the series (A13) into both sides of the equation (A5) and identifying the factors of the powers of $1/c^2$ on each side we find, for any $n \geqslant 1$,

$$\frac{\partial \overset{n}{\mathbf{Z}}_1}{\partial x^i} = -V_i \frac{\partial \overset{n-1}{\mathbf{Z}}_1}{\partial t}, \tag{A14}$$

with the convention that $\overset{0}{\mathbf{Z}}_1 = \mathbf{y}_1(t)$. The equations (A14) are to be solved using the condition of fixed point $\mathbf{y}_1$ [cf. (A6)], which implies that, $\forall n \geqslant 1$,

$$\overset{n}{\mathbf{Z}}_1(\mathbf{y}_1(t),t) = \mathbf{0}. \tag{A15}$$

The solution of (A14) and (A15) is found by induction over n. As an induction hypothesis suppose that

$$\overset{n-1}{\mathbf{Z}}_1 = \frac{(-)^{n-1}}{(n-1)!}\left(\frac{\partial}{\partial t}\right)^{n-2}[(\mathbf{V}.\mathbf{r}_1)^{n-1}\mathbf{v}_1], \tag{A16}$$

where $\mathbf{r}_1 = \mathbf{x} - \mathbf{y}_1$, and where the partial time derivatives act on t keeping the space coordinate $\mathbf{x}$ fixed: for instance, $\partial \mathbf{r}_1 / \partial t = -\mathbf{v}_1$ and $\partial \mathbf{v}_1 / \partial t = d\mathbf{v}_1 / dt = \mathbf{a}_1$, where $\mathbf{a}_1$ is the acceleration. Notice that (A16) satisfies the condition (A15) because it involves $n-2$ partial time derivatives while there is a factor $(\mathbf{V}.\mathbf{r}_1)^{n-1}$ inside the brackets, so after differentiation there will remain at least one factor $\mathbf{V}.\mathbf{r}_1$ making the result be zero when $\mathbf{x} = \mathbf{y}_1$. Inserting (A16) into the right-hand side of (A14) we obtain the equation to be satisfied for the next-order coefficient,

$$\frac{\partial \overset{n}{\mathbf{Z}}_1}{\partial x^i} = V_i \frac{(-)^n}{(n-1)!}\left(\frac{\partial}{\partial t}\right)^{n-1}[(\mathbf{V}.\mathbf{r}_1)^{n-1}\mathbf{v}_1], \tag{A17}$$

which can be rewritten equivalently in the form

$$\frac{\partial \overset{n}{\mathbf{Z}}_1}{\partial x^i} = \frac{\partial}{\partial x^i}\left\{\frac{(-)^n}{n!}\left(\frac{\partial}{\partial t}\right)^{n-1}[(\mathbf{V}.\mathbf{r}_1)^{n}\mathbf{v}_1]\right\}, \tag{A18}$$

showing that the most general solution is necessarily of the type

$$\overset{n}{\mathbf{Z}}_1 = \frac{(-)^n}{n!}\left(\frac{\partial}{\partial t}\right)^{n-1}[(\mathbf{V}.\mathbf{r}_1)^{n}\mathbf{v}_1] + \mathbf{C}(t), \tag{A19}$$

where $\mathbf{C}(t)$ denotes an arbitrary vector depending only on time t. However, this vector must be zero on account of the fact that the result should be zero when $\mathbf{x} = \mathbf{y}_1$. Therefore we have proved by induction that

$$\overset{n}{\mathbf{Z}}_1 = \frac{(-)^n}{n!}\left(\frac{\partial}{\partial t}\right)^{n-1}[(\mathbf{V}.\mathbf{r}_1)^{n}\mathbf{v}_1], \tag{A20}$$

so the vector $\mathbf{z}_1$ solving at once (A5) and (A6), or equivalently (A1), takes the form of the rather interesting infinite series

$$\mathbf{z}_1 = \mathbf{y}_1 + \sum_{n=1}^{+\infty} \frac{(-)^n}{c^{2n} n!}\left(\frac{\partial}{\partial t}\right)^{n-1}[(\mathbf{V}.\mathbf{r}_1)^{n}\mathbf{v}_1], \tag{A21}$$

which constitutes the solution needed for our work in Sec. III. Furthermore, subtracting $\mathbf{x}$ from this solution and contracting with $\mathbf{V}$ we obtain after a short calculation the quantity τ_1 which was defined in (A7b):

$$\tau_1 = t + \sum_{n=1}^{+\infty} \frac{(-)^n}{c^{2n} n!} \left(\frac{\partial}{\partial t} \right)^{n-1} [(\mathbf{V}.\mathbf{r}_1)^n]. \tag{A22}$$

Now, recall that the latter quantity τ_1 is such that $\mathbf{z}_1 = \mathbf{y}_1(\tau_1)$. Therefore, we see that we can find an alternative expression of the vector $\mathbf{z}_1$ by inserting into $\mathbf{y}_1(\tau_1)$ the series expansion (A22) found for τ_1. Using an infinite Taylor expansion we are led to

$$\mathbf{z}_1 = \mathbf{y}_1 + \sum_{p=0}^{+\infty} \frac{1}{(p+1)!} \frac{d^p \mathbf{v}_1}{dt^p} \left(\sum_{n=1}^{+\infty} \frac{(-)^n}{c^{2n} n!} \left(\frac{\partial}{\partial t} \right)^{n-1} [(\mathbf{V}.\mathbf{r}_1)^n] \right)^{p+1}. \tag{A23}$$

Each of the terms is composed of $p+1$ sums; accordingly we introduce $p+1$ summation indices $n_1, \ldots, n_p, n_{p+1}$ so that

$$\mathbf{z}_1 = \mathbf{y}_1 + \sum_{p=0}^{+\infty} \frac{1}{(p+1)!} \frac{d^p \mathbf{v}_1}{dt^p} \sum_{n_1=1}^{+\infty} \cdots \sum_{n_p=1}^{+\infty} \sum_{n_{p+1}=1}^{+\infty} \frac{(-)^{n_1 + \ldots + n_{p+1}}}{c^{2(n_1 + \ldots + n_{p+1})}} \times \left(\frac{\partial}{\partial t} \right)^{n_1 - 1} \left[\frac{(\mathbf{V}.\mathbf{r}_1)^{n_1}}{n_1!} \right] \cdots \left(\frac{\partial}{\partial t} \right)^{n_p - 1} \left[\frac{(\mathbf{V}.\mathbf{r}_1)^{n_p}}{n_p!} \right] \left(\frac{\partial}{\partial t} \right)^{n_{p+1} - 1} \left[\frac{(\mathbf{V}.\mathbf{r}_1)^{n_{p+1}}}{n_{p+1}!} \right]. \tag{A24}$$

Next we pose $k = n_1 + \cdots + n_p + n_{p+1}$, replace the index n_{p+1} by k, and operate $p+1$ commutations of summations to arrive at

$$\mathbf{z}_1 = \mathbf{y}_1 + \sum_{k=1}^{+\infty} \frac{(-)^k}{c^{2k}} \sum_{p=0}^{k-1} \frac{1}{(p+1)!} \frac{d^p \mathbf{v}_1}{dt^p} \sum_{n_1=1}^{q_1} \cdots \sum_{n_p=1}^{q_p} \times \left(\frac{\partial}{\partial t} \right)^{n_1 - 1} \left[\frac{(\mathbf{V}.\mathbf{r}_1)^{n_1}}{n_1!} \right] \cdots \left(\frac{\partial}{\partial t} \right)^{n_p - 1} \left[\frac{(\mathbf{V}.\mathbf{r}_1)^{n_p}}{n_p!} \right] \left(\frac{\partial}{\partial t} \right)^{n_{p+1} - 1} \left[\frac{(\mathbf{V}.\mathbf{r}_1)^{n_{p+1}}}{n_{p+1}!} \right], \tag{A25}$$

in which $n_{p+1} = k - \Sigma_{i=1}^{p} n_i$ and $q_j = 1 + \Sigma_{i=j}^{p+1} (n_i - 1)$ (with $1 \leqslant j \leqslant p$). We must identify the latter complicated expression with the simpler form of the vector $\mathbf{z}_1$ given by (A21). From identifying the powers of $1/c^2$ in both expressions we immediately obtain

$$\left(\frac{\partial}{\partial t} \right)^{k-1} \left[\frac{(\mathbf{V}.\mathbf{r}_1)^k}{k!} \mathbf{v}_1 \right] = \sum_{p=0}^{k-1} \frac{1}{(p+1)!} \frac{d^p \mathbf{v}_1}{dt^p} \sum_{n_1=1}^{q_1} \cdots \sum_{n_p=1}^{q_p} \times \left(\frac{\partial}{\partial t} \right)^{n_1 - 1} \left[\frac{(\mathbf{V}.\mathbf{r}_1)^{n_1}}{n_1!} \right] \cdots \left(\frac{\partial}{\partial t} \right)^{n_p - 1} \left[\frac{(\mathbf{V}.\mathbf{r}_1)^{n_p}}{n_p!} \right] \left(\frac{\partial}{\partial t} \right)^{n_{p+1} - 1} \left[\frac{(\mathbf{V}.\mathbf{r}_1)^{n_{p+1}}}{n_{p+1}!} \right]. \tag{A26}$$

Finally, from using the binomial formula for the derivative of a product, we can identify on each side of the latter equation the coefficients of each $d^p \mathbf{v}_1 / dt^p$, and we arrive at the relation, valid for any p and any $k \geqslant p+1$,

$$\sum_{n_1=1}^{q_1} \cdots \sum_{n_p=1}^{q_p} \left(\frac{\partial}{\partial t} \right)^{n_1 - 1} \left[\frac{(\mathbf{V}.\mathbf{r}_1)^{n_1}}{n_1!} \right] \cdots \left(\frac{\partial}{\partial t} \right)^{n_p - 1} \left[\frac{(\mathbf{V}.\mathbf{r}_1)^{n_p}}{n_p!} \right] \left(\frac{\partial}{\partial t} \right)^{n_{p+1} - 1} \left[\frac{(\mathbf{V}.\mathbf{r}_1)^{n_{p+1}}}{n_{p+1}!} \right] = \frac{(p+1)(k-1)!}{(k-1-p)!} \left(\frac{\partial}{\partial t} \right)^{k-p-1} \left[\frac{(\mathbf{V}.\mathbf{r}_1)^k}{k!} \right]. \tag{A27}$$

The latter relation actually represents a quite general mathematical formula because we have specified nothing about the scalar product $\mathbf{V}.\mathbf{r}_1$. Therefore, the relation (A27) holds in fact in the case of an arbitrary sufficiently differentiable function $f(t)$, so

$$\sum_{n_1=1}^{q_1}\cdots\sum_{n_p=1}^{q_p}\left(\frac{d}{dt}\right)^{n_1-1}\left[\frac{f^{n_1}}{n_1!}\right]\cdots\left(\frac{d}{dt}\right)^{n_p-1}\left[\frac{f^{n_p}}{n_p!}\right]\left(\frac{d}{dt}\right)^{n_{p+1}-1}\left[\frac{f^{n_{p+1}}}{n_{p+1}!}\right]$$
$$=\frac{(p+1)(k-1)!}{(k-1-p)!}\left(\frac{d}{dt}\right)^{k-p-1}\left[\frac{f^k}{k!}\right]. \tag{A28}$$

The equivalence obtained above between the formula (A1) and the differential equation (A5) together with the auxiliary condition (A6) shows *indirectly* that the mathematical formula (A28) is correct. However, a *direct* proof of this formula has been found by Tanaka, Sasaki, and Tagoshi (private communication). Here we reproduce their proof in the particular case where $p=1$, so that $q_1=k-1$ and $n_2=k-n$ (where $n\equiv n_1$), in which case the formula reads, for any $k\geqslant 2$,

$$\sum_{n=1}^{k-1}\left(\frac{d}{dt}\right)^{n-1}\left[\frac{f^n}{n!}\right]\left(\frac{d}{dt}\right)^{k-n-1}\left[\frac{f^{k-n}}{(k-n)!}\right]=2(k-1)\left(\frac{d}{dt}\right)^{k-2}\left[\frac{f^k}{k!}\right]. \tag{A29}$$

We replace $f(t)$ in (A29) by its Fourier transform, $f(t)=\int_{-\infty}^{+\infty}(d\omega/2\pi)e^{i\omega t}\tilde{f}(\omega)$, and readily find that in order to prove the formula (A29) it suffices to prove the statement that the equation

$$\sum_{n=1}^{k-1}\binom{k}{n}(\omega_{(1}+\omega_2+\cdots+\omega_n)^{n-1}(\omega_{n+1}+\cdots+\omega_{k)})^{k-n-1}=2(k-1)(\omega_1+\omega_2+\cdots+\omega_k)^{k-2} \tag{A30}$$

holds identically for any family of real frequencies $\omega_1,\ \ldots,\ \omega_k$. Most importantly, the parentheses around indices on the left side of (A30) indicate the complete symmetrization over the k frequencies $\omega_1,\ \ldots,\ \omega_k$ [in addition, $\binom{k}{n}$ denotes the binomial coefficient]. Let us single out one of the frequencies, for instance ω_k, and rewrite (A30) in a form involving an explicit symmetrization over the other $k-1$ frequencies, $\omega_1,\ \ldots,\ \omega_{k-1}$, only:

$$\sum_{n=1}^{k-1}\binom{k-1}{n}(\omega_{(1}+\cdots+\omega_n)^{n-1}(\omega_{n+1}+\cdots+\omega_{k-1)}+\omega_k)^{k-n-1}$$
$$=(k-1)(\omega_1+\omega_2+\cdots+\omega_k)^{k-2} \tag{A31}$$

(in which we have simplified a factor 2 on both sides of the equation). Furthermore, let us replace in the latter formula ω_k by some sum $\omega_k+\cdots+\omega_{k+s}$, and symmetrize over the whole set of frequencies $\omega_1,\ \ldots,\ \omega_{k+s}$. This yields, for any s,

$$\sum_{n=1}^{k-1}\binom{k-1}{n}(\omega_{(1}+\cdots+\omega_n)^{n-1}(\omega_{n+1}+\cdots+\omega_{k+s)})^{k-n-1}$$
$$=(k-1)(\omega_1+\omega_2+\cdots+\omega_{k+s})^{k-2}. \tag{A32}$$

Now we prove that the equation (A30), or equivalently (A31), is true by induction on the integer k. Therefore, our induction hypothesis is that (A31) is correct for *any* $k\leqslant K$, and from this we want to show that it is correct again for $k=K+1$. Note that from our induction hypothesis we know that (A32) is also correct for any $k\leqslant K$ and *any* s. Consider the sum defined by the left side of (A31) in the case where $k=K+1$, say

$$S_{K+1}=\sum_{n=1}^{K}\binom{K}{n}(\omega_{(1}+\cdots+\omega_{n})^{n-1}(\omega_{n+1}+\cdots+\omega_{K)}+\omega_{K+1})^{K-n}, \tag{A33}$$

where we recall that one of the frequencies, i.e., ω_{K+1}, is "artificially" singled out. However, S_{K+1} is also given by half the left-hand side of (A30) and is symmetric in $\omega_1, \ldots, \omega_{K+1}$. We want to show that S_{K+1} is equal to the right-hand side of (A31) with $k=K+1$. To this end, we transform S_{K+1} with the help of the binomial formula, and obtain after a short calculation

$$S_{K+1}=\sum_{l=0}^{K-1}\frac{\omega_{K+1}^{l}}{l!}\frac{K!}{(K-l)!}\sum_{n=1}^{K-l}\binom{K-l}{n}(\omega_{(1}+\cdots+\omega_{n})^{n-1}(\omega_{n+1}+\cdots+\omega_{K)})^{K-n-l}. \tag{A34}$$

Now we have two sums over l and n, and it is easy to recognize that the second sum, over n, can be simplified as soon as $l\geqslant 1$ by means of (A32) which is correct by induction under the condition that $k\leqslant K$ and for any s. Posing $K-l=k-1$ and $k+s=K$ we see that this condition is realized if and only if $l\geqslant 1$. After simplification we find

$$S_{K+1}=K(\omega_1+\cdots+\omega_{K+1})^{K-1}+\Psi_{K+1}(\omega_1,\ldots,\omega_K), \tag{A35}$$

where the first term is the result we want to obtain, and where the second term is a certain function of the frequencies $\omega_1, \ldots, \omega_K$ but which does *not* depend on ω_{K+1}. The expression of Ψ_{K+1} is given for completeness as

$$\Psi_{K+1}=\sum_{n=1}^{K}\binom{K}{n}(\omega_{(1}+\cdots+\omega_{n})^{n-1}(\omega_{n+1}+\cdots+\omega_{K)})^{K-n}-K(\omega_1+\cdots+\omega_K)^{K-1}. \tag{A36}$$

Now we use the fact that S_{K+1} is actually fully symmetric with respect to the $K+1$ frequencies $\omega_1, \ldots, \omega_{K+1}$. Therefore the function Ψ_{K+1} must be a pure constant, independent on any ω_n. Furthermore, we know also that S_{K+1} is a homogeneous polynomial of degree $K-1$ in all the $\omega_1, \ldots, \omega_{K+1}$, so this constant must in fact be zero: $\Psi_{K+1}=0$. Finally we are able to conclude on the desired result,

$$S_{K+1}=K(\omega_1+\cdots+\omega_{K+1})^{K-1}. \tag{A37}$$

Incidentally, notice that the equality $\Psi_{K+1}=0$ is itself a consequence of the same mathematical formula, since it follows from setting $k=K+1$ and posing $\omega_{K+1}=0$ in (A31).

(Received 31 January 2001; accepted for publication 22 May 2001)

We study the nonlinear spinor field in a Kerr–Schild background by first looking for solitonic solutions in the absence of rotation, given that in the special relativistic limit there are solitonic solutions in this approximation. Since for the scalar field problem at least two independent radial functions are needed for the solitonic solutions to exist, we introduce a dilation field by deforming the Kerr–Schild metric by a Weyl factor. We find that for the parameter space studied there are no solitonic solutions in the spherically symmetric approximation. While in the present work we have studied the spinor field, we also had in mind a corresponding study of a scalar field in the same background where it may be of interest for describing a rotating stellar soliton. The proposed strategy in both cases begins by looking for solitonic solutions in the absence of rotation and then continues by perturbatively correcting for the rotation required by the angular dependence of the Kerr background. The strategy appears to be unsuccessful. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1388031]

I. INTRODUCTION

Elementary particle solitons have been extensively investigated at the level of special relativity first in the context of Abelian theories and later in non-Abelian theories. In the Abelian case the solitons are stabilized by the conservation of physical charges and in the non-Abelian theories by topological constraints.

At the general relativistic level less is known. In particular the influence of the gravitational field on the known special relativistic structures has not been extensively studied. There have been, however, many studies of boson stars, which present a similar formal problem, but concern stellar structure rather than elementary particles.

At the level of particle physics, one has an eigenvalue problem that attempts to model the elementary particles similar to the way that the Schrödinger equation models atoms and nuclei. In the $1/N$ limit of standard theory Witten and collaborators have described a solitonic model of baryons.[1]

In examining string and supergravity theories from this viewpoint one finds two kinds of solitons. In the first class are the black-hole solitons which concentrate mass within a lump but are not true solitons since they carry central singularities and horizons. Typical of the second class are the topological solitons discovered by Strominger: these are five-branes immersed in a ten-dimensional space. Since they are singularity free they resemble solitons but are more precisely described as instantons, since their metric is Euclidean. Although nontopological solitons have not been found in these theories it is natural to ask if they exist in these or in other string or supergravity theories or in other completions of Einstein theory.

The present paper, a continuation of earlier exploratory studies along these lines,[2] promotes the nonlinear spinor soliton to the general relativistic level. The original nonlinear spinor field,[3]

[a)]Electronic mail: acadavid@galileo.csun.edu

characterized by a free spinor Lagrangian plus a quartic spinor interaction, was motivated by the then recently discovered universal Fermi interaction, and the conjecture that solitonic solutions of this equation might model the elementary particles. A current scenario might describe quarks and leptons while the quartic interaction would have to be mediated by heavy bosons. In the earlier model it turned out that this equation admitted only a small number of solitonic solutions in a way depending on the value of the ''Fermi constant,'' which could be tuned to allow, for example, only three generations. Here we take the step of adding gravitational couplings to the original picture; and although the coupled spinor-gravitational field does not fall out of any of the currently favored fundamental theories, the solitons so defined should be of interest because of the fundamental character of both the spinor and gravitational fields.

The organization of the paper is as follows. In Sec. II the Lagrangian of the nonlinear spinor in a gravitational field is introduced. Sections III, IV, and V describe various basic aspects of the Kerr–Schild background including the effects of the Weyl rescaling of the metric with a dilation field. Sections VI–IX, introduce the spin connection, present the spinor field field equations, and display the contribution of the spinor to the energy momentum tensor. Section X discusses the full set of Einstein equations for a spinor in a Weyl rescaled Kerr–Schild background. Before attempting the solution of the full set of equations, we consider the special relativistic limit in Secs. XI and XII. Finally in Sec. XIII we present the results of the numerical treatment of the full set of equations. We end with a discussion of the results.

II. FORMULATION

We shall investigate solitons formed by the interaction of a nonlinear spinor field with the Einstein gravitational field. These two fields are to be codetermined by the following action:

$$S=\int d^4x\sqrt{-g}(R-KL), \tag{2.1}$$

where

$$L=g^{\mu\lambda}{:}\overline{\psi}\gamma_\mu\nabla_\lambda\psi{:}-V(I). \tag{2.2}$$

Here

$$\nabla_\lambda=\partial_\lambda+\Gamma_\lambda, \tag{2.3}$$

where Γ_λ is the spin connection satisfying

$$\partial_\lambda\gamma_\mu-\Gamma^\sigma_{\lambda\mu}\gamma_\sigma+(\gamma_\mu,\Gamma_\lambda)=0 \tag{2.4}$$

in terms of the Christoffel connection $\Gamma^\sigma_{\lambda\mu}$. The notation: requires that the enclosed expression be symmetrized and Hermitized. The interaction $V(I)$, which may be rather general, may be chosen to generalize the universal Fermi interaction. For simplicity, however, we choose I to be the scalar $\overline{\psi}\psi$.

Then the energy momentum tensor is

$$\theta_{\mu\lambda}=\frac{\partial L}{\partial g^{\mu\lambda}}-\frac{1}{2}Lg_{\mu\lambda} \tag{2.5}$$

and the gravitational equations of motion are

$$R_{\mu\lambda}=K\Theta_{\mu\lambda}, \quad K=-8\pi\frac{k}{c^2}, \tag{2.6}$$

where K is Newton's constant and

$$\Theta_{\mu\lambda} = \theta_{\mu\lambda} - \tfrac{1}{2}\theta g_{\mu\lambda}. \tag{2.7}$$

By (2.2) one finds

$$\Theta_{\mu\lambda} := \overline{\psi}\gamma_\mu \nabla_\lambda \psi : - \tfrac{1}{2} V(I) g_{\mu\lambda}. \tag{2.8}$$

In addition to the gravitational field equation (2.6) one has the following spinor field equation:

$$g^{\mu\lambda}\gamma_\mu \nabla_\lambda \psi - \frac{\partial V}{\partial \overline{\psi}} = 0. \tag{2.9}$$

The coupled equations (2.6) and (2.9) determine the structure of the soliton.

III. KERR–SCHILD METRIC

Solutions of the Dirac equation in the presence of an assigned time independent gravitational field have been discussed. These include solutions in a gravitational background produced by a rotating source such as a rotating star.[4–6] For a rotating source the full Kerr–Schild background metric is required.

Here the role of the rotating source is played by the spinor field itself, since it necessarily carries angular momentum. The present problem is more difficult, however, than the problem of a rotating star since the spinor and gravitational fields are here codetermined while in the example of the star the gravitational field is a given background. On the other hand we know from the special relativistic problem[3] that there are solitonic eigenfunctions of a spinor field in the background described by a spherical potential.

We shall therefore assume a spherically symmetric degenerate form of the Kerr–Schild gravitational field with the understanding that it may be necessary to add more structure in order to obtain a more refined solution.

IV. THE STATIC KERR–SCHILD METRIC

Let us describe a gravitational field defined by the following Kerr–Schild metric:

$$g_{\alpha\beta} = \eta_{\alpha\beta} - 2m \ell_\alpha \ell_\beta. \tag{4.1}$$

Here $\eta_{\alpha\beta}$ is Minkowskian with the signature $(1, -1, -1, -1)$ and ℓ_α is a null static field:

$$\ell^\alpha \ell_\alpha = 0, \tag{4.2}$$

$$\frac{\partial \ell_\alpha}{\partial t} = 0. \tag{4.3}$$

For this metric

$$\det g = \det \eta = -1. \tag{4.4}$$

Set

$$\ell^\alpha = \ell^0 (1, \vec{\lambda}). \tag{4.5}$$

Then

$$\lambda_k \lambda_k = 1. \tag{4.6}$$

In the general case

$$\partial_i \lambda_j = \alpha P_{ij} + \beta \Lambda_{ji}, \tag{4.7}$$

where

$$P_{ij} = \delta_{ij} - \lambda_i \lambda_j, \tag{4.8}$$

$$\Lambda_{ij} = \epsilon_{ijk} \lambda_k. \tag{4.9}$$

Both α and β are harmonic functions. The function α may be regarded as a Newtonian potential in the presence of rotation, while β is the specific angular momentum of the source. In both the rotating and nonrotating cases the λ_i describe the paths followed by infalling particles. The divergence and curl of $\vec{\lambda}$ are determined by α and β, respectively.

At this point we leave the general formulation and focus in the spherically symmetric case. In this context λ_i is given by

$$\lambda_i = \frac{x_i}{r}, \quad r^2 = x_i x_i. \tag{4.10}$$

Then

$$\partial_i \lambda_j = \frac{1}{r}(\delta_{ij} - \lambda_i \lambda_j) \tag{4.11}$$

and α is exactly the Newtonian potential while β vanishes. Then also

$$\partial_i \lambda_i = \frac{2}{r}, \tag{4.12}$$

$$\partial_i \lambda_j - \partial_j \lambda_i = 0, \tag{4.13}$$

$$\lambda^i \partial_i \lambda_j = \lambda^i \partial_j \lambda_i = 0. \tag{4.14}$$

In the Newtonian case α is also ℓ_0^2. It is useful to introduce two scalar fields, C and D, by

$$C \ell_\alpha = -\ell^\mu \partial_\mu \ell_\alpha \tag{4.15}$$

and

$$D = \partial_\mu \ell^\mu. \tag{4.16}$$

Then

$$C = \lambda_k \partial_k \ell_0 = \frac{d\ell_0}{dr} = \ell_0' \tag{4.17}$$

$$D = \ell_0' + \frac{2}{r} \ell_0. \tag{4.18}$$

The Christoffel connection is a quadratic form in m:

$$\Gamma^\mu_{\alpha\beta} = \overset{1}{\Gamma}{}^\mu_{\alpha\beta} + \overset{2}{\Gamma}{}^\mu_{\alpha\beta}, \tag{4.19}$$

where

$$\overset{1}{\Gamma}{}^{\mu}_{\alpha\beta}=\tfrac{1}{2}\,\eta^{\mu\tau}(\partial_{\alpha}h_{\beta\tau}+\partial_{\beta}h_{\alpha\tau}-\partial_{\tau}h_{\alpha\beta}) \tag{4.20}$$

and

$$\overset{2}{\Gamma}{}^{\mu}_{\alpha\beta}=-4m^{2}C\not{\ell}^{\mu}\not{\ell}_{\alpha}\not{\ell}_{\beta}. \tag{4.21}$$

Here

$$h_{\alpha\beta}=g_{\alpha\beta}-\eta_{\alpha\beta}=-2m\not{\ell}_{\alpha}\not{\ell}_{\beta}. \tag{4.22}$$

Also

$$\Gamma^{\mu}_{\mu\alpha}=0, \tag{4.23}$$

$$\not{\ell}_{\mu}\Gamma^{\mu}_{\alpha\beta}=-2C\not{\ell}_{\alpha}\not{\ell}_{\beta}, \tag{4.24}$$

$$\not{\ell}^{\alpha}\Gamma^{\mu}_{\alpha\beta}=2C\not{\ell}^{\mu}\not{\ell}_{\beta}. \tag{4.25}$$

The Ricci tensor is

$$R_{00}=(2m^{2}\varphi-m)\nabla^{2}\varphi, \tag{4.26}$$

$$R_{0k}=2m^{2}(\varphi\nabla^{2}\varphi)\lambda_{k}, \tag{4.27}$$

$$R_{jk}=\delta_{jk}\frac{2m}{r}\left(\varphi'+\frac{2\varphi}{r}\right)+\lambda_{j}\lambda_{k}\left[m\left(\varphi''-\frac{4\varphi}{r^{2}}\right)+2m^{2}\varphi\nabla^{2}\varphi\right]. \tag{4.28}$$

Here $\varphi=\not{\ell}_{0}^{2}$. The gravitational field described by the special assumptions that we have made is now defined completely by the function $\varphi(r)$ which is exactly the Newtonian potential if there is no rotation.

V. THE RESCALED KERR–SCHILD METRIC

Because of the back action of the spinor field acting through its energy momentum tensor it is necessary to introduce a second gravitational potential. To do this we rescale the Kerr–Schild metric by introducing the dilaton field, $\sigma(r)$, as follows:

$$\overline{g}_{\alpha\beta}=e^{2\sigma(r)}g_{\alpha\beta}. \tag{5.1}$$

The rescaled connection is now

$$\overline{\Gamma}^{\mu}_{\alpha\beta}=\Gamma^{\mu}_{\alpha}+\delta^{\mu}_{\alpha}\partial_{\beta}\sigma+\delta^{\mu}_{\beta}\partial_{\alpha}\sigma-g_{\alpha\beta}g^{\mu\tau}\partial_{\tau}\sigma \tag{5.2}$$

and the Ricci tensor then becomes

$$R_{\alpha\beta}=\overset{0}{R}_{\alpha\beta}-2\sigma_{\alpha\beta}-[\Delta_{2}\sigma+2\Delta_{1}\sigma]g_{\alpha\beta}, \tag{5.3}$$

$$\Delta_{1}\sigma=g^{\mu\lambda}\partial_{\mu}\sigma\partial_{\lambda}\sigma, \tag{5.4}$$

$$\Delta_{2}\sigma=g^{\mu\lambda}\sigma_{,\mu\lambda}, \tag{5.5}$$

$$\sigma_{\mu\lambda}=\sigma_{,\mu\lambda}-\sigma_{,\mu}\sigma_{,\lambda} \tag{5.6}$$

or

$$R_{\mu\lambda}=\overset{0}{R}_{\mu\lambda}-\Delta_{\mu\lambda} \tag{5.7}$$

where

$$\Delta_{\mu\lambda}=2\sigma_{\mu\lambda}+g_{\mu\lambda}\Delta_c \tag{5.8}$$

and

$$\overset{0}{R}_{\mu\lambda}=R_{\mu\lambda}\quad(\sigma=0). \tag{5.9}$$

One finds

$$\Delta_{00}=2m(1-2m\varphi)\varphi'\sigma'+(1-2m\varphi)\Delta_c, \tag{5.10}$$

$$\Delta_{0k}=\{-4m^2\varphi\varphi'\sigma'-2m\varphi\Delta_c\}\lambda_k, \tag{5.11}$$

$$\Delta_{jk}=\left[2(1-2m\varphi)\frac{\varphi'}{r}-\Delta_c\right]\delta_{jk} +2\left[\sigma''-\frac{\sigma'}{r}-(\sigma')^2-m\left(\varphi'-\frac{2}{r}\varphi\right)\sigma'-2m^2\varphi\sigma'\varphi'-2m\varphi\Delta_c\right]\lambda_j\lambda_k, \tag{5.12}$$

and

$$\Delta_c=\Delta_2\sigma+2\Delta_1\sigma, \tag{5.13}$$

$$\Delta_2\sigma=-\nabla^2\sigma+2m\varphi\sigma''+2m\left(\varphi'+\frac{2}{r}\varphi\right)\sigma', \tag{5.14}$$

$$\Delta_1\sigma=(2m\varphi-1)(\sigma')^2. \tag{5.15}$$

The gravitational field is now defined by the two scalar functions $\varphi(r)$ and $\sigma(r)$. The Ricci tensor becomes

$$R_{00}=(\hat{\varphi}-1)[\tfrac{1}{2}\nabla^2\hat{\varphi}+\hat{\varphi}'\sigma'+\Delta_c], \tag{5.16}$$

$$R_{0k}=\hat{\varphi}[\tfrac{1}{2}\nabla^2\hat{\varphi}+\hat{\varphi}'\sigma'+\Delta_c]\lambda_k, \tag{5.17}$$

$$R_{jk}=R^a\eta_{jk}+R^b\lambda_j\lambda_k, \tag{5.18}$$

where

$$R^a=-\frac{1}{r}\left(\hat{\varphi}'+\frac{2}{r}\hat{\varphi}\right)-2(1-\hat{\varphi})\frac{\sigma'}{r}-\Delta_c, \tag{5.19}$$

$$R^b=\frac{1}{2}\hat{\varphi}''-\frac{1}{r^2}\hat{\varphi}+\frac{1}{2}\hat{\varphi}\nabla^2_{\hat{\varphi}}-2\left[\sigma''-\frac{\sigma'}{r}-(\sigma')^2-\left(\frac{\hat{\varphi}'}{2}-\frac{1}{r}\hat{\varphi}\right)\sigma'-\frac{1}{2}\hat{\varphi}\hat{\varphi}'\sigma'-\hat{\varphi}\Delta_c\right], \tag{5.20}$$

$$\hat{\varphi}=2m\varphi, \tag{5.21}$$

$$\Delta_c = -\nabla^2\sigma + \hat{\varphi}\sigma'' + \left(\hat{\varphi}' + \frac{2}{r}\hat{\varphi}\right)\sigma' + 2(\hat{\varphi}-1)(\sigma')^2. \tag{5.22}$$

VI. THE SPIN CONNECTION

The Dirac matrices corresponding to the Kerr–Schild metric (before rescaling) may be chosen as follows:[5]

$$\gamma_\alpha = \eta_\alpha - \sqrt{2m}\,\ell_\alpha \eta_5, \tag{6.1}$$

where

$$(\eta_\alpha, \eta_\beta)_+ = 2\eta_{\alpha\beta}, \tag{6.2}$$

$$\eta_5 = \eta_0\eta_1\eta_2\eta_3. \tag{6.3}$$

A choice more useful for computing the spin connection is[7]

$$\gamma_\alpha = \eta_\alpha - m\ell_\alpha\hat{\tau}, \tag{6.4}$$

where

$$\hat{\tau} = \ell^\mu \eta_\mu \tag{6.5}$$

or

$$\gamma_\alpha = e^\mu_\alpha \eta_\mu \tag{6.6}$$

with

$$e^\mu_\alpha = \delta^\mu_\alpha - m\ell_\alpha\ell^\mu. \tag{6.7}$$

If $g_{\mu\lambda}$ is rescaled, then γ_μ must also be rescaled and

$$\overline{\gamma}_\mu = \overline{e}^{\lambda}_{\mu}\eta_\lambda, \tag{6.8}$$

where

$$\overline{e}^{\lambda}_{\mu} = e^{\sigma(r)}e^\lambda_\mu \tag{6.9}$$

while the new spin connection $\overline{\Gamma}_\lambda$ must satisfy

$$\partial_\lambda\overline{\gamma}_\mu - \overline{\Gamma}^\alpha_{\mu\lambda}\overline{\gamma}_\alpha + (\overline{\gamma}_\mu, \overline{\Gamma}_\lambda) = 0. \tag{6.10}$$

Here the Cristoffel connection $\overline{\Gamma}^\alpha_{\mu\lambda}$ is given by (5.2).

Let us set

$$\Gamma_\lambda = g_{\lambda\alpha\beta}(\eta^\alpha, \eta^\beta) = 2g_{\lambda[\alpha\beta]}\eta^\alpha\eta^\beta, \tag{6.11}$$

$$\overline{\Gamma}_\lambda = \overline{g}_{\lambda\alpha\beta}(\overline{\eta}^\alpha, \overline{\eta}^\beta) = 2\overline{g}_{\lambda[\alpha\beta]}\overline{\eta}^\alpha\overline{\eta}^\beta. \tag{6.12}$$

Then (6.10) leads to the following relations:

$$-8\overline{g}_{\lambda[\beta\rho]} = (e^{-1})^\mu_\beta\overline{\Gamma}^\alpha_{\mu\lambda}e_{\alpha\rho} + (e^{-1})^\mu_\beta\partial_\lambda e_{\mu\rho} + \eta_{\rho\beta}\partial_\lambda\sigma. \tag{6.13}$$

Since the second and third terms are symmetric in β and ρ, they will cancel when multiplied by the commutator in (6.12) and therefore may be dropped. Then

$$-8\overline{g}_{\lambda[\beta\rho]}=(e^{-1})^{\mu}_{\beta}\overline{\Gamma}^{\alpha}_{\mu\lambda}e_{\alpha\rho}. \tag{6.14}$$

Set

$$\overline{\Gamma}^{\mu}_{\alpha\lambda}=\Gamma^{\mu}_{\alpha\lambda}+\Delta^{\mu}_{\alpha\lambda}, \tag{6.15}$$

$$\overline{g}_{\lambda[\beta\rho]}=g_{\lambda[\beta\rho]}+E_{\lambda[\beta\rho]}. \tag{6.16}$$

Then

$$-4E_{\lambda\beta\rho}=(e^{-1})^{\mu}_{\beta}\Delta^{\alpha}_{\mu\lambda}e_{\alpha\rho}+\eta_{\beta\rho}\partial_{\lambda}\sigma, \tag{6.17}$$

where

$$\Delta^{0}_{\mu\lambda}=\delta^{\alpha}_{\mu}\partial_{\lambda}\sigma+\delta^{\alpha}_{\lambda}\partial_{\mu}\sigma-g_{\mu\lambda}g^{\alpha\tau}\partial_{\tau}\sigma. \tag{6.18}$$

Since $E_{\lambda\beta\rho}$ is antisymmetric in β and ρ, we may drop the second term in (6.17). Reduction of (6.14) and (6.17) gives

$$g^{\alpha\beta}_{\mu}=-\frac{m}{4}\partial^{\alpha}(\not{\ell}_{\mu}\not{\ell}^{\beta}), \tag{6.19}$$

$$E^{\alpha\beta}_{\mu}=\tfrac{1}{4}[e^{\alpha}_{\mu}\partial^{\beta}\sigma-(\not{\ell}^{\mu}\partial_{\mu}\sigma)\not{\ell}^{\alpha}\delta^{\beta}_{\mu}], \tag{6.20}$$

$$\overline{\Gamma}_{\mu}=\tfrac{1}{4}[-m\partial^{\alpha}(\not{\ell}_{\mu}\not{\ell}^{\beta})+e^{\alpha}_{\mu}\partial^{\beta}\sigma-m\not{\ell}^{\alpha}\delta^{\beta}_{\mu}\nabla\sigma](\gamma_{\alpha},\gamma_{\beta}), \tag{6.21}$$

where

$$\nabla\sigma=\not{\ell}^{\alpha}\partial_{\alpha}\sigma. \tag{6.22}$$

VII. THE SPINOR FIELD EQUATIONS

In the rescaled Kerr–Schild metric Eq. (2.12) becomes

$$\overline{\gamma}^{\mu}(\partial_{\mu}+\overline{\Gamma}_{\mu})\psi-\frac{\partial V}{\partial\overline{\psi}}=0, \tag{7.1}$$

where $\overline{\Gamma}_{\mu}$ is the spin connection and $\partial V/\partial\psi$ represents all the nonlinear interactions. We shall assume a four-component spinor and adopt the following ansatz:

$$\psi=Z\Omega+W\beta\Omega \tag{7.2}$$

with

$$\Omega=\frac{1}{\sqrt{2}}\begin{pmatrix}1\\0\\\lambda_3\\\lambda_+\end{pmatrix},\quad \beta=\begin{pmatrix}I&0\\0&-I\end{pmatrix}, \tag{7.3}$$

when $\vec{\lambda}$ is the three-vector defined by (4.5) and $\lambda_+=\lambda_1+i\lambda_2$. If Z and W are complex conjugates so that

$$Z-\tfrac{1}{2}(F+iG),$$
$$W=\tfrac{1}{2}(F-iG), \tag{7.4}$$

then

$$\psi=\frac{1}{\sqrt{2}}e^{i\omega t}\begin{pmatrix} F \\ 0 \\ i\,G\lambda_3 \\ i\,G\lambda_+ \end{pmatrix}=\frac{1}{\sqrt{2}}e^{i\omega t}\begin{pmatrix} F \\ 0 \\ i\,G\cos\theta \\ i\,G\sin\theta e^{i\phi} \end{pmatrix}. \tag{7.5}$$

If the ambient space is flat and ψ is described by (7.5) then ψ is also an eigenfunction of the Dirac angular momentum with spin 1/2. Therefore in the limit of weak gravitational field we may require that ψ approach (7.5).[3]

By (6.5)

$$\hat{\tau}\Omega=0,$$
$$\hat{\tau}\beta\Omega=2\not{\ell}_0\Omega. \tag{7.6}$$

Define

$$\tau=\eta_k\lambda_k=-\eta^k\lambda_k, \tag{7.7}$$

then

$$\tau\Omega=\beta\Omega,$$
$$\tau\beta\Omega=-\Omega \tag{7.8}$$

also

$$\hat{\tau}^2=0, \quad \tau^2=-1, \tag{7.9}$$

$$\frac{d\tau}{dr}=0. \tag{7.10}$$

The following identity is also useful:

$$\eta_s\partial_s=\tau\left(\frac{d}{dr}+\frac{1}{r}\right)-\frac{1}{r}\tau\beta k, \tag{7.11}$$

where

$$k=\beta(\vec{\Sigma}\vec{L}+1), \quad \vec{L}=\vec{r}\times\vec{p}. \tag{7.12}$$

Here

$$\vec{\Sigma}=\begin{pmatrix} \vec{\sigma} & 0 \\ 0 & \vec{\sigma} \end{pmatrix}. \tag{7.13}$$

Note also

$$k\beta=\beta k, \tag{7.14}$$
$$k\Omega=\Omega. \tag{7.15}$$

To reduce (7.1) let us next compute

$$\gamma^\mu \partial_\mu \psi = \eta^\mu \partial_\mu \psi + m \hat{\tau}^{\not\mu} \partial_\mu \psi. \tag{7.16}$$

By (7.2) and (7.11) we find

$$\overline{\gamma}^\mu \partial_\mu \psi = e^\sigma \left[(1-2m\varphi) W' + i\omega(1+2m\varphi) W + (W-Z)\frac{1}{r} \right] \Omega$$
$$- e^\sigma \left[Z' - i\omega Z + (Z-W)\left(\frac{1}{r}\right) \right] \beta\Omega. \tag{7.17}$$

By (6.8) and (6.21) the spin connection gives the contribution

$$\overline{\gamma}^\mu \overline{\Gamma}_\mu \psi = (W f_2 \Omega + Z f_1 \beta\Omega) e^\sigma, \tag{7.18}$$

where

$$f_1 = \tfrac{3}{2}\sigma', \tag{7.19}$$

$$f_2 = 3m\sigma'\varphi - \frac{3}{2}\sigma' - m\left(\varphi' + \frac{2}{r}\varphi \right). \tag{7.20}$$

Let us choose the invariant nonlinear interaction to be a functional of

$$I = \tilde{\psi}\psi$$
$$= \overline{S}W + Z\overline{W}. \tag{7.21}$$

Then the nonlinear term in the equation of motion is

$$\frac{\partial V}{\partial \overline{\psi}} = \frac{dV}{dI}\frac{\partial I}{\partial \overline{\psi}} \tag{7.22}$$

$$= V' \psi. \tag{7.23}$$

For definiteness we take

$$V(I) = m_0 I + \frac{g}{2} I^2, \quad m_0 > 0, \ g < 0. \tag{7.24}$$

Then

$$\frac{\partial V}{\partial \overline{\psi}} = (m_0 + gI)\psi = [m_0 Z + g(\overline{Z}W + \overline{W}Z)Z]\Omega + [m_0 W + g(\overline{Z}W + \overline{W}Z)W]\beta\Omega \tag{7.25}$$

and the differential equation (7.1) becomes by (7.17) and (7.18)

$$\mathcal{Z}\Omega + \mathcal{W}(\beta\Omega) = 0, \tag{7.26}$$

where

$$\mathcal{Z}=(1-2m\varphi)W'+(W-Z)\frac{1}{r}+[i\omega(1+2m\varphi)+f_2]W-e^{-\sigma}[m_0+g(\bar{Z}W+\bar{W}Z)]Z \tag{7.27}$$

and

$$\mathcal{W}=-Z'+(i\omega+f_1)Z-(Z-W)\frac{1}{r}-e^{-\sigma}[m_0+g(\bar{Z}W+\bar{W}Z)]W. \tag{7.28}$$

The spinors Ω and $\beta\Omega$ are orthogonal:

$$\Omega^{+}(\beta\eta)=0. \tag{7.29}$$

Then by (7.26)

$$\mathcal{Z}=\mathcal{W}=0. \tag{7.30}$$

By (7.27) and (7.28) one sees that (7.30) implies two complex differential equations for z and w or four real equations for real components (Z_1,Z_2,W_1,W_2).

VIII. THE SOURCE OF THE GRAVITATIONAL FIELD

The source of the gravitational field, the energy-momentum tensor of the spinor field, is described by (2.8).

Let us consider

$$:\bar{\psi}\bar{\gamma}_\alpha\bar{\nabla}_\beta\psi: \tag{8.1}$$

where $\bar{\psi}$ is the usual Dirac adjoint and where

$$\nabla_\beta=\partial_\beta+\bar{\Gamma}_\beta. \tag{8.2}$$

Here $\bar{\Gamma}_\beta$ is the spin connection given by (6.21).

Let us decompose the bilinear part of the energy-momentum tensor as follows:

$$\overset{0}{\Theta}_{\alpha\beta}=:\bar{\psi}\bar{\gamma}_\alpha\partial_\beta\psi:, \tag{8.3}$$

$$\overset{1}{\Theta}_{\alpha\beta}=:\bar{\psi}\bar{\gamma}_\alpha\bar{\Gamma}_\beta\psi: \tag{8.4}$$

where ψ is given by (7.2).

It turns out that all the matrix elements of (8.3) and (8.4) are expressible in terms of λ_k and μ_k given by

$$\lambda_k=\Omega^{\dagger}\eta_k\beta\Omega \tag{8.5}$$

and

$$\mu_k=\Omega^{\dagger}\eta_k\Omega. \tag{8.6}$$

Here λ_k is the three-vector defined by (4.5) and alternatively expressed as

$$\lambda_k=(\sin\theta\cos\phi,\sin\theta\sin\phi,\cos\theta) \tag{8.7}$$

while $\vec{\mu}$ is an imaginary vector orthogonal to $\vec{\lambda}$ and given by

$$\mu_k = i\epsilon_{ks3}\lambda_s . \tag{8.8}$$

One finds that the gravitational equations are of the form

$$A\lambda_k + B\mu_k = 0 \tag{8.9}$$

and since $\vec{\lambda}$ and $\vec{\mu}$ are orthogonal

$$A = B = 0. \tag{8.10}$$

The corresponding gravitational equations then reduce to

$$B = \overline{W}Z - \overline{Z}W = 0 \tag{8.11}$$

becomes a constraint on the components of the spinor ψ.

Equation (8.11) implies

$$W = uZ, \tag{8.12}$$

where u is a real function. One finds for the complete energy-momentum tensor:

$$\Theta_{\alpha\beta} = \overset{0}{\Theta}_{\alpha\beta} + \overset{1}{\Theta}_{\alpha\beta} - \tfrac{1}{2}Vg_{\alpha\beta}, \tag{8.13}$$

$$\Theta_{00} = \frac{e^{\sigma}}{2}\left\{\left[\left(1 - \frac{3\hat{\varphi}}{2} + \varphi^2\right)\sigma' + \frac{(\hat{\varphi}-1)}{2}\,\frac{\hat{\varphi}'}{2}\right]\Delta + \left[\left(\frac{\hat{\varphi}}{2} - \frac{\hat{\sigma}^2}{2}\right)\sigma' - \frac{\hat{\varphi}\hat{\varphi}'}{4}\right]\Sigma\right\} - \frac{1}{2}(1-\hat{\varphi})e^{2\sigma}V, \tag{8.14}$$

$$\begin{aligned}\Theta_{0j} = \Bigg[\Bigg\{\Bigg[\frac{1}{2}\left(1 - \frac{\hat{\varphi}}{2}\right)\Sigma' + \frac{\hat{\varphi}}{2}\Delta'\Bigg] + \frac{\Delta}{4}\left[\frac{\hat{\varphi}'}{2}(\hat{\varphi}-1) + \sigma'\left(-3\,\frac{\hat{\varphi}}{2} + \hat{\varphi}^2\right)\right] \\ + \frac{\Sigma}{4}\left[-\frac{\hat{\varphi}'}{2}(\hat{\varphi}'+1) + \sigma'\left(1 - \frac{\hat{\varphi}}{2} - \hat{\varphi}^2\right)\right]\Bigg\}e^{\sigma} + \frac{1}{2}\,\hat{\varphi}Ve^{2\sigma}\Bigg]\lambda_j\end{aligned} \tag{8.15}$$

after having dropped the μ_j term

$$\begin{aligned}\Theta_{jk} = \Bigg[\Bigg\{\Bigg[\left(\frac{\hat{\varphi}}{2} - 1\right)\sigma' + \frac{1}{r}\,\frac{\hat{\varphi}}{2} - \frac{2}{r}\Bigg]\frac{\Delta}{2} + \left[\frac{\hat{\varphi}}{2}\sigma' + \frac{1}{r}\,\frac{\hat{\varphi}}{2}\right]\frac{\Sigma}{2}\Bigg\}e^{\sigma} - \frac{1}{2}Ve^{2\sigma}\Bigg]\eta_{jk} \\ + \Bigg[\Bigg\{\Bigg[-\frac{\hat{\varphi}}{2}\Sigma' + \left(1 + \frac{\hat{\varphi}}{2}\right)\Delta'\Bigg] + \left[\frac{\hat{\varphi}}{2r} - \frac{2}{r} + \frac{\hat{\varphi}\hat{\varphi}'}{4} + \left(-1 + \frac{\hat{\varphi}}{2} + \hat{\varphi}^2\right)\sigma'\right]\frac{\Delta}{2} \\ + \left[\frac{\hat{\varphi}}{2r} - \left(1 + \frac{\hat{\varphi}}{2}\right)\frac{\hat{\varphi}'}{2} - \left(\frac{\hat{\varphi}}{2} + \hat{\varphi}^2\right)\sigma'\right]\frac{\Sigma}{2}\Bigg\}e^{\sigma} + \frac{1}{2}\,\hat{\varphi}Ve^{2\sigma}\Bigg]\lambda_j\lambda_k .\end{aligned} \tag{8.16}$$

Here

$$\begin{aligned}\Sigma &= \overline{\psi}\eta_0\psi = |Z|^2 + |W|^2, \\ \Delta &= |Z|^2 - |W|^2.\end{aligned} \tag{8.17}$$

Let us also write

$$\Theta_{jk} = \Theta^a\eta_{jk} + \Theta^b\lambda_j\lambda_k .$$

IX. REDUCTION OF THE SPINOR EQUATION

Because of the constraint (8.12) ($W=uZ$) it is now possible to show that one may reduce the equations (7.30) from a system of four real equations with four real functions to two real equations with two real functions.

Set

$$\alpha=1-2m\varphi,$$
$$\beta=1+2m\varphi. \tag{9.1}$$

Then

$$\mathcal{Z}=\alpha W'+\frac{1}{r}(W-Z)+[i\beta\omega+f_2]W-e^{-\sigma}[m_0+g(\overline{Z}W+\overline{W}Z)]Z=0, \tag{9.2}$$

$$\mathcal{W}=Z'-(i\omega+f_1)Z-\frac{1}{r}(W-Z)+e^{-\sigma}[m_0+g(\overline{Z}W+\overline{W}Z)]W=0. \tag{9.3}$$

Equation (9.2) and (9.3) may be combined by eliminating Z'/Z. Then

$$\alpha u'+[\alpha u^2+(1-\alpha)u-1]\frac{1}{r}+i\omega(\alpha+1)u+(f_2+\alpha f_1)u$$
$$-e^{-\sigma}[m_0+g(\overline{Z}W+\overline{W}Z)](1+\alpha u^2)=0. \tag{9.4}$$

Since all terms in this equation are real except $2i\omega(\alpha+1)u$, it follows that $\omega=0$.

It then follows from (8.12) and (9.3) that Z'/Z is also real or that the argument of Z is constant and may be equated to zero. Then Z may be taken real, and we may therefore take both W and Z real in (9.2) and (9.3).

$$\alpha W'+(W-Z)\frac{1}{r}+f_2W-e^{-\sigma}[m_0+2gWZ]Z=0, \tag{9.5}$$

$$Z'-f_1Z-(W-Z)\frac{1}{r}+e^{-\sigma}[m_0+2gWZ]W=0. \tag{9.6}$$

X. GRAVITATIONAL FIELD EQUATIONS

The gravitational equations (2.6) may be reduced to the following four equations:

$$(1-\hat{\varphi})[-\tfrac{1}{2}\nabla^2\hat{\varphi}-\hat{\varphi}'\sigma'-\Delta_c]=K\Theta_{00}, \tag{10.1}$$

$$\hat{\varphi}\left[\frac{1}{2}\nabla^2\hat{\varphi}+\hat{\varphi}'\sigma'+\Delta_c\right]\lambda_k=K\Theta_{0k}, \tag{10.2}$$

$$\left[\frac{1}{r}\left(\hat{\varphi}'+\frac{2\hat{\varphi}}{r}\right)-2(1-\hat{\varphi})\frac{\sigma'}{r}+\Delta_c\right]=-K\Theta^a, \tag{10.3}$$

$$\frac{\hat{\varphi}''}{2}-\frac{2\hat{\varphi}}{r^2}+\frac{1}{2}\hat{\varphi}\nabla^2\hat{\varphi}-2\left[\sigma''-\frac{\sigma'}{r}-(\sigma')^2-\left(\frac{\hat{\varphi}'}{2}-\frac{1}{r}\hat{\varphi}\right)\sigma'-\frac{1}{2}\hat{\varphi}\hat{\varphi}'\sigma'-\hat{\varphi}\Delta_c\right]=K\Theta^b, \tag{10.4}$$

where $\hat{\varphi}=2m\varphi$,

$$\Theta_{jk}=\Theta^{a}\eta_{jk}+\Theta^{b}\lambda_{j}\lambda_{k}. \tag{10.5}$$

Δ_c is given by (5.13), Θ by (8.14)–(8.16). By (10.1) and (10.2)

$$\hat{\varphi}\Theta_{00}+(\Theta_{0k}\lambda_{k})(1-\hat{\varphi})=0. \tag{10.6}$$

To study these equations near the origin impose solitonic boundary conditions requiring that all fields be finite with flat tangents at the origin. Then

$$\hat{\varphi}'(0)=\sigma'(0)=Z'(0)=W'(0)=0, \tag{10.7}$$

$$\Delta_c(0)=[-\nabla^2\sigma+\hat{\varphi}\sigma'']_{r=0}. \tag{10.8}$$

From (8.17)

$$\Delta(0)=0, \quad \Sigma(0)=2Z^2. \tag{10.9}$$

By (8.14)–(8.17)

$$[\Theta_{00}]_{r=0}=\frac{e^{2\sigma}}{2}[\hat{\varphi}(0)-1]V[I(0)], \tag{10.10}$$

$$[\Theta_{0k}]_{r=0}=\frac{e^{2\sigma}}{2}V[I(0)]\hat{\varphi}(0)\lambda_{k}, \tag{10.11}$$

$$[\Theta^{a}_{jk}]_{r=0}=\left[\frac{\Sigma}{4}\left(\frac{\hat{\varphi}}{r}\right)e^{\sigma}-\frac{e^{2\sigma}}{2}V\right]_{r=0}\eta_{jk}, \tag{10.12}$$

$$[\Theta^{b}_{jk}]_{r=0}=\left[\frac{\Sigma}{4}\left(\frac{\hat{\varphi}}{r}\right)e^{\sigma}+\hat{\varphi}e^{2\sigma}\frac{V}{2}\right]_{r=0}\lambda_{j}\lambda_{k}. \tag{10.13}$$

By (10.3)

$$\lim_{r\to 0}\left\{2\hat{\varphi}(r)-2r^2\left[(1-\hat{\varphi}(r))\frac{\sigma'(r)}{r}-\frac{\hat{\varphi}}{2}\sigma''+\frac{\nabla^2\sigma}{2}\right]\right\}=\lim_{r\to 0}\frac{K}{2}r^2\left(\hat{\varphi}\frac{\Sigma}{r}-e^{2\sigma}V\right). \tag{10.14}$$

Therefore

$$\hat{\varphi}(0)=0. \tag{10.15}$$

The vanishing of $\hat{\varphi}(r)$ at the origin now implies the additional reduction of (10.1)

$$-\frac{1}{2}\hat{\varphi}''(0)+\sigma''(0)=-\frac{K}{2}e^{2\sigma(0)}V[I(0)]. \tag{10.1$'$}$$

XI. THE SPECIAL RELATIVISTIC EIGENVALUE PROBLEM

In a previous study of a nonlinear scalar field coupled to the gravitational field it was found that the eigensolutions of the complete set of differential equations is critically dependent on the behavior of the nonlinear component alone. By following the earlier argument we shall now find, however, that the pattern for the nonlinear spinor problem is quite different.

As before, we begin by associating an approximately conserved function with the nonlinear equations after they have been decoupled from the gravitational field. In this special relativistic limit where $(m=0,\ \sigma=0)$ we have $f_1=f_2=0$. After deletion of the mass and nonlinear coupling the two equations (9.5) and (9.6) become

$$W'-\frac{dV}{dI}Z+\frac{W-Z}{r}=0, \tag{11.1}$$

$$Z'+\frac{dV}{dI}W-\frac{W-Z}{r}=0. \tag{11.2}$$

We consider the auxiliary equations obtained by deleting the explicit dependence on r,

$$W'-\mathcal{V}Z=0, \tag{11.3}$$

$$Z'+\mathcal{V}W=0, \tag{11.4}$$

where

$$\mathcal{V}=\frac{dV}{dI}. \tag{11.5}$$

Any invariant function $(\mathcal{F})$ associated with these equations satisfies

$$\mathcal{F}'=\frac{\partial\mathcal{F}}{\partial W}W'+\frac{\partial\mathcal{F}}{\partial Z}Z'=0 \tag{11.6}$$

or

$$\mathcal{F}'=\mathcal{V}\left(W\frac{\partial}{\partial Z}-Z\frac{\partial}{\partial Z}\right)\mathcal{F}=0. \tag{11.7}$$

Hence if F is a functional of W^2+Z^2, it will be conserved for any solution of the set (11.3), (11.4).

For the complete equations (11.1) and (11.2) however, we have

$$\mathcal{F}'=\frac{\partial\mathcal{F}}{\partial W}\left(\mathcal{V}Z+\frac{Z-W}{r}\right)+\frac{\partial\mathcal{F}}{\partial Z}\left(-\mathcal{V}W-\frac{Z-W}{r}\right)=\left(\frac{\partial\mathcal{F}}{\partial W}-\frac{\partial\mathcal{F}}{\partial Z}\right)\frac{Z-W}{r} \tag{11.8}$$

$$=2(W-Z)\frac{\partial\mathcal{F}}{\partial\Sigma}\left(\frac{Z-W}{r}\right). \tag{11.9}$$

Then

$$\mathcal{F}'=-2\frac{\partial\mathcal{F}}{\partial\Sigma}(W-Z)^2. \tag{11.10}$$

In the simplest case

$$\mathcal{F}(\Sigma)=\Sigma. \tag{11.11}$$

Then

$$\mathcal{F}'=-\frac{2(W-Z)^2}{r}\leqslant 0. \tag{11.12}$$

According to (11.3) and (11.4) the representative point moves in the circle ($\Sigma = \text{const}$) in the $W-Z$ plane. According to (11.1) and (11.2) the motion of this point deviates from the circle to satisfy (11.12), which directs the motion always toward lower values of F, i.e., toward the origin. The representative point will therefore spiral into the origin.

If the corresponding curve in configuration space represents an eigensolution it must satisfy the following boundary conditions at the origin and at ∞:

At $r=0$,

$$W' = Z' = 0 \tag{11.13}$$

and at $r=\infty$,

$$W' = Z' = W = Z = 0. \tag{11.14}$$

To satisfy these boundary conditions on Eqs. (11.1) and (11.2) the eigensolution must begin at a point on the line $W=Z$ and it must end at the origin.

For the particular choice of (2.9) we have

$$I = 2ZW. \tag{11.15}$$

The $\mathcal{V}$ is constant on the hyperbolas

$$WZ = \text{constant} \tag{11.16}$$

and along the asymptote $\mathcal{V}$ is a function of Z^2.

In an earlier discussion of the special relativistic limit the Dirac spinor was taken to be (7.5). As long as there is no gravitational coupling there is no problem with this ansatz, and if one chooses V to be given by (7.25) one finds according to Eqs. (16a), (16b) of Ref. 3

$$F' + \mu G + 2\gamma(G^2 - F^2)G = 0, \tag{11.17}$$

$$G' + \mu F + \frac{2}{r}G + 2\gamma(G^2 - F^2)F = 0, \tag{11.18}$$

where we also set $\omega = 0$ and μ and γ are the. Here F and G are the large and small components of ψ as given by (7.5). The dissipative function $\bar{H}$ associated with these equations is

$$\bar{H} = \mu(G^2 - F^2) + \gamma(G^2 - F^2)^2 \tag{11.19}$$

leading to a phase portrait with two attractions.

To compare (11.18) and (11.19) with the present equations (11.1) and (11.2) set

$$f = W + Z, \tag{11.20}$$

$$g = W - Z. \tag{11.21}$$

Then (11.1) and (11.2) become

$$f' + \mathcal{V}g = 0, \tag{11.22}$$

$$g' - \mathcal{V}f + \frac{2g}{r} = 0, \tag{11.23}$$

where

$$\mathcal{V} = m_0 + \gamma I \tag{11.24}$$

and

$$I=2WZ+\tfrac{1}{2}(f^2-g^2). \tag{11.25}$$

Then

$$f'+m_0g+\frac{\gamma}{2}(f^2-g^2)g=0, \tag{11.26}$$

$$g'-m_0f+\frac{2g}{2}-\frac{\gamma}{2}(f^2-g^2)f=0. \tag{11.27}$$

Here f and g are large and small components in (11.26) and (11.27) just as F and G are large and small components in (11.17) and (11.18).

There is a term by term correspondence between the pair (11.26), (11.27) and the pair (11.17), (11.18) except for signs. The difference in signs, however, gives rise to a completely different phase portrait for the dissipative function in the two cases. In particular, there is only one attractor associated with (11.26) and (11.27) while there are two attractors in the other case.

The distinction between the two cases may be pushed a little further as follows.

The dissipative function for the (f, g) pair may be chosen as a function of (f^2+g^2) since

$$\frac{d}{dr}(f^2+g^2)=-\frac{4g^2}{r}\leqslant 0 \tag{11.28}$$

by (11.26) and (11.27). The corresponding argument for the (F, G) pair yields

$$\frac{d}{dr}(F^2-G^2)=-\frac{4G^2}{r}\leqslant 0. \tag{11.29}$$

Therefore one may choose a function of f^2+g^2 in one case and of F^2-G^2 in the other to qualify as a dissipative function. In the (F, G) case we chose the dissipative function to be the Hamiltonian of the associated mechanical problem (with the explicit r term deleted), i.e., the Hamiltonian equations corresponding to the Hamiltonian (11.19) are the differential equations (11.17) and (11.18) where G plays the role of the momentum. The corresponding step with the (f, g) pair is not possible because (11.26) and (11.27) are not derivable from a Hamiltonian as one may see as follows.

If a Hamiltonian did exist for this set then we would have

$$\begin{aligned}\frac{\partial^2 H}{\partial q\,\partial p}&=\frac{\partial \dot{q}}{\partial q}(q,p),\\ \frac{\partial^2 H}{\partial p\,\partial q}&=-\frac{\partial \dot{p}}{\partial p}(q,p),\end{aligned} \tag{11.30}$$

or

$$\frac{\partial \dot{q}(p,q)}{\partial q}=-\frac{\partial \dot{q}(q,p)}{\partial p}. \tag{11.31}$$

Since f and g play the roles of the generalized coordinate and momentum, respectively, and since r plays the role of the time, the condition (11.31) reads for the pair (f, g),

$$\frac{\partial f'(f,g)}{\partial f}=-\frac{\partial g'(f,g)}{\partial g}. \tag{11.32}$$

Since this relation is not satisfied for Eqs. (11.26) and (11.27), there is no corresponding Hamiltonian.

Additionally one cannot retain the (F,G) description with (8.11) since the pair (8.11), (7.4), implies

$$Z^2 = W^2 \tag{11.33}$$

and therefore either $F=0$ or $G=0$.

XII. BEHAVIOR AT LARGE r

At large r we require that all functions and their first and second derivatives vanish. We also drop all terms in $\Theta_{\mu\nu}$ of order $1/r$. Then by (10.1)–(10.4) in the limit

$$\Theta_{\mu\nu} = 0 \tag{12.1}$$

and by (8.15)–(8.17)

$$V(I) = 0. \tag{12.2}$$

By (7.25) and the preceding equation

$$I = 0, \quad \frac{2\mu}{\gamma}. \tag{12.3}$$

Let us choose $I=0$. Then

$$\lim_{r\to 0}(f^2 - g^2) = 0 \tag{12.4}$$

by (11.26).

In the limit (11.27) and (11.28) become

$$f' + \mu g = 0, \tag{12.5}$$

$$g' - \mu f + \frac{2g}{r} = 0, \tag{12.6}$$

or

$$g'' + \frac{2}{r}g' + \mu^2 g - \frac{2}{r^2}g = 0. \tag{12.7}$$

f and g are of opposite parity and since $f(0)\neq 0$ we take f even. Then to order $1/r$,

$$f = \frac{\sin \mu\nu}{r} \tag{12.8}$$

and

$$g = \frac{\cos \mu\nu}{r}. \tag{12.9}$$

In contrast to this behavior the (F,G) pair approach zero as $e^{\mu\nu}/r$.

XIII. SOLUTIONS OF THE GRAVITATIONAL FIELD EQUATIONS

First we consider the solutions to the gravitational field equations (10.1)–(10.5) when the matter fields are set to zero.

Equation (10.1) gives

$$\hat{\varphi}''-(1-2\hat{\varphi})\sigma''=-\frac{2}{r}\hat{\varphi}'-4\sigma'\hat{\varphi}'+\frac{2}{r}(1-2\hat{\varphi})\sigma'+2(1-2\hat{\varphi})(\sigma')^2. \tag{13.1}$$

Multiplying (10.5) by $\lambda^j\lambda^k$ and contracting we obtain

$$(1+2\hat{\varphi})\hat{\varphi}''-(3-4\hat{\varphi}^2)\sigma''=-\frac{2}{r}(1+2\hat{\varphi})\hat{\varphi}'-(4+8\hat{\varphi})\sigma'\hat{\varphi}'+\frac{1}{r}(2-8\hat{\varphi}^2)\sigma'-8\hat{\varphi}^2(\sigma')^2. \tag{13.2}$$

The preceding two equations can be combined to solve for $\hat{\varphi}''$ and σ'':

$$\sigma''=(\sigma')^2 \tag{13.3}$$

and

$$\hat{\varphi}''=-\frac{2}{r}\hat{\varphi}'-4\sigma'\hat{\varphi}'+\frac{2}{r}(1-2\hat{\varphi})\sigma'+3(1-2\hat{\varphi})(\sigma')^2. \tag{13.4}$$

Equation (13.3) gives a solution of the form

$$\sigma\sim-\log(r), \tag{13.5}$$

which when substituted into (13.4) leads to

$$\hat{\varphi}\sim\pm r^2. \tag{13.6}$$

It is apparent that the coupling of the dilaton field with the Kerr–Schild scalar does not give a finite theory. We have proceeded to study the full set of equations (10.1)–(10.5), including the matter fields, in order to find out if these fields provide the necessary attractive properties to yield finite soliton type solutions.

Once again we selected Eq. (10.1) and the contraction of Eq. (10.5) with $\lambda^j\lambda^k$,

$$\sigma''=(\sigma')^2-K\frac{e^{\sigma}}{4}\left[4Z'Z-4W'W(1+2\hat{\varphi})+Z^2\left(\sigma'-4\frac{\hat{\varphi}'\hat{\varphi}}{(1-2\hat{\varphi})}\right)+W^2\sigma'(1-2\hat{\varphi})\right], \tag{13.7}$$

$$\hat{\varphi}''=-\frac{2}{r}\hat{\varphi}'-4\sigma'\hat{\varphi}'+\frac{2}{r}(1-2\hat{\varphi})\sigma'+3(1-2\hat{\varphi})(\sigma')^2-K\frac{e^{\sigma}}{4}\left[Z^2\left[(3-2\hat{\varphi})\sigma'-4\frac{(1-\hat{\varphi})}{(1-2\hat{\varphi})}\hat{\varphi}'\right]\right.$$
$$\left.+W^2[(4\hat{\varphi}^2-1)\sigma'+2\hat{\varphi}']+2Z'Z(1-2\hat{\varphi})+2W'W(4\hat{\varphi}^2-1)-2e^{\sigma}V\right]. \tag{13.8}$$

To look for numerical solutions it is necessary to recast Eqs. (9.6), (9.7), (13.7), and (13.8) in dimensionless form. This was accomplished by introducing a fundamental length r_0 to rescale the variable r and a fundamental field strength ψ_0 to rescale the fermionic fields. The equations of interest depend on three parameters: $\beta=m_0r_0^2$, $\gamma=gr_0^2\psi_0^2/2$ and $\delta=K\psi_0^2$. To validate the numerical analysis we used two different methods: the MATLAB differential equation suite[8] and the subroutine SDRIV2 from the SLATE package.[9]

We explored a large portion of the three-dimensional parameter space looking for finite solutions for the fields σ, $\hat{\varphi}$, W, and Z. By systematically exploring the three-dimensional parameter

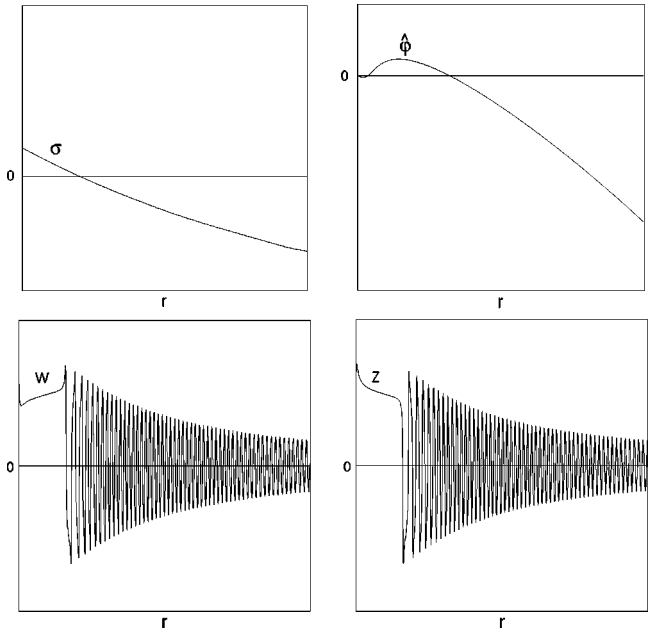

FIG. 1. Type A solution with nonsingular fields at finite r. The parameter values are: $\beta=0.044$, $\gamma=14.257$, and $\delta=-0.001$ (*since* K is negative).

space two types of solutions were encountered. The solutions of type A are shown in Fig. 1. While the fermion fields settle into the damped oscillations which characterize the special relativistic solutions, the fields σ and $\hat{\varphi}$, while finite at small r, tend to $-\infty$ for large values of r. These solutions are characterized by a strong coupling for the four fermion interaction (γ) in comparison to the mass (β) and the fermion field strength (δ). The values of the parameters for the solutions displayed in the figure are: $\beta=0.044$, $\gamma=14.257$, and $\delta=-0.001$ (since K is negative). We have not discovered a systematic relation between the values of the parameters that lead to a solution of type A. However the general pattern is $\delta \ll \beta \ll \gamma$. The other solution encountered, that we identify as type B, presents damped oscillations for the fermion fields while the σ and $\hat{\varphi}$ fields are positive and monotonically increasing. This solution becomes singular at finite r when the term $(2\hat{\varphi}-1)$, in Eqs. (9.5), (13.7) and (13.8), vanishes. We did not find any systematic relation between the relative values of the parameters that lead to the solution of type B. Since the equations are nonlinear, the solutions are very sensitive to the parameter values. A change in the fourth significant figure in one of the parameters can lead to a change in the output from a type A to a type B solution.

From the numerical analysis it appears that the gravitational sector dominates and the fields σ and $\hat{\varphi}$ follow the general trend of Eqs. (13.5) and (13.6) when there is no coupling to matter. While the numerical work performed does not constitute an exhaustive proof for the nonexistence of finite solutions as $r\to\infty$, it appears to be unlikely that there is a combination of parameters that would lead to such solutions.

XIV. DISCUSSION

It is known that at least two independent radial functions are needed for the solitonic solutions of the field equations that describe gravitational and scalar fields.[7] There are therefore two independent radial functions in our ansatz for the present problem in which the gravitational field is coupled to a Dirac field. In our case, however, the second (Weyl) field would be described as a dilaton if it were localized.

In the original special relativistic problem it was found that there were no solitons for arbitrary values of the ''Fermi coupling constant.'' In fact even when there were, there were only a few

eigensolutions of the nonlinear equation. Initially encouraged by this result we set to look for numerical solutions of the equations for the gravitational and fermion fields. We explored systematically a large portion of the three-dimensional parameter space and only encountered the singular solutions of type A and B described in sec. XIII. While the solutions of type B are very common, those of type A occur for a particular ordering of the relative strengths of the parameters. We found that a variation in the fourth significant figure in any of the parameters could lead to a ''jump'' from a type A to a type B solution. While this does not constitute a definite proof of the nonexistence of finite solutions we think that it is unlikely that any combination of parameters may yield a result different from the singular solutions of type A and B.

In light of our failure to find a localized soliton in an earlier study,[2] it may be further argued that the choice of a dilaton field for the second function makes a solution unlikely. In that work we proved that there are soliton solutions of the interacting gravitational, electromagnetic, scalar, and dilaton fields only if the dilaton field is excluded. Aside from the problem of the dilaton we have also shown (in Secs. XI and XII) that the non linear spinor field behaves quite differently in the special relativistic and general relativistic problems. For these reasons we now believe that the rescaled and spherically degenerate Kerr–Schild metric probably does not admit a spinor solution.

We have studied only the spherically problem. There is then the possibility that one would find a solitonic solution if the full angular dependence of the Kerr solution were restored. In fact the Kerr background was chosen in the first place to allow for the backaction on the gravitational field of the angular momentum carried by the spinor field.

Our original strategy was based on the expectation that there were solitons in the spherically symmetric background, as there are in the special relativistic problem, and that these solutions could then be improved by perturbatively taking into account the angular dependence of the Kerr geometry. In view of the present results this strategy no longer seems promising.

Noncanonical quantization of gravity. II. Constraints and the physical Hilbert space

John R. Klauder[a)]
Departments of Physics and Mathematics, University of Florida, Gainesville, Florida 32611

(Received 27 February 2001; accepted for publication 8 May 2001)

The program of quantizing the gravitational field with the help of affine field variables is continued. For completeness, a review of the selection criteria that singles out the affine fields, the alternative treatment of constraints, and the choice of the initial (before imposition of the constraints) ultralocal representation of the field operators is initially presented. As analogous examples demonstrate, the introduction and enforcement of the gravitational constraints will cause sufficient changes in the operator representations so that all vestiges of the initial ultralocal field operator representation disappear. To achieve this introduction and enforcement of the constraints, a well characterized phase space functional integral representation for the reproducing kernel of a suitably regularized physical Hilbert space is developed and extensively analyzed. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1385375]

I. INTRODUCTION AND THE MAIN POINTS OF PAPER I

In a previous paper[1] (hereafter referred to as P-I) an introduction and outline of a program of noncanonical quantization of the gravitational field was presented. The key concepts in the present approach are (i) a careful selection of the basic kinematical variables, (ii) the use of a quantization procedure that treats all constraints alike, (iii) the use of ultralocal field operator representations prior to introducing constraints, and (iv) the imposition of the gravitational constraints, a process in which all traces of the temporary ultralocal representation characteristics are replaced with the physically relevant ones. In this section, we briefly review topics (i), (ii), and (iii) which have largely been discussed already in P-I.

A. Nature of the basic gravitational variables

One of the central requirements for the present program is the preservation, on quantization, of the positive–definite character of the spatial part of the classical metric $g_{ab}(x)$, $a,b\in\{1,2,3\}$ (or more generally $a,b\in\{1,\ldots,s\}$ in an s-dimensional space, $s\geqslant 1$). Insisting on this requirement leads us to adopt *affine commutation relations* (in contrast, for example, to canonical commutation relations) which are expressed in terms of the local metric field operators $\hat{g}_{ab}(x)$ $[=\hat{g}_{ba}(x)]$ [which were denoted by $\sigma_{ab}(x)$ in P-I] and suitable local ''scale'' field operators $\hat{\pi}^c_d(x)$ [which were denoted by $\kappa^c_d(x)$ in P-I]. The word ''local'' here is intended to mean that these expressions only become operators after smearing with suitable spatial test functions. In units where $\hbar=1$, which are commonly assumed throughout this paper, the basic set of affine commutation relations reads

$$
\begin{aligned}
&[\,\hat{\pi}^a_b(x),\,\hat{\pi}^c_d(y)\,]=\tfrac{1}{2}i[\,\delta^c_b\hat{\pi}^a_d(x)-\delta^a_d\hat{\pi}^c_b(x)\,]\,\delta(x,y),\\
&[\,\hat{g}_{ab}(x),\,\hat{\pi}^c_d(y)\,]=\tfrac{1}{2}i[\,\delta^c_a\hat{g}_{bd}(x)+\delta^c_b\hat{g}_{ad}(x)\,]\,\delta(x,y),\\
&[\,\hat{g}_{ab}(x),\,\hat{g}_{cd}(y)\,]=0.
\end{aligned}
\tag{1}
$$

a)Electronic mail: klauder@phys.ufl.edu

These commutation relations are translations of identical Poisson brackets (modulo $i\hbar$, of course) for corresponding classical fields, namely, the spatial metric $g_{ab}(x)$ and the mixed-valence ("scale") field $\pi^c_d(x) \equiv g_{bd}(x)\pi^{bc}(x)$, along with the usual Poisson brackets between the metric field $g_{ab}(x)$ and the canonical momentum field $\pi^{cd}(x)$. While *classically* there is essentially nothing to be gained by using the field $\pi^c_d(x)$ rather than $\pi^{cd}(x)$, *quantum mechanically* the situation changes completely. This change arises because the affine commutation relations—and *only* the affine commutation relations—admit local self-adjoint operator solutions for both $\hat{g}_{ab}(x)$ and $\hat{\pi}^c_d(x)$ which in addition have the property that $\hat{g}_{ab}(x) > 0$ for all x. This latter property means that for any nonvanishing set $\{u^a\}$ of real numbers and any nonvanishing, non-negative test function, $f(x) \geqslant 0$, that

$$\int f(x)u^a \hat{g}_{ab}(x)u^b \, d^3x > 0. \tag{2}$$

Other choices of basic variables fail this test. For example, self-adjoint canonical variables lead to metrics that have spectra unbounded below as well as above, while triad fields and their canonical partners lead to metrics that are non-negative, but not necessarily positive definite.

B. How quantum constraints are to be imposed

Since gravity is a reparametrization invariant theory, it follows that the dynamics—indeed, *the entire physical content of the gravitational field*—enters through imposition of the relevant constraints, specifically, the diffeomorphism and Hamiltonian constraints.[2,3] These constraints lead to an open set of *first-class* constraints in the classical theory, but on quantization and in virtue of an anomaly (or, alternatively, a factor ordering problem), they give rise to a set of operator constraints that, partially at least, are *second class* in nature. There exist several methods to deal with the quantum theory of second-class constraints in the literature, but generally such methods treat the first- and second-class constraints, and thereby the variables on which they depend, in fundamentally different ways.

An exception to the rule of a different operator treatment for first- and second-class constraints is offered by the *projection operator method* approach to the quantization of systems with constraints.[4–6] The projection operator method was already discussed in P-I, and that discussion also included several elementary applications of the technique to simple, few degree-of-freedom systems. We do not repeat that discussion here. Instead, we simply observe that, rather than impose the self-adjoint quantum constraints in the idealized (Dirac) form $\Phi_\alpha |\psi\rangle_{\text{phys}} = 0$, $\alpha \in \{1,\ldots,A\}$, on vectors $|\psi\rangle_{\text{phys}}$ in a putative physical Hilbert space, $|\psi\rangle_{\text{phys}} \in \mathfrak{H}_{\text{phys}}$, we define a (possibly regularized) $\mathfrak{H}_{\text{phys}} \equiv \mathbb{E}\mathfrak{H}$, in which $\mathbb{E}$ denotes a *projection operator* defined by

$$\mathbb{E} = \mathbb{E}(\Sigma_\alpha \Phi^2_\alpha \leqslant \delta(\hbar)^2), \tag{3}$$

where $\delta(\hbar)$ is a positive *regularization parameter* (not a δ-function!) and we have assumed that $\Sigma_\alpha \Phi^2_\alpha$ is self-adjoint. As a final step, the parameter $\delta(\hbar)$ is reduced as much as required, and, in particular, when some second-class constraints are involved, $\delta(\hbar)$ ultimately remains strictly positive. This general procedure treats all constraints simultaneously and treats them all on an equal basis.

C. Why ultralocal fields are relevant

In quantizing any theory with constraints, including reparametrization invariant theories, we invariably follow the rule: *Quantize first, reduce second*, also used by Dirac.[3]

Remark: Some other quantization procedures reduce (i.e., impose constraints) first and quantize second, a scheme that may lead to different and generally incorrect results, especially when the physical phase space (the quotient of the constraint surface by the gauge transformations) is non-Euclidean.[7] We do not comment further on these alternative procedures.

It must be strongly emphasized that in the initial quantization phase of this pair of operations, one must remain neutral toward, or even better, blind to any specifics of the constraints to be imposed. In particular, in the initial, quantization phase, reparametrization invariance requires that basic fields are statistically independent at any spatial separation; correlations between fields that are spatially separated, and which originate from the particular physics of the theory under discussion, will arise only after the relevant constraints are imposed. Before the constraints are ever discussed, the nature of the field operators is *ultralocal*, the name given to field-operator representations which are, in fact, statistically independent for all distinct spatial points. The primary representation already presented in P-I for the basic local affine quantum field operators, and before constraints have been introduced, is for this very reason ultralocal in character. In the present paper, we shall discuss the relevant constraints for gravity and argue, to the extent possible at present, that the imposition of the constraints leads to field operator representations that are no longer ultralocal in character. Indeed, we shall argue that all traces of an initial ultralocal representation disappear when the constraints are fully enforced.

Remark: As an illustration of these general procedures, it is important at this point to observe that a relativistic free field of mass m (and, in addition, well-defined interacting fields) can be quantized starting from a reparametrization invariant formulation and with an initial field operator representation that is ultralocal in nature.[8] After imposing the appropriate constraint, it may be shown, by a suitable modification of the reproducing kernel—see Sec. IV for a brief discussion—how the conventional and *non*ultralocal field operator representation for the relativistic free field of an *arbitrary* mass m emerges, as well as how the conventional propagator for such a system also arises.

D. Outline of remaining sections

In Sec. II, we discuss in some detail the formulation of the initial stage of quantization in the absence of the gravitational constraints. In Sec. III, the gravitational constraints are introduced, and a novel, but generally familiar, functional integral representation of the desired expressions is developed. Finally, in Sec. IV, and aided by the use of several analogies, we present a lengthy discussion of the virtues, as we see them, of the specific functional integral representation developed in this paper.

II. REPRODUCING KERNEL FOR THE ORIGINAL HILBERT SPACE, AND ITS FUNCTIONAL INTEGRAL REPRESENTATION

A. Basic field operator representation and the original Hilbert space

For reasons briefly sketched above, we adopt as basic local field operators the positive–definite, local self-adjoint metric operators $\hat{g}_{ab}(x)$, and the local self-adjoint ''scale'' operators $\hat{\pi}^c_d(x)$, which satisfy the affine commutation relations (1) in the ''original'' Hilbert space $\mathfrak{H}$. Here $x=\{x^a\}_{a=1}^3$ denotes the coordinates (each with the dimension of *length*) of a point in a classical topological space $\mathcal{S}$, which, for the sake of discussion, we may assume is topologically equivalent to $\mathbb{R}^3$. The term $\delta(x,y)$ which enters the affine commutation relations is a Dirac δ-function ''scalar density'' with dimensions $(\text{length})^{-3}$. Moreover, the affine commutation relations uniquely tell us that $\hat{\pi}^c_d(x)$ transforms as a mixed-valence tensor density of weight one and has the engineering dimensions of an *action* (due to $\hbar$) times $(\text{length})^{-3}$, i.e., $\mathsf{M/LT}$ in terms of mass (M), length (L), and time (T). We require that $\hat{g}_{ab}(x)$ transform as a covariant tensor of rank two, and that $\hat{g}_{ab}(x)$ is dimensionless.

1. An auxiliary, but temporary, structure

For purposes of the present section, we shall need to augment the classical topological space $\mathcal{S}$ with one additional structure, namely a volume form. Specifically, we adopt a real, positive scalar density of weight one, $b(x)$, $0<b(x)<\infty$, $x\in\mathcal{S}$, with which we may define, at each point, an invariant volume form $dV\equiv b(x)d^3x$. Additionally, in keeping with its transformation properties, we further insist that $b(x)$ has the dimensions of L^{-3}.

The introduction of the auxiliary structure represented by $b(x)$ is required *before the constraints are introduced, but whatever choice is made, it will* disappear completely *after the constraints are fully enforced.*

More explicitly, several arguments are offered below to justify the introduction of the auxiliary structure represented by the function $b(x)$, $x \in \mathcal{S}$, prior to the introduction of the constraints. In Secs. III and IV, we will observe that we expect all the irrelevant freedom present in $b(x)$ to be ''squeezed out'' by the constraints and replaced with another, *non*arbitrary structure with the same dimensions. This is exactly the process observed in other cases that have been explicitly dealt with, and the particular case of a reparametrization invariant relativistic free field will be summarized in Sec. IV.[8]

2. Original reproducing kernel

Dual to the local operators $\hat{g}_{ab}(x)$ and $\hat{\pi}^c_d(x)$, we next introduce two real, c-number functions $\pi^{ab}(x)$ $[=\pi^{ba}(x)]$ and $\gamma^d_c(x)$, which, initially, may be taken as smooth functions of compact support. Here π^{ab} transforms as a contravariant tensor density of rank two and has dimensions M/LT, while γ^d_c transforms as a mixed tensor and is dimensionless. With $|\eta\rangle$—called the *fiducial vector*—an as yet unspecified unit vector in $\mathfrak{H}$, we consider the set of unit vectors (in units where $\hbar = 1$) each of which is given by

$$|\pi,\gamma\rangle \equiv e^{i\int \pi^{ab}(x)\hat{g}_{ab}(x)d^3x}\, e^{-i\int \gamma^d_c(x)\hat{\pi}^c_d(x)d^3x}\,|\eta\rangle. \tag{4}$$

As π^{ab} and γ^d_c range over the space of smooth functions of compact support, such vectors form a set of *coherent states*.

The complex functional $\langle \pi'',\gamma''|\pi',\gamma'\rangle$ formed by the inner product of two such coherent states will be a functional of fundamental importance in the present study of gravity. In particular, the functional $\langle \pi'',\gamma''|\pi',\gamma'\rangle$, whatever form it takes, is manifestly a positive–definite functional that fulfills the defining condition that

$$\sum_{j,k=1}^{J} \alpha^*_j \alpha_k \langle \pi_j,\gamma_j|\pi_k,\gamma_k\rangle \geqslant 0 \tag{5}$$

for general sets $\{\alpha_j\}$ and $\{\pi_j,\gamma_j\}$ for any $J<\infty$. Furthermore, $\langle \pi'',\gamma''|\pi',\gamma'\rangle$ is always a continuous functional in some natural functional topology, e.g., a topology defined by the particular expression itself.[9] As a continuous, positive–definite functional, it follows that we may adopt the expression $\langle \pi'',\gamma''|\pi',\gamma'\rangle$ as a *reproducing kernel*, and use it to define an associated *reproducing kernel Hilbert space* $\mathcal{C}$.[10] Let two elements of a dense set of elements in $\mathcal{C}$ be given by

$$\begin{aligned} \psi(\pi,\gamma) &\equiv \sum_{j=1}^{J} \alpha_j \langle \pi,\gamma|\pi_j,\gamma_j\rangle, \quad J<\infty, \\ \phi(\pi,\gamma) &\equiv \sum_{k=1}^{K} \beta_k \langle \pi,\gamma|\overline{\pi}_k,\overline{\gamma}_k\rangle, \quad K<\infty, \end{aligned} \tag{6}$$

where $\{\overline{\pi}_k,\overline{\gamma}_k\}_{k=1}^K$ denotes another independent set of (real) fields. These are continuous functionals of the fields π and γ. As the inner product of these two elements we adopt

$$(\psi,\phi) \equiv \sum_{j=1}^{J}\sum_{k=1}^{K} \alpha^*_j \beta_k \langle \pi_j,\gamma_j|\overline{\pi}_k,\overline{\gamma}_k\rangle. \tag{7}$$

We complete the space of functions by including the limit point of all Cauchy sequences in the norm $\|\psi\| \equiv (\psi,\psi)^{1/2}$.

The result of the above construction is the (separable) reproducing kernel Hilbert space $\mathcal{C}$ composed of bounded, continuous functionals. Moreover, the Hilbert space $\mathcal{C}$ provides an especially useful functional representation of our original Hilbert space, which was referred to as the "primary container" in P-I.

B. Choice of the fiducial vector and explicit form of the reproducing kernel

As argued in Sec. I, the representation of the basic field operators $\hat{g}_{ab}$ and $\hat{\pi}_d^c$ must be ultralocal prior to the introduction of any constraints. To fulfill this requirement, it is necessary that

$$\langle \pi'', \gamma'' | \pi', \gamma' \rangle = \exp\left\{ - \int b(x) d^3x \, L[\pi''(x), \gamma''(x); \pi'(x), \gamma'(x)] \right\} \tag{8}$$

for some dimensionless scalar function L. This function is determined by the representation of the affine field operators and the fiducial vector $|\eta\rangle$, and as minimum conditions we require that

$$\langle \eta | \hat{g}_{ab}(x) | \eta \rangle \equiv \tilde{g}_{ab}(x), \tag{9}$$

$$\langle \eta | \hat{\pi}_d^c(x) | \eta \rangle \equiv 0. \tag{10}$$

Here, $\tilde{g}(x) \equiv \{\tilde{g}_{ab}(x)\}$ is a fixed, smooth, positive–definite metric function determined by the choice of $|\eta\rangle$ (see P-I). Whether $\mathcal{S}$ is compact or noncompact, the choice of $\tilde{g}(x)$ will determine the topology of the spacelike surfaces under consideration; if $\mathcal{S}$ is noncompact, then $\tilde{g}(x)$ also determines the asymptotic form of the spacelike surfaces under consideration.

For reasons to be offered below, we choose $|\eta\rangle$ so that the overlap function of two coherent states is given (when $\hbar = 1$) by

$$\langle \pi'', \gamma'' | \pi', \gamma' \rangle = \exp\left[-2 \int b(x) d^3x \times \ln\left(\frac{\det\{\frac{1}{2}[g''^{ab}(x) + g'^{ab}(x)] + \frac{1}{2} i b(x)^{-1} [\pi''^{ab}(x) - \pi'^{ab}(x)]\}}{\{\det[g''^{ab}(x)] \det[g'^{ab}(x)]\}^{1/2}} \right) \right]. \tag{11}$$

Several comments about this basic expression are in order.

Initially, regarding (11), we observe that γ'' and γ' do *not* appear in the explicit functional form given. In particular, the smooth matrix γ has been replaced by the smooth matrix g which is defined at every point by

$$g(x) \equiv e^{\gamma(x)/2} \tilde{g}(x) e^{\gamma(x)^T/2} \equiv \{g_{ab}(x)\}, \tag{12}$$

where $\gamma(x)^T$ denotes the transpose of the matrix $\gamma(x)$. Observe that the so-defined matrix $\{g_{ab}(x)\}$ is manifestly positive–definite for all x. The map $\gamma \to g$ is clearly many-to-one since γ has *nine* independent variables at each point while g, which is symmetric, has only *six*. In view of this functional dependence *we may denote the given functional in (11) by* $\langle \pi'', g'' | \pi', g' \rangle$, *and henceforth we shall adopt this notation exclusively*.

1. Single affine matrix degree of freedom

An elementary example of the notational change from γ to g may be seen quite directly in what occurs for a *single* affine matrix degree of freedom (in contrast to a field of such degrees of freedom). To that end, and following Ref. 11 closely, we introduce the Lie algebra for affine matrix self-adjoint operator degrees of freedom composed of the symmetric 3×3 matrix $\{\sigma_{ab}\}$ and the 3×3 matrix $\{\kappa_d^c\}$, which together obey the affine commutation relations [cf. (1)]

$$[\kappa_b^a,\kappa_d^c]=i\tfrac{1}{2}(\delta_b^c\kappa_d^a-\delta_d^a\kappa_b^c),$$

$$[\sigma_{ab},\kappa_d^c]=i\tfrac{1}{2}(\delta_a^c\sigma_{db}+\delta_b^c\sigma_{ad}), \tag{13}$$

$$[\sigma_{ab},\sigma_{cd}]=0.$$

We choose the faithful, irreducible representation for which the operator matrix $\{\sigma_{ab}\}$ is symmetric and positive definite, and which is unique up to unitary equivalence. Furthermore, we choose a representation which diagonalizes $\{\sigma_{ab}\}$ as $k\equiv\{k_{ab}\}$, which we refer to as the k-representation. In the associated L^2 representation space, and for arbitrary real matrices $F=\{F^{ab}\}$, $F^{ba}=F^{ab}$, and $B=\{B_d^c\}$, it follows that

$$U[F,B]\psi(k)\equiv e^{iF^{ab}\sigma_{ab}}e^{-iB_d^c\kappa_c^d}\psi(k)=(\det[S])^2e^{iF^{ab}k_{ab}}\psi(SkS^T), \tag{14}$$

where $S\equiv e^{-B/2}=\{S_b^a\}$ and $(SkS^T)_{ab}\equiv S_a^ck_{cd}S_b^d$. The given transformation is unitary within the inner product defined by

$$\int_+\psi(k)^*\psi(k)dk, \tag{15}$$

where $dk\equiv\Pi_{a\leqslant b}\,dk_{ab}$, and the "+" sign denotes an integration over only that part of the six-dimensional k-space where the elements form a symmetric, positive–definite matrix, $\{k_{ab}\}>0$. To define coherent states we choose an extremal weight vector,

$$\eta(k)\equiv C(\det[k])^{\beta-1}e^{-\beta\,\mathrm{tr}[\tilde{G}^{-1}k]}, \tag{16}$$

where $\beta>0$, $\tilde{G}=\{\tilde{G}_{ab}\}$ is a fixed positive–definite matrix, C is determined by normalization, and tr denotes the trace. This choice leads to the expectation values

$$\langle\eta|\sigma_{ab}|\eta\rangle=\int_+\eta(k)^*k_{ab}\eta(k)dk=\tilde{G}_{ab}, \tag{17}$$

$$\langle\eta|\kappa_d^c|\eta\rangle=\int_+\eta(k)^*\kappa_d^c\eta(k)dk=0. \tag{18}$$

In the k-representation, it follows that the affine matrix coherent states are given by

$$\langle k|F,B\rangle\equiv C(\det[S])^2(\det[SkS^T])^{\beta-1}\,e^{i\,\mathrm{tr}[Fk]}\,e^{-\beta\,\mathrm{tr}[\tilde{G}^{-1}SkS^T]}. \tag{19}$$

Observe that what really enters the functional argument is the positive–definite matrix $G^{-1}\equiv S^T\tilde{G}^{-1}S$ where we set $G\equiv\{G_{ab}\}$. Thus without loss of generality we can drop the label B (or equivalently S) and replace it with G. Hence the affine matrix coherent states become

$$\langle k|F,G\rangle\equiv C'(\det[G^{-1}])^{\beta}(\det[k])^{\beta-1}\,e^{i\,\mathrm{tr}[Fk]}\,e^{-\beta\,\mathrm{tr}[G^{-1}k]}, \tag{20}$$

where $C'=C(\det[\tilde{G}])^{\beta}$ is a new normalization constant. It is now straightforward to determine that

$$\begin{aligned}\langle F'',G''|F',G'\rangle&=\int_+\langle F'',G''|k\rangle\langle k|F',G'\rangle dk\\&=\left[\frac{\{\det[G''^{-1}]\det[G'^{-1}]\}^{1/2}}{\det\{\frac{1}{2}[(G''^{-1}+G'^{-1})+i\beta^{-1}(F''-F')]\}}\right]^{2\beta}.\end{aligned} \tag{21}$$

In arriving at this result, we have used normalization of the coherent states to eliminate the constant C'.

2. Lattice construction

Suppose now that we consider an independent lattice of such matrix degrees of freedom and build the corresponding coherent state overlap as the product of ones just like (21). Let $\mathbf{n}$ label a lattice site and let $\mathbf{n}\in\mathbf{N}$, which in turn is a finite subset of $\mathbb{Z}^3$. In that case the coherent state overlap is given by

$$\langle F'',G''|F',G'\rangle_{\mathbf{N}}=\prod_{\mathbf{n}\in\mathbf{N}}\left[\frac{\{\det[G''^{-1}_{[\mathbf{n}]}]\det[G'^{-1}_{[\mathbf{n}]}]\}^{1/2}}{\det\{\frac{1}{2}[(G''^{-1}_{[\mathbf{n}]}+G'^{-1}_{[\mathbf{n}]})+i\beta^{-1}_{[\mathbf{n}]}(F''_{[\mathbf{n}]}-F'_{[\mathbf{n}]})]\}}\right]^{2\beta_{[\mathbf{n}]}}. \tag{22}$$

As our next step we wish to take a limit in which the number of independent matrix degrees of freedom tends to infinity in such a way that not only does the lattice size diverge but also the lattice spacing tends to zero so that, loosely speaking, the lattice points approach the points of the space $\mathcal{S}$. In order for the limit to be nonzero, it is necessary that the exponent $\beta_{[\mathbf{n}]}\to 0$ in a suitable way. To that end we set

$$\beta_{[\mathbf{n}]}\equiv b_{[\mathbf{n}]}\Delta, \tag{23}$$

where Δ has the dimensions L^3, and thus $b_{[\mathbf{n}]}$ has the dimensions L^{-3}. In addition we need to let $F^{ab}_{[\mathbf{n}]}\equiv\pi^{ab}_{[\mathbf{n}]}\Delta$, and we rename $G_{ab[\mathbf{n}]}$ as $g_{ab[\mathbf{n}]}$ and call the matrix elements of $G^{-1}_{[\mathbf{n}]}$ by $g^{ab}_{[\mathbf{n}]}$. With these changes (22) becomes

$$\langle \pi'',g''|\pi',g'\rangle_{\mathbf{N}}\equiv\prod_{\mathbf{n}\in\mathbf{N}}\left[\frac{\{\det[g''^{ab}_{[\mathbf{n}]}]\det[g'^{ab}_{[\mathbf{n}]}]\}^{1/2}}{\det\{\frac{1}{2}[(g''^{ab}_{[\mathbf{n}]}+g'^{ab}_{[\mathbf{n}]})+ib^{-1}_{[\mathbf{n}]}(\pi''^{ab}_{[\mathbf{n}]}-\pi'^{ab}_{[\mathbf{n}]})]\}}\right]^{2b_{[\mathbf{n}]}\Delta}. \tag{24}$$

Finally, we take the limit as described above and the result is given by (11), namely,

$$\langle \pi'',g''|\pi',g'\rangle=\exp\left[-2\int b(x)d^3x \times\ln\left(\frac{\det\{\frac{1}{2}[g''^{ab}(x)+g'^{ab}(x)]+\frac{1}{2}ib(x)^{-1}[\pi''^{ab}(x)-\pi'^{ab}(x)]\}}{\{\det[g''^{ab}(x)]\det[g'^{ab}(x)]\}^{1/2}}\right)\right]. \tag{25}$$

In this way we see how the continuum result may be obtained as a limit starting from a collection of independent affine matrix degrees of freedom. The necessity of ending with an integral over the space $\mathcal{S}$ has directly led to the requirement that we introduce the scalar density $b(x)$.

C. Additional arguments favoring $b(x)$

As a further general comment about (11) or (25) we observe that $\langle \pi'',g''|\pi',g'\rangle$ is *invariant* under general (smooth, invertible) coordinate transformations $x\to\overline{x}=\overline{x}(x)$, and we say that the given expression characterizes a *diffeomorphism invariant realization* of the affine field operators. This property holds, in part, because $b(x)$ transforms as a scalar density in both places that it appears. Thus $b(x)$, which has the dimensions of L^{-3}, plays an essential dimensional and transformational role in each place that it appears. Note that if $\hbar$ is explicitly introduced into (25) or (11), it appears only in the change $[\pi''^{ab}(x)-\pi'^{ab}(x)]\to[\pi''^{ab}(x)-\pi'^{ab}(x)]/\hbar$. If one insisted on building an acceptable ultralocal positive–definite functional using only $\pi''^{ab}(x)$, $g''^{ab}(x)$, $\pi'^{ab}(x)$, $g'^{ab}(x)$, and $\hbar$, then that construction would not appear to be possible simply on dimensional grounds.

As another argument for the appearance of $b(x)$, we observe that (25) involves not only the c-number fields π and g (or γ), but the particular representation of the local operators $\hat{g}_{ab}$ and $\hat{\pi}^c_d$ as well as the choice of the fiducial vector $|\eta\rangle$. It is entirely natural that the function $b(x)$ may emerge as a needed functional parameter in defining the operator representation and/or the vector $|\eta\rangle$, and this property is explicitly illustrated in P-I.

As a final argument for the appearance of the scalar density $b(x)$, we briefly recall properties of the local operator product for ultralocal affine field operators.[1] In particular, the formal local product reads

$$\hat{g}_{ab}(x)\hat{g}_{cd}(x)=\delta(x,x)\hat{E}_{abcd}(x)+\text{l.s.t.} \tag{26}$$

Here $\hat{E}_{abcd}(x)$ is a local fourth-order covariant tensor density operator of weight -1, $\delta(x,x)$ is a divergent multiplier with dimensions L^{-3}, which arises when the ''scalar density'' delta function $\delta(x,y)$ is evaluated at coincident points, and l.s.t. denotes ''less singular terms.'' Before adopting the proper local operator product, we introduce a scalar density $b(x)$, $0<b(x)<\infty$, with dimensions L^{-3}, and consider

$$\hat{g}_{ab}(x)\hat{g}_{cd}(x)=b(x)[b(x)^{-1}\delta(x,x)]\hat{E}_{abcd}(x)+\text{l.s.t.} \tag{27}$$

Finally, we choose

$$[\hat{g}_{ab}(x)\hat{g}_{cd}(x)]_R\equiv b(x)\hat{E}_{abcd}(x)\quad(=\hat{g}_{ab}(x)\hat{g}_{cd}(x)/[b(x)^{-1}\delta(x,x)]) \tag{28}$$

as the proper renormalized (subscript R) local operator product. (Limits involving test function sequences offer a mathematically precise construction.) The given choice leads to a local operator that transforms as a tensor in the natural fashion and, moreover, carries the natural engineering dimensions. To achieve this desirable property in a local product *requires* the introduction of an auxiliary scalar density $b(x)$.

For additional properties regarding local products of the relevant affine field operators, see P-I. Essentially, all these properties are almost entirely based on the analysis of local operator products in scalar ultralocal field theories, an analysis which is described in detail, for example, in Ref. 12.

We have offered several reasons for the appearance of the scalar density $b(x)$ at the present stage of the analysis. However, we emphasize once again that $b(x)$ will disappear when the constraints are fully enforced, whatever choice was originally made. An example of the process by which this fundamental transformation takes place is presented in Sec. IV.

D. Functional integral representation for the coherent state overlap functional

For further analysis, especially when we take up the issue of introducing the constraints in Sec. III, it is useful to introduce an alternative representation of the functional expression (25). The alternative representation we have in mind is that of a specific functional integral, which, indeed, has already been introduced in P-I. That such a representation should exist is an immediate consequence of the fact that (25) fulfills a complex polarization condition, which then leads to (25) being annihilated by a negative, second-order functional derivative operator. Exponentiating this operator, times a parameter $\nu>0$, letting the resultant operator act on general functionals of π'' and g'', and including any necessary ν-dependent prefactor, will, in the limit $\nu\to\infty$, lead to a dense set of functions in the reproducing kernel Hilbert space $\mathcal{C}$. Alternatively, letting the same operator act on a suitable δ-functional will lead to the expression (25). The functional integral of interest arises in this last expression by introducing the analog of a Feynman–Kac–Stratonovich representation. The mathematics behind these foregoing several sentences is well illustrated in P-I for both a simple, single affine degree-of-freedom example as well as for the affine field theory.

The result of the operations outlined above leads to a functional integral representation for $\langle\pi'',g''|\pi',g'\rangle$ in (25), which is given (for $\hbar=1$) by

$$\langle \pi'', g'' | \pi', g' \rangle = \exp\Bigg[-2 \int b(x) d^3x \times \ln\Bigg(\frac{\det\{\frac{1}{2}[g''^{ab}(x) + g'^{ab}(x)] + \frac{1}{2} i b(x)^{-1} [\pi''^{ab}(x) - \pi'^{ab}(x)]\}}{\{\det[g''^{ab}(x)] \det[g'^{ab}(x)]\}^{1/2}} \Bigg) \Bigg]$$

$$= \lim_{\nu \to \infty} \overline{\mathcal{N}}_\nu \int \exp\Big[-i \int g_{ab} \dot{\pi}^{ab} \, d^3x \, dt \Big] \exp\Big\{ -(1/2\nu) \int [b(x)^{-1} g_{ab} g_{cd} \dot{\pi}^{bc} \dot{\pi}^{da} + b(x) g^{ab} g^{cd} \dot{g}_{bc} \dot{g}_{da}] d^3x \, dt \Big\} \prod_{x,t} \prod_{a \leqslant b} d\pi^{ab}(x,t) dg_{ab}(x,t). \tag{29}$$

Here, because of the way the new independent variable t appears on the right-hand side of this expression, it is natural to interpret t, $0 \leqslant t \leqslant T$, $T > 0$ as coordinate "time." The fields on the right-hand side all depend on space and time, i.e., $g_{ab} = g_{ab}(x,t)$, $\dot{g}_{ab} = \partial g_{ab}(x,t)/\partial t$, etc., and, importantly, the integration domain of the formal measure is strictly limited to the domain where $\{g_{ab}(x,t)\}$ is a positive–definite matrix for all x and t. For the boundary conditions, we have $\pi'^{ab}(x) \equiv \pi^{ab}(x,0)$, $g'_{ab}(x) \equiv g_{ab}(x,0)$, as well as $\pi''^{ab}(x) \equiv \pi^{ab}(x,T)$, $g''_{ab}(x) \equiv g_{ab}(x,T)$ for all x. Observe that the right-hand side holds for *any* T, $0 < T < \infty$, while the middle term is *independent of T altogether*.

Although the functional integral on the right-hand side is formal it nevertheless conveys a great deal of information. Let us first examine it from a dimensional and transformational standpoint. As presented, $\hbar = 1$; to see where $\hbar$ would appear we may simply replace each π^{ab} by $\pi^{ab}/\hbar$. With ν having the dimensions of T^{-1} and $\overline{\mathcal{N}}_\nu$ absorbing any remaining dimensions from the formal measure, then the right-hand side of (29) is dimensionally satisfactory. From the point of view of (formal) transformations under coordinate changes, it is clear, with $\overline{\mathcal{N}}_\nu$ transforming appropriately, that the right-hand side is formally invariant under coordinate transformations involving the spatial coordinates alone.

Remark: A discussion about transformations of the right-hand side under spatially dependent transformations of the time coordinate has been given in P-I and is not repeated here. It is clear that the result of the limit $\nu \to \infty$ on the right-hand side must be invariant under all such transformations simply because the middle term is independent of the time variable altogether.

As presented—and indeed as originally derived—the *result* of the functional integral (the middle term) came before the functional integral *representation* of that result (the right-hand side). However, we can also interpret (29) in the opposite order, that is, to presume that the functional integral (right-hand side) is primary and that the answer (the middle term) is the result of evaluating the functional integral. This perspective encourages us to examine the expression in the integrand of the functional integral somewhat more carefully from a traditional standpoint. We first observe that the formal, flat part of the measure has the expected appearance of the *canonical measure* for a conventional, canonical functional integral quantization of gravity. The phase factor contains an acceptable classical symplectic potential term in a formal functional integral for gravity in which the rest of the classical action—the terms involving the constraints—are absent.

Remark: This characterization is, of course, quite appropriate since we still are in the first phase of our dual approach: quantize first, reduce second. The patient reader will be rewarded with the addition of the expected constraints and Lagrange multiplier terms in the next section.

The second, ν-dependent factor in the integrand serves as a *regularizing factor* for the functional integral. Formally, as $\nu \to \infty$, such a factor disappears from the integrand leaving the expected (preconstraint) formal functional integral integrand, such as it is. However, the ν-dependent term plays a fundamentally important role within the integral itself since it *literally serves to define the functional integral*.

It is important to make this last point quite clear, and for that purpose we temporarily discuss the formal expression (with $\hbar=1$ again)

$$d\mu^{\nu}(\pi,g)=\mathcal{M}_{\nu}\exp\left\{-(1/2\nu)\int [b(x)^{-1}g_{ab}g_{cd}\dot{\pi}^{bc}\dot{\pi}^{da}+b(x)g^{ab}g^{cd}\dot{g}_{bc}\dot{g}_{da}]d^3x\,dt\right\}$$

$$\times\prod_{x,t}\prod_{a\leqslant b}d\pi^{ab}(x,t)dg_{ab}(x,t). \tag{30}$$

We assert that for fixed $b(x)$, $0<b(x)<\infty$ and fixed ν, $0<\nu<\infty$, this expression characterizes a *bona fide, countably additive, positive measure*, μ^{ν}, on the space of generalized functions $\pi^{ab}=\pi^{ab}(x,t)$ and $g_{ab}=g_{ab}(x,t)$, where for any nonvanishing u^a and any nonvanishing, nonnegative test function $f(x)\geqslant 0$, the positive–definite matrix condition $\int f(x)u^a g_{ab}(x,t)u^b\,d^3x>0$ holds for (almost) all t, $0<t<T$. The fields π^{ab} and g_{ab} satisfy the boundary conditions at $t=0$ and $t=T$ given previously. The factor $\mathcal{M}_{\nu}$ is adjusted so that the measures μ^{ν} form a semigroup with respect to combining time intervals, e.g., $0\to T$, $T>0$, and then $T\to T+T'$, $T'>0$, being equivalent to $0\to T+T'$. If $\{h_p(x)\}_{p=1}^{\infty}$ denotes an orthonormal set of test functions defined so that

$$\int h_p(x)h_q(x)b(x)d^3x=\delta_{pq}, \tag{31}$$

$$b(x)\sum_{p=1}^{\infty}h_p(x)h_p(y)=\delta(x,y), \tag{32}$$

then we assert that there exist finite, nonzero constants N_P^{ν} for all ν and all $P\in\{1,2,3,\ldots\}$ such that

$$N_P^{\nu}\int\exp\left[-i\sum_{p=1}^{P}\int g_{ab(p)}(t)\,\dot{\pi}^{ab}_{(p)}(t)dt\right]d\mu^{\nu}(\pi,g) \tag{33}$$

is well defined. In this expression,

$$g_{ab(p)}(t)\equiv\int h_p(x)g_{ab}(x,t)b(x)\,d^3x, \tag{34}$$

$$\dot{\pi}^{ab}_{(p)}(t)\equiv\int h_p(x)\,\dot{\pi}^{ab}(x,t)\,d^3x. \tag{35}$$

Moreover, the set of constants $\{N_P^{\nu}\}$ may be chosen so that

$$\langle\pi'',g''|\pi',g'\rangle\equiv\lim_{P\to\infty}\lim_{\nu\to\infty}N_P^{\nu}\int\exp\left[-i\sum_{p=1}^{P}\int g_{ab(p)}(t)\,\dot{\pi}^{ab}_{(p)}(t)\,dt\right]d\mu^{\nu}(\pi,g). \tag{36}$$

This is one of the ways that the formal functional integral (29) can be given a rigorous meaning.

There is another way to give rigorous meaning to (29) that we would also like to discuss. In this procedure we use a spatial lattice but keep the time variable t continuous. This regularization scheme takes us back to the lattice construction given earlier [cf. (24)], except now we add a phase-space path integral representation as well. For present purposes we again introduce the symbol Δ, with dimensions L^3, to denote a uniformly (coordinate) sized, small spatial cell. Then the lattice regularized path integral expression for $\langle\pi'',g''|\pi',g'\rangle_{\mathbf{N}}$ in (24) is given by[13]

$$\overline{\mathcal{N}}_\nu^{\mathbf{N}} \int e^{-i\Sigma_{\mathbf{n}} \int g_{ab[\mathbf{n}]} \dot{\pi}^{ab}_{[\mathbf{n}]} \Delta\, dt} \exp\Bigg\{ -\frac{1}{2\nu} \sum_{\mathbf{n}} \int [b^{-1}_{[\mathbf{n}]} g_{ab[\mathbf{n}]} g_{cd[\mathbf{n}]} \dot{\pi}^{bc}_{[\mathbf{n}]} \dot{\pi}^{da}_{[\mathbf{n}]} + b_{[\mathbf{n}]} g^{ab}_{[\mathbf{n}]} g^{cd}_{[\mathbf{n}]} \dot{g}_{bc[\mathbf{n}]} \dot{g}_{da[\mathbf{n}]}] \Delta\, dt \Bigg\} \prod_{\mathbf{n},t} \prod_{a \leqslant b} d\pi^{ab}_{[\mathbf{n}]}(t)\, dg_{ab[\mathbf{n}]}(t), \tag{37}$$

where $\mathbf{n} \in \mathbf{N}$, which itself is a finite subset of $\mathbb{Z}^3$. Here $\pi^{ab}_{[\mathbf{n}]}$, $g_{ab[\mathbf{n}]}$, and $b_{[\mathbf{n}]}$ represent average field values in the cell $\mathbf{n}$, and $b^{-1}_{[\mathbf{n}]} = 1/b_{[\mathbf{n}]}$. Next, we observe that there is a countably-additive, pinned, Brownian-motion measure formally defined by

$$d\mu^\nu_{\mathbf{N}}(\pi, g) \equiv \mathcal{N}_\nu^{\mathbf{N}} \exp\Bigg\{ -\frac{1}{2\nu} \sum_{\mathbf{n}} \int [b^{-1}_{[\mathbf{n}]} g_{ab[\mathbf{n}]} g_{cd[\mathbf{n}]} \dot{\pi}^{bc}_{[\mathbf{n}]} \dot{\pi}^{da}_{[\mathbf{n}]} + b_{[\mathbf{n}]} g^{ab}_{[\mathbf{n}]} g^{cd}_{[\mathbf{n}]} \dot{g}_{bc[\mathbf{n}]} \dot{g}_{da[\mathbf{n}]}] \Delta\, dt \Bigg\}$$
$$\times \prod_{\mathbf{n},t} \prod_{a \leqslant b} d\pi^{ab}_{[\mathbf{n}]}(t)\, dg_{ab[\mathbf{n}]}(t) \tag{38}$$

so that (37) becomes

$$\overline{N}_\nu^{\mathbf{N}} \int e^{-i\Sigma_{\mathbf{n}} \int g_{ab[\mathbf{n}]} \dot{\pi}^{ab}_{[\mathbf{n}]} \Delta\, dt}\, d\mu^\nu_{\mathbf{N}}(\pi, g), \tag{39}$$

where $\{\overline{N}_\nu^{\mathbf{N}}\}$ is a set of finite constants. Moreover, these constants may be chosen so that

$$\langle \pi'', g'' | \pi', g' \rangle = \lim_{\mathbf{N} \to \infty} \lim_{\nu \to \infty} \overline{N}_\nu^{\mathbf{N}} \int e^{-i\Sigma_{\mathbf{n}} \int g_{ab[\mathbf{n}]} \dot{\pi}^{ab}_{[\mathbf{n}]} \Delta\, dt}\, d\mu^\nu_{\mathbf{N}}(\pi, g). \tag{40}$$

Here, in the last step, the limit $\mathbf{N} \to \infty$ means that $\Delta \to 0$ and $\mathbf{N} \to \mathbb{Z}^3$ in such a way that all points $x \in \mathcal{S}$ are reached in a natural way. Observe that the presence of the continuous-time regularization factor in the formal functional integral for the entire space has controlled the spatial lattice regularization in a clear and natural fashion; although possible to introduce, no temporal lattice has been required to obtain a well-defined expression.

The present usage of well-defined, phase-space measures to define functional integrals in the limit that the "diffusion constant" parameter (ν) diverges is part of the general program of *continuous-time regularization*.[14] It is noteworthy that the use of a suitable *phase-space metric* to control the Brownian motion paths invariably leads to a coherent-state representation for the resultant quantum amplitude. These remarks conclude our brief excursion into a rigorous discussion of the functional integrals of present interest.

Another prospective regularization: Let us return to the formal functional integral (29) and examine that expression with regard to the scalar density $b(x)$. Superficially, in the limit $\nu \to \infty$ in which the regularizing term proportional to $(1/2\nu)$ in the exponent of the integrand formally vanishes, one might naively expect that the result of the integral would be independent of the function $b(x)$. But, no, that naive expectation is false since the result of that integral and subsequent limit, i.e., the middle term of (29), evidently depends importantly on $b(x)$. At first glance, that dependence seems highly unnatural. It may be thought—as the author did for a number of years[15]—that an alternative regularization expression may be more "natural" and would therefore be preferable. In particular, it was thought that the expression

$$\exp\Bigg\{ -(1/2\nu) \int [g^{-1/2} g_{ab} g_{cd} \dot{\pi}^{bc} \dot{\pi}^{da} + g^{1/2} g^{ab} g^{cd} \dot{g}_{bc} \dot{g}_{da}]\, d^3x\, dt \Bigg\}, \tag{41}$$

where $g = \det[g_{ab}]$, and which involves a different phase-space metric, was "better." However, in light of the discussion in the present paper, it is now evident that this expression is not even dimensionally consistent. This defect could be rectified by the introduction of a positive constant,

which we may call $\tilde{b}$, that stands in the place of the present b (next to $g^{1/2}$) and carries the dimensions L^{-3}. Indeed, we could also introduce in place of $\tilde{b}$ a positive scalar function $\tilde{b}(x)$ with dimensions L^{-3}. In any case, the failure of (41) purely on dimensional grounds, and the necessity thereby of introducing some sort of auxiliary dimensioned parameter (or function) surely renders (41) far less ''natural'' than had been previously assumed.

As another possible argument against (41), we note that if that form of a proposed regularization was used in an expression like (29) in place of the present form of regularization, there is absolutely no guarantee that the result will describe a reproducing kernel with other than a *one-dimensional reproducing kernel Hilbert space*, which is the general result for a ''random'' choice of phase-space metric. The fact that the present form of (29) generates a suitable, infinite-dimensional reproducing kernel Hilbert space is a fundamentally important feature, which, in our case, is a consequence of having started with an appropriate reproducing kernel to begin with.

Although the author has not foreclosed any possible interest in a $\tilde{b}$ modified version of the regularization (41), all present indications point to the version (30) that features the scalar density $b(x)$. This shift of allegiance has also been bolstered by the realization that the role of $b(x)$ is confined to the initial phase of quantization and that $b(x)$ will disappear entirely after the constraints are fully enforced. On the strength of this argument, it is the version based on (30) and not (41) that is analyzed in the remainder of the present paper.

III. INTRODUCTION OF THE GRAVITATIONAL CONSTRAINTS

A. Key principles in heuristic form

There are four gravitational constraint functions, the three diffeomorphism constraints

$$H_a(x) = -2\,\pi^b_{a|b}(x), \tag{42}$$

where ''|'' denotes covariant differentiation with respect to the spatial metric g_{ab}, and the Hamiltonian constraint, which, in suitable units (i.e., $c^3/G = 16\pi$), reads

$$H(x) = g(x)^{-1/2}[\,\pi^a_b(x)\,\pi^b_a(x) - \tfrac{1}{2}\pi^a_a(x)\,\pi^b_b(x)\,] + g(x)^{1/2}\,{}^{(3)}R(x), \tag{43}$$

where $g(x) \equiv \det[g_{ab}(x)]$ and ${}^{(3)}R(x)$ denotes the scalar curvature derived from the spatial metric.[16] Classically, these constraint functions vanish, and the region in phase space on which they vanish is called the *constraint hypersurface*.

It is instructive to evaluate the classical Poisson brackets between the constraint fields. For this purpose, we enlist only the basic nonvanishing Poisson bracket given by

$$\{g_{ab}(x), \pi^{cd}(y)\} = \tfrac{1}{2}(\,\delta^c_a\delta^d_b + \delta^c_b\delta^d_a)\,\delta(x,y). \tag{44}$$

It follows that

$$\{H_a(x), H_b(y)\} = \delta_{,a}(x,y)H_b(x) - \delta_{,b}(x,y)H_a(x), \tag{45}$$

$$\{H_a(x), H(y)\} = \delta_{,a}(x,y)H(x), \tag{46}$$

$$\{H(x), H(y)\} = \delta_{,a}(x,y)g^{ab}(x)H_b(x). \tag{47}$$

In these expressions, $\delta_{,a}(x,y) \equiv \partial\delta(x,y)/\partial x^a$, which transforms as a ''vector density.'' It is clear that the Poisson brackets of the constraints vanish on the constraint hypersurface because the right-hand sides of (45)–(47) all vanish there, i.e., when $H_a(x) = 0 = H(x)$ for all $x \in \mathcal{S}$. This vanishing property of the Poisson brackets is characteristic of *first-class constraints*. Often, the Poisson bracket structure of constraints is that of a Lie bracket in which case such constraints are referred to as closed first-class constraints. In order for the Poisson bracket structure to be that of a Lie bracket, it is necessary that the coefficients of the constraints on the right-hand side involve

no dynamical variables. Taken by themselves, we note from (45) that the three diffeomorphism constraint functions form a set of closed first-class constraints. However, because of the last equation (47), it is clear that the complete set of four gravitational constraint functions do *not* have a Poisson structure which is that of a Lie algebra, and consequently the gravitational constraints are said to form an open first-class system of constraints. Such a situation does not automatically imply trouble in the corresponding quantum theory, but significant difficulties do arise in a number of cases. Quantum gravity is one of those cases.

Let us proceed formally in order to see the essence of the problem. Suppose that $\mathcal{H}_a(x)$ and $\mathcal{H}(x)$ represent local self-adjoint constraint operators for the gravitational field. Standard calculations lead to the commutation relations (with $\hbar=1$)

$$[\mathcal{H}_a(x),\mathcal{H}_b(y)]=i[\,\delta_{,a}(x,y)\,\mathcal{H}_b(x)-\delta_{,b}(x,y)\,\mathcal{H}_a(x)], \tag{48}$$

$$[\mathcal{H}_a(x),\mathcal{H}(y)]=i\,\delta_{,a}(x,y)\,\mathcal{H}(x), \tag{49}$$

$$[\mathcal{H}(x),\mathcal{H}(y)]=i\tfrac{1}{2}\delta_{,a}(x,y)[\hat{g}^{ab}(x)\mathcal{H}_b(x)+\mathcal{H}_b(x)\hat{g}^{ab}(x)], \tag{50}$$

where to ensure the Hermitian character we have symmetrized the right-hand side of the last expression. In the usual Dirac approach to constraints alluded to in Sec. I, one asks that $\Phi_\alpha|\psi\rangle_{\rm phys}=0$ for all constraints. If we assert that $\mathcal{H}_a(x)|\psi\rangle_{\rm phys}=0$ and $\mathcal{H}(x)|\psi\rangle_{\rm phys}=0$, then consistency holds for the first two sets of constraint commutators, but not for the third commutator in virtue of the fact that it is almost surely the case that $\hat{g}^{ab}(x)\,|\psi\rangle_{\rm phys}\notin\mathfrak{H}_{\rm phys}$, even if it were smeared. The expected behavior is somewhat like that of the single degree-of-freedom example where $Q|\psi\rangle=0$ and $P|\psi\rangle=0$ imply for standard Heisenberg operators that $[Q,P]|\psi\rangle=i|\psi\rangle=0$, i.e., there are no nonvanishing solutions. This behavior is characteristic of second-class constraints, and as a consequence of our discussion we are led to conclude, from a quantum mechanical standpoint, that part of the gravitational constraints are *second-class constraints*.[17] For the projection operator method of constrained system quantization, however, second-class constraints cause no special difficulty and, in particular, they are treated in just the same way as first-class constraints, as already noted in Sec. I.

Remark: Some researchers prefer to modify the theory so as to eliminate the second-class nature of the gravitational constraints. Instead, we accept the second-class constraints for what they are.

Assuming that the constraint fields $\mathcal{H}_a(x)$ and $\mathcal{H}(x)$ are local self-adjoint operators, we could—as one of several different alternatives—proceed as follows. Initially, besides the real, orthonormal set of test functions $\{h_p(x)\}$ introduced in Sec. II, let us introduce an additional set of real test functions $\{f^a_{p\,A}(x)\}$, $A\in\{1,2,3\}$, with the following properties:

$$b(x)\sum_{p=1}^{\infty}\sum_{A=1}^{3} f^a_{p\,A}(x)f^b_{p\,A}(y)=\tilde{g}^{ab}(x)\,\delta(x,y), \tag{51}$$

$$\int f^a_{p\,A}(x)f_{q\,B\,a}(x)b(x)\,d^3x=\delta_{pq}\delta_{AB}\,, \tag{52}$$

where $f_{q\,B\,a}(x)\equiv\tilde{g}_{ab}(x)f^b_{q\,B}(x)$. Regarding the set of functions $\{f^a_{p\,A}(x)\}$, the index A is a dreibein index, while the index a is a three-space vector index. With the help of these sets of expansion functions, let us introduce

$$\mathcal{H}_{(p)\,A}\equiv\int f^a_{p\,A}(x)\mathcal{H}_a(x)\,d^3x, \tag{53}$$

$$\mathcal{H}_{(p)}\equiv\int h_p(x)\mathcal{H}(x)\,d^3x, \tag{54}$$

each for $1 \leqslant p < \infty$, and similarly for other vector and scalar functions. In this form as well, part of the constraint operators are second class. To accomodate all these constraints we introduce a set of projection operators defined for all $P \in \{1,2,3,\ldots\}$ and given by

$$\mathbb{E}_P \equiv \mathbb{E}(X_P^2 \leqslant \delta(\hbar)^2), \tag{55}$$

$$X_P^2 \equiv \sum_{p=1}^{P} 2^{-p} \left[\sum_{A=1}^{3} (\mathcal{H}_{(p)\,A})^2 + \mathcal{H}_{(p)}^2 \right]. \tag{56}$$

As defined, the projection operators $\mathbb{E}_P$ are regularized and they serve to define regularized physical Hilbert spaces $\mathfrak{H}_{\text{phys}} \equiv \mathbb{E}_P \mathfrak{H}$. These regularized physical Hilbert spaces may, in turn, be characterized by their own reproducing kernels

$$\langle \pi'', g'' | \mathbb{E}_P | \pi', g' \rangle, \tag{57}$$

and the regularized physical Hilbert spaces themselves may, therefore, be represented by the associated reproducing kernel Hilbert spaces.

The final step in the present construction procedure would involve suitable limits to remove the regularizations. More familiar procedures to enforce the constraints are discussed in Sec. IV.

B. Functional integral representation for the relevant projection operators

In an earlier work,[5] we have presented a very general procedure to construct the projection operator $\mathbb{E}(\Sigma_\alpha \Phi_\alpha^2 \leqslant \delta(\hbar)^2)$ by means of a universal functional integral procedure. In particular, it follows that

$$\mathbb{E}(\Sigma_\alpha \Phi_\alpha^2 \leqslant \delta(\hbar)^2) = \int \mathbf{T}\, e^{-i\int \lambda^\alpha(t)\Phi_\alpha\, dt}\, \mathcal{D}R(\lambda), \tag{58}$$

where $\mathbf{T}$ denotes the time-ordering operator, $\{\lambda^\alpha(t)\}_{\alpha=1}^{A}$, $0 \leqslant t < T$, denotes a set of c-number "Lagrange multiplier" functions, and $\mathcal{D}R(\lambda)$ denotes a formal measure on such functions. A suitable measure R may be determined as follows: First, introduce a Gaussian integral over the set $\{\lambda^\alpha(t)\}$ so that

$$\mathcal{N}_\gamma \int \mathbf{T}\, e^{-i\int \lambda^\alpha(t)\Phi_\alpha\, dt}\, e^{(i/4\gamma)\int \Sigma_\alpha \lambda^\alpha(t)^2\, dt}\, \mathcal{D}\lambda = e^{-i\gamma \Sigma_\alpha \Phi_\alpha^2}. \tag{59}$$

Second, and last, integrate over γ according to the rule

$$\lim_{\zeta \to 0^+} \lim_{L \to \infty} \int_{-L}^{L} \frac{\sin\{\gamma[\delta(\hbar)^2 + \zeta]\}}{\pi\gamma} e^{-i\gamma \Sigma_\alpha \Phi_\alpha^2}\, d\gamma = \mathbb{E}(\Sigma_\alpha \Phi_\alpha^2 \leqslant \delta(\hbar)^2). \tag{60}$$

The inclusion of the variable ζ and the limit $\zeta \to 0^+$ ensures that we include the equality sign in the argument of $\mathbb{E}$. Observe that this construction is entirely independent of the nature of the set of constraints $\{\Phi_\alpha\}$.

Next, we continue to proceed formally in order to envisage how the projection operator method may be used in the case of gravity. Adopting the foregoing analysis, we suggest that

$$\mathbb{E}_P = \mathbb{E}\left(\sum_{p=1}^{P} 2^{-p} \left[\sum_{A=1}^{3} (\mathcal{H}_{(p)\,A})^2 + \mathcal{H}_{(p)}^2 \right] \right) = \int \mathbf{T}\, e^{-i\Sigma_{p=1}^{P} \int [\Sigma_{A=1}^{3} N_{(p)\,A}\, \mathcal{H}_{(p)\,A} + N_{(p)} \mathcal{H}_{(p)}]\, dt}\, \mathcal{D}R(N^a, N) \tag{61}$$

for an appropriately defined formal measure R. Observe that the integral over the measure R may well integrate over degrees of freedom that are not present in the time-ordered product (such as for

$p>P$); however, there is no harm in doing so since R is already defined so that $\int \mathcal{D}R=1$. We may also go one step further and assert that as $P\to\infty$ we obtain the formal expression

$$\mathbb{E}=\int \mathbf{T}\, e^{-i\int [N^a\mathcal{H}_a+N\mathcal{H}]\, d^3x\, dt}\, \mathcal{D}R(N^a,N), \tag{62}$$

which, heuristically at least, realizes the projection operator that projects the original Hilbert space onto a correspondingly regularized physical Hilbert space.

C. Functional integral representation of the reproducing kernel for the physical Hilbert space

In Sec. II, we presented in (25) a continuous-time regularized functional integral representation of the reproducing kernel $\langle \pi'',g''|\pi',g'\rangle$ for the original Hilbert space. The reproducing kernel for the (regularized) physical Hilbert space is given, in turn, by the expression $\langle \pi'',g''|\mathbb{E}|\pi',g'\rangle$. In order to give this latter expression a functional integral representation we first regard

$$\int\, [N^a\mathcal{H}_a+N\mathcal{H}]\, d^3x \tag{63}$$

as a time-dependent ''Hamiltonian'' for some fictitious theory, in which case

$$\begin{aligned}
&\langle \pi'',g''|\mathbf{T}\, e^{-i\int [N^a\mathcal{H}_a+N\mathcal{H}]\, d^3x\, dt}|\pi',g'\rangle \\
&\quad=\lim_{\nu\to\infty}\overline{\mathcal{N}}_\nu\int\, \exp\left\{-i\int\, [g_{ab}\dot\pi^{ab}+N^aH_a+NH]d^3x\, dt\right\} \\
&\qquad\times\exp\left\{-(1/2\nu)\int\, [b(x)^{-1}g_{ab}g_{cd}\dot\pi^{bc}\dot\pi^{da}+b(x)g^{ab}g^{cd}\dot g_{bc}\dot g_{da}]\, d^3x\, dt\right\} \\
&\qquad\times\prod_{x,t}\prod_{a\leqslant b}\, d\pi^{ab}(x,t)\, dg_{ab}(x,t).
\end{aligned} \tag{64}$$

In this expression, there appear symbols $H_a(\pi,g)$ and $H(\pi,g)$ corresponding to the quantum operators $\mathcal{H}_a$ and $\mathcal{H}$. Superficially, these symbols may (formally) be identified with the classical diffeomorphism and Hamiltonian constraint functions, in which case the expression (64) contains in its phase, and up to a surface term, the full Einstein action. Thus (64) comes ever closer to looking like a more traditional functional integral for gravity.

However, before integrating over the functions N^a and N and completing the story, we need to caution the reader that $\hbar$ is not zero (but rather one) and therefore the symbols H_a and H may not coincide with their usual classical expressions. All we can say at present is that H_a is a symbol for the operator $\mathcal{H}_a$, $a=1,2,3$, and that H is a symbol for the operator $\mathcal{H}$. The connection between symbol and operator is implicitly contained in (64), and since, for the moment, the functions N_a and N are general functions within our control, we may use that fact to assert that

$$\begin{aligned}
&\langle \pi'',g''|\int\, [M^a(y)\mathcal{H}_a(y)+M(y)\mathcal{H}(y)]d^3y|\pi',g'\rangle \\
&\quad=\lim_{\nu\to\infty}\overline{\mathcal{N}}_\nu\int\, e^{-i\int g_{ab}\dot\pi^{ab}d^3x\, dt}\int\, [M^a(y)H_a(y,s)+M(y)H(y,s)]d^3y \\
&\qquad\times\exp\left\{-(1/2\nu)\int\, [b(x)^{-1}g_{ab}g_{cd}\dot\pi^{bc}\dot\pi^{da}+b(x)g^{ab}g^{cd}\dot g_{bc}\dot g_{da}]d^3x\, dt\right\} \\
&\qquad\times\prod_{x,t}\prod_{a\leqslant b}\, d\pi^{ab}(x,t)dg_{ab}(x,t)
\end{aligned} \tag{65}$$

for any smooth (test) functions M^a and M and for any time s, $0<s<T$. Equation (65) gives an implicit connection between symbol and operator for the present theory. We observe that the more traditional connection between symbol and operator that normally holds for Wiener-regularized coherent-state path integrals[14] is unavailable in the present case since we are dealing with so-called weak coherent states for which no resolution of unity exists; see Refs. 1 and 13.

In addition, thanks to analyticity in the present case, the diagonal matrix elements of an operator uniquely determine the operator, and so we can also assert the connection between symbol and operator (given by setting $\pi'',g''=\pi',g'$),

$$\begin{aligned}\int\ & [M^a(y)\langle \pi',g'|\mathcal{H}_a(y)|\pi',g'\rangle + M(y)\langle \pi',g'|\mathcal{H}(y)|\pi',g'\rangle]d^3y \\ &= \lim_{\nu\to\infty}\overline{\mathcal{N}}_\nu\int e^{-i\oint g_{ab}\dot{\pi}^{ab}\,d^3x\,dt}\int [M^a(y)H_a(y,s)+M(y)H(y,s)]d^3y \\ &\quad\times\exp\left\{-(1/2\nu)\int [b(x)^{-1}g_{ab}g_{cd}\dot{\pi}^{bc}\dot{\pi}^{da}+b(x)g^{ab}g^{cd}\dot{g}_{bc}\dot{g}_{da}]d^3x\,dt\right\} \\ &\quad\times\prod_{x,t}\prod_{a\leqslant b}d\pi^{ab}(x,t)dg_{ab}(x,t),\end{aligned} \tag{66}$$

again for smooth functions M^a and M and any s, $0<s<T$. We note that $\langle \pi',g'|\mathcal{H}_a(y)|\pi',g'\rangle$ and $\langle \pi',g'|\mathcal{H}(y)|\pi',g'\rangle$ denote still other symbols that are often associated with the local operators $\mathcal{H}_a(x)$ and $\mathcal{H}(x)$, respectively. In (66), the notation $\oint g_{ab}\dot{\pi}^{ab}\,d^3x\,dt$ means that only closed paths in phase space enter, i.e., just those paths for which the functions

$$\pi^{ab}(x,0)=\pi^{ab}(x,T)\equiv\pi'^{ab}(x), \tag{67}$$

$$g_{ab}(x,0)=g_{ab}(x,T)\equiv g'_{ab}(x) \tag{68}$$

for all $x\in\mathcal{S}$. Note that a *closed* line integral in phase space involves just the symplectic form, and the result of the integral $\oint g_{ab}\dot{\pi}^{ab}\,d^3x\,dt$ is *invariant* under any (smooth) change of canonical coordinates.

Reproducing kernel for the physical Hilbert space: We now complete the story by interpreting the otherwise arbitrary c-number functions N^a and N as Lagrange multiplier functions and integrating them out of (64). Since N^a and N are not dynamical variables that must enter the formal phase-space functional integral measure in a prescribed way (i.e., as "$dp\,dq$"), we are free to integrate them as we choose—and we choose to integrate them in such a way as to *enforce the quantum constraints*, at least in a regulated fashion. As explained above, one natural way to achieve our goal involves the formal integration measure $\mathcal{D}R(N^a,N)$.

Combining several steps previously described, we now assert that the reproducing kernel for the regularized physical Hilbert space has the phase-space functional integral representation given by

$$\begin{aligned}\langle \pi'',g''|\mathbb{E}|\pi',g'\rangle &= \int \langle \pi'',g''|\mathbf{T}e^{-i\int[N^a\mathcal{H}_a+N\mathcal{H}]d^3x\,dt}|\pi',g'\rangle\mathcal{D}R(N^a,N) \\ &= \lim_{\nu\to\infty}\overline{\mathcal{N}}_\nu\int e^{-i\int[g_{ab}\dot{\pi}^{ab}+N^aH_a+NH]d^3x\,dt} \\ &\quad\times\exp\left\{-(1/2\nu)\int [b(x)^{-1}g_{ab}g_{cd}\dot{\pi}^{bc}\dot{\pi}^{da}+b(x)g^{ab}g^{cd}\dot{g}_{bc}\dot{g}_{da}]d^3x\,dt\right\} \\ &\quad\times\left[\prod_{x,t}\prod_{a\leqslant b}d\pi^{ab}(x,t)dg_{ab}(x,t)\right]\mathcal{D}R(N^a,N).\end{aligned} \tag{69}$$

In this final expression we have reached our primary goal, at least from a formal perspective. Despite the general appearance of (69), we emphasize once again that this representation has been based on the affine commutation relations and *not* on any canonical commutation relations. Later, we shall discuss a more careful definition of this formal expression along lines introduced in Sec. II, but for now let us examine (69) for its own sake.

We first comment on the range of integration for the "lapse" variable $N(x,t)$, a subject of recurrent interest.[18] Our view is that the range $-\infty<N(x,t)<\infty$ is the proper range when quantizing the theory. After all, in the Hamiltonian viewpoint, *space–time is a derived structure* of the classical theory. In principle, the issue here is no more complicated than for the reparametrized one-dimensional free particle. For this example, the original classical action is $I=\int[p\dot{q}-\frac{1}{2}p^2]dt$, where $\dot{q}\equiv dq/dt$, and has solutions $p(t)=p_o$ and $q(t)=p_o t+q_o$. The reparametrized version is given by $I'=\int[pq^*+st^*-\lambda(s+\frac{1}{2}p^2)]d\tau$, where $q^*\equiv dq/d\tau$, $t^*\equiv dt/d\tau$, and has solutions $p(\tau)=p_o$, $s(\tau)=s_o=-\frac{1}{2}p_o^2$, $t(\tau)\equiv\int_0^\tau\lambda(\sigma)d\sigma$, and $q(\tau)=t(\tau)p_o+q_o$. The function $\lambda(\tau)$ is essentially arbitrary. If, for example, $\lambda(\tau)=3\tau^2-1$, i.e., $t(\tau)=\tau(\tau^2-1)$, the solution seems "to go backward in time," but that interpretation gives to the variable τ an unwarranted physical significance. The given solution is not wrong, it just repeats itself for a while. We can avoid a repeating behavior, e.g., by simply dropping the interval $-1\leqslant\tau<1$. No such issues occur if we require that $\lambda(\tau)>0$ for all τ, in which case τ does indeed merit the name of "reparametrized time." By analogy, the function $N(x,t)$—which we have loosely called the lapse function—only deserves that name when, in the classical solution space, we insist that $N(x,t)>0$; otherwise it is just another Lagrange multiplier function, no more and no less.

When one starts from a classical perspective, with its focus on physically relevant functions $N(x,t)$ which are strictly positive, it is a conceptual leap to change to functions $N(x,t)$ that can take on both signs.[18] However, when one starts from the quantum theory, as we have done, there is no such leap to make.

As a second topic regarding (69) we focus on its general structure. With H_a and H formally equal to the constraint functions of gravity (possibly up to terms in $\hbar$,) the action appearing in the phase factor is indeed appropriate to gravity.[18] Moreover, the domain of integration is restricted to positive-definite metrics $\{g_{ab}(x,t)\}>0$. Indeed, the particular ν-dependent regularizing phase-space metric in (69) *prevents the metric variable* $\{g_{ab}\}$ *from escaping the positive–definite domain.*

As a useful analogy, we note that the two-dimensional phase space metric

$$\beta^{-1}q^2\,dp^2+\beta q^{-2}\,dq^2 \tag{70}$$

is geodesically complete in the half-space $(p,q)\in\mathbb{R}\times\mathbb{R}^+$, and when it is part of a Brownian motion measure, as in the formal expression [cf., (38)]

$$\mathcal{N}e^{-(1/2\nu)\int[\beta^{-1}q^2\dot{p}^2+\beta q^{-2}\dot{q}^2]dt}\,\mathcal{D}p\,\mathcal{D}q, \tag{71}$$

it automatically restricts the Brownian motion trajectories to the half-space $\mathbb{R}\times\mathbb{R}^+$.

Last, we comment on the formal functional integration measure in (69), specifically for the Lagrange multiplier functions N^a and N. The formal measure $\mathcal{D}R$ has been defined earlier and is unlike conventional measures chosen for such variables. As emphasized here, and elsewhere,[5] the measure $\mathcal{D}R$ is *designed to implement the quantum constraints*—as befits a quantum theory—and it has *not* been selected to enforce the classical constraints. Observe well that we have not "blindly postulated" the functional integral (69), but instead it has been *derived* as a specific functional integral representation of the well-chosen quantum matrix elements on the left-hand side. Unfamiliar as the measure $\mathcal{D}R$ may appear, we maintain that $\mathcal{D}R$—or some other measure equivalent to it—is the proper measure to choose to achieve our goal. Whether different treatments of the Lagrange multiplier functions that have been adopted by other workers are indeed equivalent or not to the use of $\mathcal{D}R$ is an interesting question, but it is not one we pursue here.

IV. DISCUSSION

In the preceding analysis, we have been strongly guided by the operator structure of the assumed theory of affine quantum gravity, and this discussion has led us to the formal functional integral representation (69) for the desired matrix elements. As was previously the case [cf. (29)], we now wish to turn (69) around and adopt the formal functional integral as our starting point and, in effect, use that expression to *define* the reproducing kernel for the regularized physical Hilbert space. Specifically, for that purpose, let us focus on the formal expression

$$\lim_{\nu\to\infty}\overline{\mathcal{N}}_\nu\int e^{i\int[\pi^{ab}\dot{g}_{ab}-N^aH_a-NH]d^3x\,dt}\exp\Bigg\{-(1/2\nu)\int[b(x)^{-1}g_{ab}g_{cd}\dot{\pi}^{bc}\dot{\pi}^{da}$$

$$+b(x)g^{ab}g^{cd}\dot{g}_{bc}\dot{g}_{da}]d^3x\,dt\Bigg\}\mathcal{D}\pi\,\mathcal{D}g\,\mathcal{D}R(N^a,N). \tag{72}$$

Note the change of the kinematic term, which simply amounts to a phase factor in the definition of the coherent states. Also we have introduced the common shorthand $\mathcal{D}\pi\,\mathcal{D}g$ for the bracketed term in (69). For the sake of discussion, we shall refer to (72) as the ''nonstandard expression.'' Our goal in this section is to discuss the nonstandard expression and see what steps are necessary to give it a proper meaning. We shall do so in a three step procedure: First, we compare the ''standard'' (see below) and ''nonstandard'' expressions. Second, we discuss a regularization and its removal that ultimately involves the elimination of the scalar density $b(x)$. Third, we examine the aspect of the problem that normally accounts for the perturbative nonrenormalizability of the gravitational field.

A. First look at the nonstandard expression

It is interesting to compare (72) with what we refer to as the standard expression for a phase-space functional integral for gravity. By the ''standard expression'' we mean the formal functional integral

$$\mathcal{M}\int e^{i\int[\pi^{ab}\dot{g}_{ab}-N^aH_a-NH]d^3x\,dt}\mathcal{D}\pi\,\mathcal{D}g\,\mathcal{D}N, \tag{73}$$

where $\mathcal{D}N\equiv\Pi_{x,t}dN(x,t)\Pi_a\,dN^a(x,t)$. In several important ways, the standard expression is *very* different than the nonstandard expression. Let us first comment on some of those differences. Much as it would be nice to think otherwise, one must recognize that the standard expression (73) is *totally undefined* as it stands; it is little more than a fancy way of writing $0\times(\infty)$. It begs for a definition as the limit of meaningful expressions [much as $0\times(\infty)$ may, for example, be defined as $\lim_{x\to 0}x\times(7/x)=7$], but what set of meaningful expressions should be chosen in the gravitational case is far from clear. A lattice limit? But then, what form should the regularized lattice expressions take? Symmetry and covariance offer only limited guidance. In point of fact, this same question faces any standard phase-space path integral, even that for a single degree of freedom in which a conventional lattice definition—as originally envisaged by Tobocman[19]—makes certain assumptions about the nature of the phase-space coordinates which may or may not be true.

Remark: The skeptical reader is urged to propose a lattice prescription to quantize the nonrelativistic free particle of unit mass by a phase-space path integral whose Hamiltonian H is expressed in canonical coordinates p and q such that $H=\frac{1}{2}(p^2+q^2)$.

A further complication of the standard functional integral expression (73) arises from the *unbounded nature* of the formal integral $\int\cdots\mathcal{D}N$ over the Lagrange multiplier variables. This choice of integration measure, which is designed to enforce the classical constraints and thereby reduce the classical phase space before quantization, necessitates *gauge fixing* (to eliminate concomitant divergences) which reduces the classical phase space further to the physical phase space (at least locally) where each point labels a physically distinct state. Quantization on the reduced phase space is formally aided by the introduction of some additional factor (e.g., a Faddeev–

Popov determinant, or its analogue), which may well lead to significant (Gribov) ambiguities which require a substantial modification of the functional integral,[20,7] and give rise to serious problems (such as unitary violation) within a BRST formulation.[21]

Nonstandard expression: Let us raise similar issues regarding the nonstandard expression (72). Although (72) is formal as it stands, it can, to a considerable extent, already be regarded as ''nearly'' well defined. As noted in Sec. II, we can combine several factors together to make, for all finite ν, a positive, countably additive, pinned measure on generalized functions. What makes (72) not well defined is the fact that the formal integrand does not constitute an integrable function with respect to that measure. We have already encountered that problem in Sec. II before any constraints were introduced, and we found that we could overcome that problem by regularizing the integrand and removing that regularization as a final step. Superficially, the same property holds when the constraint functions are present (say for fixed Lagrange multiplier values), save for one very important distinction (involving the field operator representation) which we shall address in the second point of discussion below.

Regarding the integration over the Lagrange multiplier variables, we emphasize the vast difference afforded by the projection operator method. First and foremost is the fact that *no gauge fixing* is introduced, no ghosts are used, no Faddeev–Popov determinant (or its analogue) arises, and consequently, no Gribov ambiguities can exist. These properties arise, largely, because $\int \mathcal{D}R(N^a,N)=1$, while $\int \mathcal{D}N=\infty$. The difference here could not be greater, and it arises because in the former case one quantizes first and reduces second, while in the latter case one reduces first and quantizes second. Except in basically trivial cases, the second option is fraught with substantial obstacles.[7]

One of the most significant differences between the standard and the nonstandard expressions refers to the representation of the quantum mechanical amplitudes that is involved. For the standard expression, it is usually assumed that (73) leads to a representation in which the metric field operator $\hat{g}_{ab}(x)$ is diagonalized and thus is sharply represented. In combination with any needed auxiliary factor in the functional integral, diffeomorphism invariance suggests that (73) depends only on the ''geometry'' of the initial and final three surfaces, and not on the details of any specific metric expressions.[16,18] An analogous view is also prominent in the associated ''loop quantum gravity'' in which, e.g., bras and kets depend only on knot invariants as labels of ''physically'' distinguishable states.[22] In contrast, the representation afforded by the nonstandard expression (72) is that of a *coherent-state representation*, which depends on smooth metric g_{ab} and momentum π^{ab} fields, that represent not *sharp* operator (eigen)values but suitable *mean* values, e.g.,

$$\langle \pi,g|\hat{\pi}^{ab}(x)|\pi,g\rangle=\pi^{ab}(x), \tag{74}$$

$$\langle \pi,g|\hat{g}_{ab}(x)|\pi,g\rangle=g_{ab}(x), \tag{75}$$

$$\langle \pi,g|\hat{\pi}^{b}_{a}(x)|\pi,g\rangle=g_{ac}(x)\pi^{cb}(x). \tag{76}$$

Note well, that besides the local self-adjoint metric $\hat{g}_{ab}(x)$ and scale field $\hat{\pi}^{b}_{a}(x)$ operators, we have used the momentum *bilinear form* $\hat{\pi}^{ab}(x)$ (which is *not* a local operator) in the first of these expressions. These expectations are not gauge invariant, nor should they be, since they are taken in the ''original'' Hilbert space where the constraints are not fulfilled. The gauge invariant part of the metric field, for example, and in so far as the regularized physical Hilbert space is concerned, is determined by the matrix elements

$$\langle \pi'',g''|\mathbb{E}g_{ab}(x)\mathbb{E}|\pi',g'\rangle, \tag{77}$$

which is an expression that does not require restricting the functional dependence of the bras and kets.

B. Second look at the nonstandard expression

In interpreting (72) we have concluded above that we must first regularize the integrand in order to obtain an integrable function. For the kinematic term $\int \pi^{ab}\dot{g}_{ab}\, d^3x\, dt$—and even for the diffeomorphism constraint contribution $-\int N^a H_a\, d^3x\, dt$—any natural regularization, such as one based on the expansion functions $\{h_p(x)\}$ and $\{f^a_{pA}(x)\}$, or a lattice formulation as discussed in Sec. II, will be compatible regularizations. For these terms alone, the limit of the regularized functional integral as the regularization is removed will converge to the desired result. The implication of this fact is that these parts of the integrand are compatible with the initial (ultralocal) representation of the field operators; in fact, they are compatible with any diffeomorphism invariant realization. However, when it comes time to consider the Hamiltonian constraint, the behavior is quite different. While it is true that regularizing the Hamiltonian constraint will lead to a set of well-defined functional integrals, the limit of such regularized expressions will *not* converge to an acceptable result. There are two basic and important reasons for this unsatisfactory behavior, one of which (wrong field operator representation) we will deal with in this section, the other of which (perturbative nonrenormalizability of gravity) we will discuss in the next section.

The first reason for the lack of a suitable convergence of the regularized nonstandard functional integral relates to the fact that the representation of the field operators needed to satisfy the Hamiltonian constraint is unitarily inequivalent to the ultralocal representation imposed in the initial stage of the quantization procedure. It is at the present stage of the analysis that we finally encounter the fact that our initial choice of field operator representation is incompatible with making the Hamiltonian constraint operator $\mathcal{H}(x)$ into a densely defined local operator. Stated otherwise, using the ultralocal operator representation, the operator $\int N(x,t)\mathcal{H}(x)d^3x\, dt$, for any nonzero smooth function $N(x,t)$, has only the zero vector in its domain. This defect must be fixed before proceeding, and in so doing we will be explicitly led to a new representation of the field operators, one that is unitarily inequivalent to our starting (ultralocal) representation. In the process of effecting this change of representation, the scalar density $b(x)$ will disappear from the scene entirely.

1. Pedagogical example

It is pedagogically useful to outline an analogous story for a simpler and more familiar example. Consider general, locally self-adjoint field and momentum operators, $\hat{\phi}(x)$ and $\hat{\pi}(x)$, $x\in\mathbb{R}^3$, which satisfy the canonical commutation relations

$$[\hat{\phi}(x),\hat{\pi}(y)]=i\,\delta(x-y). \tag{78}$$

Build a set of coherent states

$$|\pi,\phi\rangle\equiv e^{i[\hat{\phi}(\pi)-\hat{\pi}(\phi)]}|\eta\rangle, \tag{79}$$

where $\hat{\phi}(\pi)\equiv\int\hat{\phi}(x)\pi(x)d^3x$ and $\hat{\pi}(\phi)\equiv\int\hat{\pi}(x)\phi(x)d^3x$, with π and ϕ real test functions, and $|\eta\rangle$ is a normalized but otherwise unspecified fiducial vector. Note well that the choice of $|\eta\rangle$ in effect determines the representation of the canonical field operators. We next present a portion of the story from Ref. 8.

We initially choose $|\eta\rangle$ to correspond to an ultralocal representation such that

$$\langle\pi'',\phi''|\pi',\phi'\rangle=\exp\left\{\frac{1}{2}i\int[\phi''(x)\pi'(x)-\pi''(x)\phi'(x)]d^3x\right\}$$
$$\times\exp\left(-\frac{1}{4}\int\{M(x)^{-1}[\pi''(x)-\pi'(x)]^2+M(x)[\phi''(x)-\phi'(x)]^2\}d^3x\right). \tag{80}$$

Here $M(x)$, $0<M(x)<\infty$, is an arbitrary (smooth) function of the ultralocal representation with the dimensions of M. The given ultralocal field operator representation is in fact unitarily inequivalent for each distinct function $M(x)$. [Note well that $M(x)$ here plays the role of $b(x)$ in the present paper.]

We wish to apply this formulation to describe the *relativistic free field of mass m* for which the Hamiltonian operator is formally given by

$$\mathcal{H}=\frac{1}{2}\int :\{\hat{\pi}(x)^2+[\nabla\hat{\phi}(x)]^2+m^2\hat{\phi}(x)^2\}:d^3x. \tag{81}$$

If we build this operator out of the field and momentum operators in the ultralocal representation, then no matter what vector is used to define : :, $\mathcal{H}$ will have only the zero vector in its domain. We need to change the field operator representation, which means we have to change the fiducial vector from $|\eta\rangle$ to $|0;m\rangle$, the true ground state of the proposed Hamiltonian operator $\mathcal{H}$.

Let us first regularize the formal Hamiltonian $\mathcal{H}$. To that end, let $\{u_n(x)\}$ denote a complete set of real, orthonormal functions on $\mathbb{R}^3$ and define the sequence of kernels, for all $N\in\{1,2,3,\ldots\}$, given by

$$K_N(x,y)\equiv\sum_{n=1}^{N} u_n(x)u_n(y), \tag{82}$$

which converges to $\delta(x-y)$ as a distribution when $N\to\infty$. Let

$$\hat{\phi}_N(x)\equiv\int K_N(x,y)\,\hat{\phi}(y)\,d^3y, \tag{83}$$

$$\hat{\pi}_N(x)\equiv\int K_N(x,y)\,\hat{\pi}(y)d^3y, \tag{84}$$

and with these operators build the sequence of regularized Hamiltonian operators

$$\mathcal{H}_N\equiv\frac{1}{2}\int :\{\hat{\pi}_N(x)^2+[\nabla\hat{\phi}_N(x)]^2+m^2\hat{\phi}_N(x)^2\}:d^3x \tag{85}$$

for all N, where : : denotes normal order with respect to the ground state $|0;m\rangle_N$ of $\mathcal{H}_N$.

We would like to have a constructive way to identify the ground state of $\mathcal{H}_N$. For this purpose consider the set

$$S_N\equiv\left\{\frac{\Sigma_{j,k=1}^{J}\,a_j^*a_k\langle\pi_j,\phi_j|e^{-\mathcal{H}_N^2}|\pi_k,\phi_k\rangle}{\Sigma_{j,k=1}^{J}\,a_j^*a_k\langle\pi_j,\phi_j|\pi_k,\phi_k\rangle}:J<\infty\right\} \tag{86}$$

for general sets $\{a_j\}$ (not all zero), $\{\pi_j\}$, and $\{\phi_j\}$. (How these expressions may be generated is discussed in Ref. 8.) As N grows, the general element in S_N becomes exponentially small, save for elements that correspond to vectors which well approximate the ground state $|0;m\rangle_N$. Suitable linear combinations can convert the original reproducing kernel $\langle\pi'',\phi''|\pi',\phi'\rangle$ to the reproducing kernel $\langle\pi'',\phi'';m|\pi',\phi';m\rangle_N$ which is based on a fiducial vector that has the form $|0;m\rangle_N$ for the first N degrees of freedom and is unchanged for the remaining degrees of freedom. Finally, we may take the limit $N\to\infty$ which then leads to

$$\langle \pi'', \phi''; m | \pi', \phi'; m \rangle = \exp\left\{ \frac{1}{2} i \int [\tilde{\phi}''^*(k)\tilde{\pi}'(k) - \tilde{\pi}''^*(k)\tilde{\phi}'(k)] d^3k \right\}$$
$$\times \exp\left(-\frac{1}{4} \int \{\omega(k)^{-1} |\tilde{\pi}''(k) - \tilde{\pi}'(k)|^2 + \omega(k) |\tilde{\phi}''(k) - \tilde{\phi}'(k)|^2\} d^3k \right), \tag{87}$$

where $\omega(k) \equiv \sqrt{k^2 + m^2}$ and $\tilde{\pi}(k) \equiv (2\pi)^{-3/2} \int e^{-ik\cdot x} \pi(x) d^3x$, etc. The procedure sketched above is referred to as *recentering the coherent states* or equivalently as *recentering the reproducing kernel*. This form of reproducing kernel is no longer ultralocal and contains no trace of the scalar function $M(x)$, whatever form it may have had. Moreover, and this is an important point, the new representation is fully compatible with the Hamiltonian $\mathcal{H}$ being a non-negative, self-adjoint operator. Indeed, the expression for the propagator is given by

$$\langle \pi'', \phi''; m | e^{-i\mathcal{H}T} | \pi', \phi'; m \rangle = L'' L' \exp\left[\int \tilde{\zeta}''^*(k) e^{-i\omega(k)T} \tilde{\zeta}'(k) d^3k \right], \tag{88}$$

where

$$\tilde{\zeta}(k) \equiv [\omega(k)^{1/2} \tilde{\phi}(k) + i\omega(k)^{-1/2} \tilde{\pi}(k)] / \sqrt{2}, \tag{89}$$

$$L \equiv \exp\left[-\frac{1}{2} \int |\tilde{\zeta}(k)|^2 d^3k \right]. \tag{90}$$

The definition offered by (88) is continuous in T, which is the principal guarantor that the expression

$$\mathcal{H} = \frac{1}{2} \int :\{\hat{\pi}(x)^2 + [\nabla \hat{\phi}(x)]^2 + m^2 \hat{\phi}(x)^2\}: d^3x, \tag{91}$$

where : : denotes normal ordering with respect to the ground state $|0; m\rangle$ of the operator $\mathcal{H}$, is a self-adjoint operator as desired.

Let us summarize the basic content of the present pedagogical example. Even though we started with a very general ultralocal representation, as characterized by the general function $M(x)$, we have forced a complete change of representation to one compatible with the Hamiltonian operator for a relativistic free field of arbitrary mass m. In so doing all trace of the initial arbitrary function $M(x)$ has disappeared, and in its place, effectively speaking, has appeared the pseudodifferential operator $\sqrt{-\nabla^2 + m^2}$ having only its dimension (mass) in common with the original function $M(x)$. The original ultralocal representation is completely gone. [Remark: A moments reflection should convince the reader that a comparable analysis can be made for either the interacting ϕ_2^4 or ϕ_3^4 model as well, both of which satisfy (78), showing that the general argument is not limited just to free theories; see Ref. 8.]

2. Strong coupling gravity

The discussion in the present paper has been predicated on the assumption that we are analyzing the gravitational field and therefore the classical Hamiltonian is that given in (43). However, it is pedagogically instructive if we briefly comment on an approximate theory—based on the so-called ''strong coupling approximation''[23]—where the Hamiltonian constraint (43) is replaced by the expression

$$H_{\mathrm{SCA}}(x) \equiv g(x)^{-1/2} [\pi_b^a(x) \pi_a^b(x) - \tfrac{1}{2} \pi_a^a(x) \pi_b^b(x)] + 2\Lambda g(x)^{1/2}, \tag{92}$$

in which the term proportional to ${}^{(3)}R(x)$ has been dropped, and where we have also introduced the cosmological constant Λ (with dimensions L^{-2}) and an associated auxiliary term in the Hamiltonian. The result is a model for which the new Hamiltonian constraint (92) is indeed compatible with some form of an ultralocal representation. The proper form of that ultralocal representation may be determined by a similar procedure, i.e., by studying an analogue of the set S_N, and by recentering the reproducing kernel based on ensuring that the quantum version of $H_{\rm SCA}(x)$ is a local self-adjoint operator. In so doing, we note that it may happen that not all arbitrariness of the original scalar density $b(x)$ is "squeezed out" by the recentering procedure described above. This situation occurs because a one-parameter arbitrariness generally remains for typical ultralocal models.[12] [Any remaining arbitrariness in the ultralocal case is in contrast with that of the true Hamiltonian constraint for gravity for which we expect no trace of the original function $b(x)$ to remain.] These remarks conclude our discussion of strong coupling gravity.

C. Third look at the nonstandard expression

The preceding discussion has been based on the assumption that some fiducial vector can be found compatible with the Hamiltonian operator constraint, or stated otherwise, that the Hamiltonian constraint can actually be realized as a local self-adjoint operator. This requirement is by no means obvious, and it is to this issue that we now turn our attention. The difficulty arises because the naive form of the Hamiltonian constraint operator almost surely needs some form of renormalization if it is going to be well defined. If perturbation theory is any guide, we not only expect that there will be renormalization counterterms, but because gravity is perturbatively nonrenormalizable, one may expect an infinite number of distinct counterterms. On the other hand, as we next argue, it is possible that perturbation theory is not a very reliable guide in the case of perturbatively nonrenormalizable theories.

1. Nonrenormalizable scalar fields

Consider the case of perturbatively nonrenormalizable quartic, self-interacting scalar fields, i.e., the so-called ϕ^4_n theories, where the space–time dimension $n \geqslant 5$. On the one hand, viewed perturbatively, such theories entail an infinite number of distinct counterterms. On the other hand, the continuum limit of a straightforward Euclidean lattice formulation leads to a quasifree theory—a genuinely *noninteracting* theory—whatever choice is made for the renormalized field strength, mass, and coupling constant.[24] In the author's view both of these results are unsatisfactory. Instead, it is possible that an *intermediate behavior* holds true, even though that cannot be proven yet. Let us illustrate an analogous but simpler situation where the conjectured intermediate behavior can be rigorously established.

Consider an ultralocal quartic interacting scalar field, which, viewed classically, is nothing but the relativistic ϕ^4_n model with all the spatial gradients in the usual free term dropped. As a mathematical model of quantum field theory, an ultralocal model is readily seen to be perturbatively nonrenormalizable, while the continuum limit of a straightforward lattice formulation becomes quasifree, basically because of the vise grip of the Central Limit Theorem. Perturbative nonrenormalizability and lattice-limit triviality is similar to the behavior for relativistic ϕ^4_n models, but for the simpler ultralocal model for which an intermediate approach can be rigorously proven to hold.[12] Roughly speaking, a characterization of this intermediate behavior is the following: From a functional integral standpoint, and for any positive value of the quartic coupling constant, the quartic interaction acts like a *hard-core* in history space projecting out certain contributions that would otherwise be allowed by the free theory alone. This phenomenon takes the form of a nonstandard, nonclassical counterterm in the Hamiltonian that does *not* vanish as the coupling constant of the quartic interaction vanishes. Specifically, for the model in question, the additional counterterm is *a counterterm for the kinetic energy* and is formally proportional to $\hbar^2/\phi(x)^2$, which in form is not unlike the centripetal potential that arises in spherical coordinates in three-dimensional quantum mechanics. In summary, inclusion of a formal additional interaction proportional to $\hbar^2/\phi(x)^2$ in the Hamiltonian density is sufficient to result in a well-defined and nontrivial

(i.e., non-Gaussian) quantum theory for interacting ultralocal scalar models. In addition, it may be shown[12] that the classical limit of such quantum theories reproduces the classical model with which one started.

The foregoing brief summary holds rigorously for the ultralocal scalar fields, and it is conjectured that a suitable counterterm would lead to an acceptable intermediate behavior for the relativistic models ϕ_n^4, $n \geqslant 5$. What form should the counterterm take in the case of the relativistic ϕ_n^4 models? We can make a plausible suggestion guided by the following general principle that holds in the ultralocal case: The counterterm should be an ultralocal (because the kinetic energy is ultralocal) potential term arising from the kinetic energy. For the relativistic field that argument suggests the counterterm should again be proportional to $\hbar^2/\phi(x)^2$. It is also part of this general conjecture that the same counterterm is not limited to ϕ_n^4 models, but should be effective for other nonrenormalizable interactions, e.g., such as ϕ_n^6, $n \geqslant 4$, etc. The full argument available at present to support this conjecture appears in Chap. 11 of Ref. 12. (It may even be possible to examine this proposal by means of suitable Monte Carlo studies, but so far this challenge has not been taken up.)

Note well that the hard-core picture of nonrenormalizable interactions leads to such interactions behaving as *discontinuous perturbations*: Once turned on, such interactions cannot be completely turned off. Stated otherwise, as the nonlinear coupling constant is reduced toward zero, the theory passes continuously to a ''pseudofree'' theory—different than the ''free'' theory—*which retains the effects of the hard core*. The interacting theory is *continuously connected* to the pseudofree theory, and may even possess some form of perturbation theory about the pseudofree theory. Evidently, the presence of the hard-core interaction makes any perturbation theory developed about the original unperturbed theory almost totally meaningless.

2. Nonrenormalizable gravity

Although the differences between gravity and nonrenormalizable scalar interaction are significant in their details, there are certain similarities we wish to draw on. Most importantly, one can argue[25] that the nonlinear contributions to gravity act as a hard-core interaction in a quantization scheme, and thus the general picture sketched above for nonrenormalizable scalar fields should apply to gravity as well. Assuming that the analogy holds further, there should be a nonstandard, nonclassical counterterm that incorporates the dominant, irremovable effects of the hard-core interaction. Accepting the principle that in such cases perturbation theory offers no clear hint as to what counterterms should be chosen, we appeal to the guide used in the scalar case. Thus, as our proposed counterterm, we look for an ultralocal potential arising from the kinetic energy that appears in the Hamiltonian constraint. In fact, the only ultralocal potential that has the right transformation properties is proportional to $\hbar^2 g(x)^{1/2}$. Thus we are led to conjecture that the ''nonstandard counterterm'' is none other than a term like the familiar cosmological constant contribution. Unlike the scalar field which required an unusual term proportional to $1/\phi(x)^2$, the gravitational case has resulted in suggesting a term proportional to an ''old friend,'' namely $g(x)^{1/2}$. At first glance, it seems absurd that such a harmless looking term could act to ''save'' the nonrenormalizability of gravity. In its favor we simply note that the analogy with how other nonrenormalizable theories are ''rescued'' is too strong to dismiss the present proposal out of hand—and of course one must resist any temptation ''to think perturbatively.'' Any attempt to consider this possibility must wait until another occasion; we hope to return to this subject elsewhere.

As one small aspect of this problem, let us briefly discuss how the factor $\hbar^2$ arises in the gravitational case. Merely from a *dimensional* point of view, we note that (the first term of) the local kinetic energy operator has a formal structure given by

$$-\frac{16\pi G}{c^3}\hbar^2\left(\frac{\delta}{\delta g_{cb}(x)}\, g_{ac}(x)\, g(x)^{-1/2}\, g_{bd}(x)\, \frac{\delta}{\delta g_{da}(x)} - \cdots\right), \tag{93}$$

where we have restored the factor $16\pi G/c^3$. Thus the anticipated counterterm is proportional to $(G\hbar^2/c^3)g(x)^{1/2}$. We next cast this term into the usual form for a contribution to the potential part of the Hamiltonian constraint, namely, in a form proportional to $(c^3/G)\Lambda g(x)^{1/2}$. Hence, to recast our anticipated counterterm into this form, we need a factor proportional to

$$\frac{G^2\hbar^2}{c^6} \equiv l^4_{\text{Planck}} \approx (10^{-33}\,\text{cm})^4. \tag{94}$$

In the classical symbol for the Hamiltonian constraint operator, this factor is multiplied by an expectation value with dimensions L^{-6} originating from the density nature of the two momentum factors and leading to an overall factor with the dimensions L^{-2} that is proportional to $\hbar^2$ as claimed. Let us call the resultant counterterm $\Lambda_C\, g(x)^{1/2}$. Since the sign of the DeWitt metric that governs the kinetic energy term is indefinite, it is not even possible to predict the sign of Λ_C. However, one thing appears certain. While the proposed counterterm $\Lambda_C\, g(x)^{1/2}$ is certainly not cosmological in origin, its influence may well be.

The foregoing scenario has assumed the hard-core model of nonrenormalizable interactions applies to the theory of gravity. However, that may well not be the case, and, instead, some other counterterm(s) may be required to cure the theory of gravity. Note well that the general structure of our approach to quantize gravity is largely insensitive to just what form of regularization and renormalization is required. In particular, the use of the affine field variables, the application of the projection operator method to impose constraints, and the development of the nonstandard phase-space functional integral representation for the reproducing kernel of the regularized physical Hilbert space all have validity quite independently of the form in which the Hamiltonian constraint is ultimately turned into a local self-adjoint operator. Although we have outlined one particular version in which the Hamiltonian constraint may possibly be made into a densely defined local operator, we are happy to keep an open mind about the procedure by which this ultimately may take place since many different ways in which this process can occur are fully compatible with the general principles of our proposed quantization scheme for the gravitational field.

Analytic torsion of all vector bundles over an elliptic curve

A. Berthomieu[a)]
Laboratoire Emile Picard UMR CNRS No 5580, Université Paul Sabatier, 118 Route de Narbonne, 31062 Toulouse Cedex 4, France

(Received 20 November 2000; accepted for publication 29 May 2001)

The spectrum of the Hodge–Laplace operator of all holomorphic vector bundles (with parallel curvature metrics) over a flat elliptic curve is shown to be the union of the spectra of some infinite set of (explicit) finite rank matrices. The analytic torsion is then deduced by direct computation. Another evaluation of the analytic torsion is then performed using Bismut, Gillet, and Soulé's comparison formula for short exact sequences of vector bundles. This is a test for this method which could be useful when direct calculation is hopeless. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1390329]

I. INTRODUCTION

Analytic torsion for holomorphic Hermitian vector bundles over complex manifolds was introduced by Ray and Singer in Ref. 1. In the case of a Riemann surface, it equals the determinant of some Laplacian, and is as such an important tool in string theory.[2] More recently, it appeared as a part of the direct image of vector bundles in Arakelov geometry.[3,4] Explicit computations have been performed in the case of line bundles over Riemann surfaces,[1,5–7] complex projective spaces,[8–11] complex tori,[1,12,13] Θ divisors on Abelian varieties,[14] certain quotients of $K3$ surfaces,[15] compact Lie groups[16] and for equivariant bundles on compact symmetric spaces,[17] locally symmetric spaces of noncompact type,[18] and complex homogeneous spaces.[19] The purpose here is to evaluate the analytic torsion of all vector bundles (of any rank) over a one-dimensional complex torus, i.e., an elliptic curve, by two different methods.

In Sec. II, I show that thanks to Atiyah's classification[20] the problem reduces to bundles of the type $F_r \otimes L$, where F_r is a particular rank r flat indecomposable vector bundle and L is a line bundle. Three cases are to be studied: L is either trivial, or flat and nontrivial or of positive degree: the results are then stated at the end of Sec. II (see theorem 4 below). The first method is performed in Sec. III: the spectrum of the Hodge–Laplace operator is shown to be the union of the spectra of some infinite set of explicit matrices; the analytic torsion is then obtained by direct application of the zeta-regularization procedure. The second method presented in Sec. IV uses Bismut, Gillet, and Soulé's formula (theorem 0.3 of Ref. 21) for short exact sequences of vector bundles. Although this method provides less information (on the spectrum) it has the advantage that the calculation of the Bott–Chern transgression form[22] entering in the formula is the same in the three cases, and that it could be useful in other contexts where direct information on the spectrum is not available. Methods of the same kind appear in Refs. 11 and 12 using different comparison formulas from the one used here.

II. CLASSIFICATION OF VECTOR BUNDLES AND ANALYTIC TORSION

A. Results from Atiyah's classification

Let E be any elliptic curve (i.e., a one-dimensional complex torus). Atiyah classified in Ref. 20 all indecomposable vector bundles over an elliptic curve, (see Refs. 23–26 for further developments). For any holomorphic vector bundle F on E, let $\Gamma(F)$ denote the space of global holomorphic sections of F.

a)Electronic mail: berthomi@picard.ups-tlse.fr

Proposition (Ref. 20 theorem 5 (i)): For any $r \geqslant 1$ there exists a unique (up to holomorphic isomorphism) indecomposable vector bundle F_r of rank *r and degree 0 for which*

$$\dim \Gamma(F_r) = 1.$$

Theorem 1: *(see Ref. 23 proposition 2.1 and remark page 63.) For any $r \in \mathbb{N}$ and $d \in \mathbb{Z}$ let $k = (d,r)$ be their greatest common divisor, then for any indecomposable vector bundle $V_{r,d}$ of rank r and degree d over E there exists an elliptic curve E', an isogeny $\iota : E' \to E$ of degree r/k, and a line bundle L' over E' of degree d/k such that*

$$V_{r,d} = \iota_*(L' \otimes F'_k).$$

[*F'_k stands for the unique rank k indecomposable flat vector bundle over E' such that* $\dim \Gamma(F'_k) = 1$.]

Proof: Let $\iota : E' \to E$ be any isogeny of degree r/k, because of the preceding proposition, one has $\iota^* F_k = F'_k$. Then for any bundle B on E',

$$\iota_*(B \otimes F'_k) = (\iota_* B) \otimes F_k .$$

Now if B is a line bundle, if $d/k = \deg B$ and r/k are coprime, $\iota_* B$ is indecomposable (cf. Ref. 23, proposition 2.1). Then $(\iota_* B) \otimes F_k$ is indecomposable too (cf. Ref. 20, lemma 2.3) and of desired rank and degree. Finally all indecomposable bundles on E of rank r and degree d are obtained by tensoring $(\iota_* B) \otimes F_k$ by some flat line bundle L on E [cf. Ref. 20, theorem 5 (ii)] then clearly $\iota^* L$ is a flat line bundle on E' and

$$(\iota_* B) \otimes F_k \otimes L = \iota_*(B \otimes \iota^* L) \otimes F_k = \iota_*(B \otimes \iota^* L \otimes F'_k)$$

one sets $L' = B \otimes \iota^* L$ and the theorem is proved. □

B. Semihomogeneity

Definition: A bundle G on E is said to be semihomogeneous if for any $z \in E$ there exists a flat line bundle L on E such that the translated bundle equals

$$t_z^* G = G \otimes L.$$

Theorem: *Any indecomposable bundle on E is semihomogeneous.*

Proof: It suffices to check it for bundles of the form $L \otimes F_r$ for any r and any line bundle L. Any F_r and any flat line bundle is easily seen to be translation invariant, and so is any bundle of the form $L \otimes F_r$ where L is a flat line bundle. If L is some nonzero degree line bundle, then $t_z^* L \otimes L^{-1}$ is clearly a flat line bundle so that L is semihomogeneous. The same holds then for $L \otimes F_r$. □

Proposition 2: Reciprocally, for any flat line bundle L and any nonzero degree indecomposable bundle G there exists some $z \in E$ (not necessarily unique) such that

$$G \otimes L \cong t_z^* G.$$

Proof: Of course it is enough to check it for $F_r \otimes B$ where B is a nonzero degree line bundle. F_r being translation invariant, only the case of B is relevant. But this is a consequence of Ref. 27, theorem 1 (p. 77) and proposition (p. 80). □

C. Reduction of the problem

Let F be any holomorphic vector bundle on E. Fix some translation invariant Kähler metric on E and choose some hermitian metric on F, consider the Cauchy–Riemann operator $\overline{\partial} : \Gamma^\infty(E,F) \to \Gamma^\infty(E, T^{*(0,1)}E \otimes F)$ and its adjoint $\overline{\partial}^* : \Gamma^\infty(E, T^{*(0,1)}E \otimes F) \to \Gamma^\infty(E,F)$ with respect

to L^2 metrics. (Here and throughout, Γ^∞ stands for the space of $\mathcal{C}^\infty$ sections of the indicated bundle on the indicated manifold). The Hodge–Laplace operator is then $\Delta^{0,0}=\overline{\partial}^*\overline{\partial}$ on $\Gamma^\infty(E,F)$ and $\Delta^{0,1}=\overline{\partial}\overline{\partial}^*$ on the space $\Gamma^\infty(E,T^{*(0,1)}E\otimes F)$ of forms of complex type (0,1) on E with values in F. The definition of the analytic torsion (Ref. 1, definition 1.2) reduces here to

$$\Theta(F)=\sqrt{\det{}'\,\Delta^{0,1}}=\sqrt{\det{}'\,\Delta^{0,0}},$$

$\det'$ being the ζ-regularized product of nonzero eigenvalues (the second equality follows from Hodge theory). More precisely, let P be the orthogonal projection on the orthocomplement of $\operatorname{Ker}\Delta^{(0,1)}$ in $\Gamma^\infty(E,T^{*(0,1)}E\otimes F)$, the function

$$\zeta_F(s)=\operatorname{Tr}(\Delta^{-s}P)=\frac{1}{\Gamma(s)}\int_0^{+\infty}t^{s-1}\operatorname{Tr}(P\exp(-t\Delta^{(0,1)}))dt \tag{1}$$

is holomorphic for $\operatorname{Re}(s)>1$, has a meromorphic continuation to $\mathbb{C}$, and one sets

$$\Theta(F)=\exp-\tfrac{1}{2}\zeta_F'(0).$$

Theorem: *If F is any vector bundle on E, if the metric on E is translation invariant, then the analytic torsions of F and its dual F^* (endowed with the dual metric) coincide. (In fact the spectra of the Hodge–Laplace operators coincide.)*

Proof: This result is due to Poincaré duality (it is valid for any complex manifold with parallel-metrized trivial canonical bundle): the obvious coupling

$$F\times(T^{*(0,1)}E\otimes F^*)\to T^{*(0,1)}E$$

with the fact that $T^{*(0,1)}E$ has a nonzero parallel section $d\overline{z}$ induces a duality

$$\Gamma^\infty(E,F)\tilde{\to}\Gamma^\infty(E,T^{*(0,1)}E\otimes F),$$

which commutes with the Hodge–Laplace operators. Of course the same result holds for $\Gamma^\infty(E,T^{*(0,1)}E\otimes F)\tilde{\to}\Gamma^\infty(E,F^*)$. By Hodge theory the positive eigenvalues on $\Gamma^\infty(E,F)$ and $\Gamma^\infty(E,T^{*(0,1)}E\otimes F)$ coincide (with multiplicity). So the analytic torsions coincide. □

Note that the analytic torsion (respectively, the spectrum) of a bundle of the form $F\oplus G$ is simply the product (respectively, the union) of the analytic torsions (respectively, of the spectra) of F and G provided the metric on $F\oplus G$ is the direct sum of metrics on F and G.

Now if $\iota:E'\to E$ is an isogeny and F a bundle on E', then the spectra of the Hodge–Laplace operators of F on E' and of ι_*F on E coincide, provided ι is isometric and the metric on ι_*F is the push-forward metric, so the analytic torsions also coincide (these two last arguments were used in Ref. 12, Sec. 4.2).

Moreover analytic torsions of F and its translate t_z^*F also coincide provided the metric on E is translation invariant and under obvious conditions on the metrics of F and t_z^*F.

For all these reasons, the problem is reduced to the calculation in the case of $L\otimes F_r$ for all line bundles L of non-negative degree; note that the result only depends on the degree of L if it is positive because of proposition 2. This of course does not hold if L is flat.

Remark: From the calculation for particular metrics [the metric on E will be taken translation invariant and the metrics on the bundles will be specified later—see (5) below], the general case can be deduced by using the anomaly formula of Ref. 28 (theorem 1.23) which relates analytic torsions for two different couples of metrics (on E and F) to the ratio of L^2 norms on harmonic forms (which in positive degree are holomorphic hence independent of the metrics) and an integral over E of explicitly computable quantities. The computation which is performed in Sec. IV is of the same sort.

D. Known results for line bundles

The case of nonflat line bundles over complex tori has been studied in Ref. 12, Sec. 4.2 and Ref. 13, yielding to the following result.

Theorem: *A line bundle L of degree $d>0$ endowed with its canonical translation invariant curvature metric over a flat elliptic curve of volume η has spectrum:*

$$\left\{\frac{2\pi nd}{\eta}, n\in\mathbb{N}\right\}$$

on sections with multiplicity d for any eigenvalue.

The spectrum on (0,1)-forms coincide by Hodge theory for positive eigenvalues, there is no zero eigenvalue on (0,1)-forms since $d>0$.

Proof: I recall the argument of Ref. 13: The Hodge–Laplace operator is explicitly calculated in some holomorphic trivialization of F to be

$$-2\frac{\partial^2}{\partial z\partial\overline{z}}+\frac{2\pi d}{\eta}\underline{z}\frac{\partial}{\partial\overline{z}}$$

on sections and

$$-2\frac{\partial^2}{\partial z\partial\overline{z}}+\frac{2\pi d}{\eta}\underline{z}\frac{\partial}{\partial\overline{z}}+\frac{2\pi d}{\eta}$$

on L-valued (0,1)-forms. On the one hand this shows that tensoring with the parallel form $d\overline{z}$ provides a bijection between the λ-eigenspace on sections and the $(\lambda+2\pi d/\eta)$-eigenspace on (0,1)-forms. On the other hand Hodge theory provides a bijection between eigenspaces on sections and on (0,1)-forms corresponding to the same positive eigenvalue. Harmonic forms are determined by cohomology, so there are none in degree (0,1) and the space of harmonic sections has dimension d, from which all the eigenspaces can be recovered by successive use of the two preceding bijections. The same trick applies for higher dimensional complex tori provided the line bundle has a nondegenerate (not necessarily positive) first Chern class (see Ref. 13). □

Note (for later use), that it follows that there exists a spectral orthonormal L^2-base $(\alpha_{j,k})_{\substack{j\in\mathbb{N}\\1\leq k\leq d}}$ of $\Gamma^\infty(E,A)$ which verifies for any j and k:

$$\overline{\partial}\alpha_{j,k}=\sqrt{\frac{\pi jd}{\eta}}\,\alpha_{j-1,k}d\overline{z}. \tag{2}$$

Explicit calculation then yields

Corollary: The analytic torsion of a line bundle L of degree $d>0$ endowed with its canonical translation invariant curvature metric over a flat elliptic curve of volume η equals

$$\Theta(L)=\left(\frac{d}{\eta}\right)^{-d/4}.$$

Now theorem 1 asserts that any indecomposable bundle F of coprime degree d and rank r over E is the direct image of some degree d line bundle L over another elliptic curve E' by a degree r isogeny $\iota:E'\to E$. Thus

Corollary: If an indecomposable bundle F of coprime degree $d\neq 0$ and rank r over E is endowed with the push-forward by the above isogeny of the canonical parallel-curvature metric of the line bundle L then its spectrum is given by

$$\left\{\frac{2\pi n|d|}{r\eta}, n\in\mathbb{N}\right\},$$

where all positive eigenvalues have multiplicity $|d|$ both on sections and on (0,1)-forms and the zero eigenvalue has multiplicity $|d|$ on sections if $d>0$, $|d|$ on (0,1)-forms if $d<0$ and 0 otherwise. Its analytic torsion is

$$\Theta(F)=\left(\frac{|d|}{r\eta}\right)^{-|d|/4}.$$

Note that from Ref. 24, Appendix A, the vector bundles referred to in this corollary are exactly the stable ones. The push-forward metric on them is in this case Hermite–Einstein.

I recall now some basic facts about flat line bundles: There exists some lattice Λ in $\mathbb{C}$ [endowed with its canonical metric $(z_1,z_2)\to z_1\overline{z_2}$] such that E is isomorphic and isometric to $\mathbb{C}/\Lambda$. (Any two flat metrics on E only differ from some multiplicative positive real factor.) Λ can be chosen to be generated by x and $x\tau$ where x is a positive real number and:

$$-\tfrac{1}{2}<\mathrm{Re}\,\tau\leqslant\tfrac{1}{2},\quad |\tau|>1$$

(τ is the modular invariant of E and of course $\eta=x^2\,\mathrm{Im}\,\tau$). Let Λ^* be the dual lattice to Λ:

$$\Lambda^*=\{\gamma\in\mathbb{C}/\mathrm{Im}(\gamma\overline{u})\in\mathbb{Z}\ \text{ for any }\ u\in\Lambda\}=\frac{1}{\eta}\Lambda.$$

Then it is a standard fact that the Hodge–Laplace operator on functions and (0,1)-forms (i.e., for the trivial line bundle) has spectrum

$$\{2\pi^2|\gamma|^2\ ,\gamma\in\Lambda^*\},$$

the eigenspaces being provided by Fourier decomposition. [The Hodge–Laplace operator is the half of the ''usual'' (Riemannian) Laplacian].

The flat line bundles are parametrized by the dual elliptic curve $\hat{E}=\mathbb{C}/\Lambda^*$, and in a canonical holomorphic trivialization, global $\mathcal{C}^\infty$ sections of the flat line bundle $L_{\hat{\alpha}}$ corresponding to $\hat{\alpha}\in\hat{E}$ are simply Λ-periodic multiples of the function $\exp(2\pi i\,\mathrm{Im}(\alpha\overline{z}))$ where $\alpha\in\mathbb{C}$ is any pre-image of $\hat{\alpha}\in\hat{E}$. The eigenspaces are then once more provided by Fourier decomposition, i.e., spanned by the

$$\varphi_{\alpha+\gamma}(z)=\frac{1}{\sqrt{\eta}}\exp(2\pi i\,\mathrm{Im}((\alpha+\gamma)\overline{z})) \tag{3}$$

for $\gamma\in\Lambda^*$ ($1/\sqrt{\eta}$ provides L^2-orthonormality), and the spectrum is given by

$$\{2\pi^2|\alpha+\gamma|^2,\gamma\in\Lambda^*\}.$$

In both cases the analytic torsion is given by Kronecker limit formulas:

Theorem 3: *The analytic torsion of $L_{\hat{\alpha}}$ for nonzero $\hat{\alpha}$ equals*

$$\Theta(L_{\hat{\alpha}})=e^{-\pi\,\mathrm{Im}\,\tau(b^2-b+1/6)}\prod_{k=-\infty}^{+\infty}|1-e^{2\pi i(|k|\tau+\varepsilon_k\sqrt{\eta\,\mathrm{Im}\,\tau}\alpha)}|$$

(cf. Ref. 1, theorem 4.1) where $\varepsilon_k=\mathrm{sign}(k+\frac{1}{2})$ and $b=\sqrt{\eta/\mathrm{Im}\,\tau}\,\mathrm{Im}\,\alpha$ is supposed to lie in $[0,1]$ (by choosing some suitable preimage of $\hat{\alpha}$ in $\mathbb{C}$). The analytic torsion of the trivial line bundle on E equals

$$\Theta(\mathcal{O})=\sqrt{2\,\eta\,\mathrm{Im}\,\tau}e^{-\pi\,\mathrm{Im}\,\tau/6}\prod_{k>0}|1-e^{2\pi ik\tau}|^2.$$

Note that here $\alpha=(\eta \operatorname{Im}\tau)^{-1/2}(a+b\tau)$, and the corresponding character verifies: $\chi_{\hat{\alpha}}(n+m\tau)=\exp 2\pi i(-am+bn)$. This explains little differences with Ref. 1.

E. Statement of the results

Proposition: F_r is given by the following automorphy factor:

$$\phi_u(V,z)=(M(u)V,z+u)$$

for $u\in\Lambda$ and $V\in\mathbb{C}^r$ with

$$M(u)=\begin{pmatrix} 1 & \overline{u} & \frac{\overline{u}^2}{2} & \cdots & \frac{\overline{u}^{r-1}}{(r-1)!} \\ 0 & \ddots & \ddots & \ddots & \vdots \\ \vdots & \ddots & \ddots & \ddots & \frac{\overline{u}^2}{2} \\ \vdots & & \ddots & \ddots & \overline{u} \\ 0 & \cdots & \cdots & 0 & 1 \end{pmatrix}.$$

Proof: The proposed vector bundle on E is topologically trivial spanned by the following $\mathcal{C}^\infty$ sections:

$$\rho_{1,r}=\begin{pmatrix} 1 \\ 0 \\ \vdots \\ 0 \end{pmatrix} \quad \rho_{2,r}=\begin{pmatrix} \overline{z} \\ 1 \\ 0 \\ \vdots \\ 0 \end{pmatrix} \quad \cdots \quad \rho_{r,r}=\begin{pmatrix} \frac{\overline{z}^{r-1}}{(r-1)!} \\ \vdots \\ \overline{z} \\ 1 \end{pmatrix}, \tag{4}$$

which verify for any $2\leqslant q\leqslant r$:

$$\overline{\partial}\rho_{q,r}=\rho_{q-1,r}d\overline{z} \text{ and } \overline{\partial}\rho_{1,r}=0.$$

Thus $\rho_{1,r}$ spans $\Gamma(F_r)$ and $\rho_{r,r}d\overline{z}$ generates $H^1(F_r)$.

Now it follows from theorem 5 and corollary 2 of Ref. 20 that F_r is characterized by $\dim\Gamma(F_r)=1$ and the existence of nonsplit exact sequences for any r and s:

$$0\to F_s\to F_r\to F_{r-s}\to 0.$$

Here the exact sequence is obviously provided by the maps

$$\begin{pmatrix} \varsigma_1 \\ \vdots \\ \varsigma_s \end{pmatrix}\mapsto\begin{pmatrix} \varsigma_1 \\ \vdots \\ \varsigma_s \\ 0 \\ \vdots \\ 0 \end{pmatrix} \text{ and } \begin{pmatrix} \varsigma_1 \\ \vdots \\ \varsigma_s \\ \varsigma_{s+1} \\ \vdots \\ \varsigma_r \end{pmatrix}\mapsto\begin{pmatrix} \varsigma_{s+1} \\ \vdots \\ \varsigma_r \end{pmatrix}$$

and the morphism $\Gamma(F_{r-s})\to H^1(F_s)$ associated to it maps $\rho_{1,r-s}$ to the class of $\rho_{s,s}\,d\overline{z}$. □

The preceding sections $\rho_{q,r}$ will be taken pointwise orthogonal of constant norm ν_q. One considers then the $\sigma_q:=(1/\nu_q)\rho_{q,r}$ which give a pointwise orthonormal frame of F_r and verify:

$$\overline{\partial}\sigma_q=\frac{\nu_{q-1}}{\nu_q}\sigma_{q-1}d\overline{z}=:\lambda_q\sigma_{q-1}d\overline{z} \tag{5}$$

(of course λ_1 vanishes). (This metric on F_r is of course not Hermite–Einstein since F_r is not stable.)

The following sections are devoted to the proof of

Theorem 4: *(i) The analytic torsion of F_r equals*

$$\Theta(F_r)=\sqrt{\prod_{q=2}^{r}(2|\lambda_q|^2)}\exp\left(\frac{-\eta}{2\pi}\sum_{q=2}^{r}|\lambda_q|^2\right)(2\eta\,\mathrm{Im}\,\tau)^{r/2}e^{-r\pi\,\mathrm{Im}\,\tau/6}\prod_{k>0}|1-e^{2\pi ik\tau}|^{2r}.$$

(ii) If $L_{\hat{\alpha}}$ is a nontrivial flat line bundle on E, choose a preimage α of $\hat{\alpha}$ such that $b=\sqrt{\eta/\mathrm{Im}\,\tau}\,\mathrm{Im}\,\alpha$ lies in $[0,1]$, the analytic torsion of $F_r\otimes L_{\hat{\alpha}}$ equals

$$\Theta(F_r\otimes L_{\hat{\alpha}})=\exp\left(-\frac{\eta}{2\pi}\sum_{q=2}^{r}|\lambda_q|^2\right)e^{-r\pi\,\mathrm{Im}\,\tau(b^2-b+1/6)}\prod_{k=-\infty}^{+\infty}|1-e^{2\pi i(|k|\tau+\varepsilon_k\sqrt{\eta\,\mathrm{Im}\,\tau}\alpha)}|^r,$$

where (as before) $\varepsilon_k=\mathrm{sign}(k+\frac{1}{2})$.

(iii) If A is a degree d line bundle on E, the analytic torsion of $F_r\otimes A$ equals

$$\Theta(F_r\otimes A)=\left(\frac{d}{\eta}\right)^{-dr/4}\exp\left(-\frac{\eta}{2\pi}\sum_{q=2}^{r}|\lambda_q|^2\right)\prod_{\ell=2}^{r}\left(\sum_{j=0}^{\ell-1}\left(\frac{\pi d}{\eta}\right)^{-j}\frac{|\lambda_{\ell-j+1}|^2\cdots|\lambda_\ell|^2}{j!}\right)^{d/2}$$

(the $j=0$ term in the last sum is to be taken equal to 1).

(iv) An indecomposable vector bundle V on E of nonzero degree d and rank r with greatest common divisor $(d,r)=k$ is the direct image by an isogeny of degree r/k of $F_k\otimes A$ where A is a line bundle of degree d/k. Put on V the push-forward by this isogeny of the metric on $F_k\otimes A$ considered in (iii)

$$\Theta(V)=\left(\frac{|d|}{r\eta}\right)^{-|d|/4}\exp\left(-\frac{r\eta}{2k\pi}\sum_{q=2}^{k}|\lambda_q|^2\right)\prod_{\ell=2}^{k}\left(\sum_{j=0}^{\ell-1}\left(\frac{\pi|d|}{r\eta}\right)^{-j}\frac{|\lambda_{\ell-j+1}|^2\cdots|\lambda_\ell|^2}{j!}\right)^{|d|/2k}.$$

Note that part *(iv)* is a direct consequence of part *(iii)*.

III. DIRECT CALCULATION

A. The Hodge–Laplace operator in matricial form

Consider the L^2 normalized spectral base $(\varphi_{\alpha+\gamma})_{\gamma\in\Lambda^*}$ of $\Gamma^\infty(E,L_{\hat{\alpha}})$. The fact that the $(\sigma_q)_{1\leqslant q\leqslant r}$ provide a pointwise orthonormal base of F_r ensures that $(\sigma_q\otimes\varphi_{\alpha+\gamma})_{\gamma\in\Lambda^*}^{1\leqslant q\leqslant r}$ is a L^2 orthonormal base of $\Gamma^\infty(E,F_r\otimes L_{\hat{\alpha}})$. Previous calculations (5), (3) yield

$$\overline{\partial}(\sigma_q\otimes\varphi_{\alpha+\gamma})=\lambda_q\sigma_{q-1}\otimes\varphi_{\alpha+\gamma}d\overline{z}+\pi(\alpha+\gamma)\sigma_q\otimes\varphi_{\alpha+\gamma}d\overline{z}.$$

The adjoint $\overline{\partial}^*$ is then easily deduced:

$$\overline{\partial}^*(\sigma_q\otimes\varphi_{\alpha+\gamma}d\overline{z})=2\overline{\lambda}_{q+1}\sigma_{q+1}\otimes\varphi_{\alpha+\gamma}+2\pi(\overline{\alpha}+\overline{\gamma})\sigma_q\otimes\varphi_{\alpha+\gamma}.$$

The factor 2 is due to the fact that $\|d\overline{z}\|^2=2$. The Hodge–Laplace operator $\Delta=\overline{\partial}^*\overline{\partial}$ then reads:

$$\Delta(\sigma_q\otimes\varphi_{\alpha+\gamma})=(2\pi^2|\alpha+\gamma|^2+2|\lambda_q|^2)\sigma_q\otimes\varphi_{\alpha+\gamma}+2\pi(\overline{\alpha}+\overline{\gamma})\lambda_q\sigma_{q-1}\otimes\varphi_{\alpha+\gamma}$$
$$+2\pi(\alpha+\gamma)\overline{\lambda}_{q+1}\sigma_{q+1}\otimes\varphi_{\alpha+\gamma}.$$

Thus for any $\gamma\in\Lambda^*$, the matrix of Δ in the (invariant) subspace $\mathrm{Vect}\{\sigma_q\otimes\varphi_{\alpha+\gamma},1\leqslant q\leqslant r\}$ reads:

$$\mathcal{M}_{\alpha,\gamma,r}=\begin{pmatrix} 2\pi^2|\alpha+\gamma|^2 & 2\pi(\overline{\alpha}+\overline{\gamma})\lambda_2 & 0 & \dots & 0 \\ 2\pi(\alpha+\gamma)\overline{\lambda_2} & 2\pi^2|\alpha+\gamma|^2+2|\lambda_2|^2 & \ddots & \ddots & \vdots \\ 0 & \ddots & \ddots & \ddots & 0 \\ \vdots & \ddots & \ddots & \ddots & 2\pi(\overline{\alpha}+\overline{\gamma})\lambda_r \\ 0 & \dots & 0 & 2\pi(\alpha+\gamma)\overline{\lambda_r} & 2\pi^2|\alpha+\gamma|^2+2|\lambda_r|^2 \end{pmatrix}.$$

The spectrum of Δ consists of the union of the spectra of the $\mathcal{M}_{\alpha,\gamma,r}$ when γ goes around Λ^*.

In the same vein consider the L^2 normalized spectral base $(\alpha_{j,k})_{\substack{j\in\mathbb{N}\\1\leqslant k\leqslant d}}$ of $\Gamma^\infty(E,A)$ [cf. (2)]. Then clearly $(\sigma_q\otimes\alpha_{j,k})_{1\leqslant q\leqslant r,1\leqslant k\leqslant d,j\in\mathbb{N}}$ is an L^2 orthonormal base of $\Gamma^\infty(E,F_r\otimes A)$ for which

$$\overline{\partial}(\sigma_q\otimes\alpha_{j,k})=\lambda_q\sigma_{q-1}\otimes\alpha_{j,k}d\overline{z}+\sqrt{\frac{\pi jd}{\eta}}\,\sigma_q\otimes\alpha_{j-1,k}d\overline{z},$$

$$\overline{\partial}^*(\sigma_q\otimes\alpha_{j,k}d\overline{z})=2\overline{\lambda}_{q+1}\sigma_{q+1}\otimes\alpha_{j,k}+2\sqrt{\frac{\pi(j+1)d}{\eta}}\,\sigma_q\otimes\alpha_{j+1,k}, \tag{6}$$

$$\begin{aligned}\Delta(\sigma_q\otimes\alpha_{j,k})=&\left(2|\lambda_q|^2+\frac{2\pi jd}{\eta}\right)\sigma_q\otimes\alpha_{j,k}+2\lambda_q\sqrt{\frac{\pi(j+1)d}{\eta}}\,\sigma_{q-1}\otimes\alpha_{j+1,k}\\&+2\overline{\lambda}_{q+1}\sqrt{\frac{\pi jd}{\eta}}\,\sigma_{q+1}\otimes\alpha_{j-1,k}.\end{aligned}$$

Thus if $\ell\geqslant r$, the subspaces $\mathcal{V}_{\ell,k}:=\mathrm{Vect}\{\sigma_q\otimes\alpha_{j,k},q+j=\ell\}$ have dimension r and are respected by Δ. The matrix of Δ in the base $(\sigma_q\otimes\alpha_{\ell-q,k})_{1\leqslant q\leqslant r}$ reads:

$$\mathcal{M}_{r,k,\ell}=\begin{pmatrix} \frac{2\pi(\ell-1)d}{\eta} & 2\lambda_2\sqrt{\frac{\pi(\ell-1)d}{\eta}} & 0 & \dots & 0 \\ 2\overline{\lambda}_2\sqrt{\frac{\pi(\ell-1)d}{\eta}} & 2|\lambda_2|^2+\frac{2\pi(\ell-2)d}{\eta} & \ddots & \ddots & \vdots \\ 0 & \ddots & \ddots & \ddots & 0 \\ \vdots & \ddots & \ddots & \ddots & 2\lambda_r\sqrt{\frac{\pi(\ell-r+1)d}{\eta}} \\ 0 & \dots & 0 & 2\overline{\lambda}_r\sqrt{\frac{\pi(\ell-r+1)d}{\eta}} & 2|\lambda_r|^2+\frac{2\pi(\ell-r)d}{\eta} \end{pmatrix}$$

and it does not depend on k. But if $1\leqslant\ell\leqslant r-1$, then $\mathcal{V}_{\ell,k}:=\mathrm{Vect}\{\sigma_q\otimes\alpha_{j,k},q+j=\ell\}$ has dimension ℓ, it is respected by Δ whose matrix in the base $(\sigma_q\otimes\alpha_{\ell-q,k})_{1\leqslant q\leqslant\ell}$ reads (it remains independent of k):

$$\mathcal{M}_{r,k,\ell}=\begin{pmatrix} \frac{2\pi(\ell-1)d}{\eta} & 2\lambda_2\sqrt{\frac{\pi(\ell-1)d}{\eta}} & 0 & \cdots & 0 \\ 2\overline{\lambda_2}\sqrt{\frac{\pi(\ell-1)d}{\eta}} & 2|\lambda_2|^2+\frac{2\pi(\ell-2)d}{\eta} & \ddots & \ddots & \vdots \\ 0 & \ddots & \ddots & \ddots & 0 \\ \vdots & \ddots & \ddots & \ddots & 2\lambda_\ell\sqrt{\frac{\pi d}{\eta}} \\ 0 & \cdots & 0 & 2\overline{\lambda_\ell}\sqrt{\frac{\pi d}{\eta}} & 2|\lambda_\ell|^2 \end{pmatrix}.$$

For $\ell\geqslant r+1$ the matrices $\mathcal{M}_{r,k,\ell}$ are invertible but for $\ell\leqslant r$ they all have a one-dimensional kernel spanned by

$$\left(\sum_{q=1}^{\ell}\frac{(-1)^q}{\sqrt{(\ell-q)!}}\lambda_{q+1}\lambda_{q+2}\cdots\lambda_\ell\left(\frac{\pi d}{\eta}\right)^{q/2}\sigma_q\otimes\alpha_{\ell-q,k}\right)$$

(the product $\lambda_{q+1}\lambda_{q+2}\cdots\lambda_\ell$ is to be taken equal to 1 in the $q=\ell$ term of the sum).

B. Calculation of the analytic torsion

1. The case of $F_r\otimes L_{\hat{\alpha}}$ for a nontrivial flat bundle $L_{\hat{\alpha}}$

The characteristic polynomials $P_{\alpha,\gamma,r}(X)=\det(\mathcal{M}_{\alpha,\gamma,r}-X\mathrm{Id})$ verify

$$P_{\alpha,\gamma,r}(X)=(2\pi^2|\alpha+\gamma|^2+2|\lambda_r|^2-X)P_{\alpha,\gamma,r-1}(X)-4\pi^2|\alpha+\gamma|^2|\lambda_r|^2P_{\alpha,\gamma,r-2}(X)$$

from which it is easily deduced that

$$\begin{aligned}P_{\alpha,\gamma,r}(X)=(-X)^r&+\left(2r\pi^2|\alpha+\gamma|^2+2\sum_{q=2}^{r}|\lambda_q|^2\right)(-X)^{r-1}\\&+\left[2r(r-1)\pi^4|\alpha+\gamma|^4+4(r-2)\pi^2|\alpha+\gamma|^2\sum_{q=2}^{r}|\lambda_q|^2+4\sum_{p<q}(|\lambda_p|^2|\lambda_q|^2)\right]\\&\times(-X)^{r-2}+\cdots+(2\pi^2|\alpha+\gamma|^2)^r.\end{aligned}$$

Thus the following symmetric functions of eigenvalues of $\mathcal{M}_{\alpha,\gamma,r}$ equal

$$\sum_{\mu\in\mathrm{Spec}\,\mathcal{M}_{\alpha,\gamma,r}}\mu^2=4r\pi^4|\alpha+\gamma|^4+16\pi^2|\alpha+\gamma|^2\sum_{q=2}^{r}|\lambda_q|^2+4\sum_{q=2}^{r}|\lambda_q|^4,$$

$$\sum_{\mu\in\mathrm{Spec}\,\mathcal{M}_{\alpha,\gamma,r}}(\mu-2\pi^2|\alpha+\gamma|^2)^2=8\pi^2|\alpha+\gamma|^2\sum_{q=2}^{r}|\lambda_q|^2+4\sum_{q=2}^{r}|\lambda_q|^4,$$

then if $\zeta_{\hat{\alpha},r}$ (respectively, $\zeta_{\hat{\alpha}}$) stands for the zeta function (1) of $F_r\otimes L_{\hat{\alpha}}$ (respectively of $L_{\hat{\alpha}}$)

$$\zeta_{\hat{\alpha},r}(s)=\sum_{\mu\in\operatorname{Spec}\Delta}\mu^{-s}$$

$$=\sum_{\gamma\in\Lambda^*}(2\pi^2|\alpha+\gamma|^2)^{-s}\sum_{\mu\in\operatorname{Spec}\mathcal{M}_{\alpha,\gamma,r}}\left[\left(\frac{\mu}{2\pi^2|\alpha+\gamma|^2}\right)^{-s}-1+1\right]$$

$$=r\sum_{\gamma\in\Lambda^*}(2\pi^2|\alpha+\gamma|^2)^{-s}+\sum_{\gamma\in\Lambda^*}(2\pi^2|\alpha+\gamma|^2)^{-s}$$

$$\times\sum_{\mu\in\operatorname{Spec}\mathcal{M}_{\alpha,\gamma,r}}\left[-s\log\frac{\mu}{2\pi^2|\alpha+\gamma|^2}+\frac{s^2}{2}\left(\log\frac{\mu}{2\pi^2|\alpha+\gamma|^2}\right)^2+s^3f(\alpha,\gamma,r,s)\right].$$

But $\det\mathcal{M}_{\alpha,\gamma,r}=(2\pi^2|\alpha+\gamma|^2)^r$ so that

$$\sum_{\mu\in\operatorname{Spec}\mathcal{M}_{\alpha,\gamma,r}}\log\frac{\mu}{2\pi^2|\alpha+\gamma|^2}$$

vanishes:

$$\zeta_{\hat{\alpha},r}(s)=r\zeta_{\hat{\alpha}}(s)+\frac{s^2}{2}\sum_{\gamma\in\Lambda^*}(2\pi^2|\alpha+\gamma|^2)^{-s}\left[\sum_{\mu\in\operatorname{Spec}\mathcal{M}_{\alpha,\gamma,r}}\left(\frac{\mu}{2\pi^2|\alpha+\gamma|^2}-1\right)^2+g(\alpha,\gamma,r,s)\right]$$

$$+s^3\sum_{\gamma\in\Lambda^*}(2\pi^2|\alpha+\gamma|^2)^{-s}f(\alpha,\gamma,r,s).$$

For any norm $\|\ \|$ on matrices there exists a positive constant c_r such that for any $\gamma\in\Lambda^*$,

$$\|\mathcal{M}_{\alpha,\gamma,r}-2\pi^2|\alpha+\gamma|^2\mathrm{Id}\|\leqslant c_r\sqrt{2\pi^2|\alpha+\gamma|^2}$$

so that there exist positive constants c_1 and c_2 which verify for any α and γ:

$$|g(\alpha,\gamma,r,s)|\leqslant c_1(2\pi^2|\alpha+\gamma|^2)^{-3/2},$$

$$|f(\alpha,\gamma,r,s)|\leqslant c_2(2\pi^2|\alpha+\gamma|^2)^{-3/2}.$$

These bounds on f and g ensure that the derivative at $s=0$ of the corresponding terms vanish (they are products of s^2 times functions which are holomorphic around 0). So

$$\zeta'_{\hat{\alpha},r}(0)=r\zeta'_{\hat{\alpha}}(0)+\left.\frac{\mathrm{d}}{\mathrm{d}s}\right|_{s=0}\left[\frac{s^2}{2}\sum_{\gamma\in\Lambda^*}(2\pi^2|\alpha+\gamma|^2)^{-s-2}\times\left(8\pi^2|\alpha+\gamma|^2\sum_{q=2}^{r}|\lambda_q|^2+4\sum_{q=2}^{r}|\lambda_q|^4\right)\right]$$

$$=r\zeta'_{\hat{\alpha}}(0)+\left.\frac{\mathrm{d}}{\mathrm{d}s}\right|_{s=0}\left[\frac{s^2}{2}\left(4\zeta_{\hat{\alpha}}(s+1)\sum_{q=2}^{r}|\lambda_q|^2+4\zeta_{\hat{\alpha}}(s+2)\sum_{q=2}^{r}|\lambda_q|^4\right)\right].$$

Finally $\zeta_{\hat{\alpha}}$ is holomorphic around 0 and 2 and has a simple pole at $s=1$ which is easily calculated from the Minakshisundaram–Pleijel formula:

$$\operatorname{Tr}\exp -t\Delta_{\hat{\alpha}}=\frac{\eta}{2\pi t}+\mathcal{O}(t) \quad \text{as} \quad t\to 0,$$

$$\begin{aligned}\zeta_{\hat{\alpha}}(s)&=\frac{1}{\Gamma(s)}\int_0^\infty t^{s-1}\operatorname{Tr}(\exp -t\Delta_{\hat{\alpha}})\mathrm{d}t\\&=\frac{1}{\Gamma(s)}\int_0^1 t^{s-1}\left(\frac{\eta}{2\pi t}\right)\mathrm{d}t+\frac{1}{\Gamma(s)}\int_0^1 t^{s-1}\left(\operatorname{Tr}(\exp -t\Delta_{\hat{\alpha}})-\frac{\eta}{2\pi t}\right)\mathrm{d}t\\&\quad+\frac{1}{\Gamma(s)}\int_1^\infty t^{s-1}\operatorname{Tr}(\exp -t\Delta_{\hat{\alpha}})\mathrm{d}t\\&=\frac{\eta}{2\pi(s-1)\Gamma(s)}+\frac{1}{\Gamma(s)}\int_0^1 t^{s-1}\left(\operatorname{Tr}(\exp -t\Delta_{\hat{\alpha}})-\frac{\eta}{2\pi t}\right)\mathrm{d}t\\&\quad+\frac{1}{\Gamma(s)}\int_1^\infty t^{s-1}\operatorname{Tr}(\exp -t\Delta_{\hat{\alpha}})\mathrm{d}t\\&=\frac{\eta}{2\pi(s-1)}+\mathcal{O}(1) \quad \text{as} \quad s\to 1.\end{aligned}$$

(Here $\Delta_{\hat{\alpha}}$ is the Hodge–Laplace operator for $L_{\hat{\alpha}}$.) Thus

$$\zeta'_{\hat{\alpha},r}(0)=r\zeta'_{\hat{\alpha}}(0)+\frac{\eta}{\pi}\sum_{q=2}^{r}|\lambda_q|^2,$$

$$\log(\Theta(F_r\otimes L_{\hat{\alpha}}))=r\log(\Theta(L_{\hat{\alpha}}))-\frac{\eta}{2\pi}\sum_{q=2}^{r}|\lambda_q|^2,$$

$$\Theta(F_r\otimes L_{\hat{\alpha}})=\exp\left(-\frac{\eta}{2\pi}\sum_{q=2}^{r}|\lambda_q|^2\right)e^{-r\pi\,\mathrm{Im}\,\tau(b^2-b+1/6)}\prod_{k=-\infty}^{+\infty}|1-e^{2\pi i(|k|\tau+\varepsilon_k\sqrt{\eta\,\mathrm{Im}\,\tau}\alpha)}|^r$$

(with the notations of theorem 3). This proves part (*ii*) of theorem 4.

2. The case of F_r

The difference here is that $\mathcal{M}_{0,0,r}$ has kernel of rank one spanned by the section σ_1; it is then straightforward to calculate the product of nonvanishing eigenvalues of $\mathcal{M}_{0,0,r}$ (which is diagonal):

$$\det'(\mathcal{M}_{0,0,r})=2^{r-1}\left(\prod_{q=2}^{r}|\lambda_q|^2\right).$$

Then

$$\zeta_{F_r}(s)=\sum_{\mu\in\operatorname{Spec}\Delta_{F_r}\setminus\{0\}}\mu^{-s}=\sum_{\mu\in\operatorname{Spec}\mathcal{M}_{0,0,r}\setminus\{0\}}\mu^{-s}+\sum_{\gamma\in\Lambda^*\setminus\{0\}}\sum_{\mu\in\mathcal{M}_{0,\gamma,r}}\mu^{-s}.$$

The second term is treated exactly as before so that

$$\zeta'_{F_r}(0)=-\log\det'(\mathcal{M}_{0,0,r})+r\zeta'_{\mathcal{O}}(0)+\frac{\eta}{\pi}\sum_{q=2}^{r}|\lambda_q|^2,$$

$$\log\Theta(F_r)=\frac{1}{2}\sum_{q=2}^{r}\log(2|\lambda_q|^2)+r\log\Theta(\mathcal{O})-\frac{\eta}{2\pi}\sum_{q=2}^{r}|\lambda_q|^2,$$

$$\Theta(F_r)=\sqrt{\prod_{q=2}^{r}(2|\lambda_q|^2)}\exp\left(\frac{-\eta}{2\pi}\sum_{q=2}^{r}|\lambda_q|^2\right)(2\eta\,\mathrm{Im}\,\tau)^{r/2}e^{-r\pi\,\mathrm{Im}\,\tau/6}\prod_{k>0}|1-e^{2\pi ik\tau}|^{2r}$$

(with the notations of theorem 3). This proves part *(i)* of theorem 4.

3. The case of $F_r \otimes A$ where A is a line bundle of degree $d>0$

First of all, consider the matrices

$$\mathcal{M}^*_\ell = \begin{pmatrix} 2|\mu_\ell|^2 + \frac{2\pi(\ell-1)d}{\eta} & 2\mu_{\ell-1}\sqrt{\frac{\pi(\ell-1)d}{\eta}} & 0 & \dots & 0 \\ 2\overline{\mu}_{\ell-1}\sqrt{\frac{\pi(\ell-1)d}{\eta}} & 2|\mu_{\ell-1}|^2 + \frac{2\pi(\ell-2)d}{\eta} & \ddots & \ddots & \vdots \\ 0 & \ddots & \ddots & \ddots & 0 \\ \vdots & \ddots & \ddots & \ddots & 2\mu_1\sqrt{\frac{\pi d}{\eta}} \\ 0 & \dots & 0 & 2\overline{\mu}_1\sqrt{\frac{\pi d}{\eta}} & 2|\mu_1|^2 \end{pmatrix}$$

then one directly obtains

$$\begin{aligned} \det \mathcal{M}^*_\ell &= \left(\frac{2\pi(\ell-1)d}{\eta} + 2|\mu_\ell|^2\right)\det \mathcal{M}^*_{\ell-1} - 4|\mu_{\ell-1}|^2 \frac{\pi(\ell-1)d}{\eta}\det \mathcal{M}^*_{\ell-2} \\ &= 2^\ell |\mu_1|^2|\mu_2|^2\cdots|\mu_\ell|^2. \end{aligned} \tag{7}$$

Now set

$$\mathcal{M}_\ell = \begin{pmatrix} \frac{2\pi(\ell-1)d}{\eta} & 2\mu_{\ell-1}\sqrt{\frac{\pi(\ell-1)d}{\eta}} & 0 & \dots & 0 \\ 2\overline{\mu}_{\ell-1}\sqrt{\frac{\pi(\ell-1)d}{\eta}} & 2|\mu_{\ell-1}|^2 + \frac{2\pi(\ell-2)d}{\eta} & \ddots & \ddots & \vdots \\ 0 & \ddots & \ddots & \ddots & 0 \\ \vdots & \ddots & \ddots & \ddots & 2\mu_1\sqrt{\frac{\pi d}{\eta}} \\ 0 & \dots & 0 & 2\overline{\mu}_1\sqrt{\frac{\pi d}{\eta}} & 2|\mu_1|^2 \end{pmatrix}$$

and consider the characteristic polynomials

$$P^*_\ell(X) = \det(\mathcal{M}^*_\ell - X\mathrm{Id}),$$

$$P_\ell(X) = \det(\mathcal{M}_\ell - X\mathrm{Id}) = (-X)^\ell + (-X)^{\ell-1}\mathrm{Tr}\,\mathcal{M}_\ell + \dots + (-X)\det{}'\,\mathcal{M}_\ell,$$

where $\det'\mathcal{M}_\ell$ is the product of nonzero eigenvalues of $\mathcal{M}_\ell$ [of course $\det\mathcal{M}_\ell$ vanishes from (7)]. The obvious relation

$$P^*_\ell(X) = P_\ell(X) + 2|\mu_\ell|^2 P^*_{\ell-1}(X)$$

yields

$$P_\ell(X)=\left(\frac{2\pi(\ell-1)d}{\eta}-X\right)P^*_{\ell-1}(X)-4|\mu_{\ell-1}|^2\frac{\pi(\ell-1)d}{\eta}P^*_{\ell-2}(X)$$
$$=\left(\frac{2\pi(\ell-1)d}{\eta}-X\right)P_{\ell-1}(X)-2|\mu_{\ell-1}|^2X\,P^*_{\ell-2}(X)$$

from which one successively deduces

$$\det'\,\mathcal{M}_\ell=\frac{2\pi(\ell-1)d}{\eta}\det'\,\mathcal{M}_{\ell-1}+2|\mu_{\ell-1}|^2\det\mathcal{M}^*_{\ell-2}$$
$$=2^{\ell-1}\sum_{j=0}^{\ell-1}\left(\frac{\pi d}{\eta}\right)^{\ell-1-j}(\ell-1)(\ell-2)\cdots(j+1)\prod_{i=1}^{j}|\mu_i|^2.$$

Thus changing μ_i by $\lambda_{\ell+1-i}$ yields for $\ell\leqslant r$,

$$\det'\,\mathcal{M}_{r,k,\ell}=\left(\frac{2\pi d}{\eta}\right)^{\ell-1}(\ell-1)!\sum_{j=0}^{\ell-1}\left(\frac{\pi d}{\eta}\right)^{-j}\frac{|\lambda_{\ell-j+1}|^2|\lambda_{\ell-j+2}|^2\cdots|\lambda_\ell|^2}{j!},$$

where the $j=0$ term of the sum is to be taken equal to 1.

The characteristic polynomials $P_{r,k,\ell}(X)=\det(\mathcal{M}_{r,k,\ell}-X\mathrm{Id})$ verify for $\ell\geqslant r$,

$$P_{r,k,\ell}(X)=\left(2|\lambda_r|^2+\frac{2\pi(\ell-r)d}{\eta}-X\right)P_{r-1,k,\ell}(X)-4|\lambda_r|^2\frac{\pi(\ell-r+1)d}{\eta}P_{r-2,k,\ell}(X)$$

from which one deduces:

$$P_{r,k,\ell}(X)=(-X)^r+(-X)^{r-1}\left[\frac{2\pi d}{\eta}\left(r\ell-\frac{r(r+1)}{2}\right)+2\sum_{q=2}^{r}|\lambda_q|^2\right]$$
$$+(-X)^{r-2}\left[4\sum_{p<q}(|\lambda_p|^2|\lambda_q|^2)\right.$$
$$\left.+\frac{4\pi d}{\eta}\left((r-2)\ell\sum_{q=2}^{r}|\lambda_q|^2+\sum_{q=2}^{r}|\lambda_q|^2\left[-\frac{(r-1)(r-2)}{2}-2(r-q)\right]\right)\right.$$
$$\left.+\frac{4\pi^2d^2}{\eta^2}r(r-1)\left(\frac{\ell^2}{2}-\frac{(r+1)\ell}{2}+\frac{(r+1)(3r+2)}{24}\right)\right]$$
$$+\cdots+\left(\frac{2\pi d}{\eta}\right)^r(\ell-1)(\ell-2)\cdots(\ell-r).$$

Thus one gets the following symmetric functions of the eigenvalues of $\mathcal{M}_{r,k,\ell}$:

$$\sum_{\mu\in\operatorname{Spec}\mathcal{M}_{r,k,\ell}}\mu^2=\frac{4\pi^2d^2r}{\eta^2}\ell^2+\ell\left[-\frac{4\pi^2d^2}{\eta^2}r(r+1)+\frac{16\pi d}{\eta}\sum_{q=2}^{r}|\lambda_q|^2\right]$$
$$+\frac{4\pi^2d^2}{\eta^2}\frac{r(r+1)(2r+1)}{3}+\frac{4\pi d}{\eta}\sum_{q=2}^{r}(-8r+4q+2)|\lambda_q|^2+4\sum_{q=2}^{r}|\lambda_q|^4,$$

$$\sum_{\mu\in\operatorname{Spec}\mathcal{M}_{r,k,\ell}}\left(\mu-\frac{2\pi\ell d}{\eta}\right)^2=\frac{2\pi^2d^2r(r+1)(2r+1)}{3\eta^2}+\frac{8\pi d(\ell+1)}{\eta}\sum_{q=2}^{r}|\lambda_q|^2$$
$$+\frac{16\pi d}{\eta}\sum_{q=2}^{r}q|\lambda_q|^2+4\sum_{q=2}^{r}|\lambda_q|^4$$

from which as before if $\zeta_{r,d}$ stands for the zeta function (1) of $F_r\otimes A$,

$$\zeta_{r,d}(s)=\sum_{\mu\in\operatorname{Spec}\Delta\setminus\{0\}}\mu^{-s}$$
$$=d\sum_{\ell\leqslant r}\sum_{\mu\in\operatorname{Spec}\mathcal{M}_{r,k,\ell}\setminus\{0\}}\mu^{-s}+d\sum_{\ell>r}\left(\frac{2\pi\ell d}{\eta}\right)^{-s}\sum_{\mu\in\operatorname{Spec}\mathcal{M}_{r,k,\ell}}\left[\left(\frac{\eta\mu}{2\pi\ell d}\right)^{-s}-1+1\right]$$
$$=d\sum_{\ell\leqslant r}\cdots+dr\sum_{\ell>r}\left(\frac{2\pi\ell d}{\eta}\right)^{-s}+d\sum_{\ell>r}\left(\frac{2\pi\ell d}{\eta}\right)^{-s}$$
$$\times\left[\sum_{\mu\in\operatorname{Spec}\mathcal{M}_{r,k,\ell}}-s\log\frac{\eta\mu}{2\pi\ell d}+\frac{s^2}{2}\left(\log\frac{\eta\mu}{2\pi\ell d}\right)^2+s^3f(r,\ell,s)\right]$$
$$=d\sum_{\ell\leqslant r}\cdots+dr\sum_{\ell>r}\left(\frac{2\pi\ell d}{\eta}\right)^{-s}-ds\sum_{\ell>r}\left(\frac{2\pi\ell d}{\eta}\right)^{-s}\log\frac{(\ell-1)(\ell-2)\cdots(\ell-r)}{\ell^r}$$
$$+\frac{ds^2}{2}\sum_{\ell>r}\left(\frac{2\pi\ell d}{\eta}\right)^{-s}\left(\sum_{\mu\in\operatorname{Spec}\mathcal{M}_{r,k,\ell}}\left(\frac{\eta\mu}{2\pi\ell d}-1\right)^2+g(r,\ell,s)+2sf(r,\ell,s)\right).$$

As before there exist constants c_f and c_g such that for any ℓ,

$$|f(r,\ell,s)|\leqslant c_f\left(\frac{2\pi\ell d}{\eta}\right)^{-3/2},$$

$$|g(r,\ell,s)|\leqslant c_g\left(\frac{2\pi\ell d}{\eta}\right)^{-3/2},$$

so that the corresponding terms do not contribute to $\zeta'_{r,d}(0)$. Thus

$$\zeta'_{r,d}(0)=-d\sum_{\ell=2}^{r}\log\det{}'\,\mathcal{M}_{r,k,\ell}+dr\,\frac{\mathrm{d}}{\mathrm{d}s}\Big|_{s=0}\left[\left(\frac{2\pi d}{\eta}\right)^{-s}\left(\zeta(s)-\sum_{\ell=1}^{r}\ell^{-s}\right)\right]$$
$$-d\,\frac{\mathrm{d}}{\mathrm{d}s}\Big|_{s=0}\left[s\sum_{\ell>r}\left(\frac{2\pi\ell d}{\eta}\right)^{-s}\sum_{m=1}^{r}\log\frac{\ell-m}{\ell}\right]$$
$$+d\,\frac{\mathrm{d}}{\mathrm{d}s}\Big|_{s=0}\left[\frac{s^2}{2}\sum_{\ell>r}\left(\frac{2\pi\ell d}{\eta}\right)^{-s-2}\left(\frac{2\pi^2d^2r(r+1)(2r+1)}{3\eta^2}\right.\right.$$
$$\left.\left.+\frac{8\pi d(\ell+1)}{\eta}\sum_{q=2}^{r}|\lambda_q|^2+\frac{16\pi d}{\eta}\sum_{q=2}^{r}q|\lambda_q|^2+4\sum_{q=2}^{r}|\lambda_q|^4\right)\right]$$

(where ζ stands for the Riemann zeta function).

Lemma:

$$r\,\frac{\mathrm{d}}{\mathrm{d}s}\Big|_{s=0}\left[\left(\frac{2\pi d}{\eta}\right)^{-s}\left(\zeta(s)-\sum_{\ell=1}^{r}\ell^{-s}\right)\right]-\frac{\mathrm{d}}{\mathrm{d}s}\Big|_{s=0}\left[s\sum_{\ell>r}\left(\frac{2\pi\ell d}{\eta}\right)^{-s}\sum_{m=1}^{r}\log\left(\frac{\ell-m}{\ell}\right)\right]$$
$$=\frac{r^2}{2}\log\left(\frac{2\pi d}{\eta}\right)-\frac{r}{2}\log(2\pi)+\sum_{j=1}^{r-1}\log(j!).$$

Thus, simplifying the last term as in the case of $F_r\otimes L_{\hat{\alpha}}$ one obtains:

$$\zeta'_{r,d}(0)=-d\sum_{\ell=2}^{r}\log\left(\left(\frac{2\pi d}{\eta}\right)^{\ell-1}(\ell-1)!\sum_{j=0}^{\ell-1}\left(\frac{\pi d}{\eta}\right)^{-j}\frac{|\lambda_{\ell-j+1}|^2\cdots|\lambda_\ell|^2}{j!}\right)+d\,\frac{r^2}{2}\log\left(\frac{2\pi d}{\eta}\right)$$
$$-\frac{dr}{2}\log(2\pi)+d\sum_{j=1}^{r-1}\log(j!)+d\left(\sum_{q=2}^{r}|\lambda_q|^2\right)\frac{\mathrm{d}}{\mathrm{d}s}\Big|_{s=0}\left[2s^2\sum_{\ell>r}\left(\frac{2\pi\ell d}{\eta}\right)^{-s-1}\right]$$
$$=-d\sum_{\ell=2}^{r}\log\left(\sum_{j=0}^{\ell-1}\left(\frac{\pi d}{\eta}\right)^{-j}\frac{|\lambda_{\ell-j+1}|^2\cdots|\lambda_\ell|^2}{j!}\right)$$
$$+\frac{dr}{2}\log\left(\frac{2\pi d}{\eta}\right)-\frac{dr}{2}\log(2\pi)+\frac{\eta}{\pi}\sum_{q=2}^{r}|\lambda_q|^2,$$

$$\log\Theta(F_r\otimes A)=\frac{d}{2}\sum_{\ell=2}^{r}\log\left(\sum_{j=0}^{\ell-1}\left(\frac{\pi d}{\eta}\right)^{-j}\frac{|\lambda_{\ell-j+1}|^2\cdots|\lambda_\ell|^2}{j!}\right)-\frac{dr}{4}\log\left(\frac{d}{\eta}\right)-\frac{\eta}{2\pi}\sum_{q=2}^{r}|\lambda_q|^2\,,$$

$$\Theta(F_r\otimes A)=\prod_{\ell=2}^{r}\left(\sum_{j=0}^{\ell-1}\left(\frac{\pi d}{\eta}\right)^{-j}\frac{|\lambda_{\ell-j+1}|^2\cdots|\lambda_\ell|^2}{j!}\right)^{d/2}\left(\frac{d}{\eta}\right)^{-dr/4}\exp\left(-\frac{\eta}{2\pi}\sum_{q=2}^{r}|\lambda_q|^2\right).$$

This proves part *(iii)* of theorem 4.

Proof (of the lemma): Let $\tilde{\gamma}$ be the Euler constant:

$$\tilde{\gamma}=\lim_{n\to\infty}\left(\sum_{k=1}^{n}\frac{1}{k}-\log n\right)=\lim_{s\to0}\left(\zeta(1+s)-\frac{1}{s}\right)$$

then for any $1\leqslant m\leqslant r$:

$$\sum_{\ell>r}\left(\log\frac{\ell-m}{\ell}+\frac{m}{\ell}\right)=m\tilde{\gamma}+\log\left(\frac{r!}{(r-m)!}\right)-\sum_{\ell=1}^{r}\frac{m}{\ell}.$$

The proposed quantity then equals

$$\begin{aligned}
&=-r\log\left(\frac{2\pi d}{\eta}\right)(\zeta(0)-r)+r\left(\zeta'(0)+\sum_{\ell=2}^{r}\log\ell\right)\\
&\quad-\frac{\mathrm{d}}{\mathrm{d}s}\Big|_{s=0}\left[s\left(\frac{2\pi d}{\eta}\right)^{-s}\sum_{\ell>r}\frac{-r(r+1)}{2}\ell^{-s-1}\right]\\
&\quad-\frac{\mathrm{d}}{\mathrm{d}s}\Big|_{s=0}\left[s\left(\frac{2\pi d}{\eta}\right)^{-s}\sum_{\ell>r}\ell^{-s}\sum_{m=1}^{r}\left(\log\frac{\ell-m}{\ell}+\frac{m}{\ell}\right)\right]\\
&=r\left(r+\frac{1}{2}\right)\log\left(\frac{2\pi d}{\eta}\right)-\frac{r}{2}\log(2\pi)+r\log(r!)+\frac{r(r+1)}{2}\\
&\quad\times\frac{\mathrm{d}}{\mathrm{d}s}\Big|_{s=0}\left[s\left(\frac{2\pi d}{\eta}\right)^{-s}\left(\zeta(s+1)-\sum_{\ell=1}^{r}\ell^{-s-1}\right)\right]-\sum_{\ell>r}\sum_{m=1}^{r}\left(\log\frac{\ell-m}{\ell}-\frac{\ell-m}{\ell}\right)\\
&=r\left(r+\frac{1}{2}\right)\log\left(\frac{2\pi d}{\eta}\right)-\frac{r}{2}\log(2\pi)+r\log(r!)-\frac{r(r+1)}{2}\log\left(\frac{2\pi d}{\eta}\right)\\
&\quad+\frac{r(r+1)}{2}\left(\tilde{\gamma}-\sum_{\ell=1}^{r}\frac{1}{\ell}\right)-\sum_{m=1}^{r}\left(m\tilde{\gamma}+\log\frac{r!}{(r-m)!}-\sum_{\ell=1}^{r}\frac{m}{\ell}\right)
\end{aligned}$$

from which the lemma immediately follows. □

IV. SECOND EVALUATION OF THE ANALYTIC TORSION

A. Bismut, Gillet, and Soulé's formula

Let ξ be any holomorphic Hermitian vector bundle over E. Let $H^1(\xi)$ denote the cohomology group $H^1(E,\mathcal{O}_E(\xi))$. The determinant of the cohomology of ξ is taken to be the complex line [cf. Ref. 28, (1.1)]

$$\delta(\xi)=(\det\Gamma(\xi))^{-1}\otimes\det H^1(\xi),$$

where for any vector space V, $\det V$ is the complex line $\wedge^{\dim V}V$, and for a complex line δ, δ^{-1} is its dual. Hodge theory provides an identification of the cohomology groups $\Gamma(\xi)$ and $H^1(\xi)$ with the space of harmonic sections and harmonic forms of type (0,1) with values in ξ. The L^2 inner product on $\Gamma^\infty(E,\xi)$ and $\Gamma^\infty(E,T^{*(0,1)}E\otimes\xi)$ restricted to harmonic forms gives Hermitian scalar products on $\Gamma(\xi)$ and $H^1(\xi)$.

Definition 5: The L^2 metric on $\delta(\xi)$ is the inner product associated with the Hermitian L^2 product on $\Gamma(\xi)$ *and $H^1(\xi)$. Its norm is denoted $|\ |_{L^2}$.*

The Quillen metric on $\delta(\xi)$ is the inner product whose associated norm is

$$\|\ \|_Q=|\ |_{L^2}\cdot\Theta(\xi)$$

where $\Theta(\xi)$ is the analytic torsion of ξ. (cf. Ref. 28, (1.34)).

This Quillen metric will be used in the following way: Let

$$(\Xi):\quad 0\to\xi'\to\xi\to\xi''\to 0$$

be an exact sequence of vector bundles over E. Then the ''long'' exact sequence in cohomology

$$0\to\Gamma(\xi')\to\Gamma(\xi)\to\Gamma(\xi'')\to H^1(\xi')\to H^1(\xi)\to H^1(\xi'')\to 0$$

provides an identification of complex lines:

$$\delta(\xi')\otimes\delta(\xi'')\cong\delta(\xi)$$

or equivalently a canonical element $\mathcal{T}\in\delta(\xi')\otimes\delta(\xi)^{-1}\otimes\delta(\xi'')$. On the other hand if ξ', ξ, and ξ'' are metrized, Chern–Weil theory provides explicit representatives $\mathrm{ch}(\xi')$, $\mathrm{ch}(\xi)$, and $\mathrm{ch}(\xi'')\in\Gamma^\infty(E,\wedge^{\mathrm{even}}T^*E)$ of Chern characters of ξ', ξ, and ξ'', and Bott and Chern constructed in Ref. 22 (see also Ref. 21, theorem 1.29) an explicit form $\widetilde{\mathrm{ch}}(\Xi)$ such that

$$-\frac{\overline{\partial}\partial}{2\pi i}\widetilde{\mathrm{ch}}(\Xi)=-\mathrm{ch}(\xi)+\mathrm{ch}(\xi')+\mathrm{ch}(\xi''),$$

E being endowed with a parallel (Kähler) metric, the Todd genus of E in Chern–Weil theory is simply 1 so that theorem 0.3 of Ref. 21 becomes here

Theorem 6:

$$\log\|\mathcal{T}\|_Q^2=-\int_E\widetilde{\mathrm{ch}}(\Xi),$$

where $\|\ \|_Q$ *is the metric on* $\delta(\xi')\otimes\delta(\xi)^{-1}\otimes\delta(\xi'')$ *associated with the Quillen metrics on* $\delta(\xi')$, $\delta(\xi)$ *and* $\delta(\xi'')$.

B. The transgression form

Let $\mathcal{O}$ denote the trivial line bundle on E. Recall the

Proposition: (Ref. 20, corollary 2) For any $r>0$ *there exists a short exact sequence of vector bundles on the elliptic curve* E:

$$(\Xi_r):\quad 0\to F_r\overset{v}{\to}F_{r+1}\overset{v}{\to}\mathcal{O}\to 0.$$

v maps the section $\rho_{r+1,r+1}$ of F_{r+1} to the global section 1 of $\mathcal{O}$. Consider the $\mathbb{Z}/2\mathbb{Z}$-graduated vector bundle $(F_r\oplus\mathcal{O})\oplus F_{r+1}$ with its Hermitian compatible connection ∇. Metrics on F_r and F_{r+1} are taken as in (5) so that the first map v of (Ξ_r) is an isometric immersion, the metric on $\mathcal{O}$ is supposed to be parallel and such that the global section 1 has (constant) local norm ν_{r+1}. The operator v of the exact sequence (Ξ_r) is seen as an odd endomorphism of $(F_r\oplus\mathcal{O})\oplus F_{r+1}$, let v^* be its adjoint: one then obtains an isometric immersion $v^*:\mathcal{O}\to F_{r+1}$. For any non-negative $t\in\mathbb{R}$, define the superconnection on $(F_r\oplus\mathcal{O})\oplus F_{r+1}$,

$$C_t=\nabla+\sqrt{t}(v+v^*).$$

Consider the endomorphism N_V of $(F_r\oplus\mathcal{O})\oplus F_{r+1}$ which multiplies by 0 (respectively 1, respectively, 2) the elements of F_r (respectively of F_{r+1}, respectively of $\mathcal{O}$) and Tr_s the supertrace (which is the trace on $F_r\oplus\mathcal{O}$ minus the trace on F_{r+1}). Let $\phi\in\mathrm{End}(\wedge^{\mathrm{even}}T^*E)$ be the operator which divides 2-forms on E by $2\pi i$ and leaves functions unchanged. Then from Ref. 21, definition 1.16, theorem 1.17, and corollary 1.30

$$\widetilde{\mathrm{ch}}(\Xi_r)=\phi R'(0),$$

where R is the meromorphic continuation to $\mathbb{C}$ of the holomorphic function (with values in $\Gamma^\infty(E,\wedge^{\mathrm{even}}T^*_{\mathbb{R}}E)$)

$$R(s)=\frac{-1}{\Gamma(s)}\int_0^{+\infty}t^{s-1}\,\mathrm{Tr}_s(N_V\exp-C_t^2)\mathrm{d}t.$$

If one trivializes F_r and F_{r+1} in the σ_q, one obtains from (5) that

$$\nabla\sigma_q = -\overline{\lambda}_{q+1}\sigma_{q+1}dz + \lambda_q\sigma_{q-1}d\overline{z}$$

Let ε be the endomorphism of $\wedge^\bullet T^*E$ which multiplies by $(-1)^k$ the forms of degree k. The matrix of C_t with respect to $F_r \oplus F_{r+1} \oplus \mathcal{O}$ then reads (F_r and F_{r+1} being trivialised in the σ_q and $\mathcal{O}$ in the global parallel unitary section $1/\nu_{r+1}$)

$$C_t = \begin{pmatrix}
d & \lambda_2 d\overline{z} & 0 & \cdots & 0 & \varepsilon\sqrt{t} & 0 & \cdots & \cdots & \cdots & 0 & 0 \\
-\overline{\lambda}_2 dz & d & \ddots & \ddots & \vdots & 0 & \varepsilon\sqrt{t} & \ddots & & & \vdots & \vdots \\
0 & \ddots & \ddots & \ddots & 0 & \vdots & \ddots & \ddots & \ddots & & \vdots & \vdots \\
\vdots & \ddots & \ddots & \ddots & \lambda_r d\overline{z} & \vdots & & \ddots & \ddots & \ddots & \vdots & \vdots \\
0 & \cdots & 0 & -\overline{\lambda}_r dz & d & 0 & \cdots & \cdots & 0 & \varepsilon\sqrt{t} & 0 & 0 \\
\varepsilon\sqrt{t} & 0 & \cdots & \cdots & 0 & d & \lambda_2 d\overline{z} & 0 & \cdots & \cdots & 0 & 0 \\
0 & \ddots & \ddots & & \vdots & -\overline{\lambda}_2 dz & \ddots & \ddots & \ddots & & \vdots & \vdots \\
\vdots & \ddots & \ddots & \ddots & \vdots & 0 & \ddots & \ddots & \ddots & \ddots & \vdots & \vdots \\
\vdots & & \ddots & \ddots & 0 & \vdots & \ddots & \ddots & \ddots & \ddots & & \\
\vdots & & & \ddots & \varepsilon\sqrt{t} & \vdots & & \ddots & \ddots & \ddots & \lambda_{r+1} d\overline{z} & 0 \\
0 & \cdots & \cdots & \cdots & 0 & 0 & \cdots & \cdots & 0 & -\overline{\lambda}_{r+1} dz & d & \varepsilon\sqrt{t} \\
0 & \cdots & \cdots & \cdots & 0 & 0 & \cdots & \cdots & \cdots & 0 & \varepsilon\sqrt{t} & d
\end{pmatrix}.$$

Indeed, v (and v^*) act on a differential form with values in $(F_r \oplus \mathcal{O}) \oplus F_{r+1}$ as

$$v(\theta \otimes \varsigma) = \varepsilon\theta \otimes v(\varsigma)$$

[here θ is a local differential form and ς a local section of $(F_r \oplus \mathcal{O}) \oplus F_{r+1}$]; this is a consequence of the $\mathbb{Z}/2\mathbb{Z}$-grading of $\wedge^\bullet T^*E \hat{\otimes} ((F_r \oplus \mathcal{O}) \oplus F_{r+1})$ (cf. Ref. 21, p. 57, this property is essential in proving Ref. 21, proposition 1.6). Thus

$$C_t^2 = t\mathrm{Id} + M_1 \varepsilon dz + M_2 \varepsilon d\overline{z} + M_3 dz \wedge d\overline{z},$$

where M_3 is diagonal with entries

$$|\lambda_2|^2, |\lambda_3|^2 - |\lambda_2|^2, \cdots, |\lambda_r|^2 - |\lambda_{r-1}|^2, -|\lambda_r|^2,$$

$$|\lambda_2|^2, |\lambda_3|^2 - |\lambda_2|^2, \cdots, |\lambda_{r+1}|^2 - |\lambda_r|^2, -|\lambda_{r+1}|^2,$$

$$0$$

and M_2 is the conjugated transpose of

$$M_1=\begin{pmatrix} 0 & \cdots & \cdots & 0 & 0 & \cdots & \cdots & \cdots & 0 & 0 \\ \vdots & & & \vdots & \vdots & & & & \vdots & \vdots \\ \vdots & & & \vdots & \vdots & & & & \vdots & \vdots \\ 0 & \cdots & \cdots & 0 & 0 & \cdots & \cdots & \cdots & 0 & 0 \\ 0 & \cdots & \cdots & 0 & 0 & \cdots & \cdots & \cdots & 0 & 0 \\ 0 & \ddots & & \vdots & \vdots & & & & \vdots & \vdots \\ \vdots & \ddots & \ddots & \vdots & \vdots & & & & \vdots & \vdots \\ \vdots & & 0 & 0 & \vdots & & & & \vdots & \vdots \\ 0 & \cdots & 0 & \overline{\lambda}_{r+1}\sqrt{t} & 0 & \cdots & \cdots & \cdots & 0 & 0 \\ 0 & \cdots & \cdots & 0 & 0 & \cdots & 0 & -\overline{\lambda}_{r+1}\sqrt{t} & 0 & 0 \end{pmatrix}.$$

One deduces:

$$\exp -C_t^2=e^{-t}(\mathrm{Id}-M_1\varepsilon dz-M_2\varepsilon d\overline{z}-M_3dz\wedge d\overline{z}+\tfrac{1}{2}(M_2M_1-M_1M_2)dz\wedge d\overline{z})$$

with

$$M_2M_1-M_1M_2=|\lambda_{r+1}|^2t\begin{pmatrix} 0 & \cdots & \cdots & 0 & 0 & \cdots & \cdots & \cdots & 0 & 0 \\ \vdots & \ddots & & \vdots & \vdots & & & & \vdots & \vdots \\ \vdots & & 0 & 0 & \vdots & & & & \vdots & \vdots \\ 0 & \cdots & 0 & 1 & 0 & \cdots & \cdots & \cdots & 0 & 0 \\ 0 & \cdots & \cdots & 0 & 0 & \cdots & \cdots & \cdots & 0 & 0 \\ \vdots & & & \vdots & \vdots & \ddots & & & \vdots & \vdots \\ \vdots & & & \vdots & \vdots & & 0 & 0 & 0 & \vdots \\ \vdots & & & \vdots & \vdots & & 0 & 1 & 0 & \vdots \\ 0 & \cdots & \cdots & 0 & 0 & \cdots & 0 & 0 & -1 & 0 \\ 0 & \cdots & \cdots & 0 & 0 & \cdots & \cdots & \cdots & 0 & -1 \end{pmatrix}.$$

Now

$$\mathrm{Tr}_s(N_V\mathrm{Id})=-(r+1)+2,$$

$$\mathrm{Tr}_s(N_VM_1)=\mathrm{Tr}_s(N_VM_2)=\mathrm{Tr}_s(N_VM_3)=0,$$

$$\mathrm{Tr}_s[N_V(M_2M_1-M_1M_2)]=-2|\lambda_{r+1}|^2t,$$

$$\mathrm{Tr}_s(N_V\exp -C_t^2)=(1-r-t|\lambda_{r+1}|^2dz\wedge d\overline{z})e^{-t},$$

$$R(s)=\frac{r-1}{\Gamma(s)}\int_0^{+\infty}t^{s-1}e^{-t}\mathrm{d}t+\frac{|\lambda_{r+1}|^2}{\Gamma(s)}\left(\int_0^{+\infty}t^se^{-t}\,\mathrm{d}t\right)dz\wedge d\overline{z}$$

$$=r-1+|\lambda_{r+1}|^2\frac{\Gamma(s+1)}{\Gamma(s)}dz\wedge d\overline{z}=r-1+s|\lambda_{r+1}|^2dz\wedge d\overline{z}.$$

So that if $d\,\mathrm{Vol}\ (=(i/2)dz\wedge d\overline{z})$ denotes the volume form on E:

$$\widetilde{\mathrm{ch}}(\Xi_r)=\phi R'(0)=|\lambda_{r+1}|^2\frac{dz\wedge d\overline{z}}{2\pi i}=-|\lambda_{r+1}|^2\frac{d\,\mathrm{Vol}}{\pi}. \tag{8}$$

C. Second evaluation of the analytic torsion

1. The case of F_r

From definition 5, theorem 6, and formula (8) one obtains

$$\log(\Theta(F_r))=\log(\Theta(F_{r-1}))+\log(\Theta(\mathcal{O}))+\frac{1}{2}\log|\mathcal{T}|^2_{L^2}+\frac{1}{2}\int_E-|\lambda_r|^2\frac{d\,\mathrm{Vol}}{\pi}$$

where $\mathcal{T}$ is the canonical element of $\delta(\Xi_r):=\delta(F_{r-1})\otimes\delta(F_r)^{-1}\otimes\delta(\mathcal{O})$ associated with the exact sequence

$$0\overset{0}{\to}\Gamma(F_{r-1})\to\Gamma(F_r)\overset{0}{\to}\Gamma(\mathcal{O})\to H^1(F_{r-1})\overset{0}{\to}H^1(F_r)\to H^1(\mathcal{O})\overset{0}{\to}0.$$

The indicated maps are zero maps, the other ones are isomorphisms. The choice of metrics ensures that $\Gamma(F_{r-1})\to\Gamma(F_r)$ is an isometry; the isomorphism $H^1(F_r)\to H^1(\mathcal{O})$ maps $\sigma_r d\bar{z}$ [in the notation of (4)] to $(1/\nu_r)d\bar{z}$ so that its norm in 1 (because of the particular choice of metric on $\mathcal{O}$); the isomorphism $\Gamma(\mathcal{O})\to H^1(F_{r-1})$ maps the global trivial section 1 (which has local norm ν_r) to $\rho_{r-1,r-1}d\bar{z}$ so that its norm is

$$\sqrt{2}\left|\frac{\nu_{r-1}}{\nu_r}\right|.$$

From this one obtains

$$\log|\mathcal{T}|^2_{\delta(\Xi_r)}=\log(2|\lambda_r|^2)$$

($|\ |_{\delta(\Xi_r)}$ is the norm on $\delta(\Xi_r)$ associated to $|\ |_{L^2}$ on $\delta(F_r)$, $\delta(F_{r+1})$, and $\delta(\mathcal{O})$). Thus

$$\log(\Theta(F_r))=\log(\Theta(F_{r-1}))+\log(\Theta(\mathcal{O}))+\frac{1}{2}\log(2|\lambda_r|^2)-|\lambda_r|^2\frac{\eta}{2\pi}$$

$$=r\log(\Theta(\mathcal{O}))+\frac{1}{2}\sum_{q=2}^{r}\log(2|\lambda_q|^2)-\frac{\eta}{2\pi}\left(\sum_{q=2}^{r}|\lambda_q|^2\right)$$

as previously.

2. The case of $F_r\otimes L_{\hat{\alpha}}$ for a nontrivial line bundle $L_{\hat{\alpha}}$

Lemma. If

$$(\Xi):\quad 0\to\xi'\to\xi\to\xi''\to 0$$

is a metrised short exact sequence of vector bundles and β is a metrised vector bundle, then for the exact sequence:

$$(\Xi\otimes\beta):\quad 0\to\xi'\otimes\beta\to\xi\otimes\beta\to\xi''\otimes\beta\to 0$$

one has

$$\widetilde{\mathrm{ch}}(\Xi\otimes\beta)=\widetilde{\mathrm{ch}}(\Xi)\wedge\mathrm{ch}(\beta),$$

where $\mathrm{ch}(\beta)$ *is the Chern–Weil form obtained from* β*'s Hermitian compatible connection.*

Proof: This can be seen either from direct calculation from Ref. 21, definition 1.16 and the multiplicativity of the Chern character form, or using the axiomatic definition of Bott–Chern classes in Ref. 21, sec. 1.f) and the fact that the formula holds for a split exact sequence (Ξ) (where both sides of the equality vanish). □

One thus obtains

$$\widetilde{\mathrm{ch}}(\Xi_r\otimes L_{\hat{\alpha}})=\widetilde{\mathrm{ch}}(\Xi_r)=-|\lambda_r|^2\frac{d\,\mathrm{Vol}}{\pi}$$

(which remains true for any metric on $L_{\hat{\alpha}}$). Thus as before

$$\log(\Theta(F_r\otimes L_{\hat{\alpha}}))=\log(\Theta(F_{r-1}\otimes L_{\hat{\alpha}}))+\log(\Theta(L_{\hat{\alpha}}))-\frac{|\lambda_r|^2}{2}\int_E\frac{d\mathrm{Vol}}{\pi}$$

$$=r\log(\Theta(L_{\hat{\alpha}}))-\frac{\eta}{2\pi}\left(\sum_{q=2}^{r}|\lambda_q|^2\right)$$

(because $L_{\hat{\alpha}}$, $F_r\otimes L_{\hat{\alpha}}$ and $F_{r-1}\otimes L_{\hat{\alpha}}$ are acyclic so that here the L^2 norm of $\mathcal{T}$ is canonically equal to 1).

3. The case of $F_r\otimes A$ for a nonzero degree line bundle A

As before

$$\widetilde{\mathrm{ch}}(\Xi_r\otimes A)=\widetilde{\mathrm{ch}}(\Xi_r)=-|\lambda_r|^2\frac{d\,\mathrm{Vol}}{\pi}$$

so that

$$\log(\Theta(F_r\otimes A))=\log(\Theta(F_{r-1}\otimes A))+\log(\Theta(A))+\frac{1}{2}\log|\mathcal{T}|^2_{L^2}-\frac{|\lambda_r|^2}{2}\int_E\frac{d\,\mathrm{Vol}}{\pi}$$

$\mathcal{T}$ being the canonical element of

$$\delta(F_{r-1}\otimes A)\otimes\delta(F_r\otimes A)^{-1}\otimes\delta(A)$$

associated with the exact sequence

$$0\to\Gamma(F_{r-1}\otimes A)\to\Gamma(F_r\otimes A)\to\Gamma(A)\to H^1(F_{r-1}\otimes A)\to H^1(F_r\otimes A)\to H^1(A)\to 0.$$

All the H^1 vanish, the injection $\Gamma(F_{r-1}\otimes A)\to\Gamma(F_r\otimes A)$ is isometric with orthogonal complement in $\Gamma(F_r\otimes A)$ generated by the mutually orthogonal elements

$$\left(\sum_{j=1}^{r}\frac{(-1)^j}{\sqrt{(r-j)!}}\lambda_{j+1}\lambda_{j+2}\cdots\lambda_r\left(\frac{\pi d}{\eta}\right)^{j/2}\sigma_j\otimes\alpha_{r-j,k}\right)_{1\le k\le d}.$$

They are all of norm

$$\sqrt{\sum_{j=1}^{r}\frac{|\lambda_{j+1}|^2\ldots|\lambda_r|^2}{(r-j)!}\left(\frac{\pi d}{\eta}\right)^j}$$

and project to the

$$\left(\frac{(-1)^r}{\nu_r}\left(\frac{\pi d}{\eta}\right)^{r/2}\alpha_{0,k}\right)_{1\le k\le d},$$

which make an orthogonal base of $\Gamma(A)$. Thus

$$|\mathcal{T}|^2_{L^2}=\left(\sum_{j=1}^{r}\frac{|\lambda_{j+1}|^2\ldots|\lambda_r|^2}{(r-j)!}\left(\frac{\pi d}{\eta}\right)^{j-r}\right)^d$$

the term $j=r$ in this sum is to be taken equal to 1. (The $1/\nu_r$ are ''killed'' by the particular choice of metric on $\mathcal{O}$) then

$$\begin{aligned}\log(\Theta(F_r\otimes A))&=\log(\Theta(F_{r-1}\otimes A))+\log(\Theta(A))-|\lambda_r|^2\frac{\eta}{2\pi}\\&\quad+\frac{d}{2}\log\left(\sum_{j=1}^{r}\frac{|\lambda_{j+1}|^2\ldots|\lambda_r|^2}{(r-j)!}\left(\frac{\pi d}{\eta}\right)^{j-r}\right)\\&=r\log(\Theta(A))-\frac{\eta}{2\pi}\sum_{q=2}^{r}|\lambda_q|^2+\frac{d}{2}\sum_{k=2}^{r}\log\left(\sum_{j=1}^{k}\frac{|\lambda_{j+1}|^2\ldots|\lambda_k|^2}{(k-j)!}\left(\frac{\pi d}{\eta}\right)^{j-k}\right)\end{aligned}$$

as desired.

Small time controllability of systems on compact Lie groups and spin angular momentum

Domenico D'Alessandro[a)]
Department of Mathematics, Iowa State University, Ames, Iowa 50011

(Received 17 July 2000; accepted for publication 22 May 2001)

In this article, we develop some general results on the properties of the reachable sets for right invariant bilinear systems with state varying on compact Lie groups. The main results consist of a characterization of the set of states reachable in arbitrary time from the identity of the group. This, under suitable assumptions, is proved to be a Lie subgroup of the underlying Lie group. We apply these results to the analysis of the controllability of particles with spin. The results are motivated by and generalize the results in another work [D. D'Alessandro, Sys. Control Lett. **41**, 213–221 (2000)], where the specific model of a spin $\frac{1}{2}$ particle system in an electro-magnetic field was considered. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1388197]

I. INTRODUCTION

In recent years there has been a large amount of interest in the development and application of techniques from control theory for the manipulation of the state of quantum mechanical systems (see, e.g., Refs. 1–4). In typical laboratory experiments, an electro-magnetic field is used to drive the state of a quantum system to a desired value. The electro-magnetic field is seen as a control and classical issues of control theory such as analysis of controllability and development of methods for control have a natural physical interpretation in this setting. As an application of the results in this article, we will consider the simple but important example of a particle with spin angular momentum immersed in an electro-magnetic field and perform an analysis of the controllability of this system. No restriction will be placed on the value of the spin of the particle so that the systems considered include, for example, both Helium ^{3}He and ^{4}He molecules as well as an electron and a proton. In physical situations a time varying electro-magnetic field is used to induce a rotation and an analysis of the controllability for this kind of systems tells us what rotations can be achieved at a given time. This problem was dealt with in Ref. 5 for systems of spin $\frac{1}{2}$ particles and the research there was motivated by the problem of controlling the state of quantum bits in order to achieve prescribed logic operations in quantum computing.[6] For any system of this kind the describing model is given by Schrödinger equation with the control multiplying the state variable. This is a right invariant bilinear system whose state varies on a compact Lie group.

Controllability of systems on Lie groups was dealt with in Ref. 7 and in a number of following papers. References 8 and 9 give an up-to-date account of the main results and we refer to them for further references on this topic. It is a problem of great fundamental and practical importance to characterize the set of states that can be obtained in arbitrary small time. This set is, in general, not the whole Lie group even if the control is allowed to be a general Lebesgue measurable function (see Example 8.1 in Ref. 7). To the best of the author's knowledge, a systematic study of this set has not been carried out in the literature, although sufficient conditions are available for it to be the whole Lie group.[10] In the present article, we present a study of the set of states reachable from the identity of the group at any arbitrary time. We prove that this set is either empty or it is dense in a Lie subgroup of the underlying Lie group. If an additional regularity assumption is verified (small time local controllability of the identity of the group), then this set is, in fact, a connected

a)Electronic mail: daless@iastate.edu

Lie subgroup of the underlying group. The article is organized as follows. Sections II–IV are of general interest since they deal with controllability properties of general right invariant bilinear systems on compact Lie groups. In particular, in Sec. II we describe the mathematical model we want to study and give the basic definitions. We also prove a sufficient condition for the set of states reachable at any arbitrary time from the identity to be empty. This motivates the study of this set in the following two sections. In Sec. III, we prove that this set is either empty or is dense in a Lie subgroup of the underlying Lie group and in Sec. IV we relate the property of this set to be a connected Lie subgroup to the small time local controllability of the identity of the group. If this is verified, given the correspondence between connected Lie subgroups and Lie subalgebras, the problem of characterizing the set of states reachable from the identity at any arbitrary time can be approached studying the structure of the Lie algebra. Sections V and VI contain application of these results to the system of a particle with spin in an electro-magnetic field. In particular, in Sec. V the model for this system is described as a right invariant bilinear system on a compact Lie group and the controllability analysis for this system is presented in Sec. VI.

II. SYSTEMS ON COMPACT LIE GROUPS

In this section we study general systems of the form

$$\dot{X}=AX+\sum_{i=1}^{m} B_i X u_i . \tag{1}$$

The state X varies on a compact matrix Lie group G while the matrices A, B_i, $i=1,\ldots,m$, are constant matrices belonging to the corresponding Lie algebra $\mathcal{G}$. The restriction to *matrix* Lie groups is not necessary in the following and is considered here only for the sake of concreteness. The control functions u_i, $i=1,\ldots,m$, are piecewise continuous functions defined on some interval of $\mathbf{R}^+$. The matrices B_i, $i=1,\ldots,m$, are assumed to be linearly independent although this is done without loss of generality. In fact, it is always possible to reduce the analysis of the behavior of the system (1) to this case by opportunely redefining the control functions. System (1) is right invariant in that if $X(t)$ is a solution corresponding to the initial condition equal to the identity matrix, the solution corresponding to the initial condition F is given by $X(t)F$.

The following Lie algebras and Lie groups are associated to the system in (1):

(i) $\mathcal{L}$ is the Lie algebra generated by $\{A,B_1,\ldots,B_m\}$ and $e^{\mathcal{L}}$ is the corresponding connected Lie subgroup of G.
(ii) $\mathcal{L}_0$ is the ideal in $\mathcal{L}$ generated by $\{B_1,\ldots,B_m\}$ and $e^{\mathcal{L}_0}$ is the corresponding connected Lie subgroup of G.
(iii) $\mathcal{B}$ is the Lie algebra generated by $\{B_1,\ldots,B_m\}$ and $e^{\mathcal{B}}$ is the corresponding connected Lie subgroup of G.

Notice that $\mathcal{L}_0$ has co-dimension 0 or 1 in $\mathcal{L}$ according to whether A is or is not in $\mathcal{L}_0$.

The following sets of states reachable from the identity I are associated to the system (1).

(i) $R(T)$; the set of all the possible values for $X(T)$ [solution of (1) at time T with initial condition equal to the identity I] obtained by varying the controls $u_1,\ldots,u_m$, in the set of all the piecewise continuous functions defined in $[0,T]$. This is also expressed by saying that, for every $X_f \in R(T)$, there exists a piecewise continuous control function defined in $[0,T]$ which *drives* the state of the system from the identity to X_f.
(ii) $\mathcal{R}(\leqslant T) := \cup_{0\leqslant t\leqslant T} R(t)$.
(iii) $\mathcal{R} := \cup_{0\leqslant t<\infty} R(t)$.

We have $R(0)=\mathcal{R}(\leqslant 0)=\{I\}$, and, by right invariance, the set of states reachable *from* a point $X\in G$ are given by $R(T)X$, $\mathcal{R}(\leqslant T)X$ and $\mathcal{R}X$, respectively. Therefore, a study of the states reachable from the identity gives information on the states reachable from any other point. It will be useful sometimes to consider the sets $R^{-1}(T)$. These are the sets of all the matrices X in G for

which there exist control functions, $u_1,\ldots,u_m$, driving the solution of (1) from $X\in R^{-1}(T)$ to the identity I, in time T. This is sometimes called the set of states *controllable* to the identity. By the right invariance property, the set of all the states that can be driven to a state X in time T is given by $R^{-1}(T)X$. It also follows from the right invariance that $R^{-1}(T)=[R(T)]^{-1}$ and that if X is an interior point of $R(T)$, then X^{-1} is an interior point of $R^{-1}(T)$.

From the results of Ref. 7, we have that $\mathcal{R}=G$ if and only if $\mathcal{L}=\mathcal{G}$ and, more in general, $\mathcal{R}=e^{\mathcal{L}}$. Moreover, there exists a time T such that $\mathcal{R}(\leqslant T)=e^{\mathcal{L}}$. At every time t, $R(t)\subseteq e^{At}e^{\mathcal{L}_0}$, and the interior of $R(t)$ with respect to the topology of $e^{At}e^{\mathcal{L}_0}$ is not empty. It also follows from a result in Ref. 10 that, if $\mathcal{B}=\mathcal{L}$, then $R(t)=e^{\mathcal{L}}$, for every $t>0$. This is the case for homogeneous systems $(A=0)$.[11]

The main topic of the following two sections is the study of the set of states reachable at any arbitrary time in the cases where the above recalled condition of Ref. 10 does not guarantee that it is equal to $e^{\mathcal{L}}$. More specifically, we are interested in the study of the set

$$\mathcal{A}:=\cap_{t>0}R(t). \tag{2}$$

The examples in Refs. 5 and 7 show that the set $\mathcal{A}$ might not be the whole $e^{\mathcal{L}}$. In fact, it may be empty, as the following Proposition shows.

Proposition 2.1: If $\mathcal{L}_0$ has co-dimension 1 in $\mathcal{L}$, then $\mathcal{A}$ is empty.

Proof: It follows from the above recalled result in Ref. 7 that, for every $t>0$,

$$R(t)\subseteq e^{At}e^{\mathcal{L}_0}, \tag{3}$$

and therefore $\mathcal{A}\subseteq\cap_{t>0}e^{At}e^{\mathcal{L}_0}$. The right hand side of this inclusion is the empty set, if $A\notin\mathcal{L}_0$. In order to see this, assume $\cap_{t>0}e^{At}e^{\mathcal{L}_0}\neq\varnothing$ and pick $\tau_1,\tau_2>0$, with $\tau_2-\tau_1=t$, such that

$$e^{A\tau_1}F_1=e^{A\tau_2}F_2, \tag{4}$$

for some F_1 and F_2 in $e^{\mathcal{L}_0}$. From this, it follows that

$$e^{A\tau_1}F_1F_2^{-1}e^{-A\tau_1}=e^{At}\in e^{\mathcal{L}_0}, \tag{5}$$

since $e^{\mathcal{L}_0}$ is a normal subgroup (Ref. 12, p. 106 ff.). The fact that $e^{At}\in e^{\mathcal{L}_0}$, for all $t\in\mathbf{R}$, implies $A\in\mathcal{L}_0$, which we have excluded. □

In the following, we consider the system (1) as varying on $e^{\mathcal{L}}$ and the topology on $e^{\mathcal{L}}$ is the one induced by the one of G. Since we will be studying the set $\mathcal{A}$, we can assume, from the previous proposition, that $\mathcal{L}_0=\mathcal{L}$. Since the interior of $R(t)$ is not empty in $e^{At}e^{\mathcal{L}_0}$,[7] for every t, we have, in our case, that $R(t)$ has nonempty interior in $e^{\mathcal{L}}$ for every t.

III. SET OF STATES REACHABLE AT ANY ARBITRARY TIME

In the following three theorems, we assume that $\mathcal{A}$ is not empty. This can be checked, for example, by constructing a class of controls (for example, constant controls) steering to a fixed point in G (for example, the identity) in arbitrary time.

Theorem 3.1: *Assume $\mathcal{A}$ is not empty. Then it is a semigroup and $\overline{\mathcal{A}}$ is a Lie subgroup of G, in particular it contains the identity I.*

Proof: If $X_1\in R(t_1)$, and $X_2\in R(t_2)$, then, by right invariance $X_2X_1\in R(t_1+t_2)$. If X_1 and X_2 are in $\mathcal{A}$, t_1 and t_2 can be chosen positive but otherwise arbitrary, therefore t_2+t_1 is also arbitrary and $X_2X_1\in\mathcal{A}$. This shows that $\mathcal{A}$ is a semigroup. Since $\mathcal{A}$ is a semigroup, so is $\overline{\mathcal{A}}$. The previous argument also shows that if X is in $\mathcal{A}$, then X^n is in $\mathcal{A}$ for every positive integer n. At this point, we follow an idea of Ref. 7 (Thm. 6.5) to prove that X^{-1} is in $\overline{\mathcal{A}}$. Because of compactness, the sequence $\{X^n\}$ has a convergent subsequence $X^{n(k)}$. The sequence of elements in $\mathcal{A}$, $\{X^{n(k+1)-n(k)-1}\}$, converges, as k tends to infinity, to X^{-1} and therefore $X^{-1}\in\overline{\mathcal{A}}$. Since $\overline{\mathcal{A}}$ is a closed subgroup of the Lie group G it is a Lie subgroup of G (see, e.g., Ref. 13, p. 110). □

Theorem 3.2: *Assume $\mathcal{A}$ is not empty. If $t_1<t_2$, then $\overline{R}(t_1)\subseteq\overline{R}(t_2)$.*

Proof: We prove $R(t_1)\subseteq\overline{R}(t_2)$. Let X be an element of $R(t_1)$ and $\{X_n\}$ a sequence of elements in $\mathcal{A}$ converging to the identity which is in $\overline{\mathcal{A}}$ by the previous theorem. Since every X_n is in $R(t_2-t_1)$, all the elements of the sequence $\{XX_n\}$ are in $R(t_2)$ and since this sequence converges to X, $X\in\overline{R}(t_2)$. This also proves that $\overline{R}(t_1)\subseteq\overline{R}(t_2)$. Notice that we also have $intR(t_1)\subseteq intR(t_2)$. This follows immediately from the general property (see, e.g., Ref. 10) $intR(t)=int\overline{R}(t)$, for every $t>0$. □

Theorem 3.3: *Assume $\mathcal{A}$ is not empty. Then, $e^{\mathcal{B}}\subseteq\cap_{t>0}\overline{R}(t)$.*

Proof: Assume $X_f\in e^{\mathcal{B}}$, then there exists an integer $l>0$ and l real numbers $\alpha_1,\ldots,\alpha_l$ such that (see Lemma 6.2 in Ref. 7)

$$X_f=e^{\alpha_l B_{i_l}}e^{\alpha_{l-1}B_{i_{l-1}}}\cdots e^{\alpha_1 B_{i_1}}, \tag{6}$$

with $\{i_1,i_2,\ldots,i_l\}\in\{1,2,\ldots,m\}$. Then the piecewise constant control defined on the interval $[(j-1)/n, j/n)$, $j=1,\ldots,l$, as

$$\begin{aligned} u_{i_j}&=n\alpha_j,\\ u_k&=0,\quad k\neq i_j, \end{aligned} \tag{7}$$

gives for the state of system (1) at time $1/n$

$$X_n:=e^{(A+n\alpha_l B_{i_l})(1/n)}e^{(A+n\alpha_{l-1}B_{i_{l-1}})(1/n)}\cdots e^{(A+n\alpha_1 B_{i_1})(1/n)}. \tag{8}$$

We have that $X_n\in R(1/n)$ and

$$\lim_{n\to\infty}X_n=X_f. \tag{9}$$

Fix $t>0$. For every $n>1/t$, using Theorem 3.2, we have

$$X_n\in\overline{R}(t). \tag{10}$$

This implies $X_f\in\overline{R}(t)$, and since t is arbitrary, we have $X_f\in\cap_{t>0}\overline{R}(t)$. □

IV. CONSEQUENCES OF SMALL TIME LOCAL CONTROLLABILITY

The three theorems proved in the previous section can all be sharpened if we assume *small time local controllability* for the identity element I of the group ($STLCI$). $STLCI$ means that there exists a time $T>0$ such that the identity is in the interior of the reachable set $R(t)$ for every t, $0<t\leqslant T$. This is readily seen to imply that the identity is in the interior of the reachable set $R(t)$ for every $t>0$. This also implies that the identity is in the interior of $R^{-1}(t)$ and, by right invariance, that every point X is an interior point of the set of states controllable to X in time t, which is $R^{-1}(t)X$. The main result will be Theorem 4.3 which states that under this assumption the set $\mathcal{A}$ has the structure of a Lie group whose subalgebra contains $\mathcal{B}$. The following two lemmas contain generalizations of Theorems 3.1–3.3 when $STLCI$ is verified.

Lemma 4.1: $STLCI$ implies that $\mathcal{A}$ is not empty and it is a closed Lie subgroup of G.

Proof: It is obvious that $\mathcal{A}$ is not empty since it contains at least the identity. From Theorem 4.1, all we have to prove is that $\mathcal{A}$ is closed. To see this notice that if $I\in intR(t)$, then $I\in int[R(t)]^{-1}$, namely, I is in the interior of the set of states controllable to the identity in time t. This means, by right invariance, that every $X\in e^{\mathcal{L}}$ is in the interior of the set of states controllable to X in time t, which is $[intR(t)]^{-1}X$. Now, pick $X\in\overline{\mathcal{A}}$. There exists an element $Y\in\mathcal{A}\cap[intR(t)]^{-1}X$. The point Y can be reached from I in time t and X can be reached from Y in time t. Therefore $X\in R(2t)$, and since t is arbitrary, $X\in\mathcal{A}$. □

Lemma 4.2: Assume STLCI is verified. Then $t_1<t_2$ *implies that*

$$R(t_1)\subseteq R(t_2). \tag{11}$$

Moreover, $\cap_{t>0}\overline{R}(t)=\cap_{t>0}R(t):=\mathcal{A}$. *As a consequence,* $e^{\mathcal{B}}\subseteq\mathcal{A}$.

Proof: The proof of (11) follows immediately from the fact that $I\in R(t)$ for every t. As for the second statement, assume that $X_f\in\overline{R}(\tau)$, $\forall\tau>0$. Pick $\tau=t-\epsilon$, with $t>\epsilon>0$. *STLCI* implies that X_f is in $int(R^{-1}(\epsilon)X_f)$. From $X_f\in\overline{R}(t-\epsilon)$, we obtain that $R(t-\epsilon)\cap R^{-1}(\epsilon)X_f$ is not empty. If Y is a point in it, we can steer the state of the system from the identity to Y in time $t-\epsilon$ and from Y to X_f in time ϵ. Therefore, $X_f\in R(t)$ and since t is arbitrary $X_f\in\mathcal{A}$. The fact that $e^{\mathcal{B}}\subseteq\mathcal{A}$ is immediate from Theorem 3.3. □

Theorem 4.3: *If STLCI is verified, then* $\mathcal{A}$ *is a closed, connected Lie subgroup of G whose Lie algebra contains* $\mathcal{B}$.

Proof: The result is already contained in Lemmas 4.1 and 4.2, except for the fact that $\mathcal{A}$ is connected. However, since $R(t)$ is path-connected, for every $t>0$ (see Ref. 7, Lemma 4.4), so is $\overline{R}(t)$. From Lemma 4.2, $\mathcal{A}$ is the intersection of a decreasing sequence of continua [the compact and connected sets $\overline{R}(t)$] and therefore is itself a continuum (see Ref. 14, Theorem 7, p. 212) and in particular it is connected. The second statement follows from the one to one correspondence between subalgebras of $\mathcal{G}$ and connected Lie subgroups of G. □

From Theorem 4.3, it follows that, once *STLCI* is proved, one can approach the problem of characterizing $\mathcal{A}$ at the Lie algebra level. In fact $\mathcal{A}$ is a Lie group whose Lie algebra contains $\mathcal{B}$. One can consider all the Lie algebras containing $\mathcal{B}$. In some cases, as in the case of systems with spin angular momentum considered in the next section, the only Lie algebra containing $\mathcal{B}$ is $\mathcal{L}$, so that if one proves that not every state can be reached in arbitrary time, then it immediately follows that $\mathcal{A}=e^{\mathcal{B}}$.

There have been many studies concerning the property of small time local controllability for a given point in the state space of a nonlinear system. Many results (see, e.g., Ref. 8) deal with the case in which the point is an equilibrium point of the system when the control is set to zero. We give here a criterion, based on the maximum principle.[15,8] The proof is a generalization of the one used in Ref. 5 for the case of two-level quantum systems. We use the following notation: $ad_X^0Y:=Y, ad_X^kY=[X,ad_X^{k-1}Y]$.

Theorem 4.4: *Assume there exists a time T such that, for every* $\tau\leqslant T$, *there exists a piecewise constant control* u_τ *steering from the identity to the identity in time* τ. *Denote the values assumed by the function* u_τ *by* $\mathcal{U}_\tau:=\{u_1,u_2,\ldots,u_{k(\tau)}\}$. *For a value* u_j *define the matrix*

$$F_j:=A+\sum_{i=1}^{m}B_iu_{ij}, \tag{12}$$

where u_{ij}, $i=1,\ldots,m$, *are the components of* u_j. *Assume that, for every* τ, *there exists a* $u_j\in\mathcal{U}_\tau$ *such that*

$$ad_{F_j}^nB_i, \quad n=0,1,2,\ldots,k, \quad i=1,\ldots,m, \tag{13}$$

span the whole Lie Algebra $\mathcal{L}$. *Here k is the dimension of the Lie group. Then, the system has the STLCI property.*

Proof: We apply the maximum principle for systems on Lie groups[15] in the form that gives information on the structure of reachable sets.[8] We obtain that the identity is in the interior of the reachable set at time τ, $R(\tau)$, if the only matrix $M\in\mathcal{L}$ such that

$$\left\langle M,X^{-1}(t)\left(A+\sum_{i=1}^{m}B_iu_{ij}\right)X(t)\right\rangle=\min_{v_1,\ldots,v_m}\left\langle M,X^{-1}(t)\left(A+\sum_{i=1}^{m}B_iv_i\right)X(t)\right\rangle=\text{const} \tag{14}$$

is the zero matrix.[15] Since u_j is finite, (14) implies that

$$\langle M, X^{-1}(t)B_iX(t)\rangle \equiv 0, \quad i=1,\ldots,m, \tag{15}$$

in some interval of positive measure, $[t_1,t_2]\subseteq[0,\tau]$. Differentiating (15) n times at t_1, one obtains

$$\langle M, X^{-1}(t_1)ad_{F_j}^n B_iX(t_1)\rangle = 0, \quad n=1,2,\ldots, \tag{16}$$

and since $ad_{F_j}^n B_i$, $n=0,1,\ldots,k$, $i=1,2,\ldots,m$, span the whole Lie algebra $\mathcal{L}$, (16) and (15) with $t=t_1$ imply $M=0$. □

V. PARTICLES WITH SPIN IN AN ELECTRO-MAGNETIC FIELD

In this and the following section we apply the results obtained in the previous sections and perform the controllability analysis of a class of quantum systems. We consider a particle with spin and all the other degrees of freedom ignored under the action of an externally applied electro-magnetic field. We review the basic facts about the mathematical model in this section (see, e.g., Ref. 16) and perform the controllability analysis in the next section.

The (time varying) Hamiltonian describing the system is given by

$$H(t) := \gamma \mathbf{J}\cdot\mathbf{B} := \gamma(J_xB_x(t)+J_yB_y(t)+J_zB_z(t)). \tag{17}$$

In (17) γ is the *gyromagnetic ratio* of the particle, $J_{x,y,z}$ are the x,y,z components of the spin angular momentum operators and $B_{x,y,z}$ are the (time varying) components of the electro-magnetic field which play the role of control. $J_{x,y,z}$ are Hermitian operators on the underlying Hilbert space which satisfy the *fundamental commutation relations*

$$[J_x,J_y]=i\hbar J_z, \quad [J_y,J_z]=i\hbar J_x, \quad [J_z,J_x]=i\hbar J_y. \tag{18}$$

The theory of angular momentum in quantum mechanics originates from these relations (see, e.g., Ref. 16, Chap. 3). The evolution (rotation) operator X is obtained by solving Schrödinger equation

$$i\hbar\dot{X}(t)=H(t)X(t), \tag{19}$$

with initial condition $X(0)$ given by the identity operator. The Hamiltonian is given in (17), and we are interested here in a controllability analysis of this system, namely, we want to investigate what are the rotations that can be achieved in a particular configuration for system (19).

The spin of a particle may assume a value j which is either a positive integer or a positive half integer. For a particle with spin j the operators J_x, J_y, J_z can be represented by $2j+1\times 2j+1$ Hermitian matrices which we still denote by J_x, J_y, J_z. Defining $S_{x,y,z} := -iJ_{x,y,z}/\hbar$, we can write Schrödinger equations (19) and (17) for the evolution matrix as

$$\dot{X}(t)=\gamma(S_xB_x(t)+S_yB_y(t)+S_zB_z(t))X(t), \tag{20}$$

which has to be solved with $X(0)=I_{2j+1\times 2j+1}$. The matrices S_x, S_y, S_z satisfy the commutation relations corresponding to (18):

$$[S_x,S_y]=S_z, \quad [S_y,S_z]=S_x, \quad [S_z,S_x]=S_y. \tag{21}$$

They are skew-Hermitian and it follows immediately from (21) that they have zero trace. Therefore, they span a three-dimensional subalgebra of the Lie algebra su$(2j+1)$ of skew-Hermitian $2j+1\times 2j+1$ matrices with zero trace. We denote this three-dimensional Lie algebra by $\mathcal{G}_j$ and the corresponding connected Lie subgroup of SU$(2j+1)$ by G_j. An inner product $\langle\cdot,\cdot\rangle$ can be defined in $\mathcal{G}_j$ by

$$\langle A,B\rangle := \mathrm{Trace}(AB^*), \tag{22}$$

where B^* denotes the conjugate transpose of the matrix B. The Lie algebra $\mathcal{G}_j$ is semisimple (it is not Abelian and it has no Abelian ideal) and the Lie subgroup G_j is compact. The first statement can be verified by computing the Killing matrix $K_{ik}=\mathrm{Trace}(AdS_iAdS_k)$, $i,k=x,y,z$, and verifying that it is not degenerate (namely its determinant is different from zero). AdS_i is the matrix representation of the linear operator acting on $\mathcal{G}_j$ by $Y\to[S_i,Y]$. This is Cartan's criterion of semisimplicity (see, e.g., Ref. 17, p. 14). Compactness can be checked by applying Weyl's theorem (see, e.g., Ref. 17, p. 20), checking that the Killing matrix K_{ik} is negative definite. Both these results can also be obtained by noticing that for every j, the Lie algebra $\mathcal{G}_j$ is isomorphic to the Lie algebra su(2) [or so(3)], of skew-Hermitian 2×2 matrices with zero trace (antisymmetric real 3×3 matrices) and therefore the corresponding Lie group is isomorphic either to the Lie group of 2×2 special unitary matrices SU(2) or to the Lie group of 3×3 special orthogonal matrices SO(3), and therefore semisimplicity and compactness follow from known properties of the Lie algebras su(2) and so(3) and the corresponding Lie groups SU(2) and SO(3).

The above recalled result about the isomorphism between the Lie group G_j and SU(2) or SO(3) is crucial to the controllability analysis for spin angular momentum systems that will follow because it reduces the study to two cases: the Lie groups SU(2) and SO(3). This result appeared in a study by E. P. Wigner (Ref. 18, pp. 163–168). We state it in the following theorem.

Theorem 5.1: *G_j is isomorphic to* SO(3) *for j integer and isomorphic to* SU(2) *for j half-integer.*

VI. CONTROLLABILITY OF SPIN ANGULAR MOMENTUM

We refer to the system in the general form (1) that we repeat here,

$$\dot{X}=AX+\sum_{i=1}^{m} B_iXu_i, \tag{23}$$

where it is now understood that the matrices $A,B_1,\ldots,B_m$ are in the Lie algebras $\mathcal{G}_j$, as defined in the previous section. This general form includes all the possible geometric configurations that can be realized in a laboratory. For example, one could apply a constant electro-magnetic field and a time varying one at an angle of 30° in the $x-y$ plane so that both the components of the field in the x and y directions have a constant component (modeled by the matrix A) and a time varying component.

First notice that if two (or more) inputs are available, since we have assumed $B_1,\ldots,B_m$ linearly independent, $B_1,\ldots B_m$ generate the whole Lie algebra $\mathcal{G}_j$.[19] In this case, one can apply a result in Ref. 10 (Theorem 5.3) to conclude that $R(t)=G_j$ for every t. Therefore, the only nontrivial case is the single-input one. We also assume that A and B_1 are linearly independent in this case which, in physical terms, means that there are at least two nonparallel directions for the driving electro-magnetic field. If this is not the case, then the solution of (23) is just $X(t)=e^{\int_0^t A+B_1u(\tau)d\tau}$.

Consider now system (23) with a single input assuming the matrices A and B in su(2) [or so(3)] and the corresponding solution X in SU(2) [or SO(3)]. This is always possible because of the Lie group isomorphism of Theorem 5.1. Explicit expressions for this isomorphism are given, for example, in Ref. 20 (pp. 135–141). We write the system as

$$\dot{X}=AX+BXu. \tag{24}$$

Consider the constant input $u=-\langle A,B\rangle/\langle B,B\rangle+v$. The eigenvalues of the matrix $A+Bu$ are $0,\pm i\sqrt{v^2+p^2}$ in the so(3) case and $\pm i\sqrt{(\langle B,B\rangle/2)\,v^2+p^2}$, in the su(2) case. Here p is the magnitude of the purely imaginary conjugate eigenvalues of $A-\langle A,B\rangle/\langle B,B\rangle B$. These expressions show that the nonzero eigenvalues can be made arbitrarily large in magnitude by choosing v large, and therefore the corresponding solution of (24) returns to the identity in arbitrary small

time. This shows that the identity is in $R(t)$ for each t. Define $F:=A-\langle A,B\rangle/\langle B,B\rangle B+Bv$. Since A and B are assumed to be linearly independent so are B and F. Recalling that su(2) [and so(3)] have no two-dimensional subalgebras, it is easily seen that B, $ad_F B$ and $ad_F^2 B$ span the whole su(2) [or so(3)] so that we can apply Theorem 4.4 to conclude that the identity is in the interior of the reachable set $R(t)$ for every t. Using again the fact that su(2) [so(3)] does not have two dimensional subalgebras, we conclude from Theorem 4.3 that the set of states reachable in arbitrary time $\mathcal{A}$ for this system is either the whole group or the subgroup $e^{\mathcal{B}}$, where, in this case, $\mathcal{B}$ is the one dimensional subalgebra generated by B in (24). However, the set of states reachable in arbitrary time is not the whole group. An example of this phenomenon was given in Ref. 7 for SO(3) (Example 8.1 in Ref. 7) and, in fact, this example is somehow canonical since *every* system on SO(3) with one input has this property. In order to see this consider the system (24) and assume, without loss of generality, that A and B are orthogonal (we can always do this by shifting the input $u\rightarrow-\langle A,B\rangle/\langle B,B\rangle+v$). Moreover, by an appropriate change of coordinates and rescaling of time, we can always assume

$$A=\begin{pmatrix} 0 & 1 & 0 \\ -1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad B=\begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ -1 & 0 & 0 \end{pmatrix}, \tag{25}$$

which is the system considered in Ref. 7. The same steps can be carried on for systems varying on SU(2) with Eq.(24) and some algebraic manipulations show that not all the states can be obtained in arbitrary small time.[5] Alternatively one can use the two-to-one correspondence between SU(2) and SO(3) (Refs. 5 and 20, p. 124) and argue that, if all the states could be obtained in SU(2), in arbitrary time, the same would be true for SO(3). Applying the isomorphism of Theorem 5.1, we conclude with the following theorem.

Theorem 6.1: *Consider a system with spin under the action of an electro-magnetic field as described by Eq.* (24). *Then the set of rotations (states) that can be obtained in arbitrary time is given by the one dimensional Lie subgroup corresponding to the one dimensional Lie algebra generated by the matrix B*

During the revision of the present article the author learned about a recent article[21] where the model of spin systems is considered in the context of the theory of symmetric spaces. The result of Theorem 6.1 can also be obtained applying the results in Ref. 21. This can be done by noticing the isomorphism of $\mathcal{G}_j$ with su(2) and the fact that system (24) (with A and B orthogonal) is underlying a Cartan decomposition[17] of the Lie algebra su(2). If t_F denotes the infimum of the times $t\geqslant 0$ such that $X_f\in R(t)$, the only states X_f having $t_F=0$ are the ones in $e^{\mathcal{B}}$. Using the fact that $I\in R(t)$, $\forall t>0$, one can conclude that $e^{\mathcal{B}}=\mathcal{A}$ in this case. The analysis based on the results of Ref. 21 has the merit that can be easily generalized, to characterize, for a given time $T>0$, the set of states that can be reached in time $T+\Delta$, $\forall\Delta>0$. On the other hand, the derivation presented here, based on the general properties of the set $\mathcal{A}$ proved in the previous sections, gives further information concerning the *STLCI* property of the model.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 42, NUMBER 9 SEPTEMBER 2001

Exponentiation of the spinor representation of the Lorentz group

John Fredsted[a)]
Soeskraenten 60, Stavtrup, DK-8260 Viby J., Denmark

(Received 16 February 2001; accepted for publication 24 April 2001)

An exact finite expression for the exponentiation of the (spin $\frac{1}{2}$) spinor representation of the Lorentz group is obtained. From this expression an exact finite expression for the exponentiation of the vector representation of the Lorentz group is derived. The two expressions are compared with the literature in the special cases of either spatial rotations or boosts, only. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1388899]

I. INTRODUCTION

The Lorentz group is a Lie group. This guarantees the existence of an exponential mapping from the Lie algebra of the Lorentz group to the Lorentz group itself. Formally, each element of the group is defined as an infinite power series. Obtaining an exact finite expression for this power series is a difficult issue as the Lorentz group is non-Abelian. Concerning this issue, the Baker–Campbell–Hausdorff formula[1] is of no use as it consists of an infinite series of commutator terms which cannot in general be summed explicitly. Therefore, usual treatments of the Lorentz group are almost exclusively concerned with infinitesimal transformations[2] where only the first terms of the power series need to be considered.

However, by focusing on specific representations of the Lorentz group the issue becomes more tractable because it then reduces to the exponentiation of noncommuting matrices, instead of noncommuting generators (operators). The representations of the Lorentz group are the (single-valued) tensor representations, corresponding to tensor fields (integral spin), and the (two-valued) spinor representations, corresponding to spinor fields (half-integral spin)[3].

Based on the Cayley–Hamilton theorem, Zeni and Rodrigues[4] obtained an exact finite expression for the exponentiation of the vector representation of the Lorentz group. Their work was generalized by Barut, Zeni, and Laufer[5] to include all orthogonal groups. Using the Cayley–Hamilton theorem, too, Shimabukuro and Rosa[6] treated the semi-simple Lie groups.

Other methods for obtaining exact finite expressions for the exponentiation of various representations of various Lie groups exist in the literature. Leite and Crouch[7] used the method of Putzer[8] which, analogous to methods based on the Cayley–Hamilton theorem, is based on the calculation of eigenvalues. In connection with the Lorentz group, Clifford algebras are used in a paper by Zeni and Rodrigues[9] and in a paper by Froelich and Salingaros.[2] The methods based on the calculation of eigenvalues have the drawback that the expressions obtained with them can become quite intricate. In this article none of the methods described hitherto will be deployed.

Any field can be written in terms of (spin $\frac{1}{2}$) spinor fields.[10,11] Therefore, an exact finite expression for the exponentiation of any representation of the Lorentz group can, in principle, be derived from an expression for the (spin $\frac{1}{2}$) spinor representation of the Lorentz group. The purpose of this article is to illustrate this line of thought. First, an expression for the (spin $\frac{1}{2}$) spinor representation is obtained. Then, from that expression an expression for the vector representation is derived. Finally, these two expressions are compared with the literature in the special cases of either spatial rotations or boosts, only.

II. ALGEBRA

The Lorentz algebra is (using $\hbar=1$) given by

$$[S_i,S_j]=i\varepsilon_{ijk}S_k,$$

$$[S_i,K_j]=i\varepsilon_{ijk}K_k,$$

$$[K_i,K_j]=-i\varepsilon_{ijk}S_k,$$

where $\mathbf{S}=(S_1,S_2,S_3)$ and $\mathbf{K}=(K_1,K_2,K_3)$ are the (infinitesimal) generators of spatial rotations and boosts, respectively. (A sum over k is implicit.) In four-vector notation the Lorentz algebra takes the form

$$[M_{\alpha\beta},M_{\gamma\delta}]=i\eta_{\alpha\gamma}M_{\beta\delta}-i\eta_{\alpha\delta}M_{\beta\gamma}+i\eta_{\beta\delta}M_{\alpha\gamma}-i\eta_{\beta\gamma}M_{\alpha\delta},$$

where $\eta=\mathrm{diag}(-1,1,1,1)$ is the Minkowski metric and $M_{\alpha\beta}$ is defined by

$$M_{\alpha\beta}=\begin{pmatrix} 0 & K_1 & K_2 & K_3 \\ -K_1 & 0 & S_3 & -S_2 \\ -K_2 & -S_3 & 0 & S_1 \\ -K_3 & S_2 & -S_1 & 0 \end{pmatrix}. \tag{1}$$

The generators $\mathbf{A}=(A_1,A_2,A_3)$ and $\mathbf{B}=(B_1,B_2,B_3)$, defined by

$$\mathbf{A}=\tfrac{1}{2}(\mathbf{S}+i\mathbf{K}), \tag{2}$$

$$\mathbf{B}=\tfrac{1}{2}(\mathbf{S}-i\mathbf{K}), \tag{3}$$

obey the algebra

$$[A_i,A_j]=i\varepsilon_{ijk}A_k, \tag{4}$$

$$[B_i,B_j]=i\varepsilon_{ijk}B_k, \tag{5}$$

$$[A_i,B_j]=0. \tag{6}$$

III. SPINOR REPRESENTATION

The (spin $\frac{1}{2}$) spinor representation of the Lorentz group is given by

$$M_{\mu\nu}=\frac{1}{4i}[\gamma_\mu,\gamma_\nu], \tag{7}$$

where $\gamma_\mu=(\gamma_0,\boldsymbol{\gamma})=(\gamma_0,\gamma_1,\gamma_2,\gamma_3)$ are the Dirac matrices with (anticommutator) algebra

$$\{\gamma_\mu,\gamma_\nu\}=2\eta_{\mu\nu}.$$

A possible choice, to be used later in the article, for the Dirac matrices is

$$\gamma_0=i\begin{pmatrix} 1_2 & 0_2 \\ 0_2 & -1_2 \end{pmatrix},\quad \boldsymbol{\gamma}=\begin{pmatrix} 0_2 & \boldsymbol{\sigma} \\ \boldsymbol{\sigma} & 0_2 \end{pmatrix}, \tag{8}$$

where $\boldsymbol{\sigma}=(\sigma_1,\sigma_2,\sigma_3)$ are the Pauli matrices, 1_2 is the 2×2 identity matrix, and 0_2 is the 2×2 matrix with zero entries only.

Using Eqs. (1) and (7) the matrices **S** and **K** can be written as

$$\mathbf{S}=\frac{1}{4i}\boldsymbol{\gamma}\times\boldsymbol{\gamma}=\frac{1}{2}\gamma_0\gamma_5\boldsymbol{\gamma}, \tag{9}$$

$$\mathbf{K}=\frac{1}{4i}[\gamma_0,\boldsymbol{\gamma}]=\frac{1}{2i}\gamma_0\boldsymbol{\gamma}, \tag{10}$$

where $\gamma_5\equiv i\gamma_0\gamma_1\gamma_2\gamma_3$. From these equations and the definitions of **A** and **B** it follows that

$$\mathbf{A}=\frac{1}{2}\gamma_0\frac{1_4+\gamma_5}{2}\boldsymbol{\gamma}=\frac{1}{2}\gamma_0 P_R\boldsymbol{\gamma}, \tag{11}$$

$$\mathbf{B}=-\frac{1}{2}\gamma_0\frac{1_4-\gamma_5}{2}\boldsymbol{\gamma}=-\frac{1}{2}\gamma_0 P_L\boldsymbol{\gamma}, \tag{12}$$

where the right and left (helicity) projection operators $P_R=(1_4+\gamma_5)/2$ and $P_L=(1_4-\gamma_5)/2$, respectively, have been introduced. The properties of the projection operators imply

$$(\boldsymbol{\chi}\cdot\mathbf{A})^2=(\tfrac{1}{2})^2\boldsymbol{\chi}^2P_L, \tag{13}$$

$$(\boldsymbol{\chi}\cdot\mathbf{B})^2=(\tfrac{1}{2})^2\boldsymbol{\chi}^2P_R, \tag{14}$$

for any (complex) vector $\boldsymbol{\chi}$.

IV. EXPONENTIATION OF THE SPINOR REPRESENTATION

The exponentiation of the (spin $\frac{1}{2}$) spinor representation is given by

$$\Lambda_S=\exp[-i(\boldsymbol{\omega}\cdot\mathbf{S}+\boldsymbol{\zeta}\cdot\mathbf{K})], \tag{15}$$

where $\boldsymbol{\omega}$ and $\boldsymbol{\zeta}$ are real vectors, and **S** and **K** are given by (9) and (10). According to Eqs. (2), (3), and (6), Λ_S can be factorized as

$$\Lambda_S=\exp(-i\boldsymbol{\chi}^*\cdot\mathbf{A})\exp(-i\boldsymbol{\chi}\cdot\mathbf{B}), \tag{16}$$

where the complex vector $\boldsymbol{\chi}$ is defined by

$$\boldsymbol{\chi}=\boldsymbol{\omega}+i\boldsymbol{\zeta}. \tag{17}$$

From Eqs. (13) and (14) and the Taylor expansion of the exponential function it follows that

$$\exp(-i\boldsymbol{\chi}\cdot\mathbf{A})=1_4+[(\Phi_0-1)1_4-i\gamma_0\boldsymbol{\Phi}\cdot\boldsymbol{\gamma}]P_L, \tag{18}$$

$$\exp(-i\boldsymbol{\chi}\cdot\mathbf{B})=1_4+[(\Phi_0-1)1_4+i\gamma_0\boldsymbol{\Phi}\cdot\boldsymbol{\gamma}]P_R, \tag{19}$$

where the functions Φ_0 and $\boldsymbol{\Phi}$ are defined by

$$\Phi_0(\boldsymbol{\chi})=\cos\left(\frac{\chi}{2}\right), \tag{20}$$

$$\boldsymbol{\Phi}(\boldsymbol{\chi})=\begin{cases}\dfrac{1}{\chi}\sin\left(\dfrac{\chi}{2}\right)\boldsymbol{\chi}, & \chi\neq 0,\\[2ex] \dfrac{1}{2}\boldsymbol{\chi}, & \chi=0,\end{cases} \tag{21}$$

with the complex scalar χ defined by

$$\chi^2=\boldsymbol{\chi}^2=\boldsymbol{\omega}^2-\boldsymbol{\zeta}^2+2i\,\boldsymbol{\omega}\cdot\boldsymbol{\zeta}.$$

(The sign ambiguity in the definition of χ does not matter for its usage in this article. The case $\chi=0$ corresponds to $\boldsymbol{\omega}^2=\boldsymbol{\zeta}^2\wedge\boldsymbol{\omega}\cdot\boldsymbol{\zeta}=0$.)

From Eqs. (16), (18), and (19) it follows that

$$\begin{aligned}\Lambda_S&=1_4+[(\Phi_0^*-1)1_4-i\,\gamma_0\boldsymbol{\Phi}^*\cdot\boldsymbol{\gamma}]P_L+[(\Phi_0-1)1_4+i\,\gamma_0\boldsymbol{\Phi}\cdot\boldsymbol{\gamma}]P_R\\&=[\mathrm{Re}(\Phi_0)1_4+i\,\mathrm{Im}(\Phi_0)\,\gamma_5]+[\mathrm{Re}(\boldsymbol{\Phi})1_4+i\,\mathrm{Im}(\boldsymbol{\Phi})\,\gamma_5]\cdot i\,\gamma_5\gamma_0\boldsymbol{\gamma},\end{aligned}\tag{22}$$

which make up an exact finite expression for the exponentiation of the (spin $\frac{1}{2}$) spinor representation of the Lorentz group.

The inverse transformation Λ_S^{-1} is given by $\Lambda_S^{-1}(\boldsymbol{\chi})=\Lambda_S(-\boldsymbol{\chi})$ or, according to Eqs. (20)–(22),

$$\Lambda_S^{-1}=[\mathrm{Re}(\Phi_0)1_4+i\,\mathrm{Im}(\Phi_0)\,\gamma_5]-[\mathrm{Re}(\boldsymbol{\Phi})1_4+i\,\mathrm{Im}(\boldsymbol{\Phi})\,\gamma_5]\cdot i\,\gamma_5\gamma_0\boldsymbol{\gamma}.\tag{23}$$

V. EXPONENTIATION OF THE VECTOR REPRESENTATION

Under Lorentz transformations the Dirac matrices γ_μ transform as a four-vector

$$\Lambda_S^{-1}\gamma^\mu\Lambda_S=(\Lambda_V)^\mu{}_\nu\gamma^\nu,$$

where $(\Lambda_V)^\mu{}_\nu$ are the components of the Lorentz transformation in the vector representation. The trace properties of the Dirac matrices imply

$$(\Lambda_V)^\mu{}_\nu=\tfrac{1}{4}\mathrm{Tr}(\Lambda_S^{-1}\gamma^\mu\Lambda_S\gamma_\nu)=\tfrac{1}{4}\,\eta^{\mu\sigma}\mathrm{Tr}(\Lambda_S^{-1}\gamma_\sigma\Lambda_S\gamma_\nu).\tag{24}$$

Straightforward, but tedious, calculations, inserting the expressions for Λ_S and Λ_S^{-1} in (24) and using the standard trace properties for the Dirac matrices (and the general cyclic property of the trace), give

$$(\Lambda_V)^\mu{}_\nu=\eta^{\mu\sigma}[\Lambda^{(1)}_{\sigma\nu}+\Lambda^{(2)}_{\sigma\nu}+\Lambda^{(3)}_{\sigma\nu}],\tag{25}$$

where

$$\Lambda^{(1)}_{\mu\nu}=[\mathrm{Re}(\Phi_0)^2+\mathrm{Im}(\Phi_0)^2]\,\eta_{\mu\nu},\tag{26}$$

$$\begin{aligned}\Lambda^{(2)}_{\mu\nu}=&-2[\mathrm{Re}(\Phi_0)\mathrm{Re}(\Phi_i)+\mathrm{Im}(\Phi_0)\mathrm{Im}(\Phi_i)]\cdot\varepsilon_{0i\mu\nu}\\&+2[\mathrm{Re}(\Phi_0)\mathrm{Im}(\Phi_i)-\mathrm{Im}(\Phi_0)\mathrm{Re}(\Phi_i)]\cdot(\eta_{i\mu}\eta_{0\nu}-\eta_{i\nu}\eta_{0\mu}),\end{aligned}\tag{27}$$

$$\begin{aligned}\Lambda^{(3)}_{\mu\nu}=&[\mathrm{Re}(\Phi_i)\mathrm{Re}(\Phi_j)+\mathrm{Im}(\Phi_i)\mathrm{Im}(\Phi_j)](\eta_{i\mu}\eta_{j\nu}+\eta_{i\nu}\eta_{j\mu}-\eta_{ij}\delta_{\mu\nu})\\&+[\mathrm{Re}(\Phi_i)\mathrm{Im}(\Phi_j)-\mathrm{Im}(\Phi_i)\mathrm{Re}(\Phi_j)](\varepsilon_{0ij\mu}\eta_{0\nu}+\varepsilon_{0ij\nu}\eta_{0\mu}).\end{aligned}\tag{28}$$

Notice that $\Lambda^{(1)}_{\mu\nu}$ and $\Lambda^{(3)}_{\mu\nu}$ are symmetric matrices whereas $\Lambda^{(2)}_{\mu\nu}$ is an antisymmetric matrix.

The inverse transformation Λ_V^{-1} is, analogous to the spinor case, given by $\Lambda_V^{-1}(\boldsymbol{\chi})=\Lambda_V(-\boldsymbol{\chi})$, which corresponds to the following substitutions:

$$\Lambda^{(1)}_{\mu\nu}\to\Lambda^{(1)}_{\mu\nu},$$

$$\Lambda^{(2)}_{\mu\nu}\to-\Lambda^{(2)}_{\mu\nu}=\Lambda^{(2)}_{\nu\mu},$$

$$\Lambda^{(3)}_{\mu\nu}\to\Lambda^{(3)}_{\mu\nu}.$$

VI. SPATIAL ROTATIONS

According to (17), the case of spatial rotations, only, is characterized by $\boldsymbol{\chi}=\boldsymbol{\omega}$ for which

$$\Phi_0=\cos\left(\frac{\omega}{2}\right), \tag{29}$$

$$\boldsymbol{\Phi}=\sin\left(\frac{\omega}{2}\right)\hat{\boldsymbol{\omega}}, \tag{30}$$

where $\hat{\boldsymbol{\omega}}=\boldsymbol{\omega}/\omega$ has been introduced.

A. Spinor representation

According to Eqs. (22), (29), and (30) the Lorentz transformation for spatial rotations, only, reduces to

$$\begin{aligned}\Lambda_S&=\mathrm{Re}(\Phi_0)1_4+\mathrm{Re}(\boldsymbol{\Phi})\cdot i\gamma_5\gamma_0\boldsymbol{\gamma}\\&=\cos\left(\frac{\omega}{2}\right)1_4+\sin\left(\frac{\omega}{2}\right)\hat{\boldsymbol{\omega}}\cdot i\gamma_5\gamma_0\boldsymbol{\gamma},\end{aligned}$$

or, using the choice of Dirac matrices in (8),

$$\Lambda_S=\cos\left(\frac{\omega}{2}\right)1_4-i\sin\left(\frac{\omega}{2}\right)\begin{pmatrix}\hat{\boldsymbol{\omega}}\cdot\boldsymbol{\sigma} & 0_2\\ 0_2 & \hat{\boldsymbol{\omega}}\cdot\boldsymbol{\sigma}\end{pmatrix}. \tag{31}$$

Equation (31) agrees with Eq. (3.2.44) of Sakurai[12] for the transformation of a two-component spinor.

B. Vector representation

According to Eqs. (25), (29), and (30) the Lorentz transformation for spatial rotations, only, reduces to

$$\Lambda_V=1_4+\sin(\omega)(\hat{\boldsymbol{\omega}}\cdot\mathbf{S})+[1-\cos(\omega)](\hat{\boldsymbol{\omega}}\cdot\mathbf{S})^2, \tag{32}$$

where the matrices $\mathbf{S}$ are defined as

$$(S_i)_{\mu\nu}=-\varepsilon_{0i\mu\nu}, \tag{33}$$

in accordance with Eq. (11.91) of Jackson.[13]

VII. BOOSTS

According to (17), the case of boosts, only, is characterized by $\boldsymbol{\chi}=i\boldsymbol{\zeta}$ for which

$$\Phi_0=\cosh\left(\frac{\zeta}{2}\right), \tag{34}$$

$$\boldsymbol{\Phi}=i\sinh\left(\frac{\zeta}{2}\right)\hat{\boldsymbol{\zeta}}, \tag{35}$$

where $\hat{\boldsymbol{\zeta}}=\boldsymbol{\zeta}/\zeta$ has been introduced.

A. Spinor representation

According to (22), (34), and (35) the Lorentz transformation for boosts, only, reduces to

$$\Lambda_S = \mathrm{Re}(\Phi_0)1_4 + i\,\mathrm{Im}(\boldsymbol{\Phi})\,\gamma_5 \cdot i\gamma_5\gamma_0\boldsymbol{\gamma}$$

$$= \cosh\left(\frac{\zeta}{2}\right)1_4 - \sinh\left(\frac{\zeta}{2}\right)\hat{\boldsymbol{\zeta}}\cdot\gamma_0\boldsymbol{\gamma},$$

or, using the choice of Dirac matrices in (8),

$$\Lambda_S = \cosh\left(\frac{\zeta}{2}\right)1_4 - i\sinh\left(\frac{\zeta}{2}\right)\begin{pmatrix} 0_2 & \hat{\boldsymbol{\zeta}}\cdot\boldsymbol{\sigma} \\ -\hat{\boldsymbol{\zeta}}\cdot\boldsymbol{\sigma} & 0_2 \end{pmatrix}. \tag{36}$$

B. Vector representation

According to (25), (34), and (35) the Lorentz transformation for boosts, only, reduces to

$$\Lambda_V = 1_4 - \sinh(\zeta)(\hat{\boldsymbol{\zeta}}\cdot\mathbf{K}) + [\cosh(\zeta) - 1](\hat{\boldsymbol{\zeta}}\cdot\mathbf{K})^2, \tag{37}$$

where the matrices **K** are defined as

$$(K_i)_{\mu\nu} = \delta_{i\mu}\delta_{0\nu} + \delta_{i\nu}\delta_{0\mu}, \tag{38}$$

in accordance with Eq. (11.91) of Jackson.[13] Equation (37) agrees with Eq. (11.98) of Jackson[13].

VIII. CONCLUSION

In this article an exact finite expression for the exponentiation of the (spin $\frac{1}{2}$) spinor representation of the Lorentz group has been obtained. From that expression an exact finite expression for the exponentiation of the vector representation of the Lorentz group has been derived. The two expressions have been compared with the literature in the special cases of either spatial rotations or boosts, only.

Ruijsenaars' commuting difference operators and invariant subspace spanned by theta functions

Yasushi Komori[a)]
Institute of Physics, University of Tokyo, Komaba, 3-8-1 Komaba, Meguro-ku, Tokyo 153-8902, Japan

(Received 2 January 2001; accepted for publication 13 April 2001)

We study a family of mutually commutative difference operators introduced by Ruijsenaars. The conjugations of these operators with an appropriate function give the Hamiltonians of some relativistic quantum systems. These operators can be regarded as elliptic analogs of the Macdonald operators and their coefficients consist of the Jacobi theta functions. We show that these operators act on the space of meromorphic functions on the Cartan subalgebra of affine Lie algebras and that the space spanned by characters of a fixed positive level is invariant under the action of these operators. © *2001 American Institute of Physics.*
[DOI: 10.1063/1.1387449]

I. INTRODUCTION

In Ref. 1, Ruijsenaars introduced a family of mutually commutative operators, whose coefficients consist of theta functions, as a relativistic quantum many-body system, i.e., an elliptic difference analog of the Calogero–Moser model. Since then, these operators have been studied extensively from various points of view, in particular, by analogy with the Macdonald operators. The eigenvectors of the Macdonald operators are a two-parameter extension of the Schur functions or the characters of finite-dimensional simple Lie algebras. In the elliptic case, it was clarified in Refs. 2 and 3 that the elliptic analogs of type $A_l^{(1)}$ and $C_2^{(1)}$ have an invariant subspace in the meromorphic functions and that this space is actually spanned by the characters of the corresponding affine Lie algebra. These facts are found through studies of an extension of the Sklyanin algebra.[4] Independently, in Ref. 5, the Boltzmann weight of the matrix elements of Belavin's elliptic R-matrix was calculated using this fact implicitly.

In a series of Cherednik's papers,[6–8] it was clarified that the double affine Hecke algebra plays an essential role in Macdonald theory. There are some algebras that are considered as describing the structure of the elliptic analogs.[4,9–11] In this article, we employ yet another approach called the root algebra to these operators. Although this algebra was introduced by Cherednik, our construction is novel even in the trigonometric cases, due to the existence of spectral parameters. To be more precise, by setting these parameters appropriately, the difference operators automatically become invariant under the action of the Weyl group, while in the theory of the Hecke algebra, they are obtained through symmetrization. Following the previous works[12,13] we construct a family of mutually commuting difference operators associated with arbitrary affine root systems. These operators are shown to act on the vector space of the Weyl group invariant meromorphic functions and, furthermore, on the space spanned by the characters of a fixed positive level.

This article is organized as follows: In Sec. II, we present the notation and definitions used in this article. In Sec. III, we define the root algebras that were introduced by Cherednik in the development of the theory of affine Hecke algebras. In Sec. IV, we demonstrate some examples of the generators of a commutative subalgebra in the root algebras. In Sec. V, we give some representations of the root algebras with a spectral parameter, which consist of Jacobi's theta functions and act on the meromorphic functions on the Cartan subalgebra. We show that when we assign a

a)Electronic mail: komori@gokutan.c.u-tokyo.ac.jp

special value to the spectral parameter, the difference operators preserve the Weyl group invariant subspace. By construction, they form a commutative family. In Sec. VI, we calculate the explicit forms of these operators at this spectral parameter and observe that they can be regarded as an elliptic analog of the Macdonald operators. In twisted cases, we have the difference and quantum version of the systems that is recently proposed and is dealt with in terms of the Lax formalism.[14] We also prove that the generators are algebraically independent and thus the commutative subalgebra is isomorphic to a polynomial ring. In Sec. VII, we show in our main theorem (Theorem VII.5) that they have a finite-dimensional invariant subspace of theta functions of positive level, where the key of the proof is due to Refs. 5 and 15. The last section is devoted to the concluding remarks.

To end this section, we present two elliptic difference operators which take the simplest form among the generators respectively in the root systems of type $A_{l-1}^{(1)}$ and $A_{2l}^{(2)}$:

$$\hat{Y}_{A_{l-1}^{(1)}}^{-\lambda_1}=\sum_{j=1}^{l}\prod_{\substack{k=1\\k\neq j}}^{l}\frac{\vartheta_1(x_j-x_k-\mu)}{\vartheta_1(x_j-x_k)}\tau_j(\kappa)\prod_{k=1}^{l}\tau_k(-\kappa/l), \tag{1.1}$$

$$\begin{aligned}\hat{Y}_{A_{2l}^{(2)}}^{-\lambda_1}=&\sum_{j=1}^{l}\left(\left(\prod_{\substack{k=1\\k\neq j}}^{l}\frac{\vartheta_1(x_j-x_k-\mu)}{\vartheta_1(x_j-x_k)}\frac{\vartheta_1(x_j+x_k-\mu)}{\vartheta_1(x_j+x_k)}\right)\left(\prod_{r=0}^{3}\frac{\vartheta_r(x_j-\mu_r)}{\vartheta_r(x_j)}\frac{\vartheta_r(x_j+\kappa/2-\mu_r')}{\vartheta_r(x_j+\kappa/2)}\right)\right)\tau_j(\kappa)\\&+\sum_{j=1}^{l}\left(\left(\prod_{\substack{k=1\\k\neq j}}^{l}\frac{\vartheta_1(-x_j-x_k-\mu)}{\vartheta_1(-x_j-x_k)}\frac{\vartheta_1(-x_j+x_k-\mu)}{\vartheta_1(-x_j+x_k)}\right)\right.\\&\left.\times\left(\prod_{r=0}^{3}\frac{\vartheta_r(-x_j-\mu_r)}{\vartheta_r(-x_j)}\frac{\vartheta_r(-x_j-\kappa/2-\mu_r')}{\vartheta_r(-x_j-\kappa/2)}\right)\right)\tau_j(-\kappa)\\&+\sum_{p=0}^{3}\left(\frac{\pi}{\vartheta_1'(0)}\right)^2\frac{2}{\vartheta_1(\mu)\vartheta_1(\kappa+\mu)}\left(\prod_{r=0}^{3}\vartheta_r(\mu_{\pi_p r}+\kappa/2)\vartheta_r(\mu'_{\pi_p r})\right)\\&\times\left(\prod_{j=1}^{l}\frac{\vartheta_p(x_j-\kappa/2-\mu)}{\vartheta_p(x_j-\kappa/2)}\frac{\vartheta_p(-x_j-\kappa/2-\mu)}{\vartheta_p(-x_j-\kappa/2)}\right),\end{aligned} \tag{1.2}$$

where we have omitted an irrelevant additive constant in the $A_{2l}^{(2)}$ system, and realized the root systems in $\mathbb{C}^l$ in the standard way; $\vartheta_j(x)=\vartheta_j(x;\tau)$ is the Jacobi theta function and $\tau_i(\kappa)$ is a translation of the variable x_i by κ. π_j $(j=0,1,2,3)$ denotes the permutation: $\pi_1=\mathrm{id}$, $\pi_2=(12)\times(03)$, $\pi_3=(13)(02)$, and $\pi_0=(01)(23)$. The parameters κ, μ, μ_r, and μ_r' $(r=0,1,2,3)$ are arbitrary constants. The operator (1.1) was introduced in Ref. 1 together with the whole family of commuting difference operators, while the operator (1.2) was conjectured to be a member of a commutative family in Refs. 16 and 17. The $A_{2l}^{(2)}$-type model was referred to as *D*-type or *BC*-type in previous papers.

If we set $\kappa=l\mu/k$ in the $A_{l-1}^{(1)}$ case and $\kappa=(\mu_{\alpha_0}+2\mu_\theta+2(l-1)\mu)/k$ in the $A_{2l}^{(2)}$ case, where $\mu_{\alpha_0}=\Sigma\mu_r'$ and $\mu_\theta=(\Sigma\mu_r)/2$, then these operators have an invariant subspace which consists of the characters of level k corresponding to each affine Lie algebra. When the parameters μ, μ_θ, and μ_{α_0} are set to be unity, we see that κ reduces to $h^\vee/k$, where $h^\vee$ is the dual Coxeter number. For the derivation of these facts in each case, see Refs. 2, 18 and 19.

II. AFFINE ROOT SYSTEMS

We give some well-known facts about affine root systems and affine Weyl groups,[20–22] which are standard tools in the theory of affine Hecke algebras. Some of the definitions are slightly changed and extended so that they include twisted affine root systems. The notation is mainly due to Ref. 23.

Let $\mathfrak{g}$ be the affine Lie algebra of type $X_N^{(r)}$, $\mathfrak{h}$ its Cartan subalgebra of dim $\mathfrak{h}=l+2$, $I=\{0,...,l\}$ a set of indices, $\Pi=\{\alpha_i|i\in I\}\subset\mathfrak{h}^*$ the set of simple roots, $\Pi^\vee=\{\alpha_i^\vee|i\in I\}\subset\mathfrak{h}$ the set of simple coroots, Δ the root system, Q and $Q^\vee$ the root and coroot lattices, and P and $P^\vee$ the weight and coweight lattices:

$$Q=\bigoplus_{i\in I}\mathbb{Z}\alpha_i\subset P=\bigoplus_{i\in I}\mathbb{Z}\Lambda_i\oplus\mathbb{C}\delta\subset\mathfrak{h}^*, \tag{2.1}$$

$$Q^\vee=\bigoplus_{i\in I}\mathbb{Z}\alpha_i^\vee\subset P^\vee=\bigoplus_{i\in I}\mathbb{Z}\Lambda_i^\vee\oplus\mathbb{C}K\subset\mathfrak{h}, \tag{2.2}$$

where $\langle\alpha_i,\Lambda_j^\vee\rangle=\delta_{ij}$, $\langle\Lambda_i,\alpha_j^\vee\rangle=\delta_{ij}$, and $d=\Lambda_0^\vee$. Since the normalized invariant form is nondegenerate on $\mathfrak{h}$, we have an isomorphism $\nu:\mathfrak{h}\to\mathfrak{h}^*$ defined by

$$\langle\nu(h),h_1\rangle=(h|h_1),\quad h,h_1\in\mathfrak{h}, \tag{2.3}$$

and the induced bilinear form $(\cdot|\cdot)$ on $\mathfrak{h}^*$. Let $\mathring{I}=\{1,...,l\}$, $\mathring{\Pi}=\{\alpha_i|i\in\mathring{I}\}$, and $\mathring{\Pi}^\vee=\{\alpha_i^\vee|i\in\mathring{I}\}$. Let $\mathring{\mathfrak{h}}^*$ be the subspace of $\mathfrak{h}^*$ spanned by $\mathring{\Pi}$ over $\mathbb{C}$. For $\lambda\in\mathfrak{h}^*$, denote by $\overline{\lambda}$ the orthogonal projection of λ on $\mathring{\mathfrak{h}}^*$. Let $\mathring{Q}$ be the sublattice of Q generated by $\mathring{\Pi}$ and $\mathring{P}$ the projection of P on $\mathring{\mathfrak{h}}^*$. The dual notions $\mathring{\mathfrak{h}}$, $\overline{h}$, $\mathring{Q}^\vee$ and $\mathring{P}^\vee$ are defined similarly:

$$\mathring{Q}=\bigoplus_{i\in\mathring{I}}\mathbb{Z}\alpha_i\subset\mathring{P}=\bigoplus_{i\in\mathring{I}}\mathbb{Z}\overline{\Lambda_i}\subset\mathring{\mathfrak{h}}^*, \tag{2.4}$$

$$\mathring{Q}^\vee=\bigoplus_{i\in\mathring{I}}\mathbb{Z}\alpha_i^\vee\subset\mathring{P}^\vee=\bigoplus_{i\in\mathring{I}}\mathbb{Z}\overline{\Lambda_i^\vee}\subset\mathring{\mathfrak{h}}. \tag{2.5}$$

Let $\mathfrak{h}_\mathbb{R}$ be the $\mathbb{R}$-span of $\{\alpha_i^\vee\}_{i\in I}\cup\{d\}$ and let $\mathring{\mathfrak{h}}_\mathbb{R}$ be the $\mathbb{R}$-span of $\{\alpha_i^\vee\}_{i\in\mathring{I}}$. Let Δ^{re}, Δ^{im}, Δ_+, and Δ_- be the set of real roots, imaginary roots, positive roots, and negative roots, respectively. Then one has the disjoint unions $\Delta=\Delta^{\mathrm{re}}\cup\Delta^{\mathrm{im}}=\Delta_+\cup\Delta_-$. Let Δ_l be the set of the longest real roots. For $\alpha\in\Delta^{\mathrm{re}}$, let $\gamma_\alpha:=r$ if $\alpha\in\Delta_l$ and $\gamma_\alpha:=1$ otherwise, where r is from the type $X_N^{(r)}$. Then the real roots are written as

$$\Delta^{\mathrm{re}}=\begin{cases}\{\alpha+n\gamma_\alpha\delta|\alpha\in\mathring{\Delta},n\in\mathbb{Z}\}, & \text{if } X_N^{(r)}\neq A_{2l}^{(2)},\\ \{\alpha+n\gamma_\alpha\delta|\alpha\in\mathring{\Delta},n\in\mathbb{Z}\}\cup\{\frac{1}{2}(\alpha+(2n-1)\delta)|\alpha\in\mathring{\Delta}_l,n\in\mathbb{Z}\}, & \text{if } X_N^{(r)}=A_{2l}^{(2)}.\end{cases} \tag{2.6}$$

For $\alpha\in\Delta^{\mathrm{re}}$, let s_α be a reflection defined by

$$s_\alpha(\lambda):=\lambda-\langle\lambda,\alpha^\vee\rangle\alpha,\quad\lambda\in\mathfrak{h}^*. \tag{2.7}$$

The Weyl group $\mathring{W}$ is generated by the fundamental reflections $\{s_i:=s_{\alpha_i}|i\in\mathring{I}\}$ on $\mathfrak{h}^*$ and the affine Weyl group W is generated by $\{s_i|i\in I\}$. The defining relations are given by $s_i^2=id$ and the Coxeter relations:

$$(s_is_j)^{m_{ij}}=id,\quad\text{for } i\neq j\in I, \tag{2.8}$$

where $m_{ij}=2$ if α_i and α_j are disconnected in the Dynkin diagram and $m_{ij}=3,4,6$ if 1, 2, 3 lines respectively connect α_i and α_j. We note that there is no Coxeter relation in the affine root systems of rank 2. For $\mu\in\mathring{\mathfrak{h}}^*$, we define endomorphisms τ_μ of the vector space $\mathfrak{h}^*$ by

$$\tau_\mu(\lambda):=\lambda+\langle\lambda,K\rangle\mu-((\lambda|\mu)+\tfrac{1}{2}|\mu|^2\langle\lambda,K\rangle)\delta, \tag{2.9}$$

where $|\mu|^2$ stands for $(\mu|\mu)$. The actions of s_α,τ_μ are naturally induced on $\mathfrak{h}$ via the form $\langle\cdot,\cdot\rangle$ as follows ($h\in\mathfrak{h}$):

$$s_\alpha(h)=h-\langle\alpha,h\rangle\alpha^\vee, \tag{2.10}$$

$$\tau_\mu(h)=h+\langle\delta,h\rangle\nu^{-1}(\mu)-(\langle\mu,h\rangle+\tfrac{1}{2}|\mu|^2\langle\delta,h\rangle)K. \tag{2.11}$$

Let a_i and $a_i^\vee$ be the labels of the Dynkin diagram from Table Aff in Ref. 23. Note that $a_0=2$ if $X_N^{(r)}\neq A_{2l}^{(2)}$ and $a_0=1$ otherwise, and that $a_0^{-1}\gamma_\theta=1$. Let $\theta:=\delta-a_0\alpha_0\in\mathring{\Delta}_+$, $M:=\nu(\mathbb{Z}(\mathring{W}\cdot\theta^\vee))\subset\mathring{\mathfrak{h}}^*$. For an arbitrary lattice L, we denote by T_L the corresponding group of translations of L.

Proposition II.1: The group W is the semidirect product $W=\mathring{W}\ltimes T_M$.

Let $\hat{M}:=\{\lambda\in\mathring{\mathfrak{h}}^*|\alpha\in\Delta^{\mathrm{re}},(\alpha|\lambda)\in\gamma_\alpha\mathbb{Z}\}$. Then we see that $\hat{M}\subset\mathring{P}$ and $T_{\hat{M}}$ is normalized by $\mathring{W}$.

Definition II.2: The extended affine Weyl group $\hat{W}$ is the semidirect product $\hat{W}:=\mathring{W}\ltimes T_{\hat{M}}$.

The lattice $\hat{M}$ is taken to be the finest so that $T_{\hat{M}}$ acts on Δ, and thus the extended affine Weyl group acts on Δ. Here are the explicit description of $\hat{M}$ and its canonical basis $\{\lambda_i|i\in\mathring{I}\}$:

$$\hat{M}=\begin{cases}\nu(\mathring{P}^\vee), & \text{if } r=1,\\ \mathring{P}, & \text{otherwise}\end{cases},\quad \lambda_i=\begin{cases}\nu(\overline{\Lambda_i^\vee}), & \text{if } r=1,\\ \overline{\Lambda_i}, & \text{otherwise.}\end{cases} \tag{2.12}$$

We also use $\hat{M}_-:=\oplus_{i\in\mathring{I}}\mathbb{Z}_{\leqslant 0}\lambda_i$.

We use another action of the affine Weyl group on $\mathfrak{h}$. Fix $\kappa\in\mathbb{C}$. Let $\mathfrak{h}_\kappa:=\{h\in\mathfrak{h}|\langle\delta,h\rangle=\kappa\}$. Since W acts on $\mathfrak{h}_\kappa$, W acts on the affine space $\mathfrak{h}_\kappa\mathrm{mod}\mathbb{C}K$. We identify $\mathfrak{h}_\kappa\mathrm{mod}\mathbb{C}K$ with $\mathring{\mathfrak{h}}$ by projection. By this identification, we obtain affine transformations from $\hat{W}$ and affine linear functionals from $\langle\alpha,\cdot\rangle$ for $\alpha\in\Delta$. We denote so-obtained maps by af, so that

$$\mathrm{af}(w)(\overline{h})=\overline{w(h)},\quad \mathrm{af}(\alpha)(\overline{h})=\langle\alpha,h\rangle, \tag{2.13}$$

for $h\in\mathfrak{h}_\kappa$. Explicitly we have for $h\in\mathring{\mathfrak{h}}$

$$\mathrm{af}(\mathring{w})(h)=\mathring{w}(h),\quad \mathrm{af}(\tau_\mu)(h)=h+\kappa\nu^{-1}(\mu), \tag{2.14}$$

$$\mathrm{af}(\mathring{\alpha}+n\delta)(h)=\langle\mathring{\alpha},h\rangle+\kappa n. \tag{2.15}$$

Note that

$$\mathrm{af}(\alpha)\circ\mathrm{af}(w)=\mathrm{af}(w^{-1}\alpha). \tag{2.16}$$

We define an action of the extended affine Weyl group on the space $\mathcal{M}$ of meromorphic functions on $\mathbb{H}:=\mathring{\mathfrak{h}}/\mathring{Q}^\vee$ by

$$(wf)(h):=f(\mathrm{af}(w^{-1})h). \tag{2.17}$$

Let Ω be the subgroup of $\hat{W}$ which stabilizes the affine Weyl chamber C.

Proposition II.3: The subgroup Ω is isomorphic to $\hat{W}/W\simeq T_{\hat{M}}/T_M$ and thus Abelian. The extended affine Weyl group $\hat{W}$ is isomorphic to the semidirect product $W\rtimes\Omega$.

Definition II.4: (1) The length $\ell(w)$ of $w\in W$ is the length ℓ of the reduced decomposition:

$$w = s_{i_1} \cdots s_{i_\ell}, \quad \text{for } i_k \in I, \tag{2.18}$$

$$\ell(id) = 0. \tag{2.19}$$

(2) The length $\ell(\hat{w})$ of $\hat{w} \in \hat{W}$ is the number of the negative roots made positive by $\hat{w}$:

$$\ell(\hat{w}) := |\Delta_{\hat{w}}|, \tag{2.20}$$

$$\Delta_{\hat{w}} := \{\alpha \in \Delta_+ \cap \hat{w}\Delta_-\}, \tag{2.21}$$

which is equivalent to the definition $\ell(w)$ for $w \in W$. The reduced decomposition of $\hat{w} \in \hat{W}$ is $\hat{w} = w\omega = s_{i_1} \cdots s_{i_\ell} \omega$, where $\omega \in \Omega$ and $\ell = \ell(\hat{w}) = \ell(w)$.

The set $\Delta_{\hat{w}}$ is explicitly described as $\Delta_{\hat{w}} = \{\alpha^{(1)} = \alpha_{i_1}, \alpha^{(2)} = s_{i_1}(\alpha_{i_2}), \ldots, \alpha^{(\ell)} = w s_{i_\ell}(\alpha_{i_\ell})\}$. By definition, $\Delta_{\hat{w}}$ is independent of reduced expressions. One sees that $\Omega = \{\omega \in \hat{W}, \ell(\omega) = 0\}$.

Definition II.5: A weight $\lambda \in \hat{M}$ is said to be minuscule if $\Delta_{\tau_{-\lambda}} \subset \mathring{\Delta}_+$.

We use the following useful formulas, which can be easily derived from the previous definitions:

$$\Delta_{\tau_{\lambda_-}} = \begin{cases} \left\{ \alpha - n\gamma_\alpha \delta \,\middle|\, \alpha \in \mathring{\Delta}_+, 0 \geqslant n > \dfrac{1}{\gamma_\alpha}(\lambda_- | \alpha) \right\}, & \text{if } X_N^{(r)} \neq A_{2l}^{(2)}, \\ \left\{ \alpha - n\gamma_\alpha \delta \,\middle|\, \alpha \in \mathring{\Delta}_+, 0 \geqslant n > \dfrac{1}{\gamma_\alpha}(\lambda_- | \alpha) \right\} \cup & \\ \quad \left\{ \dfrac{1}{2}(\alpha - (2n-1)\delta) \,\middle|\, \alpha \in (\mathring{\Delta}_+)_l, 0 \geqslant n > \dfrac{1}{2}(\lambda_- | \alpha) \right\}, & \text{if } X_N^{(r)} = A_{2l}^{(2)}, \end{cases} \tag{2.22a}$$

$$\ell(\tau_{\lambda_-}) = \begin{cases} \displaystyle\sum_{\alpha \in \mathring{\Delta}_+} \left| \frac{1}{\gamma_\alpha}(\alpha | \lambda_-) \right|, & \text{if } X_N^{(r)} \neq A_{2l}^{(2)}, \\ \displaystyle\sum_{\alpha \in \mathring{\Delta}_+} |(\alpha | \lambda_-)|, & \text{if } X_N^{(r)} = A_{2l}^{(2)}, \end{cases} \tag{2.22b}$$

$$\ell(s_j \tau_{-\lambda_i}) = \ell(\tau_{-\lambda_i}) + 1, \tag{2.22c}$$

$$\ell(s_i \tau_{-\lambda_i}) = \ell(\tau_{-\lambda_i}) - 1, \tag{2.22d}$$

$$\ell(\tau_{\lambda_-} w) = \ell(\tau_{\lambda_-}) + \ell(w), \tag{2.22e}$$

$$\ell(\tau_{\lambda_- + \lambda'_-}) = \ell(\tau_{\lambda_-}) + \ell(\tau_{\lambda'_-}), \tag{2.22f}$$

where $i \neq j \in \mathring{I}$, λ_-, $\lambda'_- \in \hat{M}_-$, $w \in \mathring{W}$.

Next we summarize the definitions and properties of theta functions associated with affine Lie algebras.[23,24] In this article, we fix the coefficient of K and d as 0 and $-\tau$, respectively. Thus for $\lambda = \overline{\lambda} + k\Lambda_0 + u\delta \in \mathfrak{h}^*$, we define a function $e^\lambda = e(\lambda)$ on $\mathbb{H}$ by $e^\lambda(h) = e(\lambda)(h) := e^{2\pi i(\langle \overline{\lambda}, h \rangle) - u\tau}$. Although $e^{k\Lambda_0}$ is always 1, we leave such terms in order to see the correspondence to the theta functions in Ref. 23.

Definition II.6: Fix a non-negative integer k. A theta function of level k is a holomorphic function F on $\mathbb{H}$ such that the following condition holds:

$$F(h - \tau\nu^{-1}(\lambda)) = e^{k\lambda + k|\lambda|^2 \delta/2} F(h), \quad \text{for } \lambda \in \hat{M}. \tag{2.23}$$

Let Th^k denote the vector space over $\mathbb{C}$ of the theta functions of level k. For $\lambda \in \mathfrak{h}^*$ such that level $(\lambda)=k>0$ and $\overline{\lambda} \in \mathring{P}$, we set

$$\Theta_\lambda := e^{-|\lambda|^2 \delta/2k} \sum_{\mu \in M} e^{\tau\mu(\lambda)}, \tag{2.24}$$

It is known that $\{\Theta_\lambda | \text{level}(\lambda)=k\}$ is a basis of Th^k.

We also use

$$A_\lambda := \sum_{w \in \mathring{W}} (-1)^{\ell(w)} \Theta_{w(\lambda)}. \tag{2.25}$$

We close this section by observation of the relation between the Jacobi theta function and the theta functions introduced earlier. Consider the root system of type $A_1^{(1)}$. Then $\Pi=\{\alpha_0,\alpha_1\}$, $M=\mathbb{Z}\alpha_1$ and $(\alpha_1|\alpha_1)=2$. We have four theta functions of level 2 for $k \in \mathbb{Z}/4\mathbb{Z}$,

$$\Theta_{2\Lambda_0+k\overline{\Lambda_1}} = e(2\Lambda_0) \sum_{n \in \mathbb{Z}} e\left(-\frac{1}{2}\left(2n+\frac{k}{2}\right)^2 \delta + \left(2n+\frac{k}{2}\right)\alpha_1\right). \tag{2.26}$$

We see that level$(\rho)=h^\vee=2$:

$$A_\rho = \Theta_{2\Lambda_0+(1/2)\alpha_1} - \Theta_{2\Lambda_0-(1/2)\alpha_1} = e\left(\rho - \frac{1}{8}\delta\right) \prod_{\alpha \in \Delta_+} (1-e(-\alpha)). \tag{2.27}$$

This function is related to the Jacobi theta function as

$$-i\,\vartheta_1(\langle \alpha_1, h\rangle;\tau) = A_\rho(h). \tag{2.28}$$

Generally, if $X_N^{(r)} \neq A_{2l}^{(2)}$,

$$A_\rho(h) = e(h^\vee \Lambda_0) f(\tau) (-i)^{|\mathring{\Delta}_+|} \prod_{\alpha \in \mathring{\Delta}_+} \vartheta_1(\langle \alpha, h\rangle; \gamma_\alpha \tau), \tag{2.29}$$

for some function $f(\tau)$ which depends only on τ.

III. ROOT ALGEBRAS

We shall define the root algebras after Cherednik.[22] Let $\mathcal{T}$ be the tensor algebra over $\mathbb{C}$ generated by independent variables $\{R_\alpha | \alpha \in \Delta^{\text{re}}\}$. Then the action of $\hat{w} \in \hat{W}$ on Δ^{re} induces an action on $\mathcal{T}$ by $^{\hat{w}}: R_\alpha \mapsto R_{\hat{w}(\alpha)}$.

Definition III.1: Let $\mathcal{I}$ be the two-sided ideal in $\mathcal{T}$ which is generated by all the elements of the form for $i \neq j \in I$, and $\hat{w} \in \hat{W}$:

$$\underbrace{{}^{\hat{w}}(R_{\alpha_i} \otimes R_{s_i\alpha_j} \otimes R_{s_i s_j \alpha_i} \otimes \cdots)}_{m_{ij} \text{ factors}} - \underbrace{{}^{\hat{w}}(R_{\alpha_j} \otimes R_{s_j\alpha_i} \otimes R_{s_j s_i \alpha_j} \otimes \cdots)}_{m_{ij} \text{ factors}}. \tag{3.1}$$

The root algebra $\tilde{\mathcal{R}}$ is $\mathcal{T}/\mathcal{I}$. $\{R_\alpha | \alpha \in \Delta^{\text{re}}\}$ are called the R-matrices.

Because of the $\hat{W}$-invariance of $\mathcal{I}$, the action of $\hat{W}$ is induced on $\tilde{\mathcal{R}}$. For simplicity, we write products in $\tilde{\mathcal{R}}$ in the usual way for associative algebras.

Theorem III.2 (Cherednik): *(1) There exists a unique set* $\{R_{\hat{w}} | \hat{w} \in \hat{W}\} \subset \tilde{\mathcal{R}}$ *satisfying the relations*

$$R_{vw} = R_v {}^v R_w, \quad R_{\tau_i} = R_{\alpha_i} (i \in I), \quad R_\omega = 1, \tag{3.2}$$

where $\omega\in\Omega$, v, $w\in\hat{W}$ *and* $\ell(vw)=\ell(v)+\ell(w)$.

(2) *We have the R-matrix for* $\hat{w}\in\hat{W}$ *and its arbitrary reduced decomposition* $\hat{w}=w\omega=s_{i_1}\ldots s_{i_\ell}\omega$ *as*

$$R_{\hat{w}}=R_{\alpha^{(1)}}\ldots R_{\alpha^{(\ell)}},$$
$$\alpha^{(1)}=\alpha_{i_1},\quad \alpha^{(2)}=s_{i_1}(\alpha_{i_2}),\quad \ldots,\quad \alpha^{(\ell)}=ws_{i_\ell}(\alpha_{i_\ell})\in\Delta_{\hat{w}}. \tag{3.3}$$

Proof: If $R_{\hat{w}}$ satisfies (3.2), then $R_{\hat{w}}$ must be of the form (3.3). Thus it is sufficient to show that (3.3) is well defined.

Let $\hat{w}=s_{i_1}s_{i_2}\cdots s_{i_\ell}\omega=s_{j_1}s_{j_2}\cdots s_{j_\ell}\omega$ be any two reduced expressions. By Matsumoto's lemma, we see that one can be obtained from the other only by a sequence of Coxeter relations,

$$\begin{aligned}\hat{w}&=s_{i_1}s_{i_2}\cdots s_{i_\ell}\omega\\ &=\underbrace{s_{i_1}s_{i_2}\cdots s_{i_k}}_{w_1}\underbrace{s_is_j\cdots}_{\substack{w_2\\ m_{ij}\ \text{times}}}\underbrace{s_{i_{k+m_{ij}+1}}\cdots s_{i_\ell}\omega}_{w_3} &\text{(3.4a)}\\ &=\underbrace{s_{i_1}s_{i_2}\cdots s_{i_k}}_{w_1}\underbrace{s_js_i\cdots}_{\substack{w_2\\ m_{ij}\ \text{times}}}\underbrace{s_{i_{k+m_{ij}+1}}\cdots s_{i_\ell}\omega}_{w_3} &\text{(3.4b)}\\ &\ \ \vdots\\ &=s_{j_1}s_{j_2}\cdots s_{j_\ell}\omega.\end{aligned}$$

From the expressions (3.4a) and (3.4b), we have the corresponding elements (3.3) in the root algebra,

$$R_{w_1}{}^{w_1}\underbrace{(R_{\alpha_i}R_{s_i\alpha_j}R_{s_is_j\alpha_i}\cdots)}_{m_{ij}\ \text{factors}}{}^{w_1w_2}(R_{w_3}), \tag{3.5a}$$

$$R_{w_1}{}^{w_1}\underbrace{(R_{\alpha_j}R_{s_j\alpha_i}R_{s_js_i\alpha_j}\cdots)}_{m_{ij}\ \text{factors}}{}^{w_1w_2}(R_{w_3}), \tag{3.5b}$$

which are equivalent due to Definition III.1. By applying this argument to each step in (3.4), we conclude that $R_{\hat{w}}$ is uniquely determined by $\hat{w}$. □

Instead of the original root algebra, we use the following extension, where $\tilde{\mathcal{R}}$ is combined with the translation group $T_{\hat{M}}$:

Definition III.3: $\mathcal{R}:=\tilde{\mathcal{R}}\rtimes T_{\hat{M}}$:

$$(R\tau_\lambda)(R'\tau_\mu)=R({}^{\tau_\lambda}R')\tau_{\lambda+\mu}, \tag{3.6}$$

where R, $R'\in\tilde{\mathcal{R}}$ and λ, $\mu\in\hat{M}$.

We see that $\mathcal{R}$ is generated by $\{\tau_{\lambda_i},R_\alpha|i\in\mathring{I},\alpha\in\mathring{\Delta}\}$ if $X_N^{(r)}\neq A_{2l}^{(2)}$ and $\{\tau_{\lambda_i},R_\alpha|i\in\mathring{I},\alpha\in\mathring{\Delta},2\alpha-\delta\in\mathring{\Delta}\}$ if $X_N^{(r)}=A_{2l}^{(2)}$.

Theorem III.4: *The subalgebra* $\mathcal{S}\subset\mathcal{R}$ *generated by* $\{Y^\lambda:=R_{\tau_\lambda}\tau_\lambda|\lambda\in\hat{M}_-\}$ *forms a commutative algebra and is generated by* $\{Y^{-\lambda_i}|i\in\mathring{I}\}$.

Proof: Let $\lambda,\ \mu\in\hat{M}_-$. Then we have $\ell(\tau_\lambda)+\ell(\tau_\mu)=\ell(\tau_{\lambda+\mu})$ by the formulas (2.22), which implies that $R_{\tau_{\lambda+\mu}}$ constructed from two reduced expressions $\tau_{\lambda+\mu}=\tau_\lambda\tau_\mu=\tau_\mu\tau_\lambda$ coincides due to Theorem III.2,

$$R_{\tau_{\lambda+\mu}}=R_{\tau_\lambda}({}^{\tau_\lambda}R_{\tau_\mu})=R_{\tau_\mu}({}^{\tau_\mu}R_{\tau_\lambda}). \tag{3.7}$$

By Definition III.3 and the definition of Y^ν, we have $Y^{\lambda+\mu}=Y^\lambda Y^\mu=Y^\mu Y^\lambda$. □

IV. AFFINE ROOT SYSTEMS OF RANK 3

We present some examples of the above construction. The rank of the lowest nontrivial affine root system is 3 and there are six types of affine root systems of rank 3. We denote $\alpha=\alpha_1$ and $\beta=\alpha_2$ where $|\alpha_1|\geqslant|\alpha_2|$, and $\lambda=\lambda_1$ and $\mu=\lambda_2$, respectively. We have the following systems that are mutually commutative by construction:

$A_2^{(1)}$
$$Y^{-\lambda}=R_\alpha R_{\alpha+\beta}\tau_{-\lambda}, \tag{4.1a}$$
$$Y^{-\mu}=R_\beta R_{\alpha+\beta}\tau_{-\mu}, \tag{4.1b}$$

$C_2^{(1)}$
$$Y^{-\lambda}=R_\alpha R_{\alpha+\beta}R_{\alpha+2\beta}\tau_{-\lambda}, \tag{4.2a}$$
$$Y^{-\mu}=R_\beta R_{\alpha+2\beta}R_{\alpha+\beta}R_{\alpha+2\beta+\delta}\tau_{-\mu}, \tag{4.2b}$$

$G_2^{(1)}$
$$Y^{-\lambda}=R_\alpha R_{\alpha+\beta}R_{2\alpha+3\beta}R_{\alpha+2\beta}R_{\alpha+3\beta}R_{2\alpha+3\beta+\delta}\tau_{-\lambda}, \tag{4.3a}$$
$$Y^{-\mu}=R_\beta R_{\alpha+3\beta}R_{\alpha+2\beta}R_{2\alpha+3\beta}R_{\alpha+\beta}R_{\alpha+3\beta+\delta}R_{2\alpha+3\beta+\delta} R_{\alpha+2\beta+\delta}R_{\alpha+3\beta+2\delta}R_{2\alpha+3\beta+2\delta}\tau_{-\mu}, \tag{4.3b}$$

$A_4^{(2)}$
$$Y^{-\lambda}=R_\alpha R_{\alpha+\beta}R_{\alpha+2\beta}R_{(1/2)\alpha+(1/2)\delta}R_{\alpha+\beta+\delta}R_{(1/2)\alpha+\beta+(1/2)\delta}\tau_{-\lambda}, \tag{4.4a}$$
$$Y^{-\mu}=R_\beta R_{\alpha+2\beta}R_{\alpha+\beta}R_{(1/2)\alpha+\beta+(1/2)\delta}\tau_{-\mu}, \tag{4.4b}$$

$D_3^{(2)}$
$$Y^{-\lambda}=R_\alpha R_{\alpha+\beta}R_{\alpha+2\beta}R_{\alpha+\beta+\delta}\tau_{-\lambda}, \tag{4.5a}$$
$$Y^{-\mu}=R_\beta R_{\alpha+2\beta}R_{\alpha+\beta}\tau_{-\mu}, \tag{4.5b}$$

$D_4^{(3)}$
$$Y^{-\lambda}=R_\alpha R_{\alpha+\beta}R_{2\alpha+3\beta}R_{\alpha+2\beta}R_{\alpha+3\beta}R_{\alpha+\beta+\delta}R_{\alpha+2\beta+\delta} R_{2\alpha+3\beta+3\delta}R_{\alpha+\beta+2\delta}R_{\alpha+2\beta+2\delta}\tau_{-\lambda}, \tag{4.6a}$$
$$Y^{-\mu}=R_\beta R_{\alpha+3\beta}R_{\alpha+2\beta}R_{2\alpha+3\beta}R_{\alpha+\beta}R_{\alpha+2\beta+\delta}\tau_{-\mu}. \tag{4.6b}$$

V. ELLIPTIC *R*-MATRICES

In this section, we give a class of the representation of the root algebra which describes Ruijsenaars' elliptic difference operators associated with affine root systems.

For $\alpha\in\Delta^{\mathrm{re}}$, let $\mu_\alpha\in\mathbb{C}$ be $\hat{W}$-invariant constants: $\mu_{\hat{w}(\alpha)}=\mu_\alpha$ for $\hat{w}\in\hat{W}$. Fix $\kappa\in\mathbb{C}$ and $\xi\in\mathring{\mathfrak{h}}^*$. We define $\hat{R}_\alpha\in\mathrm{End}_{\mathbb{C}}\mathcal{M}$ for $\alpha\in\Delta^{\mathrm{re}}$ by

$$\hat{R}_\alpha:=H_\alpha(\mu_\alpha)-H_\alpha(\langle\xi,\alpha^\vee\rangle)\circ s_\alpha, \tag{5.1}$$

where $H_\alpha(\eta)\in\mathcal{M}$ acts as a multiplication operator defined by

$$H_\alpha(\eta)(h) := \frac{\vartheta_1(-\gamma_\alpha\mu_\alpha;\gamma_\alpha\tau)}{\vartheta_1(-\gamma_\alpha\eta;\gamma_\alpha\tau)} \frac{\vartheta_1(\mathrm{af}(\alpha)(h)-\gamma_\alpha\eta;\gamma_\alpha\tau)}{\vartheta_1(\mathrm{af}(\alpha)(h);\gamma_\alpha\tau)}. \tag{5.2}$$

Theorem V.1: *The map* $\pi: R_\alpha \mapsto \hat{R}_\alpha$, $\tau_\lambda \mapsto \tau_\lambda$ *induces a homomorphism from* $\mathcal{R}$ *to* $\mathrm{End}_{\mathbb{C}}\mathcal{M}$. *These R-matrices satisfy the unitarity*

$$\hat{R}_\alpha \hat{R}_{-\alpha} = \left(\frac{\vartheta_1(-\gamma_\alpha\mu_\alpha;\gamma_\alpha\tau)}{\vartheta_1'(0;\gamma_\alpha\tau)}\right)^2 (\wp(\gamma_\alpha\mu_\alpha;1,\gamma_\alpha\tau)-\wp(\gamma_\alpha\langle\xi,\alpha^\vee\rangle;1,\gamma_\alpha))\mathrm{Id}_{\mathcal{M}}. \tag{5.3}$$

Besides the above representation, we have more general forms that depend on the relation among Q, $Q^\vee$, M. For $\alpha \in \Delta^{\mathrm{re}}$, let

$$N_\alpha := \left\{ (m_\alpha, n_\alpha) \in \mathbb{R}^2_{>0} \,\middle|\, \begin{array}{c} \overline{\alpha^\vee} \in m_\alpha \mathring{Q}^\vee, \quad m_\alpha\langle\alpha, \mathring{Q}^\vee\rangle \subset \mathbb{Z}, \\ n_\alpha\gamma_\alpha\overline{\alpha^\vee} \in m_\alpha M, m_\alpha(M|\alpha) \subset n_\alpha\gamma_\alpha\mathbb{Z} \end{array} \right\}. \tag{5.4}$$

This condition is required when the root algebra acts on the vector space spanned by theta functions (Proposition VII.1) and is an elliptic analog in the representation of the Hecke algebras.[25]

We enumerate the set N_α as

$X_N^{(r)}$	root	(m_α^1, n_α^1)	(m_α^2, n_α^2)	(m_α^3, n_α^3)	(m_α^4, n_α^4)
$C_l^{(1)}$	long	(1,1)	(1,2)	(1/2,1)	(1/2,1/2)
$A_{2l-1}^{(2)}$	long	(1,1)			(1/2,1/2)
$D_{l+1}^{(2)}$	short	(1,1)	(1,2)		
$A_{2l}^{(2)}$	short	(2,1)	(2,2)	(1,1)	(1,1/2)
$A_{2l}^{(2)}$	long	(1,1/2)	(1,1)	(1/2,1/2)	(1/2,1/4)
otherwise		(1,1)			

Here we have numbered the elements of N_α for later convenience. Let $g_\alpha^j \in \mathbb{C}$ for $1 \leqslant j \leqslant 4$ $\hat{W}$-invariant constants. If $(m_\alpha^j, n_\alpha^j) \notin N_\alpha$, set $g_\alpha^j = 0$. In place of (5.2), we define

$$H_\alpha(\eta)(h) := \sum_{(m_\alpha^j, n_\alpha^j) \in N_\alpha} g_\alpha^j \frac{\vartheta_1(-n_\alpha^j\gamma_\alpha\mu_\alpha/m_\alpha^j; n_\alpha^j\gamma_\alpha\tau)}{\vartheta_1(-n_\alpha^j\gamma_\alpha\eta/m_\alpha^j; n_\alpha^j\gamma_\alpha\tau)} \frac{\vartheta_1(m_\alpha^j\mathrm{af}(\alpha)(h)-n_\alpha^j\gamma_\alpha\eta/m_\alpha^j; n_\alpha^j\gamma_\alpha\tau)}{\vartheta_1(m_\alpha^j\mathrm{af}(\alpha)(h); n_\alpha^j\gamma_\alpha\tau)}. \tag{5.5}$$

Then we have a more general representation of $\mathcal{R}$ including Theorem V.1.

Theorem V.2: *The map* π *in Theorem V.1 with* (5.5) *induces a homomorphism from* $\mathcal{R}$ *to* $\mathrm{End}_{\mathbb{C}}\mathcal{M}$. *These R-matrices satisfy the unitarity*

$$\hat{R}_\alpha \hat{R}_{-\alpha} = u_\alpha(\tau)\mathrm{Id}_{\mathcal{M}}, \tag{5.6}$$

where $u_\alpha(\tau)$ *depends only on* τ *and vanishes if* $\langle\xi,\alpha^\vee\rangle = \pm\mu_\alpha$.

Proof: We can verify the relations (3.1) case-by-case, by a direct substitution of (5.5); for details, see Refs. 26 and 15. □

Remark V.3: The function $u_\alpha(\tau)$ is explicitly given by

$$u_\alpha(\tau) = ((p_1.g_\alpha)^2, (p_2.g_\alpha)^2, (p_3.g_\alpha)^2, (p_4.g_\alpha)^2).S.d_\alpha,$$

$$S=\frac{1}{4}\begin{pmatrix}1&0&0&0\\-1&0&0&1\\-1&4&0&0\\1&-4&4&-1\end{pmatrix},\quad g_\alpha=\begin{pmatrix}\tilde{g}_\alpha^1\\\tilde{g}_\alpha^2\\\tilde{g}_\alpha^3\\\tilde{g}_\alpha^4\end{pmatrix},\quad d_\alpha=\begin{pmatrix}d_\alpha^1\\d_\alpha^2\\d_\alpha^3\\d_\alpha^4\end{pmatrix},$$

$$p_1=(2,1,1,2),\quad p_2=(0,0,1,2),\quad p_3=(0,1,1,0),\quad p_4=(0,0,1,0),$$

$$\tilde{g}_\alpha^j=g_\alpha^j\frac{\vartheta_1(-n_\alpha^j\gamma_\alpha\mu_\alpha/m_\alpha^j;n_\alpha^j\gamma_\alpha\tau)}{\vartheta_1'(0;n_\alpha^j\gamma_\alpha\tau)},$$

$$d_\alpha^j=\wp(n_\alpha^j\gamma_\alpha\mu_\alpha/m_\alpha^j;1,n_\alpha^j\gamma_\alpha\tau)-\wp(n_\alpha^j\gamma_\alpha\langle\xi,\alpha^\vee\rangle/m_\alpha^j;1,n_\alpha^j\gamma_\alpha\tau). \tag{5.7}$$

We employ these operators even for the affine root systems of rank 2, though they do not have any Coxeter relations.

We shall clarify some properties of the operators $\hat{Y}^\lambda=\pi(Y^\lambda)$.

Lemma V.4: The R-matrices $\hat{R}$ satisfy the following relations:

$$\hat{R}_{-\alpha_j}\hat{R}_{\tau_{-\lambda_i}}={}^{s_j}\hat{R}_{\tau_{-\lambda_i}}\hat{R}_{-\alpha_j},\quad \textit{for}\ \ j\neq i, \tag{5.8}$$

$$\hat{R}_{\tau_{-\lambda_i}}=\hat{R}_{\alpha_i}\mathbf{R}, \tag{5.9}$$

where **R** *is a product of some R-matrices.*

Proof: Combining (2.22), the unitarity (5.6), and an equality $s_j\tau_{-\lambda_i}=\tau_{-\lambda_i}s_j$, we obtain (5.8) for generic ξ and thus for all $\xi\in\mathring{\mathfrak{h}}^*$. The form (5.9) is due to the fact that $\ell(s_i\tau_{-\lambda_i})=\ell(\tau_{-\lambda_i})-1$ implies the exchange condition,[20] $\tau_{-\lambda_i}=s_{i_1}\cdots s_{i_\ell}\omega=s_is_{i_1}\cdots s_{i_{m-1}}s_{i_{m+1}}\cdots s_{i_\ell}\omega$ for some m.□

If the parameter ξ satisfies $\langle\xi,\alpha_i^\vee\rangle=-\mu_{-\alpha_i}$, then the R-matrix $\hat{R}_{-\alpha_i}$ reduces to the form $\hat{R}_{-\alpha_i}=2H_{-\alpha}(\mu_{-\alpha})P_i^{(-)}$, where $P_i^{(-)}$ is the antisymmetric projection $1/2(1-s_i)$. Let

$$\mathring{\rho}_\mu:=\sum_{i\in\mathring{I}}\mu_{\alpha_i}\overline{\Lambda}_i=\frac{1}{2}\sum_{\alpha\in\mathring{\Delta}_+}\mu_\alpha\alpha. \tag{5.10}$$

From these properties, we have the following theorem:

Theorem V.5: *Let $\mathcal{V}:=\mathcal{M}^{\mathring{W}}$, the $\mathring{W}$-invariant subspace of $\mathcal{M}$ and let $\xi=-\mathring{\rho}_\mu$. Then $\hat{Y}^\lambda\in\mathrm{End}_{\mathbb{C}}\mathcal{V}$.*

Proof: It is sufficient to check it for the generators $\hat{Y}^{-\lambda_i}$. By Lemma V.4, we see that $\hat{R}_{-\alpha_j}\hat{Y}^{-\lambda_i}|_{\mathcal{V}}=0$, for $j\neq i$ by (5.8), and for $j=i$ by (5.9), noting that the unitarity (5.6) vanishes. Hence $\hat{Y}^{-\lambda_i}|_{\mathcal{V}}=s_j\hat{Y}^{-\lambda_i}|_{\mathcal{V}}$ for all $j\in\mathring{I}$.

Remark V.6: The symbol Y^λ is adopted since in a certain limit, it reduces to the same one up to a constant factor as in the affine Hecke algebras, where Y^λ is defined for all $\lambda\in\hat{M}$.

Remark V.7: $\hat{Y}^\lambda$ has its inverse in $\mathrm{End}_{\mathbb{C}}\mathcal{M}$ for generic $\xi\in\mathring{\mathfrak{h}}^*$, but loses its inverse when $\xi=-\mathring{\rho}_\mu$.

VI. ELLIPTIC DIFFERENCE OPERATORS

In this section, we calculate the explicit forms of the operators $\hat{Y}^\lambda$ for some λ on the space $\mathcal{V}=\mathcal{M}^{\mathring{W}}$. Throughout this section, we fix $\xi=-\mathring{\rho}_\mu$.

Lemma VI.1 (Ruijsenaars[27]): Let $D=\Sigma_\lambda V_\lambda\tau_\lambda$ (finite sum) where $V_\lambda\in\mathcal{M}$. If $Df=0$ for all $f\in\mathcal{V}$, then $V_\lambda=0$ for all λ.

Lemma VI.2: If $wD|_{\mathcal{V}}=D|_{\mathcal{V}}$ *for* $w\in\mathring{W}$, *then* $V_\lambda=V_{w\lambda}$.

Theorem VI.3: *Let* $(-\lambda)$ *be minuscule. Then we have*

$$\hat{Y}^\lambda|_{\mathcal{V}}=\frac{1}{|\mathring{W}_\lambda|}\sum_{w\in\mathring{W}} w\left(\prod_{\substack{\alpha\in\mathring{\Delta}_+\\(\lambda|\alpha)=-\gamma_\alpha}} H_\alpha(\mu_\alpha)\tau_\lambda\right)\Bigg|_{\mathcal{V}}, \tag{6.1}$$

where $\mathring{W}_\lambda$ *is the stabilizer of* λ *in* $\mathring{W}$.

Proof: Notice that R_{τ_λ} consists of nonaffine R-matrices, R_α for $\alpha\in\mathring{\Delta}_+$, because $(-\lambda)$ is minuscule. Substituting the R-matrices (5.1) into $\hat{Y}^\lambda$ and expanding them, we see that every term includes a translation operator of the form $\tau_{w(\lambda)}w$, where

$$w=s_{\alpha(p)}\cdots s_{\alpha(1)}\in\mathring{W}, \tag{6.2}$$

$$\alpha\{q\}:=\alpha^{(m_q)},\quad 1\leqslant m_p<m_{p-1}<\cdots<m_2<m_1\leqslant\ell(\tau_\lambda), \tag{6.3}$$

and $\Delta_{\tau_\lambda}=\{\alpha^{(1)}=\alpha_{i_1},\alpha^{(2)}=s_{i_1}(\alpha_{i_2}),\ldots,\alpha^{(\ell)}=s_{i_1}s_{i_2}\cdots s_{i_{\ell-1}}(\alpha_{i_\ell})\}$ for a reduced expression $\tau_\lambda=s_{i_1}s_{i_2}\cdots s_{i_\ell}\omega$. Let us show that $w(\lambda)=\lambda$ implies $w=id$. Suppose $w(\lambda)=\lambda$ and $w\neq id$. Then we have $\ell(w\tau_\lambda)=\ell(\tau_\lambda w)$. From (2.22), $\ell(\tau_\lambda w)=\ell(\tau_\lambda)+\ell(w)>\ell(\tau_\lambda)$ while $\ell(w\tau_\lambda)<\ell(\tau_\lambda)$ by a direct calculation, which leads to a contradiction. This implies that the term including $\tau_\lambda w, w\in\mathring{W}$, appears if and only if $w=id$. The coefficient of this term can be easily calculated,

$$\prod_{\substack{\alpha\in\mathring{\Delta}_+\\(\lambda|\alpha)=-\gamma_\alpha}} H_\alpha(\mu_\alpha). \tag{6.4}$$

The $\mathring{W}$-invariance of the operator $\hat{Y}^\lambda$ and Lemma VI.2 yields the form (6.1). □

It is worth noting that as in the trigonometric case,[28] we can rewrite $\hat{Y}^\lambda$ in a simply laced root system as follows:

$$\hat{Y}^\lambda|_{\mathcal{V}}=\frac{1}{|\mathring{W}_\lambda|}\sum_{w\in\mathring{W}}\frac{(\tau_{-\mu w\lambda/\kappa}A_\rho)}{A_\rho}\tau_{w\lambda}\Bigg|_{\mathcal{V}}, \tag{6.5}$$

where we have set $\mu=\mu_\alpha$ and $g_\alpha^1=1$.

In general, it is complicated and difficult to compute explicit forms of the operators when λ is not minuscule. It is the case even in the framework of the affine Hecke algebras. There is no minuscule weight available in the root systems of type $E_8^{(1)}$, $F_4^{(1)}$, $G_2^{(1)}$, $A_{2l}^{(2)}$, $E_6^{(2)}$ and $D_4^{(3)}$. However, every root system processes the "quasi-minuscule" weight $\nu(\theta^\vee)$ in the sense of the following properties:

Lemma VI.4:

(1) $\Delta_{\tau_{-\nu(\theta^\vee)}}=\Delta_{s_\theta}\cup\{a_0^{-1}(\delta+\theta)\}$.
(2) $(\nu(\theta^\vee)|\alpha)=0$ *or* γ_α *for* $\alpha\in\mathring{\Delta}_+$, $\alpha\neq\theta$, *and* $(\nu(\theta^\vee)|\theta)=2$.
(3) $\nu(\theta^\vee)=\lambda_i$ *where* α_i *is the unique vertex connected to* α_0 *if* $X_N^{(r)}\neq A_l^{(1)}$.

Proof: We see that $s_\theta\alpha_0=s_\theta(a_0^{-1}(\delta-\theta))=a_0^{-1}(\delta+\theta)\in\Delta_+^{\mathrm{re}}$, which implies the first statement due to the expression $s_\theta s_0=\tau_{-\nu(\theta^\vee)}$. The second statement is immediate from the first and (2.22). Since $\langle\underline{\nu}(\theta^\vee),\alpha_i^\vee\rangle=\langle a_0^{-1}\theta,\alpha_i^\vee\rangle=\langle a_0^{-1}\delta-\alpha_0,\alpha_i^\vee\rangle=-\langle\alpha_0,\alpha_i^\vee\rangle$, we have $\nu(\theta^\vee)=-\Sigma_{i\in\mathring{I}}\langle\alpha_0,\alpha_i^\vee\rangle\Lambda_i$. Then the last statement follows from the tables in Refs. 20 and 23. □

Since in the root system of type $A_l^{(1)}$, every λ_i is minuscule, we have the explicit form of $\hat{Y}^{-\nu(\theta^\vee)}$ by Theorem VI.3. So we concentrate on the other root systems. Fix i as in Lemma VI.4.

By the expression $\tau_{-\nu(\theta^\vee)}=s_\theta s_0$, we have $Y^{-\nu(\theta^\vee)}=R_{s_\theta}R_{a_0^{-1}(\theta+\delta)}\tau_{-\nu(\theta^\vee)}=R_{s_\theta}\tau_{-\nu(\theta^\vee)}R_{-\alpha_0}$. For the operator $\hat{Y}^{-\nu(\theta^\vee)}$, an analogous statement to Lemma V.4 holds.

Lemma VI.5: The R-matrices $\hat{R}$ satisfy the following relations:

$$\hat{R}_{-\alpha_j}\hat{R}_{s_\theta}={}^{s_j}\hat{R}_{s_\theta}\hat{R}_{-\alpha_j},\quad \textit{for}\ \ j\neq i, \tag{6.6}$$

$$\hat{R}_{s_\theta}=\hat{R}_{\alpha_i}\mathbf{R}, \tag{6.7}$$

where **R** *is a product of some R-matrices.*

Proof: We have $s_j\tau_{-\nu(\theta^\vee)}=\tau_{-\nu(\theta^\vee)}s_j$ and $s_js_0=s_0s_j$ for $j\neq i$, since α_i is the unique vertex connected to α_0. Then s_j and $s_\theta=\tau_{-\nu(\theta^\vee)}s_0$ commute, which implies $\ell(s_js_\theta)=\ell(s_\theta)+1$ and thus (6.6). The form (6.7) follows from the fact that $\ell(s_i\tau_{-\nu(\theta^\vee)})=\ell(\tau_{-\nu(\theta^\vee)})-1$ implies $\ell(s_is_\theta)=\ell(s_\theta)-1$ and the exchange condition. □

Let $\mathring{W}_i$ be the parabolic subgroup generated by $\{s_j|j\in\mathring{I},j\neq i\}$ and $\mathcal{V}_i$ be the $\mathring{W}_i$-invariant subspace of $\mathcal{M}$.

Lemma VI.6: The operator $\hat{R}_{s_\theta}\tau_{-\nu(\theta^\vee)}$ maps $\mathcal{V}_i$ to $\mathcal{V}$ and the operator $\hat{R}_{-\alpha_0}$ maps *$\mathcal{V}$ to $\mathcal{V}_i$.*

Proof: The former statement can be shown in the same way as Theorem V.5, and the latter, directly. □

Theorem VI.7:

$$\hat{Y}^{-\nu(\theta^\vee)}\Big|_{\mathcal{V}}=\frac{1}{|\mathring{W}_{\nu(\theta^\vee)}|}\sum_{w\in\mathring{W}}w\Bigg(\Bigg(\prod_{\substack{\alpha\in\mathring{\Delta}_+\\ \langle\alpha,\theta^\vee\rangle>0}}H_\alpha(\mu_\alpha)\Bigg)\times(H_{\alpha_0^{-1}(\theta+\delta)}(\mu_{\alpha_0})\tau_{-\nu(\theta^\vee)}-H_{a_0^{-1}(\theta+\delta)}(-(\mathring{\rho}_\mu|\theta)))\Bigg)\Bigg|_{\mathcal{V}}. \tag{6.8}$$

Proof: The explicit form of $\hat{R}_{s_\theta}\tau_{-\nu(\theta^\vee)}$ on $\mathcal{V}_i$ can be computed in a similar way to Theorem VI.3. Since $Y^{-\nu(\theta^\vee)}=R_{s_\theta}\tau_{-\nu(\theta^\vee)}R_{-\alpha_0}$, we obtain the form (6.8). □

The operator (1.2) is actually (6.8) of type $A_{2l}^{(2)}$, where the terms without translations are gathered by use of identities of the theta functions. In Refs. 18 and 19, we calculated the explicit forms of $\hat{Y}^{-\lambda_j}|_{\mathcal{V}}$ for all $j\in\mathring{I}$ in this root system. The operator (6.8) in the affine root systems of type $E_8^{(1)}$, $F_4^{(1)}$, $G_2^{(1)}$ and $A_{2l}^{(2)}$ should be compared to the Macdonald(–Koornwinder) operator $D_{\theta^\vee}$ of types E_8, F_4, G_2 and BC_l respectively, while the operator (6.1) in the rest root systems of type $X_l^{(1)}$ should be compared to $E_{\nu^{-1}(\lambda_i)}$ of type X_l.[29,30] See the Appendix for details.

In order to investigate a general $\hat{Y}^\lambda$, let us define a partial order in $\hat{M}_-$. We remark that this partial order is different from that in the affine Hecke algebras.

Definition VI.8: Let $\lambda,\lambda'\in\hat{M}_-$. We write $\lambda\geqslant\lambda'$ if $\ell(\tau_\lambda)>\ell(\tau_{\lambda'})$ or $\lambda=\lambda'$.

For an arbitrary weight $\lambda\in\hat{M}_-$, we have the "leading term" of $\hat{Y}^\lambda$ with respect to the order $>$.

Theorem VI.9: *Let $\lambda\in\hat{M}_-$. Then we have*

$$\hat{Y}^\lambda|_{\mathcal{V}}=\frac{1}{|\mathring{W}_\lambda|}\sum_{w\in\mathring{W}}w\Bigg(g_\lambda^\lambda\tau_\lambda+\sum_{\lambda>\lambda'}g_{\lambda'}^\lambda\tau_{\lambda'}\Bigg)\Bigg|_{\mathcal{V}}, \tag{6.9}$$

where $g_{\lambda'}^\lambda\in\mathcal{M}$. In particular, we have $g_\lambda^\lambda=\Pi_{\alpha\in\Delta_{\tau_\lambda}}H_\alpha(\mu_\alpha)$.

Proof: Because $\hat{Y}^{\lambda}$ is $\mathring{W}$-invariant, it is sufficient to calculate the coefficients of the translations of antidominant weights. A translation $\tau_{\lambda'}, \lambda' \in \hat{M}_-$ in the expansion of $\hat{Y}^{\lambda}$ appears as $w\tau_{\lambda} = \tau_{\lambda'}\mathring{w}$ where $\mathring{w} \in \mathring{W}$ and

$$w = s_{\alpha\{p\}} \cdots s_{\alpha\{1\}} \in W, \tag{6.10}$$

$$\alpha\{q\} = \alpha^{(m_q)}, \quad 1 \leqslant m_p < m_{p-1} < \cdots < m_2 < m_1 \leqslant \ell(\tau_{\lambda}). \tag{6.11}$$

Then $\ell(\tau_{\lambda}) \geqslant \ell(w\tau_{\lambda}) = \ell(\tau_{\lambda'}, \mathring{w}) = \ell(\tau_{\lambda'}) + \ell(\mathring{w})$, which implies $\ell(\tau_{\lambda}) > \ell(\tau_{\lambda'})$ if $w \neq id$. Hence the expression (6.9). □

Theorem VI.10: *$\{\hat{Y}^{-\lambda_i} | i \in \mathring{I}\}$ are algebraically independent on $\mathcal{V}$.*

Proof: Let $Y = \Sigma_{\lambda} a_{\lambda} Y^{\lambda} \in \mathcal{S}$ with $a_{\lambda} \in \mathbb{C}$. Let M_Y be the set of all the maximal antidominant weights in the expansion of $\hat{Y}$ on $\mathcal{V}$. Then we have

$$\hat{Y}|_{\mathcal{V}} = \sum_{\lambda \in M_Y} \sum_{w \in \mathring{W}} w(a_{\lambda} g_{\lambda}^{\lambda} \tau_{\lambda} + \text{lower terms } (\lambda' > \lambda))|_{\mathcal{V}}. \tag{6.12}$$

Fix $\lambda \in M_Y$. Suppose $\hat{Y} f = 0$ for all $f \in \mathcal{V}$. Then by Lemma VI.2 $a_{\lambda} = 0$ and hence the result. □

The following statement is immediate from this theorem.

Corollary VI.11: $\mathcal{S} \simeq \mathbb{C}[T_{\hat{M}_-}]$.

VII. ACTION ON THETA FUNCTIONS OF LEVEL *K*

The aim of this section is to show that the operators $\hat{Y}^{\lambda}$ in the previous sections act on $(Th^k)^{\mathring{W}}$, the $\mathring{W}$-invariant space of the theta functions of level k, or the space of the characters. To be more precise, we identify $\hat{Y}^{\lambda}$ with an operator on $(Th^k)^{\mathring{W}}$ by restricting the domain. The basic idea is from Refs. 5 and 15, where the matrix elements of Belavin's $\mathbb{Z}_k$-symmetric elliptic R-matrix and associated K-matrices are calculated. Now it turns out that they are the elliptic difference operators of type $A_1^{(1)}$ or $A_2^{(2)}$.

Let us outline our strategy. Since the representation π in Theorem V.2 does not preserve Th^k for general $\xi \in \mathring{\mathfrak{h}}^*$, we introduce another representation $\overline{\pi}$ which always preserve this space. The images of $\mathcal{S}$ by π and $\overline{\pi}$ coincide when we set $\xi = -\mathring{\rho}_{\mu}$. As was shown, $\pi(\mathcal{S})$ at this value preserves $\mathring{W}$-invariant subspace, and so does $\overline{\pi}(\mathcal{S})$. On the other hand, $\overline{\pi}(\mathcal{S})$ preserves Th^k by construction, and so does $\pi(\mathcal{S})$. Therefore we can deduce that $\pi(\mathcal{S}) = \overline{\pi}(\mathcal{S})$ acts on $(Th^k)^{\mathring{W}}$.

Let $h_{\mu}^{\vee} := (\mathring{\rho}_{\mu} | \theta) + \mu_{\alpha_0} = \Sigma_{i \in I} \mu_{\alpha_i} a_i^{\vee}$ and $\Xi := (\xi + \mathring{\rho}_{\mu})/h_{\mu}^{\vee}$. Throughout this section, we fix $\kappa = h_{\mu}^{\vee}/k$ though some of the following statements do not require this condition.

We extend the action of τ_{λ} on $\mathcal{M}$ for arbitrary $\lambda \in \mathring{\mathfrak{h}}^*$ by $(\tau_{\lambda} f)(h) := f(h - \kappa \nu^{-1}(\lambda))$. For $\alpha \in \Delta^{\mathrm{re}}$ such that $\overline{\alpha} \in \mathring{\Delta}$, let $\overline{R}_{\alpha}$ be defined by

$$\overline{R}_{\alpha} := \tau_{\epsilon_{\alpha}} \hat{R}_{\overline{\alpha}} \tau_{\phi_{\alpha}}, \tag{7.1}$$

where $\epsilon_{\alpha} := (1/h_{\mu}^{\vee})(-(1/2)\mu_{\alpha}\overline{\alpha} - \xi + \eta_{\alpha})$, $\phi_{\alpha} := (1/h_{\mu}^{\vee})(-(1/2)\mu_{\alpha}\overline{\alpha} + \xi - \eta_{\alpha})$, and $\eta_{\alpha} \in \mathring{\mathfrak{h}}^*$ is taken arbitrary such that $\langle \eta_{\alpha}, \overline{\alpha}^{\vee} \rangle = 0$. Then $\overline{R}_{\alpha}$ is well-defined since $\overline{R}_{\alpha}$ does not depend on the choice of η_{α} and it will be soon proved that $\overline{R}_{\alpha} \in \mathrm{End}_{\mathbb{C}} \mathcal{M}$. For α such that $\overline{\alpha} \notin \mathring{\Delta}$, i.e., $\alpha \in \hat{W}\alpha_0$ in the $A_{2l}^{(2)}$ system, we need another definition for $\hat{R}_{\overline{\alpha}}$ or $H_{\overline{\alpha}}$ which is straightforward.

According to our plan, we show that this operator acts on Th^k.

Proposition VII.1: For arbitrary $\xi \in \mathring{\mathfrak{h}}^*$, $\overline{R}_{\alpha} \in \mathrm{End}_{\mathbb{C}}(Th^k)$.

Proof: For $f \in Th^k$ we check the behavior of the function

$$(\overline{R}_\alpha f)(h)=H_{\overline{\alpha}}(\mu_\alpha)(\mathrm{af}(\tau_{-\epsilon_\alpha})(h))f(\mathrm{af}(\tau_{-\phi_\alpha-\epsilon_\alpha})(h))-H_{\overline{\alpha}}(\langle\xi,\overline{\alpha^\vee}\rangle)(\mathrm{af}(\tau_{-\epsilon_\alpha})\times(h))f(\mathrm{af}(\tau_{-\phi_\alpha-s_{\overline{\alpha}}(\epsilon_\alpha)}\circ s_{\overline{\alpha}})(h)) \tag{7.2}$$

under $h\to h+\mu(\mu\in\mathring{Q}^\vee)$ and $h\to h-\tau\nu^{-1}(\lambda)(\lambda\in\hat{M})$.

For $\mu\in\mathring{Q}^\vee$, we have $(\overline{R}_\alpha f)(h)=(\overline{R}_\alpha f)(h+\mu)$ since

$$H_{\overline{\alpha}}(\eta)(h+\mu)=H_{\overline{\alpha}}(\eta)(h), \tag{7.3}$$

$$f(h+\mu)=f(h), \tag{7.4}$$

$$\mathrm{af}(\tau_\epsilon)(h+\mu)=h+\mu+\kappa\nu^{-1}(\epsilon)=\mathrm{af}(\tau_\epsilon)(h)+\mu, \tag{7.5}$$

$$\mathrm{af}(\tau_\epsilon\circ s_{\overline{\alpha}})(h+\mu)=\mathrm{af}(\tau_\epsilon\circ s_{\overline{\alpha}})(h)+s_{\overline{\alpha}}(\mu). \tag{7.6}$$

For $\lambda\in\hat{M}$, we have $(\overline{R}_\alpha f)(h-\tau\nu^{-1}(\lambda))=e^{k\lambda+k|\lambda|^2\delta/2}(\overline{R}_\alpha f)(h)$ since

$$H_{\overline{\alpha}}(\eta)(h-\tau\nu^{-1}(\lambda))=e^{-2\pi i(\overline{\alpha}|\lambda)\eta}H_{\overline{\alpha}}(\eta)(h), \tag{7.7}$$

$$f(h-\tau\nu^{-1}(\lambda))=e^{k\lambda+k|\lambda|^2\delta/2}f(h), \tag{7.8}$$

$$\phi_\alpha+\epsilon_\alpha=-k\kappa\mu_\alpha\overline{\alpha}, \tag{7.9}$$

$$\phi_\alpha+s_{\overline{\alpha}}\epsilon_\alpha=k\kappa\langle\xi,\overline{\alpha^\vee}\rangle\overline{\alpha}. \tag{7.10}$$

The holomorphy of $\overline{R}_\alpha f$, which can be checked in each case, completes the proof. □

To show that the operators $\overline{R}_\alpha$ are a representation of the root algebra, we need some statements.

Lemma VII.2: Let $\hat{w}=w\omega=s_{i_1}\cdots s_{i_\ell}\omega\in\hat{W}$ *be a reduced expression. Let*

$$\eta_n:=-\mathring{\rho}_\mu+\sum_{m=1}^{n-1}\nu_m\overline{\alpha^{(m)}}+\frac{1}{2}\nu_n\overline{\alpha^{(n)}}, \tag{7.11}$$

where $\Delta_{\hat{w}}=\{\alpha^{(1)}=\alpha_{i_1},\alpha^{(2)}=s_{i_1}(\alpha_{i_2}),\ldots,\alpha^{(\ell)}=ws_{i_\ell}(\alpha_{i_\ell})\}$,

$$\nu_n:=\begin{cases}\mu_n, & \text{if } \alpha_{i_n}\neq\alpha_0,\\ -(\mathring{\rho}_\mu|\theta), & \text{if } \alpha_{i_n}=\alpha_0,\end{cases} \tag{7.12}$$

and $\mu_n:=\mu_{\alpha^{(n)}}$. *Then* $\langle\eta_n,\overline{(\alpha^{(n)})^\vee}\rangle=0$.

Proof: Observe that if $\alpha^{(n)}=s_{i_1}\cdots s_{i_{n-1}}\alpha_{i_n}$, then $\overline{\alpha^{(n)}}=\overline{s}_{i_1}\cdots\overline{s}_{i_{n-1}}\overline{\alpha_{i_n}}$ and $\overline{(\alpha^{(n)})^\vee}=\overline{s}_{i_1}\cdots\overline{s}_{i_{n-1}}\overline{\alpha_{i_n}^\vee}$, where $\overline{s}_i:=s_i$ for $i\neq0$ and $\overline{s}_0:=s_\theta$.

$$\begin{aligned}\langle-\mathring{\rho}_\mu,\overline{(\alpha^{(n)})^\vee}\rangle&=\langle-\mathring{\rho}_\mu,\overline{s}_{i_1}\cdots\overline{s}_{i_{n-1}}\overline{\alpha_{i_n}^\vee}\rangle\\&=\langle-\mathring{\rho}_\mu+\nu_1\overline{\alpha^{(1)}},\overline{s}_{i_2}\cdots\overline{s}_{i_{n-1}}\overline{\alpha_{i_n}^\vee}\rangle\\&=\langle-\mathring{\rho}_\mu,\overline{s}_{i_2}\ldots\overline{s}_{i_{n-1}}\overline{\alpha_{i_n}^\vee}\rangle-\nu_1\langle\overline{\alpha^{(1)}},\overline{(\alpha^{(n)})^\vee}\rangle\\&\ \ \vdots\\&=-\sum_{m=1}^{n-1}\nu_m\langle\overline{\alpha^{(m)}},\overline{(\alpha^{(n)})^\vee}\rangle-\nu_n.\end{aligned} \tag{7.13}$$

Then we have

$$\left\langle -\mathring{\rho}_\mu+\sum_{m=1}^{n-1}\nu_m\overline{\alpha^{(m)}}+\frac{1}{2}\nu_n\overline{\alpha^{(n)}},\overline{(\alpha^{(n)})^\vee}\right\rangle=0. \tag{7.14}$$

□

Proposition VII.3.: Let $\hat{w}=s_{i_1}\cdots s_{i_\ell}\omega\in\hat{W}$ *be a reduced expression. Then*

$$\overline{R}_{\alpha^{(1)}}\overline{R}_{\alpha^{(2)}}\cdots\overline{R}_{\alpha^{(\ell)}}=\tau_{-\Xi}\hat{R}_{\alpha^{(1)}}\hat{R}_{\alpha^{(2)}}\cdots\hat{R}_{\alpha^{(\ell)}}\tau_{\lambda_{\hat{w}}}\tau_\Xi, \tag{7.15}$$

where $\lambda_{\hat{w}}:=(1/h_\mu^\vee)\Sigma_{n=1}^{\ell}\mu_n\overline{\alpha^{(n)}}=-(1/h_\mu^\vee)\Sigma_{\alpha\in\Delta_{\hat{w}}}\mu_\alpha\overline{\alpha}$.

Proof: We set $\eta_{\alpha^{(n)}}=\eta_n$ obtained in Lemma VII.2 and set

$$\lambda:=-\frac{1}{h_\mu^\vee}\sum_{m=1}^{\ell}\nu_m\overline{\alpha^{(m)}}, \tag{7.16}$$

$$\epsilon_n:=\frac{1}{2h_\mu^\vee}(\nu_n-\mu_n)\overline{\alpha^{(n)}},\quad 1\leqslant n\leqslant\ell, \tag{7.17}$$

so that

$$\overline{R}_{\alpha^{(1)}}\overline{R}_{\alpha^{(2)}}\cdots\overline{R}_{\alpha^{(\ell)}}=\tau_{-\Xi}(\tau_{\epsilon_1}\hat{R}_{(\overline{\alpha^{(1)}})}\tau_{\epsilon_1})(\tau_{\epsilon_2}\hat{R}_{(\overline{\alpha^{(2)}})}\tau_{\epsilon_2})\cdots(\tau_{\epsilon_\ell}\hat{R}_{(\overline{\alpha^{(\ell)}})}\tau_{\epsilon_\ell})\tau_\lambda\tau_\Xi. \tag{7.18}$$

Let $\overline{w}_n=\overline{s}_{i_1}\cdots\overline{s}_{i_n}$. Then we have

$$\epsilon_n=\begin{cases}-\overline{\alpha^{(n)}}/2=\overline{w}_{n-1}\nu(\theta^\vee)/2, & \text{if } i_n=0,\\ 0, & \text{if } i_n\neq 0,\end{cases} \tag{7.19}$$

and

$$\tau_{\epsilon_n}\hat{R}_{(\overline{\alpha^{(n)}})}\tau_{\epsilon_n}=\begin{cases}\tau_{(-\overline{\alpha^{(n)}}/2)}\hat{R}_{(\overline{\alpha^{(n)}})}\tau_{(-\overline{\alpha^{(n)}}/2)}=\hat{R}_{(\overline{w}_{n-1}\alpha_0)}\tau_{(\overline{w}_{n-1}\nu(\theta^\vee))}, & \text{if } i_n=0,\\ \hat{R}_{(\overline{\alpha^{(n)}})}=\hat{R}_{(\overline{w}_{n-1}\alpha_{i_n})}, & \text{if } i_n\neq 0,\end{cases} \tag{7.20}$$

where we have used $\tau_{(-\overline{\alpha^{(n)}}/2)}(\overline{\alpha^{(n)}})=(\overline{\alpha^{(n)}})+a_0^{-1}\delta=\overline{w}_{n-1}\alpha_0$ if $i_n=0$. By using the identities

$$\alpha^{(n)}=s_{i_1}\cdots s_{i_{n-1}}\alpha_{i_n}=\left(\prod_{\substack{m<n\\ i_m=0}}\tau_{(\overline{w}_{m-1}\nu(\theta^\vee))}\right)\overline{w}_{n-1}\alpha_{i_n}, \tag{7.21}$$

and

$$\begin{aligned}\sum_{i_m=0}\overline{w}_{m-1}\nu(\theta^\vee)+\lambda&=-\sum_{i_m=0}\overline{\alpha^{(m)}}-\frac{1}{h_\mu^\vee}\sum_{m=1}^{\ell}\mu_m\overline{\alpha^{(m)}}+\frac{1}{h_\mu^\vee}\sum_{i_m=0}(\mu_m+(\mathring{\rho}_\mu|\theta))\overline{\alpha^{(m)}}\\&=-\frac{1}{h_\mu^\vee}\sum_{m=1}^{\ell}\mu_m\overline{\alpha^{(m)}}=\lambda_{\hat{w}},\end{aligned} \tag{7.22}$$

we arrive at (7.15). □

Apply this proposition to an element that has two reduced expressions of the form

$$\hat{w}=\underbrace{s_i s_j s_i \ldots}_{m_{ij}\ \text{factors}}=\underbrace{s_j s_i s_j \ldots}_{\mathrm{m}_{ij}\ \text{factors}}, \tag{7.23}$$

for $i\neq j\in I$. Then the relation

$$\overline{R}_{\alpha_i}\overline{R}_{s_i\alpha_j}\overline{R}_{s_is_j\alpha_i}\cdots=\overline{R}_{\alpha_j}\overline{R}_{s_j\alpha_i}\overline{R}_{s_js_i\alpha_j}\cdots \tag{7.24}$$

immediately follows. Regarding $w\Pi$ for $w\in\mathring{W}$ as a set of fundamental roots in Lemma VII.2 and Proposition VII.3, we have proved the following theorem:

Theorem VII.4: *The map* $\overline{\pi}:R_\alpha\mapsto\overline{R}_\alpha$, $\tau_\lambda\mapsto\mathrm{Id}_{\mathcal{M}}$ *induces a homomorphism from* $\mathcal{R}$ *to* $\mathrm{End}_{\mathbb{C}}(Th^k)$.

For $\lambda\in\hat{M}_-$, we set $\overline{Y^\lambda}:=\overline{\pi}(Y^\lambda)=\overline{R}_{\alpha^{(1)}}\overline{R}_{\alpha^{(2)}}\cdots\overline{R}_{\alpha^{(\ell)}}\in\mathrm{End}_{\mathbb{C}}(Th^k)$. Now we are in position to prove the main theorem as follows:

Theorem VII.5: *Let* $\kappa=h^\vee_\mu/k$ *and* $\xi=-\mathring{\rho}_\mu$. *Then* $\hat{Y}^\lambda=\overline{Y^\lambda}\in\mathrm{End}_{\mathbb{C}}((Th^k)^{\hat{W}})$.

By Proposition VII.3, we have already shown

$$\overline{Y^\lambda}=\tau_{-\Xi}\hat{R}_{\alpha^{(1)}}\cdots\hat{R}_{\alpha^{(\ell)}}\tau_{\lambda'}\tau_\Xi=\tau_{-\Xi}\hat{R}_{\tau_\lambda}\tau_{\lambda'}\tau_\Xi, \tag{7.25}$$

where $\lambda'=-(1/h^\vee_\mu)\Sigma_{n=1}^{\ell}\mu_n\overline{\alpha^{(n)}}=-(1/h^\vee_\mu)\Sigma_{\alpha\in\Delta_{\tau_\lambda}}\mu_\alpha\overline{\alpha}$. Since $\Xi=0$ if we set $\xi=-\mathring{\rho}_\mu$, we have only to show that $\lambda'=\lambda$.

Due to the formulas (2.22), we have another description of λ' which can be regarded as an image of λ by some linear map:

$$-\sum_{\alpha\in\Delta_{\tau_\lambda}}\mu_\alpha\overline{\alpha}=\begin{cases}\displaystyle\sum_{\alpha\in\mathring{\Delta}_+}\frac{1}{\gamma_\alpha}\mu_\alpha(\alpha|\lambda)\alpha, & \text{if } X_N^{(r)}\neq A_{2l}^{(2)},\\ \displaystyle\sum_{\alpha\in\mathring{\Delta}_+}\frac{1}{\gamma_\alpha}\mu_\alpha(\alpha|\lambda)\alpha+\frac{1}{4}\mu_{\alpha_0}\sum_{\alpha\in(\mathring{\Delta}_+)_l}(\alpha|\lambda)\alpha, & \text{if } X_N^{(r)}=A_{2l}^{(2)}.\end{cases} \tag{7.26}$$

Lemma VII.6: Let $L:\mathring{\mathfrak{h}}^*\to\mathring{\mathfrak{h}}^*$ *be a linear map defined by* $L:\lambda\mapsto\frac{1}{2}\Sigma_{\alpha\in\mathring{\Delta}}\nu_\alpha(\alpha|\lambda)\alpha$ *where* ν_α *is* $\mathring{W}$*-invariant constant. Then* $L=a\,\mathrm{Id}_{\mathring{\mathfrak{h}}^*}$ *for some* $a\in\mathbb{C}$.

Proof: We see $L\in\mathrm{End}_{\mathring{W}}(\mathring{\mathfrak{h}}^*)$. Since $\mathring{W}$ acts on $\mathring{\mathfrak{h}}^*$ irreducibly, the statement follows from Schur's lemma.

By Lemma VII.6, we see that $-\Sigma_{\alpha\in\Delta_{\tau_\lambda}}\mu_\alpha\overline{\alpha}=a\lambda$ for some $a\in\mathbb{C}$. The following proposition completes the proof of Theorem VII.5.

Proposition VII.7. $-\Sigma_{\alpha\in\Delta_{\tau_\lambda}}\mu_\alpha\overline{\alpha}=h^\vee_\mu\lambda$.

Proof: Let L be the linear map defined in the right-hand side of (7.26). Due to Lemma VII.6, we can evaluate the factor a at any element of $\mathring{\mathfrak{h}}^*$. Recall that every root system has the quasi-minuscule weight $\nu(\theta^\vee)$, whose properties we have already investigated.

(i) $X_N^{(r)}\neq A_{2l}^{(2)}$

$$L(\nu(\theta^\vee))=\sum_{\alpha\in\mathring{\Delta}_+}\frac{1}{\gamma_\alpha}\mu_\alpha\langle\alpha,\theta^\vee\rangle\alpha=\sum_{\substack{\alpha\in\mathring{\Delta}_+\\ \langle\alpha,\theta^\vee\rangle\neq0}}\mu_\alpha\alpha+\mu_\theta\theta=a\,\nu(\theta^\vee), \tag{7.27}$$

where we have used Lemma VI.4. By applying $(\cdot|\theta)$ in the last equality, we obtain

$$a=\frac{1}{2}\sum_{\alpha\in\mathring{\Delta}_+}\mu_\alpha(\alpha|\theta)+\mu_\theta=(\mathring{\rho}_\mu|\theta)+\mu_{\alpha_0}. \tag{7.28}$$

(ii) $X_N^{(r)}=A_{2l}^{(2)}$

In a similar manner, we have

$$L(\nu(\theta^\vee))=\sum_{\substack{\alpha\in\mathring{\Delta}_+\\ \langle\alpha,\theta^\vee\rangle\neq 0}}\mu_\alpha\alpha+\sum_{\substack{\alpha\in(\mathring{\Delta}_+)_l\\ \langle\alpha,\theta^\vee\rangle\neq 0}}\frac{1}{2}\mu_{\alpha_0}\alpha=a\,\nu(\theta^\vee), \tag{7.29}$$

and consequently

$$a=(\mathring{\rho}_\mu|\theta)+\tfrac{1}{4}\mu_{\alpha_0}(\rho_l|\theta)=(\mathring{\rho}_\mu|\theta)+\mu_{\alpha_0}, \tag{7.30}$$

where

$$\rho_l=\sum_{\alpha\in(\mathring{\Delta}_+)_l}\alpha.$$

In both cases, $L(\nu(\theta^\vee))=h_\mu^\vee\nu(\theta^\vee)$ and we have $-\Sigma_{\alpha\in\Delta_{\tau_\lambda}}\mu_\alpha\overline{\alpha}=L(\lambda)=h_\mu^\vee\lambda$, as required.

Remark VII.8: Note that we also showed that

$$\sum_{\alpha\in\mathring{\Delta}}(\lambda|\alpha)(\mu|\alpha)=2h^\vee(\lambda|\mu),\quad \text{for } \lambda,\mu\in\mathring{\mathfrak{h}}^*, \tag{7.31}$$

in the nontwisted root systems. See Corollary 8.7 of Ref. 23.

VIII. CONCLUDING REMARKS

We constructed mutually commuting difference operators by means of root algebras. Since the operator is represented in a single product of affine *R*-matrices, we had only to pursue the image of each *R*-matrix and therefore succeeded in proving that they act on the characters of the irreducible representations of affine Lie algebras. However, the simultaneous diagonability of the difference operators and the procedure of the diagonalization have yet to be solved in contrast with the trigonometric cases.[6–8,31]

Since this operator was originally introduced as a quantum many-body system, the self-adjointness on the space of square integrable functions should be an important problem. In the trigonometric case, we readily see that the Macdonald operators are essentially self-adjoint on the polynomials of exponential since the operators are diagonalized in terms of the Macdonald polynomials. In the elliptic case, however, this problem is less investigated. See, for example, Refs. 32 and 33, where the two-body system is extensively studied by constructing the explicit eigenvectors, or Ref. 34 where the extensibility to positive self-adjoint operators is shown by introducing a certain measure on a torus. These systems correspond to negative levels in terms of affine Lie algebras. This problem will be discussed elsewhere.

Nishino for fruitful discussions and helpful comments. The author is a Research Fellow of the Japan Society for the Promotion of Science.

APPENDIX: RELATION TO MACDONALD OPERATORS

Let $e^{\lambda}(h)=e^{2\pi i\langle\lambda,h\rangle}(\lambda\in\mathring{\mathfrak{h}})$ be a function on $\mathbb{H}$. We set $q=e^{2\pi i\kappa}$ and $t_{\alpha}=e^{-2\pi i\mu_{\alpha}\gamma_{\alpha}}$.

Theorem A.1: *In the limit $\tau\to i\infty$, $\hat{Y}^{\lambda}$ for a minuscule weight $-\lambda$ and $\hat{Y}^{-\theta}$ reduce respectively to M^{λ} and $M^{-\theta}+c'$ where*

$$M^{\lambda}:=c_{\lambda}\sum_{w\in\mathring{W}}w\left(\prod_{\substack{\alpha\in\mathring{\Delta}_{+}\\(\lambda|\alpha)=-\gamma_{\alpha}}}\frac{1-t_{\alpha}e^{\alpha}}{1-e^{\alpha}}\tau_{\lambda}\right),\tag{A1}$$

$$M^{-\theta}:=c_{-\theta}\sum_{w\in\mathring{W}}w\left(\left(\prod_{\substack{\alpha\in\mathring{\Delta}_{+}\\(\theta|\alpha)>0}}\frac{1-t_{\alpha}e^{\alpha}}{1-e^{\alpha}}\right)\left(\frac{1-t_{\theta}qe^{\theta}}{1-qe^{\theta}}\right)(\tau_{-\theta}-1)\right),\tag{A2}$$

and for $\lambda\in\mathring{\mathfrak{h}}$,

$$c_{\lambda}:=\frac{e^{-2\pi i(\lambda|\mathring{\rho}_{\mu})}}{|\mathring{W}_{\lambda}|}.\tag{A3}$$

The term c' is given by

$$c'=r\frac{r-t_{\theta}}{r-1}\sum_{w\in\mathring{W}^{\theta}}\prod_{\alpha\in\Delta w}t_{\alpha},\tag{A4}$$

where $r=e^{2\pi i(\mathring{\rho}_{\mu}|\theta)}$ and $\mathring{W}^{\theta}$ is the minimal coset representatives of $\mathring{W}_{\theta}$, or the set of elements of smallest length in each coset in $\mathring{W}/\mathring{W}_{\theta}$.

Proof: It is sufficient to show the equation (A4). A direct calculation shows that the term c' is given by

$$c'=c_{-\theta}\frac{r-t_{\theta}}{r-1}\sum_{w\in\mathring{W}}\prod_{\substack{\alpha\in\mathring{\Delta}_{+}\\(\theta|\alpha)>0}}\frac{1-t_{\alpha}e^{w\alpha}}{1-e^{w\alpha}},\tag{A5}$$

and we see that this term is independent of h, which is implied by the following lemma related to the Poincaré polynomials. □

Lemma A.2 (cf. Ref. 35): Let $\mathring{W}^{\theta}$ be the minimal coset representatives of $\mathring{W}_{\theta}$. Then we have

$$\sum_{w\in\mathring{W}}\prod_{\substack{\alpha\in\mathring{\Delta}_{+}\\(\theta|\alpha)>0}}\frac{1-t_{\alpha}e^{w\alpha}}{1-e^{w\alpha}}=|\mathring{W}_{\theta}|\left(\sum_{w\in\mathring{W}}\prod_{\alpha\in\Delta_{w}}t_{\alpha}\right)\Big/\left(\sum_{w\in\mathring{W}_{\theta}}\prod_{\alpha\in\Delta_{w}}t_{\alpha}\right)$$

$$=|\mathring{W}_{\theta}|\sum_{w\in\mathring{W}^{\theta}}\prod_{\alpha\in\Delta_{w}}t_{\alpha}.\tag{A6}$$

Proof: Let $\Delta_{\theta}:=\{\alpha\in\mathring{\Delta}|(\theta|\alpha)=0\}$. Then one sees that Δ_{θ} is a root system whose simple roots are $\Pi_{\theta}:=\{\alpha_i\in\mathring{\Pi}|(\theta|\alpha_i)=0\}$. The parabolic subgroup generated by the reflections of Π_{θ} coincides with $\mathring{W}_{\theta}$. Then we have

$$\sum_{w\in\mathring{W}_{\theta}}\prod_{\alpha\in(\Delta_{\theta})_{+}}\frac{1-t_{\alpha}e^{w\alpha}}{1-e^{w\alpha}}=\left(\sum_{w\in\mathring{W}_{\theta}}\prod_{\alpha\in\Delta_{w}}t_{\alpha}\right).\tag{A7}$$

Since the right-hand side is independent of h, we have for any $v\in\mathring{W}$

$$\sum_{w\in \mathring{W}_\theta} \prod_{\alpha\in(\mathring{\Delta}_\theta)_+} \frac{1-t_\alpha e^{v w\alpha}}{1-e^{v w\alpha}} = \sum_{w\in \mathring{W}_\theta} \prod_{\alpha\in \mathring{\Delta}_w} t_\alpha . \tag{A8}$$

The set $\Delta^\theta=\{\alpha\in \mathring{\Delta}_+ | (\theta|\alpha)>0\}$ is $\mathring{W}_\theta$-invariant,

$$\Delta^\theta = v\Delta^\theta, \quad \text{for } v\in \mathring{W}_\theta \tag{A9}$$

Thus we have

$$\prod_{\alpha\in\Delta^\theta} \frac{1-t_\alpha e^{wv\alpha}}{1-e^{wv\alpha}} = \prod_{\alpha\in\Delta^\theta} \frac{1-t_\alpha e^{w\alpha}}{1-e^{w\alpha}}. \tag{A10}$$

From (A8) and (A10),

$$\begin{aligned}
&\left(\sum_{w\in \mathring{W}} \sum_{\alpha\in\Delta^\theta} \frac{1-t_\alpha e^{w\alpha}}{1-e^{w\alpha}}\right)\left(\sum_{w\in \mathring{W}_\theta} \prod_{\alpha\in\mathring{\Delta}_w} t_\alpha\right)\\
&\quad = |\mathring{W}| \sum_{w\in \mathring{W}^\theta} \left(\prod_{\alpha\in\Delta^\theta} \frac{1-t_\alpha e^{w\alpha}}{1-e^{w\alpha}}\right)\left(\sum_{v\in \mathring{W}_\theta} \prod_{v\in(\mathring{\Delta}_\theta)_+} \frac{1-t_\alpha e^{wv\alpha}}{1-e^{wv\alpha}}\right)\\
&\quad = |\mathring{W}_\theta| \sum_{w\in \mathring{W}^\theta} \sum_{v\in \mathring{W}_\theta} \prod_{\alpha\in\mathring{\Delta}_+} \frac{1-t_\alpha e^{wv\alpha}}{1-e^{wv\alpha}}\\
&\quad = |\mathring{W}_\theta| \sum_{w\in \mathring{W}} \prod_{\alpha\in\mathring{\Delta}_+} \frac{1-t_\alpha e^{w\alpha}}{1-e^{w\alpha}}\\
&\quad = |\mathring{W}_\theta| \left(\sum_{w\in \mathring{W}} \prod_{\alpha\in\mathring{\Delta}_w} t_\alpha\right),
\end{aligned} \tag{A11}$$

which implies the first equality. The second equality is an immediate consequence of the relation $\Delta_{uv}=\Delta_u\cup u\Delta_v$ for $u\in \mathring{W}^\theta$ and $v\in \mathring{W}_\theta$.

(Received 2 January 2001; accepted for publication 9 May 2001)

We study the elliptic Ruijsenaars models associated with arbitrary root systems, which are difference analogs of the Calogero–Moser model. We give a dense subspace in the space of square integrable functions invariant under the action of the Weyl group on a torus as a domain of its Hamiltonian and prove its essential self-adjointness by using perturbation theory. It is also clarified that these models consist of pure point spectrum. © *2001 American Institute of Physics.*

I. INTRODUCTION

The elliptic Ruijsenaars model was introduced as a relativistic analog of the Calogero–Moser system[1] and its Hamiltonian is a difference operator with elliptic function coefficients. We adopt a little different Hamiltonian from the original one in order to treat it from the viewpoint of affine root systems, which is given by

$$H_{A_{l-1}^{(1)}}=\sum_{j=1}^{l}\left(\prod_{\substack{k=1\\k\neq j}}^{l}\frac{\vartheta_1(x_j-x_k-\mu)}{\vartheta_1(x_j-x_k)}\right)^{1/2}\left(\tau_j(\kappa)\prod_{k=1}^{l}\tau_k(-\kappa/l)\right)\left(\prod_{\substack{k=1\\k\neq j}}^{l}\frac{\vartheta_1(x_j-x_k+\mu)}{\vartheta_1(x_j-x_k)}\right)^{1/2}, \tag{1.1}$$

where $\vartheta_j(x)=\vartheta_j(x;\tau)$ is the Jacobi theta function and $\tau_i(\kappa)$ is a translation of the variable x_i by κ. Besides this model, a BC-type analog was proposed by van Diejen,[2–5] whose Hamiltonian is given by

$$\begin{aligned}H_{A_{2l}^{(2)}}=&\sum_{j=1}^{l}\left(\left(\prod_{\substack{k=1\\k\neq j}}^{l}\frac{\vartheta_1(x_j-x_k-\mu)}{\vartheta_1(x_j-x_k)}\frac{\vartheta_1(x_j+x_k-\mu)}{\vartheta_1(x_j+x_k)}\right)\left(\prod_{r=0}^{3}\frac{\vartheta_r(x_j-\mu_r)}{\vartheta_r(x_j)}\frac{\vartheta_r(x_j+\kappa/2-\mu_r')}{\vartheta_r(x_j+\kappa/2)}\right)\right)^{1/2}\\&\times\tau_j(\kappa)\left(\left(\prod_{\substack{k=1\\k\neq j}}^{l}\frac{\vartheta_1(x_j-x_k+\mu)}{\vartheta_1(x_j-x_k)}\frac{\vartheta_1(x_j+x_k+\mu)}{\vartheta_1(x_j+x_k)}\right)\right.\\&\left.\times\left(\prod_{r=0}^{3}\frac{\vartheta_r(x_j+\mu_r)}{\vartheta_r(x_j)}\frac{\vartheta_r(x_j-\kappa/2+\mu_r')}{\vartheta_r(x_j-\kappa/2)}\right)\right)^{1/2}\\&+\sum_{j=1}^{l}\left(\left(\prod_{\substack{k=1\\k\neq j}}^{l}\frac{\vartheta_1(-x_j-x_k-\mu)}{\vartheta_1(-x_j-x_k)}\frac{\vartheta_1(-x_j+x_k-\mu)}{\vartheta_1(-x_j+x_k)}\right)\right.\\&\left.\times\left(\prod_{r=0}^{3}\frac{\vartheta_r(-x_j-\mu_r)}{\vartheta_r(-x_j)}\frac{\vartheta_r(-x_j-\kappa/2-\mu_r')}{\vartheta_r(-x_j-\kappa/2)}\right)\right)^{1/2}\end{aligned}$$

a)Electronic mail: komori@gokutan.c.u-tokyo.ac.jp

$$\times\tau_j(-\kappa)\Bigg(\Bigg(\prod_{\substack{k=1\\k\neq j}}^{l}\frac{\vartheta_1(-x_j-x_k+\mu)}{\vartheta_1(-x_j-x_k)}\frac{\vartheta_1(-x_j+x_k+\mu)}{\vartheta_1(-x_j+x_k)}\Bigg)$$
$$\times\Bigg(\prod_{r=0}^{3}\frac{\vartheta_r(-x_j+\mu_r)}{\vartheta_r(-x_j)}\frac{\vartheta_r(-x_j+\kappa/2+\mu_r')}{\vartheta_r(-x_j+\kappa/2)}\Bigg)\Bigg)^{1/2}$$
$$+\sum_{p=0}^{3}\left(\frac{\pi}{\vartheta_1'(0)}\right)^2\frac{2}{\vartheta_1(\mu)\vartheta_1(\kappa+\mu)}\Bigg(\prod_{r=0}^{3}\vartheta_r(\mu_{\pi_p r}+\kappa/2)\vartheta_r(\mu'_{\pi_p r})\Bigg)$$
$$\times\Bigg(\prod_{j=1}^{l}\frac{\vartheta_p(x_j-\kappa/2-\mu)}{\vartheta_p(x_j-\kappa/2)}\frac{\vartheta_p(-x_j-\kappa/2-\mu)}{\vartheta_p(-x_j-\kappa/2)}\Bigg), \tag{1.2}$$

where we have omitted an irrelevant additive constant in $A_{2l}^{(2)}$ system and realized the root systems in $\mathbb{C}^l$ in the standard way. π_j $(j=0,1,2,3)$ denotes the permutation: $\pi_1=\mathrm{id}$, $\pi_2=(12)(03)$, $\pi_3=(13)(02)$, and $\pi_0=(01)(23)$. The parameters are $\kappa,\tau\in i\mathbb{R}_{>0}$, and $\mu,\mu_j,\mu_j'\in i\mathbb{R}$ $(j=0,1,2,3)$ in order to ensure the formal self-adjointness of the Hamiltonians. Generalizations to arbitrary affine root systems are considered in Refs. 6–8.

For these models, there are many papers which treat their Hamiltonians as operators on meromorphic functions and concern their algebraic aspects such as commutativity,[1–6] relations to elliptic quantum algebras[9,10] and actions on the space of characters.[7,8,11,12] However, the self-adjointness was rarely discussed. In the two-body case, elaborate works are done by Ruijsenaars,[13–15] where infinitely many numbers of the explicit eigenvectors are constructed in the space of square integrable functions without Weyl group invariance and the completeness is to be solved. Concerning self-adjointness, the hyperbolic case should also be remarkable.[16]

The main purpose of this article is to give an appropriate domain in the space of square integrable functions which makes the Hamiltonian essentially self-adjoint. We suppose that the system is on a torus and is Weyl-group invariant as in the trigonometric models. A difficulty in the choice of the domain arises from the fact that the Hamiltonian includes the shift operators in the pure imaginary direction where the functions are not defined. Thus as a domain of the Hamiltonian, we should choose such functions as can be extended naturally to a complex region. In other words, they should be sufficiently analytic for the Hamiltonian to make sense. In this article, we employ the well-developed perturbation theory for the purpose and show that the Kato–Rellich theorem works well in the difference cases as in the differential cases.

This article is organized as follows: in Sec. II, we give definitions and basic facts about affine root systems and affine Weyl groups used in this article. In Secs. III and IV, we introduce the root algebra due to Cherednik. This algebra plays the role of the affine Hecke algebra in the trigonometric cases, and contains a commutative subalgebra which comes from the translation subgroup in affine Weyl groups. We clarify that if we give some representation on the space of meromorphic functions, one of the generators of the commutative subalgebra coincides with the conjugated Hamiltonian of the elliptic Ruijsenaars model by some function. In Sec. V, we show the essential self-adjointness of the elliptic Ruijsenaars models not of type $A_{2l}^{(2)}$. First we show the essential self-adjointness of the conjugated Hamiltonian in the square integrable functions with a weight function and then those of the original Hamiltonian without a weight function. We introduce an appropriate subspace of meromorphic functions invariant under the action of the corresponding Weyl group and regard this space as a subspace of the space of square integrable functions. Then the conjugated Hamiltonians are symmetric and semi-bounded below on this domain and thus can be extended to self-adjoint operators. The technique of integration by parts in the differential cases is replaced by the Cauchy theorem in the difference cases. Furthermore, we show that these Hamiltonians with a special coupling constant are essentially self-adjoint, in fact, and consist of only point spectrum. Then we apply the perturbation theory to these operators. We show their essential self-adjointness with the coupling constants in a neighborhood of the special point by use

of the Kato–Rellich theorem. The compactness of resolvents is inherited. In Sec. VI, we study the $A_{2l}^{(2)}$-type case. Although this model has nine arbitrary parameters and is very complicated, the method in the previous section works well in this model.

In this article, we restrict our attention to the lowest order operator acting on Weyl group invariant subspace. Although the higher order operators commute with the Hamiltonian as operators acting on the space of meromorphic functions, the commutativity in the sense of quantum mechanics requires further investigation since their domains are unclear. We hope to remove these restrictions and recover Ruijsenaars' result in the near future.

II. AFFINE ROOT SYSTEMS

We give some well-known facts about affine root systems and affine Weyl groups,[17–19] which are standard tools in the theory of affine Hecke algebras. Some of the definitions are slightly changed and extended so that they include twisted affine root systems. The notation is mainly due to Ref. 20.

Let $\mathfrak{g}$ be the affine Lie algebra of type $X_N^{(r)}$, $\mathfrak{h}$ its Cartan subalgebra of $\dim \mathfrak{h}=l+2$, $I=\{0,\ldots,l\}$ a set of indices, $\Pi=\{\alpha_i|i\in I\}\subset\mathfrak{h}^*$ the set of simple roots, $\Pi^\vee=\{\alpha_i^\vee|i\in I\}\subset\mathfrak{h}$ the set of simple coroots, Δ the root system, Q and $Q^\vee$ the root and coroot lattices, P and $P^\vee$ the weight and coweight lattices:

$$Q=\bigoplus_{i\in I}\mathbb{Z}\,\alpha_i\subset P=\bigoplus_{i\in I}\mathbb{Z}\,\Lambda_i\oplus\mathbb{C}\delta\subset\mathfrak{h}^*, \tag{2.1}$$

$$Q^\vee=\bigoplus_{i\in I}\mathbb{Z}\,\alpha_i^\vee\subset P^\vee=\bigoplus_{i\in I}\mathbb{Z}\,\Lambda_i^\vee\oplus\mathbb{C}K\subset\mathfrak{h}, \tag{2.2}$$

where $\langle\alpha_i,\Lambda_j^\vee\rangle=\delta_{ij}$, $\langle\Lambda_i,\alpha_j^\vee\rangle=\delta_{ij}$, $d=\Lambda_0^\vee$. Since the normalized invariant form is nondegenerate on $\mathfrak{h}$, we have an isomorphism $\nu:\mathfrak{h}\to\mathfrak{h}^*$ defined by

$$\langle\nu(h),h_1\rangle=(h|h_1),\quad h,h_1\in\mathfrak{h}, \tag{2.3}$$

and the induced bilinear form $(\cdot|\cdot)$ on $\mathfrak{h}^*$. Let $\mathring{I}=\{1,\ldots,l\}$, $\mathring{\Pi}=\{\alpha_i|i\in\mathring{I}\}$ and $\mathring{\Pi}^\vee=\{\alpha_i^\vee|i\in\mathring{I}\}$. Let $\mathring{\mathfrak{h}}^*$ be the subspace of $\mathfrak{h}^*$ spanned by $\mathring{\Pi}$ over $\mathbb{C}$. For $\lambda\in\mathfrak{h}^*$, denote by $\overline{\lambda}$ the orthogonal projection of λ on $\mathring{\mathfrak{h}}^*$. Let $\mathring{Q}$ be the sublattice of Q generated by $\mathring{\Pi}$ and $\mathring{P}$ the projection of P on $\mathring{\mathfrak{h}}^*$. The dual notions $\mathring{\mathfrak{h}}$, $\overline{h}$, $\mathring{Q}^\vee$ and $\mathring{P}^\vee$ are defined similarly:

$$\mathring{Q}=\bigoplus_{i\in\mathring{I}}\mathbb{Z}\,\alpha_i\subset\mathring{P}=\bigoplus_{i\in\mathring{I}}\mathbb{Z}\,\overline{\Lambda_i}\subset\mathring{\mathfrak{h}}^*, \tag{2.4}$$

$$\mathring{Q}^\vee=\bigoplus_{i\in\mathring{I}}\mathbb{Z}\,\alpha_i^\vee\subset\mathring{P}^\vee=\bigoplus_{i\in\mathring{I}}\mathbb{Z}\,\overline{\Lambda_i^\vee}\subset\mathring{\mathfrak{h}}. \tag{2.5}$$

Let $\mathfrak{h}_\mathbb{R}$ be the $\mathbb{R}$-span of $\{\alpha_i^\vee\}_{i\in I}\cup\{d\}$ and let $\mathring{\mathfrak{h}}_\mathbb{R}$ be the $\mathbb{R}$-span of $\{\alpha_i^\vee\}_{i\in\mathring{I}}$. Let Δ^{re}, Δ^{im}, Δ_+ and Δ_- be the set of real roots, imaginary roots, positive roots and negative roots, respectively. Then one has the disjoint unions $\Delta=\Delta^{\mathrm{re}}\cup\Delta^{\mathrm{im}}=\Delta_+\cup\Delta_-$. Let Δ_l be the set of the longest real roots. For $\alpha\in\Delta^{\mathrm{re}}$, let $\gamma_\alpha:=r$ if $\alpha\in\Delta_l$ and $\gamma_\alpha:=1$ otherwise, where r is from the type $X_N^{(r)}$. Then the real roots are written as

$$\Delta^{\mathrm{re}}=\begin{cases}\{\alpha+n\gamma_\alpha\delta|\alpha\in\mathring{\Delta},n\in\mathbb{Z}\}, & \text{if } X_N^{(r)}\neq A_{2l}^{(2)},\\ \{\alpha+n\gamma_\alpha\delta|\alpha\in\mathring{\Delta},n\in\mathbb{Z}\}\cup\{\frac{1}{2}(\alpha+(2n-1)\delta)|\alpha\in\mathring{\Delta}_l,n\in\mathbb{Z}\}, & \text{if } X_N^{(r)}=A_{2l}^{(2)}.\end{cases} \tag{2.6}$$

For $\alpha\in\Delta^{\mathrm{re}}$, let s_α be a reflection defined by

$$s_\alpha(\lambda) := \lambda - \langle \lambda, \alpha^\vee \rangle \alpha, \quad \lambda \in \mathfrak{h}^*. \tag{2.7}$$

The Weyl group $\mathring{W}$ is generated by the fundamental reflections $\{s_i := s_{\alpha_i} | i \in \mathring{I}\}$ on $\mathfrak{h}^*$ and the affine Weyl group W is generated by $\{s_i | i \in I\}$. The defining relations are given by $s_i^2 = id$ and the Coxeter relations:

$$(s_i s_j)^{m_{ij}} = id, \quad \text{for } i \neq j \in I, \tag{2.8}$$

where $m_{ij} = 2$ if α_i and α_j are disconnected in the Dynkin diagram and $m_{ij} = 3,4,6$ if 1,2,3 lines, respectively, connect α_i and α_j. We note that there is no Coxeter relation in the affine root systems of rank 2. For $\mu \in \mathring{\mathfrak{h}}^*$, we define endomorphisms τ_μ of the vector space $\mathfrak{h}^*$ by

$$\tau_\mu(\lambda) := \lambda + \langle \lambda, K \rangle \mu - ((\lambda|\mu) + \tfrac{1}{2}|\mu|^2 \langle \lambda, K \rangle)\delta, \tag{2.9}$$

where $|\mu|^2$ stands for $(\mu|\mu)$. The actions of s_α, τ_μ are naturally induced on $\mathfrak{h}$ via the form $\langle \cdot, \cdot \rangle$ as follows ($h \in \mathfrak{h}$):

$$s_\alpha(h) = h - \langle \alpha, h \rangle \alpha^\vee, \tag{2.10}$$

$$\tau_\mu(h) = h + \langle \delta, h \rangle \nu^{-1}(\mu) - (\langle \mu, h \rangle + \tfrac{1}{2}|\mu|^2 \langle \delta, h \rangle) K. \tag{2.11}$$

Let a_i and $a_i^\vee$ be the labels of the Dynkin diagram from Table Aff in Ref. 20. Note that $a_0 = 2$ if $X_N^{(r)} = A_{2l}^{(2)}$ and $a_0 = 1$ otherwise. Let $\theta := \delta - a_0 \alpha_0 \in \mathring{\Delta}_+$. Then $a_0^{-1} \gamma_\theta = 1$ and $\nu^{-1}(\theta) = a_0 \theta^\vee$. Let $M := \nu(\mathbb{Z}(\mathring{W} \cdot \theta^\vee)) \subset \mathring{\mathfrak{h}}^*$. For an arbitrary lattice L, we denote by T_L the corresponding group of translations of L.

Proposition II.1: The group W is the semidirect product $W = \mathring{W} \ltimes T_M$.

Let $\hat{M} := \{\lambda \in \mathring{\mathfrak{h}}^* | \alpha \in \Delta^{\mathrm{re}}, (\alpha|\lambda) \in \gamma_\alpha \mathbb{Z}\}$. Then we see that $\hat{M} \subset \mathring{P}$ and $T_{\hat{M}}$ is normalized by $\mathring{W}$.

Definition II.2: The extended affine Weyl group $\hat{W}$ is the semidirect product $\hat{W} := \mathring{W} \ltimes T_{\hat{M}}$.

The lattice $\hat{M}$ is taken to be the finest so that $T_{\hat{M}}$ acts on Δ, and thus the extended affine Weyl group acts on Δ. Here are the explicit description of $\hat{M}$ and its canonical basis $\{\lambda_i | i \in \mathring{I}\}$:

$$\hat{M} = \begin{cases} \nu(\mathring{P}^\vee), & \text{if } r = 1, \\ \mathring{P}, & \text{otherwise,} \end{cases} \qquad \lambda_i = \begin{cases} \nu(\overline{\Lambda_i^\vee}), & \text{if } r = 1, \\ \overline{\Lambda_i}, & \text{otherwise.} \end{cases} \tag{2.12}$$

We also use $\hat{M}_- := \oplus_{i \in \mathring{I}} \mathbb{Z}_{\leqslant 0} \lambda_i$.

Fix $\kappa \in \mathbb{C}$. Let $\mathfrak{h}_\kappa := \{h \in \mathfrak{h} | \langle \delta, h \rangle = \kappa\}$. Since W acts on $\mathfrak{h}_\kappa$, W acts on the affine space $\mathfrak{h}_\kappa \bmod \mathbb{C}K$. We identify $\mathfrak{h}_\kappa \bmod \mathbb{C}K$ with $\mathring{\mathfrak{h}}$ by projection. By this identification, we obtain affine transformations from $\hat{W}$ and affine linear functionals from $\langle \alpha, \cdot \rangle$ for $\alpha \in \Delta$. We denote so obtained maps by af, so that

$$\mathrm{af}(w)(\overline{h}) = \overline{w(h)}, \quad \mathrm{af}(\alpha)(\overline{h}) = \langle \alpha, h \rangle, \tag{2.13}$$

for $h \in \mathfrak{h}_\kappa$. Explicitly we have for $h \in \mathring{\mathfrak{h}}$

$$\mathrm{af}(\mathring{w})(h) = \mathring{w}(h), \quad \mathrm{af}(\tau_\mu)(h) = h + \kappa \nu^{-1}(\mu), \tag{2.14}$$

$$\mathrm{af}(\mathring{\alpha} + n\delta)(h) = \langle \mathring{\alpha}, h \rangle + \kappa n. \tag{2.15}$$

Note that

$$\mathrm{af}(\alpha) \circ \mathrm{af}(w) = \mathrm{af}(w^{-1}\alpha). \tag{2.16}$$

We define an action of the extended affine Weyl group on the space $\mathcal{M}$ of meromorphic functions on $\mathbb{H}:=\mathring{\mathfrak{h}}/\mathring{Q}^\vee$ by

$$(wf)(h):=f(\mathrm{af}(w^{-1})h). \tag{2.17}$$

Let Ω be the subgroup of $\hat{W}$ which stabilizes the affine Weyl chamber C.

Proposition II.3: The subgroup Ω is isomorphic to $\hat{W}/W\simeq T_{\hat{M}}/T_M$, thus Abelian. The extended affine Weyl group $\hat{W}$ is isomorphic to the semidirect product $W\rtimes\Omega$.

Definition II.4:

(1) The length $\ell(w)$ of $w\in W$ is the length ℓ of the reduced decomposition:

$$w=s_{i_1}\cdots s_{i_\ell},\quad \text{for } i_k\in I, \tag{2.18}$$

$$\ell(id)=0. \tag{2.19}$$

(2) The length $\ell(\hat{w})$ of $\hat{w}\in\hat{W}$ is the number of the negative roots made positive by $\hat{w}$:

$$\ell(\hat{w}):=|\Delta_{\hat{w}}|, \tag{2.20}$$

$$\Delta_{\hat{w}}:=\{\alpha\in\Delta_+\cap\hat{w}\Delta_-\}, \tag{2.21}$$

which is equivalent to the definition $\ell(w)$ for $w\in W$. The reduced decomposition of $\hat{w}\in\hat{W}$ is $\hat{w}=w\omega=s_{i_1}\cdots s_{i_\ell}\omega$, where $\omega\in\Omega$ and $\ell=\ell(\hat{w})=\ell(w)$.

The set $\Delta_{\hat{w}}$ is explicitly described as $\Delta_{\hat{w}}=\{\alpha^{(1)}=\alpha_{i_1},\alpha^{(2)}=s_{i_1}(\alpha_{i_2}),\cdots,\alpha^{(\ell)}=ws_{i_\ell}(\alpha_{i_\ell})\}$. By definition, $\Delta_{\hat{w}}$ is independent of reduced expressions. One sees that $\Omega=\{\omega\in\hat{W},\ell(\omega)=0\}$.

Definition II.5: A weight $\lambda\in\hat{M}$ is said to be minuscule if $\Delta_{\tau_{-\lambda}}\subset\mathring{\Delta}_+$.

The weight $\nu^{-1}(\theta^\vee)$ is called the quasi-minuscule weight due to the following properties:

$$\langle\alpha,\theta^\vee\rangle=0\ \text{ or }\ \gamma_\alpha,\quad \text{for } \alpha(\neq\theta)\in\mathring{\Delta}_+,\quad \langle\theta,\theta^\vee\rangle=2. \tag{2.22}$$

The quasi-minuscule weight just fails to be minuscule:

$$\Delta_{\tau_{-\nu^{-1}(\theta^\vee)}}=\Delta_{s_\theta}\cup\{a_0^{-1}(\theta+\delta)\}. \tag{2.23}$$

We give the definitions of the Jacobi theta functions. For $\Im\tau>0$, the Jacobi theta functions are defined by

$$\vartheta_1(x;\tau):=-i\sum_{n\in\mathbb{Z}}\exp\left(i\pi\left(n+\frac{1}{2}\right)^2\tau+2\pi i\left(n+\frac{1}{2}\right)x+i\pi n\right), \tag{2.24a}$$

$$\vartheta_2(x;\tau):=\sum_{n\in\mathbb{Z}}\exp\left(i\pi\left(n+\frac{1}{2}\right)^2\tau+2\pi i\left(n+\frac{1}{2}\right)x\right), \tag{2.24b}$$

$$\vartheta_3(x;\tau):=\sum_{n\in\mathbb{Z}}\exp(i\pi n^2\tau+2\pi inx), \tag{2.24c}$$

$$\vartheta_0(x;\tau):=\sum_{n\in\mathbb{Z}}\exp(i\pi n^2\tau+2\pi inx+i\pi n). \tag{2.24d}$$

These functions are expressed by infinite products:

$$\vartheta_1(x;\tau)=ip^{1/8}z^{-1/2}(p;p)_\infty(z;p)_\infty(pz^{-1};p)_\infty, \tag{2.25a}$$

$$\vartheta_2(x;\tau)=p^{1/8}z^{-1/2}(p;p)_\infty(-z;p)_\infty(-pz^{-1};p)_\infty, \tag{2.25b}$$

$$\vartheta_3(x;\tau)=(p;p)_\infty(-p^{1/2}z;p)_\infty(-p^{1/2}z^{-1};p)_\infty, \tag{2.25c}$$

$$\vartheta_0(x;\tau)=(p;p)_\infty(p^{1/2}z;p)_\infty(p^{1/2}z^{-1};p)_\infty, \tag{2.25d}$$

where $p=e^{2\pi i\tau}$, $z=e^{2\pi ix}$ and

$$(z;q_1,\cdots,q_m)_\infty:=\prod_{n_1,\cdots,n_m\in\mathbb{Z}_{\geqslant 0}}(1-q_1^{n_1}\cdots q_m^{n_m}z). \tag{2.26}$$

Define constants a_j and b_j for $j=0,1,2,3$ as

$$a_1=0,\quad b_1=0, \tag{2.27a}$$

$$a_2=1,\quad b_2=0, \tag{2.27b}$$

$$a_3=1,\quad b_3=1, \tag{2.27c}$$

$$a_0=0,\quad b_0=1. \tag{2.27d}$$

Then the zeroes of $\vartheta_j(x;\tau)$ are expressed as $\mathbb{Z}+a_j/2+(\mathbb{Z}+b_j/2)\tau$.

III. ROOT ALGEBRAS

We shall define the root algebras after Cherednik.[19] See Refs. 6–8 for the details of the proofs.

Let $\mathcal{T}$ be the tensor algebra over $\mathbb{C}$ generated by independent variables $\{R_\alpha|\alpha\in\Delta^{\mathrm{re}}\}$. Then the action of $\hat{w}\in\hat{W}$ on Δ^{re} induces an action on $\mathcal{T}$ by ${}^{\hat{w}}\!:R_\alpha\mapsto R_{\hat{w}(\alpha)}$.

Definition III.1: Let $\mathcal{I}$ be the two-sided ideal in $\mathcal{T}$ which is generated by all the elements of the form for $i\neq j\in I$, and $\hat{w}\in\hat{W}$:

$$\underbrace{{}^{\hat{w}}(R_{\alpha_i}\otimes R_{s_i\alpha_j}\otimes R_{s_is_j\alpha_i}\otimes\cdots)}_{m_{ij}\ \text{factors}}-\underbrace{{}^{\hat{w}}(R_{\alpha_j}\otimes R_{s_j\alpha_i}\otimes R_{s_js_i\alpha_j}\otimes\cdots)}_{m_{ij}\ \text{factors}}. \tag{3.1}$$

The root algebra $\tilde{\mathcal{R}}$ is $\mathcal{T}/\mathcal{I}.\{R_\alpha|\alpha\in\Delta^{\mathrm{re}}\}$ are called the R-matrices.

Because of the $\hat{W}$-invariance of $\mathcal{I}$, the action of $\hat{W}$ is induced on $\tilde{\mathcal{R}}$. For simplicity, we write products in $\tilde{\mathcal{R}}$ in the usual way for associative algebras.

Theorem III.2 (Cherednik):

(1) There exists a unique set $\{R_{\hat{w}}|\hat{w}\in\hat{W}\}\subset\tilde{\mathcal{R}}$ *satisfying the relations*

$$R_{v\,w}=R_v{}^vR_w,\quad R_{s_i}=R_{\alpha_i}\quad(i\in I),\quad R_\omega=1, \tag{3.2}$$

where $\omega\in\Omega$, $v,w\in\hat{W}$ *and* $\ell(v\,w)=\ell(v)+\ell(w)$.

(2) We have the R-matrix for $\hat{w}\in\hat{W}$ *and its arbitrary reduced decomposition* $\hat{w}=w\omega=s_{i_1}\ldots s_{i_\ell}\omega$ *as*

$$\begin{gathered}R_{\hat{w}}=R_{\alpha^{(1)}}\ldots R_{\alpha^{(\ell)}},\\ \alpha^{(1)}=\alpha_{i_1},\quad \alpha^{(2)}=s_{i_1}(\alpha_{i_2}),\quad\ldots,\quad \alpha^{(\ell)}=ws_{i_\ell}(\alpha_{i_\ell})\in\Delta_{\hat{w}}.\end{gathered} \tag{3.3}$$

Instead of the original root algebra, we work with the following extension, where $\tilde{\mathcal{R}}$ is combined with the translation group $T_{\hat{M}}$:

Definition III.3: $\mathcal{R}:=\tilde{\mathcal{R}}\rtimes T_{\hat{M}}$:

$$(R\,\tau_\lambda)(R'\,\tau_\mu)=R\,({}^{\tau_\lambda}R')\,\tau_{\lambda+\mu}, \tag{3.4}$$

where $R,R'\in\tilde{\mathcal{R}}$ and $\lambda,\mu\in\hat{M}$.

Theorem III.4: *The subalgebra $\mathcal{S}\subset\mathcal{R}$ generated by $\{Y^\lambda:=R_{\tau_\lambda}\,\tau_\lambda|\lambda\in\hat{M}_-\}$ forms a commutative algebra and is generated by $\{Y^{-\lambda_i}|i\in\mathring{I}\}$.*

IV. DIFFERENCE OPERATORS WITH ELLIPTIC FUNCTION COEFFICIENTS

In this section, we give a class of the representation of the root algebra and construct the conjugated Hamiltonians of the elliptic Ruijsenaars models associated with affine root systems.

Let $\kappa,\tau\in\mathbb{C}$ and $\Im\tau>0$. For $\alpha\in\Delta^{\mathrm{re}}$, let $\mu_\alpha\in\mathbb{C}$ be $\hat{W}$-invariant constants: $\mu_{\hat{w}(\alpha)}=\mu_\alpha$ for $\hat{w}\in\hat{W}$, such that $\langle\mathring{\rho}_\mu,\alpha^\vee\rangle\neq\mathbb{Z}/\gamma_\alpha+\tau\mathbb{Z}$, where

$$\mathring{\rho}_\mu:=\sum_{i\in\mathring{I}}\mu_{\alpha_i}\overline{\Lambda}_i=\frac{1}{2}\sum_{\alpha\in\mathring{\Delta}_+}\mu_\alpha\alpha. \tag{4.1}$$

Fix $\xi\in\mathring{\mathfrak{h}}^*$ such that $\langle\xi,\alpha^\vee\rangle\neq\mathbb{Z}/\gamma_\alpha+\tau\mathbb{Z}$ for all $\alpha\in\Delta^{\mathrm{re}}$. We define $\hat{R}_\alpha\in\mathrm{End}_{\mathbb{C}}\mathcal{M}$ for $\alpha\in\Delta^{\mathrm{re}}$ by

$$\hat{R}_\alpha:=H_\alpha(\mu_\alpha)-H_\alpha(\langle\xi,\alpha^\vee\rangle)\circ s_\alpha, \tag{4.2}$$

where $H_\alpha(\eta)$ is a multiplication operator with the following function on $\mathbb{H}$:

$$H_\alpha(\eta)(h):=\frac{\vartheta_1(-\gamma_\alpha\mu_\alpha;\gamma_\alpha\tau)}{\vartheta_1(-\gamma_\alpha\eta;\gamma_\alpha\tau)}\,\frac{\vartheta_1(\mathrm{af}(\alpha)(h)-\gamma_\alpha\eta;\gamma_\alpha\tau)}{\vartheta_1(\mathrm{af}(\alpha)(h);\gamma_\alpha\tau)}. \tag{4.3}$$

By the property (2.16), one sees that $wH_\alpha(\eta)(h)=H_{w\alpha}(\eta)(h)$ and, in particular, $\tau_\lambda\hat{R}_\alpha\tau_{-\lambda}=\hat{R}_{\tau_\lambda\alpha}={}^{\tau_\lambda}\hat{R}_\alpha$.

Theorem IV.1 (Refs. 7 and 8): *The map $\pi:R_\alpha\mapsto\hat{R}_\alpha$, $\tau_\lambda\mapsto\tau_\lambda$ induces a homomorphism from $\mathcal{R}$ to $\mathrm{End}_{\mathbb{C}}\mathcal{M}$. These R-matrices satisfy the unitarity*

$$\hat{R}_\alpha\hat{R}_{-\alpha}=\left(\frac{\vartheta_1(-\gamma_\alpha\mu_\alpha;\gamma_\alpha\tau)}{\vartheta_1'(0;\gamma_\alpha\tau)}\right)^2(\wp(\gamma_\alpha\mu_\alpha;1,\gamma_\alpha\tau)-\wp(\gamma_\alpha\langle\xi,\alpha^\vee\rangle;1,\gamma_\alpha\tau))\mathrm{Id}_{\mathcal{M}}. \tag{4.4}$$

We employ these operators even for the affine root systems of rank 2, though they do not have any Coxeter relations.

Besides the representation above, we have more general forms that depend on the relation among $Q,Q^\vee,M$.[7,8] We classified them from the viewpoint of characters of integrable highest weight modules with positive levels. In particular, the operators of type $A_{2l}^{(2)}$ include nine parameters. In the rest of this section and the next section, we study the representation in Theorem IV.1 for the type $X_N^{(r)}\neq A_{2l}^{(2)}$ and we will deal with the type $A_{2l}^{(2)}$ in Sec. VI independently. In the case $X_N^{(r)}\neq A_{2l}^{(2)}$, we have

$$a_0=1,\quad \nu^{-1}(\theta)=\theta^\vee,\quad \mu_{\alpha_0}=\mu_\theta. \tag{4.5}$$

We shall clarify some properties of the operators $\hat{Y}^\lambda=\pi(Y^\lambda)$ for minuscule weights and the quasi-minuscule weight. Let $\mathbb{T}$ be the torus $\mathring{\mathfrak{h}}_{\mathbb{R}}/\mathring{Q}^\vee\subset\mathbb{H}$. Let $\mathcal{M}^{\mathring{W}}$ be the $\mathring{W}$-invariant subspace of $\mathcal{M}$. Let $\mathcal{M}_\lambda:=\{f|f\in\mathcal{M},f$ is holomorphic in a neighborhood of $\cup_{0\leqslant a\leqslant 1}(\mathrm{af}(\tau_{-a\lambda})\mathbb{T})\}$. □

Lemma IV.2: $\hat{R}_\alpha\in\mathrm{End}_{\mathbb{C}}(\mathcal{M}_0)$ $(\alpha\in\mathring{\Delta})$. *If $\kappa\notin\mathbb{Z}/\gamma_\alpha+\mathbb{Z}\tau$, then $\hat{R}_{\theta+\delta}\in\mathrm{End}_{\mathbb{C}}(\mathcal{M}_\theta,\mathcal{M}_0)$.*

Proof: Let $\alpha\in\mathring{\Delta}$ and $f\in\mathcal{M}_0$. Then a possible pole of $\hat{R}_\alpha f$ on $\mathbb{T}$ is h_0 such that $\mathrm{af}(\alpha)(h_0)=\langle\alpha,h_0\rangle\in\mathbb{Z}$ and vanishes since

$$f(h_0)-f(\mathrm{af}(s_\alpha)(h_0))=0, \tag{4.6}$$

by $\mathrm{af}(s_\alpha)(h_0)=h_0-\langle\alpha,h_0\rangle\alpha^\vee\equiv h_0(\mathrm{mod}\,\mathring{Q}^\vee)$.

The latter statement is implied by the fact that if $\kappa\notin\mathbb{Z}/\gamma_\alpha+\mathbb{Z}\tau$ and $f\in\mathcal{M}_\theta$, the functions $H_{\theta+\delta}(\eta)(h)$ in $\hat{R}_{\theta+\delta}$, $f(h)$ and $f(h-(\langle\theta,h\rangle+\kappa)\theta^\vee)$ are holomorphic in the neighborhood of $\mathbb{T}$. □

Theorem IV.3: *Let* $\xi=-\mathring{\rho}_\mu$. *Then* $\hat{Y}^\lambda\in\mathrm{End}_{\mathbb{C}}(\mathcal{M}_\lambda^{\mathring{W}},\mathcal{M}_0^{\mathring{W}})$ *for a minuscule weight* $-\lambda$. *In addition, if* $\kappa\notin\mathbb{Z}/\gamma_\alpha+\mathbb{Z}\tau$, *then* $\hat{Y}^{-\theta}\in\mathrm{End}_{\mathbb{C}}(\mathcal{M}_{-\theta}^{\mathring{W}},\mathcal{M}_0^{\mathring{W}})$.

Proof: It is obvious that $\tau_\lambda\in\mathrm{End}_{\mathbb{C}}(\mathcal{M}_\lambda,\mathcal{M}_{-\lambda})$. By construction, $\hat{Y}^\lambda$ takes the form of $\hat{R}_\alpha\hat{R}_\beta\cdots\hat{R}_\gamma\tau_\lambda$. For a minuscule weight, we see that from Theorem III.2, $\hat{Y}^\lambda$ consists of only non affine R-matrices, thus by Lemma IV.2 and $\mathcal{M}_{-\lambda}\subset\mathcal{M}_0$, we have

$$\mathcal{M}_\lambda\xrightarrow{\tau_\lambda}\mathcal{M}_{-\lambda}\subset\mathcal{M}_0\xrightarrow{\hat{R}_\gamma}\cdots\xrightarrow{\hat{R}_\alpha}\mathcal{M}_0, \tag{4.7}$$

and $\hat{Y}^\lambda\in\mathrm{End}_{\mathbb{C}}(\mathcal{M}_\lambda,\mathcal{M}_0)$. For the quasi-minuscule weight, the rightmost R-matrix in $\hat{Y}^{-\theta}$ is $\hat{R}_{\theta+\delta}$ and the others are nonaffine R-matrices.[7,8] By Lemma IV.2, we have

$$\mathcal{M}_{-\theta}\xrightarrow{\tau_{-\theta}}\mathcal{M}_\theta\xrightarrow{\hat{R}_{\theta+\delta}}\mathcal{M}_0\xrightarrow{\hat{R}_\gamma}\cdots\xrightarrow{\hat{R}_\alpha}\mathcal{M}_0, \tag{4.8}$$

and $\hat{Y}^{-\theta}\in\mathrm{End}_{\mathbb{C}}(\mathcal{M}_{-\theta},\mathcal{M}_0)$. In Refs. 7 and 8, we have shown that if $\xi=-\mathring{\rho}_\mu$, $\hat{Y}^\lambda\in\mathrm{End}_{\mathbb{C}}(\mathcal{M}^{\mathring{W}})$, which completes the proof.

For minuscule weights $-\lambda$ and the quasi-minuscule weight θ, we have the explicit forms of the operators on the space $\mathcal{M}^{\mathring{W}}$. In the following, we fix $\xi=-\mathring{\rho}_\mu$.

Theorem IV.4 (Refs. 7 and 8): *We have*

$$\hat{Y}^\lambda|_{\mathcal{M}^{\mathring{W}}}=\frac{1}{|\mathring{W}_\lambda|}\sum_{w\in\mathring{W}}w\left(\prod_{\substack{\alpha\in\mathring{\Delta}_+\\(\lambda|\alpha)=-\gamma_\alpha}}\frac{\vartheta_1(\langle\alpha,h\rangle-\gamma_\alpha\mu_\alpha;\gamma_\alpha\tau)}{\vartheta_1(\langle\alpha,h\rangle;\gamma_\alpha\tau)}\tau_\lambda\right)\Bigg|_{\mathcal{M}^{\mathring{W}}}, \tag{4.9}$$

$$\begin{aligned}\hat{Y}^{-\theta}|_{\mathcal{M}^{\mathring{W}}}=\frac{1}{|\mathring{W}_\theta|}\sum_{w\in\mathring{W}}w\Bigg(&\left(\prod_{\substack{\alpha\in\mathring{\Delta}_+\\(\theta|\alpha)>0}}\frac{\vartheta_1(\langle\alpha,h\rangle-\gamma_\alpha\mu_\alpha;\gamma_\alpha\tau)}{\vartheta_1(\langle\alpha,h\rangle;\gamma_\alpha\tau)}\right)\\&\times\left(\frac{\vartheta_1(\langle\theta,h\rangle+\kappa-\mu_\theta;\tau)}{\vartheta_1(\langle\theta,h\rangle+\kappa;\tau)}\tau_{-\theta}-\frac{\vartheta_1(-\mu_\theta;\tau)}{\vartheta_1((\mathring{\rho}_\mu|\theta);\tau)}\frac{\vartheta_1(\langle\theta,h\rangle+\kappa+(\mathring{\rho}_\mu|\theta);\tau)}{\vartheta_1(\langle\theta,h\rangle+\kappa;\tau)}\right)\Bigg)\Bigg|_{\mathcal{M}^{\mathring{W}}},\end{aligned} \tag{4.10}$$

where $\mathring{W}_\lambda$ *is the stabilizer of* λ *in* $\mathring{W}$.

Remark IV.5: The number of the minuscule weights is the same as the order of Ω. There is no minuscule weight available in the root systems of type $E_8^{(1)}$, $F_4^{(1)}$, $G_2^{(1)}$, $A_{2l}^{(2)}$, $E_6^{(2)}$ and $D_4^{(3)}$ since their Dynkin diagrams have no automorphism. However, every root system possesses the quasi-minuscule weight $\nu(\theta^\vee)$.

The following lemma is needed in the proof of the essential self-adjointness, which indicates that the term without shift operators in $\hat{Y}^{-\theta}$ is a bounded self-adjoint operator.

Lemma IV.6: The function

$$\hat{Y}_1^{-\theta}(h) := \frac{\vartheta_1(\mu_\theta;\tau)}{\vartheta_1((\mathring{\rho}_\mu|\theta);\tau)} \frac{1}{|\mathring{W}_\theta|} \sum_{w\in\mathring{W}} \left(w\left(\prod_{\substack{\alpha\in\mathring{\Delta}_+ \\ (\theta|\alpha)>0}} \frac{\vartheta_1(\langle\alpha,h\rangle-\gamma_\alpha\mu_\alpha;\gamma_\alpha\tau)}{\vartheta_1(\langle\alpha,h\rangle;\gamma_\alpha\tau)} \right) \times\left(\frac{\vartheta_1(\langle\theta,h\rangle+\kappa+(\mathring{\rho}_\mu|\theta);\tau)}{\vartheta_1(\langle\theta,h\rangle+\kappa;\tau)} \right) \right) \tag{4.11}$$

is a function on $\mathring{\mathfrak{h}}/(\mathring{Q}^\vee+\tau\nu^{-1}(\hat{M}))$. *Moreover, if* $\tau\in i\mathbb{R}_{>0}$, $\kappa,\mu_\alpha\in i\mathbb{R}$ *and* $\kappa\notin\mathbb{Z}\tau$, *then* $\hat{Y}_1^{-\theta}(h)$ *is real-valued and continuous on* $\mathbb{T}$ *and thus has bounds*

$$-\infty<m_Y\leqslant\hat{Y}_1^{-\theta}(h)\leqslant M_Y<\infty,\quad h\in\mathbb{T}. \tag{4.12}$$

Proof: First we check that the function can be regarded as a function on $\mathring{\mathfrak{h}}/(\mathring{Q}^\vee+\tau\nu^{-1}(\hat{M}))$. For $h\to h+\beta^\vee$, the multiplicity is 1. For $h\to h+\tau\lambda(\lambda\in\nu^{-1}(\hat{M}))$, the multiplicity is

$$\exp 2\pi i\left(\sum_{\substack{\alpha\in\mathring{\Delta}_+ \\ (\theta|\alpha)>0}} \mu_\alpha\langle\alpha,\lambda\rangle-\langle\theta,\lambda\rangle(\mathring{\rho}_\mu|\theta) \right) = \exp 2\pi i\left(\sum_{\alpha\in\mathring{\Delta}_+} \frac{\mu_\alpha}{\gamma_\alpha}\langle\alpha,\theta^\vee\rangle\langle\alpha,\lambda\rangle-\mu_\theta\langle\theta,\lambda\rangle-(\mathring{\rho}_\mu|\theta)\langle\theta,\lambda\rangle \right), \tag{4.13}$$

where we have used the properties of θ (2.22). For the moment, we admit that

$$\sum_{\alpha\in\mathring{\Delta}_+} \frac{\mu_\alpha}{\gamma_\alpha}\langle\alpha,\theta^\vee\rangle\langle\alpha,\lambda\rangle=((\mathring{\rho}_\mu|\theta)+\mu_\theta)\langle\theta,\lambda\rangle, \tag{4.14}$$

then the multiplicity is 1 and the former statement follows.

Next we verify that all the poles on $\mathring{\mathfrak{h}}_\mathbb{R}$ vanish. Take $\beta\in\mathring{\Delta}$ and $h_0\in\mathring{\mathfrak{h}}_\mathbb{R}$ such that $\langle\beta,h_0\rangle\in\mathbb{Z}$ and $\langle\alpha,h_0\rangle\notin\mathbb{Z}$ for $\alpha(\neq\beta)\in\mathring{\Delta}$. Let $F(x,y;\gamma):=\vartheta_1(x+y;\gamma\tau)/\vartheta_1(x;\gamma\tau)$. Note that $F(x+1,y,\gamma)=F(x,y,\gamma)$. Then the residue at $c=0$ in the coordinate $h=h_0+c\beta^\vee/2$ is

$$\vartheta_1(-\gamma_\alpha\mu_\alpha;\gamma_\alpha\tau)\left(\sum_{\substack{w\in\mathring{W} \\ \beta\in w\Delta^\theta}} \left(\prod_{\substack{\alpha\in\Delta^\theta \\ w\alpha\neq\beta}} F(\langle w\alpha,h_0\rangle,-\gamma_\alpha\mu_\alpha;\gamma_\alpha) \right)(F(\langle w\theta,h_0\rangle+\kappa,(\mathring{\rho}_\mu|\theta);1)) \right.$$

$$\left. -\sum_{\substack{w\in\mathring{W} \\ -\beta\in w\Delta^\theta}} \left(\prod_{\substack{\alpha\in\Delta^\theta \\ w\alpha\neq-\beta}} F(\langle w\alpha,h_0\rangle,-\gamma_\alpha\mu_\alpha;\gamma_\alpha) \right)(F(\langle w\theta,h_0\rangle+\kappa,(\mathring{\rho}_\mu|\theta);1)) \right), \tag{4.15}$$

where $\Delta^\theta:=\{\alpha\in\mathring{\Delta}_+|\langle\alpha,\theta^\vee\rangle>0\}$. By replacing $w\to s_\beta w$ in the second term, we see that this residue vanishes since $\langle\beta,h_0\rangle=n\in\mathbb{Z}$ implies $s_\beta(h_0)=h_0-n\beta^\vee$ and $\langle\mathring{\Delta},\beta^\vee\rangle\in\mathbb{Z}$. By the Riemann theorem, the function is holomorphic in a neighborhood of h_0. The function $\hat{Y}_1^{-\theta}$ is real-valued on $\mathbb{T}$ because for $a\in\mathbb{R}$, $\overline{\vartheta_1(\langle\alpha,h\rangle+ia;\gamma_\alpha\tau)}=\vartheta_1(-\langle\alpha,h\rangle+ia;\gamma_\alpha\tau)$ and there exists $w_0\in\mathring{W}$ such that $w_0\mathring{\Delta}_+=\mathring{\Delta}_-$ and $w_0\theta=-\theta$.

Lemma IV.7: Let $L:\mathring{\mathfrak{h}}\to\mathring{\mathfrak{h}}$ *be a linear operator defined by*

$$L:h\mapsto\sum_{\alpha\in\mathring{\Delta}_+}\frac{\mu_\alpha}{\gamma_\alpha}\nu^{-1}(\alpha)\langle\alpha,h\rangle. \tag{4.16}$$

Then $L(h)=((\mathring{\rho}_\mu|\theta)+\mu_\theta)h$. *In particular,*

$$(\theta^\vee|L(\lambda))=\sum_{\alpha\in\mathring{\Delta}_+}\frac{\mu_\alpha}{\gamma_\alpha}\langle\alpha,\theta^\vee\rangle\langle\alpha,\lambda\rangle=((\mathring{\rho}_\mu|\theta)+\mu_\theta)\langle\theta,\lambda\rangle. \tag{4.17}$$

Proof: We see $L\in\mathrm{End}_{\mathring{W}}(\mathring{\mathfrak{h}})$. Since $\mathring{W}$ acts on $\mathring{\mathfrak{h}}^*$ irreducibly, Schur's lemma implies that $L(h)=a\,h$ for some $a\in\mathbb{C}$. We calculate this factor a. We have

$$L(\theta^\vee)=\sum_{\alpha\in\mathring{\Delta}_+}\frac{\mu_\alpha}{\gamma_\alpha}\nu^{-1}(\alpha)\langle\alpha,\theta^\vee\rangle=\sum_{\substack{\alpha\in\mathring{\Delta}_+\\ \langle\alpha,\theta^\vee\rangle\neq 0}}\mu_\alpha\nu^{-1}(\alpha)+\mu_\theta\theta^\vee=a\,\theta^\vee. \tag{4.18}$$

Applying $\langle\theta,\cdot\rangle$, we have

$$2a=\sum_{\substack{\alpha\in\mathring{\Delta}_+\\ (\alpha|\theta)\neq 0}}\mu_\alpha(\alpha|\theta)+2\mu_\theta=2(\mathring{\rho}_\mu|\theta)+2\mu_\theta, \tag{4.19}$$

thus $a=(\mathring{\rho}_\mu|\theta)+\mu_\theta$. □

V. ESSENTIAL SELF-ADJOINTNESS OF TYPE $X_N^{(r)}\neq A_{2l}^{(2)}$

A. Essential self-adjointness of elliptic Calogero–moser models

In the differential limit, the models are called the elliptic Calogero–Moser models. Because the Hamiltonians of these models are typical Schrödinger operators, we can establish the self-adjointness by use of well-developed perturbation theory.[21] First we briefly observe this fact.

The Hamiltonians of the Calogero–Sutherland models and the elliptic Calogero–Moser models are respectively given by

$$H_{\mathrm{T}}:=-\Delta+\sum_{\alpha\in\mathring{\Delta}_+}g_\alpha\frac{1}{\sin^2(2\pi\langle\alpha,h\rangle)}, \tag{5.1}$$

$$H_{\mathrm{E}}:=-\Delta+\sum_{\alpha\in\mathring{\Delta}_+}g_\alpha\wp(\langle\alpha,h\rangle;1,\gamma_\alpha\tau), \tag{5.2}$$

where the coupling constant g_α is a real number and invariant under the action of the Weyl group $\mathring{W}$ as $g_\alpha=g_{w\alpha}$. Δ is the Laplacian on $\mathbb{T}$. Let $L^2(\mathbb{T},d\mu)^{\mathring{W}}$ be the Hilbert space of $\mathring{W}$-invariant square integrable functions on $\mathbb{T}$ equipped with the inner product

$$(f,g):=\int_{\mathbb{T}}\overline{f}\cdot g\,d\mu, \tag{5.3}$$

where μ is the normalized Haar measure. We denote by $\|\cdot\|:=(\cdot,\cdot)^{1/2}$ the norm in $L^2(\mathbb{T},d\mu)^{\mathring{W}}$.

In the trigonometric case, if we adopt an appropriate domain $\mathcal{C}$ to the Hamiltonian (5.1), we can show its essential self-adjointness. Admitting this fact, we show that the elliptic models is essentially self-adjoint with the same domain.

Theorem V.1: *The Hamiltonian* (5.2) *is essentially self-adjoint on* $\mathcal{C}$.

Proof: We rewrite $H_{\mathrm{E}}=A+H_{\mathrm{T}}$, where $A=(H_{\mathrm{E}}-H_{\mathrm{T}})$. We see that

$$\|Au\| = \left(\int_{\mathbb{T}} \left| \sum_{\alpha \in \mathring{\Delta}_+} g_\alpha \left(\wp(\langle \alpha, h \rangle; 1, \gamma_\alpha \tau) - \frac{1}{\sin^2(2\pi \langle \alpha, h \rangle)} \right) u(h) \right|^2 d\mu \right)^{1/2}$$
$$\leqslant c\|u\|, \tag{5.4}$$

for a constant c, since the integrand is a continuous function on $\mathbb{T}$. This implies that A is bounded. The symmetry of the operator A is trivial. Then we deduce that $A + H_{\mathrm{T}}$ is essentially self-adjoint on $\mathcal{C}$. □

As is seen above, in the differential cases the essential self-adjointness of the elliptic models can be easily shown since they are relatively bounded to the trigonometric models with the relative bound 0 from the viewpoint of the Kato–Rellich theorem. We show that this theorem works well even in the difference cases, where we apply perturbation method to free particle systems instead of the corresponding trigonometric models.

B. Symmetry

Let $\tau \in i\mathbb{R}_{>0}$ and $\kappa, \mu_\alpha \in i\mathbb{R}$. Hereafter we fix $\xi = -\mathring{\rho}_\mu$ and restrict the domain of $\hat{Y}^\lambda$ to $\mathring{W}$-invariant functions. We treat μ_α as parameters of perturbation and suppose μ_α moves on pure imaginary numbers. Let n_0 be the number of the orbits of the roots and let $P_{\boldsymbol{\mu}} := i\mathbb{R}^{n_0}$. The topology on the space $P_{\boldsymbol{\mu}}$ of parameters $\boldsymbol{\mu} = (\mu_\alpha)$ is given by

$$d(\boldsymbol{\mu}, \boldsymbol{\mu}') := \max_{|\alpha|} \gamma_\alpha |\mu_\alpha - \mu'_\alpha|. \tag{5.5}$$

We denote $\boldsymbol{\mu}_0 = (\mu_\alpha = -\kappa) \in P_{\boldsymbol{\mu}}$ which is the start point of the perturbation.

Let $w_0 \in \mathring{W}$ such that $w_0 \mathring{\Delta}_+ = \mathring{\Delta}_-$. Then $w_0 \theta = -\theta$ and if $-\lambda$ is minuscule, $w_0 \lambda$ is also minuscule. Due to this observation, we see that the operator $\hat{Y}^\lambda$ for a minuscule weight or the quasi-minuscule weight coincides with $\hat{Y}^{-w_0\lambda}$ whose parameters κ and μ_α are replaced by $-\kappa$ and $-\mu_\alpha$, respectively. So we assume $\Im \kappa > 0$ without loss of generality. We set

$$p = e^{2\pi i \tau}, \quad q = e^{2\pi i \kappa}, \quad t_\alpha = e^{-2\pi i \mu_\alpha \gamma_\alpha}, \tag{5.6}$$

and define the meromorphic functions $m_\pm$ on $\mathbb{H}$ by

$$m_\pm(\mathbf{t} = (t_\alpha)) := e^{\pm \mathring{\rho}_\mu / \kappa} \prod_{\alpha \in \mathring{\Delta}_\pm} \frac{(e^\alpha; p^{\gamma_\alpha}, q^{\gamma_\alpha})_\infty}{(t_\alpha e^\alpha; p^{\gamma_\alpha}, q^{\gamma_\alpha})_\infty} \frac{(p^{\gamma_\alpha} q^{\gamma_\alpha} t_\alpha^{-1} e^{-\alpha}; p^{\gamma_\alpha}, q^{\gamma_\alpha})_\infty}{(p^{\gamma_\alpha} q^{\gamma_\alpha} e^{-\alpha}; p^{\gamma_\alpha}, q^{\gamma_\alpha})_\infty}. \tag{5.7}$$

We note that this function is a generalization of one introduced in Refs. 11 and 22. For the moment, we work with the variables p, q and t_α instead of τ, κ and μ_α. Let $P_{\mathbf{t}} := (0, \infty)^{n_0}$. Then t_α moves on $P_{\mathbf{t}}$. The start point $\boldsymbol{\mu}_0$ of the perturbation is $\mathbf{t}_0 = (t_\alpha = q^{\gamma_\alpha}) \in P_{\mathbf{t}}$ in this variable. The topology is induced on the space $P_{\mathbf{t}}$ by (5.6). We often write $\hat{Y}^\lambda = \hat{Y}^\lambda(\mathbf{t})$ in order to stress the dependency of $\mathbf{t}$. Let $m := m_+ m_-$ be a $\mathring{W}$-invariant function. On $\mathbb{T}$, we have $m_-(h) = m_+(-h) = \overline{m_+(h)}$ and $m(h) = (wm)(h) = (wm_+)(h)(wm_+)(-h)$ for $w \in \mathring{W}$, and in particular, $m(h)$ is an almost everywhere positive continuous function, $0 \leqslant m(\mathbf{t})(h) \leqslant M_{\mathbf{t}}$ and $\mu\{m(\mathbf{t})(h) = 0\} = 0$. Define the complex conjugate of $h = h_0 + ih_1 \in \mathbb{H}$ by $h^* = h_0 - ih_1$, where $h_0 \in \mathbb{T}$ and $h_1 \in \mathring{\mathfrak{h}}_{\mathbb{R}}$. Let $L^2(\mathbb{T}, m(\mathbf{t}) d\mu)^{\mathring{W}}$ be the Hilbert space equipped with the inner product

$$(f, g)_{\mathbf{t}} := \int_{\mathbb{T}} \overline{f(h)} g(h) m(\mathbf{t})(h). \tag{5.8}$$

For arbitrary $\lambda \in \mathring{\mathfrak{h}}^*_{\mathbb{R}}$, we see that $f \in \mathcal{M}_\lambda^{\mathring{W}}$ is continuous on $\mathbb{T}$, thus $f|_{\mathbb{T}} \in L^2(\mathbb{T}, m(\mathbf{t})d\mu)^{\mathring{W}}$. On the other hand, if $f \in L^2(\mathbb{T}, m(\mathbf{t})d\mu)^{\mathring{W}}$ almost everywhere coincides with $g \in \mathcal{M}_\lambda^{\mathring{W}}$ on $\mathbb{T}$, then it is unique. Hence we can embed $\mathcal{M}_\lambda^{\mathring{W}} \subset L^2(\mathbb{T}, m(\mathbf{t})d\mu)^{\mathring{W}}$ by restricting its domain to $\mathbb{T}$.

The function m_+ is related to $\hat{Y}^\lambda$ for minuscule weights $(-\lambda)$ and $\hat{Y}^{-\theta}$ as follows:

Proposition V.2: We have

$$\hat{Y}^\lambda(\mathbf{t}) = \frac{1}{|\mathring{W}_\lambda|} \sum_{w \in \mathring{W}} w\left(\frac{\tau_\lambda m_+(\mathbf{t})}{m_+(\mathbf{t})} \tau_\lambda \right), \tag{5.9}$$

$$\hat{Y}^{-\theta}(\mathbf{t}) = \frac{1}{|\mathring{W}_\theta|} \sum_{w \in \mathring{W}} w\left(\frac{\tau_{-\theta} m_+(\mathbf{t})}{m_+(\mathbf{t})} \tau_{-\theta} \right) + \hat{Y}_1^{-\theta}(\mathbf{t}). \tag{5.10}$$

Proof: It follows from the definition of the function m_+ (5.7) and the infinite product form of the Jacobi theta functions (2.25). □

We define the ''leading term'' of the operators $\hat{Y}^\lambda(\mathbf{t})$ which coincides with that defined in Refs. 7 and 8 in terms of a partial order in $\hat{M}_-$. For $\lambda \in \hat{M}_-$, let

$$\hat{Y}_0^\lambda(\mathbf{t}) := \frac{1}{|\mathring{W}_\lambda|} \sum_{w \in \mathring{W}} w\left(\frac{\tau_\lambda m_+(\mathbf{t})}{m_+(\mathbf{t})} \tau_\lambda \right). \tag{5.11}$$

Lemma V.3: Assume $p^n \neq q$ for $n \in \mathbb{Z}_{\geqslant 1}$. Then $\hat{Y}_0^{-\theta}(\mathbf{t}) \in \mathrm{End}_{\mathbb{C}}(\mathcal{M}_{-\theta}^{\mathring{W}}, \mathcal{M}_0^{\mathring{W}})$.

Proof: By Theorem IV.3 and Lemma IV.6, We have $\hat{Y}^{-\theta}(\mathbf{t})$, $\hat{Y}_1^{-\theta}(\mathbf{t}) \in \mathrm{End}_{\mathbb{C}}(\mathcal{M}_{-\theta}^{\mathring{W}}, \mathcal{M}_0^{\mathring{W}})$. Thus $\hat{Y}_0^{-\theta}(\mathbf{t}) = \hat{Y}^{-\theta}(\mathbf{t}) - \hat{Y}_1^{-\theta}(\mathbf{t}) \in \mathrm{End}_{\mathbb{C}}(\mathcal{M}_{-\theta}^{\mathring{W}}, \mathcal{M}_0^{\mathring{W}})$.

Lemma V.4: Let $\lambda \in \mathring{\mathfrak{h}}^*_{\mathbb{R}}$. Then $\mathcal{M}_\lambda^{\mathring{W}}$ is dense in $L^2(\mathbb{T}, m(\mathbf{t})d\mu)^{\mathring{W}}$.

Since a similar statement will be shown later, we give the proof as a remark after Proposition V.9 and proceed to the next step. The following theorem is shown similarly to the trigonometric cases[23,24] and a partial result is obtained in Ref. 25.

Theorem V.5: *Let $P_{\mathbf{t}}^{\mathrm{sym}} := (0,1)^{n_0} \subset P_{\mathbf{t}}$ and suppose $\mathbf{t} \in P_{\mathbf{t}}^{\mathrm{sym}}$. Then on $\mathcal{M}_\lambda^{\mathring{W}}$ and with respect to $(\cdot,\cdot)_{\mathbf{t}}$,*

(1) $\hat{Y}^\lambda$ for a minuscule weight is symmetric, and

(2) $\hat{Y}^{-\theta}$ is symmetric if $p < q$.

They are semi-bounded below and thus admit a self-adjoint extension.

Proof: We show that $(\hat{Y}^\lambda f, g)_{\mathbf{t}} = (f, \hat{Y}^\lambda g)_{\mathbf{t}}$ for $f, g \in \mathcal{M}_\lambda^{\mathring{W}}$.

First we prove the statement for a minuscule weight $(-\lambda)$ with the expression (5.9):

$$\begin{aligned}
(\hat{Y}^\lambda f, g)_{\mathbf{t}} &= \frac{1}{|\mathring{W}_\lambda|} \int_{\mathbb{T}} \sum_{w \in \mathring{W}} \overline{\frac{w(\tau_\lambda(m_+ f))(h)}{(w m_+)(h)}} \cdot g(h) m(h) \\
&= \frac{1}{|\mathring{W}_\lambda|} \int_{\mathbb{T}} \sum_{w \in \mathring{W}} \overline{\frac{w(\tau_\lambda(m_+ f))(h)}{(w m_+)(h)}} \cdot (w(m_+ g))(h)(w m_+)(-h) \\
&= \frac{1}{|\mathring{W}_\lambda|} \int_{\mathbb{T}} \sum_{w \in \mathring{W}} w(\overline{(\tau_\lambda(m_+ f))(h)} \cdot m_+ g(h)) \\
&= \frac{1}{|\mathring{W}_\lambda|} \int_{\mathbb{T}} \sum_{w \in \mathring{W}} w((\tau_{-\lambda}(m_- f^*))(h) \cdot m_+ g(h)),
\end{aligned} \tag{5.12}$$

where $f^*(h) := \overline{f(h^*)} \in \mathcal{M}^{\mathring{W}}_{-\lambda}$. Each term in the integrand has no poles on $\mathbb{T}$ due to the assumption $\mathbf{t} \in P^{\mathrm{sym}}_{\mathbf{t}}$ and the definition of $\mathcal{M}^{\mathring{W}}_{\lambda}$, then we can examine it separately. We have by the Cauchy theorem

$$\begin{aligned}
&\frac{1}{|\mathring{W}_\lambda|}\int_{\mathbb{T}} \sum_{w\in\mathring{W}} w((\tau_{-\lambda}(m_- f^*))(h)\cdot m_+ g(h)) \\
&\quad = \frac{|\mathring{W}|}{|\mathring{W}_\lambda|}\int_{\mathbb{T}} (\tau_{-\lambda}(m_- f^*))(h)\cdot m_+ g(h) \\
&\quad = \frac{|\mathring{W}|}{|\mathring{W}_\lambda|}\int_{\mathbb{T}} (m_- f^*)(h)\cdot (\tau_{\lambda}(m_+ g))(h) \\
&\quad = \frac{1}{|\mathring{W}_\lambda|}\int_{\mathbb{T}} \sum_{w\in\mathring{W}} w(\overline{(m_+ f)(h)}\cdot (\tau_{\lambda}(m_+ g))(h)) \\
&\quad = (f, \hat{Y}^\lambda g)_{\mathbf{t}}. \qquad (5.13)
\end{aligned}$$

For positivity, we have

$$\begin{aligned}
(\hat{Y}^\lambda f, f)_{\mathbf{t}} &= \frac{|\mathring{W}|}{|\mathring{W}_\lambda|}\int_{\mathbb{T}} (\tau_{-\lambda}(m_- f^*))(h)\cdot m_+ f(h) \\
&= \frac{|\mathring{W}|}{|\mathring{W}_\lambda|}\int_{\mathbb{T}} (\tau_{-\lambda/2}(m_- f^*))(h)\cdot (\tau_{\lambda/2}(m_+ f))(h) \\
&= \frac{|\mathring{W}|}{|\mathring{W}_\lambda|}\int_{\mathbb{T}} |(\tau_{\lambda/2}(m_+ f))(h)|^2 \\
&\geqslant 0. \qquad (5.14)
\end{aligned}$$

Next we prove the symmetry for the quasi-minuscule weight θ. Set $\lambda = -\theta$. A similar calculation for the case for a minuscule weight yields

$$\begin{aligned}
(\hat{Y}^\lambda f, g)_{\mathbf{t}} &= (\hat{Y}^\lambda_0 f, g)_{\mathbf{t}} + (\hat{Y}^\lambda_1 f, g)_{\mathbf{t}} \\
&= \frac{1}{|\mathring{W}_\lambda|}\int_{\mathbb{T}} \sum_{w\in\mathring{W}} w(\overline{(\tau_\lambda(m_+ f))(h)}\cdot m_+ g(h)) + \int_{\mathbb{T}} \overline{(\hat{Y}^\lambda_1 f)(h)}\cdot g(h) m(h) \\
&= \frac{|\mathring{W}|}{|\mathring{W}_\lambda|}\int_{\mathbb{T}} (\tau_{-\lambda}(m_- f^*))(h)\cdot m_+ g(h) + \int_{\mathbb{T}} \overline{(\hat{Y}^\lambda_1 f)(h)}\cdot g(h) m(h), \qquad (5.15)
\end{aligned}$$

where we have used Lemma V.3 to calculate the integrals above independently. It is sufficient to show that

$$\int_{\mathbb{T}} (\tau_{-\lambda}(m_- f^*))(h)\cdot m_+ g(h) = \int_{\mathbb{T}} (m_- f^*)(h)\cdot (\tau_{\lambda} m_+ g)(h) \qquad (5.16)$$

and

$$\int_{\mathrm{T}} \overline{(\hat{Y}_1^{\lambda} f)(h)} \cdot g(h) m(h) = \int_{\mathrm{T}} \overline{f(h)} \cdot (\hat{Y}_1^{\lambda} g)(h) m(h). \tag{5.17}$$

The first identity is implied by the Cauchy theorem due to $\mathbf{t} \in P_{\mathbf{t}}^{\mathrm{sym}}$, and $p<q$. The second identity follows from $\overline{\hat{Y}_1^{\lambda}(h)} = \hat{Y}_1^{\lambda}(h)$ by Lemma IV.6, which shows the symmetry. Again by Lemma IV.6,

$$(\hat{Y}^{\lambda} f, f)_{\mathbf{t}} = \frac{|\mathring{W}|}{|\mathring{W}_{\lambda}|} \int_{\mathrm{T}} |(\tau_{\lambda/2}(m_+ f))(h)|^2 + m_Y \|f\|_{\mathbf{t}}^2 \geqslant m_Y \|f\|_{\mathbf{t}}^2. \tag{5.18}$$

In both cases, the operator $\hat{Y}^{\lambda}$ is semi-bounded below. Thus they admit a self-adjoint extension by the Friedrichs–Freudenthal theorem.[26] □

C. Essential self-adjointness of unperturbed Hamiltonians

The essential self-adjointness of the unperturbed operator $\hat{Y}^{\lambda}(\mathbf{t}_0)$ on $\mathcal{M}_{\lambda}^{\mathring{W}}$ is shown directly by constructing all the eigenvectors of the leading term.

Theorem V.6: *Let* $(-\lambda)$ *be a minuscule weight or the quasi-minuscule weight* θ. *Assume*

$$\begin{aligned} &p<q, \quad \text{if } \lambda \text{ is a minuscule weight,} \\ &p<q^2, \quad \text{otherwise.} \end{aligned} \tag{5.19}$$

Then $\hat{Y}^{\lambda}(\mathbf{t}_0)$ *is essentially self-adjoint on* $\mathcal{M}_{\lambda}^{\mathring{W}}$ *and semi-bounded below with respect to* $(\cdot,\cdot)_{\mathbf{t}_0}$.

To prove Theorem V.6, we introduce the Schur functions, the characters of finite dimensional representations of simple Lie algebras. In terms of skew-symmetric functions

$$a_{\mu} := \sum_{w \in \mathring{W}} (-1)^{\ell(w)} e^{w\mu}, \tag{5.20}$$

the Schur functions are defined for $\mu \in \mathring{P}_+$ as

$$s_{\mu} := \frac{a_{\mu+\mathring{\rho}}}{a_{\mathring{\rho}}}. \tag{5.21}$$

It is well known that the Schur functions form a basis of $\mathbb{C}[\mathring{P}]^{\mathring{W}}$. Define

$$D := \prod_{\alpha \in \mathring{\Delta}} (p^{\gamma_\alpha} e^{\alpha}; p^{\gamma_\alpha})_{\infty}, \quad S_{\mu} := \frac{1}{|\mathring{W}|^{1/2}} \frac{s_{\mu}}{D}, \tag{5.22}$$

$$\mathcal{D} := \frac{1}{D} \mathbb{C}[\mathring{P}]^{\mathring{W}}. \tag{5.23}$$

Then due to the condition (5.19), one sees that $\mathcal{D} \subset \mathcal{M}_{\lambda}^{\mathring{W}}$. The functions $a_{\mathring{\rho}}$, D have the following properties:

$$w a_{\mathring{\rho}} = (-1)^{\ell(w)} a_{\mathring{\rho}}, \tag{5.24}$$

$$wD = D, \tag{5.25}$$

$$m_+(\mathbf{t}_0)=(-1)^{|\mathring{\Delta}_+|}a_{\mathring{\rho}}D, \tag{5.26}$$

$$m(\mathbf{t}_0)=a_{\mathring{\rho}}D\overline{a_{\mathring{\rho}}D}, \tag{5.27}$$

where $w\in\mathring{W}$.

Lemma V.7: $\mathbb{C}[\mathring{P}]$ *is dense in the space* $C(\mathbb{T})$ *of continuous functions on* $\mathbb{T}$ *equipped with the max norm* $\|\cdot\|_{\max}$.

Proof: $1,e^{\lambda}e^{\mu}=e^{\lambda+\mu},\overline{e^{\lambda}}=e^{-\lambda}\in\mathbb{C}[\mathring{P}]$, and for arbitrary $h,h'\in\mathbb{T}$, there exists $\lambda\in\mathring{P}$ such that $e^{\lambda}(h-h')\neq 1$. Then the statement is due to the Stone–Weierstrass theorem.

Lemma V.8: $L^2(\mathbb{T},d\mu)^{\mathring{W}}\subset L^2(\mathbb{T},m(\mathbf{t})d\mu)^{\mathring{W}}$.

Proof: The proof is implied by the inequality on $\mathbb{T}$:

$$|m(\mathbf{t})(h)|\leqslant M_{\mathbf{t}}<\infty. \tag{5.28}$$

Proposition V.9: $\mathcal{D}$ *is dense in* $L^2(\mathbb{T},m(\mathbf{t})d\mu)^{\mathring{W}}$.

Proof: Suppose $f\in L^2(\mathbb{T},m(\mathbf{t})d\mu)^{\mathring{W}}$. One sees that the measure $m(\mathbf{t})d\mu$ is regular. Hence for an arbitrary $\epsilon>0$, there exists a continuous function $\hat{f}_c$ such that $\|f-\hat{f}_c\|_{\mathbf{t}}<\epsilon/2$. Put $f_c=(\Sigma_{w\in\mathring{W}}w\hat{f}_c)/|\mathring{W}|$. Then

$$\|f-f_c\|_{\mathbf{t}}=\frac{1}{|\mathring{W}|}\left\|\sum_{w\in\mathring{W}}w(f-\hat{f}_c)\right\|_{\mathbf{t}}\leqslant\|f-\hat{f}_c\|_{\mathbf{t}}<\epsilon/2. \tag{5.29}$$

Since on $\mathbb{T}$, D is continuous and $0<m_D<|D(h)|<M_D<\infty$ and $f_c\in C(\mathbb{T})^{\mathring{W}}$, we can choose $f_p\in\mathbb{C}[\mathring{P}]^{\mathring{W}}$ such that $\|f_cD-f_p\|_{\max}<\epsilon m_D^{1/2}/(2M_{\mathbf{t}}^{1/2})$ thus $\|f_c-f_p/D\|<\epsilon/(2M_{\mathbf{t}}^{1/2})$, where we have used $\mu(\mathbb{T})=1$. Hence

$$\|f-f_p/D\|_{\mathbf{t}}\leqslant\|f-f_c\|_{\mathbf{t}}+M_{\mathbf{t}}^{1/2}\|f_c-f_p/D\|<\epsilon. \tag{5.30}$$

□

Remark V.10: As in the proof of Proposition V.9, one can show that $\mathbb{C}[\mathring{P}]^{\mathring{W}}$ is dense in $L^2(\mathbb{T},m(\mathbf{t})d\mu)^{\mathring{W}}$. Since $\mathbb{C}[\mathring{P}]^{\mathring{W}}\subset\mathcal{M}_{\lambda}^{\mathring{W}}$ for $\lambda\in\mathring{\mathfrak{h}}_{\mathbb{R}}^*$, we have the proof of Lemma V.4.

Propositon V.11: $\{S_\mu\}$ *forms a complete orthonormal system in* $L^2(\mathbb{T},m(\mathbf{t}_0)d\mu)^{\mathring{W}}$.

Proof: By Proposition V.9 and the fact that $\{S_\mu\}$ spans $\mathcal{D}$, it is sufficient to show that $(S_\mu,S_\nu)_{\mathbf{t}_0}=\delta_{\mu\nu}$. A direct calculation shows

$$\begin{aligned}(S_\mu,S_\nu)_{\mathbf{t}_0}&=\int_{\mathbb{T}}\overline{S_\mu}S_\nu m(\mathbf{t}_0)\\&=\frac{1}{|\mathring{W}|}\int_{\mathbb{T}}\left(\overline{\frac{a_{\mu+\mathring{\rho}}}{a_{\mathring{\rho}}D}}\right)\frac{a_{\nu+\mathring{\rho}}}{a_{\mathring{\rho}}D}a_{\mathring{\rho}}D\overline{a_{\mathring{\rho}}D}\\&=\frac{1}{|\mathring{W}|}\int_{\mathbb{T}}(\overline{a_{\mu+\mathring{\rho}}})a_{\nu+\mathring{\rho}}\\&=\frac{1}{|\mathring{W}|}\sum_{v,w\in\mathring{W}}(-1)^{\ell(wv)}\delta_{w(\mu+\mathring{\rho}),v(\nu+\mathring{\rho})}\\&=\delta_{\mu\nu},\end{aligned} \tag{5.31}$$

where we have used the fact that $w(\mu+\mathring{\rho})=v(\nu+\mathring{\rho})$ is equivalent to $v=w$ and $\mu=\nu$ since for $\mu\in\mathring{P}_+$, the $\mathring{W}$-orbit of $\mu+\mathring{\rho}$ meets the fundamental domain once and uniquely. □

Proposition V.12: Let $\lambda\in\hat{M}_-$. *Then*

$$\hat{Y}_0^{\lambda}(\mathbf{t}_0)S_\mu=E_\mu^{\lambda}S_\mu, \tag{5.32}$$

where

$$E_\mu^{\lambda}=\frac{1}{|\mathring{W}_\lambda|}\sum_{w\in\mathring{W}} q^{(\lambda|w(\mu+\mathring{\rho}))}\in\mathbb{R}_{>0}. \tag{5.33}$$

Proof:

$$\begin{aligned}
&\frac{1}{|\mathring{W}_\lambda|}\sum_{w\in\mathring{W}} w\left(\frac{\tau_\lambda m_+(\mathbf{t}_0)}{m_+(\mathbf{t}_0)}\tau_\lambda\right)S_\mu\\
&\quad=\frac{1}{|\mathring{W}_\lambda|}\frac{1}{|\mathring{W}|^{1/2}}\sum_{w\in\mathring{W}} w\left(\frac{\tau_\lambda a_{\mathring{\rho}}D}{a_{\mathring{\rho}}D}\tau_\lambda\left(\frac{a_{\mu+\mathring{\rho}}}{a_{\mathring{\rho}}D}\right)\right)\\
&\quad=\frac{1}{|\mathring{W}_\lambda|}\frac{1}{|\mathring{W}|^{1/2}}\sum_{w\in\mathring{W}} w\left(\frac{\tau_\lambda a_{\mu+\mathring{\rho}}}{a_{\mathring{\rho}}D}\right)\\
&\quad=\frac{1}{|\mathring{W}_\lambda|}\frac{1}{|\mathring{W}|^{1/2}}\frac{1}{a_{\mathring{\rho}}D}\sum_{w\in\mathring{W}}(-1)^{\ell(w)}w\left(\tau_\lambda\sum_{v\in\mathring{W}}(-1)^{\ell(v)}e^{v(\mu+\mathring{\rho})}\right)\\
&\quad=\frac{1}{|\mathring{W}_\lambda|}\frac{1}{|\mathring{W}|^{1/2}}\frac{1}{a_{\mathring{\rho}}D}\sum_{v,w\in\mathring{W}}(-1)^{\ell(wv)}q^{(\lambda|v(\mu+\mathring{\rho}))}e^{wv(\mu+\mathring{\rho})}\\
&\quad=\frac{1}{|\mathring{W}_\lambda|}\left(\sum_{w\in\mathring{W}} q^{(\lambda|w(\mu+\mathring{\rho}))}\right)S_\mu.
\end{aligned}\tag{5.34}$$

□

Proof of Theorem V.6: First we show that the leading term of $\hat{Y}^{\lambda}(\mathbf{t}_0)$ is essentially self-adjoint. It is sufficient to show that the range of $\hat{Y}_0^{\lambda}(\mathbf{t}_0)\pm i$ is dense in $L^2(\mathbb{T},m(\mathbf{t}_0)d\mu)^{\mathring{W}}$.[27,28] By Propositions V.11 and V.12, we have $(\hat{Y}_0^{\lambda}(\mathbf{t}_0)\pm i)S_\mu=(E_\mu^{\lambda}\pm i)S_\mu$ and deduce that its range is dense.

For a minuscule weight $(-\lambda)$, the leading term $\hat{Y}_0^{\lambda}(\mathbf{t}_0)$ coincides with the operator $\hat{Y}^{\lambda}(\mathbf{t}_0)$ itself, i.e., $\hat{Y}^{\lambda}(\mathbf{t}_0)=\hat{Y}_0^{\lambda}(\mathbf{t}_0)$. Hence the essential self-adjointness of $\hat{Y}^{\lambda}(\mathbf{t}_0)$ follows.

For the quasi-minuscule weight $-\lambda=\theta$, by Lemma IV.6, one sees that the operator $\hat{Y}_1^{\lambda}(\mathbf{t}_0)=\hat{Y}^{\lambda}(\mathbf{t}_0)-\hat{Y}_0^{\lambda}(\mathbf{t}_0)$ is a real bounded operator, which implies $\hat{Y}^{\lambda}(\mathbf{t}_0)=\hat{Y}_0^{\lambda}(\mathbf{t}_0)+\hat{Y}_1^{\lambda}(\mathbf{t}_0)$ is essentially self-adjoint.

The semi-boundedness follows from Theorem V.5 or is directly shown by $E_\mu^{\lambda}>0$ and $(\hat{Y}_1^{\lambda}(\mathbf{t}_0))(h)\geqslant m_Y$ on $\mathbb{T}$.

D. Essential self-adjointness

Now we are in position to discuss the essential self-adjointness of $\hat{Y}^{\lambda}(\mathbf{t})$.

Theorem V.13. (cf. Kato–Rellich): *Let V be a Hilbert space equipped with two equivalent inner products $(\cdot,\cdot)_1$, $(\cdot,\cdot)_2$. Suppose that T_1 and T_2 are linear operators defined on a dense subspace* D *and that T_1 is symmetric with respect to $(\cdot,\cdot)_1$ and T_2 is essentially self-adjoint with respect to $(\cdot,\cdot)_2$. If there exists $a\geqslant 0$ and $0\leqslant b<1$ such that*

$$\|(T_2-T_1)u\|_2 \leqslant a\|u\|_2+b\|T_2u\|_2, \quad u\in \mathsf{D}, \tag{5.35}$$

then T_1 *is essentially self-adjoint on* D *with respect to* $(\cdot,\cdot)_1$.

Proof: The proof is essentially due to Ref. 21. We may assume without loss of generality that there exists $a'>0$ and $0<b'<1$ such that

$$\|(T_2-T_1)u\|_2 < \|(b'T_2 \pm ia')u\|_2, \quad u\in \mathsf{D}. \tag{5.36}$$

Since T_2 is essentially self-adjoint, $(T_2\pm ic')$ has a dense range R in V and a bounded inverse. With $(T_2\pm ic')u=v$, this gives

$$\|(T_2-T_1)R(\mp ic',T_2)v\|_2 \leqslant b'\|v\|_2, \quad c'=a'/b', \quad v\in \mathsf{R}, \tag{5.37}$$

where $R(\zeta,T):=(T-\zeta)^{-1}$ denotes the resolvent of the operator T. $B_\pm := (T_2-T_1)R(\mp ic',T_2)$ is a bounded operator defined on the dense subspace R. Since $b'<1$, the Neumann series implies that the bounded inverse of the closure $1-\widetilde{B}_\pm=(1-B_\pm)^{\sim}$ exists, so that the range of $1-B_\pm$ is dense. On the other hand,

$$\begin{aligned} 1-B_\pm &= 1-((T_2\pm ic')-(T_1\pm ic'))R(\mp ic',T_2) \\ &= (T_1\pm ic')R(\mp ic',T_2), \end{aligned} \tag{5.38}$$

which shows that the range of $T_1\pm ic'$ is dense. Since $\|\cdot\|_1$ and $\|\cdot\|_2$ define the same topology on V, the range of $T_1\pm ic'$ is also dense with respect to the norm $\|\cdot\|_1$. The symmetry of T_1 completes the proof. □

Remark V.14: For Theorem V.13 it is sufficient that the topology defined by $\|\cdot\|_2$ is stronger than that defined by $\|\cdot\|_1$, i.e., $\|\cdot\|_1 \leqslant c\|\cdot\|_2$ for some $c>0$.

Proposition V.15: Let

$$P_{\mathbf{t}}^{\mathrm{iso}} := \{\mathbf{t}\in P_{\mathbf{t}} \,|\, p^{\gamma_\alpha n}q^{\gamma_\alpha m}\neq t_\alpha, n,m\in \mathbb{Z}_{\geqslant 1}\}, \tag{5.39}$$

and $\mathbf{t},\mathbf{t}'\in P_{\mathbf{t}}^{\mathrm{iso}}$. *Then* $L^2(\mathbb{T},m(\mathbf{t})d\mu)^{\mathring{W}}=L^2(\mathbb{T},m(\mathbf{t}')d\mu)^{\mathring{W}}$ *as a set. Furthermore, the identity map* $\iota: f\mapsto f$ *gives an isomorphism as a Banach space.*

Proof: The inequality on $\mathbb{T}$,

$$0<m_{\mathbf{t},\mathbf{t}'}\leqslant \frac{m(\mathbf{t})}{m(\mathbf{t}')}(h)\leqslant M_{\mathbf{t},\mathbf{t}'}<\infty, \tag{5.40}$$

leads to $L^2(\mathbb{T},m(\mathbf{t})d\mu)^{\mathring{W}}=L^2(\mathbb{T},m(\mathbf{t}')d\mu)^{\mathring{W}}$ as a set and

$$m_{\mathbf{t},\mathbf{t}'}^{1/2}\|\cdot\|_{\mathbf{t}'}\leqslant\|\cdot\|_{\mathbf{t}}\leqslant M_{\mathbf{t},\mathbf{t}'}^{1/2}\|\cdot\|_{\mathbf{t}'}. \tag{5.41}$$

□

Notice that $\mathbf{t}_0\in P_{\mathbf{t}}^{\mathrm{iso}}$ and that if $\mathbf{t}\notin P_{\mathbf{t}}^{\mathrm{iso}}$, then $L^2(\mathbb{T},m(\mathbf{t}_0)d\mu)^{\mathring{W}}\neq L^2(\mathbb{T},m(\mathbf{t})d\mu)^{\mathring{W}}$ as a set. Thus we can not apply Theorem V.13 in this case. We temporally set $\mathbf{t}\in P_{\mathbf{t}}^{\mathrm{iso}}$ for simplicity and remedy it later.

Theorem V.16: *Let* $(-\lambda)$ *be a minuscule weight or the quasi-minuscule weight* θ. *Assume* p, q *satisfy* (5.19) *and* $\mathbf{t}=(t_\alpha)\in P_{\mathbf{t}}^{\mathrm{iso}}\cap P_{\mathbf{t}}^{\mathrm{sym}}$. *If* $d(\mathbf{t},\mathbf{t}_0)<\epsilon$ *for sufficiently small* $\epsilon>0$, *then* $\hat{Y}^\lambda(\mathbf{t})$ *is essentially self-adjoint on* $\mathcal{M}_\lambda^{\mathring{W}}$ *and semi-bounded below with respect to* $(\cdot,\cdot)_{\mathbf{t}}$.

Proof: We have shown that $\hat{Y}^{\lambda}(\mathbf{t})$ is symmetric and semi-bounded below on $L^2(\mathbb{T}, m(\mathbf{t})d\mu)^{\mathring{W}}$ with domain $\mathcal{M}_{\lambda}^{\mathring{W}}$. First we show the statement for a minuscule weight. It is sufficient to prove that if $d(\mathbf{t},\mathbf{t}_0)<\epsilon$ for sufficiently small $\epsilon>0$, then there exists $0<b<1$ such that

$$\|(\hat{Y}^{\lambda}(\mathbf{t}_0)-\hat{Y}^{\lambda}(\mathbf{t}))f\|_{\mathbf{t}_0}\leqslant b\|\hat{Y}^{\lambda}(\mathbf{t}_0)f\|_{\mathbf{t}_0}, \quad f\in\mathcal{D}. \tag{5.42}$$

We estimate the left hand side of (5.42):

$$\begin{aligned}\hat{Y}^{\lambda}(\mathbf{t}_0)-\hat{Y}^{\lambda}(\mathbf{t}) &= \frac{1}{|\mathring{W}_{\lambda}|}\sum_{w\in\mathring{W}} w\left(\left(\frac{\tau_{\lambda}m_+(\mathbf{t}_0)}{m_+(\mathbf{t}_0)}-\frac{\tau_{\lambda}m_+(\mathbf{t})}{m_+(\mathbf{t})}\right)\tau_{\lambda}\right)\\ &= \frac{1}{|\mathring{W}_{\lambda}|}\sum_{w\in\mathring{W}} w\left(\delta(\mathbf{t})\frac{\tau_{\lambda}m_+(\mathbf{t}_0)}{m_+(\mathbf{t}_0)}\tau_{\lambda}\right),\end{aligned} \tag{5.43}$$

where $\delta(\mathbf{t})\in C(\mathbb{T})$ is given by

$$\delta(\mathbf{t}):=1-\left(\tau_{\lambda}\frac{m_+(\mathbf{t})}{m_+(\mathbf{t}_0)}\right)\left(\frac{m_+(\mathbf{t}_0)}{m_+(\mathbf{t})}\right). \tag{5.44}$$

Let $f\in\mathcal{D}$:

$$\begin{aligned}\|(\hat{Y}^{\lambda}(\mathbf{t}_0)-\hat{Y}^{\lambda}(\mathbf{t}))f\|_{\mathbf{t}_0}^2 &= \left\|\frac{1}{|\mathring{W}_{\lambda}|}\sum_{w\in\mathring{W}} w\left(\delta(\mathbf{t})\frac{\tau_{\lambda}m_+(\mathbf{t}_0)}{m_+(\mathbf{t}_0)}\tau_{\lambda}\right)f\right\|_{\mathbf{t}_0}^2\\ &= \frac{1}{|\mathring{W}_{\lambda}|^2}\int_{\mathbb{T}}\left|\sum_{w\in\mathring{W}} w\left(\delta(\mathbf{t})\frac{\tau_{\lambda}m_+(\mathbf{t}_0)}{m_+(\mathbf{t}_0)}\tau_{\lambda}f\right)\right|^2 m(\mathbf{t}_0)\\ &\leqslant \frac{|\mathring{W}|}{|\mathring{W}_{\lambda}|^2}\int_{\mathbb{T}}\sum_{w\in\mathring{W}}|w\delta(\mathbf{t})|^2\left|w\left(\frac{\tau_{\lambda}m_+(\mathbf{t}_0)}{m_+(\mathbf{t}_0)}\tau_{\lambda}f\right)\right|^2|wm_+(\mathbf{t}_0)|^2\\ &= \frac{|\mathring{W}|}{|\mathring{W}_{\lambda}|^2}\sum_{w\in\mathring{W}}\int_{\mathbb{T}}|w\delta(\mathbf{t})|^2|w\tau_{\lambda}(m_+(\mathbf{t}_0)f)|^2\\ &\leqslant \frac{|\mathring{W}|^2}{|\mathring{W}_{\lambda}|^2}\|\delta(\mathbf{t})\|_{\max}^2\int_{\mathbb{T}}|\tau_{\lambda}(m_+(\mathbf{t}_0)f)|^2\\ &= c(\mathbf{t})\int_{\mathbb{T}}|\tau_{\lambda}(m_+(\mathbf{t}_0)f)|^2\\ &= c(\mathbf{t})\|\tau_{\lambda}(m_+(\mathbf{t}_0)f)\|^2,\end{aligned} \tag{5.45}$$

where

$$c(\mathbf{t}):=(|\mathring{W}/\mathring{W}_{\lambda}|\|\delta(\mathbf{t})\|_{\max})^2. \tag{5.46}$$

By substituting $f=\Sigma_{\mu}b_{\mu}S_{\mu}$, $b_{\mu}\in\mathbb{C}$, we evaluate the norm as follows:

$$\int_{\mathbb{T}} |\tau_\lambda(m_+(\mathbf{t}_0)f)|^2 = \frac{1}{|\mathring{W}|}\int_{\mathbb{T}} \left| \sum_\mu b_\mu \tau_\lambda\left(a_{\mathring{\rho}} D\left(\frac{a_{\mu+\mathring{\rho}}}{a_{\mathring{\rho}} D} \right) \right) \right|^2$$

$$= \frac{1}{|\mathring{W}|}\int_{\mathbb{T}} \left| \sum_\mu b_\mu \tau_\lambda(a_{\mu+\mathring{\rho}}) \right|^2$$

$$= \frac{1}{|\mathring{W}|}\int_{\mathbb{T}} \left| \sum_\mu b_\mu \left(\sum_{v\in \mathring{W}} (-1)^{\ell(v)} q^{(\lambda|v(\mu+\mathring{\rho}))} e^{v(\mu+\mathring{\rho})} \right) \right|^2$$

$$= \frac{1}{|\mathring{W}|}\sum_\mu |b_\mu|^2 \left(\sum_{v\in \mathring{W}} q^{2(\lambda|v(\mu+\mathring{\rho}))} \right). \tag{5.47}$$

Finally we have

$$\|(\hat{Y}^\lambda(\mathbf{t}_0) - \hat{Y}^\lambda(\mathbf{t}))f\|_{\mathbf{t}_0}^2 \leqslant \frac{c(\mathbf{t})}{|\mathring{W}|}\sum_\mu |b_\mu|^2 \left(\sum_{v\in \mathring{W}} q^{2(\lambda|v(\mu+\mathring{\rho}))} \right). \tag{5.48}$$

Then we compute the right hand side of (5.42). By Proposition V.11,

$$\|\hat{Y}^\lambda(\mathbf{t}_0)f\|_{\mathbf{t}_0}^2 = \left\| \sum_\mu b_\mu \frac{1}{|\mathring{W}_\lambda|}\left(\sum_{w\in \mathring{W}} q^{(\lambda|w(\mu+\mathring{\rho}))} \right) S_\mu \right\|_{\mathbf{t}_0}^2$$

$$= \sum_\mu |b_\mu|^2 \frac{1}{|\mathring{W}_\lambda|^2}\left(\sum_{w\in \mathring{W}} q^{(\lambda|w(\mu+\mathring{\rho}))} \right)^2. \tag{5.49}$$

Since

$$\sum_{w\in \mathring{W}} q^{2(\lambda|w(\mu+\mathring{\rho}))} < \left(\sum_{w\in \mathring{W}} q^{(\lambda|w(\mu+\mathring{\rho}))} \right)^2, \tag{5.50}$$

we arrive at

$$\|(\hat{Y}^\lambda(\mathbf{t}_0) - \hat{Y}^\lambda(\mathbf{t}))f\|_{\mathbf{t}_0} < (|\mathring{W}|^{1/2}\|\delta(\mathbf{t})\|_{\max})\|\hat{Y}^\lambda(\mathbf{t}_0)f\|_{\mathbf{t}_0}. \tag{5.51}$$

We can show that $\delta(\mathbf{t})\to 0$ in $C(\mathbb{T})$, when $\mathbf{t}\to\mathbf{t}_0$ in $P_{\mathbf{t}}$. Equivalently, for $\mathbf{t}$ such that $d(\mathbf{t},\mathbf{t}_0)<\epsilon$ for sufficiently small $\epsilon>0$,

$$(|\mathring{W}|^{1/2}\|\delta(\mathbf{t})\|_{\max}) \leqslant 1, \tag{5.52}$$

which shows the essentially self-adjointness of $\hat{Y}^\lambda(\mathbf{t})$ with Proposition V.15 and Theorem V.13. See the Appendix for detail about (5.52).

For the quasi-minuscule weight $-\lambda=\theta$, we perform a perturbation from an essentially self-adjoint operator $\hat{Y}_0^\lambda(\mathbf{t}_0)$ instead of $\hat{Y}^\lambda(\mathbf{t}_0)$, i.e., we show there exist $a\geqslant 0$ and $0<b<1$ such that

$$\|(\hat{Y}_0^\lambda(\mathbf{t}_0) - \hat{Y}^\lambda(\mathbf{t}))f\|_{\mathbf{t}_0} \leqslant a\|f\|_{\mathbf{t}_0} + b\|\hat{Y}_0^\lambda(\mathbf{t}_0)f\|_{\mathbf{t}_0}, \quad f\in\mathcal{D}. \tag{5.53}$$

A similar calculation yields

$$\|(\hat{Y}_0^\lambda(\mathbf{t}_0) - \hat{Y}^\lambda(\mathbf{t}))f\|_{\mathbf{t}_0} \leqslant M_Y\|f\|_{\mathbf{t}_0} + (|\mathring{W}|^{1/2}\|\delta(\mathbf{t})\|_{\max})\|\hat{Y}_0^\lambda(\mathbf{t}_0)f\|_{\mathbf{t}_0}, \quad f\in\mathcal{D}, \tag{5.54}$$

where M_Y is an upper bound of $\hat{Y}_1^{\lambda}(\mathbf{t})$ in Lemma IV.6. □

Corollary V.17: Under the same condition in Theorem V.16, $\hat{Y}^{\lambda}(\mathbf{t})$ consists of pure point spectrum.

Proof: By the proof of Theorem V.13

$$R(ic',\hat{Y}^{\lambda}(\mathbf{t})^{\sim})=R(ic',\hat{Y}_0^{\lambda}(\mathbf{t}_0)^{\sim})(1-\widetilde{B}_-)^{-1}. \tag{5.55}$$

Since $\hat{Y}_0^{\lambda}(\mathbf{t}_0)^{\sim}$ consists of only point spectrum, its resolvent is a compact operator. Combining the fact that compact operators form an ideal in bounded operators, we deduce that the resolvent $R(ic',\hat{Y}^{\lambda}(\mathbf{t})^{\sim})$ is compact and thus $\hat{Y}^{\lambda}(\mathbf{t})$ consists of pure point spectrum. □

Remark V.18: In Theorem V.5, we have roughly estimated a lower bound of the operator $\hat{Y}^{\lambda}(\mathbf{t})$. We can estimate it more accurately. A lower bound of the operator $\hat{Y}_0^{\lambda}(\mathbf{t}_0)$ is obtained as

$$\begin{aligned}\frac{1}{|\mathring{W}_{\lambda}|}\sum_{w\in\mathring{W}} q^{(\lambda|w(\mu+\mathring{\rho}))} &\geqslant \frac{|\mathring{W}|}{|\mathring{W}_{\lambda}|}\left(\prod_{w\in\mathring{W}} q^{(\lambda|w(\mu+\mathring{\rho}))}\right)^{1/|\mathring{W}|}\\ &=|\mathring{W}/\mathring{W}_{\lambda}|, \quad \text{for all } \mu\in\mathring{P}_+.\end{aligned} \tag{5.56}$$

Thus for a minuscule weight, from (5.14),

$$\begin{aligned}(\hat{Y}^{\lambda}(\mathbf{t})f,f)_{\mathbf{t}} &= \frac{|\mathring{W}|}{|\mathring{W}_{\lambda}|}\int_{\mathrm{T}}|(\tau_{\lambda/2}(m_+(\mathbf{t})f))(h)|^2\\ &\geqslant b_{\lambda}\frac{|\mathring{W}|}{|\mathring{W}_{\lambda}|}\int_{\mathrm{T}}|(\tau_{\lambda/2}(m_+(\mathbf{t}_0)f))(h)|^2\\ &\geqslant \frac{b_{\lambda}}{|\mathring{W}_{\lambda}|}(\hat{Y}^{\lambda}(\mathbf{t}_0)f,f)_{\mathbf{t}_0}\\ &\geqslant \frac{b_{\lambda}}{|\mathring{W}_{\lambda}|}|\mathring{W}/\mathring{W}_{\lambda}|(f,f)_{\mathbf{t}_0}\\ &\geqslant \frac{b_{\lambda}m_{\mathbf{t}_0,\mathbf{t}}}{|\mathring{W}_{\lambda}|}|\mathring{W}/\mathring{W}_{\lambda}|(f,f)_{\mathbf{t}},\end{aligned} \tag{5.57}$$

where

$$b_{\lambda}=\min_{T}\left|\tau_{\lambda/2}\frac{m_+(\mathbf{t})}{m_+(\mathbf{t}_0)}\right|^2\geqslant 0. \tag{5.58}$$

If t_{α} satisfies

$$p^{\gamma_{\alpha}n}q^{\gamma_{\alpha}m/2}\neq t_{\alpha}, \quad n,m\in\mathbb{Z}_{\geqslant 1}, \tag{5.59}$$

then b_{λ} is positive and $\hat{Y}^{\lambda}(\mathbf{t})$ is positive definite. As for the quasi-minuscule weight, from (5.18),

$$
\begin{aligned}
(\hat{Y}^{\lambda}(\mathbf{t})f,f)_{\mathbf{t}} &= \frac{|\mathring{W}|}{|\mathring{W}_{\lambda}|}\int_{\mathbb{T}}|(\tau_{\lambda/2}(m_{+}(\mathbf{t})f))(h)|^2 + m_Y\|f\|_{\mathbf{t}}^2 \\
&\geqslant b_{\lambda}\frac{|\mathring{W}|}{|\mathring{W}_{\lambda}|}\int_{\mathbb{T}}|(\tau_{\lambda/2}(m_{+}(\mathbf{t}_0)f))(h)|^2 + m_Y\|f\|_{\mathbf{t}}^2 \\
&= \frac{b_{\lambda}}{|\mathring{W}_{\lambda}|}(\hat{Y}_0^{\lambda}(\mathbf{t}_0)f,f)_{\mathbf{t}_0} + m_Y\|f\|_{\mathbf{t}}^2 \\
&\geqslant \frac{1}{|\mathring{W}_{\lambda}|}(b_{\lambda}m_{\mathbf{t}_0,\mathbf{t}}|\mathring{W}/\mathring{W}_{\lambda}| + m_Y|\mathring{W}_{\lambda}|)(f,f)_{\mathbf{t}}. \qquad (5.60)
\end{aligned}
$$

We have postponed the case $\mathbf{t}\notin P_{\mathbf{t}}^{\mathrm{iso}}$. In this case, $L^2(\mathbb{T},m(\mathbf{t}_0)d\mu)^{\mathring{W}} \neq L^2(\mathbb{T},m(\mathbf{t})d\mu)^{\mathring{W}}$ as a set. In fact, the identity map $\iota: f\mapsto f$ is bounded and injective. The boundedness follows from the inequality $\|\cdot\|_{\mathbf{t}}\leqslant M_{\mathbf{t},\mathbf{t}_0}^{1/2}\|\cdot\|_{\mathbf{t}_0}$ where the constant $M_{\mathbf{t},\mathbf{t}_0}$ is from (5.40), and the injectivity follows from the fact that the measures of the zeroes of the functions $m(\mathbf{t}_0)$ and $m(\mathbf{t})$ are 0 with respect to μ. Moreover, we see that the range of ι is dense in $L^2(\mathbb{T},m(\mathbf{t})d\mu)^{\mathring{W}}$. Motivated by this observation, we need the following theorem which is a generalization of Theorem V.13.

Theorem V.19: *Let V_1 and V_2 be Hilbert spaces respectively equipped with inner products $(\cdot,\cdot)_1$ and $(\cdot,\cdot)_2$. Let $\iota: V_2\to V_1$ be a bounded and injective linear operator such that the range of ι is dense in V_1. Suppose that T_1 and T_2 are linear operators in V_2 defined on a dense subspace D and that $\iota\circ T_1\circ\iota^{-1}|_{\iota(\mathsf{D})}$ is symmetric in V_1 with respect to $(\cdot,\cdot)_1$ and T_2 is essentially self-adjoint in V_2 with respect to $(\cdot,\cdot)_2$. If there exist $a\geqslant 0$ and $0\leqslant b<1$ such that*

$$
\|(T_2-T_1)u\|_2 \leqslant a\|u\|_2 + b\|T_2u\|_2, \quad u\in\mathsf{D}, \qquad (5.61)
$$

then $\iota\circ T_1\circ\iota^{-1}|_{\iota(\mathsf{D})}$ is essentially self-adjoint on $\iota(\mathsf{D})$ with respect to $(\cdot,\cdot)_1$.

Proof: First we notice that the image by ι of a dense subspace W in V_2 is dense in V_1, which is shown as follows. Take arbitrary $u_1\in V_1$ and $\epsilon>0$. Then there exists $u_2\in V_2$ such that $\|u_1-\iota(u_2)\|_1<\epsilon/2$. For this u_2, there exists $u_2'\in W$ such that $\|u_2-u_2'\|_2<\epsilon/(2\|\iota\|)$. Hence we have

$$
\begin{aligned}
\|u_1-\iota(u_2')\|_1 &\leqslant \|u_1-\iota(u_2)\|_1 + \|\iota(u_2)-\iota(u_2')\|_1 \\
&\leqslant \|u_1-\iota(u_2)\|_1 + \|\iota\|\|u_2-u_2'\|_2 \\
&< \epsilon. \qquad (5.62)
\end{aligned}
$$

By the proof of Theorem V.13 and Remark V.14, we see that the range of $T_1\pm ic'$ is dense in V_2. Because $\iota\circ T_1\circ\iota^{-1}\pm ic'\,\mathrm{Id}_{V_1}|_{\iota(\mathsf{D})} = \iota\circ(T_1\pm ic'\,\mathrm{Id}_{V_2})\circ\iota^{-1}|_{\iota(\mathsf{D})}$, the assertion is proved. □

By Theorem V.19, we have removed the condition $\mathbf{t}\in P_{\mathbf{t}}^{\mathrm{iso}}$ in Theorem V.16 and Corollary V.17. We summarize the result obtained in this section.

Theorem V.20: *Let $(-\lambda)$ be a minuscule weight or the quasi-minuscule weight θ. Assume*

$$
\begin{cases} p<q, & \text{if } \lambda \text{ is a minuscule weight,} \\ p<q^2, & \text{otherwise} \end{cases} \qquad (5.63)
$$

and $\mathbf{t}=(t_\alpha)\in P_{\mathbf{t}}^{\mathrm{sym}}$. If $d(\mathbf{t},\mathbf{t}_0)<\epsilon$ for sufficiently small $\epsilon>0$, then $\hat{Y}^{\lambda}(\mathbf{t})$ is essentially self-adjoint on $\mathcal{M}_{\lambda}^{\mathring{W}}$ and semi-bounded below with respect to $(\cdot,\cdot)_{\mathbf{t}}$. $\hat{Y}^{\lambda}(\mathbf{t})$ consists of pure point spectrum.

So far, we have discussed the self-adjointness of the operators obtained from the formal Hamiltonians by gauge-transformation. We give the definitions of the Hamiltonians of the elliptic Ruijsenaars models by removing the weight functions. We define multiplication operators:

$$m^{-1/2}:L^2(\mathbb{T},d\mu)^{\mathring{W}}\to L^2(\mathbb{T},md\mu)^{\mathring{W}},\qquad f\mapsto fm^{-1/2},\tag{5.64}$$

$$m^{1/2}:L^2(\mathbb{T},md\mu)^{\mathring{W}}\to L^2(\mathbb{T},d\mu)^{\mathring{W}},\qquad f\mapsto fm^{1/2}.\tag{5.65}$$

These operators are bounded with norms $\|m^{-1/2}\|=\|m^{1/2}\|=1$ since

$$\|fm^{-1/2}\|_{\mathbf{t}}=\|f\|,\quad f\in L^2(\mathbb{T},d\mu)^{\mathring{W}},\tag{5.66}$$

$$\|fm^{1/2}\|=\|f\|_{\mathbf{t}},\quad f\in L^2(\mathbb{T},md\mu)^{\mathring{W}},\tag{5.67}$$

where we have used $\mu\{m=0\}=0$ for (5.66). In fact, $m^{-1/2}$ and $m^{1/2}$ are unitary operators and $(m^{1/2})^*=m^{-1/2}$. Then the composite $H^\lambda:=m^{1/2}\circ\hat{Y}^\lambda\circ m^{-1/2}$ is a densely defined linear operator with domain $\mathcal{M}^{\mathring{W}}_\lambda m^{1/2}$ on $L^2(\mathbb{T},d\mu)^{\mathring{W}}$.

Definition V.21: Fix an affine root system $X_N^{(r)}\neq A_{2l}^{(2)}$. Let $\kappa,\tau\in i\mathbb{R}_{>0}$. For $\alpha\in\Delta^{\mathrm{re}}$, let $\mu_\alpha\in i\mathbb{R}$ be $\hat{W}$-invariant constants such that $\langle\mathring{\rho}_\mu,\alpha^\vee\rangle\neq\mathbb{Z}/\gamma_\alpha+\tau\mathbb{Z}$. The elliptic Ruijsenaars model associated with affine root system $X_N^{(r)}$ is a quantum many-body system on $\mathbb{T}=\mathring{\mathfrak{h}}_{\mathbb{R}}/\mathring{Q}^\vee$, and its Hamiltonian is given by $H^\lambda=m^{1/2}\circ\hat{Y}^\lambda\circ m^{-1/2}$ and is expressed as

$$H^\lambda=\frac{1}{|\mathring{W}_\lambda|}\sum_{w\in\mathring{W}}w\left(\prod_{\substack{\alpha\in\mathring{\Delta}_+\\(\lambda|\alpha)=-\gamma_\alpha}}\frac{\vartheta_1(\langle\alpha,h\rangle-\gamma_\alpha\mu_\alpha;\gamma_\alpha\tau)}{\vartheta_1(\langle\alpha,h\rangle;\gamma_\alpha\tau)}\right)^{1/2}\times\tau_\lambda\left(\prod_{\substack{\alpha\in\mathring{\Delta}_+\\(\lambda|\alpha)=-\gamma_\alpha}}\frac{\vartheta_1(\langle\alpha,h\rangle+\gamma_\alpha\mu_\alpha;\gamma_\alpha\tau)}{\vartheta_1(\langle\alpha,h\rangle;\gamma_\alpha\tau)}\right)^{1/2},\tag{5.68a}$$

for a minuscule weight λ in $X_N^{(r)}\neq E_8^{(1)}$, $F_4^{(1)}$, $G_2^{(1)}$, $E_6^{(2)}$ or $D_4^{(3)}$, and

$$\begin{aligned}H^{-\theta}=&\frac{1}{|\mathring{W}_\theta|}\sum_{w\in\mathring{W}}w\left(\left(\prod_{\substack{\alpha\in\mathring{\Delta}_+\\(\theta|\alpha)>0}}\frac{\vartheta_1(\langle\alpha,h\rangle-\gamma_\alpha\mu_\alpha;\gamma_\alpha\tau)}{\vartheta_1(\langle\alpha,h\rangle;\gamma_\alpha\tau)}\right)\left(\frac{\vartheta_1(\langle\theta,h\rangle+\kappa-\mu_\theta;\tau)}{\vartheta_1(\langle\theta,h\rangle+\kappa;\tau)}\right)\right)^{1/2}\\&\times\tau_{-\theta}\left(\left(\prod_{\substack{\alpha\in\mathring{\Delta}_+\\(\theta|\alpha)>0}}\frac{\vartheta_1(\langle\alpha,h\rangle+\gamma_\alpha\mu_\alpha;\gamma_\alpha\tau)}{\vartheta_1(\langle\alpha,h\rangle;\gamma_\alpha\tau)}\right)\left(\frac{\vartheta_1(\langle\theta,h\rangle-\kappa+\mu_\theta;\tau)}{\vartheta_1(\langle\theta,h\rangle-\kappa;\tau)}\right)\right)^{1/2}\\&-\frac{\vartheta_1(-\mu_\theta;\tau)}{\vartheta_1((\mathring{\rho}_\mu|\theta);\tau)}\sum_{w\in\mathring{W}}w\left(\left(\prod_{\substack{\alpha\in\mathring{\Delta}_+\\(\theta|\alpha)>0}}\frac{\vartheta_1(\langle\alpha,h\rangle-\gamma_\alpha\mu_\alpha;\gamma_\alpha\tau)}{\vartheta_1(\langle\alpha,h\rangle;\gamma_\alpha\tau)}\right)\right.\\&\left.\times\left(\frac{\vartheta_1(\langle\theta,h\rangle+\kappa+(\mathring{\rho}_\mu|\theta);\tau)}{\vartheta_1(\langle\theta,h\rangle+\kappa;\tau)}\right)\right)\end{aligned}\tag{5.68b}$$

for the quasi-minuscule weight θ in $X_N^{(r)}=E_8^{(1)}$, $F_4^{(1)}$, $G_2^{(1)}$, $E_6^{(2)}$ or $D_4^{(3)}$.

We return to the original variables τ,κ,μ_α and rewrite Theorem V.20 by using the unitarity of $m^{-1/2}$ and $m^{1/2}$.

Theorem V.22: *Let*

$$P_{\boldsymbol{\mu}}^{\mathrm{sym}}:=\{\boldsymbol{\mu}=(\mu_\alpha)\mid \mu_\alpha\in i\mathbb{R}_{<0}\}, \tag{5.69}$$

and λ *be minuscule or quasi-minuscule. If*

$$\begin{gathered} 2|\kappa|<|\tau|, \quad X_N^{(r)}=E_8^{(1)},\ F_4^{(1)},\ G_2^{(1)},\ E_6^{(2)}\ \ or\ \ D_4^{(3)}, \\ |\kappa|<|\tau|, \quad otherwise, \end{gathered} \tag{5.70}$$

and $\boldsymbol{\mu}\in P_{\boldsymbol{\mu}}^{\mathrm{sym}}$ *satisfies* $|\mu_\alpha+\kappa|<\epsilon$ *for sufficiently small* $\epsilon>0$, *then the Hamiltonian* H^λ *(5.68) is essentially self-adjoint and semi-bounded below with domain* $\mathcal{M}_\lambda^{\mathring{W}}m^{1/2}$ *on* $L^2(\mathbb{T},d\mu)^{\mathring{W}}$ *and consists of pure point spectrum.*

We summarize the constraints of parameters τ,κ,μ_α that appeared above.

(1) $\kappa,\tau\in i\mathbb{R}_{>0}$, $\mu_\alpha\in i\mathbb{R}$ $(\alpha\in\Delta^{\mathrm{re}})$,

(2) $\langle\mathring{\rho}_\mu,\alpha^\vee\rangle\neq\mathbb{Z}/\gamma_\alpha+\tau\mathbb{Z}$,

(3) $\mu_\alpha\in i\mathbb{R}_{<0}$,

$|\kappa|<|\tau|$, if $X_N^{(r)}=E_8^{(1)},\ F_4^{(1)},\ G_2^{(1)},\ E_6^{(2)}$ or $D_4^{(3)}$,

(4) $2|\kappa|<|\tau|$, if $X_N^{(r)}=E_8^{(1)},\ F_4^{(1)},\ G_2^{(1)},\ E_6^{(2)}$ or $D_4^{(3)}$,

$|\kappa|<|\tau|$, otherwise,

(5) $|\mu_\alpha+\kappa|<\epsilon$ for sufficiently small $\epsilon>0$. More precisely, $\boldsymbol{\mu}$ is sufficient to satisfy $(|\mathring{W}|^{1/2}\|\delta(\mathbf{t})\|_{\max})\leqslant 1$.

In these conditions, conditions 1 and 2 are necessary. Condition 1 is required for the Hamiltonian to be a formally self-adjoint, or Hermite. By condition 2, the Hamiltonian for the quasi-minuscule weight is well-defined since the operator includes $(\mathring{\rho}_\mu|\theta)$ in the denominator. Condition 3 is essential if we choose the domain $\mathcal{M}_\lambda^{\mathring{W}}m^{1/2}$ since this condition is necessary for the Hamiltonian to be symmetric. Condition 4 enables us to construct a complete set of eigenfunctions of $\hat{Y}^\lambda(\mathbf{t}_0)$ in $\mathcal{M}_\lambda^{\mathring{W}}m^{1/2}$. Conditions 5 is set by a technical reason, i.e., depends on the perturbation. Condition 5 comes from the existence of the Neumann series in the perturbation. We may have a chance to remove conditions 3 and 4 by introducing a proper domain, and condition 5 by use of another way such as a perturbation from the trigonometric operators, i.e., the Macdonald operators.

VI. ESSENTIAL SELF-ADJOINTNESS OF TYPE $X_N^{(r)}=A_{2l}^{(2)}$

In this section, we show the essential self-adjointness of the elliptic Ruijsenaars model of type $A_{2l}^{(2)}$. For most part, we omit proofs, since they are complicated but essentially the same as in the previous sections. Sometimes we provide proofs or remarks. Throughout this section we fix the root system to $A_{2l}^{(2)}$. Here are some data concerning to this root system:

$$a_0=2, \quad \nu^{-1}(\theta)=2\theta^\vee, \quad \theta\in 2\mathring{P}, \quad \alpha_0=\tfrac{1}{2}(\delta-\theta), \quad \alpha_0^\vee=K-2\theta^\vee. \tag{6.1}$$

We begin with a general representation including Theorem IV.1. Let $\kappa,\tau\in i\mathbb{R}_{>0}$. Let $\mu_\alpha\in i\mathbb{R}$ be $\hat{W}$-invariant constants: $\mu_{\hat{w}(\alpha)}=\mu_\alpha$ for $\hat{w}\in\hat{W}$ such that $\langle\mathring{\rho}_\mu,\alpha^\vee\rangle\neq(\mathbb{Z}+\tau\mathbb{Z})/\gamma_\alpha$, where

$$\mathring{\rho}_\mu := \sum_{i\in I}^{\circ} \mu_{\alpha_i} \overline{\Lambda}_i = \frac{1}{2} \sum_{\alpha\in \mathring{\Delta}_+} \mu_\alpha \alpha. \tag{6.2}$$

Let $g_j, g_j' \in \mathbb{R}$ for $j=0,1,2,3$. Fix $\xi \in \mathring{\mathfrak{h}}^*$ such that $\langle \xi, \alpha^\vee \rangle \neq (\mathbb{Z}+\tau\mathbb{Z})/\gamma_\alpha$ for all $\alpha \in \Delta^{\mathrm{re}}$. We define $\hat{R}_\alpha \in \mathrm{End}_{\mathbb{C}}\mathcal{M}$ for $\alpha \in \Delta^{\mathrm{re}}$ by the same form as (4.2),

$$\hat{R}_\alpha := H_\alpha(\mu_\alpha) - H_\alpha(\langle \xi, \alpha^\vee \rangle) \circ s_\alpha, \tag{6.3}$$

where $H_\alpha(\eta)$ is a multiplication operator with the following function on $\mathbb{H}$:

$$H_\alpha(\eta)(h) := \begin{cases} \dfrac{\vartheta_1(-\mu_\alpha;\tau)}{\vartheta_1(-\eta;\tau)} \dfrac{\vartheta_1(\mathrm{af}(\alpha)(h)-\eta;\tau)}{\vartheta_1(\mathrm{af}(\alpha)(h);\tau)}, & \alpha \in \Delta_m, \\ \dfrac{\vartheta_1(-\mu_\alpha;\tau)}{\vartheta_1(-\eta;\tau)} \left(\displaystyle\sum_{j=0}^{3} g_j \frac{\vartheta_j(\mathrm{af}(\alpha)(h)-\eta;\tau)}{\vartheta_j(\mathrm{af}(\alpha)(h);\tau)} \right), & \alpha \in \Delta_s, \\ \dfrac{\vartheta_1(-2\mu_\alpha;\tau)}{\vartheta_1(-2\eta;\tau)} \left(\displaystyle\sum_{j=0}^{3} g_j' \frac{\vartheta_j(\mathrm{af}(\alpha)(h)/2-2\eta;\tau)}{\vartheta_j(\mathrm{af}(\alpha)(h)/2;\tau)} \right), & \alpha \in \Delta_l. \end{cases} \tag{6.4}$$

Theorem VI.1: *The map* $\pi: R_\alpha \mapsto \hat{R}_\alpha, \tau_\lambda \mapsto \tau_\lambda$ *induces a homomorphism from* $\mathcal{R}$ *to* $\mathrm{End}_{\mathbb{C}}\mathcal{M}$. *These R-matrices satisfy the unitarity*

$$\hat{R}_\alpha \hat{R}_{-\alpha} = u(\tau)\mathrm{Id}_{\mathcal{M}}, \tag{6.5}$$

where $u(\tau)$ *is independent of* $h \in \mathbb{H}$.

Analogous statements to Lemmas IV.2 and IV.6, and Theorems IV.3 and IV.4 hold for this representation.

Lemma VI.2: $\hat{R}_\alpha \in \mathrm{End}_{\mathbb{C}}(\mathcal{M}_0)$ $(\alpha \in \mathring{\Delta})$. *If* $\kappa \notin \mathbb{Z}_{\geqslant 1}\tau$, then $\hat{R}_{(\theta+\delta)/2} \in \mathrm{End}_{\mathbb{C}}(\mathcal{M}_{\theta/2}, \mathcal{M}_0)$.

Proof: From Lemma IV.2, $\hat{R}_\alpha \in \mathrm{End}_{\mathbb{C}}\mathcal{M}_0$ for $\alpha \in \mathring{\Delta}_m$. Thus it is sufficient to investigate long roots $\alpha \in \mathring{\Delta}_l$. Note that only the terms for $j=1,2$ have poles on $\mathbb{T}$. Let $f \in \mathcal{M}_0$. Then a possible pole h_0 on $\mathbb{T}$ is such that $\mathrm{af}(\alpha)(h_0) \in 2\mathbb{Z}$ for $j=1$ and $\mathrm{af}(\alpha)(h_0) \in 2\mathbb{Z}+1$ for $j=2$. By the property (6.1) $\mathrm{af}(s_\alpha)(h_0) = h_0 - \mathrm{af}(\alpha)(h_0)\alpha^\vee \equiv h_0 (\mathrm{mod}\, \mathring{Q}^\vee)$, and thus the pole on $\mathbb{T}$ vanishes.

We show the latter part. If $\kappa \notin \mathbb{Z}_{\geqslant 1}\tau$ and $f \in \mathcal{M}_\theta$, the functions $H_{(\theta+\delta)/2}(\eta)(h)$ in $\hat{R}_{(\theta+\delta)/2}$, $f(h)$ and $f(h-(\langle \theta, h\rangle + \kappa)\theta^\vee)$ are holomorphic in the neighborhood of $\mathbb{T}$. □

Theorem VI.3: *Let* $\xi = -\mathring{\rho}_\mu$. *If* $\kappa \notin \mathbb{Z}_{\geqslant 1}\tau$, *then* $\hat{Y}^{-\theta/2} \in \mathrm{End}_{\mathbb{C}}(\mathcal{M}^{\overset{\circ}{W}}_{-\theta/2}, \mathcal{M}^{\overset{\circ}{W}}_{0})$.

In the following, we fix $\xi = -\mathring{\rho}_\mu$.

Theorem VI.4:

$$\begin{aligned} \hat{Y}^{-\theta/2} = \frac{1}{|\mathring{W}_\theta|} \sum_{w\in \mathring{W}}^{\circ} w \Bigg(& \left(\prod_{\substack{\alpha \in (\mathring{\Delta}_m)_+ \\ (\theta|\alpha)>0}} \frac{\vartheta_1(\langle \alpha, h\rangle - \mu_\alpha;\tau)}{\vartheta_1(\langle \alpha, h\rangle;\tau)} \right) \left(\sum_{j=0}^{3} g_j' \frac{\vartheta_j(\langle \theta, h\rangle/2 - 2\mu_\theta;\tau)}{\vartheta_j(\langle \theta, h\rangle/2;\tau)} \right) \\ & \times \Bigg(\sum_{j=0}^{3} g_j \Bigg(\frac{\vartheta_j(\langle \theta, h\rangle/2 + \kappa/2 - \mu_{\alpha_0};\tau)}{\vartheta_j(\langle \theta, h\rangle/2 + \kappa/2;\tau)} \tau_{-\theta/2} \\ & - \frac{\vartheta_1(-\mu_{\alpha_0};\tau)}{\vartheta_1((\mathring{\rho}_\mu|\theta);\tau)} \frac{\vartheta_j(\langle \theta, h\rangle/2 + \kappa/2 + (\mathring{\rho}_\mu|\theta);\tau)}{\vartheta_j(\langle \theta, h\rangle/2 + \kappa/2;\tau)} \Bigg) \Bigg) \Bigg). \end{aligned} \tag{6.6}$$

In $A_{2l}^{(2)}$ case, we can calculate the explicit form of the second term of $\hat{Y}^{-\theta/2}$ up to a constant term.

Lemma VI.5: Set $\mu=\mu_\alpha$, $\alpha\in\Delta_m$. *The function*

$$\begin{aligned}\hat{Y}_1^{-\theta/2}(h):=&\frac{\vartheta_1(\mu_{\alpha_0};\tau)}{\vartheta_1((\mathring{\rho}_\mu|\theta);\tau)}\frac{1}{|\mathring{W}_\theta|}\sum_{w\in\mathring{W}}w\Bigg(\Bigg(\prod_{\substack{\alpha\in(\mathring{\Delta}_m)_+\\(\theta|\alpha)>0}}\frac{\vartheta_1(\langle\alpha,h\rangle-\mu;\tau)}{\vartheta_1(\langle\alpha,h\rangle;\tau)}\Bigg)\\&\times\Bigg(\sum_{j=0}^3 g'_j\frac{\vartheta_j(\langle\theta,h\rangle/2-2\mu_\theta;\tau)}{\vartheta_j(\langle\theta,h\rangle/2;\tau)}\Bigg)\Bigg(\sum_{j=0}^3 g_j\frac{\vartheta_j(\langle\theta,h\rangle/2+\kappa/2+(\mathring{\rho}_\mu|\theta);\tau)}{\vartheta_j(\langle\theta,h\rangle/2+\kappa/2;\tau)}\Bigg)\Bigg)\\=&\frac{\vartheta_1(\mu_{\alpha_0};\tau)\vartheta_1(\kappa;\tau)}{\vartheta_1(\mu;\tau)\vartheta_1(\kappa+\mu;\tau)}\sum_{j=0}^3 g_j\Bigg(\Bigg(\sum_{k=0}^3 g'_{\pi_j k}\frac{\vartheta_k(\kappa/2+2\mu_\theta;\tau)}{\vartheta_k(\kappa/2;\tau)}\Bigg)\\&\times\Bigg(\prod_{\alpha\in\mathring{\Delta}_l}\frac{\vartheta_j(\langle\alpha,h\rangle/2-\kappa/2-\mu;\tau)}{\vartheta_j(\langle\alpha,h\rangle/2-\kappa/2;\tau)}\frac{\vartheta_j(-\langle\alpha,h\rangle/2-\kappa/2-\mu;\tau)}{\vartheta_j(-\langle\alpha,h\rangle/2-\kappa/2;\tau)}\Bigg)\Bigg)\\&+F(\kappa,\mu,\mu_\theta,\mu_{\alpha_0}),\end{aligned}\tag{6.7}$$

where $F(\kappa,\mu,\mu_\theta,\mu_{\alpha_0})$ *is independent of* h, *and* π_j *are the elements of* $\mathfrak{S}_4$ *defined by* $\pi_1=id$, $\pi_2=(12)(03)$, $\pi_3=(13)(02)$, *and* $\pi_0=(01)(23)$, *is a function on* $\mathring{\mathfrak{h}}/(\mathring{Q}^\vee+\tau\nu^{-1}(\mathring{P}))$. *Moreover, if* $\kappa\notin\mathbb{Z}_{\geqslant 1}\tau$, *then* $\hat{Y}_1^{-\theta/2}(h)$ *is real-valued and continuous on* $\mathbb{T}$ *and thus has bounds*

$$-\infty<m_Y\leqslant\hat{Y}_1^{-\theta/2}(h)\leqslant M_Y<\infty,\quad h\in\mathbb{T}.\tag{6.8}$$

Proof: The proof is similar to that of Lemma IV.6. We show the equation (6.7). It is easy to see that the right hand side is periodic with respect to $\mathring{Q}^\vee+\tau\nu^{-1}(\mathring{P})$. The multiplicities of the left hand side are

$$\begin{aligned}&1,\quad h\to h+\beta^\vee\ (\beta^\vee\in\mathring{Q}^\vee),\\&\exp 2\pi i\Bigg(\sum_{\alpha\in\mathring{\Delta}_+}\frac{\mu_\alpha}{\gamma_\alpha}\langle\alpha,\theta^\vee\rangle\langle\alpha,\lambda\rangle-\langle\mathring{\rho}_\mu,\theta^\vee\rangle\langle\theta,\lambda\rangle\Bigg)=1,\quad h\to h+\tau\lambda\quad(\lambda\in\nu^{-1}(\mathring{P})),\end{aligned}\tag{6.9}$$

where we have used the properties of θ (6.1) and

$$\sum_{\alpha\in\mathring{\Delta}_+}\frac{\mu_\alpha}{\gamma_\alpha}\langle\alpha,\theta^\vee\rangle\langle\alpha,\lambda\rangle=\langle\mathring{\rho}_\mu,\theta^\vee\rangle\langle\theta,\lambda\rangle,\tag{6.10}$$

which will be implied by Lemma VI.6. By using $\{\alpha\in\mathring{\Delta}_m\,|\,(\alpha|\theta)>0\}=\{(\alpha+\theta)/2\,|\,\alpha\in\mathring{\Delta}_l,\alpha\neq\pm\theta\}$ and comparing the poles on both sides, we deduce the equality.

The latter part of the statement is clear from the right hand side. □

Lemma VI.6: Let $L:\mathring{\mathfrak{h}}\to\mathring{\mathfrak{h}}$ *be a linear operator defined by*

$$L:h\mapsto\sum_{\alpha\in\mathring{\Delta}_+}\frac{\mu_\alpha}{\gamma_\alpha}\nu^{-1}(\alpha)\langle\alpha,h\rangle.\tag{6.11}$$

Then $L(h)=(\mathring{\rho}_\mu|\theta)h$. *In particular,*

$$(\theta^\vee|L(\lambda))=\sum_{\alpha\in\mathring{\Delta}_+}\frac{\mu_\alpha}{\gamma_\alpha}\langle\alpha,\theta^\vee\rangle\langle\alpha,\lambda\rangle=\langle\mathring{\rho}_\mu,\theta^\vee\rangle\langle\theta,\lambda\rangle.\tag{6.12}$$

Remark VI.7: In Lemmas IV.7 and VI.6 the difference of the existence of the term μ_θ comes from $\gamma_\theta=2$ in $A_{2l}^{(2)}$.

Remark VI.8: The explicit form of $\hat{Y}_1^{\lambda}$ can be calculated due to the properties particular to $A_{2l}^{(2)}$, such as $\{\alpha\in\mathring{\Delta}_m \mid (\alpha|\theta)>0\}=\{(\alpha+\theta)/2 \mid \alpha\in\mathring{\Delta}_l, \alpha\neq\pm\theta\}$.

Lemma VI.9: Let $\nu_j\in\mathbb{C}$, $(j=0,1,2,3)$. *Set*

$$\nu=\sum_{j=0}^{3}\nu_j, \tag{6.13}$$

$$f_j=\frac{\vartheta_1(\nu_j;\tau)}{\vartheta_1(\nu;\tau)}\prod_{\substack{k=0\\k\neq j}}^{3}\frac{\vartheta_{\pi_j k}(\nu_k;\tau)}{\vartheta_{\pi_j k}(0;\tau)}=\frac{\vartheta_1(\nu_j;\tau)}{\vartheta_1(\nu;\tau)}\frac{\pi}{\vartheta_1'(0;\tau)}\prod_{\substack{k=0\\k\neq j}}^{3}\vartheta_{\pi_j k}(\nu_k;\tau). \tag{6.14}$$

Then the following identity holds:

$$\sum_{j=0}^{3}f_j\frac{\vartheta_j(x-\nu;\tau)}{\vartheta_j(x;\tau)}=\prod_{j=0}^{3}\frac{\vartheta_j(x-\nu_j;\tau)}{\vartheta_j(x;\tau)}. \tag{6.15}$$

Unfortunately, we do not have a weight function for the operator $\hat{Y}^{-\theta/2}$ due to the term including a sum. However, if we employ the product form obtained in Lemma VI.9, we can construct a weight function. Let $p=e^{2\pi i\tau}$, $q=e^{2\pi i\kappa}$, $t=e^{-2\pi i\mu}$ for $\alpha\in\Delta_m$, $t_j=e^{-2\pi i\mu_j}$ for $\alpha\in\Delta_s$, and $t_j'=e^{-2\pi i\mu_j'}$ for $\alpha\in\Delta_l$ and apply Lemma VI.9 so that $2\mu_\theta=\Sigma\mu_j$ and $\mu_{\alpha_0}=\Sigma\mu_j'$.

The parameters $\boldsymbol{\mu}=(\mu,\mu_0,\mu_1,\mu_2,\mu_3,\mu_0',\mu_1',\mu_2',\mu_3')$ and $\mathbf{t}=(t,t_0,t_1,t_2,t_3,t_0',t_1',t_2',t_3')$ are supposed to move on $P_{\boldsymbol{\mu}}:=i(-\infty,\infty)^9$ and $P_{\mathbf{t}}:=(0,\infty)^9$, respectively. Let $m_\pm$ be meromorphic functions on $\mathbb{H}$ defined by

$$\begin{aligned}m_\pm(\mathbf{t}):=e^{\pm\mathring{\rho}_\mu'/\kappa}&\prod_{\alpha\in(\mathring{\Delta}_m)_\pm}\frac{(e^\alpha;p,q)_\infty}{(te^\alpha;p,q)_\infty}\frac{(pqt^{-1}e^{-\alpha};p,q)_\infty}{(pqe^{-\alpha};p,q)_\infty}\\&\times\prod_{\alpha\in(\mathring{\Delta}_l)_\pm}\left(\left(\prod_{j=0}^{3}\frac{((-1)^{a_j}p^{b_j/2}e^{\alpha/2};p,q)_\infty}{((-1)^{a_j}p^{b_j/2}t_je^{\alpha/2};p,q)_\infty}\frac{((-1)^{a_j}p^{1-b_j/2}qt_j^{-1}e^{-\alpha/2};p,q)_\infty}{((-1)^{a_j}p^{1-b_j/2}qe^{-\alpha/2};p,q)_\infty}\right)\right.\\&\left.\times\left(\prod_{j=0}^{3}\frac{((-1)^{a_j}p^{b_j/2}q^{1/2}e^{\alpha/2};p,q)_\infty}{((-1)^{a_j}p^{b_j/2}q^{1/2}t_j'e^{\alpha/2};p,q)_\infty}\frac{((-1)^{a_j}p^{1-b_j/2}q^{1/2}t_j'^{-1}e^{-\alpha/2};p,q)_\infty}{((-1)^{a_j}p^{1-b_j/2}q^{1/2}e^{-\alpha/2};p,q)_\infty}\right)\right),\end{aligned} \tag{6.16}$$

where

$$\mathring{\rho}_\mu':=\frac{1}{2}\left(\sum_{\alpha\in\mathring{\Delta}_m}\mu\alpha+\sum_{\alpha\in\mathring{\Delta}_l}\frac{\mu_1+\mu_2+\mu_1'+\mu_2'}{2}\alpha\right), \tag{6.17}$$

and the constants a_j and b_j are defined in (2.27).

Proposition VI.10: We have

$$\hat{Y}^{-\theta/2}(\mathbf{t})=\hat{Y}_0^{-\theta/2}(\mathbf{t})+\hat{Y}_1^{-\theta/2}(\mathbf{t}), \tag{6.18}$$

$$\hat{Y}_0^{-\theta/2}(\mathbf{t}):=\sum_{w\in\mathring{W}}w\left(\frac{\tau_{-\theta/2}m_+(\mathbf{t})}{m_+(\mathbf{t})}\tau_{-\theta/2}\right). \tag{6.19}$$

Lemma VI.11: Assume $p^n\neq q$ *for* $n\in\mathbb{Z}_{\geqslant 1}$. *Then* $\hat{Y}_0^{-\theta/2}(\mathbf{t})\in\mathrm{End}_{\mathbb{C}}(\mathcal{M}_{-\theta/2}^{\mathring{W}},\mathcal{M}_0^{\mathring{W}})$.

Theorem VI.12: *Let* $P_{\mathbf{t}}^{\mathrm{sym}} := \{t \in P_{\mathbf{t}} \mid 0<t<1, 0<t_j<p^{-b_j/2}, 0<t_j'<p^{-b_j/2}q^{-1/2}\} \subset P_{\mathbf{t}}$ *and suppose* $\mathbf{t} \in P_{\mathbf{t}}^{\mathrm{sym}}$. *If* $p<q$, *then* $\hat{Y}^{-\theta/2}$ *is symmetric and semi-bounded below on* $\mathcal{M}^{\mathring{W}}_{-\theta/2}$ *with respect to* $(\cdot,\cdot)_{\mathbf{t}}$, *and thus admits a self-adjoint extension.*

In contrast to the other root systems, we can choose several start points of the perturbation. The essential self-adjointness of $\hat{Y}^{-\theta/2}(\mathbf{t}_n)$ on $\mathcal{M}^{\mathring{W}}_{-\theta/2}$ is shown directly in the case

$$0<p<q^{c_n}, \tag{6.20}$$

where

$$\mathbf{t}_0 := (q,1,1,1,1,1,q,q,1), \quad c_0 := 1, \tag{6.21a}$$

$$\mathbf{t}_1 := (q,1,1,1,1,q,q,q,1), \quad c_1 := 2, \tag{6.21b}$$

$$\mathbf{t}_2 := (q,1,1,1,1,1,q,q,q), \quad c_2 := 2, \tag{6.21c}$$

$$\mathbf{t}_3 := (q,1,1,1,1,q,q,q,q), \quad c_3 := 2. \tag{6.21d}$$

We define

$$D_n := \prod_{\alpha \in \mathring{\Delta}} (p^{\gamma_\alpha} e^{\alpha}; p^{\gamma_\alpha})_\infty \times \begin{cases} 1, & \text{if } n=0, \\ \displaystyle\prod_{\alpha \in \Delta_l} (p^{1/2} e^{\alpha/2}; p)_\infty, & \text{if } n=1, \\ \displaystyle\prod_{\alpha \in \Delta_l} (-p^{1/2} e^{\alpha/2}; p)_\infty, & \text{if } n=2, \\ \displaystyle\prod_{\alpha \in \Delta_l} (p e^{\alpha}; p^2)_\infty, & \text{if } n=3, \end{cases} \tag{6.22}$$

and

$$S_{\mu,n} := \frac{1}{|\mathring{W}|^{1/2}} \frac{s_\mu}{D_n}, \quad \mathcal{D}_n := \frac{1}{D_n} \mathbb{C}[\mathring{P}]^{\mathring{W}}, \tag{6.23}$$

where s_μ is the same as in the previous section. Then, due to the condition (6.20), one sees that $\mathcal{D}_n \subset \mathcal{M}^{\mathring{W}}_{-\theta/2}$.

Proposition VI.13: $\mathcal{D}_n$ *is dense in* $L^2(\mathbb{T}, m(\mathbf{t})d\mu)^{\mathring{W}}$. $\{S_{\mu,n}\} \subset \mathcal{D}_n$ *form a complete orthonormal system in* $L^2(\mathbb{T}, m(\mathbf{t}_n)d\mu)^{\mathring{W}}$ *and are the eigenvectors of the leading term* $\hat{Y}_0^\lambda(\mathbf{t}_n)$ *for* $\lambda \in \mathring{P}_-$:

$$\hat{Y}_0^\lambda(\mathbf{t}_n) S_{\mu,n} = E_\mu^\lambda S_{\mu,n}, \tag{6.24}$$

where

$$E_\mu^\lambda = \frac{1}{|\mathring{W}_\lambda|} \sum_{w \in \mathring{W}} q^{(\lambda | w(\mu+\mathring{\rho}))} \in \mathbb{R}_{>0}. \tag{6.25}$$

Theorem VI.14: *Assume* $p<q^{c_n}$. *Then* $\hat{Y}^{-\theta/2}(\mathbf{t}_n)$ *is essentially self-adjoint on* $\mathcal{M}^{\mathring{W}}_{-\theta/2}$ *and semi-bounded below with respect to* $(\cdot,\cdot)_{\mathbf{t}_n}$.

Theorem VI.15: *Assume* $p<q^{c_n}$ *and* $\mathbf{t}\in P_{\mathbf{t}}^{\mathrm{sym}}$. *If* $d(\mathbf{t},\mathbf{t}_n)<\epsilon$ *for sufficiently small* $\epsilon>0$, *then* $\hat{Y}^{\lambda}(\mathbf{t})$ *is essentially self-adjoint on* $\mathcal{M}_{\lambda}^{\mathring{W}}$, *semi-bounded below with respect to* $(\cdot,\cdot)_{\mathbf{t}}$ *and consists of pure point spectrum*.

Using Lemma VI.9, the expression of $\hat{Y}_1^{-\theta/2}$ in (6.7) and the identity

$$2\prod_{j=0}^{3}\vartheta_j(x)=\vartheta_1(2x)\frac{\vartheta_1'(0)}{\pi}, \tag{6.26}$$

we have the following.

Defintion VI.16: Fix the affine root system $X_N^{(r)}=A_{2l}^{(2)}$. Let $\kappa,\tau\in i\mathbb{R}_{>0}$. Let $\mu,\mu_j,\mu_j'\in i\mathbb{R},(j=0,1,2,3)$ and

$$\mu_\alpha=\begin{cases}\mu, & \text{if } \alpha\in\Delta_m,\\ \displaystyle\sum_{j=0}^{3}\mu_j', & \text{if } \alpha\in\Delta_s,\\ \displaystyle\sum_{j=0}^{3}\mu_j/2, & \text{if } \alpha\in\Delta_l,\end{cases} \tag{6.27}$$

so that $\langle\mathring{\rho}_\mu,\alpha^\vee\rangle\neq(\mathbb{Z}+\tau\mathbb{Z})/\gamma_\alpha$. The elliptic Ruijsenaars model associated with affine root system $A_{2l}^{(2)}$ is a quantum many-body system on $\mathbb{T}=\mathring{\mathfrak{h}}_{\mathbb{R}}/\mathring{Q}^\vee$, and its Hamiltonian is given by $H^{-\theta/2}=m^{1/2}\circ\hat{Y}^{-\theta/2}\circ m^{-1/2}$ and is expressed as

$$H^{-\theta/2}=\frac{1}{|\mathring{W}_\theta|}\sum_{w\in\mathring{W}}w(U_0(\boldsymbol{\mu})^{1/2}\circ\tau_{-\theta/2}\circ U_0(-\boldsymbol{\mu})^{1/2})+U_1(\boldsymbol{\mu})+U_2(\boldsymbol{\mu}), \tag{6.28}$$

where

$$U_0(\boldsymbol{\mu})(h):=\left(\prod_{\substack{\alpha\in(\mathring{\Delta}_m)_+\\(\theta|\alpha)>0}}\frac{\vartheta_1(\langle\alpha,h\rangle-\mu;\tau)}{\vartheta_1(\langle\alpha,h\rangle;\tau)}\right)\left(\prod_{j=0}^{3}\frac{\vartheta_j(\langle\theta,h\rangle/2-\mu_j;\tau)}{\vartheta_j(\langle\theta,h\rangle/2;\tau)}\,\frac{\vartheta_j(\langle\theta,h\rangle/2+\kappa/2-\mu_j';\tau)}{\vartheta_j(\langle\theta,h\rangle/2+\kappa/2;\tau)}\right), \tag{6.29}$$

$$\begin{aligned}U_1(\boldsymbol{\mu})(h):=\sum_{j=0}^{3}&\left(\frac{\pi}{\vartheta_1'(0;\tau)}\right)^2\frac{2}{\vartheta_1(\mu;\tau)\vartheta_1(\kappa+\mu;\tau)}\left(\prod_{k=0}^{3}\vartheta_k(\mu_{\pi_j k}+\kappa/2;\tau)\vartheta_k(\mu'_{\pi_j k};\tau)\right)\\&\times\left(\prod_{\alpha\in\mathring{\Delta}_l}\frac{\vartheta_j(\langle\alpha,h\rangle/2-\kappa/2-\mu;\tau)}{\vartheta_j(\langle\alpha,h\rangle/2-\kappa/2;\tau)}\,\frac{\vartheta_j(-\langle\alpha,h\rangle/2-\kappa/2-\mu;\tau)}{\vartheta_j(-\langle\alpha,h\rangle/2-\kappa/2;\tau)}\right),\end{aligned} \tag{6.30}$$

and $U_2(\boldsymbol{\mu}):=F(\kappa,\mu,\mu_\theta,\mu_{\alpha_0})$ is a constant.

Theorem VI.17: *Let*

$$P_{\boldsymbol{\mu}}^{\mathrm{sym}}:=\{\boldsymbol{\mu}=(\mu,\{\mu_j\},\{\mu_j'\})\,|\,\mu\in i\mathbb{R}_{<0},\quad \mu_j'\in i\mathbb{R}_{<b_j\Im\tau/2},\quad \mu_j\in i\mathbb{R}_{<b_j\Im\tau/2+\Im\kappa/2}\}, \tag{6.31}$$

and

$$\boldsymbol{\mu}_0:=-(\kappa,0,0,0,0,0,\kappa,\kappa,0),\quad c_0=1, \tag{6.32a}$$

$$\boldsymbol{\mu}_1:=-(\kappa,0,0,0,0,\kappa,\kappa,\kappa,0),\quad c_1=2, \tag{6.32b}$$

$$\boldsymbol{\mu}_2:=-(\kappa,0,0,0,0,0,\kappa,\kappa,\kappa),\quad c_2=2, \tag{6.32c}$$

$$\boldsymbol{\mu}_3 := -(\kappa,0,0,0,0,\kappa,\kappa,\kappa,\kappa), \quad c_3 = 2. \tag{6.32d}$$

If $c_n|\kappa| < |\tau|$ *and* $\boldsymbol{\mu} \in P_{\boldsymbol{\mu}}^{\mathrm{sym}}$ *satisfies* $d(\boldsymbol{\mu},\boldsymbol{\mu}_n) < \epsilon$ *for some* $n \in \{0,1,2,3\}$ *and sufficiently small* $\epsilon > 0$, *then the Hamiltonian* $H^{-\theta/2}$ (6.28) *is essentially self-adjoint and semi-bounded below with domain* $\mathcal{M}^{\mathring{W}}_{-\theta/2} m^{1/2}$ *on* $L^2(\mathbb{T}, d\mu)^{\mathring{W}}$ *and consists of pure point spectrum.*

ACKNOWLEDGMENTS

The author would like to express his gratitude to Professor S. N. M. Ruijsenaars for valuable discussions and useful comments on the manuscript, and for giving a detailed lecture on his results, in particular, the construction of eigenvectors. Thanks are also due to Dr. K. Takemura, Professor A. Kuniba, and Dr. A. Nishino for fruitful discussions. The author is a Research Fellow of the Japan Society for the Promotion of Science.

APPENDIX A: Equation (5.52)

Lemma A.1: Let $x \in \mathbb{C}$ *and* $\mu \in i\mathbb{R}$. *Then*

$$|\vartheta_1(x+\mu;\tau) - \vartheta_1(x;\tau)| \leqslant |\phi(\Im x,\mu;\tau)|, \tag{A1}$$

$$|\vartheta_1(x+\mu;\tau)| \leqslant |\varphi(\Im x,\mu;\tau)|, \tag{A2}$$

where

$$\phi(y,z;\tau) := 4\sum_{n\in\mathbb{Z}} \exp\left(i\pi\left(n-\frac{1}{2}\right)^2\tau\right)\cosh((2n-1)\pi y)\sin((2n-1)\pi z), \tag{A3}$$

$$\varphi(y,z;\tau) := 4\sum_{n\in\mathbb{Z}} \exp\left(i\pi\left(n-\frac{1}{2}\right)^2\tau\right)\cosh((2n-1)\pi y)\cos((2n-1)\pi z) \tag{A4}$$

are holomorphic functions on $\mathbb{C}^2$.

Proof: For $a \in \mathbb{C}$ and $b \in \mathbb{R}$, we have

$$\begin{aligned}|\sin(a+bi) - \sin a| &= |\sin a(\cosh b - 1) + i\cos a \sinh b| \\ &\leqslant (|\sin a| + |\cos a|)|\sinh b| \\ &\leqslant 2\cosh(\Im a)|\sinh b|. \end{aligned} \tag{A5}$$

Set $p = \exp(2\pi i\tau)$. By using (2.24),

$$\begin{aligned}|\vartheta_1(x+\mu;\tau) - \vartheta_1(x;\tau)| &= \left|2\sum_{n\in\mathbb{Z}} p^{(n-1/2)^2/2}(\sin(2n-1)\pi(x+\mu) - \sin(2n-1)\pi\mu)\right| \\ &\leqslant 4\sum_{n\in\mathbb{Z}} p^{(n-1/2)^2/2}\cosh((2n-1)\pi\Im x)|\sinh((2n-1)\pi\Im\mu)| \\ &= |\phi(\Im x,\mu;\tau)|. \end{aligned} \tag{A6}$$

The series converges uniformly absolutely on any compacts on $\mathbb{C}^2$. The latter part can be shown similarly. □

Lemma A.2: Let $a,b \in \mathbb{R}$ *and* $\tau \in i\mathbb{R}$. *Then* $|\vartheta_1(a+ib;\tau)| \geqslant |\vartheta_1(ib;\tau)|$.

Proof: We can assume $b \geqslant 0$ without loss of generality. Let $z = e^{2\pi i(a+ib)}$ and $p = e^{2\pi i\tau}$. Then $|z| \leqslant 1$, $0 < p < 1$ and $|1 - p^n z| \geqslant 1 - p^n|z| \geqslant 0$ for $n \geqslant 0$ and, by using the product form, we have

$$|\vartheta_1(a+ib;\tau)| \geqslant p^{1/8}|z|^{-1/2}(p;p)_\infty(|z|;p)_\infty(p|z|;p)_\infty = |\vartheta_1(ib;\tau)|. \tag{A7}$$

□

Lemma A.3: Let $a_i, b_i \in \mathbb{C}$ *for* $1 \leqslant i \leqslant n$. *Then*

$$\left|\prod_{i=1}^{n} a_i - \prod_{i=1}^{n} b_i\right| \leqslant n\Big(\max_{1\leqslant i\leqslant n}|a_i-b_i|\Big)\Big(\max_{1\leqslant i\leqslant n}\{|a_i|,|b_i|\}\Big)^{n-1}. \tag{A8}$$

Proof: The statement is implied by the following equality:

$$\prod_{i=1}^{n} a_i - \prod_{i=1}^{n} b_i = \sum_{j=1}^{n}\left(\prod_{i=1}^{j-1} a_i\right)(a_j-b_j)\left(\prod_{i=j+1}^{n} b_i\right). \tag{A9}$$

□

Proposition A.4: $\delta(\mathbf{t}) \to 0$ *in* $C(\mathbb{T})$ *as* $\mathbf{t} \to \mathbf{t}_0$ *in* $P_{\mathbf{t}}$.

Proof: First we show the cases for minuscule weights. Let $\Delta_\lambda := \{\alpha \in \mathring{\Delta}_+ | (\lambda|\alpha) = -\gamma_\alpha\}$. Recall that

$$\delta(\mathbf{t}) = 1 - \prod_{\alpha\in\Delta_\lambda} \frac{\vartheta_1(\langle\alpha,h\rangle - \gamma_\alpha\mu_\alpha;\gamma_\alpha\tau)}{\vartheta_1(\langle\alpha,h\rangle + \gamma_\alpha\kappa;\gamma_\alpha\tau)}. \tag{A10}$$

By applying Lemmas A.1, A.3, and A2 we have

$$\|\delta(\mathbf{t})\|_{\max} \leqslant \frac{|\Delta_\lambda||\phi(r\Im\kappa, d(\boldsymbol{\mu},\boldsymbol{\mu}_0);\tau)||\varphi(r\Im\kappa, d(\boldsymbol{\mu},\boldsymbol{\mu}_0);\tau)|^{|\Delta_\lambda|-1}}{\Pi_{\alpha\in\Delta_\lambda}|\vartheta_1(\gamma_\alpha\kappa;\gamma_\alpha\tau)|}, \tag{A11}$$

where r is from $X_N^{(r)}$ and we have used the monotonicity of ϕ and φ. Since $|\phi(a,0;\tau)| = 0$ and $|\varphi(a,\cdot;\tau)|$ is bounded in the neighborhood of the origin, it follows that $\|\delta(\mathbf{t})\|_{\max} \to 0$ as $d(\mathbf{t},\mathbf{t}_0) \to 0$.

The case for the quasi-minuscule weight is similarly shown. □

Supergeneralization of Duffin–Kemmer–Petiau Algebra and Lie superalgebra osp(N,M)

Susumu Okubo[a)]
Department of Physics and Astronomy, University of Rochester, Rochester, New York 14627

(Received 23 February 2001; accepted for publication 21 May 2001)

We will consider a supergeneralization of the Duffin–Kemmer–Petiau algebra. It has been shown to be intimately related to the Lie super algebra osp(N,M). We will also discuss its representations. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1386928]

The Duffin–Kemmer–Petiau algebra (hereafter referred to as DKP algebra) in the N-dimensional carrier space is defined by the relation

$$\beta_\mu\beta_\nu\beta_\lambda+\beta_\lambda\beta_\nu\beta_\mu=\delta_{\mu\nu}\beta_\lambda+\delta_{\nu\lambda}\beta_\mu \tag{1}$$

for $\mu,\nu,\lambda=1,2,\ldots,N$. For the case of $N=4$, it is well known (see, e.g., the article[1] by Krajcik and Nieto for an interesting historical account of the subject) that dimensions of its irreducible representations are restricted to one, five, and ten, and that the associated linear equation

$$\left(\sum_{\mu=1}^{4}\beta_\mu\frac{\partial}{\partial x_\mu}-m\right)\psi=0$$

specifies the spin 0 and 1 Klein–Gordon equations, respectively, for cases of five- and ten-dimensional realizations.

Fishbach *et al.*[2] have classified representations of the DKP algebra by reducing the problem to that of the Lie algebra so($N+1$) as follows. They first note that Eq. (1) implies the validity of

$$[[\beta_\mu,\beta_\nu],\beta_\lambda]=\delta_{\nu\lambda}\beta_\mu-\delta_{\mu\lambda}\beta_\nu \tag{2}$$

as well as

$$(\beta_\mu)^3=\beta_\mu. \tag{3}$$

Conversely, they show that Eqs. (2) and (3) lead to Eq. (1). Next, setting

$$J_{\mu\nu}=[\beta_\mu,\beta_\nu], \tag{4a}$$

$$J_{0\mu}=-J_{\mu0}=\beta_\mu, \tag{4b}$$

$$J_{00}=0, \tag{4c}$$

for $\mu,\nu,\lambda=1,2,\ldots,N$, it is easy to prove that Eq. (2) gives the so($N+1$) Lie algebra of

$$J_{AB}=-J_{BA}, \tag{5a}$$

$$[J_{AB},J_{CD}]=g_{BC}J_{AD}+g_{AD}J_{BC}-g_{AC}J_{BD}-g_{BD}J_{AC}, \tag{5b}$$

a)Electronic mail: okubo@pas.rochester.edu

now for values of A,B,C,D being $0,1,2,\ldots,N$. Here, we have set

$$g_{AB}=\begin{cases}\delta_{AB} & \text{if } A,B\neq 0\\ -1 & \text{if } A=B=0\\ 0 & \text{otherwise .}\end{cases} \tag{6}$$

Moreover, the constraint relation (3) is rewritten as

$$(J_{0\mu})^3=J_{0\mu}, \tag{7}$$

which restricts possible representations of the so$(N+1)$. Fishbach *et al.*[2] succeeded to specify all irreducible representations of the DKP algebra in terms of those of the corresponding so$(N+1)$ Lie algebra. Their results then can be more explicitly restated as follows. Let $T_{a_1a_2\ldots a_m}$ for a non-negative integer m to be a completely antisymmetric tensor for values of $a_1,a_2,\ldots,a_m$ to be $0,1,2,\ldots,N$. Then, the action of J_{AB} to the tensor is assumed to be given by

$$J_{AB}T_{a_1a_2\ldots a_m}=\sum_{j=1}^{m}\{g_{Ba_j}T_{a_1\ldots a_{j-1}Aa_{j+1}\ldots a_m}-g_{Aa_j}T_{a_1\ldots a_{j-1}Ba_{j+1}\ldots a_m}\}. \tag{8}$$

Moreover, if N is odd and $N+1=2m$, then the tensor must be chosen[3] to be either self-conjugate or anti-self-conjugate for the representation to remain irreducible. In other words, we can impose the condition

$$T_{a_1a_2\ldots a_m}=\pm\frac{1}{m!}\sum_{b_1,b_2,\ldots,b_m=1}^{2m}\epsilon_{a_1\ldots a_mb_1\ldots b_m}T_{b_1b_2\ldots b_m} \tag{9}$$

for the Levi-Civita symbol $\epsilon_{a_1\ldots a_mb_1\ldots b_m}$ in $2m$ dimension. Similarly, we can restrict the values of m to be $0\leqslant m\leqslant\frac{1}{2}(N+1)$ for the general tensor, since the other cases of $m>\frac{1}{2}(N+1)$ can be reduced[3] to the former by the use of the Levi–Civita symbol in a similar way.

In order to see more explicitly that this gives the realizations of the original DKP algebra, we introduce two completely antisymmetric tensors of rank n and $n+1$, respectively, for $m=n+1$ by

$$\phi^{(n+1)}_{\mu_1\ldots\mu_{n+1}}=T_{\mu_1\mu_2\ldots\mu_{n+1}}, \tag{10a}$$

$$\psi^{(n)}_{\mu_1\ldots\mu_n}=T_{0\mu_1\mu_2\ldots\mu_n} \tag{10b}$$

for values of $\mu_1,\mu_2,\ldots,\mu_{n+1}$ to range now to be $1,2,\ldots,N$. The possible values of n which specify the irreducible representations of the DKP algebra may be restricted to

$$0\leqslant n\leqslant\tfrac{1}{2}(N-1). \tag{10c}$$

Then, from Eqs. (4b) and (8), the action of β_μ's to those tensors are given by

$$\beta_\lambda\psi^{(n)}_{\mu_1\ldots\mu_n}=\phi^{(n+1)}_{\lambda\mu_1\ldots\mu_n}, \tag{11a}$$

$$\beta_\lambda\phi^{(n+1)}_{\mu_1\mu_2\ldots\mu_{n+1}}=\sum_{j=1}^{n+1}(-1)^{j-1}\delta_{\lambda\mu_j}\psi^{(n)}_{\mu_1\ldots\mu_{j-1}\mu_{j+1}\ldots\mu_{n+1}}. \tag{11b}$$

We can readily verify that these relations are consistent with the validity of Eq. (1). Moreover, for the case of $N=2n+1$ being odd, Eq. (11) can be replaced by a single relation of

$$\beta_\lambda \psi^{(n)}_{\mu_1 \ldots \mu_n} = \pm \frac{1}{n!} \sum_{\nu_1 \nu_2, \ldots, \nu_n = 1}^{N} \epsilon_{\lambda \mu_1 \ldots \mu_n \nu_1 \ldots \nu_n} \psi^{(n)}_{\nu_1 \ldots \nu_n} \tag{12}$$

in view of Eq. (9) now for $2n+1$ dimensional Levi-Civita symbol $\epsilon_{\lambda \mu_1 \ldots \nu_n}$. For $N=4$, these give the five-dimensional representation space consisting of ψ_0 and ϕ_μ for $n=0$, and ten-dimensional space spanned by ψ_μ and $\phi_{\mu\nu}$ with $\phi_{\mu\nu} = -\phi_{\nu\mu}$ for $n=1$, reproducing the well known fact of Ref. 1.

We have digressed into the representation theory of the DKP algebra in detail for the following reason. Let

$$\epsilon_{\mu\nu} = -\epsilon_{\nu\mu} \tag{13}$$

be a constant symplectic tensor, and consider now

$$\beta_\mu \beta_\nu \beta_\lambda - \beta_\lambda \beta_\nu \beta_\mu = \epsilon_{\mu\nu} \beta_\lambda - \epsilon_{\lambda\nu} \beta_\mu \tag{14}$$

for $\mu, \nu, \lambda = 1,2, \ldots, M$. Here we used the letter M instead of N for a reason which will become clear soon. We may call the algebra generated by β_μ's satisfying Eq. (14) a para-Duffin–Kemmer–Petiau algebra (hereafter referred to as PDKP algebra). In contrast to the DKP algebra, the new PDKP is now infinite dimensional. In particular, we will not have a simple polynomial constraint such as Eq. (3). Nevertheless, the analysis of the PDKP algebra will proceed analogously to the DKP case, except for the fact that the role of the Lie algebra so$(N+1)$ is now replaced by the Lie superalgebra osp$(1,M)$.[4,5]

First we note that Eq. (14) gives

$$[\{\beta_\mu, \beta_\nu\}, \beta_\lambda] = \epsilon_{\nu\lambda} \beta_\mu + \epsilon_{\mu\lambda} \beta_\nu \tag{15}$$

instead of Eq. (2), where $\{\beta_\mu, \beta_\nu\}$ is the anticommutator, i.e.,

$$\{\beta_\mu, \beta_\nu\} = \beta_\mu \beta_\nu + \beta_\nu \beta_\mu . \tag{16}$$

We now introduce J_{AB} by

$$J_{\mu\nu} = \{\beta_\mu, \beta_\nu\}, \tag{17a}$$

$$J_{0\mu} = -J_{\mu 0} = \beta_\mu , \tag{17b}$$

$$J_{00} = 0, \tag{17c}$$

together with g_{AB} for $A,B = 0,1,2 \ldots, M$ by

$$g_{AB} = \begin{cases} \epsilon_{AB} & \text{if } A,B = 1,2, \ldots, M \\ -1 & \text{if } A = B = 0 \\ 0 & \text{otherwise .} \end{cases} \tag{18}$$

We next define

$$[J_{AB}, J_{CD}\} = J_{AB} J_{CD} - (-1)^{(\sigma(A)+\sigma(B))(\sigma(C)+\sigma(D))} J_{CD} J_{AB} \tag{19}$$

as usual, where $\sigma(A)$ is the grade (or parity) given by

$$\sigma(A) = \begin{cases} 0 & \text{if } A = 0 \\ 1 & \text{if } A = 1,2, \ldots, M. \end{cases} \tag{20}$$

From Eq. (15), we can then verify the fact that J_{AB}'s now give the Lie super algebra osp(1,M), i.e.,

$$\text{(i)}\quad J_{AB}=-(-1)^{\sigma(A)\sigma(B)}J_{BA}, \tag{21a}$$

$$\text{(ii)}\quad [J_{AB},J_{CD}\}=g_{BC}J_{AD}-(-1)^{\sigma(A)\sigma(B)}g_{AC}J_{BD}-(-1)^{\sigma(C)\sigma(D)}g_{BD}J_{AC}+(-1)^{\sigma(A)\sigma(B)+\sigma(C)\sigma(D)}g_{AD}J_{BC}, \tag{21b}$$

$$\text{(iii)}\quad g_{AB}=(-1)^{\sigma(A)\sigma(B)}g_{BA}, \tag{21c}$$

$$\text{(iv)}\quad g_{AB}=0 \quad \text{if} \quad \sigma(A)\neq\sigma(B). \tag{21d}$$

Before going into further details, it may be worthwhile to emphasize the fact[4] that osp(1,M) is the only simple Lie superalgebra possessing the nice property that any of its finite dimensional representation is always fully reducible. We also note that a representation of the PDKP algebra is irreducible, if and only if the corresponding one of osp(1,N) is irreducible. Analogous to the DKP case, we now consider the completely superantisymmetric tensor $T_{a_1a_2\ldots a_m}$, which satisfies

$$T_{a_1\ldots a_ja_{j+1}\ldots a_m}=-(-1)^{\sigma(a_j)\sigma(a_{j+1})}T_{a_1\ldots a_{j+1}a_j\ldots a_m} \tag{22}$$

for the interchange of two adjacent indices a_j and a_{j+1} for $a_1,a_2,\ldots,a_m=0,1,2,\ldots,M$. The action of J_{AB} to this tensor is given by

$$J_{AB}T_{a_1a_2\ldots a_m}=\sum_{j=1}^{m}(-1)^{\Sigma_j(A,B)}\{g_{Ba_j}T_{a_1\ldots a_{j-1}Aa_{j+1}\ldots a_m}-(-1)^{\sigma(A)\sigma(B)}g_{Aa_j}T_{a_1\ldots a_{j-1}Ba_{j+1}\ldots a_m}\} \tag{23a}$$

where we have set for simplicity

$$\Sigma_j(A,B)=(\sigma(A)+\sigma(B))(\sigma(a_1)+\sigma(a_2)+\cdots+\sigma(a_{j-1})). \tag{23b}$$

Equations (23a) and (23b) are the analogs of Eq. (8) of the DKP case. We have to verify the fact that the tensor $T_{a_1\ldots a_m}$ supplies the representation space not only of the osp(1,M) but also of the PDKP algebra. For this, we first note that $T_{a_1a_2\ldots a_m}$ contain the zero index at most once in view of Eq. (22). We then introduce two tensors $\phi^{(n+1)}_{\mu_1\ldots\mu_{n+1}}$ and $\psi^{(n)}_{\mu_1\ldots\mu_n}$ again by Eqs. (10a) and (10b). However, in contrast to the DKP case, they are now completely symmetric in $\mu_1,\mu_2,\ldots,\mu_{n+1}$ instead of being completely antisymmetric because of Eq. (22). Then, Eqs. (17b) and (23a) lead to

$$\beta_\lambda\psi^{(n)}_{\mu_1\ldots\mu_n}=\phi^{(n+1)}_{\lambda\mu_1\ldots\mu_n}, \tag{24a}$$

$$\beta_\lambda\phi^{(n+1)}_{\mu_1\ldots\mu_{n+1}}=\sum_{j=1}^{n+1}\epsilon_{\lambda\mu_j}\psi^{(n)}_{\mu_1\ldots\mu_{j-1}\mu_{j+1}\ldots\mu_{n+1}}, \tag{24b}$$

which replace Eq. (11). We can explicitly verify now that Eqs. (24a) and (24b) are consistent with the PDKP relation of Eq. (14), i.e., they offer the desired irreducible realizations of the algebra. Since both tensors $\phi^{(n+1)}_{\mu_1\ldots\mu_{n+1}}$ and $\psi^{(n)}_{\mu_1\ldots\mu_n}$ are completely symmetric, there is no restriction such as in Eq. (10c) to the values of n. In particular, the PDKP algebra has an infinite number of finite dimensional irreducible representations in contrast to the case of the DKP algebra, reflecting the fact that the former is infinite dimensional. We also note that Rittenberg and Scheunert[6] have given a correspondence between representations of osp(1,2N) and so($2N+1$).

We must yet prove that the PDKP algebra has no finite dimensional irreducible representation other than those given by Eqs. (24a) and (24b) except for the trivial one of $\beta_\mu = 0$. Since there is no analog of the relation such as Eq. (3), this is more difficult to do. However, we could achieve it by studying the representations of osp$(1,M)$ corresponding to general tensors, and then by showing its incompatibility with Eq. (14) except for the case of the completely superantisymmertric realization. We will not go into details, however, since the demonstration is quite cumbersome.

At this point, we may speculate what will happen, if we consider the relation

$$\beta_\mu \beta_\nu \beta_\lambda - \beta_\lambda \beta_\nu \beta_\mu = \delta_{\mu\nu}\beta_\lambda - \delta_{\lambda\nu}\beta_\mu \tag{25}$$

for $\mu, \nu, \lambda = 1,2,\ldots,M$ instead of Eq. (14). At first glance, Eq. (25) would appear to be a more natural choice as the counterpart of the DKP algebra. We shall, however, prove in the following that Eq. (25) will admit only the trivial solution $\beta_\mu = 0$ identically, unless $M = 1$. Supose $M \geqslant 2$. Then for any two index μ, and λ satisfying $\mu \neq \lambda$, we choose $\mu = \nu \neq \lambda$, so that Eq. (25) gives

$$\beta_\mu^2 \beta_\lambda - \beta_\lambda \beta_\mu^2 = \beta_\lambda \quad \text{if} \quad \mu \neq \lambda. \tag{26}$$

We will prove that the validity of Eq. (26) implies $\beta_\mu = 0$ as follows. We multiply β_λ to both sides of Eq. (26) from the left- and right-hand sides to find

$$\beta_\mu^2 \beta_\lambda^2 - \beta_\lambda \beta_\mu^2 \beta_\lambda = \beta_\lambda^2,$$

$$\beta_\lambda \beta_\mu^2 \beta_\lambda - \beta_\lambda^2 \beta_\mu^2 = \beta_\lambda^2.$$

Adding both, this gives

$$\beta_\mu^2 \beta_\lambda^2 - \beta_\lambda^2 \beta_\mu^2 = 2\beta_\lambda^2 \quad \text{if} \quad \mu \neq \lambda. \tag{27}$$

Interchanging the role of μ and λ, Eq. (27) leads then to

$$\beta_\lambda^2 = -\beta_\mu^2 \quad \text{if} \quad \mu \neq \lambda.$$

In that case, the left-hand side of Eq. (26) is calculated to be

$$\beta_\mu^2 \beta_\lambda - \beta_\lambda \beta_\mu^2 = (-\beta_\lambda^2)\beta_\lambda - \beta_\lambda(-\beta_\lambda^2) = 0$$

and hence Eq. (26) requires the validity of $\beta_\lambda = 0$ identically.

We next show that both DKP and PDKP algebras are special cases of a larger supergeneralization of the DKP algebra. Let us consider $M+N$ indices $1,2,\ldots,M+N$ and divide them into two sets of

$$V_0 = \{1,2,\ldots,N\}, \tag{28a}$$

$$V_1 = \{N+1, N+2, \ldots, N+M\} \tag{28b}$$

and assign

$$\sigma(a) = \begin{cases} 0 & \text{if } a \in V_0 \\ 1 & \text{if } a \in V_1 \end{cases} \tag{29}$$

so that V_0 and V_1 correspond, respectively, to bosonic and fermionic indices. Similarly, we introduce g_{ab} for $a, b = 1,2,\ldots,M+N$ by

$$g_{ab}=\begin{cases}\delta_{\mu\nu} & \text{if } a=\mu,\ \ b=\nu\epsilon V_0\\ \epsilon_{\mu\nu} & \text{if } a=\mu,\ \ b=\nu\epsilon V_1\\ 0 & \text{otherwise,}\end{cases} \tag{30}$$

which satisfies

$$\text{(i)}\ \ g_{ba}=(-1)^{\sigma(a)\sigma(b)}g_{ab}, \tag{31a}$$

$$\text{(ii)}\ \ g_{ab}=0 \quad \text{if} \quad \sigma(a)\neq\sigma(b). \tag{31b}$$

Suppose that β_a for $a=1,2,\ldots,M+N$ now satisfy

$$\beta_a\beta_b\beta_c+(-1)^{\Sigma(a,b,c)}\beta_c\beta_b\beta_a=g_{ab}\beta_c+g_{bc}\beta_a, \tag{32a}$$

where for simplicity we have set

$$\Sigma(a,b,c)=\sigma(a)\sigma(b)+\sigma(b)\sigma(c)+\sigma(c)\sigma(a). \tag{32b}$$

We note that Eq. (32a) remains invariant under $a\leftrightarrow c$, if we note the validity of

$$g_{ba}=(-1)^{\Sigma(a,b,c)}g_{ab} \tag{33}$$

by Eqs. (31a) and (31b). For special cases of $V_1=0$ (or $M=0$) and $V_0=0$ (or $N=0$), Eqs. (32a) and (32b) reproduce Eqs. (1) and (14), respectively. We may call the algebra generated by β_a's satisfying Eqs. (32a) and (32b) the super DKP algebra or DKP superalgebra. We also note that Eq. (32a) is invariant under $\beta_a\rightarrow-\beta_a$ and $\beta_a\rightarrow(-1)^{\sigma(a)}\beta_a$.

Setting

$$J_{ab}=\beta_a\beta_b-(-1)^{\sigma(a)\sigma(b)}\beta_b\beta_a \tag{34}$$

and introducing the general commutator again by

$$[J_{ab},\beta_c\}=J_{ab}\beta_c-(-1)^{(\sigma(a)+\sigma(b))\sigma(c)}\beta_cJ_{ab}, \tag{35}$$

Eqs. (32a) and (32b) give

$$[J_{ab},\beta_c\}=g_{bc}\beta_a-(-1)^{\sigma(a)\sigma(b)}g_{ac}\beta_b. \tag{36}$$

We can now construct the Lie super algebra osp$(N+1,M)$ as follows. We set

$$\beta_a=J_{0a}=-J_{a0}, \tag{37a}$$

$$J_{00}=0, \tag{37b}$$

as well as

$$g_{0a}=g_{a0}=0, \quad g_{00}=-1, \quad \sigma(0)=0 \tag{37c}$$

for $a=1,2,\ldots,M+N$. We note that the new index zero is a bosonic one and can be incorporated into V_0. The enlarged algebra for J_{AB} with $A,B=0,1,2,\ldots,M+N$ satisfies Eq. (21). Therefore, it realizes the Lie superalgebra osp$(N+1,M)$. The special cases of $M=0$ and $N=0$ will reproduce the Lie algebra so$(N+1)$ and osp$(1,M)$, respectively, of the DKP and PDKP algebras.

The realization of the super DKP algebra is again related to the completely superantisymmetric tensor representation. However, we will not go into details, since we will present another and more direct way to construct it, shortly.

We remark that the Lie super algebra osp$(N+1,M)$ based upon a similar construction has also appeared in a study[7] of para-statistics in which bosons and fermions no longer commute with each other. A simpler osp(1,2) algebra occurs[8] as the Clebsch–Gordan algebra of combined spin $\frac{1}{2}$ and 1 representations of the angular momentum algebra so(3).

Finally, we can construct the direct realization of the DKP superalgebra without recourse to osp$(N+1,M)$ as follows. Let g_{ab} be a constant tensor again satisfying the condition

$$\text{(i)} \quad g_{ba}=(-1)^{\sigma(a)\sigma(b)}g_{ab}, \tag{38a}$$

$$\text{(ii)} \quad g_{ab}=0 \quad \text{if} \quad \sigma(a)\neq\sigma(b). \tag{38b}$$

Suppose that a set of operators Q_a and $\overline{Q}_a$ satisfy

$$Q_a\overline{Q}_bQ_c+(-1)^{\Sigma(a,b,c)}Q_c\overline{Q}_bQ_a=g_{ab}Q_c+g_{bc}Q_a, \tag{39a}$$

$$\overline{Q}_aQ_b\overline{Q}_c+(-1)^{\Sigma(a,b,c)}\overline{Q}_cQ_b\overline{Q}_a=g_{ab}\overline{Q}_c+g_{bc}\overline{Q}_a. \tag{39b}$$

If we introduce 2×2 matrices β_a by

$$\beta_a=\begin{pmatrix} 0 & Q_a \\ \overline{Q}_a & 0 \end{pmatrix}, \tag{40}$$

it is easy to see that they define the DKP superalgebra, i.e.,

$$\beta_a\beta_b\beta_c+(-1)^{\Sigma(a,b,c)}\beta_c\beta_b\beta_a=g_{ab}\beta_c+g_{bc}\beta_a. \tag{41}$$

We can find a realization of operators Q_a and $\overline{Q}_a$ satisfying Eqs. (39a) and (39b) as generalized annihilation and creation operators by

$$Q_a\overline{Q}_b+(-1)^{\sigma(a)\sigma(b)}\overline{Q}_bQ_a=g_{ab}, \tag{42a}$$

$$Q_aQ_b+(-1)^{\sigma(a)\sigma(b)}Q_bQ_a=0, \tag{42b}$$

$$\overline{Q}_a\,\overline{Q}_b+(-1)^{\sigma(a)\sigma(b)}\overline{Q}_b\,\overline{Q}_a=0. \tag{42c}$$

Setting

$$V_o=\{a|\sigma(a)=0\}, \tag{43a}$$

$$V_1=\{a|\sigma(a)=1\}, \tag{43b}$$

Q_a and $\overline{Q}_b$ for $a,b\epsilon V_0$ with $g_{ab}=\delta_{ab}$ then form the usual annihilation and creation operators of fermions, while those for $a,b\epsilon V_1$ with $g_{ab}=\epsilon_{ab}$ correspond to quasibosonic system. However, we note that bosonic operators now anticommute with fermionic ones.

In order to construct representations of the super DKP algebra, we introduce the Fock space by

$$Q_a|0\rangle=0, \tag{44a}$$

$$\overline{Q}_{a_1}\,\overline{Q}_{a_2}\ldots\overline{Q}_{a_m}|0\rangle=|a_1,a_2,\ldots,a_m\rangle \tag{44b}$$

from the vacuum state $|0\rangle$. We then calculate

$$\beta_c\begin{pmatrix} |a_1a_2\ldots a_m\rangle \\ |b_1b_2\ldots b_n> \end{pmatrix}=\begin{pmatrix} Q_c|b_1b_2\ldots b_n\rangle \\ |ca_1a_2\ldots a_m> \end{pmatrix}. \tag{45}$$

Moreover, we note

$$Q_c|b_1b_2\ldots b_n\rangle=\sum_{j=1}^{n}(-1)^{\Sigma_j}g_{cb_j}|b_1\ldots b_{j-1}b_{j+1}\ldots b_n\rangle, \tag{46a}$$

$$\Sigma_j\equiv j-1+\sigma(c)(\sigma(b_1)+\sigma(b_2)+\cdots+\sigma(b_{j-1})). \tag{46b}$$

We see that a set consisting of such two-component state vectors with $m=n+1$ for a fixed value of n forms a representation space of the

DKP superalgebra. If we identify

$$\psi^{(n)}_{a_1a_2\ldots a_n}=\begin{pmatrix} 0 \\ |a_1a_2\ldots a_n\rangle \end{pmatrix}, \tag{47a}$$

$$\phi^{(n+1)}_{a_1\ldots a_{n+1}}=\begin{pmatrix} |a_1a_2\ldots a_{n+1}\rangle \\ 0 \end{pmatrix}, \tag{47b}$$

then Eqs. (45) and (46) lead to

$$\beta_c\psi^{(n)}_{a_1a_2\ldots a_n}=\phi^{(n+1)}_{ca_1a_2\ldots a_n}, \tag{48a}$$

$$\beta_c\phi^{(n+1)}_{a_1a_2\ldots a_{n+1}}=\sum_{j=1}^{n+1}(-1)^{\Sigma_j}g_{ca_j}\psi^{(n)}_{a_1\ldots a_{j-1}a_{j+1}\ldots a_{n+1}} \tag{48b}$$

The special cases of $M=0$ and $N=0$ will then reproduce Eqs. (11) and (24), respectively. However, the above-given representation may not be irreducible for some cases because of the self-conjugate condition like Eq. (12) for antisymmetric tensor indices. The problem is somewhat involved and will be discussed elsewhere.

Returning to Eq. (45), consider now the case of $m\neq n+1$. We must then double the number of states by adding another two-component vectors now with $m\leftrightarrow n+1$. However, this leads in general to reducible representations.

There exists another realization of Eq. (39) in terms of the Cuntz algebra[9] generated by a single relation of

$$Q_a\overline{Q_b=}g_{ab}. \tag{49}$$

In this case, Eq. (45) is now rewritten as

$$\beta_c\begin{pmatrix} |a_1\ldots a_m\rangle \\ |b_1\ldots b_n \end{pmatrix}=\begin{pmatrix} g_{cb_1}|b_2\ldots b_n\rangle \\ |ca_1a_2\ldots a_m\rangle \end{pmatrix}. \tag{50}$$

This gives, however, reducible representations even for the case of $m=n+1$.

In ending this note, consider an $M+N$ dimensional supermanifold with N bosonic coordinate $x_1,x_2,\ldots,x_N$ and M fermionic Grassmann coordinate $z_1,z_2,\ldots,z_M$. We set $z_j=x_{j+N}$ for $j=1,2,\ldots,M$, and consider the wave equation

$$\left(\sum_{a=1}^{N+M} \beta_a \frac{\partial}{\partial x_a} - m \right) \xi = 0. \tag{51}$$

Then, Eq. (41) will lead to the generalized Klein–Gordon equation

$$\left(\sum_{\mu=1}^{N} \frac{\partial^2}{\partial x_\mu \partial x_\mu} + \sum_{j,k=1}^{M} \epsilon_{jk} \frac{\partial^2}{\partial z_j \partial z_k} \right) \xi = m^2 \xi \tag{52}$$

assuming $m \neq 0$.

On the correlation functions of the vector bundle generalization of the *bc*-system

Matthias Schork[a)]
FB Mathematik, J. W. Goethe-Universität, 60054 Frankfurt, Germany

(Received 30 October 2000; accepted for publication 22 May 2001)

It is shown that the determinants of the correlation functions of the generalized bc-system introduced recently are given as pullbacks of the non-Abelian theta divisor. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1388198]

I. INTRODUCTION

The usual bc-system appearing in bosonic string theory[1,2] is very well understood[1–4] and has also been considered in a rigorous algebro-geometric way by Raina.[5,6] Assuming some natural physical axioms, Raina showed the existence and uniqueness of the correlation functions and was able to rederive the explicit expressions using the geometry of the theta divisor. It is important to note that one considers in this approach not the quantum fields b,c themselves (which should be ''operator valued sections'' of certain line bundles), but their correlation functions inheriting the symmetries of the operators. A closely related cousin of the bc-sytem based on a Hermitian vector bundle of rank r was introduced in Ref. 7 and the existence and uniqueness of correlation functions was established for a particular class of bundles. The hope was that the correlation functions of this bc_r-system are determined completely by the geometry of the non-Abelian theta divisor, in complete analogy to the usual rank one case. Since at the time of writing the necessary formulas were lacking, this remained a hope, but in the meantime Ref. 8 appeared, providing some useful results. Unfortunately, only the determinants of the correlation functions can be described with the help of the results of Ref. 8, so there is still much to be done to realize this hope and it is unclear whether one will be able to do so along the lines pursued here.

In the second section we briefly recall the geometry of the system of rank one before we consider the higher rank case in the third section. Some of the difficulties concerning the current and the energy-momentum tensor are indicated. For the convenience of the reader we have stated the required result of Ref. 8 in an appendix. In the following Σ_g will be a Riemann surface of genus $g \geqslant 2$ with canonical bundle $K \equiv K_{\Sigma_g}$. The group of (isomorphism classes of) line bundles of degree d will be denoted by $Pic^d(\Sigma_g)$ and there is the canonical theta divisor $\Theta := \{L \in Pic^{g-1}(\Sigma_g) \mid h^0(\Sigma_g, L) \neq 0\} \subset Pic^{g-1}(\Sigma_g)$. We will denote by α^{-1} the inverse of the line bundle α and by $E^\vee$ the dual of the vector bundle E.

II. THE *bc*-SYSTEM REVISITED

Let $\alpha \in Pic^{g-1}(\Sigma_g) \backslash \Theta$, i.e., α is a line bundle of degree $g-1$ and satisfies $h^0(\Sigma_g, \alpha) = 0$. In the associated bc-system—given by an action $S \sim \int b \bar{\partial} c$—the field c (respectively, b) is a section of α (respectively, $K \otimes \alpha^{-1}$); note that there will be zero modes of neither b nor c due to our assumption on α. The propagator $\langle b(z)c(w) \rangle$ is then a meromorphic section of the line bundle $(K \otimes \alpha^{-1}) \boxtimes \alpha := \pi_1^*(K \otimes \alpha^{-1}) \otimes \pi_2^*(\alpha)$ over $\Sigma_g \times \Sigma_g$ having a simple pole on the diagonal $\Delta \subset \Sigma_g \times \Sigma_g$; here $\pi_i : \Sigma_g \times \Sigma_g \to \Sigma_g$, for $i = 1,2$, is the canonical projection onto the ith factor. Using the map $\phi_\alpha : \Sigma_g \times \Sigma_g \to Pic^{g-1}(\Sigma_g)$, given by $\phi_\alpha((z,w)) := \mathcal{O}(z-w) \otimes \alpha$, we pull back the theta divisor from $Pic^{g-1}(\Sigma_g)$ to obtain[5]

a)Electronic mail: schork@math.uni-frankfurt.de

$$\phi_\alpha^*(\mathcal{O}(\Theta)) \simeq (K\otimes\alpha^{-1})\boxtimes\alpha\otimes\mathcal{O}(\Delta). \tag{1}$$

Thus, the propagator is a meromorphic section of $\phi_\alpha^*(\mathcal{O}(\Theta))\otimes\mathcal{O}(-\Delta)$. Since the normalized section of $\phi_\alpha^*(\mathcal{O}(\Theta))$ is given by the (uniquely determined) theta function with characteristic α, i.e., by $\vartheta[\alpha](z-w)/\vartheta[\alpha](0)$, and the normalized section of $\mathcal{O}(\Delta)$ is given by the prime form $E(z,w)$, we get the desired result:

$$\langle b(z)c(w)\rangle = \frac{\vartheta[\alpha](z-w)}{\vartheta[\alpha](0)E(z,w)} \equiv S_\alpha(z,w). \tag{2}$$

In the case that α is an even theta characteristic, i.e., $\alpha^2=K$, the Szegö-kernel S_α—consequently the propagator also—is antisymmetric in its arguments.

In an analogous fashion one has maps $\phi_\alpha^n:(\Sigma_g\times\Sigma_g)^n\to Pic^{g-1}(\Sigma_g)$, given by

$$\phi_\alpha^n((z_1,w_1),\ldots,(z_n,w_n)) := \mathcal{O}\left(\sum_{i=1}^n z_i - \sum_{i=1}^n w_i\right)\otimes\alpha; \tag{3}$$

note that $\phi_\alpha^1=\phi_\alpha$ from above. The pullback of Θ under ϕ_α^n is given by[5,6]

$$(\phi_\alpha^n)^*(\mathcal{O}(\Theta))r \simeq (K\otimes\alpha^{-1})\boxtimes\alpha\boxtimes\cdots\boxtimes(K\otimes\alpha^{-1})\boxtimes\alpha\otimes\mathcal{O}(D_n), \tag{4}$$

where D_n is the divisor of poles and zeros

$$D_n := \sum_{1\le i<j\le 2n}(-1)^{i+j+1}\Delta_{ij} \tag{5}$$

and Δ_{ij} is the divisor where the ith and jth coordinates coincide. Hence, the $2n$-point function $\langle b(z_1)\cdots c(w_n)\rangle$ is given as the normalized section of $(\phi_\alpha^n)^*(\mathcal{O}(\Theta))\otimes\mathcal{O}(-D_n)$. Since the first factor leads to a theta function and the second to a product of prime forms, we obtain an explicit expression for the $2n$-point functions. Comparing the expression for the four-point function with the determinant of propagators (the bc-system is free, so the two expressions should coincide according to Wick's rule), we obtain the trisecant identity of Fay.[5,9] Now, let us turn to the higher rank case.

III. THE bc_r-SYSTEM

Let us denote by $\mathcal{U}_g(r,d)$ the moduli space of stable vector bundles of rank r and degree d on Σ_g; note that $\mathcal{U}_g(1,d)=Pic^d(\Sigma_g)$. In the case of higher rank we also have a natural "non-Abelian" theta divisor $\Theta_r := \{F\in\mathcal{U}_g(r,r(g-1)) \mid h^0(\Sigma_g,F)\neq 0\}\subset\mathcal{U}_g(r,r(g-1))$; for this see, e.g., Ref. 7 and the references given therein. The simplest bc_r-system is the one where no zero modes occur. For this to happen we have to choose $E\in\mathcal{U}_g(r,r(g-1))\backslash\Theta_r$. Then the field c (respectively, b) is a section of E (respectively, $K\otimes E^\vee$) and the action is given by $S\sim\int b\bar{\partial}_E c$, where a Hermitian metric on E is used to yield a good integrand. Consequently, the propagator $\langle b(z)c(w)\rangle$ is a meromorphic section of $(K\otimes E^\vee)\boxtimes E$ over $\Sigma_g\times\Sigma_g$ having a simple pole on the diagonal Δ. It is given[7] by the non-Abelian Szegö-kernel $S_E(z,w)$ as defined by Fay,[10] but explicit expressions are very difficult to obtain. In the following we will denote the highest nonvanishing exterior power of a vector bundle F by $\det(F)$. The determinant of the propagator is a section of $\det((K\otimes E^\vee)\boxtimes E)=\det(K\otimes E^\vee)\boxtimes\det(E)$. Since K is a line bundle and $E^\vee$ has rank r, we have

$$\det(K\otimes E^\vee) = K^{\otimes r}\otimes\det(E^\vee), \tag{6}$$

so that the determinant of the propagator is a meromorphic section of

$$(K^{\otimes r}\otimes\det(E^\vee))\boxtimes\det(E). \tag{7}$$

Now we need the geometric ingredients which are analogous to those used in the rank one case above. For $E \in \mathcal{U}_g(r, r(g-1))$ there is a map

$$\phi_E : \Sigma_g \times \Sigma_g \to \mathcal{U}_g(r, r(g-1)), \tag{8}$$

defined by $\phi_E((z,w)) := \mathcal{O}(z-w) \otimes E$. Since tensoring with a line bundle preserves stability and since $\deg(L \otimes E) = r\deg(L) + \deg(E)$ for any line bundle L, the map ϕ_E is indeed well defined. According to Ref. 8, the pullback of the non-Abelian theta divisor is given in complete analogy to (1) by

$$\phi_E^*(\mathcal{O}(\Theta_r)) \simeq (K^{\otimes r} \otimes \det(E^\vee)) \boxtimes \det(E) \otimes \mathcal{O}(\Delta)^{\otimes r}$$

[see Eq. (A2) in the Appendix]. Since we observed above (7) that the determinant of the propagator is a section of the line bundle $(K^{\otimes r} \otimes \det(E^\vee)) \boxtimes \det(E) = \phi_E^*(\mathcal{O}(\Theta_r)) \otimes \mathcal{O}(-\Delta)^{\otimes r}$, we can summarize these observations as follows.

Proposition 1: Let $E \in \mathcal{U}_g(r, r(g-1)) \backslash \Theta_r$ and ϕ_E as in (8). *Then the determinant of the propagator $\langle b(z)c(w) \rangle$ of the associated bc_r-system is a meromorphic section of the line bundle $\phi_E^*(\mathcal{O}(\Theta_r)) \otimes \mathcal{O}(-\Delta)^{\otimes r}$. In particular, one has for $z \sim w$ the expected singularity* $\det\langle b(z)c(w) \rangle \sim (z-w)^{-r}$.

Note that the above method gives only the determinant of the propagator. The propagator is given by $\langle b(z)c(w) \rangle = S_E(z,w)$, so that we identify the determinant of the non-Abelian Szegö-kernel as a pullback of the non-Abelian theta divisor:

$$\det(S_E(z,w)) \text{ is the meromorphic section of } \phi_E^*(\mathcal{O}(\Theta_r)) \otimes \mathcal{O}(-\Delta)^{\otimes r}.$$

In the rank one case we could use the fact that a section of $\phi_\alpha^*(\mathcal{O}(\Theta))$ is given by a theta function to obtain explicit expressions. The one-dimensionality of the space of theta functions (of level one) is expressed by $h^0(Pic^{g-1}(\Sigma_g), \mathcal{O}(\Theta)) = 1$. It is a fundamental result of Ref. 11 (and was essential for the mathematical proofs of the Verlinde formula, cf. Ref. 12) that this can be generalized to "non-Abelian theta functions," i.e., we have $h^0(\mathcal{U}_g(r, r(g-1)), \mathcal{O}(\Theta_r)) = 1$. This may be used to give an alternative proof of the existence and uniqueness of the propagator (and the higher correlation functions). On the other hand, it is well known[12] that this space of non-Abelian theta functions is very closely related to the space of conformal blocks of the Wess–Zumino–Witten (WZW) model on Σ_g with $\mathfrak{g} = \mathfrak{sl}(r, \mathbb{C})$ and level $k = 1$. Thus, there is indeed a geometrical connection between the bc_r-system and the above-mentioned WZW-model, as conjectured in Ref. 7.

In the usual bc-system the $U(1)$-current j_α is defined[3] by $j_\alpha(z) = -:b(z)c(z):$, where the dots indicate a regularization, which consists of subtracting the singularity in the operator product expansion of $b(z)c(w)$ before taking the limit $w \to z$. Thus, the one-point function of the current is given by

$$\langle j_\alpha(z) \rangle := -\lim_{w \to z} \left(\langle b(z)c(w) \rangle - \frac{1}{z-w} \right) = -a_0(z;\alpha), \tag{9}$$

where we have used (2) and the expansion of the Szegö-kernel, $S_\alpha(z,w) = 1/(z-w) + a_0(w;\alpha) + a_1(w;\alpha)(z-w) + \cdots$. Inserting the explicit expression for a_0 given in Ref. 10, one recovers the usual result.[13] In the bc_r-system associated to E the field b (respectively, c) is a section of $K \otimes E^\vee$ (respectively, E), so we expect that the regularized product $b(z)c(w)$ yields on the diagonal a section of $K \otimes \mathrm{End}(E)$. Defining the current J_E as above,

$$\langle J_E(z) \rangle := -\lim_{w \to z} \left(\langle b(z)c(w) \rangle - \frac{I}{z-w} \right) = -\lim_{w \to z} \left(S_E(z,w) - \frac{I}{z-w} \right),$$

we can now use the expansion of Fay's non-Abelian Szegö-kernel, $S_E(z,w) = I/(z-w) + a_0(w;E) + a_1(w;E)(z-w) + \cdots$, to obtain

$$\langle J_E(z)\rangle = -a_0(z;E),$$

in complete analogy to the rank one case above. According to p. 29 in Ref. 10, $a_0(z;E)$ is indeed a section of $K\otimes \mathrm{End}(E)$, as expected. In contrast to the rank one case, explicit expressions for the coefficients $a_i(z;E)$ are lacking. According to Raina[14,15] the geometric interpretation of this subtraction process requires that one considers the occuring bundles not on the diagonal $\Delta \simeq \Sigma_g \subset \Sigma_g \times \Sigma_g$, but on the first infinitesimal neighborhood of Δ. Following this approach he was able to give a complete treatment of the current j_α of the usual bc-system and rederive the explicit expressions known in the physical literature. It would be very beautiful if one had an analogous treatment of the current J_E of the bc_r-system.

Let us now consider the $2n$-point function $\langle b(z_1)c(w_1)\cdots b(z_n)c(w_n)\rangle$, which is a meromorphic section of the vector bundle $(K\otimes E^\vee)\boxtimes E\boxtimes\cdots\boxtimes(K\otimes E^\vee)\boxtimes E$ having simple poles (respectively, zeros) whenever two arguments of different (respectively, same) type coincide. In close analogy to the rank one case (3) we define a map

$$\phi_E^n : (\Sigma_g\times\Sigma_g)^n \to \mathcal{U}_g(r, r(g-1)),$$

$$((z_1,w_1),\ldots,(z_n,w_n)) \mapsto \mathcal{O}\left(\sum_{i=1}^n z_i - \sum_{i=1}^n w_i\right)\otimes E;$$

note that again $\phi_E^1 = \phi_E$. According to Ref. 8, the pullback of the non-Abelian theta divisor is then given in analogy to (4) by

$$(\phi_E^n)^*(\mathcal{O}(\Theta_r)) \simeq (K^{\otimes r}\otimes \det(E^\vee))\boxtimes\det(E)\boxtimes\cdots\boxtimes(K^{\otimes r}\otimes\det(E^\vee))\boxtimes\det(E)\otimes\mathcal{O}(D_n)^{\otimes r},$$

where D_n is the divisor defined in (5) [see Eq. (A1) in the Appendix]. Thus, using (6), we see that the (appropriately interpreted) determinant of the $2n$-point function is a section of $(\phi_E^n)^*(\mathcal{O}(\Theta_r))\otimes\mathcal{O}(-D_n)^{\otimes r}$. We collect these observations in the following proposition.

Proposition 2: Let $E\in\mathcal{U}_g(r,r(g-1))\backslash\Theta_r$ and $\phi_E^n:(\Sigma_g\times\Sigma_g)^n\to\mathcal{U}_g(r,r(g-1))$ be the map defined above. Then the determinant of the $2n$-point function $\langle b(z_1)\cdots c(w_n)\rangle$ of the associated bc_r-system is a meromorphic section of the line bundle $(\phi_E^n)^*(\mathcal{O}(\Theta_r))\otimes\mathcal{O}(-D_n)^{\otimes r}$.

Note that Proposition 2 reduces to Proposition 1 for $n=1$, since $D_1=\Delta_{12}\equiv\Delta$. As mentioned at the end of the last section, Raina was able to deduce the Fay identity from a comparison of two different representations of the four-point functions.[5,6] Since the bc_r-system is a free system, it was conjectured in Ref. 7 that a similar procedure should lead to a "non-Abelian Fay identity." The above results are by far too weak to establish such an identity, but nevertheless might provide a nontrivial check. A very promising result into the desired direction is contained in Ref. 8; a closely related result from a different point of view can be found in Ref. 16.

In the usual bc-system the four-point function $\langle b(z_1)c(w_1)b(z_2)c(w_2)\rangle$ is very important, since considering the limits $w_1\to z_1$, $w_2\to z_2$ of its regularized explicit form yields the two-point function $\langle j_\alpha(z_1)j_\alpha(z_2)\rangle$ of the current.[13] Considering, furthermore, the regularized limit $z_2\to z_1$, one obtains the one-point function of the energy-momentum tensor T_α:

$$\langle T_\alpha(z)\rangle := \frac{1}{2}\lim_{w\to z}\left(\langle j_\alpha(z)j_\alpha(w)\rangle - \frac{1}{(z-w)^2}\right) = a_1(z;\alpha) - \frac{1}{2}\partial_z a_0(z;\alpha); \tag{10}$$

in the second equation we have used again the coefficients a_i of the Szegö-kernel S_α. Inserting the explicit expressions for the a_i given in Ref. 10 yields the result of the physical literature.[4,17,18] Raina and Biswas have managed to give an algebro-geometric description of the energy-momentum tensor, this time using the second infinitesimal neighborhood of the diagonal.[15,19] In the bc_r-system the associated energy-momentum tensor T_E should be given as the limit of the regularized two-point function of the current J_E, i.e., $T_E(z)\sim :J_E(z)\otimes J_E(z):$. Local computations for the operator product expansion of $J_E(z)\otimes J_E(w)$ suggest, that—due to the non-Abelian struc-

ture coming from the higher rank—additional terms with a simple pole will appear and have to be subtracted, too. The main problem is that one does not have an explicit expression for the four-point function. In particular, there seems to be no straightforward generalization of Wick's rule, meaning here that one could calculate the four-point function as some kind of determinant of propagators. One expects that a relation similar to (10)—involving this time $a_0(z;E), a_1(z;E)$ and $\partial_z a_0(z;E)$—holds also in the higher rank case, where the additional tensor product structure will be involved. The naive expectation is that $\langle T_E(z)\rangle$ is a section of $K^{\otimes 2}\otimes \mathrm{End}(E)^{\otimes 2}$, but this is already false in the rank one case. Due to the regularization procedure the conformal symmetry is lost,[20] so that $12\langle T_\alpha(z)\rangle$ is a projective connection,[21] transforming as some kind of "perturbed" quadratic differential. One may wonder whether there is an analogous geometric structure lurking behind $\langle T_E(z)\rangle$.

IV. DISCUSSION

We have seen that the determinants of the correlation functions of the bc_r-system can be written as pullbacks of the non-Abelian theta divisor. It is not clear whether one can describe the correlation functions themselves within the approach pursued here. The current J_E was defined by $J_E(z)\sim :b(z)c(z):$, which can be written locally [where we write the field c as $c=(c_1,\ldots,c_r)^t$ and similarly for b] as $J_{E,ij}(z)\sim :b^j(z)c^i(z):$. Locally one can also define currents $J^a_{ij}\sim :b^j(T^a c)^i:$ for a simple Lie algebra $\mathfrak{g}$ with generators $\{T^a\}$. It is well known that the traces of J^a, i.e., $j^a:=\mathrm{Tr}(J^a)\sim :b^i T^a_{ij} c^j:$, give rise to a current algebra, thus to representations of the affine Lie algebra $\hat{\mathfrak{g}}$, (see p. 646 in Ref. 22). These affine Lie algebras correspond to WZW models, so that one expects that a geometric definition of the currents J^a [together with the $U(1)$-current J_E] should give a geometric interpretation of the non-Abelian bosonization.[23]

We hope that a further examination of the bc_r-system will uncover more interesting connections to the geometry of the non-Abelian theta divisor as well as to the corresponding WZW model. As should be clear from the above remarks and the discussion in Ref. 7, the main obstacle for further progress is that a suitably generalized Wick's rule lacks. If one had some kind of suitably generalized determinant DET for these matrices with matrix-valued entries, Wick's rule for the four-point function would mean that $\langle b(z_1)c(w_1)b(z_2)c(w_2)\rangle=\mathrm{DET}(\langle b(z_i)c(w_j)\rangle)$ and that one could use the right-hand side for all the computations indicated above, in particular for the energy-momentum tensor.

APPENDIX: A RESULT OF GÓMEZ GONZÁLES AND PLAZA MARTÍN

Here we state a recent result of Gómez Gonzáles and Plaza Martín concerning the pullback of the non-Abelian theta divisor Θ_r under the "addition morphism"; this is Theorem 3.1 in Ref. 8. From our point of view they are working not with a single system, but with a family parametrized by some scheme S. Their setup is as follows (we have slightly changed their notation to be consistent with the one used above). Let S be a scheme and Σ_g an irreducible proper smooth algebraic curve of genus $g\geqslant 2$ over $\mathbb{C}$ (i.e., a Riemann surface). We denote by $\mathcal{U}_g^{ss}(r,d)$ the moduli space of (equivalence classes of) semistable vector bundles of rank r and degree d on Σ_g; Seshadri proved that $\mathcal{U}_g^{ss}(r,d)$ is the natural compactification of $\mathcal{U}_g(r,d)$ from above.[24] The closure of Θ_r from above in $\mathcal{U}_g^{ss}(r,r(g-1))$ is again a divisor, which we also denote by Θ_r. Let $\mathcal{E}$ be a semistable bundle of rank r and degree $r(g-1)$ on $\Sigma_g\times S$; we interpret this as a family $\{\mathcal{E}_s\}_{s\in S}$ (with $\mathcal{E}_s\equiv\mathcal{E}_{|\Sigma_g\times\{s\}}$) of semistable bundles $\mathcal{E}_s\in\mathcal{U}_g^{ss}(r,r(g-1))$ on $\Sigma_g\times\{s\}\simeq\Sigma_g$. Let us furthermore introduce a map $\psi_{\mathcal{E}}:S\to\mathcal{U}_g^{ss}(r,r(g-1))$ by associating to $s\in S$ the restriction of $\mathcal{E}$ to $\Sigma_g\times\{s\}\simeq\Sigma_g$, i.e., $\psi_{\mathcal{E}}(s)=\mathcal{E}_s$. For each $n\in\mathbb{N}$ we now introduce the relative version of the generalization of (3), namely,

$$\phi^n_{\mathcal{E};S}:(\Sigma_g\times\Sigma_g)^n\times S\to\mathcal{U}_g^{ss}(r,r(g-1)),$$

$$((z_1,w_1),\ldots,(z_n,w_n),s)\mapsto\mathcal{O}\left(\sum_{i=1}^n z_i-\sum_{i=1}^n w_i\right)\otimes\mathcal{E}_s.$$

For $1\leqslant i\leqslant 2n$ there are natural projections p_i (respectively, π_i) from $(\Sigma_g\times\Sigma_g)^n\times S$ onto Σ_g (respectively, $\Sigma_g\times S$), where in both cases the image Σ_g is the ith component of $(\Sigma_g\times\Sigma_g)^n$. Let us denote the highest exterior product of a bundle F by $\det(F)$.

Theorem (Gómez Gonzáles, Plaza Martín): *Let $\mathcal{E}$ be a semistable vector bundle on $\Sigma_g\times S$ of rank r and degree $r(g-1)$. Then there is an isomorphism of line bundles on $(\Sigma_g\times\Sigma_g)^n\times S$:*

$$(\phi^n_{\mathcal{E};S})^*(\mathcal{O}(\Theta_r))\simeq\mathcal{O}(D_n)^{\otimes r}\otimes\left\{\bigoplus_{i=1}^{n}\left[\pi^*_{2i-1}(\det(\mathcal{E}^\vee))\otimes p^*_{2i-1}(K^{\otimes r})\otimes\pi^*_{2i}(\det(\mathcal{E}))\right]\right\}\otimes\psi^*_{\mathcal{E}}(\mathcal{O}(\Theta_r)),$$

where D_n is given in (5).

We will use this result in the very special case of a trivial family, i.e., we choose S to be a point $\{s_0\}$. We identify π_i and p_i and neglect the trivial map $\psi_{\mathcal{E}}$. Furthermore, the "family" $\mathcal{E}=\{\mathcal{E}_s\}_{s\in\{s_0\}}$ parametrized by one point is just one bundle $\mathcal{E}_{s_0}=\mathcal{E}_{|\Sigma_g\times\{s_0\}}$, which we denote by E. Then the formula of the theorem reduces to

$$\begin{aligned}(\phi^n_E)^*(\mathcal{O}(\Theta_r))&\simeq\mathcal{O}(D_n)^{\otimes r}\otimes\bigoplus_{i=1}^{n}\{p^*_{2i-1}(\det(E^\vee)\otimes K^{\otimes r})\otimes p^*_{2i}(\det(E))\}\\&\simeq\mathcal{O}(D_n)^{\otimes r}\otimes(K^{\otimes r}\otimes\det(E^\vee))\boxtimes\det(E)\boxtimes\cdots\boxtimes(K^{\otimes r}\otimes\det(E^\vee))\boxtimes\det(E),\end{aligned}\tag{A1}$$

where we have written $\phi^n_E:=\phi^n_{E;\{s_0\}}$. In particular, choosing $n=1$ one obtains with $D_1=\Delta_{12}\equiv\Delta$ and the abbreviation $\phi_E:=\phi^1_E$ the result

$$\phi^*_E(\mathcal{O}(\Theta_r))\simeq\mathcal{O}(\Delta)^{\otimes r}\otimes(K^{\otimes r}\otimes\det(E^\vee))\boxtimes\det(E).\tag{A2}$$

Quasigraded Lie algebras on hyperelliptic curves and classical integrable systems

T. Skrypnyk[a)]
Institute for Theoretical Physics, Metrologichna st., 14 b, 03143, Kiev, Ukraine

(Received 27 September 2000; accepted for publication 28 February 2001)

A new family of infinite-dimensional Lie algebras on hyperelliptic curves is constructed. We show them to be quasigraded and explicitly find their central extensions. We also show, that constructed algebras in the case of zero central charge possess infinite number of invariant functions. Besides, they admit a decomposition into the direct sum of two subalgebras. These two facts together enables one to use them to construct new integrable systems. In such a way we find new integrable Hamiltonian systems, which are direct higher rank generalizations of the integrable systems of Steklov–Liapunov, associated with the e(3) algebra and Steklov–Veselov associated with the so(4) algebra. Besides we give hyperelliptic Lax representation for the generalized Euler tops. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1379066]

I. INTRODUCTION

The main purpose of the present paper is to introduce new integrable systems of Euler–Arnold-type on the finite-dimensional Lie algebras. It is known, that such systems admit Lax-pair representations (see Ref. 1),

$$\frac{dL(t)}{dt}=[L(t),M(t)], \tag{1}$$

where L and M are some matrix depending on the dynamical variables.

Almost in all cases the Lax operator depends also on an additional parameter, the so-called "spectral parameter," w: $L=L(w)$. This dependence permits to construct large number of integrals of motion via the expansion of functions $I^k(w)=\mathrm{Tr}\,L(w)^k$ in the series of the powers of the spectral parameter. Usually dependence of the Lax operator on w is rational or elliptic.

The natural approach to construction of new types of integrable systems is the search for the solutions of Lax equations with other (more complicated) dependence on the spectral parameter. We will solve this problem for the case of $L(w)$ with the hyperelliptic dependence on the spectral parameter.

Our approach is based on the usage of infinite-dimensional Lie algebras. It is known (see Refs. 2–4) that a group theoretical explanation of the integrability of Lax equations on finite-dimensional Lie algebras with the rational spectral parameters is based on the loop algebras, i.e., algebras of the form $\mathfrak{g}\otimes P(\lambda,\lambda^{-1})$. In the works (Refs. 5–7) it was shown, that the Lax equation with the elliptic spectral parameters on the algebra so(3) and some of its extensions could be obtained from the infinite-dimensional Lie algebras of the elliptic functions with the values in so(3) via the Kostant–Adler scheme (Refs. 8 and 9, see also Refs. 2–4).

We generalize construction of Ref. 6 on the case of classical matrix algebras of higher rank and investigate corresponding finite-dimensional integrable systems. Growth of the rank of algebra requires automatic growth of the genus of the curve. As a result we obtain algebras of gl(n)-, so(n)-, and sp(n)-valued functions on the hyperelliptic curves of genus $\mathfrak{g}$, where $n=2g+2$ or

a)Electronic mail: tskrypnyk@imath.kiev.ua

$n=2g+1$, or, to be more precise, on its double covering. Obtained algebras have many nice properties. They are quasigraded. They possess infinite number of invariant functions. They possess central extensions. In the rational degeneration of the curve they coincides with the ordinary loop algebras. So they could be viewed as ''hyperelliptic'' generalizations of the loop algebras.

There exists other higher genus generalization of the loop algebras, the so-called Krichiver–Novikov algebras (Ref. 10) of the matrix-valued holomorphic functions on the Riemanian surfaces with two punctured points. But Krichiver–Novikov algebras do not admit Kostant–Adler scheme compatible with quasigrading (see Ref. 11). Hence this generalization can not be used for producing new integrable systems with the spectral parameter on the higher genus curves.

Contrary to the Krichiver–Novikov algebras our algebras admit the Kostant–Adler scheme, and hence, could be used for constructing integrable systems.

Using our algebra as hidden symmetry algebra we obtain new integrable systems on $\mathfrak{g}\oplus\mathfrak{g}$ that describe two interacting generalized rigid bodies. This system is a direct higher rank generalization of the integrable case of Steklov and Veselov (see Ref. 12) on $so(4)=so(3)\oplus so(3)$. We also obtain new integrable systems on the semidirect sum $\mathfrak{g}+\mathfrak{g}$, that generalize the integrable case of Steklov–Liapunov on e(3) (see Ref. 13). Both systems possess natural hyperelliptic Lax representations. Besides, we find hyperelliptic Lax representation for the generalized Euler tops.

The structure of the discovered algebras provides the possibility of giving a two-dimensional generalization of the constructed integrable systems via the finite-gap extension method (see Refs. 5–7). We will return to this problem in our subsequent publications.

II. QUASIGRADED ALGEBRAS ON HYPERELLIPTIC CURVES

A. Hyperelliptic curve embedded in $\mathbb{C}^n$

Let us consider in the space $\mathbb{C}^n$ with the coordinates $w_1,w_2,\ldots,w_n$ the following system of quadrics:

$$w_i^2-w_j^2=a_j-a_i, \quad i,j=1,n, \tag{2}$$

where a_i are arbitrary complex numbers. Rank of this system is $n-1$, so substitution

$$w_i^2=w-a_i,$$

solves these equations. Moreover if we put $y=\prod_{i=1}^{n} w_i$ we obtain the equation of the hyperelliptic curve $\mathcal{H}$,

$$y^2=\prod_{i=1}^{n}(w-a_i). \tag{3}$$

Hence Eqs. (2) define embedding of the hyperelliptic curve $\mathcal{H}$ into the linear space C^n. Variable w is a local parameter on the curve and a_i its branching points.

Example 1: In the $n=3$ case all of these objects have a well-known analytical description. Indeed in this case curve under the consideration is elliptic. Its uniformization is made by the Weierstrass $\mathfrak{p}$-function and its derivative: $w=\mathfrak{p}(u)$, $y=1/2\mathfrak{p}'(u)$. Functions w_i are expressed via Jacobi elliptic functions (see Ref. 14), $w_1=1/\mathrm{sn}(u)$, $w_2=\mathrm{dn}(u)/\mathrm{sn}(u)$, $w_3=\mathrm{cn}(u)/\mathrm{sn}(u)$.

B. Classical Lie algebras

Let $\mathfrak{g}$ denote one of the classical matrix Lie algebras $\mathrm{gl}(n)$, $\mathrm{so}(n)$, and $\mathrm{sp}(n)$ over the field of the complex numbers. For the subsequent we will need a special form of their bases. Let us explicitly construct them. Let $I_{ij}\in \mathrm{Mat}(n,\mathbb{C})$ be a matrix defined as follows:

$$(I_{ij})_{ab}=\delta_{ia}\delta_{jb}.$$

Evidently, a basis in the algebra gl(n) could be built from the matrices $X_{ij}\equiv I_{ij}, i,j\in 1,...,n$. The commutation relations in gl(n) will have the following standard form:

$$[X_{ij},X_{kl}]=\delta_{kj}X_{il}-\delta_{il}X_{kj}.$$

The basis in the algebra so(n) could be chosen as $X_{ij}\equiv I_{ij}-I_{ji}$, $i,j\in 1,...,n$, with the following commutation relations:

$$[X_{ij},X_{kl}]=\delta_{kj}X_{il}-\delta_{il}X_{kj}+\delta_{jl}X_{ki}-\delta_{ki}X_{jl},$$

and "skew-symmetry" property $X_{ij}=-X_{ji}$.

The basis in the algebra sp(n) consists of the matrices $X_{ij}=I_{ij}-\epsilon_i\epsilon_j I_{-i-j}$, $i,j\in -n,\ldots,-1,1,...,n$, with the commutation relations

$$[X_{ij},X_{kl}]=\delta_{kj}X_{il}-\delta_{il}X_{kj}+\epsilon_i\epsilon_j(\delta_{j-l}X_{k-i}-\delta_{k-i}X_{-jl}),$$

and additional property $X_{ij}=-\epsilon_i\epsilon_j X_{-j-i}$, where $\epsilon_j=\operatorname{sign} j$.

C. Algebras on the curve

For the basic elements X_{ij} of all three algebras gl(n), so(n), and sp(n) we introduce the following algebra-valued functions on the curve $\mathcal{H}$, or to be more precise on its double covering,

$$X_{ij}^{+}(w)=X_{ij}\otimes w_i w_j,\quad X_{ij}^{-}(w)=X_{ij}\otimes w^{-1}w_i w_j. \tag{4}$$

Here we put $w_{-i}\equiv w_i$ in the case of sp(n). We will need the following definition (Ref. 10):

Definition 1: Infinite-dimensional Lie algebra $\tilde{\mathfrak{g}}$ is called $\mathbb{Z}$ quasigraded if there exists such $p,q\in\mathbb{Z}_+$ that

$$\tilde{\mathfrak{g}}=\sum_{j\in\mathbb{Z}}\tilde{\mathfrak{g}}_j,\quad \text{such that}\quad [\tilde{\mathfrak{g}}_i,\tilde{\mathfrak{g}}_j]\subset\sum_{k=-p}^{q}\tilde{\mathfrak{g}}_{i+j+k}. \tag{5}$$

The following theorem holds true:

Theorem 1: *(i) Functions $X_{ij}^{+}(w)$ and $X_{ij}^{-}(w)$ generate infinite-dimensional $\mathbb{Z}$ quasigraded Lie algebra $\tilde{\mathfrak{g}}_{\mathcal{H}}$.*
(ii) There exists a decomposition: $\tilde{\mathfrak{g}}_{\mathcal{H}}=\tilde{\mathfrak{g}}_{\mathcal{H}}^{+}+\tilde{\mathfrak{g}}_{\mathcal{H}}^{-}$, *where $\tilde{\mathfrak{g}}_{\mathcal{H}}^{+}$ and $\tilde{\mathfrak{g}}_{\mathcal{H}}^{-}$ are generated by $X_{ij}^{+}(w)$ and $X_{ij}^{-}(w)$, correspondingly.*

Proof: Let us introduce the following algebra-valued functions on the double covering of the curve $\mathcal{H}$:

$$X_{ij}^{n}=X_{ij}\otimes w^n w_i w_j.$$

To prove the theorem we will need the explicit form of their commutation relations:

Proposition 1: Elements X_{ij}^{n} form closed algebra with the following commutation relations:

$$(1)\quad [X_{ij}^{n},X_{ij}^{m}]=\delta_{kj}X_{il}^{n+m+1}-\delta_{il}X_{kj}^{n+m+1}+a_i\delta_{il}X_{kj}^{n+m}-a_j\delta_{kj}X_{il}^{n+m}\quad \text{for the gl}(n), \tag{6a}$$

$$(2)\quad [X_{ij}^{n},X_{ij}^{m}]=\delta_{kj}X_{il}^{n+m+1}-\delta_{il}X_{kj}^{n+m+1}+\delta_{jl}X_{ki}^{n+m+1}-\delta_{ik}X_{jl}^{n+m+1}+a_i\delta_{il}X_{kj}^{n+m}-a_j\delta_{kj}X_{il}^{n+m}$$
$$+a_i\delta_{ik}X_{jl}^{n+m}-a_j\delta_{jl}X_{ki}^{n+m}\quad \text{for the so}(n), \tag{6b}$$

$$(3)\quad [X_{ij}^{n},X_{ij}^{m}]=\delta_{kj}X_{il}^{n+m+1}-\delta_{il}X_{kj}^{n+m+1}+\epsilon_i\epsilon_j(\delta_{j-l}X_{k-i}^{n+m+1}-\delta_{i-k}X_{j-l}^{n+m+1})+a_i\delta_{il}X_{kj}^{n+m}$$
$$-a_j\delta_{kj}X_{il}^{n+m}+a_i\epsilon_i\epsilon_j(a_i\delta_{i-k}X_{j-l}^{n+m}-a_j\delta_{j-l}X_{k-i}^{n+m})\quad \text{for the sp}(n). \tag{6c}$$

Let us put

$$\tilde{\mathfrak{g}}_{\mathcal{H}} = \mathrm{Span}_{\mathbb{C}}\{X_{ij}^{m},\ m \in \mathbb{Z}\}.$$

From Proposition 1 follows that $\tilde{\mathfrak{g}}_{\mathcal{H}}$ is quasigraded. Besides, let us define the following subspaces:

$$\tilde{\mathfrak{g}}_{\mathcal{H}}^{+} = \mathrm{Span}_{\mathbb{C}}\{X_{ij}^{m}, m \geqslant 0\}, \tilde{\mathfrak{g}}_{\mathcal{H}}^{-} = \mathrm{Span}_{\mathbb{C}}\{X_{ij}^{-m}, m > 0\}.$$

From Proposition 1 follows that they are subalgebras. Taking into account that $X_{ij}^{+}(w) = X_{ij}^{0}$, $X_{ij}^{-}(w) = X_{ij}^{-1}$ and Proposition 1, it is easy to see that elements $X_{ij}^{+}(w)$ generate subalgebra $\tilde{\mathfrak{g}}_{\mathcal{H}}^{+}$ and elements $X_{ij}^{-}(w)$ generate subalgebra $\tilde{\mathfrak{g}}_{\mathcal{H}}^{-}$. Hence $X_{ij}^{+}(w)$ and $X_{ij}^{-}(w)$ generate $\tilde{\mathfrak{g}}_{\mathcal{H}}$. Theorem is proved.

Example 2: Let $\mathfrak{g} = \mathrm{so}(3)$. In this case the constructed algebra will coincide with the ''even'' subalgebra of the algebra of hidden symmetry of Landau–Lifschits equations (Ref. 5). Indeed, putting $X_k \equiv \epsilon_{ijk} X_{ij}$, we obtain the following commutation relations (Ref. 6):

$$[X_i^n, X_j^m] = \epsilon_{ijk} X_k^{n+m+1} + \epsilon_{ijk} a_k X_k^{n+m}.$$

Remark 1: From Proposition 1 follows, that in the rational degeneration of $\mathcal{H}$,

$$y^2 = w^n,$$

i.e., when $a_i = 0$, we obtain, that $w_i = \sqrt{w}$ and, hence, $\tilde{\mathfrak{g}}_{\mathcal{H}} = \tilde{\mathfrak{g}}$, where $\tilde{\mathfrak{g}}$ is a loop algebra.

Remark 2: Although algebra $\tilde{\mathfrak{g}}_{\mathcal{H}}$ was defined over the field of complex numbers, analogous construction, evidently, is also valid in the case when main field is $\mathbb{R}$. We have only to require in this case that $a_i \in \mathbb{R}$.

III. CENTRAL EXTENSION

To have the full analogy with the loop algebra, and keeping in mind possible application to quantum integrable systems, in this subsection we define central extensions of the algebras $\tilde{\mathfrak{g}}_{\mathcal{H}}$. First we are reminded of the following definition (see Ref. 10):

Definition 2: Cocycle χ on the quasigraded algebra is called local if

$$\chi(X_{ij}^{m}, X_{kl}^{n}) = 0, \quad \text{for all } |n+m| > K \text{ and for some } K \in \mathbb{Z}_{+}.$$

Let $(X|Y) = c_n \,\mathrm{tr}\, XY$, where $c_n = 2n$ for $\mathrm{gl}(n)$, $c_n = (n-2)$ for $\mathrm{so}(n)$, $c_n = (2n+2)$ for $\mathrm{sp}(n)$, be a standard invariant form on the classical Lie algebras $\mathrm{gl}(n)$, $\mathrm{so}(n)$ or $\mathrm{sp}(n)$. Let us define on $\tilde{\mathfrak{g}}_{\mathcal{H}}$ the following bilinear form:

$$\chi(X(w), Y(w)) = \oint \left(X(w) \middle| \frac{dY(w)}{dw} \right) dw, \tag{7}$$

where 1-cycle γ in the complex plane of variable w encircles point $w = 0$. The following theorem holds true:

Theorem 2: *(i) Bilinear form χ is skew-symmetric and satisfies the properties of the cocycle, and hence, determines a central extension of $\tilde{\mathfrak{g}}_{\mathcal{H}}$: $\hat{\mathfrak{g}}_{\mathcal{H}} = \tilde{\mathfrak{g}}_{\mathcal{H}} + \mathbb{C}c$ by the following formula:*

$$[X(w) + \alpha c, Y(w) + \beta c]' = [X(w), Y(w)] + \chi(X(w), Y(w))c.$$

(ii) Cocycle χ is local and its values on the bases elements are calculated by the following formulas:

$$\chi(X_{ij}^{m}, X_{kl}^{n}) = \chi^{mn}(a_i, a_j)(X_{ij}|X_{kl}), \tag{8}$$

where

$$\chi^{mn}(a_i, a_j) = (n+1)\delta_{n+m+2,0} - (n+1/2)(a_i + a_j)\delta_{n+m+1,0} + n a_i a_j \delta_{n+m,o}. \tag{9}$$

Proof: Skew symmetry of χ follows from the symmetry of $(\,|\,)$ and skew symmetry of the operator of differentiation. The skew symmetry of the differentiation operator is easy to prove by partial integration. We need only to prove, that integrated function is one-valued. Indeed, under the arbitrary values of the indices *i,j,k,l,* it is not true because it will contain square roots of the type, $w_i=\pm\sqrt{w-a_i}$. But direct calculation of the values of the invariant form $(\,|\,)$ on the bases vectors X_{ij} shows that expression (8) is not zero if and only if $i=l$, $j=k$ or $i=\pm k$, $j=\pm l$. Indeed: $(X_{ij}|X_{kl})=2n\delta_{il}\delta_{jk}$ for gl(n), $(X_{ij}|X_{kl})=(n-2)(\delta_{il}\delta_{jk}-\delta_{ik}\delta_{jl})$ for so(n), $(X_{ij}|X_{kl})=(2n+2)\times(\delta_{il}\delta_{jk}-\epsilon_i\epsilon_j\delta_{i-k}\delta_{j-l})$ for sp(n). Taking this into account we obtain

$$\begin{aligned}\chi(X^m_{ij},X^n_{kl})&=(X_{ij}|X_{kl})\left(\oint_\gamma w^m w_i w_j d(w^n w_k w_l)\right)\\&=(X_{ij}|X_{kl})\left(\oint_\gamma d(w^{n+m}w_i w_j w_k w_l)-\oint_\gamma w^n w_k w_l d(w^m w_i w_j)\right)\\&=-(X_{kl}|X_{ij})\left(\oint_\gamma w^n w_k w_l d(w^m w_i w_j)\right)\\&=-\chi(X^n_{kl},X^m_{ij}).\end{aligned}$$

This proves skew symmetry of the differentiation operation under the integral on the basic vectors and, hence on all algebras $\tilde{\mathfrak{g}}_{\mathcal{H}}$. Let us prove the cocycle property,

$$\chi([X(w),Y(w)],Z(w)])+\chi([Z(w),X(w)],Y(w)])+\chi([Y(w),Z(w)],X(w)])=0.$$

It is enough to consider the case when elements $X(w),Y(w),Z(w)$ coincide with the basis vectors. Let

$$F(X^p_{ij},X^s_{kl},X^t_{mn})\equiv\chi([X^p_{ij},X^s_{kl}],X^t_{mn})])+\chi([X^t_{mn},X^p_{ij}],X^s_{kl}])+\chi([X^s_{kl},X^t_{mn}],X^p_{ij}]).$$

Then taking into account the symmetry and Ad_G-invariance of $(\,|\,)$, we obtain

$$F(X^p_{ij},X^s_{kl},X^t_{mn})=([X_{ij},X_{kl}]|X_{mn})\oint_\gamma d(w^{p+s+t}w_i w_j w_k w_l w_m w_n).$$

Taking into account the explicit form of the commutation relation and invariant form, we see that function under the integration is one-valued. Hence, the correspondent integral is identically equal to zero. Part (i) is proved. Formula (8) follows from the arguments used in proof of part (i). Explicitly,

$$\chi^{mn}(a_i,a_j)=\left(\oint_\gamma w^m w_i w_j d(w^n w_i w_j)\right)=n\oint_\gamma w_i^2 w_j^2 w^{n+m-1}dw+1/2\oint_\gamma(w_i^2+w_j^2)w^{m+n}dw.$$

Taking into account that $w_i^2=w-a_i$ we obtain formula (9). Locality of cocycle follows from its explicit form. Theorem is proved.

Example 3: In the case of rational degeneration $a_i=0$ we obtain the following cocycle on the loop algebra:

$$\chi(X^m_{ij},X^n_{kl})=(n+1)\,\delta_{n+m+2,0}(X_{ij}|X_{kl}).$$

It passes to the standard one after passing to the standard basis by renaming the indices $m\to m-1$, $n\to n-1$.

IV. COADJOINT REPRESENTATION AND ITS INVARIANTS

To define the coadjoint representation we have to define $\tilde{\mathfrak{g}}^*_{\mathcal{H}}$. We assume that $\tilde{\mathfrak{g}}^*_{\mathcal{H}} \subset \mathfrak{g} \otimes A$, where A is an algebra of function on the double covering of the curve $\mathcal{H}$. Let us define the invariant pairing between $L(w) \in \tilde{\mathfrak{g}}^*_{\mathcal{H}}$ and $X(w) \in \tilde{\mathfrak{g}}_{\mathcal{H}}$ in the following way:

$$\langle X(w), L(w) \rangle_f = c_r \operatorname{res}_{w=0} f^{-1}(w) y^{-1}(w) (X(w) | Y(w)), \tag{10}$$

where $f(w)$ is arbitrary function on the curve $\mathcal{H}$. It is easy to show that element dual to X^{-m}_{ij} with respect to this pairing is $Y^m_{ij} \equiv (X^{-m}_{ij})^* = [w^{m-1} f(w) y(w) / w_i w_j] X^*_{ij}$. Hence the general element of the dual space has the following form:

$$L(w) = \sum_{m \in Z} \sum_{i,j=1}^{n} l^m_{ij} \frac{w^{m-1} f(w) y(w)}{w_i w_j} X^*_{ij}. \tag{11}$$

Coadjoint action of algebra $\tilde{\mathfrak{g}}_{\mathcal{H}}$ on its dual space $\tilde{\mathfrak{g}}^*_{\mathcal{H}}$ coincides with commutator,

$$\mathrm{ad}^*_{X(w)} L(w) = [L(w), X(w)]. \tag{12}$$

Explicitly co-adjoint action of the algebra has the following form:

$$(1)\ [X^n_{ij}, Y^m_{kl}] = \delta_{kj} Y^{n+m+1}_{il} - \delta_{il} Y^{n+m+1}_{kj} + a_j \delta_{il} Y^{n+m}_{kj} - a_i \delta_{kj} Y^{n+m}_{il} \quad \text{for the } \mathrm{gl}(n),$$

$$(2)\ [X^n_{ij}, Y^m_{kl}] = \delta_{kj} Y^{n+m+1}_{il} - \delta_{il} Y^{n+m+1}_{kj} + \delta_{jl} Y^{n+m+1}_{ki} - \delta_{ik} Y^{n+m+1}_{il} + a_j \delta_{il} Y^{n+m}_{kj} - a_i \delta_{kj} Y^{n+m}_{il} + a_j \delta_{ik} Y^{n+m}_{jl} - a_i \delta_{jl} Y^{n+m}_{ki} \quad \text{for the } \mathrm{so}(n),$$

$$(3)\ [X^n_{ij}, Y^m_{kl}] = \delta_{kj} Y^{n+m+1}_{il} - \delta_{il} Y^{n+m+1}_{kj} + \epsilon_i \epsilon_j (\delta_{j-l} Y^{n+m+1}_{k-i} - \delta_{i-k} Y^{n+m+1}_{j-l}) + a_j \delta_{il} Y^{n+m}_{kj} - a_i \delta_{kj} Y^{n+m}_{il} + \epsilon_i \epsilon_j (a_j \delta_{i-k} Y^{n+m}_{j-l} - a_i \delta_{j-l} Y^{n+m}_{k-i}) \quad \text{for the } \mathrm{sp}(n).$$

It is evident from the above formulas, that $\tilde{\mathfrak{g}}^*_{\mathcal{H}}$ is a quasigraded $\tilde{\mathfrak{g}}_{\mathcal{H}}$-module,

$$\tilde{\mathfrak{g}}^*_{\mathcal{H}} = \sum_{m \in \mathbb{Z}} (\tilde{\mathfrak{g}}^*_{\mathcal{H}})_m,$$

where $(\tilde{\mathfrak{g}}^*_{\mathcal{H}})_m = \mathrm{Span}_C \{ Y^m_{ij} | i,j = 1,...,n \}$.

Remark 3: Putting $f(w) = y(w)$ in the definition of the elements of dual space we obtain, $\tilde{\mathfrak{g}}^*_{\mathcal{H}} = \tilde{\mathfrak{g}}_{\mathcal{H}}$, i.e., dual element to each element of $\tilde{\mathfrak{g}}_{\mathcal{H}}$ belongs to $\tilde{\mathfrak{g}}_{\mathcal{H}}$. If $f(w) \neq y(w)$, then generally speaking, spaces $\tilde{\mathfrak{g}}^*_{\mathcal{H}}$ and $\tilde{\mathfrak{g}}_{\mathcal{H}}$, considering as subspaces in the algebra of functions on the double covering of the curve $\mathcal{H}$, do not coincide.

Remark 4: If $f = 1$ and $\mathfrak{g} = \mathrm{so}(n)$ elements of $\tilde{\mathfrak{g}}_{\mathcal{H}} + \tilde{\mathfrak{g}}^*_{\mathcal{H}}$ form a closed algebra. This will be an analog of the algebra of hidden symmetry of Landau–Lifschits equations (see Ref. 5). Unfortunately, for $n > 4$ it does not admit a Kostant–Adler scheme and cannot be used for the construction of integrable systems. That is why we will not consider it here.

From the explicit form of coadjoint action (12) follows the next statement:

Proposition 2: Functions $I^k_m(L(w)) = r \epsilon s_{w=0} w^{-m-1} Tr\, L(w)^k$, *where* $m \in \mathbb{Z}$, *are invariants of a coadjoint representation.*

Hence constructed Lie algebras not only admit decomposition into a direct sum of two subalgebras but also possess an infinite number of invariant functions. This permits us to use them in construction of integrable systems.

V. INTEGRABLE SYSTEMS FROM HYPERELLIPTIC ALGEBRAS

A. First Lie–Poisson structure

In the space $\tilde{\mathfrak{g}}^*_{\mathcal{H}}$ it is possible to define many Lie–Poisson structures using different pairings. We will use the pairing (10) with $f(w)=w$,

$$\langle X(w),L(w)\rangle_{-1}=c_n \operatorname{res}_{w=0} w^{-1}y^{-1}(w)(X(w)|Y(w)). \tag{13}$$

It defines brackets on $P(\tilde{\mathfrak{g}}^*_{\mathcal{H}})$ in the following way:

$$\{F(L),G(L)\}=\sum_{l,m\in Z}\sum_{i,j,p,s=1}^{n}\langle L(w),[X^{-l}_{ij},X^{-m}_{ps}]\rangle_{-1}\frac{\partial G}{\partial l^l_{ij}}\frac{\partial F}{\partial l^m_{ps}}. \tag{14}$$

From Proposition 2 follows the next statement:

Proposition 3: Functions $I^k_m(L(w))$ are central for brackets $\{\ ,\ \}$.

Taking into account that $l^m_{ij}=\langle L(w),X^{-m}_{ij}\rangle_{-1}$ it is easy to show that for the coordinate functions l^m_{ij} brackets (14) will have the following form:

$$(1)\ \{l^n_{ij},l^m_{ij}\}=\delta_{kj}l^{n+m-1}_{il}-\delta_{il}l^{n+m-1}_{kj}+a_i\delta_{il}l^{n+m}_{kj}-a_j\delta_{kj}l^{n+m}_{il}\quad \text{for the } \mathrm{gl}(n), \tag{15a}$$

$$\begin{aligned}(2)\ \{l^n_{ij},l^m_{ij}\}&=\delta_{kj}l^{n+m-1}_{il}-\delta_{il}l^{n+m-1}_{kj}+\delta_{jl}l^{n+m-1}_{ki}-\delta_{ik}l^{n+m-1}_{il}+a_i\delta_{il}l^{n+m}_{kj}-a_j\delta_{kj}l^{n+m}_{il}\\&\quad+a_i\delta_{ik}l^{n+m}_{jl}-a_j\delta_{jl}l^{n+m}_{ki}\quad \text{for the } \mathrm{so}(n),\end{aligned} \tag{15b}$$

$$\begin{aligned}(3)\ \{l^n_{ij},l^m_{ij}\}&=\delta_{kj}l^{n+m-1}_{il}-\delta_{il}l^{n+m-1}_{kj}+\epsilon_i\epsilon_j(\delta_{j-l}l^{n+m-1}_{k-i}-\delta_{i-k}l^{n+m-1}_{j-l})+a_i\delta_{il}l^{n+m}_{kj}\\&\quad-a_j\delta_{kj}l^{n+m}_{il}+a_i\epsilon_i\epsilon_j(a_i\delta_{i-k}l^{n+m}_{j-l}-a_j\delta_{j-l}l^{n+m}_{k-i})\quad \text{for the } \mathrm{sp}(n).\end{aligned} \tag{15c}$$

From the explicit form of the Poisson brackets follows that Lie–Poisson brackets in the subspaces $(\tilde{\mathfrak{g}}^*_{\mathcal{H}})_-=\Sigma^{\infty}_{m=0}(\tilde{\mathfrak{g}}^*_{\mathcal{H}})_{-m}$ and $(\tilde{\mathfrak{g}}^*_{\mathcal{H}})_+=\Sigma^{\infty}_{m=1}(\tilde{\mathfrak{g}}^*_{\mathcal{H}})_m$, up to the reverse of the sign of the upper indices, repeat commutation relations of the algebras $\tilde{\mathfrak{g}}^+_{\mathcal{H}}$ and $\tilde{\mathfrak{g}}^-_{\mathcal{H}}$, correspondingly. This, evidently, is the result of the following duality, $(\tilde{\mathfrak{g}}^+_{\mathcal{H}})^*=(\tilde{\mathfrak{g}}^*_{\mathcal{H}})_-$, $(\tilde{\mathfrak{g}}^-_{\mathcal{H}})^*=(\tilde{\mathfrak{g}}^*_{\mathcal{H}})_+$.

B. Second Lie–Poisson structure and Poisson subspaces

Let us introduce into the space $\tilde{\mathfrak{g}}^*_{\mathcal{H}}$ a new Poisson brackets $\{,\}_0$, which are a Lie–Poisson brackets for the algebra $\tilde{\mathfrak{g}}^0_{\mathcal{H}}$, where $\tilde{\mathfrak{g}}^0_{\mathcal{H}}=\tilde{\mathfrak{g}}^-_{\mathcal{H}}\oplus\tilde{\mathfrak{g}}^+_{\mathcal{H}}$. Explicitly, the brackets have the following form:

$$\{l^n_{ij},l^m_{kl}\}_0=-\{l^n_{ij},l^m_{kl}\},\quad n,m>0,\quad \{l^n_{ij},l^m_{kl}\}_0=\{l^n_{ij},l^m_{kl}\},\quad n,m\leqslant 0,$$

$$\{l^n_{ij},l^m_{kl}\}_0=0,\quad m\leqslant 0,\quad n>0\quad \text{or}\quad n\leqslant 0,\quad m>0.$$

Let subspace $\mathcal{M}_{s,p}\subset\tilde{\mathfrak{g}}^*_{\mathcal{H}}$ be defined as follows:

$$\mathcal{M}_{s,p}=\sum_{m=-s+1}^{p}(\tilde{g}^*_{\mathcal{H}})_m.$$

Brackets $\{,\}_0$ could be correctly restricted to $\mathcal{M}_{s,p}$. It follows from the next Proposition:

Proposition 4: Subspaces $\mathcal{J}_{p,s}=\Sigma^{-p-1}_{m=-\infty}(\tilde{\mathfrak{g}}_{\mathcal{H}})_m+\Sigma^{\infty}_{m=s}(\tilde{\mathfrak{g}}_{\mathcal{H}})_m$ are ideals in $\tilde{\mathfrak{g}}^0_{\mathcal{H}}$.

Proof follows from the explicit form of commutation relations in $\tilde{\mathfrak{g}}^0_{\mathcal{H}}$.

Now we are ready to prove the following important theorem:

Theorem 3: *Functions $\{I^k_m(L)\}$ commutes with respect to the restriction of the brackets $\{,\}_0$ on $\mathcal{M}_{s,p}$.*

Proof: It follows from the combination of Kostant–Adler scheme and previous Proposition. Indeed, due to the fact that $\{I^k_m(L)\}$ are Casimir functions on $\tilde{\mathfrak{g}}^*_{\mathcal{H}}$ they form a commutative

subalgebra with respect to the brackets $\{,\}_0$ (see Ref. 4). Hence they will stay commutative after the restriction to $\mathcal{M}_{s,p}=(\tilde{\mathfrak{g}}^0_{\mathcal{H}}/\mathcal{J}_{p,s})^*$, due to the fact, that projection onto quotient algebra is a canonical homomorphism. That proves the theorem.

C. Hamiltonian systems

We will consider Hamiltonian systems on $\mathcal{M}_{s,p}$ of the following form:

$$\frac{dl^k_{ij}}{dt}=\{l^k_{ij},H(l^m_{kl})\}_0, \tag{16}$$

where the Hamiltonian H is one of the functions I^k_m or their linear combination. These equations could be written in the Lax pair form (Ref. 4),

$$\frac{dL(w)}{dt}=[L(w),M(w)], \tag{17}$$

where $L(w)\in\mathcal{M}_{s,p}$, and the second operator is defined as follows: $M(w)=(P_- - P_+)\nabla H(L(w))$. Here $P_\pm$ are projection operators on the subalgebra $\tilde{\mathfrak{g}}^\pm_{\mathcal{H}}$,

$$\nabla H(L(w))=\sum_{k=-p}^{s-1}\sum_{ij=1}^{n}\frac{\partial H}{\partial l^k_{ij}}X^{-k}_{ij} \tag{18}$$

is an algebra-valued gradient of H.

Thus we have achieved our initial goal of constructing Hamiltonian systems admitting the Lax pair representation with the hyperelliptic spectral parameter and possessing a large number of mutually commuting (see Theorem 3) integrals of motion. In the next section we will consider several important examples.

VI. INTEGRABLE SYSTEMS IN FINITE-DIMENSIONAL QUOTIENTS

The most interesting examples from the physical point of view usually arises in the spaces $\mathcal{M}_{s,p}$ with small s and p. We will consider the case $|s+p|\leqslant 2$. We will assume that curve $\mathcal{H}$ is nondegenerated, i.e., $a_i\neq a_j$ for $i\neq j$. This requirement is necessary for completeness of the family of constructed commuting functions.

The basic algebra in all examples will be $\mathfrak{g}=\mathrm{so}(n)$, but analogous results are valid for $\mathfrak{g}=\mathrm{gl}(n)$ and $\mathfrak{g}=\mathrm{sp}(n)$. We chose for all examples the $\mathrm{so}(n)$ algebra because correspondent integrable systems are the most direct generalizations of classical integrable systems connected with so(3), so(4), and e(3).

A. Hyperelliptic Lax representation for the generalized Euler tops

Let us consider subspace $\mathcal{M}_{0,1}$. It is evident that $\mathcal{M}_{0,1}=(\tilde{\mathfrak{g}}^+_{\mathcal{H}}/\mathcal{J}_{1,0})^*=\mathfrak{g}^*$. The corresponding Lax operator $L(w)\in\mathcal{M}_{0,1}$ has the following form:

$$L(w)=w\sum_{i,j=1,n}l^{(1)}_{ij}\frac{y(w)}{w_iw_j}X^*_{ij}.$$

Let us consider the most interesting case $\mathfrak{g}=\mathrm{so}(n)$. In this case we have, $X^*_{ij}=X_{ij}$, $l^{(1)}_{ji}=-l^{(1)}_{ij}$. Lie–Poisson brackets between the coordinate functions $l^{(1)}_{ij}$ have the standard form,

$$\{l^{(1)}_{ij},l^{(1)}_{kl}\}=\delta_{kj}l^{(1)}_{il}-\delta_{il}l^{(1)}_{kj}+\delta_{jl}l^{(1)}_{ki}-\delta_{ki}l^{(1)}_{jl}.$$

Commuting integrals are constructed using expansions in the powers of w of the functions, $I_k(w)=\mathrm{Tr}(L(w))^k$. We are especially interested in the quadratic Hamiltonians. Let

$$h(w)\equiv I_2(w)=\sum_{s=2}^{n} h_s(l_{ij}^{(1)})w^s=w^2\sum_{ij}\left(\prod_{k\neq i,j}(w-a_k)\right)(l_{ij}^{(1)})^2.$$

We obtain

$$h_2=\left(\prod_k a_k\right)\sum_{i,j=1}^{n}\frac{(l_{ij}^1)^2}{a_ia_j},$$

$$\cdots$$

$$h_{n-1}=\sum_{i,j=1}^{n}\left(\sum_{k=1}^{n} a_k-(a_i+a_j)\right)(l_{ij}^{(1)})^2,$$

$$h_n=\sum_{i,j=1}^{n}(l_{ij}^{(1)})^2.$$

The last function in this set is a Casimir function, previously $n-1$ defined the nontrivial flows on each coadjoint orbit in $\mathfrak{g}^*$. For the Hamiltonian of the generalized rigid body we take $H(l_{ij}^{(1)})\equiv 1/2h_{n-1}(l_{ij}^{(1)})$. Equations of motion are

$$\frac{dL(w)}{dt}=[L(w),M(w)],$$

where the M operator has the following form:

$$M(w)=\sum_{ij}\left(\sum_{k=1}^{n} a_k-(a_i+a_j)\right)l_{ij}^{(1)}w^{-1}w_iw_jX_{ij}.$$

To show explicitly, that this is indeed a generalization of the ordinary rigid body case, and we will consider the standard so(3) case:

Example 4: Let $n=3$, i.e., $\mathfrak{g}=\mathrm{so}(3)$ and corresponding curve $\mathcal{H}$ is elliptic. Let us pass to the variables $l_k=\epsilon_{ijk}l_{ij}^{(1)}$ which are dual to the standard basis $X_k=\epsilon_{ijk}X_{ij}$ in the algebra so(3) and obtain the standard Lie brackets for coordinates of the momentum vector. In this case we have two independent integrals—Casimir function and Hamiltonian,

$$h_3=\sum_{i,j=1}^{3}(l_{ij}^{(1)})^2=\sum_{k=1}^{3}l_k^2,\quad h_2=\sum_{i,j=1}^{3}(a_1+a_2+a_3-(a_i+a_j))(l_{ij}^{(1)})^2=\sum_{k=1}^{3}a_kl_k^2.$$

It is evident that h_2 coincides with the standard rigid body (Euler top) Hamiltonian, where $a_k=I_k^{-1}$. Direct calculations give the following elliptic $L-M$ pair for Euler top:

$$L(w)=w\sum_{k=1}^{3}l_kw_kX_k,\quad M(w)=w^{-1}\sum_{k=1}^{3}a_kl_k\frac{y(w)X_k}{w_k}.$$

Correspondent Lax equations coincide with the equations of movement of the rigid body.

B. Generalized interacting tops

Let us consider subspace $\mathcal{M}_{1,1}$. In the case $a_i\neq 0$, as it follows from the arguments below, $(\tilde{\mathfrak{g}}_{\mathcal{H}}^{+}/\mathcal{J}_{1,1})\approx\mathfrak{g}\oplus\mathfrak{g}$. Hence $\mathcal{M}_{1,1}=(\mathfrak{g}\oplus\mathfrak{g})^*$. The corresponding Lax operator $L(w)\in\mathcal{M}_{1,1}$ has the following form:

$$L(w)=\sum_{i,j=1}^{n}(l_{ij}^{(0)}+wl_{ij}^{(1)})\frac{y(w)}{w_iw_j}X_{ij}^{*}.$$

Let us again consider the so(n) case and put $X_{ij}^{*}=X_{ij}$. Lie–Poisson brackets between the coordinate functions $l_{ij}^{(0)}$, $l_{ij}^{(1)}$, where $l_{ji}^{(k)}=-l_{ij}^{(k)}$, $k=0,1$, have the following form:

$$\{l_{ij}^{(0)},l_{kl}^{(0)}\}=-a_i\delta_{il}l_{kj}^{(0)}+a_j\delta_{kj}l_{il}^{(0)}-a_i\delta_{ik}l_{jl}^{(0)}+a_j\delta_{jl}l_{ki}^{(0)},$$

$$\{l_{il}^{(1)},l_{kl}^{(1)}\}=\delta_{kj}l_{il}^{(1)}-\delta_{il}l_{kj}^{(1)}+\delta_{jl}l_{ki}^{(1)}-\delta_{ki}l_{jl}^{(1)},$$

$$\{l_{ij}^{(0)},l_{kl}^{(1)}\}=0.$$

Putting $b_i=a_i^{1/2}$ and making the change of variables, $l_{ij}=l_{ij}^{(1)}$, $m_{ij}=l_{ij}^{(0)}/b_ib_j$, we obtain canonical coordinates of the direct sum of two algebras so(n),

$$\{m_{ij},m_{kl}\}=\delta_{kj}m_{il}-\delta_{il}m_{kj}+\delta_{jl}m_{ki}-\delta_{ki}m_{jl},$$

$$\{l_{ij},l_{kl}\}=\delta_{ki}l_{il}-\delta_{il}l_{kj}+\delta_{jl}l_{ki}-\delta_{ki}l_{jl},$$

$$\{l_{ij},m_{kl}\}=0.$$

Commuting integrals are constructed using expansions in the powers of w of the functions, $I_k(w)=\mathrm{Tr}(L(w))^k$. As in the previous example, we are mainly interested in the quadratic integrals. Let

$$h(w)\equiv I_2(w)=\sum_{s=0}^{n}h_s(l_{ij}^{(0)},l_{ij}^{(1)})w^s=\sum_{ij}\left(\prod_{k\neq i,j}(w-a_k)\right)(l_{ij}^{(0)}+wl_{ij}^{(1)})^2.$$

By straightforward calculations, making the described above replacement of variables we obtain

$$h_0=(-1)^{n-2}(b_1^2b_2^2\cdots b_n^2)\sum_{i,j=1}^{n}m_{ij}^2$$

$$h_1=(-1)^{n-1}\sum_{i,j=1}^{n}\left(\sum_{k\neq i,j}\frac{b_1^2b_2^2\cdots b_n^2}{b_k^2}\right)(m_{ij})^2-2\frac{b_1^2b_2^2\cdots b_n^2}{b_ib_j}m_{ij}l_{ij}$$

$$\cdots$$

$$h_{n-1}=-\sum_{i,j=1}^{n}\left(\sum_{k=1}^{n}b_k^2-(b_i^2+b_j^2)\right)l_{ij}^2-2b_ib_jm_{ij}l_{ij}$$

$$h_n=\sum_{i,j=1}^{n}(l_{ij})^2.$$

It is evident, that functions h_0 and h_n are invariants. Functions $h_1,\ldots,h_{n-1}$ generate nontrivial Hamiltonian flows. For the Hamiltonian of the generalized interacting rigid bodies we can take either h_{n-1} or h_1. Correspondent M-operator and Lax equations are calculated straightforwardly.

Example 5: Let $n=3$. In this case, making standard replacement of variables $l_i=\epsilon_{ijk}l_{ij}$, $m_i=\epsilon_{ijk}m_{ij}$ we obtain the following set of commuting functions:

$$h_0=\sum_{k=1}^{n}m_k^2,\quad h_1\left(\sum_{k=1}^{n}\left(\frac{b_1b_2b_3}{b_k^2}\right)(m_k)^2-2b_km_kl_k\right),$$

$$h_2=\sum_{i,j=1}^{n}\left(b_k^2 l_k^2-2\frac{b_1b_2b_3}{b_k}m_k l_k\right),\quad h_3=\sum_{k=1}^{n} l_k^2.$$

Here h_0, h_3, invariant functions and h_1, h_2 are two independent integrals discovered by Veselov (Ref. 12). Commutation relations between coordinates l_k and m_k of so(4) are standard,

$$\{l_i,l_j\}=\epsilon_{ijk}l_k,\ \{m_i,m_j\}=\epsilon_{ijk}m_k,\quad \{m_i l_j\}=0.$$

C. Generalized Steklov–Liapunov system

The last class of integrable systems we wish to consider here will be integrable systems that generalize classical integrable system of Steklov–Liapunov on $e(3)=so(3)+R^3$. Let us consider subspace $\mathcal{M}_{0,2}=(\tilde{\mathfrak{g}}^{+}_{\mathcal{H}}/\mathcal{J}_{2,0})^*$. It is easy to show that $\mathcal{M}_{0,2}=(\mathfrak{g}+\mathfrak{g})^*$. Corresponding Lax operator $L(w)\in\mathcal{M}_{0,2}$ has the following form:

$$L(w)=w\left(\sum_{i,j=1}^{n}(l_{ij}^{(1)}+wl_{ij}^{(2)})\frac{y(w)}{w_i w_j}X_{ij}^{*}\right).$$

We will again be concentrating on the $\mathfrak{g}=so(n)$ case and put $X_{ij}^{*}=X_{ij}$. Lie–Poisson brackets between coordinate functions $l_{ji}^{(1)}$, $l_{ji}^{(2)}$, where $l_{ji}^{(k)}=-l_{ij}^{(k)}$, $k=1,2$, are the following:

$$\{l_{ij}^{(1)},l_{ij}^{(1)}\}=\delta_{kj}l_{il}^{(1)}-\delta_{il}l_{kj}^{(1)}+\delta_{jl}l_{ki}^{(1)}-\delta_{ik}l_{jl}^{(1)}+a_i\delta_{il}l_{kj}^{(2)}-a_j\delta_{kj}l_{il}^{(2)}+a_i\delta_{ik}l_{jl}^{(2)}-a_j\delta_{jl}l_{ki}^{(2)},$$

$$\{l_{ij}^{(1)},l_{ij}^{(2)}\}=\delta_{kj}l_{il}^{(2)}-\delta_{il}l_{kj}^{(2)}+\delta_{jl}l_{ki}^{(2)}-\delta_{ik}l_{jl}^{(2)},$$

$$\{l_{ij}^{(2)},l_{ij}^{(2)}\}=0.$$

Commuting integrals are constructed using expansion in the powers of w of the functions, $I_k(w)=\mathrm{Tr}(L(w))^k$. We are again interested mainly in quadratic integrals. Let

$$h(w)\equiv I_2(w)=w^2\sum_{s=0}^{n}h_{s+2}(l_{ij}^{(1)},l_{ij}^{(2)})w^s=w^2\sum_{ij}\left(\prod_{k\neq i,j}(w-a_k)\right)(l_{ij}^{(1)}+wl_{ij}^{(2)})^2.$$

Direct calculations give

$$h_2=(-1)^{n-2}\sum_{i,j=1}^{n}\frac{a_1a_2\cdots a_n}{a_ia_j}(l_{ij}^{(1)})^2$$

$$\cdots$$

$$h_{n+1}=(-1)\left(\sum_{i,j=1}^{n}\left(\sum_{k=1}^{n}a_k-(a_i+a_j)\right)(l_{ij}^{(2)})^2-2l_{ij}^{(1)}l_{ij}^{(2)}\right),$$

$$h_{n+2}=\sum_{i,j=1}^{n}(l_{ij}^{(2)})^2.$$

Change of variables, $l_{ij}^{(1)}=l_{ij}-1/2(a_i+a_j)p_{ij}$, $l_{ij}^{(2)}=p_{ij}$ transform described above brackets to the canonical brackets on the half-direct sum $so(n)+so(n)$,

$$\{l_{ij},l_{kl}\}=\delta_{kj}l_{il}-\delta_{il}l_{kj}+\delta_{jl}l_{ki}-\delta_{ik}l_{jl},$$

$$\{l_{ij},p_{kl}\}=\delta_{kj}p_{il}-\delta_{il}p_{kj}+\delta_{jl}p_{ki}-\delta_{ik}p_{jl},$$

$$\{p_{ij},p_{kl}\}=0.$$

After such transformation we obtain the following set of Hamiltonians:

$$h_2=(-1)^{n-2}\sum_{i,j=1}^{n}\frac{a_1a_2\cdots a_n}{a_ia_j}(l_{ij}-1/2(a_i+a_j)p_{ij})^2$$

$$\cdots$$

$$h_{n+1}=(-1)\left(\sum_{k=1}^{n}a_k\right)\left(\sum_{i,j=1}^{n}p_{ij}^2\right)-2\left(\sum_{i,j=1}^{n}l_{ij}p_{ij}\right),$$

$$h_{n+2}=\sum_{i,j=1}^{n}p_{ij}^2.$$

Last two functions are invariant functions. First $n-1$ gives nontrivial flows on $\mathfrak{g}^*$. We will choose the function $H=h_2$ for the Hamiltonian function. The correspondent M operator is

$$M(w)=2\sum_{i,j=1}^{n}\frac{a_1a_2\cdots a_n}{a_ia_j}(l_{ij}-1/2(a_i+a_j)p_{ij})w^{-1}w_iw_jX_{ij}.$$

The Lax equation has the standard form (1).

Example 6: Let $n=3$. In this case, after the replacement of variables: $l_k=\epsilon_{ijk}l_{ij}$, $p_k=\epsilon_{ijk}p_{ij}$ we obtain the standard Lie–Poisson brackets on $\epsilon(3)^*$,

$$\{l_i,l_i\}=\epsilon_{ijk}l_k,\ \{l_i,p_j\}=\epsilon_{ijk}p_k,\ \{p_i,p_j\}=0,$$

and the following Hamiltonian:

$$H=(-1)^{n-2}\sum_{k=1}^{n}a_k(l_k-1/2(a_1+a_2+a_3-a_k)p_k)^2.$$

Up to the rescaling of momenta $p_i:p_i\to 2\sigma p_i$ Hamiltonian H coincides with the Hamiltonian of the Steklov–Liapunov system in the form of Kotter (Ref. 15).

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 42, NUMBER 9 SEPTEMBER 2001

Lie algebras associated with the exponential solutions of nonautonomous linear differential equations

Rodolfo Suárez[a] and Leonardo Sáenz
Departamento de Matemáticas, Universidad Autónoma Metropolitana-Iztapalapa, Apdo. Postal 55-534, 09000, México, D.F., México

(Received 23 April 1999; accepted for publication 26 March 2001)

A new free Lie algebra structure generated by a continuous set of operators is introduced. The Friedrichs' criterion, which is known for a finite (countable) number of generators, is extended to the continuous case. Based on Friedrichs' criterion, we obtain an explicit expression for the coefficients of the Magnus expansion, which is central for one to get approximately the exponential solutions of nonautonomous linear differential equations. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1383558]

I. INTRODUCTION

Consider the solution to the equation

$$\frac{\mathrm{d}U}{\mathrm{d}t}=H(t)u(t) \tag{1}$$

in the form

$$U(t)=\exp\Omega(t), \tag{2}$$

where $U(t)$, $H(t)$ are operators and $U(0)=I$ is the identity. The problem underlying this paper is to obtain $\Omega(t)$ in terms of the operator $H(t)$. Magnus[1] found the solution to (1) and (2) using a recursive method to express $\Omega(t)$ in the form of a series of multiple commutators[2]

$$\begin{aligned}\Omega(t)=&\int_0^t H(t_1)\mathrm{d}t_1+\frac{1}{2}\int_0^t\int_0^{t_1}[H(t_1),H(t_2)]\mathrm{d}t_1\,\mathrm{d}t_2\\&+\frac{1}{6}\int_0^t\int_0^{t_1}\int_0^{t_2}[[H(t_1),H(t_2)],H(t_3)]\mathrm{d}t_1\,\mathrm{d}t_2\,\mathrm{d}t_3\\&+\frac{1}{6}\int_0^t\int_0^{t_1}\int_0^{t_2}[H(t_1),[H(t_2),H(t_3)]]\mathrm{d}t_1\,\mathrm{d}t_2\,\mathrm{d}t_3+\cdots,\end{aligned} \tag{3}$$

where $[H_1,H_2]=H_1H_2-H_2H_1$ and the omitted terms are multiple integrals of the multiple commutators of H, of increasing orders. This expression is called the *Magnus expansion*. Several methods have been derived from the Magnus expansion which proved to be powerful tools for solving time-dependent problems. Those methods have been successfully applied to different fields of mathematics and physics.[2–5] Therefore, it is important to count with formulas (or efficient algorithms) to obtain the coefficients of the expansion (3). Motivated by this reason, recursive expressions for the n-order terms of the series were obtained[5–7] using different techniques. In

[a]Electronic mail: rsua@xanum.uam.mx

particular, there are explicit formulas for the *fourth*,[5] *fifth*,[8] and sixth[9] order terms. As far as we know the only explicit formula of all orders has been given by Mielnik and Plebañski.[10] One of the objectives of this paper is to present a new formula (36)[11] for the coefficients of the Magnus expansion which results to be equivalent to the formula of Mielnik and Plebañski.

On the other hand, the Magnus expansion is the continuous analog to the *Baker–Campbell–Hausdorff formula*[12–14]

$$z=x+y+\tfrac{1}{2}[x,y]+\tfrac{1}{12}([[x,y],y]+[[y,x],x])+\cdots. \tag{4}$$

This formula is derived by writing $e^z=e^xe^y$, where x,y are elements of a noncommutative algebra. Friedrichs[15] proved that z is an element of the free Lie algebra generated by $\{x,y\}$. An interesting problem is to prove an analogous result for $\Omega(t)$, that means, is $\Omega(t)$ an element of a Lie algebra generated by $\{H(t):t\in\mathbb{R}\}$? In this paper we introduce certain algebraic structures which are useful to extend to the continuous case the most important results of the discrete case.[16] The relation between both problems is based on the following heuristic approach to the solution to problem (1) using formula (4):

Let $0=s_0<s_1<\ldots<s_n=t$ be a partition of the interval $[0,t]$. If we consider $H(t)$ constant and equal to $H(s_i)$ in the interval $[s_{i-1},s_i]$ and we define the operators

$$U_n(t)=\exp(H(s_n)\Delta s_n)\exp(H(s_{n-1})\Delta s_{n-1})\ldots\exp(H(s_1)\Delta s_1), \tag{5}$$

where $\Delta s_i=s_i-s_{i-1}$, it follows that $U_n(t)\to U(t)$ if $\max \Delta s_i\to 0$. Now, if we denote z of (4) by $x\#y$ and we use operation # in (5), we obtain that

$$U_n(t)=\exp(H(s_n)\Delta s_n\#H(s_{n-1})\Delta s_{n-1}\#\cdots\#H(s_1)\Delta s_1).$$

Observe that $\Omega_n(t)=H(s_n)\Delta s_n\#H(s_{n-1})\Delta s_{n-1}\#\cdots\#H(s_1)\Delta s_1$ is contained in the Lie algebra generated by $\{H(s_1),H(s_2),\ldots,H(s_n)\}$. Considering the limit when $n\to\infty$ or $\Delta s_i\to 0$, we have that $U(t)=\exp\Omega(t)$, where

$$\Omega(t)=\lim_{\max \Delta s_1\to 0}(H(s_n)\Delta s_n\#H(s_{n-1})\Delta s_{n-1}\#\ldots\#H(s_1)\Delta s_1).$$

Based on this heuristic idea,[10] we introduce here an adequate mathematical framework that puts the work of Magnus[1] in a precise form. To this end we extend the following results.[16] First we prove the continuous analog to *Friedrichs' criterion*. This criterion is the simplest way to decide when an element of an algebra is a *Lie element*. Once one knows that an element is a Lie element, it is easier to determine it explicitly. By the use of Friedrichs' criterion, we prove the Magnus' theorem and propose a formula (proved in Saenz and Suárez[11]) for the coefficients of the expansion (the *Magnus formula*). In this paper we concentrate on algebraic problems, however, a simple proof of the convergence of the Magnus' expansion for a sufficiently small t, provided that $H(t)$ is a local integrable and bounded operator, is included. The local convergence issue of the Magnus expansion has been treated in several papers.[4,6,17] Very few attempts have been made with respect to the global convergence problem.[1,18–21]

There are several other works where the mathematical formalization of the Magnus expansion has been addressed by considering different frameworks. Chen[22] proposed a generalization of the path integral. In particular, he proves that if a function $u(t)$ is a Lie element for every $t\in[a,b]$, then both

$$\int_a^b u(t)dt,\quad \frac{\mathrm{d}u(t)}{\mathrm{d}t}$$

are also Lie elements. However, the proof of Magnus' theorem, for that kind of path integration, is not constructive. In Huillet *et al.*[23] the authors use *grupoids* to simplify notation, but Magnus' theorem was not proved. Formula (3) was taken from Magnus,[1] since the paper is more in the direction of considering the nonstationary evolution equations as a canonical factorization into an infinite product of exponentials.[20] On the other hand, Strichartz[24] is closely related to our work. It involves an extension to the definitions considered in Jacobson[16] for the discrete case. The problem is that the obtained explicit formula is very complicated. Searching for a less computationally involved formulation, Duleba[25] introduced a method based on Hall basis. In our paper, the difference is the introduction of the ''algebras of coefficients'' (Volterra series) which give us at least two advantages: Local convergence of (3), implied by local integrability and boundedness of $H(t)$ (instead of the analyticity required in Strichartz[24]), and second, the calculation of the expansion coefficients is straightforward. We choose, as was proposed in Mielnik and Plebañski,[10] the use of ''algebras of coefficients'' instead of ''multiple commutators,'' in order to express $\Omega(t)$ as a series whose *n*-order term is given by only one multiple integral. By this way, the problem is transferred to the calculation of the series coefficients. It is worth mentioning that the *n*-order coefficient can be calculated [see formula (36)] without knowing the lower order coefficients.[10] In the other mentioned methods the terms of the expansion were calculated by a recursive algorithm.

A new and very interesting use of the Magnus expansion, initiated in Iserles and Nørsett,[6] is the solution of linear differential equations in Lie groups and homogeneous spaces. It concerns the retention of the Lie group structure by the truncated approximations of (3). For instance to solve dynamical systems which stay on a prescribed manifold or classical Hamiltonian systems.[26–28] Related to this idea, in the last few years, there has been an increasing interest in the design of efficient numerical integration techniques which preserve important qualitative properties of differential equations. It has been shown that a numerical method, based on Magnus expansions,[9,26,29–31] performs consistently better than the classical Runge–Kutta methods, especially for systems with high oscillations or complicated asymptotic behavior.[27,32,33]

As was previously mentioned, formulas (3) and (4) have been applied to different fields of mathematics and physics. For example in the theory of groups,[34–37] control theory,[23,38,39] partial differential equations,[40] nonlinear ordinary differential equations,[3,32,41] Lie groups,[6,30,42] and differential geometry.[22] In physics, they have been used in quantum mechanics, semiclassical atomic collisions theory, neutron transport, laser physics, multiphoton excitation of molecules, pulsed magnetic resonance spectra, magnetic lenses, optical lenses, plasma physics, the solar neutrino problem, high-resolution nuclear magnetic resonance spectroscopy, and Hamiltonian systems (celestial mechanics). There is an extensive list of references of applications to physics.[2–5]

The rest of the paper is organized as follows. Section II contains the preliminary definitions. In Sec. III we introduce the algebras and ordered linear spaces, which extend the definitions contained in Jacobson,[16] in order to characterize in an algebraic way the sets to which $\Omega(t)$ belongs. Section IV provides Friedrichs' criterion. In Sec. V we prove the Magnus expansion using Friedrichs' criterion, and present an application of this formula to the determination of the uniform exponential stability of a nonautonomous linear systems. Finally, Appendices A and B include the proofs of the main results.

II. PRELIMINARIES

Let F be the field of real or complex numbers ($\mathbb{R}$ or $\mathbb{C}$, respectively) and S_n be the group of permutations of order n.

Definition 1: The algebra of permutations of n elements, FS_n, *is the set of formal sums of the form:*

$$\sum_{i=1}^{n!} r_i \sigma_i ,$$

where $r_i \in F$, $\sigma_i \in S_n$, *and* $\sigma_j \neq \sigma_k$ *if* $j \neq k$.

The operations of addition, product, and multiplication by a scalar give to FS_n the structure of an associative algebra with unit over F. The identity of FS_n is the identity permutation of S_n which we denote by 1.

Now, let X be a linear space over F, and let $t>0$ and $n\in\mathbb{N}$. We denote by $\mathfrak{F}(T^n,X)$ the linear space of integrable functions a: $T^n\subset\mathbb{R}^n\to X$, where $T=[0,t]$. Each permutation $\sigma\in S_n$ can be identified with the following linear operator over $\mathfrak{F}(T^n,X)$:

$$\sigma a(t_1,\ldots,t_n)=a(t_{\sigma(1)},\ldots,t_{\sigma(n)}). \tag{6}$$

Defining $(\sigma_1\sigma_2)a=\sigma_1(\sigma_2 a)$, the rule (6) agrees with the evaluation of the product of two permutations from right to left. The rule (6) extends to the elements of FS_n linearly in the following way: If $a\in\mathfrak{F}(T^n,X)$, then

$$\left(\sum_{i=1}^{n!} r_i\sigma_i\right)a=\sum_{i=1}^{n!} r_i\sigma_i a.$$

Let us define two special elements D_n and E_n of FS_n:

$$D_n=\frac{1}{n}(1-C_{1,2})(1-C_{1,3})\ldots(1-C_{1,n}) \tag{7}$$

and

$$E_n=\frac{1}{n}(1-C_{1,n}^{-1})(1-C_{1,n-1}^{-1})\ldots(1-C_{1,2}^{-1}), \tag{8}$$

where 1 denotes the identity permutation and $C_{1,k}$ is the following cyclic permutation in S_n:

$$C_{1,k}=\begin{pmatrix}1 & 2 & \ldots & k-1 & k\\ k & 1 & \ldots & k-2 & k-1\end{pmatrix}. \tag{9}$$

In particular, if B is an associative algebra over F, with $\mathcal{H}\in\mathfrak{F}(T^n,B)$ and $\mathcal{H}(t_1,\ldots,t_n)=H(t_1)\ldots H(t_n)$, we have that D_n corresponds to the next Lie array:[10]

$$D_n(\mathcal{H}(t_1,\ldots,t_n))=D_n(H(t_1)\ldots H(t_n))=\frac{1}{n}[\ldots[[H(t_1),H(t_2)],H(t_3)],\ldots,H(t_n)], \tag{10}$$

where $[H_1,H_2]=H_1H_2-H_2H_1$. As we can see, nD_n corresponds to the linear transformation $\mathcal{O}$ given in Jacobson[16] for the discrete case. The most important property of the objects D_n and E_n is that they are idempotent, that is,

$$D_n^2=D_n \tag{11}$$

and

$$E_n^2=E_n. \tag{12}$$

A proof for (11) is outlined in Magnus *et al.*[43]

Let $N_n(t)$ be the commutative algebra over F of the functions of $\mathfrak{F}(T^n,F)$ which are zero almost everywhere in $T^n=[0,t]^n$. It is easy to prove that

$$FS_n(N_n(t))=N_n(t).$$

In particular

$$E_n(N_n(t))\subset N_n(t). \tag{13}$$

III. ALGEBRAS AND ORDERED LINEAR SPACES OF CONTINUOUS RANGE

Definition 2: Let $A_n(t)$ be a linear subspace of the Banach space $\mathcal{L}_p$ of functions defined in $T^n=[0,t]^n$ with values in F. For $n=0$, $A_0(t)=F$. The set of infinite sequences

$$A(t)=\prod_{n=0}^{\infty} A_n(t)=\{\{a_n\}_{n=0}^{\infty}:a_n\in A_n(t)\}$$

is called an algebra of coefficients *if it satisfies.*

(1) For every $\sigma\in S_n$ and $a\in A_n(t)$, we have that $\sigma a\in A_n(t)$.

(2) Given $a\in A_k(t)$ and $b\in A_m(t)$, the function $a\circ b$ is an element of $A_{k+m}(t)$, where

$$(a\circ b)(t_1,\ldots,t_{k+m})=a(t_1,\ldots,t_k)b(t_{k+1},\ldots,t_{k+m}). \tag{14}$$

The algebraic operations in $A(t)$ are defined in the following way: Let, $a,b\in A(t)$, $a=\{a_n\}_{n=0}^{\infty}$, $b=\{b_n\}_{n=0}^{\infty}$, with a_n, $b_n\in A_n(t)$, and $\alpha\in F$, then

$$a+b=\{a_n+b_n\}_{n=0}^{\infty},$$

$$\alpha a=\{\alpha a_n\}_{n=0}^{\infty},$$

$$ab=\{c_n\}_{n=0}^{\infty},$$

where $c_n=\Sigma_{k=0}^{n} a_k\circ b_{n-k}$. As it is easy to prove, the defined operations are closed in $A(t)$.

Proposition 3: $A(t)$ is an associative algebra with unit over F.

Since $A_n(t)\subset\mathcal{L}_p$, we understand that equality (14) is considered among elements in $\mathcal{L}_p$, that is, (14) is verified almost everywhere in T^n. This convention will follow from now on.

Example 4: If $A_n(t)$ is the linear space of continuous real functions of n variables, then $A(t)=\Pi_{n=0}^{\infty}A_n(t)$ satisfies conditions 1 and 2 of definition 2, thus it is an algebra of coefficients. The concept of algebra of coefficients is used in the definition of Volterra series which are frequently applied to the solution of Control problems.[44]

The next definition is motivated by (13).

Definition 5: Let $n\geqslant 2$. An element $a\in A_n(t)$ is called an ordered coefficient of degree *n if*

$$E_n a=a, \tag{15}$$

where E_n is given by (8).

In the finite case, as a consequence of the Dynkin–Specht–Wever's theorem,[16] Eq. (15) is satisfied by any Lie element.

Example 6: If $a(t_1,t_2)=t_1-t_2\in A_2(t)$, then $a(t_1,t_2)$ is an ordered coefficient of degree two:

$$E_2(a(t_1,t_2))=(\tfrac{1}{2}(1-C_{1,2}^{-1}))a(t_1,t_2)=\tfrac{1}{2}(a(t_1,t_2)-a(t_2,t_1))$$
$$=\tfrac{1}{2}(t_1-t_2-(t_2-t_1))=t_1-t_2=a(t_1,t_2).$$

But not necessarily every element of $A_2(t)$ *must be an ordered coefficient, for example,* $b(t_1,t_2)=t_1+t_2\in A_2(t)$ *is not an ordered coefficient of degree two:*

$$E_2(b(t_1,t_2))=(\tfrac{1}{2}(1-C_{1,2}^{-1}))b(t_1,t_2)=\tfrac{1}{2}b((t_1,t_2)-b(t_2,t_1))=\tfrac{1}{2}(t_1+t_2-(t_2+t_1))=0.$$

Denote by $\Lambda_n(t)$ the set of ordered coefficients of degree n in $A_n(t)$ for $n\geqslant 2$. Note that $\Lambda_n(t)$ is a linear subspace of $A_n(t)$. This is deduced from the fact that $E_n^2=E_n$ by (12), and therefore $\Lambda_n(t)=E_n(A_n(t))$.

Definition 7: The ordered linear space $\Lambda(t)$ *is the set of infinite sequences* $\Pi_{n=0}^{\infty}\Lambda_n(t)$, *with* $\Lambda_0(t)=\{0\}$ *and* $\Lambda_1(t)=A_1(t)$. *Every element of* $\Lambda(t)$ *is called a* sequence of ordered coefficients.

Observe that $\Lambda(t)$ is a linear subspace of $A(t)$. Now, let us define the operator $E:A(t)\rightarrow A(t)$ as the linear transformation such that, if $a=\{a_n\}_{n=0}^{\infty}$, we have that

$$E(a)=\{b_n\}_{n=0}^{\infty}, \tag{16}$$

where $b_0=0$, $b_1=a_1$, and $b_n(t_1,\ldots,t_n)=E_n(a_n(t_1,\ldots,t_n))$ for $n\geqslant 2$.

By the definition of a sequence of ordered coefficients and the fact that $E_n^2=E_n$ we obtain the next Proposition.

Proposition 8: The operator E is a projection, that is $E^2=E$, *and the range of E is equal to* $\Lambda(t)$.

The operator E is an *ordering operator*; this means that E forces the elements of the algebra $A(t)$ to acquire the structure of a sequence of ordered coefficients. The concept of ordering operator, as well as the analysis of other examples, can be found in Mielnik and Plebañski.[10]

Let G be a Hilbert space over the field F and A be the algebra of continuous operators over G, that is, A is the algebra of continuous linear transformations from the linear space G into itself. Following Jacobson,[16] let us define the free algebra $\mathcal{A}=F\oplus A\oplus(A\otimes A)\oplus\ldots$ and its extension to the formal series $\overline{\mathcal{A}}$, where $\oplus$ denotes the direct sum of linear spaces. The algebras $\mathcal{A}$ and $\overline{\mathcal{A}}$ are associative algebras with unit. To avoid any confusion between the usual product of operators defined in A with the free product given in the last two algebras we denote this last product by $\odot$. The problem of convergence of series in $\overline{\mathcal{A}}$ can be addressed using valuations.[16] Since G is a Hilbert space, it has a norm associated with its inner product. On the other hand, this norm allows us to define a standard norm in the algebra of operators A. This norm induces, in the natural way, a norm in the homogeneous spaces[45] $A\otimes\ldots\otimes A$. Let then $H:\mathbb{R}\rightarrow A$ be a continuous function which becomes zero only in a finite set of points of the interval $T=[0,t]$. It follows that every product of the form $H(t_1)\odot\ldots\odot H(t_n)$ is a continuous function of n variables. If we take $a_n\in A_n(t)$, we obtain that the function of n real variables $a_n(t_1,\ldots,t_n)H(t_1)\odot\ldots\odot H(t_n)$ is integrable over $T^n=[0,t]^n$. Therefore the integral

$$\int_0^t\cdots\int_0^t a_n(t_1,\ldots,t_n)H(t_1)\odot\ldots\odot H(t_n)\mathrm{d}t_1\ldots\mathrm{d}t_n \tag{17}$$

is defined and it is a homogeneous element of degree n in $\overline{\mathcal{A}}$.

With all these considerations we formulate the following

Definition 9: The algebra of continuous range $\mathcal{A}(t)$ *is the subset of* $\overline{\mathcal{A}}$ *whose elements can be given in the form*

$$a_0+\sum_{n=1}^{\infty}\int_0^t\cdots\int_0^t a_n(t_1,\ldots,t_n)H(t_1)\odot\ldots\odot H(t_n)\mathrm{d}t_1\ldots\mathrm{d}t_n, \tag{18}$$

where $\{a_n\}_{n=0}^{\infty}\in A(t)$.

It is not difficult to see that $\mathcal{A}(t)$ is a subalgebra of $\overline{\mathcal{A}}$. In particular, the multiplication, defined by (14), is closed in $\mathcal{A}(t)$.

Let us define the function $\Phi: A(t) \to \mathcal{A}(t)$, for $a = \{a_n\}_{n=0}^{\infty} \in A(t)$, by

$$\Phi(a) = a_0 + \sum_{n=1}^{\infty} \int_0^t \cdots \int_0^t a_n(t_1,\ldots,t_n) H(t_1) \odot \ldots \odot H(t_n) \mathrm{d}t_1 \ldots \mathrm{d}t_n . \tag{19}$$

Φ is an epimorphism between associative algebras with unit.

Note that, since H is continuous and null only on a finite set of points of $[0,t]$ then, if for every $s \in (0,t]$ it occurs that

$$\int_0^s \cdots \int_0^s a_n(t_1,\ldots,t_n) H(t_1) \odot \ldots \odot H(t_n) \mathrm{d}t_1 \ldots \mathrm{d}t_n = 0,$$

necessarily $a_n = 0$ (in $\mathcal{L}_p$). Hence, every element of $\mathcal{A}(t)$ is uniquely determined by the series (18). As Φ is an epimorphism between $A(t)$ and $\mathcal{A}(t)$, we have the following Proposition.

Proposition 10: $A(t)$ and $\mathcal{A}(t)$ are isomorphic as associative algebras with unit. The isomorphism is given by Φ.

Definition 11: The ordered linear space of continuous range $\Gamma(t)$ *is the subset of elements of $\mathcal{A}(t)$ written in the form*

$$\sum_{n=1}^{\infty} \int_0^t \cdots \int_0^t u_n(t_1,\ldots,t_n) H(t_1) \odot \ldots \odot H(t_n) \mathrm{d}t_1 \ldots \mathrm{d}t_n ,$$

where $\{u_n\}_{n=0}^{\infty} \in \Lambda(t)$ (note that $u_0 = 0$). Every element of $\Gamma(t)$ is called an ordered element.

Since $\Gamma(t) = \Phi(\Lambda(t))$, $\Gamma(t)$ is a linear subspace of $\mathcal{A}(t)$.

Remark 1: Every ordered element can be rewritten in the following way:

$$\int_0^t u_1(t_1) H(t_1) \mathrm{d}t_1 + \sum_{n=2}^{\infty} \frac{1}{n} \int_0^t \cdots \int_0^t u_n(t_1,\ldots,t_n) [\ldots[H(t_1),H(t_2)],\ldots,H(t_n)] \mathrm{d}t_1 \ldots \mathrm{d}t_n$$

(the Lie product $[\cdot]$ is defined with respect to the free product $\odot$). This is a consequence of the next equation that is satisfied by any ordered coefficient a_n,

$$\int_0^t \cdots \int_0^T a_n(t_1,\ldots,t_n) H(t_1) \odot \ldots \odot H(t_n) \mathrm{d}t_1 \ldots \mathrm{d}t_n = \frac{1}{n} \int_0^t \cdots \int_0^t a_n(t_1,\ldots,t_n) \times [\ldots[[H(t_1),H(t_2)],H(t_3)],\ldots,H(t_n)] \mathrm{d}t_1 . \tag{20}$$

The proof of Eq. (20) follows by reordering the indexes of a_n, using the *Fubini's Theorem*, and transferring the permutations to the products of the operator H in the following way

$$\int_0^t \cdots \int_0^t a_n(t_1,\ldots t_n) H(t_1)\odot\ldots\odot H(t_n)\mathrm{d}t_1\ldots\mathrm{d}t_n$$

$$= \int_0^t \cdots \int_0^t E_n(a_n(t_1,\ldots,t_n)) H(t_1)\odot\ldots\odot H(t_n)\mathrm{d}t_1\ldots\mathrm{d}t_n$$

$$= \frac{1}{n}\int_0^t \cdots \int_0^t \left(\left(\prod_{k=2}^{n} (1-C_{1,n-k+2}^{-1}) \right)(a_n(t_1,\ldots,t_n)) \right) H(t_1)\odot\ldots\odot H(t_n)\mathrm{d}t_1\ldots\mathrm{d}t_n$$

$$= \frac{1}{n}\int_0^t \cdots \int_0^t \left(\left(1+\sum_{i=2}^{n} (-1)^{i-1} \sum_{n\geqslant j_{i-1}>\ldots>j_1\geqslant 2} C_{1,j_{i-1}}^{-1}\ldots C_{1,j_1}^{-1} \right)(a_n(t_1,\ldots,t_n)) \right)$$
$$\times H(t_1)\odot\ldots\odot H(t_n)\mathrm{d}t_1\ldots\mathrm{d}t_n$$

$$= \frac{1}{n}\int_0^t \cdots \int_0^t a_n(t_1,\ldots,t_n) H(t_1)\odot\ldots\odot H(t_n)\mathrm{d}t_1\ldots\mathrm{d}t_n$$
$$+ \frac{1}{n}\sum_{i=2}^{n} (-1)^{i-1} \sum_{n\geqslant j_{i-1}>\ldots>j_1\geqslant 2} \int_0^t \cdots \int_0^t (C_{1,j_{i-1}}^{-1}\cdots C_{1,j_1}^{-1}(a_n(t_1,\ldots,t_n)))$$
$$\times H(t_1)\odot\ldots\odot H(t_n)\mathrm{d}t_1\ldots\mathrm{d}t_n.$$

$$= \frac{1}{n}\int_0^t \cdots \int_0^t a_n(t_1,\ldots,t_n) H(t_1)\odot\ldots\odot H(t_n)\mathrm{d}t_1\ldots\mathrm{d}t_n$$
$$+ \frac{1}{n}\sum_{i=2}^{n} (-1)^{i-1} \sum_{n\geqslant j_{i-1}>\ldots>j_1\geqslant 2} \int_0^t \cdots \int_0^t C_{1,j_1}\ldots C_{1,j_{i-1}}((C_{1,j_{i-1}}^{-1}\ldots C_{1,j_1}^{-1}(a_n(t_1,\ldots,t_n)))$$
$$\times H(t_1)\odot\ldots\odot H(t_n))\mathrm{d}t_1\ldots\mathrm{d}t_n$$

$$= \frac{1}{n}\int_0^t \cdots \int_0^t a_n(t_1,\ldots,t_n) H(t_1)\odot\ldots\odot H(t_n)\mathrm{d}t_1\ldots\mathrm{d}t_n$$
$$+ \frac{1}{n}\sum_{i=2}^{n} (-1)^{i-1} \sum_{2\leqslant j_1<\ldots<j_{i-1}\leqslant n} \int_0^t \cdots \int_0^t a_n(t_1,\ldots,t_n)$$
$$\times (C_{1,j_1}\ldots C_{1,j_{i-1}}(H(t_1)\odot\ldots\odot H(t_n)))\mathrm{d}t_1\ldots\mathrm{d}t_n$$

$$= \int_0^t \cdots \int_0^t a_n(t_1,\ldots,t_n) \left(\frac{1}{n} \left(1+\sum_{i=2}^{n} (-1)^{i-1} \sum_{2\leqslant j_1<\ldots<j_{i-1}\leqslant n} C_{1,j_1}\ldots C_{1,j_{i-1}} \right) \right.$$
$$\left. \times (H(t_1)\odot\ldots\odot H(t_n)) \right) \mathrm{d}t_1\ldots\mathrm{d}t_n$$

$$= \int_0^t \cdots \int_0^t a_n(t_1,\ldots,t_n) \left(\left(\frac{1}{n}\prod_{k=2}^{n} (1-C_{1,k}) \right)(H(t_1)\odot\ldots\odot H(t_n)) \right) \mathrm{d}t_1\ldots\mathrm{d}t_n$$

$$= \frac{1}{n}\int_0^t \cdots \int_0^t a_n(t_1,\ldots,t_n)[\ldots[[H(t_1),H(t_2)],H(t_3)],\ldots,H(t_n)]\mathrm{d}t_1\ldots\mathrm{d}t_n. \qquad \square$$

Finally we consider convergence problems in the algebra of operators A. We propose the following definitions.

Definition 12: The algebra of convergent coefficients $\mathfrak{A}(t)$ *is the set of elements* $a=\{a_n\}_{n=0}^{\infty}\in A(t)$ *such that the series*

$$a_0 I+\sum_{n=1}^{\infty}\int_0^t\cdots\int_0^t a_n(t_1,\ldots,t_n)H(t_1)\ldots H(t_n)\mathrm{d}t_1\ldots\mathrm{d}t_n \tag{21}$$

converges absolutely in A, where I is the identity operator.

$\mathfrak{A}(t)$ is a subalgebra of $A(t)$. The Cauchy product of two series provides the closure of the product in $\mathfrak{A}(t)$.

Let us consider now the function $\Xi:\mathfrak{A}(t)\to A$, defined for $a=\{a_n\}_{n=0}^{\infty}\in\mathfrak{A}(t)$, by

$$\Xi(a)=a_0 I+\sum_{n=1}^{\infty}\int_0^t\cdots\int_0^t a_n(t_1,\ldots,t_n)H(t_1)\ldots H(t_n)\mathrm{d}t_1\ldots\mathrm{d}t_n\,. \tag{22}$$

Definition 13: The linear space of convergent ordered coefficients $\mathfrak{L}(t)$ *is defined as* $\mathfrak{L}(t)=\Lambda(t)\cap\mathfrak{A}(t)$; *that is, the sequences of ordered coefficients such that the series* (21) *converges absolutely in A. Every element of* $\mathfrak{L}(t)$ *is called a* sequence of convergent ordered coefficients.

As an example of a coefficients algebra we introduce the finite dimensional coefficients algebra which will be used in order to obtain a formula for the coefficients of the Magnus expansion.

Let us define the step function

$$\overline{\theta}(\tau)=\begin{cases}1 & \text{if } \tau>0\\ 0 & \text{if } \tau\leqslant 0\end{cases}$$

and the functions of n variables

$$\theta_{i,j}(t_1,\ldots,t_n)=\overline{\theta}(t_i-t_j), \tag{23}$$

for $1\leqslant i,j\leqslant n$, with $i\neq j$. Notice that $\theta_{i,j}=1-\theta_{j,i}$ almost everywhere in $\mathbb{R}^n$. Establish the functions

$$\theta^n_{\mathbf{i},\mathbf{j}}(t_1,\ldots,t_n)=\theta_{i_1,j_1}\ldots\theta_{i_k,j_k},$$

where $\mathbf{i}=(i_1,\ldots,i_k)$ and $\mathbf{j}=(j_1,\ldots,j_k)$, with $1\leqslant k\leqslant n-1$, and the indexes (i_p,j_p) are ordered in the lexicographic sense. Also, let $\Theta^n_1(t_1,\ldots,t_n)=1$. Define $A^f_n(t)$ as the linear subspace of the linear space $\mathcal{L}_p$ over $\mathbb{R}$ generated by the restrictions of Θ^n_1 and $\theta^n_{\mathbf{i},\mathbf{j}}$ to T^n. The multiplication between elements of $A^f_n(t)$ and $A^f_m(t)$ is defined in the same way as in (14), that is, it is defined for $\theta^n_{\mathbf{i},\mathbf{j}}\in A^f_n(t)$ and $\theta^m_{\mathbf{i}',\mathbf{j}'}\in A^f_m(t)$ as

$$\theta^n_{\mathbf{i},\mathbf{j}}\circ\theta^m_{\mathbf{i}',\mathbf{j}'}=\theta^{n+m}_{\mathbf{i}'',\mathbf{j}''}\,,$$

where $\mathbf{i}''=(i_1,\ldots,i_k,n+i'_1,\ldots,n+i'_r)$ and $\mathbf{j}''=(j_1,\ldots,j_k,n+j'_1,\ldots,n+j'_r)$. Now, the product extends linearly.

Note that $A^f_n(t)$ is a finite dimensional linear space. The coefficients algebra $\Pi_{n=0}^{\infty}A^f_n(t)$ is called the *finite dimensional coefficients algebra* and it is denoted by $A^f(t)$. Associated with this coefficients algebra we denote by $\Lambda^f_n(t)$, $\Lambda^f(t)$, $\mathcal{A}^f(t)$, $\Gamma^f(t)$, $\mathfrak{A}^f(t)$, and $\mathfrak{L}^f(t)$ the remainder linear spaces. Since $\Lambda^f_n(t)\subset A^f_n(t)$, then $\Lambda^f_n(t)$ is finite dimensional.

IV. FRIEDRICHS' CRITERION

Following Jacobson (Ref. 16), let us take the tensor product of the algebra $\mathcal{A}$ with itself, that is, $\mathcal{A}\otimes\mathcal{A}$ and its associated formal algebra $\overline{\mathcal{A}\otimes\mathcal{A}}$. The elements of $\overline{\mathcal{A}\otimes\mathcal{A}}$ are of the form

$$\sum_{n=0}^{\infty}\sum_{m=0}^{\infty} d_{m,n-m}, \tag{24}$$

where $d_{m,m-n}=c_{n,m}(a_m\otimes b_{n-m})$, with $c_{n,m}\in F$, and a_m, b_{n-m} are homogeneous elements of $\mathcal{A}$ of degrees m and $n-m$, respectively. If the element $d_{i,j}$ is not null, we call it a *homogeneous element of degree* (i,j). It follows immediately that every element of $\overline{\mathcal{A}\otimes\mathcal{A}}$ can be written, in a unique form, as a series (24) of homogeneous elements of different degrees (i,j). The free product given in $\overline{\mathcal{A}}$ will be related to the new product given in $\overline{\mathcal{A}\otimes\mathcal{A}}$ in the usual way, that is, if $\alpha,\beta,\gamma,\delta$ are in $\overline{\mathcal{A}}$ one obtains

$$(\alpha\odot\beta)\otimes(\gamma\odot\delta)=(\alpha\otimes\gamma)\odot(\beta\otimes\delta).$$

Remark 2: Taking advantage of the tensor notation let us consider the subalgebra $\mathcal{A}(t)\otimes\mathcal{A}(t)$ *of* $\overline{\mathcal{A}\otimes\mathcal{A}}$ *as the algebra whose elements can be written in the following form*:

$$\begin{aligned}
&a_{0,0}(1\otimes 1)+\int_0^t a_{1,0}(t_1)(H(t_1)\otimes 1)\mathrm{d}t_1+\int_0^t a_{0,1}(t_1)(1\otimes H(t_1))\mathrm{d}t_1)\\
&\quad+\sum_{n=2}^{\infty}\Bigg(\int_0^t\cdots\int_0^t a_{n,0}(t_1,\ldots,t_n)((H(t_1)\odot\ldots\odot H(t_n))\otimes 1)\mathrm{d}t_1\ldots\mathrm{d}t_n\\
&\quad+\sum_{m=1}^{n-1}\int_0^t\cdots\int_0^t a_{n,m}(t_1,\ldots,t_n)(H(t_1)\odot\ldots\odot H(t_{n-m}))\otimes(H(t_{n-m+1})\odot\ldots\odot H(t_n))\mathrm{d}t_1\ldots\mathrm{d}t_n\\
&\quad+\int_0^t\cdots\int_0^t a_{n,n}(t_1,\ldots,t_n)(1\otimes(H(t_1)\odot\ldots\odot H(t_n)))\mathrm{d}t_1\ldots\mathrm{d}t_n\Bigg),
\end{aligned}\tag{25}$$

with $a_{n,m}\in A_n(t)$. *Note that every integral of* (25) *is a homogeneous element of degree* $(n-m,m)$. □

For $a=\{a_n\}_{n=0}^{\infty}$ in $A(t)$ let the function $\Phi':A(t)\to\mathcal{A}(t)\otimes\mathcal{A}(t)$ be defined by

$$\begin{aligned}
\Phi'(a)=a_0(1\otimes 1)+\sum_{n=1}^{\infty}\int_0^t\cdots\int_0^t a_n(t_1,\ldots,t_n)(H(t_1)\otimes 1+1\otimes H(t_1))\odot\ldots\odot(H(t_n\otimes 1+1\\
\otimes H(t_n))\mathrm{d}t_1\ldots\mathrm{d}t_n.
\end{aligned}$$

It is easy to prove that Φ' is a homomorphism between associative algebras with unit.

Finally, we define $\Delta:\mathcal{A}(t)\to\mathcal{A}(t)\otimes\mathcal{A}(t)$ as the homomorphism that makes the following chart commutative:

$$\begin{array}{ccc}
A(t) & \overset{\Phi^{-1}}{\underset{\Phi}{\leftrightarrows}} & \mathcal{A}(t)\\
& \searrow_{\Phi'} & \vdots\Delta\\
& & \mathcal{A}(t)\otimes\mathcal{A}(t).
\end{array}$$

Another way to define Δ is $\Delta=\Phi'\circ\Phi^{-1}$ ($\circ$ denotes composition). Even more concretely,

$$\Delta\left(a_0+\sum_{n=1}^{\infty}\int_0^t\cdots\int_0^t a_n(t_1,\ldots,t_n)H(t_1)\odot\ldots\odot H(t_n)\mathrm{d}t_1\ldots\mathrm{d}t_n\right)$$

$$=a_0(1\otimes 1)+\sum_{n=1}^{\infty}\int_0^t\cdots\int_0^t a_n(t_1,\ldots,t_n)(H(t_1)\otimes 1+1\otimes H(t_1))$$

$$\odot\ldots\odot(H(t_n)\otimes 1+1\otimes H(t_n))\mathrm{d}t_1\ldots\mathrm{d}t_n. \tag{26}$$

Observe that Δ is a homomorphism between associative algebras with unit, because it is the composition of Φ' and Φ^{-1}. On the other hand, Δ is the continuous analog to the *diagonal map* defined in Ref. 16.

We finish this section by presenting Friedrichs' criterion, which is the continuous extension to Friedrichs' theorem.[16]

Theorem 14: *(Friedrichs' criterion). An element α of $\mathcal{A}(t)$ is in $\Gamma(t)$, that is, α is an ordered element, if and only if $\Delta\alpha=\alpha\otimes 1+1\otimes\alpha$.*

See the proof in Appendix B.

V. MAGNUS EXPANSION

Let us define, given an element x of $\overline{\mathcal{A}}$ or $\overline{\mathcal{A}\otimes\mathcal{A}}$, the series

$$\exp x=e+x+\frac{x^2}{2!}+\cdots+\frac{x^n}{n!}+\cdots$$

and

$$\log(e+x)=x-\frac{x^2}{2}+\frac{x^3}{3}-\cdots+(-1)^{n+1}\frac{x^n}{n}+\cdots, \tag{27}$$

where e represents the identity element. Remember that if x is in the bilateral ideal $\overline{\mathcal{A}^{(1)}}=\overline{A\oplus(A\otimes A)\oplus\ldots}$, then $\exp x$ and $\log(1+x)$ converge, that is, they are elements of $\overline{\mathcal{A}}$. For convergent cases we have the identities $\exp(\log(1+x))=1+x$ and $\log(\exp x)=x$; furthermore, if $x\odot y=y\odot x$, then $\exp x\odot\exp y=\exp(x+y)$ and $\log((1+x)\odot(1+y))=\log(1+x)+\log(1+y)$.

In the following we are interested primarily in the log series. In order to apply the identities presented before, we will consider only convergent series. For the elements of $\mathcal{A}(t)$, written of the form $1+\beta$ with β in $\mathcal{A}(t)^{(1)}=\mathcal{A}(t)\cap\overline{\mathcal{A}^{(1)}}$, it gives a very important case of convergence in $\mathcal{A}(t)$ under the series log which will be examined in the sequel.

Proposition 15: For every α in $\mathcal{A}(t)$ given in the form

$$\alpha=1+\sum_{n=1}^{\infty}\int_0^t\cdots\int_0^t a_n(t_1,\ldots,t_n)H(t_1)\odot\ldots\odot H(t_n)\mathrm{d}t_1\ldots\mathrm{d}t_n,$$

we have that $\log\alpha$ *is an element of* $\mathcal{A}(t)$.

Proof: Denote $\beta=\alpha-1$ by

$$\beta=\sum_{n=1}^{\infty}\int_0^t\cdots\int_0^t b_{1,n}(t_1,\ldots,t_n)H(t_1)\odot\ldots\odot H(t_n)\mathrm{d}t_1\ldots\mathrm{d}t_n,$$

where $b_{1,n}=a_n$ for every $n\geqslant 1$. The successive powers of β are given by the following expression:

$$\beta^m=\sum_{n=1}^{\infty}\int_0^t\cdots\int_0^t b_{m,n}(t_1,\ldots,t_n)H(t_1)\odot\ldots\odot H(t_n)\mathrm{d}t_1\ldots\mathrm{d}t_n.$$

Thus β^m are elements of $\mathcal{A}(t)$. Note that the homogeneous component of lowest degree in β^m must be at least of degree m. Therefore, by (27), we have that $\log \alpha$ is given by

$$\log \alpha = \sum_{n=1}^{\infty} \int_0^t \cdots \int_0^t \left(\sum_{m=1}^{n} \frac{(-1)^{m+1}}{m} b_{m,n}(t_1,\ldots,t_n) \right) H(t_1) \odot \ldots \odot H(t_n) \mathrm{d}t_1 \ldots \mathrm{d}t_n ,$$

which is an element of $\mathcal{A}(t)$ as we wanted to prove. ■

Since Δ is a homomorphism between associative algebras with unit, we have that, if $\log \alpha \in \mathcal{A}(t)$, then

$$\Delta(\log \alpha) = \log(\Delta \alpha). \tag{28}$$

Until now we have considered t fixed. Nevertheless, it is useful to consider the elements of $\mathcal{A}(t)$ and $\mathcal{A}(t) \otimes \mathcal{A}(t)$ as functions of t. Hence, we define the derivative with respect to t of α, $\mathrm{d}\alpha/\mathrm{d}t$, as the derivative of each element. This derivative is not necessarily an element of $\mathcal{A}(t)$ or $\mathcal{A}(t) \otimes \mathcal{A}(t)$, but certainly it is in $\overline{\mathcal{A}}$ or in $\overline{\mathcal{A} \otimes \mathcal{A}}$, respectively. Finally, the derivative of the tensor product of two elements $\alpha(t)$ and $\beta(t)$ of $\mathcal{A}(t)$ is given by the rule

$$\frac{\mathrm{d}}{\mathrm{d}t}(\alpha(t) \otimes \beta(t)) = \frac{\mathrm{d}}{\mathrm{d}t} \alpha(t) \otimes \beta(t) + \alpha(t) \otimes \frac{\mathrm{d}}{\mathrm{d}t} \beta(t). \tag{29}$$

The following is the Magnus theorem[1] which is the continuous analog of the Baker–Campbell–Hausdorff's theorem.[16]

Theorem 16: *Let $H(t)$ be a continuous function from $\mathbb{R}$ to the linear space of bounded operators over a Hilbert space G that is null only on a finite set of points. Let $U(t)$ be the solution of*

$$\frac{\mathrm{d}U}{\mathrm{d}t} = H(t)U(t), \quad U(0) = I, \tag{30}$$

where I denotes the identity operator. Then, if $U(t)$ has a logarithm $\Omega(t)$ given by the series (27) (*putting I instead of e*) *and this series converges absolutely in A, there exists an element $\psi(t)$ of $\mathcal{L}^f(t)$ (that is, a sequence of finite dimensional convergent ordered coefficients) such that $\Omega(t) = \Xi(\psi(t))$.*

Proof: The solution $U(t)$ to (28) is given by the series

$$U(t) = I + \int_0^t H(t_1)\mathrm{d}t_1 + \int_0^t \int_0^{t_1} H(t_1)H(t_2)\mathrm{d}t_1\,\mathrm{d}t_2 + \int_0^t \int_0^{t_1} \int_0^{t_2} H(t_1)H(t_2)H(t_3)\mathrm{d}t_1\,\mathrm{d}t_2\,\mathrm{d}t_3 + \cdots . \tag{31}$$

Let us examine the "differential" equation in $\overline{\mathcal{A}}$ associated with (30):

$$\frac{\mathrm{d}}{\mathrm{d}t} \alpha(t) = H(t) \odot \alpha(t), \quad \alpha(0) = 1. \tag{32}$$

The solution to (32) is similar to (31) and it is given by

$$\alpha(t) = 1 + \int_0^t H(t_1)\mathrm{d}t_1 + \int_0^t \int_0^{t_1} H(t_1) \odot H(t_2)\mathrm{d}t_1\,\mathrm{d}t_2 + \int_0^t \int_0^{t_1} \int_0^{t_2} H(t_1) \odot H(t_2) \odot H(t_3)\mathrm{d}t_1\,\mathrm{d}t_2\,\mathrm{d}t_3 + \cdots . \tag{33}$$

This can be proved by derivating component to component. Rewriting (33) in the following way (see (23)):

$$\alpha(t)=1+\int_0^t H(t_1)\mathrm{d}t_1+\sum_{n=2}^{\infty}\int_0^t\cdots\int_0^t \theta_{1,2}\ldots\theta_{n-1,n}H(t_1)\odot\ldots\odot H(t_n)\mathrm{d}t_1\ldots\mathrm{d}t_n, \tag{34}$$

it becomes clear that $\alpha(t)$ is contained in $\mathcal{A}^f(t)$. By Proposition 15 we have that $\log\alpha(t)\in\mathcal{A}^f(t)$. By (29):

$$\frac{\mathrm{d}}{\mathrm{d}t}(\alpha(t)\otimes\alpha(t))=\frac{\mathrm{d}}{\mathrm{d}t}\alpha(t)\otimes\alpha(t)+\alpha(t)\otimes\frac{\mathrm{d}}{\mathrm{d}t}\alpha(t),$$

and from (32) we have

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}t}(\alpha(t)\otimes\alpha(t))&=(H(t)\odot\alpha(t))\otimes\alpha(t)+\alpha(t)\otimes(H(t)\odot\alpha(t))\\&=(H(t)\otimes 1+1\otimes H(t))\odot(\alpha(t)\otimes\alpha(t)).\end{aligned}$$

Therefore, we get

$$\frac{\mathrm{d}}{\mathrm{d}t}(\alpha(t)\otimes\alpha(t))=(H(t)\otimes 1+1\otimes H(t))\odot(\alpha(t)\otimes\alpha(t)),$$

with $\alpha(0)\otimes\alpha(0)=1\otimes 1$, which compared to (32) and taking into account (34) implies directly

$$\Delta(\alpha(t))=\alpha(t)\otimes\alpha(t). \tag{35}$$

So then, if $\omega(t)=\log\alpha(t)$, applying successively (28) and (35) we obtain

$$\begin{aligned}\Delta(\omega(t))=\Delta(\log\alpha(t))=\log(\Delta(\alpha(t)))&=\log(\alpha(t)\otimes\alpha(t))\\&=\log((\alpha(t)\otimes 1)\odot(1\otimes\alpha(t)))\\&=\log(\alpha(t)\otimes 1)+\log(1\otimes\alpha(t))\\&=(\log\alpha(t))\otimes 1+1\otimes\log\alpha(t)=\omega(t)\otimes 1+1\otimes\omega(t).\end{aligned}$$

It follows, by Friedrichs' criterion, that $\omega(t)=\log\alpha(t)$ is an element contained in $\Gamma^f(t)$. Consequently, $\psi(t)=\Phi^{-1}(\omega(t))$ is an element of $\Lambda^f(t)$. Finally, since it holds that $\Xi(\psi(t))=\Omega(t)=\log U(t)$, $\psi(t)$ is an element of $\mathfrak{A}^f(t)$, from where, we conclude that $\psi(t)\in\mathcal{L}^f(t)$ and $\Xi(\psi(t))=\Omega(t)$. ■

If $H(t)$ and $U(t)$ fulfill the conditions of Theorem 16 it is easy to get an expression for $\Omega(t)$ in terms of $H(t)$. Remember that $U(t)$ is given by

$$U(t)=I+\int_0^t H(t_1)\mathrm{d}t_1+\sum_{n=2}^{\infty}\int_0^t\cdots\int_0^t \theta_{1,2}\ldots\theta_{n-1,n}H(t_1)\ldots H(t_n)\mathrm{d}t_1\ldots\mathrm{d}t_n.$$

Hence, applying the log series to $U(t)$ and calculating up to the third term, we have that $\Omega(t)$ is as follows:

$$\begin{aligned}\Omega(t)=&\int_0^t H(t_1)\mathrm{d}t_1+\int_0^t\int_0^t\left(\theta_{1,2}-\frac{1}{2}\right)H(t_1)H(t_2)\mathrm{d}t_1\,\mathrm{d}t_2\\&+\int_0^t\int_0^t\int_0^t\left(\theta_{1,2}\theta_{2,3}-\frac{1}{2}\theta_{1,2}-\frac{1}{2}\theta_{2,3}+\frac{1}{3}\right)\times H(t_1)H(t_2)H(t_3)\mathrm{d}t_1\,\mathrm{d}t_2\,\mathrm{d}t_3+\cdots.\end{aligned}$$

Since the coefficients associated with $\Omega(t)$ are ordered, by (20) this allows one to rewrite the previous series in the following way:

$$\Omega(t)=\int_0^t H(t_1)\mathrm{d}t_1+\frac{1}{2}\int_0^t\int_0^t\left(\theta_{1,2}-\frac{1}{2}\right)[H(t_1),H(t_2)]\mathrm{d}t_1\,\mathrm{d}t_2$$
$$+\frac{1}{3}\int_0^t\int_0^t\int_0^t\left(\theta_{1,2}\theta_{2,3}-\frac{1}{2}\theta_{1,2}-\frac{1}{2}\theta_{2,3}+\frac{1}{3}\right)\times[[H(t_1),H(t_2)],H(t_3)]\mathrm{d}t_1\,\mathrm{d}t_2\,\mathrm{d}t_3+\cdots.$$

Finally, integrating we obtain the *Magnus expansion:*

$$\Omega(t)=\int_0^t H(t_1)\mathrm{d}t_1+\frac{1}{2}\int_0^t\int_0^{t_1}[H(t_1),H(t_2)]\mathrm{d}t_1\,\mathrm{d}t_2$$
$$+\frac{1}{6}\int_0^t\int_0^{t_1}\int_0^{t_2}[[H(t_1),H(t_2)],H(t_3)]\mathrm{d}t_1\,\mathrm{d}t_2\,\mathrm{d}t_3$$
$$+\frac{1}{6}\int_0^t\int_0^{t_1}\int_0^{t_2}[H(t_1),[H(t_2),H(t_3)]]\mathrm{d}t_1\,\mathrm{d}t_2\,\mathrm{d}t_3+\cdots.$$

Remark 3: From the fact that $\omega(t)$ is a Lie-element (Theorem 16) one can obtain an explicit expression for the coefficients of the Magnus expansion $\Omega(t)$, which we call the Magnus formula:[11]

$$\Omega(t)=\int_0^t H(t_1)\mathrm{d}t_1+\sum_{n=2}^{\infty}\frac{1}{n}\int_0^t\cdots\int_0^t L_n[\ldots[H(t_1),H(t_2)],\ldots,H(t_n)]\mathrm{d}t_1\,\mathrm{d}t_2\ldots\mathrm{d}t_n, \qquad (36)$$

where

$$L_n=\sum_{i=1}^{n}\frac{(-1)^{i+1}}{i}\sum_{j_1<j_2<\ldots<j_{n-i}<n}\prod_{m=1}^{n-i}\theta_{j_m j_m+1}.$$

□

As a corollary of (36) we get the local convergence of the Magnus formula (see also Refs. 6 and 17):

Proposition 17: Let $H(t)$ be a continuous function from $\mathbb{R}$ to the linear space of bounded operators over a Hilbert space G that is null only on a finite set of points. Let M be a positive real number such that $\|H(t)\|\leqslant M$ for all t. Then, the Magnus expansion converges for all $t\in[0,1/(2M))$.

Proof: It is easy to see that the coefficient L_n provides 2^{n-1} multiple integrals. Hence, we have that

$$\|\Omega(t)\|\leqslant\sum_{n=1}^{\infty}2^{n-1}M^n t^n.$$

Applying the division criterion, we obtain that $\Omega(t)$ converges if

$$t\leqslant\frac{1}{2M}.$$

□

As an example of a global result which follows immediately from the Magnus expansion, we will present a simple proof of a well-known result for the stability of triangular systems.

Consider the following triangular system:

$$\begin{cases} \dot{x}_1 = a_{11}(t)x_1 + & a_{12}(t)x_2 + \ldots + & a_{1n}(t)x_n \\ \dot{x}_2 = & a_{22}(t)x_2 + \ldots + & a_{2n}(t)x_n \\ \vdots & & \vdots \\ \dot{x}_n = & & a_{nn}(t)x_n \end{cases} . \tag{37}$$

Let us represent (37) in the following way:

$$\dot{U}(t) = H(t)U(t),$$

where

$$U(t) = \begin{pmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{pmatrix}, \quad H(t) = \begin{pmatrix} a_{11}(t) & a_{12}(t) & \ldots & a_{1n}(t) \\ 0 & a_{22}(t) & \ldots & a_{2n}(t) \\ \vdots & \vdots & & \vdots \\ 0 & 0 & \ldots & a_{nn}(t) \end{pmatrix}.$$

The triangular matrix $H(t)$ can be represented as the sum $H(t) = D(t) + N(t)$, where $D(t)$ is the principal diagonal matrix and $N(t)$ is the nilpotent superior triangular matrix. In order to obtain an exponential solution, we apply the Magnus expansion (36). Thus we have

$$\Omega(t) = \int_0^t H(t_1)\mathrm{d}t_1 + \frac{1}{2}\int_0^t \int_0^{t_1} [H(t_1), H(t_2)]\mathrm{d}t_1\,\mathrm{d}t_2 + \ldots$$

$$= \begin{pmatrix} \int_0^t a_{11}(t_1)\mathrm{d}t_1 & & & 0 \\ & \int_0^t a_{22}(t_1)\mathrm{d}t_1 & & \\ & & \ddots & \\ 0 & & & \int_0^t a_{nn}(t_1)\mathrm{d}t_1 \end{pmatrix} + \hat{N}(t),$$

where $\hat{N}(t)$ is a nilpotent superior triangular matrix. Therefore the matrix $(1/t)\Omega(t)$ is given in the next form

$$(1/t)\Omega(t) = \begin{pmatrix} \frac{1}{t}\int_0^t a_{11}(t_1)\mathrm{d}t_1 & & & * \\ & \frac{1}{t}\int_0^t a_{22}(t_1)\mathrm{d}t_1 & & \\ & & \ddots & \\ 0 & & & \frac{1}{t}\int_0^t a_{nn}(t_1)\mathrm{d}t_1 \end{pmatrix}. \tag{38}$$

Since the eigenvalues of matrix (38) are the Lyapunov exponents

$$\lambda_i = \frac{1}{t}\int_0^t a_{ii}(t_1)\mathrm{d}t_1 \quad \text{for } i = 1,\ldots,n,$$

then, we have the following result:

Proposition 18: System (37) *is uniformly exponentially stable if there exist positive numbers* τ, ν *such that, for all* $t>\tau$, $(1/t)\int_0^t a_{ii}(t_1)\mathrm{d}t_1 \leqslant -\nu$ *for* $i=1,...,n$.

The proof follows from the next criterion on the uniform exponential stability of a nonautonomous linear system:[46]

Proposition 19: A sufficient condition for a linear system to be uniformly exponentially stable is that the eigenvalues of the $n\times n$ *matrix* $(1/t)\Omega(t)$ *be bounded as functions of* t *and have real parts* $\leqslant -\nu$ *for all* $t>\tau$ *for some positive numbers* ν *and* τ.

APPENDIX A: THE ALGEBRA OF PERMUTATIONS

In this Appendix we prove the properties of the permutations $C_{1,k}$ which are relevant in the proof of the main results of this paper.

Proposition 20: Let $m>0$ *and* $i_1<\ldots<i_m$ *be any* m *positive integers. Now let us take the* (i_m-m) *positive integers smaller than* i_m *and different from the previous ones and let us call them* $i_{m+1}<\ldots<i_{i_m}$. *Then*

$$C_{1,i_1}\ldots C_{1,i_m}=\begin{pmatrix} 1 & 2 & \ldots & m & m+1 & \ldots & i_m \\ i_m & i_{m-1} & \ldots & i_1 & i_{m+1} & \ldots & i_{i_m} \end{pmatrix}. \tag{A1}$$

Proof: The proof follows by induction over m, assuming that $i_1\geqslant 2$. The case $i_1=1$ follows immediately from the fact $C_{1,1}=1$.

For $m=1$ the equality holds (A1) since from (7):

$$C_{1,i_1}=\begin{pmatrix} 1 & 2 & \ldots & i_1 \\ i_1 & 1 & \ldots & i_1-1 \end{pmatrix}.$$

Suppose that (A1) holds for $m=k$. We will prove it for $m=k+1$.

Let $i_1<\ldots<i_{k+1}$ with $i_{k+2}<\ldots<i_{i_{k+1}}$ be the first i_{k+1} positive integers. By the induction hypothesis,

$$C_{1,i_1}\ldots C_{1,i_k}=\begin{pmatrix} 1 & 2 & \ldots & k & k+1 & \ldots & i_k \\ i_k & i_{k-1} & \ldots & i_1 & i_{k+2} & \ldots & i_{i_k+1} \end{pmatrix}.$$

Note that $i_{i_{k+1}}<i_k<i_{k+1}$. Hence

$$C_{1,i_1}\ldots C_{1,i_k}C_{1,i_{k+1}}=\begin{pmatrix} 1 & 2 & \ldots & k & k+1 & \ldots & i_k \\ i_k & i_{k-1} & \ldots & i_1 & i_{k+2} & \ldots & i_{i_k+1} \end{pmatrix}C_{1,i_{k+1}},$$

From (7):

$$\begin{aligned}&\begin{pmatrix} 1 & 2 & \ldots & k & k+1 & \ldots & i_k \\ i_k & i_{k-1} & \ldots & i_1 & i_{k+2} & \ldots & i_{i_k+1} \end{pmatrix}C_{1,i_{k+1}} \\ &\quad=\begin{pmatrix} 1 & 2 & \ldots & k & k+1 & \ldots & i_k \\ i_k & i_{k-1} & \ldots & i_1 & i_{k+2} & \ldots & i_{i_k+1} \end{pmatrix}\begin{pmatrix} 1 & 2 & \ldots & i_{k+1} \\ i_{k+1} & 1 & \ldots & i_{k+1}-1 \end{pmatrix} \\ &\quad=\begin{pmatrix} 1 & 2 & \ldots & k+1 & k+2 & \ldots & i_{k+1} \\ i_{k+1} & i_k & \ldots & i_1 & i_{k+2} & \ldots & i_{i_{k+1}} \end{pmatrix}.\end{aligned}$$

■

Corollary 21:

$$C_{1,2}\ldots C_{1,n}=\begin{pmatrix}1 & 2 & \ldots & n-1 & n\\ n & n-1 & \ldots & 2 & 1\end{pmatrix}.$$

Corollary 22: Let $n\geqslant m>0$ and let $i_1<\ldots<i_m$ be m positive integers less or equal to n. Take now the $n-m$ positive integers less or equal to n that are different from the previous ones and let us call them $i_{m+1}<\ldots<i_n$. Then

$$C_{1,i_1}\ldots C_{1,i_m}=\begin{pmatrix}1 & 2 & \ldots & m & m+1 & \ldots & n\\ i_m & i_{m-1} & \ldots & i_1 & i_{m+1} & \ldots & i_n\end{pmatrix}.$$

Proof: It follows from Proposition 20 noting that $i_k=k$ for $k\geqslant i_m+1$. ■

From the above-given corollary one obtains the following results:

Corollary 23:

$$C_{1,i_1}\ldots C_{1,i_m}C_{1,2}\ldots C_{1,m}=\begin{pmatrix}1 & \ldots & m & m+1 & \ldots & n\\ i_1 & \ldots & i_m & i_{m+1} & \ldots & i_n\end{pmatrix}.$$

Corollary 24: $C^{-1}_{1,n}\ldots C^{-1}_{1,2}C^{-1}_{1,i_m}\ldots C^{-1}_{1,i_1}=C^{-1}_{1,i_n}\ldots C^{-1}_{1,i_{m+1}}$.

Corollary 25: $(C_{1,n})^m C^{-1}_{1,m}\ldots C^{-1}_{1,2}\ C^{-1}_{1,i_m}\ldots\ C^{-1}_{1,i_1}=C^{-1}_{1,n-m}\ldots C^{-1}_{1,2}C^{-1}_{1,i_n}\ldots C^{-1}_{1,i_{m+1}}$.

The next Lemma is used in the proof of Friedrichs' criterion.

Lemma 26: For n odd:

$$nE_n-n=\sum_{i=1}^{[[n/2]]}\left[(-1)^i(n-i)\prod_{k=2}^{i}C^{-1}_{1,i-k+2}+(-1)^{n-i}i\prod_{k=i+1}^{n}C^{-1}_{1,n-k+i+1}\right]\sigma_{n,n-1},$$

where E_n is given by (8), *$[[\cdot]]$ is the "largest-integer-less-or-equal-than" function, and*

$$\sigma_{n,m}=\left(\prod_{k=2}^{n-m}C^{-1}_{1,n-m-k+2}\right)\rho_{n,m},$$

with

$$\rho_{n,m}=\sum_{n\geqslant i_{n-m}>\ldots>i_1\geqslant 1}C^{-1}_{1,i_{n-m}}\ldots C^{-1}_{1,i_1}.$$

Proof: First, notice that given $C_{1,1}=1$ we can rewrite $\rho_{n,m}$ in a way more useful to our purposes:

$$\rho_{n,m}=\sum_{n\geqslant j_{n-m-1}>\ldots>j_1\geqslant 2}C^{-1}_{1,j_{n-m-1}}\ldots C^{-1}_{i,j_1}+\sum_{n\geqslant l_{n-m}>\ldots>l_1\geqslant 2}C^{-1}_{1,l_{n-m}}\ldots C^{-1}_{1,l_1}$$

(for $m=n-1$ the first summation is reduced to be equal to 1),

$$\begin{aligned}\rho_{n,m}&=\sum_{i=1}^{[[n/2]]}\left[(-1)^i(n-i)\prod_{k=2}^{i}C^{-1}_{1,i-k+2}+(-1)^{n-i}i\prod_{k=i+1}^{n}C^{-1}_{1,n-k+i+1}\right]\sigma_{n,n-1}\\ &=\sum_{i=1}^{[[n/2]]}\left[(-1)^i(n-i)\prod_{k=2}^{i}C^{-1}_{1,i-k+2}+(-1)^{n-i}i\prod_{k=i+1}^{n}C^{-1}_{1,n-k+i+1}\right]\left(\prod_{k=2}^{i}C^{-1}_{1,i-k+2}\right)\rho_{n,n-1}.\end{aligned}$$

As a consequence of Corollary 21 we have that $(\Pi_{k=2}^{i}C^{-1}_{1,i-k+2})^2=1$. Moreover,

$$\prod_{k=i+1}^{n} C^{-1}_{1,n-k+i+1} \prod_{k=2}^{i} C^{-1}_{1,i-k+2} = \prod_{k=2}^{n} C^{-1}_{1,n-k+2}.$$

Hence

$$\rho_{n,m} = \sum_{i=1}^{[[n/2]]} \left[(-1)^i (n-i) + (-1)^{n-i} i \prod_{k=2}^{n} C^{-1}_{1,n-k+2} \right] \rho_{n,n-1}$$
$$= \sum_{i=1}^{[[n/2]]} (-1)^i (n-i) \rho_{n,n-1} + \sum_{i=1}^{[[n/2]]} (-1)^{n-i} i \prod_{k=2}^{n} C^{-1}_{1,n-k+2} \rho_{n,n-1}.$$

Replacing in the second summation the index i by $n-i$ we obtain

$$\rho_{n,m} = \sum_{i=1}^{[[n/2]]} (-1)^i (n-i) \rho_{n,n-1} + \sum_{i=[[n/2]]+1}^{n-1} (-i)^i (n-i) \prod_{k=2}^{n} C^{-1}_{1,n-k+2} \rho_{n,i}.$$

Now, as a consequence of Corollary 24, we have that $\Pi_{k=2}^{n} C^{-1}_{1,n-k+2} \rho_{n,i} = \rho_{n,n-i}$. Hence

$$\rho_{n,m} = \sum_{i=1}^{[[n/2]]} (-1)^i (n-i) \rho_{n,n-1} + \sum_{i=[[n/2]]+1}^{n-1} (-i)^i (n-i) \rho_{n,n-i}$$

$$= \sum_{i=1}^{n-1} (-1)^i (n-i) \rho_{n,n-i}$$

$$= \sum_{i=1}^{n-1} (-1)^i (n-i) \left(\sum_{n \geqslant j_{i-1} > \ldots > j_i \geqslant 2} C^{-1}_{1,j_{i-1}} \ldots C^{-1}_{i,j_1} \right.$$
$$\left. + \sum_{n \geqslant l_i > \ldots > l_1 \geqslant 2} C^{-1}_{1,l_i} \ldots C^{-1}_{1,l_1} \right)$$

$$= \sum_{i=1}^{n-1} (-1)^i (n-i) \sum_{n \geqslant j_{i-1} > \ldots > j_1 \geqslant 2} C^{-1}_{i,j_{i-1}} \ldots C^{-1}_{1,j_1}$$
$$+ \sum_{i=1}^{n-1} (-1)^i (n-i) \sum_{n \geqslant l_i > \ldots > l_1 \geqslant 2} C^{-1}_{i,l_1} \ldots C^{-1}_{1,l_1}.$$

Replacing in the second double summation the index i by $i-1$ we obtain

$$\rho_{n,m} = \sum_{i=1}^{n-1} (-1)^i (n-i) \sum_{n \geqslant j_{i-1} > \ldots > j_i \geqslant 2} C^{-1}_{1,j_{i-1}} \ldots C^{-1}_{i,j_1}$$
$$+ \sum_{i=2}^{n} (-1)^{i-1} (n-i+1) \sum_{n \geqslant l_{i-1} > \ldots > l_1 \geqslant 2} C^{-1}_{1,l_{i-1}} \ldots C^{-1}_{1,l_1}.$$

Changing now the indexes l_k by j_k we have

$$\rho_{n,m}=\sum_{i=1}^{n-1}(-1)^i(n-i)\sum_{n\geqslant j_{i-1}>\ldots>j_i\geqslant 2}C^{-1}_{1,j_{i-1}}\ldots C^{-1}_{i,j_1}$$
$$+\sum_{i=2}^{n}(-1)^{i-1}(n-i+1)\sum_{n\geqslant j_{i-1}>\ldots>j_i\geqslant 2}C^{-1}_{1,j_{i-1}}\ldots C^{-1}_{1,j_1}$$
$$=-(n-1)+\sum_{i=2}^{n-1}(-1)^i(n-i)\sum_{n\geqslant j_{i-1}>\ldots>j_1\geqslant 2}C^{-1}_{1,j_{i-1}}\ldots C^{-1}_{1,j_1}$$
$$+\sum_{i=2}^{n-1}(-1)^{i-1}(n-i+1)\sum_{n\geqslant j_{i-1}>\ldots>j_1\geqslant 2}C^{-1}_{1,j_{i-1}}\ldots C^{-1}_{1,j_1}+(-1)^{n-1}\prod_{k=2}^{n}C^{-1}_{1,n-k+2}$$
$$=-(n-1)+\sum_{i=2}^{n-1}((-1)^i(n-i)+(-1)^{i-1}(n-i+1))\sum_{n\geqslant j_{i-1}>\ldots>j_1\geqslant 2}C^{-1}_{1,j_{i-1}}\ldots C^{-1}_{1,j_1}$$
$$+(-1)^{n-1}\prod_{k=2}^{n}C^{-1}_{1,n-k+2}$$
$$=-(n-1)+\sum_{i=2}^{n-1}(-1)^{i-1}(-n+i+n-i+1)\sum_{n\geqslant j_{i-1}>\ldots>j_1\geqslant 2}C^{-1}_{1,j_{i-1}}\ldots C^{-1}_{1,j_1}$$
$$+(-1)^{n-1}\prod_{k=2}^{n}C^{-1}_{1,n-k+2}$$
$$=-(n-1)+\sum_{i=2}^{n-1}(-1)^{i-1}\sum_{n\geqslant j_{i-1}>\ldots>j_1\geqslant 2}C^{-1}_{1,j_{i-1}}\ldots C^{-1}_{1,j_1}+(-1)^{n-1}\prod_{k=2}^{n}C^{-1}_{1,n-k+2}$$

■

APPENDIX B: PROOF OF FRIEDRICHS' CRITERION

($\Rightarrow$)
If $\alpha\in\Gamma(t)$ then there exists $a=\{a_n\}_{n=0}^{\infty}\in\Lambda(t)$ such that $\alpha=\Phi(a)$. Since a is in $\Lambda(t)$ we have that $a=E(a)$. This, by (16), implies that $a_0=0$ and $a_n=E_n(a_n)$, for $n\geqslant 2$. Therefore,

$$\alpha=\Phi(a)=\sum_{n=1}^{\infty}\int_0^t\cdots\int_0^t a_n(t_1,\ldots,t_n)H(t_1)\odot\ldots\odot H(t_n)\mathrm{d}t_1\ldots\mathrm{d}t_n$$
$$=\int_0^t a_1(t_1)H(t_1)\mathrm{d}t_1+\sum_{n=2}^{\infty}\int_0^t\cdots\int_0^t E_n(a_n(t_1,\ldots,t_n))H(t_1)$$
$$\odot\ldots\odot H(t_n)\mathrm{d}t_1\ldots\mathrm{d}t_n. \tag{B1}$$

Applying Δ [given by (26)] to (B1) we obtain

$$\Delta\alpha=\int_0^t a_1(t_1)(H(t_1)\otimes 1+1\otimes H(t_1))\mathrm{d}t_1+\sum_{n=1}^{\infty}\int_0^t\cdots\int_0^t E_n(a_n(t_1,\ldots,t_n))(H(t_1)\otimes 1+1\otimes H(t_1))\odot\ldots\odot(H(t_n)\otimes 1+\otimes H(t_n))\mathrm{d}t_1\ldots\mathrm{d}t_n.$$

By (20), every multiple integral can be reordered in the following way:

$$\Delta\alpha=\int_0^t a_1(t_1)(H(t_1)\otimes 1+1\otimes H(t_1))\mathrm{d}t_1+\sum_{n=2}^{\infty}\frac{1}{n}\int_0^t\cdots\int_0^t a_n(t_1,\ldots,t_n)[\ldots[H(t_1)\otimes 1+1\otimes H(t_1),\ H(t_2)\otimes 1+1\otimes H(t_2)],\ldots,H(t_n)\otimes 1+1\otimes H(t_n)]\mathrm{d}t_1\ldots\mathrm{d}t_n. \tag{B2}$$

The Lie product $[\cdot]$ is defined with respect to the free product $\odot$. By induction one can prove that

$$[\ldots[H(t_1)\otimes 1+1\otimes H(t_1),H(t_2)\otimes 1+1\otimes H(t_2)],\ldots,H(t_n)\otimes 1+1\otimes H(t_n)]=[\ldots[H(t_1),H(t_2)],\ldots,H(t_n)]\otimes 1+1\otimes[\ldots[H(t_1),H(t_2)],\ldots,H(t_n)].$$

Applying this property to (B2), one obtains

$$\begin{aligned}\Delta\alpha=&\int_0^t a_1(t_1)(H(t_1)\otimes 1+1\otimes H(t_1))\mathrm{d}t_1+\sum_{n=2}^{\infty}\frac{1}{n}\int_0^t\cdots\int_0^t a_n(t_1,\ldots,t_n)\\&\times([\ldots[H(t_1),H(t_2)],\ldots,H(t_n)]\otimes 1+1\otimes[\ldots[H(t_1),H(t_2)],\ldots,H(t_n)])\mathrm{d}t_1\ldots\mathrm{d}t_n\\=&\left(\int_0^t a_1(t_1)H(t_1)\mathrm{d}t_1+\sum_{n=2}^{\infty}\frac{1}{n}\int_0^t\cdots\int_0^t a_n(t_1,\ldots,t_n)[\ldots[H(t_1),H(t_2)],\ldots,H(t_n)]\mathrm{d}t_1\ldots\mathrm{d}t_n\right)\\&\otimes 1+1\otimes\left(\int_0^t a_1(t_1)H(t_1)\mathrm{d}t_1+\sum_{n=2}^{\infty}\frac{1}{n}\int_0^t\cdots\int_0^t a_n(t_1,\ldots,t_n)\right.\\&\left.\times\ [\ldots[H(t_1),H(t_2)],\ldots,H(t_n)]\mathrm{d}t_1\ldots\mathrm{d}t_n\right).\end{aligned}$$

Finally, using (20) it holds:

$$\begin{aligned}\Delta\alpha=&\left(\int_0^t a_1(t_1)H(t_1)\mathrm{d}t_1+\sum_{n=2}^{\infty}\int_0^t\cdots\int_0^t E_n(a_n(t_1,\ldots,t_n))H(t_1)\odot\ldots\odot H(t_n)\mathrm{d}t_1\ldots\mathrm{d}t_n\right)\\&\otimes 1+1\otimes\left(\int_0^t a_1(t_1)H(t_1)\mathrm{d}t_1+\sum_{n=2}^{\infty}\int_0^t\cdots\int_0^t E_n(a_n(t_1,\ldots,t_n))H(t_1)\odot\ldots\odot H(t_n)\mathrm{d}t_1\ldots\mathrm{d}t_n\right)\\=&\left(\sum_{n=1}^{\infty}\int_0^t\cdots\int_0^t a_n(t_1,\ldots,t_n)H(t_1)\odot\ldots\odot H(t_n)\mathrm{d}t_1\ldots\mathrm{d}t_n\right)\\&\otimes 1+1\otimes\sum_{n=1}^{\infty}\int_0^t\cdots\int_0^t a_n(t_1,\ldots,t_n)H(t_1)\odot\ldots\odot H(t_n)\mathrm{d}t_1\ldots\mathrm{d}t_n=\alpha\otimes 1+1\otimes\alpha.\end{aligned}$$

($\Leftarrow$)
Let $\alpha=\Phi(a)$, $a=\{a_n\}_{n=0}^{\infty}\in A(t)$, as usual. Calculating $\Delta\alpha$ we find that:

$$\Delta\alpha = a_0(1\otimes 1) + \sum_{n=1}^{\infty} \int_0^t \cdots \int_0^t a_n(t_1,\ldots,t_n) \prod_{m=1}^{n} \odot (H(t_m)\otimes 1 + 1\otimes H(t_m))\,\mathrm{d}t_1 \ldots \mathrm{d}t_n$$

$$= a_0(1\otimes 1) + \int_0^t a_1(t_1)(H(t_1)\otimes 1 + 1\otimes H(t_1))\,\mathrm{d}t_1$$

$$+ \sum_{n=2}^{\infty} \int_0^t \cdots \int_0^t a_n(t_1,\ldots,t_n) \Bigg(\Bigg(\prod_{m=1}^{n} \odot H(t_m) \Bigg) \otimes 1$$

$$+ \sum_{m=1}^{n-1} \sum_{\substack{S_j \subset J_n \\ \#S_j = m}} \Bigg(\Bigg(\prod_{p\in J_n\setminus S_j} \odot H(t_p) \Bigg) \otimes \Bigg(\prod_{q\in S_j} \odot H(t_q) \Bigg) \Bigg) + 1 \otimes \prod_{m=1}^{n} \odot H(t_m) \Bigg)$$

$$\times \mathrm{d}t_1 \ldots \mathrm{d}t_n,$$

where $J_n = \{1,\ldots,n\}$, S_j and $J_n \setminus S_j$ are ordered sets. Taking into account that $a_0(1\otimes 1) = a_0 \otimes 1 = 1 \otimes a_0$, integrating separately, and reordering it results

$$\Delta\alpha = \alpha\otimes 1 + 1\otimes\alpha - a_0(1\otimes 1) + \sum_{n=2}^{\infty} \int_0^t \cdots \int_0^t a_n(t_1,\ldots,t_n) \Bigg(\sum_{m=1}^{n-1} \sum_{\substack{S_j \subset J_n \\ \#S_j = m}} \Bigg(\Bigg(\prod_{p\in J_n\setminus S_j} \odot H(t_p) \Bigg)$$

$$\otimes \Bigg(\prod_{q\in S_j} \odot H(t_q) \Bigg) \Bigg) \Bigg) \mathrm{d}t_1 \ldots \mathrm{d}t_n.$$

By hypothesis, $\Delta\alpha = \alpha\otimes 1 + 1\otimes\alpha$. Then, we obtain

$$-a_0(1\otimes 1) + \sum_{n=2}^{\infty} \sum_{m=1}^{n-1} \int_0^t \cdots \int_0^t a_n(t_1,\ldots,t_n) \times \sum_{\substack{S_j \subset J_n \\ \#S_j = m}} \Bigg(\Bigg(\prod_{p\in J_n\setminus S_j} \odot H(t_p) \Bigg)$$

$$\otimes \Bigg(\prod_{q\in S_j} \odot H(t_q) \Bigg) \Bigg) \mathrm{d}t_1 \ldots \mathrm{d}t_n = 0. \tag{B3}$$

First, this implies that $a_0 = 0$. On the other hand, it can be noted that every multiple integral of the previous expression represents a homogeneous element of different degree (i, j) in $\overline{\mathcal{A}\otimes\mathcal{A}}$. Therefore the equality (B3) holds if and only if every multiple integral is null. Hence,

$$\int_0^t \cdots \int_0^t a_n(t_1,\ldots,t_n) \sum_{\substack{S_j \subset J_n \\ \#S_j = m}} \Bigg(\Bigg(\prod_{p\in J_n\setminus S_j} \odot H(t_p) \Bigg) \otimes \Bigg(\prod_{q\in S_j} \odot H(t_q) \Bigg) \Bigg) \mathrm{d}t_1 \ldots \mathrm{d}t_n = 0 \tag{B4}$$

for $n \geqslant 2$ and for m between 1 and $n-1$. We are interested now in the summation that is behind the integral sign. First, we have that for every S_j, $J_n \setminus S_j = \{i_1,\ldots,i_{n-m}\}$ and $S_j = \{i_{n-m+1},\ldots,i_n\}$; more precisely, $i_1 < \ldots < i_{n-m}$ and $i_{n-m+1} < \ldots < i_n$, are all of them different, and together are J_n. Hence, using permutations and, from Corollary 23 in Appendix A:

$$\sum_{\substack{S_j\subset J_n\\ \#S_j=m}}\left(\left(\prod_{p\in J_n S_j}\odot H(t_p)\right)\otimes\left(\prod_{q\in S_j}\odot H(t_q)\right)\right)$$

$$=\sum_{\substack{i_1<\ldots<i_{n-m}\\ i_{n-m+1}<\ldots<i_n}}\begin{pmatrix}1 & \ldots & n-m & n-m+1 & \ldots & n\\ i_1 & \ldots & i_{n-m} & i_{n-m+1} & \ldots & i_n\end{pmatrix}$$

$$\times\left(\left(\prod_{p=1}^{n-m}\odot H(t_p)\right)\otimes\left(\prod_{q=n-m+1}^{n}\odot H(t_q)\right)\right)$$

$$=\sum_{1\leqslant i_1<\ldots<i_{n-m}\leqslant n}C_{1,i_1}\ldots C_{1,i_{n-m}}C_{1,2}\ldots C_{1,n-m}\left(\left(\prod_{p=1}^{n-m}\odot H(t_p)\right)\otimes\left(\prod_{q=n-m+1}^{n}\odot H(t_q)\right)\right).$$

Substituting this in (B4) we obtain

$$\int_0^t\cdots\int_0^t a_n(t_1,\ldots,t_n)\sum_{1\leqslant i_1<\ldots<i_{n-m}\leqslant n}C_{1,i_1}\ldots C_{1,i_{n-m}}C_{1,2}\ldots C_{1,n-m}\left(\left(\prod_{p=1}^{n-m}\odot H(t_p)\right)\right.$$
$$\left.\otimes\left(\prod_{q=n-m+1}^{n}\odot H(t_q)\right)\right)\mathrm{d}t_1\ldots\mathrm{d}t_n=0.$$

Applying (20) to the previous integral, and ordering the indexes in the product of $H(t)$ we get:

$$\int_0^t\cdots\int_0^t\left(\sum_{n\geqslant i_{n-m}>\ldots>i_1\geqslant 1}C^{-1}_{1,n-m}\ldots C^{-1}_{1,2}C^{-1}_{1,i_{n-m}}\ldots C^{-1}_{1,i_1}(a_n(t_1,\ldots,t_n))\right)\left(\prod_{p=1}^{n-m}\odot H(t_p)\right)$$
$$\otimes\left(\prod_{q=n-m+1}^{n}\odot H(t_q)\right)\mathrm{d}t_1\ldots\mathrm{d}t_n=0.$$

Conveying that $\Pi_{k=2}^{1}C^{-1}_{1,1-k+2}=1$, another way to represent the previous equation is

$$\int_0^t\cdots\int_0^t\left(\prod_{k=2}^{n-m}C^{-1}_{1,n-m-k+2}\sum_{n\geqslant i_{n-m}>\ldots>i_1\geqslant 1}C^{-1}_{1,i_{n-m}}\ldots C^{-1}_{1,i_1}(a_n(t_1,\ldots,t_n))\right)\left(\prod_{p=1}^{n-m}\odot H(t_p)\right)$$
$$\otimes\left(\prod_{q=n-m+1}^{n}\odot H(t_q)\right)\mathrm{d}t_1\ldots\mathrm{d}t_n=0.$$

Denoting by

$$\rho_{n,m}=\sum_{n\geqslant i_{n-m}>\ldots>i_1\geqslant 1}C^{-1}_{1,i_{n-m}}\ldots C^{-1}_{1,i_1}$$

and

$$\sigma_{n,m}=\left(\prod_{k=2}^{n-m}C^{-1}_{1,n-m-k+2}\right)\rho_{n,m},$$

we arrive at the fact that the previous integral vanishes if any only if $\sigma_{n,m}(a_n)=0$. Since this must be satisfied for each integral, we obtain the following infinite system of equations:

$$\sigma_{n,m}(a_n)=0\quad\text{for } n\geqslant 2\ \text{ and }\ 1\leqslant m\leqslant n-1.$$

These equations are not independent among themselves. To reduce them, applying Corollary 25 it results that

$$\sigma_{n,i}=(C_{1,n}^{m})\sigma_{n,n-i}.$$

Therefore, the reduced system, denoting by $[[\cdot]]$ the "largest-integer-less-or-equal-than" function, is given by:

$$\sigma_{n,m}(a_n)=0, \text{ for } n\geqslant 2 \text{ and } m \text{ between } \left[\left[\frac{n+1}{2}\right]\right] \text{ and } n-1. \tag{B5}$$

From this it will infer that $E_n(a_n)=a_n$ for $n\geqslant 2$, or equivalently $(nE_n-n)a_n=0$ for $n\geqslant 2$.

Recall that

$$nE_n=\prod_{k=2}^{n}(1-C_{1,n-k+2}^{-1})=1+\sum_{i=2}^{n}(-1)^{i-1}\sum_{n\geqslant j_{i-1}>\ldots>j_1\geqslant 2}C_{1,j_{i-1}}^{-1}\ldots C_{1,j_1}^{-1}$$

or equivalently

$$nE-n=-(n-1)+\sum_{i=2}^{n}(-1)^{i-1}\sum_{n\geqslant j_{i-1}>\ldots>j_1\geqslant 2}C_{1,j_{i-1}}^{-1}\ldots C_{1,j_1}^{-1}.$$

For n odd it yields:

$$nE_n-n=\sum_{i=1}^{[[n/2]]}\left[(-1)^i(n-i)\prod_{k=2}^{i}C_{1,i-k+2}^{-1}+(-1)^{n-i}i\prod_{k=i+1}^{n}C_{1,n-k+i+1}^{-1}\right]\sigma_{n,n-1}.$$

The proof that $(nE_n-n)a_n=0$ for the odd case, considering the system of Eqs. (B5), is given in Lemma 26 in Appendix A.

For n even we have:

$$nE_n-n=\sum_{i=1}^{n/2-1}\left[(-1)^i(n-i)\prod_{k=2}^{i}C_{1,i-k+2}^{-1}+(-1)^{n-i}i\prod_{k=i+1}^{n}C_{1,n-k+i+1}^{-1}\right]\sigma_{n,n-1}$$
$$+(-1)^{n/2}\frac{n}{2}\left(\prod_{k=2}^{n/2}C_{1,n/2-k+2}^{-1}\right)\sigma_{n,n/2}.$$

The proof that $(nE_n-n)a_n=0$ for the even case is similar to the odd case, thus, it will be omitted. Hence we conclude $\alpha\in\Gamma(t)$, and the proof of Friedrichs' criterion is complete. ■

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 42, NUMBER 9 SEPTEMBER 2001

Discontinuities in Dirac eigenfunction expansions

Radosław Szmytkowski[a)]
Atomic Physics Division, Department of Atomic Physics and Luminescence, Faculty of Applied Physics and Mathematics, Technical University of Gdańsk, Narutowicza 11/12, PL 80–952 Gdańsk, Poland

(Received 9 March 2001; accepted for publication 22 May 2001)

An expansion, over a finite interval, of a two-component function in a basis of eigenfunctions of a one-dimensional regular Dirac differential operator with separated homogeneous boundary conditions imposed at ends of the interval is considered. It is shown that at the ends of the domain the expansion does not converge to the expanded function unless the latter obeys at these points the same homogeneous boundary conditions as the basis eigenfunctions. General results obtained in the work are illustrated by an analytically solvable example. The problem is related to the R-matrix theory for Dirac particles. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1389471]

I. INTRODUCTION

In theoretical physics one frequently encounters the situation that a given function, defined over some domain, is expanded in a functional basis. Among a variety of bases used in such expansions, those generated by differential eigenvalue problems are of major importance. Properties of expansions in series of eigenfunctions of differential operators were extensively investigated by generations of mathematicians and mathematical physicists and their results are contained in a vast literature of the subject (cf. Refs. 1–6 and references therein).

Expansions, over a finite interval, of a given two-component function in a basis of eigenfunctions of a one-dimensional regular Dirac differential operator with separated homogeneous boundary conditions were studied, for instance, in Refs. 5 and 6. However, in these monographs only a particular case, when at ends of an interval an expanded function obeys the same boundary conditions as basis eigenfunctions, was considered. One may imagine expansion problems in which at end points a two-component function to be expanded is admitted to satisfy boundary conditions that differ from those obeyed by basis eigenfunctions. Problems of that kind are not of purely academic interest and are met in applications of relativistic quantum mechanics (e.g., in the R-matrix theory for Dirac particles[7–9]). It is also very likely that they may be encountered in a mathematical modeling of one-dimensional magnetohydrodynamical phenomena where differential operators of the Dirac type occur.[10,11] We have not found any mathematical study of such problems in available literature and it is a purpose of this work to fill in this gap to some extent. We concentrate on the interesting and important question concerning convergence of an eigenfunction expansion at ends of a domain. We prove that at these points the expansion does not converge to the expanded function unless the latter obeys there the same homogeneous boundary conditions as the basis functions. (That result is by no means obvious since in an analogous problem concerning expansions of one-component functions in bases generated by second-order Sturm–Liouville eigensystems the expansions do converge at the end points except the very special case when basis eigenfunctions are forced to vanish at these points!) Still we show that magnitudes of jumps in both components of the expansion may be precisely determined and we provide relevant expressions. These general results are illustrated by an analytically solvable example.

II. THE PROBLEM

Consider the eigenproblem consisting of the Dirac differential system

$$\begin{pmatrix} p(x)-\lambda_n\rho(x) & -d/dx+t(x) \\ d/dx+t(x) & q(x)-\lambda_n\rho(x) \end{pmatrix}\begin{pmatrix} f_n(x) \\ g_n(x) \end{pmatrix}=0 \quad (x_1\leqslant x\leqslant x_2) \tag{2.1}$$

augmented by the separated boundary conditions

$$f_n(x_i)\cos\alpha_i+g_n(x_i)\sin\alpha_i=0 \quad (i=1,2). \tag{2.2}$$

It is assumed that the interval $[x_1,x_2]\subset\mathbb{R}$ is finite, that $p(x)$, $q(x)$, $t(x)$, and $\rho(x)$ are real, bounded and continuous functions of the variable $x\in[x_1,x_2]$, with the additional constraint $\rho(x)>0$, and that α_1 and α_2 are real parameters. Under these assumptions the eigensystem (2.1) and (2.2) has an infinite number of discrete nondegenerate real eigenvalues λ_n.[5,6] The associated eigenfunctions are orthogonal in the sense of

$$\int_{x_1}^{x_2}dx\rho(x)[f_n(x)f_{n'}(x)+g_n(x)g_{n'}(x)]=0 \quad (\lambda_n\neq\lambda_{n'}). \tag{2.3}$$

If they are chosen to be real and normalized so that

$$\int_{x_1}^{x_2}dx\rho(x)[f_n(x)f_{n'}(x)+g_n(x)g_{n'}(x)]=\delta_{nn'}, \tag{2.4}$$

they obey the closure relation

$$\sum_{n=-\infty}^{\infty}\begin{pmatrix} f_n(x) \\ g_n(x) \end{pmatrix}(f_n(x') \;\; g_n(x'))=\frac{\delta(x-x')}{\sqrt{\rho(x)\rho(x')}}\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \quad (x_1<x,x'<x_2), \tag{2.5}$$

where $\delta(x-x')$ is the Dirac delta function defined so that[12–14]

$$\int_a^b dx'\,\delta(x-x')\phi(x')=\begin{cases} 0 & \text{for } x<a<b \text{ or } a<b<x, \\ \phi(x) & \text{for } a<x<b, \\ \dfrac{1}{2}\phi(x) & \text{for } a=x<b \text{ or } a<x=b \end{cases} \tag{2.6}$$

for any interval $[a,b]\subset\mathbb{R}$ and any sufficiently regular function $\phi(x)$ defined on $[a,b]$.

Let $(F(x)\;G(x))^{\mathrm{T}}$ be an arbitrary two-component function with continuous components of bounded variation in $[x_1,x_2]$. Its expansion in the set of eigenfunctions of the problem (2.1) and (2.2) is defined as

$$\begin{pmatrix} \overline{F}(x) \\ \overline{G}(x) \end{pmatrix}=\sum_{n=-\infty}^{\infty}C_n\begin{pmatrix} f_n(x) \\ g_n(x) \end{pmatrix} \quad (x_1\leqslant x\leqslant x_2) \tag{2.7}$$

with the coefficients

$$C_n=\int_{x_1}^{x_2}dx\rho(x)[f_n(x)F(x)+g_n(x)G(x)]. \tag{2.8}$$

The closure relation (2.5) implies that

$$\begin{pmatrix} F(x) \\ G(x) \end{pmatrix} = \begin{pmatrix} \overline{F}(x) \\ \overline{G}(x) \end{pmatrix} \quad (x_1 < x < x_2). \tag{2.9}$$

The validity of Eqs. (2.5) and (2.9) is restricted to the *open* interval (x_1, x_2). Since both functions $(F(x) \quad G(x))^{\mathrm{T}}$ and $(\overline{F}(x) \quad \overline{G}(x))^{\mathrm{T}}$ are defined in the *closed* interval $[x_1, x_2]$, we ask the question: how are these functions related at the end points x_1 and x_2?

III. THE SOLUTION

To answer the question posed above, we have to consider an extension of the closure relation (2.5) to the case when one of the variables is fixed at x_i. In analogy with (2.5), we postulate

$$\sum_{n=-\infty}^{\infty} \begin{pmatrix} f_n(x_i) \\ g_n(x_i) \end{pmatrix} (f_n(x) \quad g_n(x)) = \frac{\delta(x-x_i)}{\rho(x_i)} \begin{pmatrix} I_i & J_i \\ K_i & L_i \end{pmatrix} \quad (x_1 \leqslant x \leqslant x_2), \tag{3.1}$$

where I_i, J_i, K_i, and L_i are yet unknown constants. Notice that, because of the boundary conditions (2.2), these constants are not independent but are related through

$$J_i = K_i = -I_i \cot \alpha_i, \quad L_i = I_i \cot^2 \alpha_i. \tag{3.2}$$

Hence, it follows that Eq. (3.1) may be rewritten in the form

$$\sum_{n=-\infty}^{\infty} \begin{pmatrix} f_n(x_i) \\ g_n(x_i) \end{pmatrix} (f_n(x) \quad g_n(x)) = \frac{I_i \delta(x-x_i)}{\rho(x_i)} \begin{pmatrix} 1 & -\cot \alpha_i \\ -\cot \alpha_i & \cot^2 \alpha_i \end{pmatrix} \quad (x_1 \leqslant x \leqslant x_2). \tag{3.3}$$

From Eqs. (2.7) and (2.8) we have

$$\begin{pmatrix} \overline{F}(x_i) \\ \overline{G}(x_i) \end{pmatrix} = \int_{x_1}^{x_2} dx \rho(x) \sum_{n=-\infty}^{\infty} \begin{pmatrix} f_n(x_i) \\ g_n(x_i) \end{pmatrix} (f_n(x) \quad g_n(x)) \begin{pmatrix} F(x) \\ G(x) \end{pmatrix}, \tag{3.4}$$

and, on substituting here Eq. (3.3) and performing integration, we obtain

$$\begin{pmatrix} \overline{F}(x_i) \\ \overline{G}(x_i) \end{pmatrix} = \begin{pmatrix} \frac{1}{2} I_i F(x_i) - \frac{1}{2} I_i G(x_i) \cot \alpha_i \\ \frac{1}{2} I_i G(x_i) \cot^2 \alpha_i - \frac{1}{2} I_i F(x_i) \cot \alpha_i \end{pmatrix}. \tag{3.5}$$

Equation (3.5) implies

$$\overline{F}(x_i) \cos \alpha_i + \overline{G}(x_i) \sin \alpha_i = 0, \tag{3.6}$$

which might be also inferred from Eqs. (2.7) and (2.2).

To answer completely the question raised at the end of Sec. II, we have to determine the constants I_1 and I_2. To this end, let us choose

$$\begin{pmatrix} F(x) \\ G(x) \end{pmatrix} = \begin{pmatrix} f_k(x) \\ g_k(x) \end{pmatrix} \quad (x_1 \leqslant x \leqslant x_2), \tag{3.7}$$

where the function on the right is an eigenfunction of the system (2.1) and (2.2). Because of the orthonormality relation (2.4), in this particular case from Eq. (2.8) we infer

$$C_n = \delta_{nk} \tag{3.8}$$

and thus

$$\begin{pmatrix} \overline{F}(x) \\ \overline{G}(x) \end{pmatrix} = \begin{pmatrix} f_k(x) \\ g_k(x) \end{pmatrix} \quad (x_1 \leqslant x \leqslant x_2). \tag{3.9}$$

Utilizing Eqs. (3.7) and (3.9) in Eq. (3.5), we arrive at the homogeneous algebraic system

$$\begin{pmatrix} \frac{1}{2}I_i - 1 & -\frac{1}{2}I_i \cot\alpha_i \\ -\frac{1}{2}I_i \cot\alpha_i & \frac{1}{2}I_i \cot^2\alpha_i - 1 \end{pmatrix} \begin{pmatrix} f_k(x_i) \\ g_k(x_i) \end{pmatrix} = 0. \tag{3.10}$$

Since $f_k(x_i)$ and $g_k(x_i)$ do not vanish simultaneously, one has

$$\det \begin{pmatrix} \frac{1}{2}I_i - 1 & -\frac{1}{2}I_i \cot\alpha_i \\ -\frac{1}{2}I_i \cot\alpha_i & \frac{1}{2}I_i \cot^2\alpha_i - 1 \end{pmatrix} = 0, \tag{3.11}$$

hence, it follows that

$$I_i = 2\sin^2\alpha_i . \tag{3.12}$$

In Appendix A we present an alternative derivation of that result.

Having determined the constants I_i, from Eqs. (3.3), (3.5), and (3.12) we deduce

$$\sum_{n=-\infty}^{\infty} \begin{pmatrix} f_n(x_i) \\ g_n(x_i) \end{pmatrix} (f_n(x) \quad g_n(x)) = \frac{\delta(x-x_i)}{\rho(x_i)} \begin{pmatrix} 2\sin^2\alpha_i & -\sin 2\alpha_i \\ -\sin 2\alpha_i & 2\cos^2\alpha_i \end{pmatrix} \quad (x_1 \leqslant x \leqslant x_2) \tag{3.13}$$

and

$$\begin{pmatrix} \overline{F}(x_i) \\ \overline{G}(x_i) \end{pmatrix} = \begin{pmatrix} F(x_i)\sin^2\alpha_i - \frac{1}{2}G(x_i)\sin 2\alpha_i \\ G(x_i)\cos^2\alpha_i - \frac{1}{2}F(x_i)\sin 2\alpha_i \end{pmatrix}. \tag{3.14}$$

These two equations constitute the main result of this article.

If Eq. (3.14) is rewritten in the form

$$\begin{pmatrix} \overline{F}(x_i) \\ \overline{G}(x_i) \end{pmatrix} = \begin{pmatrix} F(x_i) - [F(x_i)\cos\alpha_i + G(x_i)\sin\alpha_i]\cos\alpha_i \\ G(x_i) - [F(x_i)\cos\alpha_i + G(x_i)\sin\alpha_i]\sin\alpha_i \end{pmatrix}, \tag{3.15}$$

it is immediately seen that, since the sine and the cosine never vanish simultaneously, at the end point $x = x_i$ one has

$$\begin{pmatrix} \overline{F}(x_i) \\ \overline{G}(x_i) \end{pmatrix} = \begin{pmatrix} F(x_i) \\ G(x_i) \end{pmatrix} \tag{3.16}$$

if and only if

$$F(x_i)\cos\alpha_i + G(x_i)\sin\alpha_i = 0, \tag{3.17}$$

i.e., if and only if the function to be expanded obeys at $x = x_i$ the same homogeneous boundary condition as the basis eigenfunctions. If the boundary condition (3.17) is not satisfied, Eqs. (2.9) and (3.15) imply that at $x = x_i$ the eigenfunction expansion (2.7) has a discontinuity

$$\lim_{x \to x_i} \begin{pmatrix} \overline{F}(x) \\ \overline{G}(x) \end{pmatrix} - \begin{pmatrix} \overline{F}(x_i) \\ \overline{G}(x_i) \end{pmatrix} = \begin{pmatrix} F(x_i)\cos^2\alpha_i + \frac{1}{2}G(x_i)\sin 2\alpha_i \\ \frac{1}{2}F(x_i)\sin 2\alpha_i + G(x_i)\sin^2\alpha_i \end{pmatrix}. \tag{3.18}$$

This fact was not realized in early formulations of the R-matrix theory for Dirac particles[7,8] which resulted in errors corrected by Szmytkowski and Hinze.[15,16]

It should be emphasized that the previous results are specific for bases generated by Dirac differential eigenproblems; the reader is asked to consult Appendix B on the analogous problem for second-order Sturm–Liouville eigensystems.

It is interesting to consider Eqs. (3.13) and (3.14) in two particular cases. The first case is

$$\cos\alpha_i=0\Rightarrow\sin\alpha_i=\pm 1. \tag{3.19}$$

Then Eqs. (3.13) and (3.14) become, respectively,

$$\sum_{n=-\infty}^{\infty}\begin{pmatrix} f_n(x_i)\\ g_n(x_i)\end{pmatrix}(f_n(x)\quad g_n(x))=\frac{\delta(x-x_i)}{\rho(x_i)}\begin{pmatrix}2&0\\0&0\end{pmatrix}\quad (x_1\leqslant x\leqslant x_2), \tag{3.20}$$

$$\begin{pmatrix}\overline{F}(x_i)\\ \overline{G}(x_i)\end{pmatrix}=\begin{pmatrix}F(x_i)\\0\end{pmatrix}. \tag{3.21}$$

It is seen that in this case the expansion converges at $x=x_i$ in the upper component but fails to converge in the lower one unless $G(x_i)=0$. The second case to be considered is

$$\sin\alpha_i=0\Rightarrow\cos\alpha_i=\pm 1. \tag{3.22}$$

Then

$$\sum_{n=-\infty}^{\infty}\begin{pmatrix} f_n(x_i)\\ g_n(x_i)\end{pmatrix}(f_n(x)\quad g_n(x))=\frac{\delta(x-x_i)}{\rho(x_i)}\begin{pmatrix}0&0\\0&2\end{pmatrix}\quad (x_1\leqslant x\leqslant x_2) \tag{3.23}$$

and

$$\begin{pmatrix}\overline{F}(x_i)\\ \overline{G}(x_i)\end{pmatrix}=\begin{pmatrix}0\\G(x_i)\end{pmatrix}, \tag{3.24}$$

i.e., at $x=x_i$ the expansion converges in the lower component but fails to converge in the upper one unless $F(x_i)=0$.

IV. AN ILLUSTRATIVE EXAMPLE

As an example illustrating the general results obtained earlier, in this section we discuss the particular case when the Dirac eigenvalue problem (2.1) and (2.2) is

$$\begin{pmatrix}-\lambda_n & -d/dx\\ d/dx & -\lambda_n\end{pmatrix}\begin{pmatrix}f_n(x)\\ g_n(x)\end{pmatrix}=0\quad (0\leqslant x\leqslant b), \tag{4.1}$$

$$f_n(0)=0,\quad f_n(b)\cos\beta+g_n(b)\sin\beta=0. \tag{4.2}$$

Comparing Eqs. (4.1) and (4.2) with (2.1) and (2.2), one identifies

$$\rho(x)\equiv 1,\quad x_1=0,\quad x_2=b,\quad \alpha_1=0,\quad \alpha_2=\beta. \tag{4.3}$$

Solving the system (4.1) and (4.2), one finds that its eigenvalues are

$$\lambda_n=\frac{\pi n-\beta}{b},\quad n=0,\pm 1,\pm 2,\ldots, \tag{4.4}$$

while corresponding eigenfunctions, normalized according to

$$\int_0^b dx[f_n(x)f_{n'}(x)+g_n(x)g_{n'}(x)]=\delta_{nn'}, \tag{4.5}$$

are

$$\begin{pmatrix} f_n(x) \\ g_n(x) \end{pmatrix}=\frac{1}{\sqrt{b}}\begin{pmatrix} \sin\lambda_n x \\ \cos\lambda_n x \end{pmatrix} \quad (0\leqslant x\leqslant b). \tag{4.6}$$

A. The closure relation and its extension

To verify that eigensolutions to the system (4.1) and (4.2) do obey Eqs. (2.5) and (3.13), we should investigate the series

$$\sum_{n=-\infty}^{\infty}\begin{pmatrix} f_n(x) \\ g_n(x) \end{pmatrix}(f_n(x') \quad g_n(x'))=\begin{pmatrix} I(x,x') & J(x,x') \\ K(x,x') & L(x,x') \end{pmatrix} \tag{4.7}$$

in the domain $0\leqslant x,x'\leqslant b$. We begin with considering the series

$$I(x,x')=\sum_{n=-\infty}^{\infty} f_n(x)f_n(x') \tag{4.8}$$

in the extended domain $-\infty<x,x'<\infty$. To sum it, we construct a sequence of finite sums

$$I_N(x,x')=\sum_{n=-N}^{N} f_n(x)f_n(x')=\frac{1}{b}\sum_{n=-N}^{N}\sin[(\pi n-\beta)x/b]\sin[(\pi n-\beta)x'/b]. \tag{4.9}$$

Obviously, one has

$$I(x,x')=\lim_{N\to\infty} I_N(x,x'). \tag{4.10}$$

The sum in Eq. (4.9) is easily found to be

$$\begin{aligned} I_N(x,x')=&\frac{\sin[\pi(2N+1)(x-x')/2b]}{2b\sin[\pi(x-x')/2b]}\cos[\beta(x-x')/b] \\ &-\frac{\sin[\pi(2N+1)(x+x')/2b]}{2b\sin[\pi(x+x')/2b]}\cos[\beta(x+x')/b]. \end{aligned} \tag{4.11}$$

With the aid of the formula

$$\lim_{N\to\infty}\frac{\sin(2N+1)\pi x}{\sin\pi x}=\sum_{n=-\infty}^{\infty}\delta(x-n) \quad (N\in\mathbb{N}), \tag{4.12}$$

which is well known in the theory of Fourier series,[17] from Eqs. (4.10) and (4.11) we infer

$$I(x,x')=\sum_{n=-\infty}^{\infty}[\delta(x-x'-2nb)-\delta(x+x'-2nb)]\cos 2n\beta. \tag{4.13}$$

Let us now restrict to the case when $0<x,x'<b$. Then

$$-b<x-x'<b, \quad 0<x+x'<2b. \tag{4.14}$$

It is evident that under the constraints (4.14) the argument of the first delta in the summand in Eq. (4.13) may vanish if and only if $n=0$, while the argument of the second delta never vanishes. Consequently, in this case all but one term on the right side of Eq. (4.13) are effectively zero and the latter equation reduces to

$$I(x,x')=\delta(x-x') \quad (0<x,x'<b), \tag{4.15}$$

in agreement with the result that may be inferred from Eqs. (2.5) and (4.3).

Next we concentrate on the case $0\leqslant x\leqslant b$ and $x'=0$. This case is the simplest one since then Eq. (4.13) becomes

$$I(x,0)=\sum_{n=-\infty}^{\infty}[\delta(x-2nb)-\delta(x-2nb)]\cos 2n\beta=0 \quad (0\leqslant x\leqslant b), \tag{4.16}$$

which agrees with the result that may be obtained from Eqs. (4.3) and (3.13).

Finally, we consider the most interesting case $x'=b$. Then

$$\begin{aligned} I(x,b)&=\sum_{n=-\infty}^{\infty}[\delta(x-(2n+1)b)-\delta(x-(2n-1)b)]\cos 2n\beta \\ &=2\sin\beta\sum_{n=-\infty}^{\infty}\delta(x-(2n+1)b)\sin[(2n+1)\beta] \quad (-\infty<x<\infty). \end{aligned} \tag{4.17}$$

If $0\leqslant x\leqslant b$, the argument of the delta may vanish if and only if $n=0$; the remaining terms in the series are effectively zero and Eq. (4.17) reduces to

$$I(x,b)=2\sin^2\beta\,\delta(x-b) \quad (0\leqslant x\leqslant b), \tag{4.18}$$

which again agrees with the result that may be deduced from Eqs. (4.3) and (3.13).

The reader will find no difficulty in verifying that in the domain $0\leqslant x,x'\leqslant b$ the remaining three matrix elements on the right side of Eq. (4.7) are identical with those deduced from Eqs. (2.5), (4.3), and (3.13).

B. The expansion problem

Consider now the expansion of the two-component function

$$\begin{pmatrix} F(x) \\ G(x) \end{pmatrix}=\frac{1}{\sqrt{b}}\begin{pmatrix} \sin\lambda x \\ \cos\lambda x \end{pmatrix} \quad (0\leqslant x\leqslant b), \tag{4.19}$$

where λ is a real parameter, in the basis (4.6). The expansion is

$$\begin{pmatrix} \overline{F}(x) \\ \overline{G}(x) \end{pmatrix}=\sum_{n=-\infty}^{\infty}\frac{C_n}{\sqrt{b}}\begin{pmatrix} \sin\lambda_n x \\ \cos\lambda_n x \end{pmatrix} \quad (0\leqslant x\leqslant b) \tag{4.20}$$

with the expansion coefficients given by

$$C_n=\frac{1}{b}\int_0^b dx[\sin\lambda_n x\sin\lambda x+\cos\lambda_n x\cos\lambda x]=\frac{\sin(\lambda_n-\lambda)b}{(\lambda_n-\lambda)b}. \tag{4.21}$$

On utilizing the relationship

$$\sin(\lambda_n-\lambda)b=\frac{\sin(\lambda b+\beta)\sin\lambda_n b}{\sin\beta}, \tag{4.22}$$

which stems from elementary trigonometry and from the boundary condition (4.2), the expansion (4.20) becomes

$$\begin{pmatrix} \overline{F}(x) \\ \overline{G}(x) \end{pmatrix} = \frac{\sin(\lambda b+\beta)}{\sqrt{b}\sin\beta} \sum_{n=-\infty}^{\infty} \frac{\sin\lambda_n b}{(\lambda_n-\lambda)b} \begin{pmatrix} \sin\lambda_n x \\ \cos\lambda_n x \end{pmatrix} \quad (0\leqslant x\leqslant b). \tag{4.23}$$

Below we shall attempt to sum the series on the right side of Eq. (4.23) at the end points $x=0$ and $x=b$.

Let us begin with the end point $x=0$. Then the expansion (4.23) becomes

$$\begin{pmatrix} \overline{F}(0) \\ \overline{G}(0) \end{pmatrix} = \frac{\sin(\lambda b+\beta)}{\sqrt{b}\sin\beta} \sum_{n=-\infty}^{\infty} \frac{\sin\lambda_n b}{(\lambda_n-\lambda)b} \begin{pmatrix} 0 \\ 1 \end{pmatrix}. \tag{4.24}$$

It is obvious that $\overline{F}(0)=0$ while evaluation of $\overline{G}(0)$ requires summation of the series

$$S_1 = \sum_{n=-\infty}^{\infty} \frac{\sin\lambda_n b}{(\lambda_n-\lambda)b}. \tag{4.25}$$

To perform the summation, we rewrite S_1 as follows:

$$S_1 = \sum_{n=-\infty}^{\infty} \frac{(-)^{n+1}\sin\beta}{\pi n-(\lambda b+\beta)} = \sin\beta\left[\frac{1}{\lambda b+\beta} + \sum_{n=1}^{\infty}(-)^n \frac{2(\lambda b+\beta)}{(\lambda b+\beta)^2-(\pi n)^2}\right]. \tag{4.26}$$

On making use of the known[18] partial fraction expansion of $1/\sin z$,

$$\frac{1}{\sin z} = \frac{1}{z} + \sum_{n=1}^{\infty}(-)^n \frac{2z}{z^2-(\pi n)^2}, \tag{4.27}$$

we obtain

$$S_1 = \frac{\sin\beta}{\sin(\lambda b+\beta)}, \tag{4.28}$$

hence, it follows that

$$\begin{pmatrix} \overline{F}(0) \\ \overline{G}(0) \end{pmatrix} = \frac{1}{\sqrt{b}} \begin{pmatrix} 0 \\ 1 \end{pmatrix}. \tag{4.29}$$

The same result may be inferred from Eqs. (3.14), (4.3), and (4.19).

Next we turn to the case of the end point $x=b$. Then the object of our interest is the series

$$\begin{pmatrix} \overline{F}(b) \\ \overline{G}(b) \end{pmatrix} = \frac{\sin(\lambda b+\beta)}{\sqrt{b}\sin\beta} \sum_{n=-\infty}^{\infty} \frac{\sin\lambda_n b}{(\lambda_n-\lambda)b} \begin{pmatrix} \sin\lambda_n b \\ \cos\lambda_n b \end{pmatrix}. \tag{4.30}$$

To sum it, we have to consider the series

$$S_2 = \sum_{n=-\infty}^{\infty} \frac{\sin^2\lambda_n b}{(\lambda_n-\lambda)b}, \tag{4.31}$$

$$S_3 = \sum_{n=-\infty}^{\infty} \frac{\sin\lambda_n b\cos\lambda_n b}{(\lambda_n-\lambda)b}. \tag{4.32}$$

Of these, only S_2 has to be investigated since, because of Eqs. (4.2) and (4.6), we have

$$S_3 = -S_2 \cot\beta. \tag{4.33}$$

To deal with the series S_2, we rewrite it in the following way:

$$S_2 = \sum_{n=-\infty}^{\infty} \frac{\sin^2\beta}{\pi n - (\lambda b + \beta)} = -\sin^2\beta \left[\frac{1}{\lambda b + \beta} + \sum_{n=1}^{\infty} \frac{2(\lambda b + \beta)}{(\lambda b + \beta)^2 - (\pi n)^2} \right]. \tag{4.34}$$

Hence, because of the known[18] partial fraction expansion of $\cot z$,

$$\cot z = \frac{1}{z} + \sum_{n=1}^{\infty} \frac{2z}{z^2 - (\pi n)^2}, \tag{4.35}$$

we find

$$S_2 = -\sin^2\beta \cot(\lambda b + \beta). \tag{4.36}$$

Consequently, Eq. (4.30) becomes

$$\begin{pmatrix} \overline{F}(b) \\ \overline{G}(b) \end{pmatrix} = \frac{1}{\sqrt{b}} \begin{pmatrix} -\sin\beta \cos(\lambda b + \beta) \\ \cos\beta \cos(\lambda b + \beta) \end{pmatrix}. \tag{4.37}$$

The same result may be inferred from Eqs. (3.14), (4.3), and (4.19).

ACKNOWLEDGMENTS

I am grateful to Professor J. Hinze for valuable discussions and to Dr. D. Andrae and M. Gruchowski for commenting on the manuscript. The work was sponsored in part by the Polish State Committee for Scientific Research under Grant No. 228/P03/99/17 and by the Deutscher Akademischer Austauschdienst through the NATO Science Fellowship. Support rendered by the Alexander von Humboldt Foundation is also gratefully acknowledged.

APPENDIX A: AN ALTERNATIVE DERIVATION OF EQ. (3.12)

Consider an auxiliary inhomogeneous boundary value problem

$$\begin{pmatrix} p(x) - \lambda\rho(x) & -d/dx + t(x) \\ d/dx + t(x) & q(x) - \lambda\rho(x) \end{pmatrix} \begin{pmatrix} f(x) \\ g(x) \end{pmatrix} = 0 \quad (x_1 \leqslant x \leqslant x_2), \tag{A1}$$

$$f(x_i)\cos\alpha_i + g(x_i)\sin\alpha_i = A_i \quad (i = 1,2), \tag{A2}$$

where the functions $p(x)$, $q(x)$, $t(x)$ and $\rho(x)$ are the same that appear in Eq. (2.1), $\lambda \in \mathbb{R}$, $\lambda \neq \lambda_n$, $A_i \in \mathbb{R}$, and $A_1^2 + A_2^2 \neq 0$. We construct the series

$$\begin{pmatrix} \overline{f}(x) \\ \overline{g}(x) \end{pmatrix} = \sum_{n=-\infty}^{\infty} c_n \begin{pmatrix} f_n(x) \\ g_n(x) \end{pmatrix} \quad (x_1 \leqslant x \leqslant x_2) \tag{A3}$$

with the coefficients defined by

$$c_n = \int_{x_1}^{x_2} dx \rho(x) [f_n(x) f(x) + g_n(x) g(x)]. \tag{A4}$$

It is obvious that, because of regularity of $(f(x) \quad g(x))^{\mathrm{T}}$ [implied by Eq. (A1)], one has

$$\begin{pmatrix} \overline{f}(x) \\ \overline{g}(x) \end{pmatrix} = \begin{pmatrix} f(x) \\ g(x) \end{pmatrix} \quad (x_1 < x < x_2) \tag{A5}$$

[cf. Eq. (2.9)] but, because of Eq. (2.2) and the definition (A3),

$$\overline{f}(x_i)\cos\alpha_i + \overline{g}(x_i)\sin\alpha_i = 0. \tag{A6}$$

To find a convenient expression for the coefficients (A4), we premultiply Eq. (2.1) by $(f(x) \quad g(x))^{\mathrm{T}}$, Eq. (A1) by $(f_n(x) \quad g_n(x))^{\mathrm{T}}$, subtract and integrate the result over the interval $[x_1, x_2]$. This yields

$$(\lambda_n - \lambda)\int_{x_1}^{x_2} dx\,\rho(x)[f_n(x)f(x) + g_n(x)g(x)] = [f_n(x)g(x) - f(x)g_n(x)]\Big|_{x_1}^{x_2}, \tag{A7}$$

hence, on making use of the boundary conditions (2.2) and (A2) and the definition (A4), it follows

$$c_n = \frac{A_2 f_n(x_2)}{(\lambda_n - \lambda)\sin\alpha_2} - \frac{A_1 f_n(x_1)}{(\lambda_n - \lambda)\sin\alpha_1}. \tag{A8}$$

Next, let us operate from the left on both sides of Eq. (A9) with the differential operator appearing in Eq. (A1). Because of Eq. (2.1), this gives

$$\begin{pmatrix} p(x) - \lambda\rho(x) & -d/dx + t(x) \\ d/dx + t(x) & q(x) - \lambda\rho(x) \end{pmatrix} \begin{pmatrix} \overline{f}(x) \\ \overline{g}(x) \end{pmatrix} = \rho(x) \sum_{n=-\infty}^{\infty} c_n(\lambda_n - \lambda) \begin{pmatrix} f_n(x) \\ g_n(x) \end{pmatrix} \quad (x_1 \leqslant x \leqslant x_2) \tag{A9}$$

or, after utilizing the result (A8),

$$\left[\frac{d}{dx} + t(x)\right]\overline{f}(x) + [q(x) - \lambda\rho(x)]\overline{g}(x) = \frac{A_2}{\sin\alpha_2}\rho(x)\sum_{n=-\infty}^{\infty} f_n(x_2)g_n(x) - \frac{A_1}{\sin\alpha_1}\rho(x)\sum_{n=-\infty}^{\infty} f_n(x_1)g_n(x) \quad (x_1 \leqslant x \leqslant x_2) \tag{A10}$$

and

$$\left[-\frac{d}{dx} + t(x)\right]\overline{g}(x) + [p(x) - \lambda\rho(x)]\overline{f}(x) = \frac{A_2}{\sin\alpha_2}\rho(x)\sum_{n=-\infty}^{\infty} f_n(x_2)f_n(x) - \frac{A_1}{\sin\alpha_1}\rho(x)\sum_{n=-\infty}^{\infty} f_n(x_1)f_n(x) \quad (x_1 \leqslant x \leqslant x_2). \tag{A11}$$

Right sides of Eqs. (A10) and (A11) may be transformed if one makes use of Eq. (3.3). This results in

$$\left[\frac{d}{dx} + t(x)\right]\overline{f}(x) + [q(x) - \lambda\rho(x)]\overline{g}(x) = -\frac{A_2 I_2 \cot\alpha_2}{\sin\alpha_2}\delta(x - x_2) + \frac{A_1 I_1 \cot\alpha_1}{\sin\alpha_1}\delta(x - x_1) \quad (x_1 \leqslant x \leqslant x_2), \tag{A12}$$

$$\left[-\frac{d}{dx}+t(x)\right]\overline{g}(x)+[p(x)-\lambda\rho(x)]\overline{f}(x)=\frac{A_2I_2}{\sin\alpha_2}\delta(x-x_2)-\frac{A_1I_1}{\sin\alpha_1}\delta(x-x_1)$$
$$(x_1\leqslant x\leqslant x_2). \tag{A13}$$

In the following step, we integrate Eqs. (A12) and (A13) either from x_1 to $x<x_2$, passing then to the limit $x\downarrow x_1$, or from $x>x_1$ to x_2, passing then to the limit $x\uparrow x_2$. The results may be compactly written as

$$f(x_i)-\overline{f}(x_i)=\frac{A_iI_i\cot\alpha_i}{2\sin\alpha_i}, \tag{A14}$$

$$g(x_i)-\overline{g}(x_i)=\frac{A_iI_i}{2\sin\alpha_i}. \tag{A15}$$

After supplementing Eqs. (A14) and (A15) by the boundary condition (A6), we obtain a set of three linear algebraic equations for three unknowns I_i, $\overline{f}(x_i)$ and $\overline{g}(x_i)$. Solving this set for I_i, one obtains

$$I_i=2\sin^2\alpha_i, \tag{A16}$$

which coincides with Eq. (3.12).

APPENDIX B: EXPANSIONS IN EIGENFUNCTIONS OF SECOND-ORDER STURM–LIOUVILLE SYSTEMS

Consider the second-order Sturm–Liouville eigensystem

$$\frac{d}{dx}\left(p(x)\frac{df_n(x)}{dx}\right)+q(x)f_n(x)-\lambda_n\rho(x)f_n(x)=0 \quad (x_1\leqslant x\leqslant x_2), \tag{B1}$$

$$f_n(x_i)\cos\alpha_i+p(x_i)f_n'(x_i)\sin\alpha_i=0 \quad (i=1,2) \tag{B2}$$

on the finite interval $[x_1,x_2]\subset\mathbb{R}$. Here $p(x)$, $q(x)$, and $\rho(x)$ are real, bounded and continuous functions of the variable $x\in[x_1,x_2]$, with the additional constraints $\rho(x)>0$, $p(x)\in C^1([x_1,x_2])$, and $p(x)\neq 0$, while α_1 and α_2 are real constants. Provided the eigenfunctions to the system (B1) and (B2) have been normalized according to

$$\int_{x_1}^{x_2}dx\rho(x)f_n(x)f_{n'}(x)=\delta_{nn'}, \tag{B3}$$

it holds

$$\sum_{n=0}^{\infty}f_n(x)f_n(x')=\frac{\delta(x-x')}{\sqrt{\rho(x)\rho(x')}} \quad (x_1<x,x'<x_2) \tag{B4}$$

and

$$\sum_{n=0}^{\infty}f_n(x_i)f_n(x)=\frac{I_i\delta(x-x_i)}{\rho(x_i)} \quad (x_1\leqslant x\leqslant x_2), \tag{B5}$$

where

$$I_i=\begin{cases}2 & \text{for } \sin\alpha_i\neq 0\\ 0 & \text{for } \sin\alpha_i=0.\end{cases} \tag{B6}$$

Equations (B5) and (B6) may be obtained in a way similar to that in which Eq. (3.13) has been derived.

Let $F(x)$ be any continuous function of bounded variation in $[x_1,x_2]$. Then, it follows from Eqs. (B4)–(B6) that its eigenfunction expansion, defined as

$$\overline{F}(x)=\sum_{n=0}^{\infty} f_n(x)\int_{x_1}^{x_2} dx'\rho(x')f_n(x')F(x') \quad (x_1\leqslant x\leqslant x_2), \tag{B7}$$

has the following properties:

$$\overline{F}(x)=F(x) \quad (x_1<x<x_2), \tag{B8}$$

$$\overline{F}(x_i)=\begin{cases}F(x_i) & \text{for } \sin\alpha_i\neq 0,\\ 0 & \text{for } \sin\alpha_i=0.\end{cases} \tag{B9}$$

[12] In some cases it is convenient to define the Dirac delta function in the following way (Ref. 13):
$$\int_a^b dx'\,\delta(x-x')\phi(x')=\begin{cases}0 & \text{for } x<a<b \text{ or } a<b<x\\ \phi(x) & \text{for } a\leqslant x\leqslant b\end{cases},$$
for any interval $[a,b]\subset\mathbb{R}$ and any function $\phi(x)$ that is sufficiently regular in $[a,b]$. This definition, which differs from the one used in the present work, is usually adopted in the R-matrix theory when a Bloch operator is employed (Ref. 14). Either definition of the delta is correct as long as it is used consistently.

Comment on "Exact constructions of square-root Helmholtz operator symbols: The focusing quadratic profile" [J. Math. Phys. 41, 4881 (2000)]

(Received 4 April 2001; accepted for publication 11 May 2001)

 [DOI: 10.1063/1.1388032]

In a recent article, Fishman *et al.*[1] gave the exact, standard and Weyl symbol constructions for both the inverse square root and the square-root Helmholtz operators for a position-dependent refractive index field of the form

$$K^2(z)=K_0^2-\omega^2 z^2, \tag{1}$$

where $K(\cdot)$ denotes the refractive index field, K_0, ω are positive constants, and the z axis is perpendicular to the propagation direction, which is along the x axis. The form of K given in Eq. (1) is known as the focusing quadratic profile.[1]

In Ref. 1, an extensive, in-depth analytical study is carried out and numerical results are presented in the form of two-dimensional graphs illustrating cross sections of the real and imaginary parts of the operator symbol surfaces over the pq plane. Unfortunately, a subsequent reexamination of the numerical results given in Ref. 1 has revealed that the computer program used to generate the first five of the six figures corresponding to the standard operator symbol (Ref. 1, Figs. 7–11), $h^s_{\mathbf{B}}(p,q)$, contained erroneous code.[2] Of the five figures in question, however, it is only in the first three (Ref. 1, Figs. 7–9) that the effects of the flawed computer code are immediately apparent. [As we will see, the last two of these five figures (Ref. 1, Figs. 10 and 11) appear to be virtually identical to their correct counterparts.]

The purpose of the present communication is to point out these erroneous figures and to give their corrected versions for the record. To this end, we return to Ref. 1, Eq. (III.40) and evaluate the contour integral appearing in that expression along the path $\mathcal{L}=\mathcal{C}''=\Gamma_1''+\Gamma_2''+\Gamma_3''$ in the complex τ plane in the indicated direction (see Ref. 1, Fig. 6). After simplifying, we find that the standard operator symbol corresponding to Eq. (1) is

$$h^s_{\mathbf{B}}(p,q)=h^s_{\mathbf{B},1}(p,q)+h^s_{\mathbf{B},2}(p,q)+h^s_{\mathbf{B},3}(p,q) \quad (Y\neq 0,1,2,3,\ldots), \tag{2}$$

where $\tau=x+\mathrm{i}y$, $Y=K_0^2(\bar{k}/\omega)$, p is the Fourier parameter, q replaces z as the transverse coordinate, and

$$h^s_{\mathbf{B},1}(p,q)=-\mathrm{i}(\omega/(\bar{k}\pi))^{1/2}\int_0^{1/Y}\mathrm{d}x\,\exp[Yx-(\chi/2)\tanh[2x]+\mathrm{i}Z(\operatorname{sech}[2x]-1)]\sqrt{\operatorname{sech}[2x]}$$
$$\times\{Y-\chi\operatorname{sech}^2[2x]-2\mathrm{i}Z\operatorname{sech}[2x]\tanh[2x]-\tanh[2x]\}\,x^{-1/2}, \tag{3}$$

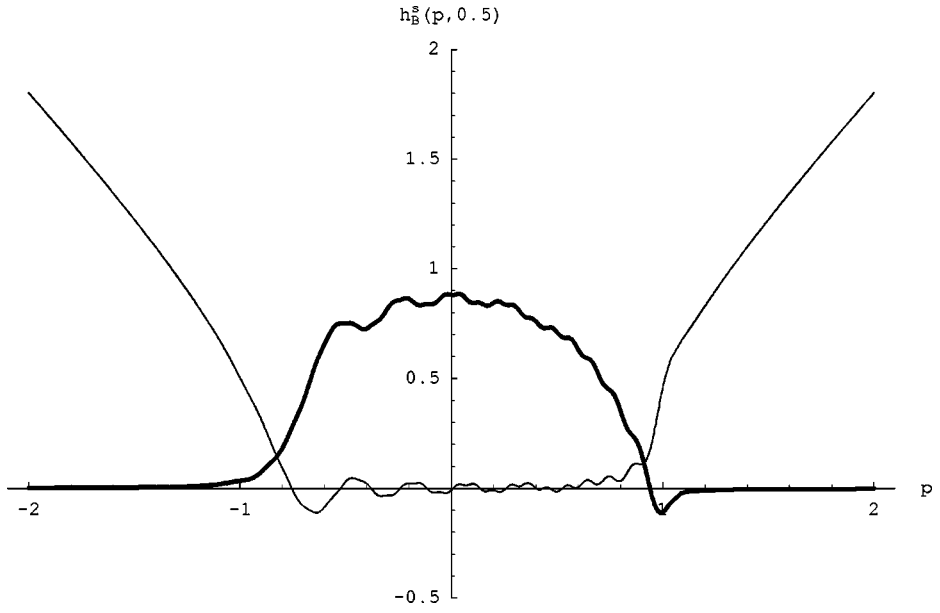

FIG. 1. (corrected form of Ref. 1, Fig. 7). $h^s_{\mathbf{B}}(p,q)$ vs p for $K^2(q)=K_0^2-\omega^2q^2$ with $K_0=\omega=1$, $q=0.5$, and $\overline{k}=50.5$. Bold line: Re$[h^s_{\mathbf{B}}(p,0.5)]$. Thin line: Im$[h^s_{\mathbf{B}}(p,0.5)]$.

$$h^s_{\mathbf{B},2}(p,q)=(2\omega/(\overline{k}\pi))^{1/2}\int_0^{2\pi}\mathrm{d}y\,\exp[Y(1/Y+\mathrm{i}y)-(\chi/2)\tanh[2(1/Y+\mathrm{i}y)]$$
$$+\mathrm{i}Z(\mathrm{sech}[2(1/Y+\mathrm{i}y)]-1)]$$
$$\times\exp[-(1/Y+\mathrm{i}y)]_2F_1[1/2,1;1;-\exp[-4(1/Y+\mathrm{i}y)]]$$
$$\times\{Y-\chi\,\mathrm{sech}^2[2(1/Y+\mathrm{i}y)]$$
$$-2\mathrm{i}Z\,\mathrm{sech}[2(1/Y+\mathrm{i}y)]\tanh[2(1/Y+\mathrm{i}y)]-\tanh[2(1/Y+\mathrm{i}y)]\}(1/Y+\mathrm{i}y)^{-1/2},\quad(4)$$

$$h^s_{\mathbf{B},3}(p,q)=-\pi^{-1}(\omega/\overline{k})^{1/2}\exp[\mathrm{i}\pi(2Y+3/4)]\int_0^{2\pi}\mathrm{d}y\,\Phi[\exp[2\mathrm{i}\pi Y],1/2,1-\mathrm{i}(1/Y+\mathrm{i}y)/(2\pi)]$$
$$\times\exp[-(1/Y+\mathrm{i}y)]_2F_1[1/2,1;1;-\exp[-4(1/Y+\mathrm{i}y)]]$$
$$\times\exp[Y(1/Y+\mathrm{i}y)-(\chi/2)\tanh[2(1/Y+\mathrm{i}y)]+\mathrm{i}Z(\mathrm{sech}[2(1/Y+\mathrm{i}y)]-1)]$$
$$\times\{Y-\chi\,\mathrm{sech}^2[2(1/Y+\mathrm{i}y)]-2\mathrm{i}Z\,\mathrm{sech}[2(1/Y+\mathrm{i}y)]\tanh[2(1/Y+\mathrm{i}y)]$$
$$-\tanh[2(1/Y+\mathrm{i}y)]\},\quad(5)$$

and where $\overline{k}(>0)$ is a reference wave number, $\chi=\overline{k}(p^2+\omega^2q^2)/\omega$, $Z=\overline{k}pq$, $\Phi[\xi,\sigma,\Delta]=\Sigma_{n=0}^{\infty}\xi^n/(\Delta+n)^{\sigma}$ is the Lerch transcendent,[3,4] ${}_2F_1[a,b;c;\xi]$ is the hypergeometric function defined in terms of the Gauss series,[3,5] and we have taken $\mathrm{R}=1/Y$ (see Ref. 1, Fig. 6 and p. 4921). In the expression for $h^s_{\mathbf{B}}(p,q)$ [i.e., Eq. (2)], $h^s_{\mathbf{B},1}(p,q)$ denotes the contribution arising from $\Gamma_1''+\Gamma_3''$, which was combined and simplified using the identity given in [Ref. 1, Eq. (III. 20)] with $m=1$, while the sum $h^s_{\mathbf{B},2}(p,q)+h^s_{\mathbf{B},3}(p,q)$ represents the contribution from the single line segment Γ_2'' (see Ref. 1, Fig. 6).

Having expressed $h^s_{\mathbf{B}}(p,q)$ as the sum of three, one-dimensional definite integrals, we are now in a position to numerically evaluate these integrals and plot the corrected figures. To accomplish this, MATHEMATICA 4.0 (see Ref. 3) was employed. This particular software package was chosen

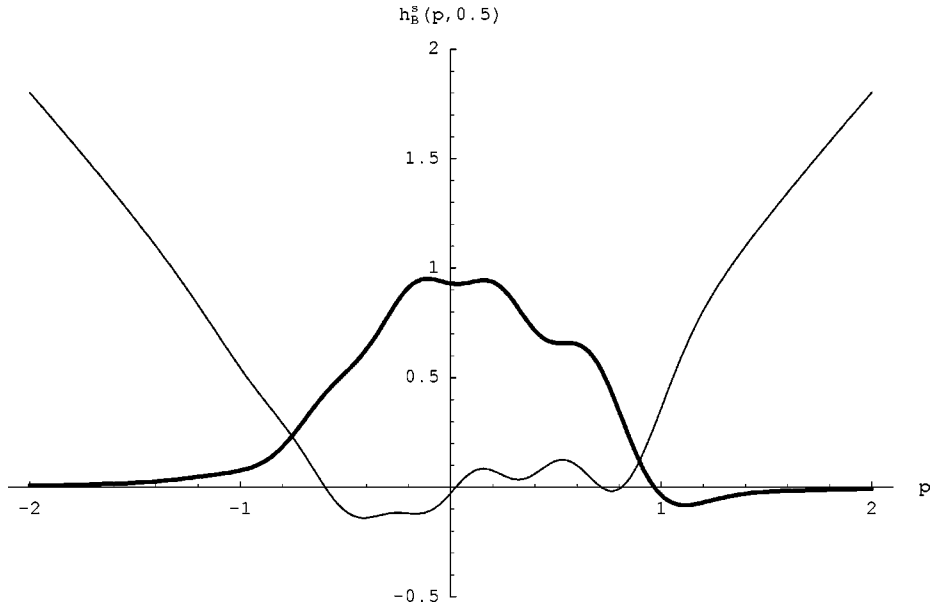

FIG. 2. (corrected form of Ref. 1, Fig. 8). $h^s_{\mathbf{B}}(p,q)$ vs p for $K^2(q)=K_0^2-\omega^2q^2$ with $K_0=\omega=1$, $q=0.5$, and $\overline{k}=10.5$. Bold line: Re$[h^s_{\mathbf{B}}(p,0.5)]$. Thin line: Im$[h^s_{\mathbf{B}}(p,0.5)]$.

because of its robust, adaptive numerical integration routines, it offers the Lerch transcendent and the ${}_2F_1$ hypergeometric as built-in functions that are tabulated for complex values of their arguments, and it is equipped with flexible graphics capabilities.

Obviously, for $q=0.5$ and $\overline{k}=50.5$, 10.5 the differences between the correct figures, Figs. 1 and 2, and the erroneous figures (Ref. 1, Figs. 7 and 8, respectively) are very pronounced, especially in terms of their oscillatory behavior. Note, however, that as the value of $\overline{k}$ is reduced, the

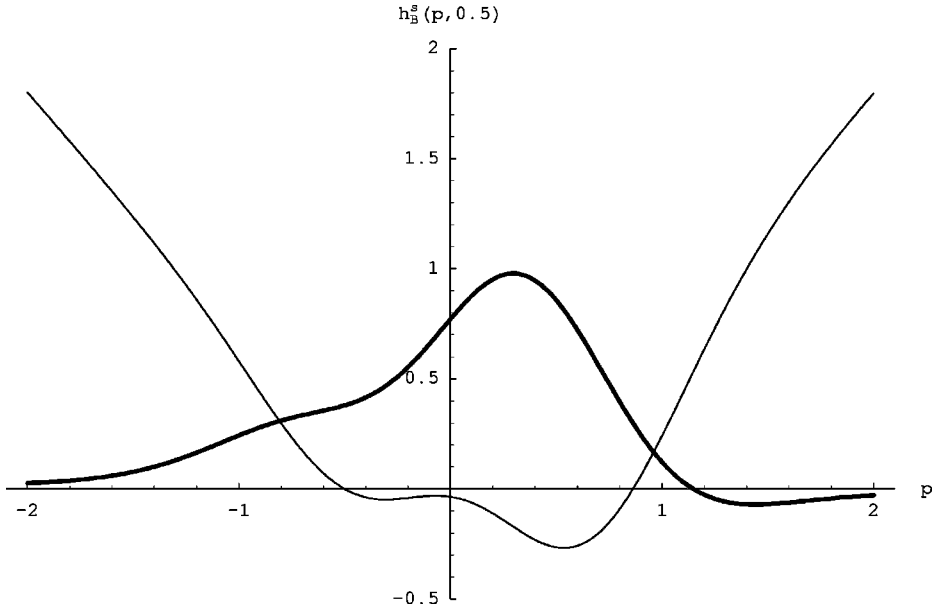

FIG. 3. (corrected form of Ref. 1, Fig. 9). $h^s_{\mathbf{B}}(p,q)$ vs p for $K^2(q)=K_0^2-\omega^2q^2$ with $K_0=\omega=1$, $q=0.5$, and $\overline{k}=3.5$. Bold line: Re$[h^s_{\mathbf{B}}(p,0.5)]$. Thin line: Im$[h^s_{\mathbf{B}}(p,0.5)]$.

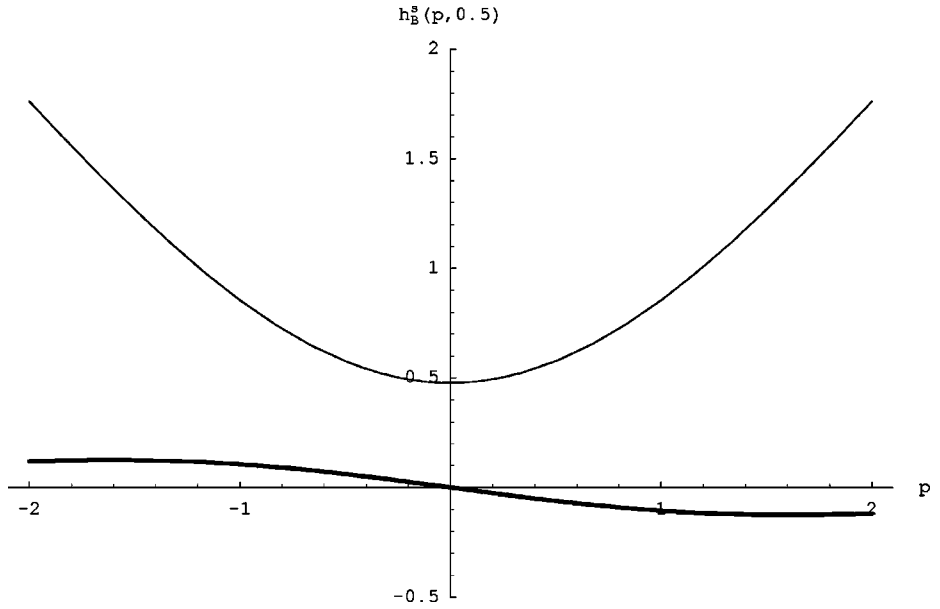

FIG. 4. (corrected form of Ref. 1, Fig. 10). $h^s_{\mathbf{B}}(p,q)$ vs p for $K^2(q)=K_0^2-\omega^2q^2$ with $K_0=\omega=1$, $q=0.5$, and $\overline{k}=0.5$. Bold line: Re$[h^s_{\mathbf{B}}(p,0.5)]$. Thin line: Im$[h^s_{\mathbf{B}}(p,0.5)]$.

last two erroneous figures corresponding to $q=0.5$ (Ref. 1, Figs. 9 and 10) approach their correct counterparts, Figs. 3 and 4, respectively. In fact, for $q=\overline{k}=0.5$ the correct and erroneous figures, that is, Fig. 4 and Ref. 1, Fig. 10, respectively, are virtually indistinguishable. Moreover, Figs. 1–4, all of which were plotted for $q=0.5$, exemplify the behavior of $h^s_{\mathbf{B}}(p,q)$ for the same value of q within the profile's well. Consider now Ref. 1, Fig. 11 and its correct counterpart Fig. 5, which were plotted for $q=1.5$ and therefore represent $h^s_{\mathbf{B}}(p,q)$ outside the well. Interestingly,

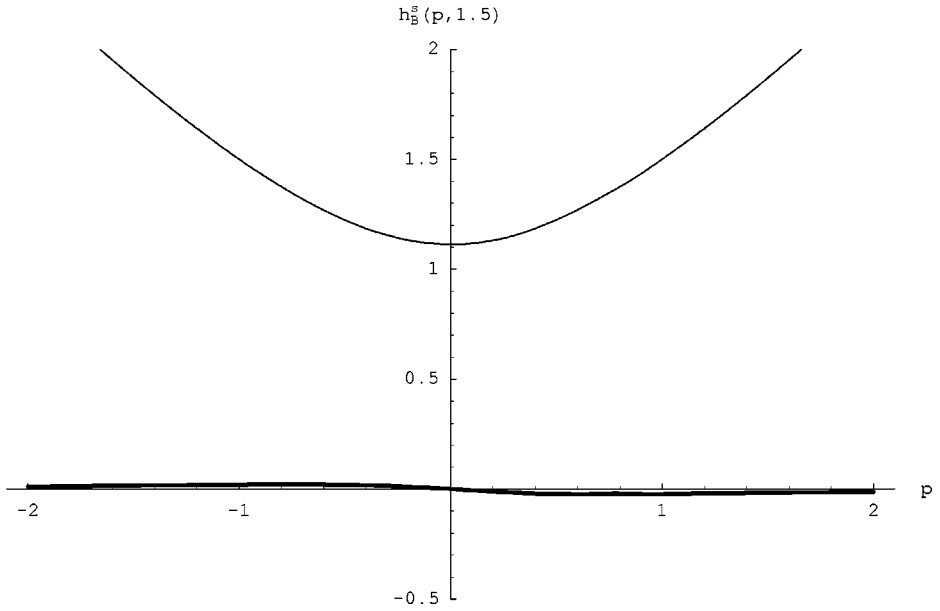

FIG. 5. (corrected form of Ref. 1, Fig. 11). $h^s_{\mathbf{B}}(p,q)$ vs p for $K^2(q)=K_0^2-\omega^2q^2$ with $K_0=\omega=1$, $q=1.5$, and $\overline{k}=10.5$. Bold line: Re$[h^s_{\mathbf{B}}(p,1.5)]$. Thin line: Im$[h^s_{\mathbf{B}}(p,1.5)]$.

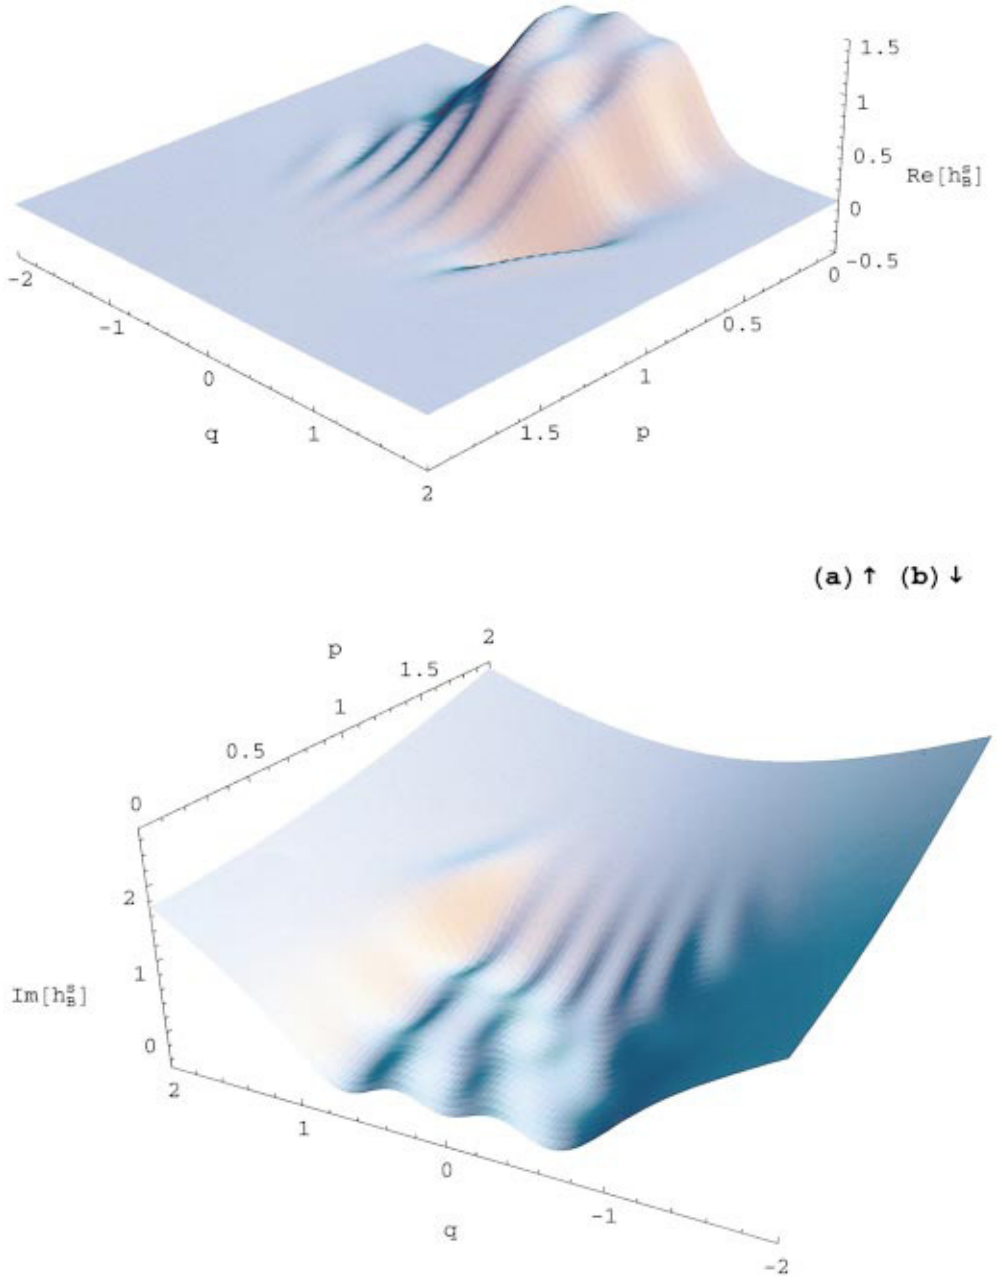

FIG. 6. (Color.) $h^s_{\mathbf{B}}(p,q)$ vs p and q for $K^2(q)=K_0^2-\omega^2q^2$ with $K_0=\omega=1$ and $\overline{k}=10.5$. (a) Re$[h^s_{\mathbf{B}}(p,q)]$. (b) Im$[h^s_{\mathbf{B}}(p,q)]$.

considering the relatively large value of $\overline{k}(=10.5)$ used, a comparison of these two figures reveals that they too are almost identical.

Finally, so as to give the reader a more complete picture, portions of the real and imaginary parts of the operator symbol surface corresponding to $h^s_{\mathbf{B}}(p,q)$ with $\overline{k}=10.5$ are given in Figs. 6(a) and 6(b), respectively. As mentioned earlier, Figs. 2 and 5 depict cross sections of the surfaces shown in Fig. 6 for fixed values of $q(=0.5,1.5)$ while Ref. 1, Fig. 12 does the same (correctly) for fixed $p(=0)$. When these cross sections are compared with the actual surfaces, however, it quickly becomes evident that the former provides very limited insight into the nature of the latter. Indeed, it appears quite difficult to grasp the intricate oscillatory structure exhibited by these

surfaces by simply viewing a collection of various cross sections. The reader is referred to Ref. 1, pp. 4922–4924 for details on the analytical properties of the surfaces appearing in Fig. 6.

The author was supported by a CORE/ONR/NRL Postdoctoral Fellowship (PE 602435 N). The author acknowledges several discussions with Professor Louis Fishman concerning the validity of the figures presented in this communication and thanks him for the critical reading of an earlier draft of this work.

(Received 1 June 1999; accepted for publication 10 July 2001)

The one-dimensional matrix Schrödinger equation is considered when the matrix potential is self-adjoint with entries that are integrable and have finite first moments. The small-energy asymptotics of the scattering coefficients are derived, and the continuity of the scattering coefficients at zero energy is established. When the entries of the potential have also finite second moments, some more detailed asymptotic expansions are presented. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1398059]

I. INTRODUCTION

Consider the matrix Schrödinger equation

$$\psi''(k,x)+k^2\psi(k,x)=Q(x)\psi(k,x), \quad x\in\mathbf{R}, \tag{1.1}$$

where $x\in\mathbf{R}$ is the spatial coordinate, the prime denotes the derivative with respect to x, k^2 is the energy, $Q(x)$ is an $n\times n$ self-adjoint matrix potential, i.e., $Q(x)^\dagger=Q(x)$ with the dagger standing for the matrix conjugate transpose, and $\psi(k,x)$ is either an $n\times 1$ or an $n\times n$ matrix function. We use $\|\cdot\|$ to denote the (Euclidean) norm of a vector or the operator norm of a matrix. Let $L^1_m(\mathbf{R};\mathbf{C}^{n\times n})$ with $m\geqslant 0$ denote the Banach space of all measurable $n\times n$ matrix functions f for which $(1+|x|)^m\|f(x)\|$ is integrable on $\mathbf{R}$. If $n=1$, we denote this space by $L^1_m(\mathbf{R})$. In this paper we always assume that Q is self-adjoint and belongs to $L^1_1(\mathbf{R};\mathbf{C}^{n\times n})$. Certain results will be obtained under the assumption that $Q\in L^1_2(\mathbf{R};\mathbf{C}^{n\times n})$, but we will clearly indicate when this stronger assumption is needed. We use $\mathbf{C}^+$ to denote the upper-half complex plane and write $\overline{\mathbf{C}^+}$ for $\mathbf{C}^+\cup\mathbf{R}$.

Among the $n\times n$ solutions of (1.1) are the so-called Jost solution from the left, $f_l(k,x)$, and the Jost solution from the right, $f_r(k,x)$, satisfying the asymptotic boundary conditions

$$e^{-ikx}f_l(k,x)=I_n+o(1) \text{ and } e^{-ikx}f_l'(k,x)=ikI_n+o(1), \quad x\to+\infty, \tag{1.2}$$

$$e^{ikx}f_r(k,x)=I_n+o(1) \text{ and } e^{ikx}f_r'(k,x)=-ikI_n+o(1), \quad x\to-\infty, \tag{1.3}$$

where I_n denotes the identity matrix of order n. The existence of the Jost solutions can be established as in the scalar ($n=1$) case[1,2] by using the appropriate integral equations[3,4] [cf. (2.2), (2.3), and Theorem 2.1 in our paper].

For each $k\in\mathbf{R}\backslash\{0\}$ we have

$$f_l(k,x)=a_l(k)e^{ikx}+b_l(k)e^{-ikx}+o(1), \quad x\to-\infty, \tag{1.4}$$

a)Electronic mail: aktosun@math.msstate.edu
b)Electronic mail: klaus@math.vt.edu
c)Electronic mail: cornelis@krein.sc.unica.it

$$f_{\rm r}(k,x)=a_{\rm r}(k)e^{-ikx}+b_{\rm r}(k)e^{ikx}+o(1), \quad x\to+\infty, \tag{1.5}$$

where $a_{\rm l}(k)$, $b_{\rm l}(k)$, $a_{\rm r}(k)$, and $b_{\rm r}(k)$ are some $n\times n$ matrix functions of k. These matrix functions enter the scattering matrix $\mathbf{S}(k)$ defined in (2.22), and our primary aim is the analysis of the small-k behavior of $\mathbf{S}(k)$.

The motivation for this paper comes from our interest in the inverse scattering problem for (1.1), namely the recovery of Q from an appropriate set of data involving the scattering matrix. As is known from the scalar case, it is important to have detailed information about the behavior of $\mathbf{S}(k)$ for small k. For example,[1,2] this information is used to characterize the scattering data, so as to ensure that the potential Q constructed from the data at hand belongs to a certain class of functions such as $L^1_1(\mathbf{R})$ or $L^1_2(\mathbf{R})$. The inverse scattering problem for (1.1) when $n>1$ has been considered by several authors,[4–10] but we are not aware of any in-depth study of the small-k behavior of $\mathbf{S}(k)$. Not even the continuity of the scattering matrix at $k=0$ seems to have been established when $Q\in L^1_1(\mathbf{R};\mathbf{C}^{n\times n})$; for example, in Ref. 6 (p. 294), the continuity at $k=0$ of the transmission coefficients is *assumed*. In the scalar case it is well known[1,2,11,12] that the continuity of $\mathbf{S}(k)$ at $k=0$ is easy to establish if $Q\in L^1_2(\mathbf{R})$, but not if only $Q\in L^1_1(\mathbf{R})$. In the matrix case, the situation is somewhat different. The decay of $Q(x)$ as $x\to\pm\infty$ plays an important role, but there are further complications due to the particular structure of the solution space of (1.1) at $k=0$. From the scalar case it is known[1,2,11] that the behavior of the solutions of (1.1) at $k=0$ makes it necessary to distinguish between two cases, the *generic case* and the *exceptional case*, and that the small-k behavior of $\mathbf{S}(k)$ is different in each case. If $n>1$, the situation is more complicated because the exceptional case gives rise to a variety of possibilities depending on the Jordan structure of a certain matrix associated with the solution space of (1.1) at $k=0$. In this paper we clarify the connection between the solutions of (1.1) at $k=0$ and the behavior of $\mathbf{S}(k)$ near $k=0$. As a result, we are able to prove the continuity of the scattering matrix at $k=0$ when $Q\in L^1_1(\mathbf{R};\mathbf{C}^{n\times n})$ and to obtain more detailed asymptotic expansions when $Q\in L^1_2(\mathbf{R};\mathbf{C}^{n\times n})$. The inverse problem is not considered here; we may report on it elsewhere.

This paper is organized as follows. In Sec. II we establish our notations and review some basic known results on the solutions of (1.1). Since this material is standard, we refer the reader to the literature for proofs and more details. In Sec. II we also give various characterizations of the generic and exceptional cases. In Sec. III we prove the continuity of the scattering matrix at $k=0$ in the generic case, and we obtain some more detailed asymptotic results when $Q\in L^1_2(\mathbf{R};\mathbf{C}^{n\times n})$. The exceptional case is treated in Sec. IV; the main results are contained in Theorem 4.6 when $Q\in L^1_1(\mathbf{R};\mathbf{C}^{n\times n})$ and in Theorem 4.7 when $Q\in L^1_2(\mathbf{R};\mathbf{C}^{n\times n})$, where we prove the continuity and differentiability of $\mathbf{S}(k)$ at $k=0$, respectively. In Sec. V we discuss some special cases that illustrate the results of Sec. IV. Finally, the Appendix contains the proof of Proposition 4.2, which is a key result needed to establish Theorems 4.6 and 4.7.

II. SCATTERING COEFFICIENTS AND A CASE DISTINCTION

In this section we review some basic results about those solutions of (1.1) that are relevant to scattering theory, and we define the scattering coefficients and some related quantities. We also elaborate on the distinction between the generic case and the exceptional case which will play an important role in the subsequent sections.

We define the Faddeev functions $m_{\rm l}(k,x)$ and $m_{\rm r}(k,x)$ by

$$m_{\rm l}(k,x)=e^{-ikx}f_{\rm l}(k,x), \quad m_{\rm r}(k,x)=e^{ikx}f_{\rm r}(k,x). \tag{2.1}$$

From (1.2), (1.3), and (2.1) it follows that

$$m_{\rm l}(k,x)=I_n+\frac{1}{2ik}\int_x^\infty dy\,[e^{2ik(y-x)}-1]Q(y)m_{\rm l}(k,y), \tag{2.2}$$

$$m_{\rm r}(k,x)=I_n+\frac{1}{2ik}\int_{-\infty}^{x}dy\,[e^{2ik(x-y)}-1]Q(y)m_{\rm r}(k,y). \tag{2.3}$$

Some properties of the matrix functions $m_{\rm l}(k,x)$ and $m_{\rm r}(k,x)$ are summarized in the next theorem and its corollary. The proofs of these results can be obtained as in the scalar case and we refer the reader to the literature;[2–4,11] in particular, see Theorem 1.4.1 in Ref. 3 and Theorem 1 in Ref. 4. We denote differentiation with respect to k by an overdot and use C for suitable constants that do not depend on x or k.

Theorem 2.1: *If $Q\in L^1_1(\mathbf{R};\mathbf{C}^{n\times n})$, then, for each $x\in\mathbf{R}$, the functions $m_{\rm l}(k,x)$, $m_{\rm r}(k,x)$, $m'_{\rm l}(k,x)$, and $m'_{\rm r}(k,x)$ are analytic in $k\in\mathbf{C}^+$* and *continuous in $k\in\overline{\mathbf{C}^+}$; moreover*

$$m_{\rm l}(k,x)=I_n+o(1),\quad m'_1(k,x)=o(1/x),\quad x\to+\infty, \tag{2.4}$$

$$m_{\rm r}(k,x)=I_n+o(1),\quad m'_{\rm r}(k,x)=o(1/x),\quad x\to-\infty,$$

$$\|m_{\rm l}(k,x)\|\leq C[1+\max\{0,-x\}],\quad \|m_{\rm r}(k,x)\|\leq C[1+\max\{0,x\}],\quad k\in\overline{\mathbf{C}^+}. \tag{2.5}$$

In addition, if $Q\in L^1_2(\mathbf{R};\mathbf{C}^{n\times n})$, then $\dot m_{\rm l}(k,x)$ and $\dot m_{\rm r}(k,x)$ exist, are analytic in $\mathbf{C}^+$, continuous in $\overline{\mathbf{C}^+}$, and satisfy the estimates

$$\|\dot m_{\rm l}(k,x)\|\leq C(1+x^2),\quad \|\dot m_{\rm r}(k,x)\|\leq C(1+x^2),\quad k\in\overline{\mathbf{C}^+}.$$

In the following an asterisk will be used to denote complex conjugation. From (2.1) and Theorem 2.1 we get the following.

Corollary 2.2: Assume $Q\in L^1_1(\mathbf{R};\mathbf{C}^{n\times n})$. Then, for each fixed $x\in\mathbf{R}$, the four matrix functions $f_{\rm l}(-k^*,x)^\dagger$, $f_{\rm r}(-k^*,x)^\dagger$, $f'_1(-k^*,x)^\dagger$, and $f'_{\rm r}(-k^*,x)^\dagger$ are analytic in $k\in\mathbf{C}^+$ and continuous in $\overline{\mathbf{C}^+}$. Moreover, if $Q\in L^1_2(\mathbf{R};\mathbf{C}^{n\times n})$, then these functions are differentiable with respect to $k\in\overline{\mathbf{C}^+}$.

The scattering coefficients will be defined in terms of certain Wronskians involving the Jost solutions. We first state a standard result about such Wronskians, which is a consequence of the selfadjointness of Q. Let $[F;G]=FG'-F'G$ denote the Wronskian of two square matrix functions $F(x)$ and $G(x)$.

Proposition 2.3: For $k\in\mathbf{C}$, let $\phi(k,x)$ be any $n\times p$ solution and $\psi(k,x)$ any $n\times q$ solution of (1.1). Then the $p\times q$ Wronskian matrix $[\phi(\pm k^*,x)^\dagger;\psi(k,x)]$ is independent of x.

As a result of Proposition 2.3 the matrices $a_{\rm l}(k)$, $b_{\rm l}(k)$, $a_{\rm r}(k)$, and $b_{\rm r}(k)$ appearing in (1.4) and (1.5) can be expressed in terms of certain Wronskians of the Jost solutions as follows:

$$a_{\rm l}(k)=\frac{1}{2ik}[f_{\rm r}(-k^*,x)^\dagger;f_{\rm l}(k,x)],\quad k\in\overline{\mathbf{C}^+}\backslash\{0\}, \tag{2.6}$$

$$a_{\rm r}(k)=-\frac{1}{2ik}[f_1(-k^*,x)^\dagger;f_{\rm r}(k,x)],\quad k\in\overline{\mathbf{C}^+}\backslash\{0\}, \tag{2.7}$$

$$b_{\rm l}(k)=-\frac{1}{2ik}[f_{\rm r}(k,x)^\dagger;f_{\rm l}(k,x)],\quad k\in\mathbf{R}\backslash\{0\}, \tag{2.8}$$

$$b_{\rm r}(k)=\frac{1}{2ik}[f_1(k,x)^\dagger;f_{\rm r}(k,x)],\quad k\in\mathbf{R}\backslash\{0\}. \tag{2.9}$$

Alternatively, it is sometimes convenient to use the integral representations

$$a_{\rm l}(k)=I_n-\frac{1}{2ik}\int_{-\infty}^{\infty}dx\,Q(x)m_{\rm l}(k,x), \tag{2.10}$$

$$a_{\rm r}(k)=I_n-\frac{1}{2ik}\int_{-\infty}^{\infty}dx\,Q(x)m_{\rm r}(k,x), \tag{2.11}$$

$$b_{\rm l}(k)=\frac{1}{2ik}\int_{-\infty}^{\infty}dx\,e^{2ikx}\,Q(x)m_1(k,x), \tag{2.12}$$

$$b_{\rm r}(k)=\frac{1}{2ik}\int_{-\infty}^{\infty}dx\,e^{-2ikx}\,Q(x)m_{\rm r}(k,x), \tag{2.13}$$

which follow from (1.4), (1.5), and (2.1)–(2.5). Also, with the help of (1.2)–(1.5) and (2.6)–(2.9), we obtain

$$a_{\rm r}(-k^*)^\dagger=a_{\rm l}(k),\quad k\in\overline{\mathbf{C}^+}\backslash\{0\}, \tag{2.14}$$

$$b_{\rm r}(k)=-b_{\rm l}(k)^\dagger,\quad k\in\mathbf{R}\backslash\{0\}, \tag{2.15}$$

$$a_{\rm l}(k)^\dagger a_{\rm l}(k)=b_{\rm l}(k)^\dagger b_{\rm l}(k)+I_n,\quad k\in\mathbf{R}\backslash\{0\}, \tag{2.16}$$

$$a_{\rm r}(k)^\dagger a_{\rm r}(k)=b_{\rm r}(k)^\dagger b_{\rm r}(k)+I_n,\quad k\in\mathbf{R}\backslash\{0\}, \tag{2.17}$$

$$a_{\rm l}(-k)^\dagger b_{\rm l}(k)=b_{\rm l}(-k)^\dagger a_{\rm l}(k),\quad k\in\mathbf{R}\backslash\{0\}, \tag{2.18}$$

$$a_{\rm r}(-k)^\dagger b_{\rm r}(k)=b_{\rm r}(-k)^\dagger a_{\rm r}(k),\quad k\in\mathbf{R}\backslash\{0\}. \tag{2.19}$$

We define the transmission coefficient from the left, $T_{\rm l}(k)$, and the transmission coefficient from the right, $T_{\rm r}(k)$, by

$$T_{\rm l}(k)=a_{\rm l}(k)^{-1},\quad T_{\rm r}(k)=a_{\rm r}(k)^{-1}, \tag{2.20}$$

provided the inverses on the right-hand sides exist, and we define the reflection coefficient from the left, $L(k)$, and the reflection coefficient from the right, $R(k)$, by

$$L(k)=b_{\rm l}(k)a_{\rm l}(k)^{-1},\quad R(k)=b_{\rm r}(k)a_{\rm r}(k)^{-1}. \tag{2.21}$$

From (2.16) and (2.17) we see that $a_{\rm l}(k)$ and $a_{\rm r}(k)$ are nonsingular for $k\in\mathbf{R}\backslash\{0\}$. In $\mathbf{C}^+$, $a_{\rm l}(k)$ and $a_{\rm r}(k)$ are nonsingular except possibly at a finite number of points on the positive imaginary axis where[4] both $\det a_{\rm l}(k)=0$ and $\det a_{\rm r}(k)=0$; at these points, $T_{\rm l}(k)$ and $T_{\rm r}(k)$ have simple poles[8] corresponding to the bound states of (1.1). For $Q\in L_2^1(\mathbf{R};\mathbf{C}^{n\times n})$ the finiteness of the number of bound states has already been established in Refs. 4 and 13. We note that even if $Q\notin L_2^1(\mathbf{R};\mathbf{C}^{n\times n})$ but $Q\in L_1^1(\mathbf{R};\mathbf{C}^{n\times n})$, the finiteness follows from the (operator) inequality $Q(x)\geqslant-\|Q(x)\|I_n$ and the fact that in one dimension a scalar potential in $L_1^1(\mathbf{R})$ can support at most a finite number of bound states. Alternatively, the finiteness of the number of bound states will follow from the results of this paper (cf. Theorems 3.1 and 4.6), which show that $k=0$ cannot be an accumulation point for poles of either $T_{\rm l}(k)$ or $T_{\rm r}(k)$. Because of this latter property we will study the asymptotic behavior of the transmission coefficients as $k\to0$ through values in $\overline{\mathbf{C}^+}$. The reflection coefficients, on the other hand, in general do not have analytic extensions off the real axis, so their asymptotics will be studied for real k only. The $n\times n$ matrix functions $T_{\rm l}(k)$, $T_{\rm r}(k)$, $R(k)$, and $L(k)$ are referred to as scattering coefficients, and the $2n\times2n$ matrix

$$\mathbf{S}(k)=\begin{bmatrix}T_{\rm l}(k) & R(k)\\ L(k) & T_{\rm r}(k)\end{bmatrix}, \tag{2.22}$$

is called the scattering matrix.

From (2.15)–(2.17), we get

$$T_{\rm l}(k)^{\dagger}R(k)+L(k)^{\dagger}T_{\rm r}(k)=0, \quad k\in\mathbf{R}\backslash\{0\},$$

$$T_{\rm l}(k)^{\dagger}T_{\rm l}(k)+L(k)^{\dagger}L(k)=I_n, \quad k\in\mathbf{R}\backslash\{0\}, \tag{2.23}$$

$$T_{\rm r}(k)^{\dagger}T_{\rm r}(k)+R(k)^{\dagger}R(k)=I_n, \quad k\in\mathbf{R}\backslash\{0\}, \tag{2.24}$$

and hence, for $k\in\mathbf{R}\backslash\{0\}$, $\mathbf{S}(k)$ is unitary. Using (2.14) we obtain

$$T_{\rm r}(k)=T_{\rm l}(-k^*)^{\dagger}, \quad k\in\overline{\mathbf{C}^+}\backslash\{0\}, \tag{2.25}$$

whenever $a_{\rm r}(k)$ is nonsingular, and from (2.18) and (2.19) we get

$$L(-k)^{\dagger}=L(k), \quad R(-k)^{\dagger}=R(k), \quad k\in\mathbf{R}\backslash\{0\}.$$

In order to study $\mathbf{S}(k)$ in the small-energy limit, we need to make an important case distinction which involves the solutions to (1.1) with $k=0$, i.e., the solutions to

$$\phi''(x)=Q(x)\phi(x), \quad x\in\mathbf{R}. \tag{2.26}$$

We already know from (2.1) and Theorem 2.1 that $f_{\rm l}(0,x)$ is a solution of (2.26) satisfying $f_{\rm l}(0,x)=I_n+o(1)$ and $f_{\rm l}'(0,x)=o(1/x)$ as $x\to+\infty$. According to basic asymptotic results for systems of linear differential equations (Theorem 1.5.1 of Ref. 3), (2.26) also has an $n\times n$ matrix solution, $\phi_{\rm l}(x)$, satisfying

$$\phi_{\rm l}(x)=xI_n+o(x), \quad \phi_{\rm l}'(x)=I_n+o(1), \quad x\to+\infty.$$

Thus the columns of $f_{\rm l}(0,x)$ together with the columns of $\phi_{\rm l}(x)$ form a fundamental set of $2n$ vector solutions for (2.26). Any vector solution $\phi(x)$ of (2.26) can be written as

$$\phi(x)=f_{\rm l}(0,x)\,\eta_1+\phi_{\rm l}(x)\,\eta_2, \tag{2.27}$$

where $\eta_1,\eta_2\in\mathbf{C}^n$ are uniquely determined by $\phi(x)$. It follows from (2.27) that a vector solution of (2.26) is bounded as $x\to+\infty$ if and only if $\eta_2=0$, i.e., if and only if $\phi(x)=f_{\rm l}(0,x)\,\eta_1$ for some $\eta_1\in\mathbf{C}^n$. Moreover, in this case $\lim_{x\to+\infty}\phi(x)=\eta_1$ exists. This means that if a solution is bounded at $+\infty$, then it also has a limit as $x\to+\infty$. Also, (2.27) implies that any solution of (2.26) that is $o(x)$ as $x\to+\infty$ is necessarily bounded at $x=+\infty$ and any solution that is $o(1)$ as $x\to+\infty$ must be the zero solution. Similar results hold at $x=-\infty$; in particular, any solution of (2.26) that is $o(x)$ as $x\to-\infty$ is necessarily bounded at $x=-\infty$ and has a limit as $x\to-\infty$, and any solution that is $o(1)$ as $x\to-\infty$ must be the zero solution.

From (2.1)–(2.3) we see that $f_{\rm l}(0,x)$ and $f_{\rm r}(0,x)$ obey the integral equations

$$f_{\rm l}(0,x)=I_n+\int_x^{\infty}dy\,(y-x)Q(y)f_{\rm l}(0,y), \tag{2.28}$$

$$f_{\rm r}(0,x)=I_n-\int_{-\infty}^{x}dy\,(y-x)Q(y)f_{\rm r}(0,y). \tag{2.29}$$

In the subsequent analysis the two Wronskian matrices

$$\Delta_{\rm l}=[f_{\rm r}(0,x)^{\dagger};f_{\rm l}(0,x)], \quad \Delta_{\rm r}=-[f_{\rm l}(0,x)^{\dagger};f_{\rm r}(0,x)], \tag{2.30}$$

will play a key role. By Proposition 2.3, $\Delta_{\rm l}$ and $\Delta_{\rm r}$ are independent of x, and from (2.30) it follows that

$$\Delta_{\rm l}=\Delta_{\rm r}^{\dagger}. \tag{2.31}$$

The importance of these Wronskians lies in the fact that they are related to the transmission coefficients via (2.20) and

$$\Delta_{\rm l}=\lim_{k\to 0} 2ika_{\rm l}(k), \quad \Delta_{\rm r}=\lim_{k\to 0} 2ika_{\rm r}(k), \tag{2.32}$$

where the limits are taken from within $\overline{\mathbf{C}^+}$; (2.32) follows from (2.6), (2.7), and Corollary 2.2.

Evaluating the first Wronskian in (2.30) as $x\to-\infty$ and using (2.28) we obtain

$$\Delta_{\rm l}=\lim_{x\to-\infty} f_{\rm l}'(0,x)=-\int_{-\infty}^{\infty} dy\, Q(y) f_{\rm l}(0,y). \tag{2.33}$$

Similarly, from (2.29) and (2.30), letting $x\to+\infty$, we get

$$\Delta_{\rm r}=-\lim_{x\to+\infty} f_{\rm r}'(0,x)=-\int_{-\infty}^{\infty} dy\, Q(y) f_{\rm r}(0,y). \tag{2.34}$$

From (2.28) and (2.29) we also infer that

$$f_{\rm l}(0,x)=x\Delta_{\rm l}+o(x), \quad x\to-\infty,$$

$$f_{\rm r}(0,x)=-x\Delta_{\rm r}+o(x), \quad x\to+\infty. \tag{2.35}$$

Now we are ready to introduce the distinction between the exceptional case and the generic case. Let

$$\mathcal{N}=\{\xi\in\mathbf{C}^n: f_{\rm l}(0,x)\xi \text{ is bounded on } \mathbf{R}\}. \tag{2.36}$$

Then we say that the generic case occurs if $\mathcal{N}=\{0\}$ and we say that the exceptional case occurs if $\mathcal{N}\neq\{0\}$. These two cases can be characterized in other ways. We choose the above definition as our starting point and will arrive at some other characterizations as we go along.

We observe that the generic case occurs if and only if (2.26) has no bounded nontrivial solution. The exceptional case occurs if and only if there exists at least one nontrivial bounded solution. As the next theorem shows, we can alternatively characterize the two cases by means of the subspace

$$\mathcal{M}=\{\chi\in\mathbf{C}^n: f_{\rm r}(0,x)\chi \text{ is bounded on } \mathbf{R}\}. \tag{2.37}$$

Then the generic (exceptional) case occurs if and only if $\mathcal{M}=\{0\}$ ($\mathcal{M}\neq\{0\}$).

We mention that when $n=1$ the exceptional case occurs if and only if $f_{\rm l}(0,x)$ and $f_{\rm r}(0,x)$ are linearly dependent, i.e., the Wronskian $[f_{\rm r}(0,x);f_{\rm l}(0,x)]$ is zero. In our paper we generalize this characterization to the matrix case. In the scalar case it is also known that the generic (exceptional) case occurs if $T_{\rm l}(0)=0$ ($T_{\rm l}(0)\neq 0$). This will also turn out be true in the matrix case, but we do not use this property as our primary characterization because it is implicitly based on the assumption that $T_{\rm l}(k)$ is continuous at $k=0$, something we first need to prove.

The next theorem further clarifies the relations among the two cases, the Wronskians in (2.31), and the subspaces $\mathcal{N}$ and $\mathcal{M}$.

Theorem 2.4: *Assume* $Q\in L_1^1(\mathbf{R};\mathbf{C}^{n\times n})$. *Then we have*

(i) *The generic case occurs if and only if* $\Delta_{\rm l}$, *or equivalently* $\Delta_{\rm r}$, *is nonsingular.*
(ii) $\mathcal{N}=\text{Ker } \Delta_{\rm l}$ *and* $\mathcal{M}=\text{Ker } \Delta_{\rm r}$.
(iii) $\dim \mathcal{N}=\dim \mathcal{M}$.

Proof: If $\Delta_{\rm l}$ is nonsingular, then (2.35) implies that every solution of (2.26) of the form $f_{\rm l}(0,x)\eta$, with some nonzero vector $\eta\in\mathbf{C}^n$, becomes unbounded as $x\to-\infty$. Hence, if $\Delta_{\rm l}$ is nonsingular, then (2.26) has no bounded nontrivial solutions; so the generic case occurs. Con-

versely, suppose the generic case (i.e., $\mathcal{N}=\{0\}$) occurs and Δ_l is singular. Then, by (2.35), for any nonzero $\xi\in\mathrm{Ker}\ \Delta_l$, we have $f_l(0,x)\xi=o(x)$ as $x\to-\infty$. Hence, by the remarks following (2.26) and (2.27), $f_l(0,x)\xi$ is bounded, i.e., $\xi\in\mathcal{N}$ and thus $\mathcal{N}\neq\{0\}$. This is a contradiction. Therefore, in the generic case, Δ_l cannot be singular. This proves (i) for Δ_l. In view of (2.31), the assertion also holds if Δ_l is replaced by Δ_r. To prove (ii), suppose that $\xi\in\mathrm{Ker}\ \Delta_l$. Then, by (2.35), $f_l(0,x)\xi=o(x)$ as $x\to-\infty$. Hence $f_l(0,x)\xi$ is bounded and so $\xi\in\mathcal{N}$. Conversely, if $\xi\in\mathcal{N}$, then $f_l(0,x)\xi$ is bounded and, therefore, again by (2.35), $\Delta_l\xi=0$. This proves the first equality in (ii). The second equality is proved similarly. Finally, (iii) follows immediately from (2.31). ■

III. SMALL-*k* BEHAVIOR IN THE GENERIC CASE

In this section we analyze the behavior of the scattering coefficients near $k=0$ in the generic case. In order to state the next theorem, which is the main result of this section, we introduce the matrices

$$E_l=\int_{-\infty}^{\infty}dx\,xQ(x)m_l(0,x),\quad E_r=\int_{-\infty}^{\infty}dx\,xQ(x)m_r(0,x),\tag{3.1}$$

$$G_l=\int_{-\infty}^{\infty}dx\,Q(x)\dot{m}_l(0,x),\quad G_r=\int_{-\infty}^{\infty}dx\,Q(x)\dot{m}_r(0,x).$$

The quantities E_l and E_r will also play a role in Sec. IV.

Theorem 3.1: *Assume Q is a generic potential in $L^1_m(\mathbf{R};\mathbf{C}^{n\times n})$ for $m=1$ or 2. Then the scattering coefficients satisfy the following:*

(i) *If $m=1$, then*

$$T_l(k)=2ik\Delta_l^{-1}+o(k),\quad T_r(k)=2ik\Delta_r^{-1}+o(k),\quad k\to0\ \text{ in }\ \overline{\mathbf{C}^+},$$
$$R(k)=-I_n+o(1),\quad L(k)=-I_n+o(1),\quad k\to0\ \text{ in }\ \mathbf{R}.$$

(ii) *If $m=2$, then*

$$T_l(k)=2ik\Delta_l^{-1}+k^2\Delta_l^{-1}[4I_n+2iG_l]\Delta_l^{-1}+o(k^2),\quad k\to0\ \text{ in }\ \overline{\mathbf{C}^+},$$
$$T_r(k)=2ik\Delta_r^{-1}+k^2\Delta_r^{-1}[4I_n+2iG_r]\Delta_r^{-1}+o(k^2),\quad k\to0\ \text{ in }\ \overline{\mathbf{C}^+},$$
$$L(k)=-I_n+2ik[I_n+E_l]\Delta_l^{-1}+o(k),\quad k\to0\ \text{ in }\ \mathbf{R},$$
$$R(k)=-I_n+2ik[I_n-E_r]\Delta_r^{-1}+o(k),\quad k\to0\ \text{ in }\ \mathbf{R}.$$

Proof: Using the fact that in the generic case Δ_l and Δ_r are invertible, (i) is a consequence of (2.6)–(2.9), (2.20), (2.21), (2.32), and Corollary 2.2. When $Q\in L^1_2(\mathbf{R};\mathbf{C}^{n\times n})$, expanding the integrals in (2.10)–(2.13) as

$$a_l(k)=\frac{1}{2ik}\Delta_l+I_n+\frac{i}{2}G_l+o(1),\quad k\to0\ \text{ in }\ \overline{\mathbf{C}^+},\tag{3.2}$$

$$b_l(k)=-\frac{1}{2ik}\Delta_l+E_l-\frac{i}{2}G_l+o(1),\quad k\to0\ \text{ in }\ \mathbf{R},\tag{3.3}$$

$$a_r(k)=\frac{1}{2ik}\Delta_r+I_n+\frac{i}{2}G_r+o(1),\quad k\to0\ \text{ in }\ \overline{\mathbf{C}^+},\tag{3.4}$$

$$b_r(k)=-\frac{1}{2ik}\Delta_r-E_r-\frac{i}{2}G_r+o(1),\quad k\to0\ \text{ in }\ \mathbf{R},\tag{3.5}$$

and using (2.20) and (2.21) we obtain (ii). ■

For later use we remark that when $Q \in L^1_2(\mathbf{R};\mathbf{C}^{n\times n})$, E_l and E_r can be expressed in terms of certain Wronskians, namely

$$I_n + E_l = i[\dot{f}_r(0,x)^\dagger; f_l(0,x)], \quad I_n - E_r = -i[\dot{f}_l(0,x)^\dagger; f_r(0,x)]. \tag{3.6}$$

Note that the Wronskians in (3.6) are independent of x because $\dot{f}_l(0,x)$ and $\dot{f}_r(0,x)$ are also solutions of (2.26). The expressions in (3.6) follow easily from (2.28), (2.29), and the corresponding integral equations for $\dot{f}_l(0,x)$ and $\dot{f}_r(0,x)$ [cf. (A.20)]. Moreover, we have $G_r = -G_l^\dagger$ and $E_r = E_l^\dagger + iG_l^\dagger$, as can be seen by using (2.14), (2.15), and (3.2)–(3.5).

Theorem 3.1 shows that if the generic case occurs, then $T_l(0) = 0$. In the next section we will see that the converse is also true.

IV. SMALL-*k* BEHAVIOR IN THE EXCEPTIONAL CASE

Recall that in the exceptional case (2.26) has at least one bounded nontrivial solution. In this section we analyze how this affects the small-k properties of $\mathbf{S}(k)$, and we prove in the exceptional case the continuity of $\mathbf{S}(k)$ at $k=0$ when $Q \in L^1_1(\mathbf{R};\mathbf{C}^{n\times n})$ and its differentiability when $Q \in L^1_2(\mathbf{R};\mathbf{C}^{n\times n})$. It turns out that when $Q \in L^1_1(\mathbf{R};\mathbf{C}^{n\times n})$ the exceptional case gives rise to certain technical complications that necessitate a careful study of certain asymptotic expansions. Since the proof of one result, namely Proposition 4.2, is especially long, that proof is given in the Appendix.

Recall the definitions of the subspaces $\mathcal{N}$ and $\mathcal{M}$ given in (2.36) and (2.37), respectively. There is a natural mapping from $\mathcal{N}$ to $\mathcal{M}$, which we denote by Γ, defined as follows. For every $\xi \in \mathcal{N}$, let

$$\chi = \lim_{x\to-\infty} f_l(0,x)\xi, \tag{4.1}$$

and put

$$\chi = \Gamma\xi. \tag{4.2}$$

Note that, by (2.36), $f_l(0,x)\xi$ is bounded and hence, by the discussion below (2.27), the limit in (4.1) exists. To see that Γ maps $\mathcal{N}$ into $\mathcal{M}$, we note that (4.1) implies

$$\lim_{x\to-\infty} [f_l(0,x)\xi - f_r(0,x)\chi] = 0.$$

Hence $f_l(0,x)\xi - f_r(0,x)\chi$ is a solution of (2.26) which approaches zero as $x\to-\infty$; therefore, it must be identically zero and we have

$$f_l(0,x)\xi = f_r(0,x)\chi, \quad x \in \mathbf{R}. \tag{4.3}$$

Hence $f_r(0,x)\chi$ is bounded, which implies $\chi \in \mathcal{M}$.

Proposition 4.1: Assume $Q \in L^1_1(\mathbf{R};\mathbf{C}^{n\times n})$. Then Γ is a bijection between $\mathcal{N}$ and $\mathcal{M}$.

Proof: We have already seen that Γ maps $\mathcal{N}$ into $\mathcal{M}$. The map Γ is injective, for if $\Gamma\xi = 0$, then, by (4.2) and (4.3), $f_l(0,x)\xi = 0$ for all $x \in \mathbf{R}$ and hence $\xi = 0$. It is also onto, because for every $\chi \in \mathcal{M}$, $\lim_{x\to+\infty} f_r(0,x)\chi = \xi$ exists, and hence (4.3) holds; thus $\chi = \Gamma\xi$. ∎

The mapping Γ will make its appearance as a restriction to $\mathcal{N}$ of certain linear transformations defined on all of $\mathbf{C}^n$. One such representation immediately follows from (4.3). We can pick any x_0 for which $f_r(0,x_0)$ is invertible and write

$$\Gamma = [f_r(0,x_0)^{-1} f_l(0,x_0)]|_{\mathcal{N}}, \tag{4.4}$$

where the symbol $|_{\mathcal{N}}$ denotes the restriction to the subspace $\mathcal{N}$. Recall that when $n=1$, Γ becomes a constant, so that (4.4) expresses the fact that, in the exceptional case, the two Jost solutions at

k$k=0$ are linearly dependent. Clearly, (4.4) is valid whenever $Q\in L^1_1(\mathbf{R};\mathbf{C}^{n\times n})$. Another representation of Γ that will play a role in this section is only valid when $Q\in L^1_2(\mathbf{R};\mathbf{C}^{n\times n})$. It follows from (2.28) which, for any $\xi\in\mathcal{N}$, implies

$$\chi=\lim_{x\to-\infty} f_{\rm l}(0,x)\xi=\xi+\int_{-\infty}^{\infty} dy\, yQ(y)[f_{\rm l}(0,y)\xi], \tag{4.5}$$

where we have also used (2.33) and the fact that $\Delta_{\rm l}\xi=0$. Note that the integral on the right-hand side of (4.5) exists when $Q\in L^1_1(\mathbf{R};\mathbf{C}^{n\times n})$ because $f_{\rm l}(0,y)\xi$ is bounded. However, without the vector ξ in the integrand, the integral in general does not exist as a matrix-valued integral, because some column vectors of the matrix $f_{\rm l}(0,y)$ may grow linearly as $y\to-\infty$. In fact, according to (2.35), this is always the case unless $\Delta_{\rm l}=0$. On the other hand, if $Q\in L^1_2(\mathbf{R};\mathbf{C}^{n\times n})$, then the integral in (4.5) without the vector ξ in it exists as a matrix-valued integral and, in view of (3.1), we can write $\chi=(I_n+E_{\rm l})\xi$. In other words, we have

$$\Gamma=(I_n+E_{\rm l})|_{\mathcal{N}} \text{ provided } Q\in L^1_2(\mathbf{R};\mathbf{C}^{n\times n}). \tag{4.6}$$

We will also need representations for Γ^{-1}. To this end we assume, without loss of generality, that $f_{\rm l}(0,0)$ is invertible. If not, we can perform a shift of the origin and use the fact that $f_{\rm l}(0,x)$ is invertible for x sufficiently large. We define

$$\mathcal{R}=f_{\rm l}(0,0)^{-1}f_{\rm r}(0,0), \tag{4.7}$$

and note that, by (4.3),

$$\mathcal{R}|_{\mathcal{M}}=\Gamma^{-1}. \tag{4.8}$$

Another representation for Γ^{-1} is obtained by using the integral relation for $f_{\rm r}(0,x)$ given in (2.29). If $Q\in L^1_2(\mathbf{R};\mathbf{C}^{n\times n})$, then, for any $\chi\in\mathcal{M}$, by using (2.29), (2.34), and the fact that $\Delta_{\rm r}\chi=0$, we obtain

$$\xi=\lim_{x\to+\infty} f_{\rm r}(0,x)\chi=\chi-\left[\int_{-\infty}^{\infty} dy\, yQ(y)f_{\rm r}(0,y)\right]\chi,$$

and thus, by (3.1), $\xi=(I_n-E_{\rm r})\chi$. Therefore,

$$\Gamma^{-1}=(I_n-E_{\rm r})|_{\mathcal{M}} \text{ provided } Q\in L^1_2(\mathbf{R};\mathbf{C}^{n\times n}).$$

After these preparations we are ready to begin the analysis of the small-k asymptotics of $\mathbf{S}(k)$ in the exceptional case. We first consider the Wronskian

$$W(k)=[f_{\rm r}(-k^*,x)^\dagger;f_{\rm l}(k,x)],\quad k\in\overline{\mathbf{C}^+},$$

which appears in (2.6) and, as seen from (2.20), is related to the transmission coefficient $T_{\rm l}(k)$ by

$$T_{\rm l}(k)=2ikW(k)^{-1}. \tag{4.9}$$

The method employed here to study $W(k)$ is patterned after that used in Ref. 12 in the scalar case. Unless otherwise stated, we will assume that k is real. This suffices for all the auxiliary results leading up to our main result given in Theorem 4.6. There we will extend the asymptotics from the real axis to $\mathbf{C}^+$ with the help of a Phragmén–Lindelöf theorem.

Using $[f_{\rm l}(0,x)^\dagger;f_{\rm l}(0,x)]=0$ we first write $W(k)$ in the form

$$W(k)=f_{\rm r}(-k,0)^\dagger[f_{\rm l}(0,0)^\dagger]^{-1}\Omega_1+\Omega_2 f_{\rm l}(0,0)^{-1}f_{\rm l}(k,0),$$

where we have defined

$$\Omega_1 = f_l(0,0)^\dagger f_l'(k,0) - f_l'(0,0)^\dagger f_l(k,0),$$

$$\Omega_2 = f_r(-k,0)^\dagger f_l'(0,0) - f_r'(-k,0)^\dagger f_1(0,0).$$

The quantities Ω_1 and Ω_2 can be written as Wronskians by means of a new solution, $\varphi(k,x)$, of (1.1), which is defined by the initial conditions

$$\varphi(k,0) = f_1(0,0), \quad \varphi'(k,0) = f_l'(0,0), \tag{4.10}$$

so that

$$\varphi(0,x) = f_1(0,x). \tag{4.11}$$

Then we have

$$W(k) = f_r(-k,0)^\dagger [f_l(0,0)^\dagger]^{-1} [\varphi(k,x)^\dagger; f_l(k,x)] + [f_r(-k,x)^\dagger; \varphi(k,x)] f_l(0,0)^{-1} f_l(k,0). \tag{4.12}$$

We mention that the particular choice of the solution $\varphi(k,x)$ is motivated by the fact that there is a crucial estimate, namely (A8) of the Appendix, for the difference $[\varphi(k,x) - \varphi(0,x)]\xi$ with $\xi \in \mathcal{N}$, which plays a key role in the proof of the next proposition. Since the proof of this proposition is lengthy, it is given in the Appendix.

Proposition 4.2: Assume $Q \in L^1_m(\mathbf{R}; \mathbf{C}^{n\times n})$ for $m = 1$ or 2. Then, as $k \to 0$ in $\mathbf{R}$ we have

$$[\varphi(k,x)^\dagger; f_l(k,x)] = \sum_{j=1}^{m} k^j Y_j + o(k^m), \tag{4.13}$$

where

$$Y_1 = iI_n, \quad Y_2 = \int_0^\infty dz\, [f_l(0,z)^\dagger f_l(0,z) - I_n],$$

and

$$[f_r(-k,x)^\dagger; \varphi(k,x)] = \sum_{j=0}^{m-1} k^j X_j + o(k^{m-1}), \tag{4.14}$$

with

$$X_0 = \Delta_1, \quad X_1 = i[I_n + E_1].$$

For $\xi \in \mathcal{N}$ we have

$$[f_r(-k,x)^\dagger; \varphi(k,x)]\xi = \sum_{j=1}^{m} k^j \check{X}_j \xi + o(k^m), \tag{4.15}$$

$$\check{X}_1 = i\Gamma, \quad \check{X}_2 = \int_{-\infty}^0 dz\, [f_r(0,z)^\dagger f_r(0,z) - I_n]\Gamma.$$

The notational differences between (4.14) and (4.15) are justified by the fact that in (4.15) the coefficient $\check{X}_1$ is used when $m = 1$, while in (4.14) the corresponding coefficient X_1 is used only when $m = 2$. Of course, if $m = 2$, then $\check{X}_1 = X_1|_{\mathcal{N}}$, by (4.6).

Our first goal is to find the leading terms in the asymptotics of $W(k)^{-1}$ as $k \to 0$. For this purpose it is convenient to temporarily replace the factors multiplying the Wronskians in (4.12) by their limits as $k \to 0$. That is, we consider the simpler expression

$$Z(k)=\mathcal{R}^{\dagger}[\varphi(k,x)^{\dagger};f_{\rm l}(k,x)]+[f_{\rm r}(-k,x)^{\dagger};\varphi(k,x)], \tag{4.16}$$

where we have used (4.7) via its adjoint. In order to further motivate the use of $Z(k)$, we note that on account of (4.12) and (4.16) we can write

$$W(k)^{-1}=f_{\rm l}(k,0)^{-1}f_{\rm l}(0,0)[Z(k)+\Theta_1(k)+\Theta_2(k)]^{-1}, \tag{4.17}$$

where

$$\Theta_1(k)=\mathcal{R}^{\dagger}[\varphi(k,x)^{\dagger};f_{\rm l}(k,x)][f_{\rm l}(k,0)^{-1}f_{\rm l}(0,0)-I_n], \tag{4.18}$$

$$\Theta_2(k)=\{f_{\rm r}(-k,0)^{\dagger}[f_{\rm l}(0,0)^{\dagger}]^{-1}-\mathcal{R}^{\dagger}\}[\varphi(k,x)^{\dagger};f_{\rm l}(k,x)]f_{\rm l}(k,0)^{-1}f_{\rm l}(0,0), \tag{4.19}$$

provided the second inverse on the right-hand side of (4.17) exists. The existence of this inverse will be established below, where we show that $Z(k)^{-1}$ exists for sufficiently small k and satisfies $Z(k)^{-1}=O(1/k)$ as $k\to 0$. This, together with the fact that, in view of (4.13) and Corollary 2.2, $\Theta_1(k)$ and $\Theta_2(k)$ are both $o(k)$ as $k\to 0$, implies

$$W(k)^{-1}=f_{\rm l}(k,0)^{-1}f_{\rm l}(0,0)Z(k)^{-1}\{I_n+[\Theta_1(k)+\Theta_2(k)]Z(k)^{-1}\}^{-1}, \tag{4.20}$$

where the inverse of the matrix inside the braces exists provided k is sufficiently small. This explains why we focus on $Z(k)$ in the next result, which is an immediate consequence of (4.16) and Proposition 4.2.

Corollary 4.3: Suppose that $Q\in L^1_m(\mathbf{R};\mathbf{C}^{n\times n})$ *for* $m=1$ *or* 2. *Then, as* $k\to 0$ *in* $\mathbf{R}$

$$Z(k)=\sum_{j=0}^{m-1}k^jV_j+o(k^{m-1}), \tag{4.21}$$

$$V_0=\Delta_1,\quad V_1=i[I_n+E_1+\mathcal{R}^{\dagger}].$$

Moreover, for $\xi\in\mathcal{N}$, *we have*

$$Z(k)\xi=\sum_{j=1}^{m}k^j\check{V}_j\xi+o(k^m), \tag{4.22}$$

$$\check{V}_1=i[\Gamma+\mathcal{R}^{\dagger}],$$

$$\check{V}_2=\mathcal{R}^{\dagger}\int_0^{\infty}dz\,[f_{\rm l}(0,z)^{\dagger}f_{\rm l}(0,z)-I_n]+\int_{-\infty}^{0}dz\,[f_{\rm r}(0,z)^{\dagger}f_{\rm r}(0,z)-I_n]\Gamma.$$

Now our task is to identify those matrix elements of $Z(k)^{-1}$ that dominate as $k\to 0$. To do this we choose a Jordan basis for Δ_1 as follows. We assume that there are κ Jordan chains indexed by α for $\alpha=1,...,\kappa$, each consisting of n_α vectors $u_{\alpha j}$, with $j=1,...,n_\alpha$, satisfying the relations

$$\begin{cases}(\Delta_1-\lambda_\alpha)u_{\alpha 1}=0,\\ (\Delta_1-\lambda_\alpha)u_{\alpha j}=u_{\alpha(j-1)},\quad j=2,...,n_\alpha.\end{cases} \tag{4.23}$$

Here λ_α is an eigenvalue of Δ_1, $u_{\alpha 1}$ is the corresponding eigenvector belonging to the αth chain, and the vectors $u_{\alpha j}$ with $j\neq 1$ are the generalized eigenvectors. We assume that the eigenvalue 0 of Δ_1 has geometric multiplicity μ and algebraic multiplicity ν; thus $\Sigma_{\alpha=1}^{\mu}n_\alpha=\nu$ and $\mu=\dim\ \mathcal{N}\geqslant 1$. We arrange the vectors of the Jordan basis in a list which is ordered according to the rule that $u_{\alpha j}$ comes before $u_{\beta s}$ if and only if $\alpha<\beta$ or $\alpha=\beta$ and $j<s$. In other words, this is the ''dictionary order'' of the two two-letter words αj and βs. It is necessary to specify an order on the Jordan basis because later we will have to perform certain permutations on these basis vectors.

We further assume that the first μ Jordan chains belong to the eigenvalue 0 of Δ_1 so that $\{u_{11},u_{21},\ldots,u_{\mu 1}\}$ forms a basis for the kernel of Δ_1. We will also need the adjoint Jordan basis $\{w_{\alpha j}\}$ whose vectors, for $\alpha=1,\ldots,\kappa$, satisfy $w_{\alpha j}^{\dagger}u_{\rho t}=\delta_{\alpha\rho}\delta_{jt}$, where $\delta_{\alpha\beta}$ denotes the Kronecker delta, and

$$\begin{cases}(\Delta_{\mathrm{r}}-\lambda_{\alpha}^{*})w_{\alpha n_{\alpha}}=0,\\ (\Delta_{\mathrm{r}}-\lambda_{\alpha}^{*})w_{\alpha j}=w_{\alpha(j+1),}\quad j=1,\ldots,n_{\alpha}-1.\end{cases}$$

Thus the set $\{w_{1n_1},\ldots,w_{\mu n_{\mu}}\}$ forms a basis for the kernel of Δ_{r}. The transition matrix from the standard basis to the Jordan basis will be denoted by $\mathcal{S}$. Given any $n\times n$ matrix M in the standard basis, we use $\tilde{M}$, where $\tilde{M}=\mathcal{S}^{-1}M\mathcal{S}$, to denote the matrix representation of M in the Jordan basis $\{u_{\alpha j}\}$. Then from (4.23) it follows that $\tilde{\Delta}_1$ has the appearance

$$\tilde{\Delta}_1=\bigoplus_{\alpha=1}^{\kappa}J_{n_{\alpha}}(\lambda_{\alpha}),\tag{4.24}$$

where $J_{n_{\alpha}}(\lambda_{\alpha})$ is the Jordan block with λ_{α} appearing on the diagonal and 1 on the first superdiagonal.

In the notation introduced above we can view the pair αj as a ''block index'' in the sense that α indicates the Jordan block (resp. the Jordan chain) to which the vector $u_{\alpha j}$ belongs, and j indicates the position within that block. Generalizing this notation, we will sometimes use block indices to designate the matrix elements of matrices represented in the Jordan basis $\{u_{\alpha j}\}$. Then the matrix elements of $\tilde{M}=\mathcal{S}^{-1}M\mathcal{S}$ in block index notation are given by

$$\tilde{M}_{\beta s;\alpha j}=w_{\beta s}^{\dagger}Mu_{\alpha j}.\tag{4.25}$$

An important observation about $\tilde{Z}(k)$ is that it has μ columns, namely those with ''addresses'' $\alpha 1$ for $\alpha=1,\ldots,\mu$ which are $O(k)$, and these are the only columns with this property. Any other column contains at least one element that tends to a nonzero limit as $k\to 0$. Now, as we shall see below, the entries of $\tilde{Z}(k)$ which determine the leading asymptotic behavior of $\tilde{Z}(k)^{-1}$ as $k\to 0$ form a submatrix of $\tilde{Z}(k)$ consisting of columns $\alpha 1$ and rows βn_{β}, where α and β both belong to $\{1,\ldots,\mu\}$. It is, therefore, convenient to perform suitable permutations of the columns and rows of $\tilde{Z}(k)$ in order to collect these particular matrix elements in a $\mu\times\mu$ diagonal block of a new matrix, called $\mathcal{Z}(k)$. The formal definition of these permutations and their implementation are as follows. Let π_1 be the permutation

$$\pi_1:(1,\ldots,\nu)\mapsto(q_1,\ldots,q_{\nu}),$$

where

$$q_{\tau}=\begin{cases}n_1+\cdots+n_{\tau-1}+1, & \tau=1,\ldots,\mu,\\ \tau-\mu+\alpha, & \tau=\mu+1,\ldots,\nu,\end{cases}\tag{4.26}$$

and $\alpha\in\{1,\ldots,\mu\}$ is the unique integer such that, for given τ and μ,

$$n_1+n_2+\cdots+n_{\alpha-1}-\alpha+j=\tau-\mu,$$

for some $j\in\{2,\ldots,n_{\alpha}\}$. Note that, since $n_{\alpha}\geqslant 1$, the quantity $n_1+n_2+\cdots+n_{\alpha-1}-\alpha$ is a nondecreasing function of α. Similarly, let π_2 be the permutation

$$\pi_2:(1,\ldots,\nu)\mapsto(\sigma_1,\ldots,\sigma_{\nu}),$$

where

$$\sigma_\alpha = \begin{cases} n_1 + \cdots + n_\alpha, & \alpha = 1,...,\mu, \\ \alpha - \mu + \rho - 1, & \alpha = \mu+1,...,\nu, \end{cases} \tag{4.27}$$

and $\rho \in \{1,...,\mu\}$ is the unique integer such that, for given α and μ

$$n_1 + n_2 + \cdots + n_{\rho-1} - \rho + s = \alpha - \mu,$$

for some $s \in \{2,...,n_\rho\}$. To implement these permutations we let $\hat{e}_j$ for $j = 1,...,\nu$ denote the column vectors of the standard basis in $\mathbf{C}^\nu$ and let Π_1 be the $\nu \times \nu$ permutation matrix whose jth column vector is $\hat{e}_{q_j}$, and let Π_2 be the $\nu \times \nu$ permutation matrix whose kth row vector is $\hat{e}^\dagger_{\sigma_k}$. Now observe that, if M is any $\nu \times \nu$ matrix, then the matrix $\Pi_2 M \Pi_1$ can be thought of as being obtained from M by a permutation of the columns according to π_1 and a permutation of the rows according to π_2. In order to apply these operations to $\tilde{Z}(k)$ we define

$$P_1 = \mathrm{diag}\{\Pi_1, I_{n-\nu}\}, \quad P_2 = \mathrm{diag}\{\Pi_2, I_{n-\nu}\},$$

$$\mathcal{Z}(k) = P_2 \tilde{Z}(k) P_1 = P_2 \mathcal{S}^{-1} Z(k) \mathcal{S} P_1, \tag{4.28}$$

and we partition $\mathcal{Z}(k)$ as

$$\mathcal{Z}(k) = \begin{bmatrix} \mathcal{A}(k) & \mathcal{B}(k) \\ \mathcal{C}(k) & \mathcal{D}(k) \end{bmatrix}, \tag{4.29}$$

where $\mathcal{A}(k)$ has size $\mu \times \mu$ and, consequently, $\mathcal{D}(k)$ has size $(n-\mu)\times(n-\mu)$. Then $\mathcal{A}(k)$ coincides with the submatrix of $\tilde{Z}(k)$ consisting of the elements in columns $\alpha 1$ and rows sn_s, where $1 \leqslant \alpha \leqslant \mu$ and $1 \leqslant s \leqslant \mu$. As we have already indicated above, the matrix $\mathcal{A}(k)$ determines the leading asymptotic behavior of $\mathcal{Z}(k)^{-1}$ as $k \to 0$. The next two propositions provide the necessary information about the behavior of the four matrix blocks in (4.29).

Proposition 4.4: Assume $Q \in L^1_m(\mathbf{R}; \mathbf{C}^{n\times n})$ for $m = 1$ or 2. Then the matrices $\mathcal{A}(k)$, $\mathcal{B}(k)$, $\mathcal{C}(k)$, and $\mathcal{D}(k)$ appearing in (4.29) behave near $k = 0$, with $k \in \mathbf{R}$, as

$$\mathcal{A}(k) = \sum_{j=1}^{m} k^j \mathcal{A}_j + o(k^m), \quad \mathcal{B}(k) = \sum_{j=1}^{m-1} k^j \mathcal{B}_j + o(k^{m-1}), \tag{4.30}$$

$$\mathcal{C}(k) = \sum_{j=1}^{m} k^j \mathcal{C}_j + o(k^m), \quad \mathcal{D}(k) = \sum_{j=0}^{m-1} k^j \mathcal{D}_j + o(k^{m-1}), \tag{4.31}$$

where in the expansion for $\mathcal{B}(k)$ the sum is absent when $m = 1$. Moreover, $\mathcal{A}_1$ and $\mathcal{D}_0$ are invertible.

Proof: We give the proof only for $\mathcal{B}(k)$; the proofs for the other matrices are similar. Let e_j for $j = 1,...,n$ denote the standard basis vectors in $\mathbf{C}^n$. Let $s \in \{1,...,\mu\}$ and first suppose that $p \in \{1,...,\nu-\mu\}$. Then we have

$$\mathcal{B}(k)_{sp} = e_s^\dagger \mathcal{Z}(k) e_{\mu+p} = e_s^\dagger P_2 \tilde{Z}(k) P_1 e_{\mu+p} = [\hat{e}^\dagger_{\sigma_s} \ 0] \tilde{Z}(k) \begin{bmatrix} \hat{e}_{q_{\mu+p}} \\ 0 \end{bmatrix}$$

$$= e^\dagger_{\sigma_s} \tilde{Z}(k) e_{q_{\mu+p}} = \tilde{Z}(k)_{\sigma_s q_{\mu+p}} = \tilde{Z}(k)_{sn_s;\alpha j},$$

where α and j are determined by (4.26) with $\tau = \mu + p \leqslant \nu$; hence $2 \leqslant j \leqslant n_\alpha$ and $1 \leqslant \alpha \leqslant \mu$. Thus it follows from (4.25) and Corollary 4.3 that $\mathcal{B}(k)_{sp} = o(1)$ if $m = 1$ and $\mathcal{B}(k)_{sp} = k\mathcal{B}_{1,sp} + o(k)$ if

$m=2$. Specifically, we have $\mathcal{B}_{1,sp}=w^{\dagger}_{sn_s}V_1u_{\alpha j}$, where V_1 is given in (4.21). It remains to consider the matrix elements with $p\in\{n-\nu+1,...,\nu-\mu\}$. Since $P_1e_{\mu+p}=e_{\mu+p}$, we obtain

$$\mathcal{B}(k)_{sp}=\tilde{Z}(k)_{\sigma_s(\mu+p)}=\tilde{Z}(k)_{sn_s;\alpha j}=w^{\dagger}_{sn_s}Z(k)u_{\alpha j},$$

where α and j are determined by the equation $n_1+\cdots+n_{\alpha-1}+j=\mu+p$; note that $\mu+p>\nu$ and thus $\alpha\geqslant\mu+1$. Since $s\leqslant\mu$, by using Corollary 4.3, we conclude that $\mathcal{B}(k)_{sp}=o(1)$ if $m=1$, and $\mathcal{B}(k)_{sp}=k\mathcal{B}_{1,sp}+o(k)$ with $\mathcal{B}_{1,sp}=w^{\dagger}_{sn_s}V_1u_{\alpha j}$ if $m=2$.

To prove that $\mathcal{A}_1$ is invertible we first note that for s and $j\in\{1,...,\mu\}$, we have

$$\mathcal{A}(k)_{sj}=\tilde{Z}(k)_{\sigma_s q_j}=\tilde{Z}(k)_{sn_s;j1}=w^{\dagger}_{sn_s}Z(k)u_{j1},$$

and thus, by (4.21)

$$\mathcal{A}_{1,sj}=w^{\dagger}_{sn_s}V_1u_{j1}=iw^{\dagger}_{sn_s}[\Gamma+\mathcal{R}^{\dagger}]u_{j1}. \tag{4.32}$$

We show that the kernel of the transformation $\mathcal{A}_1:\mathbf{C}^{\mu}\mapsto\mathbf{C}^{\mu}$ is trivial. Suppose there is a vector $(c_1,\ldots,c_{\mu})$ such that $\Sigma_{j=1}^{\mu}\mathcal{A}_{1,sj}c_j=0$ for $s=1,...,\mu$. Let $\xi=\Sigma_{j=1}^{\mu}c_ju_{j1}$ and $\chi=\Gamma\xi$ [cf. (4.2)]. Since $\chi\in\mathcal{M}$, it is a linear combination of the vectors $w_{1n_1},\ldots,w_{\mu n_{\mu}}$ and hence $\chi^{\dagger}V_1\xi=0$. On the other hand, by using (4.7), we obtain

$$\chi^{\dagger}V_1\xi=i\chi^{\dagger}[\Gamma+\mathcal{R}^{\dagger}]\xi=i(\|\chi\|^2+\|\xi\|^2),$$

which is nonzero unless $c_1=\cdots=c_{\mu}=0$. Hence $\mathcal{A}_1$ is invertible. Finally, from (4.28), (4.29), and Corollary 4.3, we get

$$\mathcal{D}_0=\mathrm{diag}\{I_{\nu-\mu},J_{n_{\mu+1}},\ldots,J_{n_{\kappa}}\}, \tag{4.33}$$

where $J_{n_{\alpha}}$ are the matrices appearing in (4.24). Clearly, $\mathcal{D}_0$ is invertible. ■

Next we study the behavior of the inverse of the matrix defined in (4.29) near $k=0$.

Proposition 4.5: Assume $Q\in L^1_m(\mathbf{R};\mathbf{C}^{n\times n})$ for $m=1$ or 2. Then as $k\to0$ in $\mathbf{R}$ we have the following:

(i) *If $m=1$, then*

$$\mathcal{Z}(k)^{-1}=\begin{bmatrix}(1/k)\mathcal{A}_1^{-1}+o(1/k) & o(1/k)\\ -\mathcal{D}_0^{-1}\mathcal{C}_1\mathcal{A}_1^{-1}+o(1) & \mathcal{D}_0^{-1}+o(1)\end{bmatrix}. \tag{4.34}$$

(ii) *If $m=2$, then*

$$\mathcal{Z}(k)^{-1}=\frac{1}{k}\mathcal{Z}_{-1}+\mathcal{Z}_0+o(1), \tag{4.35}$$

where

$$\mathcal{Z}_{-1}=\mathrm{diag}\{\mathcal{A}_1^{-1},0\}, \tag{4.36}$$

$$\mathcal{Z}_0=\begin{bmatrix}-\mathcal{A}_1^{-1}\mathcal{A}_2\mathcal{A}_1^{-1}+\mathcal{A}_1^{-1}\mathcal{B}_1\mathcal{D}_0^{-1}\mathcal{C}_1\mathcal{A}_1^{-1} & -\mathcal{A}_1^{-1}\mathcal{B}_1\mathcal{D}_0^{-1}\\ -\mathcal{D}_0^{-1}\mathcal{C}_1\mathcal{A}_1^{-1} & \mathcal{D}_0^{-1}\end{bmatrix}. \tag{4.37}$$

Proof: We exploit the fact that

$$\begin{bmatrix}I_{\mu} & -\mathcal{B}(k)\mathcal{D}(k)^{-1}\\ 0 & I_{n-\mu}\end{bmatrix}\mathcal{Z}(k)\begin{bmatrix}I_{\mu} & 0\\ -\mathcal{D}(k)^{-1}\mathcal{C}(k) & I_{n-\mu}\end{bmatrix}=\mathrm{diag}\{\mathcal{U}(k),\mathcal{D}(k)\}, \tag{4.38}$$

where

$$\mathcal{U}(k)=\mathcal{A}(k)-\mathcal{B}(k)\mathcal{D}(k)^{-1}\mathcal{C}(k).$$

By (4.30), (4.31), and Proposition 4.4, we have

$$\mathcal{B}(k)\mathcal{D}(k)^{-1}\mathcal{C}(k)=o(k),\quad \mathcal{A}(k)=k\mathcal{A}_1+o(k),$$

with $\det \mathcal{A}_1\neq 0$, and hence we conclude that, for small enough nonzero k, $\mathcal{U}(k)$ is invertible and

$$\mathcal{U}(k)^{-1}=\begin{cases}(1/k)\mathcal{A}_1^{-1}+o(1/k), & m=1,\\ (1/k)\mathcal{A}_1^{-1}-\mathcal{A}_1^{-1}\mathcal{A}_2\mathcal{A}_1^{-1}+\mathcal{A}_1^{-1}\mathcal{B}_1\mathcal{D}_0^{-1}\mathcal{C}_1\mathcal{A}_1^{-1}+o(1), & m=2.\end{cases} \tag{4.39}$$

As a result, from (4.38) we obtain

$$\mathcal{Z}(k)^{-1}=\begin{bmatrix}\mathcal{U}(k)^{-1} & -\mathcal{U}(k)^{-1}\mathcal{B}(k)\mathcal{D}(k)^{-1}\\ -\mathcal{D}(k)^{-1}\mathcal{C}(k)\mathcal{U}(k)^{-1} & \mathcal{D}(k)^{-1}\mathcal{C}(k)\mathcal{U}(k)^{-1}\mathcal{B}(k)\mathcal{D}(k)^{-1}+\mathcal{D}(k)^{-1}\end{bmatrix},$$

and hence (4.34)–(4.37) follow by using (4.30), (4.31), and (4.39). ■

The primary conclusion of Proposition 4.5 is that $\mathcal{Z}(k)^{-1}$ has a $1/k$-singularity at $k=0$ if $\dim \mathcal{N}\geqslant 1$. Therefore, $\tilde{Z}(k)^{-1}$ and $Z(k)^{-1}$ have a similar behavior. Indeed, from (4.28) and (4.35) we infer that

$$Z(k)^{-1}=\sum_{j=0}^{m-1} k^{j-1}Z_{j-1}+o(k^{m-2}),\quad k\to 0 \ \text{ in } \mathbf{R}, \tag{4.40}$$

where

$$Z_{-1}=\mathcal{S}P_1\mathcal{Z}_{-1}P_2\mathcal{S}^{-1},\quad Z_0=\mathcal{S}P_1\mathcal{Z}_0P_2\mathcal{S}^{-1}. \tag{4.41}$$

This leads us to the main result of this section. We will lift the restriction that k be real and allow $k\in\overline{\mathbf{C}^+}$ in the asymptotics of the transmission coefficients.

Theorem 4.6: *Assume* $Q\in L^1_1(\mathbf{R};\mathbf{C}^{n\times n})$ *and* $\dim \mathcal{N}\geqslant 1$. *Then the scattering coefficients are continuous at* $k=0$, *and we have*

$$T_{\mathrm{l}}(k)=2iZ_{-1}+o(1),\quad T_{\mathrm{r}}(k)=-2iZ_{-1}^{\dagger}+o(1),\quad k\to 0 \ \text{ in } \overline{\mathbf{C}^+}, \tag{4.42}$$

$$\operatorname{Im} T_{\mathrm{l}}(0)=\operatorname{Ker}\ \Delta_1,\quad \operatorname{Ker}\ T_{\mathrm{l}}(0)=\operatorname{Im}\Delta_1, \tag{4.43}$$

$$\operatorname{Im} T_{\mathrm{r}}(0)=\operatorname{Ker}\ \Delta_{\mathrm{r}},\quad \operatorname{Ker}\ T_{\mathrm{r}}(0)=\operatorname{Im}\Delta_{\mathrm{r}}, \tag{4.44}$$

$$L(k)=-I_n+\Gamma T_{\mathrm{l}}(0)+o(1),\quad R(k)=-I_n+\Gamma^{-1}T_{\mathrm{l}}(0)^{\dagger}+o(1),\quad k\to 0 \ \text{ in } \mathbf{R}, \tag{4.45}$$

$$\operatorname{Ker}\{I_n+L(0)\}=\operatorname{Ker}\ T_{\mathrm{l}}(0),\quad \operatorname{Ker}\ T_{\mathrm{r}}(0)=\operatorname{Ker}\{I_n+R(0)\}, \tag{4.46}$$

$$\operatorname{Im}\{I_n+L(0)\}=\operatorname{Im} T_{\mathrm{r}}(0),\quad \operatorname{Im}\{I_n+R(0)\}=\operatorname{Im} T_{\mathrm{l}}(0). \tag{4.47}$$

Proof: For $k\in\mathbf{R}$, the continuity of the transmission coefficients and (4.42) follow immediately from (2.25), (4.9), (4.20), (4.40), and (4.41). To extend the asymptotic formulas in (4.42) from $k\in\mathbf{R}$ to $k\in\overline{\mathbf{C}^+}$ we first note that

$$\det W(k)=[\det Z(k)][1+o(1)]=[\det \mathcal{Z}(k)][1+o(1)]=C_0k^{\mu}[1+o(1)],\quad k\to 0 \ \text{ in } \mathbf{R},$$

where $C_0=(-1)^{\nu-\mu}(\det \mathcal{A}_1)(\det\ \mathcal{D}_0)\neq 0$. This follows from (4.20), (4.28), (4.30), (4.36), (4.38), Proposition 4.4, and the fact that $(\det P_1)(\det P_2)=(-1)^{\nu-\mu}$. It follows that $k^{-\mu}\det W(k)\to C_0$ as

$k\to 0$ along the real axis. Since $\det W(k)$ extends as an analytic function to $\mathbf{C}^+$, there is a constant C such that $|k^{-\mu}\det W(k)|\leq C|k|^{-\mu}$ for k near 0 in $\overline{\mathbf{C}^+}$. Appealing to some theorems of Phragmén–Lindelöf (e.g., Theorems 1.4.1–1.4.4 in Ref. 14) we conclude that $k^{-\mu}\det W(k)\to C_0$ as $k\to 0$ in $\overline{\mathbf{C}^+}$. Thus there is a set $\Sigma_\epsilon=\{k\in\overline{\mathbf{C}^+}: 0<|k|<\epsilon\}$, with ϵ sufficiently small, on which $|\det W(k)|\geq C_1|k|^{\mu}$ for some constant C_1. Recalling the cofactor representation of the inverse of a matrix we conclude that

$$\|W(k)^{-1}\|\leq C_2|k|^{-\mu},\quad k\in\Sigma_\epsilon,$$

for some constant C_2. Since $T_l(k)\to T_l(0)$ as $k\to 0$ along the real axis, we can apply a Phragmén–Lindelöf theorem to $2ikW(k)^{-1}$ and conclude that, by (4.9), $T_l(k)\to T_l(0)$ as $k\to 0$ in $\overline{\mathbf{C}^+}$. This, together with (2.25), completes the proof of (4.42).

To prove (4.43) we note that (4.24) and (4.26) imply Ker $\tilde{\Delta}_l=\mathrm{Span}\{e_{q_1},\ldots,e_{q_\mu}\}$. Thus, in view of the form of $\mathcal{Z}_{-1}$ given in (4.36), we have

$$\mathrm{Im}\{P_1\mathcal{Z}_{-1}P_2\}=P_1\left\{\begin{bmatrix}u\\0\end{bmatrix}: u\in\mathbf{C}^\mu\right\}=P_1\mathrm{Span}\{e_1,\ldots,e_\mu\}=\mathrm{Ker}\ \tilde{\Delta}_l.$$

Since $\Delta_l=\mathcal{S}\tilde{\Delta}_l\mathcal{S}^{-1}$, the first equality in (4.43) follows from (4.41) and (4.42). To prove the second equality we note that

$$\mathrm{Im}\,\tilde{\Delta}_l=\mathrm{Span}\{e_k:\ k\notin\{\sigma_1,\ldots,\sigma_\mu\}\},$$

which follows from (4.24) and (4.25). Therefore,

$$\begin{aligned}\mathrm{Ker}\{\mathcal{Z}_{-1}P_2\}&=\left\{w\in\mathbf{C}^n: P_2w=\begin{bmatrix}0\\v\end{bmatrix},\quad v\in\mathbf{C}^{n-\mu}\right\}\\&=\{w\in\mathbf{C}^n: e_k^\dagger P_2w=0,\quad k=1,...,\mu\}\\&=\{w\in\mathbf{C}^n: e_{\sigma_k}^\dagger w=0,\quad k=1,...,\mu\}\\&=\mathrm{Im}\,\tilde{\Delta}_l.\end{aligned}$$

This implies Ker $T_l(0)=\mathrm{Im}\,\Delta_l$ and thus the second equality in (4.43) is proved. The equalities in (4.44) follow from (4.43) by taking adjoints and using the fact that $(\mathrm{Ker}\ M)^\perp=\mathrm{Im}\,M^\dagger$ for any $n\times n$ matrix M.

To prove the remaining assertions we use

$$f_l(k,x)T_l(k)=f_r(-k,x)+f_r(k,x)L(k),\quad k\in\mathbf{R}\backslash\{0\},\tag{4.48}$$

$$f_r(k,x)T_r(k)=f_l(-k,x)+f_l(k,x)R(k),\quad k\in\mathbf{R}\backslash\{0\},\tag{4.49}$$

which can be derived with the help of (1.4) and (1.5). From (4.48) and the continuity of $T_l(k)$ it immediately follows that $L(k)$ is continuous at $k=0$ and we have

$$f_r(0,x)[I_n+L(0)]=f_l(0,x)T_l(0).\tag{4.50}$$

Now choose x such that $f_r(0,x)$ is invertible and multiply (4.50) from the left by $f_r(0,x)^{-1}$. Owing to (4.4) and the first equation in (4.43), we can replace $f_r(0,x)^{-1}f_l(0,x)$ by Γ. Hence the first relation in (4.45) follows. Similarly, the second relation in (4.45) is obtained from (4.49). The two equalities in (4.46) are immediate consequences of (4.45). Finally, (4.47) follows from (4.43), (4.45), and Proposition 4.1. ■

From (4.43), (4.44), Proposition 2.4(i), and Theorem 3.1 we infer that the exceptional case occurs if and only if $T_l(0)\neq 0$. Moreover, (4.43), (4.46), and Theorem 3.1 show that $L(0)$ and $R(0)$ each have eigenvalue -1 if and only if $\Delta_l\neq 0$. In view of (2.23) and (2.24) we also have $\|L(0)\|=\|R(0)\|=1$ if and only if $\Delta_l\neq 0$. The case $\Delta_l=0$ can be called the purely exceptional case because then we have $\mathcal{N}=\mathcal{M}=\mathbf{C}^n$. This case is further analyzed in Example 5.4 of the next section.

Theorem 4.7: *Assume* $Q\in L^1_2(\mathbf{R};\mathbf{C}^{n\times n})$ *and* $\dim\mathcal{N}\geqslant 1$. *Then the scattering coefficients are differentiable at* $k=0$ *and*

$$T_l(k)=T_l(0)+k\dot{T}_l(0)+o(k),\quad k\to 0\ \text{ in }\ \overline{\mathbf{C}^+},\tag{4.51}$$

with

$$\dot{T}_l(0)=2i[Z_0-f_l^{-1}(0,0)\dot{f}_l(0,0)Z_{-1}+iH_1+iH_2],\tag{4.52}$$

where Z_{-1} *and* Z_0 *are given in (4.41) and*

$$H_1=Z_{-1}\mathcal{R}^\dagger f_l^{-1}(0,0)\dot{f}_l(0,0)Z_{-1},\quad H_2=Z_{-1}\dot{f}_r(0,0)^\dagger[f_l(0,0)^\dagger]^{-1}Z_{-1}.$$

Moreover,

$$T_r(k)=T_l(0)^\dagger-k^*\dot{T}_l(0)^\dagger+o(k),\quad k\to 0\ \text{ in }\ \overline{\mathbf{C}^+},$$

$$L(k)=-I_n+(I_n+E_l)T_l(0)+k\dot{L}(0)+o(k),\quad k\to 0\ \text{ in }\ \mathbf{R},$$

$$R(k)=-I_n+(I_n-E_r)T_r(0)+k\dot{R}(0)+o(k),\quad k\to 0\ \text{ in }\ \mathbf{R},$$

where E_l *and* E_r *are as in (3.1) and*

$$\dot{L}(0)=[I_n+E_l]\dot{T}_l(0)+i[\dot{f}_r(0,x)^\dagger;\dot{f}_l(0,x)]T_l(0),$$

$$\dot{R}(0)=[I_n-E_r]\dot{T}_r(0)-i[\dot{f}_l(0,x)^\dagger;\dot{f}_r(0,x)]T_r(0).$$

Proof: To prove (4.51) and (4.52) for $k\to 0$ in $\mathbf{R}$, we first note the expansions

$$f_l(k,0)^{-1}f_l(0,0)=I_n-kf_l(0,0)^{-1}\dot{f}_l(0,0)+o(k),$$

$$f_r(-k,0)^\dagger[f_l(0,0)^\dagger]^{-1}=\mathcal{R}^\dagger-k\dot{f}_r(0,0)^\dagger[f_l(0,0)^\dagger]^{-1}+o(k),$$

$$\Theta_1(k)=-ik^2\mathcal{R}^\dagger f_l(0,0)^{-1}\dot{f}_l(0,0)+o(k^2),$$

$$\Theta_2(k)=-ik^2\dot{f}_r(0,0)^\dagger[f_l(0,0)^\dagger]^{-1}+o(k^2),$$

which follow from (4.18), (4.19), together with (4.7) and Proposition 4.2. Inserting these expansions in (4.20) and using (4.9) we obtain (4.51) and (4.52). As with (4.42) we can use a Phragmén–Lindelöf argument to extend the result to $\overline{\mathbf{C}^+}$. To find the expansions for $L(k)$ and $R(k)$ we first note that the existence of $\dot{T}_l(0)$, together with (4.48) and (4.49), implies the existence of $\dot{L}(0)$ and $\dot{R}(0)$. Differentiating (4.48) with respect to k and taking the Wronskian with $\dot{f}_r(0,x)^\dagger$, we obtain

$$[\dot{f}_r(0,x)^\dagger;f_r(0,x)]\dot{L}(0)=[\dot{f}_r(0,x)^\dagger;\dot{f}_l(0,x)]T_l(0)+[\dot{f}_r(0,x)^\dagger;f_l(0,x)]\dot{T}_l(0),\tag{4.53}$$

where we have used $[\dot{f}_{\rm r}(0,x)^\dagger;\dot{f}_{\rm r}(0,x)]=0$. Using the integral relation (2.29) and that for $\dot{f}_{\rm r}(0,x)$ [cf. (A.20)] we obtain $[\dot{f}_{\rm r}(0,x)^\dagger;f_{\rm r}(0,x)]=-iI_{\rm n}$. Inserting this together with (3.6) in (4.53) and using (4.47) we get the expansion for $L(k)$. The proof of the expansion for $R(k)$ is similar. ■

V. EXAMPLES

In this section we consider some special cases that illustrate various details of the analysis in Sec. IV. With the exception of Example 5.4 we only consider $T_{\rm l}(k)$.

Example 5.1: Let $n=1$ with $Q\in L_2^1(\mathbf{R})$ and assume the exceptional case occurs. Then $Z(k)=\tilde{Z}(k)=\mathcal{Z}(k)=\mathcal{A}(k)$, and these are all scalar functions. We choose $\xi=1=w$ and put $\gamma=\Gamma=f_{\rm l}(0,0)/f_{\rm r}(0,0)$, where now γ is a real nonzero constant. Since $T_{\rm l}(k)=T_{\rm r}(k)$, we denote the transmission coefficient by $T(k)$. By (4.32) we have $\mathcal{A}_1=i(\gamma^2+1)/\gamma$,

$$\mathcal{A}_2=\gamma^{-1}\int_0^\infty dz\,[f_{\rm l}(0,z)^\dagger f_{\rm l}(0,z)-I_n]+\gamma\int_{-\infty}^0 dz\,[f_{\rm r}(0,z)^\dagger f_{\rm r}(0,z)-I_n],$$

so that

$$T(k)=\frac{2\gamma}{\gamma^2+1}+\frac{2ik\gamma\Xi}{(\gamma^2+1)^2}+o(k),\quad k\to 0\ \text{ in }\ \overline{\mathbf{C}^+},\tag{5.1}$$

where we have defined

$$\Xi=\gamma[\dot{f}_{\rm r}(0,x);\dot{f}_{\rm l}(0,x)]+\int_0^\infty dz\,[f_{\rm l}(0,z)^2-1]+\gamma^2\int_{-\infty}^0 dz\,[f_{\rm r}(0,z)^2-1].$$

In deriving (5.1) we have used the identity

$$\frac{\dot{f}_{\rm l}(0,x)}{f_{\rm r}(0,x)}+\frac{\dot{f}_{\rm r}(0,x)}{f_{\rm l}(0,x)}=-i[\dot{f}_{\rm r}(0,x);\dot{f}_{\rm l}(0,x)],\tag{5.2}$$

which can be verified as follows. Since $f_{\rm r}(0,x)$ and $\dot{f}_{\rm r}(0,x)$ are linearly independent solutions of (2.26), we can write

$$\dot{f}_{\rm l}(0,x)=c_1 f_{\rm r}(0,x)+c_2\dot{f}_{\rm r}(0,x),$$

and evaluate c_1 and c_2 as

$$c_1=-i[\dot{f}_{\rm r}(0,0);\dot{f}_{\rm l}(0,0)],\quad c_2=-\frac{1}{\gamma},$$

so that (5.2) follows. It seems that the expansion (5.1) is new under the assumption $Q\in L_2^1(\mathbf{R})$.

Example 5.2: Assume $Q\in L_1^1(\mathbf{R};\mathbf{C}^{n\times n})$ and suppose that $\tilde{\Delta}_1$ consists of one single Jordan block of size $n\geqslant 2$ associated with the eigenvalue 0. Thus $\kappa=1$, $\mu=1$, and $n=n_1=\nu$.

In this case we can simplify the notation by setting $u_{1j}=u_j$, for $j=1,...,n$. Then u_1 is the eigenvector for the eigenvalue 0 of Δ_1, that is $\mathcal{N}=\text{Span}\{u_1\}$. The adjoint basis is $\{w_1,\ldots,w_n\}$ and we have $\mathcal{M}=\text{Span}\{w_n\}$. The mapping Γ maps u_1 to a multiple of w_n, i.e., $\Gamma_{u1}=c_3 w_n$ for some $c_3\neq 0$. Moreover, $\mathcal{A}(k)$ is a scalar function and from (4.32) we obtain

$$\mathcal{A}_1=\frac{i}{c_3^*}(|c_3|^2\|w_n\|^2+\|u_1\|^2),$$

where we have used (4.7) via $\mathcal{R}w_n=(1/c_3)u_1$. The permutation matrices appearing in (4.28) are given by

$$P_1=I_n, \quad P_2=\begin{bmatrix} 0 & 0 & \dots & 0 & 1 \\ 1 & 0 & \dots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \dots & 0 & 0 \\ 0 & 0 & \dots & 1 & 0 \end{bmatrix}.$$

Using (4.41) and (4.42) we obtain

$$\tilde{T}_1(0)=\begin{bmatrix} 0 & 0 & \dots & 0 & 2/c_4 \\ 0 & 0 & \dots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \dots & 0 & 0 \\ 0 & 0 & \dots & 0 & 0 \end{bmatrix},$$

where

$$c_4=\frac{1}{c_3^*}(|c_3|^2\|w_n\|^2+\|u_1\|^2), \quad \tilde{T}_1(0)=\mathcal{S}^{-1}T_1(0)\mathcal{S}.$$

Example 5.3: This example illustrates the situation where $\tilde{\Delta}_1$ in (4.24) consists of two Jordan blocks. We assume $Q\in L_1^1(\mathbf{R};\mathbf{C}^{n\times n})$ and let $n=3$, $\mu=2$, $n_1=1$, $n_2=2$, $\nu=3$, and $\kappa=2$, so that Δ_1 has the Jordan form

$$\tilde{\Delta}_1=\begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{bmatrix}.$$

The Jordan basis is $\{u_{11},u_{21},u_{22}\}$, where $\{u_{11},u_{21}\}$ is a basis for $\mathcal{N}$, and the adjoint basis is $\{w_{11},w_{21},w_{22}\}$, where $\{w_{11},w_{22}\}$ is a basis for $\mathcal{M}$. In this case the rows of $\tilde{Z}(k)$ need to be permuted according to $\pi_2\colon(1,2,3)\mapsto(1,3,2)$, whereas no permutation of the columns is required. Thus we have

$$P_1=I_3, \quad P_2=\begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix}.$$

Then $\mathcal{A}(k)$ is a 2×2 matrix and

$$\mathcal{A}_1=\begin{bmatrix} w_{11}^\dagger V_1 u_{11} & w_{11}^\dagger V_1 u_{21} \\ w_{22}^\dagger V_1 u_{11} & w_{22}^\dagger V_1 u_{21} \end{bmatrix},$$

where V_1 is given in (4.21). Hence we obtain

$$\tilde{T}_1(0)=\frac{1}{\det \mathcal{A}_1}\begin{bmatrix} w_{22}^\dagger V_1 u_{21} & 0 & -w_{11}^\dagger V_1 u_{21} \\ -w_{22}^\dagger V_1 u_{11} & 0 & w_{11}^\dagger V_1 u_{11} \\ 0 & 0 & 0 \end{bmatrix}.$$

Example 5.4: This is the purely exceptional case mentioned above Theorem 4.7. We assume $Q \in L_1^1(\mathbf{R};\mathbf{C}^{n\times n})$ with $n>1$. We have $\Delta_1=0$, which implies $\mu=\nu=\kappa=n$. Then $\mathcal{N}=\mathcal{M}=\mathbf{C}^n$, and thus no restrictions are necessary in (4.4) and (4.8); that is, we have $\mathcal{R}=\Gamma^{-1}$. Moreover, $P_1=P_2=I_n$. It follows that

$$\mathcal{A}_1=i\mathcal{S}^{-1}[\Gamma+(\Gamma^{-1})^\dagger]\mathcal{S},$$

and thus, since $\mathcal{Z}_{-1}=\mathcal{A}_1^{-1}$, we obtain

$$T_l(0)=2i\mathcal{S}(\mathcal{S}\mathcal{A}_1)^{-1}=2\Gamma^\dagger(\Gamma\Gamma^\dagger+I_n)^{-1}.$$

For the reflection coefficients, after some straightforward manipulations, we find

$$L(0)=(\Gamma\Gamma^\dagger-I_n)(\Gamma\Gamma^\dagger+I_n)^{-1},\quad R(0)=(I_n-\Gamma^\dagger\Gamma)(\Gamma^\dagger\Gamma+I_n)^{-1}.$$

Example 5.5: Suppose $Q(x)$ is even and belongs to $L_1^1(\mathbf{R};\mathbf{C}^{n\times n})$. This implies that $f_r(0,x)=f_l(0,-x)$ and from (2.31), (2.33), and (2.34) we conclude that Δ_1 is self-adjoint. Hence Δ_1 is diagonalizable and there are no Jordan chains of length greater than 1. We have $\mu=\nu$, $n_\alpha=1$ for $1\leqslant\alpha\leqslant\kappa$, and $\kappa=n$. We also have $P_1=P_2=I_n$. It is possible that Δ_1 has some nonzero eigenvalues, so $\mu<n$ in general. If $\xi\in\mathcal{N}$, then

$$f_l(0,x)\xi=f_r(0,-x)\xi,$$

which implies that $f_r(0,x)\xi$ is bounded. This means $\xi\in\mathcal{M}$ and hence $\mathcal{N}=\mathcal{M}$. Furthermore, using (4.2) and (4.3) we conclude that

$$f_l(0,x)\chi=f_r(0,-x)\chi=f_l(0,-x)\xi, \tag{5.3}$$

where $\xi\in\mathcal{N}$ and $\chi=\Gamma\xi$. Letting $x\to-\infty$, we see that $\Gamma\chi=\xi$, that is

$$\Gamma^2=I_\mu. \tag{5.4}$$

It follows that Γ is diagonalizable because $(I_\mu\pm\Gamma)^p=2^{p-1}(I_\mu\pm\Gamma)$ for $p\geqslant1$ and has eigenvalues ±1. Let $\epsilon_\pm$ denote the corresponding multiplicities ($\epsilon_++\epsilon_-=\mu$). Since $n_\alpha=1$, we put $u_{\alpha1}=u_\alpha$ for the vectors of the Jordan basis for Δ_1 and assume that they are normalized and arranged such that

$$\Gamma u_\alpha=u_\alpha,\quad \alpha=1,...,\epsilon_+,$$

$$\Gamma u_\alpha=-u_\alpha,\quad \alpha=\epsilon_++1,...,\mu.$$

We also set $w_{sn_s}=w_s$, so that $w_s^\dagger u_\alpha=\delta_{s\alpha}$ for $s=1,...,n$ and $\alpha=1,...,n$. Note that as a consequence of (5.3), $\epsilon_+(\epsilon_-)$ is the number of linearly independent bounded even (odd) solutions of (2.26). Then from (4.8) and (5.4) we conclude that

$$w_s^\dagger\mathcal{R}^\dagger u_\alpha=(\Gamma^{-1}w_s)^\dagger u_\alpha=(\Gamma w_s)^\dagger u_\alpha=w_s^\dagger\Gamma^\dagger u_\alpha, \tag{5.5}$$

where $\Gamma^\dagger$ is the adjoint of Γ as a mapping from $\mathcal{N}$ to itself. Using (5.5) in (4.32) we obtain $\mathcal{A}_{1,sj}=iw_s^\dagger[\Gamma+\Gamma^\dagger]u_j$, and therefore

$$(\mathcal{A}_1^{-1})_{sj}=-iw_s^\dagger[\Gamma+\Gamma^\dagger]^{-1}u_j.$$

As a result, from (4.36), (4.41), and (4.42) we deduce that

$$T_l(0)=[2(\Gamma+\Gamma^\dagger)^{-1}]\oplus0,$$

where the direct sum refers to the direct decomposition $\mathbf{C}^n=\mathcal{N}\oplus\mathcal{N}'$ with

$$\mathcal{N}' = \mathrm{Span}\{u_{\mu+1},\ldots,u_n\}.$$

APPENDIX: PROOF OF PROPOSITION 4.2

Proof: Since the assertions of Proposition 4.2 concern the small-k asymptotics, we assume that k lies in a fixed interval $[-\delta, \delta]$ with $\delta > 0$. In the following C is used to denote various constants that may depend on the choice of δ but not on k or x.

The solution $\varphi(k,x)$ of (1.1) defined by the initial conditions (4.10) satisfies the integral equation

$$\varphi(k,x) = f_1(0,0)\cos kx + f_1'(0,0)\left(\frac{\sin kx}{k}\right) + \frac{1}{k}\int_0^x dy\, \sin[k(x-y)]Q(y)\varphi(k,y), \tag{A1}$$

which can be solved by iteration. A standard Gronwall inequality shows that

$$\|\varphi(k,x)\| \leqslant C(1+|x|), \quad x \in \mathbf{R}. \tag{A2}$$

Therefore, by using (A1) and (A2), it follows that for each $k \in \mathbf{R}\backslash\{0\}$ we have

$$\varphi(k,x) = \alpha_\pm(k)e^{ikx} + \beta_\pm(k)e^{-ikx} + \epsilon_\pm(k,x), \tag{A3}$$

where $\epsilon_\pm(k,x)$ and $\epsilon_\pm'(k,x)$ are both $o(1)$ as $x \to \pm\infty$, and where

$$\alpha_\pm(k) = \frac{1}{2}f_1(0,0) + \frac{1}{2ik}f_1'(0,0) + \frac{1}{2ik}\int_0^{\pm\infty} dy\, e^{-iky}Q(y)\varphi(k,y), \tag{A4}$$

$$\beta_\pm(k) = \frac{1}{2}f_1(0,0) - \frac{1}{2ik}f_1'(0,0) - \frac{1}{2ik}\int_0^{\pm\infty} dy\, e^{iky}Q(y)\varphi(k,y).$$

From (A3) and (A4), together with (1.2) and (1.3), it follows that:

$$[\varphi(k,x)^\dagger; f_1(k,x)] = 2ik\alpha_+(k)^\dagger = ikf_1(0,0)^\dagger - f_1'(0,0)^\dagger - \int_0^\infty dz\, e^{ikz}\varphi(k,z)^\dagger Q(z), \tag{A5}$$

$$[f_r(-k,x)^\dagger; \varphi(k,x)] = 2ik\alpha_-(k) = ikf_1(0,0) + f_1'(0,0) - \int_{-\infty}^0 dz\, e^{-ikz}Q(z)\varphi(k,z). \tag{A6}$$

In order to control the remainder terms in the subsequent asymptotic expansions, we will need the estimates

$$\|\varphi(k,x) - \varphi(0,x)\| \leqslant C(1+\max\{0,-x\})\left(\frac{kx}{1+|k||x|}\right)^2, \tag{A7}$$

$$\|[\varphi(k,x) - \varphi(0,x)]\xi\| \leqslant C\left(\frac{kx}{1+|k||x|}\right)^2\|\xi\|, \quad \xi \in \mathcal{N}. \tag{A8}$$

The term $\max\{0,-x\}$ in (A7) accounts for the fact that $\varphi(0,x)$ is in general unbounded and $O(x)$ as $x \to -\infty$. In (A8), this term is absent because $\varphi(0,x)\xi$ is bounded when $\xi \in \mathcal{N}$. We omit the

proofs of (A7) and (A8) here because (A7) follows from (A1) by some standard estimates and (A8) can be proved by mimicking the proof in the scalar case (see Lemma 2.2 in Ref. 12).

Now consider the integral on the right-hand side of (A5) and write it as

$$\int_0^\infty dz\, e^{ikz}\varphi(k,z)^\dagger Q(z)=A_1(k)+A_2(k), \tag{A9}$$

where

$$A_1(k)=\int_0^\infty dz\, e^{ikz}\varphi(0,z)^\dagger Q(z), \tag{A10}$$

$$A_2(k)=\int_0^\infty dz\, e^{ikz}[\varphi(k,z)^\dagger-\varphi(0,z)^\dagger]Q(z). \tag{A11}$$

When $m=1$, from (A.10) we get

$$\begin{cases} A_1(k)=\displaystyle\int_0^\infty dz\,\varphi(0,z)^\dagger Q(z)+ik\int_0^\infty dz\, z\varphi(0,z)^\dagger Q(z)+\mathcal{F}(k), \\ \qquad =-f_1'(0,0)^\dagger+ik[f_1(0,0)^\dagger-I_n]+\mathcal{F}(k), \end{cases} \tag{A12}$$

where

$$\mathcal{F}(k)=\int_0^\infty dz\,(e^{ikz}-1-ikz)\varphi(0,z)^\dagger Q(z). \tag{A13}$$

Note that $\mathcal{F}(k)$ is $o(k)$ by (4.11), the boundedness of $f_1(0,z)$ on $[0,+\infty)$, and the estimate

$$|e^{ikz}-1-ikz|\leqslant\frac{Cz^2}{1+z},\quad z\geqslant 0.$$

In deriving (A12) we have also used the relations

$$\begin{cases} \displaystyle\int_0^\infty dz\,\varphi(0,z)^\dagger Q(z)=-f_1'(0,0)^\dagger, \\ \displaystyle\int_0^\infty dz\, z\varphi(0,z)^\dagger Q(z)=f_1(0,0)^\dagger-I_n, \end{cases} \tag{A14}$$

which follow from (2.28). Using (A7) in (A11) we see that

$$A_2(k)=o(k). \tag{A15}$$

Combining (A5), (A9), (A12), and (A15) we obtain

$$[\varphi(k,x)^\dagger;f_1(k,x)]=ikI_n+o(k),$$

which agrees with (4.13) for $m=1$.

Now consider (A5) for $m=2$, that is, $Q\in L_2^1(\mathbf{R};\mathbf{C}^{n\times n})$. In this case we can expand the remainder $\mathcal{F}(k)$ in (A12) as

$$\mathcal{F}(k)=\int_0^\infty dz\,\frac{(ikz)^2}{2}\varphi(0,z)^\dagger Q(z)+o(k^2), \tag{A16}$$

where we have used (A7), (A13), and the estimate

$$\left| e^{ikz} - 1 - ikz + \frac{k^2 z^2}{2} \right| \leqslant \frac{C(|k|z)^3}{1+|k|z}, \quad z \geqslant 0.$$

The integral in (A16) can be expressed in a form that does not involve Q explicitly. To see this, substitute $\varphi''(0,z)^\dagger$ for $\varphi(0,z)^\dagger Q(z)$ and replace the upper limit of integration by N. Then integrate by parts twice and let $N \to +\infty$. This gives

$$-\frac{k^2}{2}\left[\int_0^\infty dz\, z^2 \varphi''(0,z) \right]^\dagger = -\frac{k^2}{2} \lim_{N\to+\infty} \mathcal{G}_N^\dagger = -k^2 \int_0^\infty dz\, [f_1(0,z)^\dagger - I_n],$$

where we have defined

$$\mathcal{G}_N = N^2 \varphi'(0,N) - 2N[\varphi(0,N) - I_n] + 2\int_0^N dz\, [\varphi(0,z) - I_n].$$

Thus

$$\mathcal{F}(k) = -k^2 \int_0^\infty dz\, [f_1(0,z)^\dagger - I_n] + o(k^2). \tag{A17}$$

In the derivation of (A17) we have also used

$$\varphi'(0,N) = o(1/N^2), \quad \varphi(0,N) - I_n = o(1/N), \quad \varphi(0,N) - I_n \in L^1(\mathbf{R}^+; \mathbf{C}^{n\times n}). \tag{A18}$$

These properties follow directly from (2.28) and (4.11). The expression (A17) for $\mathcal{F}(k)$ has the advantage that it allows us to combine $\mathcal{F}(k)$ with another term that arises from the expansion of $A_2(k)$. To see this we return to (A11). In order to expand the difference $\varphi(k,x) - \varphi(0,x)$, we use the variation of parameters formula in the form

$$\varphi(k,x) = \varphi(0,x) + ik^2 f_1(0,x) \int_0^x dz\, \dot{f}_1(0,z)^\dagger \varphi(k,z) + ik^2 \dot{f}_1(0,x) \int_0^x dz\, f_1(0,z)^\dagger \varphi(k,z). \tag{A19}$$

We briefly mention some details of the derivation of (A19) because there is a useful identity that falls out in the process. We write (2.26) as a first-order system with $2n$ components and note that a fundamental matrix $\Psi(x)$ for this system and its inverse $\Psi(x)^{-1}$ are given by

$$\Psi(x) = \begin{bmatrix} f_1(0,x) & \dot{f}_1(0,x) \\ f_1'(0,x) & \dot{f}_1'(0,x) \end{bmatrix}, \quad \Psi(x)^{-1} = i \begin{bmatrix} \dot{f}_1'(0,x)^\dagger & -\dot{f}_1(0,x)^\dagger \\ f_1'(0,x)^\dagger & -f_1(0,x)^\dagger \end{bmatrix}.$$

By taking $x \to +\infty$ and using (2.4), one can prove that $\det \Psi(x) = i$. For this and also later we need to use certain asymptotic information about the functions $\dot{f}_1(0,x)$ and $\dot{f}_1'(0,x)$. It suffices to mention that $\dot{f}_1(0,x)$ is the unique solution of the integral equation

$$\dot{f}_1(0,x) = ixI_n + \int_x^\infty dy\, (y-x) Q(y) \dot{f}_1(0,y), \tag{A20}$$

which, incidentally, shows that $\dot{f}_1(0,x)$ is also a matrix solution of (2.26). Moreover, a Gronwall inequality gives

$$\|\dot{f}_1(0,x)\| \leqslant C(1+|x|), \quad x \in \mathbf{R}. \tag{A21}$$

The identity $\Psi(x)^{-1}\Psi(x) = I_{2n}$ is easily verified by using the Wronskian relations

$$[f_1(0,x)^\dagger; f_1(0,x)] = [\dot{f}_1(0,x)^\dagger; \dot{f}_1(0,x)] = 0,$$

$$[f_1(0,x)^\dagger; \dot{f}_1(0,x)] = [\dot{f}_1(0,x)^\dagger; f_1(0,x)] = iI_n,$$

which follow from (2.28), (A20), and the first formula in (A18) which indicates that $f_1'(0,x) = o(1/x^2)$ as $x \to +\infty$. Then (A19) is an easy consequence of the variation of parameters formula for first-order systems. The useful identity alluded to above appears when we write out the identity $\Psi(x)\Psi(x)^{-1} = I_{2n}$ (in this order!) in terms of the entries of the matrices involved. Among the resulting identities we find

$$f_1'(0,x)\dot{f}_1(0,x)^\dagger + \dot{f}_1'(0,x) f_1(0,x)^\dagger = iI_n,$$

which will be useful later.

By iterating (A19) once and using (4.11) we obtain

$$\varphi(k,x) = \varphi(0,x) + ik^2 f_1(0,x) \int_0^x dz\, \dot{f}_1(0,z)^\dagger f_1(0,z) + ik^2 \dot{f}_1(0,x) \int_0^x dz\, f_1(0,z)^\dagger f_1(0,z) + \rho(k,x), \tag{A22}$$

where $\rho(k,x)$ obeys

$$\|\rho(k,x)\| \leq Ck^2(1+|x|)^2 \left(\frac{kx}{1+|k|x|} \right)^2. \tag{A23}$$

This estimate follows by using (A7) and (A21). Taking the adjoint of $A_2(k)$ given in (A11) and expanding the exponential function there we get

$$A_2(k)^\dagger = \int_0^\infty dz\, Q(z)[\varphi(k,z) - \varphi(0,z)] + o(k^2), \tag{A24}$$

where we have used (A7) to determine the order of the error term. Now we insert (A22) into (A24) and proceed as in the derivation of (A17), using $\dot{f}_1''(0,x) = Q(x)\dot{f}_1(0,x)$ and two integrations by parts. We also use (A21), (A23), and the property $\dot{f}_1'(0,N) - iI_n = o(1/N)$ as $N \to +\infty$, which follows from (A20). The result is

$$\int_0^\infty dz\, Q(z)[\varphi(k,z) - \varphi(0,z)] = k^2 \int_0^\infty dz\, [f_1(0,z) - I_n] - k^2 \int_0^\infty dz\, [f_1(0,z)^\dagger f_1(0,z) - I_n] + o(k^2). \tag{A25}$$

Combining (A9), (A12), (A17), (A24), and (A25) we obtain

$$[\varphi(k,x)^\dagger; f_1(k,x)] = ikI_n + k^2 \int_0^\infty dz\, [f_1(0,z)^\dagger f_1(0,z) - I_n] + o(k^2),$$

which is the desired result in (4.13) for $m = 2$.

To prove (4.14) we return to the Wronskian in (A6). If $m = 1$, we have

$$\begin{cases} \displaystyle\int_{-\infty}^0 dz\, e^{-ikz} Q(z)\varphi(k,z) = \int_{-\infty}^0 dz\, Q(z)\varphi(0,z) + o(1), \\ \qquad\qquad = -\Delta_1 + f_1'(0,0) + o(1), \end{cases} \tag{A26}$$

where we have used (2.28) and (A14). The order of the error term is again a consequence of (A7). Substituting (A26) in (A6) we get (4.14) for $m = 1$. If $m = 2$, we have

$$\int_{-\infty}^{0} dz\, e^{-ikz} Q(z)\varphi(k,z) = -\Delta_1 + f_1'(0,0) - ik\int_{-\infty}^{0} dz\, zQ(z)\varphi(0,z) + o(k), \tag{A27}$$

and, using (3.1), (A14), and (A27) we obtain

$$\int_{-\infty}^{0} dz\, zQ(z)\varphi(0,z) = I_n + E_1 - f_1(0,0). \tag{A28}$$

Substituting this in (A6) we get

$$[f_r(-k,x)^\dagger; \varphi(k,x)] = \Delta_1 + ik(I_n + E_1) + o(k),$$

proving (4.14) when $m=2$.

It remains to prove (4.15). So pick $\xi \in \mathcal{N}$ and assume $m=1$. Then $\varphi(0,x)\xi$ stays bounded as $x \to -\infty$, which has the same effect on the integral in (A6), when it acts on ξ, as if m were 2. In particular, (A28) now becomes

$$\int_{-\infty}^{0} dz\, zQ(z)[\varphi(0,z)\xi] = \Gamma\xi - f_1(0,0)\xi,$$

where we have used (2.28) and (4.5). Since $\Delta_1\xi = 0$, from (A27) we obtain

$$\int_{-\infty}^{0} dz\, e^{-ikz} Q(z)[\varphi(k,z)\xi] = f_1'(0,0)\xi - ik\Gamma\xi + ikf_1(0,0)\xi + o(k).$$

Substituting this expression in (A6) we get

$$[f_r(-k,x)^\dagger; \varphi(k,x)]\xi = ik\Gamma\xi + o(k),$$

which agrees with (4.15) for $m=1$. If $m=2$ and $\xi \in \mathcal{N}$, then we can carry the expansion in (A27) further as in the case of (A9) and (A11). To obtain the corresponding coefficients in the expansion we could proceed by using variation of parameters in terms of the solutions $f_r(0,x)$ and $\dot{f}_l(0,x)$. However, there is a simpler approach that exploits the connection between the left and right Jost solutions for (1.1) under the substitution $x \mapsto -x$, that is, under the transformation $Q(x) \mapsto Q^\#(x)$, where $Q^\#(x) = Q(-x)$. We use the superscript # to indicate that a given quantity pertains to (1.1) with potential $Q^\#$. It is straightforward to show that

$$f_r(k,x) = f_l^\#(k,-x), \quad f_l(k,x) = f_r^\#(k,-x). \tag{A29}$$

We now introduce a solution $\omega(k,x)$ of (1.1) satisfying the initial conditions

$$\omega(k,0) = f_r(0,0), \quad \omega'(k,0) = f_r'(0,0).$$

Then it follows from (4.3) and (4.10) that for $\xi \in \mathcal{N}$ we have

$$\varphi(k,x)\xi = \omega(k,x)\chi, \tag{A30}$$

where $\chi = \Gamma\xi$. Since, by (4.10) and (A29)

$$\varphi^\#(k,0) = f_1^\#(k,0) = f_r(k,0), \quad \varphi^{\#\prime}(k,0) = f_1^{\#\prime}(k,0) = -f_r'(k,0),$$

we get $\varphi^\#(k,x) = \omega(k,-x)$, which, together with (A30), yields $\varphi^\#(k,-x)\chi = \varphi(k,x)\xi$. In the following argument we use the more elaborate notation. $[G(k,x); H(k,x)]_{(x_0)}$ to denote the Wronskian of two matrix functions $G(k,x)$ and $H(k,x)$ evaluated at $x = x_0$. Then we have

$$\begin{cases} [f_{\rm r}(-k,x)^{\dagger};\varphi(k,x)]_{(x)}\xi=[f_1^{\#}(-k,-x)^{\dagger};\varphi^{\#}(k,-x)]_{(x)}\chi \\ \qquad\qquad\qquad\qquad =-[f_1^{\#}(-k,x)^{\dagger};\varphi^{\#}(k,x)]_{(-x)}\chi \\ \qquad\qquad\qquad\qquad =[\varphi^{\#}(k,x)^{\dagger};f_1^{\#}(-k,x)]_{(-x)}^{\dagger}\chi \\ \qquad\qquad\qquad\qquad =[\varphi^{\#}(-k,x)^{\dagger};f_1^{\#}(-k,x)]_{(x)}^{\dagger}\chi, \end{cases} \tag{A31}$$

where in the the last step we have used the fact that the Wronskian is constant and that $\varphi(k,x)$ is an even function of k. The latter follows from the fact that the initial conditions in (4.10) are independent of k. Now the Wronskian on the right-hand side of (A31) is of the same form as that in (4.13). We can, therefore, apply the expansion given there. Then the integrand of Y_2 involves $f_1^{\#}(0,z)$ which can be rewritten in terms of $f_{\rm r}(0,z)$ by means of (A29). Using also (4.2), we obtain (4.15). The proof of Proposition 4.2 is now complete. ■

Continuum quantum systems as limits of discrete quantum systems. III. Operators

Laurence Barker[a)]
Department of Mathematics, Bilkent University, 06533 Bilkent, Ankara, Turkey

(Received 29 September 2000; accepted for publication 12 July 2001)

Convergence of a ''discrete'' operator to a ''continuum'' operator is defined. As examples, the circular rotor, the one-dimensional box, the harmonic oscillator, and the fractional Fourier transform are realized as limits of finite-dimensional quantum systems. Limits, thus defined, preserve algebraic structure. The results prepare for a sequel in which some affine canonical transforms will be ''discretized.'' © *2001 American Institute of Physics.* [DOI: 10.1063/1.1398582]

I. INTRODUCTION

The continuum fractional Fourier transform of Namias[1] is the limit of two discrete fractional Fourier transforms, namely, the Kravchuk function FRFT and the Harper function FRFT (see Refs. 2 and 3). Some very straightforward continuum quantum systems, such as the circular rotor, the one-dimensional box and the harmonic oscillator, can easily be realized as limits of equally straightforward finite-dimensional systems whose Hamiltonians are difference operators. For many purposes, the above assertions are clear enough without ''limit'' being understood to have any abstract meaning; nevertheless, the goal of this article is to assign an appropriate general meaning to ''limit,'' to state the above assertions precisely, and to prove them. It is not that we object to the usual common sense techniques—on the contrary, we shall validate them—but subsequently, in a sequel,[4] some ideas pioneered by Atakishiyev–Chumakov–Wolf[5] will be developed: continuum affine canonical transforms and continuum complex-order Fourier transforms will be realized as limits of analogous finite-dimensional transforms. In that application, common sense would not suffice.

Consider a Hilbert space $\mathcal{L}_\infty$, and Hilbert spaces $\mathcal{L}_n$, where the index n runs over some infinite set of positive integers. In Sec. II, we shall interface $\mathcal{L}_\infty$ with the spaces $\mathcal{L}_n$, and we shall assign a meaning to equations of the form

$$\hat{K}_\infty = \lim_n \hat{K}_n,$$

where $\hat{K}_\infty$ is a bounded operator on $\mathcal{L}_\infty$, and each $\hat{K}_n$ is a bounded operator on $\mathcal{L}_n$. In Sec. III, we shall assign a meaning to equations of the form

$$\mathcal{K}_\infty = \lim_n \mathcal{K}_n,$$

where $\mathcal{K}_\infty$ and $\mathcal{K}_n$ are quantum systems on $\mathcal{L}_\infty$ and $\mathcal{L}_n$, respectively. Convergence of vectors has already been discussed in two prequels to the present article. The first prequel[6] explains how $\mathcal{L}_\infty$ is to be interfaced with the spaces $\mathcal{L}_n$, and gives meaning to equations of the form

$$\psi_\infty = \lim_n \psi_n,$$

a)Electronic mail: barker@fen.bilkent.edu.tr.

where $\psi_\infty \in \mathcal{L}_\infty$ and $\psi_n \in \mathcal{L}_n$. Some of the main definitions and results from Ref. 6 are briefly recalled later in Sec. II. The second prequel[7] shows that widely used limiting techniques are in accordance with the definition of convergence.

With a view to applications, we might think of $\mathcal{L}_\infty$ as a ''continuum'' space, perhaps the Hilbert space formed from the space of square-integrable functions on a differentiable manifold. We might think of each space $\mathcal{L}_n$ as a ''discrete'' space, perhaps a Hilbert space with a coordinate system such that the coefficients of a vector may be interpreted as sample-point values of a function on the manifold. In the case where the manifold is $\mathbb{R}$, Digernes–Varadarájan–Varadhan[8] established a continuum-discrete correspondence—characterized in terms of limits—by embedding each $\mathcal{L}_n$ in $\mathcal{L}_\infty$. Our approach is more concerned with preservation of algebraic structure (linearity, inner products, composition, tensor products). We interface $\mathcal{L}_\infty$ with the spaces $\mathcal{L}_n$ by realizing the sequence $(\mathcal{L}_n)_n$ as an inductive resolution of $\mathcal{L}_\infty$. The definition of an inductive resolution (recalled in Sec. II) is entirely algebraic, and, by this virtue, it relieves us of any need to assign any abstract meaning to the jargon ''continuum'' and ''discrete.'' (As every physicist knows, these two terms often refer to different sides of the same coin.)

The preservation of algebraic structure will be crucial in Ref. 4, where we shall be considering some Lie groups with several degrees of freedom. In subsequent work, we shall present a more systematic study of a way in which ''continuum'' (usually infinite-dimensional) representations of Lie groups may be realized as limits of ''discrete'' (usually finite-dimensional) representations. (Part of the motive for this is to seek criteria for a system of numerically calculated transforms to respect ''continuum'' composition laws.) The results we give later, in Sec. III, and the applications we note in Sec. IV, all concern the special case of one-parameter groups. This special case is helpful as a stepping-stone because some of the concerns that arise in the general case reduce to trivialities here.

However, one-parameter systems are of interest in their own right, and can naturally be regarded as quantum dynamical systems, or, to use the language of Parthasarathy,[9] quantum stochastic processes. (Let us not quibble about the flexible definitions of these terms.) Thus, we are led back to a question addressed by Digernes–Varadarájan–Varadhan.[8] To what extent are spectra in the ''continuum'' scenario related to spectra in the ''discrete'' scenario? This question is explored in Sec. V. The author would like to thank the referee for some useful suggestions concerning Sec. V. Although the material there is still only an initial foray into the matter, it was absent from the previous version of this article.

General motives for a continuum-discrete correspondence—characterized in terms of limits, and preserving algebraic structure—are noted in the prequels, Refs. 6 and 7. Some more extensive references for applications may be found in those two papers. The *Gedankenexperiment* in Ref. 7, Sec. 2, gives a heuristic introduction to our line of approach.

II. INDUCTION OF BOUNDED OPERATORS

By an **operator** on a Hilbert space $\mathcal{L}$, we mean a linear map $\mathcal{D}\to\mathcal{L}$, where the domain $\mathcal{D}$ is a dense subspace of $\mathcal{L}$. Every bounded operator on $\mathcal{L}$ extends uniquely to a bounded operator on $\mathcal{L}$ with domain $\mathcal{L}$. Henceforth, all our bounded operators on a Hilbert space $\mathcal{L}$ shall be deemed to have domain $\mathcal{L}$. We write $U(\mathcal{L})$ for the group of unitary operators on $\mathcal{L}$.

We must briefly review some of the definitions and results of Ref. 6. Consider a Hilbert space $\mathcal{L}_\infty$, a dense subspace $\mathcal{S}$ of $\mathcal{L}_\infty$, an infinite set of positive integers $\mathcal{N}$, Hilbert spaces $\mathcal{L}_n$ for each $n \in \mathcal{N}$, and linear maps $\mathrm{res}_n : \mathcal{S} \to \mathcal{L}_n$. (The results below may easily be extended to the case where $\mathcal{N}$ is any directed set, as in Ref. 6.)

The linear maps res_n, called the **restriction maps**, are required to satisfy the reciprocity condition

$$\langle \phi | \chi \rangle = \lim_{n \in \mathcal{N}} \langle \mathrm{res}_n(\phi) | \mathrm{res}_n(\chi) \rangle$$

for all $\phi,\chi\in\mathcal{S}$. The sequence $(\mathcal{L}_n)_n$, equipped with the sequence $(\mathrm{res}_n)_n$, is called an **inductive resolution** of $\mathcal{L}_\infty$.

Given a vector $\psi\in\mathcal{L}_\infty$, and vectors $\psi_n\in\mathcal{L}_n$ for sufficiently large $n\in\mathcal{N}$ (not necessarily for all $n\in\mathcal{N}$), we say that the sequence $(\psi_n)_n$ **converges** to ψ_∞ provided the norms $\|\psi_n\|$ are bounded and

$$\langle\phi|\psi_\infty\rangle=\lim_{n\in\mathcal{N}}\langle\mathrm{res}_n(\phi)|\psi_n\rangle$$

for all $\phi\in\mathcal{S}$. The Riesz representation theorem guarantees that $(\psi_n)_n$ converges to at most one vector in $\mathcal{L}_\infty$. When $(\psi_n)_n$ converges to ψ_∞, we call ψ_∞ the **limit** of $(\psi_n)_n$, and we write $\psi_\infty=\lim_{n\in\mathcal{N}}\psi_n$. Note that $\phi=\lim_{n\in\mathcal{N}}\mathrm{res}_n(\phi)$ for all $\phi\in\mathcal{S}$.

Let us recall some results that we shall need from Ref. 6.

Theorem 2.1: (Ref. 6, Theorem 2.4) *Any vector $\psi_\infty\in\mathcal{L}_\infty$ is the limit of some sequence $(\psi_n)_n$, and, furthermore, the vectors $\psi_n\in\mathcal{L}_n$ may be chosen such that $\|\psi_\infty\|=\|\psi_n\|$ for all n.*

Let $\mathcal{B}_\infty=\{\beta_{j,\infty}:j\in J_\infty\}$ be any enumerated orthonormal basis for $\mathcal{L}_\infty$. Here, $J_\infty=\mathbb{N}$ if $\mathcal{L}_\infty$ is infinite-dimensional, while $J_\infty=\{0,1,\ldots,d-1\}$ if $\mathcal{L}_\infty$ has finite dimension d. By Ref. 6, Theorem 3.1, there exist $\mathcal{B}_n$, indexed by $n\in\mathcal{N}$, where each $\mathcal{B}_n$ is an enumerated orthonormal set $\mathcal{B}_n=\{\beta_{j,n}:j\in J_n\}$ in $\mathcal{L}_n$, and

$$\beta_{j,\infty}=\lim_{n\in\mathcal{N}}\beta_{j,n}$$

for all $j\in J_\infty$. Note that, for each basis vector $\beta_{j,\infty}$ in $\mathcal{L}_\infty$, a corresponding basis vector $\beta_{j,n}$ in $\mathcal{L}_n$ need not exist for all n, but the $\beta_{j,n}$ must exist for sufficiently large n.

As explained in Ref. 6, Sec. 3, the $\mathcal{B}_n$ cannot always be chosen such that each $\mathcal{B}_n$ is a basis. (In all our applications in Sec. IV, each of our chosen $\mathcal{B}_n$ is a basis. We also mention that, in all these applications, $\mathcal{L}_\infty$ is infinite-dimensional, $\mathcal{N}$ is a set of positive integers, and each $\mathcal{L}_n$ has finite dimension n.) We let $\mathcal{L}_n^\perp$ denote the subspace of $\mathcal{L}_n$ orthogonally complementary to the span of $\mathcal{B}_n$. Given a vector $\psi_\infty\in\mathcal{L}_\infty$, we write

$$\psi_\infty=\sum_{j=0}^{\infty}c_{j,\infty}\beta_{j,\infty}$$

with the understanding that $c_{j,n}=0$ for all $j\in\mathbb{N}-J_\infty$. Given $\psi_n\in\mathcal{L}_n$, we write

$$\psi_n=\psi_n^\perp+\sum_{j=0}^{\infty}c_{j,n}\beta_{j,n}$$

where $\psi_n^\perp\in\mathcal{L}_n^\perp$, and $c_{j,n}=0$ for all $j\in\mathbb{N}-J_n$. (Of course, if $\mathcal{B}_n$ is a basis, then $\psi_n^\perp=0$.) For later convenience, we define $\beta_{j,\infty}:=0$ when $j\in\mathbb{N}-J_\infty$, and $\beta_{j,n}:=0$ when $j\in\mathbb{N}-J_n$. Thus $c_{j,\infty}=\langle\beta_{j,\infty}|\psi_\infty\rangle$ and $c_{j,n}=\langle\beta_{j,n}|\psi_n\rangle$ for all $j\in\mathbb{N}$.

Theorem 2.2: (Ref. 6, Theorem 3.4) *Using the notation above, $\psi_\infty=\lim_{n\in\mathcal{N}}\psi_n$ if and only if the norms $\|\psi_n\|$ are bounded, and $c_{j,\infty}=\lim_{n\in\mathcal{N}}c_{j,n}$ for all $j\in J_\infty$.*

We can now turn to convergence of operators. Let $\hat{K}_\infty$ be a bounded operator on $\mathcal{L}_\infty$, and for sufficiently large $n\in\mathcal{N}$, let $\hat{K}_n$ be a bounded operator $\mathcal{L}_n$. We say that the sequence $(\hat{K}_n)_n$ **converges** to $\hat{K}_\infty$ provided the norms $\|\hat{K}_n\|$ are bounded, and for all $\psi_\infty\in\mathcal{L}_\infty$, and all sequences $(\psi_n)_n$ with $\psi_n\in\mathcal{L}_n$ and $\psi_\infty=\lim_{n\in\mathcal{N}}(\psi_n)$, we have

$$\hat{K}_\infty\psi_\infty=\lim_{n\in\mathcal{N}}(\hat{K}_n\psi_n).$$

Theorem 2.1 ensures that the sequence $(\hat{K}_n)_n$ converges to at most one bounded operator on $\mathcal{L}_\infty$. When $(\hat{K}_n)_n$ converges to $\hat{K}_\infty$, we call $\hat{K}_\infty$ the **limit** of $(\hat{K}_n)_n$, and we write $\hat{K}_\infty=\lim_{n\in\mathcal{N}}\hat{K}_n$.

Remark 2.3: Given bounded operators $\hat{K}_\infty = \lim_{n\in\mathcal{N}} \hat{K}_n$ *and* $\hat{K}'_\infty = \lim_{n\in\mathcal{N}} \hat{K}'_n$, *and given* $\lambda,\lambda' \in \mathbb{C}$, *then* $\lambda\hat{K}_\infty + \lambda'\hat{K}'_\infty = \lim_{n\in\mathcal{N}}(\lambda\hat{K}_n + \lambda'\hat{K}'_n)$ *and* $\hat{K}_\infty\hat{K}'_\infty = \lim_{n\in\mathcal{N}} \hat{K}_n\hat{K}'_n$.

Proof: This is obvious. □

Theorem 2.4: *Given any bounded* $\hat{K}_\infty$ *on* $\mathcal{L}_\infty$, *then there exist bounded operators* $\hat{K}_n$ *on each* $\mathcal{L}_n$ *such that* $\hat{K}_\infty = \lim_{n\in\mathcal{N}} \hat{K}_n$ *and* $\|\hat{K}_n\| = \|\hat{K}_\infty\|$ *for all* $n \in \mathcal{N}$.

Proof: Let $\mathcal{B}_\infty$ and $\mathcal{B}_n$ be as above. We define

$$K_{j,k} = \langle \beta_{j,\infty} | \hat{K}_\infty \beta_{k,\infty} \rangle$$

for all $j,k \in \mathbb{N}$. (Note that $K_{j,k} = 0$ unless j and k both belong to J_∞.) On each space $\mathcal{L}_n$, we define an operator $\hat{K}'_n$ annihilating $\mathcal{L}_n^\perp$ and such that

$$K_{j,k} = \langle \beta_{j,n} | \hat{K}'_n \beta_{k,n} \rangle$$

for all $j,k \in J_n$. Consider vectors $\psi_\infty \in \mathcal{L}_\infty$ and $\psi_n \in \mathcal{L}_n$ such that $\psi_\infty = \lim_n \psi_n$. Let the coefficients $c_{j,\infty}$ and $c_{j,n}$ be as above. Then

$$\|\hat{K}'_n \psi_n\|^2 = \sum_{j=0}^{\infty} \left| \sum_{k=0}^{\infty} K_{j,k} c_{k,n} \right|^2 \leqslant \|\hat{K}_\infty\|^2 \|\psi_n\|^2.$$

So the norms $\|\hat{K}'_n\|$ are bounded by $\|\hat{K}_\infty\|$. Given $\epsilon > 0$, then there exists a positive integer N and complex numbers $c_0, \ldots, c_{N-1}$ such that

$$\sum_{j=0}^{N-1} \left| \sum_{k=0}^{N-1} K_{j,k} c_k \right|^2 \geqslant (\|\hat{K}_\infty\| - \epsilon)^2 \sum_{j=0}^{N-1} |c_j|^2.$$

For sufficiently large $n \in \mathcal{N}$, we have $\{0,\ldots,N-1\} \cap J_\infty \subseteq J_n$, whereupon $\|\hat{K}'_n\| \geqslant \|\hat{K}_\infty\| - \epsilon$. Therefore, $\|\hat{K}_\infty\| = \lim_{n\in\mathcal{N}} \|\hat{K}'_n\|$.

We claim that $\hat{K}_\infty = \lim_n \hat{K}'_n$. Let $\phi \in \mathcal{S}$. For each n, let $\phi_n := \mathrm{res}_n(\phi)$. To prove the claim, it suffices to show that

$$\langle \phi | \hat{K}_\infty \psi_\infty \rangle = \lim_n \langle \phi_n | \hat{K}'_n \psi_n \rangle.$$

For each $j \in \mathbb{N}$, let $a_{j,\infty} := \langle \beta_{j,\infty} | \phi \rangle$ and $a_{j,n} := \langle \beta_{j,n} | \phi_n \rangle$. Thus

$$\phi = \sum_{j=0}^{\infty} a_{j,\infty} \beta_{j,\infty} \quad \text{and} \quad \phi_n = \phi_n^\perp + \sum_{j=0}^{\infty} a_{j,n} \beta_{j,n},$$

where $\psi_n^\perp \in \mathcal{L}_n^\perp$. We have

$$\langle \phi_n | \hat{K}'_n \psi_n \rangle = \sum_{j,k=0}^{\infty} \overline{a}_{j,n} K_{j,k} c_{k,n}$$

and a similar equation holds for $\langle \phi | \hat{K}_\infty \psi_n \rangle$. (By absolute convergence properties, all the sums we consider can be rearranged.) We have

$$|\langle \phi | \hat{K}_\infty \psi_\infty \rangle - \langle \phi_n | \hat{K}'_n \psi_n \rangle| \leqslant \left| \sum_{j,k=0}^{\infty} \overline{a}_{j,\infty} K_{j,k} (c_{k,\infty} - c_{k,n}) \right| + \left| \sum_{j,k=0}^{\infty} (\overline{a}_{j,\infty} - \overline{a}_{j,n}) K_{j,k} c_{k,n} \right|.$$

(Using the boundedness of $\hat{K}_\infty$, it is easy to check that these sums are absolutely convergent.) Letting C be an upper bound for the norms $\|\psi_n\|$, then

$$\sum_{j=0}^{\infty}\left|\sum_{k=0}^{\infty}K_{j,k}c_{k,n}\right|^2\leqslant C^2\|\hat{K}_\infty\|^2$$

for sufficiently large n. Part of Ref. 6, Lemma 3.3, says that $\Sigma_{j=0}^{\infty}|a_{j,\infty}-a_{j,n}|^2\leqslant\epsilon^2$ for sufficiently large n. Hence

$$\left|\sum_{j,k=0}^{\infty}(\overline{a}_{j,\infty}-\overline{a}_{j,n})\hat{K}_{j,k}c_{k,n}\right|\leqslant\epsilon C\|\hat{K}_\infty\|.$$

We may insist that $C\geqslant\|\psi_\infty\|$. Thereupon,

$$\sum_{j=0}^{\infty}\left|\sum_{k=0}^{\infty}K_{j,k}(c_{k,\infty}-c_{k,n})\right|^2\leqslant 4C^2\|\hat{K}_\infty\|^2$$

for sufficiently large n. The series $\Sigma_{j=0}^{\infty}|a_{j,\infty}|^2$ converges (to $\|\phi\|^2$), so there exists a positive integer M such that $\Sigma_{j=M}^{\infty}|a_{j,\infty}|^2\leqslant\epsilon^2$. We have

$$\left|\sum_{j=M}^{\infty}\sum_{k=0}^{\infty}\overline{a}_{j,\infty}K_{j,k}(c_{k,\infty}-c_{k,n})\right|\leqslant 2\epsilon C\|\hat{K}_\infty\|$$

for large n. To prove the claim, it now suffices to show that

$$\left|\sum_{j=0}^{M-1}\sum_{k=0}^{\infty}\overline{a}_{j,\infty}K_{j,k}(c_{k,\infty}-c_{k,n})\right|=O(\epsilon).$$

Let $j\in\mathbb{N}$. Suppose there exists some $\delta>0$ such that, for every positive integer L, there exist complex numbers $c_L,c_{L+1},\ldots$ satisfying

$$\sum_{k=L}^{\infty}|c_k|^2\leqslant 1\quad\text{and}\quad\left|\sum_{k=L}^{\infty}K_{j,k}c_k\right|>\delta.$$

Then there exist complex numbers $c_0,c_1,\ldots$ and integers $0=L_0<L_1<\cdots$ such that each $K_{j,k}c_k$ is a non-negative real, and

$$\sum_{k=L_{r-1}}^{L_r-1}|c_k|^2\leqslant\frac{1}{n^2}\ \text{and}\ \sum_{k=L_{r-1}}^{L_r-1}K_{j,k}c_k>\frac{\delta}{2n}$$

for all positive integers r. The series $\Sigma_{k=0}^{\infty}|c_k|^2$ converges while the series $\Sigma_{k=0}^{\infty}K_{j,k}c_k$ diverges. This contradicts the boundedness of $\hat{K}_\infty$. We deduce that, for any positive real B, there exists a positive integer L such that, for all complex numbers $c_L,c_{L+1},\ldots$ satisfying $\Sigma_{k=L}^{\infty}|c_k|^2\leqslant B$, we have $|\Sigma_{k=L}^{\infty}K_{j,k}c_k|\leqslant\epsilon/M$. For large n, we have $\Sigma_{k=0}^{\infty}|c_{k,\infty}-c_{k,n}|^2\leqslant 4C^2$. So there exists a positive integer L such that, for large n, and for all $j<M$, we have

$$\left|\sum_{k=L}^{\infty}K_{j,k}(c_{k,\infty}-c_{k,n})\right|\leqslant\epsilon/M.$$

Each $|a_{j,\infty}|\leqslant\|\phi\|$, so

$$\left|\sum_{j=0}^{M-1}\sum_{k=L}^{\infty}\overline{a}_{j,\infty}K_{j,k}(c_{k,\infty}-c_{k,n})\right|\leqslant\epsilon\|\phi\|$$

for large n. The claim will follow when we have shown that

$$\left| \sum_{j=0}^{M-1} \sum_{k=0}^{L-1} \overline{a}_{j,\infty} K_{j,k} (c_{k,\infty} - c_{k,n}) \right| = O(\epsilon)$$

for large n. By Theorem 2.2, $c_{k,\infty} = \lim_{n \in \mathcal{N}} c_{k,n}$. The claim is established.

To finish the argument, we must replace the operators $\hat{K}'_n$ with operators $\hat{K}_n$ on $\mathcal{L}_n$ such that $\|\hat{K}_n\| = \|\hat{K}_\infty\|$ for all $n \in \mathcal{N}$. We may assume that $\|\hat{K}_\infty\| = 1$. From the first paragraph of the argument, $\|\hat{K}'_n\|$ converges to 1. So $\hat{K}_n \neq 0$ for large n. When $\hat{K}'_n \neq 0$, we put $\hat{K}_n = \hat{K}'_n / \|\hat{K}'_n\|$, otherwise we put $\hat{K}_n = \hat{1}$. Then each $\|\hat{K}_n\| = 1$, and $\|\hat{K}_n - \hat{K}'_n\| \to 0$. Since the norms $\|\psi_n\|$ are bounded, $\|\hat{K}_n \psi_n - \hat{K}'_n \psi_n\| \to 0$. It was shown in Ref. 6, Remark 2.3, that, for $\theta_\infty \in \mathcal{L}_\infty$ and $\theta_n, \chi_n \in \mathcal{L}_n$ satisfying $\theta_\infty = \lim_{n \in \mathcal{N}} \theta_n$ and $\lim_{n \in \mathcal{N}} \|\theta_n - \chi_n\| = 0$, we have $\theta_\infty = \lim_{n \in \mathcal{N}} \chi_n$. Therefore, $\hat{K}_\infty \psi_\infty = \lim_{n \in \mathcal{N}} \hat{K}_n \psi_n$. □

Corollary 2.5: Given any bounded Hermitian operator $\hat{H}_\infty$ on $\mathcal{L}_\infty$, then there exist bounded Hermitian operators $\hat{H}_n$ on each $\mathcal{L}_n$ such that $\hat{H}_\infty = \lim_{n \in \mathcal{N}} \hat{H}_n$ and $\|\hat{H}_n\| = \|\hat{H}_\infty\|$ for each $n \in \mathcal{N}$.

Proof: In the proof of Theorem 2.4, if $\hat{K}_\infty$ is Hermitian, then so is each $\hat{K}_n$. □

In order to accommodate the possibility of working with a compound of several quantum stochastic processes (for example, a quantum system with several particles), we must discuss tensor products of inductive resolutions, and we must show how the limits of vectors and operators are compatible with the tensor product. Let $\mathcal{L}'_\infty$ be a Hilbert space, and let $\mathcal{S}'$ be a dense subspace of $\mathcal{L}'_\infty$. For each $n \in \mathcal{N}$, let $\mathcal{L}'_n$ be a Hilbert space, and let $\mathrm{res}'_n : \mathcal{S}' \to \mathcal{L}_n$ be restriction maps. Then $\mathcal{L}_\infty \otimes \mathcal{L}'_\infty$ has an inductive resolution with restriction maps $\mathrm{res}_n \otimes \mathrm{res}'_n : \mathcal{S} \otimes \mathcal{S}' \to \mathcal{L}_n \otimes \mathcal{L}'_n$. Given limits of vectors $\psi_\infty = \lim_n \psi_n$ and $\psi'_\infty = \lim_n \psi'_n$ in $\mathcal{L}_\infty$ and $\mathcal{L}'_\infty$, respectively, it is clear that we have a limit of vectors $\psi_\infty \otimes \psi'_\infty = \lim_n \psi_n \otimes \psi'_n$. By considering orthonormal coordinates and applying Ref. 6, Theorem 3.4, it is easy to check that limits of bounded operators preserve tensor products in the same way. (Warning: we are not invoking Ref. 6, Theorem 3.4, gratuitously. Not every sequence in $\mathcal{L}_n \otimes \mathcal{L}'_n$ converging to $\psi_\infty \otimes \psi'_\infty$ has terms of the form $\psi_n \otimes \psi'_n$.) These (rather trivial) remarks show that the limits behave well in the (rather banal) case of a fixed finite number of noninteracting processes. Presumably, they also behave well with respect to symmetric and antisymmetric tensor products, and with respect to the construction of free, symmetric, and antisymmetric Fock spaces (see Ref. 9, Chap. II). We leave that matter for further research.

III. CONVERGENCE OF QUANTUM SYSTEMS
